(Remember we are in the case $a_0 < 1$.) However, Hopf's version of the maximum principle asserts that if w_ϵ is not constant (= 0) then $\frac{\partial w_\epsilon}{\partial z_2}^+(z_0) \leq 0$ and $\frac{\partial w_\epsilon}{\partial z_2}^-(z_0) \geq 0$, and at least one of these values is nonzero. Consequently

$$a_0 \frac{\partial w_\epsilon}{\partial z_2}^+ (z_0) - \frac{\partial w_\epsilon}{\partial z_2}^- (z_0) < 0,$$

and this represents a contradiction. Corresponding to a minimum we would have $w_\epsilon(z_0) \leq 0$, and the same argument as above would lead to a contradiction (unless $w_\epsilon = 0$).

We may therefore conclude that the extremal values of w_ϵ are always attained on ∂P_ϵ. Let d_0 denote the constant

$$d_0 = \sin \gamma\delta.$$

It follows that $0 < d_0$ and that d_0 only depends on γ and δ. It is quite easy to see that

$$|w_\epsilon(z)| \leq K_0 d_0^{-1} M_0^\gamma (1+\alpha^2)^{\gamma/2}$$

on $\{z_1 = M_0, \ \ 0 \leq z_2 \leq \alpha M_0\}$ and that

$$|w_\epsilon(z)| \leq C_0 d_0^{-1}$$

on $\{z_2 = \alpha z_1,\ \alpha M_0 \leq z_2 \leq 1/2\epsilon\}$. Together these two estimates show that

$$|w_\epsilon(z)| \leq C_0' \quad \text{on } \partial P_\epsilon,$$

with $C_0' = d_0^{-1} \max(C_0, K_0 M_0^\gamma (1+\alpha^2)^{\gamma/2})$. Since the extremal values of w_ϵ are attained on the boundary of P_ϵ, we immediately conclude that $|w_\epsilon(z)| \leq C_0'$ in P_ϵ, and thus

$$|W_\epsilon(z)| \leq C_0' |z|^{-\gamma} \quad \text{in } P_\epsilon,$$

exactly as desired (for $a_0 < 1$).

In the case $a_0 > 1$ we introduce the function $\mu = r^{-\gamma} \cos\gamma\theta$. We now calculate

$$\begin{aligned}\frac{\partial \mu}{\partial z_2} = \sin\theta \frac{\partial \mu}{\partial r} + \frac{\cos\theta}{r}\frac{\partial \mu}{\partial \theta} &= -\gamma r^{-\gamma-1}(\sin\theta\cos\gamma\theta + \cos\theta\sin\gamma\theta)\\ &= -\gamma r^{-\gamma-1}\sin(\gamma+1)\theta.\end{aligned}$$

Therefore

$$\mu(z) > 0 \quad \text{for } z \in \overline{P_\epsilon} \quad \text{and} \quad \frac{\partial \mu}{\partial z_2} < 0 \quad \text{for } z \in P_\epsilon.$$

The argument from before works in an identical fashion with this function, since the signs of $1 - a_0$ and $\frac{\partial}{\partial z_2}\mu$ have both changed, so that $\frac{1}{\mu}(1 - a_0)\frac{\partial}{\partial z_2}\mu$ stays positive. The constant d_0 gets replaced by

$$d_0' = \cos \gamma\theta_\alpha > 0,$$

with $\theta_\alpha = \arctan \alpha$. This shows that

$$|W_\epsilon(z)| \leq C_0'|z|^{-\gamma} \quad \text{in } P_\epsilon,$$

exactly as desired (for $a_0 > 1$ as well). □

Based on the two previous lemmas it is now fairly simple to prove the following proposition.

Proposition 4.3. *There exists a constant C, independent of ϵ, such that the functions U_ϵ satisfy*

$$|U_\epsilon(z)| \leq C|z|^{-1/2}, \quad \left|\frac{\partial}{\partial z_1}U_\epsilon(z)\right| \leq C|z|^{-3/2}, \text{ and } \left|\left(\frac{\partial}{\partial z_1}\right)^2 U_\epsilon(z)\right| \leq C|z|^{-5/2}$$

for $z \in \Phi(\Omega_+) \cap \{z_2 < 1/2\epsilon\}$.

Proof. Select $0 < \alpha$ so that $\arctan \alpha < \pi/3$, and select $0 < M$ so that $2 < \alpha M$, and so that the line $\{z_1 = M\}$ does not intersect the "inner" boundary S. Elliptic regularity results (in combination with the uniform energy bound for U_ϵ) easily give

$$|U_\epsilon(M, z_2)| \leq K \quad \text{for } 0 \leq z_2 \leq \alpha M,$$

with K independent of ϵ. We also have that $U_\epsilon(z)z_1^{1/2} \to 0$ as $z_1 \to \infty$ (uniformly on $0 \leq z_2 \leq 1/2\epsilon$). Indeed, U_ϵ decreases exponentially as $z_1 \to \infty$. From Lemma 4.1 we know that

$$|U_\epsilon(z)| \leq C|z|^{-1/2} \quad \text{on } \{z_2 = \alpha z_1,\ \alpha M \leq z_2 \leq 1/2\epsilon\}.$$

Application of Lemma 4.2 with $\gamma = 1/2$ now gives

$$|U_\epsilon(z)| \leq C'|z|^{-1/2} \quad \text{on } \{M \leq z_1,\ 0 \leq z_2 \leq \min(\alpha z_1,\ 1/2\epsilon)\},$$

with C' independent of ϵ. For $0 \leq z_1$, $\max(\alpha M, \alpha z_1) \leq z_2 \leq 1/2\epsilon$ it follows immediately from Lemma 4.1 that $|U_\epsilon(z)| \leq C|z|^{-1/2}$. For z outside S, $0 \leq z_1 \leq M$ and $0 \leq z_2 \leq \alpha M$ (the remainder of $\Phi(\Omega_+) \cap \{0 \leq z_1,\ z_2 \leq 1/2\epsilon\}$) elliptic regularity results yield that $|U_\epsilon(z)| \leq C \leq C|z|^{-1/2}$. In summary, we have thus verified that

$$|U_\epsilon(z)| \leq C|z|^{-1/2} \quad \text{in } \Phi(\Omega_+) \cap \{0 \leq z_1,\ z_2 < 1/2\epsilon\}.$$

A similar argument (e.g., using $U_\epsilon(-z_1, z_2)$ in place of $U(z_1, z_2)$) proves the same estimate in $\Phi(\Omega_+) \cap \{z_1 \leq 0,\ z_2 < 1/2\epsilon\}$, thus completing the proof of the first assertion of this proposition. Almost identical arguments with $\gamma = 3/2$ and $\gamma = 5/2$ lead to the desired estimates for $\frac{\partial}{\partial z_1}U_\epsilon$ and $\left(\frac{\partial}{\partial z_1}\right)^2 U_\epsilon$, respectively. Note that these functions also solve the type of boundary value problem required in Lemma 4.2. □

Since $U_\epsilon \to U$, $\frac{\partial}{\partial z_1}U_\epsilon \to \frac{\partial}{\partial z_1}U$ and $\left(\frac{\partial}{\partial z_1}\right)^2 U_\epsilon \to \left(\frac{\partial}{\partial z_1}\right)^2 U$ pointwise inside $\Phi(\Omega_+) \setminus \{z_2 = 1/2\}$ (Proposition 3.1) and since U, $\frac{\partial}{\partial z_1}U$, and $\left(\frac{\partial}{\partial z_1}\right)^2 U$ are all continuous in $\Phi(\Omega_+)$, we derive from the above proposition the following corollary.

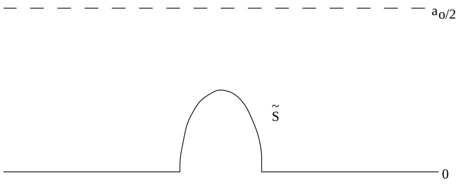

Fig. 9. *The stretched geometry. The dashed line represents the location of the discontinuity of the coefficient $\tilde{A}$.*

Corollary 4.4. *There exists a constant C such that*

$$|U(z)| \leq C|z|^{-1/2}, \quad \left|\frac{\partial}{\partial z_1}U(z)\right| \leq C|z|^{-3/2}, \text{ and } \left|\left(\frac{\partial}{\partial z_1}\right)^2 U(z)\right| \leq C|z|^{-5/2}$$

for $z \in \Phi(\Omega_+)$.

Based on the use of Proposition 4.3 we are able to establish improved estimates for U_ϵ and U that immediately lead to a proof of our main theorem.

5. The improved estimates. We extend the function A to all of the halfplane $0 < z_2$ by setting it to 1 in the domain bounded by $S = \Phi(\partial\Omega \cap \{x_2 > 0\})$ and $\{z_2 = 0\}$, and we introduce the new variables $\tilde{z} = (\tilde{z}_1, \tilde{z}_2)$ as follows:

$$\tilde{z}_1 = z_1, \quad \tilde{z}_2 = a_0 \int_0^{z_2} \frac{1}{A(s)}\, ds = \begin{cases} z_2 + \frac{a_0 - 1}{2}, & z_2 > 1/2, \\ a_0 z_2, & z_2 < 1/2. \end{cases} \tag{20}$$

The transformed function $\tilde{U}(\tilde{z}) = U(z)$ solves

$$\left[\left(\frac{\tilde{A}(\tilde{z}_2)}{a_0}\right)^2 \left(\frac{\partial}{\partial \tilde{z}_1}\right)^2 + \left(\frac{\partial}{\partial \tilde{z}_2}\right)^2\right] \tilde{U} = 0 \quad \text{for } \tilde{z} \in \tilde{\Phi}(\Omega_+),$$

with the domain $\tilde{\Phi}(\Omega_+)$ defined by

$$\tilde{z} \in \tilde{\Phi}(\Omega_+) \quad \text{if and only if } z \in \Phi(\Omega_+).$$

See Figure 9. We have illustrated the stretched "inner" boundary $\tilde{S}$ as the upper half of an ellipse.

The function $\tilde{A}$ is defined by $\tilde{A}(\tilde{z}_2) = A(z_2)$, where $\tilde{z}_2$ and z_2 are related by the second formula in (20). From the above definitions it follows immediately that

$$\triangle_{\tilde{z}} \tilde{U} = 0 \quad \text{for } a_0/2 < \tilde{z}_2$$

and

$$\triangle_{\tilde{z}} \tilde{U} = \left(1 - \frac{1}{a_0^2}\right) \left(\frac{\partial}{\partial \tilde{z}_1}\right)^2 \tilde{U} \quad \text{for } \tilde{z} \in \tilde{\Phi}(\Omega_+) \cap \{\tilde{z}_2 < a_0/2\}.$$

Similarly,

$$\triangle_{\tilde{z}} \tilde{U}_\epsilon = 0 \quad \text{for } a_0/2 < \tilde{z}_2 < \frac{1 + \epsilon(a_0 - 1)}{2\epsilon}$$

and

$$\triangle_{\tilde{z}}\tilde{U}_\epsilon = (1-\frac{1}{a_0^2})\left(\frac{\partial}{\partial \tilde{z}_1}\right)^2 \tilde{U}_\epsilon \quad \text{for } \tilde{z} \in \tilde{\Phi}(\Omega_+) \cap \{\tilde{z}_2 < a_0/2\}.$$

Let $\tilde{E}$ denote the domain bounded by the inner boundary $\tilde{S}$ and $\{\tilde{z}_2 = 0\}$. In Figure 9 it is represented by the inside of the half-ellipse. We now extend both $\tilde{U}$ (and $\tilde{U}_\epsilon$) to all of the halfplane $0 < \tilde{z}_2$ (the strip $0 < \tilde{z}_2 < \frac{1+\epsilon(a_0-1)}{2\epsilon}$) in such a way that the extensions are zero on $\tilde{z}_2 = 0$ and are $C^{2,\beta}$ bounded in a neighborhood of $\tilde{E}$ (independently of ϵ). This may be done since, near $\tilde{S}$, $\tilde{U}$ and $\tilde{U}_\epsilon$ are C^∞ and uniformly bounded in all C^k norms (due to elliptic regularity results and the uniform energy estimate). As a consequence we get that

$$\begin{aligned}
&\triangle_{\tilde{z}}\tilde{U} = 0 \quad \text{for } a_0/2 < \tilde{z}_2,\\
&\triangle_{\tilde{z}}\tilde{U} = \left(1-\frac{1}{a_0^2}\right)\left(\frac{\partial}{\partial \tilde{z}_1}\right)^2 \tilde{U} + f(\tilde{z}) \quad \text{for } 0 < \tilde{z}_2 < a_0/2,
\end{aligned}$$

where f is uniformly bounded and supported in the closure of $\tilde{E}$. We also get that

$$\begin{aligned}
&\triangle_{\tilde{z}}\tilde{U}_\epsilon = 0 \quad \text{for } a_0/2 < \tilde{z}_2 < \frac{1+\epsilon(a_0-1)}{2\epsilon},\\
&\triangle_{\tilde{z}}\tilde{U}_\epsilon = \left(1-\frac{1}{a_0^2}\right)\left(\frac{\partial}{\partial \tilde{z}_1}\right)^2 \tilde{U}_\epsilon + f_\epsilon(\tilde{z}) \quad \text{for } 0 < \tilde{z}_2 < a_0/2,
\end{aligned}$$

where the f_ϵ are uniformly bounded (independently of ϵ) and supported in the closure of $\tilde{E}$. The functions $\tilde{U}$, $\tilde{U}_\epsilon$ and the gradients $\nabla_{\tilde{z}}\tilde{U}$, $\nabla_{\tilde{z}}\tilde{U}_\epsilon$ are continuous across the line $\tilde{z}_2 = a_0/2$, so the above piecewise formulas entirely describe (the distributions) $\triangle_{\tilde{z}}\tilde{U}$ and $\triangle_{\tilde{z}}\tilde{U}_\epsilon$. Let g_ϵ denote the function $g_\epsilon = (1-\frac{1}{a_0^2})\left(\frac{\partial}{\partial \tilde{z}_1}\right)^2\tilde{U}_\epsilon + f_\epsilon$ (in $\tilde{E}$) and define

$$\begin{aligned}
\tilde{V}_\epsilon^*(\tilde{z}) = \frac{a_0^2-1}{4\pi a_0^2}\int_{\{(s,t)\,:\,0<t<a_0/2\}\setminus\tilde{E}} \Bigg[&\log(|\tilde{z}_1-s|^2+|\tilde{z}_2-t|^2)\\
&-\log(|\tilde{z}_1-s|^2+|\tilde{z}_2+t|^2)\Bigg]\left(\frac{\partial}{\partial s}\right)^2\tilde{U}_\epsilon(s,t)\,dsdt\\
+\frac{1}{4\pi}\int_{\tilde{E}}\Bigg[&\log(|\tilde{z}_1-s|^2+|\tilde{z}_2-t|^2)\\
&-\log(|\tilde{z}_1-s|^2+|\tilde{z}_2+t|^2)\Bigg]g_\epsilon(s,t)\,dsdt.
\end{aligned}$$

It is not difficult to see that $\tilde{V}_\epsilon^*$ satisfies

$$\begin{aligned}
&\triangle_{\tilde{z}}\tilde{V}_\epsilon^* = 0 \quad \text{for } a_0/2 < \tilde{z}_2,\\
&\triangle_{\tilde{z}}\tilde{V}_\epsilon^* = \left(1-\frac{1}{a_0^2}\right)\left(\frac{\partial}{\partial \tilde{z}_1}\right)^2 \tilde{U}_\epsilon + f_\epsilon(\tilde{z}) \quad \text{for } 0 < \tilde{z}_2 < a_0/2, \quad \text{and}\\
&\tilde{V}_\epsilon^* = 0 \quad \text{at } \tilde{z}_2 = 0.
\end{aligned}$$

$\tilde{V}_\epsilon^*$ and $\nabla_{\tilde{z}}\tilde{V}_\epsilon^*$ are continuous across the line $\tilde{z}_2 = a_0/2$, so the above piecewise formula entirely describes (the distribution) $\triangle_{\tilde{z}}V_\epsilon^*$. The second order derivative $\left(\frac{\partial}{\partial \tilde{z}_1}\right)^2\tilde{V}_\epsilon^*$ is also continuous across the line $\tilde{z}_2 = a_0/2$, but the second order derivative $\left(\frac{\partial}{\partial \tilde{z}_2}\right)^2 \tilde{V}_\epsilon^*$ is in general discontinuous.

Lemma 5.1. *For any fixed ϵ we have that*

$$|\tilde{V}_\epsilon^*(\tilde{z})| \to 0, \qquad \left|\frac{\partial}{\partial \tilde{z}_1}\tilde{V}_\epsilon^*(\tilde{z})\right| \to 0, \quad \textit{and} \ \left|\left(\frac{\partial}{\partial \tilde{z}_1}\right)^2 \tilde{V}_\epsilon^*(\tilde{z})\right| \to 0$$

as $|\tilde{z}_1| \to \infty$, uniformly for $\tilde{z} \in \{0 < \tilde{z}_2 < \frac{1+\epsilon(a_0-1)}{2\epsilon}\}$.

Proof. Since the function g_ϵ is uniformly bounded independently of ϵ, and since

$$\log(|\tilde{z}_1 - s|^2 + |\tilde{z}_2 - t|^2) - \log(|\tilde{z}_1 - s|^2 + |\tilde{z}_2 + t|^2) = -2t\frac{2(\tilde{z}_2 + \theta)}{|\tilde{z}_1 - s|^2 + |\tilde{z}_2 + \theta|^2},$$

where $-a_0/2 < \theta < a_0/2$ (when $0 < t < a_0/2$), it follows immediately that the last integral in the definition of $\tilde{V}_\epsilon^*$,

$$\frac{1}{4\pi}\int_{\tilde{E}} \left[\log(|\tilde{z}_1 - s|^2 + |\tilde{z}_2 - t|^2) - \log(|\tilde{z}_1 - s|^2 + |\tilde{z}_2 + t|^2)\right] g_\epsilon(s,t)\, dsdt,$$

converges to 0 as $|\tilde{z}_1| \to \infty$ (uniformly for $0 < \tilde{z}_2 < \frac{1+\epsilon(a_0-1)}{2\epsilon}$). Let $\tilde{E}^c$ denote the set

$$\tilde{E}^c = \{(s,t) \ : \ 0 < t < a_0/2\} \setminus \tilde{E}.$$

The first integral in the definition of $\tilde{V}_\epsilon^*$ may be bounded by

$$\begin{aligned} C\int_{\tilde{E}^c \cap \{|\tilde{z}_1 - s| < |\tilde{z}_1|/2\}} \Big[\big|\log(|\tilde{z}_1 - s|^2 + |\tilde{z}_2 - t|^2)\big| & \\ + \big|\log(|\tilde{z}_1 - s|^2 + |\tilde{z}_2 + t|^2)\big| \Big] & \left|\left(\frac{\partial}{\partial s}\right)^2 \tilde{U}_\epsilon(s,t)\right| dsdt \\ +C\int_{\tilde{E}^c \cap \{|\tilde{z}_1 - s| \geq |\tilde{z}_1|/2\}} t\frac{|\tilde{z}_2 + \theta|}{|\tilde{z}_1 - s|^2 + |\tilde{z}_2 + \theta|^2} & |\left(\frac{\partial}{\partial s}\right)^2 \tilde{U}_\epsilon(s,t)|\, dsdt. \end{aligned} \tag{21}$$

As $|\tilde{z}_1| \to \infty$ (for $0 < \tilde{z}_2 < \frac{1+\epsilon(a_0-1)}{2\epsilon}$) the second integral in (21) is bounded by

$$C_\epsilon \frac{1}{|\tilde{z}_1|^2}\int_{\tilde{E}^c} |\left(\frac{\partial}{\partial s}\right)^2 \tilde{U}_\epsilon(s,t)|\, dsdt,$$

which clearly approaches 0 (the integral in this estimate is uniformly bounded in ϵ according to Proposition 4.3). For $0 < \tilde{z}_2 < \frac{1+\epsilon(a_0-1)}{2\epsilon}$, $0 < t < a_0/2$ we have

$$|\log(|\tilde{z}_1 - s|^2 + |\tilde{z}_2 - t|^2)| \leq |\log(|\tilde{z}_1 - s|^2)| + K_\epsilon$$

and

$$|\log(|\tilde{z}_1 - s|^2 + |\tilde{z}_2 + t|^2)| \leq |\log(|\tilde{z}_1 - s|^2)| + K_\epsilon,$$

so that the first integral in (21) becomes bounded by

$$\begin{aligned} C_\epsilon \int_{\tilde{E}^c \cap \{|\tilde{z}_1 - s| < |\tilde{z}_1|/2\}} (|\log(|\tilde{z}_1 - s|^2)| + 1)\left|\left(\frac{\partial}{\partial s}\right)^2 \tilde{U}_\epsilon(s,t)\right| dsdt & \\ \leq C_\epsilon e^{-c_\epsilon|\tilde{z}_1|}\int_{\tilde{E}^c \cap \{|\tilde{z}_1 - s| < |\tilde{z}_1|/2\}} (|\log(|\tilde{z}_1 - s|^2)| + 1)\, dsdt & \\ \leq C_\epsilon e^{-c_\epsilon|\tilde{z}_1|}|\tilde{z}_1|\,|\log(|\tilde{z}_1|^2)| \quad \text{as } |\tilde{z}_1| \to \infty. & \end{aligned}$$

Here we used that $|\tilde{z}_1 - s| < |\tilde{z}_1|/2 \Rightarrow |s| > |\tilde{z}_1|/2$, and that $\left| \left(\frac{\partial}{\partial s}\right)^2 \tilde{U}_\epsilon(s,t)\right|$ decreases exponentially in $|s|$ (uniformly in t, for fixed ϵ). This proves that the first integral in the definition of $\tilde{V}_\epsilon^*$ converges to 0 as $|\tilde{z}_1| \to \infty$ (uniformly for $0 < \tilde{z}_2 < \frac{1+\epsilon(a_0-1)}{2\epsilon}$) and it thus verifies the asymptotic statement concerning $\tilde{V}_\epsilon^*$. For the first and second order derivatives of $\tilde{V}_\epsilon^*$ with respect to $\tilde{z}_1$ we write (for $|\tilde{z}_1|$ large)

$$\begin{aligned}\left(\frac{\partial}{\partial \tilde{z}_1}\right)^k \tilde{V}_\epsilon^*(\tilde{z}) = & \frac{a_0^2-1}{4\pi a_0^2} \int_{\{(s,t)\ :\ 0<t<a_0/2\}\setminus \tilde{E}} \Bigg[\log(|\tilde{z}_1 - s|^2 + |\tilde{z}_2 - t|^2) \\ & - \log(|\tilde{z}_1 - s|^2 + |\tilde{z}_2 + t|^2)\Bigg] \left(\frac{\partial}{\partial s}\right)^{2+k} \tilde{U}_\epsilon(s,t)\, dsdt \\ & + \frac{1}{4\pi} \int_{\tilde{E}} \Bigg[\left(\frac{\partial}{\partial \tilde{z}_1}\right)^k \log(|\tilde{z}_1 - s|^2 + |\tilde{z}_2 - t|^2) \\ & - \left(\frac{\partial}{\partial \tilde{z}_1}\right)^k \log(|\tilde{z}_1 - s|^2 + |\tilde{z}_2 + t|^2)\Bigg] g_\epsilon(s,t)\, dsdt\end{aligned}$$

and apply an argument very similar to that above. □

Let $H(x,y)$ denote the function

$$H(x,y) = \frac{2(y^2 - x^2)}{(x^2+y^2)^2}.$$

For $a_0/2 < \tilde{z}_2$ a fairly straightforward computation gives

$$\begin{aligned}\left(\frac{\partial}{\partial \tilde{z}_1}\right)^2 \tilde{V}_\epsilon^*(\tilde{z}_1, \tilde{z}_2) = \frac{a_0^2-1}{4\pi a_0^2} \int_{\{(s,t)\ :\ 0<t<a_0/2\}\setminus \tilde{E}} & \big[H(\tilde{z}_1 - s, \tilde{z}_2 - t) \\ & - H(\tilde{z}_1 - s, \tilde{z}_2 + t)\big] \left(\frac{\partial}{\partial s}\right)^2 \tilde{U}_\epsilon(s,t)\, dsdt \\ + \frac{1}{4\pi} \int_{\tilde{E}} \left[H(\tilde{z}_1 - s, \tilde{z}_2 - t) - H(\tilde{z}_1 - s, \tilde{z}_2 + t)\right] & g_\epsilon(s,t)\, dsdt.\end{aligned}$$

By use of Taylor's formula we now get

$$\begin{aligned}& \left(\frac{\partial}{\partial \tilde{z}_1}\right)^2 \tilde{V}_\epsilon^*(\tilde{z}_1, \tilde{z}_2) \\ & \quad = -\frac{a_0^2-1}{4\pi a_0^2} \int_{\{(s,t)\ :\ 0<t<a_0/2\}\setminus \tilde{E}} 2t\ H_y(\tilde{z}_1 - s, \tilde{z}_2 + \theta) \left(\frac{\partial}{\partial s}\right)^2 \tilde{U}_\epsilon(s,t)\, dsdt \\ & \qquad - \frac{1}{4\pi} \int_{\tilde{E}} 2t\ H_y(\tilde{z}_1 - s, \tilde{z}_2 + \theta) g_\epsilon(s,t)\, dsdt, \end{aligned} \tag{22}$$

where θ lies between $-a_0/2$ and $a_0/2$ (and depends on $\tilde{z}_1 - s$, $\tilde{z}_2$ and t). The derivative H_y is given by

$$|H_y(x,y)| = \left| \frac{y(12x^2 - 4y^2)}{(x^2+y^2)^3} \right| \le C y^{-3}, \quad 1 < y. \tag{23}$$

From Proposition 4.3 we know that

$$\left|\left(\frac{\partial}{\partial s}\right)^2 \tilde{U}_\epsilon(s,t)\right| \le C(s^2+t^2)^{-5/4}$$

for $(s,t) \in \tilde{E}^c$. We also know that g_ϵ is uniformly bounded on $\tilde{E}$, independently of ϵ. Combining these two facts with (22) and (23) we now conclude that

$$\left|\left(\frac{\partial}{\partial \tilde{z}_1}\right)^2 \tilde{V}^*_\epsilon(\tilde{z}_1,\tilde{z}_2)\right| \le C\tilde{z}_2^{-3}, \quad 1+a_0/2 < \tilde{z}_2, \tag{24}$$

with C independent of ϵ. By an entirely similar argument (taking just one derivative, or no derivative at all) we obtain the estimates

$$\left|\frac{\partial}{\partial \tilde{z}_1}\tilde{V}^*_\epsilon(\tilde{z}_1,\tilde{z}_2)\right| \le C\tilde{z}_2^{-2} \quad \text{and} \quad \left|\tilde{V}^*_\epsilon(\tilde{z}_1,\tilde{z}_2)\right| \le C\tilde{z}_2^{-1} \quad \text{for } 1+a_0/2 < \tilde{z}_2. \tag{25}$$

The estimates (24) and (25) are stronger than the corresponding estimates (14) and (15) (with $p=2$) by a factor of $\tilde{z}_2^{-1/2}$. Not surprisingly, these estimates for $\tilde{V}^*_\epsilon$ lead to improvements of the results of Lemma 4.1 by a factor of $|z|^{-1/2}$.

Lemma 5.2. *Let $0<\alpha$. Then there exists C, independent of ϵ, such that*

$$|U_\epsilon(z)| \le C|z|^{-1}, \quad \left|\frac{\partial}{\partial z_1}U_\epsilon(z)\right| \le C|z|^{-2}, \quad \textit{and} \quad \left|\left(\frac{\partial}{\partial z_1}\right)^2 U_\epsilon(z)\right| \le C|z|^{-3}$$

for $z \in \{\max(2,\alpha|z_1|) \le z_2 \le 1/2\epsilon\}$.

Proof. The function $\tilde{U}_\epsilon - \tilde{V}^*_\epsilon$ satisfies

$$\begin{aligned} \triangle(\tilde{U}_\epsilon - \tilde{V}^*_\epsilon) &= 0 \quad \text{for } 0 < \tilde{z}_2 < \frac{1+\epsilon(a_0-1)}{2\epsilon}, \\ \tilde{U}_\epsilon - \tilde{V}^*_\epsilon &= 0 \quad \text{at } \tilde{z}_2 = 0, \\ \tilde{U}_\epsilon - \tilde{V}^*_\epsilon &= O(\epsilon) \quad \text{at } \tilde{z}_2 = \frac{1+\epsilon(a_0-1)}{2\epsilon}, \end{aligned}$$

and for any fixed ϵ, $\tilde{U}_\epsilon - \tilde{V}^*_\epsilon \to 0$ as $|\tilde{z}_1| \to \infty$ (uniformly for $0 < \tilde{z}_2 < \frac{1+\epsilon(a_0-1)}{2\epsilon}$). The desired estimate for U_ϵ follows by an application of the maximum principle just as in the proof of Lemma 4.1 (possibly with a smaller coefficient α') and then a return to the z coordinates. The estimates for $\frac{\partial}{\partial z_1}U_\epsilon$ and $\left(\frac{\partial}{\partial z_1}\right)^2 U_\epsilon$ follow in a completely similar manner. □

Based on Lemma 4.2 and Lemma 5.2 it is now possible to establish the following proposition.

Proposition 5.3. *There exists a constant C, independent of ϵ, such that the functions U_ϵ satisfy*

$$|U_\epsilon(z)| \le C|z|^{-1}, \quad \left|\frac{\partial}{\partial z_1}U_\epsilon(z)\right| \le C|z|^{-2}, \; \textit{and} \; \left|\left(\frac{\partial}{\partial z_1}\right)^2 U_\epsilon(z)\right| \le C|z|^{-3}$$

for $z \in \Phi(\Omega_+) \cap \{z_2 < 1/2\epsilon\}$.

Proof. The proof is exactly the same as that of Proposition 4.3. □

Taking the limit $\epsilon \to 0$, we conclude just as before.

Corollary 5.4. *There exists a constant C, such that*

$$|U(z)| \le C|z|^{-1}, \quad \left|\frac{\partial}{\partial z_1}U(z)\right| \le C|z|^{-2}, \ \textit{and} \ \left|\left(\frac{\partial}{\partial z_1}\right)^2 U(z)\right| \le C|z|^{-3}$$

for $z \in \Phi(\Omega_+)$.

6. The proof of the main theorem. Going back to the function $\tilde{U}$, one can check that it has the representation formula

$$\begin{aligned}\tilde{U}(\tilde{z}) = \frac{a_0^2-1}{4\pi a_0^2}\int_{\{(s,t)\ :\ 0<t<a_0/2\}\setminus\tilde{E}} \Bigg[\log(|\tilde{z}_1-s|^2+|\tilde{z}_2-t|^2) \\ -\log(|\tilde{z}_1-s|^2+|\tilde{z}_2+t|^2)\Bigg]\left(\frac{\partial}{\partial s}\right)^2\tilde{U}(s,t)\,dsdt \\ +\frac{1}{4\pi}\int_{\tilde{E}}\Bigg[\log(|\tilde{z}_1-s|^2+|\tilde{z}_2-t|^2) \\ -\log(|\tilde{z}_1-s|^2+|\tilde{z}_2+t|^2)\Bigg]g(s,t)\,dsdt,\end{aligned} \tag{26}$$

where g denotes the function

$$g = \left(1-\frac{1}{a_0^2}\right)\left(\frac{\partial}{\partial\tilde{z}_1}\right)^2\tilde{U}+f$$

in $\tilde{E}$. To see this, it suffices to notice that the right hand side of (26) satisfies the same equation and the same boundary condition as $\tilde{U}$ and to verify that it also converges to zero as $|\tilde{z}|$ tends to infinity. The fact that the two integrals in (26) converge to zero for $0 < \tilde{z}_2 < K$ as $|\tilde{z}_1| \to \infty$ follows from an argument very similar to that used in the proof of Lemma 5.1. (One compensates for the fact that $\tilde{U}$ does not necessarily decrease exponentially in z_1 by using the decay estimate of Corollary 4.4.) As we shall observe later, it is not difficult to prove that these two integrals are also bounded by $C\tilde{z}_2^{-1}$ (uniformly in $\tilde{z}_1$) as $\tilde{z}_2 \to \infty$. A combination of these two facts yields that the right hand side in the formula (26) converges to zero as $|\tilde{z}| \to \infty$, which now implies that it is indeed a representation of $\tilde{U}$. For $a_0/2 < \tilde{z}$ we calculate

$$\begin{aligned}\frac{\partial}{\partial z_2}\tilde{U}(\tilde{z}) = \frac{a_0^2-1}{4\pi a_0^2}\int_{\{(s,t):\ 0<t<a_0/2\}\setminus\tilde{E}}\Bigg[\frac{2(\tilde{z}_2-t)}{|\tilde{z}_1-s|^2+|\tilde{z}_2-t|^2} \\ -\frac{2(\tilde{z}_2+t)}{|\tilde{z}_1-s|^2+|\tilde{z}_2+t|^2}\Bigg]\left(\frac{\partial}{\partial s}\right)^2\tilde{U}(s,t)\,dsdt \\ +\frac{1}{4\pi}\int_{\tilde{E}}\left[\frac{2(\tilde{z}_2-t)}{|\tilde{z}_1-s|^2+|\tilde{z}_2-t|^2}-\frac{2(\tilde{z}_2+t)}{|\tilde{z}_1-s|^2+|\tilde{z}_2+t|^2}\right]g(s,t)\,dsdt.\end{aligned}$$

Introducing $K(x,y) = \frac{2y}{x^2+y^2}$, we obtain

$$\begin{aligned}\frac{\partial}{\partial z_2}\tilde{U}(\tilde{z}) = -\frac{a_0^2-1}{4\pi a_0^2}\int_{\{(s,t)\ :\ 0<t<a_0/2\}\setminus\tilde{E}} 2tK_y(\tilde{z}_1-s,\tilde{z}_2+\theta)\left(\frac{\partial}{\partial s}\right)^2\tilde{U}(s,t)\,dsdt \\ -\frac{1}{4\pi}\int_{\tilde{E}}2tK_y(\tilde{z}_1-s,\tilde{z}_2+\theta)g(s,t)\,dsdt,\end{aligned}$$

with θ lying between $-a_0/2$ and $a_0/2$ (and depending on $\tilde{z}_1 - s$, $\tilde{z}_2$, and t). Since $|K_y(x,y)| = |\frac{2(x^2-y^2)}{(x^2+y^2)^2}| \le Cy^{-2}, 1 < y$, the known decay of $\left(\frac{\partial}{\partial s}\right)^2 \tilde{U}$ (Corollary 4.4) and the boundedness of g imply

$$\left|\frac{\partial}{\partial \tilde{z}_2}\tilde{U}(\tilde{z})\right| \le C\tilde{z}_2^{-2}, \quad 1 + a_0/2 < \tilde{z}_2. \tag{27}$$

An argument identical to that given just above (taking no derivative) would immediately yield that the two integrals in the right hand of the formula (26) are bounded by $C\tilde{z}_2^{-1}$. (We needed this fact earlier when we showed that (26) is indeed a representation of $\tilde{U}$.) Rewritten in terms of the z coordinates, (27) gives

$$\left|\frac{\partial}{\partial z_2}U(z)\right| \le Cz_2^{-2}, \quad 1/2 + c < z_2, \tag{28}$$

for some $0 < c$. Using the fact that

$$\left(\frac{\partial}{\partial z_2}A(z_2)\frac{\partial}{\partial z_2}U(z)\right) = -A(z_2)\left(\frac{\partial}{\partial z_1}\right)^2 U(z) = O(|z|^{-3}), \quad z \in \Phi(\Omega_+), \tag{29}$$

as asserted by Corollary 5.4, we are now able to prove the following lemma.

Lemma 6.1. *There exists a constant C, such that*

$$\left|\frac{\partial}{\partial z_2}U(z)\right| \le C|z|^{-2}$$

for $z \in \Phi(\Omega_+) \setminus \{z_2 = 1/2\}$.

Proof. From (28) it follows immediately that

$$\left|\frac{\partial}{\partial z_2}U(z)\right| \le Cz_2^{-2} \le C|z|^{-2} \quad \text{for } \max(1/2 + c, |z_1|) \le z_2. \tag{30}$$

For $0 < z_2$ and $\max(K, z_2) \le |z_1|$ (with K sufficiently large) we have that

$$\left(A\frac{\partial}{\partial z_2}U\right)(z_1,z_1) - \left(A\frac{\partial}{\partial z_2}U\right)(z_1,z_2) = \int_{z_2}^{z_1}\left(\frac{\partial}{\partial z_2}A\frac{\partial}{\partial z_2}U\right)(z_1,t)\,dt,$$

and therefore

$$\begin{aligned}\left|\left(A\frac{\partial}{\partial z_2}\right)U(z_1,z_2)\right| &\le C|z|^{-2} + C\int_{z_2}^{z_1}(|z_1|^2 + |t|^2)^{-3/2}\,dt\\ &\le C|z|^{-2} \quad \text{for } \max(K, z_2) \le |z_1|.\end{aligned} \tag{31}$$

Here we have used the estimates (29) and (30) (and the fact that we may select $K > 1/2 + c$) to derive the first inequality. Based on a combination of (30) and (31) we conclude that

$$\left|\frac{\partial}{\partial z_2}U(z)\right| \le C|z|^{-2} \quad \text{for } |z| > \sqrt{2}K, \ z \notin \{z_2 = 1/2\}.$$

The function A is discontinuous across $\{z_2 = 1/2\}$ and the derivative $\frac{\partial}{\partial z_2}U$ is not properly defined there; this is why we subtract the set $\{z_2 = 1/2\}$. The above estimate in combination with an elliptic regularity estimate (for $|z|$ small) immediately leads to the desired result. $\square$

Combining Corollary 5.4 and Lemma 6.1 we finally arrive at the following theorem.

THEOREM 6.2. *The solution, $u \in H^1(\Omega)$, to the boundary value problem* (1)–(2)*, with conductivity a given by* (3) *(and ϕ smooth) is in $W^{1,\infty}(\Omega)$ for any fixed $0 < a_0 < \infty$.*

Proof. We already know (cf. [4]) that $u \in C^{\beta}(\Omega)$ for some $\beta > 0$. From standard elliptic regularity results we also know that u is smooth, and therefore bounded, near $\partial\Omega$. It thus suffices to prove that $\nabla u \in L^{\infty}(\Omega)$. As already explained earlier (in section 2) we may restrict attention to u that are odd in the x_1-axis. For such u, it suffices to show that $|\nabla u| \leq C$ in $\Omega_+ \setminus \{x_1^2 + (x_2-1)^2 = 1\} = (\Omega \cap \{0 < x_2\}) \setminus \{x_1^2 + (x_2-1)^2 = 1\}$. The solution u has the form

$$u(x) = U \circ \Phi(x),$$

where U has been studied in the preceding three sections. We calculate

$$\nabla u(x) = D\Phi^t(x)(\nabla_z U)(\Phi(x)). \tag{32}$$

The matrix $D\Phi$ is given by

$$D\Phi = \begin{pmatrix} \dfrac{\partial z_1}{\partial x_1} & \dfrac{\partial z_1}{\partial x_2} \\ \dfrac{\partial z_2}{\partial x_1} & \dfrac{\partial z_2}{\partial x_2} \end{pmatrix},$$

and a simple computation yields

$$\left|\frac{\partial z_i}{\partial x_j}\right| = \left|\frac{\delta_{ij}(x_1^2+x_2^2) - 2x_i x_j}{(x_1^2+x_2^2)^2}\right| \leq C\frac{1}{x_1^2+x_2^2}, \qquad x \in \Omega_+. \tag{33}$$

At the same time, Corollary 5.4 and Lemma 6.1 give that

$$|\nabla_z U(\Phi(x))| \leq C|\Phi(x)|^{-2} = C(x_1^2+x_2^2) \quad \text{for } x \in \Omega_+ \setminus \{x_1^2 + (x_2-1)^2 = 1\}. \tag{34}$$

Combining (32), (33), and (34) we finally obtain

$$|\nabla u(x)| \leq C \qquad x \in \Omega_+ \setminus \{x_1^2 + (x_2-1)^2 = 1\},$$

as desired. $\square$

Remark. In the appendix we shall see that the case which formally corresponds to $a_0 = 0$ admits solutions that are discontinuous at the origin. Thus, it would not be reasonable to expect the solution u (given fixed boundary data) to have a gradient that is uniformly bounded, independently of a_0. The L^{∞} norm of $|\nabla u|$ may well become unbounded as a_0 approaches 0. By duality the same phenomenon may also occur as a_0 approaches ∞.

7. Appendix.

In this appendix we give a short review of what happens in the two cases that at least formally correspond to $a_0 = 0$ and $a_0 = \infty$. In both cases the relevant boundary value problems live in $\Omega \setminus \{\text{the fibers}\}$. They require that

$$\triangle u^0 = \triangle u^{\infty} = 0 \quad \text{in } \Omega \setminus \{\text{the fibers}\}, \tag{35}$$

with

$$\frac{\partial}{\partial n} u^0 = 0 \quad \text{on the boundaries of the fibers,} \tag{36}$$

and

$$u^\infty = \text{ constant on the boundary of each fiber,} \tag{37}$$

respectively. The constants in the boundary condition (37) are not arbitrary; they are those (or rather, it is that) for which the energy expression attains its smallest value. On the boundary $\partial\Omega$, the two solutions satisfy the common boundary condition

$$u^0 = u^\infty = \phi.$$

Given smooth boundaries, the solutions u^0 and u^∞ would be obtained as limits of the solution to (1), as a_0 tends to 0 and as a_0 tends to ∞, respectively. We suspect that the same holds true for boundaries with cusps as here, but we have not carried out the analysis. This is why we use the terminology "formally corresponding to $a_0 = 0$ and $a_0 = \infty$."

In the transformed variables $z = \Phi(x)$, with Φ as before, (35)–(37) become

$$\triangle U^0 = \triangle U^\infty = 0 \quad \text{in } \{z \in \Phi(\Omega), \; -1/2 < z_2 < 1/2\}, \tag{38}$$

with

$$\frac{\partial}{\partial z_2} U^0 = 0 \quad \text{on } z_2 = \pm 1/2 \tag{39}$$

and

$$U^\infty = c_\pm \quad \text{on } z_2 = \pm 1/2, \tag{40}$$

respectively. The common boundary condition on $\partial\Omega$ transforms into

$$U^0 = U^\infty = \phi \circ \Phi^{-1} \quad \text{on } \Phi(\partial\Omega).$$

For the moment we restrict attention to the boundary value problem for U^0. At the very end of this section, we return to make some remarks about the boundary value problem for U^∞. As mentioned previously, any solution to this boundary value problem may be written as a sum of two harmonic functions in $\{z \in \Phi(\Omega), -1/2 < z_2 < 1/2\}$, one which is even in the z_1-axis and one which is odd. These two functions have somewhat different behavior. We first consider the even function, which, when restricted to the interval $0 < z_2 < 1/2$, is a solution to

$$\begin{aligned} \triangle U^0 = \quad & \text{in } \{z \in \Phi(\Omega), \;\; 0 < z_2 < 1/2\}, \\ \frac{\partial}{\partial z_2} U^0 = 0 \quad & \text{on } \{z_2 = 1/2\} \text{ and on } \{z \in \Phi(\Omega), \;\; z_2 = 0\}, \\ U^0 = \phi \circ \Phi^{-1} \quad & \text{on } \{z \in \Phi(\partial\Omega), \;\; 0 < z_2\}. \end{aligned} \tag{41}$$

Separation of variables now immediately gives that U^0 must have the form

$$U^0(z_1, z_2) = \beta_0 + \sum_{n=1}^\infty \beta_n \cos(2n\pi z_2) e^{-2n\pi z_1} \quad \text{for } z_1 \text{ sufficiently positive,} \tag{42}$$

$$U^0(z_1, z_2) = \beta_0' + \sum_{n=1}^\infty \beta_n' \cos(2n\pi z_2) e^{2n\pi z_1} \quad \text{for } z_1 \text{ sufficiently negative.} \tag{43}$$

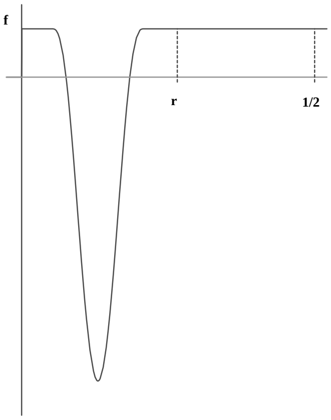

Fig. 10. *The function f.*

Conversely, any function, U^0, that is defined by (42) for $z_1 > 0$ and by (43) for $z_1 < 0$ is a solution to

$$\triangle U^0 = 0 \quad \text{in } \{z_1 \neq 0\}$$

with boundary conditions

$$\frac{\partial}{\partial z_2} U^0 = 0 \quad \text{on } \{z_2 = 0\} \text{ and on } \{z_2 = 1/2\}.$$

We shall now use this fact to construct a rather large class of solutions.

Select β_0 and β_0' arbitrarily, and let $f(z_2)$ denote any smooth, even, and periodic function with period 1, such that $f(z_2) = \beta_0' - \beta_0$ for $r < z_2 < 1/2$ $(0 < r)$ and such that $\int_0^{1/2} f(s)\, ds = 0$. A graph of such a function on the interval $(0, 1/2)$ is illustrated in Figure 10. The value of r is selected small enough, so that the line segment $\{z_1 = 0, \;\; 0 < z_2 < r\}$ lies inside $\Phi(\mathbb{R}^2 \setminus \Omega)$.

Let β_n, $n \geq 1$, be the cosine Fourier coefficients of the function $f/2$, i.e.,

$$2 \sum_{n=1}^{\infty} \beta_n \cos(2n\pi z_2) = f(z_2). \tag{44}$$

Since the integral of f is zero, the expansion does not contain any 0th order term. Since f is smooth, the β_n converge very fast to zero.

Let β'_n, $n \geq 1$, be given by

$$\beta'_n = -\beta_n, \tag{45}$$

and consider U^0 defined by (42) for $z_1 > 0$, and by (43) for $z_1 < 0$. Due to (44), (45), and the fact that $f(z_2) = \beta'_0 - \beta_0$ for $r < z_2 < 1/2$, we observe that U^0 is continuous across the line segment $\{z_1 = 0, \quad r < z_2 < 1/2\}$. The fact that $\beta'_n = -\beta_n$ ensures that $\frac{\partial}{\partial z_1} U^0$ is even in z_1 and thus automatically continuous across the line segment $\{z_1 = 0, r < z_2 < 1/2\}$. We conclude that this U^0 is indeed harmonic in all of $\Phi(\Omega) \cap \{0 < z_2 < 1/2\}$ and satisfies the boundary conditions

$$\frac{\partial}{\partial z_2} U^0 = 0 \quad \text{on } \{z_2 = 1/2\} \quad \text{and on } \{z \in \Phi(\Omega), \quad z_2 = 0\}.$$

The values of U^0 on $\Phi(\partial\Omega) \cap \{0 < z_2\}$ (the remainder of the boundary) naturally depend on f and correspond to a particular choice of ϕ.

Since β_0 and β'_0 were chosen arbitrarily we have $\beta'_0 \neq \beta_0$ in general. In the z coordinates β_0 and β'_0 are the limits of U^0 at $z_1 = +\infty$ and $z_1 = -\infty$, respectively. In the x-coordinates these are the limits of u^0 as we approach the origin through the cusp on the right and through the cusp on the left, respectively.

We have thus constructed a family of solutions which are discontinuous at the origin (and are even in the x_1-axis). They exhibit the behavior typicial of solutions when the data ϕ has an odd component with respect to the x_2-axis (and is even in the x_1-axis).

If the data ϕ is even in both the x_2- and the x_1-axis, then we must necessarily have $\beta'_n = \beta_n$ for all $0 \leq n$ (in the expansion (42) and (43)) and so u^0 has to be continuous at the origin. If the data ϕ is odd in the x_1-axis then it is very easy, again by separation of variables, to see that u^0 is continuous at the origin (its value is zero).

In all the cases considered above the function u^0 is C^∞ inside each of the cusps and all its derivatives (of order ≥ 1) vanish at the origin.

Let us now briefly return to the case $a_0 = \infty$. When ϕ is even in the x_1-axis, separation of variables readily gives that $U^\infty(z)$ must have the form

$$U^\infty(z_1, z_2) - c_0 = \sum_{n=1}^{\infty} \beta_n \cos((2n+1)\pi z_2) e^{-(2n+1)\pi z_1} \quad \text{for } z_1 \text{ sufficiently positive,}$$

$$U^\infty(z_1, z_2) - c_0 = \sum_{n=1}^{\infty} \beta'_n \cos((2n+1)\pi z_2) e^{(2n+1)\pi z_1} \quad \text{for } z_1 \text{ sufficiently negative,}$$

where c_0 is the common value attained on the fibers (there is just one constant value, due to the evenness of the solution). It follows immediately that u^∞ is continuous at 0 (in the x-coordinates), and that all its derivatives vanish at 0. When ϕ is odd in the x_1-axis, so are u^∞ and U^∞. Separation of variables thus yields

$$U^\infty(z_1, z_2) - 2c_0 z_2 = \sum_{n=1}^{\infty} \beta_n \sin(2n\pi z_2) e^{-2n\pi z_1} \quad \text{for } z_1 \text{ sufficiently positive,} \tag{46}$$

$$U^\infty(z_1, z_2) - 2c_0 z_2 = \sum_{n=1}^{\infty} \beta'_n \sin(2n\pi z_2) e^{2n\pi z_1} \quad \text{for } z_1 \text{ sufficiently negative,} \tag{47}$$

where c_0 is the value attained on the upper fiber. However, in this case the requirement that u^∞ be H^1 in the x-coordinates implies that the gradients ∇u^∞ and ∇U^∞ must be L^2 in the x- and in the z-coordinates, respectively. Thus, c_0 must be equal to 0. It follows, using the representation (46) and (47), that u^∞ is continuous at $x = 0$ (it has value 0), and that, similarly, all its derivatives vanish at $x = 0$.

The fact that all the solutions are C^∞ when regarded as functions in just each individual cusp would also follow from the analysis in [7].

As mentioned earlier, it would be very interesting to analyze the geometric setting when the fibers are close but not quite touching, say, the cross-sections are ϵ apart vertically. A few things can be said related to the calculations carried out above, as the distance ϵ tends to 0. When the boundary data ϕ has an odd component with respect to the x_2-axis and is otherwise even in the x_1-axis, then the singularity mentioned above for u^0 gives rise to a gradient (an x_1-derivative $\frac{\partial}{\partial x_1} u^0_\epsilon(0)$) which becomes unbounded as ϵ tends to zero. The solution u^∞ for the case of a ϕ, which is even in the x_2-axis but has an odd component with respect to the x_1-axis, is related to the previous solution by harmonic conjugation (rotation of the gradient by 90 degrees). We thus in general, in this case, also obtain a gradient (an x_2-derivative $\frac{\partial}{\partial x_2} u^\infty_\epsilon(0)$) which becomes unbounded as ϵ tends to zero. This in spite of the fact that there is no irregularity in the "limiting" solution when the fibers touch. The rate at which this gradient becomes unbounded has actually been calculated in [2], for a special solution corresponding to uniform antiplane shear (see also [9]). For this special solution, the rate turns out to be $\epsilon^{-1/2}$; we believe this is the generic rate for the above mentioned symmetries in the boundary data. It should also be mentioned that for two touching fibers and $0 < a_0 < \infty$, Budiansky and Carrier [2] calculate a finite value for the stress $\left(a \frac{\partial}{\partial x_2} u\right)(0)$ of the same special (antiplane shear) solution. This calculation relates $\left(a \frac{\partial}{\partial x_2} u\right)(0)$ to the "shear at infinity."

Acknowledgments. This work was initiated while Eric Bonnetier was visiting the Department of Mathematics at Rutgers University; it was completed while Michael Vogelius was visiting the Centre Emile Borel at the Institut Henri Poincaré. The hospitality of these two institutions is gratefully acknowledged. Both authors would like to thank Ivo Babuska of the University of Texas for stimulating discussions and communications that provoked their initial interest in this problem.

BEHAVIOR OF SOLUTIONS NEAR THE FLAT HATS OF STATIONARY SOLUTIONS FOR A DEGENERATE PARABOLIC EQUATION*

SHINGO TAKEUCHI†

Abstract. The behavior of solutions u of the degenerate parabolic equation $u_t = \lambda(|u_x|^{p-2}u_x)_x + |u|^{q-2}u(1-|u|^r)$, defined in $(0,1)\times(0,+\infty)$, is discussed. It is well known that there exists a stationary solution ϕ which has an open set Ω where it is identically ± 1. We call a graph $\{(x,\phi(x)); x\in\Omega\}$ flat hats. We investigate the behavior of $u(x,t)$ near $(x,t)\in\Omega\times[0,+\infty)$ where $|u(x,t)-\phi(x)|$ is very small. We will give a sufficient condition for initial data u_0 that the intersection points between the flat hats of ϕ and u never change as a function of t along $u(\cdot,t;u_0)$. Even if the condition failed, it is also proved that the changing area of the intersection points is uniformly bounded for t. Moreover we study stability properties for the positive stationary solution and the sign-changing stationary solutions.

Key words. degenerate parabolic equation, p-Laplace operator, flat hat, comparison theorem, intersection comparison

1. Problem and results.

In this paper we discuss the behavior of solutions of the following degenerate parabolic equation:

$$\text{(P)}\qquad \begin{cases} u_t = \lambda(|u_x|^{p-2}u_x)_x + f(u), & (x,t)\in(0,1)\times(0,+\infty),\\ u(0,t)=u(1,t)=0, & t\in(0,+\infty),\\ u(x,0)=u_0(x), & x\in(0,1), \end{cases}$$

where $p>2$ and λ is a positive parameter. The p-Laplace operator $\operatorname{div}(|\nabla u|^{p-2}\nabla u) = (|u_x|^{p-2}u_x)_x$ appears in the study of motions of non-Newtonian fluids in rheology (see, e.g., [2]). Many authors have studied (P) with $f\equiv 0$ or a source type $f(u)=|u|^{q-2}u$ (for example, [1, 3, 4, 7, 11, 12, 13, 14, 16]), and in particular, the latter case has been extensively investigated in view of a blow-up problem. For a source-absorption type $f(u)=|u|^{q-2}u(1-|u|^r)$, there are a few works by Guedda–Veron [8], Kamin–Veron [10], and Takeuchi–Yamada [15].

We will recall the work of [15] for $f(u)=|u|^{q-2}u(1-|u|^r)$ with $q\ge 2$ and $r>0$. For any initial datum $u_0\in L^2=L^2(0,1)$, there exists a unique global strong solution $u(\cdot;u_0)$ of (P), which belongs to $C([0,+\infty);L^2)\cap C((0,+\infty);W_0^{1,p})$ [15, Theorem 2.1]. We can also see that $u(t;u_0)$ approaches its ω-limit set $\omega(u_0)$ as $t\to+\infty$ and that $\omega(u_0)$ is included in E_λ, which is the set of all solutions of

$$\text{(SP)}\qquad \begin{cases} \lambda(|\phi_x|^{p-2}\phi_x)_x + f(\phi) = 0, & x\in(0,1),\\ \phi(0)=\phi(1)=0 \end{cases}$$

[15, Theorem 2.2], so that $u(t;u_0)$ converges to E_λ as $t\to+\infty$.

The structure of E_λ in the degenerate diffusion case $p > 2$ is very different from that in the linear diffusion case $p = 2$. For $p = 2$, all solutions of (SP) satisfy $|\phi(x)| < 1$ for $x \in [0, 1]$, E_λ is a discrete set for any $\lambda > 0$, and stability properties of all functions in E_λ are studied well (for example, see [9, pp. 118–128]). In case $p > 2$, if λ is sufficiently small, there exist solutions of (SP) for which the set $\{x \in [0, 1]; |\phi(x)| = 1\}$ is nonempty and E_λ consists of a discrete set and some continua ([15, Theorems 3.1–3.3], [8], and [10]). We will explain these facts more concretely. For $p > 2$, define

$$\Lambda_l := (l+1)\left\{\frac{\lambda(p-1)}{p}\right\}^{1/p}\int_0^1 (F(1)-F(\xi))^{-1/p}d\xi, \quad l = 0, 1, 2, \dots ,$$

where $F(\xi) = \int_0^\xi f(s)ds$. Then $\{\Lambda_l\}_{l=0}^\infty$ is well defined and is strictly increasing. For $\Lambda_{2l+1} < 1$, we define a family of open intervals $\{\Omega_k\}_{k=0}^l$ by

$$\Omega_k := \begin{cases} (\Lambda_0, \Lambda_0 + c_0), & k = 0, \\ (\Lambda_{2k} + \sum_{j=0}^{k-1} c_j, \Lambda_{2k} + \sum_{j=0}^{k} c_j), & k = 1, 2, \dots , l, \end{cases}$$

and a family of closed intervals $\{\Pi_k\}_{k=0}^{l+1}$ by

$$\Pi_k := \begin{cases} [0, \Lambda_0], & k = 0, \\ [\Lambda_{2k-2} + \sum_{j=0}^{k-1} c_j, \Lambda_{2k} + \sum_{j=0}^{k-1} c_j], & k = 1, 2, \dots , l, \\ [\Lambda_{2l} + \sum_{j=0}^{l} c_j, 1], & k = l + 1, \end{cases}$$

where $\{c_j\}_{j=0}^l$ is any finite sequence satisfying

$$c_j > 0 \quad \text{and} \quad \sum_{j=0}^{l} c_j = 1 - \Lambda_{2l+1}. \tag{1.1}$$

Note that $|\Omega_k| = c_k$ and

$$2|\Pi_0| = 2|\Pi_{l+1}| = |\Pi_k| = \Lambda_1, \qquad k = 1, 2, \dots , l,$$
$$[0, 1] = \bigcup_{k=0}^{l} \Omega_k \cup \bigcup_{k=0}^{l+1} \Pi_k \quad \text{(disjoint union)}.$$

When $\lambda > 0$ satisfies $\Lambda_{2l+1} < 1$ for some l, there exists a solution $\phi = \phi_l$ having exactly l-zero points in $(0, 1)$ with $\phi_x(0) > 0$ such that it is expressed as

$$\phi(x) = \begin{cases} (-1)^k, & x \in \Omega_k,\ k = 0, 1, 2, \dots , l, \\ g(x), & x \in \Pi_0, \\ (-1)^k g\left(x - \Lambda_{2k-1} - \sum_{j=0}^{k-1} c_j\right), & x \in \Pi_k,\ k = 1, 2, \dots , l, \\ (-1)^{l+1} g(x-1), & x \in \Pi_{l+1}, \end{cases} \tag{1.2}$$

where g is a continuously differentiable, strictly monotone increasing and odd function on $[-\Lambda_0, \Lambda_0]$ satisfying $g'(0) = \{pF(1)/\lambda(p-1)\}^{1/p}$, $g(\Lambda_0) = 1$, and $g'(\Lambda_0) = 0$. (Clearly, a stationary solution satisfying $\phi_x(0) < 0$ has a similar expression to (1.2).)

Since we can choose $\{c_j\}_{j=0}^{l}$ arbitrarily as long as it satisfies (1.1), such solutions generate a continuum in E_λ. In the expression (1.2), each Ω_k, $k = 0, 1, \dots, l$, is called a *flat core of* ϕ and we set $\Omega := \bigcup_{k=0}^{l} \Omega_k$. The graph of ϕ on each Ω_k is said to be a *flat hat of* ϕ, and the graph of ϕ on each Π_k is called a *layer of* ϕ. In [15], little information on the stability for such stationary solutions has been obtained though we have discussed stability properties of stationary solutions without flat hats. In this connection, the self-similar solutions with flat parts of degenerate parabolic equations are well known and play an important role for the blow-up solution. This is a so-called countable Q-set of profiles (cf. [1, 7]).

Our purpose is to study the behavior of nonstationary solution u of (P) when it stays in a neighborhood of a stationary solution with flat hats. Before stating our results, we will prepare a set of functions. Let $\Lambda_{2l+1} < 1$ and let ϕ be a solution of (SP) with l-zero points. For any compact subset I in Ω and any open neighborhood J of I in Ω, we define

$$U_0(I, J) := \{u_0 \in C([0,1]); u_0(x) = \phi(x) \text{ if } x \in I,\ u_0(x) \neq \phi(x) \text{ if } x \in J \setminus I\}.$$

For any (x,t) where solution u of (P) intersects flat hats of ϕ, the reaction effect for u disappears and there exists only the diffusion effect for u, whose coefficient is $\lambda(p-1)|u_x|^{p-2}$. When u_0 touches ϕ anywhere in its flat hats, we can expect that $u(t; u_0)$ keeps on touching ϕ there and that the touching area does not spread out. In fact, this is right if u_0, which touches the flat hats, is very close to ϕ in the following sense.

Theorem 1.1. *Let $\Lambda_{2l+1} < 1$ and let ϕ be a solution of* (SP) *with flat hats and l-zero points. Take any $\varepsilon \in (0, r)$, any connected compact subset $I := [a, b]$ in Ω, any open neighborhood J of I in Ω, and any open neighborhoods $N(a)$ and $N(b)$ in J. Then there exists $\delta_0 = \delta_0(\varepsilon, I, J, N(a), N(b)) > 0$ with the following property*:

> *For any $\delta \in (0, \delta_0)$ there exists an open neighborhood J_δ of I in J such that if $u_0 \in U_0(I, J)$, $\|u_0 - \phi\|_\infty < \delta$, and for $z = a$ and $z = b$*
>
> $$|u_0(x) - \phi(x)| \le \left(\frac{p-2}{p}\right)^{p/(p-2)} \left\{\frac{p(r-\varepsilon)}{2\lambda(p-1)}\right\}^{1/(p-2)} |x - z|^{p/(p-2)}, \quad x \in N(z),$$
>
> *then $u(\cdot, t; u_0) \in U_0(I, J_\delta)$ for all $t \in [0, +\infty)$ and $|J \setminus J_\delta| \to 0$ as $\delta \to 0$.*

In case u_0 crosses a flat hat transversely, the diffusion may cause their intersection points to change as a function of t along $u(t; u_0)$. The following result assures that the area on which the intersections may change is uniformly bounded for t.

Theorem 1.2. *Let $\Lambda_{2l+1} < 1$ and let ϕ be a solution of* (SP) *with flat hats and l-zero points. Take any point x_0 in Ω and any open neighborhood J of x_0 in Ω. Then there exists $\delta_0 = \delta_0(x_0, J) > 0$ with the following property*:

> *For any $\delta \in (0, \delta_0)$ there exist open sets P_δ and J_δ such that $x_0 \in P_\delta \subset \overline{P_\delta} \subset J_\delta \subset J$ and that, if $u_0 \in U_0(\{x_0\}, J)$ and $\|u_0 - \phi\|_\infty < \delta$, then*
>
> $$u(x, t; u_0) \neq \phi(x) \qquad \textit{for } (x,t) \in (J_\delta \setminus P_\delta) \times [0, +\infty),$$
>
> *and $|P_\delta|$, $|J \setminus J_\delta| \to 0$ as $\delta \to 0$.*

The proofs of Theorems 1.1 and 1.2 rely on the comparison theorem. Phase-plain analysis for (SP) will help us to find suitable comparison functions. Combining the proofs of these theorems, we can see the behavior of $u(\cdot; u_0)$ for more general u_0.

Theorems 1.1 and 1.2 give information about the motion of intersection points between u and the flat hats of ϕ. We can regard the analysis for intersections as one of *intersection comparison* (see [5, 6, 14]). When the asymptotic behavior is concerned, it is very important to study the stability of the positive stationary solution ϕ_0 with a flat hat. Our previous result [15] says only that ϕ_0 is attractive with respect to L^∞-norm. In this paper we can also prove that ϕ_0 is asymptotically stable in the following sense.

THEOREM 1.3. *Let ϕ_0 be the positive stationary solution with a flat hat. For any $\varepsilon > 0$, there exists $\delta > 0$ such that $\|u_0 - \phi_0\|_\infty < \delta$ implies $\|u(t; u_0) - \phi_0\|_\infty < \varepsilon$ for all $t \in [0, +\infty)$. Furthermore, $u(t; u_0) \to \phi_0$ in L^∞ as $t \to +\infty$.*

From these theorems for flat hats, we may assert that flat hats of stationary solutions give little disturbance to nonstationary solutions. The proof of Theorem 1.3 uses the following *weak comparison theorem*, which enables us to choose piecewise smooth functions as comparison functions. (The definitions of a *weak upper solution* and a *weak lower solution* are given in Definition 3.1.)

THEOREM 1.4. *Let u and v be a weak upper and a weak lower solution of* (P) *in $[0, T]$ for initial data u_0 and v_0, respectively. If $u_0(x) \geq v_0(x)$ almost everywhere (a.e.) $x \in (0, 1)$, then $u(x, t) \geq v(x, t)$ for a.e. $(x, t) \in (0, 1) \times (0, T)$.*

A weak comparison theorem for (P) with $f \equiv 0$ is given by DiBenedetto [3] and Kilpeläinen–Lindqvist [11]. Though results of this sort don't seem to be entirely new, we will make sure of its proof.

Owing to Theorem 1.4, we can also obtain information on stability properties of sign-changing stationary solutions ϕ_l ($l \geq 1$) with flat hats. In [15], we have shown that the sign-changing solutions with adjoining layers (i.e., $c_j = 0$ for some j in (1.1)) are all unstable in Lyapunov's sense. On the other hand, if we are concerned with the sign-changing solutions whose layers are separated by flat hats, no information has been derived for stability properties of each solution. In the present paper, we will prove that each ϕ_l is *conditionally stable*, i.e., stable for initial data that satisfy a certain condition for the shape near layers of ϕ_l.

The content of this paper is as follows. In section 2, constructing comparison functions with the aid of the phase-plain analysis, we prove Theorems 1.1 and 1.2. Moreover, a remark for more general u_0 is given. Section 3 is devoted to the proof of a weak comparison theorem. In sections 4 and 5, we show Theorem 1.3 and give some stability properties of sign-changing stationary solutions with flat hats by choosing suitable comparison functions.

2. Local behavior of solutions near flat hats. In this section we show Theorems 1.1 and 1.2 by the comparison theorem in [15] with use of suitable comparison functions and give a comment on the local behaviors of nonstationary solutions. First of all, we prepare the following lemma, which plays an important role in constructing comparison functions.

LEMMA 2.1. *For each $M > 0$, there exists a unique function $h^* = h^*_M$ satisfying the following properties*:

(i) *there exists a unique $x_M > 0$ such that $h^*(x_M) = M + 1$,*

(ii) *h^* is strictly monotone increasing in $(0, x_M)$,*

(iii) *h^* is a solution of the initial value problem*:

$$\begin{cases} \lambda(|h^*_x|^{p-2} h^*_x)_x + f(h^*) = 0, & x \in (0, x_M), \\ h^*(0) = 1, \quad h^*_x(0) = 0, \end{cases}$$

(iv) $h^*_{M_1}(x) = h^*_{M_2}(x)$ *for* $x \in (0, M_1)$, *where* $0 < M_1 \leq M_2$.
Furthermore, for any $\varepsilon \in (0, r)$ *there exists* $\theta = \theta(h^*) \in (0, x_M)$ *such that*

$$C_\varepsilon^- x^{p/(p-2)} \leq h^*(x) - 1 \leq C_\varepsilon^+ x^{p/(p-2)} \quad \textit{for } x \in [0, \theta), \tag{2.1}$$

where

$$C_\varepsilon^\pm = \left(\frac{p-2}{p}\right)^{p/(p-2)} \left\{\frac{p(r \pm \varepsilon)}{2\lambda(p-1)}\right\}^{1/(p-2)}.$$

Proof. The first half of the assertion is directly deduced from the phase plain analysis (see [15]). We note that x_M is given by

$$x_M = \left\{\frac{\lambda(p-1)}{p}\right\}^{1/p} \int_1^{1+M} (F(1) - F(\xi))^{-1/p} d\xi < +\infty$$

for $p > 2$. Moreover, it is easy to see that h^* satisfies

$$x = \left\{\frac{\lambda(p-1)}{p}\right\}^{1/p} \int_1^{h^*(x)} (F(1) - F(\xi))^{-1/p} d\xi \quad \text{for } x \in (0, x_M). \tag{2.2}$$

Observe that for any $\varepsilon \in (0, r)$ there exists $\eta > 0$ such that

$$\left(\frac{r-\varepsilon}{2}\right)(\xi - 1)^2 \leq F(1) - F(\xi) \leq \left(\frac{r+\varepsilon}{2}\right)(\xi - 1)^2 \quad \text{for } \xi \in (1, 1+\eta). \tag{2.3}$$

Thus taking small $\theta \in (0, x_M)$ such that $h^*(x) < 1 + \eta$ for $x \in (0, \theta)$, we have by (2.2) and (2.3)

$$\left(\frac{2}{r+\varepsilon}\right)^{1/p} \leq \frac{p-2}{p}\left\{\frac{p}{\lambda(p-1)}\right\}^{1/p} \frac{x}{(h^*(x)-1)^{1-2/p}} \leq \left(\frac{2}{r-\varepsilon}\right)^{1/p}$$

for $x \in (0, \theta)$. Therefore we obtain (2.1). □

Remark 2.1. Let g be a function appearing in (1.2). One can also show that for any $\varepsilon \in (0, r)$, g satisfies

$$C_\varepsilon^-(\Lambda_0 - x)^{p/(p-2)} \leq 1 - g(x) \leq C_\varepsilon^+(\Lambda_0 - x)^{p/(p-2)} \quad \text{for } x \in (\Lambda_0 - \theta, \Lambda_0)$$

with some $\theta = \theta(g) \in (0, \Lambda_0)$, where C_ε^- and C_ε^+ are the same constants as in Lemma 2.1.

Setting $h_*(x) := -h^*(-x)$ and $y_M := \Lambda_0 - g^{-1}(1 - M)$ for $M > 0$, we will show Theorems 1.1 and 1.2.

Proof of Theorem 1.1. We discuss only the case $\phi(x) \equiv 1$ on I since the case $\phi(x) \equiv -1$ on I is treated in the same way.

Let $I = [a, b]$, $J = (a_0, b_0)$, $N(a) \setminus (a, b) = (a_1, a]$, $N(b) \setminus (a, b) = [b, b_1)$ with $a_0 < a_1 < a \leq b < b_1 < b_0$ and let $\varepsilon \in (0, r)$ be any number. Take any $M > 0$ and fix it. Define

$$\phi^*(x; M, I) := \begin{cases} h^*(-x + a), & x \in [a - x_M, a], \\ 1, & x \in [a, b], \\ h^*(x - b), & x \in (b, b + x_M], \\ +\infty, & x \in [0, a - x_M) \cup (b + x_M, 1], \end{cases}$$

and

$$(2.4)\quad \phi_*(x;M,I) := \begin{cases} h_*(x-a+\Lambda_1), & x \in [a-\Lambda_1-x_M, a-\Lambda_1),\\ g(x-a+\Lambda_0), & x \in [a-\Lambda_1, a),\\ 1, & x \in [a,b],\\ -g(x-b-\Lambda_0), & x \in (b, b+\Lambda_1],\\ h_*(-x+b+\Lambda_1), & x \in (b+\Lambda_1, b+\Lambda_1+x_M],\\ -\infty, & x \in [0, a-\Lambda_1-x_M) \cup (b+\Lambda_1+x_M, 1], \end{cases}$$

where g is the function appearing in (1.2). By Lemma 2.1 and Remark 2.1 there exist $\theta(h^*) \in (0, x_M)$ and $\theta(g) \in (0, \Lambda_0)$ such that

$$(2.5)\qquad \begin{cases} C_\varepsilon^-(a-x)^{p/(p-2)} \le \phi^*(x;M,I) - 1, & x \in (a-\theta(h^*), a],\\ C_\varepsilon^-(x-b)^{p/(p-2)} \le \phi^*(x;M,I) - 1, & x \in [b, b+\theta(h^*)), \end{cases}$$

$$(2.6)\qquad \begin{cases} C_\varepsilon^-(a-x)^{p/(p-2)} \le 1 - \phi_*(x;M,I), & x \in (a-\theta(g), a],\\ C_\varepsilon^-(x-b)^{p/(p-2)} \le 1 - \phi_*(x;M,I), & x \in [b, b+\theta(g)). \end{cases}$$

Put $\theta := \min\{a-a_1, b_1-b, \theta(h^*), \theta(g)\}$. Fix $\delta_0 > 0$ such that $\delta_0 < \min\{h^*(\theta)-1, 1-g(\theta)\}$, $\delta_0 < \phi(x) - \phi_*(x;M,I)$ for $x \in [0,1] \setminus J$ and that $x_{\delta_0},\ y_{\delta_0} < \min\{a-a_0, b_0-b\}$. Note $\delta_0 \in (0, \min\{1, M\})$. We will show that δ_0 satisfies the assertion.

Let $\delta \in (0, \delta_0)$ and assume $u_0 \in U_0(I,J)$, $\|u_0 - \phi\|_\infty < \delta$ and

$$(2.7)\qquad \begin{cases} |u_0(x) - 1| \le C_\varepsilon^-(a-x)^{p/(p-2)}, & x \in (a_1, a],\\ |u_0(x) - 1| \le C_\varepsilon^-(x-b)^{p/(p-2)}, & x \in [b, b_1). \end{cases}$$

From (2.5), (2.6), and (2.7) we have

$$\phi_*(x;\delta_0,I) \le u_0(x) \le \phi^*(x;\delta_0,I), \quad x \in (a-\theta, b+\theta).$$

In addition, since h^* and g are strictly increasing functions, we see

$$(2.8)\qquad \begin{cases} u_0(x) \le \phi^*(x;M,I), & x \in (a-x_M, b+x_M),\\ u_0(x) \ge \phi_*(x;M,I), & x \in (a-\Lambda_1-x_M, b+\Lambda_1+x_M). \end{cases}$$

Here we have used the fact that $u_0(x) > \phi(x) - \delta > \phi(x) - \delta_0 > \phi_*(x;M,I)$ for $x \in [0,1] \setminus J$. If $\|u_0 - \phi\|_\infty < \delta$, then $-1-\delta < u_0(x) < 1+\delta$ for $x \in [0,1]$; therefore $u \equiv 1+\delta$ (resp., $u \equiv -1-\delta$) is an upper solution (resp., a lower solution) for (P). Thus the comparison theorem [15, Theorem 2.3] yields that $|u(x,t;u_0)| \le 1+\delta$ for $(x,t) \in [0,1] \times [0,+\infty)$; in particular,

$$(2.9)\qquad \begin{cases} u(x,t;u_0) \le 1+\delta \le \phi^*(x;M,I) = 1+M\\ \qquad\qquad\qquad \text{at } x = a-x_M \text{ and } x = b+x_M,\\ u(x,t;u_0) \ge -1-\delta \ge \phi_*(x;M,I) = -1-M\\ \qquad\qquad\qquad \text{at } x = a-\Lambda_1-x_M \text{ and } x = b+\Lambda_1+x_M \end{cases}$$

for all $t \in [0, +\infty)$. Therefore, by virtue of (2.8) and (2.9), the comparison theorem gives

(2.10)
$$\begin{cases} u(x,t;u_0) \leq \phi^*(x;M,I), & (x,t) \in [a - x_M, b + x_M] \times [0,+\infty), \\ u(x,t;u_0) \geq \phi_*(x;M,I), & (x,t) \in [a - \Lambda_1 - x_M, b + \Lambda_1 + x_M] \times [0,+\infty); \end{cases}$$

therefore we conclude

$$u(x,t;u_0) = 1 = \phi(x) \text{ for all } (x,t) \in I \times [0,+\infty). \tag{2.11}$$

It remains to show that there exists an open neighborhood J_δ of I in J such that $u(x,t;u_0) \neq \phi(x)$ for $x \in J_\delta \setminus I$. The set $J \setminus I$ consists of two connected sets $[a_0, a)$ and $(b, b_0]$. Without loss of generality we can assume that

$$\begin{aligned} u_0(x) &< \phi(x) \quad \text{if } x \in [a_0, a), \\ u_0(x) &> \phi(x) \quad \text{if } x \in (b, b_0]. \end{aligned} \tag{2.12}$$

We will show that there exist $a_\delta \in (0, a-a_0)$ and $b_\delta \in (0, b_0-b)$, which are independent of u_0, such that

$$u(x,t;u_0) < \phi(x) \quad \text{if } x \in [a_0 + a_\delta, a), \tag{2.13}$$
$$u(x,t;u_0) > \phi(x) \quad \text{if } x \in (b, b_0 - b_\delta] \tag{2.14}$$

for all $t \in [0,+\infty)$ and that $a_\delta,\ b_\delta \to 0$ as $\delta \to 0$. Take any a_δ satisfying $x_\delta < a_\delta < x_{\delta_0}$ $(< \min\{a - a_0, b_0 - b\})$. Then we have

$$u_0(x) \leq \phi^*(x; M, [a_0 + a_\delta, a]), \quad x \in [a_0 + a_\delta - x_M, a + x_M].$$

From (2.12), for any $\xi \in (0, a - a_0 - a_\delta)$ there exists $\eta \in (0, h^*(a_\delta) - 1 - \delta)$ such that

$$u_0(x) < \phi^*(x; M, [a_0 + a_\delta, a - \xi]) - \eta, \quad x \in [a_0 + a_\delta - x_M, a - \xi + x_M]. \tag{2.15}$$

Define

$$u^*(x,t) := \phi^*(x; M, [a_0 + a_\delta, a - \xi]) - \eta e^{-Rt}$$

for $(x,t) \in [a_0 + a_\delta - x_M, a - \xi + x_M] \times [0,+\infty)$, where R is a positive number such that $R > -f'(1+M)$. Then

$$u(x,t;u_0) \leq 1 + \delta < u^*(x,t) \quad \text{at } x = a_0 + a_\delta - x_M \text{ and } x = a - \xi + x_M$$

for all $t \in [0,+\infty)$ and by an easy calculation

$$\begin{aligned} &u^*_t - \lambda(|u^*_x|^{p-2}u^*_x)_x - f(u^*) \\ &\quad = \eta R e^{-Rt} + f(\phi^*) - f(\phi^* - \eta e^{-Rt}) \\ &\quad \geq \eta e^{-Rt}(R + f'(1+M)) \\ &\quad > 0; \end{aligned}$$

therefore u^* is an upper solution of (P). Therefore, it follows from the comparison theorem that

$$u(x,t;u_0) \leq u^*(x,t) < \phi^*(x; M, [a_0 + a_\delta, a - \xi]) = \phi(x)$$

for $(x,t) \in [a_0 + a_\delta, a - \xi] \times [0, +\infty)$. Since $\xi \in (0, a - a_0 - a_\delta)$ is arbitrary, we can conclude

$$u(x,t;u_0) < \phi(x) \text{ for } (x,t) \in [a_0 + a_\delta, a) \times [0, +\infty).$$

We can choose a_δ such that $a_\delta \to 0$ as $\delta \to 0$; therefore (2.13) holds true.

The proof of (2.14) is similar to that of (2.13) if we use the following comparison function u_* instead of u^*. Let b_δ be any number satisfying $y_\delta < b_\delta < y_{\delta_0}$ and $\phi_*(x; M, [b, b_0 - b_\delta]) < \phi(x) - \delta$ for $x \in [0,1] \setminus J$. For any $\xi \in (0, b_0 - b_\delta - b)$ there exists $\eta \in (0, 1 - g(\Lambda_0 - b_\delta) - \delta)$ such that

$$u_0(x) > \phi_*(x; M, [b + \xi, b_0 - b_\delta]) + \eta, \quad x \in [b + \xi - \Lambda_1 - x_M, b_0 - b_\delta + \Lambda_1 + x_M]. \tag{2.16}$$

We have only to define

$$u_*(x,t) := \phi_*(x; M, [b + \xi, b_0 - b_\delta]) + \eta e^{-Rt}$$

for $(x,t) \in [b + \xi - \Lambda_1 - x_M, b_0 - b_\delta + \Lambda_1 + x_M] \times [0, +\infty)$, where $R > -f'(1 + M)$. Thus the proof is accomplished. □

Proof of Theorem 1.2. We give the proof in the case $\phi(x_0) = 1$. Let $J = (a_0, b_0)$ with $a_0 < x_0 < b_0$ and fix $\delta_0 > 0$ satisfying $2x_{\delta_0}$, $2y_{\delta_0} < \min\{x_0 - a_0, b_0 - x_0\}$. Without loss of generality we may assume that

$$u_0(x) < \phi(x) \quad \text{if } x \in [a_0, x_0), \tag{2.17}$$

$$u_0(x) > \phi(x) \quad \text{if } x \in (x_0, b_0]. \tag{2.18}$$

Then we can show the assertion by following the arguments used in the latter half of the proof of Theorem 1.1 with $a = b = x_0$. However, we should take $\xi = a_\delta$ in case (2.17) (resp., $\xi = b_\delta$ in case (2.18)). For such ξ, it is possible to take η satisfying (2.15) because $2a_\delta < 2x_{\delta_0} < \min\{x_0 - a_0, b_0 - x_0\}$ (resp., (2.16) because $2b_\delta < 2y_{\delta_0} < \min\{x_0 - a_0, b_0 - x_0\}$). □

We will give a remark associated with Theorems 1.1 and 1.2. In the proofs of these theorems, $\phi^*(\cdot; M, I)$ and $\phi_*(\cdot; M, I)$ are essential. Let $u_0 \in C([0,1])$. If only u_0 satisfies (2.8) for some $I = [a,b]$ $(\subset \Omega)$ and $M > \max\{\|u_0\|_\infty - 1, 0\}$, then $u(\cdot, t; u_0)$ satisfies (2.10) and hence (2.11). Similarly if u_0 satisfies

$$\begin{gathered} u_0(x) < \phi^*(x; M, I), \quad x \in (a - x_M, b + x_M) \\ (\text{resp., } u_0(x) > \phi_*(x; M, I), \quad x \in (a - \Lambda_1 - x_M, b + \Lambda_1 + x_M)) \end{gathered}$$

for some $I = [a,b]$ $(\subset \Omega)$ and the same M above, then in a similar way as (2.15) (resp., (2.16)) we obtain

$$\begin{gathered} u(x,t;u_0) < \phi(x) \quad \text{for } (x,t) \in I \times [0, +\infty) \\ (\text{resp., } u(x,t;u_0) > \phi(x) \quad \text{for } (x,t) \in I \times [0, +\infty)). \end{gathered}$$

Therefore when u_0 is given, it is possible to see the local behavior of $u(x,t;u_0)$ in $\Omega \times [0, +\infty)$ as long as we can take such comparison functions ϕ^* and ϕ_*. We can weaken the assumption $\|u_0 - \phi\|_\infty < \delta$ as u_0 lies in a neighborhood of ϕ on a local domain. Indeed, to know the behavior of intersection points between the flat hats of ϕ and u, we have only to take ϕ^* and ϕ_* as above.

3. Weak comparison theorem. In this section we show a weak comparison theorem (Theorem 1.4). The definition of a weak upper or lower solution of (P) is given by the following.

DEFINITION 3.1. *If $u \in C([0,T];L^2) \cap L^p(0,T;W^{1,p}) \cap L^{q+r}(0,T;L^{q+r})$ satisfies the following inequalities, then it is called a weak upper solution of* (P) *in* $[0,T]$*:*

$$\tag{3.1} \begin{cases} \displaystyle\int_0^1 u\varphi(x,t)dx + \int_0^t \int_0^1 (-u\varphi_t + |u_x|^{p-2}u_x\varphi_x)(x,\tau)dxd\tau \\ \qquad \displaystyle\geq \int_0^1 u_0\varphi(x,0)dx + \int_0^t \int_0^1 f(u)\varphi(x,\tau)dxd\tau \qquad \textit{for all } t \in [0,T], \\ u(0,t) \geq 0, \quad u(1,t) \geq 0 \qquad \textit{for a.e. } t \in (0,T) \end{cases}$$

for all functions $\varphi \in W^{1,2}(0,T;L^2) \cap L^p(0,T;W_0^{1,p}) \cap L^\infty([0,1]\times[0,T])$ satisfying $\varphi \geq 0$. A function u is called a weak lower solution if (3.1) *holds true with "$\geq$" replaced by "$\leq$."*

Remark 3.1. (i) In Definition 3.1, $u \in L^\alpha(0,T;L^\alpha)$ with $\alpha = q+r$; therefore $f(u)$ belongs to $L^{\alpha/(\alpha-1)}(0,T;L^{\alpha/(\alpha-1)}) \subset L^1(0,T;L^1)$. Therefore the second term of the right-hand side of (3.1) converges. (ii) The strong solution of (P) becomes a weak upper and a weak lower solution (see [15]).

Remark 3.2. Let $0 = a_0 < a_1 < \cdots < a_n < a_{n+1} = 1$ and let $\{u_i : [a_i, a_{i+1}] \to \mathbb{R}\}$ be a family of functions such that

$$u_i(a_{i+1}) = u_{i+1}(a_{i+1}), \qquad i = 0, 1, \dots, n-1,$$

and

$$\tag{3.2} \begin{cases} u_{i,t} \geq \lambda(|u_{i,x}|^{p-2}u_{i,x})_x + f(u_i), & (x,t) \in (a_i, a_{i+1}) \times (0,T), \\ u_0(0,t) \geq 0,\ u_n(1,t) \geq 0, & t \in (0,T), \\ u_{i,x}(a_{i+1}-0,t) \geq u_{i+1,x}(a_{i+1}+0,t), & t \in (0,T). \end{cases}$$

If u is defined by $u = u_i$ for $x \in [a_i, a_{i+1}]$, then it is easily seen that u is a weak upper solution of (P). If u satisfies (3.2) with "$\geq$" replaced by "$\leq$," then u becomes a weak lower solution of (P).

The following lemma plays an important role in proving Theorem 1.4.

LEMMA 3.1. *Let u be a weak upper solution of* (P) *in* $[0,T]$ *and take any $h \in (0,T)$. Then u satisfies the inequalities*

$$\tag{3.3} \int_0^1 ([u]_{h,t}\varphi + [|u_x|^{p-2}u_x]_h\varphi_x - [f(u)]_h\varphi)(x,t)dx \geq 0$$

for all $t \in (0, T-h)$ and for all $\varphi \in W_0^{1,p}$ satisfying $\varphi \geq 0$, where $[\phi]_h$ means the Steklov average of ϕ, i.e.,

$$[\phi]_h(x,t) := \begin{cases} \displaystyle\frac{1}{h}\int_t^{t+h} \phi(x,\tau)d\tau, & t \in (0, T-h], \\ 0, & t \in (T-h, T). \end{cases}$$

For a weak lower solution v, (3.3) *holds true with "$\geq$" replaced by "$\leq$."*

Proof. Take any $t \in (0, T-h)$ and $\varphi \in W_0^{1,p}$ satisfying $\varphi \geq 0$. Define the following cut-off function:

$$\eta^n(\tau) := \begin{cases} 0, & \tau \in [0, t-1/n), \\ \displaystyle\int_{t-\tau}^{1/n} \rho^n(s)ds, & \tau \in [t-1/n, T], \end{cases}$$

where $\rho^n(s) := n\rho(ns)$ and $\rho \in C_0^\infty(-\infty, +\infty)$ is a function satisfying that $\rho(s) \geq 0$, $\rho(s) = 0$ if $|s| \geq 1$, and $\int_{-\infty}^{+\infty} \rho(s)ds = 1$. Note that $\eta^n(\tau) = 1$ for all $\tau \in [t+1/n, T]$.

We set

$$\varphi^n(x,\tau) := \varphi(x)\eta^n(\tau)$$

for $(x,\tau) \in [0,1] \times [0,T]$ and $n \geq 1$. Since $\varphi^n \in C^1([0,T]; W_0^{1,p})$, we have (3.1) with φ and t replaced by φ^n and $t+h$, respectively:

$$\begin{aligned} &\int_0^1 u(x,t+h)\varphi(x)\eta^n(t+h)dx \\ &\quad + \int_0^{t+h}\int_0^1 \{-u(x,\tau)\varphi(x)\eta_t^n(\tau) + |u_x(x,\tau)|^{p-2}u_x(x,\tau)\varphi_x(x)\eta^n(\tau)\}dxd\tau \\ &\quad \geq \int_0^{t+h}\int_0^1 f(u(x,\tau))\varphi(x)\eta^n(\tau)dxd\tau. \end{aligned} \tag{3.4}$$

In (3.4) it is easy to see

$$\int_0^1 u(x,t+h)\varphi(x)\eta^n(t+h)dx \longrightarrow \int_0^1 u(x,t+h)\varphi(x)dx$$

and

$$\begin{aligned} &\int_0^{t+h}\int_0^1 f(u(x,\tau))\varphi(x)\eta^n(\tau)dxd\tau \\ &\quad = \int_{t-1/n}^{t+1/n} \eta^n \int_0^1 f(u)\varphi dxd\tau + \int_{t+1/n}^{t+h}\int_0^1 f(u)\varphi dxd\tau \\ &\quad \longrightarrow \int_t^{t+h}\int_0^1 f(u)\varphi(x)dxd\tau \end{aligned}$$

as $n \to +\infty$. The remaining term is expressed as

$$\begin{aligned} &\int_{t-1/n}^{t+1/n}\int_0^1 (-u\varphi\eta_t^n + |u_x|^{p-2}u_x\varphi_x\eta^n)dxd\tau + \int_{t+1/n}^{t+h}\int_0^1 |u_x|^{p-2}u_x\varphi_x dxd\tau \\ &\quad = -\int_{t-1/n}^{t+1/n} \rho^n(t-\tau)\int_0^1 u\varphi dxd\tau + \int_{t-1/n}^{t+1/n} \eta^n \int_0^1 |u_x|^{p-2}u_x\varphi_x dxd\tau \\ &\qquad + \int_{t+1/n}^{t+h}\int_0^1 |u_x|^{p-2}u_x\varphi_x dxd\tau. \end{aligned}$$

One can show that the right-hand side of the above equality converges to

$$-\int_0^1 u(x,t)\varphi(x)dx + \int_t^{t+h}\int_0^1 |u_x|^{p-2}u_x\varphi_x dxd\tau \quad \text{as } n \to +\infty.$$

Therefore, letting $n \to +\infty$ in (3.4) we obtain

$$\begin{aligned}\int_0^1 u(x,t+h)\varphi(x)dx - \int_0^1 u(x,t)\varphi(x)dx + \int_t^{t+h}\int_0^1 |u_x|^{p-2}u_x\varphi_x dx d\tau \\ \geq \int_t^{t+h}\int_0^1 f(u)\varphi(x)dxd\tau.\end{aligned} \tag{3.5}$$

Dividing (3.5) by h and recalling the definition of Steklov average we get

$$\int_0^1 [u]_{h,t}\varphi(x)dx + \int_0^1 [|u_x|^{p-2}u_x]_h\varphi_x dx \geq \int_0^1 [f(u)]_h\varphi(x)dx. \qquad \square$$

Proof of Theorem 1.4. Let u and v be a weak upper and a weak lower solution of (P). For every $\tau \in (0,t)$ such that $u(\tau),\ v(\tau) \in W^{1,p}$ and $h \in (0, T-\tau)$, Lemma 3.1 yields

$$\begin{aligned}\int_0^1 \{([v]_{h,t} - [u]_{h,t})(\tau)\varphi \\ + ([|v_x|^{p-2}v_x]_h - [|u_x|^{p-2}u_x]_h)(\tau)\varphi_x - ([f(v)]_h - [f(u)]_h)(\tau)\varphi\}dx \leq 0\end{aligned}$$

for any $\varphi \in W_0^{1,p}$. Putting $\varphi(x) = ([v(x,\tau) - u(x,\tau)]_h)_+ \in W_0^{1,p}$, where $w_+(x) := \max\{w(x), 0\}$, we obtain

$$\begin{aligned}\frac{1}{2}\frac{d}{dt}\int_0^1 ([v-u]_h)_+^2(x,\tau)dx + \int_0^1 [|v_x|^{p-2}v_x - |u_x|^{p-2}u_x]_h([v-u]_h)_{+,x}dx \\ \leq \int_0^1 [f(v)-f(u)]_h([v-u]_h)_+dx.\end{aligned}$$

Integrating the above inequality over $(0,t)$ and letting $h \to 0$ (see [3, Chapter I, Lemma 3.2]), we see that the second term of the left-hand side becomes nonnegative because of the monotonicity of the p-Laplace operator. Therefore

$$\begin{aligned}\frac{1}{2}\int_0^1 (v-u)_+^2(x,t)dx - \frac{1}{2}\int_0^1 (v_0-u_0)_+^2(x)dx \\ \leq \int_0^t\int_0^1 (f(v)-f(u))(v-u)_+dxd\tau \\ \leq C\int_0^t\int_0^1 (v-u)_+^2(x,\tau)dxd\tau,\end{aligned}$$

where $C = \sup\{f'(s); s \in \mathbb{R}\} < +\infty$. By Gronwall's inequality,

$$\|(v-u)_+(t)\| \leq \|(v_0-u_0)_+\|e^{Ct}.$$

By the assumption, the right-hand side of this inequality vanishes; therefore the assertion follows. $\square$

Remark 3.3. In sections 4 and 5, we will apply Theorem 1.4 by choosing continuous functions (in $[0,1]\times[0,T]$) as weak upper and lower solutions. Therefore, the comparison holds for all $t \in [0,T]$.

4. Stability of ϕ_0. In this section we prove Theorem 1.3 by using Theorem 1.4.

Proof of Theorem 1.3. Let ϕ_0 be the positive solution of (SP) with a flat hat. Since the attractivity has been proved in [15], it suffices to show the stability of ϕ_0.

Let any $\varepsilon > 0$ be fixed. First we will show the stability of ϕ_0 from above. For any $\eta > 0$, we define

$$\phi_\eta^*(x) := \min\{-\phi_*(x+\eta;\eta,\{-\Lambda_0\}), 1+\eta, -\phi_*(x-\eta;\eta,\{1+\Lambda_0\})\}$$

for $x \in [0,1]$, where ϕ_* is the function appearing in (2.4). If $\eta > 0$ is sufficiently small, then

$$\phi_0(x) < \phi_\eta^*(x) < \phi_0(x) + \varepsilon, \quad x \in [0,1].$$

Setting $u^*(x,t) := \phi_\eta^*(x)$ for $(x,t) \in [0,1] \times [0,+\infty)$, we see from Remark 3.2 that u^* is a weak upper solution. Therefore, taking $\delta > 0$ such that $\phi_0(x) + \delta < \phi_\eta^*(x)$ for $x \in [0,1]$, we conclude from Theorem 1.4 that for any u_0 satisfying $u_0(x) < \phi_0(x) + \delta$

$$u(x,t;u_0) \le u^*(x,t) = \phi_\eta^*(x) < \phi_0(x) + \varepsilon \text{ for } (x,t) \in [0,1] \times [0,+\infty). \tag{4.1}$$

Next we will prove the stability of ϕ_0 from below. Consider the following initial value problem:

$$\text{(IP)} \qquad \begin{cases} \lambda(|\phi_x|^{p-2}\phi_x)_x + f(\phi) = 0, \\ \phi(0) = 0, \quad \phi_x(0) = \alpha, \end{cases}$$

where α is a positive parameter. It is known in [15] that the solution $\phi(\cdot;\alpha)$ of (IP) is a continuously differentiable and strictly monotone increasing function on $[0, X(\alpha)]$, where $X(\alpha)$ satisfies $\phi_x(X(\alpha);\alpha) = 0$. Note that the function g, which generates the layers of ϕ_0, is identical with $\phi(\cdot;\alpha_0)$ on $[0, X(\alpha_0)] = [0, \Lambda_0]$, where $\alpha_0 := \{pF(1)/\lambda(p-1)\}^{1/p}$. Let $\xi > 0$ be any sufficiently small number and fix it. We can see in [15] that $X(\alpha_0 - \xi) < X(\alpha_0)$ and that $\phi(x;\alpha_0 - \xi) < \phi_0(x)$ for $x \in (0, X(\alpha_0 - \xi))$. Putting

$$\tilde{\phi}(x;\alpha_0-\xi) := \begin{cases} -\infty, & x \in (-\infty, -X(\alpha_0-\xi)), \\ -\phi(-x;\alpha_0-\xi), & x \in [-X(\alpha_0-\xi), 0), \\ \phi(x;\alpha_0-\xi), & x \in [0, X(\alpha_0-\xi)], \\ +\infty, & x \in (X(\alpha_0-\xi), +\infty), \end{cases}$$

we define

$$\phi_*^\eta(x) := \min\{\tilde{\phi}(x-\eta;\alpha_0-\xi), \tilde{\phi}(X(\alpha_0-\xi);\alpha_0-\xi), -\tilde{\phi}(x-1+\eta;\alpha_0-\xi)\}$$

for $x \in [0,1]$. If $\eta \in (0, X(\alpha_0) - X(\alpha_0 - \xi))$ is sufficiently small, one can show

$$\phi_0(x) - \varepsilon < \phi_*^\eta(x) < \phi_0(x), \quad x \in [0,1].$$

Observe that $u_*(x,t) := \phi_*^\eta(x)$ is a weak lower solution of (P) in $[0,1] \times [0,+\infty)$. Therefore, taking $\delta > 0$ such that $\phi_*^\eta(x) < \phi_0(x) - \delta$ for $x \in [0,1]$, one can see from Theorem 1.4 that for any u_0 satisfying $\phi_0(x) - \delta < u_0(x)$

$$\phi_0(x) - \varepsilon < \phi_*^\eta(x) = u_*(x,t) \le u(x,t;u_0) \text{ for } (x,t) \in [0,1] \times [0,+\infty). \tag{4.2}$$

Finally, combining (4.1) and (4.2), we see that $\|u_0 - \phi_0\|_\infty < \delta$ implies $\|u(t;u_0) - \phi_0\|_\infty < \varepsilon$ for all $t \in [0,+\infty)$. □

5. Conditional stability of ϕ_l. In this section we will discuss a conditional stability of each sign-changing solution ϕ_l of (SP) with flat hats by using the comparison functions used in the previous sections.

We will discuss the case $l = 1$. Recall that ϕ_1 is expressed as

$$\phi_1(x) = \begin{cases} g(x), & x \in \Pi_0 = [0, \Lambda_0), \\ 1, & x \in \Omega_0 = [\Lambda_0, \Lambda_0 + c_0], \\ -g(x - \Lambda_1 - c_0), & x \in \Pi_1 = (\Lambda_0 + c_0, \Lambda_2 + c_0), \\ -1, & x \in \Omega_1 = [\Lambda_2 + c_0, \Lambda_2 + c_0 + c_1], \\ g(x-1), & x \in \Pi_2 = (\Lambda_2 + c_0 + c_1, 1], \end{cases}$$

where c_0 and c_1 are any positive numbers satisfying $c_0 + c_1 = 1 - \Lambda_3 > 0$. We introduce the following two functions:

$$\overline{\phi^*_\delta}(x) := \min\{-\phi_*(x+\delta; \delta, \{-\Lambda_0\}), 1+\delta, -\phi_*(x-\delta; \delta, \{\Lambda_2 + c_0\})\}, \quad x \in [0,1],$$

and

$$\overline{\phi_*^\delta}(x) := \begin{cases} +\infty, & x \in [0, \Lambda_1 + c_0 + \delta), \\ \max\{-\tilde{\phi}(x - \Lambda_1 - c_0 - \delta; \alpha_0 - \xi), & \\ \qquad -\tilde{\phi}(X(\alpha_0 - \xi); \alpha_0 - \xi), \tilde{\phi}(x - 1 + \delta; \alpha_0 - \xi)\}, & x \in [\Lambda_1 + c_0 + \delta, 1]. \end{cases}$$

We define

$$\Phi^*_\delta(x) := \min\{\overline{\phi^*_\delta}(x), \overline{\phi_*^\delta}(x)\}, \quad x \in [0,1].$$

Similarly, making use of the two functions

$$\underline{\phi^*_\delta}(x) := \begin{cases} \min\{\tilde{\phi}(x-\delta; \alpha_0 - \xi), \tilde{\phi}(X(\alpha_0 - \xi); \alpha_0 - \xi), & \\ \qquad -\tilde{\phi}(x - \Lambda_1 - c_0 + \delta; \alpha_0 - \xi)\}, & x \in [0, \Lambda_1 + c_0 - \delta], \\ -\infty, & x \in (\Lambda_1 + c_0 - \delta, 1], \end{cases}$$

and

$$\underline{\phi_*^\delta}(x) := \max\{\phi_*(x+\delta; \{\Lambda_0 + c_0\}), -1-\delta, \phi_*(x-\delta; \{1 + \Lambda_0\})\}, \quad x \in [0,1],$$

we define

$$\Phi_*^\delta(x) := \max\{\underline{\phi^*_\delta}(x), \underline{\phi_*^\delta}(x)\}, \quad x \in [0,1].$$

Then ϕ_1 is sandwiched between Φ^*_δ and Φ_*^δ. More precisely, it holds that

$$\phi_1(\Lambda_0 + c_0 - \delta) = \Phi_*^\delta(\Lambda_0 + c_0 - \delta), \tag{5.1}$$

$$\phi_1(\Lambda_2 + c_0 + \delta) = \Phi^*_\delta(\Lambda_2 + c_0 + \delta) \tag{5.2}$$

and that $\Phi_*^\delta(x) < \phi_1(x) < \Phi^*_\delta(x)$ for all $x \in [0,1] \setminus \{\Lambda_0 + c_0 - \delta, \Lambda_2 + c_0 + \delta\}$. Furthermore, we can observe that Φ^*_δ and Φ_*^δ are a weak upper and a weak lower solution, respectively. Therefore, for any u_0 whose graph lies in the shaded portion of Figure 5.1, the solution $u(x, t; u_0)$ keeps on staying within the portion; therefore ϕ_1 is conditionally stable for such initial data. We should note that Φ^*_δ and Φ_*^δ have "bumps" at $x = \Lambda_0 + c_0 - \delta$ and $\Lambda_2 + c_0 + \delta$ as seen in (5.1) and (5.2). These bumps make the shaded portion narrow and play a role making $u(t; u_0)$ cling to the layer of ϕ_1.

To see the conditional stability of ϕ_l for general $l \geq 1$, it is sufficient to form bumps near each layer as is exhibited in Figure 5.2 (the case $l = 2$).

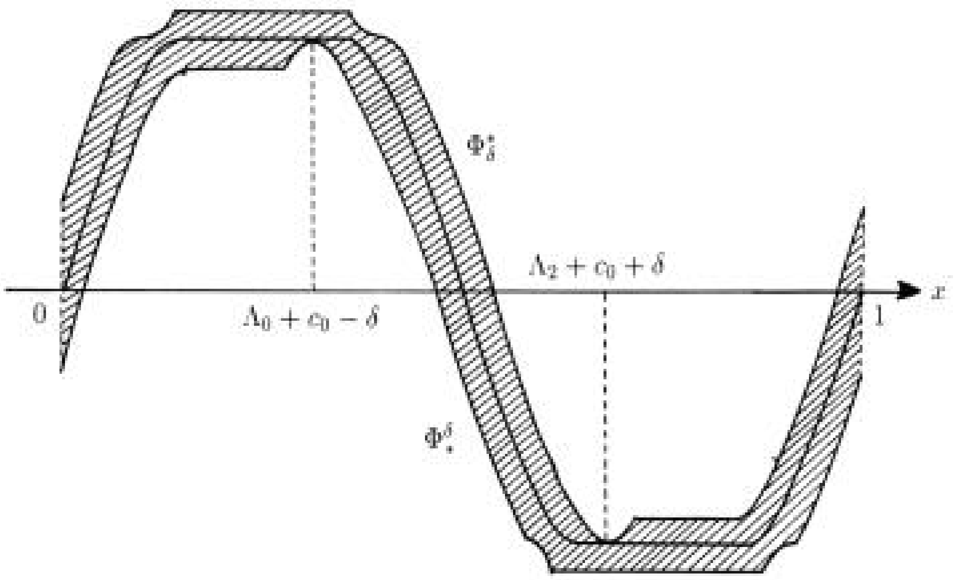

FIG. 5.1. *Domain of stability for ϕ_1.*

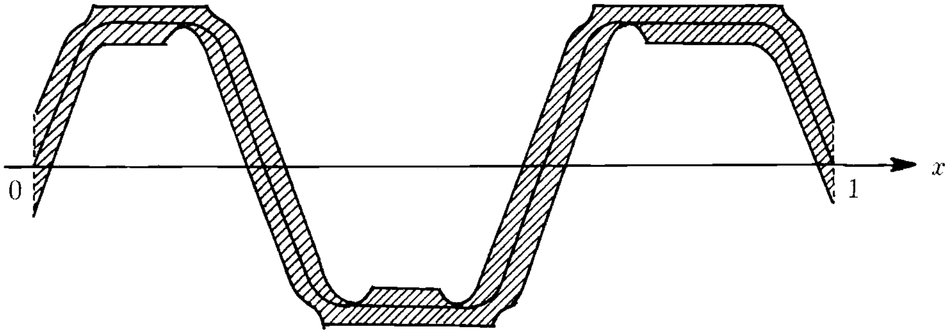

FIG. 5.2. *Domain of stability for ϕ_2.*

Acknowledgments. The author wishes to express his hearty thanks to Professor Yoshio Yamada for many useful suggestions. He also thanks the referees for some comments related to blow-up problems.

AN INEQUALITY INVOLVING THE GENERALIZED HYPERGEOMETRIC FUNCTION AND THE ARC LENGTH OF AN ELLIPSE[*]

ROGER W. BARNARD[†], KENT PEARCE[†], AND KENDALL C. RICHARDS[‡]

Abstract. In this paper we verify a conjecture of M. Vuorinen that the Muir approximation is a lower approximation to the arc length of an ellipse. Vuorinen conjectured that $f(x) = {}_2F_1(\frac{1}{2}, -\frac{1}{2}; 1; x) - [(1 + (1 - x)^{3/4})/2]^{2/3}$ is positive for $x \in (0, 1)$. The authors prove a much stronger result which says that the Maclaurin coefficients of f are nonnegative. As a key lemma, we show that ${}_3F_2(-n, a, b; 1 + a + b, 1 + \epsilon - n; 1) > 0$ when $0 < ab/(1 + a + b) < \epsilon < 1$ for all positive integers n.

1. Introduction.

Let a and b be the semiaxes of an ellipse with eccentricity $e = \sqrt{a^2 - b^2}/a$. Let $L(a, b)$ denote the arc length of the ellipse. Without loss of generality we can take one of the semiaxes, say a, to be 1. Legendre's complete elliptic integral of the second kind can be defined by

$$E(r) = \int_0^{\pi/2} \sqrt{1 - r^2 \sin^2 t}\, dt.$$

Elliptic integrals are so named because of their connection with $L(a, b)$. In turn, these are related to Gauss's hypergeometric functions, ${}_2F_1$, defined by

$${}_2F_1(a_1, a_2; b_1; z) = \sum_{n=0}^{\infty} \frac{(a_1)_n (a_2)_n}{(b_1)_n n!} z^n$$

with the Appell (or Pochhammer) symbol $(a)_n = a(a+1)\cdots(a+n-1)$ for $n \geq 1$ and $(a)_0 = 1, a \neq 0$. We shall need the generalized hypergeometric function, ${}_pF_q$, defined by

$${}_pF_q(a_1, a_2, \ldots, a_p; b_1, b_2, \ldots, b_q; z) = \sum_{n=0}^{\infty} \frac{(a_1)_n \cdot (a_2)_n \cdots (a_p)_n}{(b_1)_n \cdot (b_2)_n \cdots (b_q)_n} \frac{z^n}{n!}$$

(see [12, p. 73]). It was noted by Maclaurin in 1742 (see [2]) that

$$L(1, b) = 4E(e) = 2\pi {}_2F_1(\tfrac{1}{2}, -\tfrac{1}{2}; 1; e^2).$$

There are various references, books, and articles, which discuss the relationships between elliptic integrals and hypergeometric functions (see [3], [7]) and their role in

applications to physics (see [11], [9]) and in geometric function theory (see [10], [3]). From antiquity several more easily computable approximations to $L(a,b)$ have been suggested. The Almkvist–Berndt survey article [2] has an extensive discussion of these approximations. These approximations and their historical and recent connections to the approximations of π can be found in the Borweins' book [6]. An excellent source for all of the above ideas is the Anderson–Vamanamurthy–Vuorinen book *Conformal Invariants, Inequalities, and Quasiconformal Mappings* [3].

In 1883, it was proposed by Muir (see [2]) that $L(1,b)$ could be simply approximated by $2\pi[(1+b^{3/2})/2]^{2/3}$. A close numerical examination of the error in this approximation lead M. Vuorinen to pose Problem 5.6 in [13]. This was announced at several international conferences. Letting $x = 1-b^2$, he asked whether the Muir approximation

$$g(x) = \left(\frac{1+(1-x)^{3/4}}{2}\right)^{2/3}$$

is a lower approximation for the value given by the hypergeometric function

$$h(x) = {}_2F_1\left(\tfrac{1}{2}, -\tfrac{1}{2}; 1; x\right),$$

that is, whether

$$h(x) - g(x) \geq 0 \text{ for all } x \in (0,1).$$

We shall prove the following much stronger result.

THEOREM 1.1. *Let $g(x) = \sum_{n=0}^{\infty} a_n x^n$ and $h(x) = \sum_{n=0}^{\infty} A_n x^n$. Then,*

$$a_k \leq A_k \text{ for all } k = 0,1,2,\ldots,n,\ldots. \tag{1.1}$$

In particular, the function $f(x) \equiv [h(x)-g(x)]/x^4$ is convex and increasing from $(0,1]$ onto $(\alpha,\beta]$, where $\alpha = 2^{-14} = 0.000061\cdots$ and $\beta = (2/\pi) - 2^{-2/3} = 0.006659\cdots$.

Remarks. The ideas and techniques used to prove Lemma 2.1 and Theorem 1.1 will be used in [5] to determine surprising hierarchical relationships among the 13 historical approximations to $L(a,b)$ discussed in [2]. These approximations range over four centuries from Kepler's in 1642 to Almkvist's in 1985 and include two from Ramanujan.

2. Proof of main results. The proof of Theorem 1.1 requires the following lemma.

LEMMA 2.1. *Suppose $a,b>0$. Then, for any ϵ satisfying $\frac{ab}{1+a+b} < \epsilon < 1$,*

$${}_3F_2(-n,a,b;1+a+b,1+\epsilon-n;1) > 0 \quad \textit{for all integers } n \geq 1.$$

For the reader's convenience, we include the following classical identities.

Identity 1 (see [1, p. 558, eq. (15.2.24)]). If $|z|<1$, then

$$(c-b-1)\cdot {}_2F_1(a,b;c;z) = (c-1)\cdot {}_2F_1(a,b;c-1;z) - b\cdot\ {}_2F_1(a,b+1;c;z).$$

Identity 2 (see [12, p. 60, Thm. 21]). If $|z|<1$, then

$${}_2F_1(a,b;c;z) = (1-z)^{c-a-b}\cdot {}_2F_1(c-a,c-b;c;z).$$

Identity 3 (see [8, p. 59, eq. (3.1.1)]). If $F = {}_3F_2$, then

$$F(-n,a,b;c,d;1) = \frac{(d-b)_n}{(d)_n} F(-n,c-a,b;c,1+b-d-n;1).$$

Identity 4 (see [12, p. 82, eq. (14)]). If $F = {}_3F_2$ and $|z| < 1$, then

$$\begin{aligned}(a_1 - a_2) \cdot F(&a_1,a_2,a_3;b_1,b_2;z) \\ &= a_1 \cdot F(a_1+1,a_2,a_3;b_1,b_2;z) - a_2 \cdot F(a_1,a_2+1,a_3;b_1,b_2;z).\end{aligned}$$

Proof of Lemma 2.1. Using an idea suggested in [4], we let $F = {}_3F_2$ and consider the generating function

$$f(r) = \sum_{n=0}^{\infty} \frac{-(-\epsilon)_n}{n!} F(-n,a,b;1+a+b,1+\epsilon-n;1)r^n = \sum_{n=0}^{\infty} c_n r^n,$$

where $|r| < 1$. Note that $-(-\epsilon)_n > 0$ for $0 < \epsilon < 1$ and for all $n \geq 1$. Thus we seek to verify that $c_n > 0$ for all $n \geq 1$.

In this direction, we have

$$\begin{aligned}
f(r) &= \sum_{n=0}^{\infty} \frac{-(-\epsilon)_n}{n!} \sum_{k=0}^{n} \frac{(-n)_k (a)_k (b)_k}{(a+b+1)_k (1+\epsilon-n)_k k!} r^n \\
&= \sum_{n=0}^{\infty} \frac{-(-\epsilon)_n}{(1)_n} \sum_{k=0}^{n} \frac{\frac{(-1)^k (1)_n}{(1)_{n-k}} (a)_k (b)_k}{(a+b+1)_k \frac{(-1)^k (-\epsilon)_n}{(-\epsilon)_{n-k}} k!} r^n \\
&\qquad \left\{\text{using } (\alpha)_{n-k} = \tfrac{(-1)^k (\alpha)_n}{(1-\alpha-n)_k} \text{ and } (1)_n = n!\right\} \\
&= -\sum_{n=0}^{\infty} \sum_{k=0}^{n} \left(\frac{(a)_k (b)_k}{(a+b+1)_k k!} r^k \right) \left(\frac{(-\epsilon)_{n-k}}{(n-k)!} r^{n-k} \right) \\
&= -\sum_{n=0}^{\infty} \left(\frac{(-\epsilon)_n}{(n)!} r^n \right) \sum_{k=0}^{\infty} \left(\frac{(a)_k (b)_k}{(a+b+1)_k k!} r^k \right) \qquad \text{(see [12, p. 57, eq. (2)])} \\
&= -(1-r)^{\epsilon}\ {}_2F_1(a,b;a+b+1;r).
\end{aligned}$$

Differentiating, we have

$$\begin{aligned} f'(r) = \epsilon(1-r)^{\epsilon-1}\ &{}_2F_1(a,b;a+b+1;r) \\ - \frac{ab(1-r)^{\epsilon}}{(a+b+1)}\ &{}_2F_1(a+1,b+1;a+b+2;r). \end{aligned} \tag{2.1}$$

An application of Identity 1 followed by Identity 2 to ${}_2F_1(a+1,b+1;a+b+2;r)$ yields

$$\begin{aligned}
&\frac{ab(1-r)^{\epsilon}}{(a+b+1)} {}_2F_1(a+1,b+1;a+b+2;r) \\
&\quad = \frac{b(1-r)^{\epsilon}}{(a+b+1)} [(a+b+1) \cdot {}_2F_1(a+1,b+1;a+b+1;r) \\
&\quad - (b+1) \cdot {}_2F_1(a+1,b+2;a+b+2;r)] \\
&\quad = (1-r)^{\epsilon-1} \left[b \cdot {}_2F_1(a,b;a+b+1;r) - \frac{b(b+1)}{(a+b+1)} \cdot {}_2F_1(a,b+1;a+b+2;r) \right].
\end{aligned}$$

Thus (2.1) becomes

$$\begin{aligned}
f'(r) &= (1-r)^{\epsilon-1}\Bigg[(\epsilon-b)\cdot {}_2F_1(a,b;a+b+1;r) \\
&\quad + \frac{b(b+1)}{(a+b+1)}\cdot {}_2F_1(a,b+1;a+b+2;r)\Bigg] \\
&= (1-r)^{\epsilon-1}\sum_{n=0}^{\infty}\frac{(a)_n}{n!}\left[\frac{(b)_n(\epsilon-b)}{(a+b+1)_n}+\frac{b(b+1)(b+1)_n}{(a+b+1)(a+b+2)_n}\right]r^n \\
&= (1-r)^{\epsilon-1}\sum_{n=0}^{\infty}\frac{(a)_n}{n!}\left[\frac{(b)_n(\epsilon-b)}{(a+b+1)_n}+\frac{(b+1)(b)_n(b+n)}{(a+b+1)_n(a+b+1+n)}\right]r^n \qquad (2.2) \\
&= (1-r)^{\epsilon-1}\sum_{n=0}^{\infty}\frac{(a)_n(b)_n}{(a+b+1)_n(a+b+1+n)n!} \\
&\quad \times\left[(\epsilon-b)(a+b+1+n)+(b+1)(b+n)\right]r^n \\
&= (1-r)^{\epsilon-1}\sum_{n=0}^{\infty}\frac{(a)_n(b)_n}{(a+b+1)_n(a+b+1+n)n!} \qquad (2.3) \\
&\quad \times\left[\epsilon(a+b+1+n)+n-ab\right]r^n,
\end{aligned}$$

where (2.2) makes use of $\alpha(\alpha+1)_n=(\alpha)_n(\alpha+n)$. If $\frac{ab}{a+b+1}<\epsilon<1$, then the expression in (2.3) is the product of two series with all positive Maclaurin series coefficients. Hence f' has all positive Maclaurin series coefficients which is equivalent to the desired result. □

Corollary 2.2. *Let $T_n = {}_3F_2\left(-n,\frac{3}{2},\frac{1}{2};2,\frac{5}{4}-n;1\right)$. Then, for all integers $n\geq 8$,*

$$T_{n+1}>T_n>0.$$

Proof. Let $F={}_3F_2$ and $B_n=\left(\frac{3}{4}-n\right)_n/\left(\frac{5}{4}-n\right)_n$. Using Identity 3, we have that

$$T_n=B_nF\left(-n,\tfrac{1}{2},\tfrac{1}{2};2,\tfrac{1}{4};1\right).$$

Direct calculation reveals that $T_9>T_8>0>T_7>\cdots>T_2=T_1$. Now suppose that $T_n>T_{n-1}>0$ for some $n\geq 9$ and note that $B_{n+1}/B_n=\left(n+\frac{1}{4}\right)/\left(n-\frac{1}{4}\right)$. Then,

$$\begin{aligned}
T_{n+1} &= B_{n+1}F\left(-n-1,\tfrac{1}{2},\tfrac{1}{2};2,\tfrac{1}{4};1\right) \\
&= \frac{B_{n+1}}{\left(n+\frac{3}{2}\right)}\left[(n+1)F\left(-n,\tfrac{1}{2},\tfrac{1}{2};2,\tfrac{1}{4};1\right)+\tfrac{1}{2}F\left(-n-1,\tfrac{3}{2},\tfrac{1}{2};2,\tfrac{1}{4};1\right)\right] \qquad (2.4) \\
&= \frac{B_{n+1}(n+1)}{B_n\left(n+\frac{3}{2}\right)}T_n+\frac{B_{n+1}}{2\left(n+\frac{3}{2}\right)}F\left(-n-1,\tfrac{3}{2},\tfrac{1}{2};2,\tfrac{1}{4};1\right) \\
&= \frac{\left(n+\frac{1}{4}\right)(n+1)}{\left(n-\frac{1}{4}\right)\left(n+\frac{3}{2}\right)}T_n+\frac{B_{n+1}}{2\left(n+\frac{3}{2}\right)}F\left(-n-1,\tfrac{3}{2},\tfrac{1}{2};2,\tfrac{1}{4};1\right) \\
&> T_n+\frac{B_{n+1}}{2\left(n+\frac{3}{2}\right)}F\left(-n-1,\tfrac{3}{2},\tfrac{1}{2};2,\tfrac{1}{4};1\right),
\end{aligned}$$

where (2.4) follows from Identity 4, and the inequality holds because $\frac{(n+1/4)(n+1)}{(n-1/4)(n+3/2)} > 1$ and $T_n > 0$. Since $B_{n+1} < 0$, we shall have that $T_{n+1} > T_n > 0$ provided we show that $F(-n-1, \frac{3}{2}, \frac{1}{2}; 2, \frac{1}{4}; 1) < 0$. To this end, we again apply Identity 3 to observe that

$$F\left(-n-1, \tfrac{3}{2}, \tfrac{1}{2}; 2, \tfrac{1}{4}; 1\right) = \frac{\left(-\frac{1}{4}\right)_{n+1}}{\left(\frac{1}{4}\right)_{n+1}} F\left(-n-1, \tfrac{1}{2}, \tfrac{1}{2}; 2, \tfrac{1}{4}-n; 1\right).$$

Since

$$\frac{\left(-\frac{1}{4}\right)_{n+1}}{\left(\frac{1}{4}\right)_{n+1}} < 0,$$

we need to show that

$$F\left(-n-1, \tfrac{1}{2}, \tfrac{1}{2}; 2, \tfrac{1}{4}-n; 1\right) > 0.$$

Letting $m = n+1$, $a = b = \frac{1}{2}$, and $\epsilon = \frac{1}{4}$, it follows from Lemma 2.1 that

$$F\left(-n-1, \tfrac{1}{2}, \tfrac{1}{2}; 2, \tfrac{1}{4}-n; 1\right) = F(-m, a, b; a+b+1, 1+\epsilon-m; 1) > 0.$$

Hence $T_{n+1} > T_n > 0$ for all integers $n \geq 8$ by induction. □

Proof of Theorem 1.1. Clearly,

$$A_n = \frac{\left(\frac{1}{2}\right)_n \left(-\frac{1}{2}\right)_n}{n!n!}.$$

Computing the logarithmic derivative of g we have

$$\frac{g'(x)}{g(x)} = -\frac{1}{2}\left(\frac{(1-x)^{-\frac{1}{4}}}{1+(1-x)^{\frac{3}{4}}}\right),$$

which implies

$$\left(\sum_{n=0}^{\infty}(n+1)a_{n+1}x^n\right)\left((1-x)^{\frac{1}{4}}+1-x\right) = -\frac{1}{2}\sum_{n=0}^{\infty}a_n x^n. \tag{2.5}$$

The coefficients of x^n of the left-hand side of (2.5) are obtained from the Cauchy product of the two terms. Solving for a_{n+1} yields (by extracting the nth and $(n-1)$st terms from the Cauchy product)

$$a_{n+1} = \frac{1}{2(n+1)}\left[\left(\frac{5}{4}n-\frac{1}{2}\right)a_n - \sum_{k=0}^{n-2}(k+1)a_{k+1}\frac{\left(-\frac{1}{4}\right)_{n-k}}{(n-k)!}\right]. \tag{2.6}$$

We now verify (1.1) using an inductive argument. Clearly, the coefficients of the terms a_k in (2.6) are nonnegative. Computation gives: $a_0 = A_0 = 1,\ a_1 = A_1 = -1/4,\ a_2 = A_2 = -3/64,\ a_3 = A_3 = -5/2^8,\ a_4 = -11/2^{10}$ and $A_4 = -175/2^{14}$. Suppose that the inequality in (1.1) holds for $4 \leq k \leq n$. From (2.6) we have

$$\text{(2.7) } a_{n+1} \leq \frac{1}{2(n+1)}\left[\left(\frac{5}{4}n-\frac{1}{2}\right)\frac{\left(\frac{1}{2}\right)_n\left(-\frac{1}{2}\right)_n}{n!n!} - \sum_{k=0}^{n-2}(k+1)\frac{\left(\frac{1}{2}\right)_{k+1}\left(-\frac{1}{2}\right)_{k+1}}{(k+1)!(k+1)!}\frac{\left(-\frac{1}{4}\right)_{n-k}}{(n-k)!}\right].$$

We need to show that the right-hand side of (2.7) is less than or equal to $A_{n+1} = \frac{\left(\frac{1}{2}\right)_{n+1}\left(-\frac{1}{2}\right)_{n+1}}{(n+1)!(n+1)!}$, that is,

$$\begin{aligned}\left(\frac{5}{4}n-\frac{1}{2}\right)\frac{\left(\frac{1}{2}\right)_n\left(-\frac{1}{2}\right)_n}{n!n!} &- 2(n+1)\frac{\left(\frac{1}{2}\right)_{n+1}\left(-\frac{1}{2}\right)_{n+1}}{(n+1)!(n+1)!} \\ &\le \sum_{k=0}^{n-2}(k+1)\frac{\left(\frac{1}{2}\right)_{k+1}\left(-\frac{1}{2}\right)_{k+1}}{(k+1)!(k+1)!}\frac{\left(-\frac{1}{4}\right)_{n-k}}{(n-k)!}.\end{aligned} \tag{2.8}$$

After adding the $(n-1)$st and nth terms of the right-hand side of (2.8) to inequality (2.8) and then simplifying, we use $(a)_{k+1} = (a+k)(a)_k$, $(a)_{n-k} = (-1)^k(a)_k/(1-a-n)_k$, the fact that $(-n)_k = 0$ for $k \geq n+1$, and the definition of ${}_3F_2$ to obtain

$$\frac{\left(\frac{1}{2}\right)_n\left(-\frac{1}{2}\right)_n}{n!n!}\cdot\frac{(2n-1)}{4(n+1)} \le -\left(\frac{1}{4}\right)\left(-\frac{1}{4}\right)_n\frac{{}_3F_2\left(-n,\frac{1}{2},\frac{3}{2};2,\frac{5}{4}-n;1\right)}{n!},$$

or equivalently

$${}_3F_2\left(-n,\tfrac{1}{2},\tfrac{3}{2};2,\tfrac{5}{4}-n;1\right) \geq \frac{\left(\frac{1}{2}\right)_n^2}{\left(-\frac{1}{4}\right)_n(n+1)!}. \tag{2.9}$$

Clearly, the right-hand side of (2.9) is negative for all $n \geq 1$. Inequality (2.9) can be explicitly verified for $0 \leq n \leq 7$. For $n \geq 8$, inequality (2.9) follows from Corollary 2.2. Thus, the inequality in (1.1) also holds for $k = n+1$. Hence, by induction (1.1) holds for all $k \in \mathbb{N} \cup \{0\}$.

Finally, the convexity and monotonicity of f are clear. By l'Hôpital's rule, $f(0^+) = A_4 - a_4 = 1/2^{14} = 1/16384$, while the value of $f(1)$ is clear. □

Acknowledgments. The authors would like to thank the referees for their many helpful suggestions which helped to considerably improve the paper.

THE POLES OF THE RESOLVENT FOR THE EXTERIOR NEUMANN PROBLEM OF ANISOTROPIC ELASTICITY*

MISHIO KAWASHITA† AND GEN NAKAMURA‡

Abstract. The poles of the resolvent and the asymptotic behavior of the local energy for the exterior Neumann problem of elastic wave equations are considered. For the most general class of anisotropic elastic media, the existence of the poles approaching the real axis is proved if the Rayleigh surface waves exist at least locally. The rate of their convergence to the real axis is estimated. Some results which show that the local energy hardly escapes from any neighborhood of the boundary are also presented. These results are considered as an influence of the existence of the Rayleigh surface waves.

The local existence condition of the Rayleigh surface waves is given in terms of the surface impedance tensor, which is essentially equal to the principal part of the Neumann operator in the elliptic region. Unlike isotropic elastic media, the Rayleigh surface waves exist only locally for anisotropic elastic media. Nevertheless, the local existence of the Rayleigh surface waves is enough to prove the same results as those for the isotropic case.

Key words. anisotropic elastic media, the Rayleigh surface waves, poles of the resolvent, local energy decay, the surface impedance tensor, trapping

Introduction. It is well known that as a phenomenon of the propagation of the singularities, the Rayleigh surface wave which propagates along the boundary of an elastic body never penetrates into the body. One of our interests in this paper is to reconsider the Rayleigh surface wave as a phenomenon of the propagation of the energy. Especially, we want to prove that the energy of the Rayleigh surface wave penetrates into the body and the decay rate of the energy is slower than any negative power of time as time tends to infinity.

In order to state our results more precisely, let Ω be an exterior domain in $\mathbf{R}^n$ $(n \geq 3)$ with C^∞ and compact boundary Γ. We consider the domain Ω as a general anisotropic elastic medium with a traction free boundary. For the displacement vector $u(t,x) = {}^t(u_1(t,x), \dots, u_n(t,x))$, motions of the elastic medium are described by the following mixed problem:

$$\text{(0.1)} \qquad \begin{cases} (\partial_t^2 - A(x,\partial_x))u(t,x) = 0 & \text{in} \quad \mathbf{R} \times \Omega, \\ N(x,\partial_x)u(t,x) = 0 & \text{on} \quad \mathbf{R} \times \Gamma, \\ u(0,x) = f_1(x), \quad \partial_t u(0,x) = f_2(x) & \text{on} \quad \Omega. \end{cases}$$

In (0.1), the differential operator $A(x,\partial_x)$ is of the form

$$A(x,\partial_x)u = \sum_{i,l=1}^{n} \partial_{x_i}(C_{il}(x)\partial_{x_l}u),$$

*Received by the editors January 13, 1997; accepted for publication (in revised form) May 22, 1998; published electronically March 21, 2000.

†Faculty of Education, Ibaraki University, Mito, Ibaraki, 310-8512, Japan (kawasita @mito.ipc.ibaraki.ac.jp).

‡Department of Mathematics, Faculty of Engineering, Gunma University, Kiryu 376-8515, Japan (nakamura@math.sci.gunma-u.ac.jp).

and the boundary operator $N(x,\partial_x)$ is the conormal derivative of $A(x,\partial_x)$, which is represented as $N(x,\partial_x)u=\sum_{i,l=1}^{n}\nu_i(x)C_{il}(x)\partial_{x_l}u|_\Gamma$, where $\nu(x)={}^t(\nu_1(x),\nu_2(x),\dots,\nu_n(x))$ is the unit outer normal vector of Γ at $x\in\Gamma$.

The (j,k)-components $C_{ijkl}(x)$ of the $n\times n$-matrix $C_{il}(x)$ are called the elastic tensor. Due to the symmetry of $C_{ijkl}(x)$ given as assumption (A.1) below, the boundary condition in (0.1) describes the stress-free condition of the boundary.

It is well known that there is a surface wave called the Rayleigh surface wave (cf. Achenbach [1], Barnett and Lothe [2], Chadwick and Smith [3], Taylor [23]). Concerning the Rayleigh surface wave as a phenomenon of propagation of singularities, the singularities stay over the boundary and never go out from the boundary. Therefore, if the Rayleigh surface wave exists globally, it is "trapped" on the boundary.

In scattering theory, there is a principle asserting that the existence of trapped singularities of solutions yields poles of the resolvent and it also affects the behavior of the local energy decay of solutions. There are many works on this principle, especially for the acoustic wave equation (cf., e.g., Ikawa [5], Ralston [16], Vainberg [24]).

For isotropic elastic media, the Rayleigh surface waves exist globally in time. Hence, in this case, there are many works from the point of view in scattering theory (cf. [6], [10], [12], [18], [19], [20], [21], and [25]). Stefanov and Vodev [21] showed that there are poles of the resolvent approaching the real axis. However, for anisotropic elastic media, we do not know whether the Rayleigh surface waves exist globally in time even if they exist locally. Nevertheless, we can prove the same property for the resolvent. As a by-product of the proof, we can also prove that the local energy of solutions never decay at the rate of any negative power of time.

Throughout this paper, we suppose each component of the elastic tensor $C_{ijkl}(x)$ is of the form $C_{ijkl}(x)=C^0_{ijkl}+C^1_{ijkl}(x)$, where each C^0_{ijkl} is a real constant and $C^1_{ijkl}(x)$ is a real-valued C^∞ function on $\mathbf{R}^n$ with compact support. Denote by C^0_{il} (resp., $C^1_{il}(x)$) the matrices whose (j,k)-component is C^0_{ijkl} (resp., $C^1_{ijkl}(x)$). We set

$$A^0(\partial_x)u=\sum_{i,l=1}^{n}\partial_{x_i}(C^0_{il}\partial_{x_l}u),\qquad A^1(x,\partial_x)u=\sum_{i,l=1}^{n}\partial_{x_i}(C^1_{il}(x)\partial_{x_l}u).$$

Note that $A(x,\partial_x)u=A^0(\partial_x)u+A^1(x,\partial_x)u$.

Further, we always assume the following physically natural assumptions:

$$\text{(A.1)}\qquad C_{ijkl}(x)=C_{jikl}(x)=C_{lkji}(x)\quad\text{for any } x\in\mathbf{R}^n \text{ and } i,j,k,l=1,\dots,n;$$

(A.2) there is a constant $\delta>0$ such that

$$\sum_{i,j,k,l=1}^{n}C_{ijkl}(x)\epsilon_{kl}\bar{\epsilon}_{ij}\ge\delta\sum_{i,j=1}^{n}|\epsilon_{ij}|^2$$

for any $x\in\mathbf{R}^n$ and $n\times n$-symmetrix matrix (ϵ_{ij}).

From (A.1) and (A.2), we can define the outgoing (resp., incoming) resolvent $R^+(z)$ (resp., $R^-(z)$) as follows. The resolvent $R^\pm(z)$ of the stationary problem

$$\text{(0.2)}\qquad\begin{cases}(A(x,\partial_x)+z^2)v(x;z)=f(x) & \text{in}\quad\Omega,\\ N(x,\partial_x)v(x;z)=0 & \text{on}\quad\Gamma\end{cases}$$

is a $B(L^2(\Omega),\ H^2(\Omega))$-valued holomorphic function in $\pm\text{Im}\ z < 0$. For any $a > 0$ with $\Gamma \subset B_a = \{x \in \mathbf{R}^n\,;\ |x| < a\}$, $R^{\pm}(z)$ can be continued meromorphically as a $B(L^2_a(\Omega), H^2(\Omega_a))$-valued function on $\widetilde{\mathbf{C}}_{\pm}$, where $L^2_a(\Omega) = \{f \in L^2(\Omega)\,;\ f(x) = 0$ in $|x| > a\}$, $\Omega_a = \Omega \cap B_a$ and $\widetilde{\mathbf{C}}_{\pm} = \mathbf{C}$ if n is odd and $\widetilde{\mathbf{C}}_{+} = \{z \in \mathbf{C} \setminus \{0\}\,;\ -3\pi/2 < \arg z < \pi/2\}$, $\widetilde{\mathbf{C}}_{-} = \{|z|\exp(-\sqrt{-1}\arg z)\,;\ z \in \widetilde{\mathbf{C}}_{+}\}$ if n is even (see Appendix A). This extended operator $R^+(z)$ (resp., $R^-(z)$) is called the outgoing (resp., incoming) resolvent and $v^+(x; z) = R^+(z)f(x)$ (resp., $v^-(x; z) = R^-(z)f(x)$) is the outgoing (resp., incoming) solution of (0.2).

Unlike the isotropic case, the Rayleigh surface waves do not always exist. The necessary and sufficient condition (ERW) for their existence, i.e., existence of the Rayleigh surface waves, is given in terms of the surface impedance tensor. If the space dimension is three, the condition (ERW) coincides with the condition given in Nakamura [15]. The condition (ERW) was first introduced by Barnett and Lothe [2] for the homogeneous (i.e., $C^1_{il}(x) = 0$) anisotropic elastic medium with flat boundaries. The precise definition of the condition (ERW) and the surface impedance tensor are given in section 1.

The first purpose of this paper is to show that the existence of the Rayleigh surface waves affects the location of the poles of the resolvent. Concerning this, we have the following theorem.

Theorem 0.1. *Assume that* (A.1) *and* (A.2) *hold and that the space dimension* n *is odd. If the Rayleigh surface waves appear, that is, the condition* (ERW) *in section* 1 *is satisfied, then for any constants* C_0, $C_1 > 0$ *and integer* $N > 0$, *the resolvent* $R^{\pm}(z)$ *has poles in the region* $0 \leq \pm\text{Im}\ z \leq C_0|\text{Re}\ z|^{-N}$, $|\text{Re}\ z| \geq C_1$.

Note that the condition (ERW) is automatically satisfied for the isotropic case. Furthermore, we know the explicit form of the principal symbol of the Neumann operator in the elliptic region. In [21], they used this fact essentially in proving the result corresponding to Theorem 0.1 for the isotropic case. However, the condition (ERW) only gives the fact that the principal symbol of the Neumann operator is locally simple characteristic in the elliptic region. Nevertheless, this is enough to show Theorem 0.1.

From Theorem 0.1, we can show in the next corollary the existence of the poles of the resolvents approaching the real axis.

Corollary 0.2. *Under the same assumption as in Theorem* 0.1, *there exists a sequence of distinct poles* z_j $(j = 1, 2, \dots)$ *of* $R^{\pm}(z)$ *satisfying*

$$0 \leq \pm\text{Im}\ z_j \leq C_N|\text{Re}\ z_j|^{-N}, \qquad (j = 1, 2, \dots)\ \textit{for all}\ N \in \mathbf{N}.$$

In the homogeneous case (i.e., $C^1_{il}(x) = 0$), as in Iwashita and Shibata [9], Iwashita [8], if we further assume that the characteristic roots of $A^0(\xi) = \sum_{i,l=1}^n C^0_{il}\xi_i\xi_l$ are of constant multiplicity for all $\xi \in \mathbf{R}^n \setminus \{0\}$, the resolvent is holomorphic on the real axis except the origin. Note that in the homogeneous isotropic case (i.e., $C^1_{il}(x) = 0$ and $C^0_{ijkl} = \lambda^0\delta_{ij}\delta_{lk} + \mu^0(\delta_{il}\delta_{jk} + \delta_{ik}\delta_{jl})$) these additional assumptions are also satisfied.

The second purpose of this paper is to consider the asymptotic behavior of the local energy. We define the local energy of the solution $u(t, x)$ of (0.1) at time t in a region D as

$$\mathbf{E}(u, D, t) = \frac{1}{2}\int_D \left\{ \sum_{i,j,k,l=1}^n C_{ijkl}(x)\partial_{x_l}u_k(t, x)\overline{\partial_{x_i}u_j(t, x)} + |\partial_t u(t, x)|^2 \right\} dx.$$

For any $a > 0$ with $\Gamma \subset B_a$ and integer $m \geq 0$, we set

$$p_{m,a}(t) = \sup \left\{ \frac{\mathbf{E}(u, \Omega_a, t)}{\left\|\nabla_x f_1\right\|^2_{H^m(\Omega)} + \left\|f_2\right\|^2_{H^m(\Omega)}} \, ; \, 0 \neq f \in C_0^\infty(\overline{\Omega} \cap B_a) \right\},$$

where $u(t, x)$ is the solution of problem (0.1) with the initial data $f = {}^t(f_1, f_2)$. We call $p_{m,a}(t)$ the uniform decay rate of the local energy. Our second purpose is to show that the existence of the Rayleigh surface waves also affects the behavior of the uniform decay rate.

For acoustic waves, Ralston [16] shows that if there exists a trapping ray of geometrical optics (i.e., the existence of trapping singularities of solutions of the acoustic wave equation), the uniform decay rate $p_{0,a}(t)$ in the sense of Morawetz [14] never tends to 0 as $t \to \infty$. For isotropic elastic media, as in [10] and [11], we have the same conclusion as in the acoustic case because there exist trapping singularities due to the global existence of the Rayleigh surface waves.

For $p_{m,a}(t)$ with $m \geq 1$, however, by the argument of Walker [26], we can show $\lim_{t\to\infty} p_{m,a}(t) = 0$ even in the general homogeneous anisotropic case. In fact, from (A.1) and (A.2), the proof given by Shibata and Soga [17] implies the local energy decay property; that is, $\lim_{t\to\infty} \mathbf{E}(u, D, t) = 0$ if D is bounded. This property and Rellich compactness theorem give the basis on Walker's proof.

In the isotropic case, Ikehata and Nakamura [6] showed that for any $\alpha > 0$ and $m \geq 0$, we cannot have an estimate of the form $p_{m,a}(t) \leq C \exp(-\alpha t)$ if Γ is the unit sphere in $\mathbf{R}^3$. For general boundary, as in [12], the uniform decay rate $p_{m,a}(t)$ ($m \geq 1$) never allows an estimate from above by any negative power of time.

Even in the general anisotropic case, we obtain the same conclusions as in the isotropic case.

THEOREM 0.3. *We assume that* (A.1) *and* (A.2) *are satisfied. If we further assume the condition* (ERW) *holds, then for any $a > 0$ with $\Gamma \subset B_a$, we have*

(1) $\lim_{t\to\infty} p_{0,a}(t) \neq 0$,

(2) $\lim_{t\to\infty} p_{m,a}(t) t^\gamma = \infty$ *for any $\gamma > 0$,* $m \in \mathbf{N} \cup \{0\}$.

Thus, although we only assume the local existence condition (ERW) of the Rayleigh surface waves, we have such conclusions for $p_{m,a}(t)$. This is quite surprising, because the local existence of the Rayleigh surface waves does not mean that there exist trapping singularities. It affects the local energy decay property of the solution which is a global property of the solution.

1. Existence of the Rayleigh surface waves and the surface impedance tensor.

Here we review the definition of the surface impedance tensor and its relationship to the existence of the Rayleigh surface waves. For the hypersurface $\Gamma \subset \mathbf{R}^n$, the restriction to Γ of the cotangent bundle $T^*(\mathbf{R}^n)$ has the orthogonal decomposition $T^*(\mathbf{R}^n)|_\Gamma = N^*(\Gamma) \oplus (N^*(\Gamma))^\perp$ by the Euclidian metric on $\mathbf{R}^n$, where $N^*(\Gamma)$ is the conormal bundle of $\Gamma \subset \mathbf{R}^n$. Note that the canonical map $(N^*(\Gamma))^\perp \ni \zeta \mapsto \zeta|_{T^*(\Gamma)} \in T^*(\Gamma)$ is isometric, where the fiber metric $\left\|\zeta\right\|_\Gamma$ of the cotangent bundle $T^*(\Gamma)$ is the one induced by the Euclidian metric on $\mathbf{R}^n$. We regard the unit outer normal vector $\nu(x)$ as a C^∞-section of the conormal bundle $N^*(\Gamma)$ by $\sum_{j=1}^n \nu_j(x) dx_j$.

(i) Elliptic region and limiting velocity. Let $s : \widetilde{U} \ni \sigma = {}^t(\sigma_1, \ldots, \sigma_{n-1}) \mapsto s(\sigma) \in U \subset \Gamma$ be a local coordinates system, where $\widetilde{U} \subset \mathbf{R}^{n-1}$ is an open set. The coordinates of $\mathbf{R} \times U$ are given by $\kappa : \mathbf{R} \times \widetilde{U} \ni (t, \sigma) \mapsto (t, s(\sigma)) \in \mathbf{R} \times U$. $\tilde{s} : T^*(\widetilde{U}) \to T^*(U)$

and $\tilde{\kappa} : T^*(\mathbf{R} \times \widetilde{U}) \to T^*(\mathbf{R} \times U)$ denote the local triviality of $T^*(\Gamma)$ and $T^*(\mathbf{R} \times \Gamma)$, respectively.

Definition 1.1. *The elliptic region $\mathcal{E} \subset T^*(\mathbf{R} \times \Gamma) \setminus \{0\}$ of the operator $\partial_t^2 - A(x, \partial_x)$ and the elliptic region $\mathcal{E}_\Gamma \subset T^*(\Gamma)$ of the operator $A(x, \partial_x) + z^2$ are defined by*

$$\begin{aligned}(\tilde{\kappa})^{-1}\mathcal{E} = \{(t, \sigma, \tau, \eta) \in T^*(\mathbf{R} \times \widetilde{U}) \ ; \ &\det(\tau^2 I - \sigma_p(A)(s(\sigma), \theta(\sigma, \eta, q))) = 0 \\ &\textit{has no real root as a polynomial in } q\,\}\end{aligned}$$

and

$$(\tilde{s})^{-1}\mathcal{E}_\Gamma = \{(\sigma, \eta) \in T^*(\widetilde{U}) \ ; \ (t, \sigma, 1, \eta) \in \tilde{\kappa}^{-1}(\mathcal{E}) \quad \textit{for some } t \in \mathbf{R}\},$$

respectively. Here $\sigma_p(A)(x, \xi) = \sum_{i,l=1}^n C_{il}(x)\xi_i\xi_l$ is the principal symbol of the operator $A(x, \partial_x)$ and the vector $\theta = {}^t(\theta_1, \dots, \theta_n) = \theta(\sigma, \eta, q)$ is defined by $\sum_{j=1}^n \theta_j dx_j = \sum_{j=1}^{n-1} \eta_j d\sigma_j + q \sum_{j=1}^n \nu_j(s(\sigma))dx_j$ in $(T^*(\mathbf{R}^n)|_\Gamma)^{\mathbf{C}}$, i.e., the complexification of the vector bundle $T^*(\mathbf{R}^n)|_\Gamma$.

Note that the elliptic region $\mathcal{E}$ (resp., $\mathcal{E}_\Gamma$) is well defined as an open conic subset in $T^*(\mathbf{R} \times \Gamma)$ (resp., an open subset in $T^*(\Gamma)$).

Definition 1.2. *The limiting velocity $v_L(\zeta)$ at $\zeta \in T^*(\Gamma) \setminus \{0\}$ is defined by*

$$(\tilde{s}^* v_L)(\sigma, \eta) = \inf\{c_i(\sigma, \eta, \phi)(\cos\phi)^{-1} \ ; \ i = 1, 2, \dots, n, |\phi| < \pi/2\},$$

where $c_i(\sigma, \eta, \phi)$ $(i = 1, 2, \dots, n)$ are the positive real roots of the polynomial in c

$$\det(c^2 I - \sigma_p(A)(s(\sigma), \tilde{\theta}(\sigma, \eta, \phi))) = 0$$

with $\tilde{\theta}(\sigma, \eta, \phi) = (\cos\phi)\theta(\sigma, \eta, 0)|\eta|_\Gamma^{-1} + (\sin\phi)\nu(s(\sigma))$, $|\eta|_\Gamma = \left\|s((\sigma, \eta))\right\|_\Gamma$.

Note that the limiting velocity v_L is well defined as a continuous function on $T^*(\Gamma) \setminus \{0\}$, homogeneous of order 0, $(\tilde{s}^* v_L)(\sigma, -\eta) = (\tilde{s}^* v_L)(\sigma, \eta)$ for any $(\sigma, \eta) \in T^*(\widetilde{U})$. By Definitions 1.1 and 1.2, we have $\mathcal{E} = \{(t, \tau, \zeta) \in T^*(\mathbf{R}) \times T^*(\Gamma) \ ; \ |\tau| < v_L(\zeta) \left\|\zeta\right\|_\Gamma\}$ and $\mathcal{E}_\Gamma = \{\zeta \in T^*(\Gamma) \ ; \ 1 < v_L(\zeta) \left\|\zeta\right\|_\Gamma\}$.

(ii) Surface impedance tensor. Now we introduce the surface impedance tensor. We fix $(\sigma, \eta) \in T^*(\Gamma)$, $\tau \in \mathbf{R}$ with $(\sigma, \eta/\tau) \in \mathcal{E}_\Gamma$ and set $\tilde{\nu} = -\nu(s(\sigma))$, $m = \theta(\sigma, \eta, 0)|\eta|_\Gamma^{-1}$, $v = \tau/|\eta|_\Gamma$. Noting that $|m|^2 = \sum_{j=1}^n m_j^2 = 1$, $m \cdot \tilde{\nu} = 0$, we recall the Stroh formalism in [2], [3], [15], and [22] used to define the surface impedance tensor. We consider solutions $u(t, x)$ of equation $(\partial_t^2 - A(s(\sigma), \partial_x))u(t, x) = 0$ of the form $u(t, x) = a\exp(\sqrt{-1}k(m \cdot x + p\tilde{\nu} \cdot x - vt))$ with positive parameter k. We seek such solutions decaying exponentially in $\tilde{\nu} \cdot x$, which is equivalent to finding p with $\operatorname{Im} p > 0$ and $a \neq 0$ satisfying $(v^2 - A(s(\sigma), m + p\tilde{\nu}))a = 0$. Since $|v| < \tilde{s}^* v_L(\sigma, \eta)$, we always have such a pair of p and a. For them, we set $l = -\sum_{i,l=1}^n \tilde{\nu}_i C_{il}(s(\sigma))(m_l + p\tilde{\nu}_l)a$.

Setting $\xi = {}^t({}^t a, {}^t l) \in \mathbf{C}^{2n}$, we can seek p and these vectors a and l by the so called Stroh's eigenvalue problem $(N - p)\xi = 0$, where

$$\begin{aligned}&N = \\ &-\begin{pmatrix} \langle\tilde{\nu}, \tilde{\nu}\rangle^{-1}\langle\tilde{\nu}, m\rangle & \langle\tilde{\nu}, \tilde{\nu}\rangle^{-1} \\ \langle m, \tilde{\nu}\rangle\langle\tilde{\nu}, \tilde{\nu}\rangle^{-1}\langle\tilde{\nu}, m\rangle - \langle\tilde{\nu}, \tilde{\nu}\rangle^{-1} & \langle m, \tilde{\nu}\rangle^{-1}\langle\tilde{\nu}, \tilde{\nu}\rangle^{-1} \end{pmatrix}\end{aligned}$$

with $\langle b, \tilde{b}\rangle = \sum_{i,l=1}^n (C_{il}(s(\sigma)) - v^2 m_i m_l)b_i\tilde{b}_l = \sum_{i,l=1}^n (C_{il}(s(\sigma)) - \tau^2|\eta|_\Gamma^{-4}\, \theta_i(\sigma, \eta, 0)\theta_l(\sigma, \eta, 0))b_i\tilde{b}_l$ for $b = {}^t(b_1, \dots, b_n)$, $\tilde{b} = {}^t(\tilde{b}_1, \dots, \tilde{b}_n)$.

Since $|v| < \tilde{s}^* v_L(\sigma, \eta)$, N has $2n$ nonreal eigenvalues p_α ($\alpha = 1, 2, \ldots, 2n$) accounting with multiplicity. We order them so that $\mathrm{Im}\, p_\alpha > 0$ and $p_{\alpha+n} = \overline{p_\alpha}$ (for $\alpha = 1, 2, \ldots, n$). We take generalized eigenvectors ξ_α ($\alpha = 1, 2, \ldots, 2n$) corresponding to the eigenvalues p_α. We write the first n-components of ξ_α as a_α and the last n-components of ξ_α as l_α, so that $\xi_\alpha = {}^t({}^t a_\alpha, {}^t l_\alpha)$. Then, as in [2], [3], and [15], there is an $n \times n$-matrix $Z = Z(\sigma, \eta, \tau)$ such that $l_\alpha = \sqrt{-1} Z a_\alpha$ ($\alpha = 1, 2, \ldots, n$) hold. This matrix is called the surface impedance tensor.

The surface impedance tensor is well defined as an $n \times n$-matrix valued function in $\mathcal{E}$ independent of time t and is homogeneous of order 0 in (σ, η). In fact, as in [2], [3], and [15], we can represent $Z(\sigma, \eta, \tau)$ as follows:

$$Z(\sigma,\eta,\tau) = -(Q^{-1}(\sigma,\eta,\tau) + \sqrt{-1} Q^{-1}(\sigma,\eta,\tau) S(\sigma,\eta,\tau)),$$

where

$$S(\sigma,\eta,\tau) = -(2\pi)^{-1} \int_0^{2\pi} \langle w(\phi), w(\phi)\rangle^{-1} \langle w(\phi), \eta(\phi)\rangle \, d\phi,$$
$$Q(\sigma,\eta,\tau) = -(2\pi)^{-1} \int_0^{2\pi} \langle w(\phi), w(\phi)\rangle^{-1} \, d\phi,$$

$w(\phi) = -(\sin\phi)\theta(\sigma, \eta/|\eta|_\Gamma, 0) + (\cos\phi)(-\nu(s(\sigma)))$, $\eta(\phi) = (\cos\phi)\theta(\sigma, \eta/|\eta|_\Gamma, 0) + (\sin\phi)$ $(-\nu(s(\sigma)))$.

We also denote by $Z(\zeta, \tau)$ ($\zeta \in T^*(\Gamma)$, $\tau \in \mathbf{R}$ with $(t, \tau, \zeta) \in \mathcal{E}$ for some $t \in \mathbf{R}$) the surface impedance tensor defined globally in $\mathcal{E}$. By the facts in [2] and [3], the surface impedance tensor $Z(\zeta, \tau)$ is a Hermite matrix for any (ζ, τ) and has a limit as τ tends to $\|\zeta\|_\Gamma v_L(\zeta)$, which is also denoted by $Z(\zeta, \|\zeta\|_\Gamma v_L(\zeta))$ hereafter; that is, Z is continuous in $\overline{\mathcal{E}} \subset T^*(\mathbf{R} \times \Gamma)\{0\}$.

(iii) Condition (ERW). Now we state the condition (ERW) ensuring the existence of the Rayleigh surface waves.

(ERW) There exists a point $\zeta^0 \in T^*(\Gamma)$ such that the Hermite matrix $Z(\zeta^0, v_L(\zeta^0) \|\zeta^0\|_\Gamma)$ is not nonnegative definite.

In the three dimensional case, it is the same conditon as in Theorem 12 of Barnett and Lothe [2]. Nakamura [15] shows the existence of the Rayleigh surface waves in the sense of propagation of singularities by deducing a good property for the principal symbol of the (time dependent) Neumann operator from the condition in Barnett and Lothe [2] (cf. Theorems 2.2, 2.3, and 2.4 in [15]). By the historical reasons above, we adopt the condition (ERW) as a condition describing the existence of the Rayleigh surface waves.

2. Outline of proof. In this section, we give our plan to show Theorems 0.1 and 0.3. Both theorems are shown by contradiction arguments. In both cases, the denial of theorems implies estimates of the resolvent near the real axis. Eventually, this fact becomes inconsistent to the assumption (ERW).

For Theorem 0.1, by an argument similar to the proof of Proposition 1 in Stefanov and Vodev [21], we can obtain the following proposition.

Proposition 2.1. *Assume that* (A.1) *and* (A.2) *hold and that n is odd. If Theorem* 0.1 *is not true, that is, the resolvent $R^{\pm}(z)$ is holomorphic in the region* $|\mathrm{Im}\, z| \le C|\mathrm{Re}\, z|^{-m_0}$, $|\mathrm{Re}\, z| \ge C'$ *with some fixed constants $C, C' > 0$ and $m_0 > 0$,* *then there exist constants* $C_0, C_1, C_2 > 0$ *such that*

$$\begin{aligned} &\left\|R^{\pm}(z)f\right\|_{H^2(\Omega_a)} \le C_2|z|^{m_0+3n+5}\left\|f\right\|_{L^2(\Omega)} \\ &\text{for any } f \in L^2_a(\Omega), z \in \widetilde{\mathbf{C}}_{\pm}, |\mathrm{Im}\ z| \le C_0|\mathrm{Re}\ z|^{-(m_0+3n+4)}, |\mathrm{Re}\ z| \ge C_1. \end{aligned} \tag{2.1}$$

For Theorem 0.3, if it is not true, we have an estimate $p_{m,a}(t) \le Ct^{-\gamma}$ with some fixed constants $C, \gamma > 0$, $m \in \mathbf{N}$ and $a > 0$ satisfying $\Gamma \subset B_a$. Then, like the proof of Lemma 7.3 in [12], we can prove an estimate like (2.1). Therefore, in both cases, it only suffices to derive a contradiction by assuming the estimate (2.1) and the condition (ERW).

We argue as follows. First, in the elliptic region, we approximate the Neumann operator by a pseudodifferential operator $B_N(z)$ with (complex) parameter z. The operator $B_N(z)$ is nonelliptic due to the condition (ERW) (cf. sections 4 and 5).

Second, we construct a pseudodifferential operator $P(z)$ with a symbol defined on the whole $T^*(\Gamma)$ such that $P(z)$ is an extension of $z^{2N-1}B_{2N}(z)$ and it is elliptic in $T^*(\Gamma)$ except where $B_{2N}(z)$ is nonelliptic.

Third, we show the existence of a sequence z_j $(j = 1, 2, \dots)$ with the properties that $P(z_j)$ has null solutions and $\lim_{j\to\infty} \mathrm{Re}\ z_j = \infty$. This is done by showing a contradiction under the assumption such that these z_j $(j = 1, 2, \dots)$ do not exist. We start with preparing a priori estimates of the Neumann operator $T^{\pm}(z)$ and the resolvent (cf. section 3). Using these a priori estimates and the fact that outgoing and incoming Neumann operators are essentially the same in the elliptic region, we have a priori estimates of $B_{2N}(z)$ in $\mathrm{Im}\ z \ne 0$. These estimates imply the invertibility of $P(z)$ for z with sufficiently large $|\mathrm{Im}\ z|$ and $\mathrm{Re}\ z$. Then, from the denial of the existence of z_j, the same argument as in [21] implies the estimates $\left\|f\right\|_{L^2(\Gamma)} \le C|z|^{-2N+1}(\log z)^{-1}\left\|P(z)f\right\|_{L^2(\Gamma)}$ for any $f \in C^\infty(\Gamma)$ and real $z >> 1$ (cf. (7.11) in section 7). Then the condition (ERW) allows us to construct an approximation solution of $P(z)$ which breaks the above estimate (cf. section 7).

Last, we take null solutions f_j of $P(z_j)$ with $\left\|f_j\right\|_{L^2(\Gamma)} = 1$ $(j = 1, 2, \dots, n)$. Then the functions f_j are asymptotically null solutions of $B_{2N}(z_j)$ (cf. Theorem 6.1). On the other hand, by the estimate (2.1), we can show an estimate of $B_{2N}(z)$ (cf. (6.1) in section 6). However, this estimate is inconsistent with the existence of the asymptotic null solutions of $B_{2N}(z_j)$ if N is sufficiently large (cf. section 6).

The prototype of this procedure is proposed by Stefanov and Vodev [21] to show the existence of the poles of the resolvent in the isotropic case. In this case, we know the form of the principal symbol of the Neumann operator. The arguments in [21] are based on this fact. In the anisotropic case, however, we cannot know such a global structure of the principal symbol of the Neumann operator. Hence, this is the main difficulty in the anisotropic case which requires a new idea.

From the condition (ERW), we can only show that the principal symbol of the Neumann operator is "real principal type" locally (cf. Proposition 5.2). This is the reason why we can only know the local existence of the Rayleigh surface waves from the condition (ERW). In our argument, however, this is enough to show results analogous to those in the isotropic case. Furthermore, our procedure is quite general, which can be applied to other equations.

3. The Neumann operator. We start by introducing the Neumann operator $T^{\pm}(z)$ for the reduced problem which plays a crucial role in proving the main theorems.

We consider the reduced elastic wave equation with an inhomogeneous Dirichlet datum $g(x)$,

$$(3.1)\qquad \begin{cases} (A(x,\partial_x)+z^2)v^\pm(x;z)=0 & \text{in} \quad \Omega, \\ v^\pm(x;z)=g(x) & \text{on} \quad \Gamma, \\ \ v^+(x;z) \text{ is outgoing (resp., } v^-(x;z) \text{ is incoming),} & \end{cases}$$

where "outgoing" and "incoming" are defined as similar manners as in the Introduction. We denote by $U^+(z)$ (resp., $U^-(z)$) the outgoing (resp., incoming) solution operator of (3.1). The Neumann operator $T^\pm(z)$ is defined as

$$T^\pm(z)g(x) = N(x,\partial_x)U^\pm(z)g(x)|_\Gamma.$$

Since the operator $U^+(z)$ (resp., $U^-(z)$) can be represented by the outgoing (resp., incoming) resolvent of the reduced problem for mixed problem with Dirichlet boundary condition, the Neumann operator $T^\pm(z)$ is a $B(H^{3/2}(\Gamma), H^{1/2}(\Gamma))$-valued holomorphic function in $\pm\mathrm{Im}\ z<0$, and it can be continued meromorphically in $\widetilde{\mathbf{C}}_\pm$. Moreover, $(T^\pm(z))^{-1}$ is a $B(H^{1/2}(\Gamma), H^{3/2}(\Gamma))$-valued holomorphic function in $\pm\mathrm{Im}\ z<0$ and meromorphic function in $\widetilde{\mathbf{C}}_\pm$, since $(T^\pm(z))^{-1}$ is represented by $R^\pm(z)$.

Lemma 3.1. *Assume that* (A.1) *and* (A.2) *hold. If the resolvent satisfies the estimate* (2.1)*, the inverse* $(T^\pm(z))^{-1}$ *of the Neumann operator is holomorphic in* $|\mathrm{Im}\ z| \le C_0|\mathrm{Re}\ z|^{-(m_0+3n+4)}$, $|\mathrm{Re}\ z|\ge C_1$ *and there is a constant* $C_3>0$ *such that*

$$\begin{aligned} &\|(T^\pm(z))^{-1}\|_{L^2(\Gamma)} \le C_3|z|^{m_0+3n+7}\,\|f\|_{L^2(\Gamma)} \\ &\qquad \textit{for any } f \in C^\infty(\Gamma), |\mathrm{Im}\ z|\le C_0|\mathrm{Re}\ z|^{-(m_0+3n+4)}, |\mathrm{Re}\ z|\ge C_1, \end{aligned}$$

where $C_0, C_1>0$ *are the same constant as in Proposition* 2.1.

Proof. From the relation between $(T^\pm(z))^{-1}$ and $R^\pm(z)$, we have the holomorphicity of $(T^\pm(z))^{-1}$ and the estimate

$$\begin{aligned} &\|(T^\pm(z))^{-1}\|_{B(H^{1/2}(\Gamma))} \le C|z|^{m_0+3n+7} \\ &\qquad \text{in } |\mathrm{Im}\ z| \le C_0|\mathrm{Re}\ z|^{-(m_0+3n+4)}, |\mathrm{Re}\ z|\ge C_1. \end{aligned}$$

Noting the duality relation $((T^+(z))^{-1}g,h)_{L^2(\Gamma)} = (g,(T^-(\overline{z}))^{-1}h)_{L^2(\Gamma)}$ and the following property of the Sobolev norm

$$\|g\|_{H^s(\Gamma)} \le C(s)\sup\{|(g,h)_{L^2(\Gamma)}|(\|h\|_{H^{-s}(\Gamma)})^{-1}\,;\, 0\ne h\in C^\infty(\Gamma)\},$$

we obtain the estimate

$$\begin{aligned} &\|(T^\pm(z))^{-1}\|_{B(H^{-1/2}(\Gamma))} \le C|z|^{m_0+3n+7} \\ &\qquad \text{in } |\mathrm{Im}\ z| \le C_0|\mathrm{Re}\ z|^{-(m_0+3n+4)}, |\mathrm{Re}\ z|\ge C_1; \end{aligned}$$

(cf. section 2 in [12]). Hence, well-known interpolation results give us Lemma 3.1.

We also need the following lemma.

Lemma 3.2. *If we assume* (A.1) *and* (A.2) *are satisfied, there exists a constant* $C>0$ *such that for any* $\delta>0$ *we have*

$$\begin{aligned} &\|(T^\pm(z))^{-1}\|_{B(L^2(\Gamma))} \le C(1+\delta)|\mathrm{Im}\ z|^{-1}, \\ &\|R^\pm(z)\|_{B(L^2(\Omega),H^1(\Omega))} \le C(1+\delta)^{1/2}|\mathrm{Im}\ z|^{-1} \\ &\textit{for any } z\in\widetilde{\mathbf{C}}_\pm, \pm\mathrm{Im}\ z<0, |\mathrm{Im}\ z|\le\delta|\mathrm{Re}\ z|, \mathrm{Re}\ z\ge 1. \end{aligned}$$

Proof. For a function $g \in C^\infty(\Gamma)$ and $z \in \widetilde{\mathbf{C}}_\pm$, $\pm\mathrm{Im}\ z < 0$, we take the outgoing (resp., incoming) solution $w^+(x;z)$ (resp., $w^-(x;z)$) of the problem

$$\begin{cases} (A(x,\partial_x) + z^2)w^\pm(x;z) = 0 & \text{in} \quad \Omega, \\ N(x,\partial_x)w^\pm(x;z) = g(x) & \text{on} \quad \Gamma, \end{cases}$$

respectively. Since $w^\pm(x;z)$ is a L^2-solution, integration by parts gives

$$\begin{aligned} \sum_{i,l=1}^{n} (C_{il}(\cdot)\partial_{x_l} w^\pm(\cdot;z), \partial_{x_i} w^\pm(\cdot;z))_{L^2(\Omega)} + (\mathrm{Im}\ z)^2 \left\| w^\pm(\cdot;z) \right\|^2_{L^2(\Omega)} \\ = (\mathrm{Re}\ z)^2 \left\| w^\pm(\cdot;z) \right\|^2_{L^2(\Omega)} + \mathrm{Re}\ (g, w^\pm(\cdot;z))_{L^2(\Gamma)}, \end{aligned} \tag{3.2}$$

$$2\mathrm{Re}\ z \mathrm{Im}\ z \left\| w^\pm(\cdot;z) \right\|^2_{L^2(\Omega)} = -\mathrm{Im}\ (g, w^\pm(\cdot;z))_{L^2(\Gamma)}. \tag{3.3}$$

Recall the well-known estimate, that is, for any $a > 0$ with $\Gamma \subset B_a$, there exists $C_a > 0$ such that

$$\begin{aligned} \left\| v|_\Gamma \right\|^2_{L^2(\Gamma)} \leq & C_a\{\epsilon \left\| \nabla_x v \right\|^2_{L^2(\Omega_a)} + \epsilon^{-1} \left\| v \right\|^2_{L^2(\Omega_a)}\} \\ & \text{for any } \ 0 < \epsilon \leq 1, v \in H^1(\Omega_a). \end{aligned}$$

For $z \in \widetilde{\mathbf{C}}_\pm$ with $\pm\mathrm{Im}\ z < 0$, we use the estimate for $\epsilon = |\mathrm{Re}\ z|^{-1}$, $v = w^\pm(\cdot;z)$, which yields

$$\begin{aligned} |\mathrm{Re}\ z| \left\| w^\pm(\cdot;z)|_\Gamma \right\|^2_{L^2(\Gamma)} \leq C_a \Big\{ & \left\| \nabla_x w^\pm(\cdot;z) \right\|^2_{L^2(\Omega_a)} \\ & + |\mathrm{Re}\ z|^2 \left\| w^\pm(\cdot;z) \right\|^2_{L^2(\Omega_a)} \Big\}. \end{aligned} \tag{3.4}$$

The estimate (3.4), the equalities (3.2), (3.3), and the Korn's inequality (cf. Shibata and Soga [17] or Ito [7]) imply

$$|\mathrm{Re}\ z| \left\| w^\pm(\cdot;z)|_\Gamma \right\|^2_{L^2(\Gamma)} \leq C_a C \left(1 + \frac{|\mathrm{Re}\ z|}{|\mathrm{Im}\ z|} \right) |(g, w^\pm(\cdot;z))_{L^2(\Gamma)}|$$

with some fixed constant $C > 0$. Since $(T^\pm(z))^{-1}g(x) = w^\pm(\cdot;z)|_\Gamma$, the estimate gives us Lemma 3.2 for $(T^\pm(z))^{-1}$.

Next we turn to show the estimate of $R^\pm(z)$. Putting $v^\pm(x;z) = R^\pm(z)f(x)$ and integrating by parts we obtain

$$\begin{aligned} \sum_{i,l=1}^{n} (C_{il}(\cdot)\partial_{x_l} v^\pm(\cdot;z), \partial_{x_i} v^\pm(\cdot;z))_{L^2(\Omega)} + (\mathrm{Im}\ z)^2 \left\| v^\pm(\cdot;z) \right\|^2_{L^2(\Omega)} \\ = (\mathrm{Re}\ z)^2 \left\| v^\pm(\cdot;z) \right\|^2_{L^2(\Omega)} - \mathrm{Re}\ (f, v^\pm(\cdot;z))_{L^2(\Omega)}, \\ 2\mathrm{Re}\ z \mathrm{Im}\ z \left\| v^\pm(\cdot;z) \right\|^2_{L^2(\Omega)} = \mathrm{Im}\ (f, v^\pm(\cdot;z))_{L^2(\Omega)} \end{aligned}$$

for $z \in \widetilde{\mathbf{C}}_\pm$, $\pm\mathrm{Im}\ z < 0$. From the equalities above, it follows that

$$\begin{aligned} \left\| \nabla_x v^\pm(\cdot;z) \right\|^2_{L^2(\Omega)} \leq C & \left\| v^\pm(\cdot;z) \right\|_{L^2(\Omega)} \\ & \Big\{ (\mathrm{Re}\ z)^2 \left\| v^\pm(\cdot;z) \right\|_{L^2(\Omega)} + \left\| f \right\|_{L^2(\Omega)} \Big\}, \\ 2|\mathrm{Re}\ z \mathrm{Im}\ z| \left\| v^\pm(\cdot;z) \right\|_{L^2(\Omega)} \leq & \left\| f \right\|_{L^2(\Omega)}, \end{aligned}$$

where we use the Korn's inequality to deduce the estimate of $\nabla_x v^{\pm}(\cdot; z)$. The estimate implies Lemma 3.2 for $R^{\pm}(z)$.

4. Approximation operators of the Neumann operator. In this section, we construct an approximate operator of the Neumann operator in the elliptic region $\mathcal{E}_\Gamma$ via constructing an approximation of the Poisson operator $U^{\pm}(z)$. Let $s^k : \widetilde{U}_k \ni \sigma = (\sigma_1, \dots, \sigma_{n-1}) \mapsto s^k(\sigma) \in U_k \subset \Gamma$ $(k = 1, 2, \dots, N_0)$ be a local coordinates system satisfying $\Gamma = \cup_{k=1}^{N_0} U_k$. For s^k, we denote by $\widetilde{s}^k$ the local triviality of $T^*(U_k)$. For sufficiently small $b_0 > 0$, the functions $x^k(r, \sigma) = s^k(\sigma) - r\nu(s^k(\sigma))$ defined in $|r| \le b_0$, $\sigma \in \widetilde{U}_k (k = 1, \dots, N_0)$ give us a local coordinate system in $\mathbf{R}^n$ near Γ.

To begin, we construct a cutoff operator $X(z)$ in the elliptic region. Take functions $\phi_k(x) \in C_0^\infty(U_k)$ $(k = 1, \dots, N_0)$ such that $\sum_{k=1}^{N_0} (\phi_k(x))^2 = 1$ on Γ. For fixed open sets $W_0 \subset W_1 \subset \mathcal{E}_\Gamma$ with $\overline{W_0} \subset W_1$, $\overline{W_1} \subset \mathcal{E}_\Gamma$, which are chosen in Lemma 5.1 in section 5 precisely, we take functions $a(\zeta) \in C^\infty(T^*(\Gamma))$ satisfying $a(\zeta) = I$ near W_0, $\operatorname{supp} a \subset W_1$. We define the cutoff operator $X(z)$ as

$$(X(z)f)(x) = \sum_{k=1}^{N_0} \phi_k(x)((s^k)^{-1})^*[Op_z(a^k)(s^k)^*[\phi_k(\cdot)f(\cdot)]](x), \tag{4.1}$$

where $a^k(\sigma, \eta) = (\tilde{s}^k)^* a(\sigma, \eta)$. Here, for $u(\sigma') \in C_0^\infty(\widetilde{U}_k)$, $Op_z(a^k)$ is a pseudodifferential operator with a parameter z defined as

$$Op_z(a^k)u(\sigma) = (2\pi)^{1-n} z^{n-1} \int\int e^{\sqrt{-1}z(\sigma-\sigma')\cdot\eta} a^k(\sigma, \eta) u(\sigma')\, d\sigma'\, d\eta.$$

Note that $Op_z(a^k)$ is well defined for any $z \in \mathbf{C}$ since $\operatorname{supp} a^k$ is compact (for the properties of pseudodifferential operators with a parameter, see [4] or [20]).

Choose functions $\widetilde{\psi}_k(\sigma) \in C_0^\infty(\widetilde{U}_k)$ satisfying $\widetilde{\psi}_k(\sigma) = 1$ near $\operatorname{supp} \widetilde{\phi}_k$, where $\widetilde{\phi}_k(\sigma) = ((s^k)^*\phi_k)(\sigma) \in C_0^\infty(\widetilde{U}_k)$, and cutoff functions $\varphi_k(x) \in C_0^\infty(\mathbf{R}^n)$ such that

$$\begin{aligned} &\varphi_k(x^k(r, \sigma)) = 1 \quad \text{near } r = 0, \sigma \in \operatorname{supp} \widetilde{\phi}_k, \\ &\operatorname{supp} \varphi_k \subset \{x^k(r, \sigma)\ ;\ |r| < b_0, \sigma \in \widetilde{U}_k\}. \end{aligned}$$

Now, we construct an approximation $U_N(z) = \sum_{k=1}^{N_0} U_N^k(z)$ of the Poisson operator $U^{\pm}(z)$ of the form

$$\begin{aligned} U_N^k(z)f(x^k(r, \sigma)) = \varphi_k(x^k(r, \sigma))(2\pi)^{1-n} z^{n-1} \int\int e^{\sqrt{-1}z(\sigma-\sigma')\cdot\eta} u_z^{k,N}(r, \sigma, \eta) \\ \cdot \widetilde{\psi}_k(\sigma')(s^k)^*(\phi_k(\cdot)f(\cdot))(\sigma')\, d\sigma' d\eta \end{aligned}$$

so that $U_N(z)$ satisfies the following equation:

$$\begin{cases} (A(x, \partial_x) + z^2)U_N(z)f(x) = V_N(z)f(x) & \text{in} \quad \Omega, \\ U_N(z)f(x) = X(z)f(x) & \text{on} \quad \Gamma, \end{cases} \tag{4.2}$$

where the operator $V_N(z)$ represents the remainder terms in the approximation.

We seek $u_z^{k,N}(r, \sigma, \eta)$ as $u_z^{k,N}(r, \sigma, \eta) = \sum_{l=0}^{N-1} u_{z,l}^k(r, \sigma, \eta)$. Putting $U_N(z)$ into (4.2), we obtain equations which $u_{z,l}^k$ have to satisfy on each local coordinate. From now on, we do not write the suffix k, referring to the local coordinate U_k, if it is clear from the context.

The change of variables $(r,\sigma)\mapsto x(r,\sigma)=s(\sigma)-r\nu(s(\sigma))$ transforms the operator $A(x,\partial_x)$ to $\widetilde{A}(r,\sigma,\partial_r,\partial_\sigma)$, which yields $\exp(-\sqrt{-1}z\sigma\cdot\eta)\{\widetilde{A}(r,\sigma,\partial_r,\partial_\sigma)+z^2\}(\exp(\sqrt{-1}z\sigma\cdot\eta)v)=\{\widetilde{A}^{(0)}(r,\sigma,\partial_r,\sqrt{-1}z\eta)+\widetilde{A}^{(1)}(r,\sigma,\partial_r,\partial_\sigma,\sqrt{-1}z\,\eta)+\widetilde{A}^{(2)}(r,\sigma,\partial_\sigma)\}v$, where $\widetilde{A}^{(j)}$ is a homogeneous polynomial in ∂_r and $\sqrt{-1}z\eta$ of order $2-j$. Expanding each coefficient of $\widetilde{A}^{(j)}$ into a power series of r at $r=0$, putting the terms of $\exp(-\sqrt{-1}z\,\sigma\cdot\eta)\{\widetilde{A}(r,\sigma,\partial_r,\partial_\sigma)+z^2\}(\exp(\sqrt{-1}z\sigma\cdot\eta)u_z^N(r,\sigma,\eta))$ with the same order together by the rule that the terms ∂_r and z have order 1, and the power $r^j(j\geq 0)$ and the function $u_{z,j}(r,\sigma,\eta)$ have order $-j$, we obtain

$$\text{(4.3)}\qquad \begin{cases} (\widetilde{A}^{(0)}(0,\sigma,\partial_r,\sqrt{-1}z\eta)+z^2)u_{z,l}(r,\sigma,\eta)=\mathcal{R}_l(r,\sigma,\eta;z) \\ \qquad\qquad\qquad \text{in} \quad r>0, \\ u_{z,l}(0,\sigma,\eta)=\delta_{0,l}\widetilde{\phi}(\sigma)a(\sigma,\eta) \end{cases}$$

for $l=0,1,\dots,N-1$, where $\delta_{0,l}$ is Kronecker's delta and

$$\begin{aligned}\mathcal{R}_l(r,\sigma,\eta;z)=-\Big\{&\sum_{j=1}^{l}\frac{1}{j!}r^j(\partial_r^j\widetilde{A}^{(0)})(0,\sigma,\partial_r,\sqrt{-1}z\eta)u_{z,l-j}\\ &+\sum_{j=0}^{l-1}\frac{1}{j!}r^j(\partial_r^j\widetilde{A}^{(1)})(0,\sigma,\partial_r,\partial_\sigma,\sqrt{-1}z\eta)u_{z,l-1-j}\\ &+\sum_{j=0}^{l-2}\frac{1}{j!}r^j(\partial_r^j\widetilde{A}^{(2)})(0,\sigma,\partial_\sigma)u_{z,l-2-j}\Big\}.\end{aligned}$$

Here we have used the convention for the summentions with respect to j in the right-hand side, that is, each of their sums is zero if there is no j in the summations.

To solve (4.3), we follow the argument in Chapter 6 of Kumano-go [13]; however, we need further consideration to handle complex parameter z. Since $\widetilde{A}^{(0)}(0,\sigma,\zeta,\eta)=\sigma_p(A)(s(\sigma),\theta(\sigma,\eta,\zeta))$, the set $\mathcal{N}(\sigma,\eta)=\{\zeta\in\mathbf{C}\,;\det(I-\widetilde{A}^{(0)}(0,\sigma,\zeta,\eta))=0\}$ does not intersect the real axis for any $(\sigma,\eta)\in\tilde{s}^{-1}(W_1)\subset\tilde{s}^{-1}(\mathcal{E}_\Gamma)$ (cf. Definition 1.1). Choose a bounded Jordan curve $\mathcal{C}$ enclosing the set $\cup_{(\sigma,\eta)\in\tilde{s}^{-1}(W_1)}\{\zeta\in\mathcal{N}(\sigma,\eta)\,;\operatorname{Im}\zeta>0\}$ and belonging to the set $\{\zeta\,;2d_0<\operatorname{Im}\zeta<2d_0'\}$ for some fixed constants $0<d_0<d_0'$.

Because of the asymptotic behavior

$$-(I-\widetilde{A}^{(0)}(0,\sigma,\zeta,\eta))^{-1}=\Big(\sum_{i,l=1}^{n}C_{il}(s(\sigma))\nu_i(s(\sigma))\nu_l(s(\sigma))\Big)^{-1}\zeta^{-2}+O(|\zeta|^{-3})$$
$$\text{as}\quad |\zeta|\to\infty\quad \text{in } \mathbf{C},$$

and the existence of $(I-\widetilde{A}^{(0)}(0,\sigma,\zeta,\eta))^{-1}$ for any $\zeta\in\mathbf{R}$, $(\sigma,\eta)\in\tilde{s}^{-1}(W_1)$, $(\int_{\mathcal{C}}(I-\widetilde{A}^{(0)}(0,\sigma,\zeta,\eta))^{-1}\,d\zeta)^{-1}$ exists for any $(\sigma,\eta)\in\tilde{s}^{-1}(W_1)$. Thus, we can define the function $v(z,\sigma,\eta)$ by

$$\text{(4.4)}\qquad \begin{aligned}v(z,\sigma,\eta)=\int_{\mathcal{C}}&e^{\sqrt{-1}z\cdot\zeta}(I-\widetilde{A}^{(0)}(0,\sigma,\zeta,\eta))^{-1}\,d\zeta\\ &\cdot\Big(\int_{\mathcal{C}}(I-\widetilde{A}^{(0)}(0,\sigma,\zeta,\eta))^{-1}\,d\zeta\Big)^{-1}.\end{aligned}$$

LEMMA 4.1. *There exists a constant $\delta_1 > 0$ depending only upon Γ, W_1, $C_{il}(x)|_\Gamma$, and the solutions $u_{z,l}(r,\sigma,\eta)$ of the equation* (4.3) *such that*

(1) $u_{z,l}$ *are* C^∞ *in* $(r,\sigma,\eta) \in [0,\infty) \times \tilde{s}^{-1}(W_1)$,*holomorphic in* z,$|\mathrm{Im}\ z| \leq \delta_1 \mathrm{Re}\ z$,

(2) $|(\partial_r^{\beta_0}\partial_\sigma^\beta\partial_\eta^\alpha u_{z,l})(r,\sigma,\eta)| \leq C_{\beta_0,\beta,\alpha}|z|^{-l+\beta_0}e^{-d_l(\mathrm{Re}\ z)r}$ *for any* $(r,\sigma,\eta) \in [0,\infty) \times \tilde{s}^{-1}(W_1), |\mathrm{Im}\ z| \leq \delta_1 \mathrm{Re}\ z$, *where* $d_l = 2^{-1}(1+2^{-l})d_0 > 0$,

(3) *there is a function* $\tilde{u}_l(r,\sigma,\eta) \in C^\infty([0,\infty) \times \tilde{s}^{-1}(W_1))$*satisfying* $u_{z,l}(r,\sigma,\eta) = z^{-l}\tilde{u}_l(zr,\sigma,\eta)$ *for any* $(r,\sigma,\eta) \in [0,\infty) \times \tilde{s}^{-1}(W_1), z > 0$.

Proof. For $l = 0$, $u_{z,0}$ is given by $u_{z,0}(r,\sigma,\eta) = \widetilde{\phi}(\sigma)a(\sigma,\eta)v(zr,\sigma,\eta)$. We assume Lemma 4.1 is true for $u_{z,j}(j = 0,1,\dots,l-1)$. Following Kumano-go [13], for $z > 0$, we set

$$w_z(r,\sigma,\eta) = (2\pi)^{-1}z^{-1}\int_{\mathbf{R}} e^{\sqrt{-1}z\zeta r}(I - \widetilde{A}^{(0)}(0,\sigma,\zeta,\eta))^{-1} \cdot \mathcal{F}_z[\widetilde{\mathcal{R}}_l(\cdot,\sigma,\eta;z)](\zeta)\,d\zeta,$$

where $\mathcal{F}_z[k](\zeta) = \int_{\mathbf{R}} \exp\{-\sqrt{-1}z\zeta r'\}k(r')\,dr'$, $\widetilde{\mathcal{R}}_l(r,\sigma,\eta;z) = \mathcal{R}_l(r,\sigma,\eta;z)$ if $r \geq 0$, $\widetilde{\mathcal{R}}_l(r,\sigma,\eta;z) = 0$ if $r < 0$. Then we can give $u_{z,l}$ as $u_{z,l}(r,\sigma,\eta) = w_z(r,\sigma,\eta) - v(zr,\sigma,\eta)w_z(0,\sigma,\eta)$. Thus, (3) in Lemma 4.1 follows from assumption of induction, since $\mathcal{F}_z[\widetilde{\mathcal{R}}_l(\cdot,\sigma,\eta;z)](\zeta) = z^{-1}\mathcal{F}_1[\widetilde{\mathcal{R}}_l(z^{-1}\cdot,\sigma,\eta;z)](\zeta)$ holds.

We continue w_z analytically in z. Change of variable and change of contour imply

$$(\partial_r^j w_z)(r,\sigma,\eta) = (2\pi)^{-1}z^{-2}\int_{-\infty+\sqrt{-1}\gamma}^{\infty+\sqrt{-1}\gamma}(\sqrt{-1}\zeta)^j e^{\sqrt{-1}\zeta r} \cdot(I - \widetilde{A}^{(0)}(0,\sigma,z^{-1}\zeta,\eta))^{-1}\mathcal{F}_1[\widetilde{\mathcal{R}}_l(\cdot,\sigma,\eta;z)](\zeta)\,d\zeta \tag{4.5}$$

for any $j = 0,1$, $0 \leq \gamma \leq d_l'z$, $z > 0$, where $d_l' = 2^{-1}(d_l + d_{l-1})$. Since the properties (1), (2) for $u_{z,j}$ $(j = 0,1,\dots,l-1)$ ensure holomorphicity of $\mathcal{F}_1[\widetilde{\mathcal{R}}_l(\cdot,\sigma,\eta;z)](\zeta)$ in $\mathrm{Im}\ \zeta \leq d_l'\mathrm{Re}\ z$ with an estimate

$$|\zeta^j\partial_\sigma^\beta\partial_\eta^\alpha(\mathcal{F}_1[\widetilde{\mathcal{R}}_l(\cdot,\sigma,\eta;z)](\zeta))| \leq C_{\alpha,\beta}|z|^{-l+2+j} \tag{4.6}$$

for any $\zeta, z \in C$, $\mathrm{Im}\ \zeta \leq d_l'\mathrm{Re}\ z$, $(\sigma,\eta) \in \tilde{s}^{-1}(W_1)$, $|\mathrm{Im}\ z| \leq \delta_1|\mathrm{Re}\ z|$, and $j = 0,1$.

Now we move the parameter z in the complex plane and seek the region of z in which the integral (4.5) is still valid. We set $\zeta' = z^{-1}\zeta$. Since $\mathrm{Im}\ \zeta' = -\frac{\mathrm{Im}\ z}{\mathrm{Re}\ z}(\mathrm{Re}\ \zeta') + (\frac{\mathrm{Re}\ z}{|z|^2} + \frac{(\mathrm{Im}\ z)^2}{|z|^2\mathrm{Re}\ z})\mathrm{Im}\ \zeta$, the image of the line $\mathrm{Im}\ \zeta = \gamma$ by the map $\zeta' = z^{-1}\zeta$ is contained in the region $|\mathrm{Im}\ \zeta'| \leq \delta'|\mathrm{Re}\ \zeta'| + d_l'$ if z stays in $|\mathrm{Im}\ z| \leq \delta'|\mathrm{Re}\ z|$, and $0 \leq \gamma \leq d_l'\mathrm{Re}\ z$. Choose $\delta_2 > 0$ depending only upon Γ, W_1, and $C_{il}(x)|_\Gamma$ $(i,l = 1,\dots,n)$ as $\{\zeta'\,;\,|\mathrm{Im}\ \zeta'| \leq \delta_2|\mathrm{Re}\ \zeta'| + d_l'\,\} \cap \mathcal{N}(\sigma,\eta) = \phi$ for any $(\sigma,\eta) \in \tilde{s}^{-1}(W_1)$ so that the integral (4.5) is well defined in $|\mathrm{Im}\ z| \leq \min\{\delta_1,\delta_2\}\mathrm{Re}\ z$, $0 < \gamma \leq \tilde{d}_l\mathrm{Re}\ z$, and $\partial_r^j w_z$ $(j = 0,1)$ is holomorphic in z, where $\delta_1 > 0$ is the constant specified in Lemma 4.1 for $u_{z,j}$ $(j = 0,1,\dots,l-1)$. Thus, $\partial_r^j u_{z,l}$ $(j = 0,1)$ can be also continued analytically in $|\mathrm{Im}\ z| \leq \min\{\delta_1,\delta_2\}\mathrm{Re}\ z$. From the equation of $u_{z,l}$ for $z > 0$, it follows that $u_{z,l}$ satisfies (4.3) for z in $|\mathrm{Im}\ z| \leq \min\{\delta_1,\delta_2\}\mathrm{Re}\ z$ and the property (1) in Lemma 4.1 by the analytic continuation.

To show property (2), we choose $\gamma = d_l'\mathrm{Re}\ z$ in the integral (4.5) and change the variable $\mathrm{Re}\ \zeta$ to $\gamma\mathrm{Re}\ \zeta$. Since $1 \geq |z^{-1}\mathrm{Re}\ z| \geq (1+\delta'^2)^{-1/2} > 0$ in $|\mathrm{Im}\ z| \leq \delta'\mathrm{Re}\ z$, by (4.6), we have the estimate of $\partial_r^j\partial_\sigma^\beta\partial_\eta^\alpha u_{z,l}$ for $j = 0,1$ as in property (2). Thus, (4.3) implies the property (2) inductively. By the definition $\delta_2 > 0$ in each step of induction, we can choose $\delta_1 > 0$ in Lemma 4.1 independent of $u_{z,l}$. This completes the proof of Lemma 4.1.

From Lemma 4.1, it follows that

$$\begin{aligned}(4.7)\qquad &|\partial_r^{\beta_0}\partial_\sigma^{\beta}\partial_\eta^{\alpha}\{e^{-\sqrt{-1}z\sigma\eta}(\widetilde{A}(r,\sigma,\partial_r,\partial_\sigma)+z^2)(e^{\sqrt{-1}z\sigma\eta}u_z^N(r,\sigma,\eta))\}|\\ &\qquad\le C_{\beta_0,\beta,\alpha,N}|z|^{-N+2+\beta_0}e^{-(d_0/2)(\mathrm{Re}\ z)r}\end{aligned}$$

for any $(r,\sigma,\eta)\in[0,\infty)\times\tilde{s}^{-1}(W_1)$, $|\mathrm{Im}\ z|\le\delta_1\mathrm{Re}\ z$ and $u_z^N(0,\sigma,\eta)=\widetilde{\phi}(\sigma)a(\sigma,\eta)$. By the procedure of the construction, there is a constant $a>0$ with $\Gamma\subset B_a$ satisfying

$$(4.8)\qquad \mathrm{supp}\ (V_N(z)f)\subset\overline{\Omega}\cap B_a\quad\text{for any } f\in C^\infty(\Gamma)\text{ and } |\mathrm{Im}\ z|\le\delta_1\mathrm{Re}\ z.$$

Furthermore, from (4.7) it follows that for any $b_0>0$, there exist constants $C_{N,b_0}>0$, $b_1>0$ such that

$$\begin{aligned}(4.9)\qquad &\|V_N(z)f\|_{L^2(\Omega)}\le C_{N,b_0}|z|^{-N+2}\|f\|_{L^2(\Gamma)}\\ &\text{for any } f\in C^\infty(\Gamma),\ |\mathrm{Im}\ z|\le b_0\log(\mathrm{Re}\ z),\ \mathrm{Re}\ z\ge b_1.\end{aligned}$$

In fact, it follows from the L^2-boundness theorem of pseudodifferential operator (cf. Gérard [4]), since supp $u_{z,l}^k\subset[0,\infty)\times((\tilde{s}^k)^{-1}(W_1)\cap(\text{ supp }\widetilde{\phi}_k\times\mathbf{R}^n))$ for $l=0,1,\dots,N-1$, and we can consider that the operator $V_N(z)$ is a finite sum of pseudodifferential operators on $\widetilde{U}_k$ with real parameter Re z having symbols estimated like (4.7) as long as z stays in $|\mathrm{Im}\ z|\le b_0\log(\mathrm{Re}\ z)$ and $|\mathrm{Im}\ z|\le\delta_1\mathrm{Re}\ z$.

Using the approximation $U_N(z)$ of $U^\pm(z)$, we define the approximation $B_N(z)$ of the Neumann operator by

$$B_N(z)f(x)=(N(x,\partial_x)U_N(z)f)|_\Gamma.$$

By (4.2), the uniqueness of problem (3.1) implies

$$\begin{aligned}&U^\pm(z)X(z)=U_N(z)-R^\pm(z)V_N(z)+U^\pm(z)\gamma_\Gamma\cdot R^\pm(z)V_N(z)\\ &\qquad\text{for any }\ \pm\,\mathrm{Im}\ z<0,|\mathrm{Im}\ z|\le\delta_1\mathrm{Re}\ z,\end{aligned}$$

where γ_Γ is the trace operator on Γ. From the definition of $T^\pm(z)$, it follows that

$$T^\pm(z)X(z)=B_N(z)+T^\pm(z)\gamma_\Gamma R^\pm(z)V_N(z),$$

which yields

$$\begin{aligned}(4.10)\qquad &X(z)=(T^\pm(z))^{-1}B_N(z)+\gamma_\Gamma R^\pm(z)V_N(z)\\ &\text{for any }\ z\in\widetilde{\mathbf{C}}_\pm,\pm\mathrm{Im}\ z<0,|\mathrm{Im}\ z|\le\delta_1\mathrm{Re}\ z,\mathrm{Re}\ z\ge 1.\end{aligned}$$

Note that (4.10) is still valid in a region in $|\mathrm{Im}\ z|\le\delta_1\mathrm{Re}\ z$ wherever $(T^\pm(z))^{-1}$ and $R^\pm(z)$ are continued analytically because of the analyticity of $V_N(z)$ in $|\mathrm{Im}\ z|\le\delta_1\mathrm{Re}\ z$.

From the form of $U_N(z)$, the operator $B_N(z)$ is of the form

$$\begin{aligned}(4.11)\qquad B_N(z)f(x)=\sum_{k=1}^{N_0}&\varphi_k(x)((s^k)^{-1})^*[Op_z(b_z^{k,N}(\sigma,\eta)\widetilde{\psi}_k(\sigma'))\\ &\cdot(s^k)^*(\phi_k(\cdot)f(\cdot))](x),\end{aligned}$$

where $b_z^{k,N}(\sigma,\eta)=\sum_{j=0}^{N-1}z^{1-j}b_j^k(\sigma,\eta)$ with $b_j^k\in C_0^\infty((\tilde{s}^k)^{-1}(W_1))$ independent of N. Moreover, there exists a function $l_0(\zeta)\in C^\infty(\mathcal{E}_\Gamma)$ such that $b_0^k(\sigma,\eta)=\widetilde{\phi}_k(\sigma)a^k(\sigma,\eta)$ $((\tilde{s}^k)^*l_0)(\sigma,\eta)$. Note that $((\tilde{s}^k)^*l_0)(\sigma,\eta)$ is given by

$$\begin{aligned}((\tilde{s}^k)^*l_0)(\sigma,\eta)=&-\sum_{i,l=1}^{n}C_{il}(s^k(\sigma))\nu_i(s^k(\sigma))\nu_l(s^k(\sigma))(\partial_r v^k)(0,\sigma,\eta)\\&+\sqrt{-1}\sum_{i,l=1}^{n}C_{il}(s^k(\sigma))\nu_i(s^k(\sigma))\theta_l^k(\sigma,\eta,0),\end{aligned}$$

where $v^k(r,\sigma,\eta)$ is defined as (4.4) in the coordinate $[0,\infty)\times\widetilde{U}_k$. In what follows, we call the function l_0 the principal part of the operator $B_N(z)$.

Before finishing this section, we describe some properties of the operators $B_N(z)$, $X(z)$ with $\mu=\operatorname{Im}z$ as a family of pseudodifferential operators with real parameter $\lambda=\operatorname{Re}z$. We set $\Lambda_{a_0,a_1}=\{z=\lambda+\sqrt{-1}\mu\in\mathbf{C}|\,|\mu|\le a_0\log\lambda,\lambda\ge a_1\}$. Denote by $\Psi_{\rho,\delta}^{m,k}(\Gamma:[\lambda_1,\infty))$ the space of pseudodifferential operators with real parameter on Γ with local symbols $a_\lambda(\sigma,\eta)$ satisfying

$$|\partial_\sigma^\beta\partial_\eta^\alpha a_\lambda(\sigma,\eta)|\le C_{\alpha,\beta}|\lambda|^{k+\rho|\alpha|+\delta|\beta|}(1+|\eta|)^{m-|\alpha|}\qquad\text{for all }\sigma,\eta\in\mathbf{R}^n\text{ and }\lambda\ge\lambda_1.$$

PROPOSITION 4.2. (1) *For any fixed $a_0>0$, the operator $B_N(\lambda+\sqrt{-1}\mu)$ belongs to $\Psi_{0,0}^{-\infty,1}(\Gamma:[1,\infty))$ uniformly in μ with $\lambda+\sqrt{-1}\mu\in\Lambda_{a_0,1}$. The principal symbol $\sigma_p(B_N(\lambda+\sqrt{-1}\mu))$ is*

$$\sigma_p(B_N(\lambda+\sqrt{-1}\mu))=z\Big\{a\cdot l_0-\sqrt{-1}\frac{\mu}{\lambda}H_{rad}(a\cdot l_0)\Big\},$$

where H_{rad} is the radial vector field on $T^*(\Gamma)$ defined by $(\tilde{s}^{-1})_*H_{rad}=\sum_{j=1}^n\eta_j\frac{\partial}{\partial\eta_j}$ for any local triviality $\tilde{s}$.

(2) *The formal adjoint operator $(B_N(\lambda+\sqrt{-1}\mu))^*$ belongs to $\Psi_{0,0}^{-\infty,1}(\Gamma:[1,\infty))$ uniformly in μ with $\lambda+\sqrt{-1}\mu\in\Lambda_{a_0,1}$ and it satisfies*

$$\sigma_p((B_N(\lambda+\sqrt{-1}\mu))^*)=\overline{z}\Big\{a\cdot l_0+\sqrt{-1}\frac{\mu}{\lambda}H_{rad}(a\cdot l_0)\Big\}.$$

In particular, $\sigma_p((B_N(\lambda+\sqrt{-1}\mu))^*)-\sigma_p(B_N(\lambda-\sqrt{-1}\mu))\in\Psi_{0,0}^{-\infty,0}(\Gamma:[1,\infty))$.

(3) *$X(\lambda+\sqrt{-1}\mu)\in\Psi_{0,0}^{-\infty,1}(\Gamma:[1,\infty))$ uniformly in μ with $\lambda+\sqrt{-1}\mu\in\Lambda_{a_0,1}$ and we have*

$$\sigma_p(X(\lambda+\sqrt{-1}\mu))=a-\sqrt{-1}\frac{\mu}{\lambda}H_{rad}(a).$$

5. Properties of the principal part $l_0(\zeta)$. By the definition of the surface impedance tensor $Z(\zeta,\tau)$ and the principal part $l_0(\zeta)$ of the approximation operator $B_N(z)$, we have

$$l_0(\zeta)=\|\zeta\|_\Gamma Z(\zeta,1)\qquad\text{for any }\zeta\in\mathcal{E}_\Gamma. \tag{5.1}$$

In this section, we show properties of $l_0(\zeta)$, which are crucial in proving Theorems 0.1 and 0.3 by the surface impedance tensor.

We set $\Sigma = \{\zeta \in \mathcal{E}_\Gamma\,;\, \det(Z(\zeta,1)) = 0\}$. The set Σ is a closed subset in $\mathcal{E}_\Gamma$.

LEMMA 5.1. *There exist open sets W_0 and W_1 in $\mathcal{E}_\Gamma$ such that $\Sigma \subset W_0$, $\overline{W_0} \subset W_1$, $\overline{W_1} \subset \mathcal{E}_\Gamma$, where the closure $\overline{W_i}$ of W_i $(i = 0, 1)$ is taken in the topology of $T^*(\Gamma)$. Furthermore,*

$$l_0(\zeta) \in C^\infty(\overline{W_1}) \textit{ is a Hermite matrix for any } \zeta \in \overline{W_1};$$
$$l_0(\zeta) \textit{ is an invertible matrix for any } \zeta \in W_0 \setminus \Sigma.$$

Note. In what follows, we use the open sets W_0 and W_1 chosen in Lemma 5.1 as the open sets used for constructing the approximation operator $B_N(z)$ in section 4.

Proof. Take a local coordinate $s(\sigma)$ in section 1. The surface impedance tensor $Z(\sigma,\eta,\tau)$ expressed by the local triviality $\tilde{s}$ induced by s has eigenvalues $\zeta_1(\sigma,\eta,\tau), \dots, \zeta_n(\sigma,\eta,\tau)$ which are real-valued, continuous in $(\sigma,\eta) \in T^*(\widetilde{U})$, $0 < \tau \le \hat{v}(\sigma,\eta)|\eta|_\Gamma$ and real analytic in $0 < \tau < \hat{v}(\sigma,\eta)|\eta|_\Gamma$, and homogeneous of order 0 in (η,τ), where $\hat{v}(\sigma,\eta) = (\tilde{s}^* v_L)(\sigma,\eta)$. Moreover, for any $j = 1, 2, \dots, n$, we have

$$\partial_\tau \zeta_j(\sigma,\eta,\tau) < 0 \quad \text{in } 0 < \tau < \hat{v}(\sigma,\eta)|\eta|_\Gamma, \tag{5.2}$$
$$\zeta_j(\sigma,\eta,0) > 0 \tag{5.3}$$

(cf. Lemma 4.1 in Nakamura [15]).

Set $I = \{j\,;\, \zeta_j(\sigma,\eta,\hat{v}(\sigma,\eta)|\eta|_\Gamma) < 0$ for some $(\sigma,\eta) \in T^*(\widetilde{U})\}$. Since property (5.2) implies $\tilde{s}^{-1}(\Sigma) = \cup_{j\in I}\{(\sigma,\eta) \in T^*(\widetilde{U})\,;\, \zeta_j(\sigma,\eta,1) = 0, 1 < \hat{v}(\sigma,\eta)|\eta|_\Gamma\}$, by (5.2) and (5.3) we have $\tilde{s}^{-1}(\Sigma) \subset \{(\sigma,\eta) \in T^*(\widetilde{U})\,;\, 1 + \epsilon_0 \le \hat{v}(\sigma,\eta)|\eta|_\Gamma \le \epsilon_0^{-1}\} \subset \mathcal{E}_\Gamma$ with a fixed $\epsilon_0 > 0$. This means the set Σ is a compact set in $\mathcal{E}_\Gamma$ so that we can choose open sets W_0 and W_1 as in Lemma 5.1. Since $Z(\zeta,\tau)$ is a Hermite matrix, the rest of the proof is obvious.

Next we show how the condition (ERW) reflects on a property of $l_0(\zeta)$, which is given by Nakamura [15] in the three dimensional case.

PROPOSITION 5.2. *If we assume that the condition* (ERW) *holds, there exists a local coordinate $s : \widetilde{U} \to U$ and a point $(\sigma^0,\eta^0) \in \tilde{s}^{-1}(\mathcal{E}_\Gamma)$, an open neighborhood $\widetilde{W}$ of (σ^0,η^0) in $\tilde{s}^{-1}(W_0)$, a real-valued C^∞-function $\lambda(\sigma,\eta)$ on $\widetilde{W}$, and an $n \times n$-matrix valued C^∞-function $q(\sigma,\eta)$ on $\widetilde{W}$ such that*

$$\lambda(\sigma^0,\eta^0) = 1,\ (\nabla_\eta\lambda)(\sigma^0,\eta^0) \ne 0,\ q(\sigma^0,\eta^0) \ne 0 \ \textit{and}$$
$$(\tilde{s}^* l_0)(\sigma,\eta)q(\sigma,\eta) = 0 \ \textit{on } \lambda(\sigma,\eta) = 1,\ (\sigma,\eta) \in \widetilde{W}.$$

Proof. From (5.1), it suffices to show the same statement for the function $Z(\zeta,1)$. By the condition (ERW), we can choose a local coordinate $\widetilde{U} \to U \subset \Gamma$ such that $\zeta_1(\sigma',\eta',\hat{v}(\sigma',\eta')|\eta'|_\Gamma) < 0$ for some $(\sigma',\eta') \in T^*(\widetilde{U})$ by reenumeration of the eigenvalues $\zeta_1, \zeta_2, \dots, \zeta_n$ if it is necessary. From Lemma 4.1 of Nakamura [15], we can find a conic neighborhood $\widetilde{W}_1$ of (σ',η') in $T^*(\widetilde{U})$, a real-valued, positive, and continuous function $\lambda(\sigma,\eta)$ on $\widetilde{W}_1$ homogeneous of order 1 in η satisfying

$$\zeta_1(\sigma,\eta,\lambda(\sigma,\eta)) = 0, \quad 0 < \lambda(\sigma,\eta) < \hat{v}(\sigma,\eta)|\eta|_\Gamma \quad \text{for any } (\sigma,\eta) \in \widetilde{W}_1.$$

We can reenumerate the eigenvalues $\zeta_2, \dots, \zeta_n$ satisfying $\zeta_j(\sigma', \eta', \lambda(\sigma', \eta')) = 0$ for $j = 1, 2, \dots, r_0$ and $\zeta_{j'}(\sigma', \eta', \lambda(\sigma', \eta')) \neq 0$ for $j' = r_0 + 1, \dots, n$ with an integer $1 \leq r_0 \leq n$. We can assume that $\zeta_j(\sigma, \eta, \lambda(\sigma, \eta)) \neq 0$ for any $j = r_0 + 1, \dots, n$, $(\sigma, \eta) \in \widetilde{W}_1$. Starting from $\widetilde{W}_1$, define sequences of open sets $\widetilde{V}_j$ and $\widetilde{W}_j$ $(j = 2, \dots, r_0)$ as $\widetilde{V}_j = \{(\sigma, \eta) \in \widetilde{W}_{j-1}; \zeta_j(\sigma, \eta, \lambda(\sigma, \eta)) \neq 0\}$ and $\widetilde{W}_j = \widetilde{V}_j$ if $\widetilde{V}_j \neq \phi$, $\widetilde{W}_j = \widetilde{W}_{j-1}$ if $\widetilde{V}_j = \phi$. Set $\tilde{I} = \{1\} \cup \{j;\ \widetilde{V}_j = \phi\}$. Then it is obvious that the open set $\widetilde{W}_{r_0}$ is not empty and $\zeta_j(\sigma, \eta, \lambda(\sigma, \eta)) = 0$, $\zeta_{j'}(\sigma, \eta, \lambda(\sigma, \eta)) \neq 0$ for any $(\sigma, \eta) \in \widetilde{W}_{r_0}$, $j \in \tilde{I}$, $j' \in \{1, \dots, n\} \setminus \tilde{I}$.

Now, we show $\lambda(\sigma, \eta) \in C^\infty(\widetilde{W}_{r_0})$. Set $F(\sigma, \eta, \tau) = \det(Z(\sigma, \eta, \tau))$. Since $F(\sigma, \eta, \tau) = \Pi_{j=1}^n \zeta_j(\sigma, \eta, \tau)$ for any $(\sigma, \eta) \in \widetilde{W}_{r_0}$, from (5.2) we have

$$(\partial_\tau^l F)(\sigma, \eta, \lambda(\sigma, \eta)) = 0, \quad (l = 0, 1, \dots, r-1), \quad (\partial_\tau^r F)(\sigma, \eta, \lambda(\sigma, \eta)) \neq 0,$$

where we denote by r the number of the element of $\tilde{I}$. This gives $\lambda(\sigma, \eta) \in C^\infty(\widetilde{W}_{r_0})$ since $\lambda(\sigma, \eta)$ is an implicit function of equation $(\partial_\tau^{r-1} F)(\sigma, \eta,\ \lambda(\sigma, \eta)) = 0$ with $\partial_\tau(\partial_\tau^{r-1} F)(\sigma, \eta, \lambda(\sigma, \eta)) \neq 0$.

We can choose a point $(\sigma^0, \eta^0) \in \widetilde{W}_{r_0}$ and an open neighborhood $\widetilde{W}$ satisfying $\lambda(\sigma^0, \eta^0) = 1$, $\widetilde{W} \subset \widetilde{W}_{r_0} \cap \mathcal{E}_\Gamma$, because (5.3) ensures $0 < \lambda(\sigma, \eta) < \hat{v}(\sigma, \eta)|\eta|_\Gamma$ in $\widetilde{W}_{r_0}$. Since $\lambda(\sigma, \eta)$ is positive and homogeneous of order 1, we have $(\nabla_\eta \lambda)(\sigma, \eta) \neq 0$ on $\widetilde{W}$. We can also take a constant $c_0 > 0$ satisfying $|\zeta_j(\sigma, \eta, 1)| < c_0$, $|\zeta_l(\sigma, \eta, 1)| > c_0$ on $\widetilde{W}$ for $j \in \tilde{I}$, $l \in \{1, \cdots, n\} \setminus \tilde{I}$ by shrinking $\widetilde{W}$ if it is necessary. Set $q(\sigma, \tau) = (2\pi\sqrt{-1})^{-1} \int_{|\zeta| = c_0} (\zeta - Z(\sigma, \eta, 1))^{-1}\, d\zeta \in C^\infty(\widetilde{W})$. Then $Z(\sigma, \eta, 1) q(\sigma, \eta) = 0$ for $(\sigma, \eta) \in \widetilde{W}$ with $\lambda(\sigma, \eta) = 1$ is obvious because $\zeta_j(\sigma, \eta, 1) = 0$ on $\lambda(\sigma, \eta) = 1$, $(\sigma, \eta) \in \widetilde{W}$ $j \in \tilde{I}$. Since $q(\sigma^0, \eta^0)$ is the eigenprojection of $Z(\sigma^0, \eta^0, 1)$ to the eigenspace $\mathrm{Ker}, (Z(\sigma^0, \eta^0, 1)) \neq \{0\}$, $q(\sigma^0, \eta^0) \neq 0$. This completes the proof of Proposition 5.2.

6. Asymptotic null solution of $B_N(z)$.

Theorems 0.1 and 0.3 are proved by using asymptotic null solutions of $B_N(z)$ described in the following theorem.

Theorem 6.1. *Assume that the condition* (ERW) *holds. Then, for any integer N, there exist a sequence of function f_j $(j = 1, 2, \dots)$ and a sequence z_j $(j = 1, 2, \dots)$, a constant $C_N > 0$ such that the following* (1) $\sim$ (3) *hold. These are*

(1) $f_j \in C^\infty(\Gamma)$, $\quad \|f_j\|_{L^2(\Gamma)} = 1$ *for any* $j = 1, 2, \dots$,

(2) *for any integer* $N' > 0$, *there is a constant* $C_{N,N'} > 0$ *such that*

$$\|(I - X(z_j)) f_j\|_{L^2(\Gamma)} \leq C_{N,N'} |\mathrm{Re}\ z_j|^{-N'}$$

$$\|B_{2N}(z_j) f_j\|_{L^2(\Gamma)} \leq C_{N,N'} |\mathrm{Re}\ z_j|^{-N'} \quad \textit{for any } j = 1, 2, \dots ,$$

(3) $|\mathrm{Im}\ z_j| \leq C_N |\mathrm{Re}\ z_j|^{-2N+1}$ *for any* $j = 1, 2, \dots$.

Proof of Theorems 0.1 *and* 0.3. If Theorem 0.1 or Theorem 0.3 is not true, from the equality (4.10), the estimate (4.9), the property (4.8), and Lemma 3.1, it follows that

$$\begin{aligned} \|X(z) f\|_{L^2(\Gamma)} \leq C|z|^{m_0 + 3n + 7} \{ &\|B_{2N}(z) f\|_{L^2(\Gamma)} \\ &+ |z|^{-2N+2} \|f\|_{L^2(\Gamma)} \} \\ \text{for any } f \in C^\infty(\Gamma), z \in \widetilde{\mathbf{C}}_\pm, &\mathrm{Re}\ z \geq C_1, \\ &|\mathrm{Im}\ z| \leq C_0 |\mathrm{Re}\ z|^{-(m_0 + 3n + 4)}, \end{aligned} \tag{6.1}$$

with some fixed C, C_0, C_1, and $m_0 > 0$. This estimate is inconsistent with Theorem 6.1 for $2N > m_0 + 3n + 9$. Thus, we have proved Theorems 0.1 and 0.3 are true.

The rest of this paper is devoted to showing Theorem 6.1. Hereafter, we fix $a_0 > 0$ and $N \in \mathbf{N}$. Define a pseudodifferential operator $P(z)$ by

$$P(z) = z^{2N-1} B_{2N}(z) + \sqrt{-1}(I - X(z))(z^2 - \triangle_\Gamma)^N \quad z \in \Lambda_{a_0,1},$$

where $-\triangle_\Gamma$ is the Laplace–Beltrami operator on Γ. The expression (4.11) implies that $P(z)$ is a $B(H^{s+2N}(\Gamma), H^s(\Gamma))$-valued entire function for any $s \in \mathbf{R}$. The statement (1) in Proposition 4.2 says $P(\lambda + \sqrt{-1}\mu) \in \Psi_{0,0}^{2N,2N}(\Gamma : [1,\infty))$ uniformly in μ with $\lambda + \sqrt{-1}\mu \in \Lambda_{a_0,1}$. By $\sigma_p(P(\lambda+\sqrt{-1}\mu))(\zeta) = z^{2N-1}\sigma_p(B_{2N}(\lambda+\sqrt{-1}\mu))(\zeta) + \sqrt{-1}(1 - \sigma_p(X(\lambda + \sqrt{-1}\mu)))z^{2N}(1 + \|\zeta\|_\Gamma^2)^N$ and Lemma 5.1, there is a constant $a_1 > 0$ such that $P(\lambda + \sqrt{-1}\mu) \in \Psi_{0,0}^{2N,2N}(\Gamma : [1,\infty))$ $(\lambda + \sqrt{-1}\mu \in \Lambda_{a_0,a_1})$ is elliptic in $T^*(\Gamma) \setminus \Sigma$ including every infinite point (cf. [21]; for definition of ellipticity for pseudodifferential operator with parameter, see [4]).

We explain our plan to show Theorem 6.1. Consider $P(z)$ as an operator on $L^2(\Gamma)$ with domain $D(P(z)) = H^{2N}(\Gamma)$ for any $z \in \Lambda_{a_0,a_1}$.

Proposition 6.2. *If we assume the condition* (ERW) *holds, there exists a sequence* $z_j \in \Lambda_{a_0,a_1} (j = 1, 2, \dots)$ *such that* $\lim_{j\to\infty} \operatorname{Re} z_j = \infty$ *and* $\operatorname{Ker} P(z_j) \neq \{0\}$ *for any* $j = 1, 2, \dots$.

After proving Proposition 6.2, we choose $f_j \in \operatorname{Ker} P(z_j)$ $\|f_j\|_{L^2(\Gamma)} = 1$ and show that $\{z_j\}$ and $\{f_j\}$ satisfy all properties in Theorem 6.1.

We give a proof of Proposition 6.2 in section 7. In the rest of this section, we show Theorem 6.1 by Proposition 6.2.

Proof of Theorem 6.1. The property (1) is obvious, for $P(\lambda + \sqrt{-1}\mu)$ is elliptic at every infinite point (see [4] for the terminology "infinite point"). Unfortunately, since our pseudodifferential operators with nonreal parameters do not generate algebra, we have to deal with them as pseudodifferential operators with real parameters. Recalling (4.1), we consider $X(\lambda + \sqrt{-1}\mu)$ as a pseudodifferential operator with real parameter λ, that is,

$$X(\lambda + \sqrt{-1}\mu)f(x) = \sum_{k=1}^{N_0} \phi_k(x)((s^k)^{-1})^*[Op_\lambda(\tilde{a}^k_{\lambda,\mu})(s^k)^*[\phi_k(\cdot)f(\cdot)]](x),$$

where for any positive integer M,

$$\begin{aligned}\tilde{a}^k_{\lambda,\mu}(\sigma,\eta) &= \left(1 + \sqrt{-1}\frac{\mu}{\lambda}\right)^n \sum_{|\alpha|<M} \sum_{\beta+\gamma\le\alpha} \frac{\alpha!}{(\alpha-\beta)!\beta!\gamma!(\alpha-\beta-\gamma)!} \\ &\cdot \left(-\sqrt{-1}\frac{\mu}{\lambda}\right)^{|\beta+\gamma|} \lambda^{-|\alpha|+|\beta+\gamma|}\eta^\gamma(-\sqrt{-1}\partial_{\sigma'})^{\alpha-(\beta+\gamma)}\partial_\eta^{\alpha-\beta}(a^k(\sigma,\eta)\widetilde{\psi}_k(\sigma'))|_{\sigma'=\sigma} \\ &+ r_{M,\lambda,\mu}(\sigma,\eta),\end{aligned}$$

with $r_{M,\lambda,\mu}(\sigma,\eta) \in S_{0,0}^{-M,-M+\epsilon}(\mathbf{R}^{n-1} \times \mathbf{R}^{n-1} : [1,\infty))$, $\lambda + \sqrt{-1}\mu \in \Lambda_{a_0,1}$ for any $\epsilon > 0$ and $\widetilde{\psi}_k \in C_0^\infty(\widetilde{U}_k)$ is the one chosen in section 4.

From the estimate $|(1 + \sqrt{-1}\mu/\lambda)^n \sum_{|\alpha|<M}(-\sqrt{-1}\mu/\lambda)^{|\alpha|} - 1| \le C_M|\mu/\lambda|^M$ for any $\lambda + \sqrt{-1}\mu \in \Lambda_{a_0,1}$, we can divide $\tilde{a}^k_{\lambda,\mu}(\sigma,\eta)$ as

$$\tilde{a}^k_{\lambda,\mu}(\sigma,\eta) = \widetilde{\psi}_k(\sigma)a^k(\sigma,\eta) + \tilde{a}^{k,1}_{M,\lambda,\mu}(\sigma,\eta) + \tilde{a}^{k,2}_{M,\lambda,\mu}(\sigma,\eta),$$

where $\tilde{a}^{k,1}_{M,\lambda,\mu}(\sigma,\eta) \in S_{0,0}^{0,0}(\mathbf{R}^{n-1} \times \mathbf{R}^{n-1} : [1,\infty))$, $\operatorname{supp} \tilde{a}^{k,1}_{M,\lambda,\mu}(\sigma,\eta) \subset \widetilde{U}_k \times \mathbf{R}^{n-1}_\eta \setminus (\tilde{s}^k)^{-1}(W_0)$, $\tilde{a}^{k,2}_{M,\lambda,\mu}(\sigma,\eta) \in S_{0,0}^{0,-M+\epsilon}(\mathbf{R}^{n-1}\times\mathbf{R}^{n-1} : [1,\infty))$ for $\epsilon > 0$. Since $(s^k)^*\phi_k(\sigma)\cdot$

$\widetilde{\psi}_k(\sigma) = 1$ on $\widetilde{U}_k$, $a^k(\sigma,\eta) = (\tilde{s}^k)^* a(\sigma,\eta) \in S^{0,0}_{0,0}(\mathbf{R}^{n-1} \times \mathbf{R}^{n-1} : [1,\infty))$, $a = I$ near W_0, the decomposition means

$$I - X(\lambda + \sqrt{-1}\mu) = A^{(1)}_{M,\lambda,\mu} + A^{(2)}_{M,\lambda,\mu},$$

where $A^{(1)}_{M,\lambda,\mu} \in \Psi^{0,0}_{0,0}(\Gamma : [1,\infty))$, $A^{(2)}_{M,\lambda,\mu} \in \Psi^{0,-M+\epsilon}_{0,0}(\Gamma : [1,\infty))$ for any $\epsilon > 0$ and the essential support of the local symbol of $A^{(1)}_{M,\lambda,\mu}$ in any local coordinate does not meet the pullback of W_0 by the local triviality. Hence, for any positive integer M and M', we have

$$\begin{aligned}\left\|(I - X(z_j))(z_j^2 - \triangle_\Gamma)^l f_j\right\|_{L^2(\Gamma)} &\le \sum_{k=1}^{2} \left\|A^{(k)}_{M,\mathrm{Re}\ z_j,\mathrm{Im}\ z_j}(z_j^2 - \triangle_\Gamma)^l f_j\right\|_{L^2(\Gamma)} \\ &\le C_{M',M,l}|\mathrm{Re}\ z_j|^{-M'} + C_M|\mathrm{Re}\ z_j|^{-M+1}\left\|(z_j^2 - \triangle_\Gamma)^l f_j\right\|_{L^2(\Gamma)}.\end{aligned}$$

In fact, for the term $A^{(1)}_{M,\lambda,\mu}((\lambda + \sqrt{-1}\mu)^2 - \triangle_\Gamma)^l$, we can use a standard argument since $P(z_j)f_j = 0$ and $P(\lambda + \sqrt{-1}\mu)$ is elliptic on $T^*(\Gamma) \setminus W_0$ containing every infinite point. For the second term, we use only L^2-boundness theorem for $A^{(2)}_{M,\lambda,\mu}$. Noting that $\|f_j\|_{H^{2N}(\Gamma)} \le C|\mathrm{Re}\ z_j|^{2N}$ for any $j = 1, 2, \dots$, with some fixed constant $C > 0$ which follows from an a priori estimate (7.3) stated in section 7, we obtain $\left\|(I - X(z_j))(z_j^2 - \triangle_\Gamma)^l f_j\right\|_{L^2(\Gamma)} \le C_{N'}|\mathrm{Re}\ z_j|^{-N'}$ for $l = 0, 1, \dots, 2N$. By the definition of $P(z)$, the estimate of $B_{2N}(z_j)f_j$ is obvious. Thus, we have the statement (2) in Theorem 6.1.

Last, we show property (3) in Theorem 6.1. We can assume Im $z_j \ne 0$. From the equality (4.10), the estimate (4.9), and Lemma 3.2, it follows that

$$\begin{aligned}\|X(z)f\|_{L^2(\Gamma)} \le C|\mathrm{Im}\ z|^{-1}\Big\{ &\|B_{2N}(z)f\|_{L^2(\Gamma)} \\ &+ |\mathrm{Re}\ z|^{-2N+1}\|f\|_{L^2(\Gamma)}\Big\} \\ &\text{for any } f \in C^\infty(\Gamma), z \in \Lambda_{a_0,1}, \mathrm{Im}\ z \ne 0,\end{aligned} \tag{6.2}$$

because $X(z) = (T^\pm(z))^{-1}B_{2N}(z) + (T^\pm(z))^{-1}(B_{2N'}(z) - B_{2N}(z)) + \gamma_\Gamma R^\pm(z)V_{2N'}(z)$ for any $N' > N$ and $B_{2N'}(\lambda + \sqrt{-1}\mu) - B_{2N}(\lambda + \sqrt{-1}\mu) \in \Psi^{-2N+1,-2N+1}_{0,0}(\Gamma : [1,\infty))$ uniformly in μ with $\lambda + \sqrt{-1}\mu \in \Lambda_{a_1,1}$. Putting z_j and f_j into (6.1) and using (2) in Theorem 6.1, we have

$$1 - C_{N'}|\mathrm{Re}\ z_j|^{-N'} \le C|\mathrm{Im}\ z_j|^{-1}\{C_{N'}|\mathrm{Re}\ z_j|^{-N'} + |\mathrm{Re}\ z_j|^{-2N+1}\},$$

which yields (3) since $z_j \in \Lambda_{a_0,a_1}$. This completes the proof of Theorem 6.1.

7. Null solutions of $P(z)$.

In this section, we show Proposition 6.2. Since the proof is not short, we divide it into three steps to obtain it.

Step 1. (a priori estimates). We show that there are constants $C > 0$ and $b_0 \ge a_1$ such that

$$\|f\|_{L^2(\Gamma)} \le C|\mathrm{Im}\ z|^{-1}|z|^{-2N+1}\|P(z)f\|_{L^2(\Gamma)}, \tag{7.1}$$

$$\|f\|_{L^2(\Gamma)} \le C|\mathrm{Im}\ z|^{-1}|z|^{-2N+1}\|(P(z))^*f\|_{L^2(\Gamma)} \tag{7.2}$$

$$\text{for any } f \in C^\infty(\Gamma), z \in \Lambda_{a_0,b_0}, |\mathrm{Im}\ z| \ge b_0,$$

where $(P(z))^*$ is the formal adjoint operator defined by the ordinary $L^2(\Gamma)$ inner product. Furthermore, there are constants C, $C' > 0$ such that

$$\|f\|_{H^{2N}(\Gamma)} \leq C\,\|P(z)f\|_{L^2(\Gamma)} + C'|\text{Re } z|^{2N}\,\|f\|_{L^2(\Gamma)} \quad \text{for any } f \in C^\infty(\Gamma), z \in \Lambda_{a_0,a_1}. \tag{7.3}$$

Proof of (7.1), (7.2), *and* (7.3). Choose a function $e \in C^\infty(T^*(\Gamma))$ satisfying $e(\zeta) = I$ near Σ, supp $e \subset W_0$. We introduce a cutoff operator E_λ ($\lambda > 1$) defined by

$$E_\lambda f(x) = \sum_{k=1}^{N_0} \phi_k(x)((s^k)^{-1})^*[Op_\lambda(e^k)(s^k)^*[\phi_k(\cdot)f(\cdot)]](x),$$

where $e^k(\sigma,\eta) = (\tilde{s}^k)^* e(\sigma,\eta)$. Here, we have used the same notations as in section 4.

By ellipticity of $P(z)$ on $T^*(\Gamma) \setminus \Sigma$, there is a pseudodifferential operator $Q_{\lambda,\mu} \in \Psi_{0,0}^{-2N,-2N}(\Gamma : [1,\infty))$ uniformly in μ with $\lambda + \sqrt{-1}\mu \in \Lambda_{a_0,a_1}$ such that

$$I - E_\lambda = Q_{\lambda,\mu} P(\lambda + \sqrt{-1}\mu) - R_{\lambda,\mu} \tag{7.4}$$

for some $R_{\lambda,\mu} \in \Psi_{0,0}^{-1,-1}(\Gamma : [1,\infty))$ uniformly in μ with $\lambda + \sqrt{-1}\mu \in \Lambda_{a_0,a_1}$. Thus, we have

$$\begin{aligned} \|(I - E_\lambda)f\|_{L^2(\Gamma)} \leq C|\lambda|^{-2N}\,&\|P(\lambda + \sqrt{-1}\mu)f\|_{L^2(\Gamma)} \\ &+ C'|\lambda|^{-1}\,\|f\|_{L^2(\Gamma)} \\ &\text{for any } f \in C^\infty(\Gamma), \lambda + \sqrt{-1}\mu \in \Lambda_{a_0,a_1}, \end{aligned} \tag{7.5}$$

with some constants $C > 0$ and $C' > 0$.

From the estimate (6.2) of $B_{2N}(z)$, we have

$$\begin{aligned} \|E_\lambda f\|_{L^2(\Gamma)} \leq C|\mu|^{-1}\,&\|E_\lambda B_{2N}(\lambda + \sqrt{-1}\mu)f\|_{L^2(\Gamma)} \\ &+ C'(|\lambda|^{-1} + |\mu|^{-1})\,\|f\|_{L^2(\Gamma)} \\ &\text{for any } f \in C^\infty(\Gamma), \lambda + \sqrt{-1}\mu \in \Lambda_{a_0,a_1}, \mu \neq 0. \end{aligned} \tag{7.6}$$

In fact, since $\sigma_p(X(\lambda + \sqrt{-1}\mu)E_\lambda) = (a - (\sqrt{-1}\mu/\lambda)H_{rad}(a)) \cdot e = e = \sigma_p(E_\lambda)$ by the property (3) of Proposition 4.2 and $a = I$ near W_0, and $[B_{2N}(\lambda + \sqrt{-1}\mu), E_\lambda] \in \Psi_{0,0}^{0,0}(\Gamma : [1,\infty))$, it follows that

$$\begin{aligned} \|E_\lambda f\|_{L^2(\Gamma)} &\leq \|X(\lambda + \sqrt{-1}\mu)E_\lambda f\|_{L^2(\Gamma)} + C'|\lambda|^{-1}\,\|f\|_{L^2(\Gamma)}, \\ \|B_{2N}(\lambda + \sqrt{-1}\mu)E_\lambda f\|_{L^2(\Gamma)} &\leq \|E_\lambda B_{2N}(\lambda + \sqrt{-1}\mu)f\|_{L^2(\Gamma)} \\ &\quad + C'\,\|f\|_{L^2(\Gamma)}. \end{aligned}$$

We also have $E_\lambda(I - X(\lambda + \sqrt{-1}\mu)) \in \Psi_{0,0}^{-\infty,-1}(\Gamma : [1,\infty))$, since supp $e \subset T^*(\Gamma)$ is compact and $\sigma_p(E_\lambda) - \sigma_p(E_\lambda X(\lambda + \sqrt{-1}\mu)) = 0$. From this fact, it follows that $E_\lambda(I - X(\lambda + \sqrt{-1}\mu))((\lambda + \sqrt{-1}\mu)^2 - \triangle_\Gamma)^N \in \Psi_{0,0}^{0,-1+2N}(\Gamma : [1,\infty))$, Thus, noting that $B_{2N}(z) = z^{-2N+1}(P(z) - \sqrt{-1}(I - X(z))(z^2 - \triangle_\Gamma)^N)$, by the estimate (7.6) we obtain

$$\begin{aligned} &\|E_\lambda f\|_{L^2(\Gamma)} \leq C|\mu|^{-1}|z|^{-2N+1}\,\|P(z)f\|_{L^2(\Gamma)} + C'(|\lambda|^{-1} + |\mu|^{-1})\,\|f\|_{L^2(\Gamma)} \\ &\quad \text{for any } f \in C^\infty(\Gamma), \lambda + \sqrt{-1}\mu \in \Lambda_{a_0,a_1}, \mu \neq 0. \end{aligned}$$

The estimate above and the estimate (7.5) yield (7.1).

To prove (7.2), we note that $(P(\lambda+\sqrt{-1}\mu))^*$ is also an elliptic operator on $T^*(\Gamma)\setminus\Sigma$ including every infinite point. Moreover, $(B_{2N}(z))^*$ has an estimate

$$\begin{aligned}\left\|X(\overline{z})f\right\|_{L^2(\Gamma)} \leq & C|\mathrm{Im}\ z|^{-1}\left\|(B_{2N}(z))^*f\right\|_{L^2(\Gamma)}\\ &+C(|\mathrm{Re}\ z|^{-1}+|\mathrm{Im}\ z|^{-1})\left\|f\right\|_{L^2(\Gamma)}\\ &\text{for any } f\in C^\infty(\Gamma), z\in\Lambda_{a_0,1}, \mathrm{Im}\ z\neq 0,\end{aligned}$$

by the property (2) in Proposition 4.2 and the estimate (6.2). Thus, the same argument to show (7.1) implies the estimate (7.2).

Since $Q_{\lambda,\mu}\in\Psi_{0,0}^{-2N,-2N}(\Gamma:[1,\infty))$, $E_\lambda\in\Psi_{0,0}^{-\infty,0}(\Gamma:[1,\infty))$, and $R_{\lambda,\mu}\in\Psi_{0,0}^{-1,-1}(\Gamma:[1,\infty))$ we have $\left\|Q_{\lambda,\mu}f\right\|_{H^s(\Gamma)}\leq C\left\|f\right\|_{L^2(\Gamma)}$, $\left\|E_\lambda f\right\|_{H^s(\Gamma)}\leq C|\lambda|^s\left\|f\right\|_{L^2(\Gamma)}$, and $\left\|R_{\lambda,\mu}f\right\|_{H^s(\Gamma)}\leq C\{\left\|f\right\|_{H^{s-1}(\Gamma)}+|\lambda|^{s-1}\left\|f\right\|_{L^2(\Gamma)}\}$ for any $f\in C^\infty(\Gamma)$, $\lambda+\sqrt{-1}\mu\in\Lambda_{a_0,a_1}$, $s=0,1,\ldots,2N$. Thus, from (7.4), it follows that

$$\begin{aligned}\left\|f\right\|_{H^s(\Gamma)}\leq & C\left\|P(\lambda+\sqrt{-1}\mu)f\right\|_{L^2(\Gamma)}+C(\left\|f\right\|_{H^{s-1}(\Gamma)}+|\lambda|^s\left\|f\right\|_{L^2(\Gamma)})\\ \text{for any } f\in & C^\infty(\Gamma), \lambda+\sqrt{-1}\mu\in\Lambda_{a_0,a_1}, s=0,1,\ldots,2N.\end{aligned}$$

Hence, by induction on s, we obtain (7.3).

Step 2. (realization of $P(z)$). As in section 6, we consider the operator $P(z): L^2(\Gamma)\to L^2(\Gamma)$, $D(P(z))=H^{2N}(\Gamma)$ for any $z\in\Lambda_{a_0,b_0}$. Here, we show that

(7.7) for any $z\in\Lambda_{a_0,b_0}$, $|\mathrm{Im}\ z|\geq b_0$, the operator $P(z)$ has the inverse $(P(z))^{-1}\in B(L^2(\Gamma),H^{2N}(\Gamma))$ such that for some fixed $C>0$, we have

$$\begin{aligned}\left\|(P(z))^{-1}f\right\|_{L^2(\Gamma)}\leq C|\mathrm{Im}\ z|^{-1}|z|^{-2N+1}\left\|f\right\|_{L^2(\Gamma)}\\ \text{for any } f\in L^2(\Gamma), z\in\Lambda_{a_0,b_0}, |\mathrm{Im}\ z|\geq b_0,\end{aligned}$$

(7.8) $(P(z))^{-1}$ is a $B(L^2(\Gamma),H^{2N}(\Gamma))$-valued finitely meromorphic function in $\mathbf{C}$,

(7.9) $$\begin{aligned}&\{\,z_0\in\mathbf{C}\,;\,z_0 \text{ is a pole of } (P(z))^{-1}\}\\ &\qquad=\{\,z_0\in\mathbf{C}\,;\,\mathrm{Ker}\ P(z_0)\neq\{0\}\,\}.\end{aligned}$$

Proof. To get (7.7), it suffices to check $P(z)$ is bijective. The estimate (7.1) says $P(z)$ is one-to-one. The estimates (7.1) and (7.3) imply the range $R(P(z))$ of $P(z)$ is closed in $L^2(\Gamma)$. If $0\neq f\in L^2(\Gamma)$ orthogonal to $R(P(z))$ exists, the function f have to satisfy $(P(z))^*f=0$ in $H^{-2N}(\Gamma)$ by duality, where $(P(z))^*$ is the realization of the formal adjoint operator of $P(z)$ by the inner product of $L^2(\Gamma)$. Thus, ellipticity of $(P(\lambda+\sqrt{-1}\mu))^*$ at every infinite point ensures $f\in C^\infty(\Gamma)$, which means $f=0$ because of the estimate (7.2). Hence, the operator $P(z)$ ($z\in\Lambda_{a_0,b_0}$, $|\mathrm{Im}\ z|\geq b_0$) is bijective.

To show (7.8), we decompose $P(z)$ as $P(z)=\sqrt{-1}(I-K(z))(I-\triangle_\Gamma)^N$, where $K(z)=K_1(z)+K_2(z)$, $K_1(z)=I-(I+(z^2-1)(I-\triangle_\Gamma)^{-1})^N=\sum_{j=1}^N\binom{N}{j}(z^2-1)^{N-j}(I-\triangle_\Gamma)^{-j}$, $K_2(z)=X(z)(I+(z^2-1)(I-\triangle_\Gamma)^{-1})^N+\sqrt{-1}z^{2N-1}B_{2N}(z)(I-\triangle_\Gamma)^{-N}$. From the form of $K(z)$ and compactness of Γ, it follows that $K(z)$ is a $B(L^2(\Gamma))$-valued entire function and is a compact operator for any $z\in\mathbf{C}$. By (7.7), $-\sqrt{-1}P(z)(I-\triangle_\Gamma)^{-N}\in B(L^2(\Gamma))$ has the inverse for $z\in\Lambda_{a_0,b_0}$, $|\mathrm{Im}\ z|\geq b_0$.

It means that there exists the inverse $(I - K(z))^{-1} \in B(L^2(\Gamma))$ for $z \in \Lambda_{a_0,b_0}$, $|\mathrm{Im}\ z| \geq b_0$. The analytic Fredholm theorem implies $(I - K(z))^{-1}$ is a $B(L^2(\Gamma))$-valued finitely meromorphic function in $\mathbf{C}$ whose poles are discrete. This completes the proof of (7.8). From (7.8), the property (7.9) is obvious.

Step 3. (deduction of inconsistency). It suffices to prove that for any fixed $b \geq b_0$, there exists $z_0 \in \Lambda_{a_0,b}$ such that Ker $P(z_0) \neq \{0\}$. In this step, we show it by deriving a contradiction.

Assume that there is a constant $b \geq b_0$ satisfying Ker $P(z) = \{0\}$ for any $z \in \Lambda_{a_0,b}$ as the hypothesis in the present contradiction argument. From (7.8), (7.9), the hypothesis implies the operator $(P(z))^{-1}$ is holomorphic in $\Lambda_{a_0,b}$. Then, by the argument proving Lemma 3 of Stefanov and Vodev [21], we also have the estimate

$$\left\|(P(z))^{-1}\right\| \leq Ce^{C|z|^{n+1}} \quad \text{on } \Lambda_{a_0/2,b'}, \tag{7.10}$$

with some fixed constants $C > 0$ and $b' \geq b$. Since the operator $z^{2N-1}(\log z)(P(z))^{-1}$ is uniformly bounded in the boundary of $\Lambda_{a_0/2,b'}$ as a $B(L^2(\Gamma))$-valued function because of the estimate (7.1), we obtain

$$\left\|(P(z))^{-1}\right\|_{B(L^2(\Gamma))} \leq C|\log z|^{-1}|z|^{-2N+1} \quad \text{on } \Lambda_{a_0/2,b'}.$$

In fact, we can use the Phragmén and Lindelöf theorem to the operator $z^{2N-1}(\log z)$ $(P(z))^{-1}$ by the a priori estimate (7.10). Thus, from the hypothesis of the contradiction argument, it follows that there exist constants $C > 0$ and $b' \geq b$ such that

$$\begin{aligned}\left\|f\right\|_{L^2(\Gamma)} &\leq C|\log z|^{-1}|z|^{-2N+1}\left\|P(z)f\right\|_{L^2(\Gamma)} \\ &\text{for any } f \in C^\infty(\Gamma), z \geq b'.\end{aligned} \tag{7.11}$$

Next, we show the estimate (7.11) is incompatible with Proposition 5.2 deduced from the assumption (ERW). For the local coordinate $s : \widetilde{U} \to U$ in Proposition 5.2, we choose functions ϕ, $\psi_j \in C_0^\infty(\widetilde{U})$, $(j = 1, 2)$ satisfying $\phi(\sigma) = 1$ near $\sigma = \sigma^0$, $\psi_1(\sigma) = 1$ near supp ϕ, $\psi_2(\sigma) = 1$ near supp ψ_1, we set $\Psi_j(x) = (s^{-1})^*\psi_j(x)$ $(j = 1, 2)$. From supp $(I - \Psi_2) \cap$ supp $\Psi_1 = \phi$, it follows $\left\|(I - \Psi_2)P(z)\Psi_1\right\|_{B(L^2(\Gamma))} \leq C_{N'}|z|^{-N'}$ for any $z \geq 1$. Thus, by the estimate (7.11), we have

$$\begin{aligned}\left\|\phi u\right\|_{L^2(\mathbf{R}_\sigma^{n-1})} &\leq C|z|^{-2N+1}|\log z|^{-1}\left\|\widetilde{P}(z)\phi u\right\|_{L^2(\mathbf{R}_\sigma^{n-1})} \\ &\qquad + C_{N'}|z|^{-N'}\left\|\phi u\right\|_{L^2(\mathbf{R}_\sigma^{n-1})} \\ &\text{for any } u \in C^\infty(\mathbf{R}_\sigma^{n-1}), z \geq b',\end{aligned} \tag{7.12}$$

where $\widetilde{P}(z)v(\sigma) = (s^*\Psi_2 P(z)\Psi_1(s^{-1})^*v)(\sigma)$ $(v \in C_0^\infty(\mathbf{R}_\sigma^{n-1}))$. Note that $\widetilde{P}(z) \in \Psi_{0,0}^{2N,2N}(\mathbf{R}^{n-1} : [1, \infty))$ and $\sigma_p(\widetilde{P}(z))(\sigma, \eta) = z^{2N}\psi_1(\sigma)\{(\tilde{s}^*a)(\sigma, \eta)\ (\tilde{s}^*l_0)(\sigma, \eta) + \sqrt{-1}$ $(1 - (\tilde{s}^*a)(\sigma, \eta))(1 + |\eta|_\Gamma^2)^N\}$.

Since $\widetilde{W}$ in Proposition 5.2 meets $\tilde{s}^{-1}(W_0)$, for $\tilde{s}((\sigma^0, \eta^0)) \in \Sigma \subset W_0$, we can choose a function $a_0(\sigma, \eta) \in C_0^\infty(\widetilde{U} \times \mathbf{R}^{n-1})$ satisfying $a_0(\sigma, \eta) = 1$ near (σ^0, η^0), supp $a_0 \subset \tilde{s}^{-1}(W_0) \cap \widetilde{W} \cap ($(supp $\psi_2) \times \mathbf{R}^{n-1})$. We set $\tilde{q}(\sigma, \eta) = a_0(\sigma, \eta)q(\sigma, \eta)$, where $q(\sigma, \eta)$ is the function in Proposition 5.2. Note that $\widetilde{P}(z)\phi Op_z(\tilde{q}) \in \Psi_{0,0}^{2N,2N}(\mathbf{R}^{n-1} :$ $[1, \infty))$ and $\sigma_p(\widetilde{P}(z)\phi Op_z(\tilde{q}))(\sigma, \eta) = z^{2N}\phi(\sigma)a_0(\sigma, \eta)(\tilde{s}^*l_0)(\sigma, \eta)q(\sigma, \eta)$.

The property $\lambda(\sigma^0, \eta^0) = 1$, $(\partial_\eta\lambda)(\sigma^0, \eta^0) \neq 0$ for the function λ in Proposition 5.2 ensures existence of a C^∞-function $S(\sigma)$ in an open neighborhood $\widetilde{V} \subset \widetilde{U}$ of σ^0

satisfying $\lambda(\sigma, \nabla_\sigma S(\sigma)) = 1$ in $\widetilde{V}$, $(\nabla_\sigma S)(\sigma^0) = \eta^0$. For the function $S(\sigma)$ and any function $\varphi \in C_0^\infty(\widetilde{V})$, we consider a function $\exp(\sqrt{-1}zS(\sigma))\varphi(\sigma)$ $(z \geq 1)$. From the expanding theorem of pseudodifferential operator and $\sigma_p(\widetilde{P}(z)\phi Op_z(\tilde{q}))(\sigma, \nabla_\sigma S(\sigma))$ $= z^{2N}\phi(\sigma)a_0(\sigma,\eta)\ (\tilde{s}^* l_0)(\sigma,\eta)q(\sigma,\eta)|_{\eta=\nabla_\sigma S(\sigma)} = 0$ by Proposition 5.2, it follows that

$$\left\|\widetilde{P}(z)\phi Op_z(\tilde{q})(e^{\sqrt{-1}zS(\cdot)}\varphi(\cdot))\right\|_{L^2(\mathbf{R}_\sigma^{n-1})} \leq C|z|^{2N-1},$$
$$\left\|Op_z(\tilde{q})(e^{\sqrt{-1}zS(\cdot)}\varphi(\cdot)) - e^{\sqrt{-1}zS(\cdot)}\tilde{q}(\cdot, \nabla_\sigma S(\cdot))\varphi(\cdot)\right\|_{L^2(\mathbf{R}_\sigma^{n-1})} \leq C|z|^{-1}$$

for any $z \geq 1$ with a fixed constant $C > 0$. Hence, putting the function $u(\sigma) = Op_z(\tilde{q})(e^{\sqrt{-1}zS(\cdot)}\varphi(\cdot))(\sigma)$ into the estimate (7.12), we obtain

$$\left\|\phi(\cdot)\tilde{q}(\cdot, \nabla_\sigma S(\cdot))\varphi(\cdot)\right\|_{L^2(\mathbf{R}_\sigma^{n-1})} \leq C|\log z|^{-1} \qquad \text{for any } z \geq b',$$

which yields $q(\sigma^0, \eta^0) = 0$ by taking the limit as $z \to \infty$. This conclusion, however, make an inconsistency because $q(\sigma^0, \eta^0) \neq 0$ as in Proposition 5.2. This completes the proof of Proposition 6.2.

Appendix A. Meromorphic continuation of the resolvent. Here, we give a proof of properties of $R^\pm(z)$ used throughout in the present paper. We use notations introduced in the Introduction.

Theorem A.1. *Assume that* (A.1) *and* (A.2) *are satisfied and that every coefficient* $C^1_{ijkl}(x)$ *belongs to the space* $C_0^\infty(\mathbf{R}^n)$. *Then, the resolvent* $R^\pm(z)$ *can be continued as a* $B(L_a^2(\Omega), H^2(\Omega_a))$*-valued finitely meromorphic function in* $\widetilde{\mathbf{C}}_\pm$, *and the set consisting of poles of* $R^\pm(z)$ *is a discrete set.*

To prove Theorem A.1, we need the properties of the outgoing (resp., incoming) resolvent $R_0^+(z)$ (resp., $R_0^-(z)$) for the free space problem, that is,

$$\begin{cases} (A^0(\partial_x) + z^2)v(x;z) = f(x) & \text{in} \quad \mathbf{R}^n, \\ v(x;z) \text{ is outgoing (resp., incoming).} \end{cases}$$

Note that $R_0^\pm(z)$ is a $B(L^2(\mathbf{R}^n), H^2(\mathbf{R}^n))$-valued holomorphic function in $\pm\text{Im } z < 0$.

Theorem A.2. *Assume that* (A.1) *and* (A.2) *hold. Then for any* $a > 0$, $R_0^\pm(z)$ *is continued analytically in* $\widetilde{\mathbf{C}}_\pm$ *as* $B(L_a^2(\Omega), H^2(\Omega_a))$*-valued function. Furthermore, there exist constants* $C_a > 0$, $T_a > 0$ *such that*

$$\left\|R_0^\pm(z)f\right\|_{H^{2-j}(B_a)} \leq C_a|z|^{1-j}e^{T_a|\text{Im } z|}\left\|f\right\|_{L^2(\mathbf{R}^n)}$$
$$\textit{for any } f \in L_a^2(\mathbf{R}^n), z \in \widetilde{\mathbf{C}}_\pm \textit{ and } j = 0, 1, 2.$$

Proof of Theorem A.2. Consider the Cauchy problem for the operator $\partial_t^2 - A^0(\partial_x)$,

$$\text{(a.1)} \qquad \begin{cases} (\partial_t^2 - A^0(\partial_x))u(t,x) = 0 & \text{in} \quad \mathbf{R} \times \mathbf{R}^n, \\ u(0,x) = 0, \quad \partial_t u(0,x) = f(x) & \text{on} \quad \mathbf{R}^n. \end{cases}$$

Since $R_0^\pm(z)f(x) = -\int_0^\infty \exp(\mp\sqrt{-1}zt)u(t,x)\,dt$ for $\pm\text{Im } z < 0$, to show Theorem A.2, it is important to know the properties of the solution of (a.1).

Set $C_{min} = \inf_{\omega \in S^{n-1}} \min\{(A(\omega)x, x)_{\mathbf{C}^n}\ ;\ x \in \mathbf{C}^n, |x| = 1\} > 0$, where $(\cdot,\cdot)_{\mathbf{C}^n}$ means the standard inner product of $\mathbf{C}^n$.

Theorem A.3. *Assume that* (A.1) *and* (A.2) *are satisfied. Choose fixed* $a > 0$. *Then the solution of the Cauchy problem* (a.1) *satisfies*

(i) *in odd n case,* $u(t,x) = 0$ *in* $t > C_{min}^{-1}(a+|x|)$ *if* $f \in L_a^2(\mathbf{R}^n)$,

(ii) *in even n case,* $u(t,x)$ *is* C^∞ *in* $t > C_{min}^{-1}(a+|x|)$ *and can be continued analytically in t to the region* $\operatorname{Re} t > C_{min}^{-1}(a+|x|)$ *if* $f \in L_a^2(\mathbf{R}^n)$. *Moreover, for any* $\epsilon > 0$, *we have an estimate*

$$|(\partial_t^l \partial_x^\alpha u)(t,x)| \le C_{l,\alpha,\epsilon}(1+|t|)^{-(n-1)-l-|\alpha|} \left\|f\right\|_{L^2(\mathbf{R}^n)}$$
$$\text{for all } f \in L_a^2(\mathbf{R}^n), \operatorname{Re} t > C_{min}^{-1}(a+|x|)+\epsilon,$$

with a constant $C_{l,\alpha,\epsilon} > 0$ *depending only on l, α, and* $\epsilon > 0$.

According to Vainberg's argument (cf. [24]), we can also prove Theorem A.2 from Theorem A.3. Thus, to obtain Theorem A.2, it suffices to show Theorem A.3.

Proof of Theorem A.3. By the argument in Wilcox [27], there is a positive integer d $(1 \le d \le n)$ such that all eigenvalues of $A^0(\xi) = \sum_{i,l=1}^n C_{il}^0 \xi_i \xi_l$ can be enumerated as $0 < \lambda_1(\xi) \le \lambda_2(\xi) \le \cdots \le \lambda_d(\xi)$. Each $\lambda_j(\xi)$ is a continuous even function, homogeneous of order 2 and $\lambda_j(\xi) \ge C_{min}|\xi|^2$ for any $\xi \in \mathbf{R}^n$ $(j = 1, \ldots, d)$.

Wilcox [25] also shows that there exists a closed conic set $\mathcal{O} \subset \mathbf{R}^n$ which is measure zero in $\mathbf{R}^n$, that is, $S^{n-1} \cap \mathcal{O}$ is measure zero in S^{n-1}, such that

$$\lambda_1(\xi) < \lambda_2(\xi) < \cdots < \lambda_d(\xi) \quad \text{for any } \xi \in \mathbf{R}^n \setminus \mathcal{O}, \tag{a.2}$$

and each $\lambda_j(\xi)$ is real analytic in $\mathbf{R}^n \setminus \mathcal{O}$.

From (a.2), we can define the eigenprojector $P_j(\xi)$ corresponding to the eigenvalues $\lambda_j(\xi)$ as $P_j(\xi) = (2\pi\sqrt{-1})^{-1} \int_{|\zeta - \lambda_j(\xi)| = \gamma_j(\xi)} (\zeta - A^0(\xi))^{-1}\, d\zeta$, where $\gamma_j(\xi) = 3^{-1} \inf\{|\lambda_i(\xi) - \lambda_j(\xi)|\ ;\ i \ne j, i, j = 1, \ldots, d\} > 0$. By definition, every $P_j(\xi)$ is real analytic in $\mathbf{R}^n \setminus \mathcal{O}$, homogenous of order 0, and even function. For any $\xi \in \mathbf{R}^n \setminus \mathcal{O}$, they satisfy $A^0(\xi) = \sum_{i=1}^d \lambda_i(\xi) P_i(\xi)$ and

$$P_i(\xi)P_j(\xi) = \delta_{ij} P_j(\xi),\ P_j(\xi) = (P_j(\xi))^*,\ \sum_{j=1}^d P_j(\xi) = I. \tag{a.3}$$

Since the property (a.3) implies $\left\|P_j(\xi)\right\|_{B(\mathbf{C}^n)} = 1$ for any $\xi \in \mathbf{R}^n \setminus \mathcal{O}$, $j = 1, \ldots, d$, each $P_j(\xi)$ is bounded measurable function in $\mathbf{R}^n$. Hence, for any $f \in C_0^\infty(\mathbf{R}^n)$, we can represent the solution $u(t,x)$ in the form

$$u(t,x) = (2\pi)^{-n} \int_{\mathbf{R}^n} e^{\sqrt{-1}\xi \cdot x} \sum_{j=1}^d \frac{\sin(t\mu_j(\xi))}{\mu_j(\xi)} P_j(\xi) \hat{f}(\xi)\, d\xi, \tag{a.4}$$

where $\mu_j(\xi) = \sqrt{\lambda_j(\xi)}$, $\hat{f}(\xi) = \int_{R^n} \exp(-\sqrt{-1}\xi \cdot x) f(x)\, dx$. In fact, the function defined by the integral in (a.4) is well defined as a C^∞-function and satisfies (a.1). Changing the integral in (a.4) to the poler coordinate, we obtain

$$\begin{aligned} u(t,x) = 2^{-1}(2\pi)^{1-n}\sqrt{-1} \sum_{j=1}^d \int_{S^{n-1}} \mu_j(\omega)^{-1} P_j(\omega),& \\ \mathcal{F}^{-1}[|p|^{n-2}\kappa(p)(\mathcal{F}\mathcal{R}f)](\omega \cdot x - t\mu_j(\omega), \omega)\, d\omega& \end{aligned} \tag{a.5}$$

because of the property $\hat{f}(p\omega) = (\mathcal{F}\mathcal{R}f)(p,\omega)$ (cf. section 2 in [17]), where $\mathcal{R}$ is the Radon transform defined by

$$(\mathcal{R}g)(s,\omega) = \int_{x \cdot \omega = s} g(x)\, dS_x \ \text{ for } \ (s,\omega) \in \mathbf{R} \times S^{n-1}$$

and $(\mathcal{F}k)(p) = \int_{\mathbf{R}} \exp(-\sqrt{-1}ps)k(s)\,ds$ is the Fourier transform. We use the representation (a.5) to show Theorem A.3.

First, we consider the odd dimensional case. If this is the case, we have $\mathcal{F}^{-1}[|\cdot|^{n-2}\kappa(\cdot)(\mathcal{F}\mathcal{R}f)](s,\omega) = (-\sqrt{-1}\partial_s)^{n-2}\mathcal{R}f(s,\omega)$. Since $\mathcal{R}f(s,\omega) = 0$ in $|s| \geq a$ for any $f \in C_0^\infty(B_a)$, the representation (a.5) implies $u(t,x) = 0$ for any (t,x) satisfying $|\omega \cdot x - t\mu_j(\omega)| \geq a$ for all $\omega \in S^{n-1}$. Hence, we have the statement (i) in Theorem A.3 with assumption $f \in C_0^\infty(B_a)$. In fact,

$$|\omega \cdot x - t\mu_j(\omega)| \geq C_{\min}t - |x| > a \text{ if } t > C_{\min}^{-1}(|x| + a). \tag{a.6}$$

Noting that problem (a.1) is well posed in $C^1(\mathbf{R} : L^2(\mathbf{R}^n)) \cap C(\mathbf{R} : H^1(\mathbf{R}^n))$, we obtain Theorem A.3 in the odd n case.

Second, we consider the even dimensional case. Note that

$$\mathcal{F}^{-1}[|\cdot|^{n-2}\kappa(\cdot)(\mathcal{F}\mathcal{R}f)](p,\omega) = (\sqrt{-1})^{3-n}\partial_p^{n-2}(\mathcal{H}\mathcal{R}f)(p,\omega), \tag{a.7}$$

where $(\mathcal{H}k)(p) = \pi^{-1}\lim_{\epsilon\to 0}\int_{|p'|\geq\epsilon} k(p-p')/p'\,dp'$ is the Hilbert transform. From (a.6) and (a.7), it follows that

$$u(t,x) = c_n \sum_{j=1}^{d} \int_{S^{n-1}} \mu_j(\omega)^{-1}P_j(\omega) \int_{|p'|\leq a} \frac{(\mathcal{R}f)(p',\omega)}{(\omega\cdot x - \mu_j(\omega)t - p')^{n-1}}\,dp'\,d\omega$$
$$\text{for any } t > C_{\min}^{-1}(a + |x|),\ f \in C_0^\infty(B_a),$$

with some constant $c_n \in \mathbf{C}$. The representation implies the statement (ii) if $f \in C_0^\infty(B_a)$, because $\left\|\mathcal{R}f(\cdot,\omega)\right\|_{L^2(\mathbf{R}^n)} \leq Ca^{(n-1)/2}\left\|f\right\|_{L^2(\mathbf{R}^n)}$ for any $\omega \in S^{n-1}$, $f \in C_0^\infty(B_a)$ with some constant $C > 0$. Hence, by a density argument, we obtain (ii) in Theorem A.3. This completes the proof of Theorem A.3. Hence, we also have Theorem A.2.

Proof of Theorem A.1. We can write down $R_0^\pm(z)$ in $\pm\text{Im } z < 0$ as

$$R_0^\pm(z)f(x) = (2\pi)^{-n}\int_{\mathbf{R}^n} e^{\sqrt{-1}x\cdot\xi}\sum_{j=1}^{d}\frac{P_j(\xi)\hat{f}(\xi)}{z^2 - \lambda_j(\xi)}\,d\xi \quad (f \in L^2(\mathbf{R}^n))$$

because the properties of $\lambda_j(\xi)$ and $P_j(\xi)$ imply well-definedness of the function defined by the integral above and it gives us an L^2-solution of $(A^0(\partial_x) + z^2)v(x;z) = f(x)$. From the expression and the argument in section 2 of Iwashita and Shibata [9], it follows that for the free space resolvent $R_0^\pm(z)$, $R_0^\pm(0)$ is well defined and $R_0^\pm(z)$ is continuous on $\{0\} \cup \widetilde{\mathbf{C}}_\pm$ since the operators defined by multiplier $|\xi|^2P_j(\xi)/\lambda_j(\xi)$ are $L^2(\mathbf{R}^n)$ bounded. Hence, using analytic Fredholm theory like as in section 2 of [9], we can obtain Theorem A.1.

Acknowledgments. A part of the work was done when the first author was staying at UCLA in 1995. The first author would like to thank Professor James Ralston for his kindness and hospitality and to thank UCLA for the pleasant conditions. ON THE SPLITTING TRICK AND WAVELET FRAME PACKETS[*]

DI-RONG CHEN[†]

Abstract. This paper presents a detailed analysis of the "splitting trick" which splits, for example, the half-shifts of a function into the shifts of two functions. When a Riesz basis of a shift-invariant subspace is split, the optimal bounds of the resulting Riesz basis are obtained. Most importantly, by the splitting trick we built wavelet frame packets as orthogonal wavelet packets constructed by Coifman and Meyer. Their algorithms for finding best basis for a function also apply to our setting.

1. Introduction.

The aim of this paper is to construct wavelet frame packets, in which there are many frames. It is a generalization of wavelet packets. Meanwhile the efficient algorithms for finding best basis in wavelet packets apply to wavelet frame packets.

Let $\mathcal{H}$ be a separable Hilbert space. A sequence $\{f_k\}_{k=1}^{\infty} \subseteq \mathcal{H}$ is called a frame of $\mathcal{H}$ if there are constants A and B, $0 < B \leq A < \infty$ such that

$$B\|f\|^2 \leq \sum_{k=1}^{\infty} |\langle f, f_k\rangle|^2 \leq A\|f\|^2 \quad \forall f \in \mathcal{H}, \tag{1.1}$$

where $\|\cdot\|$ and $\langle\cdot,\cdot\rangle$ are the norm and inner product of $\mathcal{H}$, respectively. The frame bounds are the smallest A and largest B that can be used in (1.1). If we can choose $A = B$ in (1.1), then $\{f_k\}_{k=1}^{\infty}$ is a tight frame with bound A. In particular, when $A = B = 1$, we have the reconstruction formula

$$f = \sum_{k=1}^{\infty} \langle f, f_k\rangle f_k, \tag{1.2}$$

which looks exactly as in the orthonormal basis case.

A frame of $L_2 := L_2(\mathbb{R}^s)$ of form $\{2^{k/2}\psi(2^k\cdot{-\alpha}) \mid k \in \mathbb{Z}, \alpha \in \mathbb{Z}^s, \psi \in \Psi\}$ is called a wavelet frame, where Ψ is a finite set of $L_2(\mathbb{R}^s)$. In [11], some explicit constructions of wavelet frames and some conditions ensuring the existence of such frames were given.

If a wavelet frame $\{2^{k/2}\psi(2^k\cdot -\alpha) \mid k \in \mathbb{Z}, \alpha \in \mathbb{Z}^s, \psi \in \Psi\}$ is an orthonormal basis of L_2, Ψ is called a (orthonormal) wavelet set. Usually, a wavelet set is derived from a given multiresolution analysis of L_2. The construction of wavelet sets has been

discussed in a great number of papers. The problem has been settled more successfully in case $s = 1$ than $s > 1$. One of the difficulties in the latter case is that there is not a common and useful method to solve the problem of matrix extension; see, e.g., [1], [4], [14], [15], [18], and [19].

For a given multiresolution analysis and the corresponding orthonormal wavelet basis of $L_2(\mathbb{R}^s)$, wavelet (basis) packets were constructed by Coifman and Meyer. This construction is an important generalization of that of wavelet sets. There are many orthonormal bases in the wavelet packets. Efficient algorithms for finding the best possible basis do exist (in the context of signal analysis application); however, as pointed out in [11] and [12, pp. 97–99], for certain wavelet applications in signal analysis, frames are more suitable than orthonormal bases, due to the redundancy in frames. It is therefore worthwhile to generalize the construction of wavelet packets to the frame case.

Indeed, orthogonality cannot always be considered to be a crucial property of the wavelet basis [12, Chapter 8], and there has been an extensive study of other wavelet systems, such as prewavelets and biorthogonal wavelets ([1], [5], [7], [9], [14], [17], etc.) as well as nonorthogonal wavelet packets ([6] and [8]). These sequences are Riesz bases of L_2.

A sequence $\{f_k\}_{k=1}^{\infty} \subseteq \mathcal{H}$ is a Riesz basis for $\mathcal{H}$ if there are some constants A and B, $0 < B \leq A < \infty$, such that any $f \in \mathcal{H}$ can be represented as a series $f = \sum_{k=1}^{\infty} c_k f_k$ converging in $\mathcal{H}$ with

$$B\|f\|^2 \leq \sum_{k=1}^{\infty} |c_k|^2 \leq A\|f\|^2. \tag{1.3}$$

The Riesz basis bounds are the smallest A and largest B that can be used in (1.3).

We recall that a Riesz basis with bounds A and B is a frame with bounds A and B. Conversely, a frame $\{f_k\}_{k=1}^{\infty}$ is a Riesz basis provided $f_1, f_2, \ldots$ are linearly independent in the following sense: any f_{k_0} does not belong to the closure of all finitely linear combinations of elements in $\{f_k\}_{k \neq k_0}$.

The main tool used in wavelet packets is the splitting trick (Daubechies' terminology; cf. [12]), which breaks the half integer shifts, for example, of a function into the integer shifts of two functions. One of the basic results in [6] and [8] says that, even in the nonorthogonal case, as long as finitely many steps of splitting are applied, the resulting sequence is still a Riesz basis. On the other hand, the existing estimates for corresponding bounds are known to be suboptimal (cf. [8]). Moreover, the methods of [6] and [8] do not apply to the frame case. In any event, the condition number of the resulting Riesz basis may be large: a result in [8] shows that infinitely many splitting steps may lead to a system that is not a Riesz basis any more.

The paper is organized as follows. We review some basic concepts and results about shift-invariant spaces and prove a characterization of a frame in shift-invariant spaces in section 2. In section 3 we analyze in detail the splitting trick in shift-invariant spaces and obtain the sharp inequalities that correspond to this process. With these inequalities it can be proved easily that, if we apply at most L splittings to a frame (Riesz basis, respectively) of a shift-invariant space, the resulting sequence is still a frame (Riesz basis, respectively). In section 4 we consider the splitting trick on frames (Riesz bases, respectively) of L_2. We shall prove that as long as finitely many splitting steps are applied, the resulting sequence is a frame (Riesz basis, respectively) of L_2. In particular, if the matrix associated with the splitting is unitary, then the resulting sequence is a frame (Riesz basis, respectively) with bounds $A' \leq A$ and $B' \geq B$, where A and B are the bounds of the original sequence. In this case the splitting can be applied at infinitely many times.

We wish to compare our work with [6] and [8]. First, we work in a more general setting. In fact we don't need refinability of the underlying functions as well as a multiresolution. In our deduction only the properties of shift-invariant spaces are employed. Those properties were developed by de Boor, DeVore, and Ron and used extensively in multiresolution analysis, wavelets, and approximation theory. Second, even in the Riesz basis case, our estimation for the bounds of the resulting Riesz bases is sharper than that in either [6] or [8].

In the rest of the paper we assume that $\mathcal{H}$ is either L_2 or a subspace of $L_2(\mathbb{R}^s)$. Moreover, for simplicity of notations, we present only results for $L_2(\mathbb{R})$. However, all conclusions have their counterparts in $L_2(\mathbb{R}^s), s > 1$.

2. Shift-invariant spaces. For later use we review briefly some basic concepts and results for shift-invariant spaces. Then we prove a characterization for the integer shifts of a finite set to be a frame.

A linear space S of functions from $\mathbb{R}$ to $\mathbb{C}$ is called 2^{-k} shift-invariant if it is invariant under 2^{-k} shifts; that is,

$$f \in S \ \Rightarrow f(\cdot - 2^{-k}\alpha) \in S \quad \forall \alpha \in \mathbb{Z}.$$

For a finite set $\Phi \subseteq L_2 := L_2(\mathbb{R})$, we denote by $\mathcal{S}_0^k(\Phi)$ the (finite) linear span of the 2^{-k} shifts of the functions in Φ. Thus a function $f \in \mathcal{S}_0^k(\Phi)$ has the form

$$f = \sum_{\varphi \in \Phi} \sum_{\alpha \in \mathbb{Z}} c_{\varphi\alpha} \varphi(\cdot - 2^{-k}\alpha),$$

where the sequence of coefficients $\{c_{\varphi\alpha}\}_{\varphi \in \Phi, \alpha \in \mathbb{Z}}$ is finitely supported. Obviously $\mathcal{S}_0^k(\Phi)$ is the smallest 2^{-k} shift-invariant space containing Φ.

If Φ is a subset of L_2, we write $\mathcal{S}^k(\Phi)$ for the closure of $\mathcal{S}_0^k(\Phi)$ in L_2. We use the notation $\mathcal{S}^k(\varphi)$ instead of $\mathcal{S}^k(\{\varphi\})$ when Φ consists of a single function φ.

The following characterization of $\mathcal{S}^k(\Phi)$ in terms of Fourier transforms of $\phi \in \Phi$ was given by de Boor, DeVore, and Ron [2]:

$$\mathcal{S}^k(\Phi) = \left\{ f \in L_2 \mid \widehat{f} = \sum_{\varphi \in \Phi} \tau_\varphi \widehat{\varphi}, \ \tau_\varphi \ \text{ is } \ 2^{k+1}\pi\text{-periodic}, \ \varphi \in \Phi \right\}, \tag{2.1}$$

where $\widehat{f}$ is the Fourier transform of $f \in L_2$,

$$\widehat{f}(\omega) := \int_{-\infty}^{\infty} f(x) e^{-ix\omega} dx.$$

In [3] the bracket product of two functions $f, g \in L_2$ is defined by

$$[f, g](\omega) := \sum_{\alpha \in \mathbb{Z}} \widehat{f}(\omega + 2\alpha\pi) \overline{\widehat{g}}(\omega + 2\alpha\pi).$$

It was first introduced by Jia and Micchelli [14] with some decay conditions on f and g. We note that the series converges absolutely for almost every $\omega \in \mathbb{R}$. Thus $[f, g]$ is well defined almost everywhere (a.e.). Moreover $[f, g] \in L_1[0, 2\pi]$. The Gramian matrix of a finite set $\Phi \subseteq L_2$ is given by $G(\Phi) := ([\varphi, \psi])_{\varphi, \psi \in \Phi}$. It is a nonnegative definite matrix for almost every ω.

Following [2], we say that Φ provides a quasi basis for $\mathcal{S}^0(\Phi)$ (that is, their integer shifts is a quasi basis) if

$$\det G(\Phi)(\omega) > 0 \quad \text{a.e. } \omega \in \sigma(\Phi) := \{\omega | \text{ rank } G(\Phi)(\omega) > 0\}.$$

The shifts of Φ are quasi-stable if there are two positive constants A and B such that

$$BI \leq G(\Phi) \leq AI \quad \text{a.e. } \omega \in \sigma(\Phi), \tag{2.2}$$

where I is the identity matrix of the same order as $G(\Phi)$ and, as usual, $M_1 \leq M_2$ for two $n \times n$ nonnegative definite matrices M_1 and M_2 means that for any $X = (x_1, \ldots, x_n) \in \mathbb{C}^n$ with X^* its complex conjugate,

$$XM_1X^* \leq XM_2X^*.$$

The bounds of a quasi-stable basis are the smallest A and largest B such that the inequalities in (2.2) hold.

The concepts of quasi basis and quasi-stable basis apply to $\mathcal{S}^k(\Phi), k \neq 0$, by scaling. We define the scaling operator sc on L_2 by $sc : f \to 2^{1/2}f(2\cdot), f \in L_2$. If Φ is a subset of L_2 and k is an integer, let $sc^k\Phi = \{\, sc^k f \,|\, f \in \Phi\}$. It is easily seen that $\mathcal{S}^k(\Phi) = sc^k\mathcal{S}^0(sc^{-k}\Phi)$ for any finite set Φ of L_2. The 2^{-k} shifts $\{\varphi(\cdot - 2^{-k}\alpha)|\alpha \in \mathbb{Z}, \varphi \in \Phi\}$ of Φ are said to form a quasi basis (quasi-stable basis, respectively) for $\mathcal{S}^k(\Phi)$ if and only if the integer shifts of $sc^{-k}\Phi$ form a quasi basis (quasi-stable basis, respectively) for $\mathcal{S}^0(sc^{-k}\Phi)$. In the case that the 2^{-k} shifts of Φ form a quasi-stable basis for $\mathcal{S}^k(\Phi)$, its bounds are defined to be those of the quasi-stable basis $\{\, (sc^{-k}\varphi)(\cdot - \alpha) \mid \varphi \in \Phi,\ \alpha \in \mathbb{Z}\}$ for $\mathcal{S}^0(sc^{-k}\Phi)$.

We recall that $\{\varphi(\cdot - \alpha)|\alpha \in \mathbb{Z}, \varphi \in \Phi\}$ is a Riesz basis with bounds A and B for $\mathcal{S}^0(\Phi)$ if and only if A is the smallest constant and B is the largest constant such that

$$BI \leq G(\Phi) \leq AI \quad \text{a.e. } \omega.$$

Therefore a Riesz basis $\{\varphi(\cdot - \alpha)|\alpha \in \mathbb{Z}, \varphi \in \Phi\}$ is a quasi-stable basis with $\sigma(\Phi) = \mathbb{R}$.

We begin our study with a characterization of when $\{\varphi(\cdot - \alpha)|\alpha \in \mathbb{Z}, \varphi \in \Phi\}$ is a frame for $\mathcal{S}^0(\Phi)$.

THEOREM 2.1. *Let $\Phi = \{\varphi_k\}_{k=1}^n \subseteq L_2$. Then for arbitrary nonnegative constants A and B, the following conditions are equivalent:*

$$B||f||^2 \leq \sum_{k=1}^n \sum_{\alpha\in\mathbb{Z}} |\langle f, \varphi_{k\alpha}\rangle|^2 \leq A||f||^2 \quad \forall f \in \mathcal{S}^0(\Phi), \tag{2.3}$$

$$BG(\Phi) \leq G^2(\Phi) \leq AG(\Phi) \quad \text{a.e.} \tag{2.4}$$

Proof. For any $f \in L_2$ we have by Plancherel's theorem

$$\sum_{k=1}^n \sum_{\alpha\in\mathbb{Z}} |\langle f, \varphi_{k\alpha}\rangle|^2 = \frac{1}{2\pi} \sum_{k=1}^n \int_0^{2\pi} |[f, \varphi_k]|^2, \tag{2.5}$$

(cf. [12, p. 67]), where $\varphi_\alpha(\cdot) = \varphi(\cdot - \alpha)$ for any $\varphi \in L_2$ and $\alpha \in \mathbb{Z}$.

For $f \in \mathcal{S}^0(\Phi)$, by (2.1), we can find a 2π-periodic mapping $m(\omega) = (m_1(\omega), \ldots, m_n(\omega)), \mathbb{R} \to \mathbb{C}^n$ such that

$$\widehat{f} = \sum_{l=1}^n m_l \widehat{\varphi}_l, \tag{2.6}$$

which yields

$$[f, \varphi_k] = \sum_{l=1}^{n} m_l [\varphi_l, \varphi_k], \quad k = 1, \dots, n.$$

Therefore it follows from (2.5) that

$$\sum_{k=1}^{n} \sum_{\alpha \in \mathbb{Z}} |\langle f, \varphi_{k\alpha} \rangle|^2 = \frac{1}{2\pi} \sum_{k=1}^{n} \int_0^{2\pi} \left| \sum_{l=1}^{n} m_l [\varphi_l, \varphi_k] \right|^2$$

$$= \frac{1}{2\pi} \int_0^{2\pi} \sum_{l,j=1}^{n} m_l \overline{m}_j \sum_{k=1}^{n} [\varphi_l, \varphi_k] \overline{[\varphi_j, \varphi_k]} = \frac{1}{2\pi} \int_0^{2\pi} m G^2(\Phi) m^*.$$

On the other hand, it follows from Plancherel's theorem and (2.6) that

$$\|f\|^2 = \frac{1}{2\pi} \int_0^{2\pi} [f, f] = \frac{1}{2\pi} \int_0^{2\pi} m G(\Phi) m^*. \tag{2.7}$$

Thus we conclude that (2.3) is equivalent to

$$B \int_0^{2\pi} m G(\Phi) m^* \le \int_0^{2\pi} m G^2(\Phi) m^* \le A \int_0^{2\pi} m G(\Phi) m^* \tag{2.8}$$

for any 2π-periodic mapping m with

$$m G(\Phi) m^* \in L_1[0, 2\pi]. \tag{2.9}$$

For any (Lebesgue) measurable set $E \subseteq [0, 2\pi]$, replacing m in (2.8) by a 2π-periodic mapping that is equal to $m\chi_E$ for $\omega \in [0, 2\pi]$, we see that (2.8) is indeed equivalent to

$$B \int_E m G(\Phi) m^* \le \int_E m G^2(\Phi) m^* \le A \int_E m G(\Phi) m^*,$$

where χ_E is, as usual, the characteristic function of E. Lebesgue's theorem about Lebesgue point yields that

$$B m G(\Phi) m^* \le m G^2(\Phi) m^* \le A m G(\Phi) m^* \quad \text{a.e.}$$

for any m satisfying (2.9).

Since the entries of $G(\Phi)$ are all in $L_1[0, 2\pi]$, any 2π-periodic mapping m with $\|m_k\|_\infty < \infty, 1 \le k \le n$, satisfies (2.9). Therefore (2.4) and (2.8) are equivalent. The proof is complete.

Remark 2.2. After completing the first version of the manuscript, the author became aware that Ron and Shen [20] had established Theorem 2.1 by a different method.

If $\Phi = \{\varphi_k\}_{k=1}^n$ provides a quasi basis for $\mathcal{S}^0(\Phi)$, then $G(\Phi)(\omega)$ is invertible for $\omega \in \sigma(\Phi)$. Therefore (2.4) is equivalent to

$$B \le G(\Phi) \le A \quad \text{a.e. on } \sigma(\Phi).$$

Therefore we have proved the following known result.

Corollary 2.3. *Φ provides a quasi-stable basis for $\mathcal{S}^0(\Phi)$ if and only if Φ provides a quasi basis for $\mathcal{S}^0(\Phi)$ and $\{\varphi_k(\cdot - \alpha) \mid \alpha \in \mathbb{Z}, 1 \le k \le n\}$ is a frame for $\mathcal{S}^0(\Phi)$.*

3. The splitting trick in shift-invariant spaces. Now we establish some inequalities about the splitting trick. These inequalities are essential to the construction of wavelet frame packets.

LEMMA 3.1. *Assume $\Phi = \{\varphi_k\}_{k=1}^n \subseteq L_2$. Let $\Psi = \{\psi_j\}_{j=1}^n \subseteq \mathcal{S}^0(\Phi)$ be given by*

$$\widehat{\psi}_j = \sum_{k=1}^n P_{jk}\widehat{\varphi}_k, \quad j = 1, \dots, n, \tag{3.1}$$

where P_{jk} are 2π-periodic functions, $j, k = 1, \dots, n$. If for $P = (P_{jk})_{j,k=1}^n$, there are some constants C' and C such that

$$C'I \leq P^*P \leq CI \quad \text{a.e. on } \sigma(\Phi), \tag{3.2}$$

then

$$\begin{aligned} &C' \sum_{k=1}^n \sum_{\alpha\in\mathbb{Z}} |\langle f, \varphi_{k\alpha}\rangle|^2 \leq \sum_{j=1}^n \sum_{\alpha\in\mathbb{Z}} |\langle f, \psi_{j\alpha}\rangle|^2 \\ &\leq C \sum_{k=1}^n \sum_{\alpha\in\mathbb{Z}} |\langle f, \varphi_{k\alpha}\rangle|^2 \quad \forall f \in L_2, \end{aligned} \tag{3.3}$$

where, as before, $\varphi_{k\alpha} = \varphi_k(\cdot - \alpha)$ and $\psi_{j\alpha} = \psi_j(\cdot - \alpha)$.

Moreover, if Φ provides a quasi-stable basis, (3.2) *and* (3.3) *are equivalent.*

Proof. For any $f \in L_2$ we have by (3.1) that

$$[f, \psi_j] = \sum_{k=1}^n \overline{P}_{jk}[f, \varphi_k], \quad j = 1, \dots, n.$$

Consequently

$$\begin{aligned} \sum_{j=1}^n |[f, \psi_j]|^2 &= \sum_{k,k'=1}^n \left(\sum_{j=1}^n \overline{P}_{jk} P_{jk'} \right) [f, \varphi_k]\overline{[f, \varphi_{k'}]} \\ &= XP^*PX^*, \end{aligned}$$

where $X = X(\omega) = ([f, \varphi_1], \dots, [f, \varphi_n])$.

It follows from (2.5) that (3.3) is equivalent to the inequalities

$$C' \int_0^{2\pi} XX^* \leq \int_0^{2\pi} XP^*PX^* \leq C \int_0^{2\pi} XX^* \quad \forall f \in L_2. \tag{3.4}$$

For any measurable set $E \subseteq [0, 2\pi]$ and $f \in L_2$ we define a function g by letting

$$\widehat{g}(\omega) = \widehat{f}(\omega) \sum_{\alpha\in\mathbb{Z}} \chi_E(\omega + \alpha).$$

Then $g \in L_2$ and $[g, \varphi_k] = [f, \varphi_k]\chi_E$. Since the measurable sets E are arbitrary we observe, as in the proof of Theorem 2.1, that (3.4) is equivalent to

$$C'XX^* \leq XP^*PX^* \leq CXX^* \text{ a.e.}$$

Since $X(\omega) = 0$ for any $f \in L_2$ and $\omega \in [0, 2\pi]\backslash\sigma(\Phi)$, we actually have proved that (3.3) holds if and only if

$$C'XX^* \leq XP^*PX^* \leq CXX^* \quad \text{a.e.} \quad \text{on } \sigma(\Phi) \tag{3.5}$$

for any $X = ([f, \varphi_1], \ldots, [f, \varphi_n])$ with $f \in L_2$. On the other hand, (3.2) means that (3.5) holds for any $X \in \mathbb{C}^n$. Therefore (3.2) implies (3.3).

Assume further that Φ provides a quasi-stable basis. We claim that for any 2π-periodic and measurable mapping $X = X(\omega) = (x_1(\omega), \ldots, x_n(\omega))$ with $X(\omega) = 0$ for $\omega \in [0, 2\pi]\backslash\sigma(\Phi)$ and $||x_k||_\infty < \infty, 1 \leq k \leq n$, there is some $f \in L_2$ satisfying

$$X = ([f, \varphi_1], \ldots, [f, \varphi_n]).$$

Indeed, let f be defined by (2.6) with $m = XG^{-1}(\Phi)$ for $\omega \in \sigma(\Phi)$ and $m = 0$ for $\omega \in [0, 2\pi]\backslash\sigma(\Phi)$. Since

$$mG(\Phi)m^* = XG^{-1}(\Phi)X^*,\ \omega \in \sigma(\Phi),$$

and all entries of $G^{-1}(\Phi)$ belong to $L_\infty(\sigma(\Phi))$, we have $mGm^* \in L_1(\sigma(\Phi))$. Therefore $f \in \mathcal{S}^0(\Phi)$ and f satisfies the required equality.

Since, for any fixed $\omega \in \sigma(\Phi), X$ in (3.5) may range over the whole $\mathbb{C}^n$, (3.2) is equivalent to (3.3). The proof is complete.

THEOREM 3.2 (splitting trick). *Let $\varphi \in L_2$ and $\{\psi_j\}_{j=0}^1 \subseteq \mathcal{S}^1(\varphi)$ be given by*

$$\widehat{\psi}_j(\omega) = \sqrt{2}m_j(\omega/2)\widehat{\varphi}(\omega), \quad j = 0, 1, \tag{3.6}$$

for some 2π-periodic $m_j, j = 0, 1$. Define the matrix $M(\omega) := (m_j(\omega + k\pi))_{j,k=0}^1$. Then the condition that

$$C'I \leq M^*(\omega/2)M(\omega/2) \leq CI \quad \textit{a.e. on } \sigma(\Phi) \tag{3.7}$$

implies that for any $f \in L_2$

$$\begin{aligned} &C' \sum_{\alpha\in\mathbb{Z}} |\langle f, \varphi(\cdot - \alpha/2)\rangle|^2 \\ &\leq \sum_{j=0,1} \sum_{\alpha\in\mathbb{Z}} |\langle f, \psi_{j\alpha}\rangle|^2 \\ &\leq C \sum_{\alpha\in\mathbb{Z}} |\langle f, \varphi(\cdot - \alpha/2)\rangle|^2. \end{aligned} \tag{3.8}$$

Moreover, if $\{\varphi(\cdot - \alpha/2)\}_{\alpha\in\mathbb{Z}}$ is a quasi-stable basis, then (3.7) *and* (3.8) *are equivalent.*

Proof. Define $\varphi_k(\cdot) = \varphi(\cdot - k/2), k = 0, 1$. Then $\mathcal{S}^1(\varphi) = \mathcal{S}^0(\Phi)$, where $\Phi = \{\varphi_k\}_{k=0}^1$, and (3.6) may be represented as (3.1) for $n = 2$ and some 2π-periodic $P_{jk}, j, k = 0, 1$.

Recall that the matrix $P = (P_{jk})_{jk=0}^1$ is associated with M by the equation (cf. [17] and [18, p. 86]),

$$M(\omega) = P(2\omega)U(\omega) \tag{3.9}$$

with the matrix

$$U(\omega) = \frac{1}{\sqrt{2}} \begin{pmatrix} 1 & 1 \\ e^{-i\omega} & -e^{-i\omega} \end{pmatrix}$$

being 2π-periodic and unitary for any ω. Therefore

$$M^*(\omega/2)M(\omega/2) = U^*(\omega/2)P^*(\omega)P(\omega)U(\omega/2) \quad \forall \omega \in \mathbb{R}.$$

The theorem follows immediately from Lemma 3.1 and the equivalence of (3.2) and (3.7).

COROLLARY 3.3. *Suppose that the conditions of Theorem* 3.2 *are satisfied. Assume furthermore that* $0 < C' \leq C < \infty$ *and* $\{\varphi(\cdot - \alpha/2) \mid \alpha \in \mathbb{Z}\}$ *is a frame (quasi-stable basis, Riesz basis, respectively) of* $\mathcal{S}^1(\varphi)$ *with bounds* A *and* B. *Then* $\{\psi_j(\cdot - \alpha) \mid 0 \leq j \leq 1,\ \alpha \in \mathbb{Z}\}$ *is also a frame (quasi-stable basis, Riesz basis, respectively) of* $\mathcal{S}^1(\varphi)$ *with bounds* $A' \leq CA$ *and* $B' \geq C'B$.

Proof. The conclusion in the frame case is obvious by Theorem 3.2. As for the quasi-stable basis case, we note that $\mathcal{S}^0(\Psi) = \mathcal{S}^0(\Phi)$, where $\Phi = \{\varphi_k\}_{k=0}^1$ is as given in the proof of Theorem 3.2 and $\Psi = \{\psi_k\}_{k=0}^1$. It follows from the equality $G(\Psi) = PG(\Phi)P^*$ that $\text{rank}G(\Psi) = \text{rank}G(\Phi)$ for any ω. Moreover, by assumption, Φ provides a quasi-stable basis of $\mathcal{S}^0(\Phi)$ with bounds A and B. Since we already know that $\{\psi_j(\cdot - \alpha) \mid 0 \leq j \leq 1,\ \alpha \in \mathbb{Z}\}$ is also a frame of $\mathcal{S}^0(\Phi)$ with bounds $A' \leq CA$ and $B' \geq C'B$, the conclusion follows from Corollary 2.3.

Remark 3.4. The analogue of Theorem 3.2 and Corollary 3.3 hold when $\mathcal{S}^1(\varphi)$ and $m_j(2^{-1}\omega)$ are replaced by $\mathcal{S}^{j_0}(\varphi)$ and $m_j(2^{-j_0}\omega)$, respectively, where $j_0 \in \mathbb{Z}$ is any integer.

In what follows, we need to apply several splitting steps. To this end it is useful to introduce some index sets. Let $\mathcal{M} = \bigcup_{k=1}^{\infty}\{0,1\}^k$ and $\mathcal{M}_L = \bigcup_{k=1}^{L}\{0,1\}^k, L < \infty$. For any $\varepsilon = (\varepsilon_1, \ldots, \varepsilon_k) \in \mathcal{M}$ we set $|\varepsilon| = k$ and $l_\varepsilon = \sum_{j=1}^{k} 2^{-j}\varepsilon_j$. Associated with ε is a dyadic interval $I_\varepsilon = [l_\varepsilon, l_\varepsilon + 2^{-|\varepsilon|})$.

A subset $\mathcal{N} \subseteq \mathcal{M}$ is called an admissible set if $L_\varepsilon = \{I_\varepsilon\}, \varepsilon \in \mathcal{N}$, partition the unit interval [0,1). This means that [0,1) is the union of $I_\varepsilon, \varepsilon \in \mathcal{N}$, any of which does not intersect the others. Both of the following $\mathcal{N}$ are admissible sets: $\mathcal{N} = \{\varepsilon \,|\, |\varepsilon| = k\}$, where $k > 0$ fixed; $\mathcal{N} = \{(0), (1,0), (1,1,0), (1,1,1,0), (1,1,1,1,0), \ldots\}$.

LEMMA 3.5. *The following statements are true:*

(i) *Given two dyadic intervals,* I_ε *and* I_τ, *either their intersection is empty or one contains the other.*

(ii) *Let* $\mathcal{N}$ *be an admissible set. For any* $\varepsilon = (\varepsilon_1, \ldots, \varepsilon_k) \in \mathcal{N}$ *and any* $\varepsilon_{k+1}, \ldots, \varepsilon_j$,

$$\varepsilon' := (\varepsilon_1, \ldots, \varepsilon_k, \varepsilon_{k+1}, \ldots, \varepsilon_j) \notin \mathcal{N},$$

where $k < j$.

(iii) *If* $\mathcal{N} \subseteq \mathcal{M}_L$ *is an admissible set and* $\varepsilon = (\varepsilon_1, \ldots, \varepsilon_L) \in \mathcal{N}$, *then*

$$\varepsilon^0 := (\varepsilon_1, \varepsilon_2, \ldots, \varepsilon_{L-1}, 1 - \varepsilon_L) \in \mathcal{N}.$$

Proof. To prove (i) we assume that $I_\varepsilon \cap I_\tau$ is not empty and, without loss of generality, assume $|\tau| \leq |\varepsilon|$. It follows from the definition that $I_\tau \subseteq I_\varepsilon$. Moreover $I_\tau = I_\varepsilon$ if and only if $|\tau| = |\varepsilon|$.

The verification of (ii) is easy by noting that $I_{\varepsilon'} \subseteq I_\varepsilon$.

As for the proof of (iii), we observe that $\mathcal{N}$ contains no $\tau \neq \varepsilon^0$ such that $I_{\varepsilon^0} \subseteq I_\tau$. For, otherwise, we have also $I_\varepsilon \subseteq I_\tau$, a contradiction. Note that $\mathcal{N} \subseteq \mathcal{M}_L$ is admissible. ε^0 must belong to $\mathcal{N}$. The proof is complete.

Given $\varphi \in L_2$ and 2π-periodic functions $m_j, j = 0, 1$, we apply the splitting trick, as in Theorem 3.2, to $\mathcal{S}^{j_0}(\varphi)$ and their resulting subspaces successively, where $j_0 \in \mathbb{Z}$

fixed, getting a sequence of resulting functions φ_ε (we adopt the notation φ_ε instead of ψ's as in Theorem 3.2) given by their Fourier transform

$$\widehat{\varphi}_\varepsilon(\omega) = 2^{|\varepsilon|/2}\widehat{\varphi}(\omega)\prod_{j=1}^{k} m_{\varepsilon_j}(2^{j-1-j_0}\omega), \tag{3.10}$$

where $\varepsilon = (\varepsilon_1, \dots, \varepsilon_k)$. However, some conditions to ensure $\varphi_\varepsilon \in L_2$, and hence $\varphi_\varepsilon \in \mathcal{S}^{j_0}(\varphi)$ should be imposed on $m_j, j = 0, 1$. The following lemma gives such conditions. The proof is easy and thus omitted.

LEMMA 3.6. *Let $\varphi \in L_2$ and φ_ε be as given by* (3.10). *If the measurable and 2π-periodic functions m_j satisfy $\|m_j\|_\infty < \infty, j = 0, 1,$ then $\varphi_\varepsilon \in \mathcal{S}^{j_0}(\varphi)$.*

Remark 3.7. Let c^ε be the sequence of coefficients $\{c^\varepsilon_\alpha\}_{\alpha\in\mathbb{Z}}$, where

$$c^\varepsilon_\alpha := \langle f, \varphi_\varepsilon(\cdot - 2^{|\varepsilon|-j_0}\alpha)\rangle, \quad \alpha \in \mathbb{Z}.$$

It is worth pointing out the well-known fact that the coefficients can be computed by Mallat's algorithm successively whenever the coefficients $\langle f, \varphi(\cdot - 2^{-j_0}\alpha)\rangle$, $\alpha \in \mathbb{Z}$, are given. This is due to the relation between φ_ε and φ. In fact, if we set $m_j(\omega) := \sum_{\beta\in\mathbb{Z}} h_{j\beta}e^{-i\beta\omega}, j = 0, 1,$ then

$$c^{(\varepsilon_1,\dots,\varepsilon_k)}_\alpha = F_{\varepsilon_k}c^{(\varepsilon_1,\dots,\varepsilon_{k-1})}(\alpha), \quad \alpha \in \mathbb{Z},$$

where $F_j, j = 0, 1,$ is an operator from $l_2(\mathbb{Z})$ into $l_2(\mathbb{Z})$,

$$F_j s(\alpha) = \sqrt{2}\sum_\beta s_\beta \overline{h}_{j\beta-2\alpha}, \quad s \in l_2(\mathbb{Z}).$$

Let $m_j, j = 0, 1$, satisfy the condition in Lemma 3.6. Denote by $\Lambda(\omega)$ and $\lambda(\omega)$, for a.e. $\omega \in \mathbb{R}$, the maximal and minimal eigenvalues, respectively, of the matrix $M^*(\omega/2)M(\omega/2)$. Then the functions $\Lambda(\omega)$ and $\lambda(\omega)$ are in fact 2π-periodic by (3.9). Moreover, they are measurable. Let $\Lambda = \|\Lambda(\omega)\|_\infty$ and $\lambda = \|\lambda(\omega)\|_\infty$. Then

$$\lambda I \le M^*M \le \Lambda I, \quad \text{a.e.} \tag{3.11}$$

Now we can generalize Theorem 3.2 as follows.

THEOREM 3.8. *Let Λ and λ be defined as above. Assume $\varphi \in L_2$ and define φ_ε as in* (3.10). *Then for any admissible set $\mathcal{N} \subseteq \mathcal{M}_L$, $L < \infty$ fixed, we have for any $f \in L_2$ and $j_0 \in \mathbb{Z}$*

$$\begin{aligned} &B_L\sum_{\alpha\in\mathbb{Z}}|\langle f, \varphi(\cdot - 2^{-j_0}\alpha)\rangle|^2 \\ &\le \sum_{\varepsilon\in\mathcal{N}}\sum_{\alpha\in\mathbb{Z}}|\langle f, \varphi_\varepsilon(\cdot - 2^{|\varepsilon|-j_0}\alpha)\rangle|^2 \\ &\le A_L\sum_{\alpha\in\mathbb{Z}}|\langle f, \varphi(\cdot - 2^{-j_0}\alpha)\rangle|^2, \end{aligned} \tag{3.12}$$

where $A_L = \max\{1, \Lambda^L\}$ and $B_L = \min\{1, \lambda^L\}$.

Consequently, if $M(\omega)$ is unitary almost everywhere, then for any admissible set $\mathcal{N} \subseteq \mathcal{M}$ (not necessarily $\mathcal{N} \subseteq \mathcal{M}_L$) we have for $f \in L_2$

$$\sum_{\varepsilon\in\mathcal{N}}\sum_{\alpha\in\mathbb{Z}}|\langle f, \varphi_\varepsilon(\cdot - 2^{|\varepsilon|-j_0}\alpha)\rangle|^2 = \sum_{\alpha\in Z}|\langle f, \varphi(\cdot - 2^{-j_0}\alpha)|^2. \tag{3.13}$$

Proof. We observe first that if $M(\omega)$ is unitary for almost every ω, then $\Lambda = \lambda = 1$. Therefore the equality (3.13) follows from (3.12). It remains to prove (3.12).

To prove (3.12) we work by induction. When $L = 1$, $A_L \geq \Lambda$ and $B_L \leq \lambda$. Therefore (3.12) follows from (3.8) and (3.11).

Suppose that (3.12) holds for $L = L_0$. Assume that $\mathcal{N} \subset \mathcal{M}_{L_0+1}$ is an admissible set. We divide it into two parts, $\mathcal{N} = \mathcal{N}_{L_0+1} \cup (\mathcal{N} \cap \mathcal{M}_{L_0})$, where

$$\mathcal{N}_L = \{\, \varepsilon \,|\, \varepsilon \in \mathcal{N} \quad \text{and} \quad |\varepsilon| = L\}.$$

For any $\varepsilon = (\varepsilon_1, \ldots, \varepsilon_{L_0+1}) \in \mathcal{N}_{L_0+1}$, it follows from Lemma 3.5 that

$$\varepsilon^0 = (\varepsilon_1, \varepsilon_2, \ldots, \varepsilon_{L_0}, 1 - \varepsilon_{L_0+1}) \in \mathcal{N}_{L_0+1}.$$

Associated with any pair of $\varepsilon, \varepsilon_0 \in \mathcal{N}_{L_0+1}$, we set

$$\tau = (\varepsilon_1, \ldots, \varepsilon_{L_0}). \tag{3.14}$$

Appealing to the analogy of Theorem 3.2 (see Remark 3.4) we obtain for $f \in L_2$

$$\begin{aligned}
&\lambda \sum_{\alpha \in \mathbb{Z}} |\langle f, \varphi_\tau(\cdot - 2^{L_0 - j_0}\alpha)\rangle|^2 \\
&\leq \sum_{\alpha \in \mathbb{Z}} \big(|\langle f, \varphi_\varepsilon(\cdot - 2^{L_0+1-j_0}\alpha)\rangle|^2 + |\langle f, \varphi_{\varepsilon^0}(\cdot - 2^{L_0+1-j_0}\alpha)\rangle|^2 \big) \\
&\leq \Lambda \sum_{\alpha \in \mathbb{Z}} |\langle f, \varphi_\tau(\cdot - 2^{L_0 - j_0}\alpha)\rangle|^2 .
\end{aligned} \tag{3.15}$$

Since $\mathcal{N}' = \mathcal{N}_{L_0} \cup \{\tau\}_{\varepsilon \in \mathcal{N}_{L_0+1}} \subseteq \mathcal{M}_{L_0}$ is an admissible set, where τ is associated with ε by (3.14) for any $\varepsilon \in \mathcal{N}_{L_0+1}$, it follows from the induction assumption that for $f \in L_2$

$$\begin{aligned}
&B_{L_0} \sum_{\alpha \in \mathbb{Z}} |\langle f, \varphi(\cdot - 2^{-j_0}\alpha)|^2 \\
&\leq \sum_{\alpha \in \mathbb{Z}} \Big(\sum_{\delta \in \mathcal{N} \cap \mathcal{M}_{L_0}} |\langle f, \varphi_\delta(\cdot - 2^{|\delta| - j_0}\alpha)\rangle|^2 + \sum_{\tau} |\langle f, \varphi_\tau(\cdot - 2^{L_0 - j_0}\alpha)\rangle|^2 \Big) \\
&\leq A_{L_0} \sum_{\alpha \in \mathbb{Z}} |\langle f, \varphi(\cdot - 2^{-j_0}\alpha)\rangle|^2 .
\end{aligned}$$

Now (3.15) implies (3.12) for $L = L_0 + 1$. The proof is complete.

It is very important that A_L and B_L in (3.12) are independent of j_0.

Corollary 3.9. *In addition to the conditions of Theorem* 3.2 *we assume that* $0 < \lambda \leq \Lambda < \infty$ *and* $\{\varphi(\cdot - 2^{-j_0}\alpha) \mid \alpha \in \mathbb{Z}\}$ *is a frame (Riesz basis, respectively) of* $\mathcal{S}^{j_0}(\varphi)$ *with bounds A and B. Then for any admissible set* $\mathcal{N} \subseteq \mathcal{M}_L$*, where* $L < \infty$ *is fixed, the sequence*

$$\{\varphi_\varepsilon(\cdot - 2^{|\varepsilon| - j_0}\alpha) | \alpha \in \mathbb{Z}, \varepsilon \in \mathcal{N}\} \tag{3.16}$$

is a frame (Riesz basis, respectively) of $\mathcal{S}^{j_0}(\varphi)$ *with bounds* A' *and* B' *with* $A' \leq AA_L$ *and* $B' \geq BB_L$*.*

Consequently, (3.16) *is a frame (Riesz basis, respectively) with bounds A and B for any admissible set $\mathcal{N}$ when M is unitary everywhere.*

Proof. The conclusions about the frame case follow easily from a special case of Theorem 3.8, in which (3.12) need hold only for any $f \in \mathcal{S}^{j_0}(\varphi)$.

To prove the result about the Riesz basis case, we need only to verify that the sequence in (3.16) is a Riesz basis. Since $\{\, \varphi(\cdot - 2^{-j_0}\alpha) \mid \alpha \in \mathbb{Z} \,\}$ is a Riesz basis of $\mathcal{S}^{j_0}(\phi)$, by applying the analogy of Corollary 3.3 for $\mathcal{S}^{j_0}(\varphi)$ (see Remark 3.4) and the resulting subspaces successively, we conclude that the sequence (3.16) is indeed a Riesz basis. The proof is complete.

4. Wavelet frame packets. In this section we construct the wavelet frame packets for L_2. The general theory is illustrated with an example of compactly supported tight wavelet frame packets.

THEOREM 4.1. *Let S be a subset of $\mathbb{Z}^2$ and $\{\psi_k(\cdot - 2^{-j}\alpha)|\alpha \in \mathbb{Z}, (k,j) \in S\}$ a frame (Riesz basis, respectively) with bounds A and B for L_2. Assume that $\mathcal{N}(k,j) \subset \mathcal{M}_L$ is an admissible set for any $(k,j) \in S$, where $L < \infty$ is independent of $(k,j) \in S$. Let m_0 and m_1 satisfy the conditions of Lemma* 3.6, *and the associated matrix $M(\omega) = ((m_j(\omega + k\pi))_{j,k=0}^1$ satisfies* (3.11) *for some λ and Λ with $0 < \lambda \le \Lambda < \infty$. Moreover, let $\psi_{k\varepsilon}$ be as given in* (3.10) *by replacing φ with ψ_k, and let A_L and B_L be as given in Theorem* 3.8. *Then the sequence*

$$\{\psi_{k\varepsilon}(\cdot - 2^{|\varepsilon|-j}\alpha)|\alpha \in \mathbb{Z}, \varepsilon \in \mathcal{N}(k,j) \text{ and } (k,j) \in S\} \tag{4.1}$$

is a frame (Riesz basis, respectively) of L^2 with bounds $A' \le AA_L$ and $B' \ge BB_L$.

Remark 4.2. If $\mathcal{N}(k,j)$ is empty for some $(k,j) \in S$, we take no splitting on the corresponding sequence $\{\psi_k(\cdot - 2^{-j}\alpha)|\alpha \in \mathbb{Z}\}$.

The proof of Theorem 4.1 is the same as that of Corollary 3.9 in section 3 only with the difference in that we should use the inequality (3.12) for all $f \in L_2$. We omit it.

Since there is a large variety of choices of $\mathcal{N}(k,j)$ for any $(k,j) \in S$, we can pick many frames from (4.1). Combining the terminologies of wavelet frames and wavelet packets, we call all these frames the wavelet frame packets.

Remark 4.3. It is easily seen that A_L and B_L^{-1} defined in Theorem 3.8 grow at most exponentially for large L. Therefore, the estimation for the bounds of the resulting frames (Riesz bases, respectively) in Theorem 4.1 is sharper than that in [8].

On the other hand, if the matrix $M(\omega)$ is unitary for any ω, we have $A_L = B_L = 1$ for any L. It implies that the bounds of the resulting frames (Riesz bases, respectively) are unchanged. These bounds are optimal. In this case, the estimation of [6] cannot give the optimal bounds.

As stated in Remark 3.7, the coefficients of a function f with respect to sequence in (4.1) may be computed by Mallat's algorithm. It is possible to find a best frame for a given f. The algorithm is the same as in wavelet packets [10].

Example 4.4 (tight wavelet frame packets). Let m_0 be a 2π-periodic trigonometric such that

$$m_0(0) = 1, \quad |m_0(\omega)|^2 + |m_0(\omega + \pi)|^2 = 1.$$

Define φ and ψ by $\widehat{\varphi}(\omega) = \prod_{k=1}^{\infty} m_0(2^{-k}\omega)$ and $\widehat{\psi}(\omega) = m_1(\omega/2)\widehat{\varphi}(\omega/2)$, respectively, where as usual, $m_1(\omega) = e^{-i\omega}\overline{m}_0(\omega + \pi)$. It is easy to see that the matrix $M(\omega) = (m_j(\omega + k\pi))_{j,k=0}^1$ is unitary for any ω.

It was proved in [16] that $\{2^{k/2}\psi(2^k \cdot - \alpha)\}_{k,\alpha\in\mathbb{Z}}$ is a tight frame for L_2 with bound 1. This corresponds to the case $\psi_k(\cdot) := 2^{k/2}\psi(2^k \cdot)$ and $S = \{\,(k,k) \mid k \in \mathbb{Z}\,\}$ in (4.1).

We are more interested in the sequence

$$\{\varphi(\cdot-\alpha),\ \psi_k(\cdot-2^{-k}\alpha)\mid\alpha\in\mathbb{Z},k\geq 0\}. \tag{4.2}$$

From the proof of [12, Proposition 6.2.3] we see that the sequence (4.2) is also a tight frame of L_2 with bound 1.

As in (3.10), we define for $k>0$ and $\varepsilon=(\varepsilon_1,\dots,\varepsilon_k)$ the function $\psi_{k\varepsilon}$ by

$$\widehat{\psi}_{k\varepsilon}(\omega)=\widehat{\psi}(2^{-k}\omega)\prod_{j=1}^{k}m_{\varepsilon_j}(2^{-j}\omega)=\prod_{j=1}^{\infty}m_{\varepsilon_j}(2^{-j}\omega),$$

where $\varepsilon_{k+1}=1$ and $\varepsilon_j=0$ for $j\geq k+2$. The last equality follows from the relation between $\widehat{\psi}$ and $\widehat{\phi}$. If we split the 2^{-k} shifts of $\psi_k,k>0$, exactly k times at all possibilities, the resulting sequence is the set of integer shifts of all functions $\psi_{k\varepsilon}$ $\forall\varepsilon$ with $|\varepsilon|=k$. Therefore, taking (4.2) as the original frame, we get the following resulting frame:

$$\{\varphi(\cdot-\alpha),\psi(\cdot-\alpha),\psi_{k\varepsilon}(\cdot-\alpha)\mid\alpha\in\mathbb{Z},|\varepsilon|=k,k>0\}. \tag{4.3}$$

By the unitary property of the matrix M and Theorem 4.1, (4.3) is also a tight frame of L_2 with bound 1.

Adopting the notation of [10], we can check easily that (4.3) is nothing but the sequence

$$\{W_n(\cdot-\alpha)|n\geq 0,\alpha\in\mathbb{Z}\}, \tag{4.4}$$

where W_n is defined by its Fourier transform

$$\widehat{W_n}(\omega)=\prod_{j=1}^{\infty}m_{\varepsilon_j}(2^{-j}\omega),\quad n=\sum_{j=1}^{\infty}2^{j-1}\varepsilon_j. \tag{4.5}$$

Besides (4.4) we may obtain many tight frames of L_2 as follows. In fact, as in [10], for any partition $P=\{I_{kn}\}$ of the nonnegative integers of the form $I_{kn}=\{2^kn,\dots,2^k(n+1)-1\}$ we consider the set

$$\{2^{\frac{k}{2}}W_n(2^k\cdot-\alpha)|I_{kn}\in P,\alpha\in\mathbb{Z}\}. \tag{4.6}$$

We claim that (4.6) is a tight frame of L_2 with bound 1. Indeed, for any I_{nk}, we define $\varepsilon_j,j>k$, by $n=\sum_{j=k+1}^{\infty}2^{j-k-1}\varepsilon_j$ and the function $\widetilde{W}_{nk}(\cdot)=2^{\frac{k}{2}}W_n(2^k\cdot)$. It follows from (4.5) that

$$\widehat{\widetilde{W}}_{nk}(\omega)=2^{-k/2}\widehat{W}_n(2^{-k}\omega)=2^{-k/2}\prod_{j=1}^{\infty}m_{\varepsilon_{j+k}}(2^{-j-k}\omega).$$

For any $\varepsilon=(\varepsilon_1,\dots,\varepsilon_k)$ we define $\widetilde{W}_{nk\varepsilon}$ as in (3.10) by replacing φ with $\widetilde{W}_{nk}$. Then

$$\widehat{\widetilde{W}}_{nk\varepsilon}(\omega)=\prod_{j=1}^{\infty}m_{\varepsilon_j}(2^{-j}\omega).$$

Consequently,

$$\widetilde{W}_{nk\varepsilon}=W_{n'},\quad n'=2^kn+\sum_{j=1}^{k}2^{j-1}\varepsilon_j.$$

By assumption on $P = \{I_{kn}\}$ we have

$$\{\widetilde{W}_{nk\varepsilon} | |\varepsilon| = k, I_{kn} \in P\} = \{W_{n'} | n' \in \mathbb{Z}, n' \geq 0\}.$$

This means that the set $\{\widetilde{W}_{nk\varepsilon}(\cdot - \alpha) | |\varepsilon| = k, I_{kn} \in P$ and $\alpha \in \mathbb{Z}\}$ is just the sequence (4.4) and, therefore, a tight frame with bound 1 for L_2. On the other hand, the equality (3.13) yields that for any $f \in L_2$

$$\sum_{I_{kn} \in P} \sum_{\alpha \in \mathbb{Z}} |\langle f, \widetilde{W}_{nk}(\cdot - 2^{-k}\alpha)\rangle|^2 = \sum_{I_{kn} \in P} \sum_{|\varepsilon| = k} \sum_{\alpha \in \mathbb{Z}} |\langle f, \widetilde{W}_{nk\varepsilon}(\cdot - \alpha)\rangle|^2.$$

We conclude that $\{ \widetilde{W}_{nk}(\cdot - 2^{-k}\alpha) \mid I_{kn} \in P, \alpha \in \mathbb{Z} \}$ is also a tight frame with bound 1. Note that the last sequence is just (4.6). Therefore, for any $P = \{I_{nk}\}$ as above, the sequence (4.6) is a tight frame with bound 1, as claimed .

By formula (1.2) any $f \in L_2$ can be represented as a convergent series in L_2:

$$f(x) = \sum_{I_{kn} \in P} \sum_{\alpha} c_{\alpha}^{nk} 2^{k/2} W_n(2^k x - \alpha)$$

with coefficients $c_{\alpha}^{nk} = \langle f, 2^{k/2} W_n(2^k \cdot - \alpha)\rangle$.

Acknowledgments. The author thanks the late Prof. R. L. Long of the Institute of Mathematics, Chinese Academy of Sciences, for his valuable help and the referees for their thoughtful and valuable comments that improve the presentation of the paper significantly. The author also thanks Dr. Z. Shen for making available to him a copy of [20] before it appeared.

POINTWISE DECAY OF SOLUTIONS AND OF HIGHER DERIVATIVES TO NAVIER–STOKES EQUATIONS[*]

CHERIF AMROUCHE[†], VIVETTE GIRAULT[‡], MARIA ELENA SCHONBEK[§], AND TOMAS P. SCHONBEK[¶]

Abstract. In this paper we study the space-time asymptotic behavior of the solutions, and their derivatives, to the incompressible Navier–Stokes equations in dimension $2 \le n \le 5$. Using moment estimates we obtain that strong solutions to the Navier–Stokes equations which decay in L^2 at the rate of $\|u(t)\|_2 \le C(t+1)^{-\mu}$ will have the following pointwise space-time decay, for $0 \le k \le n/2$:

$$|D^\alpha u(x,t)| \le C_{k,m} \frac{1}{(t+1)^{\rho_0}(1+|x|^2)^{k/2}},$$

where $\rho_O = (1-2k/n)(m/2+\mu+n/4)$, $|\alpha| = m$ and $\mu > \frac{n}{4}$.

Key words. Navier–Stokes equations, derivatives, pointwise algebraic decay

1. Introduction.

In this paper, we study the space-time decay of solutions to the incompressible Navier–Stokes equations in $\mathbb{R}^n$

$$\begin{aligned} u_t + u\cdot\nabla u + \nabla p &= \triangle u\,, \\ \operatorname{div} u &= 0\,, \\ u(x,0) = u_0(x) &\in \mathbf{X}\,, \end{aligned} \tag{1.1}$$

and of their derivatives. We assume $2 \le n \le 5$ and the space $\mathbf{X}$ will be specified below. Using moment techniques, we show that strong solutions and their derivatives of all orders decay pointwise at an algebraic rate as $|x| \to \infty$ and $t \to \infty$.

Questions of decay of solutions to the Navier–Stokes equations in different norms have been studied, among others, by Knightly [6], Kajikiya and Miyakawa [4], Kato [5], Kozono [7], Kozono and Ogawa [8], Schonbek [13], [10], Wiegner [18], and Zhang [20]. Of particular interest in the direction of the present paper are the results by S. Takahashi [17]. In this reference, Takahashi studies the pointwise decay of solutions with zero initial data to the Navier–Stokes equations with an external force, as well as the decay of the first derivatives of these solutions. Using a weighted-equation approach, he obtains pointwise decay rates both in time and space. The external force is assumed to decay at an algebraic rate in both space and time and the solutions are assumed bounded in some weighted $L^{q,s}$ norms, with $n/q + 2/s = 1$ and $q, s \in [2,\infty]$,

(the limiting Serrin class), where $L^{q,s}$ denotes the space of all $u : \mathbb{R}^n \times (0, \infty) \to \mathbb{R}^n$ such that

$$\left\{ \int_0^\infty \left(\int_{\mathbf{R}^n} |u(x,t)|^q dx \right)^{s/q} dt \right\}^{1/s} < \infty.$$

Our results complement and extend Takahashi's results in the sense that in our case we have nonzero initial data but zero external force. Moreover, we are able to establish decay for derivatives of all orders. We note that since we are obtaining decay results for derivatives, we will work directly with strong solutions. These results can be derived for weak solutions provided we start at a sufficiently large time. Since in this case we are already in the regime where the solutions are smooth, we prefer to simplify notation and work directly with smooth solutions. The reader can also refer to [17], which presents a very detailed outline of what other authors in the field have done with related questions.

It is already clear at the level of the heat equation that there is a relation between the time decay and the space decay. This kind of balance will also be found for solutions to the Navier–Stokes equations. In particular the balance relation we obtain between the decay in space and in time coincides with the relation for the heat equation when we consider the solutions themselves.

The plan of the paper is the following. We begin with a section of notation (section 2). In section 3, we construct a solution of the Navier–Stokes equations as the limit of a sequence of solutions of a linearized approximation of the Navier–Stokes equations. By standard uniqueness results, this solution coincides with the one constructed by Kato in [5]. We recall some essential estimates on the moments of this sequence of approximate solutions and of their derivatives and then we show that these bounds are also valid for the limit solution and its derivatives. The first bounds we obtain are not sufficient for yielding a uniform time decay; they are valid for all time but depend on time. However, owing to the results of [11], we already have uniform bounds for the moments, though not for the moments of the derivatives; for this reason we dedicate section 4 to showing that these moments are also bounded independently of time. The last section deals with the space-time pointwise decay of the solution, which follows from the uniform bound of the moments and an appropriate form of the Gagliardo–Nirenberg inequality.

2. Notation and assumptions.

Let $\alpha = (\alpha_1, \dots, \alpha_n)$ be a multi-index with $\alpha_i \geq 0$. We will use the notation

$$D^\alpha = \frac{\partial^{|\alpha|}}{\partial x_1^{\alpha_1} \cdots \partial x_n^{\alpha_n}}\,, \tag{2.1}$$

where

$$|\alpha| = \alpha_1 + \cdots + \alpha_n\,, \tag{2.2}$$

and

$$D_i = \frac{\partial}{\partial x_i}\,. \tag{2.3}$$

For any integer $m \geq 0$, we set

$$D^m f(x) = \left(\sum_{|\alpha|=m} |D^\alpha f(x)|^2 \right)^{1/2},$$

where $x = (x_1, \ldots, x_n)$. The L^2 norm (or energy norm) will be denoted by

$$\|u\| = \|u(.,t)\|_2 = \left[\int_{\mathbf{R}^n} |u(x,t)|^2 dx\right]^{1/2}, \tag{2.4}$$

where $dx = dx_1 \cdots dx_n$. More generally we denote the L^p norm for $1 \leq p < \infty$ by

$$\|u(.,t)\|_p = \left[\int_{\mathbf{R}^n} |u(x,t)|^p dx\right]^{1/p} \tag{2.5}$$

and the L^∞ norm by

$$\|u(.,t)\|_\infty = \text{ess sup}_x |u(x,t)|. \tag{2.6}$$

The H^m norm is defined by

$$\|u(.,t)\|_{H^m} = \left[\int_{\mathbf{R}^n} \sum_{|\alpha| \leq m} |D^\alpha u(x,t)|^2 dx\right]^{1/2}. \tag{2.7}$$

In what follows, we assume that $u = u(x,t) = (u_1(x,t), \ldots, u_n(x,t))$ is a global solution of the Navier–Stokes equations with the following decay: there exist constants $C, \mu > n/4$ such that

$$\|u(t)\|_2 \leq C(t+1)^{-\mu} \quad \text{for } t \geq 0\,. \tag{2.8}$$

Under these conditions, assuming as always $2 \leq n \leq 5$, it is proved in [12] that the decay given by (2.8) generalizes to

$$\|D^j u(t)\|_2 \leq C(t+1)^{-\mu - j/2} \quad \text{for } t \geq 0\,, j = 0, 1, 2, \ldots\,. \tag{2.9}$$

We recall the Gagliardo–Nirenberg inequality; if $f \in H^m$, then

$$\|D^j f\|_\infty \leq C \|f\|_2^{1-a} \|D^m f\|_2^a\,,$$

with $a = a_{jm} = \frac{j + \frac{n}{2}}{m}$, as long as $j + \frac{n}{2} < m$. Taking m large enough (assuming we can do this) we get from (2.8) and (2.9)

$$\|D^j u(t)\|_\infty \leq C(t+1)^{-\mu - j/2 - n/4} \quad \text{for } j = 0, 1, \ldots\,. \tag{2.10}$$

Combining (2.9) and (2.10) we get as in [12]

$$\|D^j u(t)\|_p \leq C(t+1)^{-\mu - j/2 - n/4(1-2/p)} \quad \text{for } j = 0, 1, \ldots \tag{2.11}$$

for $p \in [2, \infty]$, $t > 0$.

Since we are interested in decay of derivatives and hence in smooth solutions, we are going to work with solutions that start with small data, or the results we establish will only be valid for large t.

The main idea in order to obtain pointwise decay is to prove decay of the moments and then combine this with an appropriate Gagliardo–Nirenberg inequality to yield decay in L^∞, whence the pointwise decay. With this in mind, we introduce the following weighted spaces:

$$f \in L^{r_1}_\nu \quad \text{iff} \quad \left(\int_{\mathbf{R}^n} |x|^{\nu r_1} |f|^{r_1}\, dx\right)^{1/r_1} < \infty. \tag{2.12}$$

For $s = 0, 1, 2, \ldots$, we define the (s, α) moments

$$M_{s,\alpha}(t) = \int_{\mathbf{R}^n} |x|^s |D^\alpha u(x,t)|^2 \, dx,$$

and in particular for $s \geq 0$, $t \geq 0$, we define the moment of order s of u by

$$M_s((u)(t)) = M_{s,0}(t) = \int_{\mathbf{R}^n} |x|^s |u(x,t)|^2 \, dx = \Big(\|u(t)\|_{L^2_{s/2}} \Big)^2 .$$

Finally, define for $s, m = 0, 1, 2, \ldots$,

$$\tilde{M}_{s,m}(t) = \sum_{|\alpha|=m} M_{s,\alpha}(t) = \int_{\mathbf{R}^n} |x|^s |D^m u(x,t)|^2 \, dx.$$

3. Preliminaries. To start our calculations we need to recall some weighted-norms estimates satisfied by approximate solutions to the Navier–Stokes equations [11]. These solutions satisfy a "linearized Navier–Stokes equation," in which both the convective and the pressure terms are linearized in "explicit form." To this purpose, the pressure is expressed as a product of Riesz transforms. Specifically, we construct the sequence $\{u^\ell\}$ of approximate solutions as follows: $v = u^{\ell+1}$ is the solution of

$$\begin{aligned} v_t - \Delta v + u^\ell \cdot \nabla v + \nabla P(u^\ell, v) &= 0, \\ \operatorname{div} v &= 0, \\ v(0) &= u_0 \, , \end{aligned} \tag{3.1}$$

with initial approximation $u^0 = u_0$ and u_0 in an appropriate space. The solution v is constructed locally by a fixed-point argument and then is extended by a priori estimates. It is unique by construction. The bilinear operator P is defined by

$$P(u, v) = \sum_{j,k} R_j R_k (u_j v_k) \, ,$$

where $u = (u_1, \ldots, u_n)$, $v = (v_1, \ldots, v_n)$ are functions from $\mathbf{R}^n$ to $\mathbf{R}^n$, and R_j denotes the Riesz transforms,

$$\widehat{[R_j f]}(\xi) = -i \frac{\xi_j}{|\xi|} \hat{f}(\xi) \quad \text{for } 1 \leq j \leq n \, .$$

When $u^\ell = v$ we recover the Navier–Stokes equations, since the pressure p and the velocity u of the Navier–Stokes equations are related by

$$\Delta p = - \sum_{j,k} \frac{\partial^2}{\partial x_j \partial x_k} (u_j u_k) \, ,$$

hence

$$\hat{p}(\xi, t) = - \sum_{j,k} \frac{\xi_j \xi_k}{|\xi|^2} \widehat{u_j u_k}(\xi, t),$$

and

$$p = \sum_{j,k} R_j R_k (u_j u_k) = P(u, u).$$

The linearization (3.1) is of the type used by Caffarelli, Kohn, and Nirenberg in [1], by Kajikiya and Miyakawa in [4], by Leray in [9], and by Sohr, von Wahl, and Wiegner in [14]. The advantage of making the linearization explicit is that we can apply to the sequence $\{u^\ell\}$ well-known properties of the Riesz transforms, such as their boundedness in L^p-spaces (see [15]) and in weighted L^p-spaces satisfying the Muckenhoupt condition (see [3], [16]), in order to obtain bounds for the solutions of the Navier–Stokes equations and of their moments. We expect that our proofs for establishing bounds in weighted L^p-spaces, with some modifications, could be used for the approximating solutions constructed by Caffarelli, Kohn, and Nirenberg [1], by Kajikiya and Miyakawa [4], and by Sohr, von Wahl, and Wiegner [14].

In [11] we constructed the solution to (3.1) via a fixed-point method. We recall briefly the construction, referring to [11] for details. Let

$$F(x,t) = F(t)(x) = (4\pi t)^{-n/2} e^{-|x|^2/4t}$$

be the fundamental solution of the heat equation in n space variables and set

$$H(u,v) = u \cdot \nabla v + \nabla P(u,v)\,.$$

If v solves (3.1), then v has the expression

$$v(t) = F(t) * u_0 - \int_0^t F(t-s) * H(u^\ell, v)(s)\, ds. \tag{3.2}$$

For $u, \varphi \in L^2([0,T], H^1(\mathbf{R}^n)^n)$, we define

$$\begin{aligned} \mathcal{M}_u\varphi(t) &= \int_0^t F(t-s) * [u\cdot\nabla\varphi(s) + \nabla P(u,\varphi)(s)]\; ds \\ &= \int_0^t F(t-s) * H(u,\varphi)(s)\, ds \end{aligned} \tag{3.3}$$

and

$$\mathcal{L}_u\varphi(t) = F(t) * u_0 - \mathcal{M}_u\varphi(t). \tag{3.4}$$

The integral version (3.2) of (3.1) linearized with respect to u^ℓ becomes

$$v = \mathcal{L}_{u^\ell}(v);$$

that is, the solution to the linearized Navier–Stokes equation (3.1) can be obtained as a fixed point of the operator $\mathcal{L}_{u^\ell}$ (see [11]). We prove in [11] that for some $T > 0$, $T = \infty$ for small data, the sequence $\{u^\ell\}$ converges in $C([0,T], L^2 \cap L^r)$ to a weak solution of the Navier–Stokes equations, provided the data is in $L^2 \cap L^r$ and $r > n$. If the data is also in H^1 and is sufficiently small, the solution will be smooth. These are the solutions we will be interested in. Although Kato [5] has obtained smooth solutions with small data in $L^2 \cap L^n$, we do not use his construction because we want to ensure that the solutions also lie in the appropriate weighted space whenever the data belong to that space too. However, our solutions are clearly Hopf–Leray solutions (see [11, Theorem 2.4]); furthermore, in the notation used by Fabes, Jones, and Riviere in [2], they are in $L^{p,\tilde{q}}(\mathbb{R}^n \times (0,T))$ for every $T > 0$ for some $r > n, \tilde{q} > 2$

(see (3.6) below). By the uniqueness results of section V of [2] our solutions coincide with the solutions of Kato.

In [11] we needed to introduce numbers ν, q, r, r_1 satisfying the relations

$$0 \leq \nu < n, \quad 2 \leq r_1 \leq r, \quad 1 \leq q \leq \infty, \quad r > n\,, \tag{3.5}$$

$$\frac{1}{q} < \frac{\nu}{2} - \frac{n}{2r} + \frac{1}{2}, \quad \frac{1}{r} \leq \frac{1}{r_1} + \frac{\nu}{n} < 1 - \frac{1}{r}\,. \tag{3.6}$$

We recall Lemma 2.2 of [11], which we state here for convenience:

Lemma 3.1. *Assume the function u satisfies*

$$u \in C([0,T], W^{m,r}(\mathbf{R}^n)^n) \cap L^q([0,T], (W^{m,r_1}(\mathbf{R}^n)^n).$$

There exists a constant $K(T,u)$ of the form

$$K(T,u) = C(T)\left(\|u\|_{C_T(W^{m,r})} + \|u\|_{L^q_T(W^{m,r_1})}\right)$$

with $C(T)$ independent of u such that if $D^\alpha u_0 \in L^{r_1}_\nu \cap L^r(\mathbf{R}^n)^n$ for $|\alpha| \leq m$, then the fixed point v of $\mathcal{L}_u$ satisfies $D^\alpha v \in C([0,T], L^{r_1}_\nu(\mathbf{R}^n))$ for $|\alpha| \leq m$ and

$$\|D^\alpha v(t)\|_{L^{r_1}_\nu} \leq C(T)\left(\|u_0\|_{W^{m,r_1}} + \sum_{|\beta|\leq m} \|D^\beta u_0\|_{L^{r_1}_\nu}\right) + K(T,u)\left(\|u_0\|_{W^{m,r}} + \|u_0\|_{W^{m,r_1}}\right).$$

If u is a strong solution of the Navier–Stokes equations, then u is the fixed point of $\mathcal{L}_u$; moreover, $r, r_1 \geq 2$ so that $K(T,u)$ is finite if $2 \leq n \leq 5$ by (2.11) for every $T > 0$. The following corollary is immediate.

Corollary 3.2. *Assume $2 \leq n \leq 5$, conditions (3.5), (3.6), and let u be a strong solution of the Navier–Stokes equations with data $u_0 \in W^{m,r} \cap W^{m,r_1} \cap H^1(\mathbf{R}^n)^n$. Then*

$$\|D^\alpha u(t)\|_{L^{r_1}_\nu} \leq C(T)C_0, \tag{3.7}$$

where C_0 depends only on appropriate norms of the data.

4. Decay of moments of derivatives. In order to obtain the decay of moments of derivatives, we will first need to establish uniform bounds. Once these are obtained, the decay will follow by a Hölder inequality between the (m,s) moments and the L^2 norm of the derivatives.

Theorem 4.1. *Let u_0 be as in Corollary 3.2. Let u be a strong solution of the Navier–Stokes equations with data u_0 satisfying*

$$\|u(t)\|_2 \leq C(t+1)^{-\mu}, \quad \textit{where } \mu > \frac{n}{4} - \frac{1}{2}\,. \tag{4.1}$$

Then

$$\tilde{M}_{s,m}(t) \leq C(t+1)^{-(2\mu+m)(1-\frac{s}{n})}\,, \tag{4.2}$$

for $m = 0, 1, 2, \ldots,$ $s = 0, 1, \ldots, n$.

Proof. As before we note that if the data is sufficiently small then this solution u exists. In particular, if $u \in H^2 \cap L^\infty$, then all the derivatives of higher order are in L^6 (see [12]). Moreover, inequalities (2.9), (2.10), and (2.11) will hold.

For the proof, note that the case $s = 0$ is covered by (2.9). Assuming $s > 0$ from now on, we proceed by induction on m. Each induction step is dealt with following the approach of Theorem 4.1 of [11] (where the case $m = 0$ is proved). As in [11, Theorem 4.1] the estimate for $0 < s < n$ will follow from the estimates for $s = 0$ and $s = n$ by Hölder interpolation. Indeed, let $1/p = (n-s)/n$, $1/p' = s/n$, and $|\alpha| = m$; we have

$$\begin{aligned} M_{s,\alpha}(t) = \int_{\mathbf{R}^n} |x|^s |D^\alpha u|^2\, dx &\le \left(\int_{\mathbf{R}^n} |D^\alpha u|^2\, dx\right)^{1/p} \left(\int_{\mathbf{R}^n} |x|^n |D^\alpha u|^2\, dx\right)^{1/p'} \\ &= M_{0,\alpha}(t)^{1-\frac{s}{n}} M_{n,\alpha}(u)(t)^{\frac{s}{n}} \le C(t+1)^{-(2\mu+m)(1-\frac{s}{n})} M_{n,\alpha}(u)(t)^{\frac{s}{n}}. \end{aligned}$$

Thus, if $M_{n,\alpha}(u)(t)$ is uniformly bounded, we have

$$\tilde{M}_{s,m}(t) \le C(t+1)^{-(2\mu+m)(1-\frac{s}{n})}\,.$$

It suffices thus to prove the estimate for $s = n$, which merely says that $\tilde{M}_{n,m}(t)$ is bounded uniformly with respect to t, for $t > 0$. In other words, it suffices to prove

$$\sup_{t>0} \tilde{M}_{n,m}(t) < \infty \tag{4.3}$$

for $m = 0, 1, \dots$.

Let α be a multi-index with $|\alpha| = m$. For a function g and a multi-index β, we set $g_\beta = D^\beta g$. By Leibniz's product formula, differentiating (1), we obtain

$$u_{\alpha t} = \Delta u_\alpha - \sum_{\beta+\gamma=\alpha} \begin{pmatrix} \alpha \\ \beta \end{pmatrix} u_\beta \cdot \nabla u_\gamma - \nabla p_\alpha;$$

dot multiplying by $|x|^s u_\alpha$ and using that $\operatorname{div} u = 0$ and $\operatorname{div} u_\alpha = 0$, we get, after some technical but straightforward manipulations,

$$\begin{aligned} |x|^s u_{\alpha t} \cdot u_\alpha = &-|x|^s |\nabla u_\alpha|^2 + \frac{s}{2}(s-2+n)|x|^{s-2}|u_\alpha|^2 + \frac{s}{2}|x|^{s-2}(x\cdot u)|u_\alpha|^2 \\ &-|x|^s \sum_{\beta+\gamma=\alpha,\beta\neq 0} \begin{pmatrix} \alpha \\ \beta \end{pmatrix} (u_\beta \cdot \nabla u_\gamma)\cdot u_\alpha + s|x|^{s-2}(x\cdot u_\alpha) p_\alpha \\ &+ \operatorname{div} E_{s,\alpha}\,, \end{aligned}$$

where

$$E_{s,\alpha} = \frac{|x|^s}{2}\nabla(|u_\alpha|^2) - \frac{s}{2}|x|^{s-2}|u_\alpha|^2 x - \frac{|x|^s}{2}|u_\alpha|^2 u - |x|^s u_\alpha p_\alpha.$$

One can prove now, as in Lemma 6.1, Appendix B of [11], that

$$\liminf_{R\to\infty} \int_{|x|=R} |E_{s,\alpha}|\, dS = 0.$$

More precisely, the proof is a repetition of the arguments in the above mentioned lemma, where we replace u by u_α and use the appropriate estimates for the derivatives obtained in [12]. Thus

$$\int_{\mathbf{R}^n} \operatorname{div} E_{s,\alpha}\, dx = 0\,,$$

and we obtain

$$\frac{1}{2}\frac{d}{dt}M_{s,\alpha}(t) = A(t) + B(t) + C(t) + D(t), \tag{4.4}$$

where

$$\begin{aligned} A(t) &= -\int_{\mathbf{R}^n} |x|^s |\nabla u_\alpha|^2\,dx + \frac{s}{2}(s-2+n)M_{s-2,\alpha}(t)\frac{s}{2}(s-2+n)M_{s-2,\alpha}(t),\\ B(t) &= \frac{s}{2}\int_{\mathbf{R}^n} |x|^{s-2}(x\cdot u)|u_\alpha|^2\,dx,\\ C(t) &= -\sum_{\beta+\gamma=\alpha,\beta\neq 0}\begin{pmatrix}\alpha\\ \beta\end{pmatrix}\int_{\mathbf{R}^n}|x|^s(u_\beta\cdot\nabla u_\gamma)\cdot u_\alpha\,dx,\\ D(t) &= s\int_{\mathbf{R}^n}|x|^{s-2}(x\cdot u_\alpha)p_\alpha\,dx. \end{aligned}$$

Assume $m = 0$. Recall that we write M_s for $M_{s,0}$. We prove by induction on s that there exists $C \geq 0$ such that $M_s(u)(t) \leq C$ for all $t \geq 0$, $s = 1, \ldots, n$. We begin considering the case $s = 2$; the case $s = 1$ follows by interpolation between the cases $s = 0$ and $s = 2$ and induction can then proceed in steps of 2; i.e., M_k bounded implies M_{k+2} bounded.

If A, B, C, D are as in (4.4) for $|\alpha| = m = 0$, $s = 2$, we get $A(t) \leq nM_{0,0}(u)(t) = n\|u(t)\|_2^2$, $C(t) = 0$ and

$$\begin{aligned} B(t) &\leq \int_{\mathbf{R}^n}|x||u|^3\,dx \leq M_2(u)(t)^{1/2}\|u(t)\|_4^2,\\ D(t) &\leq M_2(u)(t)^{1/2}\|p(t)\|_2^2 \leq CM_2(u)(t)^{1/2}\|u(t)\|_4^2 \end{aligned}$$

so that by (4.4)

$$\frac{d}{dt}M_2(u)(t) \leq CM_2(u)(t)^{1/2}\|u(t)\|_4^2 + n\|u(t)\|_2^2. \tag{4.5}$$

By (2.11) (with $j = 0$ and $p = 4$)

$$\|u(t)\|_4 \leq C(t+1)^{-\mu-n/8};$$

it follows from this and (4.1)

$$\frac{d}{dt}M_2(u)(t) \leq n(t+1)^{-2\mu} + CM_2(u)(t)^{1/2}(t+1)^{-\delta}$$

with $\delta = 2\mu + n/4$. A bit of elementary arithmetic yields

$$\frac{d}{dt}M_2(u)(t) \leq n(t+1)^{-2\mu} + C(t+1)^{-\delta} + CM_2(u)(t)(t+1)^{-\delta}.$$

Since the moments are bounded (time dependent) and since $\delta > 1$ it follows by Gronwall's inequality that

$$M_2(u)(t) \leq Ce^{\int_0^\infty (t+1)^{-\delta}dt} \leq \text{const}$$

proving the case $s = 2$. Assume now $s > 2$. In this case

$$A(t) \leq \frac{s}{2}(s + n - 2)M_{s-2}(u)(t), \tag{4.6}$$

$$B(t) \leq \int_{\mathbf{R}^n} |x|^{s-1}|u|^3\,dx \leq M_s(u)(t)^{(s-1)/s}\|u(t)\|_{s+2}^{(s+2)/s}, \tag{4.7}$$

$$D(t) \leq \int_{\mathbf{R}^n} |x|^{s-1}|u||p|\,dx \leq CM_s(u)(t)^{(s-1)/s}\|u(t)\|_{s+2}^{(s+2)/s}. \tag{4.8}$$

Inequality (4.7) is an immediate consequence of Hölder's inequality (with exponents $s/(s-1)$ and s). For (4.8) notice first that, by Hölder's inequality,

$$\begin{aligned}\int_{\mathbf{R}^n} |x|^{s-1}|u||p|\,dx &\leq \left(\int_{\mathbf{R}^n} |x|^s|u|^2\,dx\right)^{1/2}\left(\int_{\mathbf{R}^n} |x|^{s-2}|p|^2\,dx\right)^{1/2}\\ &= M_s(u)(t)^{1/2}\|p\|_{L^2_\nu}\end{aligned}$$

with $\nu = s/2 - 1$. Then $n/(n-\nu) < 2$ (since $s < n+2$) hence the Riesz transforms are bounded in L^2_ν (see [11, Lemma 5.1]); since $p = -\sum_{j,k} R_jR_k(u_ju_k)$, we get

$$\begin{aligned}\|p\|_{L^2_\nu} &\leq C\|\,|u|^2\|_{L^2_\nu}\\ &= C\left(\int_{\mathbf{R}^n} |x|^{s-2}|u|^4\,dx\right)^{1/2} \leq M_s(u)(t)^{(s-2)/2s}\|u\|_{s+2}^{(s+2)/s},\end{aligned}$$

where we factored $|u|^4 = |u|^{2-4/s}|u|^{2+4/s}$ and used Hölder's inequality with exponents $s/(s-2)$, $s/2$. Inequality (4.8) follows. To continue estimating, we get by Hölder's inequality, (4.1), and (2.10) (for $j = 0$)

$$\|u(t)\|_{s+2} \leq \|u(t)\|_2^{2/(s+2)}\|u\|_\infty^{s/(s+2)} \leq C(t+1)^{-\mu-(ns)/(4s+8)}\,;$$

by Hölder's inequality and (4.1)

$$M_{s-2}(u)(t) \leq M_s(u)(t)^{(s-2)/s}\|u(t)\|_2^{4/s} \leq C(t+1)^{-4\mu/s}M_s(u)(t)^{(s-2)/s};$$

whence combining with (4.6), (4.7), (4.8), and (4.4),

$$\begin{aligned}\frac{d}{dt}M_s(u)(t) &\leq C_1(t+1)^{-4\mu/s}M_s(u)(t)^{(s-2)/s}\\ &\qquad + C_2(t+1)^{-\mu(s+2)/s-n/4}M_s(u)(t)^{(s-1)/s}.\end{aligned}$$

We estimate the two terms on the right-hand side (R.H.S.) using $M_s^\tau \leq 1 + M_s$ for $\tau = (s-2)/s$ and $\tau = (s-1)/s$, respectively; we get

$$\frac{d}{dt}M_s(u)(t) \leq C_1(t+1)^{-\rho} + C_2(t+1)^{-\rho}M_s(u)(t),$$

where

$$\rho = \min\left\{\frac{4\mu}{s}, \frac{s+2}{s}\mu + \frac{n}{4}\right\} > 1.$$

Integrating from 0 to t, considering that

$$\int_0^t (\sigma+1)^{-\rho}\,d\sigma \leq \int_0^\infty (\sigma+1)^{-\rho}\,d\sigma = \frac{1}{\rho - 1} < \infty,$$

we get

$$M_s(u)(t) \leq C\,(1 + M_s(u)(0)) + C\int_0^t (\sigma+1)^{-\rho} M_s(u)(\sigma)\,d\sigma.$$

By Gronwall's lemma,

$$M_s(u)(t) \leq C\,(1 + M_s(u)(0))\, e^{\int_0^\infty (\sigma+1)^{-\rho}\,d\sigma} \leq C_0 < \infty$$

which completes the proof of the case $m = 0$.

Assume now m is a positive integer and that the estimates (4.2) have been proved up to $m-1$; $s = 0, \ldots, n$. Let $|\alpha| = m$. Time dependent bounds for $M_{s,\alpha}(u)(t)$ are easily established by induction on s, $0 \leq s \leq n$. In fact, the case $s = 0$ is (as already mentioned) immediate and the induction proceeds by means of energy estimates which are quite straightforward and as such will be omitted; the reader can refer to [11] for details of a similar proof. With this established, to obtain the uniform bound we proceed as follows. Let $A(t)$, $B(t)$, $C(t)$, $D(t)$ be as in (4.4) with $s = n$.

Bound for $A(t)$.

Notice first that if $n = 2$ then

$$A(t) \leq 2M_{0,\alpha}(t) \leq C_0(1+t)^{-2\mu-1}\,, \tag{4.9}$$

where $2\mu > n/2 = 1$. Suppose now that $3 \leq n \leq 5$; by Hölder's inequality and by (2.9),

$$M_{n-2,\alpha}(t) \leq M_{n,\alpha}(t)^{(n-2)/n}\|u_\alpha(t)\|_2^{4/n} \leq C(1+t)^{-\rho} M_{n,\alpha}(t)^{(n-2)/n},$$

with $\rho = (4/n)(\mu + m/2) > 1$. In general, from now on, ρ denotes a constant > 1, not the same one in all inequalities. By the definition of $A(t)$, using also

$$(1+t)^{-\rho} M_{n,\alpha}(t)^{(n-2)/n} \leq \frac{2}{n}(1+t)^{-\rho} + \frac{n-2}{n}(1+t)^{-\rho} M_{n,\alpha}(t),$$

we prove that

$$|A(t)| \leq C(1+t)^{-\rho}\left(1 + \tilde{M}_{n,m}(t)\right)\,. \tag{4.10}$$

Bound for $B(t)$.

$$\begin{aligned} |B(t)| &= \left|\frac{n}{2}\int_{\mathbf{R}^n} |x|^{n-2}(x\cdot u)|u_\alpha|^2\,dx\right| \leq \frac{n}{2}\int_{\mathbf{R}^n} |x|^{n-1}|u||u_\alpha|^2\,dx \\ &\leq \frac{n}{2}\|u_\alpha\|_2^{2/n}\|u\|_\infty \left(\tilde{M}_{n,m}(t)\right)^{(n-1)/n}\,, \end{aligned}$$

so that by (2.9) and (2.10),

$$\begin{aligned} |B(t)| &\leq C(1+t)^{-\rho}\left(\tilde{M}_{n,m}(t)\right)^{(n-1)/n} \\ &\leq C(1+t)^{-\rho}\left(1 + \tilde{M}_{n,m}(t)\right), \end{aligned}$$

where this time $\rho = (2/n)(\mu + m/2) + \mu + n/4 > 1$.

Bound for $C(t)$.

Note that C(t) is a sum in terms of α and β, where $|\beta| + |\gamma| = |\alpha|$ and $\beta \neq 0$. The general term in $C(t)$ can be estimated by

$$\int_{\mathbf{R}^n} |x|^n \, |(u_\beta \cdot \nabla u_\gamma) \cdot u_\alpha| \, dx \leq \|D^j u\|_\infty \tilde{M}_{n,\ell}(t)^{1/2} \tilde{M}_{n,m}(t)^{1/2},$$

where $j = \min(|\beta|, |\gamma| + 1)$, $\ell = \max(|\beta|, |\gamma| + 1)$, so that $0 \leq j \leq [m/2]$, $[(m+1)/2] \leq \ell \leq m$, and $j + \ell = m + 1$. When $\ell = m$, and so $j = 1$, (2.10) implies a bound of the form

$$C(1+t)^{-(\mu+n/4+1)} \tilde{M}_{n,m}(t).$$

The terms with $\ell < m$ are bounded, using the induction hypothesis and (2.10), by

$$C(1+t)^{-(\mu+n/4+j/2)} \tilde{M}_{n,m}(t)^{1/2},$$

and we obtain again an estimate of the form

$$|C(t)| \leq C(1+t)^{-\rho} \left(1 + \tilde{M}_{n,m}(t)\right), \tag{4.11}$$

where $\rho > 1$.

Bound for $D(t)$.

Since the Riesz transforms are bounded in L^2_ν with $\nu = (n-2)/2$, and D^α commutes with the Riesz transforms, we can write

$$p_\alpha = D^\alpha p = \sum_{j,k} R_j R_k [D^\alpha (u_j u_k)] = \sum_{k,j,\beta+\gamma=\alpha} \begin{pmatrix} \alpha \\ \beta \end{pmatrix} R_j R_k (u_{\beta,j} u_{\gamma,k}),$$

and we have

$$\begin{aligned} |D(t)| &= \left| n \int_{\mathbf{R}^n} |x|^{n-2} (x \cdot u_\alpha) p_\alpha \, dx \right| \\ &\leq C \int_{\mathbf{R}^n} |x|^{n-1} |u_\alpha| |p_\alpha| \, dx \leq C \tilde{M}_{n,m}(t)^{1/2} \|p_\alpha\|_{L^2_\nu} \\ &\leq C \tilde{M}_{n,m}(t)^{1/2} \sum_{\beta+\gamma=\alpha} \| |u_\beta| |u_\gamma| \|_{L^2_\nu} . \end{aligned}$$

Then Hölder's inequality gives

$$\begin{aligned} \| |u_\beta| |u_\gamma| \|_{L^2_\nu} &= \left(\int_{\mathbf{R}^n} |x|^{n-2} |D^\beta u|^2 |D^\gamma u|^2 \, dx \right)^{1/2} \\ &\leq C \|D^j u\|_\infty \|D^\ell u\|_2^{1/n} \tilde{M}_{n,\ell}(t)^{(n-2)/2n}, \end{aligned}$$

with $j = \min(\beta, \gamma)$, $\ell = \max(\beta, \gamma)$ (so $0 \leq j \leq m/2$). Once more we apply (2.9), (2.10) to get $\|D^j u\|_\infty \|D^\ell u\|_2^{1/n} \leq C(1+t)^{-\rho}$ with $\rho = (1/n)(\mu + \ell/2) + \mu + n/4 + j/2 > 1$. By the induction hypothesis $\tilde{M}_{n,\ell}(t)$ is bounded uniformly in t if $\ell < m$, so all terms with $\ell < m$ in the last estimate for D can be bounded by $C(1+t)^{-\rho}$ and the remaining term is bounded by

$$C(1+t)^{-\rho} \tilde{M}_{n,m}(t)^{(n-2)/2n} \leq C(1+t)^{-\rho} \left(1 + \tilde{M}_{n,m}(t)\right)$$

so that $D(t)$ has a bound of the same type as $A(t)$, $B(t)$, $C(t)$. Combining all the above estimates, we derive

$$\frac{d}{dt}\tilde{M}_{n,m}(t) \leq C(1+t)^{-\rho} + C(1+t)^{-\rho}\tilde{M}_{n,m}(t)\,,$$

where $\rho > 1$. Hence, integrating in this inequality, we find

$$\tilde{M}_{n,m}(t) \leq \left(\tilde{M}_{n,m}(0) + \frac{C}{\rho-1}\right) + C\int_0^t (s+1)^{-\rho}\tilde{M}_{n,m}(s)\,ds.$$

Then Gronwall's lemma implies

$$\tilde{M}_{n,m}(t) \leq \left(\tilde{M}_{n,m}(0) + \frac{C}{\rho-1}\right) e^{c/(\rho-1)}\,,$$

thus proving that $\tilde{M}_{n,m}(t)$ is bounded uniformly with respect to t for $t > 0$. □

Note. We took some pains to avoid having to bound $\|D^j u\|_\infty$ for $j > [(m+1)/2]$. In this way, bounds on the L^2-norm of derivatives of order m will give (sometimes) all the needed L^∞ bounds on the $D^j u$'s.

The next theorem establishes the spatial and time decay of strong solutions to equations for which the moments decay.

Theorem 4.2. *Let $2 \leq n \leq 5$. With the assumptions of Theorem 4.1, let u be a strong solution u of the Navier–Stokes equations with data u_0. Let $k \leq n/2$. Then*

$$|D^\alpha u(x,t)| \leq C_{k,m}\frac{1}{(t+1)^{\rho_0}(1+|x|^2)^{k/2}}\,, \tag{4.12}$$

where $\rho_0 = (\mu + m/2 + n/4)(1-2k/n)$ and $|\alpha| = m$.

Proof. Note that n is restricted to the values $2 \leq n \leq 5$ for which we have estimates for the moments. The main tools for the proof are Theorem 4.1 and the Gagliardo–Nirenberg inequality. Let

$$v(x,t) = (1+|x|^2)^{k/2}D^\alpha u(x,t)\,.$$

By Leibniz's formula, we have

$$D^s v = \sum_{j=0}^{s} c_j^s (1+|x|^2)^{\frac{k-j}{2}} D^{s-j}u_\alpha\,. \tag{4.13}$$

Together with the decay of the moments of derivatives given by Theorem 4.1, this formula implies that

$$\|D^s v\|_2 \leq C_0\sum_{j=0}^{s}(1+t)^{-(\mu+m/2+(s-j)/2)(1-2(k-j)/n)}\,. \tag{4.14}$$

Since the function $f(j) = (\mu + m/2 + (s-j)/2)(1-2(k-j)/n)$ is increasing, it has a minimum at $j = 0$. Thus we have

$$\|D^s v\|_2 \leq C_0(1+t)^{-(\mu+m/2+s/2)(1-2k/n)}\,. \tag{4.15}$$

In particular when $s = 0$,

$$\|v\|_2 \leq C_0(1+t)^{-(\mu+m/2)(1-2k/n)}\,. \tag{4.16}$$

Let us apply the Gagliardo–Nirenberg inequality with $a = n/(2s) < 1$, provided $n/2 < s$, i.e., $s > [n/2]$, to get

$$\|v(\cdot,t)\|_\infty \leq \|v(\cdot,t)\|_2^{1-a} \|D^s v(\cdot,t)\|_2^a \,. \tag{4.17}$$

Combining with (4.16) and (4.15) yields

$$|(1+|x|^2)^{k/2} D^\alpha u(x,t)| \leq ||v(t)||_\infty \leq C_0 (1+t)^{-\rho_0} \,,$$

where

$$\begin{aligned} \rho_0 &= (1-2k/n)\left((\mu + m/2 + s/2)n/(2s) + (1-n/(2s))(\mu + m/2)\right) \\ &= (1-2k/n)(\mu + m/2 + n/4) \,. \end{aligned}$$

We note that the above value of ρ_0 is independent of s. Thus we could have obtained it using only the s derivative with $s > [n/2]$. In particular note that when $n = 3$, it suffices to use $s = 2$ and $\rho_0 = (\mu + m/2 + 3/4)(1 - 2k/3)$. The proof is complete. □

4.1. Comparison with the heat equation. It is easy to show that the fundamental solution of the heat equation,

$$E(x,t) = (4\pi t)^{-n/2} e^{-|x|^2/4t} \,,$$

which is the linear part of the Navier–Stokes equations, has the following asymptotic behavior:

$$|D^\alpha E(x,t)| \leq c_0 |x|^{-a} t^{-b},$$

where $a + 2b = n + m$, with $m = |\alpha|$. It is also easy to show that there is a large class of solutions to the heat equation which will have the same type of decay. For instance solutions such that the data satisfies $u_0 \in \mathcal{K}$ where

$$\mathcal{K} = \{u_0 : u_0(y) \geq e^{-y^2/4t_0}\}$$

will have the above type of decay, provided we are considering $t \geq t_0 + \varepsilon$. In the case of solutions to the Navier–Stokes equations, if we take $\mu = n/4$, the relation that holds between the decay in space and in time is

$$2\rho_0 + 2k = m + n - \frac{2km}{n} \,.$$

For $k = 0$, we recover the decay of the heat equation, but this only gives decay in time. If $m = 0$ we recover the relation $2\rho_0 + 2k = n$; i.e., we have the same decay relation in space and in time as for solutions to the heat equation.

Final remarks. We expect that our results can be extended easily to dimensions 6 and 7 using the L^2 decay results, for derivatives of higher order, recently obtained by Wiegner [19].

Acknowledgment. The authors wish to thank the referee for many helpful suggestions which resulted in a significantly improved paper.

ASYMPTOTIC EXPANSIONS OF SYMMETRIC STANDARD ELLIPTIC INTEGRALS[*]

JOSÉ L. LÓPEZ[†]

Abstract. Symmetric standard elliptic integrals are considered when one of their parameters is larger than the others. The distributional approach is used for deriving five convergent expansions of these integrals in inverse powers of the respective five possible asymptotic parameters. Four of these expansions also involve a logarithmic term in the asymptotic variable. Coefficients of these expansions are obtained by recurrence. For the first four expansions these coefficients are expressed in terms of elementary functions, whereas coefficients of the fifth expansion involve nonelementary functions. The convergence speed of any of these expansions increases for increasing difference between the asymptotic variable and the remaining ones. All the expansions are accompanied by an error bound at any order of the approximation.

1. Introduction. Elliptic integrals (EI) are integrals of the type $\int R(x,y)dx$, where $R(x,y)$ is a rational function of x and y, with y^2 a polynomial of the third or fourth degree in x. When the polynomial y^2 does not have a repeated factor and $R(x,y)$ contains some odd power of y, EI cannot, in general, be expressed in terms of elementary functions. Legendre showed that all EI can be expressed in terms of three standard EI (Legendre's normal EI) [14].

The three complete EI of the first, second, and third kind are particularly important cases of the respective three standard EI. These integrals and the three standard EI are special nonelementary functions that play an important role in several mathematical problems. The first complete EI appears as a certain limit in the theory of iterated number sequences based on the arithmetic geometric mean [18, sect. 12.1.2]. Standard EI are related to theta functions and the Weierstrass elliptic function [18, sect. 12.3]. EI constitute a basic ingredient of certain geometrical [11] and statistical [17] problems.

EI are also involved in several physical problems. The period of a simple pendulum in a constant gravitational field can be expressed in terms of the first complete EI [18, sect. 12.1.1]. The zeros of EI can be used for determining an upper bound for the number of limit cycles of certain Hamiltonian systems [19]. EI are related to certain problems of electromagnetism [20].

A survey of properties of the standard EI can be found, for example, in [1, chap. 17], [2], or [18, chap. 12]. However, as it has been shown by Carlson [5, 6, 7, 8, 9], for numerical computations it is more convenient to use symmetric standard EI instead of Legendre's normal EI. (Legendre's normal EI are connected with the symmetric standard EI by means of simple formulas [18, eq. (12.33)].) A very complete table of the three symmetric standard EI can be found in [5, 6, 7, 8, 9]. They are defined as

follows:

$$R_F(x,y,z)=\frac{1}{2}\int_0^\infty \frac{dt}{\sqrt{(t+x)(t+y)(t+z)}},$$

$$R_D(x,y,z)=\frac{3}{2}\int_0^\infty \frac{dt}{\sqrt{(t+x)(t+y)(t+z)^3}},$$

$$R_J(x,y,z,p)=\frac{3}{2}\int_0^\infty \frac{dt}{\sqrt{(t+x)(t+y)(t+z)}(t+p)},$$

where we assume that the parameters x, y, z are nonnegative. We assume also that they are distinct (otherwise these integrals reduce to elementary functions). If the fourth argument of R_J is negative, the Cauchy principal value of R_J can be written in terms of R_F and R_J with all the arguments nonnegative [10]. Therefore, we will consider $p>0$ and $p\neq x,\ y,\ z$ (otherwise R_J reduces to R_D).

On the other hand, the asymptotic approximation of EI has not been exhaustively investigated: classical methods for approximation of integrals cannot be applied. Some results concerning approximations of EI can be found for example in [2] and [13]. However, the more recent results about the asymptotic behavior of these integrals have been obtained by Carlson, Gustafson, and Wong: R_F, R_D, and R_J may be written as a convolution and the method of regularization [22, chap. 6, sect. 7] can be applied.

When one of the parameters of the integrals tends to zero or infinity, the first (and sometimes the second too) term of the asymptotic expansion of R_F, R_D, and R_J, as well as a quite accurate bound for the first error term, has been obtained by Gustafson [12]. Higher terms of the expansion and higher error bounds are not explicitly derived in that work because of the complexity of the Mellin transforms involved in their calculation. Using a very clever analytical trick [10], Carlson and Gustafson have sharpened the bounds for the first error terms obtained in [12] in the case of one parameter going to infinity. Besides, they supply in [10] very accurate bounds for the first error term of the totally symmetric EI of the second kind. Moreover, for all the symmetric EI, they consider also the case of several parameters going to infinity.

Complete convergent expansions of R_F, R_D, and R_J (and not only first terms) have been obtained by Carlson using Mellin transform techniques [3]. Although these expansions have an attractively simple structure, explicit computation of the terms of the expansions is not straightforward and the upper bound on the truncation error is not quite satisfactory [3, sect. 5]. Carlson and Gustafson have solved this problem for $R_F(x,y,z)$ in [4], where an algorithm for computing the coefficients of the convergent expansion of $R_F(x,y,z)$ in terms of Legendre functions and their derivatives is derived. Moreover, accurate error bounds are given at any order of the approximation.

In this paper we try to solve for R_D and R_J the problem that Carlson and Gustafson have solved for R_F. That is, we consider complete convergent expansions for R_D and R_J when one of their parameters x, y, z, or p is large. Then, we face the challenge of obtaining easy algorithms for computing the coefficients of these expansions (in terms of elementary functions when it is possible) and simple expressions for the error bounds at any order of the approximation. For completeness, we also include R_F in this project.

For this purpose, in section 2, we make a review of the asymptotic expansions of Stieltjes [22, chap. 6, sect. 2] and generalized Stieltjes transforms (see [21, Theorem

2 and Example 1]): the distributional approach is used in Lemmas 2.5 and 2.6 and Theorems 2.4 and 2.7 for deriving complete expansions of a certain family of integrals which contains R_F, R_D, and R_J.

On the other hand, using Lemmas 2.8 and 2.9, we obtain simple expressions for the error bounds in the expansions of this family of integrals in Propositions 2.10 and 2.11. In section 3 we apply the results of section 2 for deriving complete convergent expansions of $R_F(x,y,z)$, $R_D(x,y,z)$, $R_D(x,z,y)$, $R_J(x,y,z,p)$, and $R_J(x,y,p,z)$ for large z. They are presented in Corollaries 3.1–3.8 accompanied by error bounds at any order of the approximation. Numerical examples are shown as an illustration. A brief summary and a few comments are postponed to section 4.

2. Distributional approach.

The procedure for deriving convergent expansions of the integrals R_F, R_D, and R_J is based on the distributional approach. It requires the concepts of rapidly decreasing functions and tempered distributions.

DEFINITION 2.1. *We denote by $\mathcal{S}$ the space of rapidly decreasing functions (infinitely differentiable functions $\varphi(t)$ defined on $[0,\infty)$ that, together with their derivatives, approach zero more rapidly than any power of t^{-1} as $t\to\infty$).*

DEFINITION 2.2. *We denote by $\langle\Lambda,\varphi\rangle$ the image of a tempered distribution Λ (a continuous linear functional defined over $\mathcal{S}$) acting over a function $\varphi\in\mathcal{S}$. Recall that we can associate to any locally integrable function $g(t)$ on $[0,\infty)$ a tempered distribution Λ_g defined by*

$$\langle\Lambda_g,\varphi\rangle=\int_0^\infty g(t)\varphi(t)dt.$$

DEFINITION 2.3. *For a locally integrable function $f(t)$ on $(0,\infty)$, we denote by $M[f;w]$ the Mellin transform of $f(t)$ or its analytic continuation. It is defined by*

$$M[f;w]=\int_0^\infty t^{w-1}f(t)dt \tag{2.1}$$

when the integral converges.

The derivation of convergent expansions of $R_J(x,y,z,p)$ for large p is based on the following theorem proved in [22, chap. 6, Theorem 1].

THEOREM 2.4. *Let $f(t)$ be a locally integrable function on $[0,\infty)$, and $\{A_k\}$ be a sequence of complex numbers and let $f(t)$ satisfy, for $n=1,2,3,\dots$,*

$$f(t)=\sum_{k=0}^{n-1}\frac{A_k}{t^{k+\alpha}}+f_n(t),$$

where $f_n(t)=\mathcal{O}(t^{-n-\alpha})$ as $t\to\infty$ and $0<\alpha<1$. Then, for $p>0$ and $n=1,2,3,\dots$,

$$\int_0^\infty\frac{f(t)}{t+p}dt=\frac{\pi}{\sin(\alpha\pi)}\sum_{k=0}^{n-1}(-1)^k\frac{A_k}{p^{k+\alpha}}+\sum_{k=0}^{n-1}(-1)^k\frac{M[f;k+1]}{p^{k+1}}+R_n(p). \tag{2.2}$$

The remainder term satisfies

$$R_n(p)=n!\int_0^\infty\frac{f_{n,n}(t)dt}{(t+p)^{n+1}}, \tag{2.3}$$

where $f_{n,n}(t)$ is defined by

$$f_{n,n}(t)=\frac{(-1)^n}{(n-1)!}\int_t^\infty (u-t)^{n-1}f_n(u)du. \tag{2.4}$$

Convergent expansions of $R_F(x,y,z)$, $R_D(x,y,z)$, $R_D(x,z,y)$, and $R_J(x,y,z,p)$ for large z can be derived from [21, Theorem 2] (see also Example 1 there). This result has been proved by using Mellin transform techniques and, as it is suggested by Wong [21, Example 1], it can also be proved by using the distributional approach. We carry out Wong's proposal in the following two lemmas and Theorem 2.7. The first lemma is proved in [22, chap. 6, Lemma 2].

LEMMA 2.5. *Let $f(t)$ be as in Theorem* 2.4 *but with $\alpha=1$. Then, for any integer $n\geq 1$ and for any function $\varphi\in\mathcal{S}$ we have*

$$\langle f,\varphi\rangle=-\sum_{k=0}^{n-1}\frac{A_k}{k!}\langle\log(t),\varphi^{(k+1)}\rangle+\sum_{k=0}^{n-1}\frac{B_k}{k!}\langle\delta,\varphi^{(k)}\rangle+(-1)^n\langle f_{n,n},\varphi^{(n)}\rangle,$$

where f, $f_{n,n}$, and $\log(t)$ *denote the tempered distributions associated with the locally integrable functions $f(t)$, $f_{n,n}(t)$, and* $\log(t)$*, respectively; δ is the delta distribution in the origin; and*

$$\begin{aligned}B_k&=A_k\sum_{j=1}^{k}\frac{1}{j}+\lim_{w\to k+1}\left\{M[f;w]+\frac{A_k}{w-k-1}\right\}\\&=A_k\sum_{j=1}^{k}\frac{1}{j}+\int_0^1 t^k f_k(t)dt+\int_1^\infty t^k f_{k+1}(t)dt,\end{aligned}\tag{2.5}$$

empty sums being understood as zero.

LEMMA 2.6. *Let $f(t)$ be as in Theorem* 2.4 *with* $0<\alpha\leq 1$. *Define, for* $t\in[0,\infty)$, $z>0$, $\eta>0$, *and* $\alpha+\rho>1$,

$$\varphi_\eta(t)=\frac{e^{-\eta t}}{(t+z)^\rho}\in\mathcal{S}.$$

Then, for $k=0,1,2,\ldots$ and $n=1,2,3,\ldots$, the following identities hold:

$$\lim_{\eta\to 0}\langle f,\varphi_\eta\rangle=\int_0^\infty\frac{f(t)}{(t+z)^\rho}dt,$$

$$\lim_{\eta\to 0}\langle\delta,\varphi_\eta^{(k)}\rangle=\frac{(-1)^k(\rho)_k}{z^{k+\rho}},$$

where $(\rho)_k$ denotes the Pochhammer's symbol,

$$\lim_{\eta\to 0}\langle\log(t),\varphi_\eta^{(k+1)}\rangle=\frac{(-1)^{k+1}}{z^{k+\rho}}(\rho)_k\big(\log(z)-\gamma-\psi(k+\rho)\big),$$

where γ is the Euler constant and ψ the digamma function and

$$\lim_{\eta\to 0}\langle f_{n,n},\varphi_\eta^{(n)}\rangle=(-1)^n(\rho)_n\int_0^\infty\frac{f_{n,n}(t)}{(t+z)^{n+\rho}}dt.$$

Proof. The first identity is trivial by using the dominated convergence theorem. The second one follows after a simple computation. On the other hand,

$$\langle \log(t), \varphi_\eta^{(k+1)} \rangle = (-1)^{k+1} \sum_{j=0}^{k+1} \binom{k+1}{j} \eta^j (\rho)_{k+1-j} \int_0^\infty \frac{e^{-\eta t}\log(t)}{(t+z)^{k+\rho+1-j}} dt.$$

For $j \leq k$ or $j = k+1$ and $\rho > 1$, the integrand of each integral on the right-hand side of the above equation is absolutely dominated by the integrable function $\log(t)(t+z)^{j-k-\rho-1}\ \forall\, \eta, t \geq 0$ and is therefore finite. For $j = k+1$ and $\rho \leq 1$, we divide the interval $[0,\infty)$ in the above integral at the point $t = 1$. On the interval $[0,1]$ the integral is finite for $\eta \geq 0$. In the interval $[1,\infty)$ we use the bound $\log(t) \leq \log(t+z)$, perform the change of variable $\eta t = u$, and divide again the resulting u-interval $[\eta,\infty)$ at the point $u = 1 - \eta z$ (assume $\eta \leq (1+z)^{-1}$). In the u-interval $[\eta, 1-\eta z]$ we use the bound $(u+\eta z)^\rho \geq u + \eta z$. After straightforward operations we obtain that the integral on the t-interval $[1,\infty)$ is $\mathcal{O}\left(\eta^{\rho-1}\log^2(\eta)\right)$ as $\eta \to 0$. Therefore,

$$\lim_{\eta\to 0} \langle \log(t), \varphi_\eta^{(k+1)} \rangle = (-1)^{k+1} (\rho)_{k+1} \int_0^\infty \frac{\log(t)}{(t+z)^{k+\rho+1}} dt.$$

Now using formula [16, p. 489, eq. (7)], we obtain the third identity. The fourth identity follows from the dominated convergence theorem, the local integrability of $f_{n,n}(t)$ on $[0,\infty)$, and the behavior $f_{n,n}(t) = \mathcal{O}(t^{-\alpha})$ as $t \to \infty$ [22, p. 296]. □

THEOREM 2.7. *Let $f(t)$ be a locally integrable function on $[0,\infty)$ and $\{A_k\}$ a sequence of complex numbers and let $f(t)$ have the following asymptotic expansion for large t and $n = 1, 2, 3, \ldots$:*

$$f(t) = \sum_{k=0}^{n-1} \frac{A_k}{t^{k+1}} + f_n(t), \tag{2.6}$$

where $f_n(t) = \mathcal{O}(t^{-n-1})$ as $t \to \infty$. Then, for $z, \rho > 0$ and $n = 1, 2, 3, \ldots$,

$$\int_0^\infty \frac{f(t)}{(t+z)^\rho} dt = \sum_{k=0}^{n-1} \frac{(-1)^k}{k! z^{k+\rho}} (\rho)_k \left[A_k\big(\log(z) - \gamma - \psi(k+\rho)\big) + B_k\right] + R_n(z), \tag{2.7}$$

where, for $k = 0, 1, 2, \ldots$, the coefficients B_k are given by

$$\begin{aligned} B_k &= A_k \sum_{j=1}^k \frac{1}{j} + \lim_{w\to k+1} \left\{ M[f;w] + \frac{A_k}{w-k-1} \right\} \\ &= A_k \sum_{j=1}^k \frac{1}{j} + \lim_{T\to\infty} \left\{ \int_0^T t^k f(t) dt - \sum_{j=0}^{k-1} A_j \frac{T^{k-j}}{k-j} - A_k \log(T) \right\}, \end{aligned} \tag{2.8}$$

empty sums being understood as zero. The remainder term is given by

$$R_n(z) = (\rho)_n \int_0^\infty \frac{f_{n,n}(t)}{(t+z)^{n+\rho}} dt, \tag{2.9}$$

where $f_{n,n}(t)$ is defined in (2.4).

Proof. From Lemmas 2.5 and 2.6 we obtain immediately (2.7), (2.9), and the first line in (2.8). Introducing

$$f_k(t)=f(t)-\sum_{j=0}^{k-1}\frac{A_j}{t^{j+1}}$$

in the second line of (2.5) and performing simple manipulations we obtain the second line in (2.8). □

A bound for the error term in the expansions given in Theorems 2.4 and 2.7 will be obtained in Propositions 2.10 and 2.11, respectively, when the function $f(t)$ has the form

$$f(t)=\prod_{k=1}^{m}\frac{1}{(t+x_k)^{\mu_k}}, \tag{2.10}$$

where $m\in\mathbb{N}$, $x_1,\dots,x_m$ are nonnegative parameters at least one different from zero, and $\mu_1,\dots,\mu_m>0$. Define

$$\mu=\sum_{k=1}^{m}\mu_k>0.$$

For $\mu\notin\mathbb{N}$, the asymptotic expansion of $f(t)$ in $t=\infty$ is given, for $n=1,2,3,\dots$, by

$$f(t)=\sum_{k=0}^{n-1}\frac{A_k}{t^{k+\mu-\lfloor\mu\rfloor}}+f_n(t), \tag{2.11}$$

where

$$A_0=A_1=\cdots=A_{\lfloor\mu\rfloor-1}=0 \qquad \text{if } \lfloor\mu\rfloor\ge 1,$$

$$A_{k+\lfloor\mu\rfloor}=\lim_{u\to 0}\frac{1}{k!}\frac{d^k}{du^k}\left(u^{-\mu}f(u^{-1})\right) \qquad \text{for } k=0,1,2,\dots, \tag{2.12}$$

and $f_n(t)=\mathcal{O}(t^{-n-\mu+\lfloor\mu\rfloor})$ as $t\to\infty$. Then, we have the following result.

LEMMA 2.8. *For $\mu\notin\mathbb{N}$ and $\forall\ t\in[0,\infty)$, the remainder term $f_n(t)$ and the coefficients A_n in the expansion* (2.11)–(2.12) *of the function $f(t)$ defined in* (2.10) *verify*

$$|f_n(t)|\le\frac{|A_n|}{t^{n+\mu-\lfloor\mu\rfloor}} \quad \text{for } n\ge\lfloor\mu\rfloor, \qquad |f_n(t)|\le\frac{|A_{n-1}|}{t^{n+\mu-\lfloor\mu\rfloor-1}} \quad \text{for } n\ge\lfloor\mu\rfloor+1, \tag{2.13}$$

and sign$(f_n(t))$ = sign(A_n) = sign$((-1)^{n-\lfloor\mu\rfloor})$ for $n\ge\lfloor\mu\rfloor$.

Proof. The Taylor expansion of $u^{-\mu}f(u^{-1})$ at $u=0$ is given by

$$u^{-\mu}f(u^{-1})\equiv\prod_{k=1}^{m}(1+x_ku)^{-\mu_k}=\sum_{k=0}^{n-\lfloor\mu\rfloor-1}A_{k+\lfloor\mu\rfloor}u^k+u^{-\mu}f_n(u^{-1}).$$

Applying the binomial formula for the derivative of a product we realize that the n-esim u-derivative of $u^{-\mu}f(u^{-1})$ has the same sign as $(-1)^n$ $\forall\ u\in[0,\infty)$. Then,

$\text{sign}(A_n) = \text{sign}(-1)^{n-\lfloor\mu\rfloor}$ for $n \geq \lfloor\mu\rfloor$ and, by the Lagrange formula for the remainder $u^{-\mu}f_n(u^{-1})$, we obtain that $\text{sign}(f_n(t)) = \text{sign}(-1)^{n-\lfloor\mu\rfloor}$ for $n \geq \lfloor\mu\rfloor$ and $\forall\, t \in [0,\infty)$. Therefore, two consecutive error terms $f_n(t)$ and $f_{n+1}(t)$ in the expansion of $f(t)$ have opposite sign. After applying the error test (see, for example, [15, p. 68] or [22, p. 38]) we obtain the first inequality in (2.13). The second inequality follows from the first one and

$$f_n(t) = f_{n-1}(t) - \frac{A_{n-1}}{t^{n+\mu-\lfloor\mu\rfloor-1}}. \qquad \square$$

On the other hand, for $\mu \in \mathbb{N}$, the asymptotic expansion in $t = \infty$ of the function $f(t)$ defined in (2.10) is given, for $n = 1, 2, 3, \ldots$, by

$$f(t) = \sum_{k=0}^{n-1} \frac{A_k}{t^{k+1}} + f_n(t), \tag{2.14}$$

where

$$A_0 = A_1 = \cdots = A_{\mu-2} = 0 \qquad \text{if } \mu \geq 2,$$

$$A_{k+\mu-1} = \lim_{u\to 0} \frac{1}{k!}\frac{d^k}{du^k}\left(u^{-\mu}f(u^{-1})\right) \qquad \text{for } k = 0, 1, 2, \ldots, \tag{2.15}$$

and $f_n(t) = \mathcal{O}(t^{-n-1})$ as $t \to \infty$. Then, we have the following lemma.

LEMMA 2.9. *For $\mu \in \mathbb{N}$ and $\forall\, t \in [0,\infty)$, the remainder term $f_n(t)$ and the coefficients A_n in the expansion* (2.14)–(2.15) *of the function $f(t)$ defined in* (2.10) *verify*

$$|f_n(t)| \leq \frac{|A_n|}{t^{n+1}} \qquad \text{for } n \geq \mu - 1, \qquad |f_n(t)| \leq \frac{|A_{n-1}|}{t^n} \qquad \text{for } n \geq \mu, \tag{2.16}$$

and sign$(f_n(t))$ = sign(A_n) = sign$((-1)^{n-\mu+1})$ for $n \geq \mu - 1$.

Proof. The proof is similar to the proof of Lemma 2.8 replacing $\lfloor\mu\rfloor$ by $\mu - 1$. $\square$

PROPOSITION 2.10. *If the function $f(t)$ of Theorem* 2.4 *has the form* (2.10) *with $\mu \notin \mathbb{N}$ then, $\forall\, p > 0$ and $n \geq \lfloor\mu\rfloor$, the error term $R_n(p)$ in the expansion* (2.2) *satisfies*

$$0 \leq (-1)^{\lfloor\mu\rfloor} R_n(p) \leq \frac{\pi|A_n|}{|\sin(\pi\mu)|p^{n+\mu-\lfloor\mu\rfloor}}, \tag{2.17}$$

providing the expansion (2.2) *of an asymptotic character for large p.*

Proof. The parameter α in Theorem 2.4 equals $\mu - \lfloor\mu\rfloor$ in Lemma 2.8. Using now $\text{sign}(f_n(u)) = \text{sign}((-1)^{n-\lfloor\mu\rfloor})\ \forall\ u \in [0,\infty)$ in (2.4) and (2.3) we obtain $(-1)^{\lfloor\mu\rfloor}R_n(p) \geq 0$. Introducing the first bound of (2.13) on the right-hand side of (2.4) and performing the change of variable $u = tv$ we obtain

$$|f_{n,n}(t)| \leq \frac{\Gamma(\mu - \lfloor\mu\rfloor)}{\Gamma(n+\mu-\lfloor\mu\rfloor)}\frac{|A_n|}{t^{\mu-\lfloor\mu\rfloor}} \qquad \forall \quad t \in [0,\infty).$$

Introducing this bound in (2.3) and after the change of variable $t = pu$ we obtain (2.17). $\square$

PROPOSITION 2.11. *If the function $f(t)$ of Theorem 2.7 has the form (2.10) with $\mu \in \mathbb{N}$ then, $\forall\ z > 0$ and $n \geq \mu$, the error term $R_n(z)$ in the expansion (2.7) satisfies the bounds*

$$0 \leq -(-1)^\mu R_n(z) \leq \frac{\pi\Gamma(n+\rho-1/2)}{\Gamma(\rho)\Gamma(n+1/2)} \frac{\bar{A}_n}{z^{n+\rho-1/2}}, \tag{2.18}$$

where $\bar{A}_n = \max\{|A_n|, |A_{n-1}|\}$ and

$$|R_n(z)| \leq \left[na|A_{n-1}| + |A_n|\big(S_n(z,a,\rho) + T_n(z,a,\rho)\big)\right] \frac{(\rho)_n}{n! z^{n+\rho}}, \tag{2.19}$$

where a is an arbitrary positive number,

$$S_n(z,a,\rho) = \min\left\{\frac{nz\left[(a+z)^{n+\rho-1} - z^{n+\rho-1}\right]}{a(n+\rho-1)(a+z)^{n+\rho-1}}, \psi(n+1)+\gamma\right\}, \tag{2.20}$$

and

$$\begin{aligned} T_n(z,a,\rho) &= \frac{z^{n+\rho}}{(n+\rho)(a+z)^{n+\rho}} F\left(n+\rho, 1; n+\rho+1; \frac{z}{a+z}\right) \\ &\leq \left(\frac{z}{a+z}\right)^\rho \left(\log\left(1+\frac{z}{a}\right) - \sum_{k=1}^{n-1} \frac{z^k}{k(z+a)^k}\right), \end{aligned} \tag{2.21}$$

where $F(b,c;d;z)$ is the hypergeometric function. For large z and fixed n, the optimum value for a is given by

$$a = \frac{|A_n|}{n|A_{n-1}|}. \tag{2.22}$$

Any of these bounds provides the expansion (2.7) of an asymptotic character for large z.

Proof. From Lemma 2.9, $\mathrm{sign}(f_n(u)) = \mathrm{sign}((-1)^{n-\mu+1})\ \forall\ u \in [0,\infty)$. Introducing this in (2.4) and (2.9) we obtain $(-1)^\mu R_n(z) \leq 0$. To obtain the bound (2.19) we divide the integral on the right-hand side of (2.4) by a fixed point $u = a \geq t$ and use the second bound of (2.16) in the integral over $[t,a]$ and the first bound of (2.13) in the integral over $[a,\infty)$. Using $u - t \leq u$ in the integral over $[t,a]$ we obtain

$$\begin{aligned} |f_{n,n}(t)| &\leq \frac{1}{(n-1)!}\left[|A_{n-1}|\log\left(\frac{a}{t}\right) + \frac{|A_n|}{nt}\left(1 - \left(1-\frac{t}{a}\right)^n\right)\right] \\ &\leq \frac{1}{(n-1)!}\left[|A_{n-1}|\log\left(\frac{a}{t}\right) + \frac{|A_n|}{a}\right] \qquad \forall\ t \in [0,a], \qquad a > 0. \end{aligned} \tag{2.23}$$

On the other hand, $\forall\ t \in [0,\infty)$ we introduce the first bound of (2.13) on the right-hand side of (2.4) and perform the change of variable $u = tv$. We obtain

$$|f_{n,n}(t)| \leq \frac{|A_n|}{n!}\frac{1}{t} \qquad \forall \quad t \in [0,\infty). \tag{2.24}$$

We divide the integral on the right-hand side of (2.9) at the point $t = a$ and use the bound (2.24) in the integral over $[a,\infty)$. Now, if we use the second bound of (2.23) in the integral over $[0,a]$ we obtain

$$|R_n(z)| \le \frac{(\rho)_n}{n!}\left[\frac{|A_n|S_n(z,a,\rho)}{z^{n+\rho}} + n|A_{n-1}|\int_0^a \frac{\log(a/t)}{(t+z)^{n+\rho}}dt \right. \\ \left. +|A_n|\int_a^\infty \frac{dt}{t(t+z)^{n+\rho}}\right], \tag{2.25}$$

where $S_n(z,a,\rho)$ is given by the first quantity between the brackets in (2.20). If instead of this, we use the first bound of (2.23) in the integral over $[0,a]$, expand $(1-t/a)^n$, and use the bound $(t+z)\ge z$ and [1, eq. (6.3.6)] we obtain again (2.25), but with $S_n(z,a,\rho)$ replaced by $\psi(n+1)+\gamma$.

A bound for the first integral on the right-hand side of (2.25) is given by $a/z^{n+\rho}$. After the change of variable $t=a/u$ in the second integral and using [18, eqs. (5.4)–(5.5)], we obtain (2.19) with $T_n(z,a,\rho)$ given by the right-hand side of the first line in (2.21). If, instead of computing exactly the second integral in (2.25), we use the bound $(t+z)^\rho \ge (a+z)^\rho$ $\forall$ $t\ge a$ and the equality [16, p. 31, eq. (4)], we obtain the second line in (2.21).

Finally, if we get rid of irrelevant terms for large z, the right-hand side of (2.19), as a function of a, has a minimum for a given in (2.22).

For obtaining the second inequality in (2.18), using Lemma 2.9 we have, for $n\ge\mu$, $|f_n(t)|\le|A_n|t^{-n-1/2}$ if $t\ge1$ and $|f_n(t)|\le|A_{n-1}|t^{-n-1/2}$ if $t\le1$. Therefore, $|f_n(t)|\le\bar A_n t^{-n-1/2}$ $\forall$ $t\in[0,\infty)$ and $n\ge\mu$. Then, $f_n(t)$ satisfies the first bound of (2.13) with μ replaced by $1/2$ and $|A_n|$ by $\bar A_n$. Repeating now the calculations of the proof of Proposition 2.10 we obtain the second inequality in (2.18). □

Remark 2.12. For large n and fixed z, the bound (2.19) (with a given in (2.22)) *contains an extra asymptotic factor* $\log(n)$ with respect to the bound (2.18), whereas for large z and fixed n, it *contains an extra asymptotic factor* $\log(z)/\sqrt{z}$. Therefore, (2.19) is more suitable for large z and (2.18) is more suitable for large n.

3. Expansions of the symmetric standard EIs.

Convergent expansions of R_F, R_D, and R_J for large values of one of their parameters are obtained as corollaries of Theorem 2.4 or 2.7. Error bounds for the remainder terms in these expansions follow from Propositions 2.10 and 2.11. We derive the explicit expansions and error bounds for the remainders in the following subsections.

3.1. Expansion of $R_F(x,y,z)$ for large z.

Corollary 3.1. *A uniformly convergent expansion of* $R_F(x,y,z)$ *for* $0\le x<y\le z$ *is given, for* $n=1,2,3,\dots,$ *by*

$$R_F(x,y,z) = \frac{1}{2\sqrt{z}}\sum_{k=0}^{n-1}\frac{(-1)^k}{k!z^k}\left(\frac{1}{2}\right)_k\left[A_k^F(x,y)\left(\log(z)-\gamma-\psi\left(k+\frac{1}{2}\right)\right)\right. \\ \left. +B_k^F(x,y)\right] + R_n^F(x,y,z), \tag{3.1}$$

where, for $k=0,1,2,\dots,$

$$A_k^F(x,y) = (-1)^k\sum_{j=0}^{k}\frac{(1/2)_j(1/2)_{k-j}}{j!(k-j)!}x^j y^{k-j} \tag{3.2}$$

and coefficients $B_k^F(x,y)$ *are given by the recursion*

$$B_{k+2}^F = \frac{A_{k+2}^F}{k+1} + \frac{xyA_k^F + (x+y)A_{k+1}^F + 2A_{k+2}^F}{k+2} + \frac{2k+3}{2k+4}(x+y)\left[\frac{A_{k+1}^F}{k+1} - B_{k+1}^F\right] - \frac{k+1}{k+2}xyB_k^F, \tag{3.3}$$

empty sums being understood as zero and

$$B_0^F = -2\log\left(\frac{\sqrt{x}+\sqrt{y}}{2}\right), \qquad B_1^F = (x+y)\log\left(\frac{\sqrt{x}+\sqrt{y}}{2}\right) - \sqrt{xy}. \tag{3.4}$$

For $n = 1, 2, 3, \ldots,$ *the remainder* $R_n^F(x,y,z)$ *is positive and a bound for* $R_n^F(x,y,z)$ *is given by the right-hand side of* (2.18) *or* (2.19) *putting* $\rho \equiv 1/2$ *and* $A_n \equiv A_n^F(x,y)$ *given above. In particular, two error bounds are given by*

$$\begin{aligned} R_n^F(x,y,z) &\leq \frac{1}{2n!}\left(\frac{1}{2}\right)_n \left[1 + \psi(n+1) + \gamma + \log\left(1 + \frac{nz|A_{n-1}^F|}{|A_n^F|}\right)\right]\frac{|A_n^F|}{z^n\sqrt{z}}, \\ R_n^F(x,y,z) &\leq \frac{\sqrt{\pi}(n-1)!}{\Gamma(n+1/2)}\frac{\bar{A}_n^F}{z^n}, \end{aligned} \tag{3.5}$$

where $\bar{A}_n^F = \max\{|A_n^F|, |A_{n-1}^F|\}$.

Proof. The integral $2R_F(x,y,z)$ has the form considered in Theorem 2.7 with

$$f(t) \equiv f^F(t) = \frac{1}{\sqrt{(t+x)(t+y)}} = \sum_{k=0}^{n-1}\frac{A_k^F}{t^{k+1}} + f_n^F(t), \tag{3.6}$$

where $f_n^F(t) = \mathcal{O}(t^{-n-1})$ as $t \to \infty$ and $\rho = 1/2$. Therefore, the asymptotic expansion of $2R_F(x,y,z)$ for large z follows from (2.7) in Theorem 2.7. Coefficients $A_k \equiv A_k^F(x,y)$ in (2.6) are trivially given by (3.2).

For calculating $B_k \equiv B_k^F(x,y)$ we consider the second line in (2.8). Define, for $k = 0, 1, 2, \ldots,$

$$I_k^F(x,y,T) \equiv \int_0^T t^k f^F(t)dt \equiv \int_0^T \frac{t^k}{\sqrt{(t+x)(t+y)}}dt$$

and

$$\sigma_k^F(x,y) \equiv \lim_{T\to\infty}\left\{I_k^F(x,y,T) - \sum_{j=0}^{k-1}A_j^F\frac{T^{k-j}}{k-j} - A_k^F\log(T)\right\}. \tag{3.7}$$

Integrals $I_k^F(x,y,T)$ satisfy the recursion

$$I_{k+2}^F = \frac{1}{2(k+2)}\left[2T^{k+1}\sqrt{(T+x)(T+y)} - (2k+3)(x+y)I_{k+1}^F - 2(k+1)xyI_k^F\right]. \tag{3.8}$$

On the other hand, from the differential equation $2(t+x)(t+y)(f^F)' + (2t+x+y)f^F = 0$, we obtain, for $k = 0, 1, 2, \ldots,$

$$2(k+2)A_{k+2}^F + (2k+3)(x+y)A_{k+1}^F + 2(k+1)xyA_k^F = 0. \tag{3.9}$$

Now we substitute $I^F_{k+2}(x,y,T)$ in the definition (3.7) of $\sigma^F_{k+2}(x,y)$ with the right-hand side of (3.8), expand the term $\sqrt{(T+x)(T+y)}$ in inverse powers of T, and use recursion (3.9). We obtain

$$2(k+2)\sigma^F_{k+2}=2xyA^F_k+2(x+y)A^F_{k+1}+2A^F_{k+2}-(2k+3)(x+y)\sigma^F_{k+1}-2(k+1)xy\sigma^F_k,$$

from which (3.3) follows easily by using the second lines in (2.8) and (3.9). Integrals $I^F_0(x,y,T)$ and $I^F_1(x,y,T)$ may be calculated by using formula [16, p. 53, eqs. (3) and (8)]. Then, from the second line in (2.8) and using $A^F_0=1$ and $A^F_1=-(x+y)/2$ we obtain (3.4).

Function $f^F(t)$ satisfies the conditions of Proposition 2.11 with $\mu=1$. Therefore, $R^F_n(x,y,z)\geq 0$ and the bounds (2.18) and (2.19) hold for $2R^F_n(x,y,z)$ setting $\rho\equiv 1/2$ and $A_n\equiv A^F_n(x,y)$ given in (3.2). In particular, introducing (2.22) in (2.19) we obtain the first line of (3.5).

Introducing the bound $|A^F_n|\leq y^n$ in the second line of (3.5) we obtain, for $n\geq 1$,

$$R^F_n(x,y,z)\leq C(y,z)\frac{y^n}{z^n\sqrt{n}}, \tag{3.10}$$

where $C(y,z)$ is independent of n. Therefore, expansion (3.1) is uniformly convergent for $y\leq z$. □

Remark 3.2. An alternative (and explicit) expression for the coefficients $B^F_k(x,y)$ can be obtained from the first line in (2.8). Using the equality [16, p. 303, eq. (24)] and the reflection formula of the gamma function [1, eq. (6.1.17)] we have, for $w\notin\mathbb{Z}$,

$$M[f^F;w]=\frac{\pi}{\sin(\pi w)}\frac{x^w}{\sqrt{xy}}F\left(w,\frac{1}{2};1;1-\frac{x}{y}\right)\qquad \text{if } \ y>x>0,$$

$$M[f^F;w]=\frac{\sqrt{\pi}}{\sin(\pi w)}\frac{\Gamma(w-1/2)}{\Gamma(w)}y^{w-1}\qquad \text{if } \ y>x=0 \ \text{ and } \ \frac{3}{2}-w\notin\mathbb{N}.$$

Subtracting the pole $-A_k/(w-k-1)$ and taking the limit $w\to k+1$ we obtain

$$B^F_k(x,y)=A^F_k(x,y)\sum_{j=1}^{k}\frac{1}{j}-(-1)^kC^F_k(x,y), \tag{3.11}$$

where

$$C^F_k(0,y)=\frac{(1/2)_ky^k}{k!}\left(\psi\left(k+\frac{1}{2}\right)-\psi(k+1)+\log(y)\right) \tag{3.12}$$

and

(3.13)
$$C^F_k(x,y)=x^k\sqrt{\frac{x}{y}}\left(\log(x)F\left(k+1,\frac{1}{2};1;1-\frac{x}{y}\right)+F'\left(k+1,\frac{1}{2};1;1-\frac{x}{y}\right)\right)$$

for $x>0$, where $F'(a,b;c;z)$ denotes the first derivative of $F(a,b;c;z)$ with respect to the argument a.

Remark 3.3. Formulas (3.11)–(3.13) provide coefficients B^F_k in expansion (3.1) of an explicit expression which may be useful for analytical purposes. On the other hand, recurrence (3.3)–(3.4) involves only elementary functions and may be more appropriate for numerical computations. Similar comments can be made about the coefficients B^D_k in the expansion of $R_D(x,z,y)$ for large z given in section 3.3.

Table 3.1 shows a numerical example of the approximation supplied by expansion (3.1).

Table 3.1

where $A_0^D(x,y) = 0$ and, for $k = 1,2,3,\dots$,

$$A_k^D(x,y) = (-1)^{k-1}\sum_{j=0}^{k-1}\frac{(1/2)_j(3/2)_{k-j-1}}{j!(k-j-1)!}x^j y^{k-j-1}. \tag{3.16}$$

Coefficients $B_k^D(x,y)$ for $k = 0,1,2,\dots$ are given by the recurrence

$$\begin{aligned} B_{k+2}^D = {} & \frac{A_{k+2}^D}{k+2} + \frac{xyA_k^D + (x+y)A_{k+1}^D + 2A_{k+2}^D}{k+1} \\ & + \left[\frac{x-y}{2k+2} - x - y\right]\left[B_{k+1}^D - \frac{A_{k+1}^D}{k+1}\right] - xyB_k^D, \end{aligned} \tag{3.17}$$

empty sums being understood as zero and

$$B_0^D = \frac{2}{y-x}\left(1-\sqrt{\frac{x}{y}}\right), \qquad B_1^D = 1 + \frac{2y}{x-y}\left(1-\sqrt{\frac{x}{y}}\right) - 2\log\left(\frac{\sqrt{x}+\sqrt{y}}{2}\right). \tag{3.18}$$

For $n = 1,2,3,\dots$, the remainder term $\bar{R}_n^D(x,z,y)$ is negative,

$$|\bar{R}_1^D(x,z,y)| \le \frac{3}{2\sqrt{z}(r-z)} + \frac{3}{4\sqrt{(z-r)^3}}\log\left[\frac{\sqrt{z}+\sqrt{z-r}}{\sqrt{z}-\sqrt{z-r}}\right] \tag{3.19}$$

if $r \equiv \min\{x,y\} > 0$,

$$|\bar{R}_1^D(x,z,y)| \le \frac{3}{y\sqrt{z}} - \frac{3\pi}{4\sqrt{z^3}}F\left(\frac{3}{2},\frac{3}{2};2;1-\frac{y}{z}\right) \qquad \text{if } \; y > x \ge 0, \tag{3.20}$$

and, for $n = 2,3,4,\dots$, a bound for $|\bar{R}_n^D(x,z,y)|$ is given by the right-hand side of (2.18) or (2.19) setting $\rho \equiv 1/2$ and $A_n \equiv A_n^D(x,y)$ given above. In particular, two error bounds are given, for $n \ge 2$, by

$$\begin{aligned} |\bar{R}_n^D(x,z,y)| &\le \frac{3}{2n!}\left(\frac{1}{2}\right)_n\left[1+\psi(n)+\gamma+\log\left(1+\frac{nz|A_{n-1}^D|}{|A_n^D|}\right)\right]\frac{|A_n^D|}{z^n\sqrt{z}}, \\ |\bar{R}_n^D(x,z,y)| &\le \frac{\sqrt{\pi}(n-1)!}{\Gamma(n+1/2)}\frac{\bar{A}_n^D}{z^n}, \end{aligned} \tag{3.21}$$

where $\bar{A}_n^D = \max\{|A_n^D|, |A_{n-1}^D|\}$.

Proof. The integral $(2/3)R_{D}(x,z,y)$ has the form required in Theorem 2.7 with

$$f(t)\equiv f^{D}(t)=\frac{1}{\sqrt{(t+x)(t+y)^3}}=\sum_{k=0}^{n-1}\frac{A_k^{D}}{t^{k+1}}+f_n^{D}(t),$$

where $f_n^{D}(t)=\mathcal{O}(t^{-n-1})$ as $t\to\infty$ and $\rho=1/2$. Therefore, the asymptotic expansion of $(2/3)R_{D}(x,z,y)$ follows from (2.7) in Theorem 2.7. Trivially, the coefficients $A_k\equiv A_k^{D}(x,y)$ in (2.6) satisfy $A_0^{D}=0$ and, for $k=1,2,3,\dots$, they are given by (3.16).

Recurrence (3.17)–(3.18) for $B_k^{D}(x,y)$ follows from the second line in (2.8). Its derivation follows the pattern of derivation of (3.3)–(3.4) in Corollary 3.1. We define, for $k=0,1,2,\dots$,

$$I_k^{D}(x,y,T)\equiv\int_0^T f^{D}(t)dt\equiv\int_0^T\frac{t^k}{\sqrt{(t+x)(t+y)^3}}dt$$

and

$$\sigma_k^{D}(x,y)\equiv\lim_{T\to\infty}\left\{I_k^{D}(x,y,T)-\sum_{j=0}^{k-1}A_j^{D}\frac{T^{k-j}}{k-j}-A_k^{D}\log(T)\right\}. \tag{3.22}$$

Integrals $I_k^{D}(x,y,T)$ satisfy the recurrence

$$I_{k+2}^{D}=\frac{T^{k+1}}{k+1}\sqrt{\frac{T+x}{T+y}}+\left(\frac{x-y}{2k+2}-x-y\right)I_{k+1}^{D}-xyI_k^{D}. \tag{3.23}$$

On the other hand, from the differential equation $2(t+x)(t+y)(f^{D})'+(4t+3x+y)f^{D}=0$, we obtain, for $k=0,1,2,\dots$,

$$2(k+1)A_{k+2}^{D}+(2(k+1)(x+y)+y-x)A_{k+1}^{D}+2(k+1)xyA_k^{D}=0. \tag{3.24}$$

Now we substitute $I_{k+2}^{D}(x,y,T)$ in the definition (3.22) of $\sigma_{k+2}^{D}(x,y)$ by the right-hand side of (3.23), expand the term $\sqrt{(T+x)/(T+y)}$ in inverse powers of T, and use the recurrence (3.24). We obtain

$$2(k+1)\sigma_{k+2}^{D}=2xyA_k^{D}+2(x+y)A_{k+1}^{D}+2A_{k+2}^{D}+(x-y-2(k+1)(x+y))\sigma_{k+1}^{D}-2(k+1)xy\sigma_k^{D},$$

from which (3.17) follows easily by using the second lines in (2.8) and (3.24). Integrals $I_0^{D}(x,y,T)$ and $I_1^{D}(x,y,T)$ can be calculated by using formulas [16, p. 53, eqs. (6) and (8)]. Then, from the second line in (2.8), $A_0^{D}=0$, and $A_1^{D}=1$ we obtain (3.18).

Function $f^{D}(t)$ has the form required in Proposition 2.11 with $\mu=2$. Therefore, $\bar{R}_n^{D}(x,z,y)\le 0$ and the bounds (2.18) and (2.19) hold for $(2/3)\bar{R}_n^{D}(x,z,y)$ setting $\rho=1/2$ and $A_n\equiv A_n^{D}(x,y)$ given in (3.16) for $n=2,3,4,\dots$. In particular, the first line of (3.21) follows after introducing (2.22) in inequality (2.19). On the other hand, $A_0^{D}=0$ means $f_1^{D}(t)=f^{D}(t)$. Introducing the bounds $f^{D}(u)\le(u+r)^{-2}$ if $r=\min\{x,y\}>0$ or $f^{D}(u)\le\sqrt{u}(u+y)^{-3/2}$ if $y>x\ge 0$ in the definition (2.4) of $f_{1,1}(t)$ and using [16, p. 52, eq. (6)] or [16, p. 53, eq. (4)], respectively, we obtain (3.19) and (3.20).

Using the second line of (3.21) and $|A_{n+1}^{D}(x,y)|\le(n+1)s^n$, where $s=\max\{x,y\}$, we obtain, for $n\ge 1$,

$$|\bar{R}_n^{D}(x,z,y)|\le C(s,z)\frac{s^n\sqrt{n}}{z^n},$$

Table 3.3

Second, third, and sixth columns represent $R_D(1,z,2)$, approximation (3.15) for $n=1$, and approximation (3.15) for $n=2$, respectively. Fourth and seventh columns represent the respective relative error $-\bar{R}_n^D(1,z,2)/R_D(1,z,2)$. Fifth and last columns represent the respective error bounds given by (2.19).

z	$R_D(1,z,2)$	1st-order approx.	Relative error	Relative error bound	2nd-order approx.	Relative error	Relative error bound
10	0.2390532443	0.2778629050	0.162	0.2021314366	0.2508051822	0.0492	0.0870637346
20	0.1784332265	0.1964787444	0.101	0.1221700356	0.1811001790	0.0149	0.0238026222
50	0.1180725686	0.1242640688	0.0524	0.0612672806	0.1184298191	0.00303	0.0043925602
100	0.0852097498	0.0878679657	0.0312	0.0357104912	0.0852853865	0.000888	0.0012264633
200	0.0610194998	0.0621320343	0.0182	0.0205219425	0.0610351563	0.000257	0.0003410757

where $C(s,z)$ is independent of n. Therefore, expansion (3.15) is uniformly convergent for $s<z$. $\square$

Remark 3.6. An alternative (and explicit) expression for the coefficients $B_k^D(x,y)$ can be obtained by using the first equality in (2.8) and

$$M[f^D;w]=\frac{\pi(1-w)x^w}{\sin(\pi w)\sqrt{xy^3}}F\left(w,\frac{3}{2};2;1-\frac{x}{y}\right)\qquad \text{if } \ x,y>0,\quad w\notin\mathbb{Z},$$

or

$$M[f^D;w]=\frac{2\sqrt{\pi}y^{w-2}}{\sin(\pi(w-1))}\frac{\Gamma(w-1/2)}{\Gamma(w-1)}\qquad \text{if } \ y>x=0,\quad w\notin\mathbb{Z},\quad \frac{3}{2}-w\notin\mathbb{N}.$$

The derivation of these formulas is similar to the derivation of $M[f^F;w]$ in Remark 2.12. Subtracting the pole $-A_k^D/(w-k-1)$ and taking the limit $w\to k+1$ we obtain, for $k=0,1,2,\dots$,

$$B_k^D(x,y)=A_k^D(x,y)\sum_{j=1}^{k}\frac{1}{j}+(-1)^kC_k^D(x,y), \tag{3.25}$$

where $C_0^F(0,y)=2/y$,

$$C_k^F(0,y)=\frac{2k(1/2)_k y^{k-1}}{k!}\big(\psi(k+1/2)-\psi(k)+\log(y)\big)\qquad \text{for } \ k=1,2,3,\dots,$$

and, for $k=0,1,2,\dots$ and $x,y>0$,

$$C_k^F(x,y)=x^k\sqrt{\frac{x}{y^3}}\left[(1+k\log(x))F\left(k+1,\frac{3}{2};2;1-\frac{x}{y}\right)+kF'\left(k+1,\frac{3}{2};2;1-\frac{x}{y}\right)\right].$$

Table 3.3 shows a numerical example of the approximation supplied by expansion (3.15).

3.4. Expansion of $R_J(x,y,z,p)$ for large z.

Corollary 3.7. *A uniformly convergent expansion of $R_J(x,y,z,p)$ for $0<p<z$ and $0\le x<y<z$ is given, for $n=1,2,3,\dots$, by*

$$\begin{aligned}R_J(x,y,z,p)=\frac{3}{2\sqrt{z}}\sum_{k=0}^{n-1}\frac{(-1)^k}{k!z^k}\left(\frac{1}{2}\right)_k&\left[A_k^J(x,y,p)\left(\log(z)-\gamma-\psi\left(k+\frac{1}{2}\right)\right)\right.\\ &\left.+B_k^J(x,y,p)\right]+R_n^J(x,y,z,p),\end{aligned} \tag{3.26}$$

where $A_0^J(x,y,p)=0$ *and, for* $k=1,2,3,\dots,$

$$A_k^J(x,y,p)=\sum_{j=0}^{k-1}(-p)^{k-j-1}A_j^F(x,y), \tag{3.27}$$

where $A_j^F(x,y)$ *are given in* (3.2). *Coefficients* $B_k^J(x,y,p)$ *are given by the recurrence*

$$B_{k+1}^J=B_k^F-pB_k^J+A_{k+1}^J\sum_{j=1}^{k+1}\frac{1}{j}+(pA_k^J-A_k^F)\sum_{j=1}^{k}\frac{1}{j}, \qquad k=0,1,2,\dots, \tag{3.28}$$

where $B_k^F(x,y)$ *are given by* (3.3)–(3.4) *(or* (3.11)–(3.13)*), empty sums must be understood as zero, and*

$$B_0^J=\frac{2}{\sqrt{|(p-x)(p-y)|}}\log\left[\frac{\sqrt{p(p-x)}+\sqrt{p(p-y)}}{\sqrt{y(p-x)}+\sqrt{x(p-y)}}\right] \qquad \text{if}\ \ p>x,y, \tag{3.29}$$

$$B_0^J=\frac{2}{\sqrt{|(p-x)(p-y)|}}\log\left[\frac{\sqrt{x(y-p)}+\sqrt{y(x-p)}}{\sqrt{p(x-p)}+\sqrt{p(y-p)}}\right] \qquad \text{if}\ \ p<x,y, \tag{3.30}$$

$$\begin{aligned} B_0^J=\frac{1}{\sqrt{|(p-x)(p-y)|}}&\left[\sin^{-1}\left(\frac{x+y-2p}{y-x}\right)\right.\\ &\left.-\sin^{-1}\left(\frac{2xy-p(x+y)}{p(y-x)}\right)\right] \qquad \text{if}\ \ x<p<y. \end{aligned} \tag{3.31}$$

For $n=1,2,3,\dots,$ *the remainder term* $R_n^J(x,y,z,p)$ *is negative,*

$$|R_1^J(x,y,z)|\le\frac{3}{2\sqrt{z}(r-z)}+\frac{3}{4\sqrt{(z-r)^3}}\log\left[\frac{\sqrt{z}+\sqrt{z-r}}{\sqrt{z}-\sqrt{z-r}}\right] \tag{3.32}$$

if $r\equiv\min\{x,y,p\}>0,$

$$|R_1^J(x,y,z)|\le\frac{3}{r\sqrt{z}}-\frac{3\pi}{4\sqrt{z^3}}F\left(\frac{3}{2},\frac{3}{2};2;1-\frac{r}{z}\right) \tag{3.33}$$

if $r\equiv\min\{y,p\}>0$ *or* $r\equiv\min\{x,p\}>0,$ *and, for* $n=2,3,4,\dots,$ *a bound for* $(2/3)|R_n^J(x,y,z,p)|$ *is given by the right-hand side of* (2.18) *or* (2.19) *putting* $\rho\equiv1/2$ *and* $A_n\equiv A_n^J(x,y,p)$ *given above. In particular, two error bounds are given, for* $n\ge2$, *by*

$$\begin{aligned} |R_n^J(x,y,z,p)|&\le\frac{3}{2n!}\left(\frac{1}{2}\right)_n\left[1+\psi(n+1)+\gamma+\log\left(1+\frac{nz|A_{n-1}^J|}{|A_n^J|}\right)\right]\frac{|A_n^J|}{z^n\sqrt{z}},\\ |R_n^J(x,y,z,p)|&\le\frac{\sqrt{\pi}(n-1)!}{\Gamma(n+1/2)}\frac{\bar{A}_n^J}{z^n}, \end{aligned} \tag{3.34}$$

where $\bar{A}_n^J=\max\{|A_n^J|,|A_{n-1}^J|\}$.

Proof. The integral $(2/3)R_J(x,y,z,p)$ has the form required in Theorem 2.7 with

$$f(t)\equiv f^J(t)=\frac{1}{\sqrt{(t+x)(t+y)(t+p)}}=\sum_{k=0}^{n-1}\frac{A_k^J}{t^{k+1}}+f_n^J(t),$$

Table 3.4

Second, third, and sixth columns represent $R_J(1,2,z,3)$, approximation (3.26) *for $n=1$, and approximation* (3.26) *for $n=2$, respectively. Fourth and seventh columns represent the respective relative error $-R_n^J(1,2,z,3)/R_J(1,2,z,3)$. Fifth and last columns represent the respective error bounds given in* (2.19).

z	$R_J(1,2,z,3)$	1st-order approx.	Relative error	Relative error bound	2nd-order approx.	Relative error	Relative error bound

100	0.0679464537	0.0704421421	0.0367	0.0447835297	0.0680375155	0.00134	0.0018883978
200	0.0487571525	0.0498101164	0.0216	0.0256831788	0.0487761541	0.000390	0.0005263141

where $f_n^J(t)=\mathcal{O}(t^{-n-1})$ as $t\to\infty$ and $\rho=1/2$. The asymptotic expansion of $(2/3)R_J(x,y,z,p)$ for large z follows from (2.7) in Theorem 2.7. Trivially, $A_0^J=0$ and, for $k=1,2,3,\ldots$ coefficients A_k^J are given by (3.27).

Recurrence (3.28) for $B_k^J(x,y,p)$ follows from the second line in (2.8). We define, for $k=0,1,2,\ldots,$

$$I_k^J(x,y,p,T)\equiv\int_0^T t^k f^D(t)dt\equiv\int_0^T\frac{t^k}{\sqrt{(t+x)(t+y)}(t+p)}dt$$

and

$$\sigma_k^J(x,y,p)\equiv\lim_{T\to\infty}\left\{I_k^J(x,y,p,T)-\sum_{j=0}^{k-1}A_j^J\frac{T^{k-j}}{k-j}-A_k^J\log(T)\right\}. \tag{3.35}$$

Integrals $I_k^J(x,y,p,T)$ satisfy the recurrence $I_{k+1}^J=I_k^F-pI_k^J$. Then, (3.28) follows easily by using (2.8), (3.7), (3.27), and (3.35). Integral $I_0^J(x,y,p,T)$ may be calculated by using [16, pp. 53, 54, eqs. (8)–(11)]. Then, from the second line in (2.8) and $A_0^J=0$ we obtain (3.29)–(3.31).

Function $f^J(t)$ has the form required in Proposition 2.11 with $\mu=2$. Therefore, $R_n^J(x,y,z,p)\le 0$ and the bounds (2.18) and (2.19) hold for $(2/3)R_n^J(x,y,z,p)$ setting $\rho=1/2$ and $A_n\equiv A_n^J(x,y,p)$ given in (3.27) for $n=2,3,4,\ldots$. In particular, the first line of (3.34) follows after introducing (2.22) in inequality (2.19). On the other hand, $A_0^J=0$ means $f_1^J(t)=f^J(t)$. Then, after a similar calculation to the one used for deriving (3.19) and (3.20), we obtain (3.32) and (3.33).

Using the second line of (3.34) and the bound $|A_{n+1}^J(x,y,p)|\le(n+1)s^n$, where $s=\max\{x,y,p\}$, we obtain, for $n\ge 1$,

$$|R_n^J(x,y,z,p)|\le C(s,z)\frac{s^n\sqrt{n}}{z^n},$$

where $C(s,z)$ is independent of n. Therefore, expansion (3.26) is uniformly convergent for $s<z$. □

Table 3.4 shows a numerical example of the approximation supplied by expansion (3.26).

3.5. Expansion of $R_J(x,y,z,p)$ for large p.

Corollary 3.8. *A uniformly convergent expansion of $R_J(x,y,z,p)$ for $0\le x<y<z<p$ is given, for $n=1,2,3,\ldots,$ by*

$$R_J(x,y,z,p)=\frac{3}{2}\sum_{k=0}^{n-1}\frac{D_k^J(x,y,z)}{p^{k+1}}-\frac{3\pi}{2\sqrt{p}}\sum_{k=0}^{n-1}\frac{C_k^J(x,y,z)}{p^k}+\bar{R}_n^J(x,y,z,p), \tag{3.36}$$

where $C_0^J(x,y,z)=0$ *and, for* $k=1,2,3,\ldots,$

$$C_k^J(x,y,z)=\sum_{j=0}^{k-1}\sum_{s=0}^{k-j-1}\frac{(1/2)_j(1/2)_s(1/2)_{k-j-s-1}}{j!s!(k-j-s-1)!}x^jy^sz^{k-j-s-1}. \tag{3.37}$$

Coefficients $D_k^J(x,y,z)$ *are given by the recurrence*

$$\begin{aligned}D_{k+3}^J=&\frac{1}{2k+5}\left[2(k+2)(x+y+z)D_{k+2}^J-(2k+3)(xy+xz+yz)D_{k+1}^J\right.\\&\left.+2(k+1)xyzD_k^J\right],\end{aligned} \tag{3.38}$$

$$D_0^J(x,y,z)=2R_F(x,y,z), \tag{3.39}$$

$$D_1^J(x,y,z)=\frac{2}{3}(z-x)(y-z)R_D(x,y,z)+2zR_F(x,y,z)+2\sqrt{\frac{xy}{z}}, \tag{3.40}$$

and

$$D_2^J(x,y,z)=\frac{2}{3}(x+y+z)D_1^J(x,y,z)-\frac{2}{3}(xy+xz+yz)R_F(x,y,z)-\frac{2}{3}\sqrt{xyz}. \tag{3.41}$$

For $n=1,2,3,\ldots,$ *the remainder term* $\bar{R}_n^J(x,y,z,p)$ *is negative and a bound is given by*

$$|\bar{R}_n^J(x,y,z,p)|\le\frac{3\pi C_n^J(x,y,z)}{2p^n\sqrt{p}}. \tag{3.42}$$

Proof. The integral $(2/3)R^J(x,y,z,p)$ has the form required in Theorem 2.4 with

$$f(t)\equiv\bar{f}^J(t)=\frac{1}{\sqrt{(t+x)(t+y)(t+z)}}=-\sum_{k=0}^{n-1}\frac{(-1)^kC_k^J}{t^{k+1/2}}+\bar{f}_n(t), \tag{3.43}$$

where $\bar{f}_n(t)=\mathcal{O}(t^{-n-1/2})$ as $t\to\infty$ and $\alpha=1/2$. Therefore, the asymptotic expansion of $(2/3)R^J(x,y,z,p)$ for large p is given by (2.2). Coefficients $A_k\equiv-(-1)^kC_k^J(x,y,z)$ are trivially given for $k=1,2,3,\ldots,$ by (3.37) and $C_0^J(x,y,z)=0$. Coefficients $D_k^J(x,y,z)\equiv(-1)^kM[\bar{f}^J;k+1]$ in (2.2) represent the analytic continuation of the Mellin transform of $\bar{f}^J(t)$ evaluated in $k+1$. The Mellin transform of the function $\bar{f}^J(t)$ given in (3.43) is defined by (2.1) for $0<\mathrm{Re}(w)<3/2$. We divide the integration path in this formula at $t=1$ and, in the integral over $[1,\infty)$, we substitute $\bar{f}^J(t)$ by the right-hand side of (3.43) with n replaced by $n+1$:

$$M[\bar{f}^J;w]=\int_0^1t^{w-1}\bar{f}^J(t)dt+\sum_{k=0}^{n}\frac{(-1)^kC_k^J(x,y,z)}{w-k-1/2}+\int_1^\infty t^{w-1}\bar{f}_{n+1}^J(t)dt.$$

The first integral is an analytic function of w for $\mathrm{Re}(w)>0$. The second integral is analytic for $\mathrm{Re}(w)<n+3/2$. Therefore, this formula gives the analytic continuation of $M[\bar{f}^J;w]$ to the strip $0<\mathrm{Re}(w)<n+3/2$ (which has simple poles at $w=k+1/2$,

$k=0,1,2,\ldots,n$). We evaluate $M[\bar f^J;w]$ above at the point $w=k+1$ and replace $\bar f^J_{n+1}(t)$ in the last integral by $\bar f^J(t)+\sum_{k=0}^n(-1)^kC_k^Jt^{-k-1/2}$. After straightforward operations we obtain

$$D_k^J(x,y,z)=(-1)^k\lim_{T\to\infty}\left\{\int_0^T t^k\bar f^J(t)dt+\sum_{j=0}^k\frac{(-1)^jC_j^JT^{k-j+1/2}}{k-j+1/2}\right\}. \tag{3.44}$$

We define, for $s>0$,

$$\alpha_k(x,y,z,s,T)\equiv\sqrt{s}\int_0^T\frac{t^k}{\sqrt{(t+x)(t+y)(t+z)(t+s)}}dt$$

and

$$I_k(x,y,z,T)\equiv\int_0^T\frac{t^k}{\sqrt{(t+x)(t+y)(t+z)}}dt=\lim_{s\to\infty}\alpha_k(x,y,z,s,T).$$

Integrals $\alpha_k(x,y,z,s,T)$ satisfy the recurrence

$$\begin{aligned}2T^{k+1}\sqrt{s(T+x)(T+y)(T+z)(T+s)}&=2(k+3)\alpha_{k+4}\\&+(2k+5)(x+y+z+s)\alpha_{k+3}+2(k+2)(xy+xz+xs+yz+ys+zs)\alpha_{k+2}\\&+(2k+3)(xyz+xys+xzs+yzs)\alpha_{k+1}+2(k+1)xyzs\alpha_k.\end{aligned}$$

Taking the limit $s\to\infty$ we obtain that the integrals $I_k(x,y,z,T)$ satisfy the recurrence

$$\begin{aligned}I_{k+3}=\frac{1}{2k+5}\Big[&2T^{k+1}\sqrt{(T+x)(T+y)(T+z)}-2(k+2)(x+y+z)I_{k+2}\\&-(2k+3)(xy+xz+yz)I_{k+1}-2(k+1)xyzI_k\Big].\end{aligned}\tag{3.45}$$

On the other hand, from the differential equation $2(t+x)(t+y)(t+z)(\bar f^J)'+(3t^2+2(x+y+z)t+xy+xz+yz)\bar f^J=0$, we obtain, for $k=0,1,2,\ldots$,

$$2(k+1)C_{k+2}^J-(2k+1)(x+y+z)C_{k+1}^J+2k(xy+xz+yz)C_k^J-(2k-1)xyzC_{k-1}^J=0. \tag{3.46}$$

If we expand the term $\sqrt{(T+x)(T+y)(T+z)}$ in (3.45) in inverse powers of T and use the recurrence (3.46) and the definition (3.44), we obtain the recurrence (3.38). Using (3.44) we see that D_0^J is trivially given by (3.39). Integrating $I_1(x,y,z)$ by parts in (3.44) and using [16, p. 71, eq. (10)] and [18, eq. (12.33)] we obtain (3.40). Equation (3.41) follows after straightforward operations.

Function $f^J(t)$ satisfies the conditions of Proposition 2.10 with $\mu=3/2$. Therefore, $\bar R_n^J(x,y,z,p)\le 0$ and the bound (2.17) holds for $(2/3)\bar R_n^J(x,y,z,p)$ setting $A_n\equiv(-1)^nC_n^J$, and (3.42) follows. Using (3.42) and the bound $|C_{n+1}^J(x,y,z)|\le(3/2)_nz^n/n!$, we obtain, for $n\ge1$,

$$|\bar R_n^J(x,y,z,p)|\le C(z,p)\frac{\sqrt{n}z^n}{p^n},$$

where $C(z,p)$ is independent of n. Therefore, expansion (3.36) is uniformly convergent for $z<p$. □

Table 3.5

Second, third, and sixth columns represent $R_J(1,2,3,p)$, approximation (3.36) for $n = 2$, and approximation (3.36) for $n = 3$, respectively. Fourth and seventh columns represent the respective relative error $-\bar{R}_n^J(1,2,3,p)/R_J(1,2,3,p)$. Fifth and last columns represent the respective error bounds given by (3.42).

				Relative			Relative
		2nd-order	Relative	error	3rd-order	Relative	error
z	$R_J(1,2,3,p)$	approx.	error	bound	approx.	error	bound

Table 3.5 shows a numerical example of the approximation supplied by expansion (3.36).

Remark 3.9. A bound for the n-esim remainder term in any of the expansions given in Corollaries 3.1–3.8 has the form $C(s,z)\sqrt{n}(s/z)^n$ for $n \geq 1$, where z is the asymptotic variable, s is a bound for the remaining variables, and $C(s,z)$ is independent of n. Therefore, the convergence rate of these expansions increases for decreasing value of the quotient s/z.

4. Conclusions. Following Wong's proposal [21, Example 1], the distributional approach has been used in Theorem 2.7 for deriving an alternative proof for the asymptotic expansion of the generalized Stieltjes transforms (see [21, Theorem 2 and Example 1]). Using this result we have derived convergent expansions of $R_F(x,y,z)$, $R_D(x,y,z)$, $R_D(x,z,y)$, and $R_J(x,y,z,p)$ for $x,y,p < z$ in Corollaries 3.1–3.7, respectively. On the other hand, using the asymptotic expansion of the Stieltjes transforms [22, chap. 6, sect. 2, Theorem 1], we have obtained a convergent expansion of $R_J(x,y,z,p)$ for $x,y,z < p$ in Corollary 3.8. Functions $f(t)$ in the integrand of R_F, R_D, and R_J (and, in general, functions $f(t)$ given in (2.10)) are to a special kind of function: the remainder terms in their asymptotic expansions in inverse powers of t satisfy the error test. This fundamental property is used in Propositions 2.10 and 2.11 for deriving an error bound for the remainder in the asymptotic expansions given in Theorems 2.4 and 2.7 at any order of the approximation. In particular, it has been derived for the expansions of R_F, R_D, and R_J in Corollaries 3.1–3.8. These bounds have been obtained from the error test and, as numerical computations show (see Tables 3.1–3.5), they exhibit a remarkable accuracy. Moreover, these bounds show that the expansions are convergent when the asymptotic variable is greater than the remaining ones and that the convergence rate increases as this difference between the asymptotic variable and the remaining ones increases.

Expansions given in Corollaries 3.1–3.8 are generalizations of the corresponding first-order approximations given by Carlson and Gustafson [10]. Nevertheless, the complete expansion of the first EI given in Corollary 3.1 was already obtained by Carlson and Gustafson [4] and, as well as in Corollary 3.1, the coefficients of the expansion are given by a recurrence [4, eq. (1.7)]. Complete expansions for R_D and R_J for the asymptotic parameters considered in Corollaries 3.4–3.8 were also obtained by Carlson and Gustafson [3]. But a recurrence for the calculation of the coefficients is not given in [3] and error bounds supplied there are not quite satisfactory. The advantage of the approach presented here is that it supplies a simple algorithm for the calculation of the coefficients of these expansions and more accurate error bounds at any order of the approximation. This algorithm is explicitly given in Corollaries 3.1–3.8. Moreover, coefficients of the expansions of $R_F(x,y,z)$, $R_D(x,y,z)$, $R_D(x,z,y)$, and $R_J(x,y,z,p)$

for large z are given in terms of elementary functions, whereas coefficients of the expansion of $R_J(x,y,z,p)$ for large p are given in terms of $R_F(x,y,z)$ and $R_D(x,y,z)$.

For large z, the error bounds supplied in Corollaries 3.1–3.7 are slightly more accurate than the error bounds given in [10] for the first order approximation of $R_D(x,z,y)$, $R_F(x,y,z)$, and $R_J(x,y,z,p)$ and slightly less accurate for the first-order approximation of $R_D(x,y,z)$ and the second-order approximation of $R_F(x,y,z)$. When considering first-order approximations to $R_J(x,y,z,p)$ for large p, a comparison between the error bounds given in Corollary 3.8 and the error bounds given in [10] is more complicated because they are concerned with different approximations. On the other hand, at any order of the approximation, error bounds given in [4, eqs. (1.20) and (3.40)] are more accurate for large values of n than the error bound given in Corollary 3.1 and less accurate for small n.

The distributional approach should succeed for deriving complete uniform asymptotic expansions of symmetric EI too. This challenge is postponed for further investigations.

Acknowledgments. This work was stimulated by conversations with Nico Temme, whose continued interest has been quite encouraging. I am grateful to the anonymous referees for their careful examination of the paper and their helpful suggestions.

A SYSTEM OF DEGENERATE PARABOLIC EQUATIONS FROM PLASMA PHYSICS: THE LARGE TIME BEHAVIOR*

M. BERTSCH† AND S. KAMIN‡

Abstract. The authors study the large time behavior of solutions of a strongly coupled system of degenerate parabolic equations describing the heat and mass transfer in a one-dimensional plasma. The model was introduced by Hyman and Rosenau, and the existence of solutions was studied in our earlier paper. The results of this paper describe how the large time behavior depends on some of the parameters in the equations.

Key words. nonlinear system, plasma physics, large time behavior, degenerate parabolic equations

1. Introduction.

We consider the following system of nonlinear partial differential equations:

$$\text{(I)}\qquad \begin{cases} \rho_t = (\varphi_1(T)\rho^{a_1}\rho_x)_x & \text{in } Q := \mathbb{R}\times\mathbb{R}^+, \\ (\rho T)_t = (\varphi_2(T)\rho^{a_2+1}T_x)_x + (T\varphi_1(T)\rho^{a_1}\rho_x)_x & \text{in } Q, \\ \rho(x,0) = \rho_0(x) & \text{for } x\in\mathbb{R}, \\ T(x,0) = T_0(x) & \text{for } x\in\mathcal{P}_0\ , \end{cases}$$

where

$$\mathcal{P}_0 = \{x\in\mathbb{R} : \rho_0(x) > 0\}\ . \tag{1.1}$$

Here x is a one-dimensional spatial coordinate, t indicates time, $\rho(x,t)$ and $T(x,t)$ are nonnegative functions to be determined, ρ_0 and T_0 are given nonnegative and continuous functions, a_1 and a_2 are positive constants, and φ_1 and φ_2 are smooth positive functions.

System (I) was introduced by Rosenau and Hyman [12], [13] to study the effect of nonlinearly coupled mass and heat diffusion in a plasma which slowly diffuses in a strong magnetic field. In this context ρ and T denote the density and ionic temperature of the plasma, and φ_1 and φ_2 are power-type functions of T. The last term in the differential equation for the temperature T represents the heat transport due to mass diffusion.

In an earlier paper [5] we have constructed a solution of Problem (I). In the present paper we describe the large time behavior of this solution in the case where

ρ_0 is integrable in $\mathbb{R}$, i.e., the case of finite total mass. As we shall see below, this behavior is quite different in the cases $a_1 \le a_2$ and $a_1 > a_2$; in other words, the large time behavior depends on the parameter values of a_1 and a_2.

To explain our results we introduce the precise hypotheses on the data:

(H1) $\varphi_i \in C^2(\mathbb{R}^+), \varphi_i > 0$ in $\mathbb{R}^+$, $a_i \in \mathbb{R}^+$ $(i = 1, 2)$;

(H2) $\rho_0 \in C(\mathbb{R}) \cap L^\infty(\mathbb{R}) \cap L^1(\mathbb{R})$, $\rho_0 \ge 0$ and $\rho_0 \not\equiv 0$ in $\mathbb{R}$, $\mathcal{P}_0 \subseteq \mathbb{R}$ is defined by (1.1);

(H3) $T_0 \in C(\mathcal{P}_0)$ and $0 < \nu_0 \le T_0 \le \nu_1$ in $\mathcal{P}_0$ for some constants ν_0 and ν_1.

Since $a_1 > 0$, the equation for ρ degenerates at points where ρ vanishes (if $\varphi_1 \equiv 1$, we obtain the well-known porous medium equation; see, for example, [1]). The equation does not always possess classical solutions. Therefore we have to introduce solutions in a weak sense, and in addition define T only in the set

$$\mathcal{P} = \{(x,t) \in \overline{Q} : \rho(x,t) > 0\}. \tag{1.2}$$

Definition 1.1. *A pair* (ρ, T) *is called a solution of Problem* (I) *if*

(i) $\rho \in C(\overline{Q}) \cap L^\infty(Q)$, $T \in C(\mathcal{P}) \cap L^\infty(\mathcal{P})$, *where* $\mathcal{P}$ *is defined by* (1.2)*;*

(ii) $\rho \ge 0$ *in* Q, $T \ge \mu$ *in* $\mathcal{P}$ *for some* $\mu > 0$*;*

(iii) $(\rho^{a_1+1})_x \in L^2_{\mathrm{loc}}(\overline{Q})$, $T_x \in L^2_{\mathrm{loc}}(\mathcal{P})$, $\rho^{a_2+1}T_x \in L^2(S)$ *for any bounded measurable set* $S \subseteq \mathcal{P}$*;*

(iv) *for any* $\psi \in C^{1,1}(\overline{Q})$ *with compact support*

$$\int_{\mathcal{P}_0} \rho_0(x)\psi(x,0)dx + \int\int_{\mathcal{P}} \Big(\rho\psi_t - \frac{1}{a_1+1}\varphi_1(T)(\rho^{a_1+1})_x\psi_x\Big)dxdt = 0$$

and

$$\int_{\mathcal{P}_0} \rho_0(x)T_0(x)\psi(x,0)dx + \int\int_{\mathcal{P}} \Big(\rho T\psi_t - \rho^{a_2+1}\varphi_2(T)T_x\psi_x \\ - \frac{1}{a_1+1}T\varphi_1(T)(\rho^{a_1+1})_x\psi_x\Big)dxdt = 0,$$

where the set $\mathcal{P}_0$ *is defined by* (1.1)*.*

In [5] we have constructed a solution as the limit of classical solutions $(\rho_\epsilon, T_\epsilon)$ of the following approximate problem:

$$(\mathrm{I}_\epsilon) \quad \begin{cases} \rho_t = (\varphi_1(T)\rho^{a_1}\rho_x)_x & \text{in } Q_\epsilon = (-L_\epsilon, L_\epsilon) \times \mathbb{R}^+, \\ (\rho T)_t = (\varphi_2(T)\rho^{a_2+1}T_x)_x + (T\varphi_1(T)\rho^{a_1}\rho_x)_x & \text{in } Q_\epsilon, \\ \rho(x,0) = \rho_{0\epsilon}(x), T(x,0) = T_{0\epsilon}(x) & \text{for } x \in (-L_\epsilon, L_\epsilon), \\ \rho_x(\pm L_\epsilon, t) = T_x(\pm L_\epsilon, t) = 0 & \text{for } t > 0. \end{cases}$$

Here $\epsilon \in (0, \rho^*)$, where

$$\rho^* = \sup\{\rho_0(x), x \in \mathbb{R}\},$$

$L_\epsilon > 0$, $\rho_{0\epsilon}$, $T_{0\epsilon} \in C^\infty([-L_\epsilon, L_\epsilon])$, $\rho'_{0\epsilon}(\pm L_\epsilon) = T'_{0\epsilon}(\pm L_\epsilon) = 0$,

$$0 < \epsilon \le \rho_{0\epsilon} \le \rho^*, \quad \nu_0 \le T_{0\epsilon} \le \nu_1 \text{ in } (-L_\epsilon, L_\epsilon),$$

and $\rho_{0\epsilon} \to \rho_0$ in $C_{\mathrm{loc}}(\mathbb{R})$, $T_{0\epsilon} \to T_0$ in $C_{\mathrm{loc}}(\mathcal{P}_0)$ and $L_\epsilon \to \infty$ as $\epsilon \to 0^+$. Since $\rho_0 \in L^1(\mathbb{R})$ we assume that L_ϵ and $\rho_{0\epsilon}$ are chosen such that, for sufficiently small values of $\epsilon > 0$,

$$\int_{-L_\epsilon}^{L_\epsilon} \rho_{0\epsilon}(x)dx = M := \int_{-\infty}^{\infty} \rho_0(x)dx. \tag{1.3}$$

In [5] we have shown that there exist $\rho \in C(\overline{Q})$, $T \in C(\mathcal{P})$ and a sequence $\epsilon_n \to 0^+$ such that

$$\rho_n := \rho_{\epsilon_n} \to \rho \text{ in } C_{\text{loc}}(\overline{Q}) \text{ and } T_n := T_{\epsilon_n} \to T \text{ in } C_{\text{loc}}(\mathcal{P}) \text{ as } n \to \infty, \tag{1.4}$$

and we have proved that (ρ, T) is a solution of Problem (I). In addition ρ and T are classical solutions of the system in the set $\mathcal{P}$, and

$$\rho_n \to \rho \text{ and } T_n \to T \text{ in } C^{2,1}_{\text{loc}}(\mathcal{P}\backslash\{t=0\}) \text{ as } n \to \infty. \tag{1.5}$$

The uniqueness of the solution is not known.

Now we are ready to describe the large time behavior of ρ and T. First we observe that

$$\rho(x,t) \le \mathcal{C}\|\rho_0\|_{L^1(\mathbb{R})} t^{-1/(a_1+2)} \quad \text{for} \quad (x,t) \in Q,$$

where the constant $\mathcal{C}$ depends only on a_1 and min/max $\varphi(s)$ for $s \in [\nu_0, \nu_1]$. This decay rate is essentially a result for the equation for ρ, in which $\varphi_1(T(x,t))$ is considered as a given function (see section 2 for some results concerning the porous medium equation with nonconstant coefficients).

Our main result is the behavior of $\rho(x,t)$ and $T(x,t)$ as $t \to \infty$.

Theorem 1.2 (large time behavior). *Let hypotheses* (H1)–(H3) *be satisfied and let* (ρ, T) *be the solution of Problem* (I) *defined by* (1.4). *Then there exist positive constants* η_0 *and* η_1 *and functions* $\overline{R} \in C(\mathbb{R}) \cap C^2((-\eta_0, \eta_1))$ *and* $\overline{T} \in C^1((-\eta_0, \eta_1))$ *such that*

(i) $\overline{R} > 0$ *in* $(-\eta_0, \eta_1)$, $\overline{R} = 0$ *in* $\mathbb{R}\backslash(-\eta_0, \eta_1)$, *and* $\nu_0 \le \overline{T} \le \nu_1$ *in* $(-\eta_0, \eta_1)$;

(ii) *for any* $C > 0$

$$t^{1/(a_1+2)}\rho(x,t) \to \overline{R}(xt^{-1/(a_1+2)}) \textit{ as } t \to \infty \tag{1.6}$$

uniformly with respect to x *satisfying* $-Ct^{1/(a_1+2)} \le x \le Ct^{1/(a_1+2)}$, *and for any* $\epsilon > 0$

$$T(x,t) \to \overline{T}(xt^{-1/(a_1+2)}) \textit{ as } t \to \infty \tag{1.7}$$

uniformly with respect to x *satisfying*

$$-(\eta_0 - \epsilon)t^{1/(a_1+2)} \le x \le (\eta_1 - \epsilon)t^{1/(a_1+2)};$$

(iii) *the function* $\overline{\rho}$ *defined by*

$$\overline{\rho}(x,t) = t^{-1/(a_1+2)}\overline{R}(xt^{-1/(a_1+2)})$$

is a (self-similar) solution of the equation

$$\rho_t = \Big(\varphi_1\big(\overline{T}(xt^{-1/(a_1+2)})\big)\rho^{a_1}\rho_x\Big)_x \tag{1.8}$$

with initial data Dirac's δ*-function multiplied by* $M = \|\rho_0\|_{L^1(\mathbb{R})}$:

$$\int_{\mathbb{R}} \psi(x)\overline{\rho}(x,t)dx \to M\psi(0) \textit{ as } t \to 0^+ \tag{1.9}$$

for all $\psi \in C(\mathbb{R})$ *with compact support;*

(iv) *if* $a_1 \geq a_2$, *then*

$$\overline{T}(\eta) = \text{const.} = \frac{\int_{\mathcal{P}_0} \rho_0(x) T_0(x) dx}{M} \ , \tag{1.10}$$

and if $a_1 < a_2$, *then there exist initial data* (ρ_0, T_0) *such that* $(\overline{T})_x \not\equiv 0$.

Given the function $\overline{T}(\eta)$, substitution of the self-similar solution $\overline{\rho}(x,t)$ in (1.8) yields the following ordinary differential equation for $\overline{R}(\eta)$ in the set where $\overline{R} > 0$:

$$\Big(\varphi_1(\overline{T}(\eta)) \overline{R}^{a_1} \overline{R}'\Big)' = -\frac{1}{a_1+2} (\eta \overline{R})'. \tag{1.11}$$

Integrating twice we obtain the formula

$$\overline{R}^{a_1}(\eta) = \left(C - \frac{a_1}{a_1+2} \int_0^\eta \frac{s}{\varphi_1(\overline{T}(s))} ds \right)_+ \ ,$$

where we have used the notation $a_+ := \max\{a, 0\}$ for $a \in \mathbb{R}$. The integration constant C is uniquely determined by the initial mass M (condition (1.9)):

$$\int_{\mathbb{R}} \overline{R}(\eta) d\eta = M = \|\rho_0\|_{L^1(\mathbb{R})}.$$

In the case of the "classical" porous medium equation ($\varphi_1 \equiv 1$) $\overline{\rho}(x,t)$ is the Barenblatt solution [3]

$$\overline{\rho}(x,t) = t^{-1/(a_1+2)} \left(C - \frac{a_1 \eta^2}{2(a_1+2)} \right)_+^{1/a_1} \ , \quad \eta = x t^{-\frac{1}{a_1+2}}.$$

It is well known [10], [14] that the Barenblatt solution describes the large time behavior of solutions of the porous medium equation with finite total mass M.

The most interesting part of Theorem 1.2 seems to be part (iv). If $a_1 \geq a_2$, T becomes constant as $t \to \infty$, i.e., the temperature converges to its average value given by (1.10), and, for large values of t, ρ behaves as the Barenblatt solution with the same total mass. However, if $a_1 < a_2$ the temperature does not always reach its average value, and ρ behaves asymptotically as a solution of (1.11) which may be different from the Barenblatt solution. Physically we could give the following interpretation of this parameter dependence: if $a_1 < a_2$ the diffusivity $\varphi_2(T)\rho^{a_2}$ of the heat diffusion is, for large values of t, i.e., for small values of ρ, much smaller than the diffusivity $\varphi_1(T)\rho^{a_1}$ of the mass diffusion, and apparently the heat diffusion is too weak to make the temperature constant as $t \to \infty$. In the case of an initial boundary value problem Rosenau and Hyman [12] conjectured such phenomena studying separable solutions and presenting numerical evidence.

In the proof of Theorem 1.2 we decouple the two equations of the system as much as possible. For this purpose, we introduce the mass (or Lagrangian) variable

$$y = \int_{-\infty}^x \rho(s,t) ds \in [0, M] \quad \text{for} \quad t \geq 0, \tag{1.12}$$

where M is the total initial mass, defined by (1.3).

In [5] we have shown that the transformation $(x,t) \to (y,t)$ leads to the following set of equations for $\hat{\rho}(y,t) \equiv \rho(x,t)$ and $\hat{T}(y,t) \equiv T(x,t)$:

$$(1.13) \qquad \begin{cases} \hat{\rho}_t = \hat{\rho}^2(\varphi_1(\hat{T})\hat{\rho}^{a_1}\hat{\rho}_y)_y & \text{in } (0,M)\times\mathbb{R}^+, \\ \hat{T}_t = (\varphi_2(\hat{T})\hat{\rho}^{a_2+2}\hat{T}_y)_y & \text{in } (0,M)\times\mathbb{R}^+. \end{cases}$$

System (1.13) was used in our paper [5] to prove the existence of a solution of Problem (I). The advantage of the mass variable is that the second term in the equation for T, which represents the heat transport due to the diffusion of mass, disappears and this fact allows us to study the large time behavior of T as a function of y and t. Subsequently the information about the behavior of the coefficient $\varphi_1(T(x,t))$ in the porous medium equation for ρ is sufficient to determine the large time behavior of ρ.

The paper is organized as follows. In section 2 we list some properties of the porous medium equation with nonconstant coefficients. The essential part of the results we refer to in section 2 are obtained in our paper [7]. In fact our study of the porous medium equation with nonconstant coefficients was inspired by our work on the system. It is worth mentioning here that the main difficulty in this study is that we do not have much information about the smoothness of the coefficient $A(x,t)$ (see section 2) but only its upper and lower bounds. In section 3 we introduce the scaling of ρ, while in section 4 we prove the convergence of T as $t\to\infty$ in terms of the Lagrangian coordinates. In section 5, we translate the results of the former sections in terms of the original x-variable and prove Theorem 1.2, and in section 6, we obtain some estimates used in previous sections.

Finally we mention that in [8] the existence of a solution of the Cauchy and boundary value problem has been recently proved in the case of higher spatial dimension.

2. The porous medium equation with nonconstant coefficients. In this section we collect some results about the problem

$$(\text{II}) \qquad \begin{cases} u_t = (A(x,t)(u^m)_x)_x & \text{in } Q, \\ u(x,0) = u_0(x) \geq 0 & \text{for } x \in \mathbb{R}, \end{cases}$$

where the assumptions on the data are the following.

Assumption A1. $m>1$, $A \in L^\infty(Q)$, $0<\lambda\leq A(x,t)\leq\Lambda$ (a.e.) in Q for some constants λ and Λ, $u_0 \in L^\infty(\mathbb{R})\cap C(\mathbb{R})$ and $u_0 \geq 0$ in $\mathbb{R}$.

We observe that the equation for $\rho(x,t)$ in System (I) reduces to the one in Problem (II) if we set $A(x,t) = \frac{1}{m}\varphi(T(x,t))$, $m = a_1+1$.

As we already pointed out in the introduction we have the right to use only the information on the coefficient $A(x,t)$ which is supplied to us by the solution of the system. Thus in general this coefficient is not smooth, but on the other hand it is known by (1.4) and (1.5) that $\rho(x,t) = \lim \rho_{\epsilon_n}(x,t)$. Therefore we give the following definition.

Definition 2.1. *Let $A_n(x,t)$ be a sequence of functions ($n=1,2,\dots$) such that each A_n is defined in the domain $\Omega_n = (-L_n,L_n)\times\mathbb{R}^+$, $L_n\to\infty$ as $n\to\infty$. Moreover assume that A_n satisfies*

$$A_n(x,t) \in L^\infty(\Omega_n)\cap C^{2,2}(\overline{\Omega}_n), \quad 0\leq\lambda\leq A_n(x,t)\leq\Lambda \quad \text{in} \quad \Omega_n,$$

where λ and Λ do not depend on n. Suppose that $A_n\to A$ in $L^1_{\text{loc}}(Q)$. Let u_n be the *classical solution of the problem*

$$(\mathrm{II}_n) \qquad \begin{cases} \frac{\partial u}{\partial t} = \frac{\partial}{\partial x} A_n \frac{\partial u^m}{\partial x} & \text{in } \Omega_n, \\ \frac{\partial u}{\partial x}(\pm L_n, t) = 0 & \text{for } t > 0, \\ u(x,0) = u_{0n}(x) & \text{for } x \in (-L_n, L_n), \end{cases}$$

where u_{0n} is a smooth positive function, $u_{0n} \to u_0$ in $C_{\mathrm{loc}}(\mathbb{R})$ as $n \to \infty$, and, if $u_0 \in L^1(\mathbb{R})$, then

$$\int_{-L_n}^{L_n} u_{on}(x)dx = \int_{-\infty}^{\infty} u_0(x)dx.$$

Suppose that

$$u_n(x,t) \to u(x,t) \quad \text{in} \quad C_{\mathrm{loc}}(Q) \quad \text{and} \quad \frac{\partial u_n^m}{\partial x} \to \frac{\partial u^m}{\partial x} \textit{ weakly in } L^2_{\mathrm{loc}}(Q).$$

Then the limit function u is said to be a solution of the Cauchy problem (II). *Obviously $u(x,t)$ satisfies the equation*

$$\frac{\partial u}{\partial t} = \frac{\partial}{\partial x} A \frac{\partial u^m}{\partial x}$$

in the sense of distributions and $u(x,0) = u_0(x)$.

The definition given above is equivalent to Definition 6.1 in [7]. Therefore we use the results of this paper below.

The following properties hold for a solution of Problem (II) in the sense of the above definition [7, section 6].

Proposition 2.2. *Let Assumption* A1 *be satisfied. Then for any compact set $K \subset \mathbb{R}$ the modulus of continuity of u in $K \times [0,T]$ depends only on $\sup_Q u, T, \lambda, \Lambda$ and the modulus of continuity of u_0 in an open neighborhood $\widetilde{K}$ of K.*

Proposition 2.3 (positivity property). *Let Assumption* A1 *be satisfied and let $u(x_0,t_0) > 0$ for some $x_0 \in \mathbb{R}$ and $t_0 > 0$ (respectively, $t_0 \geq 0$ if $u_0 \in C(\mathbb{R})$). Then*

$$u(x_0,t) > 0 \quad \textit{for} \quad t > t_0.$$

Proposition 2.4 (decay rate). *Let assumption* A1 *be satisfied and let $u_0 \in L^1(\mathbb{R})$. Then there exists a constant $C > 0$ which depends only on m, λ, and Λ such that*

$$u(x,t) \leq C\|u_0\|_{L^1(\mathbb{R})} t^{-1/(m+1)} \quad \textit{for} \quad (x,t) \in Q.$$

Propositions 2.2, 2.3, 2.4 are proved for smooth $A(x,t)$ in [9],[6] and [4],[15] correspondingly.

Proposition 2.5 (concentration of mass [7, Theorems 3.1 and 6.1]). *Let Assumption* A1 *be satisfied, let $u_0 \not\equiv 0$, $u_0 \in L^1(\mathbb{R})$, and let $M > 0$ denote*

$$M = \int_{\mathbb{R}} u_0(x)dx.$$

Let $v(x,t) = \int_{-\infty}^{x} u(s,t)ds$. Then for any $\epsilon > 0$ small enough there exist $a > 0$ and $b > 0$ such that

$$\begin{aligned} &\textit{if} \quad x \geq \eta t^{\frac{1}{m+1}} + a, \quad \textit{then} \quad v \geq M - \epsilon; \\ &\textit{if} \quad x \leq -\eta t^{\frac{1}{m+1}} - b, \quad \textit{then} \quad v \leq \epsilon, \end{aligned}$$

where η is a constant which does not depend on ϵ.

PROPOSITION 2.6 (expanding of mass [7, Theorems 3.2 and 6.1]). *Let Assumption* A1 *be satisfied and let u_0, M, and v be the same as in Proposition* 2.5. *For any $\epsilon > 0$ small enough there exist $a > 0$ and $b > 0$ such that*

$$\begin{aligned}&\text{if}\quad x \le \eta_1 t^{\frac{1}{m+1}} - b, \quad \text{then}\quad v \le M - \epsilon;\\ &\text{if}\quad x \ge -\eta_1 t^{\frac{1}{m+1}} + a, \quad \text{then}\quad v \ge \epsilon,\end{aligned}$$

where η_1 is a constant which does not depend on ϵ.

PROPOSITION 2.7 (lower bound in the set containing most of the mass [7, Theorems 4.1 and 6.2]). *Let Assumption* A1 *be satisfied and let u_0, M, and v be the same as in Proposition* 2.5. *For any $\epsilon > 0$ small enough there exist c_0 and T such that*

$$\text{if } t > T \quad \text{and} \quad \epsilon \le v(x,t) \le M - \epsilon,$$

then

$$u(x,t) \ge \frac{c_0}{t^{\frac{1}{m+1}}}.$$

PROPOSITION 2.8 (large time behavior [7, Theorems 5.2 and 6.3]). *Suppose that $u_0 \in L^1(\mathbb{R}) \cap L^\infty(\mathbb{R})$, $u_0 \not\equiv 0$ in $\mathbb{R}$, and that there exists $a \in C(0,M)$ such that*

$$A(x,t) - a\Big(\int_{-\infty}^{x} u(s,t)ds\Big) \to 0 \quad \text{as} \quad t \to \infty, \quad \text{uniformly with}$$
$$\text{respect to } x \text{ satisfying } \epsilon < \int_{-\infty}^{x} u(s,t)ds < M - \epsilon\ .$$

Then there exist positive constants η_0 and η_1 and a function $\overline{R} \in C(\mathbb{R})$ such that

(i) $\overline{R} \in C^2((-\eta_0,\eta_1))$, $\overline{R} > 0$ *in* $(-\eta_0,\eta_1)$, *and* $\overline{R} = 0$ *in* $\mathbb{R}\backslash(-\eta_0,\eta_1)$;

(ii) *for any $C > 0$*

$$t^{1/(m+1)}u(x,t) - \overline{R}(xt^{-1/(m+1)}) \to 0 \quad \text{as} \quad t \to \infty$$

uniformly with respect to x satisfying $-Ct^{1/(m+1)} \le x \le Ct^{1/(m+1)}$;

(iii) *the function $\overline{u}$ defined by*

$$\overline{u}(x,t) = t^{-1/(m+1)}\overline{R}(xt^{-1/(m+1)})$$

is a self-similar solution of the equation

$$\frac{\partial u}{\partial t} = \frac{\partial}{\partial x}\left(a\Big(\int_{-\infty}^{x} u(s,t)ds\Big)\frac{\partial u^m}{\partial x}\right)$$

satisfying

$$u(x,0) = M\delta(x),$$

where $\delta(x)$ denotes the Dirac measure.

Remark 2.1. Propositions 2.3, 2.5–2.8 are known for the porous medium equation with $A(x,t) \equiv 1$ (see [1], [10]). The main ingredient in the proofs is the comparison with explicit solutions such as self-similar solutions and separable solutions. In Problem (II), however, there are no specific solutions and a different study is required.

3. Lagrangian coordinates and rescaling. We begin this section with noting the two conservation laws

$$\int_{-\infty}^{\infty} \rho(x,t)dx = \int_{-\infty}^{\infty} \rho_0(x)dx \tag{3.1}$$

and

$$\int_{-\infty}^{\infty} \rho(x,t)T(x,t)dx = \int_{-\infty}^{\infty} \rho_0(x)T_0(x)dx. \tag{3.2}$$

These equalities both hold for the approximating sequences; therefore, by Proposition 2.5 (concentration of mass) and Proposition 2.2 (equicontinuity of the sequence ρ_{ϵ_n}), one may pass to the limit.

Now consider system (1.13) where y denotes the mass variable. Setting

$$\tau = \log(t+1) \ ,$$

we consider y and τ as independent variables and introduce the rescaled density

$$\underline{R}(y,\tau) \equiv (t+1)^{1/(a_1+2)}\hat{\rho}(y,t) \ .$$

Defining $\underline{T}(y,\tau) \equiv \hat{T}(y,t)$, we shall denote $\underline{R}(y,\tau)$ and $\underline{T}(y,\tau)$ by $R(y,\tau)$ and $T(y,\tau)$, and we obtain the following equations for R and T:

$$R_\tau = R^2\big(\varphi_1(T)R^{a_1}R_y\big)_y + \frac{1}{a_1+2}R \quad \text{in} \quad (0,M)\times\mathbb{R}^+ \tag{3.3}$$

and

$$T_\tau = e^{\gamma\tau}\big(\varphi_2(T)R^{a_2+2}T_y\big)_y \quad \text{in} \quad (0,M)\times\mathbb{R}^+, \tag{3.4}$$

where we have set

$$\gamma = \frac{a_1-a_2}{a_2+2} \ . \tag{3.5}$$

We shall denote $R(y,0)$ and $T(y,0)$, respectively, by $R_0(y)$ and $T_0(y)$.

Observe that we have assumed that ρ and T are classical solutions of the original equations, but actually this is only known in the set $\mathcal{P}$ [5, Theorem 3.1]. To make the above transformation precise we first perform it for the smooth approximating solution $(\rho_n(x,t), T_n(x,t))$ of Problem I_{ϵ_n}.

Let

$$y = \int_{-L_{\epsilon_n}}^{x} \rho_n(s,t)ds \in [0,M] \quad \text{for} \quad -L_{\epsilon_n} \le x \le L_{\epsilon_n} \quad \text{and} \quad t \ge 0 \ .$$

It follows from (1.3) that if $-L_\epsilon < x < L_\epsilon$ and $t > 0$, then $0 \le y \le M$. The pair of strictly positive functions $R_n(y,\tau) \equiv (t+1)^{1/(a_1+2)}\rho_n(x,t)$ and $T_n(y,\tau) \equiv T_n(x,t)$ with corresponding initial functions R_{0n} and T_{0n} is the unique classical solution of the problem

$$\begin{cases} R_\tau = R^2(\varphi_1(T)R^{a_1}R_y)_y + \frac{1}{a_1+2}R & \text{in } (0,M)\times\mathbb{R}^+, \\ T_\tau = e^{\gamma\tau}(\varphi_2(T)R^{a_2+2}T_y)_y & \text{in } (0,M)\times\mathbb{R}^+, \\ R_y(0,\tau) = R_y(M,\tau) = T_y(0,\tau) = T_y(M,\tau) = 0 & \text{for } \tau > 0, \\ R(y,0) = R_{0n}(y), \ T(y,0) = T_{0n}(y) & \text{for } 0 < y < M. \end{cases}$$

Proposition 3.1. *Let $R(y,\tau)$, $T(y,\tau)$, $R_n(y,\tau)$ and $T_n(y,\tau)$ be defined as above. Then $R \in C((0,M)\times[0,\infty))$ and $T \in C_{\rm loc}(\mathcal{P}')$, where we have set*

$$\mathcal{P}' := \{(y,\tau) \in (0,M)\times[0,\infty) : R(y,\tau) > 0\},$$

$R, T \in C^{2,1}_{\rm loc}(\mathcal{P}')$, R, T satisfy (3.3) and (3.4) in $\mathcal{P}'\backslash\{t=0\}$ and, as $n\to\infty$,

$$\begin{aligned} &R_n \to R \quad in \quad C_{\rm loc}\big((0,M)\times[0,\infty)\big) \cap C^{2,1}_{\rm loc}(\mathcal{P}'\backslash\{t=0\}),\\ &T_n \to T \quad in \quad C_{\rm loc}(\mathcal{P}') \cap C^{2,1}_{\rm loc}(\mathcal{P}'\backslash\{t=0\})\ . \end{aligned}$$

If $\rho_0(x) > 0$ for all $x \in \mathbb{R}$, then $R, T \in C^{2,1}((0,M)\times[0,\infty))$ and

$$R_n \to R \quad and \quad T_n \to T \quad \text{in} \quad C^{2,1}_{\rm loc}((0,M)\times(0,\infty)) \quad as \quad n\to\infty.$$

The proof follows at once from (1.4), (1.5), and the relations $y_x = \rho$, $y_t = \varphi_1(T)\rho^{a_1}\rho_x$ and

$$\lim_{n\to\infty}\Big\| \int_{-\infty}^{x} \rho(s,t)ds - \int_{-L_{\epsilon_n}}^{x} \rho_n(s,t)ds \Big\|_{L^\infty(Q_{\epsilon_n})} = 0. \qquad \square$$

Applying Propositions 2.4, 2.6, and 2.7 to the first equation in system (I) we get the following result.

Proposition 3.2. *There exists a constant $\mathcal{C}$ such that*

$$R(y,\tau) \le \mathcal{C} \quad in \quad [0,M]\times[0,\infty). \tag{3.6}$$

For any $\epsilon \in (0, \frac{1}{2}M)$ there exist constants $\tau_\epsilon \ge 0$ and $\delta_\epsilon > 0$ such that

$$R \ge \delta_\epsilon \quad in \quad (\epsilon, M-\epsilon)\times(\tau_\epsilon,\infty). \tag{3.7}$$

If $\rho_0(y) > 0$ for $0 < y < M$, we may choose $\tau_\epsilon = 0$.

4. Large time behavior of T. In this section we consider the behavior of the temperature $T(y,\tau)$ as $\tau\to\infty$. The main result is the following theorem.

Theorem 4.1. *Let $M > 0$ be defined by (1.3) and*

$$T_\infty := \frac{1}{M}\int_0^M T_0(y)dy.$$

(i) *If $a_1 \ge a_2$, then*

$$T(\cdot,\tau) \to T_\infty \quad in \quad C_{\rm loc}\big((0,M)\big) \quad as \quad \tau\to\infty.$$

(ii) *If $a_1 < a_2$, then there exists a function $\sigma \in C(0,M)$ such that*

$$\begin{aligned} &T(\cdot,\tau) \to \sigma \quad in \quad C_{\rm loc}\big((0,M)\big) \quad as \quad \tau\to\infty,\\ &\nu_0 \le \sigma \le \nu_1 \quad in \quad (0,M), \quad and \quad \frac{1}{M}\int_0^M \sigma(y)dy = T_\infty. \end{aligned} \tag{4.1}$$

There exist ρ_0 and T_0 such that $\sigma \not\equiv T_\infty$ in $(0,M)$.

We observe that we do not expect *uniform* convergence of T in $(0,M)$ as $\tau \to \infty$; for example, if $\rho_0(x)$ is positive for all $x \in \mathbb{R}$ and if $T_0(x) = 2 + \sin x$, we conjecture that $T(y,\tau)$ oscillates wildly near $y = 0$ and $y = M$.

Proof. Let γ be defined by (3.5) and define $\overline{\tau}(\tau)$ for $\tau \geq 0$ by

$$\overline{\tau} = \begin{cases} \int_0^\tau e^{\gamma s} ds = \gamma^{-1}(e^{\gamma\tau} - 1) & \text{if } \gamma \neq 0, \\ \tau & \text{if } \gamma = 0. \end{cases}$$

Observe that

$$\overline{\tau}(\infty) = \infty \quad \text{if} \quad \gamma \geq 0 \quad (\Leftrightarrow a_1 \geq a_2) \tag{4.2}$$

and

$$\overline{\tau}(\infty) = -\frac{1}{\gamma} < \infty \quad \text{if} \quad \gamma < 0 \quad (\Leftrightarrow a_1 < a_2). \tag{4.3}$$

The function $T(y,\overline{\tau}) \equiv T(y,\tau)$ satisfies the equation

$$T_{\overline{\tau}} = \big(\varphi_2(T) R^{a_2+2} T_y\big)_y \quad \text{in} \quad (0,M) \times \big(0, \overline{\tau}(\infty)\big). \tag{4.4}$$

Let $\epsilon > 0$. By (3.6) and (3.7) there exists $\overline{\tau}_\epsilon \in [0, \overline{\tau}(\infty))$ such that T is a classical solution of the uniformly parabolic equation (4.4) in the set $[\frac{1}{2}\epsilon, M - \frac{1}{2}\epsilon] \times [\overline{\tau}_\epsilon, \overline{\tau}(\infty))$. By standard estimates on linear uniformly parabolic equations [11, Chapter 3, Theorem 10.1], for any $\overline{\tau}^*_\epsilon \in (\overline{\tau}_\epsilon, \overline{\tau}(\infty))$ there exist constants $\alpha \in (0,1)$ and C such that

$$\|T\|_{C^{\alpha,\alpha/2}([\epsilon,M-\epsilon]\times[\overline{\tau}^*_\epsilon,\overline{\tau}^*])} \leq C \quad \text{for} \quad \overline{\tau}^* < \overline{\tau}^*_\epsilon < \overline{\tau}(\infty), \tag{4.5}$$

where C does not depend on $\overline{\tau}^*$.

We begin with part (ii): $a_1 < a_2$. By (4.3) and (4.5) there exists $\sigma \in C^\alpha([\epsilon, M-\epsilon])$ such that

$$T(\cdot, \overline{\tau}) \to \sigma \quad \text{in} \quad C([\epsilon, M-\epsilon]) \quad \text{as} \quad \overline{\tau} \to \overline{\tau}(\infty) < \infty.$$

Since $\epsilon > 0$ is arbitrary and σ does not depend on ϵ, we have proved (4.1). Since $\nu_0 \leq T(y,\tau) \leq \nu_1$ in $(0,M) \times \mathbb{R}^+$ and since T satisfies the conservation law (3.2)

$$\int_0^M T(y,\tau) dy = \int_0^M T_0(y) dy = M T_\infty \quad \text{for} \quad \tau > 0, \tag{4.6}$$

the proof of (ii) is complete if we construct an example in which σ is nonconstant in $(0,M)$.

Let $\rho_0, T_0 \in C^1([0,M])$ such that $\rho_0 > 0$, $T_0' \geq 0$, and $T_0' \not\equiv 0$ in $(0,M)$. By Proposition 3.2 the lower bound (3.7) for $R(y,\tau)$ holds with $\tau_\epsilon = 0$ for all $\epsilon > 0$. By Proposition 3.1. the function $T(y,\overline{\tau})$ is a classical solution of (4.4), and its partial derivative $T_y(y,\overline{\tau})$ satisfies the equation

$$(T_y)_{\overline{\tau}} = \big(\varphi_2(T) R^{a_2+2} (T_y)_y\big)_y + \Big(\big(\varphi_2'(T) T_y R^{a_2+2} + \varphi_2(T)(R^{a_2+2})_y\big) T_y\Big)_y .$$

It follows from the approximation of T by T_n that $T_y \geq 0$ (we may assume that $T_{0n}'(y) > 0$). Then for any $\epsilon > 0$ the equation for T_y is uniformly parabolic in $[\frac{1}{2}\epsilon, M - \frac{1}{2}\epsilon] \times [0, \overline{\tau}(\infty))$ and the strong maximum principle implies that

$$T_y(y, \overline{\tau}) > 0 \quad \text{in} \quad (0,M) \times \big(0, \overline{\tau}(\infty)\big).$$

It follows from the estimates for T_y and R_y, which will be proved in Lemmas 6.1 and 6.2 below, that the coefficients of the equation for T_y (considered as a linear equation) are uniformly bounded in $(\epsilon, M-\epsilon)\times(\frac{1}{2}\overline{\tau}_\infty, \overline{\tau}_\infty)$. Hence T_y satisfies Harnack's inequality [2, Theorem 3], and $\sigma' > 0$ in $(0, M)$, which completes the proof of (ii).

It remains to prove part (i).

If $a_1 \geq a_2$, it follows from (4.2) and (4.5) that for any $\epsilon \in (0, \frac{1}{2}M)$ there exist a sequence $\overline{\tau}_n \to \infty$ as $n \to \infty$ and a function $\sigma \in C^{\alpha,\alpha/2}([\epsilon, M-\epsilon]\times[0,1])$ such that

$$T(y, \overline{\tau}_n + \overline{\tau}) \to \sigma(y, \overline{\tau}) \quad \text{in} \quad C\big([\epsilon, M-\epsilon]\times[0,1]\big) \quad \text{as} \quad n \to \infty.$$

Clearly $\nu_0 \leq \sigma \leq \nu_1$ in $[\epsilon, M-\epsilon]\times[0,1]$.

We claim that

$$\int_0^1 \int_\epsilon^{M-\epsilon} T_y^2(y, \overline{\tau}_n + \overline{\tau})dyd\overline{\tau} \to 0 \quad \text{as} \quad n \to \infty. \tag{4.7}$$

Accepting (4.7) for the moment, we find that

$$T_y(y, \overline{\tau}_n + \overline{\tau}) \to 0 \quad \text{in} \quad L^2\big((\epsilon, M-\epsilon)\times(0,1)\big) \quad \text{as} \quad n \to \infty$$

and hence $\sigma_y \in L^2((\epsilon, M-\epsilon)\times(0,1))$ and

$$\sigma_y = 0 \quad \text{a.e. in} \quad (\epsilon, M-\epsilon)\times(0,1).$$

Thus

$$\sigma(y, \overline{\tau}) = g_\epsilon(\overline{\tau}) \quad \text{a.e. in} \quad (\epsilon, M-\epsilon)\times(0,1)$$

for some function $g_\epsilon \in C([0,1])$, and it follows from the conservation law (4.6) that

$$MT_\infty = \int_\epsilon^{M-\epsilon} T(y, \overline{\tau}_n + \overline{\tau})dy + O(\epsilon) \to Mg_\epsilon(\overline{\tau}) + O(\epsilon) \quad \text{as} \quad n \to \infty.$$

Hence $\sigma \equiv T_\infty$ a.e. in $(0, M)\times(0,1)$ and we obtain part (i) of Theorem 4.1.

It remains to prove (4.7). Let $T_n(y, \overline{\tau})$ be the smooth function $T_n(y, \tau)$ in terms of the variable $\overline{\tau}$ instead of τ. Then $T_n(y, \overline{\tau})$ is the solution of

$$\begin{cases} T_{\overline{\tau}} = (\varphi_2(T)R^{a_2+2}T_y)_y & \text{in } (0, M)\times\mathbb{R}^+, \\ T_y(0, \overline{\tau}) = T_y(M, \overline{\tau}) = 0 & \text{for } \overline{\tau} > 0, \\ T(y, 0) = T_{0n}(y) & \text{for } 0 < y < M. \end{cases}$$

Multiplying the equation by T_n and integrating by parts we get that for any $0 \leq \overline{\tau}_1 \leq \overline{\tau}_2$

$$\int_{\overline{\tau}_1}^{\overline{\tau}_2} \int_0^M \varphi_2 R_n^{a_2+2} T_{ny}^2 dyd\overline{\tau} = \frac{1}{2}\int_0^M T_n^2(y, \overline{\tau}_2)dy - \frac{1}{2}\int_0^M T_n^2(y, \overline{\tau}_2)dy.$$

Now let $n \to \infty$. Then, by Proposition 3.1,

$$\int_0^\infty \int_0^M R^{a_2+2} T_y^2 dyd\overline{\tau} < \infty.$$

We now apply Proposition 3.2 and conclude that for any $\epsilon \in (0, \frac{1}{2}M)$ there exists a constant C_ϵ such that

$$\int_0^\infty \int_\epsilon^{M-\epsilon} T_y^2 dyd\overline{\tau} \leq C_\epsilon. \tag{4.8}$$

From (4.8) follows (4.7). $\square$

5. Proof of Theorem 1.2. In this section we prove our main result.

First we have to go back from the (y,τ)-variables to the (x,t)-variables. Since $y_x = \rho$, the transformation $(x,t) \mapsto (y,\tau)$ is invertible as a map from $\mathcal{P}$ to $\mathcal{P}'$. Thus it follows from Theorem 4.1 and Proposition 3.2 that for any $\epsilon \in (0, \frac{1}{2}M)$

$$T(x,t) - \sigma\Big(\int_{-\infty}^{x} \rho(s,t)ds\Big) \to 0 \quad \text{as} \quad t \to \infty, \quad \text{uniformly with}$$

$$\text{respect to} \quad x \quad \text{satisfying} \quad \epsilon < \int_{-\infty}^{x} \rho(s,t)ds < M - \epsilon. \tag{5.1}$$

Hence we may apply Proposition 2.8 with $m = a_1 + 1$, $u = \rho$, $A(x,t) = \frac{1}{m}\varphi_1(T(x,t))$, and $a(v) = \frac{1}{m}\varphi_1(\sigma(v))$ for $0 < v < M$ (observe that $\rho(x,t)$ is constructed as the limit of the solutions of Problem (I_ϵ), the first equation of which is equivalent to the equation in Problem (II_n) with $m = a_1 + 1$, $u_n = \rho_n$, and $A_n(x,t) = \frac{1}{m}\varphi_1(T_n(x,t))$. So there exists $\overline{R}(\eta)$ with the properties listed in Proposition 2.8. In particular (1.6) holds, which, combined with Proposition 2.5, implies that

$$\begin{aligned} &\int_{-\infty}^{x} \rho(s,t)ds - \int_{-\infty}^{xt^{-1/(a_1+2)}} \overline{R}(z)dz \\ &= \int_{-\infty}^{x} \big(\rho(s,t)ds - t^{-1/(a_1+2)}\overline{R}(st^{-1/(a_1+2)})\big)ds \to 0 \quad \text{as} \quad t \to \infty, \end{aligned}$$

uniformly with respect to $x \in \mathbb{R}$. Hence, by Theorem 4.1, for all $\epsilon > 0$

$$T(x,t) - \sigma\Big(\int_{-\infty}^{xt^{-1/(a_1+2)}} \overline{R}(z)dz\Big) \to 0 \quad \text{as} \quad t \to \infty,$$

uniformly with respect to x satisfying $-(\eta_0 - \epsilon)t^{1/(a_1+2)} \le x \le (\eta_1 - \epsilon)t^{1/(a_1+2)}$; so we have obtained (1.7) with

$$\overline{T}(\eta) := \sigma\Big(\int_{-\infty}^{\eta} \overline{R}(z)dz\Big) \quad \text{for} \quad -\eta_0 < \eta < \eta_1. \qquad \square$$

6. Estimates for the spatial derivatives. In this section we prove estimates for R_y and T_y which were used in section 4.

LEMMA 6.1. *Let $\epsilon \in (0, \frac{1}{2}M)$ and let $\tau_{\epsilon/2} \ge 0$ be defined by Proposition 3.2. Then there exists a constant $C_\epsilon > 0$ such that*

$$|R_y| \le C_\epsilon \quad \text{in} \quad [\epsilon, M-\epsilon] \times [\tau_\epsilon + \epsilon, \infty).$$

Proof. Let $\tau_0 \ge \tau_{\epsilon/2}$. Integrating by parts (3.3) for $R_n(y,\tau)$ in the set $(0,M) \times (\tau_0, \tau_0+1)$, we obtain that

$$\begin{aligned} 2\int_{\tau_0}^{\tau_0+1}\int_0^M \varphi_1(T_n)R_n^{a_1+1}R_{ny}^2 dy d\tau &= \int_0^M R_n(y,\tau_0+1)dy \\ &- \int_0^M R_n(y,\tau_0)dy - \frac{1}{a_1+2}\int_{\tau_0}^{\tau_0+1}\int_0^M R_n dy d\tau. \end{aligned} \tag{6.1}$$

By Propositions 3.1 and 3.2 and by (6.1)

$$\begin{aligned}
2\int_{\tau_0}^{\tau_0+1}&\int_{\frac{1}{2}\epsilon}^{M-\frac{1}{2}\epsilon}\varphi_1(T)R^{a_1+1}R_y^2dyd\tau\\
&=2\lim_{n\to\infty}\int_{\tau_0}^{\tau_0+1}\int_{\frac{1}{2}\epsilon}^{M-\frac{1}{2}\epsilon}\varphi_1(T_n)R_n^{a_1+1}R_{ny}^2dyd\tau\\
&\le 2\lim_{n\to\infty}\int_{\tau_0}^{\tau_0+1}\int_0^M\varphi_1(T_n)R_n^{a_1+1}R_{ny}^2dyd\tau\\
&=\lim_{n\to\infty}\Big(\int_0^M R_n(y,\tau_0+1)dy-\int_0^M R_n(y,\tau_0)dy-\frac{1}{a_1+2}\int_{\tau_0}^{\tau_0+1}\int_0^M R_ndyd\tau\Big)\\
&=\int_0^M R(y,\tau_0+1)dy-\int_0^M R(y,\tau_0)dy-\frac{1}{a_1+2}\int_{\tau_0}^{\tau_0+1}\int_0^M Rdyd\tau,
\end{aligned}$$

and hence, by Proposition 3.2,

$$\int_{\tau_0}^{\tau_0+1}\int_{\frac{1}{2}\epsilon}^{M-\frac{1}{2}\epsilon}R_y^2dyd\tau\le C_\epsilon \tag{6.2}$$

for some constant C_ϵ which does not depend on $\tau_0\ge\tau_{\epsilon/2}$.

By (6.2) there exists $y_0\in(\frac{1}{2}\epsilon,M-\frac{1}{2}\epsilon)$ such that

$$\int_{\tau_0}^{\tau_0+1}R_y^2(y_0,\tau)d\tau\le\frac{C_\epsilon}{M-\epsilon}.$$

Dividing (3.3) by $-R^2$ we obtain the equation

$$\Big(\frac{1}{R}\Big)_\tau=\Big(\varphi_1(T)R^{a_1+2}\Big(\frac{1}{R}\Big)_y\Big)_y-\frac{1}{(a_1+2)R}\quad\text{in}\quad\Big(\frac{1}{2}\epsilon,M-\frac{1}{2}\epsilon\Big)\times(\tau_{\epsilon/2},\infty).$$

Setting

$$z(y,\tau)=\int_{y_0}^{y}\frac{1}{R(s,\tau)}ds-\int_{\tau_0}^{\tau}\varphi\big(T(y_0,s)\big)R^{a_1}(y_0,s)R_y(y_0,s)ds$$

for $\frac{1}{2}\epsilon\le y\le M-\frac{1}{2}\epsilon$ and $\tau_0\le\tau\le\tau_0+1$, we have that

$$z_y=\frac{1}{R}\quad\text{in}\quad\Big(\frac{1}{2}\epsilon,M-\frac{1}{2}\epsilon\Big)\times(\tau_0,\tau_0+1),$$

and z satisfies in the set $(\frac{1}{2}\epsilon,M-\frac{1}{2}\epsilon)\times(\tau_0,\tau_0+1)$ the equation

(6.3)
$$z_\tau=\varphi_1(T)R^{a_1+2}z_{yy}-\frac{1}{a_1+2}z-\frac{1}{a_1+2}\int_{\tau_0}^{\tau}\varphi_1\big(T(y_0,s)\big)R^{a_1}(y_0,s)R_y(y_0,s)ds.$$

But $\varphi_1(T)R^{a_1+2}$ is uniformly Hölder continuous, and since for any $\tau_0\le\tau\le\tau+h\le\tau_0+1$

$$\Big|\int_{\tau}^{\tau+h}\varphi_1\big(T(y_0,s)\big)R^{a_1}(y_0,s)R_y(y_0,s)ds\Big|\le K\sqrt{h}\int_{\tau}^{\tau+h}R_y^2(y_0,s)ds\le\frac{KC_\epsilon}{M-\epsilon}\sqrt{h}$$

for some K which does not depend on τ_0, the last term at the right-hand side of (6.3) is also Hölder continuous. Hence it follows from standard local estimates for linear uniformly parabolic equations [11, Chapter 4, Theorem 10.1] that

$$z_{yy} \quad \text{is Hölder continuous in} \quad [\epsilon, M-\epsilon] \times [\epsilon, 1],$$

uniformly with respect to $\tau_0 \geq \tau_\epsilon$. The proof is completed by the observation that

$$R_y = -R^2 \Big(\frac{1}{R} \Big)_y = -R^2 z_{yy} \ . \qquad \square$$

For the gradient T_y we obtain a stronger result than the mere bound on T_y.

LEMMA 6.2. *Let σ be defined by Theorem* 4.1. *Then $\sigma \in C^1_{\text{loc}}((0,M))$ and*

$$T_y(\cdot, \tau) \to \sigma' \quad \textit{in} \quad C_{\text{loc}}((0,M)) \quad \textit{as} \quad \tau \to \infty.$$

Proof. Let $\epsilon > 0$ and let τ and $\overline{\tau}_\epsilon$ be defined as in the proof of Theorem 4.1. Setting

$$w(y,\overline{\tau}) = \varphi_2\big(T(y,\overline{\tau})\big) T_y(y,\overline{\tau}) \quad \text{in} \quad \Big(\frac{1}{2}\epsilon, M - \frac{1}{2}\epsilon\Big) \times \big(\overline{\tau}_\epsilon, \overline{\tau}(\infty)\big),$$

we obtain from (4.4) that w satisfies the equation

$$w_{\overline{\tau}} = \big(\varphi_2(T) T_{\overline{\tau}}\big)_y = \big(\varphi_2 R^{a_2+2} w_y + \varphi_2 (R^{a_2+2})_y w\big)_y$$

in $D_\epsilon = (\frac{1}{2}\epsilon, M - \frac{1}{2}\epsilon) \times (\overline{\tau}_\epsilon, \overline{\tau}(\infty))$. By Proposition 3.1 this linear equation is uniformly parabolic in D_ϵ and, by Lemma 6.1, its coefficients are uniformly bounded. Hence it follows from [11, Chapter 3, Theorem 8.1] that w, and hence also T_y, is bounded in $C^\alpha([\epsilon, M-\epsilon] \times [\overline{\tau}^*_\epsilon, \overline{\tau}^*])$ for some $\alpha \in (0,1)$ and for all $\overline{\tau}_\epsilon < \overline{\tau}^*_\epsilon < \overline{\tau}^* < \overline{\tau}(\infty)$; since the bound does not depend on $\overline{\tau}^*$, the result follows immediately. $\square$

THE ENTROPY RATE ADMISSIBILITY CRITERION AND THE ENTROPY CONDITION FOR A PHASE TRANSITION PROBLEM: THE ISOTHERMAL CASE[*]

HARUMI HATTORI[†]

Abstract. In this paper, first, we discuss the relation between the entropy rate admissibility criterion and the entropy condition for a phase transition problem. In the context of the Riemann problem, we consider the compatibility of the above admissibility criteria. Then, combining the two criteria, we study the Riemann problems. We discuss the cases where the initial strains are given in the different phases and where they are given in the same phase.

Key words. phase transition, entropy rate admissibility criterion, entropy condition, hyperbolic-elliptic mixed type system

1. Introduction.

We study the relation between the entropy rate admissibility criterion and the entropy condition and then discuss the Riemann problems using the two criteria for a system describing a phase transition problem. The system we discuss is a hyperbolic-elliptic mixed type and given by

$$\begin{aligned} v_t - u_x &= 0, \\ u_t - f(v)_x &= 0, \end{aligned} \tag{1.1}$$

where v, u, and f are strain, velocity, and stress, respectively. We assume that f is a smooth nonmonotone function of v as depicted in Figure 1.1. It is important to note that if f' is nonnegative, the system is hyperbolic and if f' is negative, the system is elliptic. In our case there are two intervals $(0,\alpha]$ and $[\beta,\infty)$ where the system is hyperbolic. They are called the α-phase and β-phase, respectively. We assume that f'' is negative in the α-phase and positive in the β-phase. The interval (α,β) is called the spinodal region and physically unobservable. The horizontal line for which the areas A and B are equal is called the Maxwell stress. The values of v in the α-phase and β-phase at which the Maxwell stress intersect f are denoted by v_α and v_β, respectively. The states $(0,v_\alpha]$ and $[v_\beta,\infty)$ are stable, $(v_\alpha,\alpha]$ and $[\beta,v_\beta)$ are metastable, and (α,β) is unstable. The values γ and δ in the α and β-phases are the values of v at which $f(\gamma)=f(\beta)$ and $f(\delta)=f(\alpha)$, respectively. The Riemann problem is a special initial value problem of (1.1) in which the initial data are given by

$$(v,u)(x,0) = \begin{cases} (v_\ell,u_\ell), & x<0, \\ (v_r,u_r), & x>0, \end{cases} \tag{1.2}$$

where v_ℓ, u_ℓ, v_r, and u_r are constants. We consider the two cases where v_ℓ and v_r are given in the different phases and given in the same phase. We seek a self-similar solution in which constant states are separated by the elementary waves and

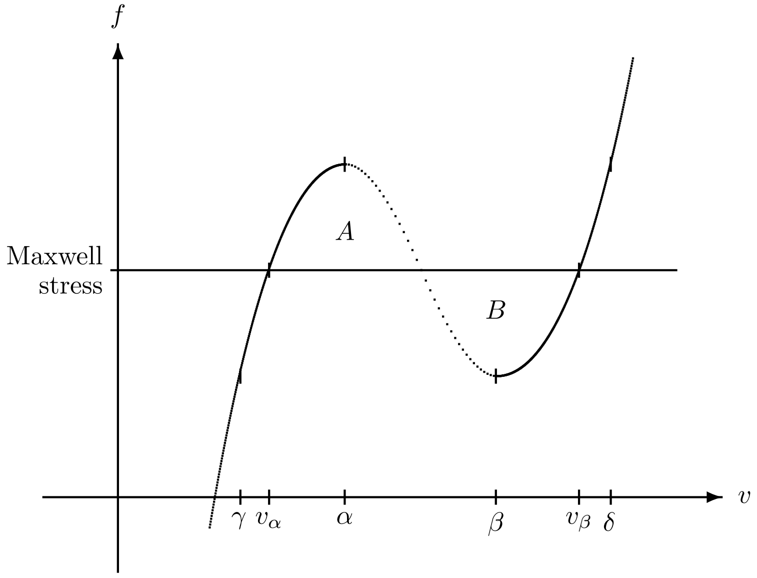

FIG. 1.1.

the phase boundaries. If the solution contains the phase boundaries, we have one or more parameter family of solutions. The above system is an isothermal case. The word "entropy" is not appropriate, yet commonly used; see page 98 in [26]. The nonisothermal system where the thermodynamical effect is taken into account will be discussed in the future.

The purpose of this paper is twofold. First, we study the relation between the entropy rate admissibility criterion and the entropy condition in the context of the Riemann problem. The entropy rate admissibility criterion was proposed by Dafermos [2] for hyperbolic systems. This criterion roughly says that the admissible solution minimizes the rate of entropy decay among the all possible solutions. Both criteria have been used for hyperbolic systems and it is well known that the entropy rate admissibility criterion is more discernible than the entropy condition. On the other hand, the relation between two criteria is not well understood for mixed-type systems. In sections 3 and 4, we study the relation between these criteria for the above mixed-type system. We minimize the entropy rate among the one or more parameter family of solutions if the phase boundaries are involved. It is not clear if the entropy condition is satisfied across phase boundaries. We show, among other things, that there exists a solution minimizing the entropy rate in which the phase boundary violates the entropy condition. We also show that if there are three phase boundaries, at least one phase boundary violates the entropy condition and that there is a solution with three phase boundaries which has a lower entropy rate than the solution with single phase boundary.

Second, the results in section 3 motivate us to consider the Riemann problem using both criteria as the admissibility criterion. In section 4 we propose that the admissible solution to the Riemann problem is the solution that minimizes the entropy rate admissibility criterion among all self-similar solutions satisfying the entropy condition. We call this criterion entropy-entropy rate admissibility criterion. More precisely, we discuss the minimization problems of the following form:

Minimize:	the entropy rate
Subject to:	the entropy condition
	and the characteristic conditions

The specific forms are given in (4.1)–(4.3) in the case of the one-phase boundary problem and in (4.16)–(4.18) in the case of the two-phase boundary problem. In the first case v_ℓ and v_r are specified in the different phases and in the second case v_ℓ and v_r are specified in the same phase. From the results in section 3, there is only one phase boundary in the first case and either two or no phase boundaries in the second case. Imposing both criteria, we obtain a closed and bounded region of parameters in which the entropy rate is minimized. If v_ℓ and v_r are specified in the same phase, there are three cases depending on the relation between the backward and forward wave curves from (v_ℓ, u_ℓ) and (v_r, u_r), respectively. If they do not intersect, two phase boundaries are necessary to solve the Riemann problem. If they intersect at (v_m, u_m), there are two solution configurations. One configuration is the usual one for the hyperbolic system where three constant states (v_ℓ, u_ℓ), (v_m, u_m), and (v_r, u_r) are separated by the backward and forward waves. The other configuration is the one where five constant states are separated by the backward wave, two phase boundaries moving in the opposite directions, and the forward wave. We will show that if v_m is in the metastable state, the solution with two phase boundaries may become admissible. On the other hand, if v_m is in the stable state, the solution with no phase boundary is admissible. Shearer [28] discussed the nonuniqueness of the Riemann problem if v_ℓ and v_r are specified in the same phase. With the combined criterion, we can single out the admissible solution.

Various admissibility criteria have been proposed for hyperbolic systems, for example, the Lax condition, the Liu's condition, the viscosity criterion, the entropy condition, and the entropy rate admissibility criterion; see [18], [22], [2]. The relations among the various admissibility criteria have been discussed extensively in the hyperbolic case. Lax considered the equivalence of Lax shock condition and the entropy criterion [19]. Dafermos discussed this problem for the entropy rate admissibility criterion and the viscosity criterion [2], [3]. It is important to consider whether they can be extended to the mixed-type systems and the relation among these criteria. In this paper we study these problems confining our attention to the criteria based on the entropy.

It is common to model phase transition phenomena in solid from continuum mechanics by using a nonmonotone constitutive relation. The Riemann problem of system (1.1) was discussed in various literature. James [16] initiated the Riemann problem for this type of problem. He proposed the one-parameter family of solutions for the Riemann problem if v_ℓ and v_r are given in the different phases. In the inviscid approaches different admissibility criteria were used to select a physically relevant solution. Abeyaratne and Knowles [1] proposed the kinetic relation for phase boundaries and discussed the Riemann problem using the kinetic relation and the initiation criterion. Hattori [9], [10] used the entropy rate admissibility criterion proposed by Dafermos [2], [3] for hyperbolic systems. Pence [25] and Lin and Pence [21] also used the entropy rate admissibility criterion to discuss phase transition problems. Shearer [27] considered the problem assuming that all the stationary phase boundaries are admissible. Keyfitz [17] discussed the Riemann problem from the point of view of the "hysteresis" approach. As far as the Cauchy problem is concerned, Le Floch [20] has shown the existence of global solutions in BV space if f is trilinear, and Pego and Serre [24] considered the instability of the Glimm scheme. Hattori [12] has shown the existence of weak solutions in the case where f is nonlinear. Another approach is to add the higher spatial derivatives of v and u to smooth out the shock discontinuities and phase boundaries. Slemrod [29], [30] discussed the effects of viscosity and capillarity and proposed the viscosity-capillarity criterion. Shearer [28] considered the issue of nonuniqueness for the Riemann problem using this criterion. Slemrod [31] also discussed the limiting viscosity approach. Fan extended this approach and obtained series of results [4], [5], [6]. He also compared the various admissibility criteria [7]. The results of Fan and Slemrod are summarized in [8]. Hattori and Mischaikow [13] considered the soft loading problem with viscosity and capillarity. Hsiao [15], Hoff and Khodja [14], and Pego [23] considered the role of the viscosity.

This paper consists of 4 sections. In section 2, we discuss preliminary necessary to this paper. In section 3 we discuss the relation between the entropy condition and the entropy rate admissibility criterion. In section 3.1, first we show that if there are three or more phase boundaries for a solution of the Riemann problem, at least one of the phase boundaries violates the entropy condition. Then we discuss the compatibility issue in the case of one phase boundary and a shock wave. We show that there exists an entropy violating phase boundary if the backward wave or forward wave is a shock wave even if the solution satisfies the entropy rate admissibility criterion. In section 3.2, we study the possibility of having three or more phase boundaries in connecting the different phases. Specifically we study the case where there are three phase boundaries connecting different phases. We consider the case where three phase boundaries coalesce and see if a phase boundary is stable against perturbations by three phase boundaries. It turns out that even for a one-phase solution satisfying the entropy rate admissibility criterion, there exists a three-phase boundary solution with lower entropy rate. In section 4, based on the results in section 3, we study the Riemann problems employing the entropy-entropy rate admissibility criterion. In section 4.1, we discuss the case where v_ℓ and v_r are given in the different phases. We show that the entropy condition and the characteristic conditions define the closed and bounded region in the backward (or forward) wave curve where we minimize the entropy rate. In section 4.2, we consider the case where v_ℓ and v_r are given in the same phase. As in section 4.1, we show that there is a closed and bounded region in which the entropy rate is minimized. We show that the results in Theorem 4.7 generalize Fan's result [7] and classify (v_ℓ, u_ℓ) and (v_r, u_r) according to which type of solutions we observe.

2. Preliminary. In this section we summarize the preliminary necessary for this paper.

1. *Elementary waves:* We call the rarefaction wave and the shock wave the elementary waves. The backward wave curve (BWC) $B^r(v_o, u_o)$ is the set of (v, u) connected to (v_o, u_o) on the right by the backward rarefaction or shock wave. It satisfies the following relation:

$$\begin{array}{lll} \text{Rarefaction curve:} & u = u_o + \int_{v_o}^{v} \lambda(w)dw, & \left\{ \begin{array}{ll} v \le v_o & \text{if } f \text{ is convex,} \\ v \ge v_o & \text{if } f \text{ is concave,} \end{array} \right. \\ \text{Shock curve:} & u = u_o - \sigma_b(v_o, v)(v - v_o), & \left\{ \begin{array}{ll} v \ge v_o & \text{if } f \text{ is convex,} \\ v \le v_o & \text{if } f \text{ is concave,} \end{array} \right. \end{array}$$

where $\lambda(w) = \sqrt{f'(w)}$ and $\sigma_b(v_o, v) = -\sqrt{\frac{f(v)-f(v_o)}{v-v_o}}$. The forward wave curve (FWC) $F^r(v_o, u_o)$ is defined in a similar manner:

Rarefaction curve: $u = u_o - \int_{v_o}^{v} \lambda(w)dw,\qquad \begin{cases} v \geq v_o & \text{if } f \text{ is convex,} \\ v \leq v_o & \text{if } f \text{ is concave,} \end{cases}$

Shock curve: $u = u_o - \sigma_f(v_o, v)(v - v_o),\qquad \begin{cases} v \leq v_o & \text{if } f \text{ is convex,} \\ v \geq v_o & \text{if } f \text{ is concave,} \end{cases}$

where $\lambda(w) = \sqrt{f'(w)}$ and $\sigma_f(v_o, v) = \sqrt{\frac{f(v)-f(v_o)}{v-v_o}}$. We define $B^{\ell}(v_o, u_o)$ and $F^{\ell}(v_o, u_o)$ as the sets of (v, u) connected to (v_o, u_o) on the left by the corresponding waves. If the above inequalities are reversed, we obtain the corresponding relations.

2. *Phase boundary:* A phase boundary is the line of discontinuity in the xt-plane across which the phase changes. It satisfies the Rankine–Hugoniot condition. The phase boundary curve $P^r((v_o, u_o))$ (or $P^{\ell}((v_o, u_o))$) is the set of (v, u) connected to (v_o, u_o) on the right (or left) by the phase boundary and satisfies the following relations:

$$u = u_o - \sigma(v_o, v)(v - v_o),$$

where $\sigma(v_o, v) = \pm\sqrt{\frac{f(v)-f(v_o)}{v-v_o}}$ and v_o and v are in the different phases. If the line segment joining $(v_o, f(v_o))$ and $(v, f(v))$ intersect f, the value of v is denoted by v_*.

3. *Admissibility criteria:* The weak solutions for (1.1) are not unique and to choose a physically relevant solution we employ admissibility criteria. There are two criteria that we use in this paper. The entropy rate admissibility criterion is the criterion that was proposed by Dafermos [2], [3]. This criterion roughly says that the rate of entropy (the energy) production is the smallest for the admissible solution. The entropy for (1.1) is given by

$$\eta = \frac{1}{2}u^2 + \int f(v)dv.$$

The rate of decay of the total energy is given by

$$E \equiv D_+\eta = \sum_{\text{jump discontinuities}} \sigma(v_-, v_+)A(v_-, v_+), \tag{2.1}$$

where $\sigma(v_-, v_+)$ is the speed of the jump discontinuity and

$$A(v_-, v_+) = \left[\frac{1}{2}(f(v_-) + f(v_+))(v_+ - v_-) - \int_{v_-}^{v_+} f(w)dw\right].$$

Here v_- and v_+ are the values of v on the left and right of a jump discontinuity. We denote

$$E(v_-, v_+) = \sigma(v_-, v_+)A(v_-, v_+).$$

The entropy rate admissibility criterion postulates that the solution is admissible if it solves (1.1) and minimizes (2.1).

The entropy condition is the criterion imposing that the entropy decreases across discontinuities. This is equivalent to requiring that

$$E(v_-, v_+) = \sigma(v_-, v_+)A(v_-, v_+) \leq 0$$

holds across each discontinuity.

Whenever $A(v_-, v_+) = 0$, the line segment joining $(v_-, f(v_-))$ and $(v_+, f(v_+))$ intersect f. We denote the value of v at which the line segment intersect f by v_e. We assume that v_e is in the elliptic region for all values of v_- and v_+ in the different hyperbolic regions satisfying $A(v_-, v_+) = 0$. We discuss the case where this condition is not satisfied at the end of section 4.

4. *The Riemann problem:* If v_ℓ and v_r are specified in the different phases, the solutions of the Riemann problem consist of the constant states separated by the backward wave, odd numbers of phase boundaries, and the forward wave. If v_ℓ and v_r are specified in the same phase, the solutions of the Riemann problem consist of the constant states separated by the backward wave, even numbers of phase boundaries, and the forward wave. In each case the middle constant states separating the phase boundaries are denoted by (v_i, u_i), $(i = 1, \ldots, n+1)$, where n is the number of phase boundaries and in this case we have an n-parameter family of solutions for the Riemann problem. In Lemma 3.1 it will be shown that there is no backward or forward wave between phase boundaries.

3. Entropy and entropy rate.

3.1. One phase boundary. In this subsection we study the compatibility of the entropy rate admissibility criterion and the entropy condition in the context of the Riemann problem. We mainly discuss the case where v_ℓ and v_r are given in the different phases. We assume without loss of generality that v_ℓ is in the α-phase and v_r is in the β-phase. Specifically, we show that there are cases where we have an entropy violating phase boundary if the forward or backward wave is a shock. Using the convexity of f, we have the following lemma.

Lemma 3.1. *If the two phase boundaries satisfy the entropy condition, there is no backward or forward waves between the two phase boundaries.*

Proof. Denote by (v_1, u_1), (v_2, u_2), and so on the constant states from left to right that are separated by the phase boundaries and waves. Consider the case where v_1 is in the α-phase and the first phase boundary connecting (v_1, u_1) and (v_2, u_2) is a backward phase boundary. The other cases are proved similarly. Since $\sigma(v_1, v_2) \leq 0$, we have $A(v_1, v_2) \geq 0$. Therefore, if there is a wave connecting (v_2, u_2) and (v_3, u_3), the wave speed is larger than $|\sigma(v_1, v_2)|$ and this implies the wave must move forward. Then, the phase boundary connecting (v_3, u_3) and (v_4, u_4) must also move forward. The entropy condition requires that $A(v_3, v_4) = -A(v_4, v_3) < 0$ and the characteristic condition requires that $\lambda_3 \leq \sigma(v_3, v_4)$ or $\sigma(v_2, v_3) \leq \sigma(v_3, v_4)$. It is not difficult to show that it is impossible to satisfy both conditions. For example, if $v_3 < v_2$, we have a forward shock wave connecting (v_2, u_2) and (v_3, u_3). In this case we see that $\lambda_3 < \sigma(v_2, v_3) \leq \sigma(v_3, v_4)$ holds. Then, we can easily show that from the convexity of f, $A(v_3, v_4) < 0$ can not be satisfied; see Figure 3.1. The case where $v_3 > v_2$ can be shown similarly.

Lemma 3.2. *If the two phase boundaries move in the same direction, one of the phase boundaries violates the entropy condition.*

Proof. Consider the case where the two phase boundaries move backward. The case where two phase boundaries move forward can be treated similarly. Suppose the two phase boundaries are separated by the constant states (v_1, u_1), (v_2, u_2), and (v_3, u_3) from left to right. Since $\sigma(v_1, v_2) < 0$, $A(v_1, v_2) \geq 0$ must hold. Now that $\sigma(v_1, v_2) < \sigma(v_2, v_3) < 0$, we have $v_2 < v_3$ if the phase boundary is subsonic at v_1 ($|\sigma(v_1, v_2)| < \lambda(v_1)$), and $v_2 > v_3$ if the phase boundary supersonic at v_1 ($|\sigma(v_1, v_2)| > \lambda(v_1)$); see Figures 3.2 and 3.3. In the first case, $0 \leq A(v_1, v_2) < A(v_3, v_2)$. Since $A(v_3, v_2) = -A(v_2, v_3)$, we see $\sigma(v_2, v_3)A(v_2, v_3) > 0$. Therefore, the second phase

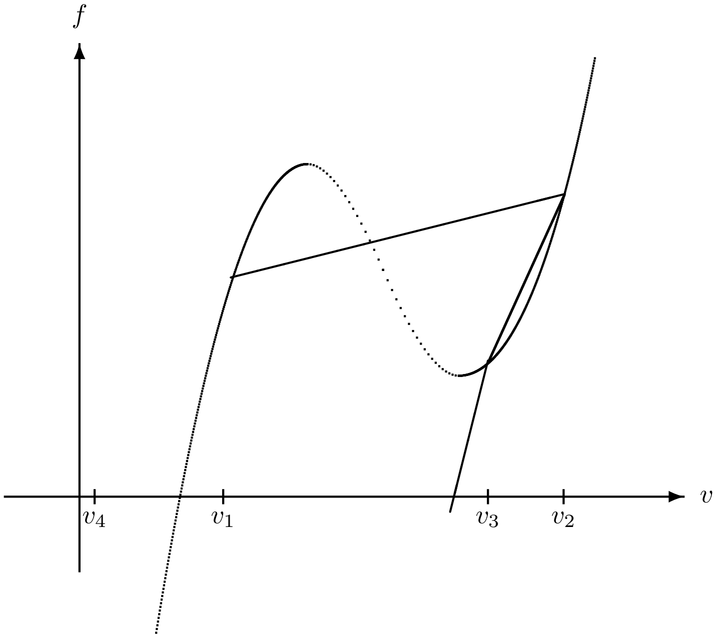

Fig. 3.1.

boundary violates the entropy condition. In the second case, there are two subcases as in Figure 3.3. If we choose $v_3 = v_3'$, then $A(v_2, v_3) < 0$ and $\sigma(v_2, v_3)A(v_2, v_3) > 0$. This violates the entropy condition. If we choose $v_3 = v_3''$, then since we assume that v_e is always in the elliptic region, $A(v_2, v_3) < 0$. This again violates the entropy condition.

Lemma 3.3. *Suppose that v_ℓ is specified in the α-phase and v_r is specified in the β-phase. If there are more than one phase boundary in the resolution of the Riemann problem, at least one of them violates the entropy condition.*

Proof. We consider the case where we have three phase boundaries in the resolution of the Riemann problem. We denote the middle constant states by (v_1, u_1), (v_2, u_2), (v_3, u_3), and (v_4, u_4) from left to right. From the result of Lemma 3.2, the only way that three phase boundaries would be compatible with the entropy condition is if the first phase boundary moves backward, the second phase boundary is stationary, and the third phase boundary moves forward. Since $\sigma(v_1, v_2) < 0$, $A(v_1, v_2) \geq 0$ must hold and $\sigma(v_2, v_3) = 0$, these imply that $A(v_3, v_2) > 0$. Now $v_2 < v_4$, we have $A(v_3, v_4) > 0$ and consequently, $\sigma(v_3, v_4)A(v_3, v_4) > 0$. This is a contradiction.

With the above lemmas as a motivation, we consider the solution to the Riemann problem where v_ℓ and v_r are in the α-phase and β-phase, respectively, and there is only one phase boundary. In what follows we assume that the constant states (v_ℓ, u_ℓ), (v_1, u_1), (v_2, u_2), and (v_r, u_r) are separated by a backward wave, a phase boundary, and a forward wave. We regard u_1 as the independent variable and derive the differential equations for v_1, v_2, and u_2 and the derivatives of the entropy rate. We have four possible cases because there are two possibilities for the backward and forward waves.

(i) Both backward and forward waves are shocks.

(ii) The backward wave is a rarefaction wave and the forward wave is a shock.

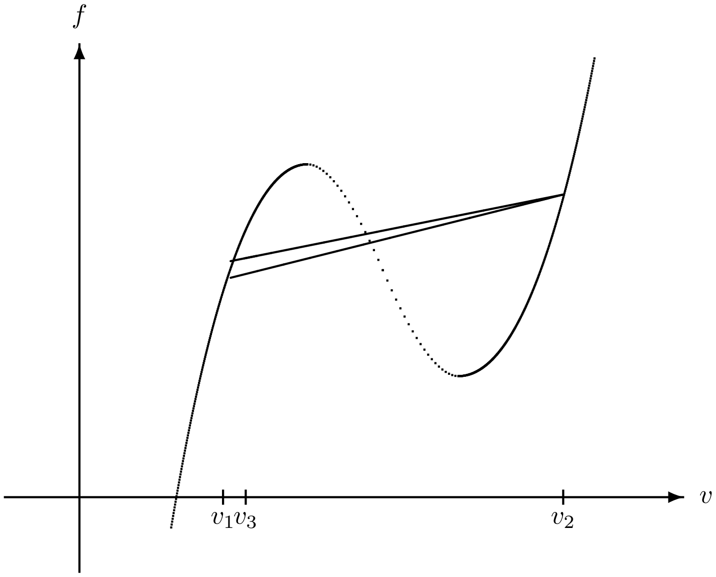

Fig. 3.2.

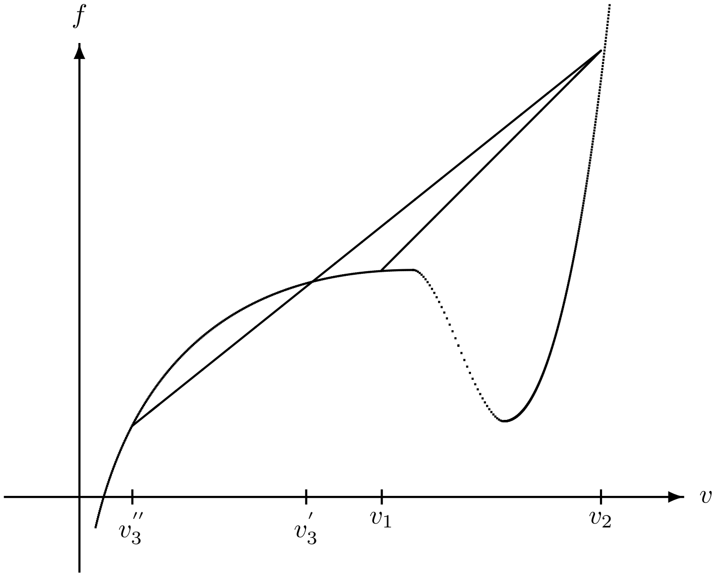

Fig. 3.3.

(iii) The backward wave is a shock and the forward wave is a rarefaction wave.

(iv) Both backward and forward waves are rarefaction waves.

For example, in case (i) we have

$$u_1 = u_\ell - \sigma_b(v_1 - v_\ell), \tag{3.1}$$

$$u_2 = u_1 - \sigma_p(v_2 - v_1), \tag{3.2}$$

$$u_r = u_2 - \sigma_f(v_r - v_2), \tag{3.3}$$

where $\sigma_b = -\sqrt{\frac{f_1 - f_\ell}{v_1 - v_\ell}}$, $\sigma_p = \pm\sqrt{\frac{f_2 - f_1}{v_2 - v_1}}$ (+ for the forward and − for the backward phase boundary), and $\sigma_f = \sqrt{\frac{f_r - f_2}{v_r - v_2}}$. If the backward wave or the forward wave is a rarefaction wave, (3.1) or (3.3) is replaced by

$$u_1 = u_\ell + \int_{v_\ell}^{v_1} \lambda(w)dw \tag{3.4}$$

or

$$u_r = u_2 - \int_{v_2}^{v_r} \lambda(w)dw, \tag{3.5}$$

where $\lambda(w) = \sqrt{f'(w)}$, respectively.

For the backward wave differentiating (3.1) or (3.4), we have

$$\frac{dv_1}{du_1} = -\frac{2\sigma_b}{\lambda_1^2 + \sigma_b^2} \tag{3.6}$$

or

$$\frac{dv_1}{du_1} = \frac{1}{\lambda_1}. \tag{3.7}$$

For the phase boundary differentiating (3.2), we obtain

$$(\lambda_2^2 + \sigma_p^2)\frac{dv_2}{du_1} + 2\sigma_p\frac{du_2}{du_1} = (\lambda_1^2 + \sigma_p^2)\frac{dv_1}{du_1} + 2\sigma_p. \tag{3.8}$$

The derivative of σ_p is expressed as

$$\frac{d\sigma_p}{du_1} = \frac{1 - \frac{du_2}{du_1} - \sigma_p(\frac{dv_2}{du_1} - \frac{dv_1}{du_1})}{(v_2 - v_1)}.$$

For the forward wave differentiating (3.3) or (3.5), we obtain

$$(\lambda_2^2 + \sigma_f^2)\frac{dv_2}{du_1} + 2\sigma_f\frac{du_2}{du_1} = 0 \tag{3.9}$$

or

$$\lambda_2\frac{dv_2}{du_1} + \frac{du_2}{du_1} = 0. \tag{3.10}$$

Combining (3.8) and (3.9), we have

$$\frac{dv_2}{du_1} = \frac{\sigma_f\{2\sigma_p + (\lambda_1^2 + \sigma_p^2)\frac{dv_1}{du_1}\}}{\sigma_f(\lambda_2^2 + \sigma_p^2) - \sigma_p(\lambda_2^2 + \sigma_f^2)}, \tag{3.11}$$

$$\frac{du_2}{du_1} = -\frac{(\lambda_2^2 + \sigma_f^2)\{2\sigma_p + (\lambda_1^2 + \sigma_p^2)\frac{dv_1}{du_1}\}}{2\{\sigma_f(\lambda_2^2 + \sigma_p^2) - \sigma_p(\lambda_2^2 + \sigma_f^2)\}} \tag{3.12}$$

in the case where the forward wave is a shock wave. Combining (3.8) and (3.10), we obtain

$$\frac{dv_2}{du_1} = \frac{\{2\sigma_p + (\lambda_1^2 + \sigma_p^2)\frac{dv_1}{du_1}\}}{(\lambda_2 - \sigma_p)^2}, \tag{3.13}$$

$$\frac{du_2}{du_1} = -\frac{\lambda_2\{2\sigma_p + (\lambda_1^2 + \sigma_p^2)\frac{dv_1}{du_1}\}}{(\lambda_2 - \sigma_p)^2} \tag{3.14}$$

in the case where the forward wave is a rarefaction wave.

The entropy rate is given by

$$E = E_b + E_p + E_f,$$

where

$$E_b = \begin{cases} \sigma_b A(v_\ell, v_1), & v_\ell > v_1, \\ 0, & v_\ell \le v_1, \end{cases}$$

$$E_p = \sigma_p A(v_1, v_2),$$

$$E_f = \begin{cases} \sigma_f A(v_2, v_r), & v_r < v_2, \\ 0, & v_r \ge v_2. \end{cases}$$

The derivatives of entropy rate are given as follows:

$$\frac{dE_b}{du_1} = \begin{cases} \frac{1}{4\sigma_b}(\lambda_1^2 - \sigma_b^2)A_{1\ell}\frac{dv_1}{du_1}, & v_\ell > v_1, \\ 0, & v_\ell \le v_1, \end{cases}$$

$$\frac{dE_p}{du_1} = \frac{1 - \frac{du_2}{du_1} - \sigma_p(\frac{dv_2}{du_1} - \frac{dv_1}{du_1})}{(v_2 - v_1)} A(v_1, v_2) + \sigma_p \frac{dA(v_1, v_2)}{du_1}, \tag{3.15}$$

$$\frac{dE_f}{du_1} = \begin{cases} -\frac{1}{4\sigma_f}(\lambda_2^2 - \sigma_f^2)A_{2r}\frac{dv_2}{du_1}, & v_r < v_2, \\ 0, & v_r \ge v_2, \end{cases}$$

where

$$A_{1\ell} = 3f_1 - f_\ell - \frac{2\int_{v_l}^{v_1} f(w)dw}{v_1 - v_\ell},$$

$$A_{2r} = 3f_2 - f_r - \frac{2\int_{v_2}^{v_r} f(w)dw}{v_r - v_2}.$$

As we can see, if we replace σ_f or σ_b by λ_2 or $-\lambda_1$, respectively, we can obtain the case where we have the rarefaction waves. The following lemma asserts that if v_ℓ and v_r are close to v_α and v_β, respectively, and u_ℓ and u_r are close, the solution of the Riemann problem with $dE/du_1 = 0$ locally minimizes the entropy rate. This was first shown in [11].

LEMMA 3.4. *There exists a neighborhood of $v_\ell = v_\alpha$, $v_r = v_\beta$, $u_\ell = u_c$, and $u_r = u_c$, where u_c is a constant, such that the Riemann problem has a solution which satisfies locally the entropy rate admissibility criterion.*

Proof. Denote dE/du_1 by $F(u_1; v_\ell, v_r, u_\ell, u_r)$. Then, in each case of (i) to (iv) we can easily show that

$$F(u_\alpha; v_\alpha, v_\beta, u_c, u_c) = 0,$$

$$\begin{aligned}\frac{dF}{du_1}(u_\alpha; v_\alpha, v_\beta, u_c, u_c) &= 2\frac{d\sigma_p}{du_1}\frac{dA(v_1,v_2)}{du_1}\\ &= \left(1-\frac{du_2}{du_1}\right)\left(\lambda_1^2\frac{dv_1}{du_1}+\lambda_2^2\frac{dv_2}{du_1}\right)\\ &= 2\frac{\lambda_1(\lambda_1+\lambda_2)}{\lambda_2} > 0,\end{aligned}$$

where u_α is the value of u_1 corresponding to v_α and λ_1 and λ_2 are evaluated at v_α and v_β, respectively. Therefore, the implicit function theorem applies.

The main assumption in Lemma 3.3 was that each discontinuity satisfies the entropy condition. If the middle constant states are chosen so that the entropy rate admissibility criterion is satisfied, one question is whether the phase boundary satisfies the entropy condition.

THEOREM 3.5. *If the forward or backward wave is a shock, there exists a solution to the Riemann problem in which the entropy rate admissibility criterion is locally satisfied but the phase boundary does not satisfy the entropy condition.*

Proof. First consider the case where the both forward and backward waves are rarefaction waves. The derivative of the entropy rate is given by

$$\begin{aligned}\text{(3.16)}\quad \frac{dE}{du_1} &= \frac{1-\frac{du_2}{du_1}-\sigma_p(\frac{dv_2}{du_1}-\frac{dv_1}{du_1})}{(v_2-v_1)}A(v_1,v_2)+\sigma_p\frac{dA(v_1,v_2)}{du_1}\\ &= \frac{\lambda_1+\sigma_p}{\lambda_1(\lambda_2-\sigma_p)}\left\{\frac{(\lambda_1+\lambda_2)A(v_1,v_2)}{(v_2-v_1)}+(v_2-v_1)(\lambda_1\lambda_2+\sigma_p^2)\sigma_p\right\}.\end{aligned}$$

This shows that in order that $\frac{dE}{du_1}=0$, $\sigma_p A(v_1,v_2)\le 0$ must hold. The left-hand side is exactly the entropy rate of the phase boundary and this shows that the entropy condition is satisfied across the phase boundary.

Next, consider the case where at least one of the elementary waves is a shock. As an example we consider the case where f is convex near v_α and v_β and the backward waves is a shock. We construct a solution in which the backward wave is a shock, the phase boundary is on the Maxwell stress, and the forward wave is a rarefaction wave. This construction is possible. First, choose $v_1 = v_\alpha$, $v_2 = v_\beta$, and $u_1 = u_2 = u_c$, where u_c is a constant. Then, choose (v_ℓ, u_ℓ) and (v_r, u_r) on $B^\ell(v_\alpha, u_c)$ and $F^r(v_\beta, u_c)$, respectively, so that we have the backward shock and the forward rarefaction wave. We should choose them so that Lemma 3.4 applies. In this case $v_\ell < v_\alpha$ and $v_r > v_\beta$. The derivative of the entropy rate is given by

$$\frac{dE}{du_1} = \frac{dE_b}{du_1}+\frac{dE_p}{du_1}.$$

At the Maxwell stress $\frac{dE_p}{du_1}=0$, $\frac{d^2E_p}{du_1^2}>0$, and $\frac{dE_b}{du_1}<0$. Therefore, in order that the entropy rate admissibility criterion be satisfied, u_1 must increase. Since $\frac{d^2E_p}{du_1^2}>0$ at the Maxwell stress, $\frac{dE_p}{du_1}>0$ for $u_1>u_\alpha$ and $\frac{dE_p}{du_1}<0$ for $u_1<u_\alpha$. Therefore, the

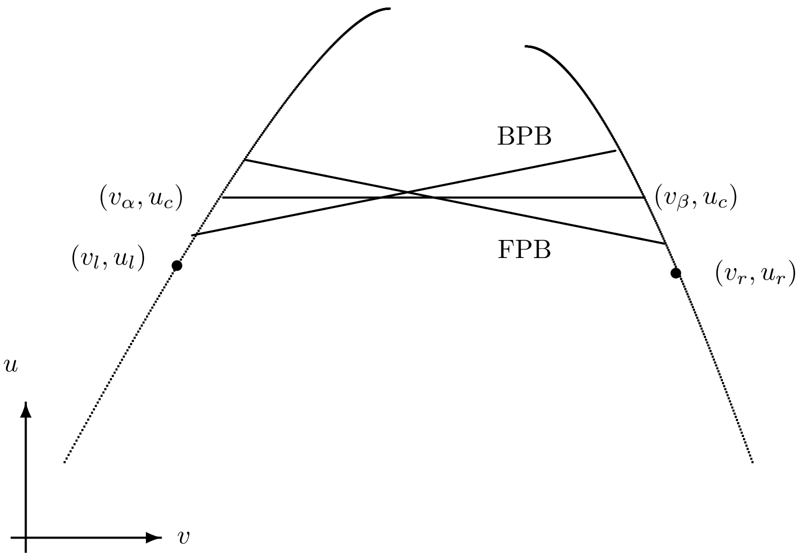

Fig. 3.4.

solution guaranteed by Lemma 3.4 implies that $u_1 > u_\alpha$ should be satisfied in order that the entropy rate admissibility criterion holds. From the differential equations for v_1 and v_2, we see that they increase as we increase u_1. Then from Figure 3.4 we see that we must have the forward phase boundary. Since $\sigma_p > 0$ and $f(v_1)$ and $f(v_2)$ are above the Maxwell line, E_p is positive and it violates the entropy condition.

3.2. Three phase boundaries. In this subsection, we examine the perturbation of a phase boundary against three phase boundaries. It is still interesting to see if there are cases where the solution to the Riemann problem with three phase boundaries has lower entropy rate than the solution with one phase boundary, even though it was shown in section 3.1 that if there are three or more phase boundaries, at least one of them violates the entropy condition. We denote the constant states in the resolution of the Riemann problem by (v_ℓ, u_ℓ), (v_1, u_1), (v_2, u_2), (v_3, u_3), (v_3, u_3), (v_r, u_r). We take u_1, u_2, and u_3 as independent variables and derive the necessary differential equations. We see if the Hessian of E is positive definite when the three phase boundaries coalesce and the coalesced phase boundary gives the local minimum in Lemma 3.4. We obtain the derivatives in the case where both the forward and backward waves are shock waves, since we can take the limit as σ_f approaches λ_4 or σ_b approaches $-\lambda_1$ if we have rarefaction waves. We use $\doteq$ to denote that the quantity is evaluated when the three phase boundaries coalesce.

From the Rankin–Hugoniot conditions we have

$$u_1 = u_\ell - \sigma_b(v_1 - v_\ell), \tag{3.17}$$

$$u_2 = u_1 - \sigma_{p_1}(v_2 - v_1), \tag{3.18}$$

$$u_3 = u_2 - \sigma_{p_2}(v_3 - v_2), \tag{3.19}$$

$$u_4 = u_3 - \sigma_{p_3}(v_4 - v_3), \tag{3.20}$$

$$u_r = u_4 - \sigma_f(v_r - v_4), \tag{3.21}$$

where $\sigma_b < 0$ and $\sigma_f > 0$. If the backward wave or the forward wave is a rarefaction wave, (3.17) or (3.21) is replaced by

$$u_1 = u_\ell + \int_{v_\ell}^{v_1} \lambda(w)dw \tag{3.22}$$

or

$$u_r = u_2 - \int_{v_2}^{v_r} \lambda(w)dw, \tag{3.23}$$

respectively. From (3.17) we have

$$\frac{\partial v_1}{\partial u_1} = -\frac{2\sigma_b}{\lambda_1^2 + \sigma_b^2}, \quad \frac{\partial v_1}{\partial u_2} = 0, \quad \frac{\partial v_1}{\partial u_3} = 0. \tag{3.24}$$

From (3.18) we see

$$\begin{aligned} \frac{\partial v_2}{\partial u_1} &= \frac{2\sigma_{p_1}}{\lambda_2^2 + \sigma_{p_1}^2} + \frac{\lambda_1^2 + \sigma_{p_1}^2}{\lambda_2^2 + \sigma_{p_1}^2}\frac{\partial v_1}{\partial u_1}, \\ \frac{\partial v_2}{\partial u_2} &= -\frac{2\sigma_{p_1}}{\lambda_2^2 + \sigma_{p_1}^2}, \quad \frac{\partial v_2}{\partial u_3} = 0. \end{aligned} \tag{3.25}$$

From (3.19) we see

$$\begin{aligned} \frac{\partial v_3}{\partial u_1} &= \frac{\lambda_2^2 + \sigma_{p_2}^2}{\lambda_3^2 + \sigma_{p_2}^2}\frac{\partial v_2}{\partial u_1}, \\ \frac{\partial v_3}{\partial u_2} &= \frac{2\sigma_{p_2}}{\lambda_3^2 + \sigma_{p_2}^2} + \frac{\lambda_2^2 + \sigma_{p_2}^2}{\lambda_3^2 + \sigma_{p_2}^2}\frac{\partial v_2}{\partial u_2}, \\ \frac{\partial v_3}{\partial u_3} &= -\frac{2\sigma_{p_2}}{\lambda_3^2 + \sigma_{p_2}^2}. \end{aligned} \tag{3.26}$$

From (3.20) and (3.21) we have

$$\begin{aligned} 2\sigma_{p_3}\frac{\partial u_4}{\partial u_1} + (\lambda_4^2 + \sigma_{p_3}^2)\frac{\partial v_4}{\partial u_1} &= (\lambda_3^2 + \sigma_{p_3}^2)\frac{\partial v_3}{\partial u_1}, \\ 2\sigma_f\frac{\partial u_4}{\partial u_1} + (\lambda_4^2 + \sigma_f^2)\frac{\partial v_4}{\partial u_1} &= 0, \end{aligned}$$

$$\begin{aligned} \frac{\partial v_4}{\partial u_1} &= \frac{\sigma_f(\lambda_3^2 + \sigma_{p_3}^2)\frac{\partial v_3}{\partial u_1}}{\{\sigma_f(\lambda_4^2 + \sigma_{p_3}^2) - \sigma_{p_3}(\lambda_4^2 + \sigma_f^2)\}}, \\ \frac{\partial u_4}{\partial u_1} &= -\frac{(\lambda_4^2 + \sigma_f^2)(\lambda_3^2 + \sigma_{p_3}^2)\frac{\partial v_3}{\partial u_1}}{2\{\sigma_f(\lambda_4^2 + \sigma_{p_3}^2) - \sigma_{p_3}(\lambda_4^2 + \sigma_f^2)\}}. \end{aligned} \tag{3.27}$$

In the same way we have

$$\begin{aligned} \frac{\partial v_4}{\partial u_2} &= \frac{\sigma_f(\lambda_3^2 + \sigma_{p_3}^2)\frac{\partial v_3}{\partial u_2}}{\{\sigma_f(\lambda_4^2 + \sigma_{p_3}^2) - \sigma_{p_3}(\lambda_4^2 + \sigma_f^2)\}}, \\ \frac{\partial u_4}{\partial u_2} &= -\frac{(\lambda_4^2 + \sigma_f^2)(\lambda_3^2 + \sigma_{p_3}^2)\frac{\partial v_3}{\partial u_2}}{2\{\sigma_f(\lambda_4^2 + \sigma_{p_3}^2) - \sigma_{p_3}(\lambda_4^2 + \sigma_f^2)\}}, \end{aligned} \tag{3.28}$$

$$\frac{\partial v_4}{\partial u_3} = \frac{\sigma_f\{2\sigma_{p_3} + (\lambda_3^2 + \sigma_{p_3}^2)\frac{\partial v_3}{\partial u_3}\}}{\{\sigma_f(\lambda_4^2 + \sigma_{p_3}^2) - \sigma_{p_3}(\lambda_4^2 + \sigma_f^2)\}}, \tag{3.29}$$

$$\frac{\partial u_4}{\partial u_3} = -\frac{(\lambda_4^2 + \sigma_f^2)\{2\sigma_{p_3} + (\lambda_3^2 + \sigma_{p_3}^2)\frac{\partial v_3}{\partial u_3}\}}{2\{\sigma_f(\lambda_4^2 + \sigma_{p_3}^2) - \sigma_{p_3}(\lambda_4^2 + \sigma_f^2)\}}.$$

From the above relations we see that

$$\frac{\partial v_3}{\partial u_2} = \frac{\partial v_4}{\partial u_2} = \frac{\partial u_4}{\partial u_2} = 0 \quad \text{as far as } \sigma_{p_1} = \sigma_{p_2}$$

and

$$\frac{\partial v_4}{\partial u_3} = \frac{\partial u_4}{\partial u_3} = 0 \quad \text{as far as } \sigma_{p_2} = \sigma_{p_3}.$$

Lemma 3.6. *We have the following relations for the second derivatives of u and v:*

$$\frac{\partial^2 v_3}{\partial u_2^2} = \frac{\partial^2 v_4}{\partial u_2^2} = \frac{\partial^2 u_4}{\partial u_2^2} = 0 \quad \textit{as far as } \sigma_{p_1} = \sigma_{p_2} \tag{3.30}$$

and

$$\frac{\partial^2 v_4}{\partial u_3^2} = \frac{\partial^2 u_4}{\partial u_3^2} = 0 \quad \textit{as far as } \sigma_{p_2} = \sigma_{p_3}. \tag{3.31}$$

Proof. For (3.30) we need to show that

$$\frac{\partial}{\partial u_2}\left\{2\sigma_{p_2} + (\lambda_2^2 + \sigma_{p_2}^2)\frac{\partial v_2}{\partial u_2}\right\} = 0 \quad \text{as far as } \sigma_{p_1} = \sigma_{p_2}.$$

It is easy to see that

$$\frac{\partial(\sigma_{p_2} - \sigma_{p_1})}{\partial u_2} = \frac{1 - \sigma_{p_2}(\frac{\partial v_3}{\partial u_2} - \frac{\partial v_2}{\partial u_2})}{(v_3 - v_2)} - \frac{1 + \sigma_{p_1}(\frac{\partial v_2}{\partial u_2} - \frac{\partial v_1}{\partial u_2})}{(v_2 - v_1)}$$

is zero as far as $\sigma_{p_1} = \sigma_{p_2}$. Therefore,

$$2\sigma_{p_2} + (\lambda_2^2 + \sigma_{p_2}^2)\frac{\partial v_2}{\partial u_2} = \frac{2(\lambda_2^2 - \sigma_{p_1}\sigma_{p_2})(\sigma_{p_2} - \sigma_{p_1})}{\lambda_2^2 + \sigma_{p_1}^2}$$

is zero as far as $\sigma_{p_1} = \sigma_{p_2}$. For (3.31) we need to show that

$$\frac{\partial}{\partial u_2}\left\{2\sigma_{p_3} + (\lambda_3^2 + \sigma_{p_3}^2)\frac{\partial v_3}{\partial u_3}\right\} = 0 \quad \text{as far as } \sigma_{p_2} = \sigma_{p_3}.$$

This can be shown in the similar way.

The entropy rate is given by

$$E = E_b + \sigma_{p_1}A(v_1, v_2) + \sigma_{p_2}A(v_2, v_3) + \sigma_{p_3}A(v_3, v_4) + E_f,$$

where

$$E_b = \begin{cases} \sigma_b A(v_\ell, v_1), & v_\ell > v_1, \\ 0, & v_\ell \le v_1, \end{cases}$$

and

$$E_f = \begin{cases} \sigma_f A(v_4, v_r), & v_r > v_4, \\ 0, & v_r \le v_4. \end{cases}$$

As the purpose of this section is to study the perturbation of a single phase boundary against three phase boundaries, in what follows we discuss the case where both backward and forward waves are rarefaction waves.

The first derivatives of E are given by

$$\begin{aligned} \frac{\partial E}{\partial u_1} = {} & \frac{\partial \sigma_{p_1}}{\partial u_1} A(v_1, v_2) + \sigma_{p_1} \frac{\partial A(v_1, v_2)}{\partial u_1} \\ & + \frac{\partial \sigma_{p_2}}{\partial u_1} A(v_2, v_3) + \sigma_{p_2} \frac{\partial A(v_2, v_3)}{\partial u_1} \\ & + \frac{\partial \sigma_{p_3}}{\partial u_1} A(v_3, v_4) + \sigma_{p_3} \frac{\partial A(v_3, v_4)}{\partial u_1}, \end{aligned} \tag{3.32}$$

$$\begin{aligned} \frac{\partial E}{\partial u_2} = {} & \frac{\partial \sigma_{p_1}}{\partial u_2} A(v_1, v_2) + \sigma_{p_1} \frac{\partial A(v_1, v_2)}{\partial u_2} \\ & + \frac{\partial \sigma_{p_2}}{\partial u_2} A(v_2, v_3) + \sigma_{p_2} \frac{\partial A(v_2, v_3)}{\partial u_2} \\ & + \frac{\partial \sigma_{p_3}}{\partial u_2} A(v_3, v_4) + \sigma_{p_3} \frac{\partial A(v_3, v_4)}{\partial u_2}, \end{aligned} \tag{3.33}$$

$$\begin{aligned} \frac{\partial E}{\partial u_3} = {} & \frac{\partial \sigma_{p_2}}{\partial u_3} A(v_2, v_3) + \sigma_{p_2} \frac{\partial A(v_2, v_3)}{\partial u_3} \\ & + \frac{\partial \sigma_{p_3}}{\partial u_3} A(v_3, v_4) + \sigma_{p_3} \frac{\partial A(v_3, v_4)}{\partial u_3}. \end{aligned} \tag{3.34}$$

LEMMA 3.7. *If three phase boundaries coalesce, $\frac{\partial E}{\partial u_2} = \frac{\partial E}{\partial u_3} = 0$. Furthermore, if the coalesced phase boundaries is identical to the one in the previous section, $\frac{\partial E}{\partial u_1} = 0$.*

Proof. It is not difficult to show that $\frac{\partial E}{\partial u_2} = \frac{\partial E}{\partial u_3} = 0$ when three phase boundaries coalesce. For $\frac{\partial E}{\partial u_1}$, we show that it reduces to the same form as $\frac{\partial E_p}{\partial u_1}$ in the previous section when the three phase boundaries coalesce. When the three phase boundaries coalesce, we have

$$\begin{aligned} \frac{\partial E}{\partial u_1} \doteq {} & \frac{1 + \sigma_{p_1} \frac{\partial v_1}{\partial u_1}}{(v_2 - v_1)} A(v_1, v_2) + \frac{-\frac{\partial u_4}{\partial u_1} - \sigma_{p_3} \frac{\partial v_4}{\partial u_1}}{(v_4 - v_3)} A(v_3, v_4) \\ & + \sigma_{p_1} \frac{1}{2} \{ f_1'(v_2 - v_1) - (f_2 - f_1) \} \frac{\partial v_1}{\partial u_1} + \sigma_{p_3} \frac{1}{2} \{ f_4'(v_4 - v_3) - (f_4 - f_3) \} \frac{\partial v_4}{\partial u_1}. \end{aligned}$$

Note that when the three phase boundaries coalesce, $\frac{\partial u_4}{\partial u_1}$ and $\frac{\partial v_4}{\partial u_1}$ reduces to $\frac{\partial u_2}{\partial u_1}$ and $\frac{\partial v_2}{\partial u_1}$ in the previous section. Therefore, it is easy to see that when the three phase boundaries coalesce, $\frac{\partial E}{\partial u_1}$ reduces to the same form as $\frac{\partial E_p}{\partial u_1}$ in the previous section.

We consider the case where the three phase boundaries coalesce and the coalesced phase boundary is identical to the phase boundary that attains the local minimum in section 3.1. We denote such values of v_1 and v_2 satisfying Lemma 3.4 by $\bar{v}_1$

and $\bar{v}_2$, respectively, and $\bar{\sigma}_p$ is the speed of that phase boundary. We assume that $v_1 = v_3 = \bar{v}_1$, $v_2 = v_4 = \bar{v}_2$, $\lambda_1 = \lambda_3 = \bar{\lambda}_1$, $\lambda_2 = \lambda_4 = \bar{\lambda}_2$, and $\sigma_{p_1} = \sigma_{p_2} = \sigma_{p_3} = \bar{\sigma}_p$. In this case $\frac{\partial E}{\partial u_1} = \frac{\partial E}{\partial u_2} = \frac{\partial E}{\partial u_3} = 0$ holds. Note that the phase boundary $\bar{\sigma}_p$ is close to the Maxwell stress. We compute the Hessian matrix H of E when the three phase boundaries coalesce. Denote the components of the Hessian of E by e_{ij} $(i, j = 1, 2, 3)$.

Lemma 3.8. *Both e_{22} and e_{33} are zero when the three phase boundaries coalesce.*

Proof. We consider $\frac{\partial^2 E}{\partial u_3^2}$. $\frac{\partial^2 E}{\partial u_2^2}$ is proved similarly. From Lemma 3.6 we have

$$\begin{aligned}
\frac{\partial^2 E}{\partial u_3^2} \doteq & -\frac{2\frac{\partial \sigma_{p_2}}{\partial u_3}\frac{\partial v_3}{\partial u_3} + \sigma_{p_2}\frac{\partial^2 v_3}{\partial u_3^2}}{(v_3 - v_2)} A(v_2, v_3) + \frac{1 + \sigma_{p_2}\frac{\partial v_3}{\partial u_3}}{(v_2 - v_3)}\{f_3'(v_3 - v_2) - (f_3 - f_2)\}\frac{\partial v_3}{\partial u_3} \\
& + \sigma_{p_2}\left[\frac{1}{2}\{f_3'(v_3 - v_2) - (f_3 - f_2)\}\frac{\partial^2 v_3}{\partial u_3^2} + \frac{1}{2}f_3''(v_3 - v_2)\frac{\partial v_3}{\partial u_3}\frac{\partial v_3}{\partial u_3}\right] \\
& + \frac{2\frac{\partial \sigma_{p_3}}{\partial u_3}\frac{\partial v_3}{\partial u_3} + \sigma_{p_3}\frac{\partial^2 v_3}{\partial u_3^2}}{(v_4 - v_3)} A(v_3, v_4) + \frac{1 + \sigma_{p_3}\frac{\partial v_3}{\partial u_3}}{(v_4 - v_3)}\{f_3'(v_4 - v_3) - (f_4 - f_3)\}\frac{\partial v_3}{\partial u_3} \\
& + \sigma_{p_3}\left[\frac{1}{2}\{f_3'(v_4 - v_3) - (f_4 - f_3)\}\frac{\partial^2 v_3}{\partial u_3^2} + \frac{1}{2}f_3''(v_4 - v_3)\frac{\partial v_3}{\partial u_3}\frac{\partial v_3}{\partial u_3}\right].
\end{aligned}$$

Noting that $\frac{\partial \sigma_{p_2}}{\partial u_3} = \frac{\partial \sigma_{p_3}}{\partial u_3}$ when the three phase boundaries coalesce, we have $\frac{\partial^2 E}{\partial u_3^2} \doteq 0$.

Next, we compute one of the off-diagonal elements e_{23}.

Lemma 3.9. *The e_{23} component of Hessian is not zero in general when the three phase boundaries coalesce.*

Proof. When three phase boundaries coalesce,

$$\begin{aligned}
\frac{\partial^2 E}{\partial u_2 \partial u_3} \doteq & \left\{-\frac{\partial v_2}{\partial u_2} - \frac{\partial v_3}{\partial u_3} - 2\sigma_{p_2}\frac{\partial v_2}{\partial u_2}\frac{\partial v_3}{\partial u_3} - \sigma_{p_2}\frac{\partial^2 v_3}{\partial u_2 \partial u_3}(v_3 - v_2)\right\}\frac{A(v_2, v_3)}{(v_3 - v_2)^2} \\
& - \frac{1 + \sigma_{p_2}\frac{\partial v_2}{\partial u_2}}{(v_2 - v_3)}\frac{1}{2}\{f_3'(v_3 - v_2) - (f_3 - f_2)\}\frac{\partial v_3}{\partial u_3} \\
& + \frac{1 + \sigma_{p_2}\frac{\partial v_3}{\partial u_3}}{(v_2 - v_3)}\frac{1}{2}\{f_2'(v_3 - v_2) - (f_3 - f_2)\}\frac{\partial v_2}{\partial u_2} \\
& + \sigma_{p_2}\frac{1}{2}(f_2' - f_3')\frac{\partial v_2}{\partial u_2}\frac{\partial v_3}{\partial u_3} \\
& - \left\{\frac{\partial^2 u_4}{\partial u_2 \partial u_3} + \sigma_{p_3}\left(\frac{\partial^2 v_4}{\partial u_2 \partial u_3} - \frac{\partial^2 v_3}{\partial u_2 \partial u_3}\right)\right\}\frac{A(v_3, v_4)}{(v_4 - v_3)} \\
& + \sigma_{p_3}\left\{\frac{1}{2}\{f_4'(v_4 - v_3) - (f_4 - f_3)\}\frac{\partial^2 v_4}{\partial u_2 \partial u_3}\right\}.
\end{aligned}$$

From Theorem 3.5, when we have the rarefaction wave, we see

$$A(v_3, v_4) = -(v_4 - v_3)^2\frac{(\lambda_3\lambda_4 + \sigma_{p_3}^2)\sigma_{p_3}}{\lambda_3 + \lambda_4}. \tag{3.35}$$

The lowest order terms are $O(\bar{\sigma}_p)$ and obtained as follows:

$$\begin{aligned}
\frac{\partial^2 E}{\partial u_2 \partial u_3} \doteq & \frac{1}{2}f_3'\frac{\partial v_3}{\partial u_3} - \frac{1}{2}f_2'\frac{\partial v_2}{\partial u_2} \\
& - \frac{\partial^2 u_4}{\partial u_2 \partial u_3}\frac{A(v_3, v_4)}{(v_4 - v_3)} + \sigma_{p_3}\frac{1}{2}f_4'(v_4 - v_3)\frac{\partial^2 v_4}{\partial u_2 \partial u_3} + O(\bar{\sigma}_p^2)
\end{aligned}$$

$$
\begin{aligned}
&\doteq -\frac{\partial^2 u_4}{\partial u_2 \partial u_3}\frac{A(v_3,v_4)}{(v_4-v_3)} + \sigma_{p_3}\frac{1}{2}f_4'(v_4-v_3)\frac{\partial^2 v_4}{\partial u_2 \partial u_3} + O(\bar{\sigma}_p^2)\\
&\doteq \frac{1}{(\lambda_4-\sigma_{p_3})^2}\left(-2\frac{\lambda_3\lambda_4^2\sigma_{p_3}}{\lambda_3+\lambda_4} + \lambda_4^2\sigma_{p_3}\right) + O(\bar{\sigma}_p^2)\\
&\doteq \left(\frac{\bar{\lambda}_2-\bar{\lambda}_1}{\bar{\lambda}_1+\bar{\lambda}_2}\right)\bar{\sigma}_p + O(\bar{\sigma}_p^2).
\end{aligned}
$$

Therefore, there exists a neighborhood of v_α and v_β where $e_{_{23}}$ component of Hessian is not zero if $\bar{\sigma}_p \neq 0$ provided that $\bar{\lambda}_2 \neq \bar{\lambda}_1$ holds.

The above two lemmas show the following.

LEMMA 3.10. *The Hessian of E is in general not positive definite when the three phase boundaries coalesce.*

Proof. From the above lemmas, it is easy to see that the Hessian has the following form when three phase boundaries coalesce:

$$
\begin{pmatrix} e_{11} & e_{12} & e_{13}\\ e_{12} & 0 & e_{23}\\ e_{13} & e_{23} & 0 \end{pmatrix}.
$$

The characteristic equation for the eigenvalues is given by

$$
g(\lambda) \equiv \lambda^3 - e_{11}\lambda^2 - (e_{12}^2+e_{13}^2+e_{23}^2)\lambda - 2e_{12}e_{13}e_{23} + e_{11}e_{23}^2 = 0.
$$

If e_{23} is not zero,

$$
g'(\lambda) = 3\lambda^2 - 2e_{11}\lambda - (e_{12}^2+e_{13}^2+e_{23}^2) = 0
$$

has two real roots with different signs. Since $g(\lambda)=0$ must have three real roots, at least one of the roots of $g(\lambda)=0$ must be negative.

The above lemma implies that if a vector $\vec{u} = (u_1,u_2,u_3)^T$ satisfies

$$
\vec{u}^T H \vec{u} < 0 \tag{3.36}
$$

and

$$
\nabla(\sigma_{p_{i+1}} - \sigma_{p_i}) \cdot \vec{u} \geq 0, \quad i = 1,2, \tag{3.37}
$$

there is a direction of $\vec{u}$ in which the solutions with three phase boundaries have the lower entropy rate than the solution with one phase boundary. First we obtain the direction of $\vec{u}$ which is compatible with the inequalities

$$
\sigma_{p_1} \leq \sigma_{p_2} \leq \sigma_{p_3}.
$$

For this purpose we compute the gradient vectors of the differences when three phase boundaries coalesce. They are given as follows:

$$
\begin{aligned}
&\nabla(\sigma_{p_3} - \sigma_{p_2})\\
&\doteq \left\langle \frac{-\frac{\partial u_4}{\partial u_1} - \sigma_{p_3}(\frac{\partial v_4}{\partial u_1} - \frac{\partial v_3}{\partial u_1})}{(v_4-v_3)} - \frac{\sigma_{p_2}(\frac{\partial v_3}{\partial u_1} - \frac{\partial v_2}{\partial u_1})}{(v_2-v_3)}, \frac{1+\sigma_{p_2}\frac{\partial v_2}{\partial u_2}}{(v_2-v_3)}, 0 \right\rangle,
\end{aligned} \tag{3.38}
$$

$$
\begin{aligned}
&\nabla(\sigma_{p_2} - \sigma_{p_1})\\
&\doteq \left\langle \frac{\sigma_{p_2}(\frac{\partial v_3}{\partial u_1} - \frac{\partial v_2}{\partial u_1})}{(v_2-v_3)} - \frac{1-\sigma_{p_1}(\frac{\partial v_2}{\partial u_1} - \frac{\partial v_1}{\partial u_1})}{(v_2-v_1)}, 0, \frac{1+\sigma_{p_2}\frac{\partial v_3}{\partial u_3}}{(v_2-v_3)} \right\rangle.
\end{aligned} \tag{3.39}
$$

The gradient vector for $(\sigma_{p_3} - \sigma_{p_1})$ can be obtained by adding the above gradient vectors.

In what follows we discuss an example where we can construct a solution to the Riemann problem with three phase boundaries which has the lower entropy rate than the solution in section 3.1. For this purpose we consider the phase boundary for which $\bar{\sigma}_p(\bar{\lambda}_2 - \bar{\lambda}_1) < 0$.

Theorem 3.11. *Consider the solution to the Riemann problem of section* 3.1 *for which*

$$\bar{\sigma}_p(\bar{\lambda}_2 - \bar{\lambda}_1) < 0 \tag{3.40}$$

is satisfied. Suppose that both the forward and backward waves are rarefaction waves. Assume also that $\bar{v}_1$ and $\bar{v}_2$ are close to v_α and v_β, respectively, so that (3.40) *implies that $\frac{\partial^2 E}{\partial u_2 \partial u_3} < 0$. Then, there exists a solution to the same Riemann problem with three phase boundaries which has a lower entropy rate.*

Proof. Since $\frac{\partial^2 E}{\partial u_2 \partial u_3} = \frac{\partial}{\partial u_2}(\frac{\partial E}{\partial u_3}) < 0$, we see that the direction $\vec{u} = \langle 0, 1, 1\rangle$ is compatible with both (3.36) and (3.37). This shows that as we increase u_2, $\frac{\partial E}{\partial u_3}$ decreases. Since $\frac{\partial E}{\partial u_3} = 0$ when the phase boundaries coalesce, $\frac{\partial E}{\partial u_3} < 0$ as we increase u_2. Therefore, if we now increase u_3, then E decreases.

4. Riemann problems.

4.1. One phase boundary. The results in the previous section motivate that we should use both the entropy rate admissibility criterion and the entropy condition as the admissibility criteria. In this subsection using these criteria, we discuss the Riemann problem (1.1) and (1.2) where v_ℓ and v_r are specified in the α-phase and β-phase, respectively. Lemma 3.3 implies that we need to consider only one phase boundary. Since the both backward and forward waves are constructed so that the entropy condition is satisfied across shock discontinuities, we need to impose that $\sigma_p A(v_1, v_2) \leq 0$ be satisfied across the phase boundary. We also require that the speed of the phase boundary in absolute value is less than or equal to that of the backward and forward wave. We apply the entropy rate admissibility criterion among the solutions satisfying the above conditions. Therefore, we have the following optimization problem:

$$\min E \tag{4.1}$$

subject to the entropy condition

$$\sigma_p A(v_1, v_2) \leq 0, \tag{4.2}$$

the characterisitic conditions

$$\sigma_b \text{ or } -\lambda_1 \leq \sigma_p \leq \sigma_f \text{ or } \lambda_2, \tag{4.3}$$

and

$$\begin{aligned} u_1 &= u_l + \begin{cases} -\sigma_b(v_1 - v_\ell), & v_\ell > v_1, \\ \int_{v_\ell}^{v_1} \lambda(w)dw, & v_\ell \leq v_1, \end{cases} \\ u_2 &= u_1 - \sigma_p(v_2 - v_1), \\ u_r &= u_2 - \begin{cases} \sigma_f(v_r - v_2), & v_r < v_2, \\ \int_{v_2}^{v_r} \lambda(w)dw, & v_r \geq v_2, \end{cases} \end{aligned} \tag{4.4}$$

where

$$E = E_b + \sigma_p A(v_1, v_2) + E_f$$

and

$$E_b = \begin{cases} \sigma_b A(v_\ell, v_1), & v_\ell > v_1, \\ 0, & v_\ell \le v_1, \end{cases}$$

$$E_f = \begin{cases} \sigma_f A(v_2, v_r), & v_r < v_2, \\ 0, & v_r \ge v_2. \end{cases}$$

We take one of v_1, u_1, v_2, u_2 as an independent variable. The admissible solution is the solution to the Riemann problem (1.1) and (1.2) satisfying the above minimization problem. We say that a solution is feasible if it satisfies (4.2) and (4.3). We denote this criterion the entropy-entropy rate admissibility criterion. This type of problem was discussed in [25] in the case where there are no shock waves. It should be noted that if the speed of the phase boundary is close to σ_b or σ_f, the line connecting $(v_1, f(v_1))$ and $(v_2, f(v_2))$ will intersect the graph of f three times in the hyperbolic region. It should be interesting to see that this criterion will choose such a solution as an admissible solution.

We construct the admissible solution for given (v_ℓ, u_ℓ) and (v_r, u_r). For this purpose, we find the region of (v_1, u_1) where (4.2) and (4.3) are satisfied for a given forward wave curve $F^\ell(v_r, u_r)$. We call this region the feasible region. We define the curves called the stationary phase boundary curve, the equal area curve, and the equal speed curve. These curves correspond to the equality signs in (4.2) and (4.3). We can also define these curves for a given backward wave curve.

Definition 4.1. *The stationary phase boundary curve (SC) is the curve consisting of the points (v_1, u_1) satisfying*

$$f(v_1) = f(v_2), \quad u_1 = u_2 \tag{4.5}$$

as (v_2, u_2) moves along the forward wave curve. This v_1 satisfies $\gamma \le v_1 \le \alpha$ and exists if $\beta \le v_2 \le \delta$. We can similarly define the stationary phase boundary curve corresponding to the forward wave curve.

Taking u_2 as an independent variable and differentiating $f(v_1) = f(v_2)$ with respect to u_2, we obtain

$$\frac{dv_1}{du_2} = \frac{\lambda_2^2}{\lambda_1^2} \frac{dv_2}{du_2},$$

where

$$\frac{dv_2}{du_2} = \begin{cases} -\frac{1}{\lambda_2}, & v_2 \le v_r, \\ -\frac{2\sigma_f}{\lambda_2^2 + \sigma_f^2}, & v_2 > v_r. \end{cases}$$

We see that this curve has a negative slope in the vu-plane.

Definition 4.2. *The equal area curve (EAC) is the curve consisting of the points (v_1, u_1) satisfying*

$$A(v_1, v_2) = 0, \quad u_2 = u_1 - \sigma_p(v_2 - v_1) \tag{4.6}$$

as (v_2, u_2) *moves along the forward wave curve.*

Differentiating the equations in (4.6) with respect to u_2, we have

$$\frac{dv_1}{du_2} = -\frac{\lambda_2^2 - \sigma_p^2}{\lambda_1^2 - \sigma_p^2}\frac{dv_2}{du_2},$$

$$\frac{du_1}{du_2} = \frac{\{(\lambda_2^2 + \sigma_p^2)(\lambda_1^2 - \sigma_p^2) + (\lambda_2^2 - \sigma_p^2)(\lambda_1^2 + \sigma_p^2)\}\frac{dv_2}{du_2}}{2\sigma_p(\lambda_2^2 - \sigma_p^2)} + 1.$$

Therefore, we obtain

$$\frac{dv_1}{du_1} = -\frac{\sigma_p(\lambda_2^2 - \sigma_p^2)\frac{dv_2}{du_2}}{(\lambda_1^2\lambda_2^2 - \sigma_p^4)\frac{dv_2}{du_2} + \sigma_p(\lambda_1^2 - \sigma_p^2)}.$$

It is easy to see that as long as $-\lambda_1 < \sigma_p < \lambda_2$,

$$\frac{dv_1}{du_1} < (\text{or } >)\ 0 \quad \text{if} \quad \sigma_p > (\text{or } <)\ 0.$$

Suppose (v_β, u_2) is on the forward wave curve. Then, this curve starts from (v_α, u_2).

There are two types of equal speed curves. They are denoted by ESC-I and ESC-II.

Definition 4.3. *The ESC-*I *is the curve consisting of the points* (v_1, u_1) *satisfying*

$$u_2 = u_1 - \sigma_p(v_2 - v_1), \tag{4.7}$$

where

$$\sigma_p = \begin{cases} -\lambda_1, & v_1 \geq v_\ell, \\ \sigma_b, & v_1 < v_\ell, \end{cases} \tag{4.8}$$

as (v_2, u_2) *moves along the forward wave curve. If* (δ, u_2) *is on the forward wave curve, then this curve starts from* (α, u_2), *and if* $v_1 < v_\ell$, *the line segment joining* $(v_2, f(v_2))$ *and* $(v_1, f(v_1))$ *passes through* $(v_\ell, f(v_\ell))$.

Definition 4.4. *The ESC-*II *is the curve consisting of the points* (v_1, u_1) *satisfying*

$$u_2 = u_1 - \sigma_p(v_2 - v_1), \tag{4.9}$$

where

$$\sigma_p = \begin{cases} \lambda_2, & v_2 \leq v_r, \\ \sigma_f, & v_2 > v_r, \end{cases} \tag{4.10}$$

as (v_2, u_2) *moves along the forward wave curve. If* (β, u_2) *is on the forward wave curve, this curve starts from* (γ, u_2), *and if* $v_r < v_2$, *the line segment joining* $(v_2, f(v_2))$ *and* $(v_1, f(v_1))$ *passes through* $(v_r, f(v_r))$.

Remark 4.1. We can define ESC-I and ESC-II for a backward wave curve in a similar manner. In the case of ESC-I, if (v_1, u_1) moves along the backward wave curve, σ_p is equal to the speed of the forward wave curve, and if $v_2 > v_r$, the line segment joining $(v_2, f(v_2))$ and $(v_1, f(v_1))$ passes through $(v_r, f(v_r))$. It should be noted that for $v_r < v_2$ the ESC-I and the forward wave curve coalesce. In the case of ESC-II, if (v_1, u_1) moves along the backward wave curve, σ_p is equal to the speed of the backward wave curve and if $v_1 < v_\ell$, the line segment joining $(v_2, f(v_2))$ and $(v_1, f(v_1))$ passes through $(v_\ell, f(v_\ell))$.

Differentiating (4.7) and (4.8), we obtain

$$\frac{dv_1}{du_1} = -\frac{2\lambda_1(\lambda_2^2 - \lambda_1^2)\frac{dv_2}{du_2}}{\{(\lambda_2^2 + \lambda_1^2)\frac{dv_2}{du_2} - 2\lambda_1\}f_1''(v_2 - v_1) - 2\lambda_1^2(\lambda_2^2 - \lambda_1^2)\frac{dv_2}{du_2}}, \quad v_1 \geq v_l,$$

and

$$\frac{dv_1}{du_1} = \frac{2\sigma_p(v_1 - v_\ell)(\lambda_2^2 - \sigma_p^2)\frac{dv_2}{du_2}}{\{2\sigma_p + (\lambda_2^2 + \sigma_p^2)\frac{dv_2}{du_2}\}(v_2 - v_\ell)(\lambda_1^2 - \sigma_p^2) - (\lambda_1^2 + \sigma_p^2)(v_1 - v_\ell)(\lambda_2^2 - \sigma_p^2)\frac{dv_2}{du_2}},$$
$$v_1 < v_l,$$

as (v_2, u_2) moves along the forward wave curve. Since $f_1'' < 0$, $\lambda_1^2 > \sigma_p^2$, $\lambda_2^2 > \sigma_p^2$, and $\lambda_2 > \lambda_1$ holds if $v_1 \geq v_l$, $\frac{dv_1}{du_1}$ is positive. If $\sigma_p = -\lambda_1$, the slope of the backward phase boundary touches the graph of f. If $\sigma_p = \sigma_b$, the constant state (v_1, u_1) degenerates to a line in the xt-plane, and we interpret that there is no backward wave and that (v_ℓ, u_ℓ) is directly connected to (v_2, u_2). This phase boundary satisfies the entropy condition. It should be noted that for $v_1 < v_l$ the ESC-I and the backward wave curve from $(v_\ell, u_2 + \sigma_p(v_2 - v_1))$ coalesce.

Differentiating (4.9) and (4.10), we obtain

$$\frac{dv_1}{du_1} = -\frac{2\sigma_p}{\lambda_1^2 + \sigma_p^2}$$

as (v_2, u_2) moves along the forward wave curve. Note that $\frac{dv_1}{du_1}$ is negative. If $\sigma_p = \sigma_f$, the constant state (v_2, u_2) degenerates to a line in the xt-plane, and we interpret that there is no forward wave and that (v_r, u_r) is directly connected to (v_1, u_1). This phase boundary also satisfies the entropy condition.

Before discussing the Riemann problems, we state lemmas concerning the relation between the curves defined above.

LEMMA 4.5. *The EAC and SC do not intersect.*

Proof. Consider the case where the EAC and SC for a given forward wave curve intersect at (v_1, u_1). Since both EAC and SC are for the same forward wave curve from (v_r, u_r), for the connection between (v_r, u_r) and (v_1, u_1) through SC, we have

$$u_r - \left\{ \begin{array}{c} \int_{v_r}^{v_2'} \lambda(w)dw \\ \sigma_{f'}(v_2' - v_r) \end{array} \right\} = u_1, \tag{4.11}$$

where v_2' is the value of v on the forward wave curve satisfying $f(v_2') = f(v_1)$ and $\sigma_{f'} = \sqrt{\frac{f(v_2') - f(v_r)}{v_2' - v_r}}$. We have the rarefaction wave if $v_2' \leq v_r$ and the shock wave if $v_2' > v_r$. We also have

$$u_r - \left\{ \begin{array}{c} \int_{v_r}^{v_2} \lambda(w)dw \\ \sigma_f(v_2 - v_r) \end{array} \right\} - \sigma_p(v_1 - v_2) = u_1, \tag{4.12}$$

where v_2 is the value of v on the forward wave curve. We have the rarefaction wave if $v_2 \leq v_r$ and the shock wave if $v_2 > v_r$. The relation (4.12) holds for every connection between (v_r, u_r) and (v_1, u_1) with the forward wave and the phase boundary including

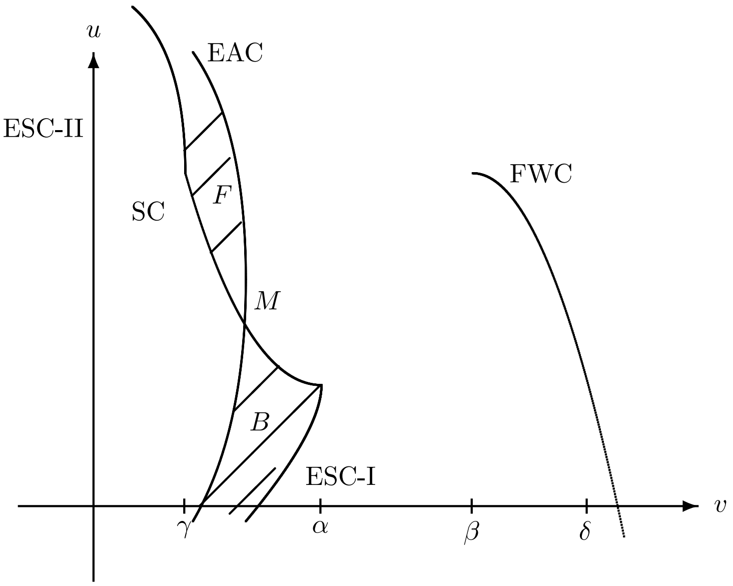

FIG. 4.1.

the one satisfying the equal area condition. From the above two relations, in order for the two curves to meet, we have

$$\left\{ \begin{array}{c} \int_{v_r}^{v_2} \lambda(w)dw \\ \sigma_f(v_2 - v_r) \end{array} \right\} + \sigma_p(v_1 - v_2) = \left\{ \begin{array}{c} \int_{v_r}^{v_2'} \lambda(w)dw \\ \sigma_{f'}(v_2' - v_r) \end{array} \right\}. \tag{4.13}$$

The equality obviously holds if $v_2 = v_2'$. The question is if this holds for other values of v_2. Consider the case where v_r and v_1 are connected by the shock wave. The derivative of the right-hand side with respect to v_2 is given by

$$-\frac{(\sigma_f - \sigma_p)(\lambda_2^2 - \sigma_f\sigma_p)}{2\sigma_f\sigma_p}.$$

Since $|\sigma_p| < \sigma_f < \lambda_2$ holds, the equality in (4.13) holds only when $v_2 = v_2'$. This shows that the EAC and SC do not meet. The case of the rarefaction wave can be shown in a similar way.

THEOREM 4.6. *There exists an absolute minimum for the problems* (4.1), (4.2), (4.3), *and* (4.4). *Furthermore, there exists a neighborhood of $v_\ell = v_\alpha$, $v_r = v_\beta$, $u_\ell = u_c$, and $u_r = u_c$, where u_c is a constant, such that the Riemann problem has a unique solution satisfying the entropy-entropy rate admissibility criterion.*

Proof. Combining the above curves, we obtain the feasible region; see Figure 4.1. In this figure the shaded regions are the feasible regions. Depending on how the backward wave intersects with the shaded region, we obtain three cases.

(a) The backward wave intersects with the region F in Figure 4.1.

(b) The backward wave goes through the point M in Figure 4.1.

(c) The backward wave intersects with the region B in Figure 4.1.

In Figure 4.1, F (or B) stands for the fact that the phase moves forward (or backward) if the backward wave curve intersect this region and the v-coordinate of M is v_α. The

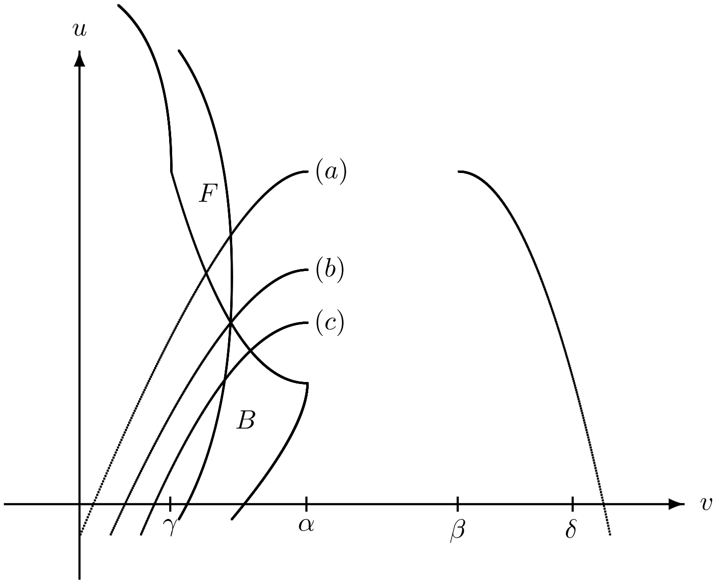

FIG. 4.2.

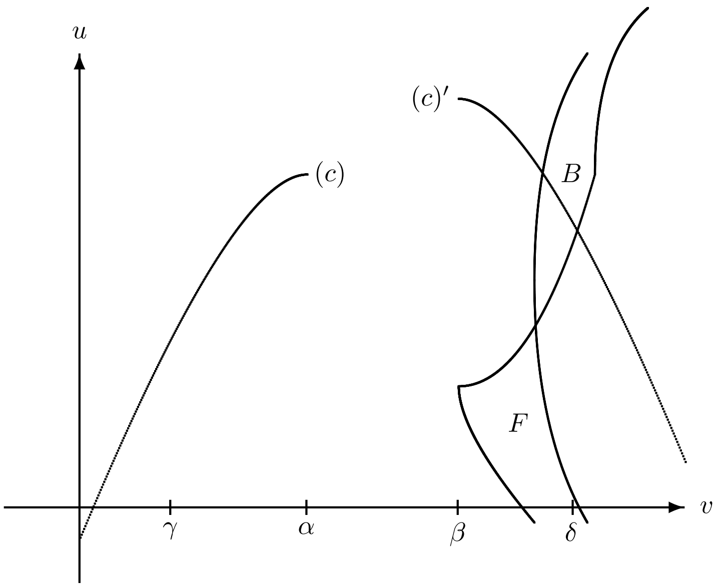

FIG. 4.3.

backward wave curve corresponding to cases (a), (b), and (c) are drawn in Figure 4.2. In case (a) we move (v_1, u_1) along the backward wave curve in the feasible region and find the minimum of the entropy rate. In case (b), only the stationary phase boundary is allowed. In case (c) it is not clear if the backward wave and EAC intersect. To circumvent this difficulty, we change the role of the backward wave curve

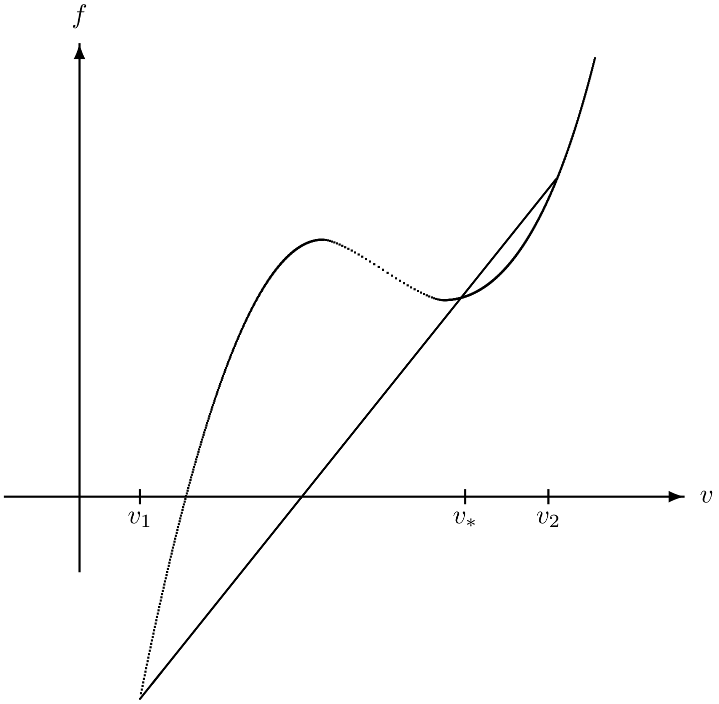

FIG. 4.4.

and the forward wave curve and draw the SC, EAC, and ESC-I, II for the backward wave curve. This is depicted in Figure 4.3. The forward wave curve corresponding to case (c) is given by (c)$'$. It is clear now that we move (v_2, u_2) along the forward wave curve in the feasible region and find the minimum of the entropy rate. The relation between the EAC and ESC-II is not clear. For example, they may intersect. Even if this occurs, the phase boundary connecting (v_1, u_1) and (v_2, u_2) satisfies the entropy condition provided that (v_1, u_1) or (v_2, u_2) is on the ESC-II from the forward wave curve or backward wave curve, respectively. Therefore, an admissible solution always exists. Combining the above result with Lemma 3.4, we see that there exists a neighborhood of $v_\ell = v_\alpha$, $v_r = v_\beta$, $u_\ell = u_c$, and $u_r = u_c$, where u_c is a constant, such that the Riemann problem has a unique solution satisfying the entropy-entropy rate admissibility criterion.

Remark 4.2. If the backward or forward wave curve crosses the ESCs, there are cases where the line segment joining $(v_1, f(v_1))$ and $(v_2, f(v_2))$ intersect with the graph of f at another v in the hyperbolic region. We denote this v by v_*. In this case we may have multiple solutions. One solution consists of v_ℓ, v_1, v_2, and v_r and another solution consists of v_ℓ, v_1, v_*, and v_r. For example, suppose v_* is in the β-phase; see Figure 4.4. For each value of v_r in the β-phase the solution with v_* is not feasible except when $v_* = v_r$ since the characteristic condition (4.3) is not satisfied. If $v_* = v_r$, the constant state v_2 degenerate into a line in the xt-plane. In this case we interpret that v_1 and $v_* = v_r$ are connected by a phase boundary and there is no forward wave.

4.2. Two phase boundaries. In this subsection we construct the solution to the Riemann problem where both v_ℓ and v_r are given in the same phase. We assume that they are given in the α-phase. There are two possibilities. One possibility is that there is no phase boundary and the middle constant state (v_m, u_m) is connected to (v_ℓ, u_ℓ) and (v_r, u_r) by the backward wave and the forward wave, respectively. This is what we observe in the hyperbolic case. This solution will be referred to as the solution with no phase boundary. Another possibility is that the solution has five constant states (v_ℓ, u_ℓ), (v_1, u_1), (v_2, u_2), (v_3, u_3), and (v_r, u_r) which are separated by the backward wave, two phase boundaries, and the forward wave, respectively, from left to right. In this case v_1 and v_3 are in the α-phase and v_2 is in the β-phase. This solution will be referred to as the solution with two phase boundaries. From Lemmas 3.1 and 3.2, there are four possible connections as in section 3. For example, if both the backward and forward waves are shocks, we have

$$u_2 = u_\ell - \sigma_b(v_1 - v_\ell) - \sigma_{p_1}(v_2 - v_1), \tag{4.14}$$

$$u_r = u_2 - \sigma_{p_2}(v_3 - v_2) - \sigma_f(v_r - v_3), \tag{4.15}$$

where $\sigma_b = -\sqrt{\frac{f_1 - f_\ell}{v_1 - v_\ell}}$, $\sigma_{p_1} = -\sqrt{\frac{f_2 - f_1}{v_2 - v_1}}$, $\sigma_{p_2} = \sqrt{\frac{f_3 - f_2}{v_3 - v_2}}$, and $\sigma_f = -\sqrt{\frac{f_3 - f_r}{v_3 - v_r}}$. We regard v_1 and v_3 as functions of v_2 and u_2 and take partial derivatives. Then, we obtain

$$\frac{\partial v_1}{\partial v_2} = \frac{-\sigma_b(\sigma_{p_1}^2 + \lambda_2^2)}{(-\sigma_b + \sigma_{p_1})(\lambda_1^2 - \sigma_b\sigma_{p_1})}, \quad \frac{\partial v_1}{\partial u_2} = \frac{-2\sigma_b\sigma_{p_1}}{(-\sigma_b + \sigma_{p_1})(\lambda_1^2 + \sigma_b\sigma_{p_1})},$$

$$\frac{\partial v_3}{\partial v_2} = \frac{\sigma_f(\sigma_{p_2}^2 + \lambda_2^2)}{(\sigma_f - \sigma_{p_2})(\lambda_3^2 - \sigma_f\sigma_{p_2})}, \quad \frac{\partial v_3}{\partial u_2} = \frac{2\sigma_f\sigma_{p_2})}{(\sigma_f - \sigma_{p_2})(\lambda_3^2 - \sigma_f\sigma_{p_2})}.$$

If the backward or forward wave is a rarefaction wave, we replace σ_b or σ_f with $-\lambda_1$ or λ_2, respectively. Note that there are singularities if $\sigma_{p_1} = \sigma_b$ or $-\lambda_1$ and $\sigma_{p_2} = \sigma_f$ or λ_3.

The optimization problem is given by

$$\min E \tag{4.16}$$

subject to

$$\sigma_{p_1} A(v_1, v_2) \le 0, \quad \sigma_{p_2} A(v_2, v_3) \le 0 \tag{4.17}$$

and

$$\sigma_b \text{ or } -\lambda_1 \le \sigma_{p_1} \le 0 \le \sigma_{p_2} \le \sigma_f \text{ or } \lambda_3, \tag{4.18}$$

and

$$\begin{aligned} u_2 &= u_\ell + \left\{ \begin{array}{c} -\sigma_b(v_1 - v_\ell) \text{ (if } v_\ell > v_1) \\ \int_{v_\ell}^{v_1} \lambda(w)dw \text{ (if } v_\ell \le v_1) \end{array} \right\} - \sigma_{p_1}(v_2 - v_1), \\ u_r &= u_2 - \sigma_{p_2}(v_3 - v_2) - \left\{ \begin{array}{c} \sigma_f(v_r - v_3) \text{ (if } v_r > v_3) \\ \int_{v_3}^{v_r} \lambda(w)dw \text{ (if } v_r \le v_3) \end{array} \right\}, \end{aligned} \tag{4.19}$$

where

$$E = E_b + \sigma_{p_1} A(v_1, v_2) + \sigma_{p_2} A(v_2, v_3) + E_f$$

and

$$E_b = \begin{cases} \sigma_b A(v_\ell, v_1), & v_\ell > v_1, \\ 0, & v_\ell \leq v_1, \end{cases}$$

$$E_f = \begin{cases} \sigma_f A(v_3, v_r), & v_r > v_3, \\ 0, & v_r \leq v_3. \end{cases}$$

We take (v_2, u_2) as independent variables. Lemma 3.2 implies that it is enough to consider the case where two phase boundaries satisfy the condition in (4.18).

As in the previous subsection we draw the backward wave curve and the forward wave curve from (v_ℓ, u_ℓ) and (v_r, u_r), respectively. Denote the intersection point by (v_m, u_m) if it exists. There are three cases depending on the relation between the two curves.

(d) Two curves do not intersect.

(e) Two curves intersect and $v_m > v_\alpha$. Therefore, v_m is in the metastable state.

(f) Two curves intersect and $v_m \leq v_\alpha$. Therefore, v_m is in the stable state.

In case (d) we measure the gap between the BWC and FWC by the difference of u on the BWC and FWC at $v = \alpha$.

Theorem 4.7. *In case* (d) *there exists an absolute minimum for the minimization problem* (4.16), (4.17), (4.18), *and* (4.19). *if the gap between the BWC and FWC is small. In case* (e) *there exists an absolute minimum for the minimization problem which is smaller than the solution with no phase boundary provided that*

$$\frac{\partial E}{\partial v_2} > 0 \tag{4.20}$$

holds at $(v_2, u_2) = (v_s, u_s)$. *On the other hand, in case* (f) *there is no solution with two phase boundaries satisfying the condition* (4.17). *Therefore, the solution with no phase boundary is admissible in this case.*

Proof. In each case we identify the region of (v_2, u_2) where the solution satisfies (4.17) and (4.18). We call this region the feasible region. The construction is similar to the previous subsection. For a given backward wave curve $B^r(v_\ell, u_\ell)$, we draw the curves satisfying the equalities in (4.17) and (4.18). Since $\sigma_{p_1} \leq 0$, we have

$$u_2 = u_1 - \sigma_{p_1}(v_2 - v_1) \geq u_1.$$

This implies that the feasible region lies above the stationary curve of the backward wave curve. Also, we draw the curves satisfying the equalities in (4.17) and (4.18) for a given forward wave curve $F^\ell(v_r, u_r)$. The feasible region lies below the stationary curve of the forward wave curve. The results corresponding to cases (d), (e), and (f) are given in Figures 4.5, 4.6, and 4.7, respectively. In Figure 4.6 the point S at which two stationary phase boundaries meet is denoted by (v_s, u_s). In case (d) we need two phase boundaries to connect (v_ℓ, u_ℓ) and (v_r, u_r). In case (e) the condition (4.20) implies that the solutions with two phase boundaries have lower entropy rates than the solution with no phase boundary provided that (4.20) holds at $v_2 = v_s$, where the constant state (v_2, u_2) degenerates into a vertical line in the xt-plane. FIG. 4.7.

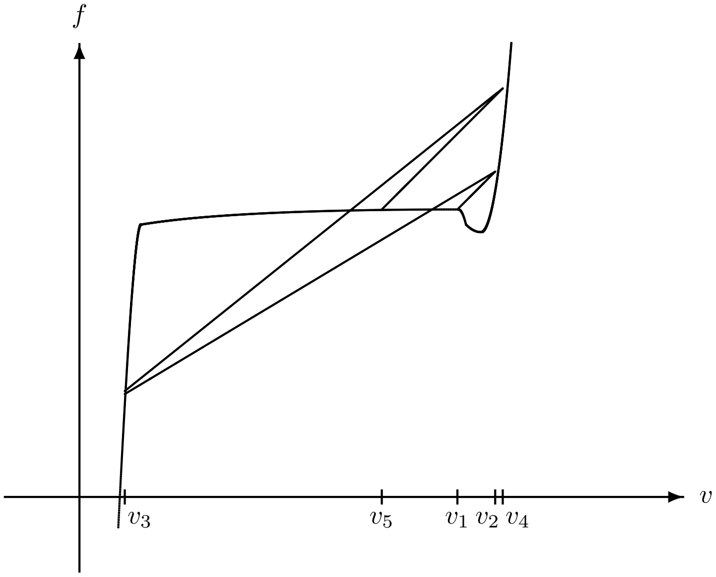

FIG. 4.8.

$\frac{\partial E}{\partial u_2} = 0$ at $(v_2, u_2) = (v_s, u_s)$. In cases (d) and (e) we move (v_2, u_2) in the shaded regions and find the minimum of the entropy rate. In case (f) there is no region where (4.17) and (4.18) are satisfied. In this case we observe the admissible solution with no phase change.

Remark 4.3. In case (d) if the gap between the forward wave and backward wave curves is large, the relation between EAC and ESC-II is not clear. For example, EAC and ESC-II from the backward wave curve or from the forward wave curve may intersect. Even if this occurs, we have an admissible solution as long as two ESC-IIs intersect.

Remark 4.4. In [28] Shearer discussed the nonuniqueness of the Riemann problem. He has observed that when (v_ℓ, u_ℓ) and (v_r, u_r) are connected by the backward rarefaction wave and the forward rarefaction wave, there exists another solution where (v_ℓ, u_ℓ) and (v_r, u_r) are connected by the backward rarefaction wave, the backward phase boundary, the forward phase boundary, and the forward rarefaction wave. He has shown that there are cases where both solutions are admissible if the viscosity-capillarity criterion is employed. Fan [7] compared two types of solutions discussed in Shearer and has shown that the solution with two phase boundaries has the lower entropy rate. The results in Theorem 4.7 generalize Fan's result and classify (v_ℓ, u_ℓ) and (v_r, u_r) according to which type of solutions we observe.

Remark 4.5. It should be noted that Figures 4.1–4.7 are for the case where v_e defined in section 2 is in the spinodal region. If this condition is violated, Lemma 3.2 may not hold. The equal speed curves and the equal area curves may intersect if the gap between the forward and backward waves is large. If this happens, we may observe a situation depicted in Figure 4.8. In this figure, v_1 is connected to v_2 by a backward phase boundary and then v_2 is connected to v_3 by another backward phase boundary. Note that the second phase boundary intersects with the hyperbolic region. If we allow this type of phase boundary, the above two backward phase boundaries satisfy the entropy condition and the solution to the Riemann problem with three or more phase boundaries may become feasible. For example, in Figure 4.8 v_3 can be connected to v_4 by a forward phase boundary and then to v_5 by another forward phase boundary. Therefore, if we identify $v_1 = v_\ell$ and $v_4 = v_r$, and disregard the connection from v_4 to v_5, we see that the solution with three phase boundaries becomes feasible if v_ℓ and v_r are specified in the different phases. If we identify $v_1 = v_\ell$ and $v_5 = v_r$, then we see that the solution with four phase boundaries becomes feasible if v_ℓ and v_r are specified in the same phase.

Acknowledgments. The author is thankful to the referees for their comments through which he was able to improve the paper.

PARAMETRIC RESONANCE IN WAVE EQUATIONS WITH A TIME-PERIODIC POTENTIAL*

JEFFERY COOPER†

Abstract. We consider the wave equation in three space dimensions perturbed by a time-periodic potential with compact support in space, multiplied by a small parameter, ε. When $\varepsilon = 0$, the scattering theory of Lax and Phillips defines scattering frequencies which describe the decay of solutions in the neighborhood of the support of the potential. For $\varepsilon > 0$, scattering frequencies are defined; they are analogous to Floquet exponents. We show that when the frequency of the time-periodic potential is a multiple of the real part of a scattering frequency σ_0 for the time-independent case, resonance occurs. When ε increases from zero, the scattering frequency σ_0 splits in a symmetric fashion, defining outgoing solutions which decay faster or slower than those of the time-independent problem. An example is given in the case of spherical symmetry of the potential.

1. Introduction.

Consider the wave equation with a time-dependent potential

$$u_{tt} - \Delta u + q_0(x)u + \varepsilon p(t)q_1(x)u = 0. \tag{1.1}$$

Here $p(t)$ has period T and ε is a small parameter. We think of this equation as a PDE generalization of Hill's equation

$$u''(t) + q_0 u + \varepsilon p(t)u = 0. \tag{1.2}$$

If the period T of p is a suitable multiple of $2\pi/\sqrt{q_0}$, a resonance occurs, producing an exponentially growing solution of (1.2)(see [9]).

We look for similar behavior for the solutions of (1.1). Our study is motivated by our interest in the behavior of scattering frequencies for (1.1) when q_0 and q_1 have compact support in R^3.

In section 2 we recall some elements of Kato's treatment of analytic perturbations of linear operators [4]. In section 3 we apply this theory to an abstract evolution equation in a complex Hilbert space H,

$$u_t = Au + \varepsilon p(t)Qu. \tag{1.3}$$

We assume that A generates a strongly continuous semigroup of contraction operators $U(t)$ on H and that Q is a bounded operator on H. We assume that A and Q take real vectors into real vectors. For certain values of T, $U(T)$ will have a real eigenvector λ_0. We assume that λ_0 is an isolated point of the spectrum of $U(T)$ with finite multiplicity and no generalized eigenvalues. We show that when p has period T, the eigenvalue λ_0 splits in a symmetric fashion into several branches $\lambda_j(\varepsilon)$ determined by the eigenvectors of A.

In section 4, we apply the results of section 3 to (1.1) defined for $(x,t) \in R^3 \times R$ where $q_0(x)$ and $q_1(x)$ have compact support. We do not apply the theory directly to the solutions of (1.1) but rather to a local semigroup $Z(t)$ associated with the solutions of (1.1) with $\varepsilon = 0$. This local semigroup (discussed by Lax and Phillips in [6]) describes the behavior of the solutions in a neighborhood of the support of the scattering potential. In particular $Z(t)$ is compact and has eigenvalues $\exp(i\sigma t)$. The complex numbers σ are called the *scattering frequencies* for (1.1) with $\varepsilon = 0$. The finite energy solutions of (1.1) with $\varepsilon = 0$ decay exponentially in the local energy norm which corresponds to the fact that the scattering frequencies σ satisfy $Im(\sigma) > 0$. Scattering frequencies are also defined for (1.1) when $\varepsilon \neq 0$ (see [1]). In [2], it was shown that the scattering frequencies of (1.1) depend on ε in a continuous fashion. Numerical computations of the scattering frequencies for equations like (1.1) were done in [7] and [8]. These computations showed that the effect of the periodic perturbation may be to force some of the scattering frequencies to the lower half plane, corresponding to exponentially growing solutions of (1.1). In this paper we show that if $\sigma_0 = \nu_0 + i\kappa_0$ is a scattering frequency for (1.1) with $\varepsilon = 0$, with no generalized eigenvectors, and $T = 2\pi/\nu_0$, then σ_0 splits into several branches when $\varepsilon \neq 0$. The directions of the splitting are symmetric with respect to the origin and with respect to the imaginary axis. An example of this splitting is given for spherically symmetric solutions when q_0 and q_1 are real constants. In this case the resonant scattering frequency splits along a vertical line with one branch heading south and one branch heading north. At this time we are still unable to show that as ε increases, one of the resonant scattering frequencies crosses the real axis.

Finally we remark that there is a large literature which treats the Schrödinger equation with a time-periodic potential (for a survey, see the article of Howland [3]). This approach, which uses a quasi energy, did not seem to yield any additional results because of the special nature of the semigroup $Z(t)$. Furthermore our results do not seem to apply to the Schrödinger case because of our hypothesis that the eigenvalue λ_0 be an isolated point of the spectrum of $U(T)$.

2. Analytic perturbation theory.

In this section we recall several results from the theory of analytic perturbations of the spectrum of a bounded operator. The standard reference is Kato [4].

Let $\varepsilon \to L(\varepsilon)$ be a holomorphic family of bounded linear operators on a complex Hilbert space H, defined on a neighborhood of $\varepsilon = 0$. We abbreviate $L(0)$ by writing simply L. $L(\varepsilon)$ may be expanded in a power series, convergent in the operator norm,

$$L(\varepsilon) = L + \varepsilon L_1 + \varepsilon^2 L_2 + \cdots . \tag{2.1}$$

$L_n = L^{(n)}(0)/n!$ are bounded operators on H.

Let $\lambda_0 \in C$ be an isolated point of the spectrum of L which is an eigenvalue of geometric and algebraic multiplicity m. In this case we can apply the finite dimensional theory. λ_0 is a semisimple eigenvalue in the terminology of Kato. The eigenvalue λ_0 may split into several branches $\{\lambda_1(\varepsilon), \ldots, \lambda_s(\varepsilon)\}$, $1 \leq s \leq m$. Let $D = \{|\varepsilon| < \varepsilon_0\}$ and $D_0 = D - \{0\}$.

Theorem 2.1. *Each of the branches $\lambda_j(\varepsilon)$ is differentiable at $\varepsilon = 0$ and holomorphic on D_0 for ε_0 sufficiently small.*

Let Γ be a small circle that encloses λ_0 and $\lambda_j(\varepsilon)$ for $|\varepsilon| \leq \varepsilon_0$, and such that Γ does not meet any other part of the spectrum of $L(\varepsilon)$. Let $R(\zeta, \varepsilon) = (L(\varepsilon) - \zeta)^{-1}$ be the resolvant. Then define

$$P(\varepsilon) = -\frac{1}{2\pi i}\int_\Gamma R(\zeta,\varepsilon)d\zeta. \tag{2.2}$$

$P(\varepsilon)$ is the projection on the total eigenspace corresponding to the eigenvalues $\{\lambda_1(\varepsilon), \ldots, \lambda_s(\varepsilon)\}$.

THEOREM 2.2. *$\varepsilon \to P(\varepsilon)$ is holomorphic on D. The dimension of the range of $P(\varepsilon)$ is constant, equal to m.*

Let E denote the (finite dimensional) eigenspace of λ_0 and let $P = P(0)$ denote the projection onto E. Note that the adjoint of P, P^*, is the projection onto the eigenspace E^* of L^* for the eigenvalue $\bar{\lambda_0}$. It is easy to verify that

$$P^* = -\frac{1}{2\pi i}\int_{\Gamma^*} R^*(\zeta,0)d\zeta, \tag{2.3}$$

where Γ^* is a small circle containing $\bar{\lambda_0}$.

Because λ_0 is a semisimple eigenvalue, the function $\varepsilon \to (L(\varepsilon) - \lambda_0)P(\varepsilon)$ is holomorphic on D and vanishes at $\varepsilon = 0$. Thus it may be expanded in a convergent power series

$$(L(\varepsilon) - \lambda_0)P(\varepsilon) = \sum_1^\infty \varepsilon^n \tilde{L}_n. \tag{2.4}$$

The operators $\tilde{L}_n$ are determined from the L_n as follows. First we expand $R(\zeta,\varepsilon)$ in a power series in ε:

$$R(\zeta,\varepsilon) = R(\zeta) + R_1(\zeta)\varepsilon + R_2(\zeta)\varepsilon^2 + \cdots \tag{2.5}$$

where $R(\zeta) = R(\zeta,0)$ and

$$R_1(\zeta) = -R(\zeta)L_1R(\zeta), \tag{2.6}$$

$$R_2(\zeta) = -R(\zeta)L_2R(\zeta) + R(\zeta)L_1R(\zeta)L_1R(\zeta). \tag{2.7}$$

Now since

$$(L(\varepsilon) - \lambda_0)P(\varepsilon) = -\frac{1}{2\pi i}\int_\Gamma (\zeta - \lambda_0)R(\zeta,\varepsilon)d\zeta, \tag{2.8}$$

we may substitute the expansion (2.5) into (2.8) and use (2.6) and (2.7) to yield the expressions for $\tilde{L_1}$ and $\tilde{L_2}$,

$$\tilde{L_1} = \frac{1}{2\pi i}\int_\Gamma (\zeta - \lambda_0)R(\zeta)L_1R(\zeta)d\zeta, \tag{2.9}$$

$$\tilde{L_2} = \frac{1}{2\pi i}\int_\Gamma (\zeta - \lambda_0)[R(\zeta)L_2R(\zeta) - R(\zeta)L_1R(\zeta)L_1R(\zeta)]d\zeta. \tag{2.10}$$

We can get more explicit expressions for $\tilde{L_1}$ and $\tilde{L_2}$ using the Laurent expansion for $R(\zeta)$ at λ_0:

$$R(\zeta) = -P(\zeta - \lambda_0)^{-1} + \sum_1^\infty S^n(\zeta - \lambda_0)^n, \tag{2.11}$$

where S is the *reduced resolvent* of L. S is defined by $S = (L - \lambda_0)^{-1}(I - P)$ on the range of $I - P$, and $S = 0$ on E. Substitute (2.11) into (2.9) and (2.10) and perform the residue calculation. We obtain

$$\tilde{L}_1 = PL_1P, \tag{2.12}$$

$$\begin{aligned} \tilde{L}_2 &= PL_2P - PL_1PL_1S - PL_1SL_1P - SL_1PL_1P \\ &= PL_2P - \tilde{L}_1L_1S - SL_1\tilde{L}_1 - PL_1SL_1P. \end{aligned} \tag{2.13}$$

THEOREM 2.3. *For each branch $\lambda_j(\varepsilon)$, $\lambda_j'(0)$ is an eigenvalue of $\tilde{L}_1$. Furthermore if $\varphi(\varepsilon)$ is a continuous family of eigenvectors of $L(\varepsilon)$ with eigenvalue $\lambda_j(\varepsilon)$,*

$$L(\varepsilon)\varphi(\varepsilon) = \lambda_j(\varepsilon)\varphi(\varepsilon), \tag{2.14}$$

then $\varphi(0)$ is an eigenvector of $\tilde{L}_1$,

$$\tilde{L}_1\varphi(0) = \lambda_j'(0)\varphi(0). \tag{2.15}$$

Proof. For each ε, let $\varphi(\varepsilon)$ be an eigenvector of $L(\varepsilon)$ with eigenvalue $\lambda_j(\varepsilon)$, that is, (2.14). We may assume that $\|\varphi(\varepsilon)\| = 1$. Then because the unit ball in H is weakly compact, we can extract a subsequence $\varepsilon_k \to 0$ such that $\varphi(\varepsilon_k) \to w$ weakly in H. Since $\|\varphi(\varepsilon_k)\| = 1$ we also have $\varphi(\varepsilon_k) \to w$ strongly in H. We rewrite the left side of (2.4) as

$$\begin{aligned} (L(\varepsilon_k) - \lambda_0)P(\varepsilon_k)\varphi(\varepsilon_k) &= (L(\varepsilon_k) - \lambda_j(\varepsilon_k) + \lambda_j(\varepsilon_k) - \lambda_0)\varphi(\varepsilon_k) \\ &= (\lambda_j(\varepsilon_k) - \lambda_0)\varphi(\varepsilon_k). \end{aligned}$$

Then dividing (2.4) by ε_k we have

$$\frac{\lambda(\varepsilon_k) - \lambda_0}{\varepsilon_k}\varphi(\varepsilon_k) = \tilde{L}_1\varphi(\varepsilon_k) + \sum_{n=2}^{\infty} \varepsilon_k^{n-1}\tilde{L}_n\varphi(\varepsilon_k).$$

We take the limit as $k \to \infty$ and deduce that $\lambda_j'(0)w = \tilde{L}_1 w$. Of course, the same results hold if $\varphi(\varepsilon)$ is any continuous family of eigenvectors satisfying (2.14).

If $\lambda_j'(0)$ is a semisimple eigenvalue of $\tilde{L}_1$, we may apply Theorem 2.1, and deduce that $\lambda_j(\varepsilon)$ is twice differentiable at $\varepsilon = 0$.

THEOREM 2.4. *Assume that $\varphi(\varepsilon)$ is a continuous family of eigenvectors satisfying* (2.14). *Assume that $\tilde{L}_1 = 0$. Then $\lambda_j'(0) = 0$ for each j and $\varphi(0)$ is an eigenvector of $\tilde{L}_2$ with eigenvalue $2\lambda_j''(0)$,*

$$\tilde{L}_2\varphi(0) = 2\lambda_j''(0)\varphi(0). \tag{2.16}$$

Note that in this case, (2.13) becomes

$$\tilde{L}_2 = PL_2P - PL_1SL_1P. \tag{2.17}$$

Proof. Since $\tilde{L}_1 = 0$, (2.5) yields

$$\begin{aligned} \tilde{L}_2\varphi(\varepsilon) + \sum_{n=3}^{\infty} \varepsilon^{n-2}\tilde{L}_n\varphi(\varepsilon) &= \frac{L(\varepsilon) - \lambda_0}{\varepsilon^2}P(\varepsilon)\varphi(\varepsilon) \\ &= \frac{\lambda(\varepsilon) - \lambda_0}{\varepsilon^2}\varphi(\varepsilon). \end{aligned}$$

Now taking the limit as $\varepsilon \to 0$ yields (2.16).

3. Parametric resonance. Let H be a complex Hilbert space, with scalar product (u,v) and norm $\|u\|$. Let A be the generator of a C_0 contraction semigroup $U(t)$ on H, $\|U(t)\| \leq 1$. Let Q be a bounded operator on H and let $p(t)$ be a continuous, real valued function. We assume

$$u \in D(A) \iff \bar{u} \in D(A), \qquad \overline{Au} = A\bar{u}, \qquad \overline{Qu} = Q\bar{u}, \tag{3.1}$$

and

$$p \text{ has period } T \text{ with } \int_0^T p(t)dt = 0. \tag{3.2}$$

We consider the abstract differential equation for a function $t \to u(t)$ taking values in H,

$$\frac{du}{dt} = Au + \varepsilon p(t)Qu, \tag{3.3}$$

where ε is a small parameter.

We assume that $\mu = -\kappa_0 + i\nu_0$, with $\kappa_0 \geq 0$ and $\nu_0 > 0$, is an eigenvalue of A with geometric and algebraic multiplicity $m \geq 1$. Thus there are independent eigenvectors

$$A\varphi_j = \mu\varphi_j, \qquad j = 1, \dots, m. \tag{3.4}$$

Because of (3.1), $\bar{\mu}$ is also an eigenvalue for A, with eigenvectors $\bar{\varphi}_j$:

$$A\bar{\varphi}_j = \bar{\mu}\bar{\varphi}_j, \qquad j = 1, \dots, m.$$

Finally we assume

$$\nu_0 = 2\pi/T \tag{3.5}$$

and we assume that

$$\lambda_0 = e^{\mu T} = e^{-\kappa_0 T} \tag{3.6}$$

is an isolated point of the spectrum of $U(T)$.

It follows that λ_0 is an eigenvalue of $U(T)$ of algebraic and geometric multiplicity $2m$. Let E denote the $2m$ dimensional eigenspace.

The solution of the initial value problem for (3.3) is given by an evolution operator $U_\varepsilon(t,s)$ for $s \leq t$; see Kato [5]. Integrating (3.3), we have

$$U_\varepsilon(t,s) = U(t-s) + \varepsilon \int_s^t U(t-\tau)p(\tau)QU_\varepsilon(\tau,s)d\tau \quad \text{for} \quad s \leq t. \tag{3.7}$$

THEOREM 3.1. *$\varepsilon \to U_\varepsilon(t,s)$ is an entire holomorphic family of bounded evolution operators $U_\varepsilon(t,s) : H \to H$ for $s \leq t$.*

Proof. We compute the derivatives of $U_\varepsilon(t,s)$ at $\varepsilon = 0$ formally, and show that these derivatives yield a convergent power series. For $f \in H$ and s fixed, let

$$z(t,\varepsilon) = U_\varepsilon(t,s)f, \qquad t \geq s.$$

Then $z(t,\varepsilon)$ satisfies

$$z(t,\varepsilon) = U(t-s)f + \varepsilon \int_s^t U(t-\tau)p(\tau)Qz(\tau,\varepsilon)d\tau.$$

Formally differentiating, we see that

$$\frac{\partial z(t,\varepsilon)}{\partial\varepsilon} = \int_s^t U(t-\tau)p(\tau)Qz(\tau,\varepsilon)d\tau + \varepsilon\int_s^t U(t-\tau)p(\tau)Q\frac{\partial z(\tau,\varepsilon)}{\partial\varepsilon}d\tau, \tag{3.8}$$

so that

$$z_1(t) \equiv \frac{\partial z(t,0)}{\partial\varepsilon} = \int_s^t U(t-\tau)p(\tau)Qz_0(\tau)d\tau, \tag{3.9}$$

where $z_0(\tau) = U(\tau)f$. In general we have

$$z_n(t) \equiv \frac{\partial^n z(t,0)}{\partial\varepsilon^n} = n\int_s^t U(t-\tau)p(\tau)Qz_{n-1}(\tau)d\tau. \tag{3.10}$$

Let $\alpha = \max|p(t)|$. Equation (3.10) yields the inequality

$$\begin{aligned}\|z_n(t)\| &\le n\alpha\int_s^t \|U(t-\tau)\|\|Q\|\|z_{n-1}(\tau)\|d\tau\\ &\le n\alpha\|Q\|\int_s^t \|z_{n-1}(\tau)\|d\tau.\end{aligned}$$

By induction we find that

$$\|z_n(t)\| \le (\alpha\|Q\|(t-s))^n\|f\|.$$

Thus $z(t,\varepsilon)$ has the convergent power series

$$z(t,\varepsilon) = \sum_0^\infty \frac{z_n(t)\varepsilon^n}{n!} \tag{3.11}$$

with

$$\|z(t,\varepsilon)\| \le \sum_0^\infty \frac{(\alpha\|Q\|(t-s)|\varepsilon|)^n}{n!}\|f\| \le e^{\alpha\|Q\|(t-s)|\varepsilon|}\|f\|.$$

The theorem is proved.

Now we wish to apply the results of section 2 to the holomorphic family of operators

$$\varepsilon \to L(\varepsilon) \equiv U_\varepsilon(T,0)$$

and investigate the behavior of the eigenvalues that split from λ_0 for $\varepsilon \ne 0$. From (3.9) and (3.10) we see that

$$L_1 f = \int_0^T U(T-s)p(s)QU(s)fds, \tag{3.12}$$

and

$$L_2 f = \int_0^T U(T-s)p(s)QU(s)\int_0^s U(s-\tau)p(\tau)QU(\tau)fd\tau ds. \tag{3.13}$$

To get more information about how the eigenvalue λ_0 splits, we use the $2m$ dimensional basis of eigenvectors of E, arranged as follows:

$$\varphi_1, \bar{\varphi}_1, \ldots, \varphi_m, \bar{\varphi_m}. \tag{3.14}$$

We introduce a basis for the $2m$ dimensional eigenspace E^* of $U(T)^*$ (with the same real eigenvalue $\lambda_0 = \exp(-\kappa_0 T)$). Let $\psi_1, \ldots, \psi_m$ be the eigenvectors of A^* with eigenvalue $\bar{\mu}$:

$$A^*\psi_j = \bar{\mu}\psi_j, \qquad j = 1, \ldots, m.$$

Then, because of (3.1), $\bar{\psi}_j$ are also eigenvectors of A^*

$$A^*\bar{\psi}_j = \mu\bar{\psi}_j, \qquad j = 1, \ldots, m.$$

We take the basis of E^* as $\psi_1, \bar{\psi}_1, \ldots, \psi_m, \bar{\psi}_m$. We observe that

$$(\varphi_j, \bar{\psi}_k) = 0, \qquad 1 \leq j, \qquad k \leq m, \tag{3.15}$$

whence

$$(\bar{\varphi}_j, \psi_k) = \overline{(\varphi_j, \bar{\psi}_k)} = 0, \qquad 1 \leq j, \qquad k \leq m.$$

This is easily seen since

$$\mu(\varphi_j, \bar{\psi}_k) = (A\varphi_j, \bar{\psi}_k) = (\varphi_j, A^*\bar{\psi}_k) = (\varphi_j, \mu\bar{\psi}_k) = \bar{\mu}(\varphi_j, \bar{\psi}_k).$$

Since we assume $\nu_0 = Im(\mu) > 0$, this implies (3.15).

Let N be the $2m \times 2m$ matrix consisting of the 2×2 blocks

$$N_{i,j} = \begin{bmatrix} (\varphi_i, \psi_j) & (\bar{\varphi}_i, \psi_j) \\ (\varphi_i, \bar{\psi}_j) & (\bar{\varphi}_i, \bar{\psi}_j) \end{bmatrix}, \qquad i, j = 1, \ldots, m. \tag{3.16}$$

We let M be the $2m \times 2m$ matrix consisting of the 2×2 blocks

$$M_{i,j} = \begin{bmatrix} (L_1\varphi_i, \psi_j) & (L_1\bar{\varphi}, \psi_j) \\ (L_1\varphi_i, \bar{\psi}_j) & (L_1\bar{\varphi}_i, \bar{\psi}_j) \end{bmatrix}, \qquad i, j = 1, \ldots, m. \tag{3.17}$$

Here L_1 is given by (3.12).

THEOREM 3.2. *Assume* (3.1) *and* (3.2). *Then the values $\rho_j = \lambda_j'(0)$ of the derivatives of the branches $\lambda_j(\varepsilon)$ are the roots of the characteristic equation*

$$\det(\rho N - M) = 0. \tag{3.18}$$

Furthermore, the roots ρ of (3.18) are symmetric with respect to the origin and with respect to the real axis.

Proof. From Theorem 2.3, we know that the derivatives $\lambda_j'(0)$ are the eigenvalues of $\tilde{L_1} = L_1PL_1$. Let w be an eigenvector of $\tilde{L_1}$ with eigenvalue ρ,

$$\rho w = \tilde{L_1}w = PL_1w, \tag{3.19}$$

because $w \in E$. Now take scalar products with ψ_j and $\bar{\psi}_j$ in (3.19),

$$\rho(w, \psi_j) = (PL_1w, \psi_j) = (L_1w, P^*\psi_j) = (L_1w, \psi_j) \tag{3.20}$$

and

$$\rho(w, \bar{\psi}_j) = (L_1 w, \bar{\psi}_j) \tag{3.21}$$

because $\psi_j, \bar{\psi}_j \in E^*$ and $P^* = I$ on E^*. Since $w \in E$, we can express w uniquely as

$$w = \sum_{j=1}^{m} a_{2j-1}\varphi_j + \sum_{j=1}^{m} a_{2j}\bar{\varphi}_j.$$

Substituting this expression into (3.20) and (3.21) yields

$$\rho N a = M a,$$

where $a = (a_1, a_2, \ldots, a_{2m})$. This is equivalent to (3.18).

By (3.15), the blocks

$$N_{i,j} = \begin{bmatrix} n_{i,j} & 0 \\ 0 & \bar{n}_{i,j} \end{bmatrix},$$

where $n_{i,j} = (\varphi_i, \psi_j)$.

To compute the elements of $M_{i,j}$, we use (3.12).

$$\begin{aligned}(L_1\varphi_i, \psi_j) &= \int_0^T (U(T-s)p(s)QU(s)\varphi_i, \psi_j)ds = \int_0^T p(s)(QU(s)\varphi_i, U(T-s)^*\psi_j)ds \\ &= \int_0^T p(s)e^{\mu s}(Q\varphi_i, e^{\bar{\mu}(T-s)}\psi_j) = e^{\mu T}(Q\varphi_i, \psi_j)\int_0^T p(s)ds = 0\end{aligned}$$

by (3.2). Because $U(t)$ and Q take real vectors into real vectors,

$$(L_1\bar{\varphi}_i, \bar{\psi}_j) = \overline{(L_1\varphi_i, \psi_j)} = 0.$$

Furthermore,

$$\begin{aligned} m_{i,j} \equiv (L_1\bar{\varphi}_i, \psi_j) &= e^{\mu T}(Q\bar{\varphi}_i, \psi_j)\int_0^T p(s)e^{(\bar{\mu}-\mu)s}ds \\ &= e^{-\kappa_0 T}(Q\bar{\varphi}_i, \psi_j)p_2, \end{aligned} \tag{3.22}$$

where

$$p_2 = \int_0^T p(t)e^{-2i\nu_0 t}dt.$$

Also $(L_1\varphi_i, \bar{\psi}_j) = \overline{(L_1\bar{\varphi}_i, \psi_j)}$. Thus the 2×2 blocks $M_{i,j}$ have the form

$$M_{i,j} = \begin{bmatrix} 0 & m_{i,j} \\ \bar{m}_{i,j} & 0 \end{bmatrix}.$$

The matrix $\rho N - M$ consists of the 2×2 blocks

$$\rho N_{i,j} - M_{i,j} = \begin{bmatrix} \rho n_{i,j} & -m_{i,j} \\ -\bar{m}_{i,j} & \rho\bar{n}_{i,j} \end{bmatrix}.$$

Let $l(\rho) = \det(\rho N - M)$, whence $\overline{l(\rho)} = \det(\bar\rho \bar N - \bar M)$ with blocks

$$\bar\rho \bar N_{i,j} - \bar M_{i,j} = \begin{bmatrix} \bar\rho \bar n_{i,j} & -\bar m_{i,j} \\ -m_{i,j} & \bar\rho n_{i,j} \end{bmatrix}.$$

Now interchange rows $2i-1$ and $2i$, $i = 1, \ldots, m$ and columns $2j-1$ and $2j$, $j = 1, \ldots, m$ of $\bar\rho \bar N - \bar M$. These row and column interchanges yield $\bar\rho N - M$. Hence

$$\overline{l(\rho)} = \det(\bar\rho \bar N - \bar M) = \det(\bar\rho N - M) = l(\bar\rho).$$

Thus $l(\rho)$ has real coefficients so that the roots come in conjugate pairs.

Next we show that $l(-\rho) = l(\rho)$. In fact $l(-\rho) = \det(-\rho N - M)$ and $-\rho N - M$ has the 2×2 blocks

$$\begin{bmatrix} -\rho n_{i,j} & -m_{i,j} \\ -\bar m_{i,j} & -\rho \bar n_{i,j} \end{bmatrix}.$$

Multiply the odd numbered rows by -1 and the even numbered columns by -1. These row and column operations on $-\rho N - M$ yield $\rho N - M$. Hence

$$l(-\rho) = \det(-\rho N - M) = \det(\rho N - M) = l(\rho).$$

This completes the proof of Theorem 3.2.

Remark. Let $\lambda_j(\varepsilon)$ be a branch of the eigenvalues splitting from λ_0, with eigenvector $\varphi_j(\varepsilon)$. Then the first term in an asymptotic expansion of $\varphi_j(\varepsilon)$ is an eigenvector of $\lambda_j'(0)N - M$.

When $\tilde L_1 = 0$, we see in (2.13) that

$$\tilde L_2 = PL_2P - PL_1SL_1P,$$

where S is the reduced resolvant: Let K be the $2m \times 2m$ matrix consisting of the 2×2 blocks

$$(3.23)\quad K_{i,j} = \begin{bmatrix} (L_2\varphi_i - L_1SL_1\varphi_i, \psi_j) & (L_2\bar\varphi_i - L_1SL_1\bar\varphi_i, \psi_j) \\ (L_2\varphi_i - L_1SL_1\varphi_i, \bar\psi_j) & (L_2\bar\varphi_i, -L_1SL_1\bar\varphi_i, \bar\psi_j) \end{bmatrix}, \quad i, j = 1, \ldots, m.$$

THEOREM 3.3. *Assume* (3.1) *and* (3.2). *Suppose that* $p_2 = 0$ *and that* $\det(N) \neq 0$. *Then* $\tilde L_1 = 0$ *so that* $\lambda_j'(0) = 0$ *for each of the branches* $\lambda_j(\varepsilon)$. *In this case,* $\lambda_j(\varepsilon)$ *is twice differentiable at* $\varepsilon = 0$ *and* $\rho_j = 2\lambda_j''(0)$ *are the roots of the characteristic equation*

$$(3.24)\qquad \det(\rho N - K) = 0.$$

The roots of (3.24) are symmetric with respect to the real axis.

Proof. Since N is assumed to be invertible, the matrix for $\tilde L_1 = PL_1P$ in the basis (3.14) for the eigenspace E is $N^{-1}M$. In fact, for $f \in H$, the projection can be expressed

$$Pf = \sum_{j=1}^{m} c_{2j-1}\varphi_j + \sum_{j=1}^{m} c_{2j}\bar\varphi_j,$$

where

$$c = N^{-1}((f, \psi_1), (f, \bar\psi_1), \ldots, (f, \psi_m), (f, \bar\psi_m)).$$

Now taking $f = L_1 g$ with

$$g = \sum_{j=1}^{m} a_{2j-1}\varphi_j + \sum_{j=1}^{m} a_{2j}\bar{\varphi}_j$$

we see that

$$((f,\psi_1),(f,\bar{\psi}_1),\ldots,(f,\psi_m),(f,\bar{\psi}_m)) = Ma.$$

Thus the coordinates of $\tilde{L}_1 g = PL_1 g$ are related to the coordinates of g by $c = N^{-1}Ma$.

Now assuming $p_2 = 0$, we see by (3.22) that $M = 0$, whence $\tilde{L}_1 = 0$. Thus $\lambda_j'(0) = 0$ for all branches of $\lambda_j(\varepsilon)$. By Theorem 3.1, λ_j is twice differentiable at $\varepsilon = 0$, and for each branch, $\rho_j = 2\lambda_j''(0)$ is an eigenvalue of $\tilde{L}_2$. If w is an eigenvector of $\tilde{L}_2$ with eigenvalue ρ,

$$\rho w = \tilde{L}_2 w,$$

we take scalar product with ψ_j and $\bar{\psi}_j$ to obtain

$$\rho(w,\psi_j) = (\tilde{L}_2,\psi_j)$$

$$= (PL_2 w - PL_1 S L_1 w, \psi_j) = (L_2 w - L_1 S L_1 w, \psi_j)$$

and similarly for $\bar{\psi}_j$. Then writing $w = \sum a_{2j-2}\varphi_j + a_{2j}\bar{\varphi}_j$, we deduce, as in the proof of Theorem 3.2, that $\rho N a = K a$ where K is given by (3.23). Finally we note that because L and S take real vectors into real vectors, the blocks $K_{i,j}$ have the form

$$K_{i,j} = \begin{bmatrix} k_{i,j} & l_{i,j} \\ \bar{l}_{i,j} & \bar{k}_{i,j} \end{bmatrix}.$$

It follows easily that if ρ satisfies (3.24), then so does $\bar{\rho}$.

Remark. The proof of Theorems 3.2 and 3.3 actually depends only on (3.7). Once this formula is established, we do not need to know the differential equation solved by $U_\varepsilon(t,s)$.

4. Scattering frequencies. We apply the results of sections 2 and 3 to the wave equation in three space dimensions with a time-periodic potential. Let $q_0(x) \in L^\infty(R^3)$, $x \in R^3$, with $q_0(x) \geq 0$ and $q_0(x) = 0$ for $|x| > 1$. We assume that $q_0(x) > 0$ on some open subset. Next let $q_1(x) \in L^\infty(R^3)$ be real valued with $q_1(x) = 0$ for $|x| > 1$. We consider the wave equations

$$u_{tt} - \Delta u + q_0(x)u = 0 \tag{4.1}$$

and

$$u_{tt} - \Delta u + q_0(x)u + \varepsilon p(t) q_1(x) u = 0, \tag{4.2}$$

where $p(t)$ is real valued, continuous, and has period T with

$$\int_0^T p(t)dt = 0. \tag{4.3}$$

We write (4.1) and (4.2) as systems

$$u_t = Au \tag{4.4}$$

and

$$u_t = Au + \varepsilon p(t) Q u, \tag{4.5}$$

where now u is a pair, $u = [u(x,t), u_t(x,t)]$. A is the matrix differential operator

$$A = \begin{bmatrix} 0 & 1 \\ \Delta - q_0 & 0 \end{bmatrix} \tag{4.6}$$

and

$$Q = \begin{bmatrix} 0 & 1 \\ q_1 & 0 \end{bmatrix}. \tag{4.7}$$

The finite energy space H for (4.4) and (4.5) is the space of pairs $f = [f_1, f_2]$ which is the closure of $C_0^\infty(R^3) \times L^2(R^3)$ in the energy norm

$$\|f\| = \left[\int_{R^3} [|\nabla f_1|^2 + q_0 |f_1|^2] dx + \int_{R^3} |f_2|^2 dx\right]^{1/2}.$$

The scalar product on H is

$$(f, g) = \int_{R^3} [\nabla f_1 \cdot \nabla \bar{g}_1 + q_0 f_1 \bar{g}_1 + f_2 \bar{g}_2] dx.$$

It is well known that A generates a unitary group $U(t) : H \to H$. Applying Theorem 3.1, we see that the finite energy solutions of (4.5) are given by an evolution operator $V_\varepsilon(t, s) : H \to H$, and that $\varepsilon \to V_\varepsilon(t, s)$ is an entire function with values in the space of bounded operators on H.

We shall not apply the results of section 3 directly to (4.4) and (4.5). In fact, A has no eigenvalues. Instead we study the behavior of the solutions in a neighborhood of the support of the potential. In [6] Lax and Phillips developed a framework to treat this situation. We recall some elements of that framework. First we make a decomposition of the space of data H into subspaces which represent solutions which have left the region of the potential (outgoing), those which have not reached the region of the potential (incoming), and the remainder which interacts with the potential. The *outgoing subspace* is

$$D^+ = \{f \in H : U_0(t) f = 0 \text{ in } |x| \le t + 1, t > 0\}$$

and the *incoming subspace* is

$$D^- = \{f \in H : U_0(t) f = 0 \text{ in } |x| \le |t| + 1, t < 0\}.$$

Here $U_0(t)$ is the unitary group of the free wave equation (with $q_0 = 0$). We can decompose H as an orthogonal direct sum

$$H = D^+ \oplus K \oplus D^-. \tag{4.8}$$

Let P_+ be the orthogonal projection on the *orthogonal complement* of D^+, which is $D^- \oplus K$. P_- will denote the orthogonal projection onto $D^+ \oplus K$. Note that for $f \in D^\pm$, $f = 0$ in $|x| < 1$. Hence for any $f \in H$,

$$P_\pm f = f \quad \text{for} \quad |x| < 1. \tag{4.9}$$

Next we introduce the localized semigroup and evolution operator. We define

$$Z(t) = P_+ U(t) P_- \qquad \text{for} \quad t \geq 0. \tag{4.10}$$

Because $U(t)D^+ \subset D^+$ for $t \geq 0$, $Z(t)f = 0$ for $f \in D^\pm$. For $f \in K$, $Z(t)f \in K$. $Z(t)$ is in fact a contraction semigroup on K. We denote its generator by B, $Z(t) = \exp(tB)$.

Singularities of the solutions of (4.1) propagate with speed one and are unimpeded by the potential. Hence for $f \in H$, $U(t)f$ is smooth in $\{|x| < 1\}$ for $|t| > 2$. This implies that the spectrum of B is discrete, consisting of eigenvalues μ_j, with $Re(\mu_j) < 0$. Furthermore, any vertical strip in the complex plane contains at most a finite number of eigenvalues. The *scattering frequencies* for (4.1) are the complex numbers

$$\sigma_j = \nu_j + i\kappa_j$$

such that $i\sigma_j = \mu_j$. Note that $\kappa_j > 0$.

Because $Z(t)$ is compact, the eigenspace associated with each eigenvalue μ_j is finite dimensional. Assuming there are no generalized eigenvectors, solutions of (4.1) with data of compact support have an asymptotic expansion

$$u(x,t) \approx \sum_j e^{i\sigma_j t} v_j(x)$$

which approximates u in the local energy norm. The v_j are outgoing scattering eigensolutions of

$$-\Delta v + q_0(x)v = \sigma^2 v.$$

They satisfy the outgoing Sommerfeld radiation condition. The pair $[v_j, \mu_j v_j]$ does not belong to H because v_j grows exponentially as $|x| \to \infty$. However, for $|x| < 1$, the pair $[v_j, \mu_j v_j]$ agrees with an eigenvector φ_j of B with eigenvalue μ_j and

$$Z(t)\varphi_j = e^{\mu_j t}\varphi_j. \tag{4.11}$$

Now we define the localized evolution operator. Let

$$Z_\varepsilon(t,s) = P_+ V_\varepsilon(t,s) P_-.$$

Lemma 4.1. *$Z_\varepsilon(t,s)$ is a holomorphic family of evolution operators on K. Z_ε and Z satisfy the integral relation* (3.7).

Proof. That $Z_\varepsilon(t,s)$ is an evolution operator on K was shown in [1]. The holomorphic property is immediate because $\varepsilon \to V_\varepsilon(t,s)$ is holomorphic.

We need only verify that Z_ε and Z satisfy the integral relation (3.7). However, $U(t)$ and $V_\varepsilon(t,s)$ do satisfy this relation:

$$V_\varepsilon(t,s) = U(t-s) + \varepsilon \int_0^t U(t-\tau)p(\tau)QV_\varepsilon(\tau,s)ds.$$

Apply the projection P_+ to each term in this equation. Using the definitions of Z and Z_ε we find that for $f \in K$,

$$Z_\varepsilon(t,s)f = Z(t-s)f + \varepsilon \int_s^t Z(t-\tau)p(\tau)QV_\varepsilon(\tau,s)f d\tau.$$

But $QV_\varepsilon(\tau,s)f = QP_+V_\varepsilon(\tau,s)f = QZ_\varepsilon(\tau,s)f$ because $P_+g = g$ for $|x| < 1$. The lemma is proved.

Finally, after this lengthy preparation, we can apply the results of sections 2 and 3 to the semigroup $Z(t)$ and the evolution operator $Z_\varepsilon(t,s)$.

Let $\sigma_0 = \nu_0 + i\kappa_0$ be a scattering frequency of (4.1) with $\nu_0 > 0$. Thus $\mu_0 = i\sigma_0$ is an eigenvalue of B. $\lambda_0 = \exp(\mu_0 T) = \exp(i\sigma_0 T) = \exp(-\kappa_0 T) > 0$ is an eigenvalue of $Z(T)$.

Theorem 4.2. *Assume that the eigenvalue μ_0 has geometric and algebraic multiplicity m. Choose $T = 2\pi/\nu_0$, and assume that p is real valued, continuous, and satisfies* (3.2). *Then the scattering frequency σ_0 splits into s branches $\sigma_j(\varepsilon)$, $1 \le s \le m$. $\sigma_j(\varepsilon)$ is differentiable at $\varepsilon = 0$ and holomorphic in a punctured complex neighborhood of $\varepsilon = 0$.*

Proof. The general theory of section 2 applies here with $L(\varepsilon) = Z_\varepsilon(T,0)$. We need to verify that $\lambda_0 = \exp(\mu_0 T)$ is an isolated point of the spectrum of $L = L(0) = Z(T)$. But this follows because, as noted before, each vertical strip in the complex plane contains only a finite number of eigenvalues μ of B. This means that in each annulus centered at zero, $Z(T)$ has only a finite number of eigenvalues.

If $\lambda_j(\varepsilon)$ is a branch of the eigenvalues splitting from λ_0, then $\lambda_j'(0)$ exists. Now

$$\sigma_j(\varepsilon) = \frac{\log(\lambda_j(\varepsilon))}{iT}$$

are the branches of the scattering frequencies splitting from σ_0. They are holomorphic in a punctured neighborhood of $\varepsilon = 0$, and differentiable at $\varepsilon = 0$ with

$$\sigma_j'(0) = \frac{\lambda_j'(0)}{iT\lambda_0} = \frac{e^{\kappa_0 T}\lambda_j'(0)}{iT}. \tag{4.12}$$

This ends the proof of Theorem 4.2.

Corollary 4.3. *Let $\sigma_j(\varepsilon)$ be the branches of the scattering frequency which split from resonant scattering frequency σ_0. The $\sigma_j'(0)$ have complex values α such that if α is such a direction, then so is $-\bar{\alpha}$ and so is $-\alpha$.*

This is an immediate consequence of Theorem 3.2, the remark at the end of section 3, and (4.12).

Example 1. We specialize the discussion to the case where q_0 is a real constant, $q_0 > 0$ on $\{|x| < 1\}$, and $q_1(x) \equiv 1$ on $\{|x| < 1\}$. If σ_0 is a scattering frequency of (4.1) that corresponds to a spherically symmetric scattering eigenfunction, then the perturbed solution of (4.2) will also be spherically symmetric. Thus we restrict our attention to spherically symmetric solutions of (4.1) and (4.2). We make the change of dependent variable $z(r,t) = ru(r,t)$. z now satisfies

$$z_{tt} - z_{rr} = \begin{cases} -q_0 z, & 0 < r < 1, \\ 0, & r > 1, \end{cases}$$

$$z(0,t) = 0,$$

$$z(r,0) = f_1(r), \qquad z_t(r,0) = f_2(r).$$

Now if $f_1 = f_2 = 0$ for $r > 1$, then $z = z(t-r)$ for $t \geq 0$ and $r > 1$. Thus, in this case, the values of z are completely determined by the solution of the initial boundary value problem

$$z_{tt} - z_{rr} + q_0 z = 0, \qquad 0 < r < 1, \tag{4.13}$$

$$z(0,t) = 0, \qquad z_t + z_r = 0 \quad \text{on} \quad r = 1, \tag{4.14}$$

$$z(r,0) = f_1(r), \qquad z_t(r,0) = f_2(r).$$

Because $P_\pm f = f$ for $|x| < 1$, and $Z(t)f = P_+U(t)P_-f$, we see that when $f = 0$ for $|x| > 1$, $Z(t)f = U(t)f$ on $\{|x| < 1\}$. Consequently, in the case of spherical symmetry, the solutions of the localized evolution equation

$$\frac{dv}{dt} = Bv$$

are exactly the solutions of (4.13), (4.14), with $v = [z, z_t]$. The eigenfunctions of B are the spatial factors of the solutions of (4.13), (4.14) of the form $z(r,t) = \exp(\mu t)w(r)$ where w satisfies

$$-w_{rr} + q_0 + \mu^2 = 0,$$

$$w(0) = 0, \qquad \mu w(1) + w_r(1) = 0.$$

It is convenient to seek the solutions of this problem in the form $w(r) = \sin(\gamma r)$. γ and μ must satisfy

$$\gamma^2 + \mu^2 + q_0 = 0, \qquad \mu \sin(\gamma) + \gamma \cos(\gamma) = 0. \tag{4.15}$$

Writing μ in terms of a scattering frequency, $\mu = i\sigma_0$, we see that for large q_0, γ and σ_0 have the asymptotic approximations

$$\gamma(q_0) = n\pi(1 + i/\sqrt(q_0) - 1/q_0) + O(q_0^{-3/2}),$$

$$\sigma_0(q_0) = \sqrt{\gamma^2 + q_0}.$$

We have taken the roots γ and σ_0 in the first quadrant. There is another root $\bar{\gamma}$ and corresponding root $-\bar{\sigma_0}$, which corresponds to $\bar{\mu}$.

In this case, the eigenvalue $\mu = i\sigma_0$ is simple ($m = 1$). The eigenfunctions of B and B^* are

$$\varphi(r) = \begin{bmatrix} \sin(\gamma r)/r \\ i\sigma_0 \sin(\gamma r)/r \end{bmatrix} \quad \text{and} \quad \psi(r) = \begin{bmatrix} \sin(\bar{\gamma})/r \\ i\bar{\sigma}_0 \sin(\bar{\gamma} r)/r \end{bmatrix}, \qquad 0 < r < 1.$$

The matrices M and N are 2×2 and the characteristic equation $\det(\rho N - M) = 0$ has the roots

$$\rho = \pm\frac{|m_{1,1}|}{|n_{1,1}|}.$$

Here

$$n_{1,1} = (\varphi, \psi), \qquad \text{and} \quad m_{1,1} = e^{-\kappa_0 T} p_2(Q\bar{\varphi}, \psi).$$

Thus the scattering frequency σ_0 splits into two branches with

$$\sigma'(0) = \pm i\frac{|p_2(Q(\bar{\varphi}, \psi)|}{T|(\varphi, \psi)|}.$$

Remark. Computations show that when $p_2 \neq 0$, the branches of the resonant scattering frequency move vertically on the line $Re(\sigma) = Re(\sigma_0)$ as $\varepsilon \uparrow$, and eventually one of the branches crosses the real axis. This means that for $\varepsilon > 0$ sufficiently large, there are outgoing eigensolutions of the perturbed problem (4.2) that grow exponentially as $t \to \infty$. We hope to prove this in the future.

LOW-FREQUENCY ELECTROMAGNETIC SCATTERING*

H. AMMARI† AND J.-C. NÉDÉLEC†

Abstract. The main result of this paper is to reduce the calculation of higher-order terms in the asymptotic expansions of the electric and magnetic fields at low frequencies to the solutions of certain canonical problems. Our approach is based on coupling the power series representation of the scattered fields with expansion of the exact nonlocal radiation condition. We also provide a new and simple variational proof of the convergence of the electric and magnetic fields solutions of the scattering problem for the Maxwell equations as the frequency goes to zero. Besides its theoretical interest, our analysis is motivated by its application to the numerical computation of the higher-order terms. These higher-order terms may be combined to Padé approximations to enlarge the domain of applicability of the low-frequency scattering to predict more accurately the reponse of diffraction problems for heteregeneous Maxwell's equations in the resonance region where the wavelength and the dimension of the dielectric material are of the same order.

1. Introduction and statement of the problem.

The scattering of electromagnetic waves from bounded objects whose dimensions are small compared with the length of the incident wave has been the subject of considerable study for more than a century. This problem is of interest in geophysics, astrophysics, electrical engineering, physics of the atmosphere and ocean, medicine, biology, and other fields. The study of wave scattering at low frequencies was pioneered by Rayleigh [33], who continued this work until his death. His contributions in this area provide the foundation on which almost all subsequent work is based. A low-frequency asymptotic for Maxwell's boundary-value problem and transmission problem has been given, for instance, by Müller and Niemeyer [26], Stevenson [34], Kleinman [19], Werner [41] and [39], Picard [29], Kleinman–Senior [20], Weck and Witsch [38], Kress [21], Ramm et al. [32], Ramm [30], and Ramm–Somersalo [31]. Kleinman and Senior systematized the calculation of the dominant term in the low-frequency limit for electromagnetic problems involving impenetrable, penetrable, nonlossy, and lossy obstacles. With boundary integral methods, Werner [40], [42], [41], [39] and Kress [21] obtained the limit of the solution to the scattering problem by a perfectly conducting object for Maxwell's equations. Kriegsmann and Reiss [22] used matched asymptotic expansions to align together the local and far-field approximations at low frequencies.

One of our main motivations in this paper is to reduce the calculation of the higher-order terms which are the Taylor coefficients in the asymptotic expansion of the electric and magnetic fields with respect to the frequency. By combining these higher-order terms and Padé approximations, we may enlarge the domain of applicability of the low-frequency scattering to predict more accurately the response of diffraction problems for heterogeneous Maxwell's equations in the resonance region where the wavelength and the dimension of the dielectric material are of the same order. We

may also gain insight into the spectrum of singularities of the fields as functions of the frequency: the set of resonances. This program is in the spirit of "the method of variation of boundaries" introduced recently by Bruno and Reitich [6], [7], [8], [9], [10], [11]. Their new method is very attractive. Many numerical experiments show that it has several orders of magnitude more accurate than other classical methods such as integral or variational formalisms. The implementation of our "null-frequency method" is in progress and numerical results in the resonance region for Maxwell's equations as well as the Helmholtz equation will be published in a forthcoming paper.

In the present paper we restrict ourselves to presenting, in some detail, the derivation and well-posedness of higher-order terms and the proof of convergence of the electric and magnetic fields as the frequency goes to zero by a simple variational method.

In fact, our present work is closely related to the work of Picard [29] who proved the convergence for nonhomogeneous Maxwell's equations using Hilbert space concepts. The approach of Picard [29] is based on the limiting absorption principle for a modified first-order Maxwell system to overcome the fact that the case $\omega = 0$ is embedded in the continuous spectrum of the modified first-order Maxwell operator. He reformulated Maxwell's equations in the following way:

$$\Big(M + N - \omega\Big)\, U^\omega \;=\; F^\omega,$$

where

$$M = \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & \dfrac{i}{\varepsilon}\,\overrightarrow{\mathrm{curl}} & 0 \\ 0 & \dfrac{i}{\mu}\,\overrightarrow{\mathrm{curl}} & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}, \quad N = \begin{pmatrix} 0 & i\,\mathrm{div}\,\varepsilon & 0 & 0 \\ i\,\overrightarrow{\mathrm{grad}} & 0 & 0 & 0 \\ 0 & 0 & 0 & i\,\overrightarrow{\mathrm{grad}} \\ 0 & 0 & i\,\mathrm{div}\,\mu & 0 \end{pmatrix},$$

and

$$U^\omega = \begin{pmatrix} 0 \\ E^\omega \\ H^\omega \\ 0 \end{pmatrix}.$$

Here ε is the electric permittivity, μ the magnetic permeability, E^ω the electric field, H^ω the magnetic field, and F^ω a given vector function with a bounded support. His method cannot be easily extended to obtain the rate of the convergence of the electric and magnetic fields with higher-order terms since the assumption of the support of F^ω is crucial for his proof (Theorem 3, p. 70). In none of the works cited above is a variational method for calculating the higher-order terms given or convergence with these terms analyzed. This is our basic aim in the present paper. We also provide a new and simple variational proof of the convergence of the electric and magnetic fields as the frequency goes to zero. Our approach is based on coupling the power series representation of the scattered fields with expansion of the exact nonlocal radiation condition. To the best of our knowledge, this approach is new; it is different from those mentioned above.

We first formulate the scattering problem equivalently on a ball B_R of radius R containing the inhomogeneity by making use of an adequate Steklov–Poincaré operator on the sphere $S_R = \partial B_R$ called, throughout what follows, the electromagnetic operator. Either the expression of this pseudodifferential operator or the variational formulation used here for Maxwell's equations is now well known (see, for instance, [17] and [27]). Then, the electric and magnetic fields, as well as the electromagnetic operator, are expanded in a power series with respect to the frequency. Making use of some properties of the Hankel functions, we show that in the asymptotic expansion of the electromagnetic operator with respect to the frequency, all the coefficients which are pseudodifferential operators are of an order less than the order of the electromagnetic operator. This important result is an essential tool which will permit us to derive the appropriate boundary conditions satisfied by the higher order terms of the electric and magnetic fields on the sphere S_R. These boundary conditions on the fictive surface S_R complete the reduction of the calculation of the higher-order terms in the asymptotic expansions of the electric and magnetic fields to two canonical problems which are uniquely solvable. A variational proof of the convergence with these higher-order terms will be given in the last part of this paper. Let us note that in addition to the difficulty coming from the asymptotic expansion of the electromagnetic operator, there is another difficulty that is due to a lack of coerciveness in the variational formulation. This difficulty is overcome by using a compactness result (see, for example, Lemma 5.2).

The extension of this approach to handle scattering problems by dielectric objects containing conducting bodies is presented in [4] where the dependence of the asymptotics on the topological properties of the conductors is completely shown.

Let us now introduce the scattering problem. Suppose that a bounded inhomogeneity characterized by permittivity ε and permeability μ is illuminated by a time-harmonic electromagnetic wave given by $(E^{in}_\omega, H^{in}_\omega)$ (where E^{in}_ω is the electric field and H^{in}_ω is the magnetic field). The incoming wave $(E^{in}_\omega, H^{in}_\omega)$ is assumed to be a classical solution of the Maxwell system

$$\begin{cases} \overrightarrow{\text{curl}}\, H^{in}_\omega \;=\; -i\omega\varepsilon_0\, E^{in}_\omega, \\ \overrightarrow{\text{curl}}\, E^{in}_\omega \;=\; i\omega\mu_0\, H^{in}_\omega \end{cases}$$

in all of R^3 except possibly for a finite number of points located outside a sphere strictly containing the inhomogeneity. This incoming field will interact with the inhomogeneity to give rise to a scattered field $(E^{sc}_\omega, H^{sc}_\omega)$. Let ε, μ be two functions of the spatial variable x; ε_0 and μ_0 two positive constants; and $r = |x|$. The total field (E^ω, H^ω) satisfies the time-harmonic Maxwell system

$$\begin{cases} \overrightarrow{\text{curl}}\, H^\omega \;=\; -i\omega\varepsilon\, E^\omega \quad \text{in } R^3, \\ \overrightarrow{\text{curl}}\, E^\omega \;=\; i\omega\mu\, H^\omega \quad \text{in } R^3, \\ H^\omega \;=\; H^{sc}_\omega + H^{in}_\omega \quad \text{in } R^3, \\ E^\omega \;=\; E^{sc}_\omega + E^{in}_\omega \quad \text{in } R^3, \\ \lim_{r\to+\infty}\left(\sqrt{\mu_0}\, H^{sc}_\omega \wedge x - r\sqrt{\varepsilon_0}\, E^{sc}_\omega\right) \;=\; 0. \end{cases} \tag{1.1}$$

We assume that the electric permittivity and the magnetic permeability, ε and μ, respectively, are in $L^\infty(R^3)$. In the next section, we will add some restrictive conditions regarding the regularity of these coefficients to ensure the uniqueness of a solution to (1.1). We also assume that the inhomogeneity is bounded so that there exists a constant $R_0 > 0$ such that $\varepsilon(x) = \varepsilon_0$ and $\mu(x) = \mu_0$ if $r = |x| \geq R_0$. The support of the function $\varepsilon - \varepsilon_0$, denoted by $\mathrm{Supp}(\varepsilon - \varepsilon_0)$, and that of $\mu - \mu_0$ are included in the ball $B_{R_0} = \{|x| < R_0\}$.

For some fixed $R > R_0$ we define the ball $B_R = \{x \in R^3, |x| < R\}$ and the sphere $S_R = \{x \in R^3, |x| = R\}$.

The present study is concerned with the analysis of the behavior of the fields (E^ω, H^ω) solutions of (1.1) as the frequency ω tends to zero. Our aim in this paper is to prove the convergence of the fields (E^ω, H^ω) and to reduce the calculation of higher-order terms to solutions of certain canonical problems. A similar program was carried out by the authors (with Laouadi) for the scattering problem from a small conductor embedded in a homogeneous chiral media [3]. For this problem, the authors employed representations of electric and magnetic fields to reformulate the scattering problem as an integral equation over the scattering surface and to represent the fields in terms of surface fields. Using a Hodge decomposition of the tangent fields, the authors characterized the dependence of the asymptotics on the topological properties of the scatterer and have shown the effect of the chirality admittance. The extension of the present study to the scattering of electromagnetic waves in a chiral media from a small inhomogeneity does not lead to any specific difficulty apart from much more cumbersome notations and calculations.

Now we introduce some standard notation. For any smooth vector field w, we denote by w_{S_R} its tangential component on S_R:

$$w_{S_R} = -n \wedge (n \wedge w) \quad \text{on } S_R.$$

For any smooth function f or any vector field u defined on S_R, we get an extension of each one to $R^3 \setminus \overline{B_R}$ by setting

$$\forall\, x \in R^3 \setminus \overline{B_R}, \quad \tilde{f}(x) = f\left(\frac{x}{|x|}\right), \quad \tilde{u}(x) = u\left(\frac{x}{|x|}\right).$$

We also introduce the following boundary differential operators:

the tangential gradient of a function f: $\overrightarrow{\mathrm{grad}}_{S_R} f = \overrightarrow{\mathrm{grad}}\, \tilde{f}|_{S_R}$,

the surface divergence of a field u: $\mathrm{div}_{S_R} u = \mathrm{div}\, \tilde{u}|_{S_R}$,

the vector rotational of a function: $\overrightarrow{\mathrm{curl}}_{S_R} f = \overrightarrow{\mathrm{curl}}\, (fn)|_{S_R}$,

the scalar rotational of a vector: $\mathrm{curl}_{S_R} u = n \,.\, \overrightarrow{\mathrm{curl}}\, \tilde{u}|_{S_R}$,

the Laplace–Beltrami operator on S_R defined on scalar functions by

$$\Delta_{S_R} f = \mathrm{div}_{S_R} \overrightarrow{\mathrm{grad}}_{S_R} f = -\mathrm{curl}_{S_R} \overrightarrow{\mathrm{curl}}_{S_R} f.$$

To state our boundary-value problem in a suitable mathematical form, we shall use the following notation for the usual functional spaces [15], [35]:

$\mathcal{D}'(B_R)$ is the space of distributions in B_R.

$L^2(B_R)$ is the space of complex square integrable functions defined in B_R.

$L^\infty(R^3)$ is the space of bounded functions defined in R^3.

$H^1(B_R) = \{\varphi \in L^2(B_R), \overrightarrow{\mathrm{grad}}\, \varphi \in (L^2(B_R))^3\}$.

$H^1_0(B_R) = \{\varphi \in H^1(B_R), \varphi = 0 \,\mathrm{on}\, S_R\}$.

$H(\mathrm{curl}, B_R) = \{u \in (L^2(B_R))^3, \overrightarrow{\mathrm{curl}}\, u \in (L^2(B_R))^3\}$.

$H_0(\mathrm{curl}, B_R) = \{\ u \in H(\mathrm{curl}, B_R), u \wedge n = 0 \text{ on } B_R\ \}$.

$TL^2(S_R) = \{c \in (L^2(S_R))^3, c \,.\, n = 0\}$.

$TH^s(S_R) = \{c \in (H^s(S_R))^3, c\,.\,n = 0\}$.

$TH^{-1/2}(\mathrm{curl}, S_R) = \{c \in (H^{-1/2}(S_R))^3, c\,.\,n = 0, \mathrm{curl}_{\partial\Omega}\, c \in H^{-1/2}(S_R)\}$.

$TH^{-1/2}(\mathrm{div}, S_R) = \{c \in (H^{-1/2}(S_R))^3, c\,.\,n = 0, \mathrm{div}_{S_R}\, c \in H^{-1/2}(S_R)\}$.

$TH^{-1/2}(\mathrm{curl}, S_R)$ and $TH^{-1/2}(\mathrm{div}, S_R)$ are Hilbert spaces. Finally, we recall without proof the following well-known duality result due to Paquet [28]: $TH^{-1/2}(\mathrm{curl}, S_R) = (TH^{-1/2}(\mathrm{div}, S_R))'$.

2. The exterior electromagnetic operator for Maxwell's equations. In this section we give an explicit construction of the electromagnetic operator T^ω defined for a tangential vector field $g^\omega \in TH^{-1/2}(\mathrm{curl}, S_R)$ by

$$T^\omega(g^\omega) = \mathcal{H}^\omega \wedge n, \tag{2.1}$$

where

$$\begin{cases} \overrightarrow{\mathrm{curl}}\,\mathcal{H}^\omega = -i\omega\varepsilon_0\,\mathcal{E}^\omega \quad \text{in } R^3 \setminus \overline{B_R}, \\ \overrightarrow{\mathrm{curl}}\,\mathcal{E}^\omega = i\omega\mu_0\,\mathcal{H}^\omega \quad \text{in } R^3 \setminus \overline{B_R}, \\ \mathcal{E}^\omega_{S_R} = g^\omega \quad \text{on } S_R, \\ \lim_{r\to+\infty}\left(\sqrt{\mu_0}\,\mathcal{H}^\omega \wedge x - r\sqrt{\varepsilon_0}\,\mathcal{E}^\omega\right) = 0. \end{cases} \tag{2.2}$$

In order to prove the convergence of solutions to Maxwell's equations (1.1) as $\omega \to 0$, we also need the operator D^ω defined by

$$D^\omega : g^\omega \in TH^{-1/2}(\mathrm{curl}, S_R) \mapsto \mathcal{E}^\omega \cdot n. \tag{2.3}$$

Since $\mathcal{E}^\omega$ satisfies

$$\mathcal{E}^\omega = \frac{i}{\omega\varepsilon_0}\overrightarrow{\mathrm{curl}}\mathcal{H}^\omega,$$

it follows that

$$D^\omega(g^\omega) = \frac{i}{\omega\varepsilon_0}\mathrm{div}_{S_R} T^\omega(g^\omega),$$

and then the explicit expression of the operator D^ω will be deduced from that of the operator T^ω. Our basic aim in this section is to analyze the dependence of both the operators T^ω and D^ω on the frequency ω. It should be noted that a similar asymptotic analysis was considered by Lassas [23] from the point of view of inverse problems.

We start by representing the boundary data in terms of suitable vector basis functions on S_R. Following [13], let $(Y_l^m)_{-l\le m\le l}$ be an orthonormal sequence of spherical harmonics of order l on the unit sphere Σ, normalized such that

$$\int_\Sigma Y_l^m \cdot \overline{Y}_{l'}^{m'} = \delta_{l,l'}\,\delta_{m,m'}.$$

The basis functions for tangential fields on S_R are then

$$G_l^m = \frac{1}{\sqrt{l(l+1)}}\,\overrightarrow{\mathrm{grad}}_{S_R}\,Y_l^m \text{ and } R_l^m = n \wedge G_l^m \quad \text{for } -l \le m \le l,\ l \ge 1.$$

The tangential vector fields G_l^m and R_l^m are an orthonormal basis on the unit sphere (in the L^2 inner product). It follows that any tangential vector field $g \in TL^2(S_R)$ can be written in the form

$$g = \sum_{l=1}^{+\infty} \sum_{m=-l}^{l} \alpha_l^m \, G_l^m + \beta_l^m \, R_l^m. \tag{2.4}$$

Spaces of either scalar or vector functions on S_R can be characterized by the summability of weighted sums of their expansion coefficients. Using the series coefficients (see [17]), the norm on the space $TH^s(S_R)$ can be characterized by

$$||g||^2_{TH^s(S_R)} = \sum_{l=1}^{+\infty} \sum_{m=-l}^{l} \Big(1 + l(l+1)\Big)^s \Big(|\alpha_l^m|^2 + |\beta_l^m|^2\Big);$$

the norm on the space $H^s(S_R)$ by

$$||\varphi||^2_{H^s(S_R)} = \sum_{l=1}^{+\infty} \sum_{m=-l}^{l} \Big(1 + l(l+1)\Big)^s |\varphi_l^m|^2,$$

where

$$\varphi = \sum_{l=1}^{+\infty} \sum_{m=-l}^{l} \varphi_l^m \, Y_l^m;$$

the norm on the space $TH^{-1/2}(\text{curl}, S_R)$ by

$$||g||^2_{TH^{-1/2}(\text{curl},S_R)} = \sum_{l=1}^{+\infty} \sum_{m=-l}^{l} \sqrt{1 + l(l+1)}\, |\beta_l^m|^2 + \frac{1}{\sqrt{1 + l(l+1)}}\, |\alpha_l^m|^2;$$

and the norm on the space $TH^{-1/2}(\text{div}, S_R)$ by

$$||g||^2_{TH^{-1/2}(\text{div},S_R)} = \sum_{l=1}^{+\infty} \sum_{m=-l}^{l} \sqrt{1 + l(l+1)}\, |\alpha_l^m|^2 + \frac{1}{\sqrt{1 + l(l+1)}}\, |\beta_l^m|^2.$$

Throughout this paper, we assume for simplicity in exposition that $\varepsilon_0 \, \mu_0 = 1$ and $R = 1$. Now, if we expand the tangential vector field g^ω in the form

$$g^\omega = \sum_{l=1}^{+\infty} \sum_{m=-l}^{l} \alpha_l^m(\omega) \, G_l^m + \beta_l^m(\omega) \, R_l^m, \tag{2.5}$$

we have the following explicit representation for $T^\omega(g^\omega)$ (see Appendix A):

$$T^\omega(g^\omega) = \sqrt{\frac{\varepsilon_0}{\mu_0}} \sum_{l=1}^{+\infty} \sum_{m=-l}^{l} \frac{\alpha_l^m(\omega)}{\gamma_l(\omega)} \, G_l^m + \frac{\beta_l^m(\omega)\gamma_l(\omega)}{i\omega} \, R_l^m, \tag{2.6}$$

where

$$\gamma_l(\omega) = 1 + \omega \frac{(h_l^{(1)})'(\omega)}{h_l^{(1)}(\omega)}. \tag{2.7}$$

From (2.6), we deduce that the operator D^ω introduced in (2.3) is given by

$$D^\omega(g^\omega) = \sum_{l=1}^{+\infty} \sum_{m=-l}^{l} \frac{\sqrt{l(l+1)}}{\gamma_l(\omega)} \alpha_l^m(\omega) Y_l^m \tag{2.8}$$

for any $g^\omega \in TH^{-1/2}(\text{curl}, S_R)$ in the form (2.5).

Now, we summarize the mapping properties of the exterior electromagnetic operator T^ω.

LEMMA 2.1. *There exists a constant C such that for any $g \in TH^{-1/2}(\text{curl}, S_R)$ the following inequality holds:*

$$||T^\omega(g)||_{TH^{-1/2}(\text{div},S_R)} \leq C\, ||g||_{TH^{-1/2}(\text{curl},S_R)}. \tag{2.9}$$

Furthermore,

$$\Re e \Big(T^\omega(g), g\Big) > 0 \tag{2.10}$$

for any $g \neq 0$ in $TH^{-1/2}(\text{curl}, S_R)$, where $(,)$ denotes the duality between $TH^{-1/2}(\text{div}, S_R)$ and $TH^{-1/2}(\text{curl}, S_R)$.

Proof. (2.9) is proved in [17]. Thus, only the last part of the lemma needs proving. From

$$\Big(T^\omega(g), g\Big) = \sqrt{\frac{\varepsilon_0}{\mu_0}} \sum_{l=1}^{+\infty} \sum_{m=-l}^{l} i\omega \frac{|\alpha_l^m|^2}{\gamma_l(\omega)} + \frac{|\beta_l^m|^2 \gamma_l(\omega)}{i\omega},$$

we obtain that

$$\Re e \Big(T^\omega(g), g\Big) = \sqrt{\frac{\varepsilon_0}{\mu_0}} \sum_{l=1}^{+\infty} \sum_{m=-l}^{l} \omega \frac{|\alpha_l^m|^2}{|\gamma_l(\omega)|^2} \Im m\, (\gamma_l(\omega)) + \frac{|\beta_l^m|^2}{\omega} \Im m\, (\gamma_l(\omega)).$$

The fact that $\Im m\,(\gamma_l(\omega)) > 0$ (see, for instance, [27]) implies that (2.9) holds for any $g \neq 0$ in $TH^{-1/2}(\text{curl}, S_R)$. □

Our next result shows that D^ω is continuous as a map

$$D^\omega : TH^{-1/2}(\text{curl}, S_R) \mapsto H^{-1/2}(S_R).$$

LEMMA 2.2. *There exists a constant C such that for any $g \in TH^{-1/2}(\text{curl}, S_R)$ the following inequality holds:*

$$||D^\omega(g)||_{H^{-1/2}(S_R)} \leq C\, ||g||_{TH^{-1/2}(\text{curl},S_R)}. \tag{2.11}$$

Proof. Using the fact that there exist positive constants C_1 and C_2 such that $\forall\, l$ (see, for instance, [13])

$$C_1\, l \leq |\gamma_l(\omega)| \leq C_2\, l,$$

we obtain

$$\begin{aligned} ||D^\omega(g)||^2_{H^{-1/2}(S_R)} &= \sum_{l=1}^{+\infty} \sum_{m=-l}^{l} \frac{l(l+1)}{|\gamma_l|^2(\omega)} \frac{1}{\sqrt{l(l+1)}} |\alpha_l^m|^2, \\ &\leq C \sum_{l=1}^{+\infty} \sum_{m=-l}^{l} \frac{1}{\sqrt{l(l+1)}} |\alpha_l^m|^2, \\ &\leq C\, ||g||^2_{TH^{-1/2}(\text{curl},S_R)}, \end{aligned}$$

where the constant C is independent of g. The dependence of the constant C on the frequency ω can be explicitly characterized. ▯

Now we wish to analyze the asymptotic behavior of the operators T^ω and D^ω as the frequency ω tends to zero. We start by recalling some well-known results on the logarithmic derivative of the Hankel function $h_l^{(1)}$. Following [27], we have

$$\omega \frac{(h_l^{(1)})'(\omega)}{h_l^{(1)}(\omega)} = -\frac{p_l(\omega)}{q_l(\omega)} + i\frac{\omega}{q_l(\omega)},$$

where

$$\begin{cases} p_l(t) = c_l^0 + 2c_l^1 \dfrac{1}{t^2} + \cdots + (l+1)c_l^l \dfrac{1}{t^{2l}}, \\ q_l(t) = c_l^0 + c_l^1 \dfrac{1}{t^2} + \cdots + c_l^l \dfrac{1}{t^{2l}}, \end{cases}$$

and

$$c_l^m = \frac{(m+l)!(2m)!}{4^m (m!)^2 (l-m)!}.$$

Therefore, we can write $\gamma_l(\omega)$ in the form

$$\gamma_l(\omega) = 1 - \frac{(l+1)c_l^l + \cdots + (\omega)^{2l} c_l^0}{c_l^l + \cdots + (\omega)^{2l} c_l^0} + i\frac{(\omega)^{2l+1}}{c_l^l + \cdots + (\omega)^{2l} c_l^0}. \tag{2.12}$$

First, we have the following lemmas. The proofs are given in Appendix B.

Lemma 2.3. *The following inequality holds:*

$$\frac{(l+1-m)\, c_l^{l-m}}{c_l^l} < 1 \tag{2.13}$$

$\forall\, l \geq 1$ *and* $m = 1$ *to* l.

Lemma 2.4. *There exist* ω_0 *and a constant* C *independent of* ω *and* l *such that for* $0 < \omega < \omega_0$ *and* $l \geq 1$ *the following estimate holds:*

$$\left|\frac{1}{\gamma_l(\omega)} + \frac{1}{l}\right| \leq \frac{C}{l^2}\,\omega. \tag{2.14}$$

Next, from (2.12) and (2.13), we obtain the following results.

Lemma 2.5. *There exists* $\omega_0 > 0$ *such that*

$$\gamma_l(\omega) = \sum_{j=0}^{+\infty} \gamma_l^j \omega^j \quad \forall\, 0 < \omega < \omega_0$$

$\forall\, l \geq 1$ *(*ω_0 *is independent of* l*). Furthermore, for any* $j \geq 1$ *there exists a constant* C_j *independent of* l *such that*

$$\left|\frac{\gamma_l^j}{\gamma_l^0}\right| \leq C_j \quad \forall\, l \geq 1. \tag{2.15}$$

LEMMA 2.6. *Let $\left(\delta_l^j\right)_{j\geq 0, l\geq 1}$ be defined by*

$$\frac{1}{\gamma_l(\omega)} = \frac{1}{\gamma_l^0}\sum_{j=0}^{+\infty}\delta_l^j\omega^j. \tag{2.16}$$

For any $j \geq 1$ there exists a constant C_j independent of l such that

$$|\delta_l^j| \leq C_j \quad \forall\, l \geq 1. \tag{2.17}$$

With the help of these results, we obtain the following two results which are crucial for our asymptotic analysis at low frequencies.

LEMMA 2.7. *The operator*

$$D^\omega - D : TH^{-1/2}(\mathrm{curl}, S_R) \mapsto H^{-1/2}(S_R)$$

is compact, where D is defined for any $g \in TH^{-1/2}(\mathrm{curl}, S_R)$ in the form (2.4) *by*

$$D(g) = -\sum_{l=1}^{+\infty}\sum_{m=-l}^{l}\sqrt{\frac{l+1}{l}}\,\alpha_l^m\,Y_l^m.$$

Furthermore, there exists ω_0 such that for $0 < \omega < \omega_0$ the following inequality holds:

$$||(D^\omega - D)(g)||_{H^{1/2}(S_R)} \leq C\,\omega\,||g||_{TH^{-1/2}(\mathrm{curl}, S_R)},$$

where the constant C independent of ω.

Proof. Let g be in $TH^{-1/2}(\mathrm{curl}, S_R)$. We have

$$(D^\omega - D)(g) = \sum_{l=1}^{+\infty}\sum_{m=-l}^{l}\sqrt{l(l+1)}\left(\frac{1}{\gamma_l(\omega)} + \frac{1}{l}\right)\alpha_l^m\,Y_l^m.$$

Therefore, by (2.14) we obtain that there exists a constant C independent of ω such that

$$\begin{aligned}||(D^\omega - D)(g)||^2_{H^{1/2}(S_R)} &\leq C\,\omega^2\sum_{l=1}^{+\infty}\sum_{m=-l}^{l}\sqrt{1+l(l+1)}\,\frac{1}{l^2}\,|\alpha_l^m|^2\\ &\leq 3C\,\omega^2\sum_{l=1}^{+\infty}\sum_{m=-l}^{l}\frac{1}{\sqrt{1+l(l+1)}}\,|\alpha_l^m|^2 + \sqrt{1+l(l+1)}\,|\beta_l^m|^2\\ &\leq 3C\,\omega^2\,||g||^2_{TH^{-1/2}(\mathrm{curl}, S_R)},\end{aligned}$$

and thus we have the claim. □

The operator D is then in some sense the limit of the operator D^ω as ω tends to zero. Now, by using Lemma 2.5, we also verify without any difficulty that we have the following.

LEMMA 2.8. *There exists a constant C such that for any $g \in TH^{-1/2}(\mathrm{curl}, S_R)$ the following inequality holds:*

$$||T_j^\omega(g)||_{TH^{-1/2}(\mathrm{div}, S_R)} \leq C\,||g||_{TH^{-1/2}(\mathrm{curl}, S_R)}, \tag{2.18}$$

where the operator T_j^ω *is defined for any* $g \in TH^{-1/2}(\mathrm{curl}, S_R)$ *in the form* (2.4) *by*

$$\begin{aligned} T_j^\omega(g) &= \sqrt{\frac{\varepsilon_0}{\mu_0}} \sum_{l=1}^{+\infty} \sum_{m=-l}^{l} i\omega \, \frac{\alpha_l^m}{\gamma_l^0} \, \sum_{p=0}^{j} \delta_l^p \omega^p \, G_l^m \\ &\qquad + \frac{\beta_l^m \gamma_l^0}{i\omega} \sum_{p=0}^{j} \frac{\gamma_l^p}{\gamma_l^0} \omega^p \, R_l^m . \end{aligned}$$

Proof. Let g be in $TH^{-1/2}(\mathrm{curl}, S_R)$. We have

$$\begin{aligned} ||T_j^\omega(g)||^2_{TH^{-1/2}(\mathrm{div}, S_R)} &= \frac{\varepsilon_0}{\mu_0} \sum_{l=1}^{+\infty} \sum_{m=-l}^{l} \sqrt{1 + l(l+1)} \, \omega^2 \, \left| \frac{\alpha_l^m}{\gamma_l^0} \right|^2 \, \left| \sum_{p=0}^{j} \delta_l^p \omega^p \right|^2 \\ &\qquad + \frac{1}{\sqrt{1 + l(l+1)}} \, \left| \frac{\beta_l^m \gamma_l^0}{\omega} \right|^2 \left| \sum_{p=0}^{j} \frac{\gamma_l^p}{\gamma_l^0} \omega^p \right|^2 . \end{aligned}$$

Therefore, from Lemmas 2.5 and 2.6, we can show that there exists a constant C_j such that

$$\begin{aligned} ||T_j^\omega(g)||^2_{TH^{-1/2}(\mathrm{div}, S_R)} &\leq C_j \sum_{l=1}^{+\infty} \sum_{m=-l}^{l} \frac{\sqrt{1 + l(l+1)}}{l^2} \, |\alpha_l^m|^2 + \frac{l^2}{\sqrt{1 + l(l+1)}} \, |\beta_l^m|^2 \\ &\leq 3C_j \sum_{l=1}^{+\infty} \sum_{m=-l}^{l} \frac{1}{\sqrt{1 + l(l+1)}} \, |\alpha_l^m|^2 + \sqrt{1 + l(l+1)} \, |\beta_l^m|^2 \\ &\leq 3C_j \, ||g||^2_{TH^{-1/2}(\mathrm{curl}, S_R)}, \end{aligned}$$

and thus we have the claim. $\square$

3. The variational problem for Maxwell's equations. Several proofs of the existence of solutions to the scattering problem for nonhomogeneous Maxwell's equations in unbounded domains are now known. The proof of the existence and uniqueness of a solution for the case when ε and μ are in $\mathcal{C}^2$ was first given by Müller [25]. Abboud and Nédélec [2] proved existence and uniqueness for Maxwell's equations under the same regularity assumptions on the dielectric coefficients ε and μ but they are possibly discontinuous across the interface dielectric medium/exterior domain. They used the standard Sobolev space H^1 as a basis of their variational problem. Costabel [14] used another modified bilinear form coercive over H^1 to establish the existence of a solution in a bounded domain. Kirsch and Monk [17], [18] obtained a simple variational proof of the existence of a solution based on the use of the space $H(\mathrm{curl}, \Omega)$ where Ω is a smooth bounded domain. The crucial points in their analysis are the Hodge decomposition of the space $H(\mathrm{curl}, \Omega)$ and the compact embedding of the set $\{u \in H(\mathrm{curl}, \Omega) : \int_\Omega \varepsilon u \cdot \overrightarrow{\mathrm{grad}} \, \varphi = 0 \quad \forall \varphi \in H^1(\Omega)\}$ into $(L^2(\Omega))^3$. Note that the use of the Hodge decomposition of the space $H(\mathrm{curl}, \Omega)$ is a well-known idea for the study of Maxwell's equations in bounded domains (see Birman and Solomyak [5] and Leis [24]). Abboud [1] has analyzed the scattering of electromagnetic waves from periodic gratings in three dimensions. His method is very close to [17] but the compactness result that he used is quite different. More recently, Hazard and Lenoir [16] obtained by adding a regularizing term such as $\overrightarrow{\mathrm{grad}}\,\mathrm{div}$ in the time-harmonic Maxwell's equations an elliptic problem similar to the vector Helmholtz equation.

For the uniqueness of a solution to the scattering problem from inhomogeneities, several results are also known, but the list of such results is still incomplete. In fact, under certain regularity assumptions on ε and μ, namely ε and μ are $\mathcal{C}^{1,1}$ in every subdomain of the dielectric medium, it can be shown that a principle of unique continuation is valid (see Vogelsang [36], Colton and Kress [12]). As a consequence we would have that any solution of Maxwell's equations is unique. For our purposes, since ε and μ are assumed to be in $L^\infty(B_R)$, we have to suppose that the Maxwell system (1.1) has at most only one solution.

Now, following Kirsch and Monk [18], for instance, to obtain a variational formulation of the Maxwell system (1.1) in $H(\text{curl}, B_R)$ we shall first eliminate the magnetic field H^ω from (1.1). We simply substitute $H^\omega = \frac{1}{i\omega\mu}\overrightarrow{\text{curl}}\, E^\omega$ into $\overrightarrow{\text{curl}}\, H^\omega = -i\omega\varepsilon E^\omega$ to obtain

$$\overrightarrow{\text{curl}}\, \frac{1}{\mu}\, \overrightarrow{\text{curl}}\, E^\omega - \omega^2 \varepsilon\, E^\omega \;=\; 0 \quad \text{in } B_R. \tag{3.1}$$

If we multiply (3.1) by a test function Φ in $H(\text{curl}, B_R)$, integrate over B_R, and using integration by parts, we obtain

$$\int_{B_R} \frac{1}{\mu}\, \overrightarrow{\text{curl}}\, E^\omega \,\cdot\, \overrightarrow{\text{curl}}\, \Phi - \omega^2 \int_{B_R} \varepsilon\, E^\omega \,\cdot\, \Phi - \Big(\overrightarrow{\text{curl}}\, E^\omega \,\wedge\, n, \Phi_{S_R}\Big) \;=\; 0, \tag{3.2}$$

where the last term in this equation is to take, in the sense of the duality $TH^{-1/2}(\text{div}, S_R)$, $TH^{-1/2}(\text{curl}, S_R)$. Now, using the definition of the electromagnetic operator T^ω, we may write

$$\begin{aligned} &\int_{B_R} \frac{1}{\mu}\, \overrightarrow{\text{curl}}\, E^\omega \,\cdot\, \overrightarrow{\text{curl}}\, \Phi - \omega^2 \int_{B_R} \varepsilon\, E^\omega \,\cdot\, \Phi \\ &-i\omega\mu_0 \Big(T^\omega(E^\omega_{S_R}), \Phi_{S_R}\Big) \;=\; i\omega\mu_0 \,\Big(g^{in}_\omega, \Phi_{S_R}\Big), \end{aligned} \tag{3.3}$$

where

$$g^{in}_\omega \;=\; T^\omega(E^{in}_{\omega,S_R}) - H^{in}_\omega \,\wedge\, n. \tag{3.4}$$

We have from [17] or [27] the following.

LEMMA 3.1. *Suppose that the Maxwell system* (4.1) *admits at most one solution. Then the variational equation* (3.3) *is uniquely solvable in* $H(\text{curl}, B_R)$.

4. The derivation of the higher-order terms. This section is probably the most important section of this article because essentially all of what follows is either based on or motivated by the results we are about to discuss. We proceed formally to reduce the calculation of higher-order terms to the solutions of certain canonical problems. Then we shall show that each of these problems admits a unique solution. This will be accomplished with the help of the lemmas given above. The convergence of the electric and magnetic fields with these higher-order terms is the basic aim of the next section. Let us first recall that the electric and magnetic fields are solutions of the following scattering problem:

$$\left\{ \begin{aligned} &\overrightarrow{\text{curl}}\, H^\omega \;=\; -i\omega\varepsilon\, E^\omega \quad \text{in } B_R, \\ &\overrightarrow{\text{curl}}\, E^\omega \;=\; i\omega\mu\, H^\omega \quad \text{in } B_R, \\ &T^\omega(E^\omega_{S_R}) - H^\omega \,\wedge\, n \;=\; T^\omega(E^{in}_{\omega,S_R}) - H^{in}_\omega \,\wedge\, n \quad \text{on } S_R, \end{aligned} \right. \tag{4.1}$$

where we have replaced the Silver–Müller radiation condition by the exact nonlocal boundary condition

$$T^\omega(E^\omega_{S_R}) - H^\omega \wedge n = T^\omega(E^{in}_{\omega,S_R}) - H^{in}_\omega \wedge n \tag{4.2}$$

on the artificial boundary S_R.

Let us now formally expand the electric and the magnetic fields (E^ω, H^ω) in a power series of the frequency ω:

$$\begin{cases} E^\omega = \displaystyle\sum_{j=0}^{+\infty} E^j\,\omega^j, \\ H^\omega = \displaystyle\sum_{j=0}^{+\infty} H^j\,\omega^j, \end{cases} \tag{4.3}$$

where the fields (E^j, H^j) are in $H(\text{curl}, B_R) \times H(\text{curl}, B_R)$. Therefore, the tangential component of the electric field on S_R can be written in the form

$$E^\omega_{S_R} = \sum_{l=1}^{+\infty}\sum_{m=-l}^{l} u^m_l(\omega)\,G^m_l + v^m_l(\omega)\,R^m_l,$$

where its expansion coefficients $u^{m,j}_l$ and $v^{m,j}_l$ have the following expansion forms with respect to the frequency ω:

$$\begin{cases} u^m_l(\omega) = \displaystyle\sum_{j=0}^{+\infty} u^{m,j}_l \omega^j, \\ v^m_l(\omega) = \displaystyle\sum_{j=0}^{+\infty} v^{m,j}_l \omega^j. \end{cases}$$

From the exact nonlocal boundary condition (4.2) on S_R we obtain that

$$\sqrt{\frac{\varepsilon_0}{\mu_0}}\sum_{l=1}^{+\infty}\sum_{m=-l}^{l} i\omega\frac{1}{\gamma^0_l}\left(\sum_{j=0}^{+\infty}\delta^j_l\omega^j\right)\left(\sum_{j=0}^{+\infty}u^{m,j}_l\omega^j\right)G^m_l$$
$$+\frac{\gamma^0_l}{i\omega}\left(\sum_{j=0}^{+\infty}\frac{\gamma^j_l}{\gamma^0_l}\omega^j\right)\left(\sum_{j=0}^{+\infty}v^{m,j}_l\omega^j\right)R^m_l - \sum_{j=0}^{+\infty}\Big(H^j \wedge n\Big)\,\omega^j = g^{in}_\omega,$$

where g^{in}_ω is defined by (3.4). Now, using the fact that

$$\left(\sum_{j=0}^{+\infty}\delta^j_l\omega^j\right)\left(\sum_{j=0}^{+\infty}u^{m,j}_l\omega^j\right) = \sum_{j=0}^{+\infty}\left(\sum_{p=0}^{j}\delta^{j-p}u^{m,p}_l\right)\omega^j$$

and

$$\left(\sum_{j=0}^{+\infty}\frac{\gamma^j_l}{\gamma^0_l}\omega^j\right)\left(\sum_{j=0}^{+\infty}v^{m,j}_l\omega^j\right) = \sum_{j=0}^{+\infty}\left(\sum_{p=0}^{j}\frac{\gamma^{j-p}}{\gamma^0_l}v^{m,p}_l\right)\omega^j,$$

we obtain

$$\begin{aligned}&\sqrt{\frac{\varepsilon_0}{\mu_0}}\sum_{l=1}^{+\infty}\sum_{m=-l}^{l} i\omega\frac{1}{\gamma_l^0}\sum_{j=0}^{+\infty}\left(\sum_{p=0}^{j}\delta_l^{j-p}u_l^{m,p}\right)\omega^j\, G_l^m\\ &+\frac{\gamma_l^0}{i\omega}\sum_{j=0}^{+\infty}\left(\sum_{p=0}^{j}\frac{\gamma_l^{j-p}}{\gamma_l^0}v_l^{m,p}\right)\omega^j\, R_l^m-\sum_{j=0}^{+\infty}\Big(H^j\,\wedge\,n\Big)\,\omega^j\;=\;g_\omega^{in}.\end{aligned}\tag{4.4}$$

If we assume that the incident electric field E_ω^{in} is analytic with respect to ω, we can write the quantity g_ω^{in} in the form

$$g_\omega^{in}\;=\;\frac{1}{\omega}\,g_{-1}^{in}+\sum_{j=0}^{+\infty}g_j^{in}\,\omega^j,$$

since $\gamma_l(\omega)$ is analytic with respect to ω in a real neighborhood of 0.

Now we shall show how to obtain the fields (E^j, H^j). Upon inserting the expansions (4.3) of (E^ω, H^ω) in the system (4.1), we get

$$\begin{cases}\overrightarrow{\operatorname{curl}}\,E^0\;=\;0\quad\text{in } B_R,\\ \overrightarrow{\operatorname{curl}}\,H^0\;=\;0\quad\text{in } B_R,\\ \operatorname{div}\varepsilon\,E^0\;=\;0\quad\text{in } B_R,\\ \operatorname{div}\mu\,H^0\;=\;0\quad\text{in } B_R\end{cases}\tag{4.5}$$

and more generally

$$\begin{cases}\overrightarrow{\operatorname{curl}}\,E^{j+1}\;=\;i\mu\,H^j\quad\text{in } B_R,\\ \overrightarrow{\operatorname{curl}}\,H^{j+1}\;=\;-i\varepsilon\,E^j\quad\text{in } B_R,\\ \operatorname{div}\varepsilon\,E^{j+1}\;=\;0\quad\text{in } B_R,\\ \operatorname{div}\mu\,H^{j+1}\;=\;0\quad\text{in } B_R.\end{cases}\tag{4.6}$$

To complete the derivation of the canonical problem satisfied by the field E^j or the field H^j, we need to find a boundary condition satisfied by these fields on S_R. Identifying different terms in the identity (4.4) and by following increasing powers of the frequency ω, we obtain

$$\begin{cases}-i\sqrt{\dfrac{\varepsilon_0}{\mu_0}}\displaystyle\sum_{l=1}^{+\infty}\sum_{m=-l}^{l}\gamma_l^0 v_l^{m,0}\,R_l^m\;=\;g_{-1}^{in},\\ -i\sqrt{\dfrac{\varepsilon_0}{\mu_0}}\displaystyle\sum_{l=1}^{+\infty}\sum_{m=-l}^{l}\gamma_l^0\left(\frac{\gamma_l^1}{\gamma_l^0}v_l^{m,0}+v_l^{m,1}\right)R_l^m-H^0\,\wedge\,n\;=\;g_0^{in}\end{cases}\tag{4.7}$$

and more generally

$$\begin{aligned}&i\sqrt{\frac{\varepsilon_0}{\mu_0}}\sum_{l=1}^{+\infty}\sum_{m=-l}^{l}\frac{1}{\gamma_l^0}\left(\sum_{p=0}^{j}\delta_l^{j-p}u_l^{m,p}\right)G_l^m\\ &-\gamma_l^0\left(\sum_{p=0}^{j+2}\frac{\gamma_l^{j+2-p}}{\gamma_l^0}v_l^{m,p}\right)R_l^m-H^{j+1}\,\wedge\,n\;=\;g_{j+1}^{in},\quad j\geq 0.\end{aligned}\tag{4.8}$$

We first derive a boundary condition on $S_R (R = 1)$ satisfied by the field E^0. Since

$$\left\{ \begin{array}{lcl} \operatorname{div}_{S_R} G_l^m & = & -\sqrt{l(l+1)}\, Y_l^m, \\ \operatorname{div}_{S_R} R_l^m & = & 0, \end{array} \right. \tag{4.9}$$

then by taking the surface divergence of the identity (4.4) for $j = 0$ we obtain

$$-\sqrt{\frac{\varepsilon_0}{\mu_0}} \sum_{l=1}^{+\infty} \sum_{m=-l}^{l} \frac{i}{\gamma_l^0} u_l^{m,0} \sqrt{l(l+1)}\, Y_l^m - \operatorname{div}_{S_R} \Big(H^1 \wedge n \Big) \;=\; \operatorname{div}_{S_R} \Big(g_1^{in} \Big). \tag{4.10}$$

Here we have used the fact that $\delta_l^0 = 1$. However, from (4.1) we see that

$$\operatorname{div}_{S_R} (H^1 \wedge n) \;=\; \overrightarrow{\operatorname{curl}}\, H^1 \, \cdot \, n \;=\; -i\varepsilon_0\, E^0 \, \cdot \, n \quad \text{on } S_R.$$

Thus

$$-\sum_{l=1}^{+\infty} \sum_{m=-l}^{l} \frac{1}{\gamma_l^0} u_l^{m,0} \sqrt{l(l+1)}\, Y_l^m + \, E^0 \, \cdot \, n \;=\; -\frac{i}{\varepsilon_0} \operatorname{div}_{S_R} \Big(g_1^{in} \Big). \tag{4.11}$$

Now, let the operator

$$K : H^s(S_R) \mapsto H^{s+1}(S_R)$$

(for our purposes $s = -3/2$) be defined by

$$K(\varphi) \;=\; \sum_{l=1}^{+\infty} \sum_{m=-l}^{l} -\frac{1}{\gamma_l^0}\, \varphi_l^m Y_l^m,$$

$(\gamma_l^0 = l)$ for $\varphi \in H^s(S_R)$ of the form $\varphi \;=\; \sum_{l=1}^{+\infty} \sum_{m=-l}^{l} \varphi_l^m Y_l^m$. Using the fact that $u_l^{m,0} \;=\; 0 \,\forall\, l \geq 1$ and $m = -l$ to l, the definition of the operator K, and the boundary condition on S_R (4.11), we obtain that E^0 satisfies on S_R

$$E^0 \, \cdot \, n - \, K(\operatorname{div}_{S_R} E_{S_R}^0) \;=\; -\frac{i}{\varepsilon_0} \operatorname{div}_{S_R} (g_1^{in}). \tag{4.12}$$

Let us observe that the operator K is related to the operator D by

$$D(g) = K(\operatorname{div}_{S_R} g) \quad \forall\, g \in TH^{-1/2}(\operatorname{curl}, S_R).$$

Now, to derive a boundary condition on S_R satisfied by the field H^0, we carry out the same procedure. Let us first observe that from (4.7) we can deduce that

$$\begin{aligned} \operatorname{div}_{S_R} (H_{S_R}^0) \quad = \quad & -i\sqrt{\frac{\varepsilon_0}{\mu_0}} \sum_{l=1}^{+\infty} \sum_{m=-l}^{l} \sqrt{l(l+1)} \gamma_l^0\, v_l^{m,1}\, Y_l^m - \operatorname{curl}_{S_R} g_0^{in} \\ & -i\sqrt{\frac{\varepsilon_0}{\mu_0}} \sum_{l=1}^{+\infty} \sum_{m=-l}^{l} \sqrt{l(l+1)} \gamma_l^1\, v_l^{m,0}\, Y_l^m. \end{aligned}$$

But

$$-\sum_{l=1}^{+\infty} \sum_{m=-l}^{l} \sqrt{l(l+1)} v_l^{m,1}\, Y_l^m \;=\; \operatorname{div}_{S_R} (E^1 \wedge n) \;=\; i\mu_0\, H^0 \, \cdot \, n.$$

Thus,

$$i\mu_0\, H^0\ \cdot\ n + \sum_{l=1}^{+\infty}\sum_{m=-l}^{l} \sqrt{l(l+1)}v_l^{m,1}\, Y_l^m\ =\ 0. \tag{4.13}$$

Making use of the operator K, we can rewrite (4.13) in the more suitable form

$$\begin{aligned} H^0\ \cdot\ n -\ K(\mathrm{div}_{S_R}\, H^0_{S_R})\ &=\ -i\mu_0\, K(\mathrm{curl}_{S_R}\, g_0^{in}) \\ &- \sum_{l=1}^{+\infty}\sum_{m=-l}^{l} \frac{\sqrt{l(l+1)}\gamma_l^1}{\gamma_l^0}\, v_l^{m,0}\, Y_l^m. \end{aligned} \tag{4.14}$$

More generally, assume that the fields (E^i, H^i) are known for $i = 0$ to j; we wish to derive boundary conditions satisfied by the fields (E^{j+1}, H^{j+1}) on the fictive boundary S_R. From (4.8) it follows that

$$\begin{aligned} &\sqrt{\frac{\varepsilon_0}{\mu_0}} \sum_{l=1}^{+\infty}\sum_{m=-l}^{l} i\frac{1}{\gamma_l^0}\left(\sum_{p}^{j-1} \delta_l^{j-1-p} u_l^{m,p}\right) G_l^m \\ &-i\gamma_l^0 \left(\sum_{p=0}^{j+1} \frac{\gamma_l^{j+1-p}}{\gamma_l^0} v_l^{m,p}\right) R_l^m - H^j\ \wedge\ n\ =\ g_j^{in}, \end{aligned}$$

and so

$$\begin{aligned} -i\sqrt{\frac{\varepsilon_0}{\mu_0}} \sum_{l=1}^{+\infty}\sum_{m=-l}^{l} \gamma_l^0 v_l^{m,j+1}\, R_l^m &= g_j^{in} + H^j\ \wedge\ n \\ &-i\sqrt{\frac{\varepsilon_0}{\mu_0}} \sum_{l=1}^{+\infty}\sum_{m=-l}^{l} \frac{1}{\gamma_l^0}\left(\sum_{p=0}^{j-1} \delta_l^{j-1-p} u_l^{m,p}\right) G_l^m \\ &+i\sqrt{\frac{\varepsilon_0}{\mu_0}} \sum_{l=1}^{+\infty}\sum_{m=-l}^{l} \gamma_l^0 \left(\sum_{p=0}^{j} \frac{\gamma_l^{j+1-p}}{\gamma_l^0} v_l^{m,p}\right) R_l^m. \end{aligned} \tag{4.15}$$

Thus, the expansion coefficients $(v_l^{m,j+1})_{l\geq 1, -l\leq m\leq l}$ are determined. Furthermore, it is easy to see that

$$\begin{aligned} &\mathrm{div}_{S_R} \left\{\sum_{l=1}^{+\infty}\sum_{m=-l}^{l} +i\frac{1}{\gamma_l^0}\left(\sum_{p=0}^{j+1} \delta_l^{j+1-p} u_l^{m,p}\right) G_l^m\right\} \\ &=\ \mathrm{div}_{S_R}\,(H^{j+2}\wedge n) + \mathrm{div}_{S_R}\,(g_{j+2}^{in}), \\ &=\ -i\varepsilon_0\, E^{j+1}\ \cdot\ n + \mathrm{div}_{S_R}\,(g_{j+2}^{in}). \end{aligned}$$

Thus,

$$i\varepsilon_0\, E^{j+1}\ \cdot\ n + i\sum_{l=1}^{+\infty}\sum_{m=-l}^{l} \frac{\sqrt{l(l+1)}}{\gamma_l^0}\left(\sum_{p=0}^{j+1} \delta_l^{j+1-p} u_l^{m,p}\right) Y_l^m\ =\ \mathrm{div}_{S_R}\,(g_{j+2}^{in}).$$

Finally, we obtain that E^{j+1} satisfies on S_R the following boundary condition:

$$\begin{aligned} &E^{j+1} \cdot n - K(\mathrm{div}_{S_R}(E^{j+1}_{S_R})) = -\frac{i}{\varepsilon_0}\mathrm{div}_{S_R}\left(g^{in}_{j+2}\right) \\ &+\sum_{l=1}^{+\infty}\sum_{m=-l}^{l}\frac{\sqrt{l(l+1)}}{\gamma_l^0}\left(\sum_{p=0}^{j}\delta_l^{j+1-p}u_l^{m,p}\right)Y_l^m. \end{aligned}$$

Similarly, the following identity holds for the field H^{j+1}:

$$\mathrm{div}_{S_R}(H^{j+1}_{S_R}) + i\sum_{l=1}^{+\infty}\sum_{m=-l}^{l}\gamma_l^0\sqrt{l(l+1)}\sum_{p=0}^{j+2}\frac{\gamma_l^{j+2-p}}{\gamma_l^0}v_l^{m,p}\,Y_l^m = \mathrm{curl}_{S_R}(g^{in}_{j+1}), \tag{4.16}$$

which can be rewritten in the form

$$\begin{aligned} &\mathrm{div}_{S_R}(H^{j+1}_{S_R}) + i\sum_{l=1}^{+\infty}\sum_{m=-l}^{l}\gamma_l^0\sqrt{l(l+1)}v_l^{m,j+2}\,Y_l^m = \mathrm{curl}_{S_R}(g^{in}_{j+1}) \\ &+i\sqrt{\frac{\varepsilon_0}{\mu_0}}\sum_{l=1}^{+\infty}\sum_{m=-l}^{l}\gamma_l^0\sqrt{l(l+1)}\sum_{p=0}^{j+1}\frac{\gamma_l^{j+2-p}}{\gamma_l^0}v_l^{m,p}\,Y_l^m, \end{aligned}$$

where the expansion coefficients $(v_l^{m,j+1})_{l\geq 1, -l\leq m\leq l}$ are known from the identity (4.15). Making use of the operator K, we see that

$$\begin{aligned} &K(\mathrm{div}_{S_R}(H^{j+1}_{S_R})) - i\sum_{l=1}^{+\infty}\sum_{m=-l}^{l}\sqrt{l(l+1)}v_l^{m,j+2}\,Y_l^m = K(\mathrm{curl}_{S_R}(g^{in}_{j+1})) \\ &-i\sum_{l=1}^{+\infty}\sum_{m=-l}^{l}\sqrt{l(l+1)}\sum_{p=0}^{j+1}\frac{\gamma_l^{j+2-p}}{\gamma_l^0}v_l^{m,p}\,Y_l^m. \end{aligned}$$

But

$$\begin{aligned} -\sum_{l=1}^{+\infty}\sum_{m=-l}^{l}\sqrt{l(l+1)}v_l^{m,j+2}\,Y_l^m &= \mathrm{div}_{S_R}(E^{j+2}\wedge n) \\ &= i\mu_0\,H^{j+1}\cdot n. \end{aligned}$$

Thus

$$\begin{aligned} &K(\mathrm{div}_{S_R}(H^{j+1}_{S_R})) - H^{j+1}\cdot n = i\mu_0\,K(\mathrm{curl}_{S_R}(g^{in}_{j+1})) \\ &-\sum_{l=1}^{+\infty}\sum_{m=-l}^{l}\sqrt{l(l+1)}\sum_{p=0}^{j+1}\frac{\gamma_l^{j+2-p}}{\gamma_l^0}v_l^{m,p}\,Y_l^m \quad \text{on } S_R. \end{aligned}$$

To summarize, we have the following lemma.

LEMMA 4.1. *Assume that the electric and magnetic fields (E^ω, H^ω) admit the asymptotic expansions* (4.3). *Then we have*

$$\begin{cases} \overrightarrow{\mathrm{curl}}\,E^0 = 0 \quad \text{in } B_R, \\ \mathrm{div}\,\varepsilon\,E^0 = 0 \quad \text{in } B_R, \\ E^0\cdot n - K(\mathrm{div}_{S_R}(E^0_{S_R})) = -\frac{i}{\varepsilon_0}\mathrm{div}_{S_R}(g_1^{in}) \quad \text{on } S_R, \end{cases} \tag{4.17}$$

$$(4.18)\qquad \begin{cases} \overrightarrow{\mathrm{curl}}\, H^0 \;=\; 0 \quad \textit{in } B_R, \\ \mathrm{div}\, \mu\, H^0 \;=\; 0 \quad \textit{in } B_R, \\ H^0 \,\cdot\, n - K(\mathrm{div}_{S_R}\,(H^0_{S_R})) \;=\; -i\mu_0\, K(\mathrm{curl}_{S_R}\,(g_0^{in})) \\ -\displaystyle\sum_{l=1}^{+\infty}\sum_{m=-l}^{l} \sqrt{l(l+1)}\frac{\gamma_l^1}{\gamma_l^0} v_l^{m,0}\, Y_l^m \quad \textit{on } S_R, \end{cases}$$

$$(4.19)\qquad \begin{cases} \overrightarrow{\mathrm{curl}}\, E^{j+1} \;=\; i\mu\, H^j \quad \textit{in } B_R, \\ \mathrm{div}\, \varepsilon\, E^{j+1} \;=\; 0 \quad \textit{in } B_R, \\ E^{j+1} \,\cdot\, n - \; K(\mathrm{div}_{S_R}\,(E^{j+1}_{S_R})) \;=\; -\dfrac{i}{\varepsilon_0}\,\mathrm{div}_{S_R}\,(g_{j+2}^{in}) \\ +\displaystyle\sum_{l=1}^{+\infty}\sum_{m=-l}^{l} \frac{\sqrt{l(l+1)}}{\gamma_l^0}\left(\sum_{p=0}^{j}\delta_l^{j+1-p}u_l^{m,p}\right) Y_l^m \quad \textit{on } S_R, \end{cases}$$

and

$$(4.20)\qquad \begin{cases} \overrightarrow{\mathrm{curl}}\, H^{j+1} \;=\; -i\varepsilon\, E^j \quad \textit{in } B_R, \\ \mathrm{div}\, \mu\, H^{j+1} \;=\; 0 \quad \textit{in } B_R, \\ H^{j+1} \,\cdot\, n - K(\mathrm{div}_{S_R}\,(H^{j+1}_{S_R})) \;=\; -i\mu_0\, K(\mathrm{curl}_{S_R}\,(g_{j+1}^{in})) \\ -\displaystyle\sum_{l=1}^{+\infty}\sum_{m=-l}^{l} \sqrt{l(l+1)}\sum_{p=0}^{j+1}\frac{\gamma_l^{j+2-p}}{\gamma_l^0} v_l^{m,p}\, Y_l^m \quad \textit{on } S_R. \end{cases}$$

Now, in order to prove the existence of a solution to the boundary-value problems (4.19) and (4.20) we must analyze in some detail the boundary conditions satisfied by the fields (E^j, H^j) on S_R. We shall prove the following lemma, which is essential to reduce the calculation of higher-order terms $(E^j, H^j)_{j\geq 1}$ to a certain canonical problem.

LEMMA 4.2. (a) *Assume that E^i is in $H(\mathrm{curl}, B_R)$ for $i = 1$ to j. Then the quantity*

$$-\frac{i}{\varepsilon_0}\mathrm{div}_{S_R}\,(g_{j+2}^{in}) + \sum_{l=1}^{+\infty}\sum_{m=-l}^{l} \frac{\sqrt{l(l+1)}}{\gamma_l^0}\left(\sum_{p=0}^{j}\delta_l^{j+1-p}u_l^{m,p}\right) Y_l^m$$

is in $H^{-1/2}(S_R)$.

(b) *Assume that E^i is in $H(\mathrm{curl}, B_R)$ for $i = 1$ to $j+1$. Then the quantity*

$$-i\mu_0\, K(\mathrm{curl}_{S_R}\,(g_{j+1}^{in})) - \sum_{l=1}^{+\infty}\sum_{m=-l}^{l} \sqrt{l(l+1)}\sum_{p=0}^{j+1}\frac{\gamma_l^{j+2-p}}{\gamma_l^0} v_l^{m,p}\, Y_l^m$$

is in $H^{-1/2}(S_R)$.

Proof. This lemma follows immediately from Lemma 2.8. □

We also need the following results.

Lemma 4.3. *The boundary-value problem*

$$\left\{\begin{array}{l} \operatorname{div} \varepsilon \,\overrightarrow{\operatorname{grad}}\, \psi \;=\; 0 \quad \textit{in } B_R, \\ \partial_n \psi -\; K(\Delta_{S_R}\, \psi) \;=\; f \in H^{-1/2}(S_R) \end{array}\right. \tag{4.21}$$

is uniquely solvable in $H^1(B_R)$ *within an additive constant.*

Proof. It is easy to see that if $\psi \in H^1(B_R)$ satisfies (4.21), then it is solution of the variational equation

$$a(\psi,\psi_t) = \int_{B_R} \varepsilon \,\overrightarrow{\operatorname{grad}}\, \psi \,\overrightarrow{\operatorname{grad}}\psi_t + \sum_{l=1}^{+\infty} \sum_{m=-l}^{l} (l+1)\, \psi_l^m \,(\psi_t)_l^m \;=\; \int_{S_R} f\, \psi_t \quad \forall\, \psi_t \in H^1(B_R),$$

where ψ_l^m and $(\psi_t)_l^m$ are the expansion coefficents of ψ and ψ_t on S_R. Since

$$a\Big(\psi,\overline{\psi}\Big) \geq \int_{B_R} \varepsilon\, |\overrightarrow{\operatorname{grad}}\, \psi\,|^2,$$

the lemma follows then from the Lax–Milgram theorem by using a version of Poincaré's inequality. □

Next, we have to prove the following lemma.

Lemma 4.4. *Let* f *be in* $H(\operatorname{curl}, B_R)$ *such that* $\operatorname{div} f = 0$ *in* B_R*,* $q \in L^\infty(B_R)$*, and* $\varphi \in H^{-1/2}(S_R)$*. The boundary-value problem*

$$\left\{\begin{array}{l} \overrightarrow{\operatorname{curl}}\, u \;=\; f \quad \textit{in } B_R, \\ \operatorname{div} q\, u \;=\; 0 \quad \textit{in } B_R, \\ u \,\cdot\, n -\; K(\operatorname{div}_{S_R} u_{S_R}) \;=\; \varphi \quad \textit{on } S_R \end{array}\right. \tag{4.22}$$

is uniquely solvable in $H(\operatorname{curl}, B_R)$*.*

Proof. Since $f \in H(\operatorname{curl}, B_R)$ satisfies $\operatorname{div} f = 0$ in B_R, we can find $v \in H(\operatorname{curl}, B_R)$ such that $\operatorname{div} q\, v = 0$ and $f = \overrightarrow{\operatorname{curl}}\, v$ in B_R. Put $\tilde{u} = u - v$; then $\tilde{u}$ satisfies

$$\left\{\begin{array}{l} \overrightarrow{\operatorname{curl}}\, \tilde{u} \;=\; 0 \quad \text{in } B_R, \\ \operatorname{div} q\, \tilde{u} \;=\; 0 \quad \text{in } B_R, \\ \tilde{u} \,\cdot\, n -\; K(\operatorname{div}_{S_R} \tilde{u}_{S_R}) \;=\; \tilde{\varphi} \quad \text{on } S_R, \end{array}\right.$$

where

$$\tilde{\varphi} \;=\; \varphi - v \,\cdot\, n +\; K(\operatorname{div}_{S_R} v_{S_R})$$

is in $H^{-1/2}(S_R)$. But $\overrightarrow{\operatorname{curl}}\, \tilde{u} = 0$ in B_R implies that $\tilde{u} = \overrightarrow{\operatorname{grad}}\, \psi$, where ψ is in $H^1(B_R)$. Lemma 4.4 follows then immediately from Lemma 4.3. □

We note that the operator $K(\Delta_{S_R})$ is the Dirichlet–Neumann operator associated with the Laplace equation in $\mathbb{R}^3 \setminus \overline{B_R}$.

Finally, we can then state the following.

Theorem 4.5. *Assume that the electric and magnetic fields* (E^ω, H^ω) *admit the asymptotic expansions* (4.3)*. Then the fields* (E^j, H^j) *are determined as the unique solutions of the boundary-value problems* (4.17)–(4.20) *in* $H(\operatorname{curl}, B_R)$*.*

5. Convergence result. Now let M be an integer. Let (E^j, H^j) for $j = 0$ to M be defined recursively as the unique solutions of the boundary-value problems (4.17)–(4.20). Our aim in this section is to prove that the quantities

$$\left\| E^\omega - \sum_{j=0}^{M} E^j\,\omega^j \right\|_{(L^2(B_R))^3}, \qquad \left\| H^\omega - \sum_{j=0}^{M} H^j\,\omega^j \right\|_{(L^2(B_R))^3}$$

are of order $0(\omega^{M+1})$ which justifies the asymptotic expansions (4.3) of the electric and magnetic fields with respect to ω. The next theorem provides a new and simple proof of the convergence of the electric and magnetic fields solutions of scattering problems for Maxwell's equations as frequency tends to zero. In our proof of the convergence we shall need the following lemmas.

Lemma 5.1. *The boundary-value problem*

$$\begin{cases} \overrightarrow{\operatorname{curl}}\, v \;=\; 0 \textit{ in } B_R, \\ \operatorname{div} \varepsilon\, v \;=\; 0 \quad \textit{in } B_R, \\ v\,\cdot\, n -\, D(v_{S_R}) \;=\; 0 \quad \textit{on } S_R \end{cases} \tag{5.1}$$

has only the trivial solution in $H(\operatorname{curl}, B_R)$.

Proof. Since $D(v_{S_R}) = K(\operatorname{div}_{S_R} v_{S_R})$ the result follows from Lemma 4.4. □

Lemma 5.2. *Assume that* $q \in L^\infty(B_R)$ *and* $q = 1$ *in a neighborhood of* B_R. *Let*

$$V = \Big\{ w \in H(\operatorname{curl}, B_R), \operatorname{div} q\, w \;=\; 0 \text{ in } B_R, w\,\cdot\, n -\; D(w_{S_R}) \in H^{1/2}(S_R) \Big\}.$$

Then the embedding $V \hookrightarrow (L^2(B_R))^3$ *is compact.*

Proof. We first verify that the embedding

$$\Big\{ w \in H(\operatorname{curl}, B_R), \operatorname{div} q\, w \;=\; 0 \text{ in } B_R, w\,\cdot\, n -\; D(w_{S_R}) = 0 \Big\} \hookrightarrow (L^2(B_R))^3,$$

is compact. Let w be in this space. Since $\overrightarrow{\operatorname{curl}}\, w \in (L^2(B_R))^3$ there exists $\tilde{w}$ such that $\overrightarrow{\operatorname{curl}}\, \tilde{w} = \overrightarrow{\operatorname{curl}}\, w, \operatorname{div} qw = 0$, and $w\,.\,n = 0$ on S_R. Therefore, $w = \tilde{w} + \overrightarrow{\operatorname{grad}}\varphi$, where φ satisfies

$$\begin{cases} \operatorname{div} \varepsilon\, \overrightarrow{\operatorname{grad}}\, \psi \;=\; 0 \quad \text{in } B_R, \\ \partial_n \psi -\; K(\Delta_{S_R}\, \psi) \;\in H^{1/2}(S_R) \quad \text{on } S_R. \end{cases}$$

The boundary condition $\partial_n \psi - K(\Delta_{S_R}\, \psi) \in H^{1/2}(S_R)$ on S_R shows that $\varphi \in H^{3/2}(S_R)$ and so the claim is obtained from Weber's embedding theorems [37]. The lemma holds then from the fact that the embeddings $(H^1(B_R))^3 \hookrightarrow (L^2(B_R))^3$ and

$$\Big\{ w \in H(\operatorname{curl}, B_R), \operatorname{div} q\, w \;=\; 0 \text{ in } B_R, w\,\cdot\, n -\; D(w_{S_R}) = 0 \Big\} \hookrightarrow (L^2(B_R))^3$$

are compact. □

We can state the main result of this section.

Theorem 5.3. *Let* M *be an integer. Let* (E^j, H^j) *for* $j = 0$ *to* M *be defined recursively as the unique solutions of the boundary-value problems* (4.17)–(4.20). *There* *exists* $\omega_0 > 0$ *such that for* $0 < \omega < \omega_0$ *the following estimates hold:*

$$(5.2)\qquad \left\{ \begin{array}{ll} \left\| E^\omega - \sum_{j=0}^{M} E^j\,\omega^j \right\|_{(L^2(B_R))^3} & \leq C\,\omega^{M+1}, \\ \left\| H^\omega - \sum_{j=0}^{M} H^j\,\omega^j \right\|_{(L^2(B_R))^3} & \leq C\,\omega^{M+1}, \end{array} \right.$$

where the constant C *is independent of* ω.

Proof. It is easy to see that the field $E^\omega - E^0$ satisfies

$$(5.3)\qquad \left\{ \begin{array}{l} \overrightarrow{\mathrm{curl}}\,\frac{1}{\mu}\,\overrightarrow{\mathrm{curl}}\,(E^\omega - E^0) - \omega^2\varepsilon\,(E^\omega - E^0) \,=\, \omega^2\varepsilon E^0 \quad \text{in } B_R, \\ \mathrm{div}\,\varepsilon\,(E^\omega - E^0) \,=\, 0 \quad \text{in } B_R, \\ \overrightarrow{\mathrm{curl}}\,(E^\omega - E^0)\,\wedge\,n \,=\, i\omega\mu_0\left(T^\omega(E^\omega_{S_R} - E^0_{S_R}) - g^{in}_\omega\right) \\ +i\omega\mu_0\,T^\omega(E^0_{S_R}) \quad \text{on } S_R. \end{array} \right.$$

If we multiply the Maxwell's equations by $\overline{(E^\omega - E^0)}$, integrate over B_R, and use integration by parts, we obtain

$$(5.4)\qquad \begin{array}{l} \displaystyle\int_{B_R} \frac{1}{\mu}\,|\overrightarrow{\mathrm{curl}}\,(E^\omega - E^0)|^2 - \omega^2 \int_{B_R} \varepsilon\,|E^\omega - E^0|^2 \\ -i\omega\mu_0\Big(T^\omega(E^\omega_{S_R} - E^0_{S_R}), E^\omega_{S_R} - E^0_{S_R}\Big) \\ \displaystyle = \omega^2 \int_{B_R} \varepsilon\,E^0\,\cdot\,\overline{(E^\omega - E^0)} + i\omega\mu_0\left(g^{in}_\omega - T^\omega(E^0_{S_R}), E^\omega_{S_R} - E^0_{S_R}\right). \end{array}$$

Next, using the operator D^ω, we may write

$$(5.5)\qquad \begin{array}{rcl} (E^\omega - E^0)\,\cdot\,n & = & D^\omega(E^\omega_{S_R} - E^0_{S_R}) + D^\omega(E^0_{S_R}) + \,K(\mathrm{div}_{S_R}\,E^0_{S_R}) \\ & & \displaystyle -\frac{i}{\varepsilon_0}\,\mathrm{div}_{S_R}\,(g^{in}_1) + E^{in}_\omega\,\cdot\,n - D^\omega(E^{in}_{\omega,S_R}). \end{array}$$

We are now in position to prove Theorem 5.3. Let us first observe that

$$T^\omega(E^0_{S_R}) - \frac{1}{\omega}g^{in}_{-1} \,=\, \sqrt{\frac{\varepsilon_0}{\mu_0}}\sum_{l=1}^{+\infty}\sum_{m=-l}^{l}\frac{1}{\gamma^0_l}\,v^{m,0}_l\,G^m_l + 0(\omega),$$

where $0(\omega)$ is in $TH^{-1/2}(\mathrm{div}, S_R)$. If we assume that the quantity

$$\frac{1}{\omega}||E^\omega - E^0||_{(L^2(B_R))^3}$$

is not bounded then from (5.4) we can deduce that

$$v^\omega \,=\, \frac{E^\omega - E^0}{||E^\omega - E^0||_{(L^2(B_R))^3}}$$

is such that its curl is bounded (uniformly in ω) in $(L^2(B_R))^3$ and so it converges weakly in $\{w \in H(\mathrm{curl}, B_R), \mathrm{div}\varepsilon w = 0 \text{ in } B_R\}$ to a certain v. It is easy to see that $\overrightarrow{\mathrm{curl}} v = 0$, $\mathrm{div}\varepsilon v = 0$ in B_R and

$$v^\omega \cdot n - D(v^\omega_{S_R}) = (D^\omega - D)\left(\frac{E^\omega}{||E^\omega - E^0||_{(L^2(B_R))^3}}\right).$$

From Lemma 2.7, it follows that the following identity holds:

$$\left\|(D^\omega - D)\left(\frac{E^\omega}{||E^\omega - E^0||_{(L^2(B_R))^3}}\right)\right\|_{H^{1/2}(S_R)} \leq C\,\omega\,||v^\omega||_{H(\mathrm{curl},B_R)},$$

where C is a constant independent of ω and then by Lemma 5.1 we obtain that $v = 0$ and Lemma 5.2 implies that $v^\omega \to 0$ in $(L^2(B_R))^3$, strongly. This leads to a contradiction. The quantity $||E^\omega - E^0||_{(L^2(B_R))^3}$ is then of order ω. Now, in order to prove that $||H^\omega - H^0||_{(L^2(B_R))^3}$ is of order ω we observe that

$$\begin{aligned}
&\int_{B_R} \frac{1}{\mu}\,|\overrightarrow{\mathrm{curl}}\,(E^\omega - E^0 - \omega E^1)|^2 - \omega^2 \int_{B_R} \varepsilon\,|E^\omega - E^0 - \omega E^1|^2 \\
&-i\omega\mu_0\Big(T^\omega(E^\omega_{S_R} - E^0_{S_R} - \omega E^1_{S_R}), E^\omega_{S_R} - E^0_{S_R} - \omega E^1_{S_R}\Big) \\
&= \omega^2 \int_{B_R} \varepsilon\,E^0 \cdot \overline{(E^\omega - E^0 - \omega E^1)} \\
&+i\omega\mu_0\Big(g^{in}_\omega - T^\omega(E^0_{S_R}) - \omega T^\omega(E^1_{S_R}), E^\omega_{S_R} - E^0_{S_R} - \omega E^1_{S_R}\Big).
\end{aligned} \tag{5.6}$$

Since the quantity

$$\begin{aligned}
&|(g^{in}_\omega - T^\omega(E^0_{S_R}) - \omega T^\omega(E^1_{S_R}), E^\omega_{S_R} - E^0_{S_R} - \omega E^1_{S_R})| \\
&= 0(\omega)\,||E^\omega_{S_R} - E^0_{S_R} - \omega E^1_{S_R}||_{TH^{-1/2}(\mathrm{curl},S_R)},
\end{aligned}$$

it follows by the same argument that $||E^\omega - E^0 - \omega E^1||_{(L^2(B_R))^3}$ is of order ω^2. But

$$\frac{1}{\mu}\,\overrightarrow{\mathrm{curl}}\,(E^\omega - E^0 - \omega E^1) = i\omega(H^\omega - H^0).$$

Thus, from (5.6), we can deduce that $\omega^2\,||H^\omega - H^0||^2_{(L^2(B_R))^3}$ is of order ω^4 and then $||H^\omega - H^0||_{(L^2(B_R))^3}$ is of order ω. Now, since

$$\overrightarrow{\mathrm{curl}}\,\frac{1}{\mu}\,\overrightarrow{\mathrm{curl}}\left(E^\omega - \sum_{j=0}^{M} E^j\,\omega^j\right) - \omega^2\varepsilon\left(E^\omega - \sum_{j=0}^{M} E^j\,\omega^j\right) = \omega^{M+1}\varepsilon\Big(E^{M-1} + \omega E^M\Big)$$

in B_R, proceeding in a similar way, we obtain that the estimate

$$\left\|E^\omega - \sum_{j=0}^{M} E^j\,\omega^j\right\|_{(L^2(B_R))^3} = 0(\omega^{M+1})$$

holds for any integer M. To complete the proof of Theorem 5.3, we see that from

$$\left\|E^\omega - \sum_{j=0}^{M+1} E^j\,\omega^j\right\|_{(L^2(B_R))^3} = 0(\omega^{M+2}),$$

the variational equation

$$\begin{aligned}
&\int_{B_R} \frac{1}{\mu} \left| \overrightarrow{\mathrm{curl}} \left(E^\omega - \sum_{j=0}^{M+1} E^j\, \omega^j \right) \right|^2 - \omega^2 \int_{B_R} \varepsilon \left| E^\omega - \sum_{j=0}^{M+1} E^j\, \omega^j \right|^2 \\
&-i\omega\mu_0 \left(T^\omega \left(E^\omega_{S_R} - \sum_{j=0}^{M+1} E^j\, \omega^j \right), E^\omega_{S_R} - \sum_{j=0}^{M+1} E^j_{S_R}\, \omega^j \right) \\
&= \omega^{M+2} \int_{B_R} \varepsilon \left(E^M + \omega E^{M+1} \right) \cdot \left(\overline{E}^\omega - \sum_{j=0}^{M+1} \overline{E}^j\, \omega^j \right) \\
&+i\omega\mu_0 \left(g^{in}_\omega - T^\omega \left(\sum_{j=0}^{M+1} E^j_{S_R}\, \omega^j \right), E^\omega_{S_R} - \sum_{j=0}^{M+1} E^j_{S_R}\, \omega^j \right),
\end{aligned}$$

and the fact that the quantity

$$\left| \left(g^{in}_\omega - \sum_{j=0}^{M} T^\omega (E^j_{S_R}) \omega^j, E^\omega_{S_R} - \sum_{j=0}^{M} E^j_{S_R}\, \omega^j \right) \right|$$

is of order $0(\omega^M)\, ||E^\omega_{S_R} - \sum_{j=0}^{M} E^j_{S_R}\, \omega^j ||_{TH^{-1/2}(\mathrm{curl}, S_R)}$, we have

$$\omega^2 \int_{B_R} \mu \,|H^\omega - \sum_{j=0}^{M} H^j\, \omega^j|^2 \;=\; 0(\omega^{2M+4}).$$

Therefore, the quantity $||H^\omega - \sum_{j=0}^{M} H^j\, \omega^j||_{(L^2(B_R))^3}$ is of order $0(\omega^{M+1})$. □

Appendix A. The electromagnetic operator.

In this appendix, we give the explicit expression of the operator T^ω. Let us recall the standard vector basis functions for Maxwell's equations

$$\left\{ \begin{aligned} M_l^m(x) \;&=\; \overrightarrow{\mathrm{curl}} \Big(x\, h_l^{(1)}(\omega\sqrt{\varepsilon_0\mu_0})\, Y_l^m(x) \Big), \\ N_l^m(x) \;&=\; \frac{1}{i\omega\sqrt{\varepsilon_0\mu_0}}\, \overrightarrow{\mathrm{curl}}\, M_l^m(x), \end{aligned} \right.$$

where $h_l^{(1)}$ denotes the spherical Hankel functions of the first kind and order l. From the definitions of G_l^m and R_l^m, it is easy to see that

$$\begin{aligned} &-n \wedge \Big(n \,\wedge\, N_l^m(x) \Big) \\ &= -\frac{i}{\omega\sqrt{\varepsilon_0\mu_0}} \sqrt{l(l+1)} \left(h_l^{(1)}(\omega\sqrt{\varepsilon_0\mu_0}) + \omega\sqrt{\varepsilon_0\mu_0} \Big(h_l^{(1)} \Big)' (\omega\sqrt{\varepsilon_0\mu_0}) \right) G_l^m(x) \end{aligned}$$

and

$$-n \wedge \Big(n \,\wedge\, M_l^m(x) \Big) \;=\; -\sqrt{l(l+1)}\, h_l^{(1)}(\omega\sqrt{\varepsilon_0\mu_0})\, R_l^m(x)$$

on $S_R(R=1)$. Now, if we expand the tangential vector field g^ω in the form

$$g^\omega \;=\; \sum_{l=1}^{+\infty} \sum_{m=-l}^{l} \alpha_l^m(\omega)\, G_l^m + \beta_l^m(\omega)\, R_l^m,$$

the solution of Maxwell's equations (2.2) satisfying the outgoing radiation condition can be written for $|x| > R = 1$ in the form (see, for instance, [13])

$$\mathcal{E}^\omega(x) \;=\; \sum_{l\geq 1} \sum_{m=-l}^{l} \Big(\delta_l^m(\omega)\, M_l^m(x) + \theta_l^m(\omega)\, N_l^m(x) \Big),$$

with uniform convergence on compact subsets of $|x| > R$, where

$$\delta_l^m(\omega) \;=\; -\frac{\beta_l^m(\omega)}{\sqrt{l(l+1)}\, h_l^{(1)}(\omega\sqrt{\varepsilon_0\mu_0})}$$

and

$$\theta_l^m(\omega) \;=\; \frac{i\omega\sqrt{\varepsilon_0\mu_0}\,\alpha_l^m(\omega)}{\sqrt{l(l+1)}\,\Big(h_l^{(1)}(\omega\sqrt{\varepsilon_0\mu_0}) + \omega\sqrt{\varepsilon_0\mu_0}\Big(h_l^{(1)}\Big)'(\omega\sqrt{\varepsilon_0\mu_0})\,\Big)}.$$

Since

$$\begin{cases} \overrightarrow{\text{curl}}\, M_l^m(x) \;=\; i\omega\sqrt{\varepsilon_0\mu_0}\, N_l^m(x), \\ \overrightarrow{\text{curl}}\, N_l^m(x) \;=\; -i\omega\sqrt{\varepsilon_0\mu_0}\, M_l^m(x), \end{cases}$$

the magnetic field $\mathcal{H}^\omega$ is given by

$$\mathcal{H}^\omega(x) \;=\; \frac{1}{\mu_0} \sum_{l\geq 1} \sum_{m=-l}^{l} \Big(\delta_l^m(\omega)\, N_l^m(x) - \theta_l^m(\omega)\, M_l^m(x) \Big).$$

Therefore, we have the following explicit representation for the operator T^ω:

$$T^\omega(g^\omega) \;=\; \sqrt{\frac{\varepsilon_0}{\mu_0}} \sum_{l=1}^{+\infty} \sum_{m=-l}^{l} i\omega \frac{\alpha_l^m(\omega)}{\gamma_l(\omega)}\, G_l^m + \frac{\beta_l^m(\omega)\gamma_l(\omega)}{i\omega}\, R_l^m,$$

where

$$\gamma_l(\omega) \;=\; 1 + \omega \frac{(h_l^{(1)})'(\omega)}{h_l^{(1)}(\omega)}.$$

Appendix B. Proofs of Lemmas 2.3–2.6.

In this appendix we shall give the proofs of Lemmas 2.3–2.6.

Proof of Lemma 2.3. It is easy to see that

$$\frac{l\, c_l^{l-1}}{c_l^l} \;<\; 1 \text{ and } \frac{c_l^m}{c_l^{m+1}} \;<\; 1, \quad m = 0 \text{ to } l-1.$$

By rewriting the quantity

$$\frac{(l+1-m)\,c_l^{l-m}}{c_l^l} = \frac{(l+1-m)\,c_l^{l-1}}{c_l^l}\,\frac{c_l^{l-2}}{c_l^{l-1}}\cdots\frac{c_l^{l-m}}{c_l^{l-m+1}},$$

we obtain the claim.

Proof of Lemma 2.4. For ω small enough, combining

$$\left|\frac{1}{\gamma_l(\omega)}+\frac{1}{l}\right| \le \omega \sup_{0<\omega_1<\omega}\left|\frac{\gamma_l'(\omega_1)}{\gamma_l^2(\omega_1)}\right|$$

and the following identity, which follows from the explicit form (2.12) of γ_l and Lemma 2.3, we obtain

$$\sup_{0<\omega_1<\omega}\left|\frac{\gamma_l'(\omega_1)}{\gamma_l^2(\omega_1)}\right| \le \frac{C}{l^2}\,\omega,$$

where $l \ge 1$ and the constant C is independent of ω and l, which thus gives the claim.

Next, from (2.12) and (2.13), we shall prove Lemma 2.5.

Proof of Lemma 2.5. Let

$$Q_l(t) = t^{2l}q_l(t) = c_l^l\left(1+\cdots+\frac{c_l^0}{c_l^l}t^{2l}\right).$$

From Lemma 2.3, it follows that there exists a complex neighborhood V of zero such that for any $l \ge 1$, $Q_l(t)$ does not have a zero in V. We can deduce that there exists a ball $B_r (r > 0)$ such that the function $\omega \mapsto \gamma_l(\omega)$ is analytic in B_r. (2.15) follows from the fact that there exists a constant C independent of ω such that

$$|\gamma_l(\omega)| \le C|\gamma_l^0| \quad \forall\, \omega \in \partial B_r.$$

Proof of Lemma 2.6. By using the fact that there exists a complex neighborhood V of zero such that

$$P_l(t) = t^{2l}p_l(t) + it^{2l}$$

does not have a zero in V, the identity (2.16) holds. (2.17) is easily deduced from (2.14).

LOCALIZATION OF SOLUTIONS OF EXTERIOR DOMAIN PROBLEMS FOR THE POROUS MEDIA EQUATION WITH RADIAL SYMMETRY*

B. H. GILDING† AND J. GONCERZEWICZ‡

Abstract. The paper concerns the radially symmetric Cauchy–Dirichlet and Cauchy–Neumann problems for the porous media equation in the domain comprising the spatial variable and the temporal variable t in the exterior of the unit ball in $\mathbb{R}^n$ and the bounded interval $(0, T)$, respectively. The subject of study is the behavior of solutions when the initial data are compactly supported and the boundary data become unbounded as $t \uparrow T$. Necessary and sufficient conditions for localization, estimates of the size of the blow-up set, and a number of allied results are obtained.

Key words. porous media equation, radial symmetry, localization, blow-up, peaking, comparison principle, self-similar solution

1. Statement of problems and results.

We consider two problems for the nonlinear partial differential equation

$$\frac{\partial u}{\partial t} = r^{1-n} \frac{\partial}{\partial r} \left(r^{n-1} \frac{\partial u^m}{\partial r} \right), \tag{1.1}$$

where

$$n \geq 1 \quad \text{and} \quad m > 1$$

are real parameters, for (r, t) in the domain

$$Q := (1, \infty) \times (0, T) \quad \text{with} \quad 0 < T < \infty.$$

Both problems have the initial condition

$$u(r, 0) = u_0(r) \quad \text{for } 1 < r < \infty, \tag{1.2}$$

where u_0 is a bounded, nonnegative, measurable function defined on the interval $(1, \infty)$ which vanishes for large r.

Problem 1.1. Equation (1.1) in Q subject to (1.2) and the Dirichlet boundary condition

$$u(1, t) = f(t) \quad \text{for } 0 < t < T.$$

Problem 1.2. Equation (1.1) in Q subject to (1.2) and the Neumann boundary condition

$$-\frac{\partial u^m}{\partial r}(1,t) = g(t) \quad \text{for } 0 < t < T.$$

In these problems f and g are nonnegative, measurable functions defined on the interval $(0,T)$ which are bounded on every interval $(0,\tau)$ with $0 < \tau < T$.

Problems 1.1 and 1.2 are prompted by the study of the porous media equation $\partial u/\partial t = \Delta u^m$ in which t denotes time and Δ the Laplace operator in $\mathbb{R}^n$. This equation is well known as an outstanding benchmark for the study of quasilinear degenerate parabolic equations of second order. In contrast to a nondegenerate parabolic equation, when $m > 1$ this equation displays finite speed of propagation. This is to say that in an unbounded spatial domain with initial data possessing compact support, the solution retains compact support with respect to the spatial variable at all later times. The boundary of the support of the solution constitutes an interface with some established regularity. Simultaneously the solution may fail to solve the equation classically at this free boundary. It is known that the support of the solution cannot shrink in time and in an infinite time-span will eventually fill the whole spatial domain [3, 4, 23, 27, 36]. The present interest is in the solution of the porous media equation in the spatial domain comprising the exterior of the unit ball in $\mathbb{R}^n$ with Dirichlet or Neumann boundary conditions on the surface of the ball. Specifically, the interest is in the behavior of the solution and its support when the boundary data become unbounded as some critical finite time T is approached. A pertinent question, in this case, is whether or not the support of the solution may fill the whole domain at the critical time. If it does not, and the support of the solution remains bounded, the solution is said to exhibit localization. A closely related question is whether or not the volume of the subdomain in which the solution itself becomes unbounded as the critical time is approached is bounded. If this volume is bounded, the solution is said to display effective localization [31]. As a foundation for analyzing these questions we shall consider the restriction to radially symmetric solutions of the problems. In this event one arrives at Problems 1.1 and 1.2, with r denoting radius and n a positive integer.

The last thirty years have seen considerable advances in the understanding of the phenomena of localization and effective localization of solutions of initial-boundary-value problems for degenerate and nondegenerate quasilinear parabolic equations of second order (which include the porous media equation as a special case) and in domains of one or more spatial dimensions with diverse geometries. In particular, much knowledge has been acquired from the investigation of self-similar and "approximately self-similar" solutions of the equation in hand. For an encyclopedic and instructive overview of the study of the phenomena of localization and effective localization, including an exhaustive survey of antecedent literature, we recommend to the reader the monograph [31].

Notwithstanding the above remarks, excepting in recent papers of Shishkov [32] and Shishkov and Shchelkov [33], the questions of localization for Problems 1.1 and 1.2 for $n > 1$ do not appear to have been treated previously in the literature. Analysis has concentrated on the Cauchy–Dirichlet problem in rectangular spatial domains with convenient conditions on the boundary data, and especially on the Cauchy–Dirichlet problem in the case $n = 1$ under the assumption that the boundary data function f

is continuous and increasing. In this context it has been said that solutions are in a *peaking regime* and T is called the *peaking time* [15, 30].

To clarify our study further, let us state what is understood by a solution of Problems 1.1 and 1.2.

Definition 1.3. *A real function u defined on Q is said to be a weak solution of Problem* 1.1 *if, for any $0 < \tau < T$, u is nonnegative, bounded, and continuous in $(1,\infty) \times (0,\tau]$ and u satisfies the identity*

$$\int_0^\tau \int_1^\infty \left\{ r^{n-1} u \frac{\partial \varphi}{\partial t} + u^m \frac{\partial}{\partial r} \left(r^{n-1} \frac{\partial \varphi}{\partial r} \right) \right\} dr\, dt \\ + \int_1^\infty r^{n-1} u_0(r) \varphi(r,0)\, dr + \int_0^\tau f^m(t) \frac{\partial \varphi}{\partial r}(1,t)\, dt = 0$$

for all nonnegative $\varphi \in C^{2,1}([1,\infty) \times [0,\tau])$ which vanish for $t = \tau$, $r = 1$, and large r.

Definition 1.4. *A real function u defined on Q is said to be a weak solution of Problem* 1.2 *if, for any $0 < \tau < T$, u is nonnegative, bounded, and continuous in $(1,\infty) \times (0,\tau]$ and u satisfies the identity*

$$\int_0^\tau \int_1^\infty \left\{ r^{n-1} u \frac{\partial \varphi}{\partial t} + u^m \frac{\partial}{\partial r} \left(r^{n-1} \frac{\partial \varphi}{\partial r} \right) \right\} dr\, dt \\ + \int_1^\infty r^{n-1} u_0(r) \varphi(r,0)\, dr + \int_0^\tau g(t) \varphi(1,t)\, dt = 0$$

for all nonnegative $\varphi \in C^{2,1}([1,\infty) \times [0,\tau])$ which vanish for $t = \tau$ and large r and are such that $\partial\varphi/\partial r$ vanishes for $r = 1$.

The theory developed for initial-boundary-value problems for the porous media equation in one spatial dimension [3, 4, 23, 27] readily extends to Problems 1.1 and 1.2. This can be explained formally by the observation that (1.1) can be written as $\partial u/\partial t = \partial^2 u^m/\partial r^2 + (n-1)r^{-1}\partial u^m/\partial r$, which differs from the porous media equation in one spatial dimension merely by an extra term containing a first order derivative preceded by a coefficient of fixed sign which is not singular for $r > 1$. Correspondingly, Problems 1.1 and 1.2 each admit a unique weak solution u which has a derivative $\partial u^m/\partial r$ in $C(Q)$, is such that $(\partial u^m/\partial r)(r,\cdot) \in L^1(0,t)$ for every $(r,t) \in Q$, and is a classical solution of (1.1) at any point in Q where it is positive. For details, see [19].

Set

$$\zeta_0 := \sup \left\{ r \in (1,\infty) : \int_r^\infty u_0(x)\, dx > 0 \right\},$$

with the convention that this is equal to 1 if the supremum is taken over the empty set. Since u_0 vanishes for large r, this quantity is finite. Furthermore, by results in [18], if one defines

$$\zeta(t) := \sup\{ r \in (1,\infty) : u(r,t) > 0 \} \quad \text{for } 0 < t < T$$

with the convention that this variable is equal to 1 if the supremum is taken over the empty set, then ζ is a nondecreasing continuous function on $(0,T)$ such that $\zeta(t) \to \zeta_0$ as $t \downarrow 0$. Thus one can define

$$\zeta(T) := \sup\{\zeta(t) : 0 < t < T\}. \tag{1.3}$$

Following [11, 15, 31], u will be said to be *localized* if $\zeta(T) < \infty$.

For a weak solution u of Problem 1.1 or 1.2 we define the *blow-up set*

$$\Omega := \left\{ r \in (1,\infty) : \limsup_{t \uparrow T} u(r,t) = \infty \right\}. \tag{1.4}$$

In applications where the porous media equation is considered as a nonlinear model of heat conduction, this blow-up set is sometimes referred to as the *zone of heat intensification*. An alternative definition for such a set is

$$\Omega^* := \left\{ r \in (1,\infty) : \limsup_{t \uparrow T} \int_r^\infty x^{n-1} u(x,t)\, dx = \infty \right\}. \tag{1.5}$$

Considering (1.1) once more as a model of nonlinear heat conduction, this set represents the complement of the region in which the total energy remains finite. Under our standing convention that the supremum of the empty set is 1, let

$$\omega := \sup \Omega \quad \text{and} \quad \omega^* := \sup \Omega^*. \tag{1.6}$$

In view of a comparison principle for solutions of Problems 1.1 and 1.2, which is the natural extension of a similar principle for solutions of the porous media equation in one spatial dimension (details of which can be found in [19]), both of the blow-up sets Ω and Ω^* are either empty or an interval with infimum 1, i.e.,

$$(1,\omega) \subseteq \Omega \subseteq \overline{(1,\omega)} \quad \text{and} \quad (1,\omega^*) \subseteq \Omega^* \subseteq \overline{(1,\omega^*)}.$$

Furthermore, u and $\partial u^m / \partial r$ are continuous in $(\omega,\infty) \times (0,T]$,

$$\zeta(T) < \infty \quad \text{if and only if} \quad \omega < \infty,$$

and

$$\Omega^* \subseteq \Omega \subseteq (1, \zeta(T)). \tag{1.7}$$

Following [30, 31], it will be said that u is *effectively localized* if $\omega < \infty$, and *metastably localized* if $\omega^* < \infty$.

In the case $n = 1$, a definitive characterization of the occurrence of localization under the assumption that u_0 is continuous on $[1,\infty)$ and that f is continuous and monotonic increasing on $[0,T)$ and satisfies the compatibility condition $f(0) = u_0(1)$ was published in [15]. It was proven that localization occurs if and only if

$$\mathcal{C}^* := \limsup_{t \uparrow T} \frac{\int_0^t f^m(s)\, ds}{f(t)} \tag{1.8}$$

is finite. Moreover, defining

$$\ell(r) := \limsup_{t \uparrow T} (T-t)^{1/(m-1)}\, u(r,t) \quad \text{for } r > 1 \tag{1.9}$$

for a weak solution u of Problem 1.1, if localization occurs then $\ell(r) < \infty$ for all $r > 1$, whereas if localization does not occur then $\ell(r) = \infty$ for all $r > 1$. Furthermore, it was shown that if $r \in \Omega$ then $u(r,t) \to \infty$ as $t \uparrow T$. Finally in [15], estimates of the size of the blow-up set Ω were derived.

Shortly after the article [15] was published, another paper [11] in which localization for Problem 1.1 with $n = 1$ was characterized appeared. This article, by Cortazar and Elgueta, examined the problem under the assumption that u_0 is continuous on $(1, \infty)$ and that f is continuous on $(0, T)$. The result established was that Problem 1.1 exhibits localization if and only if

$$\mathcal{C} := \limsup_{t \uparrow T} (T - t)^{1/(m-1)} \int_0^t f^m(s)\, ds \tag{1.10}$$

is finite. It turns out that this criterion of Cortazar and Elgueta [11] represents the superior result, since it does not rely on the assumption that f is monotonic, and, as we shall see in an appendix, if f is continuous and nondecreasing, the conditions $\mathcal{C} < \infty$ and $\mathcal{C}^* < \infty$ are equivalent. The Cauchy–Neumann problem with $n = 1$ was also examined by Cortazar and Elgueta, under the assumption that u_0 is Lipschitz continuous on $[1, \infty)$. For this problem, they showed that localization occurs if and only if

$$\mathcal{C} := \limsup_{t \uparrow T} (T - t)^{1/(m-1)} \int_0^t g(s)\, ds \tag{1.11}$$

is finite.

The first contribution of the present paper will be to demonstrate the following.

THEOREM 1.5. *For any weak solution u of Problem* 1.1 *or Problem* 1.2 *there holds $\omega^* = \omega$.*

It follows that for a solution of Problem 1.1 or 1.2 the concepts of localization, effective localization, and metastable localization are all equivalent. Moreover, with the possible exception $\Omega^* = (1, \omega)$ and $\Omega = (1, \omega]$ with $1 < \omega < \infty$, the blow-up sets Ω and Ω^* coincide.

Specifically concerning the Cauchy–Dirichlet problem, we prove the next result.

THEOREM 1.6. *Let u be a weak solution of Problem* 1.1 *and let $\mathcal{C}$ be defined by* (1.10)*. Then $\omega < \infty$ if and only if $\mathcal{C} < \infty$.*

Thus the result of Cortazar and Elgueta [11] can be obtained under weaker assumptions on the initial and boundary data. Moreover, this result extends from $n = 1$ to every $n \geq 1$.

We shall also extend the results on the nature of blow-up which were obtained in [15] by demonstrating the following two theorems. The extension represents a weakening of the assumptions on the initial and boundary data, an enlargement on the conclusions, and, last but not least, a generalization from $n = 1$ to $n \geq 1$. By the statement that f is nondecreasing, we mean that $\operatorname{ess\,sup}\{f(s) : 0 < s < t\} \leq \operatorname{ess\,inf}\{f(s) : t < s < T\}$ for all $0 < t < T$.

THEOREM 1.7. *Let u be a weak solution of Problem* 1.1 *and $\mathcal{C}$ be specified by* (1.10)*. Define $\ell(r)$ by* (1.9) *and*

$$L(r) := \begin{cases} \mathcal{C} & \text{for } r = 1, \\ \limsup_{t \uparrow T} (T - t)^{1/(m-1)} \int_0^t u^m(r, s)\, ds & \text{for } r > 1. \end{cases} \tag{1.12}$$

(i) *Suppose that $\mathcal{C} < \infty$. Then $\ell^{m-1}, L \in C(1, \infty) \cap W^{1,\infty}_{\mathrm{loc}}(1, \infty)$, ℓ and L are strictly decreasing on $(1, \omega]$ and $[1, \omega]$, respectively, and $\ell \equiv L \equiv 0$ on (ω, ∞).*

(ii) *Suppose that $\mathcal{C} = \infty$. Then $\ell(r) = L(r) = \infty$ for all $r > 1$.*

Furthermore, if f is nondecreasing, then $u(\cdot, t) \to \infty$ as $t \uparrow T$ uniformly on $(1, r)$ for every $1 < r < \omega$.

THEOREM 1.8. *Let u_1 and u_2 be two weak solutions of Problem* 1.1 *with corresponding initial data functions $u_{0,i}$, boundary data functions f_i, parameters $\mathcal{C}_i$ defined by* (1.10)*, and functions ℓ_i and L_i defined by* (1.9) *and* (1.12) *for $i = 1, 2$. If*

$$\limsup_{t\uparrow T} (T-t)^{1/(m-1)} \int_0^t \{f_1^m(s) - f_2^m(s)\}\, ds \le 0, \tag{1.13}$$

then $L_1(r) \le L_2(r)$ for all $r \ge 1$. Moreover, if

$$(T-t)^{1/(m-1)} \int_0^t \max\{f_1^m(s) - f_2^m(s), 0\}\, ds \to 0 \qquad \text{as } t \uparrow T, \tag{1.14}$$

then $\ell_1(r) \le \ell_2(r)$ for all $r > 1$.

Regarding the size of the blow-up sets, we establish the next estimate.

THEOREM 1.9. *Let u be a weak solution of Problem* 1.1 *for which $\mathcal{C} < \infty$, where $\mathcal{C}$ is defined by* (1.10)*. Then*

$$1 + \mu\, \{\sigma(\mathcal{C})\}^{(m-1)/2m} \le \omega \le 1 + \nu\, \{\sigma(\mathcal{C})\}^{(m-1)/2m},$$

where μ and ν are positive constants which depend only on m and n, and

$$\sigma(\mathcal{C}) := \begin{cases} \mathcal{C} & \text{for } n < 2, \\ \mathcal{C}\, \{1 + \ln(1+\mathcal{C})\}^{-1} & \text{for } n = 2, \\ \mathcal{C}\, (1+\mathcal{C})^{-(m-1)(n-2)/\{(m-1)n+2\}} & \text{for } n > 2. \end{cases} \tag{1.15}$$

It follows that the size of the blow-up sets Ω and Ω^* may be estimated solely in terms of the critical parameter $\mathcal{C}$. Specifically, if $\mathcal{C} > 0$ then $\omega = \omega^* > 1$, while if $\mathcal{C} = 0$ then $\omega = \omega^* = 1$. This improves results in [15] where, in the case $n = 1$ and under the more restrictive assumptions on the initial and boundary data, estimates of the size of the blow-up set Ω in terms of the parameter defined by (1.8) and kindred parameters were obtained.

Concerning the Cauchy–Neumann problem, our main results on localization and blow-up are as follows.

THEOREM 1.10. *Let u be a weak solution of Problem* 1.2 *and let $\mathcal{C}$ be defined by* (1.11)*. Then $\omega < \infty$ if and only if $\mathcal{C} < \infty$.*

THEOREM 1.11. *Let u be a weak solution of Problem* 1.2 *and $\mathcal{C}$ be specified by* (1.11)*. Define $\ell(r)$ by* (1.9) *and*

$$L(r) := \begin{cases} \mathcal{C} & \text{for } r = 1, \\ \limsup_{t\uparrow T} (T-t)^{1/(m-1)} \left(-r^{n-1} \int_0^t \frac{\partial u^m}{\partial r}(r,s)\, ds\right) & \text{for } r > 1. \end{cases} \tag{1.16}$$

Then, verbatim, conclusions (i) *and* (ii) *of Theorem* 1.7 *hold. Furthermore, if g is nondecreasing, then $u(\cdot, t) \to \infty$ as $t \uparrow T$ uniformly on $(1, r)$ for every $1 < r < \omega$.*

THEOREM 1.12. *Let u_1 and u_2 be two weak solutions of Problem* 1.2 *with corresponding initial data functions $u_{0,i}$, boundary data functions g_i, parameters $\mathcal{C}_i$ defined by* (1.11)*, and functions ℓ_i and L_i defined by* (1.9) *and* (1.16) *for $i = 1, 2$. If*

$$\limsup_{t\uparrow T} (T-t)^{1/(m-1)} \int_0^t \{g_1(s) - g_2(s)\}\, ds \le 0,$$

then $L_1(r) \leq L_2(r)$ *for all* $r \geq 1$. *Moreover, if*

$$(T-t)^{1/(m-1)} \int_0^t \max\{g_1(s) - g_2(s), 0\}\, ds \to 0 \qquad \textit{as } t \uparrow T,$$

then $\ell_1(r) \leq \ell_2(r)$ *for all* $r > 1$.

Theorem 1.13. *Let* u *be a weak solution of Problem* 1.2 *for which* $\mathcal{C} < \infty$, *where* $\mathcal{C}$ *is defined by* (1.11). *Then*

$$1 + \mu \left\{\sigma(\mathcal{C})\right\}^{(m-1)/(m+1)} \leq \omega \leq 1 + \nu \left\{\sigma(\mathcal{C})\right\}^{(m-1)/(m+1)},$$

where μ *and* ν *are positive constants which depend only on* m *and* n, *and*

$$\sigma(\mathcal{C}) := \mathcal{C}\,(1+\mathcal{C})^{-(m-1)(n-1)/\{(m-1)n+2\}}. \tag{1.17}$$

Theorem 1.10 shows that the result of Cortazar and Elgueta [11] for Problem 1.2 in the case $n = 1$ holds for arbitrary $n \geq 1$. Also in the case $n = 1$ it can be obtained under less restrictive assumptions on the boundary and initial data functions. Concurrently, Theorem 1.13 states that the size of the blow-up sets Ω and Ω^* can be estimated solely in terms of the critical parameter $\mathcal{C}$ given by (1.11). As a matter of fact, taking Theorems 1.5, 1.10, and 1.13 together, we see that $\omega = \omega^* = \infty$ when $\mathcal{C} = \infty$, $1 < \omega = \omega^* < \infty$ if $0 < \mathcal{C} < \infty$, and $\omega = \omega^* = 1$ if $\mathcal{C} = 0$. Theorem 1.11 provides the extension of the results in [15] on the behavior of ℓ for the Cauchy–Dirichlet problem in the case $n = 1$ to the Cauchy–Neumann problem and to every $n \geq 1$.

This paper is organized as follows. After this introduction, we present the major tools which we use to prove our theorems. These are special comparison principles, which we establish in section 2, particular self-similar solutions of the porous media equation, whose existence we justify in section 3, and regularity estimates for solutions of (1.1), which we derive in section 4. Since Theorem 1.5 is an easy consequence of one of these estimates, we shall also prove this theorem in section 4. Thereafter, in section 5 we present the bulk of our analysis for Problem 1.1. In a sequence of subsections, we prove, in the following order, Theorem 1.6, Theorem 1.8, Theorem 1.7, Theorem 1.9, and an additional result (Theorem 5.17) on the magnitude of the variables ℓ and L defined by (1.9) and (1.12) for a solution u of the Cauchy–Dirichlet problem. In section 6, we repeat the story for the Cauchy–Neumann problem, treating successively Theorem 1.10, Theorem 1.12, Theorem 1.11 (dependent upon a lemma whose proof we postpone), Theorem 1.13, and a result (Theorem 6.11) on the magnitude of the variables ℓ and L defined by (1.9) and (1.16) for a solution u of Problem 1.2. Finally, in section 7, we comment on the results which can be obtained for the Cauchy–Neumann problem when g is not necessarily nonnegative, and complete the proof of the lemma postponed from section 6.

Using the group-invariance properties of the porous media equation, by a rescaling argument our results also apply to the analogous problems for (1.1) in the domain $(r_0, \infty) \times (0, T)$ for any $r_0 > 0$. One may wonder what is to be expected for the limiting situation with $r_0 = 0$. "Back of an envelope" calculations which we have carried out indicate that the problem of solving (1.1) in $(0, \infty) \times (0, T)$ with the boundary condition $u(0, t) = f(t)$ for $0 < t < T$ and the initial condition $u(r, 0) = u_0(r)$ for $r > 0$ is ill posed when $n > 1$. In particular, if $n > 1$ is an integer then as $r_0 \downarrow 0$, solutions of the problem of (1.1) in $(r_0,\infty)\times(0,T)$ with the boundary condition $u(r_0,t)=f(t)$ for $0<t<T$ and the initial condition $u(r,0)=u_0(r)$ for $r>r_0$ for a function u_0 defined on $(0,\infty)$ converge to the radially symmetric solution of the Cauchy problem for the porous media equation in $\mathbb{R}^n\times(0,T)$ with initial data $u(\boldsymbol{x},0)=u_0(|\boldsymbol{x}|)$. The same destiny appears to await solutions of the problem of (1.1) in $(r_0,\infty)\times(0,T)$ with the boundary condition $-(\partial u^m/\partial r)(r_0,t)=g(t)$ for $0<t<T$ and the initial condition $u(r,0)=u_0(r)$ for $r>r_0$. However, solutions of this problem with the boundary condition $-r_0^{n-1}(\partial u^m/\partial r)(r_0,t)=g(t)$ will converge formally to the solution of the equation $\partial u/\partial t=\Delta u^m+\chi g(t)\delta(\boldsymbol{x})$ in $\mathbb{R}^n\times(0,T)$ with initial data $u(\boldsymbol{x},0)=u_0(|\boldsymbol{x}|)$, where χ is the $(n-1)$-dimensional measure of the surface of the unit ball in $\mathbb{R}^n$.

Our results can also be invoked to study the localization and effective localization of solutions of initial-boundary-value problems for the porous media equation in arbitrary spatial domains in $\mathbb{R}^n$. The only tool needed is an adequate comparison principle. Consider, for instance, the equation $\partial u/\partial t=\Delta u^m$ in $\mathcal{Q}:=D\times(0,T)$ subject to the initial condition $u(\boldsymbol{x},0)=u_0(\boldsymbol{x})$ for $\boldsymbol{x}\in D$ and the boundary condition $u(\boldsymbol{x},t)=f(\boldsymbol{x},t)$ for $(\boldsymbol{x},t)\in\partial D\times(0,T)$, where D is an open subset of $\mathbb{R}^n$, and the complement of $\overline{D}$ is bounded, simply connected, and not empty. By analysis in [12, 13, 29], under the hypotheses that ∂D is smooth, u_0 is a nonnegative function in $L^\infty(D)\cap L^1(D)$, and f is a nonnegative function in $C(\partial D\times[0,T))$, this problem has a unique weak solution, $u\in C(\overline{D}\times(0,\tau])\cap L^\infty(D\times(0,\tau])$ for every $0<\tau<T$, which satisfies a comparison principle. Furthermore, if $\mathbf{0}\notin\overline{D}$ and there exists a finite ζ_0 such that $u_0(\boldsymbol{x})=0$ for all $\boldsymbol{x}\in D$ with $|\boldsymbol{x}|\geq\zeta_0$, then one can define a nondecreasing function $\zeta(t):=\inf\{r:u(\boldsymbol{x},t)=0$ for all $\boldsymbol{x}\in D$ with $|\boldsymbol{x}|\geq r\}$ for $0<t<T$, $\zeta(T)$ by (1.3), and the blow-up set $\Omega:=\{\boldsymbol{x}\in D:\limsup_{t\uparrow T}u(\boldsymbol{x},t)=\infty\}$. Let $M:=\operatorname{ess\,sup}\{u_0(\boldsymbol{x}):\boldsymbol{x}\in D\}$, $r_1:=\min\{|\boldsymbol{x}|:\boldsymbol{x}\in\partial D\}$, and $r_2:=\max\{|\boldsymbol{x}|:\boldsymbol{x}\in\partial D\}$. Define $u_{0,1}(r):=0$ for $r>r_1$, $u_{0,2}(r):=M$ for $r_2<r<\zeta_0$, and $u_{0,2}(r):=0$ for $r\geq\zeta_0$, $f_1(t):=\inf\{f(\boldsymbol{x},s):(\boldsymbol{x},s)\in\partial D\times[t,T)\}$, and $f_2(t):=\max\{\max\{f(\boldsymbol{x},s),M\}:(\boldsymbol{x},s)\in\partial D\times[0,t]\}$ for $0\leq t<T$. In this case, setting $D_i:=\{\boldsymbol{x}\in\mathbb{R}^n:|\boldsymbol{x}|>r_i\}$, there is a radially symmetric solution u_i of the porous media equation in $\mathcal{Q}_i:=D_i\times(0,T)$ satisfying $u_i(\boldsymbol{x},0)=u_{0,i}(|\boldsymbol{x}|)$ for $\boldsymbol{x}\in D_i$, and $u_i(\boldsymbol{x},t)=f_i(t)$ for $(\boldsymbol{x},t)\in\partial D_i\times(0,T)$, for $i=1,2$. Employing the available comparison principle to compare each solution with constant solutions, it can be deduced that $u(\boldsymbol{x},t)\leq f_2(t)$ for all $(\boldsymbol{x},t)\in\mathcal{Q}$ and $u_1(\boldsymbol{x},t)\leq f_1(t)$ for all $(\boldsymbol{x},t)\in\mathcal{Q}_1$; cf. [15]. Subsequently, using the principle to compare the solutions with one another, it can be concluded that $u_1\leq u$ in $\mathcal{Q}$ and $u\leq u_2$ in $\mathcal{Q}_2$. If, by the way, $r_1=r_2$, it suffices to define $f_1(t):=\min\{f(\boldsymbol{x},t):\boldsymbol{x}\in\partial D\}$ and $f_2(t):=\max\{f(\boldsymbol{x},t):\boldsymbol{x}\in\partial D\}$, and the first comparison argument in the foregoing discussion can be skipped. Now, subject to the scaling mentioned above, u_1 and u_2 fall within the scope of our results. Defining $\mathcal{C}_i$ by (1.10) with f replaced by f_i for $i=1,2$ and recalling the notation μ, ν, and σ from Theorem 1.9, we find the following. If $\mathcal{C}_2<\infty$, then $\zeta(T)<\infty$ and $\Omega\subseteq\{\boldsymbol{x}\in D:|\boldsymbol{x}|\leq\varpi_2\}$, where

$$\varpi_2:=r_2\left(1+\nu\left\{\sigma(r_2^{-2m/(m-1)}\mathcal{C}_2)\right\}^{(m-1)/2m}\right).$$

If $\mathcal{C}_1<\infty$, then $\{\boldsymbol{x}\in D:|\boldsymbol{x}|<\varpi_1\}\subseteq\Omega$, where

$$\varpi_1:=r_1\left(1+\mu\left\{\sigma(r_1^{-2m/(m-1)}\mathcal{C}_1)\right\}^{(m-1)/2m}\right);$$

while $\zeta(T)=\infty$ and $\Omega=D$ if $\mathcal{C}_1=\infty$. Similar arguments can be applied to Cauchy–Neumann problems and to problems involving spatial domains which are the exterior of a cylinder and spatial domains which are wedge-shaped. See, for instance, [31] for a discussion of how a solution dependent on a single spatial variable can be deployed to study localization for a problem in a spatial domain given in two dimensions by a quarter-plane.

2. Comparison principles. The principal key to our results is a comparison principle of a kind, first exposed and referred to as a "shifting-comparison principle" by Vázquez [34, 35]. This kind of comparison principle has been further developed in [1, 11, 16]. The comparison principle does not so much concern a solution of the equation but an integral expression involving a solution.

For a solution u of Problem 1.1 this is the variable defined by

$$z(r,t) := \int_r^\infty \kappa(x,r)u(x,t)\,dx \qquad \text{for } (r,t) \in [1,\infty)\times(0,T) \tag{2.1}$$

and

$$z(r,0) := \int_r^\infty \kappa(x,r)u_0(x)\,dx \qquad \text{for } r \in [1,\infty), \tag{2.2}$$

where

$$\kappa(x,r) := \begin{cases} \left(x^{n-1}r^{2-n} - x\right)/(n-2) & \text{if } n \neq 2, \\ x\ln(x/r) & \text{if } n = 2. \end{cases} \tag{2.3}$$

The function κ satisfies the equation

$$x^{n-1}\frac{\partial}{\partial x}(x^{1-n}\kappa) = 1, \tag{2.4}$$

with $\kappa(r,r) = 0$.

Lemma 2.1. *Let z be defined by* (2.1)–(2.3). *Then $z \in C([1,\infty)\times[0,T)) \cap C^{2,1}(Q)$ and*

$$z(1,t) = z(1,0) + \int_0^t f^m(s)\,ds \qquad \textit{for all } 0 < t < T. \tag{2.5}$$

Furthermore,

$$\frac{\partial z}{\partial r} = -r^{1-n}\int_r^\infty x^{n-1}u(x,t)\,dx \le 0, \tag{2.6}$$

$$\frac{\partial}{\partial r}\left(r^{n-1}\frac{\partial z}{\partial r}\right) = r^{n-1}u(r,t) \ge 0, \tag{2.7}$$

and

$$\frac{\partial z}{\partial t} = u^m(r,t) \ge 0 \qquad \textit{for all } (r,t) \in Q. \tag{2.8}$$

Proof. The equality (2.5) follows from the definition of a weak solution of Problem 1.1. The proof of this is identical to the proof of the first lemma in [14] and we omit it. Also let us note that for any $r_0 > 1$ the function

$$\widetilde{u}(r,t) := r_0^{-2/(m-1)}u(r_0 r,t) \tag{2.9}$$

is a weak solution of Problem 1.1 with correspondingly scaled initial data and with boundary data

$$\widetilde{f}(t) := {r_0}^{-2/(m-1)} u(r_0, t). \tag{2.10}$$

Whence, applying (2.5) to the corresponding variable $\widetilde{z}$, reformulating the resulting equality in terms of the original variable, and finally writing r instead of r_0, we deduce

$$z(r,t) = z(r,0) + \int_0^t u^m(r,s)\,ds \quad \text{for all } (r,t) \in Q. \tag{2.11}$$

Clearly then, z is continuous in $[1,\infty) \times [0,T)$. Differentiating (2.1) we find (2.6) and (2.7), while differentiating (2.11) yields (2.8). □

It follows that when n is a positive integer, z is a radially symmetric solution of the equation $\partial z/\partial t = |\Delta z|^{m-1}\Delta z$ in $\{\boldsymbol{x} \in \mathbb{R}^n : |\boldsymbol{x}| > 1\} \times (0,T)$. This equation has been called the *dual porous medium equation* and has been studied in [9, 20]. The relations (2.5) and (2.11) can be interpreted as a principle of conservation of momentum.

The comparison principle involving the variable z is the following.

PROPOSITION 2.2 (comparison principle). *Let u_1 and u_2 be two weak solutions of Problem* 1.1 *with corresponding functions z_i defined by* (2.1)–(2.3) *for $i = 1, 2$. Let*

$$Q_\tau := (1,\infty) \times (0,\tau] \quad \textit{for } 0 < \tau < T. \tag{2.12}$$

Then

$$z_1(r,\tau) - z_2(r,\tau) \le \max\{z_1(x,t) - z_2(x,t) : (x,t) \in \overline{Q_\tau} \setminus Q_\tau\} \tag{2.13}$$

for all $(r,\tau) \in Q$.

Proof. To begin with, suppose that u_1 and u_2 are bounded classical solutions of (1.1) in the closure of Q_τ such that $u_i(r,t) \ge \varepsilon$ for all $(r,t) \in \overline{Q_\tau}$ and $u_i(r,0) = \varepsilon$ for large enough r, for $i = 1, 2$, and some $\varepsilon > 0$. In this case, following the discussion above, it can be shown that

$$w(r,t) := \int_r^\infty \kappa(x,r)(u_1 - u_2)(x,t)\,dx \tag{2.14}$$

is a well-defined bounded $C^{2,1}(\overline{Q_\tau})$ function satisfying the equation

$$\frac{\partial w}{\partial t} = \gamma \frac{\partial^2 w}{\partial r^2} + (n-1)\frac{\gamma}{r}\frac{\partial w}{\partial r}, \tag{2.15}$$

where

$$\gamma(r,t) := m \int_0^1 \{\theta u_1(r,t) + (1-\theta) u_2(r,t)\}^{m-1}\,d\theta \tag{2.16}$$

in Q_τ. Subsequently, applying the classical maximum principle [37] to (2.15),

$$w(r,t) \le \sup\{w(x,s) : (x,s) \in \overline{Q_\tau} \setminus Q_\tau\} \quad \text{for all } (r,t) \in Q_\tau. \tag{2.17}$$

Now, the original weak solutions u_1 and u_2 may be constructed in Q_τ as the limit of a sequence of bounded classical solutions of (1.1) with the previously described properties [18]. Hence, utilizing this construction process, one may obtain (2.17) with w defined by (2.14) for the original solutions. Rewriting (2.17) for this w yields $(z_1 - z_2)(r,t) \leq \max\{(z_1 - z_2)(x,s) : (x,s) \in \overline{Q_\tau} \setminus Q_\tau\}$ for all $(r,t) \in Q_\tau$. This gives the desired result. □

For a weak solution u of Problem 1.2 the role of the variable z defined above is filled by

$$z(r,t) := \int_r^\infty x^{n-1} u(x,t)\,dx \quad \text{for } (r,t) \in [1,\infty) \times (0,T) \tag{2.18}$$

with

$$z(r,0) := \int_r^\infty x^{n-1} u_0(x)\,dx \quad \text{for } r \in [1,\infty). \tag{2.19}$$

This variable has the following properties.

LEMMA 2.3. *Let z be defined by* (2.18) *and* (2.19). *Then $z \in C([1,\infty) \times [0,T)) \cap C^{1,1}(Q)$ and*

$$z(1,t) = z(1,0) + \int_0^t g(s)\,ds \quad \textit{for all } 0 < t < T. \tag{2.20}$$

Furthermore,

$$\frac{\partial z}{\partial r} = -r^{n-1} u(r,t) \leq 0 \tag{2.21}$$

and

$$\frac{\partial z}{\partial t} = -r^{n-1} \frac{\partial u^m}{\partial r} \quad \textit{for all } (r,t) \in Q. \tag{2.22}$$

Proof. The proof of this lemma is similar to the proof of Lemma 2.1. The identity (2.20) may be obtained from the definition of a solution. Moreover, it may be derived under the assumption that

$$g \in L^1(0,\tau) \quad \text{for every } 0 < \tau < T \tag{2.23}$$

and irrespective of the assumption that g is nonnegative. Consequently, since it is known that $\partial u^m/\partial r \in C(Q)$ and $(\partial u^m/\partial r)(r,\cdot) \in L^1(0,\tau)$ for every $(r,\tau) \in Q$, applying a scaling argument similar to that in the proof of Lemma 2.1, we may deduce that

$$z(r,t) = z(r,0) - r^{n-1} \int_0^t \frac{\partial u^m}{\partial r}(r,s)\,ds \quad \text{for all } 0 < t < T. \tag{2.24}$$

The rest of the lemma then follows straightforwardly analogous to Lemma 2.1. □

When $n = 1$ the function z is a solution of $\partial z/\partial t = \nabla \cdot (|\nabla z|^{m-1} \nabla z)$ in $\{x \in \mathbb{R} : |x| > 1\} \times (0,T)$. The identities (2.20) and (2.24) can be interpreted as a principle of conservation of mass.

PROPOSITION 2.4 (comparison principle). *Let u_1 and u_2 be two weak solutions of Problem* 1.2 *with corresponding functions z_i defined by* (2.18) *and* (2.19) *for $i = 1,2$. Then* (2.13) *holds for all $(r,\tau) \in Q$, with Q_τ defined by* (2.12).

Proof. If u_1 and u_2 are classical solutions of (1.1) in the closure of some domain Q_τ and have the other properties stated at the start of the proof of Proposition 2.2, then it can be verified that

$$w(r,t) := \int_r^\infty x^{n-1}(u_1 - u_2)(x,t)\,dx$$

is a classical solution of the equation

$$\frac{\partial w}{\partial t} = \gamma \frac{\partial^2 w}{\partial r^2} + \left\{(1-n)\frac{\gamma}{r} + \frac{\partial \gamma}{\partial r}\right\} \frac{\partial w}{\partial r},$$

where γ is once more defined by (2.16) in Q_τ. The proof of this theorem may be subsequently completed similarly to that of the previous one. □

3. Self-similar solutions.

3. Self-similar solutions. The second major tool which we use in our analysis is the existence of self-similar solutions of (1.1).

The first class of self-similar solutions of (1.1) which we consider is the generalization of the waiting-time solution of the one-dimensional porous media equation discovered by Kalashnikov [21].

PROPOSITION 3.1. *There exists a strictly decreasing, continuous function ρ defined on $(0,1]$ with $\rho(1) = 0$, such that for any $a > 0$ and $\tau \geq T$ the function*

$$U(r,t;a,\tau) := \begin{cases} (\tau - t)^{-1/(m-1)} a^{2/(m-1)} \rho(r/a) & \textit{for } r < a, \\ 0 & \textit{otherwise} \end{cases} \tag{3.1}$$

is a weak solution of Problems 1.1 *and* 1.2 *with appropriate initial and boundary data.*

Proof. Making the formal substitution of (3.1) into (1.1), one finds that ρ satisfies the ordinary differential equation

$$(m-1)x^{1-n}(x^{n-1}(\rho^m)')' = \rho. \tag{3.2}$$

Correspondingly, the existence of the self-similar solution (3.1) can be proven by manipulation in the definition of a weak solution of Problems 1.1 and 1.2 once the next lemma is established. □

LEMMA 3.2. *Equation* (3.2) *has a unique positive solution ρ for $x < 1$ satisfying*

$$\rho(1) = (\rho^m)'(1) = 0 \tag{3.3}$$

which is extendible onto $(0,1)$ and strictly decreasing in this interval. Furthermore,

$$(\rho^m)'(x) \sim -\lambda_0 x^{1-n} \qquad \textit{as } x \downarrow 0 \tag{3.4}$$

and

$$\rho^{(m-1)/2}(x) \sim \lambda_1(1-x) \qquad \textit{as } x \uparrow 1, \tag{3.5}$$

where λ_0 is a positive number and $\lambda_1 := \{(m-1)/2m(m+1)\}^{1/2}$.

Proof. To prove the existence, we shall use a contraction mapping argument which is commonly applied for treating this kind of initial-value problem [5, 6, 17, 24, 28]. Multiplying (3.2) by $2x^{2(n-1)}(\rho^m)'(x)$, integrating from x to 1, and using (3.3) gives

$$\{x^{n-1}(\rho^m)'(x)\}^2 = \frac{2m}{(m-1)(m+1)} x^{2(n-1)} \rho^{m+1}(x) + \frac{4m(n-1)}{(m-1)(m+1)} \int_x^1 y^{2n-3} \rho^{m+1}(y)\,dy.$$

Hence a solution ρ of (3.2), (3.3) satisfies $(\rho^m)'(x) < 0$ and

$$(\rho^{(m-1)/2})'(x) = -\lambda_1 \left\{ 1 + 2(n-1)x^{2(1-n)} \int_x^1 y^{2n-3} \left(\frac{\rho(y)}{\rho(x)} \right)^{m+1} dy \right\}^{1/2}$$

for all $x < 1$. Subsequently, integrating from x to 1 a second time,

$$\begin{aligned} &\rho^{(m-1)/2}(x) \\ &\quad = \lambda_1 \int_x^1 \left\{ 1 + 2(n-1)y^{2(1-n)} \int_y^1 \eta^{2n-3} \left(\frac{\rho(\eta)}{\rho(y)} \right)^{m+1} d\eta \right\}^{1/2} dy. \end{aligned} \tag{3.6}$$

It follows that

$$\begin{aligned} \lambda_1(1-x) &\leq \rho^{(m-1)/2}(x) \\ &\leq \lambda_1 \int_x^1 \left\{ 1 + 2(n-1)y^{2(1-n)} \int_y^1 \eta^{2n-3}\, d\eta \right\}^{1/2} dy \\ &= \lambda_1 \int_x^1 y^{1-n}\, dy \leq \lambda_1(1-x)x^{1-n} \end{aligned} \tag{3.7}$$

for all $x < 1$. Now let $\mathcal{S}$ denote the set of functions $\phi \in C([1-\delta, 1])$ such that $\lambda_1 \leq \phi(x) \leq \lambda_1(1-\delta)^{1-n}$ for all $1-\delta \leq x \leq 1$ for some $0 < \delta < 1$, and define the mapping M on $\mathcal{S}$ by

$$\begin{aligned} &M(\phi)(x) \\ &:= \frac{\lambda_1}{1-x} \int_x^1 \left\{ 1 + 2(n-1)y^{2(1-n)} \int_y^1 \eta^{2n-3} \left(\frac{(1-\eta)\phi(\eta)}{(1-y)\phi(y)} \right)^{2(m+1)/(m-1)} d\eta \right\}^{1/2} dy \end{aligned}$$

for all $1-\delta \leq x < 1$. It is possible to show that if δ is chosen small enough, M maps $\mathcal{S}$ into itself and moreover is a contraction with respect to the $C([1-\delta, 1])$-norm. Therefore, since $\mathcal{S}$ is closed with respect to this norm, M has a unique fixed point $\phi \in \mathcal{S}$ by the contraction mapping principle. Setting $\rho(x) = (1-x)^{2/(m-1)}\phi^{2/(m-1)}(x)$, it follows that there is a unique function ρ satisfying (3.6) for $1-\delta < x < 1$ for small enough δ. Whence, retracing the above argument, problem (3.2), (3.3) has a unique positive solution ρ for $1-\delta < x < 1$ for small enough δ. In view of the a priori estimate (3.7), this solution is continuously and uniquely extendible onto $(0, 1)$, by standard theory for ordinary differential equations.

To prove (3.4) we multiply (3.2) by $x^{n-1}/(m-1)$ and integrate from x to 1, to obtain

$$-(\rho^m)'(x) = \frac{1}{m-1} x^{1-n} \int_x^1 y^{n-1}\rho(y)\, dy. \tag{3.8}$$

Consequently, if we can show that

$$\int_0^1 y^{n-1}\rho(y)\, dy < \infty, \tag{3.9}$$

then (3.4) is proven. To verify (3.9) in the case $n \leq 2$, we use the monotonicity of ρ. Substituting $\rho(y) < \rho(x)$ in (3.8) yields

$$-(\rho^{m-1})'(x) < \frac{1}{m} x^{1-n} \int_x^1 y^{n-1}\, dy < x^{-1}$$

for any $0 < x < 1$. Hence, integrating from y to 1, we deduce that $\rho(y) < |\ln y|^{1/(m-1)}$ for every $0 < y < 1$. This is sufficient to confirm (3.9) when $n \leq 2$. To verify (3.9) in the case $n > 2$ we have to work a little harder. Fix $0 < x < 1$, and define $A := \sup\{y^{(n-2)/m}\rho(y) : x < y < 1\}$. Substituting $\rho(y) \leq Ay^{(2-n)/m}$ in the right-hand side of (3.8) and integrating give

$$\rho^m(y) < \frac{m}{(m-1)(n-2)\{(m-1)n+2\}} y^{2-n} A$$

for any $x < y < 1$. Hence, multiplying this inequality by y^{n-2}/A and subsequently optimizing the left-hand side of the resulting expression, we obtain $A^{m-1} \leq m/(m-1)(n-2)\{(m-1)n+2\}$. We therefore conclude that

$$\rho(y) \leq \left(\frac{m}{(m-1)(n-2)\{(m-1)n+2\}}\right)^{1/(m-1)} y^{(2-n)/m}$$

for all $x < y < 1$, irrespective of the value of $x > 0$. This provides (3.9) when $n > 2$. The relation (3.5) follows from (3.7). □

In the case $n = 1$, the expression (3.6) gives the function ρ explicitly as

$$\rho(x) = \left\{\frac{m-1}{2m(m+1)}(1-x)^2\right\}^{1/(m-1)}. \tag{3.10}$$

This gives rise to the waiting-time solution of the porous media equation documented in [21].

The second self-similar solution of (1.1) which we consider is the instantaneous point-source solution. This solution was discovered in the cases $n = 1$ and $n = 3$ by Zel'dovich and Kompaneets [38] and in the general case by Barenblatt [7] and Pattle [25]. It is often referred to as the Barenblatt–Pattle or Barenblatt solution [3, 4, 27, 36].

Proposition 3.3. *For any $a > 0$ and τ the function*

$$U(r,t;a,\tau) := \begin{cases} (t-\tau)^{-1/(m-1)}\xi(t)^{2/(m-1)}\rho(r/\xi(t)) & \text{for } t > \tau \text{ and } r < \xi(t), \\ 0 & \text{otherwise}, \end{cases} \tag{3.11}$$

where

$$\xi(t) := a(t-\tau)^{1/\{(m-1)n+2\}} \tag{3.12}$$

and

$$\rho(x) := \left[\frac{m-1}{2m\{(m-1)n+2\}}\left(1-x^2\right)\right]^{1/(m-1)}, \tag{3.13}$$

is a weak solution of Problems 1.1 *and* 1.2 *with appropriate initial and boundary data.*

In the case that n is a positive integer, U is formally a radially symmetric solution of

$$\frac{\partial u}{\partial t} = \Delta u^m + \chi a^{\{(m-1)n+2\}/(m-1)}\delta(\boldsymbol{x})\delta(t-\tau),$$

where

$$\chi := \int_{\{\boldsymbol{x}\in\mathbb{R}^n:|\boldsymbol{x}|<1\}} \rho(|\boldsymbol{y}|)\, d\boldsymbol{y},$$

in $\mathbb{R}^n \times \mathbb{R}$. The function U is correspondingly singular for $(r,t) = (0,\tau)$. However, since this point lies outside our study domain Q, this is of no consequence for our analysis.

4. Regularity estimates. Our final principal tool comprises two estimates of the regularity of solutions of Problems 1.1 and 1.2. The first of these is an elaboration of a well-known regularity result for the porous media equation in one spatial dimension due to Aronson [2]. Corresponding results for more general quasilinear parabolic equations of second order have been derived in [8, 16, 22].

PROPOSITION 4.1. *Given any* $1 \le r_0 < r_1$ *there exists a constant* K *which depends only on* m, n, *and* $\delta := (r_1 - r_0)/r_0$ *such that for any weak solution* u *of Problem* 1.1 *or* 1.2 *there holds*

$$\left|u^{m-1}(x,\tau) - u^{m-1}(y,\tau)\right| \le K\left(\tau^{-1}M^{m-1} + r_0^{-2}M^{2(m-1)}\right)^{1/2}|x-y|$$

for all $x \ge r_1$, $y \ge r_1$ *and* $0 < \tau < T$, *where* $M := \sup\{u(r,t) : (r,t) \in (r_0,\infty) \times (0,\tau]\}$.

This result may be obtained by following the method used in [2]. Full documentation is supplied in [19]. The only embellishment on the result appearing in [19] is the stated dependence on r_0 and M. This may be obtained from the invariance of (1.1) under scaling; see, for instance, the proof of the next result.

PROPOSITION 4.2. *Given any* $1 \le r_0 < r_1$ *there exists a constant* K *which depends only on* m, n, *and* $\delta := (r_1 - r_0)/r_0$ *such that for any weak solution* u *of Problem* 1.1 *or* 1.2 *there holds*

$$u(r,\tau) \le Kr^{-q}\left(\tau^{-1}N^2 + r_0^{-\{(m-1)n+2\}}N^{m+1}\right)^{1/(m+1)}$$

for all $r \ge r_1$ *and* $0 < \tau < T$, *where*

$$q := 2(n-1)/(m+1)$$

and $N := \max\{z(r_0,t) : 0 \le t \le \tau\}$ *with* z *defined by* (2.18).

Proof. We adapt the Bernstein argument as applied in [2, 16]. Fix $1 \le r_0 < r_1 < r_2$ and $0 < \tau < T$. Recall the definition of Q_τ by (2.12). Since any weak solution of Problem 1.1 or 1.2 may be constructed in Q_τ as the limit of a sequence of positive classical $C(\overline{Q_\tau})$ solutions of (1.1), without loss of generality we may suppose that u is as such. Moreover, because (1.1) is invariant under the transformation $u(r,t) \mapsto au(br, a^{m-1}b^2t)$ for any positive numbers a and b, without loss of generality we may suppose that $r_0 = 1$ and $N = 1$. Note that by (2.21) the latter means that $z(r,t) \le 1$ for all $(r,t) \in Q_\tau$. Consider now the function

$$p(r,t) := u(r,t)/\psi(z(r,t)), \tag{4.1}$$

where $\psi \in C^2([0,1])$ is such that $\psi(\eta) > 0$ and $(\psi^m)''(\eta) < 0$ for all $0 \le \eta \le 1$; for instance, $\psi(\eta) := \{(1+\eta)(2-\eta)\}^{1/m}$. Differentiating (4.1) with respect to t and successively using (1.1) to eliminate $\partial u/\partial t$, (2.22) to eliminate $\partial z/\partial t$, (4.1) to eliminate u, and (2.21) to eliminate $\partial z/\partial r$, it can be verified that p satisfies

$$\begin{aligned}\frac{\partial p}{\partial t} &= \psi^{m-1}\frac{\partial^2 p^m}{\partial r^2} + \{(n-1)r^{-1}\psi^{m-1} - 2r^{n-1}(\psi^m)'p\}\frac{\partial p^m}{\partial r} \\ &\quad - 2(n-1)r^{n-2}(\psi^m)'p^{m+1} + r^{2n-2}\psi(\psi^m)''p^{m+2}\end{aligned} \tag{4.2}$$

in Q_τ. Set $r_3 := r_2 + \delta$ and consider next the function

$$w(r,t) := t^{1/(m+1)} r^q \xi(r) p(r,t), \tag{4.3}$$

where $\xi \in C^2([r_0, r_3])$ is such that $\xi(r_0) = \xi(r_3) = 0$, $0 < \xi(r) \leq 1$ for $r_0 < r < r_3$, and $\xi(r) = 1$ for $r_1 \leq r \leq r_2$. By this construction, w is positive in $(r_0, r_3) \times (0, \tau]$ and vanishes on $[r_0, r_3] \times [0, \tau] \setminus (r_0, r_3) \times (0, \tau]$. Hence, a maximum of w in $[r_0, r_3] \times [0, \tau]$ must lie in $(r_0, r_3) \times (0, \tau]$, and at such a point

$$\frac{\partial w^m}{\partial r} = 0, \quad \frac{\partial w}{\partial t} \geq 0, \quad \text{and} \quad \frac{\partial^2 w^m}{\partial r^2} \leq 0. \tag{4.4}$$

Setting (4.3) in (4.4), this implies

$$\frac{\partial p^m}{\partial r} = -m\xi^{-1} p^m \{q r^{-1} \xi + \xi'\}, \tag{4.5}$$

$$\frac{\partial p}{\partial t} \geq -\frac{1}{m+1} t^{-1} p, \tag{4.6}$$

and

$$\frac{\partial^2 p^m}{\partial r^2} \leq m\xi^{-2}\{q(mq+1)r^{-2}\xi^2 + 2mqr^{-1}\xi\xi' + (m+1)(\xi')^2 - \xi\xi''\}p^m. \tag{4.7}$$

Thus, substituting (4.5)–(4.7) in (4.2) and thereafter using (4.3) to eliminate p, at a maximum of w in $[r_0, r_3] \times [0, \tau]$ there holds

$$-\psi(\psi^m)'' w^{m+1} \leq (\psi^m)' \Xi_1 t^{1/(m+1)} w^m + \psi^{m-1} \Xi_2 t^{2/(m+1)} w^{m-1} + \Xi_3,$$

where

$$\Xi_1 := 2r^{-(m-1)q/2}\{(mq - n + 1)r^{-1}\xi + m\xi'\},$$

$$\Xi_2 := mr^{-(m-1)q}\{q(mq - n + 2)r^{-2}\xi^2 + (2mq - n + 1)r^{-1}\xi\xi' + (m+1)(\xi')^2 - \xi\xi''\},$$

and

$$\Xi_3 := \xi^{m+1}/(m+1).$$

It follows that there are positive constants K_1, K_2, and K_3 which depend only on m, n, and $\delta = r_1 - r_0 = r_3 - r_2$ such that

$$W^{m+1} \leq K_1 \tau^{1/(m+1)} W^m + K_2 \tau^{2/(m+1)} W^{m-1} + K_3, \tag{4.8}$$

where W denotes the maximal value of w in $[r_0, r_3] \times [0, \tau]$. Now, by Young's inequality, there is a constant K_4 which depends only on m and K_1 such that

$$K_1 \tau^{1/(m+1)} W^m \leq W^{m+1}/4 + K_4 \tau, \tag{4.9}$$

and there is a constant K_5 which depends only on m and K_2 such that

$$K_2 \tau^{2/(m+1)} W^{m-1} \leq W^{m+1}/4 + K_5 \tau. \tag{4.10}$$

Plugging (4.9) and (4.10) into (4.8) yields $W \leq K_6(1+\tau)^{1/(m+1)}$ with $K_6^{m+1} := 2\max\{K_3, K_4+K_5\}$. This means that $w(r,t) \leq K_6(1+\tau)^{1/(m+1)}$ for all $(r,t) \in [r_0, r_3] \times [0,\tau]$. Hence, in particular, by (4.3) and the properties of ξ, $p(r,\tau) \leq K_6 r^{-q}(\tau^{-1}+1)^{1/(m+1)}$ for all $r_1 \leq r \leq r_2$. Using (4.1), this gives

$$u(r,\tau) \leq K r^{-q}(\tau^{-1}+1)^{1/(m+1)} \quad \text{for all } r_1 \leq r \leq r_2$$

with $K := K_6 \max\{\psi(\eta) : 0 \leq \eta \leq 1\}$. In view of the arbitrariness of r_2, this provides the required result. □

Note that it follows from Proposition 4.2 that for a radially symmetric solution u of the porous media equation in $\mathbb{R}^n \times (0,T)$ we have the estimate

$$\|u(\cdot,t)\|_{L^\infty(E_{2R})} \leq K\left(R^{-n}\|u\|_{L^\infty(0,t;L^1(E_R))} + R^{-q}t^{-1/(m+1)}\|u\|^{2/(m+1)}_{L^\infty(0,t;L^1(E_R))}\right),$$

where $E_R := \{\boldsymbol{x} \in \mathbb{R}^n : |\boldsymbol{x}| > R\}$, for any $R > 0$ and $0 < t < T$, with a constant K which depends only on m and n.

As well as being of some interest in its own right, Proposition 4.2 provides a means to prove Theorem 1.5.

Proof of Theorem 1.5. Suppose that $r \in \Omega$. Then, by definition, $\sup\{u(r,t) : 0 < t < T\} = \infty$. Let $1 < r_0 < r$. Proposition 4.2 subsequently implies that $\sup\{z(r_0,t) : 0 \leq t < T\} = \infty$, where z is defined by (2.18). Hence, $r_0 \in \Omega^*$ by definition. This means that $(1,r) \subseteq \Omega^*$ for all $r \in \Omega$. Combining this deduction with (1.6) and (1.7) gives the theorem. □

5. The Cauchy–Dirichlet problem.

5.1. Notation. Let u denote a given weak solution of Problem 1.1 with initial data function u_0 and boundary data function f. Note the next result which can be proven following analysis in [15] or alternatively, by adapting the proof of the analogous result for the Cauchy–Neumann problem presented in section 6.

LEMMA 5.1. *Suppose that f is nondecreasing and $u_0 \equiv 0$. Then $u(r,t) \geq u(r_0,t_0)$ for all $1 < r \leq r_0$ and $0 < t_0 \leq t < T$.*

Recall the definitions (1.4)–(1.6) and (1.9) and, for the Cauchy–Dirichlet problem, the definition of $\mathcal{C}$ by (1.10), L by (1.12), and z by (2.1)–(2.3). For completeness, define

$$z(r,T) := \lim_{t\uparrow T} z(r,t) \tag{5.1}$$

for $r \geq 1$, which limit exists by (2.5) and (2.11). By (2.5) and (2.11) the definition of L is equivalent to

$$L(r) = \limsup_{t\uparrow T}\,(T-t)^{1/(m-1)}\,z(r,t) \quad \text{for } r \geq 1. \tag{5.2}$$

Let

$$v(r,t) := (T-t)^{1/(m-1)}u(r,t) \quad \text{for } (r,t) \in Q, \tag{5.3}$$

and note that

$$\ell(r) = \limsup_{t\uparrow T} v(r,t) \quad \text{for } r > 1.$$

For convenience we shall denote the variable z defined for an arbitrary solution of the Cauchy–Dirichlet problem for (1.1) by (2.1)–(2.3) and (5.1) with a capital letter when it applies to a self-similar solution. Thus we set

$$Z(r,t;a,\tau) := \int_r^\infty \kappa(x,r)U(x,t;a,\tau)\,dx \tag{5.4}$$

for any $(r,t) \in [1,\infty) \times [0,T)$. Furthermore, we shall introduce a subscript w to indicate when this concerns the self-similar solution of waiting-time type. Substituting (2.3) and (3.1) in (5.4), using (3.2), and thereafter applying partial integration to simplify the resulting expression reveal that

$$Z_w(r,t;a,\tau) = (m-1)a^{2m/(m-1)}(\tau-t)^{-1/(m-1)}\rho^m(r/a)$$

for all $t < \tau$ and $r < a$. Let

$$\mathcal{A}(c) := (m-1)c^{2m/(m-1)}\rho^m(1/c). \tag{5.5}$$

Since ρ has the properties stated in Lemma 3.2, this defines an unbounded, strictly increasing, continuously differentiable function $\mathcal{A}$ on $[1,\infty)$ with $\mathcal{A}(1) = 0$. Subsequently we can state that

$$Z_w(r,t;a,\tau) = \begin{cases} (\tau-t)^{-1/(m-1)}r^{2m/(m-1)}\mathcal{A}(a/r) & \text{if } r < a, \\ 0 & \text{otherwise} \end{cases}$$

for any $(r,t) \in [1,\infty) \times [0,T)$.

Analogous to what we have done for the waiting-time solution, we define the variable $Z_s(r,t;a,\tau)$ for the instantaneous point-source solution. Substituting (2.3), (3.11), and (3.13) in (5.4), noting that $\rho = -\{(m-1)n+2\}x^{-1}(\rho^m)'$, and thereafter applying partial integration yield

$$\begin{aligned} &Z_s(r,t;a,\tau) \\ &\quad = \{(m-1)n+2\}(t-\tau)^{-1/(m-1)}\xi(t)^{\{(m-1)n+2\}/(m-1)}r^{2-n}\int_{r/\xi(t)}^1 x^{n-3}\rho^m(x)\,dx \end{aligned}$$

for all $t > \tau$ and $r < \xi(t)$, where $\xi(t)$ is given by (3.12). Hence, if we define

$$\mathcal{B}(c) := \{(m-1)n+2\}c^{\{(m-1)n+2\}/(m-1)}\int_{1/c}^1 x^{n-3}\rho^m(x)\,dx, \tag{5.6}$$

we can state that

$$Z_s(r,t;a,\tau) = \begin{cases} (t-\tau)^{-1/(m-1)}r^{2m/(m-1)}\mathcal{B}(\xi(t)/r) & \text{if } t > \tau \text{ and } r < \xi(t), \\ 0 & \text{otherwise} \end{cases}$$

for all $(r,t) \in \overline{Q}$, where $\mathcal{B}$ is defined, continuously differentiable, strictly increasing, and unbounded on $[1,\infty)$ and such that $\mathcal{B}(1) = 0$.

Let β and α denote the inverse of the functions $\mathcal{A}$ and $\mathcal{B}$, respectively. Thus α and β are strictly increasing, continuous, and unbounded functions on $[0,\infty)$ such that $\alpha(0) = \beta(0) = 1$. Finally, define the strictly increasing function $\gamma \in C([0,\infty))$ with $\gamma(0) = 1$ by

$$\{\gamma(\mathcal{C})\}^{2m/(m-1)}\,\mathcal{A}(\alpha(\mathcal{C})/\gamma(\mathcal{C})) = 2^{-1/(m-1)}\mathcal{C}. \tag{5.7}$$

These functions have the following property.

LEMMA 5.2. *There are positive constants μ and ν such that* $\max\{\beta(\mathcal{C}),\gamma(\mathcal{C})\} \geq 1+\mu\{\sigma(\mathcal{C})\}^{(m-1)/2m}$ *and* $\alpha(\mathcal{C}) \leq 1+\nu\{\sigma(\mathcal{C})\}^{(m-1)/2m}$ *for all* $\mathcal{C} \geq 0$, *where* σ *is defined by* (1.15).

Proof. In view of the known properties of α, β, and γ, to prove the lemma it is enough to show that

$$\alpha(\mathcal{C})-1 \sim \alpha_0\,\{\sigma(\mathcal{C})\}^{(m-1)/2m} \qquad \text{as } \mathcal{C}\downarrow 0, \tag{5.8}$$

$$\alpha(\mathcal{C})-1 \sim \alpha_1\,\{\sigma(\mathcal{C})\}^{(m-1)/2m} \qquad \text{as } \mathcal{C}\to\infty, \tag{5.9}$$

$$\beta(\mathcal{C})-1 \sim \beta_1\,\{\sigma(\mathcal{C})\}^{(m-1)/2m} \qquad \text{as } \mathcal{C}\to\infty, \tag{5.10}$$

and

$$\gamma(\mathcal{C})-1 \sim \gamma_0\,\{\sigma(\mathcal{C})\}^{(m-1)/2m} \qquad \text{as } \mathcal{C}\downarrow 0 \tag{5.11}$$

for some positive numbers α_0, α_1, β_1, and γ_0. To verify (5.8), note that combining (5.5) and (3.5) there holds

$$\mathcal{A}(c) \sim \mathcal{A}_0(c-1)^{2m/(m-1)} \qquad \text{as } c\downarrow 1 \tag{5.12}$$

for some constant $\mathcal{A}_0>0$. This readily yields (5.8) with $\alpha_0=\mathcal{A}_0^{(1-m)/2m}$. Next, with regard to (5.9), we see that combination of (5.5) and (3.4) implies

$$\mathcal{A}(c) \sim \mathcal{A}_1 c^{2m/(m-1)}\int_{1/c}^{1} x^{1-n}\,dx \qquad \text{as } c\to\infty$$

for some constant $\mathcal{A}_1>0$, whence, by a change of variables,

$$\mathcal{C} \sim \mathcal{A}_1\,\{\alpha(\mathcal{C})\}^{2m/(m-1)}\int_{1}^{\alpha(\mathcal{C})} y^{n-3}\,dy \qquad \text{as } \mathcal{C}\to\infty. \tag{5.13}$$

After suitable manipulation this shows that $\alpha(\mathcal{C}) \sim \alpha_1\mathcal{C}^{(m-1)/2m}$ with $\alpha_1=\{(2-n)/\mathcal{A}_1\}^{(m-1)/2m}$ when $n<2$, $\alpha(\mathcal{C}) \sim \alpha_1(\mathcal{C}/\ln\mathcal{C})^{(m-1)/2m}$ with $\alpha_1=\{2m/(m-1)\mathcal{A}_1\}^{(m-1)/2m}$ when $n=2$, and $\alpha(\mathcal{C}) \sim \alpha_1\mathcal{C}^{(m-1)/\{(m-1)n+2\}}$ with $\alpha_1=\{(n-2)/\mathcal{A}_1\}^{(m-1)/\{(m-1)n+2\}}$ when $n>2$. Together this is equivalent to (5.9). To verify (5.10), observe that substituting (3.13) in (5.6) there holds

$$\mathcal{B}(c) \sim \mathcal{B}_1 c^{\{(m-1)n+2\}/(m-1)}\int_{1/c}^{1} x^{n-3}\,dx \qquad \text{as } c\to\infty$$

for some constant $\mathcal{B}_1>0$, whence, changing variables,

$$\mathcal{C} \sim \mathcal{B}_1\,\{\beta(\mathcal{C})\}^{\{(m-1)n+2\}/(m-1)}\int_{1}^{\beta(\mathcal{C})} y^{1-n}\,dy \qquad \text{as } \mathcal{C}\to\infty.$$

The relation (5.10) subsequently follows by a similar argument to that used to deduce (5.9) from (5.13). One finds $\beta_1=\{(2-n)/\mathcal{B}_1\}^{(m-1)/2m}$ when $n<2$, $\beta_1=\{2m/(m-1)\mathcal{B}_1\}^{(m-1)/2m}$ when $n=2$, and $\beta_1=\{(n-2)/\mathcal{B}_1\}^{(m-1)/\{(m-1)n+2\}}$ when $n>2$. Finally, to obtain (5.11), we observe that by (5.7) and (5.12), $\mathcal{A}_0\{\alpha(\mathcal{C})-\gamma(\mathcal{C})\}^{2m/(m-1)} \sim 2^{-1/(m-1)}\mathcal{C}$ as $\mathcal{C}\downarrow 0$. Together with (5.8) this gives (5.11) with $\gamma_0=(1-2^{-1/2m})\alpha_0$. □

5.2. The proof of Theorem 1.6. In this subsection we essentially prove that localization, effective localization, and metastable localization occur if and only if $\mathcal{C} < \infty$. We use the next five lemmas.

LEMMA 5.3. *Let u_1 and u_2 be any two weak solutions of Problem* 1.1 *with corresponding functions $u_{0,i}$, f_i, L_i, and z_i for $i = 1, 2$. Suppose that* (1.13) *holds. Then $L_1(r) \leq L_2(r)$ for all $r \geq 1$. Moreover, if* $\sup\{z_1(1,t) - z_2(1,t) : 0 \leq t < T\} < \infty$, *then $z_1(r,T) < \infty$ for all $r \geq 1$ such that $z_2(r,T) < \infty$.*

Proof. By Proposition 2.2 and Lemma 2.1,

$$z_1(r,t) \leq z_2(r,t) + z_1(1,\tau) + \max\{(z_1 - z_2)(1,s) : \tau \leq s \leq t\} \tag{5.14}$$

for all $r \geq 1$ and $0 < \tau < t < T$. As a consequence,

$$\begin{aligned}(T-t)^{1/(m-1)} z_1(r,t) &\leq (T-t)^{1/(m-1)} z_2(r,t) + (T-t)^{1/(m-1)} z_1(1,\tau) \\ &\quad + \max\{\max\{(T-s)^{1/(m-1)}(z_1 - z_2)(1,s) : \tau \leq s \leq t\}, 0\}\end{aligned} \tag{5.15}$$

for all $r \geq 1$ and $0 < \tau < t < T$. Letting $t \uparrow T$ and thereafter $\tau \uparrow T$ in (5.15) yields the main conclusion of the lemma. The subsidiary conclusion may be obtained by passing to the limit $t \uparrow T$ in (5.14). □

LEMMA 5.4. *If $c > 1$ is such that $\mathcal{A}(c) > \mathcal{C}$, then*

$$L(r) \leq r^{2m/(m-1)} \mathcal{A}(\max\{c/r, 1\}) \quad \textit{for all } r \geq 1$$

and $z(r,T) < \infty$ for all $r \geq c$.

Proof. Taking $z_1 = z$ and $z_2 = Z_w(\cdot, \cdot; c, T)$, this lemma is a corollary of the previous one. □

LEMMA 5.5. *If $c > 1$ is such that $\mathcal{B}(c) < \mathcal{C}$, then $z(r,T) = \infty$ for all $1 < r < c$.*

Proof. By definition, there exists a sequence of values $\{t_i\}_{i=1}^{\infty} \subset (0,T)$ such that $t_i \to T$ as $i \to \infty$, and $(T - t_i)^{1/(m-1)} z(1,t_i) > \mathcal{B}(c)$ for any $i \geq 1$. Fix i and set $a_i := c(T - t_i)^{-1/\{(m-1)n+2\}}$. Then $z(1,t) \geq z(1,t_i) > (T - t_i)^{-1/(m-1)} \mathcal{B}(c) = Z_s(1,T; a_i, t_i) \geq Z_s(1,t; a_i, t_i)$ for all $t_i < t < T$, while $z(r,t) \geq 0 = Z_s(r,t; a_i, t_i)$ for all $r \geq 1$ and $0 \leq t \leq t_i$. Proposition 2.2 subsequently states that $z(r,t) \geq Z_s(r,t; a_i, t_i)$ for all $(r,t) \in Q$. This gives

$$z(r,T) \geq Z_s(r,T; a_i, t_i) = (T - t_i)^{-1/(m-1)} r^{2m/(m-1)} \mathcal{B}(c/r)$$

for all $1 < r < c$. Letting $i \to \infty$ yields the lemma. □

LEMMA 5.6. *Suppose that $L(r_0) < \infty$ for some $r_0 \geq 1$. Then for any $r > r_0$,*

$$\sup\left\{\int_r^\infty x^{n-1} v(x,t)\,dx : 0 < t < T\right\} < \infty.$$

Moreover, if $z(r_0,T) < \infty$, then $r \notin \Omega^*$.

Proof. By (2.4),

$$\begin{aligned}z(r_0,t) &= \int_{r_0}^r \kappa(x,r_0) u(x,t)\,dx + \int_r^\infty \{x^{1-n}\kappa(x,r_0)\} x^{n-1} u(x,t)\,dx \\ &\geq r^{1-n}\kappa(r,r_0) \int_r^\infty x^{n-1} u(x,t)\,dx\end{aligned} \tag{5.16}$$

for all $0 < t < T$. Multiplying (5.16) by $(T-t)^{1/(m-1)}$ and letting $t \uparrow T$ yields the first conclusion of the lemma, while letting $t \uparrow T$ in (5.16) directly gives the second conclusion. □

LEMMA 5.7. *If $z(r,T) = \infty$ for some $r > 1$, then $r \in \Omega$.*

Proof. This follows immediately from (2.11). □

With the last four lemmas it is easy to prove Theorem 1.6. Suppose that $\mathcal{C} < \infty$. Then by Lemma 5.4, $z(r,T) < \infty$ for all $r > \alpha(\mathcal{C})$. This implies that $\omega^* < \infty$ by Lemma 5.6 and (1.6). On the other hand, if $\mathcal{C} = \infty$, then by Lemma 5.5, $z(r,T) = \infty$ for all $r > 1$. Thus, by Lemma 5.7 and (1.6), $\omega = \infty$. Recalling Theorem 1.5 gives the required result.

5.3. The proof of Theorem 1.8. To establish our fourth theorem, we employ four more lemmas.

LEMMA 5.8. *Suppose that $L(r_0) < \infty$ for some $r_0 \geq 1$. Then*

$$L(r) \leq r^{2m/(m-1)}\mathcal{A}(\max\{r_1/r, 1\}) \quad \text{for all } r \geq r_0, \tag{5.17}$$

and $z(r,T) < \infty$ for all $r > r_1$, where

$$r_1 := r_0\alpha(r_0^{-2m/(m-1)}L(r_0)). \tag{5.18}$$

Proof. We apply the scaling technique employed in the proof of Lemma 2.1. The function $\widetilde{u}$ given by (2.9) is a weak solution of Problem 1.1 with correspondingly scaled initial values, with boundary values (2.10), and with the parameter defined by (1.10) taking the value $r_0^{-2m/(m-1)}L(r_0)$. The present lemma may subsequently be obtained by applying Lemma 5.4 to $\widetilde{u}$ and interpreting the conclusions in terms of the original solution. □

LEMMA 5.9. *If $\mathcal{C} = \infty$, then $L(r) = \ell(r) = \infty$ for all $r > 1$.*

Proof. If $\mathcal{C} = \infty$, then $z(r,T) = \infty$ for all $r > 1$ by Lemma 5.5. Subsequently, by Lemma 5.8, $L(r) = \infty$ for all $r > 1$. However, by the definition of ℓ and L,

$$L(r) \leq (m-1)\ell^m(r) \quad \text{for every } r > 1. \qquad \square \tag{5.19}$$

LEMMA 5.10. *If $\mathcal{C} < \infty$ then $v^{m-1} \in L^\infty(\tau, T; W^{1,\infty}(r_0, \infty))$ for every $(r_0, \tau) \in Q$.*

Proof. Fix $1 < r_0 < r_1 < r_2$ and $0 < \tau < T$. By Proposition 4.2,

$$u(r,t) \leq K_0\left\{t^{-1}N_0^2(t) + N_0^{m+1}(t)\right\}^{1/(m+1)}$$

for all $r \geq r_1$ and $0 < t < T$, where K_0 is some constant which depends only on m, n, r_0, and r_1, and

$$N_0(t) := \sup\left\{\int_{r_0}^\infty x^{n-1}u(x,s)\,dx : 0 < s \leq t\right\}.$$

Hence,

$$v(r,t) \leq K_0\left\{\tau^{-1}TN_1^2(t) + N_1^{m+1}(t)\right\}^{1/(m+1)} \tag{5.20}$$

for all $r \geq r_1$ and $\tau \leq t < T$, where

$$N_1(t) := \sup\left\{(T-s)^{1/(m-1)}\int_{r_0}^\infty x^{n-1}u(x,s)\,dx : 0 < s \leq t\right\}.$$

Simultaneously, by Proposition 4.1,

$$\left|u^{m-1}(x,t) - u^{m-1}(y,t)\right| \leq K_1\left\{t^{-1}M_0^{m-1}(t) + M_0^{2(m-1)}(t)\right\}^{1/2}|x-y|$$

for all $x \geq r_2$, $y \geq r_2$, and $0 < t < T$, where K_1 is some constant which depends only on m, n, r_1, and r_2 and

$$M_0(t) := \sup\{u(r,s) : r \geq r_1, 0 < s \leq t\}.$$

Hence,

$$\left|v^{m-1}(x,t) - v^{m-1}(y,t)\right| \leq K_1 \left\{\tau^{-1}TM_1^{m-1}(t) + M_1^{2(m-1)}(t)\right\}^{1/2} |x-y| \tag{5.21}$$

for all $x \geq r_2$, $y \geq r_2$, and $\tau \leq t < T$, where

$$M_1(t) := \sup\{v(r,s) : r \geq r_1, 0 < s \leq t\}.$$

Now, since $L(1) = \mathcal{C} < \infty$, N_1 is bounded on $(0,T)$ by Lemma 5.6. Thus, from (5.20), we deduce that $v^{m-1} \in L^\infty((r_1,\infty)\times(\tau,T))$. In turn, because u itself is bounded in $(1,\infty)\times(0,\tau]$, this means that M_1 is bounded on $(0,T)$. Subsequently from (5.21) we deduce that $v^{m-1} \in L^\infty(\tau,T;W^{1,\infty}(r_2,\infty))$. These deductions provide the lemma, in the light of the arbitrariness of r_0, r_1, and r_2. □

LEMMA 5.11. *Let u_1 and u_2 be any two weak solutions of Problem* 1.1 *with corresponding functions $u_{0,i}$, f_i, ℓ_i, and z_i, and parameters $\mathcal{C}_i$ for $i = 1,2$. Suppose that* (1.14) *holds. Then $\ell_1(r) \leq \ell_2(r)$ for all $r > 1$.*

Proof. We borrow ideas from [14, 26]. Since when $\mathcal{C}_2 = \infty$ the result is immediate from Lemma 5.9, without loss of generality we may assume that $\mathcal{C}_2 < \infty$. Define $u_{0,3}(r) := \max\{u_{0,1}(r), u_{0,2}(r)\}$ for $r > 1$, and $f_3(t) := \max\{f_1(t), f_2(t)\}$ for $0 < t < T$. Denote by u_3 the solution of Problem 1.1 with initial data function $u_{0,3}$ and boundary data function f_3. Let ℓ_3, $\mathcal{C}_3$, z_3, and v_3 be defined in the obvious way. Note that $\mathcal{C}_3 = \mathcal{C}_2$ by hypothesis (1.14). Now, by the comparison principle for solutions of Problem 1.1 [18, 19], $u_i(r,t) \leq u_3(r,t)$ for all $(r,t) \in Q$ and $i = 1,2$. Hence, $\ell_1(r) \leq \ell_3(r)$ for all $r > 1$. Subsequently, it suffices to show that

$$\ell_3(r) \leq \ell_2(r) \quad \text{for all } r > 1. \tag{5.22}$$

To do this, note that Lemma 5.10 can be applied to both u_2 and u_3 since $\mathcal{C}_2 = \mathcal{C}_3 < \infty$. Applying an argument in [2, 14, 26], this lemma means that for every $(r_0,\tau) \in Q$ each of the functions $v_i(r,t)$ with $i = 2,3$ is uniformly Hölder continuous with respect to r with exponent

$$\iota := \min\{1, 1/(m-1)\}$$

in $[r_0,\infty)\times[\tau,T)$. Subsequently, for fixed $r_0 > 1$ and $0 < \tau < T$, the function $v_3 - v_2$ is uniformly Hölder continuous with respect to r with exponent ι in $[r_0,\infty)\times[\tau,T)$. In particular, this means that

$$(v_3 - v_2)(x,t) \geq (v_3 - v_2)(r_0,t) - K(x-r_0)^\iota \tag{5.23}$$

for all $x \geq r_0$ and $\tau \leq t < T$, for some positive constant K. Now, by (2.1), the nonnegativity of $v_3 - v_2$, and (2.4),

$$\begin{aligned}(T-t)^{1/(m-1)}(z_3 - z_2)(1,t) &= \int_1^\infty \kappa(x,1)(v_3 - v_2)(x,t)\,dx \\ &\geq \int_{r_0}^r \kappa(x,1)(v_3 - v_2)(x,t)\,dx \\ &\geq \kappa(r_0,1)\int_{r_0}^r (v_3 - v_2)(x,t)\,dx\end{aligned} \tag{5.24}$$

for any $r \geq r_0$ and $\tau \leq t < T$. Subsequently, choosing $r := r_0 + K^{-1/\iota}(v_3 - v_2)^{1/\iota}(r_0, t)$ and substituting (5.23) in (5.24), we deduce that

$$\left\{\frac{\iota+1}{\iota}\frac{K}{\kappa(r_0,1)}\,(T-t)^{1/(m-1)}\,(z_3-z_2)(1,t)\right\}^{\iota/(\iota+1)} \geq (v_3-v_2)(r_0,t)$$

for all $\tau \leq t < T$. Passing to the limit $t \uparrow T$, using (5.2), (1.12), and (1.14), this inequality implies $\ell_3(r_0) \leq \ell_2(r_0)$, whence, because, $r_0 > 1$ was arbitrary, (5.22) is obtained. □

Lemmas 5.3 and 5.11 together constitute Theorem 1.8.

5.4. The proof of Theorem 1.7. We build up the proof of Theorem 1.7 from the analysis so far in five steps. We make each step the content of a lemma. The first two are concerned with the properties of L and the others with the properties of ℓ.

LEMMA 5.12. *If $\mathcal{C} < \infty$, then* (i) $L(r_0) \geq r_0^{2m/(m-1)}\mathcal{A}(\omega/r_0)$ *for all* $1 \leq r_0 \leq \omega$, (ii) $L(r_0) > L(r)$ *for all* $1 \leq r_0 < r \leq \omega$, *and* (iii) $L(r) = 0$ *for all* $r > \omega$.

Proof. Fix $1 \leq r_0 \leq \omega$ and define r_1 by (5.18). By Lemma 5.8, $z(r,T) < \infty$ for all $r > r_1$. Thus, by Lemma 5.6 and Theorem 1.5, $r_1 \geq \omega$. Rewriting $r_1 \geq \omega$ provides part (i). Next, substituting (5.5) in (5.17), there holds

$$L(r) \leq (m-1)r_1^{2m/(m-1)}\rho^m(r/r_1) \qquad \text{for any } r_0 \leq r \leq r_1,$$

where ρ is the function from Lemma 3.2. Hence, because ρ is strictly decreasing on $(0,1]$,

$$L(r) < (m-1)r_1^{2m/(m-1)}\rho^m(r_0/r_1) = r_0^{2m/(m-1)}\mathcal{A}(r_1/r_0) = L(r_0)$$

for any $r_0 < r \leq r_1$. Thus, since $r_1 \geq \omega$, part (ii) is proven. Part (iii) is a simple consequence of (5.2) and Lemma 5.7. □

LEMMA 5.13. *If $\mathcal{C} < \infty$ then $L \in C(1,\infty) \cap W^{1,\infty}_{\mathrm{loc}}(1,\infty)$.*

Proof. Integrating (2.7) we determine that

$$z(r_1,t)\int_{r_0}^{r_2} x^{1-n}\,dx \leq z(r_0,t)\int_{r_1}^{r_2} x^{1-n}\,dx + z(r_2,t)\int_{r_0}^{r_1} x^{1-n}\,dx \tag{5.25}$$

for any $1 \leq r_0 < r_1 < r_2$ and $0 < t < T$. Hence, multiplying by $(T-t)^{1/(m-1)}$ and then letting $t \uparrow T$, (5.25) holds with $L(r_i)$ in lieu of $z(r_i,t)$ for $i \in \{0,1,2\}$. This means that subject to a transformation of its argument, the function L is convex in $[1,\infty)$. The stated regularity follows from this. □

LEMMA 5.14. *Let ρ be the function from Lemma* 3.2. *If $c > 1$ is such that for some $0 < \tau < T$ there holds $f(t) \leq (T-t)^{-1/(m-1)}c^{2/(m-1)}\rho(1/c)$ for almost all $\tau < t < T$, then v is bounded in Q, and $\ell(r) \leq c^{2m/(m-1)}\rho(\min\{r/c,1\})$ for all $r > 1$.*

Proof. Let $U(\cdot,\cdot;a,T)$ be the solution of (1.1) defined in Proposition 3.1. By hypothesis, $U(1,t;c,T) \geq f(t)$ for almost all $\tau < t < T$. Consequently, we can choose an a so large that $U(1,t;a,T) \geq f(t)$ for almost all $0 < t < T$ and $U(r,0;a,T) \geq u_0(r)$ for almost all $r > 1$. The comparison principle [18, 19] for solutions of Problem 1.1 then says that $U(r,t;a,T) \geq u(r,t)$ for all $(r,t) \in Q$. This gives the first conclusion of the lemma. The second one is a corollary of Lemma 5.11 taking $u_1 = u$ and $u_2 = U(\cdot,\cdot;c,T)$. □

LEMMA 5.15. *Let ρ be the function from Lemma* 3.2. *If $\mathcal{C} < \infty$ then* (i) $\ell(r_0) \geq \omega^{2/(m-1)}\rho(r_0/\omega)$ *for all* $1 < r_0 \leq \omega$, (ii) $\ell(r_0) > \ell(r)$ *for all* $1 < r_0 < r \leq \omega$, *and* (iii) $\ell(r) = 0$ *for all* $r > \omega$.

Proof. Fix $r_0 > 1$, and note that $\ell(r_0) < \infty$ by Lemma 5.10. Applying the scaling trick used to obtain Lemma 5.8 from Lemma 5.4. Lemma 5.14 yields

$$\ell(r) \leq r_1^{2/(m-1)}\rho(\min\{r/r_1, 1\}) \quad \text{for all } r > r_0, \tag{5.26}$$

where $r_1 \geq r_0$ is such that

$$\ell(r_0) = r_1^{2/(m-1)}\rho(r_0/r_1). \tag{5.27}$$

In particular this means that $\ell(r_1) = 0$. By (5.19) this in turn implies that $L(r_1) = 0$. Therefore, by Lemma 5.12 part (ii), $r_1 \geq \omega$. Substituting this estimate in (5.27) gives part (i). On the other hand, in view of the monotonicity of ρ, (5.26) and (5.27) imply that $\ell(r) \leq \ell(r_0)$ for all $r > r_0$ with equality only if $\min\{r/r_1, 1\} = r_0/r_1$, i.e., $r_1 = r_0$. However, by (5.27), the latter is the case if and only if $\ell(r_0) = 0$. Thus, we deduce that $\ell(r) < \ell(r_0)$ for all $r > r_0$ such that $\ell(r_0) > 0$. Recalling part (i), this yields part (ii). Part (iii) follows immediately from the definitions of ℓ and ω. □

The assertions of Theorem 1.7 concerning ℓ and L can be distilled from Lemmas 5.9, 5.10, 5.12, 5.13, and 5.15. To prove Theorem 1.7 it therefore remains to show that when f is nondecreasing, $u(\cdot, t) \to \infty$ as $t \uparrow T$ uniformly on $(1, r)$ for every $1 < r < \omega$. However, since for this purpose, without loss of generality we may suppose that $u_0 \equiv 0$, this follows from Lemma 5.1.

5.5. The proof of Theorem 1.9. To prove Theorem 1.9 we shall use one additional lemma.

LEMMA 5.16. *If $a > 1$ is such that $\mathcal{A}(a) < \mathcal{C}$ then $z(r, T) = \infty$ for all $1 < r < a$ for which $r^{2m/(m-1)}\mathcal{A}(a/r) > 2^{-1/(m-1)}\mathcal{A}(a)$.*

Proof. The proof of this lemma is rather similar to that of Lemma 5.5. By definition, there exists a sequence of values $\{t_i\}_{i=1}^{\infty} \subset (0, T)$ such that $t_i \to T$ as $i \to \infty$, and $(T - t_i)^{1/(m-1)}z(1, t_i) > \mathcal{A}(a)$ for any $i \geq 1$. Fix i and set $\tau_i := 2T - t_i$. Then $z(1, t) \geq z(1, t_i) > (T - t_i)^{-1/(m-1)}\mathcal{A}(a) = Z_w(1, T; a, \tau_i) \geq Z_w(1, t; a, \tau_i)$ for all $t_i < t < T$. Proposition 2.2 subsequently states that $z(r, t) \geq Z_w(r, t; a, \tau_i) - \max\{Z_w(1, s; a, \tau_i) : 0 \leq s \leq t_i\} = Z_w(r, t; a, \tau_i) - Z_w(1, t_i; a, \tau_i)$ for all $(r, t) \in Q$. Hence, $z(r, T) \geq Z_w(r, T; a, \tau_i) - Z_w(1, t_i; a, \tau_i) = (T - t_i)^{-1/(m-1)}\{r^{2m/(m-1)}\mathcal{A}(a/r) - 2^{-1/(m-1)}\mathcal{A}(a)\}$ for all $1 < r < a$. Letting $i \to \infty$ yields the result. □

Now, Lemmas 5.4, 5.5, and 5.16 imply that $z(r, T) < \infty$ for all $r > \alpha(\mathcal{C})$, $z(r, T) = \infty$ for all $1 < r < \beta(\mathcal{C})$, and $z(r, T) = \infty$ for all $1 < r < \gamma(\mathcal{C})$, respectively. While, by Lemmas 5.7 and 5.6, $z(r, T) < \infty$ for all $r > \omega$, and $z(r, T) = \infty$ for all $1 < r < \omega^*$. Combining these conclusions with Theorem 1.5 yields

$$\max\{\beta(\mathcal{C}), \gamma(\mathcal{C})\} \leq \omega \leq \alpha(\mathcal{C}). \tag{5.28}$$

Theorem 1.9 is subsequently an immediate consequence of Lemma 5.2.

5.6. On the size of ℓ and L. Our last result on Problem 1.1 provides some quantitative information on the way blow-up occurs.

THEOREM 5.17. *Let u be a weak solution of Problem 1.1 for which $0 < \mathcal{C} < \infty$ where $\mathcal{C}$ is defined by (1.10). Let ℓ and L be defined by (1.9) and (1.12). Also, let ρ be the function from Lemma 3.2 and let α be the inverse of the function $\mathcal{A}$ defined by (5.5). Then*

$$\omega \leq \alpha(\mathcal{C}), \tag{5.29}$$

$$\mathcal{A}(\omega/r) \leq r^{-2m/(m-1)}L(r) \leq \mathcal{A}(\alpha(\mathcal{C})/r) \quad \textit{for all } 1 \leq r \leq \omega, \tag{5.30}$$

and

$$\ell(r) \geq \omega^{2/(m-1)}\rho(r/\omega) \quad \textit{for all } 1 < r \leq \omega. \tag{5.31}$$

(a) *If furthermore*

$$(T-t)^{1/(m-1)} \int_0^t f^m(s)\,ds \to \mathcal{C} \quad \textit{as } t \uparrow T,$$

then (5.29) *and* (5.30) *hold with equality.*

(b) *If furthermore*

$$\operatorname{ess\,sup}\{(T-s)^{1/(m-1)} f(s) : t < s < T\} \to (m-1)^{-1/m}\mathcal{C}^{1/m} \quad \textit{as } t \uparrow T,$$

then (5.29)–(5.31) *hold with equality.*

Proof. The main assertions have virtually been established already. The inequality (5.29), the left-hand inequality in (5.30), and (5.31) are restatements of (5.28), Lemma 5.12 part (i), and Lemma 5.15 part (i). The remaining inequality in (5.30) may be obtained by letting $c \downarrow \alpha(\mathcal{C})$ in Lemma 5.4. Moreover, under the additional hypothesis of part (a), applying Lemma 5.3 with $z_1 = Z_w(\cdot, \cdot; \alpha(\mathcal{C}), T)$ and $z_2 = z$ yields

$$L(r) \geq r^{2m/(m-1)}\mathcal{A}(\alpha(\mathcal{C})/r) > 0 \quad \text{for all } 1 \leq r < \alpha(\mathcal{C}). \tag{5.32}$$

Hence, by Lemma 5.12 part (iii), equality in (5.29) is obtained, and part (a) is proven. Let us therefore assume that the hypothesis of part (b) holds. In this case, Lemma 5.14 gives

$$\ell(r) \leq \{\alpha(\mathcal{C})\}^{2/(m-1)}\,\rho(r/\alpha(\mathcal{C})) \quad \text{for all } 1 < r \leq \alpha(\mathcal{C}). \tag{5.33}$$

Simultaneously, integrating (2.7), there holds

$$\begin{aligned} z(r_0,t)\int_{r_1}^{r_2} x^{1-n}\,dx + z(r_2,t)\int_{r_0}^{r_1} x^{1-n}\,dx \\ = z(r_1,t)\int_{r_0}^{r_2} x^{1-n}\,dx + \int_{r_0}^{r_1}\int_{r_1}^{r_2}\int_x^y x^{1-n}y^{1-n}\eta^{n-1}u(\eta,t)\,d\eta\,dy\,dx \end{aligned}$$

for any $1 \leq r_0 < r_1 < r_2$ and $0 < t < T$. Taking $r_0 = 1$, $r_1 = r$, and $r_2 = \alpha(\mathcal{C})$, multiplying by $(T-t)^{1/(m-1)}$, letting $t \uparrow T$ in an appropriate fashion, using (5.2) and (1.10), and employing Fatou's lemma which is justified by Lemma 5.14, this gives

$$\begin{aligned} \mathcal{C}\int_r^{\alpha(\mathcal{C})} x^{1-n}\,dx \leq L(r)\int_1^{\alpha(\mathcal{C})} x^{1-n}\,dx \\ + \int_1^r\int_r^{\alpha(\mathcal{C})}\int_x^y x^{1-n}y^{1-n}\eta^{n-1}\ell(\eta)\,d\eta\,dy\,dx \end{aligned} \tag{5.34}$$

for all $1 < r < \alpha(\mathcal{C})$. Repeating the above calculation with the solution $U(\cdot, \cdot; \alpha(\mathcal{C}), T)$ from Proposition 3.1 instead of u, one obtains

$$\begin{aligned} \mathcal{C}\int_r^{\alpha(\mathcal{C})} x^{1-n}\,dx = r^{2m/(m-1)}\mathcal{A}(\alpha(\mathcal{C})/r)\int_1^{\alpha(\mathcal{C})} x^{1-n}\,dx \\ + \int_1^r\int_r^{\alpha(\mathcal{C})}\int_x^y x^{1-n}y^{1-n}\eta^{n-1}\{\alpha(\mathcal{C})\}^{2/(m-1)}\rho(\eta/\alpha(\mathcal{C}))\,d\eta\,dy\,dx \end{aligned} \tag{5.35}$$

for all $1 < r < \alpha(\mathcal{C})$. Combining (5.33), (5.34), and (5.35) yields (5.32). This once again implies equality in (5.29) and (5.30). The outstanding conclusion subsequently follows from (5.31) and (5.33). $\square$

In the case $n = 1$, the functions $\mathcal{A}$ and α can be computed explicitly from the function ρ given by (3.10).

6. The Cauchy–Neumann problem.

6.1. Notation. We shall retain the conventions used in the study of the Cauchy–Dirichlet problem in the previous section. We let u denote a given weak solution of Problem 1.2 with initial data function u_0 and boundary data function g. We have the following result in lieu of Lemma 5.1.

LEMMA 6.1. *Suppose that g is nondecreasing and $u_0 \equiv 0$. Then $u(r,t) \geq u(r_0,t_0)$ for all $1 < r \leq r_0$ and $0 < t_0 \leq t < T$.*

Proof. We use a technique applied in [10]. Pick $0 < \tau < T$ and $0 < \varepsilon < T - \tau$. Define $u_{0,\varepsilon}(r) := u(r,\varepsilon)$ for $r > 1$, and $g_\varepsilon(t) := g(t+\varepsilon)$ for $0 < t < \tau$. Consider Problem 1.2 restricted to the domain Q_τ with initial data $u_{0,\varepsilon}$ and boundary data g_ε. By the general theory, this problem admits a unique weak solution $u_\varepsilon(r,t) = u(r,t+\varepsilon)$. Furthermore, since $u_{0,\varepsilon}(r) \geq 0 = u_0(r)$ for all $r > 1$ and $g_\varepsilon(t) = g(t+\varepsilon) \geq g(t)$ for almost all $0 < t < \tau$, there holds $u_\varepsilon(r,t) \geq u(r,t)$ for all $(r,t) \in Q_\tau$. Thus $u(r,t+\varepsilon) \geq u(r,t)$ for all $(r,t) \in Q_\tau$. In view of the arbitrariness of ε and τ, this yields the monotonicity of u with respect to t. In fact, since u is a classical solution of (1.1) at any point in Q where it is positive, it yields $(\partial u/\partial t)(r,t) \geq 0$ for all $(r,t) \in Q$ such that $u(r,t) > 0$. Hence, by (1.1), $(\partial(r^{n-1}\partial u^m/\partial r)/\partial r)(r,t) \geq 0$ for all such points. Recalling that $\partial u^m/\partial r \in C(Q)$, noting that as a consequence of the nonnegativity of u there holds $(\partial u^m/\partial r)(r,t) = 0$ for all $(r,t) \in Q$ such that $u(r,t) = 0$, and recalling that $u(r,t) = 0$ for all $r > \zeta(t)$ and $0 < t < T$, this implies that $(\partial u^m/\partial r)(r,t) \leq 0$ for all $(r,t) \in Q$. Hence, we also have the monotonicity of u with respect to r. $\square$

We employ the notation (1.5), (1.6), (1.9), and (5.3). We define $\mathcal{C}$ by (1.11), L by (1.16), and z by (2.18) and (2.19) and for completeness set

$$z(r,T) := \limsup_{t \uparrow T} z(r,t).$$

We let

$$Z(r,t;a,\tau) := \int_r^\infty x^{n-1} U(x,t;a,\tau)\,dx$$

for any $(r,t) \in [1,\infty) \times [0,T)$ for one of the self-similar solutions U of the equation, and add a subscript w if the self-similar solution is that of waiting-time type and a subscript s if it is that of instantaneous point-source type. Performing calculations analogous to those we have carried in section 5 we obtain

$$Z_w(r,t;a,\tau) = \begin{cases} (\tau - t)^{-1/(m-1)} r^{\{(m-1)n+2\}/(m-1)} \mathcal{A}(a/r) & \text{if } r < a, \\ 0 & \text{otherwise} \end{cases}$$

for all $(r,t) \in [1,\infty) \times [0,T)$, where now

$$\mathcal{A}(c) := c^{\{(m-1)n+2\}/(m-1)} \int_{1/c}^1 x^{n-1} \rho(x)\,dx \tag{6.1}$$

for $c \geq 1$, with ρ constructed in Lemma 3.2. Similarly

$$Z_s(r,t;a,\tau) \\ = \begin{cases} (t-\tau)^{-1/(m-1)} r^{\{(m-1)n+2\}/(m-1)} \mathcal{B}(\xi(t)/r) & \text{if } t > \tau \text{ and } r < \xi(t), \\ 0 & \text{otherwise} \end{cases}$$

for all $(r,t) \in \overline{Q}$, where

$$\mathcal{B}(c) := c^{\{(m-1)n+2\}/(m-1)} \int_{1/c}^{1} x^{n-1} \rho(x)\, dx$$

for $c \geq 1$, with ξ and ρ defined by (3.12) and (3.13). The functions $\mathcal{A}$ and $\mathcal{B}$ are unbounded, strictly increasing, and continuously differentiable on $[1,\infty)$ and are such that $\mathcal{A}(1) = \mathcal{B}(1) = 0$. We shall denote by α and β the inverse of the functions $\mathcal{A}$ and $\mathcal{B}$, respectively. Finally, define the function $\gamma \in C([0,\infty))$ with $\gamma(0) = 1$ by

$$\{\gamma(\mathcal{C})\}^{\{(m-1)n+2\}/(m-1)} \mathcal{A}(\alpha(\mathcal{C})/\gamma(\mathcal{C})) = 2^{-1/(m-1)}\mathcal{C}.$$

The proof of the following is similar to the proof of Lemma 5.2 and we omit it.

LEMMA 6.2. *There are positive constants μ and ν such that* $\max\{\beta(\mathcal{C}), \gamma(\mathcal{C})\} \geq 1 + \mu\{\sigma(\mathcal{C})\}^{(m-1)/(m+1)}$ *and* $\alpha(\mathcal{C}) \leq 1 + \nu\{\sigma(\mathcal{C})\}^{(m-1)/(m+1)}$ *for all* $\mathcal{C} \geq 0$*, where* σ *is defined by* (1.17).

6.2. The proof of Theorem 1.10. The proofs of the next two lemmas are almost identical to those of their counterparts Lemmas 5.4 and 5.5 in the previous section, and will be omitted. The third lemma below is a consequence of the definitions of Ω^* and z.

LEMMA 6.3. *If* $c > 1$ *is such that* $\mathcal{A}(c) > \mathcal{C}$ *then*

$$L(r) \leq r^{\{(m-1)n+2\}/(m-1)} \mathcal{A}(\max\{c/r, 1\}) \quad \text{for all } r \geq 1$$

and $z(r,T) < \infty$ *for all* $r \geq c$.

LEMMA 6.4. *If* $c > 1$ *is such that* $\mathcal{B}(c) < \mathcal{C}$*, then* $z(r,T) = \infty$ *for all* $1 < r < c$.

LEMMA 6.5. *There holds* $z(r,T) = \infty$ *for some* $r > 1$ *if and only if* $r \in \Omega^*$.

With these lemmas we may complete the proof of Theorem 1.10. Suppose that $\mathcal{C} < \infty$, then by Lemma 6.3, $z(r,T) < \infty$ for all $r > \alpha(\mathcal{C})$. Hence, by Lemma 6.5, $\omega^* < \infty$. On the other hand if $\mathcal{C} = \infty$, then by Lemma 6.4, $z(r,T) = \infty$ for all $r > 1$. Whence, by Lemma 6.5, $\omega^* = \infty$. The desired result consequently follows from Theorem 1.5.

6.3. The proof of Theorem 1.12. Comparing the Cauchy–Neumann and Cauchy–Dirichlet problems, Theorem 1.12 is the counterpart of Theorem 1.8. The last-mentioned theorem was proven in two steps, viz., Lemma 5.3 and Lemma 5.11. The analogous lemmas for the Cauchy–Neumann problem can be formulated and proven without any extra difficulty. Details will not be presented.

6.4. The proof of Theorem 1.11. The proof of Theorem 1.11 can be completed similarly to the proof of Theorem 1.7 once we have established Lemmas 6.7–6.9 below. Therefore, we shall not dwell on any details beyond the proofs of these lemmas. As a means to obtaining Lemma 6.7, we use Lemma 6.6 below. This plays the role for Problem 1.2 which Lemma 5.8 does for Problem 1.1. However, for technical reasons, we defer the proof of this lemma until the next section.

LEMMA 6.6. *Suppose that $L(r_0) < \infty$ for some $r_0 > 1$. Then*

$$L(r) \leq r^{\{(m-1)n+2\}/(m-1)} \mathcal{A}(\max\{r_1/r, 1\}) \quad \text{for all } r \geq r_0,$$

and $z(r,T) < \infty$ for all $r > r_1$, where $r_1 := r_0 \alpha(r_0^{-\{(m-1)n+2\}/(m-1)} L(r_0))$.

LEMMA 6.7. *If $\mathcal{C} < \infty$ then* (i) *$L(r) \geq r^{\{(m-1)n+2\}/(m-1)} \mathcal{A}(\omega/r)$ for all $1 \leq r \leq \omega$,* (ii) *$L(r_0) > L(r)$ for all $1 \leq r_0 < r \leq \omega$, and* (iii) *$L(r) = 0$ for all $r > \omega$. On the other hand if $\mathcal{C} = \infty$, then $L(r) = \infty$ for all $r > 1$.*

Proof. This lemma follows from Lemma 6.6 in the same way as Lemmas 5.9 and 5.12 follow from Lemma 5.8. □

LEMMA 6.8. *Let ρ be the function from Lemma* 3.2. *If $\mathcal{C} < \infty$ then* (i) *$v^{m-1} \in L^\infty(\tau, T; W^{1,\infty}(r_1, \infty))$ for every $(r_1, \tau) \in Q$,* (ii) *$\ell(r) \geq \omega^{2/(m-1)} \rho(r/\omega)$ for all $1 < r \leq \omega$,* (iii) *$\ell(r_1) > \ell(r)$ for all $1 < r_1 < r \leq \omega$, and* (iv) *$\ell(r) = 0$ for all $r > \omega$. On the other hand if $\mathcal{C} = \infty$, then $\ell(r) = \infty$ for all $r > 1$.*

Proof. Fix $r_0 > 1$. Then the function $\widetilde{u}$ defined by (2.9) is a solution of Problem 1.1 with correspondingly scaled initial data and boundary data given by (2.10). Denote, associated with $\widetilde{u}$, the parameter $\widetilde{\mathcal{C}}$ defined by (1.10). By Theorem 1.10, u is effectively localized if and only if $\mathcal{C} < \infty$. However, by Theorem 1.6, $\widetilde{u}$ is effectively localized if and only if $\widetilde{\mathcal{C}} < \infty$. Consequently, $\widetilde{\mathcal{C}} < \infty$ if and only if $\mathcal{C} < \infty$. The present lemma may now be deduced by applying Lemmas 5.9, 5.10, and 5.15 to $\widetilde{u}$, transferring the conclusions to u, and finally, letting $r_0 \downarrow 1$. □

LEMMA 6.9. *If $\mathcal{C} < \infty$ then $L \in C(1,\infty) \cap W^{1,\infty}_{\mathrm{loc}}(1,\infty)$.*

Proof. By (2.18) there holds

$$z(r_0, t) = z(r,t) + \int_{r_0}^{r} x^{n-1} u(x,t)\, dx \quad \text{for all } 1 < r_0 < r$$

and $0 < t < T$. Multiplying this inequality by $(T-t)^{1/(m-1)}$, letting $t \uparrow T$, and employing Fatou's lemma which is justified by the previous lemma give

$$L(r_0) \leq L(r) + \int_{r_0}^{r} x^{n-1} \ell(x)\, dx \quad \text{for all } 1 < r_0 < r.$$

In light of Lemmas 6.7 and 6.8, this provides the stated regularity. □

6.5. The proof of Theorem 1.13. With regard to Theorem 1.13 we employ one more lemma. Its proof is almost a facsimile of the proof of Lemma 5.16 and is not included.

LEMMA 6.10. *If $a > 1$ is such that $\mathcal{A}(a) < \mathcal{C}$ then $z(r,T) = \infty$ for all $1 < r < a$ for which $r^{\{(m-1)n+2\}/(m-1)} \mathcal{A}(a/r) > 2^{-1/(m-1)} \mathcal{A}(a)$.*

Now, suppose that $\mathcal{C} < \infty$. Then by Lemma 6.3, there holds $z(r,T) < \infty$ for all $r > \alpha(\mathcal{C})$, while by Lemmas 6.4 and 6.10, there holds $z(r,T) = \infty$ for all $1 < r < \max\{\beta(\mathcal{C}), \gamma(\mathcal{C})\}$. Recalling Lemma 6.5 and Theorem 1.5, this gives (5.28). Theorem 1.13 follows from Lemma 6.2.

6.6. On the size of ℓ and L. Analogous to Theorem 5.17 for the Cauchy–Dirichlet problem, the next result can be obtained for Problem 1.2, where, in the case $n = 1$, the functions $\mathcal{A}$ and α can be computed explicitly from the function ρ given by (3.10).

THEOREM 6.11. *Let u be a weak solution of Problem* 1.2 *for which $0 < \mathcal{C} < \infty$ where $\mathcal{C}$ is defined by* (1.11). *Let ℓ and L be defined by* (1.9) *and* (1.16). *Also, let ρ*

be the function from Lemma 3.2 *and let α be the inverse of the function $\mathcal{A}$ defined by* (6.1)*. Then*

$$\omega \leq \alpha(\mathcal{C}), \tag{6.2}$$

$$\mathcal{A}(\omega/r) \leq r^{-\{(m-1)n+2\}/(m-1)}L(r) \leq \mathcal{A}(\alpha(\mathcal{C})/r) \quad \textit{for all } 1 < r \leq \omega, \tag{6.3}$$

and

$$\ell(r) \geq \omega^{2/(m-1)}\rho(r/\omega) \quad \textit{for all } 1 < r \leq \omega. \tag{6.4}$$

(a) *If furthermore*

$$(T-t)^{1/(m-1)}\int_0^t g(s)\,ds \to \mathcal{C} \qquad \textit{as } t \uparrow T,$$

then (6.2) *and* (6.3) *hold with equality.*

(b) *If furthermore*

$$\operatorname{ess\,sup}\{(T-s)^{m/(m-1)}g(s) : t < s < T\} \to (m-1)^{-1}\mathcal{C} \qquad \textit{as } t \uparrow T,$$

then (6.2)–(6.4) *hold with equality.*

7. The remaining details. Without the assumption that g is nonnegative and bounded on every interval $(0,\tau)$ with $0 < \tau < T$, it is a priori unclear whether the Cauchy–Neumann problem (Problem 1.2) admits a nonnegative solution. Notwithstanding, if we suppose that the problem has a nonnegative solution which can be constructed as the limit of a sequence of positive solutions of (1.1), a number of our results can still be shown to hold. In particular, under the assumption (2.23), Lemma 2.3 remains true. Consequently, mutatis mutandi, it is also possible to obtain Proposition 2.4, and Lemmas 6.3 and 6.5. It follows that with $\mathcal{C}$ defined by (1.11), as long as (2.23) holds, even if g changes sign and is unbounded, the criterion $\mathcal{C} < \infty$ remains sufficient for the localization, effective localization, and metastable localization of a nonnegative solution of Problem 1.2 which can be constructed as the limit of a sequence of positive solutions of (1.1).

It is this observation which enables us to prove Lemma 6.6.

Proof of Lemma 6.6. We apply the scaling technique used in the proof of Lemmas 2.1 and 5.8. The function $\widetilde{u}$ given by (2.9) is a weak solution of Problem 1.2 with correspondingly scaled initial data, and with boundary data

$$\widetilde{g}(t) := r_0^{-(m+1)/(m-1)}\frac{\partial u^m}{\partial r}(r_0,t), \tag{7.1}$$

for which the parameter defined by (1.11) takes the value $r_0^{-\{(m-1)n+2\}/(m-1)}L(r_0)$. Applying Lemma 6.3 to the rescaled problem, which can now be justified with the help of the above remarks, gives that which is required. □

As a consequence of Lemma 6.6, for any solution u of Problem 1.2 which can be constructed as the limit of a sequence of positive solutions of (1.1) and whose boundary data satisfy (2.23), with the variables otherwise as defined in Theorem 1.11, we can still obtain Theorems 1.11 and 6.11.

Appendix. For the one-dimensional case, under appropriate assumptions on u_0 and f, it was shown in [15] that Problem 1.1 displays localization if and only if the parameter $\mathcal{C}^*$ defined by (1.8) is finite. On the other hand, in [11] it was shown that this problem displays localization if and only if the parameter $\mathcal{C}$ defined by (1.10) is finite. This naturally raises the question if there is a discrepancy in these criteria, and if not, which is to be preferred. In both [15] and [11] it was hypothesized that f is continuous. The key to resolving the question of the relation between the criteria is the observation that in [15] the additional hypothesis that f is nondecreasing was imposed. In this appendix we show that with this additional hypothesis the two criteria are equivalent. Thus, also being applicable when f is not monotonic, the criterion of Cortazar and Elgueta [11] constitutes the superior result.

Let $f \in C(0,T)$ be nondecreasing. Fix $0 < t < T$ and set

$$\tau := \{t + (m-1)T\}/m. \tag{A.1}$$

Then, noting that $t < \tau < T$, there holds

$$\begin{aligned} f(t) &= (\tau - t)^{-1/m} \left\{ \int_t^\tau f^m(t)\, ds \right\}^{1/m} \\ &\le (\tau - t)^{-1/m} \left\{ \int_t^\tau f^m(s)\, ds \right\}^{1/m} \\ &\le (\tau - t)^{-1/m} \left\{ \int_0^\tau f^m(s)\, ds \right\}^{1/m}. \end{aligned}$$

Subsequently multiplying both sides of this last inequality by $(T-t)^{1/(m-1)}$ and using (A.1) we deduce

$$(T-t)^{1/(m-1)} f(t) \le m^{1/(m-1)} (m-1)^{-1/m} \left\{ (T-\tau)^{1/(m-1)} \int_0^\tau f^m(s)\, ds \right\}^{1/m}.$$

This means that

$$\limsup_{t \uparrow T} \, (T-t)^{1/(m-1)} \, f(t) \le m^{1/(m-1)} (m-1)^{-1/m} \mathcal{C}^{1/m}. \tag{A.2}$$

However, if (A.2) holds, by Lemma A2 in [15] with $\phi(t) = (T-t)^{-1/(m-1)}$ we have

$$\mathcal{C}^* \le m \left\{ m^{1/(m-1)} (m-1)^{-1/m} \mathcal{C}^{1/m} \right\}^{m-1}. \tag{A.3}$$

On the other hand, by Lemma 5 in [15] there holds

$$\mathcal{C} \le (m-1)^{-1/(m-1)} \left\{ \mathcal{C}^* \right\}^{m/(m-1)}. \tag{A.4}$$

Combining (A.3) and (A.4) yields

$$(m-1)^{1/m} \mathcal{C}^{(m-1)/m} \le \mathcal{C}^* \le m^2 (m-1)^{(1-m)/m} \mathcal{C}^{(m-1)/m}.$$

This shows that under the hypothesis that f is nondecreasing and continuous, the criteria of [15] and [11] are equivalent.

BLOWUP FOR SYSTEMS OF CONSERVATION LAWS[*]

HELGE KRISTIAN JENSSEN[†]

Abstract. We give examples of finite time blowup in sup-norm and total variation for 3×3-systems of strictly hyperbolic conservation laws. The exact solutions are explicitly constructed. In the case of sup-norm blowup we also provide an example where all other p-norms, $1 \leq p < \infty$, remain uniformly bounded. Finally we consider appropriate rescalings for the different types of blowup.

Key words. systems of conservation laws, blowup, total variation, sup-norm, rescaling

1. Introduction.

We consider systems of conservation laws of the form

$$U_t + F(U)_x = 0 \tag{1.1}$$

with initial data

$$U(x, 0) = U_0(x), \tag{1.2}$$

where $U(x,t) = (u(x,t), v(x,t), w(x,t)) \in \mathbb{R}^3$ and $F : \mathbb{R}^3 \to \mathbb{R}^3$ is smooth and strictly hyperbolic; i.e., the Jacobian DF has real and distinct eigenvalues. We assume that each characteristic field is either genuinely nonlinear or linearly degenerate in the sense of Lax [21].

The existence of a weak entropy solution to the Cauchy problem for an $n \times n$-system of the form (1.1) has been established in two main cases. Either the total variation (T.V.) of the initial data is assumed to be sufficiently small, or one considers systems of two equations. In the seminal paper [15] Glimm introduced a functional consisting of a linear term giving the total variation of the solution and a quadratic term measuring the amount of waves generated by future collisions. For data close to a constant state and with small total variation the functional is decreasing in time, and a compactness argument yields a weak entropy solution to (1.1), (1.2). This solution is constructed by Glimm's scheme [15, 22] or by wave front-tracking [4, 5, 27].

Various extensions and refinements of the original result have been given. Young [33] proves a third-order estimate for wave interactions and uses this together with a reordering technique to obtain L^∞-stability for solutions constructed by Glimm's scheme. In [31] Temple and Young derive sufficient conditions for existence of solutions to 3×3-systems with a 2-Riemann invariant when the data has small amplitude but possibly large variation. The same class of systems is considered in [32] where existence of solutions up to any prescribed time is established for data with arbitrarily large total variation and correspondingly small sup-norm. In both this work and in the work by Cheverry, a new length scale for the Cauchy problem was introduced. Using this, Cheverry [10] has showed how to relax the restriction on the variation of the initial data for $n \times n$-systems where all the fields are genuinely nonlinear. Schochet [28] shows that for $n \times n$-systems with "almost planar interactions" the conditions on the

[†] S.I.S.S.A., Via Beirut 4, Trieste 34014, Italy (jenssen@sissa.it).

initial data can be relaxed. Recently Bressan and Goatin [7] have considered Temple class systems where all fields are genuinely nonlinear. They prove the existence of an L^1-continuous semigroup for L^∞-data with possible infinite total variation.

For the case $n = 2$ stronger results have been obtained. Glimm and Lax [16] considered a large class of 2×2-systems and proved global existence of a weak solution under the much weaker assumption that the *oscillation* of the initial data is sufficiently small. Several works establish existence with large data for gas dynamics [11, 12, 23, 25, 26]. Similar results have been obtained by applying the theory of compensated compactness [13, 14]. Serre [30] has studied the case of 2×2 Temple class systems for which one has global existence for data with bounded variation. See [2] for L^1-continuous dependence in this case. Alber [1] has proved local existence for isentropic gas dynamics where the data have compact support and bounded variation. For an extension of this result to $n \times n$-systems, see [29]. A local uniqueness result in the case of small BV perturbations of (possibly large) Riemann data was established in [6]. For existence and continuous dependence for special systems with data in L^∞, see [3, 8].

Recent results on 3×3-systems by several authors [17, 18, 20, 24, 34] show that the restriction to 2×2-systems for these stronger results is essential. More specifically the authors consider the possibility of blowup in finite time of total variation or sup-norm. These works present special classes and explicit examples of systems for which different types of behavior can be found. In [18] Jeffrey gave an example of blowup in finite time of the sup-norm (and, hence, also of total variation) for a 3×3-system. The system is strictly hyperbolic and linearly degenerate in each characteristic family, and the solution is smooth. A weakness of this example is that the system is not in conservative form. Young [34] constructs exact solutions to 3×3-systems with periodic initial data. Depending on the choice of initial data and the interaction coefficients one gets different types of behavior. These include arbitrarily large magnifications of total variation and p-norms ($1 \leq p \leq \infty$) in finite time, decay rates like $1/(1 + t)$, exponential growth and decay, and time periodic solutions. The systems are linearly degenerate in each family (constant eigenvalues) so that the regularizing effect of genuine nonlinearity is absent and all nonlinear effects are due to the geometrical nonlinearities of the wave curves in state space. In [20] Joly, Metivier, and Rauch presented a class of systems which are genuinely nonlinear in all three fields. Using the theory of weakly nonlinear geometric optics, the authors show the existence of systems with periodic initial data where the variation grows arbitrarily large and the sup-norm is amplified by arbitrary large factors in finite time. A common feature of the works [20] and [34] is the use of initial data in BV_{loc} with sufficiently small amplitude such that the solution remains local in state space. In the former case, this guarantees that all Riemann problems can be solved uniquely, while in the latter it guarantees that the methods of weakly nonlinear geometric optics can be applied. For further work on the methods of nonlinear geometric optics applied to systems of conservation laws, see [9, 19, 24]. Recently Bressan and Shen [8] have given an example to the effect that the Cauchy problem is not well posed for 3×3-systems if one allows data with infinite total variation.

The works of Young and Joly, Metivier, and Rauch show that one cannot extend the Glimm–Lax theory to larger systems. In particular it is not possible to prove global existence for general 3×3-systems by deriving uniform BV-estimates. However, given these results it is still conceivable that one could obtain general global existence results for $n \times n$-systems, $n \geq 3$, even in the case of large data. We shall see that this is

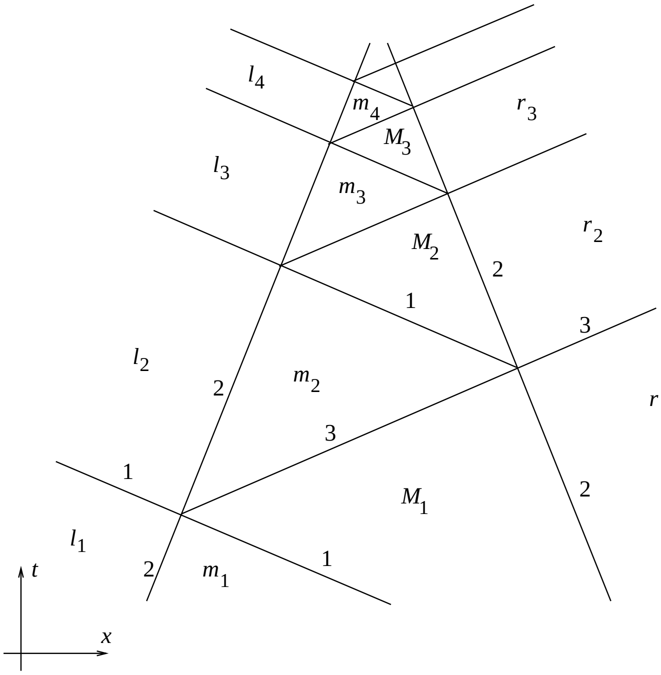

FIG. 1. *Interaction pattern.*

not possible. In what follows we present a class of 3×3-systems for which one can prescribe initial data such that the solution blows up in finite time. We will consider blowup in both sup-norm and total variation. That is, we give a class of examples for which there exists a time T, $0 < T < \infty$, such that

$$\lim_{t \to T^-} \|U(\cdot,t)\|_\infty = +\infty, \tag{1.3}$$

and we also give a class of examples for which there exists a time T, $0 < T < \infty$, such that

$$\lim_{t \to T^-} \text{T.V. } [U(\cdot,t)] = +\infty \quad \text{while} \quad \|U(\cdot,t)\|_\infty \quad \text{remains bounded.} \tag{1.4}$$

Both types of examples are constructed by considering a situation where two 2-shocks approach each other while 1- and 3-shocks are being reflected between the 2-shocks; see Figure 1. By carefully choosing the flux function and the initial data, we obtain the above behaviors. More precisely, we get examples where the waves are magnified at each interaction, which yields blowup in sup-norm, and where the solution is periodic in state space, yielding blowup in total variation. The examples differ from the examples given in [20], [34] both in the mechanism of blowup (i.e., the particular interaction pattern) and in the fact that one actually gets *infinite* sup-norm or total variation in *finite time*. To have blowup in sup-norm the 2-shocks must be sufficiently strong, and to have to blowup in total variation the strength of the 2-shocks must be chosen in a particular way to give periodicity in state space. However, the initial 1- and 3-waves can be arbitrarily weak. We also give an example where the sup-norm blows up while the p-norms of $U(\cdot,t)$ remain uniformly bounded as $t \to T^-$. These are, to the best of my knowledge, the first examples of this type.

The paper is organized as follows. In the next section we give the systems we will consider, we note their main properties, and we formulate the main result. In section 3 we consider Riemann problems and we derive a criteria for a Riemann problem to have a unique solution. Section 4 contains the proof of the main result. We also present rescalings which describe the asymptotics in the various cases of blowup. In the last section we collect some additional observations and comment on open problems.

2. Class of systems and statement of main result. We want to set up an interaction pattern like the one in Figure 1 where two 2-shocks approach each other while 1- and 3-waves (which will be contact discontinuities) are reflected back and forth between the 2-shocks. Note that this requires at least three equations; i.e., it is not possible to get an interaction pattern like this for 2×2-systems. We do this by constructing solutions to 3×3-systems of the form (1.1) where the flux function F has the form

$$F(U) \equiv F(u, v, w) = \begin{pmatrix} ua(v) + w \\ \Gamma(v) \\ u(\lambda_0^2 - a^2(v)) - wa(v) \end{pmatrix}. \tag{2.1}$$

Here $\lambda_0 > 0$ is a constant and $a(v)$ will be chosen later to obtain the types of behavior stated in Theorem 2.1. To simplify the analysis we assume that $\Gamma(v)$ has the following properties:

(i) $\Gamma(v)$ is strictly convex;

(ii) $-\lambda_0 < \gamma(v) \equiv \Gamma'(v) < \lambda_0$ for all $v \in \mathbb{R}$;

(iii) $\Gamma(0) = 0$ and $\Gamma(-v) = \Gamma(v)$ for all $v \in \mathbb{R}$.

It is readily checked that the eigenvalues of the Jacobian DF are

$$\lambda_1 = -\lambda_0, \qquad \lambda_2 = \gamma(v), \qquad \lambda_3 = +\lambda_0. \tag{2.2}$$

Thus (ii) guarantees that the system is strictly hyperbolic. Also, since the first and third eigenvalues are constants, the 1-waves to the left of the left 2-wave and the 3-waves to the right of the right 2-wave, respectively, do not interact (see Figure 1). The first and third eigenvectors are given by

$$r_1 = \begin{pmatrix} 1 \\ 0 \\ -(\lambda_0 + a(v)) \end{pmatrix}, \qquad r_3 = \begin{pmatrix} 1 \\ 0 \\ \lambda_0 - a(v) \end{pmatrix}. \tag{2.3}$$

Note that the second equation in the system is a decoupled scalar conservation law for v with a strictly convex flux. It follows that the second characteristic field is genuinely nonlinear. The first and third fields are linearly degenerate so that all 1-waves and 3-waves are contact discontinuities. It follows that shock and rarefaction curves coincide in the first and third families, and these are straight lines in planes with $v =$ constant.

Remark. This class of systems is a modification of the examples considered by Young [34]. The difference is that we have introduced nonlinearity in the second field. As in [34] we construct *exact* solutions.

We say that a solution of (1.1), (1.2) has an *interaction pattern* as in Figure 1 if the initial data consist of four constant states U_{l_1}, U_{m_1}, U_{M_1}, and U_{r_1} (ordered from left to right) and the Riemann problem

- (U_{l_1}, U_{m_1}) gives rise to a single 2-shock with positive speed;
- (U_{m_1}, U_{M_1}) gives rise to a single contact discontinuity of the first family;

- (U_{M_1}, U_{r_1}) gives rise to a single 2-shock with negative speed.

Note that the v-component does not change across 1- and 3-waves. Since the second equation is a scalar conservation law for v with a convex flux satisfying $\Gamma(0) = 0$, it follows that the solution has an interaction pattern as in Figure 1 if and only if $0 < v_{l_1} > v_{m_1} = v_{M_1} > v_{r_1} < 0$. We now state the main result of the paper.

THEOREM 2.1. *Let the flux F be given by* (2.1). *Then for a suitable choice of $a(v)$, $\Gamma(v)$, λ_0, and initial states U_{l_1}, U_{m_1}, U_{M_1}, and U_{r_1}, the solution of* (1.1), (1.2) *has an interaction pattern as in Figure* 1 *and satisfies one of the following relations.*

(a) *There exists a time T, $0 < T < \infty$, such that*

$$\lim_{t \to T^-} \|U(\cdot, t)\|_\infty = +\infty. \tag{2.4}$$

(b) *There exist a constant $C > 0$ and a time T, $0 < T < \infty$, such that*

$$\lim_{t \to T^-} \textit{T.V.}\ [U(\cdot, t)] = +\infty, \ \textit{while}\ \|U(\cdot, t)\|_\infty < C \ \textit{for all}\ t < T. \tag{2.5}$$

In the case of blowup in sup-norm one may choose the parameters so that all other p-norms of $U(\cdot, t)$, $1 \le p < \infty$, remain uniformly bounded as $t \to T^-$. Moreover, in all cases the system remains uniformly strictly hyperbolic in the sense that there is a $\delta > 0$ such that $-\lambda_0 + \delta < \gamma(v(x, t)) < \lambda_0 - \delta$ for all $(x, t) \in \mathbb{R} \times [0, T)$.

3. Riemann problems.

In this section we consider the Riemann problem for the system (1.1), i.e., the Cauchy problem when the data consist of two constant states,

$$U_0(x) = \begin{cases} U_l & \text{if } x < 0, \\ U_r & \text{if } x > 0. \end{cases} \tag{3.1}$$

We will consider only the case in which $v_l > v_r$ since this is all we need to construct solutions with the properties described in the theorem. The solution of the Riemann problem then consists of a contact discontinuity of the first family connecting U_l to some state U^-, followed by a 2-shock connecting U^- to some state U^+, followed by a contact discontinuity of the third family connecting U^+ to U_r.

We first parameterize the integral curves of the first and third family by s. These are straight lines and the parameterizations are readily obtained from (2.3). We let $D_j[s; (\bar{u}, \bar{v}, \bar{w})]$ denote the integral curve of the jth field, $j = 1, 3$, through the point $(\bar{u}, \bar{v}, \bar{w})$. Thus the first and third wave curves are given by

$$D_1[s; (\bar{u}, \bar{v}, \bar{w})] = \begin{pmatrix} s + \bar{u} \\ \bar{v} \\ -s(\lambda_0 + a(\bar{v})) + \bar{w} \end{pmatrix} \tag{3.2}$$

and

$$D_3[s; (\bar{u}, \bar{v}, \bar{w})] = \begin{pmatrix} s + \bar{u} \\ \bar{v} \\ s(\lambda_0 - a(\bar{v})) + \bar{w} \end{pmatrix}. \tag{3.3}$$

To find the expression for the 2-shock curve through $(\bar{u}, \bar{v}, \bar{w})$, we use the Rankine–Hugoniot condition. This states that if the solution contains a discontinuity with speed $\bar{\gamma}$, then

$$[F(U)] = \bar{\gamma}[U], \tag{3.4}$$

where $[\cdot]$ denotes the jump across the discontinuity. Let the left and right states be $(\bar{u},\bar{v},\bar{w})$ and (u,v,w), respectively. With the flux given by (2.1) the Rankine–Hugoniot condition takes the form

$$ua(v)+w-\bar{u}a(\bar{v})-\bar{w}=\bar{\gamma}(u-\bar{u}), \tag{3.5}$$

$$\Gamma(v)-\Gamma(\bar{v})=\bar{\gamma}(v-\bar{v}), \tag{3.6}$$

$$u(\lambda_0^2-a^2(v))-wa(v)-\bar{u}(\lambda_0^2-a^2(\bar{v}))+\bar{w}a(\bar{v})=\bar{\gamma}(w-\bar{w}). \tag{3.7}$$

These relations yield three curves. Along two of these v is constant and they coincide with D_1 and D_3. The third is the 2-shock curve for which we use v as a parameter. Given the point $(\bar{u},\bar{v},\bar{w})$, (3.6) gives the speed of the 2-shock,

$$\bar{\gamma}=\frac{\Gamma(v)-\Gamma(\bar{v})}{v-\bar{v}}. \tag{3.8}$$

Substituting this into (3.5) gives w expressed by u and v. Using this and (3.8) in (3.7) then yields u as a function of v. The expressions for u and w are given by

$$u=u(v;(\bar{u},\bar{v},\bar{w}))=\bar{u}+\frac{a(v)-a(\bar{v})}{\lambda_0^2-\bar{\gamma}^2}\Big(\bar{u}(a(\bar{v})-\bar{\gamma})+\bar{w}\Big) \tag{3.9}$$

and

$$w=w(v;(\bar{u},\bar{v},\bar{w}))=\bar{w}+(\bar{\gamma}-a(v))[u(v;(\bar{u},\bar{v},\bar{w}))-\bar{u}]-\bar{u}(a(v)-a(\bar{v})). \tag{3.10}$$

Note that these expressions are linear in $\bar{u}$ and $\bar{w}$.

We next use the solution of the Rankine–Hugoniot equations to derive a criteria to determine when the Riemann problem (U_l,U_r) has a unique solution. Let s_1 and s_3 denote the change in parameter across the 1-wave connecting U_l to U^- and the 3-wave connecting U^+ to U_r, respectively. Then

$$U^-=D_1[s_1;U_l], \tag{3.11}$$

$$U^+=\begin{pmatrix}u(v_r;U^-)\\ v_r\\ w(v_r;U^-)\end{pmatrix}, \tag{3.12}$$

and

$$U_r=D_3[s_3;U^+]. \tag{3.13}$$

This yields three equations, one for the speed of the 2-shock, given by

$$\bar{\gamma}=\frac{\Gamma(v_r)-\Gamma(v_l)}{v_r-v_l}, \tag{3.14}$$

while the other two are *linear* equations for the unknown strengths s_1 and s_3. These equations can be written in the form

$$s_1(\bar{\gamma}+\lambda_0)+s_3(\bar{\gamma}-\lambda_0)=A, \tag{3.15}$$

$$s_1[(\bar{\gamma}-\lambda_0)+(a(v_r)-a(v_l))]+s_3(\bar{\gamma}-\lambda_0)=B, \tag{3.16}$$

where A and B are functions of U_l, U_r. Thus the Riemann problem (U_l,U_r) has a unique solution if and only if

$$\lambda_0\neq\bar{\gamma},\ \text{ and } a(v_r)-a(v_l)-2\lambda_0\neq 0. \tag{3.17}$$

The first condition is always fulfilled by the mean value theorem and assumption (ii) on the flux Γ. In the proof of part (a) and (b) of Theorem 2.1 we will choose λ_0, v_r, v_l, and $a(v)$ such that the second condition is also satisfied at each interaction.

4. Proof of main result. We now construct examples with the properties stated in Theorem 2.1. Fix a $V > 0$ and let the v-component of the states to the left of the left 2-shock be V, let the v-component of the states between the two 2-shocks be 0, and let the v-component of the states to the right of the right 2-shock be $-V$. As noted above, this guarantees that the solution has an interaction pattern as in Figure 1. Also, since each state lies in one of the planes $v \equiv V$, $v \equiv 0$, or $v \equiv -V$, it is clear that the solution is uniformly strictly hyperbolic.

We next consider left interactions in which a 1-wave hits the left 2-shock from the right. Let the states l, m, M, l', and m' be as in Figure 2. Let the strength (i.e., the change in the parameter s) of the incoming 1-wave be S, while the transmitted 1-wave has strength T, and the reflected 3-wave has strength R. The given quantities are u_l, $v_l = v_{l'} = V$, w_l, $v_m = v_M = v_{m'} = 0$, and S, from which we want to compute the strengths T and R. Starting at l and going either via m or via l' and m' yield two expressions for the state M. This gives two linear equations for the strengths T an R. We have

$$M = D_1[S; m] = D_1[S; (u(0; l), 0, w(0; l))] \tag{4.1}$$

and

$$M = D_3[R; m'] = D_3[R; (u(0; l'), 0, w(0; l'))], \tag{4.2}$$

where $l' = D_1[T; l]$. We denote the speed of the left 2-shock by $\bar{\gamma}$, i.e.,

$$\bar{\gamma} = \frac{\Gamma(0) - \Gamma(V)}{-V} = \frac{\Gamma(V)}{V}. \tag{4.3}$$

We solve (4.1), (4.2) for T and R by using the expressions for the wave curves from above. A straightforward calculation yields

$$T = \alpha S, \qquad R = \beta S, \tag{4.4}$$

where the magnification coefficients α and β are given by

$$\alpha = \frac{2\lambda_0}{2\lambda_0 + a(V) - a(0)}, \qquad \beta = \frac{\lambda_0 + \bar{\gamma}}{\lambda_0 - \bar{\gamma}} \left(\frac{a(0) - a(V)}{2\lambda_0 + a(V) - a(0)} \right). \tag{4.5}$$

Note that these coefficients depend only on λ_0, a, and V. Next consider the situation where a 3-wave hits the right 2-wave. Let the states l, M, M', r', and r be as in Figure 3, and let the strength of the incoming 3-wave, the reflected 1-wave, and the transmitted 3-wave be S, R, and T, respectively. The given quantities are now u_l, $v_l = v_M = v_{M'} = 0$, w_l, $v_r = v_{r'} = -V$, and S, from which we want to compute the strengths T and R. Starting at l and going either via M or via M' and r' yield two expressions for the state r. This gives two linear equations for the strengths T and R. We have

$$r = (u(-V; M), -V, w(-V; M)),$$

where $M = D_3[S; l]$. Also

$$r = D_3[T; r'] = D_3[T; (u(-V; M'), -V, w(-V; M'))],$$

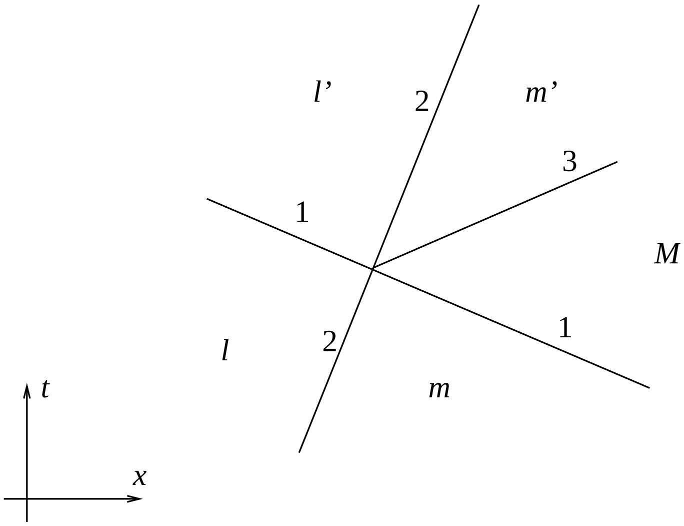

Fig. 2. *Left interaction.*

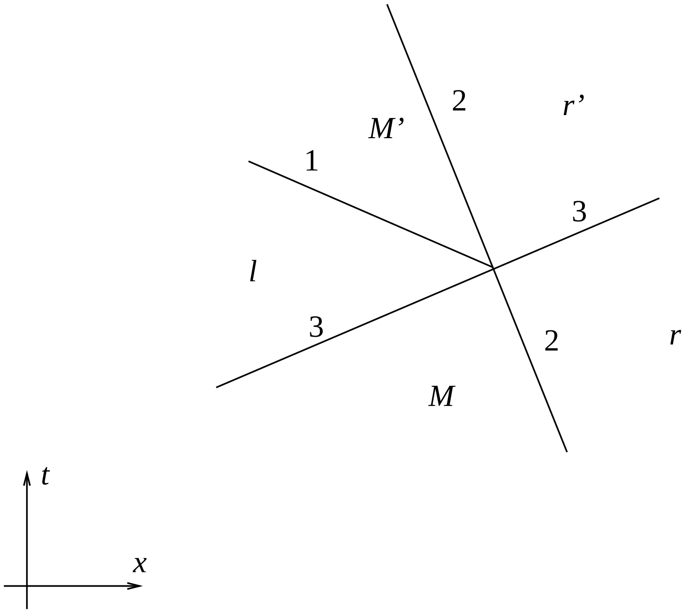

Fig. 3. *Right interaction.*

where $M' = D_1[R; l]$. We denote the speed of the right 2-shock by $\tilde{\gamma}$. By the properties of Γ we have

$$\tilde{\gamma} = \frac{\Gamma(-V) - \Gamma(0)}{-V} = -\frac{\Gamma(V)}{V} = -\bar{\gamma}. \tag{4.6}$$

Using the expressions for the wave curves we have

$$T = \delta S, \qquad R = \varepsilon S, \tag{4.7}$$

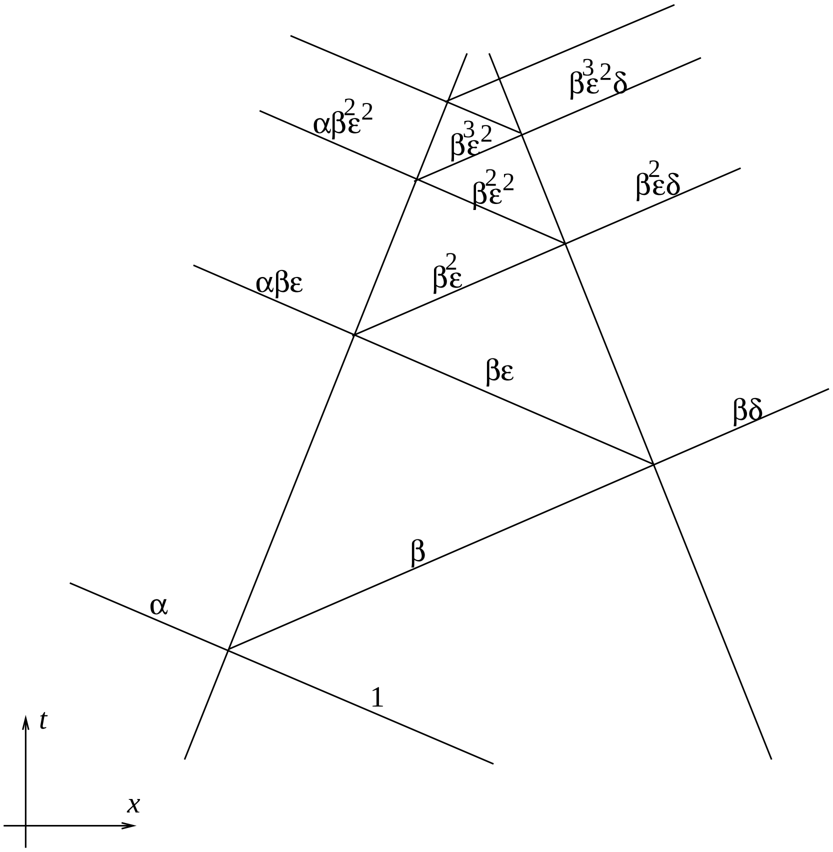

FIG. 4. *Wave strengths when first incoming* 1*-wave has strength* 1.

where the magnification coefficients δ and ε are given by

$$\delta = \frac{2\lambda_0}{2\lambda_0 + a(0) - a(-V)}, \qquad \varepsilon = \frac{\lambda_0 + \bar{\gamma}}{\lambda_0 - \bar{\gamma}} \left(\frac{a(-V) - a(0)}{2\lambda_0 + a(0) - a(-V)} \right). \tag{4.8}$$

As for the left interaction, the coefficients depend only on λ_0, a, and V.

Figure 4 shows the strengths of the various waves assuming that the first incoming 1-wave has strength 1.

We are now ready to choose a, V, and λ_0 so that the solution has the behavior stated in Theorem 2.1. We choose $\lambda_0 = 1$, and we let

$$\Gamma(v) = \frac{2}{\pi} \int_0^v \arctan(\xi)\, d\xi, \tag{4.9}$$

for which the properties (i)–(iii) are satisfied.

To prove part (a) we assume that $a(v) = v$. With this choice we have

$$\alpha = \delta \text{ and } \beta = \varepsilon.$$

Also, since $V > 0$, the criteria (3.17) is fulfilled, so that every Riemann problem occurring can be solved uniquely. We now refer to Figure 4 and observe that if

$|\beta| = |\varepsilon| > 1$, then the strengths of the 1- and 3-waves grow exponentially as a function of the number of interactions. Since there is an infinite number of interactions in finite time, it follows that the sup-norm tends to infinity in finite time provided $|\beta| > 1$. We have

$$|\beta| = \left(\frac{1+\bar{\gamma}}{1-\bar{\gamma}}\right)\left(\frac{V}{2+V}\right).$$

Since

$$\lim_{V\to\infty} \bar{\gamma} = 1,$$

it follows that $|\beta| > 1$ for V large enough. This completes the proof of part (a) of Theorem 2.1. An alternative is to choose V so that $\beta = \varepsilon = -1$. In this case the strengths of the transmitted 1- and 3-waves are constant and the sup-norm increases linearly as a function of the number of interactions taken place.

To prove part (b) we assume that $a(v) = v^2$. The criteria (3.17) is satisfied for the interactions along the left 2-shock, while it is satisfied for the interactions along the right 2-shock if and only if $|V| \neq \sqrt{2}$. Referring to Figures 1 and 4, we observe that

$$\begin{gathered}
l_1 = l_3 = l_5 = \ \cdots\ ,\ l_2 = l_4 = l_6 = \ \cdots\ ,\\
m_1 = m_3 = m_5 = \ \cdots\ ,\ m_2 = m_4 = m_6 = \ \cdots\ ,\\
M_1 = M_3 = M_5 = \ \cdots\ ,\ M_2 = M_4 = M_6 = \ \cdots\ ,\\
r_1 = r_3 = r_5 = \ \cdots\ ,\ r_2 = r_4 = r_6 = \ \cdots
\end{gathered}$$

if and only if the magnification factors β and ε satisfy

$$\beta\varepsilon = -1.$$

Thus, if we can choose $V \neq \sqrt{2}$ such that $\beta\varepsilon = -1$, then the solution is periodic in state space. With $a(v) = v^2$ we have

$$\beta\varepsilon = -\left(\frac{1+\bar{\gamma}}{1-\bar{\gamma}}\right)^2 \frac{V^4}{4-V^4}.$$

With $\Gamma(v)$ as above it is easily established that the equation $\beta\varepsilon = -1$ has a unique positive solution $V = V^*$. Also, $V^* \neq \sqrt{2}$ so that the criteria (3.17) is satisfied. We thus have a solution which is periodic in state space. Since there is an infinite number of interactions in finite time, it follows that the total variation tends to infinity in finite time while the sup-norm remains bounded. This completes the proof of part (b) of Theorem 2.1.

4.1. $\mathbf{L^p}$-norms. Having established the existence of solutions which blow up in either sup-norm or total variation, it is interesting to see whether one can have blowup in sup-norm while all other p-norms ($1 \leq p < \infty$) of $U(\cdot, t)$ remain bounded. Of course, as $U(\cdot, t)$ takes constant nonzero values outside large enough compact intervals, this refers to the p-norms computed over some compact interval. We shall see that this is indeed the case where the sup-norm increases as slowly as possible. This corresponds to the case noted above where the sup-norm increases linearly as a function of the number of collisions, i.e., when $\beta = \varepsilon = -1$. We give initial data such that the solution has an interaction pattern as in Figure 5. That is, at time $t = 0$ a 2-shock and a 3-wave (of strength 1) start at $x = -L$ and another 2-shock starts at $x = +L$. Denote the speeds of the 2-shocks by $\pm\bar{\gamma}$, and let x_n, t_n be the coordinates of the nth interaction. We have

$$x_n = (-1)^{n+1} b^n L, \qquad t_n = \frac{L}{\bar{\gamma}}(1 - b^n), \tag{4.10}$$

where

$$b = \frac{\lambda_0 - \bar{\gamma}}{\lambda_0 + \bar{\gamma}}. \tag{4.11}$$

Referring to Figure 5 and using the expressions for the 1- and 3-wave curves, one checks that the states in this case are given as follows:

$$l_{n+1} = l_1 - \alpha n r_1(+V), \tag{4.12}$$

$$m_{n+1} = m_1 + n[r_3(0) - r_1(0)], \tag{4.13}$$

$$M_{n+1} = M_1 + n[r_3(0) - r_1(0)], \tag{4.14}$$

$$r_{n+1} = r_1 + \alpha n r_3(-V). \tag{4.15}$$

Now let t be a time between t_{2n} and t_{2n+1}. It is readily checked that the part of $\|U(\cdot,t)\|_p^p$ corresponding to the part of the solution between the two 2-shocks is bounded by a term of the form $Cb^n n^p$, while the part of $\|U(\cdot,t)\|_p^p$ corresponding to the solution to the left and right of the two 2-shocks are bounded by sums of the form

$$C \sum_{k=1}^{n} b^{2k} k^p. \tag{4.16}$$

Since $0 < b < 1$, this shows that the p-norms are indeed bounded for all values of $p \in [1, \infty)$. This completes the proof of the theorem.

5. Rescalings and time-periodic solutions.

A standard technique for studying blowup phenomena is to introduce rescaled coordinates. One seeks rescalings of both the independent and dependent variables so that the rescaled solution is nontrivial and more easily described.

Consider the type of blowup described by part (b) of Theorem 2.1. Since the solution in this case is periodic in state space, a natural question is whether one can find a rescaling of the independent variables which yields a *time-periodic* solution to a corresponding 3×3-system of hyperbolic equations. We will briefly describe a suitable rescaling which describes the blowup of case (b) of Theorem 2.1. We will find that the rescaled solution is periodic for large enough times on every compact interval.

Again, we give initial data such that the solution has an interaction pattern as in Figure 5. We denote the blowup time by T, i.e., $T = L/\bar{\gamma}$. Denoting the rescaled time by $\tau = \tau(t)$, we want $\tau(t_{n+1}) - \tau(t_n)$ to be constant and equal to twice the period. The simplest way of obtaining this is to define τ by

$$\tau = -\ln(T - t). \tag{5.1}$$

To have a periodic solution we must rescale the space variable such that the curves corresponding to the 2-shocks are vertical straight lines. Denoting the new space variable by η, we rescale the x-variable as follows:

$$\eta = \frac{x}{T - t}. \tag{5.2}$$

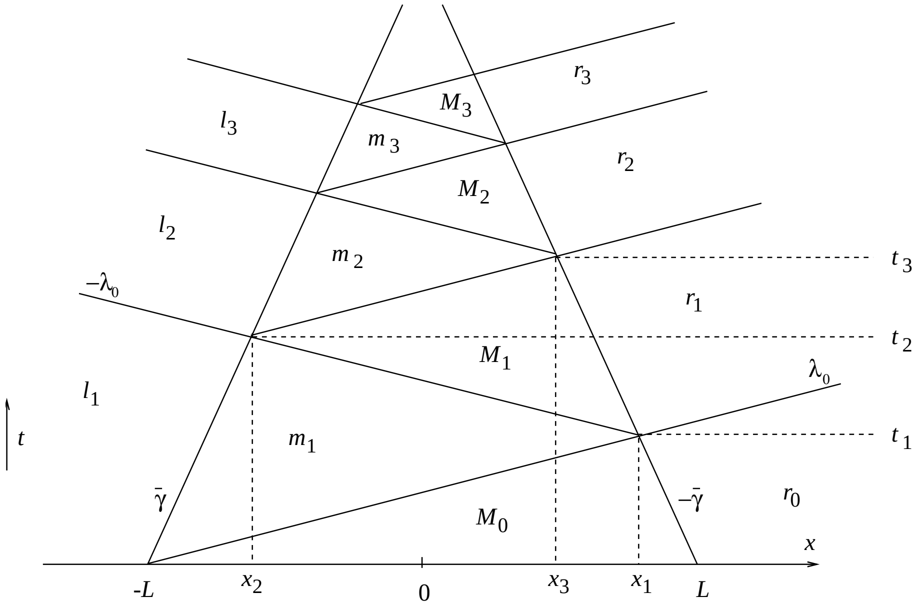

FIG. 5. *Before scaling.*

The straight lines of the 2-shocks are then mapped to the two lines $\eta \equiv \pm L/T = \pm\bar{\gamma}$, while the straight lines of the contact discontinuities are mapped to τ-translates of exponential curves of the form

$$\eta(\tau) = \pm[T(\lambda_0 - \bar{\gamma})e^{\tau} - \lambda_0].$$

The corresponding solution is then τ-periodic with period $-2\ln b$; see Figure 6. Thus the solution of (1.1) for which we have blowup in total variation may alternatively be described as a solution of the rescaled system

$$U_\tau + \eta U_\eta + F(U)_\eta = 0, \tag{5.3}$$

which is such that given any compact interval there is a time after which the solution is time-periodic on this interval.

For the case of blowup in sup-norm one has a similar result. We describe this without going into details. The scaling of the independent variables is again given by (5.1) and (5.2), while the scaling of the dependent variable is different in the two cases $|\beta| > 1$ and $\beta = -1$. The new dependent variables should be

$$\tilde{U} = \frac{U}{(T-t)^\rho}, \qquad \tilde{U} = -\frac{U}{\ln(T-t)},$$

respectively. Here $\rho = \ln\beta^2/\ln b$. The rescaled solution will tend to constant values on the η–intervals $(-\infty, -\bar{\gamma})$ and $(\bar{\gamma}, \infty)$, while it is time-periodic with period $-2\ln b$ on the middle interval $[-\bar{\gamma}, \bar{\gamma}]$.

6. Additional observations. Consider the system (1.1) with flux (2.1) obtained by replacing $\Gamma(v)$ with

$$\Gamma(v,k) = \frac{2}{\pi}\int_0^v \arctan(k\xi)\,d\xi. \tag{6.1}$$

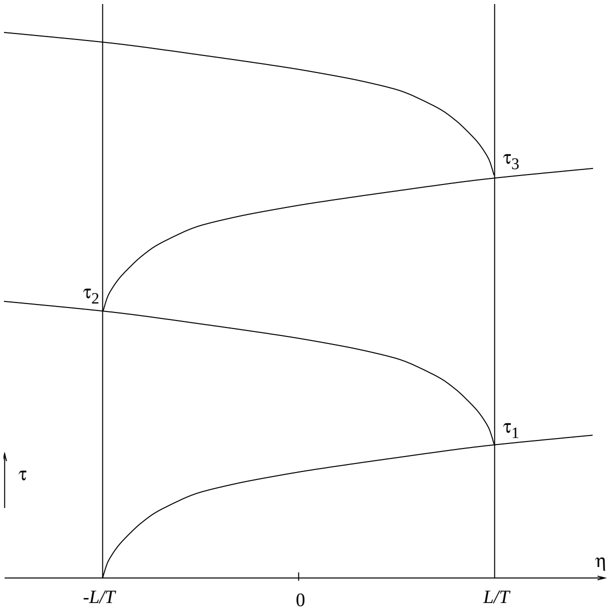

Fig. 6. *After scaling.*

By choosing large values for k it is easy to show that for any $\delta > 0$ one can find a system with initial data U_0 for which either

(i) $\|U_0\|_\infty < \delta$ and the solution of (1.1), (1.2) satisfies the conclusion of part (a) of Theorem 2.1

or

(ii) T.V. $[U_0] < \delta$ and the solution of (1.1), (1.2) satisfies the conclusion of part (b) of Theorem 2.1.

However, if one has an interaction pattern as in Figure 1, then the total variation of the initial data is bounded by $6\|U_0\|_\infty$. It follows by Glimm's result that it is impossible to find a *fixed* system with an interaction pattern as in Figure 1 and with the property that given any $\delta > 0$, there is a U_0 with $\|U_0\|_\infty < \delta$ and such that either of the behaviors in Theorem 2.1 occur.

We observe that the presence of infinitely many interactions in finite time does not necessarily imply that the solution ceases to exist. For example, in the case where $a(v) = v$, if we choose V so that $|\beta| < 1$, then the states to the left of the left 2-shock and the states to the right of the right 2-shock will converge to some states l_∞ and r_∞, respectively. These states then define a new Riemann problem at time $t = T$ at the point where the two 2-shocks meet. Solving this yields a 1-wave with speed $-\lambda_0$, a 3-wave with speed $+\lambda_0$, and a 2-shock with an intermediate speed. All other 1- and 3-waves from earlier interactions are prolonged and do not interact.

We observe that the type of interaction pattern as in Figure 1 is exactly what goes wrong with front-tracking for systems if one does not include a simplified Riemann solver for weak interactions. If one were to try to solve each Riemann problem in an exact manner (by solving for shocks exactly and by approximating rarefaction waves with many small shocks), then the examples above show that one may end up with infinitely many fronts in finite time. See [3, 5] for the definition of simplified Riemann solvers.

The systems considered above are quite artificial. First of all it would be interesting to obtain similar results for systems where all fields are genuinely nonlinear. In this case there are additional problems due to the possible interaction of transmitted 1- or 3-waves. The waves created in these interactions could interact with the 2-waves before infinitely many fronts have been created, and the analysis would be more complicated. Another basic problem is to understand the role played by entropies. Apart from the fact that the existence of a (strictly) convex entropy precludes blowup in L^2, very little seems to be known.

Also note that the systems we consider are in some sense opposite to the most interesting physical example of gas dynamics. For the Euler equations, the first and third fields are genuinely nonlinear while the second field is linearly degenerate. In this case, for initial data with large total variation and correspondingly small sup-norm, the results of Temple and Young [31, 32] show that one cannot have more than exponential growth in total variation. The problem of whether blowup in sup-norm is possible for gas dynamics when the data have large sup-norm remains open.

Acknowledgments. I thank A. Bressan for suggesting this problem. I am indebted to B. Piccoli, C. Dafermos, H. Holden, C. Cheverry, and G.-Q. Chen for enlightening discussions. This work was completed at the Mittag-Leffler Institute, and I thank director K. O. Widman and his staff for providing excellent working conditions.

ON THE MULTIPLICITY OF SOLUTIONS OF TWO NONLOCAL VARIATIONAL PROBLEMS[*]

XIAOFENG REN[†] AND JUNCHENG WEI[‡]

Abstract. We study two nonlocal variational problems in this paper. One models microphase separation of diblock copolymers and the other models solid-solid phase transformations that lead to fine structures. We study a parameter range where the problems can be approximated by their asymptotic limits. We find all the local minimum solutions of the limiting problems. Because these local minima are isolated, and hence stable under perturbation, near them there exist local minimum solutions of the original problems.

Key words. nonlocal variational problems, Γ-convergence, isolated local minima, *BV* functions

AMS subject classifications. 49K15, 49K20, 34D15

PII. S0036141098348176

1. Introduction.

Two nonlocal variational problems are studied in this paper. The first one is

$$\mathcal{I}_\epsilon(u) = \begin{cases} \displaystyle\int_\Omega \left\{ \frac{\epsilon}{2}|\nabla u|^2 + \frac{1}{\epsilon}W(u) + \frac{1}{2}|(-\gamma^2\Delta)^{-1/2}(u-m)|^2 \right\} dx, \\ \qquad\qquad\qquad\qquad\qquad\qquad \text{if } u \in \mathcal{A}_m \cap W^{1,2}(\Omega), \\ \infty \qquad\qquad\qquad\qquad\qquad\qquad \text{if } u \in \mathcal{A}_m \backslash W^{1,2}(\Omega). \end{cases} \tag{1.1}$$

Ω is a bounded and smooth domain in R^d. ϵ and γ are both positive numbers. ϵ is small and γ is fixed.

W is a balanced double-well function with two global minima at -1 and 1, i.e., $W(t) \geq 0$ and $W(t) = 0$ if and only if $t = -1$ or 1. We also assume that W is continuous and there exist $k \geq 2$, $K_1 > 0$, $K_2 > 0$, and $\bar{t} > 1$ such that for all t, $|t| > \bar{t}$,

$$K_1|t|^k \leq W(t) \leq K_2|t|^k. \tag{1.2}$$

$-\gamma^2\Delta$ is the Laplacian operator, multiplied by the constant $-\gamma^2$, with the Neumann boundary condition. The outward normal vector field of $\partial\Omega$ is denoted by n. It is known that the operator

$$-\gamma^2\Delta : \left\{ u \in W^{2,2}(\Omega) : \int_\Omega u = 0, \ \frac{\partial u}{\partial n}|_{\partial\Omega} = 0 \right\} \to \left\{ u \in L^2(\Omega) : \int_\Omega u = 0 \right\}$$

is an isomorphism. The inverse of $-\gamma^2\Delta$ is self-adjoint and positive. We denote its positive square root by $(-\gamma^2\Delta)^{-1/2}$. This is a nonlocal operator.

The admissible set of $\mathcal{I}_\epsilon$ is

$$\mathcal{A}_m = \left\{ u \in L^2(\Omega) : \frac{1}{|\Omega|}\int_\Omega u\, dx = m \right\} \tag{1.3}$$

with the restriction $m \in (-1,1)$. For a measurable set Ω in R^d, $|\Omega|$ denotes its Lebesgue measure. In $\mathcal{A}_m$ we use the metric so that the distance between u and v is $\|u-v\|_2$, the $L^2(\Omega)$-norm of $u-v$. The choice of $L^2(\Omega)$ (as opposed to the choice of $L^1(\Omega)$ in the literature of Γ-convergence) is natural because of the nonlocal part, $(-\gamma^2\Delta)^{-1/2}$, of the functional.

In the study of diblock copolymers, a model was introduced in Ohta and Kawasaki [11] and Bahiana and Oono [1]. It asserts that the free energy of a diblock copolymer takes the form

$$\begin{aligned}&\mathcal{F}_{\epsilon,\sigma}(u) = \int_\Omega \left\{ \frac{\epsilon^2}{2}|\nabla u|^2 + W(u) + \frac{\sigma}{2}|(-\Delta)^{-1/2}(u-m)|^2 \right\} dx,\\ &\frac{1}{|\Omega|}\int_\Omega u\, dx = m.\end{aligned}$$

In a diblock copolymer, a linear-chain molecule consists of two subchains grafted covalently to each other. The subchains are made of two different monomer units, represented by $u=-1$ and $u=1$, respectively. The different subchains tend to segregate below some critical temperature, but as they are chemically bonded, only local microphase separation occurs. The connectivity of the two monomer units leads to the long range interaction term $\frac{\sigma}{2}|(-\Delta)^{-1/2}(u-m)|^2$ in the free energy. The parameter σ is proportional to the inverse of the square root of the total chain length of the copolymer. $\frac{\epsilon^2}{2}|\nabla u|^2$ represents the interfacial energy density at bonding points. The parameter ϵ is proportional to the thickness of interfaces between the two monomers. The double-well potential W prefers segregated monomers to a mixture. m stands for the mass ratio of the two monomer units. When this free energy is being minimized, the first term prefers large blocks of monomers, therefore reducing the combined size of interfaces between the two monomers. The third term, on the other hand, likes rapid oscillation between the two monomers. These two tendencies are competing. The process of reaching a stable configuration is known as microseparation. The results of our paper show that in a parameter range, namely $0 < \epsilon \approx \sigma \ll 1$, the monomer components in the copolymer develop blocks of a finite scale. For more references on the mathematical aspects of diblock copolymers we refer the reader to Nishiura and Ohnishi [10], where a different parameter range, $0 < \epsilon \ll \sigma \ll 1$, is studied. The functional studied in Müller [9] can also be written in the form of this model with $m=0$. There the parameter range is $0 < \epsilon \ll \sigma \approx 1$.

The second problem is

$$\mathcal{J}_\epsilon(u) = \begin{cases} \displaystyle\int_\Omega \left\{ \frac{\epsilon}{2}|\nabla u|^2 + \frac{1}{\epsilon}W(u) - \frac{1}{2}u^2 + \frac{1}{2}|(-\gamma^2\Delta+1)^{-1/2}u|^2 \right\} dx, & \\ \qquad\qquad\qquad\qquad\qquad\qquad \text{if } u \in \mathcal{A}_m \cap W^{1,2}(\Omega), & \\ \infty \qquad\qquad\qquad\qquad\qquad\qquad \text{if } u \in \mathcal{A}_m \backslash W^{1,2}(\Omega) & \end{cases} \tag{1.4}$$

in the same admissible set $\mathcal{A}_m$, (1.3). W satisfies the same conditions as in $\mathcal{I}_\epsilon$. The operator

$$-\gamma^2\Delta + 1 : \ \left\{ u \in W^{2,2}(\Omega) : \frac{\partial u}{\partial n}|_{\partial\Omega} = 0 \right\} \to L^2(\Omega)$$

is an isomorphism. Again we denote the positive square root of the inverse of $-\gamma^2\Delta+1$ by $(-\gamma^2\Delta+1)^{-1/2}$.

In studying solid-solid phase transformations, Ren and Truskinovsky proposed in [12] a model of 1-dimensional elastic bars that develop a mixture of two phase variants. Let u be the strain field of a deformed elastic bar. The stored energy is

$$\mathcal{F}_\epsilon(u) = \int_0^1 \left\{ \frac{\epsilon^2}{2}|\nabla u|^2 + W(u) - \frac{\epsilon}{2}u^2 + \frac{\epsilon}{2}|(-\gamma^2\Delta + 1)^{-1/2}u|^2 \right\} dx,$$

$$\int_0^1 u\,dx = m,$$

where m is the total displacement of the bar. $W(u)$ is the local part of the energy density. It is assumed to be nonconvex. It prefers the two phase variants, $u = -1$ and $u = 1$. $\frac{\epsilon^2}{2}|\nabla u|^2$ is the short range self-interaction of the strain field and $-\frac{\epsilon}{2}u^2 + \frac{\epsilon}{2}[(-\gamma^2\Delta + 1)^{-1/2}u]^2$ is the long range self-interaction. Similar to the copolymer model, these two competing factors lead to a mixture of the two phase variants. The result of this paper again shows the characteristic scale of each phase in the mixture.

When we study $\mathcal{I}_\epsilon$ and $\mathcal{J}_\epsilon$, we will show that as ϵ tends to 0, $\mathcal{I}_\epsilon$ and $\mathcal{J}_\epsilon$ both converge to their limiting problems, defined in (2.1) and (4.1). The convergence falls in the general theory of Γ-limits.

Then we will study the 1-dimensional cases, $\Omega = (0,1)$, of $\mathcal{I}_\epsilon$ and $\mathcal{J}_\epsilon$. We find all local minima of the limiting problems. It turns out that these local minima of the limiting problems are isolated, and near them there are local minima of $\mathcal{I}_\epsilon$ and $\mathcal{J}_\epsilon$ if ϵ is sufficiently small.

For each positive integer ν, we set

$$x_1 = \frac{1-m}{2\nu},\ x_2 = x_1 + \frac{1+m}{\nu},\ x_3 = x_2 + \frac{1-m}{\nu}, \dots,\ x_\nu = x_{\nu-1} + \frac{1+(-1)^\nu m}{\nu}.$$

We also set $x_0 = 0$ and $x_{\nu+1} = 1$. We define a step function $U_{\nu,1} \in \mathcal{A}_m$ so that

$$U_{\nu,1}(x) = (-1)^i \text{ if } x \in (x_{i-1}, x_i),\ i = 1, 2, \dots, \nu+1. \tag{1.5}$$

In a similar way for each positive integer ν, we set

$$z_1 = \frac{1+m}{2\nu},\ z_2 = z_1 + \frac{1-m}{\nu},\ z_3 = z_2 + \frac{1+m}{\nu}, \dots,\ z_\nu = z_{\nu-1} + \frac{1-(-1)^\nu m}{\nu}.$$

We also set $z_0 = 0$ and $z_{\nu+1} = 1$. We define $U_{\nu,2} \in \mathcal{A}_m$ so that

$$U_{\nu,2}(x) = (-1)^{(i-1)} \text{ if } x \in (z_{i-1}, z_i),\ i = 1, 2, \dots, \nu+1. \tag{1.6}$$

We denote an open ball in $\mathcal{A}_m$ centered at u of radius δ by $B_\delta(u)$, i.e., $B_\delta(u) = \{v \in \mathcal{A}_m : \|v - u\|_2 < \delta\}$.

Our main result of the paper is the following theorem.

THEOREM 1.1. *Let $\Omega = (0,1)$. For each positive integer N we can find $\delta > 0$ such that*

(1) *$\{B_\delta(U_{\nu,1}), B_\delta(U_{\nu,2}) : \nu = 1, 2, \dots, N\}$ is a family of $2N$ mutually disjoint open balls in $\mathcal{A}_m$;*

(2) *there exists $\epsilon_0 > 0$ such that for all $\epsilon < \epsilon_0$, every ν, $\nu = 1, 2, \dots, N$, there exist a local minimum $u_{\epsilon,\nu,1}$ of $\mathcal{I}_\epsilon$ (or $\mathcal{J}_\epsilon$) in $B_\delta(U_{\nu,1})$ and a local minimum $u_{\epsilon,\nu,2}$ in $B_\delta(U_{\nu,2})$ satisfying $\lim_{\epsilon\to 0} \|u_{\epsilon,\nu,1} - U_{\nu,1}\|_2 = 0$ and $\lim_{\epsilon\to 0} \|u_{\epsilon,\nu,2} - U_{\nu,2}\|_2 = 0$.*

Our second result describes the global minima of $\mathcal{I}_\epsilon$ and $\mathcal{J}_\epsilon$.

THEOREM 1.2. *Let $\Omega = (0,1)$ and u_ϵ be a global minimum of $\mathcal{I}_\epsilon$ (or $\mathcal{J}_\epsilon$). There exists a countable set $\mathcal{C} \subset R$ with the following properties.*

(1) *If* $\frac{(1-m^2)^2}{24\gamma^2 c_0} \notin \mathcal{C}$, *there exists a positive integer* ν_* *so that for every* $\delta > 0$ *there is* ϵ_0 *so that if* $\epsilon < \epsilon_0$, u_ϵ *is in the open ball* $B_\delta(U_{\nu_*,1})$ *or* $B_\delta(U_{\nu_*,2})$.

(2) *If* $\frac{(1-m^2)^2}{24\gamma^2 c_0} \in \mathcal{C}$, *there exists a positive integer* ν_* *so that for every* $\delta > 0$ *there is* ϵ_0 *so that if* $\epsilon < \epsilon_0$, u_ϵ *is in one of the following four open balls:* $B_\delta(U_{\nu_*,1})$, $B_\delta(U_{\nu_*,2})$, $B_\delta(U_{\nu_*+1,1})$, *or* $B_\delta(U_{\nu_*+1,2})$.

c_0 *is given in* (2.2), *and* $\mathcal{C}$ *and* ν_* *are defined near the end of section* 3.

If we take N in Theorem 1.1 to be greater than ν_* in Theorem 1.2 and δ in Theorem 1.2 to be the same as the δ in Theorem 1.1, then every global minimum u_ϵ for small ϵ is a local minimum shown to exist in Theorem 1.1.

In the proof of Theorem 1.2 the reader will see that if the functional is $\mathcal{I}_\epsilon$, $|\nu_* - \max\{1, (\frac{(1-m^2)^2}{12\gamma^2 c_0})^{1/3}\}| < 1$. The estimate of ν_* is weaker in the case of $\mathcal{J}_\epsilon$. There ν_* is close to $(\frac{(1-m^2)^2}{12\gamma^2 c_0})^{1/3}$ only if c_0 is small.

If $W \in C^1(R)$, the local minima $u_{\epsilon,\nu,1}$, $u_{\epsilon,\nu,2}$, and the global minimum u_ϵ of $\mathcal{I}_\epsilon$, together with a v and a λ, solve the Euler equation of $\mathcal{I}_\epsilon$:

$$\begin{aligned}
&-\epsilon\Delta u + \frac{1}{\epsilon}W'(u) + v = \lambda, \ x \in \Omega,\\
&-\gamma^2\Delta v = u - m, \ x \in \Omega,\\
&\frac{\partial u}{\partial n}|_{\partial\Omega} = 0, \ \ \frac{\partial v}{\partial n}|_{\partial\Omega} = 0,\\
&\frac{1}{|\Omega|}\int_\Omega u\,dx = m, \ \frac{1}{|\Omega|}\int_\Omega v\,dx = 0.
\end{aligned}$$

For $\mathcal{J}_\epsilon$ the Euler equation is

$$\begin{aligned}
&-\epsilon\Delta u + \frac{1}{\epsilon}W'(u) - u + v = \lambda, \ x \in \Omega,\\
&-\gamma^2\Delta v + v = u, \ x \in \Omega,\\
&\frac{\partial u}{\partial n}|_{\partial\Omega} = 0, \ \frac{\partial v}{\partial n}|_{\partial\Omega} = 0,\\
&\frac{1}{|\Omega|}\int_\Omega u\,dx = m.
\end{aligned}$$

We point out that there is a large literature on the local variational problem, $\mathcal{I}_\epsilon$ without $\frac{1}{2}|(-\gamma^2\Delta)^{-1/2}(u-m)|^2$ term, and its Γ-limit. We refer to Modica [7] for the Γ-limit and Kohn and Sternberg [6] for local minimum solutions. We also refer the reader to Dal Maso [3] for the general Γ-convergence theory.

The presence of the nonlocal terms, $\frac{1}{2}|(-\gamma^2\Delta)^{-1/2}(u-m)|^2$ in $\mathcal{I}_\epsilon$ and $\frac{1}{2}|(-\gamma^2\Delta + 1)^{-1/2}u|^2$ in $\mathcal{J}_\epsilon$, gives us local minima with arbitrarily many transitional layers. This contrasts sharply with the local problem, where, according to a result of Carr, Gurtin, and Slemrod [2], every local minimum must be monotone.

We will only present the complete proof of Theorems 1.1 and 1.2 for $\mathcal{I}_\epsilon$. In section 2 we identify the limiting problem of $\mathcal{I}_\epsilon$ and show that the existence of isolated local minima of the limiting problem implies the existence of local minima of $\mathcal{I}_\epsilon$. Then in section 3 we prove that the limiting problem admits many isolated local minima, hence proving Theorem 1.1. Theorem 1.2 is also proved in that section. The study of J_ϵ is quite similar to that of $\mathcal{I}_\epsilon$. We list the modifications one needs in order to obtain the theorems for $\mathcal{J}_\epsilon$ in section 4.

2. The Γ-limit of $\mathcal{I}_\epsilon$. Associated with $\mathcal{I}_\epsilon$ is the variational problem

$$\mathcal{I}_0(u) = \begin{cases} \dfrac{c_0}{2}\|Du\|(\Omega) + \displaystyle\int_\Omega \frac{1}{2}|(-\gamma^2\Delta)^{-1/2}(u-m)|^2\,dx, \\ \qquad\qquad\qquad\qquad\qquad \text{if } u \in \mathcal{A}_m \cap BV(\Omega,\{-1,1\}), \\ \infty \qquad\qquad\qquad\qquad\quad \text{if } u \in \mathcal{A}_m \backslash BV(\Omega,\{-1,1\}) \end{cases} \tag{2.1}$$

for $u \in \mathcal{A}_m$. Here

$$c_0 = \sqrt{2}\int_{-1}^{1}(W(s))^{1/2}ds. \tag{2.2}$$

$BV(\Omega,\{-1,1\}) = \{u \in BV(\Omega) : u(x) = -1 \text{ or } 1 \text{ for almost everywhere (a.e.) } x \in \Omega\}$. $BV(\Omega)$ is the space of functions of bounded variation. We refer the reader to [4, Chap. 5, pp. 166–226] for its properties. $\|Du\|$ is the absolute value of the distributional derivative Du of u, regarded as a finite nonnegative measure on Ω. $\|Du\|(\Omega)$ is the size of Ω under this measure.

Proposition 2.1.

(1) *For every family* $\{u_\epsilon\} \subset \mathcal{A}_m$ *with* $\lim_{\epsilon\to 0} u_\epsilon = u$,

$$\liminf_{\epsilon\to 0}\mathcal{I}_\epsilon(u_\epsilon) \geq \mathcal{I}_0(u).$$

(2) *For every* $u \in \mathcal{A}_m \cap BV(\Omega,\{-1,1\})$, *there exists a family* $\{u_\epsilon\} \subset \mathcal{A}_m$ *such that* $\lim_{\epsilon\to 0} u_\epsilon = u$, *and*

$$\limsup_{\epsilon\to 0}\mathcal{I}_\epsilon(u_\epsilon) \leq \mathcal{I}_0(u).$$

Proof. We define three functionals on $\mathcal{A}_m$:

$$\mathcal{H}_\epsilon(u) = \begin{cases} \displaystyle\int_\Omega \left\{\frac{\epsilon}{2}|\nabla u|^2 + \frac{1}{\epsilon}W(u)\right\}dx & \text{if } u \in \mathcal{A}_m \cap W^{1,2}(\Omega), \\ \infty & \text{if } u \in \mathcal{A}_m \backslash W^{1,2}(\Omega), \end{cases} \tag{2.3}$$

$$\mathcal{H}_0(u) = \begin{cases} \dfrac{c_0}{2}\|Du\|(\Omega) & \text{if } u \in \mathcal{A}_m \cap BV(\Omega,\{-1,1\}), \\ \infty & \text{if } u \in \mathcal{A}_m \backslash BV(\Omega,\{-1,1\}), \end{cases} \tag{2.4}$$

and

$$\mathcal{K}(u) = \int_\Omega \frac{1}{2}[(-\gamma^2\Delta)^{-1/2}(u-m)]^2\,dx, \quad u \in \mathcal{A}_m. \tag{2.5}$$

Then $\mathcal{I}_\epsilon = \mathcal{H}_\epsilon + \mathcal{K}$ and $\mathcal{I}_0 = \mathcal{H}_0 + \mathcal{K}$. After making some minor modifications (change $L^1(\Omega)$ to $L^2(\Omega)$) in the proof of Propositions 1 and 2 in Modica [7], we find (1) for every family $\{u_\epsilon\} \subset \mathcal{A}_m$ with $\lim_{\epsilon\to 0} u_\epsilon = u$,

$$\liminf_{\epsilon\to 0}\mathcal{H}_\epsilon(u_\epsilon) \geq \mathcal{H}_0(u);$$

(2) for every $u \in \mathcal{A}_m \cap BV(\Omega,\{-1,1\})$, there exists a family $\{u_\epsilon\} \subset \mathcal{A}_m$ such that $\lim_{\epsilon\to 0} u_\epsilon = u$, and

$$\limsup_{\epsilon\to 0}\mathcal{H}_\epsilon(u_\epsilon) \leq \mathcal{H}_0(u).$$

Then we note that $\mathcal{K} : \mathcal{A}_m \to R$ is a continuous functional. Hence the two statements about $\mathcal{H}_\epsilon$ and $\mathcal{H}_0$ are carried over to $\mathcal{I}_\epsilon$ and $\mathcal{I}_0$. □

The notion of Γ-convergence is indeed defined by the two properties of Proposition 2.1. So $\mathcal{I}_\epsilon$ Γ-converges to $\mathcal{I}_0$.

Throughout the rest of this paper we assume $\Omega = (0,1)$.

PROPOSITION 2.2. *Let ϵ_n be a sequence of positive numbers converging to* 0*, and let $\{u_n\}$ be a sequence in $\mathcal{A}_m$. If $\mathcal{I}_{\epsilon_n}(u_n)$ is bounded above in n, then $\{u_n\}$ is relatively compact in $\mathcal{A}_m$ and its cluster points belong to $BV((0,1),\{-1,1\})$.*

Proof. We set

$$\phi(t) = \int_{-1}^{t} W^{1/2}(s)ds. \tag{2.6}$$

Then (1.2) implies

$$|\phi(t)| \le C + C|t|^{\frac{k}{2}+1}.$$

Set $v_n = \phi(u_n)$. As shown in Modica and Mortola [8], v_n is bounded in $W^{1,1}(0,1)$. For by (1.2) and $k \ge 2$, we find

$$|v_n| \le C + C|u_n|^{\frac{k}{2}+1} \le C + CW(u_n).$$

Therefore $\{v_n\}$ is bounded in $L^1(0,1)$. On the other hand,

$$\int_0^1 |v_n'|\, dx = \int_0^1 W^{1/2}(u_n)|u_n'|\, dx$$

$$\le \frac{\sqrt{2}}{2}\left(\int_0^1 \left[\frac{\epsilon_n}{2}|u_n'|^2 + \frac{1}{\epsilon_n}W(u_n)\right] dx\right) \le \frac{\sqrt{2}}{2}\mathcal{I}_{\epsilon_n}(u_n).$$

Therefore $\{v_n\}$ is bounded in $W^{1,1}(0,1)$. The Sobolev imbedding theorem asserts that $\{v_n\}$ is relatively compact in $L^p(0,1)$ for all $1 \le p < \infty$.

Now consider $u_n = \phi^{-1}(v_n)$. (1.2) and (2.6) imply that ϕ^{-1} is continuous and increasing, and there exists $\bar{t} > 0$ such that ϕ^{-1} is Lipschitz continuous for $|t| \ge \bar{t}$. We can find C such that for all t

$$|\phi^{-1}(t)| \le C + C|t|, \ |\phi^{-1}(t)|^p \le C + C|t|^p. \tag{2.7}$$

To prove that $\{u_n\}$ is relatively compact we show that every subsequence of $\{u_n\}$ has an L^2-convergent further subsequence. Let us recall Vitali's convergence theorem [5, p. 203].

Vitali's convergence theorem. *Let $\{f_n\}$ be a sequence in $L^p(\Omega,\mu)$, $1 \le p < \infty$, and f be an μ-measurable function such that $f_n \to f$ μ-a.e.. Then $f \in L^p(\Omega,\mu)$ and $\|f_n - f\|_p \to 0$ if and only if*

1. *for each $\varepsilon > 0$, there exists a μ-measurable set $A_\varepsilon \subset \Omega$ such that $\mu(A_\varepsilon) < \infty$ and $\int_{\Omega\setminus A_\varepsilon} |f_n|^p\, d\mu < \varepsilon$ for all n; and*
2. *for each $\varepsilon > 0$, there is $\delta > 0$ such that for every μ measurable set E, $\mu(E) < \delta$ implies $\int_E |f_n|^p\, d\mu < \varepsilon$ for all n.*

Part 1 of Vitali's convergence theorem is not needed here because $(0,1)$ itself has finite Lebesgue measure. Let $\{u_{n_l}\}$ be a subsequence of $\{u_n\}$. Then there are a subsequence of $\{v_{n_l} = \phi(u_{n_l})\}$, denoted by $\{v_{n_{l_m}}\}$, and $v \in L^p(0,1)$ such that $v_{n_{l_m}} \to v$ in $L^p(0,1)$ and $v_{n_{l_m}} \to v$ a.e. Then $u_{n_{l_m}} \to \phi^{-1}(v)$ a.e. Applying Vitali's convergence theorem to $v_{n_{l_m}}$, we find that for every $\varepsilon > 0$ there is $\delta > 0$ such that for every measurable set E, $|E| < \delta$ implies $\int_E |v_{n_{l_m}}|^p \, dx < \varepsilon$ for all n. Then (2.7) implies

$$\int_E |u_{n_{l_m}}|^p \, dx \le \int_E (C + C|v_{n_{l_m}}|^p) \, dx < C\delta + C\varepsilon.$$

Now Vitali's convergence theorem applied to $\{u_{n_{l_m}}\}$ asserts that $u_{n_{l_m}} \to \phi^{-1}(v)$ in $L^p(0,1)$, particularly in $L^2(0,1)$.

Let u be a cluster point of $\{u_n\}$, i.e., there exists a subsequence $\{u_{n_l}\}$ such that $u_{n_l} \to u$ in $L^2(0,1)$ as $l \to \infty$. Fatou's lemma and the boundedness of $\mathcal{I}_{\epsilon_n}(u_n)$ imply that

$$0 \le \int_0^1 W(u) \le \lim_{l\to\infty} \int_0^1 W(u_{n_l}) \, dx \le \lim_{l\to\infty} \epsilon_{n_l} \mathcal{I}_{\epsilon_{n_l}}(u_{n_l}) = 0.$$

Then for a.e. $x \in (0,1)$, $u(x) = -1$ or 1. If we consider $v_{n_l} = \phi(u_{n_l})$, then the boundedness of $\{v_{n_l}\}$ in $W^{1,1}(0,1)$, proved earlier, implies that $\phi(u)$, the L^1-limit of $\{v_{n_l}\}$, is a BV function [4, Thm. 1, p. 172]. $\phi(u)$ only takes two values, $\phi(-1)$ and $\phi(1)$. Then $\phi(u) = \phi(-1) + \frac{\phi(1)-\phi(-1)}{2}(u+1)$. Hence u is also a BV function. $\square$

A useful property following Propositions 2.1 and 2.2 is that isolated local minima of the Γ-limit persist under small perturbation. It was used in Kohn and Sternberg [6], (see also Dal Maso [3]). We include this property and its proof below for completeness.

PROPOSITION 2.3. *Let $\delta > 0$ and $u_0 \in \mathcal{A}_m$ be such that $\mathcal{I}_0(u_0) < \mathcal{I}_0(u)$ for all $u \in B_\delta(u_0)$ with $u \ne u_0$. Then there exists $\epsilon_0 > 0$ such that for all $\epsilon < \epsilon_0$ there exists $u_\epsilon \in B_{\delta/2}(u_0)$ with $\mathcal{I}_\epsilon(u_\epsilon) \le \mathcal{I}_\epsilon(u)$ for all $u \in B_{\delta/2}(u_0)$. In addition* $\lim_{\epsilon\to 0} \|u_\epsilon - u_0\|_2 = 0$.

Proof. Let $u_{\epsilon,n}$ be a sequence in $B_{\delta/2}(u_0)$ so that

$$\lim_{n\to\infty} \mathcal{I}_\epsilon(u_{\epsilon,n}) = \inf_{u\in B_{\delta/2}(u_0)} \mathcal{I}_\epsilon(u).$$

The standard argument shows that after passing to a subsequence, again denoted by $u_{\epsilon,n}$, there exists $u_\epsilon \in \overline{B}_{\delta/2}(u_0)$ such that $u_{\epsilon,n} \to u_\epsilon$ in $L^2(0,1)$, $u_{\epsilon,n} \to u_\epsilon$ weakly in $W^{1,2}(0,1)$, and

$$\mathcal{I}_\epsilon(u_\epsilon) = \lim_{n\to\infty} \mathcal{I}_\epsilon(u_{\epsilon,n}) = \inf_{u\in B_{\delta/2}(u_0)} \mathcal{I}_\epsilon(u).$$

Next we claim $u_\epsilon \in B_{\delta/2}(u_0)$ if ϵ is small enough. Otherwise there exists a sequence $\epsilon_l \to 0$, such that $\|u_{\epsilon_l} - u_0\|_2 = \delta/2$ and

$$\mathcal{I}_{\epsilon_l}(u_{\epsilon_l}) = \inf_{u\in B_{\delta/2}(u_0)} \mathcal{I}_{\epsilon_l}(u).$$

Part 2 of Proposition 2.1 asserts that there exists a sequence v_{ϵ_l} in $B_{\delta/2}(u_0)$, if l is large enough, such that

$$\limsup_{l\to\infty} \mathcal{I}_{\epsilon_l}(v_{\epsilon_l}) \le \mathcal{I}_0(u_0).$$

Therefore,

$$\limsup_{l\to\infty} \mathcal{I}_{\epsilon_l}(u_{\epsilon_l}) \le \limsup_{l\to\infty} \mathcal{I}_{\epsilon_l}(v_{\epsilon_l}) \le \mathcal{I}_0(u_0).$$

Proposition 2.2 then asserts that, after passing to a subsequence, again denoted by u_{ϵ_l}, there exists $\overline{u}_0$ such that $u_{\epsilon_l} \to \overline{u}_0$ in $L^2(0,1)$, and $\|\overline{u}_0 - u_0\|_2 = \delta/2$. Part 1 of Proposition 2.1 now implies

$$\mathcal{I}_0(\overline{u}_0) \le \liminf_{l\to\infty} \mathcal{I}_{\epsilon_l}(u_{\epsilon_l}) \le \mathcal{I}_0(u_0).$$

This contradicts the condition that $\mathcal{I}_0(u_0) < \mathcal{I}_0(u)$ for all $u \in B_\delta(u_0)$ with $u \ne u_0$. Therefore u_ϵ is in the open ball $B_{\delta/2}(u_0)$, i.e., u_ϵ is a local minimum.

To show $u_\epsilon \to u_0$ in $L^2(0,1)$ as $\epsilon \to 0$, we assume that there exists a sequence $\epsilon_l \to 0$ such that $\|u_{\epsilon_l} - u_0\|_2 = \delta_0 < \delta/2$. Then arguing like above, we have $\widetilde{u}_0$ such that, after passing to a subsequence, again denoted by u_{ϵ_l}, $u_{\epsilon_l} \to \widetilde{u}_0$ and $\|\widetilde{u}_0 - u_0\|_2 = \delta_0$. Then by part 1 of Proposition 2.1,

$$\mathcal{I}_0(\widetilde{u}_0) \le \liminf_{l\to\infty} \mathcal{I}_{\epsilon_l}(u_{\epsilon_l}) \le \mathcal{I}_0(u_0),$$

which is again a contradiction. □

3. The local minima of $\mathcal{I}_0$.

A function u in $BV((0,1),\{-1,1\})$, up to a set of Lebesgue measure 0, is a step function. $u(x)$ switches between -1 and 1 at finitely many points $x_1, x_2, \dots, x_\nu$, with $0 < x_1 < x_2 < \cdots < x_\nu < 0$. A formal description is as follows.

For $u \in BV((0,1),\{-1,1\})$ we define set $E_u = \{x \in (0,1) : u(x) = -1\}$. The perimeter of E_u in $(0,1)$ is $\|D\chi_{E_u}\|(0,1)$, where χ_{E_u} is the characteristic function of E_u. The measure $\|D\chi_{E_u}\|$ is often written as $\|\partial E_u\|$. Clearly $\|\partial E_u\| = \frac{\|Du\|}{2}$.

The reduced boundary of E_u, a subset of $(0,1)$, is denoted by $\partial^* E_u$ (see [4, section 5.7, pp. 194–207] for the definition and properties of reduced boundaries). The structure theorem for sets of finite perimeter [4, Thm. 1 (iii), p. 189] asserts that $\|\partial E_u\| = H^0 | \partial^* E_u$, the 0-dimensional Hausdorff measure restricted on $\partial^* E_u$. The 0-dimensional Hausdorff measure is the counting measure. Therefore $\partial^* E_u$ is a set of finitely many points in $(0,1)$ and $\|\partial E_u\|(0,1) = \frac{\|Du\|(0,1)}{2}$ is the number of the points in $\partial^* E_u$.

$\partial^* E_u$ is simply $\{x_1, x_2, \dots, x_\nu\}$, the set of points where $u(x)$ switches, and

$$\frac{\|Du\|(0,1)}{2} = \nu.$$

If $u \in \mathcal{A}_m \cap BV((0,1),\{-1,1\})$, $\frac{\|Du\|(0,1)}{2}$ has to be nonzero. Otherwise u would be a constant. Then $u = -1$ for a.e. $x \in (0,1)$ or $u = 1$ for a.e. $x \in (0,1)$. In either case $\int_0^1 u \ne m$. So we have the following mutually disjoint decomposition:

$$\begin{aligned} &\mathcal{A}_m \cap BV((0,1),\{-1,1\}) = \cup_1^\infty A_\nu, \text{ where} \\ &A_\nu = \left\{ u \in \mathcal{A}_m \cap BV((0,1),\{-1,1\}) : \frac{\|Du\|(0,1)}{2} = \nu \right\}. \end{aligned} \tag{3.1}$$

Proposition 3.1. *For every $u \in A_\nu$, $u \ne U_{\nu,1}$, and $u \ne U_{\nu,2}$, we have $\mathcal{I}_0(U_{\nu,1}) = \mathcal{I}_0(U_{\nu,2}) < \mathcal{I}_0(u)$.*

Proof. For each $u \in A_\nu$, let us denote $\partial^* E_u$ by $\{x_1, x_2, \ldots, x_\nu\}$, where $0 < x_1 < x_2 \cdots < x_\nu < 1$. Since $\|Du\|(x_i, x_{i+1}) = 0$ for each i and (x_i, x_{i+1}) is connected, $u = -1$ for a.e. $x \in (x_i, x_{i+1})$ or $u = 1$ for a.e. $x \in (x_i, x_{i+1})$. And it follows from the definition of reduced boundaries [4, p. 194] that $u(x)$ must jump from -1 to 1 or 1 to -1 when x moves from (x_{i-1}, x_i) to (x_i, x_{i+1}). We can further decompose A_ν into two disjoint sets:

$$\begin{aligned} A_{\nu,1} &= \{u \in A_\nu : u = -1 \text{ for a.e. } x \in (0, x_1)\}, \\ A_{\nu,2} &= \{u \in A_\nu : u = 1 \text{ for a.e. } x \in (0, x_1)\}. \end{aligned} \tag{3.2}$$

For $u \in A_{\nu,1}$ the constraint $\int_0^1 u = m$ becomes $-2x_1 + 2x_2 - \cdots + 2(-1)^\nu x_\nu - (-1)^\nu = m$, and for $u \in A_{\nu,2}$ the constraint $\int_0^1 u = m$ becomes $2x_1 - 2x_2 - \cdots - 2(-1)^\nu x_\nu + (-1)^\nu = m$.

Now $A_{\nu,1}$ can be identified with the set

$$\begin{aligned} S_{\nu,1} = \Big\{&(x_1, \ldots, x_\nu) \in R^\nu : 0 < x_1 < \cdots x_\nu < 1, \\ &-x_1 + x_2 - \cdots + (-1)^\nu x_\nu = \frac{m + (-1)^\nu}{2}\Big\}, \end{aligned} \tag{3.3}$$

and $A_{\nu,2}$ can be identified with the set

$$\begin{aligned} S_{\nu,2} = \Big\{&(x_1, \ldots, x_\nu) \in R^\nu : 0 < x_1 < \cdots x_\nu < 1, \\ &x_1 - x_2 - \cdots - (-1)^\nu x_\nu = \frac{m - (-1)^\nu}{2}\Big\}. \end{aligned} \tag{3.4}$$

$S_{\nu,1}$ and $S_{\nu,2}$ are two bounded open subsets of two $\nu - 1$ dimensional hyper-planes of R^ν.

We take $u \in A_{\nu,1} \cong S_{\nu,1}$ and $\{x_1, x_2, \ldots, x_\nu\}$, $x_1 < \cdots < x_\nu$, to be $\partial^* E_u$. We compute $\mathcal{K}(u)$. Let v be the solution of

$$-\gamma^2 v'' = u - m, \ v'(0) = v'(1) = 0, \ \int_0^1 v = 0.$$

Denote the Green's function of this equation by $G(x, y)$. Then

$$\begin{aligned} \mathcal{K}(u) &= \frac{1}{2} \int_0^1 [(-\gamma^2 \Delta)^{-1/2} (u - m)]^2 \, dx \\ &= \frac{1}{2} \int_0^1 (u - m) v \, dx \\ &= \frac{1}{2} \left[\int_0^{x_1} (-1 - m) v + \int_{x_1}^{x_2} (1 - m) v + \cdots + \int_{x_\nu}^1 ((-1)^{\nu+1} - m) v \right]. \end{aligned}$$

Treating $\mathcal{K}$ as a function of $(x_1, x_2, \ldots, x_\nu)$ in $S_{\nu,1}$, we calculate

$$\frac{\partial \mathcal{K}}{\partial x_1} = \frac{1}{2} \left[-2v(x_1) + \int_0^1 (u - m) \frac{\partial v}{\partial x_1} \, dx \right].$$

Since

$$\begin{aligned} \frac{\partial v}{\partial x_1}(x) = \frac{\partial}{\partial x_1} \bigg[&\int_0^{x_1} (-1 - m) G(x, y) dy + \int_{x_1}^{x_2} (1 - m) G(x, y) dy + \cdots \\ &+ \int_{x_\nu}^1 ((-1)^{\nu+1} - m) G(x, y) dy \bigg] \\ = -2G(x, x_1),& \end{aligned}$$

we deduce

$$\begin{aligned}\frac{\partial \mathcal{K}}{\partial x_1} &= \frac{1}{2}\left[-2v(x_1) + \int_0^1 (u-m)(-2)G(x,x_1)\,dx\right]\\ &= -2v(x_1).\end{aligned}$$

The same argument applied to other x_i yields

$$\nabla \mathcal{K} = 2(-v(x_1), v(x_2), \dots, (-1)^\nu v(x_\nu)). \tag{3.5}$$

Since $\int_0^1 u = m$, or $-x_1 + x_2 - \dots + (-1)^\nu x_\nu = \frac{m+(-1)^\nu}{2}$, the Lagrange multiplier method asserts that if $(x_1, x_2, \dots, x_\nu)$ is a critical point of $\mathcal{K}$ in $S_{\nu,1}$, there exists λ such that

$$\nabla \mathcal{K} = \lambda(-1, 1, -1, \dots, (-1)^\nu),$$

which, together with (3.5), implies

$$v(x_1) = v(x_2) = \dots = v(x_\nu). \tag{3.6}$$

On (x_1, x_2), v solves the linear equation $-\gamma^2 v'' = 1 - m$. Then $v(x_1) = v(x_2)$ implies that v is symmetric about $(x_1 + x_2)/2$, and hence $v'(x_1) = -v'(x_2)$. On intervals $(0, x_1)$ and (x_2, x_3), v satisfies the linear equation $-\gamma^2 v'' = -1 - m$. Since v also satisfies the conditions $v(x_1) = v(x_2)$, $v'(x_1) = -v'(x_2)$, $v(x_2) = v(x_3)$, and $v'(0) = 0$, we conclude by solving the equation on $(0, x_1)$ and (x_2, x_3) that v on $(0, x_1)$ is a reflection of v on $(x_2, (x_2 + x_3)/2)$. Hence the length of $(0, x_1)$ is half that of (x_2, x_3). In the next step we compare intervals (x_2, x_3) and (x_4, x_5) and similarly find that they have the same length. By repeating this argument we conclude that the intervals where $u = -1$ all have the same length with the exception of $(0, x_1)$ and $(x_\nu, 1)$ if $u = -1$ there, whose length is half. The same can be said for the intervals where $u = 1$. Taking $-x_1 + x_2 - \dots + (-1)^\nu x_\nu = \frac{m+(-1)^\nu}{2}$ into consideration, we find

$$x_1 = \frac{1-m}{2\nu}, x_2 = x_1 + \frac{1+m}{\nu}, \dots, x_\nu = x_{\nu-1} + \frac{1+(-1)^\nu m}{\nu}.$$

We have proved that $\mathcal{K}$ has a unique critical point $(x_1, x_2, \dots, x_\nu)$ in $S_{\nu,1}$. We denote the function in $A_{\nu,1}$ whose reduced boundary is $\{x_1, x_2, \dots, x_\nu\}$ by $U_{\nu,1}$ (also defined in (1.5)). We proceed to prove that $U_{\nu,1}$ minimizes $\mathcal{K}$ in $A_{\nu,1}$. We first compute $\mathcal{K}(U_{\nu,1})$. Let v be the solution of

$$-\gamma^2 v'' = U_{\nu,1} - m,\ v'(0) = v'(1) = 0,\ \int_0^1 v = 0.$$

Then

$$\mathcal{K}(U_{\nu,1}) = \frac{1}{2}\int_0^1 (U_{\nu,1} - m)v = \frac{\gamma^2}{2}\int_0^1 |v'|^2.$$

On $(0, x_1)$ $v'(x) = \frac{-1-m}{-\gamma^2}x + v'(0) = \frac{-1-m}{-\gamma^2}x$. Then

$$\frac{\gamma^2}{2}\int_0^{x_1} |v'|^2 = \frac{\gamma^2}{2}\frac{-\gamma^2}{3(-1-m)}(v'(x_1))^3.$$

On (x_1, x_2) $v'(x) = \frac{1-m}{-\gamma^2}(x - x_1) + v'(x_1)$. Then

$$\frac{\gamma^2}{2}\int_{x_1}^{x_2} |v'|^2 = \frac{\gamma^2}{2}\frac{-\gamma^2}{3(1-m)}[(v'(x_2))^3 - (v'(x_1))^3].$$

After finding $\frac{\gamma^2}{2}\int_{x_i}^{x_{i+1}} |v'|^2$ on each (x_i, x_{i+1}) and summing over i, we deduce

$$\mathcal{K}(U_{\nu,1}) = \frac{\gamma^4}{3(1-m^2)}[(v'(x_1))^3 - (v'(x_2))^3 + (v'(x_3))^3 + \cdots + (-1)^{\nu+1}(v'(x_\nu))^3].$$

Since we also know $v'(x_1) = -v'(x_2) = v'(x_3) = \cdots = (-1)^{\nu+1}v'(x_\nu)$ and $v'(x_1) = \frac{-1-m}{-\gamma^2}\frac{1-m}{2\nu} = \frac{1-m^2}{2\gamma^2\nu}$, we find

$$\mathcal{K}(U_{\nu,1}) = \frac{(1-m^2)^2}{24\gamma^2\nu^2}. \tag{3.7}$$

A similar computation in $A_{\nu,2}$ finds $U_{\nu,2}$ (defined by (1.6)) and again

$$\mathcal{K}(U_{\nu,2}) = \frac{(1-m^2)^2}{24\gamma^2\nu^2}. \tag{3.8}$$

We now show that $\mathcal{K}(u) > \mathcal{K}(U_{\nu,1})$ for every $u \in A_{\nu,1} \cong S_{\nu,1}$, $u \neq U_{\nu,1}$. If this is not the case, since there is only one critical point, $U_{\nu,1}$, in $S_{\nu,1}$, there must be a sequence $\{(x_{n,1}, x_{n,2}, \ldots, x_{n,\nu})\}$ converging to a point $(y_1, y_2, \ldots, y_\nu)$ on the boundary of $S_{\nu,1}$ ($S_{\nu,1}$ is considered as a subset of R^ν) such that

$$\lim_{n\to\infty} \mathcal{K}(x_{n,1}, x_{n,2}, \ldots, x_{n,\nu}) \leq \mathcal{K}(U_{\nu,1}).$$

For the point $(y_1, y_2, \ldots, y_\nu)$ to be on the boundary of $S_{\nu,1}$, at least two of 0, $y_1, \ldots, y_\nu$, 1 must be identical. Then $(y_1, y_2, \ldots, y_\nu)$ is identified as a point in $S_{\nu',1}$ or $S_{\nu',2}$, corresponding to $A_{\nu',1}$ or $A_{\nu',2}$ for some $\nu' < \nu$. Let us denote this point by $(z_1, z_2, \ldots, z_{\nu'})$ and assume, without the loss of generality, $(z_1, z_2, \ldots, z_{\nu'}) \in S_{\nu',1}$. We ask whether $U_{\nu',1}$ is the strict global minimum of $\mathcal{K}$ in $A_{\nu',1}$. If so,

$$\mathcal{K}(U_{\nu',1}) \leq \mathcal{K}(z_1, z_2, \ldots, z_{\nu'}) = \lim_{n\to\infty} \mathcal{K}(x_{n,1}, x_{n,2}, \ldots, x_{n,\nu}) \leq \mathcal{K}(U_{\nu,1}),$$

which, since $\nu' < \nu$, is inconsistent with (3.7), where $\mathcal{K}(U_{\nu,1}) = \mathcal{K}(U_{\nu,2})$ decreases in ν. If $U_{\nu',1}$ is not the strict global minimum of $\mathcal{K}$ in $A_{\nu',1}$, we use the same argument on $U_{\nu',1}$ and end up in a $A_{\nu'',1}$ or $A_{\nu'',2}$ with $\nu'' < \nu'$. This process stops at $\nu = 1$, and there, since $A_{1,1}$ has only one element $U_{1,1}$ and $A_{1,2}$ has only one element $U_{1,2}$, we find $\mathcal{K}(U_{1,1}) = \mathcal{K}(U_{1,2}) \leq \mathcal{K}(U_{\nu,1})$, which is inconsistent with (3.7) or (3.8). So we have proved that $U_{\nu,1}$ is the strict global minimum of $\mathcal{K}$ in $A_{\nu,1}$. And since for $u \in A_{\nu,1}$, $\mathcal{I}_0(u) = c_0\nu + \mathcal{K}(u)$, Proposition 3.1 is proved. □

PROPOSITION 3.2. *Let N be a positive integer. One can find $\delta > 0$ such that*

(1) *$\{B_\delta(U_{\nu,1}), B_\delta(U_{\nu,2}) : \nu = 1, 2, \ldots, N\}$ is a family of $2N$ mutually disjoint open balls in $\mathcal{A}_m$;*

(2) *for all $u \in B_\delta(U_{\nu,1})$, $\nu = 1, 2, \ldots, N$, with $u \neq U_{\nu,1}$, $\mathcal{I}_0(U_{\nu,1}) < \mathcal{I}_0(u)$, and for all $u \in B_\delta(U_{\nu,2})$ with $u \neq U_{\nu,2}$, $\mathcal{I}_0(U_{\nu,2}) < \mathcal{I}_0(u)$.*

Proof. Let N be a positive integer and $\nu \in \{1, 2, \ldots, N\}$. We consider $U_{\nu,1}$. The study of $U_{\nu,2}$ is the same.

Take δ to be a positive number to be specified later. Let $u \in B_\delta(U_{\nu,1})$, $u \neq U_{\nu,1}$. If $u \in A_\nu$, then Proposition 3.1 implies Proposition 3.2. So we assume $u \in \mathcal{A}_m \backslash A_\nu$. Then if $u \in (\mathcal{A}_m \backslash A_\nu) \backslash BV((0,1),\{-1,1\})$, $\mathcal{I}_0(U_{\nu,1}) < \mathcal{I}_0(u) = \infty$. So we need only to consider $u \in (\mathcal{A}_m \backslash A_\nu) \cap BV((0,1),\{-1,1\})$.

Because of (3.1), the positive integer $\frac{\|Du\|(0,1)}{2}$ is either $\leq \nu - 1$ or $\geq \nu + 1$. We study these two cases separately.

First we prove that the case $\frac{\|Du\|(0,1)}{2} \leq \nu - 1$ does not happen if δ is small enough. We claim that there is $\delta > 0$ such that for all $u \in B_\delta(U_{\nu,1}) \cap BV((0,1),\{-1,1\})$, $\frac{\|Du_n\|(0,1)}{2} \geq \nu$. Otherwise there exist $\delta_n \to 0$ and $u_n \in B_{\delta_n}(U_{\nu,1}) \cap BV((0,1),\{-1,1\})$ such that $\frac{\|Du\|(0,1)}{2} \leq \nu - 1$. Then $u_n \to U_{\nu,1}$ in $L^2(0,1)$ implies (see [4, Thm. 1, p. 172])

$$2\nu = \|DU_{\nu,1}(0,1)\| \leq \liminf_{n\to\infty} \|Du_n\|(0,1) \leq 2(\nu - 1),$$

a contradiction.

Second we consider the case $\frac{\|Du\|(0,1)}{2} \geq \nu + 1$. Here

$$\begin{aligned}\mathcal{I}_0(u) &\geq c_0(\nu+1) + \int_0^1 \frac{1}{2}[(-\gamma^2\Delta)^{-1/2}(u-m)]^2\,dx \\ &= \mathcal{I}_0(U_{\nu,1}) + c_0 + \mathcal{K}(u) - \mathcal{K}(U_{\nu,1}).\end{aligned}$$

Denote the norm of bounded linear operator $(-\gamma\Delta)^{-1/2}$ from $\{u \in L^2(0,1) : \int_0^1 u = 0\}$ to $L^2(0,1)$ by $\|(-\gamma\Delta)^{-1/2}\|$. Estimate

$$\begin{aligned}&|\mathcal{K}(u) - \mathcal{K}(U_{\nu,1})| \\ &= \frac{1}{2}|\, \|(-\gamma\Delta)^{-1/2}(u-m)\|_2^2 - \|(-\gamma\Delta)^{-1/2}(U_{\nu,1}-m)\|_2^2\,| \\ &= \frac{1}{2}|\, \|(-\gamma\Delta)^{-1/2}(u-m)\|_2 - \|(-\gamma\Delta)^{-1/2}(U_{\nu,1}-m)\|_2\,| \\ &\quad \cdot \{\|(-\gamma\Delta)^{-1/2}(u-m)\|_2 + \|(-\gamma\Delta)^{-1/2}(U_{\nu,1}-m)\|_2\} \\ &\leq \frac{1}{2}\|(-\gamma\Delta)^{-1/2}(u-U_{\nu,1})\|_2 \\ &\quad \cdot \{\|(-\gamma\Delta)^{-1/2}(u-U_{\nu,1})\|_2 + 2\|(-\gamma\Delta)^{-1/2}(U_{\nu,m}-m)\|_2\} \\ &\leq \frac{\|(-\gamma\Delta)^{-1/2}\|^2}{2}\|u-U_{\nu,1}\|_2\{\|u-U_{\nu,1}\|_2 + 2\|U_{\nu,m}\|_2 + 2\|m\|_2\} \\ &\leq \frac{\|(-\gamma\Delta)^{-1/2}\|^2}{2}\delta\{\delta + 2 + 2m\}.\end{aligned}$$

We obtain, choosing δ sufficiently small,

$$\mathcal{I}_0(u) \geq \mathcal{I}_0(U_{\nu,1}) + c_0 - \frac{\|(-\gamma\Delta)^{-1/2}\|^2}{2}\delta\{\delta + 2 + 2m\} > \mathcal{I}_0(U_{\nu,1}).$$

Since there are only finitely many ν, we can choose δ so that it is independent of ν. We can also make $\{B_\delta(U_{\nu,1}), B_\delta(U_{\nu,2}) : \nu = 1, 2, \ldots, N\}$ mutually disjoint by having δ small enough. □

PROPOSITION 3.3. *$\{U_{\nu,1}, U_{\nu,2} : \nu = 1, 2, 3 \ldots\}$ is the set of all local minima of $\mathcal{I}_0$ (or $\mathcal{J}_0$).*

Proof. According to Proposition 3.2, each element in $\{U_{\nu,1}, U_{\nu,2} : \nu = 1, 2, \ldots\}$ is a local minimum of $\mathcal{I}_0$. On the other hand, if u is a local minimum of $\mathcal{I}_0$, it must be in $A_{\nu,i}$ for some $i = 1$ or 2 and $\nu = 1, 2, \ldots$. And in each $A_{\nu,i} \cong S_{\nu,i}$ there is only one critical point $U_{\nu,i}$ of $\mathcal{I}_0$ considered as a function on $S_{\nu,i}$. Then $u = U_{\nu,i}$. □

Theorem 1.1 follows immediately from Propositions 2.3 and 3.2. To prove Theorem 1.2, we note from (3.7) and (3.8) that

$$\mathcal{I}_0(U_{\nu,1}) = \mathcal{I}_0(U_{\nu,2}) = c_0\nu + \frac{(1-m^2)^2}{24\gamma^2\nu^2}. \tag{3.9}$$

Set

$$g(t) = c_0 t + \frac{(1-m^2)^2}{24\gamma^2 t^2}$$

for $t \geq 1$. Denote the global minimum of this convex function by t_0:

$$t_0 = \max\left\{1, \left(\frac{(1-m^2)^2}{12\gamma^2 c_0}\right)^{1/3}\right\}.$$

Let $[t_0]$ be the greatest integer less than or equal to t_0. Compare $g([t_0])$ and $g([t_0+1])$. Depending on $\frac{(1-m^2)^2}{24\gamma^2 c_0}$, we have $g([t_0]) = g([t_0+1])$ or $g([t_0]) \neq g([t_0+1])$. Let $\mathcal{C} \subset R$ be the set so that when $\frac{(1-m^2)^2}{24\gamma^2 c_0} \in \mathcal{C}$, $g([t_0]) = g([t_0+1])$. In this case we set $\nu_* = [t_0]$. And if $\frac{(1-m^2)^2}{24\gamma^2 c_0} \notin \mathcal{C}$, i.e., $g([t_0]) \neq g([t_0+1])$, we set

$$\nu_* = \begin{cases} [t_0] & \text{if } g([t_0]) < g([t_0]+1), \\ [t_0]+1 & \text{if } g([t_0]) > g([t_0]+1). \end{cases}$$

So if $\frac{(1-m^2)^2}{24\gamma^2 c_0} \notin \mathcal{C}$, for every $\nu \neq \nu_*$,

$$\mathcal{I}_0(U_{\nu_*,1}) = \mathcal{I}_0(U_{\nu_*,2}) < \mathcal{I}_0(U_{\nu,1}) = \mathcal{I}_0(U_{\nu,2}),$$

and if $\frac{(1-m^2)^2}{24\gamma^2 c_0} \in \mathcal{C}$, for every ν, $\nu \neq \nu_*$, and $\nu \neq \nu_* + 1$,

$$\mathcal{I}_0(U_{\nu_*,1}) = \mathcal{I}_0(U_{\nu_*,2}) = \mathcal{I}_0(U_{\nu_*+1,1}) = \mathcal{I}_0(U_{\nu_*+1,2}) < \mathcal{I}_0(U_{\nu,1}) = \mathcal{I}_0(U_{\nu,2}).$$

The case $\frac{(1-m^2)^2}{24\gamma^2 c_0} \notin \mathcal{C}$ is generic. $\mathcal{C}$ is a countable set.

Let u_ϵ be a global minimum of $\mathcal{I}_\epsilon$. The existence of u_ϵ follows from the standard argument as in the proof of Proposition 2.3. Propositions 2.1 and 2.2 imply that every sequence $\{u_{\epsilon_n}\}$ of u_ϵ has a convergent subsequence, and if u_0 is the limit of a subsequence, u_0 must be a global minimum of $\mathcal{I}_0$ in $\mathcal{A}_m \cap BV((0,1), \{-1,1\})$. The decomposition (3.1) and Proposition 3.1 imply that $u_0 = U_{\nu,1}$ or $U_{\nu,2}$ for some ν. And by the definition of ν_*, $\nu = \nu_*$ if $\frac{(1-m^2)^2}{24\gamma^2 c_0} \notin \mathcal{C}$ and $\nu = \nu_*$ or ν_*+1 if $\frac{(1-m^2)^2}{24\gamma^2 c_0} \in \mathcal{C}$. This proves Theorem 1.2.

4. The study of $\mathcal{J}_\epsilon$.

All results in sections 2 and 3 are valid for $\mathcal{J}_\epsilon$. In this section we indicate the modifications needed to prove these results for $\mathcal{J}_\epsilon$.

The condition (1.2) implies that for all small ϵ, $\mathcal{J}_\epsilon$ is bounded from below. The lower bound can be made independent of small ϵ.

The Γ-limit of $\mathcal{J}_\epsilon$ is

$$\mathcal{J}_0(u) = \begin{cases} \dfrac{c_0}{2}\|Du\|(\Omega) - \dfrac{|\Omega|}{2} + \displaystyle\int_\Omega \frac{1}{2}|(-\gamma^2\Delta+1)^{-1/2}u|^2\,dx, & \\ \qquad\qquad\qquad\qquad \text{if } u \in \mathcal{A}_m \cap BV(\Omega, \{-1,1\}), & \\ \infty \qquad\qquad\qquad\quad \text{if } u \in \mathcal{A}_m \backslash BV(\Omega, \{-1,1\}) & \end{cases} \tag{4.1}$$

for $u \in \mathcal{A}_m$. Define

$$\mathcal{L}(u) = \int_\Omega \frac{1}{2}\{-u^2 + [(-\gamma^2\Delta + 1)^{-1/2}u]^2\}\, dx \tag{4.2}$$

for $u \in \mathcal{A}_m$. Thus $\mathcal{J}_\epsilon = \mathcal{H}_\epsilon + \mathcal{L}$ and $\mathcal{J}_0 = \mathcal{H}_0 + \mathcal{L}$.

As in the proof of Proposition 3.1, we study $\mathcal{L}(u)$ for $u \in A_{\nu,1} \cong S_{\nu,1}$. Let $\{x_1, x_2, \dots, x_\nu\}$ be $\partial^* E_u$. Let v be the solution of

$$-\gamma^2 v'' + v = u,\ v'(0) = v'(1) = 0,$$

and let $G(x, y)$ be the Green's function of this equation. Then

$$\begin{aligned}\mathcal{L}(u) &= \frac{1}{2}\int_0^1 (-u^2 + uv)\\ &= \frac{1}{2}\left[-1 + \int_0^{x_1}(-1)v + \int_{x_1}^{x_2} v + \cdots + \int_{x_\nu}^1 (-1)^{\nu+1} v\right].\end{aligned}$$

We then find, treating $\mathcal{L}$ as a function of $x_1, x_2, \dots, x_\nu$,

$$\nabla\mathcal{L} = 2(-v(x_1), v(x_2), \dots, (-1)^\nu v(x_\nu)).$$

Again we see that at a critical point $(x_1, \dots, x_\nu)$, $v(x_1) = v(x_2) = \cdots = v(x_\nu)$. The same symmetry argument as in the proof of Proposition 3.1 shows that

$$x_1 = \frac{1-m}{2\nu}, x_2 = x_1 + \frac{1+m}{\nu}, \dots, x_\nu = x_{\nu-1} + \frac{1 + (-1)^\nu m}{\nu}.$$

We again obtain $U_{\nu,1}$.

The calculation of $\mathcal{L}(U_{\nu,1})$ is a bit more complex. Let v be the solution of

$$-\gamma^2 v'' + v = U_{\nu,1},\ v'(0) = v'(1) = 0.$$

Then

$$\mathcal{L}(U_{\nu,1}) = -\frac{1}{2} + \frac{1}{2}\int_0^1 U_{\nu,1} v\, dx.$$

On an subinterval of $(0, 1)$, say (a,b), where $U_{\nu,1} = \alpha \in \{-1, 1\}$,

$$\frac{1}{2}\int_a^b U_{\nu,1} v = \frac{\alpha}{2}\int_a^b v = \frac{\alpha}{2}\int_a^b (\gamma^2 v'' + \alpha) = \frac{\alpha\gamma^2}{2}[v'(b) - v'(a)] + \frac{\alpha^2}{2}(b - a).$$

This implies

$$\begin{aligned}\mathcal{L}(U_{\nu,1}) &= -\gamma^2[v'(x_1) - v'(x_2) + v'(x_3) - \cdots + (-1)^{\nu+1} v'(x_\nu)]\\ &= -\gamma^2 \nu v'(x_1).\end{aligned}$$

We now need to calculate $v'(x_1)$. On $(0, x_1)$ $v(x) = -1 + C' \cosh(x/\gamma)$ and on (x_1, x_2) $v(x) = 1 + C'' \cosh((x - \frac{x_1+x_2}{2})/\gamma)$ for some appropriate C' and C''. They and their derivatives match at x_1. Therefore,

$$\begin{cases} -1 + C' \cosh\left(\dfrac{x_1}{\gamma}\right) = 1 + C'' \cosh\left(\dfrac{x_1 - x_2}{2\gamma}\right), \\[2ex] \dfrac{C'}{\gamma}\sinh\left(\dfrac{x_1}{\gamma}\right) = \dfrac{C''}{\gamma}\sinh\left(\dfrac{x_1 - x_2}{2\gamma}\right). \end{cases}$$

Solving this system we find

$$\begin{cases} C' = \dfrac{2\sinh(\frac{x_2-x_1}{2\gamma})}{\sinh(\frac{1}{\gamma\nu})}, \\[2ex] C'' = \dfrac{-2\sinh(\frac{x_1}{\gamma})}{\sinh(\frac{1}{\gamma\nu})}. \end{cases}$$

Recall that $x_1 = \frac{1-m}{2\nu}$, $x_2 - x_1 = \frac{1+m}{\nu}$, and $\frac{x_1+x_2}{2} = \frac{1}{\nu}$. Then

$$v'(x_1) = \frac{2\sinh(\frac{1+m}{2\gamma\nu})\sinh(\frac{1-m}{2\gamma\nu})}{\gamma\sinh(\frac{1}{\gamma\nu})}.$$

Going back to $\mathcal{L}(U_{\nu,1})$, we find

$$\mathcal{L}(U_{\nu,1}) = \mathcal{L}(U_{\nu,2}) = -\frac{2\gamma\nu\sinh(\frac{1+m}{2\gamma\nu})\sinh(\frac{1-m}{2\gamma\nu})}{\sinh(\frac{1}{\gamma\nu})},$$

and hence the key formula

$$\mathcal{J}_0(U_{\nu,1}) = \mathcal{J}_0(U_{\nu,2}) = c_0\nu - \frac{2\gamma\nu\sinh(\frac{1-m}{2\gamma\nu})\sinh(\frac{1+m}{2\gamma\nu})}{\sinh(\frac{1}{\gamma\nu})}, \tag{4.3}$$

analogous to (3.9).

We need to show that (1) $\mathcal{L}(U_{\nu,1}) = \mathcal{L}(U_{\nu,2})$ is decreasing in ν in order to prove Proposition 3.1 for $\mathcal{J}_0$, and (2) $\mathcal{J}_0(U_{\nu,1}) = \mathcal{J}_0(U_{\nu,2})$ is convex in ν in order to prove Theorem 1.2 for $\mathcal{J}_\epsilon$.

For $t > 0$ define

$$g(t) = c_0 t - \frac{2\gamma t\sinh(\frac{1-m}{2\gamma t})\sinh(\frac{1+m}{2\gamma t})}{\sinh(\frac{1}{\gamma t})}.$$

Compute g' and g''.

$$\begin{aligned} g'(t) = c_0 - \frac{2\gamma}{t(\sinh\frac{p_1+p_2}{t})^2}\Big\{ & t\sinh\frac{p_1}{t}\sinh\frac{p_2}{t}\sinh\frac{p_1+p_2}{t} \\ & -p_1\cosh\frac{p_1}{t}\sinh\frac{p_2}{t}\sinh\frac{p_1+p_2}{t} \\ & -p_2\sinh\frac{p_1}{t}\cosh\frac{p_2}{t}\sinh\frac{p_1+p_2}{t} \\ & +(p_1+p_2)\sinh\frac{p_1}{t}\sinh\frac{p_2}{t}\cosh\frac{p_1+p_2}{t}\Big\}, \\ g''(t) = \frac{4\gamma}{(t\sinh\frac{1}{\gamma t})^3}\Big\{ & \cosh\frac{1}{\gamma t}\left[p_1^2\left(\sinh\frac{p_2}{t}\right)^2 + p_2^2\left(\sinh\frac{p_1}{t}\right)^2\right] \\ & -2p_1p_2\sinh\frac{p_1}{t}\sinh\frac{p_2}{t}\Big\}, \end{aligned}$$

where $p_1 = \frac{1-m}{2\gamma}$ and $p_2 = \frac{1+m}{2\gamma}$. Since $\cosh\frac{1}{\gamma t} > 1$,

$$g''(t) > \frac{4\gamma}{(t\sinh\frac{1}{\gamma t})^3}\left\{p_1^2\left(\sinh\frac{p_2}{t}\right)^2 + p_2^2\left(\sinh\frac{p_1}{t}\right)^2 - 2p_1p_2\sinh\frac{p_1}{t}\sinh\frac{p_2}{t}\right\} \geq 0.$$

Like (3.9), $g(t)$ is convex in t. So $\mathcal{J}_0(U_{\nu,1}) = \mathcal{J}_0(U_{\nu,2})$ is convex in ν.

To show that $\mathcal{L}(U_{\nu.1}) = \mathcal{L}(U_{\nu,2})$ is decreasing in ν, we set

$$h(t) = -\frac{2\gamma t \sinh(\frac{1-m}{2\gamma t}) \sinh(\frac{1+m}{2\gamma t})}{\sinh(\frac{1}{\gamma t})}.$$

Then $h' = g' - c_0$ and $h'' = g''$. Near $t = \infty$ we can find Taylor's expansion

$$h'(t) = -\frac{(1-m^2)^2}{12\gamma^2}\frac{1}{t^3} + o\left(\frac{1}{t^3}\right).$$

Therefore $\lim_{t\to\infty} h'(t) = 0$. Then $h'' > 0$ implies that $h'(t) < 0$ for all $t > 0$. So $\mathcal{L}(U_{\nu.1}) = \mathcal{L}(U_{\nu,2})$ is decreasing in ν. We also note

$$\lim_{\nu\to\infty} \mathcal{L}(U_{\nu,1}) = \lim_{\nu\to\infty} \mathcal{L}(U_{\nu,2}) = \lim_{t\to\infty} h(t) = -\frac{1-m^2}{2}.$$

The global minimum t_0 of $g(t)$, $t \geq 1$, in the case of $\mathcal{J}_0$, cannot be obtained explicitly. But its existence and uniqueness are guaranteed by the convexity of g and the fact $\lim_{t\to\infty} g'(t) = c_0 > 0$. Taylor's expansion

$$g'(t) = c_0 - \frac{(1-m^2)^2}{12\gamma^2}\frac{1}{t^3} + o\left(\frac{1}{t^3}\right)$$

implies that if c_0 is small, then t_0, and ν_* in Theorem 1.2, is close to $(\frac{(1-m^2)^2}{12\gamma^2 c_0})^{1/3}$. This number is the same as the one for $\mathcal{I}_0$.

Therefore it can be argued heuristically that as c_0 becomes small, the problems $\mathcal{I}_\epsilon$ and $\mathcal{J}_\epsilon$ start to converge.

Acknowledgment. Part of the work was done during an RiP stay at Mathematisches Forschungsinstitut Oberwolfach, which the authors would like to thank for its hospitality.

ON THE LARGE TIME BEHAVIOR OF SOLUTIONS OF HAMILTON–JACOBI EQUATIONS[*]

G. BARLES[†] AND PANAGIOTIS E. SOUGANIDIS[‡]

Abstract. We consider the long time behavior of viscosity solutions of first-order Hamilton–Jacobi equations with periodic space dependence. We prove, under sharp conditions, that as time goes to infinity, solutions converge to solutions of the corresponding stationary equation.

Key words. Hamilton–Jacobi equations, periodicity, ergodic problem, long time behavior, viscosity solutions, hamiltonian systems

1. Introduction.

In this article we are interested in the behavior, as $t \to +\infty$, of the viscosity solutions of first-order Hamilton–Jacobi equations of the form

$$u_t + H(x, Du) = 0 \quad \text{in } \mathbb{R}^N \times (0, +\infty) \ , \tag{1.1}$$

$$u = u_0 \quad \text{on } \mathbb{R}^N \times \{0\} \ , \tag{1.2}$$

where the hamiltonian H, the initial datum u_0, and the solution u are assumed to be real-valued continuous functions and $Du = (\frac{\partial u}{\partial x_1}, \dots, \frac{\partial u}{\partial x_N})$ denotes the gradient of u.

Throughout the paper we suppose that both H and u_0 are $\mathbb{Z}^N$-*periodic* in x, i.e., that for all $x, p \in \mathbb{R}^N$ and $z \in \mathbb{Z}^N$,

$$H(x+z, p) = H(x, p) \quad \text{and} \quad u_0(x+z) = u_0(x) \ . \tag{1.3}$$

We also assume that a comparison (uniqueness) result holds for (1.1)–(1.2). The first consequence of this assumption is the $\mathbb{Z}^N$-periodicity in x of the solution for any $t > 0$.

The study of the long time behavior of solutions of (1.1) and (1.2) first leads to an *ergodic* problem. Indeed, the first step is to show the existence of a constant c_0, depending only on H and not u_0, such that the function $u(\cdot, t) + c_0 t$ remains bounded, as $t \to +\infty$. The classical result in this direction is due to Lions, Papanicolaou, and Varadhan [7], who obtained the existence of such a constant c_0, the so-called *ergodic cost*, under the following coercivity assumption on H:

$$H(x, p) \to +\infty \quad \text{when } |p| \to +\infty, \text{ uniformly in } x \in \mathbb{R}^N. \tag{1.4}$$

Another way to define c_0 is by using the stationary Hamilton–Jacobi equation. Indeed, c_0 is the unique constant c for which the equation

$$H(x, Du) = c \quad \text{in } \mathbb{R}^N \tag{1.5}$$

has a continuous, periodic viscosity solution.

It is also worth pointing out that if $u_0 \in W^{1,\infty}(\mathbb{R}^N)$, then (1.4) yields that the function $(x,t) \mapsto u(x,t) + c_0 t$ is in $W^{1,\infty}(\mathbb{R}^N \times [0,+\infty))$. This is a key fact, since it provides the compactness in $C(\mathbb{R}^N)$ of the functions $u(\cdot,t) + c_0 t$ for $t > 0$, a fact which is essential in the study of the behavior of these functions when $t \to +\infty$. Before coming back to this question, which is the central purpose of our work, we mention that such an ergodic problem in the deterministic control framework was systematically studied by Arisawa [1, 2].

In this article we are interested in the next step, i.e., in the behavior of $u(\cdot,t)+c_0 t$ as $t \to +\infty$. To simplify the exposition, we are going to assume, without any loss of generality, that $c_0 = 0$. With this convention, the question we address here can be formulated in the following way:

Assume that $u \in W^{1,\infty}(\mathbb{R}^N \times (0,+\infty))$ or $u \in BUC(\mathbb{R}^N \times (0,+\infty))$. Is it true that, as $t \to \infty$,

$$u(\cdot,t) \to u_\infty(\cdot) \quad \textit{in } C(\mathbb{R}^N)\ , \tag{1.6}$$

where u_∞ is a viscosity solution of the stationary equation

$$H(x,Du) = 0 \quad \textit{in } \mathbb{R}^N\ ? \tag{1.7}$$

The apparent simplicity of this question is misleading. In fact, this problem has remained open for a long time. The first results on the asymptotic behavior of viscosity solutions of Hamilton–Jacobi equations were obtained in Lions [6] and in Barles [3] essentially for either x-independent cases or equations involving a suitable dependence on u. It was only very recently that Namah and Roquejoffre [8] and Fathi [5] succeeded in proving rather general results related to the above questions, which we now briefly describe and compare.

The results of [5] and [8] are obtained for equations set on compact manifolds and for hamiltonians which are convex in the p-variable and satisfy (1.4). The result of [5] was proved under the additional assumption that H is smooth and strictly convex; i.e., there exists a constant $\alpha > 0$ such that

$$D^2_{pp}H(x,p) \geq \alpha I \quad \text{ in } \mathbb{R}^N \times \mathbb{R}^N\ . \tag{1.8}$$

The proof relies on the representation of the solution u by the so-called Oleinik–Lax formula and is based on dynamical systems methods. In particular, [5] emphasizes the central role played by the Aubry–Mather set, an attractor set for the geodesics associated with the Lax–Oleinik formula. This result was revisited recently by Roquejoffre [10], who uses a combination of partial differential equations and dynamical systems methods. (See also Roquejoffre [9] for results in dimension 1.)

The approach of [8] is based on partial differential equations methods and requires a condition, which in the $\mathbb{R}^N$-framework can be stated as follows:

$$\begin{cases} \text{There exists a } C^1\text{-function } \phi \in BUC(\mathbb{R}^N) \text{ such that} \\ H(x,D\phi(x)) \leq 0 \quad \text{ in } \mathbb{R}^N \text{ and} \\ \qquad H(x,p+D\phi(x)) > H(x,D\phi(x)) \text{ for all } x \in \mathbb{R}^N \text{ and } p \in \mathbb{R}^N\backslash\{0\}. \end{cases} \tag{1.9}$$

The two key arguments of [8] are that $u(\cdot,t)$ is decreasing (and therefore uniformly convergent) on the set $K = \{x \in \mathbb{R}^N : H(x,D\phi(x)) = 0\}$—note that this set is necessarily a nonempty subset of $\mathbb{R}^N$ as a consequence of the fact that $c_0 = 0$—and that there is a strong comparison principle for the Dirichlet problem

$$H(x, Dw) = 0 \text{ in } \mathbb{R}^N \backslash K, \qquad w = \varphi \text{ on } \partial K,$$

where φ is a continuous function. This last property holds because ϕ is a (local) strict subsolution of the equation in $\mathbb{R}^N \backslash K$. The strong comparison principle for viscosity solutions then allows the use of the half-relaxed limits methods.

Here we provide a generalization of these two types of results. In particular, we are able to treat hamiltonians which are not necessarily convex and to remove the assumptions on the regularity of H and ϕ. Moreover the $\mathbb{Z}^N$-periodic setting we chose here for the sake of simplicity can be replaced without any additional difficulty by a general compact manifold one. It is, however, worth mentioning that some kind of compactness assumption on the domain is necessary at least to apply our strategy of proof.

Our main argument, which is completely different from those given in [5], [8], [9], and [10] can be described roughly in the following way: We first show that

$$||(u_t)^-(\cdot, t)||_{L^\infty(\mathbb{R}^N)} \to 0 \quad \text{as } t \to +\infty \ . \tag{1.10}$$

For the reader's convenience we provide in section 3, under simplified assumptions, a formal argument which shows why such property should be true. In fact, the formulation of the precise results (Theorems 3.1 and 3.2) is a bit more general but unfortunately rather technical. The main consequence of (1.10) is that the ω-limit set of the function $u(\cdot, t)$ contains only subsolutions of (1.7). In turn, this property is enough to prove (1.6). It is in this last step that the compactness property of the domain seems to play a key role.

This paper is organized as follows: In section 2 we state the assumptions and the main results of the paper. Section 3 is devoted to the statement of the weak versions of (1.10) which are proved in the appendix. In section 4 we prove the main results and in section 5 we discuss the main assumptions on the hamiltonian and some extensions.

2. The main results and their applications. To formulate the main results we recall that we are interested in the asymptotic behavior of solutions $u \in BUC(\mathbb{R}^N \times [0, \infty))$ of the initial value problem

$$\begin{cases} u_t + H(x, Du) = 0 & \text{in } \mathbb{R}^N \times (0, \infty), \\ u = u_0 & \text{on } \mathbb{R}^N \times \{0\}, \end{cases} \tag{2.1}$$

under the assumptions that

$$\text{(H1)} \quad \begin{cases} H \text{ is continuous in } \mathbb{R}^N \times \mathbb{R}^N \text{ and } \mathbb{Z}^N\text{-}\textit{periodic} \text{ with respect to } x, \\ \text{i.e., for all } x, p \in \mathbb{R}^N \text{ and } z \in \mathbb{Z}^N, \\ \qquad H(x + z, p) = H(x, p). \end{cases}$$

We also assume the following.

(H2) There exists a viscosity subsolution $\phi \in BUC(\mathbb{R}^N)$ of $H(x, D\phi) \leq 0$ in $\mathbb{R}^N$.

$$\text{(H3)} \quad \begin{cases} \text{Either } u \text{ and } \phi \text{ are in } W^{1,\infty}(\mathbb{R}^N \times (0, \infty)) \text{ or there exists a} \\ \text{continuous function } m : [0, +\infty) \to \mathbb{R}^+ \text{ such that } m(0^+) = 0 \\ \text{and, for all } x, y \in \mathbb{R}^N \text{ and } p \in \mathbb{R}^N, \\ \qquad |H(x, p) - H(y, p)| \leq m(|x - y|(1 + |p|)), \end{cases}$$

and

$$\text{(H4)}\quad \begin{cases} \text{there exist } \eta > 0 \text{ and } \psi(\eta) > 0 \text{ such that, if } H(x, p+q) \geq \eta \text{ and} \\ H(x,q) \leq 0 \text{ for some } x \in A \subset \mathbb{R}^N,\ p, q \in \mathbb{R}^N, \text{ then, for all } \mu \in (0,1], \\ \\ \qquad\qquad \mu H\Big(x, \mu^{-1}p + q\Big) \geq H(x, p+q) + \psi(\eta)(1-\mu). \end{cases}$$

Note that if H is C^1 in p, then (H4) reduces to

$$\text{(H4)}'\quad \begin{cases} \qquad\qquad H_p(x, p+q)\cdot p - H(x,p+q) \geq \psi(\eta), \\ \\ \text{for any } x \in A,\ p, q \in \mathbb{R}^N \text{ such that } H(x,p+q) \geq \eta \text{ and } H(x,q) \leq 0. \end{cases}$$

The final assumption is as follows.

$$\text{(H5)}\quad \begin{cases} \text{There exists a, possibly empty, compact subset } K \text{ of } \mathbb{R}^N \text{ such that} \\ \\ \quad \text{(i)}\quad H(x,p) \geq 0 \text{ on } K \times \mathbb{R}^N, \text{ and} \\ \\ \quad \text{(ii)}\quad \text{for all } \delta > 0, \text{ (H4) holds with } A = (K_\delta)^c \text{ for all } \eta > 0, \\ \qquad\quad \text{where } (K_\delta)^c = \{x \in \mathbb{R}^N : d(x,K) > \delta\} \text{ with } \psi \text{ depending on } \delta. \end{cases}$$

The result about the asymptotic behavior of the solution u of (1.1) and (1.2) is the following.

THEOREM 2.1. *Assume that* (H1)–(H3) *and* (H5) *hold. If* $u \in BUC(\mathbb{R}^N \times (0,\infty))$ *is a* $\mathbb{Z}^N$*-periodic in* x *solution of* (1.1), *then there exists a* $\mathbb{Z}^N$*-periodic* $\overline{u} \in BUC(\mathbb{R}^N)$ *such that*

(i) $H(x, D\bar{u}) = 0$ *in* $\mathbb{R}^N$, *and*

(ii) $u(x,t) \to \bar{u}(x)$, *uniformly in* $\mathbb{R}^N$, *as* $t \to \infty$.

Before stating a variant of this result, which holds under simpler hypotheses on H, we want to point out that it is generally rather difficult to show that the solution u of (1.1)–(1.2) is actually in $BUC(\mathbb{R}^N \times (0,\infty))$. The classical existence results provide a solution which is only in $BUC(\mathbb{R}^N \times (0,T))$ for all $T > 0$ (see Barles [4]). To the best of our knowledge, as we already mentioned in the introduction, the only general result which gives the compactness in $C(\mathbb{R}^N)$ of the functions $u(\cdot, t)$—the important information—is the one obtained by Lions, Papanicolaou, and Varadhan [7] (see also Namah and Roquejoffre [8]) under the following assumption:

(H6) $\qquad H(x,p) \to \infty$ as $|p| \to \infty$, uniformly in $x \in \mathbb{R}^N$.

As a consequence of this, the reader can replace in any of our results the assumption "$u \in W^{1,\infty}(\mathbb{R}^N \times (0,\infty))$" with "(H6) and $u_0 \in W^{1,\infty}(\mathbb{R}^N)$" and in the same way "$u \in BUC(\mathbb{R}^N \times (0,\infty))$" with "(H6) and $u_0 \in BUC(\mathbb{R}^N)$," which implies in both cases the existence of such a solution.

It is also worth mentioning that if we assume that the sets $\{p \in \mathbb{R}^N : H(x,p) \leq 0\}$ are bounded uniformly for $x \in \mathbb{R}^N$ and that (H4) holds with $A = \mathbb{R}^N$, then (H6) are a direct consequence of (H4). Hence, in these cases we do not lose any generality by assuming (H6).

Finally we write about the existence of a BUC-subsolution ϕ as an assumption. In fact, this property together with the global boundedness of u is a direct consequence of the definition of c_0 (recall that we assume $c_0 = 0$).

To state a variant of Theorem 2.1 we introduce the following simpler hypotheses.

$$\text{(H7)}\quad \begin{cases} \text{There exists a family } (\phi_\varepsilon)_{\varepsilon>0} \text{ of } C^1(\mathbb{R}^N) \cap W^{1,\infty}(\mathbb{R}^N)\text{-functions, which} \\ \text{are uniformly bounded in } \varepsilon > 0 \text{ and satisfy} \\ \\ \qquad\qquad H(x, D\phi_\varepsilon) \leq \varepsilon \quad \text{in } \mathbb{R}^N\ . \end{cases}$$

(H8) For every $x \in \mathbb{R}^N$, the function $p \mapsto H(x,p)$ is locally Lipschitz.

$$\text{(H9)}\quad\begin{cases}\text{There exists a, possibly empty, compact subset } K \text{ of } \mathbb{R}^N \text{ such that}\\ \text{(i)}\ \ H(x,p)\geq 0 \text{ on } K\times\mathbb{R}^N, \text{ and}\\ \text{(ii)}\ \text{if } H(x,p)\geq\eta>0 \text{ and } d(x,K)\geq\eta, \text{ then for all sufficiently}\\ \qquad \text{small, compared to } \eta,\ \varepsilon>0,\\ H_p(x,p)\cdot(p-D\phi_\varepsilon(x))-H(x,p)\geq\psi(\eta)>0 \ \text{ for all } x \text{ and a.e. in } p.\end{cases}$$

We have the following theorem.

THEOREM 2.2. *Assume* (H1) *and* (H7)–(H9). *Then any $\mathbb{Z}^N$-periodic in x solution $u\in W^{1,\infty}(\mathbb{R}^N\times(0,\infty))$ of* (2.1) *converges, uniformly in x, as $t\to\infty$, to a $\mathbb{Z}^N$-periodic in x solution $\bar{u}$ of* (1.7).

The differences between Theorem 2.1 and Theorem 2.2 (which are not so obvious at first glance) will become clear in their proofs. Indeed, to prove Theorem 2.2 we will use Theorem 3.2, the proof of which is far simpler than the one of Theorem 3.1, which provides the key argument in the proof of Theorem 2.1.

On the other hand, for hamiltonians H, which are convex in p, and for Lipschitz continuous solutions, Theorem 2.2 is as general as Theorem 2.1 since, in particular, the existence of the ϕ_ε can be obtained from (H2) by a standard regularization argument.

Here we discuss in detail the two classes of examples presented in the introduction and show how they follow from the above theorems. We also present an example not covered by [5], [8], [9], and [10].

(i) *The Namah–Roquejoffre case.* The hamiltonian H is assumed to be of the form

$$H(x,p)=F(x,p)-f(x), \tag{2.2}$$

where

$$\begin{cases}F\in C(\mathbb{R}^N\times\mathbb{R}^N) \text{ is } \mathbb{Z}^N\text{-periodic in } x, \text{ convex in } p, \text{ and}\\ F(x,p)>F(x,0)\equiv 0 \text{ for all } x\in\mathbb{R}^N \text{ and } p\in\mathbb{R}^N\backslash\{0\},\end{cases} \tag{2.3}$$

and

$$\begin{cases}f \text{ is continuous, } \mathbb{Z}^N\text{-periodic in } x,\ f\geq 0 \text{ on } \mathbb{R}^N, \text{ and}\\ K_f=\{x\in\mathbb{R}^N : f(x)=0\} \text{ is a nonempty compact subset of } \mathbb{R}^N.\end{cases} \tag{2.4}$$

In [8] the authors considered Lipschitz continuous solutions. Hence (H1), (H3) are clearly satisfied, while (H7) is satisfied with $\phi_\varepsilon\equiv 0$. It only remains to check (H8) and (H9). To this end, we observe that the convexity of H in p yields (H8). Moreover, for all x and for almost all $p\in\mathbb{R}^N$,

$$H(x,0)\geq H(x,p)+H_p(x,p)(0-p),$$

and, hence,

$$H_p(x,p)\cdot p-H(x,p)\geq H(x,0)=f(x).$$

It follows that (H9) is satisfied with $K=K_f$. Indeed, it is clear that if $d(x,K_f)\geq\delta$, then $f(x)\geq\psi(\delta)>0$, with ψ independent of η.

Finally it is worth pointing out that the result is also true when (H7) holds with $\phi_\varepsilon\equiv\phi\in C^1(\mathbb{R}^N)\cap W^{1,\infty}(\mathbb{R}^N)$. This is a consequence of the above analysis after changing u to $u-\phi$ in the equation.

(ii) *The Fathi case and extensions.* The main assumption on H in this case is that

$$\left\{ \begin{array}{l} H \text{ is } C^1(\mathbb{R}^N \times \mathbb{R}^N) \text{ and there exists } \alpha > 0 \text{ such that} \\ \qquad\qquad D^2_{pp}H(x,p) \geq \alpha \text{ Id} \text{ in } \mathcal{D}'(\mathbb{R}^N \times \mathbb{R}^N). \end{array} \right. \tag{2.5}$$

It is immediate from (2.5), at least when $H \in C^2(\mathbb{R}^N \times \mathbb{R}^N)$, that for all $x, q \in \mathbb{R}^N$ and for almost all $p \in \mathbb{R}^N$,

$$H(x,q) \geq H(x,p) + H_p(x,p) \cdot (q-p) + \frac{\alpha}{2}|p-q|^2,$$

and, hence,

$$H_p(x,p+q) \cdot p - H(x,p+q) \geq -H(x,q) + \frac{\alpha}{2}|p|^2.$$

If $H(x,q) \leq 0$ and $H(x,p+q) \geq \eta$, it is clear that there exists $\psi(\eta) > 0$ such that $|p| \geq \psi(\eta)$. In this case we may take $K = \emptyset$ in (H9). When H is not smooth, we argue by approximations. Note that in [5] H is assumed to be smooth.

(iii) *Another example.* Consider a hamiltonian H of the form

$$H(x,p) = \psi(x,p)F\Big(x, \frac{p}{|p|}\Big) - f(x), \tag{2.6}$$

where $f \in C(\mathbb{R}^N)$ is nonnegative and $\mathbb{Z}^N$-periodic in x; $F \in C(\mathbb{R}^N \times \mathbb{R}^N \backslash \{0\})$ is continuous, strictly positive, bounded, and $\mathbb{Z}^N$-periodic in x; and $\psi(x,p) = |p + q(x)|^2 - |q(x)|^2$, where $q \in C(\mathbb{R}^N)$ is $\mathbb{Z}^N$-periodic in x. In addition we assume that for some $x_0 \in \mathbb{R}^N$, $q(x_0) = 0$ and $f(x_0) = 0$. It turns out then that $c_0 = 0$ and ϕ can be chosen to be any constant.

It is a bit tedious but straightforward to check that H satisfies the assumptions of Theorem 2.1 but neither (2.3)–(2.4) nor (2.5).

3. Some preliminary results.

Here we present two results about the behavior in time, and for large times, of solutions of (1.1). These results are of independent interest themselves. Their proofs, however, are rather technical. In order not to confuse the issue here and for the reader's convenience, we present them in the appendix.

Both results hold for hamiltonians which are not necessarily periodic in x. Instead of restating the assumption of the previous section here, without the (H1) and for any domain, we first introduce the assumption that

(H1)′ H is uniformly continuous on $\mathbb{R}^N \times \overline{B}_R$, for all $R > 0$ where $\overline{B}_R = \{p \in \mathbb{R}^N : |p| \leq R\}$

and summarize the other hypotheses as follows:

(H10) $\left\{ \begin{array}{l} \text{(H1)}', \text{(H2), (H3), and (H4) hold for } (x,p) \in \Omega \times \mathbb{R}^N, \text{ with } \Omega \text{ a given open} \\ \text{subset of } \mathbb{R}^N, \text{ and } w \in BUC(\bar{\Omega} \times [0,\infty)) \text{ a solution of (1.1) in } \Omega \times (0,\infty). \end{array} \right.$

Before we state the main result, we remark that we may assume, without any loss of generality, that

$$w - \phi \geq 1 \quad \text{in } \bar{\Omega} \times [0, +\infty). \tag{3.1}$$

Indeed, the form of H allows the change ϕ to $\phi - K$ for any constant K. Since $w \in BUC(\bar{\Omega} \times [0,\infty))$, to achieve (3.1) it suffices to choose K sufficiently large.

We also need to introduce, for $\eta > 0$, the functions

$$\mu_\eta(t) = \min_{x\in\bar{\Omega}, s\geq t}\Big[\frac{w(x,s)-\phi(x)+2\eta(s-t)}{w(x,t)-\phi(x)}\Big], \tag{3.2}$$

and

$$\chi_\eta(t) = \min_{x\in\partial\Omega, s\geq t}\Big[\frac{w(x,s)-\phi(x)+2\eta(s-t)}{w(x,t)-\phi(x)}\Big]. \tag{3.3}$$

It follows easily that μ_η, $\chi_\eta : [0,\infty) \to \mathbb{R}$ are uniformly continuous and that $0 \leq \mu_\eta \leq \chi_\eta \leq 1$. Finally, if $\Omega = \mathbb{R}^N$, we define $\chi_\eta \equiv -\infty$.

The first result is the following.

Theorem 3.1. *Assume* (H10). *Then there exists a constant C depending only on w and ϕ such that*

$$\mu_\eta(t) \geq 1 + \inf_{\theta\leq t}[(\chi_\eta(\theta)-1)e^{-C\psi(\eta)(t-\theta)}] \wedge (\mu_\eta(0)-1)e^{-C\psi(\eta)t}. \tag{3.4}$$

Moreover, if $w\big|_{\partial\Omega}$ converges, uniformly in $x \in \partial\Omega$, as $t \to \infty$, then, for all $s \geq t$ and $x \in \bar{\Omega}$,

$$w(x,t) - w(x,s) - 2\eta(s-t) \leq \delta_\eta(t),$$

where $\delta_\eta : [0,\infty) \to [0,\infty)$ is such that $\delta_\eta(t) \to 0$ as $t \to \infty$.

We continue with some preliminaries for the second result, which is also proved in the appendix. To this end, we consider the solution $w \in BUC(\overline{\Omega} \times (0,\infty))$ of the equation

$$\frac{\partial w}{\partial t} + F(x,w,Dw) = 0 \quad \text{in } \Omega \times (0,\infty), \tag{3.5}$$

where

(H11) $\qquad F$ is uniformly continuous on $\bar{\Omega} \times [-R,R] \times \bar{B}_R$, for all $R > 0$,

$$\text{(H12)}\quad \begin{cases} \text{either } w \in W^{1,\infty}(\mathbb{R}^N \times (0,\infty)) \text{ or for each } R > 0, \text{ there exists a} \\ \text{continuous function } m_R : [0,\infty) \to [0,\infty) \text{ such that } m_R(0^+) = 0 \\ \text{and, for all } x, y \in \bar{\Omega},\ p \in \mathbb{R}^N, \text{ and } w \in [-R,R], \\ \qquad |F(x,w,p) - F(y,w,p)| \leq m_R(|x-y|(1+|p|)), \end{cases}$$

and

$$\text{(H13)}\qquad \frac{\partial F}{\partial w}(x,w,p) \geq \psi(\eta) > 0 \text{ a.e., if } F(x,w,p) \geq \eta > 0.$$

To state the result we need to introduce, for $\eta > 0$, the functions

$$M_\eta(t) = \sup_{x\in\bar{\Omega}, s\geq t}[w(x,t) - w(x,s) - 2\eta(s-t)] \tag{3.6}$$

and

$$X_\eta(t) = \sup_{x\in\partial\Omega, s\geq t}[w(x,t) - w(x,s) - 2\eta(s-t)], \tag{3.7}$$

with the convention that $X_\eta = -\infty$ if $\partial\Omega = \phi$.

We have the following theorem.

THEOREM 3.2. *Assume* (H11), (H12), *and* (H13). *Then for all* $\eta > 0$ *and* $t \geq 0$,

$$M_\eta(t) = \sup_{\theta \leq t}[X_\eta(\theta)e^{-\psi(\eta)(t-\theta)}] \vee M_\eta(0)e^{-\psi(\eta)t}. \tag{3.8}$$

Moreover, if $w\big|_{\partial\Omega}$ *converges, uniformly in* $x \in \partial\Omega$, *as* $t \to \infty$, *then, for all* $s \geq t$ *and* $x \in \bar{\Omega}$, *we have*

$$w(x,t) - w(x,s) - 2\eta(s-t) \leq \delta_\eta(t),$$

where $\delta_\eta : [0,\infty) \to [0,\infty)$ *is such that* $\delta_\eta(t) \to 0$ *as* $t \to \infty$.

The conclusions of Theorems 3.1 and 3.2 are in some sense weak versions of (1.10). For the reader's convenience we present below a formal argument, which explains why (1.10) should hold.

To this end let us assume that w is a smooth solution of (3.5) in $\mathbb{R}^N \times (0,\infty)$. A straightforward application of the maximum principle yields that the function $t \mapsto \|(w_t)^-\|_\infty$ is decreasing in time. If (1.10) were not true, then there must exist some $\eta > 0$ and t_0 such that for all $t \geq t_0$,

$$\|(w_t)^-\|_\infty \geq \eta. \tag{3.9}$$

Let $z = w_t$ and $m(t) = \|z^-\|_\infty$. Differentiating (3.5) with respect to t, we find that

$$z_t + F_w(x,w,t,Dw)z + D_pF \cdot Dz = 0.$$

It then follows that

$$m' + F_w(x,w,t,Dw)m = 0.$$

Using (3.9) and (H13) we find

$$m' + \psi(\eta)m = 0,$$

which yields

$$m(t) = m(t_0)e^{-\psi(\eta)(t-t_0)}.$$

Letting $t \to \infty$ contradicts (3.9).

4. The proofs of Theorems 2.1 and 2.2. We begin with the following proof.

Proof of Theorem 2.1. 1. Assumption (H5) yields that u is decreasing on K and, hence, $u\big|_K$ converges, uniformly in x, as $t \to \infty$.

2. Consider the function χ_η defined by (3.3), with $\Omega = (K_\eta)^c$, where, for $\eta > 0$, $K_\eta = \{x \in \mathbb{R}^N : d(x,K) \geq \eta\}$. Step 1 and the uniform of continuity of u then imply that

$$\varliminf_{t\to\infty} \chi_\eta(t) \geq 1 - \nu(\eta), \quad \text{where} \quad \nu(\eta) \to 0 \quad \text{as} \quad \eta \to 0.$$

Using this last observation and applying Theorem 3.1 we obtain that

$$\varliminf_{t\to\infty} \mu_\eta(t) \geq 1 - \tilde{\nu}(\eta), \quad \text{where} \quad \tilde{\nu}(\eta) \to 0 \quad \text{as} \quad \eta \to 0.$$

Therefore, for all $s > 0$ and for all $(x,t) \in (K_\eta)^c \times [0,s]$, we have

$$u(x,t) - u(x,s) - 2\eta(s-t) \le \tilde{\delta}_\eta(t), \tag{4.1}$$

where

$$\overline{\lim_{t\to\infty}}\, \tilde{\delta}_\eta(t) \le \tilde{\nu}(\eta).$$

3. Since the family $(u(\cdot,t))_{t\ge 0}$ is compact in $BUC(\mathbb{R}^N)$ and the functions $u(\cdot,t)$ are periodic in x for all t, we may consider a subsequence $u(\cdot,T_n)$, with $T_n \to +\infty$, converging uniformly in $\mathbb{R}^N$.

The maximum principle for viscosity solutions implies that for any $n,p \in \mathbb{N}$, we have

$$\|u(\cdot,T_n+\cdot) - u(\cdot,T_p+\cdot)\|_{L^\infty(\mathbb{R}^N\times(0,\infty))} \le \|u(\cdot,T_n) - u(\cdot,T_p)\|_{L^\infty(\mathbb{R}^N)}\ . \tag{4.2}$$

It follows from this inequality that $(u(\cdot,T_n+\cdot))_n$ is a Cauchy sequence in $BUC(\mathbb{R}^N\times(0,\infty))$ and therefore it converges uniformly to a function $u_\infty \in BUC(\mathbb{R}^N\times(0,\infty))$.

4. Using (4.1) we find, for all $0 \le t \le s$ and for all $x \in (K_\eta)^c$,

$$u(x,t+T_n) - u(x,s+T_n) - 2\eta(s-t) \le \tilde{\delta}_\eta(t+T_n).$$

Letting $n\to\infty$ and then $\eta \to 0$ yields, for all $0 \le t \le s$ and for all $x \in (K)^c$,

$$u_\infty(x,t) - u_\infty(x,s) \le 0, \tag{4.3}$$

i.e., that u_∞ is increasing in t for $x \in (K)^c$.

On an other hand, step 1 yields that $u\big|_K$ converges, uniformly in x, as $t\to\infty$. Hence u_∞ is constant in time on K.

5. The stability property of viscosity solutions applied to the sequence $(u(\cdot,T_n+\cdot))_n$ then implies that u_∞ is a solution of

$$(u_\infty)_t + H(x,Du_\infty) = 0 \quad \text{in} \quad \mathbb{R}^N\times(0,\infty),$$

and, since u_∞ is increasing in t for all $x\in\mathbb{R}^N$,

$$H(x,Du_\infty(\cdot,t)) \le 0 \quad \text{in } \mathbb{R}^N\times\{t\} \text{ and for all } t>0.$$

Again, the stability implies

$$H(x,Du_\infty(\cdot,0)) \le 0 \quad \text{in } \mathbb{R}^N.$$

This last assertion shows that *any function in the ω-limit set of u is a subsolution of the stationary equation in $\mathbb{R}^N$.*

6. The uniform convergence of $u(\cdot,T_n+\cdot)$ to u_∞ on $\mathbb{R}^N\times(0,\infty)$ yields

$$-o_n(1) + u_\infty(x,t) \le u(x,T_n+t) \le u_\infty(x,t) + o_n(1) \quad \text{in } \mathbb{R}^N. \tag{4.4}$$

Since $u_\infty \in BUC(\mathbb{R}^N\times(0,\infty))$ is increasing with respect to t, it follows that $u_\infty(\cdot,t) \to \overline{u}(\cdot)$, uniformly in x, as $t\to\infty$.

Finally, taking the relaxed half-limits $\limsup^*$ and $\liminf_*$ in t[1] in (4.4) yields

$$-o_n(1) + \overline{u}(x) \le \underline{\lim}_* u(x) \le \overline{\lim}^* u(x) \le \overline{u}(x) + o_n(1) \quad \text{in } \mathbb{R}^N.$$

[1] For $z \in BUC(\mathbb{R}^N\times(0,\infty))$, $\limsup^* z(x) = \limsup_{\substack{y\to x\\ t\to\infty}} z(y,t)$ and $\liminf_* z(x) = \liminf_{\substack{y\to x\\ t\to\infty}} z(y,t)$.

Letting $n \to +\infty$, we obtain

$$\underline{\lim}_* u = \overline{\lim}^* u = \overline{u} \quad \text{in } \mathbb{R}^N,$$

which yields the *uniform convergence of* $u(\cdot,t)$ *to* $\overline{u}(\cdot)$ *as* $t \to \infty$.

7. Finally, by the stability result, the limit of u, as $t \to \infty$, which we still denote by $\overline{u}$, is a (viscosity) solution of $H(x, D\overline{u}) = 0$ in $\mathbb{R}^N$.

We continue with the following proof.

Proof of Theorem 2.2. 1. For each $\epsilon > 0$, we define

$$w^\varepsilon = -\exp[-(u - \phi_\varepsilon)].$$

It is then immediate that

$$w_t^\epsilon + F(x, w^\epsilon, Dw^\epsilon) = 0 \quad \text{in } \mathbb{R}^N \times (0,\infty),$$

where, for $x, p \in \mathbb{R}^N$ and $w \in \mathbb{R}$,

$$F(x,w,p) = -wH\left(x, -\frac{p}{w} + D\phi_\epsilon(x)\right). \tag{4.5}$$

After this change of variable, the proof consists essentially in following readily the proof of Theorem 2.1, replacing only the use of Theorem 3.1 by the use of Theorem 3.2.

2. It is straightforward to verify that F satisfies assumptions (H11), (H12), and (H13) of Theorem 3.2. Therefore, for all $\eta > 0$, for all $x \in (K_\eta)^c$, and for all $t \geq 0$, we have

$$w_\epsilon(x,t) - w_\epsilon(x,s) - \eta(s-t) \leq \tilde{\delta}_\eta(t)\ , \tag{4.6}$$

where $\tilde{\delta}_\eta(t) \to 0$ as $t \to +\infty$.

3. The functions w_ε are uniformly bounded, since u is bounded and the ϕ_ε's are uniformly bounded in ε. Since

$$u(x,t) - u(x,s) = -\log(-w_\epsilon(x,t)) + \log(-w_\epsilon(x,s))\ ,$$

there exists a constant $\tilde{C} > 0$ such that, for all $x \in (K_\eta)^c$ and for all $s \geq t$, we have

$$u(x,t) - u(x,s) \leq \tilde{C}\left[\eta(s-t) + \tilde{\delta}_\eta(t)\right]\ .$$

4. Using this last inequality, the conclusion follows by applying readily the arguments of the proof of Theorem 2.1.

5. Remarks and extensions. A natural question is whether one needs an assumption like, for example, (H4)$'$, on H. The example of the eikonal equation

$$u_t + |Du| = 0 \quad \text{in } \mathbb{R}^N \times (0,+\infty) \tag{5.1}$$

shows that, if we restrict our attention to convex hamiltonians, (H5)(ii) is not necessary to obtain the convergence. Indeed, in this example, we can apply either the result of [8] or Theorem 2.1, since assumption (H5)(i) holds with $K = \mathbb{R}^N$.

The following one-dimensional example shows, however, that, except for equations like (5.1), such an extension does not seem to be possible. Indeed, consider the problem

$$\begin{cases} u_t + |u_x + \alpha| - |\alpha| = 0 & \text{in } \mathbb{R} \times (0,+\infty), \\ u(x,0) = \sin(x) & \text{in } \mathbb{R}. \end{cases} \tag{5.2}$$

If $\alpha > 1$ it is easily checked that the unique viscosity solution of (5.2) is

$$u(x,t) = \sin(x-t) \ ,$$

which is clearly in $W^{1,\infty}(\mathbb{R}^N \times (0,+\infty))$ but does not converge as $t \to +\infty$. For the hamiltonian $H(p) = |p+\alpha| - |\alpha|$, the quantity $H_p \cdot p - H$ vanishes for p such that $\alpha(p+\alpha) \geq 0$ and, therefore, it does not satisfy any of the (H4)-type assumptions.

On the contrary, we remark that Theorem 2.2 applies to the equation

$$u_t + |u_x + \alpha|^2 - |\alpha|^2 = 0 \quad \text{in } \mathbb{R} \times (0,+\infty) \ ,$$

which essentially has the same limiting equation as (5.2), in the sense that both limiting equations have the same viscosity solutions. This example shows that some kind of strict convexity-type property is really playing a role in the asymptotic behavior of the solutions of Hamilton–Jacobi equations.

Typically assumption (H4)$'$ implies that the set $\{p \in \mathbb{R}^N : H(x,p+q) \leq 0\}$ is starshaped. This geometric condition alone does not seem to be sufficient as is shown by (5.2) above. On the other hand, if H is strictly convex and $c_0 = 0$, then any function F which equals H on the set $\{H > 0\}$ and is strictly negative on the set $\{H < 0\}$ satisfies the assumptions of Theorem 2.1.

Appendix. To prove Theorem 3.1 we need the following.

LEMMA A.1. *Under the assumptions of Theorem* 3.1, *the function* μ_η *defined by* (3.2) *is a viscosity solution of the variational inequality*

$$\max(\mu_\eta'(t) + C\psi(\eta)(\mu_\eta(t) - 1), \mu_\eta(t) - \chi_\eta(t)) \geq 0 \quad \textit{in } (0,+\infty). \tag{A.1}$$

Assuming for the moment this lemma we proceed with the following.

Proof of Theorem 3.1. 1. The first part of the claim follows from the facts that (A.1) admits a comparison principle and the right-hand side of (3.4) is a solution of the variational inequality (A.1) with initial datum $\mu_\eta(0)$.

2. The uniform convergence of $w\big|_{\partial\Omega}$ implies that $\chi_\eta(t) \to 1$ as $t \to \infty$. Then (3.4) yields that $\mu_\eta(t) \to 1$ as $t \to \infty$.

It then follows for all $x \in \overline{\Omega}$ and all $s \geq t$ that

$$\mu_\eta(t)(w(x,t) - \phi(x)) - w(x,s) + \phi(x) - 2\eta(s-t) \leq 0,$$

and, hence,

$$w(x,t) - w(x,s) - 2\eta(s-t) \leq \max_{x \in \bar{\Omega}}((1-\mu_\eta(t))(w(x,t) - \phi(x)).$$

It is now clear that the right-hand side of this last inequality tends to 0 as $t \to \infty$. □

Proof of Lemma A.1. 1. Let $\widetilde{\psi} \in C^1((0,+\infty))$ and t be a strict local minimum point of $\mu - \widetilde{\psi}$. Since there is nothing to check if $\mu_\eta(t) \geq \chi_\eta(t)$, we may assume that $\mu_\eta(t) < \chi_\eta(t)$, and, in particular, $\mu_\eta(t) < 1$.

2. For $\varepsilon > 0$ and $\alpha > 0$ we introduce the function

$$\Psi^{\varepsilon,\alpha}(x,y,z,t,s) = \frac{w(x,s) - \phi(z) + 2\eta(s-t)}{w(y,t) - \phi(z)} + \frac{|x-y|^2}{2\varepsilon} + \frac{|x-z|^2}{2\varepsilon} - \widetilde{\psi}(t) + \alpha|x|^2.$$

Classical arguments from the theory of viscosity solutions (see, for example, Barles [3]) yield that the function $\Psi^{\varepsilon,\alpha}$ achieves its minimum over $\overline{\Omega}\times\overline{\Omega}\times\overline{\Omega}\times\{(\tau,s)\backslash s\geq \tau, \tau\in[t-\delta,t+\delta]\}$ at some point $(\bar x,\bar y,\bar z,\bar t,\bar s)$ (as usual we drop the dependence of $\bar x,\bar y,\bar z,\bar t$, and $\bar s$ in ε and α for the sake of simplicity of notations). Moreover, as $(\varepsilon,\alpha)\to(0,0)$, we have

$$\text{(A.2)}\qquad \begin{cases} \text{(i)}\ \ \bar\mu = \dfrac{w(\bar x,\bar s)-\phi(\bar z)+2\eta(\bar s-\bar t)}{w(\bar y,\bar t)-\phi(\bar z)} \to \mu_\eta(t), \\[2ex] \text{(ii)}\ \ \dfrac{|\bar x-\bar y|^2}{2\varepsilon},\quad \dfrac{|\bar x-\bar z|^2}{2\varepsilon}\to 0,\ \ \alpha|\bar x|^2\to 0, \\[2ex] \text{and} \\[2ex] \text{(iii)}\ \ \bar s>\bar t \text{ and } \bar x,\bar y,\bar z\in\Omega \text{ for } \varepsilon \text{ and } \alpha \text{ small enough,} \end{cases}$$

with the last point being a consequence of the inequality $\mu_\eta(t)<\chi_\eta(t)$.

3. Set

$$\text{(A.3)}\qquad P=\frac{1}{\bar\mu}\frac{(\bar y-\bar x)}{\varepsilon}(w(\bar y,\bar t)-\phi(\bar z)) \ \text{ and }\ Q=\frac{1}{1-\bar\mu}\frac{(\bar z-\bar x)}{\varepsilon}(w(\bar y,\bar t)-\phi(\bar z)).$$

The viscosity inequalities for $w(x,s)$, $w(y,t)$, and ϕ are

$$\text{(A.4)}\qquad \begin{cases} \text{(i)}\ \ -2\eta+H(\bar x,\bar\mu P+(1-\bar\mu)Q+2\alpha\bar x(w(\bar y,\bar t)-\phi(\bar z)))\geq 0, \\[2ex] \text{(ii)}\ \ -\widetilde{\psi}'(\bar t)(w(\bar y,\bar t)-\phi(\bar z))-2\eta\bar\mu^{-1}+H(\bar y,P)\leq 0, \\[2ex] \text{and} \\[2ex] \text{(iii)}\ \ H(\bar z,Q)\leq 0. \end{cases}$$

Using (A.2(ii)) and (A.2(iii)), we may rewrite (A.4) as

$$\text{(A.5)}\qquad \begin{cases} \text{(i)}\ \ -2\eta+H(\bar z,\bar\mu P+(1-\bar\mu)Q)+\tilde n_\varepsilon(\alpha)+\xi(\varepsilon,\alpha)\geq 0, \\[2ex] \text{(ii)}\ \ -\widetilde{\psi}'(\bar t)(w(\bar y,\bar t)-\phi(\bar z))-2\eta\bar\mu^{-1}+H(\bar z,P)-\xi(\varepsilon,\alpha)\leq 0, \\[2ex] \text{and} \\[2ex] \text{(iii)}\ \ H(\bar z,Q)\leq 0, \end{cases}$$

where $\tilde n_\varepsilon(\alpha)\to 0$ when $\alpha\to 0$ if ε is fixed and $\xi(\varepsilon,\alpha)\to 0$ when $(\varepsilon,\alpha)\to(0,0)$.

4. Set

$$\widetilde{P}=\bar\mu(P-Q).$$

If ε and α are chosen sufficiently small and α is small compared to ε, then (A.5(i)) yields

$$H(\bar z,\widetilde{P}+Q)\geq\eta\,,$$

while (A.5(iii)) reads

$$H(\bar{z}, Q) \leq 0.$$

Moreover, again if ε and α are chosen small enough, (A.2(i)) implies that $0 < \bar{\mu} < 1$. Assumption (H4) with $\mu = \bar{\mu}$ then yields

$$\bar{\mu} H(\bar{z}, P) \geq H(\bar{z}, \widetilde{P} + Q) + \psi(\eta)(1 - \bar{\mu}). \tag{A.6}$$

Dividing (A.5(i)) by $\bar{\mu}$ and subtracting (A.5(ii)) we obtain

$$\widetilde{\psi}'(\bar{t})(w(\bar{y}, \bar{t}) - \phi(\bar{z})) + \frac{1}{\bar{\mu}} H(\bar{z}, \widetilde{P} + Q) - H(\bar{z}, P) \geq -\tilde{n}_\varepsilon(\alpha) - \xi(\varepsilon, \alpha)\Big(\frac{1}{\bar{\mu}} + 1\Big), \tag{A.7}$$

and, in view of (A.6),

$$\widetilde{\psi}'(\bar{t})(w(\bar{y}, \bar{t}) - \phi(\bar{z})) + \frac{\psi(\eta)(\bar{\mu} - 1)}{\bar{\mu}} \geq -\tilde{n}_\varepsilon(\alpha) - \xi(\varepsilon, \alpha)\Big(\frac{1}{\bar{\mu}} + 1\Big). \tag{A.8}$$

Dividing by $w(\bar{y}, \bar{t}) - \phi(\bar{z}) \geq 1$, and letting $\alpha \to 0$ and then $\varepsilon \to 0$ we obtain

$$\widetilde{\psi}'(t) + C\psi(\eta) \frac{(\mu_\eta(t) - 1)}{\mu_\eta(t)} \geq 0.$$

Since $0 \leq \mu_\eta(t) \leq 1$, this reduces to

$$\widetilde{\psi}'(t) + C\psi(\eta)(\mu_\eta(t) - 1) \geq 0. \qquad \square$$

We continue with the following proof.

Proof of Theorem 3.2. Since the variational inequality (A.9) below admits a comparison principle, the conclusion follows immediately from the lemma which is stated and proved below. □

LEMMA A.2. *Under the assumptions of Theorem* 2.2, *the function* M_η *defined by* (3.6) *is a viscosity subsolution of the variational inequality*

$$\min[M' + \psi(\eta) M, M - X_\eta] \leq 0 \quad \textit{in } (0, \infty). \tag{A.9}$$

Proof. 1. M_η is clearly positive, as it can be seen by letting $s = t$, uniformly continuous, and bounded, since $w \in BUC(\mathbb{R}^N \times (0, \infty))$.

2. Let $\Phi \in C^1((0, \infty))$ and assume that τ is a local maximum point of $M_\eta - \Phi$ in $[\tau - \delta, \tau + \delta]$ for some $\delta > 0$. Since there is nothing to show if $M_\eta(\tau) \leq X_\eta(\tau)$, we may assume that $M_\eta(\tau) > X_\eta(\tau) \geq 0$.

3. Consider, for $x, y \in \mathbb{R}^N$, $t \in [\tau - \delta, \tau + \delta]$, and $s \geq t$, the function

$$\Psi^{\varepsilon,\alpha}(x, y, t, s) = w(x, t) - w(y, s) - \frac{|x - y|^2}{2\varepsilon^2} - 2\eta(s - t) - \alpha(|x|^2 + |y|^2) - \Phi(t).$$

Classical arguments from the theory of viscosity solutions yield (see [3]) that the function $\Psi^{\varepsilon,\alpha}$ achieves its maximum at some point $(\bar{x}, \bar{y}, \bar{t}, \bar{s})$ and that, when $(\varepsilon, \alpha) \to (0,0)$,

$$\text{(A.10)} \qquad \begin{cases} \text{(i)} \;\; \Psi^{\varepsilon,\alpha}(\bar{x}, \bar{y}, \bar{t}, \bar{s}) \to M_\eta(\tau), \\[2ex] \text{(ii)} \;\; \alpha(|\bar{x}|^2 + |\bar{y}|^2) \to 0, \; \dfrac{|\bar{x} - \bar{y}|^2}{\varepsilon^2} \to 0, \\[2ex] \text{(iii)} \;\; w(\bar{x}, \bar{t}) - w(\bar{y}, \bar{s}) > M_\eta(\bar{t}), \\[2ex] \text{and} \\[2ex] \text{(iv)} \;\; \bar{x}, \bar{y} \in \Omega \text{ and } |\bar{t} - \bar{s}| > 0, \text{ for } (\varepsilon, \alpha) \text{ small, since} \\ \qquad M_\eta(\tau) > X_\eta(\tau) \geq 0. \end{cases}$$

Using (H12) and (H13) we may rewrite the viscosity inequalities

$$\Phi'(\bar{t}) - 2\eta + F(\bar{x}, w(\bar{x}, \bar{t}),\ p + 2\alpha\bar{x}) \leq 0 \quad \text{and} \quad -2\eta + F(\bar{y}, w(\bar{y}, \bar{s}),\ p - 2\alpha\bar{y}) \geq 0,$$

where $p = \frac{(\bar{x} - \bar{y})}{\varepsilon^2}$ as

$$\text{(A.11)} \begin{cases} \text{(i)} \;\; \Phi'(\bar{t}) - 2\eta + F(\bar{x}, w(\bar{x}, \bar{t}), \bar{p}) + \tilde{n}_\varepsilon(2\alpha|\bar{x}|) \leq 0 \\[2ex] \text{and} \\[2ex] \text{(ii)} \;\; -2\eta + F(\bar{x}, w(\bar{y}, \bar{s}), \bar{p}) + m_R(|\bar{x} - \bar{y}|(1 + |p|)) + \tilde{n}_\varepsilon(2\alpha|\bar{y}|) \geq 0. \end{cases}$$

Using (A.10(ii)) we obtain that $F(\bar{x}, w(\bar{y}, \bar{s}), \bar{p}) > \eta$ for α and ε small enough. Since $w(\bar{x}, \bar{t}) \geq w(\bar{y}, s)$, using sufficiently small ε and α in (A.10(iii)) and (H10), yields

$$F(\bar{x}, w(\bar{x}, \bar{t}), \bar{p}) - F(\bar{x}, w(\bar{y}, \bar{s}), \bar{p}) \geq \psi(\eta)(w(\bar{x}, \bar{t}) - w(\bar{y}, \bar{s})) \geq \psi(\eta) M_\eta(\bar{t}).$$

Finally, subtracting (A.11(ii)) for (A.11(i)) we obtain

$$\Phi'(\bar{t}) + \psi(\eta) M_\eta(\bar{t}) + \tilde{n}_\varepsilon(\alpha) + \widetilde{m}(\varepsilon) \leq 0,$$

and we conclude, letting first $\alpha \to 0$ and then $\varepsilon \to 0$. □

THE SHAPE OF THE TALLEST COLUMN: CORRECTED*

STEVEN J. COX† AND C. MAEVE MCCARTHY‡

Abstract. Our summary of the work of Keller and Niordson (*J. Math. Mech.* 16, pp. 433–446, 1966) was inaccurate. We offer a correction.

Key words. isolated eigenvalue, continuous spectrum

AMS subject classifications. 35L15, 49J99, 73H05

PII. S0036141099354958

Our criticism [1] of the work of Keller and Niordson [2] was not accurate. Following Proposition 2.1 on page 549 of [1] we stated that "Keller and Niordson's calculation of $c = \lambda_1/24$ suggests that their design gives rise to an isolated eigenvalue, $\lambda_1 = 24c$, just below the continuous spectrum." We followed this statement with the misrepresentation "Their result, however, was predicated on the false assumption that (2.4) possessed a purely discrete spectrum." We wish to replace this statement with "Their result, however, assumed the existence, that cannot be taken for granted, of such an isolated eigenvalue for a in a neighborhood of the optimal design." We regret the misrepresentation.

NONCLASSICAL SHOCKS AND KINETIC RELATIONS: STRICTLY HYPERBOLIC SYSTEMS*

BRIAN T. HAYES[†] AND PHILIPPE G. LEFLOCH[‡]

Abstract. We consider strictly hyperbolic systems of conservation laws whose characteristic fields are not genuinely nonlinear, and we introduce a framework for the nonclassical shocks generated by diffusive or diffusive-dispersive approximations. A nonclassical shock does not fulfill the Liu entropy criterion and turns out to be undercompressive.

We study the Riemann problem in the class of solutions satisfying a single entropy inequality, the only such constraint available for general diffusive-dispersive approximations. Each nongenuinely nonlinear characteristic field admits a *two-dimensional wave set*, instead of the classical one-dimensional wave curve. In specific applications, these wave sets are narrow and resemble the classical curves. We find that even in strictly hyperbolic systems, nonclassical shocks with arbitrarily small amplitudes occur. The Riemann problem can be solved uniquely using nonclassical shocks, provided an additional constraint is imposed: we stipulate that the entropy dissipation across any nonclassical shock be a given constitutive function. We call this admissibility criterion a *kinetic relation*, by analogy with similar laws introduced in material science for propagating phase boundaries. In particular, the kinetic relation may be expressed as a function of the propagation speed. It is derived from traveling waves and, typically, depends on the ratio of the diffusion and dispersion parameters.

Key words. conservation laws, hyperbolic entropy, shock wave, kinetic relation, nonclassical shock

1. Introduction.

In this paper, we consider discontinuous solutions to hyperbolic systems of conservation laws that do not fulfill the classical entropy criteria, carrying over to systems the discussion we initiated in [22] for scalar equations with nonconvex fluxes. We develop a framework for the existence and uniqueness of the *nonclassical* shock waves that arise as limits of diffusive-dispersive approximations. It is natural to constrain the solutions to the hyperbolic system with an entropy inequality for a *single*, strictly convex entropy pair. This condition is weaker than the Liu [41] entropy criterion.

A *nonclassical shock* is defined as one that does not satisfy the Liu criterion. It turns out that such a shock is *undercompressive*: the number of characteristics impinging on the discontinuity is smaller than that imposed by the (classical) Lax shock inequalities. Such waves are underdetermined (in the sense of linear analysis) and sensitive to the form of the diffusive-dispersive mechanism.

The focus of this work is on strictly hyperbolic systems where one (or more) characteristic field lacks genuine nonlinearity, such as those describing the dynamics of elastic materials or magnetic fluids. A key observation is that undercompressive shocks may arise for such systems through balanced diffusive and dispersive mechanisms: this

is the case even for shocks having *arbitrary small* amplitude. We concentrate here on the Riemann problem which is fundamental in the theory of conservation laws. A typical Riemann solution combines classical (shock and rarefaction) waves and nonclassical shocks. The numerical analysis of nonclassical shocks is investigated in a companion paper [23].

We build here upon extensive activity on undercompressive waves for nonstrictly hyperbolic systems and systems with change of type. In the examples studied in the literature, the undercompressive waves have finite strength; they were found to be necessary in order to solve the Riemann problem and, therefore, reflect a property of the flux-function of the system. We refer the reader to Azevedo et al. [3], Freistühler [18], Isaacson, Marchesin, and Plohr [28], Isaacson et al. [27], Keyfitz [31], Liu and Zumbrun [46, 47], Schecter and Shearer [52], Slemrod [59], and the references therein.

The basic concepts and the analysis of the traveling waves associated with such nonstandard discontinuities and a resolution of the Riemann problem for some mathematical models can be also found in [28, 32, 44, 45, 58]. The large-time asymptotic stability of under- or overcompressive shocks (the number of impinging characteristics in the latter is larger) is proven in [19, 43, 46, 47]. Liu and Zumbrun observe [47] that, for undercompressive shocks, the asymptotic state for large times cannot be determined solely from the mass of the initial perturbation, but must also take into account the diffusive effects of a parabolic augmented system of equations.

Several examples from continuum mechanics are known to exhibit undercompressive shocks. The system of magnetohydrodynamics lacks both genuine nonlinearity and strict hyperbolicity (Brio and Wu [5]). It has been observed numerically, as well as analytically, that nonstandard shock waves not fulfilling the classical entropy criteria arise with certain approximations.

MHD shocks may be either undercompressive or overcompressive. Those shocks are called nonstandard or intermediate in the MHD literature and are critical to the understanding of important phenomena such as the effect of the solar wind (Wu [63]). For various results on the Riemann problem for a rotationally invariant model in MHD, we refer to [4, 6, 8, 17, 32, 65]. See also [21] for another model. There is also an extensive literature on phase boundaries in materials admitting phase transformations of the austenite-martensite type. When the stress-strain relation for a material is decreasing on an interval, the system of elastodynamics is of the hyperbolic-elliptic type. Propagating phase boundaries are still another example of undercompressive waves. They are fundamental to understanding phase transformation processes. See [15, 26, 56, 57, 59] as well as [1, 2, 38, 61, 62]. See also [48] for a general review on the nonlinear waves arising in fluids and materials, with or without phase transitions.

A pioneering study of the effect of vanishing diffusion and dispersion terms in scalar conservation laws can be found in Schonbek [53] using the compensated compactness method. She proved a convergence theorem toward weak solutions. LeFloch and Natalini [39] used the concept of measure-valued solution and established convergence results assuming that the diffusion dominates the dispersion.

The works by Wu [64] and Jacobs, McKinney, and Shearer [30] established the first existence result of undercompressive shocks for the modified KdV–Burgers equation and motivated us in [22].

The present series of papers [22, 23] is intended as a contribution toward unifying ideas behind some of the above works. We pursue a better understanding of simple models giving rise to undercompressive shocks. Deriving entropy criteria for their selection is one of the main challenges in the field. The classical criteria developed by Dafermos [10, 11, 12], Lax [34, 35], Liu [41, 42], Oleinik [50], etc., cannot be applied directly. In contrast to previous works, we focus here primarily on strictly hyperbolic systems having nongenuinely nonlinear characteristic fields.

Given a strictly convex entropy pair, we first endeavor to describe the set of all solutions to the Riemann problem that satisfy a single entropy inequality. Allowing nonclassical shocks leads to a lack of uniqueness for the Riemann problem and a *multi-parameter family* of solutions can be constructed. Our construction is an extension to Liu's theorem on the resolution of the Riemann problem which was based on what is now called the Liu criterion. This analysis provides a complete description of all the Riemann solutions generated by any diffusive-dispersive approximation compatible with a given entropy pair (section 2). We observe that characterizing limits of approximate sequences of solutions to hyperbolic systems via pointwise relations on the propagating discontinuities in the limiting solution may not be possible in the most general situation (see, for instance, Glimm [20] and LeFloch and Tzavaras [40]). In this regard, our analysis is pertinent toward describing the *set* of all possible such limits. In our presentation, pointwise constraints are added afterward.

Next we investigate a way of selecting a unique nonclassical solution. We propose to make the selection based on the entropy dissipation, which is a fundamental quantity from both mathematical and physical standpoints. We stipulate that the entropy dissipation of a nonclassical shock be a given function, the "kinetic function." It may be assumed, for instance, that the kinetic function depends only on the *speed of the nonclassical shock*. We call such an admissibility criterion a *kinetic relation* by analogy with similar laws introduced in material science.

Therefore this generalizes to strictly hyperbolic systems the notion of kinetic relation known for the hyperbolic-elliptic system of phase transitions (Abeyaratne and Knowles [1, 2] and Truskinovsky [61, 62]; see also LeFloch [38]) and for nonconvex scalar conservation laws (Hayes and LeFloch [22] and Kulikovsky [33]). The paper by Truskinovsky [62] includes a review of these issues in material science.

In section 2, we construct a unique solution to the Riemann problem in the class of nonclassical solutions when the kinetic relation is enforced. For some Riemann data choosing between the classical solution and the nonclassical one may be still necessary (see section 2). When a specific augmented system including diffusive/dispersive effects is provided, the entropy dissipation and therefore the kinetic function can be determined. Small-scale effects neglected in the mathematical modeling at the hyperbolic level are essential to understanding the behavior of nonclassical shocks. The kinetic function can be obtained from the equation of the traveling wave solutions associated with the diffusive-dispersive model.

Classical and nonclassical shock are very different in nature. The classical shocks are associated with the continuum spectrum of the traveling wave equation and the nonclassical shocks with its discrete spectrum. Typically, given a (left) state, and restricting attention to a given wave family, there exists a one-parameter family of right states that can be attained with a classical shock, but a single right state can be attained by a nonclassical shock.

In several systems arising in the applications in continuum mechanics, the entropy dissipation is related to the total energy and may be viewed as a force driving the propagation of the nonclassical propagating discontinuities. We also consider here the Riemann problems with large amplitude for two specific examples of interest: a system from nonlinear elastodynamics based on a nonconvex strain-stress law, which is a strictly hyperbolic system with two nongenuinely nonlinear fields (sections 3 and 4), and a model from magnetohydrodynamics, which has an umbilic point and one linearly degenerate characteristic field (section 5). In these examples we demonstrate numerically that certain diffusive-dispersive approximations generate nonclassical shocks.

The kinetic relation may be used in the design of a numerical scheme consistent with the underlying regularization, avoiding the (costly) resolution of small-scale effects. Hou, LeFloch, and Rosakis [25] proposed recently, for computing propagating phase boundaries in a two-dimensional plate, a consistent method based on the level set formulation. For difference schemes generating nonclassical shocks, one can consult [23, 24].

2. A framework for nonclassical shocks in systems.

2.1. Preliminaries. Here we shall motivate the definition of nonclassical solution. Consider a system of hyperbolic conservation laws:

$$\partial_t u + \partial_x f(u) = 0, \qquad u(x,t) \in \mathcal{U}, \tag{2.1}$$

where $\mathcal{U}$ is a convex and open subset of $\mathbb{R}^N$ and the flux-function $f : \mathcal{U} \to \mathbb{R}^N$ is a smooth mapping. We assume that the system is endowed with a strictly convex entropy pair (U, F); that is, $\nabla F^T = \nabla U^T Df$ and $\nabla^2 U(u) \geq C\, Id$ with $C > 0$. This, in particular, implies that the system is hyperbolic, although not necessarily strictly hyperbolic.

Suppose that the "good" solutions to (2.1) according to some underlying physical interpretation are to be obtained as limits of a diffusive-dispersive approximation scheme of the form

$$\partial_t u_\epsilon + \partial_x f(u_\epsilon) = \epsilon\, \partial_x\big(B_1(u_\epsilon)\partial_x u_\epsilon\big) + \epsilon^2\, \partial_x\big(B_2(u_\epsilon)\partial_{xx} u_\epsilon\big) \tag{2.2}$$

as $\epsilon \to 0$ ($\epsilon > 0$). When B_1 and B_2 are $N \times N$ matrix-valued functions, the regularization (2.2) (together with the conditions (2.3) below) describes one large class of systems, which includes the examples in the applications we will be interested in. (The important issue of the existence of a solution u_ϵ satisfying (2.2) is out of the scope of the present paper.)

We shall say that the pair (U, F) is *compatible* with the approximation scheme (2.2) if the following conditions hold:

• The first term in the right-hand side of (2.2) is *dissipative* for the entropy U, in the sense that

$$\nabla^2 U(v) B_1(v) \text{ is a positive matrix for all } v \in \mathcal{U}. \tag{2.3i}$$

• The second term in (2.2) is *conservative* for U, in the sense that there exist $N \times N$ matrix-valued functions B_3 and B_4 such that

$$\partial_x v^T \nabla^2 U(v)^T B_2(v) \partial_{xx} v \;=\; \partial_t\big(\partial_x v^T B_3(v) \partial_x v\big) \;+\; \partial_x\big(\partial_x v^T B_4(v) \partial_x v\big) \tag{2.3ii}$$

for any solution $v : \mathbb{R} \times \mathbb{R}_+ \to \mathcal{U}$ to (2.2), and

$$B_3(v) \text{ is a nonnegative matrix for all } v \in \mathcal{U}. \tag{2.3iii}$$

Note in passing that trivial linear entropies always satisfy (2.3) but are of no use for our purpose of selecting solutions to (2.1). When (2.3) holds and $\partial_x u_\epsilon$ vanishes at infinity, one can (formally) derive from (2.2) an entropy inequality. Indeed we obtain

$$\begin{aligned}\partial_t\big(U(u_\epsilon) + {}& \epsilon^{\,2}\,\partial_x u_\epsilon^T B_3(u_\epsilon)\partial_x u_\epsilon\big) + \partial_x F(u_\epsilon)\\ ={}& \epsilon\,\partial_x\big(\nabla U(u_\epsilon)^T B_1(u_\epsilon)\partial_x u_\epsilon\big) - \epsilon\,\partial_x u_\epsilon \nabla^2 U(u_\epsilon) B_1(u_\epsilon)\partial_x u_\epsilon\\ &+ \epsilon^2\,\partial_x\big(\nabla U(u_\epsilon)^T B_2(u_\epsilon)\partial_{xx} u_\epsilon\big) - \epsilon^2\,\partial_x\big(\partial_x u_\epsilon B_4(u_\epsilon)\partial_x u_\epsilon\big),\end{aligned}$$

which yields the balance law

$$\begin{aligned}\int_{\mathbb{R}} U(u_\epsilon(t))\,dx \,+\, \epsilon^2 \int_{\mathbb{R}} &\partial_x u_\epsilon(t)^T B_3(u_\epsilon(t))\partial_x u_\epsilon(t)\,dx\\ &+ \epsilon \int_0^t \int_{\mathbb{R}} \partial_x u_\epsilon^T \nabla^2 U(u_\epsilon) B_1(u_\epsilon)\partial_x u_\epsilon\,dxds\\ &= \int_{\mathbb{R}} U(u_\epsilon(0))\,dx \,+\, \epsilon^2 \int_{\mathbb{R}} \partial_x u_\epsilon(0)^T B_3(u_\epsilon(0))\partial_x u_\epsilon(0)\,dx\end{aligned} \tag{2.4}$$

for all $t \geq 0$ and an entropy inequality for $u = \lim_{\epsilon\to 0} u_\epsilon$ of

$$\partial_t U(u) + \partial_x F(u) \,\leq\, 0. \tag{2.5}$$

We observe that

• an arbitrary entropy for (2.1) need not be compatible with the given regularization (2.2), and the inequality (2.5) *need not hold* for an arbitrary entropy;

• the estimate (2.4) provides an a priori control on u_ϵ and its derivatives, which may be used to apply the compensated compactness method, at least if $N \leq 2$. When the latter applies the sequence u_ϵ is shown to converge to a weak solution to (2.1), (2.5). See [53, 22] and sections 4 and 5 of this paper.

As an illustration, consider the case of a scalar equation ($N = 1$) and

$$\partial_t u_\epsilon + \partial_x f(u_\epsilon) = \epsilon\,\partial_{xx} u_\epsilon + \alpha\,\epsilon^2\,\partial_{xxx} u_\epsilon, \tag{2.6}$$

where α is a real parameter. It is easily checked that the conditions (2.3) hold for $U(u) = u^2$ with $B_1 = 1$, $B_2 = \alpha$, $B_3 = \alpha/2$, and $B_4 = 0$. The estimate (2.4) reduces to

$$\int_{\mathbb{R}} u_\epsilon(t)^2\,dx \,+\, 2\,\epsilon \int_0^T \int_{\mathbb{R}} |\partial_x u_\epsilon|^2\,dxds \,=\, \int_{\mathbb{R}} u_\epsilon(0)^2\,dx, \tag{2.7}$$

and we get the inequality

$$\partial_t U(u) + \partial_x F(u) \,\leq\, 0, \qquad F'(u) := u\,f'(u).$$

Observe that, for nonquadratic entropies, (2.3) is generally violated and the inequality (2.5) does not hold, as was pointed out in Hayes and LeFloch [22].

The scaling in (2.6) is important. The diffusion dominant regularization

$$\partial_t u_\epsilon + \partial_x f(u_\epsilon) = \epsilon\,\partial_{xx} u_\epsilon + \delta\,\partial_{xxx} u_\epsilon \tag{2.8}$$

with $\delta = o(\epsilon^2)$ would bring us back to the classical theory of conservation laws, while the dispersion dominant case (2.8) with $\epsilon^2 = o(\delta)$ is the subject of the Lax–Levermore theory [36, 37]. Limiting solutions in the latter case are not weak solutions to (2.1).

This motivates us to constrain the solutions to (2.1) with the single entropy inequality (2.5). Not surprisingly, when one characteristic field (or more) of the system

(2.1) is not genuinely nonlinear, the entropy inequality will be shown to be too lax to guarantee uniqueness even for the Riemann problem. The forthcoming analysis is built upon this elementary observation.

Our analysis in [22] of the nonclassical shocks for scalar conservation laws relied on the violation of the Oleinik criterion. For systems we shall say that a shock is classical if it satisfies the Liu criterion. Definition 2.1 restates this concept.

Definition 2.1. *A propagating discontinuity is called a* nonclassical shock *when it satisfies the entropy inequality* (2.5) *but does not fulfill the Liu entropy criterion (see* (2.18) *below).* □

2.2. Nonclassical Riemann solutions. We now study the Riemann problem for nongenuinely nonlinear systems.

- Liu has constructed a unique entropy solution to the Riemann problem for such systems [41, 42]. In his construction, every shock satisfies what is now called the Liu criterion. This is described in Lemma 2.3.
- When a single entropy inequality is used, the class of admissible solutions is larger (Lemma 2.5) and undercompressive shocks are found near a curve where genuine nonlinearity breaks down (see Lemma 2.4).
- We construct a multiparameter family of solutions to the Riemann problem in Theorem 2.6. In our construction, there are two analogous cases corresponding to a minimum or a maximum of the wave speed at the point where genuine nonlinearity is lost.

This extends Liu's construction to encompass all possible limits of diffusive-dispersive approximations compatible with a given entropy pair (U, F). A further admissibility criterion will be necessary to ensure uniqueness of the entropy solution. This will be developed in subsection 2.3.

Remark 2.2. Liu's criterion is consistent with the regularization (2.2) with $B_1(u) = I$ and $B_2(u) = 0$. The latter regularization happens to be compatible with *any* convex entropy to (2.1) since, then, (2.3i) is equivalent to the convexity assumption on U and (2.3ii) and (2.3iii) are trivially satisfied. Henceforth the inequalities (2.5) in this particular case hold for *all* convex entropy pairs. However, the Liu criterion need not be satisfied by limits of more general diffusive approximations or by diffusive-dispersive ones.

We now assume that $\mathcal{U} := B(u_*, R)$ is a ball with center u_* and radius $R > 0$, and, for each u and u' in $\mathcal{U}$, the matrix $A(u, u') := \int_0^1 Df(m\,u + (1-m)\,u')\,dm$ admits N real and distinct eigenvalues $\bar\lambda_1(u, u') < \bar\lambda_2(u, u') < \cdots < \bar\lambda_N(u, u')$ and corresponding basis of right eigenvectors $\bar r_j(u, u')$ and left eigenvectors $\bar l_j(u, u')$. Throughout this section we normalize the basis so that $\bar l_j(u, u') \cdot \bar r_j(u, u') = \delta_{ij}$.

It is assumed that the wave speeds $\lambda_j(u, u')$ are strictly separated in the sense that there exist *disjoint* intervals $\big[\lambda_j^{\min}, \lambda_j^{\max}\big]$, $j = 1, 2, \ldots, N$, such that

$$\lambda_j^{\min} < \bar\lambda_j(u, u') < \lambda_j^{\max} \tag{2.9}$$

for all $u, u' \in \mathcal{U}$. We also set $\lambda_j(u) := \bar\lambda_j(u, u)$, $r_j(u) := \bar r_j(u, u)$, and $l_j(u) := \bar l_j(u, u)$. When (2.1) is strictly hyperbolic, the condition (2.9) is satisfied if $\mathcal{U}$ is a sufficiently small neighborhood of u_*.

We are interested in systems admitting $N - P$ genuinely nonlinear characteristic fields and $P \le N$ nongenuinely nonlinear characteristic fields. In the latter case the scalar-valued function $u \to \nabla\lambda_j(u) \cdot r_j(u)$ does not keep a constant sign. We assume that there is a subset with P elements, $\mathbf{P} \subset \big\{1, 2, \ldots, N\big\}$ such that, for $j \notin \mathbf{P}$,

$\nabla\lambda_j(u)\cdot r_j(u) > 0$ for all u (after suitable normalization of the eigenvectors), and for $j \in \mathbf{P}$, the set

$$\mathcal{M}_j = \big\{u \in \mathcal{U} \,|\, \nabla\lambda_j(u)\cdot r_j(u) = 0\big\}$$

is a smooth affine manifold with dimension $N-1$ containing the point u_*. For simplicity in the presentation we do not include linearly degenerate fields.

We denote by $\mu_j(u)$ a scalar-valued function satisfying $\nabla\mu_j \cdot r_j \equiv 1$. When the j-field is genuinely nonlinear, one takes $\mu_j(u) = \lambda_j(u)$. The function μ_j will be used to parameterize the wave curves. We assume that μ_j can be chosen such that

$$\mu_j(u) = 0 \qquad \text{iff} \qquad \nabla\lambda_j(u)\cdot r_j(u) = 0,$$

and either

$$\text{(2.10a)} \qquad \text{Case A: } \mu_j(u) \quad \text{and} \quad \nabla\lambda_j(u)\cdot r_j(u) \quad \text{have the same sign,}$$

or

$$\text{(2.10b)} \qquad \text{Case B: } \mu_j(u) \quad \text{and} \quad \nabla\lambda_j(u)\cdot r_j(u) \quad \text{have the opposite sign.}$$

In particular $\nabla\lambda_j \cdot r_j$ changes sign across $\mathcal{M}_j$. In Case A, $\mu_j(u) = 0$ is associated with a minimum of the wave speed, while in Case B it is associated with a maximum. In the scalar case, (2.10a) means that there is a state u_* such that the function f is strictly concave for $u < u_*$ and strictly convex for $u > u_*$. Typical examples are $f(u) = u^3$ in the case (2.10a) and $f(u) = -u^3$ in the case (2.10b); in both cases one can choose $\mu(u) = u$. As we will see, the cases (2.10a) and (2.10b) lead to wave curves with different properties.

The Riemann problem, (2.1) with initial data

$$\text{(2.11)} \qquad u(x,0) = \begin{cases} u_l & \text{for } x < 0, \\ u_r & \text{for } x > 0, \end{cases}$$

and u_r and u_l fixed in $\mathcal{U}$, plays an important role in the theory of hyperbolic conservation laws. Since the problem is invariant under the transformation $(x,t) \to (\beta\, x, \beta\, t)$ (with $\beta > 0$), it is natural to search for self-similar solutions depending only on x/t. We now define the one-parameter families of shock and rarefaction waves to be used as building blocks in the resolution of the Riemann problem.

Given a state $u_0 \in \mathcal{U}$ and $j = 1, 2, \dots, N$, let $\mathcal{O}_j(u_0) = \big\{v_j(\epsilon_j; u_0) \in \mathcal{U}\big\}$ be the integral curve of the vector field r_j issued from u_0, so that

$$\text{(2.12)} \qquad \frac{dv_j}{d\epsilon_j}(\epsilon_j; u_0) = r_j\big(v_j(\epsilon_j; u_0)\big), \qquad v_j(\epsilon_{j,0}; u_0) = u_0.$$

Note that $r_j(u_0)$ is the tangent vector of the curve $\mathcal{O}_j(u_0)$ at the point u_0. Using the normalization of the function μ_j, one checks that

$$\mu_j\big(v_j(\epsilon_j; u_0)\big) = \epsilon_j;$$

therefore there should be no confusion in using the notation $mu_j = \epsilon_j$. In other words, μ_j is viewed as both a function of u and as a parameter along the wave curves.

We also consider the Hugoniot locus

$$\mathcal{H}_j(u_0) := \big\{ w \,|\, -s\,\big(w - u_0\big) + f(w) - f(u_0) = 0 \big\}. \tag{2.13}$$

The Rankine–Hugoniot relation is equivalent to saying that there exists an index j and a scalar-valued coefficient $\alpha(u_0, w)$ such that

$$w - u_0 = \alpha(u_0, w)\, \bar{r}_j(u_0, w), \qquad s = \bar{\lambda}_j(u_0, w). \tag{2.14}$$

By the implicit function theorem, the Hugoniot set decomposes (locally near u_0, at least) into N Hugoniot curves $\mathcal{H}_j(u_0) = \big\{ w_j(\mu_j; u_0) \in \mathcal{U} \big\}$, passing through u_0 and having the tangent vector $r_j(u_0)$ at u_0. Since $\nabla \mu_j \cdot r_j > 0$, the coefficient $\alpha(u_0, w_j)$ in (2.14) has the same sign as that of $\mu_j(w_j) - \mu_j(u_0)$. Along the j-curve, the shock speed satisfies

$$\bar{\lambda}_j(u_0, w_j) = \lambda_j(u_0) + \frac{\mu_j}{2}\, \nabla \lambda_j(u_0) \cdot r_j(u_0) + O(\mu_j^2). \tag{2.15}$$

Taking a suitable subset $B(u_*, R')$ of $\mathcal{U} = B(u_*, R)$ if necessary, one can assume that the curves $\mathcal{O}_j(u_0)$ and $\mathcal{H}_j(u_0)$ extend up to the boundary of $\mathcal{U}$. Furthermore we assume that, for $j \in \mathbf{P}$, these curves are *transverse to the manifold* $\mathcal{M}_j$: each Hugoniot curve and each integral curve intersect the manifold at exactly one point. Observe that when R is small enough, it is sufficient to assume that the vector field r_j is transverse to the manifold $\mathcal{M}_j$. Our construction here applies, however, to the case that R is not necessarily small. The tranversality assumption implies that, for $j \in \mathbf{P}$, the wave speed $\mu_j \to \lambda_j\big(v_j(\mu_j; u_0)\big)$ has exactly one critical point along each integral curve. It will be checked in Lemma 2.3 below that, for $j \in \mathbf{P}$, the shock speed $\mu_j \to \bar{\lambda}_j(u_0, w_j(\mu_j; u_0))$ also admits (at most) one critical point along the Hugoniot curve.

Finally we introduce another assumption about the Hugoniot curve, for all $w_j(\mu_j; u_0)$ with $\mu_j \neq \mu_j(u_0)$,

$$l_j(w_j) \cdot \frac{dw_j}{d\mu_j} \;>\; 0, \tag{2.16i}$$

$$\big(\mu_j - \mu_j(u_0)\big)\, l_j(w_j) \cdot (w_j - u_0) \;>\; 0. \tag{2.16ii}$$

Both conditions in (2.16) trivially hold for weak shocks, since $l_j(u_0) \cdot r_j(u_0) = 1$.

Discontinuous solutions being not unique in general, it is customary to select the "admissible" weak solutions via an entropy criterion acting on discontinuities. From physical, mathematical, and numerical standpoints, it is desirable that an admissible solution to the Riemann problem exist, be unique, and depend continuously upon its initial states in a certain topology. In the classical approach, a wave curve $\mathcal{W}_j(u)$ is indeed defined by piecing together (admissible) parts of the above curves. The Lax shock inequalities [34, 35] are fundamental for stability and are used for weak shocks in the neighborhood of a point of genuine nonlinearity. A j-shock connecting u_0 to u_1 with speed $\lambda_j(u_0, u_1)$ is admissible in the sense of Lax iff

$$\lambda_j(u_0) \geq \bar{\lambda}_j(u_0, u_1) \geq \lambda_j(u_1). \tag{2.17}$$

Note that the inequalities $\lambda_{j-1}(u_0) < \bar{\lambda}_j(u_0, u_1) < \lambda_{j+1}(u_1)$ are obtained as a direct consequence of (2.9). When the characteristic fields are genuinely nonlinear, applying the Lax criterion leads to uniquely defined wave curves and to a unique solution for the Riemann problem. Each wave curve contains two distinct parts, half of the Hugoniot curve and half of the integral curve.

When one or more characteristic fields are not genuinely nonlinear, Liu proposed that, along the Hugoniot curve $\mathcal{H}_j(u_0)$, the following criterion holds:

$$\bar{\lambda}_j(u_0, w_j(\mu_j; u_0)) \geq \bar{\lambda}_j(u_0, u_1) \tag{2.18}$$

for all μ_j between $\mu_j(u_0)$ and $\mu_j(u_1)$; in other words, the shock speed for μ_j in the above range achieves its *minimum* at the point u_1. Liu [42] constructed a unique wave curve based on the condition (2.18). The wave curves may be composed of more than two pieces, and the Riemann solution contains composite waves mixing shocks and rarefactions.

It is known that (2.8), (2.17), and (2.18) are equivalent for shocks of weak amplitude and genuinely nonlinear fields. This is not true for systems having nongenuinely nonlinear fields. In the present paper we attempt to construct a wave curve based on (2.5) of the wave curves of Liu. However, instead of one-parameter wave curves we arrive here to two-parameter sets, which we call “wave sets.” In this construction it is important to distinguish several types of discontinuities.

An arbitrary j-shock connecting u_0 to u_1 can be either *a Lax shock*, in which case (2.17) holds, *an undercompressive shock* satisfying either

$$\bar{\lambda}_j(u_0, u_1) \leq \min\bigl(\lambda_j(u_0), \lambda_j(u_1)\bigr) \text{ or} \tag{2.19}$$

$$\bar{\lambda}_j(u_0, u_1) \geq \max\bigl(\lambda_j(u_0), \lambda_j(u_1)\bigr), \tag{2.20}$$

or *a rarefaction shock*:

$$\lambda_j(u_0) < \bar{\lambda}_j(u_0, u_1) < \lambda_j(u_1). \tag{2.21}$$

The properties of the wave speeds and shock speeds are described in Lemmas 2.3 and 2.4. (See Figure 2.1 for a graphical representation.) The entropy dissipation is dealt with in Lemma 2.5.

LEMMA 2.3. *Let u_0 be given with $\mu_j(u_0) > 0$ and consider the Hugoniot curve $\mathcal{H}_j(u_0)$ for $= j = 1, 2, \dots, N$. Suppose that* (2.10*a*) *(resp.,* (2.10*b*)*) holds. Then the wave speed $\mu_j \to g(\mu_j; u_0) := \lambda_j(w_j(\mu_j; u_0))$ is decreasing (resp., increasing) for $\mu_j < 0$ and increasing (resp., decreasing) for $\mu_j > 0$ and achieves its minimum (resp., maximum) at $\mu_j = 0$.*

There exists $\mu_j^\star(u_0) \leq 0$ such that the shock speed $\mu_j \to h(\mu_j; u_0) := \bar{\lambda}_j(u_0, w_j(\mu_j; u_0))$ is decreasing (resp., increasing) for $\mu_j < \mu_j^\star(u_0)$ and increasing (resp., decreasing) for $\mu_j > \mu_j^\star(u_0)$ and achieves its minimum (resp., maximum) at $\mu_j^\star(u_0)$.

The wave speed and the shock speed coincide at the critical value of the shock speed:

$$g(\mu_j^\star(u_0); u_0) = h(\mu_j^\star(u_0); u_0). \tag{2.22}$$

Moreover we have in case (2.10*a*)

$$\begin{aligned} &h(\mu_j; u_0) - g(\mu_j; u_0) > 0 \qquad \textit{for } \ \mu_j \in \bigl(\mu_j^\star(u_0), \mu_j(u_0)\bigr), \\ &h(\mu_j; u_0) - g(\mu_j; u_0) < 0 \qquad \textit{for } \ \mu_j < \mu_j^\star(u_0) \ \ \textit{or} \ \ \mu_j > \mu_j(u_0), \end{aligned} \tag{2.23a}$$

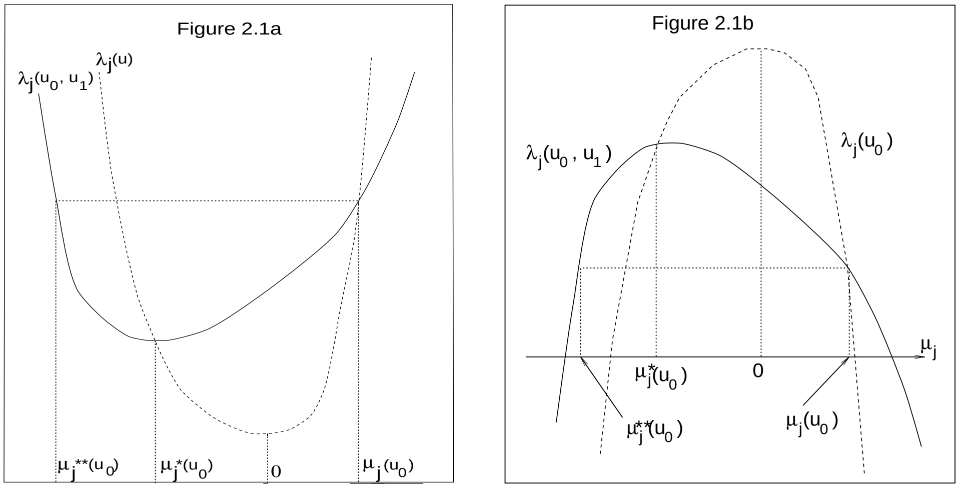

FIG. 2.1. *Wave speed and shock speed for* (a) *the case* (2.10a), (b) *the case* (2.10b).

and in the case (2.10b) *we have*

$$\begin{aligned} &h(\mu_j; u_0) - g(\mu_j; u_0) < 0 \qquad \textit{for } \mu_j \in \big(\mu_j^\star(u_0), \mu_j(u_0)\big), \\ &h(\mu_j; u_0) - g(\mu_j; u_0) > 0 \qquad \textit{for } \mu_j < \mu_j^\star(u_0) \ \textit{ or } \ \mu_j > \mu_j(u_0). \end{aligned} \tag{2.23b}$$

When $\mu_j(u_0) = 0$*, the same properties hold with* $\mu_j^\star(u_0) = 0$*.*

Lemma 2.3 includes, as a special case, the situation that the point $w_j(\mu_j^\star(u_0); u_0)$ belongs to the boundary of $\mathcal{U}$, in which case $\big\{\mu_j < \mu_j^\star(u_0)\big\}$ is empty. We denote by $\mu_j^{\star\star}(u_0)$, with $\mu_j^{\star\star}(u_0) < \mu_j^\star(u_0)$, the point of the Hugoniot curve such that

$$h(\mu_j^{\star\star}(u_0); u_0) = h(\mu_j(u_0); u_0) \tag{2.24}$$

when such a point exists. In the following, we tacitly assume that both points, $\mu_j^\star(u_0)$ and $\mu_j^{\star\star}(u_0)$, exist and belong to the interior of $\mathcal{U}$, the discussion below being much simpler in other cases. Lemma 2.3 is due to Liu [42] and, for completeness, a proof is given in the appendix.

LEMMA 2.4. *Let* u_0 *be given with* $\mu_j(u_0) \geq 0$ *and consider the Hugoniot curve* $\mathcal{H}_j(u_0)$*.*

(1) *Suppose that* (2.10a) *holds. A shock connecting* u_0 *to* $u_1 = w_j(\mu_j(u_1); u_0)$ *is*

$$\begin{aligned} &\textit{a rarefaction shock if } \mu_j(u_1) > \mu_j(u_0) \ \textit{ or } \ \mu_j(u_1) < \mu_j^{\star\star}(u_0); \\ &\textit{a Lax shock if } \mu_j(u_1) \in \big[\mu_j^\star(u_0), \mu_j(u_0)\big]; \\ &\textit{an undercompressive shock if } \mu_j(u_1) \in \big[\mu_j^{\star\star}(u_0), \mu_j^\star(u_0)\big). \end{aligned} \tag{2.25a}$$

In the second case the shock also satisfies the (stronger) Liu criterion.

(2) *Suppose that* (2.10b) *holds. A shock connecting* u_0 *to* $u_1 = w_j(\mu_j(u_1); u_0)$ *is*

$$\begin{aligned} &\textit{a Lax shock if } \mu_j(u_1) \geq \mu_j(u_0) \ \textit{ or } \ \mu_j(u_1) \leq \mu_j^{\star\star}(u_0); \\ &\textit{a rarefaction shock if } \mu_j(u_1) \in \big(\mu_j^\star(u_0), \mu_j(u_0)\big); \\ &\textit{an undercompressive shock if } \mu_j(u_1) \in \big(\mu_j^{\star\star}(u_0), \mu_j^\star(u_0)\big]. \end{aligned} \tag{2.25b}$$

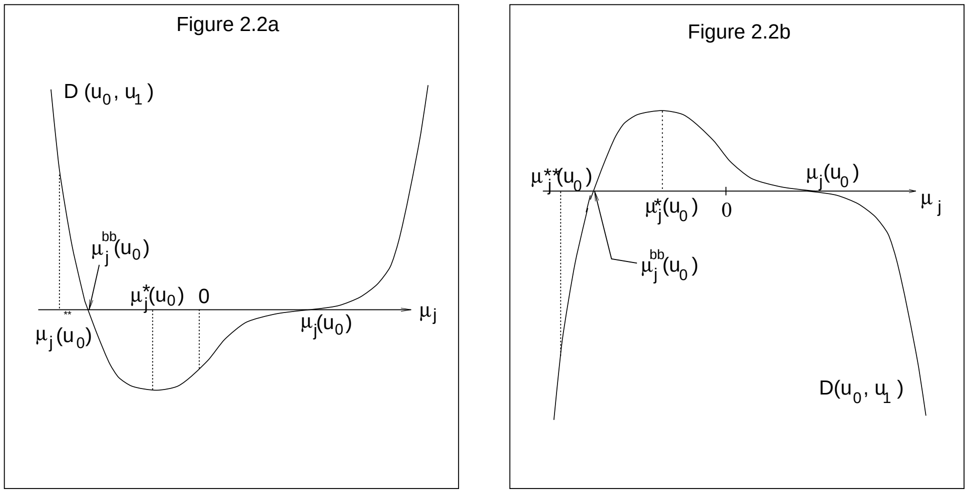

FIG. 2.2. *Entropy dissipation for* (a) *the case* (2.10a), (b) *the case* (2.10b).

In the first case the shock also satisfies the (stronger) Liu criterion.

LEMMA 2.5. *Let* u_0 *be given with* $\mu_j(u_0) \geq 0$ *and consider the Hugoniot curve* $\mathcal{H}_j(u_0)$. *Suppose that* (2.10a) *(resp.,* (2.10b)*) holds.*

(1) *The entropy dissipation* $\mu_j \to D(u_0, w_j(\mu_j; u_0))$ *vanishes at* $\mu_j(u_0)$ *and at a point* $\mu_j^{\flat\flat}(u_0)$ *in the interval* $\big(\mu_j^{\star\star}(u_0), \mu_j^\star(u_0)\big)$. *The entropy dissipation is decreasing (resp., increasing) for* $\mu_j < \mu_j^\star(u_0)$, *increasing (resp., decreasing) for* $\mu_j > \mu_j^\star(u_0)$, *and achieves a negative maximum value (resp., a positive maximum value) at the critical point of the wave speed, that is,* $\mu_j^\star(u_0)$.

(2) *A shock satisfying* (2.8) *cannot be a rarefaction shock. As a corollary, a nonclassical shock is undercompressive and satisfies* $\mu_j \in \big(\mu_j^{\flat\flat}(u_0), \mu_j^\star(u_0)\big)$ *(resp.,* $\mu_j \in \big(\mu_j^{\star\star}(u_0), \mu_j^{\flat\flat}(u_0)\big)$*).*

(3) *Any shock satisfying the Liu criterion* (2.18) *also satisfies the entropy inequality* (2.8).

For u_l and u_r given in $\mathcal{U}$, the Riemann problem (2.1), (2.11) admits up to a P-parameter family of solutions containing N separated wave fans, each of them being composed of (at most) two waves. Specifically we obtain the following description of the classical and nonclassical waves.

Consider a j-wave fan with left-hand state u_0 and right-hand state u with $\mu_j(u_0) \geq 0$. For $j \notin \mathbf{P}$, the wave fan is either a rarefaction wave if $\mu_j(u) > \mu_j(u_0)$, or a classical shock if $\mu_j(u) < \mu_j(u_0)$. For $j \in \mathbf{P}$, we have the following.

Case A. Assume that (2.10a) holds and $j \in \mathbf{P}$. Assume first that $\mu_j(u_0) > 0$. The j-wave fan using only classical waves contains

(1) either a rarefaction from u_0 to $u \in \mathcal{O}_j(u_0)$ if $\mu_j(u) > \mu_j(u_0)$,

(2) a classical shock from u_0 to $u \in \mathcal{H}_j(u_0)$ if $\mu_j(u) \in \big(\mu_j^\star(u_0), \mu_j(u_0)\big)$,

(3) or a classical shock from u_0 to $u^\star := w_j(\mu^\star(u_0); u_0\big)$ followed by an attached rarefaction connecting to $u \in \mathcal{O}_j(u^\star)$ if $\mu_j(u) < \mu_j^\star(u_0)$.

This completes the description of the classical wave curve $\mathcal{W}_j^c(u_0)$ for Case A.

THEOREM 2.6A. *The* j*-wave fan may also contain a nonclassical* j*-shock connecting* u_0 *to* any state $u^\flat \in \mathcal{H}_j(u_0)$ *with* $\mu_j(u^\flat) \in \big(\mu_j^{\flat\flat}(u_0), \mu_j^\star(u_0)\big)$ *followed by*

(1) *either a* nonattached *rarefaction connecting* $u^\flat$ *to* $u \in \mathcal{O}_j(u^\flat)$ *if* $\mu_j(u) < \mu_j(u^\flat)$,

(2) *or by a classical shock connecting $u^\flat$ to $u \in \mathcal{H}_j(u^\flat)$ if $\mu_j(u) > \mu_j(u^\flat)$.*

This defines a two-parameter family of u that can be reached from u_0 by nonclassical solutions. For a given $u^\flat$, the classical shock with largest strength and connecting $u^\flat$ to some $u = u^\sharp \in \mathcal{H}_j(u^\flat)$ is characterized by the condition $\bar\lambda_j(u^\flat, u^\sharp) = \bar\lambda_j(u_0, u^\flat)$ and, in that situation, one also has $u^\sharp \in \mathcal{H}_j(u_0)$. In particular the nonclassical shock with largest possible strength connects the point $u^{\flat\flat} := w_j(\mu_j^{\flat\flat}(u_0); u_0)$ to the point $u^{\sharp\sharp} := w_j(\mu^{\sharp\sharp}(u_0); u^{\flat\flat})$, where $\mu^{\sharp\sharp}(u_0)$ is defined by $u^{\sharp\sharp} \in H_j(u_0)$. Moreover one has

$$\mu_j^{\star\star}(u_0) \le \mu_j^{\flat\flat}(u_0) \le \mu_j^{\flat}(u_0) \le \mu_j^{\star}(u_0) \le \mu_j^{\sharp}(u_0) \le \mu_j^{\sharp\sharp}(u_0) \le \mu_j(u_0). \tag{2.26}$$

In the special case that $\mu_j(u_0) = 0$, the j-wave curve is the j-integral curve issuing from u_0.

Case B. Assume that (2.10b) holds and $j \in \mathbf{P}$. Assume first that $\mu_j(u_0) > 0$. The j-wave fan using only classical waves contains

(1) either a classical shock connecting u_0 to $u \in \mathcal{H}_j(u_0)$ if either $\mu_j(u) \ge \mu_j(u_0)$ or $\mu_j(u) \le \mu_j^{\star\star}(u_0)$,

(2) a rarefaction connecting u_0 to $u \in \mathcal{O}_j(u_0)$ if $\mu_j(u) \in \big[0, \mu_j(u_0)\big]$,

(3) or a rarefaction wave connecting u_0 to a point u_1, followed by an attached classical shock connecting to $u \in \mathcal{H}_j(u_1)$ with $\mu_j(u) = \mu_j^{\star\star}(u_1)$, if $\mu_j(u) \in \big(\mu_j^{\star\star}(u_0), 0\big)$. (In this case the set of u does not describe a rarefaction or shock curve.)

This completes the description of the classical wave curve $\mathcal{W}_j^c(u_0)$.

THEOREM 2.6B. *The j-wave fan may also contain*

(1) *either a rarefaction to $u \in \mathcal{O}_j(u_0)$ if $\mu_j(u) \in \big(0, \mu_j(u_0)\big)$, possibly followed by a* nonattached *nonclassical shock connecting u_1 to u, if $\mu_j(u) \in \big(\mu_j^{\star\star}(u_1), \mu_j^{\flat\flat}(u_1)\big)$ (in this case the set of u does not describe a rarefaction or shock curve),*

(2) *or a classical shock to $u_1 \in \mathcal{H}_j(u_0)$ with $\mu_j(u_1) > \mu_j(u_0)$, followed by a nonclassical shock connecting to $u \in \mathcal{H}_j(u_1)$, if $\mu_j(u) \in \big(\mu_j^{\star\star}(u_1), \mu_j^{\flat\flat}(u_1)\big)$.*

This defines a two-parameter family of u that can be reached from u_0 by nonclassical solutions.

Assume finally that $\mu_j(u_0) = 0$. Then the j-wave curve is the j-Hugoniot curve issuing from u_0 and correspond to classical shocks.

Based on these results, we introduce the following terminology. Given u_0, the set of all states that can be reached using only j-waves will be called the *j-wave set* issuing from u_0 and be denoted by $\mathcal{S}_j(u_0)$ by analogy with the notion of j-wave curve known for classical solutions. We shall call a curve in the wave set a *composite curve* when it is not a part of a rarefaction or shock curve. The wave set in both cases (2.10a) and (2.10b) is represented in Figures 2.3(a) and 2.3(b), respectively. The case that $\mu_j(u_0) < 0$ is analogous and is omitted. We now give a proof of Lemmas 2.4 and 2.5 and Theorem 2.6.

REMARK 2.7. (1) Our analysis shows that, under the assumptions made in this section, the Lax inequalities and the Liu criterion are *equivalent* (Lemma 2.4), which, at first, may appear surprising. The Lax inequalities are sufficient to select a unique solution for shocks with small amplitude near a point where $\nabla\lambda_j \cdot r_j$ vanishes. The Liu criterion is necessary for shocks of moderate amplitude when the product $\nabla\lambda_i \cdot r_i$ changes sign several times along the Hugoniot curve.

(2) When the system (2.1) has a sufficiently large family of entropies (e.g., when $N \le 2$), the formulas (2.28)–(2.29) derived below may be used to establish the converse of item (3) of Lemma 2.5, i.e., limits of regularizations compatible with all entropies (such as (2.2) with $D_\epsilon = \epsilon\, \partial_x u_\epsilon$), necessarily satisfy the Liu criterion.

(3) It may be of interest to search for the weakest constraint on undercompressive

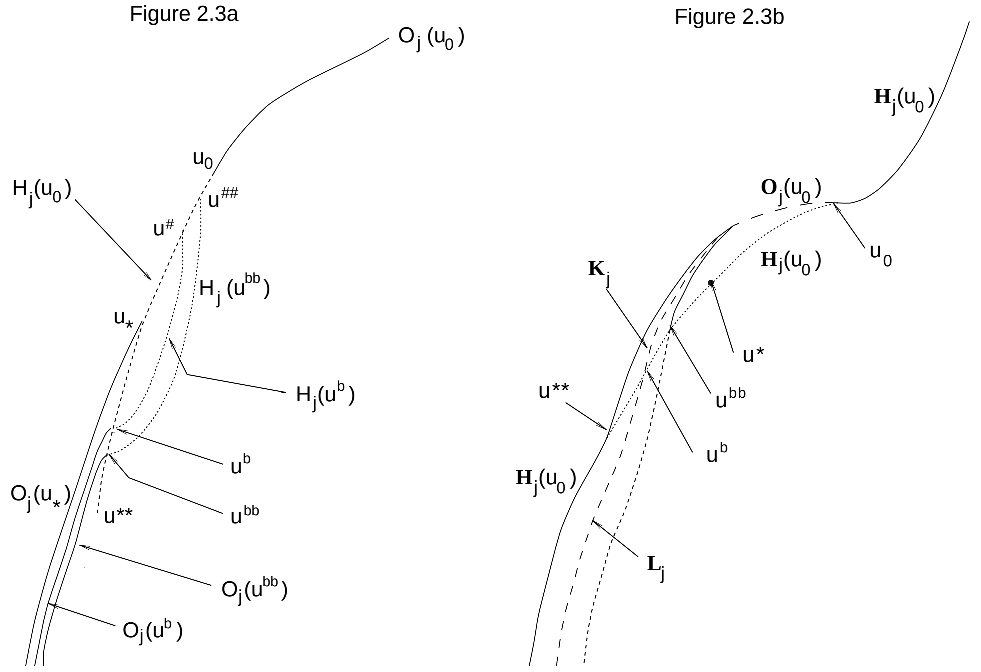

FIG. 2.3. *Wave set* $\mathcal{S}_j(u_0)$ *issuing from* u_0 *for* (a) *the case* (2.10a), (b) *the case* (2.10b).

shocks that can result from imposing one entropy inequality like (2.8). We shall say that a subset $\mathcal{W}_j^{max}(u_0)$ of $\mathcal{U}$ is a *maximal j-wave set* for the system (2.1) if it contains all the j-wave sets for arbitrary entropies. For instance a maximal wave set for the case (2.10a) is obtained by taking $\mu_j^{bb}(u_0) = \mu_j^{\star\star}(u_0)$ in Theorem 2.6; this follows readily from the formula (2.28)–(2.29). In the scalar case with $N = 1$ and $f(u) = u^3$, one has $\mu_j(u_0) = u_0$ and $\mu_j^{\star\star}(u_0) = -2\,u_0$. The scalar case is degenerated and $\mathcal{W}^c(u_0) = \mathcal{W}^{nc}(u_0) = \mathcal{W}^{max}(u_0) = \mathbb{R}$; the interval $[-2\,u_0, u_0]$ is the maximal interval of states that can be reached from u_0 by using a classical or nonclassical shock. □

Proof of Lemma 2.4. Consider for instance the case (2.10a), the case (2.10b) being similar. Lemma 2.3 states that the function $\mu_j \to \bar{\lambda}_j(u_0, w_j(\mu_j; u_0)) - \bar{\lambda}_j(w_j(\mu_j; u_0))$ is positive for $\mu_j > \mu_j^\star(u_0)$ and negative for $\mu_j < \mu_j^\star(u_0)$. On the other hand the function $\mu_j \to \bar{\lambda}_j(u_0, w_j(\mu_j; u_0)) - \lambda_j(u_0)$ is positive for $\mu_j < \mu_j^{\star\star}(u_0)$ or $\mu_j > \mu_j(u_0)$ and negative for $\mu_j \in \big(\mu_j^{\star\star}(u_0), \mu_j(u_0)\big)$. The classification follows easily from these two properties. □

Proof of Lemma 2.5. Using the compatibility condition on the entropy pair, i.e., $\nabla F^T = \nabla U^T Df$, and the Rankine–Hugoniot relation (2.13), the entropy dissipation for a shock connecting u_0 to $w_j(\mu_j; u_0)$ is found to be

$$
\begin{aligned}
&(2.27)\\
&D(u_0, w_j(\mu_j; u_0))\\
&= \int_{\mu_j(u_0)}^{\mu_j} \nabla U(w_j(\zeta_j)) \left\{\bar{\lambda}_j(u_0, w_j(\mu_j)) - Df(w_j(\zeta_j))\right\} \frac{dw_j}{d\zeta_j}(\zeta_j)\, d\zeta_j,\\
&= \int_{\mu_j(u_0)}^{\mu_j} \frac{dw_j}{d\zeta_j}(\zeta_j) \cdot \nabla^2 U(w_j(\zeta_j)) \left\{\bar{\lambda}_j(u_0, w_j(\zeta_j)) \big(w_j(\zeta_j) - u_0\big) - f(w_j(\zeta_j)) + f(u_0)\right\} d\zeta_j.
\end{aligned}
$$

Using once more the Rankine–Hugoniot relation, we get

$$D(u_0, w_j) = \int_{\mu_j(u_0)}^{\mu_j} \left\{ \bar{\lambda}_j(u_0, w_j(\mu_j)) - \bar{\lambda}_j(u_0, w_j(\zeta_j)) \right\} m_j(\zeta_j)\, d\zeta_j, \tag{2.28}$$

where

$$m_j(\zeta_j) := \frac{dw_j}{d\zeta_j}(\zeta_j) \cdot \nabla^2 U(w_j(\zeta_j)) \big(w_j(\zeta_j) - u_0\big) \tag{2.29}$$

has the same sign as $\mu_j - \mu_j(u_0)$. The system (2.1) being strictly hyperbolic, it can be checked that

$$\frac{dw_j}{d\mu_j} \cdot \nabla^2 U(w_j) \;=\; l_j(w_j),$$

which, combined with (2.16ii), shows that $m_j(\zeta_j) > 0$ for $\zeta_j \neq \mu_j(u_0)$.

The occurrence of nonclassical shocks depends on the sign of the entropy dissipation. The integrand in (2.28) has the same sign as $\bar{\lambda}_j(u_0, w_j(\mu_j)) - \bar{\lambda}_j(u_0, w_j(\zeta_j))$, which is nonpositive when the Liu entropy criterion (2.18) holds. It follows that the entropy dissipation is negative as long as the Liu criterion holds. This proves item (3) of Lemma 2.5.

When, instead, the shock satisfies the inequalities (2.21), we have

$$\bar{\lambda}_j(u_0, w_j(\mu_j)) - \bar{\lambda}_j(u_0, w_j(\zeta_j)) \geq 0. \tag{2.30}$$

This indeed is an easy consequence of the facts that $\mu_j \to \bar{\lambda}_j(u_0, w_j(\mu_j))$ is a monotone function (see Lemma 2.3) and that $\bar{\lambda}_j(u_0, u_0) = \lambda_j(u_0) \leq \bar{\lambda}_j(u_0, w_j(\mu_j))$. Combining (2.28) and (2.30) shows that the entropy dissipation is negative for rarefaction shocks. This proves item (2) of Lemma 2.5.

Finally we can establish item (1) by differentiating the formula (2.28) with respect to μ_j:

$$\frac{\partial}{\partial \mu_j} D(u_0, w_j) = \int_{\mu_j(u_0)}^{\mu_j} \frac{\partial}{\partial \mu_j} \bar{\lambda}_j(u_0, w_j)\, m_j(\zeta_j)\, d\zeta_j.$$

This yields a relation between the derivative of the entropy dissipation and that of the shock speed:

$$\frac{\partial}{\partial \mu_j} D(u_0, w_j) = b(w_j) \frac{\partial}{\partial \mu_j} \lambda_j(u_0, w_j), \qquad b(w_j) := \int_{\mu_j(u_0)}^{\mu_j} m_j(\zeta_j)\, d\zeta_j, \tag{2.31}$$

with $C_1\, |w_j - u_0|^2 \leq b(w_j) \leq C_2\, |w_j - u_0|^2$ for some positive constants C_1 and C_2. Note that the dissipation has a critical point either when the shock speed has a critical point or at the point u_0.

From the properties of the shock speed in Lemma 2.3, it follows therefore that $D(u_0, w_j)$ is decreasing for $\mu_j < \mu_j^\star(u_0)$ and increasing for $\mu_j > \mu_j^\star(u_0)$. From its definition, it is clear that $D(u_0, w_j)$ vanishes at $\mu_j(u_0)$. Moreover, we checked that it is positive for $\mu_j < \mu_j^{\star\star}(u_0)$. Therefore there exists a unique point, say, $\mu_j^{\flat\flat}(u_0)$, in the interval $\big(\mu_j^{\star\star}(u_0), \mu_j^\star(u_0)\big)$ where the dissipation vanishes. This completes the proof of Lemma 2.5. □

Proof of Theorem 2.6. We construct the wave set $\mathcal{S}_j(u_0)$ for $u_0 \in \mathcal{U}$ and $j \in \mathbf{P}$. The construction for $j \notin \mathbf{P}$ is classical and $\mathcal{S}_j(u_0)$ is the classical wave curve $\mathcal{W}_j(u_0)$.

Case A. For $u_0 \in \mathcal{M}_j$, either of the conditions (2.8) or (2.18) shows that the wave set $\mathcal{W}_j^{nc}(u_0)$ coincides locally with the integral curve $\mathcal{O}_j(u_0)$. This is because the wave speed is increasing when moving away from u_0 in either direction. The construction is complete for $u_0 \in \mathcal{M}_j$.

We now consider a point u_0 away from the manifold. For definiteness we assume that $\mu_j(u_0) > 0$; the other case could be treated similarly. The construction of the wave curve will use the values $\mu_j^{\star\star}(u_0) < \mu_j^\star(u_0) \le \mu_j(u_0)$ introduced in Lemma 2.3.

For $\mu_j > \mu_j(u_0)$, the state u_0 can be connected to any point on $\mathcal{O}_j(u_0)$ since the wave speed λ_j is increasing for μ_j increasing. Therefore the wave curve $\mathcal{W}_j(u_0)$ coincides with the rarefaction curve $\mathcal{O}_j(u_0)$ for $\mu_j \ge \mu_j(u_0)$.

For μ_j decreasing from $\mu_j(u_0)$, the shock speed is decreasing as long as μ_j remains larger than the critical value $\mu_j^\star(u_0)$. Therefore all the points in the Hugoniot curve $\mathcal{H}_j(u_0)$ with $\mu_j \in [\mu_j^\star(u_0), \mu_j(u_0)]$ can be reached from u_0 by a classical shock satisfying the Liu criterion. According to Lemma 2.5, the entropy dissipation remains negative in the whole range $\mu_j \in [\mu_j^{\flat\flat}(u_0), \mu_j(u_0)]$. Thus the points of the Hugoniot curve $\mathcal{H}_j(u_0)$ with $\mu_j \in [\mu_j^{\flat\flat}(u_0), \mu_j^\star(u_0)]$ can also be reached from u_0 but, now, with a nonclassical shock.

These are the only admissible solutions with a single j-wave issuing from u_0.

Consider now an admissible one-wave solution joining u_0 to u_1. If $\mu_j(u_1) > \mu_j^\star(u_0)$, then no further j-wave can be constructed from u_1. The state $u_1^\star$ with $\mu_j(u_1) = \mu_j^\star(u_0)$ can be connected to any point u_2 in the rarefaction curve $\mathcal{O}_j(u_1)$ with $\mu_j(u_2) \le \mu_j^\star(u_0)$. This covers the whole range of values μ_j and corresponds to the classical wave curve.

We now describe all nonclassical solutions with two j-waves. Consider an admissible one-wave solution joining u_0 to $u^\flat$ with $\mu_j(u^\flat) \in \big[\mu_j^{\flat\flat}(u_0), \mu_j^\star(u_0)\big)$. According to Lemma 2.3, the wave speed is increasing with μ_j decreasing from $\mu_j(u^\flat)$, so $u^\flat$ can be connected to any point u_2 in the rarefaction curve $\mathcal{O}_j(u^\flat)$ with $\mu_j(u_2) \le \mu_j(u^\flat)$. Observe that the nonclassical shock is not attached to the rarefaction fan, i.e.,

$$\bar{\lambda}_j(u_0, u^\flat) < \lambda_j(u^\flat). \tag{2.32}$$

This describes all the solutions containing a nonclassical shock followed by a rarefaction; no further j-wave may follow the rarefaction.

Consider again an admissible one-wave solution joining u_0 to $u^\flat$ with $\mu_j(u^\flat) \in \big[\mu_j^{\flat\flat}(u_0), \mu_j^\star(u_0)\big)$. By (2.32), the shocks with small strength issuing from $u^\flat$ have a larger speed than that of the nonclassical shock, i.e., $\bar{\lambda}_j(u^\flat, u_2) \approx \lambda_j(u^\flat) > \bar{\lambda}_j(u_0, u^\flat)$ for all states u_2 close to $u^\flat$. Hence the speeds have the proper ordering and $u^\flat$ may be connected to any $u_2 \in \mathcal{H}_j(u^\flat)$, at least in the small. Such a shock is also admissible (according to the Liu criterion) since the wave speed is decreasing when μ_j increases (Lemma 2.3.).

This construction can be continued, for $u^\flat$ fixed, until u_2 violates either of the two conditions

$$\bar{\lambda}_j(u^\flat, u_2) > \bar{\lambda}_j(u_0, u^\flat) \text{ or} \tag{2.33}$$

$$D(u^\flat, u_2) \le 0. \tag{2.34}$$

Actually, as $\mu_j(u_2)$ increases from $\mu_j(u^\flat)$, one reaches a maximum value $\mu_j^\sharp$, in which equality holds in (2.33), while the shock is still classical and therefore (2.34) still holds.

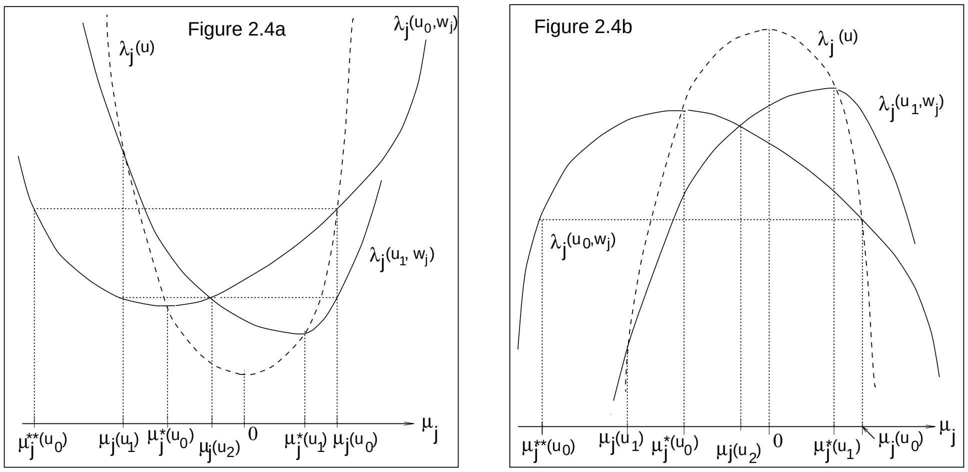

Fig. 2.4. *Graphs of the two shock speeds for* (a) *the case* (2.10a), (b) *the case* (2.10b).

To check the latter, consider the graphs of the two functions $h(\mu_j) := \bar{\lambda}_j(u_0, w_j(\mu_j; u_0))$ and $k(\mu_j) := \bar{\lambda}_j(u^\flat, w_j(\mu_j; u^\flat))$. See Figure 2.4(a). By symmetry of the Rankine–Hugoniot relation, one has $\bar{\lambda}_j(u^\flat, u_0) = \bar{\lambda}_j(u_0, u^\flat)$, so

$$s := h(\mu_j(u^\flat)) = k(\mu_j(u_0)). \tag{2.35}$$

In view of their monotonicity properties, the two graphs must intersect at exactly one point $\mu_j^\sharp$ in the interval $\big(\mu_j(u^\flat), \mu_j(u_0)\big)$. We define $u_2^\sharp$ by the conditions $\mu_j(u_2^\sharp) = \mu_j^\sharp$ and $u_2^\sharp \in \mathcal{H}_j(u^f lat)$.

We claim that, actually,

$$h(\mu_j^\sharp) = k(\mu_j^\sharp) = s \qquad \text{and} \qquad u_2^\sharp \in \mathcal{H}_j(u_0). \tag{2.36}$$

Namely, from the Rankine–Hugoniot relations

$$-s\big(u^\flat - u_0\big) + f(u^\flat) - f(u_0) \;=\; 0 \qquad \text{and} \qquad -\,s\big(u_2^\sharp - u^\flat\big) + f(u_2^\sharp) - f(u^\flat) \;=\; 0,$$

we deduce that $-s\big(u_2^\sharp - u_0\big) + f(u_2^\sharp) - f(u_0) \;=\; 0$, which proves (2.36).

It follows (see Figure 2.4(a)) that (2.33) holds for all $\mu_j(u_2) < \mu_j(u_2^\sharp)$, and the equality holds in (2.33) at the critical value $u_2^\sharp$. Moreover, since $\mu_j(u_2^\sharp) < \mu_j^\star(u_0)$, the shock speed is decreasing on the interval $\big(\mu_j(u^\flat), \mu_j(u_2^\sharp)\big)$ and any shock from $u^\flat$ to u_2 (with $\mu_j(u_2) \le \mu_j(u_2^\sharp)$) satisfies the Liu criterion.

We have the inequalities $\mu_j(u^\flat) < \mu_j^\star(u_0) < \mu_j(u_2^\sharp) < \mu_j(u_0)$. As $\mu_j(u^\flat)$ increases, $\mu_j(u_2^\sharp)$ decreases and eventually both quantities approach the limiting value $\mu_j^\star(u_0)$. As $\mu_j(u^\flat)$ decreases, $\mu_j(u_2^\sharp)$ increases and eventually $\mu_j(u^\flat)$ approaches the limiting value $\mu_j^{\flat\flat}(u_0)$, while $\mu_j(u_2^\sharp)$ approaches some limiting value, say, $\mu_j^{\sharp\sharp}(u_0)$. It is tedious but straightforward to check from the properties of the wave speeds that no third wave can follow a two-wave fan. See Figure 2.2(a) for a representation of the wave set $\mathcal{S}_j(u_0)$.

Case B. For $u_0 \in \mathcal{M}_j$, it is not hard to see, using either of the conditions (2.8) or (2.18), that $\mathcal{W}_j(u_0)$ coincides locally with the Hugoniot curve $\mathcal{H}_j(u_0)$. This is because the wave speed is decreasing when moving away from u_0 in either direction. The construction is complete for $u_0 \in \mathcal{M}_j$.

Consider the case $\mu_j(u_0) > 0$. For $\mu_j > \mu_j(u_0)$, the state u_0 can be connected to any point on $\mathcal{H}_j(u_0)$ since the wave speed is decreasing for μ_j increasing. For $\mu_j < \mu_j(u_0)$, the wave speed is, locally, increasing for μ_j decreasing. So u_0 can be connected to a point on $\mathcal{O}_j(u_0)$ by a rarefaction. This remains possible until μ_j reaches the value 0. It is also possible to connect any point $u_1 \in \mathcal{O}_j(u_0)$ with $\mu_j(u_1) \in \big[0, \mu_j(u_0)\big]$ to a point $u_2 \in \mathcal{H}_j(u_1)$ provided

$$\bar{\lambda}_j(u_1, u_2) = \lambda_j(u_1). \tag{2.37}$$

This construction covers the range $\mu_j \in \big[\mu_j^{\star\star}(u_0), 0\big]$. It is also possible to connect u_0 directly to a point $u \in \mathcal{H}_j(u_0)$ with $\mu_j(u) \leq \mu_j^{\star\star}(u_0)$, since the shock speed in this range satisfies the Liu criterion.

This completes the construction of the classical wave curve $\mathcal{W}_j^c(u_0)$.

We now describe all nonclassical solutions with two j-waves. Consider an admissible one-wave solution from u_0 to u_1. Suppose first $\mu_j(u) \in \big(0, \mu_j(u_0)\big)$ so that $u_1 \in \mathcal{O}_j(u_0)$. One can connect u_1 to $u_2 \in \mathcal{H}_j(u_0)$ by a shock provided both conditions

$$\bar{\lambda}_j(u_1, u_2) \geq \lambda(u_1), \tag{2.38}$$

$$D(u_1, u_2) \, \leq \, 0 \tag{2.39}$$

hold. From the graph of the entropy dissipation, we know that (2.39) is equivalent to

$$\mu_j(u_2) \leq \mu_j^{\flat\flat}(u_0).$$

In view of the graph of the shock speed, (2.38) reads

$$\mu_j^{\flat\flat}(u_1) \leq \mu_j(u_2) \leq \mu_j^{\star}(u_1).$$

Since we always have $\mu_j^{\flat\flat}(u_0) \in \big[\mu_j^{\star\star}(u_0), \mu_j^{\star}(u_0)\big]$, it follows that the admissible interval in the case under consideration is $\mu_j(u_2) \in \big[\mu_j^{\star\star}(u_0), \mu_j^{\flat\flat}(u_0)\big]$. Moreover such a shock is classical only when $\mu_j(u_2) \leq \mu_j^{\star\star}(u_0)$, that is, only when $\mu_j(u_2) = \mu_j^{\star\star}(u_0)$.

Suppose now that $\mu_j(u) \geq \mu_j(u_0)$ so that $u_1 \in \mathcal{H}_j(u_0)$. One can connect u_1 to a point $u_2 \in \mathcal{H}_j(u_1)$ provided

$$\bar{\lambda}_j(u_1, u_2) \geq \bar{\lambda}_j(u_0, u_1) \tag{2.40}$$

and

$$D(u_1, u_2) \, \leq \, 0. \tag{2.41}$$

The condition (2.41) is equivalent to saying $\mu_j(u_2) \leq \mu_j^{\flat\flat}(u_1)$. As μ_j decreases from $\mu_j^{\flat\flat}(u_0)$, the speed $\bar{\lambda}_j(u_1, u_2)$ satisfies (2.40), decreases, and eventually reaches the value $\bar{\lambda}_j(u_0, u_1)$. Since $u_1 \in \mathcal{H}_j(u_0)$ and $u_2 \in \mathcal{H}(u_1)$, the same argument as in the case (2.10a) shows that for that value of μ_j, one has $u_2 \in \mathcal{H}_j(u_0)$. This completes the proof of Theorem 2.6. □

2.3. Selection by kinetic relations. In view of Theorem 2.6, the wave set $\mathcal{S}_j(u_0)$ is a two-dimensional manifold when $j \in \mathbf{P}$. It is our objective now to select a nonclassical wave curve $\mathcal{W}_j^{nc}(u_0)$ in the wave set. Heuristically, it is sufficient to determine one free parameter needed for each nongenuinely nonlinear wave family. One may postulate that for each state u_0, there exists a *single* right state u_1 that can be reached by a nonclassical shock for any $j \in \mathbf{P}$. This is indeed what happens when defining nonclassical shocks as limits of diffusive-dispersive regularizations. We propose to select the admissible nonclassical shocks by considering their entropy dissipation and stipulate the knowledge of an additional jump-like relation on the nonclassical discontinuities. The derivation of such an additional relation for limits of diffusive-dispersive regularizations is discussed later in this subsection.

The following definition stipulates that the entropy dissipation

$$D(u_0, u_1) = -s\ (U(u_1) - U(u_0)) + F(u_1) - F(u_0)$$

of a nonclassical shock, with speed $s = \bar{\lambda}_j(u_0, u_1)$ and connecting u_0 to u_1, is a given "constitutive function" representing certain small-scale properties that have been neglected at the hyperbolic level of modeling. In the following we suppose, for the sake of definiteness, that the condition (2.10a) is satisfied. Dealing with the case (2.10b) requires some modification of the analysis in this subsection. (See also section 3 in which both cases arise.)

We denote by $BV \cap L^\infty$ the space of measurable and bounded functions that have bounded variation in space and time. This space is natural for systems of conservation laws. Functions in $BV \cap L^\infty$ admit traces in a measure theoretic sense [14], so that (2.42) below has a meaning almost everywhere with respect to the one-dimensional Hausdorff measure.

Definition 2.8. *For each $j \in \mathbf{P}$, let $\phi_j : \mathcal{U} \to \mathbb{R}_-$ be a given function. A solution $u(x,t) \in BV \cap L^\infty$ to* (2.1), (2.8) *is called an admissible nonclassical entropy solution if it satisfies the entropy inequality and the entropy dissipation of any nonclassical j-shock in u ($j \in \mathbf{P}$), connecting u_0 to u_1, satisfies*

$$D(u_0, u_1) = \phi_j(u_0). \tag{2.42}$$

We refer to (2.42) as a *kinetic relation* and to ϕ_j as the *kinetic function* for the family j since they determine the propagation of the nonclassical shocks. The kinetic function could also be expressed as a function of the right state u_1 (which need not be equivalent to (2.42)) or—and this is physically more realistic—as a function of a variable "symmetric" in u_0 and u_1, such as the shock speed, or—for problems in fluid dynamics and material science—the mass flux across the discontinuity, etc. Here we shall focus attention on kinetic functions depending solely on the shock speed s, i.e.,

$$D(u_0, u_1) = \varphi(s), \tag{2.43}$$

where φ need be defined only on the union of intervals $\Lambda = \bigcup_{j \in \mathbf{P}} \left[\lambda_j^{\min}, \lambda_j^{\max}\right]$. For scalar conservation laws and under suitable monotonicity conditions, the kinetic function can always be expressed as a function of the shock speed. The same is true for the kinetics generated by diffusive-dispersive regularizations for the systems of two equations studied later in sections 3–5.

In many physical systems, the entropy dissipation is related to the mechanical energy and may be viewed as *a force driving the propagation* of the nonclassical shocks; it is natural to provide a one-to-one relationship between the propagation speed and the driving force. This standpoint was emphasized by Abeyaratne and Knowles [1] for propagating phase boundaries in solids undergoing phase transformations.

In the following we show that the kinetic relation selects a unique curve $\mathcal{W}_j^{nc}(u_0)$ corresponding to nonclassical solutions in the wave set $\mathcal{S}_j(u_0)$. Denote by $D_j^\star(u_0)$ the *maximal negative value* of the entropy dissipation $D(u_0, u_1)$ along the Hugoniot curve $\mathcal{H}_j(u_0)$:

$$D_j^\star(u_0) = \min_{u_1 \in \mathcal{H}_j(u_0)} D(u_0, u_1).$$

Actually the maximum is achieved at the critical value $\mu_j^\star(u_0)$ for the shock speed. Consider also the entropy dissipation as a function of s, say, $d^\star(s)$ defined as

$$d^\star(s) = \max \big\{ D_j^\star(u_0) \,|\, u_0 \in \mathcal{U},\, j \in \mathbf{P}, \quad \lambda_j\big(u_0, w_j(\mu_j^\star(u_0); u_0)\big) = s \big\}. \tag{2.44}$$

(The value is taken to be $-\infty$ when no u_0 satisfies the constraint.) Note that $D_j^\star$ and $d^\star$ are computable from the expression of the flux f in the examples studied in sections 3–5 below.

Theorem 2.9 below shows that knowing the entropy dissipation of the admissible nonclassical shocks determines a unique solution of the Riemann problem. To solve the Riemann problem, we assume that $\big\{ r_k(u, u') \big\}$ is a basis of $\mathbb{R}^N$ for arbitrary u, $u' \in \mathcal{U}$. (This is always true when R is small enough.)

Theorem 2.9. *Suppose that the system satisfies the condition* (2.10a).

(1) *For $j \in \mathbf{P}$, let $\phi_j : \mathcal{U} \to \mathbb{R}_-$ be a continuous function satisfying*

$$D_j^\star(u_0) \le \phi_j(u_0) \le 0 \qquad \textit{for all } u_0 \in \mathcal{U},\, j \in \mathbf{P}. \tag{2.45}$$

Let $u_0 \in \mathcal{U}$ and $j \in \mathbf{P}$ be given. From the wave set $\mathcal{S}_j(u_0)$, there exists a unique wave curve $\mathcal{W}_j^{nc}(u_0)$ using nonclassical shocks satisfying the kinetic relation (2.42). *For u_l and u_r in $\mathcal{U}$, the Riemann problem* (2.1), (2.11) *admits a unique solution in the class of admissible nonclassical entropy solutions obtained by intersection of the curves $\mathcal{W}_j^{nc}$. Furthermore, the solution depends continuously in the L^1 norm upon its end states.*

(2) *Let $\varphi : \Lambda \to \mathbb{R}_-$ be a Lipschitz continuous function satisfying*

$$d^\star(s) \le \varphi(s) \le 0, \quad \frac{d\varphi}{ds}(s) \le 0 \qquad \textit{for all } s \in \Lambda. \tag{2.46}$$

For the kinetic relation (2.43), *the conclusions are the same as in Case* 1.

(3) *In both Cases* 1 *and* 2 *above, there exist two values $\mu_j^\flat(u_0)$ and $\mu_j^\sharp(u_0)$, with*

$$\mu_j^{\star\star}(u_0) \le \mu_j^{\flat\flat}(u_0) \le \mu_j^\flat(u_0) \le \mu_j^\star(u_0) \le \mu_j^\sharp(u_0) \le \mu_j^{\sharp\sharp}(u_0) \le \mu_j(u_0), \tag{2.47}$$

such that the nonclassical wave curve is composed of the following four pieces:

$$\mathcal{W}_j^{nc}(u_0) = \begin{cases} \mathcal{O}_j(u_0) & \textit{for all } \mu_j \ge \mu_j(u_0), \\ \mathcal{H}_j(u_0) & \textit{for all } \mu_j^\sharp(u_0) \le \mu_j \le \mu_j(u_0), \\ \mathcal{H}_j(u^\flat) & \textit{for all } \mu_j^\flat(u_0) \le \mu_j < \mu_j^\sharp(u_0), \\ \mathcal{O}_j(u^\flat) & \textit{for all } \mu_j \le \mu_j^\flat(u_0), \end{cases}$$

where $u^\flat := w_j\big(\mu_j^\flat(u_0); u_0\big)$. The curve $\mathcal{W}_j^{nc}(u_0)$ is continuous and monotone in the parameter μ_j, and is of class C^2 except at $\mu_j = \mu_j^\sharp(u_0)$, where it is generally only Lipschitz continuous.

We can recover the classical curve $\mathcal{W}_j^c(u_0)$ with the (maximal) choice

$$\phi_j(u_0) = D_j^\star(u_0). \tag{2.48}$$

In that case the classical and nonclassical shocks in the solution have the same propagation speed, and the two waves are indistinguishable in the (x,t) plane. On the other hand it is not possible to use part of the classical wave curve, say, for values $\mu_j > \mu_j^c$, and switch to the nonclassical wave curve, say, for values $\mu_j < \mu_j^c$, at least as far as a Riemann solution depending continuously upon its end states is sought. The latter seems to be a natural requirement, at least in view of the examples studied so far in the literature. Furthermore the classical wave curve $\mathcal{W}_j^c(u_0)$ is always admissible, since Definition 2.8 does not prevent us from solving the Riemann problem by using classical waves only. Therefore, even after imposing the kinetic relation, there exist *two* wave curves to choose from for each nongenuinely nonlinear family, $\mathcal{W}_j^c(u_0)$ and $\mathcal{W}_j^{nc}(u_0)$. It would be interesting to connect this nonuniqueness with instability in solutions to an augmented diffusive-dispersive system with vanishing small-scale parameters.

Proof of Theorem 2.9. Let $u_0 \in \mathcal{U}$ and $j \in \mathbf{P}$ be given. In view of the definition (2.44) of the maximal entropy dissipation and the assumption (2.45), the criterion (2.42) selects a unique nonclassical shock along the Hugoniot curve $\mathcal{H}_j(u_0)$, say, $u^\flat = w_j(\mu_j^\flat(u_0), u_0)$. Once this state is selected, the construction in Theorem 2.6 determines a unique wave curve $\mathcal{W}_j^{nc}(u_0)$ having the form described in item (3) of the theorem. This curve is continuous in the parameter μ_j which by construction is monotone increasing along it. It is of class C^2 at the point $\mu_j(u_0)$ and $\mu_j^\flat(u_0)$ since classical rarefaction curves and shock curves have second-order contact. Finally, along the wave curve, the speeds of the (rarefaction or shock) waves change continuously. To see that, at the point $\mu_j^\sharp(u_0)$, one has to compare, on one hand, the shock speed of the nonclassical shock and, on the other hand, the shock speeds of the nonclassical shock and the classical one. Actually all three terms coincide at $\mu_j^\sharp(u_0)$:

$$\lim_{\substack{\mu_j \to \mu_j^\sharp(u_0) \\ \mu_j > \mu_j^\sharp(u_0)}} \bar{\lambda}_j(u_0, w_j(\mu_j, u_0)) = \lim_{\substack{\mu_j \to \mu_j^\sharp(u_0) \\ \mu_j < \mu_j^\sharp(u_0)}} \bar{\lambda}_j\big(u^\flat, w_j(\mu_j; u^\flat)\big) = \bar{\lambda}_j\big(u_0, u^\flat\big).$$

The continuous dependence of the wave speeds implies the L^1 continuous dependence of the solution. Finally, having constructed the Lipschitz continuous wave curves $\mathcal{W}_j^{nc}$ for $j \in \mathbf{P}$ and the smooth wave curves $\mathcal{W}_j^c$ for $j \notin \mathbf{P}$, and using the condition that $\big\{r_k(u,u')\big\}$ is a basis of $\mathbb{R}^N$ for arbitrary u, u', we can solve the Riemann problem with data in $\mathcal{U}$: combining together the wave curves, we apply the theorem of implicit functions for Lipschitz continuous curves. (For a reference see Isaacson and Temple [29].) The Riemann problem admits a unique solution, at least with data in $B(u_*, R') \subset \mathcal{U}$, with $R' << R$. This proves the items (1) and (3).

In order to use the criterion (2.43), one observes that the entropy dissipation $D(u_0,u_1)$ along the Hugoniot curve—when expressed as a function of the shock speed s—is increasing from its lower value $D_j^\star(u_0)$ at $s^\star = \bar{\lambda}_j\big(u_0, w_j(\mu_j^\star(u_0); u_0)\big)$ to the value 0 at $s = \bar{\lambda}_j\big(u_0, w_j(\mu_j^{\flat\flat}(u_0); u_0)\big)$. On the other hand, the function $\varphi(s)$ is assumed to be decreasing in the same interval and by (2.44), (2.46), one has $\varphi(s^\star) \geq d^\star(s) \geq D_j^\star(u_0)$. Thus there exists a unique point $\mu_j = \mu_j^\flat(u_0)$ such that the kinetic relation (2.43) is satisfied. This wave curve shares the same properties as that in the case (2.42). □

Remark 2.10. (1) The assumption that the kinetic function be a decreasing function of the shock speed may be motivated in the following way. Consider a scalar conservation law ($N = 1$) with the flux $f(u) = u^3$ and the entropy $U(u) = u^2/2$. Consider a *linear* relation for nonclassical shocks, say, between the left state u_0 and the right state u_1,

$$u_1 = g(u_0) := \beta\, u_0. \tag{2.49}$$

According to the theory in this section, one must have $\beta \in (-1, -1/2)$. Plugging (2.49) into the definition of the entropy dissipation $D(u_0, u_1)$ the kinetic relation corresponding to (2.49) can be computed:

$$\begin{aligned}\varphi(s) := D\big(u_0, g(u_0)\big) &= -\,(1+\beta)(1-\beta)^3\, u^4\\ &= -\,(1+\beta)(1-\beta)^3(1+\beta+\beta^2)^{-2}\, s^2,\end{aligned}$$

which indeed is a decreasing function of s in the interesting range $s > 0$.

(2) In the classical solution, the value of the intermediate state (if any) in the Riemann solution varies continuously as $u_1 \in \mathcal{W}_j^c(u_0)$ describes the wave curve; the solution in the (x,t) plane varies continuously in the L^1 norm and its total variation is a continuous function of the end points. For the nonclassical wave curve, the wave speeds only are continuous, and the total variation of the Riemann solution is not a continuous function of the endpoints. □

To conclude this section, we explain how to determine the kinetic function, needed in (2.42) or (2.43). Consider a sequence of solutions u^ϵ to a regularized version of (2.1) of the form (2.2). Assume for the sake of this presentation that the u^ϵ remain bounded in the total variation norm and converge to a limiting solution u to (2.1), (2.5). Suppose also that the system admits an entropy pair that is compatible with the regularization (2.2). We know that the entropy inequality (2.5) is too lax to guarantee uniqueness for the Riemann problem. Another Rankine–Hugoniot relation, in addition to the set of conservation laws contained in (2.1), is in principle sufficient to select a unique nonclassical solution.

The concepts of entropy and entropy dissipation are fundamental in the theory of hyperbolic conservation laws. It seems mathematically natural to go beyond the entropy *inequality* (2.8) and instead write the entropy *balance*:

$$\partial_t U(u) + \partial_x F(u) = \mu_U \le 0. \tag{2.50}$$

Here μ_U is a bounded, nonpositive Borel measure, which provides partial information on the small-scale effects in the regularization sequence that generated the solution u. The dissipation measure generated by a regularization (2.2) satisfying the condition (2.3) is

$$\mu_U := w - \star \lim_{\epsilon \to 0}\ \epsilon\, \partial_x u_\epsilon^T \nabla^2 U(u_\epsilon) B_1(u_\epsilon) \partial_x u_\epsilon. \tag{2.51}$$

Since u solves (2.1), the measure μ_U has its support included in the union of the set of points of approximate discontinuity of u.

The mass of the measure along the curve of discontinuity is the entropy dissipation $D(.,.)$.

Of course the knowledge of the measure μ_U in (2.50) is required only for nonclassical shocks, since the propagation of a *classical* shock is uniquely determined by the Rankine–Hugoniot relation

$$-\bar\lambda_j(u_0, u_1)\,\big(u_1 - u_0\big) + f(u_1) - f(u_0) = 0$$

and the entropy *inequality*

$$-\bar\lambda_j(u_0,u_1)\ (U(u_1)-U(u_0))+F(u_1)-F(u_0)\le 0.$$

The entropy dissipation measure μ_U for a *nonclassical* shock, as determined by (2.51), in general, will depend upon the left state u_0 and the shock speed, $s=\bar\lambda_j(u_0,u_1)$. The kinetic relation generated by (2.2) can be determined, at least at a formal level, from an analysis of admissible traveling wave solutions to (2.2). Different approximations to (2.1) will result, in general, in different kinetic relations. Consider a traveling wave solution $u_\epsilon(x,t)=w((x-s\,t)/\epsilon)$ to (2.2), that is a solution to the ordinary differential equation in $\xi=(x-s\,t)/\epsilon$

$$-s\,w'+f(w)'=\big(B_1(w)\,w'\big)'+\big(B_2(w)\,w''\big)' \tag{2.52}$$

satisfying the following boundary conditions

$$\begin{aligned}&\lim_{\xi\to-\infty}w(\xi)=u_0, &&\lim_{\xi\to\infty}w(\xi)=u_1,\\ &\lim_{\xi\to\pm\infty}w'(\xi)=0, &&\lim_{\xi\to\pm\infty}w''(\xi)=0.\end{aligned} \tag{2.53}$$

The equation (2.52) can be integrated once:

$$-s\,(w-u_0)+f(w)-f(u_0)=B_1(w)\,w'+B_2(w)\,w''. \tag{2.54}$$

The internal structure of the nonclassical shock is represented by the trajectory $\xi\to w(\xi)$, which can be used to determine the entropy dissipation measure. Namely, at the hyperbolic level we have

$$\begin{aligned}D(u_0,u_1)&=-\bar\lambda_j(u_0,u_1)\,\big(U(u_1)-U(u_0)\big)-F(u_1)+F(u_0)\\ &=\int_{\mathbb R}\nabla U(w)\cdot\big(-\bar\lambda_j(u_0,u_1)+Df(w)\big)\,w'\,d\xi\\ &=-\int_{\mathbb R}w'\cdot\nabla^2U(w)\cdot\big(-\bar\lambda_j(u_0,u_1)\,(w-u_0)+f(w)-f(u_0)\big)\,d\xi.\end{aligned}$$

Using (2.54) for the traveling wave and the conditions (2.3), we obtain

$$D(u_0,u_1)=-\int_{\mathbb R}(w')^T\nabla^2U(w)B_1(w)\,w'\,d\xi\le 0. \tag{2.55}$$

In the examples arising in continuum mechanics, at least, the entropy dissipation for a nonclassical shock, computed from (2.55), can be expressed as a function of the state u_0 (or, equivalently, u_1). (See also section 4.1.)

3. Nonclassical shocks in elastodynamics (1).

We now turn to a model arising in the theory of elastic materials, which is strictly hyperbolic and admits two nongenuinely nonlinear characteristic fields. This section restricts attention to the Riemann problem and extends the analysis of section 2 to arbitrarily large initial data.

3.1. Preliminaries.

Consider the system of elastodynamics

$$\begin{aligned}\partial_t v-\partial_x\sigma(w)&=0,\\ \partial_t w-\partial_x v&=0,\end{aligned} \tag{3.1}$$

where the real-valued functions v and w represent the velocity and gradient deformation, respectively. The stress-strain law is assumed to have the form

$$\sigma(w) = w^3 + m^2\, w, \qquad m > 0. \tag{3.2}$$

The focus here is on Riemann data

$$v(x,0),\, w(x,0) = \begin{cases} v_l, w_l, & x < 0, \\ v_r, w_r, & x > 0, \end{cases} \tag{3.3}$$

for constants $v_l, w_l, \dots$. We note that (3.1)–(3.2) is invariant under any of the transformations:

$$w \to -w, \quad v \to -v, \tag{3.4i}$$

$$v \to v + \bar{v} \quad \text{(for any constant } \bar{v}\text{)}, \tag{3.4ii}$$

$$x \to -x, \quad v \to -v. \tag{3.4iii}$$

We may write (3.1) in the general form (2.1) by setting $u = (v,w)$, $f(u) = -\big(\sigma(w), v\big)$. The system is strictly hyperbolic with eigenvalues $\lambda_1(v,w) = -c(w) < 0 < \lambda_2(v,w) = c(w)$, where the sound speed is defined by $c(w) = \sqrt{3\,w^2 + m^2}$. Since the wave speeds are independent of v, the notation $\lambda_1(w) = -c(w)$ and $\lambda_2(w) = c(w)$ is also used. The wave speeds are strictly separated: they keep different signs and are bounded away from zero. The right eigenvectors may be chosen as $r_i(v,w) = (\pm c(w), 1)$ for $i = 1, 2$.

We consider the wave curves for the system (3.1). The Hugoniot locus $\mathcal{H}_1(v_0, w_0)$ consists of all the states (v_1, w_1) connected to (v_0, w_0) on the left by a discontinuity with speed $s < 0$. Similarly, $\mathcal{H}_2(v_0, w_0)$ corresponds to the discontinuities with speed $s > 0$. The Rankine–Hugoniot condition gives

$$-s = \frac{v - v_0}{w - w_0} = \frac{\sigma(w) - \sigma(w_0)}{v - v_0}. \tag{3.5}$$

A discontinuity connecting (v_0, w_0) to (v, w) therefore travels with speed $s = \pm\, \bar{c}(w_0; w)$, where we use the notation $\bar{c}(w_0; w) = \sqrt{w_0^2 + w_0\, w + w^2 + m^2}$. Observe that $\bar{c}(w; w) = c(w)$. We emphasize that $\bar{c}(w_0; w)$ is the magnitude of the shock speed and is always positive. From (3.5) we obtain

$$\mathcal{H}_1(v_0, w_0) \;=\; \Big\{ v \in \mathbb{R} \,|\, v - v_0 \;=\; \bar{c}(w_0; w)\,(w - w_0) \Big\}, \tag{3.6}$$

$$\mathcal{H}_2(v_0, w_0) \;=\; \Big\{ v \in \mathbb{R} \,|\, v - v_0 \;=\; -\,\bar{c}(w_0; w)\,(w - w_0) \Big\}. \tag{3.7}$$

In addition, the rarefaction waves are based on the integral curves of the vector fields r_j:

$$\mathcal{O}_1(v_0, w_0) \;=\; \Big\{ v \in \mathbb{R} \,|\, v - v_0 \;=\; \int_{w_0}^{w} c(z)\, dz \Big\}, \tag{3.8}$$

$$\mathcal{O}_2(v_0, w_0) \;=\; \Big\{ v \in \mathbb{R} \,|\, v - v_0 \;=\; -\int_{w_0}^{w} c(z)\, dz \Big\}. \tag{3.9}$$

The system (3.1)–(3.2) is not genuinely nonlinear since $\nabla\lambda_1(w)\cdot r_1(w) = -3\,w/c(w)$ and $\nabla\lambda_2(w)\cdot r_2(w) = 3\,w/c(w)$, which vanish on the (one-dimensional) manifold $\mathcal{M} = \mathcal{M}_1 = \mathcal{M}_2 = \big\{(v,w)\,|\, w = 0\big\}$. In order to uniquely solve the Riemann problem, we now apply appropriate entropy criteria. Away from the line $w = 0$, the system has two genuinely nonlinear fields; therefore, for shocks with small amplitude, the Lax shock inequalities may be used.

3.2. Liu's construction of a unique solution. Here we briefly summarize the Liu's construction for the system (3.1). For a point (v, w) in $\mathcal{H}_1(v_0, w_0)$, the Liu entropy criterion implies the Lax shock inequalities, $-c(w_0) \geq -\bar{c}(w_0; w) \geq -c(w)$, and, as pointed out in section 2, is actually equivalent to them since the stress-strain relation has a single inflexion point. Defining

$$\kappa = w/w_0, \tag{3.10}$$

and using the expressions for $c(w)$ and $\bar{c}(w_0; w)$, one sees that the admissible region for $\mathcal{H}_1(v_0, w_0)$ consists of all (v, w) with

$$\kappa \in (-\infty, -2] \cup [1, +\infty)\,. \tag{3.11}$$

For $\mathcal{H}_2(v_0, w_0)$, the shock speed is positive and the Liu criterion leads to the interval

$$\kappa \in [-1/2, 1]\,. \tag{3.12}$$

Note in passing that the intervals found in (3.11) and (3.12) are independent of m. We now utilize (3.11)–(3.12) and construct the classical wave curves $\mathcal{W}_j^c(v_0, w_0)$. Consider a point (v_0, w_0) with $w_0 > 0$. By (3.4ii), $\mathcal{W}_j^c(v_0', w_0)$ for $v_0' \neq v_0$ is a suitable translate of $\mathcal{W}_j^c(v_0, w_0)$, while (3.4i) allows the construction for $w_0 > 0$ to be simply extended to the case $w_0 < 0$.

The wave curves are easily defined locally. These curves are $\mathcal{H}_1(v_0, w_0)$, $\mathcal{O}_1(v_0, w_0)$, $\mathcal{H}_2(v_0, w_0)$, and $\mathcal{O}_2(v_0, w_0)$ for values $w > w_0$, $w < w_0$, $w < w_0$, and $w > w_0$, respectively. Note that since $\nabla\lambda_i \cdot r_i = \pm 3\,w/c(w)$ changes signs only along curves crossing $w = 0$, we see immediately that the curves $\mathcal{H}_1(v_0, w_0)$ and $\mathcal{O}_2(v_0, w_0)$ may be extended to all points (v, w) such that $w > w_0$. These two curves correspond to functions $w \to v(w)$ that are increasing and decreasing, respectively, according to the formulas (3.6) and (3.9).

We now turn to those wave curves which cross the line $w = 0$. For $0 < w \leq w_0$, we have $\nabla\lambda_i \cdot r_i < 0$, so that all points (v, w) in this region, lying on $\mathcal{O}_1(v_0, w_0)$, may be arrived at by a single 1-rarefaction. This construction changes for $w < 0$: when $-2\,w_0 < w < 0$, there is a critical point on the rarefaction curve, say, $(v_*, w_*) \in \mathcal{O}_1(v_0, w_0)$ with $w_* > 0$, for which $\bar{c}(w_0; , w_*) = c(w_*)$. This point satisfies $w_* = -w/2$.

According to the Liu criterion, in order to reach a point (v, w) from (v_0, w_0), having $-2\,w_0 < w < 0$, the solution proceeds along $\mathcal{O}_1(v_0, w_0)$ until it reaches (v_*, w_*), at which point it jumps on $\mathcal{H}_1(v_*, w_*)$ to (v, w). We denote this composite curve by

$$\begin{aligned} \mathcal{K}_1(v_0, w_0) = \Big\{ (v, w) \,|\, &\text{ there exists } (v_*, w_*) \in \mathcal{O}_1(v_0, w_0), \quad 0 < w_* < w_0, \\ &\text{such that } w = -2\,w_* \text{ and } (v, w) \in \mathcal{H}_1(v_*, w_*) \Big\}. \end{aligned} \tag{3.13}$$

It may be shown that along $\mathcal{K}_1(v_0, w_0)$, v is monotone increasing with w. When $w \le -2\,w_0$, the curve $\mathcal{K}_1(v_0, w_0)$ may be continued, by virtue of (3.11), as a single 1-shock, i.e., $(v, w) \in \mathcal{H}_1(v_0, w_0)$, when $w \le -2\,w_0$ and v is thus given by the Rankine–Hugoniot relation (3.5). Note that $\mathcal{K}_1(v_0, w_0)$ joins $\mathcal{H}_1(v_0, w_0)$ at the point $(v_{**}, w_*) = (v_{**}, -2\,w_0) \in \mathcal{H}_1(v_0, w_0)$, and $\mathcal{K}_1(v_0, w_0)$ joins $\mathcal{O}_1(v_0, w_0)$ at the point $(0, v_0) \in \mathcal{O}_1(v_0, w_0)$. We summarize in the next lemma.

LEMMA 3.1. *The classical* 1*-wave curve from a point* $(v_0, w_0), w_0 > 0$*, is the union of four pieces:*

$$\mathcal{W}_1^c(v_0, w_0) \;=\; \begin{cases} \mathcal{H}_1(v_0, w_0) & \textit{for } \; w > w_0, \\ \mathcal{O}_1(v_0, w_0) & \textit{for } \; 0 \le w \le w_0, \\ \mathcal{K}_1(v_0, w_0) & \textit{for } \; -2\,w_0 \le w < 0, \\ \mathcal{H}_1(v_0, w_0) & \textit{for } \; w < -2\,w_0. \end{cases}$$

It is a monotone increasing curve of class $\mathcal{C}^\infty$*, extending from* $(v, w) = (-\infty, -\infty)$ *to* $(v, w) = (+\infty, +\infty)$*.*

The construction of the 2-wave curve is similar and we summarize its properties as follows.

LEMMA 3.2. *The classical* 2*-wave curve from* (v_0, w_0)*, with* $w_0 > 0$*, is the union of three pieces:*

$$\mathcal{W}_2^c(v_0, w_0) \;=\; \begin{cases} \mathcal{O}_2(v_0, w_0) & \textit{for } \; w > w_0, \\ \mathcal{H}_2(v_0, w_0) & \textit{for } \; -w_0/2 \le w \le w_0, \\ \mathcal{O}_2(v_*, w_*) & \textit{for } \; w < -w_0/2, \end{cases}$$

where $(v_*, w_*) \in \mathcal{H}_2(v_0, w_0)$ *and* $w_* = -w_0/2$*. It is a monotone decreasing curve of class* $\mathcal{C}^\infty$*, extending from* $(v, w) = (+\infty, -\infty)$ *to* $(v, w) = (-\infty, +\infty)$*.*

The infinite extent in v of the 2-wave curve follows from the fact that the integral curves in (3.9) have no horizontal asymptotes. This completes the construction of the wave curves based on the Liu criterion. A unique solution exists for arbitrary Riemann data. It can be checked that this solution depends continuously upon its initial states.

3.3. Two-parameter family of nonclassical entropy solutions. We apply Definition 2.1 to the system (3.1) and construct a two-parameter family of solutions. Definition 2.1 is based on a specific convex entropy pair, which we take here to be

$$U(v, w) = \frac{v^2}{2} + \frac{w^4}{4} + m^2\,\frac{w^2}{2}, \qquad F(v, w) = -v\,\sigma(w). \tag{3.14}$$

This choice is based on the physically motivated regularization studied in section 4. A brief computation leads to the following formula for the entropy dissipation:

$$D(v_-, w_-; v_+, w_+) = -s\big(\bar w (m^2 + \bar{w^2})\,[w] + \bar v\,[v]\big)\big(m^2 \bar w + \bar{w^3}\big)\,[v] - \bar v\,[\sigma(w)] \tag{3.15}$$

with $[\alpha] = \alpha_+ - \alpha_-$ and $\bar\alpha = (\alpha_+ + \alpha_-)/2$. We now substitute the Rankine–Hugoniot relations (3.5) to get

$$D(v_-, w_-; v_+, w_+) = \bar w\,\bar{w^2}\;[v] - \bar{w^3}\;[v] = -\frac{1}{2}\bar w\;[w]^2\;[v]\,.$$

The entropy inequality (2.8), (3.14) therefore reduces to

$$\bar w\;[v] \ge 0 \tag{3.16}$$

(for $[w] \neq 0$). If we now utilize (3.6)–(3.7) for $\mathcal{H}_1(v_-, w_-)$ and $\mathcal{H}_2(v_-, w_-)$, we find that

$$D(v_-, w_-; v_+, w_+) = \frac{s}{2}\,[w]^3\,\bar{w}. \tag{3.17}$$

We recall that $s < 0$ for $\mathcal{H}_1(v_-, w_-)$ and $s > 0$ for $\mathcal{H}_2(v_-, w_-)$. From now on we express the entropy dissipation as a function of w_- and w_+ alone: $D(w_-; w_+)$. The admissible nonclassical shocks from (v_-, w_-) to (v_+, w_+) must therefore satisfy

(3.18)
$$|w_+| \geq |w_-| \quad \text{along} \quad \mathcal{H}_1(v_-, w_-), \qquad |w_+| \leq |w_-| \quad \text{along} \quad \mathcal{H}_2(v_-, w_-).$$

Since $\mathcal{H}_1(v_-, w_-)$, restricted by the condition (3.8), forms a nonconnected set, we denote the portion of $\mathcal{H}_1(v_-, w_-)$ with $w_+ \geq w_-$ by $\mathcal{H}_1^+(v_-, w_-)$, while that portion having $w_+ \leq -w_-$ will be denoted by $\mathcal{H}_1^-(v_-, w_-)$.

We now introduce solutions containing nonclassical shocks. Consider a point (v_0, w_0) with $w_0 > 0$. Owing to transformations (3.4), a translation in v_0 simply effects the same translation in the entire solution; furthermore, we can obtain the wave curves for $w_0 < 0$ by switching the signs of both w and v. We begin by discussing the 1-wave curves. As in the classical case, the solution may leave (v_0, w_0) along $\mathcal{O}_1(v_0, w_0)$ and proceed until it reaches the point $(\tilde{v}, \tilde{w})$ with $\tilde{w} = 0$.

Lemma 3.3. *From any point $(v_1, w_1) \in \mathcal{O}_1(v_0, w_0)$, with $0 < w_1 < w_0$, it is possible to jump to a point $(v_2, w_2) \in \mathcal{H}_1^-(v_1, w_1)$ with $w_2 \in [-2\,w_1, -w_1]$.*

Proof of Lemma 3.3. By (3.18), one has $w_2^2 - w_1^2 \geq 0$. In addition, for the shock to follow the rarefaction, one needs $0 > -\bar{c}(w_1; w_2) \geq \lambda_1(w_1)$, so that $(w_2 + 2\,w_1)(w_2 - w_1) \leq 0$. The intersection of these two regions is the interval $-2\,w_1 \leq w_2 \leq -w_1$. Of the points w_2 in this interval, only the right-hand boundary $w_2 = -2\,w_1$ corresponds to a classical shock. ☐

As (v_1, w_1) varies from (v_0, w_0) to $(\tilde{v}, 0)$, along $\mathcal{O}_1(v_0, w_0)$, the set of image points, $\{(v_2, w_2)\}$, of these nonclassical shocks covers a bounded region. We refer to these wave fans as $\mathcal{O}_1$-$\mathcal{H}_1^-$ nonclassical solutions. From (3.18), it is also possible to leave (v_0, w_0) by a shock, i.e., to jump to $(v_1, w_1) \in \mathcal{H}_1(v_0, w_0)$ for $|w_1| \geq |w_0|$. We note that for $w_1 \geq w_0$ and for $w_1 \leq -2\,w_0$, these are classical shocks. In addition we have the following.

Lemma 3.4. *From a point $(v_1, w_1) \in \mathcal{H}_1^+(v_0, w_0)$, it is possible to jump via a nonclassical shock to $(v_2, w_2) \in \mathcal{H}_1^-(v_1, w_1)$ with $-w_0 - w_1 \leq w_2 \leq -w_1$. The points with $w_2 = -w_0 - w_1$ lie on $\mathcal{H}_1(v_0, w_0)$. The region containing a classical shock along $\mathcal{H}_1^+(v_0, w_0)$, followed by a nonclassical shock along $\mathcal{H}_1^-(v_1, w_1)$, extends indefinitely to the left in w_2, and down in v_2.*

Proof of Lemma 3.4. Once again (3.18) gives $|w_2| \geq |w_1|$, and for the nonclassical shock to follow the classical one, one must also have $-\bar{c}(w_1; w_2) \geq -\bar{c}(w_0; w_1)$. Manipulating the expression for s leads to $|2\,w_2 + w_1| \leq |2\,w_0 + w_1|$, and, using the fact that $0 < w_0 < w_1$, this has the solution $-w_0 - w_1 \leq w_2 \leq w_0$. Combining this with the entropy inequality leads to $-w_0 - w_1 \leq w_2 \leq -w_1$.

For $w_2 = -w_1 - w_0$, one has $-\bar{c}(w_0; w_1) = -\bar{c}(w_0; w_2)$ and, by using the Rankine–Hugoniot condition (3.5), one can show that $(v_2, w_2) \in \mathcal{H}_1^-(v_0, w_0)$. Since $w_2 \leq -2w_0$, the point (v_2, w_2) is in the classical portion of this Hugoniot curve.

According to (3.18), a point $(v_1, w_1) \in \mathcal{H}_1^+(v_0, w_0)$ may have w_1 arbitrarily large and positive, so that $w_2 \leq -w_1$ can be arbitrarily large and negative. A calculation using the Hugoniot curve shows that

$$\begin{aligned} v_2 &= v_0 + \bar{c}(w_0; w_1)\,(w_1 - w_0) + \bar{c}(w_1; w_2)\,(w_2 - w_1) \\ &\le v_0 + \bar{c}(w_0; w_1)\,(w_1 - w_0) - 2\,w_1\,c(w_1), \end{aligned}$$

so that as $w_1 \to +\infty$ with (v_0, w_0) fixed, we have $v_2 \le -w_1^2\,(1 + o(1)) \to -\infty$, so the upper boundary, and hence the entire region, tends to negative infinity, as $w_2 \to -\infty$. There is no horizontal asymptote. ∎

We refer to these 2-wave fans as $\mathcal{H}_1^+$-$\mathcal{H}_1^-$ nonclassical solutions. A similar argument shows that no $\mathcal{O}_1$-$\mathcal{H}_1^-$ or $\mathcal{H}_1^+$-$\mathcal{H}_1^-$ wave fan may be connected to *additional* states by a 1-wave.

We now turn to the 2-wave family, again taking (v_0, w_0) with $w_0 > 0$. In this case, $\lambda_2(w) = \sqrt{3\,w^2 + m^2}$ is increasing with w, so that any point $(v_1, w_1) \in \mathcal{O}_2^+(v_0, w_0)$, i.e., with $w_1 \ge w_0$, may be connected to (v_0, w_0) via a 2-rarefaction. We may not continue from (v_1, w_1) to a point $(v_2, w_2) \in \mathcal{H}_2(v_1, w_1)$, since the entropy inequality, which gives $|w_2| \le |w_1|$, and the proper ordering of wave speeds, which implies $w_2 \ge w_1$, have only the degenerate point $(v_2, w_2) = (v_1, w_1)$ of intersection. If instead we leave (v_0, w_0) via $\mathcal{H}_2(v_0, w_0)$, the entropy inequality permits us to proceed to the left, until we reach $(\tilde{v}, \tilde{w}) \in \mathcal{H}_2(v_0, w_0)$ with $\tilde{w} = -w_0$. Note that this shock is nonclassical for $-w_0 \le w_1 < -w_0/2$.

Lemma 3.5. *For $(v_1, w_1) \in \mathcal{H}_2(v_0, w_0)$ with $-w_0 \le w_1 \le -w_0/2$, it is possible to connect to a point $(v_2, w_2) \in \mathcal{H}_2(v_1, w_1)$ with $w_1 \le w_2 \le -w_0 - w_1$. This part of the curve $\mathcal{H}_2(v_1, w_1)$ extends until it reaches a point $(v_2, w_2) = (v_2, -w_0 - w_1) \in \mathcal{H}_2(v_0, w_0)$.*

Proof of Lemma 3.5. Starting from a point $(v_1, w_1) \in \mathcal{H}_2(v_0, w_0)$, we proceed with a 2-shock on the right, to a point $(v_2, w_2) \in \mathcal{H}_2(v_1, w_1)$. The entropy inequality forces $|w_2| \le |w_1|$. In addition, the requirement that $c(w_1; w_2) \ge c(w_0; w_1) \ge 0$ implies that $|2\,w_2 + w_1| \ge |2\,w_0 + w_1|$. Since $w_0 \ge |w_2|$, we must take $w_1 \le 0$. The condition then becomes $|2\,w_2 - |w_1|| \ge 2\,w_0 - |w_1|$, so that w_2 must also be nonpositive. Some manipulation gives $w_2 \le -w_0 - w_1 \le 0$, so that in combination with (3.18) we have $w_2 \in [w_1, -w_0 - w_1]$, and w_1 has the restriction that $w_1 \le -w_0 - w_1$, so that $w_1 \le -w_0/2$. This leads to $w_1 \in [-w_0, -w_0/2]$. At the right-hand end of this interval, $w_1 = -w_0/2$, the shock is classical. ∎

As w_1 varies about the interval $[-w_0, -w_0/2]$, the set $\{(v_2, w_2)\}$ of image points attainable from (v_0, w_0) by a nonclassical shock, followed by a second shock, fill up a bounded region. This second shock is always a classical one, across which w does not change signs. Points on this second shock may not, therefore, be connected to a further rarefaction or shock wave. We now consider rarefaction waves originating at a point on $\mathcal{H}_2(v_0, w_0)$.

Lemma 3.6. *A point $(v_1, w_1) \in \mathcal{H}_2(v_0, w_0)$, with $-w_0 \le w_1 \le -w_0/2$, may be connected to any point $(v, w) \in \mathcal{O}_2(v_1, w_1)$ having $w \le w_1$.*

Proof of Lemma 3.6. Since $\lambda_2(w)$ is increasing for $|w|$ increasing, if points (v_1, w_1) can be found so that $c(w_1) \ge c(w_0; w_1) \ge 0$, then the rarefaction curves $\mathcal{O}_2(v_1, w_1)$ may be continued indefinitely to the left. The condition on wave speeds reduces to $(2w_1 + w_0)(w_1 - w_0) \ge 0$, so that we must have $w_1 \le -w_0/2$. Thus any (v_1, w_1) with $w_1 \in [-w_0, -w_0/2]$ can serve as the origin of a 2-rarefaction. Note that the classical shock-rarefaction occurs for $w_1 = -w_0/2$. ∎

From (3.8)–(3.9), all of the (classical and nonclassical) integral curves have $v \to +\infty$ as $w \to -\infty$. As w_1 varies from $-w_0/2$ to $-w_0$, the set of points that may be reached by a nonclassical 2-shock, followed by a rarefaction, forms an unbounded

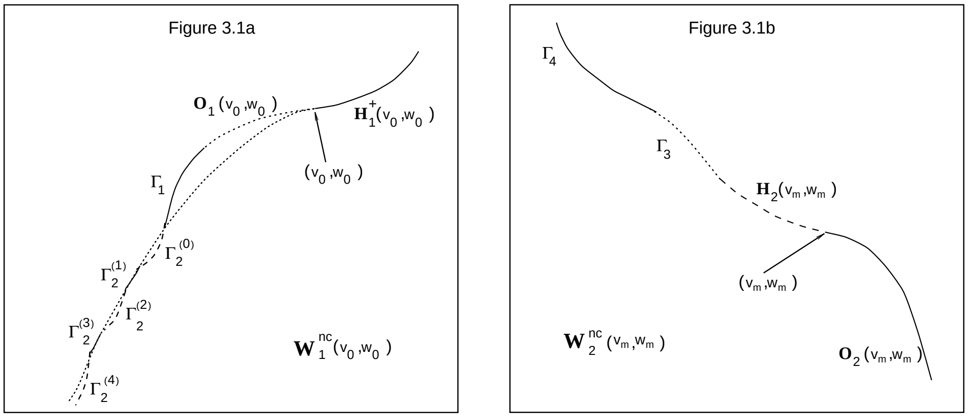

FIG. 3.1. *Wave curve for* (a) *the* 1*-wave family,* (b) *the* 2*-wave family.*

strip in the (v, w)-plane. These rarefaction curves may not be further joined to 2-shock curves, since the entropy inequality and the proper wave speed ordering (the shock must travel faster than the maximum wave speed of the rarefaction fan) lead to incompatible intervals in w. We summarize the above results in this subsection by stating the following.

THEOREM 3.7. *The solutions to* (3.1)–(3.3) *satisfying a single entropy inequality form a one-parameter family in each of the two characteristic fields. The shock speeds* s_1 *and* s_2 *of the nonclassical shocks in the* 1*- and* 2*-wave families, respectively, may be used as the parameters. Given a left-hand state* (v_0, w_0) *and denoting the left-hand state of the nonclassical shock by* (v_-, w_-)*, there are nonclassical solutions in the* 1*-family for* s_1 *satisfying*

$$max\left\{ -\sqrt{w_0^2 + w_0\, w_- + w_-^2 + m^2}\,,\, -\sqrt{3\, w_-^2 + m^2} \right\} \;\le s_1 \;\le\; -\sqrt{w_-^2 + m^2},$$

and in the 2*-family for* s_2 *satisfying*

$$\sqrt{(3/4)w_-^2 + m^2} \;\le\; s_2 \;\le\; \sqrt{w_-^2 + m^2}.$$

3.4. Unique admissible nonclassical entropy solution. In this section, we construct the nonclassical wave curves $\mathcal{W}_j^{nc}(v_0, w_0)$, $j = 1, 2$, displayed in Figure 3.1. For a solution connecting $u_0 = (v_0, w_0)$ to $u_1 = (v_1, w_1)$, we label the successive states, according to increasing wave speed, by $u_0, u_{i_1} = (v_{i_1}, w_{i_1}), u_m = (v_m, w_m), u_{i_2} = (v_{i_2}, w_{i_2})$, and u_1. For classical shocks or rarefactions in the 1-wave and 2-waves curves, the points u_{i_1} and u_{i_2}, respectively, degenerate into u_0 and u_1, respectively. Nonclassical 1-shocks always connect u_{i_1} to a range of u_m, while nonclassical 2-shocks join u_m to a range of u_{i_2}. In the classical cases where shocks are attached to rarefactions, one always has $w_m = -2w_{i_1}$ and/or $w_{i_2} = -w_m/2$.

Depending on u_0 and u_1, a nonclassical shock may appear in either $\mathcal{H}_1$, or $\mathcal{H}_2$, or both. To select the unique nonclassical shock from among the one-parameter families of solutions found in the previous subsection, we will utilize a *kinetic relation*, stipulating that any nonclassical 2-shocks from u_m to u_{i_2} must satisfy

$$D(w_m; w_{i_2}) = \varphi(s), \tag{3.19}$$

where φ is the kinetic function depending upon the shock speed s. For a given left-hand state (v_m, w_m), we show that the kinetic relation produces a unique right-hand state (v_{i_2}, w_{i_2}), where w_{i_2} depends only on w_m, and not on v_m, say, $w_{i_2} = g(w_m)$. From Lemmas 3.3 and 3.4, $w_{i_2} \in [-w_m, -w_m/2)$.

In order to select a unique nonclassical shock in the 1-wave family, a symmetry of system (3.1) is utilized: the nonclassical 1-shock from u_{i_1} to u_m is selected from among the possible nonclassical 1-shocks from u_{i_1}, if the kinetic relation (3.19) is satisfied for $w_{i_2} = w_{i_1}$. We begin with the kinetic relation for $\mathcal{H}_2$-shocks, divorced from their role in the solution of the Riemann problem, and consider nonclassical $\mathcal{H}_2$-shocks from (v_-, w_-) to (v_+, w_+).

Theorem 3.8. *Denote by $I = [m, \infty)$ the range of positive shock speeds, s, and consider a kinetic function $\varphi(s)$ having the following properties:*

$$\frac{d\varphi}{ds} < 0 \quad \textit{for} \quad s \in I, \tag{3.20}$$

$$\varphi(s) \leq 0 \quad \textit{for all} \quad s \in I, \tag{3.21}$$

$$\varphi(s) \geq -\frac{3}{4} s\,(s^2 - m^2)^2 \quad \textit{for } s \in I. \tag{3.22}$$

Then the kinetic relation (3.19) *selects a unique value of the right-hand state $w_+ = g(w_-)$, from among the nonclassical shocks in $\mathcal{H}_2(v_-, w_-)$.*

Proof of Theorem 3.8. Without loss of generality, we take $w_- > 0$. From (3.17), we have

$$D(w_-; w_+) = \bar{c}(w_-; w_+)(w_+ - w_-)^3 (w_+ + w_-)/4, \tag{3.23}$$

and, from the previous subsection, $-w_- \leq w_+ < -w_-/2$ for the $\mathcal{H}_2$ nonclassical shock. The following calculation shows that the entropy dissipation of (3.23) is monotone in w_+:

$$\frac{\partial D(w_-; w_+)}{\partial w_+} = (2\,w_+ + w_-)\,(5\,w_+^2 + 4\,w_+ w_- + 3\,w_-^2 + 4\,m^2)\,\frac{(w_+ + w_-)^2}{2\,\bar{c}(w_-; w_+)}. \tag{3.24}$$

We rewrite the second factor in (3.24) as $3\,w_+^2 + w_-^2 + 2\,(w_+ + w_-)^2 + 4\,m^2 > 0$. So only the first factor may change sign, and therefore

$$\partial D/\partial w_+ < 0 \quad \text{along} \quad \mathcal{H}_2(v_-, w_-) \quad \text{for} \quad w_+ < -w_-/2, \tag{3.25}$$

so that D is monotone decreasing in w_+ for nonclassical 2-shocks.

For fixed $w_- > 0$ and $w_+ < -w_-/2$,

$$\frac{\partial c(w_-; w_+)}{\partial w_+} = \frac{2w_+ + w_-}{2\,\bar{c}(w_-; w_+)} < 0, \tag{3.26}$$

so that combined with (3.25), this shows that in the region of admissible nonclassical 2-shocks, D is increasing with s. Therefore by (3.20), the functions $D(w_-; w_+)$ and $\varphi(s)$ can have at *most* one intersection point.

We now verify that conditions (3.21) and (3.22) ensure one such intersection. Initially, by (3.18), we have $D(w_-; w_+) \leq 0$. Condition (3.21) is therefore a natural upper bound on φ. In addition, the maximum negative entropy dissipation for a given w_- occurs at the "classical" endpoint, $w_+ = -w_-/2$, of the admissible nonclassical interval. At this point, $s = \sqrt{3\,w_-^2/4 + m^2}$ and by (3.24),

$$\begin{aligned} D(w_-; -w_-/2) &= s\,(-3\,w_-/2)^3\,(w_-/2)/4 \\ &= -\frac{3}{4}s\,(s^2 - m^2)^2\,. \end{aligned} \tag{3.27}$$

Thus, if $\varphi(s)$ remains within the bounds (3.21) and (3.22), the kinetic relation (3.19) must have a unique solution. This completes the proof of Theorem 3.8. □

Remark. The construction of Theorem 3.8 cannot be extended to cover the nonclassical 1-shocks, i.e., to the interval $s \in (-\infty, -m]$, as the following argument demonstrates. For the admissible, nonclassical 1-shock region, $-2w_- < w_+ \le -w_-$, one finds again that the entropy dissipation D is monotonically increasing with s. This compels us to take $\varphi'(s) < 0$ in $(-\infty, -m]$. On the other hand, we also require $\varphi(s) \le 0$, and $\varphi(s) \ge 3s(s^2 - m^2)/4$, with this latter function increasing to zero at the right-hand endpoint of the interval. No kinetic function ϕ can possibly satisfy this combination of constraints over the whole interval of s.

We therefore abandon the idea of having independently prescribed kinetics for each of the families of waves. Instead, we will show existence and uniqueness for the Riemann problem under an assumption of *symmetric kinetics.* With symmetric kinetics, *a nonclassical $\mathcal{H}_1$-shock from w_{i_1} to w_m is selected if the kinetic relation for $\mathcal{H}_2$ selects a shock from w_m to $w_{i_2} = w_{i_1}$.* For the case of nonclassical shocks in both families, this assumption results in the two nonclassical shocks being mirror images of each other across the w-axis in the (x, w)-plane. We will see in section 4 that a numerical scheme for (3.1) produces such symmetric nonclassical shocks.

We motivate a symmetric choice of w_{i_1} by noting that system (3.1) is invariant under the transformation $x \to -x, \quad v \to -v$. Thus to any nonclassical 2-shock from (v_m, w_m) to (v_{i_2}, w_{i_2}), there corresponds a nonclassical 1-shock from (v_{i_1}, w_{i_1}) to (v_m, w_m) with $w_{i_1} = w_{i_2}$. These shocks are actually antisymmetric in v and have $v_{i_1} = 3v_{i_2} - 2v_m$. Whether or not such nonclassical shocks are admissible depends on the relative values of w_0 and w_{i_1}, as the following lemma shows.

Lemma 3.9. *Consider a point u_0, where $w_0 > 0$ without loss of generality. For $0 < w_{i_1} < w_0$, the nonclassical* 1*-shock from w_{i_1} to w_m where $w_m = h(w_{i_1})$ is determined by the kinetic relation* (3.19) *is always an admissible nonclassical* 1*-shock. For $w_{i_1} > w_0$, the nonclassical shock from w_{i_1} to w_m, where $w_{i_1} = w_{i_2}$ and $w_{i_2} = g(w_m)$, is determined from the $\mathcal{H}_2$ kinetics, is only admissible if $w_m \in (-w_{i_2} - w_l, -w_{i_2}]$.*

Remark. The function $h(w_{i_1})$ for the symmetric kinetics in the 1-wave family is the inverse of $g(\cdot)$, which yields the right-hand state for nonclassical 2-shocks. Since, as we will show in Theorem 3.10, the function $g(\cdot)$ is monotone in its argument, such an inverse exists and is well defined.

Proof of Lemma 3.9. For $w_{i_1} > 0$, we have $w_m < 0$ and $w_{i_2} > 0$. By Lemma 3.3, $w_{i_2} \in I_2 := (-w_m/2, -w_m]$. For $w_{i_1} < w_0$, which corresponds to the rarefaction/nonclassical 1-shock wave-fan, $w_m \in I_1 = (-2w_{i_1}, -w_{i_1}] = (-2w_{i_2}, -w_{i_2}]$, and therefore $w_{i_2} \in I_2$ iff $w_m \in I_1$.

In the case $w_{i_1} > w_0$, Lemma 3.4 stipulates that there can be a nonclassical shock joining u_{i_1} to u_m, if $w_m \in I_3 = (-w_{i_1} - w_0, -w_{i_1}]$, and by the symmetric kinetics assumption, $I_3 = (-w_{i_2} - w_0, -w_{i_2}]$. Meanwhile, for the nonclassical 2-shock, $w_m \in (-2w_{i_2}, -w_{i_2}]$ which contains the interval I_3, since $w_0 < w_{i_2}$. □

Remark. The intervals I_3 and I_4 are almost identical for $w_0 \approx w_{i_1}$. When $w_{i_1} \gg w_0$, however, the interval I_3 becomes an ever-diminishing fraction of I_4, relegated to the upper end containing the "most" nonclassical shocks. As $w_{i_2} \to \infty$, unless the kinetic relation selects $w_{i_2} = -w_m$, no admissible, symmetric 1-shock can be constructed.

We prepare for the construction of the nonclassical wave curves, with a given kinetics, by proving that the 2-shocks selected by (3.19) have $w_+ = g(w_-)$ monotone decreasing in w_-.

THEOREM 3.10. *For a nonclassical* 2*-shock between* (v_-, w_-) *and* (v_+, w_+), *with* $w_+ = g(w_-)$ *selected by the kinetic relation* (3.19),

$$\frac{d\,g(w_-)}{d\,w_-} < 0 \quad \textit{for} \;\; s \in [m, \infty)\,. \tag{3.28}$$

Proof of Theorem 3.10. In light of the Rankine–Hugoniot condition, we may view the selection of a unique right-hand state, w_+, alternatively as the selection of a unique (nonclassical) shock speed, $s(w_-)$. Thus we may reexpress the kinetic relation (3.19) as

$$\mathcal{D}(w_-; s) = \varphi(s). \tag{3.29}$$

Taking the derivative with respect to w_- in (3.29) gives

$$\frac{\partial \mathcal{D}}{\partial w_-} + \frac{\partial \mathcal{D}}{\partial s}\,\frac{\partial s}{\partial w_-} = \varphi'(s)\,\frac{\partial s}{\partial w_-}. \tag{3.30}$$

Rearrangement of (3.30) leads to

$$\frac{\partial s}{\partial w_-} = \frac{\partial \mathcal{D}/\partial w_-}{\varphi' - \partial \mathcal{D}/\partial s}\,. \tag{3.31}$$

Comparing the functions D and $\mathcal{D}$, we find

$$\frac{\partial D}{\partial w_-} = \frac{\partial \mathcal{D}}{\partial w_-} \quad \text{and} \quad \frac{\partial D}{\partial w_+}\,\frac{\partial w_+}{\partial s} = \frac{\partial \mathcal{D}}{\partial s}. \tag{3.32}$$

For the $\mathcal{H}_2$ nonclassical shocks, we have from Theorem 3.8 that $\partial D/\partial w_+ < 0$ and $\partial w_+/\partial s < 0$, so that by (3.32) we have $\partial \mathcal{D}/\partial s > 0$. In addition, since $\varphi' < 0$ by (3.20), the denominator in (3.31) is always negative. We now use the first equality of (3.32) to compute the sign of the numerator in (3.31).

We regard s as a parameter and compute the derivative of (3.23) with respect to w_-, where we have

$$w_+^2 = -w_-\,w_+ + S - w_-^2 \tag{3.33}$$

from the Rankine–Hugoniot relation; here we have defined $S = s^2 - m^2$. We note that $3\,w_-^2/4 \le S \le w_-^2$. Taking the derivative of (3.33) gives $w'_+ = -(w_+ + 2w_-)/(2w_+ + w_-)$. A straightforward calculation from (3.23) using these quantities results in

$$\frac{\partial D}{\partial w_-} = \frac{-2\,\bar{c}(w_-; w_+)}{2w_+ + w_-}\left[S - \frac{3\,w_-}{2}(w_- + w_+)\right](\,S - 3\,w_-^2\,)\,. \tag{3.34}$$

The first factor is positive, since $\bar{c}(w_-; w_+) > 0$ and $2\,w_+ + w_- < 0$. The second factor in (3.34) is greater than or equal to $S - 3\,w_-^2/4$ and so is also positive. Finally, from the above bounds on S, the third factor in (3.33) is negative. Thus from (3.34) we have $\partial D/\partial w_- < 0$ for Case A. This implies, from (3.31), that $\partial s/\partial w_- > 0$. The result (3.28) then follows from the Rankine–Hugoniot condition. This completes the proof of Theorem 3.10. $\square$

Corollary 3.11. *The nonclassical* 1*-shock between* (v_{i_1}, w_{i_1}) *and* (v_m, w_m) *with* $w_{i_1} = w_{i_2}$ *from symmetric kinetics, where* $w_{i_2} = g(w_m)$*, has the monotonicity property*

$$\frac{d\,h(w_{i_1})}{d\,w_{i_1}} < 0 \quad \textit{for} \quad s \in (-\infty, -m]. \tag{3.35}$$

We now turn to construction of the nonclassical wave curves, beginning with $\mathcal{W}_1^{nc}(v_0, w_0)$. The point $u_0 = (v_0, w_0)$ is arbitrary, but we take $w_0 > 0$ here for definiteness. Just as in the Liu construction, the wave-curve may be extended indefinitely to the right, along the classical portion of the $\mathcal{H}_1(v_0, w_0)$ curve. Similarly, $\mathcal{W}_1^{nc}(v_0, w_0)$ may be continued to the left until it reaches the point $(v, w) = (\tilde{v}, 0)$, with $\tilde{v}$ given by (3.10), along the integral curve $\mathcal{O}_1(v_0, w_0)$.

To extend this 1-wave curve into the region with $w < 0$, we utilize the symmetric kinetics. For $0 \le w_{i_1} < w_0$, it is possible by Lemma 3.3 and Corollary 3.11 to connect (v_0, w_0) to a point $(v_m, h(w_{i_1}))$, with $-2w_0 < h(w_{i_1}) \le 0$, by an $\mathcal{O}_1$-$\mathcal{H}_1^-$ wave fan. The union of these points, as w_{i_1} varies between w_0 and zero, is given by the curve

$$\begin{aligned} \Gamma_1 = \Big\{ &(v_m, w_m) \in \mathcal{H}_1^-(v_{i_1}, w_{i_1}) \mid w_m = h(w_{i_1}) \in (-2\,w_{i_1}, -w_{i_1}], \\ &w_{i_1} \in \mathcal{O}_1(v_0, w_0),\ \ 0 < w_{i_1} < w_0 \Big\}. \end{aligned} \tag{3.36}$$

By the monotonicity property of $w_m = h(w_{i_1})$, the left-hand endpoint of Γ_1, which represents a single nonclassical shock, must be the point $(v, w) = (v_0^*, h(w_0)) \in \mathcal{H}_1^-(v_0, w_0)$, where the value of v_0^* is found from the Hugoniot curve (3.6).

According to Lemma 3.9, when $w_{i_1} > w_0$ there will be a nonclassical $\mathcal{H}_1^+$-$\mathcal{H}_1^-$ wave fan, connecting (v_0, w_0) to $(v_m, h(w_{i_1}))$ iff

$$\psi_h(w_{i_1}; w_0) = h(w_{i_1}) + w_{i_1} + w_0 \ge 0 \tag{3.37}$$

holds, where $h(w_{i_1})$ is the value of w_m selected by the kinetic relation for w_{i_1}. Note that the monotonicity property, from Corollary 3.11, of h does not imply the satisfaction or failure of condition (3.37) and, for a very general kinetic function $\varphi(s)$ in Theorem 3.8, there may be successive intervals in $w_{i_1} > w_0$ where nonclassical shocks are alternately allowed or disallowed.

Since $h(w_{i_1})$ changes smoothly with w_{i_1}, we must have $\psi_h(w_{i_1}; w_0) = 0$ in (3.37) just before it becomes negative, for a slightly larger w_{i_1}. From Lemma 3.4, equality in (3.37) implies that $(v_m, h(w_{i_1}))$ lies on the classical shock curve $\mathcal{H}_1^-(v_0, w_0)$.

We therefore augment the symmetric kinetics for the 1-wave nonclassical shocks by the additional requirement that *if, for a given* w_0*, we have* $\psi_h(w_{i_1}; w_0) < 0$*, at some* $w_m = h(w_{i_1})$*, determined from symmetric kinetics, then the point* $(v_m, w_m) \in \mathcal{W}_1^{nc}(v_0, w_0)$ *is chosen by requiring* $(v_m, w_m) \in \mathcal{H}_1^-(v_0, w_0)$.

By Lemma 3.9, $\psi_h(w_0; w_0) \ge 0$. If there is strict inequality, the nonclassical $\mathcal{H}_1^+$-$\mathcal{H}_1^-$ wave fan will persist until $w_{i_1} = \tilde{w}_1$, where ψ_h switches from positive to negative. Note that $\tilde{w}_1 = w_0$ if $\psi_h(w_0; w_0) = 0$. According to our augmented symmetric kinetics, we continue $\mathcal{W}_1^{nc}(v_0, w_0)$ as a portion of $\mathcal{H}_1^-(v_0, w_0)$ until $w_{i_1} = \tilde{w}_2$, where ψ_h changes from negative to positive. The next segment—to the left of the previous one, as w_m is decreasing with increasing w_{i_1}—of $\mathcal{W}_1^{nc}(v_0, w_0)$ will be a nonclassical one, continuing until $w_{i_1} = \tilde{w}_3$, and so on.

This pattern of alternating classical and nonclassical portions of $\mathcal{W}_1^{nc}(v_0, w_0)$ may continue indefinitely. Regardless of the pattern of classical and nonclassical curves, it follows from Lemmas 3.1 and 3.4 that for (v_m, w_m) on $\mathcal{W}_1^{nc}(v_0, w_0)$, we have $v_m \to -\infty$ as $w_m \to -\infty$.

Let $\{\tilde{w}_k\}$, $\quad k = 0, 1, 2, \dots$, with $\tilde{w}_0 = w_0 \leq \tilde{w}_1 < \tilde{w}_2 < \cdots$, be the set of points where $w_{i_1} \geq w_0$ has $\psi_h(w_{i_1}; w_0) = 0$. From the above argument, $\psi_h(w_{i_1}; w_0) > 0$ for $\tilde{w}_{2k} < w_{i_1} < \tilde{w}_{2k+1}$, while $\psi_h(w_{i_1}; w_0) < 0$ when $\tilde{w}_{2k+1} < w_{i_1} < \tilde{w}_{2k+2}$. We can then describe the portions of allowable nonclassical $\mathcal{H}_1^+$-$\mathcal{H}_1^-$ wave fans by

$$\begin{aligned}\Gamma_2^{(2k)} = \Big\{ &(v_m, w_m) \in \mathcal{H}_1^-(v_{i_1}, w_{i_1}) \mid w_m = h(w_{i_1}), (v_{i_1}, w_{i_1}) \in \mathcal{H}_1^+(v_0, w_0), \\ &\tilde{w}_{2k} \leq w_{i_1} \leq \tilde{w}_{2k+1} \Big\}\end{aligned} \tag{3.38}$$

for $k = 0, 1, 2, \dots$. The right-hand endpoint of $\Gamma_2^{(0)}$ represents a single nonclassical shock from (v_0, w_0) to the point $(v_0^*, h(w_0))$, so that this precisely matches the left-hand endpoint of the curve Γ_1, calculated previously. The curve $\mathcal{W}_1^{nc}(v_0, w_0)$ is therefore continuous at $w_m = h(w_0)$. The left-hand endpoint of $\Gamma_2^{(0)}$, as well as both endpoints of $\Gamma_2^{(2k)}$ for $k > 0$, join continuously to the (classical) Hugoniot curve $\mathcal{H}_1^-(v_0, w_0)$, according to Lemma 3.4. We denote the segments of $\mathcal{H}_1^-(v_0, w_0)$, used in this construction, by

$$\begin{aligned}\Gamma_2^{(2k+1)} = \Big\{ &(v_m, w_m) \in \mathcal{H}_1^-(v_0, w_0), \mid w_m = h(w_{i_1}), (v_{i_1}, w_{i_1}) \in \mathcal{H}_1^+(v_0, w_0), \\ &\tilde{w}_{2k+1} \leq w_{i_1} \leq \tilde{w}_{2k+2} \Big\}\end{aligned} \tag{3.39}$$

for $k = 0, 1, 2, \dots$. The curve $\mathcal{W}_1^{nc}(v_0, w_0)$ is then given by

$$\mathcal{W}_1^{nc}(v_0, w_0) = \begin{cases} \mathcal{H}_1^+(v_0, w_0) & \text{for } w > w_0, \\ \mathcal{O}_1(v_0, w_0) & \text{for } 0 \leq w \leq w_0, \\ \Gamma_1 & \text{for } h(w_0) \leq w < 0, \\ \Gamma_2^{(0)} \cup \Gamma_2^{(1)} \cup \Gamma_2^{(2)} \cup \cdots & \text{for } w < h(w_0), \end{cases} \tag{3.40}$$

where $h(w_0) < 0$ is determined by symmetric kinetics, and w_0 is taken to be positive. Together, the above union of curves stretches continuously from $(v, w) = (-\infty, -\infty)$ to $(v, w) = (\infty, \infty)$.

We complete the discussion of $\mathcal{W}_1^{nc}(v_0, w_0)$ by showing that it increases monotonically in v as a function of w. Since the classical portions of this curve are known from Lemma 3.1 to be monotone increasing in w, it remains to show that the nonclassical segments are also increasing. The next lemma shows that, in fact, the curves Γ_1 and $\Gamma_2^{(2k)}$ are monotone increasing.

LEMMA 3.12. *Suppose* $(v_m, w_m) \in \Gamma_1$ *or* $(v_m, w_m) \in \Gamma_2^{(2k)}$. *Then* v_m *is monotonically increasing with* w_m.

Proof of Lemma 3.12. For the point (w_m, v_m) on Γ_1, one calculates that

$$\frac{dv_m}{dw_{i_1}} = -\frac{\left(\bar{c}(w_{i_1}; w_m) - \bar{c}(w_{i_1})\right)^2}{2\,\bar{c}(w_{i_1}; w_m)} + \frac{dw_m}{dw_{i_1}}\left(c(w_{i_1}; w_m) + \frac{(w_m - w_{i_1})(2\,w_m + w_{i_1})}{2\,c(w_{i_1}; w_m)}\right).$$

The first term is nonpositive, while the coefficient of the dw_m/dw_{i_1} can be shown to be positive. Since we have $dh(w_{i_1})/dw_{i_1} < 0$, from Corollary 3.11, it follows that $dv_m/dw_{i_1} < 0$, and so Γ_1 increases from left to right in w. It can further be shown that for $(v_m, w_m) \in \Gamma_2^{(2k)}$,

$$\frac{dv_m}{dw_{i_1}} = (\bar{c}(w_0; w_{i_1}) - \bar{c}(w_m; w_{i_1})) \left(1 - \frac{\bar{c}^2(w_{i_1})}{\bar{c}(w_0; w_{i_1}) - \bar{c}(w_m; w_{i_1})}\right) + \frac{dw_m}{dv_{i_1}} \left(\bar{c}(w_{i_1}; w_m) + \frac{(2\, w_m + w_{i_1})(w_m - w_{i_1})}{2\, \bar{c}(w_{i_1}; w_m)}\right).$$

Since we have the inequalities $\bar{c}(w_{i_1}) \geq \bar{c}(w_0; w_{i_1}) \geq \bar{c}(w_{i_1}; w_m) \geq 0$, the first term is negative, while the coefficient of dw_m/dv_{i_1} is again positive. Applying Corollary 3.11, regarding the sign of $dh(w_{i_1})/dw_{i_1}$, yields the desired monotonicity for v_m as a function of w_m. □

We now turn to the construction of $\mathcal{W}_2^{nc}(v_m, w_m)$. For this discussion, $u_m = (v_m, w_m)$ is taken to be arbitrary. Alternatively, we can view this point as $u_m \in \mathcal{W}_1^{nc}(v_0, w_0)$ for some $u_0 = (v_0, w_0)$. To be definite, we take $w_m > 0$, but this discussion could be extended to $w_m < 0$ with little complication. We are interested in the set of points $u_1 = (v_1, w_1)$ that can be connected to u_m through either a rarefaction, classical shock, shock-rarefaction, or a pair of shocks with positive wave speeds; in the latter two cases, there will be an intermediate state, $u_{i_2} = (v_{i_2}, w_{i_2})$, between u_m and u_1. A specific kinetic function has been imposed, so that the kinetic relation (3.19) selects a unique value $w_{i_2} = g(w_m)$ from among the possible nonclassical shocks in $\mathcal{H}_2(v_m, w_m)$.

As in the classical case (see Lemma 3.2), when $w > w_m$, this portion of $\mathcal{W}_2^{nc}(v_m, w_m)$ is just $\mathcal{O}_2(v_m, w_m)$. Similarly, when $0 < w < w_m$, we have that this section of $\mathcal{W}_2^{nc}(v_m, w_m)$ matches the classical shock curve $\mathcal{H}_2(v_m, w_m)$. To determine how far this classical shock curve penetrates into the region $w < 0$, however, the specific kinetics must be taken into account, as we do below.

The point $u_{i_2} \in \mathcal{H}_2(v_m, w_m)$, with $-w_m \leq w_{i_2} < -w_m/2$, is the unique right-hand state for the nonclassical shock, determined by the kinetic relation (3.19). From u_{i_2}, the solution may be continued, according to Lemma 3.6, along $\mathcal{O}_2(v_{i_2}, w_{i_2})$ for $w < w_{i_2}$. We denote this portion of $\mathcal{W}_2^{nc}(v_m, w_m)$ by

$$\Gamma_4 = \left\{ (v, w) \in \mathcal{O}_2(v_{i_2}, w_{i_2}) \mid w_{i_2} = g(w_m), \quad -\infty < w \leq w_{i_2} \right\}. \tag{3.41}$$

According to Lemma 3.6, one may also continue from u_{i_2} to $u_1 = (v_1, w_1) \in \mathcal{H}_2(v_{i_2}, w_{i_2})$ for $w_{i_2} \leq w_1 \leq -w_m - w_{i_2}$. This portion of $\mathcal{W}_2^{nc}(v_m, w_m)$ will be labeled by

$$\Gamma_3 = \left\{ (v, w) \in \mathcal{H}_2(v_{i_2}, w_{i_2}) \mid w_{i_2} = g(w_m), \quad w_{i_2} \leq w \leq -w_m - w_{i_2} \right\}. \tag{3.42}$$

For $u_1 \in \mathcal{H}_2(v_{i_2}, w_{i_2})$, with $w_1 = -w_m - w_{i_2}$, we saw in Lemma 3.5 that $u_1 \in \mathcal{H}_2(v_m, w_m)$ as well. We may therefore complete the construction of $\mathcal{W}_2^{nc}(v_m, w_m)$ in a continuous manner by extending the classical portion of $\mathcal{H}_2(v_m, w_m)$ until $w = -w_m - w_{i_2}$. This continuous, nonclassical 2-wave curve is then given by

$$\mathcal{W}_2^{nc}(v_m, w_m) = \begin{cases} \mathcal{O}_2(v_m, w_m) & \text{for } w > w_m, \\ \mathcal{H}_2(v_m, w_m) & \text{for } -w_m - w_{i_2} < w \leq w_m, \\ \Gamma_3 & \text{for } w_{i_2} \leq w \leq -w_m - w_{i_2}, \\ \Gamma_4 & \text{for } w < w_{i_2}, \end{cases} \tag{3.43}$$

where $w_{i_2} = g(w_m)$ comes from the kinetic relation (3.19). We now show that the curve $\mathcal{W}_2^{nc}(u_m)$ of (3.43) has v monotone decreasing with w.

LEMMA 3.13. *The curve $\mathcal{W}_2^{nc}(v_m, w_m)$ defined in* (3.43) *is continuous, with v monotone decreasing in w, from $(v, w) = (-\infty, \infty)$ to $(v, w) = (\infty, -\infty)$. Furthermore, $\mathcal{W}_2^{nc}(v_m, w_m)$ is $\mathcal{C}^{\in}$ except at $w = -w_m - w_{i_2}$, where it is merely continuous.*

Proof of Lemma 3.13. The monotonicity of $\mathcal{W}_2^{nc}(v_m, w_m)$ follows from it being the continuous union of four monotone decreasing curves: Γ_4, which is a portion of $\mathcal{O}_2(v_{i_2}, w_{i_2})$, has v decreasing for increasing w by (3.9). This integral curve naturally joins $\mathcal{H}_2(v_{i_2}, w_{i_2})$ at u_{i_2} with second-order contact, so that Γ_3 and Γ_4, together, form a $\mathcal{C}^{\in}$ curve. By (3.7), we have Γ_3 decreasing as w increases.

From Lemma 3.6, Γ_3 and $\mathcal{H}_2(v_m, w_m)$ meet at $w = -w_m - w_{i_2}$, implying continuity. The remaining portion of $\mathcal{W}_2^{nc}(v_m, w_m)$ is classical, and its continuity and monotonicity follow from Lemma 3.2.

The infinite extent, in v, of $\mathcal{W}_2^{nc}(v_m, w_m)$ follows from the divergence of the integral in (3.9), as $|w| \to \infty$. This proves Lemma 3.13. □

Combining Lemmas 3.12 and 3.13, regarding the infinite extent, continuity, and the respective monotonicities of the nonclassical wave curves, $\mathcal{W}_1^{nc}(v_0, w_0)$ and $\mathcal{W}_2^{nc}(v_m, w_m)$, we have in the following theorem our main result of this section.

THEOREM 3.14. *Given a point (v_0, w_0), the Riemann problem for system* (3.1) *with initial data (u_0, u_1), where $u_1 = (v_1, w_1)$ is an arbitrary point, has a unique solution in the class of nonclassical shocks, given a kinetic function $\varphi(s)$ satisfying assumptions* (3.20)–(3.22), *and assuming augmented symmetric kinetics for the* 1*-wave family.*

4. Nonclassical shocks in elastodynamics (2).

4.1. Convergence result.

For the model of section 3, the convergence of some approximations toward weak solutions is easily established, applying the method of compensated compactness (Murat [49], Tartar [60], DiPerna [13]) as we show in this subsection. With no uniqueness result available for nonclassical solutions, only subsequences of solutions can be shown to converge. It is one of the challenging open problems in this area to extend the kinetic relation, introduced in this paper for traveling waves, to more general solutions. This is because the kinetic relation has been introduced for functions of bounded variation, while the compensated compactness approach provides solutions in a functional space of less regular functions (i.e., L^p).

Consider the augmented version of the elastodynamics system:

$$\begin{aligned} \partial_t v - \partial_x \sigma(w) &= \epsilon\, \partial_{xx} v - \alpha\, \epsilon^2\, \partial_{xxx} w, \\ \partial_t w - \partial_x v &= 0, \end{aligned} \tag{4.1}$$

where ϵ and α are positive constants. Here σ is given by (3.2) as in section 3. Regularization terms as in the right-hand side of (4.1) were first studied by Slemrod (see [59] and Fan and Slemrod [15]) for the case that σ is decreasing in some interval, which models phase transitions in materials or in fluids; therein the dispersion term models the capillarity effect of the fluid. As we can demonstrate numerically, the sign of the dispersion term in (4.1) corresponds to that where nonclassical behavior is observed.

As the coefficients in front of the diffusion and dispersion terms vanish, the solutions to (4.1) converge to a nonclassical solution to the hyperbolic model (3.1). Observe that the presence of the dispersion term in the right-hand side of the first equation in (4.1) (and the absence of diffusion in the second equation) prevents obtaining an L^∞ bound by the theory of invariant regions à la Chuey, Conley, and Smoller [7]. The theorem below uses L^p estimates, instead.

Define the internal energy W by $W'(w) = \sigma(w)$. From (3.2) one gets $W(w) = \big(w^4 + 2\,m^2\,w^2\big)/4$.

THEOREM 4.1. (1) *Let $\big(v^\epsilon, w^\epsilon\big)$, with $\alpha \geq 0$ fixed, be a family of solutions to* (4.1) *assuming at $t = 0$ a Cauchy data $\big(v_0^\epsilon, w_0^\epsilon\big)$ satisfying uniform bounds in ϵ in the following spaces:*

$$v_0^\epsilon \in L^1(\mathbb{R}) \cap L^2(\mathbb{R}), \qquad w_0^\epsilon \in L^1(\mathbb{R}) \cap L^4(\mathbb{R}), \qquad \epsilon^{1/2}\,\partial_x w_0^\epsilon \in L^2(\mathbb{R}). \tag{4.2}$$

Then the sequences v^ϵ and w^ϵ remain uniformly bounded in $L^\infty\big(\mathbb{R}_+, L^2(\mathbb{R})\big)$ and $L^\infty\big(\mathbb{R}_+, L^4(\mathbb{R})\big)$, respectively, and converge almost everywhere to limiting functions v and w, solutions to the hyperbolic system (3.1).

(2) *The entropy pair $(U, F) = \big(v^2/2 + W(w), -v\,\sigma(w)\big)$ is compatible in the sense* (2.3) *with the diffusive-dispersive regularization* (4.1). *Limits of traveling wave solutions to* (4.1), *additionally, satisfy the entropy inequality*

$$\partial_t\left(\frac{v^2}{2} + W(w)\right) - \partial_x\big(v\,\sigma(w)\big) \leq 0. \tag{4.3}$$

We do not expect the entropy inequalities

$$\partial_t U(v, w) + \partial_x F(v, w) \leq 0, \tag{4.4}$$

with $U(v, w) \neq v^2/2 + W(w)$ (up to a linear function of v and w), to hold in general.

Proof of Theorem 4.1. The bounds in L^2 and L^4 follow from the following standard energy estimate. Multiplying the first equation in (4.1) by σ and the second one by v, we arrive at

$$\partial_t\big(W(w)+v^2/2\big)-\partial_x\big(v\,\sigma(w)\big) \;=\; -\epsilon\,|\partial_x v|^2+\epsilon\,\partial_x\big(v\,\partial_x v\big)-\alpha\,\epsilon^2\,\partial_x\big(v\,\partial_{xx} w\big)+\alpha\,\epsilon^2\partial_x v\,\partial_{xx} w.$$

Using the second equation in (4.1), we rewrite $\partial_x v\,\partial_{xx} w = \partial_t w\,\partial_{xx} w = \partial_x\big(\partial_t w\,\partial_x w\big) - \partial_t\big(|\partial_x w|^2/2\big)$. Therefore we obtain the following entropy balance:

$$\begin{aligned}&\partial_t\big(W(w) + v^2/2 + \alpha\,\epsilon^2\,|\partial_x w|^2/2\big) - \partial_x\big(v\,\sigma(w)\big)\\ &\;= -\epsilon\,|\partial_x v|^2 + \epsilon\,\partial_{xx}\big(v^2/2\big) - \alpha\,\epsilon^2\,\partial_x\big(v\,\partial_{xx} w\big) + \alpha\,\epsilon^2\partial_x\big(\partial_x v\,\partial_x w\big).\end{aligned} \tag{4.5}$$

This leads to the following uniform bound:

$$\begin{aligned}&\int_{\mathbb{R}}\big(W(w) + v^2/2 + \alpha\,\epsilon^2\,|\partial_x w|^2/2\big)(T)\,dx + \int_0^T\int_{\mathbb{R}}\epsilon\,|\partial_x v|^2\,dxdt\\ &= \int_{\mathbb{R}}\big(W(w) + v^2/2 + \alpha\,\epsilon^2\,|\partial_x w|^2/2\big)(0)\,dx \leq O(1),\end{aligned} \tag{4.6}$$

where we have used (4.2) and where $O(1)$ denotes a constant independent on ϵ.

Multiply the first equation in (4.1) by $\partial_x w$ and integrate in space and time to write, on one hand,

$$\begin{aligned}&\int_0^T\int_{\mathbb{R}}\big(\partial_x w\,\partial_t v - \partial_x w\,\sigma_w(w)\partial_x w\big)\,dxdt\\ &= \left[\int_{\mathbb{R}}\partial_x w\,v\,dx\right]_0^T - \int_0^T\int_{\mathbb{R}}\partial_{xx} v\,v\,dxdt - \int_0^T\int_{\mathbb{R}}\sigma_w(w)\,|\partial_x w|^2\,dxdt\\ &= \int_{\mathbb{R}}\partial_x w(T)\,v(T)\,dx - \int_{\mathbb{R}}\partial_x w(0)\,v(0)\,dx + \int_0^T\int_{\mathbb{R}}|\partial_x v|^2\,dxdt\\ &\quad - \int_0^T\int_{\mathbb{R}}\sigma_w(w)\,|\partial_x w|^2\,dxdt\end{aligned}$$

and, on the other hand,

$$\begin{aligned}
&\int_0^T \int_{\mathbb{R}} \partial_x w \left(\epsilon\, \partial_{xx} v - \alpha\, \epsilon^2\, \partial_{xxx} w\right) dxdt \\
&= \int_0^T \int_{\mathbb{R}} \epsilon\, \partial_x w\, \partial_{tx} w\, dxdt + \alpha\, \epsilon^2 \int_0^T \int_{\mathbb{R}} |\partial_{xx} w|^2\, dxdt \\
&= \left[\epsilon \int_{\mathbb{R}} |\partial_x w|^2/2\, dx\right]_0^T + \alpha\, \epsilon^2 \int_0^T \int_{\mathbb{R}} |\partial_{xx} w|^2\, dxdt.
\end{aligned}$$

Observe that

$$\left| \int_{\mathbb{R}} \partial_x w(T)\, v(T)\, dx \right| \le \epsilon \int_{\mathbb{R}} |\partial_x w(T)|^2/2\, dx + \big(2\epsilon\big)^{-1} \int_{\mathbb{R}} |v(T)|^2\, dx,$$

and similarly for the term $\partial_x w(0)\, v(0)$. Finally, combining the above formulas, we obtain

$$\begin{aligned}
&\int_0^T \int_{\mathbb{R}} \epsilon\, \sigma_w(w)\, |\partial_x w|^2\, dxdt + \alpha\, \epsilon^2 \int_0^T \int_{\mathbb{R}} |\partial_{xx} w|^2\, dxdt \\
&\quad \le \int_0^T \int_{\mathbb{R}} \epsilon\, |\partial_x v|^2\, dxdt + \epsilon^2 \int_{\mathbb{R}} |\partial_x w(0)|^2\, dx + \int_{\mathbb{R}} |v(T)|^2/2\, dx, + \int_{\mathbb{R}} |v(0)|^2/2\, dx.
\end{aligned} \tag{4.7}$$

Combining (4.6) and (4.7) and using the form (3.2) of the function σ, we obtain the uniform bounds

$$\int_{\mathbb{R}} \big(v(T)^2 + w(T)^2 + w(T)^4\big)\, dx + \int_{\mathbb{R}} \alpha\, \epsilon\, |\partial_x w(T)|^2\, dx \le O(1), \tag{4.8}$$

$$\int_0^T \int_{\mathbb{R}} \big(\epsilon\, |\partial_x v|^2 + \epsilon\, |\partial_x w|^2 + \alpha\, \epsilon^2\, |\partial_{xx} w|^2\big)\, dxdt \le O(1). \tag{4.9}$$

Using the $L^2 \times L^4$ bound derived for the sequence (v_ϵ, w_ϵ), we introduce a Young measure representing possible oscillations in the sequence as $\epsilon \to 0$. The estimates (4.8)–(4.9) are the basis for applying DiPerna's argument in [13], which shows that the Young measure satisfies the so-called Tartar commutation equation. The standard reduction theorem, stating that it must reduce to a Dirac mass, does not apply here since the support of the Young measure is not bounded.

Instead, the work by Shearer [55] and Serre and Shearer [54] based on L^p estimates does apply. The system (3.1) is strictly hyperbolic and the constitutive equation σ possesses a single inflection point. The theorem in [54] implies that there exists a limiting function $(v, w) \in L^\infty(L^2 \times L^4)$ such that the sequence strongly converges to (v, w) in the sense

$$\begin{aligned}
v_\epsilon &\to v \text{ in } L^p \text{ for all } p < 2, \\
w_\epsilon &\to w \text{ in } L^p \text{ for all } p < 2.
\end{aligned} \tag{4.10}$$

Observe that (4.10) suffices for the passage to the limit in (4.1) and in order to derive (3.1): the nonlinearity $\sigma(w)$ is cubic while we have a control of w in L^4 by the entropy estimate (4.6).

Showing that the natural entropy of the system (3.1) is compatible with the regularization (4.1) is easy from (2.3). It is a classical matter (see Schonbek [53] and, also, Hayes and LeFloch [22] for the analogous case of scalar equations with vanishing diffusion and dispersion) to check that, in view of (4.8)–(4.9), the right-hand side of (4.5) converges to zero in the sense of distributions. The entropy flux does converge to its corresponding limit since $\sigma(w^\epsilon)$ converges strongly to $\sigma(w)$. The term $\alpha\,\epsilon\,\partial_t|\partial_x w_\epsilon|^2$ converges to zero in the sense of distributions thanks to (4.8)–(4.9). Let us, equivalently, check that the product of v and $\alpha\,\epsilon^2\,\partial_{xxx}w$ converges to zero. Namely, for each smooth function θ with compact support,

$$\begin{aligned}
&\left|\int_0^T\int_{\mathbb{R}} \epsilon^2\, v\,\partial_{xxx}w\,\theta\,dxdt\right| \\
&\le \left|\int_0^T\int_{\mathbb{R}} \epsilon^2\,\partial_x v\,\partial_{xx}w\,\theta\,dxdt\right| + \left|\int_0^T\int_{\mathbb{R}} \epsilon^2\, v\,\partial_{xx}w\,\partial_x\theta\,dxdt\right| \\
&\le O(1)\,\epsilon^2\,\|\partial_x v\|_{L^2((0,T)\times\mathbb{R})}\,\|\partial_{xx}w\|_{L^2((0,T)\times\mathbb{R})} + O(1)\,\epsilon^2\,\|v\|_{L^2((0,T)\times\mathbb{R})}\,\|\partial_{xx}w\|_{L^2((0,T)\times\mathbb{R})} \\
&\le O(1)\,\epsilon^{1/2} + O(1)\,\epsilon \;\to\; 0.
\end{aligned}$$

Further estimates are needed to treat the entropy term in general, since we know only that $W(w^\epsilon)$ is bounded in $L^\infty_t(L^1_x)$ and, therefore, could a priori converge to a bounded Radon measure. However, in the special case of (smooth) traveling wave solutions to (4.1), it is straightforward to deduce (4.3) follows from the entropy balance (4.5), since all of the terms in the right-hand side of (4.5) have a conservative form but one which is nonpositive. □

We now comment upon the derivation a kinetic relation for (3.1) associated with the regularization (4.1). After rescaling by ϵ, a traveling wave solution (v, w) to (4.1), connecting (v_0, w_0) to (v_1, w_1) and having the speed s, satisfies the following third order system of ODEs:

$$\begin{aligned}
s\,w' + v' &= 0, \\
s\,v' + \sigma(w)' &= -v'' + \alpha\,w'''
\end{aligned}$$

together with the conditions $v(\xi) \to v_0$, $w(\xi) \to w_0$ at $\xi \to -\infty$, and $v(\xi) \to v_1$, $w(\xi) \to w_1$ at $\xi \to +\infty$. We also assume that w', w'', and w''' vanish at $\pm\infty$. Eliminating the variable v, we obtain an equation for the scalar-valued function w:

$$-s^2\,w' + \sigma(w)' = s\,w'' + \alpha\,w'''.$$

Integrating once, we obtain

$$-s^2\,\big(w - w_0\big) + \sigma(w) - \sigma(w_0) = s\,w' + \alpha\,w''. \tag{4.11}$$

Given a value for the shock speed s, there exist up to three states that solve the equation giving the equilibrium points of (4.11), i.e.,

$$-s^2\,\big(w - w_0\big) + \sigma(w) - \sigma(w_0) = 0. \tag{4.12}$$

Namely, these are w_0 itself and (at most) two additional points w_1 and w_2. Since the cubic $\sigma(w) = w^3 + m^2 w$ has no quadratic term, one must have $w_0 + w_1 + w_2 = 0$. Consider the case that w_0 is chosen such that $w_0 > 0$ and $w_1 < w_2 < 0$ which holds in a certain range of values for s.

Consider for instance waves of the second characteristic family propagating with $s > 0$. From the Liu criterion, it follows that a traveling wave connecting w_0 to w_1 represents a classical shock, while a connection from w_0 to w_2 is a nonclassical shock. A typical feature of (4.11) is the following one [62]: there exists a critical value for the slope $s^\sharp$ such that a traveling wave trajectory connecting to w_1 exists for speeds $s > s^\sharp$ and there exists a connection to w_2 when $s = s^\sharp$.

We emphasize that, given w_0, there exist a unique state w_2 and a unique speed such that w_0 and w_2 can be connected by a nonclassical shock. The traveling wave analysis therefore allows us to write, say,

$$w_2 = g(w_0) \qquad \text{and} \qquad s = s(w_0). \tag{4.13}$$

Using (4.13), the entropy dissipation of the nonclassical shocks can be computed as a function of the left state of the shock. This determines the kinetic function ϕ:

$$\phi(w_0) := D(w_0, w_2) = D\big(w_0, g(w_0)\big). \tag{4.14}$$

Provided the relation $s = s(w_0)$ is one-to-one, one can rewrite (4.14) and obtain the kinetic function expressed as a function of the propagation speed, that is,

$$\varphi(s) := \phi(w_0) \qquad \text{with } s^2 = w_0^2 + g(w_0)^2 + w_0\, g(w_0) + m^2. \tag{4.15}$$

The possibility of writing the kinetic function as a function of a single variable (here w), and hence as a function of the speed s, is a special property of the system (3.1) *and* the regularization (4.1). Other regularizations to (3.1), for which a scalar equation like (4.11) could not be derived, may require a kinetic function of the general form $\phi(v_0, w_0)$.

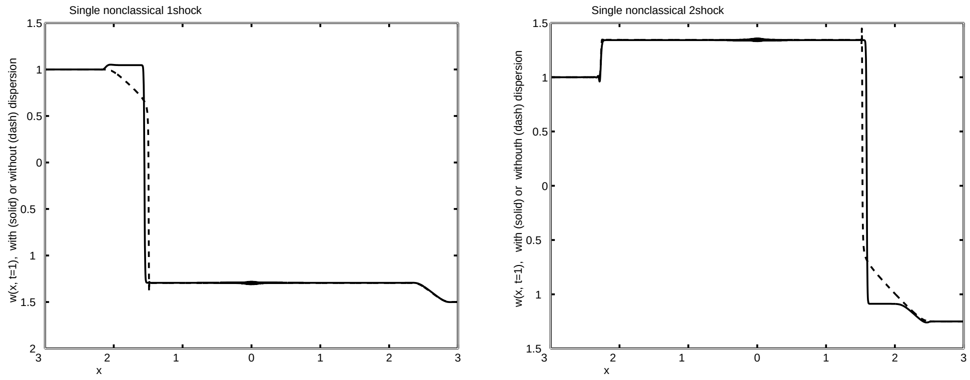
4.2. Numerical experiments. The paper [23] is devoted to the numerical analysis of nonclassical shocks in finite difference schemes. Our purpose here is to illustrate that nonclassical shocks do indeed appear.

In this subsection, we solve the Riemann problem numerically and confirm some of the results enumerated in section 3. We employ the following semidiscrete approximation to the augmented system

$$\begin{aligned} \frac{dv_k}{dt} - \frac{1}{2\,\Delta}\big(\sigma(w_{k+1}) - \sigma(w_{k-1})\big) &= \frac{\epsilon}{\Delta^2}\big(v_{k+1} - 2\,v_k + v_{k-1}\big) \\ &\quad - \frac{\alpha\,\epsilon^2}{2\,\Delta^3}\big(w_{k+2} - 2\,w_{k+1} + 2\,w_{k-1} - w_{k-2}\big), \\ \frac{dw_k}{dt} - \frac{1}{2\,\Delta}\big(v_{k+1} - v_{k-1}\big) &= 0 \end{aligned} \tag{4.16}$$

for functions $w_k(t)$ and $v_k(t)$, where Δ denotes the spatial mesh-size. We integrate this system of ODEs using a fourth-order Runge–Kutta explicit scheme, taking as large a time-step τ as possible. We define $\lambda = \tau/\Delta$. Here we are interested in the continuous model (4.16) for small ϵ. (See [23] for results on numerical schemes.) The following figures may be taken to represent features of the continuous model (4.1): we carefully checked that reducing the mesh size further virtually does not change the numerical results.

The Riemann initial data for the numerical scheme is implemented as $(v_k(0), w_k(0)) = (v_l, w_l)$ for $k \le 0$ and (v_r, w_r) for $k > 0$. In Figures 4.1–4.2, we plot the numerical solution for several choices of initial data and parameters ϵ and α. From these figures,



(a)

(b)

Fig. 4.1. *Single nonclassical shock:* (a) *nonclassical* 1*-shock,* (b) *nonclassical* 2*-shock.*

we may compare the classical and nonclassical solutions. All the tests are performed on the interval $x \in [-3, 3]$ and with $m = 1$ in (3.2).

In Figure 4.1(a), we use the initial data $(v_l, w_l) = (1, 1)$ and $(v_r, w_r) = (-1.5, -2)$. The parameters are chosen to be $\Delta = 1/400$, $\lambda = .2$. The component w of the numerical solution is represented in Figure 4.1(a): the dashed line and the solid line correspond to $\alpha = 0$ and $\alpha = 10$, respectively. In the second case we do observe nonclassical behavior, i.e., a nonclassical 1-shock.

Figure 4.1(b) is similar to Figure 4.1(a), except that $(v_r, w_r) = (-1.25, 6)$. The dashed line represents a nonclassical 2-shock.

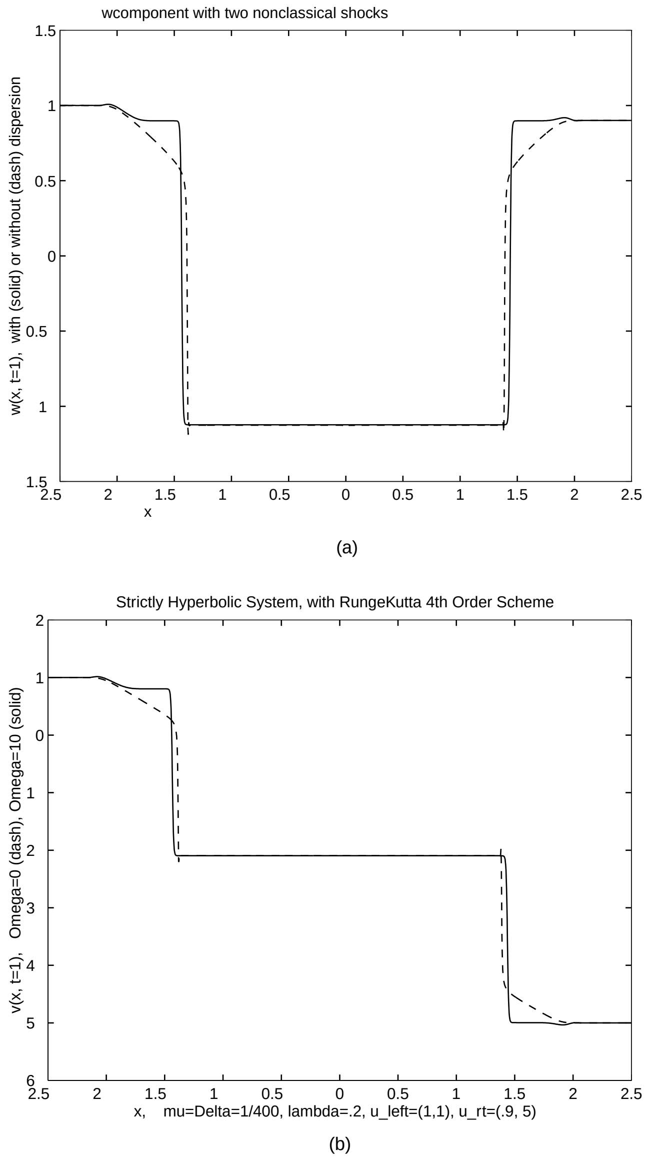
Figure 4.2 shows an example of a solution containing two nonclassical shocks, a 1-shock propagating in the left direction and a 2-shock going to the right. This is obtained with a suitable choice of the right state: $(v_r, w_r) = (.9, -5)$. The other parameters are the same as before. Figures 4.2(a) and 4.2(b) show the w- and v-component of the numerical solution, respectively.

5. Nonclassical shocks in magnetohydrodynamics.

5.1. Preliminaries. This section deals with a system, introduced by Freistühler [16], arising in the modeling of small amplitude solutions to conservation laws that are rotationally invariant:

$$\begin{aligned} &\partial_t v + \partial_x\big((v^2 + w^2)\, v\big) = 0, \\ &\partial_t w + \partial_x\big((v^2 + w^2)\, w\big) = 0. \end{aligned} \tag{5.1}$$

In magnetohydrodynamics, (v, w) represents transverse components of the magnetic field. This model is relevant to explain certain features observed in the solar wind around the Earth: Cohen and Kulsrud [8] and Wu and Kennel [65]. The model and its variants also arise in nonlinear elasticity. See also the interesting paper by Brio and Hunter [4]. The study of MHD traveling waves has a long history in the mathematical literature (consult, for instance, Conley and Smoller [9]). The system (5.1) has attracted attention of many researchers in recent years: Chen [6], Freistühler [17], Keyfitz and Kranzer [32], Liu and Wang [44], etc. Freistühler and Liu [19] established the nonlinear stability of overcompressive shocks for a parabolic regularization of the system (5.1).



(a)

(b)

FIG. 4.2. *Nonclassical shocks in both characteristic families:* (a) *w-component,* (b) *v-component.*

For smooth solutions, one can use polar coordinates

$$v = r\,\cos\theta, \qquad w = r\,\sin\theta, \qquad r \geq 0, \qquad \theta \in [0, 2\pi), \tag{5.2}$$

and rewrite (5.1) as

$$\partial_t r + \partial_x r^3 = 0, \tag{5.3}$$

$$\partial_t \theta + r^2\,\partial_x \theta = 0. \tag{5.4}$$

The equation (5.3) is a scalar conservation law with a nonconvex (cubic) flux. We deduce from (5.3) that $\lambda_2 = 3\,r^2$ is a wave speed for (5.1); it is the fast mode of the system and the corresponding characteristic field therefore fails to be genuine nonlinear. On the other hand, (5.4) is linearly degenerate since the slow mode wave speed $\lambda_1 = r^2$ is independent of θ.

Observe that the system is strictly hyperbolic everywhere but at the so-called *umbilic point* $v = w = 0$ or equivalently $r = 0$. The change of variable (5.2) is in fact ill defined at $r = 0$ since the angle θ may be arbitrary. The structure (5.3)–(5.4) reflects the property of invariance by rotation or isotropy of (5.1). There exists two main wave families:

- the *rotational discontinuities* keep the radius r constant while the angle θ may vary arbitrarily. Any entropy inequality would be satisfied by rotational discontinuities.
- the *fast shocks* keep the angle θ constant *modulo* π while the radius r may vary arbitrarily. An entropy inequality would select admissible fast shocks among all possible such shocks. Note that a rotational discontinuity always precedes a fast shock.

Consider now particular solutions to (5.1) such that $w = \rho\, v$, where ρ is a given constant. Such solutions will be called *coplanar* in this section. Then both equations in (5.1) reduce to the same equation,

$$\partial_t v + \left(1 + \rho^2\right) \partial_x v^3 \,=\, 0, \tag{5.5}$$

which is a scalar conservation law with cubic flux. Therefore, when the initial data for (5.1) are coplanar, one can attempt to solve the system (5.1) by solving the reduced equation (5.5). This is a saddle issue: the transformation $w = \rho\, v$ need not be compatible with a given regularization added to the right-hand side of (5.1). However, in several instances the solutions to (5.5) turn out to be relevant to describe the solutions to (5.1). Note finally that the "natural" entropy for (5.1),

$$U(v,w) = \frac{1}{2}\left(v^2 + w^2\right) = \frac{r^2}{2}, \qquad F(v,w) = \frac{3}{4}\left(v^2 + w^2\right)^2 = \frac{3\, r^4}{4}, \tag{5.6}$$

reduces, when $w = \rho\, v$, to an entropy pair for (5.5),

$$U(v) = \frac{1}{2} v^2, \qquad F(v,w) = \frac{3}{4}\left(1 + \rho^2\right) v^4, \tag{5.7}$$

which happens to be the one used in [22].

5.2. Unique admissible nonclassical entropy solution. The existence and properties of the nonclassical shocks for the cubic conservation law (5.3) were investigated in Hayes and LeFloch [22]. The equation (5.3), however, is supplemented with the constraint that $r \geq 0$, which prevents us from truly solving (5.3) independently of (5.4) for θ, even for coplanar initial data. The definitions in section 2 extend easily to (5.1) even though the system is not strictly hyperbolic. We are interested in solutions satisfying the single entropy inequality

$$\frac{1}{2}\partial_t\left(v^2 + w^2\right) + \frac{3}{4}\partial_x\left(v^2 + w^2\right)^2 \leq 0. \tag{5.8}$$

Our aim is to investigate the uniqueness of the nonclassical solutions for the system (5.1). Relying on the analysis in [22] we state, without proof, the following result.

THEOREM 5.1. *Consider the Riemann problem for the system* (5.1) *with initial data* (v_l, w_l) *and* (v_r, w_r). *When the data are noncoplanar, then there exists a unique* *solution to the Riemann problem satisfying the entropy inequality* (5.8): *it contains a rotational discontinuity connecting* (v_l, w_l) *to a point* (v_*, w_*) *with* $v_l^2 + w_l^2 = v_*^2 + w_*^2$ *followed by either a fast shock or a rarefaction connecting to* (v_r, w_r).

When the data are coplanar and the angles θ_l *and* θ_r *associated with the initial data satisfy* $\theta_r = \theta_r$ *(mod.* π*), the Riemann problem has a unique solution containing either a classical shock or a rarefaction.*

When the data are coplanar and $\theta_r = \pi + \theta_r$ *(mod.* π*), the Riemann problem admits a one-parameter family of entropy solutions containing a nonclassical shock connecting* (v_l, w_l) *to a point* (v_*, w_*) *with*

$$v_l^2 + w_l^2 \le v_*^2 + w_*^2 \le v_l^2 + w_l^2, \tag{5.9}$$

followed by either a fast shock or a rarefaction connecting to (v_r, w_r).

In the latter case, we can impose across the nonclassical shock a kinetic relation of the form

$$-s\,\frac{1}{2}\big[v^2 + w^2\big] + \frac{3}{4}\big[\big(v^2 + w^2\big)^2\big] = \varphi(s), \tag{5.10}$$

where the kinetic function $\varphi(s)$ *satisfies the property* $(s \ge 0)$

$$\begin{aligned} -\frac{3}{4}s^2 \;\le\; \varphi(s) \;\le\; 0, \\ \frac{d\varphi}{ds}(s) \;\le\; 0. \end{aligned} \tag{5.11}$$

A unique solution is selected by (5.10) *in the one-parameter family of solutions. This solution depends continuously (in the* L^1 *norm) on its end states for* coplanar *initial data.*

We refer to Hayes and LeFloch [22] for further details on the Riemann solution to the cubic conservation law (5.3). A solution to (5.1) using only classical shock waves always exists. We emphasize that the one-parameter family of solutions constructed in Theorem 5.1 includes as special cases the classical Riemann solution (defined from the Oleinik criterion) and the Riemann solution using a rotational discontinuity followed by a fast shock. For noncoplanar data, the Riemann solution constructed in Theorem 5.1 does not depend continuously upon its initial states. (Consider "quasi-coplanar" initial data.) It is conceivable that this lack of continuity may be related to physical instabilities in MHD fluid which cannot be fully described by the model (5.1).

The coplanar discontinuities connecting (r_L, θ_L) to (r, θ) with $r \in (0, r_L/2)$ and $\theta = \theta_L + \pi$ are *overcompressive* shock waves. They possess nonunique traveling wave profiles, due to the existence of a component θ. When viewed as shock to the underlying scalar cubic conservation law, they are *classical* shocks, however.

5.3. Convergence result. As we now demonstrate it numerically in section 5.4 below, the solutions found in Theorem 5.1 may arise from diffusive-dispersive regularizations of (5.1). We consider here the system $(\epsilon > 0,\ \alpha \in \mathbb{R})$

$$\begin{aligned} \partial_t v + \partial_x(v\,(v^2 + w^2)) = \epsilon\,\partial_{xx} v + \alpha\,\epsilon\,\partial_{xx} w, \\ \partial_t w + \partial_x(w\,(v^2 + w^2)) = \epsilon\,\partial_{xx} w - \alpha\,\epsilon\,\partial_{xx} v, \end{aligned} \tag{5.12}$$

called the derivative nonlinear Schrödinger–Burgers system. The right-hand side of (5.12) represents diffusive-dispersive effects arising in magnetic fluids due to the so-called Hall effect. When the ion inertia dispersion α can be neglected, (5.12) reduces to the Cohen–Kulsrud–Burgers (CKB) equations and converges, as $\epsilon \to 0$, to classical solutions. When $\alpha \neq 0$, the operator $\alpha\,\partial_{xx}$ in the right-hand side of (5.12) generates dispersion effect and nonclassical solutions may be obtained.

THEOREM 5.2. (1) *Let $\big(v^\epsilon, w^\epsilon\big)$ with $\alpha \in (-1,1)$ fixed be a family of solutions to* (5.12) *assuming at $t = 0$ a Cauchy data $\big(v_0^\epsilon, w_0^\epsilon\big)$ such that*

$$v_0^\epsilon, w_0^\epsilon \in L^2(\mathbb{R}) \cap L^4(\mathbb{R}) \tag{5.13}$$

uniformly in ϵ. Then $\big(v^\epsilon, w^\epsilon\big)$ is bounded in $L^\infty\big(\mathbb{R}_+, L^2(\mathbb{R}) \cap L^4(\mathbb{R})\big)$ and converges almost everywhere to a limiting function (v, w), a solution to (5.1) *in the sense of distributions.*

(2) *The pair $(U, F) = \big((v^2 + w^2)/2,\, 3\,(v^2 + w^2)^2/4\big)$ is compatible in the sense* (2.3) *with the diffusive-dispersive regularization* (5.12). *Limits of traveling wave solutions to* (5.12) *additionally satisfy the entropy inequality* (5.8).

Proof of Theorem 5.2. The proof relies on the compensated compactness method of DiPerna [13] and more specifically the results in Chen [6]. We restrict attention to deriving the main a priori estimates needed in applying the theory, referring to [6, 13] for the details. The following entropy balance follows by multiplying the equations in (5.12) by v and w, respectively:

$$\begin{aligned}\tfrac{1}{2}\partial_t\big(v^2 + w^2\big) + \tfrac{3}{4}\partial_x\big(v^2 + w^2\big)^2 \;=\; & -\epsilon\,|\partial_x v|^2 - \epsilon\,|\partial_x w|^2 \\ & + \epsilon\,\partial_x\big(v\,\partial_x v + w\,\partial_x w\big) + \alpha\,\epsilon\,\partial_x\big(v\,\partial_x w - w\,\partial_x v\big).\end{aligned} \tag{5.14}$$

Integrating (5.14) over $(0, T) \times \mathbb{R}$ yields

$$\int_{\mathbb{R}} \frac{1}{2}\big(v^2 + w^2\big)(T)\,dx + \int_0^T \int_{\mathbb{R}} \epsilon\,\big(|\partial_x v|^2 + |\partial_x w|^2\big)\,dxdt \;\le\; \int_{\mathbb{R}} \frac{1}{2}\big(v^2 + w^2\big)(0)\,dx \;\le\; O(1). \tag{5.15}$$

Observe that the dispersive terms canceled out in this derivation, so that the estimate (5.15) does not depend on the coefficient $\alpha \in \mathbb{R}$.

We now multiply (5.14) on both sides by $v^2 + w^2$ and integrate over $\mathbb{R}$ to get

$$\begin{aligned}&\frac{d}{dt}\int_{\mathbb{R}} \frac{1}{4}\big(v^2 + w^2\big)^2\,dx + \int_{\mathbb{R}} \frac{1}{2}\partial_x\big(v^2 + w^2\big)^3\,dx \\ &\quad = -\int_{\mathbb{R}} \epsilon\,\big(v^2 + w^2\big)\,\big(|\partial_x v|^2 + |\partial_x w|^2\big)\,dx - \int_{\mathbb{R}} \epsilon\,\big|\partial_x\big(v^2 + w^2\big)\big|^2\,dx \\ &\qquad + \int_{\mathbb{R}} \alpha\,\epsilon\,\big(v^2 + w^2\big)\,\partial_x\big(v\,\partial_x w - w\,\partial_x v\big)\,dx.\end{aligned} \tag{5.16}$$

Thus we obtain

$$\begin{aligned}&\int_{\mathbb{R}} \frac{1}{4}\big(v^2 + w^2\big)^2(T)\,dx + \int_0^T \int_{\mathbb{R}} \epsilon\,\big(v^2 + w^2\big)\,\big(|\partial_x v|^2 + |\partial_x w|^2\big)\,dxdt \\ &\quad + \int_0^T \int_{\mathbb{R}} \epsilon\,\big|\partial_x\big(v^2 + w^2\big)\big|^2\,dxdt \\ &\quad = \int_{\mathbb{R}} \frac{1}{4}\big(v^2 + w^2\big)^2(0)\,dx + \int_0^T \int_{\mathbb{R}} \alpha\,\epsilon\,\big(v^2 + w^2\big)\,\big(v\,\partial_x w - w\,\partial_x v\big)\,dxdt.\end{aligned} \tag{5.17}$$

When $|\alpha| < 1$, the integrand of the last term in the right-hand side of (5.17) can be estimated by integrands of the left-hand side, namely,

$$\begin{aligned}\left|\alpha\,\epsilon\,\partial_x\big(v^2+w^2\big)\,\big(v\,\partial_x w - w\,\partial_x v\big)\right| &\le \frac{\alpha}{2}\,\epsilon\,\left|\partial_x\big(v^2+w^2\big)\right|^2 + \frac{\alpha}{2}\,\epsilon\,\left|v\,\partial_x w - w\,\partial_x v\right|^2\\ &\le \frac{\alpha}{2}\,\epsilon\,\left|\partial_x\big(v^2+w^2\big)\right|^2 + \alpha\,\epsilon\,\left|v\,\partial_x w\right|^2 + \alpha\,\epsilon\,\left|w\,\partial_x v\right|^2\\ &\le \frac{\alpha}{2}\,\epsilon\,\left|\partial_x\big(v^2+w^2\big)\right|^2\\ &\qquad + \alpha\,\epsilon\,\big(v^2+w^2\big)\,\big(|\partial_x v|^2 + |\partial_x w|^2\big).\end{aligned}$$

Therefore (5.17) implies

$$\begin{aligned}\int_{\mathbb{R}} \frac{1}{4}\big(v^2+w^2\big)^2(T)\,dx + \int_0^T \int_{\mathbb{R}} \big(1-\alpha/2\big)\,\epsilon\,\big(v^2+w^2\big)\,\big(|\partial_x v|^2 + |\partial_x w|^2\big)\,dxdt\\ + \int_0^T \int_{\mathbb{R}} \big(1-\alpha\big)\,\epsilon\,\left|\partial_x\big(v^2+w^2\big)\right|^2\,dxdt \;\le\; 0.\end{aligned} \tag{5.18}$$

The estimates (5.15) and (5.18) provide L^p uniform bounds for v^ϵ and w^ϵ, together with some derivative estimates. These estimates can be used along the lines of the proof in Schonbek [53] (and [22]) to show that a Young measure associated with (v^ϵ, w^ϵ) satisfies Tartar's commutation equation. The reduction theorem in [6] may be extended to L^p Young measures and shows that

$$\begin{aligned}&v^\epsilon \to v, \qquad w^\epsilon \to w &&\text{in the weak sense,}\\ &v_\epsilon^2 + w_\epsilon^2 \to v^2 + w^2 &&\text{in the strong sense.}\end{aligned} \tag{5.19}$$

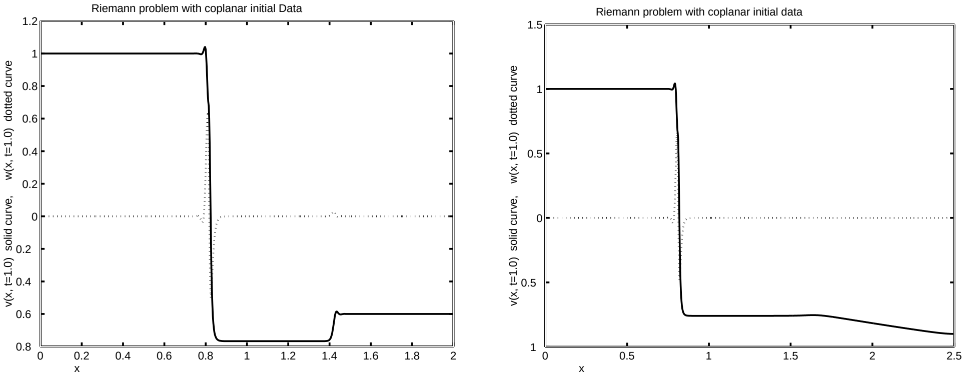
One can pass to the limit in (5.12) and deduce (5.1) as $\epsilon \to 0$.

Item (2) of the theorem follows from (5.14) and the uniform estimates (5.18). Observe that the first two terms in the right-hand side of (5.14) are nonpositive and converge to nonnegative bounded measures. The third term converges to zero in the sense of distributions. On the other hand the last term in the right-hand side of (5.14), due to the dispersive terms in (5.12), does not contribute to the dissipation measure (for the quadratic entropy only); namely, for each smooth function θ with compact support, one has

$$\begin{aligned}\left|\int_0^T \int_{\mathbb{R}} \epsilon\,\partial_x\big(v\,\partial_x w - w\,\partial_x v\big)\,\theta\,dxdt\right| &\le \int_0^T \int_{\mathbb{R}} \epsilon\,\left|v\,\partial_x w\right|\,\partial_x\theta\,dxdt\\ &\quad + \int_0^T \int_{\mathbb{R}} \epsilon\,\left|w\,\partial_x v\right|\,\partial_x\theta\,dxdt\\ &\le O(1)\,\epsilon\,\|v\,\partial_x w\|_{L^2\big((0,T)\times\mathbb{R}\big)}\\ &\quad + O(1)\,\epsilon\,\|v\,\partial_x w\|_{L^2\big((0,T)\times\mathbb{R}\big)}\\ &\le O(1)\,\epsilon^{1/2} \;\to\; 0.\end{aligned}$$

This completes the proof of Theorem 5.2. □

5.4. Numerical experiments. For coplanar initial data, we numerically demonstrate the existence of nonclassical shocks. We employ the following semidiscrete



(a) (b)

FIG. 5.1. *The slow shock is nonclassical: it cannot be a rotational wave, since across this shock,* $|u_m|^2 < |u_l|^2$.

approximation to the system (5.12):

$$
\begin{aligned}
&\frac{dv_k}{dt} + \frac{1}{2\,\Delta}\big(v_{k+1}\,(v_{k+1}^2 + w_{k+1}^2) - v_{k-1}\,(v_{k-1}^2 + w_{k-1}^2)\big)\\
&\qquad\qquad = \frac{\epsilon}{\Delta^2}\big(v_{k+1} - 2\,v_k + v_{k-1}\big) + \frac{\alpha\,\epsilon}{\Delta^2}\big(w_{k+1} - 2\,w_k + w_{k-1}\big),\\
&\frac{dw_k}{dt} + \frac{1}{2\,\Delta}\big(w_{k+1}\,(v_{k+1}^2 + w_{k+1}^2) - w_{k-1}\,(v_{k-1}^2 + w_{k-1}^2)\big)\\
&\qquad\qquad = \frac{\epsilon}{\Delta^2}\big(w_{k+1} - 2\,w_k + w_{k-1}\big) - \frac{\alpha\,\epsilon}{\Delta^2}\big(v_{k+1} - 2\,v_k + v_{k-1}\big)
\end{aligned}
\tag{5.20}
$$

for functions $v_k(t)$ and $w_k(t)$, where Δ denotes the spatial mesh-size. We integrate this system of ODEs in the same fashion as in subsection 4.2. The Riemann initial data for the numerical scheme are implemented as $(v_k(0), w_k(0)) = (v_l, w_l)$ for $k \le 0$ and (v_r, w_r) for $k > 0$.

In Figure 5.1, we plot the numerical results for two different coplanar data. The parameters are chosen to be $\Delta = 1/400$, $\epsilon = 1/800$, and $\alpha = 5/2$. In Figure 5.1(a), we use the initial data $(v_l, w_l) = (1, 0)$ and $(v_r, w_r) = (-.6, 0)$. The solid and the dotted lines represent the v- and w-components of the solution at the time $t = 1$, respectively. In Figure 5.1(b), we picture the results obtained with, instead, $(v_r, w_r) = (-.85, 0)$.

Appendix: Proof of Lemma 2.3. We follow Liu in [42] and treat the case (2.10a). The case (2.10b) is entirely similar. The statement on the wave speed follows easily from our assumption that $\nabla\lambda_j \cdot r_j$ changes sign only once along a shock curve. Let us show that the shock speed satisfies similar properties. By differentiating the Rankine–Hugoniot relation (2.13), we get

$$
-\frac{\partial}{\partial\mu_j}\bar\lambda_j(u_0, w_j)(w_j - u_0) + \big(Df(w_j) - \bar\lambda_j(u_0, w_j)\big)\frac{dw_j}{d\mu_j} \;=\; 0. \tag{A.1}
$$

Using the decompositions

$$
w_j - u_0 = \sum_{k=1}^{N} \alpha_k(u_0, w_j)\, r_k(w_j)
$$

and

$$\frac{dw_j}{d\mu_j} = \sum_{k=1}^{N} \beta_k(u_0, w_j)\, r_k(w_j),$$

we deduce that, for $k = 1, 2, \dots, N$,

$$-\frac{\partial}{\partial \mu_j} \bar{\lambda}_j(u_0, w_j)\, \alpha_k(u_0, w_j) + \big(\lambda_k(w_j) - \bar{\lambda}_j(u_0, w_j)\big)\, \beta_k(u_0, w_j) \;=\; 0.$$

In particular, for $k = j$,

$$\frac{\partial}{\partial \mu_j} \bar{\lambda}_j(u_0, w_j)\, \alpha_j(u_0, w_j) = \big(\lambda_j(w_j) - \bar{\lambda}_j(u_0, w_j)\big)\, \beta_j(u_0, w_j).$$

In view of our assumption (2.21), the coefficient $\alpha_j(u_0, w_j) = l_j(w_j) \cdot (w_j - u_0)$ has the same sign as $\mu_j - \mu_j(u_0)$, while $\beta_j(u_0, w_j) = l_j(w_j) \cdot dw_j / d\mu_j$ is strictly positive. Therefore for $\mu_j > \mu_j(u_0)$ we have

$$\begin{aligned} &\frac{\partial}{\partial \mu_j} \bar{\lambda}_j(u_0, w_j) = 0 \text{ (resp., } > 0 \text{ or } < 0\big) \quad \text{iff} \\ &\lambda_j(w_j) - \bar{\lambda}_j(u_0, w_j) = 0 \text{ (resp., } < 0 \text{ or } > 0\big), \end{aligned} \tag{A.2}$$

while for $\mu_j < \mu_j(u_0)$ the reversed inequalities are satisfied. Moreover it follows from (A.1) that (up to a multiplicative factor)

$$\frac{dw_j}{d\mu_j} \;=\; r_j(w_j) \quad \text{if} \quad \frac{\partial}{\partial \mu_j} \bar{\lambda}_j(u_0, w_j) \;=\; 0. \tag{A.3}$$

Denote by $\mu_j^\star(u_0)$ a point achieving the equality in (A.2). We now prove that, at the critical point $\mu_j = \mu_j^\star(u_0)$,

$$\begin{aligned} &\frac{\partial^2}{\partial \mu_j^2} \bar{\lambda}_j(u_0, w_j) = 0 \text{ (resp., } > 0 \text{ or } < 0\big) \quad \text{iff} \\ &\nabla \lambda_j(w_j) \cdot r_j(w_j) = 0 \,\text{(resp., } < 0 \text{ or } > 0\big) \end{aligned} \tag{A.4}$$

if $\mu_j^\star(u_0) > \mu_j(u_0)$, while the reversed inequalities are satisfied if $\mu_j^\star(u_0) < \mu_j(u_0)$. Namely, first rewrite the relation (A.1) (by using (A.3)) in the form

$$\begin{aligned} &\big(Df(w_j) - \bar{\lambda}_j(u_0, w_j)\big) \left(\frac{dw_j}{d\mu_j} - r_j(w_j)\right) \\ &\quad = \frac{\partial}{\partial \mu_j} \bar{\lambda}_j(u_0, w_j)(w_j - u_0) - \big(\lambda_j(w_j) - \bar{\lambda}_j(u_0, w_j)\big)\, r_j(w_j). \end{aligned} \tag{A.5}$$

Differentiating (A.5) once more, we obtain

$$\begin{aligned} &\frac{\partial}{\partial \mu_j} \big(Df(w_j) - \bar{\lambda}_j(u_0, w_j)\big) \left(\frac{dw_j}{d\mu_j} - r_j(w_j)\right) \\ &+ \big(Df(w_j) - \bar{\lambda}_j(u_0, w_j)\big) \left(\frac{d^2 w_j}{d\mu_j^2} - \frac{\partial}{\partial \mu_j} r_j(w_j)\right) \\ &= \frac{\partial^2}{\partial \mu_j^2} \bar{\lambda}_j(u_0, w_j)(w_j - u_0) + \frac{\partial}{\partial \mu_j} \bar{\lambda}_j(u_0, w_j) \frac{dw_j}{d\mu_j} \\ &- \frac{\partial}{\partial \mu_j} \big(\lambda_j(w_j) - \bar{\lambda}_j(u_0, w_j)\big)\, r_j(w_j) - \big(\lambda_j(w_j) - \bar{\lambda}_j(u_0, w_j)\big) \frac{\partial}{\partial \mu_j} r_j(w_j). \end{aligned}$$

Plugging the value $\mu_j = \mu_j^\star(u_0)$ in the above formula and using (A.2)–(A.3), we obtain

$$\begin{aligned}\big(Df(w_j) - \bar\lambda_j(u_0, w_j)\big)\left(\frac{d^2 w_j}{d\mu_j^2} - \frac{\partial}{\partial\mu_j} r_j(w_j)\right) &= \frac{\partial^2}{\partial\mu_j^2}\bar\lambda_j(u_0, w_j)(w_j - u_0)\\ &\quad - \frac{\partial}{\partial\mu_j}\lambda_j(w_j)\, r_j(w_j).\end{aligned}$$

Multiplying the latter by $l_j(w_j)$ and observing that $\bar\lambda_j(u_0, w_j) = \lambda_j(w_j)$ so that the left-hand side vanishes, we arrive at

$$\begin{aligned}\frac{\partial^2}{\partial\mu_j^2}\bar\lambda_j(u_0, w_j)\, l_j(w_j)\cdot(w_j - u_0) &= \frac{\partial}{\partial\mu_j}\lambda_j(w_j)\\ &= \nabla\lambda_j(w_j)\cdot r_j(w_j).\end{aligned}$$

The desired result (A.4) follows immediately from the above formula and assumption (2.21ii).

We now use the notation $g(\mu_j) := \lambda_j(w_j(\mu_j; u_0))$ and $h(\mu_j) := \bar\lambda_j(u_0, w_j(\mu_j; u_0))$. The property (A.2) shows that (2.24a) is satisfied for values μ_j close enough to $\mu_j(u_0)$, at least. Consider the largest value $\mu_j < \mu_j(u_0)$ such that $h(\zeta_j) - g(\zeta_j) > 0$ holds for all $\zeta \in (\mu_j, \mu_j(u_0)$. Call this value $\mu_j^\star(u_0)$ and observe that $h(\mu_j^\star(u_0)) = g(\mu_j^\star(u_0))$. In view of (A.2) one also has $h'(\mu_j^\star(u_0)) = 0$.

Assume that $\mu_j^\star(u_0) > 0$. In view of (A.4), one has $h''(\mu_j^\star(u_0)) > 0$ since $\mu_j^\star(u_0) > 0$. Thus the function should decrease for $\mu_j < \mu_j^\star(u_0)$ at least in a small neighborhood of $\mu_j^\star(u_0)$. According to (A.2), the wave speed should then be above the shock speed in this range, and so the wave speed g should be nonincreasing. The function g is increasing near $\mu_j(u_0)$ and nonincreasing near $\mu_j^\star(u_0)$, so g must have a critical point in the interval $\big[\mu_j^\star(u_0), \mu_j(u_0)\big)$. Since the only critical point of the wave speed is $\mu_j = 0$ and $\mu_j^\star(u_0) > 0$ by assumption, we reach a contradiction. Henceforth, one must have $\mu_j^\star(u_0) \le 0$.

Finally the shock speed is monotone in the whole region $\mu_j < \mu_j^\star(u_0)$, since otherwise that would imply the existence of a critical point for the function g, which is not possible. This completes the proof of Lemma 2.3. □

Acknowledgments. Part of this work was carried out while the second author was visiting the Institute for Mathematics and Its Applications (IMA), Minneapolis, MN, in September 1995 and January 1996.

The authors learned that D. Marchesin, B. Plohr, and K. Zumbrun recently observed that undercompressive shocks may arise in strictly hyperbolic systems. In a recent and interesting preprint by H. Freistühler, the selection of undercompressive shocks in hyperbolic systems and their stability in the multidimensional setting is also investigated.

UNIFORM ASYMPTOTIC FORMULA FOR ORTHOGONAL POLYNOMIALS WITH EXPONENTIAL WEIGHT*

W.-Y. QIU† AND R. WONG‡

Abstract. Let $\{p_n(x)\}_{n\geq 0}$ be the set of orthonormal polynomials with respect to the exponential weight $w(x) = e^{-v(x)}$, where $v(x) = x^{2m} + \cdots$ is a monic polynomial of degree $2m$ with $m \geq 2$ and is even. An asymptotic approximation is obtained for $p_n(x)$, as $n \to \infty$, which holds uniformly for $0 \leq x \leq O(n^{1/2m})$. As a corollary, a three-term asymptotic expansion is also derived for the zeros of these polynomials.

Key words. orthogonal polynomials, exponential weight, uniform asymptotic approximation, turning point, zeros

1. Introduction.

Let $\{p_n(x)\}_{n\geq 0}$ be the set of orthonormal polynomials with respect to the exponential weight function

$$w(x) = e^{-v(x)}, \qquad x \in (-\infty, \infty), \tag{1.1}$$

where $v(x) = x^{2m} + \cdots$ is a monic polynomial of degree $2m$ with $m \geq 2$. That is, the polynomials $p_n(x)$ satisfy

$$\int_{-\infty}^{\infty} p_n(x)p_k(x)w(x)dx = \begin{cases} 1, & n = k, \\ 0, & n \neq k. \end{cases} \tag{1.2}$$

Let $\gamma_n > 0$ denote the leading coefficient of $p_n(x), n = 0, 1, 2, \ldots$. Then the polynomials satisfy the three-term recurrence relation

$$(x - b_n)p_n(x) = a_{n+1}p_{n+1}(x) + a_n p_{n-1}(x), \tag{1.3}$$

where $a_0 = 0, a_n = \gamma_{n-1}/\gamma_n$ and

$$b_n = \int_{-\infty}^{\infty} x p_n^2(x)w(x)dx, \qquad n = 0, 1, 2, \ldots. \tag{1.4}$$

In [6], Nevai studied the asymptotic behavior of $p_n(x)$ when $w(x) = e^{-x^4}$ and obtained a Plancherel–Rotach type asymptotic formula for these polynomials. The behavior of their zeros has been investigated by Máté, Nevai, and Totik [4]. More precisely, they have derived a two-term expansion for the largest zero of $p_n(x)$. Similar results have been obtained by Sheen [8], when $w(x) = e^{-x^6}$. Recently, Bo and Wong [2] reconsidered the orthogonal polynomial $p_n(x)$ when $w(x) = e^{-x^4}$. They constructed an asymptotic formula which holds uniformly in an interval containing even the critical

value $x = (4n/3)^{1/4}$. As an application of their result, they derived a four-term asymptotic expansion for the kth zero of $p_n(x)$ for any fixed $k = 1, 2, \ldots, n$.

For the weight function (1.1) with $v(x)$ being convex, Chen and Ismail [3] proved that $p_n(x)$ satisfies the differential recurrence relation

$$p_n'(x) = -B_n(x)p_n(x) + A_n(x)p_{n-1}(x), \qquad n = 0, 1, 2, \ldots, \tag{1.5}$$

where

$$A_n(x) = a_n \int_{-\infty}^{\infty} \frac{v'(x) - v'(y)}{x - y} p_n^2(y)w(y)dy \tag{1.6}$$

and

$$B_n(x) = a_n \int_{-\infty}^{\infty} \frac{v'(x) - v'(y)}{x - y} p_n(y)p_{n-1}(y)w(y)dy. \tag{1.7}$$

Note that if $v(x)$ is even, then it has the form

$$v(x) = \sum_{k=0}^{m} v_k x^{2k}, \qquad v_m = 1, \qquad m \geq 2, \tag{1.8}$$

and we have

$$\frac{v'(x) - v'(y)}{x - y} = 2\sum_{k=1}^{m} k v_k \sum_{l=0}^{2k-2} x^{2k-2-l} y^l. \tag{1.9}$$

In this paper, we shall assume that $v(x)$ is a convex and even polynomial of the form (1.8), which is also the main case considered by Chen and Ismail [3, Theorem 4.3 and section 5]. It is easily seen that when $v(x)$ is convex, the function $A_n(x)$ in (1.6) is positive. Furthermore, when $v(x)$ is of the form (1.8), we have $b_n = 0$ by (1.4), and the recurrence relation (1.3) becomes

$$xp_n(x) = a_{n+1}p_{n+1}(x) + a_n p_{n-1}(x). \tag{1.10}$$

One of the main result in [3] is that the function

$$Y_n(x) = \frac{p_n(x)}{\sqrt{A_n(x)}}\, e^{-v(x)/2} \tag{1.11}$$

satisfies the second-order differential equation

$$Y''(x) + V(x, n)Y(x) = 0, \tag{1.12}$$

where

$$\begin{aligned} V(x,n) = {} & A_n(x)A_{n-1}(x)\frac{a_n}{a_{n-1}} + B_n'(x) + \frac{1}{2}v''(x) + \frac{1}{2}\frac{A_n''(x)}{A_n(x)} \\ & - \left[B_n(x) + \frac{1}{2}v'(x)\right]^2 - \frac{A_n'(x)}{A_n(x)}\left[B_n(x) + \frac{1}{2}v'(x)\right] - \frac{3}{4}\left[\frac{A_n'(x)}{A_n(x)}\right]^2. \end{aligned} \tag{1.13}$$

Let the zeros of $p_n(x)$ be denoted by $x_{n,n} < \cdots < x_{n,2} < x_{n,1}$. Based on the differential equation (1.12), Chen and Ismail also showed that the largest zero $x_{n,1}$ has the asymptotic formula

$$x_{n,1} \approx X_n - i_1 \left(\frac{2a_n}{6A_n^2(2a_n)}\right)^{1/3}, \tag{1.14}$$

where i_1 is the first positive zero of Airy's function defined in [9, pp. 18 and 377] and

$$X_n = \sqrt{4a_n^2 + 2a_n/A_n(2a_n)}. \tag{1.15}$$

Moreover, they conjectured that the kth zero $x_{n,k}$ satisfies

$$x_{n,k} \approx X_n - i_k \left(\frac{2a_n}{6A_n^2(2a_n)} \right)^{1/3}, \tag{1.16}$$

where i_k is the kth positive zero of Airy's function.

In this paper, we shall extend the method used in [2] to derive an asymptotic formula for $p_n(x)$ with the weight function given by (1.1) and (1.8), which holds uniformly in an interval containing the critical value $x = 2a_n$. Our method is based on the turning-point theory developed in [7, Chap. 11]. Also, we shall construct a three-term asymptotic expansion for the zero $x_{n,k}$ for any fixed k. In particular, we shall establish the conjecture stated in (1.16).

2. Transformation to canonical form. In this section, we first show that the coefficient function $V(x,n)$ in (1.12) has turning points and then use the Liouville transformation to bring it to a canonical form. To this end, we note that the functions $A_n(x)$ and $B_n(x)$ in (1.6) and (1.7) satisfy the identity

$$B_n(x) + B_{n+1}(x) = \frac{x}{a_n} A_n(x) - v'(x); \tag{2.1}$$

see [3, (2.2)]. Differentiating both sides of (2.1) gives

$$B_n'(x) + B_{n+1}'(x) = \frac{A_n(x)}{a_n} + \frac{x}{a_n} A_n'(x) - v''(x). \tag{2.2}$$

By inserting (2.1) and (2.2) in (1.13), it can be verified that

$$\begin{aligned} V(x,n) = {} & \left[1 - \frac{x^2}{(2a_n)^2}\right] A_n^2(x) - A_n(x)\left[A_n(x) - A_{n-1}(x)\frac{a_n}{a_{n-1}}\right] \\ & - \frac{x}{2a_n} A_n(x)[B_n(x) - B_{n+1}(x)] + \frac{A_n(x)}{2a_n} \\ & + \frac{1}{2}[B_n'(x) - B_{n+1}'(x)] - \frac{1}{4}[B_n(x) - B_{n+1}(x)]^2 \\ & - \frac{1}{2}\frac{A_n'(x)}{A_n(x)}[B_n(x) - B_{n+1}(x)] + \frac{1}{2}\frac{A_n''(x)}{A_n(x)} - \frac{3}{4}\left(\frac{A_n'(x)}{A_n(x)}\right)^2. \end{aligned} \tag{2.3}$$

This equation gives the first indication that $V(x,n)$ has two turning points located at or near $x = \pm 2a_n$. Let

$$\lambda = 2a_n \qquad \text{and} \qquad x = \lambda w, \tag{2.4}$$

and define

$$W(\lambda, w) \equiv Y(\lambda w). \tag{2.5}$$

Equation (1.12) now becomes

$$\frac{d^2W}{dw^2} = U(\lambda w, n)W, \tag{2.6}$$

where

$$U(\lambda w, n) = -\lambda^2 V(\lambda w, n). \tag{2.7}$$

From (2.3), we have

$$\begin{aligned} U(\lambda w, n) = {} & \lambda^2(w^2-1)A_n^2(\lambda w) + \lambda^2 A_n(\lambda w)\left[A_n(\lambda w) - A_{n-1}(\lambda w)\frac{a_n}{a_{n-1}}\right] \\ & + \lambda^2 A_n(\lambda w) w[B_n(\lambda w) - B_{n+1}(\lambda w)] - \lambda A_n(\lambda w) \\ & + \frac{\lambda^2}{4}[B_n(\lambda w) - B_{n+1}(\lambda w)]^2 - \frac{\lambda^2}{2}[B_n'(\lambda w) - B_{n+1}'(\lambda w)] \\ & + \frac{\lambda^2}{2}\frac{A_n'(\lambda w)}{A_n(\lambda w)}[B_n(\lambda w) - B_{n+1}(\lambda w)] - \frac{\lambda^2}{2}\frac{A_n''(\lambda w)}{A_n(\lambda w)} + \frac{3\lambda^2}{4}\left[\frac{A_n'(\lambda w)}{A_n(\lambda w)}\right]^2. \end{aligned} \tag{2.8}$$

To derive an asymptotic expansion for $U(\lambda w, n)$, as $\lambda \to \infty$, we first need to find the corresponding expansions for $A_n(\lambda w)$ and $B_n(\lambda w)$.

Put

$$c_{n,k,l} = \int_{-\infty}^{\infty} x^l p_n(x) p_{n-k}(x) w(x) dx, \qquad n, l \geq 0, \qquad n \geq k. \tag{2.9}$$

From the recurrence relation (1.10), it is readily verified by induction that p_n is an odd polynomial when n is odd and $p_n(x)$ is an even polynomial when n is even. Since $w(x)$ is also an even function by (1.8), it follows from (2.9) that

$$c_{n,k,l} = 0 \qquad \text{if} \quad k+l \quad \text{is odd.} \tag{2.10}$$

Applying (1.10) l times, we obtain

$$x^l p_n(x) = \sum_{k=-l}^{l} d_{n,k,l}\, p_{n-k}(x). \tag{2.11}$$

Substituting (2.11) in (2.9), we get by orthonormality

$$c_{n,k,l} = \begin{cases} d_{n,k,l}, & |k| \leq l, \\ 0, & |k| > l. \end{cases} \tag{2.12}$$

Hence (2.11) becomes

$$x^l p_n(x) = \sum_{k=-l}^{l} c_{n,k,l}\, p_{n-k}(x). \tag{2.13}$$

Coupling (1.10) and (2.9) gives

$$\begin{aligned} c_{n,k,l} &= \int_{-\infty}^{+\infty} x^{l-1} p_n(x)[a_{n-k+1}\, p_{n-k+1}(x) + a_{n-k}\, p_{n-k-1}(x)] w(x) dx \\ &= a_{n-k+1} \int_{-\infty}^{+\infty} x^{l-1} p_n(x)\, p_{n-(k-1)}(x) w(x) dx \\ &\quad + a_{n-k} \int_{-\infty}^{+\infty} x^{l-1} p_n(x)\, p_{n-(k+1)}(x) w(x) dx \\ &= a_{n-k+1}\, c_{n,k-1,l-1} + a_{n-k}\, c_{n,k+1,l-1}. \end{aligned}$$

So we also have the recurrence relation

$$c_{n,k,l} = a_{n-k}\, c_{n,k+1,l-1} + a_{n-k+1}\, c_{n,k-1,l-1}. \tag{2.14}$$

LEMMA 2.1. (i) *When $k+l$ is odd or $|k| > l$, we have $c_{n,k,l} = 0$.* (ii) *When $k+l$ is even and $|k| \le l, c_{n,k,l}$ is a sum of (monic) monomials of the form $a_{n-j_1}a_{n-j_2}\cdots a_{n-j_l}$; that is,*

$$c_{n,k,l} = \sum_{j_1,j_2,\ldots,j_l} a_{n-j_1}a_{n-j_2}\cdots a_{n-j_l}, \tag{2.15}$$

where $k-l \le j_i \le k+l-1$ and $1 \le i \le l$. (iii) *There are $\binom{l}{\frac{1}{2}(k+l)}$ nonzero terms in the summation on the right-hand side of* (2.15). (iv) *The sum of all indices $j_1,\ldots,j_l$ of nonzero terms in* (2.15) *is equal to*

$$s_{k,l} = \sum_{j=0}^{l-1}\sum_{s=0}^{j}\binom{j}{s}\left[(k+j-2s)\binom{l-j}{\frac{1}{2}(k+l)-s} - \binom{l-j-1}{\frac{1}{2}(k+l)-s-1}\right]. \tag{2.16}$$

Proof. Statement (i) is given in (2.10) and (2.12). Statement (ii) can be shown by repeated application of (2.14) l times. Note that each time when we apply (2.14), the k-index in the first term on the right-hand side goes up by one, whereas the k-index in the second term goes down by one. Furthermore, when $|k| > l$, we have $c_{n,k,l} = 0$. Statement (iii) is proved by induction. When $l = 1$, we have $k = \pm 1$ since $|k| \le l$ and $k+l$ is even by hypothesis. From (2.14), we have $c_{n,1,1} = a_n$ and $c_{n,-1,1} = a_{n+1}$. Hence, in either case, there is only one term on the right-hand side of (2.15); i.e., statement (iii) holds when $l = 1$. Assume that it holds for $l = \tilde{l}-1$. Then $c_{n,k,\tilde{l}-1}$ has $\binom{\tilde{l}-1}{\frac{1}{2}(k+\tilde{l}-1)}$ nonzero terms whenever $k+\tilde{l}-1$ is even. Thus, by (2.14), when $k+\tilde{l}$ is even, $c_{n,k,\tilde{l}}$ has $\binom{\tilde{l}-1}{\frac{1}{2}(k+\tilde{l})} + \binom{\tilde{l}-1}{\frac{1}{2}(k+\tilde{l}-2)}$ nonzero terms. In view of the identity

$$\binom{N}{M} = \binom{N-1}{M} + \binom{N-1}{M-1}, \tag{2.17}$$

it follows that statement (iii) also holds for $l = \tilde{l}$. To prove statement (iv), we again use induction. By (iii), $s_{1,1} = 0$ and $s_{-1,1} = -1$. Direct calculation shows that the right-hand side of (2.16) is also equal to 0 when $l = 1$ and $k = 1$, and -1 when $l = 1$ and $k = -1$, thus establishing (iv) in this case. Next, assume that (2.16) holds for $l = \tilde{l}-1$. Then k must satisfy $-\tilde{l}+1 \le k \le \tilde{l}-1$ and $k+\tilde{l}-1$ must be even. Consider the case $l = \tilde{l}$, $-\tilde{l} \le k \le \tilde{l}$ and $k+\tilde{l}$ even. From (2.14), one can see that

$$s_{k,\tilde{l}} = k\binom{\tilde{l}-1}{\frac{1}{2}(k+\tilde{l})} + s_{k+1,\tilde{l}-1} + (k-1)\binom{\tilde{l}-1}{\frac{1}{2}(k+\tilde{l})-1} + s_{k-1,\tilde{l}-1} \tag{2.18}$$

for $-\tilde{l} \le k \le \tilde{l}$ and $k+\tilde{l}$ even; here we have assumed that $s_{k,l} = 0$ if $|k| > l$. In particular, when $k = \pm\tilde{l}$,

$$s_{\tilde{l},\tilde{l}} = \tilde{l} - 1 + s_{\tilde{l}-1,\tilde{l}-1}, \qquad s_{-\tilde{l},\tilde{l}} = -\tilde{l} + s_{-\tilde{l}+1,\tilde{l}-1}. \tag{2.19}$$

From (2.18), we have by the induction hypothesis

$$s_{k,\tilde{l}} = k\binom{\tilde{l}}{\frac{1}{2}(k+\tilde{l})} - \binom{\tilde{l}-1}{\frac{1}{2}(k+\tilde{l})-1}$$

$$\tag{2.20} +\sum_{j=0}^{\tilde{l}-2}\sum_{s=0}^{j}\binom{j}{s}\left[(k+j-2s+1)\binom{\tilde{l}-j-1}{\frac{1}{2}(k+\tilde{l})-s}-\binom{\tilde{l}-j-2}{\frac{1}{2}(k+\tilde{l})-s-1}\right]$$

$$+\sum_{j=0}^{\tilde{l}-2}\sum_{s=0}^{j}\binom{j}{s}\left[(k+j-2s-1)\binom{\tilde{l}-j-1}{\frac{1}{2}(k+\tilde{l})-s-1}-\binom{\tilde{l}-j-2}{\frac{1}{2}(k+\tilde{l})-s-2}\right].$$

After reindexing the last term on the right-hand side of (2.20) and applying (2.17), it can be shown that

$$\tag{2.21} s_{k,\tilde{l}}=\sum_{j=0}^{\tilde{l}-1}\sum_{s=0}^{j}\binom{j}{s}\left[(k+j-2s)\binom{\tilde{l}-j}{\frac{1}{2}(k+\tilde{l})-s}-\binom{\tilde{l}-j-1}{\frac{1}{2}(k+\tilde{l})-s-1}\right],$$

which is exactly (2.16). The first two terms on the right-hand side of (2.20) are included in the last sum with $j=0$. When $k=\pm l$, (2.16) reduces

$$s_{\tilde{l},\tilde{l}}=\sum_{j=0}^{\tilde{l}-1}(\tilde{l}-1-j) \qquad \text{and} \qquad s_{-\tilde{l},\tilde{l}}=\sum_{j=0}^{\tilde{l}-1}(\tilde{l}-j),$$

which agree with what can be obtained from (2.19) directly, thus proving the case $l=\tilde{l}$. This completes the proof of the lemma. □

We now proceed to find the asymptotic behavior of $A_n(x)$ and $B_n(x)$. Substituting (1.9) into (1.6) and (1.7), we get

$$A_n(x)=2a_n\sum_{k=1}^{m}kv_k\sum_{l=0}^{2k-2}x^{2k-l-2}c_{n,0,l}$$

and

$$B_n(x)=2a_n\sum_{k=1}^{m}kv_k\sum_{l=0}^{2k-2}x^{2k-l-2}c_{n,1,l}.$$

In view of (2.10), the last two equations can be written as

$$\tag{2.22} A_n(x)=2a_n\sum_{k=0}^{m-1}(k+1)v_{k+1}\sum_{l=0}^{k}x^{2k-2l}c_{n,0,2l}$$

and

$$\tag{2.23} B_n(x)=2a_n\sum_{k=1}^{m-1}(k+1)v_{k+1}\sum_{l=0}^{k-1}x^{2k-2l-1}c_{n,1,2l+1}.$$

In [1], Bauldry, Máté, and Nevai proved that for any $N>0$, there exist constants $\eta_1,\ldots,\eta_N$ such that

$$\tag{2.24} a_n=(L_m n)^{1/2m}\left[1+\frac{\eta_1}{n^{1/m}}+\frac{\eta_2}{n^{2/m}}+\cdots+\frac{\eta_N}{n^{N/m}}+O\left(\frac{1}{n^{(N+1)/m}}\right)\right]$$

as $n \to \infty$, where

$$L_m = \frac{m!(m-1)!}{(2m)!}. \tag{2.25}$$

These coefficients $\eta_1, \eta_2, \ldots$ will be determined later in section 3. In the special case $v(x) = x^{2m}$, Máté, Nevai, and Zaslavsky [5] earlier have given the result

$$a_n = (L_m n)^{1/2m}\left[1 + \frac{\eta}{n^2} + O\left(\frac{1}{n^4}\right)\right] \qquad \text{as } n \to \infty, \tag{2.26}$$

where η is some constant independent of n. Since $\lambda = 2a_n$ by (2.4), we also have from (2.24) $\lambda = 2(L_m n)^{1/2m}[1 + O(n^{-1/m})]$ or, equivalently,

$$n = \frac{\lambda^{2m}}{2^{2m}L_m}\left[1 + O\left(\frac{1}{\lambda^2}\right)\right]. \tag{2.27}$$

Note that $n^{-1/m} = O(\lambda^{-2})$. Taking $N = m$ in (2.24) gives

$$a_{n-j} = [L_m(n-j)]^{1/2m}\left[1 + \frac{\eta_1}{(n-j)^{1/m}} + \cdots + \frac{\eta_m}{(n-j)} + O\left(\frac{1}{n^{1+1/m}}\right)\right]$$

for any integer j. Upon simplification, we get

$$a_{n-j} = (L_m n)^{1/2m}\left[1 - \frac{j}{2mn} + O\left(\frac{1}{n^2}\right)\right]\left[1 + \frac{\eta_1}{n^{1/m}} + \cdots + \frac{\eta_m}{n} + O\left(\frac{1}{n^{1+1/m}}\right)\right]. \tag{2.28}$$

Comparing (2.28) with (2.24) yields

$$a_{n-j} = a_n\left[1 - \frac{j}{2mn} + O\left(\frac{1}{n^{1+1/m}}\right)\right]. \tag{2.29}$$

Substituting (2.29) in (2.15), we have

$$c_{n,k,l} = \binom{l}{\frac{1}{2}(k+l)} a_n^l \left[1 + \frac{\tilde{c}_{k,l}}{2mn} + O\left(\frac{1}{n^{1+1/m}}\right)\right], \tag{2.30}$$

where $\tilde{c}_{k,l} = -s_{k,l}/\binom{l}{\frac{1}{2}(k+l)}$, $s_{k,l}$ being defined in (2.16). Inserting (2.30) into (2.22) and (2.23), we obtain

$$\begin{aligned} A_n(x) = 2a_n \sum_{k=0}^{m-1} & (k+1)v_{k+1} \\ & \cdot \sum_{l=0}^{k} x^{2k-2l} a_n^{2l} \binom{2l}{l} \left[1 + \frac{\tilde{c}_{0,2l}}{2mn} + O\left(\frac{1}{n^{1+1/m}}\right)\right] \end{aligned} \tag{2.31}$$

and

$$\begin{aligned} B_n(x) = 2a_n \sum_{k=1}^{m-1} & (k+1)v_{k+1} \\ & \cdot \sum_{l=0}^{k-1} x^{2k-2l-1} a_n^{2l+1} \binom{2l+1}{l+1} \left[1 + \frac{\tilde{c}_{1,2l+1}}{2mn} + O\left(\frac{1}{n^{1+1/m}}\right)\right]. \end{aligned} \tag{2.32}$$

Put $x = \lambda w$. Since $2a_n = \lambda$, it follows from (2.27) that

$$\begin{aligned} A_n(\lambda w) = \lambda \sum_{k=0}^{m-1} & (k+1)v_{k+1}\lambda^{2k} \\ & \cdot \sum_{l=0}^{k} w^{2k-2l}2^{-2l}\binom{2l}{l}\left[1 + \frac{\tilde{d}_{2l}}{\lambda^{2m}} + O\left(\frac{1}{\lambda^{2m+2}}\right)\right] \end{aligned} \tag{2.33}$$

and

$$\begin{aligned} B_n(\lambda w) = \lambda \sum_{k=1}^{m-1} & (k+1)v_{k+1}\lambda^{2k} \\ & \cdot \sum_{l=0}^{k-1} w^{2k-2l-1}2^{-2l-1}\binom{2l+1}{l+1}\left[1 + \frac{\tilde{d}_{2l+1}}{\lambda^{2m}} + O\left(\frac{1}{\lambda^{2m+2}}\right)\right], \end{aligned} \tag{2.34}$$

where $\tilde{d}_{2l} = 2^{2m}L_m\tilde{c}_{0,2l}/2m$ and $\tilde{d}_{2l+1} = 2^{2m}L_m\tilde{c}_{1,2l+1}/2m$. Note that $A_n(\lambda w)$ and $B_n(\lambda w)$ are polynomials in w of degree $2m-2$ and $2m-3$, respectively. Formulas (2.33) and (2.34) clearly imply that

$$\begin{aligned} A_n(\lambda w) &= \sum_{k=0}^{m-1}(k+1)v_{k+1}\lambda^{2k+1}\sum_{l=0}^{k} w^{2k-2l}2^{-2l}\binom{2l}{l} + O\left(\frac{1}{\lambda}\right) \\ &\sim \lambda^{2m-1}mv_m\sum_{l=0}^{m-1} w^{2m-2l-2}2^{-2l}\binom{2l}{l} \end{aligned} \tag{2.35}$$

and

$$\begin{aligned} B_n(\lambda w) &= \sum_{k=1}^{m-1}(k+1)v_{k+1}\lambda^{2k+1}\sum_{l=0}^{k-1} w^{2k-2l-1}2^{-2l-1}\binom{2l+1}{l+1} + O\left(\frac{1}{\lambda}\right) \\ &\sim \lambda^{2m-1}mv_m\sum_{l=0}^{m-2} w^{2m-2l-3}2^{-2l-1}\binom{2l+1}{l+1}. \end{aligned} \tag{2.36}$$

Since $A_n(\lambda w)$ and $B_n(\lambda w)$ are polynomials in w, the last two asymptotic formulas hold uniformly with respect to w in any bounded interval. In fact, from here on, all O-symbols will be used to mean that they are uniform with respect to w in any bounded interval, except for cases otherwise indicated.

In (2.31), we now replace n by $n-1$. Coupling the resulting formula with (2.29), we obtain

$$\begin{aligned} A_{n-1}(x)\frac{a_n}{a_{n-1}} = 2a_n & \sum_{k=0}^{m-1}(k+1)v_{k+1} \\ & \cdot \sum_{l=0}^{k} w^{2k-2l}a_n^{2l}\binom{2l}{l}\left[1 + \frac{\tilde{c}_{0,2l} - 2l}{2mn} + O\left(\frac{1}{n^{1+1/m}}\right)\right]. \end{aligned} \tag{2.37}$$

In terms of λ, (2.37) can be written as

$$\begin{aligned} A_{n-1}(\lambda w)\frac{a_n}{a_{n-1}} = \lambda & \sum_{k=0}^{m-1}(k+1)v_{k+1}\lambda^{2k} \\ & \cdot \sum_{l=0}^{k} w^{2k-2l}2^{-2l}\binom{2l}{l}\left[1 + \frac{\tilde{d}'_{2l}}{\lambda^{2m}} + O\left(\frac{1}{\lambda^{2m+2}}\right)\right], \end{aligned}$$

where $\tilde{d}'_{2l} = \tilde{d}_{2l} - \frac{l}{m}2^{2m}L_m$. Hence

$$A_{n-1}(\lambda w)\frac{a_n}{a_{n-1}} = \sum_{k=0}^{m-1}(k+1)v_{k+1}\lambda^{2k+1}\sum_{l=0}^{k} w^{2k-2l}2^{-2l}\binom{2l}{l} + O\left(\frac{1}{\lambda}\right). \tag{2.38}$$

A comparison of (2.35) and (2.38) gives

$$A_n(\lambda w) - A_{n-1}(\lambda w)\frac{a_n}{a_{n-1}} = O\left(\frac{1}{\lambda}\right). \tag{2.39}$$

In a similar manner, it can be shown that

$$B_n(\lambda w) - B_{n+1}(\lambda w) = O\left(\frac{1}{\lambda}\right). \tag{2.40}$$

By differentiating (2.22) and using (2.30), we have

$$\begin{aligned} A'_n(\lambda w) = \sum_{k=1}^{m-1}&(k+1)v_{k+1}\lambda^{2k} \\ &\cdot \sum_{l=0}^{k-1} 2(k-l)w^{2k-2l-1}2^{-2l}\binom{2l}{l}\left[1 + \frac{\tilde{d}_{2l}}{\lambda^{2m}} + O\left(\frac{1}{\lambda^{2m+2}}\right)\right], \end{aligned}$$

from which it follows that

$$A'_n(\lambda w) = O(\lambda^{2m-2}). \tag{2.41}$$

The same analysis yields

$$B'_n(\lambda w) = O(\lambda^{2m-2}), \tag{2.42}$$

$$A''_n(\lambda w) = O(\lambda^{2m-3}), \tag{2.43}$$

and

$$B'_n(\lambda w) - B'_{n+1}(\lambda w) = O\left(\frac{1}{\lambda^2}\right). \tag{2.44}$$

We now return to the function $U(\lambda w, n)$ in (2.8) and write

$$U(\lambda w, n) = U_0(\lambda w, n) + U_1(\lambda w, n) + U_2(\lambda w, n), \tag{2.45}$$

where

$$U_0(\lambda w, n) = \lambda^2(w^2-1)A_n^2(\lambda w), \tag{2.46}$$

$$\begin{aligned} U_1(\lambda w, n) = \lambda^2 A_n(\lambda w)&\left[A_n(\lambda w) - A_{n-1}(\lambda w)\frac{a_n}{a_{n-1}}\right] \\ &+ \lambda^2 A_n(\lambda w)w[B_n(\lambda w) - B_{n+1}(\lambda w)] - \lambda A_n(\lambda w), \end{aligned} \tag{2.47}$$

and

$$\begin{aligned} U_2(\lambda w, n) = \frac{\lambda^2}{4}&[B_n(\lambda w) - B_{n+1}(\lambda w)]^2 - \frac{\lambda^2}{2}[B'_n(\lambda w) - B'_{n+1}(\lambda w)] \\ &+ \frac{\lambda^2}{2}\frac{A'_n(\lambda w)}{A_n(\lambda w)}[B_n(\lambda w) - B_{n+1}(\lambda w)] - \frac{\lambda^2}{2}\frac{A''_n(\lambda w)}{A_n(\lambda w)} + \frac{3\lambda^2}{4}\left[\frac{A'_n(\lambda w)}{A_n(\lambda w)}\right]^2. \end{aligned} \tag{2.48}$$

From the asymptotic results in (2.35), (2.39)–(2.41), (2.43), and (2.44), it follows that

$$U_0(\lambda w, n) = O(\lambda^{4m}), \tag{2.49}$$

$$U_1(\lambda w, n) = O(\lambda^{2m}), \tag{2.50}$$

and

$$U_2(\lambda w, n) = O(1). \tag{2.51}$$

With these order estimates, the differential equation in (2.6) can be expressed as

$$\frac{d^2}{dw^2} W(\lambda, w) = [\lambda^{4m} H_0(\lambda, w) + \lambda^{2m} H_1(\lambda, w) + H_2(\lambda, w)] W(\lambda, w), \tag{2.52}$$

where $H_0(\lambda, w) = \lambda^{-4m} U_0(\lambda w, n), H_1(\lambda, w) = \lambda^{-2m} U_1(\lambda w, n)$, and $H_2(\lambda, w) = U_2(\lambda w, n)$. From the definitions of $H_0(\lambda, w)$ and $H_1(\lambda, w)$, it is clear that they are polynomials in w. Since $A_n(\lambda w) \neq 0, H_2(\lambda, w)$ is a real analytic function of w. Note that for each $i = 0, 1, 2$, we have $H_i(\lambda, w) = O(1)$. Since

$$H_0(\lambda, w) = \lambda^{-4m+2}(w^2 - 1) A_n^2(\lambda w) \tag{2.53}$$

vanishes only at $w = \pm 1$, (2.52) has two turning points, one at $w = 1$ and the other at $w = -1$. From the recurrence relation (1.10), it can be readily verified by induction that $p_n(x)$ satisfies the reflection formula

$$p_n(x) = (-1)^n p_n(-x). \tag{2.54}$$

Thus we need consider only the turning point $w = +1$.

2.1. Liouville transformation. Following [7, p. 398], we make the Liouville transformation

$$\zeta \left(\frac{d\zeta}{dw} \right)^2 = H_0(\lambda, w), \qquad Z = \left(\frac{d\zeta}{dw} \right)^{1/2} W. \tag{2.55}$$

Integration of the first equation in (2.55) gives

$$\zeta(\lambda, w) = \begin{cases} \left[\dfrac{3}{2} \dfrac{1}{\lambda^{2m-1}} \displaystyle\int_1^w \sqrt{t^2 - 1}\, A_n(\lambda t) dt \right]^{2/3}, & w \geq 1, \\ -\left[\dfrac{3}{2} \dfrac{1}{\lambda^{2m-1}} \displaystyle\int_w^1 \sqrt{1 - t^2}\, A_n(\lambda t) dt \right]^{2/3}, & |w| \leq 1. \end{cases} \tag{2.56}$$

Setting

$$\hat{H}_0(\lambda, w) = \frac{H_0(\lambda, w)}{\zeta}, \tag{2.57}$$

we have from (2.55)

$$Z = \hat{H}_0^{1/4}(\lambda, w) W. \tag{2.58}$$

Note that $d\zeta/dw = \hat{H}_0^{1/2}(\lambda, w) > 0$ for $w \neq 1$, and hence that the relation in (2.56) defines a one-to-one correspondence between w and ζ. Since (2.35) holds uniformly for w in bounded intervals, we have

$$\zeta(\lambda, w) \to \zeta_\infty(w) \tag{2.59}$$

uniformly for bounded w, where

$$\zeta_\infty(w) = \begin{cases} \left[\frac{3}{2}mv_m \sum_{l=0}^{m-1} 2^{-2l}\binom{2l}{l}\int_1^w \sqrt{t^2-1}\, t^{2m-2l-2}dt\right]^{2/3}, & w \geq 1, \\ -\left[\frac{3}{2}mv_m \sum_{l=0}^{m-1} 2^{-2l}\binom{2l}{l}\int_w^1 \sqrt{1-t^2}\, t^{2m-2l-2}dt\right]^{2/3}, & |w| \leq 1. \end{cases}$$

(2.60)

Put $u = \lambda^{2m}$. The Liouville transformation (2.55) then takes (2.52) into the form

$$\frac{d^2Z}{d\zeta^2} = \{u^2\zeta + u\phi(\lambda,\zeta) + \psi(\lambda,\zeta)\}Z, \tag{2.61}$$

where

$$\phi(\lambda,\zeta) = \frac{H_1(\lambda,w)}{\hat{H}_0(\lambda,w)} = \frac{H_1(\lambda,w)}{H_0(\lambda,w)}\zeta \tag{2.62}$$

and

$$\psi(\lambda,\zeta) = \frac{H_2(\lambda,w)}{\hat{H}_0(\lambda,w)} - \frac{1}{\hat{H}_0(\lambda,w)^{3/4}}\frac{d^2}{dw^2}\left(\frac{1}{\hat{H}_0(\lambda,w)^{1/4}}\right). \tag{2.63}$$

The following result is an analogue of Lemma 3.1 in [7, p. 399]. If $f(\lambda,x)$ represents a function of x with a parameter λ, it will be understood that $f^{(k)}(\lambda,x)$ denotes the kth derivative of f with respect to x.

Lemma 2.2. *In a given interval (a,b), let $f(\lambda,x)$ be an n-times continuously differentiable function of x, and let $x_0 \in (a,b)$. Define*

$$g(\lambda,x) = \begin{cases} \frac{1}{(x-x_0)^{3/2}}\int_{x_0}^x (t-x_0)^{1/2}f(\lambda,t)dt, & x \geq x_0, \\ \frac{1}{(x_0-x)^{3/2}}\int_x^{x_0} (x_0-t)^{1/2}f(\lambda,t)dt, & x < x_0. \end{cases} \tag{2.64}$$

Then $g(\lambda,x)$ is n-times continuously differentiable with respect to x. Moreover, if $f(\lambda,x)$ and its derivatives $f^{(k)}(\lambda,x)$, respectively, tend to $f_\infty(x)$ and its derivatives $f_\infty^{(k)}(x)$ uniformly in a closed subinterval of (a,b), then $g(\lambda,x)$ and its derivatives $g^{(k)}(\lambda,x)$ also, respectively, tend to

$$g_\infty(x) = \begin{cases} \frac{1}{(x-x_0)^{3/2}}\int_{x_0}^x (t-x_0)^{1/2}f_\infty(t)dt, & x \geq x_0, \\ \frac{1}{(x_0-x)^{3/2}}\int_x^{x_0} (x_0-t)^{1/2}f_\infty(t)dt, & x < x_0, \end{cases} \tag{2.65}$$

and its derivatives $g_\infty^{(k)}(x)$ uniformly in this closed subinterval.

Proof. Since the proof of this result is similar to that of Lemma 3.1 in [7, p. 399], we present here only a brief outline of the argument. Consider $x \in [x_0, b)$. By repeated use of the mean-value theorem and repeated integration by parts, it can be shown that

$$g^{(k)}(\lambda,x) = \frac{1}{(x-x_0)^{k+3/2}}\int_{x_0}^x (t-x_0)^{k+1/2}f^{(k)}(\lambda,t)dt, \qquad x > x_0,$$

and

$$g^{(k)}(\lambda, x) \longrightarrow \frac{1}{k+\frac{3}{2}} f^{(k)}(\lambda, x_0) \qquad\qquad \text{as } x \to x_0$$

for $k = 0, 1, \ldots, n$. These two results also hold when $\lambda = \infty$. This establishes the first part of the lemma. If for any $\varepsilon > 0$ we have $|f^{(k)}(\lambda, x) - f_\infty^{(k)}(x)| < \varepsilon$ uniformly for x in a closed subinterval of (a, b), then it can be verified that

$$|g^{(k)}(\lambda, x) - g_\infty^{(k)}(x)| < \frac{\varepsilon}{k+\frac{3}{2}}$$

also uniformly for x in that subinterval, thus proving the second part of the lemma. □

To apply the above result, we replace the variable x by w and take $(a, b) = (-1, \infty)$, $x_0 = 1$, and

$$f(\lambda, w) = \left[\frac{H_0(\lambda, w)}{w-1}\right]^{1/2} = \frac{1}{\lambda^{2m-1}}(w+1)^{1/2} A_n(\lambda w). \tag{2.66}$$

Let $g(\lambda, w)$ be defined as in (2.64); i.e.,

$$g(\lambda, w) = \begin{cases} \dfrac{1}{(v-1)^{3/2}} \displaystyle\int_1^w (v-1)^{1/2} f(\lambda, v)dv, & w \geq 1, \\ \dfrac{1}{(1-w)^{3/2}} \displaystyle\int_w^1 (1-v)^{1/2} f(\lambda, v)dv, & |w| \leq 1. \end{cases} \tag{2.67}$$

By Lemma 2.2, $g(\lambda, w)$ is n-times continuously differentiable in $(-1, \infty)$. Moreover, the limits of $g(\lambda, w)$ and its derivatives $g^{(k)}(\lambda, w)$, as $\lambda \to \infty$, exist uniformly on $[-1+\varepsilon, M]$ for any $0 < \varepsilon \ll 1$ and $1 \ll M < \infty$. Note that $g(\lambda, w) > 0$ since $f(\lambda, w) > 0$, and that from (2.56) and (2.67) we have

$$\frac{\zeta(\lambda, w)}{w-1} = \left[\frac{3}{2} g(\lambda, w)\right]^{2/3}.$$

Hence, it follows that $\zeta(\lambda, w)/(w-1)$ is nonvanishing, and that $\zeta(\lambda, w)$ is n-times continuously differentiable. Furthermore, the limits of the derivatives $\zeta^{(k)}(\lambda, w)$, as $\lambda \to \infty$, exist uniformly on $[-1+\varepsilon, M]$. In particular,

$$\zeta'(\lambda, 1) = \lim_{w \to 1} \frac{\zeta(\lambda, w)}{w-1} = \left[\frac{3}{2} g(\lambda, 1)\right]^{2/3} = 2^{1/3} \left[\frac{A_n(\lambda)}{\lambda^{2m-1}}\right]^{2/3} > 0$$

for all λ. When $w \neq 1$, we have already seen that $\zeta'(\lambda, w) = [\hat{H}_0(\lambda, w)]^{1/2} > 0$. Therefore, $\zeta'(\lambda, w)$ is a positive and differentiable function in $(-1, \infty)$. By (2.57), $\hat{H}_0(\lambda, w)$ is also n-times continuously differentiable and has a uniform limit, as $\lambda \to \infty$, on closed subintervals of $(-1, \infty)$. For sufficiently large λ, $\hat{H}_0(\lambda, w)$ is strictly positive in $[-1+\varepsilon, M]$. By using the chain rule and the inverse function theorem, it is evident from (2.62) and (2.63) that $\phi(\lambda, \zeta)$ and $\psi(\lambda, \zeta)$ are n-times continuously differentiable with respect to ζ. By (2.59), $\zeta(\lambda, -1+\varepsilon) \to \zeta_\infty(-1+\varepsilon)$ and $\zeta(\lambda, M) \to \zeta_\infty(M)$ as $\lambda \to \infty$, and by (2.60) we have $\zeta_\infty(-1+\varepsilon) < 0$ and $\zeta_\infty(M) > 0$. The limits of $\phi(\lambda, \zeta), \psi(\lambda, \zeta)$ and all their derivatives exist uniformly on the closed interval $[\zeta_\infty(-1+\varepsilon), \zeta_\infty(M)]$.

Motivated by (2.13) in [2], we define

$$\Phi(\zeta) = \Phi(\lambda, \zeta) = \begin{cases} \dfrac{1}{2\zeta^{1/2}} \displaystyle\int_0^\zeta \frac{\phi(\lambda, v)}{v^{1/2}} dv, & \zeta > 0, \\ \dfrac{1}{2(-\zeta)^{1/2}} \displaystyle\int_\zeta^0 \frac{\phi(\lambda, v)}{(-v)^{1/2}} dv, & \zeta < 0. \end{cases} \tag{2.68}$$

As in the proof of Lemma 2.2, it can be shown that $\Phi(\zeta)$ is continuous at $\zeta = 0$ and

$$\Phi(0) = \phi(\lambda, 0).$$

Integration by parts gives

$$\Phi'(\lambda, \zeta) = \frac{\pm 1}{2|\zeta|^{3/2}} \int_0^\zeta |v|^{1/2} \phi'(\lambda, v) dv,$$

where the ± signs depend on $\zeta > 0$ or $\zeta < 0$, and by the mean-value theorem, $\Phi'(\lambda, \zeta)$ is continuous at $\zeta = 0$. From Lemma 2.2, it follows that $\Phi(\lambda, \zeta)$ has n-times continuous derivatives and that all its derivatives tend to their limits, as $\lambda \to \infty$, uniformly on $[\zeta_\infty(-1+\varepsilon), \zeta_\infty(M)]$. As a consequence, $\Phi(\zeta)$ and its derivatives $\Phi^{(k)}(\zeta), k = 1, \ldots, n$, are uniformly bounded on $[\zeta_\infty(-1+\varepsilon), \zeta_\infty(M)]$ for all sufficiently large λ.

2.2. Asymptotic solutions. In the following, we wish to present two linearly independent asymptotic solutions to (2.61). This result is analogous to Theorem 1 in [2] or Theorem 3.1 in [7, p. 399]. Before stating the theorem, we first recall the modulus function $M(x)$ and the weight function $E(x)$ associated with the Airy functions $\mathrm{Ai}(x)$ and $\mathrm{Bi}(x)$; cf. [7, p. 395]. Let c denote the negative root of the equation

$$\mathrm{Ai}(x) = \mathrm{Bi}(x)$$

of smallest absolute value. Define $E(x) = 1$ for $-\infty < x \le c$,

$$E(x) = \{\mathrm{Bi}(x)/\mathrm{Ai}(x)\}^{1/2}, \qquad c \le x < \infty,$$

and

$$M(x) = \{E^2(x)\,\mathrm{Ai}^2(x) + E^{-2}(x)\,\mathrm{Bi}^2(x)\}^{1/2},$$

where $E^{-1}(x) = 1/E(x)$. The phase function $\theta(x)$ is defined by

$$E(x)\,\mathrm{Ai}(x) = M(x)\sin\theta(x), \qquad E^{-1}(x)\,\mathrm{Bi}(x) = M(x)\cos\theta(x),$$

or, equivalently,

$$\theta(x) = \tan^{-1}\{E^2(x)\,\mathrm{Ai}(x)/\mathrm{Bi}(x)\}.$$

Modulus and phase functions are also needed for the derivatives of the Airy functions, and they are defined by

$$E(x)\,\mathrm{Ai}'(x) = N(x)\sin\omega(x), \qquad E^{-1}(x)\,\mathrm{Bi}'(x) = N(x)\cos\omega(x).$$

For convenience, we introduce the function (cf. [7, p. 429])

$$G(\zeta) = G(\lambda, \zeta) = \zeta\Phi'^2 + 2\Phi\Phi' + \frac{\Phi\Phi'^2}{u} + \frac{3\Phi''^2 - 2\Phi'\Phi''' - 2u\Phi'''}{4u^2(1 + \Phi'/u)^2}, \tag{2.69}$$

where Φ is given in (2.68) and $u = \lambda^{2m}$. The error control function is then defined by

$$\Psi(\zeta) = \Psi(\lambda,\zeta) = \int_0^\zeta \frac{\psi(v) - G(v)}{1 + \Phi'(v)/u}\left\{v + \frac{\Phi(v)}{u}\right\}^{-\frac{1}{2}} dv, \tag{2.70}$$

where $\psi(v) = \psi(v,\lambda)$ is given in (2.63); cf. [7, p. 399] and [2, (2.18)]. Clearly the integral in (2.70) is convergent for sufficiently large values of u and, as $\lambda \to \infty$, $\Psi(\lambda,\zeta)$ tends to a limiting function $\Psi_\infty(\zeta)$ uniformly on the interval $[\zeta_\infty(-1+\varepsilon), \zeta_\infty(M)]$ containing the origin $\zeta = 0$.

Here and thereafter, we shall often use f or $f(\zeta)$ to represent $f(\lambda,\zeta)$. For instance, both Φ and $\Phi(\zeta)$ will mean the function $\Phi(\lambda,\zeta)$ defined in (2.68).

THEOREM 2.3. *Equation* (2.61) *has a pair of twice continuously differentiable solutions $Z_1(\lambda,\zeta)$ and $Z_2(\lambda,\zeta)$, given by*

$$Z_1(\lambda,\zeta) = \left(1 + \frac{\Phi'(\zeta)}{u}\right)^{-\frac{1}{2}}\left\{\mathrm{Ai}\left(u^{2/3}\zeta + \frac{\Phi(\zeta)}{u^{1/3}}\right) + \varepsilon_1(\lambda,\zeta)\right\}, \tag{2.71}$$

$$Z_2(\lambda,\zeta) = \left(1 + \frac{\Phi'(\zeta)}{u}\right)^{-\frac{1}{2}}\left\{\mathrm{Bi}\left(u^{2/3}\zeta + \frac{\Phi(\zeta)}{u^{1/3}}\right) + \varepsilon_2(\lambda,\zeta)\right\}. \tag{2.72}$$

For sufficiently large λ, the error terms satisfy

$$\begin{aligned} &|\varepsilon_1(\lambda,\zeta)| \Big/ M\left(u^{2/3}\zeta + \frac{\Phi(\zeta)}{u^{1/3}}\right),\ |\varepsilon_1'(\lambda,\zeta)| \Big/ \left(u^{2/3} + \frac{\Phi'(\zeta)}{u^{1/3}}\right) N\left(u^{2/3}\zeta + \frac{\Phi(\zeta)}{u^{1/3}}\right) \\ &\quad \le \frac{K\pi}{u} E^{-1}\left(u^{2/3}\zeta + \frac{\Phi(\zeta)}{u^{1/3}}\right)\mathcal{V}_{\zeta,\zeta_\infty(M)}(\Psi(\xi)) \exp\left\{\frac{K_0}{u}\mathcal{V}_{\zeta,\zeta_\infty(M)}(\Psi(\xi))\right\} \end{aligned} \tag{2.73}$$

and

$$\begin{aligned} &|\varepsilon_2(\lambda,\zeta)| \Big/ M\left(u^{2/3}\zeta + \frac{\Phi(\zeta)}{u^{1/3}}\right),\ |\varepsilon_2'(\lambda,\zeta)| \Big/ \left(u^{2/3} + \frac{\Phi'(\zeta)}{u^{1/3}}\right) N\left(u^{2/3}\zeta + \frac{\Phi(\zeta)}{u^{1/3}}\right) \\ &\quad \le \frac{K\pi}{u} E\left(u^{2/3}\zeta + \frac{\Phi(\zeta)}{u^{1/3}}\right)\mathcal{V}_{\zeta_\infty(-1+\varepsilon),\zeta}(\Psi(\xi)) \exp\left\{\frac{K_0}{u}\mathcal{V}_{\zeta_\infty(-1+\varepsilon),\zeta}(\Psi(\xi))\right\}, \end{aligned} \tag{2.74}$$

where K, K_0 are positive constants, $\mathcal{V}_{a,b}(f)$ denotes the total variation of a function $f(\zeta)$ on an interval (a,b), and $\zeta_\infty(w)$ is the function given in (2.59)–(2.60).

Since the argument used in the proof of this theorem is along the same line as that for Theorem 3.1 in [7, p. 399], it will not be included in this paper.

From (2.73), we have

$$\varepsilon_1(\lambda,\zeta) = E^{-1}\left(u^{2/3}\zeta + \frac{\Phi(\zeta)}{u^{1/3}}\right) M\left(u^{2/3}\zeta + \frac{\Phi(\zeta)}{u^{1/3}}\right) O(u^{-1})$$

$$\varepsilon_1'(\lambda,\zeta) = E^{-1}\left(u^{2/3}\zeta + \frac{\Phi(\zeta)}{u^{1/3}}\right) N\left(u^{2/3}\zeta + \frac{\Phi(\zeta)}{u^{1/3}}\right) O(u^{-1/3}).$$

In view of the asymptotic results [7, pp. 395–396]

$$E(x) \sim 2^{1/2}\exp\left(\frac{2}{3}x^{3/2}\right), \qquad M(x) \sim \pi^{-1/2}x^{-1/4} \qquad (x \to +\infty),$$

$$M(x) \sim \pi^{-1/2}(-x)^{-1/4} \qquad (x \to -\infty),$$

and

$$N(x) \sim \pi^{-1/2}|x|^{1/4} \qquad (x \to \pm\infty),$$

it follows that

$$\varepsilon_1(\lambda,\zeta) = O(u^{-1}), \qquad \varepsilon_1'(\lambda,\zeta) = O(u^{-1/6}) \tag{2.75}$$

as $\lambda \to \infty$, uniformly for ζ in $[\zeta_\infty(-1+\varepsilon), \zeta_\infty(M)]$. Moreover, if $\zeta \in [\zeta_\infty(-1+\varepsilon), \zeta_\infty(1-\varepsilon)]$, then

$$\varepsilon_1(\lambda,\zeta) = O(u^{-7/6}), \qquad \varepsilon_1'(\lambda,\zeta) = O(u^{-1/6}). \tag{2.76}$$

(Recall that $\zeta_\infty(1-\varepsilon)$ is negative.) If $\zeta \in [\zeta_\infty(1+\varepsilon), \zeta_\infty(M)]$, then both $\varepsilon_1(\lambda,\zeta)$ and $\varepsilon_1'(\lambda,\zeta)$ are exponentially small, since $\zeta_\infty(1+\varepsilon)$ is positive.

3. Uniform asymptotic formula for $p_n(x)e^{-v(x)/2}$. We first recall the asymptotic formula

$$\mathrm{Ai}(x) \sim \frac{1}{2\pi^{1/2}x^{1/4}} \exp\left(-\frac{2}{3}x^{3/2}\right)$$

and

$$\mathrm{Bi}(x) \sim \frac{1}{\pi^{1/2}x^{1/4}} \exp\left(\frac{2}{3}x^{3/2}\right)$$

as $x \to \infty$. Since the function $Y_n(x)$ in (1.11) is exponentially small as $x \to \infty$, by (2.5) and (2.58) there exists a constant $C(n)$ such that

$$Y_n(x) = C(n)\hat{H}_0(\lambda,w)^{-1/4} Z_1(\lambda,\zeta), \tag{3.1}$$

where Z_1 is the asymptotic solution given in (2.71). Substituting (1.11), (2.1), and (2.71) into (3.1), we have

$$\begin{aligned} p_n(x)e^{-v(x)/2} = \ & C(n)\lambda^{m-\frac{1}{2}}\left(\frac{\zeta}{w^2-1}\right)^{1/4}\left(1+\frac{\Phi'(\zeta)}{u}\right)^{-1/2} \\ & \cdot \{\mathrm{Ai}(X(\zeta)) + \varepsilon_1(\lambda,\zeta)\}, \end{aligned} \tag{3.2}$$

where $X(\zeta)$ is defined by

$$X(\zeta) = u^{2/3}\zeta + \frac{\Phi(\lambda,\zeta)}{u^{1/3}}. \tag{3.3}$$

Next we need to find a formula for $C(n)$ as $n \to \infty$. Put $x = 0$ and, equivalently, $w = 0$. Then (3.2) gives

$$\begin{aligned} p_n(0)e^{-v_0/2} = \ & C(n)\lambda^{m-\frac{1}{2}}(-\zeta(\lambda,0))^{1/4}\left(1+\frac{\Phi'(\lambda,\zeta(\lambda,0))}{u}\right)^{-1/2} \\ & \cdot \{\mathrm{Ai}[X(\zeta(\lambda,0))] + \varepsilon_1(\lambda,\zeta(\lambda,0))\}. \end{aligned} \tag{3.4}$$

First we consider the left-hand side of (3.4). From the recurrence relation (1.10), we have

$$p_n(0) = \begin{cases} 0, & n = 2k+1, \\ (-1)^k\gamma_0\dfrac{a_1a_3\cdots a_{2k-1}}{a_2a_4\cdots a_{2k}}, & n = 2k. \end{cases} \tag{3.5}$$

From (2.29), we also have

$$\begin{aligned} a_{n-1} &= a_n\left[1-\frac{1}{2mn}+O\left(\frac{1}{n^{1+1/m}}\right)\right] \\ &= a_n\left(1-\frac{1}{2mn}\right)\left[1+O\left(\frac{1}{n^{1+1/m}}\right)\right]. \end{aligned}$$

The last equation gives

$$\frac{a_{2k-1}}{a_{2k}} = \left(1-\frac{1}{4mk}\right)\left[1+O\left(\frac{1}{k^{1+1/m}}\right)\right].$$

Simple calculation shows

$$\prod_{k=1}^{n}\left(1-\frac{1}{4mk}\right)=\frac{\Gamma(n+1-\frac{1}{4m})}{\Gamma(n+1)\Gamma(1-\frac{1}{4m})} = n^{-1/4m}[1+O(n^{-1})]/\Gamma(1-\tfrac{1}{4m}). \tag{3.6}$$

Here use has been made of an asymptotic formula on the ratio of two gamma functions [7, p. 118]. It is easily seen that the infinite product $\prod_{k=1}^{\infty}[1+O(\frac{1}{k^{1+1/m}})]$ converges, say, to a finite value $\tilde{A}_1$. Then it is readily verifiable that

$$\prod_{k=1}^{n}\left[1+O\left(\frac{1}{k^{1+1/m}}\right)\right]=\tilde{A}_1\left[1+O\left(\frac{1}{n^{1/m}}\right)\right]. \tag{3.7}$$

Hence, when n is even, we obtain from (3.5)

$$p_n(0) = (-1)^{n/2}\gamma_0\prod_{k=1}^{n/2}\left(1-\frac{1}{4mk}\right)\prod_{k=1}^{n/2}\left[1+O\left(\frac{1}{k^{1+1/m}}\right)\right].$$

By (3.6) and (3.7), we get

$$p_n(0) = (-1)^{n/2}\tilde{A}_2 n^{-1/4m}[1+O(n^{-1/m})], \tag{3.8}$$

where $\tilde{A}_2 = 2^{1/4m}\gamma_0\tilde{A}_1/\Gamma(1-\frac{1}{4m})$.

Next we consider the right-hand side of (3.4). To simplify the notations, we put $\zeta_0 = \zeta(\lambda,0)$ and $X_0 = X(\zeta(\lambda,0))$. Note that when $\zeta \in [\zeta_\infty(-1+\varepsilon),\zeta_\infty(1-\varepsilon)] \subset (-\infty,0)$, or equivalently, $w \in [-1+\varepsilon,1-\varepsilon]$, we have $X(\zeta) = u^{2/3}\zeta+\Phi(\zeta)/u^{1/3} \to -\infty$ uniformly; thus, $X(\zeta_0) \to -\infty$. Recall the asymptotic formula [7, p. 392]

$$\begin{aligned} \mathrm{Ai}(-x) = \frac{1}{\pi^{1/2}x^{1/4}} \ &\left\{\cos\left(\frac{2}{3}x^{3/2}-\frac{\pi}{4}\right)[1+O(x^{-3})]\right. \\ &\left. +\ \sin\left(\frac{2}{3}x^{3/2}-\frac{\pi}{4}\right)\left[\frac{5}{48}x^{-3/2}+O(x^{-9/2})\right]\right\} \end{aligned} \tag{3.9}$$

as $x \to +\infty$. When ζ is bounded away from 0, $X(\zeta) = O(u^{2/3})$ and we thus have

$$\mathrm{Ai}(X(\zeta)) = \frac{1}{\pi^{1/2}[-X(\zeta)]^{1/4}}\left\{\cos\left(\frac{2}{3}[-X(\zeta)]^{3/2}-\frac{\pi}{4}\right)+O(u^{-1})\right\} \tag{3.10}$$

uniformly for $\zeta \in [\zeta_\infty(-1+\varepsilon),\zeta_\infty(1-\varepsilon)]$. In particular,

$$\mathrm{Ai}(X(\zeta_0)) = \frac{1}{\pi^{1/2}[-X(\zeta_0)]^{1/4}}\left\{\cos\left(\frac{2}{3}[-X(\zeta_0)]^{3/2}-\frac{\pi}{4}\right)+O(u^{-1})\right\}. \tag{3.11}$$

To proceed further, we need to derive an asymptotic formula for $\frac{2}{3}[-X(\zeta_0)]^{3/2}-\frac{\pi}{4}$, which is given in (3.25) below.

Recall from (2.56) that we have

$$\zeta(\lambda,w)=-\left[\frac{3}{2}\frac{1}{\lambda^{2m-1}}\int_w^1\sqrt{1-t^2}A_n(\lambda t)dt\right]^{2/3}$$

when $|w|<1$. Let

$$I(\lambda,w)=\frac{1}{\lambda^{2m-1}}\int_w^1\sqrt{1-t^2}A_n(\lambda t)dt=\frac{2}{3}[-\zeta(\lambda,w)]^{3/2}. \tag{3.12}$$

Inserting (2.33) in (3.12) yields

$$\begin{aligned}I(\lambda,w)=\frac{1}{\lambda^{2m-2}}&\sum_{k=0}^{m-1}(k+1)v_{k+1}\lambda^{2k}\\&\cdot\sum_{l=0}^{k}\left\{2^{-2l}\binom{2l}{l}\int_w^1\sqrt{1-t^2}t^{2k-2l}dt\left[1+\frac{\tilde{d}_{2l}}{\lambda^{2m}}+O\left(\frac{1}{\lambda^{2m+2}}\right)\right]\right\}.\end{aligned} \tag{3.13}$$

Note that when $w=0$, the integral in (3.13) is a beta function and we have

$$\begin{aligned}\int_0^1\sqrt{1-t^2}\,t^{2k-2l}dt&=\frac{1}{2}B\left(k-l+\frac{1}{2},\frac{3}{2}\right)\\&=\frac{\Gamma(k-l+\frac{1}{2})\Gamma(\frac{3}{2})}{2\Gamma(k-l+2)}\\&=\frac{\pi}{2}\frac{1}{2^{2k-2l+1}(k-l+1)}\binom{2k-2l}{k-l}.\end{aligned}$$

Substituting this into (3.13), and then reindexing, we get

$$\begin{aligned}I(\lambda,0)=&\frac{\pi}{2}\frac{1}{\lambda^{2m}}\sum_{k=0}^{m-1}(k+1)v_{k+1}\frac{\lambda^{2k+2}}{2^{2k+1}}\sum_{l=0}^{k}\frac{1}{l+1}\binom{2k-2l}{k-l}\binom{2l}{l}\\&+\frac{\pi}{2}\frac{1}{\lambda^{4m}}\sum_{k=0}^{m-1}(k+1)v_{k+1}\frac{\lambda^{2k+2}}{2^{2k+1}}\sum_{l=0}^{k}\frac{\tilde{d}_{2l}}{l+1}\binom{2k-2l}{k-l}\binom{2l}{l}+O\left(\frac{1}{\lambda^{2m+2}}\right).\end{aligned} \tag{3.14}$$

For convenience, we put

$$D_{2k}=\sum_{l=0}^{k}\frac{\tilde{d}_{2l}}{l+1}\binom{2l}{l}\binom{2k-2l}{k-l}.$$

Using the combinatorial identity

$$\sum_{l=0}^{k}\frac{1}{l+1}\binom{2l}{l}\binom{2k-2l}{k-l}=\binom{2k+1}{k+1},$$

which can be proved by induction, (3.14) can be simplified to

$$\begin{aligned}I(\lambda,0)=&\frac{\pi}{2}\frac{1}{\lambda^{2m}}\sum_{k=0}^{m-1}(k+1)v_{k+1}\lambda^{2k+2}2^{-(2k+1)}\binom{2k+1}{k+1}\\&+\frac{\pi}{2}\frac{1}{\lambda^{2m}}mv_m2^{-(2m-1)}D_{2m-2}+O\left(\frac{1}{\lambda^{2m+2}}\right).\end{aligned} \tag{3.15}$$

When $\zeta \in [\zeta_\infty(-1+\varepsilon), \zeta_\infty(1-\varepsilon)]$, $\Phi(\lambda,\zeta)$ is bounded for large λ. Hence it follows from (3.3) that

$$\begin{aligned}\frac{2}{3}[-X(\zeta)]^{3/2} &= \frac{2}{3}u(-\zeta)^{3/2}\left[1+\frac{3}{2}\frac{\Phi(\lambda,\zeta)}{\zeta u}+O(u^{-2})\right]\\ &= \lambda^{2m}I(\lambda,w)-(-\zeta)^{1/2}\Phi(\lambda,\zeta)+O(\lambda^{-2m}).\end{aligned}\tag{3.16}$$

When $w=0$, $\zeta=\zeta_0\neq 0$ and (3.16) becomes

$$\frac{2}{3}[-X(\zeta_0)]^{3/2}-\frac{\pi}{4}=\lambda^{2m}I(\lambda,0)-(-\zeta_0)^{1/2}\Phi(\lambda,\zeta_0)-\frac{\pi}{4}+O(\lambda^{-2m}).\tag{3.17}$$

Observe that the limit of the second term on the right-hand side of (3.17) exists as $\lambda\to\infty$. Inserting (3.15) in (3.17) gives

$$\begin{aligned}\frac{2}{3}[-X(\zeta_0)]^{3/2}-\frac{\pi}{4} &= \frac{\pi}{2}\sum_{k=0}^{m-1}(k+1)v_{k+1}\lambda^{2k+2}2^{-(2k+1)}\binom{2k+1}{k+1}\\ &\qquad \frac{\pi}{2}mv_m2^{-(2m-1)}D_{2m-2}-(-\zeta_0)^{1/2}\Phi(\lambda,\zeta_0)-\frac{\pi}{4}+O(\lambda^{-2}).\end{aligned}\tag{3.18}$$

On the other hand, using integration by parts and orthogonality, we have

$$\begin{aligned}&\int_{-\infty}^{\infty}v'(x)p_n(x)p_{n-1}(x)e^{-v(x)}dx\\ &=\int_{-\infty}^{\infty}[p_n'(x)p_{n-1}(x)+p_n(x)p_{n-1}'(x)]e^{-v(x)}dx\\ &=n\frac{\gamma_n}{\gamma_{n-1}}\int_{-\infty}^{\infty}p_{n-1}^2(x)e^{-v(x)}dx=\frac{n}{a_n}.\end{aligned}\tag{3.19}$$

Substituting $v'(x)=2\sum_{k=1}^m kv_kx^{2k-1}$ into (3.19) and applying (2.9), we also have

$$\begin{aligned}&\int_{-\infty}^{\infty}v'(x)p_n(x)p_{n-1}(x)e^{-v(x)}dx\\ &=2\sum_{k=1}^{m}kv_kc_{n,1,2k-1}=2\sum_{k=0}^{m-1}(k+1)v_{k+1}c_{n,1,2k+1}.\end{aligned}\tag{3.20}$$

Coupling (3.19) and (3.20) gives

$$n=2a_n\sum_{k=0}^{m-1}(k+1)v_{k+1}c_{n,1,2k+1};\tag{3.21}$$

see [2, (1.2)]. Inserting (2.30) in (3.21), and noting that $2a_n=\lambda$, we have

$$n=\lambda\sum_{k=0}^{m-1}(k+1)v_{k+1}\binom{2k+1}{k+1}2^{-(2k+1)}\lambda^{2k+1}\left[1+\frac{\tilde c_{1,2k+1}}{2mn}+O\left(\frac{1}{n^{1+1/m}}\right)\right].$$

By (2.27) and the relationship between $\tilde c_{1,2k+1}$ and $\tilde d_{2k+1}$ given in the statement following (2.34), we obtain

$$\begin{aligned} n &= \sum_{k=0}^{m-1}(k+1)v_{k+1}\lambda^{2k+2}2^{-(2k+1)}\binom{2k+1}{k+1}\left[1+\frac{\tilde{d}_{2k+1}}{\lambda^{2m}}+O\left(\frac{1}{\lambda^{2m+2}}\right)\right] \\ &= \sum_{k=0}^{m-1}(k+1)v_{k+1}\lambda^{2k+2}2^{-(2k+1)}\binom{2k+1}{k+1} \\ &\quad + mv_m 2^{-(2m-1)}\binom{2m-1}{m}\tilde{d}_{2m-1}+O(\lambda^{-2}). \end{aligned} \tag{3.22}$$

Recall from (2.25) that $L_m = \frac{m!(m-1)!}{(2m)!}$, and hence $L_k^{-1} = 2k\binom{2k-1}{k}$. Thus on one hand we have

$$\begin{aligned} n &= \sum_{k=1}^{m} v_k\lambda^{2k}2^{-2k}L_k^{-1} + 2^{-2m}L_m^{-1}\tilde{d}_{2m-1}+O(\lambda^{-2}) \\ &= 2^{-2m}L_m^{-1}u\left[1+v_{m-1}\frac{L_m}{L_{m-1}}2^{-2(m-1)}\frac{1}{u^{1/m}}+v_{m-2}\frac{L_m}{L_{m-2}}2^{-2(m-2)}\frac{1}{u^{2/m}}\right. \\ &\qquad \left. +\cdots+v_1\frac{L_m}{L_1}2^{-2}\frac{1}{u^{1-1/m}}+\frac{\tilde{d}_{2m-1}}{u}+O\left(\frac{1}{u^{1+1/m}}\right)\right], \end{aligned} \tag{3.23}$$

and on the other hand we have by (2.24)

$$u = 2^{2m}L_m n\left[1+\frac{\tau_1}{n^{1/m}}+\frac{\tau_2}{n^{2/m}}+\cdots+\frac{\tau_m}{n}+O\left(\frac{1}{n^{1+1/m}}\right)\right], \tag{3.24}$$

since $2a_n = \lambda$ and $\lambda^{2m} = u$. Inserting (3.24) in (3.23) and comparing the coefficients of $n^{-k/m}$ for $k = 0,\ldots,m$, we can determine the coefficients $\tau_1,\tau_2,\ldots,\tau_m$. The first two are given by

$$\begin{aligned} \tau_1 &= -2^{-2m}\frac{L_m}{L_{m-1}}L_m^{-1/m}v_{m-1}, \\ \tau_2 &= -2^{-2m}\frac{L_m}{L_{m-2}}L_m^{-2/m}v_{m-2}+\left(1-\frac{1}{m}\right)\tau_1^2. \end{aligned}$$

Since $a_n = u^{1/2m}/2$, we can also determine the coefficients $\eta_1,\eta_2,\ldots,\eta_m$ in (2.24). For instance, we have

$$\begin{aligned} \eta_1 &= -\frac{2^{-2m}}{2m}\frac{L_m}{L_{m-1}}L_m^{-1/m}v_{m-1}, \\ \eta_2 &= -\frac{2^{-2m}}{2m}\frac{L_m}{L_{m-2}}L_m^{-2/m}v_{m-2}+\left(m-\frac{3}{2}\right)\eta_1^2. \end{aligned}$$

Comparing (3.22) with (3.18) gives

$$\frac{2}{3}[-X(\zeta_0)]^{3/2}-\frac{\pi}{4} = \frac{\pi}{2}n+\beta(\lambda), \tag{3.25}$$

where

$$\begin{aligned} \beta(\lambda) &= \frac{\pi}{2}mv_m 2^{-(2m-1)}\left[D_{2m-2}-\binom{2m-1}{m}\tilde{d}_{2m-1}\right] \\ &\qquad -(-\zeta_0)^{1/2}\Phi(\lambda,\zeta_0)-\frac{\pi}{4}+O(\lambda^{-2}). \end{aligned} \tag{3.26}$$

Since $\zeta_0 = \zeta(\lambda, 0)$ and $\Phi(\lambda, \zeta_0)$ have limits as $\lambda \to \infty$, so does $\beta(\lambda)$ as $\lambda \to \infty$.

Substituting (3.3) and (3.25) in (3.10), we get

$$\text{(3.27)}\quad \mathrm{Ai}(X(\zeta_0)) = \pi^{-1/2}u^{-1/6}(-\zeta_0)^{-1/4}[1+O(u^{-1})]\left\{\cos\left(\frac{\pi}{2}n+\beta(\lambda)\right)+O(u^{-1})\right\},$$

which can be simplified to

$$\text{(3.28)}\qquad \mathrm{Ai}(X(\zeta_0)) = \pi^{-1/2}u^{-1/6}(-\zeta_0)^{-1/4}\left\{\cos\left(\frac{\pi}{2}n+\beta(\lambda)\right)+O(u^{-1})\right\}.$$

We need both of these results in our later discussions. Inserting (3.28) in (3.4) and noting that $\varepsilon_1(\lambda, \zeta_0) = O(u^{-7/6})$ and $u = \lambda^{2m}$, we have

$$\text{(3.29)}\qquad \begin{aligned} p_n(0)e^{-v_0/2} &= C(n)\pi^{-1/2}u^{1/3-1/4m} \\ &\quad \cdot \left\{\cos\left(\frac{\pi}{2}n\right)\cos\beta(\lambda) - \sin\left(\frac{\pi}{2}n\right)\sin\beta(\lambda)+O(u^{-1})\right\}. \end{aligned}$$

Now we differentiate both sides of (3.2) and then set $x = 0$ and, correspondingly, $w = 0$. This leads to

$$\text{(3.30)}\qquad \begin{aligned} &p_n'(0)\ \ e^{-v_0/2} = \\ &C(n)\lambda^{m-3/2}\left\{\frac{1}{4}(-\zeta_0)^{-3/4}(-\zeta_0')\left(1+\frac{\Phi'(\zeta_0)}{u}\right)^{-1/2}[\mathrm{Ai}(X(\zeta_0))+\varepsilon_1(\lambda,\zeta_0)]\right. \\ &-\frac{1}{2}(-\zeta_0)^{1/4}\left(1+\frac{\Phi'(\zeta_0)}{u}\right)^{-3/2}\frac{\Phi''(\zeta_0)}{u}\zeta_0'[\mathrm{Ai}(X(\zeta_0))+\varepsilon_1(\lambda,\zeta_0)] \\ &\left.+(-\zeta_0)^{1/4}\left(1+\frac{\Phi'(\zeta_0)}{u}\right)^{-1/2}\zeta_0'[\mathrm{Ai}'(X(\zeta_0))X'(\zeta_0)+\varepsilon_1'(\lambda,\zeta_0)]\right\}. \end{aligned}$$

By using the differential recurrence relation (1.5) and the fact that $B_n(x)$ is an odd function, we obtain

$$\text{(3.31)}\qquad p_n'(0) = A_n(0)p_{n-1}(0).$$

From (2.55) and (2.53), we also have

$$\text{(3.32)}\qquad \zeta_0' = \hat{H}_0(\lambda, 0)^{1/2} = (-\zeta_0)^{-1/2}\frac{A_n(0)}{\lambda^{2m-1}}.$$

Recall again that $u = \lambda^{2m}$. Hence, inserting (3.31) and (3.32) in (3.30) yields

$$\text{(3.33)}\qquad \begin{aligned} &p_{n-1}(0)e^{-v_0/2} = C(n)\lambda^{m-1/2}\left\{-\frac{1}{4u}(-\zeta_0)^{-5/4}\left(1+\frac{\Phi'(\zeta_0)}{u}\right)^{-1/2}[\mathrm{Ai}(X(\zeta_0))+\varepsilon_1(\lambda,\zeta_0)]\right. \\ &\qquad -\frac{1}{2}(-\zeta_0)^{-1/4}\left(1+\frac{\Phi'(\zeta_0)}{u}\right)^{-3/2}\frac{\Phi''(\zeta_0)}{u^2}[\mathrm{Ai}(X(\zeta_0))+\varepsilon_1(\lambda,\zeta_0)] \\ &\qquad \left.+\frac{1}{u}(-\zeta_0)^{-1/4}\left(1+\frac{\Phi'(\zeta_0)}{u}\right)^{-1/2}[\mathrm{Ai}'(X(\zeta_0))X'(\zeta_0)+\varepsilon_1'(\lambda,\zeta_0)]\right\}. \end{aligned}$$

The first term inside the curly brackets in (3.33) is of order $O(u^{-7/6})$ since $\mathrm{Ai}(X(\zeta_0)) = O(u^{-1/6})$ (cf. (3.28)), and the second term inside the brackets is of order $O(u^{-13/6})$. Since $X'(\zeta_0) = u^{2/3}(1 + \Phi'(\zeta_0)/u)$ by (3.3) and $\varepsilon_1'(\lambda, \zeta) = O(u^{-1/6})$ by (2.76), the third term is equal to

$$(-\zeta_0)^{-1/4}u^{-1/3}\left(1 + \frac{\Phi'(\zeta_0)}{u}\right)^{1/2}\mathrm{Ai}'(X(\zeta_0)) + O(u^{-7/6}).$$

Hence it follows from (3.33) that

$$\begin{aligned} p_{n-1}(0)e^{-v_0/2} &= C(n)\lambda^{m-1/2} \\ &\quad \cdot \left\{(-\zeta_0)^{-1/4}u^{-1/3}\left(1 + \frac{\Phi'(\zeta_0)}{u}\right)^{1/2}\mathrm{Ai}'(X(\zeta_0)) + O(u^{-7/6})\right\}. \end{aligned} \tag{3.34}$$

Using the asymptotic formula [7, p. 392]

$$\mathrm{Ai}'(-x) = \frac{x^{1/4}}{\pi^{1/2}}\left\{\sin\left(\frac{2}{3}x^{3/2} - \frac{\pi}{4}\right) + O(x^{-3/2})\right\}, \qquad x \to \infty,$$

we have from (3.3) and (3.25)

$$\mathrm{Ai}'(X(\zeta_0)) = \pi^{-1/2}(-\zeta_0)^{1/4}u^{1/6}\left\{\sin\left(\frac{\pi}{2}n + \beta(\lambda)\right) + O(u^{-1})\right\}; \tag{3.35}$$

cf. (3.28). Coupling (3.34) and (3.35) yields

$$\begin{aligned} p_{n-1}(0)e^{-v_0/2} &= C(n)\pi^{-1/2}u^{1/3-1/4m} \\ &\quad \cdot \left\{\sin\left(\frac{\pi}{2}n\right)\cos\beta(\lambda) + \cos\left(\frac{\pi}{2}n\right)\sin\beta(\lambda) + O(u^{-1})\right\}. \end{aligned} \tag{3.36}$$

When n is even, we have $p_{n-1}(0) = 0$, $\sin(\frac{\pi}{2}n) = 0$, and $\cos(\frac{\pi}{2}n) = (-1)^{n/2}$. Thus, from (3.36), we obtain $\sin\beta(\lambda) = O(u^{-1})$, from which it follows that $\cos\beta(\lambda) = \delta[1 + O(u^{-2})]$, where $\delta = 1$ or -1. When n is odd, we obtain $p_n(0) = 0$, $\cos(\frac{\pi}{2}n) = 0$, and $\sin(\frac{\pi}{2}n) = (-1)^{(n-1)/2}$. From (3.29), we again obtain $\sin\beta(\lambda) = O(u^{-1})$ and $\cos\beta(\lambda) = \delta[1 + O(u^{-2})]$. Since $\beta(\lambda)$ has a limit as $\lambda \to \infty$, we always have

$$\cos\beta(\lambda) = \delta[1 + O(u^{-2})] \qquad \text{as } \lambda \to \infty, \tag{3.37}$$

regardless of whether n is even or odd. Inserting (3.8) and (3.37) in (3.29) when n is even and in (3.36) when n is odd, we obtain

$$\tilde{A}_2 n^{-1/4m}e^{-v_0/2}[1 + O(n^{-1/m})] = C(n)\pi^{-1/2}\delta u^{1/3-1/4m}[1 + O(u^{-1})],$$

which in turn gives

$$C(n) = An^{-1/4m}u^{1/4m-1/3}[1 + O(u^{-1/m})], \tag{3.38}$$

where $A = \tilde{A}_2\delta^{-1}\pi^{1/2}e^{-v_0/2}$. Substituting (3.38) into (3.2) gives

$$p_n(x)e^{-v(x)/2} = An^{-1/4m}u^{1/6}\left(\frac{\zeta}{w^2 - 1}\right)^{1/4}\{\mathrm{Ai}(X(\zeta)) + \varepsilon_1(\lambda, \zeta)\}[1 + O(u^{-1/m})]. \tag{3.39}$$

This formula holds uniformly for $w \in [-1+\varepsilon, M]$.

Our next task is to determine the constant A. To this end, we restrict w to the interval $[-1+\varepsilon, 1-\varepsilon]$. By inserting (3.10), (2.76), and (3.3) in (3.39), we have

$$\begin{aligned} p_n(x)e^{-v(x)/2} = {} & A\pi^{-1/2}n^{-1/4m}(1-w^2)^{-1/4} \\ & \cdot \left\{\cos\left(\frac{2}{3}[-X(\zeta)]^{3/2} - \frac{\pi}{4}\right) + O(u^{-1})\right\}[1+O(u^{-1/m})] \end{aligned} \tag{3.40}$$

uniformly for $w \in [-1+\varepsilon, 1-\varepsilon]$, which can be simplified to

$$\begin{aligned} p_n(x)e^{-v(x)/2} = {} & A\pi^{-1/2}n^{-1/4m}(1-w^2)^{-1/4} \\ & \cdot \left\{\cos\left(\frac{2}{3}[-X(\zeta)]^{3/2} - \frac{\pi}{4}\right) + O(u^{-1/m})\right\}. \end{aligned} \tag{3.41}$$

Squaring both sides of the last equation gives

$$\begin{aligned} p_n^2(x)e^{-v(x)} = {} & A^2\pi^{-1}n^{-1/2m}(1-w^2)^{-1/2}\left\{\cos^2\left(\frac{2}{3}[-X(\zeta)]^{3/2} - \frac{\pi}{4}\right) + O(u^{-1/m})\right\} \\ = {} & \frac{1}{2}A^2\pi^{-1}n^{-1/2m}(1-w^2)^{-1/2}\left\{\sin\left(\frac{4}{3}[-X(\zeta)]^{3/2}\right) + 1 + O(u^{-1/m})\right\}. \end{aligned} \tag{3.42}$$

On account of (1.2) and (2.4), we have

$$1 = \int_{-\infty}^{\infty} p_n^2(x)e^{-v(x)}dx \geq \lambda\int_{-1+\varepsilon}^{1-\varepsilon} p_n^2(x)e^{-v(x)}dw.$$

From (3.42), it follows that

$$\begin{aligned} 1 \geq \frac{\lambda}{2}A^2\pi^{-1}n^{-1/2m} & \left[\int_{-1+\varepsilon}^{1-\varepsilon} \frac{1}{\sqrt{1-w^2}}\sin\left(\frac{4}{3}[-X(\zeta)]^{3/2}\right)dw\right. \\ & \left. + \int_{-1+\varepsilon}^{1-\varepsilon} \frac{dw}{\sqrt{1-w^2}} + O(u^{-1/m})\right]. \end{aligned} \tag{3.43}$$

Let us consider for a moment the function

$$\xi = \xi(w) = \frac{4}{3}(-\zeta)^{3/2}\left(1 + \frac{\Phi(\zeta)}{u\zeta}\right)^{3/2}.$$

Clearly

$$\begin{aligned} \xi'(w) = {} & -2(-\zeta)^{1/2}\left(1 + \frac{\Phi(\zeta)}{u\zeta}\right)^{3/2}\zeta'(\lambda, w) \\ & + 2(-\zeta)^{3/2}\left(1 + \frac{\Phi(\zeta)}{u\zeta}\right)^{1/2}\frac{1}{u}\frac{d}{dw}\frac{\Phi(\zeta)}{\zeta}. \end{aligned}$$

The first term on the right-hand side is negative for $w \in [-1+\varepsilon, 1-\varepsilon]$ and for λ sufficiently large, the second term tends to zero, uniformly for $w \in [-1+\varepsilon, 1-\varepsilon]$, as $\lambda \to \infty$. Thus, when λ is sufficiently large, we have $\xi'(w) < 0$. Therefore, the mapping $w \mapsto \xi$ is one-to-one on the interval $[-1+\varepsilon, 1-\varepsilon]$. Since

$$\frac{4}{3}[-X(\zeta)]^{3/2} = u \cdot \frac{4}{3}(-\zeta)^{3/2}\left(1+\frac{\Phi(\zeta)}{u\zeta}\right)^{3/2},$$

the first integral inside the square brackets in (3.43) is equal to

$$I_0 = \int_{\xi(-1+\varepsilon)}^{\xi(1-\varepsilon)} \frac{1}{\sqrt{1-\omega^2(\xi)}}\frac{1}{\xi'(\omega(\xi))}\sin(u\xi)d\xi,$$

where $\omega(\xi)$ is the inverse of $\xi = \xi(w)$. The Riemann–Lebesgue lemma infers that this integral tends to 0 as $\lambda \to \infty$, or equivalently, as $u \to \infty$. By (2.27),

$$\lambda n^{-1/2m} \to 2L_m^{1/2m} \tag{3.44}$$

as $\lambda \to \infty$. Hence, letting $\lambda \to \infty$ in (3.43), we obtain

$$1 \geq 2A^2\pi^{-1}L_m^{1/2m} \cdot \arcsin(1-\varepsilon).$$

Since ε is arbitrary, it follows that

$$A^2 \leq L_m^{-1/2m}. \tag{3.45}$$

To show that the reverse inequality also holds, we consider the identity

$$\int_{-\infty}^{\infty}\left(1-\frac{x^2}{\lambda^2}\right)p_n^2(x)e^{-v(x)}dx = 1-\frac{1}{\lambda^2}(a_{n+1}^2+a_n^2), \tag{3.46}$$

which can be obtained by squaring both sides of the recurrence relation (1.10) and using the orthonormal property (1.2). From (2.4) and (2.54), it is evident that

$$\int_{-\infty}^{\infty}\left(1-\frac{x^2}{\lambda^2}\right)p_n^2(x)e^{-v(x)}dx \leq 2\lambda\int_0^1(1-w^2)p_n^2(x)e^{-v(x)}dw.$$

Divide the interval of integration on the right-hand side at $w = 1-\varepsilon n^{-\alpha}$, $\alpha > 0$, and denote by I_1 and I_2 the integrals corresponding, respectively, to the subintervals $[0, 1-\varepsilon n^{-\alpha}]$ and $[1-\varepsilon n^{-\alpha}, 1]$. Thus,

$$\int_{-\infty}^{\infty}\left(1-\frac{x^2}{\lambda^2}\right)p_n^2(x)e^{-v(x)}dx \leq 2\lambda I_1 + 2\lambda I_2. \tag{3.47}$$

Since $\zeta(\lambda, w)$ is continuous in $[-1+\varepsilon, M]$ and has limit as $\lambda \to \infty$, $\zeta(\lambda, w)$ is uniformly bounded there. By the same reasoning, $\zeta/(w^2-1)$ is uniformly bounded in this interval. Furthermore, in view of (3.3) and (2.75), $\mathrm{Ai}(X(\zeta))$ and $\varepsilon_1(\lambda,\zeta)$ are also uniformly bounded in $[-1+\varepsilon, M]$. Hence, by virtue of (3.39), there exists a constant K such that

$$p_n^2(x)e^{-v(x)} \leq A^2n^{-1/2m}u^{1/3}K$$

uniformly for $w \in [-1+\varepsilon, M]$, from which it follows that

$$\begin{aligned} 0 \leq 2\lambda I_2 &= 2\lambda\int_{1-\varepsilon u^{-\alpha}}^{1}(1-w^2)p_n^2(x)e^{-v(x)}dw \\ &\leq 2\lambda A^2n^{-1/2m}u^{1/3}K\varepsilon u^{-\alpha}(2\varepsilon u^{-\alpha}-\varepsilon^2u^{-2\alpha}) \\ &= 8A^2KL_m^{1/2m}\varepsilon^2u^{1/3-2\alpha}[1+O(1)], \end{aligned} \tag{3.48}$$

where we have also made use of (3.44). We choose $\alpha > 1/6$ so that $2\lambda I_2 \to 0$ as $\lambda \to \infty$.

Now consider the integral I_1. When $w \in (0,1)$, by the mean-value theorem, $\zeta(\lambda, w) = \zeta'(\lambda, \omega_\lambda)(w-1)$, where $\omega_\lambda \in (w,1)$. Since $\zeta'(\lambda, w) \to \zeta'_\infty(w)$ uniformly on [0,1] and $\zeta'_\infty(w) > 0$ on [0,1] (see section 2), there exists a constant $K_1 > 0$ such that $-\zeta(\lambda, w) > K_1(1-w)$ uniformly for $w \in (0,1)$ and for all sufficiently large λ. Hence, when $0 < w < 1 - \varepsilon u^{-\alpha}$, we have $-\zeta(\lambda, w) \geq K_1 \varepsilon u^{-\alpha}$, from which it follows from (3.3) that

$$-X(\zeta) \geq K_1 \varepsilon u^{2/3-\alpha}(1 - |\Phi(\zeta)| u^{\alpha-1}/K_1\varepsilon) \geq \frac{1}{2} K_1 \varepsilon u^{2/3-\alpha}$$

for sufficiently large u and for $0 < \alpha < 1$ since $\Phi(\zeta)$ is bounded. Hence, if $\alpha < 2/3$, then $-X(\zeta) \to +\infty$. Also, we have $-X(\zeta) = u^{2/3}(-\zeta)[1 + O(u^{\alpha-1})]$ and $[-X(\zeta)]^{-3/2} = O(u^{3\alpha/2-1})$ uniformly for $w \in [0, 1-\varepsilon u^{-\alpha}]$. By (3.9), we have for $1/6 < \alpha < 2/3$

$$\begin{aligned} \mathrm{Ai}(X(\zeta)) &= \pi^{-1/2} u^{-1/6} (-\zeta)^{-1/4} [1 + O(u^{\alpha-1})] \\ &\quad \cdot \left\{ \cos\left(\frac{2}{3}[-X(\zeta)]^{3/2} - \frac{\pi}{4} \right) + O(u^{3\alpha/2-1}) \right\}, \end{aligned} \tag{3.49}$$

which may be simplified to

$$\mathrm{Ai}(X(\zeta)) = \pi^{-1/2} u^{-1/6} (-\zeta)^{-1/4} \left\{ \cos\left(\frac{2}{3}[-X(\zeta)]^{3/2} - \frac{\pi}{4} \right) + O(u^{-1/2}) \right\} \tag{3.50}$$

with $\alpha = 1/3$. Substituting (3.50) into (3.39) and squaring both sides give

$$p_n^2(x) e^{-v(x)} = A^2 \pi^{-1} n^{-1/2m} (1-w^2)^{-1/2} \left\{ \cos^2\left(\frac{2}{3}[-X(\zeta)]^{3/2} - \frac{\pi}{4} \right) + O(u^{-1/m}) \right\}. \tag{3.51}$$

Inserting this in I_1, we obtain

$$2\lambda I_1 = 2\lambda \pi^{-1} A^2 n^{-1/2m} \int_0^{1-\varepsilon u^{-\alpha}} \sqrt{1-w^2} \left\{ \cos^2\left(\frac{2}{3}[-X(\zeta)]^{3/2} - \frac{\pi}{4} \right) + O(u^{-1/m}) \right\} dw,$$

which in turn gives

$$\begin{aligned} 2\lambda I_1 = \lambda \pi^{-1} A^2 n^{-1/2m} &\left[\int_0^{1-\varepsilon u^{-\alpha}} \sqrt{1-w^2} \sin\left(\frac{4}{3}[-X(\zeta)]^{3/2} \right) dw \right. \\ &\left. + \int_0^{1-\varepsilon u^{-\alpha}} \sqrt{1-w^2} dw + O(u^{-1/m}) \right]. \end{aligned} \tag{3.52}$$

As before, the Riemann–Lebesgue lemma infers that the first integral inside the square brackets in (3.52) tends to 0 as $\lambda \to \infty$. From (3.44) and the result

$$\int \sqrt{1-w^2} dw = \frac{1}{2} \left(w\sqrt{1-w^2} + \arcsin w \right),$$

it follows that

$$2\lambda I_1 \to \frac{1}{2} A^2 L_m^{1/2m} \qquad \text{as } \lambda \to \infty.$$

Since $\lambda = 2a_n$ and $a_{n+1} \sim a_n$, we have $1 - \frac{1}{\lambda^2}(a_{n+1}^2 + a_n^2) \to \frac{1}{2}$ as $\lambda \to \infty$. In view of (3.46) and (3.47), we get

$$1 \le A^2 L_m^{1/2m}. \tag{3.53}$$

Coupling (3.45) and (3.53) yields

$$A = L_m^{-1/4m}. \tag{3.54}$$

From (3.39), we obtain

$$\begin{aligned} p_n(x)e^{-v(x)/2} &= L_m^{-1/4m} n^{-1/4m} u^{1/6} \\ &\quad \cdot \left(\frac{\zeta}{w^2-1}\right)^{1/4} \{\mathrm{Ai}(X(\zeta)) + \varepsilon_1(\lambda,\zeta)\}[1 + O(u^{-1/m})]. \end{aligned} \tag{3.55}$$

Since $\varepsilon_1(\lambda,\zeta) = O(u^{-1})$ uniformly on $[-1+\varepsilon, M]$ by (2.75) and $u = 2^{2m}L_m n[1 + O(n^{-1/m})]$ by (2.24), we have from (3.55) the following main result.

THEOREM 3.1. *For any positive and fixed numbers $\varepsilon \ll 1$ and $1 \ll M$, the asymptotic formula*

$$p_n(x)e^{-v(x)/2} = 2^{m/3} L_m^{1/6-1/4m} n^{1/6-1/4m} \left(\frac{\zeta}{w^2-1}\right)^{1/4} \{\mathrm{Ai}(X(\zeta)) + O(n^{-1/m})\} \tag{3.56}$$

holds uniformly for $w \in [-1+\varepsilon, M]$, where $x = \lambda w$, ζ is defined in (2.56), *and $X(\zeta)$ is defined in* (3.3).

4. Asymptotic formula for the zeros of $p_n(x)$.

Let the zeros of $p_n(x)$ be arranged in decreasing order:

$$-\infty < x_{n,n} < x_{n,n-1} < \cdots < x_{n,2} < x_{n,1} < \infty, \tag{4.1}$$

and let $w_{n,k}$ and $\zeta_{n,k}$ denote the corresponding values determined by (2.4) and (2.56), respectively. Since $\zeta(\lambda, w)$ is an increasing function for $w \in (-1, \infty)$, (4.1) implies

$$-\infty < \zeta_{n,n} < \zeta_{n,n-1} < \cdots < \zeta_{n,2} < \zeta_{n,1} < \infty. \tag{4.2}$$

In view of the fact that

$$\lim_{w \to 1} \frac{\zeta}{w^2-1} = \frac{1}{2}\zeta'(\lambda, 1) > 0,$$

it follows from (3.55) that $\zeta_{n,k}$ is the kth root of the equation

$$\mathrm{Ai}(X(\zeta)) + \varepsilon_1(\lambda,\zeta) = 0, \tag{4.3}$$

where $X(\zeta)$ is defined in (3.3) and $\varepsilon_1(\lambda,\zeta)$ satisfies the estimates in (2.73). Let $\tilde{a}_k$ denote the kth negative zero of the Airy function $\mathrm{Ai}(x)$. Since $\varepsilon_1(\lambda,\zeta) = O(u^{-1})$, it is reasonable to expect that

$$\zeta_{n,k} \approx \zeta_n(\tilde{a}_k),$$

where $\zeta_n(\tilde{a}_k)$ is uniquely determined by

$$X(\zeta_n(\tilde{a}_k)) = u^{2/3}\zeta_n(\tilde{a}_k) + \frac{\Phi(\lambda, \zeta_n(\tilde{a}_k))}{u^{1/3}} = \tilde{a}_k \tag{4.4}$$

since $X(\zeta)$ is monotonically increasing for large λ. Note that $\zeta = \zeta(\lambda, w)$ is uniformly bounded on $[-1+\varepsilon, M]$ and $\Phi(\lambda,\zeta)$ is also uniformly bounded for $\zeta \in [\zeta_\infty(-1+\varepsilon), \zeta_\infty(M)]$. Hence, it follows from (4.4) that $\zeta_n(\tilde{a}_k)$ is negative when λ (or, equivalently, n) is sufficiently large.

Now we consider equation (4.3) and recall the estimate in (2.73). In what follows, we shall suppose that λ is sufficiently large so that

$$\frac{K\pi}{u}\mathcal{V}_{\zeta,\zeta_\infty(M)}(\Psi(\xi)) \exp\left\{\frac{K_0}{u}\mathcal{V}_{\zeta,\zeta_\infty(M)}(\Psi(\xi))\right\} < \frac{1}{2}. \tag{4.5}$$

For convenience, we put

$$\rho_1(\lambda,\zeta) = \varepsilon_1(\lambda,\zeta)E(X(\zeta))/M(X(\zeta)) \tag{4.6}$$

and

$$\sigma_1(\lambda,\zeta) = \frac{K\pi}{u}\mathcal{V}_{\zeta,\zeta_\infty(M)}(\Psi(\xi)) \exp\left\{\frac{K_0}{u}\mathcal{V}_{\zeta,\zeta_\infty(M)}(\Psi(\xi))\right\}. \tag{4.7}$$

From (2.73) and (4.5), we have $|\rho_1(\lambda,\zeta)| \le \sigma_1(\lambda,\zeta) < 1/2$. In terms of the phase function $\theta(x)$ associated with $\mathrm{Ai}(x)$, (4.3) can be written as

$$\sin\theta(X(\zeta)) = -\rho_1(\lambda,\zeta) \tag{4.8}$$

on account of (4.6). From the definition of the phase function, it is readily seen that $\theta(x) = \pi/4$ when $x \ge c$. Hence, for $X(\zeta) \ge c$, we have $\sin\theta(X(\zeta)) = 1/\sqrt{2}$. However, the absolute value of the right-hand side of (4.8) is less than 1/2. Thus, it follows that (4.3) has no roots when $X(\zeta) \ge c$. That is, all the roots $\zeta_{n,k}$ of (4.3) lie in the interval $X(\zeta) < c$. Since $X(\zeta) = u^{2/3}\zeta + \Phi(\zeta)/u^{1/3} \ge c$ when $\zeta \ge 0$ and λ is sufficiently large, (4.3) has no roots for $\zeta \ge 0$ and λ sufficiently large. Recall that $\zeta \ge 0$ corresponds to $w \ge 1$ by (2.56), and that $w \ge 1$ corresponds to $x \ge \lambda$ by (2.4). Therefore, in view of (3.55), the polynomial $p_n(x)$ has no zero in $x \ge \lambda$. By symmetry, $p_n(x)$ also has no zero in $x \le -\lambda$. That is, all zeros of $p_n(x)$ lie in the interval $-\lambda < x < \lambda$; equivalently, the corresponding values $\zeta_{n,k}$ all lie in $-\zeta(\lambda,-1) < \zeta < 0$. In this range and when $X(\zeta) < c$, (4.8), which is equivalent to (4.3), can be written as

$$\theta(X(\zeta)) - k\pi - (-1)^{k-1}\arcsin\{\rho_1(\lambda,\zeta)\} = 0, \tag{4.9}$$

where k is an arbitrary integer. In what follows, we shall show that the left-hand side of (4.9) is a decreasing function of ζ for $X(\zeta) < c$. In view of the identity [7, p. 404]

$$\theta'(x) = -1/\{\pi M^2(x)\} \qquad \text{for} \quad x \le c \tag{4.10}$$

and the fact that $M(x) \ne 0$, $\theta'(x)$ is strictly negative for all $x \le c$. Thus, to prove that the derivative of the function on the left-hand side of (4.9) is strictly less than zero, it suffices to show that

$$\{1 - \rho_1^2(\lambda,\zeta)\}^{-1/2}|\rho_1'(\lambda,\zeta)| < |\theta'(X(\zeta))|X'(\zeta). \tag{4.11}$$

Also, since $E(x) = 1$ for $x \leq c$, by (4.6) we have

$$\rho_1'(\lambda, \zeta) = \frac{\varepsilon_1'(\lambda, \zeta)}{M(X(\zeta))} - \frac{M'(X(\zeta))}{M^2(X(\zeta))} X'(\zeta)\varepsilon_1(\lambda, \zeta).$$

From (2.73) and (4.7), it follows that

$$\begin{aligned} |\rho_1'(\lambda, \zeta)| \leq & \frac{N(X(\zeta))X'(\zeta)\sigma_1(\lambda, \zeta)}{M(X(\zeta))} + \frac{M'(X(\zeta))X'(\zeta)}{M(X(\zeta))}\sigma_1(\lambda, \zeta) \\ = & \{N(X(\zeta)) + M'(X(\zeta))\} \frac{X'(\zeta)\sigma_1(\lambda, \zeta)}{M(X(\zeta))} \end{aligned}$$

and

$$\{1 - \rho_1^2(\lambda, \zeta)\}^{-1/2} |\rho_1'(\lambda, \zeta)| \leq \frac{\{N(X(\zeta)) + M'(X(\zeta))\}}{\{1 - \rho_1^2(\lambda, \zeta)\}^{1/2}} \frac{X'(\zeta)\sigma_1(\lambda.\zeta)}{M(X(\zeta))}. \tag{4.12}$$

Hence, it is evident that (4.11) holds if

$$\frac{\{N(X(\zeta)) + M'(X(\zeta))\}}{\{1 - \rho_1^2(\lambda, \zeta)\}^{1/2}} \frac{X'(\zeta)\sigma_1(\lambda.\zeta)}{M(X(\zeta))} < |\theta'(X(\zeta))| X'(\zeta).$$

By (4.10) and the estimate $|\rho_1(\lambda, \zeta)| \leq \sigma_1(\lambda, \zeta)$, we only need to prove that

$$\frac{\sigma_1(\lambda, \zeta)}{\{1 - \sigma_1^2(\lambda, \zeta)\}^{1/2}} < \frac{1}{\pi M(X(\zeta))\{N(X(\zeta)) + M'(X(\zeta))\}}. \tag{4.13}$$

The left-hand side of (4.13) is less than $1/\sqrt{3} = 0.577\ldots$, since $\sigma_1(\lambda, \zeta) < 1/2$. The right-hand side of (4.13) is a decreasing function of $X(\zeta)$ by Lemma 5.1 in [7, p. 404]. When $X(\zeta) = c$, its value is

$$\frac{1}{\pi \operatorname{Ai}(c) \left\{ \operatorname{Ai}'(c) + \operatorname{Bi}'(c) + \sqrt{2 \operatorname{Ai}'^2(c) + 2 \operatorname{Bi}'^2(c)} \right\}} = 0.708\ldots.$$

Therefore, (4.13) and (4.11) are both satisfied. This proves that the left-hand side of (4.9) is monotonically decreasing in ζ for every k.

From the estimate

$$|\arcsin \rho_1(\lambda, \zeta)| < \arcsin \frac{1}{2} = \frac{\pi}{6} \tag{4.14}$$

and the fact that

$$\theta(c) = \frac{\pi}{4},$$

one easily verifies that if $k \leq 0$, then the value of the left-hand side of (4.9) is greater than zero when $X(\zeta) = c$. Since the left-hand side of (4.9) is a decreasing function, (4.9) has no roots when $X(\zeta) \leq c$.

Let b_k denote the kth negative zero of $\operatorname{Bi}(x)$, and let $\zeta_n(b_k)$ be uniquely determined by

$$X(\zeta_n(b_k)) = b_k. \tag{4.15}$$

For any given positive integer k, from (4.14) and the result [7, p. 404]

$$\theta(b_k) = (k - \frac{1}{2})\pi,$$

it is readily seen that the left-hand side of (4.9) is negative when $\zeta = \zeta_n(b_k)$ and positive when $\zeta = \zeta_n(b_{k+1})$. Hence, in the range

$$b_{k+1} < X(\zeta) < b_k \tag{4.16}$$

or, equivalently, $\zeta_n(b_{k+1}) < \zeta < \zeta_n(b_k)$, (4.9) has a root $\tilde{\zeta}_{n,k}$. Since the left-hand side of (4.9) is decreasing in ζ, this is the only root of (4.9) for a fixed k, and the sequence $\tilde{\zeta}_{n,n} < \tilde{\zeta}_{n,n-1} < \cdots < \tilde{\zeta}_{n,1}$ includes all the roots of (4.8). Comparing with (4.2) and (4.3), we conclude that $\tilde{\zeta}_{n,k}$ must be equal to $\zeta_{n,k}$.

Next we investigate the relationship between the zero $\zeta_{n,k}$ and the kth zero $\tilde{a}_k$ of $\mathrm{Ai}(x)$. For $\zeta = \zeta_{n,k}$, we have, by the mean-value theorem,

$$\theta(X(\zeta)) = \theta(\tilde{a}_k) + (X(\zeta) - \tilde{a}_k)\theta'(\xi),$$

where $\xi \in (b_{k+1}, b_k)$. Recall from [7, p. 404] that $\theta(\tilde{a}_k) = k\pi$. Hence, by (4.9),

$$X(\zeta) - \tilde{a}_k = (-1)^{k-1} \arcsin\{\rho_1(\lambda, \zeta)\}/\theta'(\xi). \tag{4.17}$$

Using the inequalities $|\rho_1(\lambda, \zeta)| \leq \sigma_1(\lambda, \zeta) < 1/2$ and $\sin t > 3t/\pi$ for $0 < t < \pi/6$, we obtain

$$|X(\zeta) - \tilde{a}_k| \leq \frac{\pi}{3}\sigma_1(\lambda, \zeta)/|\theta'(\xi)|. \tag{4.18}$$

Since $|\theta'(\xi)|$ is decreasing in ξ (see [7, p. 404]) and $\sigma_1(\lambda, \zeta)$ is decreasing in ζ, it follows that

$$|X(\zeta) - \tilde{a}_k| \leq \alpha_k, \tag{4.19}$$

where

$$\alpha_k = \frac{\pi}{3}\sigma_1(\lambda, \zeta_n(b_{k+1}))/|\theta'(b_k)|. \tag{4.20}$$

(Recall that here $\zeta = \zeta_{n,k} \in (\zeta_n(b_{k+1}), \zeta_n(b_k))$.) In view of (4.10) and (4.7), (4.20) gives

$$\alpha_k = \frac{\pi^2}{3}M^2(b_k)\sigma_1(\lambda, \zeta_n(b_{k+1})) = M^2(b_k)O(u^{-1}). \tag{4.21}$$

Much of the above argument is patterned after that given in [7, pp. 406–407]. Coupling (4.21) with (4.19) and noting that $X(\zeta) = u^{2/3}\zeta + \Phi(\zeta)/u^{1/3}$ and $\zeta = \zeta_{n,k}$, we obtain

$$u^{2/3}\zeta_{n,k} + \frac{\Phi(\zeta_{n,k})}{u^{1/3}} = \tilde{a}_k + O(u^{-1}). \tag{4.22}$$

Since $\Phi(\zeta_{n,k})$ is bounded for all n and k, we have the preliminary approximation $\zeta_{n,k} = \tilde{a}_k u^{-2/3} + O(u^{-1})$. Note that for any fixed k, $\zeta_{n,k} \to 0$ as $n \to \infty$ (or, equivalently, as $u \to \infty$). By the mean-value theorem,

$$\Phi(\zeta_{n,k}) = \Phi(0) + \Phi'(\xi)\zeta_{n,k} = \Phi(0) + O(u^{-2/3}), \tag{4.23}$$

where $\xi_{n,k} < \xi < 0$ and we have used the boundedness of $\Phi'(\xi)$. Substituting (4.23) into (4.22) gives

$$\zeta_{n,k} = \tilde{a}_k u^{-2/3} - \Phi(0)u^{-1} + O(u^{-5/3}). \tag{4.24}$$

Recall that $\Phi(\zeta) = \Phi(\lambda, \zeta)$ depends on λ (or $u = \lambda^{2m}$); see (2.68). Hence we need to find an approximate value for $\Phi(0)$. From the equation following (2.68), we have

$$\Phi(0) = \phi(\lambda, 0), \tag{4.25}$$

where $\phi(\lambda, \zeta)$ is given in (2.62). In view of (2.53),

$$\phi(\lambda, \zeta) = \frac{H_1(\lambda, w)}{H_0(\lambda, w)}\zeta = \frac{\lambda^{4m-2}H_1(\lambda, w)}{(w+1)A_n^2(\lambda w)}\frac{\zeta}{w-1}. \tag{4.26}$$

Since $\zeta = 0$ corresponds to $w = 1$, putting $\zeta = 0$ and $w = 1$ in (4.26) yields

$$\phi(\lambda, 0) = \frac{\lambda^{4m-2}H_1(\lambda, 1)}{2A_n^2(\lambda)}\zeta'(\lambda, 1). \tag{4.27}$$

In accordance with (2.47) and the definition $H_1(\lambda, w) = \lambda^{-2m}U_1(\lambda w, n)$,

$$H_1(\lambda, 1) = \lambda^{-2m+1}A_n(\lambda)\left\{\lambda\left[A_n(\lambda) - A_{n-1}(\lambda)\frac{a_n}{a_{n-1}} + B_n(\lambda) - B_{n+1}(\lambda)\right] - 1\right\}. \tag{4.28}$$

Coupling (2.33) and the equation following (2.37) yields

$$\begin{aligned}&\lambda\left[A_n(\lambda) - A_{n-1}(\lambda)\frac{a_n}{a_{n-1}}\right]\\ &= \frac{2^{2m}L_m}{m\lambda^{2m-1}}\sum_{k=1}^{m-1}(k+1)v_{k+1}\lambda^{2k+1}\sum_{l=1}^{k}2^{-2l}l\binom{2l}{l} + O(\lambda^{-2}).\end{aligned} \tag{4.29}$$

In a similar manner, one can show by using (2.34) that

$$\begin{aligned}&\lambda\left[B_n(\lambda) - B_{n+1}(\lambda)\right]\\ &= -\frac{2^{2m}L_m}{m\lambda^{2m-1}}\sum_{k=1}^{m-1}(k+1)v_{k+1}\lambda^{2k+1}\sum_{l=0}^{k-1}2^{-2l-1}(l+1)\binom{2l+1}{l+1} + O(\lambda^{-2}).\end{aligned} \tag{4.30}$$

Since the leading terms on the right-hand side of (4.29) and (4.30) are equal, we have

$$\lambda\left[A_n(\lambda) - A_{n-1}(\lambda)\frac{a_n}{a_{n-1}} + B_n(\lambda) - B_{n+1}(\lambda)\right] = O(\lambda^{-2}). \tag{4.31}$$

Inserting (4.31) in (4.28) gives

$$\frac{\lambda^{2m-1}H_1(\lambda, 1)}{A_n(\lambda)} = -1 + O(\lambda^{-2}). \tag{4.32}$$

A combination of (4.25), (4.27), (4.32), and the equation preceding (2.68) leads to

$$\Phi(0) = -2^{-2/3}\left(\frac{A_n(\lambda)}{\lambda^{2m-1}}\right)^{-1/3} + O(\lambda^{-2}). \tag{4.33}$$

Coupling (4.33) and (4.24) gives

$$\zeta_{n,k} = \tilde{a}_k u^{-2/3} + 2^{-2/3}\left(\frac{A_n(\lambda)}{\lambda^{2m-1}}\right)^{-1/3} u^{-1} + O\left(u^{-(1+1/m)}\right). \tag{4.34}$$

Let $w = \Omega(\zeta) = \Omega(\lambda, \zeta)$ denote the inverse of the function $\zeta = \zeta(w) = \zeta(\lambda, w)$. Note that $\zeta_{n,k} = \zeta(w_{n,k})$ and $x_{n,k} = \lambda w_{n,k} = u^{1/2m} w_{n,k}$. Hence, it follows from (4.34) that

$$x_{n,k} = u^{1/2m}\Omega\left\{\tilde{a}_k u^{-2/3} + 2^{-2/3}\left(\frac{A_n(\lambda)}{\lambda^{2m-1}}\right)^{-1/3} u^{-1} + O\left(u^{-(1+1/m)}\right)\right\}.$$

By the mean-value theorem, we obtain

$$x_{n,k} = u^{1/2m}\Omega\left\{\tilde{a}_k u^{-2/3} + 2^{-2/3}\left(\frac{A_n(\lambda)}{\lambda^{2m-1}}\right)^{-1/3} u^{-1}\right\} + O\left(u^{-(1+1/2m)}\right). \tag{4.35}$$

To proceed further, we expand $\Omega(\zeta)$ into the Maclaurin series

$$\Omega(\zeta) = \Omega(0) + \Omega'(0)\zeta + \frac{1}{2}\Omega''(0)\zeta^2 + \cdots. \tag{4.36}$$

Since $\zeta(1) = 0$, we have $\Omega(0) = 1$. By the equation preceding (2.68),

$$\Omega'(0) = \frac{1}{\zeta'(1)} = 2^{-1/3}\left(\frac{A_n(\lambda)}{\lambda^{2m-1}}\right)^{-2/3}. \tag{4.37}$$

To get the value of $\Omega''(0)$, we need to find $\zeta''(1)$. By continuity, $\zeta^{(k)}(1) = \lim_{w\to 1}\zeta^{(k)}(w)$ for any positive integer k. Let $f(\lambda, w)$ and $g(\lambda, w)$ be given as in (2.66) and (2.67), respectively. By differentiating both sides of the equation

$$\zeta(w) = (w-1)\left[\frac{3}{2}g(\lambda, w)\right]^{2/3} \tag{4.38}$$

twice, we obtain

$$\zeta''(1) = 2\left[\frac{3}{2}g(\lambda, 1)\right]^{-1/3} g'(\lambda, 1). \tag{4.39}$$

From an equation in the proof of Lemma 2.2, we also have

$$g(\lambda, 1) = \frac{2}{3}f(\lambda, 1) = \frac{2\sqrt{2}}{3\lambda^{2m-1}}A_n(\lambda) \tag{4.40}$$

and

$$g'(\lambda, 1) = \frac{2}{5}f'(\lambda, 1) = \frac{1}{5\sqrt{2}\lambda^{2m-1}}A_n(\lambda) + \frac{2\sqrt{2}}{5\lambda^{2m-1}}\lambda A_n'(\lambda); \tag{4.41}$$

cf. (2.66). A combination of (4.40), (4.41), and (4.39) gives

$$\zeta''(1) = \frac{\sqrt{2}}{5}\left[\frac{A_n(\lambda)}{\lambda^{2m-1}} + \frac{4A_n'(\lambda)}{\lambda^{2m-2}}\right]\left[\frac{\sqrt{2}A_n(\lambda)}{\lambda^{2m-1}}\right]^{-1/3}, \tag{4.42}$$

and hence

$$\Omega''(0) = -\frac{\zeta''(1)}{\zeta'(1)^3} = -\frac{\sqrt{2}}{5}\left[\frac{A_n(\lambda)}{\lambda^{2m-1}} + \frac{4A_n'(\lambda)}{\lambda^{2m-2}}\right]\left[\frac{\sqrt{2}A_n(\lambda)}{\lambda^{2m-1}}\right]^{-7/3}. \tag{4.43}$$

Taking

$$\zeta = \tilde{a}_k u^{-2/3} + 2^{-2/3}\left(\frac{A_n(\lambda)}{\lambda^{2m-1}}\right)^{-1/3} u^{-1} \tag{4.44}$$

in (4.36), we obtain

$$\begin{aligned}\Omega(\zeta) = \Omega(0) + \Omega'(0)&\left\{\tilde{a}_k u^{-2/3} + 2^{-2/3}\left(\frac{A_n(\lambda)}{\lambda^{2m-1}}\right)^{-1/3} u^{-1}\right\}\\ &+\frac{1}{2}\Omega''(0)\left\{\tilde{a}_k u^{-2/3} + 2^{-2/3}\left(\frac{A_n(\lambda)}{\lambda^{2m-1}}\right)^{-1/3} u^{-1}\right\}^2 + O(u^{-2}).\end{aligned} \tag{4.45}$$

Inserting (4.37) and (4.43) in (4.45), we get

$$\begin{aligned}\Omega(\zeta) = 1 + 2^{-1/3}&\left(\frac{A_n(\lambda)}{\lambda^{2m-1}}\right)^{-2/3}\tilde{a}_k u^{-2/3} + \frac{1}{2}\left(\frac{A_n(\lambda)}{\lambda^{2m-1}}\right)^{-1} u^{-1}\\ &-\frac{\sqrt{2}}{10}\left[\frac{A_n(\lambda)}{\lambda^{2m-1}} + \frac{4A_n'(\lambda)}{\lambda^{2m-2}}\right]\left[\frac{\sqrt{2}A_n(\lambda)}{\lambda^{2m-1}}\right]^{-7/3}\tilde{a}_k^2 u^{-4/3} + O(u^{-5/3}).\end{aligned} \tag{4.46}$$

When $m = 2$, (4.46) and (4.35) together give the four-term expansion

$$\begin{aligned}x_{n,k} = u^{1/4} + 2^{-1/3}&\left(\frac{A_n(\lambda)}{\lambda^3}\right)^{-2/3}\tilde{a}_k u^{-5/12} + \frac{1}{2}\left(\frac{A_n(\lambda)}{\lambda^3}\right)^{-1} u^{-9/12}\\ &-\frac{\sqrt{2}}{10}\left[\frac{A_n(\lambda)}{\lambda^3} + \frac{4A_n'(\lambda)}{\lambda^2}\right]\left[\frac{\sqrt{2}A_n(\lambda)}{\lambda^3}\right]^{-7/3}\tilde{a}_k^2 u^{-13/12} + O(u^{-15/12}).\end{aligned} \tag{4.47}$$

From (2.33) and the equation following (2.40),

$$\frac{A_n(\lambda)}{\lambda^{2m-1}} = \sum_{k=1}^{m} k^2 v_k 2^{-2k+1}\binom{2k}{k} u^{-1+k/m} + O(u^{-1}) \tag{4.48}$$

and

$$\frac{A_n'(\lambda)}{\lambda^{2m-2}} = \frac{4}{3}\sum_{k=2}^{m} k^2(k-1) v_k 2^{-2k+1}\binom{2k}{k} u^{-1+k/m} + O(u^{-1}), \tag{4.49}$$

where use has been made of the following two combinatorial identities:

$$\sum_{l=0}^{k-1} 2^{-2l}\binom{2l}{l} = 2^{-2k+1} k\binom{2k}{k}, \tag{4.50}$$

$$\sum_{l=0}^{k-1}(k-l)2^{-2l}\binom{2l}{l} = \frac{2}{3}2^{-2k-1}(k+1)k\binom{2k+2}{k+1}, \tag{4.51}$$

which can be proved by using induction. When $m = 2$, (4.48) and (4.49) simplify to

$$\frac{A_n(\lambda)}{\lambda^3} = 3 + v_1 u^{-1/2} + O(u^{-1}) \tag{4.52}$$

and

$$\frac{A_n'(\lambda)}{\lambda^2} = 4 + O(u^{-1}). \tag{4.53}$$

Inserting (4.52) and (4.53) into (4.47), we obtain

$$\begin{aligned} x_{n,k} = u^{1/4} &+ \frac{\tilde{a}_k}{18^{1/3}} u^{-5/12} + \frac{1}{6} u^{-9/12} - \frac{1}{9}\left(\frac{2}{3}\right)^{2/3} v_1 u^{-11/12} \\ &- \frac{19\tilde{a}_k^2}{90 \cdot 2^{2/3} \cdot 3^{1/3}} u^{-13/12} + O(u^{-15/12}). \end{aligned} \tag{4.54}$$

By (2.26), $u = 2^{2m} L_m n[1 + O(n^{-2})] = \frac{4}{3} n[1 + O(n^{-2})]$ when $v(x) = x^{2m}$. Hence, if $v_1 = 0$, then (4.54) agrees with the formula recently given by Bo and Wong [2], except for the order estimate of the remainder.

When $m \geq 3$, $1/2m - 4/3 \leq -(1 + 1/2m)$. Thus (4.35) and (4.46) give only a three-term expansion

$$\begin{aligned} x_{n,k} = u^{1/2m} &+ 2^{-1/3} \left(\frac{A_n(\lambda)}{\lambda^{2m-1}}\right)^{-2/3} \tilde{a}_k u^{-2/3+1/2m} \\ &+ \frac{1}{2} \left(\frac{A_n(\lambda)}{\lambda^{2m-1}}\right)^{-1} u^{-1+1/2m} + O(u^{-1-1/2m}). \end{aligned} \tag{4.55}$$

Note that $\lambda = 2a_n$, $u = (2a_n)^{2m}$, and the quantity X_n in (1.15) satisfies

$$X_n \approx \lambda + \frac{1}{2A_n(\lambda)} = u^{1/2m} + \frac{1}{2}\left(\frac{A_n(\lambda)}{\lambda^{2m-1}}\right)^{-1} u^{-1+1/2m}. \tag{4.56}$$

Since $\tilde{a}_k = -i_k/3^{1/3}$, our result (4.55) indeed agrees with (1.15) and (1.16) conjectured by Chen and Ismail [3].

Substituting (4.48) into (4.55), we obtain the second main result of this paper.

THEOREM 4.1. *Let the zeros of the polynomial $p_n(x)$ be enumerated in decreasing order: $-\infty < x_{n,n} < \cdots < x_{n,2} < x_{n,1} < \infty$, and let $u = (2a_n)^{2m}$. For each fixed k, we have*

$$x_{n,k} = u^{1/2m} + 2^{-1/3} \sigma_n(u)^{-2/3} \tilde{a}_k u^{-2/3+1/2m} + \frac{1}{2} \sigma_n(u)^{-1} u^{-1+1/2m} + O(u^{-1-1/2m}),$$

where

$$\sigma_n(u) = \sum_{k=1}^{m} k^2 v_k 2^{-2k+1} \binom{2k}{k} u^{-1+k/m}$$

and

$$u = 2^{2m} L_m n \left[1 + \sum_{k=1}^{m} \tau_k n^{-k/m} + O(n^{-1-1/m})\right]. \tag{4.57}$$

The coefficients τ_k in (4.57) can be determined by (3.23). Furthermore, if $m = 2$, then we have the five-term expansion (4.54).

5. The case $v(x) = x^{2m}$. In this section, we consider only the special case $v(x) = x^{2m}$. Although special, this is an important case. Here we observe that (2.22) and (2.23) simplify to

$$A_n(x) = 2a_n m \sum_{l=0}^{m-1} x^{2m-2l-2} c_{n,0,2l} \tag{5.1}$$

and

$$B_n(x) = 2a_n m \sum_{l=0}^{m-2} x^{2m-2l-3} c_{n,1,2l+1}. \tag{5.2}$$

Thus, instead of (2.24), we have (2.26):

$$a_n = (L_m n)^{1/2m}\left[1 + \frac{\eta}{n^2} + O\left(\frac{1}{n^4}\right)\right], \qquad n \to \infty. \tag{5.3}$$

Let $\lambda = 2a_n$ and $u = \lambda^{2m}$. Then

$$u = 2^{2m} L_m n\left[1 + \frac{2m\eta}{n^2} + O\left(\frac{1}{n^4}\right)\right]. \tag{5.4}$$

Note that the order estimate in (5.3) is much better than that in (2.24). As a result, (2.29) becomes

$$a_{n-j} = a_n\left[1 - \frac{j}{2mn} + O\left(\frac{1}{n^2}\right)\right], \tag{5.5}$$

and (2.30) becomes

$$c_{n,k,l} = \binom{l}{\frac{1}{2}(k+l)} a_n^l\left[1 + \frac{\tilde{c}_{k,l}}{2mn} + O\left(\frac{1}{n^2}\right)\right]. \tag{5.6}$$

Furthermore, all capital Os in sections 2–4 such as

$$O\left(\frac{1}{n^{1+1/m}}\right), \quad O\left(\frac{1}{\lambda^{2m+2}}\right), \quad \text{and} \quad O\left(\frac{1}{u^{1+1/m}}\right)$$

are to be replaced by

$$O\left(\frac{1}{n^2}\right), \qquad O\left(\frac{1}{\lambda^{4m}}\right), \qquad \text{and} \qquad O\left(\frac{1}{u^2}\right),$$

respectively.

Because of these changes, we now have

$$A_n(\lambda w) = m\lambda^{2m-1} \sum_{l=0}^{m-1} w^{2m-2l-2} 2^{-2l} \binom{2l}{l}\left[1 + \frac{\tilde{d}_{2l}}{\lambda^{2m}} + O\left(\frac{1}{\lambda^{4m}}\right)\right], \tag{5.7}$$

$$B_n(\lambda w) = m\lambda^{2m-1} \sum_{l=0}^{m-2} w^{2m-2l-3} 2^{-2l-1} \binom{2l+1}{l+1}\left[1 + \frac{\tilde{d}_{2l+1}}{\lambda^{2m}} + O\left(\frac{1}{\lambda^{4m}}\right)\right], \tag{5.8}$$

$$A_{n-1}(\lambda w)\frac{a_n}{a_{n-1}} = m\lambda^{2m-1}\sum_{l=0}^{m-1} w^{2m-2l-2}2^{-2l}\binom{2l}{l}\left[1+\frac{\tilde{d}'_{2l}}{\lambda^{2m}}+O\left(\frac{1}{\lambda^{4m}}\right)\right], \tag{5.9}$$

and

$$A'_n(\lambda w) = 2m\lambda^{2m-2}\sum_{l=0}^{m-2}(m-l-1)w^{2m-2l-3}2^{-2l}\binom{2l}{l}\left[1+\frac{\tilde{d}_{2l}}{\lambda^{2m}}+O\left(\frac{1}{\lambda^{4m}}\right)\right], \tag{5.10}$$

instead of some of the equations in section 2 such as (2.33) and (2.34). Let us rewrite (5.7) in the form

$$\begin{aligned}\frac{A_n(\lambda w)}{\lambda^{2m-1}} &= m\sum_{l=0}^{m-1} w^{2m-2l-2}2^{-2l}\binom{2l}{l}\\ &\quad+\frac{2^{2m}L_m}{2}\left[\sum_{l=1}^{m-1} w^{2m-2l-2}2^{-2l}\binom{2l}{l}\tilde{c}_{0,2l}\right]u^{-1}+O(u^{-2}).\end{aligned} \tag{5.11}$$

Here use has been made of the facts that $\tilde{d}_0 = 0$ and $\tilde{d}_{2l} = 2^{2m}L_m\tilde{c}_{0,2l}/2m$. For convenience, we put

$$\bar{A}_0(w) = m\sum_{l=0}^{m-1} w^{2m-2l-2}2^{-2l}\binom{2l}{l}$$

and

$$\bar{A}_1(w) = \frac{2^{2m}L_m}{2}\left[\sum_{l=1}^{m-1} w^{2m-2l-2}2^{-2l}\binom{2l}{l}\tilde{c}_{0,2l}\right]$$

so that (5.11) becomes

$$\frac{A_n(\lambda w)}{\lambda^{2m-1}} = \bar{A}_0(w)+\bar{A}_1(w)u^{-1}+O(u^{-2}). \tag{5.12}$$

Inserting (5.12) in (2.56), and reexpanding, we get

$$\zeta = \zeta(\lambda, w) = \bar{\zeta}_0(w)+\bar{\zeta}_1(w)u^{-1}+O(u^{-2}), \tag{5.13}$$

where $\bar{\zeta}_0(w) = \zeta_\infty(w)$ is given in (2.60), that is,

$$\bar{\zeta}_0(w) = \begin{cases} \left[\frac{3}{2}m\sum_{l=0}^{m-1}2^{-2l}\binom{2l}{l}\int_1^w \sqrt{t^2-1}t^{2m-2l-2}dt\right]^{2/3}, & w \geq 1,\\ -\left[\frac{3}{2}m\sum_{l=0}^{m-1}2^{-2l}\binom{2l}{l}\int_w^1 \sqrt{1-t^2}t^{2m-2l-2}dt\right]^{2/3}, & |w| < 1,\end{cases} \tag{5.14}$$

and

$$\bar{\zeta}_1(w) = \begin{cases} \frac{2^{2m}L_m}{2\bar{\zeta}_0^{1/2}}\sum_{l=1}^{m-1}2^{-2l}\tilde{c}_{0,2l}\binom{2l}{l}\int_1^w \sqrt{t^2-1}t^{2m-2l-2}dt, & w \geq 1,\\ -\frac{2^{2m}L_m}{2(-\bar{\zeta}_0)^{1/2}}\sum_{l=1}^{m-1}2^{-2l}\tilde{c}_{0,2l}\binom{2l}{l}\int_w^1 \sqrt{1-t^2}t^{2m-2l-2}dt, & |w| < 1.\end{cases} \tag{5.15}$$

We now return to (2.68). A combination of (2.62), (2.55), and (2.53) gives

$$\Phi(\zeta)=\begin{cases}\dfrac{1}{2\zeta^{1/2}}\displaystyle\int_1^w\frac{\lambda^{2m-1}H_1(\lambda,t)}{(t^2-1)^{1/2}A_n(\lambda t)}dt, & w>1,\\ \dfrac{1}{2(-\zeta)^{1/2}}\displaystyle\int_w^1\frac{\lambda^{2m-1}H_1(\lambda,t)}{(1-t^2)^{1/2}A_n(\lambda t)}dt, & |w|<1.\end{cases}\tag{5.16}$$

Recall that $\tilde{d'}_{2l}=\tilde{d}_{2l}-l2^{2m}L_m/m$. Hence, by (5.7) and (5.9),

$$\lambda\left[A_n(\lambda w)-A_{n-1}(\lambda w)\frac{a_n}{a_{n-1}}\right]=2^{2m}L_m\sum_{l=0}^{m-1}w^{2m-2l-2}2^{-2l}l\binom{2l}{l}+O\left(\frac{1}{\lambda^{2m}}\right).\tag{5.17}$$

Similarly, we obtain

$$\lambda w[B_n(\lambda w)-B_{n+1}(\lambda w)]=-2^{2m}L_m\sum_{l=1}^{m-1}w^{2m-2l}2^{-2l}2l\binom{2l-1}{l}+O\left(\frac{1}{\lambda^{2m}}\right);\tag{5.18}$$

cf. (2.39) and (2.40). Since $H_1(\lambda,w)=\lambda^{-2m}U_1(\lambda w,n)$, combining the last two equations with (2.47), we have

$$\frac{\lambda^{2m-1}H_1(\lambda,w)}{A_n(\lambda w)}=2^{2m}L_m(1-w^2)\sum_{l=1}^{m-1}w^{2m-2l-2}2^{-2l}l\binom{2l}{l}-1+O(u^{-1}).\tag{5.19}$$

Inserting (5.19) in (5.16) gives

$$\Phi(\zeta)=\begin{cases}-\dfrac{2^{2m}L_m}{2\zeta^{1/2}}\displaystyle\sum_{l=1}^{m-1}2^{-2l}l\binom{2l}{l}\int_1^w\sqrt{t^2-1}t^{2m-2l-2}dt-\frac{\cosh^{-1}w}{2\zeta^{1/2}}+O(u^{-1}), & w>1,\\ \dfrac{2^{2m}L_m}{2(-\zeta)^{1/2}}\displaystyle\sum_{l=1}^{m-1}2^{-2l}l\binom{2l}{l}\int_w^1\sqrt{1-t^2}t^{2m-2l-2}dt-\frac{\cos^{-1}w}{2(-\zeta)^{1/2}}+O(u^{-1}), & |w|<1.\end{cases}$$

Since $\zeta(\lambda,w)=\bar{\zeta}_0(w)+\bar{\zeta}_1(w)u^{-1}+O(u^{-2})$, it follows that

$$\Phi(\zeta)=\Phi_0(w)+O(u^{-1}),\tag{5.20}$$

where

$$\Phi_0(w)=\begin{cases}-\dfrac{2^{2m}L_m}{2\bar{\zeta}_0^{1/2}}\displaystyle\sum_{l=1}^{m-1}2^{-2l}l\binom{2l}{l}\int_1^w\sqrt{t^2-1}t^{2m-2l-2}dt-\frac{\cosh^{-1}w}{2\bar{\zeta}_0^{1/2}}, & w>1,\\ \dfrac{2^{2m}L_m}{2(-\bar{\zeta}_0)^{1/2}}\displaystyle\sum_{l=1}^{m-1}2^{-2l}l\binom{2l}{l}\int_w^1\sqrt{1-t^2}t^{2m-2l-2}dt-\frac{\cos^{-1}w}{2(-\bar{\zeta}_0)^{1/2}}, & |w|<1.\end{cases}$$

If we let

$$\bar{\Phi}_0(w)=\Phi_0(w)+\bar{\zeta}_1(w),\tag{5.21}$$

then

$$X(\zeta) = u^{2/3}\zeta + \frac{\Phi(\zeta)}{u^{1/3}} = u^{2/3}\bar{\zeta}_0 + \frac{\bar{\Phi}_0(w)}{u^{1/3}} + O(u^{-4/3}). \tag{5.22}$$

By the mean-value theorem,

$$\mathrm{Ai}(X(\zeta)) = \mathrm{Ai}\left(u^{2/3}\bar{\zeta}_0 + \frac{\bar{\Phi}_0}{u^{1/3}}\right) + O(u^{-4/3}). \tag{5.23}$$

Using (5.3) instead of (2.24), the results in (3.8) and (3.38) can be improved to read

$$p_n(0) = (-1)^{n/2} A_2 n^{-\frac{1}{4m}} [1 + O(n^{-1})]$$

and

$$C(n) = A n^{-1/4m} u^{1/4m-1/3} [1 + O(u^{-1})],$$

respectively. Therefore, (3.55) becomes

$$\begin{aligned} p_n(x)e^{-v(x)/2} = L_m^{-1/4m} n^{-1/4m} u^{1/6} \left(\frac{\zeta}{w^2-1}\right)^{1/4} \{&\mathrm{Ai}(X(\zeta)) \\ &+ O(\varepsilon_1(\lambda,\zeta))\}[1 + O(u^{-1})]. \end{aligned} \tag{5.24}$$

Since $\varepsilon_1(\lambda,\zeta) = O(u^{-1})$ uniformly for $w \in [-1+\varepsilon, M]$, we get

$$p_n(x)e^{-v(x)/2} = L_m^{-1/4m} n^{-1/4m} u^{1/6} \left(\frac{\zeta}{w^2-1}\right)^{1/4} \{\mathrm{Ai}(X(\zeta)) + O(u^{-1})\}. \tag{5.25}$$

When $w \in [-1+\varepsilon, 1-\varepsilon]$, we have the sharper estimate $\varepsilon_1(\lambda,\zeta) = O(u^{-7/6})$. Since $X(\zeta) = u^{2/3}\zeta(1 + \Phi(\zeta)/u) = O(u^{2/3})$ when $\zeta \in [\zeta_\infty(-1+\varepsilon), \zeta_\infty(1-\varepsilon)]$, we also have $\mathrm{Ai}(X(\zeta)) = O(u^{-1/6})$. Substituting these into (5.24) gives

$$p_n(x)e^{-v(x)/2} = L_m^{-1/4m} n^{-1/4m} u^{1/6} \left(\frac{\zeta}{w^2-1}\right)^{1/4} \{\mathrm{Ai}(X(\zeta)) + O(u^{-7/6})\} \tag{5.26}$$

uniformly for $w \in [-1+\varepsilon, 1-\varepsilon]$.

Inserting (5.4), (5.13), and (5.23) in (5.25) and (5.26), we obtain the following theorem.

THEOREM 5.1. *When $v(x) = x^{2m}$, the asymptotic formula*

$$\begin{aligned} p_n(x)e^{-x^{2m}/2} &= 2^{m/3} L_m^{1/6-1/4m} n^{1/6-1/4m} \left(\frac{\bar{\zeta}_0}{w^2-1}\right)^{1/4} \\ &\quad \cdot \left\{\mathrm{Ai}\left(u^{2/3}\bar{\zeta}_0 + \frac{\bar{\Phi}_0}{u^{1/3}}\right) + O(u^{-1})\right\} \end{aligned} \tag{5.27}$$

holds uniformly for $w \in [-1+\varepsilon, M]$. Furthermore, we have

$$\begin{aligned} p_n(x)e^{-x^{2m}/2} &= 2^{m/3} L_m^{1/6-1/4m} n^{1/6-1/4m} \left(\frac{\bar{\zeta}_0}{w^2-1}\right)^{1/4} \\ &\quad \cdot \left\{\mathrm{Ai}\left(u^{2/3}\bar{\zeta}_0 + \frac{\bar{\Phi}_0}{u^{1/3}}\right) + O(u^{-7/6})\right\} \end{aligned} \tag{5.28}$$

holding uniformly for $w \in [-1+\varepsilon, 1-\varepsilon]$. Here $\bar{\zeta}_0$ and $\bar{\Phi}_0$ are defined, respectively, in (5.14) *and* (5.21)*, and u is given in* (5.4).

Note that $\tilde{c}_{0,2} = 1$, and hence that when $m = 2$,

$$\bar{\Phi}_0(w) = \begin{cases} -\dfrac{1}{2\bar{\zeta}_0^{1/2}} \cosh^{-1} w, & w > 1, \\ -\dfrac{1}{2(-\bar{\zeta}_0)^{1/2}} \cos^{-1} w, & |w| < 1. \end{cases}$$

Thus we can easily check that our result coincides with that given by Bo and Wong [2].

To conclude the paper, we consider the zeros of $p_n(x)$ when $v(x) = x^{2m}$. Putting $w = 1$ in (5.19), we have

$$\frac{\lambda^{2m-1} H_1(\lambda, 1)}{A_n(\lambda)} = -1 + O(u^{-1}).$$

Comparing it with (4.32), we obtain

$$\Phi(0) = -2^{-2/3} \left(\frac{A_n(\lambda)}{\lambda^{2m-1}} \right)^{-1/3} + O(\lambda^{-2m});$$

cf. (4.33). As in section 4, we insert it in (4.24) to get

$$\zeta_{n,k} = \tilde{a}_k u^{-2/3} + 2^{-2/3} \left(\frac{A_n(\lambda)}{\lambda^{2m-1}} \right)^{-1/3} u^{-1} + O(u^{-5/3}), \tag{5.29}$$

where $\zeta_{n,k} = \zeta(\lambda, w_{n,k})$, $x_{n,k} = \lambda w_{n,k}$, and $x_{n,k}$ is the kth zero of $p_n(x)$. By inversion,

$$x_{n,k} = u^{1/2m} \Omega \left\{ \tilde{a}_k u^{-2/3} + 2^{-2/3} \left(\frac{A_n(\lambda)}{\lambda^{2m-1}} \right)^{-1/3} u^{-1} \right\} + O(u^{-5/3+1/2m}); \tag{5.30}$$

cf. (4.35). Note that (4.46) always holds. Hence

$$\begin{aligned} x_{n,k} = u^{1/2m} &+ 2^{-1/3} \left(\frac{A_n(\lambda)}{\lambda^{2m-1}} \right)^{-2/3} \tilde{a}_k u^{-2/3+1/2m} + \frac{1}{2} \left(\frac{A_n(\lambda)}{\lambda^{2m-1}} \right)^{-1} u^{-1+1/2m} \\ &- \frac{\sqrt{2}}{10} \left[\frac{A_n(\lambda)}{\lambda^{2m-1}} + \frac{4A_n'(\lambda)}{\lambda^{2m-2}} \right] \left[\frac{\sqrt{2} A_n(\lambda)}{\lambda^{2m-1}} \right]^{-7/3} \tilde{a}_k^2 u^{-4/3+1/2m} + O(u^{-5/3+1/2m}). \end{aligned} \tag{5.31}$$

Since (5.7) and (5.10) can be written as

$$\frac{A_n(\lambda w)}{\lambda^{2m-1}} = m \sum_{l=0}^{m-1} w^{2m-2l-2} 2^{-2l} \binom{2l}{l} + O\left(\frac{1}{\lambda^{2m}} \right)$$

and

$$\frac{A_n'(\lambda w)}{\lambda^{2m-2}} = 2m \sum_{l=0}^{m-2} (m-l-1) w^{2m-2l-3} 2^{-2l} \binom{2l}{l} + O\left(\frac{1}{\lambda^{2m}} \right),$$

putting $w = 1$ and using (4.50) and (4.51), we have

$$\frac{A_n(\lambda)}{\lambda^{2m-1}} = 2^{-2m+1} m L_m^{-1} + O(u^{-1}) \tag{5.32}$$

and

$$\frac{A_n'(\lambda)}{\lambda^{2m-2}} = \frac{4}{3}2^{-2m+1}m(m-1)L_m^{-1} + O(u^{-1}), \tag{5.33}$$

where we have also made use of (2.25). Substituting (5.32) and (5.33) into (5.31), we obtain

$$\begin{aligned} x_{n,k} &= u^{1/2m} + \frac{2^{(4m-1)/3}}{(2m)^{2/3}}L_m^{2/3}\tilde{a}_k u^{-2/3+1/2m} + \frac{2^{2m}L_m}{4m}u^{-1+1/2m} \\ &\quad - \frac{16m-13}{120}\frac{2^{8m/3}}{m^{4/3}}L_m^{4/3}\tilde{a}_n^2 u^{-4/3+1/2m} + O(u^{-5/3+1/2m}). \end{aligned} \tag{5.34}$$

By (5.4), (5.34) can be rewritten in the form

$$\begin{aligned} x_{n,k} &= 2(L_m n)^{1/2m} + \frac{L_m^{1/2m}}{m^{2/3}}\tilde{a}_k n^{-2/3+1/2m} + \frac{L_m^{1/2m}}{2m}n^{-1+1/2m} \\ &\quad - \frac{(16m-13)L_m^{1/2m}}{60m^{4/3}}\tilde{a}_n^2 n^{-4/3+1/2m} + O(n^{-5/3+1/2m}). \end{aligned} \tag{5.35}$$

NONLINEAR PYRAMID TRANSFORMS BASED ON MEDIAN-INTERPOLATION*

DAVID L. DONOHO[†] AND THOMAS P.-Y. YU[‡]

Abstract. We introduce a nonlinear refinement subdivision scheme based on *median-interpolation*. The scheme constructs a polynomial interpolating adjacent block medians of an underlying object. The interpolating polynomial is then used to impute block medians at the next finer triadic scale. Perhaps surprisingly, expressions for the refinement operator can be obtained in closed-form for the scheme interpolating by polynomials of degree $D = 2$. Despite the nonlinearity of this scheme, convergence and regularity can be established using techniques reminiscent of those developed in analysis of linear refinement schemes.

The refinement scheme can be deployed in multiresolution fashion to construct a nonlinear pyramid and an associated forward and inverse transform. In this paper we discuss the basic properties of these transforms and their possible use in removing badly non-Gaussian noise. Analytic and computational results are presented to show that in the presence of highly non-Gaussian noise, the coefficients of the nonlinear transform have much better properties than traditional wavelet coefficients.

Key words. pyramid transform, subdivision scheme, wavelet, median, robust statistics, nonlinear analysis, interpolation

1. Introduction.

Recent theoretical studies [14, 13] have found that the orthogonal wavelet transform offers a promising approach to noise removal. They assume that one has noisy samples of an underlying function f

$$y_i = f(t_i) + \sigma z_i,\ i = 1, \dots, n, \tag{1.1}$$

where $(z_i)_{i=1}^n$ is a standard Gaussian white noise and σ is the noise level. In this setting, they show that one removes noise successfully by applying a wavelet transform, thresholding the wavelet coefficients, and inverting the transform. Here "success" means near-asymptotic minimaxity over a broad range of classes of smooth f. Other efforts [20, 17] have shown that the Gaussian noise assumption can be relaxed slightly; in the presence of non-Gaussian noise that is not too heavy-tailed (e.g., the density has sufficiently rapid decay at $\pm\infty$), one can use level-dependent thresholds which are somewhat higher than in the Gaussian case and continue to obtain near-minimax results.

1.1. Strongly non-Gaussian noise.

In certain settings, data exhibit strongly non-Gaussian noise distributions; examples include analogue telephony [30], radar signal processing [1], and laser radar imaging [19]. By strongly non-Gaussian we mean subject to very substantial deviations much more frequently than under Gaussian assumptions.

Thresholding of linear wavelet transforms *does not* work well with strongly non-Gaussian noise. Consider model (1.1) in a specific case: let (z_i) be independently and identically Cauchy distributed. The Cauchy distribution has no moments $\int x^\ell f(x)dx$ for $\ell = 1, 2, \ldots$, in particular neither mean nor variance.

Under this model, typical noise realizations $(z_i)_{i=1}^n$ contain a few astonishingly large observations: the largest observation is of size $O(n)$. (In comparison, for Gaussian noise, the largest observation is of size $O(\sqrt{\log(n)})$.) Moreover, a linear wavelet transform of independently and identically distributed (i.i.d.) Cauchy noise does not result in independent, nor identically distributed wavelet coefficients. In fact, coefficients at coarser scales are more likely to be affected by the perturbing influence of the few large noise values, and so one sees a systematically larger stochastic dispersion of coefficients at coarse scales. Invariance of distribution across scale and $O(\sqrt{\log(n)})$ behavior of maxima are fundamental to the results on wavelet denoising in [13, 14]. The Cauchy situation therefore lacks key quantitative properties which were used in denoising in the Gaussian case.

It is not just that this situation lacks properties which would make the proofs "go through." If we try to apply ideas which were successful under Gaussian theory we meet with abject failure, as simple computational examples given later will illustrate.

1.2. Median-interpolating pyramid transform. Motivated by this situation, this paper develops a kind of *nonlinear "wavelet transform."* The need to abandon linearity is clear a priori. It is well known that linearity of approach is essentially tantamount to a Gaussian assumption and that non-Gaussian assumptions typically lead to highly nonlinear approaches. For example, maximum likelihood estimators in classical statistical models are often linear in the Gaussian case, but highly nonlinear under Cauchy and similar assumptions.

Central to our approach is the notion of *median-interpolating* (MI) refinement scheme. Given data about the medians of an object on triadic blocks at a coarse scale, we predict the medians of triadic blocks at the next finer scale. We do this by finding a median-interpolating polynomial—a polynomial with the same coarse-scale block medians—and then calculating the block medians of this polynomial for blocks at the next finer scale. The procedure is nonlinear: the interpolating polynomial is a nonlinear functional of the coarse-scale medians; and the imputed finer-scale medians are nonlinear functionals of the interpolating polynomial. Perhaps surprisingly, in the case of interpolation by quadratic polynomials, the interpolating polynomial and its finer-scale medians can both be found in closed-form.

Using MI refinement, we can build forward and inverse transforms which can be computed rapidly and which exhibit favorable robustness and regularity properties.

The forward transform deploys the median in a multiresolution pyramid; it computes "block medians" over all triadic cells. MI refinement is used to predict medians of finer-scale blocks from coarser-scale blocks; the resulting prediction errors are recorded as transform coefficients.

The inverse transform undoes this process; using coarser-scale coefficients it builds MI predictions of finer-scale coefficients; adding in the prediction errors recorded in the transform array leads to exact reconstruction.

This way of building transforms from refinement schemes is similar to the way interpolating wavelet transforms are built from Deslauriers–Dubuc interpolating schemes in [9] and in the way biorthogonal wavelet transforms are built from average-interpolating refinement in [10]. The basic idea is to use data at coarser scales to predict data at finer scales and to record the prediction errors as coefficients associated with the finer scales. Despite structural similarities our MI-based transforms exhibit important differences:

- Both the forward and inverse transforms can be nonlinear;
- The transforms are based on a triadic pyramid and a 3-to-1 decimation scheme;
- The transforms are expansive (they map n data into $\sim 3/2n$ coefficients).

Terminologically, because the forward transform is expansive, it should be called a *pyramid transform* rather than a wavelet transform. We call the transform itself the *median-interpolating pyramid transform* (MIPT).

The bulk of our paper is devoted to analysis establishing two key properties of these transforms.

- *Regularity.* Take block medians at a single level and refine to successively finer and finer levels using the quadratic polynomial MI scheme. Detailed analysis shows that the successive refinements converge uniformly to a continuous limit with Hölder-α regularity for some $\alpha > 0$. We prove that $\alpha > .0997$ and we give computational and analytical evidence pointing to $\alpha > 1 - \epsilon$ for all $\epsilon > 0$.

  This result shows that MIPT has important similarities to linear wavelet and pyramid transforms. For example, it provides a notion of nonlinear multiresolution analysis: just as in the linear MRA case, one can decompose an object into "resolution levels" and examine the contributions of different levels separately; each level contributes a regular curve oscillating with wavelength comparable to the given resolution, with large oscillations in the spatial vicinity of significant features.
- *Robustness.* It is well known that the median is robust against heavy-tailed noise distributions [21, 22]. In the present setting this phenomenon registers as follows. We are able to derive thresholds for noise removal in the MIPT which work well for *all* distributions in rather large classes, irrespective of the heaviness of the tails. In particular, we show that at all but the finest scales, the same thresholds work for both Gaussian and Cauchy data. Hence a noise-removal scheme based on thresholding of MIPT coefficients depends only very weakly on assumptions about noise distribution.

There is considerable applied interest in developing median-based multiscale transforms, as one can see from [2, 23, 28, 29, 26]. The analysis we give here suggests that our framework will turn out to have strong theoretical justification and may provide applied workers with helpful new tools.

1.3. Contents.

Section 2 introduces the notion of median-interpolating refinement, shows how one of the simplest instances may be computed efficiently, gives computational examples, and proves some basic properties. Section 3 establishes convergence and smoothness results for the quadratic median-interpolating refinement scheme. Section 4 develops a nonlinear pyramid transform and describes properties of transform coefficients. Proofs of these properties are recorded in section 6. Section 5 applies the pyramid transform to the problem of removing highly non-Gaussian noise.

2. Median-interpolating refinement schemes.

In this section we describe a notion of two-scale refinement which is nonlinear in general, and which yields an interesting analogue of the refinement schemes occurring in the theory of biorthogonal wavelets.

2.1. Median-interpolation. Given a function f on an interval I, let $\mathrm{med}(f|I)$ denote a median of f for the interval I, defined by

$$\mathrm{med}(f|I) = \inf\{\mu : m(t \in I : f(t) \geq \mu) \geq m(t \in I : f(t) \leq \mu)\}, \tag{2.1}$$

where $m()$ denotes Lebesgue measure on $\mathbb{R}$.

Now suppose we are given a triadic array $\{m_{j,k}\}_{k=0}^{3^j-1}$ of numbers representing the medians of f on the triadic intervals $I_{j,k} = [k3^{-j}, (k+1)3^{-j})$:

$$m_{j,k} = \mathrm{med}(f|I_{j,k}), \quad 0 \leq k < 3^j, \quad j \geq 0.$$

The goal of median-interpolating refinement is to use the data at scale j to infer behavior at the finer scale $j+1$, obtaining imputed medians of f on intervals $I_{j+1,k}$. Obviously we are missing the information to impute perfectly; nevertheless we can try to do a reasonable job.

We employ *polynomial-imputation.* Starting from a fixed even integer D, it involves two steps.

[M1] **(Interpolation).** For each interval $I_{j,k}$, find a polynomial $\pi_{j,k}$ of degree $D = 2A$ satisfying the *median-interpolation condition*:

$$\mathrm{med}(\pi_{j,k}|I_{j,k+l}) = m_{j,k+l} \quad \text{for} \quad -A \leq l \leq A. \tag{2.2}$$

[M2] **(Imputation).** Obtain (pseudo-) medians at the finer scale by setting

$$\tilde{m}_{j+1,3k+l} = \mathrm{med}(\pi_{j,k}|I_{j,3k+l}) \quad \text{for} \quad l = 0, 1, 2. \tag{2.3}$$

An example is given in Figure 2.1 for degree $D = 2$. Some questions come up naturally:

[Q1] Is there a unique polynomial $\pi_{j,k}$ satisfying the nonlinear equations (2.2)?
[Q2] If so, is there an effective algorithm to find it?
[Q3] If so, what are the properties of such a procedure?

2.1.1. Average-interpolation. A scheme similar to the above, with "med" replaced by "ave," is relatively easy to study and provides useful background. Given a function f on an interval I, write $\mathrm{ave}(f|I) = |I|^{-1} \int_I f(t)dt$ for the average value of f over the interval I. Now suppose we are given a triadic array $\{a_{j,k}\}_{k=0}^{3^j-1}$ of numbers representing the averages of f on the triadic intervals $I_{j,k}$. Average-interpolating refinement uses the data at scale j to impute behavior at the finer scale $j+1$, obtaining the (pseudo-) averages of f on intervals $I_{j+1,k}$. Fix an even integer D, it runs as follows:

[A1] **(Interpolation).** For each interval $I_{j,k}$, find a polynomial $\pi_{j,k}$ of degree $D = 2A$ satisfying the *average-interpolation condition*:

$$\mathrm{ave}(\pi_{j,k}|I_{j,k+l}) = a_{j,k+l} \quad \text{for} \quad -A \leq l \leq A. \tag{2.4}$$

[A2] **(Imputation).** Obtain (pseudo-) cell averages at the finer scale by setting

$$\overline{a}_{j+1,3k+l} = \mathrm{ave}(\pi_{j,k}|I_{j,3k+l}) \quad \text{for } l = 0, 1, 2. \tag{2.5}$$

This type of procedure has been implemented and studied in (the dyadic case) [10, 11]. The analogues of questions [Q1]–[Q2] have straightforward "Yes" answers. For any degree D one can find coefficients $c_{h,l}^{(D)}$ for which

$$\overline{a}_{j+1,3k+l} = \sum_{h=-A}^{A} c_{h,l}^{(D)} a_{j,k+h}, \quad l = 0, 1, 2, \tag{2.6}$$

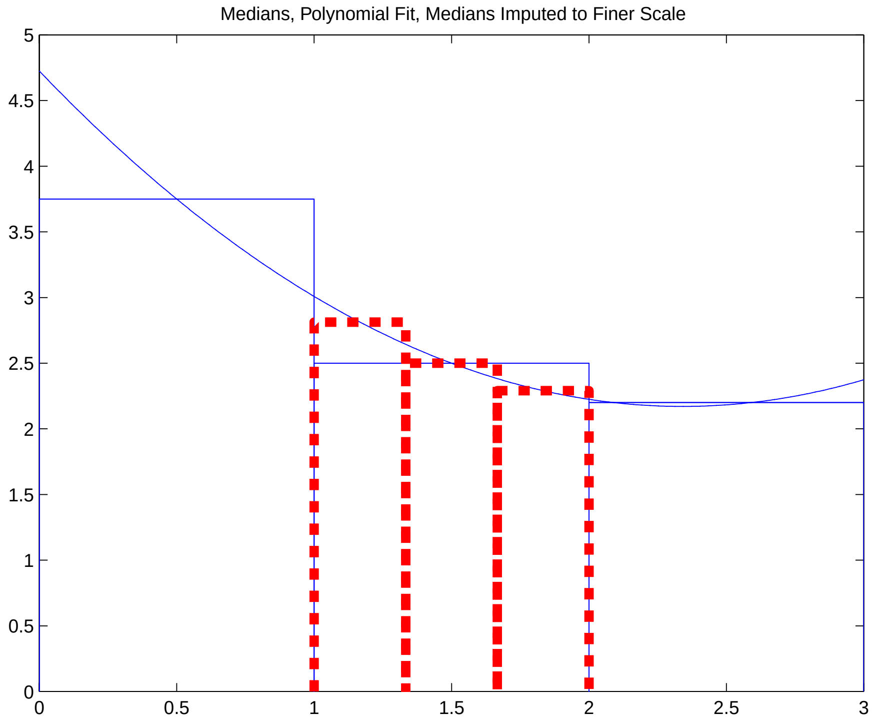

FIG. 2.1. *Median-interpolation, $D = 2$. The rectangular blocks surrounded by solid lines correspond to $m_{0,0}, m_{0,1}, m_{0,2}$, the blocks surrounded by thickened dashed lines correspond to imputed medians $\tilde{m}_{1,2}, \tilde{m}_{1,3}, \tilde{m}_{1,4}$, the parabola corresponds to the median-interpolant $\pi_{0,1}$.*

exhibiting the fine-scale imputed averages $\overline{a}_{j+1,k}$'s as linear functionals of the coarse-scale averages $a_{j,k}$. Moreover, using analytic tools developed in wavelet theory [4] and in refinement subdivision schemes [8, 16] one can establish various nice properties of refinement by average-interpolation—see below.

2.1.2. $D = 0$. We return to median-interpolation. The case $D = 0$ is the simplest by far; in that case one is fitting a constant function $\pi_{j,k}(t) = \text{Const}$. Hence $A = 0$, and (2.2) becomes $\pi_{j,k}(t) = m_{j,k}$. The imputation step (2.3) then yields $m_{j+1,3k+l} = m_{j,k}$ for $l = 0, 1, 2$. Hence refinement proceeds by imputing a constant behavior at finer scales.

2.1.3. $D = 2$. The next simplest case is $D = 2$ and will be the focus of attention in this article. To apply (2.2) with $A = 1$, we must find a quadratic polynomial solving

$$\text{med}(\pi_{j,k}|I_{j,k+l}) = m_{j,k+l} \quad \text{for } l = -1, 0, 1. \tag{2.7}$$

In general this is a system of nonlinear equations. One can ask [Q1]–[Q3] above for this system. The answers come by studying the operator $\Pi_{(2)} : \mathbb{R}^3 \to \mathbb{R}^3$ defined as the solution to the problem: given $[m_1, m_2, m_3]$, find $[a, b, c]$ such that the quadratic polynomial $\pi(x) = a + bx + cx^2$ satisfies

$$\text{med}(\pi|[0, 1]) = m_1, \tag{2.8}$$

$$\operatorname{med}(\pi|[1,2]) = m_2, \tag{2.9}$$

$$\operatorname{med}(\pi|[2,3]) = m_3. \tag{2.10}$$

In this section, we work out explicit algebraic formulae for $\Pi_{(2)}$. It will follow from these that (2.7) *has an unique solution, for every* m_1, m_2, m_3, and that this solution is a Lipschitz function of the m_i.

$\Pi_{(2)}$ possesses two purely formal invariance properties which are useful below.

- *Reversal equivariance.* If $\Pi_{(2)}(m_1, m_2, m_3) = a + bx + cx^2$, then $\Pi_{(2)}(m_3, m_2, m_1) = a + b(3-x) + c(3-x)^2$.
- *Affine equivariance.* If $\Pi_{(2)}(m_1, m_2, m_3) = \pi$, then $\Pi_{(2)}(a + bm_1, a + bm_2, a + bm_3) = a + b\pi$.

Reversal equivariance is, of course, tied to the fact that median-interpolation is a spatially symmetric operation. From affine equivariance, it follows that when $m_2 - m_1 \neq 0$ we have

$$\begin{aligned}\Pi_{(2)}(m_1, m_2, m_3) &= m_1 + \Pi_{(2)}(0, m_2 - m_1, m_3 - m_1) \\ &= m_1 + (m_2 - m_1)\Pi_{(2)}\left(0, 1, 1 + \frac{m_3 - m_2}{m_2 - m_1}\right).\end{aligned} \tag{2.11}$$

Thus $\Pi_{(2)}$ is characterized by its action on very special triples; it is enough to study the univariate function $\Pi_{(2)}(0, 1, 1 + d)$, $d \in \mathbb{R}$. (The exceptional case when $m_2 - m_1 = 0$ can be handled easily; see the discussion after the proof of Proposition 2.2.)

To translate (2.8)–(2.10) into manageable algebraic equations, we begin with the following proposition.

PROPOSITION 2.1 (median-imputation, $D = 2$). *Suppose the quadratic polynomial* $\pi(x)$ *has its extremum at* x^*. *Let* $s = q - p$.

[L] *If* $x^* \notin [p + s/4, p + 3s/4]$, *then*

$$\operatorname{med}(\pi(x)|[p, q]) = \pi((p + q)/2). \tag{2.12}$$

[N] *If* $x^* \in [p + s/4, p + 3s/4]$, *then*

$$\operatorname{med}(\pi(x)|[p, q]) = \pi(x^* \pm s/4). \tag{2.13}$$

Proof. We assume x^* is a minimizer (the case of a maximizer being similar). The key fact is that $\pi(x)$, being a quadratic polynomial, is symmetric about x^* and monotone increasing in $|x - x^*|$.

If $x^* \in [p + s/4, p + 3s/4]$, then $[x^* - s/4, x^* + s/4] \subseteq [p, q]$, $\{x \in [p, q] \mid \pi(x) \leq \pi(x^* \pm s/4)\} = [x^* - s/4, x^* + s/4]$. Thus $m\{x \in [p, q] \mid \pi(x) \leq \pi(x^* \pm s/4)\} = s/2 = m\{x \in [p, q] \mid \pi(x) \geq \pi(x^* \pm s/4)\}$, which implies $\operatorname{med}(\pi(x)|[p, q]) = \pi(x^* \pm s/4)$.

If $x^* < p + s/4$, then $\{x \in [p, q] \mid \pi(x) \leq \pi((p + q)/2)\} = [p, p + s/2]$ and $\{x \in [p, q] \mid \pi(x) \geq \pi((p + q)/2)\} = [p + s/2, q]$ have equal measure. Thus $\operatorname{med}(\pi(x)|[p, q]) = \pi((p + q)/2)$. The same conclusion holds when $x^* > p + 3s/4$. Thus we have (2.12). ▯

The two cases identified above will be called the "Linear" and "Nonlinear" cases. Equations (2.8)–(2.10) always give rise to a system of three algebraic equations in three variables a, b, c. Linearity refers to dependence on these variables. When (2.13) is invoked, $x^* = -b/2c$, and so the evaluation of π—at a location depending on x^*—is a nonlinear functional.

A similar division into cases occurs when we consider median-interpolation.

PROPOSITION 2.2 (median-interpolation, $D = 2$). $\Pi_{(2)}(0, 1, 1 + d) = a + bx + cx^2$ *can be computed by the following formulae:*

[N1] *If* $\frac{7}{3} \le d \le 5$, *then* $x^* \in [\frac{1}{4}, \frac{3}{4}]$, *and*

$$a = 11 + \frac{7}{2}d - \frac{5}{2}r, \;\; b = -\frac{32}{3} - \frac{13}{3}d + \frac{8}{3}r, \;\; c = \frac{8}{3} + \frac{4}{3}d - \frac{2}{3}r, \tag{2.14}$$

where $r = \sqrt{16 + 16d + d^2}$.

[N2] *If* $\frac{1}{5} \le d \le \frac{3}{7}$, *then* $x^* \in [\frac{9}{4}, \frac{11}{4}]$, *and*

$$a = -\frac{3}{2} - 2d + \frac{1}{2}d - \frac{5}{2}r, \; b = -\frac{11}{3} + \frac{16}{3}d - \frac{4}{3}r, \; c = -\frac{4}{3} - \frac{8}{3}d + \frac{2}{3}r, \tag{2.15}$$

where $r = \sqrt{1 + 16d + 16d^2}$.

[N3] *If* $-3 \le d \le -\frac{1}{3}$, *then* $x^* \in [\frac{5}{4}, \frac{7}{4}]$, *and*

$$a = -\frac{7}{12} + \frac{1}{12}d + \frac{r}{12}, \;\; b = \frac{13}{10} - \frac{3}{10}d - \frac{r}{5}, \;\; c = -\frac{4}{15} + \frac{4}{15}d + \frac{r}{15}, \tag{2.16}$$

where $r = -\sqrt{1 - 62d + d^2}$.

[L] *In all other cases,*

$$a = -\frac{7}{8} + \frac{3}{8}d, \;\; b = 2 - d, \;\; c = -\frac{1}{2} + \frac{d}{2}. \tag{2.17}$$

Proof. Fix a polynomial π. To calculate its block medians on blocks $[0, 1]$, $[1, 2]$, $[2, 3]$, we can apply Proposition 2.1 successively to the choices $[p, q] = [0, 1]$, $[1, 2]$, $[2, 3]$. We see that either the extremum of π lies in the middle half of one of the three intervals $[0, 1]$, $[1, 2]$, $[2, 3]$ or it does not. If it does not lie in the middle half of any interval, the relation of the block medians to the coefficients is linear. If it does lie in the middle half of some interval, the relation of the block medians to the coefficients will be linear in two of the blocks—those where the extremum does not lie—and nonlinear in the block where the extremum does lie. Hence there are four basic cases to consider: (i) $x^* \in [1/4, 3/4]$, (ii) $x^* \in [9/4, 11/4]$, (iii) $x^* \in [5/4, 7/4]$, and (iv) $x^* \notin [1/4, 3/4] \cup [9/4, 11/4] \cup [5/4, 7/4]$. The first three involve some form of nonlinearity; the remaining case is linear.

Now to *solve for* a polynomial π with prescribed block medians, we can see at this point that *if we knew in advance the value of* $x^*(\pi)$, we could identify one of cases (i)–(iv) as being operative. It is easy to set up for any one of these cases a system of algebraic equations defining the desired quadratic polynomial. By writing down the system explicitly and solving it, either by hand or with the assistance of an algebraic software tool, we can obtain explicit formulae for the coefficients π. This has been done for cases (i)–(iv) and results are recorded above in (2.14)–(2.17). We omit the detailed calculation.

At this point, we have identified four different cases relating polynomials to their block medians. Within a given case, the relationship between a polynomial and its block medians is one-one. However, it remains for the moment at least conceivable that for a given collection of block medians, there would be two different cases which gave the same block medians, and hence nonunique interpolation.

We are rescued by a small miracle: *with six exceptions, a given set of block medians is consistent with exactly one of the four cases.*

To understand this, note that each of the four cases, involving a hypothesis on x^*, is consistent with block medians $[0, 1, 1 + d]$ only for a special set of values of d. We now proceed to identify the set of values of d which may arise in each given case,

case by case (but out of numerical order). Starting with case (iv), we can show that *if* $x^* \notin [1/4, 3/4] \cup [9/4, 11/4] \cup [5/4, 7/4]$*, then the associated block medians* $[0, 1, 1+d]$ *must obey* $d \notin [7/3, 5] \cup [1/5, 3/7] \cup [-3, -1/3]$. As we are in case (iv), formula (2.17) gives $\Pi_{(2)}(0, 1, 1+d) = (-7/8 + 3/8d) + (2-d)x + ((d-1)/2)x^2$, and hence

$$x^* = (d-2)/(d-1). \tag{2.18}$$

By a routine calculation, case (iv) and (2.18) combine to conclude that $d \notin [-3, -1/3] \cup [1/5, 3/7] \cup [7/3, 5]$. For future reference, set $\mathcal{L} = ([-3, -1/3] \cup [1/5, 3/7] \cup [7/3, 5])^c$.

Now turn to case (i); we can show that *if* $x^* \in [1/4, 3/4]$*, then the associated block medians* $[0, 1, 1+d]$ *must obey* $d \in [7/3, 5]$. As we are in case (i), formula (2.14) applies, and

$$x^* = \frac{32 + 13d - 8\sqrt{16 + 16d + d^2}}{4(4 + 2d - \sqrt{16 + 16d + d^2})}. \tag{2.19}$$

This and $x^* \in [1/4, 3/4]$ combine to conclude that $d \in [7/3, 5]$. For future reference, set $\mathcal{N}_1 = [7/3, 5]$.

Similar calculations show that in case (ii) we have *if* $x^* \in [9/4, 11/4]$*, then the associated block medians* $[0, 1, 1+d]$ *must obey* $d \in \mathcal{N}_2 \equiv [1/5, 3/7]$. Also in case (iii) we have *if* $x^* \in [5/4, 7/4]$*, then the associated block medians* $[0, 1, 1+d]$ *must obey* $d \in \mathcal{N}_3 \equiv [-3, -1/3]$.

We now have a collection of 4 sets: $\mathcal{L}$ and $\mathcal{N}_i$, $i = 1, 2, 3$. The sets have disjoint interiors and together cover the whole range of possible values for d. For d in the interior of one of these sets, exactly one of the four cases is able to generate the block medians $[0, 1, 1+d]$. The exceptional values of d, not in the interior of one of the sets, lie in the intersection of one of the nonlinear branches $\mathcal{N}_i$ and the linear branch $\mathcal{L}$. They are $-3, -1/3, 1/5, 3/7, 7/3, 5$. Analysis "by hand" shows that at each exceptional value of d, the formula for cases (iv) and the formula for the appropriate case (i)–(iii) give identical polynomials. Formally, one sees that if $a_L(d)$, $b_L(d)$, $c_L(d)$ denote formulas from one of the expressions (2.14)–(2.17) associated with an interval immediately to the left of an exceptional value (d_E, say), and $a_R(d)$, $b_R(d)$, $c_R(d)$ denote corresponding formulas associated with the interval immediately to the right of that same exceptional value, then

$$\lim_{d \uparrow d_E} a_L(d) = \lim_{d \downarrow d_E} a_R(d)$$

and similarly for b_L, b_R, c_L, c_R.

Thus the formulas listed above *cohere globally.* Each individual formula gives $a(d)$, $b(d)$, and $c(d)$ valid on the hypothesis that x^* lies in a certain range; but because of the continuous joining at the exceptional values, the different formulas combine to produce globally monotone functions of d. See Figure 2.2. □

The degenerate case $m_2 - m_1 = 0$ can be handled as follows: (i) if $m_1 = m_2 = m_3$, then $\Pi_{(2)}(m_1, m_2, m_3) = m_1$; (ii) otherwise $m_3 - m_2 \neq 0$, then use reversal equivariance followed by the formulae in Proposition 2.2. Notice that [N1]–[N3] are nonlinear rules, whereas [L] is linear. Figure 2.2 illustrates the nonlinearity of $\Pi_{(2)}$. Panels (a)–(c) show $a(d), b(d)$, and $c(d)$, where $a(d) + b(d)x + c(d)x^2 = \Pi_{(2)}(0, 1, d+1)$. Panel (d) shows $\partial a/\partial d$. Proposition 2.2 implies that $\Pi_{(2)}$ is basically *linear* outside

$$\mathcal{N} = \left\{ [m_1, m_2, m_3] \;\middle|\; \frac{m_3 - m_2}{m_2 - m_1} \in \mathcal{N}_0 \right\}, \tag{2.20}$$

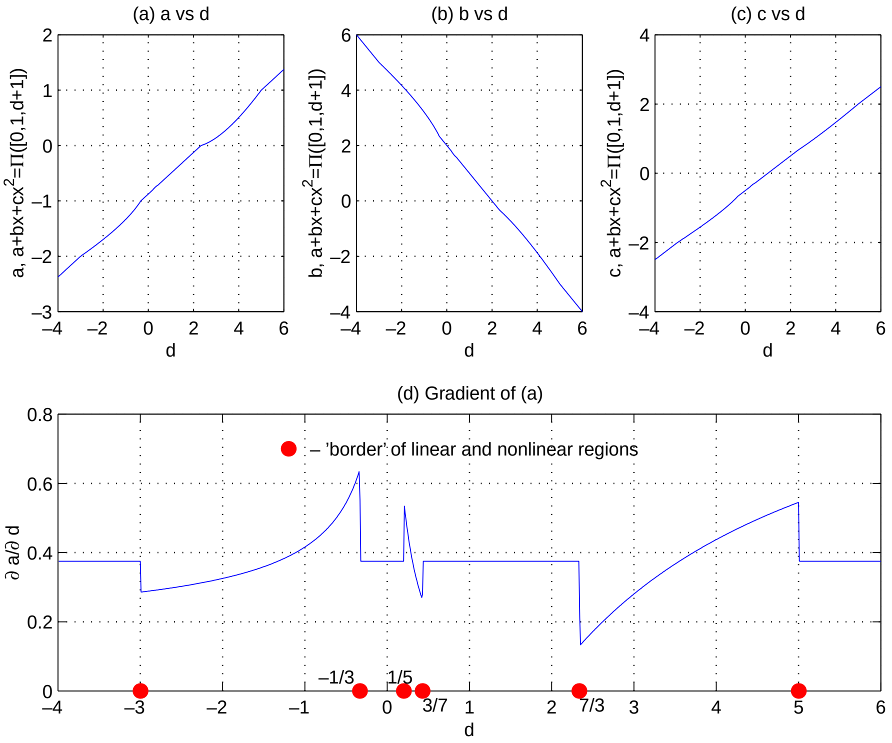

Fig. 2.2. *Nonlinearity structure of* $\Pi_{(2)}$.

where

$$\mathcal{N}_0 = [-3, -1/3] \cup [1/5, 3/7] \cup [7/3, 5]. \tag{2.21}$$

Precisely, if $\mu, \beta, a\mu + b\beta \in \mathcal{N}^c$, then

$$\Pi_{(2)}(a\mu + b\beta) = a\,\Pi_{(2)}(\mu) + b\,\Pi_{(2)}(\beta).$$

Figure 2.2(d) illustrates this point.

We now combine Propositions 2.1 and 2.2 to obtain closed-form expressions for the two-scale median-interpolating refinement operator in the quadratic case. First of all, Proposition 2.1 implies the well-posedness of median-interpolation in the case $D = 2$. Hence there exists a median-interpolating refinement operator $Q : \mathbb{R}^3 \to \mathbb{R}^3$ such that if $\pi = \pi_{j,k}$ is the fitted polynomial satisfying

$$\text{med}(\pi | I_{j,k+l}) = m_l \quad \text{for} \quad -1 \le l \le 1. \tag{2.22}$$

Then

$$Q([m_{-1}, m_0, m_1]) = [\text{med}(\pi | I_{j,3k}), \text{med}(\pi | I_{j,3k+1}), \text{med}(\pi | I_{j,3k+2})]. \tag{2.23}$$

Note that the refinement calculation is *independent* of the scale and spatial indices j and k, so Q is indeed a map from $\mathbb{R}^3$ to $\mathbb{R}^3$.

The operator Q shares two equivariance properties with $\Pi_{(2)}$:

- *Reversal equivariance.*

  $Q(m_1, m_2, m_3) = -\text{reverse}(Q(-m_3, -m_2, -m_1))$, where $\text{reverse}(p, q, r) = (r, q, p)$.

- *Affine equivariance.*

$$Q(a + bm_1, a + bm_2, a + bm_3) = a + b\,Q(m_1, m_2, m_3).$$

Q is characterized by its action on triplets $(0, 1, 1 + d)$, since if $m_2 - m_1 \neq 0$,

$$Q(m_1, m_2, m_3) = m_1 + (m_2 - m_1)Q\left(0, 1, 1 + \frac{m_3 - m_2}{m_2 - m_1}\right), \tag{2.24}$$

while if $m_2 - m_1 = 0$ and $m_3 - m_2 \neq 0$, then $Q(m_1, m_2, m_3) = \text{reverse}(Q(m_3, m_2, m_1))$ and $Q(m_3, m_2, m_1)$ can then be calculated from (2.24). Of course, when $m_2 - m_1 = m_3 - m_2 = 0$, $Q(m_1, m_2, m_3) = m_1$.

We now derive a closed-form expression for $Q(0, 1, 1 + d) = (q_1(d), q_2(d), q_3(d))$, say. By reversal equivariance, $q_3(d) = 1 + d - dq_1(\frac{1}{d})$ if $d \neq 0$. If $d = 0$, the median-interpolant of $(0, 1, 1 + d)$, π, is given by [L] of Proposition 2.2, with its maximum $x^* = 2$. A simple calculation gives $q_3(0) = \pi(\frac{11}{6}) = \frac{10}{9}$. We now work on obtaining expressions for q_1 and q_2.

PROPOSITION 2.3 (median-refinement, $D = 2$).

$$q_1(d) = \begin{cases} \frac{59}{27} + \frac{7}{27}d - \frac{8}{27}\sqrt{16 + 16d + d^2} & \textit{if } d \in [\frac{7}{3}, 5], \\ \frac{26}{27} + \frac{16}{27}d - \frac{4}{27}\sqrt{1 + 16d + 16d^2} & \textit{if } d \in [\frac{1}{5}, \frac{3}{7}], \\ \frac{77}{135} + \frac{13}{135}d + \frac{8}{135}\sqrt{1 - 62d + d^2} & \textit{if } d \in [-3, -\frac{1}{3}], \\ -\frac{1}{288}\frac{323 - 214d + 35d^2}{-1 + d} & \textit{if } d \in [-11, -3], \\ \frac{7}{9} - \frac{d}{9} & \textit{otherwise}; \end{cases} \tag{2.25}$$

$$q_2(d) = \begin{cases} -\frac{1}{270}\frac{1097 - 1174d + 17d^2 + (278 - 8d)\sqrt{1 - 62d + d^2}}{-4 + 4d - \sqrt{1 - 62d + d^2}} & \textit{if } d \in [-\frac{10}{7}, -\frac{7}{10}], \\ \frac{23}{30} + \frac{7}{30}d + \frac{1}{15}\sqrt{1 - 62d + d^2} & \textit{if } d \in [-3, -\frac{1}{3}] \backslash [-\frac{10}{7}, -\frac{7}{10}], \\ 1 & \textit{otherwise}. \end{cases} \tag{2.26}$$

Proof. Let π denote the median-interpolant of $(0, 1, 1 + d)$ associated with intervals $[0, 1], [1, 2], [2, 3]$. Recall that median-interpolation follows four branches [N1]–[N3] and [L] (cf. Proposition 2.2), whereas median-imputation follows two branches [N] and [L] (cf. Proposition 2.1.) The main task is to identify ranges of d for which median-interpolation and median-imputation use specific combinations of branches. The refinement result can then be described by obtaining algebraic expressions for each of those ranges. The calculations are similar to those in the proof of Proposition 2.2.

For q_1, there are five distinct cases:

1. $d \in [\frac{7}{3}, 5] \Rightarrow x^* \in [\frac{1}{4}, \frac{3}{4}]$: interpolation by branch [N1] and imputation by branch [L];
2. $d \in [\frac{1}{5}, \frac{3}{7}] \Rightarrow x^* \in [\frac{9}{4}, \frac{11}{4}]$: interpolation by branch [N2] and imputation by branch [L];
3. $d \in [-3, -\frac{1}{3}] \Rightarrow x^* \in [\frac{5}{4}, \frac{7}{4}]$: interpolation by branch [N3] and imputation by branch [L];

4. $d \in [-11, -3] \Rightarrow x^* \in [\frac{13}{12}, \frac{5}{4}]$: interpolation by branch [L] and imputation by branch [N];
5. $d \notin [\frac{7}{3}, 5] \cup [\frac{1}{5}, \frac{3}{7}] \cup [-3, -\frac{1}{3}] \cup [-11, -3] \Rightarrow x^* \in [\frac{13}{12}, \frac{5}{4}]$: interpolation by branch [L] and imputation by branch [L].

In each case, use the corresponding formulae in Proposition 2.2 to calculate π and then evaluate $q_1(d) = \mathrm{med}(\pi|[1, \frac{4}{3}])$ by Proposition 2.1.

For q_2, there are three distinct cases:

1. $d \in [-\frac{10}{7}, -\frac{7}{10}] \Rightarrow x^* \in [\frac{17}{12}, \frac{19}{12}]$: interpolation by branch [N3] and imputation by branch [N];[1]
2. $d \in [-3, -\frac{10}{7}] \cup [-\frac{7}{10}, -\frac{1}{3}] \Rightarrow x^* \in [\frac{5}{4}, \frac{17}{12}] \cup [\frac{19}{12}, \frac{7}{4}]$: interpolation by branch [N3] and imputation by branch [L];
3. $d \notin [-3, -\frac{1}{3}] \Rightarrow x^* \notin [\frac{5}{4}, \frac{7}{4}]$: $\mathrm{med}(\pi|[1, 2]) = \mathrm{med}(\pi|[4/3, 5/3]) = \pi(3/2) \equiv 1$.

In the first two cases, again use the corresponding formulae in Proposition 2.2 to calculate π followed by evaluating $q_2(d) = \mathrm{med}(\pi|[\frac{4}{3}, \frac{5}{3}])$ using Proposition 2.1. □

2.1.4. $D > 2$. Higher degree median-interpolation is also well-posed: [Q1] in section 2.1 has an affirmative answer for *all* integers A. A nonconstructive proof was found independently by the second author and Goodman [18]. However, it seems difficult to obtain a closed-form expression for the nonlinear refinement operator in case $D > 2$. It is possible to develop an iterative algorithm for MI that seems to converge exponentially fast to the median-interpolating polynomial for orders $D > 2$; see [15]. Experience with this algorithm suggests that MI is stable even for orders $D > 2$.

2.2. Multiscale refinement. The two-scale refinement scheme described in section 2 applied to an initial median sequence $(\tilde{m}_{j_0,k})_k \equiv (m_{j_0,k})_k$ implicitly defines a (generally nonlinear) refinement operator $R_{MI} = R$

$$R((\tilde{m}_{j,k})_k) = (\tilde{m}_{j+1,k})_k, \qquad j \geq j_0. \tag{2.27}$$

We can associate resulting sequences $(\tilde{m}_{j,k})_k$ with piecewise constant functions on the line via

$$\tilde{f}_j(\cdot) = \sum_{k=-\infty}^{\infty} \tilde{m}_{j,k}\, 1_{I_{j,k}}(\cdot) \text{ for } j \geq j_0. \tag{2.28}$$

This defines a sequence of piecewise constant functions defined on successively finer and finer meshes.

In case $D = 0$, we have

$$\tilde{f}_{j_0+h} = f_{j_0} \text{ for all } h \geq 0,$$

so the result is just a piecewise constant object taking value $m_{j_0,k}$ on $I_{j_0,k}$.

In case $D = 2$, we have no closed-form expression for the result. The operator R is nonlinear, and proving the existence of a limit $\tilde{f}_{j+h}$ as $h \to \infty$ requires work.

We mention briefly what can be inferred about multiscale average-interpolation from experience in subdivision schemes and in wavelet analysis. Fix $D \in \{2, 4, \dots\}$, and let $\overline{R} = \overline{R}^{(D)}$ denote the average-interpolation operator implicitly defined by (2.6).

[1] It is worth mentioning that this is the only case where *both* the interpolation and imputation are done using *nonlinear* rules.

Set $a_{0,k} = 1_{\{k=0\}}$. Iteratively refine this sequence by the rule $(a_{j+1,k})_k = \overline{R}((a_{j,k})_k)$. Define

$$\overline{f}_j(\cdot) = \sum_{k=-\infty}^{\infty} a_{j,k}\, 1_{I_{j,k}}(\cdot) \qquad \text{for } j \geq j_0. \tag{2.29}$$

The resulting sequence of $\overline{f}_j$ converges as $j \to \infty$ to a continuous limit $\phi = \phi^{(D)}$. This is called the fundamental solution of the multiscale refinement process. Due to the linearity of average-interpolation, if we refine an arbitrary bounded sequence $(a_{j_0,k})_k$ we get a continuous limit which is a superposition of shifted and dilated fundamental solutions:

$$\overline{f}(t) = \sum a_{j_0,k}\phi(2^{j_0}t - k). \tag{2.30}$$

For median-interpolation, such a superposition result cannot hold because of the nonlinearity of the refinement scheme for $D = 2, 4, \ldots$.

Figure 2.3 illustrates the application of multiscale refinement. Panel (a) shows the $D = 2$ refinement of three Kronecker sequences $m_{0,k}^{k'} = 1_{\{k=k'\}}$, $k' = 0, 1, 2$, as well as refinement of a Heaviside sequence $1_{\{k \geq 3\}}$. Panel (b) shows the $D = 2$ refinement of a Heaviside sequence $1_{\{k \geq 0\}}$. The sequence refined in (b) is the superposition of sequences refined in (a). Panel (c) gives a superposition of shifts of (a) for $k \geq 0$; if an analogue of (2.30) held for median refinement, this should be equal to panel (b). Panel (d) gives the discrepancy, (b)–(c). Note the vertical scales. While the discrepancy from "superposability" is not large, it is definitely nonzero and not simply an artifact of rounding or other numerical processes.

3. Convergence of median-interpolation, $D = 2$.

We now study some convergence properties of iterative median-interpolation. It turns out that for any bounded sequence $(m_{0,k})_k$, the sequence of nonlinear refinements $\tilde{f}_j$ converges to a bounded uniformly continuous limit $f(t)$. Moreover the limit has global Hölder exponent $\alpha > 0$. In this section, we will simplify notation and "drop tildes"; we denote a typical member of a refinement sequence by $m_{j,k}$ rather than $\tilde{m}_{j,k}$.

3.1. Weak convergence and stability.

Let Q be the refinement operator as defined in (2.23), and denote $Q^j = Q \circ \cdots \circ Q$ (Q composed with itself j times). We first show that, with any initial sequence $\{m_{j_0,k}\}$, $\{f_j\}$ converges at a dense set of points.

LEMMA 3.1. *For any* $[m_1, m_2, m_3] \in \mathbb{R}^3$, *the limit* $\lim_{j\to\infty} Q^j([m_1, m_2, m_3])$ *exists.*

Proof. Let $T_{j,k}$ denote the triple of intervals $[I_{j,k-1}, I_{j,k}, I_{j,k+1}]$. If π is the median-interpolant of $[m_1, m_2, m_3]$ on $T_{j_0,k}$, then it is also the interpolant for $Q([m_1, m_2, m_3])$ on the triple $T_{j_0+1,3k+1}$ arising from triadic subdivision of the central interval of $T_{j_0,k}$. If we refine the central subinterval of $T_{j_0+1,3k+1}$, we see that π continues to be the interpolant of the resulting medians. In fact, π is the interpolant for $Q^j([m_1, m_2, m_3])$ on the triple arising from the jth such generation of subdivision of central intervals, i.e., for $T_{j_0+j,\, 3^jk+(3^j-1)/2}$ for every $j > 0$. As $j \to \infty$, the sequence of sets $(T_{j_0+j,\, 3^jk+(3^j-1)/2})_j$ collapses to the midpoint of $I_{j_0,k}$. Therefore, by continuity of π and continuity of the imputation operator,

$$\lim_{j\to\infty} Q^j([m_1, m_2, m_3]) = [m, m, m], \text{ where } m = \pi\left(3^{-j_0}\left(k + \frac{1}{2}\right)\right),$$

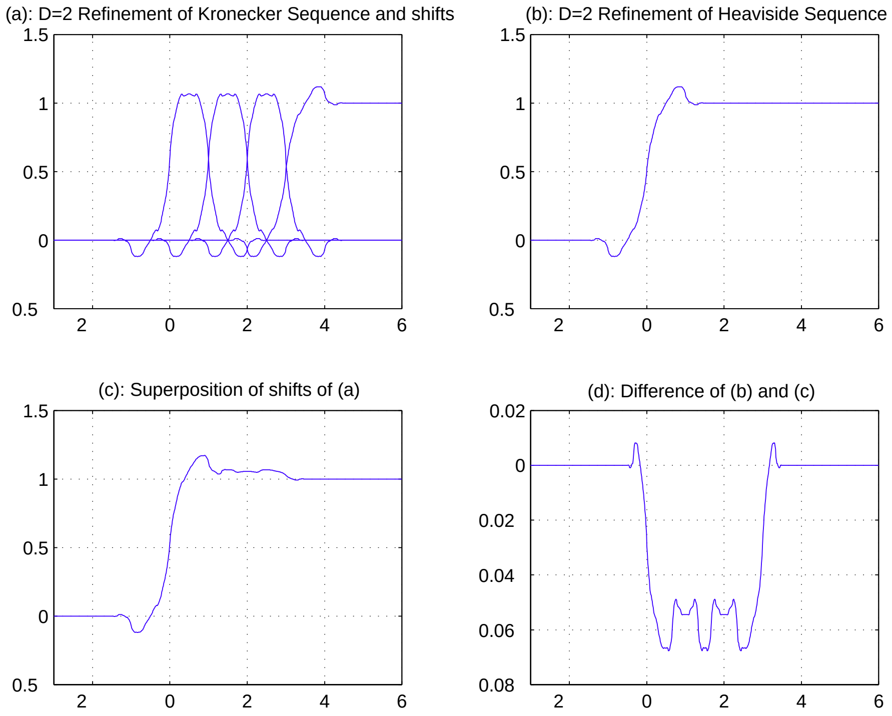

FIG. 2.3. *Discrepancy from "superposability" of multiscale median-interpolating refinement.*

the value of π at the midpoint of $I_{j_0,k}$. □

LEMMA 3.2 (convergence at triadic rationals). *For any initial median sequence* $\{m_{j_0,k}\}$*, the (nonlinear) iterative refinement scheme based on quadratic median-interpolation converges on a countable dense subset of the real line, i.e., there exists a countable dense set* $S \subset \mathbb{R}$ *and a function* $f : S \to \mathbb{R}$ *such that* $\lim_{j\to\infty} f_j(x) = f(x)$ *for every* $x \in S$.

Proof. Let $t_{j,k}$ be the midpoint of the triadic interval $I_{j,k}$. Assume we have applied the refinement scheme j_1 times to the input sequence $\{m_{j_0,k}\}_k$ (so that the values $m_{j_0+j_1,k-1}$, $m_{j_0+j_1,k}$, and $m_{j_0+j_1,k+1}$ have been calculated). We then have, for every $j > 0$, $f_{j_0+j_1+j}(t_{j_0+j_1,k}) = m^{(j)}$, where $m^{(j)}$ is the middle entry of $Q^j([m_{j_0+j_1,k-1}, m_{j_0+j_1,k}, m_{j_0+j_1,k+1}])$. By Lemma 3.1, $(m^{(j)})_j$ converges to a definite value as $j \to \infty$. We may take $S = \{t_{j,k} \mid j \geq j_0, k \in \mathbb{Z}\}$, the set of midpoints of all arbitrarily small triadic intervals, which is dense in $\mathbb{R}$. □

LEMMA 3.3. *For any* $j > 0$ *and* $k \in \mathbb{Z}$*, let* $d_{j,k} = m_{j,k} - m_{j,k-1}$*. Then*

$$|f(t_{j,k}) - m_{j,k}| \leq \frac{1}{15} \max\{|d_{j,k-1}|, |d_{j,k}|\}, \tag{3.1}$$

where the upper bound is attained if and only if $d_{j,k-1} = -d_{j,k}$.

Proof. From the proof of Lemma 3.2, $f(t_{j,k}) = \pi(t_{j,k})$, where π median-interpolates $m_{j,k-1}$, $m_{j,k}$, and $m_{j,k+1}$ for the triple $[I_{j,k-1}, I_{j,k}, I_{j,k+1}]$. Thus $|f(t_{j,k}) - m_{j,k}| = |\pi(t_{j,k}) - m_{j,k}|$. Unless $d = d_{j,k+1}/d_{j,k} \in [-3, -1/3]$, $\pi(t_{j,k}) = m_{j,k}$ and (3.1) holds trivially. When $d = d_{j,k+1}/d_{j,k} \in [-3, -1/3]$, $\pi(x)$ is given by [N3] of Proposition 2.2.

Without loss of generality, we can work with $j = 0$, $k = 0$ and denote (for simplicity) $m_i = m_{0,i}$, $i = -1, 0, 1$. Without loss of generality, we assume $\max\{|m_0 - m_{-1}|, |m_1 - m_0|\} = 1$, $m_{-1} = 0$, $m_0 = 1$ and $d = \frac{m_1 - m_0}{m_0 - m_{-1}} = m_1 - 1 \in [-1, -\frac{1}{3}]$. Then $|\pi(t_{j,k}) - m_{j,k}|/\max(|d_1|, |d_2|) = |\pi(3/2) - 1|$, where $\pi(x)$ is given by [N3] in Proposition 2.2, and we have

$$\max \frac{|\pi(t_{j,k}) - m_{j,k}|}{\max(|d_1|, |d_2|)} = \max_{d \in [-1, -\frac{1}{3}]} |a + b(3/2) + c(3/2)^2 - 1|$$
$$= \max_{d \in [-1, -\frac{1}{3}]} \left| \frac{7}{30}(d - 1) + \frac{\sqrt{1 - 62d + d^2}}{15} \right| = \frac{1}{15}.$$

The maximum is attained at $d = -1$. □

3.2. Hölder continuity. We now develop a basic tool for establishing Hölder continuity of refinement schemes.

Theorem 3.4. *Let $(m_{0,k})_k$ be a bounded sequence, and $m_{j,k}$ be the refinement sequences generated by the quadratic median-interpolating refinement scheme constructed in section 2.2. Let $d_{j,k} := m_{j,k} - m_{j,k-1}$ and $f_j := \sum_k m_{j,k} 1_{I_{j,k}}$. Suppose that for some $\alpha > 0$ and all $j \geq 0$, $\sup_k |d_{j,k}| \leq C \cdot 3^{-j\alpha}$. Then f_j converges uniformly to a bounded limit $f \in \dot{C}^\alpha$. The converse is also true if $\alpha \leq 1$.*

This is analogous to results found in the literature of linear refinement schemes (c.f. Theorem 8.1 of Rioul [25]). The proof of the forward direction uses basically the same arguments as in the linear case, except that one must deal with nonlinearity using a general affine-invariance property of medians. Similar arguments could be applied in the study of cases $D > 2$. The proof of the converse direction, on the other hand, relies on Lemma 3.3 and is therefore specific to the $D = 2$ triadic case.

Proof. ($\Rightarrow$) We show that $\{f_j\}$ is a Cauchy sequence. Consider

$$\sup_x |f_{j+1}(x) - f_j(x)| = \sup_k \max_{\epsilon = 0,1,2} |m_{j+1,3k+\epsilon} - m_{j,k}|. \tag{3.2}$$

The functions $m_{j+1,3k+\epsilon} = q_\epsilon(m_{j,k-1}, m_{j,k}, m_{j,k+1})$ obey

$$q_\epsilon(m_{j,k-1}, m_{j,k}, m_{j,k+1}) = m_{j,k} + q_\epsilon(-d_{j,k}, 0, d_{j,k+1}).$$

Moreover, by Lemma 6.2, these functions are Lipschitz: $q_\epsilon(m_1, m_2, m_3) \leq c \max_{i=1,2,3}\{|m_i|\}$. Therefore,

$$\sup_x |f_{j+1}(x) - f_j(x)| = \sup_k \max_{\epsilon = 0,1,2} |q_\epsilon(-d_{j,k}, 0, d_{j,k+1})| \leq c \sup_k |d_{j,k}| \leq c \cdot C \cdot 3^{-j\alpha}$$

and $||f_{j+p} - f_j||_\infty \leq cC(3^{-j\alpha} + \cdots + 3^{-(j+p-1)\alpha}) \leq C' 3^{-j\alpha}$. ($C'$ is independent of p.) Hence $\{f_j\}$ is a Cauchy sequence that converges uniformly to a function f. Furthermore, $f \in \dot{C}^\alpha$ because $\sup_{3^{-(j+1)} \leq |h| \leq 3^{-j}} |f(x+h) - f(x)| \leq |f(x+h) - f_j(x+h)| + |f(x) - f_j(x)| + |f_j(x+h) - f_j(x)| \leq C' 3^{-j\alpha} + C' 3^{-j\alpha} + C 3^{-j\alpha} \leq 3^\alpha (2C' + C)|h|^\alpha$.

($\Leftarrow$) If $f \in \dot{C}^\alpha$, $\alpha \leq 1$, then, by definition, $\sup_k |f(t_{j,k}) - f(t_{j,k-1})| \leq c \cdot 3^{-j\alpha}$. But

$$|m_{j,k} - m_{j,k-1}| \leq |m_{j,k} - f(x_{j,k})| + |f(t_{j,k}) - f(t_{j,k-1})| + |m_{j,k-1} - f(t_{j,k-1})|$$
$$\leq \frac{1}{15} \max\{|d_{j,k}|, |d_{j,k-1}|\} + c \cdot 3^{-j\alpha} + \frac{1}{15} \max\{|d_{j,k-1}|, |d_{j,k-2}|\}.$$

The last inequality is due to Lemma 3.3. Maximizing over k on both sides of the above inequality, followed by collecting terms, gives $\sup_k |d_{j,k}| \leq (15/13\ c) \cdot 3^{-j\alpha}$. □

3.3. Nonlinear difference scheme. As in Theorem 3.4, let $d_{j,k} = m_{j,k} - m_{j,k-1}$ denote the sequence of interblock differences. It is a typical property of any *constant-reproducing* linear refinement scheme that the difference sequences can themselves be obtained from a linear refinement scheme, called the *difference scheme*. The coefficient mask of that scheme is easily derivable from that of the original scheme; see [16, 25]. More generally, a linear refinement scheme that can reproduce all lth degree polynomials would possess $l+1$ difference (and divided difference) schemes [16]. A partial analogy to this property holds in the nonlinear case: the $D = 2$ median-interpolation scheme, being a nonlinear refinement scheme with quadratic polynomial reproducibility, happens to possess a (nonlinear) first difference scheme but no higher order ones.

Let $d_{j,k} \neq 0, d_{j,k+1} \neq 0, d_{j,k+2}$ be given. Then, by (2.24),

$$\begin{aligned}
(m_{j+1,3k}, &m_{j+1,3k+1}, m_{j+1,3k+2}) \\
&= m_{j,k-1} + d_{j,k}\, Q\left(0, 1, 1 + \frac{d_{j,k+1}}{d_{j,k}}\right) \\
&= m_{j,k-1} + d_{j,k}\, \left(q_1\left(\frac{d_{j,k+1}}{d_{j,k}}\right), q_2\left(\frac{d_{j,k+1}}{d_{j,k}}\right), q_3\left(\frac{d_{j,k+1}}{d_{j,k}}\right)\right), \\
(m_{j+1,3k+3}, &m_{j+1,3k+4}, m_{j+1,3k+5}) \\
&= m_{j,k} + d_{j,k+1} Q\left(0, 1, 1 + \frac{d_{j,k+2}}{d_{j,k+1}}\right) \\
&= m_{j,k-1} + d_{j,k} + d_{j,k+1}\left(q_1\left(\frac{d_{j,k+2}}{d_{j,k+1}}\right), q_2\left(\frac{d_{j,k+2}}{d_{j,k+1}}\right), q_3\left(\frac{d_{j,k+2}}{d_{j,k+1}}\right)\right).
\end{aligned}$$

Hence $d_{j+1,3k+1} d_{j+1,3k+2}, d_{j+1,3k+3}$ are only dependent on $d_{j,k}, d_{j,k+1}, d_{j,k+2}$ and there exist three functionals $\partial q_0 : \mathbb{R}^2 \to \mathbb{R}$, $\partial q_1 : \mathbb{R}^2 \to \mathbb{R}$, $\partial q_2 : \mathbb{R}^3 \to \mathbb{R}$ such that $d_{j+1,3k+1} = \partial q_0(d_{j,k}, d_{j,k+1})$, $d_{j+1,3k+2} = \partial q_1(d_{j,k}, d_{j,k+1})$, and $d_{j+1,3k+3} = \partial q_2(d_{j,k}, d_{j,k+1}, d_{j,k+2})$, where

$$\begin{aligned}
\partial q_0(d_0, d_1) &= d_0\left(q_2\left(\frac{d_1}{d_0}\right) - q_1\left(\frac{d_1}{d_0}\right)\right) \quad \text{(when } d_0 \neq 0\text{)}, \\
\partial q_1(d_0, d_1) &= d_0\left(q_3\left(\frac{d_1}{d_0}\right) - q_2\left(\frac{d_1}{d_0}\right)\right) \quad \text{(when } d_0 \neq 0\text{)}, \\
\partial q_2(d_0, d_1, d_2) &= d_0 + d_1 q_1\left(\frac{d_2}{d_1}\right) - d_0 q_3\left(\frac{d_1}{d_0}\right) \quad \text{(when } d_0 \neq 0 \text{ and } d_1 \neq 0\text{)}, \\
&= d_0 + d_1 q_1\left(\frac{d_2}{d_1}\right) - d_0\left(1 + \frac{d_1}{d_0} - \frac{d_1}{d_0} q_1\left(\frac{d_0}{d_1}\right)\right). \qquad (3.3)
\end{aligned}$$

The degenerate cases can be handled easily. One of those will be of use later, namely,

$$\partial q_0(0, d_1) = \frac{d_1}{9} = \lim_{d_0 \to 0} d_0\left(q_2\left(\frac{d_1}{d_0}\right) - q_1\left(\frac{d_1}{d_0}\right)\right). \qquad (3.4)$$

Similar limits hold for ∂q_1 and ∂q_2.

The difference scheme inherits two nice equivariance properties from median-interpolation:

- *Reversal equivariance.*

$$\begin{aligned}
\partial q_0(d_1, d_0) = \partial q_1(d_0, d_1), &\partial q_1(d_1, d_0) \\
&= \partial q_0(d_0, d_1), \text{ and } \partial q_2(d_2, d_1, d_0) = \partial q_2(d_0, d_1, d_2).
\end{aligned}$$

- *Affine equivariance.*

$$\partial q_\epsilon(b(d_0,d_1)) = b\,\partial q_\epsilon(d_0,d_1), \epsilon = 0,1, \text{ and}$$
$$\partial q_2(b(d_0,d_1,d_2)) = b\,\partial q_2(d_0,d_1,d_2).$$

The above discussion implies the existence of three (nonlinear) operators $\partial Q_\epsilon : \mathbb{R}^3 \to \mathbb{R}^3$, $\epsilon = 0,1,2$ that govern the difference scheme:

$$\partial Q_\epsilon([d_{j,k-1}, d_{j,k}, d_{j,k+1}]^T) = [d_{j+1,3k+\epsilon}, d_{j,3k+\epsilon}, d_{j,3k+\epsilon}]^T \text{ for all } j \geq 0, k \in \mathbb{Z}. \tag{3.5}$$

Uniform convergence will follow from the fact that these operators are *shrinking* in the sense that

$$S_\infty(\partial Q_\epsilon) := \max_{d\in\mathbb{R}^3} \frac{||\partial Q_\epsilon(d)||_\infty}{||d||_\infty} = \beta < 1, \quad \epsilon = 0,1,2. \tag{3.6}$$

As the ∂Q_ϵ are nonlinear, this is slightly weaker than being *contractive.* We will prove an inequality like this in the next section.

It is easy to check that $\partial Q_\epsilon(d) = 0$ if and only if $d = 0$ and that $S_\infty(\partial Q_{\epsilon_1} \circ \partial Q_{\epsilon_2}) \leq S_\infty(\partial Q_{\epsilon_1}) S_\infty(\partial Q_{\epsilon_2})$. In order to bound the decay rate of $\max_k |d_{j,k}|$ (and hence the critical Hölder exponent for median-interpolating refinements), we can use the estimate

$$\sup_k |d_{j,k}| \leq \sup_k |d_{0,k}| \max_{\epsilon_i=0,1,2} S_\infty(\partial Q_{\epsilon_j} \circ \cdots \circ \partial Q_{\epsilon_1}). \tag{3.7}$$

Assuming (3.6), we can bound the right-hand side of (3.7) crudely by

$$\max_{\epsilon_i=0,1,2} S_\infty(\partial Q_{\epsilon_j} \circ \cdots \circ \partial Q_{\epsilon_1}) \leq \max_{\epsilon_i=0,1,2} S_\infty(\partial Q_{\epsilon_j}) \times \cdots \times S_\infty(\partial Q_{\epsilon_1}) \tag{3.8}$$
$$= \beta^j = 3^{-j\,\alpha}, \tag{3.9}$$

where $\alpha = \log_3(1/\beta) > 0$. Hence, uniform convergence follows from Theorem 3.4.

Actually, the inequality (3.8) contains slack. It is possible to improve on it by adapting to the nonlinear case approaches developed by Rioul [25] and Dyn, Gregory, and Levin [16] in the study of linear refinement schemes. We state without proof the following: Define α_j by

$$3^{-j\alpha_j} = \max_{\epsilon_i=0,1,2} S_\infty(\partial Q_{\epsilon_j} \circ \cdots \circ \partial Q_{\epsilon_1}). \tag{3.10}$$

Let $\alpha := \sup_j \alpha_j$. Then $\lim_j \alpha_j = \alpha$ and median-interpolating refinements are $\dot{C}^{\alpha-\epsilon}$ for $\epsilon > 0$. This observation is potentially useful because it provides a way to compute *lower bounds* for the Hölder regularity of median-interpolating refinement limits. In the next section, we apply this idea with the choice of $j = 1$, which results in the crude lower bound $\alpha_1 = \log_3(135/121)$. A better bound might be obtained if one could manage to compute the right-hand side of (3.10) for a larger j.

3.4. The difference scheme is shrinking. Armed with the closed-form expression for the quadratic median-interpolating refinement scheme, we can explicitly calculate $S_\infty(\partial Q_\epsilon)$ despite the nonlinearity of the operator.

THEOREM 3.5. *$S_\infty(\partial Q_\epsilon) = 121/135 < 1$ for $\epsilon = 0,1,2$. Consequently, by Theorem* 3.4 *and* (3.7)–(3.9)*, for any bounded initial sequence $m_{0,k}$, the sequence of* *nonlinear refinements* $f_j = \sum_k m_{j,k} 1_{I_{j,k}}$ *converges uniformly to a bounded uniformly continuous function* $f \in \dot{C}^\alpha$*, where* $\alpha = \log_3(135/121) \approx 0.0997$.

Proof. See [31] for the computational details. The main idea of the proof is to verify that $\partial q_0(d_0, d_1)$ and $\partial q_1(d_0, d_1)$ are monotone increasing in d_0 for fixed d_1 and monotone increasing in d_1 for fixed d_0; and that $\partial q_2(d_0, d_1, d_2)$ is monotone decreasing in d_0 and d_2 for fixed d_1 and monotone increasing in d_1 for fixed d_0 and d_2. Thus $S_\infty(\partial q_0) := \max_{|d_0|,|d_1| \le 1} \partial q_0(d_0, d_1) = \partial q_0(1, 1) = 1/3$, and, by symmetry, $S_\infty(\partial q_1) = S_\infty(\partial q_0) = 1/3$; $S_\infty(\partial q_2) = \partial q_2(-1, 1, -1) = 121/135$. The theorem follows from the fact that $S_\infty(\partial Q_\epsilon) = \max_{i=0,1,2} S_\infty(\partial q_i)$ for $\epsilon = 0, 1, 2$. □

3.5. Discussion.

The regularity bound $\alpha \ge \log_3(135/121) \approx 0.0997$ is probably very far from sharp. We now discuss evidence suggesting that the sharp Hölder exponent is nearly 1.

3.5.1. Linearized median-interpolation.

We recall from Figure 2.2, and Propositions 2.1, 2.2, and 2.3 that there is an underlying *linear branch* associated with the median scheme. A sufficient but not necessary condition for applicability of this branch is that the block medians be consistent with a polynomial π that is monotone throughout $[a, b]$.

In the linear branch, the median functional amounts to *midpoint evaluation*: $\mathrm{med}(\pi|[a, b]) = \pi((a + b)/2)$. The resulting refinement rule is a linear scheme that we call the *LMI* scheme, with coefficient mask $[-1/9, 0, 2/9, 7/9, 1, 7/9, 2/9, 0, -1/9]$. It is a symmetric interpolatory scheme and can be viewed as a triadic variant of Deslauriers–Dubuc schemes. The mask has a positive Fourier transform, and the convergence and critical Hölder regularity of the scheme can be determined quite easily by applying the theory of linear refinement schemes [25, 5, 8].

The LMI scheme has refinement limits which are "almost Lipschitz" [31]. For any given bounded initial sequence of block values at scale 0, the LMI scheme converges to a bounded uniformly continuous limit f obeying the regularity estimate $\sup_x |f(x + h) - f(x)| \le C|h| \log(1/|h|)$. Moreover, the above global regularity bound cannot be improved. (If we study *local* rather than global regularity, it can be shown, using techniques in [5], that the bound can be improved for *most* x.)

See Figure 3.1 for pictures of median-interpolating and linearized median-interpolating refinement limits of the Kronecker sequence $\{m_{0,k} = \delta_{0,k}\}$.

3.5.2. Critical Hölder exponent conjectures.

We conjecture that MI and LMI share the same global Hölder regularity. This is a rather natural conjecture to make, since the difference between MI and LMI is actually very small—as one sees from the near-linearity of the functions displayed in Figure 2.2. In [31], computational evidence was provided to support the conjecture. In particular, the experiments there suggest the following:

1. The actual decay behavior in (3.10) is $O(j3^{-j})$, which is much faster than the rate bound calculated in Theorem 3.5. This rate would imply that median-interpolating refinement limits are almost Lipschitz. See panel (d) of Figure 3.1.
2. Both the MI refinement sequences $m^{MI}_{j,k}$ and the LMI refinement sequences $m^{LMI}_{j,k}$ appear to possess a *stationarity property*: let k^*_j be the value of k maximizing $|d^{MI}_{j,k}|$; here there exists an integer k^* such that $3^{-j} k^*_j = k^*$ for all large enough j. See panel (b) of Figure 3.1. The same phenomenon is observed for $d^{LMI}_{j,k}$; see panel (c) of Figure 3.1. Stationarity is a *provable*

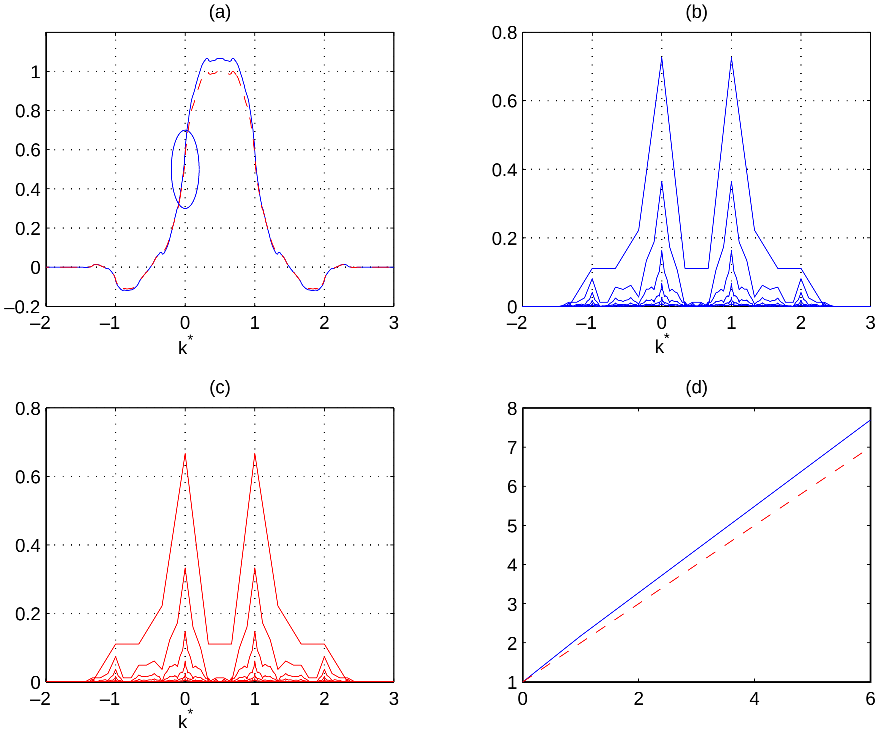

Fig. 3.1. *MI versus LMI:* (a) *MI- and LMI- refinements (solid and dashed lines, respectively) of* $m_{0,k} = \delta_{0,k}$, (b) $|d_{j,k}^{MI}|$ *versus* $k3^{-j}$, $j = 1, \ldots, 6$, (c) $|d_{j,k}^{LMI}|$ *versus* $k3^{-j}$, $j = 1, \ldots, 6$, (d) $3^j \max_k |d_{j,k}^{MI}|$ *and* $3^j \max_k |d_{j,k}^{LMI}|$ *versus* j *(solid and dashed lines, respectively).*

property of the LMI scheme. It is *empirically* a property of the MI scheme as well.

3. It appears that in the vicinity of the spatial location $x = k^*$, the limit function is monotone and (consequently) median-interpolating refinement is repeatedly using its *linear branch*. Therefore, it seems that $\sup_k |d_{j,k}^{MI}|$ and $\sup_k |d_{j,k}^{LMI}|$ share the same asymptotics. See again Figure 3.1.

A more ambitious open question is the following: Let $x \in \mathbb{R}$, and let $k_j(x)$ be defined by $x \in I_{j,k_j(x)}$. We call x an *asymptotically linear point* if, for large enough j, median-interpolation is only using its linear branch to determine $m_{j+1,k_{j+1}(x)}$ from $m_{j,k_j(x)+\epsilon}$, $\epsilon = -1, 0, 1$. In order to understand deeply the relation between median-interpolation and linearized median-interpolation, it would be useful to determine the structure of the set of asymptotically linear points.

4. Median-interpolating pyramid transform. We now apply the refinement scheme to construct a nonlinear pyramid and associated nonlinear multiresolution analysis.

4.1. Pyramid algorithms. While it is equally possible to construct pyramids for decomposition of functions $f(t)$ or of sequence data y_i, we keep an eye on applications and concentrate attention on the sequence case. So we assume we are given a discrete dataset $y_i, i = 0, \ldots, n-1$, where $n = 3^J$ is a triadic number. We aim to use the nonlinear refinement scheme to decompose and reconstruct such sequences.

ALGORITHM FMIPT: PYRAMID DECOMPOSITION.

1. *Initialization.* Fix $D \in 0, 2, 4, \ldots$ and $j_0 \geq 0$. Set $j = J$.
2. *Formation of block medians.* Calculate
$$m_{j,k} = \mathrm{med}(y_i : i/n \in I_{j,k}). \tag{4.1}$$
(Here med() refers to the discrete median rather than the continuous median.)
3. *Formation of refinements.* Calculate
$$\tilde{m}_{j,k} = R((m_{j-1,k})) \tag{4.2}$$
using refinement operators of the previous section.
4. *Formation of detail corrections.* Calculate
$$\alpha_{j,k} = m_{j,k} - \tilde{m}_{j,k}.$$
5. *Iteration.* If $j = j_0 + 1$, set $m_{j_0,k} = \mathrm{med}(y_i : i/n \in I_{j_0,k})$ and terminate the algorithm, else set $j = j - 1$ and goto 2.

ALGORITHM IMIPT: PYRAMID RECONSTRUCTION.

1. *Initialization.* Set $j = j_0 + 1$. Fix $D \in 0, 2, 4, \ldots$ and $j_0 \geq 0$, as in the decomposition algorithm.
2. *Reconstruction by refinement.*
$$(m_{j,k}) = R((m_{j-1,k})) + (\alpha_{j,k})_k.$$
3. *Iteration.* If $j = J$ goto 4, else set $j = j + 1$ and goto 2.
4. *Termination.* Set
$$y_i = m_{J,i}, \quad i = 0, \ldots, n-1.$$

An implementation is described in [31]. Important details described there include the treatment of boundary effects and efficient calculation of block medians.

DEFINITION 4.1. *Gather the outputs of the pyramidal decomposition algorithm into the sequence*
$$\theta = ((m_{j_0,k})_k, (\alpha_{j_0+1,k})_k, (\alpha_{j_0+2,k})_k, \ldots, (\alpha_{J,k})_k).$$
We call θ the MIPT of y and we write $\theta = MIPT(y)$. Applying the pyramidal reconstruction algorithm to θ gives an array which we call the inverse transform, and we write $y = MIPT^{-1}(\theta)$.

The reader may wish to check that $MIPT^{-1}(MIPT(y)) = y$ for every sequence y.

We will also use below the average-interpolating pyramid transform (AIPT), defined in a completely parallel way, using only the average-interpolation refinement operator $\overline{R}$. We write $\theta = AIPT(y)$ and $y = AIPT^{-1}(\theta)$.

Complexity. Both transforms have good computational complexity. The refinement operator for $AIPT$, in common with wavelet transforms and other multiscale algorithms, has order $O(n)$ computational complexity. The coarsening operator can be implemented with the same complexity because of a *causality* relationship:
$$\mathrm{ave}(y_i|I_{j,k}) = \mathrm{ave}(\mathrm{ave}(y_i|I_{j+1,3k}),\ \mathrm{ave}(y_i|I_{j+1,3k+1}),\ \mathrm{ave}(y_i|I_{j+1,3k+2})). \tag{4.3}$$

Similarly, the refinement operator of $MIPT$ of order $D = 2$ has complexity $O(n)$ due to the propositions of section 2.1.3. However, for the coarsening operator there is no direct causality relationship. The analogue of (4.3) obtained by replacing "ave" by "med" does not hold.

To rapidly calculate all medians over triadic blocks, one can maintain sorted lists of the data in each triadic block; the key coarsening step requires merging three sorted lists to obtain a single sorted list. This process imposes only a $\log_3(n)$ factor in additional cost. For a more detailed description of the implementation, we refer to [31]. As a result, $MIPT$ can be implemented by an $O(n \log_3 n)$ algorithm, whereas $MIPT^{-1}$ can be implemented with $O(n)$ time-complexity.

4.2. Properties. P1. *Coefficient localization.* The coefficient $\alpha_{j,k}$ in the pyramid only depends on block medians of blocks at scale $j-1$ and j which cover or abut the interval $I_{j,k}$.

P2. *Expansionism.* There are 3^{j_0} résumé coefficients $(m_{j_0,k})$ in θ and 3^j coefficients $(\alpha_{j,k})_k$ at each level j. Hence

$$\mathrm{Dim}(\theta) = 3^{j_0} + 3^{j_0+1} + \cdots + 3^J.$$

It follows that $\mathrm{Dim}(\theta) = 3^J(1 + 1/3 + 1/9 + \cdots) \sim 3/2 \cdot n$. The transform is about 50% expansionist.

P3. *Coefficient decay.* Suppose that the data $y_i = f(i/n)$ are noiseless samples of a continuous function $f \in \dot{C}^\alpha$, $0 \le \alpha \le 1$, i.e., $|f(s) - f(t)| \le C|s-t|^\alpha$ for a fixed C. Then for $MIPT$ $D = 0$ or 2, we have

$$|\alpha_{j,k}| \le C'C3^{-j\alpha}. \tag{4.4}$$

Suppose f is $\dot{C}^{r+\alpha}$ for $r = 1$ or 2, i.e., $|f^{(r)}(s) - f^{(r)}(t)| \le C|s-t|^\alpha$, for some fixed α and C, $0 < \alpha \le 1$. Then, for $MIPT$ $D = 2$,

$$|\alpha_{j,k}| \le C'C3^{-j(r+\alpha)}. \tag{4.5}$$

P4. *Gaussian noise.* Suppose that $y_i = \sigma z_i$, $i = 0, \dots, n-1$, and that z_i is i.i.d $N(0,1)$, a standard Gaussian white noise. Then

$$P(\sqrt{3^{J-j}}\,|\alpha_{j,k}| \ge \xi) \le C_1 \cdot \exp\left(-C_2 \frac{\xi^2}{\sigma^2}\right),$$

where the $C_i > 0$ are absolute constants.

These properties are things we naturally expect of linear pyramid transforms, such as those of Adelson and Burt, and P1, P3, and P4 we expect also of wavelet transforms. In fact these properties hold not just for MIPT but also for AIPT.

A key property of MIPT but *not* AIPT is the following.

P5. *Cauchy noise.* Suppose that $y_i = \sigma z_i$, $i = 0, \dots, n-1$, and that z_i is i.i.d standard Cauchy white noise. Then

$$P(\sqrt{3^{J-j}}\,|\alpha_{j,k}| \ge \xi) \le C_1' \cdot \exp\left(-C_2' \frac{\xi^2}{\sigma^2}\right),$$

where $0 \le \xi \le \sqrt{3^{J-j}}$ and the $C_i' > 0$ are absolute constants.

For a linear transform, such as AIPT, the coefficients of Cauchy noise have Cauchy distributions, and such exponential bounds cannot hold. Moreover, the spread of the resulting Cauchy distributions does not decrease with increasing j. In contrast, P5 shows that the spread of the MIPT coefficients gets smaller with larger j, and that deviations more than a few multiples of the spread are very rare.

Properties P1 and P2 need no further proof; P3–P5 are proved in the appendix.

4.3. MRA. MI refinement allows us to mimic the multiresolution analysis of wavelet theory. Given the sequence $(m_{j,k})$ of block medians of y at scale j, we may apply $J-j$ iterations of two-scale refinement to these medians, getting a sequence of length n which we can call $P_j y$. An equivalent definition is as follows:

- Decomposition. $\theta = MIPT(y)$.
- Suppression of details. Let $\tilde{\theta}$ be a partial copy of θ, where we set $\alpha_{j',k} = 0$ for $j' > j$.
- Reconstruction. $P_j y = MIPT^{-1}(\tilde{\theta})$.

P_j is a nonlinear approximation of y at the scale j, because it uses only the block medians at scale j in its construction.

We can also form $Q_j y = P_j y - P_{j-1} y$, listing the details present in the approximation at scale j but not present at scale $j-1$.

4.4. Examples. We collect here a few examples of the MIPT for $D = 2$.

Figure 4.1 shows three different noiseless signals: (a) Sinusoid; (b) Heaviside; (c) Doppler. It also shows the pyramid coefficients of noiseless data for $D = 2$.

Figure 4.2 shows an MRA decomposition of the same three signals. This display shows $P_{j_0} y$, $Q_{j_0+1} y, \ldots, Q_J y$.

5. Denoising by MIPT thresholding. We now consider applications of pyramid transforms to multiscale denoising. In general, we act as we would in the wavelet denoising case.

- *Pyramid decomposition.* Calculate $\theta = MIPT(y)$.
- *Hard thresholding.* Let $\eta_t(y) = y \cdot 1_{\{|y|>t\}}$ be the hard thresholding function and let
$$\hat{\theta} = ((m_{j_0,k})_k, (\eta_{t_{j_0+1}}(\alpha_{j_0+1,k}))_k, \ldots).$$
Here the (t_j) is a sequence of threshold levels.
- *Pyramid reconstruction.* Calculate $\hat{f} = MIPT^{-1}(\hat{\theta})$.

In this approach, coefficient amplitudes smaller than t_j are judged negligible, as noise rather than signal. Hence the thresholds t_j control the degree of noise rejection but also of valid signal rejection. One hopes, in analogy with the orthogonal transform case studied in [12], to set thresholds which are small but which are very likely to exceed every coefficient in case of a pure noise signal. If the MIPT performs as we hope, the MIPT thresholds can be set "as if" the noise were Gaussian and the transform were AIPT, even when the noise is very non-Gaussian. This would mean that the median pyramid is immune to bad effects of impulsive noise.

5.1. Choice of thresholds. Motivated by P4 and P5, we work with the "L^2-normalized" coefficients $\bar{\alpha}_{j,k} = \sqrt{3^{J-j}}\alpha_{j,k}$ in this section.

In order to choose thresholds $\{t_j\}$ which are very likely to exceed every coefficient in case of a pure noise signal, we find t_j satisfying $P(|\bar{\alpha}_{j,k}| > t_j) \le c \cdot 3^{-J}/J$ where the MIPT coefficients arise from a pure noise signal $(X_i)_{i=0}^{3^J-1}$, $X_i \sim_{i.i.d.} F$. Then we have

$$P(\exists (j,k) \text{ s.t. } |\bar{\alpha}_{j,k}| > t_j) \le c \cdot \sum_{j=j_0}^{J} \sum_{k=0}^{3^j-1} \frac{1}{J} 3^{-J} \to 0 \text{ as } J \to \infty. \tag{5.1}$$

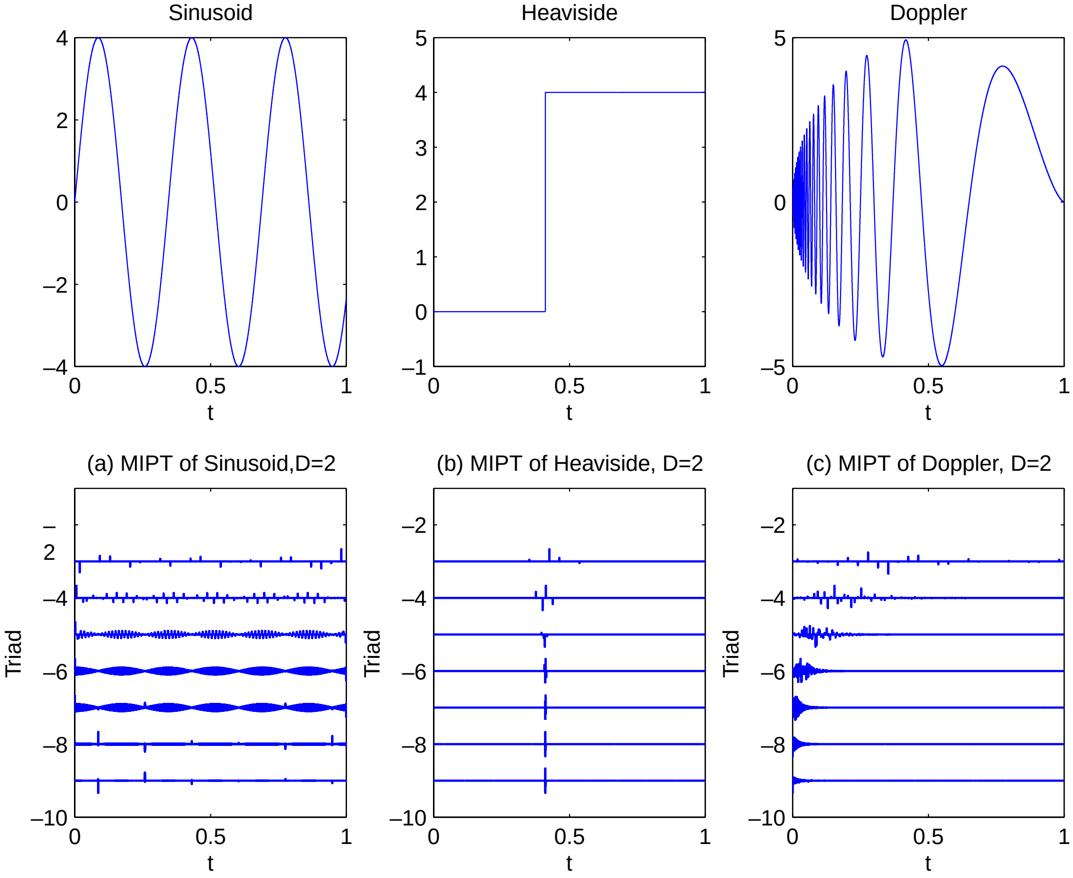

FIG. 4.1. *MIPT coefficients of three synthetic signals: Sinusoid, Heaviside, and Doppler. In each case, the plot of* $(\alpha_{j,k})_k$ *is scaled by* $\max_k |\alpha_{j,k}|$.

By (6.5), we can simply choose t_j satisfying $P(\sqrt{3^{J-j}}|\operatorname{med}(X_1, \dots, X_{3^{J-j}})| > t_j) \leq 3^{-J}/J$. Corollary 6.5 gives, when F is a symmetric law,

$$t_j := t_j(F) = \sqrt{3^{J-j}}F^{-1}\left(\frac{1}{2} + \frac{1}{2}\sqrt{1 - \left(\frac{1}{2J3^J}\right)^{\frac{2}{3^{J-j}}}}\right). \tag{5.2}$$

Careful study of (5.2) suggests to us that away from the finest scales, the magnitude of t_j is governed by the behavior of F^{-1} near $1/2$. Hence after standardizing the level and slope of F at $p = 1/2$ we expect that the threshold depends very little on F.

The discussion of the last few paragraphs has been informal, but the "weak dependence of thresholds on F" can be formalized. Consider classes of smooth distributions $\mathcal{F}(M, \eta)$ defined as follows. First, the distributions have densities f symmetric about 0, so that $F^{-1}(1/2) = 0$. Second, scale is standardized so that each density obeys $f(0) = 1/\sqrt{2\pi}$, the same as the standard Gaussian $N(0, 1)$. This is of course equivalent to setting $(F^{-1})'(1/2) = \sqrt{2\pi}$. Third, we impose on $F^{-1}(p)$ some regularity near

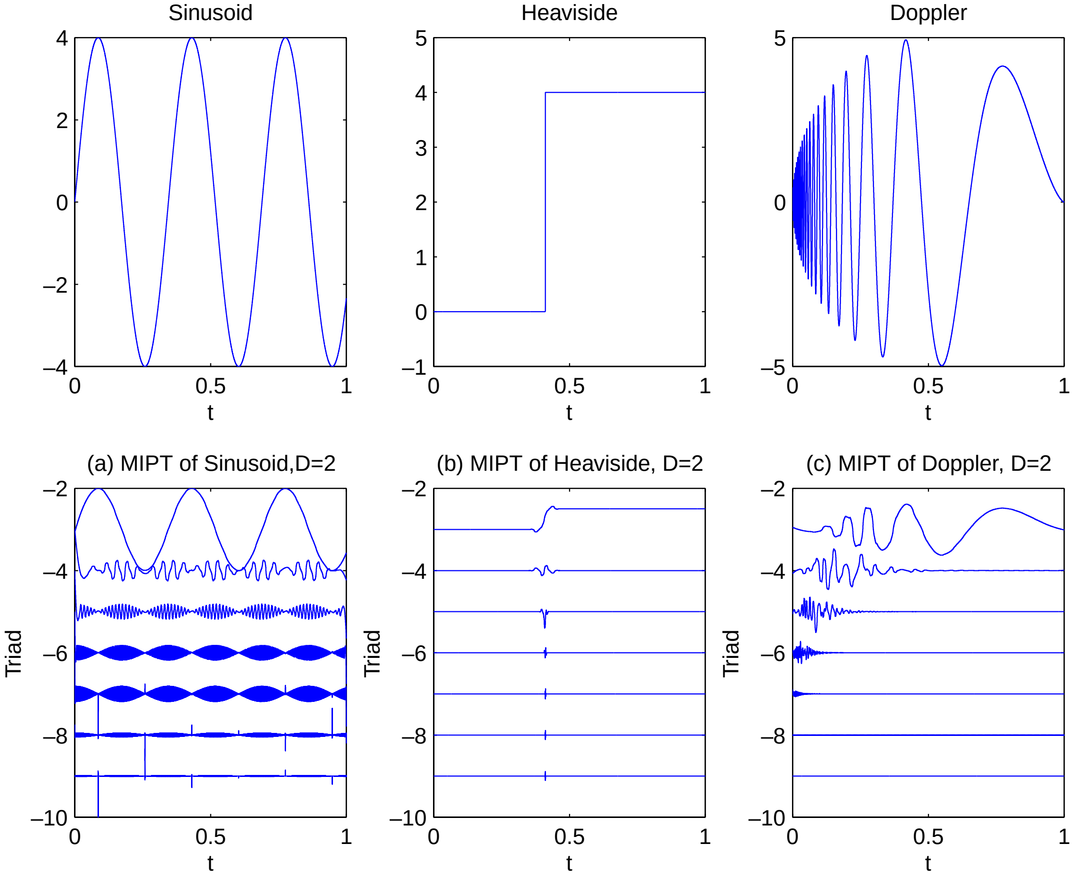

FIG. 4.2. *Nonlinear multiresolution analysis of three synthetic signals: Sinusoid, Heaviside, and Doppler. For Heaviside and Doppler, the plots of Q_j are scaled the same for all j; whereas for the Sinusoid, each Q_j is scaled by* $\max_k |(Q_j)_k|$.

$p = 1/2$: the existence of two continuous derivatives throughout $[1/2 - \eta, 1/2 + \eta]$. Our classes of symmetric distributions $\mathcal{F}(M, \eta)$ are then

$$\mathcal{F}(M,\eta) := \{F: \ f \text{ symmetric}, \ (F^{-1})'(1/2) = \sqrt{2\pi}, \ |(F^{-1})''(p)| \le M, \ |p - 1/2| \le \eta\},$$

where $M > 0$ and $0 < \eta < 1/2$ are absolute constants. The appendix proves the following theorem.

THEOREM 5.1. *For any $\epsilon > 0$ and $\theta \in (0,1)$, there exists $J^* = J^*(\epsilon, \theta, M, \eta)$ such that if $J \ge J^*$, then*

$$\max_{j \le \lfloor \theta J \rfloor} |t_j(F_1) - t_j(F_2)| \le \epsilon \qquad \textit{for all } F_1, F_2 \in \mathcal{F}(M,\eta).$$

5.2. Alpha-stable laws. Theorem 5.1 shows that a single set of MIPT thresholds can work not only for Gaussian data but also for a wide family of distributions—provided that we avoid the use of coefficients at the finest scales. To illustrate the theorem, we consider symmetric α-stable laws ($S\alpha S$) [27]. Alpha-stable laws are good models for many applications because of their high variability [24, 27].

Each symmetric α-stable law $S\alpha S$ is specified by its characteristic function $\exp(-\sigma^\alpha|\theta|^\alpha)$, with two parameters, (α,σ), $\alpha \in (0,2]$, $\sigma > 0$. The case $\alpha = 2$ is the Gaussian distribution with standard deviation $\sqrt{2}\sigma$ and density function $1/(\sqrt{2\pi}\sqrt{2}\sigma)\exp(-t^2/(4\sigma^2)$. The case $\alpha = 1$ is the Cauchy distribution with density $\sigma/(\pi(\sigma^2+t^2))$.

For our purposes, we consider $S\alpha S$ densities with σ calibrated so that the density at zero has the same value $1/\sqrt{2\pi}$ as the standard Gaussian. We denote the density and distribution of a $S\alpha S$ standardized in this way by f_α and F_α, respectively. Notice that

$$f_\alpha(t) = \frac{1}{2\pi}\int_{-\infty}^{+\infty} e^{-i\omega t}e^{-\sigma^\alpha|\omega|^\alpha}d\omega = \frac{1}{\pi}\int_0^\infty e^{-\sigma^\alpha\omega^\alpha}\cos(\omega t)d\omega \tag{5.3}$$

and therefore $f_\alpha(0) = \frac{1}{\sigma\pi}I(\alpha)$, where $I(\alpha) = \int_0^\infty e^{-\omega^\alpha}d\omega$. So f_α is properly calibrated by choosing

$$\sigma = \sigma_\alpha = \sqrt{2/\pi}\cdot I(\alpha). \tag{5.4}$$

It is clear from (5.3) that $f_\alpha(t)$ is smooth; the appendix proves the following lemma.

LEMMA 5.2. *Let $0 < \alpha_0 < 2$. $\{F_\alpha : \alpha \in [\alpha_0, 2]\}$ is a subset of a $\mathcal{F}(M,\eta)$ for appropriate M and η.*

Combining this with Theorem 5.1 gives the following corollary.

COROLLARY 5.3. *For any $\epsilon > 0$, $\theta \in (0,1)$ and $\alpha_0 \in (0,2)$, there exists $J^* = J^*(\epsilon,\theta,\alpha_0)$ such that if $J \geq J^*$, then*

$$\max_{j\leq\lfloor\theta J\rfloor}|t_j(F_{\alpha_1}) - t_j(F_{\alpha_2})| \leq \epsilon \qquad \textit{for all}\ \ \alpha_0 \leq \alpha_1,\alpha_2 \leq 2.$$

To illustrate Corollary 5.3, we compare $t_j(F_2)$ with $t_j(F_1)$ in Table 5.1.

While the Gaussian and Cauchy are widely different distributions, their MIPT thresholds are very close at coarse scales.

5.3. Denoising in Gaussian noise. In order to test the above ideas, we first report on the behavior of MIPT with Gaussian noise. Figure 5.1 shows two objects—Heaviside and Doppler—contaminated by Gaussian noise.

The figure also shows the results for (a) Doppler signal, thresholding in MIPT domain; (b) Doppler signal, thresholding in AIPT domain; (c) Heaviside signal, thresholding in MIPT domain; (d) Heaviside signal, thresholding in AIPT domain.

The thresholds t_j in both cases were set by (5.2). The performance of MIPT is comparable to the performance of AIPT, as we expect.

5.4. Denoising in heavy-tailed noise. Next we report on the behavior of MIPT with Cauchy noise. Figure 5.2 shows two objects—Heaviside and Doppler—contaminated by Cauchy noise.

The figure also shows the results for (a) Doppler signal, thresholding in MIPT domain; (b) Doppler signal, thresholding in AIPT domain; (c) Heaviside signal, thresholding in MIPT domain; (d) Heaviside signal, thresholding in AIPT domain.

The thresholds t_j for MIPT thresholding were again set by (5.2). As a control experiment, the same set of thresholds were used for AIPT thresholding. The performance of MIPT is much better than the performance of AIPT, as we expect.

Table 5.1
MIPT thresholds for Gaussian and Cauchy white noise.

6. Appendix: Proofs.

6.1. Preliminaries. Our proofs of P3–P5 rely on two basic facts about medians and median-interpolating refinement.

Lemma 6.1. *Let I be a closed interval and $||f-g||_{L^\infty(I)} \leq \epsilon$, then $|\operatorname{med}(f|I) - \operatorname{med}(g|I)| \leq \epsilon$.*

Proof. $\operatorname{med}(\cdot|I)$ is a monotone functional: $f \leq g \Rightarrow \operatorname{med}(f|I) \leq \operatorname{med}(g|I)$. If $||f-g||_{L^\infty(I)} \leq \epsilon$, then $f \leq g + \epsilon$ and

$$\operatorname{med}(f|I) \leq \operatorname{med}(g+\epsilon\,|I) = \operatorname{med}(g|I) + \epsilon.$$

By symmetry, we also get $\operatorname{med}(g|I) \leq \operatorname{med}(f|I) + \epsilon$. □

Lemma 6.2. *The operators $\Pi_{(2)}, Q_{(2)} : \mathbb{R}^3 \to \mathbb{R}^3$ are Lipschitz operators, i.e., if $\mathbf{m} = (m_1, m_2, m_3)^T$ and $\mathbf{m}' = (m_1', m_2', m_3')^T$, then $||\Pi_{(2)}(\mathbf{m}) - \Pi_{(2)}(\mathbf{m}')||_\infty \leq C \cdot ||\mathbf{m} - \mathbf{m}'||_\infty$ and $||Q_{(2)}(\mathbf{m}) - Q_{(2)}(\mathbf{m}')||_\infty \leq C' \cdot ||\mathbf{m} - \mathbf{m}'||_\infty$.*

Proof. We focus on the proof for $\Pi_{(2)}$; the proof for $Q_{(2)}$ is similar. The closed-form expressions (2.11) and (2.14–2.17) can be used to show that $a(\mathbf{m}), b(\mathbf{m}), c(\mathbf{m})$ are globally continuous, and even that they are analytic within each of the "branches" $\mathcal{N}_1 = \{\mathbf{m} : (m_3 - m_2)/(m_2 - m_1) \in [7/3, 5]\}$, $\mathcal{N}_2 = \{\mathbf{m} : (m_3 - m_2)/(m_2 - m_1) \in [1/5, 3/7]\}$, $\mathcal{N}_3 = \{\mathbf{m} : (m_3 - m_2)/(m_2 - m_1) \in [-3, -1/3]\}$, and $\mathcal{L} = \mathbb{R}^3 - \cup_{i=1}^3 \mathcal{N}_i$. In particular, $a(\mathbf{m}), b(\mathbf{m}), c(\mathbf{m})$ have bounded partial derivatives in each of $\mathcal{N}_i$ and constant partial derivatives in $\mathcal{L}$. Hence, there is a constant $C > 0$ such that if both $\mathbf{m}, \mathbf{m}'$ belong to one of $\mathcal{N}_i$ and $\mathcal{L}$, then

$$|| \left(a(\mathbf{m}), b(\mathbf{m}), c(\mathbf{m})\right)^T - \left(a(\mathbf{m}'), b(\mathbf{m}'), c(\mathbf{m}')\right)^T ||_\infty \leq C \cdot ||\mathbf{m} - \mathbf{m}'||_\infty. \tag{6.1}$$

It remains to show that (6.1) holds also without the restriction that $\mathbf{m}, \mathbf{m}'$ both have to belong to one of $\mathcal{N}_i$ and $\mathcal{L}$. Notice that each $\mathcal{N}_i$ is a *convex* set in $\mathbb{R}^3$ because

$$d_1 \leq \frac{m_3 - m_2}{m_2 - m_1} \leq d_2 \text{ and } d_1 \leq \frac{m_3' - m_2'}{m_2' - m_1'} \leq d_2$$

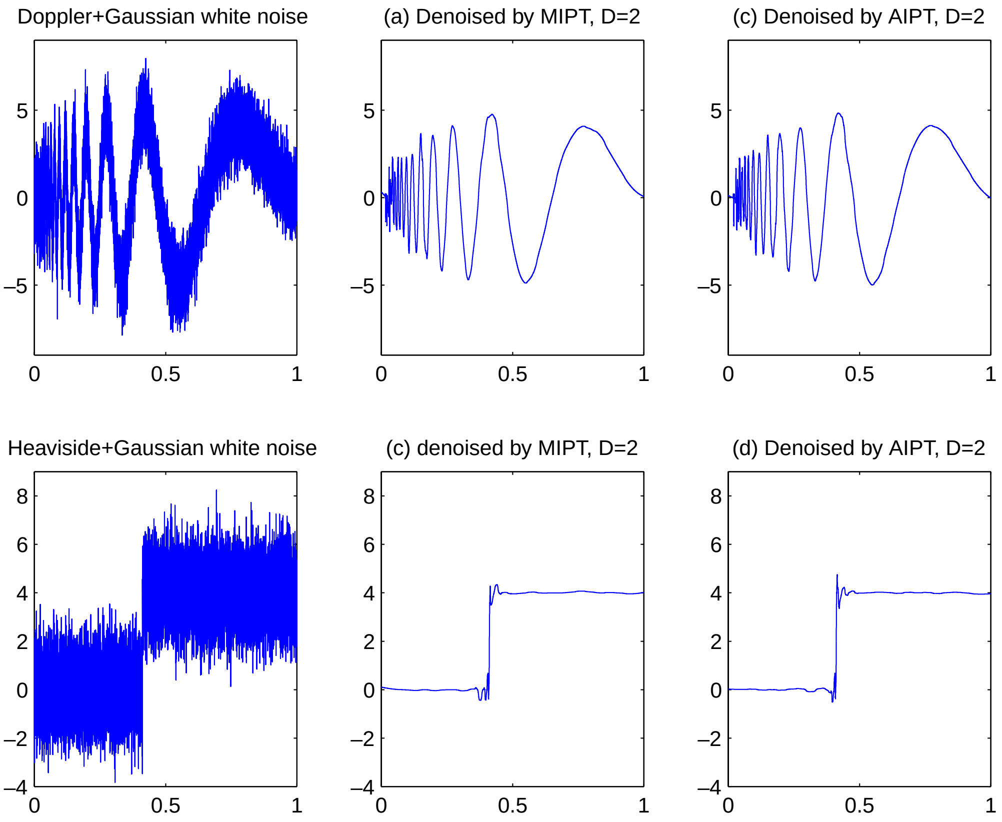

FIG. 5.1. *Denoising of Gaussian data with AIPT and MIPT thresholding.*

implies

$$d_1 \le \frac{(m_3 + t(m_3 - m_3')) - (m_2 + t(m_2 - m_2'))}{(m_2 + t(m_2 - m_2')) - (m_1 + t(m_1 - m_1'))} \le d_2 \quad \text{for all } t \in [0,1].$$

Also for each $d \in \mathbb{R}$, there is a unique $t \in \mathbb{R}$ such that $((m_3 + t(m_3 - m_3')) - (m_2 + t(m_2 - m_2')))/((m_2 + t(m_2 - m_2')) - (m_1 + t(m_1 - m_1'))) = d$. Since $\mathbb{R}$ is the disjoint union of the seven intervals $(-\infty, -3]$, $[-3, -1/3]$, $[-1/3, 1/5]$, $[1/5, 3/7]$, $[3/7, 7/3]$, $[7/3, 5]$, $[5, +\infty)$, we conclude that the line segment (in $\mathbb{R}^3$) joining $\mathbf{m}$ and $\mathbf{m}'$ is the disjoint union of at most seven subsegments each lying completely in one of the sets $\mathcal{N}_i$ and $\mathcal{L}$. Hence by replacing C by $7 \cdot C$ in (6.1) one makes the bound valid for all $\mathbf{m}$ and $\mathbf{m}'$. □

Comment. If $\mathbf{m}$, $\mathbf{m}'$ are associated with triadic intervals $I_{j,k+e}$, $e = -1, 0, 1$ and $\pi_{j,k}$ and $\pi'_{j,k}$ are the corresponding median-interpolants, then Lemma 6.2 also implies that $||\pi_{j,k} - \pi'_{j,k}||_{L^\infty(I_{j,k})} \le C||\mathbf{m} - \mathbf{m}'||_\infty$, where C is an absolute constant independent of $\mathbf{m}$, $\mathbf{m}'$, j, and k.

6.2. Proof of P3. We first recall a standard result in approximation theory.

LEMMA 6.3. *Let $f \in \dot{C}^{r+\alpha}$, $r = 0, 1, 2, \ldots$ and $0 \le \alpha \le 1$. Then there exists a constant C, proportional to the Hölder constant of f, so that for any small enough*

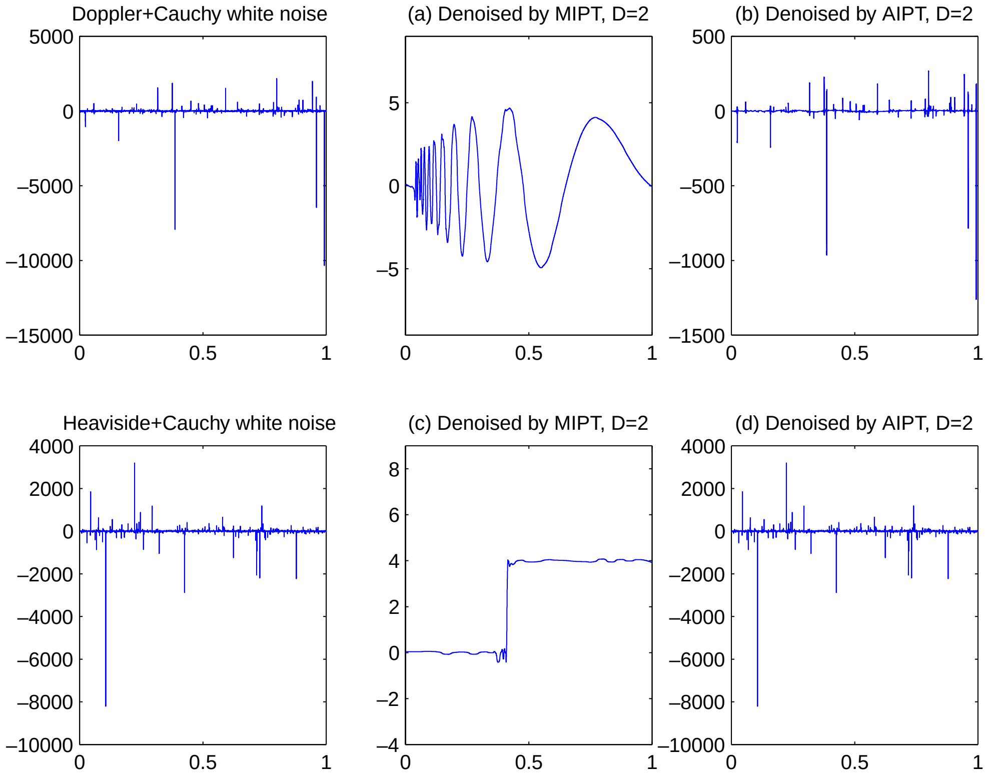

Fig. 5.2. *Denoising of Cauchy data with AIPT and MIPT thresholding.*

interval I, there is a polynomial π_I of degree r with

$$\|f - \pi_I\|_{L^\infty(I)} \le C|I|^{r+\alpha}.$$

Proof of P3. Let $f \in \dot{C}^{r+\alpha}$ ($r = 0, 1$, or 2, $0 \le \alpha \le 1$) and $I_{j,k}$ be an arbitrary triadic interval (with j large enough.) By Lemma 6.3, there exists a degree r polynomial, $\tilde{\pi}_{j,k}$, such that

$$||f - \tilde{\pi}_{j,k}||_{L^\infty(I_{j,k-1}\cup I_{j,k}\cup I_{j,k+1})} \le CC_1 3^{-(r+\alpha)j}. \tag{6.2}$$

Put for short $\epsilon = CC_1 3^{-(r+\alpha)j}$.

Recall the notation $m_{j,k} = \text{med}(f|I_{j,k})$ and let $\pi_{j,k}$ be the degree $D = 2$ polynomial that interpolates the block medians $m_{j,k'}$, $k' = k-1, \dots, k+1$. We want to show that $\pi_{j,k}$ is close to $\tilde{\pi}_{j,k}$. Denote $\tilde{m}_{j,k'} = \text{med}(\tilde{\pi}_{j,k}|I_{j,k'})$, by (6.2) and Lemma 6.1,

$$|m_{j,k'} - \tilde{m}_{j,k'}| \le \epsilon \text{ for } k' = k-1, k, k+1. \tag{6.3}$$

By Lemma 6.2 and (6.3),

$$\left\|\Pi_{(2)}(m_{j,k-1}, m_{j,k}, m_{j,k+1}) - \Pi_{(2)}(\tilde{m}_{j,k-1}, \tilde{m}_{j,k}, \tilde{m}_{j,k+1})\right\|_{L^\infty(I_{j,k})} \le c\epsilon.$$

But $\Pi_{(2)}(m_{j,k-1}, m_{j,k}, m_{j,k+1}) = \pi_{j,k}$ and $\Pi_{(2)}(\tilde{m}_{j,k-1}, \tilde{m}_{j,k}, \tilde{m}_{j,k+1}) = \tilde{\pi}_{j,k}$, hence

$$||f - \pi_{j,k}||_{L^\infty(I_{j,k})} \le ||f - \tilde{\pi}_{j,k}||_{L^\infty(I_{j,k})} + ||\pi_{j,k} - \tilde{\pi}_{j,k}||_{L^\infty(I_{j,k})} \le c''\epsilon. \tag{6.4}$$

Finally, use Lemma 6.1 and (6.4) to conclude that for $e = 0, 1, 2$,

$$|d_{j+1,3k+e}| = |\operatorname{med}(f|I_{j+1,3k+e}) - \operatorname{med}(\pi_{j,k}|I_{j+1,3k+e})| \leq c'''\epsilon$$

or to write it in a cleaner form, $|d_{j,k}| \leq c^{(iv)} \cdot C3^{-(r+\alpha)j}$, where $c^{(iv)} = c'''3^{r+\alpha}$. □

6.3. Proof of P4 and P5. Since

$$\alpha_{j,3k+\epsilon} = m_{j,3k+\epsilon} - (Q_{(2)}(m_{j-1,k-1}, m_{j-1,k}, m_{j-1,k+1}))_\epsilon$$

and $Q_{(2)}$ is Lipschitz (Lemma 6.2), there is a constant $c > 0$, independent of j and k, such that $|\alpha_{j,3k+\epsilon}| \leq c \cdot \max(|m_{j,3k+\epsilon}|, |m_{j-1,k-1}|, |m_{j-1,k}|, |m_{j-1,k+1}|)$. Boole's inequality gives for random variables W_i that

$$P(\max(W_1, \ldots, W_4) > \xi) \leq \sum_{i=1}^{4} P(W_i > \xi)$$

and so we can write

$$P(\sqrt{3^{J-j}}|\alpha_{j,k}| \geq \xi) \leq 4 \cdot P(\sqrt{3^{J-j}}|m_{j,k}| \geq \xi/c). \tag{6.5}$$

Thus, P4 and P5 boil down to the calculation of $P(\sqrt{n}|\operatorname{med}(X_1, \ldots, X_n)| \geq \xi)$ for $X_i \sim_{i.i.d.}$ Gaussian and Cauchy.

We first develop an inequality which derives from standard results in order statistics [6] and in Cramèr–Chernoff bounds on large deviations [7].

LEMMA 6.4. *Let $X_1, \ldots, X_n$ be i.i.d. with cumulative distribution function (c.d.f.) $F(\cdot)$. We have the following estimate:*

$$\begin{aligned} &P\{|(\operatorname{med}(X_1, \ldots, X_n)| \geq x\} \\ &\qquad \leq \min\left\{1, \left[2\sqrt{F(x)(1-F(x))}\right]^n + \left[2\sqrt{F(-x)(1-F(-x))}\right]^n\right\}. \end{aligned}$$

Proof. It suffices to show that $P(\operatorname{med}(X_1, \ldots, X_n) \geq x) \leq \left[2\sqrt{F(x)(1-F(x))}\right]^n$ for any $x \geq 0$. Let $I_i = 1_{(X_i \geq x)}$,

$$P\left(\operatorname{med}(X_1, \ldots, X_n) \geq x\right) \leq P\left(\sum_{i=1}^{n} I_i \geq \frac{n}{2}\right).$$

Since $I_i \sim_{\text{i.i.d.}} \text{Binomial}(1, 1-F(x))$, $S_n := \sum_{i=1}^n I_i \sim \text{Binomial}(n, 1-F(x))$. By $1_{(S_n \geq \frac{n}{2})} \leq e^{\lambda S_n} e^{-\lambda\frac{n}{2}}$ for all $\lambda > 0$, we have

$$\begin{aligned} P(S_n \geq \frac{n}{2}) &\leq \min_{\lambda>0} \mathrm{E}(e^{\lambda S_n} e^{-\lambda\frac{n}{2}}) = \min_{\lambda>0} e^{-\lambda\frac{n}{2}} \mathrm{E}(e^{\lambda\sum_1^n I_i}) \\ &= \min_{\lambda>0} e^{-\lambda\frac{n}{2}} \left(F(x) + (1-F(x))e^{\lambda}\right)^n = \left[\min_{\lambda>0} F(x)e^{-\frac{\lambda}{2}} + (1-F(x))e^{\frac{\lambda}{2}}\right]^n \\ &= \left(F(x)e^{-\frac{\lambda}{2}} + (1-F(x))e^{\frac{\lambda}{2}}|_{\lambda=\ln\left(\frac{F(x)}{1-F(x)}\right)}\right)^n = \left(2\sqrt{F(x)(1-F(x))}\right)^n. \quad \square \end{aligned}$$

COROLLARY 6.5. *Let $X_1, \ldots, X_n$ be i.i.d. with c.d.f. $F(x)$ having symmetric density f. Given $\alpha \in (0, 1/2)$, define*

$$t_{\alpha,n} := F^{-1}\left(\frac{1}{2} + \frac{1}{2}\sqrt{1 - \left(\frac{\alpha}{2}\right)^{\frac{2}{n}}}\right),$$

then

$$P\left(|\mathrm{med}(X_1,\dots,X_n)| \ge t_{\alpha,n}\right) \le \alpha.$$

We now apply Lemma 6.4 to the Gaussian and Cauchy distributions. Since they are both symmetric distributions, we have

$$\begin{aligned} P\left(\left|\sqrt{n}\ \mathrm{med}(X_1,\dots,X_n)\right| \ge \xi\right) &\le 2\cdot 2^n \sqrt{F\left(\frac{\xi}{\sqrt{n}}\right)\left(1-F\left(\frac{\xi}{\sqrt{n}}\right)\right)}^{\,n} \\ &= 2\cdot\left(\left[4F\left(y\right)\left(1-F\left(y\right)\right)\right]^{y^{-2}/2}\right)^{\xi^2} \\ &= 2\cdot\exp(\theta(y)\xi^2), \end{aligned}$$

where $y \equiv \xi/\sqrt{n}$ and $\theta(y) \equiv y^{-2}/2\cdot\log\left[4F\left(y\right)\left(1-F\left(y\right)\right)\right]$. Gaussian-type probability bounds will follow for a range $0 \le \xi \le X$ in P4 and P5, from an inequality $\sup_{[0,Y]}\theta(y) < 0$ on a corresponding range of values $0 \le y \le Y$, with $Y = X/\sqrt{n}$.

(i) Gaussian distribution: To establish P4, we need inequalities valid for $0 \le \xi < \infty$, i.e., $0 \le y < \infty$. Now

$$\sup_{y\in[2,\infty)} \theta(y) = \sup_{y\in[2,\infty)} y^{-2}/2\cdot\left[\log(1-F_2(y)) + \log(4F_2(y))\right].$$

From Mills' ratio $\int_y^\infty e^{-x^2/2}dx \le \frac{1}{y}e^{-y^2/2}$ holding for all $y > 1$, we have $\log(1-F_2(y)) \le -y^2/2 - \log(y)$. Hence

$$\sup_{y\in[2,\infty)} \theta(y) \le \sup_{y\in[2,\infty)} y^{-2}/2\cdot\left[-y^2/2 - \log(y) + \log(4)\right] = -(2-\log(2))/2 < 0.$$

On the other hand, from symmetry of F_2 and unimodality of the density f_2 we get $4F_2(y)(1-F_2(y)) = 4F_2(y)F_2(-y) \le 1 - cy^2$ on $|y| \le 2$, with $c > 0$; so

$$\sup_{y\in[0,2]} \theta(y) = \sup_{y\in[0,2]} y^{-2}/2\cdot\log(1-cy^2) \le -c/2.$$

(ii) Cauchy distribution: $F_1(x) = \frac{1}{2} + \frac{1}{\pi}\arctan\left(\sqrt{\frac{\pi}{2}}x\right)$. To get P5 we aim only for an inequality valid on $y \in [0,Y]$, with $Y = 1$, which gives a Gaussian-type inequality for $\xi \in [0,\sqrt{n}]$.

$$\theta(y) = y^{-2}/2\cdot\log\left[1 - \frac{4}{\pi^2}\arctan^2\left(\sqrt{\frac{\pi}{2}}y\right)\right] \le -y^{-2}/2\cdot\frac{4}{\pi^2}\arctan^2\left(\sqrt{\frac{\pi}{2}}y\right).$$

However, as $\arctan(y) > c\cdot y$ for $y \in [0,1]$, with $c > 0$, this gives $\theta(y) < -\frac{c^2}{\pi}$ for $y \in [0,1]$.

6.4. Proof of Theorem 5.1. Let $p = 1/(2J3^J)^2$, $n_j = 3^{J-j}$. Let j be chosen such that

$$1/2\sqrt{1-p^{1/n_j}} \le \eta. \tag{6.6}$$

Then there exist $0 < \eta_1, \eta_2 \le \eta$ such that

$$\begin{aligned} |t_j(F_1) - t_j(F_2)| &= \sqrt{n_j}\left|F_1^{-1}\left(\frac{1}{2}+\frac{1}{2}\sqrt{1-p^{\frac{1}{n_j}}}\right) - F_2^{-1}\left(\frac{1}{2}+\frac{1}{2}\sqrt{1-p^{\frac{1}{n_j}}}\right)\right| \\ &= \sqrt{n_j}\left|(F_1^{-1})''(1/2+\eta_1) - (F_2^{-1})''(1/2+\eta_2)\right|\left(\frac{1}{2}\sqrt{1-p^{\frac{1}{n_j}}}\right)^2 \\ &\le M/2\sqrt{n_j}\left(1-p^{\frac{1}{n_j}}\right), \end{aligned}$$

i.e., $|t_j(F_1) - t_j(F_2)| \leq \epsilon$ if

$$\sqrt{n_j}\left(1 - p^{\frac{1}{n_j}}\right) \leq \frac{2\epsilon}{M}. \tag{6.7}$$

Since $(1-x) \leq \log(1/x)$ for all $x \in (0,1]$, (6.6) holds for large enough J because

$$\begin{aligned}\frac{1}{2}\sqrt{1 - p^{1/n_j}} \leq \frac{1}{2}\sqrt{\log p^{-1/n_j}} &= \frac{1}{2}\sqrt{\frac{1}{n_j}\log(4 \cdot J^2 \cdot 3^{2J})} \\ &\leq \frac{1}{2}\sqrt{\frac{1}{3^{(1-\theta)J}}(\log(4) + 2\log(J) + 2J\log(3))} \to 0 \text{ as } J \to 0.\end{aligned}$$

Similarly, (6.7) holds for large enough J because

$$\begin{aligned}\sqrt{n_j}\left(1 - p^{\frac{1}{n_j}}\right) &\leq (1/\sqrt{n_j})\log p^{-1} \\ &\leq \frac{1}{\sqrt{3^{(1-\theta)J}}}(\log(4) + 2\log(J) + 2J\log(3)) \to 0 \text{ as } J \to 0. \qquad \square\end{aligned}$$

6.5. Proof of Lemma 5.2. It suffices to find M, η such that

$$\sup_{\alpha \in [\alpha_0, 2]} \sup_{p \in [\frac{1}{2}-\eta, \frac{1}{2}+\eta]} (F_\alpha^{-1})''(p) \leq M.$$

Since

$$(F_\alpha^{-1})''(p) = -\frac{f_\alpha'(F_\alpha^{-1}(p))}{[f_\alpha(F_\alpha^{-1}(p))]^3},$$

we work with F_α^{-1}, f_α, and f_α' separately.

1. Since $|F_\alpha^{-1}(p)|$ is monotone increasing in p for fixed α, and is monotone increasing in α for fixed p, we have, for any $0 < \eta < 1/2$,

$$\sup_{0<\alpha\leq 2} \sup_{1/2-\eta \leq p \leq 1/2+\eta} |F_\alpha^{-1}(p)| = F_2^{-1}(1/2 + \eta).$$

2. Now $\sup_{|t|\leq\epsilon_1} |f_\alpha(t) - f_\alpha(0)| \leq |t| \cdot \{\sup_{|t|\leq\epsilon_1} |f_\alpha'(t)|\}$. Also

$$\begin{aligned}\sup_{|t|\leq\epsilon_1} |f_\alpha'(t)| &= \sup_{|t|\leq\epsilon_1}\left|\frac{1}{\pi}\int_0^\infty e^{-\sigma_\alpha^\alpha\omega^\alpha}(-\omega)\sin(\omega t)d\omega\right| \\ &\leq \frac{1}{\pi}\int_0^\infty e^{-\sigma_\alpha^\alpha\omega^\alpha}\omega d\omega = \frac{1}{\pi}\frac{1}{\sigma_\alpha^2}\int_0^\infty e^{-\omega^\alpha}\omega d\omega \leq C_1(\alpha_0),\end{aligned}$$

where $C_1(\alpha) = \frac{1}{2}(\int_0^\infty e^{-\omega^\alpha}\omega d\omega)/(\int_0^\infty e^{-\omega^\alpha}d\omega)^2$ is defined on $(0,2]$ and is positive and monotone decreasing.

3. Similarly $\sup_{|t|\leq\epsilon_1} |f_\alpha'(t) - f_\alpha'(0)| \leq |t| \cdot \{\sup_{|t|\leq\epsilon_1} |f_\alpha''(t)|\}$. Moreover

$$\begin{aligned}\sup_{|t|\leq\epsilon_1} |f_\alpha''(t)| &= \sup_{|t|\leq\epsilon_1}\left|\frac{1}{\pi}\int_0^\infty e^{-\sigma_\alpha^\alpha\omega^\alpha}(\omega^2)\cos(\omega t)d\omega\right| \\ &\leq \frac{1}{\pi}\int_0^\infty e^{-\sigma_\alpha^\alpha\omega^\alpha}\omega^2 d\omega = \frac{1}{\pi}\frac{1}{\sigma_\alpha^3}\int_0^\infty e^{-\omega^\alpha}\omega^2 d\omega \leq C_2(\alpha_0),\end{aligned}$$

where $C_2(\alpha) = \frac{1}{2}\sqrt{\frac{\pi}{2}}(\int_0^\infty e^{-\omega^\alpha}\omega^2 d\omega)/(\int_0^\infty e^{-\omega^\alpha} d\omega)^3$ is defined on $(0, 2]$ and is positive and monotone decreasing. Therefore

$$\begin{aligned}\sup_{\alpha\in[\alpha_0,2]} \sup_{p\in[\frac{1}{2}-\eta,\frac{1}{2}+\eta]} |(F_\alpha^{-1})''(p)| &= \sup_{\alpha\in[\alpha_0,2]} \sup_{p\in[\frac{1}{2}-\eta,\frac{1}{2}+\eta]} \frac{|f'_\alpha(F_\alpha^{-1}(p))|}{|f_\alpha(F_\alpha^{-1}(p))|^3} \\ &\le \frac{|F_2^{-1}(\frac{1}{2}+\eta)|C_2(\alpha_0)}{\left|\frac{1}{\sqrt{2\pi}} - F_2^{-1}(\frac{1}{2}+\eta)C_1(\alpha_0)\right|^3}. \qquad (6.8)\end{aligned}$$

If we choose $\eta = \eta(\alpha_0) > 0$ small enough such that $F_2^{-1}(\frac{1}{2}+\eta)C_1(\alpha_0) < \frac{1}{\sqrt{2\pi}}$, then with the choice of $M = M(\alpha_0)$ defined by (6.8) we get $\{F_\alpha : \alpha_0 \le \alpha \le 2\} \subset \mathcal{F}(M(\alpha_0), \eta(\alpha_0))$. □

Reproducible research. In this paper, all computational results are reproducible, meaning that the code which generated the figures is available over the Internet, following the discipline indicated in [3]. Interested readers are directed to http://www-stat.stanford.edu/˜wavelab/.

ORTHONORMAL RIDGELETS AND LINEAR SINGULARITIES[*]

DAVID L. DONOHO[†]

Abstract. We construct a new orthonormal basis for $L^2(\mathbb{R}^2)$, whose elements are angularly integrated ridge functions—*orthonormal ridgelets*. The basis elements are smooth and of rapid decay in the spatial domain, and in the frequency domain are localized near angular wedges which, at radius $r = 2^j$, have radial extent $\Delta r \approx 2^j$ and angular extent $\Delta\theta \approx 2\pi/2^j$.

Orthonormal ridgelet expansions expose an interesting phenomenon in nonlinear approximation: they give very efficient approximations to objects such as $1_{\{x_1 \cos\theta + x_2 \sin\theta > a\}}\ e^{-x_1^2 - x_2^2}$ which are smooth away from a discontinuity along a line. The orthonormal ridgelet coefficients of such objects are *sparse*: they belong to every ℓ^p, $p > 0$. This implies that simple thresholding in the ridgelet orthobasis is, in a certain sense, a near-ideal nonlinear approximation scheme for such objects.

Orthonormal ridgelets may be viewed as L^2 substitutes for approximation by sums of ridge functions, and so can perform many of the same tasks as the ridgelet systems constructed by Candès [Ph.D. Thesis, Department of Statistics, Stanford University, Stanford, CA, 1998; *Appl. Comput. Harmon. Anal.*, 6 (1999), pp. 197–218]. Orthonormal ridgelets make available the machinery of orthogonal decompositions, which is not available for ridge functions as they are not in $L^2(\mathbb{R}^2)$.

The ridgelet orthobasis is constructed as the isometric image of a special wavelet basis for Radon space; as a consequence, ridgelet analysis is equivalent to a special wavelet analysis in the Radon domain. This means that questions of ridgelet analysis of linear singularities can be answered by wavelet analysis of point singularities. At the heart of our nonlinear approximation result is the study of a certain tempered distribution on $\mathbb{R}^2$ defined formally by $S(u, v) = |v|^{-1/2}\sigma(u/|v|)$ with σ a certain smooth bounded function; this is singular at $(u, v) = (0, 0)$ and C^∞ elsewhere. The key point is that the analysis of this point singularity by tensor Meyer wavelets yields sparse coefficients at high frequencies; this is reflected in the sparsity of the ridgelet coefficients and the good nonlinear approximation properties of the ridgelet basis.

Key words. wavelets, singularities, edges, ridge function, ridgelet, radon transform, nonlinear approximation, thresholding of wavelet coefficients

1. Introduction.

1.1. Sparse representation of singularities.

One of the most striking features of wavelet analysis is its ability to efficiently represent functions which are smooth away from *point singularities.* To see what we mean, consider the function $f_\alpha(x) = |x|^{-\alpha}w(x)$ of $x \in \mathbb{R}^2$, where $w(x)$ is a smooth window of compact support and $\alpha < 1/2$. Now f is smooth away from 0 and has a square-integrable singularity at the point $x = 0$. The coefficients of f in the Meyer orthonormal wavelet basis are *sparse*: arranging them in decreasing order of magnitude gives a sequence decaying more rapidly than any negative power of the index. In this regard, the wavelet coefficients of a point singularity behave similarly to the wavelet coefficients of a smooth function (such as $w(x)$); the sparsity of a wavelet analysis is in a sense insensitive to the presence of point singularities.

Sparsity of the wavelet coefficients has implications for the quality of partial wavelet reconstructions. If we approximate a function using just the m-best terms in

the wavelet expansion, and if the coefficients are sparse in the sense just given, then the L^2 error of best-m-term approximation decays rapidly with m—faster than any negative power of m. Hence, the fact that wavelet analysis of a point singularity yields sparse coefficients means that smooth functions with point singularities can be very efficiently approximated by partial wavelet reconstructions. This fact has significant implications in data compression and in statistical estimation. (Extensive references on these implications are given in [6], [7].

Point singularities are just one possible type of singularity. Consider the Gaussian-windowed halfspace

$$g^0(x_1, x_2) = 1_{\{x_2>0\}}\, e^{-x_1^2-x_2^2}, \qquad x \in \mathbb{R}^2. \tag{1.1}$$

This has a singularity along the line $x_2 = 0$. One can also consider the more general family

$$g(x_1, x_2; \theta^0, x^0) = 1_{\{x_1\cos(\theta^0)+x_2\sin(\theta^0)>t^0\}} e^{-x_1^2-x_2^2}, \tag{1.2}$$

where $t^0 = x_1^0 \cos(\theta^0) + x_2^0 \sin(\theta^0)$. These functions have a discontinuity along the line $t^0 = x_1 \cos(\theta^0) + x_2 \sin(\theta^0)$ and are smooth elsewhere.

For typical functions of the type (1.1)–(1.2), wavelets do *not* yield sparse coefficients as they did with $f_{0,\alpha}$. For example, in $\mathbb{R}^2$, an object of type g is easily seen to have typically at least order $O(2^j)$ standard wavelet coefficients with amplitude exceeding 2^{-j}. So the mth largest wavelet coefficient of such an object is often of size $\geq c \cdot m^{-1}$ for $c > 0$; this is much poorer decay than what we saw earlier in the case of point singularities, where the decay was faster than any negative power of m. In consequence, m-term wavelet reconstructions do not approximate such objects with the kind of efficiency we saw earlier in the case of point singularities. We can formulate this conclusion more boldly by saying that *wavelets do not efficiently approximate edges in* $\mathbb{R}^2$.

Similar conclusions are possible for Fourier methods. If we consider a function f which is compactly supported in $[0, 2\pi)^2$ and which is smooth away from a linear singularity, and we use the standard bivariate Fourier series to approximate f, we get order $m^{4/3}$ coefficients larger than c/m. So Fourier methods give coefficients which are even less sparse than wavelet coefficients. We can again formulate this conclusion more boldly by saying that *Fourier methods also do not efficiently approximate edges in* $\mathbb{R}^2$.

Observations such as these—and the relative ubiquity of edges in certain applications (such as image processing)—point to the need for better systems of harmonic analysis, ones which efficiently deal with edges, or in another terminology, transforms for which objects like g have sparse coefficients.

1.2. Orthonormal ridgelets. In this article, we introduce a new basis for functions in $L^2(\mathbb{R}^2)$: the *orthonormal ridgelets*, defined as follows. Let $(\psi_{j,k}(t) : j \in \mathbb{Z}, k \in \mathbb{Z})$ be an orthonormal basis of Meyer wavelets for $L^2(\mathbb{R})$ [14], and let $(w^0_{i_0\ell}(\theta),\ \ell = 0, \ldots, 2^{i_0}-1;\ w^1_{i,\ell}(\theta),\ i \geq i_0,\ \ell = 0, \ldots, 2^i-1)$ be an orthonormal basis for $L^2[0, 2\pi)$ made of periodized Lemarié scaling functions $w^0_{i_0\ell}$ at level i_0 and periodized Meyer wavelets $w^1_{i\ell}$ at levels $i \geq i_0$. (We suppose a particular normalization of these functions given in (2.8) below.) Let $\hat{\psi}_{j,k}(\omega)$ denote the Fourier transform of $\psi_{j,k}(t)$, and define ridgelets $\rho_\lambda(x)$, $\lambda = (j, k; i, \ell, \varepsilon)$ as functions of $x \in \mathbb{R}^2$ using the frequency-domain definition

$$\hat{\rho}_\lambda(\xi) = |\xi|^{-\frac{1}{2}} (\hat{\psi}_{j,k}(|\xi|) w^\varepsilon_{i,\ell}(\theta) + \hat{\psi}_{j,k}(-|\xi|) w^\varepsilon_{i,\ell}(\theta + \pi))/2. \tag{1.3}$$

Here the indices run as follows: $j, k \in \mathbb{Z}$, $\ell = 0, \ldots, 2^{i-1} - 1$; $i \geq i_0$, and, if $\varepsilon = 0$, $i = \max(i_0, j)$, while if $\varepsilon = 1$, $i \geq \max(i_0, j)$. Notice the restrictions on the range of i, ℓ. Let Λ denote the set of all such indices λ.

Sections 2 and 3 below establish the following theorem.

Theorem 1.1. *$(\rho_\lambda)_{\lambda \in \Lambda}$ is a complete orthonormal system for $L^2(\mathbb{R}^2)$.*

Define now $\psi^+_{j,k}(t) = \frac{1}{2\pi}\int_{-\infty}^{\infty} |\omega|^{\frac{1}{2}} \hat{\psi}_{j,k}(\omega)\ e^{i\omega t} d\omega$; this is a fractionally differentiated Meyer wavelet. Section 4 below shows the following theorem.

Theorem 1.2. *For $x = (x_1, x_2) \in \mathbb{R}^2$,*

$$\rho_\lambda(x) = \frac{1}{4\pi} \int_0^{2\pi} \psi^+_{j,k}(x_1 \cos\theta + x_2 \sin\theta) w^\varepsilon_{i,\ell}(\theta) d\theta. \tag{1.4}$$

Each $\psi^+_{j,k}(x_1 \cos\theta + x_2 \sin\theta)$ is a *ridge* function of $x \in \mathbb{R}^2$, i.e., a function of the form $r(x_1 \cos\theta + x_2 \sin\theta)$ [13]. Therefore ρ_λ is obtained by "averaging" ridge functions with ridge angles θ localized near $\theta_{i,\ell} = 2\pi\ell/2^i$; this justifies the "ridgelet" appellation.

1.3. Singularities along lines. Our purpose in this article is to show that orthonormal ridgelets yield efficient representation of objects with linear singularities. We prove in section 5 below the following result for the Gaussian-windowed halfspace $g = g^0$ defined in (1.1).

Theorem 1.3. *The number of ridgelet coefficients of g with amplitude exceeding $1/N$ grows with N more slowly than any fractional power of N.*

In section 6 we consider the general family of smooth functions with linear singularities (1.2). We show that the conclusion of Theorem 1.3 holds for every $g = g(\cdot, \cdot; \theta^0, x^0)$, where $x^0 \in \mathbb{R}^2$ and $\theta^0 \in [0, 2\pi)$. In short, the ridgelet coefficients of such g are *sparse.*

This striking phenomenon may convince the reader that wavelets and other traditional harmonic analysis tools can be substantially improved on as soon as one leaves the setting of pure point singularities.

1.4. Significance for nonlinear approximation and data compression. We now briefly describe the importance of the sparsity of ridgelet expansions for nonlinear approximation and data compression. In effect, the sparsity phenomenon means that a very few select terms will provide good approximation and a good encoding can be had with relatively few bits. Here "relatively few" means as compared with similar encoding schemes based on wavelet or Fourier coefficients.

Consider the following simple nonlinear approximation scheme. Let $\eta_\delta(y) = y 1_{\{|y|>\delta\}}$ denote the *hard thresholding nonlinearity* with threshold $\delta > 0$. With g one of the functions (1.2), define

$$\tilde{g}_\delta = \sum_\Lambda \eta_\delta(\langle g, \rho_\lambda \rangle) \rho_\lambda.$$

This is a finite sum of ridgelets, with $N(\delta) = \sum_\Lambda 1_{\{|\langle g, \rho_\lambda \rangle| > \delta\}}$ terms, built from those ridgelets having large coefficients only. As the threshold $\delta \to 0$, more terms enter the sum, and in general $N(\delta) \uparrow \infty$. Define a sequence of approximants $(\overline{g}_N)$ via $\overline{g}_{N(\delta)} = \tilde{g}_\delta$. These are nonlinear approximants, since the terms which enter in the sum are those which survive thresholding, and this depends on g.

The approximants $(\overline{g}_N)$ converge rapidly to g; from Theorem 1.3, one can see that for each $m > 0$, there is a constant C_m with

$$\|g - \overline{g}_N\|_{L^2(\mathbb{R}^2)} \leq C_m N^{-m}, \qquad N \to \infty.$$

In other words, ridgelets achieve an unlimited rate of approximation. We interpret this by saying that nonlinear ridgelet approximations behave very well for functions which are piecewise smooth, where the boundary between pieces is a line. In comparison, nonlinear wavelet approximations have similar rapid convergence properties for functions which have a punctuated smoothness, i.e., functions which are C^∞ away from isolated point singularities. However, wavelets do not exhibit similarly rapid convergence on objects with discontinuities along linear boundaries, requiring N coefficients to get $O(N^{-1})$ approximation in mean-square.

This fact can be significant for data compression as well. By simply encoding the significant ridgelet coefficients with finite accuracy approximations to the coefficients, and encoding the positions of the coefficients economically, one obtains a finite-precision ridgelet representation of an object; when that object is smooth except for singularities across linear boundaries this representation uses many fewer bits than would be required in wavelet encoding of similar precision. Simple calculations reveal that the number of bits required for ridgelet encoding to accuracy ε in mean square is nearly logarithmic in ε^{-1} as $\varepsilon \to 0$, while the number of bits required for wavelet encoding grows like ε^{-1}. The dramatic difference in growth between $\log(\varepsilon^{-1})$ and ε^{-1} as $\varepsilon \to 0$ quantifies explicitly the extent to which ridgelet methods are better suited towards dealing with edges along linear boundaries.

Ultimately, of course, one wants to go beyond the representation of objects with singularities along lines, to consider the representation of objects with singularities along curves. While ridgelets are essentially focused on dealing with straight lines rather than curves, ridgelets can be adapted to representing objects with curved edges using an appropriate multiscale localization. In effect, multiscale ridgelet expansions divide the image into small dyadic pieces on which the curved edges are nearly straight and uses ridgelet expansions on those pieces. This can be used to obtain expansions of objects with discontinuities along curved edges having significantly more rapid decay of coefficients than the traditional wavelet and Fourier methods. For further discussion on applications see [3].

1.5. On the ridgelet concept. The orthonormal ridgelets are in $L^2(\mathbb{R}^2)$ and so are to be distinguished from the approximation system called ridgelets in the pioneering work of Candès [2], [1]. In Candès' work, the phrase "ridgelet" refers specifically to a ridge function $\psi_{a,b,\theta}(x) = \psi(a(x_1\cos(\theta) + x_2\sin(\theta)) - b)a^{1/2}$, where ψ is oscillatory. As $\psi_{a,b,\theta}$ is constant along "ridges" $x_1\cos(\theta) + x_2\sin(\theta)) = \text{Const}$ and so cannot belong to L^2. This fact creates certain difficulties of construction and interpretation. In order to obtain a method of series representation, Candès constructs "ridgelet frames," where the individual elements of the so-called primal frame have the ridge structure, for appropriate (a_n, b_n, θ_n). This frame construction assumed that the object to be analyzed was supported in a compact set D; frame bounds were established under this condition which proved implicitly the existence of a dual synthesis system in $L^2(D)$. Unfortunately, the construction of dual frames was implicit, depending, for example, on the assumed D, and the properties of the dual frame elements were not available directly, and so it was unclear how to obtain any substantial insight about the structure of the frame expansions. Thus one had a system with analyzing functions of known form, but synthesizing functions of little-known form. Also, owing to the lack of orthogonality, it was unclear how to make good m-term approximations built from such frames.

In the present article we adopt a modified notion of ridgelet, abandoning insistence on the ridge-function form for the elements of the analyzing system, and instead taking the viewpoint that ridgelets should be characterized by certain localization properties they obey in a radial frequency × angular-frequency domain. The formula (1.3) shows that orthonormal ridgelets are localized in the frequency domain into elongated wedges. In polar coordinates these wedges have radial extent 2^j and angular width $2\pi/2^i$ for $i \geq j$. Under this modified notion of ridgelet, this paper shows that it is possible to explicitly construct orthonormal ridgelet bases in $L^2(\mathbb{R}^2)$, in effect, with basis functions available using the simple formula (1.3).

The orthonormal approach has the benefit that analysis functions and synthesis functions are identical and are smooth functions of rapid decay. Moreover, orthonormal ridgelets do not require the object being analyzed to have compact support. The orthonormal approach also has benefits for allowing simple, effective nonlinear approximation. Best-m-term nonlinear approximation in an orthonormal system can be based on simple thresholding ideas. A further benefit is the fact that the orthonormal ridgelet coefficients can be identified with the properties of bivariate wavelet analysis of a fractionally differentiated Radon transform. This identification is used below to show that orthonormal ridgelet coefficients are sparse when analyzing certain smooth objects with linear singularities in $\mathbb{R}^2$.

Throughout this paper, the term ridgelets refers to the system of orthonormal ridgelets introduced here, and not to ridgelet analysis based on ridge functions. We believe that our use of the ridgelets name is sensible because we can show close connections of orthonormal ridgelets to the original ridge function concept. Theorem 1.2 is an instance of this connection; see section 4 below. The companion paper [9] explores carefully the connection between orthonormal ridgelets and ridge functions and gives results showing that orthonormal ridgelets are an effective substitute for ridge function approximation. In effect, that paper shows that a ridge function $\psi^+_{j,k}(x_1\cos(\theta) + x_2\sin(\theta))$ can be approximated with high accuracy $1/N^m$ on a disk of fixed radius using a number of orthonormal ridgelets which grows basically logarithmically in N. In short, "a ridge function is essentially a sum of a few orthonormal ridgelets." This further justifies our use of the ridgelet appellation to label the basis constructed here.

1.6. Wavelet analysis in Radon space. A key structural feature in the proofs of Theorems 1.1–1.3 is the fact that ridgelet analysis is intimately connected with wavelet analysis in Radon space. If $(Rf)(t,\theta)$ denotes the Radon transform of f at direction θ and position t, and τ_λ denotes the antipodally symmetrized version of $\psi^+_{j,k} \otimes w^\varepsilon_{i,\ell}$, then section 4 below shows that

$$\langle \rho_\lambda, f\rangle = \frac{1}{4\pi}\iint Rf(t,\theta)\tau_\lambda(t,\theta)dt\, d\theta. \tag{1.5}$$

Hence orthonormal ridgelet analysis amounts to a nonorthogonal wavelet analysis in Radon space. Moreover, there is a kind of Parseval relation giving an isometry between these nonorthogonal wavelet coefficients and the orthogonal ridgelet coefficients.

Because of this connection, ridgelet analysis of g is connected with wavelet analysis of Rg and, finally, the question of efficient approximation of g by ridgelets is reduced to the question of efficient approximation of Rg by wavelets. Now, if g has a singularity along a line, then Rg has a point singularity. Hence the effectiveness of ridgelet representation of objects which are smooth away from point singularities is reduced to the question of efficiency of wavelet representation of objects which are smooth away from point singularities. In sections 5 and 6 below, where the proof of Theorem 1.3 is given, this point is made by showing that the sparsity of ridgelet coefficients of objects $g(x) = g(x;\theta^0, x^0)$ is quite explicitly connected with sparsity of the high-frequency Meyer tensor wavelet coefficients of a singularity S formally defined by $S(u,v) = |v|^{-1/2}\sigma(u/|v|)$ for a certain smooth bounded function $\sigma(u)$.

1.7. Ridgelet-wavelet duality. Besides providing a useful tool in proofs, (1.5) shows an interesting duality between ridgelets and wavelets: they are good for complementary tasks.

In some sense wavelet analysis is very effective at representing objects with isolated point singularities, i.e., it takes only a few terms to obtain a reasonable approximation to such singularities. As we have just said, (1.5) means that ridgelet analysis can be very effective at representing objects with isolated point singularities *in the Radon domain*, in other words, objects with singularities along lines.

At the same time, wavelets are not efficient at representing objects with singularities along lines; nor, *therefore*, are ridgelets effective at representing objects with point singularities. Indeed, a point singularity in real space is a singularity along a sinusoidal curve in Radon space—and so, exactly as wavelets fail to deal efficiently with singularities along curves, so must ridgelets fail to deal efficiently with point singularities.

2. An orthobasis in Radon space. For a smooth function $f(x) = f(x_1, x_2)$ of rapid decay, let Rf denote the Radon transform of f, the integral along a line $\mathcal{L}_{(\theta,t)}$, expressed using the Dirac mass δ as

$$(Rf)(t,\theta) = \int f(x)\delta(x_1\cos\theta + x_2\sin\theta - t)\ dx, \tag{2.1}$$

where we permit $\theta \in [0, 2\pi)$ and $t \in \mathbb{R}$. For more information about the Radon transform see, for example, [5], [11]. Observe that the line $\mathcal{L}_{(\theta,t)}$ is identical to the line $\mathcal{L}_{(\theta+\pi,-t)}$. As a result, Rf has the *antipodal symmetry*

$$(Rf)(-t, \theta + \pi) = (Rf)(t,\theta). \tag{2.2}$$

This is a fundamental fact about the Radon transform which affects much of the notation in what follows. We adopt the convention that F (and G and variants) typically will denote a function on $\mathbb{R} \times [0, 2\pi)$ obeying the same antipodal symmetry:

$$F(-t, \theta + \pi) = F(t,\theta). \tag{2.3}$$

To create a space of such objects, we let $[\ ,\ ]$ denote the pairing

$$[F,G] = \frac{1}{4\pi}\int_0^{2\pi}\int_{-\infty}^{\infty} F(t,\theta)\bar{G}(t,\theta)dt\ d\theta, \tag{2.4}$$

and by $L^2(dt\ d\theta)$-norm we mean $\|F\|^2 = [F,F]$. Let $\mathcal{R}$ be the closed subspace of $L^2(dt\ d\theta)$ of functions F obeying (2.3). For later use, let $P_{\mathcal{R}}F$ be the orthoprojector from $L^2(dt\ d\theta)$ onto $\mathcal{R}$, defined by

$$(P_{\mathcal{R}}F)(t,\theta) = (F(t,\theta) + F(-t,\theta+\pi))/2. \tag{2.5}$$

We recall now the Meyer wavelets $\psi_{j,k}$, $j \in \mathbb{Z}$, $k \in \mathbb{Z}$, of the introduction, and the Lemarié–Meyer periodic wavelets $(w^0_{i_0,\ell} : \ell = 0, \ldots, 2^{i_0} - 1)$, $(w^1_{i,\ell} : i \geq i_0,\ \ell = 0, \ldots, 2^i - 1)$. For convenience in proofs below, we assume that the periodic Meyer wavelets are obtained by periodization of standard Meyer wavelets for $\mathbb{R}$: with a constant γ_1,

$$w^1_{i,\ell}(\theta) = \gamma_1 \cdot \sum_{h=-\infty}^{\infty} \psi_{i,\ell+h2^i}(\theta/2\pi), \quad i \geq i_0 > 0, \quad \ell = 0, \ldots, 2^i; \tag{2.6}$$

and that the periodic Lemarié scaling functions are obtained by periodization of standard Lemarié scaling functions for $\mathbb{R}$: with a constant γ_2,

$$w^0_{i_0,\ell}(\theta) = \gamma_2 \cdot \sum_{h=-\infty}^{\infty} \phi_{i_0,\ell+h2^{i_0}}(\theta/2\pi), \quad \ell = 0, \ldots, 2^{i_0}, \tag{2.7}$$

where $\phi_{i_0,\ell}$ is a standard Lemarié scaling function. However, we suppose that $\psi_{j,k}$ and $w^\varepsilon_{i,\ell}$ are normalized differently than usual, and we arrange the scaling of $\psi_{j,k}$ and the factors γ_i so

$$\|\psi_{j,k}\|_{L^2} = \sqrt{2}\ , \qquad \|w^\varepsilon_{i,\ell}\|_{L^2[0,2\pi)} = 2\sqrt{\pi}. \tag{2.8}$$

Two closure properties of these families will be important below:

$$\psi_{j,k}(-t) = \psi_{j,1-k}(t), \tag{2.9}$$

$$w^\varepsilon_{i,\ell}(\theta + \pi) = w^\varepsilon_{i,\ell+2^{i-1}}(\theta). \tag{2.10}$$

The closure property (2.9) would *not* hold for certain other prominent wavelet families, such as Daubechies' compactly supported wavelets [4].

Define the operator of reflection of functions of one variable $(Tf)(t) = f(-t)$ and the operator of translation by half a period by $(Sg)(\theta) = g(\theta+\pi)$. Note that the space $\mathcal{R}$ consists of objects invariant under $T \otimes S$; (2.3) can be rewritten $(T \otimes S)F = F$. In fact, $P_{\mathcal{R}} = (I + T \otimes S)/2$. Set now, for $j, k \in \mathbb{Z}$ and $i \geq \max(i_0, j)$, $\ell = 0, \ldots, 2^{i-1} - 1$, $\varepsilon \in \{0, 1\}$,

$$W_\lambda(t, \theta) = P_{\mathcal{R}}(\psi_{j,k} \otimes w^\varepsilon_{i,\ell}), \tag{2.11}$$

where $\lambda = (j, k; i, \ell, \varepsilon)$. For later reference, we spell this out:

$$W_\lambda(t, \theta) = (\psi_{j,k}(t) w^\varepsilon_{i,\ell}(\theta) + \psi_{j,k}(-t) w^\varepsilon_{i,\ell}(\theta + \pi))/2. \tag{2.12}$$

In a sense, the $(W_\lambda : \lambda \in \Lambda)$ make a "tensor wavelet basis with antipodal symmetry" and, like usual wavelets, their indices have a localization interpretation. j measures "ridge scale," i measures "angular scale," k measures "ridge position," ℓ measures "angular position." W_λ is localized near a *pair* of dyadic rectangles of "height" 2^{-j} and "width" $2^{-i} \cdot 2\pi$; one has lower left corner at $[t_{j,k}, \theta_{i,\ell})$ where $t_{j,k} = k/2^j$ and $\theta_{i,\ell} = \ell/2^i$; its "twin" is at $(-t_{j,k}, \theta_{i,\ell} + \pi)$.

W_λ is oscillatory in the t-direction: $\int t^m W_\lambda\ dt\ d\theta = 0\ \forall m$, owing to the oscillatory nature of Meyer wavelets. Those W_λ with $\varepsilon = 1$ are also oscillatory in the θ direction: $\int T_m(\theta) W_\lambda(t, \theta) d\theta = 0$ for each t, for each trigonometric polynomial $T_m(\theta) = \sum_{-m}^{m} c_k\ e^{ik\theta}$ of degree $m \leq m_0$, for an appropriate $m_0 = m_0(i)$; here $m_0(i) \asymp 2^i$. However, W_λ is not oscillatory in the θ-direction if $i = i_0$ and $\varepsilon = 0$: in such cases, typically $\int 1 \cdot W_\lambda(t, \theta) d\theta \neq 0$.

By construction, $W_\lambda \in \mathcal{R}$. This explains why we impose the initially unnatural-sounding restriction $\ell < 2^{i-1}$. The definition (2.11)–(2.12) also would apparently make sense for $\ell = 2^{i-1}, \dots, 2^i - 1$, but in that range, it turns out that the resulting functions W_λ are not new: indeed $W_{\lambda'} = W_\lambda$ whenever $j' = j$, $i' = i$, $k' = 1 - k$, and $\ell' = \ell + 2^{i-1}$. Our constraint $0 \le \ell < 2^{i-1}$ removes these duplications.

LEMMA 2.1. (W_λ) *is an orthobasis for* $\mathcal{R}$.

Proof. Let

$$\begin{aligned}\tilde{\Lambda} = \{(j,k;i,l,0) : j,k \in \mathbb{Z}, i = \max(i_0,j), \ell = 0,\dots,2^i-1\} \\ \cup \quad \{(j,k;i,l,1) : j,k \in \mathbb{Z}, i \ge \max(i_0,j), \ell = 0,\dots,2^i-1\};\end{aligned} \tag{2.13}$$

in comparison with Λ, note the expanded range of ℓ. The collection $(\psi_{j,k} \otimes w^\varepsilon_{i,\ell} : (j,k;i,l,\varepsilon) \in \tilde{\Lambda})$ is a complete orthonormal system for $L^2(dt\, d\theta)$. Hence $(W_\lambda)_\lambda$, which is the image of this basis under $P_{\mathcal{R}}$, is complete in $\mathcal{R}$. It remains to see that $(W_\lambda)_\lambda$ is an orthobasis. From (2.9) and (2.10), we have

$$T\psi_{j,k} = \psi_{j,1-k}, \qquad Sw^\varepsilon_{i,\ell} = w_{i,\ell+2^{i-1}}. \tag{2.14}$$

Then, for example, with $\lambda = (j,k;i,\ell,\varepsilon)$, $\lambda' = (j',k';i'\ell'\varepsilon')$,

$$[W_\lambda, W_{\lambda'}] = \frac{1}{4}\sum_{a,a'=0}^{1} [T^a\psi_{j,k} \otimes S^a w^\varepsilon_{i,\ell},\ T^{a'}\psi_{j',k'} \otimes S^{a'} w^{\varepsilon'}_{i',\ell'}]. \tag{2.15}$$

A typical term in the sum is

$$[\psi_{j,k} \otimes w^\varepsilon_{i,\ell},\ \psi_{j',k'} \otimes w^{\varepsilon'}_{i',\ell'}] = \frac{1}{4\pi}\langle \psi_{j,k}, \psi_{j',k'}\rangle (w^\varepsilon_{i,\ell},\ w^{\varepsilon'}_{i',\ell'}),$$

where here $\langle\ ,\ \rangle$ is the inner product for $L^2(dt)$ and $(\ ,\ )$ for $L^2[0,2\pi)$. Then from our normalization of $w^\varepsilon_{i,\ell}$ (see (2.8)) we have $(w^\varepsilon_{i,\ell},\ w^{\varepsilon'}_{i',\ell'}) = \delta_{ii'}\delta_{\ell\ell'}\delta_{\varepsilon\varepsilon'}4\pi$ (taking note that for $\lambda \in \Lambda$, $\varepsilon = 0$ can occur only if $i = \max(i_0,j)$), and so

$$[\psi_{j,k} \otimes w^\varepsilon_{i,\ell},\ \psi_{j',k'} \otimes w^{\varepsilon'}_{i',\ell'}] = 2 \cdot \delta_{jj'}\delta_{kk'}\delta_{ii'}\delta_{\ell\ell'}\delta_{\varepsilon\varepsilon'},$$

at least for those combinations of i,j,k,ℓ,ε and i',j',k',ℓ',ε' which can arise from indices $\lambda, \lambda' \in \Lambda$. Other terms are handled similarly, taking into account that for cross-terms

$$\begin{aligned}\langle \psi_{j,k},\ T\psi_{j',k'}\rangle &= 2 \cdot \delta_{jj'}\delta_{k,1-k'}, \\ (w^\varepsilon_{i,\ell},\ Sw^{\varepsilon'}_{i',\ell'}) &= 4\pi \cdot \delta_{ii'}\delta_{\ell\ell'+2^{i-1}}\delta_{\varepsilon\varepsilon'}.\end{aligned}$$

Since we consider only $\ell, \ell' < 2^{i-1}$, all such cross-terms vanish. It results that of the four possible combinations of terms in (2.15), only two can ever be nonzero when $\lambda, \lambda' \in \Lambda$, and so

$$[W_\lambda, W_{\lambda'}] = \frac{1}{4}\left[2 \cdot \delta_{jj'}\delta_{kk'}\delta_{ii'}\delta_{\ell\ell'}\delta_{\varepsilon\varepsilon'} + 2\delta_{jj'}\delta_{(1-k)(1-k')}\delta_{ii'}\delta_{(\ell+2^{i-1})(\ell'+2^{i-1})}\delta_{\varepsilon\varepsilon'}\right] = \delta_{\lambda,\lambda'}.$$

3. Isometry from Radon space to real space.

We now describe an isometry $\mathcal{J}$ which maps wavelets $W_\lambda \in \mathcal{R}$ to ridgelets $\rho_\lambda \in L^2(\mathbb{R}^2)$. Because the W_λ make an orthobasis for $\mathcal{R}$, the ρ_λ must make an orthobasis for a closed subspace in $L^2(\mathbb{R}^2)$. In fact the closure of the range of $\mathcal{J}$ is all of $L^2(\mathbb{R}^2)$, so that the ridgelets are a complete orthonormal system, as promised by Theorem 1.1 of the introduction. Our construction of the isometry works via the Fourier transform, and is intended to make our introductory definition (1.3) understandable. A different construction works via Radon transform ideas and will be discussed in section 4 below.

For an $F \in \mathcal{R}$, we may Fourier transform in the first variable, producing

$$\tilde{F}(\omega,\theta) = (\mathcal{F}_1 F)(\omega,\theta) = \int_{-\infty}^{\infty} F(t,\theta)\ e^{-i\omega t}\ dt,$$

where $\mathcal{F}_1$ denotes "Fourier transformation in the first variable." Let $\tilde{\mathcal{R}}$ denote the collection $\mathcal{F}_1[\mathcal{R}]$, furnished again with the inner product $[\ ,\ ]$; then

$$[\tilde{F},\tilde{G}] = 2\pi[F,G],$$

so, up to normalization, the correspondence $F \leftrightarrow \tilde{F}$ is an isometry.

For a continuous $\tilde{F} \in \tilde{\mathcal{R}}$, we may perform "polar-to-cartesian" conversion, producing a function $\hat{f}(\xi),\ \ \xi \in \mathbb{R}^2$. This works as follows: set

$$\xi(\omega,\theta) = (\omega\cos\theta,\ \omega\sin\theta), \tag{3.1}$$

where $\omega \in \mathbb{R}$ and $\theta \in [0,2\pi)$. This is a two-to-one mapping of $\mathbb{R}\times[0,2\pi)$ onto $\mathbb{R}^2$. For functions $\tilde{F} \in \tilde{\mathcal{R}}$, one can check that $\tilde{F}(\omega,\theta) = \tilde{F}(-\omega,\theta+\pi)$ and so the definition

$$\hat{f}(\xi(\omega,\theta)) = \tilde{F}(\omega,\theta)|\omega|^{-\frac{1}{2}}, \qquad (\omega,\theta) \in \mathbb{R}\times[0,2\pi), \tag{3.2}$$

is unambiguous: either of the two pairs $(\omega,\theta),(-\omega,\theta+\pi)$ giving rise to the same value of ξ provides the same definition of $\hat{f}(\xi)$. Note that if $\tilde{F}(0,\theta) \neq 0$, then the corresponding $\hat{f}(\xi)$ must have a singularity at $\xi = 0$. However, away from $\xi = 0$, $\hat{f}$ is well-defined, and in fact $\hat{f}$ is well behaved in an L^2-sense:

$$\begin{aligned}\frac{1}{2}\int_0^{2\pi}\int_{-\infty}^{\infty} |\tilde{F}(\omega,\theta)|^2\ d\omega\ d\theta &= \frac{1}{2}\int_0^{2\pi}\int_0^{\infty} |\tilde{F}(\omega,\theta)|^2\ d\omega\ d\theta \\ &= \frac{1}{2}\int_0^{2\pi}\int_0^{\infty} |\hat{f}(\xi(r,\theta))|^2\ r\ dr\ d\theta \\ &= \int |\hat{f}(\xi)|^2\ d\xi.\end{aligned}$$

Hence, because of the $\frac{1}{4\pi}$ normalizing factor in $[,]$,

$$\|\tilde{F}\|^2_{L^2(d\omega d\theta)} = \frac{1}{2\pi}\|\hat{f}\|^2_{L^2(d\xi)}. \tag{3.3}$$

We also remark that for each W_λ, the corresponding $\tilde{W}_\lambda$ is continuous and vanishes for $|\omega| < \frac{2}{3}\pi 2^j$, hence the polar-to-cartesian conversion is well-defined for every $\tilde{W}_\lambda$. More is true. Let $\hat{f} = C(\tilde{F})$ denote the operation defined by (3.2). In fact, C extends to a linear operator, well-defined on $\tilde{\mathcal{R}}$ and bounded from $\tilde{\mathcal{R}}$ to $L^2(d\xi)$ by (3.3).

In any event, the definition $\hat{\rho}_\lambda = (C\circ\mathcal{F}_1)(W_\lambda)$ makes sense, and $(\hat{\rho}_\lambda)$ is a collection of elements of $L^2(d\xi)$; the standard two-variable inverse Fourier transform $\mathcal{F}_2^{-1}$ maps this to a collection $(\rho_\lambda) \subset L^2(dx)$. The reader should now check that this definition of ρ_λ agrees with formula (1.3) in the introduction.

Put for short $\mathcal{J} = \mathcal{F}_2^{-1} \circ C \circ \mathcal{F}_1$. Evidently this is well-defined on basis elements W_λ; we now check that it is norm-preserving:

$$\begin{aligned}
\|\rho_\lambda\|^2_{L^2(dx)} &= \frac{1}{(2\pi)^2} \int |\hat{\rho}_\lambda(\xi)|^2 \, d\xi \\
&= \frac{1}{(2\pi)^2} \int_0^\pi \int_0^\infty |\hat{\rho}_\lambda(\xi(r,\theta))|^2 \, r \, dr \, d\theta \\
&= \frac{1}{(2\pi)^2} \, \frac{1}{2} \int_0^{2\pi} \int_{-\infty}^{\infty} |\tilde{W}_\lambda(\omega,\theta)|^2 |\omega|^{-1} \, |\omega| \, d\omega \, d\theta \\
&= \frac{1}{4\pi} \int_0^{2\pi} |W_\lambda(t,\theta)|^2 \, dt \, d\theta \\
&= [W_\lambda, W_\lambda] = \|W_\lambda\|_{L^2(dt \; d\theta)}.
\end{aligned}$$

In essence, we used

$$\begin{aligned}
\|\rho_\lambda\|^2_{L^2(dx)} &= \frac{1}{(2\pi)^2} \|\hat{\rho}_\lambda\|^2_{L^2(d\xi)}, \\
\|\tilde{W}_\lambda\|^2_{L^2(d\omega \; d\theta)} &= \frac{1}{2\pi} \|\hat{\rho}_\lambda\|^2_{L^2(d\xi)}, \\
\|W_\lambda\|^2_{L^2(dt \; d\theta)} &= \frac{1}{2\pi} \|\tilde{W}_\lambda\|^2_{L^2(d\omega \; d\theta)},
\end{aligned}$$

where the first and last steps are Parseval for $\mathcal{F}_2$ and $\mathcal{F}_1$ and the middle step uses (3.3).

The argument for the angle-preserving property

$$\langle \rho_\lambda, \rho_{\lambda'} \rangle = [W_\lambda, W_{\lambda'}]$$

is entirely analogous, and shows that (ρ_λ) is an orthonormal system in $L^2(\mathbb{R}^2)$.

We now show that the system is complete. Let $h \in L^1(dx) \cap L^2(dx)$ be of L^2-norm 1, and suppose that it is a bandpass function: for constants $0 < \Omega_0 < \Omega_1 < \infty$,

$$\hat{h}(\xi) = 0, \qquad |\xi| \notin [\Omega_0, \Omega_1].$$

Consider $H(t,\theta)$ defined formally by applying the adjoint of $\mathcal{J}$:

$$H = \mathcal{J}^+ h.$$

We now build up $H = \mathcal{J}^+ h$ in stepwise fashion. There is the inverse to the polar-to-cartesian transformation C, namely, the cartesian-to-polar transformation P:

$$P(\hat{h}) = \tilde{H}(\omega,\theta) = \hat{h}(\xi(\omega,\theta))|\omega|^{+\frac{1}{2}}, \qquad \omega \in \mathbb{R}, \quad \theta \in [0, 2\pi),$$

and, with one- and two-variable Fourier transforms $\mathcal{F}_1$ and $\mathcal{F}_2$ as before:

$$\mathcal{J}^+ = \mathcal{F}_1^{-1} \circ P \circ \mathcal{F}_2.$$

This mapping is well-defined on bandpass h and has an isometry property on such h:

$$\begin{aligned}
\|\hat{h}\|^2_{L^2(d\xi)} &= (2\pi)^2 \|h\|_{L^2(dx)}, \\
\|\tilde{H}\|^2_{L^2(d\omega \; d\theta)} &= \frac{1}{2\pi} \|\hat{h}\|_{L^2(d\xi)}, \\
\|H\|^2_{L^2(dt \; d\theta)} &= \frac{1}{2\pi} \|\tilde{H}\|^2_{L^2(d\omega \; d\theta)}.
\end{aligned}$$

The first and last steps are standard Parseval relations for $\mathcal{F}_2$ and $\mathcal{F}_1$, respectively. The middle step is

$$\int_0^{2\pi}\int_{-\infty}^{\infty} |\tilde{H}(\omega,\theta)|^2 \ d\omega \ d\theta = \int_0^{2\pi}\int_0^{\infty} |h(r,\theta)|^2 \ r \ dr \ d\theta$$
$$= 2\int |h(\xi)|^2 \ d\xi.$$

Hence we get $H \in \mathcal{R}$ of $L^2(dt \ d\theta)$-norm 1. One checks that

$$[H, W_\lambda] = \langle h, \rho_\lambda\rangle, \qquad \lambda \in \Lambda.$$

By hypothesis $\|h\|_{L^2(dx)} = 1$, so the sequence $([H, W_\lambda])_\lambda$ has ℓ^2-norm 1, and so the sequence $(\langle h, \rho_\lambda\rangle)_\lambda$ has ℓ^2-norm 1. It follows that there is no nontrivial unit-norm integrable bandpass function orthogonal to all the ρ_λ; as integrable bandpass functions are dense in $L^2(dx)$, the system (ρ_λ) is complete.

4. Interpretation in Radon space. We now show that analysis of f by the system (ρ_λ) is closely related to (W_λ)-wavelet analysis of the Radon transform of f. We begin by defining the adjoint of the Radon transform so that for all sufficiently nice $G \in \mathcal{R}$ and all sufficiently nice $f \in L^2(dx)$,

$$[Rf, G] = \langle f, R^+ G\rangle, \tag{4.1}$$

which leads to

$$(R^+G)(x) = \frac{1}{4\pi}\int_0^{2\pi} G(x_1\cos\theta + x_2\sin\theta, \theta) \ d\theta. \tag{4.2}$$

This operator is also called "backprojection" in the literature of computed tomography [5].

Define the Riesz order-1/2 fractional differentiation operator Δ^+ and also the order-1/2 fractional integration operator Δ^- by the unified formula

$$(\Delta^\pm f)(t) = \frac{1}{2\pi}\int_{-\infty}^{\infty} e^{it\omega}\hat{f}(\omega)|\omega|^{\pm\frac{1}{2}} \ d\omega. \tag{4.3}$$

These unbounded operators are well-defined on functions which are sufficiently smooth (formally, the domain $\mathcal{D}(\Delta^+) = \{f : \int_{-\infty}^{\infty} |\hat{\rho}(\omega)|^2 \ |\omega| d\omega\}$) or sufficiently oscillatory (formally, the domain $\mathcal{D}(\Delta^-) = \{f : \int_{-\infty}^{\infty} |\hat{f}(\omega)|^2 \ |\omega|^{-1} \ d\omega < \infty\}$); in particular, they are well-defined on every one-dimensional Meyer wavelet $\psi_{j,k}$, owing to $\operatorname{supp}(\hat{\psi}_{j,k}) \subset \{\omega : |\omega| \in [\frac{2}{3}\pi 2^j, \ \frac{8}{3}\pi 2^j]\}$. Moreover, on the appropriate domains, they are self-adjoint; and on the appropriate domains they act as inverses of each other.

Set now, for $\lambda \in \Lambda$,

$$\tau_\lambda = (\Delta^+ \otimes I)W_\lambda, \tag{4.4}$$
$$\sigma_\lambda = (\Delta^- \otimes I)W_\lambda. \tag{4.5}$$

For example,

$$\tau_{(j,k;i,\ell,1)} = (\Delta^+\psi_{j,k} \otimes w^1_{i,\ell} + \Delta^+ T\psi_{j,k} \otimes S w^1_{i,\ell})/2.$$

A useful remark is that $\Delta^\pm T = T\Delta^\pm$ on the appropriate domains.

In accord with the description of Δ^- as an "integrator" and Δ^+ as a "differentiator" we can view σ_λ as a "smoothing" of W_λ in the t-direction while τ_λ is a "roughening" of W_λ in the t-direction. This duality reflects a more fundamental biorthogonality.

Lemma 4.1. *For $\lambda \in \Lambda$,*

$$\sigma_\lambda = R\rho_\lambda, \tag{4.6}$$

$$\rho_\lambda = R^+\tau_\lambda. \tag{4.7}$$

For $\lambda, \mu \in \Lambda$,

$$[\sigma_\lambda, \tau_\mu] = \langle \rho_\lambda, \rho_\mu \rangle = [W_\lambda, W_\mu]. \tag{4.8}$$

From this we have immediately the following corollary.

Corollary 4.2. *Let f be a finite superposition of ρ_λ's. Then*

$$f = \sum_{\lambda\in\Lambda} [Rf, \tau_\lambda]\rho_\lambda, \tag{4.9}$$

$$\|f\|^2_{L^2(dx)} = \sum_{\lambda\in\Lambda} [Rf, \tau_\lambda]^2. \tag{4.10}$$

In short, the ridgelet coefficients can be read off from an analysis of the Radon transform of f, using the set τ_λ of analyzing elements. We also have, from self-adjointness of Δ^+, the following lemma.

Lemma 4.3. *Let f be a finite superposition of ρ_λ's. Then*

$$f = \sum_{\lambda\in\Lambda} [(\Delta^+ \otimes I)Rf,\ W_\lambda]\rho_\lambda, \tag{4.11}$$

$$\|f\|^2_{L^2(dx)} = \sum_{\lambda\in\Lambda} [(\Delta^+ \otimes I)Rf,\ W_\lambda]^2. \tag{4.12}$$

So the ridgelet coefficients derive from (antipodally symmetrized) wavelet analysis of the (differentiated) Radon transform.

A clarifying interpretation emerges from these representations: the justification for our use of the term "ridgelet." As introduced by [1], the term refers to a continuous ridge function

$$\psi_{a,b,\theta}(x) = a^{-\frac{1}{2}}\psi((x_1\cos\theta + x_2\sin\theta - b)/a), \tag{4.13}$$

where $\psi(t) : \mathbb{R} \to \mathbb{R}$ is oscillatory. For comparison, Lemma 4.1 gives the representation

$$\begin{aligned}\rho_\lambda(x) &= (R^+\tau_\lambda)(x)\\ &= \frac{1}{8\pi}\int_0^{2\pi} (\psi^+_{j,k}(x_1\cos\theta + x_2\sin\theta)w^\varepsilon_{i,\ell}(\theta) + \psi^+_{j,k}(-x_1\cos\theta - x_2\sin\theta)w^\varepsilon_{i,\ell}(\theta+\pi))d\theta\\ &= \frac{1}{4\pi}\int_0^{2\pi} \psi^+_{j,k}(x_1\cos\theta + x_2\sin\theta)w^\varepsilon_{i,\ell}(\theta)d\theta.\end{aligned}$$

Here we used the observation that

$$\int_0^{2\pi} \psi^+_{j,k}(x_1\cos\theta + x_2\sin\theta)w^\varepsilon_{i,\ell}(\theta)d\theta$$

$$= \int_0^\pi (\psi^+_{j,k}(x_1 \cos\theta + x_2 \sin\theta) w^\varepsilon_{i,\ell}(\theta) + \psi_{j,k}(x_1 \cos(\theta+\pi) + x_2 \sin(\theta+\pi)) w^\varepsilon_{i,\ell}(\theta+\pi)) d\theta$$

$$= \int_0^\pi \psi^+_{j,k}(x_1 \cos\theta + x_2 \sin\theta) w^\varepsilon_{i,\ell}(\theta) d\theta + \int_0^\pi \psi^+_{j,k}(-x_1 \cos\theta - x_2 \sin\theta) w^\varepsilon_{i,\ell}(\theta+\pi) d\theta.$$

Consequently,

$$\int_0^{2\pi} (\psi^+_{j,k}(x_1 \cos\theta + x_2 \sin\theta) w^\varepsilon_{i,\ell}(\theta) + \psi^+_{j,k}(-x_1 \cos\theta - x_2 \sin\theta) w^\varepsilon_{i,\ell}(\theta+\pi)) d\theta$$
$$= 2 \int_0^{2\pi} \psi^+_{j,k}(x_1 \cos\theta + x_2 \sin\theta) w^\varepsilon_{i,\ell}(\theta) d\theta,$$

which gives Theorem 1.2 of the introduction.

Now $w^\varepsilon_{i,\ell}(\theta)$ is a function quasi-localized to an interval of length $2\pi/2^i$ near $\theta_{i,\ell} = 2\pi \cdot \ell/2^i$, with L^1-norm of size $\approx 2^{-i/2}$. Hence, roughly speaking,

$$\rho_\lambda(x) = 2^{-i/2} \text{ “Ave”}_{i,\ell}\{\psi^+_{j,k}(x_1 \cos\theta + x_2 \sin\theta)\},$$

where “Ave”$_{i,\ell}$ denotes a “signed weighted average” localized near $\theta_{i,\ell}$. In short, the *ridgelet* ρ_λ is a sort of “average” of true *ridge* functions. In this “average” the weights take both positive and negative signs, which is not usual for averages; such oscillatory weights are crucial for the orthogonality properties of the ρ_λ.

We cannot expect a tighter connection of ridgelets to ridge functions than this, since ridgelets are in $L^2(dx)$ while ridge functions are not in $L^2(dx)$ owing to constancy on ridges.

To summarize the results of this section, we have the following diagram:

$$\begin{tikzcd}
 & & (\sigma_\lambda) & & \\
(\rho_\lambda) \arrow[urr, "R"] \arrow[drr, "\mathcal{F}_2"'] & & (\tau_\lambda) \arrow[ll, "R^+"'] & & (W_\lambda) \arrow[ull, "\Delta^- \otimes I"'] \arrow[ll, "\Delta^+ \otimes I"'] \arrow[d, "\mathcal{F}_1"] \\
 & & (\hat{\rho}_\lambda) & & (\tilde{W}_\lambda). \arrow[ll, "C"']
\end{tikzcd}$$

This is a commutative diagram, so that *all* routes between vertices (ρ_λ) and (W_λ) are isometries. In particular,

$$\mathcal{J} = R^+ \circ (\Delta^+ \otimes I),$$
$$\mathcal{J}^{-1} = (\Delta^+ \otimes I) \circ R.$$

In this form, the isometries $\mathcal{J}$ and $\mathcal{J}^{-1}$ are well known in the Radon transform literature; see Helgason [12, section 1.X].

5. Ridgelet analysis of a linear singularity. Recall the function $g(x_1, x_2) = 1_{\{x_2>0\}}\, e^{-x_1^2 - x_2^2}$ of the introduction. We are now in a position to show that the ridgelet coefficients of g are sparse. A more precise version of Theorem 1.3 will be proven.

THEOREM 5.1. *Let* $\alpha_\lambda = \langle \rho_\lambda, g \rangle$, $\lambda \in \Lambda$. *For each* $p \in (0, 2]$, *the ridgelet coefficients* $(\alpha_\lambda) \in \ell^p$.

The conclusion $(\alpha_\lambda) \in \ell^p$ implies that for a constant c_p,

$$\#\{\lambda : |\alpha_\lambda| \geq \delta\} \leq c_p\ \delta^{-p} \qquad \forall\ \delta > 0,$$

showing that the coefficients decay. This, in turn, implies that the partial reconstruction

$$\tilde{g}_\delta = \sum_\lambda \eta_\delta(\langle \rho_\lambda, g \rangle)\rho_\lambda$$

with $N(\delta)$-terms, $N(\delta) = \sum_\lambda 1_{\{|\alpha_\lambda| \geq \delta\}}$, obeys

$$\|g - \tilde{g}_\delta\|_{L^2} \leq C_p'\ \delta^{(1-p/2)}, \qquad N(\delta) \leq C_p\ \delta^{-p};$$

in short, $\bar{g}_N = \tilde{g}_{N(\delta)}$ gives an N-term approximation

$$\|g - \bar{g}_N\|_{L^2} \leq C_p''\ N^{-(\frac{1}{p}-\frac{1}{2})} \qquad \forall N = 1, 2, \ldots \quad \forall p \in (0, 2].$$

The proof of Theorem 5.1 shows that ridgelets are adapted to this kind of singularity *precisely* to the same extent that wavelets are adapted to point singularities; ridgelets are successful with linear singularities *because* wavelets are successful with point singularities. As section 4 showed, ridgelet analysis "is" wavelet analysis in the Radon domain, a fact we rely on heavily in this section.

5.1. Windowing and smooth change-of-variables. According to (4.11) and (4.12), the ridgelet coefficients of a function f obey

$$\alpha_\lambda = [(\Delta^+ \otimes I)(Rf), W_\lambda], \qquad \lambda \in \Lambda, \tag{5.1}$$

at least for f which are finite sums of ridge functions. It is notationally convenient for us to work using this viewpoint. For more general f, we view $(\Delta^+ \otimes I)(Rf)$ as a distribution defined to make this relation true; i.e., so that $[(\Delta^+ \otimes I)(Rf), W_\lambda] \equiv [Rf, (\Delta^+ \otimes I)W_\lambda]$. However, $(\Delta^+ \otimes I)(Rf)$ has an explicit representation as a function, provided we use this function only to calculate integrals $[(\Delta^+ \otimes I)(Rf), W_\lambda]$ against the W_λ. This point will be clarified in section 5.2 below. Since we use this function only in this way, we will be using (5.1) without any further comment.

Our choice of g was driven by the fact that we can calculate Rg. In the appendix we derive the formula

$$(Rg)(t, \theta) = e^{-t^2}\bar{\Phi}\left(-t\left|\frac{\sin\theta}{\cos\theta}\right|\right), \qquad t \in \mathbb{R}, \quad \theta \in [0, 2\pi). \tag{5.2}$$

Now Rg has point singularities of order 0—discontinuities—at points $(0, \pi/2)$ and $(0, 3\pi/2)$ (antipodal pair). Away from these points Rg is C^∞, uniformly so outside balls $B_2((0, \frac{\pi}{2}), \delta)$ and $B_2((0, \frac{3\pi}{2}), \delta)$, $\delta > 0$.

The same structural features are true of $F = (\Delta^+ \otimes I)Rg$, except that owing to the fractional derivative in the vertical direction, the point singularities of order 0 at $(0, \pi/2)$ and $(0, 3\pi/2)$ become point singularities of order $-\frac{1}{2}$. In effect, these singularities are the heart of the matter, and we now develop some windowing tools to isolate them for careful attention and a change-of-variables to move them to the origin.

Construct a C^∞ partition of unity in θ, with windows $\nu_i(\theta)$ obeying $0 \le \nu_i(\theta) \le 1$, $\sum_{i=0}^2 \nu_i(\theta) = 1$,

$$\begin{aligned}&\mathrm{supp}(\nu_1) \subset [\pi/4,\ 3\pi/4],\\ &\mathrm{supp}(\nu_2) \subset [5\pi/4,\ 7\pi/4],\\ &\mathrm{supp}(\nu_0) \subset [0, 3\pi/8] \cup \left[\frac{5\pi}{8}\ , \frac{11\pi}{8}\right] \cup \left[\frac{13\pi}{8}\ , 2\pi\right).\end{aligned}$$

In particular $\nu_1 \equiv 1$ on $[3\pi/8,\ 5\pi/8]$, while $\nu_2 \equiv 1$ on $[11\pi/8,\ 13\pi/8]$.

Define $F_i(t,\theta) = \nu_i(\theta)F(t,\theta)$; the intention is that F_1 represent behavior near $\theta = \pi/2$, F_2 represent behavior near $\theta = 3\pi/2$, and F_0 represent "everything else." Of course $F = F_0 + F_1 + F_2$. Now F_0 is C^∞ on $\mathbb{R} \times [0, 2\pi)$ and of rapid decay in t for each θ; in other words, absolutely banal. F_1 and F_2 each contain a singularity and in some sense are mirror images of each other (antipodal symmetry again); whatever goes for one will go for the other as well. We discuss F_1 only.

Introduce variables $(\bar t, \bar\theta)$ extending over all of $\mathbb{R} \times \mathbb{R}$, with $\bar t \equiv t$ and $\bar\theta \equiv \theta$ on $\theta \in \left[\frac{\pi}{4}\ , \frac{3\pi}{4}\right]$. Define the zero-extension of F_1:

$$\bar F_1(\bar t, \bar\theta) = \begin{cases} 0 & \bar\theta \notin \left[\frac{\pi}{4}\ , \frac{3\pi}{4}\right] \\ F(\bar t, \bar\theta) & \bar\theta \in \left[\frac{\pi}{4}\ , \frac{3\pi}{4}\right] \end{cases}$$

as F_1 is C^∞ at the boundary $\theta \in \{\pi/4,\ 3\pi/4\}$, this is a C^∞ extension of F_1.

Consider now the separable change-of-variables $\bar t \leftrightarrow u$, $\bar\theta \leftrightarrow v$ defined by

$$u = \bar t, \quad v = -\mathrm{cotan}(\bar\theta);$$

define this initially on subdomain $D_1 = \mathbb{R} \times \left[\frac{\pi}{4}\ , \frac{3\pi}{4}\right]$ and extend this to all $(\bar t, \bar\theta)$ while imposing four rules:

1. $u = \bar t \ \ \forall \bar\theta$;
2. separability in $(\bar t, \bar\theta) : v = v(\bar\theta)$;
3. $v(\bar\theta)$ is C^∞ in $\bar\theta$;
4. $v'(\bar\theta) = 1$ on $\bar\theta \in [\pi/8,\ 7\pi/8]^c$.

This change-of-variables induces a function

$$G_1(u,v) = \bar F_1(\bar t, \bar\theta)$$

nicely defined on all $(u,v) \in \mathbb{R}^2$; more concretely

$$G_1(u,v) = (I \otimes \bar V_1) \circ (\Delta^+ \otimes I) \circ (e^{-u^2} \otimes I)\bar\Phi(u/|v|), \tag{5.3}$$

where $\bar V_1$ is an operator of smooth windowing in v, induced from $\nu_1(\theta)$, Δ^+ is a fractional differentiation as before, and $e^{-u^2} \otimes I$ denotes a smooth windowing in u. An important point is that under this change-of-variables, the singularity at $\bar t = 0$, $\bar\theta = \pi/2$ becomes a singularity at $u = 0$, $v = 0$.

5.2. The elementary singularity. The windowing and change-of-variables now allows us to "zoom in" on the singularities in F using standard wavelet analysis. In section 5.3, we will describe a program for systematically inferring sparsity of the W_λ-coefficients from a traditional wavelet analysis of the G_i, $i = 1, 2$. However, before continuing, we digress to explain why this approach is reasonable.

Operating purely formally for the moment, the heart of the matter concerns the "elementary" singularity $S(u,v) = |v|^{-\frac{1}{2}}\sigma(u/|v|)$, where $\sigma(t) = (\Delta^+\bar{\Phi})(t)$ with Δ^+ as before and $\bar{\Phi}(t)$ as before. Indeed,

$$S(u,v) = (\Delta^+ \otimes I)\bar{\Phi}(u/|v|)$$

and so, comparing with the definition (5.3) of $G_1(u,v)$, we see that in a sense $S(u,v)$ is "what's happening" in G_1 "near $u=0,\ v=0$."

In effect, the windowing and change-of-variables have isolated our attention on the object S; if S had very *nonsparse* wavelet coefficients, then we could expect the same to be true of G_1. As we will see, S has *sparse* wavelet coefficients at fine scales.

A key remark is that S is scale-invariant—homogeneous of order $-\frac{1}{2}$. Indeed the formula $S(u,v) = |v|^{-\frac{1}{2}}\sigma(u/|v|)$ shows immediately that

$$S(au,av) = a^{-\frac{1}{2}}S(u,v). \tag{5.4}$$

It is this scale-invariance that entitles us to call S a singularity.

In order to calculate the wavelet coefficients of S, it is convenient to operate in the frequency domain, where the Meyer wavelets we are using are most naturally defined. This in turn requires a formula for "the" Fourier transform of S. However, to be clear we pause to explain that S is a special kind of distribution and that our formula for its Fourier transform works only for special purposes.

Let $\mathcal{S}(\mathbb{R})$ denote the space of Schwartz functions, functions of a single variable which are smooth and of rapid decay, along with all of their derivatives. Let $\mathcal{S}_0(\mathbb{R})$ denote the space of Schwartz functions with all moments vanishing, i.e., with $\int t^m f(t)dt = 0$ for $m = 0,1,2,\ldots$. Let $\mathcal{S}_0(\mathbb{R}) \otimes \mathcal{S}(\mathbb{R})$ denote the linear space of Schwartz functions generated from tensor products $f(u,v) = f_0(u)f_1(v)$, where $f_0 \in \mathcal{S}_0(\mathbb{R})$ and $f_1 \in \mathcal{S}(\mathbb{R})$. Such functions have classical Fourier transforms which vanish to arbitrary order on the ω_2 axis:

$$\frac{\partial^m}{\partial\omega_1^m}\frac{\partial^n}{\partial\omega_2^n}\hat{f}(\omega_1,\omega_2) = 0, \quad \omega_1 = 0, \quad m,n = 0,1,2,\ldots.$$

Such functions "omit" entirely the frequencies $\omega = (0,\omega_2)$.

We now retract our earlier definition and define S as a linear functional on $\mathcal{S}_0(\mathbb{R}) \otimes \mathcal{S}(\mathbb{R})$. Let $\dot{H}(u,v) = \bar{\Phi}(u/|v|)$; this is a bounded function of u and v and so defines a tempered distribution: $\dot{H} \in \mathcal{S}'(\mathbb{R}^2)$. Let $f \in \mathcal{S}_0(\mathbb{R}) \otimes \mathcal{S}(\mathbb{R})$; then $(\Delta^+ \otimes I)f \in \mathcal{S}(\mathbb{R}^2)$. We define S on $f \in \mathcal{S}_0 \otimes \mathcal{S}$ via

$$\langle S, f\rangle \equiv \langle \dot{H}, (\Delta^+ \otimes I)f\rangle.$$

This definition makes sense, because $\dot{H}$ is tempered and $(\Delta^+ \otimes I)f$ is in the Schwartz class.

We now give a formula for $\hat{S}$ accurate for functions in $\mathcal{S}_0 \otimes \mathcal{S}$. That is, $\langle S, f\rangle$ is correctly calculated from $\frac{1}{4\pi^2}\langle \hat{S}, \hat{f}\rangle$ when $f \in \mathcal{S}_0 \otimes \mathcal{S}$. In particular, the formula works for calculating Meyer tensor wavelet coefficients $\langle S, \psi_{j,k} \otimes \psi_{i,\ell}\rangle$, which is our only application.

LEMMA 5.2. *The singularity S, viewed as a distribution acting on $\mathcal{S}_0(\mathbb{R}) \otimes \mathcal{S}(\mathbb{R})$, has Fourier transform*

$$\hat{S}(\omega_1,\omega_2) = -2\pi\sqrt{-1}\ \mathrm{sgn}(\omega_1)|\omega_1|^{-\frac{3}{2}}\exp\{-\omega_2^2/\omega_1^2\}, \qquad \omega_1 \neq 0. \tag{5.5}$$

The proof is given in the appendix.

The earlier definition of S as a function of two variables is compatible with this definition, in the sense that when $f \in \mathcal{S}_0 \otimes \mathcal{S}$, we actually have $\langle S, f \rangle = \iint |v|^{-1/2} \sigma(u/|v|) f(u,v) du dv$, with $\sigma(u)$ the smooth bounded function defined as the inverse Fourier transform of

$$\hat{\sigma}(\omega) = \sqrt{-\pi} \cdot |\omega|^{-1/2} \cdot \mathrm{sgn}(\omega) \cdot \exp\{-\omega^2/4\}. \tag{5.6}$$

(Note that $\sigma(u)$ has rather poor decay at ∞, so it is not in L^1 or in L^2. The preceding integral nevertheless makes sense because $f \in \mathcal{S}(\mathbb{R}^2)$.)

With a formula for the Fourier transform of S in hand, we may now calculate the Meyer wavelet coefficients of S.

Lemma 5.3. *Let $\psi_{j,k}$ denote Meyer wavelets for $\mathbb{R}$, and let $\mu = (j,k,i,\ell)$ index an orthogonal tensor wavelet basis for $\mathbb{R}^2$ with elements*

$$\psi_\mu(u,v) = \psi_{j,k}(u)\psi_{i,\ell}(v), \qquad j,k,i,\ell \in \mathbb{Z}.$$

The wavelet coefficients of the elementary singularity S,

$$A_\mu = \langle S, \psi_\mu \rangle,$$

obey the exact scaling relation

$$A_{(j,k,i,\ell)} = 2^{-j/2} A_{(0,k,i-j,\ell)}. \tag{5.7}$$

For each fixed $h \geq 0$, the doubly indexed array $(A_{(0,k,h,\ell)})_{k,\ell}$ is of rapid spatial decay in k and ℓ as $|k|, |\ell| \to \infty$. In fact, for each $m > 0$,

$$|A_{(0,k,h,\ell)}| \leq C_m \ 2^{-h/2} (1+|k|)^{-m} (1+|\ell|)^{-m}, \quad k, \ell \in \mathbb{Z}. \tag{5.8}$$

As a result, the fine-scale wavelet coefficients obey

$$\sum_{j \geq i_0} \sum_{i \geq j} \sum_{k,\ell} |A_{(j,k,i,\ell)}|^p < \infty \qquad \forall \ p > 0. \tag{5.9}$$

In short, the two-dimensional tensor Meyer coefficients give a sparse representation of the high-frequency part of the elementary point singularity $S(u,v)$, with very few "big" coefficients, and with those few "big" coefficients clustered near $(k,\ell) = (0,0)$.

Proof. The scaling relation (5.4) gives, with $h = i - j$,

$$\begin{aligned} A_{jki\ell} = \langle S, \psi_{jki\ell} \rangle &= \int S(u,v) \psi_{0,k,i-j,\ell}(2^j u, 2^j v) 2^j \ du \ dv \\ &= \int S(2^j u, 2^j v) 2^{j/2} \ \psi_{0,k,h,\ell}(2^j u, 2^j v) 2^j du dv \\ &= 2^{-j/2} \langle S, \psi_{0,k,h,\ell} \rangle = 2^{-j/2} A_{0kh\ell}, \end{aligned}$$

which establishes (5.7). This scaling relation now allows us to infer (5.9) from (5.8). In fact we can see, letting $A^{(h)}$ denote the array $(A_{0kh\ell})_{k\ell}$, that (5.8) implies that $\|A^{(h)}\|_p < \infty$ for any $p > 0$; indeed we simply apply (5.8) with m chosen so that

$mp > 1$. In fact the exponential factor $2^{-h/2}$ in (5.8) yields more: we see immediately that

$$\sum_{h=0}^{\infty} \|A^{(h)}\|_p^p = A^* < \infty.$$

To see why (5.9) follows, note that

$$\begin{aligned}\sum_{j\geq i_0} \sum_{i\geq j} \sum_{k,\ell} |A_{j,k,i,\ell}|^p &= \sum_{j\geq i_0}^{\infty} \sum_{h=0}^{\infty} \sum_{k,\ell} |A_{j,k,j+h,\ell}|^p \\ &= \sum_{j\geq i_0}^{\infty} \sum_{h=0}^{\infty} \sum_{k,\ell} |2^{-j/2} A_{0,k,h,\ell}|^p \\ &= \sum_{j\geq i_0}^{\infty} \sum_{h=0}^{\infty} (2^{-j/2} \|A^{(h)}\|_p)^p \\ &= \sum_{h=0}^{\infty} \|A^{(h)}\|_p^p \sum_{j\geq i_0}^{\infty} 2^{-jp/2} = A^*/(1-2^{-i_0 p/2}).\end{aligned}$$

Hence the key point is to establish (5.8).

Working on the Fourier side, we may write

$$A_{jki\ell} = \frac{1}{4\pi^2} \int \hat{S}(\omega_1,\omega_2) \widehat{\psi_{jk}}(\omega_1) \widehat{\psi_{i\ell}}(\omega_2) d\omega_1 d\omega_2.$$

Now using $\widehat{\psi_{h\ell}}(\omega_2) = 2^{-h/2} \hat{\psi}(\omega_2/2^h) e^{-\sqrt{-1}\omega_1 \ell/2^h}$ and $\widehat{\psi_{0k}}(\omega_1) = \hat{\psi}(\omega_1) e^{-\sqrt{-1}\omega_1 k}$, we get

$$A_{0kh\ell} = \frac{1}{4\pi^2} \int \hat{S}(\omega_1,\omega_2) \hat{\psi}(\omega_1) \hat{\psi}(\omega_2/2^h) e^{-\sqrt{-1}(\omega_1 k + \omega_2 \ell/2^h)} 2^{-h/2} d\omega_1 d\omega_2.$$

Defining a new variable $\bar{\omega}_2 = \omega_2/2^h$, we get

$$A_{0kh\ell} = \frac{1}{4\pi^2} \int \hat{A}_h(\omega_1,\bar{\omega}_2) e^{-\sqrt{-1}(\omega_1 k + \bar{\omega}_2 \ell)} d\omega_1 d\bar{\omega}_2,$$

where we defined

$$\hat{A}_h(\omega_1,\bar{\omega}_2) = \hat{S}(\omega_1,\bar{\omega}_2 2^h) \hat{\psi}(\omega_1) \hat{\psi}(\bar{\omega}_2) 2^{h/2}.$$

In short,

$$A_{0kh\ell} = A_h(k,\ell), \qquad k,\ell \in \mathbb{Z},$$

where

$$A_h(u,v) = \frac{1}{(2\pi)^2} \int \hat{A}_h(\omega_1,\omega_2)\ e^{-\sqrt{-1}(\omega_1 u + \omega_2 v)} d\omega_1 d\omega_2.$$

We note that $\hat{A}_h$ is supported in $\Omega = \{(\omega_1,\omega_2) : |\omega_i| \in [\frac{2\pi}{3}\ , \frac{8\pi}{3}], i = 1,2\}$, and that $\hat{A}_h \in C_0^\infty[\Omega]$. Now from $|f(u,v)| \leq \int |\hat{f}(\omega_1,\omega_2)| d\omega_1\ d\omega_2$ and from

$$(-\sqrt{-1})^{m+n} \cdot u^m v^n \cdot f(u,v) = \frac{1}{(2\pi)^2} \int \frac{\partial^m}{\partial^m \omega_1} \frac{\partial^n}{\partial^n \omega_2} \hat{f}(\omega_1,\omega_2) e^{-\sqrt{-1}(u\omega_1 + v\omega_2)} d\omega_1 d\omega_2$$

valid for $m, n = 0, 1, 2, \ldots$ and all sufficiently nice f, we get that for $m = 1, 2, \ldots$,

$$|A_h(k,\ell)| \le C_m \cdot \|\hat{A}_h\|_{W_1^m[\mathbb{R}^2]}(1+|k|)^{-m}(1+|\ell|)^{-m}, \quad k, \ell \in \mathbb{Z},$$

where the $W_1^m[\mathbb{R}^2]$-norm of a smooth function f is simply $\|f\|_{L^1[\mathbb{R}^2]} + \|f^{(m)}\|_{L^1[\mathbb{R}^2]}$. Consequently, (5.8) reduces merely to the assertion that for each $m = 1, 2, 3, \ldots$, there is C_m so that

$$\|\hat{A}_h\|_{W_1^m[\mathbb{R}^2]} \le C_m 2^{-h/2}.$$

Now write

$$\hat{A}_h(\omega_1,\omega_2) = B_h(\omega_1,\omega_2) \cdot \Psi(\omega_1,\omega_2), \tag{5.10}$$

where

$$\begin{aligned} \Psi(\omega_1,\omega_2) &= -2\pi\ \sqrt{-1}\ \mathrm{sgn}(\omega_1)\ |\omega_1|^{-\frac{3}{2}}\ \hat{\psi}(\omega_1)\hat{\psi}(\omega_2), \\ B_h(\omega_1,\omega_2) &= 2^{h/2}\exp\{-2^{2h}\omega_2^2/\omega_1^2\}. \end{aligned}$$

Now for a function $f \in C_0^m[\Omega]$, $\|f\|_{W_1^m[\mathbb{R}^2]} \le C'_m \|f\|_{C^m[\Omega]}$, where the $C^m[\Omega]$-norm of f refers to the smallest constant C bounding the $L^\infty[\Omega]$-norm of f and also the $L^\infty[\Omega]$ norm of every mixed partial of total degree $\le m$. Using the fact that Ψ and all of its derivatives vanish on $\partial\Omega$,

$$\|\hat{A}_h\|_{C^m[\Omega]} \le C''_m \|B_h\|_{C^m[\Omega]} \cdot \|\Psi\|_{C^m[\Omega]}, \tag{5.11}$$

and, since $\|\Psi\|_{C^m[\Omega]} \le C'''_m$, $m = 1, 2, \ldots$, we conclude that for each $m = 1, 2, \ldots$ we have an inequality of the form

$$\|\hat{A}_h\|_{W_1^m[\mathbb{R}^2]} \le C_m^{(iv)} \|B_h\|_{C^m[\Omega]}.$$

The proof is thus finished by the following lemma, which gives the required bounds on the norms of B_h.

Lemma 5.4. *For $h \ge 0$, and all $\lambda > 0$,*

$$\|B_h\|_{C^m[\Omega]} \le C_{\lambda,m}\ 2^{-\lambda 2^h}, \qquad m = 1, 2, \ldots. \tag{5.12}$$

The lemma is proved in the appendix.

5.3. Program of proof. Now that we know that the singularities "at the heart" of F have in a certain sense sparse coefficients, we are encouraged to elaborate the approach into a systematic proof that F itself has sparse coefficients.

The change-of-variables and windowing operations of section 5.1 created a series of objects which may be related to our object of interest F by

$$F = \sum_{r=1}^{2}(\tau_{1,r} \circ \tau_{2,r} \circ \tau_{3,r})G_r + (\tau_{1,0} \circ \tau_{2,0})\bar{F}_0. \tag{5.13}$$

Here the $\tau_{j,r}$ are change-of-variables operations and $\bar{F}_0$, G_1, and G_2 were all defined in section 5.1.

The terms in this sum may be arranged as in Table 5.1. In this table, cells in the same column describe objects defined on a common domain, and adjacent cells in the

Table 5.1
Relations among various functions.

	Col. 0		1		2		3
Row 0		$\overset{\tau_{1,0}}{\swarrow}$	$F_0(t,\theta)$	$\xleftarrow{\tau_{2,0}}$	$\bar{F}_0(\bar{t},\bar{\theta})$		
1	$F=\sum$	$\xleftarrow{\tau_{1,1}}$	$F_1(t,\theta)$	$\xleftarrow{\tau_{2,1}}$	$\bar{F}_1(\bar{t},\bar{\theta})$	$\xleftarrow{\tau_{3,1}}$	$G_1(u,v)$
2		$\overset{\tau_{1,2}}{\nwarrow}$	$F_2(t,\theta)$	$\xleftarrow{\tau_{2,2}}$	$\bar{F}_2(\bar{t},\bar{\theta})$	$\xleftarrow{\tau_{3,2}}$	$G_2(u,v)$

same row are objects on different domains linked by a transformation. For example $F_1(t,\theta) \xleftarrow{\tau_{2,1}} \bar{F}_1(\bar{t},\bar{\theta})$ means that there is a transformation $\tau_{2,1}$ such that $F_1 = \tau_{2,1}\bar{F}_1$; this is the change-of-variables transformation transporting a function from domain $(\bar{t},\bar{\theta})$ to the "same" function on domain (t,θ). Corresponding to each column in the table is a domain. For example, in Column 3, we have the domain of all $(u,v) \in \mathbb{R}^2$, while in Column 2, we have the domain of $(\bar{t},\bar{\theta}) \in \mathbb{R}^2$. We may associate to each such domain an orthobasis. For the domain of (u,v), we associate the orthobasis ψ_μ, where $\mu = (j,k,i,l,\varepsilon)$, and where μ runs through the set

$$\begin{aligned} M = \{&(j,k,i,\ell,0) : j,k,\ell \in \mathbb{Z}, i = \max(i_0,j)\} \\ &\cup\{(j,k,i,\ell,1) : j,k,\ell \in \mathbb{Z},\ i \geq \max(i_0,j)\}. \end{aligned} \tag{5.14}$$

For the domain of $(\bar{t},\bar{\theta})$, we associate the orthobasis $\bar{\psi}_{\bar{\mu}}(\bar{t},\bar{\theta})$, where $\bar{\mu}$ runs through the set M. For the domain of $(t,\theta) \in \mathbb{R} \times [0,2\pi)$, which occurs both in Columns 0 and 1, we associate two bases. For Column 0 we associate the antipodally symmetrized basis (W_λ) of section 2. For Column 1 we associate a standard tensor basis. Table 5.2 summarizes these choices. We may expand an object in a given column of Table 5.1 in the corresponding orthobasis for that column. We denote coefficients in Column 3 by A^1 and A^2, in Column 2 by B^0, B^1, and B^2, and coefficients in Column 1 by C^0, C^1, and C^2. Thus, for example,

$$\begin{aligned} G_1 &= \sum_\mu A^1_\mu\ \psi_\mu, \\ \bar{F}_1 &= \sum_{\bar{\mu}} B^1_{\bar{\mu}}\ \bar{\psi}_{\bar{\mu}}, \\ F_1 &= \sum_{\tilde{\lambda}} C^1_{\tilde{\lambda}}\ \tilde{\psi}_{\tilde{\lambda}}, \\ F &= \sum_\lambda \alpha_\lambda\ W_\lambda. \end{aligned}$$

Now objects in the same row of the Columns 2 and 3 of Table 5.1 are just "the same" object in different coordinate systems (i.e., we have $\bar{F}_1 = \tau_{3,1}G_1$, etc.), so the coefficients (A^r_μ) and $(B^r_{\bar{\mu}})$ for the same value of r are linearly related. Indeed, let $\psi^*_\mu(\bar{t},\bar{\theta})$ denote the "pushout" of ψ_μ from (u,v) coordinates to $(\bar{t},\bar{\theta})$ coordinates:

$$\psi^*_\mu(\bar{t},\bar{\theta}) = \psi_\mu(u(\bar{t}),v(\bar{\theta}));$$

then for $r = 1,2$ we have matrices $T_{3,r}$ such that

$$B^r = T_{3,r}A^r, \qquad r = 1,2,$$

Table 5.2
Relations between domains.

	Col. 0	1	2	3
Domain	(t,θ)	(t,θ)	$(\bar{t},\bar{\theta})$	(u,v)
Basis element	$W_\lambda(t,\theta)$	$\tilde{\psi}_{\tilde{\lambda}}(t,\theta)$	$\bar{\psi}_{\bar{\mu}}(\bar{t},\bar{\theta})$	$\psi_\mu(u,v)$
Formula	(2.12)	$\psi_{j,k}(t)w^{\varepsilon}_{i,\ell}(\theta)$	$\psi_{j,k}(\bar{t})\psi^{\varepsilon}_{i,\ell}(\theta)$	$\psi_{j,k}(u)\psi^{\varepsilon}_{i,\ell}(v)$
Index	λ	$\tilde{\lambda}=(j,k,i,l,\varepsilon)$	$\bar{\mu}=(j,k,i,l,\varepsilon)$	$\mu=(j,k,i,l,\varepsilon)$
Index set	Λ	$\{\tilde{\lambda}\}=\tilde{\Lambda}$	$\{\bar{\mu}\}=M$	$\{\mu\}=M$

where

$$(T_{3,r})_{\bar{\mu},\mu} = \langle \bar{\psi}_{\bar{\mu}}, \psi^*_\mu \rangle_{L^2(d\bar{t}d\bar{\theta})}.$$

Viewed another way, we have the diagram

$$\begin{tikzcd}
\bar{F}_1 & G_1 \arrow[l, "\tau_{3,1}"'] \arrow[d, "\mathcal{W}"] \\
B^1 \arrow[u, "\overline{\mathcal{W}}^{-1}"] & A^1, \arrow[l, "T_{3,1}"']
\end{tikzcd}$$

where $\mathcal{W}$ denotes wavelet transform using the ψ_μ basis, and $\overline{\mathcal{W}}^{-1}$ denotes inverse wavelet transform using the $\bar{\psi}_{\bar{\mu}}$ basis. That is, $T_{3,r}$ is the matrix representation of transformation $\tau_{3,r}$.

Also, as the $(\bar{t},\bar{\theta})$ and (t,θ) coordinate systems are related by periodization, and the objects in Columns 1 and 2 of the sa me row of Table 5.1 are identical on the common domain, the coefficients (B^r_μ) and $(C^r_{\tilde{\lambda}})$ are linearly related. Indeed, from (2.6) we have, for $\tilde{\lambda}=(j,k,i,\ell,\varepsilon)$,

$$C^r_{(j,k,i,\ell,\varepsilon)} = \sum_{h=-\infty}^{\infty} B^r_{(j,k,i,\ell+h2^i,\varepsilon)};$$

hence there is a matrix $T_{2,r}$ with

$$C^r = T_{2,r}B^r.$$

Finally, as

$$W_{(j,k,i,\ell,\varepsilon)} = (\tilde{\psi}_{(j,k,i,\ell,\varepsilon)} + \tilde{\psi}_{(j,1-k,i,\ell+2^{i-1},\varepsilon)})/2,$$

we have

$$2[W_{(j,k,i,\ell,\varepsilon)}, F] = [\tilde{\psi}_{(j,k,i,\ell,\varepsilon)}, F] + [\tilde{\psi}_{(j,1-k,i,\ell+2^{i-1},\varepsilon)}, F],$$

and so there is a matrix T_1 with

$$\alpha = T_1C^1 + T_1C^2 + T_1C^0.$$

That is, the same matrix T_1 represents all three transformations $\tau_{1,r}$.

Combining these remarks,

$$\alpha = \sum_{r=1}^{2}(T_1 \circ T_{2,r} \circ T_{3,r})A^r + (T_1 \circ T_{2,0})B^0. \tag{5.15}$$

Table 5.3
Relations between coefficient arrays.

	Col. 0		1		2		3
Row 0		$\overset{T_1}{\swarrow}$	C^0	$\overset{T_{2,0}}{\longleftarrow}$	B^0		
1	$\alpha = \sum$	$\overset{T_1}{\longleftarrow}$	C^1	$\overset{T_{2,1}}{\longleftarrow}$	B^1	$\overset{T_{3,1}}{\longleftarrow}$	A^1
2		$\overset{T_1}{\nwarrow}$	C^2	$\overset{T_{2,2}}{\longleftarrow}$	B^2	$\overset{T_{3,2}}{\longleftarrow}$	A^2

In short, we have a tabular arrangement at the level of coefficients as summarized in Table 5.3. Suppose that we can show that the A^r are in every ℓ^p for $r = 1, 2$, and that B^0 is in every ℓ^p, and also that every T-mapping is bounded from ℓ^p to ℓ^p for every p, $0 < p \leq 1$. It will then follow that $\alpha \in \ell^p$ for every $p > 0$.

Theorem 5.1 therefore follows from these lemmas, which focus on the range $0 < p \leq 1$, which is the important one.

Lemma 5.5. *For each $p \in (0, 1]$, T_1 is a bounded linear mapping from $\ell^p(\tilde{\Lambda})$ to $\ell^p(\Lambda)$.*

Lemma 5.6. *For each $p \in (0, 1]$, and for $r = 0, 1, 2$, $T_{2,r}$ is a bounded linear mapping from $\ell^p(M)$ to $\ell^p(\tilde{\Lambda})$.*

Lemma 5.7. *For each $p \in (0, 1]$, and for $r = 1, 2$, $T_{3,r}$ is a bounded linear mapping from $\ell^p(M)$ to $\ell^p(M)$.*

Lemma 5.8. *For each $p \in (0, 1]$, for $r = 1, 2$, $A^r \in \ell^p(M)$.*

Lemma 5.9. *For each $p \in (0, 1]$, $B^0 \in \ell^p(M)$.*

The "hardest" of these lemmas is Lemma 5.8; the analysis of section 5.2 suggests why it should be true; in effect G_1 behaves like S at high resolutions, and S has its high-resolution wavelet coefficients in every ℓ^p.

5.4. Easy pieces.

We begin with the easy Lemmas 5.5, 5.6, and 5.9.

Lemma 5.5, concerning T_1, is just the p-triangle inequality: for $p \leq 1$,

$$|C^r_{(j,k,i,\ell,\varepsilon)} + C^r_{(j,1-k,i,\ell+2^{i-1},\varepsilon)}|^p \leq |C^r_{(j,k,i,\ell,\varepsilon)}|^p + |C^r_{(j,1-k,i,\ell+2^{i-1},\varepsilon)}|^p;$$

summing over $\lambda \in \Lambda$ we get

$$\sum_{\lambda \in \Lambda} |C^r_{(j,k,i,\ell,\varepsilon)} + C^r_{(j,1-k,i,\ell+2^{i-1},\varepsilon)}|^p \leq \sum_{\tilde{\lambda} \in \tilde{\Lambda}} |C^r_{\tilde{\lambda}}|^p.$$

Lemma 5.6, concerning $T_{2,r}$, is also the p-triangle inequality:

$$\left| \sum_{h=-\infty}^{\infty} B^r_{(j,k,i,\ell+2^i \cdot h,\varepsilon)} \right|^p \leq \sum_{h=-\infty}^{\infty} |B^r_{(j,k,i,\ell+h2^i,\varepsilon)}|^p,$$

from which follows

$$\|C^r\|_{\ell^p} \leq \|B^r\|_{\ell^p}, \qquad r = 0, 1, 2; \quad p \in (0, 1].$$

Lemma 5.9, concerning B^0, is just an observation: if $\bar{F}_0(\bar{t}, \bar{\theta})$ is C^∞, with $\bar{F}_0$ and all its partial derivatives of rapid decay as $t \to \infty$, then its wavelet coefficients are in every ℓ^p, $p \in (0, 2]$.

5.5. Boundedness of $T_{3,r}$. We now consider Lemma 5.7. In principle, this is a simple matter, about the well-behavedness of the tensor wavelet transform under separable changes-of-variables. However, some of the estimation ideas play an important role in section 6, so we spell them out carefully.

Put for short $\mathbf{t}_{\mu,\mu'} = \langle \bar{\psi}_\mu, \psi^*_{\mu'} \rangle$. The norm of $T_{3,r}$ is bounded by

$$\|T_{3,r}\|_{(\ell^p \to \ell^p)} \le \sup_{\mu'} \left(\sum_\mu |\mathbf{t}_{\mu,\mu'}|^p \right)^{1/p}.$$

Let $M_0 = \{\mu : \varepsilon = 0\}$, $M_1 = \{\mu : \varepsilon = 1\}$, and let, for a,$b \in \{0,1\}$,

$$S_{a,b} = \sup_{\mu' \in M_a} \sum_{\mu \in M_b} |\mathbf{t}_{\mu,\mu'}|^p.$$

We need to show that

$$S_{a,b} < \infty, \qquad a, b \in \{0,1\}.$$

We first remark that $t_{\mu,\mu'}$ can be nonzero only if $j = j'$ and $k = k'$. We now consider four cases:

$\underline{S_{0,0}}$: here $i = i' = \max(i_0, j)$, $\varepsilon = \varepsilon' = 0$. By rapid decay of $\bar{\psi}_\mu$ and $\psi^*_{\mu'}$, we get for $m = 1, 2, \ldots$,

$$|\langle \bar{\psi}_\mu, \psi^*_{\mu'} \rangle| \le C_m \; 2^{i/2} (1 + 2^i |\bar{\theta}_{i,\ell} - \bar{\theta}^*_{i',\ell'}|)^{-m} \cdot \delta_{jj'} \delta_{kk'}.$$

Here $\bar{\theta}_{i,\ell} = \ell/2^i \cdot 2\pi$, $\bar{\theta}^*_{i',\ell'} = \bar{\theta}(\ell'/2^{i'})$. Picking m so large that $mp > 1$, and setting $t' = 2^{i'} \bar{\theta}^*_{i',\ell'}$

$$\sum_{\mu \in M_0} |\langle \bar{\psi}_\mu, \psi^*_{\mu'} \rangle|^p \le C_m \; 2^{ip/2} \sum_\ell (1 + |\ell - t'|)^{-mp} \le C_{m,p} < \infty.$$

$\underline{S_{0,1}}$: here $\varepsilon' = 0$, $\varepsilon = 1$. Now $\psi^*_{\mu'}$ is a smooth function at scale $2^{-i'}$, and as $i \ge \max(i_0, j) = \max(i_0, j') = i'$, $\bar{\psi}_\mu$ is an oscillatory function at a finer scale. As $\bar{\psi}_\mu$ has more than m vanishing moments, the m-fold integration by parts formula

$$\langle \bar{\psi}_\mu, \psi^*_{\mu'} \rangle = (-1)^m \langle \bar{\psi}_\mu^{(-m)}, (\psi^*_{\mu'})^{(m)} \rangle,$$

gives, for each $m = 1, 2, 3, \ldots$,

$$|\langle \bar{\psi}_\mu, \psi^*_{\mu'} \rangle| \le C_m \; 2^{-(i-i')(m-\frac{1}{2})} (1 + 2^{i'} |\bar{\theta}_{i,\ell} - \bar{\theta}^*_{i',\ell'}|)^{-m} \cdot \delta_{jj'} \delta_{kk'}.$$

Pick $m > 1/p + 1/2$. With $h = i - i'$ and $t' = 2^{i'} \bar{\theta}^*_{i',\ell'}$,

$$\begin{aligned} \sum_{\mu \in M_1} |\langle \bar{\psi}_\mu, \psi^*_{\mu'} \rangle|^p &\le C \sum_{h \ge 0} 2^{-h(m-\frac{1}{2})p} \sum_\ell (1 + |2^{-h}\ell - t'|)^{-mp} \\ &\le C \sum_{h \ge 0} 2^{-h(m-\frac{1}{2})p} 2^h. \end{aligned}$$

As $(m - \frac{1}{2})p > 1$, we get $S_{0,1} < \infty$.

$\underline{S_{1,0}}$: here $\varepsilon = 0$, $\varepsilon' = 1$. Now we reverse viewpoint. $\bar{\psi}_\mu$ is a smooth function at scale 2^{-i}, $i' \ge \max(i_0, j') = \max(i_0, j) = i$, and $\psi_{\mu'}$ is an oscillatory function at fine scale. Writing $\bar{\psi}^*_\mu$ for the "pullback" $\bar{\psi}_\mu(\bar{t}(u), \bar{\theta}(v))$, and $J(u,v)$ for the Jacobian $\left|\frac{d\bar{\theta}}{dv}\right|$, then

$$\langle \bar{\psi}_\mu, \psi^*_{\mu'} \rangle = \langle \bar{\psi}^*_\mu \cdot J, \psi_{\mu'} \rangle.$$

Now $\bar{\psi}_\mu \cdot J$ is smooth and of rapid decay, together with all its partial derivatives, so we get for $m = 1, 2, 3, \ldots$

$$|\langle \bar{\psi}^*_\mu \cdot J, \psi_{\mu'} \rangle| \le C_m \; 2^{-(i'-i)(m-\frac{1}{2})} (1 + 2^i |v^*_{i,\ell} - v_{i',\ell'}|)^{-m} \cdot \delta_{jj'} \delta_{kk'},$$

where $v_{i',\ell'} = \ell'/2^i$ and $v^*_{i,\ell} = v(\bar{\theta}_{i,\ell})$. Pick $m > 1/p$. Put $\ell^*(\ell) = 2^i v^*_{i,\ell}$. Now

$$|\ell^*(\ell) - \ell^*(\ell')| \ge c|\ell - \ell'|,$$

where $c = \inf_{\bar{\theta}} |v'(\bar{\theta})| > 0$; whatever t' may be,

$$\sum_\ell (1 + |\ell^*(\ell) - t'|)^{-mp} < C_{m,p}.$$

It follows that

$$\begin{aligned} \sum_{\mu \in M_0} |\langle \bar{\psi}_\mu, \psi^*_{\mu'} \rangle|^p &\le C \cdot \sum_{h \ge 0} 2^{-h(m-\frac{1}{2})p} \sum_\ell (1 + |\ell^*(\ell) - 2^{-h}\ell'|)^{-mp} \\ &\le C \cdot \sum_{h \ge 0} 2^{-h(m-\frac{1}{2})p}. \end{aligned}$$

As $(m - \frac{1}{2})p > 0$, we get $S_{1,0} < \infty$.

$\underline{S_{1,1}}$: here we have $i, i' \ge \max(i_0, j)$, $\varepsilon = \varepsilon' = 1$. We consider both cases where $\bar{\psi}_\mu$ is viewed as the oscillatory member and, alternatively, as the smooth member of the pair. In the case $i' \ge i$, $\bar{\psi}_\mu$ is the smooth member of the pair; arguing as in case $S_{1,0}$ gives

$$|\langle \bar{\psi}_\mu, \psi^*_{\mu'} \rangle| \le C \cdot 2^{-(i'-i)(m-\frac{1}{2})} (1 + 2^i |v^*_{i,\ell} - v_{i',\ell'}|)^{-m} \cdot \delta_{jj'} \delta_{kk'},$$

while if $i' \le i$, $\bar{\psi}_\mu$ is the oscillatory member of the pair; arguing as in case $S_{0,1}$ gives

$$|\langle \bar{\psi}_\mu, \psi^*_{\mu'} \rangle| \le C \cdot 2^{-(i-i')(m-\frac{1}{2})} (1 + 2^{i'} |\bar{\theta}_{i,\ell} - \bar{\theta}^*_{i',\ell'}|)^{-m} \cdot \delta_{jj'} \delta_{kk'}.$$

Pick $m > 1/2 + 1/p$. Using the above cases, and arguing as earlier, we get

$$\begin{aligned} \sum_{\mu \in M_1} |\langle \bar{\psi}_\mu, \psi^*_{\mu'} \rangle|^p &\le C \sum_{i < i'} \sum_\ell + \sum_{i \ge i'} \sum_\ell \\ &\le C \sum_{h \ge 0} 2^{-h(m-\frac{1}{2})p} + C \sum_{h \ge 0} 2^{-h(m-\frac{1}{2})p} \; 2^h. \end{aligned}$$

Because $(m - \frac{1}{2})p > 1$, we get $S_{1,1} < \infty$.

5.6. Sparsity of coefficients (A^r_μ). Now we arrive at the "heart of the matter" a second time, this time "for real." In essence, we refine the argument of Lemma 5.3. The key point is that Lemma 5.3 studied a precisely scale-invariant object, whereas now we study an object which is only asymptotically scale-invariant.

The argument is the same for $r = 1, 2$, so we consider only $r = 1$ and we omit the superscript 1.

We define $A_\mu = \langle H, (\Delta^+ \otimes I)\psi_\mu\rangle$, where

$$H(u, v) = \bar{\Phi}(u/|v|)V(u, v),$$

with $V(u, v) = e^{-u^2} \cdot \bar{V}_1(v)$ a renaming of the windowing terms in (5.3).

First, we consider the case $\varepsilon = 0$ and show that

$$\sum_{j=-\infty}^{\infty} \sum_{i=\max(i_0,j)} \sum_{k,\ell=-\infty}^{\infty} |A_{jki\ell 0}|^p \leq C^p.$$

In case $\varepsilon = 0$ and $j \leq i_0$, the sparsity of coefficients A_μ follows just from the rapid decay of $V(u, v)$ and boundedness of $\bar{\Phi}(u/|v|)$, which give

$$\sum_{j=-\infty}^{i_0} \sum_{i=i_0} \sum_{k,\ell=-\infty}^{\infty} |A_{jki\ell 0}|^p \leq C^p.$$

In case $\varepsilon = 0$ and $j > i_0$, the sparsity of coefficients A_μ follows from the argument used below in the case $\varepsilon = 1$; indeed it may be seen that the argument used there for $\Omega = \{\omega : |\omega_i| \in [2\pi/3, 8\pi/3]\}$ adapts easily to the larger set $\Omega' = \{\omega : |\omega_1| \in [2\pi/3, 8\pi/3], \omega_2 \in [-8\pi/3, 8\pi/3]\}$. This adaptation will yield

$$\sum_{j\geq i_0} \sum_{i=j} \sum_{k,\ell=-\infty}^{\infty} |A_{jki\ell 0}|^p \leq C^p.$$

So consider now the case $\varepsilon = 1$. To begin, we need a formula for the Fourier transform of $H(u, v)$, viewed as a tempered distribution in $\mathcal{S}'(\mathbb{R}^2)$. The convolution formula for tempered distributions [15] says that if $f \in \mathcal{S}'(\mathbb{R}^2)$ and $g \in \mathcal{S}(\mathbb{R}^2)$, then $(f \cdot g)\hat{} = (2\pi)^{-2}\hat{f} \star \hat{g}$. Hence

$$\hat{H} = (2\pi)^{-2} \cdot (\widehat{\dot{H}} \star \hat{V}) = \gamma_1\hat{V} + \gamma_2\hat{V} \star \beta,$$

where $\dot{H}$ is as in Lemma 8.1, and where the constants γ_r, $r = 1, 2$ can be obtained from that lemma, and where

$$\beta(\omega_1, \omega_2) = \mathrm{sgn}(\omega_1) \cdot |\omega_1|^{-2} \cdot e^{-\omega_2^2/\omega_1^2}.$$

Now obviously

$$\begin{aligned} A_\mu &= \gamma_1\langle \hat{V}, ((\Delta^+ \otimes I)\psi_\mu)\hat{}\rangle + \gamma_2\langle \hat{V} \star \beta, ((\Delta^+ \otimes I)\psi_\mu)\hat{}\rangle \\ &= \gamma_1\bar{A}_\mu + \gamma_2\tilde{A}_\mu, \end{aligned}$$

say. The first term in this expression has

$$\sum_{j=-\infty}^{\infty} \sum_{i\geq\max(i_0,j)} \sum_{k,\ell=-\infty}^{\infty} |\bar{A}_{jki\ell 1}|^p \leq C^p,$$

because V and all of its derivatives are smooth and of rapid decay. So we turn to the second term in the expression, ignoring the constant factor γ_2. To review, we wish to establish

$$\sum_{j=-\infty}^{\infty} \sum_{i\geq\max(i_0,j)} \sum_{k,\ell=-\infty}^{\infty} |\tilde{A}_{jki\ell 1}|^p \leq C^p, \tag{5.16}$$

where

$$\tilde{A}_{jki\ell 1} = \langle \hat{V} \star \beta, ((\Delta^+ \otimes I)\psi_\mu)\hat{\ } \rangle.$$

Now define $\beta_0(\xi_1, \xi_2) = (\hat{V} \star \beta)(\xi_1, \xi_2)$, and $\beta_j(\xi_1, \xi_2) = (V_j \star \beta)(\xi_1, \xi_2)$, where

$$V_j(\xi) = 2^{2j} \hat{V}(2^j \xi_1, 2^j \xi_2);$$

note that we are omitting the hat,$\hat{\ }$, from V_j, despite that fact that V_j is acting on the Fourier side and is defined in terms of $\hat{V}$. Below we will use the scaling relation

$$\beta_0(2^j\xi_1, 2^j\xi_2) = 2^{-2j}\beta_j(\xi_1, \xi_2). \tag{5.17}$$

Now

$$\begin{aligned}
\tilde{A}_{jki\ell\varepsilon} &= \iint \beta_0(\omega_1, \omega_2)|\omega_1|^{1/2}\hat{\psi}_{jk}(\omega_1)\hat{\psi}_{i\ell}(\omega_2)d\omega_1 d\omega_2 \\
&= \iint \beta_0(\omega_1, \omega_2)|\omega_1|^{1/2}\hat{\psi}(\omega_1/2^j)\hat{\psi}(\omega_2/2^i) \\
&\qquad \cdot \exp\{-\sqrt{-1}(\omega_1 k/2^j + \omega_2 \ell/2^i)\}2^{-(i+j)/2}d\omega_1 d\omega_2 \\
&= \iint \beta_0(\xi_1 2^j, \xi_2 2^i)|\xi_1 2^j|^{1/2}\hat{\psi}(\xi_1)\hat{\psi}(\xi_2) \\
&\qquad \cdot \exp\{-\sqrt{-1}(\xi_1 k + \xi_2 \ell)\}2^{(i+j)/2}d\xi_1 d\xi_2 \\
&= \iint_\Omega \hat{A}_{j,h}(\xi_1, \xi_2)\exp\{-\sqrt{-1}(\xi_1 k + \xi_2 \ell)\}d\xi_1 d\xi_2,
\end{aligned}$$

say, where we made the change-of-variables $\xi_1 = \omega_1/2^j$, $\xi_2 = \omega_2/2^i$, used the scaling relation (5.17), and where once again $\Omega = \{\omega : |\omega_i| \in [\frac{2\pi}{3}, \frac{8\pi}{3}]\}$. Here

$$\begin{aligned}
\hat{A}_{j,h}(\xi_1, \xi_2) &= \beta_j(\xi_1, \xi_2 2^h)|\xi_1|^{1/2}\hat{\psi}(\xi_1)\hat{\psi}(\xi_2)2^{-2j}2^{i/2}2^j \\
&= B_{j,h}(\xi_1, \xi_2) \cdot \Psi(\xi_1, \xi_2),
\end{aligned}$$

say, where

$$B_{j,h}(\xi_1, \xi_2) = \beta_j(\xi_1, \xi_2 2^h)2^{h/2}2^{-j/2}, \tag{5.18}$$

$$\Psi(\xi_1, \xi_2) = |\xi_1|^{1/2} \cdot \hat{\psi}(\xi_1)\hat{\psi}(\xi_2).$$

By the same type of analysis as in Lemma 5.3, we can conclude (5.16) once we establish that, for $m = 1, 2, 3, \ldots$, we have

$$\sum_{j \geq i_0} \sum_{h=0}^{\infty} \|\hat{A}_{j,h}\|^p_{C^m[\Omega]} < \infty \quad \forall p > 0.$$

Also as in (5.11) in that lemma, this will follow from the C^∞ nature of the compactly supported function $\Psi(\xi_1, \xi_2)$ and the following estimate on $B_{j,h}$.

LEMMA 5.10. *$B_{j,h} \in C^\infty[\Omega]$ $\forall$ $j \geq i_0$, and $h \geq 0$. In addition,*

$$\sum_{j \geq i_0} \sum_{h \geq 0} \|B_{j,h}\|^p_{C^m[\Omega]} < \infty, \qquad m = 1, 2, 3, \ldots. \tag{5.19}$$

The lemma is proved in the appendix.

6. Analysis of a more general linear singularity. We now consider the more general mutilated Gaussian

$$g_{\theta^0,x^0}(x) = g^0(U_{\theta^0}(x - x^0)),$$

where now g^0 is the "standard mutilated Gaussian" that was called g in section 5, U_{θ^0} is rotation by θ^0, and x^0 is a choice of origin. We will see that the sparsity properties of the ridgelet coefficients of g^0 hold equally for the ridgelet coefficients of g_{θ^0,x^0}.

The key point is to invoke the following covariance properties of the Radon transform:

1. Rotation covariance. Let $g(x) = g^0(U_{\theta^0}x)$. Then

$$(Rg)(t, \theta) = (Rg^0)(t, \theta - \theta^0).$$

2. Translation covariance. Let $g(x) = g^0(x - x^0)$. Then

$$(Rg)(t, \theta) = (Rg^0)(t - x_1^0 \cos\theta - x_2^0 \sin\theta, \theta).$$

Combining these observations with the formula

$$\alpha_\lambda = [(\Delta^+ \otimes I)Rg, W_\lambda],$$

we see that, with $F(t, \theta) = (\Delta^+ \otimes I)Rg$ and $F^0(t, \theta) = (\Delta^+ \otimes I)Rg^0$, the question of sparsity of the coefficients $(\tilde{\alpha}_\lambda : \lambda \in \Lambda)$ is equivalent to sparsity of wavelet coefficients of

$$F(t, \theta) = F^0(t - x_1^0 \cos(\theta) - x_2^0 \sin(\theta),\ \theta - \theta^0). \tag{6.1}$$

Thus we are interested in the assertion that the smooth change-of-variables,

$$\theta \mapsto \theta - \theta_0; \qquad t \mapsto t - (x_1^0 \cos(\theta) + x_2^0 \sin(\theta)) \tag{6.2}$$

preserves the sparsity of the W_λ wavelet coefficients. To some readers this may seem an innocuous change, but to wavelet experts there would seem to be plenty of reason for this transformation to cause major problems. The W_λ basis is closely connected to a simple tensor product of two wavelet bases, and for such bases, the coefficients are well known to be profoundly affected by very smooth nonlinear changes-of-variables. It turns out *in this case* that the transformation (6.2) has a banal effect on the coefficients because of three interacting factors:

(F1) The transformation of variables is very smooth (C^∞).

(F2) The transformation has a very special structure: it acts on the t variable only by translation according to a function of θ alone, and it acts as a simple shift in the θ variable.

(F3) The basis (W_λ) obeys the constraint $i \geq j$, which is especially compatible with nonlinear transformations with structural feature (F2).

As a result of this combination of factors, we have the following theorem.

THEOREM 6.1. *The coefficients of an F defined by transformation* (6.1) *belong to every ℓ^p for $p > 0$.*

This theorem will complete the proof of Theorem 1.3 of the introduction.

We now give the full argument. Let τ denote the transformation $F = \tau F_0$ defined by (6.1). Let α^0 denote the sequence of ridgelet coefficients of F^0 and α the sequence of ridgelet coefficients of F. Let T denote the matrix with entries $t_{\lambda,\lambda'} = [W_\lambda, \tau W'_\lambda]$. Then, in a pattern of reasoning already familiar from section 5.3,

$$\alpha = T\alpha^0.$$

The desired sparsity of ridgelet coefficients therefore is reduced to the following lemma.

LEMMA 6.2. *T is a bounded mapping from $\ell^p(\Lambda)$ to $\ell^p(\Lambda)$ $\forall$ $p > 0$.*

To prove this, we first observe that in the interesting range $p \in (0, 1]$,

$$\|T\|^p \leq \sup_{\lambda'} \sum_\lambda |t_{\lambda,\lambda'}|^p.$$

Recall now the approach of section 5.3, where properties of a W_λ-wavelet analysis (where antipodal symmetry is imposed on the basis elements) were inferred from a traditional wavelet analysis (without the antipodal symmetry). With $(\tilde{\psi}_\lambda)_{\tilde{\lambda}}$ denoting the orthobasis for $L^2(dtd\theta)$ without antipodal symmetry, suppose we can show the finiteness of

$$\sup_{\tilde{\lambda}'} \sum_{\tilde{\lambda}} |[\tilde{\psi}_{\tilde{\lambda}}, \tau\tilde{\psi}_{\tilde{\lambda}'}]|^p. \tag{6.3}$$

This will then imply finiteness of the norm of T.

Each sum inside the supremum of (6.3) can be interpreted as calculating the (pth power of) the ℓ^p-norm of the coefficients of $\tau\tilde{\psi}_{\tilde{\lambda}'}$. Thus we are interested in the assertion that the smooth deformation of coordinates (6.2) transforms "atoms"—individual basis elements—into "molecules"—sparse sums of basis elements. While such an assertion is not true for arbitrary deformations, it is true for deformations with the special structure considered in (F2) above, when the basis obeys the peculiar constraint $i \geq j$ mentioned in (F3).

To explain this claim, let

$$\Psi_{j,j'}(d) = \int \psi_{j,0}(t)\psi_{j',0}(t-d)dt.$$

Observe that $\Psi_{j,j'} = \Psi_{j-j',0}$; moreover, because Meyer wavelets are being used, $\Psi_{j,j'} = 0$ for $|j - j'| > 1$. Also each $\Psi_{h,0}$, for $h = 0, 1, -1$, is C^∞ and obeys, together with all of its derivatives, rapid decay estimates. Now let $\nu(\theta) = x_1^0 \cos(\theta) + x_2^0 \sin(\theta)$. The (t, θ) integral defining the wavelet coefficients can be reexpressed using $\Psi_{j,j'}$ and ν into a one-dimensional integral of θ alone:

$$\begin{aligned}[\tilde{\psi}_\lambda, \tau\tilde{\psi}_{\lambda'}] &= \frac{1}{4\pi}\int_0^{2\pi} w_{i,\ell}(\theta)w_{i',\ell'}(\theta-\theta_0)\int_{-\infty}^{\infty} \psi_{j,k}(t)\psi_{j',k'}(t-\nu(\theta))dtd\theta \\ &= \frac{1}{4\pi}\int_0^{2\pi} w_{i,\ell}(\theta)w_{i',\ell'}(\theta-\theta_0)\Psi_{j,j'}(t_{j',k'} + \nu(\theta) - t_{j,k})d\theta.\end{aligned}$$

This integral involves three terms: two wavelets and a Ψ-factor. Observe that $i \geq j$, $i' \geq j'$. Also $|j - j'| \leq 1$ in order for $\Psi \neq 0$. The $\Psi_{j,j'}$ factor may therefore be viewed as a smooth function at a scale 2^{-j}. Owing to the $i \geq j$ constraint in forming the basis, the scale of the $\Psi_{j,j'}$ factor *is coarser than the scale of the two wavelet terms $w_{i,\ell}$ and $w_{i,\ell'}$*. Indeed, the $w_{i',\ell'}(\theta + \theta_0)$ factor is either a smooth function at the same scale $2^{-j'}$ ($\approx 2^{-j}$, as $|j - j'| \leq 1$), or an oscillatory one at a finer scale $2^{-i'}$, $i' > j'$.

The $w_{i,\ell}(\theta)$ factor is either a smooth function at the same scale 2^{-j} or an oscillatory function at a finer scale.

We recall the pattern of reasoning of section 5.5, which developed decay estimates for certain inner products, which we now view as integrals involving *two* factors, a wavelet and a deformed wavelet. The pattern was (i) for two nonoscillatory factors at the same scale, use rapid decay of the factors to infer that the integral decays rapidly with increasing separation between the locations of the two factors; (ii) for factors at different scales, observe that because $i \geq j$, the finer scale factor must be oscillatory and the coarser scale factor smooth; using integration by parts, combined with rapid decay estimates on derivatives, show that the integral decays rapidly in the spatial separation of the two factors, as well as rapidly in the scale separation of the two factors.

To apply this pattern of reasoning in the present case, we may group the *three* terms in our integrand into two terms and reason as before. The grouping decision goes by cases, depending on λ and λ'. The cases are Λ_1, where $i = j$ and $i' = j'$ (the coarse-scale case); Λ_2, where $i > i' \geq j$; and Λ_3, where $i' \geq i > j$. We can then show that

$$\sum_{\lambda \in \Lambda_a} |[\tilde{\psi}_\lambda, \tau \tilde{\psi}_{\lambda'}]|^p \leq C$$

with constant C independent of λ' and of $a \in \{1, 2, 3\}$.

In the first case, we argue from rapid decay as in case $S_{0,0}$ of section 5.5. In Λ_2 and Λ_3, we argue that the product of the Ψ term with the coarser-scale wavelet (either $w_{i,\ell}(\theta)$ or $w_{i',\ell'}(\theta + \theta_0)$ as the case may be) yields a factor which obeys the same smoothness and localization bounds that the coarser-scale wavelet obeys. We then use the integration-by-parts argument of cases $S_{0,1}$ and $S_{1,0}$ in section 5.5. This completes the proof of Lemma 6.2.

7. Discussion.

7.1. Alternate ridgelet orthobasis. Another natural construction of orthobasis can be made using the ideas of sections 2–4. Define the index set

$$\begin{aligned} \Lambda' = & \{(j,k;i,l,0) : i = i_0; j,k \in \mathbb{Z};\ \ell = 0, \dots, 2^{i-1} - 1\} \\ & \cup \quad \{(j,k;i,l,1) : i \geq i_0; j,k \in \mathbb{Z};\ \ell = 0, \dots, 2^{i-1} - 1\}. \end{aligned} \tag{7.1}$$

In comparison with the set Λ, notice that we may have either $j > i$ or $j \leq i$, and that $\varepsilon = 0$ is only compatible with $i = i_0$. It is easy to see that $(W_\lambda : \lambda \in \Lambda')$ is a complete orthonormal system for $\mathcal{R}$, and so the isometry $\rho_\lambda = \mathcal{J}(W_\lambda)$ makes $(\rho_\lambda : \lambda \in \Lambda')$ a complete orthonormal system for $L^2(\mathbb{R}^2)$.

This alternate system of orthonormal ridgelets has an attractive "angular multiresolution" interpretation where angular behavior over coarser scales than 2^{-j} is represented in the transform. In the technical report version of this article [8], this basis was studied carefully. For reasons of space, we have omitted that analysis here.

7.2. Alternate *g*. Obviously the approach we have developed is not limited to the Gaussian case studied here. A natural class of examples to study is the form $g^0(x_1, x_2) = g_1(x_1) \cdot g_2(x_2)$, where $g_1 \in \mathcal{S}(\mathbb{R})$ and $g_2(x_2)$ is smooth away from a singularity at $x_2 = 0$, and on each half line is of rapid decay along with its derivatives. The simple case $g_2(x_2) = e^{-x_2} 1_{\{x_2 > 0\}}$ is rather easy to study and yields the same qualitative conclusions as in the Gaussian case.

The Fourier-domain estimation technique that we have developed here requires a considerable amount of effort to carry out. A lot of the effort is based on the fact that we are studying objects of unlimited smoothness away from the singularity, and we want to show that the rate of decay of the ridgelet coefficients is unlimited. For general results on functions of limited smoothness, assuming only qualitative properties of g, such as Hölder smoothness of order m, the task is in principle less challenging, because one hopes only to establish a limited rate of decay of the ridgelet coefficients. It would be useful to have an easier technique for coefficient estimation.

The report [8] developed an approach to estimation of ridgelet coefficients using Radon-domain estimates, rather than Fourier-domain estimates, and wavelets of compact support [4], rather than Meyer wavelets. That approach could be useful in dealing with objects with limited smoothness, and might well be easier to apply in certain situations.

7.3. Curvilinear singularity. We stress that orthonormal ridgelet analysis of an object with singularity along a curve does not, in general, yield sparse coefficients.

In effect, the Radon transform of such an object has a singularity along a curve, and not just at a point. Consider, for example, the object $g' = e^{-x_1^2-x_2^2} \cdot 1_{\{x_2 > x_1^2\}}$. Define $\Phi(a,b) = \int_a^b e^{-u^2} du$. Using the geometric viewpoint of Figure 8.1 in the appendix, with coordinates t and u rotated by angle θ from the coordinates x_1 and x_2, one can write the Radon transform Rg' as

$$(Rg')(t,\theta) = e^{-t^2} \Phi(u_-(\theta, t - t_0(\theta)), u_+(\theta, t - t_0(\theta))),$$

where $t_0(\theta)$ is the t-coordinate for which $\mathcal{L}_{(\theta,t)}$ is tangent to the parabola $x_2 = x_1^2$, and, with orientation chosen so that for $t > t_0$, $\mathcal{L}_{(\theta,t)}$ intersects the parabola, the functions $u_\pm$ are smooth functions of θ and $t - t_0$ giving the u-coordinates of the two points at which the line $\mathcal{L}_{(\theta,t)}$ intersects the parabola. The function $t_0(\theta)$ is a smooth function of θ, and for an appropriate smooth function $c(\theta)$, we have the asymptotic

$$u_+(\theta, \delta t) - u_-(\theta, \delta t) \sim c(\theta)|\delta t|^{1/2} \qquad \text{as } |\delta t| \to 0.$$

Letting $u_0(\theta)$ be the common limit of $u_\pm(\theta, \delta t)$ as $t \to t_0(\theta)$, we therefore have

$$\Phi(u_-(\theta, t - t_0(\theta)), u_+(\theta, t - t_0(\theta))) \sim e^{-u_0^2} \cdot c(\theta)|\delta t|^{1/2} \qquad \text{as } |\delta t| \to 0.$$

Hence Rg' has a singularity of order $1/2$ in the t-direction at points $(\theta, t_0(\theta))$ lying along a smooth curve.

As orthonormal ridgelet analysis amounts to a kind of wavelet analysis in the Radon domain, and as wavelet analysis of singularities along curves does not yield sparse coefficients, so the ridgelet coefficients of such an object are not sparse. The ridgelet coefficients of such a curved object decay, in general, no faster than the wavelet coefficients of the same object. However, with an appropriate multiscale localization of the ridgelet basis, a significant improvement over wavelet analysis can be obtained.

7.4. Higher dimensions. Our construction of orthonormal ridgelets relies on two facts: first, the existence of orthonormal wavelets on the circle, and second, the existence of an isometry between antipodally symmetric functions in Radon space and functions in Real space. To obtain the analogous construction straightforwardly in dimensions $d > 2$, we would need orthonormal wavelets on the sphere S^{d-1} and an isometry for higher dimensions. The isometry exists in every dimension $d \geq 2$ [12].

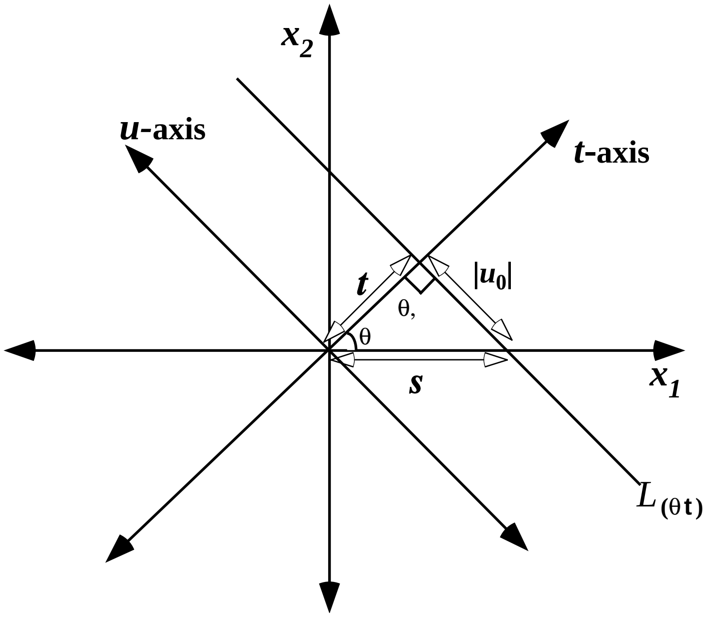

FIG. 8.1. *Geometry for calculating the Radon transform of g.*

Unfortunately, orthonormal spherical wavelets are not known for any dimension $d > 2$. The next best thing to an orthonormal system is a tight frame, which obeys a Parseval relation. The article [10] constructs tight frames of wavelet-like elements on spheres of all dimensions and so obtains tight frames of ridgelets in all dimensions $d > 2$. It also shows how to construct k-plane ridgelets (tight frame expansions substituting for functions depending on k-variables) for $k = 1, \ldots, d-1$ in every dimension $d > 2$. It is an interesting question whether results paralleling Theorem 1.3 can be had in higher dimensions d and for various codimensions k. [10] suggests that the answer is yes whenever $k = d - 1$.

8. Appendix.

8.1. Radon transform of *g*. The diagram in Figure 8.1 shows how to derive the Radon transform of g.

The Radon transform of g at (t, θ) may be viewed the integral of $e^{-x_1^2 - x_2^2}$ along that part of the line $\mathcal{L}_{(\theta,t)}$ lying inside the upper halfplane. For θ fixed, introduce orthogonal coordinates (t, u) with t the same as the t variable in the Radon transform. Thus the line of integration in the Radon transform is expressible as $\mathcal{L}_{(\theta,t)} = \{(t,u) : u \in \mathbb{R}\}$ in the new coordinates. Let u_0 denote the least value of u for which (t, u) is in both $\mathcal{L}_{(\theta,t)}$ and the upper halfplane $x_2 \geq 0$. Also, note that by orthogonality of the coordinates, $e^{-x_1^2 - x_2^2} = e^{-t^2 - u^2}$. Hence

$$(Rg)(t,\theta) = \int_{u_0}^{\infty} e^{-t^2-u^2} du = e^{-t^2} \cdot \int_{u_0}^{\infty} e^{-u^2} du = e^{-t^2} \cdot \bar{\Phi}(u_0),$$

say, where here and below $\bar{\Phi}(v) \equiv \int_v^\infty e^{-u^2} du$. Now from the geometry of the figure we can see that there is a right triangle with hypotenuse s, say, so that $|t|$ and $|u_0|$

are the lengths of the other two sides, and so

$$|t| = s\cos(\theta); \qquad |u_0| = s\sin(\theta).$$

In the range $0 \le \theta < \pi/2$, $u_0 = -\sin(\theta)/\cos(\theta)\cdot t$. Similar diagrams for other ranges of θ show that $u_0 = -|\sin(\theta)/\cos(\theta)|\cdot t$ is the correct general formula. We therefore have (5.2). $\square$

8.2. Fourier transform of $\boldsymbol{S}$. The key formula (5.5) is essentially an immediate application of the following lemma, which will be proved in a moment.

LEMMA 8.1. *Let $\dot{H}(u,v) = \bar{\Phi}(u/|v|)$. This bounded function, viewed as tempered distribution, has Fourier transform*

$$\widehat{\dot{H}} = 2\pi^{5/2}\delta_0 - 2\pi\cdot\sqrt{-1}\cdot\mathrm{sgn}(\omega_1)|\omega_1|^{-2}e^{-\omega_2^2/\omega_1^2}, \tag{8.1}$$

where δ_0 denotes the Dirac mass at $(\omega_1,\omega_2) = (0,0)$.

To use this to get (5.5), write the formula in (8.1) as $\widehat{\dot{H}} = \gamma_1\delta_0 + \widehat{\dot{H}}_1(\omega_1,\omega_2)$, with constant γ_1. Comparing the formulas in the two lemmas, we have that $\hat{S}(\omega_1,\omega_2) = \widehat{\dot{H}}_1(\omega_1,\omega_2)|\omega_1|^{1/2}$. In other words, we form $\hat{S}$ by multiplying the proper function $\widehat{\dot{H}}_1$ by $|\omega_1|^{1/2}$, while completely ignoring the singular term supported at 0. This works because

$$\begin{aligned}
\langle S, f\rangle &\equiv \langle \dot{H}, (\Delta^+\otimes I)f\rangle\\
&= \frac{1}{4\pi^2}\langle \widehat{\dot{H}}, ((\Delta^+\otimes I)f)\hat{}\,\rangle\\
&= \frac{1}{4\pi^2}\Big(\gamma_1((\Delta^+\otimes I)f)\hat{}\,(0,0)\\
&\qquad + \iint \widehat{\dot{H}}_1(\omega_1,\omega_2)|\omega_1|^{1/2}\hat{f}(\omega_1,\omega_2)d\omega_1 d\omega_2\Big)\\
&= \frac{1}{4\pi^2}\iint \widehat{\dot{H}}_1(\omega_1,\omega_2)|\omega_1|^{1/2}\hat{f}(\omega_1,\omega_2)d\omega_1 d\omega_2\\
&\equiv \frac{1}{4\pi^2}\langle \hat{S}, \hat{f}\rangle;
\end{aligned}$$

the singular term in $\widehat{\dot{H}}$ supported at the origin never enters because of the vanishing of $\hat{f}$ and $|\omega_1|^{1/2}$ there.

It is enough to establish the formula (8.1) for tensor products $f\otimes g$, i.e.,

$$\begin{aligned}
\langle \dot{H}, f\otimes g\rangle &= \frac{1}{4\pi^2}\langle 2\pi^{5/2}\delta_0, (f\otimes g)\hat{}\,\rangle\\
&\quad + \frac{1}{4\pi^2}\left\langle \frac{2\pi}{\sqrt{-1}}\frac{\mathrm{sgn}(\omega_1)}{|\omega_1|^2}e^{-\omega_2^2/\omega_1^2}, (f\otimes g)\hat{}\,\right\rangle.
\end{aligned} \tag{8.2}$$

We begin with some one-dimensional Fourier analysis. $\bar{\Phi}$ is a bounded function, and as a tempered distribution has, for $f\in\mathcal{S}$,

$$\int_{-\infty}^{\infty}\bar{\Phi}(t)f(t)dt = \frac{\sqrt{\pi}}{2}\int_{-\infty}^{\infty}f(t)dt - \frac{\sqrt{-1}}{2\pi}\int_{-\infty}^{\infty}\frac{\hat{\phi}(\omega)}{\omega}\hat{f}(\omega)d\omega, \tag{8.3}$$

where $\phi(t) = e^{-t^2}$ and where the last integral should be interpreted as

$$\int_0^\infty \hat{\phi}(\omega)(\hat{f}(\omega) - \hat{f}(-\omega))/\omega d\omega,$$

which is absolutely convergent for $f \in \mathcal{S}$. The justification of (8.3) can be obtained either by viewing $\bar{\Phi}(-t)$ as the convolution of a Heaviside function with ϕ, and using the formula for the Fourier transform of a Heaviside [11, p. 172] or directly as follows.

$\bar{\Phi}(t)$ is of the form $\frac{\sqrt{\pi}}{2} + \nu(t)$, where $\nu(t)$ is an odd bounded C^∞ function. Hence, splitting $f = f_e + f_o$ into its even and odd parts,

$$\int_{-\infty}^\infty \bar{\Phi}(t) f(t) dt = \frac{\sqrt{\pi}}{2} \int_{-\infty}^\infty f_e(u) du + \int_{-\infty}^\infty \nu(t) f_o(t) dt.$$

From $f_o \in \mathcal{S}$ and integration by parts,

$$\int_{-\infty}^\infty \nu(t) f_o(t) dt = -\int_{-\infty}^\infty \nu'(t) F_o(t) dt = \int_{-\infty}^\infty \phi(t) F_o(t) dt,$$

where $-\nu' = -(\bar{\Phi})' = \phi$, and F_o is the primitive of f_0. For an odd function $f_o \in \mathcal{S}$, the primitive F_o, viewed as a tempered distribution, has a Fourier transform which is represented by integration against a proper function, and obeys the formula

$$\hat{F}_o(\omega) = (i\omega)^{-1} \hat{f}_o(\omega).$$

Hence

$$\int_{-\infty}^\infty \phi(t) F_o(t) dt = \frac{1}{2\pi} \int \hat{\phi}(\omega) \cdot (i\omega)^{-1} \hat{f}_o(\omega) d\omega.$$

Note, however, that as f is real and f_e is even, $\hat{f}_e$ is even. This integral therefore is insensitive to the difference between $\hat{f}$ and $\hat{f}_o$:

$$\frac{1}{2\pi} \int \hat{\phi}(\omega) \cdot (i\omega)^{-1} \hat{f}(\omega) d\omega = \frac{1}{2\pi} \int \hat{\phi}(\omega) \cdot (i\omega)^{-1} \hat{f}_o(\omega) d\omega;$$

(8.3) follows.

Note now that

$$\int_{-\infty}^\infty \bar{\Phi}(u/|v|) f(u) du = \frac{\sqrt{\pi}}{2} \int_{-\infty}^\infty f(u) du - \frac{\sqrt{-1}}{2\pi} \int_{-\infty}^\infty \frac{\hat{\phi}(v\omega_1)}{\omega_1} \hat{f}(\omega_1) d\omega_1,$$

and so

$$\begin{aligned} \int_{-\infty}^\infty g(v) \int_{-\infty}^\infty \bar{\Phi}(u/|v|) f(u) du dv &= \frac{\sqrt{\pi}}{2} \Big(\int_{-\infty}^\infty f(u) du \Big) \Big(\int_{-\infty}^\infty g(v) dv \Big) \\ &\quad - \frac{\sqrt{-1}}{2\pi} \int_{-\infty}^\infty g(v) \int_0^\infty \hat{\phi}(v\omega_1) h(\omega_1) d\omega_1 dv \\ &= I + II, \end{aligned}$$

say, where $h(\omega_1) \equiv (\hat{f}(\omega_1) - \hat{f}(-\omega_1))/\omega_1$. Now as $\hat{\phi}$ is bounded and g and h are absolutely integrable on their domains, Fubini applies; hence

$$II = -\frac{\sqrt{-1}}{2\pi} \int_0^\infty h(\omega_1) \int_{-\infty}^\infty g(v) \hat{\phi}(v\omega_1) dv d\omega_1.$$

Parseval gives, for $\omega_1 \neq 0$,

$$\int_{-\infty}^{\infty} g(v)\hat{\phi}(v\omega_1)dv = \frac{1}{2\pi}\int_{-\infty}^{\infty} \hat{g}(\omega_2)\tilde{\phi}_{\omega_1}(\omega_2)d\omega_2,$$

where

$$\begin{aligned}\tilde{\phi}_{\omega_1}(\omega_2) &\equiv \int_{-\infty}^{\infty} \hat{\phi}(v\omega_1)e^{-iv\omega_2}dv \\ &= \frac{2\pi}{|\omega_1|}e^{-\omega_2^2/\omega_1^2}.\end{aligned}$$

Now

$$\frac{2\pi}{|\omega_1|}e^{-\omega_2^2/\omega_1^2}$$

is in $L^1((0,\infty)\times\mathbb{R})$; indeed, it is homogeneous of degree -1 and is integrable along the four line segments on the boundary of the unit square. It follows that we may unambiguously write

$$II = -\frac{\sqrt{-1}}{(2\pi)^2}\int_{-\infty}^{\infty}\int_0^{\infty} \hat{g}(\omega_2)h(\omega_1)\frac{2\pi}{|\omega_1|}e^{-\omega_2^2/\omega_1^2}d\omega_1 d\omega_2.$$

Unwrapping the formula for h in terms of $\hat{f}$, this becomes the second term of the desired formula (8.2). As for the first term in that formula, this follows from

$$I = \frac{\sqrt{\pi}}{2}\left(\int_{-\infty}^{\infty} f(u)du\right)\left(\int_{-\infty}^{\infty} g(v)dv\right) = \frac{\sqrt{\pi}}{2}\hat{f}(0)\hat{g}(0) = \frac{\sqrt{\pi}}{2}\langle\delta_0, \hat{f}\otimes\hat{g}\rangle. \qquad \square$$

8.3. Proof of Lemma 5.4. Define

$$\beta_t(\omega_1,\omega_2) = t\ e^{-t^4 E(\omega_1,\omega_2)},$$

where the exponent function E obeys

[E1] $E(\omega_1,\omega_2) \in C^m[\Omega]$, $m = 1,2,3,\ldots$; and

[E2] $|E(\omega_1,\omega_2)| \geq C > 0$ on Ω.

The particular case $E(\omega_1,\omega_2) = \omega_2^2/\omega_1^2$ gives $B_h = \beta_t$ with $t = 2^{h/2}$. This does have the required properties [E1]–[E2] because on Ω, $\frac{2}{3}\pi \leq |\omega_i| \leq \frac{8}{3}\pi$, and so the ratio stays well away from zero and infinity.

We will show that

$$\|\beta_t\|_{C^m[\Omega]} \leq 2^{-\lambda t}\cdot \text{const}, \qquad t > t(\lambda), \tag{8.4}$$

giving (5.12). Indeed

$$\left(\frac{\partial}{\partial\omega_1}\right)^{m_1}\left(\frac{\partial}{\partial\omega_2}\right)^{m_2}\beta_t = e^{-t^4E}\left\{\sum_{d=0}^{D_0(m_1,m_2)} P_d(t)Q_d(E, E^{(1,0)},\ldots)\right\},$$

where each P_d is a polynomial of degree $\leq D_1(m)$, each Q_d is a multivariate polynomial of degree $\leq D_2(m)$, and where the degrees in question satisfy $D_i(m) \leq C_1 + C_2(m_1 + m_2)$, $i = 0,1,2$. Here the $E^{(m_1,m_2)}$ are mixed partial derivatives of E. Hence for an $m' \leq C_1 + C_2 m$ we have

$$\|\beta_t\|_{C^m[\Omega]} \leq e^{-t^4E}\tilde{P}(t)\tilde{Q}(\|E\|_{C^{m'}[\Omega]}),$$

where $\tilde{P}$ and $\tilde{Q}$ are univariate polynomials of degree $\leq D_3(m) \leq C_1' + C_2'(m)$.

Now under [E2], $|E| > C$, and so for $\lambda > 0$, there is $t(\lambda)$ so $e^{-t^4C} < 2^{-\lambda t}$ $\forall$ $t > t(\lambda)$, giving (8.4), valid $\forall$ $\lambda > 0$. $\square$

8.4. Proof of Lemma 5.10. Throughout this section, let

$$\partial^{(m,n)} \equiv \left(\frac{\partial}{\partial \xi_1}\right)^m \left(\frac{\partial}{\partial \xi_2}\right)^n .$$

8.4.1. Auxiliary lemmas.

LEMMA 8.2. *Let* $\beta(\omega_1, \omega_2) = \mathrm{sgn}(\omega_1)|\omega_1|^{-2}\exp\{-\frac{\omega_2^2}{\omega_1^2}\}$. *Then* $\beta \in C^\infty(\mathbb{R} \times ([-8\pi/3, -2\pi/3] \cup [2\pi/3, 8\pi/3]))$. *Also*

$$\left(\frac{\partial}{\partial \omega_1}\right)^m \left(\frac{\partial}{\partial \omega_2}\right)^n \beta(\omega_1, \omega_2) = \mathrm{sgn}(\omega_1)^{m+n+1}|\omega_1|^{-2-m-n}F_{m,n}(\omega_2/\omega_1), \tag{8.5}$$

where $F_{m,n} \in \mathcal{S}(\mathbb{R})$.

Proof. Let $F \in \mathcal{S}(\mathbb{R})$. On $\omega_1 \neq 0$,

$$\frac{\partial}{\partial \omega_1}\left[|\omega_1|^{-2-\ell}F(\omega_2/\omega_1)\right] = \mathrm{sgn}(\omega_1)|\omega_1|^{-2-\ell-1}\tilde{F}(\omega_2/\omega_1),$$

where $\tilde{F}(t) = (-2-\ell)F(t) - F'(t)\cdot t$ satisfies $\tilde{F} \in \mathcal{S}(\mathbb{R})$. Similarly, on $\omega_1 \neq 0$,

$$\frac{\partial}{\partial \omega_2}\left[|\omega_1|^{-2-\ell}F(\omega_2/\omega_1)\right] = \mathrm{sgn}(\omega_1)|\omega_1|^{-2-\ell-1}\tilde{F}(\omega_2/\omega_1),$$

where now $\tilde{F}(t) = F'(t)$ and again $\tilde{F} \in \mathcal{S}(\mathbb{R})$. Repetitively applying this pair of observations gives (8.5). □

LEMMA 8.3.

$$|\partial^{(m,n)}\nu_1\beta| \leq C_{m,n}\cdot(1+|\omega_2|)^{-m-n-2}, \quad \omega \in \mathbb{R}^2. \tag{8.6}$$

Proof. First, we remark that when $\omega_1, \omega_2 \neq 0$,

$$\beta^{(m,n)}(\omega_1, \omega_2) = |\omega_1|^{-m-n-2}\cdot \mathrm{sgn}(\omega_1)^{m+n+1}\cdot F_{m,n}(\omega_2/\omega_1),$$

where $F_{m,n} \in \mathcal{S}(\mathbb{R})$; see Lemma 8.2 above. Second, putting now $\nu = \nu_1$, there are constants $C_{\ell,m}$ so that

$$\begin{aligned}\partial^{(m,n)}\nu\beta &= \partial^{(m,0)}(\nu\cdot\partial^{(0,n)}\beta)\\ &= \sum_{\ell=0}^{m} C_{\ell,m}\nu^{(\ell,0)}\beta^{(m-\ell,n)},\end{aligned}$$

where $\nu^{(\ell,0)} \equiv \partial^{(\ell,0)}\nu$. Now for $\ell > 0$, $\nu^{(\ell,0)}$ is supported in $\{\omega : |\omega_1| \in [1,2]\}$. Hence, there is $\tilde{\nu}_\ell \in \mathcal{S}(\mathbb{R}^2)$ so that

$$\nu^{(\ell,0)}(\omega) = \tilde{\nu}_\ell(\omega)\cdot \mathrm{sgn}(\omega_1)^\ell|\omega_1|^{-\ell}.$$

We have

$$|\partial^{(m,n)}\nu\beta| \leq \sum_{\ell=0}^{m}|\tilde{\nu}_\ell|\cdot|\omega_1|^{-m-n-2}|F_{n,m,\ell}(\omega_2/\omega_1)|$$

for $F_{n,m,\ell} \in \mathcal{S}(\mathbb{R})$. Now as each $F_{n,m,\ell} \in \mathcal{S}(\mathbb{R})$, we have

$$F_{n,m,l}(t) \leq C\cdot|t|^{-m-n-2} \qquad \forall|t| > 1.$$

On the set where $|\omega_2| > |\omega_1|$, this gives the inequality

$$|\omega_1|^{-m-n-2}|F_{n,m,\ell}(\omega_2/\omega_1)| \leq C \cdot |\omega_2|^{-m-n-2}$$

and on the set where $|\omega_2| < |\omega_1|$, $F_{n,m,\ell} \in \mathcal{S}(\mathbb{R})$ gives the inequality

$$|\omega_1|^{-m-n-2}|F_{n,m,\ell}(\omega_2/\omega_1)| \leq C \cdot |\omega_1|^{-m-n-2} \leq C \cdot |\omega_2|^{-m-n-2}.$$

Now on $|\omega_2| \geq 1$, $|\omega_2|^{-m-n-2} \leq C(1+|\omega_2|)^{-m-n-2}$. Equation (8.6) follows from this and supp $\nu_\ell \subset ([-1,1]^2)^c$. □

LEMMA 8.4. *For $\mu > \alpha + 1$, $\mu > 2$, $\alpha > 0$*

$$\int (1+|\omega|)^{-\mu}(1+|\xi-\omega|)^{-\alpha} d\omega \leq C_{\mu,\alpha}(1+|\xi|/2)^{-\alpha}. \tag{8.7}$$

Proof. Suppose without loss of generality that $\xi > 1$.

$$\begin{aligned}\int_{-\infty}^{\xi/2} (1+|\omega|)^{-\mu}(1+|\xi-\omega|)^{-\alpha} d\omega &\leq (1+|\xi|/2)^{-\alpha} \cdot \int_{-\infty}^{\xi/2} (1+|\omega|)^{-\mu} d\omega \\ &\leq C_\mu \cdot (1+|\xi|/2)^{-\alpha}.\end{aligned}$$

$$\begin{aligned}\int_{\xi/2}^{\infty} (1+|\omega|)^{-\mu}(1+|\xi-\omega|)^{-\alpha} d\omega &\leq \int_{\xi/2}^{\infty} (1+|\omega|)^{-\mu} d\omega \\ &= (\xi/2+1)^{1-\mu}/(\mu-1) \\ &\leq C_{\mu,\alpha}(1+|\xi|/2)^{-\alpha}, \qquad \xi > 1, \mu > \alpha+1. \qquad □\end{aligned}$$

8.4.2. Proof of (5.19). Now let $\Omega_j^h = \{(2^j \xi_1, 2^{j+h}\xi_2) : \xi \in \Omega\}$. Then from (5.17) and (5.18) we get the scaling relation

$$\|\partial^{(m,n)} B_{j,h}\|_{L^\infty[\Omega]} = (2^h)^{(n+1/2)} 2^{(m+n+3/2)j} \|\beta_0^{(m,n)}\|_{L^\infty[\Omega_j^h]}. \tag{8.8}$$

Our proof of (5.19) shows that

$$\|\beta_0^{(m,n)}\|_{L^\infty[\Omega_j^h]} \leq C_{m,n} 2^{-h(n+2)} 2^{-j(n+m+2)}; \tag{8.9}$$

it follows from this and (8.8) that

$$\|\partial^{(m,n)} B_{j,h}\|_{C^m[\Omega]} \leq C_{m,n} \cdot 2^{-h(3/2)} 2^{-j(1/2)}, \quad m = 1,2,3,\ldots,$$

from which the summability (5.19) follows immediately.

To analyze $\beta_0^{(m,n)}$, we partition the integration into two pieces via smooth windows. Let $\nu_r(\omega_1,\omega_2)$, for $r = 0,1$, denote smooth bivariate separable windows obeying $0 \leq \nu_r \leq 1$, $\nu_0(\omega) + \nu_1(\omega) \equiv 1$, $\nu_0 \equiv 1$ on $[-1,1]^2$, and $\nu_1 \equiv 1$ on $([-2,2]^2)^c$, and ν_0 and ν_1 both even in both coordinates. Now with $(\nu_r\beta)(\omega_1,\omega_2) \equiv \nu_r(\omega_1,\omega_2)\beta(\omega_1,\omega_2)$ define

$$T_0^r(\xi_1,\xi_2) = \iint V_0(\omega_1,\omega_2)(\nu_r\beta)(\xi_1-\omega_1,\xi_2-\omega_2) d\omega_1 d\omega_2,$$

so that

$$\beta_0 = T_0^0 + T_0^1,$$

T_0^1 containing contributions to β_0 arising far from $\omega = 0$, and T_0^0 containing contributions arising $\omega = 0$. Again T_0^0 involves a nonabsolutely convergent integrand, and part of the work will be to make sense of it.

About these terms we make the following claims. First, that for $m, n = 0, 1, 2, \ldots$, and $\mu > 0$,

$$|\partial^{(m,n)} T_0^0(\xi_1, \xi_2)| \leq C_{m,n,\mu} \cdot (1 + (|\xi_2| - 2)_+)^{-\mu}, \tag{8.10}$$

where $C_{m,n,\mu}$ does not depend on ξ. Second, that

$$|\partial^{(m,n)} T_0^1(\xi_1, \xi_2)| \leq C'_{m,n}\ (1 + |\xi_2|/2)^{-m-n-2}, \tag{8.11}$$

where $C'_{m,n}$ does not depend on ξ.

Combining these claims, if $\xi \in \Omega_j^h$, then for $r = 0, 1$,

$$|\partial^{(m,n)} T_0^r(\xi_1, \xi_2)| \leq C_{m,n}(1 + (2^{j+h}\frac{\pi}{3} - 2)_+)^{-m-n-2},$$

from which (8.9) follows and so the conclusion (5.19) of Lemma 5.10 is established.

We now justify the claims. Separability of the kernel ν_0 allows us to write $\nu_0(\xi_1, \xi_2) = \nu_{0,1}(\xi_1) \cdot \nu_{0,2}(\xi_2)$, and also $V_0(\xi_1, \xi_2) = V_{0,1}(\xi_1) \cdot V_{0,2}(\xi_2)$. Putting $v_1(\xi) = (\frac{\partial}{\partial \xi})^m V_{0,1}(\xi)$ and similarly for v_2, then

$$\begin{aligned}
&\iint V^{(m,n)}(\xi_1 - \omega_1, \xi_2 - \omega_2)\nu_0 \beta d\omega_1 d\omega_2 \\
&= \int_{-\infty}^{\infty} v_2(\xi_2 - \omega_2)\nu_{0,2}(\omega_2) \int_{-\infty}^{\infty} v_1(\xi_1 - \omega_1)\nu_{0,1}(\omega_1)|\omega_1|^{-2}\mathrm{sgn}(\omega_1)e^{-\omega_2^2/\omega_1^2} d\omega_1 d\omega_2 \\
&= \int_{-\infty}^{\infty} v_2(\xi_2 - \omega_2)\nu_{0,2}(\omega_2) \int_0^2 (v_1(\xi_1 - \omega_1) - v_1(\xi_1 + \omega_2))|\omega_1|^{-1} \\
&\qquad \cdot \nu_{0,1}(\omega_1)|\omega_1|^{-1} e^{-\omega_2^2/\omega_1^2} d\omega_1 d\omega_2.
\end{aligned} \tag{8.12}$$

This identity allows us to interpret $\beta_0^{(m,n)}$ as an unconditionally convergent integral. Indeed, for each $\mu > 0$, we have the following inequality valid $\forall\ \xi_1 \in \mathbb{R}$, $\omega_1 \neq 0$:

$$|v_1(\xi_1 - \omega_1) - v_1(\xi_1 + \omega_2)|/|\omega_1| \leq C_\mu \left((1 + |\xi_1 - \omega_1|)^{-\mu} + (1 + |\xi_1 + \omega_1|)^{-\mu}\right).$$

Hence, we can "cancel one factor of $|\omega_1|^{-1}$," yielding pointwise domination of the integrand defining $\beta_0^{(m,n)}$ in the final member in (8.12) by an integrable function, leading to the interpretation of the initial member as bounded according to

$$\begin{aligned}
&\left|\iint V^{(m,n)}(\xi_1 - \omega_1, \xi_2 - \omega_2)\nu_0 \beta d\omega_1 d\omega_2\right| \\
&\leq \int_{-\infty}^{\infty} |v_2(\xi_2 - \omega_2)\nu_{0,2}(\omega_2)| \int_{-\infty}^{\infty} C(1 + |\xi_1 - \omega_1|)^{-\mu}\nu_{0,1}(\omega_1)|\omega_1|^{-1}e^{-\omega_2^2/\omega_1^2} d\omega_1 d\omega_2.
\end{aligned}$$

Now because the window ν_0 is supported in $[-2, 2]^2$, this last term can be bounded by

$$\begin{aligned}
&C \cdot \int_{-2}^{2}\int_{-2}^{2} |\omega_1|^{-1}e^{-\omega_2^2/\omega_1^2} d\omega_1 d\omega_2 \times \sup_{\omega \in [-2,2]^2} |v_2(\xi_2 - \omega_2)|(1 + |\xi_1 - \omega_1|)^{-\mu} \\
&\quad \leq C \cdot (1 + (|\xi_1| - 2)_+)^{-\mu} \cdot (1 + (|\xi_2| - 2)_+)^{-\mu},
\end{aligned}$$

yielding (8.10).

Now consider (8.11). Inside the support of ν_1, we may differentiate $\nu_1\beta$ as often as we like. Applying Lemma 8.3,

$$|\partial^{(m,n)}\nu_1\beta(\omega_1,\omega_2)| \leq C_{m,n,\mu}\cdot(1+|\omega_2|)^{-m-n-2}$$

so that from the integration by parts

$$\iint V^{(m,n)}(\xi_1-\omega_1,\xi_2-\omega_2)\nu_1\beta d\omega_1 d\omega_2 = (-1)^{m+n}\iint V(\xi_1-\omega_1,\xi_2-\omega_2)(\nu_1\beta)^{(m,n)}d\omega_1 d\omega_2$$

and an argument paralleling the proof of Lemma 8.4, we have

$$\begin{aligned}&\left|\iint V^{(m,n)}(\xi_1-\omega_1,\xi_2-\omega_2)\nu_1\beta d\omega_1 d\omega_2\right|\\ &\leq \iint(1+|\xi_1-\omega_1|)^{-\mu}\cdot(1+|\xi_2-\omega_2|)^{-\mu}\cdot(1+|\omega_2|)^{-m-n-2}d\omega_1 d\omega_2\\ &\leq C\cdot(1+|\xi_2|/2)^{-m-n-2}.\end{aligned}$$

Acknowledgment. The author would like to thank Emmanuel Candès for many stimulating discussions.

RESOLUTION IN DYNAMIC EMISSION TOMOGRAPHY*

JEAN MAEGHT† AND DOMINIKUS NOLL†

Abstract. Based on a two-dimensional (2-D) Fourier analysis of the attenuated Radon transform and a 2-D version of the Shannon sampling theorem, we investigate the problem of resolution in dynamic emission tomography. As a result we provide guidelines on how to acquire and on how to filter the projection data.

Key words. dynamic emission tomography, photon transport equation, attenuated Radon transform, 2-D sampling theorem, resolution, aliasing errors, uncertainty principle, 2-D filtering

1. Introduction.

Current state-of-the-art medical imaging technologies provide extremely detailed and accurate information about human anatomy. However, the corresponding detailed information about function is not yet readily available. *Single photon emission computerized tomography* (SPECT) is a noninvasive diagnostic technology which is used to show the blood flow in the heart muscle, extent of damage in stroke patients, presence and degree of malignancy of tumors, and much else.

SPECT is able to image the function of the body through a *tracer*, a biochemical molecule labeled with radioactivity. The radioactive material is incorporated by the patient and metabolized by the organ of interest. The emissions are then recorded by a rotating SPECT camera (cf. Figure 1), and a three-dimensional (3-D) visualization is created from the two-dimensional (2-D) projection data.

Currently, the data recorded by SPECT cameras are static and qualitative. It is not possible, as yet, to measure absolute metabolic rates from the different biological processes, nor to measure the movement of molecules during biodistribution and metabolism. Recently, a major step toward the development of *dynamic* SPECT (dSPECT) has been achieved through two mathematical methods replacing the traditional filtered backprojection (FBP) method (cf. [2, 14, 16, 5]), the latter being by its nature static (cf. [18]) and not feasible for dynamic sources.

The present paper will focus on the problem of resolution in dynamic emission tomography. Results of this type have previously been obtained in static SPECT, in positron emission tomography (PET), and in computed tomography (CT), where an elaborate Fourier analysis led to the idea, among others, of *interlaced grids* which significantly improved resolution (cf. [13, 19, 20, 22]). Following these lines, we shall answer typical questions like how many positions a SPECT camera should take, how long it should stay in a given position, whether views should be recorded over 180 degrees or 360 degrees, or what the internal resolution of the camera should be if a certain spatial resolution in the reconstructed image has to be achieved. As a second application, we present some ideas on how to filter data before doing the actual inversion.

2. The model. Emission tomography is modeled by the 3-D dynamic photon transport equation (cf. [8]). It is convenient to simplify the model by assuming that scattering is negligible or, rather, to interpret it as a measurement noise. This decouples the equation and allows for splitting the 3-D reconstruction into a series of 2-D reconstructions on slices. The simplified dynamic 2-D transport equation is

$$\frac{1}{c}\,u_t(t,x,\omega,E)+\omega\cdot\nabla u(t,x,\omega,E)+\mu(x,E)\,u(t,x,\omega,E)=f(t,x,E), \tag{2.1}$$

where $u(t,x,\omega,E)$ is the (unknown) photon transport at time t and position $x\in\mathbf{R}^2$ at the energy level E in direction $\omega\in\mathbf{S}^1$, $\mu(x,E)$ is the unknown linear attenuation coefficient at position x for photons traveling with energy E, and $f(t,x,E)$ is the unknown number of photons emitted at time t, position x, at energy level E.

As opposed to X-rays, γ-rays are monochromatic, i.e., photons are emitted at a fixed energy level E_0, for instance, $E_0 = 140$keV for Technetium used in many clinical applications. Similarly, in PET, the recorded photons, originating from the annihilation of a positron with an electron, travel with $E_0 = 511$keV, the energy of the electron. Photons recorded with energy $E < E_0$ are therefore due to Compton scatter, and an energy window $\pm\Delta E$ about the expected level E_0 allows for eliminating most scattering events (cf. [25]). It is legitimate to further simplify (2.1) by omitting the reference to energy. More precisely, writing $f(t,x,E)=f(t,x)\,\delta(E-E_0)$ and $\mu(x)=\mu(x,E_0)$, the equation for the cumulative transport $u(t,x,\omega)$ integrated over the relevant energy levels $E\in[E_0-\Delta E,E_0+\Delta E]$ is

$$\frac{1}{c}\,u_t(t,x,\omega)+\omega\cdot\nabla u(t,x,\omega)+\mu(x)\,u(t,x,\omega)=f(t,x), \tag{2.2}$$

which may be solved explicitly on each line.

To do this, we have to supply boundary conditions. We assume that the unknown source and attenuation coefficient are supported on the unit disk D. We adopt the notations $\omega=(\cos\phi,\sin\phi)$ and $\omega^\perp=(-\sin\phi,\cos\phi)$. Rays may then be referenced (s,ϕ), that is, $x\cdot\omega^\perp=s$, or $x=s\omega^\perp+\tau\omega$, $\tau\geq 0$ for x on the ray so referenced. Now notice that the incoming radiation is zero, i.e.,

$$u(t,s\omega^\perp+\tau\omega,\omega)=0\quad\text{for all }\ \tau\leq\tau_0=\tau_0(s,\omega)\ \text{ and all } t$$

($x_0=s\omega^\perp+\tau_0\omega$ the entry point of the ray $x\cdot\omega^\perp=s$ into D, if any). Second, we use the fact that $u(t,x,\omega)$ has been recorded at certain times t and for certain directions ω at a camera bin located at $x_1=s\omega^\perp+\tau_1\omega$, $\tau_1=\tau_1(s,\omega)$, on the line $x\cdot\omega^\perp=s$. (Without loss, we may assume that x_1 is the exit point of the ray $x\cdot\omega^\perp$ from the disk D, if any.) That is, the observed data are of the form

$$u(t,s\omega^\perp+\tau_1\omega,\omega)=:d(s,\omega,t).$$

In fact, a SPECT camera (shown schematically in Figure 1) detects photons which arrive perpendicular to the camera surface while at a fixed angular position $\omega=(\cos\phi,\sin\phi)$.

Integrating (2.2) using the boundary conditions gives the nonlinear relation

$$\int_{\tau_0}^{\tau_1} f(t+(\tau_1-\tau)/c,s\omega^\perp+\tau\omega)\,e^{-\displaystyle\int_{\tau}^{\tau_1}\mu(s\omega^\perp+\rho\omega)\,d\rho}\,d\tau\;=\;d(s,\omega,t). \tag{2.3}$$

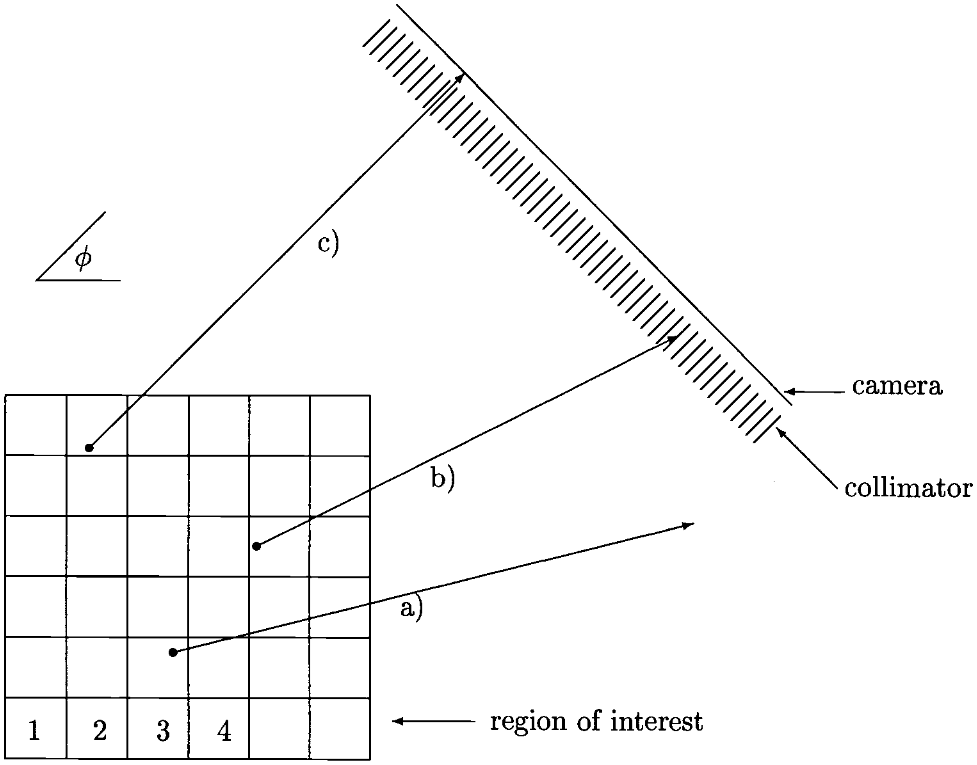

FIG. 1. *The principle of SPECT: Photons radiating from the region of interest.* (a) *Photon misses the camera,* (b) *is absorbed by the collimator,* (c) *passes the collimator and hits the camera. The camera rotates around the region of interest (schematically discretized into pixels).*

As photons are traveling with the speed of light c, in practice $t+(\tau_1-\tau_0)/c \approx t$, and (2.3) simplifies to

$$(2.4)\ R[\mu, f(t,\cdot)](s,\omega) := \int_{\tau_0}^{\tau_1} f(t, s\omega^{\perp}+\tau\omega)\, e^{-\int_{\tau}^{\tau_1} \mu(s\omega^{\perp}+\rho\omega)\,d\rho}\, d\tau \;=\; d(s,\omega,t).$$

Here $R[\mu, f]$ denotes the *attenuated Radon transform* (cf. [18, 20, 21]). Solving (2.4) simultaneously for the unknown dynamic source $f(t,x)$ and attenuation $\mu(x)$, based on the acquired data $d(s,\omega,t)$, is the mathematical problem of dSPECT. A similar equation replacing (2.4) may be found for PET using the corresponding symmetric data (see [16]).

Attempts to estimate *both* the unknown attenuation and source term from the projection data have been made by several authors. A method proposed by Natterer [18, 21] and reported to be practical in [24] uses a consistency condition to obtain an estimate of μ. This approach is feasible if the camera takes views over 360 degrees and the source is static. More recently, Dicken [9] proposed a direct inversion of (2.4). In practice, often less sophisticated ways are chosen, which consist either in neglecting attenuation or assuming constant attenuation (after tracing the contour of the patient) or in correcting data via some heuristic methods. A third way proposed in [6, 7] consists in doing a CT in parallel with the emission scan. The remaining problem of estimating f with known μ is then linear but still ill-posed (cf. [20]).

3. Fourier analysis. The way the inverse problem (2.4) is solved depends on the device. A ring SPECT camera, and similarly the PET cameras, allow for collecting a full set of angular views $d(s_j, \omega_k, t_\ell)$, (j the index for camera bins, k the index for angular positions, ℓ the index for stops) at a fixed time t_ℓ. The reconstruction algorithms are then essentially the static ones, FBP or EM algorithms, which reconstruct one static image at a time t_ℓ, obtaining the dynamic image frame by frame. The 2-D Fourier analysis of the static case being known, cf. [20, 13, 22], we may consider this case as essentially understood.

The situation changes if a rotating camera system is used. As the activity in the organ changes significantly during the scan, a rotating camera (even triple head) will not be able to collect sufficiently many views ω_k at a fixed time t_ℓ in order to reconstruct the dynamic object frame by frame. Rather, in the extreme case of a single head camera, we can scan only one position at a time, so the acquired data are $d(s_j, \omega_k, t_k)$. Ideally, the time axis t and angular position ϕ are then linked through

$$t = \frac{T}{2\pi}\,\phi, \qquad 0 \le t \le T,\ 0 \le \phi \le 2\pi \tag{3.1}$$

(T is the total acquisition time). With (3.1), reconstruction algorithms necessarily have to process all the projection data simultaneously, which leads to large size problems difficult to solve in practice (cf. [2, 16], and also [12, 5, 10, 14, 17]).

Assuming that the dynamic source is of the form $f(t,x) = g_1(t)\,h_1(x) + \cdots + g_r(t)\,h_r(x)$, its attenuated Radon transform (2.4) is

$$R[\mu, f(t,\cdot)](s,\phi) = g_1(t)\,R[\mu, h_1](s,\phi) + \cdots + g_r(t)\,R[\mu, h_r](s,\phi).$$

In the case of a rotating camera, in particular a single head camera, (3.1) leads to the ideal projection data

$$p(s,\phi) := g_1((T/2\pi)\phi)\,R[\mu, h_1](s,\phi) + \cdots + g_r((T/2\pi)\phi)\,R[\mu, h_r](s,\phi), \tag{3.2}$$

often referred to as the *sinogram* of the source $f(t,x)$, for the obvious reason that a point source scanned over 360 degrees would produce a sinoidal curve. Figures 4(c) and 4(g) show some experimental sinogram data collected over a 180-degree scan.

The principal purpose of the present paper is to perform a 2-D Fourier analysis of the sinogram $p(s,\phi)$. As a result of this analysis we obtain two practical guidelines:

(1) On *resolution.* How many stops and angular positions are required to capture a prescribed spatial resolution along with a predicted half-life? How long should an individual stop last?

(2) On *data filtering*, which is inherent to the classical FBP algorithms but has to be considered anew in dSPECT.

4. Sampling in two-dimensions. In this section, we shall be concerned with the sampling of the sinogram (3.2) of a dynamic source $f(t,x)$. In the first round we shall consider only the unattenuated Radon transform (i.e., $\mu = 0$). Later on we will indicate that the results are usually not altered if attenuation is taken into account.

We recall that the Radon transform $Rh(s,\phi)$ of a spatial function $h(x)$, being 2π-periodic in ϕ, is defined on $\mathbf{R} \times \mathbf{S}^1$, which we shall call the (s,ϕ)-plane or *physical plane.* The 2-D Fourier transform $\hat{p}$ of $p(s,\phi)$ is then defined on $\mathbf{R} \times \mathbf{Z}$, which will be referred to as the (σ, k)-plane or *frequency plane.*

A sampling operator $\mathcal{S}_{K,W}$ in the physical plane is defined by two ingredients—a *sampling lattice* $W\mathbf{Z}^2$ in the physical plane (W a 2×2-matrix) in tandem with a *spectral window* K in the frequency plane—whose replica $K + 2\pi(W^{-1})^T\ell$, $\ell \in \mathbf{Z}^2$, generated by the *dual lattice* $2\pi(W^{-1})^T\mathbf{Z}^2$ in the frequency-plane, are mutually disjoint:

$$\mathcal{S}_{K,W}p(s,\phi) := \det(W) \sum_{\ell\in\mathbf{Z}^2} p(W\ell)\,\hat{\chi}_K((s,\phi) - W\ell) \tag{4.1}$$

(χ_K the characteristic function of the set K). More formally, $\mathcal{S}_{K,W}$ may be represented using the shah-distribution $\text{Ш}(s,\phi) = \sum_{\ell\in\mathbf{Z}^2} \delta(s-\ell_1, \phi-\ell_2)$,

$$\mathcal{S}_{K,W}p = \Big(p \cdot \text{Ш}(W^{-1}\cdot)\Big) * \hat{\chi}_K,$$

a formulation which is very intuitive when we consider its Fourier transform. Replacing the analog signal p by its digitized version $p \cdot \text{Ш}(W^{-1}\cdot)$, taken at the points of the lattice $W\mathbf{Z}^2$, has the following effect: Since $\hat{\text{Ш}} = \text{Ш}$, the spectrum of the digitized signal shows the true spectrum, $\hat{p}$, but repeated periodically

$$\widehat{\big(p \cdot \text{Ш}(W^{-1}\cdot)\big)} = 2\pi \sum_{\ell\in\mathbf{Z}^2} \hat{p}(\cdot - 2\pi W^{-T}\ell)$$

along the dual lattice $2\pi W^{-T}\mathbf{Z}^2$. Consequently, if the spectral window K is well chosen, i.e., if the spectrum $\hat{p}$ is captured by K, we may fully retrieve the true signal p, simply by applying an ideal low pass filter χ_K which eliminates frequencies $\notin K$:

$$\widehat{\big(\mathcal{S}_{K,W}p\big)} = (2\pi)^{-1}\widehat{\big(p \cdot \text{Ш}(W^{-1}\cdot)\big)} \cdot \chi_K = \sum_{\ell\in\mathbf{Z}^2} \hat{p}(\cdot - 2\pi W^{-T}\ell)\cdot\chi_K. \tag{4.2}$$

In fact, 2-D versions of the Shannon sampling theorem are easily understood through (4.2): the signal p is fully retrieved from the sampled signal if its spectrum has $\text{supp}(\hat{p}) \subset K$. In our applications, however, we are dealing with compactly supported signals, whose spectra $\hat{p}$ are analytic and never fully supported on a bounded set K. We will consequently have to accept aliasing errors associated with the choice of a sampling operator (4.1). Estimating these errors is the principal task of the present section. Practical aspects will be considered later.

Let us fix $0 < \vartheta < 1$, a positive integer m, and $b > 0$. As our frequency window in the (σ, k)-plane we choose the *bowtie region* K,

$$K = \{(\sigma,k) \in \mathbf{R}\times\mathbf{Z} : |\sigma| \le b \text{ and } |k| \le |\sigma|/\vartheta + m\}, \tag{4.3}$$

which is displayed in Figure 2(a). Figure 2(c) indicates the scheme $2\pi W^{-T}\mathbf{Z}^2$ which produces nonoverlapping replica of K in the frequency plane. The sampling parameters are seen to be $\Delta k = [b/\vartheta] + 2m$ and $\Delta\sigma = b$, and the matrices W, $2\pi W^{-T}$ are

$$W = 2\pi\begin{pmatrix} \frac{1}{2b} & 0 \\ -\frac{1}{2\Delta k} & \frac{1}{\Delta k}\end{pmatrix}, \quad 2\pi(W^{-1})^T = \begin{pmatrix} 2b & b \\ 0 & \Delta k\end{pmatrix}. \tag{4.4}$$

As we shall see in our experiments, the parameter ϑ may in practice be chosen as $\vartheta \approx 1$ but for theoretical reasons has to satisfy $\vartheta \in (0,1)$.

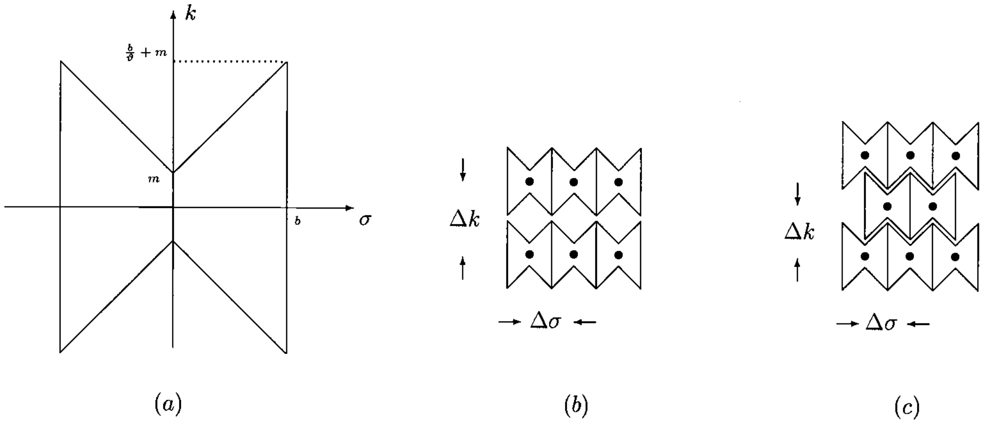

FIG. 2. (a) *shows the bowtie region K defined through* (4.3), (4.4), *while* (b) *and* (c) *show two different lattices generating disjoint replica of K. The interlaced grid* (c) *requires fewer nodes and therefore gives a better sampling scheme.*

Naturally, the identification of the essential support K of the spectrum $\hat{p}$ in tandem with the sampling lattice $W\mathbf{Z}^2$ is crucial for our principal tasks: resolution and filtering. The choice of K being ambiguous, we shall have to support our proposition (4.3) both by numerical tests and by a rigorous analysis, including error estimates. In the present section we proceed to provide those.

To formulate our main result, we need to introduce two notions for the spatial and temporal bandwidths, respectively. Concerning the spatial term, Natterer [20] considers the measures

$$\epsilon_d(h,b) = \int_{|\xi|>b} |\xi|^d |\hat{h}(\xi)|\, d\xi,$$

which may be related to appropriate Sobolev norms. In fact, using

$$\|h\|_{W^{\alpha,d}} = \left(\int_{\mathbf{R}^n} (1+|\xi|^2)^{d\alpha/2}\, |\hat{h}(\xi)|^{\alpha}\, d\xi \right)^{1/\alpha},$$

and defining the ideal *high pass filter at frequency* b, $\mathcal{H}_b$, via $\big(\mathcal{H}_b h\big)\hat{} = \hat{h}\chi_{\{|\cdot|>b\}}$, Natterer's error terms satisfy $C_1\epsilon_d(h,b) \le \|\mathcal{H}_b h\|_{W^{1,d}} \le C_2\epsilon_d(h,b)$. For the following we shall, in addition, obtain error estimates involving the Hilbert space norms $\|\mathcal{H}_b h\|_{W^{2,d}}$.

In turn, for a 2π-periodic function $g(\phi)$ with Fourier coefficients $\hat{g}_k$, low pass filtering at a frequency k obviously corresponds to truncating the Fourier series at k, and correspondingly, high pass filtering corresponds to retaining the tail $|\nu| > k$ of the series. We therefore consider the error terms

$$R_k(g) := \left(\sum_{|\nu|>k} |\hat{g}_\nu|^2 \right)^{1/2},$$

$k > 0$, which play a role similar to the norm estimates of $\mathcal{H}_b h$ above. With these notions we are ready to state the following theorem.

THEOREM 4.1. *Let ϑ, m, b and K, W be as in* (4.3), (4.4). *Choose $\vartheta' \in (\vartheta, 1)$, and let $\theta := \vartheta/\vartheta' \in (0,1)$. Consider a dynamic source of the form $f(t,x) = g(t)h(x)$ such* *that $h(x)$ is continuous and supported on the unit disk D and $g(t)$ is continuous. Let $g((T/2\pi)\phi)$ be continued periodically for $\phi \notin [0, 2\pi]$. Let $p(s,\phi)$ be the ideal sinogram of $f(t,x)$, and let $\mathcal{S}_{K,W}p(s,\phi)$ be the sinogram sampled on the lattice $W\mathbf{Z}^2$ in the (s,ϕ)-plane using the frequency window K. Then*

$$\begin{aligned}
1.\ \|p - \mathcal{S}_{K,W}p\|_\infty &= \|g\|_\infty \mathcal{O}\Big(m\epsilon_{-1}(h,b) + \epsilon_0(h,b)\Big) \\
&\quad + \|h\|_\infty \mathcal{O}\Big(\sum_{\nu=1}^{\infty} \nu R_{(1-\vartheta')(\nu+m)}(g)\Big), \\
2.\ \|p - \mathcal{S}_{K,W}p\|_2 &= \|g\|_\infty \mathcal{O}\Big(\|\mathcal{H}_b h\|_{W^{2,-\frac{1}{2}}}\Big) \\
&\quad + \|h\|_\infty \mathcal{O}\Big(\Big(\sum_{\nu=1}^{\infty} \nu R_{(1-\vartheta')(\nu+m)}(g)^2\Big)^{1/2}\Big), \\
3.\ \|p - \mathcal{S}_{K,W}p\|_2 &= \|g\|_\infty \mathcal{O}\Big(\|\mathcal{H}_b h\|_{W^{2,-\frac{1}{2}}}\Big) \\
&\quad + \|h\|_\infty \mathcal{O}\Big(b^{1/2}\Big(\sum_{\nu=1}^{\infty} R_{(1-\vartheta')(\nu+m)}(g)^2\Big)^{1/2}\Big).
\end{aligned}$$

Proof. Part 1. Notice that by Parseval's formula, $\|p\|_2 = \|\hat{p}\|_2$, where $\hat{p}$ is the 2-D Fourier transform of p, and according to [20, p. 63], $\|p\|_\infty \le \|\hat{p}\|_1$, if the corresponding norms on the frequency plane are defined through

$$\|\hat{p}\|_\alpha = \Big(\sum_{k=-\infty}^{\infty} \int_{\mathbf{R}} |\hat{p}(\sigma,k)|^\alpha \, d\sigma \Big)^{1/\alpha}. \tag{4.5}$$

By the definition of the sampling operator (4.1),

$$\hat{p} - (\mathcal{S}_{K,W}p)\hat{} = (1-\chi_K)\,\hat{p} - \sum_{\ell \ne 0} \hat{p}(\cdot - 2\pi W^{-T}\ell)\,\chi_K,$$

so we derive the estimate

$$\|(p - \mathcal{S}_{K,W}p)\hat{}\|_\alpha \le \|(1-\chi_K)\hat{p}\|_\alpha + \Big\| \sum_{\ell \ne 0} \hat{p}(\cdot - 2\pi W^{-T}\ell)\chi_K \Big\|_\alpha .$$

By the translation invariance of the Haar measure and using the fact that the translates $K + 2\pi W^{-T}\ell$ are disjoint, the second term on the right-hand side satisfies

$$\Big\| \sum_{\ell \ne 0} \hat{p}(\cdot - 2\pi W^{-T}\ell)\chi_K \Big\|_\alpha \le \|(1-\chi_K)\hat{p}\|_\alpha,$$

so all together

$$\|(p - \mathcal{S}_{K,W}p)\hat{}\|_\alpha \le 2\|(1-\chi_K)\hat{p}\|_\alpha.$$

Writing $K(k) = \{\sigma : (\sigma,k) \in K\}$, we are therefore led to estimate

$$\sum_{k=-\infty}^{\infty} \int_{\sigma \notin K(k)} |\hat{p}(\sigma,k)|^\alpha \, d\sigma. \tag{4.6}$$

To do this, we will have to distinguish the cases $\alpha = 1$ and $\alpha = 2$. For the case $\alpha = 1$, we decompose the region $(\sigma, k) \notin K$ into three parts Σ_1, Σ_2, and Σ_3:

$$\begin{aligned}
\Sigma_1 &= \{(\sigma, k) : |k| > |\sigma|/\vartheta + m\},\\
\Sigma_2 &= \{(\sigma, k) : |\sigma| > b \text{ and } |k| \leq b/\vartheta + m\},\\
\Sigma_3 &= \{(\sigma, k) : |\sigma| > b \text{ and } |k| \leq |\sigma|/\vartheta + m \text{ and } |k| \geq b/\vartheta + m\}.
\end{aligned}$$

For the case $\alpha = 2$, two domains Γ_1, Γ_2 will do:

$$\begin{aligned}
\Gamma_1 &= \{(\sigma, k) : |k| \geq m \text{ and } |\sigma| \leq \min\big(b, \vartheta(|k| - m)\big)\},\\
\Gamma_2 &= \{(\sigma, k) : |\sigma| > b\}.
\end{aligned}$$

Part 2. Let us continue collecting useful information. Let $\mathcal{F}_s p(\cdot, \phi)(\sigma)$ be the one-dimensional (1-D) Fourier transform of p with respect to s, which is again 2π-periodic in ϕ. Its kth Fourier coefficient is

$$\hat{p}(\sigma, k) =: \hat{p}_k(\sigma) = \frac{1}{2\pi} \int_0^{2\pi} \mathcal{F}_s p(\sigma, \phi) e^{-ik\phi}\, d\phi.$$

By the Fourier slice theorem [20, p. 11] we have

$$\mathcal{F}_s p(\sigma, \phi) = g((T/2\pi)\phi)\, \mathcal{F}_s[Rh(\cdot, \phi)](\sigma) = g((T/2\pi)\phi)\, \hat{h}(\sigma\omega)$$

with $\omega = (\cos\phi, \sin\phi)$. Then

$$\begin{aligned}
\hat{p}_k(\sigma) &= (2\pi)^{-1/2} \int_0^{2\pi} g((T/2\pi)\phi) \hat{h}(\sigma\omega) e^{-ik\phi}\, d\phi \\
&= (2\pi)^{-3/2} \int_0^{2\pi} g((T/2\pi)\phi) \int_D e^{-i\sigma\omega\cdot x} h(x)\, dx\ e^{-ik\phi}\, d\phi \\
&= (2\pi)^{-3/2} \int_D h(x) \int_0^{2\pi} g((T/2\pi)\phi) e^{-i\sigma|x|cos(\phi-\psi)-ik\phi}\, d\phi\, dx
\end{aligned} \tag{4.7}$$

if we put $x = |x|(\cos\psi, \sin\psi)$. Substituting the Fourier series $g((T/2\pi)\phi) = \sum_\nu \hat{g}_\nu e^{i\nu\phi}$, this becomes

$$\begin{aligned}
\hat{p}_k(\sigma) &= (2\pi)^{-3/2} \int_D h(x) e^{-ik\psi} \sum_{\nu=-\infty}^{\infty} \hat{g}_\nu \int_0^{2\pi} e^{-i\sigma|x|\cos\phi - i(k-\nu)\phi}\, d\phi\, dx \\
&= (2\pi)^{-1/2} i^k \int_D h(x) e^{-ik\psi} \sum_{\nu=-\infty}^{\infty} \hat{g}_\nu J_{k-\nu}(-\sigma|x|)\, dx, \qquad (4.8)
\end{aligned}$$

where we have used the Bessel functions $J_k(x)$ of the first kind defined through

$$J_k(x) = \frac{i^{-k}}{2\pi} \int_0^{2\pi} e^{ix\cos\phi - ik\phi}\, d\phi.$$

Part 3. Let us now consider the estimate on Σ_2 with $\alpha = 1$. As a consequence of (4.7),

$$\begin{aligned}
\int_{|\sigma|>b} |\hat{p}_k(\sigma)|\, d\sigma &\leq (2\pi)^{-1/2} \|g\|_\infty \int_{|\sigma|>b} \int_0^{2\pi} |\hat{h}(\sigma\omega)|\, d\phi\, d\sigma \\
&= (2\pi)^{-1/2} \|g\|_\infty \int_{|\xi|>b} \frac{|\hat{h}(\xi)|}{|\xi|}\, d\xi = (2\pi)^{-1/2} \|g\|_\infty \epsilon_{-1}(h, b). \qquad (4.9)
\end{aligned}$$

Now observe that $(\sigma, k) \in \Sigma_2$ only for $|k| \leq b/\vartheta + m$, so we are left with a finite number of terms (4.9). In fact

$$\begin{aligned}\|\chi_{\Sigma_2}\hat{p}\|_1 &= \sum_{|k|\leq b/\vartheta+m} \int_{|\sigma|>b} |\hat{p}_k(\sigma)|\, d\sigma \leq C\|g\|_\infty (2b/\vartheta + 2m + 1)\epsilon_{-1}(h, b) \\ &\leq C\|g\|_\infty \big(b\epsilon_{-1}(h, b) + m\epsilon_{-1}(h, b)\big) \leq C\|g\|_\infty \big(\epsilon_0(h, b) + m\epsilon_{-1}(h, b)\big), \qquad (4.10)\end{aligned}$$

where the last inequality uses (2.9) in [20, p. 66].

Part 4. Let us next discuss the estimate on Σ_3, $\alpha = 1$. According to (4.9) above, replacing b by $\vartheta(|k| - m)$ gives

$$\int_{|\sigma|\geq\vartheta(|k|-m)} |\hat{p}_k(\sigma)|\, d\sigma \leq C\|g\|_\infty \epsilon_{-1}\big(h, \vartheta(|k| - m)\big).$$

But then

$$\begin{aligned}\|\chi_{\Sigma_3}\hat{p}\|_1 &= \sum_{|k|\geq b/\vartheta+m} \int_{|\sigma|\geq\vartheta(|k|-m)} |\hat{p}_k(\sigma)|\, d\sigma \\ &\leq C\|g\|_\infty \sum_{|k|\geq b/\vartheta+m} \epsilon_{-1}(h, \vartheta(|k| - m)) \leq C\|g\|_\infty \epsilon_0(h, b), \qquad (4.11)\end{aligned}$$

where the last inequality again uses (2.9) in [20, p. 66].

Part 5. Let us catch up with the error estimate on Γ_2, $\alpha = 2$. Using (4.7), for fixed σ, and with $\omega = (\cos\phi, \sin\phi)$, Parseval's equality gives

$$\sum_{k=-\infty}^{\infty} |\hat{p}_k(\sigma)|^2 = \int_0^{2\pi} |g((T/2\pi)\phi)\, \hat{h}(\sigma\omega)|^2\, d\phi.$$

Integrating over $|\sigma| > b$ shows

$$\begin{aligned}\|\chi_{\Gamma_2}\hat{p}\|_2^2 &\leq C\|g\|_\infty^2 \int_{|\sigma|>b} \int_0^{2\pi} |\hat{h}(\sigma\omega)|^2 d\phi\, d\sigma \\ &= C\|g\|_\infty^2 \int_{|\xi|>b} \frac{|\hat{h}(\xi)|^2}{|\xi|}\, d\xi \leq C\|g\|_\infty^2 \|\mathcal{H}_b h\|_{W^{2,-\frac{1}{2}}}^2. \qquad (4.12)\end{aligned}$$

Part 6. We need to consider some technical preliminaries about Bessel functions. It is well known that $J_n(\sigma)$ decays exponentially ($n \to \infty$) for fixed σ. According to [23] even $J_n(\theta n) \to 0$ exponentially, since $0 < \theta < 1$. We'll improve this by showing that, regarding $0 < \theta < 1$, $R_n(J_\cdot(\theta n)) \to 0$ exponentially as $n \to \infty$.

According to [23, p. 255] in tandem with [1, Theorem 4.1.28], and regarding $0 < \theta < 1$, we have (for n a positive integer)

$$0 \leq J_n(\theta n) \leq (2\pi n)^{-1/2}(1 - \theta^2)^{-1/4} e^{-(n/3)(1-\theta^2)^{3/2}}.$$

Summing over $|\nu| \geq n$ and using $|J_\nu(-\sigma)| = |J_\nu(\sigma)|$, $|J_{-\nu}(\sigma)| = |J_\nu(\sigma)|$ gives

$$\begin{aligned}\sum_{|\nu|\geq n} |J_\nu(\theta n)|^2 &= 2\sum_{\nu=n}^{\infty} \big|J_\nu\big((\theta n/\nu)\cdot\nu\big)\big|^2 \\ &\leq 2\sum_{\nu=n}^{\infty} \left((2\pi\nu)^{-1/2}(1 - (\theta n/\nu)^2)^{-1/4} e^{-(\nu/3)(1-(\theta n/\nu)^2)^{3/2}}\right)^2.\end{aligned}$$

This term is easily seen to decay exponentially in n, that is,

$$|R_n(J.(\theta' n))| \le Ce^{-c(\theta)n} \tag{4.13}$$

for a constant $c(\theta) > 0$ depending on θ, and uniformly over $0 \le \theta' \le \theta$.

Part 7. Let us now consider the error estimates on Σ_1 with $\alpha = 1$. Writing

$$d_k(\sigma) := \sum_{\nu=-\infty}^{\infty} \hat{g}_\nu J_{k-\nu}(\sigma) = \big(\hat{g} * J.(\sigma)\big)_k \qquad \text{(convolution of sequences)},$$

we find using (4.8) that

$$|\hat{p}_k(\sigma)| \;\le\; C\|h\|_\infty \max_{|x|\le 1} d_k(-\sigma|x|), \tag{4.14}$$

and by the definition of Σ_1, we are led to estimate $d_k(-\sigma|x|)$ for $|\sigma| \le \vartheta(|k| - m)$, $|k| \ge m$, and $|x| \le 1$. This is done by the following steps. Observe that

$$\begin{aligned} |d_k(-\sigma|x|)| &\le \sum_{\nu=-\infty}^{\infty} |\hat{g}_\nu J_{k-\nu}(-\sigma|x|)| \\ &= \sum_{|\nu|\ge(1-\vartheta')|k|} |\hat{g}_\nu J_{k-\nu}(-\sigma|x|)| + \sum_{|\nu|<(1-\vartheta')|k|} |\hat{g}_\nu J_{k-\nu}(-\sigma|x|)| =: \mathrm{I} + \mathrm{II}. \end{aligned}$$

The first term I satisfies

$$\mathrm{I} \le \Bigg(\sum_{|\nu|\ge(1-\vartheta')|k|} |\hat{g}_\nu|^2 \Bigg)^{1/2} \Bigg(\sum_{|\nu|\ge(1-\vartheta')|k|} |J_{k-\nu}(-\sigma|x|)|^2 \Bigg)^{1/2} \le R_{(1-\vartheta')|k|}(g), \tag{4.15}$$

the second factor being ≤ 1 since $\sum_k |J_k(z)|^2 = 1$ for every z. The second term II is estimated through

$$\mathrm{II} \le \|g\|_2 \Bigg(\sum_{|\nu|<(1-\vartheta')|k|} |J_{k-\nu}(-\sigma|x|)|^2 \Bigg)^{1/2} \le \|g\|_2 R_{\vartheta'|k|}\big(J.(-\sigma|x|)\big). \tag{4.16}$$

Here the argument $-\sigma|x|$ of the Bessel coefficients satisfies

$$\big| -\sigma|x|\big| \le |\sigma| \le \vartheta(|k| - m) = \vartheta'|k| \, \frac{\vartheta(|k|-m)}{\vartheta'|k|} \le \vartheta'|k| \cdot \frac{\vartheta}{\vartheta'} = \vartheta'|k| \cdot \theta,$$

which means that $| -\sigma|x|| = \theta'\vartheta'|k|$ for some $0 \le \theta' \le \theta$. The latter allows us to apply (4.13) with $n = \vartheta'|k|$:

$$R_{\vartheta'|k|}(J.(-\sigma|x|)) \;\le\; Ce^{-\gamma(\theta)|k|} \qquad \text{for } \ |\sigma| \le \vartheta(|k| - m) \tag{4.17}$$

and some $\gamma(\theta) > 0$.

Finally, using in this order (4.14), (4.15), (4.16), and (4.17), the error term on Σ_1 is

$$\begin{aligned} \|\chi_{\Sigma_1}\hat{p}\|_1 &\le C\|h\|_\infty \max_{|x|\le 1} \sum_{|k|\ge m} \int_{|\sigma|\le\vartheta(|k|-m)} |d_k(-\sigma|x|)| \, d\sigma \\ &\le C\|h\|_\infty \sum_{|k|\ge m} (|k| - m) \Big(R_{(1-\vartheta')|k|}(g) + \|g\|_2 e^{-\gamma(\theta)|k|} \Big) \\ &\le C\|h\|_\infty \Bigg(\sum_{\nu=1}^{\infty} \nu R_{(1-\vartheta')(\nu+m)}(g) + \|g\|_2 e^{-\delta(\theta)m} \Bigg) \end{aligned} \tag{4.18}$$

for another constant $\delta(\theta) > 0$. Clearly then, (4.18) shows us that $\|\chi_{\Sigma_1}\hat{p}\|_1 = \|h\|_\infty \mathcal{O}(\sum_{\nu=1}^\infty \nu R_{(1-\vartheta')(\nu+m)}(g))$, the exponentially decaying term being negligible. Combining this with (4.10) and (4.11) gives statement 1.

Part 8. Our last step is the error estimate $\|\chi_{\Gamma 1}\hat{p}\|_2$. Notice that by the definition of Γ_1,

$$\begin{aligned}\|\chi_{\Gamma_1}\hat{p}\|_2^2 &\le \sum_{|k|\ge m} \int_{|\sigma|\le \min\{b,\vartheta(|k|-m)\}} |\hat{p}_k(\sigma)|^2\, d\sigma \\ &\le \sum_{m\le |k| \le \frac{b}{\vartheta}+m} \int_{|\sigma|\le\vartheta(|k|-m)} |\hat{p}_k(\sigma)|^2\, d\sigma + \sum_{|k|\ge \frac{b}{\vartheta}+m} \int_{|\sigma|\le b} |\hat{p}_k(\sigma)|^2\, d\sigma =: \mathrm{III}^2 + \mathrm{IV}^2.\end{aligned}$$

Using (4.14) and (4.17), we find

$$\begin{aligned}\mathrm{III}^2 &\le C\|h\|_\infty^2 \max_{|x|\le 1} \sum_{m\le |k|\le \frac{b}{\vartheta}+m} \int_{|\sigma|\le\vartheta(|k|-m)} |d_k(-\sigma|x|)|^2\, d\sigma \\ &\le C\|h\|_\infty^2 \sum_{m\le |k|\le \frac{b}{\vartheta}+m} \int_{|\sigma|\le\vartheta(|k|-m)} \left(R_{(1-\vartheta')|k|}(g) + \|g\|_2 e^{-\delta|k|}\right)^2 d\sigma,\end{aligned}$$

(4.17) being applicable since $|-\sigma|x|| \le \vartheta(|k|-m) < \vartheta'|k|$. By the triangle inequality, and on setting $\nu = |k|-m$,

$$\mathrm{III} \le C\|h\|_\infty \left(\left(\sum_{\nu=1}^{b/\vartheta} \nu R_{(1-\vartheta')(\nu+m)}(g)^2\right)^{1/2} + \|g\|_2 e^{-\gamma m}\right)$$

for another constant $\gamma > 0$. Similarly, the term IV satisfies

$$\mathrm{IV} \le C\|h\|_\infty \left(b^{1/2}\left(\sum_{\nu=b/\vartheta}^{\infty} R_{(1-\vartheta')(\nu+m)}(g)^2\right)^{1/2} + \|g\|_2 e^{-\delta m}\right).$$

So all together,

$$\|\chi_{\Gamma_1}\hat{p}\|_2 \le C\|h\|_\infty \left(\left(\sum_{\nu=1}^{\infty} \min\{\nu,b\} R_{(1-\vartheta')(\nu+m)}(g)^2\right)^{1/2} + \|g\|_2 e^{-\delta m}\right),$$

which in tandem with (4.12) responds to estimates 2 and 3, again since the exponentially decaying term is negligible. □

The function $h(x)$, supported on the unit disk D, is called *essentially bandlimited* if

$$\epsilon_0(h,b) = \int_{|\xi|>b} |\hat{h}(\xi)|\, d\xi \le Ce^{-\gamma b}$$

for certain $C > 0$, $\gamma > 0$. Equivalently, this means that $\|\mathcal{H}_b h\|_1$ decays exponentially as $b \to \infty$. By Hölder's inequality

$$\|\mathcal{H}_b h\|_{W^{2,-\frac{1}{2}}} \le \|\hat{h}\|_\infty^{1/2} \|\mathcal{H}_b h\|_1^{1/2} \le Ce^{-\gamma b/2},$$

so for an essentially bandlimited function $h(x)$, $\|\mathcal{H}_b h\|_{W^{2,-\frac{1}{2}}}$ also decays exponentially (as $b \to \infty$).

Corollary 4.2. *With the same notations as in the theorem, suppose that $b \to \infty$, $m \to \infty$, and either $m = \mathcal{O}(b)$ or $b = \mathcal{O}(m)$. Let $h(x)$ be essentially bandlimited. Then*

1. $\hat{g}_k = \mathcal{O}(|k|^{-\rho})$ *for some* $\rho > \frac{5}{2}$ *implies* $\|p - \mathcal{S}_{K,W}p\|_\infty = \mathcal{O}(m^{\frac{5}{2}-\rho}) \to 0$.
2. $\hat{g}_k = \mathcal{O}(|k|^{-\rho})$ *for some* $\rho > \frac{3}{2}$ *implies* $\|p - \mathcal{S}_{K,W}p\|_2 = \mathcal{O}(m^{\frac{3}{2}-\rho}) \to 0$.
3. $\hat{g}_k = \mathcal{O}(|k|^{-\rho})$ *for some* $\rho > 1$ *implies* $\|p - \mathcal{S}_{K,W}p\|_2 = \mathcal{O}(b^{\frac{1}{2}}m^{1-\rho})$.

Proof. Suppose $m = \mathcal{O}(b)$; then $m\epsilon_{-1}(h,b) = \mathcal{O}\big(b\epsilon_{-1}(h,b)\big) = \mathcal{O}(\epsilon_0(h,b))$. Similarly if $b = \mathcal{O}(m)$, then $m\epsilon_{-1}(h,b) = m\epsilon_{-1}(h,\mathcal{O}(m)) = \mathcal{O}(\epsilon_0(h,m))$. This shows that the terms involving $\epsilon_d(h,b)$ and $\|\mathcal{H}_b h\|_{W^{2,-\frac{1}{2}}}$ in Theorem 4.1 decay exponentially, and we are left with the error terms related to g.

To estimate these, observe that for $\rho > 1$, $\hat{g}_k = \mathcal{O}(|k|^{-\rho})$ gives $R_k(g) = \mathcal{O}(|k|^{-\rho+\frac{1}{2}})$. Then

$$R_m[R_{(1-\vartheta')\cdot}(g)] = \mathcal{O}(m^{-\rho+1}),$$

which, using statement 3 in Theorem 4.1, gives the estimate 3. Similarly, if $\rho > 3/2$, then

$$\left(\sum_{\nu=1}^{\infty} \nu R_{(1-\vartheta')(\nu+m)}(g)^2\right)^{1/2} = \mathcal{O}\left(\left(\sum_{\nu=1}^{\infty} \nu(\nu+m)^{-2\rho+1}\right)^{1/2}\right) = \mathcal{O}(m^{-\rho+\frac{3}{2}}) \to 0,$$

which, using statement 2 in Theorem 4.1, provides estimate 2.

Finally, for $\rho > \frac{5}{2}$, $R_k(g) = \mathcal{O}(|k|^{-\rho+\frac{1}{2}})$ gives

$$\sum_{\nu=1}^{\infty} \nu R_{(1-\vartheta')(\nu+m)}(g) = \mathcal{O}\left(\sum_{\nu=1}^{\infty} \nu(\nu+m)^{-\rho+\frac{1}{2}}\right) = \mathcal{O}(m^{\frac{5}{2}-\rho}),$$

as claimed in statement 1. □

The estimates 1–3 do not include the case $\hat{g}_k = \mathcal{O}(|k|^{-1})$, as $R_{(1-\vartheta')(\nu+m)}(g)$ is then no longer well behaved. This may be overcome by considering different norms, as we proceed to do. For $1 < \alpha' < 2$ and $1/\alpha + 1/\alpha' = 1$, define a norm $|\cdot|_{\alpha'}$ on the physical plane by

$$|p|_{\alpha'} := \|\hat{p}\|_\alpha = \left(\sum_{k=-\infty}^{\infty} \int_{\mathbf{R}} |\hat{p}(\sigma,k)|^\alpha \, d\sigma\right)^{1/\alpha},$$

which is in accordance with the norms $\|\hat{p}\|_\alpha$ for $\alpha = 1, 2$ employed before. Notice that for $1 < \alpha' < 2$ these norms are less natural than the classical norms $\|\cdot\|_{\alpha'}$, but at least an estimate $|\cdot|_{\alpha'} \le \|\cdot\|_{\alpha'}$ holds (see [3, p. 177]), known as the Hausdorff–Young inequality. For $\alpha' > 2$, the Hausdorff–Young inequality is no longer true, and usage of the norms $|\cdot|_{\alpha'}$ would then appear rather airy.

Corollary 4.3. *With the same hypothesis as in Corollary* 4.2*, let* $\hat{g}_k = \mathcal{O}(|k|^{-1})$*, and suppose* $h(x)$ *is essentially bandlimited.*

4. *If* $1 < \alpha' < \frac{4}{3}$*, then* $|p - \mathcal{S}_{K,W}p|_{\alpha'} = \mathcal{O}(m^{\frac{3\alpha'-4}{4\alpha'-4}}) \to 0$.
5. *If* $1 < \alpha' < 2$*, then* $|p - \mathcal{S}_{K,W}p|_{\alpha'} = \mathcal{O}(b^{\frac{\alpha'-1}{\alpha'}} m^{\frac{1}{2}-\frac{1}{\alpha'}})$.

Proof. We have to go through the proof of Theorem 4.1 with the norm $\|\hat{p} - \widehat{\big(\mathcal{S}_{K,W}p\big)}\|_\alpha$ as in (4.5), (4.6), but with different $\alpha > 2$. We estimate on the domains Γ_1, Γ_2. Now according to (4.12),

$$\|\chi_{\Gamma_2}\hat{p}\|_\alpha \le \|\hat{p}\|_\infty^{1-2/\alpha} \|\chi_{\Gamma_2}\hat{p}\|_2^{2/\alpha} \le C\|\mathcal{H}_b h\|_{W^{2,-\frac{1}{2}}}^{2/\alpha},$$

which decays exponentially, since h is essentially bandlimited. So we are left with the error estimate on Γ_1 involving the error terms for g.

Proceeding as in part 8 of the proof of Theorem 4.1, we obtain

$$\|\chi_{\Sigma_1}\hat{p}\|_\alpha^\alpha \leq C \sum_{|k|\geq m} (|k|-m)\bigg(R_{(1-\vartheta')|k|}(g)+\|g\|_2 e^{-\gamma|k|}\bigg)^\alpha = \mathcal{O}\bigg(\sum_{\nu=1}^\infty \nu R_{(1-\vartheta')(\nu+m)}(g)^\alpha\bigg),$$

the exponentially decaying term being negligible. Now obviously $\hat{g}_k = \mathcal{O}(|k|^{-1})$ implies $R_{(1-\vartheta')|k|}(g) = \mathcal{O}(|k|^{-1/2})$, so for $\alpha > 4$,

$$\sum_{\nu=1}^\infty \nu R_{(1-\vartheta')(\nu+m)}(g)^\alpha = \mathcal{O}\bigg(\sum_{\nu=1}^\infty \nu(\nu+m)^{-\alpha/2}\bigg) = \mathcal{O}(m^{2-\alpha/2}) \to 0,$$

giving $|p - \mathcal{S}_{K,W}p|_{\alpha'} = \mathcal{O}(m^{1-\alpha/4})$, which is estimate 4. Finally, if only $\alpha > 2$, we still have $\sum_\nu R_{(1-\vartheta')(\nu+m)}(g)^\alpha = \mathcal{O}(m^{1-\frac{\alpha}{2}})$, which readily gives estimate 5. This completes the proof. □

The principal message of Theorem 4.1 and its corollaries is that the aliasing error associated with a choice of the bowtie region (4.3) may be attributed to two different sources. The errors on the regions Σ_2, Σ_3 (resp., Γ_2) decay exponentially (as $b \to \infty$) if $h(x)$ is essentially bandlimited. On the other hand, the error contribution from Σ_1, and correspondingly, from Γ_1, entirely depends on g and no longer relates to the spatial bandwidth b. This error contribution decays as $m \to \infty$, but in general much slower than the other error terms. In practice, this may require choosing a rather large m, which may render an appropriate sampling difficult (cf. Figure 4). In detail, we have the following observations.

Remarks. (1) If g is of class $\mathcal{C}_{\text{per}}^\infty$ or even analytic, the error from region Σ_1, and hence the overall aliasing error, decays rapidly as the support region K grows. This is of course the case when the source is static, so we reproduce Natterer's estimates in [20, Thm. III.3.1]. Similarly, if $g(t)$ presents a full dynamic profile, starting with 0 activity, reaching its peak after uptake, and decaying back to 0 after washout, we may realistically assume that $g((T/2\pi)\phi) \in \mathcal{C}_{\text{per}}^\infty$, which again gives a fast decay as $m \to \infty$.

(2) In many practical cases, however, $g((T/2\pi)\phi)$ is not even of class $\mathcal{C}_{\text{per}}$. For instance if only a washout profile is scanned, we usually find $g(t)$ decaying like an exponential or a sum of exponentials, so $g((T/2\pi)\phi)$ is piecewise analytic but discontinuous. Here Theorem 4.1 and Corollary 4.2 are not applicable, since the Fourier coefficients of $g(t) = e^{-\lambda t}$ are $\hat{g}_k = \mathcal{O}(|k|^{-1})$. In this case, we have to retreat to the estimate 4 from Corollary 4.3, which is not entirely satisfactory, as it involves a norm $|\cdot|_{\alpha'}$ with $1 < \alpha' < 2$. One may very well argue that failure of 2-norm convergence indicates a problem in practice, and some of our experiments seem to emphasize this (cf. Figure 4).

(3) Notice that $\hat{g}_k = \mathcal{O}(|k|^{-2})$ if, according to the terminology of [3], g satisfies a *generalized Lipschitz condition of order* 2, that is, if

$$g(\phi+h) + g(\phi-h) - 2g(\phi) = \mathcal{O}(h^{-2}) \qquad \text{as } h \to 0, \tag{4.19}$$

uniformly in $\phi \in [0, 2\pi]$.

(4) The first 2-D Fourier analysis of the unattenuated Radon transform was presented in [22]. These authors calculate the spectrum of a point source $f(x) = \delta(x-a)$. Following their idea, one might consider a *dynamic point source*

$$f(t,x) = g(t)\,\delta(x-a) \tag{4.20}$$

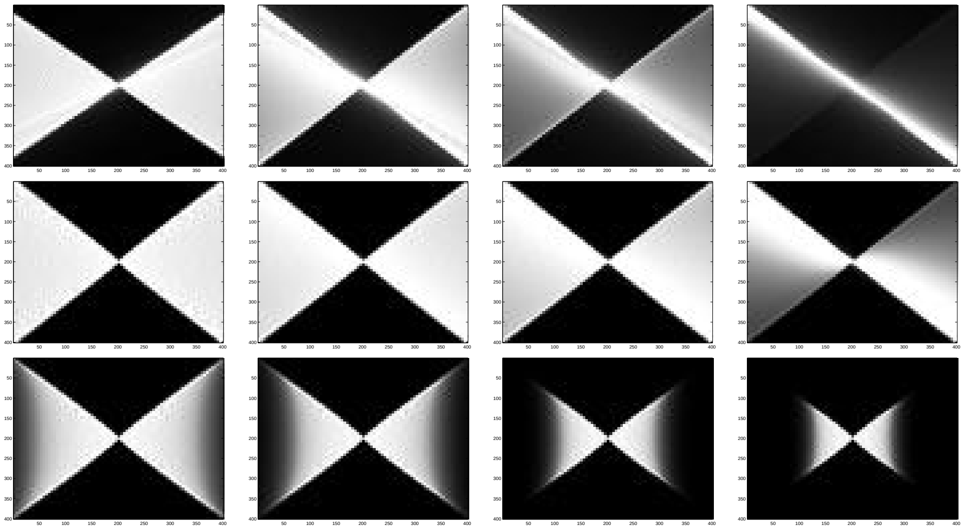

FIG. 3. *The first two lines show the effect of the dynamic* $g(t) = e^{-\lambda(2\pi/T)t}$ *on a point source located at* $a = (0.56, 0.8285) \in D$*. The first line displays the cases* $\lambda = 0.1, 0.4, 0.6,$ *and* 1.1 *(left to right). For a fast decay, the spectrum tends to emphasize a diagonal with slope related to the position* a *of the source. The second line shows the energy spectra for the same dynamics, but after doubling the data. The third line shows the effect of the spatial bandwidth* b*. This may be simulated by considering sources of the form* $h(x) = \phi_{a,\sigma}(x)$ *with* $g \equiv 1$*, where* $\phi_{a,\sigma}$ *denotes the* 2*-D Gaussian with mean* $a = (0.56, 0.8285) \in D$ *and covariance matrix* $\sigma^2 I_2$ *for different* $\sigma = 0.008, 0.01, 0.015,$ *and* 0.02 *(left to right). For* σ *not exceedingly large,* $\phi_{a,\sigma}$ *may be considered as compactly supported. Notice that* $R\phi_{a,\sigma}(s,\omega) = \phi_{a\cdot\omega^\perp}(s)$ *is a* 1*-D Gaussian, whose spectrum may be calculated analytically, cf.* [15].

located at $a \in D$ and emitting with dynamic profile $g(t)$. In fact, the energy spectrum of (4.20), while obviously not bounded in σ-direction, still decays on the region Σ_1 (as $m \to \infty$). This leads to a support region of infinite bowtie shape (see Figure 3). The point of view adopted by considering sources (4.20) is useful since it directly relates the thickness of the bowtie at $\sigma = 0$ to the dynamic profile $g(t)$.

(5) The analysis presented in Theorem 4.1 breaks down at an early stage when R is replaced by the attenuated Radon transform. Even the Fourier slice theorem is no longer available, nor has it an equally useful alter ego. This seems to limit the analysis to numerical experiments, which is of course not entirely satisfactory. Fortunately, adopting the point of view expounded in remark 4, we may interpret attenuation as a particular type of dynamics. In fact, consider a dynamic point source (4.20) located at a and attenuated through $\mu(x)$. Define the function $g_a(\phi)$ by

$$g_a(\phi) = \exp\Big\{ -\int_0^\infty \mu(a + \tau\omega)\, d\tau \Big\}, \qquad \omega = (\cos\phi, \sin\phi).$$

The attenuated Radon transform of $\delta(\cdot - a)$ is

$$\begin{aligned} R[\mu, \delta(\cdot - a)](s,\phi) &= \int_{-\infty}^\infty \delta(s\omega^\perp + \tau\omega - a)\, \exp\Big\{ -\int_\tau^\infty \mu(s\omega^\perp + \tau'\omega)\, d\tau' \Big\}\, d\tau \\ &= \exp\Big\{ -\int_{a\cdot\omega}^\infty \mu(s\omega^\perp + \tau'\omega)\, d\tau' \Big\}\, \delta(s - a\cdot\omega^\perp) \\ &= g_a(\phi)\, \delta(s - a\cdot\omega^\perp) \;=\; g_a(\phi)\, R\,\delta(\cdot - a)(s,\phi). \end{aligned}$$

Therefore, for a single camera head, according to (3.1), the sinogram of (4.20) is

$$p(s,\phi) = g((T/2\pi)\phi)\, g_a(\phi)\, R\,\delta(\cdot - a)(s,\phi). \tag{4.21}$$

The interpretation of (4.21) is that on a static point source, attenuation acts like a dynamic, while for a dynamic point source, it modulates the existing dynamics. The important point, however, is that as long as 360 degrees are scanned, $g_a(\phi)$ is smooth (as soon as $\mu(x)$ is). Therefore, one may argue that modulating the existing dynamics will not seriously slow down the convergence of the Fourier series, and attenuation will not qualitatively alter the shape of the infinite bowtie support region of the dynamic point source with profile $g(t)$. This seems to be corroborated by numerical experiments.

(6) Notice that a result similar to Theorem 4.1 and Corollary 4.2 may be obtained on a 180-degree tour. The estimates involving Bessel functions have to be modified, but the coefficients replacing $J_n(\theta n)$ still decay exponentially. What makes a 180-degree tour seem more delicate is the more serious effect of attenuation. Namely, $g_a(\phi)$, defined on $[0,\pi]$, and continued periodically outside, will now just like $g((T/\pi)\phi)$ have a discontinuity at $\phi = 0$, adding to the effect of the discontinuity of $g((T/\pi)\phi)$ at $\phi = 0$. Doubling the data in the way shown in the next section will partially remedy this (see Figure 4).

5. Experiments.

While the results in the previous section serve to theoretically justify the choice of a frequency window of bowtie shape, K, they do not readily indicate how to calculate K (or rather, m and b) in practice. To do this, we have to provide a practical guideline. Treating the error contributions from Σ_1 and Σ_2, Σ_3 separately, we propose the following approach.

For a dynamic profile $g(t)$ having $\hat{g}_k = \mathcal{O}(|k|^{-\rho})$ for some $\rho > 1$, and for a point source $\delta(\cdot - a)$ located on the unit disk D, consider the spectrum $\hat{p}$ of the sinogram p of $f(t,x) = g(t)\,\delta(x-a)$. For every frequency σ choose indices $\underline{m}(\sigma)$ and $\overline{m}(\sigma)$ such that

$$\sum_{\nu=\underline{m}(\sigma)}^{\overline{m}(\sigma)} |\hat{p}_\nu(\sigma)|^2 \;\geq\; .98^{\frac{1}{2}} \cdot \sum_{\nu=-\infty}^{\infty} |\hat{p}_\nu(\sigma)|^2, \tag{5.1}$$

uniformly over $a \in D$, which is to say that on each line $\sigma = \text{const}$, $[\underline{m}(\sigma), \overline{m}(\sigma)]$ captures 98.99% of the energy of $\hat{p}(\sigma,\cdot)$ (notice $.9899 = .98^{\frac{1}{2}}$). This procedure will, if successful for a given dynamic $g(t)$, provide an infinite region which essentially captures the energy of the spectrum $\hat{p}$ of any source of the form $f(t,x) = g(t)\,h(x)$, $h(x)$ supported on D, but not necessarily bandlimited. It is hoped that the *same* region will then emerge for a large variety of dynamic profiles $g(t)$.

As it turns out, this program is indeed realizable. Numerical experiments indicate that the desired infinite support region is an infinite bowtie as displayed in Figure 3, with a symmetry $\underline{m} = -\overline{m}$ apparent. In (4.3), the choice $\vartheta \approx 1$ seems justified, and for a large variety of profiles $g(t)$, the delimiters $\underline{m}$, $\overline{m}$ are then of the form

$$\overline{m}(\sigma) = |\sigma| + m, \quad \underline{m} = -\overline{m},$$

where $m = \overline{m}(0) > 0$ may be calculated explicitly through (5.1).

In a second step we now have to truncate the infinite bowtie at $\sigma = \pm b$ in order to define a bounded region K. This may be done by applying the same argument again, i.e., by choosing b to satisfy

$$\sum_{\nu=\underline{m}(\sigma)}^{\overline{m}(\sigma)} \int_{|\sigma|\le b} |\hat{p}_\nu(\sigma)|^2 \, d\sigma \;\ge\; .98^{\frac{1}{2}} \cdot \sum_{\nu=\underline{m}(\sigma)}^{\overline{m}(\sigma)} \int_{\mathbf{R}} |\hat{p}_\nu(\sigma)|^2 \, d\sigma \tag{5.2}$$

uniformly over $a \in D$. Clearly this step may require a discretization, conveniently done by FFT 2. The combined procedure (5.1), (5.2) specifies a region K carrying 98% of the energy of the spectrum $\hat{p}$.

A second and easier way to specify a bowtie (4.3) is to discretize the spectrum $\hat{p}$ into a frame of size $S \times S$, say, and then find a tolerance $\epsilon > 0$ to the effect that within the chosen frame, $\hat{p}\chi_{\{|\cdot|\ge\epsilon\}}$ carries 98% of the energy of $\hat{p}$. Both procedures turn out to be in good agreement, which reinforces the choice (4.3).

Let us now consider an application with experimental data, exhibiting the typical problem with a discontinuous time profile. The study shown in Figure 4 uses a phantom built at Vancouver General Hospital [4] and was performed with a Siemens Multispect-3 (MS3) triple head camera with a low energy ultra high resolution (LEUHR) collimator. Only data from one of the camera heads were used to simulate the case of a single head camera.

The phantom, a 17-ml container shown in Figure 4(a), is connected to a supply and a drain and equipped with a mixing propeller to guarantee a homogeneous flow. The container was initially filled with Tc-99 m of approximately 40 MBq radio activity. The activity was diluted and washed out through uniform water flow, producing approximately a single exponential decay with estimated half-life of 3 minutes. The plot of the total activities of the 64 views of a slice selected at the horizontal pixel position 38 is shown in Figure 4(b). The sinogram of the selected slice is shown in (c), indicating that 180 degrees have been scanned with 64 stops and a camera cross section divided into 64 bins. The time for the total scan was $T = 10$ minutes.

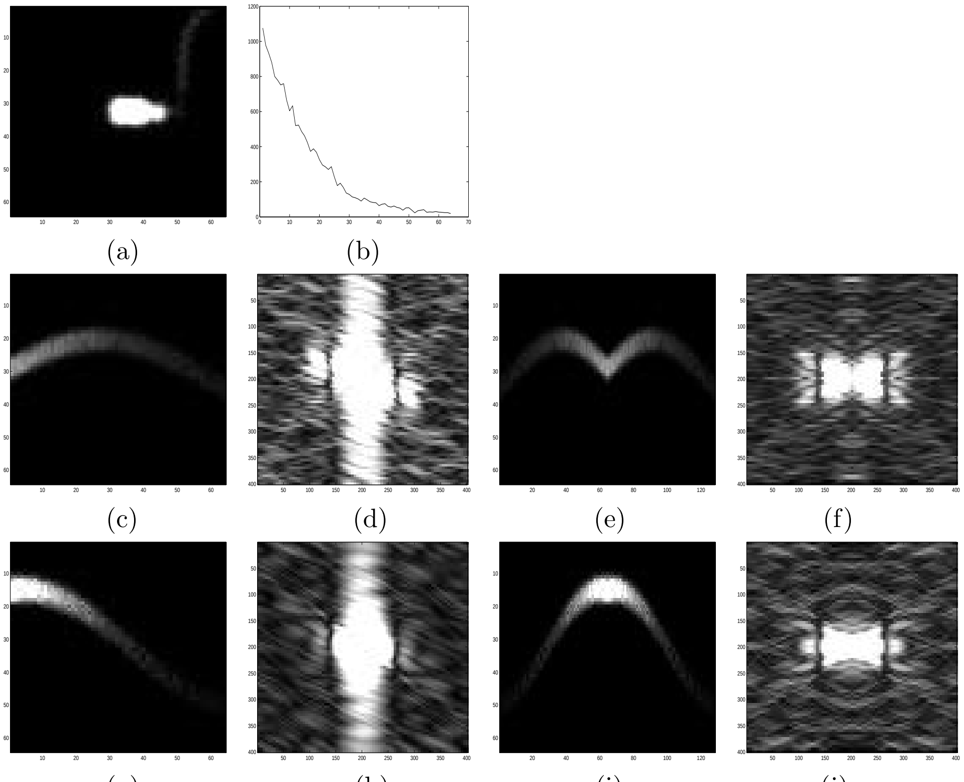
Figure 4(d) shows the energy spectrum of Figure 4(c), obtained via zero filling into a 400×400 frame, applying the 2-D FFT, taking absolute values, and rearranging the image so that high frequencies are at the edges.

The energy spectrum Figure 4(d), expected to resemble a bowtie shape, is blotted by a high energy band in vertical direction. According to theory, this high energy band should not exist here—unless some of the hypothesis on which the results in section 4 are based turned out to be violated. As a list of possible explanations we offer the following.

(1) The sinogram, being blurred by attenuation and scatter, may contain noise components not modeled in (3.2), whose spectra contribute to the vertical band.

(2) The bowtie region (4.3) was obtained under the hypothesis that the object is contained in the unit disk. While this is the case for the selected slice, we have to remember that the radiating object is 3-D, and neighboring slices contribute to the data through scatter and collimator blurring. Some of these recorded events may be mistaken as coming from outside the unit circle.

(3) The problem evoked before: the recorded data present a washout with approximately single exponential decay, see Figure 4(b), causing a discontinuity of $g((T/\pi)\phi)$ at $\phi = 0$. The high energy band visible in Figure 4(d) may indicate the failure of convergence of the Fourier series at $\phi = 0$, or rather, that a very large $m = \overline{m}(0)$ is required in (5.1).



(a) (b)

(c) (d) (e) (f)

(g) (h) (i) (j)

FIG. 4. *Experimental data from Vancouver General Hospital, obtained with a Siemens Multispect-*3 *triple head camera.*

(4) Since a 180-degree sector has been scanned, the sinogram, along with the discontinuity in time, has a singularity in the spatial variable, visible in Figure 4(e) as a kink, which may as well be responsible for the phenomenon.

In order to decide which of these items is likely to cause the phenomenon of Figure 4(c), we *double* the data by flipping the sinogram with respect to the axis $\phi = 0$, including the reverse data among a new symmetric sinogram of size 128×64, displayed in Figure 4(e). The doubled sinogram now has an increase of activity on $[-\pi, 0]$, followed by the original period of decay on $[0, \pi]$.

The effect of the doubling procedure, while theoretically improving the signal to be of class $\mathcal{C}_{\mathrm{per}}(-\pi, \pi)$, is dramatic in the case of our experiment. The energy spectrum Figure 4(f) of the doubled sinogram no longer exhibits the erratic vertical energy band and quite reasonably displays the bowtie form predicted by theory. As the decay profile of the bottle may very well be approximated by an exponential $e^{-\lambda\phi}$, the doubling procedure may even theoretically be justified. While the Fourier coefficients of $e^{-\lambda\phi}$ are $\mathcal{O}(|k|^{-1})$, the doubled signal $e^{-\lambda|\phi|}$ on $[-\pi, \pi]$ has Fourier coefficients $c_k = (1 + (-1)^{k+1} e^{-\lambda\pi}) \frac{2\lambda}{\lambda^2 + k^2} = \mathcal{O}(|k|^{-2})$. In any case, we strongly recommend the doubling procedure, particularly if the dynamic is relatively fast.

In order to indicate that the phenomenon in Figure 4(d) is not due to any of the noise effects evoked in items (1) and (2) of our list, one may create an artificial 2-D object, resembling the true slice of the bottle, with activity distribution a properly scaled 2-D Gaussian. For the dynamics one would substitute a single exponential decay found by inspecting the cumulative activity plot Figure 4(b). The result, not displayed here, shows that the Gibbs phenomenon is still apparent, reinforcing our explanation (3).

Finally, to discriminate item (3) from the possible explanation (4), we have scanned the bottle from a different position (Figure 4(a)), the sinogram of the corresponding slice shown in Figure 4(g), and selected to the effect that in the doubled sinogram in Figure 4(i) the spatial singularity is removed. The energy spectra in Figure 4(h), belonging to in Figure 4(g), and in Figure 4(j), belonging to Figure 4(i), show that the result is qualitatively the same, indicating that the phenomenon (4) is less serious than (3).

6. Resolution. We present the promised guideline on how to acquire data with a rotating SPECT camera. Consider exemplarily the case of a single camera head rotating over a 180-degree tour. Doubling the data will then give a 360-degree sinogram. Suppose the dynamic source $f(t,x)$ is of the form $g_1(t)\,h_1(x)+\cdots+g_r(t)\,h_r(x)$, with the $h_i(x)$ supported on the unit disk. Assume that the unit circle is completely visible from each camera position, which means that a camera cross section has length 2. Assume that the cross section is divided into 64 bins, giving $\Delta s = 1/32$. Since the Nyquist rate is $\Delta s = \pi/b$, the best possible bandwidth is $b = 32\pi$, a fact we may not easily debate if the resolution of the camera has to be considered a fixed technical parameter.

According to (4.4), the sampling parameters in the frequency plane are $\Delta\sigma = b$, $\Delta k = [b]+2m$, where we have chosen $\vartheta \approx 1$, as validated by the numerical experiments in section 4. Using (4.4), this gives

$$\Delta s = \frac{\pi}{b}, \qquad \Delta\phi = \frac{\pi}{[b]+2m}. \tag{6.1}$$

Let us consider the case where a washout (with decreasing activity) is scanned. As it comes out, tracer dynamics are often described by a *compartmental model* (cf. [11]), and accordingly the dynamic source is represented as a sum of exponentials

$$f(t,x) = h_1(x)\,e^{-\lambda_1(\pi/T)t} + \cdots + h_r(x)\,e^{-\lambda_r(\pi/T)t}$$

with $\lambda_i \geq 0$ (decay to 0 at infinity) and where the $h_i(x)$ are supported on the unit disk D. In practice we may usually exhibit $\lambda_i \leq \lambda$, the fastest dynamic to be expected. Then the bowtie region may be estimated by considering a source of the form $f(t,x) = h(x)\,g(t) = h(x)\,e^{-\lambda(\pi/T)t}$.

As $g((T/\pi)\phi) = e^{-\lambda\phi}$, doubling the data as suggested in our approach gives the dynamic profile $e^{-\lambda|\phi|}$ over $-\pi \leq \phi \leq \pi$. Estimating the thickness $m = m(\lambda)$ of the bowtie as a function of λ, based on (5.1), yields the approximate linear relationship

$$m(\lambda) \approx \frac{3}{8}\,\lambda + 1, \tag{6.2}$$

which we exploit a little further by considering a realistic situation comparable to the one in our experiment.

Suppose that the total acquisition time of the scan is $T = 10$ minutes, while the shortest expected half-life is of the order of 2 minutes. Then $t_{\frac{1}{2}} = T\log 2/\pi\lambda = .2T$, giving $\lambda = \log 2/.2\pi \approx 1.1$. Hence $g((T/\pi)\phi) = \exp\{(-\log 2/.2\pi)|\phi|\} = \exp\{-1.1|\phi|\}$, which through (6.2) suggests $m \approx 1.4$. In view of (6.1), this gives $\Delta\phi \approx .06 = 3.44$

degrees as satisfactory for practical purposes. The interpretation is that an appropriate sampling of the doubled signal over 360 degrees requires approximately 105 views, that is, 53 views over 180-degrees. This is not in complete agreement with the actual policies (cf. [16]), where we often prefer to take 64 views on a 180-degree tour. As our scenario ignores the noise contributions, 53 views may in practice be barely sufficient, and we consider 64 views as a practical guideline on 180 degrees.

Remark. Formula (6.1) may be interpreted as an *uncertainty principle*. Assume that a minimum $\Delta\phi$ has been specified by the user to guarantee a sufficient number of recorded counts per camera position. Then we may consider $[b] + 2m$ as fixed. So within certain limits, we may either increase m and capture faster dynamics, paying eventually by a loss in spatial resolution (by decreasing b), or we may conversely choose a better spatial resolution by increasing b, bearing the risk that some of the faster dynamics may not be adequately represented.

7. Filtering. In this last section we discuss a policy for the 2-D filtering of the sinogram data. Notice that filtering of the projection data is currently done in one dimension, that is, every projection is filtered separately. In the static case, this does not cause any particular difficulty, as the same filter may be used for all projections. To that effect, various filters have been around for years, and their application is well understood.

The situation is a little more complicated in dSPECT, as the overall activity changes from view to view. 1-D filtering may now require adapting an individual filter to each projection, and it may then seem more attractive to do a 2-D filtering, based on the insights of section 4. In particular, a 2-D filter, if based on the 2-D Fourier transform, may use the bowtie shape of the spectrum of the Radon transform, and may therefore incorporate information not easily assessed through a 1-D procedure. We therefore propose the following frequency domain based 2-D filtering procedure, which incorporates the theoretical results obtained in previous sections.

To render the situation even more interesting, we modify the experiment from section 5 by scanning four bottles of the type shown in Figure 4(a). We arrange a washout through continuous water flow of different half-lives between 2 and 6 minutes. Starting out with the 64×64 sinogram (Figure 5, top left), we double data (top row right) as done previously, and include them into a frame of zeros of considerably larger size $L \times L$ (zero filling), where usually $L = 200$ or $L = 400$. The 2-D FFT is applied to the enlarged signal. Filtering is now performed in the frequency domain by multiplying the $L \times L$ spectrum with a 2-D window function:

$$w_{m,b}(x, y) = \phi(x/b)\,\phi(y/(m + x))$$

with $-L/2 \le x, y \le L/2$ integer and parameters $m, b \le L/2$. The window function satisfies $\phi(0) = 1$, $\phi(t) = 0$ for $|t| \ge 1$ and could be any of the standard 1-D lag windows. Figure 5 (second row) displays several filters with the choice $L = 200$, b ranging from 100 to 70, and m ranging from 80 to 20.

Rows 3–6 show the effect of the 2-D filtering of these window functions. The left-hand picture shows three projections (number 4, number 19, and number 61). The dotted line shows the original data, the continuous line shows the filtered curves. The right-hand diagram shows the smoothing effect of the filters on the sum plot. The latter indicates the success of the doubling, as the same filtering applied to the simple sinogram would exhibit a Gibbs phenomenon at $\phi = 0$.

SECOND ORDER SINGULAR PERTURBATION MODELS FOR PHASE TRANSITIONS[*]

IRENE FONSECA[†] AND CARLO MANTEGAZZA[‡]

Abstract. Singular perturbation models involving a penalization of the first order derivatives have provided a new insight into the role played by surface energies in the study of phase transitions problems. It is known that if $W : \mathbb{R}^d \to [0, +\infty)$ grows at least linearly at infinity and it has exactly two potential wells of level zero at $a, b \in \mathbb{R}^d$, then the $\Gamma(L^1)$-limit of the family of functionals

$$\mathcal{F}_\varepsilon(u) := \begin{cases} \int_\Omega \left(\frac{W(u)}{\varepsilon} + \varepsilon|\nabla u|^2\right) dx & \text{if } u \in W^{1,2}(\Omega; \mathbb{R}^d), \\ \\ +\infty & \text{if } u \in L^1(\Omega; \mathbb{R}^d) \setminus W^{1,2}(\Omega; \mathbb{R}^d), \end{cases}$$

where Ω is a bounded, open set in $\mathbb{R}^N$, is given by

$$\mathcal{F}(u) := \begin{cases} \mathbf{m}\,\mathrm{Per}_\Omega(\{u = a\}) & \text{if } u \in BV(\Omega; \{a, b\}), \\ +\infty & \text{otherwise,} \end{cases}$$

for a suitable constant $\mathbf{m}$ depending on the energy density W. In this paper, and motivated by the study of phase transitions for nonlinear elastic materials, the $\Gamma(L^1)$-limit is obtained in the case where in $\mathcal{F}_\varepsilon(u)$ the penalization term $\varepsilon|\nabla u|^2$ is replaced by $\varepsilon^3|\nabla^2 u|^2$, for $u \in W^{2,2}(\Omega; \mathbb{R}^d)$. The resulting functional is of the same form as $\mathcal{F}(u)$ above.

1. Introduction.

In this paper we show that the $\Gamma(L^1)$-limit of the family of singular perturbations

$$\mathcal{F}_\varepsilon(u) := \begin{cases} \int_\Omega \left(\frac{W(u)}{\varepsilon} + \varepsilon^3|\nabla^2 u|^2\right) dx & \text{if } u \in W^{2,2}(\Omega; \mathbb{R}^d), \\ \\ +\infty & \text{if } u \in L^1(\Omega; \mathbb{R}^d) \setminus W^{2,2}(\Omega; \mathbb{R}^d), \end{cases}$$

where $W : \mathbb{R}^d \to [0, +\infty)$ grows at least linearly at infinity and has exactly two potential wells of zero level at $a, b \in \mathbb{R}^d$, is given by

$$\mathcal{F}(u) := \begin{cases} \mathbf{m}\,\mathrm{Per}_\Omega(\{u = a\}) & \text{if } u \in BV(\Omega; \{a, b\}), \\ +\infty & \text{otherwise,} \end{cases}$$

with

$$\mathbf{m} := \min\left\{ \int_{\mathbb{R}} (W(f) + |f''|^2\, dt : f \in W^{2,2}_{\mathrm{loc}}(\mathbb{R}; \mathbb{R}^d), \lim_{t\to+\infty} f(t) = b, \lim_{t\to-\infty} f(t) = a \right\}.$$

Singular perturbations of nonconvex, multiple-well variational problems may be found in gradient strain theories in plasticity, ferromagnetics, and other areas of materials science and engineering. In particular, within the context of phase transitions of nonlinear elastic materials, let $W : \mathbb{R}^{d\times N} \to [0, +\infty)$ be the stored energy density of a material with reference configuration an open, bounded set $\Omega \subset \mathbb{R}^N$, and which may undergo a phase transformation. This material instability may be due, in part, to the multiple-well profile of W. For simplicity, assume that

$$W(\xi) = 0 \text{ if and only if } \xi \in \{A, B\},$$

where $\operatorname{rank}(A - B) = 1$. Let us assume further that equilibria for fixed phase volume fraction are determined by minimum energy; physically, this model is oversimplified since it is incompatible with the frame indifference requirement; it does not take into account material symmetries, evolution is neglected, and there is no heat diffusion. Then we are led to (see [20, 22])

$$\min\left\{\int_\Omega W(\nabla u)\,dx : u \in W^{1,1}(\Omega; \mathbb{R}^d), \int_\Omega \nabla u\,dx = \mathcal{L}^N(\Omega)(\theta A + (1-\theta)B)\right\},$$

where $\theta \in (0, 1)$ is a fixed volume fraction, and $\mathcal{L}^N$ stands for the N-dimensional Lebesgue measure in $\mathbb{R}^N$. Due to the rank-one compatibility between A and B, there are infinitely many laminates with strain gradients alternating between A and B which will minimize the total bulk energy. As in the Cahn–Hilliard model for liquid-liquid phase transformations with underlying variational formulation

$$\min\left\{\int_\Omega W(u)\,dx : u \in L^1(\Omega; \mathbb{R}^d), \int_\Omega u\,dx = \mathcal{L}^N(\Omega)(\theta a + (1-\theta)b)\right\},$$

where $\{W = 0\} = \{a, b\}$, and with corresponding family of singular perturbations (see [10, 12, 13, 22, 25, 28, 29, 30, 32, 33])

$$\int_\Omega (W(u) + \varepsilon^2|\nabla u|^2)\,dx,$$

we attempt to resolve the lack of uniqueness by considering higher gradient penalizations. This is in agreement with higher strain gradient theories in plasticity. To this end, for any open set $A \subset \Omega$ we introduce the family

$$J_\varepsilon(u; A) := \int_A (W(\nabla u) + \varepsilon^2|\nabla^2 u|)\,dx.$$

The characterization of the $\Gamma(L^1)$-limit of these functionals, and, in particular, of the asymptotic behavior of minimizers as $\varepsilon \to 0^+$, is work under progress by Fonseca and Tartar [21]. Here the main difficulties are, essentially, the need to use intrinsically vectorial techniques and the proof of the locality of the $\Gamma(L^1)$-limit. The use of vectorial techniques was successfully exploited in the variational study of the eikonal equation, seen as a partial differential constraint on finite limiting energy fields when in J_ε the density W is allowed to vanish on the sphere (see [5, 8, 9, 18, 26, 27, 24]). In the attempts to ascertain locality, the problems encountered seem to stem from the higher order derivative in the model. Precisely, if we knew that the subadditivity property

$$\Gamma(L^1) - \lim_{\varepsilon\to 0^+} J_\varepsilon(u; A) \le \Gamma(L^1) - \lim_{\varepsilon\to 0^+} J_\varepsilon(u; B) + \Gamma(L^1) - \lim_{\varepsilon\to 0^+} J_\varepsilon(u; A \setminus \overline{C})$$

holds whenever A, B, C are open subsets of Ω with $C \subset\subset B \subset\subset A$, then we would be able to ensure that $\Gamma(L^1) - \lim_{\varepsilon\to 0^+} J_\varepsilon(u;\cdot)$ is a measure, and therefore Radon–Nikodym theorem and a blow-up argument around points on the laminate surfaces would easily yield

$$\Gamma(L^1) - \lim_{\varepsilon\to 0^+} J_\varepsilon(u;\Omega) := \begin{cases} \widehat{\mathbf{m}}\ \mathrm{Per}_\Omega(\{\nabla u = A\}) & \text{if } \nabla u \in BV(\Omega;\{A,B\}), \\ +\infty & \text{otherwise,} \end{cases}$$

for an appropriate surface energy density $\widehat{\mathbf{m}}$. This program may be carried out successfully in the Cahn–Hilliard model where the penalization is of first order. For this reason, and motivated in part by the need to isolate the understanding of the role played by higher order penalizations and the obstacles that they may introduce, we take a step further in the simplification of the original model for J_ε, and we consider the family $\mathcal{F}_\varepsilon$ as defined above.

We note that higher order perturbations of nonconvex problems have been studied recently within the framework of free discontinuity problems. In particular, elliptic regularizations with second order terms were proposed for the approximation of free discontinuity problems related to the Mumford–Shah model for image segmentation in computer vision (see, e.g., [3, 4, 15, 14]).

The one-dimensional problem encapsules the main features of the model. Indeed the relevant contributions of this paper may be found in the next section where, using a priori bounds provided by Gagliardo and Nirenberg inequalities, we are able to show that the limiting energy minimizers are two-phase fields with minimal interfacial perimeter. Further, the resulting interfacial energy per unit area, $\mathbf{m}$, may be computed explicitly as the solution of an auxiliary minimization problem, corresponding to the one-dimensional energetically efficient profiles which connect a at $-\infty$ to b at $+\infty$. The extension of these results to the N-dimensional case follows a standard slicing argument that enables us to reduce it to the one-dimensional setting.

2. The one-dimensional problem.

Let $W : \mathbb{R}^d \to \mathbb{R}$ be a continuous function satisfying the following hypotheses:
(H1) $W(u) = 0$ if and only if $u \in \{a, b\}$;
(H2) there exist constants $C > 0$, $R > \max\{|a|, |b|\}$, such that if $|u| > R$, then $W(u) \geq C|u| - 1/C$.

Let $I := (\alpha, \beta)$ be a fixed open interval in $\mathbb{R}$. Consider the family of functionals indexed by the parameter $\varepsilon > 0$, and defined as

$$\mathcal{F}_\varepsilon(u) := \begin{cases} \int_I \left(\frac{W(u)}{\varepsilon} + \varepsilon^3 |u''|^2\right) dt & \text{if } u \in W^{2,2}(I;\mathbb{R}^d), \\ +\infty & \text{if } u \in L^1(I;\mathbb{R}^d) \setminus W^{2,2}(I;\mathbb{R}^d). \end{cases}$$

We seek to identify the limiting states corresponding to sequences of minimizers for $\mathcal{F}_\varepsilon(\cdot)$, and to this purpose we will use the notion of $\Gamma(L^1)$-convergence. We recall some basic notions on $\Gamma(L^1)$-convergence (for a detailed, comprehensive study we refer the reader to [17]). Let Ω be an open, bounded subset of $\mathbb{R}^N$.

DEFINITION 2.1. *Let $F_n : L^1(\Omega;\mathbb{R}^d) \to [-\infty, +\infty]$ and $u \in L^1(\Omega;\mathbb{R}^d)$. We define*

$$\Gamma(L^1) - \liminf F_n(u) := \inf\left\{ \liminf_{n\to\infty} F_n(u_n) : u_n \to u \quad \text{in } L^1(\Omega;\mathbb{R}^d)\right\}$$

and

$$\Gamma(L^1) - \limsup F_n(u) := \inf\left\{ \limsup_{n\to\infty} F_n(u_n) : u_n \to u \quad \text{in } L^1(\Omega;\mathbb{R}^d)\right\}.$$

If $\Gamma(L^1) - \liminf F_n(u) = \Gamma(L^1) - \limsup F_n(u)$, *then the common value is called the* $\Gamma(L^1)$*-limit of* F_n *at* u, *and is denoted by* $\Gamma(L^1) - \lim F_n(u)$.

Moreover, given a family $F_\varepsilon : L^1(\Omega;\mathbb{R}^d) \to [-\infty,+\infty]$, $\varepsilon > 0$, *if* $u \in L^1(\Omega;\mathbb{R}^d)$, *then we say that* $\Gamma(L^1) - \lim F_\varepsilon(u) = F(u)$ *if* $F(u) = \Gamma(L^1) - \lim F_{\varepsilon_n}(u)$ *for every sequence* $\varepsilon_n \to 0^+$.

It can be shown that $F(u) = \Gamma(L^1)$-limit of F_ε at u if and only if

(i) for every sequences $\{u_n\}$ and $\{\varepsilon_n\}$ such that $u_n \to u$ in $L^1(\Omega;\mathbb{R}^d)$ and $\varepsilon_n \to 0^+$

$$F(u) \le \liminf_{n\to\infty} F_{\varepsilon_n}(u_n);$$

(ii) for every sequence $\{\varepsilon_n\}$ converging to 0^+ there exists a sequence $\{u_n\}$ such that $u_n \to u$ in $L^1(\Omega;\mathbb{R}^d)$ and

$$F(u) = \lim_{n\to\infty} F_{\varepsilon_n}(u_n).$$

In what follows C denotes a generic positive constant which may vary from one formula to the next and from line to line. Also, $\mathcal{L}^N$ stands for the Lebesgue measure in $\mathbb{R}^N$, and $B(x,\delta)$ is the ball centered at the point x and with radius $\delta > 0$.

Define

$$\mathcal{A} := \left\{ f \in W^{2,2}_{\mathrm{loc}}(\mathbb{R};\mathbb{R}^d) : f(t) = b \text{ if } t > C, f(t) = a \text{ if } t < -C \ \text{ for some } \ C > 0 \right\}$$

and

$$\mathbf{m} := \inf\left\{ \int_{\mathbb{R}} (W(f) + |f''|^2)\,dt : f \in \mathcal{A} \right\}. \tag{2.1}$$

The main theorem of this section is the following.

THEOREM 2.2. *For every* $u \in L^1(I;\mathbb{R}^d)$

$$\Gamma(L^1) - \lim_{\varepsilon\to 0^+} \mathcal{F}_\varepsilon(u) = \begin{cases} \mathbf{m}\,\mathrm{Per}_I(\{u = a\}) & \textit{if } u \in BV(I;\{a,b\}), \\ +\infty & \textit{otherwise}. \end{cases}$$

Compactness for energy bounded sequences will rely heavily on the following interpolation inequality due to Gagliardo [23] and Nirenberg [31].

PROPOSITION 2.3. *Let* Ω *be a bounded, open, Lipschitz subset of* $\mathbb{R}^N$. *If* $u \in L^1(\Omega;\mathbb{R}^d)$ *and* $\nabla^2 u \in L^2(\Omega;\mathbb{R}^d)$, *then* $u \in W^{2,2}(\Omega;\mathbb{R}^d)$ *and*

$$\|\nabla u\|_{L^{4/3}} \le C\left(\|u\|_{L^1}^{1/2} \|\nabla^2 u\|_{L^2}^{1/2} + \|u\|_{L^1} \right), \tag{2.2}$$

where $C = C(\Omega, N, d)$.

In what follows we will also use the following interpolation inequality.

LEMMA 2.4. *Let* $\varphi : (0,+\infty) \to \mathbb{R}$ *be a convex, nondecreasing function in* $\mathbb{R}^+$, *and let* J *be* $\mathbb{R}$ *or a half-line. Then for every function* $u \in L^1_{\mathrm{loc}}(J;\mathbb{R}^d)$ *with* $u'' \in L^1_{\mathrm{loc}}(J;\mathbb{R}^d)$ *we have*

$$\int_J \varphi\left(\frac{|u'|}{4d}\right)\,dt \le \frac{3}{4}\int_J [\varphi(|u|) + \varphi(|u''|)]\,dt. \tag{2.3}$$

Proof. The case where $\varphi(t) = |t|^p$ may be found in Adams [1, Lemma 4.10]. First consider the real valued case where $d = 1$. Given $u \in W^{2,1}(0,1)$, fix $\theta \in (0, 1/3)$ and $\eta \in (2/3, 1)$, and by virtue of the mean value theorem, find $\xi \in (0,1)$ such that

$$u'(\xi) = \frac{u(\theta) - u(\eta)}{\theta - \eta};$$

hence,

$$|u'(x)| \leq \frac{|u(\theta) - u(\eta)|}{|\theta - \eta|} + \int_\xi^x |u''|\, dt \leq \frac{|u(\theta) - u(\eta)|}{|\theta - \eta|} + \int_0^1 |u''|\, dt$$

for all $x \in (0,1)$, which, by the choice of θ and η, implies that

$$|u'(x)| \leq 3|u(\theta)| + 3|u(\eta)| + \int_0^1 |u''|\, dt \quad \text{for all } x \in (0,1).$$

Integrating in θ and η and multiplying both sides by 9 we get

$$\begin{aligned} |u'(x)| &\leq 3\int_0^{1/3} |u|\, dt + 3\int_{2/3}^1 |u|\, dt + \int_0^1 |u''|\, dt \\ &\leq 3\int_0^1 |u|\, dt + \int_0^1 |u''|\, dt \end{aligned}$$

for all $x \in (0,1)$. Now, dividing both sides by 4, and using the convexity and monotonicity properties of φ, together with Jensen's inequality, we obtain

$$\begin{aligned} \varphi\left(\frac{|u'(x)|}{4}\right) &\leq \varphi\left(\frac{3}{4}\int_0^1 |u|\, dt + \frac{1}{4}\int_0^1 |u''|\, dt\right) \\ &\leq \frac{3}{4}\varphi\left(\int_0^1 |u|\, dt\right) + \frac{1}{4}\varphi\left(\int_0^1 |u''|\, dt\right) \\ &\leq \frac{3}{4}\int_0^1 [\varphi(|u|) + \varphi(|u''|)]\, dt \end{aligned}$$

for all $x \in (0,1)$.

Finally, integrating in x we have

$$\int_0^1 \varphi\left(\frac{|u'|}{4}\right) dt \leq \frac{3}{4}\int_0^1 [\varphi(|u|) + \varphi(|u''|)]\, dt\,.$$

Dividing J in disjoint intervals of length 1 and applying this argument to each one of them we conclude that

$$\int_J \varphi\left(\frac{|u'|}{4}\right) dt \leq \frac{3}{4}\int_J [\varphi(|u|) + \varphi(|u''|)]\, dt\,.$$

If u takes values in $\mathbb{R}^d$, $d \geq 2$, then

$$\begin{aligned}\int_J \varphi\left(\frac{|u'|}{4d}\right) dt &\leq \int_J \varphi\left(\sum_{i=1}^d \frac{|u_i'|}{4d}\right) dt\\ &\leq \frac{1}{d}\sum_{i=1}^d \int_J \varphi\left(\frac{|u_i'|}{4}\right) dt\\ &\leq \frac{3}{4d}\sum_{i=1}^d \int_J [\varphi(|u_i|)+\varphi(|u_i''|)]\, dt\\ &\leq \frac{3}{4d}\sum_{i=1}^d \int_J [\varphi(|u|)+\varphi(|u''|)]\, dt\\ &= \frac{3}{4}\int_J [\varphi(|u|)+\varphi(|u''|)]\, dt,\end{aligned}$$

which proves the lemma. □

In that which follows we will exploit the auxiliary functions $G, H : \mathbb{R}^{2d} \to \mathbb{R}$, which take into account the energy stored on an interfacial layer

$$G(w,z) := \inf\left\{ \int_0^1 (W(g) + |g''|^2)\, dt : \; g \in C^2([0,1];\mathbb{R}^d),\, g(0) = w,\, g(1) = b,\right.$$
$$\left. g'(0) = z,\, g'(1) = 0 \right\},$$

$$H(w,z) = \inf\left\{ \int_0^1 (W(h) + |h''|^2)\, dt : \; h \in C^2([0,1];\mathbb{R}^d),\, h(0) = a,\, h(1) = w,\right.$$
$$\left. h'(0) = 0,\, h'(1) = z \right\}.$$

Testing G and H with third degree polynomials g and h, respectively, satisfying the boundary conditions, it can be shown that

$$\lim_{(w,z)\to(b,0)} G(w,z) = 0\,, \qquad \lim_{(w,z)\to(a,0)} H(w,z) = 0\,. \tag{2.4}$$

LEMMA 2.5. *The constant* $\mathbf{m}$ *is positive and*

$$\mathbf{m} = \min\left\{ \int_{\mathbb{R}} (W(f) + |f''|^2)\, dt : f \in W^{2,2}_{\mathrm{loc}}(\mathbb{R};\mathbb{R}^d),\, \lim_{t\to+\infty} f(t) = b,\, \lim_{t\to-\infty} f(t) = a \right\}.$$

Proof. Step 1. We start by proving that $\mathbf{m} > 0$. Suppose that $\mathbf{m} = 0$ and let $\{f_n\}$ be a minimizing sequence of admissible functions in $\mathcal{A}$. Let

$$S := \left\{ x \in \mathbb{R}^d : |x - a| = \frac{|b-a|}{2} \right\}.$$

By the Sobolev embedding theorem each function f_n belongs to $C^1(\mathbb{R};\mathbb{R}^d)$, and since $f_n(t) = b$ for $t > M_n$ and $f_n(t) = a$ if $t < -M_n$ for a suitable $M_n > 0$, there must exist a point $t_n \in \mathbb{R}$ such that $f_n(t_n) \in S$. By performing a simple translation in the variable, with no loss of generality, we may assume that $f_n(0) \in S$. As $\mathbf{m} = 0$, we have that $\|f_n''\|_{L^2} \to 0$; moreover, by (H2), fixed a bounded interval $J \subset \mathbb{R}$ containing the origin, $\{f_n\}$ is equibounded in $L^1(J;\mathbb{R}^d)$, and Proposition 2.3 implies that $\{f_n'\}$ is equibounded in $L^{4/3}(J;\mathbb{R}^d)$. Therefore, by the Sobolev embedding theorem it follows that $\{f_n\}$ is bounded in $W^{2,2}(J;\mathbb{R}^d)$, and we may extract a subsequence $f_{n_i}|_J$ of restricted functions converging in $W^{1,\infty}$ to an affine function $f : J \to \mathbb{R}^d$ such that $f(0) =: c \in S$. Setting $f(t) := c + tv$ for some $v \in \mathbb{R}^d$, we have

$$\begin{aligned}\mathbf{m} &= \lim_{n\to\infty} \int_{\mathbb{R}} (W(f_{n_i}) + |f_{n_i}''|^2)\, dt \\ &\geq \lim_{n\to\infty} \int_J (W(f_{n_i}) + |f_{n_i}''|^2)\, dt \\ &\geq \int_J W(c+tv)\, dt > 0\,,\end{aligned}$$

because if $\int_J W(c+tv)\, dt = 0$, then $c + tv$ should belong to $\{a, b\}$ for all $t \in J$, and therefore $v = 0$ and $c \in \{a, b\}$, which is not possible since $c \in S$. We arrived at a contradiction, and thus $\mathbf{m} > 0$.

Step 2. Next we prove that $\mathbf{m} = \widetilde{\mathbf{m}}$, where

(2.5)
$$\widetilde{\mathbf{m}} := \inf\left\{ \int_{\mathbb{R}} (W(f) + |f''|^2)\, dt : f \in W^{2,2}_{\text{loc}}(\mathbb{R};\mathbb{R}^d),\ \lim_{t\to+\infty} f(t) = b,\ \lim_{t\to-\infty} f(t) = a \right\}.$$

It is clear that $\mathbf{m} \geq \widetilde{\mathbf{m}}$.

Conversely, fix $\delta > 0$ and let f be a function admissible for $\widetilde{\mathbf{m}}$ and such that

$$\widetilde{\mathbf{m}} + \delta \geq \int_{\mathbb{R}} (W(f) + |f''|^2)\, dt.$$

We claim that we may find two sequences $\{x_i\}$ and $\{y_i\}$ converging to $+\infty$ and $-\infty$, respectively, such that

$$|f'(x_i)| + |f'(y_i)| + |f(x_i) - b| + |f(y_i) - a| \to 0 \tag{2.6}$$

as $i \to \infty$. Indeed, fix $\tau < |b-a|/2$ and consider a convex, nondecreasing function $\varphi : \mathbb{R} \to [0, +\infty)$ such that $\varphi(t) \leq t^2$ for every $t \in \mathbb{R}$, $\varphi(|y|) \leq W(y+b)$ for every $y \in B(0,\tau) \subset \mathbb{R}^d$, and $\varphi(t) = 0$ if and only if $t = 0$. To prove the existence of φ it suffices to set

$$\begin{aligned}\varphi(t) := \sup\{g : \mathbb{R} \to [0,+\infty) : g \text{ is convex, nondecreasing,}\\ g(t) \leq t^2 \text{ for all } t \in \mathbb{R},\ g(|y|) \leq W(y+b) \text{ for all } y \in B(0,\tau)\}\end{aligned}$$

and use hypothesis (H1). Let $R > 0$ be such that $|f(t) - b| < \tau$ whenever $t > R$. Applying Lemma 2.4 to the function $f - b$, and using the properties of the function φ, we obtain

$$\begin{aligned}\int_R^{+\infty} \varphi\left(\frac{|f'|}{4d}\right) dt &\leq \frac{3}{4} \int_R^{+\infty} [\varphi(|f-b|) + \varphi(|f''|)]\, dt \\ &\leq \frac{3}{4} \int_R^{+\infty} (W(f) + |f''|^2)\, dt \leq \frac{3\,(\widetilde{\mathbf{m}} + \delta)}{4}\,.\end{aligned}$$

Thus $\varphi\left(\frac{|f'|}{4d}\right)$ is integrable on $[R,+\infty)$, and so there exists a sequence of points $x_n \to +\infty$ such that $\lim_{n\to\infty}\varphi\,\left(\frac{|f'(x_n)|}{4d}\right)$=0, and since φ is monotone nondecreasing on $[0,+\infty)$, with $\varphi(t)=0$ if and only if $t=0$, we conclude that $\lim_{n\to\infty} f'(x_n)=0$. Repeating this argument with the point a in place of b, we are now in a position to assert the existence of two sequences satisfying (2.6).

Set

$$g_i(t) := g(t-x_i), \qquad h_i(t) := h(t-y_i+1),$$

where g and h are admissible for G and H, respectively, and

$$\int_0^1 (W(g)+|g''|^2)\,dt \le G(f(x_i),f'(x_i))+\delta,$$

$$\int_0^1 (W(h)+|h''|^2)\,dt \le H(f(y_i),f'(y_i))+\delta.$$

We define

$$\widetilde{f}_i(t) := \begin{cases} b & \text{if } t \ge x_i+1,\\ g_i(t) & \text{if } t\in[x_i,x_i+1],\\ f(t) & \text{if } t\in[y_i,x_i],\\ h_i(t) & \text{if } t\in[y_i-1,y_i],\\ a & \text{if } t\le y_i-1.\end{cases}$$

Clearly $\widetilde{f}_i$ is admissible for $\mathbf{m}$, and we have

$$\begin{aligned}\widetilde{\mathbf{m}}+\delta &\ge \int_{\mathbb{R}}(W(f)+|f''|^2)\,dt \ge \int_{y_i}^{x_i}(W(f)+|f''|^2)\,dt\\ &= \int_{\mathbb{R}}(W(\widetilde{f}_i)+|\widetilde{f}_i''|^2)\,dt - \int_{x_i}^{x_i+1}(W(g_i)+|g_i''|^2)\,dt\\ &\quad -\int_{y_i-1}^{y_i}(W(h_i)+|h_i''|^2)\,dt\\ &\ge \mathbf{m}-G(f(x_i),f'(x_i))-H(f(y_i),f'(y_i))-2\delta.\end{aligned}$$

The inequality $\widetilde{\mathbf{m}}\ge\mathbf{m}$ now follows by letting $\delta\to 0^+$, $i\to\infty$, and using (2.4).

Step 3. Finally, we prove that $\mathbf{m}$ is attained, or, equivalently, that $\widetilde{\mathbf{m}}$ admits a minimizer. Let $\{f_n\}$ be a minimizing sequence for $\widetilde{\mathbf{m}}$. Possibly passing to a subsequence, and making a translation change of variables, we may assume as before that $f_n(0)\in S$, where S was defined in Step 1, and that the sequence of C^1 functions $\{f_n\}$ converges in $W^{1,\infty}_{\text{loc}}$ to a C^1 function $f:\mathbb{R}\to\mathbb{R}^d$. If the function f is admissible, then it realizes the infimum, since

$$\int_{\mathbb{R}}(W(f)+|f''|^2)\,dt \le \varliminf_{n\to\infty}\int_{\mathbb{R}}(W(f_n)+|f_n''|^2)\,dt,$$

where we have used Fatou's lemma and the lower semicontinuity of the L^2 norm of the second derivative. In order to prove that f approaches a and b at infinity, set

$$L := \left\{ l\in\mathbb{R}^d \mid \ l \text{ is a limit point of } f(t) \text{ when } t\to+\infty\right\}.$$

The integrability of $W(f)$ and (H1) imply that a or b must belong to L. Suppose that $b \in L$, and that there is another limiting value $l \in L$. Note that, without loss of generality, we may assume that $l \neq a$, for if $l = a$, then, by the continuity of f, there would exist a sequence $y_i \to +\infty$ such that $f(y_i) \in S$; hence, for a subsequence (not relabelled) $f(y_i) \to l' \in S$. Consider two monotone sequences of points $\{x_i\}$ and $\{z_i\}$ such that $x_{i+1} - x_i \geq 3$, $z_i \in [x_i + 1, x_{i+1} - 1]$, $f(x_i) \to b$ and $f(z_i) \to l$, and for $0 < \delta < \min\{|l-a|, |l-b|\}$ we introduce still another constant $\widehat{\mathbf{m}}$ defined as follows:

$$\widehat{\mathbf{m}} := \inf\left\{ \int_x^y (W(g) + |g''|^2)\, dt : y - x \geq 3,\ z \in [x+1, y-1], \right. \\ \left. g \in W^{2,2}((x,y);\mathbb{R}^d),\ |g(z) - l| \leq \delta \right\}.$$

We claim that $\widehat{\mathbf{m}} = 0$. Indeed, if $\widehat{\mathbf{m}} > 0$, then there would exist n_0 such that, for $n \geq n_0$, $|f(z_n) - l| \leq \delta$, and it would follow that

$$\begin{aligned}\int_{\mathbb{R}} (W(f) + |f''|^2)\, dt &= \int_{-\infty}^{x_{n_0}} (W(f) + |f''|^2)\, dt + \sum_{i=n_0}^{\infty} \int_{x_i}^{x_{i+1}} (W(f) + |f''|^2)\, dt \\ &\geq \int_{-\infty}^{x_{n_0}} (W(f) + |f''|^2)\, dt + \sum_{i=n_0}^{\infty} \widehat{\mathbf{m}} = +\infty.\end{aligned}$$

On the other hand, we can show that the assertion $\widehat{\mathbf{m}} = 0$ leads to a contradiction. The reasoning is similar to the one used in Step 1 for the constant $\mathbf{m}$. Let $g_n \in W^{2,2}((x_n, y_n);\mathbb{R}^d)$ minimize $\widehat{\mathbf{m}}$. Translating the intervals, without loss of generality we can suppose that $z_n = 0$, thus $x_n \leq -1$ and $y_n \geq 1$, and possibly passing to a subsequence (not relabelled), we may assume that the functions g_n converge in $W^{1,\infty}([-1,1];\mathbb{R}^d)$ to an affine function $g(t) = d + tv$. Therefore

$$\begin{aligned}\widehat{\mathbf{m}} &\geq \lim_{n\to\infty} \int_{x_n}^{y_n} (W(g_n) + |g_n''|^2)\, dt \\ &\geq \lim_{n\to\infty} \int_{-1}^{1} (W(g_n) + |g_n''|^2)\, dt \\ &\geq \int_{-1}^{1} W(d + tv)\, dt > 0\,,\end{aligned}$$

because if $\int_{-1}^{1} W(d+tv)\, dt = 0$, then $d + tv$ should belong to $\{a, b\}$ for all $t \in (-1, 1)$, i.e., $v = 0$ and $d \in \{a, b\}$. This is not possible since $g_n(0) \to d$, $g_n(0) \in B(l,\delta)$, and $a, b \notin B(l, \delta)$. We conclude that $f(t) \to b$ as $t \to +\infty$.

Similarly, if $a \in L$, then $f(t)$ converges to a as $t \to -\infty$.

If the limits of f at $+\infty$ and $-\infty$ are, respectively, a and b, then $f(-t)$ is still a minimizer and it converges to b and a at, respectively, $+\infty$ and $-\infty$.

It remains to exclude the possibility that the two limits coincide. Suppose that $\lim_{t\to\pm\infty} f(t) = a$. As in Step 2, by virtue of Lemma 2.4 we can find a sequence of points $x_n \to +\infty$ such that

$$|f'(x_n)| + |f(x_n) - a| \to 0$$

and, due to the convergence of f_n to f in $W^{1,\infty}_{\mathrm{loc}}(\mathbb{R};\mathbb{R}^d)$, there exists a subsequence $\{f_{k_n}\}$ such that $f_{k_n}(x_n) \to a$ and $f'_{k_n}(x_n) \to 0$. Hence, we have

$$\begin{aligned}\int_{\mathbb{R}} (W(f_{k_n}) + |f''_{k_n}|^2)\,dt &= \int_{-\infty}^{x_n} (W(f_{k_n}) + |f''_{k_n}|^2)\,dt + \int_{x_n}^{+\infty} (W(f_{k_n}) + |f''_{k_n}|^2)\,dt \\ &\geq \int_{-\infty}^{x_n} (W(f_{k_n}) + |f''_{k_n}|^2)\,dt + \widetilde{\mathbf{m}} - H(f_{k_n}(x_n), f'_{k_n}(x_n))\,,\end{aligned}$$

and letting $n \to \infty$ we deduce that

$$\begin{aligned}\widetilde{\mathbf{m}} &\geq \limsup_{n\to\infty} \int_{-\infty}^{x_n} (W(f_{k_n}) + |f''_{k_n}|^2)\,dt + \widetilde{\mathbf{m}} \\ &\geq \limsup_{n\to\infty} \int_{-\infty}^{x_n} W(f_{k_n})\,dt + \widetilde{\mathbf{m}} \\ &= \int_{\mathbb{R}} W(f)\,dt + \widetilde{\mathbf{m}}\,.\end{aligned}$$

This would imply that f is constantly equal to a, but since $f_n(0) \in S$ for every n we also have $f(0) = \lim_{n\to\infty} f_n(0) \in S$ which is in contradiction with $a \notin S$. The case where $\lim_{t\to\pm\infty} f(t) = b$ is treated in an analogous way. □

Remark 2.6. A simple rescaling argument provides equipartition of energy. Precisely, if f realizes the minimum $\mathbf{m}$, then

$$\int_{\mathbb{R}} W(f)\,dt = 3\int_{\mathbb{R}} |f''|^2\,dt\,.$$

It suffices to use the fact that

$$\int_{\mathbb{R}} (W(f) + |f''|^2)\,dt \leq \int_{\mathbb{R}} (W(f_\lambda) + |f''_\lambda|^2)\,dt$$

for all $\lambda > 0$, where $f_\lambda(x) := f(\lambda x)$.

We now state and prove the compactness result for sequences with finite energy.

Proposition 2.7. *If $u_\varepsilon \in W^{2,2}(I;\mathbb{R}^d)$ satisfy $\liminf_{\varepsilon\to 0^+} \mathcal{F}_\varepsilon(u_\varepsilon) < +\infty$, then there exists a subsequence $\{u_{\varepsilon_n}\} \subset \{u_\varepsilon\}$ and $u \in BV(I;\{a,b\})$ such that $u_{\varepsilon_n} \to u$ in $L^1(I;\mathbb{R}^d)$. Moreover,*

$$\liminf_{\varepsilon\to 0^+} \mathcal{F}_\varepsilon(u_\varepsilon) \geq \mathbf{m}\,\mathrm{Per}_I(\{u = a\}).$$

Proof. Suppose that $\liminf_{\varepsilon\to 0^+} \mathcal{F}_\varepsilon(u_\varepsilon) =: K < +\infty$. We claim that there exists a function $u \in BV(I;\{a,b\})$ such that, up to a subsequence, $u_\varepsilon \to u$. Extract a subsequence from the start (not relabelled) realizing $\liminf_{\varepsilon\to 0^+} \mathcal{F}_\varepsilon(u_\varepsilon)$. We have

$$W(u_\varepsilon) \to 0 \text{ in } L^1, \quad ||u''||_{L^2} \leq C\varepsilon^{-3/2}.$$

By (H2)

$$||u_\varepsilon||_{L^1} \leq R\,\mathcal{L}^1(I) + \int_{\{|u_\varepsilon|>R\}} \left(\frac{1}{C^2} + \frac{1}{C}W(u_\varepsilon)\right)\,dt \leq \widetilde{C};$$

therefore, by the Gagliardo and Nirenberg inequality (2.2) we conclude that

$$||u'_\varepsilon||_{L^{4/3}} \leq C(||u_\varepsilon||^{1/2}_{L^1}||u''_\varepsilon||^{1/2}_{L^2} + ||u_\varepsilon||_{L^1}) \leq \widetilde{C}\varepsilon^{-3/4}. \tag{2.7}$$

Also

$$\mathcal{L}^1(\{|u_\varepsilon| > R\}) \to 0 \text{ as } \varepsilon \to 0^+. \tag{2.8}$$

Indeed, if $\tau := \inf\{W(\xi) : |\xi| > R\}$, then by (H1) we have $\tau > 0$, and therefore (2.8) follows from the fact that

$$0 = \lim_{\varepsilon\to 0^+} \int_I W(u_\varepsilon)\, dt \geq \limsup_{\varepsilon\to 0^+} \int_{\{|u_\varepsilon|>R\}} W(u_\varepsilon)\, dt \geq \tau \limsup_{\varepsilon\to 0^+} \mathcal{L}^1(\{|u_\varepsilon| > R\}).$$

Since $\{u_\varepsilon\}$ is bounded in L^1, we may extract a further subsequence (not relabelled) generating a Young measure $\{\nu_t\}_{t\in I}$. In particular, if $f : I \times \mathbb{R}^d \to [0, +\infty)$ is a Carathéodory function such that $\{f(\cdot, u_\varepsilon(\cdot))\}$ is equi-integrable, then $f(\cdot, u_\varepsilon(\cdot)) \rightharpoonup \bar{f}$ in L^1 where (see [11, 34])

$$\bar{f}(t) := \int_{\mathbb{R}} f(t, y) d\nu_t(y), \quad \text{almost everywhere (a.e.) } t \in I.$$

Setting $f(y) := \min\{W(y), 1\}$, it follows that

$$0 = \lim \int_I f(u_\varepsilon)\, dt = \int_I \int_{\mathbb{R}} f(y) d\nu_t(y)\, dt;$$

hence, since $f(y) = 0$ if and only $y \in \{a, b\}$, we have

$$\nu_t = \theta(t)\delta_{y=a} + (1 - \theta(t))\delta_{y=b}$$

for some $\theta \in L^\infty(I, [0, 1])$. We claim that

$$\theta \in \{0, 1\} \text{ a.e. in } I, \quad \text{i.e., } \theta = \chi_E \text{ for some measurable subset } E \subset I. \tag{2.9}$$

Suppose that the claim holds. Define

$$u(t) := a\chi_E(t) + b(1 - \chi_E(t)).$$

Then $u_\varepsilon \to u$ strongly in L^1. Indeed, let

$$\varphi(y) := \begin{cases} R\frac{y}{|y|} & \text{if } |y| > R, \\ y & \text{if } |y| \leq R. \end{cases}$$

Note that $u = \varphi(u)$, and recall that $W(y) \geq C|y| - 1/C$ if $|y| > R$, with $R > \max\{|a|, |b|\}$. Then

$$\begin{aligned} \int_I |u_\varepsilon - u|\, dt &\leq \int_I |\varphi(u_\varepsilon) - u|\, dt + 2\int_{|u_\varepsilon|>R} |u_\varepsilon|\, dt \\ &\leq \int_I |\varphi(u_\varepsilon) - u|\, dt + \frac{2}{C}\int_I W(u_\varepsilon)\, dt + \frac{2}{C^2}\mathcal{L}^1(\{|u_\varepsilon| > R\}). \end{aligned}$$

Therefore, by (2.8) and (2.9), we conclude that

$$\begin{aligned} \lim_{\varepsilon\to 0^+} \int_I |u_\varepsilon - u|\, dt &= \int_I \int_{\mathbb{R}} |\varphi(y) - u(t)| d\nu_t(y) dt \\ &= \int_E |\varphi(a) - u(t)|\, dt + \int_{I\setminus E} |\varphi(b) - u(t)|\, dt \\ &= \int_E |a - u(t)|\, dt + \int_{I\setminus E} |b - u(t)|\, dt = 0. \end{aligned}$$

To prove (2.9), define

$$X := \left\{ t \in I : \frac{1}{|B(t,\delta)|} \int_{B(t,\delta)} \theta(s)ds \in (0,1) \ \text{ for all } \ \delta > 0 \right\}.$$

We show that the cardinality of X (call it L) cannot exceed the integer part of $K/\mathbf{m}$; hence $\theta \in \{0,1\}$ a.e. and $u \in BV(I;\{a,b\})$ with $\mathbf{m}\,\mathrm{Per}_I(\{u=a\}) = \mathbf{m}\,L \le K$ which gives the result.

Indeed, suppose that there were l distinct points of I in X, $s_1 < s_2 < \cdots < s_l$. Let $\delta_0 := \min\{|s_i - s_{i+1}| : i = 1, \dots, l-1\}$. Choose $\delta_1 < \delta_0/2$ such that for all $\delta \le \delta_1$, and all $i \in \{1, \dots, l\}$,

$$\int_{B(s_i,\delta)} \theta(s)ds > 0, \qquad \int_{B(s_i,\delta)} (1-\theta(s))ds > 0.$$

Fix $0 < \eta < |b-a|/2$, let φ_η be a cut-off function with support on $B(a,\eta)$, $\varphi_\eta(a) = 1$, ψ_η is a cut-off function with support on $B(0,\eta)$, $\psi_\eta(0) = 1$, and γ_η is a cut-off function with support on $B(b,\eta)$, $\gamma_\eta(b) = 1$. By (2.7) $\psi_\eta(\varepsilon u'_\varepsilon)$ converges strongly to $\psi_\eta(0)$ in L^1, $\varphi_\eta(u_\varepsilon)$ converges in L^∞ weak-* to $\theta\varphi_\eta(a) + (1-\theta)\varphi_\eta(b)$, and we have

$$\begin{aligned}\lim_{\varepsilon\to 0^+} \int_{B(s_i,\delta_1)} \psi_\eta(\varepsilon u'_\varepsilon)\varphi_\eta(u_\varepsilon)dt &= \int_{B(s_i,\delta_1)} \psi_\eta(0)[\theta(t)\varphi_\eta(a) + (1-\theta(t))\varphi_\eta(b)]dt \\ &= \int_{B(s_i,\delta_1)} \theta(t)\,dt > 0,\end{aligned}$$

and, similarly,

$$\lim_{\varepsilon\to 0^+} \int_{B(s_i,\delta_1)} \psi_\eta(\varepsilon u'_\varepsilon)\gamma_\eta(u_\varepsilon)\,dt = \int_{B(s_i,\delta_1)} (1-\theta(t))\,dt > 0\,.$$

Thus, for each $i \in \{1, \dots, l\}$ and each $\varepsilon > 0$, we may find $x^+_{\varepsilon,i}, x^-_{\varepsilon,i} \in B(s_i,\delta_1)$ such that

$$u_\varepsilon(x^+_{\varepsilon,i}) \in B(b,\eta), u_\varepsilon(x^-_{\varepsilon,i}) \in B(a,\eta), |\varepsilon u'_\varepsilon(x^+_{\varepsilon,i})| < \eta, |\varepsilon u'_\varepsilon(x^-_{\varepsilon,i})| < \eta\,. \tag{2.10}$$

Define

$$g_{\varepsilon,i}(t) := \widehat{g_{\varepsilon,i}}\left(t - \frac{x^+_{\varepsilon,i}}{\varepsilon}\right), \quad h_{\varepsilon,i}(t) := \widehat{h_{\varepsilon,i}}\left(t - \frac{x^-_{\varepsilon,i}}{\varepsilon} + 1\right),$$

where the functions $\widehat{g_{\varepsilon,i}}$ and $\widehat{h_{\varepsilon,i}}$ are admissible for $G(u_\varepsilon(x^+_{\varepsilon,i}), \varepsilon u'_\varepsilon(x^+_{\varepsilon,i}))$ and for $H(u_\varepsilon(x^-_{\varepsilon,i}), \varepsilon u'_\varepsilon(x^-_{\varepsilon,i}))$, respectively, with

$$\int_0^1 (W(\widehat{g_{\varepsilon,i}}) + |\widehat{g_{\varepsilon,i}}''|^2)\,dt \le G(u_\varepsilon(x^+_{\varepsilon,i}), \varepsilon u'_\varepsilon(x^+_{\varepsilon,i})) + \varepsilon,$$

and

$$\int_0^1 \left(W(\widehat{h_{\varepsilon,i}}) + |\widehat{h_{\varepsilon,i}}''|^2\right)\,dt \le H(u_\varepsilon(x^-_{\varepsilon,i}), \varepsilon u'_\varepsilon(x^-_{\varepsilon,i}))) + \varepsilon.$$

Construct the functions

$$v_{\varepsilon,i}(t) := \begin{cases} b & \text{if } \ t \geq \frac{x^+_{\varepsilon,i}}{\varepsilon} + 1, \\[2ex] g_{\varepsilon,i}(t) & \text{if } t \in \left[\frac{x^+_{\varepsilon,i}}{\varepsilon}, \frac{x^+_{\varepsilon,i}}{\varepsilon} + 1\right], \\[2ex] u_\varepsilon(\varepsilon t) & \text{if } t \in \left[\frac{x^-_{\varepsilon,i}}{\varepsilon}, \frac{x^+_{\varepsilon,i}}{\varepsilon}\right], \\[2ex] h_{\varepsilon,i}(t) & \text{if } t \in \left[\frac{x^+_{\varepsilon,i}}{\varepsilon} - 1, \frac{x^+_{\varepsilon,i}}{\varepsilon}\right], \\[2ex] a & \text{if } \ t \leq \frac{x^+_{\varepsilon,i}}{\varepsilon} - 1. \end{cases}$$

Then $v_{\varepsilon,i}$ are admissible for $\mathbf{m}$, and since the intervals $[x^-_{\varepsilon,i}, x^+_{\varepsilon,i}]$ are disjoint we have

$$\begin{aligned} K &\geq \liminf_{\varepsilon \to 0^+} \sum_{i=1}^{l} \int_{x^-_{\varepsilon,i}}^{x^+_{\varepsilon,i}} \left(\frac{1}{\varepsilon} W(u_\varepsilon) + \varepsilon^3 |u''_\varepsilon|^2\right) dt \\ &= \liminf_{\varepsilon \to 0^+} \sum_{i=1}^{l} \int_{\frac{x^-_{\varepsilon,i}}{\varepsilon}}^{\frac{x^+_{\varepsilon,i}}{\varepsilon}} (W(v_{\varepsilon,i}) + |v''_{\varepsilon,i}|^2)\, dt \\ &\geq \mathbf{m} l - \limsup_{\varepsilon \to 0^+} \sum_{i=1}^{l} [H(u_\varepsilon(x^-_{\varepsilon,i}), \varepsilon u'_\varepsilon(x^-_{\varepsilon,i})) + G(u_\varepsilon(x^+_{\varepsilon,i}), \varepsilon u'_\varepsilon(x^+_{\varepsilon,i}))]. \end{aligned}$$

Letting $\eta \to 0^+$, we conclude that $K \geq \mathbf{m}\, l$, where we have used (2.4) and (2.10). The result now follows from the arbitrariness of $l \leq L$ and the fact that $\mathbf{m} > 0$ (see Lemma 2.5). $\square$

As an immediate consequence of the previous result we have the following.

Corollary 2.8. *If $u \in L^1(I; \mathbb{R}^d)$ and $\Gamma(L^1) - \liminf_{\varepsilon \to 0^+} \mathcal{F}_\varepsilon(u) < +\infty$, then the function u belongs to $BV(I; \{a, b\})$ and*

$$\Gamma(L^1) - \liminf_{\varepsilon \to 0^+} \mathcal{F}_\varepsilon(u) \geq \mathbf{m} \operatorname{Per}_I(\{u = a\}).$$

Now we turn our attention to the $\Gamma(L^1) - \limsup_{\varepsilon \to 0^+} \mathcal{F}_\varepsilon$.

Proposition 2.9. *If $u \in BV(I; \{a, b\})$, then*

$$\Gamma(L^1) - \limsup_{\varepsilon \to 0^+} \mathcal{F}_\varepsilon(u) \leq \mathbf{m} \operatorname{Per}_I(\{u = a\}).$$

Proof. Suppose that $S(u) = \{s_1, \ldots, s_l\} \subset I = (\alpha, \beta)$ is the jump set of the function u, with $\alpha < s_1 < \cdots < s_l < \beta$. Set $\delta_0 := \min\{s_{j+1} - s_j : j = 0, \ldots, l\}$, with $s_0 := \alpha$ and $s_{l+1} := \beta$, and let $I_i := [\frac{s_{i-1}+s_i}{2}, \frac{s_i+s_{i+1}}{2}]$ for $i = 1, \ldots l$. Fix $\delta \in (0, \delta_0)$ and let $f \in \mathcal{A}$ be an admissible function for $\mathbf{m}$, with $f \in W^{2,2}_{\mathrm{loc}}(\mathbb{R}; \mathbb{R}^d)$, $f(t) = b$ if $t > M$, $f(t) = a$ if $t < -M$,

$$\int_{\mathbb{R}} (W(f) + |f''|^2)\, dt \leq \mathbf{m} + \frac{\delta}{l}. \tag{2.11}$$

Consider a sequence $\varepsilon_n \to 0^+$, and choose n sufficiently large so that $\frac{\delta}{2\varepsilon_n} > M$.

Define

$$u_n(t) := \begin{cases} f\left(\frac{t-s_i}{\varepsilon_n}\right) & \text{if } t \in \left[\frac{s_{i-1}+s_i}{2}, \frac{s_{i+1}+s_i}{2}\right] \text{ and if } [u](s_i) = b-a, \\ f\left(-\frac{t-s_i}{\varepsilon_n}\right) & \text{if } t \in \left[\frac{s_{i-1}+s_i}{2}, \frac{s_{i+1}+s_i}{2}\right] \text{ and if } [u](s_i) = a-b, \\ u(t) & \text{otherwise,} \end{cases}$$

where $[u](s_i) := u(s_i) - u(s_{i-1})$ for $i = 1, \dots, l$. We note that $u_n \in W^{2,2}(I;\mathbb{R}^d)$. Indeed, if $[u](s_i) = b-a$, then $u\left(\frac{s_{i-1}+s_i}{2}\right) = a$, $u\left(\frac{s_{i+1}+s_i}{2}\right) = b$, and since

$$\frac{s_{i-1}-s_i}{2\varepsilon_n} < -\frac{\delta}{2\varepsilon_n} < -M, \qquad \frac{s_{i+1}-s_i}{2\varepsilon_n} > \frac{\delta}{2\varepsilon_n} > M,$$

we have that

$$f\left(\frac{s_{i-1}-s_i}{2\varepsilon_n}\right) = a, \quad f\left(\frac{s_{i+1}-s_i}{2\varepsilon_n}\right) = b, \quad f'\left(\frac{s_{i\pm 1}-s_i}{2\varepsilon_n}\right) = 0.$$

A similar argument applies to the case where $[u](s_i) = a-b$.

Since $u_n \to u$ in $L^1(I;\mathbb{R}^d)$ we conclude that

$$\begin{aligned}\lim_{n\to\infty} \mathcal{F}_{\varepsilon_n}(u_n) &= \lim_{n\to\infty} \sum_{i=1}^{l} \int_{I_i} \left(\frac{W(u_n)}{\varepsilon_n} + \varepsilon_n^3 |u_n''|^2\right) dt \\ &= \lim_{n\to\infty} \left\{ \sum_{i=1,\dots,l,\ [u](s_i)=b-a} \int_{\frac{s_{i-1}+s_i}{2\varepsilon_n}}^{\frac{s_{i+1}+s_i}{2\varepsilon_n}} (W(f(t)) + |f''(t)|^2)\, dt \right. \\ &\qquad \left. + \sum_{i=1,\dots,l,\ [u](s_i)=a-b} \int_{\frac{s_{i-1}+s_i}{2\varepsilon_n}}^{\frac{s_{i+1}+s_i}{2\varepsilon_n}} (W(f(-t)) + |f''(-t)|^2)\, dx \right\} \\ &= \left\{ \sum_{i=1,\dots,l,\ [u](s_i)=b-a} \int_{\mathbb{R}} (W(f(t)) + |f''(t)|^2)\, dt \right. \\ &\qquad \left. + \sum_{i=1,\dots,l,\ [u](s_i)=a-b} \int_{\mathbb{R}} (W(f(-t)) + |f''(-t)|^2)\, dt \right\} \\ &= l \int_{\mathbb{R}} (W(f) + |f''|^2)\, dt \\ &\leq \mathbf{m}\, l + \delta \\ &= \mathbf{m}\, \mathrm{Per}_I(\{u=a\}) + \delta,\end{aligned}$$

where we have used (H1) and (2.11). It suffices to let $\delta \to 0^+$. □

Remark 2.10. The arguments used in the proof of Theorem 2.2 may be easily adapted to generalize the model above to the case where

$$\mathcal{F}_\varepsilon(u) := \begin{cases} \int_\Omega \left(\frac{W(u)}{\varepsilon} + \varepsilon^{2p-1}|\nabla^2 u|^p\right) dx & \text{if } u \in W^{2,p}(\Omega;\mathbb{R}^d), \\ +\infty & \text{if } u \in L^1(\Omega;\mathbb{R}^d) \setminus W^{2,p}(\Omega;\mathbb{R}^d) \end{cases}$$

for $1 < p < +\infty$, with

$$\Gamma(L^1) - \lim_{\varepsilon \to 0^+} \mathcal{F}_\varepsilon(u) = \begin{cases} \mathbf{m}\,\mathrm{Per}_I(\{u = a\}) & \text{if } u \in BV(I; \{a, b\}), \\ +\infty & \text{otherwise,} \end{cases}$$

and now

$$\mathbf{m} := \inf \left\{ \int_{\mathbb{R}} (W(f) + |f''|^p)\, dt : f \in \mathcal{A} \right\}.$$

As usual, the scaling ε^{2p-1} in $\mathcal{F}_\varepsilon$ is the natural one obtained by testing the finiteness of energy with admissible fields u which are a and b in most of the domain, except on a transition layer of width ε. Note that here Proposition 2.3 still applies provided (2.2) is modified to read

$$\|\nabla u\|_{L^q} \le C \left(\|u\|_{L^1}^{1/2} \|\nabla^2 u\|_{L^p}^{1/2} + \|u\|_{L^1} \right)$$

with $2/q = 1 + 1/p$.

Naturally, the next step is to try to understand higher than two perturbations, i.e., how to treat

$$\mathcal{F}_\varepsilon^k(u) := \begin{cases} \int_\Omega \left(\frac{W(u)}{\varepsilon} + \varepsilon^{2k-1} |\nabla^k u|^2 \right) dx & \text{if } u \in W^{k,2}(\Omega; \mathbb{R}^d), \\ \\ +\infty & \text{if } u \in L^1(\Omega; \mathbb{R}^d) \setminus W^{k,2}(\Omega; \mathbb{R}^d), \end{cases}$$

where $k \in \mathbb{N}$. Although the methods involved may stay close to the ones introduced in this paper, this generalization does not seem to follow as immediately as the one above: last, but not least, the corresponding G and H will now require matching of all derivatives up to order $(k-1)$, and a new version of Lemma 2.4 will be in order. This analysis will be carried on in a forthcoming paper.

3. The *N*-dimensional case. Let Ω be an open, bounded, Lipschitz domain in $\mathbb{R}^N$, and consider the functionals

$$\mathcal{F}_\varepsilon(u) := \begin{cases} \int_\Omega \left(\frac{W(u)}{\varepsilon} + \varepsilon^3 |\nabla^2 u|^2 \right) dx & \text{if } u \in W^{2,2}_{\mathrm{loc}}(\Omega; \mathbb{R}^d)\ , \\ \\ +\infty & \text{if } u \in L^1(\Omega; \mathbb{R}^d) \setminus W^{2,2}_{\mathrm{loc}}(\Omega; \mathbb{R}^d) \end{cases}$$

for $\varepsilon > 0$, where W satisfies hypotheses (H1) and (H2). We recall that the constant $\mathbf{m}$ was defined in (2.1).

We start by proving L^1 compactness for energy bounded sequences.

PROPOSITION 3.1. *If* $u_\varepsilon \in W^{2,2}(\Omega; \mathbb{R}^d)$ *satisfy* $\liminf_{\varepsilon \to 0^+} \mathcal{F}_\varepsilon(u_\varepsilon) < +\infty$*, then there exists a subsequence* $\{u_{\varepsilon_n}\} \subset \{u_\varepsilon\}$ *and* $u \in BV(\Omega; \{a, b\})$ *such that* $u_{\varepsilon_n} \to u$ *in* $L^1(\Omega; \mathbb{R}^d)$.

The proof of this result uses the L^1-slicing compactness criterion introduced by Alberti, Bouchitté, and Seppecher in [2, Theorem 6.6] (see Proposition 3.2 below). Here two sequences $\{u_\varepsilon\}$ and $\{v_\varepsilon\}$ are said to be *δ-close* if $||u_\varepsilon - v_\varepsilon|| < \delta$, $\delta > 0$. When Ω is a rectangle of the form $I \times J$, with I, J open intervals, we write $x \in \Omega$ as $x = (y, z)$ with $y \in I$, $z \in J$. For every function u defined on Ω and every $y \in I$ we denote by u^y the function on J defined by $u^y(z) := u(y, z)$, and for every $z \in J$ we set $u^z(y) := u(y,z)$ for $y \in I$. The functions u^y and u^z are called *one-dimensional slices* of u.

Proposition 3.2. *Assume that the sequence $\{u_\varepsilon\}$ is equi-integrable, and suppose that for every $\delta > 0$ there exist sequences $\{v_\varepsilon\}$ and $\{w_\varepsilon\}$ δ-close to $\{u_\varepsilon\}$, and such that, $\{v^y_\varepsilon\}$ is precompact in $L^1(J;\mathbb{R}^d)$ for a.e. $y \in I$, and $\{w^z_\varepsilon\}$ is precompact in $L^1(I;\mathbb{R}^d)$ for a.e. $z \in J$. Then $\{u_\varepsilon\}$ is precompact in $L^1(\Omega;\mathbb{R}^d)$.*

Remark 3.3. We note that the original statement of Theorem 6.6 in [2] assumes that $\{u_\varepsilon\}$ is bounded in L^∞. However, it is easy to verify that the main tool involved is the use of Fréchet–Kolmogorov theorem for precompactness in L^1, which clearly holds as well when $\{u_\varepsilon\}$ is equi-integrable.

Proof of Proposition 3.1. For simplicity we suppose $N = 2$; the higher dimensional case is treated in an analogous way.

Assume first that Ω is a rectangle of the form $I \times J$, with I, J open intervals.

We denote by $\mathcal{F}^1_\varepsilon(u, A)$ the one-dimensional functional

$$\mathcal{F}^1_\varepsilon(u,A) := \begin{cases} \int_A \left(\frac{W(u)}{\varepsilon} + \varepsilon^3|u''|^2\right) dt & \text{if } u \in W^{2,2}(A;\mathbb{R}^d), \\ +\infty & \text{if } u \in L^1(A;\mathbb{R}^d) \setminus W^{2,2}(A;\mathbb{R}^d), \end{cases}$$

for every open interval A and every $u \in L^1(A;\mathbb{R}^d)$. We recall that if $u \in W^{2,2}(\Omega;\mathbb{R}^d)$, then $u^y \in W^{2,2}(J;\mathbb{R}^d)$ for a.e. $y \in I$ and $u^z \in W^{2,2}(I;\mathbb{R}^d)$ for a.e. $z \in J$, and

$$\frac{\partial^2 u}{\partial z^2}(x) = \frac{d^2 u^y}{dz^2}(z)\ ,\quad \frac{\partial^2 u}{\partial y^2}(x) = \frac{d^2 u^z}{dy^2}(y) \quad \text{for a.e. } x \in \Omega$$

(see [19, section 4.9.2]). Since $|\nabla^2 u|^2 \geq \max\left\{\left|\frac{\partial^2 u}{\partial z^2}\right|^2, \left|\frac{\partial^2 u}{\partial y^2}\right|^2\right\}$, we immediately obtain the following *slicing inequalities*:

$$\mathcal{F}_\varepsilon(u) \geq \int_I \mathcal{F}^1_\varepsilon(u^y, J)\, dy, \qquad \mathcal{F}_\varepsilon(u) \geq \int_J \mathcal{F}^1_\varepsilon(u^z, I)\, dz\,. \tag{3.1}$$

Now consider a family of functions $\{u_\varepsilon\}$ such that $\mathcal{F}_\varepsilon(u_\varepsilon) \leq C < +\infty$. Since $\int_\Omega W(u_\varepsilon)\,dx \leq C\varepsilon$, we have that $W(u_\varepsilon) \to 0$ in L^1, and therefore equi-integrability of $\{u_\varepsilon\}$ follows from (H2). Therefore, fix $\delta > 0$ and let $\delta' \in (0,\delta)$ be such that

$$\mathcal{L}^2(S) \leq \delta'|J| \quad \Longrightarrow \quad \sup_{\varepsilon>0} \int_S (|u_\varepsilon(x)| + |b|)\,dx \leq \delta\,.$$

For $\varepsilon > 0$ we define $v_\varepsilon : \Omega \to \mathbb{R}^d$ by

$$v^y_\varepsilon(z) := \begin{cases} u^y_\varepsilon(z) = u_\varepsilon(y,z) & \text{if } \mathcal{F}^1_\varepsilon(u^y_\varepsilon, J) \leq C/\delta', \\ b & \text{otherwise.} \end{cases}$$

We claim that $v^y_\varepsilon = u^y_\varepsilon$ for all $y \in I$ except at most on a set $Z_\varepsilon \subset I$ of measure smaller than δ'. Indeed, by (3.1) we have

$$C \geq \sup_{\varepsilon>0} \int_I \mathcal{F}^1_\varepsilon(u^y_\varepsilon, J)\,dy, \tag{3.2}$$

and so

$$|Z_\varepsilon| \leq |\{\mathcal{F}^1_\varepsilon(u^y_\varepsilon, J) > C/\delta'\}| \leq \frac{\delta'}{C}\int_I \mathcal{F}^1_\varepsilon(u^y_\varepsilon, J)\,dy \leq \delta',$$

and we have

$$\|u_\varepsilon - v_\varepsilon\|_1 \leq \int_{Z_\varepsilon \times J} |u_\varepsilon(x) - b|\, dx \leq \int_{Z_\varepsilon \times J} (|u_\varepsilon(x)| + |b|)\, dx \leq \delta$$

for every $\varepsilon > 0$, since $\mathcal{L}^2(Z_\varepsilon \times J) \leq \delta' |J|$. Hence the sequence $\{v_\varepsilon\}$ is δ-close to $\{u_\varepsilon\}$. Moreover, for every $y \in I$ there holds $\mathcal{F}^1_\varepsilon(v^y_\varepsilon, J) \leq C/\delta'$, where we have used the fact that $\mathcal{F}^1_\varepsilon(b, J) = 0$, and therefore Proposition 2.7 yields $L^1(J; \mathbb{R}^d)$ precompactness of $\{v^y_\varepsilon\}$. Similarly, we can construct a sequence $\{w_\varepsilon\}$ δ-close to $\{u_\varepsilon\}$ so that $\{w^z_\varepsilon\}$ is precompact in $L^1(I; \mathbb{R}^d)$ for every $z \in J$, and it suffices to now use Proposition 3.2 to conclude that the sequence $\{u_\varepsilon\}$ is precompact in $L^1(\Omega; \mathbb{R}^d)$.

The case where Ω is a general open subset of $\mathbb{R}^N$ is obtained by decomposing Ω into a countable union of closed rectangles with disjoint interiors.

The fact that the limit function u belongs to $BV(\Omega; \{a, b\})$ is showed in the proof of Proposition 3.5. □

THEOREM 3.4. *If $u \in L^1(\Omega; \mathbb{R}^d)$, then*

$$\Gamma(L^1) - \lim_{\varepsilon \to 0^+} \mathcal{F}_\varepsilon(u) = \begin{cases} \mathbf{m}\, \mathrm{Per}_\Omega(\{u = a\}) & \text{if } u \in BV(\Omega; \{a, b\}), \\ +\infty & \text{otherwise.} \end{cases}$$

We divide the proof of this theorem into two propositions concerning, respectively, the $\Gamma(L^1) - \liminf$ and the $\Gamma(L^1) - \limsup$. Although nowadays these arguments may be considered to be quite standard, and we refer the reader to [7, 16], and to [4] for the treatment of second derivatives in the study of the $\Gamma(L^1) - \limsup$; we included here the proofs of Proposition 3.5 and Proposition 3.6 for completeness and for the convenience of the reader.

PROPOSITION 3.5. *Let $u \in L^1(\Omega; \mathbb{R}^d)$. If $\Gamma(L^1) - \liminf_{\varepsilon \to 0^+} \mathcal{F}_\varepsilon(u) < +\infty$, then u belongs to $BV(\Omega; \{a, b\})$ and*

$$\Gamma(L^1) - \liminf_{\varepsilon \to 0^+} \mathcal{F}_\varepsilon(u) \geq \mathbf{m}\, \mathrm{Per}_\Omega(\{u = a\}).$$

Proof. Suppose that $\varepsilon_n \to 0^+$, $u_n \to u$ in $L^1(\Omega; \mathbb{R}^d)$ and $\mathcal{F}_{\varepsilon_n}(u_n)$ converges to $\Gamma(L^1) - \liminf_{\varepsilon \to 0^+} \mathcal{F}_\varepsilon(u) < +\infty$. Fixing an unit vector $\nu \in \mathbb{S}^{N-1}$, possibly passing to a subsequence (not relabelled), we may assume that $u_n|_{L_{y,\nu} \cap \Omega} \to u|_{L_{y,\nu} \cap \Omega}$ in $L^1(L_{y,\nu}, \mathcal{H}^1)$ for almost every line $L_{y,\nu}$ parallel to ν, where $L_{y,\nu} := \{y + s\nu : s \in \mathbb{R}\}$, $y \in \mathbb{R}^N$. By Proposition 2.8, and setting

$$u^{y,\nu}_n(t) := u_n(y + t\nu) \ \text{ for } \ \mathcal{H}^{N-1} \text{ a.e.}\, y \in \nu^\perp,$$

we have

$$\mathbf{m} \frac{|Du^{y,\nu}|(L_{y,\nu} \cap \Omega)}{|b - a|} \leq \liminf_{n \to \infty} \int_{L_{y,\nu} \cap \Omega} \left(\frac{W(u^{y,\nu}_n)}{\varepsilon_n} + \varepsilon^3_n \left| \frac{d^2 u^{y,\nu}_n}{dt^2} \right|^2 \right) dt.$$

Thus, by Fatou's lemma and the slicing properties of BV functions (see [19, section 5.10.2]),

$$\begin{aligned}
\mathbf{m}\,\mathrm{Per}_\Omega(\{u=a\}) &= \mathbf{m}\,\frac{|Du|(\Omega)}{|b-a|}\\
&= \frac{\mathbf{m}}{|b-a|}\int_{\{y\in\nu^\perp\}} |Du^{y,\nu}|(L_{y,\nu}\cap\Omega)\,d\mathcal{H}^{N-1}(y)\\
&\le \int_{\{y\in\nu^\perp\}} \liminf_{n\to\infty}\int_{L_{y,\nu}\cap\Omega}\left(\frac{W(u_n^{y,\nu})}{\varepsilon_n}+\varepsilon_n^3\left|\frac{d^2u_n^{y,\nu}}{dt^2}\right|^2\right)dt\,d\mathcal{H}^{N-1}\\
&\le \liminf_{n\to\infty}\int_{\{y\in\nu^\perp\}}\int_{L_{y,\nu}\cap\Omega}\left(\frac{W(u_n)}{\varepsilon_n}+\varepsilon_n^3|\nabla^2u_n|^2\right)dt\,d\mathcal{H}^{N-1}\\
&= \liminf_{n\to\infty}\int_\Omega\left(\frac{W(u_n)}{\varepsilon_n}+\varepsilon_n^3|\nabla^2u_n|^2\right)dx\\
&= \Gamma(L^1)-\liminf_{\varepsilon\to0^+}\mathcal{F}_\varepsilon(u). \qquad \square
\end{aligned}$$

Proposition 3.6. *For every function $u\in BV(\Omega;\{a,b\})$ we have*

$$\Gamma(L^1)-\limsup_{\varepsilon\to0^+}\mathcal{F}_\varepsilon(u)\le\mathbf{m}\,\mathrm{Per}_\Omega(\{u=a\}).$$

Proof. Let $u\in BV(\Omega;\{a,b\})$, with $u=a\chi_E+b(1-\chi_E)$, and where E is a set of finite perimeter, i.e., $\mathrm{Per}_\Omega(E)=|D\chi_E|(\Omega)<+\infty$. Since E can be approximated by a sequence of smooth sets $E_i=\widetilde{E}_i\cap\Omega$ such that $\widetilde{E}_i$ is a smooth bounded set in $\mathbb{R}^N$, $\chi_{E_i}\to\chi_E$ in $L^1(\Omega)$ and $|D\chi_{E_i}|(\Omega)\to|D\chi_E|(\Omega)$ (see Lemma 4.3 in [6]), in order to study the $\Gamma(L^1)-\limsup$ it suffices to consider a function $u:\Omega\to\mathbb{R}$ such that

$$u(x)=\begin{cases}a & \text{if } x\in E,\\ b & \text{if } x\in\Omega\setminus E,\end{cases}$$

where $E=\widetilde{E}\cap\Omega$ and $\widetilde{E}$ is a compact subset of $\mathbb{R}^N$ with a C^2 boundary. We claim that

$$\Gamma(L^1)-\limsup_{\varepsilon\to0^+}\mathcal{F}_\varepsilon(u)\le\mathbf{m}\,\mathrm{Per}_\Omega(\{u=a\}).$$

Since $M:=\partial\widetilde{E}$ is a C^2 manifold in $\mathbb{R}^N$, there exists $\delta_0>0$ such that for all $\delta<\delta_0$ the points in the tubular neighborhood U_δ of the manifold M admit a unique smooth projection onto M, where $U_\delta:=\{x\in\mathbb{R}^N:\ \mathrm{dist}(x,M)<\delta\}$.

Let $\varepsilon_n\to0^+$, and consider a sequence of functions $v_n\in W^{2,2}_{\mathrm{loc}}(\mathbb{R};\mathbb{R}^d)$ such that

$$v_n(t)=\begin{cases}a & \text{if } t\le-\frac{1}{\sqrt{\varepsilon_n}},\\ b & \text{if } t\ge\frac{1}{\sqrt{\varepsilon_n}},\end{cases}$$

and

$$\lim_{n\to\infty}\int_\mathbb{R}(W(v_n)+|v_n''|^2)\,dt=\mathbf{m}\,.$$

We define the sequence of functions $u_n:\Omega\to\mathbb{R}$

$$u_n(x):=\begin{cases}v_n(\frac{\widetilde{d}_M(x)}{\varepsilon_n}) & \text{if } x\in U_n\cap\Omega,\\ a & \text{if } x\in E\setminus U_n,\\ b & \text{if } x\in\Omega\setminus(E\cup U_n),\end{cases}$$

where $\widetilde{d}_M : \mathbb{R}^N \to \mathbb{R}$ is the signed distance function from the boundary of $\widetilde{E}$, negative inside $\widetilde{E}$, and $U_n := U_{\sqrt{\varepsilon_n}}$. We have

$$\begin{aligned}
&\limsup_{n\to\infty} \mathcal{F}_{\varepsilon_n}(u_n) = \limsup_{n\to\infty} \int_\Omega \left(\frac{W(u_n)}{\varepsilon_n} + \varepsilon_n^3 \left|\nabla^2 u_n\right|^2 \right) dx \\
&= \limsup_{n\to\infty} \left\{ \int_{U_n} \frac{W(v_n(\widetilde{d}_M(x)/\varepsilon_n))}{\varepsilon_n}\, dx + \int_{U_n} e_n^3 \left| v_n'' \nabla \widetilde{d}_M \times \nabla \widetilde{d}_M/\varepsilon_n^2 + v_n' H/\varepsilon_n \right|^2 dx \right\},
\end{aligned}$$

where H is the Hessian matrix of $\widetilde{d}_M$. Change variables via the diffeomorphism $x := F(y,t)$, where $F : M \times (-\delta_0/2, \delta_0/2) \to U_{\delta_0/2}$, $F(y,t) := y + t\nu(y)$, with $\nu(y)$ the normal vector to M at y pointing outside $\widetilde{E}$. We indicate by $J(y,t)$ the Jacobian of this transformation. Then

$$\begin{aligned}
\limsup_{n\to\infty} \mathcal{F}_{\varepsilon_n}(u_n) \le \liminf_{n\to\infty} \Bigg\{ \int_M \int_{-\sqrt{\varepsilon_n}}^{\sqrt{\varepsilon_n}} \Bigg(& \frac{W(v_n(t/\varepsilon_n))}{\varepsilon_n} \\
& + \varepsilon_n^3 \frac{\left|v_n''(t/\varepsilon_n)\right|^2}{\varepsilon_n^4} \left| \nabla \widetilde{d}_M(F(y,t)) \right|^2 \Bigg) J(y,t)\, dt\, d\mathcal{H}^{N-1}(y) \\
+ \int_M \int_{-\sqrt{\varepsilon_n}}^{\sqrt{\varepsilon_n}} \varepsilon_n^3 \frac{\left|v_n'(t/\varepsilon_n)\right|^2}{\varepsilon_n^2} & \left|H(F(y,t))\right|^2 J(y,t)\, dt\, d\mathcal{H}^{N-1}(y) \\
+ 2 \int_M \int_{-\sqrt{\varepsilon_n}}^{\sqrt{\varepsilon_n}} \varepsilon_n^3 \frac{|v_n''(t/\varepsilon_n)||v_n'(t/\varepsilon_n)|}{\varepsilon_n^3} & \left| \nabla \widetilde{d}_M(F(y,t)) \right| |H(F(y,t))| J(y,t) dt d\mathcal{H}^{N-1}(y) \Bigg\},
\end{aligned}$$

which reduces to

$$\begin{aligned}
&\limsup_{n\to\infty} \mathcal{F}_{\varepsilon_n}(u_n) \\
&\le \limsup_{n\to\infty} \Bigg\{ \int_M \int_{-\sqrt{\varepsilon_n}}^{\sqrt{\varepsilon_n}} \left(\frac{W(v_n(t/\varepsilon_n))}{\varepsilon_n} + \frac{\left|v_n''(t/\varepsilon_n)\right|^2}{\varepsilon_n} \right) J(y,t)\, dt\, d\mathcal{H}^{N-1}(y) \\
&\quad + A \int_M \int_{-\sqrt{\varepsilon_n}}^{\sqrt{\varepsilon_n}} \varepsilon_n \left|v_n'(t/\varepsilon_n)\right|^2 dt\, d\mathcal{H}^{N-1}(y) \\
&\quad + B \int_M \int_{-\sqrt{\varepsilon_n}}^{\sqrt{\varepsilon_n}} |v_n''(t/\varepsilon_n)|\, |v_n'(t/\varepsilon_n)|\, dt\, d\mathcal{H}^{N-1}(y) \Bigg\} \\
&=: \limsup_{n\to\infty} \left\{ I_1^{(n)}(u) + I_2^{(n)}(u) + I_3^{(n)}(u) \right\},
\end{aligned}$$

where we took into account the facts that the gradient of the distance is always equal to one, and that the Jacobian J and the Hessian H of the distance are uniformly bounded. We have

$$\begin{aligned}
I_1^{(n)}(u) &= \int_M \int_{-\sqrt{\varepsilon_n}}^{\sqrt{\varepsilon_n}} \left(\frac{W(v_n(t/\varepsilon_n))}{\varepsilon_n} + \frac{\left|v_n''(t/\varepsilon_n)\right|^2}{\varepsilon_n} \right) J(y,t)\, dt\, d\mathcal{H}^{N-1}(y) \\
&= \int_M \int_{-1/\sqrt{\varepsilon_n}}^{1/\sqrt{\varepsilon_n}} \left(W(v_n(s)) + \left|v_n''(s)\right|^2 \right) J(y, s\varepsilon_n)\, ds\, d\mathcal{H}^{N-1}(y) \\
&\le \left(\sup_{y\in M,\, t\in(-\sqrt{\varepsilon_n}, \sqrt{\varepsilon_n})} J(y,t) \right) \int_M \int_{\mathbb{R}} \left(W(v_n(s)) + \left|v_n''(s)\right|^2 \right) ds\, d\mathcal{H}^{N-1}(y)\,,
\end{aligned}$$

and passing to the limit in n as $n \to \infty$, we get

$$\begin{aligned}\limsup_{n\to\infty} I_1^{(n)} &\leq \left(\sup_{y\in M,\, t\in(-\sqrt{\varepsilon_n},\sqrt{\varepsilon_n})} J(y,t)\right) \mathbf{m}\,\mathcal{H}^{N-1}(M)\\ &= \left(\sup_{y\in M,\, t\in(-\sqrt{\varepsilon_n},\sqrt{e_n})} J(y,t)\right) \mathbf{m}\ \mathrm{Per}_\Omega(\{u=a\}).\end{aligned}$$

If we show that the other two integrals $I_2^{(n)}(u)$ and $I_3^{(n)}(u)$ go to zero as $n \to \infty$, then we obtain that

$$\begin{aligned}\Gamma(L^1) - \limsup_{\varepsilon\to 0^+} \mathcal{F}_\varepsilon(u) &\leq \limsup_{n\to\infty} \left(\sup_{y\in M,\, t\in(-\sqrt{\varepsilon_n},\sqrt{\varepsilon_n})} J(y,t)\right) \mathbf{m}\ \mathrm{Per}_\Omega(\{u=a\})\\ &= \mathbf{m}\ \mathrm{Per}_\Omega(\{u=a\}),\end{aligned}$$

where we used the fact that $\{\varepsilon_n\}$ is an arbitrary sequence converging to zero, and that since M is compact, $J(y,t)$ goes uniformly to one as $t \to 0$.

Finally,

$$\begin{aligned}I_2^{(n)} + I_3^{(n)} &\leq C \int_{-\sqrt{\varepsilon_n}}^{\sqrt{\varepsilon_n}} \left(\varepsilon_n |v_n'(t/\varepsilon_n)|^2 + |v_n''(t/\varepsilon_n)|\,|v_n'(t/\varepsilon_n)|\right) dt\\ &= C \int_{\mathbb{R}} \left(\varepsilon_n^2 |v_n'(s)|^2 + \varepsilon_n |v_n''(s)|\,|v_n'(s)|\right) ds\\ &\leq C\, \left(\varepsilon_n^2 \|v_n'\|_2^2 + \varepsilon_n \|v_n''\|_2\, \|v_n'\|_2\right)\\ &\leq C\, \left(\varepsilon_n^2 \|v_n'\|_2^2 + \varepsilon_n\, \|v_n'\|_2\right), \qquad (3.3)\end{aligned}$$

where we changed variables, used Hölder inequality and the fact that

$$\|v_n''\|_{L^2}^2 \leq \int_{\mathbb{R}} (W(v_n) + |v_n''|^2)\, dt \to \mathbf{m}\,.$$

Set $w_n(t) := v_n\,(t/\varepsilon_n)$. Then

$$\begin{aligned}&\limsup_{n\to\infty} \int_{-1}^{1} \left(\frac{1}{\varepsilon_n} W(w_n) + \varepsilon_n^3 |w_n''|^2\right) dt\\ &\qquad = \limsup_{n\to\infty} \int_{-\sqrt{\varepsilon_n}}^{\sqrt{\varepsilon_n}} \left(\frac{1}{\varepsilon_n} W(w_n) + \varepsilon_n^3 |w_n''|^2\right) dt\\ &\qquad = \lim_{n\to\infty} \int_{\mathbb{R}} (W(v_n) + |v_n''|^2)\, dt,\end{aligned}$$

and therefore by Proposition 2.7 and (2.7)

$$||w_n'||_{L^{4/3}(-1,1)} \leq C\varepsilon_n^{-3/4},$$

where the constant C is independent of n. Also, Hölder inequality yields

$$\begin{aligned}||w_n''||_{L^{4/3}(-1,1)} &= ||w_n''||_{L^{4/3}(-\sqrt{\varepsilon_n},\sqrt{\varepsilon_n})}\\ &\leq C||w_n''||_{L^2(-1,1)}\ \varepsilon_n^{1/6}\\ &\leq C\,\varepsilon_n^{-3/2}\ \varepsilon_n^{1/6}.\end{aligned}$$

Therefore, by the Sobolev embedding theorem

$$||w_n'||_{L^2(-1,1)} \leq C||w_n'||_{W^{1,4/3}(-1,1)} \leq C(\varepsilon_n^{-3/4} + \varepsilon_n^{-3/2}\,\varepsilon_n^{1/6}),$$

and in view of (3.3), we conclude that

$$\begin{aligned}\varepsilon_n^2 \int_R |v_n'|^2\,dt &= \varepsilon_n^3 \int_{\sqrt{\varepsilon_n}}^{\sqrt{\varepsilon_n}} |w_n'|^2\,dt \\ &\leq C\,\varepsilon_n^3\,(\varepsilon_n^{-3/4} + \varepsilon_n^{-3/2}\,\varepsilon_n^{1/6})^2 \\ &\leq C\,(\varepsilon_n^{3/2} + \varepsilon_n^{1/3}),\end{aligned}$$

and it suffices to let $n \to \infty$. □

4. Final remarks. As in the singular perturbation model for phase transitions (see [25]), the interfacial energy appears due to the need to go across an energy barrier in order to remain on the zero set of W. Indeed, if the zero set of W is a smooth, connected set, then the $\Gamma(L^1)$-limit may simply reduce to zero. As an example, consider the case where $\{W = 0\} = \mathbb{S}^{d-1}$. Then

$$\Gamma(L^1) - \lim_{\varepsilon \to 0^+} \mathcal{F}_\varepsilon(u) = \begin{cases} 0 & \text{if } u \in L^1(\Omega; \mathbb{S}^{d-1}), \\ +\infty & \text{otherwise.} \end{cases}$$

To prove this assertion, fix $u \in L^1(\Omega; \mathbb{S}^{d-1})$ and let $\{u_n\}$ be a sequence of smooth functions with compact support, converging to u in $L^1(\Omega; \mathbb{S}^{d-1})$. The existence of such an approximating sequence can be obtained as follows: there exists a point $y \in \mathbb{S}^{d-1}$ such that $u^{-1}(y)$ has zero Lebesgue measure; therefore we may assume with no loss of generality that u does not take such value y. The manifold $\mathbb{S}^{d-1} \setminus \{y\}$ is diffeomorphic to the open unit ball B of $\mathbb{R}^{d-1}$ via some smooth map Φ; hence it is sufficient to approximate the function $\Phi(u)$ in $L^1(\Omega; B)$ with a sequence of smooth functions $\{v_n\}$ with compact support and then to consider the sequence $u_n := \Phi^{-1}(v_n)$.

If now we choose a positive sequence $\varepsilon_n \to 0^+$ such that

$$\int_\Omega \varepsilon_n^3 |\nabla^2 u_n|^2\,dx \leq \frac{1}{n} \qquad \text{for every } n \in \mathbb{N},$$

we get

$$\Gamma(L^1) - \lim_{\varepsilon \to 0^+} \mathcal{F}_\varepsilon(u) \leq \liminf_{n \to \infty} \int_\Omega \left(\frac{W(u_n)}{\varepsilon_n} + \varepsilon_n^3 |\nabla^2 u_n|^2 \right) dx \leq \lim_{n \to \infty} \frac{1}{n} = 0,$$

and this proves the claim.

Finally, we remark that if we could prove that for energy bounded sequences $\{u_\varepsilon\}$, with

$$\sup_{\varepsilon > 0} \int_\Omega \left(\frac{W(u_\varepsilon)}{\varepsilon} + \varepsilon^3 |\nabla^2 u_\varepsilon|^2 \right) dx < +\infty,$$

it follows that

$$\sup_{\varepsilon > 0} \int_\Omega \varepsilon |\nabla u|^2\,dx < +\infty;$$

then most proofs would be greatly simplified, and, in particular, the compactness in L^1 (see Propositions 2.7, 3.1) would follow immediately from the compactness for the singular perturbations model studied in [10, 12, 13, 22, 25, 28, 29, 32, 33].

Acknowledgments. The authors are indebted to Luc Tartar for many enlightening discussions on this problem, and for his continuous interest and advice as the work progressed. Also, the authors would like to thank Luigi Ambrosio and Frédéric Hélein for several interesting and stimulating discussions on the subject of this paper, and Giovanni Alberti for having suggested the use of Proposition 3.2 to obtain compactness of energy bounded sequences in the vectorial case (see Proposition 3.1).

VANISHING SHEAR VISCOSITY IN THE EQUATIONS OF COMPRESSIBLE FLUIDS FOR THE FLOWS WITH THE CYLINDER SYMMETRY[*]

HERMANO FRID[†] AND VLADIMIR SHELUKHIN[‡]

Abstract. We analyze the question of the limit process when the shear viscosity goes to zero for global solutions to the Navier–Stokes equations for compressible heat conductive fluids for the flows which are invariant over cylindrical sheets.

Key words. Navier–Stokes equations, compressible fluids, vanishing shear viscosity

1. Introduction.

We study the limit of global solutions to the Navier–Stokes equations of compressible heat conductive fluids as the shear viscosity μ tends to zero. The problem of small viscosity finds many applications, for example, in the boundary layer theory [11]. We restrict ourselves to the flows between two circular coaxial cylinders and assume that the corresponding solutions depend only on the radial variable x, $\Omega = \{x : 0 < a < x < b\}$ and the time variable $t \in (0,T)$. The reduced system of the three-dimensional equations is now of the form [6]

$$\rho_t + (\rho u)_x + \frac{\rho u}{x} = 0, \tag{1.1}$$

$$\rho\left(u_t + uu_x - \frac{v^2}{x}\right) + p_x - (\lambda + 2\mu)\left(u_x + \frac{u}{x}\right)_x = 0, \qquad p = \gamma\rho\theta, \tag{1.2}$$

$$\rho\left(v_t + uv_x + \frac{uv}{x}\right) - \mu\left(v_x + \frac{v}{x}\right)_x = 0, \tag{1.3}$$

$$\rho(w_t + uw_x) - \mu\left(w_{xx} + \frac{w_x}{x}\right) = 0, \tag{1.4}$$

$$c_v\rho(\theta_t + u\theta_x) - \kappa\left(\theta_{xx} + \frac{\theta_x}{x}\right) + p\left(u_x + \frac{u}{x}\right) - \mathcal{Q} = 0, \tag{1.5}$$

$$\mathcal{Q} = \lambda\left(u_x + \frac{u}{x}\right)^2 + \mu\left\{\left(v_x - \frac{v}{x}\right)^2 + w_x^2 + 2u_x^2 + 2\left(\frac{u}{x}\right)^2\right\}. \tag{1.6}$$

Here ρ is the mass density, p is the pressure, θ is the temperature. The velocity vector $\mathbf{v} = (u, v, w)$ is given by the radial, angular, and axial velocities, respectively. We consider fluids obeying the equation of state for a polytropic fluid $p = \gamma\rho\theta$ and the Duhem inequalities $\mu \geq 0$ and $3\lambda + 2\mu \geq 0$ ($\nu = \lambda + 2\mu$) [7]. The constants $\gamma, c_v, \kappa, \lambda$, and μ are considered positive. We put $c_v = 1$; this can always be achieved by a suitable choice of units.

In the domain $Q = (0, T) \times \Omega$, we consider the initial boundary value problem given by (1.1)–(1.6) and

$$\mathbf{v} = 0, \qquad \theta_x = 0 \quad \text{at} \quad \partial\Omega, \tag{1.7}$$

$$(\rho, \mathbf{v}, \theta)|_{t=0} = (\rho_0(x), \mathbf{v}_0(x), \theta_0(x)). \tag{1.8}$$

The results that follow are valid also if the velocity vector satisfies nonhomogeneous boundary conditions corresponding to the symmetry-conserving motions of the bounding cylinders. We discuss the homogeneous case only to simplify the presentation.

Our goal is both to establish the existence and uniqueness of strong global solutions to problem (1.6)–(1.8) and to justify the passage to limit as the shear viscosity goes to zero. In particular, we prove that solutions converge in $L^2(Q)$, as $\mu \downarrow 0$, to a weak solution of (1.1)–(1.6) with $\mu = 0$. The last result can be treated as a new one in the mathematical theory of compressible fluids with $\mu = 0$ and $\lambda > 0$ [10, 12, 13].

Existence theorems for the solutions with the axial symmetry were obtained only for radial flows with $v = w = 0$ [8]. The shear viscosity limit problem was studied earlier for the flows between two parallel plates [4, 14, 15]. Notice that in the case of cylinder symmetry the velocity components influence each other not only through the energy equation but also through the momentum equations. This is the main difference between the system considered in [15] and system (1.1)–(1.6).

It should be emphasized that in sending μ to zero we keep λ fixed and positive at the same time. It enables us to control the derivatives of u to some extent but not of v and w. There are several interesting mathematical issues here. We mention two of them. The first is the strong convergence of v as $\mu \downarrow 0$. One should prove it in order to justify the passage to limit in (1.2). The bounds $\|v\|_{L^\infty(Q)} \leq c$ and $\|\mu x v_x^2\|_{L^1(Q)} \leq c$, which are shown to be uniform in μ, enable us to conclude that $v \to \overline{v}$ weakly-star in $L^\infty(Q)$ and $\mu x v_x^2 \to \chi$ weakly in $\mathcal{M}(Q)$, the space of signed Radon measures on Q, for some function $\overline{v} \in L^\infty(Q)$ and a nonnegative measure χ. Here and in what follows we use the superposed bar to denote a weak limit. Without any new bound for the derivatives of v at hand, we prove the strong convergence $v \to \overline{v}$ in $L^k(Q)$ for any $k \in [1, \infty)$ and the equality $\chi = 0$. The key idea is to verify that the limit equation

$$(x\bar{\rho}\overline{v})_t + (x\bar{\rho}\bar{u}\overline{v})_x + \bar{\rho}\bar{u}\overline{v} = 0 \quad \text{in} \quad D^{'}(Q) \tag{1.9}$$

for the weak limits $\bar{u}$, $\bar{v}$, and $\bar{\rho}$, as $\mu \downarrow 0$, is inherited with the equation

$$(x\bar{\rho}\overline{v}^2)_t + (x\bar{\rho}\bar{u}\overline{v}^2)_x + 2\bar{\rho}\bar{u}\overline{v}^2 = 0 \quad \text{in} \quad D^{'}(Q), \tag{1.10}$$

which can be derived formally from (1.9) by multiplying by $\bar{v}$ and accounting for the limit equation $(x\bar{\rho})_t + (x\bar{\rho}\bar{u})_x = 0$, in $D^{'}(Q)$. To check (1.10), we use the Lagrangian variables associated with the limit flow; this makes our approach different from that of the DiPerna and Lions [2] developed for the linear transport equation. On the other hand, it follows from (1.3) in the limit that

$$(x\bar{\rho}\overline{v^2})_t + (x\bar{\rho}\bar{u}\overline{v^2})_x + 2\bar{\rho}\bar{u}\overline{v^2} + 2\chi = 0 \quad \text{in} \quad D^{'}(Q). \tag{1.11}$$

The comparison of (1.10) and (1.11) results in the equalities $\chi = 0$ and $\overline{v^2} = \bar{v}^2$. The last implies the strong convergence $v \to \overline{v}$ at least in $L^2(Q)$.

The above idea of improvement of the weak convergence $v \to \overline{v}$ to strong goes back to the notion of renormalization introduced into PDE by DiPerna and Lions [2] and developed in [3, 4, 7, 15, 17].

One more mathematical issue is related to the convergence of the dissipation $\mathcal{Q}$ and the rate of pressure work $-p(u_x + \frac{u}{x})$, as $\mu \downarrow 0$. Both these functions are bounded in $L^1(Q)$ uniformly in μ, but we do not obtain any more bound for them. We also do not prove that u_x converges strongly. This is why the passage to limit in the energy equation is not simple. Here the key idea is to study their sum $J \equiv \mathcal{Q} - p(u_x + \frac{u}{x})$, which admits the representation $J = F(u_x + \frac{u}{x}) + J_1$, where

$$(1.12)\; F = -p + (\lambda + 2\mu)\left(u_x + \frac{u}{x}\right), \qquad J_1 = \mu\left(v_x + \frac{v}{x}\right)^2 + \mu w_x^2 - \frac{2\mu}{x}(u^2+v^2)_x.$$

The function F was introduced by Hoff [3] and he called it the *effective viscous flux* since it can be rewritten in an invariant form as $-p + (\lambda + 2\mu)\mathrm{div}\mathbf{v}$. Hoff showed that the variable F is smoother than either of its summands. The effective viscous flux helps here also. We manage to prove that $\overline{J_1} = 0$ and $\overline{F(u_x + u/x)} = F_0(\bar{u}_x + \bar{u}/x)$, where $F_0 = -\gamma\bar{\rho}\bar{\theta} + \lambda(\bar{u}_x + \bar{u}/x)$ is the effective viscous flux of the limit flow. For that we again exploit the technique exposed above.

Let us formulate the main results. Assume that the initial data verify the conditions

$$(1.13)\quad \mathbf{v}_0 \in W_0^{1,2}(\Omega); \quad \rho_0, \theta_0 \in W^{1,2}(\Omega); \quad \|\rho_0^{-1}, \theta_0^{-1}\|_{C(\overline{\Omega})} < \infty; \quad \rho_0 > 0, \theta_0 > 0.$$

From here on we use the notation $\|a, b, \dots\|^2 = \|a\|^2 + \|b\|^2 + \cdots$ for functions $a, b, \dots$ belonging to a functional space equipped with a norm $\|\cdot\|$. For later use we denote by $\|f\|$, $\|f\|_{p,\Omega}$, $\|f\|_{p,Q}$, and $\|f\|_{p,q}$ the norms in $L^2(\Omega)$, $L^p(\Omega)$, $L^p(Q)$, and $L^q(0,T; L^p(\Omega))$, respectively.

THEOREM 1.1. *Under the assumption* (1.13) *there is a unique solution of problem* (1.1)–(1.8) *such that*

$$\mathbf{v}, \theta \in L^\infty(0,T; W^{1,2}(\Omega)) \cap L^2(0,T; W^{2,2}(\Omega)),$$

$$\rho \in L^\infty(0,T; W^{1,2}(\Omega)); \quad \mathbf{v}_t, \theta_t, \rho_t \in L^2(Q), \qquad \rho > 0, \theta > 0.$$

THEOREM 1.2. *There is a sequence $\mu_n \downarrow 0$ such that the corresponding solutions $(\rho, \mathbf{v}, \theta)$ of problem* (1.1)–(1.8) *with $\mu = \mu_n$ converge as follows:*

$$u \xrightarrow{L^s(Q)} \overline{u}; \quad \theta \xrightarrow{L^r(Q)} \overline{\theta}; \quad \rho, v, w \xrightarrow{L^p(Q)} \overline{\rho}, \overline{v}, \overline{w}$$

for any $s \in [1,6)$, $r \in [1,2)$, and $p \in [1,\infty)$. In addition, $\overline{u} \in L^2(0,T; W_0^{1,2}(\Omega))$, $\overline{\theta}_x \in L^q(Q)$, $\overline{\rho} \in BV(Q)$, and the weak convergences

$$u \overset{L^2(0,T;W_0^{1,2}(\Omega))}{\rightharpoonup} \overline{u}, \qquad \theta_x \overset{L^q(Q)}{\rightharpoonup} \overline{\theta_x}, \qquad \nabla_{x,t}\rho \overset{\mathcal{M}(Q)}{\rightharpoonup} \nabla_{x,t}\overline{\rho}$$

hold where $\mathcal{M}(Q)$ is the set of the Radon measures on Q and $q \in [1, 3/2)$. The limit functions solve (1.1)–(1.8) *with $\mu = 0$ in the following sense:*

$$(1.14)\qquad \int_Q \overline{\rho}(\varphi_t + \overline{u}\varphi_x)x\,dx\,dt + \int_\Omega \rho_0\varphi(0,x)\,x\,dx = 0,$$

$$\int_Q \left(\overline{\rho}\overline{u}\psi_t + (\overline{\rho}\overline{u}^2 + \gamma\overline{\rho}\overline{\theta} - \lambda\overline{u}_x - \lambda\frac{\overline{u}}{x})\psi_x\right) x\,dx\,dt \tag{1.15}$$

$$+\int_Q \left(\overline{\rho}(\overline{v}^2 - \overline{u}^2) + \gamma\overline{\rho}\overline{\theta} - \lambda\overline{u}_x - \lambda\frac{\overline{u}}{x}\right)\psi\,dx\,dt + \int_\Omega \rho_0 u_0 \psi(0,x)x\,dx = 0,$$

$$\int_Q \overline{\rho}\overline{v}\Big(\psi_t + \overline{u}\psi_x - \frac{\overline{u}}{x}\psi\Big)x\,dx\,dt + \int_\Omega \rho_0 v_0 \psi(0,x)x\,dx = 0, \tag{1.16}$$

$$\int_Q \overline{\rho}\overline{w}(\psi_t + \overline{u}\psi_x)xdxdt + \int_\Omega \rho_0 w_0 \psi(0,x)x\,dx = 0, \tag{1.17}$$

$$\int_Q \left(\overline{\rho}\overline{\theta}\varphi_t + (\overline{\rho}\overline{\theta}\overline{u} - \kappa\overline{\theta}_x)\varphi_x + \Big(-\gamma\overline{\rho}\overline{\theta}\Big(\overline{u}_x + \frac{\overline{u}}{x}\Big) + \lambda\Big(\overline{u}_x + \frac{\overline{u}}{x}\Big)^2\Big)\varphi\right) x\,dx\,dt \tag{1.18}$$

$$+\int_\Omega \rho_0\theta_0\varphi(0,x)x\,dx = 0.$$

Here, φ and ψ are test functions such that φ, $\psi \in C^1(\overline{Q})$, $\varphi(T,x) = \psi(T,x) = 0$ for any $x \in \Omega$ and $\psi \in W_0^{1,2}(\Omega)$ for any $t \in (0,T)$.

We will sometimes employ the notation $f_r = f_x + f/x$. Observe that the operator $f \to f_r$ has the properties

$$(gh)_r = g_r h + g h_x, \qquad g_{rx} = g_{xr} - \frac{g}{x^2}, \tag{1.19}$$

$$g'(\beta)((\rho\beta)_t + (\rho u\beta)_r) = (\rho g(\beta))_t + (\rho u g(\beta))_r = 0, \tag{1.20}$$

$$\int_\Omega \varphi\psi_r x\,dx = -\int_\Omega \psi\varphi_x x\,dx, \qquad \int_\Omega x\xi_r\,dx = b\xi(b) - a\xi(a) \tag{1.21}$$

for any functions $\beta \in C^1(\overline{Q})$, $g \in C^1(\mathbb{R})$, $\varphi \in D(\Omega)$, $\psi \in D(\Omega)$, and $\xi \in D(\mathbb{R})$.

With this notation, the system (1.1)–(1.8) becomes

$$\rho_t + (\rho u)_r = 0, \tag{1.22}$$

$$(\rho u)_t + (\rho u^2)_r - \frac{\rho v^2}{x} + p_x - \nu u_{rx} = 0, \qquad p = \gamma\rho\theta, \tag{1.23}$$

$$(\rho v)_t + (\rho u v)_r + \frac{\rho u v}{x} - \mu v_{rx} = 0, \tag{1.24}$$

$$(\rho w)_t + (\rho u w)_r - \mu w_{xr} = 0, \tag{1.25}$$

$$(\rho\theta)_t + (\rho u\theta)_r - \kappa\theta_{xr} + p u_r - \mathcal{Q} = 0, \tag{1.26}$$

$$\mathcal{Q} = \nu u_r^2 + \mu v_r^2 + \mu w_x^2 - \frac{2\mu}{x}(u^2 + v^2)_x. \tag{1.27}$$

2. A priori estimates independent of $\boldsymbol{\mu}$. First of all, it follows from (1.22) that

$$\frac{d}{dt}\int_\Omega \rho x\,dx = 0. \tag{2.1}$$

This is our first a priori estimate since we look for solutions such that $\rho > 0$ and $\theta > 0$. Next, by (1.22)–(1.27), (1.19), and (1.20), we may write the equation for the total energy $e = \mathbf{v}^2/2 + \theta$ in the form

$$(\rho e)_t + (\rho u e)_r = \nu(uu_r)_r + \mu(vv_r)_r + \mu(ww_x)_r + \kappa\theta_{xr} - (pu)_r - \frac{2\mu}{x}(u^2+v^2)_x. \tag{2.2}$$

Hence,

$$\frac{d}{dt}\int_\Omega \rho e x\,dx = 0, \tag{2.3}$$

and this is our second estimate.

Another consequence of system (1.22)–(1.27) is the equation

$$\left(\rho\psi(\theta) + \gamma\rho\psi\left(\frac{1}{\rho}\right) + \rho\frac{\mathbf{v}^2}{2}\right)_t + \left(\rho u\left(\frac{\mathbf{v}^2}{2} + \psi(\theta) + \gamma(1+\ln\rho)\right)\right)_r$$

$$= \nu(uu_r)_r + \mu(vv_r)_r + \mu(ww_x)_r - p_x u + \psi^{'}(\theta)(\mathcal{Q} + \kappa\theta_{xr}) - pu_r,$$

where $\psi(s) = s - \ln s - 1$.

Again, we integrate with respect to the measure xdx to obtain

$$\frac{d}{dt}\int_\Omega \rho\left(\psi(\theta) + \gamma\psi\left(\frac{1}{\rho}\right) + \frac{\mathbf{v}^2}{2}\right)x\,dx + \int_\Omega\left(\kappa\frac{\theta_x^2}{\theta^2} + \frac{\mathcal{Q}}{\theta}\right)x\,dx = 0. \tag{2.4}$$

This is the third estimate since $\mathcal{Q} \geq 0$.

Lemma 2.1. *There is a constant c such that $\|\rho\|_{\infty,Q} \leq c$.*

Proof. First we note that this lemma provides the key estimate in the whole development, and the proof goes back to the early paper of Kazhikhov and Shelukhin [5] where considerations were made in the Lagrangian variables.

We write (1.23) in the form

$$(\rho u)_t + \left(\rho u^2 + p - \nu u_r + \int_a^x \frac{\rho}{y}(u^2 - v^2)dy\right)_x = 0.$$

Hence, the function

$$\varphi(t,x) = \int_0^t\left(\nu u_r - \rho u^2 - p - \int_a^x \frac{\rho}{y}(u^2 - v^2)dy\right)dt + \int_a^x \rho_0 u_0 dy$$

satisfies the equalities

$$\varphi_x = \rho u, \quad \varphi_t = \nu u_r - \rho u^2 - p - \int_a^x \frac{\rho}{y}(u^2 - v^2)dy. \tag{2.5}$$

Observe that $\|x\varphi_x\|_1^2 \leq \|x\rho\|_1\|x\rho u^2\|_1$ and the integral $\int_\Omega \varphi x\,dx$ equal to

$$\int_0^t \int_\Omega \left(-\rho u^2 - p - \int_a^x \frac{\rho}{y}(u^2 - v^2)\,dy\right) xdxdt + \int_\Omega x \int_a^x \rho_0 u_0\,dy\,dx$$

is uniformly bounded in $L^\infty(0,T)$ by (2.4). Thus, $\|\varphi\|_{\infty,Q} \leq c$.

Given a function $F(\varphi)$, we compute the material derivative $D_t(\rho F) \equiv (\frac{\partial}{\partial t} + u\frac{\partial}{\partial x})\rho F$. Using (2.5), we have

$$D_t(\rho F) = -\rho F u_r + \rho F' \left(\nu u_r - p - \int_a^x \frac{\rho}{y}(u^2 - v^2)\,dy\right).$$

The choice $F(\varphi) = \exp\frac{\varphi}{\nu}$ results in

$$D_t(\rho F) \leq \rho F \left|\frac{1}{\nu}\int_a^x \frac{\rho}{y}(u^2 - v^2)dy\right| \leq c\rho F.$$

Thus, the lemma is proved.

Lemma 2.2. *There is a constant c such that $\rho \geq c > 0$ and $\|\theta\|_{\infty,1} \leq c$.*

Proof. By (2.5) and with $G = \exp(-\frac{\varphi}{\nu})$, we compute

$$D_t\frac{G}{\rho} = \gamma G\theta + \frac{G}{\nu\rho}\int_a^x \frac{\rho}{y}(u^2 - v^2)dy \leq c\left(\frac{G}{\rho} + \|\theta\|_\infty\right).$$

Hence,

$$\|\frac{1}{\rho}\|_\infty \leq c\left(1 + \int_0^t \|\theta(s)\|_\infty ds\right). \tag{2.6}$$

Now, by the inequality

$$\theta^{\frac{1}{2}}(t,x) - \theta^{\frac{1}{2}}(t,y) \leq \frac{1}{2}\left\|\frac{\theta_x}{\theta}\right\|\|\rho\theta\|_1^{\frac{1}{2}}\left\|\frac{1}{\rho}\right\|_\infty^{\frac{1}{2}},$$

we conclude that

$$\|\theta\|_\infty \leq 2\|x\rho\theta\|_1 + \frac{1}{2a^2}\left\|\frac{\sqrt{x}\theta_x}{\theta}\right\|^2\|x\rho\theta\|_1\left\|\frac{1}{\rho}\right\|_\infty. \tag{2.7}$$

Combining inequalities (2.6) and (2.7), we obtain the validity of the lemma.

Lemma 2.3. *There is a constant c such that $\theta \geq c > 0$.*

Proof. We multiply (1.26) by $-z$, $z = 1/\theta$ to get $\rho D_t z \leq \kappa z_{xr} + \frac{\gamma^2\rho^2}{4\lambda}$. Consequently,

$$(\rho z^N)_t + (\rho u z^N)_r \leq \kappa z^N_{xr} + NA(t)z^N,$$

where $N \in \mathbb{N}$ and the function $A(t)$ is bounded in $L^1(0,T)$ and does not depend on N. Now we integrate the last inequality to arrive at $\|x\rho z^N\|_1 \leq \exp(Nc)\,\|x\rho_0 z_0^N\|_1$. Here, the constant c does not depend on N. Hence, the assertion of the lemma follows.

Lemma 2.4. *There is a constant c such that*

$$\|u_x, \sqrt{\mu}v_x, \sqrt{\mu}w_x\|_{2,Q} \leq c, \quad \|u\|_{\infty,2} \leq c, \quad \|uu_x\|_{3/2,Q} + \|u\|_{6,Q} + \|u\|_{\infty,4} \leq c.$$

Proof. Integrating (1.26), we obtain

$$\int_Q (\nu u_r^2 + \mu v_r^2 + \mu w_x^2) x \, dx \, dt \le \frac{\lambda}{2} \int_Q u_r^2 x \, dx \, dt + \frac{\gamma^2}{2\lambda} \int_Q \rho^2 \theta^2 x \, dx \, dt + c.$$

On the other hand,

$$\|\theta\|_{2,Q} \le \|\theta\|_{1,\infty} \|\theta\|_{\infty,1}. \tag{2.8}$$

Hence, the first estimate of the lemma is proved. The second one is now a consequence since u is bounded in $L^\infty(0,T;L^2(\Omega))$. The third estimate follows due to the inequalities $\|uu_x\|_{3/2,Q} \le \|u_x\|_{2,Q}\|u\|_{6,Q}$ and

$$\|u\|_{6,Q}^6 \le \|u\|_{2,\infty}^2 \|u\|_{\infty,4}^4, \quad \|u\|_{\infty,4}^2 \le 2\|u\|_{2,\infty}\|u_x\|_{2,Q}.$$

Lemma 2.5. *There is a constant c such that $\|v,w\|_{\infty,Q} \le c$.*

Proof. Multiplication of (1.22) by $2Nw^{2N-1}$ results in the inequality

$$(\rho w^{2N})_t + (\rho u w^{2N})_r \le \mu (w^{2N})_{xr}.$$

Hence, $\|x\rho w^{2N}\|_1 \le \|x\rho_0 w_0^{2N}\|_1$. Now, we raise to the power $\frac{1}{2N}$ and let $N \to \infty$ to see that $\|w\|_\infty \le \|w_0\|_\infty$.

Similarly,

$$\int_\Omega \rho v^{2N} x dx \le \int_\Omega \rho_0 v_0^{2N} x dx - 2N \int_0^t \int_\Omega \rho u v^{2N} dx ds.$$

By the Gronwall lemma, $\|\rho v^{2N} x\|_1 \le c \exp\left(cN \int_0^t \|u\|_\infty ds\right)$. Since the constant c does not depend on N, the estimate $|v| \le c$ follows.

Lemma 2.6. *There is a constant c such that $\|\rho_x\|_{1,\infty} \le c$ and $\|\rho_t\|_{1,Q} \le c$.*

Proof. We set $\beta = u - \nu(1/\rho)_x$ and find, by (1.22) and (1.23), that

$$(\rho\beta)_t + (\rho u \beta)_x + \frac{\rho}{x}(u^2 - v^2) = -p_x.$$

Multiplying this equality by sgnβ, we deduce

$$(\rho|\beta|)_t + (\rho u|\beta|)_x \le c(1 + \theta|\beta| + \theta|u| + u^2 + v^2 + |\theta_x|).$$

On the other hand, due to (2.4) and (2.8),

$$\|\theta_x\|_{1,Q} \le c. \tag{2.9}$$

Hence, $\|\rho\beta\|_1 \le c$ uniformly in time. Now the first conclusion of the lemma follows directly and the second one holds due to (1.22).

Lemma 2.7. *Given a number $q \in [1, 3/2)$, there is a constant c such that $\|\theta_x\|_{q,Q} \le c$.*

Proof. By above estimates, we may treat (1.26) as a linear parabolic one

$$\rho(\theta_t + u\theta_x) = \kappa\Big(\theta_{xx} + \frac{\theta_x}{x} + f\Big),$$

where the function $f(t,x)$ is bounded in $L^1(Q)$ uniformly in μ. Given a function $F(s) \in C^1(\mathbb{R})$, we have

$$\frac{d}{dt}\int_\Omega \rho F(\theta) x \, dx + \kappa \int_\Omega \theta_x^2 F^{''}(\theta) x \, dx = \int_\Omega f F^{'}(\theta) x \, dx.$$

Let us choose

$$F(\theta) = \frac{1}{1-\delta} + \frac{1+\theta}{\delta} - \frac{(1+\theta)^{1-\delta}}{\delta(1-\delta)},$$

with $\delta \in (0,1)$. We deduce that

$$\kappa \left\| \frac{\theta_x^2}{(1+\theta)^{1+\delta}} \right\|_{1,Q} \leq c_\delta(\|f\|_{1,Q} + \|\theta_0\|_1).$$

As shown in [15] (see also [9]), this inequality implies the bound formulated in the lemma.

We complete this section by proving Theorem 1.1. We argue like in [1, 14], so what follows is a brief scheme. It should be noted that from now until the end of this section the viscosity μ is considered fixed.

Proof of Theorem 1.1. First we prove by the Faedo–Galerkin method that the solution described in Theorem 1.1 exists locally. To this end, we use the finite-dimensional spaces

$$X_n^1 = \operatorname{span}\{\sin E_j(x), j = 1,\dots,n\}, \quad X_n^2 = \operatorname{span}\{\cos E_j(x), j = 1,\dots,n\},$$

$E_j(x) = \frac{j\pi(x-a)}{b-a}$, with the corresponding orthogonal projections $P_n^i : L^2(\Omega) \to X_n^i$, $i \in \{1,2\}$. We look for functions $\mathbf{v}^n \in [X_n^1]^3$, $\theta^n \in X_n^2$, and ρ^n, satisfying

$$(x\rho^n)_t + (x\rho^n u^n)_x = 0, \quad \rho^n|_{t=0} = \rho_0(x),$$

$$P_n^1(xM_n^j(t)) = 0, \quad P_n^2(xM_n^4(t)) = 0, \quad j \in \{1,2,3\},$$

$$\mathbf{v}^n(0) = P_n^1(\mathbf{v}_0), \quad \theta^n(0) = P_n^2(\theta_0),$$

where $M_n^j(t)$, $j \in \{1,2,3,4\}$, are the left-hand sides of (1.2)–(1.5), respectively, with the functions $\mathbf{v}$, θ, and ρ substituted by $\mathbf{v}^n$, θ^n, and ρ^n.

One can prove by means of the standard fixed point arguments (see [14] for details) that approximations exist on some interval $[0,T_n]$, $T_n \leq T$, with $\mathbf{v}^n \in C^1([0,T_n];[X_n^1]^3)$, $\theta^n \in C^1([0,T_n];[X_n^2])$, and ρ^n,ρ_x^n,$\rho_t^n \in L^\infty(0,T_n;L^2(\Omega))$. The next step is to verify that all the approximations are bounded uniformly in n on a same time interval $[0,T_*]$ in the norms defining the solution class in Theorem 1.1. This enables us to conclude that at least some subsequence of approximations converges on $[0,T_*]$ to a solution given by Theorem 1.1.

To prove the global existence, it remains to extend the local solution to the entire interval $[0,T]$. One can do it by deriving global estimates dependent on μ keeping the same line of arguments as in [14]. This completes the proof of global existence. As for the uniqueness, the method proposed in [14] is also applicable here.

3. Vanishing shear viscosity.

We send μ to zero and consider the problem of μ-dependence of solutions $\mathbf{s}_\mu = (\rho,\mathbf{v},\theta)$ of (1.1)–(1.8). It is implicit that the functions $\rho,\mathbf{v}$, and θ depend on μ.

Let us denote

$$C^1(\overline{Q})^T = \{\varphi \in C^1(\overline{Q}) : \varphi(T,x) = 0, x \in \Omega\},$$

$$C^1(\overline{Q})^\Pi = \{\varphi \in C^1(\overline{Q})^T : \varphi|_{\partial\Omega} = 0\}.$$

We need the following general lemma which is a chain rule formula for distribution derivatives. It can be proved by standard functional analysis considerations (see, e.g., [15]).

Lemma 3.1. *Let Ω be a bounded domain in $\mathbb{R}^N$ and $Q = (0,T) \times \Omega$. Assume $A \in L^2(0,T; W_0^{1,2}(\Omega))$, $A_0 \in L^2(\Omega)$, and $\mathbf{B}, C \in L^2(Q)$. If the equality*

$$\int_Q (A\psi_t + \mathbf{B} \cdot \nabla\psi + C\psi)dxdt + \int_\Omega A_0\psi(0,x)dx = 0$$

holds for any $\psi \in C^1(\overline{Q})^\Pi$, then the equality

$$\int_Q \left(\frac{A^2}{2}\psi_t + \mathbf{B} \cdot \nabla(A\psi) + CA\psi\right) dxdt + \int_\Omega \frac{A_0^2}{2}\psi(0,x)dx = 0$$

holds for any $\psi \in C^1(\overline{Q})^T$.

Proof of Theorem 1.2. The proof is divided into several steps. When we speak of a convergence $\mathbf{s}_\mu \to \mathbf{s}$ we will always mean that there is a sequence $\mu_n \downarrow 0$ such that $\mathbf{s}_{\mu_n} \to \mathbf{s}$. Let the vector $\overline{\mathbf{s}} = (\overline{\rho}, \overline{\mathbf{v}}, \overline{\theta})$ stand for the weak limit in $L^2(Q)$ of the sequence $\mathbf{s}_\mu$. Clearly, this limit exists by the above estimates.

Step 1. The fact that $\rho \to \overline{\rho}$ in $L^q(Q)$, $1 \le q < \infty$, follows from the uniform boundedness of ρ in $W^{1,1}(Q) \cap L^\infty(Q)$ and the Sobolev imbedding theorem.

Let us consider the sequence ρu, $\mu \downarrow 0$. By the uniform estimates, it follows from (1.23) that the sequence $(\rho u)_t$, $\mu \downarrow 0$, is also uniformly bounded in $L^2(0,T; W^{-1,2}(\Omega))$. Next, due to the inequality $\|\rho_x u\|_{1,Q} \le \|u\|_{\infty,1}\|\rho_x\|_{1,\infty}$, the sequence $(\rho u)_x$, $\mu \downarrow 0$, is bounded in $L^1(Q)$. Thus, by the Aubin–Simon theorem [16], $\rho u \to \overline{\rho u}$ in $L^2(0,T; L^1(\Omega))$. Now the inequality

$$|u^\mu - u^\nu| \le \frac{|\rho^\mu u^\mu - \rho^\nu u^\nu|}{\rho^\mu} + \left|\frac{1}{\rho^\mu} - \frac{1}{\rho^\nu}\right| |\rho^\nu u^\nu|$$

implies that $u \to \overline{u}$ in $L^1(Q)$. Since u is uniformly bounded in $L^6(Q)$ this convergence is valid in $L^q(Q)$, $q \in [1,6)$. Moreover, $\overline{u} \in L^6(Q)$.

In a similar manner we study the sequence θ, $\mu \downarrow 0$. By the above estimates and from (1.26) it follows that the sequence $(\rho\theta)_t$, $\mu \downarrow 0$, is bounded at least in $L^1(0,T; W^{-2,2}(\Omega) + L^1(\Omega))$. Again, by the inequality $\|\rho_x\theta\|_{1,Q} \le \|\theta\|_{\infty,1}\|\rho_x\|_{1,\infty}$, we conclude that the sequence $(\rho\theta)_x$, $\mu \downarrow 0$, is bounded in $L^1(Q)$. Thus, $\theta \to \overline{\theta}$ in $L^q(Q)$ for any $q \in [1, 3/2)$.

Step 2. Here we prove a strong convergence of v and w as $\mu \downarrow 0$. With the poor control of derivatives, we argue in a manner quite different from that in Step 1. First, consider the sequence w, $\mu \downarrow 0$. We start from the observation that $\overline{\rho}, \overline{u}$, and $\overline{w}$ satisfy (1.14) and (1.17) with test functions $\varphi,\psi \in W^{1,2}(Q)^T$, the closure of $C^1(\overline{Q})^T$ in $W^{1,2}(Q)$. Indeed, the set $C^1(\overline{Q})^T$ of test functions φ for equality (1.14) can be substituted by $W^{1,2}(Q)^T$ by the continuity argument. As for equality (1.17), we first, by the same argument, substitute the set $C^1(\xi_\delta(x) = \min\{\delta, \text{dist}(x, \partial\Omega)\}$. Clearly, $\psi\xi_\delta/\delta \in W^{1,2}(Q)^\Pi$ for any $\psi \in W^{1,2}(Q)^T$. Now, to justify the extension, one needs only to prove that

$$\lim_{\delta\to 0} \frac{1}{\delta} \int_Q \overline{\rho}\overline{u}\overline{w}\psi\xi_{\delta x} x dxdt = 0.$$

But this equality holds since $\overline{u} \in L^2(0,T;W_0^{1,2}(\Omega))$.

Next, we pass to the Lagrangian coordinates (t,y) by the formulas

$$y(t,x) = a + \int_a^x \overline{\rho}(t,s)s\,ds, \qquad y_x = x\overline{\rho}, \qquad y_t = -x\overline{\rho}\overline{u}. \tag{3.1}$$

Without loss of generality, we may assume that $\int_\Omega x\rho_0 dx = b-a$. Thus, with the change of variables, the functions $\overline{\mathbf{s}}(t,\cdot)$ and $\overline{\mathbf{s}}(t,y)$ are related again to the domains Ω and Q. Now, in the new coordinates, (1.17) for $\overline{w}(t,x)$ with the test set $W^{1,2}(Q)^T$ reads

$$\int_Q \overline{w}(t,y)\Psi_t(t,y)dydt + \int_\Omega w_0(y)\Psi(0,y)dy = 0. \tag{3.2}$$

This integral law holds for all $\Psi \in C^1(\overline{Q})^T$. Really, given $\Psi \in C^1(\overline{Q})^T$, the function $\psi(t,x) = \Psi(t,y(t,x))$ belongs to $W^{1,2}(Q)^T$ in view of (3.1). Clearly, the change of variables (3.1) transforms $\psi(t,x)$ into $\Psi \in C^1(\overline{Q})^T$.

Equation (3.2) implies that $\overline{w}(t,y) = w_0(y)$ almost everywhere (a.e.) on $(0,T)$, hence $\overline{w}^2(t,y) = w_0^2(y)$ a.e. on $(0,T)$ and

$$\int_Q \overline{w}^2(t,y)\Psi_t(t,y)dydt + \int_\Omega w_0^2(y)\Psi(0,y)dy = 0 \tag{3.3}$$

for all $\Psi(t,y) \in C^1(\overline{Q})^T$. By continuity argument, (3.3) holds for all $\Psi(t,y)$ such that

$$\Psi, \Psi_t \in L^1(Q), \qquad \Psi|_{t=T} = 0, \qquad \Psi \geq 0. \tag{3.4}$$

Next, multiplying (1.25) by $2xw\psi$, $\psi \in C^1(\overline{Q})^T$, integrating over Q, and sending μ to zero, we obtain

$$J_1(\psi) \equiv \int_Q \overline{\rho}\overline{w^2}(\psi_t + \overline{u}\psi_x)xdxdt + \int_\Omega \rho_0 w_0^2 \psi(0,x)xdx = 2\langle \overline{\mu x w_x^2}, \psi\rangle. \tag{3.5}$$

Here, $\overline{\mu x w_x^2}$ is a nonnegative Radon measure on Q, a weak limit of $\mu x w_x^2$ in the space of signed Radon measures on Q with finite mass. It is a simple consequence of (3.5) that

$$J_1(\psi) \geq 0 \tag{3.6}$$

for all $\psi \in W^{1,2}(Q)_+^T$, the subindex "+" denoting nonnegativity.

By switching to the Lagrangian coordinates, (3.6) reads

$$\int_Q \overline{w^2}(t,y)\Psi_t(t,y)dydt + \int_\Omega w_0^2(y)\Psi(0,y)dy \geq 0 \tag{3.7}$$

for all $\Psi(t,y) \in C^1(\overline{Q})_+^T$. It is true because any function $\Psi(t,y)$ from $C^1(\overline{Q})_+^T$ is transformed by (3.1) into the function $\psi(t,x) = \Psi(t,y(t,x))$ belonging to $W^{1,2}(Q)_+^T$. By continuity, the set (3.4) fits (3.7) as a test set as well.

Comparing (3.3) and (3.7) on the test set (3.4), we find that $\overline{w^2}(t,y) \leq \overline{w}^2(t,y)$ a.e. in Q. On the other hand, by convexity argument, $\overline{w^2}(t,y) \geq \overline{w}^2(t,y)$ a.e. in Q. Hence, $\overline{w^2}(t,x) = \overline{w}^2(t,x)$ a.e. in Q. This implies that $w \to \overline{w}$ in $L^2(Q)$. Since the sequence $w, \mu \downarrow 0$, is bounded in $L^\infty(Q)$ the last convergence holds also in $L^q(Q)$, $q \in [1,\infty)$.

We treat the sequence v, $\mu \downarrow 0$, in the same manner. Clearly, (1.16) holds with the test set $W^{1,2}(Q)^T$. The switching to the Lagrangian coordinates transforms (1.16) into

$$\int_Q \bigl(\overline{v}(t,y)\Psi_t(t,y) - \frac{\overline{v}(t,y)\bar{u}(t,y)}{x(t,y)}\Psi(t,y)\bigr)\,dy\,dt + \int_\Omega v_0(y)\Psi(0,y)\,dy = 0 \tag{3.8}$$

for all $\Psi \in C^1(\overline{Q})^T$. By Lemma 2.4, one can prove that the set

$$\Psi \in L^{\frac{6}{5}}(Q), \qquad \Psi_t \in L^1(Q), \qquad \Psi|_{t=T} = 0, \qquad \Psi \geq 0 \tag{3.9}$$

fits (3.8) as a test set.

Given $\eta(t,y) \in C^1(\overline{Q})^T$, we choose $\Psi = \eta e^U$, where $U = \int_0^t \overline{u}(s,y)/x(s,y)\,ds$. This choice is possible since $\overline{u} \in L^2(0,T;W_0^{1,2}(\Omega))$.

Denoting $V = \overline{v}(t,y)e^U$, we see that

$$\int_Q V\eta_t\,dy\,dt + \int_\Omega v_0(y)\eta(0,y)\,dy = 0$$

for all $\eta \in C^1(\overline{Q})^T$. Hence, $V(t,y) = v_0(y)$ a.e. on $(0,T)$ and we arrive at the representation formula $\overline{v}(t,y) = v_0(y)e^{-U(t,y)}$. Clearly, $V^2(t,y) = v_0^2(y)$ a.e. on $(0,T)$, i.e.,

$$\int_Q \left(\overline{v}^2(t,y)\Psi_t(t,y) - \frac{2\overline{v}^2(t,y)\bar{u}(t,y)}{x(t,y)}\Psi(t,y)\right)dy\,dt + \int_\Omega v_0^2(y)\Psi(0,y)\,dy = 0 \tag{3.10}$$

for all $\Psi \in C^1(\overline{Q})^T$. Again, we can extend the test set $C^1(\overline{Q})^T$ to (3.9).

Let us multiply (1.24) by $2xv\psi$, integrate over Q, and send μ to zero. As a result we obtain

$$\int_Q \left\{\overline{\rho}\,\overline{v^2}(\psi_t + \overline{u}\psi_x) - \frac{2}{x}\overline{\rho}\,\overline{v^2}\,\overline{u}\psi\right\} x\,dx\,dt + \int_\Omega \rho_0 v_0^2\psi(0,x)x\,dx = 2\langle\overline{\mu x v_x^2},\psi\rangle \geq 0 \tag{3.11}$$

for all $\psi \in C^1(\overline{Q})_+^T$. Here, $\overline{\mu x v_x^2}$ is a nonnegative Radon measure, whose existence is guaranteed by Lemma 2.4. Switching to the Lagrangian coordinates, we transform (3.11) into

$$\int_Q \left(\overline{v^2}\Psi_t - \frac{2}{x}\overline{v^2}\,\overline{u}\Psi\right)dydt + \int_\Omega v_0^2\Psi(0,y)dy \geq 0. \tag{3.12}$$

By the arguments above, the set (3.9) fits (3.12) as a test set. The comparison of (3.10) and (3.12) gives $\overline{v^2}(t,y) = \overline{v}^2(t,y)$. Hence, $v(t,x) \to \overline{v}(t,x)$ in $L^2(Q)$ as $\mu \to 0$. Clearly, this convergence is also valid in $L^q(Q)$, $q \in [1,\infty)$. Now it follows from (3.5) and (3.11) that

$$\langle\overline{\mu x w_x^2},\psi\rangle = 0, \qquad \langle\overline{\mu x v_x^2},\psi\rangle = 0$$

for all $\psi \in C^1(\overline{Q})^T$.

As another consequence of the above strong convergences we have that the functions $\overline{\rho}$, $\overline{\mathbf{v}}$, and $\overline{\theta}$ satisfy (1.15).

Step 3. It remains to prove (1.18). The difficulty lies on the weak limit equalities

$$\overline{-xp\left(u_x + \frac{u}{x}\right)} = -x\gamma\overline{\rho}\overline{\theta}\left(\bar{u}_x + \frac{\bar{u}}{x}\right), \qquad \overline{(\lambda+2\mu)x\left(u_x + \frac{u}{x}\right)^2} = \lambda x\left(\bar{u}_x + \frac{\bar{u}}{x}\right)^2.$$

We do not prove each of them, but rather their sum

$$\overline{xF(u_x+u/x)} = xF_0(\bar{u}_x+\bar{u}/x), \qquad F_0 = -\gamma\bar{\rho}\bar{\theta}+\lambda(\bar{u}_x+\bar{u}/x), \tag{3.13}$$

an equality of measures restricted to act on functions ψ from $C^1(\overline{Q})^T$. Here the effective viscous flux F is defined in (1.12) and F_0 is the effective fiscous flux of the limit flow. We prove (3.13) directly by applying Lemma 3.1. Actually, there is a deeper, more interesting point here: we exploit the fact discovered by Hoff [3] that the variable $-p+(\lambda+2\mu)(u_x+u/x)$ behaves better than either of its summands.

We rewrite (1.15) in the Lagrangian coordinates

$$\int_Q \left(\overline{u}\Psi_t + \left(\bar{\rho}x\Psi_y+\frac{\Psi}{x}\right)\left(\gamma\bar{\theta}-\lambda x\overline{u}_y-\frac{\lambda\overline{u}}{x\bar{\rho}}\right)+\frac{\Psi}{x}\overline{v}^2\right)dydt \tag{3.14}$$

$$+\int_\Omega u_0(y)\Psi(0,y)dy = 0.$$

As above, one can show that (3.14) holds for all $\Psi(t,y)\in C^1(\overline{Q})^\Pi$. By Lemma 3.1,

$$\int_Q\left(\frac{\overline{u}^2}{2}\Psi_t + x\left(\gamma\bar{\rho}\bar{\theta}-\lambda x\bar{\rho}\overline{u}_y-\frac{\lambda\overline{u}}{x}\right)(\overline{u}\Psi)_y\right)dydt \tag{3.15}$$

$$+\int_Q\left(\bar{\rho}\overline{v}^2-\bar{\rho}\overline{u}^2+\gamma\bar{\rho}\bar{\theta}-\lambda x\bar{\rho}\overline{u}_y-\frac{\lambda\overline{u}}{x}\right)\frac{\Psi\overline{u}}{x\bar{\rho}}dydt+\int_\Omega\frac{u_0^2}{2}(y)\Psi(0,y)dy = 0$$

for all $\Psi(t,y)\in C^1(\overline{Q})^T$. Clearly, (3.15) holds for the test set

$$\Psi\in L^\infty(Q), \qquad \Psi_t\in L^{\frac{3}{2}}(Q), \qquad \Psi_y\in L^3(Q), \qquad \Psi|_{t=T}=0. \tag{3.16}$$

Now we rewrite (3.15) in the Eulerian coordinates

$$\int_Q\left(\frac{x\bar{\rho}\overline{u}^2}{2}\psi_t+\psi_x\left(\frac{x\overline{u}^3\bar{\rho}}{2}-\lambda\overline{u}^2+\gamma x\overline{u}\bar{\rho}\bar{\theta}-\lambda x\overline{u}\overline{u}_x\right)\right)dxdt+\frac{1}{2}\int_\Omega x\rho_0u_0^2\psi(0,x)dx \tag{3.17}$$

$$+\int_Q\psi\left(x\overline{u}_x\left(\gamma\bar{\rho}\bar{\theta}-\lambda\overline{u}_x-\frac{\lambda\overline{u}}{x}\right)+\bar{\rho}\overline{u}\overline{v}^2-\bar{\rho}\overline{u}^3+\gamma\bar{\rho}\bar{\theta}\overline{u}-\lambda\overline{u}_x\overline{u}-\frac{\lambda\overline{u}^2}{x}\right)dxdt = 0.$$

This equality is valid for all $\psi\in C^1(\overline{Q})^T$ since the transformation $\psi(t,x)\to\Psi(t,y)$ maps $C^1(\overline{Q})^T$ into set (3.16).

Now we multiply (1.23) by $xu\psi$, $\psi\in C^1(\overline{Q})^T$ and send μ to zero. It results in

$$J_2-\int_Q x\psi(\gamma\bar{\rho}\bar{\theta}\bar{u}_x-\lambda\bar{u}_x^2)dxdt = \langle\overline{-xpu_x+(\lambda+2\mu)xu_x^2},\psi\rangle, \tag{3.18}$$

where J_2 is the left-hand side of equality (3.17). Clearly, equalities (3.18) and (3.13) are equivalent. This completes the proof of Theorem 1.2.

ASYMPTOTICS OF THE FAST-DIFFUSION EQUATION WITH CRITICAL EXPONENT*

VICTOR A. GALAKTIONOV[†], LAMBERTUS A. PELETIER[‡], AND JUAN L. VAZQUEZ[§]

Dedicated to the memory of Stanislav N. Kruzhkov

Abstract. We study the large-time behavior of the solutions of the initial-value problem for the nonlinear diffusion equation

$$u_t = \nabla \cdot (u^{-\sigma} \nabla u) \quad \text{in } \mathbf{R}^n \times \mathbf{R}_+ \tag{ND}$$

in dimensions $n \geq 3$ with nonnegative initial data $u(x,0) \in L^1(\mathbf{R}^n)$ when the exponent takes on the *critical value* $\sigma = 2/n$. This represents a borderline case in the study of the problem and offers marked qualitative and technical differences with the neighboring cases $\sigma \approx 2/n$, $\sigma \neq 2/n$. In particular, it marks the transition between two completely different asymptotic behavior types. It is known that solutions exist globally in time and conserve the L^1-norm for this problem. We prove that they decay exponentially in time with a complicated law:

$$\log \|u(\cdot,t)\|_\infty \sim -\kappa M^{-2/(n-2)} t^{n/(n-2)} \quad \text{as} \quad t \to \infty,$$

where $M = \int u(x,0)dx$ is the conserved mass and the constant $\kappa > 0$ depends only on the dimension n. This strongly differs from the comparatively simple self-similar asymptotics of the case $\sigma < 2/n$.

The description is split into an *inner* and an *outer* region, conveniently matched at a *transition layer*. The analysis of the outer region can be done independently and the behavior is governed by a first-order conservation law which acts as the reduced asymptotic equation. The uniqueness theory for first-order conservation laws is one of the great contributions of S. N. Kruzhkov to mathematics. The behavior in the inner parabolic region is then studied by means of a semiconvexity argument which makes it possible to translate into this region the precise behavior from the outer region.

Key words. fast-diffusion equation, Cauchy problem, asymptotic behavior, critical exponent, matched expansions, singular perturbations

1. Introduction.

This paper is devoted to describing the large-time behavior of nonnegative, finite-mass solutions of the Cauchy problem for the *fast-diffusion equation*

$$u_t = \nabla \cdot (u^{-\sigma} \nabla u) \tag{1.1}$$

posed in $Q = \mathbf{R}^n \times \mathbf{R}_+$ with space dimension $n \geq 3$ and *critical exponent*

$$\sigma = 2/n. \tag{1.2}$$

This problem has been much studied for the different values of the diffusivity exponent $\sigma \in \mathbf{R}$, and the appropriate behavior has been rigorously established in a large number of situations. It follows from these studies that the asymptotic behavior of such

equations depends strongly on the class of initial data $u(x,0)=u_0(x)$; the condition of finite mass

$$\|u_0\|_1=\int_{\mathbf{R}^n} u_0(x)dx<\infty,$$

also termed L^1-data, is the appropriate way of selecting the class of all "small" solutions with similar asymptotics. The case $\sigma=2/n$ represents a critical or borderline case for the class of L^1-solutions and has not been rigorously analyzed. It is our aim to fill this gap. A previous contribution in that direction is due to King, who performed in [Ki] a very detailed *formal* analysis of (1.1) in the so-called fast-diffusion range, i.e., $\sigma>0$. As we shall show, the behavior of the problem with critical exponent has a higher level of complexity, which is due to the fact that it represents the transition from one type of self-similar asymptotic behavior to a different type. Indeed, it is well known that for $\sigma\in(-\infty,2/n)$, the problem has a global-in-time solution which exhibits an asymptotic behavior with self-similarity of the first kind, i.e., determined by dimensional analysis, while for $\sigma\in(2/n,1)$ solutions exist only for a finite time and the extinction behavior is self-similar of the second kind. This will be explained below in greater detail. It is to be noted that in the critical case $\sigma=2/n$, the solution u does not evolve as $t\to\infty$ toward a single global self-similar solution, so a two-region analysis is needed.

Let us now give a more detailed description of the contents of the paper. As mentioned above, we consider sufficiently smooth initial data

$$u(x,0)=u_0(x)\in L^1(\mathbf{R}^n),\quad u_0(x)\geq 0. \tag{1.3}$$

A unique classical solution exists for problem (1.1)–(1.3), and conservation of mass holds [BC]:

$$\int u(x,t)\,dx=\int u_0(x)\,dx=M\in(0,\infty),\quad t>0. \tag{1.4}$$

The solution is positive for all times $t>0$. Our results can be summarized as follows. We establish the decay rate

$$\log\|u(\cdot,t)\|_\infty=-\kappa(n)\,\|u_0\|_1^{-2/(n-2)}t^{n/(n-2)}(1+o(1))\quad\text{as}\quad t\to\infty, \tag{1.5}$$

where $\kappa(n)$ is given by

$$\kappa=n(n-2)(2n\omega_n)^{2/(n-2)}$$

and ω_n denotes the volume of the unit ball in $\mathbf{R}^n$. Moreover, (1.5) gives in first approximation the asymptotic behavior of $\log(u)$ in the whole *inner region*, which is the ball of radius

$$R(t)=\exp\left\{\kappa_0\|u_0\|_1^{-2/(n-2)}t^{n/(n-2)}\right\},\quad \kappa_0=\kappa/n; \tag{1.6}$$

cf. Theorem 3.1. In other words, the profile of $\log(u)$ in the inner region becomes *flat* in first approximation. It has to be added that the solutions become asymptotically radially symmetric as $t\to\infty$. On the other hand, the analysis of the *outer region* $\{|x|>R(t)\}$ performed in section 2 gives a behavior of the form

$$\log u(r,t)\sim\frac{n}{2}\{\log(n-2)+\log t-2\log r-\log\log r\}. \tag{1.7}$$

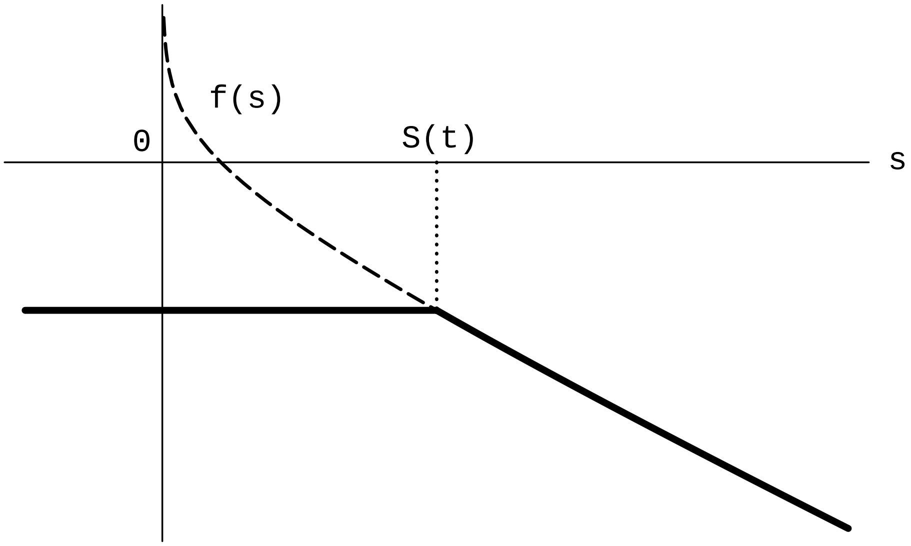

FIG. 1.1. *Asymptotic profile of* $\log(ut^{-n/2})$ *(the bold line) versus* $s = \log r$*,* $f(s) = -ns - \frac{n}{2}\log s + \frac{n}{2}\log(n-2)$*,* $S(t) = \kappa_0 M^{-2/(n-2)} t^{n/(n-2)}$.

Thus, in logarithmic scale, the profile of $u(x,t)$ has a broken shape, as sketched in Figure 1.1.

This behavior was predicted and formally analyzed in [Ki] under conditions of radial symmetry and is rigorously established below. The multiple-region structure is what makes the description of the asymptotic behavior different and more involved than for other diffusivity exponents. The present study and the proofs adapt to that structure. Thus, the outer region can be analyzed independently. After the change of variables

$$v(s,\phi,t) = r^n u(r,\phi,t), \quad s = \log r, \tag{1.8}$$

where we use standard spherical coordinates $x = (r,\phi) \in \mathbf{R}^{\mathrm{n}}$, we find that v satisfies a nonlinear convection-diffusion equation (see (2.2) and (2.24) below), where the convection part is asymptotically dominant. This is first analyzed in the radially symmetric case to which the general problem is then reduced. For radial functions, the asymptotic structure is most easily studied on a rescaled version of v, θ given by

$$\theta(\xi,\tau) = t^{\alpha} v(\xi\, t^{\alpha}, t), \quad \tau = \log t, \quad \alpha = \frac{n}{n-2}, \tag{1.9}$$

whose evolution is governed by a viscous perturbation of a nonlinear first-order conservation law (2.9). An entropy inequality plays a crucial role in the analysis; cf. Proposition 2.1. Together with the stability theorem of [GV1] it allows us to show that the viscous term is asymptotically negligible and to establish the asymptotic profile, which we call an N-wave following the usual terminology in the literature on conservation laws; see Figure 1.2.

We see that the outer region ends at a transition layer which is located at distance $R(t)$, obtained as the position of the shock of the asymptotic wave. The precise convergence result is stated in Theorem 2.3. The results obtained in the radial case

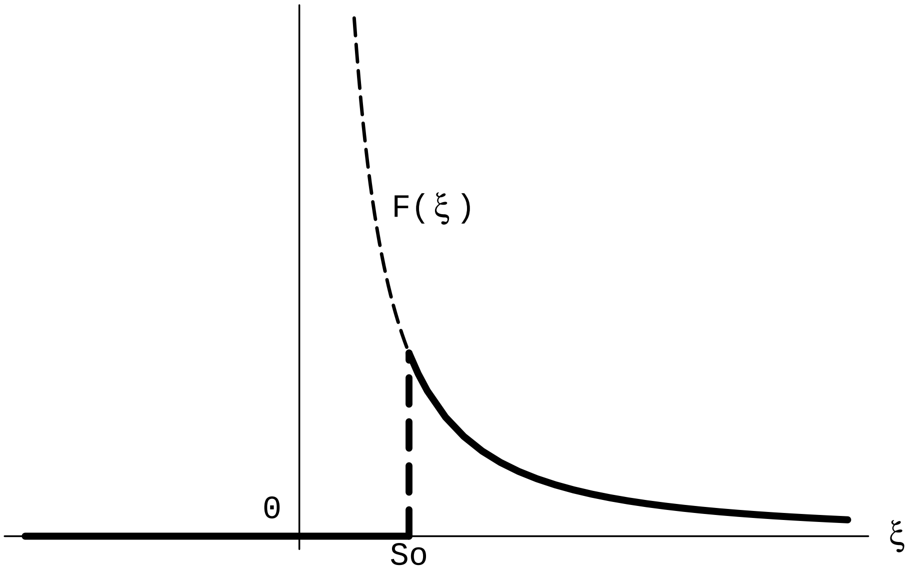

FIG. 1.2. *$v\,t^{n/(n-2)}$ (the bold line) versus $\xi = (\log r)\,t^{-n/(n-2)}$ for $t \gg 1$, $F(\xi) = (\xi/(n-2))^{-n/2}$, $s_0 = \kappa_0 M^{-2/(n-2)}$.*

are extended to general initial data thanks to the property of asymptotic radial symmetry, plus an approximation step; cf. Theorem 2.5. Summing up, the outer region is asymptotically of hyperbolic type and completely determines the whole asymptotic process, even if (1.1) is a purely diffusive equation.

The second step is to describe the behavior of the *inner* region which in terms of v is asymptotically trivial in relative size according to the previous result. However, it cannot be trivial in terms of u since the solutions are monotonically decreasing as functions of r. We thus revert to the original u variable and show that the large-time behavior is controlled by the second-order parabolic operator thanks to a semiconvexity result plus matching with the outer expansion near the transition surface $|x| = R(t)$. This allows us to get the function on the right-hand side of (1.5) as the first term in the asymptotic approximation for $\log(u)$ in the whole inner region.

Let us briefly recall the asymptotic results for $\sigma \neq 2/n$ for the sake of comparison. For $\sigma = 0$ we obtain the classical heat equation, $u_t = \Delta u$, and nonnegative, finite-mass solutions converge asymptotically toward the Gaussian kernel. The next well-studied case is the range $-\infty < \sigma < 0$, where the equation is usually written as $u_t = (1/m)\Delta(u^m)$ with $m = 1-\sigma > 1$ and is known as the porous medium equation. Any solution in our class converges to one of the self-similar *source-type* solutions first described in [ZK] and [B], precisely the one with the same mass; cf. [FK]. Accordingly, the rate of decay takes the form

$$\|u(t)\|_\infty = C(n,\sigma)M^{2k/n}t^{-k}(1+o(1)), \quad t \to \infty, \tag{1.10}$$

with $k = [(2/n) - \sigma]^{-1} > 0$, which for $\sigma = 0$ gives the well-known exponent $n/2$ of the linear case. This analysis can be extended to the subcritical fast-diffusion case, $0 < \sigma < 2/n$: the source-type solutions given by the Zel'dovich–Kompaneetz–Barenblatt formula still exist (cf. [LL]), the mass of the solutions is still conserved in time, and finite-mass solutions converge as $t \to \infty$ to the source-type solution with the same mass. The analysis breaks down as $\sigma \to 2/n$. No source-type solutions exist in this critical case $\sigma = 2/n$ as demonstrated by [BF]. We also see that the exponent $-k$ diverges, thus indicating the change of behavior and suggesting an exponential decay rate.

In the supercritical range $\sigma > 2/n$ there are no solutions with finite mass in dimensions $n = 1$ or 2 (cf. [V]), hence our restriction of the dimension. Solutions with finite mass exist if $n \geq 3$ and $2/n < \sigma < 1$. Mass is not conserved and the solutions undergo extinction in finite time [BC], so that for some $T = T(u_0) < \infty$ there holds $u(x, T) \equiv 0$. In this case (1.1) admits a unique self-similar solution of the second kind [Ki, PZ], which is proved to be asymptotically stable as $t \to T^-$ [GP]. This implies a decay rate of the form

$$\|u(t)\|_\infty = C(n, \sigma)(T - t)^\gamma(1 + o(1)), \quad t \to T^-, \tag{1.11}$$

where $T > 0$ is the extinction time, a function of σ, n, and the initial data, and $\gamma = \gamma(\sigma, n) > 0$ is the anomalous exponent. We point out that in all cases a single analysis gives a uniform asymptotic approximation of the solution and it has self-similar form.

2. Analysis of the outer region. We start our analysis of the behavior of the solutions in the outer region under the additional condition of radial symmetry on the initial data, $u_0 = u_0(r)$, $r = |x|$, so that $u = u(r, t)$ for all $t > 0$. We also impose a number of other conditions whose occurrence will be justified by the properties of the solutions of the equation. Under these assumptions we establish in this section the hyperbolic behavior in the outer region in four steps.

2.1. Radial setting: Change of variables. We consider a finite-mass, radially symmetric solution of the Cauchy problem (1.1)–(1.3). It is natural for such asymptotic problems to assume that $u_0(r) \to 0$ as $r \to \infty$ monotonically. Indeed, after a displacement of the origin of time we may suppose without loss of generality that $u_0(r)$ is decreasing due to the property of eventual monotonicity of such solutions, a proof of which we add as an appendix for the convenience of the reader. It also follows that $u_r \leq 0$ in Q by the maximum principle. For simplicity of the analysis we also impose the following monotonicity assumption on the data v_0:

$$v_0(s) \equiv r^n u_0(r) \quad \text{has a single maximum.} \tag{M}$$

This condition will be true again after shifting the origin of time for solutions with compactly supported initial data and we defer the proof to the appendix. By a suitable approximation in L^1, the results are then extended to general data; see below.

As in [Ki], we begin by performing the change of variables

$$v(s, t) = r^n u(r, t), \quad s = \log r. \tag{2.1}$$

In this way we get the following one-dimensional quasi-linear heat equation with a nonlinear convection term:

$$v_t = (v^{-2/n} v_s)_s - n(v^{(n-2)/n})_s. \tag{2.2}$$

It follows from (M) that by the strong maximum principle applied to (2.2) differentiated with respect to s, we have that for every $t > 0$, the function $v(s, t)$ has a single maximum at a point $s = s_m(t)$ so that $v_s > 0$ for $s < s_m(t)$ and $v_s < 0$ for $s > s_m(t)$.

It turns out that in the outer region the *first-order convection* term is precisely the one controlling the asymptotic behavior in the first approximation.

2.2. Entropy inequality and L^∞-bound. We must show that the first-order term on the right-hand side of (2.2) is dominant. Indeed, the situation of a diffusion-convection equation whose asymptotic behavior is convective was studied in [EVZ1] in the simpler model $v_t = v_{xx} - (v^q)_x$ in the exponent range $1 < q < 2$. See also [EVZ2] for the application to several dimensions. There the convective control manifested itself in the form of an *entropy inequality.* A similar result holds for (2.2). Before stating and proving it and deriving its consequences, let us remark that the asymptotic degeneracy of parabolic equations is a typical feature of finite-time extinction and blowup; cf. [GV2].

PROPOSITION 2.1. *For every smooth solution of* (2.2) *we have*

$$(v^{-2/n})_s \le \frac{1}{(n-2)t}. \tag{2.3}$$

Proof. Let us write (2.2) in terms of $w = v^{-2/n}$:

$$w_t = ww_{ss} - \frac{n}{2}(w_s)^2 - (n-2)ww_s.$$

Take now $z = w_s$. It satisfies

$$z_t = wz_{ss} + [(1-n)z - (n-2)w]z_s - (n-2)z^2.$$

Since this equation admits the explicit solution $Z(t) = 1/(n-2)t$ with unbounded initial data, $Z(+0) = +\infty$, we obtain (2.3) by the maximum principle. □

Remark. This estimate is the cornerstone on which the introduction of the dynamical systems analysis, section 2.3, is based. It can also be written as

$$v_s \ge -\frac{n}{2(n-2)t}\, v^{(n+2)/n}.$$

It is exact if we neglect the diffusion term, as will happen later in the asymptotic limit. Indeed, there is a family of self-similar entropy solutions of the convective equation $v_t = -n(v^{(n-2)/n})_s$ of the form

$$V(s,t) = \begin{cases} \left[\dfrac{s}{(n-2)t}\right]^{-n/2} & \text{for } s \ge s_0 t^{n/(n-2)}, \\ 0 & \text{for } s < s_0 t^{n/(n-2)}, \end{cases} \tag{2.4}$$

where $s_0 > 0$ is a free constant. These discontinuous solutions are called N-waves in the literature; cf. [S]. The free constant s_0 can easily be determined from (2.4) as a function of the preserved mass M of the solution

$$s_0 = \kappa_0 M^{-2/(n-2)}, \quad \kappa_0 = \kappa/n. \tag{2.5}$$

As a consequence, we will show that the N-waves provide the asymptotic profiles and estimate (2.3) will also be optimal for the solutions of the whole equation (2.2).

Before proceeding further we still need some other standard facts. One of them is the conservation of mass for (2.2), i.e., for every solution and every $t > 0$ we have

$$M = \int_{\mathbf{R}^n} u(x,t)\,dx = n\omega_n \int_0^\infty r^{n-1}u(r,t)\,dr = n\omega_n \int_{-\infty}^\infty v(s,t)\,ds. \tag{2.6}$$

On the other hand, the maximum principle implies that v is bounded, and in particular that $v(s,t) \leq \|v(\cdot,0)\|_\infty$. Moreover, all nonnegative and bounded solutions are actually positive and C^∞-smooth.

The entropy inequality and the conservation of mass immediately give an important a priori L^∞-estimate which controls the actual size of the solutions for large times.

Corollary 2.2. *For every solution $v(s,t)$ with mass $M > 0$ we have*

$$v(s,t) \leq CM^{n/(n-2)}t^{-n/(n-2)}. \tag{2.7}$$

Proof. This estimate is a straightforward consequence of the entropy inequality (2.3) and the mass-conservation equation (2.6). See [EVZ1, Lemma 1.2]. □

2.3. Rescaled equation and hypotheses of the stability theorem. We proceed now with the large-time analysis which is based on the dynamical systems approach of [GV1]. The first step in such an analysis is to perform a rescaling which makes the orbits of our evolution problem compact with nontrivial limits. Based on estimate (2.7), we introduce the new variables

$$\theta(\xi,\tau) = t^\alpha v(\xi\, t^\alpha, t), \quad \tau = \log t. \tag{2.8}$$

Here and below the scaling exponent has the value $\alpha = n/(n-2)$. We have the following equation for θ:

$$\theta_\tau = \mathbf{B}(\tau,\theta) \equiv \mathbf{A}(\theta) + \mathbf{e}^{-\alpha\tau}\mathbf{C}(\theta), \tag{2.9a}$$

where

$$\mathbf{A}(\theta) = -\mathbf{n}(\theta^{(\mathrm{n}-2)/\mathrm{n}})_\xi + \alpha(\xi\theta)_\xi \qquad \text{and} \qquad \mathbf{C}(\theta) = (\theta^{-2/\mathrm{n}}\theta_\xi)_\xi. \tag{2.9b}$$

The general approach of [GV1] adapts to our case as follows: we consider (2.9) as an asymptotically small perturbation of the purely convective equation

$$\theta_\tau = \mathbf{A}(\theta), \tag{2.10}$$

which is called the *limit* or *reduced* equation for (2.9). Both equations are viewed as abstract evolution equations posed in a Banach space, in this case $X = L^1(\mathbf{R}^n)$, so that a solution is viewed as a curve $u(\tau) : (0,\infty) \mapsto L^1(\mathbf{R}^n)$. In the case of (2.9) we consider the class $\mathcal{S}$ of solutions obtained by formulas (2.1) and (2.8) from the class of solutions of problem (1.1)–(1.3) stated in the introduction. In the case of the first-order equation (2.10), which is equivalent to

$$v_t = -n(v^{(n-2)/n})_s, \tag{2.11}$$

it is well known that the proper concept of solution is Kruzhkov's entropy solution [Kr], and that the autonomous operator $\mathbf{A}$ generates a semigroup of contractions in $L^1(\mathbf{R})$. We can restrict our consideration to the class $\mathcal{T}$ of nonnegative entropy solutions with fixed finite mass $M > 0$.

In this situation if the three conditions of compactness, consistency, and stability are satisfied we have the following result.

Theorem S (see [GV1]). *The ω-limit sets for the solutions $\theta(\tau) \in \mathcal{S}$ of* (2.9) *are contained in the global ω-limit set Ω^* of* (2.10). *Consequently, the orbits approach Ω^* uniformly as $\tau \to \infty$ in the $L^1(\mathbf{R}^n)$-norm.*

We recall that the ω-limit set of a solution $\theta \in \mathcal{S}$ of (2.9) is defined as

$$\omega(\theta_0) = \{v \in X : \exists\ \tau_j \to \infty \quad \text{such that} \quad \theta(\tau_j) \to v \text{ in } \ X\}. \tag{2.12}$$

The global ω-limit set Ω^* of (2.10) is defined as the closure of the set of all $v \in X$ which can be obtained as limits

$$v = \lim_{t_j \to \infty} \theta(t_j),$$

where $\theta \in \mathcal{T}$ is any solution of (2.10) and $\{t_j\}$ is any sequence which goes to infinity. In fact, only the solutions of (2.11) which can be obtained as limits of solutions of (2.9) need to be considered, and then the set Ω^* receives the name *reduced* ω-limit set of (2.11).

The three conditions to be satisfied are the following.

(H1) *Compactness of the orbits.* We must have a class $\mathcal{S}$ of weak solutions $\theta \in C([0,\infty) : X)$ of (2.9) defined for all $\tau > 0$ with values in $X = L^1(\mathbf{R}^n)$. The orbits $\{\theta(\tau) : \tau > 0\}$ must be relatively compact. Moreover, if we define the shifted orbits

$$\theta^t(\tau) = \theta(\tau + t), \quad t, \tau > 0, \tag{2.13}$$

then the sets $\{\theta^t\}_{t>0}$ must be relatively compact in $L^\infty(0,\infty : X)$.

The verification of this condition is not difficult. In particular, the boundedness of the orbits follows from the agreement between estimate (2.7) and the rescaling (2.8). Compactness comes from (2.3) and standard regularity.

(H2) *Consistency.* Given any solution $\theta \in \mathcal{S}$ and a sequence $t_j \to \infty$ such that θ^{t_j} converges to a function u in $L^\infty(0,\infty : X)$, then $u(\tau)$ is a solution of (2.10) in the class $\mathcal{T}$.

The fact that weak solutions of (2.9) give in the limit weak solutions of (2.10) is immediate. The limits are entropy solutions because of Proposition 2.1.

(H3) *Stability for the limit equation.* The set Ω^* is nonvoid, compact, and uniformly Lyapunov stable.

The Lyapunov stability of the limit set for the first-order equation (2.10), or equivalently (2.11), comes from the fact that we are dealing with a semigroup of contractions in $L^1(\mathbf{R}^n)$. On the other hand, it is known that the ω-limit set for such conservation laws consists of N-wave profiles satisfying the stationary autonomous equation; cf. [LP]. The best-known case in the literature is the equation $v_t = (v^m)_s$ with $m > 1$, where the N-wave has compact support in space. A convergence analysis in that case can be seen in [EVZ1]. The fact that the exponent $(n-2)/n$ in (2.11) is less than 1 implies that the N-wave has unbounded support with an *infinite tail* (2.4). In terms of the variables ξ and θ it reads

$$F(\xi) = \begin{cases} \left(\dfrac{\xi}{n-2}\right)^{-n/2} & \text{for } \xi \geq s_0, \\ 0 & \text{for } \xi < s_0. \end{cases} \tag{2.14}$$

In view of the conservation of mass, (2.6), the final profile is uniquely determined by the constant s_0 given in (2.5). Therefore, the reduced ω-limit set of all orbits with the given total mass of the autonomous equation (2.10) is

$$\Omega_* = \{F = F_*(\xi) \quad \text{with} \quad s_0 = \kappa_0 M^{-2/(n-2)}\}, \tag{2.15}$$

and it is uniformly stable in the L^1-metric. This completes (H3).

The survey paper [GV3] contains a general discussion of the application of these ideas to the study of evolution problems.

2.4. Outer behavior. Thanks to Theorem S we conclude that the ω-limits of the orbits of (2.9) are an N-wave as above and $\omega(\theta_0) \subseteq \Omega_*$. In view of (2.15) this yields that $\omega(\theta_0) = \{F_*(\xi)\}$, i.e., as $\tau \to \infty$,

$$\theta(\cdot,\tau) \to F_*(\cdot) \quad \text{in } L^1(\mathbf{R}). \tag{2.16}$$

In fact, as a straightforward consequence we get a stronger convergence.

THEOREM 2.3. *As $t \to \infty$ we have*

$$v(s,t) = \left[\frac{s}{(n-2)t}\right]^{-n/2} (1 + o(1)) \tag{2.17}$$

uniformly on the sets $\{s \geq (s_0 + \varepsilon)\, t^{n/(n-2)}\}$, where $\varepsilon > 0$ may be arbitrarily small, while

$$v(s,t) = o(t^{-n/(n-2)}) \tag{2.18}$$

uniformly on $\{s \leq (s_0 - \varepsilon)\, t^{n/(n-2)}\}$.

Proof. It follows from the monotonicity assumption (M) and (2.16) that the maximum $\xi_m(\tau)$ of the rescaled function $\theta(\xi,\tau)$ satisfies $\xi_m(\tau) \to s_0$ as $\tau \to \infty$. Therefore, there exists a $\tau_1 \gg 1$ such that

$$\theta_\xi(\xi,\tau) < 0 \qquad \text{for all} \qquad \xi > s_0 + \varepsilon/4, \quad \tau > \tau_1, \tag{2.19}$$

and

$$\theta_\xi(\xi,\tau) > 0 \qquad \text{for all} \qquad \xi < s_0 - \varepsilon/4, \quad \tau > \tau_1.$$

In addition, the entropy inequality (2.3) yields the lower bound

$$\theta_\xi(\xi,\tau) \geq -\frac{n}{2(n-2)}\theta^{(n+2)/n}. \tag{2.20}$$

Thus, in the outer region, for $\xi > s_0 + \varepsilon/4$, we have an upper as well as a lower bound for θ_ξ on compact subsets. This allows us to strengthen the convergence of $\theta(\cdot,\tau)$ to F_* in L^1 to uniform convergence in compact intervals. Translated to the variables s and t, this results in (2.17).

In the inner region, the L^1-convergence can be strengthened to uniform convergence to zero on compact intervals, thanks to the monotonicity of $\theta(\xi,\tau)$ with respect to ξ, and (2.18) follows by monotonicity. □

We thus conclude that convergence (2.16) is uniform on compact subsets in ξ bounded away from the point $\xi = s_0$. In terms of the original variables we get the following *outer-region expansion:*

$$u^{2/n}(r,t) = \frac{(n-2)t}{r^2 \log r}(1 + o(1)) \quad \text{as} \quad t \to \infty \tag{2.21}$$

if $r \geq \exp\{(\kappa_0 + \varepsilon) M^{-2/(n-2)}\, t^{n/(n-2)}\}$. From this outer expansion we obtain an estimate of the decay rate of the form

$$\log u(r,t) \leq -\kappa M^{-2/(n-2)}\, t^{n/(n-2)} (1 + o(1)). \tag{2.22}$$

We will show in section 3 that this estimate is correct uniformly in $\mathbf{R}^n$. Moreover, in the logarithmic scale the solution becomes flat in the inner region and takes the self-similar form given in the right-hand side of (2.22).

2.5. The nonradial case. We now generalize the previous asymptotic behavior to nonradial solutions. A basic ingredient of the proof is the principle of asymptotic symmetry that says that solutions with compactly supported initial data become almost radially symmetric for large enough times. Such results are well known [GNN] and apply to the fast-diffusion equation, as we will see. In this case we define the new variable v by means of standard spherical coordinates $x = (r, \phi)$, $\phi \in S^{n-1}$, and put $s = \log r$ and

$$v(s, \phi, t) = r^n u(r, \phi, t), \tag{2.23}$$

which satisfies the evolution equation

$$v_t = (v^{-2/n} v_s)_s + \frac{n}{n-2} L(v^{(n-2)/n}) - n(v^{(n-2)/n})_s, \tag{2.24}$$

where L is the Laplace–Beltrami operator (cf. (2.2)). With this definition the result of Theorem 2.3 is still true. The passage to general initial data is done by approximation in a second stage.

Compactly supported data. We consider problem (1.1)–(1.2) with continuous and nonnegative initial data u_0 supported in the ball of radius $a > 0$, $B_a(0)$. Let us fix the mass of the solution $M = \int u_0(x)\, dx > 0$. In a first step we use a classical argument based on reflection, due to Aleksandrov and Serrin, which proves the following result.

LEMMA 2.4. *Under the above conditions the solution of the initial-value problem satisfies*

$$u(x, t) \geq u(y, t) \tag{2.25}$$

for every $t > 0$ and every pair of points $x, y \in \mathbf{R}^n$ such that $|y| \geq |x| + a$.

A similar result is used in [CVW] for the porous-medium equation, $\sigma < 0$. As a consequence of this fact, if we consider the radial functions

$$\underline{u}(r, t) = \inf_{|x|=r} u(x, t), \quad \overline{u}(r, t) = \sup_{|x|=r} u(x, t),$$

we will have for $|x| = r > 0$

$$\underline{u}(r, t) \leq u(x, t) \leq \overline{u}(r, t)$$

and also

$$\underline{u}(r, t) \geq \overline{u}(r + a, t).$$

The next step consists of proving that these two radial functions, $\underline{u}$ and $\overline{u}$, which are a lower and upper bound for $u(\cdot, t)$, respectively, have a mass very similar to $u(\cdot, t)$ for large t. In fact, let $\varepsilon > 0$ be small and let us take $T > 0$ large enough such that the solution with initial data $\overline{u}_0(r)$ has mass less than ε inside the ball of radius $R = 2a/\varepsilon$, which is easily seen to be true thanks to the estimates of the previous section. We call

$$f(x) = u(x, T), \quad \underline{f}(r) = \underline{u}(r, T), \quad \overline{f}(r) = \overline{u}(r, T).$$

Then $\int \underline{f}(r)dx \leq M \leq \int \overline{f}(r)dx$. But we also have an estimate in the other direction. Indeed, for some $\lambda = 1+\varepsilon$, $\varepsilon > 0$ very small, we have

$$\underline{f}(r) \geq \overline{f}(\lambda r)$$

if $\lambda r \geq r + a$, i.e., $r \geq A = a/\varepsilon$. Then

$$\int_{|x|\geq A} \overline{f}(x)\,dx \geq \int_{|x|\geq A} \overline{f}(\lambda x)\,dx = \frac{1}{\lambda^n}\int_{|y|\geq \lambda A} \overline{f}(y)\,dy.$$

On the other hand, by the assumption on T the mass of $\overline{f}$ and $\underline{f}$ inside the ball $B_R(0)$ is less than ε. It follows that

$$\int_{\mathbf{R}^n} \overline{f}(x)\,dx \geq (1-n\varepsilon)\int_{\mathbf{R}^n} \overline{f}(x)\,dx - \varepsilon.$$

We easily conclude that

$$M - c\varepsilon \leq \int \underline{f}(x)\,dx \leq \int \overline{f}(x)\,dx \leq M + c\varepsilon, \quad c = n+1.$$

The final step consists of fixing as initial time a time T as above and starting the radial evolution with initial data $\overline{f}$ and $\underline{f}$, for which the asymptotic result of Theorem 2.3 is true. Then we observe that u is in between and that $\varepsilon \to 0$ as $t \to \infty$.

General case. When we assume that u_0 is merely an integrable and nonnegative function, we can approximate it from below in $L^1(\mathbf{R}^n)$ by compactly supported functions as in the previous result. The L^1-contraction property guarantees that the asymptotic limit also depends in a contractive way in L^1, hence the result.

THEOREM 2.5. *As $t \to \infty$ we have*

$$v(s,\phi,t) = \left[\frac{s}{(n-2)t}\right]^{-n/2}(1+o(1)) \tag{2.26}$$

uniformly in $\phi \in S^{n-1}$ and in s on sets of the form $\{s \geq (s_0+\varepsilon)\,t^{n/(n-2)}\}$, where $\varepsilon > 0$ may be arbitrarily small, while

$$v(s,\phi,t) = o(t^{-n/(n-2)}) \tag{2.27}$$

uniformly in $\phi \in S^{n-1}$ and in s on $\{s \leq (s_0-\varepsilon)\,t^{n/(n-2)}\}$.

3. Inner region. In this section we return to the radial solution $u(r,t)$ to derive an estimate in the inner region

$$0 \leq r \leq r_0(t) = \exp\{s_0 t^{n/(n-2)}\}, \quad s_0 = \kappa_0 M^{-2/(n-2)}. \tag{3.1}$$

Later on we extend the results to nonradial solutions.

We shall prove the following theorem in the radial case.

THEOREM 3.1. *Let $u(r,t)$ be the solution of the Cauchy problem* (1.1)–(1.3). *Then*

$$\log u(r,t) = -ns_0 t^{n/(n-2)}(1+o(1)) \quad \textit{as} \quad t\to\infty \tag{3.2}$$

uniformly in the inner region.

Proof. We proceed in several steps. Fix an $\varepsilon > 0$ small and denote

$$r_\varepsilon(t) = \exp\{(s_0+\varepsilon)\,t^{n/(n-2)}\}. \tag{3.3}$$

3.1. Interior regularity in the outer region. Set $I_\varepsilon = (s_0 + \varepsilon/2, s_0 + 3\varepsilon/2)$. We prove the following interior regularity result for (2.9).

PROPOSITION 3.2. *For $k = 1, 2, 3$ we have*

$$\left|\frac{\partial^k \theta}{\partial \xi^k}\right| \le C_k \quad \textit{for } \tau \gg 1 \textit{ and } \xi \in I_\varepsilon. \tag{3.4}$$

Proof. A gradient bound for $k = 1$ has already been proved; see (2.19)–(2.20). In order to prove a bound on the second derivative we note that in the domain $\xi \ge s_0+\varepsilon/4$ (where the limit function F_* is smooth) we can apply to (2.9) the classical Bernstein approach to prove the interior regularity. We will use the technique presented in [GV2, Proposition 5.4] for singular perturbations of first-order equations of the form (2.9). Let us review the main points and indicate the small differences. The right-hand side of (2.9) has two terms and the stationary operator $\mathbf{C}$ in the perturbation term is uniformly elliptic on the solution for $\tau \gg 1$ in $\xi \in I_\varepsilon$ and appears multiplied by an exponentially small factor. The first-order term preserves the regularity in the domain where $\theta_\xi < 0$ due to the entropy inequality. This is proved as in [GV2, p. 1125] by differentiating (2.9) with respect to ξ, performing a nonlinear change of the dependent variable $\theta_\xi = \varphi(v)$ (with a smooth function φ to be determined with the typical properties of the Bernstein method), differentiating again with respect to ξ, and setting

$$Z = \chi^2(\xi)(v_\xi)^2,$$

where the C^∞-function χ has to be chosen here with the following properties: it must be monotone and increasing, $\chi \equiv 0$ for all $\xi \le s_0 + \varepsilon/4$, and $\chi \equiv 1$ for $\xi \ge s_0 + \varepsilon/2$ (in other words, χ cuts off the shock; it does not cut off $\xi = +\infty$). We arrive at an equation of the form [GV2, (5.21)]

$$Z_\tau = A\, Z_\xi + B\, Z + e^{-\alpha\tau}\, J_1(Z)$$

with some coefficients A, B and a uniformly elliptic operator J_1. The important point is that J_1 is controlled in exactly the same way as for uniformly parabolic equations and the coefficient B satisfies $B \le 0$ in I_ε, $\tau \gg 1$. Since by the construction the function χ is not compactly supported from the right-hand side, we need some control at $\xi = +\infty$, but we may conclude that under the hypotheses on the initial data v_0, the second derivative $\theta_{\xi\xi}(\xi, \tau)$ is uniformly small for $\xi \gg 1$. Then a uniform in $\tau \gg 1$ estimate on Z in I_ε (which implies (3.4)) follows from the maximum principle as in [GV2, pp. 1126–1127].

The proof for $k = 3$ is similar. This completes the analysis. □

It is convenient now to consider the rescaled function

$$g = -\frac{n}{2}\,\theta^{-2/n} \tag{3.5}$$

("the pressure"). Then the rescaled equation (2.9) becomes

$$g_\tau = \alpha\Big(-\frac{2}{n}g + \xi g_\xi\Big) - \frac{2}{\alpha}g g_\xi + e^{-\alpha\tau}\mathbf{D}(g), \quad \mathbf{D}(g) = -\frac{2}{n}g g_{\xi\xi} + (g_\xi)^2. \tag{3.6}$$

As a consequence of Proposition 3.2, we have

$$\left|\frac{\partial^3 g}{\partial \xi^3}\right| \le C_3 \quad \text{for } \tau \gg 1 \text{ and } \xi \in I_\varepsilon. \tag{3.7}$$

3.2. Lateral analysis. From convergence (2.17) and regularity (3.7) we obtain an estimate near the lateral boundary of the inner domain of the pressure written in the original variables

$$w = -\frac{n}{2}\, u^{-2/n}. \tag{3.8}$$

It follows from (2.17) that in the outer region

$$w(r,t) = -\frac{n}{2(n-2)t}\, r^2 \log r\, (1+o(1)) \quad \text{as} \quad t \to \infty.$$

Since, in view of the interior regularity in the outer region, this asymptotic estimate can be differentiated in r twice, we arrive at the following result.

COROLLARY 3.3. *For $r = r_\varepsilon(t)$ we have*

$$\Delta w = -\psi_\varepsilon(t) \equiv -\frac{n^2}{n-2}(s_0+\varepsilon)\, t^{2/(n-2)}(1+o(1)) \quad \textit{as} \quad t \to \infty. \tag{3.9}$$

3.3. Inner semiconvexity. We now use the well-known semiconvexity approach [AB] in the inner region. Here and later on we denote by c, $c_1, \dots$ different positive constants.

PROPOSITION 3.4. *Let $\varepsilon > 0$. Then there exist a constant $c > 0$ and a $t_c > 0$ such that for $t > t_c$,*

$$\Delta w \geq -\tilde{\psi}_\varepsilon(t) \equiv -\psi_\varepsilon(t) - c \quad \textit{in the ball} \;\; B_\varepsilon(t) = \{r < r_\varepsilon(t)\}. \tag{3.10}$$

Proof. The pressure (3.8) solves in $\{w < 0\}$ the parabolic equation

$$w_t = -\frac{2}{n} w \Delta w + |\nabla w|^2.$$

Differentiating this equation twice we have that $z = \Delta w$ satisfies

$$z_t = -\frac{2}{n} w \Delta z + \frac{2(n-2)}{n} \nabla w \cdot \nabla z - \frac{2}{n} z^2 + 2 \sum_{(i,j)} \left(\frac{\partial^2 w}{\partial x_i \partial x_j} \right)^2.$$

As in [AB], using the Cauchy–Bunyakovskii–Schwarz inequality

$$\sum_{(i,j)} \left(\frac{\partial^2 w}{\partial x_i \partial x_j} \right)^2 \geq \frac{1}{n}\, z^2,$$

we arrive at a linear parabolic differential inequality of the form

$$z_t \geq -\frac{2}{n} w \Delta z + \frac{2(n-2)}{n} \nabla w \cdot \nabla z.$$

Therefore (3.10) follows from (3.9) by the maximum principle. □

3.4. Mass analysis: End of the proof. Integrating inequality (3.10) twice over $(0,r)$, we obtain the estimate

$$u(r,t) \geq u(0,t) \left(1 + \frac{r^2}{d^2(t)} \right)^{-n/2} \quad \text{in } B_\varepsilon(t), \tag{3.11}$$

where

$$d(t) = n\, u^{-1/n}(0,t)\tilde{\psi}_\varepsilon^{-1/2}(t).$$

Integrating (3.11) over $B_\varepsilon(t)$, we get the following estimate of the mass M_ε in the inner region:

(3.12)
$$M_\varepsilon(t) = n\omega_n \int_0^{r_\varepsilon(t)} r^{n-1}u(r,t)dr \ge n\omega_n u(0,t)d^n(t)\int_0^{l(t)} \eta^{n-1}(1+\eta^2)^{-n/2}d\eta,$$

with $l(t) = r_\varepsilon(t)/d(t)$. However,

$$\begin{aligned} M_\varepsilon(t) &= n\omega_n \int_{-\infty}^{(s_0+\varepsilon)t^{n/(n-2)}} v(s,t)\, ds \\ &= n\omega_n \int_{-\infty}^{s_0+\varepsilon} \theta(\xi,\tau)\, d\xi \\ &= n\omega_n(1+o(1))\int_{-\infty}^{s_0+\varepsilon} F_*(\xi)\, d\xi \quad \text{as} \quad t\to\infty. \end{aligned}$$

Therefore, the mass M_ε satisfies for small $\varepsilon > 0$

$$M_\varepsilon(t) = O(\varepsilon) \quad \text{as} \quad t\to\infty. \tag{3.13}$$

To conclude, we need to consider two cases. (i) Take a sequence $\{t_k\}\to\infty$ and assume that the sequence $\{l(t_k)\}$ is bounded. Then from (3.12) we obtain that for all $t = t_k \gg 1$,

$$M_\varepsilon(t) \ge c\, u(0,t)d^n(t)l^n(t) = c\, u(0,t)r_\varepsilon^n(t).$$

Therefore, it follows from (3.13) that $u(0,t)r_\varepsilon^n(t) \le c_1\,\varepsilon$ and hence

$$u(0,t) \le c_1\varepsilon r_\varepsilon^{-n}(t) = c_1\varepsilon \exp\{-n(s_0+\varepsilon)\, t^{n/(n-2)}\}.$$

Therefore we obtain an upper bound

$$\lim\sup_{t=t_k\to\infty} t^{-n/(n-2)}\log u(0,t) \le -n(s_0+\varepsilon). \tag{3.14}$$

(ii) Assume now that the sequence $\{l(t_k)\}$ is unbounded and without loss of generality $\{l(t_k)\}\to\infty$. Then one can calculate from (3.12) that for $t = t_k \gg 1$,

$$\begin{aligned} M_\varepsilon(t) &\ge n\omega_n\, u(0,t)d^n(t)\log l(t)(1+o(1)) \\ &= c\,\psi_\varepsilon^{-n/2}(t)\log l(t)(1+o(1)). \end{aligned} \tag{3.15}$$

As before, (3.13) yields that $\psi_\varepsilon^{-n/2}(t)\log l(t) \le c_1\varepsilon$, whence the estimate

$$\log l(t) = \frac{1}{n}\log u(0,t) + \log r_\varepsilon(t) + \frac{1}{2}\log\psi_\varepsilon(t) - c \le c_1\varepsilon\psi_\varepsilon^{n/2}(t) \le c_2\varepsilon\, t^{n/(n-2)}.$$

In view of (3.3) and (3.9) this implies that as $t = t_k\to\infty$ (cf. (3.14)),

$$\log u(0,t) \le -[ns_0 + O(\varepsilon)]t^{n/(n-2)}. \tag{3.16}$$

As a lower bound, it follows from the convergence given by (2.17) and from the eventual monotonicity property $u(r,t) \le u(0,t)$ for $t \gg 1$ (see the appendix) that

$$\log u(0,t) \ge \log u(r_\varepsilon(t),t) = -n(s_0+\varepsilon)t^{n/(n-2)}(1+o(1)). \tag{3.17}$$

From (3.16) (or (3.14)) and (3.17) we obtain uniform bounds from above and below of the solution in $B_\varepsilon(t)$ for $t \gg 1$. Since $\varepsilon > 0$ is arbitrarily small, we arrive at (3.2). □

3.5. The nonradial case. In order to extend the above inner radial analysis to the nonradial case, we just note that due to Theorem 2.5, we can bound (both above and below) the general solution $u(x,t)$ by radial ones:

$$\underline{u}(r,t) \le u(x,t) \le \overline{u}(r,t), \quad t \ge T,$$

where, by the outer analysis, the masses of $\underline{u}$ and $\overline{u}$ do not differ by more than 2ε. Indeed, the only thing we take from the outer analysis is the behavior of the solutions in a neighborhood of the inner lateral boundary $|x| = r_0(t)$ which is given by (2.26) for nonradial solutions.

4. Conclusions and final remarks.

1. We have rigorously established the two-region structure for the asymptotic behavior of finite-mass solutions of the fast-diffusion equation (1.1) with critical exponent $\sigma = 2/n$. This structure compares with the simpler one-region structure of noncritical exponents. The outer expansion has a *hyperbolic character* with natural variable $v = r^n u$, which develops an N-wave profile with a *shock* located at an exponentially growing distance $R(t)$, while it converges in relative size to the trivial state for $|x| < R(t)$. The main mathematical novelty in the proof of the hyperbolic structure is the use of entropy inequalities.

In the original variable and logarithmic scale we observe the formation of a *mesa-like profile.* Further analysis of the inner region should allow us to resolve the flatness of $\log u$ by calculating the second-order corrections which affect u as factors. The formal calculations are again given in [Ki] but a proof of those facts needs new techniques which fall outside the scope of this work.

2. We have studied the critical case in dimensions $n \ge 3$. Let us recall the situation in $n = 1, 2$, which is quite different. In dimension 1, where $\sigma = 2$, no finite-mass solutions exist, which eliminates the problem. For $n = 2$ we get the equation $u_t = \Delta \log u$. It is proved in [VER] that the Cauchy problem admits infinitely many solutions with finite mass and all of them extinguish in finite time, $T \le \|u_0\|_1/4\pi$, a striking contrast with the critical exponent for $n \ge 3$ discussed in this paper.

3. Explicit solutions are an important auxiliary tool in the investigation of nonlinear or asymptotic phenomena. Indeed, for $\sigma \ne 2/n$ the asymptotic behavior of finite-mass solutions has been described in terms of explicit self-similar solutions. No such solutions exist in the critical case, because of the nonexistence result of [BF]. However, we can exhibit self-similar solutions which represent the behavior of the outer zone. An explicit example is given by the function

$$u^{-2/n}(x,t) = \frac{|x|^2}{(n-2)t}\,\log\left(\frac{|x|}{at^\gamma}\right), \quad \gamma = \frac{n}{2(n-2)}, \tag{4.1}$$

where $a > 0$ is an arbitrary constant. The solution is defined only for $|x| > l(t) = a\,t^\gamma$, and blows up at $x = l(t)$. It has at infinity the correct behavior predicted by our results, since the rescaled function θ defined in (2.8) is given by

$$\theta^{-2/n}(\xi,\tau)=\frac{\xi}{n-2}-e^{-\alpha\tau}\left(\frac{s_0+\alpha\tau/2}{n-2}\right),\quad \alpha=2\gamma,\ \ s_0=\log a, \tag{4.2}$$

which is to be compared with F given by (2.14).

Appendix. We now prove some eventual monotonicity-like properties of radial solutions $u(r,t)$ and $v(r,t)$.

Proof of eventual monotonicity of $\boldsymbol{u(r,t)}$. According to the L^1-approximation scheme from section 2.5, it suffices to prove the property of eventual monotonicity for radial solutions $u(r,t)$ with sufficiently smooth compactly supported initial data

$$u_0(r)>0 \quad \text{for } r<R=2a/\varepsilon,\ \ u_0(r)=0 \text{ for } \ r\geq R. \tag{A.1}$$

Moreover, due to the approximation in L^1, we are free to impose a uniform slope condition on the approximating initial data $u_0\in C^1([0,R])$. Namely, we assume that

$$u_0'(R)=\mu>0, \tag{A.2}$$

where μ is chosen independent of the small approximating parameter ε.

We use the intersection comparison approach; see [GV4, p. 1100]. We compare $u(r,t)$ with a small flat solution $\tilde{u}\equiv\delta>0=\text{const}$ satisfying (1.1). By (A.1) and (A.2), $u_0(r)$ intersects the level δ exactly once. By the Sturmian argument, the number of intersections $J(t)$ does not increase so that

$$J(t)\leq 1 \quad \text{for all } t>0. \tag{A.3}$$

Since

$$u(r,t)\to 0 \quad \text{as } t\to\infty \text{ uniformly}, \tag{A.4}$$

there exists a moment $t_1>0$ such that $J(t)=1$ for all $t\in[0,t_1)$ and $J(t)=0$ for $t\geq t_1$. By the strong maximum principle (this admits a simple geometric interpretation; see [GV4]), for $t>t_1$ the solution $u(r,t)$ of a uniformly parabolic equation is strictly monotone in r.

Proof of property $\boldsymbol{(M)}$ for $\boldsymbol{v(r,t)}$. We again restrict ourselves to radial compactly supported data satisfying (A.1) and (A.2). We now apply the intersection-comparison idea from [GV4] to the radial equation (2.2).

We compare $v(r,t)$ with the stationary solutions $\tilde{v}=\delta>0$. In terms of the dependent variable u this corresponds to the comparison with the singular stationary solution $\tilde{u}=\delta r^{-n}$. It follows from (A.2) that there exists a small $\delta>0$ such that the constant solution $\tilde{v}=\delta$ intersects $v_0(r)$ exactly once for $r\approx R-0$. By continuity, the same is true for any small $t=\tau>0$. On the other hand, in terms of the corresponding solutions $u(r,t)$ and $\tilde{u}=\delta r^{-n}$ the profiles $u(r,\tau)$ ($\tau>0$ is a small time-shift which establishes a natural interior regularity of the solution) and $\tilde{u}(r)$ intersect each other exactly once for $r\approx 0$ provided that $\delta\ll 1$. Finally, we conclude that there exists $\delta>0$ sufficiently small such that the number of intersections $J(\tau)$ between the profiles $u(r,\tau)$ and $\tilde{u}(r)$ satisfies $J(\tau)=2$. Hence, by the Sturmian argument,

$$J(t)\leq 2,\quad t\geq\tau. \tag{A.5}$$

Since $v(r,t)$ satisfies the asymptotic property (A.4), the estimate above (A.5) means that there exists a moment t_1 such that $J(t_1) = 0$, $J(t) = 2$ for $t < t_1$ (and $J(t) = 0$ for all $t > t_1$ by the standard comparison). As in [GV4, section 10], using a simple geometric interpretation based on the application of the strong maximum principle for uniformly parabolic equations, one concludes that all the nonmonotonicities of $v(r,t)$ must be destroyed at this moment $t = t_1$, and the profile $v(r,t)$ has exactly one maximum and no minima for all $t > t_1$. This mimics the assumption (M) which happens eventually in time.

INTERFACE BEHAVIOR OF COMPRESSIBLE NAVIER–STOKES EQUATIONS WITH VACUUM*

TAO LUO[†], ZHOUPING XIN[‡], AND TONG YANG[§]

Abstract. In this paper, we study a one-dimensional motion of viscous gas near vacuum with (or without) gravity. We are interested in the case that the gas is in contact with the vacuum at a finite interval. This is a free boundary problem for the one-dimensional isentropic Navier–Stokes equations, and the free boundaries are the interfaces separating the gas from vacuum, across which the density changes continuously. The regularity and behavior of the solutions near the interfaces and expanding rate of the interfaces are studied. Smoothness of the solutions is discussed. The uniqueness of the weak solutions to the free boundary problem is also proved.

1. Introduction.

We consider the evolution of the interfaces separating one-dimensional isentropic viscous gases from vacuum when the gases are in contact with the vacuum on a finite interval initially, with (or without) external force. The important feature of this problem is that the density changes continuously across the interfaces separating the gases and vacuum. This models many interesting phenomena, such as gaseous stars problems in astrophysics [9]. For further physical significance and mathematical treatment of such free boundaries, we refer to the excellent survey paper of Nishida [11].

The one-dimensional isentropic viscous gas flow is governed by the compressible Navier–Stokes equations which can be rewritten, in Eulerian coordinates, as (in the case without external force)

$$\begin{aligned} &\rho_t + (\rho u)_x = 0, \\ &(\rho u)_t + (\rho u^2 + P(\rho))_x = \mu u_{xx}, \end{aligned} \tag{1.1}$$

where $x \in \mathbf{R^1}$ and $t > 0$, and $\rho = \rho(x,t)$, $u = u(x,t)$, and $P(\rho)$ denote, respectively, the density, velocity, and the pressure; $\mu > 0$ is the viscosity constant. For simplicity of presentation, we consider only the polytropic gas, i.e., $P(\rho) = A\rho^\gamma$ with $\gamma > 1$, $A > 0$ being constants.

We consider (1.1) with the initial data

$$\rho(x,0) = \rho_0(x), \qquad u(x,0) = u_0(x). \tag{1.2}$$

Our main assumption is that the entire gas initially occupies a finite interval $(a, b) \subset \mathbf{R^1}$ and is in contact with the vacuum. More precisely, the initial density $\rho_0(x)$ is supposed to satisfy

(A1) $\rho_0(x) \in C(\mathbf{R^1})$, supp$\rho_0 \subset (a, b)$, $\rho_0(x) > 0\ \forall x \in (a, b)$, and

(A2) $\rho_0^k \in H^1([a, b])$ for some constant $0 < k \leq \gamma - 1/2$.

The initial velocity, $u_0(x)$, is assumed to possess the following regularity:

(A3) $\rho_0 u_0^2$, $(\partial_x u_0)^2$, $\rho_0^{-1}(\partial_{xx} u_0)^2 \in L^1([a, b])$.

It is expected that velocity will be smooth enough up to the interfaces which separate the gas from the vacuum so that the interfaces are particle paths. Suppose $x = a(t)$ and $b = b(t)$ are two particle paths issuing from a and b, respectively, i.e.,

$$\dot{a}(t) = u(a(t), t),\ \dot{b}(t) = u(b(t), t) \tag{1.3}$$

with $a(0) = a$ and $b(0) = b$. The free boundary problem to be studied is

$$\begin{aligned} &(1.1),\ \text{in } (a(t), b(t)) \times (0, +\infty), 0 < t < +\infty,\\ &\rho(a(t), t) = \rho(b(t), t) = 0,\\ &(\rho, u)(x, 0) = (\rho_0, u_0)(x), x \in [a, b]. \end{aligned} \tag{1.4}$$

The definition of weak solutions for this free boundary problem is given by the following definition.

Definition 1.1. *A function* (ρ, u) *is called a weak solution to the free boundary problem* (1.4) *if there exist* $a(t), b(t) \in C[0, \infty)$ *such that* $\rho \in C[(0, \infty), L^2([a(t), b(t)])]$, $u \in C[(0, \infty), H^1([a(t), b(t)])]$, *and* $\lim_{x \to a(t)+} \rho(x, t) = 0 = \lim_{x \to b(t)-} \rho(x, t)$. *Furthermore,*

$$\begin{aligned} &\int_a^b \rho_0 v(x, 0) dx + \int_0^{+\infty} \int_{a(t)}^{b(t)} (\rho v_t + \rho u v_x) dx dt = 0,\\ &\int_a^b \rho_0 u_0 w(x, 0) dx + \int_0^{+\infty} \int_{a(t)}^{b(t)} (\rho u w_t + (\rho u^2 + P(\rho) + \mu u_x) w_x) dx dt = 0 \end{aligned}$$

hold for all test functions v, $w \in C_0^1(\Omega)$ *with* $\Omega = \{(x, t) | a(t) \leq x \leq b(t), 0 \leq t < +\infty\}$.

In what follows, we always use C $(C(T))$ to denote a generic positive constant depending only on the initial data (and the given time T). We now state our first result on the existence and behavior of weak solutions to the free boundary problem (1.4).

Theorem 1.2. *Let* ρ_0 *and* u_0 *satisfy* (A1)–(A3). *Then the free boundary problem* (1.4) *admits a globally defined weak solution with* $a(\cdot), b(\cdot) \in C^1[0, +\infty)$. *Moreover, the solution* $(\rho, u)(x, t)$ *has the following properties:*

(1) *Regularity of the solution.*

$\rho > 0$ *in* Q *with* $Q =: \{(x,\ t) : a(t) < x < b(t), 0 \leq t < +\infty\}$.

$$\int_{a(t)}^{b(t)} (\rho u^2 + u_x^2)(x, t) dx \leq C, \qquad 0 \leq t < +\infty, \tag{1.5}$$

$$\int_{a(t)}^{b(t)} ([(\rho^k)_x]^2 + \rho^{-1} u_{xx}^2)(x, t) dx \leq C(T), \qquad 0 \leq t \leq T, \tag{1.6}$$

for any $T > 0$.

(2) *Decay rate of the density and expanding rate of the interface.* *There exist positive constants c_i $(i = 1, 2, \ldots, 7)$, independent of the time t, such that*

$$c_1\rho_0(x_1)(1 + c_2\rho_0^\gamma(x_1)t)^{-1/\gamma} \le \rho(x,t) \le c_3\rho_0(x_1)(1 + c_4\rho_0^\gamma(x_1)t)^{-1/\gamma}, \tag{1.7}$$

where x_1 is determined uniquely by $\int_a^{x_1}\rho_0(z)dz = \int_{a(t)}^x \rho(z,t)dz$ for any x,

$$c_5(1+t)^{1/\gamma} \le b(t) - a(t) \le c_6(1+t)^{1/\gamma}, \qquad 0 \le t < \infty, \tag{1.8}$$

$$\sup\nolimits_{a(t)\le x\le b(t)}|u(x,t)| \le c_7(1+t)^{1/\gamma}, \qquad 0 \le t < \infty. \tag{1.9}$$

(3) *Behavior near the interface.*

$$\rho(x,t) \le C(T)|x - a(t)|^{1/2k}, \;\; \rho(x,t) \le C(T)|x - b(t)|^{1/2k}, \tag{1.10}$$

$$|u_x(x,t) - u_x(a(t)+,t)| \le C(T)|x - a(t)|^{(\frac{1}{4k}+\frac{1}{2})}, \tag{1.11}$$

$$|u_x(x,t) - u_x(b(t)-,t)| \le C(T)|x - b(t)|^{(\frac{1}{4k}+\frac{1}{2})} \tag{1.12}$$

for $0 \le t \le T$.

(4)

$$\int_{a(t)}^x (\rho u_t + \rho u u_x)(z,t)dx + P(\rho) = \mu u_x$$

for $a(t) < x < b(t)$ and $t > 0$, and

$$\int_{a(t)}^{b(t)} \rho u(x,t)dx = \int_a^b \rho_0 u_0(x)dx \tag{1.13}$$

for $t > 0$.

Remark 1.3. Part (3) of Theorem 1.2 is a simple consequence of (1.6). Indeed,

$$\rho^k(x,t) = \int_{a(t)}^x (\rho^k)_x dx \le \left(\int_{a(t)}^x [(\rho^k)_x]^2 dx)^{1/2}|x - a(t)|^{1/2} \le C(T)|x - a(t)|^{1/2}\right),$$

which implies (1.10). Moreover, the Hölder inequality and (1.10) give

$$\begin{aligned}
&|u_x(x,t) - u_x(a(t)+,t)| = \left|\int_{a(t)}^x u_{xx}\right| \\
&\le \left(\int_{a(t)}^x \rho^{-1}u_{xx}^2\right)^{1/2}\left(\int_{a(t)}^x \rho\right)^{1/2} \\
&\le C(T)\left(\int_{a(t)}^x (x - a(t))^{1/2k}\right)^{1/2} \\
&\le C(T)(x - a(t))^{(\frac{1}{4k}+\frac{1}{2})}.
\end{aligned}$$

Remark 1.4. It can be verified that the conservation of momentum property (1.13) holds true for the general weak solution defined in Definition 1.1 under the assumption (A_1)–(A_3) (see [10]).

Our next theorem shows that the solutions obtained in Theorem 1.2 are indeed smooth in the region $\{(x,t) : \rho(x,t) > 0\}$ if the initial data have the appropriate regularity, and the smoothness is up to the boundary if the initial density is connected to vacuum very smoothly. Precisely, we have the following theorem.

THEOREM 1.5. *Let* (ρ, u) *be the weak solution to* (1.4) *described in Theorem* 1.2. *Then it holds that*

(1) *if* $\rho_0^\alpha(\partial_x^2\rho_0)^2 \in L^1[a,b]$, *then* $\rho^{\alpha_1}(\partial_x^2\rho)^2(\cdot,t) \in L^1[a(t),b(t)]$ *with* $\alpha_1 = 2k-3+\max\{2k+3+\alpha, 6k+1\}$. *And the weak solution* (ρ,u) *to* (1.4) *is smooth in the region* $Q =: \{(x,\ t) : a(t) < x < b(t), 0 \le t < +\infty\}$ *with* $\rho(\cdot,t) \in C^{1+\lambda}(a(t),b(t))$, $u(\cdot,t) \in C^{2+\lambda}(a(t),b(t))$ *for some* $0 < \lambda < 1$ *and any* $t > 0$;

(2)

$$u_{xx}(a(t)+,t) = u_{xx}(b(t)-,t) = 0$$

if $k < \frac{1}{2}$; *furthermore*

$$\rho(\cdot,t) \in H^2[a(t),b(t)], \qquad 0 \le t \le \infty, \tag{1.14}$$

if $\alpha \le -4k$ *and* $k \le 1/4$, *and this implies* ρ_x *is Hölder continuous in the whole interval* $[a(t),b(t)]$ *for any* $t \ge 0$. *Also, the gradient of pressure satisfies*

$$|P(\rho)_x(x,t)| \le C(T)\rho^{\gamma-1} \le C(T)(|x-a(t)|^{(\gamma-1)/2k} + |x-b(t)|^{(\gamma-1)/2k}). \tag{1.15}$$

Finally, we have the following uniqueness result.

THEOREM 1.6 (uniqueness). *Assume* (A_1)–(A_3), *let* (ρ_1,u_1) *and* (ρ_2,u_2) *be two weak solutions to the free boundary problem* (1.4) *in* $0 \le t \le T$ *as described in Definition* 1.1. *Then* $(\rho_1,u_1)(x,t) = (\rho_2,u_2)(x,t)$ *in* $a(t) < x < b(t)$ *and* $0 \le t \le T$.

Remark 1.7. This uniqueness result particularly implies that the whole sequence of approximate solutions constructed in section 2 converges to a unique weak solution.

Remark 1.8. So far, all of our results are stated for the case without external force. However, one can check by modifying our analysis slightly that similar results hold true in the presence of external forces such as gravity.

The free boundary problem of one-dimensional Navier–Stokes equations with one boundary fixed was investigated by Okada in [12]; see also [11], where the global existence of the weak solutions was proved and the regularity of $(\rho^{1/2}u, u_x, \rho^{-1/2}u_{xx})(\cdot,t) \in L^2, \rho \in BV$ was obtained. Similar results were derived in [10], [13] for the equations of spherically symmetric motion of viscous gases. It also should be noticed that another interesting class of free boundary problem of viscous gases for the one-dimensional viscous gases which expands into the vacuum has been studied by many people; see [1], [2], [3], [8].

It is important and interesting to investigate the regularity of the solution to the above free boundary problem and the behavior near interfaces due to the degeneracy of vacuum. In general, we do not expect to prove the global existence of the smooth solution to the above free boundary problem because of the degeneracy. However, as we showed in Theorem 1.5, if the initial density is connected to vacuum smoothly enough, the smoothness of the solution can be up to the boundary. Also we get the clear description of the behavior of solutions near the interfaces between the gas and vacuum. For these, the first observation is that $(\rho^k)_x(\cdot,t) \in L^2$, which indicates how the density is connected to the vacuum according to the value of k. The second ingredient in our analysis to improve the regularity of the solution is an L^2-estimate of $\rho^{\alpha_1/2}\rho_{xx}$.

It should be noted that Xin [16] proved recently that the smooth solution $(\rho, u) \in H^3(\mathbf{R^1})$ of the Cauchy problem of Navier–Stokes equations with compact density must blow up in the finite time. However, the different phenomena occur for the free boundary problem (1.4). As we showed in Theorem 1.2, the smooth solution of the free boundary problem can survive for all time if the initial density is connected to vacuum very smoothly. In fact, $(\rho, u) \in H^3(\mathbf{R^1})$ implies $u = 0$ outside the interfaces [16] for the Cauchy problem. Hence the interfaces separating the gas and vacuum must be fixed, i.e., independent of the time. But the estimate (1.8) shows the interfaces for the free boundary problem (1.4) are not fixed.

We should mention that the free boundary problem of a modified Navier–Stokes equation was studied by Liu, Xin, and Yang in [8] with the boundary condition $u_x = P(\rho)$, where the initial density was assumed to connect vacuum with discontinuities, i.e., $inf_{x\in(a,b)}\rho_0(x) \geq \delta > 0$, $\rho_0(x) = 0$ when $x < a$ or $x > b$. This property can be maintained for some finite time [8], and the local existence of the weak solution was proved then.

The important progress has been made on compressible Navier–Stokes equations when the initial density is away from vacuum in several aspects, for smooth initial data or discontinuous initial data, one-dimensional or multidimensional problem. For these results, please refer to [1], [2], [3], [4], [5], [6], [14], [15], and [17].

The rest of this paper is organized as follows. In section 2, we convert the free boundary problem to a fixed boundary problem by using Lagrangian coordinates and giving some basic estimates. Based on these estimates, we study the smoothness of solutions and complete the proof of Theorem 1.5 with the L^2-estimate of $\rho^{\alpha_1/2}\rho_{xx}$ in section 3. The uniqueness result will be proved in section 4.

2. Global existence of weak solutions and the basic estimates. To solve the free boundary problem (1.4), it is convenient to convert the free boundaries to the fixed boundaries by using Lagrangian coordinates. Using the following coordinates transformation

$$y = \int_{a(t)}^{x} \rho(z,t)dz, \ \tau = t,$$

the free boundaries $x = a(t)$ and $x = b(t)$ become $\hat{a}(\tau) = 0$ and $\hat{b}(\tau) = \int_{a(t)}^{b(t)} \rho(x,t)dx = \int_a^b \rho_0(x)dx$, where $\int_a^b \rho_0(x)dx$ is the total mass initially, and without loss of generality, we normalize it to be 1. So in terms of Lagrangian coordinates, the free boundary problem (1.4) becomes

$$\begin{aligned} &\rho_\tau + \rho^2 u_y = 0, \\ &u_\tau + P(\rho)_y = (\mu\rho u_y)_y, 0 < y < 1, \tau > 0, \end{aligned} \tag{2.1}$$

with the data given by

$$\begin{aligned} (\rho, u)(y, 0) = (\rho_0(y), u_0(y)), 0 \leq y \leq 1, \\ \rho(0,t) = \rho(1,t) = 0, t > 0. \end{aligned} \tag{2.2}$$

The assumptions corresponding to (A1)–(A3) are transformed into

(A1′) $\rho_0(y) > 0$ as $y \in (0,1)$;

(A2′) $\rho_0^q \in H^1([0,1])$ with $1/2 < q = k + 1/2 \le \gamma$;
and

(A3′) $u_0, \rho_0^{1/2} u_{0y}, (\rho_0 u_{0y})_y \in L^2[0,1]$.
In addition,

$$0 < \int_0^1 (\rho_0)^{-1}(y)dy = \int_a^b 1dx = b - a < \infty. \tag{2.3}$$

It is more convenient to use t instead of τ in the case without confusion. Similarly we have the definition of weak solutions in Lagrangian coordinates corresponding to Definition 1.1.

To prove Theorem 1.2, we first prove the following Theorem 2.1.

Theorem 2.1. *Suppose* (A1′)–(A3′) *and* (2.3) *are satisfied. Then the initial-boundary value problem* (2.1) *and* (2.2) *admits a globally defined weak solution* (ρ, u) (y,t) *in* $[0,1] \times (0,\infty)$ *with the following properties:*

(1)

$$c_1\rho_0(y)(1 + c_2\rho_0^\gamma(y)t)^{-1/\gamma} \le \rho(y,t) \le c_3\rho_0(y)(1 + c_4\rho_0^\gamma(y)t)^{-1/\gamma}, 0 \le y \le 1, t > 0 \tag{2.4}$$

for some positive constant c_i $(i = 1, \ldots, 4)$ *independent of* t;

(2)

$$\int_0^1 (u^2 + \rho u_y^2 + u_t^2)(y,t)dy + \int_0^\infty \int_0^1 (\rho u_y^2 + u_t^2 + \rho u_{yet}^2)dydt \le C, 0 \le t < +\infty, \tag{2.5}$$

$$\max_{y\in[0,1]}|\rho u_y(y,t)| + \int_0^1 ([(\rho^q)_y]^2 + [(\rho u_y)_y]^2) + |u_y|)(y,t)dy \le C(T), 0 \le t \le T, \tag{2.6}$$

$$c_5(1+t)^{1/\gamma} \le \int_0^1 \rho^{-1}(y,t)dy \le c_6(1+t)^{1/\gamma},\ \max_{y\in[0,1]}|u(y,t)| \le C(1+t)^{1/\gamma}, t > 0, \tag{2.7}$$

for some positive constants c_5 *and* c_6 *independent of* t *and* $T > 0$ *is given;*

(3)

$$\int_0^y u_t(z,t)dz + P(\rho) = \rho u_y,$$

$$\int_0^1 u(y,t)dy = \int_0^1 u_0(y)dy.$$

To prove Theorem 2.1, we will construct the global solution to the initial boundary problem (2.1) and (2.2) by a slight modification of the method of lines used in [1], [8], [11], [12], [13], which can be described as follows. For simplicity, we take $\mu = 1$. For any given positive integer N, let $h = 1/N$. Consider the system of $2N$ ordinary differential equations

$$\begin{aligned} &\frac{d}{dt}\rho_{2n}^h + (\rho_{2n}^h)^2 \frac{u_{2n+1}^h - u_{2n-1}^h}{h} = 0,\\ &\frac{d}{dt}u_{2n-1}^h + \frac{P(\rho_{2n}^h) - P(\rho_{2n-2}^h)}{h}\\ &= \frac{1}{h^2}\{\rho_{2n}^h(u_{2n+1}^h - u_{2n-1}^h) - \rho_{2n-2}^h(u_{2n-1}^h - u_{2n-3}^h)\}, \end{aligned} \tag{2.8}$$

where $n = 1, 2, 3 \cdots N$, with the boundary conditions

$$\rho_0^h = \rho_{2N}^h = 0, \tag{2.9}$$

and the initial conditions

$$\rho_{2n}^h(0) = \rho_0\left(2n \cdot \frac{h}{2}\right), u_{2n-1}^h(0) = u_0\left((2n-1)\cdot\frac{h}{2}\right). \tag{2.10}$$

For $n = 1$ and N, we set $u_{-1}^h = u_{2N+1}^h = 0$.

In the following, we will use (ρ_{2n}, u_{2n-1}) instead of $(\rho_{2n}^h, u_{2n-1}^h)$ when it does not cause any confusion. For simplicity of presentation, we use $\sum$ instead of $\sum_{n=1}^N$ unless otherwise stated.

We now begin to derive some bounds on the solutions to (2.8)–(2.10). At first, standard energy estimate gives the following lemma.

Lemma 2.2. *Let $(\rho_{2n}(t), u_{2n-1}(t))$, $n = 1, 2, \ldots, N$ be the solution for* (2.8), (2.9), *and* (2.10). *Then we have*

$$\begin{aligned} &\sum\left(\frac{1}{2}u_{2n-1}^2(t) + \int_0^{\rho_{2n}(t)} s^{-2}P(s)ds\right)h\\ &\quad + \int_0^t \sum \rho_{2n}\left(\frac{u_{2n+1} - u_{2n-1}}{h}\right)^2 hds\\ &= \sum\left(\frac{1}{2}u_{2n-1}^2(0) + \int_0^{\rho_{2n}(0)} s^{-2}P(s)ds\right)h. \end{aligned} \tag{2.11}$$

Consequently, problem (2.8)–(2.10) has a unique global solution. In the next lemma, we give the decay rate of density function. The main idea for this is to get ordinary differential equations governing the density function along the particle path.

Lemma 2.3. *There exist positive constants c_i $(i = 1, \ldots, 4)$ independent of t and n such that*

$$c_1\rho_{2n}(0)(1 + c_2\rho_{2n}^\gamma(0)t)^{-1/\gamma} \le \rho_{2n}(t) \le c_3\rho_{2n}(0)(1 + c_4\rho_{2n}^\gamma(0)t)^{-1/\gamma}, n = 1, 2\cdots N, \tag{2.12}$$

for $0 \le t \le \infty$.

Proof. It follows from $(2.8)_1$ that

$$\rho_{2n}(t) = \rho_{2n}(0)\exp\left(-\int_0^t \frac{\rho_{2n}(u_{2n+1}-u_{2n-1})}{h}ds\right)$$

for $n = 1, 2, \ldots, N$, $t \geq 0$.

On the other hand, in view of $(2.8)_2$ and the boundary conditions (2.9), one has

$$\begin{aligned}
&\frac{\rho_{2n}(u_{2n+1}-u_{2n-1})}{h}\\
&=\sum_{j=1}^{n}\left[\rho_{2j}\frac{(u_{2j+1}-u_{2j-1})}{h}-\rho_{2j-2}\frac{(u_{2j-1}-u_{2j-3})}{h}\right]\\
&=\sum_{j=1}^{n}\left[\frac{d}{dt}u_{2j-1}h+(P(\rho_{2j})-P(\rho_{2j-2}))\right]\\
&=\sum_{j=1}^{n}\left(\frac{d}{dt}u_{2j-1}h\right)+P(\rho_{2n}). \qquad (2.13)
\end{aligned}$$

Thus,

$$\rho_{2n}(t) = \rho_{2n}(0)\exp\left(\sum_{j=1}^{n}(u_{2j-1}(0)-u_{2j-1}(t))h\right)\exp\left(-\int_0^t P(\rho_{2n}(s))ds\right). \qquad (2.14)$$

Since $P(\rho) = A\rho^\gamma$, one gets from (2.14) that

$$\begin{aligned}
&\frac{d}{dt}\left(\frac{1}{\gamma}\exp\left(\gamma\int_0^t P(\rho_{2n}(s))ds\right)\right)\\
&=A\rho_{2n}^{\gamma}(0)\exp\left(\gamma\sum_{j-1}^{n}(u_{2j-1}(0)-u_{2j-1}(t))h\right).
\end{aligned}$$

Integrating this over $[0,t]$ yields

$$\begin{aligned}
&\exp\left(\gamma\int_0^t P(\rho_{2n}(s))ds\right)\\
&=1+A\gamma\rho_{2n}^{\gamma}(0)\int_0^t\exp\left(\gamma\sum_{j-1}^{n}(u_{2j-1}(0)-u_{2j-1}(s))h\right)ds.
\end{aligned}$$

This, together with (2.14), leads to

$$\begin{aligned}
&\rho_{2n}(t)\\
&=\rho_{2n}(0)\exp\left(\sum_{j=1}^{n}(u_{2j-1}(0)-u_{2j-1}(t))h\right)\\
&\cdot\left\{1+A\gamma\rho_{2n}^{\gamma}(0)\int_0^t\exp\left(\gamma\sum_{j=1}^{n}(u_{2j-1}(0)-u_{2j-1}(s))h\right)ds\right\}^{-1/\gamma}. \qquad (2.15)
\end{aligned}$$

Equation (2.12) immediately follows from (2.11) and (2.15) and the Cauchy inequality. □

The next two lemmas yield uniform estimates on the approximations to derivatives.

Lemma 2.4.

$$\sum_{n=1}^{N}\rho_{2n}(\frac{u_{2n+1}-u_{2n-1}}{h})^2(t)h+\int_0^t\sum_{n=1}^{N}\dot{u}_{2n-1}^2(s)hds\le C; \tag{2.16}$$

hereafter, $\dot{f}$ denotes $\frac{df}{dt}$ for any function f of t.

Proof. Set $A_n(t)=(\rho_{2n})^{1/2}(\frac{u_{2n+1}-u_{2n-1}}{h})(t)$ and $B_n(t)=(\rho_{2n})(\frac{u_{2n+1}-u_{2n-1}}{h})(t)$ for $0\le t<+\infty$, $n=1,2,\dots,N$. A direct calculation shows that

$$\begin{aligned}&\sum A_n^2(t)h+2\sum[P(\rho_{2n})(\rho_{2n}^{-1/2})](t)A_n(t)h+2\int_0^t\sum(\dot{u}_{2n-1}^2+P'(\rho_{2n})B_n^2)(s)hds\\&=\sum A_n^2(0)h+2\sum[P(\rho_{2n})(\rho_{2n}^{-1/2})](0)A_n(0)h-\int_0^t\sum B_n(s)A_n^2(s)hds.\end{aligned} \tag{2.17}$$

It is routine to get (cf. [12])

$$\sum A_n^2(t)h+\int_0^t\sum\dot{u}_{2n-1}^2hds\le C+\int_0^t\left(\sum A_n^2(s)h\right)^2ds. \tag{2.18}$$

Since $\int_0^t\sum A_n^2(s)hds\le C$ (cf. Lemma 2.2), (2.16) follows from Gronwall's inequality. □

Lemma 2.5.

$$\sum\left(\frac{\rho_{2n}^q-\rho_{2n-2}^q}{h}\right)^2(t)h\le C(T) \tag{2.19}$$

for $0\le t\le T$, where q is the constant in (A2′).

Proof. It follows from (2.8) that

$$\begin{aligned}&\left(\rho_{2n}^q\sum_{j=1}^{n}\dot{u}_{2j-1}-\rho_{2n-2}^q\sum_{j=1}^{n-1}\dot{u}_{2j-1}\right)+\frac{P(\rho_{2n})\rho_{2n}^q-P(\rho_{2n-2})\rho_{2n-2}^q}{h}\\&=-\frac{1}{q}\frac{d}{dt}\left(\frac{\rho_{2n}^q-\rho_{2n-2}^q}{h}\right).\end{aligned} \tag{2.20}$$

Set $D_n(t)=\frac{\rho_{2n}^q-\rho_{2n-2}^q}{h}(t)$ for $n=1,2,\dots,N$ and $0\le t<\infty$. Multiplying (2.20) by $\frac{\rho_{2n}^q-\rho_{2n-2}^q}{h}$, integrating the resulting equation over $[0,t]$, and summing the obtained equations from 1 to N, one can obtain

$$\frac{1}{2q}\sum D^2(t)h\le\frac{1}{2q}\sum D^2(0)h+\int_0^t\sum\left[\rho_{2n}^q\sum_{j=1}^{n}\dot{u}_{2j-1}-\rho_{2n-2}^q\sum_{j=1}^{n-1}\dot{u}_{2j-1}\right]D_n(s)hds. \tag{2.21}$$

The last term in (2.21) can be bounded by $C\int_0^t(\Sigma\dot{u}_{2n-1}^2h+1)\Sigma D_n^2(s)hds+C$ by summation by parts. Equation (2.19) follows then. □

The next lemma, which controls the expanding rate of interfaces and the total variation of velocity, can be deduced by the standard arguments (cf. [10], [11], [12], [13]). Then we omit the proof.

Lemma 2.6.

$$\begin{aligned} &c_3^{-1}\left\{\sum_{n=1}^{N-1}\rho_{2n}^{-1}(0)h+M^{-\gamma}\sum_{n=1}^{N-1}\rho_{2n}^{\gamma-1}(0)h[(1+c_4M^{\gamma}t)^{1/\gamma}-1]\right\}\\ &\leq\sum_{n=1}^{N-1}\rho_{2n}^{-1}(t)h\\ &\leq c_1^{-1}\left\{\sum_{n=1}^{N-1}\rho_{2n}^{-1}(0)h+c_2^{1/\gamma}t^{1/\gamma}\right\}, \end{aligned}\tag{2.22}$$

where $c_i(i=1,2,3,4)$ is the constant in (2.13), $M=\max_{[0,1]}\rho_0(y)$,

$$\sum_{n=1}^{N-1}|u_{2n+1}(t)-u_{2n-1}(t)|\leq C(1+t)^{1/\gamma},\tag{2.23}$$

$$\max_{1\leq n\leq N}|u_{2n-1}|\leq C(1+t)^{1/\gamma}\tag{2.24}$$

for $0\leq t<+\infty$.

To guarantee the convergence of the approximate solutions, we still need the higher order estimates and the Hölder continuous of $(\rho_{2n},u_{2n-1},\rho_{2n}\frac{u_{2n+1}-u_{2n-1}}{h})(t)$ with respect to t in $L^2[0,1]$-norm, which are given in the following two lemmas. The proof of these two lemmas is same as that in [12], based on the estimates we have obtained so far.

Lemma 2.7.

$$\sum\dot{u}_{2n-1}^2(t)h+\int_0^t\sum\rho_{2n}\left(\frac{\dot{u}_{2n+1}-\dot{u}_{2n-1}}{h}\right)^2hds\leq C,\tag{2.25}$$

$$\sum\frac{1}{h^2}\left(\rho_{2n}\frac{u_{2n+1}-u_{2n-1}}{h}-\rho_{2n-2}\frac{u_{2n-1}-u_{2n-3}}{h}\right)^2\cdot h\leq C(T),\tag{2.26}$$

$$\max_{1\leq n\leq N}\left|\rho_{2n}\frac{u_{2n+1}-u_{2n-1}}{h}\right|\leq C(T).\tag{2.27}$$

Lemma 2.8. *For any $t,\ s\in[0,T]$, $T>0$, it holds*

$$\sum|\rho_{2n}(t)-\rho_{2n}(s)|^2h\leq C|t-s|,\tag{2.28}$$

$$\sum\||u_{2n-1}(t)-u_{2n-1}(s)|^2h\leq C|t-s|,\tag{2.29}$$

$$\begin{aligned} &\sum\left|\rho_{2n}(t)\frac{u_{2n+1}(t)-u_{2n-1}(t)}{h}-\rho_{2n}(s)\frac{u_{2n+1}(s)-u_{2n-1}(s)}{h}\right|^2h\\ &\leq C|t-s|. \end{aligned}\tag{2.30}$$

With the desired estimates Lemmas 2.2–2.8 at hand, we are now in the position to prove Theorem 2.1 (cf. [8]). Define

$$\begin{aligned} \rho_h(t,y) &= \rho_{2n}(t), \\ u_h(t,y) &= \frac{[y-(n-\frac{1}{2})h]u_{2n+1} + [(n+\frac{1}{2})h - y]u_{2n-1}(t)}{h} \end{aligned}$$

for $(n-1/2)h < y < (n+1/2)h$. Then

$$\rho_h(u_h)_y(t,y) = \rho_{2n}(t)\frac{u_{2n+1}-u_{2n-1}}{h}.$$

Our main convergence result can be stated as follows.

THEOREM 2.9. *Suppose* ($A1'$)–($A3'$) *and* (2.1) *hold. There exist a subsequence of* $\{(\rho_h, u_h)\}$ *and* $\{\rho_h(u_h)_y\}$, *still labeled by* $\{(\rho_h, u_h)\}$ *and* $\{\rho_h(u_h)_y\}$ *for convenience, such that* $\{(\rho_h, u_h)\}$ *and* $\{\rho_h(u_h)_y\}$ *converge boundedly and almost everywhere on* $[0,T]\times[0,1]$ *for any* $T > 0$.

Proof. From our estimates, we know the functions (ρ_h^q, u_h) and $(\rho_h(u_h)_y)$, as the functions of y, have uniformly bounded total variations with respect to h for any fixed t. Let $t = t_m$ ($m = 1, 2, \ldots$) be a countable set which is everywhere dense on the segment $[0,T]$. By Helly's theorem and a diagonal process, from the family of the functions $\{(\rho_h, u_h)\}$ and $\{(\rho_h(u_h)_y\}$ one can select a sequence converging boundedly and almost everywhere in $y \in [0,1]$ on the dense set $t = t_m$ ($m = 1, 2, \ldots$) in $[0,T]$. Consequently, by Lebesgue's theorem, the subsequence also converges in L^2-norm on $t = t_m$ ($m = 1, 2, \ldots, N$). Next, with the help of Lemma 2.8, it is standard to show (ρ_h, u_h), $\rho_h(u_h)_y$ converge in $L^2[0,1]$ uniformly in $t \in [0,T]$. Then we can select a subsequence converge almost everywhere in $(y,t) \in [0,1]\times[0,T]$. □

Denote the limiting functions of $\{(\rho_h, u_h)\}$ and $\{\rho_h(u_h)_y\}$ by $(\rho, u)(y,t)$ and $\rho u_y(y,t)$, respectively. Then it is easy to verify (see [8]) that $(\rho, u)(y,t)$ is the weak solution of (2.1) and (2.2). The solution satisfies the corresponding limit version of the estimates in Lemmas 2.2–2.8. Part (3) in Theorem 2.1 is the limit version of (2.13) and the following equality:

$$\sum u_{2n-1}(t)h = \sum u_{2n-1}(0)h, \qquad 0 \le t \le \infty, \tag{2.31}$$

which is a consequence of $(2.8)_2$ and the boundary condition (2.9). This completes the proof of Theorem 2.1, which, in turn, proves Theorem 1.2.

3. Smoothness of the solution. In this section, we study the smoothness of the solutions constructed in section 2 and prove Theorem 1.5. At first, we have the following L^2-estimate of $\rho^{\beta/2}\rho_{yy}$, which is crucial to the improvement of regularity of the solution.

LEMMA 3.1. *Let* (ρ, u) *be the solution to* (2.1) *and* (2.2) *constructed in section* 2. *If the initial data satisfy*

$$\int_0^1 \rho^\beta \rho_{yy}^2(y,0)dy \le C \tag{3.1}$$

for $\beta \ge 4q-2$ *(*q *is the constant in* (A2$'$)*), then*

$$\int_0^1 \rho^\beta \rho_{yy}^2(y,t)dy \le C(T) \tag{3.2}$$

for $0 \le t \le T$.

Proof. For simplicity of presentation, we will only give the a priori estimate (3.2) for smooth solutions. The general version of Lemma 3.1 can be verified by a discrete analogue as in section 2.

At first, it follows from (2.1) that

$$\rho_{ty} = -\rho\rho_y u_y - \rho u_t - \rho P(\rho)_y.$$

Differentiating the above equation with respect to y, we get

$$\rho_{tyy} + \gamma A\rho^\gamma \rho_{yy} = -\rho_{yy}\rho u_y - \rho_y(u_t + (\rho u_y)_y) - \rho u_{ty} - \gamma^2 A\rho^{\gamma-1}\rho_y^2. \tag{3.3}$$

For the resulting equation by multiplying (3.3) by $\rho^\beta\rho_{yy}$, then integrating it over $[0,1]\times[0,t]$, we estimate each term on the right-hand side as follows.

First, (2.6) implies

$$\left|\int_0^t\int_0^1 \rho^\beta\rho_{yy}^2\rho u_y dyds\right| \le C(T)\int_0^t\int_0^1 \rho^\beta\rho_{yy}^2 dyds. \tag{3.4}$$

Next, it follows from (2.5) that

$$\begin{aligned}&\left|\int_0^t\int_0^1 \rho^\beta\rho_{yy}\rho_y(u_t + (\rho u_y)_y)dyds\right|\\ &\le \int_0^t\int_0^1 \rho^\beta\rho_{yy}^2 + \int_0^t \max\nolimits_{[0,1]}\rho^\beta\rho_y^2\int_0^1(u_t^2 + (\rho u_y)_y^2)ds\\ &\le \int_0^t\int_0^1 \rho^\beta\rho_{yy}^2 dyds + C(T)\int_0^t \max\nolimits_{[0,1]}\rho^\beta\rho_y^2 ds,\end{aligned} \tag{3.5}$$

and

$$\begin{aligned}&\left|\int_0^t\int_0^1 \rho^\beta\rho_{yy}\rho u_{ty}dyds\right|\\ &\le \int_0^t\int_0^1 \rho^\beta\rho_{yy}^2 dyds + C\int_0^t\int_0^1 \rho^{2+\beta}u_{ty}^2 dyds\\ &\le \int_0^t\int_0^1 \rho^\beta\rho_{yy}^2 dyds + C,\end{aligned} \tag{3.6}$$

due to the fact that $2+\beta \ge 4q \ge 2$.

Finally, one has

$$\begin{aligned}&\left|\int_0^t\int_0^1 A\rho^{\gamma-1}\rho_y^2\rho^\beta\rho_{yy}dyds\right|\\ &\le \int_0^t\int_0^1 \rho^\beta\rho_{yy}^2 dyds + \int_0^t\int_0^1 \rho^{2\gamma-2+\beta}\rho_y^4 dyds.\end{aligned} \tag{3.7}$$

Collecting estimates (3.4)–(3.7) yields

$$\begin{aligned}&\int_0^1 \rho^\beta\rho_{yy}^2(y,t)dy + \int_0^t\int_0^1 \rho^{\beta+\gamma}\rho_{yy}^2 dyds\\ &\le C(T)\int_0^t\int_0^1 \rho^\beta\rho_{yy}^2 dyds + C\int_0^t \max\nolimits_{[0,1]}\rho^\beta\rho_y^2 ds + \int_0^t\int_0^1 \rho^{2\gamma-2+\beta}\rho_y^4 dyds.\end{aligned} \tag{3.8}$$

The last two terms in (3.8) can be estimated as follows. First,

$$
\begin{aligned}
\max_{[0,1]}|\rho^{\beta/2}\rho_y| &\leq \int_0^1 |\rho^{\beta/2}\rho_y|dy + \int_0^1 |(\rho^{\beta/2}\rho_y)_y|dy \\
&\leq \left(\int_0^1 \rho^{\beta}\rho_y^2 dy\right)^{1/2} + C\int_0^1 \rho^{\frac{\beta}{2}-1}\rho_y^2 dy + \int_0^1 |\rho^{\beta/2}\rho_{yy}|dy. \qquad (3.9)
\end{aligned}
$$

Thus , if $\frac{\beta}{2}-1 \geq 2q-2$, i.e., $\beta \geq 4q-2$, then we get

$$
\max_{[0,1]}\rho^{\beta}\rho_y^2 \leq \int_0^1 \rho^{\beta}\rho_{yy}^2 dy + C(T). \qquad (3.10)
$$

We now turn to the last term in (3.8). In view of (2.6),

$$
\begin{aligned}
&\int_0^t\int_0^1 \rho^{2\gamma-2+\beta}\rho_y^4 dyds \\
&\leq \int_0^t \max_{[0,1]}\rho^{2\gamma+\beta-2q}\rho_y^2 \int_0^1 \rho^{2q-2}\rho_y^2 dyds \\
&\leq C(T)\int_0^t \max_{[0,1]}\rho^{2\gamma+\beta-2q}\rho_y^2 ds. \qquad (3.11)
\end{aligned}
$$

Since $2\gamma \geq 2q$, (3.10) and (3.11) imply

$$
\int_0^t\int_0^1 \rho^{2\gamma-2+\beta}\rho_y^4 dyds \leq C(T)\int_0^t\int_0^1 \rho^{\beta}\rho_{yy}^2 dyds + C(T). \qquad (3.12)
$$

It follows that

$$
\int_0^1 \rho^{\beta}\rho_{yy}^2(y,t)dy \leq C(T)\int_0^t\int_0^1 \rho^{\beta}\rho_{yy}^2(y,s)dyds + C(T).
$$

This, together with Gronwall's inequality, leads to the desired estimates. □

In the next lemma, we show that the assumption in Lemma 3.1 is true when the initial data satisfy some requirement in Eulerian coordinates.

LEMMA 3.2. *If* $\beta \geq \max\{2k+3+\alpha, 6k+1\}$, *then* $\int_0^1 \rho_0^{\beta}\rho_{0yy}^2(y)dy \leq C$ *provided* (A1) *holds and* $\int_a^b \rho_0^{\alpha}\rho_{0xx}^2(x)dx \leq C$.

Proof. It is easy to check the following relation between Eulerian coordinates and Lagrangian coordinates:

$$
\rho_{yy} = \rho^{-2}\rho_{xx} - \rho^{-3}\rho_x^2. \qquad (3.13)
$$

Thus

$$
\int_0^1 \rho_0^{\beta}\rho_{0yy}^2(y)dy \leq C\int_a^b (\rho_0^{\beta-3}\rho_{0xx}^2 + \rho_0^{\beta-5}\rho_{0x}^4)(x)dx. \qquad (3.14)
$$

On the other hand, (A2) implies

$$
\int_a^b \rho_0^{\beta-5}\rho_{0x}^4(x)dx \leq \max_{[a,b]}\rho_0^{\beta-2k-3}\rho_{0x}^2 \int_a^b \rho_0^{2k-2}\rho_{0x}^2(x)dx \leq C\max_{[a,b]}\rho_0^{\beta-2k-3}\rho_{0x}^2. \qquad (3.15)
$$

Using Sobolev's lemma and (A2), we obtain

$$\begin{aligned}
&\max_{[a,b]} |\rho_0^{\frac{\beta-2k-3}{2}} \rho_{0x}| \\
&\le C \int_a^b \left\{ \left| \rho_0^{\frac{\beta-2k-3}{2}} \rho_{0x} \right| + \rho_0^{\frac{\beta-2k-5}{2}} \rho_{0x}^2 + \left| \rho_0^{\frac{\beta-2k-3}{2}} \rho_{0xx} \right| \right\} dx \\
&\le C \int_a^b \left\{ \left| \rho_0^{\beta-2k-3} \rho_{0x}^2 \right| + \rho_0^{\frac{\beta-2k-5}{2}} \rho_{0x}^2 + \rho_0^{\beta-2k-3} \rho_{oxx}^2 dx \right\} dx + C. \qquad (3.16)
\end{aligned}$$

Lemma 3.2 follows from (3.14)–(3.16). □

We claim that the desired L^2-estimate of $\rho^{\alpha_1/2}\rho_{xx}$ in Eulerian coordinate can be bounded by the obtained estimate in Lagrangian coordinate by the following lemma.

LEMMA 3.3. *Let* (ρ, u) *be the solution stated in Theorem* 1.2 *to the free boundary problem* (1.4). *Then we have, for* $0 \le t \le T$,

$$\int_{a(t)}^{b(t)} \rho^{\alpha_1} \rho_{xx}^2(x,t) dx \le C(T) \left(\int_0^1 \rho^\beta \rho_{yy}^2(y,t) dy \right)^2 + C(T), \qquad (3.17)$$

if $\alpha_1 \ge \max\{\beta + 2k - 3, 6k - 2\}$.

Proof. It follows from (3.13) that

$$\begin{aligned}
&\int_{a(t)}^{b(t)} \rho^{\alpha_1} \rho_{xx}^2(x,t) dx \\
&= \int_0^1 \rho^{-1+\alpha_1} (\rho \rho_y^2 + \rho^2 \rho_{yy})^2 (y,t) dy \\
&\le C \int_0^1 (\rho^{1+\alpha_1} \rho_y^4 + \rho^{3+\alpha_1} \rho_{yy}^2)(y,t) dy. \qquad (3.18)
\end{aligned}$$

On the other hand, (2.6) implies

$$\int_0^1 \rho^{1+\alpha_1} \rho_y^4 dy \le \max_{[0,1]} \rho^{3-2q+\alpha_1} \rho_y^2 \int_0^1 \rho^{2q-2} \rho_y^2 dy \le C(T) \max_{[0,1]} \rho^{3-2q+\alpha_1} \rho_y^2, \qquad (3.19)$$

where $q = k + 1/2$.

Using Sobolev's lemma, (2.6), and the Cauchy inequality, we get

$$\begin{aligned}
&\max_{[0,1]} |\rho^{\frac{3-2q+\alpha_1}{2}} \rho_y| \\
&\le C \int_0^1 \left\{ \left| \rho^{\frac{3-2q+\alpha_1}{2}} \rho_y \right| + \rho^{\frac{1-2q+\alpha_1}{2}} \rho_y^2 + \left| \rho^{\frac{3-2q+\alpha_1}{2}} \rho_{yy} \right| \right\} dy \\
&\le C \int_0^1 (\rho^{4-2q+\alpha_1} \rho_y^2 + \rho^{4-2q+\alpha_1} \rho_{yy}^2) dy \\
&+ C \int_0^1 \rho^{-1} dy + C \int_0^1 \rho^{\frac{1-2q+\alpha_1}{2}} \rho_y^2 dy. \qquad (3.20)
\end{aligned}$$

Lemma 3.3 follows from (3.18)–(3.20). □

We now complete the proof of Theorem 1.5. To prove part (1) in Theorem 1.5, we only need to show the Hölder continuities described there. In fact, $(1.1)_2$ is uniformly parabolic with respect to u in the region $\{(x,t), a(t)+\delta \le x \le b(t)-\delta, 0 < t \le T\}$ for any $\delta > 0$ and $T > 0$ because $\rho > 0$ in that region. Thus, the standard parabolic theory (see [7] for instance) and the regularity of ρ and u which we have obtained imply the Hölder continuities indicated in part (1) of Theorem 1.5. Part (2) in Theorem 1.5 is the consequence of part (1), (1.11), and (1.13).

4. Uniqueness theorem. This section is devoted to the proof of Theorem 1.6. For this purpose, we prove the following Theorem 4.1 first. Theorem 1.6 follows from this theorem immediately.

Theorem 4.1. *Let* $(\rho_1, u_1)(y,t)$ *and* $(\rho_2, u_2)(y,t)$ *be two weak solutions to* (2.1) *and* (2.2) *in* $[0,1]\times[0,T]$ *with the properties corresponding to Definition* 1.1. *Then* $(\rho_1, u_1) = (\rho_2, u_2)$ *in* $[0,1]\times[0,T]$.

It should be noted that Theorem 4.1 particularly implies the following theorem.

Theorem 4.2. *The whole sequence of the approximate solutions* $\{(\rho_h, u_h)\}$ *constructed in section* 2 *converges as* $h \to 0$.

Proof of Theorem 4.1. Let (ρ_1, u_1) and (ρ_2, u_2) be the solutions stated in Theorem 4.1. We let

$$\varphi(y,t) = (\rho_1-\rho_2)(y,t),\ \psi(y,t) = \int_0^y (u_1-u_2)(z,t)dz \tag{4.1}$$

for $0 \le y \le 1$ and $0 \le t \le T$.

In the following, we may assume that (ρ_1, u_1) and (ρ_2, u_2) are suitably smooth since the following estimates are valid for the solutions with the regularity indicated in Theorem 2.1 by using the Friedrichs mollifier. In view of part (3) in Theorem 2.1 and the boundary condition $(2.2)_2$, we have

$$\varphi(0,t) = \varphi(1,t) = 0, \psi(0,t) = \psi(1,t) = 0 \tag{4.2}$$

for $0 \le t \le T$.

It follows from (2.1) and part (3) in Theorem 2.1 that

$$\begin{aligned} &\left(\frac{\varphi}{\rho_1\rho_2}\right)_t + \psi_{yy} = 0,\\ &\psi_t + (P(\rho_1)-P(\rho_2)) = \rho_1\psi_{yy} + \varphi u_{2y}. \end{aligned} \tag{4.3}$$

Multiplying $(4.3)_1$ by $\rho_2^{-1}\varphi$ and $(4.3)_2$ by $\rho_1^{-1}\psi$, and using the equations for (ρ_1, u_1) and (ρ_2, u_2), we get

$$\begin{aligned} &\left(\frac{1}{2}\rho_1^{-1}\psi^2\right)_t + \psi_y^2\\ &= \rho_1^{-1}\psi\varphi u_{2y} - \frac{1}{2}\psi^2 u_{1y} - (P(\rho_1)-P(\rho_2))\rho_1^{-1}\psi, \end{aligned} \tag{4.4}$$

$$\left(\frac{1}{2}\rho_1^{-1}\rho_2^{-2}\varphi^2\right)_t + \frac{1}{2}\rho_2^{-2}\varphi^2 u_{1y} + \rho_2^{-1}\varphi\psi_{yy} = 0. \tag{4.5}$$

We multiply $(4.3)_2$ by ψ_{yy} to get

$$\left(\frac{1}{2}\psi_y\right)^2 + \rho_1\psi_{yy}^2 = (P(\rho_1)-P(\rho_2))\psi_{yy} + \varphi u_{2y}\psi_{yy} + (\psi_t\psi_y)_y. \tag{4.6}$$

Integrating (4.4)–(4.6) over $[0,1]\times[0,t]$, using the boundary condition (4.2), and noting the regularity near the boundary for (ρ_1,u_1) and (ρ_2,u_2), we get, by virtue of the Cauchy inequality and (2.4)–(2.7), that

$$\begin{aligned}
&\frac{d}{dt}\int_0^1 \rho_1^{-1}\psi^2 dy+\int_0^1 \psi_y^2(y,t)dy\\
&\le C\left[\int_0^1 \rho_1^{-1}\psi^2(y,t)dy+\int_0^1 \rho_1^{-1}\rho_2^{-2}\varphi^2(\rho_2u_{2y})^2(y,t)dy\right]\\
&+C\left[\int_0^1 \rho_1^{-1}\psi^2|\rho_1u_{1y}|(y,t)dy+\int_0^1 \rho_1^{-1}\varphi^2(y,t)dy\right]\\
&\le C(T)\left[\int_0^1 \rho_1^{-1}\psi^2(y,t)dy+\int_0^1 \rho_1^{-1}\rho_2^{-2}\varphi^2(y,t)dy\right],
\end{aligned}\tag{4.7}$$

$$\begin{aligned}
&\frac{d}{dt}\int_0^1 \rho_1^{-1}\rho_2^{-2}\varphi^2(y,t)dy\\
&\le C\int_0^1 \rho_1^{-1}\rho_2^{-2}\varphi^2|\rho_1u_{1y}|(y,t)dy+\frac{1}{4}\int_0^1 \rho_1\psi_{yy}^2(y,t)dy+C\int_0^1 \rho_1^{-1}\rho_2^{-2}\varphi^2(y,t)dy\\
&\le C(T)\int_0^1 \rho_1^{-1}\rho_2^{-2}\varphi^2(y,t)dy+\frac{1}{4}\int_0^1 \rho_1\psi_{yy}^2(y,t)dy,
\end{aligned}\tag{4.8}$$

and

$$\begin{aligned}
&\frac{d}{dt}\int_0^1 \frac{1}{2}\psi_y^2dy+\int_0^1 \rho_1\psi_{yy}^2(y,t)dy\\
&\le \frac{1}{4}\int_0^1 \rho_1\psi_{yy}^2(y,t)dy+C\int_0^1 \rho_1^{-1}\rho_2^{-2}\varphi^2(y,t)dy+C\int_0^1 \rho_1^{-1}\rho_2^{-2}\varphi^2(\rho_2u_{2y})^2(y,t)dy\\
&\le \frac{1}{4}\int_0^1 \rho_1\psi_{yy}^2(y,t)dy+C(T)\int_0^1 \rho_1^{-1}\rho_2^{-2}\varphi^2(y,t)dy
\end{aligned}\tag{4.9}$$

for $0\le t\le T$. Therefore,

$$\begin{aligned}
&\frac{d}{dt}\int_0^1 (\rho_1^{-1}\psi^2+\rho_1^{-1}\rho_2^{-2}\varphi^2+\psi_y^2)(y,t)dy\\
&+\int_0^1 (\psi_y^2+\rho_1\psi_{yy}^2)(y,t)dy\\
&\le C(T)\int_0^1 (\rho_1^{-1}\psi^2+\rho_1^{-1}\rho_2^{-2}\varphi^2)(y,t)dy
\end{aligned}\tag{4.10}$$

for $0\le t\le T$. Integrating (4.10) with respect to t, we get

$$\begin{aligned}
&\int_0^1 (\rho_1^{-1}\psi^2+\rho_1^{-1}\rho_2^{-2}\varphi^2)(y,t)dy\\
&\le C(T)\int_0^t\int_0^1 (\rho_1^{-1}\psi^2+\rho_1^{-1}\rho_2^{-2}\varphi^2)(y,s)dys.
\end{aligned}\tag{4.11}$$

Theorem 4.1 follows from (4.11) by applying Gronwall's inequality.

Theorem 4.2 is an immediate consequence of Theorem 4.1.

GROUP ANALYSIS OF DIFFERENTIAL EQUATIONS AND GENERALIZED FUNCTIONS[*]

MICHAEL KUNZINGER[†] AND MICHAEL OBERGUGGENBERGER[‡]

Abstract. We present an extension of the methods of classical Lie group analysis of differential equations to equations involving generalized functions (in particular: distributions). A suitable framework for such a generalization is provided by Colombeau's theory of algebras of generalized functions. We show that under some mild conditions on the differential equations, symmetries of classical solutions remain symmetries for generalized solutions. Moreover, we introduce a generalization of the infinitesimal methods of group analysis that allows us to compute symmetries of linear and nonlinear differential equations containing generalized function terms. Thereby, the group generators and group actions may be given by generalized functions themselves.

Key words. algebras of generalized functions, Lie symmetries of differential equations, group analysis, delta waves, Colombeau algebras

1. Introduction.

Symmetry properties of distributions and group invariant distributional solutions (in particular: fundamental solutions) to particular types of linear differential operators have been studied by Methée [22], Tengstrand [36], Szmydt and Ziemian [33], [34], [35], [38]. A systematic investigation of the transfer of classical group analysis of differential equations into a distributional setting is due to Berest and Ibragimov [2], [3], [4], [5], [18], again with a view to determining fundamental solutions of certain linear partial differential equations. A survey of the lastnamed studies including a comprehensive bibliography can be found in the third volume of [19]. As these approaches use methods from classical distribution theory, their range is confined to linear equations and linear transformations of the dependent variables.

Algebras of generalized functions offer the possibility of going beyond these limitations towards a generalization of group analysis to genuinely nonlinear problems involving singular terms, like distributions or discontinuous nonlinearities. In the present paper we develop a theory of group analysis of differential equations in algebras of generalized functions that allows a satisfactory treatment of such problems. This line of research has been initiated in [28] and has been taken up in [21]. Applications to different types of algebras of generalized functions can be found in [30] and [31].

The plan of the paper is as follows. Section 2 provides a short introduction to the theory of algebras of generalized functions in the sense of Colombeau. In section 3 we consider systems of partial differential equations together with a classical symmetry group G that transforms smooth solutions into smooth solutions. Assuming polynomial bounds on the action of G, we can extend it to generalized functions belonging to Colombeau algebras and ask whether G remains a symmetry group for generalized solutions. In section 3.1 we develop methods based on a factorization

property of the transformed system of equations. Essentially, polynomial bounds on the factors suffice to give a positive answer. In the scalar case we show this to be automatically satisfied whenever the equation contains at least one of the derivatives of the solution as an isolated term. While the conditions of section 3.1 concern some mild assumptions on the algebraic structure of the equations, section 3.2 develops a topological criterion, applicable to systems of linear equations: the existence of a $\mathcal{C}^\infty$-continuous homogeneous right inverse guarantees a positive answer as well. Along the way we give examples of nonlinear symmetry transformations of shock and delta wave solutions to linear and nonlinear systems.

The purpose of section 4 is to develop the general theory, allowing the equations and the group action (hence also its generators) to be given by generalized functions. Using the characterization of Colombeau generalized functions by their generalized pointvalues established in [27] as well as results on Colombeau solutions to ordinary differential equations (ODEs), we show that the classical procedure for computing symmetries can literally be transferred to the generalized function situation. The defining equations are derived as usual, but their solutions are sought in generalized functions. This enlarges the reservoir of possible symmetries of classical equations and allows the study of symmetries of equations with singular terms. An example is provided by a conservation law with nondifferentiable flux function.

The remainder of the introduction is devoted to fixing notations and recalling some basic definitions from group analysis of differential equations. We basically follow the notations and terminology of [29]. Thus for the action of a Lie group G on some manifold M, assumed to be an open subset of some space $\mathcal{X} \times \mathcal{U}$ of independent and dependent variables (with $\dim(\mathcal{X}) = p$ and $\dim(\mathcal{U}) = q$), we write $g \cdot (x, u) = (\Xi_g(x, u), \Phi_g(x, u))$. Transformation groups are always supposed to act regularly on M. If Ξ_g does not depend on u, the group action is called projectable. Elements of the Lie algebra $\mathfrak{g}$ of G as well as the corresponding vector fields on M will typically be denoted by $\mathbf{v}$ and the one-parameter subgroup generated by $\mathbf{v}$ by $\eta \to \exp(\eta\mathbf{v})$. $M^{(n)}$ denotes the n-jet space of M; the nth prolongation of a group action g or vector field $\mathbf{v}$ is written as $\mathrm{pr}^{(n)}g$ or $\mathrm{pr}^{(n)}\mathbf{v}$, respectively. Any system S of nth order differential equations in p dependent and q independent variables can be written in the form

$$\Delta_\nu(x, u^{(n)}) = 0, \qquad 1 \le \nu \le l,$$

where the map

$$\begin{gathered}\Delta : \mathcal{X} \times \mathcal{U}^{(n)} \to \mathbb{R}^l, \\ (x, u^{(n)}) \to (\Delta_1(x, u^{(n)}), \dots, \Delta_l(x, u^{(n)}))\end{gathered}$$

is supposed to be smooth. Hence S is identified with the subvariety

$$S_\Delta = \{(x, u^{(n)}) : \Delta(x, u^{(n)}) = 0\}$$

of $\mathcal{X} \times \mathcal{U}^{(n)}$. For any $f : \Omega \subseteq \mathcal{X} \to \mathcal{U}$, Γ_f is the graph of f and $\Gamma_f^{(n)} := \{(x, \mathrm{pr}^{(n)} f(x)) : x \in \Omega\}$ is the graph of the n-jet of f.

2. Colombeau algebras. Already at a very early stage of development of the theory of distributions it became clear that it is impossible to embed the space $\mathcal{D}'(\Omega)$ of distributions over some open subset Ω of $\mathbb{R}^n$ into an associative, commutative algebra $(\mathcal{A}(\Omega), +, \circ)$ satisfying

(i) $\mathcal{D}'(\Omega)$ is linearly embedded into $\mathcal{A}(\Omega)$ and $f(x) \equiv 1$ is the unity in $\mathcal{A}(\Omega)$.

(ii) There exist derivation operators $\partial_i : \mathcal{A}(\Omega) \to \mathcal{A}(\Omega)$ $(i = 1, \dots, n)$ that are linear and satisfy the Leibnitz rule.

(iii) $\partial_i|_{\mathcal{D}'(\Omega)}$ is the usual partial derivative $(i = 1, \dots, n)$.

(iv) $\circ|_{\mathcal{C}(\Omega)\times\mathcal{C}(\Omega)}$ coincides with the pointwise product of functions.

This is the well-known impossibility result of Schwartz [32]. Replacing $\mathcal{C}(\Omega)$ by $\mathcal{C}^{(k)}(\Omega)$ does not alter this result. On the other hand, many problems involving differentiation and nonlinearities in the presence of singular objects require a method of coping with this situation in a consistent manner (cf., e.g., [24], [26], [37]). By the above, the best possible result would consist in constructing an algebra $\mathcal{A}(\Omega)$ satisfying (i)–(iii) and

(iv′) $\circ|_{\mathcal{C}^\infty(\Omega)\times\mathcal{C}^\infty(\Omega)}$ coincides with the pointwise product of functions.

The actual construction of algebras enjoying these optimal properties is due to Colombeau [8], [9] (see also [1], [24]). The basic idea underlying his theory (in its simplest—the so-called special—form) is that of embedding the space of distributions into a factor algebra of $\mathcal{C}^\infty(\Omega)^I$ $(I = (0, 1])$ via regularization by convolution with a fixed "mollifier" $\rho \in \mathcal{S}(\mathbb{R}^n)$ with $\int \rho(x)\,dx = 1$. In order to motivate the definition below let $\rho_\varepsilon(x) := \varepsilon^{-n}\rho(\frac{x}{\varepsilon})$ and let $u \in \mathcal{E}'(\mathbb{R}^n)$ (the space of compactly supported distributions on $\mathbb{R}^n$). The sequence $(u * \rho_\varepsilon)_{\varepsilon\in I}$ converges to u in $\mathcal{D}'(\mathbb{R}^n)$. Taking this sequence as a representative of u we obtain an embedding of $\mathcal{D}'(\mathbb{R}^n)$ into the algebra $\mathcal{C}^\infty(\mathbb{R})^I$. However, embedding $\mathcal{C}^\infty(\mathbb{R}^n) \subseteq \mathcal{D}'(\mathbb{R}^n)$ into this algebra via convolution as above will not yield a subalgebra since of course $(f * \rho_\varepsilon)(g * \rho_\varepsilon) \neq (fg) * \rho_\varepsilon$ in general. The idea, therefore, is to factor out an ideal $\mathcal{N}(\mathbb{R}^n)$ such that this difference vanishes in the resulting quotient. In order to construct $\mathcal{N}(\mathbb{R}^n)$ it is obviously sufficient to find an ideal containing all differences $(f*\rho_\varepsilon)_{\varepsilon\in I} - (f)_{\varepsilon\in I}$. Taylor expansion of $f*\rho_\varepsilon - f$ shows that this term will vanish faster than any power of ε (uniformly on compact sets, in all derivatives), provided we additionally suppose that $\int \rho(x)x^\alpha\,dx = 0\,\forall\,\alpha \in \mathbb{N}_0^n$ with $|\alpha| \geq 1$. The set of all such sequences is not an ideal in $\mathcal{C}^\infty(\mathbb{R}^n)^I$, so we shall replace $\mathcal{C}^\infty(\mathbb{R}^n)^I$ by the set of *moderate* sequences $\mathcal{E}_M(\mathbb{R}^n)$ whose every derivative is bounded uniformly on compact sets by some inverse power of ε.

Thus we define the Colombeau algebra $\mathcal{G}(\Omega)$ as the quotient algebra $\mathcal{E}_M(\Omega)/\mathcal{N}(\Omega)$, where

$$\begin{aligned}\mathcal{E}_M(\Omega) := \{&(u_\varepsilon)_{\varepsilon\in I} \in \mathcal{C}^\infty(\Omega)^I : \forall K \subset\subset \Omega\ \forall \alpha \in \mathbb{N}_o^n\ \exists p \in \mathbb{N} \text{ with}\\ &\sup_{x\in K} |\partial^\alpha u_\varepsilon(x)| = O(\varepsilon^{-p}) \text{ as } \varepsilon \to 0\},\\ \mathcal{N}(\Omega) := \{&(u_\varepsilon)_{\varepsilon\in I} \in \mathcal{C}^\infty(\Omega)^I : \forall K \subset\subset \Omega\ \forall \alpha \in \mathbb{N}_o^n\ \forall q \in \mathbb{N},\\ &\sup_{x\in K} |\partial^\alpha u_\varepsilon(x)| = O(\varepsilon^{q}) \text{ as } \varepsilon \to 0\}.\end{aligned}$$

Equivalence classes of sequences $(u_\varepsilon)_{\varepsilon\in I}$ in $\mathcal{G}(\Omega)$ will be denoted by $\mathrm{cl}[(u_\varepsilon)_{\varepsilon\in I}]$. $\mathcal{G}(\Omega)$ is a differential algebra containing $\mathcal{E}'(\Omega)$ as a linear subspace via the embedding $\iota : u \to \mathrm{cl}[(u * \rho_\varepsilon)_{\varepsilon\in I}]$ depending on a mollifier $\rho \in \mathcal{S}(\mathbb{R}^n)$ as above. ι commutes with partial derivatives and coincides with $u \to \mathrm{cl}[(u)_{\varepsilon\in I}]$ on $\mathcal{D}(\Omega)$, thus rendering it a faithful subalgebra of $\mathcal{G}(\Omega)$. The functor $\Omega \to \mathcal{G}(\Omega)$ is a fine sheaf of differential algebras on $\mathbb{R}^n$ and there is a unique sheaf morphism $\hat{\iota}$ extending the above embedding to $\mathcal{C}^\infty(\,.\,) \hookrightarrow \mathcal{D}'(\,.\,) \hookrightarrow \mathcal{G}(\,.\,)$. $\hat{\iota}$ commutes with partial derivatives, and its restriction to $\mathcal{C}^\infty$ is a sheaf morphism of algebras.

We shall also consider the algebra $\mathcal{G}_\tau(\Omega) = \mathcal{E}_\tau(\Omega)/\mathcal{N}_\tau(\Omega)$ of tempered generalized functions, where

$$\mathcal{O}_M(\Omega) = \{f \in \mathcal{C}^\infty(\Omega) : \forall \alpha \in \mathbb{N}_o^n\ \exists p > 0\ \sup_{x\in\Omega}(1 + |x|)^{-p}|\partial^\alpha f(x)| < \infty\},$$

$$\begin{aligned}\mathcal{E}_\tau(\Omega) = \{&(u_\varepsilon)_{\varepsilon\in I} \in (\mathcal{O}_M(\Omega))^I : \forall\alpha \in \mathbb{N}_o^n\ \exists p > 0,\\ &\sup_{x\in\Omega}(1+|x|)^{-p}|\partial^\alpha u_\varepsilon(x)| = O(\varepsilon^{-p})\ (\varepsilon \to 0)\},\\ \mathcal{N}_\tau(\Omega) = \{&(u_\varepsilon)_{\varepsilon\in I} \in (\mathcal{O}_M(\Omega))^I : \forall\alpha \in \mathbb{N}_o^n\ \exists p > 0\ \forall\ q > 0,\\ &\sup_{x\in\Omega}(1+|x|)^{-p}|\partial^\alpha u_\varepsilon(x)| = O(\varepsilon^{q})\ (\varepsilon \to 0)\}.\end{aligned}$$

The map ι defined above is a linear embedding of $\mathcal{S}'(\mathbb{R}^n)$ into $\mathcal{G}_\tau(\mathbb{R}^n)$ commuting with partial derivatives and making

$$\mathcal{O}_C(\mathbb{R}^n) = \{f \in \mathcal{C}^\infty(\mathbb{R}^n) : \exists p > 0\ \forall\alpha \in \mathbb{N}_o^n\ \sup_{x\in\mathbb{R}^n}(1+|x|)^{-p}|\partial^\alpha f(x)| < \infty\}$$

a faithful subalgebra. Elements of $\mathcal{O}_M(\Omega)$ are called *slowly increasing*. Componentwise insertion of elements of $\mathcal{G}$ into slowly increasing functions yields well-defined elements of $\mathcal{G}$. Thus, in $\mathcal{G}$ not only polynomial combinations of distributions (e.g., δ^2) make sense but also expressions like $\sin(\delta)$ have a well-defined meaning. The importance of $\mathcal{G}_\tau(\Omega)$ for our purposes stems from the fact that elements of this algebra can even be composed with each other (again by componentwise insertion, cf. [16], [20]), a necessary prerequisite for generalizing symmetry methods; see section 4. Especially in the theory of ODEs in the generalized function context it is often useful to consider the algebra $\widetilde{\mathcal{G}}_\tau(\Omega \times \Omega')$ whose elements satisfy $\mathcal{G}$-bounds in the Ω-variables and $\mathcal{G}_\tau$-bounds in the Ω'-variables (cf. [16] or [20]). Elements of Colombeau algebras are usually denoted by capital letters with the understanding that $(u_\varepsilon)_{\varepsilon\in I}$ denotes an arbitrary representative of $U \in \mathcal{G}$.

Nonlinear operations with distributions in $\mathcal{G}(\Omega)$ depend not only on the distributions themselves but also on the regularization procedure used in the embedding process. Thus the difference of two representatives $(u_\varepsilon)_{\varepsilon\in I}$, $(v_\varepsilon)_{\varepsilon\in I}$ of generalized functions U, resp. V, may have $\mathcal{D}'$-limit 0 as $\varepsilon \to 0$ without U and V being equal in $\mathcal{G}(\Omega)$. Nevertheless U and V are to be considered "equal in the sense of distributions" or *associated* with each other ($U \approx V$). Moreover, U is called associated with some distribution w if $u_\varepsilon \to w$ in $\mathcal{D}'$. If such a w exists (which need not be the case, cf. δ^2), it is to be seen as the distributional "shadow" of U. For example, all powers of the Heaviside function are associated with each other without being equal in the algebra itself. Also, $x\delta = 0$ in $\mathcal{D}'(\mathbb{R})$, so $x\delta \approx 0$ in $\mathcal{G}(\mathbb{R})$, but $x\delta \neq 0$ in $\mathcal{G}(\mathbb{R})$. These examples illustrate a general principle: assigning nonlinear properties to elements of the vector space $\mathcal{D}'(\Omega)$ amounts to introducing additional information which is reflected in a more rigid concept of equality within $\mathcal{G}(\Omega)$ compared to that in $\mathcal{D}'(\Omega)$. This strict concept of equality allows for much more refined ways of infinitesimal modelling. On the $\mathcal{D}'$-level (the level of association) this additional information is lost in the limit-process $\varepsilon \to 0$.

Generalized numbers (i.e., the ring of constants in case Ω is connected) in any of the above algebras will be denoted by $\mathcal{R}$. Componentwise insertion of points into representatives of generalized functions yields well defined elements of $\mathcal{R}$.

We note that there exist variants of Colombeau algebras that allow a canonical embedding of distributions (independent of a fixed mollifier as above). The basic idea for constructing these algebras is to replace the index set I by the space of *all* possible mollifiers. Our choice of the special variants of Colombeau algebras is aimed at notational simplicity. However, all results presented in what follows carry over to the respective full variants of the algebras. Moreover, recently there have been introduced global versions of Colombeau algebras, defined intrinsically on manifolds and displaying the analogues of (i)–(iv) (with ∂_i replaced by Lie-derivatives with respect to smooth vector fields); see [14]. For applications of the theory to nonlinear partial differential equations (PDEs) see [24] and the literature cited therein; for applications to mathematical physics and numerics, cf. [6], [10], and [37].

3. Transfer of classical symmetry groups.

3.1. Factorization properties. The first question to be answered in trying to extend the applicability of classical group analysis to generalized solutions concerns permanence properties of classical symmetries: Let G be the symmetry group of some system S of PDEs and consider S within the framework of $\mathcal{G}(\Omega)$. Under which conditions do elements of G also transform generalized solutions into other generalized solutions? It is the aim of this and the following section to answer this question. To begin with, let us fix some terminology.

Definition 3.1. *Let G be a projectable local group of transformations acting on some open set $\mathcal{M} \subseteq \mathcal{X} \times \mathcal{U}$ according to $g \cdot (x, u) = (\Xi_g(x), \Phi_g(x, u))$. g is called slowly increasing if the map $u \to \Phi_g(x, u)$ is slowly increasing, uniformly for x in compact sets. g is strictly slowly increasing if $\Phi_g \in \mathcal{O}_M(\mathcal{M})$. If $\Omega \subseteq \mathcal{X}$, $U \in \mathcal{G}(\Omega)$ and g is (strictly) slowly increasing, the action of g on U is defined as the element*

$$gU := \mathrm{cl}[((\Phi_g \circ (id \times u_\varepsilon)) \circ \Xi_g^{-1})_{\varepsilon \in I}] \tag{3.1}$$

of $\mathcal{G}(\Xi_g(\Omega))$.

If U is a smooth function, (3.1) reproduces the classical notion of group action on functions. Henceforth we make the tacit assumption that the differential equations under consideration are of a form that allows for an insertion of elements of Colombeau generalized functions (i.e., the function Δ representing the equations on the prolongation space is slowly increasing). Also, slowly increasing group actions are always understood to be projectable. Analogous to the classical setting we give the following definition.

Definition 3.2. *Let S be some system of differential equations with p variables and q unknown functions. A solution of S in $\mathcal{G}$ is an element $U \in (\mathcal{G}(\Omega))^q$, with $\Omega \subseteq \mathcal{X}$ open, which solves the system with equality in $(\mathcal{G}(\Omega))^l$. A symmetry group of S in $\mathcal{G}$ is a local transformation group acting on $\mathcal{X} \times \mathcal{U}$ such that if U is a solution of the system in $\mathcal{G}$, $g \in G$ and $g \cdot U$ is defined, then also $g \cdot U$ is a solution of S in $\mathcal{G}$.*

Let us take a look at the transition problem from classical to generalized symmetry groups on the level of representatives. Thus, let G be a slowly increasing symmetry group of some differential equation

$$\Delta(x, u^{(n)}) = 0. \tag{3.2}$$

This means that if f is a classical solution, i.e., if $\Delta(x, \mathrm{pr}^{(n)} f(x)) = 0\ \forall x$ then also $\Delta(x, \mathrm{pr}^{(n)}(g \cdot f)(x)) = 0$. Now let $U \in \mathcal{G}(\Omega)$ be a generalized solution to (3.2). Then for any representative $(u_\varepsilon)_{\varepsilon \in I}$ of U there exists some $(n_\varepsilon)_{\varepsilon \in I} \in \mathcal{N}(\Omega)$ such that $\forall x$ and $\forall\ \varepsilon$ we have

$$\Delta(x, \mathrm{pr}^{(n)} u_\varepsilon(x)) = n_\varepsilon(x). \tag{3.3}$$

In particular, the differential equation (3.2) need not be satisfied for even one single value of ε. This basic observation displays quite fundamental obstacles to a direct utilization of the classical symmetry group properties of G in order to obtain statements on the status of G in the Colombeau-setting. Therefore we have to derive properties of symmetry groups that are better suited to allow a transfer to differential algebras. The starting point for our considerations is a slight modification of a well known factorization property of smooth maps (cf. [29, Proposition 2.10]) as follows.

PROPOSITION 3.3. *Let F be a smooth mapping from some manifold M to $\mathbb{R}^k$ $(k \leq n = \dim(M))$, let $f : (-\eta_o, \eta_o) \times M \to \mathbb{R}$ be smooth and suppose that $f(\eta, .)$ vanishes on the zero set $\mathcal{S}_F$ of F, identically in η. If F is of maximal* rank *$(= k)$ on $\mathcal{S}_F$ then there exist smooth functions $Q_1, \dots, Q_k : (-\eta_o, \eta_o) \times M \to \mathbb{R}$ such that*

$$f(\eta, m) = Q_1(\eta, m)F_1(m) + \dots + Q_k(\eta, m)F_k(m)$$

$\forall(\eta, m) \in (-\eta_o, \eta_o) \times M$. □

We are mainly interested in the following application of Proposition 3.3.

THEOREM 3.4. *Let*

$$\Delta_\nu(x, u^{(n)}) = 0, \qquad 1 \leq \nu \leq l \tag{3.4}$$

be a nondegenerate system of PDEs. Let $G = \{g_\eta : \eta \in (-\eta_o, \eta_o)\}$ be a one parameter symmetry group of (3.4) *and set $g_\eta \cdot (x, u) = (\Xi_\eta(x, u), \Phi_\eta(x, u))$. Then there exist $\mathcal{C}^\infty$-functions $Q_{\mu\nu} : (- \eta_o, \eta_o) \times \mathcal{V} \to \mathbb{R}$ $(1 \leq \mu, \nu \leq l$, $\mathcal{V}$ an open subset of $\mathcal{M}^{(n)})$ such that if $u : \Omega \subseteq \mathbb{R}^p \to \mathbb{R}^q$ is smooth and $g_\eta u$ exists we have*

$$\begin{aligned} &\Delta_\nu(\Xi_\eta(x, u(x)), \mathrm{pr}^{(n)}(g_\eta u)(\Xi_\eta(x, u(x)))) \\ &= \sum_{\mu=1}^{l} Q_{\mu\nu}(\eta, x, \mathrm{pr}^{(n)}u(x))\Delta_\mu(x, \mathrm{pr}^{(n)}u(x)) \end{aligned} \tag{3.5}$$

on the domain of $g_\eta u$ for $1 \leq \nu \leq l$.

Proof. Denote by z the coordinates on $\mathcal{M}^{(n)}$. That g_η is an element of the symmetry group of the system is equivalent with

$$\Delta(z) = 0 \Rightarrow \Delta_\nu(\mathrm{pr}^{(n)}g_\eta(z)) = 0 \quad (1 \leq \nu \leq l)$$

$\forall \eta$ and z such that this is defined. Δ is of maximal rank because (3.4) is nondegenerate. Hence, by Proposition 3.3 there exist $\mathcal{C}^\infty$-functions $Q_{\mu\nu} : (-\eta_o, \eta_o) \times \mathcal{V} \to \mathbb{R}$ $(1 \leq \mu \leq l$, $\mathcal{V}$ an open subset of $\mathcal{M}^{(n)})$ such that

$$\Delta_\nu(\mathrm{pr}^{(n)}g_\eta(z)) = \sum_{\mu=1}^{l} Q_{\mu\nu}(\eta, z)\Delta_\mu(z). \tag{3.6}$$

Now for a smooth function $u : \Omega \subseteq \mathbb{R}^p \to \mathbb{R}^q$ as in our assumption and $x \in \Omega$ we set

$$z_u(x) := (x, \mathrm{pr}^{(n)}u(x)) \in \mathcal{M}^{(n)}. \tag{3.7}$$

Then by definition $\mathrm{pr}^{(n)}g_\eta(z_u(x)) = (\Xi_\eta(x, u(x)), \mathrm{pr}^{(n)}(g_\eta u)(\Xi_\eta(x, u(x))))$, so the result follows. □

For a single PDE $\Delta(x, \mathrm{pr}^{(n)}u) = 0$, (3.5) takes the simpler form

$$\Delta(\Xi_\eta(x, u(x)), \mathrm{pr}^{(n)}(g_\eta u)(\Xi_\eta(x, u(x)))) = Q(\eta, x, \mathrm{pr}^{(n)}u(x))\Delta(x, \mathrm{pr}^{(n)}u(x)). \tag{3.8}$$

Theorem 3.4 will be one of our main tools in transferring classical symmetry groups of (systems of) PDEs into the setting of algebras of generalized functions.

PROPOSITION 3.5. *Let $\eta \to g_\eta$ be a slowly increasing one parameter symmetry group of* (3.4)*. If $P_{\mu\nu} := (Q_{\mu\nu}(\eta, \Xi_{-\eta}(\,.\,), \mathrm{pr}^{(n)} u_\varepsilon(\Xi_{-\eta}(\,.\,))))_{\varepsilon\in I}$ belongs to $\mathcal{E}_M(\Omega)$ for $1 \le \mu, \nu \le l$ and every $(u_\varepsilon)_{\varepsilon\in I} \in \mathcal{E}_M(\Omega)$, then $\eta \to g_\eta$ is a symmetry group of* (3.4) *in $\mathcal{G}$ as well. This condition is satisfied if*

$$(x, u^{(n)}) \to Q_{\mu\nu}(\eta, x, u^{(n)})$$

is slowly increasing in the $u^{(n)}$-variables, uniformly in x on compact sets for $1 \le \mu, \nu \le l$ and every η.

Proof. It suffices to observe that (3.5) gives

$$\begin{aligned}&\Delta_\nu(x, \mathrm{pr}^{(n)}(g_\eta u)(x))\\ &= \sum_{\mu=1}^{l} Q_{\mu\nu}(\eta, \Xi_{-\eta}(x), \mathrm{pr}^{(n)} u(\Xi_{-\eta}(x)))\Delta_\mu(\Xi_{-\eta}(x), \mathrm{pr}^{(n)} u(\Xi_{-\eta}(x))).\end{aligned}$$

For any solution $U \in \mathcal{G}(\Omega)$ with representative $u = (u_\varepsilon)_{\varepsilon\in I}$, this expression is in $\mathcal{N}(\Omega)$ since $P_{\mu\nu} \in \mathcal{E}_M(\Omega)$ for each μ, ν, and every $\Delta_\mu(\Xi_{-\eta}(\,.\,), \mathrm{pr}^{(n)} u(\Xi_{-\eta}(\,.\,)))$ is in $\mathcal{N}(\Omega)$ because U is a solution and $\Xi_{-\eta}$ is a diffeomorphism. □

Example 3.6. The system

$$\begin{aligned} U_t + UU_x &= 0,\\ V_t + UV_x &= 0,\\ U\,|_{\{t=0\}} = U_o, \quad V\,|_{\{t=0\}} &= V_o, \end{aligned} \tag{3.9}$$

may serve as a simplified model for a one-dimensional, elastic material of high density in a nearly plastic state. It was analyzed in [25], where solutions $U, V \in \mathcal{G}_{s,g}(\mathbb{R} \times [0,\infty))$, $U_o, V_o \in \mathcal{G}_{s,g}(\mathbb{R})$ were constructed and studied ($\mathcal{G}_{s,g}$ is a variant of the Colombeau algebra with global instead of local bounds). In the following we present some applications of the above results to this system (for a more detailed study, see [21]). For $U_o' \ge 0$ (3.9) has a unique solution (U, V) in $\mathcal{G}_{s,g}(\mathbb{R} \times [0,\infty))$ with $\partial_x U \ge 0$. We consider solutions in $\mathcal{G}_{s,g}(\mathbb{R} \times [0,\infty))$ with initial data $U_o(x) = u_L + (u_R - u_L)H(x)$ and $V_o(x) = v_L + (v_R - v_L)H(x)$, where H is a generalized Heaviside function with $H' \ge 0$, i.e., H is a member of $\mathcal{G}_{s,g}(\mathbb{R})$ with a representative $(h_\varepsilon)_{\varepsilon\in I}$ coinciding with the classical Heaviside function Y off the interval $[-\varepsilon, \varepsilon]$. For $u_L < u_R$ the solution (U, V) is associated with the rarefaction wave

$$u(x,t) = \begin{cases} u_L, & x \le u_L t,\\ \frac{x}{t}, & u_L t \le x \le u_R t,\\ u_R, & u_R t \le x, \end{cases} \tag{3.10}$$

$$v(x,t) = \begin{cases} v_L, & x \le u_L t,\\ \left(\frac{v_R - v_L}{u_R - u_L}\right)\frac{x}{t} + \left(\frac{v_L u_R - v_R u_L}{u_R - u_L}\right), & u_L t \le x \le u_R t,\\ v_R, & u_R t \le x. \end{cases} \tag{3.11}$$

However, choosing different generalized Heaviside functions for modelling the initial data U_o, respectively V_o, we may obtain a superposition of the rarefaction wave (3.10) in u with a shock wave

$$v(x,t) = v_L + (v_R - v_L)Y(x - ct) \tag{3.12}$$

with arbitrary shock speed c, $u_L \leq c \leq u_R$. We are going to construct a one parameter symmetry $\eta \to g_\eta$ of (3.9) which transforms any of the solutions (3.11), (3.12) into a shock wave solution as $\eta \to \pm\infty$. For this we employ the two-dimensional Lorentz-transformation $(\eta, (x,t)) \to (x\cosh(\eta) - t\sinh(\eta), -x\sinh(\eta) + t\cosh(\eta))$ with infinitesimal generator $X_o = -t\partial_x - x\partial_t$. Then $X := X_o + (u^2-1)\partial_u$ generates a projectable one-parameter symmetry group of (3.9). Assuming that $-1 < u_{\mathrm{L}} < u_{\mathrm{R}} < 1$, we can extend the solution (U,V) to the region $\Omega = \mathbb{R}^2 \setminus \{(x,t) : t \leq 0, u_{\mathrm{R}}t \leq x \leq u_{\mathrm{L}}t\}$ by the method of characteristics applied to representatives. Then the Lorentz-transformed solutions

$$\begin{aligned} \tilde{u}_\varepsilon(x,t) &= -\tanh(\eta - \operatorname{Artanh}(u_\varepsilon(x\cosh(\eta) + t\sinh(\eta),\\ &\qquad x\sinh(\eta) + t\cosh(\eta)))), \end{aligned} \tag{3.13}$$

$$\tilde{v}_\varepsilon(x,t) = v_\varepsilon(x\cosh(\eta) + t\sinh(\eta), x\sinh(\eta) + t\cosh(\eta)) \tag{3.14}$$

(with Artanh the inverse of tanh) are well defined at least on $\mathbb{R} \times (0,\infty)$. The factorization property (3.5) in this case reads

$$\begin{aligned} &(\partial_t \tilde{u}_\varepsilon + \tilde{u}_\varepsilon \partial_x \tilde{u}_\varepsilon)(x,t)\\ &\quad = \big((\partial_t u_\varepsilon + u_\varepsilon \partial_x u_\varepsilon)/(\cosh^3(\operatorname{Artanh}(u_\varepsilon - \eta))\cosh(\operatorname{Artanh}(u_\varepsilon)))\big)\big(\Xi_\eta^{-1}(x,t)\big) \end{aligned} \tag{3.15}$$

and similarly for the second line in (3.9), demonstrating that $(\widetilde{U}, \widetilde{V})$ is again a solution. For each η, $\widetilde{U}$ is associated with a piecewise smooth function which converges to ∓ 1 as $\eta \to \pm\infty$. Observing that the coordinate transformations in (3.13), (3.14) approach boosts in the directions $(\mp 1, 1)$ as $\eta \to \pm\infty$, we see that the functions associated with $\widetilde{V}$ converge to the shock wave $v_L + (v_R - v_L)Y(x \pm t)$ as $\eta \to \pm\infty$, for whatever solution V given in (3.11) or (3.12).

Although Proposition 3.5 provides a manageable algorithm to determine if classical symmetry groups carry over to generalized solutions it would certainly be preferable to have criteria at hand that allows us to judge directly from the given PDE if the factors $P_{\mu\nu}$ behave nicely (given slowly increasing group actions). The first step in this direction is gaining control over the behavior of the map $z \to \mathrm{pr}^{(n)} g_\eta(z)$, defined on $\mathcal{M}^{(n)}$.

Proposition 3.7. *If $\eta \to g_\eta$ is a (strictly) slowly increasing group action on $\mathcal{M}$ then $z \to \mathrm{pr}^{(n)} g_\eta(z)$ is (strictly) slowly increasing as well.*

Proof. Let $N := \dim(\mathcal{M}^{(n)})$. For $z = (z_1, \ldots, z_p, z_{p+1}, \ldots, z_q, \ldots, z_N) \in \mathcal{M}^{(n)}$ we choose some smooth function $h : \mathcal{X} \to \mathcal{U}$ satisfying $z = z_h(z_1, \ldots, z_p)$, with $z_h(x)$ as in (3.7). Then we set $x := (z_1, \ldots, z_p)$, $u = (z_{p+1}, \ldots, z_q)$, $\widetilde{x} = \Xi_\eta(x)$ and $\widetilde{u} = \Phi_\eta(x,u)$. By the definition of prolonged group actions we have to find estimates for every

$$A_s := ((\Phi_\eta \circ (id \times h)) \circ \Xi_{-\eta})^{(s)}\,(\widetilde{x}) \tag{3.16}$$

(where (s) denotes the derivative of order s) in terms of z. The above formula contains the components of $\mathrm{pr}^{(n)} g(z)$ of order s ($s \leq n$). Note that the particular choice of h has no influence on (3.16), i.e., A_s depends exclusively on z. To compute A_s explicitly we use the formula for higher order derivatives of composite functions (see [11]). Denoting by Υ_m the group of permutations of $\{1, \ldots, m\}$ we have

$$A_s(r_1, \ldots, r_s) = \sum_{i=1}^{s} \sum_{\substack{k \in \mathbb{N}^i\\ |k|=s}} \sum_{\sigma \in \Upsilon_s} \frac{1}{i!k!} (\Phi_\eta \circ (id \times h))^{(i)}((\widetilde{x}))(t_1, \ldots, t_i), \tag{3.17}$$

where

$$t_1 = \Xi_{-\eta}^{(k_1)}(\widetilde{x})(r_{\sigma(1)},\dots,r_{\sigma(k_1)}),\dots,t_i = \Xi_{-\eta}^{(k_i)}(\widetilde{x})(r_{\sigma(s-k_i+1)},\dots,r_{\sigma(s)})$$

and

$$(3.18)\ (((\Phi_\eta \circ (id \times h)))^{(i)}(x)(t_1,\dots,t_i) = \sum_{j=1}^{i} \sum_{\substack{l\in\mathbb{N}^j \\ |l|=i}} \sum_{\tau\in\Upsilon_i} \frac{1}{j!l!}\Phi_\eta^{(j)}(x,u)(s_1,\dots,s_j),$$

where

$$s_1 = (id\times h)^{(l_1)}(x)(t_{\tau(1)},\dots,t_{\tau(l_1)}),\ \dots\ ,s_j = (id\times h)^{(l_j)}(x)(t_{\tau(i-l_j+1)},\dots,t_{\tau(i)}).$$

Each s_m consists of sums of products of certain $t_{\tau(k)}$ with certain z_l and an analogous assertion holds for the $\Phi_\eta^{(j)}(x,u)(s_1,\dots,s_j)$. Hence from (3.17) and (3.18) the result follows. □

Returning to our original task of finding a priori estimates for the factors $P_{\mu\nu}$, even with the aid of Proposition 3.7 we still need some information about the explicit form of the $Q_{\mu\nu}$ to go on. In general this seems quite difficult to achieve. However, there is a large and important class of PDEs that allow a priori statements on the concrete form of the factorization. Namely, we are going to show that each scalar PDE in which at least u or one of its derivatives appears as a single term with constant coefficient belongs to this class.

Consider a scalar PDE $\Delta(x,u^{(n)})=0$ together with a symmetry group $\eta\to g_\eta$. Then we have

$$\Delta(z)=0 \quad\Rightarrow\quad \Delta(\mathrm{pr}^{(n)}g_\eta(z))=0.$$

Set $F(z) := \Delta(z)$, $f(z) := \Delta(\mathrm{pr}^{(n)}g_\eta(z))$ and $N=\dim(\mathcal{M}^{(n)})$. Suppose that in a neighborhood of some $\bar{z}$ with $F(\bar{z})=0$ we have $\frac{\partial F}{\partial z_k}>0$ for some $1\le k\le N$. Then by the implicit function theorem, locally there exists a smooth function $\psi:\mathbb{R}^{N-1}\to\mathbb{R}$ such that in a suitable neighborhood of $\bar{z}$ we have

$$F(z)=0 \quad\Leftrightarrow\quad z_k=\psi(z'),$$

where $z'=(z_1,\dots,\hat{z_k},\dots,z_N)$ (meaning that the component z_k is missing from z'). It follows that

$$F(z) = (z_k-\psi(z'))\int_0^1 \frac{\partial F}{\partial z_k}(z_1,\dots,z_{k-1},\tau z_k+(1-\tau)\psi(z'),\dots,z_N)\,d\tau,$$

and on the other hand

$$f(z) = (z_k-\psi(z'))\int_0^1 \frac{\partial f}{\partial z_k}(z_1,\dots,z_{k-1},\tau z_k+(1-\tau)\psi(z'),\dots,z_N)\,d\tau.$$

Thus in the said neighborhood we have

$$(3.19)\qquad f(z) = F(z)\frac{\int_0^1 \frac{\partial f}{\partial z_k}(z_1,\dots,z_{k-1},\tau z_k+(1-\tau)\psi(z'),\dots,z_N)d\tau}{\int_0^1 \frac{\partial F}{\partial z_k}(z_1,\dots,z_{k-1},\tau z_k+(1-\tau)\psi(z'),\dots,z_N)d\tau},$$

provided the denominator of this expression is $\neq 0$. In particular, if for some constant $c \neq 0$ we have $\frac{\partial F}{\partial z_k} \equiv c$ in a neighborhood of $\bar{z}$ then (3.19) simplifies to

$$f(z) = \frac{1}{c} F(z) \int_0^1 \frac{\partial f}{\partial z_k}(z_1, \ldots, z_{k-1}, \tau z_k + (1-\tau)\psi(z'), \ldots, z_N) d\tau. \tag{3.20}$$

After these preparations we can state the following theorem.

Theorem 3.8. *Let $\eta \to g_\eta$ be a slowly increasing symmetry group of the equation $\Delta(x, u^{(n)}) = 0$. Set $N = \dim(\mathcal{M}^{(n)})$ and suppose that $\frac{\partial \Delta}{\partial z_k} \equiv c \neq 0$ for some $p+1 \leq k \leq N$. Then $\eta \to g_\eta$ is a symmetry group of $\Delta(x, u^{(n)}) = 0$ in $\mathcal{G}$.*

Proof. Without loss of generality we may assume $c = 1$. Using the above notations we have $F(z) = z_k - \psi(z')$, so (3.20) implies

$$f(z) = F(z) \int\limits_0^1 \frac{\partial f}{\partial z_k}(z_1, \ldots, z_{k-1}, \tau z_k + (1-\tau)(z_k - F(z)), \ldots, z_N) d\tau =: F(z) Q(\eta, z).$$

From Proposition 3.7 we know that $z \to f(z)$ is slowly increasing in the $u^{(n)}$-variables (i.e., in those z_i with $i > p$), uniformly in $x = (z_1, \ldots, z_p)$ on compact sets. Since F is slowly increasing we infer that $Q(\eta, z_u(x)) \in \mathcal{E}_M(\Omega)$ for any $u \in \mathcal{E}_M(\Omega)$ (with z_u as in (3.7)). Finally,

$$\Delta(x, \mathrm{pr}^{(n)}(g_\eta u)(x)) = \Delta(\Xi_{-\eta}(x), \mathrm{pr}^{(n)} u(\Xi_{-\eta}(x))) Q(\eta, \Xi_{-\eta}(x), \mathrm{pr}^{(n)} u(\Xi_{-\eta}(x))).$$

Since $\Xi_{-\eta}$ is a diffeomorphism, it follows that if $U = \mathrm{cl}[u]$ solves the equation, so does $g_\eta U$. □

As the proof shows, we can drop the assumption $p + 1 \leq k$ if we require the group action to be strictly slowly increasing. It is clear that many PDEs satisfy the requirements of Theorem 3.8. For example, in the Hopf equation $\Delta(x, t, u, u_x, u_t) = u_t + u u_x$ or $\Delta(z_1, \ldots, z_5) = z_5 + z_3 z_4$ one can take $k = 5$. Note, however, that not every symmetry group of this equation is automatically slowly increasing. Theorem 3.8 constitutes a useful tool for transferring classical symmetry groups to Colombeau algebras.

Example 3.9. We consider the initial value problem for the nonlinear transport equation

$$\begin{aligned} &U_t + \lambda \cdot \nabla_x U = f(U), \\ &U\,|_{\{t=0\}} = U_o \end{aligned} \tag{3.21}$$

with $t \in \mathbb{R}, x, \lambda \in \mathbb{R}^n$. It has unique solutions in $\mathcal{G}(\mathbb{R}^{n+1})$, given $U_o \in \mathcal{G}(\mathbb{R}^n)$, provided $f \in \mathcal{O}_M$ is globally Lipschitz (see [24]). If in addition f is bounded and the initial data are distributions with discrete support, say $U_0(x) = \sum_{i,j} a_{ij} \delta^{(i)}(x - \xi_j)$ with $\xi_j \in \mathbb{R}^n, i \in \mathbb{N}_0^n$, then the generalized solution is associated with the delta wave $v + w$ where

$$v(x, t) = \sum_{i,j} a_{ij} \delta^{(i)}(x - \lambda t - \xi_j) \tag{3.22}$$

and w is the smooth solution to $w_t + \lambda \cdot \nabla_x w = f(w)$, $w(0) = 0$.

The vector field $X = c f(u) \partial_u$ generates an infinitesimal symmetry of (3.21) for arbitrary $c \in \mathbb{R}$. With $F(u) := \int du/f(u)$, the corresponding Lie point transformation is

$$(x, t, u) \to (\widetilde{x}, \widetilde{t}, \widetilde{u}) = (x, t, F^{-1}(c\eta + F(u))). \tag{3.23}$$

This provides a well-defined nonlinear transformation of the generalized solution $U \in \mathcal{G}(\mathbb{R}^{n+1})$, provided that the right hand side in (3.23) is slowly increasing.

In the example

$$U_t + \lambda \cdot \nabla_x U = \tanh(U) \tag{3.24}$$

the generalized solution is associated with $v(x,t)$ and w vanishes identically. Applying (3.23) we obtain (due to Theorem 3.8) the new generalized solution

$$\widetilde{U}(x,t) = \operatorname{Arsinh}\left(e^{c\eta}\sinh(U(x,t))\right) \tag{3.25}$$

(with Arsinh the inverse of sinh). We are going to show that $\widetilde{U}$ is still associated with the delta wave v in (3.22). To simplify the argument we assume $n = 1, \lambda = 0$ and $U_0(x) = \delta^{(i)}(x)$. Representatives of U, resp. $\widetilde{U}$, are $u_\varepsilon(x,t) = \operatorname{Arsinh}(e^t \sinh(\rho_\varepsilon^{(i)}(x)))$ and $\widetilde{u}_\varepsilon(x,t) = \operatorname{Arsinh}(e^{c\eta+t}\sinh(\rho_\varepsilon^{(i)}(x)))$. For $\psi \in \mathcal{D}(\mathbb{R}^2)$ we have

$$\begin{aligned} I_\varepsilon^i &:= \int\int \widetilde{u}_\varepsilon(x,t)\psi(x,t)dxdt \\ &= \int\int\int_0^1 \theta(e^{c\eta+t}, \sigma\varepsilon^{-i-1}\rho^{(i)}(x))d\sigma\varepsilon^{-i}\rho^{(i)}(x)\psi(\varepsilon x,t)dxdt, \end{aligned}$$

where $\theta(\alpha, y) := \frac{d}{dy}\operatorname{Arsinh}(\alpha\sinh(y))$ for $\alpha > 0$, $y \in \mathbb{R}$. Since θ is bounded by $\max(1,\alpha)$ and $\lim_{|y|\to\infty}\theta(\alpha,y) = 1$ it follows that $I_\varepsilon^0 \to \int \psi(0,t)dt$, so $\widetilde{U}$ is associated with the delta function on the t-axis, as desired. For $i \geq 1$ we write

$$\begin{aligned} I_\varepsilon^i = \int\int\int_0^1 &(\theta(e^{c\eta+t}, \sigma\varepsilon^{-i-1}\rho^{(i)}(x)) - 1)d\sigma\varepsilon^{-i}\rho^{(i)}(x)\psi(\varepsilon x,t)dxdt \\ &+ (-1)^i \int\int \rho(x)\partial_x^i\psi(\varepsilon x,t)dxdt. \end{aligned}$$

Here the second term converges to $(-1)^i \int \partial_x^i \psi(0,t)$ and the first term goes to zero since $\int_0^1 |\theta(\alpha,\sigma y) - 1|d\sigma \leq \frac{2|\alpha^2-1|}{\alpha|y|}(1 - e^{-|y|})$ for $y \neq 0$. This proves the claim for $\rho \in \mathcal{D}(\mathbb{R})$. For $\rho \in \mathcal{S}(\mathbb{R})$ splitting the x-integral into one from $-\frac{1}{\sqrt{\varepsilon}}$ to $\frac{1}{\sqrt{\varepsilon}}$ and one over $|x| \geq \frac{1}{\sqrt{\varepsilon}}$ gives the same result.

3.2. Continuity properties. In this section we work out a different strategy for transferring classical point symmetries into the $\mathcal{G}$-setting. This approach, suggested in [28], consists in a more topological way of looking at the transfer problem by using continuity properties of differential operators. As we have pointed out in the discussion following (3.3), the main obstacle against directly applying classical symmetry groups componentwise to representatives of generalized solutions is that the differential equations need not be satisfied componentwise. However, there are certain classes of partial differential operators that do allow such a direct application. Consider a linear partial differential operator P giving rise to an equation

$$PU = 0 \tag{3.26}$$

in $\mathcal{G}$ and let G be a classical slowly increasing symmetry group of (3.26). Furthermore, suppose that P possesses a continuous homogeneous (but not necessarily linear) right inverse Q. If $U = \mathrm{cl}[u]$ is a solution to (3.26) in $\mathcal{G}(\Omega)$ then there exists some $n \in \mathcal{N}(\Omega)$ such that

$$Pu = n.$$

Since Q is a right inverse of P this implies

$$P(u_\varepsilon - Qn_\varepsilon) = 0 \quad \forall \varepsilon \in I. \tag{3.27}$$

Also, $Qn \in \mathcal{N}(\Omega)$ due to the continuity and homogeneity assumption on Q. If $g \in G$, (3.27) implies

$$P(g(u_\varepsilon - Qn_\varepsilon)) = 0 \quad \forall \varepsilon \in I.$$

By definition,

$$P(gU) = \mathrm{cl}[P(gu)] = \mathrm{cl}[P(g(u - Qn))],$$

so gU is a solution as well. Summing up, G is a symmetry group in $\mathcal{G}$. The following result will serve to secure the existence of a right inverse as above for a large class of linear differential operators.

Proposition 3.10. *Let E, F be Fréchet spaces and A a continuous linear map from E onto F. Then A has a continuous homogeneous right inverse $B : F \to E$.*

Proof. See [23, p. 364]. □

From these preparations we conclude the following theorem.

Theorem 3.11. *Let*

$$\Delta_\nu(x, u^{(n)}) = 0, \qquad \nu = 1, \dots, l$$

be a system of linear PDEs with slowly increasing Δ_ν and let $\eta \to g_\eta$ be a slowly increasing symmetry group of this system. Assume that the operator defined by the left hand side is surjective $(\mathcal{C}^\infty(\Omega))^l \to (\mathcal{C}^\infty(\Omega))^l$. Then $\eta \to g_\eta$ is a symmetry group for the system in $\mathcal{G}(\Omega)$ as well. □

The assumptions of Theorem 3.11 are automatically satisfied for any linear partial differential operator with constant coefficients on an arbitrary convex open domain (see [17, section 10.6]).

Example 3.12. The system of one-dimensional linear acoustics

$$\begin{aligned} P_t + U_x &= 0, \\ U_t + P_x &= 0 \end{aligned} \tag{3.28}$$

is transformed via $U = V - W, P = V + W$ into

$$\begin{aligned} V_t \,+\, V_x &= 0, \\ W_t - W_x &= 0. \end{aligned} \tag{3.29}$$

Using the infinitesimal generators $\Phi(v)\partial_v + \Psi(w)\partial_w$ (Φ, Ψ arbitrary smooth functions) of (3.29) we obtain symmetry transformations for (3.28) of the form

$$\widetilde{U} = F^{-1}\left(\eta + F\left(\frac{1}{2}(P+U)\right)\right) - G^{-1}\left(\theta + G\left(\frac{1}{2}(P-U)\right)\right)$$

$$\widetilde{P} = F^{-1}\left(\eta + F\left(\frac{1}{2}(P+U)\right)\right) + G^{-1}\left(\theta + G\left(\frac{1}{2}(P-U)\right)\right)$$

with arbitrary diffeomorphisms F, G. Since (3.28) satisfies the assumptions of Theorem 3.11 on $\Omega = \mathbb{R}^2$ it follows that any slowly increasing transformation of this form is a symmetry of (3.28). In particular, this includes nonlinear transformations of distributional solutions; cf. Example 3.13.

In the remainder of this section we discuss the interplay between symmetry groups and solutions of PDEs in the sense of association. Consider

$$\Delta_\nu(x, u^{(n)}) \approx 0, \qquad 1 \le \nu \le l \tag{3.30}$$

in $\mathcal{G}$. A slowly increasing symmetry group of the corresponding system

$$\Delta(x, u^{(n)}) = 0, \qquad 1 \le \nu \le l$$

is called a symmetry group in the sense of association if it transforms solutions of (3.30) into other such solutions. The first question to be answered in this context is whether one can derive conditions on the form of the factorization (3.8) that will yield symmetry groups in the sense of association. It is clear that a sufficient condition is to suppose that Q depends exclusively on η and x. Distributional solutions to linear PDEs arise as a special case of (3.30) and have been treated in [4]. There, the validity of (3.8) with Q depending on η and x only is actually used to *define* symmetry groups in $\mathcal{D}'$. In order to remain within the classical distributional framework, the admissible group transformations in [4] are restricted to projectable ones acting linearly in the dependent variables. On the other hand, the method developed there is even applicable to linear equations containing distributional terms which allows one to use invariance methods to compute fundamental solutions.

Second, if u is a solution to $\Delta(x, u^{(n)}) = 0$ in $\mathcal{G}(\Omega)$ possessing an associated distribution, one may ask for which group actions g this implies that gu as well possesses an associated distribution. This is certainly the case for admissible transformations in the above sense. On the other hand, we have already seen in Example 3.9 that even genuinely nonlinear symmetry transformations may preserve association properties.

The next example shows that nonlinear group actions may transform distributional solutions in Examples 3.9 and 3.12 into more complicated distributional solutions or into generalized solutions in $\mathcal{G}(\mathbb{R}^2)$ not admitting associated distributions.

Example 3.13. We consider the equation $U_t + \lambda U_x = 0$ arising in (3.21) with $n = 1$ or in (3.29). We have already observed that $\widetilde{U} = F^{-1}(\eta + F(U))$ defines a symmetry transformation for arbitrary diffeomorphisms F. Here we take $F \in \mathcal{C}^\infty(\mathbb{R})$, $F' > 0$, $F(y) = \operatorname{sign}(y)\sqrt{|y|}$ for $|y| \ge 1$. We wish to compute $\widetilde{U}$ when $U \in \mathcal{G}(\mathbb{R}^2)$ is a delta wave solution $U(x,t) \approx \delta^{(i)}(x - \lambda t)$. We take U as the class of $\rho_\varepsilon^{(i)}(x - \lambda t)$ with $\rho \in \mathcal{D}([-1,1])$. We have when $\eta \ge 0$:

(i) If $i = 0$, that is, $U \approx \delta(x - \lambda t)$, then $\widetilde{U} \approx F^{-1}(\eta + F(0)) + \delta(x - \lambda t)$;

(ii) If $i = 1$, that is, $U \approx \delta'(x - \lambda t)$, then
$\widetilde{U} \approx F^{-1}(\eta + F(0)) + 2\eta \int \sqrt{|\rho'(y)|}\, dy\ \delta(x - \lambda t) + \delta'(x - \lambda t)$;

(iii) If $i \ge 2$ then $\widetilde{U}$ does not admit an associated distribution.

To see this, we may assume that $\lambda = 0$ and write $a_\varepsilon(x) := \rho_\varepsilon^{(i)}(x)$ for brevity. Note that $F^{-1}(y) = \operatorname{sign}(y)y^2$ for $|y| \ge 1$. Let $A_\varepsilon = \{x \in [-\varepsilon, \varepsilon] : |a_\varepsilon(x)| \ge (\eta + 1)^2\}$. If $x \in A_\varepsilon$ and $a_\varepsilon(x) \ge 0$ then $\eta + F(a_\varepsilon(x)) \ge 1$ and $F^{-1}(\eta + F(a_\varepsilon(x))) = \eta^2 + 2\eta\sqrt{a_\varepsilon(x)} + a_\varepsilon(x)$. Also, if $x \in A_\varepsilon$ and $a_\varepsilon(x) < 0$ then $\eta + F(a_\varepsilon(x)) \le -1$ and $F^{-1}(\eta + F(a_\varepsilon(x))) = -\eta^2 + 2\eta\sqrt{|a_\varepsilon(x)|} + a_\varepsilon(x)$. The functions $F^{-1}(\eta + F(a_\varepsilon))$, $|a_\varepsilon(x)|$ and $\sqrt{|a_\varepsilon(x)|}$ are bounded on the complement of A_ε. Thus

$$\begin{aligned}
&\int\int_{-\varepsilon}^{\varepsilon} F^{-1}(\eta + F(a_\varepsilon(x)))\psi(x,t)dxdt \\
&= \int\int_{A_\varepsilon} \Big(\pm\, \eta^2 + 2\eta\sqrt{|a_\varepsilon(x)|} + a_\varepsilon(x)\Big)\psi(x,t)dxdt + O(\varepsilon) \\
&= \int\int_{-\varepsilon}^{\varepsilon} \Big(2\eta\sqrt{|a_\varepsilon(x)|} + a_\varepsilon(x)\Big)\psi(x,t)dxdt + O(\varepsilon)
\end{aligned}$$

while

$$\int\int_{|x|\geq\varepsilon} F^{-1}(\eta + F(a_\varepsilon(x)))\psi(x,t)\, dxdt \to F^{-1}(\eta + F(0)) \int\int \psi(x,t)\, dxdt.$$

It follows that $F^{-1}(\eta + F(a_\varepsilon(x)))$ converges in $\mathcal{D}'(\mathbb{R}^2)$ if and only if $2\eta\sqrt{|a_\varepsilon|} + a_\varepsilon$ admits an associated distribution. A simple computation yields the particular results (i), (ii), (iii).

4. Generalized group actions.

Although the methods introduced in the previous sections enable an application of large classes of classical symmetry groups to elements of Colombeau algebras, they are but the first step in a theory of generalized group analysis of differential equations. In this section we develop an extension of the methods of group analysis that will allow to consider symmetry groups of differential equations whose actions are generalized functions themselves.

4.1. Generalized transformation groups.

Simple examples indicate the necessity of extending the methods of group analysis of PDEs to equations involving generalized functions themselves.

Example 4.1. Considering (3.21) in $\mathcal{G}_\tau$ with a *generalized* function $f = \mathrm{cl}[(f_\varepsilon)_{\varepsilon\in I}] \in \mathcal{G}_\tau$ we can apply the classical algorithm for calculating symmetry groups componentwise to the equation

$$\partial_t u_\varepsilon + \lambda \cdot \nabla_x u_\varepsilon = f_\varepsilon(u_\varepsilon),$$

thereby obtaining infinitesimal generators with generalized coefficient functions. Thus the question arises in which sense such generators induce symmetries of the differential equation. More generally, one can consider differential equations in $\mathcal{G}_\tau$ of the form

$$P(x, U^{(n)}) = 0,$$

where P is a generalized function.

As is indicated by Example 4.1, composition of generalized functions will inevitably occur in a generalization of group analysis. For this purpose, we shall apply suitable variants of Colombeau algebras for the following considerations, namely $\mathcal{G}_\tau(\mathbb{R}^n)$ and $\widetilde{\mathcal{G}}_\tau(\mathbb{R}\times\mathbb{R}^n) = \widetilde{\mathcal{G}}_\tau(\mathbb{R}^{1+n})$.

Definition 4.2. *A generalized group action on* $\mathbb{R}^n$ *is an element* Φ *of* $(\widetilde{\mathcal{G}}_\tau(\mathbb{R}^{1+n}))^n$ *such that*

(i) $\Phi(0, \,.\,) = \mathrm{id}$ in $(\mathcal{G}_\tau(\mathbb{R}^n))^n$;

(ii) $\Phi(\eta_1 + \eta_2, \,.\,) = \Phi(\eta_1, \Phi(\eta_2, \,.\,))$ in $(\widetilde{\mathcal{G}}_\tau(\mathbb{R}^{2+n}))^n$.

Before we turn to an infinitesimal description of generalized group actions let us shortly recall some basic definitions from [27] that are needed for a pointvalue characterization of generalized functions which in turn plays a fundamental role in the following considerations. Thus for any open set $\Omega \subseteq \mathbb{R}^n$ we set

$$\Omega_M := \{(x_\varepsilon)_{\varepsilon\in I} \in \Omega^I : \exists p > 0 \ \exists\ \eta > 0 \ |x_\varepsilon| \le \varepsilon^{-p} \ (0 < \varepsilon < \eta)\}.$$

On Ω_M we define an equivalence relation by

$$(x_\varepsilon)_{\varepsilon\in I} \sim (y_\varepsilon)_{\varepsilon\in I} \ \Leftrightarrow\ \forall q > 0 \ \exists \eta > 0 \ |x_\varepsilon - y_\varepsilon| \le \varepsilon^q \ (0 < \varepsilon < \eta)$$

and set $\widetilde{\Omega} := \Omega_M/\sim$. $\widetilde{\Omega}$ is called the set of generalized points corresponding to Ω. The set of compactly supported points is defined as

$$\widetilde{\Omega}_c = \{\widetilde{x} \in \widetilde{\Omega} : \exists \text{ representative } (x_\varepsilon)_{\varepsilon\in I} \ \exists K \subset\subset \Omega \ \exists \eta > 0 \ :\ x_\varepsilon \in K,\ \varepsilon \in (0, \eta)\}.$$

Note that for $\Omega = \mathbb{R}$ we have $\widetilde{\Omega} = \mathcal{R}$. Theorems 2.4, 2.7, and 2.10 of [27] establish that elements of $\mathcal{G}(\Omega)$, $\widetilde{\mathcal{G}}_\tau(\Omega)$ or $\widetilde{\mathcal{G}}_\tau(\Omega\times\Omega')$ are uniquely determined by their pointvalues in $\widetilde{\Omega}_c$, $\widetilde{\Omega}$, or $\widetilde{\Omega}_c \times \widetilde{\Omega}'$, respectively. For the theory of ODEs in the Colombeau framework we refer to [16].

Definition 4.3. *Let $\xi = (\xi_1, \dots, \xi_n) \in (\mathcal{G}_\tau(\mathbb{R}^n))^n$. The generalized vector field $X = \sum_{i=1}^n \xi_i(x)\partial_{x_i}$ is called $\mathcal{G}$-complete if the initial value problem*

$$\begin{aligned} \dot{x}(t) &= \xi(x(t)), \\ x(t_o) &= \widetilde{x}_o \end{aligned}$$

is uniquely solvable in $\mathcal{G}(\mathbb{R})^n$ for any $\widetilde{x}_o \in \mathcal{R}^n$ and any $t_o \in \mathbb{R}$.

Definition 4.4. *Let Φ be a generalized group action on $\mathbb{R}^n$ and set*

$$\xi := \frac{d}{d\eta}\Big|_0 \Phi(\eta, \,.\,) \in (\mathcal{G}_\tau(\mathbb{R}^n))^n.$$

If the generalized vector field $X = \sum_{i=1}^n \xi_i(x)\partial_{x_i}$ is $\mathcal{G}$-complete, then X is called the infinitesimal generator of Φ. In this case, Φ is also called $\mathcal{G}$-complete.

By [16], every generalized vector field with $\mathcal{G}_\tau$-components whose gradient is of L^∞-log-type is $\mathcal{G}$-complete. The notion of infinitesimal generator is well-defined due to the following proposition.

Proposition 4.5. *Every $\mathcal{G}$-complete generalized group action is uniquely determined by its infinitesimal generator.*

Proof. Let Φ', Φ'' be two $\mathcal{G}$-complete generalized group actions with the same infinitesimal generator $X = \sum_{i=1}^n \xi_i(x)\partial_{x_i}$. Then both functions satisfy

$$\frac{d}{d\eta}\Phi(\eta, x) = \frac{d}{d\mu}\Big|_0 \Phi(\eta + \mu, x) = \frac{d}{d\mu}\Big|_0 \Phi(\mu, \Phi(\eta, x)) = \xi(\Phi(\eta, x)).$$

Now given any $\widetilde{x} \in \mathcal{R}^n$, it follows that both $\eta \to \Phi'(\eta, \widetilde{x})$ and $\eta \to \Phi''(\eta, \widetilde{x})$ solve the initial value problem

$$\begin{aligned} \dot{x}(\eta) &= \xi(x(\eta)), \\ x(0) &= \widetilde{x}. \end{aligned}$$

By assumption this entails that $\Phi'(\,.\,, \widetilde{x}) = \Phi''(\,.\,, \widetilde{x})$ in $(\mathcal{G}(\mathbb{R}))^n$. Consequently,

$$\Phi'(\eta, \widetilde{x}) = \Phi''(\eta, \widetilde{x})$$

$\forall\eta \in \mathcal{R}_c$ and all $\widetilde{x} \in \mathcal{R}^n$. The claim now follows from [27, Theorem 2.10]. □

As in the classical theory, we are first going to investigate symmetry groups of algebraic equations.

Definition 4.6. *Let $F \in \mathcal{G}_\tau(\mathbb{R}^n)$ and let Φ be a generalized group action on $\mathbb{R}^n$. Φ is called a symmetry group of the equation*

$$F(x) = 0$$

in $\mathcal{G}_\tau(\mathbb{R}^n)$ if for any $\widetilde{x} \in \mathcal{R}^n$ with $F(\widetilde{x}) = 0 \in \mathcal{R}$ it follows that $\eta \to F(\Phi(\eta, \widetilde{x})) = 0$ in $\mathcal{G}(\mathbb{R})$ (or, equivalently, $F(\Phi(\eta, \widetilde{x})) = 0$ in $\mathcal{R}$ for every $\eta \in \mathcal{R}_c$).

A characterization of symmetry groups of (generalized) algebraic equations in terms of infinitesimal generators is provided by the following theorem.

Theorem 4.7. *Let $F \in \mathcal{G}_\tau(\mathbb{R}^n)$ be of the form*

$$F(x_1, \dots, x_n) = x_i - f(x_1, \dots, x_{i-1}, x_{i+1}, \dots, x_n)$$

for some $1 \le i \le n$ and $f \in \mathcal{G}_\tau(\mathbb{R}^{n-1})$. Let Φ be a $\mathcal{G}$-complete generalized group action with infinitesimal generator $X = \sum_{i=1}^n \xi_i(x)\partial_{x_i}$ and suppose that $x' \to \xi(x', f(x'))$ defines a generalized vector field on $\mathbb{R}^{n-1}$ such that the corresponding system of ODEs possesses a flow in $(\widetilde{\mathcal{G}}_\tau(\mathbb{R}^{1+(n-1)}))^{n-1}$. The following conditions are equivalent:

(i) *Φ is a symmetry group of $F(x) = 0$.*

(ii) *If $\widetilde{x} \in \mathcal{R}^n$ with $F(\widetilde{x}) = 0 \in \mathcal{R}$, it follows that $X(F)(\widetilde{x}) = 0$ in $\mathcal{R}$.*

Proof. (i) ⇒ (ii): Consider the function $(\eta, x) \to F(\Phi(\eta, x)) \in \widetilde{\mathcal{G}}_\tau(\mathbb{R}^{1+n})$. We have

$$\frac{d}{d\eta} F(\Phi(\eta, x)) = \sum_{i=1}^n \frac{\partial F}{\partial x_i}(\Phi(\eta, x))\xi_i(\Phi(\eta, x)) = X(F)(\Phi(\eta, x)),$$

so that $\frac{d}{d\eta}\Big|_0 F(\Phi(\eta, x)) = X(F)(x)$ in $\mathcal{G}_\tau(\mathbb{R}^n)$. Let $\widetilde{x} \in \mathcal{R}^n$ such that $F(\widetilde{x}) = 0$. Then $F(\Phi(\,.\,, \widetilde{x})) = 0$ in $\mathcal{G}(\mathbb{R})$. Thus $\frac{d}{d\eta}\Big|_0 F(\Phi(\eta, \widetilde{x})) = 0$ in $\mathcal{R}$ which means that $X(F)(\widetilde{x}) = 0$ in $\mathcal{R}$.

(ii) ⇒ (i): We assume $F(x_1, \dots, x_n) = x_n - f(x_1, \dots, x_{n-1})$ and abbreviate $(x_1, \dots, x_{n-1})$ by x'. Our first claim is that

$$\xi_n(x', f(x')) = \sum_{j=1}^{n-1} \xi_j(x', f(x'))\partial_j f(x') \text{ in } \mathcal{G}_\tau(\mathbb{R}^{n-1}).$$

Indeed, if $\widetilde{x}' \in \mathcal{R}^{n-1}$ then $F(\widetilde{x}', f(\widetilde{x}')) = 0$ in $\mathcal{R}$. Hence $X(F)(\widetilde{x}', f(\widetilde{x}')) = 0$ in $\mathcal{R}$ for all $\widetilde{x}'$ by our assumption. Our claim now follows from [27, Theorem 2.7]. Consider the following system of ODEs in $\mathcal{G}_\tau$:

$$\begin{aligned} &\dot{x}_j(t) = \xi_j(x', f(x')), \quad (j = 1, \dots, n-1), \\ &x'(0) = \widetilde{a}' \in \mathcal{R}^{n-1}. \end{aligned}$$

By our assumption, this system has a flow $(\eta, a') \to (h_1(\eta, a'), \dots, h_{n-1}(\eta, a'))$ in $(\widetilde{\mathcal{G}}_\tau(\mathbb{R}^{1+(n-1)}))^{n-1}$. Set $g_n(\eta, a) := f(h_1(\eta, a'),\dots,h_{n-1}(\eta, a'))$. Then $g_n(0, a) = f(a')$ and

$$g(\eta, a) = (g_1(\eta, a), \dots, g_n(\eta, a)) := (h_1(\eta, a'), \dots, h_{n-1}(\eta, a'), g_n(\eta, a))$$

is in $(\widetilde{\mathcal{G}}_\tau(\mathbb{R}^{1+n}))^n$. If $\widetilde{a} \in \mathcal{R}^n$ then $F(g(\eta, \widetilde{a})) = 0$ in $\mathcal{R}$ $\forall \eta \in \mathcal{R}_c$. Therefore, if we can show that $g(\,.\,, \widetilde{a}) = \Phi(\,.\,, \widetilde{a})$ in $(\mathcal{G}(\mathbb{R}))^n$ $\forall \widetilde{a}$ with $F(\widetilde{a}) = 0$, the proof is completed. Now we have $\dot{g}_j(\eta, a) = \xi_j(g_1(\eta, a), \ldots, g_n(\eta, a))$ for $1 \leq j \leq n-1$ and

$$\begin{aligned} \dot{g}_n(\eta, a) &= \sum_{i=1}^{n-1} \frac{\partial f}{\partial x_i}(g_1(\eta, a), \ldots, g_{n-1}(\eta, a))\dot{g}_i(\eta, a) \\ &= \xi_n(g_1(\eta, a), \ldots, f(g_1(\eta, a), \ldots, g_{n-1}(\eta, a))) = \xi_n(g(\eta, a)). \end{aligned}$$

If $F(\widetilde{a}) = 0$ in $\mathcal{R}$, then $\widetilde{a}_n = f(\widetilde{a}')$, so that $g(0, \widetilde{a}) = (\widetilde{a}', f(\widetilde{a}')) = \widetilde{a} = \Phi(0, \widetilde{a})$. Thus $g(\,.\,, \widetilde{a})$ and $\Phi(\,.\,, \widetilde{a})$ solve the same initial value problem. Since X is $\mathcal{G}$-complete, the claim follows. □

4.2. Symmetries of differential equations. In this section we are going to apply the above results to symmetry groups of differential equations involving generalized functions. To this end, we will first have to define generalized group actions on generalized functions. Once we have done this, by a symmetry group of a differential equation we will again mean a group action that transforms solutions into other solutions. Thus, from now on we will exclusively consider group actions on some space $\mathbb{R}^p \times \mathbb{R}^q$ of independent and dependent variables.

Definition 4.8. *A generalized group action* $\Phi \in (\widetilde{\mathcal{G}}_\tau(\mathbb{R} \times \mathbb{R}^{p+q}))^{p+q}$ *is called projectable if it is of the form*

$$\Phi(\eta, (x, u)) = (\Xi_\eta(x), \Psi_\eta(x, u)),$$

where $\Xi \in (\widetilde{\mathcal{G}}_\tau(\mathbb{R} \times \mathbb{R}^p))^p$ *and* $\Psi \in (\widetilde{\mathcal{G}}_\tau(\mathbb{R} \times \mathbb{R}^{p+q}))^q$.

The group properties in this case read

$$\Xi_{\eta_1+\eta_2} = \Xi_{\eta_1} \circ \Xi_{\eta_2} \quad \text{in } \mathcal{G}_\tau(\mathbb{R}^p)\ \forall \eta_1, \eta_2 \in \mathcal{R}_c, \tag{4.1}$$

$$\Psi_{\eta_1+\eta_2}(x, u) = \Psi_{\eta_1}(\Xi_{\eta_2}(x), \Psi_{\eta_2}(x, u)) \quad \text{in } \mathcal{G}_\tau(\mathbb{R}^{p+q})\ \forall \eta_1, \eta_2 \in \mathcal{R}_c. \tag{4.2}$$

In particular, we have

$$\Xi_\eta \circ \Xi_{-\eta} = \text{id} \quad \text{in } \mathcal{G}_\tau(\mathbb{R}^p)\ \forall \eta \in \mathcal{R}_c. \tag{4.3}$$

An adaptation of Lie group analysis to spaces of distributions faces the following fundamental problem. The methods of classical Lie group analysis of differential equations are *geometric* in the sense that group action on functions is defined via graphs, but in classical distribution theory there is no means of defining graphs of distributions. However, due to the pointvalue characterization obtained in [27] this problem can be dealt with in a satisfactory manner within Colombeau algebras.

Definition 4.9. *Let* $U \in (\mathcal{G}(\mathbb{R}^p))^q$ *and* $V \in (\mathcal{G}_\tau(\mathbb{R}^p))^q$. *The graphs of* U *and* V *are defined as*

$$\begin{aligned} \Gamma_U &:= \{(\widetilde{x}, U(\widetilde{x})) : \widetilde{x} \in \mathcal{R}_c^p\}, \\ \Gamma_V &:= \{(\widetilde{x}, V(\widetilde{x})) : \widetilde{x} \in \mathcal{R}^p\}. \end{aligned}$$

It follows directly from [27, Theorems 2.4 and 2.7] that any generalized function is uniquely determined by its graph. Our next aim is to define generalized group actions on generalized functions. As in the classical case this is done geometrically, i.e., by transformation of graphs. The following result is immediate from the definitions.

Proposition 4.10. *Let $U \in (\mathcal{G}_\tau(\mathbb{R}^p))^q$ and let Φ be a projectable generalized group action on $\mathbb{R}^p \times \mathbb{R}^q$. Then $\Phi_\eta(\Gamma_U) = \Gamma_{\Phi_\eta(U)}$ in $\mathcal{R}^{p+q}$ for each η, where $\Phi_\eta(U)$ denotes the element*

$$x \to \Psi_\eta(\Xi_{-\eta}(x), U \circ \Xi_{-\eta}(x))$$

of $(\mathcal{G}_\tau(\mathbb{R}^p))^q$. □

We are now able to give a geometric characterization of solutions of PDEs in $\mathcal{G}_\tau$.

Proposition 4.11. *Consider the system of PDEs*

$$\Delta_\nu(x, U^{(n)}) = 0, \quad 1 \le \nu \le l, \tag{4.4}$$

in $\mathcal{G}_\tau(\mathbb{R}^p))^q$ (where $\Delta \in (\mathcal{G}_\tau((\mathbb{R}^p \times \mathbb{R}^q)^{(n)}))^l$). Set

$$\mathcal{S}_\Delta := \{\widetilde{z} \in \mathcal{R}^{(n)} \,:\, \Delta_\nu(\widetilde{z}) = 0 \ (1 \le \nu \le l)\}.$$

Then $U \in (\mathcal{G}_\tau(\mathbb{R}^p))^q$ is a solution of the system if and only if $\Gamma_{\mathrm{pr}^{(n)}U} \subseteq \mathcal{S}_\Delta$.

Proof. This follows immediately from [27, Theorem 2.7]. □

Prolongation of generalized group actions can be handled in a similar fashion as in the classical theory. Thus, let Φ be a projectable generalized group action on $\mathbb{R}^p \times \mathbb{R}^q$. We want to define the nth prolongation $\mathrm{pr}^{(n)}\Phi$ as a projectable generalized group action on $(\mathbb{R}^p \times \mathbb{R}^q)^{(n)}$. Let $z \in (\mathbb{R}^p \times \mathbb{R}^q)^{(n)}$ and choose $h \in \mathcal{O}_M(\mathbb{R}^p)^q$ such that $(z_1, \dots, z_p, \mathrm{pr}^{(n)}h(z_1, \dots, z_p)) = z$. Now set

$$\mathrm{pr}^{(n)}\Phi(\eta, z) := (\Xi_\eta(z_1, \dots, z_p), \mathrm{pr}^{(n)}(\Phi_\eta(h))(\Xi_\eta(z_1, \dots, z_p))). \tag{4.5}$$

Using for h a suitable Taylor polynomial, it follows that $\mathrm{pr}^{(n)}\Phi \in (\widetilde{\mathcal{G}}_\tau(\mathbb{R} \times (\mathbb{R}^p \times \mathbb{R}^q)^{(n)})^N$ (where $N = \dim((\mathbb{R}^{p+q})^{(n)})$). Moreover, the definition does not depend on the particular choice of h, which follows exactly as in the classical case.

Lemma 4.12. *Let $\widetilde{z} \in (\mathcal{R}^p \times \mathcal{R}^q)^{(n)}$ and assume that $U \in (\mathcal{G}_\tau(\mathbb{R}^p))^q$ satisfies $(\widetilde{z}_1, \dots, \widetilde{z}_p, \mathrm{pr}^{(n)}U(\widetilde{z}_1, \dots, \widetilde{z}_p)) = \widetilde{z}$. Then*

$$\mathrm{pr}^{(n)}\Phi(\eta, \widetilde{z}) = (\Xi_\eta(\widetilde{z}_1, \dots, \widetilde{z}_p), \mathrm{pr}^{(n)}(\Phi_\eta(U))(\Xi_\eta(\widetilde{z}_1, \dots, \widetilde{z}_p))) \quad \forall \eta \in \mathcal{R}_c. \tag{4.6}$$

Proof. Let $U = \mathrm{cl}[(u_\varepsilon)_{\varepsilon \in I}]$ and choose a representative $(z_\varepsilon)_{\varepsilon \in I}$ of $\widetilde{z}$ such that

$$(z_{1\varepsilon}, \dots, z_{p\varepsilon}, \mathrm{pr}^{(n)}u_\varepsilon(z_{1\varepsilon}, \dots, z_{p\varepsilon})) = z_\varepsilon \quad \forall \varepsilon.$$

Using the chain rule as in Proposition 3.7, it follows that the right hand sides of (4.5) (with z replaced by $\widetilde{z}$) and of (4.6) have the same representative (depending *exclusively* on $(z_\varepsilon)_{\varepsilon \in I}$). □

Proposition 4.13. *$\mathrm{pr}^{(n)}\Phi$ is a generalized group action on $(\mathbb{R}^p \times \mathbb{R}^q)^{(n)}$.*

Proof. Property 4.2 (i) is clearly satisfied. Concerning (ii), according to [27, Theorem 2.7] it suffices to show that

$$\mathrm{pr}^{(n)}\Phi(\eta_1 + \eta_2, \widetilde{z}) = \mathrm{pr}^{(n)}\Phi(\eta_1, \mathrm{pr}^{(n)}\Phi(\eta_2, \widetilde{z})) \quad \forall \eta_1, \eta_2 \in \mathcal{R}_c, \ \forall\, \widetilde{z} \in (\mathcal{R}^p \times \mathcal{R}^q)^{(n)}.$$

Choose some $U \in (\mathcal{G}_\tau(\mathbb{R}^p))^q$ with $(\widetilde{z}_1, \dots, \widetilde{z}_p, \mathrm{pr}^{(n)}U(\widetilde{z}_1, \dots, \widetilde{z}_p)) = \widetilde{z}$. Then due to Lemma 4.12 we have

$$\mathrm{pr}^{(n)}\Phi(\eta_2, \widetilde{z}) = (\Xi_{\eta_2}(\widetilde{z}_1, \dots, \widetilde{z}_p), \mathrm{pr}^{(n)}(\Phi_{\eta_2}(U))(\Xi_{\eta_2}(\widetilde{z}_1, \dots, \widetilde{z}_p))).$$

By (4.6) this implies $\mathrm{pr}^{(n)}\Phi(\eta_1, \mathrm{pr}^{(n)}\Phi(\eta_2, \widetilde{z})) = \mathrm{pr}^{(n)}\Phi(\eta_1 + \eta_2, \widetilde{z})$. □

As in the classical case we therefore have (using the notations from Proposition 4.11) the following proposition.

Proposition 4.14. *Let Φ be a projectable generalized group action on $\mathbb{R}^p \times \mathbb{R}^q$ such that $\mathrm{pr}^{(n)}\Phi$ is a symmetry group of the algebraic equation $\Delta(z) = 0$. Then Φ is a symmetry group of* (4.4).

Proof. If $U \in \mathcal{G}_\tau(\mathbb{R}^p)$ is a solution of (4.4), then $\Gamma_{\mathrm{pr}^{(n)}U} \subseteq \mathcal{S}_\Delta$ by Proposition 4.11. Thus

$$\Gamma_{\mathrm{pr}^{(n)}(\Phi_\eta U)} = \mathrm{pr}^{(n)}\Phi_\eta(\Gamma_{\mathrm{pr}^{(n)}U}) \subseteq \mathcal{S}_\Delta,$$

so that, again from Proposition 4.11, the claim follows. □

Definition 4.15. *Let X be a $\mathcal{G}$-complete generalized vector field. The nth prolongation of X is defined as the infinitesimal generator of the nth prolongation of the generalized group action Φ corresponding to X:*

$$\mathrm{pr}^{(n)}X\Big|_z = \frac{d}{d\eta}\Big|_0 \mathrm{pr}^{(n)}\Phi_\eta(z),$$

provided that $\mathrm{pr}^{(n)}\Phi$ is $\mathcal{G}$-complete as well. In this case, both X and Φ are called $\mathcal{G}$-n-complete.

From Theorem 4.7 and Proposition 4.14 we immediately conclude the following theorem.

Theorem 4.16. *Under the assumptions of Proposition* 4.11, *let Φ be a $\mathcal{G}$-n-complete generalized group action on $\mathbb{R}^p \times \mathbb{R}^q$ with infinitesimal generator X such that the conditions of Theorem* 4.7 *are satisfied for Δ and $\mathrm{pr}^{(n)}\Phi$. If*

$$\mathrm{pr}^{(n)}X(\Delta)(\widetilde{z}) = 0 \quad \forall \widetilde{z} \in (\mathcal{R}^p \times \mathcal{R}^q)^{(n)} \text{ with } \Delta(\widetilde{z}) = 0,$$

then Φ is a symmetry group of (4.4). □

In order to be able to apply the same algorithm as in classical Lie theory for the determination of the symmetry group of a generalized PDE, the final step is to verify that the formulas for prolongation of vector fields carry over to generalized vector fields.

Theorem 4.17. *Let*

$$X = (x, u) \to \sum_{i=1}^{p} \xi_i(x)\partial_{x_i} + \sum_{\alpha=1}^{q} \psi_\alpha(x, u)\partial_{u^\alpha}$$

be a $\mathcal{G}$-n-complete generalized vector field with corresponding projectable group action Φ on $(\mathbb{R}^p \times \mathbb{R}^q)$. Then

$$\mathrm{pr}^{(n)}X = X + \sum_{\alpha=1}^{q} \sum_J \psi_\alpha^J(x, u^{(n)})\partial_{u_J^\alpha},$$

where $J = (j_1, \dots, j_k)$, $1 \le j_k \le p$ for $1 \le k \le n$ and

$$\psi_\alpha^J(x, u^{(n)}) = D_J(\psi_\alpha - \sum_{i=1}^{p} \xi_i u_i^\alpha) + \sum_{i=1}^{p} \xi_i u_{J,i}^\alpha.$$

Proof. Using the machinery developed so far, this is an easy modification of the proof of the classical result (see [29, Theorem 2.36]). □

We may summarize the results of this section as follows: In order to determine the symmetries of a differential equation involving generalized functions, the algorithm (as in the classical case) is to make an ansatz for the infinitesimal generators, calculate their prolongations according to Theorem 4.17, and then use Theorem 4.16 to determine the defining equations for the coefficient functions of the infinitesimal generators. The defining equations now yield PDEs in $\mathcal{G}_\tau$. Any solution of these equations that defines a $\mathcal{G}$-n-complete generator will upon integration yield a symmetry group in $\mathcal{G}_\tau$.

Example 4.18. Scalar conservation laws of the form

$$u_t + F(u)u_x = 0 \tag{4.7}$$

arise in the kinetic theory of traffic flow. Here u denotes the density, and the propagation velocity F may be a strictly decreasing function of u with one or more jumps. A typical case is a unimodal flux function (whose derivative is F) with a kink at its maximum, as supported by experimental data [15]. Convolution with a nonnegative mollifier $(\rho_\varepsilon)_{\varepsilon\in I}$ allows us to interpret F as an element of $\mathcal{G}_\tau(\mathbb{R})$ which is invertible. Thus our theory of symmetry transformations for equations with generalized nonlinearities applies. The determining equations are

$$\begin{gathered}\varphi_t + F\varphi_x = 0,\\ -\xi_x + F\tau_t + \tau F_t + \varphi F_u - F\xi_x + F^2\tau_x + \xi F_x = 0\end{gathered}$$

with infinitesimal generator $\mathbf{v} = \xi(x,t)\partial_x + \tau(x,t)\partial_t + \varphi(x,t,u)\partial_u$. As a particular solution we obtain $\mathbf{v} = xt\partial_x + t^2\partial_t + (F'(u))^{-1}(x - tF(u))\partial_u$. The corresponding generalized group action can be calculated explicitly in $\mathcal{G}_\tau$ showing that if u is a $\mathcal{G}_\tau$ -solution to (4.7) then so is

$$(x,t) \to F^{-1}\left(\eta x(1+\eta t)^{-1} + F(u(x(1+\eta t)^{-1}, t(1+\eta t)^{-1})(1+\eta t)^{-1}\right).$$

In particular, a constant state u is transformed into a generalized solution to (4.7) which, depending on the shape of F, will generally be associated with a piecewise smooth function.

Example 4.19. The nonlinear d'Alembert–Hamilton system

$$\begin{gathered}u_{tt} - u_{xx} - u_{yy} - u_{zz} = F(u),\\ u_t^2 - u_x^2 - u_y^2 - u_z^2 = G(u)\end{gathered} \tag{4.8}$$

arises in the study of relativistic field equations [7] and as a constraint in reducing the nonlinear wave equation to an ODE [12, 13]. One of its symmetries is generated by the vector field $\mathbf{v} = \varphi(u)\partial_u$ where the function φ has to satisfy

$$\begin{gathered}F\varphi_u - \varphi F_u + G\varphi_{uu} = 0,\\ 2G\varphi_u - \varphi G_u = 0\,.\end{gathered}$$

In particular, in the isotropic case $F \equiv G \equiv 0$ the function φ is arbitrary. In our theory it may be taken in $\mathcal{G}_\tau(\mathbb{R})$ subject to the $\mathcal{G}$-completeness conditions formulated above. As an example of the possible behavior of generalized transformations, consider the vector field $\mathbf{v} = \varphi(u)\partial_u$ where $\varphi \in \mathcal{G}_\tau(\mathbb{R})$ is the class of $(\varphi_\varepsilon)_{\varepsilon\in I}$ with $\varphi_\varepsilon(u) = \tanh(\frac{u}{\varepsilon})$.

Thus $\varphi(u)$ is associated with the jump function $-\mathrm{sgn}(u)$. Starting with a classical smooth solution $u = u(x,t) \in \mathcal{O}_C(\mathbb{R}^4)$ of the isotropic d'Alembert–Hamilton system ((4.8) with $F \equiv G \equiv 0$), the generalized symmetry transform generated by the vector field $\mathbf{v}$ turns $u(x,t)$ into the generalized solution $\tilde{U} \in \mathcal{G}_\tau(\mathbb{R}^4)$ with representative

$$\tilde{u}_\varepsilon(x,t) = \varepsilon \operatorname{Arsinh}\left(e^{\eta/\varepsilon} \sinh \frac{u(x,t)}{\varepsilon} \right) .$$

When $\eta > 0$, it is straightforward to check that $\tilde{U}$ is associated with the piecewise smooth function $v(x,t) = u(x,t) + \eta\,\mathrm{sgn}(u(x,t))$. The generalized symmetry this way transforms smooth solutions into discontinuous solutions.

Acknowledgments. We would like to thank M. Grosser, G. Hörmann, and P. J. Olver for several helpful discussions. A number of constructive suggestions of the two referees led to improvements in the paper.

DISCRETE AND CONTINUOUS DIRICHLET-TO-NEUMANN MAPS IN THE LAYERED CASE*

DAVID V. INGERMAN†

Abstract. Every sufficiently regular nonnegative function γ (conductivity) on the closed unit disk $\overline{\mathbb{D}}$ induces the *Dirichlet-to-Neumann map* Λ_γ on functions on $\partial\mathbb{D}$. The main inverse problems are to give a characterization of the maps Λ_γ and to find out when Λ_γ uniquely determines γ. In this paper we consider the case of conductivities that are constant on circles centered at the origin, and a discrete analogue of this so called *layered case*. We characterize a closure of the set of the layered Dirichlet-to-Neumann maps in terms of their kernels and spectra. We give sharp conditions for the uniqueness in the discrete inverse problem, and conditions on γ for the uniqueness in the continuous problem that we conjecture to be sharp. The characterization in terms of the spectra shows that continuous Dirichlet-to-Neumann maps can be viewed as limits of the discrete Dirichlet-to-Neumann maps. The characterization in terms of the kernels supports the conjecture in [D. Ingerman and J. Morrow, *SIAM J. Math. Anal.*, 29 (1998), pp. 106–115] that the *alternating property* essentially characterizes continuous Dirichlet-to-Neumann maps. The characterizations above give a new interpretation of connections between positive measures, positive definite functions, and analytic functions that map the right half-plane to itself in the Bochner and Herglotz theorems.

1. Introduction.

We first give a short outline of the paper. Precise definitions and theorems are in the next section.

Every sufficiently smooth positive function γ on the closed unit disk $\overline{\mathbb{D}}$ induces the Dirichlet-to-Neumann map Λ_γ from functions on the boundary of the disk $\partial\mathbb{D}$ to functions on $\partial\mathbb{D}$. There are two main inverse problems connected with the maps Λ_γ:

- The characterization of the Dirichlet-to-Neumann maps. (A necessary condition is known: it was shown in [8] and [4] that if $\gamma \in C^2(\overline{\mathbb{D}})$ then Λ_γ has so called alternating property, which can be thought of as a generalized Hopf's lemma property.)
- The problem of finding γ from Λ_γ. (A sufficient condition for uniqueness is known: It was recently proved in [13] that Λ_γ uniquely determines γ for $\gamma \in W^{2,p}(\overline{\mathbb{D}}) \subset C(\overline{\mathbb{D}})$, $p > 1$.)

Great progress in understanding of the discrete analogues (Dirichlet-to-Neumann maps on graphs) of these problems was made in [3] and [2]: it was shown that the discrete analogue of the alternating property essentially characterizes the discrete Dirichlet-to-Neumann maps. Also the discrete inverse problem was completely solved. The success in understanding the discrete problems gives one of the main motivations of this paper: to show a strong connection between properties of the continuous and discrete Dirichlet-to-Neumann maps.

In this paper we consider the case of conductivities that are constant on circles centered at the origin. We also consider a discrete analogue of this so called layered

†Department of Mathematics, University of Washington, Seattle, WA 98195 (ingerman@math.washington.edu).

case. We obtain a clear picture of the sets of both discrete and continuous Dirichlet-to-Neumann maps in this case. We characterize their closure in terms of their kernels and spectra.

The characterization in terms of the spectra shows that continuous Dirichlet-to-Neumann maps can be viewed as limits of the discrete Dirichlet-to-Neumann maps.

The characterization in terms of the kernels supports the conjecture in [8] that the alternating property essentially characterizes continuous Dirichlet-to-Neumann maps.

We also conjecture sharp conditions on γ for the uniqueness in the continuous inverse problem. For the discrete case, we give a new algorithm, based on the Pick–Nevalinna interpolation theorem, for the recovery of γ.

The characterizations above give a new interpretation of the connection between positive measures, positive definite functions, and analytic functions from the right half-plane to itself: these objects describe, respectively, spectral measures, kernels, and spectra of Dirichlet-to-Neumann maps in the layered case.

2. Background and main results.

2.1. Basic definitions. We first give the definition of Dirichlet-to-Neumann maps as it is usually done; see [17] for details. For the layered case, which we will consider, the restrictions on γ will be weakened, and the domain of Λ_γ will be shrunk.

Let $\gamma \in C^{1,1}(\overline{\mathbb{D}})$. A function $u \in H^1(\mathbb{D})$ is called a γ-*harmonic* function or *potential* if

$$\operatorname{div}(\gamma \nabla u) = 0 \text{ in } \mathbb{D}. \tag{2.1}$$

A potential in $\mathbb{D}$ satisfies this equation if there are no sources or sinks of current in $\mathbb{D}$.

For each $f \in H^{1/2}(\partial\mathbb{D})$ there exists a unique γ-harmonic function u such that $u|_{\partial\mathbb{D}} = f$. The Dirichlet-to-Neumann corresponding to γ maps the boundary values of a γ-harmonic function (Dirichlet data) to the current flux $\gamma\frac{\partial u}{\partial r}|_{r=1}$ at the boundary (Neumann data). In symbols

$$\Lambda_\gamma = \gamma\frac{\partial u}{\partial r}|_{r=1},$$

where u is γ-harmonic and $u|_{\partial\mathbb{D}} = f$. The operator $\Lambda_\gamma : H^{1/2}(\partial\mathbb{D}) \to H^{-1/2}(\partial\mathbb{D})$ is a self-adjoint pseudodifferential operator of order 1.

A discrete analogue of the disk $\mathbb{D}$ is a *circular planar* graph. It is a finite graph $\Gamma = (V, E, \partial\Gamma)$ imbedded into $\overline{\mathbb{D}}$, where the set V is the set of nodes of the graph, the set E is the set of edges of Γ, and $\partial\Gamma = V \cap \partial\mathbb{D}$ is the nonempty set of *boundary* nodes of Γ. The set $V - \partial\Gamma$ is the set of *interior* nodes of Γ. A conductivity γ is a positive function on the edges of Γ.

A function u on the nodes of Γ is γ-harmonic if at every interior node p it satisfies Kirchhoff's law, that is, *the total current* $I_u(p)$ *out of* p *is zero*:

$$I_u(p) = \sum_{pq \in E} \gamma(pq)(u(p) - u(q)) = 0. \tag{2.2}$$

This tells that the value of u at p is the weighted average of the values of u at the neighbors of p (neighbors are the nodes q of the graph for which $pq \in E$). It follows that γ-harmonic functions satisfy the maximum and the minimum principles. From now on we will consider only the graphs in which every interior node is topologically connected to at least one boundary node. On such graphs (and only on them) each

γ-harmonic function u is uniquely determined by its values $u|_{\partial\Gamma}$ on the boundary of Γ. The discrete Dirichlet-to-Neumann map Λ_γ is the linear map that sends the boundary values f of a γ-harmonic function u to the corresponding total current out of nodes at the boundary $I_u|_{\partial\Gamma}$. Or algebraically,

$$\Lambda_\gamma f(p) = I_u(p) = \sum_{pq\in E} \gamma(pq)(u(p) - u(q)), p \in \partial\Gamma, \tag{2.3}$$

where u is γ-harmonic and $u|_{\partial\Gamma} = f$.

2.2. Alternating property. One of the main motivations of this paper is to show a strong connection between properties of discrete and continuous Dirichlet-to-Neumann maps. An important step in this direction has been made in [8], [3], and [4], where it was shown that both discrete and continuous Dirichlet-to-Neumann maps have the *alternating property.*

THEOREM 2.1 (see [8] and [4]). *Let Λ_γ be a Dirichlet-to-Neumann map for $\gamma \in C^2(\overline{\mathbb{D}})$. Then Λ_γ has the alternating property. That is, let A and B be a pair of disjoint intervals on $\partial\mathbb{D}$ and $f \in C^\infty(\partial\mathbb{D})$, such that* supp$f \subset A$. *Then for any m distinct points $b_1, b_2, \dots, b_m \in B$, numbered* clockwise*, such that*

$$(-1)^i \Lambda f(b_i) > 0,$$

there exists m distinct points $a_1, a_2, \dots, a_m \in A$ numbered counterclockwise*, such that*

$$(-1)^i f(a_i) < 0.$$

Figure 2.1 shows the main idea of the proof: the pattern of the directions of the current flux $\Lambda_\gamma f$ on B together with the maximum and minimum principles guarantee the existence of nonintersecting curves from b's on which potential alternates in sign. Since supp$f \subset A$ these curves have to terminate at A. See [8] for a detailed proof.

The same argument can be applied to the discrete case. In fact the discrete version of the alternating property, which we define next, essentially characterizes the discrete Dirichlet-to-Neumann maps.

We identify the space of real functions on $\partial\Gamma$ with $\mathbb{R}^n$, where n is the number of points in $\partial\Gamma$.

THEOREM 2.2 ([3]). *A self-adjoint linear map $\Lambda : \mathbb{R}^n \to \mathbb{R}^n$ is a Dirichlet-to-Neumann map of a circular planar graph if and only if $\Lambda 1 = 0$ and Λ has the discrete alternating property, that is, let A, B be a pair of disjoint intervals on $\partial\mathbb{D}$ and f a function on $\partial\Gamma$ with* supp$f \subset A$. *Then for any m points ($2m \le n$) $b_1, b_2, \dots, b_m \in B \cap \partial\Gamma$, numbered clockwise and such that*

$$(-1)^i \Lambda f(b_i) > 0,$$

there exist m distinct points $a_1, a_2, \dots, a_m \in A \cap \partial\Gamma$, numbered counterclockwise such that

$$(-1)^i f(a_i) < 0.$$

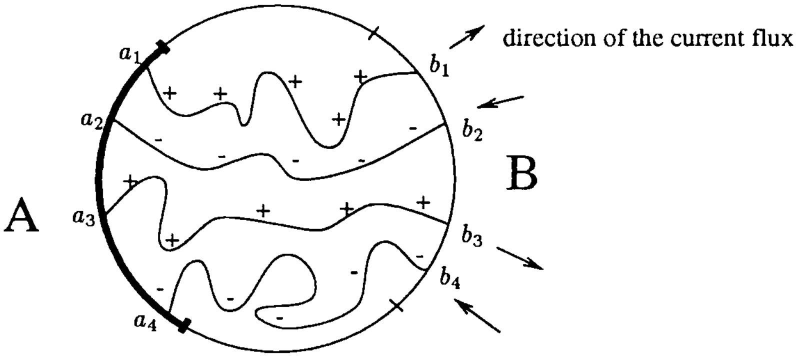

FIG. 2.1.

2.3. Right sign property. The following algebraic description of the alternating property turned out to be very useful. To state it we consider the *kernel* of Λ_γ.

For a discrete Dirichlet-to-Neumann map Λ_γ its kernel is the matrix that represents the linear operator Λ_γ.

The kernel of a continuous Dirichlet-to-Neumann map is the distribution $K(\phi, \theta)$ on $\partial\mathbb{D} \times \partial\mathbb{D}$ such that

$$\Lambda_\gamma f(\phi) = \int_0^{2\pi} K(\phi, \theta) f(\theta) d\theta. \tag{2.4}$$

The existence of K is guaranteed by the fact that Λ_γ is a pseudodifferential operator. In fact for $\gamma \in C^2(\overline{\mathbb{D}})$ K is a continuous function off the diagonal of $\partial\mathbb{D} \times \partial\mathbb{D}$, and the singularity at the diagonal is of order 2 (see [8]). The following theorem shows the equivalence of the alternating property of an operator Λ and the algebraic property of the kernel of Λ.

THEOREM 2.3 ([3]). *A symmetric matrix Λ is the kernel of a linear operator $\Lambda : \mathbb{R}^n \to \mathbb{R}^n$ that has the alternating property if and only if the kernel of Λ has the discrete* right sign *property. That is, for any two disjoint intervals $A, B \subset \partial\mathbb{D}$ and any $2m$ ($2m \leq n$) distinct points $a_1, a_2, \ldots, a_m \in A \cap \partial\Gamma$, $b_1, b_2, \ldots, b_m \in B \cap \partial\Gamma$ (as before a's are numbered counterclockwise and b's are numbered clockwise),*

$$\det\{-\Lambda(b_i, a_j)\}_{i,j=1}^m \geq 0.$$

A continuous analogue of this theorem was recently proved in [8].

THEOREM 2.4. *Let K be a distribution on $\partial\mathbb{D} \times \partial\mathbb{D}$ such that K is continuous off the diagonal and has a singularity of order 2 on the diagonal. Then the operator*

$$\Lambda f = \int K f$$

has the alternating property if and only if K has the continuous right sign *property. That is, for any two disjoint intervals $A, B \subset \partial\mathbb{D}$ and any $2m$ distinct points $a_1, a_2, \ldots, a_m \in A$, $b_1, b_2, \ldots, b_m \in B$ (a's and b's are numbered as above),*

$$\det\{-K(a_i, b_j)\}_{i,j=1}^m > 0.$$

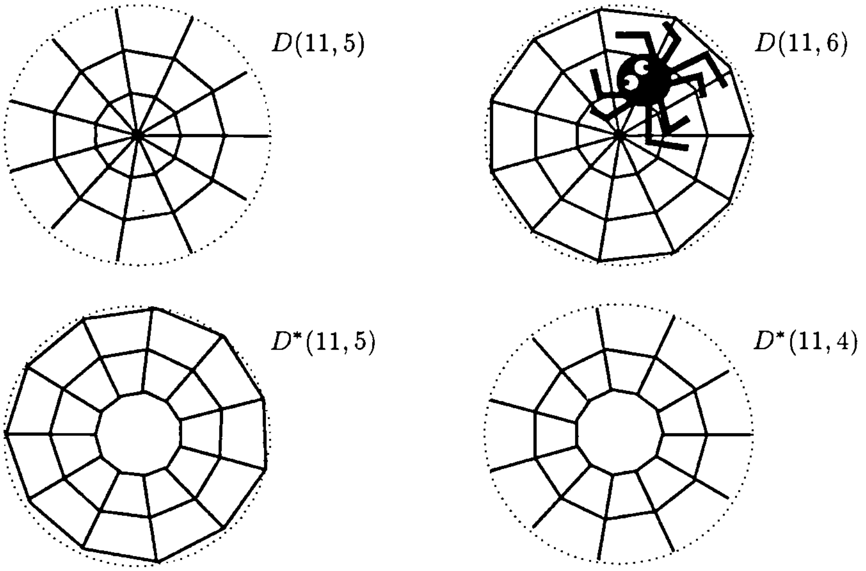

FIG. 2.2.

2.4. The layered case and the admittance function. In this paper we consider the case of conductivities that are constant on circles centered at the origin.

We now introduce a discrete analogue of the continuous layered situation. The *discrete disks* are connected circular planar graphs $D(n,l)$ and $D^*(n,l)$ of the following shapes shown in Figure 2.2, where n is the number of radial lines and l is the number of *layers*. The layers of the graphs $D(n,l)$ and $D^*(n,l)$ are minimal subsets of edges invariant under rotations of the graph by the angle $\frac{2\pi}{n}$. Each layer consists of n edges. We assume that the conductivity γ is constant on layers. Therefore, the layered conductivity is determined by l positive numbers.

We first describe the effect that the assumed form of γ has on Λ_γ. In both discrete and continuous situations the γ-harmonic functions are still γ-harmonic after rotations and reflections with respect to the origin. Therefore, the discrete and continuous Dirichlet-to-Neumann maps, corresponding to the layered conductivities γ, commute with rotations and the reflections of functions on the boundaries. For the continuous case it immediately follows that Dirichlet-to-Neumann maps commute with the Laplacian on the boundary of the disk $\frac{d^2}{d\theta^2}$. With a little more effort one gets that $\Lambda_\gamma 1 = 0$ and

$$\Lambda_\gamma e^{\pm ik\theta} = R(k)e^{\pm ik\theta}, k \in \mathbb{N}. \tag{2.5}$$

We call the function R the *admittance* function. Its values at positive integers uniquely determine Λ_γ. Let C be the set of positive measurable conductivities γ on $[0,1]$ such that for all $\epsilon > 0$

$$\int_\epsilon^1 \left(\gamma + \frac{1}{\gamma}\right) dr < \infty.$$

The results of Krein and Kac [9] (see also [5]) show that the admittance functions and therefore the Dirichlet-to-Neumann maps are well-defined on C. Let L be the set of Dirichlet-to-Neumann maps for conductivities from C. We will give it a weak topology defined by

$$\Lambda_n \to \Lambda \Leftrightarrow \Lambda_n e^{ik\theta} \to \Lambda e^{ik\theta} \Leftrightarrow R_n(|k|) \to R(|k|) \text{ for all } k \in \mathbb{Z}.$$

We will slightly abuse terminology, talking about admittance functions corresponding to the maps from $\overline{L}$.

We now will make sense of the admittance function for the discrete Dirichlet-to-Neumann maps. The discrete version of the Laplacian on the boundary of a discrete disk $D(n,l)$ or $D^*(n,l)$ is given by the $n \times n$ matrix of the form

$$\left[\frac{d^2}{d\theta^2}\right] = -\begin{pmatrix} 2 & -1 & 0 & 0 & \dots & 0 & 0 & -1 \\ -1 & 2 & -1 & 0 & \dots & 0 & 0 & 0 \\ \vdots & \vdots & \vdots & \vdots & \ddots & \vdots & \vdots & \vdots \\ 0 & 0 & 0 & 0 & \dots & -1 & 2 & -1 \\ -1 & 0 & 0 & 0 & \dots & 0 & -1 & 2 \end{pmatrix}.$$

It makes the calculations cleaner if we assume that n is odd. Throughout this section we let $n = 2m+1, m \in \mathbf{N}$. We define

$$\partial_n = \left\{\frac{2\pi j}{n}, j = -m, \dots, 0, \dots, m\right\}. \tag{2.6}$$

Direct calculation shows that $[\frac{d^2}{d\theta^2}]$ is diagonal in the orthogonal basis

$$e^{ik\theta}|_{\partial_n}, k = -m, \dots, 0, \dots, m$$

with the eigenvalues

$$-|e^{i\frac{2\pi k}{n}} - 1|^2, k = -m, \dots, 0, \dots, m.$$

We define

$$\omega_k^{(n)} = \omega_{-k}^{(n)} = |e^{i\frac{2\pi k}{n}} - 1|, k = -m, \dots, 0, \dots, m. \tag{2.7}$$

Note that

$$\lim_{n\to\infty} \frac{n}{2\pi}\omega_k^{(n)} = |k|.$$

The discrete Λ_γ commute with $[\frac{d^2}{d\theta^2}]$ and we get that the eigenvectors of the discrete Dirichlet-to-Neumann maps are the restrictions of the eigenfunctions of the continuous Dirichlet-to-Neumann maps to the boundaries of the discrete disks. In symbols,

$$\Lambda_\gamma e^{\pm ik\theta}|_{\partial_n} = R(\omega_k^{(n)}) e^{\pm ik\theta}|_{\partial_n}, k = 1, \dots, m. \tag{2.8}$$

2.5. Characterization of admittance functions. Now, to see how “close” the discrete and continuous Dirichlet-to-Neumann maps are, we need to describe their possible eigenvalues. We will give the descriptions by characterizing the discrete and continuous admittance functions.

The discrete admittance functions will turn out to be of the form of the Stieltjes' continued fractions:

$$R(\lambda) = \cfrac{1}{\cfrac{1}{\gamma_l} + \cfrac{1}{\gamma_{l-1}\lambda^2 + \cdots + \cfrac{1}{\cfrac{1}{\gamma_3} + \cfrac{1}{\gamma_2\lambda^2 + \cfrac{1}{\cfrac{1}{\gamma_1}}}}}}, \tag{2.9}$$

where γ_i's are the conductivities on the layers of the discrete disks. This explicit formula will allow us to show a one-to-one correspondence between the admittance functions of discrete disks with l layers and the Blaschke products of degree l. (This correspondence together with the Pick–Nevanlinna interpolation theorem is a key to the discrete inverse problem; see section 4.3.)

It follows from (2.9) that

$$\beta(\lambda) = \frac{R(\lambda)}{\lambda} \tag{2.10}$$

has a natural extension to an analytic function from the right half-plane $\mathbb{C}^+$ to itself. We define

$$\mathfrak{B} = \{\beta : \mathbb{C}^+ \to \mathbb{C}^+,\ \beta \text{ is analytic},\ \beta(\lambda) > 0 \text{ for } \lambda > 0\}.$$

Applying the Pick–Nevanlinna interpolation theorem (see [12], [16]), we will prove the following theorem.

THEOREM 2.5. *A linear map $\Lambda : \mathbb{R}^n \to \mathbb{R}^n$ is the Dirichlet-to-Neumann map of a discrete disk if and only if Λ is diagonal in the orthogonal basis*

$$e^{ik\theta}|_{\partial_n}, k = -m, \ldots, 0, \ldots, m,$$

$\Lambda 1 = 0$*, and there is a function β in $\mathfrak{B}$ such that*

$$\Lambda e^{\pm ik\theta}|_{\partial_n} = \omega_k^{(n)} \beta(\omega_k^{(n)}) e^{\pm ik\theta}|_{\partial_n}, k = 1, \ldots, m.$$

In other words the set of the Dirichlet-to-Neumann maps is equal to

$$\left\{ \sqrt{-\left[\frac{d^2}{d\theta^2}\right]} \beta \left(\sqrt{-\left[\frac{d^2}{d\theta^2}\right]} \right) : \beta \in \mathfrak{B} \right\}. \tag{2.11}$$

It turns out that a continuous analogue of this theorem is true. (Our proof heavily uses the characterization of spectral measures of inhomogeneous strings done by Krein and Kac [9]; see also [5].)

THEOREM 2.6. *The closure of the set of the layered Dirichlet-to-Neumann maps for conductivities in C equals*

$$\overline{L} = \left\{ \sqrt{-\frac{d^2}{d\theta^2}} \beta \left(\sqrt{-\frac{d^2}{d\theta^2}} \right) : \beta \in \mathfrak{B} \right\}. \tag{2.12}$$

Remark. Equation (2.1) in the layered case after separation of variables is sometimes replaced by the integral equation described in section 3.2 (see [14]). This allows one to define the admittance function, and therefore the Dirichlet-to-Neumann map, for conductivity given by a positive measure. This may be a cleaner setting in which one does not need to take the closure of the set of Dirichlet-to-Neumann maps to get the equality above.

2.6. The "$\gamma \leftrightarrow \frac{1}{\gamma}$" duality.

We note, without a proof, that the following identity is true; see [9] or [5]:

$$\Lambda_\gamma \Lambda_{\frac{1}{\gamma}} = \Lambda_{\frac{1}{\gamma}} \Lambda_\gamma = -\frac{d^2}{d\theta^2}.$$

DEFINITION 2.7. *Two disks $D_\gamma(n,l)$ and $D^*_{\frac{1}{\gamma}}(n,l)$ with conductivities on layers, respectively, $\{\delta_1, \xi_1, \delta_2, \xi_2, \delta_3, \dots\}$ and $\{\frac{1}{\delta_1}, \frac{1}{\xi_1}, \frac{1}{\delta_2}, \frac{1}{\xi_2}, \frac{1}{\delta_3}, \dots\}$ are called* dual.

We will show that

$$\Lambda(D^*_{\frac{1}{\gamma}})\Lambda(D_\gamma) = \Lambda(D_\gamma)\Lambda(D^*_{\frac{1}{\gamma}}) = -\left[\frac{d^2}{d\theta^2}\right].$$

Remark. We find the following result amusing. It was motivated by a question of G. Uhlmann. This question, together with the paper [16], has stimulated this paper. If γ is identically 1 on $\overline{\mathbb{D}}$ then the corresponding Dirichlet-to-Neumann map as an operator is the positive square root of the minus Laplacian on $\partial\mathbb{D}$. In symbols,

$$\Lambda_1 = \sqrt{-\frac{d^2}{d\theta^2}}.$$

The question: *Is*

$$\sqrt{-\left[\frac{d^2}{d\theta^2}\right]}$$

the Dirichlet-to-Neumann map of a circular planar graph? The answer is yes. It is an easy corollary of Theorem 2.5.

2.7. Approximation of continuous Dirichlet-to-Neumann maps by discrete ones.

Remark. We note that from the results in [8] it follows that the discrete disks give all possible Dirichlet-to-Neumann maps of circular planar graphs. In particular, the discrete disks with layered conductivity give all possible Dirichlet-to-Neumann maps Λ of circular planar graphs with the eigenvectors $e^{\pm ik\theta}|_{\partial_n}$. Therefore, for the purposes of the approximations of continuous Dirichlet-to-Neumann maps of the disk with layered conductivity by the discrete ones, one loses nothing essential considering only the discrete disks with layered conductivity and not all circular planar graphs.

The Pick–Nevalinna interpolation theorem (see [12]) lets us formulate the following "continuous is the limit of discrete" theorem.

THEOREM 2.8. *In the layered case, the eigenvectors of discrete Dirichlet-to-Neumann maps are restrictions of the eigenfunctions of the continuous Dirichlet-to-Neumann maps.*

Let $\lambda_1, \lambda_2, \ldots, \lambda_k$ be the first (corresponding to $e^{i\theta}, e^{2i\theta}, \ldots, e^{ik\theta}$) eigenvalues of a map from $\overline{L}$. Then there exists a sequence of discrete disks $\{D_n\}$ with the first eigenvalues $\lambda_1^n, \lambda_2^n, \ldots, \lambda_k^n$ such that

$$\lambda_j = \lim_{n\to\infty} \lambda_j^n, 1 \leq j \leq k.$$

Conversely, let $\{D_n\}$ be a sequence of discrete disks such that the limits above exist. Then there exists an element of $\overline{L}$ with the first k eigenvalues being equal to the limits.

2.8. Characterization of kernels: Positive definite functions. We will now show the existence and characterize the kernels of the Dirichlet-to-Neumann maps in the layered case. We show the existence by an explicit calculation of the kernel of a map from $\overline{L}$ in terms of the corresponding admittance function $R(\lambda)$. Recall that the layered Dirichlet-to-Neumann maps commute with rotations and reflections (with respect to the origin) of functions. It follows that the kernel of Λ_γ has to be of the convolution type

$$K(\phi, \theta) = h(\phi - \theta),$$

where h is a distribution on $\mathbb{R}$ such that

$$h(s) = h(s + 2\pi) = h(2\pi - s), s \in \mathbb{R}$$

and

$$\int_0^{2\pi} h(s) \cos \lambda s ds = R(\lambda), \lambda > 0.$$

To proceed we need the following representation of analytic functions that maps the right half-plane to itself (see [1]).

Theorem 2.9 (Herglotz). *A function β is in $\mathfrak{B}$ if and only if for some $c, C \geq 0$*

$$\beta(\lambda) = C\lambda + \frac{c}{\lambda} + \int_0^\infty \frac{\lambda(1+t^2)d\sigma(t)}{\lambda^2 + t^2},$$

where σ is a positive measure of bounded variation on $(0, \infty)$.

A straightforward calculation gives us the following lemma.

Lemma 2.10. *A distribution K on $\partial\mathbb{D} \times \partial\mathbb{D}$ is the kernel of a map in the closure of the set of the layered Dirichlet-to-Neumann maps if and only if*

$$K(\phi, \theta) = h(\phi - \theta),$$

where h is a distribution on $\mathbb{R}$ such that $h(s) = h(s + 2\pi) = h(2\pi - s), s \in \mathbb{R}$,

$$\int_0^{2\pi} h(s) ds = 0,$$

and for $s \in [0, 2\pi)$

$$h(s) = c\delta(0) - C\delta''(0) + \int_0^\infty t\frac{e^{-st} + e^{(s-2\pi)t}}{1 - e^{-2\pi t}}(1+t^2)d\sigma(t), \tag{2.13}$$

where $c, C \geq 0$ and σ is a positive measure of bounded variation on $(0, \infty)$.

Corollary 2.11. *The kernel of a layered Dirichlet-to-Neumann map is C^∞ off the diagonal.*

We will now explain a connection of the characterization in Lemma 2.10 with the alternating property.

Definition 2.12. *A continuous function f on a possibly infinite interval (a, b) is* positive definite *if*

$$\det\{f(x_i + y_j)\}_1^m \geq 0$$

for all $m \in \mathbb{N}$, $x_i + y_j \in (a, b)$.

It follows that f is positive definite on $(0, 2\pi)$ if and only if the kernel $K(\phi, \theta) = f(\phi - \theta)$ satisfies the right sign property. We are now one step from restating the characterization of the kernels in terms of their right sign property. We need the following classical characterization of the positive definite functions (see [10]).

Theorem 2.13 (Bochner). *A continuous function f is positive definite on a possibly infinite interval (a, b) if and only if there exists a positive σ-finite measure ν on $\mathbb{R}$ such that*

$$f(x) = \int_{-\infty}^{+\infty} e^{xt} d\nu(t).$$

We now state one of the main results of this paper.

Theorem 2.14. *A distribution K on $\partial\mathbb{D} \times \partial\mathbb{D}$ is the kernel of a map in the closure of the set of the layered Dirichlet-to-Neumann maps if and only if*

$$K(\phi, \theta) = h(\phi - \theta),$$

where h is a distribution on $\mathbb{R}$ such that $h(s) = h(s + 2\pi) = h(2\pi - s), s \in \mathbb{R}$,

$$\int_0^{2\pi} h(s) ds = 0, \qquad \int_0^{2\pi} h(s)(\cos s - 1) ds < \infty,$$

and h is positive definite on $(0, 2\pi)$.

A discrete analogue of this theorem is an easy corollary of Theorems 2.2 and 2.3 and conductivity recovery algorithm in [3].

2.9. The inverse problems.

The continuous inverse problem will be reduced to an inverse Sturm–Liouville problem studied by Krein; see [9]. We obtain the following result.

Theorem 2.15. *The map from layered conductivities to corresponding Dirichlet-to-Neumann maps is injective on C.*

Conjecture. We would conjecture that the condition above for uniqueness in the inverse problem is sharp since if for some $\epsilon > 0$

$$\int_\epsilon^1 \left(\gamma + \frac{1}{\gamma}\right) dr = \infty,$$

then electrical flow does penetrate closer than ϵ to the origin and no information about γ on $[0, \epsilon)$ can be obtained from Λ_γ.

Our main result on the discrete inverse problem can be roughly stated as the following theorem.

THEOREM 2.16. *A layered conductivity on $D(2m+1, l)$ or $D^*(2m+1, l)$ can be recovered from the corresponding Dirichlet-to-Neumann map if and only if $l \leq m$.*

(See section 4.3 for a refined version.) Theorem 2.16 follows from the general theory in [3] and [4]. In this paper the proof of the uniqueness and the conductivity recovery algorithm are much simpler due to the assumed form of the conductivity.

Our algorithm shows an intimate connection between the discrete inverse problem and the Pick–Nevalinna interpolation problem.

2.10. The case of a half-plane. One often considers the Dirichlet-to-Neumann maps of the lower half-plane with a conductivity that is constant on horizontal lines. For that layered case the following results hold. Let $\overline{L}_{half\text{-}plane}$ be defined by analogy with $\overline{L}$.

THEOREM 2.17.

$$\overline{L}_{half\text{-}plane} = \left\{ \sqrt{-\frac{d^2}{dx^2}}\beta\left(\sqrt{-\frac{d^2}{dx^2}}\right) : \beta \in \mathfrak{B} \right\}.$$

THEOREM 2.18. *A distribution K on $\mathbb{R}\times\mathbb{R}$ is the kernel of a map from $\overline{L}_{half\text{-}plane}$ if and only if*

$$K(\phi, \theta) = h(\phi - \theta),$$

where h is a distribution on $\mathbb{R}$ such that $h(s) = h(-s)$,

$$\int_0^\infty h(s)ds = 0, \qquad \int_0^\infty h(s)(\cos s - 1)ds < \infty,$$

and h is positive definite on $(0, \infty)$.

3. Continuous problem. Our assumption that γ depends only on r makes it possible to reduce our subject of study to a 1-dimensional one.

3.1. Reduction to a 1-dimensional problem.

LEMMA 3.1. *The solution to the Dirichlet problem on $\mathbb{D}$ with the boundary data $e^{ik\theta}, k \in \mathbb{Z}$ is of the form*

$$u_k(r, \theta) = a_k(r)e^{ik\theta}.$$

Proof. Suppose u is γ-harmonic and $u|_{\partial\mathbb{D}} = e^{ik\theta}$. Since the conductivity is constant on circles, for all $\epsilon > 0$

$$v(r, \theta) = u(r, \theta + \epsilon) - u(r, \theta)$$

is also γ-harmonic and $v|_{\partial\mathbb{D}} = e^{ik\theta}(e^{ik\epsilon} - 1)$. Hence, by the uniqueness of the solution of the Dirichlet problem,

$$u_k(r, \theta)(e^{ik\epsilon} - 1) = u_k(r, \theta + \epsilon) - u_k(r, \theta)$$

$$\Rightarrow u_k(r, \theta)e^{ik\epsilon} = u_k(r, \theta + \epsilon)$$

$$\Rightarrow u_k(r, \theta) = a_k(r)e^{ik\theta}. \qquad \square$$

COROLLARY 3.2. *Λ_γ and $\frac{d^2}{d\theta^2}$ have the same eigenfunctions*

$$e^{ik\theta}, k \in \mathbb{Z}.$$

We have that for $k \in \mathbb{N}$

$$\begin{cases} a_k(0) = 0, \\ a_k(1) = 1. \end{cases}$$

Writing (2.1) in polar coordinates gives

$$\frac{d}{dr}\gamma(r) r \frac{d}{dr} a_k(r) - k^2 \frac{\gamma(r)}{r} a_k(r) = 0. \tag{3.1}$$

The eigenvalue of Λ_γ corresponding to $e^{ik\theta}$ and $e^{-ik\theta}$ is

$$R(k) = \gamma \frac{da_k}{dr}(1).$$

For $\gamma \in C$ we make the change of variable

$$x = \int_r^1 \frac{dt}{t\gamma(t)}.$$

Let $x_\infty = \int_0^1 \dfrac{dt}{t\gamma(t)} \le \infty$. We have

$$\left(\frac{1}{\gamma(x)^2}\frac{d}{dx}\right)\frac{d}{dx} a_k(x) = k^2 a_k(x), x \in (0, x_\infty), \tag{3.2}$$

$$\begin{cases} a_k(0) = 1, \\ a_k(x_\infty) = 0, \end{cases}$$

and

$$R(k) = -\frac{da_k}{dx}(0).$$

The investigations by Krein and Kac, outlined in the next section, show that the admittance function R is well-defined even if the operator $\frac{1}{\gamma(x)^2}\frac{d}{dx}$ in (3.2) is replaced by $\frac{d}{dm(x)}$ where $m(x)$ is a distribution function of a positive measure. If $m(x)$ is differentiable then

$$m(x) = \int_0^x \gamma(x)^2 dx = \int_r^1 \frac{\gamma(r) dr}{r}.$$

3.2. Small vibrations of strings. We will give now, without proofs, an outline of some results of Krein and Kac; see also [5].

DEFINITION 3.3. *A* string *is a pair lm, where l is the length of the string* ($0 < l \leq \infty$) *and*

$$m = m(x), x \in [0, l]$$

is a nondecreasing function with

$$0 \leq m(x) < \infty \text{ for } 0 \leq x < l.$$

The value of m at x represents the mass of the interval $[0, x]$.

We note that this definition is slightly different from the one in [9] and [5]. Instead of considering different ways of attaching the right end of the string we allow a weightless interval at that end.

If the right end l of the string is fixed, and a pulsating force

$$F = A \sin \sqrt{\zeta} t, \zeta \notin \mathbb{R}$$

is applied to the left end in the direction perpendicular to the x-axis, the forced oscillation of the left end satisfies the law

$$y = \Omega(\zeta) A \sin \sqrt{\zeta} t.$$

The function Ω is called the *coefficient of dynamic compliance* of the string.

The amplitude function of the oscillation satisfies the following integral equation:

$$\psi(x, \zeta) = \psi(0, \zeta) + \psi'_{-}(0, \zeta)x - \zeta \int_0^x (x - s)\psi(s, \zeta) dm(s). \tag{3.3}$$

If m has the density $\rho(x) = dm/dx$ this equation has an equivalent differential form

$$\frac{1}{\rho(x)} \frac{d^2}{dx^2} \psi(x, \zeta) = -\zeta \psi(x, \zeta). \tag{3.4}$$

The integral form makes the general characterizations below possible.

Let $\phi(x, \zeta)$ and $\theta(x, \zeta)$ be the solutions of (3.3) with the boundary conditions

$$\begin{cases} \phi(0, \zeta) = 1, \\ \dfrac{d\phi}{dx}(0, \zeta) = 0 \end{cases} \quad \text{and} \quad \begin{cases} \theta(0, \zeta) = 0, \\ \dfrac{d\theta}{dx}(0, \zeta) = 1. \end{cases}$$

For every $x \in [0, x_\infty)$ the functions $\phi(x, \zeta)$ and $\theta(x, \zeta)$ are entire functions of ζ. The coefficient of dynamic compliance is determined by these fundamental solutions:

$$\Omega(\zeta) = \lim_{x \to l} \frac{\theta(x, \zeta)}{\phi(x, \zeta)}.$$

Note that

$$\psi(x, \zeta) = \phi(x, \zeta) - \frac{1}{\Omega(\zeta)} \theta(x, \zeta)$$

is the solution of (3.3) with

$$\begin{cases}\psi(0,\zeta)=1,\\ \psi(l,\zeta)=0.\end{cases}$$

The following fundamental theorem is proved in [9]; see also [5].

THEOREM 3.4. *For every function of the form*

$$\Omega(\zeta)=C-\frac{c}{\zeta}+\int_0^\infty\frac{(1+t^2)d\sigma(t)}{t^2-\zeta},\zeta\in\mathbb{C}-[0,+\infty),$$

where σ is a positive measure of bounded variation on $(0,\infty)$ there exists a unique string for which Ω serves as the coefficient of dynamic compliance. And for every string its coefficient of dynamic compliance is of this form.

The measure σ is essentially the spectral measure of the operator $\frac{1}{\rho(x)}\frac{d^2}{dx^2}$. In particular for any $x,y\in[0,x_\infty)$

$$\int_0^\infty\phi(x,\zeta)\phi(y,\zeta)(1+\zeta^2)d\sigma(\zeta)=\delta(x-y).$$

The map from the strings to their coefficients of dynamic compliance is continuous in a sense that if

$$\lim_{n\to\infty}m_n(x)\to m(x)$$

for all $x\in(0,x_\infty)$ such that x is not a jump of m then

$$\lim_{n\to\infty}\Omega_n(\zeta)\to\Omega(\zeta)\text{ for all }\zeta\in\mathbb{C}-[0,+\infty).$$

COROLLARY 3.5. *The formula*

$$\beta(\zeta)=\zeta\Omega(-\zeta^2)$$

gives a one-to-one correspondence between coefficients of dynamic compliance of strings and analytic functions

$$\beta:\mathbb{C}^+\to\mathbb{C}^+$$

with $\beta(\zeta)>0$ for $\zeta>0$.

Proof. Herglotz's theorem in the introduction of this paper. □

3.3. Corollaries of the results of Krein and Kac. We now can put several pieces together to get Theorem 2.6. From section 3.1 and Corollary 3.5 we have that

$$L\subset\left\{\sqrt{-\frac{d^2}{d\theta^2}}\beta\left(\sqrt{-\frac{d^2}{d\theta^2}}\right):\beta\in\mathfrak{B}\right\}.$$

Suppose a sequence $\{\beta_n\}\subset\mathfrak{B}$ is such that $\lim_{n\to\infty}\beta_n(k)$ exists for all $k\in\mathbb{N}$. Then (see [12]) there exists $\beta\in\mathfrak{B}$ such that $\lim_{n\to\infty}\beta_n(k)=\beta(k)$ for all $k\in\mathbb{N}$. Therefore, from the definition of convergence of Dirichlet-to-Neumann maps from section 2.4,

$$\overline{L}\subset\left\{\sqrt{-\frac{d^2}{d\theta^2}}\beta\left(\sqrt{-\frac{d^2}{d\theta^2}}\right):\beta\in\mathfrak{B}\right\}.$$

The map from strings to their coefficients of dynamic compliance is continuous in the topology described in section 3.2. The strings with differentiable mass, which correspond to conductivities from C after the change of variable (section 3.1), are obviously dense in the same topology in the set of all strings. This shows that the containment above is in fact the equality and finishes the proof of Theorem 2.6.

We will now show that the uniqueness in Theorem 3.4 implies Theorem 2.15.

For a conductivity γ in C we put in correspondence the string lm with the length

$$l = \int_0^1 \frac{dr}{r\gamma(r)} \leq \infty,$$

and the mass density

$$\rho\left(\int_r^1 \frac{dt}{t\gamma(t)}\right) = \gamma^2(r).$$

The admittance function corresponding to γ and the coefficient of dynamic compliance of the string are connected by

$$R(\lambda) = \frac{1}{\Omega(-\lambda^2)}. \tag{3.5}$$

By Corollary 3.5 we have that

$$\frac{R(\lambda)}{\lambda} : \mathbb{C}^+ \to \mathbb{C}^+$$

is analytic in $\mathbb{C}^+$ and, therefore, is determined by its values at integers (see [15]). Therefore, the Dirichlet-to-Neumann map Λ_γ determines the coefficient of dynamic compliance $\Omega(\lambda)$ of the correspondent string. Theorem 3.4 guarantees a unique corresponding string with density ρ. The conductivity can be found then by

$$\gamma\left(e^{-\int_0^x \sqrt{\rho(t)}dt}\right) = \sqrt{\rho(x)}. \tag{3.6}$$

3.4. Characterization of kernels: Positive definite functions. We will now explore the role of positive definite functions.

LEMMA 3.6. *Let*

$$f(s) = -\int_0^\infty t\frac{e^{-st} + e^{(s-2\pi)t}}{1 - e^{-2\pi t}}(1 + t^2)d\sigma(t), \qquad s \in (0, \pi), \tag{3.7}$$

where σ is a positive measure of bounded variation on $(0, \infty)$; then

$$\int_0^\pi f(s)(\cos\lambda s - 1)ds = \int_0^\infty \frac{\lambda^2(1 + t^2)d\sigma(t)}{\lambda^2 + t^2}$$

for $\lambda \in \mathbb{C}^+$.

Proof. Tonelli's theorem. □

We are now in a position to prove Theorem 2.14.

Proof. The fact that the kernel of a map from $\overline{L}$ has the properties of the Theorem 2.14 follows directly from Herglotz's theorem and Lemma 3.6. We now show the other direction.

By Bochner's theorem in section 2, if $-f$ is positive definite on $(0, 2\pi)$, there exists a σ-finite measure ν on $\mathbb{R}$ such that

$$f(s) = -\int_{-\infty}^{+\infty} e^{-st} d\nu(t), s \in (0, 2\pi).$$

Since

$$f(s) = f(2\pi - s),$$

there exists a σ-finite measure τ on $(0, \infty)$ such that

$$f(s) = -\frac{1}{2}\int_{-\infty}^{+\infty} e^{-st} + e^{-(2\pi-s)t} d\nu(t) = -\int_0^{\infty} e^{-st} + e^{-(2\pi-s)t} d\tau(t).$$

Since

$$\int_0^{\pi} f(s)(\cos s - 1) ds < \infty,$$

by Lemma 3.6 with $\lambda = 1$ and $d\tau(t) = \frac{t(1+t^2)}{1-e^{-2\pi t}} d\sigma(t)$

$$\int_0^{\infty} \frac{1 - e^{-2\pi t}}{t(1+t^2)} d\tau(t) < \infty$$

$$\Rightarrow f(s) = -\int_0^{\infty} t\frac{e^{-st} + e^{(s-2\pi)t}}{1 - e^{-2\pi t}}(1+t^2) d\sigma(t), \qquad s \in (0, \pi)$$

for a positive measure of bounded total variation σ. Invoking of Lemma 3.6 and Theorem 3.4 finishes the proof. $\square$

The arguments above can be easily transformed to give Theorems 2.17 and 2.18 for the half-plane. Lemma 3.6 should be replaced by the following lemma.

LEMMA 3.7. *Let*

$$g(s) = -\int_0^{\infty} te^{-st}(1+t^2) d\sigma(t), \qquad s \in (0, \infty), \tag{3.8}$$

where σ is a positive measure of bounded variation on $[0, \infty)$; then

$$\int_0^{\infty} g(s)(\cos \lambda s - 1) ds = \int_0^{\infty} \frac{\lambda^2(1+t^2) d\sigma(t)}{\lambda^2 + t^2}$$

for $\lambda \geq 0$.

4. Discrete problem. We will proceed in a manner similar to the continuous case.

4.1. Reduction to a 1-dimensional problem.

LEMMA 4.1. *The solution to the Dirichlet problem on D_n with the boundary data $e^{ik\theta}|_{\partial_n}$ is of the form*

$$u_k(r, \theta) = a_k(r) e^{ik\theta}.$$

Proof. Suppose u is γ-harmonic and $u|_{\partial_n} = e^{ik\theta}$. Since the conductivity is constant on layers, the function

$$v(r,\theta) = u\left(r, \theta + \frac{2\pi}{n}\right) - u(r,\theta)$$

is also γ-harmonic and $v|_{\partial_n} = e^{ik\theta}(e^{i\frac{2\pi k}{n}} - 1)$. Hence, by the uniqueness of the solution of the Dirichlet problem,

$$u_k(r,\theta)(e^{i\frac{2\pi k}{n}} - 1) = u_k\left(r, \theta + \frac{2\pi}{n}\right) - u_k(r,\theta)$$

$$\Rightarrow u_k(r,\theta)e^{i\frac{2\pi}{n}} = u_k\left(r, \theta + \frac{2\pi}{n}\right)$$

$$\Rightarrow u_k(r,\theta) = a_k(r)e^{ik\theta}. \qquad \square$$

COROLLARY 4.2. *Λ_γ and $[\frac{d^2}{d\theta^2}]$ have the same eigenvectors.*

We will now derive an explicit formula for the eigenvalues of Λ_γ in terms of γ. We will do it in a way that emphasizes the relevance of the Sturm–Liouville and beads-on-a-string inverse problems [7] to discrete impedance tomography. Let us first consider the case of $D(n,l)$ with an odd l.

Let $\{\delta_1, \xi_1, \delta_2, \xi_2, \dots, \delta_{\frac{l+1}{2}}\}$ denote the conductivities on layers of $D(n,l)$ starting from the origin. For $k \neq 0$

$$\begin{cases} a_k(0) = 0, \\ a_k(1) = 1, \\ \delta_j(a_k(r_j) - a_k(r_{j-1})) + \delta_{j+1}(a_k(r_j) - a_k(r_{j+1})) + \xi_j a_k(\omega_k^{(n)})^2 = 0. \end{cases}$$

Let $P(\lambda, r_j)$ be the unique solution of the following problem:

$$\begin{cases} P(\lambda, 0) = 0, \\ P(\lambda, r_1) = 1, \\ \delta_j(P(\lambda, r_j) - P(\lambda, r_{j-1})) + \delta_{j+1}(P(\lambda, r_j) - P(\lambda, r_{j+1})) + \lambda^2 \xi_j P(\lambda, r_j) = 0. \end{cases}$$

Let

$$Q(\lambda, r_j) = \delta_j(P(\lambda, r_j) - P(\lambda, r_{j-1})).$$

Then

$$\lambda_k^{(n)} = \frac{Q(\omega_k^{(n)}, 1)}{P(\omega_k^{(n)}, 1)}.$$

We also have

$$\begin{cases} P(\lambda, r_j) = P(\lambda, r_{j-1}) + \frac{1}{\delta_j} Q(\lambda, r_j), \\ Q(\lambda, r_j) = Q(\lambda, r_{j-1}) + \xi_{j-1}\lambda^2 P(\lambda, r_{j-1}). \end{cases} \tag{4.1}$$

Therefore,

$$\frac{Q(\lambda, r_j)}{P(\lambda, r_j)} = \frac{Q(\lambda, r_j)}{P(\lambda, r_{j-1}) + \frac{1}{\delta_j} Q(\lambda, r_j)}$$

$$= \cfrac{1}{\cfrac{1}{\delta_j} + \cfrac{P(\lambda, r_{j-1})}{Q(\lambda, r_j)}} = \cfrac{1}{\cfrac{1}{\delta_j} + \cfrac{P(\lambda, r_{j-1})}{Q(\lambda, r_{j-1}) + \xi\lambda^2 P(\lambda, r_{j-1})}}$$

$$= \cfrac{1}{\cfrac{1}{\delta_j} + \cfrac{1}{\xi_{j-1}\lambda^2 + \cfrac{Q(\lambda, r_{j-1})}{P(\lambda, r_{j-1})}}}. \tag{4.2}$$

Let

$$R(\lambda) = \cfrac{1}{\cfrac{1}{\delta_{\frac{l+1}{2}}} + \cfrac{1}{\xi_{\frac{l-1}{2}}\lambda^2 + \cdots + \cfrac{1}{\cfrac{1}{\delta_3} + \cfrac{1}{\xi_2\lambda^2 + \cfrac{1}{\cfrac{1}{\delta_2} + \cfrac{1}{\xi_1\lambda^2 + \delta_1}}}}}}. \tag{4.3}$$

Then the eigenvalues $\lambda_k^{(n)}$ of Λ_γ are

$$\lambda_k^{(n)} = R(\omega_k^{(n)}).$$

To get the similar formula for other disks one should make corresponding δ_1 or $\frac{1}{\delta_{\frac{l+1}{2}}}$ or both zero.

4.2. Characterizations of the Dirichlet-to-Neumann maps. We consider the function

$$\beta(\lambda) = \frac{1}{\lambda} R(\lambda) = \cfrac{1}{\cfrac{1}{\delta_{\frac{l+1}{2}}}\lambda + \cfrac{1}{\xi_{\frac{l-1}{2}}\lambda + \cdots + \cfrac{1}{\cfrac{1}{\delta_3}\lambda + \cfrac{1}{\xi_2\lambda + \cfrac{1}{\cfrac{1}{\delta_2}\lambda + \cfrac{1}{\xi_1\lambda + \cfrac{1}{\cfrac{1}{\delta_1}\lambda}}}}}}}. \tag{4.4}$$

The function β has the following properties:

1. β is rational,
2. $\beta(\lambda) : \mathbb{C}^+ \to \mathbb{C}^+$,
3. $\beta(\lambda) > 0$ for $\lambda > 0$,
4. $\beta(-\bar{\lambda}) = -\overline{\beta(\lambda)}$.

It turns out that these four properties characterize the continued fractions of the form (4.4); see [11].

Corollary 4.3. *The set of the discrete Dirichlet-to-Neumann maps belongs to*

$$\left\{ \sqrt{-\left[\frac{d^2}{d\theta^2}\right]}\beta\left(\sqrt{-\left[\frac{d^2}{d\theta^2}\right]}\right) : \beta \in \mathfrak{B} \right\}.$$

Let

$$\tau(z) = \frac{1-z}{1+z} : \mathbb{C}^+ \xrightarrow{1-1} \mathbb{D}. \tag{4.5}$$

The characterization in [11] can be restated as the following theorem.

Theorem 4.4. *Let*

$$B : \mathbb{D} \to \mathbb{D}$$

be a real Blaschke product. Then

$$\tau \circ B \circ \tau : \mathbb{C}^+ \to \mathbb{C}^+ \tag{4.6}$$

can be written in unique way as a continued fraction of the form (4.4) *with positive* δ_k, ξ_k. *The number of coefficients in this continued fraction is equal to the number of terms in the product.*

Conversely, every continued fraction of the form (4.4) *with positive* δ_k, ξ_k *can be written in the form* (4.6) *for some real Blaschke product* B.

The following theorem is a consequence of the Pick–Nevanlinna interpolation algorithm (see [6]; see also [12] and [16]).

Theorem 4.5. *Consider*

$$\{z_i\}, \{w_i\} \subset \mathbb{R}^+, i = 1, \dots, m.$$

There exists an analytic function

$$F : \mathbb{C}^+ \to \mathbb{C}^+,$$

$$F(z_i) = w_i, i = 1, \dots, m$$

if and only if the matrix

$$W = \left(\frac{w_i + w_j}{z_i + z_j}\right)_{i,j=1}^{m}$$

is positive semidefinite, if and only if there exists a real Blaschke product B *such that*

$$\tau \circ B \circ \tau(z_i) = w_i, i = 1, \dots, m,$$

which may not be equal to F, e.g., $F \equiv 1$.

If W is singular, the Blaschke product is unique, and the number of terms in it is equal to the size of the largest nonsingular principal minor of W.

If W is not singular there are exactly two desired Blaschke products with the number of terms m, and an infinite family of the Blaschke products with the number of terms $> m$.

Corollary 4.6. *The set of the discrete Dirichlet-to-Neumann maps contains*

$$\left\{ \sqrt{-\left[\frac{d^2}{d\theta^2}\right]}\beta\left(\sqrt{-\left[\frac{d^2}{d\theta^2}\right]}\right) : \beta \in \mathfrak{B} \right\}.$$

This finishes the proof of Theorem 2.5.

4.3. Solution of the discrete inverse problem. Let Λ be an $n \times n$, $n = 2m+1$ discrete layered Dirichlet-to-Neumann map with the nonzero eigenvalues

$$\lambda_k^{(n)}, k = 1, 2, \ldots, m.$$

Consider

$$W = \left(\frac{\lambda_i^{(n)}/\omega_i^{(n)} + \lambda_j^{(n)}/\omega_j^{(n)}}{\omega_i^{(n)} + \omega_j^{(n)}} \right)_{i,j=1}^{m}.$$

If W is singular, there is unique discrete disk $D = D(n, l)$ or $D^*(n, l)$ with unique radially symmetric conductivity γ on it, such that

$$\Lambda(D_\gamma) = \Lambda.$$

Theorems 4.4 and 4.5 give an explicit construction of $D_\gamma(n, l)$. Also, it follows that l is equal to the size of the largest nonsingular principal minor of W, in particular $l < m$.

If W is nonsingular, there are unique conductivities γ, γ' on the disks $D(n, m)$, $D^*(n, m)$, with

$$\Lambda(D_\gamma(n, m)) = \Lambda(D^*_{\gamma'}(n, m)) = \Lambda.$$

For every $D = D(n, l)$ or $D^*(n, l)$ with $l > m$ there are infinitely many condutivities γ with

$$\Lambda(D_\gamma) = \Lambda.$$

KAM THEORY AND A PARTIAL JUSTIFICATION OF GREENE'S CRITERION FOR NONTWIST MAPS*

AMADEU DELSHAMS† AND RAFAEL DE LA LLAVE‡

Abstract. We consider perturbations of integrable, area preserving nontwist maps of the annulus (those are maps in which the twist condition changes sign). These maps appear in a variety of applications, notably transport in atmospheric Rossby waves.

We show in suitable two-parameter families the persistence of critical circles (invariant circles whose rotation number is the maximum of all the rotation numbers of points in the map) with Diophantine rotation number. The parameter values with critical circles of frequency ω_0 lie on a one-dimensional analytic curve.

Furthermore, we show a partial justification of Greene's criterion: If analytic critical curves with Diophantine rotation number ω_0 exist, the residue of periodic orbits (that is, one fourth of the trace of the derivative of the return map minus 2) with rotation number converging to ω_0 converges to zero exponentially fast. We also show that if analytic curves exist, there should be periodic orbits approximating them and indicate how to compute them.

These results justify, in particular, conjectures put forward on the basis of numerical evidence in [D. del Castillo-Negrete, J.M. Greene, and P.J. Morrison, *Phys. D.*, 91 (1996), pp. 1–23]. The proof of both results relies on the successive application of an iterative lemma which is valid also for $2d$-dimensional exact symplectic diffeomorphisms. The proof of this iterative lemma is based on the deformation method of singularity theory.

1. Introduction.

1.1. The motivation.

The main goal of this paper is to provide rigorous proofs of several phenomena discovered empirically by del Castillo-Negrete, Greene, and Morrison in [CGM1]. Even if our results will apply to a more general class of maps—see Definitions 1.3, 1.4, etc., for more precise definitions—we will start by describing the results of that paper and the applications of the results we present here.

In [CGM1], the authors consider the two-parameter family of area preserving maps, called there the "quadratic standard map"

$$T_{\omega,\varepsilon}(p,q) = \big(p + \varepsilon \sin(2\pi q), q - (p + \varepsilon \sin 2\pi q)^2 + \omega \pmod 1\big)\,. \tag{1.1}$$

One motivation for such study is that qualitatively similar maps appear naturally in the study of geostrophic flows and indeed in many problems in hydrodynamics and in other applications, mentioned briefly later.

The "unperturbed" map $T_{\omega,0}$

$$T_{\omega,0}(p,q) = (p, q + \Gamma(\omega,p) \pmod 1)\,, \qquad \Gamma(\omega,p) = \omega - p^2 \tag{1.2}$$

describes a situation where particles in a fluid are moving in a laminar flow whose velocity is faster in the middle ($p = 0$) but slower as we move away from the center of the stream. This is a very common situation in fluid motion, where often the motion slows down as we move closer to edges of the stream. In many applications, it is natural to consider q as an angle. For example, in the description of the jet stream, q corresponds to the longitude and p is a range of latitudes.

The map $T_{\omega,0}$ is an integrable map, since all the circles with fixed p are invariant under $T_{\omega,0}$ and the motion in them is a rigid rotation with rotation number $\Gamma(\omega, p)$. The quantity $\partial\Gamma/\partial p$—usually called the twist—measures the anisochronicity—i.e., the rate of change of frequencies among different invariant circles. The condition $\partial\Gamma/\partial p \neq 0$ is called the "twist condition," and a map which satisfies the twist condition is called a (monotone) twist map. This twist condition does not hold in any map $T_{\omega,0}$ given in (1.2), since $\partial\Gamma/\partial p$ changes sign in $p = 0$. Accordingly, $T_{\omega,0}$ is called a nontwist map. Note that changing of sign is stronger than the twist vanishing in some circle but being otherwise positive. These are the small twist maps, which also appear in many applications. The relevance of the twist condition comes from the celebrated KAM theorem which establishes that the invariant circles whose frequency satisfies a Diophantine condition persist under a small enough—in a smooth norm—area preserving perturbation with zero mean flux. That is to say, twist mappings under perturbation look integrable for a large area. Nontwist maps, on the other hand, experience new phenomena in the area where the twist changes sign. (See later in this introduction for more references.)

The extra term modified by the small parameter ε is representative of the maps that arise when one considers the physical effect of a small periodic oscillation transverse to the channel flow. Such phenomena occur frequently in hydrodynamics when channel flows are destabilized through a Hopf bifurcation. This happens in jet flows in the atmosphere due to Rossby waves. We refer to [C] and [CM] for a detailed description of the fluid mechanics motivation of such models, in particular for the justification of the use of a two-dimensional approximation. In this interpretation, the existence of invariant circles is very important, since they are complete barriers for the mixing of the material in the pole—one of the edges of the latitude p—with the material near the equator—the other edge of p. In the particular model for the atmosphere, these barriers give rise to the creation of "ozone holes" since they isolate the ozone created in the tropics from the regions near the poles.

For area preserving perturbations of twist maps, the twist theorem (see [He] for a quantitative version and [BHS] for an exhaustive description of KAM theory), ensures the persistence, for $|\varepsilon|$ small enough, of those invariant curves with a Diophantine rotation number ω_0:

$$\exists C > 0, \theta \geq 0 : |k \cdot \omega_0 - m|^{-1} \leq C|k|^{\theta-1} \ \forall \ k \in \mathbb{Z}, m \in \mathbb{Z} \setminus \{0\}. \tag{1.3}$$

The set of Diophantine numbers has full measure. A paradigmatic example is $(\sqrt{5} - 1)/2$, which satisfies the inequalities above for $\theta = 0$.

Unfortunately, given a Diophantine rotation number ω_0, the twist theorem cannot be applied to the map $T_{\omega_0,\varepsilon}$ close to the invariant circle $p = 0$, since the twist condition breaks, and moreover the associated rotation number ω_0 lies on the boundary of the range of the rotation numbers $\Gamma(\omega_0, p)$. The paper [CGM1] finds numerically—among other results—numerical evidence for the following claim.

Claim 1.1. *Let $\omega_0 = (\sqrt{5} - 1)/2$. Then, for $|\varepsilon| \ll 1$ there is a smooth curve $\omega(\varepsilon)$ with $\omega(0) = \omega_0$ such that*

(a) *if $\omega > \omega(\varepsilon)$, then $T_{\omega,\varepsilon}$ admits two invariant circles with rotation number ω_0,*
(b) *If $\omega < \omega(\varepsilon)$, then $T_{\omega,\varepsilon}$ admits no invariant circles with rotation number ω_0,*
(c) *If $\omega = \omega(\varepsilon)$, then $T_{\omega(\varepsilon),\varepsilon}$ admits an invariant circle with rotation number ω_0.*

The circle in (c), moreover, is "critical," that is, there exists a change of variables $(p, q) \to (A, \varphi)$ in its neighborhood in such a way that

$$h^{-1} \circ T_{\omega(\varepsilon),\varepsilon} \circ h(A, \varphi) = (A, \varphi + \omega_0 + \kappa A^2) + O(A^3), \qquad \kappa \neq 0$$

(in fact, $\kappa < 0$ for the example in (1.1)).

It is worth noticing that the method used in [CGM1] to assess the existence of the invariant circles is the Greene's criterion, introduced in [Gr]. This criterion asserts that there exists an invariant circle with rotation number ω_0 if and only if

$$\mathrm{Res}(O_{m,n}) := \frac{1}{4}\left[\mathrm{tr}\left(DT^n_{\omega,\varepsilon}\left(O_{m,n}\right)\right) - 2\right] \underset{m/n\to\omega_0}{\longrightarrow} 0$$

for any sequence of periodic orbits O_{mn} of type m/n converging to ω_0.

For the maps $T_{\omega,\varepsilon}$ as in (1.1), the Greene's criterion can be implemented numerically very efficiently. These maps are reversible and, for reversible maps, the search for periodic orbits of type m/n (those are n-periodic orbits which make m complete turns in the angle variable q) in some symmetry lines—not all of the map—can be reduced to finding zeros of one-dimensional functions, a tractable numerical task. In the paper [CGM1] the authors succeed in implementing this criterion, and therefore they also find numerical evidence for the following claim.

Claim 1.2. *Greene's criterion applies.*

In this paper, we will prove rigorous results that justify the experimental results we stated in detail above. We will state and prove a result that justifies Claim 1.1 and another one that justifies one of the implications in Claim 1.2, namely that if there exists an invariant circle, the residue goes to zero.

To our knowledge, the converse—that is, if the residue goes to zero for any sequence of periodic orbits O_{mn} of type m/n converging to ω_0, one can find an invariant circle with rotation number ω_0—remains an open problem even for twist maps. However, we call attention to the work of [KO], which proves that if there are periodic orbits of twist maps which are, in a precise sense, well distributed, one can find an invariant circle with rotation number related to that of the periodic orbit. We also note that if the renormalization group picture can be justified, at least to a certain extent, the Greene's criterion will also be justified and indeed several improvements on that give precise asymptotics of the residue (see [McK]).

It is worth remarking that an easy argument, which we will detail later in Proposition 4.4, shows that if there is a critical invariant circle as above, indeed it is approximated by periodic orbits of type m/n with m/n converging to ω_0. Hence, this criterion is rather effective.

The general theory we will develop will not depend on the exact form for the map but on qualitative features that can be verified in the realistic models. Of course, the map (1.1) is a concrete model introduced for the purpose of discovering qualitative features through numerical calculations.

We also point out that other models having nontwist maps have appeared with other motivations. For example, they appear in celestial mechanics in problems such as the "critical inclination" [K] and in the study of billiards with a boundary moving periodically in time [KMOP1], [KMOP2] or in the study of the motion of particles in magnetic fields [ZZSUC]. As a matter of fact, since the iterates of a twist map are not, in general, twist maps, we expect that they also appear as descriptions of regions of iterates of twist maps. (See, e.g., [BST], [Si].)

These nontwist maps exhibit a very rich phenomenology that has only now started to be explored. The papers cited above as well as [VG], [HH1], [HH2], [Si], [Ha1], [Ha2] contain descriptions and studies of a wealth of phenomena such as “scaling relations,” “reconnection,” “meandering curves,” etc., that deserve to be investigated further. Notably in [Si], [Ha1], there are studies of new phenomena that happen in higher dimensional nontwist maps. In a very recent paper [DMS], it is shown that a generic unfolding of the tripling bifurcation of a fixed point of an area preserving map gives rise to nontwist maps and therefore critical invariant curves appear.

1.2. The methodology. In this paper, we will develop rigorous techniques that can produce results on two problems of the ones mentioned above: The existence of critical invariant circles and the validity of Greene’s criterion. Needless to say, we hope that the techniques that we develop for this purpose (e.g., finding appropriate normal forms and quantitative error estimates of them in neighborhoods) can eventually be used in the study of some of these other phenomena.

About the method of proof we note that there are two basic methods in KAM theory to prove the persistence of invariant tori of exact symplectic mappings or Hamiltonian flows. One is based on applying successive transformations close to the invariant torus and another one is based on solving functional equations that express invariance. Both methods have complementary advantages. The functional equation method leads to very crisp proofs and they are more natural for numerical implementations. On the other hand, the methods based on transformation theory yield more information about the behavior of the map on a neighborhood of the invariant torus.

Since in this paper we wanted to discuss the partial justification of Greene’s criterion, we certainly needed a method based on the transformation theory and it was natural to use the same method for the proof of the persistence of the invariant tori. In the future, we plan to come back to the functional method, especially in connection with a numerical implementation.

The proof we present here will be based on the deformation method. This method was introduced in the study of singularities of mappings [TL], [Mat] and it is very well suited for the study of equivalence of maps in situations where geometric structures are present [BLW], like families of exact symplectic diffeomorphisms. One can also use it for the regular KAM theorem [Ll]. In our case, the use of the deformation method is very natural since the unknown involves a family of maps.

Note that in this situation we are trying to study the persistence of invariant circles whose frequency is on the boundary of the frequencies that are present on the integrable map. This is in contrast with KAM theory, where the nondegeneracy conditions—the so-called twist condition or the more sophisticated Rüssmann conditions (see [BHS, Chapter 4])—imply that the frequency under study is in the interior of the frequencies of the invariant circles in the integrable case.

Since the frequency we want to study is on the boundary of the frequencies, it is not difficult to consider a perturbation of the integrable case in which there is no invariant circle with the frequency we want. (It suffices to consider an integrable perturbation in which we just add—or subtract—an extra rotation so that all the invariant circles persist, but their rotation number is changed.)

Speaking heuristically, what we will do is to consider the regular perturbation theory supplemented with a choice of $\omega(\varepsilon)$. The regular perturbation theory may force the ω_0 out of the range of frequencies, but we will find the extra rotation $\omega(\varepsilon)$ that puts it on the boundary. Since in this method of proof one needs to consider families all the time, the use of the deformation method seems particularly well justified.

On a more technical level, we note that the proof will be based on an iterative lemma (Lemma 3.6) that describes how it is possible to obtain transformations that reduce the system to integrable. Moreover, we will present bounds on the error of this reduction depending on the domain. This iterative lemma can be applied repeatedly in different ways depending on how one plays the tradeoff between domain loss and accuracy. One can try to make the error decrease very fast at the price that the domain decreases very fast or one can make the error decrease slowly on a larger domain. In this way, one can obtain a unified approach towards KAM theory and towards exponentially small estimates, which we will show justify Greene's criterion. This approach has precedents in [DG1]. Since the iterative lemma, as well as the deformation method are widely applicable, we have developed it in an arbitrary dimension. The geometric considerations that lead to the KAM theorem for critical circles and to the Greene's criterion seem to be different in higher dimensions, so we have postponed the discussion of this part.

1.3. The results.

Now we turn to making all these ideas more precise.

Definition 1.3. *We say that a circle S, invariant under an area preserving map T of $\mathbb{R}\times\mathbb{T}^1 \equiv M$, is a critical invariant circle if there exists a canonical transformation $h : [-\delta,\delta]\times\mathbb{T}^1 \to M$ in such a way that*

$$h^{-1}\circ T\circ h(A,\varphi) = (A, \varphi+\omega_0+\kappa A^2) + O(A^3)$$

with $\kappa \neq 0$ and $h(\{0\}\times\mathbb{T}^1) = S$.

Remark. The definition of a critical circle includes in its hypothesis that the motion on the circle is conjugate to a rotation of ω_0. We will not include the ω_0 in the notation since it will be understood from the context.

We also recall—and we will develop it in more detail later in Lemma 4.2—that there is an analogue of Birkhoff normal form in a neighborhood of an invariant circle with a Diophantine rotation. (In the twist map case, this was also considered in [OS, FL].) Given $N \in \natural$, it is possible to find coefficients $\kappa_1,\dots,\kappa_N$ and a canonical transformation h such that

$$h^{-1}\circ T\circ h(A,\varphi) = (A, \varphi+\omega_0+\kappa_1 A+\kappa_2 A^2+\cdots+\kappa_M A^M) + O(A^{M+1}). \tag{1.4}$$

The coefficients $\kappa_1,\dots,\kappa_N$ are uniquely defined and are properties of the invariant circle. In this language, critical circles are those for which $\kappa_1 = 0$, $\kappa_2 \neq 0$.

Definition 1.4. *We will call an invariant circle nondegenerate when the normal form* (1.4) *does not vanish identically. That is, we can find $M \in \natural$ such that $\kappa_1 = \cdots = \kappa_{M-1} = 0$, $\kappa_M \neq 0$.*

Our result to justify Claim 1.1 is the following theorem.

Theorem 1.5. *Let ω_0 be a Diophantine number as in* (1.3), *$f_{\omega,\varepsilon}$ be a family of mappings from $\mathbb{R}^1\times\mathbb{T}^1$ to itself satisfying*

(i) *$f_{\omega,\varepsilon}(p,q)$ is analytic in*

$$|\omega-\omega_0| < \rho_0\ , \quad |\varepsilon| < \rho_0\ , \quad |\Im\, q| < \beta_0\ , \quad |p| < \rho_0$$

and takes real values for ω,ε,p,q real;

(ii) *$f_{\omega,\varepsilon}$ is exact symplectic $\forall\omega,\varepsilon$,*

(iii) *$f_{\omega,0}(p,q) = (p, q+\Gamma(\omega,p))$ with*

$$\Gamma(\omega_0,0)=\omega_0, \qquad \frac{\partial}{\partial p}\Gamma(\omega_0,0)=0,$$
$$\frac{\partial^2}{\partial p^2}\Gamma(\omega_0,0)=t<0, \qquad \frac{\partial}{\partial \omega}\Gamma(\omega_0,0)=s>0.$$

Then, we can find a $\delta > 0$ and an analytic function ω defined for $|\varepsilon|$ sufficiently small and taking real values for ε real in such a way that

(a) *$f_{\omega(\varepsilon),\varepsilon}$ has exactly one critical invariant circle in $[-\delta,\delta]\times\mathbb{T}^1$;*

(b) *if $\omega < \omega(\varepsilon)$, $f_{\omega,\varepsilon}$ has no points in $[-\delta,\delta]\times\mathbb{T}^1$ with rotation number ω_0, and if $\omega > \omega(\varepsilon)$ there are two invariant circles of $f_{\omega,\varepsilon}$ in $[-\delta,\delta]\times\mathbb{T}^1$ which are not critical.*

Remark. It is possible to change hypothesis (iii) of Theorem 1.5, to be that t is positive. It suffices to change the inequalities between ω, $\omega(\varepsilon)$ in part (b) of the conclusions and the proof goes through without change (similarly if s is negative in (iii)).

The precise meaning in which Greene's criterion can be justified in the following theorem.

Theorem 1.6. *Let $f_{\omega,\varepsilon}$ be an analytic area preserving diffeomorphism of the annulus. Assume that $f_{\omega,\varepsilon}$ admits an analytic invariant circle on which the motion is analytically conjugate to a rotation with Diophantine number ω_0 and which is nondegenerate in the sense of Definition* 1.4.

Then, we can find $C_1, C_2, \mu > 0$ (depending on ω_0, the map, and the torus) such that for any sequence of periodic orbits O_n of type p_n/q_n which are converging to the analytic invariant circle and such that $|\omega_0 - p_n/q_n| \le 1/q_n$, we have

$$\operatorname{Res}(O_n) \le C_1 \exp\left(-C_2|\omega_0 - p_n/q_n|^{-\mu}\right). \tag{1.5}$$

We will also show that there is one such sequence of periodic orbits converging to the nondegenerate circle. Of course, when the circle is critical, depending on the sign of $\omega - p_n/q_n$ we will find either two or four periodic orbits. For more general nondegenerate circles, when M is even we will find two or four periodic orbits of type p_n/q_n depending on the sign of $\omega - p_n/q_n$ and when M is odd we will find two irrespective of the sign or $\omega - p_n/q_n$.

Remark. The proof that the residue goes to zero faster than any power is significantly easier than the proof with an explicit rate.

2. The deformation method.

In this section we recall the basis of the deformation method for symplectic maps. This method was introduced in singularity theory [TL], [Mat], but it was remarked later that it can be used very effectively to obtain structure theorems for volume preserving maps of a manifold [Mo1], or for symplectic maps [W] giving a very direct proof of Darboux theorem. More details and other applications can be found in [LMM], [Ll], [BLW] and in several other places.

In this section, the dimension of the space will not play a role, so we will consider M a $2d$-dimensional manifold.

We recall that a 2-form ϖ on M is a symplectic form if it is closed and has full rank. (Of course, the fact that ϖ has full rank implies that the dimension of M is even; this is why we chose the notation $2d$ for it.) We will be especially interested in the case when ϖ is exact. That is, there exist a 1-form ϑ such that $\varpi = d\vartheta$.

A diffeomorphism f is symplectic when $f_*\varpi = \varpi$. For ϖ exact, this is equivalent to $d(f_*\vartheta - \vartheta) = 0$. We say that a symplectic map f is exact when $f_*\vartheta - \vartheta = dS$ for some function S, called the primitive function of f.

Given a family of diffeomorphisms f_ε, we denote by $\mathcal{F}_\varepsilon$ the vector field defined by

$$\frac{d}{d\varepsilon} f_\varepsilon = \mathcal{F}_\varepsilon \circ f_\varepsilon \tag{2.1}$$

and refer to $\mathcal{F}_\varepsilon$ as the generator of f_ε. Note that a family determines the generator and, conversely, by the uniqueness theorem for ordinary differential equations (ODEs), a family is determined by its initial point f_0 and its generator, when the generator is $\mathcal{C}^1$. (We will always assume that this is the case.)

The main idea of the deformation method is to always work with the generators, which, when the families are differentiable enough so that the uniqueness theorem for ODEs applies, is equivalent to working with the families. When the diffeomorphisms are symplectic, further simplifications are possible. Using Cartan's formula for Lie derivatives and that ϖ is closed we obtain

$$\begin{aligned} \frac{d}{d\varepsilon} f_{\varepsilon *}\varpi &= f_{\varepsilon *}(d(i(\mathcal{F}_\varepsilon)\varpi) + i(\mathcal{F}_\varepsilon)\, d\varpi) = f_{\varepsilon *}(d(i(\mathcal{F}_\varepsilon)\varpi)), \\ \frac{d}{d\varepsilon} f_{\varepsilon *}\vartheta &= d(f_{\varepsilon *}(i(\mathcal{F}_\varepsilon))\vartheta) + f_{\varepsilon *}(i(\mathcal{F}_\varepsilon)\varpi). \end{aligned} \tag{2.2}$$

If f_ε is symplectic, $\frac{d}{d\varepsilon} f_{\varepsilon *}\varpi = 0$, and then we see that

$$d(i(\mathcal{F}_\varepsilon)\varpi) = 0. \tag{2.3}$$

If f_ε is exact symplectic, $d\left(\frac{d}{d\varepsilon} S_\varepsilon\right) - f_{\varepsilon *} d(i(\mathcal{F}_\varepsilon)\varpi) = f_{\varepsilon *}(i(\mathcal{F}_\varepsilon)\vartheta)$ and, therefore,

$$i(\mathcal{F}_\varepsilon)\varpi = dF_\varepsilon \tag{2.4}$$

with $F_\varepsilon = \left(\frac{d}{d\varepsilon} S_\varepsilon\right) \circ f_\varepsilon - i(\mathcal{F}_\varepsilon)\vartheta$.

Conversely, if $\mathcal{F}_\varepsilon$ satisfies (2.3) or (2.4) and f_0 is symplectic or exact symplectic, the family f_ε is symplectic or exact symplectic as can be seen integrating (2.2).

Within this paper, we will refer to F_ε as the Hamiltonian for the family f_ε. Note that given f_ε, (2.4) determines F_ε up to a function of zero differential hence, constant on each connected component of its domain of definition. This justifies calling F_ε "the Hamiltonian" if we think of Hamiltonians as equivalent when they differ in a function with zero differential. This identification is natural since two Hamiltonian differing by a function with zero differential generate the same dynamics.

Conversely, for a $\mathcal{C}^2$ Hamiltonian F_ε, given that ϖ is full rank, (2.4) determines $\mathcal{F}_\varepsilon$, and it is $\mathcal{C}^1$. This $\mathcal{F}_\varepsilon$ and f_0 determine f_ε by the uniqueness result for ODEs.

Hence, for sufficiently smooth families it is equivalent to work with the Hamiltonians and the initial points of the families.

The main idea of the deformation method for exact symplectic maps is to reformulate all the problems in terms of Hamiltonians. As it turns out, the equations involving generators are linear. This is to be expected since we can heuristically think of generators as infinitesimal transformations and all the equations among infinitesimal quantities are linear. Moreover, using Hamiltonians, the otherwise complicated constraint of the transformations being exact symplectic is implemented automatically, and the resulting equations involve only functions. Hence, rather than dealing with nonlinear equations among diffeomorphisms satisfying nonlinear constraints, we just have to deal with a linear equation among functions.

We will follow the convention of denoting families in lowercase f_ε, their generators in calligraphic font $\mathcal{F}_\varepsilon$, and the Hamiltonians in uppercase F_ε.

PROPOSITION 2.1. *Let $f_\varepsilon, g_\varepsilon$ be exact symplectic families and k an exact symplectic diffeomorphism. Then, the Hamiltonian of the families formed out of them are given in the following table.*

Family	Hamiltonian
$f_\varepsilon \circ g_\varepsilon$	$F_\varepsilon + f_{\varepsilon *} G_\varepsilon = F_\varepsilon + G_\varepsilon \circ f_\varepsilon^{-1}$
f_ε^{-1}	$-F_\varepsilon \circ f_\varepsilon$
$g_\varepsilon^{-1} \circ f_\varepsilon \circ g_\varepsilon$	$F_\varepsilon \circ g_\varepsilon - G_\varepsilon \circ g_\varepsilon + G_\varepsilon \circ f_\varepsilon^{-1} \circ g_\varepsilon$
$k^{-1} \circ f_\varepsilon \circ k$	$F_\varepsilon \circ k$
$f_\varepsilon \circ k$	F_ε

The computations needed to work out this table can be found in [LMM], [BLW]. In the latter paper one can find similar tables for volume preserving or contact families.

Since in perturbation theory one does not always have a family of diffeomorphisms but just two diffeomorphisms that are close, it is worth remarking that given two symplectic diffeomorphisms that are close, one can always interpolate them by a family with small Hamiltonian. If the two maps are exact, the family can be chosen to be exact. This is an immediate consequence of the general fact that symplectic (or exact symplectic) maps form a Banach manifold (see [W]). We just sketch a direct construction whose details appear in [BLW]. An alternative, old fashioned proof can be obtained using generating functions. (Interpolate the generating functions.) Unfortunately, since it is impossible to obtain generating functions that are globally defined, one has to also use partitions of unity and fragmentation lemmas and the proof becomes cumbersome.

Given f_0, f_1 symplectic and close enough, we can find a family of diffeomorphisms f_ε interpolating between them (e.g., $f_\varepsilon(x) = \exp_{f_0(x)} \varepsilon \exp_{f_0(x)}^{-1} f_1(x)$ where exp is the Riemannian exponential map). The family f_ε will not be symplectic. In general, $f_{\varepsilon *}\varpi = \varpi_\varepsilon$ where ϖ_ε is a family of symplectic forms. Note that, by our assumptions $\varpi_0 = \varpi_1 = \varpi$. Using Moser's construction [Mo1]—we refer to [LMM], [BLW] for the elementary justification of the smooth dependence on parameters in Moser's construction—we can find h_ε close to the identity in such a way that $h_{\varepsilon *}\varpi_\varepsilon = \varpi$. Moreover, $h_0 = h_1 = \mathrm{Id}$. Then $\tilde{f}_\varepsilon = h_\varepsilon \circ f_\varepsilon$ satisfies $\tilde{f}_0 = f_0$, $\tilde{f}_1 = f_1$, $\tilde{f}_{\varepsilon *}\varpi = \varpi$. If $\varpi = d\vartheta$ then $\varpi_\varepsilon = d\vartheta_\varepsilon$ with $\vartheta_\varepsilon = f_{\varepsilon *}\vartheta$. Also $(h_\varepsilon \circ f_\varepsilon)_* \vartheta - \vartheta$ is closed. It is then possible to choose g_ε close to the identity in such a way that $(g_\varepsilon \circ h_\varepsilon \circ f_\varepsilon)_* \vartheta - \vartheta$ is exact (e.g., on the annulus choose translations in the radial direction and in another manifolds choose a displacement in a neighborhood of paths that generate the homology).

We have, therefore, established the following lemma.

LEMMA 2.2. *Let f_0 be a $\mathcal{C}^\infty$ (resp., $\mathcal{C}^\omega$) symplectic (resp., exact symplectic) diffeomorphism of a manifold.*

If f_1 is a symplectic (resp., exact symplectic) diffeomorphism close to f_0 we can find a $\mathcal{C}^\infty$ (resp., $\mathcal{C}^\omega$) family f_ε of symplectic (resp., exact symplectic) diffeomorphisms interpolating between f_0 and f_1.

Moreover, we can arrange that the generators and therefore the Hamiltonians of the isotopy are arbitrarily small in the $\mathcal{C}^\infty$ (resp., $\mathcal{C}^\omega$) topology by assuming that f_1 is arbitrarily close to f_0.

3. Proof of Theorem 1.5 using the deformation method.

3.1. Heuristic discussion. The proof we present here starts with the observation that the result would be obvious if we had a family of the form

$$i_{\omega,\varepsilon}(p,q) = (p, q + \Omega(\omega,\varepsilon,p)) \tag{3.1}$$

in which the p is conserved and the q is translated by $\Omega(\omega,\varepsilon,p)$, which depends on p and on external parameters and is close to the frequency $\Gamma(\omega,p)$ satisfying hypothesis (iii) of Theorem 1.5. We will refer to such families as integrable.

If we require that the set $p = p_0$ is an invariant circle with rotation ω_0, we obtain the implicit equation

$$\Omega(\omega,\varepsilon,p_0) = \omega_0\ . \tag{3.2}$$

The possibility of finding solutions of (3.2) is described by singularity theory and the phenomenon of a critical invariant circle corresponds to the situation when $\Omega(\omega,\varepsilon,p_0)-\omega_0$ has a fold:

$$\Omega(\omega,\varepsilon,p_0) - \omega_0 = 0, \qquad \partial_p\Omega(\omega,\varepsilon,p_0) = 0.$$

The equation for $\omega(\varepsilon)$ is precisely the equation for the edge of a fold. We will parameterize the folding surface (3.2) as the set of points $(\Upsilon(\varepsilon,p),\varepsilon,p)$ for an appropriate function Υ:

$$\Omega(\omega,\varepsilon,p) = \omega_0 \iff \omega = \Upsilon(\varepsilon,p). \tag{3.3}$$

Then, a critical invariant circle takes place at $p = p_0 = p_0(\varepsilon)$ if $\partial_p\Upsilon(\varepsilon,p_0) = 0$, and $\omega(\varepsilon) = \Upsilon(\varepsilon,p_0(\varepsilon))$.

A standard technique in KAM theory is to make changes of variables so that in the new system of coordinates, the properties of the map are apparent from its expression. In the present case, we try to find g_ε in such a way that

$$\tilde{f}_{\omega,\varepsilon} = g_\varepsilon^{-1} \circ f_\varepsilon \circ g_\varepsilon \tag{3.4}$$

has the desired form (3.1).

Unfortunately, in general it is not possible to obtain a change of variables reducing to (3.1) in the whole phase space. We only know how to do it approximately in a subset of the domain in (ω,ε,p) for which $\Omega(\omega,\varepsilon,p) = \omega_0$.

Hence we will use an iterative scheme in which at step n, the system will be (described in the notation of the deformation method by the initial point of the isotopy and the generating Hamiltonian)

$$f^n_{\omega,0}(p,q) = (p, q+\Gamma(\omega,p)); \qquad F^n_{\omega,\varepsilon}(p,q) = I^n_{\omega,\varepsilon}(p) + E^n_{\omega,\varepsilon}(p,q), \tag{3.5}$$

where $E^n_{\omega,\varepsilon}$ is "small" in a neighborhood of $\{p = 0\}$.

The Hamiltonian $I^n_{\omega,\varepsilon}(p)$ corresponds to a deformation of the form

$$i^n_{\omega,\varepsilon}(p,q) = (p, q + \Omega^n(\omega,\varepsilon,p)), \tag{3.6}$$

where

$$\Omega^n(\omega,\varepsilon,p) = \Gamma(\omega,p) + \int_0^\varepsilon ds \frac{\partial}{\partial p} I^n_{\omega,s}(p) \tag{3.7}$$

when we assume that $i_{\omega,0} = f_{\omega,0}$. Hence, the $I^n_{\omega,\varepsilon}$ should be thought of as the integrable part of the Hamiltonian $F^n_{\omega,\varepsilon}$. We will think of $E^n_{\omega,\varepsilon}$ as an error term that is to be made smaller and smaller in the iterative process.

Remark. We note that the decomposition of a Hamiltonian into an integrable part and an small part is not uniquely defined. A particularly natural one would be to take the integrable part to be the average over the q. Nevertheless, we will not be assuming that this natural decomposition is taken, just that such a decomposition exists.

Remark. Note that when we consider perturbations of an integrable system, we can write the integrable part in Ω and, hence, assume that $I^0_{\omega,\varepsilon}(p) = 0$.

The main ingredient of the proof of Theorem 1.5 will be an algorithm that, given a family as in (3.5), finds a transformation $g^n_{\omega,\varepsilon}$ defined in a neighborhood of the surface $\Omega^n(\varepsilon, \omega, p) = \omega_0$ such that setting $f^{n+1}_{\omega,\varepsilon} = (g^n_{\omega,\varepsilon})^{-1} \circ f^n_{\omega,\varepsilon} \circ g^n_{\omega,\varepsilon}$ we have

$$F^{n+1}_{\omega,\varepsilon}(p,q) = I^{n+1}_{\omega,\varepsilon}(p) + E^{n+1}_{\omega,\varepsilon}(p,q),$$

where $E^{n+1}_{\omega,\varepsilon}$ is much smaller than $E^n_{\omega,\varepsilon}$ and $I^{n+1}_{\omega,\varepsilon}$ differs little from $I^n_{\omega,\varepsilon}$ in a domain which will be chosen appropriately (a smaller neighborhood of the surface $\Omega^{n+1} = \omega_0$).

Since Ω^{n+1} is close to Ω^n, the folding surfaces defined by $\Omega^{n+1} = \omega_0$ and by $\Omega^n = \omega_0$ are very close. Quantitative estimates will show that the $E^n_{\omega,\varepsilon}$'s decrease superexponentially and that the $g^n_{\omega,\varepsilon}$'s differ from the identity by a superexponentially small quantity in neighborhoods of the surfaces $\Omega^{n+1} = \omega_0$. As it turns out, we will have to choose these neighborhoods to become superexponentially thinner. The transformations will be defined in these thin slivers in the ω, ε, p coordinates and in domains in q which include complex extensions of $\mathbb{T}^1$ so that the size of the imaginary extension of the domain remains bounded from below.

Similarly, the functions Ω^n converge to a function Ω^∞. Therefore, the surfaces $\hat{\Omega}^n \equiv (g^1 \circ \cdots \circ g^n)^{-1}\{\Omega^n = \omega_0\}$ converge to a surface $\hat{\Omega}^\infty$. Since each of the surfaces $\{\Omega^n = \omega_0\}$ is foliated by smooth circles invariant by $F \circ g^1 \circ \cdots \circ g^n$ up to superexponentially small errors, it follows that $\hat{\Omega}^\infty$ is foliated by smooth circles invariant by F.

For the benefit of experts, we point out that an alternative method to prove Theorem 1.5 could have been to use the nondegeneracy in ω to prove a KAM theorem for all small enough ε and p. (That is, we fix ε and p, but allow ourselves to choose the ω.) Even if not all methods to prove KAM theorems would have worked, it seems that methods based on the “translated curve method” works since one can use the ω to adjust the frequency. Then, one needs to prove the analytic dependence of the circle on the parameter ε and to prove that there is indeed a fold.

The method we develop in this paper seems more appealing since one has an understanding of the folding surface at all the stages of the iteration and it is certainly not longer to write in all detail.

Moreover, we can use much of the technology developed along these lines, to prove the partial converse of Greene's theorem. In particular, Lemma 3.6 is the crux of the iterative step in the proofs of both problems. The difference between the KAM theorem and the proof of the exponentially small estimates that imply Greene's criterion lies only in different choices on how we iterate the method. In the KAM theorem, we lose domain very fast and drive the errors to zero very fast. In the exponentially small estimates, we reduce the domains more slowly and do not obtain convergence, but the estimates are valid in a larger domain.

We also call attention to the fact that Lemma 3.6 is valid in any dimension. It is only the geometric considerations about domains that one uses to conclude Theorem 1.5 and Theorem 1.6 that require the fact that we are working in an annulus. We think that this restriction can be lifted with some small amount of extra effort.

3.2. Notation and elementary estimates. Since the iterative step will rely on making transformations on functions in such a way that the errors become smaller, we will need to define appropriate norms. We will also need to be able to manipulate sets where our transformations will be defined. (As usual in KAM theory, one has to consider functions defined in decreasing sets). In this section, we collect the definitions of the norms, parameterizations of sets that we will use later as well as some elementary lemmas and propositions dealing with them.

Since Lemma 3.6 is valid in any number of dimensions, we will be considering maps in $\mathbb{R}^d \times \mathbb{T}^d$ till the end of section 3.5.

We recall the standard definition that $\omega_0 \in \mathbb{R}^d$ is said to be Diophantine of exponent θ if we can find a $C > 0$ such that $\forall k \in \mathbb{Z}^d, m \in \mathbb{Z}$ we have

$$|k \cdot \omega_0 - m|^{-1} \leq C|k|^{\theta - 1}. \tag{3.8}$$

This is the definition of Diophantine vectors that appears naturally in KAM theory for maps. (The definition that appears naturally in KAM theory for flows is slightly different.)

Besides the above standard definition, in this paper we will use the following notations.

We will denote by $I_{a,b}$ the real interval $[a,b]$, by $B_{x,c}$ the closed ball in $\mathbb{R}^d$ with center $x \in \mathbb{R}^d$ and radius $c > 0$, and by $\mathbb{T}^d$ the d-dimensional torus $\mathbb{R}^d/\mathbb{Z}^d$.

We will also denote by $I_{a,b,\delta} = \{z \in \mathbb{C} \mid d(z, I_{a,b}) \leq \delta\}$, $B_{x,c,\delta} = \{z \in \mathbb{C}^d \mid d(z, I_{a,b}) \leq \delta\}$. Similarly we will denote by $\mathbb{T}^d_\beta$ the complex extensions on the torus $\mathbb{T}^d$ of a distance β.

Given a set $U = B_{x_1,c_1,\delta} \times I_{a_2,b_2,\delta} \times B_{x_3,b_3,\delta}$ and a function $\Omega : U \to \mathbb{C}^d$, we will denote for $\alpha, \beta > 0$

$$\begin{aligned} \Sigma_{\beta,U} &= \{(\omega, \varepsilon, p, q) \mid (\omega, \varepsilon, p) \in U, |\Im\, q| \leq \beta\} = U \times \mathbb{T}^d_\beta, \\ \Sigma_{\Omega,\alpha,\beta,U} &= \{(\omega, \varepsilon, p, q) \in \Sigma_{\beta,U} \mid |\Omega(\omega, \varepsilon, p) - \omega_0| \leq \alpha\}. \end{aligned} \tag{3.9}$$

The way to think about $\Sigma_{\Omega,\alpha,\beta,U}$ is as the Cartesian product of a thin film—of width α, which will be extremely small in the proof—around a portion of surface given by the equation $\Omega(\omega, \varepsilon, p) = \omega_0$ and a complex extension of width β of the torus. The parameter U just limits which portion of the surface we are considering and it plays a somewhat minor role.

Note that, for the sake of notation, we are suppressing some of the parameters on which $\Sigma_{\Omega,\alpha,\beta,U}$ depends. Notably ω_0. We hope that this does not lead to confusion in the proof since the values of these parameters will be kept fixed. The ω_0 will be that appearing in Theorem 1.5 and, hence, will not change throughout the proof.

We will introduce the notation U_σ to denote a domain formed by restricting the domain only in the variable p by an amount $\sigma > 0$, that is, $U = B_{x_1,c_1,\delta} \times I_{a_2,b_2,\delta} \times B_{x_3,b_3,\delta-\sigma}$.

This will be used later since we need to reduce the domains in phase space (to guarantee that compositions make sense) but the domains in parameters are not affected.

Given a complex domain Σ, we will denote by $\|F\|_\Sigma \equiv \sup_{x \in \Sigma} |F(x)|$ and by χ^Σ the Banach space of functions analytic in Σ (analytic in the interior and continuous up to the boundary) equipped with the norm $\|\cdot\|_\Sigma$. In particular, for $\Sigma = \Sigma_{\beta,U}$, $\Sigma = \Sigma_{\Omega,\alpha,\beta,U}$ of the form (3.9), for typographical reasons, we will write $\|\cdot\|_{\Sigma_{\beta,U}}$ as $\|\cdot\|_{\beta,U}$ and $\|\cdot\|_{\Sigma_{\Omega,\alpha,\beta,U}}$ as $\|\cdot\|_{\Omega,\alpha,\beta,U}$.

For a function $F : U \times \mathbb{T}^d_\beta \to \mathbb{C}$, where $U = B_{x_1,c_1,\delta} \times I_{a_2,b_2,\delta} \times B_{x_3,b_3,\delta}$, we define the partial Fourier expansion

$$F_{\omega,\varepsilon}(p,q) = \sum_{k\in\mathbb{Z}^d} \hat{F}_{\omega,\varepsilon;k}(p) e^{2\pi i\, k\cdot q}.$$

The coefficients are unique in the regularity classes we will be considering.

For this kind of functions depending on parameters, we will use the notation ∇ to denote the derivatives with respect to the variables, not with respect to the parameters. Hence

$$\nabla F_{\omega,\varepsilon}(p,q) = \left(\frac{\partial}{\partial p} F_{\omega,\varepsilon}(p,q), \frac{\partial}{\partial q} F_{\omega,\varepsilon}(p,q) \right).$$

In the cases that we will need to consider derivatives with respect to the parameters, we will write them explicitly.

We recall that the well-known Cauchy inequalities allow us to bound derivatives (in a domain) and Fourier coefficients of a function in terms of its size in a (slightly larger) domain.

Lemma 3.1. *Let $U = B_{x_1,c_1,\delta} \times I_{a_2,b_2,\delta} \times B_{x_3,b_3,\delta}$, $\tilde{U} \subset U$ be a domain that is at a distance $\sigma > 0$ from the complement of U, and $F : U \times \mathbb{T}^d_\beta \to \mathbb{C}$ analytic. Then,*

$$\begin{aligned} \|\nabla^m F\|_{\beta-\sigma,\tilde{U}} &\le K\sigma^{-m} \|F\|_{\beta,\tilde{U}}, \\ \|\partial^m_\omega F\|_{\beta,\tilde{U}}, \|\partial^m_\varepsilon F\|_{\beta,\tilde{U}} &\le K\sigma^{-m} \|F\|_{\beta,\tilde{U}}, \\ |\hat{F}_{\omega,\varepsilon;k}(p)| &\le K e^{-2\pi\beta|k|} \|F\|_{\beta,\{(\omega,\varepsilon,p)\}}. \end{aligned}$$

The well-known proof is based on expressing the Fourier coefficients or derivatives as integrals over paths and deforming them in the complex domain. It can be found in many reference books and we will not reproduce it here.

3.3. The iterative step. In this subsection, we will specify the iterative step of the algorithm and we develop quantitative estimates that will later lead to the possibility of iterating it and showing it converges. Most of these estimates will be used also in Theorem 1.6 on the partial justification of Greene's criterion.

We recall that for the purposes of the iterative lemma, Lemma 3.6, the dimension of the space will be irrelevant, so we will state the results in the $2d$-annulus $\mathbb{R}^d \times \mathbb{T}^d$.

At the beginning of the iterative step, we will be given a family of exact symplectic maps $f_{\omega,\varepsilon}$ defined on a subset of $\mathbb{R}^d \times \mathbb{T}^d$ endowed with the standard symplectic structure.

$$f_{\omega,0}(p,q) = (p, q + \Gamma(\omega,p)), \qquad F_{\omega,\varepsilon}(p,q) = I_{\omega,\varepsilon}(p) + E_{\omega,\varepsilon}(p,q), \tag{3.10}$$

where $F_{\omega,\varepsilon}$, the Hamiltonian of the deformation $f_{\omega,\varepsilon}$, is defined in a set $\Sigma_{\Omega,\alpha,\beta,U}$ of the type described in (3.9), with

$$U = B_{\omega_0,\gamma,\delta} \times I_{[-1,1],\delta} \times B_{0,\gamma,\delta}$$

for some $\gamma > 0$, $0 < \delta < 1$, where ω_0 is a Diophantine vector (e.g., it satisfies (3.8)) and

$$\Omega(\omega, \varepsilon, p) = \Gamma(\omega, p) + \int_0^\varepsilon ds \frac{\partial}{\partial p} I_{\omega,s}(p). \tag{3.11}$$

Since $\Omega(\omega, 0, p) = \Gamma(\omega, p)$, from the hypotheses of Theorem 1.5 we will also assume that Ω is nondegenerate, that is, that we have

$$\left\|(\partial_\omega \Omega)^{-1}\right\|_U \leq A, \qquad \left\|(\partial_p^2 \Omega)^{-1}\right\|_U \leq B. \tag{3.12}$$

The goal of the iterative step is to determine $g_{\omega,\varepsilon}$, $g_{\omega,0} = \mathrm{Id}$, in such a way that $\tilde{f}_\varepsilon = g_{\omega,\varepsilon}^{-1} \circ f_{\omega,\varepsilon} \circ g_{\omega,\varepsilon}$ has Hamiltonian

$$\tilde{F}_{\omega,\varepsilon}(p, q) = \tilde{I}_{\omega,\varepsilon}(p) + \tilde{E}_{\omega,\varepsilon}(p, q), \tag{3.13}$$

where $\tilde{I}_{\omega,\varepsilon}$, $\tilde{E}_{\omega,\varepsilon}$ will be defined in a slightly smaller domain than $I_{\omega,\varepsilon}$, $E_{\omega,\varepsilon}$ and where $\tilde{E}_{\omega,\varepsilon}$ is much smaller than $E_{\omega,\varepsilon}$ and $\tilde{I}_{\omega,\varepsilon} - I_{\omega,\varepsilon}$ is of the same order of magnitude as $E_{\omega,\varepsilon}$ with all these functions defined in an slightly smaller domain than the original ones.

According to Proposition 2.1, the Hamiltonian of $g_{\omega,\varepsilon}^{-1} \circ f_{\omega,\varepsilon} \circ g_{\omega,\varepsilon}$ is

$$F_{\omega,\varepsilon} \circ g_{\omega,\varepsilon} - G_{\omega,\varepsilon} \circ g_{\omega,\varepsilon} + G_{\omega,\varepsilon} \circ f_{\omega,\varepsilon}^{-1} \circ g_{\omega,\varepsilon}. \tag{3.14}$$

Heuristically, assuming that $G_{\omega,\varepsilon}$ and $E_{\omega,\varepsilon}$ are small and of the same order—and therefore that $g_{\omega,\varepsilon} - \mathrm{Id}$ and $f_{\omega,\varepsilon} - i_{\omega,\varepsilon}$ are small, where $i_{\omega,\varepsilon}$ is the integrable part of $f_{\omega,\varepsilon}$ as in (3.6)—the main terms in (3.14) are

$$F_{\omega,\varepsilon} - G_{\omega,\varepsilon} + G_{\omega,\varepsilon} \circ i_{\omega,\varepsilon}^{-1}.$$

Hence, to make the new error $\tilde{E}_{\omega,\varepsilon}$ zero in this linear approximation, we need to determine $G_{\omega,\varepsilon}$ in such a way that these main terms give just an integrable system (which we will call $\tilde{I}_{\omega,\varepsilon}$). This is formulated as the equation for $G_{\omega,\varepsilon}$, $\tilde{I}_{\omega,\varepsilon}$, given $F_{\omega,\varepsilon}$:

$$\tilde{I}_{\omega,\varepsilon}(p) = F_{\omega,\varepsilon}(p, q) - G_{\omega,\varepsilon}(p, q) + G_{\omega,\varepsilon} \circ i_\omega^{-1}(p, q).$$

Equivalently, we look for an approximate solution of

$$\Delta_{\omega,\varepsilon}(p) = E_{\omega,\varepsilon}(p, q) - G_{\omega,\varepsilon}(p, q) + G_{\omega,\varepsilon} \circ i_\omega^{-1}(p, q), \tag{3.15}$$

where $\Delta_{\omega,\varepsilon}(p) := \tilde{I}_{\omega,\varepsilon}(p) - I_{\omega,\varepsilon}(p)$.

This approximate solution will be used to construct a $g_{\omega,\varepsilon}$, which will lead to a Hamiltonian which is much closer to integrable.

Indeed, the approximate solution of (3.15) will be chosen as an exact solution of

$$\Delta_{\omega,\varepsilon}(p) = E_{\omega,\varepsilon}(p, q) - G_{\omega,\varepsilon}(p, q) + G_{\omega,\varepsilon}(p, q - \omega_0) \tag{3.16}$$

which can be solved by taking Fourier coefficients. We will show that, if we restrict ourselves to a domain $\Sigma_{\Omega,\alpha,\tilde{\beta},\tilde{U}}$, with α very small, the solutions of (3.16) solve (3.15) up to errors that can be controlled by α. Then, the system will be reduced very approximately to a new integrable one. If the frequency function Ω is nondegenerate, we can apply the implicit function theorem and express the domain in terms of the new frequency function $\tilde{\Omega}$. We call attention to the fact that it is only in this last step that the nondegeneracy of the frequency function is used.

To justify the above heuristic argument, we will just find the $g_{\omega,\varepsilon}$ obtained by the procedure detailed above and estimate rigorously the remainder after we conjugate the original problem with it. This task will take most of the present section. We will collect all the estimates systematically and, at the end of the section we will formulate the final result precisely. Once we have these results, we will also need to estimate how the integrable part has changed and, in particular, how much the folding surface Σ and its parameterization Υ introduced in (3.3) have changed. This is the task we will undertake in the next section. Then, in a subsequent section, we will show that the procedure can be iterated indefinitely (when some of the arbitrary choices are made appropriately), and that the transformations converge to a limiting transformation that reduces the system to integrable.

3.4. The iterative step. Estimates. In this subsection, we present detailed quantitative estimates for the iterative step that we described informally in the previous section.

Following standard practice, we denote by K sufficiently large positive constants that depend only on the dimension, the number ω_0, and other elements that remain constant during the proof and denote by K^{-1} all sufficiently small positive constants. We will also need to assume that some quantities related to the integrable part of the system remain bounded under the iteration. We will use K_1, K_2 for these constants that depend on the integrable part. The constants K may depend on these K_1, K_2 but not vice versa. When we discuss the iteration, we will see that these K_1, K_2 are chosen in the first step and then they remain unaltered. In particular, we will need to assume that the constants A and B that quantify the nondegeneracy assumptions (3.12) satisfy

$$A \leq K_1, \quad B \leq K_2. \tag{3.17}$$

Recall that the goal was, given a Hamiltonian with an error term E, defined in a set $\Sigma_{\Omega,\alpha,\beta,U}$ of the form defined in (3.9), to perform a transformation that has an error term $\tilde{E}$ which is much smaller even if defined in a smaller set $\Sigma_{\tilde{\Omega},\tilde{\alpha},\tilde{\beta},\tilde{U}}$.

As it turns out, we will take a number σ and take $\tilde{\beta} = \beta - \alpha - 4\sigma$, $\tilde{U} = U_{4\sigma}$. At the n step σ_n will be $\sigma_0 2^{-n}$, but α will have to decrease superexponentially.

Our goal will be to show that, under appropriate hypotheses, which we will assume inductively, we can perform the transformation and obtain estimates of the form

$$\|\tilde{E}\|_{\tilde{\Omega},\tilde{\alpha},\tilde{\beta},\tilde{U}} \leq K\sigma^{-\tau}\|E\|_{\Omega,\alpha,\beta,U}(\|E\|_{\Omega,\alpha,\beta,U} + \tilde{\alpha}) \tag{3.18}$$

for some fixed positive number τ (we will show later that it suffices to take $\tau = 2\nu + 3$ where $\nu = \theta + d - 1$, and θ is the Diophantine exponent of ω_0).

We will also establish that Υ and $\tilde{\Upsilon}$—the parameterizations (3.3) of the surfaces $\Omega = \omega_0$ and $\tilde{\Omega} = \omega_0$, respectively—are defined in very similar domains and differ by a small amount

$$\|\Upsilon - \tilde{\Upsilon}\|_{\tilde{U}} \leq K\sigma^{-1}\|E\|_{\Omega,\alpha,\beta,U}. \tag{3.19}$$

The proof will be conveniently divided into two parts. In the first one, we obtain estimates in terms of the old domains parameterized by Ω and α. In this first part—culminated in Lemma 3.6—we will not need to use any nondegeneracy hypothesis in

Ω and indeed ω and ε will just go along for the ride. In a second part of the inductive step, we adjust the domains to the new frequency map. This part will require that we assume that Ω is nondegenerate and we will have to lose some domain in ω. This division is natural since the first part is exactly the same as that used in the proof of Theorem 1.6.

Remark. For the experts in KAM theory, we call attention to the fact that the right-hand side of (3.18) is not quadratic in $\|E\|_{\Omega,\alpha,\beta,U}$—the size of the error. Nevertheless, the linear term is multiplied by the number $\tilde{\alpha}$. As we will see in the following subsection, as $\tilde{\alpha}$ goes to zero superexponentially with the number of steps taken, it is possible to recover the superexponential convergence of KAM theory that beats the small divisors.

As is customary in KAM theory, in order to be able to carry out the iterative step, we will need to assume that certain quantities are sufficiently small with respect to others—so that, for example, compositions have domains that match, implicit function theorems can be applied, etc. As it will turn out all the conditions necessary to perform the iterative step will be implied by smallness conditions of $\|E\|_{\Omega,\alpha,\beta,U}$ with respect to other quantities. Since the iterative step implies that this goes to zero extremely fast, the conditions will be recovered from one step to the next.

Hence, for the proof of Theorem 1.5, the main result of this subsection will be Lemma 3.7 below, which states that, under some explicit conditions, the iterative step can be performed and that the result satisfies (3.18) and (3.19).

Since the proof of Lemma 3.7 will consist in walking through the steps outlined before and just record the conditions needed for them to go through, it is natural to start with the proof of the lemma and postpone its precise statement.

Using Proposition 2.1, the Hamiltonian of $g^{-1}_{\omega,\varepsilon} \circ f_{\omega,\varepsilon} \circ g_{\omega,\varepsilon}$—if it is possible to define all the compositions—is $I_{\omega,\varepsilon} \circ g_{\omega,\varepsilon} + E_{\omega,\varepsilon} \circ g_{\omega,\varepsilon} - G_{\omega,\varepsilon} \circ g_{\omega,\varepsilon} + G_{\omega,\varepsilon} \circ f^{-1}_{\omega,\varepsilon} \circ g_{\omega,\varepsilon}$, which adding and subtracting appropriate terms becomes

$$\begin{aligned}
&\overline{I_{\omega,\varepsilon} \circ g_{\omega,\varepsilon}} + (I_{\omega,\varepsilon} \circ g_{\omega,\varepsilon} - \overline{I_{\omega,\varepsilon} \circ g_{\omega,\varepsilon}})\\
&+\overline{E_{\omega,\varepsilon}}\\
&+(E_{\omega,\varepsilon} - \overline{E_{\omega,\varepsilon}}) + (E_{\omega,\varepsilon} \circ g_{\omega,\varepsilon} - E_{\omega,\varepsilon})\\
&-G_{\omega,\varepsilon} + (-G_{\omega,\varepsilon} \circ g_{\omega,\varepsilon} + G_{\omega,\varepsilon})\\
&+G_{\omega,\varepsilon} \circ T^0 + (G_{\omega,\varepsilon} \circ i^{-1}_{\omega,\varepsilon} - G_{\omega,\varepsilon} \circ T^0) + (G_{\omega,\varepsilon} \circ f^{-1}_{\omega,\varepsilon} \circ g_{\omega,\varepsilon} - G_{\omega,\varepsilon} \circ i^{-1}_{\omega,\varepsilon}),
\end{aligned} \tag{3.20}$$

where we have used the notation $\overline{\quad\quad}$ to indicate average over the q variables and $T^0(p, q) = (p, q - \omega_0)$.

The main idea will be to show that it is possible to choose $G_{\omega,\varepsilon}$ in such a way that the first terms in the last three lines of (3.20) add to zero. That is,

$$E_{\omega,\varepsilon} - \overline{E_{\omega,\varepsilon}} - G_{\omega,\varepsilon} + G_{\omega,\varepsilon} \circ T^0 = 0 \tag{3.21}$$

and that this $G_{\omega,\varepsilon}$ satisfies estimates which will guarantee that the compositions we used are indeed defined. (We call attention to the fact that (3.21) is the linearized equation that always appears in KAM theory.) Then, the transformed system will have an integrable part $\tilde{I}_{\omega,\varepsilon} = \overline{I_{\omega,\varepsilon} \circ g_{\omega,\varepsilon}} + \overline{E_{\omega,\varepsilon}}$ and the other terms appearing in (3.20) will be the error part of the new Hamiltonian. We will estimate them and show that, in a precise sense, they will be smaller than the other ones.

Remark. For the experts in KAM theory, we note that this procedure has two error terms that are linear in G—and hence first order in E— namely $(G_{\omega,\varepsilon} \circ i^{-1}_{\omega,\varepsilon} - G_{\omega,\varepsilon} \circ T^0)$ and $(I_{\omega,\varepsilon} \circ g_{\omega,\varepsilon} - \overline{I_{\omega,\varepsilon} \circ g_{\omega,\varepsilon}})$—recall that I will not be converging to zero.

Even if full details will be given later, we advance that for the first term, in the domains that we are considering, $i_{\omega,\varepsilon}^{-1}$ and T^0 are indeed close and the distance is measured by $\tilde{\alpha}$. The mean value theorem will give an estimate that contains the factor $\|E\|\tilde{\alpha}$ multiplied by the small divisors. This is the estimate that appears in one of the terms in (3.18). The second term will turn out to be quadratic because of the fact that $g_{\omega,\varepsilon}$ is exact symplectic. This is the only place in all the estimates where we use that the maps are exact symplectic.

As usual in KAM theory, we start by obtaining bounds on $G_{\omega,\varepsilon}$ and we will use them to obtain bounds on all the other terms.

Lemma 3.2. *For any $E_{\omega,\varepsilon}(p,q)$ defined in $\Sigma_{\Omega,\alpha,\beta,U}$, we can find unique $\Delta_{\omega,\varepsilon}(p)$, $G_{\omega,\varepsilon}(p,q)$ satisfying*

$$\Delta_{\omega,\varepsilon}(p) = E_{\omega,\varepsilon}(p,q) - G_{\omega,\varepsilon}(p,q) + G_{\omega,\varepsilon}(p,q-\omega_0)$$
$$\int_{\mathbb{T}^d} G_{\omega,\varepsilon}(p,q)\,dq = 0.$$

Moreover, these Δ, G satisfy

$$\|G\|_{\beta-\sigma,U} \le K\sigma^{-\nu}\,\|E\|_{\beta,U}\,, \qquad \|\Delta\|_{\beta,U} \le \|E\|_{\beta,U}\,, \tag{3.22}$$

where $\nu = \theta + d - 1$.

Proof. The proof is quite standard. We note that integrating in q we have

$$\Delta_{\omega,\varepsilon}(p) = \overline{E_{\omega,\varepsilon}}(p) := \int_{\mathbb{T}^d} dq\, E_{\omega,\varepsilon}(p,q), \tag{3.23}$$

hence, the first estimate in (3.22) follows.

If we take Fourier transforms in the variable q we obtain

$$\hat{G}_{\omega,\varepsilon;k}(p) = \frac{1}{(e^{-2\pi i k\cdot\omega_0} - 1)}\hat{E}_{\omega,\varepsilon;k}(p). \tag{3.24}$$

By the Cauchy estimates of Lemma 3.1, we have $|\hat{E}_{\omega,\varepsilon;k}(p)| \le Ke^{-2\pi\beta|k|}\,\|E\|_{\beta,U}$ and, by the Diophantine assumptions, $|e^{-2\pi i k\omega_0} - 1|^{-1} \le C|k|^{\theta-1}$. Hence,

$$|\hat{G}_{\omega,\varepsilon;k}(p)| \le K|k|^{\theta-1}e^{-2\pi\beta|k|}\,\|E\|_{\beta,U}$$

and, therefore

$$\begin{aligned}\|G\|_{\beta-\sigma,U} &\le \textstyle\sum_{k\in\mathbb{Z}^d} |\hat{G}_{\omega,\varepsilon;k}(p)|e^{2\pi(\beta-\sigma)|k|} \le K\left(\sum_{k\in\mathbb{Z}^d}|k|^{\theta-1}e^{-2\pi\sigma|k|}\right)\|E\|_{\beta,U}\\ &\le K\left(\textstyle\sum_{l\in\natural}|l|^{\theta-1+d-1}e^{-2\pi\sigma l}\right)\|E\|_{\beta,U} \le K\sigma^{-\nu}\,\|E\|_{\beta,U}\,,\end{aligned}$$

where $\nu = \theta + d - 1$.

We refer to [SM] for more details but point out that it is possible to obtain better exponents in σ (see, e.g., [Ru]). Of course, since the rest of the proof goes through for any exponent, this does not affect the subsequent reasoning. □

A small generalization of these estimates is in the following proposition.

Proposition 3.3. *With the notation of Lemma* 3.2

$$\|\nabla^m G\|_{\beta-\sigma,U_\sigma} \le K\sigma^{-\nu-m}\,\|E\|_{\beta,U}\,. \tag{3.25}$$

Proof. Using Lemma 3.1 and (3.24) we obtain that, for $(\omega, \varepsilon, p) \in U_\sigma$, we have

$$|\partial_p^i \hat{G}_{\omega,\varepsilon;k}(p)| \le K\sigma^{-(i+\theta-1)} e^{-2\pi|k|\beta} \|E\|_{\beta,U}. \tag{3.26}$$

Similarly, we have

$$|\partial_q^j(\hat{G}_{\omega,\varepsilon;k}(p)e^{2\pi i k\cdot q})| \le K|k|^j |\hat{G}_{\omega,\varepsilon;k}(p)| \le K|k|^{j+\theta-1} e^{-2\pi|k|\beta} \|E\|_{\beta,U}. \tag{3.27}$$

On $\Sigma_{\beta-\sigma,U_\sigma}$ we have $|\Im q| \le \beta - \sigma$ and hence $|e^{2\pi i k\cdot q}| \le e^{2\pi|k|(\beta-\sigma)}$. Therefore, using the above estimates (3.26) and (3.27) in the same way as in Lemma 3.2, we obtain the desired result. □

Now, we can prove estimates for the flow of $G_{\omega,\varepsilon}$.

PROPOSITION 3.4. *Assume that the conditions of Proposition* 3.3 *are met and that, furthermore,*

$$K\sigma^{-\nu-1} \|E\|_{\beta,U} \le \sigma/2. \tag{3.28}$$

Then

(i) *for* $(\omega, \varepsilon, p, q) \in \Sigma_{\beta-2\sigma,U_{2\sigma}}$, *the flow* $g_{\omega,\varepsilon}(p,q)$ *generated by the Hamiltonian* $G_{\omega,\varepsilon}$ *is well defined, and* $(\omega, \varepsilon, g_{\omega,\varepsilon}(p,q)) \in \Sigma_{\beta-\sigma,U_\sigma}$;

(ii) $\|g - \mathrm{Id}\|_{\beta-2\sigma,U_{2\sigma}} \le \|\nabla G\|_{\beta-\sigma,U_\sigma} \le K\sigma^{-\nu-1} \|E\|_{\beta,U}$.

Proof. It follows from hypothesis (3.28), Proposition 3.3, and the local existence theorem for solutions of ODEs. □

From now on, we will assume that (3.28) holds, and we will proceed to estimate the terms in (3.20).

By Proposition 3.4, the compositions $G_{\omega,\varepsilon} \circ g_{\omega,\varepsilon}$, $E_{\omega,\varepsilon} \circ g_{\omega,\varepsilon}$ are well defined on $\Sigma_{\beta-2\sigma,U_{2\sigma}}$. Using the mean value theorem and Cauchy inequalities from Lemma 3.1, we can bound

$$\|G - G\circ g\|_{\beta-2\sigma,U_{2\sigma}} \le \|\nabla G\|_{\beta-\sigma,U_\sigma} \|g - \mathrm{Id}\|_{\beta-2\sigma,U_{2\sigma}} \le K\sigma^{-2\nu-2} \|E\|^2_{\beta,U}, \tag{3.29}$$

$$\|E - E\circ g\|_{\beta-2\sigma,U_{2\sigma}} \le \|\nabla E\|_{\beta-\sigma,U_\sigma} \|g - \mathrm{Id}\|_{\beta-2\sigma,U_{2\sigma}} \le K\sigma^{-\nu-2} \|E\|^2_{\beta,U}. \tag{3.30}$$

These estimates show that two of the terms in (3.20) are quadratically small in the original error.

Now, we turn to estimate the last term in (3.20), which, as we will show, will also be quadratic in $\|E\|$. The reason is that $f_{\omega,\varepsilon}$ and $i_{\omega,\varepsilon}$ satisfy differential equations whose difference can be controlled by $\|E\|$ and the same initial conditions. Hence, $\|f^{-1} - i^{-1}\| \le K\|E\|$ under some mild extra assumptions that guarantee that domains match, etc., and we can now apply the mean value theorem. The precise details are a walk through the standard proof of the existence and uniqueness for ODEs, as we detail below.

First, we recall that $i_{\omega,\varepsilon}$ has the form (3.6): $i_{\omega,\varepsilon}(p,q) = (p, q + \Omega(\omega,\varepsilon,p))$, with $\Omega(\omega,\varepsilon,p)$ given in (3.11), and we note that $i^{-1}_{\omega,\varepsilon}(p,q) = (p, q - \Omega(\omega,\varepsilon,p))$. Hence, for

$$\|i - T_0\|_U = \left\|i^{-1} - T_0\right\|_U = \|\Omega - \omega_0\|_U \le \alpha \tag{3.31}$$

we have

$$(\omega,\varepsilon,p,q) \in \Sigma_{\beta-\alpha,U} \Longrightarrow (\omega,\varepsilon,i_{\omega,\varepsilon}(p,q)), \left(\omega,\varepsilon,i^{-1}_{\omega,\varepsilon}(p,q)\right) \in \Sigma_{\beta,U}. \tag{3.32}$$

Assuming

$$\left\|\frac{\partial\Omega}{\partial p}\right\|_U \le K_3 \tag{3.33}$$

(where without loss of generality, we assume, to simplify some formulas that $K_3 > 1$), we can bound

$$\|\nabla i\|_U = \left\|\nabla i^{-1}\right\|_U \le K. \tag{3.34}$$

We recall now that $f_{\omega,\varepsilon}$ is the solution of

$$\begin{aligned} f_{\omega,\varepsilon}(x) &= f_{\omega,0}(x) + \textstyle\int_0^\varepsilon ds\, \mathcal{F}_{\omega,s} \circ f_{\omega,s}(x) \\ &= f_{\omega,0}(x) + \textstyle\int_0^\varepsilon ds\, \left[\mathcal{I}_{\omega,\varepsilon} \circ f_{\omega,s}(x) + \mathcal{E}_{\omega,\varepsilon} \circ f_{\omega,s}(x)\right] \end{aligned} \tag{3.35}$$

while $i_{\omega,\varepsilon}$ satisfies $i_{\omega,\varepsilon}(x) = i_{\omega,0}(x) + \int_0^\varepsilon ds\, \mathcal{I}_{\omega,s} \circ i_{\omega,s}(x)$, with $f_{\omega,0}(x) = i_{\omega,0}(x)$. By hypothesis (3.28), using standard arguments of ODEs based on the Gronwall inequality, we get that for $(\omega,\varepsilon,p,q) \in \Sigma_{\beta-\alpha-2\sigma,U_{2\sigma}}$, the flow $f_{\omega,\varepsilon}(p,q)$ is well defined, and satisfies

$$(\omega,\varepsilon,p,q) \in \Sigma_{\beta-\alpha-2\sigma,U_{2\sigma}} \Longrightarrow (\omega,\varepsilon,f_{\omega,\varepsilon}(p,q)) \in \Sigma_{\beta-\sigma,U_\sigma}, \tag{3.36}$$

$$\|f - i\|_{\beta-\alpha-2\sigma,U_{2\sigma}} \le e^{K_3} \|\nabla E\|_{\beta-\sigma,U_\sigma} \le K\sigma^{-1} \|E\|_{\beta,U}. \tag{3.37}$$

From (3.34), and Lemma 3.1 applied to (3.37), we can bound $\nabla f_{\omega,\varepsilon}$:

$$\|\nabla f\|_{\beta-\alpha-3\sigma,U_{3\sigma}} \le \|\nabla i\|_U + \|\nabla(f-i)\|_{\beta-\alpha-3\sigma,U_{3\sigma}} \le K. \tag{3.38}$$

Applying the implicit function theorem to the estimates above, it turns out that for $(\omega,\varepsilon,p,q) \in \Sigma_{\beta-\alpha-2\sigma,U_{2\sigma}}$, $f^{-1}_{\omega,\varepsilon}(p,q)$ is well defined, satisfies $\left(\omega,\varepsilon,f^{-1}_{\omega,\varepsilon}(p,q)\right) \in \Sigma_{\beta-\sigma,U_\sigma}$, and

$$\left\|f^{-1} - i^{-1}\right\|_{\beta-\alpha-2\sigma,U_{2\sigma}} \le K\sigma^{-1}\| \, \|E\|_{\beta,U}. \tag{3.39}$$

As before, from (3.34), and Lemma 3.1 applied to (3.39), we can bound $\nabla f^{-1}_{\omega,\varepsilon}$:

$$\left\|\nabla f^{-1}\right\|_{\beta-\alpha-3\sigma,U_{3\sigma}} \le K. \tag{3.40}$$

Using the mean value theorem, (3.40), and the bounds on $g_{\omega,\varepsilon} - \mathrm{Id}$ established in Proposition 3.4, we obtain

$$\left\|f^{-1} - f^{-1} \circ g\right\|_{\beta-\alpha-3\sigma,U_{3\sigma}} \le K\sigma^{-\nu-1} \|E\|_{\beta,U}. \tag{3.41}$$

Putting together (3.39) and (3.41), by the triangle inequality, we obtain

$$\left\|f^{-1} \circ g - i^{-1}\right\|_{\beta-\alpha-3\sigma,U_{3\sigma}} \le K\sigma^{-\nu-1} \|E\|_{\beta,U}. \tag{3.42}$$

Using the mean value theorem, the estimates in Proposition 3.3, and (3.42), we can bound the last term in (3.20) as

$$\left\|G \circ f^{-1} \circ g - G \circ i^{-1}\right\|_{\beta-\alpha-3\sigma,U_{3\sigma}} \le K\sigma^{-2\nu-2} \|E\|^2_{\beta,U}. \tag{3.43}$$

Now we turn our attention to the first term in (3.20). It will depend on the approximate expression $g^0_{\omega,\varepsilon} = \mathrm{Id} + \int_0^\varepsilon ds\, \mathcal{G}_{\omega,s}$ for $g_{\omega,\varepsilon}$:

$$g^0_{\omega,\varepsilon}(p,q) = \left(p - \int_0^\varepsilon ds\, \frac{\partial}{\partial q} G_{\omega,s}(p,q)\ , q + \int_0^\varepsilon ds\, \frac{\partial}{\partial p} G_{\omega,s}(p,q)\right). \tag{3.44}$$

Proposition 3.5. *Under our standing hypotheses, we have*

$$\left\|g - g^0\right\|_{\beta-2\sigma,U_{2\sigma}} \leq K\sigma^{-2\nu-3}\left\|E\right\|^2_{\beta,U}.$$

Proof. Note that our standing assumptions imply

$$\left\|g^0 - \mathrm{Id}\right\|_{\beta-\sigma,U_\sigma} \leq \left\|\nabla G\right\|_{\beta-\sigma,U_\sigma} \leq K\sigma^{-\nu-1}\left\|E\right\|_{\beta,U}$$

and consequently $\left(\omega, \varepsilon, g^0_{\omega,\varepsilon}(p,q)\right) \in \Sigma_{\beta-\sigma,U_\sigma}$ for $(\omega,\varepsilon,p,q) \in \Sigma_{\beta-\alpha-2\sigma,U_{2\sigma}}$.

We can write $g_{\omega,\varepsilon}$ as the solution of a fixed point problem. Namely,

$$g_{\omega,\varepsilon} = \mathrm{Id} + \int_0^\varepsilon ds\, \mathcal{G}_{\omega,s} \circ g_{\omega,s} \equiv \mathcal{T}(g)_{\omega,\varepsilon},$$

and we have the identity

$$\mathcal{T}(g^0)_{\omega,\varepsilon} - g^0_{\omega,\varepsilon} = \int_0^\varepsilon ds\, [\mathcal{G}_{\omega,s} \circ g^0_{\omega,s} - \mathcal{G}_{\omega,s}].$$

If we estimate the integrand of the right-hand side (R.H.S.) by the mean value theorem, we have

$$\begin{aligned}\left\|\mathcal{T}(g^0) - g^0\right\|_{\beta-2\sigma,U_{2\sigma}} &\leq \left\|\nabla^2 G\right\|_{\beta-\sigma,U_\sigma}\left\|g^0 - \mathrm{Id}\right\|_{\beta-\sigma,U_\sigma} \\ &\leq K\sigma^{-2\nu-3}\left\|E\right\|^2_{\beta,U}.\end{aligned} \tag{3.45}$$

We also obtain, under (3.28), that $\mathcal{T}$ is a contraction of factor 1/2. Hence, there is a fixed point of $\mathcal{T}$ whose distance from $g^0_{\omega,\varepsilon}$ is not bigger than $1/(1-1/2) = 2$ times the R.H.S. of (3.45). □

We note that, because $I_{\omega,\varepsilon}(x)$ does not depend on q, denoting by Π_p, Π_q the projections on the p and q components, respectively, we have for $x = (p,q)$

$$\begin{aligned}I_{\omega,\varepsilon}(g_{\omega,\varepsilon}(x)) &= I_{\omega,\varepsilon}(\Pi_p g_{\omega,\varepsilon}(x)) \\ &= I_{\omega,\varepsilon}(p) + \partial_p I_{\omega,\varepsilon}(p)\Pi_p\left[g_{\omega,\varepsilon}(x) - x\right] + R_2\left(\omega,\varepsilon,x,g_{\omega,\varepsilon}(x)\right) \\ &= I_{\omega,\varepsilon}(p) + \partial_p I_{\omega,\varepsilon}(p)\Pi_p\left[g^0_{\omega,\varepsilon}(x) - x\right] \\ &\quad + \partial_p I_{\omega,\varepsilon}(p)\Pi_p\left[g_{\omega,\varepsilon}(x) - g^0_{\omega,\varepsilon}(x)\right] + R_2\left(\omega,\varepsilon,x,g_{\omega,\varepsilon}(x)\right),\end{aligned} \tag{3.46}$$

where we have denoted by R_2 the remainder of the second order Taylor expansion in p.

Note that $\Pi_p\left[g^0_{\omega,\varepsilon}(x) - x\right] = \partial_q G_{\omega,\varepsilon}(x)$ (see (3.44)) and that $\overline{\partial_q G_{\omega,\varepsilon}} = 0$ since q is a periodic variable. Hence, observing that $\partial_p I$ is independent of q, we obtain

$$\overline{\partial_p I \int_0^\varepsilon ds\, \partial_q G_{\omega,s}} = 0. \tag{3.47}$$

That is, the second term in the R.H.S. of the formula of (3.46) has zero average. We call attention to the fact that this is the only part in the whole proof of the estimates where we use the exact symplectic character of the deformation, which is equivalent to the fact that G is a function on the annulus and not just on the universal cover.

Since $I_{\omega,\varepsilon}$ depends only on p we have that $\overline{I_{\omega,\varepsilon}} = I_{\omega,\varepsilon}$.

Under the assumption

$$\left\|\nabla^2 I\right\|_{\beta-\sigma,U_\sigma} \le K_4 \tag{3.48}$$

we can bound the last two terms in (3.46) by terms that are quadratic in $\|E\|$.

Since the last two terms in (3.46) are the only ones that contribute to $I_{\omega,\varepsilon}\circ g_{\omega,\varepsilon} - \overline{I_{\omega,\varepsilon}\circ g_{\omega,\varepsilon}}$, we obtain from Proposition 3.5

$$\left\|I\circ g - \overline{I\circ g}\right\|_{\beta-2\sigma,U_{2\sigma}} \le K\sigma^{-2\nu-3}\left\|E\right\|^2_{\beta,U}. \tag{3.49}$$

The only term in (3.20) that remains to be estimated is $G_{\omega,\varepsilon}\circ i^{-1}_{\omega,\varepsilon} - G_{\omega,\varepsilon}\circ T^0$. We note that, by (3.31), we have

$$\left\|i^{-1} - T^0\right\|_U \le \alpha.$$

Therefore, using the estimates in Proposition 3.3,

$$\left\|G\circ i^{-1} - G\circ T^0\right\|_{\sigma,U_{\beta-\alpha-\sigma}} \le K\sigma^{-\nu-1}\alpha\left\|E\right\|_{\beta,U}. \tag{3.50}$$

If we add the estimates in (3.29), (3.30), (3.43), (3.49), and (3.50), for the terms that have to be bounded in (3.20), and claim them only in the domain $\Sigma_{\beta-\alpha-4\sigma,U_{4\sigma}}$, which is smaller than any of the domains in which we have bounds, we obtain

$$\left\|\tilde{E}\right\|_{\beta-\alpha-4\sigma,U_{4\sigma}} \le K\sigma^{-\tau}\left\|E\right\|_{\beta,U}\left(\left\|E\right\|_{\beta,U} + \alpha\right), \tag{3.51}$$

where $\tau := 2\nu+3$ and $\left\|\Omega-\omega_0\right\|_U \le \alpha$.

We also notice that from Proposition 3.4 and (3.36), it follows that if $(\omega,\varepsilon,p,q)\in \Sigma_{\beta-\alpha-4\sigma,U_{4\sigma}}$, then $\left(\omega,\varepsilon,g^{-1}_{\omega,\varepsilon}\circ f_{\omega,\varepsilon}\circ g_{\omega,\varepsilon}(p,q)\right)\in\Sigma_{\beta-\sigma,U_\sigma}$.

On the set $\Sigma_{\Omega,\alpha,\beta\alpha-4\sigma,U_{4\sigma}}$ introduced in (3.9), (3.51) reads as

$$\|\tilde{E}\|_{\Omega,\alpha,\beta-\alpha-4\sigma,U_{4\sigma}} \le K\sigma^{-\tau}\|E\|_{\Omega,\alpha,\beta,U}(\|E\|_{\Omega,\alpha,\beta,U}+\alpha). \tag{3.52}$$

This is very similar to the estimates desired in (3.18) and it only differs from them in the fact that the norm in the left-hand side (L.H.S.) of (3.52) is referred to as the domain specified by Ω and not by $\tilde{\Omega}$.

To remedy that, we will estimate the change in Ω and the attendant change in the parameterizations Υ of the surface and the domain Σ. Using that the frequency function Ω is nondegenerate, this will allow us to transform the expression of the domain in which we have improved estimates into an expression involving the new frequency function.

We will find it convenient to state formally what we have already accomplished without using nondegeneracy conditions in Ω. We call attention that this lemma will also play an important role in the proof of Theorem 1.6. Later, we will prove Lemma 3.7 that takes into account the change in the frequency function and which indeed uses the nondegeneracy assumptions in Ω.

LEMMA 3.6. *Given the Hamiltonian $F = I + E$ of $f_{\omega,\varepsilon}$ introduced in* (3.10), *choose G, Δ as given by Lemma* 3.2, *and consider the new Hamiltonian $\tilde{F} = \tilde{I} + \tilde{E}$ of $g^{-1}_{\omega,\varepsilon}\circ f_{\omega,\varepsilon}\circ g_{\omega,\varepsilon}$ as given in* (3.13). *Assume that σ is such that* (3.28), (3.33), *and* (3.48) *are met, and let $\tau = 2\nu+3$. Then*

$$\|\tilde{E}\|_{\Omega,\alpha,\beta-\alpha-4\sigma,U_{4\sigma}} \le K\sigma^{-\tau}\|E\|_{\Omega,\alpha,\beta,U}(\|E\|_{\Omega,\alpha,\beta,U}+\alpha), \tag{3.53}$$

$$\|\Delta\|_{\Omega,\alpha,\beta,U} \le \|E\|_{\Omega,\alpha,\beta,U}, \qquad \|\nabla\Delta\|_{\Omega,\alpha,\beta-\sigma,U_\sigma} \le K\sigma^{-1}\|E\|_{\Omega,\alpha,\beta,U}. \tag{3.54}$$

The way of interpreting these estimates is that (3.53) indicates that, after the transformation, the resulting Hamiltonian is essentially an integrable one (albeit in a smaller domain): the right-hand side of (3.53) consists on two terms, one of which is quadratic in $\|E\|$ and the other one contains $\|E\|\alpha$. If we choose α sufficiently small, we will be able to make the R.H.S. of (3.53) much smaller than the original one. This will overcome the small divisors $\sigma^{-\tau}$.

We call attention to the fact that Lemma 3.6 does not need the nondegeneracy assumption on Ω and that it does not lose any domain in the parameters. This lemma will a basic tool for the estimates of the inductive steps both in the proof of the KAM theorem and in the justification of Greene's criterion. The difference between the two results will be that the inductive steps will have different domain losses and that we will have to apply them repeatedly in different ways, losing domain at different rates.

3.5. The KAM inductive step. Geometry of domains. To complete the work for the bounds of the inductive step in the KAM theorem, we need to study the change in Ω, the surface Σ defined by $\Omega = \omega_0$ and its natural parameterization Υ defined in (3.3). In particular, we will need to provide estimates for the changes of the bounds in (3.12) that quantify the nondegeneracy assumptions. Since we are also taking into account the derivative of Ω with respect to ω, instead of (3.33), we are going to assume

$$\left\|\frac{\partial\Omega}{\partial p}\right\|_U \leq K_3, \qquad \left\|\frac{\partial\Omega}{\partial\omega}\right\|_U \leq K_3. \tag{3.55}$$

Again, we emphasize that most of the results in this section are true for arbitrary d. The only exception is (iv) in Lemma 3.7 below.

Given the estimates that we have on Δ, it will be very easy to estimate the change in Ω and all the other estimates will follow by an application of the implicit function theorem. We note that since Δ is small, and Ω depends linearly on the integrable part, the change in Ω will be of the same order of magnitude and hence also small. All the changes in the surface and in the parameterization will be small and hence can be estimated by $\|E\|$ possibly multiplied by some factors that come from the fact that we have to involve derivatives and control them by Cauchy estimates.

More precisely, we have the following lemma.

Lemma 3.7. *Let Ω be the frequency function* (3.11) *for the family $f_{\omega,\varepsilon}$* (3.10) *defined on $\Sigma_{\Omega,\alpha,\beta,U}$ as in* (3.9). *Let Δ be given by* (3.23) *and let σ be a positive number. Assume that* (3.17), (3.28), (3.55), *and* (3.48) *hold. Consider $\tilde{\Omega}$, the new frequency function defined by*

$$\tilde{\Omega}(\omega,\varepsilon,p) = \Omega(\omega,\varepsilon,p) + \int_0^\varepsilon ds\, \frac{\partial}{\partial p}\Delta(\omega,s,p). \tag{3.56}$$

Denote by Υ and $\tilde{\Upsilon}$ the parameterizations (3.3) *corresponding to Ω and $\tilde{\Omega}$.*

Then, for any $\tilde{\alpha} \leq \alpha$ satisfying

$$K\sigma^{-1}\|E\|_{\Omega,\alpha,\beta,U} \leq \tilde{\alpha} \tag{3.57}$$

we have

(i) $\|\Omega - \tilde{\Omega}\|_{U_\sigma} \leq K\sigma^{-1}\|E\|_{\Omega,\alpha,\beta,U} \leq \tilde{\alpha}$;

(ii) *for $\tilde{\alpha}$ as before, $\tilde{\beta} = \beta - \alpha - 4\sigma$, $\tilde{U} \equiv U_{4\sigma}$, we have*

$$\Sigma_{\tilde{\Omega},\tilde{\alpha},\tilde{\beta},\tilde{U}} \subset \Sigma_{\Omega,2\alpha,\beta-4\sigma,U_{4\sigma}};$$

(iii)

$$\left\|\left(\frac{\partial}{\partial\omega}\tilde{\Omega}\right)^{-1}\right\|_{\tilde{U}} \le \left\|\left(\frac{\partial}{\partial\omega}\tilde{\Omega}\right)^{-1}\right\|_{U_{4\sigma}} \le \left\|\left(\frac{\partial}{\partial\omega}\Omega\right)^{-1}\right\|_{U} + K\sigma^{-2}\|E\|_{\Omega,\alpha,\beta,U};$$

(iv) *when* $d = 1$,

$$\left\|\left(\frac{\partial^2}{\partial p^2}\tilde{\Omega}\right)^{-1}\right\|_{\tilde{U}} \le \left\|\left(\frac{\partial^2}{\partial p^2}\tilde{\Omega}\right)^{-1}\right\|_{U_{4\sigma}} \le \left\|\left(\frac{\partial^2}{\partial p^2}\Omega\right)^{-1}\right\|_{U} + K\sigma^{-3}\|E\|_{\Omega,\alpha,\beta,U};$$

(v) $\|\Upsilon - \tilde{\Upsilon}\|_{\tilde{U}} \le K\sigma^{-1}\|E\|_{\Omega,\alpha,\beta,U}$;

(vi) *the inequalities* (3.18) *hold, that is, for* $\tau = 2\nu + 3$

$$\|\tilde{E}\|_{\tilde{\Omega},\tilde{\alpha},\tilde{\beta},\tilde{U}} \le K\sigma^{-\tau}\|E\|_{\Omega,\alpha,\beta,U}(\|E\|_{\Omega,\alpha,\beta,U} + \tilde{\alpha}).$$

Proof. Part (i) follows immediately from the formula (3.56) for $\tilde{\Omega}$ and the estimates that we have for Δ in Lemma 3.2. The last inequality in (i) is just a restatement of (3.28), which is one of the hypotheses of the lemma.

Part (ii) follows because of (3.57).

Parts (iii) and (iv) follow because we can use Cauchy estimates to estimate the derivatives of Δ. Then, we can use Cauchy estimates to bound the derivatives of Ω.

The existence of $\tilde{\Upsilon}$ and its estimates are a very simple consequence of the implicit function theorem. Recall the well-known result that if an analytic function Φ satisfies $|\Phi(0)| \le \varepsilon$ and $|\Phi'|^{-1} \le a$ on a ball around zero of radius $a\varepsilon$ there is one and only one zero in this ball. Moreover, if Φ depends analytically on parameters, the zero depends analytically on parameters. We can apply this result to $\Phi(s) = \Omega(s+\Upsilon(\varepsilon,p),\varepsilon,p)-\omega_0$ and then, the result follows.

Part (vi) is a consequence of the estimates in Lemma 3.6 and part (ii) of this lemma. □

Notice that the only places where we had to consider derivatives with respect to ω are (iii) and (v). Hence, this will be easy to adapt to the situation in the justification of the Greene's criterion where there is some degeneracy in the frequency function.

Remark. Notice also that it is only in these nondegeneracy assumptions that we have to consider the one-dimensional properties of the map. It seems that with some appropriate notion of critical circle in higher dimensions (one has to consider invariant tori with "degenerate torsion"), one could develop an analogous converging KAM process, and a subsequent geometrical interpretation could provide the structure of invariant objects nearby the critical torus.

3.6. Iteration of the KAM inductive step. Convergence. In this subsection, we verify that if we start with a sufficiently small perturbation E, the iterative step can be repeated infinitely many times and, moreover, converges to a solution. The estimates are very similar to those in the paper [Ru2] on the translated curve method. Along the rest of this section, we will assume that $d = 1$.

The main idea is that the loss of domain has to be fast—say, exponentially fast—in the variables q so that we have some domain left. On the other hand, we have to decrease superexponentially fast the variable α which controls the thickness of the approximations to the surface Σ. This will achieve that the $\|E\|$ decreases superexponentially and that, as a consequence, the process can be iterated indefinitely.

We will choose α_n, σ_n, and show that if $\|E^0\|_{\Omega^0,\alpha_0,\beta_0,U^0}$ is small enough, the iterative step described in the previous section can be repeated indefinitely and the transformations converge to a solution that indeed solves the problem.

We point out that these smallness conditions can always be adjusted by switching to another variable $\varepsilon' = \varepsilon\lambda$. If we choose λ small enough, the remainder is made arbitrarily small while all the other parameters in the problem are left unaltered. (That is, when we have families, we can obtain the smallness conditions by considering ε restricted to a small domain.) Of course, when our families are obtained by interpolating between two diffeomorphisms, as in Lemma 2.2, the smallness assumptions in the family can be accomplished by assuming that the diffeomorphisms we are interpolating are close.

We will start by picking $\sigma_n = \sigma^* 2^{-n}$, where we pick $\sigma^* < \beta_0/8$ so that β_n defined in Lemma 3.7 by $\beta_{n+1} = \beta_n - 4\sigma_n$ is bounded away from zero, and $\sigma^* < \delta/8$ so that all the domains $U^{n+1} = U^n_{\sigma_n}$ contain the open domain $U^0_{2\sigma^*}$. Now we will show that it is possible to choose α_n in such a way that if $\|E^0\|_{\Omega^0,\alpha_0,\beta_0,U^0}$ is small enough, the process can be iterated indefinitely and it converges.

Introducing the notation $e_n = \|E_n\|_{\Omega^n,\alpha_n,\beta_n,U^n}$, $a_n = \alpha_{n+1}$, $A = 2^\tau$, $C = K/\sigma^*$, the recursion equation in (vi) of Lemma 3.7 becomes

$$e_{n+1} \le CA^n\, e_n(e_n + a_n). \tag{3.58}$$

We claim the following lemma.

Lemma 3.8. *If e_0 is small enough, it is possible to choose $0 < \rho < 1$ in such a way that setting $a_n = \rho^{2^n}(AB)^{-n}$, for $B > 1$, the conditions for Lemma 3.7 are satisfied for all n and*

$$e_n \le \frac{a_n}{C\,2^n} = \frac{\rho^{2^n}}{C(2AB)^n}. \tag{3.59}$$

Proof. Assume that (3.59) holds for a certain n and that we have chosen a_n as indicated and that the iterative step can be applied at this step.

Then, by (3.58) we have

$$\begin{aligned} e_{n+1} &\le \tfrac{\rho^{2^n}}{C(2AB)^n}\left(\tfrac{\rho^{2^n}}{C(2AB)^n} + \tfrac{\rho^{2^n}}{(AB)^n}\right) CA^n \\ &= \tfrac{\rho^{2^{n+1}}}{C(2AB)^{n+1}}\tfrac{2ABC}{B^n}\left(\tfrac{1}{C\,2^n} + 1\right) \le \tfrac{\rho^{2^{n+1}}}{C(2AB)^{n+1}}\tfrac{4ABC}{B^n}. \end{aligned} \tag{3.60}$$

If $n > N_0(A,B,C)$ we have that

$$\frac{4ABC}{B^n} \le 1 \tag{3.61}$$

so that indeed the formula (3.59) holds for $n+1$.

We also observe that, if a_n and e_n are of the form that we claimed, there is an $N_1(A,B,C) \ge N_0$ so that all the hypotheses (3.17), (3.28), (3.55), (3.48), (3.57) are satisfied for $n > N_1$.

Therefore, it suffices to ensure that e_0 is so small that the iterative step can be performed N_1 times and that the inequalities (3.59) hold for $n \le N_1$. Then, the argument in (3.60) will show that (3.59) continue to hold, and that the hypotheses needed to perform the iterative step and (3.61) hold. □

Clearly, from (3.59), we obtain that the error of the solution goes to zero on the surfaces. Similarly, using the estimates in Lemma 3.7 we can show that the parameterizations Υ of the surface converge. (It suffices to check that the increments are summable.)

Moreover, defining $h^n_{\omega,\varepsilon} = g^0_{\omega,\varepsilon} \circ \cdots \circ g^n_{\omega,\varepsilon}$ we have that

$$
\begin{aligned}
\|h^n - h^{n-1}\|_{\Omega^n,\alpha_n,\beta_n,U^n} &= \|h^{n-1} \circ g^n - h^{n-1}\|_{\Omega^n,\alpha_n,\beta_n,U^n} \\
&\le \sigma_{n-1}^{-1} K \|h^{n-1}\|_{\Omega^{n-1},\alpha_{n-1},\beta_{n-1},U^{n-1}} \|g^n - \operatorname{Id}\|_{\Omega^n,\alpha_n,\beta_n,U^n}.
\end{aligned}
\tag{3.62}
$$

From (3.62) and the estimates in (ii) of Proposition 3.4, it is immediate to show by induction that $\|h^n\|_{\Omega^n,\alpha_n,\beta_n,U^n}$ remains bounded independently of n. Then, using (ii) of Proposition 3.4, the R.H.S. of (3.62) is summable in n. Hence $h^n_{\omega,\varepsilon}$ converges in the limiting domain $\Sigma_{\Omega^\infty,\alpha_\infty,\beta_\infty,U^\infty}$, with $\alpha_\infty = 0$, consisting on the points (ω,ε,p,q) with $(\omega,\varepsilon,p) \in U^\infty = U^0_{2\sigma^*}$ such that $\Omega^\infty(\omega,\varepsilon,p) = \omega_0$ and $|\Im q| \le \beta_\infty = \beta_0 - 2\sigma^* \ge \beta_0/2$.

This finishes the proof of Theorem 1.5.

4. Partial justification of Greene's criterion. To assess numerically the existence of invariant circles, the most frequently used method is the so-called Greene's criterion, formulated in [Gr] for two-dimensional maps.

This criterion asserts that a smooth invariant circle with motion smoothly conjugate to a rotation ω exists if and only if it is possible to find a sequence of periodic orbits of type m/n whose "residue" (that is, the trace of the derivative of the return map minus 2) converges to zero as the m/n converges to ω_0.

As it turns out, this criterion has not been proved to hold; nevertheless, parts of it can be established rigorously.

For standard KAM tori, Mather (see [McK, Section 1.3.2.4]) suggested a method to prove that if KAM tori existed, the residue should go to zero faster than any power of $|\omega - p_n/q_n|$. This method was implemented in [FL], [McK2] for two-dimensional maps to show that the residue is smaller than $\exp(-c|\omega - p_n/q_n|^{-\alpha})$ for some $\alpha > 0$.

The main goal of this section is to prove one of the implications of Greene's criterion for critical circles. We will prove that if a critical circle exists, then any sequence of periodic orbits converging to it has residual converging to zero. We will also show that, if a critical circle exists, indeed there is at least one such sequence. Actually, for any m/n such that $m/n < \omega$, $|m/n - \omega| \ll 1$, we can find at least two periodic orbits of type m/n and, under mild nondegeneracy conditions, at least four.

Again, we will assume in this section that $d = 1$. We note that for higher dimensional maps, in [T1] and [T2] there are versions of Greene's criterion for higher dimensional twist maps (a rigorous justification of one of the implications and numerical evidence, respectively). There are some differences between the proofs in higher dimensional cases and the case considered here of $d = 1$ and we will comment on them after the proof of our results.

The main part of the proof will consist in showing that, in a neighborhood of the invariant circle, it is possible to find changes of variables that reduce the system almost to integrable. Once we have that, the result will follow word for word the result in [FL].

Of course, the estimates near the invariant torus are a more general result than that of the Greene's criterion and they allow us to control not only the behavior of the periodic orbits but also other dynamical objects. Other papers in which similar estimates are obtained for nondegenerate circles are [OS], [PW], [JV], [DG2].

Most of the work has already been done in section 3. The estimates that we will use are the same as those of the iterative step and the only difference is that we will be in the iterative step that makes different choices. This unified approach between the KAM theorem and exponentially small estimates appears also in [DG1].

4.1. Preliminary estimates and notation. We will be considering area preserving maps f which are defined in a neighborhood of $[-\delta, \delta] \times \mathbb{T}^1$ to itself.

These maps will have the form

$$f(p, q) = (p, q + \omega_0 + \kappa p^M) + O(p^{M+1})$$

for some $\kappa \neq 0$.

By Lemma 2.2, we can find an f_ε in such a way that the $f_0(p, q) = (p, q+\omega_0+\kappa p^M)$. The Hamiltonian of this deformation will be $F_\varepsilon = O(p^{M+1})$.

We will write for these type of families $F_\varepsilon(p, q) = I_\varepsilon(p) + E_\varepsilon(p, q)$, where again I_ε will be thought of as the integrable part. We will denote by i_ε the deformation with initial point f_0 and with Hamiltonian I_ε: $i_\varepsilon(p, q) = \big(p, q + \omega_0 + \kappa p^M + \int_0^\varepsilon ds\, \partial_p I_s(p)\big)$.

We note that these families are a particular case of the families we have considered in section 3. (In particular, $\kappa < 0$ and $M = 2$ for the example (1.1).) In that section, we allowed a dependence in another parameter ω. The families we consider here can be considered as embedded in families depending on ω but such that the dependence on ω is trivial. Clearly, all the results of section 3 that do not rely on the dependence on ω being nontrivial will go through as stated using the elementary device of writing the extra variable ω and noticing that the functions we consider do not depend on ω. We will use this completely elementary device without too much of an explicit mention.

For the purposes of this section, it will be sufficient to use particular cases of the neighborhoods $\Sigma_{\Omega,\alpha,\beta,U}$. Since all the objects we will consider will not depend on ω, we will not need to consider objects that depend on this; in particular we can suppress U from the notation.

We will also introduce the simplified domains

$$\Sigma_\delta = \{(p, q, \varepsilon) \mid |p| \leq \delta, \quad |\Im\, q| \leq \delta, \quad d(\varepsilon, [0, 1)) \leq \delta\}$$

and, given a family of functions $H_\varepsilon(p, q)$, we will denote

$$\|H\|_\delta \equiv \sup_{(p,q,\varepsilon)\in\Sigma_\delta} |H_\varepsilon(p, q)|.$$

Since we will be working with functions that vanish at the origin to a high order, it is worth remarking that Cauchy bounds can be improved for them.

PROPOSITION 4.1. *Let $H_\varepsilon(p, q)$ be such that $H_\varepsilon(p, q) = p^n J_\varepsilon(p, q)$. Then, provided that the norms are defined,*

(i) $\|J\|_\delta = \delta^{-n}\|H\|_\delta$

and, for $\delta' < \delta$, we have

(ii) $\|H\|_{\delta'} \leq (\delta'/\delta)^n\|H\|_\delta$;

(iii) $\|\nabla H\|_{\delta'} \leq (n/\delta' + (\delta - \delta')^{-1})(\delta'/\delta)^n\|H\|_\delta$.

Proof. By the maximum modulus principle

$$\|H\|_\delta = \sup_{\Sigma_\delta} |H_\varepsilon(p, q)| = \sup_{\substack{|p|=\delta \\ |\Im\ q|\leq\delta \\ d(\varepsilon,[0,1])\leq\delta}} |H_\varepsilon(p, q)| = \delta^n \sup_{\Sigma_\delta} |J_\varepsilon(p, q)| = \delta^n\|J\|_\delta.$$

This proves (i). Then,

$$\|H\|_{\delta'} = \delta'^n\|J\|_{\delta'} \leq \delta'^n\|J\|_\delta = (\delta'/\delta)^n\|H\|_\delta.$$

Furthermore,

$$\begin{aligned}\|\nabla(p^n J_\varepsilon)\|_{\delta'} &= \|(np^{n-1}J_\varepsilon + p^n\partial_p J_\varepsilon, p^n\partial_q J_\varepsilon)\|_{\delta'}\\ &\leq n\delta'^{(n-1)}\delta^{-n}\|H\|_\delta + \delta'^n\|\nabla J_\varepsilon\|_{\delta'}\\ &\leq n\delta'^{-1}(\delta'/\delta)^n\|H\|_\delta + \delta'^n(\delta-\delta')^{-1}\|J_\varepsilon\|_\delta\\ &\leq (n\delta'^{-1}+(\delta-\delta')^{-1})(\delta'/\delta)^n\|H\|_\delta. \qquad \square\end{aligned}$$

4.2. Reduction of maps to integrable in a neighborhood of a Diophantine circle. The key step in the proof of Theorem 1.6 is the following. Once we prove this result, the proof will be the same as in [FL].

LEMMA 4.2. *Let ω_0 be a Diophantine number, M an integer. Let f be an analytic area preserving map of the form*

$$f(p,q) = \left(p, q+\omega_0+\kappa p^M\right) + O\left(p^{M+1}\right)$$

for some $\kappa \neq 0$. Then,

(i) *for every $N \in \natural$ we can find an analytic canonical transformation such that*

$$g_N^{-1}\circ T\circ g_N(p,q) = (p, q+\Omega_N(p)) + R_N(p,q) \tag{4.1}$$

with Ω_N analytic, $\Omega_N(p) = \omega_0 + \kappa p^M + O(p^{M+1})$, and $|R_N(p,q)| \leq C_N|p|^N$.

(ii) *Moreover, we can find $\mu_1, \mu_2 > 0$ depending only on M and the Diophantine properties of ω_0, such that for sufficiently small δ, choosing $N = K\delta^{\mu_1}$, we have*

$$\|R_N\|_\delta \leq K\exp(-K^{-1}\delta^{-\mu_2}). \tag{4.2}$$

Remark. We note that Lemma 4.2, besides giving some control on the periodic orbits that we will use to prove Theorem 1.6, also provides control over other orbits. Notably, it shows that critical circles are approximated by KAM circles. Indeed, the density of KAM circles in a neighborhood of size δ of a critical circle will be bigger than $1 - C_1\exp(-C_2\delta^{-\alpha})$ for some positive C_1, C_2, α.

Remark. We observe that the first part of the claim, the reduction to an integrable form could go through with less differentiability. If we only want that $g_N \in \mathcal{C}^4$ (which we will show is enough to show that the residue goes to zero faster than $|\omega_0 - m/n|^{N/M}$) it would suffice to assume that f is $\mathcal{C}^r$ with r depending on N and the Diophantine properties of ω_0. Of course, the quantitative estimates (4.2) depend on the analyticity properties. The first part of the claim is much easier to prove, since, as we will see, it only entails matching powers of p in an equation that expresses the desired result. We note that this is enough to show using the methods that we will develop later that if there is a finitely differentiable circle, then the residue of a periodic orbit of type m/n is smaller than a power of $|\omega_0 - m/n|$. This power can be made as large as we want by assuming that the differentiability is high enough.

Proof of (i). If we denote by $f_0(p,q) = (p, q+\omega_0+\kappa p^M)$, by Lemma 2.2 we can find an analytic family f_ε that interpolates between f_0 and f. The Hamiltonian of this family F_ε^0 will be an analytic function of (p,q,ε) in a complex neighborhood of Σ_δ.

To prove that we can find g_N so that (4.1) holds, we proceed by induction in N and assume that for some $N \geq 2$ we can write our Hamiltonian as

$$F_\varepsilon^N(p,q) = I_\varepsilon^N(p) + E_\varepsilon^N(p,q) \tag{4.3}$$

with

$$E_\varepsilon^N(p,q) = p^N R_\varepsilon^N(p,q).$$

We seek Hamiltonians $G_\varepsilon^N(p,q) = p^N S_\varepsilon^N(q)$ determined in such a way that the family g_ε^N with this Hamiltonian and starting in the identity is such that

$$j_\varepsilon = (g_\varepsilon^N)^{-1} \circ f_\varepsilon^N \circ g_\varepsilon^N \tag{4.4}$$

has a Hamiltonian which is integrable up to a higher order error in p.

We note that

$$g_\varepsilon^N(p,q) = \left(p + p^N \Delta_p(p,q), q + p^{N-1}\Delta_q(p,q)\right), \tag{4.5}$$

where Δ_p, Δ_q are analytic functions. Therefore, the compositions needed to define j_ε in (4.4) make sense in a sufficiently small neighborhood of the circle.

From Proposition 2.1 and (4.5), we can compute the Hamiltonian of j_ε

$$J_\varepsilon = I_\varepsilon^N \circ g_\varepsilon^N + (p + p^N\Delta_p)^N \cdot R_\varepsilon^N \circ g_\varepsilon - G_\varepsilon \circ g_\varepsilon^N + G_\varepsilon^N \circ (f_\varepsilon^N)^{-1} \circ g_\varepsilon^N. \tag{4.6}$$

Expanding the above formula and denoting $R_\varepsilon^N(p,q) = \sum_{i\geq 0} p^i R_\varepsilon^{N,i}(q)$—and analogously for other functions—we obtain

$$\begin{aligned} J_\varepsilon(p,q) \quad = \quad & I_\varepsilon^N(p) + p^N \overline{R_\varepsilon^{N,0}} \\ & + p^N \left\{ \left(R_\varepsilon^{N,0}(q) - \overline{R_\varepsilon^{N,0}} \right) - S_\varepsilon^N(q) + S_\varepsilon^N(q-\omega_0) \right\} + O(p^{N+1}). \end{aligned}$$

Using Lemma 3.2 we now that we can find an analytic S^N so that the term in braces is zero in the domain where the function is defined, which includes a strip around the torus. By the form of the functions, all the compositions needed to define j_ε will be defined in a sufficiently small strip around of the torus.

This establishes the first part of the claim, the fact that we can reduce to any order.

Remark. Rather than using an inductive argument, as we have done, it is possible to show that (4.1) holds to all orders by matching terms in (4.6). We note that the terms of order p^{N+m} have the form

$$R_\varepsilon^{N,m}(q) - S_\varepsilon^{N,m}(q) + S_\varepsilon^{N,m}(q-\omega_0) + \tilde{R}_\varepsilon^{N,m-1}(p,q),$$

where $\tilde{R}_\varepsilon^{N,m-1}$ is a polynomial expression in $R_\varepsilon^{N,i}$, $S_\varepsilon^{N,i}$, $i \leq m-1$ and their derivatives and the derivatives of I. Again, we can use Lemma 3.2 to prove that a solution exists to all orders in p^n.

This method clearly shows that the coefficients of the expansion in the reduction are uniquely determined by the map and the torus, and are independent of the procedure. For example, in [OS], a different procedure using generating functions is used for twist maps and one can find the remark that the coefficients of this normal form are unique. (For the situation we are considering here, generating functions are not so convenient since the mixed variables are not a good system of coordinates in a neighborhood of the invariant torus. Nevertheless, the formalism that we developed above allows us to reach the same uniqueness conclusions.)

To obtain the estimates on the remainders of the reduction, we use a slightly different procedure. We use (3.20) and determine G_ε in exactly the same way as in section 3.

We can apply Lemma 3.6—which does not depend on Ω being nondegenerate—to obtain, with the notation introduced there, (3.53) and (3.54) provided that the inductive hypothesis hold.

LEMMA 4.3. *Let Ω be the frequency function* (3.11) *defined in $\Sigma_{\Omega,\alpha,\beta,U}$ as in* (3.9)*. Let Δ be defined as in* (3.23) *and let σ be a positive number. Assume that* (3.17), (3.28), (3.33)*, and* (3.48) *hold. Consider $\tilde{\Omega}$, the new frequency function defined by*

$$\tilde{\Omega}(\omega,\varepsilon,p) = \Omega(\omega,\varepsilon,p) + \int_0^\varepsilon ds \, \frac{\partial}{\partial p}\Delta(\omega,s,p) \ . \tag{4.7}$$

Then, for any $\tilde{\alpha} \le \alpha$ satisfying

$$K\sigma^{-1}\|E\|_{\Omega,\alpha,\beta,U} \le \tilde{\alpha} \ , \tag{4.8}$$

we have

(i) $\|\Omega - \tilde{\Omega}\|_{U_\sigma} \le K\sigma^{-1}\|E\|_{\Omega,\alpha,\beta,U} \le \tilde{\alpha}$;

(ii) *for $\tilde{\alpha}$ as before, $\tilde{\beta} = \beta - \alpha - 4\sigma$, $\tilde{U} \equiv U_{4\sigma}$, we have*

$$\Sigma_{\tilde{\Omega},\tilde{\alpha},\tilde{\beta},\tilde{U}} \subset \Sigma_{\Omega,2\alpha,\beta-4\sigma,U_{4\sigma}};$$

(iii)

$$\begin{aligned} \left\| \left(\tfrac{\partial^M}{\partial p^M}\tilde{\Omega}\right)^{-1} \right\|_{\tilde{U}} &\le \left\| \left(\tfrac{\partial^M}{\partial p^M}\tilde{\Omega}\right)^{-1} \right\|_{U_{4\sigma}} \\ &\le \left\| \left(\tfrac{\partial^M}{\partial p^M}\Omega\right)^{-1} \right\|_{U} + K\sigma^{-M-1}\|E\|_{\Omega,\alpha,\beta,U}; \end{aligned}$$

(iv) *the inequalities* (3.18) *hold, that is, for $\tau = 2\nu + 3$*

$$\|\tilde{E}\|_{\tilde{\Omega},\tilde{\alpha},\tilde{\beta},\tilde{U}} \le K\sigma^{-\tau}\|E\|_{\Omega,\alpha,\beta,U}(\|E\|_{\Omega,\alpha,\beta,U} + \tilde{\alpha}).$$

The only difference between the proofs of Lemma 3.7 and Lemma 4.3 is that in Lemma 4.3 we do not need to worry about the nondegeneracy in Ω with respect to ω. Item (iii) in Lemma 4.3 is just an slight generalization of the standard implicit function theorem. □

We also note that if E is $O(p^L)$, then G is also $O(p^L)$ and, as a consequence, all the terms in the decomposition of $\tilde{E}$ according to (3.20) are $O(p^{2L-1})$ except $(G_{\omega,\varepsilon} \circ i_{\omega,\varepsilon}^{-1} - G_{\omega,\varepsilon} \circ T^0)$ which is only $O(p^{L+M})$. We note that, for high enough L, $2L-1 > L+M$ so that, for large enough L the order of tangency grows by M in each step.

We can therefore assume that if n steps, the resulting nonintegrable part is $O(p^{Mn-A})$ where A is a number that may depend only on M and not on n. The number A takes into account that in the first steps of the iteration it could happen that $2L-1$ is smaller than $L+M$.

Remark. One could have obtained slightly more sophisticated estimates taking advantage of the fact that the functions we are considering vanish with powers of p and we can use the sharper Proposition 4.1 instead of Lemma 3.1. As it turns out, this does not make an appreciable difference in the final answer and it would require that the estimates leading to Lemma 3.6 are redone.

Proof of part (ii) *of Lemma* 4.3: *Iteration of the inductive step.* Now we discuss the possibility and the effect of iterating the inductive step. Since the goals are quite different than in the iteration leading to the KAM theorem, the choices that we will make in domain losses etc. will also be quite different. In our case, we are not interested in having some analyticity domain left (the existence of an analytic torus is part of the assumptions); rather, we are interested in obtaining control of the remainders in a wide domain.

We will take

$$\alpha_{n+1} = cn^{-\eta}, \qquad \beta_n = cn^{-\gamma} \tag{4.9}$$

with η, $\gamma > 0$ chosen in such a way that

$$(\gamma + 1)\tau - \eta < 0. \tag{4.10}$$

Note that then, $\eta > \tau\gamma \geq \gamma + 1$ so that the domains in the p variable are smaller than those in the q variable. Moreover, $\sigma_n = (\beta_n - \beta_{n+1})/4 = c\gamma n^{-\gamma-1} + O(n^{-\gamma-2})$ and we can bound $\sigma_n^{-\tau} \leq Kn^{\tau(\gamma+1)}$. Note also that it also follows from (4.10) that $\eta > \tau$ and that given any $\eta > \tau$ we can chose $\gamma > 0$ in such a way that (4.10) is satisfied.

We claim that if the iterative step can be iterated N times, and c as in (4.9) is sufficiently small, we have

$$\|E^N\|_{\Omega^N,\alpha_N,\beta_N,U^N} \leq (N!)^{(\gamma+1)\tau-\eta}. \tag{4.11}$$

We can proceed by induction. Note that if (4.11) were true, we could, for $N > N_0(c)$, obtain the bound $\|E^N\|_{\Omega^N,\alpha_N,\beta_N,U^N} + \alpha_{N+1} \leq K\alpha_{N+1}$. Then,

$$\|E^{N+1}\|_{\Omega^{N+1},\alpha_{N+1},\beta_{N+1},U^{N+1}} \leq (N!)^{(\gamma+1)\tau-\eta} Kc(N+1)^{(\gamma+1)\tau-\eta}$$

which implies the result for $N+1$ when c is small enough.

We note, as in the proof of the KAM theorem, that all but one of the hypotheses of the iterative step are satisfied provided that $\|E^n\|$ is much smaller than σ_n to a fixed power. The only condition that involves the α is (4.8). Namely,

$$K\sigma^{-1}\|E\|_{\Omega,\alpha,\beta,U} \leq \tilde{\alpha}.$$

We note that, if we fix c, we have the hypotheses satisfied for $N > N_1 > N_0$. If we assume that the error is sufficiently small to start with—which can be assumed if we start in a neighborhood sufficiently small—then, we can perform the N_1 steps and then, the iteration can continue. Therefore, if the initial error $\|E^0\|$ is sufficiently small, we can iterate indefinitely. Notice that since E^0 vanishes up to order M in p it suffices to choose c sufficiently small.

Moreover, the estimates (iii) of Lemma 4.3 tell us that we can bound from below $|(\frac{\partial^M}{\partial p^M}\Omega)^{-1}|$ independently of the number of iterates. Then, the domain Σ_δ is contained in all the domains of the form $\Sigma_{\Omega^N,K\delta^{1/M},K\delta^{1/M},U^N}$ provided that U^N contains a neighborhood of the map.

With the choices of α_n β_n that we have made above in (4.9), we see that we can repeat the iterative step described in Lemma 4.3 and obtain control in a 2δ neighborhood of the circle while $cN^{-\eta} \geq K\delta^{1/M}$. That is, $N \leq K^{-1}\delta^{-1/(M\eta)}$.

As we have seen in (4.11), for N large enough—which is implied by δ small enough—we have

$$\|E^N\|_{\Omega^N,\alpha_N,\beta_N,U^N} \leq (N!)^{(\gamma+1)\tau-\eta} \leq \exp\left(-K^{-1}\delta^{-1/(M\eta)}|\log(\delta^{-1/(M\eta)})| + K\right).$$

By worsening slightly the power of δ in the first term, we can suppress the logarithm to simplify the expression

$$\|E^N\|_{\Omega^N,\alpha_N,\beta_N,U^N} \le (N!)^{(\gamma+1)\tau-\eta} \le \exp\left(-K^{-1}\delta^{-1/(M\eta)-\zeta}\right) \tag{4.12}$$

for some small $\zeta > 0$. Now, we note that the system $f_{\omega,\varepsilon}$ is obtained by solving up to time 1 the system

$$\frac{d}{d\varepsilon}x = \mathcal{F}^N_\varepsilon(x) = \mathcal{I}^N_\varepsilon(x) + \mathcal{E}^N_\varepsilon(x).$$

Applying Cauchy bounds to (4.12), we can obtain bounds for $\mathcal{E}^N$ in a δ neighborhood of the origin which are of the same form as (4.12) with an slightly bigger ζ and some bigger K.

Note that, by definition, $\mathcal{I}^N$ generates an integrable flow. Hence, applying the usual estimates for the dependence of the solutions on the vector field, we obtain the result claimed in Lemma 4.2.

Note that the argument we have given shows that we can take $\mu_1 = 1/M(\eta)$ and μ_2 any number strictly smaller. Since we only needed $(\gamma+1)\tau - \eta < 0$, we can choose η any number bigger than τ and then choose γ. Of course, the constants will be worse. $\square$

4.3. Proof of Theorem 1.6 using Lemma 4.2. A possible proof can be made following the argument in [FL].

We note that Theorem 1.6 makes statements about the trace of derivatives of F^n at fixed points of F^n. Since the trace of the derivative of a map at a fixed point is invariant under changes of coordinates, we can study the derivatives of this map in the coordinates provided by Lemma 4.2.

First, we need to obtain some idea of where the periodic orbits could be. We will need to show that if $|\omega_0 - m/n|$ is small, then the orbit is very close to the invariant circle so that, in the coordinates provided by Lemma 4.2, the orbit is close to being the orbit of an integrable system. Note that for the orbit of an integrable system, the derivative is upper triangular with a diagonal which is the identity (hence, for an integrable system the trace of the derivative is 2 and the residue is 0). A second part of the argument is a perturbation argument that shows that if the system is close to integrable, the trace of the derivative is close to 2 and, hence, the residue is small.

The first part of the argument is accomplished by the following proposition.

PROPOSITION 4.4. *For m/n sufficiently close to ω_0, any orbit of type m/n should be contained in annuli of radii $r \pm O(r^{1+\varepsilon})$ where r satisfies $\omega_0 + \kappa_M r^M = m/n$.*

We see that, when M is odd, we find one such r, namely $r = ((\omega_0 - m/n)/\kappa_M)^{1/M}$. When M is even, if $(\omega_0 - m/n)/\kappa_M$ is positive we can find two such r, namely $r = \pm\,(m/n - \omega_0)/\kappa_M)^{1/M}$ and when $(m/n - \omega_0)/\kappa_M$ is negative, we can find none. (In general, for each of the values of r that guarantee the existence of periodic orbits, they will appear in pairs: elliptic and hyperbolic.)

The argument will also show that, when we cannot find any r solving the equation, there are no periodic orbits of type m/n in a sufficiently small neighborhood of the nondegenerate circle.

Proof. If we apply the first claim of Lemma 4.2 to order $2M+2$, we obtain that, in an appropriate system of coordinates, our map can be written as

$$(p,q) \mapsto (p, q + \Omega(p)) + O\left(p^{2M+2}\right) \tag{4.13}$$

with $\Omega(p) = \kappa p^M + O(p^{M+1})$.

In the set $I = [(9/10)r, (11/10)r] \times \mathbb{T}^1$, the mapping (4.13) can be considered as a perturbation of an integrable system.

We note that the frequencies present in the integrable system in the domain considered are

$$\omega_0 + \kappa r^M[(9/10)^M, (11/10)^M] + O(r^{M+1}).$$

Note also that $\frac{d\Omega}{dp} > \kappa M r^{M-1} + O(r^M)$. This lower bound on the derivative is called the twist constant.

We recall that, by standard arguments in Diophantine approximation, we can find ω^* such that $\forall\ i \in \mathbb{Z} \forall\ j \in \mathbb{Z}$, $|\omega^* - i/j|^{-1} \leq Cj^{5/4}$ in any interval of length bigger than KC^{-1}. (It suffices to fix i, j and consider the length of the interval of ω for which the desired inequality fails. See, e.g., [AA, p. 252].)

Hence, we can find two frequencies $\omega_\pm$ such that

(a) they are Diophantine with exponent $\theta - 1 = 5/4$ and with constant $C = r^{-M}$;
(b) $\omega_- < m/n < \omega_+$;
(c) $\omega_+ - \omega_- \leq Kr^M$.

We now recall the quantitative version of the twist mapping theorem [He] that states that if we perturb an integrable system with twist constant σ defined in a range of A of diameter D, by a perturbation of $\mathcal{C}^4$ size ρ, the invariant circles corresponding to a Diophantine frequency of constant C persist provided that $C^2\rho\ \rho\sigma^{-1}/D$ are sufficiently small. Moreover, $\mathcal{C}^1$ distance of these invariant tori to the unperturbed ones can be bound by $\rho\sigma^{-1}$.

If we apply this to the circles of frequencies $\omega_\pm$ in the domain indicated, we see that $\rho = O(r^{2M+2})$, $C = O(R^{-M})$, $\sigma^{-1} = O(r^{-M+1})$, and $D \geq 2/10r$.

Hence, we conclude that these circles with frequency $\omega_\pm$ persist. Since in a sufficiently small neighborhood of the invariant circle, the map is a twist map, all the orbits with rotation number in $[\omega_-, \omega_+]$ have to be contained in the annulus bounded by these two invariant circles, in particular those of rotation number m/n.

This finishes the proof of Proposition 4.4. $\square$

For the cases where we can find an r such that the rotation number of the integrable part is m/n, we can apply Lemma 4.2 with $\delta = 2r$ with r as above to obtain that $\|R_N\|_\delta$ vanishes to order $K^{-1}|\omega - m/n|^{-\mu_1/M}$ and has size smaller than $K\exp(-K^{-1}|\omega - m/n|^{-\mu_2/M})$.

The improved Cauchy estimates, Proposition 4.1, give us that the entries on the matrix DR are smaller than

$$\begin{aligned} &2^{-K^{-1}|\omega_0 - m/n|^{-\mu_1/M}} K\exp\left(-K^{-1}|\omega_0 - m/n|^{-\mu_2/M}\right) \\ &\qquad \leq K\exp\left(-K^{-1}|\omega_0 - m/n|^{-\mu_3}\right) \end{aligned} \tag{4.14}$$

for some $\mu_3 > 0$.

We also note that the derivatives of the integrable part are of the form $DI = \left(\begin{smallmatrix} 1 & a \\ 0 & 1 \end{smallmatrix}\right)$ with a bounded independently of the number of iterates that we need to take in Lemma 4.2.

If we have a periodic orbit of type m/n, by the chain rule we have $DF^n(x) = DF(x_{n-1}) \cdots DF(x)$, where $x_i = F^i(x)$. Note that $DF(x_i) = DI(x_i) + DR(x_i)$.

Therefore, we can apply the following lemma, which appears as Lemma 3.4 of [FL].

Lemma 4.5. *Let* $\{A_i\}_{i=1}^N$ *be a set of* 2×2 *matrices of the form* $A_i = \left(\begin{smallmatrix} 1 & a_i \\ 0 & 1 \end{smallmatrix}\right)$ *with* $\sup_{1 \leq i \leq N} |a_i| \leq A$.

Let $\{B_i\}_{i=1}^N$ satisfy

$$\sup_{\substack{1\le i\le N\\ j,k=1,2}} |(B_i)_{jk} - (A_i)_{jk}| \le \varepsilon \quad \text{with } \varepsilon \le A\ .$$

Then $B = B_1 \cdots B_N$ satisfies

$$|\operatorname{Tr} B - 2| \le 2\left[\left(1 + 3\sqrt{A}\,\sqrt{\varepsilon}\,\right)^N - 1\right].$$

Applying Lemma 4.5 with $A_i = DI(x_i)$, $B_i = DF(x_i)$, we obtain that for sufficiently large n, recalling that Theorem 1.6 includes in the assumptions that $|\omega_0 - m/n| \le 1/n$ and that therefore $K\exp(-K^{-1}|\omega_0 - m/n|^{\mu_3})$ tends to zero

$$\begin{aligned} |\operatorname{Tr} DF^n(x) - 2| &\le 2\left[\left(1 + K\exp(-K^{-1}|\omega_0 - m/n|^{\mu_3})\right)^n - 1\right] \\ &\le nK\exp(-K^{-1}|\omega_0 - m/n|^{\mu_3}) \le K\exp(-K^{-1}|\omega_0 - m/n|^{\mu_4}). \end{aligned}$$

This concludes the proof of Theorem 1.6. □

We also remark that the argument that we gave to locate the periodic orbits also shows that if we have a nondegenerate critical circle, then it is approximated by periodic orbits.

In the cases that we can find an approximate r (i.e., in the case of odd M or, when M is even, that the sign of $\omega_0 - m/n$ is chosen correctly) we see that we can apply the classical Poincaré last geometric theorem [Fr] to $F^n - (0,m)$ and obtain that there are two fixed points of different index, and hence two different periodic orbits of F.

In the case that M is even and the signs are right, since we can find two rings we can obtain four periodic orbits.

Remark. Note that in order to obtain two periodic orbits using this argument, we need to use the modern version of the Poincaré theorem which includes information about the index of the fixed points of $F^n - (0,m)$. The classical Poincaré fixed point theorem (see, e.g., [St, p. 195]) does not provide information about the index and hence, we cannot exclude that the two fixed points of $F^n - (0,m)$ produced by it are part of the same orbit for F.

Remark. In our case, noting that our maps admit a generating function, we could also produce the two periodic orbits using variational methods (see [KH, Theorem 9.3.7].)

A different line of argument that produces quantitative results under stronger hypotheses is the following.

In an annulus $p \in [r - r^{1+\varepsilon}, r + r^{1+\varepsilon}]$ the map is a small perturbation of an integrable map that is nondegenerate. If this perturbation satisfies some nondegeneracy assumptions, one can find two periodic orbits of type m/n. One of them is hyperbolic and another one is elliptic. The first order calculations of these periodic orbits is sometimes called subharmonic Melnikov theory. Formal expansions, including nondegeneracy assumptions that imply that the expansions predict one pair of elliptic and hyperbolic periodic orbits can be found in [Po, sections 74 and 79]. A justification of these expansions for finitely differentiable functions that shows that, under the formal conditions derived in [Po] one can find indeed the periodic orbits with the character predicted by the expansions can be found in [LW, Chapter 2], or in [Po, section 39].

Remark. Note that the above argument only requires estimates about the trace of the derivative. The fact that the trace of the derivative can be studied requires that

$g_N \in \mathcal{C}^1$. The argument that we used to show that, in the coordinates given by g_N, the periodic orbit of period m/n is at a distance not more that $|\omega_0 - m/n|^{1/M}$ requires the twist mapping theorem with Lipschitz estimates and hence that $g_N \in \mathcal{C}^4$. The rest of the argument applying Lemma 4.5 requires only that the map $g_N \in \mathcal{C}^1$. Hence we see that if $g_N \in \mathcal{C}^4$ we have that $|\mathrm{Res}(O_{m,n})| \le K|\omega_0 - m/n|^{N/M}$. Therefore, as we remarked before, to show that the residue goes to zero faster than a power, one needs only finite differentiability and for $\mathcal{C}^\infty$ mappings one can show that the residue goes to zero faster than any power.

Remark. For a Diophantine number (1.3), it holds that $|\omega_0 - p_n/q_n|^{-1} \ge Cq_n^\tau$ for some $\tau \ge 2$, if we take p_n/q_n to be the convergents of the continued fraction expansion of ω_0. Hence, the conclusion of Theorem 1.6 can be written as

$$\mathrm{Res}(O_n) \le C_1 \exp(-C_2 q_n^{\mu'}).$$

Remark. A followup paper [CGM2] of [CGM1] goes on to find scaling relations for the invariant circles with rotation number $\omega_0 = (\sqrt{5}-1)/2$ of $T_{\omega(\varepsilon),\varepsilon}$ as ε goes to a critical value where they cease to exist. These scaling relations suggest that there is a renormalization group description of these invariant circles with the KAM circles corresponding to a trivial fixed point. If this was the case (to our knowledge nobody has yet worked out a precise formulation and computed the trivial fixed points), the residue of a periodic orbit of type F_n/F_{n+1} would go to zero superexponentially fast in n, since for the Fibonacci numbers $F_0 = F_1 = 1$, $F_{n+1} = F_n + F_{n-1}$, one has $|\omega_0 - F_n/F_{n+1}|^{-1} \approx C\omega_0^{-2n}$.

Remark. In higher dimensions, under the nondegeneracy hypotheses of the KAM theorem—which are weaker than twist hypothesis—an argument similar to the one given above has been developed in [T1]. The reduction to integrable normal form up to a very small error can be carried out. Similarly, there is an analogue of Lemma 4.5 that shows that products of sufficiently small perturbations of Jordan blocks with identity in the diagonal, still have characteristic polynomials close to $(t-1)^{2d}$. Therefore, if there is a periodic orbit in a neighborhood of the torus, not only the trace but all the other coefficients of the characteristic polynomial have to converge to those of the Jordan normal form. One important element from our present argument that does not generalize to higher dimensions is the application of the twist mapping theorem to conclude that the distance of the periodic orbits to the invariant circle is bounded by the difference of the rotation numbers. Nevertheless, it is possible to show that if there is an invariant torus, there are periodic orbits that approximate it well and that the characteristic polynomial of the derivative converges to $(t-1)^{2d}$. It has been argued—and implemented numerically in [T2]—that this convergence of the coefficients of the characteristic polynomial of the derivative can be considered as a test of the presence of a KAM torus.

We think that it should be possible to extend the methods presented here to establish one of the implications of Greene's criterion for some invariant torus that satisfy some hypothesis of nondegeneracy weaker than the twist hypothesis.

Acknowledgments. We thank D. del Castillo-Negrete and P. Morrison for many discussions about their work and for encouragement. We also thank A. Haro and C. Simó for helpful discussions and for making their unpublished results available to us. We also thank TICAM, UPC, and IMA for invitations that made this collaboration possible.

GLOBAL BEHAVIOR OF THE CAUCHY PROBLEM FOR SOME CRITICAL NONLINEAR PARABOLIC EQUATIONS[*]

J. A. AGUILAR CRESPO[†] AND I. PERAL ALONSO[†]

Abstract. The paper deals with the following nonlinear parabolic problem:

$$\begin{cases} u_t - \Delta_p u &=& \lambda \dfrac{u^{p-1}}{|x|^p} \quad x \in \mathbb{R}^N,\, t > 0, \\ u(x,0) &=& u_0(x) \geq 0, \end{cases}$$

where $1 < p < N$ and $\lambda > 0$. The existence or nonexistence (blow-up) of global solution is analyzed. Also the finite time extinction for solutions in the case $1 < p < 2$ in bounded and unbounded domains is studied. This behavior depends on the relationships between λ, N, p and the integrability of u_0.

Key words. nonlinear parabolic equations, p-laplacian, existence, behavior of solutions, critical problems, Hardy inequality

1. Introduction.

In this work the starting points are the paper by Baras and Goldstein [1] for the heat equation and the paper [12]. In the case of the heat equation the problem considered appears in a natural way by linearizing reaction-diffusion models with convex *supercritical* nonlinearities at some unbounded, *singular* solution (see [7], [13], [16], [19], and [20]).

In this paper we deal with the nonnegative solutions of the following Cauchy problem:

$$(1.1) \qquad \begin{cases} u_t - \Delta_p u &=& u_t - \operatorname{div}(|\nabla u|^{p-2}\nabla u) = \lambda \dfrac{u^{p-1}}{|x|^p} \quad x \in \mathbb{R}^N,\, t > 0, \\ u(x,0) &=& u_0(x) \geq 0, \end{cases}$$

where $1 < p < N$ and $\lambda > 0$. If $p = 2$ this problem corresponds to the problem studied in the pioneering paper [1].

Our attention will be focused on the role that the potential $|x|^{-p}$ plays. Notice that the integrability is critical since it belongs to L^q_{loc} $\forall q < N/p$ but not for $q = N/p$. Then it is a borderline case in the parabolic quasi-linear theory of regularity and uniqueness (see [8], [18], and [17]).

Before describing the main results in this work, we would like to emphasize the dependence of the results on the relation of p with respect to 2 and the relation of the parameter λ with respect to $\lambda_{N,p} = ((N-p)/p)^p$, inverse of the best constant for the Hardy inequality explained in section 2. (See also [14] and [12] for details on this topic.)

The main contributions in the paper are the following:

(I) For existence results:

(i) If $\lambda \leq \lambda_{N,p}$, the global existence holds $\forall p$, $1 < p < N$.

[*] Received by the editors June 24, 1998; accepted for publication (in revised form) October 19, 1999; published electronically May 15, 2000. This work was partially supported by D.G.E.S. (M.E.C., Spain) project PB97-0052.

[†] Departamento de Matemáticas, Universidad Autónoma de Madrid Cantoblanco, 28049 Madrid, Spain (jaa19@etna.tid.es, ireneo.peral@uam.es).

(ii) If $1 < p < 2N/(N+1)$, the global existence holds $\forall \lambda > 0$.

(iii) If $2N/(N+1) < p < N$ and $\lambda > \lambda_{N,p}$ there is no solution. The case $p = 2$ is the previous result in [1] and the case $p > 2$ is obtained in [12].

(II) For the behavior of solutions:

(i) For the Dirichlet problem in a bounded domain and if $2N/(N+1) < p < 2$, $0 < \lambda < \lambda_{N,p}$ there exists $T^* = T^*(u_0, \Omega) < \infty$, finite time of extinction.

(ii) As above for the Dirichlet problem in a bounded domain, if $1 < p < 2N/(N+2)$ and $0 < \lambda < \mu_{N,p}$, where

$$\mu_{N,p} = \lambda_{N,p}(s-1)\left(\frac{p}{p+s-2}\right)^p, \quad s = N\left(\frac{2-p}{p}\right),$$

the finite time of extinction $T^* = T^*(u_0) < \infty$ is independent of Ω. As a consequence under these restrictions on p and λ we are able to show finite time of extinction for the Cauchy problem in the whole $\mathbb{R}^N$.

(iii) We also prove that for λ large (in particular $\lambda > \lambda_{N,p}$) no extinction time exists.

We indicate some possible extensions of our results in the last section. Roughly speaking we can say that for $p \geq 2N/(N+1)$, the constant $\lambda_{N,p}$ plays an important role for the existence of solutions while, for $1 < p < 2N/(N+1)$, only the extinction in finite time depends on the Hardy inequality.

We will look for solutions obtained passing to the limit on solutions to problems in bounded domains and with truncated potential. The uniqueness is, in general, not true.

Concerning the problem about the convergence to the initial data, a complete analysis for data in L^1 when $\lambda = 0$ can be seen in [9], [10], and [21]. This kind of problem is out of the scope of this work: we limit ourselves to see that the data are attained in a weak sense. The optimal integrability condition on u_0 and the optimal way in which in general the initial data are attained for a given solution, jointly with a more detailed analysis of the blow-up, will be the subject of a future research. (See also Remark 3.6 at the end of section 3.)

The paper is organized as follows. The next section is devoted to introduce the truncated problems, the Hardy inequality, and the application of some general results by [5] in this context. In section 3 we study the existence of solutions to (1.1). The methods that we use are classical results from [8], [11], [18], and [17] in general, and in particular for the case $1 < p < 2$ we also use a self-similar solution to (1.1) with zero initial data, the above mentioned results in [5], and arguments from [4], [3], [8], and [12]. In section 4 we obtain the above quoted results about the finite extinction time if $1 < p < 2$ and λ are small enough. See [2], [8], and [15] for the case $\lambda = 0$. Notice that in our critical problem finite time extinction is a delicate property, depending on the *fast diffusion* due to the fact that $1 < p < 2$ and the reaction on the right-hand side through λ. The results about finite time extinction are (almost) optimal (see section 4). Finally, section 5 contains some remarks about the behavior (existence, uniqueness, and finite time extinction) of the solutions corresponding to more general potentials and nonlinearities. We will mainly consider $1 < p < 2$ and nonlinearities of *asymptotic power type*.

To extend the idea of sublinear and superlinear growth in the case $p = 2$, hereafter we will call the nonlinearity f subdiffusive (respectively, superdiffusive) in $u \to a$, where either $a = 0$ or $a = +\infty$, if the following holds:

$$\lim_{u\to a} \frac{f(u)}{u^{q-1}} = c_1 \quad \text{for some } q, \quad 1 < q < p, \quad (\text{respectively, } p < q).$$

2. The truncated problems and compactness arguments. Consider the problems for $1 < p < N$, $\lambda > 0$, $n > 0$:

$$\text{(2.1)} \qquad \begin{cases} u_{nt} - \Delta_p u_n &= \lambda W_n(x) u_n^{p-1}, & x \in \Omega,\ t > 0, \\ u_n(x,0) &= T_n(u_0(x)), & \\ u_n(x,t) &= 0, & x \in \partial\Omega,\ t > 0, \end{cases}$$

where $W_n(x) = T_n(|x|^{-p})$, T_n is the truncature at height n ($T_n(\zeta) = \min(n, \zeta)$ for $\zeta \geq 0$), $u_0(x) \geq 0$, $u_0 \in L^2(\Omega)$ and Ω is a bounded domain in $\mathbb{R}^N$. These problems are called the *truncated problems* since they are obtained from the following initial boundary problem with zero Dirichlet boundary data on Ω (*untruncated problem*):

$$\text{(2.2)} \qquad \begin{cases} u_t - \Delta_p u &= \lambda \dfrac{u^{p-1}}{|x|^p}, & x \in \Omega,\ t > 0, \\ u(x,0) &= u_0(x), & x \in \Omega, \\ u(x,t) &= 0, & x \in \partial\Omega,\ t > 0 \end{cases}$$

by applying the truncature T_n to both the potential $|x|^{-p}$ and the initial data. It has to be noted that

$$W_n(x) \leq |x|^{-p} \in L^r_{loc}(\mathbb{R}^N) \quad \text{uniformly, for } 1 \leq r < N/p.$$

In the particular case $1 < p < 2$ the existence of bounded weak solution u_n to (2.1) in $Q = \Omega \times (0,T)$ is shown in the following elementary way. The boundedness of the weak solution to the truncated problem will be important in section 4 to get some convenient estimates.

LEMMA 2.1. *Let $1 < p < 2$. For every $n > 0$, there exists a weak solution u_n to the truncated problem* (2.1)*. These solutions verify $0 \leq u_1 \leq u_2 \leq \cdots \leq u_n \leq \cdots$; in addition,*

$$u_n \in L^\infty(0,T; L^\infty(\Omega)) \cap L^p(0,T; W_0^{1,p}(\Omega))$$

for $T > 0$ fixed.

Proof. There exists a supersolution to the truncated problem (2.1), namely

$$\phi_n(t) = (\lambda n(2-p)(t+T_0))^{1/(2-p)}, \quad \text{where } T_0 \geq (\lambda n^{p-1}(2-p))^{-1}.$$

It has to be remarked that this supersolution does not depend on the potential; it depends only on the truncature level. Consider the following problems with $k > 0$ and n fixed ($n \geq 1$):

$$\begin{cases} (v_{n,k})_t - \Delta_p v_{n,k} &= \lambda W_n(x) v_{n,k-1}^{p-1}, & x \in \Omega,\ t > 0, \\ v_{n,k}(x,0) &= T_n(u_0(x)), & x \in \Omega, \\ v_{n,k}(x,t) &= 0, & x \in \partial\Omega,\ t > 0, \end{cases}$$

where $v_{n,0} = \phi_n$; there exists a unique weak solution $v_{n,k} \in C([0,T], L^2(\Omega)) \cap L^p(0,T; W_0^{1,p}(\Omega))$ (see [8] and [18]). Since $v_{n,0} = \phi_n \leq v_{n+1,0} = \phi_{n+1}$ and the potential and initial data are both bounded, a recurrence argument using the weak comparison principle implies $v_{n,k} \le v_{n+1,k}$, $k > 0$, because initially

$$\lambda W_n(x)\phi_n^{p-1}(t) \le \lambda W_{n+1}(x)\phi_{n+1}^{p-1}(t) \quad \text{in } Q.$$

As a consequence, taking the respective limits in each iteration, we conclude that $u_n \le u_{n+1}$. On the other hand, these weak solutions u_n of (2.1) are bounded in Q, for $T > 0$ fixed, since the supersolution ϕ_n is bounded for $T > 0$ fixed. □

In the previous result it is not possible to get a uniform L^∞-estimate.

One of the main tools is the following Hardy inequality that will be used in a systematic way in this paper.

LEMMA 2.2 (Hardy inequality). *If $1 < p < N$ and $u \in W^{1,p}(\mathbb{R}^N)$, then*

$$\int_{\mathbb{R}^N} \frac{|u|^p}{|x|^p}\,dx \le \lambda_{N,p}^{-1} \int_{\mathbb{R}^N} |\nabla u|^p\,dx, \qquad \lambda_{N,p} = \left(\frac{N-p}{p}\right)^p,$$

where $\lambda_{N,p}^{-1}$ is optimal.

A proof of this result can be found in [12]; see also [14] for $N = 1$. Notice that the constant is not attained in $W^{1,p}(\mathbb{R}^N)$.

In general, $\forall p,\ 1 < p < N$, we will use a sequence u_n as approximate solutions to obtain a solution u of (2.2) as the limit of u_n on any fixed bounded domain Ω. To this end, we need some compactness results that allow us to pass to the limit in that sequence. One of these compactness results is shown in [5] for a more general context; we adapt the proof of that result to our case as follows:

Fix $T > 0$ and $\Omega \subset \mathbb{R}^N$, a bounded domain, and let $Q = \Omega \times (0,T)$, $g_n = W_n u_n^{p-1}$. For $1 < p < N$ let us define $p^* = Np/(N-p)$, the critical Sobolev exponent. Let us first show the following lemma.

LEMMA 2.3. *If u_n, $n > 0$ is a sequence uniformly bounded in $L^p(0,T;W^{1,p}(\Omega))$, with $1 < p < N$, then*

(a) *$W_n u_n^{p-1} \in L^{p'}(0,T;W^{-1,p'}(\Omega))$, uniformly.*

(b) *$W_n u_n^{p-1} \in L^q(Q)$ uniformly for $1 \le q < (p^*)' = (1-(N-p)/(Np))^{-1}$.*

Proof. Let $g_n = W_n u_n^{p-1}$. (a) Take $\psi \in L^p(0,T;W^{1,p}(\Omega))$, $\psi \ge 0$; using Hölder and Hardy inequalities

$$\begin{aligned}
\int_0^T \int_\Omega g_n \psi\,dx\,dt &\le \int_0^T \int_\Omega \frac{u_n^{p-1}}{|x|^p}\psi\,dx\,dt = \int_0^T \int_\Omega \frac{u_n^{p-1}}{|x|^{p-1}}\frac{\psi}{|x|}\,dx\,dt \\
&\le \int_0^T \left(\int_\Omega \frac{u_n^p}{|x|^p}\,dx\right)^{(p-1)/p} \left(\int_\Omega \frac{\psi^p}{|x|^p}\,dx\right)^{1/p} dt \\
&\le \lambda_{N,p}^{-1} \left(\int_0^T \int_\Omega |\nabla u_n|^p\,dx\,dt\right)^{(p-1)/p} \left(\int_0^T \int_\Omega |\nabla \psi|^p\,dx\,dt\right)^{1/p} \\
&\le C\lambda_{N,p}^{-1} ||\psi||_{L^p(0,T;W^{1,p}(\Omega))}
\end{aligned}$$

since u_n is uniformly bounded in $L^p(0,T;W^{1,p}(\Omega))$, by hypothesis; this means that g_n is uniformly bounded as an operator in the space $L^{p'}(0,T;W^{-1,p'}(\Omega))$.

(b) If u_n is uniformly bounded in $L^p(0,T;W^{1,p}(\Omega))$, then $u_n \in W^{1,p}(\Omega)$ almost everywhere (a.e.) $t \in (0,T)$. By the Rellich–Kondrachov theorem (see, for instance, [6]), $u_n \in L^r(\Omega)$ a.e. $t \in (0,T)$ for $1 \le r < Np/(N-p)$. On the other hand, for

$q \geq 1$, Hölder inequality implies that

$$\int_0^T \int_\Omega g_n^q \, dx \, dt \leq \int_0^T \left(\int_\Omega u_n^{q(p-1)\alpha} \, dx \right)^{1/\alpha} \left(\int_\Omega |x|^{-pq\alpha/(\alpha-1)} \, dx \right)^{(\alpha-1)/\alpha} dt,$$

where $\alpha > 1$ has to be chosen so that $q(p-1)\alpha < Np/(N-p)$ and $q\alpha/(\alpha-1) < N/p$, i.e.,

$$\frac{N}{N-qp} < \alpha < \frac{N}{N-p}\frac{p}{q(p-1)}.$$

Since

$$\frac{N}{N-qp} = \frac{N}{N-p}\frac{N-p}{N-qp},$$

we can always find such an α if the following holds:

$$\frac{N-p}{N-qp} < \frac{p}{q(p-1)}, \text{ i.e., } q < \frac{Np}{Np-(N-p)} = (p^*)'.$$

In this case, we get

$$\begin{aligned} \int_0^T \int_\Omega g_n^q \, dx \, dt &\leq \int_0^T \left(\int_\Omega u_n^{q(p-1)\alpha} \, dx \right)^{1/\alpha} \left(\int_\Omega |x|^{-pq\alpha/(\alpha-1)} \, dx \right)^{(\alpha-1)/\alpha} dt \\ &\leq C(\Omega, N, p, q) \int_0^T \left(\int_\Omega |\nabla u_n|^p \, dx \right)^{q(p-1)/p} \left(\int_\Omega |x|^{-pq\alpha/(\alpha-1)} \, dx \right)^{(\alpha-1)/\alpha} dt. \end{aligned}$$

Since Ω is a bounded domain and u_n is uniformly bounded in $L^p(0,T;W^{1,p}(\Omega))$, then the two integrals above are finite. Thus, for $1 \leq q < (p^*)'$, $g_n = W_n u_n^{p-1} \in L^q(Q)$ uniformly. □

Now consider u_n the sequence of solutions to problem (2.1) and g_n as in the previous lemma. If we assume that u_n is uniformly bounded in $L^p(0,T;W^{1,p}(\Omega))$, by Lemma 2.3 we get $g_n \in L^{p'}(0,T;W^{-1,p'}(\Omega))$ and g_n is bounded in the space of Radon measures on Q, $\mathcal{M}(Q)$, since $g_n \in L^1(Q)$ uniformly. In addition, in these hypotheses, there exists u such that $u_n \rightharpoonup u$ weakly in $L^p(0,T;W^{1,p}(\Omega))$ as $n \to \infty$ (up to a subsequence; see [6, Thm. III.27]). In this way the results by Boccardo and Murat in [5] apply for (2.1), obtaining that $\nabla u_n \to \nabla u$ strongly in $(L^q(\Omega))^N$, for $q < p$, and so we get a solution to (2.2). More precisely, the result by Boccardo and Murat in this context is as follows.

LEMMA 2.4. *If $\{u_n\}$ is a sequence of solutions to the problems* (2.1)*, $n \in \mathbb{N}$, bounded in $L^p(0,T;W^{1,p}(\Omega))$, then there exists a solution $u \in L^\infty_{loc}(0,T;L^2(\Omega)) \cap L^p(0,T;W^{1,p}(\Omega))$ to the problem* (2.2) *in Ω that satisfies the equation in the sense of distributions. The initial data is attained in the sense that $u \in \mathcal{C}([0,T],W^{-1,p'}(\Omega))$.*

Proof. It suffices to adapt the proof of Theorem 4.3 in [5] to problem (2.1). □

Moreover, in the hypotheses above, Lemma 2.3 implies that there exists a function $g \in L^1(Q)$ such that $g_n \rightharpoonup g$ weakly in $L^1(Q)$ (up to a subsequence) as $n \to \infty$. In this way we can apply Theorem 4.1 in [5] for the solutions to (2.1), obtaining for $l > 0$ fixed that

$$\nabla T_l(u_n) \to \nabla T_l(u) \quad \text{strongly in } (L^p_{loc}(Q))^N.$$

This kind of argument will be used in the next section to show the existence of solution to the Cauchy problem for $\lambda < \lambda_{N,p}$ by means of the Hardy inequality.

However, if $\lambda \geq \lambda_{N,p}$ only for $1 < p < 2N/(N+1)$ it is possible to get a global weaker solution and it is necessary to follow a different strategy to show the existence of such a weaker solution to the Cauchy problem (1.1) that will be studied in subsection 3.3 following the arguments in [12] for the case of a bounded domain.

In order to solve the Cauchy problem in the case $\lambda > \lambda_{N,p}$ and $1 < p < 2N/(N+1)$ the compactness arguments are more involved. We will use as supersolution a convenient shift in time, $\bar{S}$, of the self-similar solution S to the Cauchy problem that we obtain in the next section for λ large. Assume that there exists a sequence v_n $(n > 0)$ of solutions to the following problems:

$$\begin{cases} v_{nt} - \Delta_p v_n &= \lambda W_n(x) \tilde{v}_{n-1}^{p-1}, & x \in \Omega_n,\ t > 0, \\ v_n(x,0) &= u_0(x), & x \in \Omega_n, \\ v_n(x,t) &= 0, & x \in \partial\Omega_n,\ t > 0, \end{cases}$$

where $\tilde{v}_{n-1}^{p-1}$ is the extension by zero of v_{n-1} to Ω_n, an increasing nested sequence of bounded domains, u_0 is a bounded function, and assume that v_n is uniformly bounded above by $\overline{S}$ and $u_0 \leq \overline{S}$, that is, $v_n \leq \overline{S}$ $\forall n \geq 0$. In this case we will show in the next section that it is possible to pass to the limit and obtain a solution to the Cauchy problem for $\lambda > 0$ and $1<p<2N/(N+1)$. This critical value $p_1 = 2N/(N+1)$, as we will see in section 3, corresponds with the integrability range of the self-similar solution S. It has to be remarked that the passage to the limit for $1 < p < 2N/(N+2)$ is made using Lemma 2.4. However, the passage to the limit for $2N/(N+2) \leq p < 2N/(N+1)$ is much more delicate, and needs the following lemmas shown in [12], based on the ideas in [3], [4], and [5].

LEMMA 2.5. *If $2N/(N+2) \leq p < 2N/(N+1)$ and v_n is a sequence of positive functions defined on Ω, a bounded domain, verifying that $v_n \leq \overline{S}$ and*

$$\frac{1}{k} \int_0^T \int_{\{v_n < k\}} |\nabla v_n|^p \, dx \, dt \leq M,$$

then the following estimate in the Marcinkiewitz space $\mathcal{M}^{p_2}$ holds

$$|\{(x,t) \in Q \,:\, |\nabla v_n(x,t)| > h\}| \leq C(p,N,T) h^{-p_2},$$

where $Q = \Omega \times [0,T]$, $1 \leq q < N(2-p)/p$ and $p_2 = pq/(q+1)$.

LEMMA 2.6. *In the hypotheses in Lemma 2.5, we get*

(a) $\nabla v_n \to \nabla v$ *a.e. and in measure.*

(b) $|\nabla v_n|^{p-2} \nabla v_n \to |\nabla v|^{p-2} \nabla v$ *in* L^1.

3. Existence results for the Cauchy problem. In this section we show the existence results for the Cauchy problem (1.1). The proofs are based on the compactness results contained in the previous section. We would like to emphasize the different behavior according with the values of λ: if $p \geq 2$ the role of λ is very important, while the role of the Hardy inequality is less important when $p \to 1$. To be precise we classify this section in some subsections.

3.1. A self-similar solution to the Cauchy problem for $p < 2$. Before introducing the existence results for the Cauchy problem (1.1), we are considering the Cauchy problem with $u_0 \equiv 0$ for $p < 2$ fixed. The existence of a positive self-similar solution to this problem for some values of λ and p has to be remarked, obtaining an example of nonuniqueness since the trivial solution is also a solution to this problem (see [12]). More precisely, we look for positive self-similar solutions to the Cauchy problem in all $\mathbb{R}^N$, namely, for solutions like $S(r,t) = t^\alpha f(t^\beta r)$, where $r = |x|$; hence,

$$S_t = \alpha t^{\alpha-1} f + \beta t^{\alpha+\beta-1} r f',\ S_r = t^{\alpha+\beta} f',\ S_{rr} = t^{\alpha+2\beta} f''.$$

Then necessarily
(1) the similarity exponents satisfy $(\alpha - 1) = \alpha(p-1) + \beta p$;
(2) the corresponding ordinary differential equation in the variable $\xi = t^\beta r$ is

$$\alpha f + \beta \xi f' = (p-1)|f'|^{p-2} f'' + \frac{N-1}{\xi} |f'|^{p-2} f' + \frac{\lambda}{\xi^p} |f|^{p-2} f.$$

If we look for solutions of the form $A|\xi|^\gamma$, $A > 0$, we get

$$(1) \quad \gamma = \frac{-p}{2-p}, \qquad (2) \quad |A|^{p-2} = \frac{\alpha + \beta\gamma}{(p-1)|\gamma|^p + (N-p)|\gamma|^{p-2}\gamma + \lambda}.$$

It has been shown in [12] that (2) makes sense if $\lambda > \lambda_{N,p} = ((N-p)/p)^p$, the inverse of the optimal constant in the Hardy inequality. However, if we assume $\lambda > 0$, the values of λ corresponding to the existence of such a self-similar solution are given by

$$\lambda > \mu_{N,p} = \left(\frac{p}{2-p}\right)^{p-1} \left(N - \frac{p}{2-p}\right).$$

In particular, this self-similar solution takes the form

$$S(x,t) = A(\lambda) \left(\frac{t}{|x|^p}\right)^{1/(2-p)},$$

where $x \in \mathbb{R}^N$ and

$$A(\lambda) = \left(\left(\frac{p}{2-p}\right)^{p-1} (p - N(2-p)) + \lambda(2-p)\right)^{1/(2-p)}.$$

Let us introduce the parameter $s = N(2-p)/p$ ($2-p < s < N$, since $1 < p < N$). Then

$$\mu_{N,p} = \left(\frac{p}{2-p}\right)^p (s-1) \leq \lambda_{N,p} = \left(\frac{p+s-2}{2-p}\right)^p.$$

These two critical values are related as follows:

$$\frac{\mu_{N,p}}{\lambda_{N,p}} = (s-1)\left(\frac{p}{p+s-2}\right)^p.$$

It is important to take into account the following facts:

$$\begin{array}{lll}
\mu_{N,p} < 0 \text{ for} & s < 1, \text{ i.e.,} & 2 > p > 2N/(N+1), \\
\mu_{N,p} = 0 \text{ for} & s = 1, \text{ i.e.,} & p = 2N/(N+1), \\
\mu_{N,p} > 0 \text{ for} & 1 < s < N, \text{ i.e.,} & 1 < p < 2N/(N+1), \text{ and} \\
\mu_{N,p} = \lambda_{N,p} \text{ for} & s = 2, \text{ i.e.,} & p = 2N/(N+2).
\end{array}$$

Moreover, $\mu_{N,p}$ is tangent to $\lambda_{N,p}$ at $s = 2$ or $p = 2N/(N+2)$.

The regularity of S depends only on the value of s and is as follows (cf. [12, sect. 6.2]), where $1 \leq q < s$:

$$\begin{aligned} &S \in W^{1,p}_{loc}(\mathbb{R}^N) \cap L^q_{loc}(\mathbb{R}^N), \quad && 2 < s < N, \text{ i.e.,} \quad && 1 < p < \frac{2N}{N+2}, \\ &S \in L^q_{loc}(\mathbb{R}^N), && 1 < s \leq 2, \text{ i.e.,} && \frac{2N}{N+2} \leq p < \frac{2N}{N+1}. \end{aligned}$$

Remark 3.1.

(i) Notice that if $1 < p < 2N/(N+2)$ the critical Sobolev exponent is less than 2; therefore the local integrability properties of S are better than those given by the Sobolev embedding theorem.

(ii) Note that formally there still exists such a self-similar solution in the range $2 - p < s < 1$, namely, $2N/(N+1) < p < 2$. In particular, S does not belong to L^1 locally; S is a solution to the equation away from the origin in the sense of distributions and a.e., with an *infinite mass* concentrate at $(0,0)$ as initial data. If $2N/(N+1) < p < 2$, then $\mu_{N,p} < 0$, namely, we have the nonempty interval $\lambda \in (\mu_{N,p}, 0]$ and for such values of λ the term $\lambda |x|^{-p} u^{p-1}$ is an absorption term.

(iii) Note that a positive shift in time of S, denoted by $\overline{S}(x,t) = S(x, t+t_0)$, $t_0 > 0$, can be used as a supersolution to the general Cauchy problem (1.1), whenever we can take the shift in time large enough to have $u_0 \leq \overline{S}$. □

3.2. Existence results for $\boldsymbol{\lambda < \lambda_{N,p}}$, $\boldsymbol{1 < p < N}$. Now consider the Cauchy problem (1.1) where $1 < p < N$ and $0 < \lambda < \lambda_{N,p}$. We are going to construct a solution to (1.1) as a limit of solutions of approximate problems in bounded domains, where solution in this case means a function

$$u \in L^\infty(0, \infty; L^2_{loc}(\mathbb{R}^N)) \cap L^p(0, T; W^{1,p}_{loc}(\mathbb{R}^N)) \quad \forall T > 0$$

that verifies the equation in (1.1) in the sense of distributions.

In particular, we are assuming that there exists a ball B in $\mathbb{R}^N$ centered at the origin such that $u_0 \in \mathcal{C}_0(\overline{B})$, $u_0 \geq 0$ in B.

THEOREM 3.2. *If $1 < p < N$, $0 < \lambda < \lambda_{N,p}$ and $u_0 \in \mathcal{C}_0(\overline{B})$, $u_0 \geq 0$ in B, then there exists a global solution to* (1.1)*, u, which is obtained as the limit of the solutions u_k of the following problems:*

$$\text{(3.1)} \qquad \left\{ \begin{array}{rcll} u_{kt} - \Delta_p u_k & = & \lambda \dfrac{u_k^{p-1}}{|x|^p}, & x \in B_k,\ t > 0, \\ u_k(x,0) & = & u_0(x), & x \in B_k, \\ u_k(x,t) & = & 0, & x \in \partial B_k,\ t > 0, \end{array} \right.$$

where B_k is the ball of radius k in $\mathbb{R}^N$ centered at the origin. Moreover this solution attains the initial data in the sense that

$$\lim_{t \to 0} \int_{\mathbb{R}^N} u(x,t)\phi(x)\,dx = \int_{\mathbb{R}^N} u_0(x)\phi(x)\,dx \ \forall \phi \in W^{1,p}_0(B_R),\ R > 0.$$

Proof. In these hypotheses, fix $T > 0$ and $R > 0$ large enough such that $B \subset B_R$, and let $Q_R = B_R \times (0,T)$. We know the following facts:

(a) By Theorem 4.1 in [12], there exists a global solution $u_k \geq 0$ for (3.1), verifying

$$u_k \in L^\infty(0, \infty; L^2(B_k)) \cap L^p(0, T; W^{1,p}(B_k)) \quad \forall T > 0,$$

and

$$u_{kt} \in L^2((\epsilon,\infty)\times B_k) \quad \forall \epsilon > 0.$$

(b) If we multiply the equation in (3.1) by u_k and integrate by parts on $B_k \supset B_R$ for k large enough, we get by the Hardy inequality

$$\int_{B_k} u_k^2(x,T)\,dx + \gamma \int_0^T \int_{B_k} |\nabla u_k(x,t)|^p\,dx\,dt \le \int_{B_k} u_0^2(x)\,dx, \qquad \gamma > 0.$$

This implies that the sequence u_k is uniformly bounded in $L^p(0,T;W^{1,p}(B_R))$, and, by Lemma 2.4, we get the existence of $u \in L^\infty_{loc}(0,T;L^2(Q_R)) \cap L^p(0,T;W_0^{1,p}(Q_R))$ such that

$$u_t - \Delta_p u = \lambda \frac{u^{p-1}}{|x|^p}$$

in $\mathcal{D}'(Q_R)$. By a classical argument (see, for instance, [18, p. 156]) we get that $u(x,0) = u_0(x)$ in the sense that

$$\lim_{t\to 0} \int_{\mathbb{R}^N} u(x,t)\phi(x)\,dx = \int_{\mathbb{R}^N} u_0(x)\phi(x)\,dx \; \forall \phi \in W_0^{1,p}(B_R).$$

In addition, since $u_k \to u$ strongly in $L^p_{loc}(Q_R)$, $\nabla u_k \to \nabla u$ strongly in $L^q(Q_R)$, $1 \le q < p$, and $\nabla T_l u_k \to \nabla T_l u$ strongly in $L^p_{loc}(Q_R)$ (see section 2), then we obtain $u_k \to u$ strongly in $W^{1,q}_{loc}(Q_R)$, $1 \le q < p$ and $T_l u_k \to T_l u$ strongly in $W^{1,p}_{loc}(Q_R)$. □

Remark 3.3. If we take $u_0 \in L^r(B)$, with $r \ge 2$, the result is also true, since B is a bounded domain. This allows us to take $u_0 \in L^s(B)$, where $s \ge 2$ (that is, $1 < p \le 2N/(N+2)$). Moreover, this result is also true for $u_0 \in L^2(\mathbb{R}^N)$; the proof is obtained in a similar way by taking truncatures of u_0 on every B_k. □

3.3. Existence results for $\lambda > 0$, $1 < p < 2N/(N+1)$. The existence of solution for the Cauchy problem (1.1) with $\lambda > 0$ and $1 < p < 2N/(N+1)$ is shown in this subsection. The proof relies on an iteration process similar to those in [12], using the self-similar solution S corresponding to λ suitably shifted in time as a supersolution.

Let B denote a ball in $\mathbb{R}^N$; we have the following result.

THEOREM 3.4. *If $1 < p < 2N/(N+1)$, $\lambda > 0$ and $u_0 \in \mathcal{C}_0(\overline{B})$, $u_0 \ge 0$ in B, then there exists a solution u to* (1.1) *in the sense of distributions, which is obtained as the limit of the sequence given by the iterations ($n > 0$)*

$$\left\{\begin{array}{rcll} v_{nt} - \Delta_p v_n &=& \lambda W_n(x)\tilde{v}_{n-1}^{p-1}, & x \in B_{n+1},\ t > 0,\\ v_n(x,0) &=& u_0(x), & x \in B_{n+1},\\ v_n(x,t) &=& 0, & x \in \partial B_{n+1},\ t > 0, \end{array}\right.$$

with

$$\left\{\begin{array}{rcll} v_{0t} - \Delta_p v_0 &=& 0, & x \in B_1,\ t > 0,\\ v_0(x,0) &=& u_0(x), & x \in B_1,\\ v_0(x,t) &=& 0, & x \in \partial B_1,\ t > 0, \end{array}\right.$$

where $\tilde{v}_{n-1} = v_{n-1}$ in B_n, $\tilde{v}_{n-1} = 0$ in $\mathbb{R}^N \setminus B_n$, and B_n is the ball of radius n centered at the origin in $\mathbb{R}^N$.

In fact, if $1 < p < 2N/(N+2)$ *then* $u \in L^\infty(0,\infty; L^2_{loc}(\mathbb{R}^N)) \cap L^p(0,T; W^{1,p}_{loc}(\mathbb{R}^N))$. *This solution satisfies the initial data in the sense of distributions.*

Proof. Since $\lambda > 0$, there exists a self-similar supersolution to the Cauchy problem with zero initial data, S. Let $\overline{S}$ denote a shift in time of S so that $u_0 \le \overline{S}$ (u_0 is bounded). Then we have in B_1

$$\begin{array}{rcll} v_{0t} - \Delta_p v_0 = 0 & \le & \lambda \dfrac{\overline{S}^{p-1}}{|x|^p} = \overline{S}_t - \Delta_p \overline{S}, & x \in B_1,\ t > 0, \\ v_0(x,0) = u_0(x) & \le & \overline{S}(x,0), & x \in B_1, \\ v_0(x,t) = 0 & \le & \overline{S}(x,t), & x \in \partial B_1,\ t > 0. \end{array}$$

Then we conclude that $\tilde{v}_1 \le \overline{S}$. Therefore, by recurrence, it is easy to show that $\tilde{v}_n \le \overline{S}\ \forall n > 0$.

Fix $T > 0$ and $R > 0$ large enough such that $B \subset B_{R+1}$ and take a cutoff function $\varphi = \varphi(x) \in \mathcal{C}_0^\infty(B_{R+1})$, $\varphi \equiv 1$ in B_R, $0 \le \varphi \le 1$ and $|\nabla \varphi| \le C$ in $A_R = B_{R+1} \setminus B_R$ (notice that φ does not depend on t). Let $Q_R = B_R \times (0,T)$ and take $n > R+1$ so that $B_{R+1} \subset B_n$.

Case I. Consider $1 < p < 2N/(N+2)$; since $v_n \in W_0^{1,p}(B_n)$ and $\varphi \in \mathcal{C}_0^\infty(B_{R+1})$, then $v_n \varphi^p \in W_0^{1,p}(B_{R+1})$; if we multiply by $v_n \varphi^p$ the equation satisfied by v_n and integrate, we obtain

$$\int_{B_{R+1}} v_{nt} v_n \varphi^p + \int_{B_{R+1}} \langle |\nabla v_n|^{p-2} \nabla v_n, \nabla(v_n \varphi^p) \rangle = \lambda \int_{B_{R+1}} W_n \tilde{v}_{n-1}^{p-1} v_n \varphi^p.$$

Since $\tilde{v}_{n-1} \le \overline{S}$ and $v_n \le \overline{S}$ in B_n, and integrating on the interval $[0,T]$, we get

$$\begin{aligned} &\frac{1}{2} \int_{B_{R+1}} v_n^2(x,T) \varphi^p + \int_0^T \int_{B_{R+1}} |\nabla v_n|^p \varphi^p \\ &\quad + p \int_0^T \int_{A_R} v_n \varphi^{p-1} \langle |\nabla v_n|^{p-2} \nabla v_n, \nabla \varphi \rangle \\ &\quad \le \frac{1}{2} \int_{B_{R+1}} u_0^2 \varphi^p + \lambda \int_0^T \int_{B_{R+1}} W_n \overline{S}^p. \end{aligned}$$

Using Young and Hölder inequalities,

$$\begin{aligned} \frac{1}{2} \quad & \int_{B_{R+1}} v_n^2(x,T) \varphi^p + \int_0^T \int_{B_R} |\nabla v_n|^p \varphi^p + \int_0^T \int_{A_R} |\nabla v_n|^p \varphi^p \\ & \le \frac{1}{2} \int_{B_{R+1}} u_0^2 \varphi^p - p \int_0^T \int_{A_R} v_n \varphi^{p-1} \langle |\nabla v_n|^{p-2} \nabla v_n, \nabla \varphi \rangle + \lambda \int_0^T \int_{B_{R+1}} W_n \overline{S}^p \\ & \le \frac{1}{2} \int_{B_{R+1}} u_0^2 + p \int_0^T \int_{A_R} (|\nabla v_n| \varphi)^{p-1} v_n |\nabla \varphi| + \lambda \int_0^T \int_{B_{R+1}} W_n \overline{S}^p \\ & \le \frac{1}{2} \int_{B_{R+1}} u_0^2 + \int_0^T \int_{A_R} (|\nabla v_n| \varphi)^p + C_1(p) \int_0^T \int_{A_R} v_n^p \\ & + \lambda \int_0^T \left(\int_{B_{R+1}} W_n^{2/(2-p)} \right)^{(2-p)/2} \left(\int_{B_{R+1}} \overline{S}^2 \right)^{p/2}. \end{aligned}$$

Since we can simplify the terms involving $\varphi^p |\nabla v_n|^p$ on A_R, we obtain, again using

Young inequality and the facts $v_n \le \overline{S}$ in B_n and $W_n \le |x|^{-p}$,

$$\begin{aligned}&\frac{1}{2}\int_{B_R} v_n^2(x,T) + \int_0^T\int_{B_R} |\nabla v_n|^p \\ &\quad \le \frac{1}{2}\int_{B_{R+1}} u_0^2 + C_1(p)\int_0^T\int_{A_R} \overline{S}^p \\ &\quad + \lambda\left(\frac{2-p}{2}\int_0^T\int_{B_{R+1}} |x|^{-2p/(2-p)} + \frac{p}{2}\int_0^T\int_{B_{R+1}} \overline{S}^2\right).\end{aligned}$$

If we define

$$\beta(T) = \int_{B_{R+1}} u_0^2 + C_1(p)\int_0^T\int_{A_R} \overline{S}^p + \lambda(2-p)\int_0^T\int_{B_{R+1}} |x|^{-2p/(2-p)} + \lambda p\int_0^T\int_{B_{R+1}} \overline{S}^2,$$

then $\beta(T)$ is uniformly bounded, since $1 < p < 2N/(N+2)$ and $\overline{S} \in L^q_{loc}(\mathbb{R}^N)$ with $q > 2$. Therefore, we get

$$\int_{B_R} v_n^2(x,T) \le \beta(T) \le c(\lambda, p, T, R, N, ||u_0||_2).$$

This gives a uniform bound for the norm of v_n in $L^2(B_R)$; in addition, since

$$\int_0^T\int_{B_R} |\nabla v_n|^p \le \beta(T) \le c(\lambda, p, T, R, N, ||u_0||_2),$$

we have that the sequence v_n is uniformly bounded in the space $L^p(0,T;W^{1,p}(B_R))$. In this way we can pass to the limit by Lemma 2.4, obtaining a positive global solution u to (1.1) in $\mathcal{D}'(Q_R)$ with $\lambda > 0$ and $1 < p < 2N/(N+2)$. Here the initial data is attained in the same sense as in Theorem 3.2 because we have the same kind of uniform estimates.

Case II. Now let $2N/(N+2) \le p < 2N/(N+1)$; in this range, the regularity of $\overline{S}$ (see section 3.1) implies that the sequence v_n converges in L^q to some $v \le \overline{S}$, for $1 \le q < s \le 2$; so we cannot follow the previous argument in order to show the existence result. We introduce the sets

$$C_{R,k} = B_R \cap \{v_n\varphi^p \ge k\}, \quad \overline{C}_{R,k} = B_R \cap \{v_n\varphi^p < k\}, \quad A_{R,k} = \overline{C}_{R+1,k} \setminus \overline{C}_{R,k}.$$

If we multiply by $T_k(v_n\varphi^p)$ the equation satisfied by v_n and integrate on B_{R+1}, we obtain

$$\int_{B_{R+1}} v_{nt}T_k(v_n\varphi^p) + \int_{B_{R+1}} \langle|\nabla v_n|^{p-2}\nabla v_n, \nabla(T_k(v_n\varphi^p))\rangle = \lambda\int_{B_{R+1}} W_n\tilde{v}_{n-1}^{p-1}T_k(v_n\varphi^p),$$

that is (remember that φ does not depend on t),

$$\begin{aligned}&\frac{1}{2}\int_{\overline{C}_{R+1,k}} (v_n^2)_t\varphi^p + k\int_{C_{R+1,k}} v_{nt} + \int_{\overline{C}_{R+1,k}} \langle|\nabla v_n|^{p-2}\nabla v_n, \nabla(v_n\varphi^p)\rangle \\ &= \lambda\int_{B_{R+1}} W_n\tilde{v}_{n-1}^{p-1}T_k(v_n\varphi^p).\end{aligned}$$

Integrating on $[0,T]$, we get (note that $\tilde{v}_{n-1} \le \overline{S}$ and $0 \le \varphi \le 1$)

$$\begin{aligned}&\frac{1}{2}\int_{\overline{C}_{R+1,k}} v_n^2(x,T)\varphi^p + \\ &\int_0^T\int_{\overline{C}_{R+1,k}} \varphi^p|\nabla v_n|^p + p\int_0^T\int_{A_{R,k}} \varphi^{p-1} v_n\langle|\nabla v_n|^{p-2}\nabla v_n, \nabla\varphi\rangle \\ &\le \frac{1}{2}\int_{\overline{C}_{R+1,k}} u_0^2\varphi^p + k\int_{C_{R+1,k}} u_0 + \lambda k\int_0^T\int_{B_{R+1}} W_n\overline{S}^{p-1}.\end{aligned}$$

This last integral is bounded whenever $2N/(N+2) \le p < 2N/(N+1)$ and u_0 is bounded. On the other hand, note that if $v_n < k$, then $v_n\varphi^p < k$. In other words

$$B_R \cap \{v_n\varphi^p < k\} \supset B_R \cap \{v_n < k\}.$$

Thus, using the Young inequality in a similar way to the case $1 < p < 2N/(N+2)$,

$$\begin{aligned}&\frac{1}{2}\int_{B_R\cap\{v_n<k\}} v_n^2(x,T) + \int_0^T\int_{B_R\cap\{v_n<k\}} |\nabla v_n|^p + \int_0^T\int_{A_{R,k}} \varphi^p|\nabla v_n|^p \\ &\quad\le \frac{1}{2}\int_{\overline{C}_{R+1,k}} u_0^2\varphi^p + \lambda k C(R) + p\int_0^T\int_{A_{R,k}} (\varphi|\nabla v_n|)^{p-1}(v_n|\nabla\varphi|) \\ &\quad\le \frac{1}{2}\int_{B_{R+1}} u_0^2 + \lambda k C(R) + \int_0^T\int_{A_{R,k}} (|\nabla v_n|\varphi)^p + C_1(p)\int_0^T\int_{A_{R,k}} v_n^p.\end{aligned}$$

So we can simplify the terms involving $(|\nabla v_n|\varphi)^p$ on $A_{R,k}$ and, using the fact that $v_n \le \overline{S}$ in B_{n+1}, we obtain

$$\begin{aligned}&\frac{1}{2}\int_{B_R\cap\{v_n<k\}} v_n^2(x,T) + \int_0^T\int_{B_R\cap\{v_n<k\}} |\nabla v_n|^p \\ &\quad\le \frac{1}{2}\int_{B_{R+1}} u_0^2 + \lambda k C(R) + C_1(p)\int_0^T\int_{A_{R,k}} \overline{S}^p.\end{aligned}$$

Though $\overline{S} \in L^q_{loc}$ for $1 \le q < s$ in the range $2N/(N+2) \le p < 2N/(N+1)$, it has to be noted that the last integral is finite, since we are integrating on $A_{R,k}$, which does not contain the origin. Then

$$\frac{1}{k}\int_0^T\int_{B_R\cap\{v_n<k\}} |\nabla v_n|^p\,dx\,dt \le M,$$

where M does not depend on n; this inequality allows us to use Lemmas 2.5 and 2.6, obtaining the existence of a solution u to (1.1) in Q_R with $\lambda > 0$ and $2N/(N+2) \le p < 2N/(N+1)$ in the sense of distributions. Moreover, $u \in L^\infty_{loc}((0,\infty), L^q(\mathbb{R}^N))$ and $|\nabla u| \in \mathcal{M}^{p_2}$, where $\mathcal{M}^{p_2}$ is the Marcinkiewitz space and $p_2 = pq/(q+1)$ with $1 \le q < s = N(2-p)/p$.

The argument to see how the initial data is attained is slightly different in this case. We take into account the integrability of the upper bound S. Following the calculations in [21, p. 330] and since $p < 2$ we are able to prove that $|\nabla u|^{p-1} \in L^r_{loc}$ with $1 < r < p/(2p-2)$. Then we can say that

$$\lim_{t\to 0}\int_{\mathbb{R}^N} u(x,t)\phi(x)\,dx = \int_{\mathbb{R}^N} u_0(x)\phi(x)\,dx \ \forall\phi \in W_0^{1,r/(r-1)}(B_R),\ R > 0. \qquad \square$$

3.4. Blow-up for $\lambda > \lambda_{N,p}$, $p > 2$. Following the ideas in [12], we can show the existence of blow-up for any solution to (1.1) for $p > 2$ and $\lambda > \lambda_{N,p}$, with positive initial data. More precisely we have the following result.

THEOREM 3.5. *Consider the problem*

$$\left\{\begin{array}{rcll} u_t - \Delta_p u &=& \dfrac{\lambda}{|x|^p}|u|^{p-2}u, & x \in \mathbb{R}^N, \quad N > p > 2,\, t > 0,\, \lambda > \lambda_{N,p}, \\ u(x,0) &=& f(x), & x \in \mathbb{R}^N, \end{array}\right. \tag{3.2}$$

where $p > 2$, $\lambda > \lambda_{N,p}$, $f \in L^\infty$, $f \geq 0$, and $f > \delta > 0$ in a neighborhood of the origin. Then (3.2) *has no local solution, in the sense that for any $\epsilon > 0$, there exists $r(\epsilon) > 0$ such that $\lim_{n\to\infty} u_n(x,t) = \infty$ if $|x| \leq r(\epsilon)$ and $t \geq \epsilon$, where u_n are the solutions to the problems with the truncated potentials $W_n(x)$.*

See [12] for the proof of a bounded domain and notice that the case $\Omega = \mathbb{R}^N$ is an elementary consequence.

Remark 3.6. Some final comments to this section are in order.

(i) With some modifications of the methods in [9], [10], and [21] and taking into account the precise construction, for the solutions founded above it should be possible to get a best result about the convergence to the initial data (for instance in L^1_{loc}). Notice that the integrability properties of the upper bound S in the interval $2N/(N+2) < p < 2N/(N+1)$ suggest the conjecture that this behavior must be true for a wider class of initial data, namely, this problem is connected with the question of the optimal regularity of the initial data, and one of the difficulties is the nonuniqueness.

(ii) We get *instantaneous and regionally complete blow-up*, in particular in all L^r-norms, if $p > 2$. If $1 < p < 2N/(N+1)$, according to the previous section, we have *instantaneous blow-up* in L^∞, but some norms are finite and this fact allows us to construct weaker global solutions. In the linear case ($p = 2$) the representation of the solutions by the Green's function implies *infinite speed of propagation* and this is the point that makes easy to prove that the blow-up is complete. In our case, if $p > 2$, the speed of propagation is finite if $\lambda = 0$, and the argument to prove that $\lim_{n\to\infty} u_n(x,t) = \infty$ $\forall (x,t) \in \Omega \times (0,\infty)$ must be different. This seems to be an open question. □

4. Finite time extinction.

4.1. Extinction results. Let Ω be a bounded domain in $\mathbb{R}^N$. If $||\cdot||_q$ denotes the norm in the space $L^q(\Omega)$, we have the following results.

PROPOSITION 4.1. *Let Ω be a bounded domain in $\mathbb{R}^N$; if u is a solution of*

$$\left\{\begin{array}{rcll} u_t - \Delta_p u &=& \lambda\dfrac{u^{p-1}}{|x|^p}, & x \in \Omega,\, t > 0, \\ u(x,0) &=& u_0(x) \in L^2(\Omega), \quad u_0 \geq 0, & \\ u(x,t) &=& 0, & x \in \partial\Omega,\, t > 0, \end{array}\right.$$

where $2N/(N+2) \leq p < 2$ and $0 < \lambda < \lambda_{N,p}$, then there exists a finite time $T^\star$ depending on $N, p, \lambda, |\Omega|$ and $||u_0||_2$ such that

$$u(\cdot,t) \equiv 0 \qquad \forall t \geq T^\star.$$

Moreover, $0 < T^\star \leq \gamma_1 ||u_0||_2^{2-p} |\Omega|^{\frac{p}{2}+\frac{p}{N}-1}$ where γ_1 is a positive constant depending only on N, p, λ.

Proof. Notice that $2N/(N+2) \le p < 2$ implies $s = N(2-p)/p \le 2$ and $p^* > 2$. The part (a) of the proof of Theorem 3.2 shows the existence of a solution u to this problem. If we multiply the equation by u and integrate on Ω, we get by the Hardy inequality

$$\frac{1}{2}\frac{d}{dt}||u(x,t)||_2^2 + \int_\Omega |\nabla u(x,t)|^p\,dx = \lambda \int_\Omega \frac{u^p}{|x|^p}\,dx \le \lambda\lambda_{N,p}^{-1}\int_\Omega |\nabla u(x,t)|^p\,dx.$$

Then, if $\lambda < \lambda_{N,p}$, there exists $\gamma = \gamma(N,p,\lambda) > 0$ such that

$$\frac{1}{2}\frac{d}{dt}||u(x,t)||_2^2 + \gamma\int_\Omega |\nabla u(x,t)|^p dx \le 0.$$

Now, if $2N/(N+2) \le p$, then $p^* = Np/(N-p) \ge 2$, and

$$||u(x,t)||_{p^*} \le \gamma_{N,p}||\nabla u(x,t)||_p.$$

Therefore

$$\frac{1}{2}\frac{d}{dt}||u(x,t)||_2^2 + \gamma||u(x,t)||_{p^*}^p \le 0.$$

Hölder inequality implies that

$$\int_\Omega |u(x,t)|^2\,dx \le |\Omega|^{(p^*-2)/p^*}\left(\int_\Omega |u(x,t)|^{p^*}\,dx\right)^{2/p^*}.$$

Thus

$$\frac{1}{2}\frac{d}{dt}||u(x,t)||_2^2 + \gamma|\Omega|^{1-p/2-p/N}||u(x,t)||_2^p \le 0,$$

and we obtain

$$||u(x,T)||_2 \le ||u_0||_2\left(1 - \frac{(2-p)\gamma|\Omega|^{1-p/2-p/N}T}{||u_0||_2^{2-p}}\right)_+^{1/(2-p)}. \qquad \square$$

Proposition 4.2. *Consider $\Omega \subset \mathbb{R}^N$ a bounded domain and let u be the solution of*

$$(4.1) \qquad \begin{cases} u_t - \Delta_p u &= \lambda\dfrac{u^{p-1}}{|x|^p}, & x \in \Omega,\ t > 0,\\ u(x,0) &= u_0(x) \in L^2(\Omega)\cap L^s(\Omega), \quad u_0 \ge 0, & \\ u(x,t) &= 0, & x \in \partial\Omega,\ t > 0,\end{cases}$$

obtained as the limit of the sequence u_n of solutions to the corresponding truncated problem (2.1)*, where $1 < p < 2N/(N+2)$ ($s = N(2-p)/p > 2$) and $0 < \lambda < \mu_{N,p}$. Then there exists a finite time $T^\star$ depending only upon N, p, λ and $||u_0||_s$, such that*

$$u(\cdot,t) \equiv 0 \qquad \forall t \ge T^\star.$$

Moreover, $0 < T^\star \le \gamma_2||u_0||_s^{2-p}$, $1 < p < 2N/(N+2)$ where γ_2 is a positive constant depending only upon N, p, λ.

Proof. Observe that $u_n \in L^\infty(\Omega) \cap W_0^{1,p}(\Omega)$ by Lemma 2.1; then u_n^{s-1} is an admissible test function. By multiplying u_n^{s-1} by the equation satisfied by u_n, we get

$$\begin{aligned}\frac{1}{s}\frac{d}{dt}||u_n(x,t)||_s^s + \mu_{N,p}\lambda_{N,p}^{-1}\int_\Omega |\nabla u_n^{(p+s-2)/p}(x,t)|^p\,dx \\ = \lambda\int_\Omega W_n(x)u_n^{p+s-2}(x,t)\,dx.\end{aligned} \tag{4.2}$$

Since

$$\int_\Omega |\nabla u_n^{(p+s-2)/p}|^p = (s-1)\frac{\lambda_{N,p}}{\mu_{N,p}}\int_\Omega u_n^{s-2}|\nabla u_n|^p,$$

we can conclude that $u_n^{(p+s-2)/p} \in W_0^{1,p}(\Omega)$; therefore, using the Hardy inequality in the right-hand side of (4.2), we obtain

$$\begin{aligned}\frac{1}{s}\frac{d}{dt}||u_n(x,t)||_s^s + \mu_{N,p}\lambda_{N,p}^{-1}\int_\Omega |\nabla u_n^{(p+s-2)/p}(x,t)|^p dx \\ \le \lambda\lambda_{N,p}^{-1}\int_\Omega |\nabla u_n^{(p+s-2)/p}(x,t)|^p\,dx.\end{aligned}$$

If $\lambda < \mu_{N,p}$, then there exists $\gamma = \gamma(N,p,\lambda) > 0$ such that

$$\frac{1}{s}\frac{d}{dt}||u_n(x,t)||_s^s + \gamma\int_\Omega |\nabla u_n^{(p+s-2)/p}(x,t)|^p\,dx \le 0.$$

Since, by Sobolev,

$$\int_\Omega u_n^s(x,t)\,dx = \int_\Omega u_n^{p^*(p+s-2)/p}(x,t)\,dx \le \gamma_{N,p}\left(\int_\Omega |\nabla u_n^{(p+s-2)/p}(x,t)|^p\,dx\right)^{N/(N-p)},$$

we obtain

$$\frac{1}{s}\frac{d}{dt}||u_n(x,t)||_s^s + \gamma||u_n(x,t)||_s^{p+s-2} \le 0.$$

Therefore we conclude that

$$||u_n(x,T)||_s \le ||u_0||_s\left(1 - \frac{(2-p)\gamma T}{||u_0||_s^{2-p}}\right)_+^{1/(2-p)}.$$

That is, there exists a uniform finite extinction time for any solution of the truncated problem corresponding to (4.1). Since u is obtained as the limit of the nondecreasing (see Lemma 2.1) sequence u_n, then there exists a finite extinction time $T^\star$ for u too, namely,

$$0 < T^\star \le \gamma_2||u_0||_s^{2-p}. \qquad \square$$

Remark 4.3. In the hypotheses in the previous result, we also get that the solution u obtained as the limit of the sequence of solutions to the truncated problems belongs to $L^\infty(0,T^\star;L^s(\Omega))$, $s > 2$. $\square$

Remark 4.4. If $\lambda = 0$, that is, in the homogeneous case, similar results have been shown in [2] (see also [15] and [8, Chap. VIII, sections 2 and 3]) which depend only on N and p (if $\lambda < 0$ one obtains similar results). However, if $\lambda > 0$, then λ must be small enough to obtain finite time extinction. $\square$

Remark 4.5. The following question seems to be an open problem: the existence of finite time extinction for some solutions of (4.1) for $\lambda \in [\mu_{N,p}, \lambda_{N,p}]$ (in bounded domains and in $\mathbb{R}^N$). In some sense, this is equivalent to a uniqueness result in the regularity class L^s, since it is possible to find solutions in $\mathbb{R}^N$ which do not have finite time extinction in this range of λ and do not belong to L^s (see subsection 4.2). On the other hand, a similar estimate can be shown for the finite time extinction of the solutions of the truncated problems, u_n, if $\lambda < \lambda_1(n)\mu_{N,p}/\lambda_{N,p}$, where $\lambda_1(n)$ is the first eigenvalue associated with the following elliptic problem:

$$\left\{\begin{array}{rcll} -\Delta_p \phi_1 & = & \lambda_1(n) W_n(x) \phi_1^{p-1}, & x \in \Omega, \\ \phi_1 & = & 0, & x \in \partial\Omega \end{array}\right.$$

(see subsection 5.3 for more details). Since $\lambda_1(n) \searrow \lambda_{N,p}$ as $n \to \infty$, we obtain again the bound $\lambda < \mu_{N,p}$ for the finite time extinction of the solutions of the untruncated problem. $\square$

We would like to emphasize that the finite extinction time estimate obtained in Proposition 4.2 does not depend on $|\Omega|$ for $\lambda < \mu_{N,p} \le \lambda_{N,p}$ and $s > 2$. This is the main result that we will use in the proof of the finite time extinction for the Cauchy problem with $0 < \lambda < \mu_{N,p}$ and $1 < p < 2N/(N+2)$.

THEOREM 4.6. *If $1 < p < 2N/(N+2)$ $(s > 2)$, $0 < \lambda < \mu_{N,p}$ and $u_0 \in L^2(\mathbb{R}^N) \cap L^s(\mathbb{R}^N)$, there exists a finite time extinction $T^\star$ (depending only upon N, p, λ and u_0) for u, the solution of* (1.1) *obtained in Theorem* 3.2, *such that*

$$u(\cdot, t) \equiv 0 \ \forall t \ge T^\star \text{ and } 0 < T^\star \le \gamma_2 ||u_0||_s^{2-p},$$

where γ_2 is a positive constant depending only upon N, p, λ.

Proof. In these hypotheses, we can use Theorem 3.2 to obtain u, a solution to (1.1) as the limit of the sequence u_k, the approximate solutions of (3.1). Each u_k has a finite time extinction which does not depend on the domain and is uniformly bounded by Proposition 4.2. Therefore, there exists a finite time extinction for u. $\square$

Remark 4.7. If we take an unbounded domain Ω instead of $\mathbb{R}^N$, we can use a sequence of approximate nested domains with finite measure in order to get the same conclusions. In particular, it has to be noted that the proofs of Propositions 4.1 and 4.2 are also valid for an unbounded domain with finite measure. $\square$

4.2. Nonextinction results. In this subsection we will show that for $\lambda > \lambda_{N,p}$ there is no finite time extinction for the solutions to (2.2) in bounded domains with positive initial data and, as a consequence, for the solutions of the Cauchy problem (1.1). After that, we will show that there exists at least a solution to (1.1) with $\mu_{N,p} < \lambda \le \lambda_{N,p}$ which does not have finite time extinction; the existence of the self-similar solution S for this range of λ plays a fundamental role in the proof of this result.

PROPOSITION 4.8. *Let $\Omega \subset \mathbb{R}^N$ a bounded domain and consider u, a solution of the untruncated problem* (2.2) *with $\lambda > \lambda_{N,p}$ and $1 < p < 2$. Then there exists no finite time extinction for u.*

Proof. In [12, sect. 8], it is shown, following the ideas in [11], that $w(x,t) = ct^{1/(2-p)}\phi_1(x)$ is a subsolution to the problem

$$\begin{cases} u_t - \Delta_p u &= \lambda \dfrac{u^{p-1}}{|x|^p}, & x \in \Omega,\, t > 0, \\ u(x,0) &= 0, & x \in \Omega, \\ u(x,t) &= 0, & x \in \partial\Omega,\, t > 0 \end{cases}$$

for $\lambda > \lambda_{N,p}$, where ϕ_1 verifies

$$\begin{cases} -\Delta_p \phi_1 &= \lambda_1(n) W_n(x) \phi_1^{p-1}, & x \in \Omega, \\ \phi_1 &= 0, & x \in \partial\Omega, \end{cases}$$

$\lambda_1(n)$ being the first eigenvalue of the previous problem, for n large enough such that $\lambda_1(n) < \lambda$. Then w is also a subsolution to the problem (2.2). Since w cannot have finite time extinction, there exists no finite time extinction for any solution to (2.2) (observe that $w(x,0) = 0$). □

Remark 4.9. As a consequence of Proposition 4.8, we conclude that there exists no finite time extinction for any solution to the corresponding Cauchy problem if $\lambda > \lambda_{N,p}$ and $u_0(x) > 0$ in a ball in $\mathbb{R}^N$. □

Moreover, if we take $\lambda > \mu_{N,p}$, we know that there exists a self-similar solution S to the Cauchy problem with zero initial data in the range $1 < p < 2N/(N+1)$ (see section 3.1). In this way we obtain for the same problem a solution with finite time extinction (the trivial solution) and a solution which does not have finite time extinction (S; observe that $S \notin L^s_{loc}(\mathbb{R}^N)$). We are showing that, in this range, there exists at least a solution of the Cauchy problem with positive initial data which does not have finite time extinction.

THEOREM 4.10. *If $1 < p < 2N/(N+1)$, $\mu_{N,p} < \lambda$, $u_0 \geq \delta > 0$ on a ball B and there exists a shift in time of S, $\overline{S}$, such that $u_0 \leq \overline{S}$, then there exists a solution of the Cauchy problem* (1.1) *with no finite time extinction.*

Proof. Assume that u_0 is bounded (if not, take $T_k(u_0)$). Consider the following iteration for $k > 0$:

$$\begin{cases} v_{kt} - \Delta_p v_k &= \lambda \dfrac{\tilde{v}_{k-1}^{p-1}}{|x|^p}, & x \in B_k,\, t > 0, \\ v_k(x,0) &= u_0(x), & x \in B_k, \\ v_k(x,t) &= S(x,t), & x \in \partial B_k,\, t > 0, \end{cases}$$

where $v_0 = \overline{S}$, $\tilde{v}_k = v_k$ in B_k, $\tilde{v}_k = S$ in $\mathbb{R}^N \setminus B_k$, B_k being the ball of radius k centered at the origin in $\mathbb{R}^N$. For a fixed $T > 0$, we make a separate study for the cases $1 < p < 2N/(N+2)$ and $2N/(N+2) \leq p < 2N/(N+1)$:

(a) Assume $1<p<2N/(N+2)$; in this range we know that $\overline{S} \in L^p(0,T;W^{1,p}(B_1))$ (see section 3.1). In addition, by means of a similar calculation to the one carried out in the proof of Lemma 2.3(a), we have

$$\frac{\overline{S}^{p-1}}{|x|^p} \in L^{p'}(0,T;W^{-1,p'}(B_1)).$$

Therefore, since $\overline{S}_t \in L^{p'}(0,T;W^{-1,p'}(B_1))$ too, and $v_1 = S$ on ∂B_1, we can apply the results in [18], obtaining the existence of a unique solution to the problem corresponding to $k = 1$, namely,

$$v_1 \in \mathcal{C}(0,T;L^2(B_1)) \cap L^p(0,T;W^{1,p}(B_1)).$$

Hence, $\tilde{v}_1 \in L^p(0,T;W^{1,p}(B_2))$ and $|x|^{-p}\tilde{v}_1^{p-1} \in L^{p'}(0,T;W^{-1,p'}(B_2))$, which in turn implies the existence of v_2, a solution to the problem corresponding to $k = 2$, etc. Moreover,

$$\begin{array}{rcll} v_{1t} - \Delta_p v_1 = \lambda \dfrac{\overline{S}^{p-1}}{|x|^p} & = & \overline{S}_t - \Delta_p \overline{S}, & x \in B_1,\ t > 0, \\ v_1(x,0) = u_0(x) & \leq & \overline{S}(x,0), & x \in B_1, \\ v_1(x,t) = S(x,t) & \leq & \overline{S}(x,t), & x \in \partial B_1,\ t > 0, \end{array}$$

and

$$\begin{array}{rcll} v_{1t} - \Delta_p v_1 = \lambda \dfrac{\overline{S}^{p-1}}{|x|^p} & \geq & \lambda \dfrac{S^{p-1}}{|x|^p} = S_t - \Delta_p S, & x \in B_1,\ t > 0, \\ v_1(x,0) = u_0(x) & \geq & 0 = S(x,0), & x \in B_1, \\ v_1(x,t) & = & S(x,t), & x \in \partial B_1,\ t > 0; \end{array}$$

therefore we conclude that

$$S \leq v_1 \leq v_0 = \overline{S} \qquad \text{in } B_1.$$

In a similar way, if we assume $S \leq v_{k-1} \leq \overline{S}$ in B_{k-1}, then v_k verifies $S \leq v_k \leq \overline{S}$ in B_k. If we now take a cut function φ and proceed as in the proof of Theorem 3.4, we can pass to the limit and obtain a solution v of the Cauchy problem with no finite time extinction, since the approximate solutions v_k imply that $v \geq S$.

(b) If $2N/(N+2) \leq p < 2N/(N+1)$, then $\overline{S} \in L^q_{loc}(\mathbb{R}^N)$ for $1 \leq q < s$ (see section 3.1). Assume $k = 1$ and take the approximate problems, for $n > 0$,

$$\left\{ \begin{array}{rcll} w_{nt} - \Delta_p w_n & = & \lambda f_n = \lambda T_n(|x|^{-p}\overline{S}^{p-1}), & x \in B_1,\ t > 0, \\ w_n(x,0) & = & u_0(x), & x \in B_1, \\ w_n(x,t) & = & T_n(S(x,t)), & x \in \partial B_1,\ t > 0. \end{array} \right.$$

Since the right-hand side in the previous equation and the boundary data are both bounded, we can apply the results in [18] to obtain the existence of a unique $w_n \in L^p(0,T;W^{1,p}(B_1))$. Moreover, we can show that $w_n \leq \overline{S}$, since $(w_n - \overline{S})_+ = 0$ on the parabolic boundary of the cylinder $B_1 \times (0,T)$,

$$(w_n - \overline{S})_t - (\Delta_p w_n - \Delta_p \overline{S}) = \lambda(T_n(|x|^{-p}\overline{S}^{p-1}) - |x|^{-p}\overline{S}^{p-1}) \leq 0,$$

and we can take $(w_n - \overline{S})_+$ as a test function to integrate the inequality above, which yields $w_n \leq \overline{S}$. In the same way we can show that

$$w_1 \leq w_2 \leq \cdots \leq w_n \leq \cdots \leq \overline{S}.$$

That is, we have a monotone sequence in $L^p(0,T;W^{1,p}(B_1))$ uniformly bounded by $\overline{S}$. If we define

$$v_1 = \lim_{n\to\infty} w_n \leq \overline{S},$$

we can proceed as in the proof of Theorem 3.4 (multiplying by $T_l(w_n\varphi^p)$ the equation satisfied by w_n, where φ is a cut function on a ball $B \subset B_1$ which does not depend on t) in order to show

$$\frac{1}{l}\int_0^T \int_{B\cap\{w_n<l\}} |\nabla w_n|^p \, dx \, dt \leq M,$$

where M does not depend on l.

Therefore there exists $v_1 \leq \overline{S}$ verifying the equation corresponding to $k = 1$ in $\mathcal{D}'(B \times (0,T))$, for any ball $B \subset B_1$ and $v_1(x,0) = u_0(x)$ in B_1, $v_1(x,t) = S(x,t)$ on ∂B_1, since v_1 is the pointwise limit of the approximate solutions w_n. By repeating this procedure for each $k > 1$, we obtain a solution v_k of the equation corresponding to k in $\mathcal{D}'(B_R \times (0,T))$, where B_R is any ball in $\mathbb{R}^N$, for k large enough.

In this way, we have found for $2N/(N+2) \leq p < 2N/(N+1)$ a sequence of functions uniformly bounded from above by $\overline{S}$ and, by recurrence, bounded from below by $S \leq v_k$ in B_k. Thus, using the same arguments as those in the proof of Theorem 3.4, we can find a solution v of the Cauchy problem (1.1) as the limit of v_k as $k \to \infty$, where $\mu_{N,p} < \lambda$ and $2N/(N+2) \leq p < 2N/(N+1)$, with no finite time extinction, since the lower bounds for the approximate solutions v_k imply that $v \geq S$. □

5. Further results.

Let $\Omega \subset \mathbb{R}^N$ be a bounded domain and take $1 < p < 2$ and $p < N$. Consider the problem

$$\begin{cases} u_t - \Delta_p u = \lambda V(x) u^{p-1}, \quad x \in \Omega \subset \mathbb{R}^N,\ t > 0,\ \lambda > 0, \\ u(x,0) = u_0(x) \in L^2(\Omega), \qquad u_0(x) \geq 0, \\ u(x,t) = 0,\ x \in \partial\Omega,\ t > 0, \end{cases} \tag{5.1}$$

with $V \in L^q(\Omega)$, $q > 1$, and $V(x) \geq 0$. One can show the existence of a solution to (5.1) for λ small enough and q large enough, respectively, by means of the techniques used in section 3. This is a particular case of the following general problem:

$$\begin{cases} u_t - \Delta_p u = \lambda V(x) f(u), \quad x \in \Omega \subset \mathbb{R}^N,\ t > 0, \\ u(x,0) = u_0(x) \in L^2(\Omega), \quad u_0(x) \geq 0, \\ u(x,t) = 0,\ x \in \partial\Omega,\ t > 0, \end{cases} \tag{5.2}$$

where we are assuming that $f(\sigma)$ is a continuous nondecreasing function for $\sigma \geq 0$, $f(0) = 0$, and $f(\sigma) > 0$ for $\sigma \in (0, M]$. In some cases, we can show the existence of a solution to (5.2) (the proofs of the following results only deal with the main estimates needed to pass to the limit in the way shown in section 3).

5.1. Global existence with unbounded initial data.

THEOREM 5.1.

(A) *If there exists some $\eta \in [0,2]$ such that $V \in L^{2/(2-\eta)}(\Omega)$ and*

$$\frac{f(\sigma)}{\sigma^{\eta-1}} \to C \geq 0 \qquad \text{as } \sigma \to \infty$$

then there exists a global solution to (5.2) *such that*

$$u \in L^\infty_{loc}([0,\infty); L^2(\Omega)) \cap L^p_{loc}((0,\infty); W_0^{1,p}(\Omega)).$$

(B) *If $1 < p < 2N/(N+2)$, ($s = N(2-p)/p > 2$), $V \in L^{s/(2-\eta)}(\Omega)$ for some $\eta \in [0,2]$ and*

$$\frac{f(\sigma)}{\sigma^{\eta-1}} \to C \geq 0 \qquad \text{as } \sigma \to \infty,$$

then there exists a global solution to (5.2) *verifying*

$$u \in L^\infty_{loc}([0,\infty); L^s(\Omega)) \qquad u^{(p+s-2)/p} \in L^p_{loc}((0,\infty); W_0^{1,p}(\Omega)).$$

Proof. (A) Let u be a solution to problem (5.2). For $T > 0$, we get, using Hölder and Young inequalities and integrating in $[0, T]$,

$$\frac{1}{2}\int_\Omega u^2(x,T)\,dx + \int_0^T \int_\Omega |\nabla u(x,t)|^p\,dx\,dt$$
$$\leq \frac{1}{2}\int_\Omega u_0^2(x)\,dx + C_q T\int_\Omega V^q(x)\,dx + \int_0^T \int_\Omega (f(u(x,t))u(x,t))^{q'}\,dx\,dt.$$

By hypothesis, there exists some $\eta \in [0,2]$ such that $V \in L^q(\Omega)$, with $q = 2/(2-\eta)$; this implies that

$$\frac{(f(\sigma)\sigma)^{q'}}{\sigma^2} = \left(\frac{f(\sigma)}{\sigma^{(q-2)/q}}\right)^{q'} = \left(\frac{f(\sigma)}{\sigma^{\eta-1}}\right)^{q'} \to C \quad \text{ as } \sigma \to \infty.$$

Hence $(f(u)u)^{q'} \leq Cu^2$; in other words,

$$\begin{aligned}\frac{1}{2}\int_\Omega u^2(x,T)\,dx \quad &+ \quad \int_0^T \int_\Omega |\nabla u(x,t)|^p\,dx\,dt \\ &\leq \quad \frac{1}{2}\int_\Omega u_0^2(x)\,dx + C_q T\int_\Omega V^q(x)\,dx + C\int_0^T \int_\Omega u^2(x,t)\,dx\,dt.\end{aligned}$$

Gronwall inequality implies that

$$\int_\Omega u^2(x,T)dx \leq e^{CT}\int_\Omega (u_0^2(x) + C_q T V^q(x))\,dx\,dt.$$

That is, $u(\cdot,T) \in L^2(\Omega)$, and so $u \in L^\infty_{loc}([0,\infty); L^2(\Omega))$. Moreover, we also get

$$\int_0^T \int_\Omega |\nabla u(x,t)|^p\,dx\,dt < \infty;$$

hence $u \in L^p_{loc}([0,\infty) : W_0^{1,p}(\Omega))$.

(B) By multiplying the equations satisfied by the solutions u_n of the truncated problems corresponding to (5.2) (they are bounded by Lemma 2.1) by u_n^{s-1} and integrating in $[0, T]$ for $T > 0$ we have, using Hölder and Young inequalities,

$$\frac{1}{s}\int_\Omega u_n^s(x,T)\,dx + \frac{\mu_{N,p}}{\lambda_{N,p}}\int_0^T \int_\Omega |\nabla u_n^{(p+s-2)/p}(x,t)|^p\,dx\,dt$$
$$\leq \frac{1}{s}\int_\Omega u_0^s(x)\,dx + C_q T\int_\Omega V^q(x)\,dx + \int_0^T \int_\Omega (f(u(x,t))u_n^{s-1}(x,t))^{q'}\,dx\,dt.$$

By hypothesis, there exists some $\eta \in [0,2]$ such that $q = s/(2-\eta)$; this implies that

$$\frac{(f(\sigma)\sigma^{s-1})^{q'}}{\sigma^s} = \left(\frac{f(\sigma)}{\sigma^{(q-s)/q}}\right)^{q'} = \left(\frac{f(\sigma)}{\sigma^{\eta-1}}\right)^{q'} \to C \quad \text{ as } \sigma \to \infty.$$

Hence $(f(u_n)u_n^{s-1})^{q'} \leq Cu_n^s$; in other words,

$$\begin{aligned}\frac{1}{s}\int_\Omega u_n^s(x,T)\,dx \quad &+ \quad \frac{\mu_{N,p}}{\lambda_{N,p}}\int_0^T \int_\Omega |\nabla u_n^{(p+s-2)/p}(x,t)|^p\,dx\,dt \\ &\leq \quad \frac{1}{s}\int_\Omega u_0^s(x)\,dx + C_q T\int_\Omega V^q(x)\,dx + C\int_0^T \int_\Omega u_n^s(x,t)\,dx\,dt.\end{aligned}$$

Gronwall inequality implies that

$$\int_\Omega u_n^s(x,T)\,dx \le e^{CT}\int_\Omega (u_0^s(x)+C_qTV^q(x))\,dx.$$

That is, passing to the limit in the nondecreasing sequence u_n, we get $u(x,T)\in L^s(\Omega)$, and so $u\in L^\infty_{loc}([0,\infty);L^s(\Omega))$. On the other hand, we also have $u^{(p+s-2)/p}\in L^p_{loc}((0,\infty);W_0^{1,p}(\Omega))$. □

Remark 5.2. If $1<p<2N/(N+2)$, then there exists η such that $p<\eta<2$ and $2/(2-\eta)<N/p$. Therefore, Theorem 5.1 implies the existence of a global solution to (5.2) for supercritical V and superdiffusive η. □

5.2. Some remarks about uniqueness.

LEMMA 5.3. *Consider the problem*

$$\left\{\begin{array}{rcll} u_t-\Delta_p u &=& \lambda f(u), & x\in\Omega\subset\mathbb{R}^N,\ t>0,\\ u(x,0) &=& 0, & \\ u(x,t) &=& 0, & x\in\partial\Omega,\ t>0. \end{array}\right. \tag{5.3}$$

If there exists some η such that $1<p<\eta\le 2$ and

$$\frac{f(\sigma)}{\sigma^{\eta-1}}\to C \qquad \text{as } \sigma\to 0,$$

then the unique solution $u\in C([0,T];L^s(\Omega))\cap L^p([0,T],W_0^{1,p}(\Omega))$ is $u\equiv 0$, where $s=2$ if $2N/(N+2)\le p<2$ and $s=N(2-p)/p$ if $1<p<2N/(N+2)$.

Proof. The case $2N/(N+2)\le p<2$ was essentially covered in [12, Lemma 8.6].

If $1<p<2N/(N+2)$, we follow a similar argument multiplying the equation by u^{s-1}. Then

$$\frac1s\int_\Omega u^s(x,T)dx+\frac{\mu_{N,p}}{\lambda_{N,p}}\int_0^T\int_\Omega|\nabla u^{(p+s-2)/p}(x,t)|^p\,dx\,dt$$
$$=\lambda\int_0^T\int_\Omega f(u(x,t))u^{s-1}(x,t)\,dx\,dt.$$

By Sobolev, we get

$$\frac1s\int_\Omega u^s(x,T)\,dx+C_{N,p}\int_0^T\left(\int_\Omega u^s(x,t)\,dx\right)^{(N-p)/N}dt$$
$$\le\lambda\int_0^T\int_\Omega f(u(x,t))u^{s-1}(x,t)\,dx\,dt.$$

Calling now $y(t)\equiv(\int_\Omega u^s(x,t)\,dx)^{1/s}$, for $T>0$ small enough, we obtain

$$0\le y^s(T)\le\int_0^T(C_{|\Omega|}\lambda y^{\eta+s-2}(t)-C_{N,p}y^{p+s-2}(t))\,dt.$$

Since $\eta>p$, this implies that $y(T)\equiv 0$ for every $T>0$, that is, $u\equiv 0$, and hence the limit verifies $u\equiv 0$. □

With respect to the nonuniqueness, assume f is concave in $[0,M]$ with

$$\int_0^M\frac{d\sigma}{f^{-1}(\sigma)}<\infty.$$

It may be checked that, in these hypotheses, $h(\sigma) = \sigma/f(\sigma)$ is an increasing function and $h(\sigma) \to 0$ as $\sigma \to 0$. In addition, if $\mu = \mu(t)$ is given by

$$\int_0^{\mu} \frac{d\sigma}{f(\sigma)} = t, \qquad t \geq 0,$$

then μ is well-defined, it is continuous, and nonnegative in $[0, t_0]$, where

$$t_0 = \int_0^M \frac{d\sigma}{f(\sigma)}$$

and μ solves (see [11])

$$\begin{cases} \dfrac{d\mu}{dt} &= f(\mu), \qquad 0 \leq t \leq t_0, \\ \mu(0) &= 0. \end{cases}$$

Take λ_1, the first eigenvalue of $-\Delta_p$, in the bounded domain Ω with zero boundary data and the corresponding normalized eigenfunction $\phi_1 \leq 1$ (see [11]). Then we can show the following lemma.

LEMMA 5.4. *Consider the problem* (5.2) *where* $1 < p < 2$, $V \equiv 1$, $u_0 \equiv 0$. *If* f *is concave in* $[0, M]$ *with*

$$\int_0^M \frac{d\sigma}{f^{-1}(\sigma)} < \infty$$

and

$$\frac{\sigma^{p-1}}{f(\sigma)} = \frac{h(\sigma)}{\sigma^{2-p}} \to C \qquad as\ \sigma \to 0,$$

where $C \in [0, \lambda_1^{-1})$, *then there exists* $\tau > 0$ *such that the solution of* (5.2) *is not unique in* $0 \leq t \leq \tau$, $0 \leq u \leq M$.

Remark 5.5. For instance, we can apply Lemmas 5.3 and 5.4 to the following particular cases:

1. If $f(\sigma) = \lambda\sigma^{\eta-1}$, where $p < \eta \leq 2$, we have uniqueness.
2. If $f(\sigma) = \lambda\sigma^{\eta-1}$, where $1 < \eta < p$ or $f(\sigma) = \lambda\sigma^{p-1}$ with $\lambda > \lambda_1$, then we have nonuniqueness. □

It has to be noted that nonuniqueness for zero initial data implies nonexistence of finite time extinction for the solutions of the corresponding problems with nonnegative initial data (see next subsection).

5.3. Finite time extinction. If u is a solution of (5.1), using the Hölder inequality and following the proof of Proposition 4.1, we get

$$||u(x,T)||_2 \leq ||u_0||_2 \left(1 - \frac{(2-p)\gamma|\Omega|^{1-p/2-p/N}T}{||u_0||_2^{2-p}}\right)_+^{1/(2-p)}$$

for $2N/(N+2) \leq p < 2$, $q > N/p$, $\lambda < (C||V||_q)^{-1}$ and $\gamma = \gamma(N, p, \Omega, \lambda) > 0$. For instance, in the particular case $V(x) = |x|^{-\beta}$, we obtain the result for $\beta < p$.

On the other hand, let $\mu_{N,p}$, s be defined as in section 3.1. If $1 < p < 2N/(N+2)$ ($s > 2$), then we can multiply the equation in the truncated problem corresponding to (5.1) (see section 2) by u_n^{s-1}, where u_n is the weak solution of the truncated problem. Then we get, using again the Hölder inequality and following the proof of Proposition 4.2, since the supersolution ϕ_n introduced in section 2 does not depend on the potential V,

$$||u_n(x,T)||_s \leq ||u_0||_s \left(1 - \frac{(2-p)\gamma T}{||u_0||_s^{2-p}}\right)_+^{1/(2-p)},$$

where $\lambda < C_{N,p}||V||_q^{-1}$ (the smaller $||V||_q$ is, the larger the range for λ again), and γ depends on N, p, λ and $||V||_q$ with $q = N/p$. Therefore, we get the result for the solution u to (5.1) obtained as the limit of the nondecreasing sequence u_n.

In this way we can see that there exists a finite extinction time for the solutions of (5.1) if λ is small enough.

Now consider ϕ_1, a solution to the eigenvalue elliptic problem

$$\left\{ \begin{array}{rcll} -\Delta_p \phi_1 & = & \lambda_1 V(x)\phi_1^{p-1}, & x \in \Omega \subset \mathbb{R}^N, \\ \phi & = & 0, & x \in \partial\Omega, \end{array} \right. \tag{5.4}$$

where $V \in L^q(\Omega)$, with $q > N/p$, and λ_1 is the first eigenvalue for $-\Delta_p$ with the weight V in Ω and zero boundary data, that is,

$$\lambda_1 = \inf_{\phi \in W_0^{1,p}(\Omega)} \frac{\int_\Omega |\nabla\phi|^p}{\int_\Omega V(x)\phi^p}.$$

Then, multiplying the equation in (5.1) by u, we get, for $\lambda < \lambda_1$,

$$\frac{1}{2}\frac{d}{dt}||u(x,t)||_2^2 + \gamma \int_\Omega |\nabla u(x,t)|^p \, dx \leq 0$$

with $\gamma > 0$, so that we get again the estimate above for the finite extinction time of u if $2N/(N+2) \leq p < 2$ (cf. proof of Proposition 4.1).

If we multiply the equation satisfied by the weak solution u_n of the truncated problem corresponding to (5.1) by u_n^{s-1}, and $\lambda << \lambda_1$, there exists $\gamma > 0$ such that

$$\frac{1}{s}\frac{d}{dt}||u_n(x,t)||_s^s + \gamma \int_\Omega |\nabla u_n^{(p+s-2)/p}(x,t)|^p \, dx \leq 0,$$

and we obtain again finite time extinction for the solutions of (5.1) obtained as the limit of the sequence u_n, $1 < p < 2N/(N+2)$, independently on the domain (cf. proof of Proposition 4.2).

In particular, if we are dealing with $V \in L^q(\mathbb{R}^N)$, $q > N/p$, and $\lambda < \lambda_1 \mu_{N,p}/\lambda_{N,p}$, then there exists a finite extinction time for the solutions of the corresponding Cauchy problem which are obtained as the limit as $k \to \infty$ of the solutions u_k of the Dirichlet problems (5.1) on $\Omega = B_k$, the ball of radius k centered at the origin in $\mathbb{R}^N$.

However, if $\lambda > \lambda_1$, then any solution to (5.1) cannot have finite time extinction, since $w(x,t) = ct^{1/(2-p)}\phi_1(x)$ is a positive subsolution of (5.1), for c small enough (see proof of Proposition 4.8). Hence there is a gap for the values of λ (the interval $[\lambda_1 \mu_{N,p}/\lambda_{N,p}, \lambda_1]$) in which the question of the existence of a finite extinction time remains open.

Therefore we can summarize the results obtained in the following statement.

PROPOSITION 5.6. *If $1 < p < 2$ and u is a solution of* (5.1) *then there exists a finite time $T^\star$ depending only upon N, p, λ, u_0 and $||V||_q$ such that*

$$u(\cdot, t) \equiv 0 \qquad \forall t \geq T^\star.$$

Moreover,

$$0 < T^\star \leq \gamma_1 ||u_0||_2^{2-p} |\Omega|^{\frac{p}{2} + \frac{p}{N-1}},\ 2N/(N+2) \leq p < 2,\ q > N/p,\ \lambda < \lambda_1,$$

$$0 < T^\star \leq \gamma_2 ||u_0||_s^{2-p},\ 1 < p < 2N/(N+2),\ q > N/p,\ \lambda < \lambda_1 \frac{\mu_{N,p}}{\lambda_{N,p}},$$

$$0 < T^\star \leq \gamma_2 ||u_0||_s^{2-p},\ 1 < p < 2N/(N+2),\ q = N/p,\ \lambda < \gamma_{N,p}^{-\frac{(N-p)}{N}} ||V||_q^{-1} \frac{\mu_{N,p}}{\lambda_{N,p}},$$

where γ_1 and γ_2 are positive constants depending only upon N, p, λ and $||V||_q$. Note that $|x|^{-p} \in \cap L^q_{loc}(\mathbb{R}^N)$ for every $q < N/p$.

Remark 5.7. A similar result is obtained for a solution of (5.2) where the general nonlinearity $f(\sigma)$ verifies $f(\sigma) \leq C\sigma^{p-1}$, for $1 < p < 2$, namely, there exists a finite extinction time if

1. $\lambda < \lambda_1/C$ for $2N/(N+2) \leq p \leq 2$.
2. $\lambda < \lambda_1 \mu_{N,p}/(C\lambda_{N,p})$ for $1 < p \leq 2N/(N+2)$. □

IDENTIFICATION OF TWO-PHASE FREE BOUNDARY ARISING IN PLASMA PHYSICS[*]

JUNE-YUB LEE[†] AND JIN KEUN SEO[‡]

Abstract. We try to estimate the shape and the location of two-phase free boundary which has been studied in [A. Friedman and Y. Liu, *Ann. Scuola Norm. Sup. Pisa Cl. Sci.* (4), 22 (1995), pp. 375–448] to model a stationary magnetohydrodynamics system. A sufficient condition is obtained to check whether a test disk is included in the plasma region D surrounded by a two-phase free boundary. In the test disk technique, only two simply verifiable conditions are used and indispensableness of the conditions is demonstrated using an example. The technique is applicable to select some of test disks placed in the domain Ω, which gives a rough guess on the shape of plasma region. Next we draw some geometrical properties of plasma region D when the domain Ω possesses a kind of convexity. It is proved that if Ω itself contains the mirror image of the right portion $\{x \in \Omega : x \cdot \xi > t\}$ of the domain with respect to a line $\{x : x \cdot \xi = t\}$ for all $t > t_0$, then so does the plasma region.

Key words. two-phase free boundary, test disk technique, dumbbell shaped domain, moving plane method, symmetric convex domain

1. Introduction.

A two-phase free boundary problem is a mathematical model to find an interface between two disjoint domains on which solutions satisfy different types of governing equations. Such problems arise in various physical and engineering systems and an example we consider originates from a magnetohydrodynamics system which consists of vacuum and plasma region [6, 8]. During the last 20 years, significant progress in the study of free boundary problems has been made and many results regarding existence and regularity of the solutions have been obtained [2, 3, 4, 5]. However, information about global shape of the interfaces is more desired in many practical situations than regularity results.

Our main interest is to develop new techniques to estimate the size, the location, and some geometric properties of the region D surrounded by a two-phase free boundary. In particular, we consider a free boundary problem in a toroidally symmetric tokamak machine with two-dimensional cross section Ω. Not much has been known in this direction and many fundamental questions are still yet to be answered. For example, we still don't know whether D is convex provided Ω is convex. Though this particular question in the case of one-phase free boundary has been studied in several papers [1, 7, 10], the arguments cannot be directly applicable to our two-phase problem. Identifying the exact shape of the free boundary is not an easy task and it is partially due to the global dependency on the geometry of Ω and counterexamples of uniqueness of the plasma region.

We start with mathematical description of our free boundary problem and readers interested in the derivation of this problem and its physical meaning may consult our

previous paper [8], the paper by Friedman and Liu [6], and its references. Suppose Ω is a bounded domain in $\mathbf{R}^n$ with $\mathcal{C}^2$ boundary $\partial\Omega$ and c, μ are given positive and nonnegative constants, respectively. In [6], Friedman and Liu considered a free boundary problem to find a solution u, a positive constant λ, and an interface between the plasma region D and the vacuum region satisfying the following equations:

$$\Delta u = 0 \text{ in } \{x : u(x) > 0\} \ \text{ with } \ u|_{\partial\Omega} = c, \tag{1.1}$$

$$\Delta u + \lambda u = 0 \text{ in } \{x : u(x) \leq 0\} \ \text{ with } \int_{\{u\leq 0\}} u^2 = 1, \tag{1.2}$$

$$\left|\nabla u^+\right|^2 - \left|\nabla u^-\right|^2 = \mu^2 \text{ along the interface } \partial D, \tag{1.3}$$

where the plasma region D is the interior of the set $\{x \in \Omega : u(x) \leq 0\}$ and where ∇u^- and ∇u^+ denote the nontangential limits of ∇u from D and from the vacuum region $\Omega\backslash D$, respectively. It is proved that there exists a minimizer u_μ of the following minimizing problem:

$$\mathcal{M}_\mu^\Omega \left| \begin{array}{l} \text{Minimize} \quad J_\mu(u) := \int_\Omega |\nabla u|^2 dx - \mu^2 \left|\{x \in \Omega : u(x) \leq 0\}\right| \\ \text{within the class} \quad \mathcal{K} = \{u \in H^1(\Omega) \ : \ u|_{\partial\Omega} = c, \ \int_{\{u\leq 0\}} u^2 = 1\}, \end{array}\right.$$

where $|D|$ denotes Lebesgue measure of set D. It is also proved that the minimizer u_μ^Ω satisfies (1.1)–(1.3) and for $n = 2$ the boundary of the plasma region ∂D_μ^Ω is smooth. Throughout this paper, u_μ^Ω denotes a minimizer of $\mathcal{M}_\mu^\Omega$ and $D_\mu^\Omega = \mathit{interior}\{u_\mu^\Omega \leq 0\}$ denotes the corresponding plasma region. The subscript$_\mu$ or the superscript$^\Omega$ will be omitted when there is not confusion. Note that the plasma region D_μ^Ω is not a single valued function with respect to μ and Ω but depends on the choice of u_μ^Ω since there might exist many minimizers u_μ for given μ and Ω.

We present in Lemma 2.1 that $|D_\mu|$ increases as μ increases, regardless of the choices of u_μ, and the energy functional J_μ is differentiable almost everywhere as shown below,

$$J_\mu(u_\mu) := J_0(u_0) - \int_0^\mu 2\lambda |D_\lambda| d\lambda.$$

In order to investigate the location and the size of D_μ, it is natural to check if a test ball in the domain is included in D_μ. Our main result in Theorem 2.2 is about a sufficient condition for a ball B to be included in the plasma region D_μ. We state the theorem in two-dimensional case although the arguments could be easily extended on higher dimension provided that the free boundary is sufficiently smooth. Let B be an open disk contained in Ω of size large enough to satisfy $\frac{|\partial B|}{|B|} \leq \mu$. Suppose the solution h_B of the Dirichlet–Laplace problem, $\Delta h_B = 0$ in $\Omega \setminus B$ with the boundary data $h_B = 1$ on $\partial\Omega$ and $h_B = 0$ on ∂B, satisfies a testing condition

$$|\nabla h_B| \leq \mu \text{ on } \partial B;$$

then the test disk B is included in the plasma region D_μ

$$B \subset D_\mu.$$

Two brief comments can be made regarding the theorem. First, the theorem contains useful tools to guess the plasma region by placing many test disks on the domain and selecting some of them. Second, the size limit condition $\frac{|\partial B|}{|B|} \leq \mu$ in the theorem is indispensable and a theorem conjecture without this condition has a counterexample which is shown in Example 2.3.

In section 3, we investigate some geometrical properties of plasma region D^{Ω}. This kind of work is possible when there is some limitation on the domain Ω and two natural domain properties are maybe symmetry and convexity. Our previous paper [8] gives some results on symmetric convex domains. In order to improve such results, we introduce a new concept which is named mirror covering domain. A domain Ω is called a mirror covering domain with respect to a line $T_\xi(t_0)$ if Ω itself contains the mirror image of the right portion $\{x \in \Omega : x \cdot \xi > t\}$ of the domain with respect to a line $\{x : x \cdot \xi = t\}$ for all $t > t_0$. In Theorem 3.1, we obtain mirror image covering properties which says that if the domain Ω is a mirror covering domain with respect to $T_\xi(t_0)$, then so does the plasma region. Our previous result in [8] proves a similar theorem, that is, if Ω is symmetric and convex with respect to x_2-axis, then so is D_μ. Our new theorem significantly improves our old result and is also applicable to more general domains which need not to be symmetric. The proof of the theorem is based on the moving plane method which was used in the paper by J. Serrin [11] who deals with one-phase free boundary.

2. The size and the location of the plasma region. The problem $\mathcal{M}_\mu^\Omega$ might have more than one solution (see [8]) and, in such a case, u_μ denotes any possible minimizers and D_μ denotes corresponding plasma region.

LEMMA 2.1. *For $\mu_1 < \mu_2$, $J(\mu) := J_\mu(u_\mu)$ and the corresponding energy $\int_\Omega |\nabla u_\mu|^2$ satisfies the following inequalities:*

$$(\mu_2^2 - \mu_1^2)|D_{\mu_1}| < J(\mu_1) - J(\mu_2) < (\mu_2^2 - \mu_1^2)|D_{\mu_2}|, \tag{2.1}$$

$$\int_\Omega |\nabla u_{\mu_1}|^2 < \int_\Omega |\nabla u_{\mu_2}|^2, \tag{2.2}$$

and the energy functional J is uniquely characterized by

$$J(\mu) = J(0) - \int_0^\mu 2\lambda |D_\lambda| d\lambda. \tag{2.3}$$

Proof. It is obvious that $J_{\mu_2}(u_{\mu_1}) \neq J_{\mu_2}(u_{\mu_2})$. Suppose not; u_{μ_1} is also a minimizer of the problem $\mathcal{M}_{\mu_2}^\Omega$ and therefore from (1.3), u_{μ_1} has to satisfy

$$|\nabla u_{\mu_1}^+|^2 - |\nabla u_{\mu_1}^-|^2 = \mu_2^2 \quad \text{on } \partial D_{\mu_1},$$

which is a contradiction since a minimizer u_{μ_1} for $\mathcal{M}_{\mu_1}^\Omega$ has μ_1^2 gradient square jump. Similarly, $J_{\mu_1}(u_{\mu_1}) \neq J_{\mu_1}(u_{\mu_2})$. Since u_{μ_1} and u_{μ_2} are minimizers of $\mathcal{M}_{\mu_1}^\Omega$ and $\mathcal{M}_{\mu_2}^\Omega$, respectively,

$$J_{\mu_1}(u_{\mu_1}) < J_{\mu_1}(u_{\mu_2}) = J_{\mu_2}(u_{\mu_2}) + (\mu_2^2 - \mu_1^2)|D_{\mu_2}|, \tag{2.4}$$

$$J_{\mu_2}(u_{\mu_2}) < J_{\mu_2}(u_{\mu_1}) = J_{\mu_1}(u_{\mu_1}) - (\mu_2^2 - \mu_1^2)|D_{\mu_1}|. \tag{2.5}$$

These inequalities give the lower and the upper bounds of $J(\mu_1) - J(\mu_2)$ in (2.1) which states that $J(\mu)$ is monotone decreasing and Lipschitz continuous and D_μ is increasing with respect to μ. (Note: $|D_\mu|$ could depend on the choice of a minimizer.)

To prove (2.2), we rewrite (2.4) in terms of $\int_\Omega |\nabla u_{\mu_1}|^2$ and $\int_\Omega |\nabla u_{\mu_2}|^2$.

$$\int_\Omega |\nabla u_{\mu_1}|^2 - \mu_1^2 |D_{\mu_1}| < \int_\Omega |\nabla u_{\mu_2}|^2 - \mu_1^2 |D_{\mu_2}| \tag{2.6}$$

and $|D_{\mu_1}| < |D_{\mu_2}|$ proves (2.2).

Since $|D_\mu|$ is monotone increasing and $\lim_{\mu\to\infty} |D_\mu| = \Omega$, $|D_\mu|$ as a function of μ is continuous except on countably many points. Therefore, (2.1) proves that $J(\mu)$ is differentiable almost everywhere and $J(\mu) = J(0) - \int_0^\mu 2\lambda |D_\lambda| d\lambda$. □

We assume $c = 1$ and $n = 2$ for simplicity in the later part of the section. For a given open subset F of Ω with smooth boundary, let h_F be the solution of the Dirichlet problem

$$\begin{aligned} \Delta h_F = 0 \quad &\text{in} \quad \Omega \setminus \bar{F}, \\ h_F|_F \equiv 0\ , \quad &h_F|_{\partial\Omega} = 1, \end{aligned}$$

and $\lambda(F)$ be the smallest eigenvalue of Δ for the Dirichlet problem in the domain F.

THEOREM 2.2. *Let B be an open disk contained in Ω with $\frac{|\partial B|}{|B|} \le \mu$. Suppose that the harmonic function h_B satisfies the estimate*

$$|\nabla h_B^+| \le \mu \text{ on } \partial B,$$

where ∇h_B^+ denotes the gradient of h_B from the outside of B. Then

$$B \subset D_\mu.$$

Proof. For simplicity of the notation, let $u := u_\mu$ and $D := D_\mu$. To derive a contradiction, assume $D^* := D \cup B \neq D$. Let $\tilde{u}$ be a function defined as the normalized first eigenfunction of Δ with Dirichlet boundary condition in D^* and the harmonic function h_{D^*} in $\Omega \setminus \overline{D}^*$; then it satisfies

$$J_\mu(\tilde{u}) = J_\mu(h_{D^*}) + \lambda(D^*). \tag{2.7}$$

Therefore, the fact that u is a minimizer of J_μ leads

$$J_\mu(\tilde{u}) - J_\mu(u) = J_\mu(h_{D^*}) + \lambda(D^*) - J_\mu(h_D) - \lambda(D) \ge 0.$$

Since $\lambda(D^*) < \lambda(D)$,

$$J_\mu(h_{D^*}) - J_\mu(h_D) > 0. \tag{2.8}$$

On the other hand, it is easy to derive the following inequalities from the assumption $|\nabla h_B^+| \le \mu$ on ∂B using the maximum principle and the Hopf lemma,

$$|\nabla h_{D^*}^+| < \mu \quad \text{on } \partial B \cap \partial D^* \quad \text{and} \quad |\nabla h_{D^*}^+| < |\nabla u^+| \quad \text{on } \partial D \cap \partial D^*. \tag{2.9}$$

Using integration by parts over the region where u is harmonic,

$$\int_{\Omega\setminus\bar{D}} |\nabla u|^2 = \int_{\partial\Omega} \frac{\partial u}{\partial \nu} = \int_{\partial D} |\nabla u^+|, \tag{2.10}$$

where ν denotes the unit out normal vector to the boundary. Similarly, we obtain

$$\int_{\Omega\setminus\bar{D}^*} |\nabla h_{D^*}|^2 = \int_{\partial D^*} |\nabla h_{D^*}^+|. \tag{2.11}$$

Using (2.9), (2.10), and (2.11),

$$\begin{aligned}(2.12)\ & J_\mu(h_{D^*}) - J_\mu(h_D)\\ &= \int_{\partial D^*} |\nabla h_{D^*}^+| - \int_{\partial D} |\nabla u^+| + \mu^2|D| - \mu^2|D^*|\\ &= \int_{\partial D\cap\partial D^*} \left(|\nabla h_{D^*}^+| - |\nabla u^+|\right) + \int_{\partial B\setminus\bar{D}} |\nabla h_{D^*}^+| - \int_{\partial D\cap B} |\nabla u^+| - \mu^2|E|\\ &< \int_{\partial D\cap\partial D^*} \left(|\nabla h_{D^*}^+| - |\nabla u^+|\right) + \mu\left(|\partial B\setminus\bar{D}| - |\partial D\cap B| - \mu|E|\right)\\ &\le \mu\left(|\partial B\setminus\bar{D}| - |\partial D\cap B| - \mu|E|\right),\end{aligned}$$

where $E = B\setminus D \neq \emptyset$.

In order to derive a contradiction using (2.8) and (2.12), it suffices to prove the following inequality:

$$I := |\partial B\setminus\bar{D}| - |\partial D\cap B| - \mu|E| \le 0.$$

This quantity is purely geometric and we can, without loss of generality, assume that the arc $\Gamma = \partial B\setminus\bar{D}$ has only one connected component since we can estimate total I by adding the values of I for each components in the case of multicomponent Γ. For simplicity, we assume that B is centered at the origin with radius ρ and the arc Γ is in the range $\theta = 0$ and $\theta = \alpha$. Let $L(t,\theta)$ be the ray joining $(t\cos\theta, t\sin\theta)$ to $(\rho\cos\theta, \rho\sin\theta)$ and $r(\theta)$ be the smallest nonnegative number such that $L(t,\theta)$ does not intersect D for all $r(\theta) < t < \rho$. It is easy to see that the $(r(\theta)\cos\theta, r(\theta)\sin\theta)$ lies on the set $\partial D\cap B$ and

$$\begin{aligned}|\partial D\cap B| &\ge \int_0^\alpha r(\theta)d\theta,\\ |E| &\ge \int_0^\alpha \frac{1}{2}\left[\rho^2 - r^2(\theta)\right]d\theta.\end{aligned}$$

Therefore,

$$\begin{aligned}I &\le \alpha\rho - \int_0^\alpha r(\theta)d\theta - \mu\int_0^\alpha \frac{1}{2}\left[\rho^2 - r^2(\theta)\right]d\theta\\ &= \int_0^\alpha \left[\rho - r(\theta)\right]\left[1 - \mu\frac{\rho + r(\theta)}{2}\right]d\theta\\ &\le 0.\end{aligned}$$

The last inequality is true since the assumption $\frac{|\partial B|}{|B|} = \frac{2}{\rho} \le \mu$ implies $\frac{1}{2}\mu\rho \ge 1$. This completes the proof. □

In Theorem 2.2, the condition $\frac{|\partial B|}{|B|} \le \mu$ is quite unusual and one might think this condition should be removed. We will, however, show that the condition is indispensable in the theorem by constructing a disk B such that $B\cap D_\mu = \emptyset$ even though $|\nabla h_B| \le \mu$ on ∂B for given $\Omega, \mu = 1$. (μ is set to be 1 for simplicity of the description.)

Let u^Ω denote a minimizer of the problem $\mathcal{M}_\mu^\Omega$ as usual and let $\tilde{u}^\Omega$ denote a minimizer of the functional

$$(2.13)\qquad \tilde{J}^\Omega(\phi) = \int_\Omega |\nabla\phi|^2 - \mu^2|\{\phi = 0\}|$$

within the class $\tilde{\mathcal{K}} = \{\phi \in H^1(\Omega) : \phi = 1 \text{ on } \partial\Omega\}$. This new problem is identical to $\mathcal{M}_\mu^\Omega$ except that $\int_{\{u\leq 0\}} u^2 = 1$ condition is missing. Note that the solutions of these problems are known when Ω is a disk B_a of radius a. (Detailed computation can be found in [8].) In summary, the minimizers u^{B_a} and $\tilde{u}^{B_a}$ are positive outside of a disk of radius r_c and the corresponding energy functional values can be explicitly computed as follows:

$$J_{\mu=1}^{B_a}(u^{B_a}) = \inf_{0<r<a} \left(\frac{2\pi}{\log a/r} + \frac{\lambda(B_1)}{r^2} - \pi r^2 \right)$$

and

$$\tilde{J}_{\mu=1}^{B_a}(\tilde{u}^{B_a}) = \inf_{0<r<a} \left(\frac{2\pi}{\log a/r} - \pi r^2 \right).$$

For example, $J_1^{B_e} \approx 6.045$ with $r_c \approx 1.550$, $\tilde{J}_1^{B_e} = 0$ with $\tilde{u}^{B_e} \equiv 1$ for $a = e \approx 2.718$ and $J_1^{B_{2e}} \approx -30.989$ with $r_c \approx 4.315$, $\tilde{J}_1^{B_{2e}} \approx -31.300$ with $r_c \approx 4.311$ for $a = 2e \approx 5.437$.

Example 2.3. *Let Ω be a dumbbell shaped domain consists of two disks and a narrow connecting bridge:*

$$\Omega = B_L \cup B_R \cup T_\epsilon, \tag{2.14}$$

where $B_L = B_e(0,0)$ is a disk centered at the origin and of radius e, $B_R = B_{2e}(4e,0)$ of radius $2e$, and T_ϵ is a narrow bridge $\{(x_1,x_2) : e-\epsilon < x_1 < 2e+\epsilon, |x_2| < \epsilon\}$. If ϵ is sufficiently small, a test disk $B = B_1(0,0)$ satisfies

$$|\nabla h_B| \leq \mu = 1. \tag{2.15}$$

However, the intersection of the plasma region D_μ and the test disk B is empty

$$D_\mu \cap B = \emptyset. \tag{2.16}$$

Proof. It is easy to show that the gradient of h_B on ∂B is bounded by $\mu = 1$. Define $w(x) = \log|x|$ in $1 \leq |x| \leq e$. Then $\Delta w = 0$ in $B_L \backslash B$ and $w|_{\partial B_L} = 1, w|_{\partial B} = 0$. From the maximum principle, $h_B \leq w$ in $B_L \setminus \bar{B}$, therefore, $|\nabla h_B(x)| \leq |\nabla w(x)| = 1$ on $|x| = 1$ by the Hopf lemma. Hence the disk B satisfies the condition $|\nabla h_B| \leq \mu = 1$.

Next we want to show that B does not intersect with D_μ. Note that this may happen since one of two conditions in Theorem 2.2 is missing; $\frac{|\partial B|}{|B|} = 2 \not\leq \mu = 1$. For sufficiently small ϵ, it is possible to prove that

$$D_\mu \subseteq B_{e-\epsilon}(0,0) \cup B_{2e-\epsilon}(4e,0). \tag{2.17}$$

Here we will just give a brief sketch of the proof of (2.17). Suppose that there exists a point $p \in \partial D_\mu$ in the ϵ-neighborhood of $\partial\Omega$, *distance*$(p, \partial\Omega) \leq \epsilon$; then $|\nabla u_\mu^+(p)| > \frac{C}{\epsilon}$ for some fixed constant C and $|\nabla u_\mu^-(p)| > \frac{C}{\epsilon} - \mu^2$ from the interface condition (1.3). Therefore, for $\epsilon \leq \frac{C}{\mu^2}$, p must lie on the boundary of the negative part of the plasma region, $p \in \partial\{u_\mu < 0\}$. Recall that D_μ has exactly one connected negative set and the negative set has finite measure bounded below since the smallest eigenvalue of the Laplacian operator on the negative set is bounded, $\lambda(\{u_\mu < 0\}) < J^\Omega(\mu) + \mu^2|\Omega|$. So there exists a nonzero measure connected negative set near the ϵ-neighborhood of the boundary $\partial\Omega$. It draws a contradiction to the fact that $J^\Omega(\mu)$ is bounded since

$|\nabla u^+|$ is of order $\frac{1}{\epsilon}$ along the boundary of the negative set with nonzero length and the harmonic function defined on $\Omega \setminus \bar{D}$ generates unbounded energy near the point p as ϵ approaches 0.

Hence the plasma region D_μ is away from ϵ-neighbor of $\partial\Omega$, that is, $D_\mu = D_L \cup D_R$ where $D_L = D_\mu \cap B_L$ and $D_R = D_\mu \cap B_R$. Also, $u_\mu < 0$ on either D_L or D_R and $u_\mu \equiv 0$ in the other set, if it is not empty. Let u_μ^ϵ be defined as follows: $u_\mu^\epsilon = u_\mu$ in D_μ, $u_\mu^\epsilon = 1$ in $\Omega \setminus B_R \cup B_L$, and u_μ^ϵ is the harmonic function in $B_R \cup B_L \setminus D_\mu$ with boundary data $u_\mu^\epsilon = 1$ on $\partial(B_L \cup B_R)$ and $u_\mu^\epsilon = 0$ on ∂D_μ. Then the energy difference is quite small:

$$J_\mu^\Omega(u_\mu^\epsilon) = J_\mu^\Omega(u_\mu) + O(\epsilon) \tag{2.18}$$

and we can view $J_\mu^\Omega(u_\mu^\epsilon)$ as a sum of contributions from B_L and from B_R, separately. Two possible cases exist. First, B_L contains $u_\mu < 0$ set and B_R does not. Second, B_R does and B_L does not.

Case 1. $J_\mu^\Omega(u_\mu^\epsilon) \geq J_\mu^{B_L}(u_\mu^{B_L}) + \tilde{J}_\mu^{B_R}(\tilde{u}_\mu^{B_R}) \approx 6.045 - 31.300 = -25.255.$

Case 2. $J_\mu^\Omega(u_\mu^\epsilon) \geq \tilde{J}_\mu^{B_L}(\tilde{u}_\mu^{B_L}) + J_\mu^{B_R}(u_\mu^{B_R}) \approx 0.000 - 30.989 = -30.989.$

Since $J_\mu^\Omega(u_\mu^\epsilon) \geq J_\mu^\Omega(u_\mu) = J_\mu^\Omega(u_\mu^\epsilon) - O(\epsilon)$, we can conclude that the second case gives the minimal energy. Thus, $\{u_\mu < 0\} \subset B_R$ and

$$\tilde{J}_\mu^{B_L}(u_\mu) \leq O(\epsilon). \tag{2.19}$$

Now we want to prove $D_L = \emptyset$. At a glance over (2.19), one may guess that it must be $u_\mu \approx 1$ in B_L; however, there exists a counterexample of such a conclusion. To avoid such a mistake, the radius of B_L and μ should be taken into account. Suppose D_L is not an empty set; then $u_\mu \equiv 0$ in D_L and the interface condition (1.3) gives $|\nabla u_\mu| = \mu = 1$ on ∂D_L. Since $u_\mu = 1 + O(\epsilon)$ on ∂B_L, we have

$$\begin{aligned}
\tilde{J}_\mu^{B_L}(u_\mu) &= \int_{B_L} |\nabla u_\mu|^2 - |D_L| \\
&= \int_{\partial B_L} \frac{\partial u_\mu}{\partial \nu} u_\mu - |D_L| \\
&= \int_{\partial B_L} \frac{\partial u_\mu}{\partial \nu} - |D_L| + O(\epsilon) \\
&= \int_{\partial D_L} |\nabla u_\mu| - |D_L| + O(\epsilon) \\
&= |\partial D_L| - |D_L| + O(\epsilon).
\end{aligned}$$

Therefore it follows from (2.19) that

$$|\partial D_L| - |D_L| \leq O(\epsilon),$$

that is,

$$\frac{|\partial D_L|}{|D_L|} \leq 1 + O(\epsilon).$$

It follows from an elementary geometry that $|D_L| \geq 4\pi + O(\epsilon)$ to satisfy the above perimeter to area ratio. Let $r_0 = \sup\{|x| : x \in D_L\}$ and x_0 be a point on ∂D_L such that $|x_0| = r_0$. Then it must be $r_0 \geq 2 + O(\epsilon)$. Let H be the harmonic function in $B_L \setminus \bar{B}_{r_0}$ with the boundary condition $H = u_\mu$ on ∂B_L and $H = 0$ on ∂B_{r_0}. By maximum principle,

$$\begin{aligned} 1 = \mu = |\nabla u_\mu(x_0)| \geq |\nabla H(x_0)| &= \frac{1}{r_0(1-\log r_0)} + O(\epsilon) \\ &\geq \frac{1}{2(1-\log 2)} + O(\epsilon) > 1.629 + O(\epsilon), \end{aligned}$$

which is not possible. This proves $D_L = \emptyset$. □

This example shows that the condition $\frac{|\partial B|}{|B|} \leq \mu$ is indispensable in the disk covering theorem. D_μ can be exactly found if the disk covering technique method is able to check whether a point (or a disk with arbitrary small radius) is included inside of D_μ; however, this is not possible. As μ gets larger, the radius of the test disk can be chosen smaller, so the technique allows us to find a better approximation of the shape of the free boundary. It seems reasonable that detection of the interface with large jump of the normal derivatives along the interface is easier than that with small jump corresponding to small μ.

3. The mirror image covering properties.

In this section we want to find geometric properties of the plasma region D in some class of domains Ω. Our basic motivation is derived from the idea of the moving plane method used by Serrin [11]. We now introduce a new concept of mirror covering domain to describe our results. For a real number $t \in \mathbf{R}$ and a unit vector $\xi \in \mathbf{R}^2$, let us denote the hyperplane with normal vector ξ passing through $t\xi$ by $T_\xi(t) = \{x : x \cdot \xi = t\}$, the right-hand side portion of the domain by $\Sigma_\xi^\Omega(a) = \{x \in \Omega : x\cdot\xi > a\} = \Omega \cap \cup_{t>a} T_\xi(t)$, and the reflected image of $\Sigma_\xi^\Omega(a)$ with respect to $T_\xi(a)$ by $\tilde{\Sigma}_\xi^\Omega(a) = \{x' : x' = x + 2(\xi\cdot x - a)\xi, x \in \Sigma_\xi^\Omega(a)\}$. Then a domain Ω is called a mirror covering domain with respect to a line $T_\xi(t_0)$ if $\tilde{\Sigma}_\xi^\Omega(t) \subset \Omega$ for all $t > t_0$.

THEOREM 3.1. *For given $\mu \geq 0$, let u be a minimizer of $\mathcal{M}_\mu^\Omega$ and D be the corresponding plasma region. Suppose Ω is a mirror covering with respect to $T_\xi(a)$,*

$$\tilde{\Sigma}_\xi^\Omega(t) \subset \Omega \text{ for all } t > a. \tag{3.1}$$

Then so is the plasma region D,

$$\tilde{\Sigma}_\xi^D(a) \subset D. \tag{3.2}$$

Proof. Let

$$t_0 := \inf\{t \geq a : \tilde{\Sigma}_\xi^D(t) \subset D\}.$$

It suffices to prove $t_0 = a$. Suppose not, that is, $t_0 > a$. Then, as in the proof of Serrin [11], the following two events may occur: (i) $\tilde{\Sigma}_\xi^D(t_0)$ becomes internally tangent to the boundary of D at some point P not on $T_\xi(t_0)$. (ii) $T_\xi(t_0)$ is orthogonal to the boundary of D.

Let us introduce the reflected function v defined as follows:

$$v(x') := u(x) \quad \text{for } x' \in \tilde{\Sigma}_\xi^\Omega(t_0), \tag{3.3}$$

where x' is the reflected point of x across $T_\xi(t_0)$. Let $w := v - u$ in $\tilde{\Sigma}_\xi^\Omega(t_0)$. Then w satisfies

$$\begin{aligned}(\Delta+\lambda)w &= 0 \quad \text{in } \tilde{\Sigma}_\xi^D(t_0),\\ \Delta w &= 0 \quad \text{in } \tilde{\Sigma}_\xi^\Omega(t_0)\setminus \bar{D},\\ w &\geq 0 \quad \text{on } \partial\tilde{\Sigma}_\xi^D(t_0) \text{ and } \partial\tilde{\Sigma}_\xi^\Omega(t_0).\end{aligned}$$

Hence, using the monotonicity property of the first eigenvalue λ of the domain D and the maximum principle,

$$w > 0 \text{ in } \tilde{\Sigma}_\xi^D(t_0), \tag{3.4}$$

$$w > 0 \text{ in } \tilde{\Sigma}_\xi^\Omega(t_0)\setminus \bar{D}. \tag{3.5}$$

Using these inequality properties, we want to draw a contradiction to case (i) and case (ii), respectively. The proof is rather technical and the proof for the second case requires quite tedious computation.

Case (i). Since $w = 0$ at the contact point $P \in \partial\tilde{\Sigma}_\xi^D(t_0)$, by the Hopf lemma

$$\nabla w^+(P)\cdot\nu(P) > 0 \quad \text{and} \quad \nabla w^-(P)\cdot\nu(P) < 0,$$

where ∇w^+ and ∇w^- denote the gradients of w from outside and inside of $\tilde{\Sigma}_\xi^D(t_0)$, respectively, and $\nu(P)$ denotes the outer normal vector of $\partial\tilde{\Sigma}_\xi^D(t_0)$. Therefore,

$$|\nabla v^+(P)| = \nabla v^+(P)\cdot\nu(P) > \nabla u^+(P)\cdot\nu(P) = |\nabla u^+(P)|$$

and similarly,

$$|\nabla v^-(P)| < |\nabla u^-(P)|.$$

Hence by the inequalities above and the transmission condition (1.3) on the free boundary, we obtain a contradiction,

$$\mu^2 = |\nabla v^+(P)|^2 - |\nabla v^-(P)|^2 > |\nabla u^+(P)|^2 - |\nabla u^-(P)|^2 = \mu^2.$$

Case (ii). Let P be an orthogonal intersection point of $T_\xi(t_0)$ and D. We may assume $\nu(P) = e_2$ without loss of generality. Let $X_{\pm h} := P \pm he_1 + he_2$ and $Y_{\pm h} := P \pm he_1 - he_2$. For sufficiently small $h > 0$, $X_{\pm h}$ are in the vacuum region and $Y_{\pm h}$ are in the plasma region since the free boundary in two dimensions is smooth. Thus, we can derive two Taylor expansions for u near $X_{\pm h}$ and $Y_{\pm h}$, separately. Using the fact that u^+ is harmonic in $\Omega\setminus\overline{D}$,

$$\begin{aligned}u(X_{\pm h}) &= \partial_2 u^+(P)h \pm \partial_{12}u^+(P)h^2 + \frac{1}{2}(\partial_1^2+\partial_2^2)u^+(P)h^2 + O(h^3)\\ &= \partial_2 u^+(P)h \pm \partial_{12}u^+(P)h^2 + O(h^3).\end{aligned} \tag{3.6}$$

Similarly, since $\Delta u^- + \lambda u^- = 0$ in D, we obtain

$$\begin{aligned}u(Y_{\pm h}) &= -\partial_2 u^-(P)h \mp \partial_{12}u^-(P)h^2 + \frac{1}{2}(\partial_1^2+\partial_2^2)u^-(P)h^2 + O(h^3)\\ &= -\partial_2 u^-(P)h \mp \partial_{12}u^-(P)h^2 + O(h^3).\end{aligned} \tag{3.7}$$

The transmission condition (1.3) gives

$$(\partial_2 u^+(P))^2 - (\partial_2 u^-(P))^2 = \mu^2 \tag{3.8}$$

and

$$\partial_2 u^+(P)\partial_{12} u^+(P) = \partial_2 u^-(P)\partial_{12} u^-(P). \tag{3.9}$$

From (3.6), (3.7), (3.8), and (3.9), we obtain

$$|u(X_{\pm h})|^2 - |u(Y_{\pm h})|^2 = \mu^2 h^2 + O(h^4).$$

Therefore,

$$|u(X_h)|^2 - |u(Y_h)|^2 - (|u(X_{-h})|^2 - |u(Y_{-h})|^2) = O(h^4). \tag{3.10}$$

On the other hand, it follows from the maximum principle on w in (3.4), (3.5) that, for sufficiently small $h > 0$,

$$0 < |u(X_h)|^2 - |u(X_{-h})|^2 \quad \text{and} \quad 0 < |u(Y_{-h})|^2 - |u(Y_h)|^2. \tag{3.11}$$

Therefore, (3.10), (3.11) implies

$$|u(X_h)|^2 - |u(X_{-h})|^2 = O(h^4).$$

The same computation using (3.6) gives

$$|u(X_h)|^2 - |u(X_{-h})|^2 = 4h^3 \partial_2 u^+(P)\partial_{12} u^+(P) + O(h^4)$$

and we obtain $\partial_{12} u^+(P) = 0$ by comparing these two expressions. Therefore,

$$w(X_{-h}) = u(X_h) - u(X_{-h}) = O(h^3).$$

Hence, to derive a contradiction, it suffices to prove that

$$\lim_{h \to 0^+} \frac{w(X_{-h})}{h^{3-\delta}} = \infty \text{ for some } \delta > 0.$$

To do this, let us estimate w near P in a different way. We may assume $P = 0$ without loss of generality. Let us start with a truncated cone A with vertex P:

$$A := \left\{ (r, \theta) : 0 < r < r_0 \, , \; \frac{1.1}{2}\pi < \theta < \frac{1.9}{2}\pi \right\},$$

where $r_0 > 0$ is chosen so small that A is contained in $\tilde{\Sigma}^{\Omega}_{\xi}(t_0) \setminus \bar{D}$.

Define a bounded harmonic function ϕ on A as follows:

$$\phi(r, \theta) := r^{\frac{2}{0.8}} \sin\left(\frac{2}{0.8}\theta - \frac{1.1}{0.8}\pi \right).$$

Then

$$\phi(r, \frac{1.1}{2}\pi) = \phi(r, \frac{1.9}{2}\pi) = 0 \quad (0 < r < r_0).$$

Since $w > 0$ in $\tilde{\Sigma}_\xi^\Omega(t_0) \setminus \bar{D}$, $w > 0$ on $\partial A \setminus \{P\}$. Therefore, there is a positive constant C by the maximum principle so that

$$\phi(r,\theta) \leq Cw(r,\theta) \quad \text{ for all } x \in A.$$

Hence, if $0 < \delta < 3 - \frac{2}{0.8}$, then

$$\infty = \lim_{r \to 0} \frac{\phi(r,\theta)}{|r|^{3-\delta}} \leq C \lim_{r \to 0} \frac{w(r,\theta)}{|r|^{3-\delta}}.$$

This completes the proof. □

An open set Ω is said to be convex in ξ-direction if the intersection of Ω and any straight line with the direction ξ is an interval.

Corollary 3.2. *Let Ω be symmetric with respect to x_2-axis and convex in e_1-direction where e_i refers to a unit vector in the positive x_i direction. Then D is also symmetric with respect to x_2-axis and convex in e_1-direction.*

The mirror covering theorem tells us that the plasma region on each of two disks in a dumbbell shaped domain with thin and long connecting bridge is connected using mirrors passing the center points of the disks. However, the theorem does not tell us whether the number of plasma components is one or more. In fact, in some dumbbell shaped domain case presented in the paper [6], the plasma region consists of two or more components. Therefore, it is interesting to know the condition under which D is assured to be connected. We still do not know whether D is connected even in convex domain Ω; however, the following corollary provides a sufficient condition for a plasma region D to be connected.

Corollary 3.3. *Let B be a disk satisfying the requirements in Theorem* 2.2. *Suppose $\bigcup_{t>a} \tilde{\Sigma}_\xi^\Omega(t) \subset \Omega$ whenever $T_\xi(a)$ is a tangent line of ∂B. Then D is connected.*

GLOBAL CONTINUATION VIA HIGHER-GRADIENT REGULARIZATION AND SINGULAR LIMITS IN FORCED ONE-DIMENSIONAL PHASE TRANSITIONS*

TIMOTHY J. HEALEY† AND HANSJÖRG KIELHÖFER‡

Abstract. We consider a standard "higher-gradient" model for forced phase transitions in one-dimensional, shape-memory solids. We prescribe a parameter-dependent body forcing. The component of the potential energy corresponding to conventional elasticity is characterized by a nonconvex stored energy function of the strain. Our main goal is to show that global solution branches of the regularized problem converge to a global branch of weak solutions in the limit of vanishing "capillarity" (the coefficient of the higher-gradient term). The existence of global branches for the regularized, semilinear problem is routine, based upon the Leray–Schauder degree. In the physically meaningful case when the body force is everywhere nonnegative, we obtain uniform a priori bounds via a subtle maximum principle. This together with topological connectivity arguments yields the existence of global branches of weak solutions to the zero-capillarity problem. Moreover, by examining the singular limits of various supplementary conservation laws (satisfied by all solutions of the regularized problem), we show that the above-mentioned weak solutions also minimize the potential energy of the zero-capillarity problem.

1. Introduction.

Since the influential paper of Ericksen [13], the use of nonconvex stored energy functions in nonlinear elasticity as a model for martensitic phase transformations in solids is well known. In the context of one-dimensional problems, Ericksen constructed global energy minimizers possessing an arbitrary number of "phase boundaries," i.e., singular points of the associated Euler–Lagrange ordinary differential equation. In higher–dimensional models, the analogous stored energy function is allowed to violate rank-one convexity, i.e., the resulting Euler–Lagrange equations can lose ellipticity (e.g., cf. [5], [29]). Consequently, such problems are ostensibly beyond the reach of many well-known methods of nonlinear analysis—in particular, degree-theoretic methods.

Generalized degree-theoretic methods [19] were recently employed to obtain global continuation results in problems of three-dimensional nonlinear elastostatics [18]. However, the resulting solution continua are characterized not only by the usual two Rabinowitz alternatives [28], but also by the possibility that the solution branch may "terminate" due to loss of local injectivity, ellipticity, and/or the complementing condition (cf. [18, Theorem 4.1]). Physically meaningful constitutive hypotheses ruling out loss of local injectivity along global solution continua have been recently obtained in [17]. However, the potential loss of ellipticity and/or violation of the complementing condition are direct consequences of the construction of the degree. On the other

hand, explicit examples involving homogeneous families of deformations (e.g., cf. [6], [27]) suggest that solution continua do not terminate along solution branches at the first occurrence of loss of ellipticity or failure of the complementing condition. In other words, it should be possible to obtain global branches of genuinely weak solutions in boundary value problems of nonlinear elastostatics.

In recent years many investigators have returned to original ideas of Van Der Waals [33] and Cahn and Hilliard [9] for overcoming the difficulties associated with "sharp-interface" models (loss of ellipticity). Specifically, a small term, usually quadratic in the next highest gradient of the dependent variable, is added to the energy density, which penalizes the formation of interfaces. The resulting higher-order, semilinear Euler–Lagrange equations are nonsingular, and there are many examples in the literature demonstrating the smoothening effects of small "capillarity" (the strength of the penalty term); e.g., cf. [8], [23], [26], [31], [32]. A fruitful method of analysis in such models, usually in the absence of loading, combines singular-perturbation analysis with direct methods in the calculus of variations to obtain information about energy minimizers and minimizing sequences for vanishing capillarity; cf. [8], [22], [25].

In this work we propose a different method for such problems in the presence of loading, which is complementary to the above-mentioned approach, and which potentially addresses the limitations of the global results in [18]. Namely, for parameter-dependent problems, the semilinear Euler–Lagrange equations (for small capillarity) are amenable to standard global continuation methods; cf. [28]. Our idea is to analyze the global solution continuum in the limit of vanishing capillarity, with the ultimate goal of extracting (global branches of) weak solutions of the original, zero-capillarity problem. In some sense, this is tacitly carried out in [8], [26], [23], [32] for a one-dimensional Van Der Waals problem (Ericksen's model with capillarity), where the existence of one-parameter families of solutions is obtained via phase-plane analyses. Degree-theoretic continuation methods furnish a much more general and versatile approach to existence in such problems. Finally, we mention that existence results (via the phase plane) combined with direct methods in the calculus of variations provide very detailed results in [8].

In this paper we present a model problem for which we are able to carry out the above-mentioned program in detail. The outline of the work is as follows. In section 2 we formulate a one-dimensional problem, characterized by a nonconvex stored energy function and small capillarity and subjected to a one-parameter family of body forces, the presence of the latter of which rules out the possibility of a phase-plane analysis. We then perform a standard continuation analysis via the Leray–Schauder degree (cf. [28]) to obtain global branches of solutions.

In section 3 we make the physically reasonable assumption that the body force is everywhere nonnegative. For problems characterized by single-well stored energy functions (nonconvex, with one global minimum and no other local extrema), we then show that the global solution branch of section 2 is unbounded in the Cartesian product of parameter space and an appropriate function space. Moreover, from a subtle version of the maximum principle, we deduce that every nontrivial solution on the branch is a decreasing function on its domain $[0, 1]$, which in turn enables a uniform a priori bound. In section 4 we investigate problems incorporating a double-well stored energy function (nonconvex, with precisely two local minima and one local maximum). The approach of section 3 fails in this case, since we are not able to show that the branch is unbounded, with monotonicity properties of solutions possibly being lost.

Instead, we introduce another homotopy parameter, connecting a given single-well problem to a double-well problem. We then perform a delicate continuation analysis from the single-well problem, to obtain unbounded solution branches for the double-well problem. From here the maximum principle is again employed to show that the solutions are decreasing, and we obtain a uniform a priori bound on solutions.

In section 5 we study the singular limit of solutions for vanishing capillarity. Specifically, we fix the loading parameter and consider sequences of solutions as the small penalty term goes to zero. The uniform a priori bounds and the monotonicity properties obtained in sections 3 and 4 yield detailed pointwise convergence properties (via Helly's theorem [24]) from which we can extract weak solutions of the zero-capillarity problem. Any such limiting solution is shown to possess one discontinuity in strain for large enough loading. More surprisingly, we are also able to show that the first and second Erdmann–Weierstrass corner conditions [14] (which are necessary for a strong minimum of the potential energy) are fulfilled at such a discontinuity. Together these dictate that the jump in strain occurs in accordance with the Maxwell condition. The first corner condition follows from an easy argument. The proof for the second corner condition is much more delicate; we argue via pointwise convergence of two conservation laws (identities) that are satisfied by all classical solutions of the problem with nonzero capillarity. Finally, using topological tools introduced in [1], we show that the set of all such limiting solutions (letting the loading parameter vary) comprises an unbounded branch of weak solutions—thus going beyond the limitations of [18]—albeit in this one-dimensional setting.

In section 6 we specialize to the case of dead loading and consider the stability of the limiting solutions obtained in section 5 (i.e., energy minimization properties of solutions). In this case weak solutions satisfy an algebraic equation, and for sufficiently large loading, we are able to show that the limiting continuum contains truly weak solutions. A standard application of the relaxation theorem, combined with the Maxwell condition obtained in section 5, shows that for fixed loading, each such weak solution on the limiting curve is a global energy minimizer for the zero-capillarity problem. The stability of our solutions for small, nonzero capillarity is unclear. However, in the dead-load case one can obtain global energy minimizers to the small-capillarity problem directly and show by methods similar to those of sections 4 and 5 that sequences of such minimizers also converge to the global energy minimizer of the zero-capillarity problem; cf. [3]. Whence, for sufficiently small capillarity and fixed loading, solutions from our global continua are arbitrarily "close" to the global energy minimizer.

2. Global analysis of the regularized problem.

We consider the potential energy functional

$$V_\varepsilon(\lambda, u) \equiv \int_0^1 \left[\frac{\varepsilon}{2}(u'')^2 + W(u') + B(\lambda, u, x)\right] dx \tag{2.1}$$

associated with a one-dimensional elastic medium. Here $u(x) \in \mathbb{R}$ is the displacement of the material point $x \in [0, 1]$, B is the loading potential, W is the stored energy function of classical nonlinear elasticity, $\varepsilon > 0$ is the capillarity (or higher-gradient elasticity) coefficient, and $\lambda \in \mathbb{R}$ is a loading parameter. We impose zero displacement at $x = 0$:

$$u(0) = 0. \tag{2.2}$$

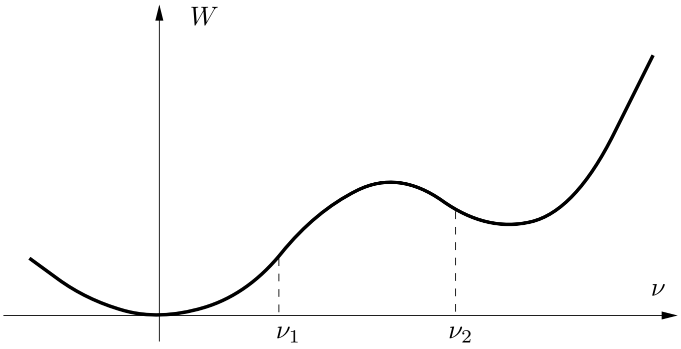

FIG. 2.1.

The Euler–Lagrange equation of equilibrium is

$$-\varepsilon u'''' + \frac{d}{dx}[W'(u')] + b(\lambda, u, x) = 0, \qquad 0 < x < 1, \tag{2.3}$$

with natural boundary conditions

$$u''(0) = u''(1) = 0, \qquad \varepsilon u'''(1) = W'(u'(1)), \tag{2.4}$$

where $b(\lambda, u, x) = -B_u(\lambda, u, x)$ is the "live" loading.

We assume that

$$\begin{aligned} &b \text{ is continuous, } b(0,\cdot,\cdot) \equiv 0,\\ &\text{and } W \text{ is of class } C^2 \text{ and nonconvex.}\end{aligned} \tag{2.5}$$

More precisely, we suppose that there are numbers $0 < \nu_1 < \nu_2$ such that

$$\begin{aligned} &W(\nu) \geq W(0) = 0 \qquad \text{for all } \nu \in \mathbb{R},\\ &\lim_{\nu\to\pm\infty} W(\nu) \to \infty,\\ &W'(0) = 0, \qquad W'(\nu) < 0, \qquad \nu \in (-\infty, 0),\\ &W''(\nu) > 0, \qquad \nu \in (-\infty, \nu_1) \cup (\nu_2, \infty),\\ &W''(\nu) < 0, \qquad \nu \in (\nu_1, \nu_2).\end{aligned} \tag{2.6}$$

A typical graph of W is depicted in Figure 2.1. We frequently denote the "stress" by $\sigma(\nu) \equiv W'(\nu)$. It is easy to see that our boundary value problem (2.2), (2.3), (2.4) is equivalent to

$$\begin{aligned} &u' = z,\\ &-\varepsilon z'' + \sigma(z) = \int_x^1 b(\lambda, u(\tau), \tau)d\tau, \qquad 0 < x < 1,\\ &u(0) = z'(0) = z'(1) = 0,\\ &\int_0^1 \sigma(z(x))dx = \int_0^1 \left[\int_x^1 b(\lambda, u(\tau), \tau)d\tau\right] dx.\end{aligned} \tag{2.7}$$

We now convert (2.7) into an operator form more convenient for global analysis.

We first define linear operators S, T as follows:

$$\begin{aligned}&w = Sf \quad \text{is the unique solution of}\\ &w' = f,\ 0 < x < 1,\ w(0) = 0\\ &\text{for } f \in C^0([0,1]).\end{aligned} \tag{2.8}$$

$$\begin{aligned}&v = Tg \quad \text{is the unique solution of}\\ &v'' = g,\ 0 < x < 1,\\ &v'(0) = v'(1) = 0, \qquad \int_0^1 v dx = 0 \quad \text{for } g \in \left\{ y \in C^0([0,1]) : \int_0^1 y dx = 0 \right\}.\end{aligned} \tag{2.9}$$

Then $S : Y \to X$ and $T : Y_1 \to Z$ are bounded, where Y, Y_1, X, Z denote the Banach spaces of continuous (continuously differentiable) functions $Y = C^0([0,1])$,

$$\begin{aligned}Y_1 &= \left\{ y \in C^0([0,1]) : \int_0^1 y dx = 0 \right\}, X = \{y \in C^1([0,1]) : y(0) = 0\},\\ Z &= \left\{ y \in C^2([0,1]) : y'(0) = y'(1) = 0, \int_0^1 y dx = 0 \right\},\end{aligned}$$

each of which is equipped with the usual supremum norm on $C^k([0,1]), k = 0, 1, 2$, denoted by $\| \cdot \|_\infty, \| \cdot \|_X, \| \cdot \|_Z$, respectively. We further define $Y_0 = \{y \in C^0[(0,1)] : y(0) = 0\}$ with norm $\| \cdot \|_\infty$.

Next we set

$$\mu = \int_0^1 z dx,\ v = z - \mu. \tag{2.10}$$

Finally we define the triple

$$\mathbf{w} \equiv (u, v, \mu) \in \mathcal{W} \equiv Y_0 \times Y_1 \times \mathbb{R}, \tag{2.11}$$

where $\mathcal{W}$ is endowed with the norm $\|\mathbf{w}\|_{\mathcal{W}} = \|u\|_\infty + \|v\|_\infty + |\mu|$. Then (2.7) is equivalent to

$$\mathbf{w} - H_\varepsilon(\lambda, \mathbf{w}) = \mathbf{0}, \tag{2.12}$$

where $H_\varepsilon : \mathbb{R} \times \mathcal{W} \to \mathcal{W}$ is defined by

$$\begin{aligned}H_\varepsilon(\lambda, \mathbf{w}) \equiv \Bigg(S(v + \mu), \frac{1}{\varepsilon}\, T \Bigg\{ &\sigma(v + \mu)\\ &- \int_x^1 b(\lambda, u, \tau) d\tau - \int_0^1 \left[\sigma(v + \mu) - \int_x^1 b(\lambda, u, \tau) d\tau \right] dx \Bigg\},\\ &\int_0^1 \left[\sigma(v + \mu) - \int_x^1 b(\lambda, u, \tau) d\tau \right] dx + \mu \Bigg).\end{aligned} \tag{2.13}$$

Since $S : Y \to Y_0$ and $T : Y_1 \to Y_1$ are compact, it readily follows that $\mathbf{w} \mapsto H_\varepsilon(\lambda, \mathbf{w})$ is compact.

From (2.5), (2.7)–(2.10), it is straightforward to verify that any solution $(\lambda, \mathbf{w}) =$

(λ, u, v, μ) delivers a classical solution $(\lambda, u, z) = (\lambda, u, v + \mu)$ of (2.7) and a classical solution (λ, u) of (2.2)–(2.4). Note that (2.7) and (2.10) give $\mu = u(1)$.

In view of (2.5), (2.6), we have

$$H_\varepsilon(0, \mathbf{0}) = \mathbf{0}, \tag{2.14}$$

and the Fréchet derivative of $\mathbf{w} \mapsto H_\varepsilon(\lambda, \mathbf{w})$ at $(0, \mathbf{0})$ is readily calculated:

$$D_{\mathbf{w}} H_\varepsilon(0, \mathbf{0})[\mathbf{h}] = \left(S(h_2 + h_3), \frac{1}{\varepsilon} W''(0) T h_2, (1 + W''(0)) h_3 \right) \tag{2.15}$$

for all $\mathbf{h} = (h_1, h_2, h_3) \in Y_0 \times Y_1 \times \mathbb{R}$. Using $W''(0) > 0$ (cf. (2.6)), it is easy to show that $[I - D_{\mathbf{w}} H_\varepsilon(0, \mathbf{0})] : \mathcal{W} \to \mathcal{W}$ is injective and thus bijective by the Riesz–Schauder theory (where "I" denotes the identity map).

Accordingly, from the implicit function theorem we have the following.

Proposition 2.1. *Equation* (2.12) *has a local curve of solutions*

$$(\lambda, \mathbf{w}) = (\lambda, \tilde{\mathbf{w}}(\lambda)), \qquad |\lambda| < \delta, \tag{2.16}$$

where $\tilde{\mathbf{w}}(0) = \mathbf{0}$. *Moreover,* (2.16) *yields all solutions of* (2.12) *in a sufficiently small neighborhood of* $(0, \mathbf{0})$.

The Leray–Schauder degree is well defined for $\mathbf{w} \mapsto \mathbf{w} - H_\varepsilon(\lambda, \mathbf{w})$, and from Proposition 2.1 we have

$$deg(I - H_\varepsilon(0, \cdot), B(\mathbf{0}), 0) = \pm 1, \tag{2.17}$$

where $B(\mathbf{0}) \subset \mathcal{W}$ denotes a sufficiently small ball centered at $\mathbf{w} = \mathbf{0}$.

A well-known argument [28], employing the homotopy invariance of the Leray–Schauder degree, yields the following.

Proposition 2.2. *Equation* (2.12) *admits a global branch of solution continua, denoted by* $\mathcal{C}_\varepsilon \subset \mathbb{R} \times \mathcal{W}$, *containing the local curve* (2.16) *and characterized by at least one of the following alternatives:*

(i) $\mathcal{C}_\varepsilon$ *is unbounded in* $\mathbb{R} \times \mathcal{W}$,

(ii) $\mathcal{C}_\varepsilon - \{(0, \mathbf{0})\}$ *is connected.*

Remark 2.3. *From* (2.5) *and* (2.7), *we note that our formulation* (2.12), (2.13) *implies* $\mathcal{C}_\varepsilon$ *is also a continuum in* $\mathbb{R} \times \tilde{Y}_o \times \tilde{Y}_1 \times \mathbb{R}$, *where* $\tilde{Y}_i = Y_i \cap C^1([0, 1])$, $i = 0, 1$, *each of which is endowed with the usual supremum norm on* $C^1([0, 1])$.

3. Detailed solution properties for single-well-potential problems.

The second alternative of Proposition (2.2) implies that problem (2.12) at $\lambda = 0$, viz., $\mathbf{w} = H_\varepsilon(0, \mathbf{w})$, admits at least one nontrivial solution $\mathbf{w} \neq \mathbf{0}$, which in turn, from (2.5), (2.9) means that the boundary value problem

$$\begin{aligned} \varepsilon z'' - \sigma(z) &= 0, \qquad 0 < x < 1, \\ z'(0) = z'(1) &= 0 \end{aligned} \tag{3.1}$$

has at least one solution $z \not\equiv 0$ in $[0, 1]$. However, if we assume that W is a *single-well potential*, i.e., in addition to (2.6), impose

$$\sigma(\nu) = W'(\nu) > 0, \qquad \nu \in (0, \infty), \tag{3.2}$$

then a standard phase-plane analysis shows that $z \equiv 0$ is the only solution of (3.1); cf. [8]. Accordingly, we have the following.

Proposition 3.1. *Under the additional hypothesis* (3.2), *the global continuum* $\mathcal{C}_\varepsilon$ *of Proposition* 2.2 *is characterized solely by alternative* (i), *i.e.*, $\mathcal{C}_\varepsilon$ *is unbounded. Moreover, if we define*

$$\mathcal{C}_\varepsilon^{+(-)} = \begin{array}{l}\textit{component of}\, \mathcal{C}_\varepsilon - \{(0,\mathbf{0})\},\\ \textit{containing}\, \{(\lambda, \tilde{\mathbf{w}}(\lambda)) : 0 < \lambda < \delta(-\delta < \lambda < 0)\},\end{array} \tag{3.3}$$

we then have the disjoint union $\mathcal{C}_\varepsilon = \mathcal{C}_\varepsilon^+ \cup \{(0,\mathbf{0})\} \cup \mathcal{C}_\varepsilon^-$, *where* $\mathcal{C}_\varepsilon^+$ *and* $\mathcal{C}_\varepsilon^-$ *are each unbounded in* $\mathbb{R} \times \mathcal{W}$.

Remark 3.2. *We suspend hypothesis* (3.2) *later in section* 4.

Next we define

$$P \equiv \{h \in C^1([0,1]) : h < 0 \text{ in } (0,1), h(0) = h(1) = 0,\ h'(0) < 0,\ h'(1) > 0\}. \tag{3.4}$$

Throughout the remainder of this work, we further assume that the body force satisfies the following physically realistic assumption (e.g., gravitation):

$$\begin{array}{ll} b(\lambda, u(x), x) \geq 0, \qquad 0 \leq x \leq 1, \qquad \text{and} \\ b(\lambda, \cdot) \not\equiv 0 \quad \text{for all } \lambda > 0, u \in Y_0. \end{array} \tag{3.5}$$

We then obtain the following.

Theorem 3.3. *Under the hypotheses of section* 1 *and the additional assumptions* (3.2) *and* (3.5), *it follows that* $(\lambda, u, v, \mu) \in \mathcal{C}_\varepsilon^+$ *implies*

$$z' = v' \in P.$$

Proof. First we show that $\frac{d}{dx}\tilde{z}(\lambda) = \frac{d}{dx}(\tilde{v}(\lambda) + \tilde{\mu}(\lambda)) \in P$ for all $0 < \lambda < \delta$, for δ sufficiently small; cf. (2.16) and (3.3). Indeed, for $0 < \lambda < \delta$, we have $\|\tilde{z}(\lambda)\|_\infty \leq \|\tilde{v}(\lambda)\|_\infty + |\tilde{\mu}(\lambda)| < \gamma(\delta)$, with $\gamma(\delta) \searrow 0$ as $\delta \searrow 0$. Hence, from $(2.6)_4$ we find

$$\sigma'(\tilde{z}(\lambda)) = W''(\tilde{z}(\lambda)) > 0 \quad \text{for all } x \in [0,1], \tag{3.6}$$

with δ sufficiently small. Differentiation of $(2.7)_2$ and $(2.7)_3$ shows that $h = \frac{d}{dx}\tilde{z}(\lambda)$ is a solution of

$$\begin{aligned} \varepsilon h'' - [\sigma'(\tilde{z}(\lambda))]h &= b(\lambda, \tilde{u}(\lambda), \cdot), \qquad 0 < x < 1, \\ h(0) = h(1) &= 0. \end{aligned}$$

In view of (3.5), (3.6), and the maximum principle, we conclude that $\frac{d}{dx}\tilde{z}(\lambda) \in P$ for all $0 < \lambda < \delta$.

Since P is open in $C^1([0,1])$, and $\frac{d}{dx}\tilde{z}(\lambda) \in P$, $0 < \lambda < \delta$, it follows that if $z' = v' \notin P$ for $(\lambda, u, v, \mu) \in \mathcal{C}_\varepsilon^+$, then there is a sequence $\{(\lambda_j, u_j, v_j, \mu_j)\} \subset \mathcal{C}_\varepsilon^+$ such that $(\lambda_j, u_j, v_j, \mu_j) \to (\lambda, u, v, \mu)$ in $\mathbb{R} \times \tilde{Y}_0 \times \tilde{Y}_1 \times \mathbb{R}$ (cf. Remark 2.3), with $z_j' = v_j' \in P$ and $z' = v' \in \partial P$, i.e.,

$$z' \leq 0 \text{ in } (0,1) \text{ and/or } z''(0) = 0 \text{ and/or } \ z''(1) = 0. \tag{3.7}$$

But again by (2.7), we see that $h = z'$ is a solution of

$$\begin{array}{c} \varepsilon h'' - [\sigma'(z)]^+ h = b(\lambda, u, \cdot) + [\sigma'(z)]^- z', \qquad 0 < x < 1, \\ h(0) = h(1) = 0, \end{array} \tag{3.8}$$

where for any continuous function $p(x)$ on $[0,1]$,

$$p(x)^{+(-)} \equiv \begin{cases} p(x) & \text{for all } x \in [0,1] \text{ such that } p(x) \geq (\leq)\, 0, \\ 0 & \text{otherwise.} \end{cases}$$

In particular, the right-hand side of (3.8) is nonnegative and does not vanish identically; cf. (3.5), (3.7). Accordingly, (3.7) contradicts the maximum principle ($z' \equiv 0$ is not possible, due to (3.5)), and thus $z' \in P$. □

With Theorem 3.3 in hand, we can now obtain an a priori bound on $\mathcal{C}_\varepsilon^+$ that is crucial to our forthcoming limit analysis in section 5, provided that we make a final assumption on the loading:

$$b(\lambda, u(x), x) \leq \tilde{b}(\lambda, x) \tag{3.9}$$

for all $\lambda > 0, u \in Y_0$, where $\tilde{b}$ is some continuous, nonnegative function; cf. (3.5).

Remark 3.4. *Note that* (3.9) *is automatic in the case of "dead loading," i.e., when b is independent of u. We return to this special case in section* 6.

Theorem 3.5. *Given the hypotheses of Theorem* 3.3 *and assumption* (3.9)*, then for any* $(\lambda, u, v, \mu) \in \mathcal{C}_\varepsilon^+$, *with* $z = v+\mu$, *there is a positive constant* $M(\lambda)$, *independent of* ε, *such that*

$$\|z\|_\infty \leq M(\lambda), \tag{3.10}$$

where $M(\lambda)$ *depends upon* λ *through* $F(\lambda) = \int_0^1 \tilde{b}(\lambda, x)dx$ *and the graph of* $\sigma = W'$. *Moreover,*

$$\|u\|_{C^1([0,1])} \leq 2M(\lambda). \tag{3.11}$$

Accordingly, the projection of $\mathcal{C}_\varepsilon^+$ *on the* λ*-axis is* $(0, \infty)$, *i.e.,* (2.12) *(and thus,* (2.2)–(2.4) *or* (2.7)*) has at least one solution for each* $\lambda \in (0, \infty)$.

Proof. From (2.4), (2.7), and Theorem 3.3, we see that

$$\begin{aligned} &z' < 0, \qquad 0 < x < 1, \\ &\sigma(z(1)) = \varepsilon z''(1) > 0, \\ &-\varepsilon z''(0) > 0. \end{aligned} \tag{3.12}$$

In view of (2.6) and (3.2), a typical graph of σ is depicted in Figure 3.1. In particular, $(3.12)_2$ implies that $z(1) > 0$, and thus $(3.12)_1$ yields

$$\|z\|_\infty = z(0). \tag{3.13}$$

Finally, $(2.7)_2$ combined with (3.9) and $(3.12)_3$ gives

$$\sigma(z(0)) < \int_0^1 b(\lambda, u(x), x)dx \leq \int_0^1 \tilde{b}(\lambda, x)dx = F(\lambda), \tag{3.14}$$

where $F(\lambda) > 0$. Then (3.10) follows from (3.13) and (3.14) with $M(\lambda) \equiv \max\{\nu : \sigma(\nu) = F(\lambda)\}$; cf, Figure 3.1. Inequality (3.11) is an easy consequence of $(2.7)_1$, $(2.7)_3$, and (3.10). From the development above, we have $z > 0$ and monotone decreasing on $[0,1]$. Then by virtue of (2.10) and (3.13), we see that the positive numbers $v(0)$, $|v(1)|$ and μ are each bounded above by $\|z\|_\infty$. Thus, by (2.7) and (3.10), we conclude

$$\|\mathbf{w}\|_{\mathcal{W}} = \|u\|_\infty + \|v\|_\infty + |\mu| \leq 3M(\lambda), \tag{3.15}$$

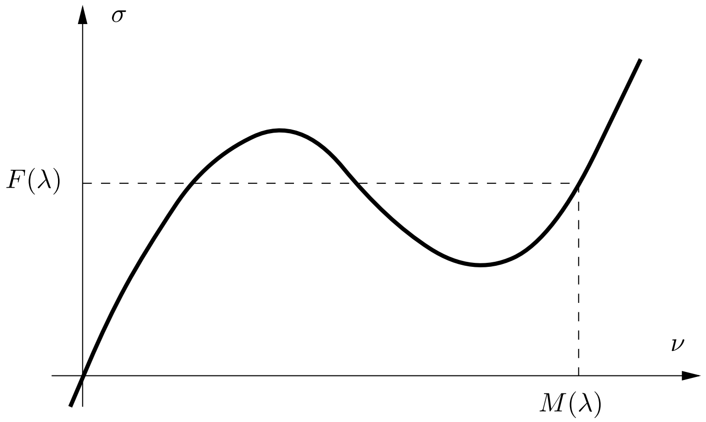

Fig. 3.1.

for all $(\lambda, \mathbf{w}) \in \mathcal{C}_\varepsilon^+$. Since $\mathcal{C}_\varepsilon^+$ is unbounded, the last claim follows directly from (3.15). □

Remark 3.6. *Note that* $b(0,\cdot,\cdot) \equiv 0$ *implies* $M(0) = 0$, *which is consistent with the fact that* $z \equiv 0$ *is the only solution of* (3.1).

4. Detailed solution properties for double-well-potential problems. In the absence of assumption (3.2), in which case we call $W(\nu)$ a *double-well potential* (cf. Figure 2.1), we cannot directly obtain Theorems 3.3 and 3.5 as in section 3. Indeed, without (3.2), we do not have Proposition 3.1, in which case the solution continuum $\mathcal{C}_\varepsilon$ could form a bounded "loop," cf. Proposition 2.2 (ii). Moreover, $\mathcal{C}_\varepsilon^+$ (cf. (3.3)) may have components in the "half-space" $(-\infty, 0) \times \mathcal{W}$. Thus the positivity of b could be lost (cf. (3.5)), in which case the maximum principle arguments in the proof of Theorem 3.3 fail. Of course the results of Theorem 3.3 and Theorem 3.5 still hold along part of $\mathcal{C}_\varepsilon^+$, which we record now for convenience. Define $\mathcal{L}_\varepsilon^+ \subset \mathcal{C}_\varepsilon^+ \cap ((0,\infty) \times \mathcal{W})$ to be the connected subset such that $\overline{\mathcal{L}_\varepsilon^+}$ contains the point $(\lambda, \mathbf{w}) = (0, \mathbf{0})$. We then have the following.

Corollary 4.1. *Assume that* $W(\nu)$ *is a double-well potential (i.e., suspend assumption* (3.2)*). Then the results of Theorem* 3.3 *and Theorem* 3.5 *hold for all* $(\lambda, \mathbf{w}) \in \mathcal{L}_\varepsilon^+$.

Remark 4.2. *Returning to the proof of Theorem* 3.5, *note that in this case the graph of* $\sigma = W'$ *intersects the positive* ν*-axis; cf. Figure* 4.1. *Whence,* $M(0) > 0$ *for double-well potentials; in particular,* (3.1) *has more than one constant solution. Consequently,* $\mathcal{L}_\varepsilon^+$ *could be bounded. Thus, in contrast to the results of section* 3, *we do not yet know if problem* (2.7) *has a solution for a given* $\lambda > 0$ *when* $W(\nu)$ *is a two-well potential; cf.* Theorem 3.5.

In the remainder of this section we establish the existence of an unbounded solution set for (2.7) $(\lambda > 0)$, with properties similar to those given in Theorems 3.3 and 3.5, in the absence of assumption (3.2). To begin, let $W_1(\nu)$ be a potential satisfying (2.6) and (3.2), while $W_2(\nu)$ is another potential that satisfies conditions (2.6) but not (3.2); i.e., $W_1(\nu)$ has a "single well," while $W_2(\nu)$ has a "double well." We then define the homotopy

$$\tilde{W}(\nu, \tau) \equiv (1-\tau)W_1(\nu) + \tau W_2(\nu), \qquad 0 \le \tau \le 1. \tag{4.1}$$

The basic idea is to substitute $\tilde{W}(\nu, \tau)$ into our formulation from section 2. At $\tau = 0$,

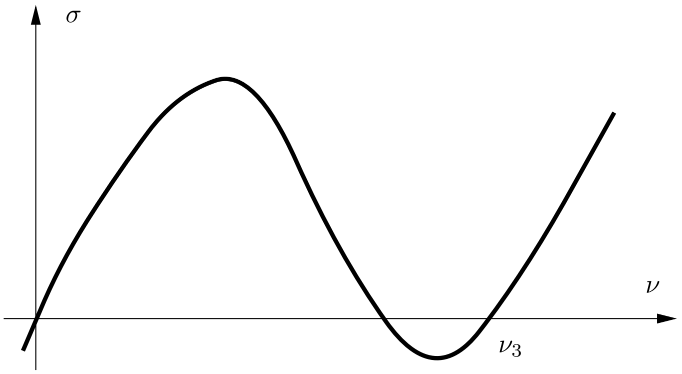

FIG. 4.1.

we then have the results of section 3; we now show that continuation in "τ" yields solutions with similar properties at $\tau = 1$.

Substitution of $\tilde{\sigma}(\nu, \tau) = \tilde{W}_\nu(\nu, \tau)$ into (2.12), (2.13) yields a two-parameter problem, which we henceforth denote by

$$\mathbf{w} - \tilde{H}_\varepsilon(\tau, \lambda, \mathbf{w}) = 0, \tag{4.2}$$

where $\tilde{H}_\varepsilon : \mathbb{R} \times \mathbb{R} \times \mathcal{W} \to \mathcal{W}$; cf. (2.11). Clearly

$$\tilde{H}_\varepsilon(0, \lambda, \mathbf{w}) \equiv H_\varepsilon(\lambda, \mathbf{w}), \tag{4.3}$$

(cf. (2.13), (4.1)), while (4.3) at $\tau = 1$ represents a given two-well-potential problem, solutions of which we hope to construct.

First we define a continuous mapping $\hat{H}_\varepsilon : \mathbb{R} \times \mathcal{W} \to \mathcal{W}$, as follows:

$$\hat{H}_\varepsilon(\theta, \mathbf{w}) \equiv \begin{cases} \tilde{H}_\varepsilon(0, \theta, \mathbf{w}), & \theta \le \lambda_0, \\ \tilde{H}_\varepsilon(\theta - \lambda_0, \lambda_0, \mathbf{w}), & \lambda_0 \le \theta \le \lambda_0 + 1, \\ \tilde{H}_\varepsilon(1, \theta - 1, \mathbf{w}), & \theta \ge \lambda_0 + 1, \end{cases} \tag{4.4}$$

where $\lambda_0 > 0$ is fixed. We then consider the problem

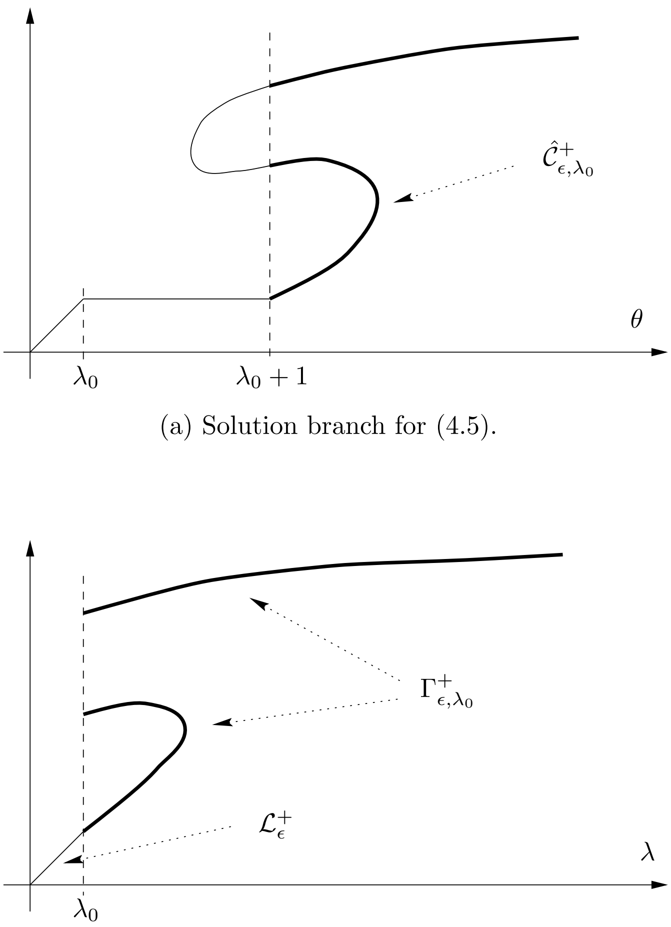
$$\mathbf{w} - \hat{H}_\varepsilon(\theta, \mathbf{w}) = \mathbf{0}. \tag{4.5}$$

It is easy to check that the mapping $\hat{H}_\varepsilon$ and problem (4.5) fulfill the hypotheses of Propositions 2.2 and 3.1. Accordingly, we have the following.

PROPOSITION 4.3. *Equation* (4.5) *admits an unbounded branch of solutions containing the point* $(0, \mathbf{0})$, *denoted* $\hat{\mathcal{C}}_{\varepsilon,\lambda_0} \subset \mathbb{R} \times \mathcal{W}$. *In addition, if we define* $\hat{\mathcal{C}}^{+(-)}_{\varepsilon,\lambda_0}$ *as in* (3.3), *then we have the disjoint union* $\hat{\mathcal{C}}_{\varepsilon,\lambda_0} = \hat{\mathcal{C}}^{+}_{\varepsilon,\lambda_0} \cup \{(0, \mathbf{0})\} \cup \hat{\mathcal{C}}^{-}_{\varepsilon,\lambda_0}$, *where* $\hat{\mathcal{C}}^{+}_{\varepsilon,\lambda_0}$ *and* $\hat{\mathcal{C}}^{-}_{\varepsilon,\lambda_0}$ *are each unbounded.*

Next we continue to retrace our steps from section 3.

THEOREM 4.4. *Given assumptions* (3.2) *(for* $\tilde{W}_\nu(\nu, 0) = \tilde{\sigma}(\nu, 0)$*) and* (3.5), *it follows that* $(\theta, u, v, \mu) \in \hat{\mathcal{C}}^{+}_{\varepsilon,\lambda_0}$, *with* $z = v + \mu$, *implies* $z' = v' \in P$; *cf.* (3.4). *Moreover, we again have uniform (independent of* ε*) bounds*



(a) Solution branch for (4.5).

(b) Solution branch for (4.2) at $\tau = 1$.

FIG. 4.2.

$$\begin{aligned} &\|z\|_\infty \leq M(\lambda) \\ (4.6) \qquad &\textit{and} \\ &\|u\|_{C^1([0,1])} \leq 2M(\lambda), \end{aligned}$$

where $M(\lambda)$ *is defined as in the proof of Theorem* 3.5 *for* $0 < \lambda = \theta \leq \lambda_0$ *(with* $\tau = 0$*) and also for* $\lambda = \theta - 1 \geq \lambda_0$ *(with* $\tau = 1$*). For* $\lambda = \lambda_0$*, and* $\lambda_0 \leq \theta \leq \lambda_0 + 1$*,* M *depends upon* θ *via*

$$M(\theta) = \max_\nu \{\nu : \tilde{\sigma}(\nu, \theta - \lambda_0) = F(\lambda_0)\}, \qquad \textit{where } F(\lambda) \textit{ is as defined in } (3.14).$$

Proof. The proof is identical to the combined proofs of Theorem 3.3 and 3.5, except that the analogue of (3.14) now reads

$$\begin{array}{ll} \sigma(z(0), 0) < F(\lambda), & 0 < \lambda = \theta \leq \lambda_0, \\ \sigma(z(0), \theta - \lambda_0) < F(\lambda_0), & \lambda_0 \leq \theta \leq \lambda_0 + 1, \\ \sigma(z(0), 1) < F(\lambda), & \lambda = \theta - 1 \geq \lambda_0. \end{array}$$

Estimates (4.6) then follow as before from the graph of $\tilde{\sigma}$; cf. Figure 3.1. $\square$

By construction, the solution sets

$$\Gamma^-_{\varepsilon,\lambda_0} \equiv \hat{\mathcal{C}}_{\varepsilon,\lambda_0} \cap ((-\infty,\lambda_0] \times \mathcal{W}) \equiv \mathcal{C}_\varepsilon \cap ((-\infty,\lambda_0] \times \mathcal{W})$$

and

$$\Gamma^+_{\varepsilon,\lambda_0} \equiv \hat{\mathcal{C}}^+_{\varepsilon,\lambda_0} \cap ([\lambda_0+1,\infty) \times \mathcal{W}), \tag{4.7}$$

which solve (4.2) at $\tau = 0$ and at $\tau = 1$, respectively, are unbounded. In particular, the estimates (4.6) insure that the double-well problem ($\tau = 1$) has at least one solution for every value of $\lambda \geq \lambda_0$.

REMARK 4.5. $\Gamma^+_{\varepsilon,\lambda_0}$ *need not be a continuum; it could comprise a union of disjoint continua. To see this, suppose that* $\mathcal{L}^+_\varepsilon$ *is bounded, and choose* $\lambda_0 > 0$ *sufficiently small. An easy argument via the implicit function theorem shows that* $\mathcal{L}^+_\varepsilon \cap ([\lambda_0,\infty) \times \mathcal{W}) \subset \Gamma^+_{\varepsilon,\lambda_0}$. *Since* $\Gamma^+_{\varepsilon,\lambda_0}$ *is unbounded, it must have an unbounded disjoint component. We illustrate this schematically in Figure* 4.2.

5. Singular limit analysis. In this section we demonstrate that the classical solutions of (2.2)–(2.4) ($\varepsilon > 0$) obtained in the previous sections converge to a global continuum of weak solutions of (2.3) ($\varepsilon = 0$) in the limit as $\varepsilon \searrow 0$. For the one-well problem of section 3, we fix $\lambda \in (0,\infty)$ with $\varepsilon = \varepsilon_k$, $\varepsilon_k \searrow 0$, we denote a classical solution of (2.2)–(2.4) from $\mathcal{C}^+_{\varepsilon_k}$ by u_k, and we consider sequences $\{u_k\} \subset C^1([0,1])$ and $\{z_k\} = \{u_k'\} \subset C^0([0,1])$. For double-well problems (cf. section 4), we fix $\theta \in (0,\infty)$ and consider sequences of solutions from $\hat{\mathcal{C}}^+_{\varepsilon_k,\lambda_0}$ as above.

By virtue of either (3.10), (3.11), or (4.6), we have the uniform bounds

$$\begin{aligned} \|z_k\|_\infty &\leq M(\lambda) \\ &\text{and} \\ \|u_k\|_{C^1([0,1])} &\leq 2M(\lambda) \quad \text{for all } k \in \mathbb{N}. \end{aligned} \tag{5.1}$$

From the latter and compact embedding, we conclude immediately that

$$u_k \to u_* \quad \text{in} \qquad C^0([0,1]). \tag{5.2}$$

In addition to $(5.1)_1$, we have from either Theorem 3.3 or Theorem 4.4 the monotonicity property

$$z_k' < 0, \qquad 0 < x < 1 \quad \text{for all } k \in \mathbb{N}. \tag{5.3}$$

By Helly's (selection principle) theorem (cf. [24, section 24]), it then follows that $\{z_k\}$ has a subsequence that converges pointwise on $[0,1]$ to a nonincreasing function, denoted

$$z_k \to z_*, \tag{5.4}$$

where z_* has at most a countable number of discontinuities on $[0,1]$. Moreover, by Lebesgue's differentiation theorem [30], it follows that z_* possesses a classical derivative almost everywhere (a.e.); in particular

$$z_*' \leq 0 \quad \text{a.e. in} \quad [0,1]. \tag{5.5}$$

We also note from (2.7), (5.1), and Lebesgue's dominated convergence theorem that

$$\begin{aligned} u_*(x) &= \int_0^x z_*(\tau)d\tau, \qquad \text{and hence} \\ u_*' &= \ z_* \quad \text{a.e.} \end{aligned} \tag{5.6}$$

Next we show that u_* satisfies (2.3) with $\varepsilon = 0$.

THEOREM 5.1. *The limit u_* is a weak solution of* (2.3) *for* $\varepsilon = 0$ (*with* $\lambda \in (0, \infty)$ *fixed*). *Moreover, $u_*' = z_*$ has at most one "jump" discontinuity at, say, $x = a$ and possesses a classical derivative for all $x \neq a$. In particular,* (5.5) *holds pointwise on* $[0, a) \cup (a, 1]$.

Proof. We evaluate (2.7) at ε_k, u_k, z_k, multiply by a test function φ, and integrate by parts to obtain

$$-\int_0^1 \varepsilon_k z_k \varphi'' = \int_0^1 \left[-\sigma(z_k) + \int_x^1 b(\lambda, u_k(\tau), \tau) d\tau \right] \varphi dx \tag{5.7}$$

for all $\varphi \in C_0^\infty(0, 1)$. In view of (5.1), the continuity of σ and b, and the dominated convergence theorem, the limit of (5.7) as $k \to \infty$ yields

$$0 = \int_0^1 \left[-\sigma(z_*) + \int_x^1 b(\lambda, u_*(\tau), \tau) d\tau \right] \varphi dx \tag{5.8}$$

for all test functions φ, which proves

$$\sigma(z_*(x)) = \int_x^1 b(\lambda, u_*(\tau), \tau) d\tau \quad \text{for all} \quad x \in [0, 1]. \tag{5.9}$$

Then $(5.6)_1$, (5.9) and the continuity of b yield

$$\sigma \circ z_* \in C^1[0, 1]. \tag{5.10}$$

Moreover, (3.5) and (5.9) show that $\sigma \circ z_*$ is monotone decreasing on $[0, 1]$. Hence, (5.5) and the graph of σ (cf. Figures 3.1, 4.1) then show that z_* can suffer at most one jump discontinuity. Finally, if we "invert" σ in (5.9) (on the two branches of z_*, for which σ is monotone increasing), we conclude that z_* is C^1 on $[0, a) \cup (a, 1]$. □

COROLLARY 5.2. *The limit u_* satisfies the Euler–Lagrange equation* (*for* (2.1) *with* $\varepsilon = 0$);

$$W''(u_*')u_*'' + b(\lambda, u_*, x) = 0 \quad \text{a.e. in } [0, 1]. \tag{5.11}$$

Proof. Differentiation of (5.9) (cf. (5.10)), using (5.6) and the differentiability of z_* (cf. (5.5)), yields (5.11). □

Our calculations thus far leave the location of a possible jump, say, at $x = a$, indeterminate. This is easy to see, e.g., for dead loading, in which case (5.9) reduces to

$$\sigma(z_*(x)) = \int_x^1 b(\lambda, \tau) d\tau \equiv F(\lambda, x). \tag{5.12}$$

Referring to Figure 3.1, we see that z_* can have at most one jump (again by monotonicity) but that there are infinitely many choices for $\sigma(z_*(a^+)) = \sigma(z_*(a^-))$.

(In this case, any value between the local minimum value and the local maximum value of σ will do.) We now provide an additional argument to show that the jump in z_* must occur in accordance with the second Erdmann–Weierstrass corner condition.

Theorem 5.3. *The limiting strain* $u'_* = z_*$ *satisfies the second corner condition:*

$$W(z_*) - z_*\sigma(z_*) \quad \text{is continuous on } [0,1]. \tag{5.13}$$

Proof. If z_* is continuous on $[0,1]$, then (5.13) is obvious. Accordingly, we assume that z_* has a single "jump" discontinuity at $x = a$, where $0 < a \le 1$. (Note that $a = 1$ is possible only for double-well potentials, since in that case σ is no longer positive on all of $(0, \infty)$; cf. Figure 4.1.) Consider the sequences $\{u_k\}, \{z_k = u'_k\}$ for fixed $\lambda \in (0,\infty)$ or fixed $\theta \in (0,\infty)$ as before. Observe that any classical solution u_k of (2.3) with $\varepsilon = \varepsilon_k$ satisfies the Noether-type conservation law

$$\begin{aligned} W(z_k) - z_k\sigma(z_k) = \tfrac{1}{2}\varepsilon_k(z'_k)^2 - \varepsilon_k z''_k z_k \\ + \int_0^x b(\lambda, u_k(\tau), \tau) z_k(\tau) d\tau + c_k, \end{aligned} \tag{5.14}$$

where $c_k = W(z_k(0)) - z_k(0)\sigma(z_k(0)) + \varepsilon_k z''_k(0) z_k(0)$. (One can easily verify (5.14) via direct differentiation. In the absence of the inhomogeneous body force, one obtains (5.14) from the invariance of (2.3) under $x \to x - \alpha$ via Noether's theorem.) The idea is to take the pointwise limit of (5.14) and show that the left-hand side is continuous as $k \to \infty$. We now split a large part of the proof into the following two lemmas.

Lemma 5.4. $\lim_{k\to\infty} \varepsilon_k z''_k z_k = 0$ *for every* $x \in [0,1]$.

Proof. From $(2.7)_2$ we have

$$\varepsilon_k z''_k z_k = \left[\sigma(z_k) - \int_x^1 b(\lambda, u_k(\tau), \tau) d\tau\right] z_k. \tag{5.15}$$

Using (5.1), (5.2), (5.4), and the dominated convergence theorem, we find that the right-hand side of (5.15) converges pointwise to $[\sigma(z_*) - \int_x^1 b(\lambda, u_*(\tau), \tau) d\tau] z_*$ on $[0,1]$. Hence (5.9) gives the desired result. □

Lemma 5.5.

$$\lim_{k\to\infty} \varepsilon_k (z'_k)^2 = 0 \ \textit{a.e. on } [0,1]. \tag{5.16}$$

Proof. We first establish (5.16) on $[0,a)$. From $(2.7)_2$ we note that any classical solution pair (u_k, z_k) satisfies the Hamiltonian-type conservation law

$$\begin{aligned} \tfrac{1}{2}\varepsilon_k(z'_k)^2 = & \left[W(z_k(\cdot)) - \left(\int_{(\cdot)}^1 b(\lambda, u_k(\tau), \tau) d\tau\right) z_k\right]\Bigg|_0^x \\ & - \int_0^x b(\lambda, u_k(\tau), \tau) z_k(\tau) d\tau. \end{aligned} \tag{5.17}$$

(Equation (5.17) is readily verified from $(2.7)_2$ via direct integration. If one views "x" as a time-like variable in $(2.7)_2$, then (5.17) expresses balance of "energy".) By the dominated convergence theorem, the right-hand side of (5.17) converges pointwise on $[0,a)$ to

$$\begin{aligned} & \left[W(z_*(\cdot)) - \left(\int_{(\cdot)}^1 b(\lambda, u_*(\tau), \tau) d\tau\right) z_*\right]\Bigg|_0^x \\ & - \int_0^x b(\lambda, u_*(\tau), \tau) z_*(\tau) d\tau. \end{aligned} \tag{5.18}$$

On the other hand, (5.9) and the properties of z_* imply that

$$\sigma(z_*)z_*' = \left(\int_x^1 b(\lambda, u_*(\tau), \tau)d\tau\right) z_*' \quad \text{pointwise on } [0,a) \cup (a,1]. \tag{5.19}$$

Integration of (5.19) from 0 to x ($x < a$) and integration by parts shows that (5.18) vanishes identically on $[0,a)$; i.e., (5.16) holds pointwise on $[0,a)$. If $a = 1$, then we are finished. If $a < 1$, then we consider a different version of (5.17), viz.,

$$\begin{aligned} \frac{1}{2}\varepsilon_k(z_k')^2 = &- \left[W(z_k(\cdot)) - \left(\int_{(\cdot)}^1 b(\lambda, u_k(\tau), \tau)d\tau\right) z_k\right]\Bigg|_x^1 \\ &+ \int_x^1 b(\lambda, u_k(\tau), \tau)z_k(\tau)d\tau. \end{aligned} \tag{5.20}$$

In the limit as $k \to \infty$ of (5.20), the right-hand side converges pointwise on $(a,1]$ to the same terms with "$*$" in place of "k." On the other hand, integration of (5.19) from x to 1 ($x > a$) and integration by parts shows that the right-hand side of (5.20) with "$k = *$" vanishes identically on $(a,1]$. □

Proof of Theorem 5.3 (continued). By (5.1) the proof of Lemma 5.4 shows also that the sequence $(\varepsilon_k z_k'' z_k)$ is pointwise bounded on $[0,1]$. We now take the pointwise limit $k \to \infty$ of (5.14) (passing, if necessary, to a subsequence such that $\varepsilon_k z_k''(0)z_k(0)$ converges), using Lemmas 5.4 and 5.5, which yields

$$W(z_*) - z_*\sigma(z_*) = \int_0^x b(\lambda, u_*(\tau), \tau)d\tau + c_*, \tag{5.21}$$

where $c_* = W(z_*(0)) - z_*(0)\sigma(z_*(0))$. □

The continuity of $\sigma(z_*)$ (cf. (5.10)), often referred to as the first Erdmann–Weierstrass corner condition, combined with (5.13) yields the Maxwell "equal-area" rule for $\sigma(z_*(a^+)) = \sigma(z_*(a^-))$:

$$W(z_*(a^-)) - W(z_*(a^+)) = \sigma(z_*(a^-))\left[z_*(a^-) - z_*(a^+)\right]. \tag{5.22}$$

The two corner conditions are both necessary for $V_0(\lambda, u)$ (cf. (2.1)) to have a minimum at u_*. We return to this issue in section 6 in the context of dead loading.

Our last result in this section is to show that the limiting set of weak solutions of (2.3) ($\varepsilon = 0$) for $\lambda \geq 0$ is a continuum. Here we directly employ the point-set topological arguments of [1]. We first observe that (5.1) and (5.4) imply $\|z_*\|_\infty \leq M(\lambda)$, and thus, in view of (5.6), we conclude (for fixed $\lambda > 0$ or fixed $\theta > 0$)

$$\begin{aligned} &z_k \to z_* = u_*' \quad \text{in } L^p(0,1) \text{ and} \\ &u_k \to u_* \quad \text{in } W^{1,p}(0,1) (p \geq 1), \end{aligned} \tag{5.23}$$

where $\varepsilon = \varepsilon_k \searrow 0$ as before. Accordingly, for single-well problems we define

$$\begin{aligned} \Sigma_0^+ = \Big\{&(\lambda, u) \in \mathbb{R} \times W^{1,p}(0,1) : (\lambda_k, u_k, v_k, \mu_k) \in \overline{\mathcal{C}_{\varepsilon_k}^+}, \\ &\lambda_k \to \lambda, u_k \to u \text{ in } W^{1,p}(0,1) \text{ as } \varepsilon_k \searrow 0\Big\}. \end{aligned} \tag{5.24}$$

For double-well problems, we define

$$\begin{aligned}\Sigma^+_{0,\lambda_0} = \Big\{(\theta, u) \in \mathbb{R} \times W^{1,p}(0,1) : (\theta_k, \nu_k, \mu_k) \in \overline{\hat{\mathcal{C}}^+_{\varepsilon_k\lambda_0}},\\ \theta_k \to \theta, u_k \to u \text{ in } W^{1,p}(0,1) \text{ as } \varepsilon_k \to \infty\Big\}.\end{aligned} \tag{5.25}$$

For $\varepsilon > 0$, it is convenient to introduce the solution sets

$$\begin{aligned}&\Sigma^+_{\varepsilon} = \Big\{(\lambda, u) : (\lambda, u, v, \mu) \in \overline{\mathcal{C}^+_{\varepsilon}}\Big\}, && \text{(a)}\\ &\Sigma^+_{\varepsilon,\lambda_0} = \Big\{(\theta, u) : (\theta, u, v, \mu) \in \overline{\mathcal{C}^+_{\varepsilon,\lambda_0}}\Big\}, && \text{(b)}\end{aligned} \tag{5.26}$$

which like $\overline{\mathcal{C}^+_{\varepsilon}}$ and $\overline{\hat{\mathcal{C}}^+_{\varepsilon,\lambda_0}}$, respectively, comprise continua; i.e., Σ^+_{ε} and $\Sigma^+_{\varepsilon,\lambda_0}$ are each connected and (locally) compact.

Next let $B_R \subset W^{1,p}(0,1)$ denote the closed ball of radius "R," centered at the origin. For any number $\gamma_0 > 0$, we consider the sets

$$A = \{0\} \times B_{2M(0)} \quad \text{and} \quad B = \{\gamma_0\} \times B_{2M(\gamma_0)}, \tag{5.27}$$

where "M" is the constant (independent of ε) in the estimates (5.1). Both A and B are closed subsets of the Banach space $\mathbb{R} \times W^{1,p}(0,1)$. Henceforth we define the subsets $\Upsilon_{\varepsilon,\gamma_0}$ via either

$$\Upsilon^+_{\varepsilon,\gamma_0} \equiv \Sigma^+_{\varepsilon} \cap \big([0,\gamma_0] \times W^{1,p}(0,1)\big)$$

or

$$\Upsilon^+_{\varepsilon,\gamma_0} \equiv \Sigma^+_{\varepsilon,\lambda_0} \cap \big([0,\gamma_0] \times W^{1,p}(0,1)\big), \tag{5.28}$$

depending on whether we are interested in solutions from $\mathcal{C}^+_{\varepsilon}$ or $\hat{\mathcal{C}}^+_{\varepsilon,\lambda_0}$, respectively. The following construction is valid in either case. By (5.1) we have

$$\begin{aligned}&A \cap \Upsilon^+_{\varepsilon_k,\gamma_0} \neq \emptyset \text{ and } B \cap \Upsilon^+_{\varepsilon_k,\gamma_0} \neq \emptyset\\ &\text{are not separated in } \Upsilon^+_{\varepsilon_k,\gamma_0} \text{ for any } \varepsilon_k \searrow 0.\end{aligned} \tag{5.29}$$

To complete the argument, we need the following.

LEMMA 5.6. *For each neighborhood N of $\Sigma^+_0 \cap \big([0,\gamma_0] \times W^{1,p}(0,1)\big)$ (or of $\Sigma^+_{0,\lambda_0} \cap \big([0,\gamma_0] \times W^{1,p}(0,1)\big)$, there is a $k \in \mathbb{N}$ such that $\Upsilon^+_{\varepsilon_k,\gamma_0} \subset N$.*

Proof. We give an argument for Σ^+_0—the generalization to Σ^+_{0,λ_0} is obvious.

We argue by contradiction; i.e., assume there is a neighborhood N_0 of $\Sigma^+_0 \cap ([0,\gamma_0] \times W^{1,p}(0,1))$ such that $(\lambda_k, u_k) \in \Upsilon^+_{\varepsilon_k,\gamma_0}$ and $(\lambda_k, u_k) \notin N_0$ for all $k \in \mathbb{N}$. But for some subsequence, then we have $\lambda_k \to \lambda \in [0,\gamma_0]$ and $u_k \to u \in B_{2M_0}$ in $W^{1,p}(0,1)$. The latter follows from the fact that the uniform estimates (5.1) now hold with the constant $M_0 = \max\{M(\lambda) : 0 \leq \lambda \leq \gamma_0\}$ in place of $M(\lambda)$, and from a repetition of the arguments in this section. In particular, $(\lambda, u) \in \Sigma^+_0 \cap \big([0,\gamma_0] \times W^{1,p}(0,1)\big)$, i.e., $(\lambda_k, u_k) \in N_0$ for all $k \geq k_0(N_0) \in \mathbb{N}$, which is a contradiction. □

In view of properties (5.29) and Lemma 5.6, the main theorem of [1, section 3] yields that $\Sigma^+_0 \cap \big([0,\gamma_0] \times W^{1,p}(0,1)\big)$ and $\Sigma^+_{0,\lambda_0} \cap \big([0,\gamma_0] \times W^{1,p}(0,1)\big)$ are each connected and compact. Since this construction holds for any $\gamma_0 > 0$, we may conclude the following.

THEOREM 5.7. *Σ^+_0 and $\Sigma^+_{0,\lambda_0} \subset \mathbb{R} \times W^{1,p}(0,1)$ are each continua having projection $[0,\infty)$ on the parameter axis.*

Finally, in keeping with the notation of section 3, we define

$$\Gamma^+_{0,\lambda_0} \equiv \Sigma^+_{0,\lambda_0} \cap ([\lambda_0 + 1, \infty) \times W^{1,p}(0,1)), \tag{5.30}$$

which is the portion of the limiting continuum containing solutions of the double-well problem.

6. Minimizing properties of solutions for dead loading. For any weak solution of (2.3) with $\varepsilon = 0$ on the limiting continuum, $(\lambda, u_*) \in \Sigma^+_0$ or Γ^+_{0,λ_0}, we have from section 4 that the strain $z_* = u'_*$ suffers (at most) a single jump at some location $x = a(\lambda)$, where the Maxwell condition is satisfied; cf. (5.22). As mentioned in section 5, the latter is a necessary condition for u_* to minimize (2.1) for $\varepsilon = 0$ (at a given value of λ). In fact, given the nonconvexity of $W(\nu)$, the minimization of the functional (2.1) $\varepsilon = 0$ depends delicately upon the behavior of the loading potential $u \mapsto B(\lambda, u, x)$ [7], [12]; the minimum need not be attained in general. Accordingly, we focus in this section on the important case of "dead loading," viz.,

$$B(\lambda, u, x) \equiv -b(\lambda, x)u, \tag{6.1}$$

where the loading, $b = -B_u$, is now independent of u but otherwise satisfies condition (3.5) (note that (3.9) is now automatic).

We first observe that for a given value of $\lambda > 0$, a limiting strain $z_*(\lambda) = \frac{d}{dx}u_*(\lambda)$ satisfies the algebraic equation (5.12), which can be solved analytically as follows. We first consider single-well potential problems, i.e., we impose (3.2). For a given stress function $\sigma = W'(\nu)$, let $0 < \nu_1 < \nu_2$ denote the strains corresponding to the local maximum, $\sigma_m = \sigma(\nu_1)$, and local minimum, $\sigma(\nu_2)$, and let σ_M denote the Maxwell stress, as defined by the "equal-area" rule (5.22), cf. Figure 6.1. Since $x \mapsto z_*(x)$ and $x \mapsto F(\lambda, x)$ are each monotone decreasing, we can characterize solutions of (5.12) in terms of the magnitude of $F(\lambda, 0)$. In particular, for $F(\lambda, 0)$ sufficiently large, there are solutions such that $z_*(\lambda)$ has a single jump, where (5.22) now determines the location of the jump, $0 < a(\lambda) < 1$; cf. Figure 6.1. A typical profile corresponding to Figure 6.1 is depicted in Figure 6.2.

Finally, if we let $\sigma^{-1}_{\pm}$ denote the unique inverses of σ on $[0, \nu_1]$, $[\nu_2, \infty)$, respectively, we can express solutions of (5.12) analytically and hence, characterize Σ^+_0.

PROPOSITION 6.1. *If* $0 < F(\lambda_*, 0) < \sigma_M$, *then at* $\lambda = \lambda_*$ *there is only one (lower) solution* $(\lambda_*, u_*) \in \Sigma^+_0$, *where* $z_* = u'_*$ *is given by*

$$z_*(x, \lambda_*) = \sigma^{-1}_+(F(\lambda_*, x)). \tag{6.2}$$

If $F(\lambda_*, 0) > \sigma_m$, *then again there is only one (jump) solution* $(\lambda_*, u_*) \in \Sigma^+_0$, *where* $z_* = u'_*$ *now suffers a jump discontinuity:*

$$z_*(x, \lambda_*) = \begin{cases} \sigma^{-1}_-(F(\lambda_*, x)), & 0 \le x \le a(\lambda_*), \\ \sigma^{-1}_+(F(\lambda_*, x)), & a(\lambda_*) < x \le 1. \end{cases} \tag{6.3}$$

Here $0 < a(\lambda_*) < 1$ *is the unique solution of*

$$F(\lambda_*, a) = \sigma_M. \tag{6.4}$$

If $F(\lambda_*, 0) = \sigma_M$, *the lower solution* (6.2) *and the jump solution* (6.3), (6.4) *coincide (a.e. on* $[0, 1]$*). Consequently, there is only one solution point* $(\lambda_*, u_*) \in \Sigma^+_0$ *at* $\lambda = \lambda_*$, *where* u'_* *is characterized (say) by* (6.2) *a.e. on* $[0, 1]$. *Within a loading regime*

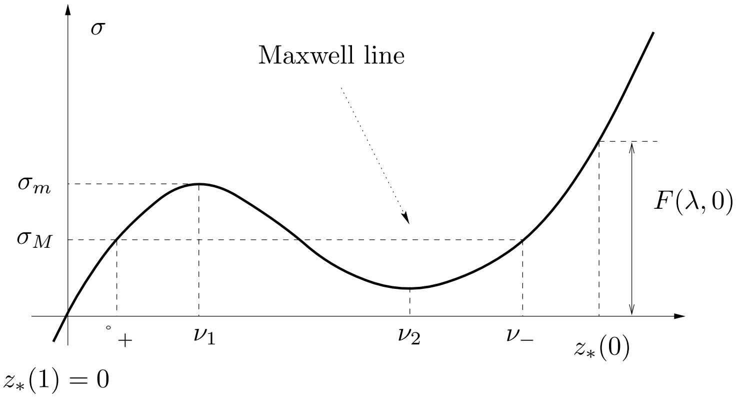


Fig. 6.1.

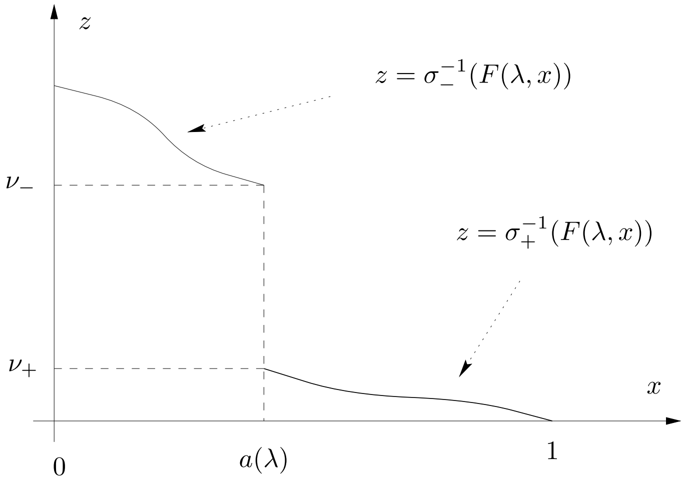

Fig. 6.2.

$\sigma_M < F(\lambda_*, 0) \leq \sigma_m$, *either or both solutions corresponding to* (6.2) *and* (6.3), (6.4), *respectively, may belong to* Σ_0^+. *Moreover, in that case suppose that* λ_* *belongs to some interval "I" such that* $F(\lambda, 0) \geq \sigma_M$ *for all* $\lambda \in I$ *and* $F(\lambda_0, 0) > \sigma_m$ *for some* $\lambda_0 \in I$. *Then* Σ_0^+ *contains a jump solution* (λ_*, u_*); *i.e.,* $u'_* = z_*$ *is characterized by* (6.3), (6.4).

Proof. The existence of the solutions (6.2) and (6.3), (6.4) to (5.12) and their uniqueness for $0 < F(\lambda_*, 0) < \sigma_M$ and $F(\lambda_*, 0) > \sigma_m$, respectively, are obvious. Accordingly, the associated solutions (λ_*, u_*) necessarily belong to the unbounded solution branch Σ_0^+ in those two cases. Within the regime $\sigma_M < F(\lambda_*, 0) \leq \sigma_m$ it is easy to see from (6.4) that $a(\lambda_*) > 0$, and the two solutions (6.2) and (6.3) of (5.12) are obviously distinct. Our limit analysis of section 5 provides no information about which one (or both) belongs to Σ_0^+ at $\lambda = \lambda_*$. However, given the extra loading information provided in the statement of the theorem, then (6.3), (6.4) define a curve of solutions for all $\lambda \in I$, and the jump solution at $\lambda = \lambda_0$ belongs to Σ_0^+ (by the same reasoning given at the beginning of the proof). Since Σ_0^+ is a continuum, it also contains the entire curve of jump solutions for all $\lambda \in I$, which includes λ_*.

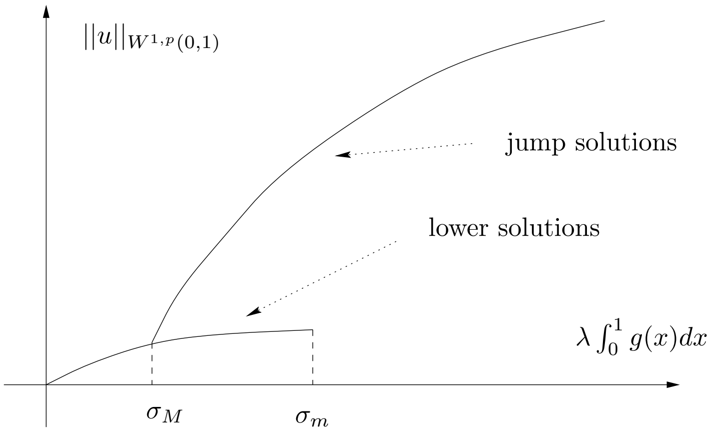

FIG. 6.3. *Solution branches for* (5.12) *in the case of a single-well potential with monotone loading.*

Finally, from the smoothness of $F(\lambda, x)$ and the monotonicity of $x \mapsto F(\lambda, x)$, we see that $a(\lambda)$ is continuous on any interval $[\lambda_1, \lambda_2]$ such that $F(\lambda, 0) \geq \sigma_M$ for all $\lambda \in [\lambda_1, \lambda_2]$. Moreover, $a(\lambda) \searrow 0$ as $\lambda \to \lambda_*$ whenever $F(\lambda_*, 0) = \sigma_M$ for $\lambda_* \in [\lambda_1, \lambda_2]$. Whence, (6.2) and (6.3), (6.4) are equal a.e. on $[0, 1]$ at $\lambda = \lambda_*$. □

In the important, special case of *monotone loading*, i.e., $b(\lambda, x) \equiv \lambda g(x)$, the loading condition stated at the end of Proposition 6.1 is always fulfilled. Moreover, (5.12) admits two intersecting curves of solutions: a terminating segment of lower solutions and an unbounded curve of jump solutions, both of which we depict schematically in Figure 6.3. Since Σ_0^+ is a continuum we immediately conclude the following.

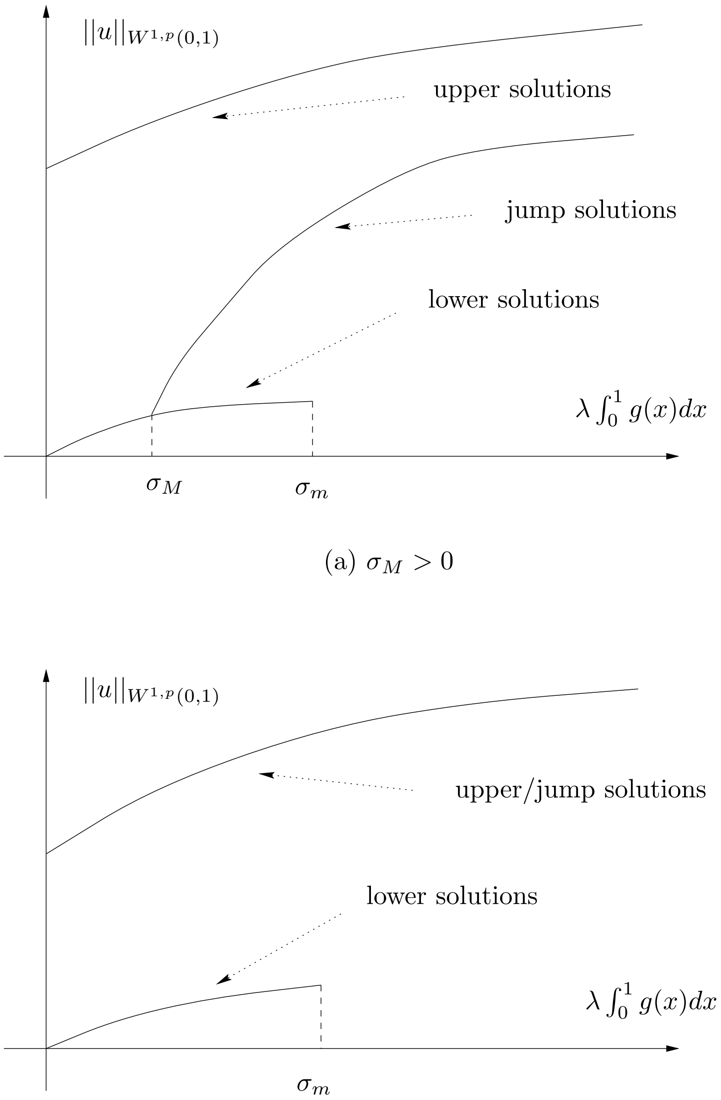
COROLLARY 6.2. *In the case of monotone loading, the limiting continuum* Σ_0^+ *contains a segment of lower solutions, characterized by* (6.2) *for* $0 \leq \lambda_* \int_0^1 g(x)dx \leq \sigma_M$, *and an unbounded curve of jump solutions; cf.* (6.3), (6.4) *for* $\lambda_* \int_0^1 g(x)dx \geq \sigma_M$. *In particular, for* $\sigma_M < \lambda_* \int_0^1 g(x)dx \leq \sigma_m$, Σ_0^+ *contains a jump solution* (λ_*, u_*).

Next we turn to two-well-potential problems. In this case, (6.2) and (6.3), (6.4) yield solutions of (5.12) (depending upon the magnitude of $F(\lambda_*, 0)$ as before). In addition, (5.12) now possesses another curve of smooth *upper* solutions,

$$\tilde{z}(x, \lambda) = \sigma_-^{-1}(F(\lambda, x)) \tag{6.5}$$

for all $\lambda \geq 0$. Note that $\tilde{z}(1, \lambda) = \nu_3$, where $\nu_3 > 0$ denotes the third zero of $\sigma(\nu)$; cf. Figure 4.1. Actually (6.3), (6.4), and (6.5) are distinct, provided that the Maxwell stress is positive, i.e., $\sigma_M > 0$. Our assumptions (2.6) allow for the possibility $\sigma_M = 0$, in which case $a(\lambda) \equiv 1$ (cf. (6.4)), and hence (6.3), (6.4), and (6.5) are identical on $0 \leq x < 1$. At any rate, for any value of $\lambda > 0$, (5.12) has either two or three solutions. This is best illustrated for monotone loading, $b(\lambda, x) = \lambda g(x)$, as shown schematically in Figure 6.4. However, unlike the single-well problem it is not immediately clear which solutions belong to the limiting set Γ_{0,λ_0}^+, cf. (5.30). We now take this up.

By construction, the unbounded continuum Σ_{0,λ_0}^+ (cf. Theorem 5.7) contains weak solutions of (2.3), $\varepsilon = 0$, for the single-well problem, for the homotopy between the single-well and the double-well problem, and for the double-well problem (the latter corresponding to Γ_{0,λ_0}^+); cf. sections 4 and 5. In particular, for the homotopy portion there is, by continuity, a number τ_0 with $0 < \tau_0 < 1$, or equivalently a parameter value θ_0 with $\lambda_0 < \theta_0 < \lambda_0 + 1$ (cf. (4.1) (4.4)), such that $\tilde{W}_\nu(\nu, \tau_0) = \tilde{\sigma}(\nu, \tau_0)$ has a double



(a) $\sigma_M > 0$

(b) $\sigma_M = 0$

FIG. 6.4. *Solution branches for* (5.12) *in the case of a double-well potential with monotone loading.*

zero at $\tau = \tau_0$, i.e., $\tilde{\sigma}(\nu_3, \tau_0) = \tilde{\sigma}_\nu(\nu_3, \tau_0) = 0$; cf. Figures 3.1 and 4.1. Moreover, all solution pairs belonging to $\Sigma^+_{0,\lambda_0} \cap ([0, \theta_0) \times W^{1,p}(0, 1))$ solve one-well problems; as such, they are characterized precisely as in Proposition 6.1. On the other hand, $\Sigma^+_{0,\lambda_0} \cap ((\theta_0, \infty) \times W^{1,p}(0, 1))$ contains only solutions of two-well problems.

PROPOSITION 6.3. *First suppose $\sigma_M > 0$. Then for any $\lambda_0 > 0$ and for all $\lambda_* \geq \lambda_0$, the limiting solution set Γ^+_{0,λ_0} contains only solution pairs (λ_*, u_*), where $z_* = u'_*$ is of the type* (6.2) *and/or* (6.3), (6.4)*, as described (in terms of the magnitude of $F(\lambda_*, 0)$) in Proposition* 6.1 *and in Corollary* 6.2 *for monotone loading. If $\sigma_M = 0$, then Γ^+_{0,λ_0} may contain upper solutions* (6.5) *(a.e. on* $[0, 1]$*) and/or lower solutions*

(6.2). *However, if* $F(\lambda_*, 0) > \sigma_m$ *for some* $\lambda_* \geq \lambda_0$ *(which is always satisfied, e.g., in the case of monotone loading) then* Γ^+_{0,λ_0} *contains the upper solution branch defined by* (6.5) *(a.e. on* $[0,1]$*) for all* $\lambda \geq \lambda_0$.

Proof. Let $\tilde{\sigma}_M(\tau)$ and $\tilde{\sigma}_m(\tau)$ denote the Maxwell stress and the local maximum stress, respectively, associated with (4.1) for each $0 \leq \tau \leq 1$. First, for $\sigma_M = \tilde{\sigma}_M(1) > 0$, we observe from (6.2)–(6.5) that

$$\|\tilde{z}(\lambda) - z_*(\lambda)\|_{L^p(0,1)} = \|\tilde{z}(\lambda) - z_*(\lambda)\|_{L^p(a(\lambda),1)} > 0 \tag{6.6}$$

for all $\lambda > 0$ (with the understanding that $a(\lambda) \equiv 0$ in (6.2)). In particular, the corresponding displacements, $\tilde{u}(\lambda)$ and $u_*(\lambda)$ (cf. (5.6)), satisfy

$$\|\tilde{u}(\lambda) - u_*(\lambda)\|_{W^{1,p}(0,1)} > 0 \text{ for all } \lambda > 0. \tag{6.7}$$

We now argue by contradiction, viz., suppose that Γ^+_{0,λ_0} and thus Σ^+_{0,λ_0} (cf. (5.30)) contain solution points $(\lambda_*, \tilde{u})$ where $\tilde{u}'$ is of the type (6.5) for $\lambda_* \geq \lambda_0$. We denote by "S" the curve of upper solutions defined by (6.5) for all $\tau_0 \leq \tau \leq 1$ and for all $\lambda \geq \lambda_0$. Recall that the solution set $R \equiv \Sigma^+_{0,\lambda_0} \cap ([0, \theta_0) \times W^{1,p}(0,1))$ contains no upper solutions. By virtue of (6.7), we then conclude that $\overline{R}$ and S are separated in $\mathbb{R} \times W^{1,p}(0,1))$. Since Σ^+_{0,λ_0} is a continuum, $\Sigma^+_{0,\lambda_0} \cap ([\theta_0, \infty) \times W^{1,p}(0,1))$ must contain lower and/or jump solutions, as described in Proposition 6.1. Again by (6.7), we then conclude that S is separated from Σ^+_{0,λ_0}, and hence $S \cap \Gamma^+_{0,\lambda_0} = \emptyset$; cf. (5.30).

Next we assume that $\sigma_M = \tilde{\sigma}_M(1) = 0$, in which case we have already noted that (6.5) and (6.3), (6.4) coincide a.e. on $[0,1]$. Thus, (6.2) and (6.5) define the only possible solutions of (5.12). In addition, if $F(\lambda_*, 0) > \sigma_m = \tilde{\sigma}_m(1)$ for some $\lambda_* \geq \lambda_0$, then (6.5) is the only solution of (5.12) at $\lambda = \lambda_*$. Again, in view of (6.7) and the fact that Σ^+_{0,λ_0} is a continuum, we conclude that the entire curve of upper solutions, (6.5) for all $\lambda \geq \lambda_0$, is contained in Σ^+_{0,λ_0} and hence in Γ^+_{0,λ_0} as well. □

To establish our "stability" (minimum) result, we need the following reasonable growth condition on the stored energy function:

$$|W'(\xi)| \leq c_1 + c_2|\xi|^{p-1} \tag{6.8}$$

for positive constants c_1, c_2, and integer $p \geq 1$.

Next we consider $(\lambda_*, u_*) \in \Sigma^+_0$ for single-well problems and $(\lambda_*, u_*) \in \Gamma^+_{0,\lambda_0}$ for double-well problems. In either case, for $\sigma_M > 0$, we henceforth assume that u_* is a lower solution (6.2) for $0 \leq F(\lambda_*, 0) \leq \sigma_M$ and a jump solution for $F(\lambda_*, 0) > \sigma_M$. For $\sigma_M = 0$, we assume that u_* is an upper solution (6.5) (a.e. on $[0,1]$). Loading conditions sufficient for these assumptions are given in Propositions 6.1 and 6.3. In particular, all such loading conditions are satisfied in the case of monotone loading.

THEOREM 6.4. *With* (λ_*, u_*) *as described above, suppose that* (6.8) *holds. Then* $V_0(\lambda_*, u)$ *attains its minimum at* u_*, *i.e.,*

$$\min_u \{V_0(\lambda_*, u) : u \in W^{1,p}(0,1), u(0) = 0\} = V_0(\lambda_*, u_*), \tag{6.9}$$

where V_0 *corresponds to* (2.1) *with* $\varepsilon = 0$, u_* *is the limiting displacement given by* (5.23)*, and* $1 \leq p < \infty$.

Proof. We first consider the convex minimization problem

$$\min_u \{V_0^{**}(\lambda_*, u) : u \in W^{1,p}(0,1), u(0) = 0\}, \tag{6.10}$$

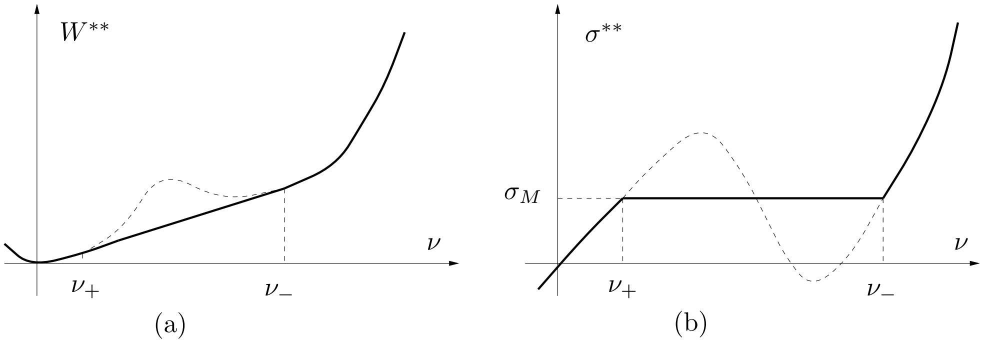


FIG. 6.5.

where $V_0^{**}(\lambda_*, u) = \int_0^1 [W^{**}(u') - b(\lambda_*)u]dx$, and

$$W^{**}(\xi) \equiv \sup\{g(\xi) : g(\xi) \leq W(\xi), g \text{ convex}\}. \tag{6.11}$$

In particular, we have (cf., e.g., [11, section A.2])

$$\sigma^{**}(\xi) = {W^{**}}'(\xi) = \begin{cases} \sigma(\xi), & \xi \in (-\infty, \nu_+] \cup [\nu_-, \infty), \\ \sigma_M, & \xi \in (\nu_+, \nu_-), \end{cases} \tag{6.12}$$

as depicted in Figure 6.5, where ν_+, ν_- and σ_M are as defined before. Condition (6.8) ensures that V_0^{**} is Gateaux differentiable; cf. [11, section 3.4].

Moreover, in view of (6.12) and the stated properties of u_*, we conclude that

$$\begin{aligned} < \delta V_0^{**}(\lambda_*, u_*), \eta > \; &\equiv \int_0^1 [\sigma^{**}(z_*)\eta' - b(\lambda_*)\eta]dx \\ &= \int_0^1 [\sigma(z_*)\eta' - b(\lambda_*)\eta]dx = 0, \end{aligned} \tag{6.13}$$

for all test functions $\eta \in W^{1,p}(0,1)$ satisfying $\eta(0) = 0$ (where the left-hand side of (6.13) denotes the Gateaux derivative of $u \mapsto V_0^{**}(\lambda_*, u)$ at u_*). In particular, u_* is a weak solution of the Euler–Lagrange equation for $V_0^{**}(\lambda_*, u)$. Also, by virtue of (2.5), (2.6), (6.10), and (6.11), we readily see that $u \mapsto V_0^{**}(\lambda_*, u)$ is convex on $\{u \in W^{1,p}(0,1) : u(0) = 0\}$. Hence, we conclude (cf. [11, section 3.1])

$$\begin{aligned} \min_u V_0^{**}(\lambda_*, u) &= V_0^{**}(\lambda_*, u_*) \\ &= V_0(\lambda_*, u_*), \end{aligned} \tag{6.14}$$

where the second equality follows from (6.10), (6.11) and the stated properties of u_*. Finally, from (6.11) we observe that

$$V_0^{**}(\lambda_*, u) \leq V_0(\lambda_*, u) \quad \text{for all } u \in W^{1,p}(0,1), \tag{6.15}$$

which, when combined with (6.14), gives the desired result. □

7. Concluding remarks. For dead loading (6.1) and $\varepsilon > 0$, the energy functional (2.1) is equivalent to

$$\tilde{V}_\varepsilon(\lambda, z) = \int_0^1 \left[\frac{\varepsilon}{2}(z')^2 + W(z) - F(\lambda, x)z\right] dx, \tag{7.1}$$

the direct minimization of which can be carried out along the lines of [3]. In particular, it can be shown that the global minimizer, say, $\tilde{z}_\varepsilon$, is monotone decreasing on $[0, 1]$, and moreover there is a subsequence $z_{\varepsilon_k} \to z_*$ pointwise on $[0, 1]$. This strongly suggests that (for each fixed λ) our solutions z_ε, obtained on global solution continua in sections 2–4, coincide with the minimizer $\tilde{z}_\varepsilon$. However, this need not be the case—e.g., the solution continuum $\mathcal{C}_\varepsilon^+$ (cf. section 3) could certainly contain turning points. Hence, for a given value of λ, there can be three (or more) distinct, monotone decreasing solutions, at least one of which must be a saddle point of (7.1). However, since both (sub)sequences converge to z_*, it is straightforward to show that

$$\|z_{\varepsilon_k} - \tilde{z}_{\varepsilon_k}\|_{L^p(0,1)} \to 0 \quad \text{as } k \to \infty. \tag{7.2}$$

We emphasize that the results of sections 3–5 yield global solution continua, in the limit of vanishing capillarity, for a general class of parameter-dependent live loadings. For sufficiently large loading (e.g., monotonic in the parameter), we prove that the limiting solution continuum possesses weak solutions characterized by a single jump, at which the two Erdmann–Weierstrass corner conditions [14] are always satisfied. The specialization to dead loading in section 6 represents the simplest case for which satisfaction of the corner conditions is enough to deduce that the limiting weak solution also minimizes the (zero-capillarity) energy. Of course in the dead-load case, the direct minimization of energy is also fruitful. Note that the general results of section 5 hold in cases where the direct minimization of energy (zero-capillarity) may be difficult or even ill-posed; e.g., cf. [12]. Also, the minimum energy approach provides no information about solution continua as the loading is varied.

Generalizations of our results, e.g., to more general loadings and/or higher-dimensional models, are complicated by the need for uniform a priori bounds (e.g., (5.1)) for convergence. Recently, a similar analysis of a two-dimensional Cahn–Hilliard problem with rectangular symmetry has been analyzed by the second-named author [20]. This is essentially a two-dimensional version of the problem considered in [8]. In [20] the a priori estimates rely upon a subtle combination of the maximum principle and symmetry arguments related to those in [16]. Also, a two-dimensional version of Helly's pointwise convergence theorem for functions having appropriate monotonicities is obtained there. Using the Erdmann–Weierstrass corner conditions, the minimization properties of the limiting weak solutions are proved in [21].

Finally we note that global branches of weak solutions for some elastic string problems have been obtained by regularization and singular limits in [2]. There the possible vanishing of the tension causes the singularity, and the regularization chosen is not physical. Here our small-capillarity solutions are also of physical significance.

Acknowledgment. The authors thank Phoebus Rosakis for valuable comments throughout various stages of this work.

A COMPLETE SOLUTION CHARACTERIZING SMOOTH REFINABLE FUNCTIONS[*]

VLADIMIR PROTASOV[†]

Dedicated to the memory of Mary Panfyorova

Abstract. In this paper we study univariate two-scale refinement equations $\varphi(x) = \sum_{k\in\mathbb{Z}} c_k \varphi (2x-k)$, where the coefficients $c_k \in \mathbb{C}$ satisfy an exponential decay assumption. We show that any refinement equation that has a smooth solution can be reduced to the well-studied case of complete sum rules: $\sum_k (-1)^k k^n c_k = 0, \quad n = 0, \dots, L$, where L depends on regularity of the solution. This result makes it possible to extend previously known results on refinable functions and subdivision schemes from the case of complete sum rules to the general case. As a corollary we obtain sharp necessary conditions for the existence of smooth refinable functions and the convergence of corresponding cascade algorithms. Other applications concern polynomial spaces spanned by integer translates of a refinable function and one special property of linear operators associated to refinement equations.

Key words. refinement equations, regularity, reducibility, tree, cascade algorithm

1. Introduction.

Functional equations of the type

$$\varphi(x) = \sum_{k=0}^{N} c_k \varphi(qx-k)$$

(*q-scale refinement equations*), where $c_k \in \mathbb{C}$, $q \geq 2$ is an integer, have found a lot of applications in wavelets theory [C], [CD1], [DL2], [CH], [HC], in subdivision algorithms in approximation theory and curve design [CDM], [DGL1], [DGL2], [DD], [M], [DyL], and in probability theory [DDL]. We restrict ourselves in this paper to the case $q = 2$, especially as this case is the most important one in applications. Nevertheless all our results can be applied for general integer values of $q \geq 2$. We say that a function $\varphi \in L_1(\mathbb{R})$ is a *refinable function* if it has a compact support and satisfies a two-scale refinement equation

$$\varphi(x) = \sum_{k=0}^{N} c_k \varphi(2x-k). \tag{1}$$

It was shown in [DL1] that any refinement equation has at most one compactly supported L_1-solution up to normalization. This solution, if it exists at all, has its support in the segment $[0, N]$ [DD], [DL1]. A necessary condition for the existence of this solution is $\sum c_k = 2^r$ for some natural r. Moreover, it is sufficient to consider only the main case

$$\sum_k c_k = 2, \quad \int \varphi(x)dx = 1, \tag{2}$$

because the other cases can be reduced to (2) by integration of the refinable function and a suitable normalization [DL1]. Thus we consider (1) and assume below that condition (2) is satisfied.

The existence and regularity of refinable functions have been studied by many authors in great detail [DL1], [DL2], [CH], [HC], [CDM], [LW], [V].

In much of the literature this problem is investigated by the frequency domain approach, i.e., by considering the Fourier transform of (1)

$$\widehat{\varphi}(\xi) = m_0\Big(\frac{\xi}{2}\Big)\widehat{\varphi}\Big(\frac{\xi}{2}\Big), \tag{3}$$

where the trigonometric polynomial $m_0(\xi) = \frac{1}{2}\sum_{k=0}^{N} c_k e^{-i\xi k}$ is the *mask* of the equation. Another approach, which uses linear algebraic tools in the time domain, has also been successfully applied [DL2], [CH], [CDM], [W1], [W2]. This approach is based on the fact that values of a continuous refinable function $\varphi(x)$ can be calculated consequently at all dyadic points. An explicit formula for $\varphi(x)$ can be expressed by infinite products of the two special matrices T_0 and T_1 (see [DL1], [CH] or formulas (21) and (22) in this paper). In the case $\varphi \in L_p$ the calculation of $\varphi(x)$ at dyadic points is replaced by the calculation of integrals of φ over the dyadic intervals (see [LW], [W2], or formula (23)). The existence and smoothness of solutions are studied by properties of corresponding linear operators (see [DL1] for details).

Many of the works on refinable functions deal with the one special case (the case of *complete sum rules*). Namely, if we study L times differentiable solutions of (1), then we assume that the coefficients $\{c_k\}$ satisfy the *sum rules* of order L, i.e., the following $L+1$ conditions:

$$m_0^{(n)}(\pi) = \frac{1}{2}\sum_k (-1)^k k^n c_k = 0, \quad n = 0, \dots, L. \tag{4}$$

In particular the first sum rule

$$\sum_k c_{2k} = \sum_k c_{2k+1} = 1 \tag{5}$$

has been assumed in almost all papers devoted to continuous or L_1-solutions of (1). The sum rules, which were elaborated in [DL1] and [CDM], simplify many problems on refinable functions. In the frequency domain approach the sum rules make it possible to reduce the mask of the equation to the form

$$m_0(\xi) = \left(\frac{1+e^{-i\xi}}{2}\right)^{L+1} q(\xi)$$

and then analyze the smoothness of refinable function by estimating the polynomial $q(\xi)$. This method was applied in [DD], [D]. In the time domain approach the sum rules allow us to obtain very explicit expressions for the common eigenspaces of operators T_0 and T_1 and actually to reduce these operators to a block-diagonal form [DL2], [HC].

A quite different approach to the study of refinement equations was proposed in the works of Herve [He1], [He2] and of Cohen and Daubechies [CD2]. These works deal with refinement equations with infinitely many terms

$$\varphi(x) = \sum_{k\in\mathbb{Z}} c_k \varphi(2x-k) \tag{6}$$

under the exponential decay assumption on the coefficients $\{c_k\}$:

$$|c_k| < Ce^{-\gamma|k|}, \quad k \in \mathbb{Z}, \tag{7}$$

for some constants $\gamma > 0,\ C > 0$. The technique based on the study of spectral properties of the *transfer operator* made it possible to obtain very sharp information for the Sobolev regularity of solution of (6). These results were also obtained for the case of holding sum rules: $m_0^{(n)}(\pi) = 0,\ n = 0,\dots,L$, where $m_0(\xi) = \frac{1}{2}\sum_k e^{-i\xi k}$ is the mask of the equation. The estimation of the Sobolev exponent established in [He1], [He2], and [CD2] actually depends on the order L of sum rules.

In addition, a lot of interesting results on local regularity [DL2], fractal properties [W2], [DL2], and L^2-regularity [LW], [CD1] of refinable functions were obtained for the case when sum rules (4) hold. However, this is just a particular, although very important, case of refinement equations. The sum rules are not necessary for the existence of smooth refinable functions. Corresponding examples are well known [DL2], [CDM]. For instance, the equation

$$\varphi(x) = \frac{1}{3}\varphi(2x) + \frac{2}{3}\varphi(2x-1) + \frac{1}{3}\varphi(2x-2) + \frac{2}{3}\varphi(2x-3) \tag{8}$$

has a continuous compactly supported solution (see [P]); nevertheless, none of the sum rules holds. Moreover, as we shall see in section 4, there are a lot of refinement equations without the sum rules that have, nevertheless, “good” smooth solutions. However, all attempts to get rid of the sum rules and consider the general case have always significantly complicated the problem. The estimations of regularity of refinable functions obtained in the works [D], [DL2], [DD], [He2], [Hu], [CD2] depend on the order of sum rules that hold for corresponding refinement equations. As a rule the results obtained for the case of complete sum rules are much sharper than the results in the general case. Now let us formulate the following questions.

Question 1. Is the case of complete sum rules a very special case in the theory of refinement equations? Is it possible to extend the results mentioned above from this case to all refinable functions?

Question 2. Why do all the most interesting examples of refinement equations which have ever appeared in applications satisfy the sum rules? Can refinement equations without sum rules be useful in applications?

Question 3. How to obtain necessary conditions for the existence of smooth solutions of refinement equations that would be sharp in some sense?

In the next section we formulate the “theorems of reduction.” Then we discuss each of these questions. Questions 2 and 3 have been considered in the literature, and some important results were obtained. We will mention them in the next section.

2. Theorems of reduction. Denote, as usual, by $C^L(\mathbb{R}),\ L \geq 0$ the space of L times continuously differentiable functions. Let $C^0(\mathbb{R})$ denote the space $C(\mathbb{R})$; let $W_p^L(\mathbb{R}), L \geq 0, p \in [1,\infty]$ denote the Sobolev space (the space of functions whose Lth derivatives are in $L^p(\mathbb{R})$), and let $W_p^0(\mathbb{R})$ denote the space $L^p(\mathbb{R})$. Let us denote by Π_L the space of polynomials of degree at most L. For a compactly supported function $\varphi(x)$ denote by $\mathcal{V}_\varphi$ the space that is spanned by integer translates of the function φ, i.e.,

$$\mathcal{V}_\varphi = \left\{ \sum_{k\in\mathbb{Z}} \lambda_k \varphi(x-k), \quad \lambda_k \in \mathbb{C} \right\}.$$

Now consider an arbitrary function $f \in C(\mathbb{R})$. Let L be the maximal integer such that $f \in C^L(\mathbb{R})$. Then the Hölder exponent of this function is $L + \beta_m$, where β_m is the supremum of the values β such that for some constant $C(\beta)$ the inequality $\|f^{(L)}(x+y) - f^{(L)}(x)\|_{C(\mathbb{R})} \leq C(\beta)|y|^\beta$ holds for any $y \in \mathbb{R}$. The Hölder exponent in the space W_p^L is defined as above by the substitution of $L^p(\mathbb{R})$ instead of $C(\mathbb{R})$. The Sobolev exponent s_p of a function $\varphi(x)$ is defined for any $p \in [1, +\infty)$ as

$$s_p(\varphi) = \sup \left\{ s \in \mathbb{R} \Big| \int\limits_{\mathbb{R}} |\widehat{\varphi}(\xi)|^p (1 + |\xi|^{ps}) d\xi < \infty \right\}.$$

We say that two functions have equal smoothness if both the following conditions are satisfied:

(1) These functions belong to the same functional space (C^L or W_p^L) and have equal Hölder exponents in that space.

(2) They have equal Sobolev exponent for any $p \geq 1$.

We also say that (6) (under conditions (2) and (7)) and its L^1-solution $\varphi(x)$ are *reducible* if for some integer $L \geq 0$, $\varphi \in W_1^L(\mathbb{R})$ (or $s_p(\varphi) > L$ for some $p \geq 1$) hold, and the sum rules of order L do not hold, i.e., at least one of the $L+1$ conditions (4) is not satisfied.

The opposite case is said to be *irreducible*, or the *case of complete sum rules.* If we denote by $L_{\max}$ the maximal integer $L \geq 0$ such that $\varphi \in W_1^L(\mathbb{R})$ or $s_p(\varphi) > L$ for some $p \geq 1$, then we have the following:

A refinement equation and its L^1-solution are irreducible if and only if sum rules of order $L_{\max}$ hold.

Now we formulate the first theorem of reduction.

THEOREM 1 (the case of finitely many terms). *For any reducible solution $\varphi(x)$ of* (1) *there exist a constant $\theta \in \mathbb{R}$ and a function $\psi(x)$ such that the following hold:*

(1) $\theta = \frac{\pi(2l+1)}{2^n}$ *for some $n \in \{0, \dots, N-2\}$ and $l \in \{0, \dots, 2^n - 1\}$. Moreover, $\frac{\theta}{2}$ and $\frac{\theta}{2} + \pi$ are roots of the equation $m_0(\xi) = 0$.*

(2) $\varphi(x) = \psi(x) - e^{i\theta}\psi(x-1)$.

(3) $\operatorname{supp} \psi(x) \subset [0, N-1]$.

(4) *The function $\psi(x)$ satisfies the refinement equation*

$$\psi(x) = \sum_{k=0}^{N-1} \tilde{c}_k \psi(2x - k),$$

where $\tilde{c}_k$ are coefficients of the polynomial

$$\sum_{k=0}^{N-1} \tilde{c}_k e^{-i\xi k} = 2\tilde{m}_0(\xi) = 2\frac{m_0(\xi)(1 - e^{i(\theta-\xi)})}{1 - e^{i(\theta - 2\xi)}}.$$

(5) *The functions φ and ψ have an equal smoothness.*

(6) $\mathcal{V}_\varphi = \mathcal{V}_\psi$.

Thus it is possible to pass from every reducible equation to an equation with complete sum rules by at most $N-1$ steps of reduction. Each step can be realized easily by exhaustion of a finite number of values θ (item 1 of Theorem 1). Furthermore, this passage preserves the smoothness of function and decreases the order of equation. Therefore, (in relation to Question 1) the case of complete sum rules is not particular but rather general. The results about the existence and smoothness of refinable functions can be extended from the case of complete sum rules to all refinable functions without any difficulty.

To generalize this result to refinement equations with infinitely many terms we formulate the second theorem of reduction. We consider (6) and assume that there exist constants $\gamma, C > 0$ such that the fast decay condition (7) is satisfied. Also we assume as before conditions (2).

Theorem 2. *Suppose $\varphi(x)$ is an L^1-solution of a reducible refinement equation* (6)*; then there exist a constant $\theta \in \mathbb{R}$ and a function $\psi(x)$ such that the following hold:*

(1) $\theta = \frac{\pi(2l+1)}{2^n}$ *for some integers $n \geq 0$ and $l \in \{0, \dots, 2^n - 1\}$. Moreover, the numbers $\frac{\theta}{2}$ and $\frac{\theta}{2} + \pi$ are roots of the equation $m_0(\xi) = 0$.*

(2) $\varphi(x) = \psi(x) - e^{i\theta}\psi(x-1)$.

(3) *The function $\psi(x)$ satisfies the refinement equation*

$$\psi(x) = \sum_{k\in\mathbb{Z}} \tilde{c}_k \psi(2x - k),$$

where the coefficients $\tilde{c}_k$ are defined from the equality

$$\sum_{k\in\mathbb{Z}} \tilde{c}_k e^{-i\xi k} = 2\tilde{m}_0(\xi) = 2\frac{m_0(\xi)(1 - e^{i(\theta-\xi)})}{1 - e^{i(\theta-2\xi)}}.$$

(4) *The functions φ and ψ have an equal smoothness.*

Condition (7) implies that the mask m_0 of (6) is holomorphic in the strip $\Gamma = \{\xi \in \mathbb{C}, \ \ |Im\ \xi| < \gamma\}$. Therefore the mask has at most finitely many zeros on the segment $[0, 2\pi]$. Thus, it is possible to pass from every refinement equation having a smooth solution to an irreducible equation by finitely many steps of reduction. So the technique, which was developed in the works [He1], [He2], and [CD2] (to estimate the Sobolev regularity of solutions of (6) in terms of the spectral radius of the corresponding transfer operator), is extended from the case of complete sum rules to the general case. Let us also note that Theorem 2 can be formulated without the assumption $\varphi \in L^1(\mathbb{R})$ (Remark 1). On the other hand, the exponential decay assumption (condition (7)) is essential for Theorem 2 to hold (Remark 9).

Question 2 has been discussed in the literature. In particular it was shown in [DGL2] that the first sum rule (condition (5)) is necessary for the convergence of subdivision scheme or, in other terms, for convergence of the *cascade algorithm* to a continuous refinable function. In section 6 we shall obtain a sharp necessary condition for a cascade algorithm to converge to a C^L-refinable function (Corollaries 7 and 8). Another result of that section reduces the problem of convergence of cascade algorithms from the general case to the case of complete sum rules (Proposition 2).

The sum rules have also found applications in the study of wavelets. Daubechies in [D] proved that the sum rules of order L are necessary for the orthogonality of wavelets constructed by refinable functions from C^L. Then Villemoes [V] showed that the first sum rule is necessary for refinable functions to possess the Riesz basis property in L^2. In section 4 we supplement these results. Namely we prove that for any $p \in [1, \infty]$ the sum rules of order L are necessary for a refinable function from W_p^L to possess the Riesz basis property in L^p (Corollary 3). This means in particular that integer translates of a reducible function cannot form a multiresolution analysis (see [C] for definitions).

We next make several comments about Question 3. Some necessary conditions for the existence of a W_p^L-solution of refinement equation were discussed in [CH], [W1] (the condition in terms of the joint spectral radius), and in [CDM] (the condition in terms of the geometric mean). We shall obtain a condition on zeros of polynomial $m_0(\xi)$ (Corollary 1) that can be easily verified for a given refinement equation (Remark 3). This condition is sharp in the sense that all its cases are realized (Corollary 2).

The other results of this paper concern the polynomial space spanned by integer translates of refinable function (Theorem 3) and special properties of the linear operators T_0 and T_1 associated to a reducible refinement equation (section 5).

3. Proof of Theorems 1 and 2.

The proof will be split into several lemmas.

LEMMA 1. *Suppose a function $\varphi(x)$ is an L^1-solution of (6) such that $\varphi \in W_1^L(\mathbb{R})$ or $s_p(\varphi) > L$, where $L \geq 0,\ p \geq 1$; then*

$$\widehat{\varphi}^{(r)}(2\pi n) = 0 \tag{9}$$

for every $n \in \mathbb{Z} \setminus \{0\}$ and $r = 0, \ldots, L$.

Proof. It follows from condition (7) that the function $m_0(\xi)$ is holomorphic in the strip $\Gamma = \{\xi \in \mathbb{C},\ \ |Im\ \xi| < \gamma\}$. Further, by iterating equality (3) k times ($k \geq 1$) we obtain

$$\widehat{\varphi}(\xi) = \widehat{\varphi}\left(\frac{\xi}{2^k}\right)\prod_{l=1}^{k} m_0\left(\frac{\xi}{2^l}\right). \tag{10}$$

It follows from (2) that $m_0(0) = 1$, hence the product $\prod_{l=1}^{k} m_0(\frac{\xi}{2^l})$ converges uniformly in every compact subset of Γ as $k \to \infty$. This shows that the function $\widehat{\varphi}(\xi)$ is holomorphic in Γ. Now if we recall that $\widehat{\varphi}(0) = 1$ (condition (2)), we obtain

$$\widehat{\varphi}(\xi) = \prod_{l=1}^{\infty} m_0\left(\frac{\xi}{2^l}\right), \quad \xi \in \Gamma. \tag{11}$$

(This is a well-known formula of solutions of refinement equations; see [D].)

Further, take arbitrary $\varepsilon \in (0, \min\{\gamma, 2\pi\})$ such that $\widehat{\varphi}(\xi)$ does not vanish in the disk $\Omega_\varepsilon = \{\xi \in \mathbb{C},\ |\xi| < \varepsilon\}$. Take also a $\delta \in [0, \varepsilon)$ and integers $n \neq 0,\ k \geq 1$. Substituting $2^{k+1}\pi n + \delta$ for ξ in (10), we get

$$\widehat{\varphi}(2\pi n 2^k + \delta) = \widehat{\varphi}\left(2\pi n + \frac{\delta}{2^k}\right)\prod_{l=1}^{k} m_0\left(2\pi n 2^{k-l} + \frac{\delta}{2^l}\right) = \widehat{\varphi}\left(2\pi n + \frac{\delta}{2^k}\right)\prod_{l=1}^{k} m_0\left(\frac{\delta}{2^l}\right).$$

It follows from (10) that there is a constant $C_\varepsilon > 0$ such that the inequality

$$\inf_{z \in \Omega_\varepsilon}\left|\prod_{l=1}^{k} m_0(\frac{z}{2^l})\right| > C_\varepsilon$$

holds for all $k \geq 1$. Therefore,

$$|\widehat{\varphi}(2\pi n 2^k + \delta)| > C_\varepsilon |\widehat{\varphi}(2\pi n + \delta 2^{-k})|. \tag{12}$$

Now suppose that $\varphi(x)$ is in $W_1^L(\mathbb{R})$; then $\xi^L \widehat{\varphi}(\xi) \to 0$ as $\xi \to \infty$ along the real axis. Combining this and (12) we see that for any $\delta \in [0, \varepsilon)$

$$(2\pi n 2^k + \delta)^L \widehat{\varphi}\left(2\pi n + \frac{\delta}{2^k}\right) \to 0 \text{ as } k \to \infty.$$

Hence the function $\widehat{\varphi}(\xi)$ has zero of order at least $L+1$ at the point $\xi = 2\pi n$. This proves Lemma 1 in the case $\varphi \in W_1^L$.

In the case $s_p > L$ we have $\int |\widehat{\varphi}(\xi)|^p(1+|\xi|^{pL})|d\xi < \infty$. On the other hand,

$$\int |\widehat{\varphi}(\xi)|^p(1+|\xi|^{pL})|d\xi \geq \sum_{k\in\mathbb{N}} \int\limits_{\varepsilon/2}^{\varepsilon} |\widehat{\varphi}(2\pi n 2^k + \delta)|^p(1+|(2\pi n 2^k+\delta)|^{pL})d\delta$$

$$> \sum_{k\in\mathbb{N}} C_\varepsilon \int\limits_{\varepsilon/2}^{\varepsilon} |\widehat{\varphi}(2\pi n + \delta 2^{-k})|^p(1+|(2\pi n 2^k+\delta)|^{pL})d\delta.$$

Since this series converges, we see that

$$\int\limits_{\varepsilon/2}^{\varepsilon} |\widehat{\varphi}(2\pi n + \delta 2^{-k})|^p(1+|(2\pi n 2^k+\delta)|^{pL})d\delta \to 0 \quad \text{as } k \to \infty.$$

Applying the mean value theorem, we get

$$|\widehat{\varphi}(2\pi n + \eta_k 2^{-k})|^p(1+|(2\pi n 2^k+\eta_k)|^{pL}) \to 0 \quad \text{as } k \to \infty,$$

where $\eta_k \in (\varepsilon/2, \varepsilon)$. This implies that the function $\widehat{\varphi}(\xi)$ has zero of order at least $L+1$ at the point $\xi = 2\pi n$. Lemma 1 is proved. □

Before we formulate the next lemma let us introduce some notation.

Consider a binary tree. The vertex of the tree is said to be an *nth level vertex* if its distance to the root of the tree is equal to n. The root has level 0. To every vertex of the tree we shall associate a number as follows: put π at the root, then put $\frac{\pi}{2}$ and $\frac{3\pi}{2}$ at the vertices on the first level. Let the number α be associated to a vertex on the nth level; then the numbers $\alpha/2$ and $\alpha/2+\pi$ are associated to its neighbors on the $(n+1)$st level. Thus there are the numbers

$$\frac{\pi(2l+1)}{2^n}, \qquad l = 0, \ldots, 2^n - 1,$$

on the nth level of the tree. For convenience we shall identify a vertex and the corresponding number. We shall call a family of vertices (or numbers) $\mathcal{A}$ a *minimal cut set* (of the tree) if every infinite path (all the paths are without backtracking) starting at the root of the tree includes exactly one element of $\mathcal{A}$. For instance a one-element set $\mathcal{A} = \{root\} = \{\pi\}$ is a minimal cut set. It is easily shown that every minimal cut set is finite. We define the *type* of the set $\mathcal{A}$ to be the maximal level of its elements.

Definition 1. We say that (6) satisfies *the condition of order* L ($L \geq 0$) if there exist $L+1$ minimal cut sets of the tree $\mathcal{A}_0, \ldots, \mathcal{A}_L$, perhaps intersecting, such that the polynomial $\prod_{k=0}^{L}\prod_{\alpha\in\mathcal{A}_k}(1-e^{i(\alpha-\xi)})$ is a divisor of the mask $m_0(\xi)$.

In other words, all the sets $\mathcal{A}_0, \ldots, \mathcal{A}_L$ consist of roots of the mask $m_0(\xi)$ and if a vertex α belongs to k sets simultaneously ($k \geq 1$), then α is a root of $m(\xi)$ with multiplicity at least k.

It is easy to see that the condition of order L is equivalent to the following one: *every infinite path* $\alpha_0 \to \alpha_1 \to \cdots$ *starting at the root of the tree includes at least* $L+1$ *zeros of the function* $m_0(\xi)$ *(counting with multiplicity).*

LEMMA 2. *An L^1-solution $\varphi(\xi)$ of refinement equation* (6) *satisfies the equality* (9) *for every $n \in \mathbb{Z} \setminus \{0\}$ and $r = 0, \dots, L$ if and only if this equation satisfies the condition of order L.*

Proof. Suppose the function $\varphi(\xi)$ satisfies condition (9) for every $n \in \mathbb{Z} \setminus \{0\}$ and $r = 0, \dots, L$. Take any infinite path $\pi = \alpha_0 \to \alpha_1 \to \cdots$. Since $\widehat{\varphi}(\xi)$ is holomorphic in the strip Γ (see the proof of Lemma 1) it follows that there exists an integer $k \geq 2$ such that $\widehat{\varphi}(\alpha_{k-1}) \neq 0$. Then equality (10) yields

$$\widehat{\varphi}(2^k \alpha_{k-1}) = \widehat{\varphi}(\alpha_{k-1}) \prod_{l=1}^{k} m_0(2^{k-l}\alpha_{k-1}) = \widehat{\varphi}(\alpha_{k-1}) \prod_{t=0}^{k-1} m_0(\alpha_t).$$

Since $2^k \alpha_{k-1} = 2\pi n$ for some integer $n \neq 0$, it follows that the function $\widehat{\varphi}(\xi)$ has zero of order at least $L+1$ at the point $2^k \alpha_{k-1}$. Consequently the set $\{\alpha_0, \dots, \alpha_{k-1}\}$ contains at least $L+1$ roots of the mask $m_0(\xi)$ (counting with multiplicity). So every infinite path starting at the root of the tree includes at least $L+1$ zeros of m_0. Hence the condition of order L is satisfied.

Conversely, suppose (6) has an L^1-solution $\varphi(x)$ and satisfies the condition of order L for some $L \geq 0$. Take any nonzero integer n. Let $n = 2^k n_1$, where n_1 is an odd integer. If we replace ξ by $2\pi n$ in (11) we obtain

$$\widehat{\varphi}(2\pi n) = \prod_{l=1}^{\infty} m_0(2\pi n 2^{-l}) = m_0(0)^k \prod_{t=0}^{\infty} m_0(\pi n_1 2^{-t}) = \prod_{t=0}^{\infty} m_0(\alpha_t),$$

where α_t is a vertex of the tree such that $\alpha_t \equiv \pi n_1 2^{-t} \pmod{2\pi}$. It follows from the condition of order L that the infinite path $\pi = \alpha_0 \to \alpha_1 \to \cdots$ includes at least $L+1$ zeros of $m_0(\xi)$ (counting with multiplicity). Hence the point $2\pi n$ is a zero of $\widehat{\varphi}(\xi)$ of order at least $L+1$; this completes the proof of Lemma 2. □

Lemmas 1 and 2 imply the following statement: if (6) has an L^1-solution φ such that $\varphi \in W_1^L(\mathbb{R})$ or $s_p(\varphi) > L$, then this equation satisfies the condition of order L. Thus there are $L+1$ minimal cut sets $\mathcal{A}_0, \dots, \mathcal{A}_L$ consisting of roots of equation $m_0(\xi) = 0$. If all these sets are trivial, i.e., $\mathcal{A}_0 = \cdots = \mathcal{A}_L = \{\pi\}$, then the sum rules of order L hold. Otherwise, if (6) is reducible, then at least one of the sets $\mathcal{A}_0, \dots, \mathcal{A}_L$ consists of more than one element. Let $\mathcal{A}_0$ be such a set. Then there is a vertex θ of the tree such that both vertices $\frac{\theta}{2}$ and $\frac{\theta}{2} + \pi$ belong to $\mathcal{A}_0$. It is clear that θ has a form $\theta = \pi(2l+1)2^{-n}$, where $n \geq 0$ is an integer and $l \in \{0, \dots, 2^n - 1\}$. Furthermore, in the case of finitely many terms (equation (1)) we have $n \leq N-2$. Indeed, since the polynomial $m_0(\xi)$ has at most N zeros on the interval $(0, 2\pi)$, we see that $Card\ \mathcal{A}_0 \leq N$ and hence the type of $\mathcal{A}_0$ is at most $N-1$. So the level of the vertex θ is at most $N-2$. This proves item 1 of Theorems 1 and 2. If we prove the next lemma, then the proof of Theorem 2 will be completed.

LEMMA 3. *Let $\varphi(x)$ be an L^1-solution of* (6). *For any $\alpha \in \mathbb{R}$ such that $m_0(\frac{\alpha}{2}) = m_0(\frac{\alpha}{2} + \pi) = 0$, there exists a function $\psi(x)$ such that the following hold:*

(a) $\varphi(x) = \psi(x) - e^{i\alpha}\psi(x-1)$.

(b) *The function $\psi(x)$ satisfies the refinement equation*

$$\psi(x) = \sum_{k \in \mathbb{Z}} \tilde{c}_k \psi(2x - k),$$

where $\tilde{c}_k$ are defined by the equality

$$\sum_{k \in \mathbb{Z}} \tilde{c}_k e^{-i\xi k} = 2\tilde{m}_0(\xi) = 2\frac{m_0(\xi)(1 - e^{i(\alpha - \xi)})}{1 - e^{i(\alpha - 2\xi)}}.$$

(c) *The functions φ and ψ have equal smoothness.*

Proof. Since $\frac{\alpha}{2}$ and $\frac{\alpha}{2}+\pi$ are roots of the mask $m_0(\xi)$, it follows that the function

$$p(\xi) = \sum_{k\in\mathbb{Z}} p_k e^{-ik\xi} = \frac{m_0(\xi)}{1-e^{i(\alpha-2\xi)}}$$

is holomorphic in the strip Γ as well as $m_0(\xi)$ (see the proof of Lemma 1). Therefore the Fourier coefficients $\{p_k\}$ have an exponential decay. Let us define a function ψ by the equality

$$\psi(x) = \sum_{k\in\mathbb{Z}} p_k \varphi(2x-k). \tag{13}$$

It follows easily that ψ is in $L^1(\mathbb{R})$ as well as φ. Further, the Fourier transform of both sides of (13) yields

$$\widehat{\psi}(\xi) = \widehat{\varphi}(\xi/2)p(\xi/2). \tag{14}$$

Hence,

$$\widehat{\varphi}(\xi) = \widehat{\varphi}(\xi/2)m_0(\xi/2) = \widehat{\varphi}(\xi/2)p(\xi/2)(1-e^{i(\alpha-\xi)}) = \widehat{\psi}(\xi)(1-e^{i(\alpha-\xi)}).$$

Thus,

$$\widehat{\varphi}(\xi) = \widehat{\psi}(\xi)(1-e^{i(\alpha-\xi)}). \tag{15}$$

The last equality implies that

$$\varphi(x) = \psi(x) - e^{i\alpha}\psi(x-1). \tag{16}$$

Since the coefficients $\{p_k\}$ have an exponential decay we see that transfer (13) from the function φ to ψ does not decrease the smoothness of function nor does inverse transfer (16). This yields that φ and ψ have an equal smoothness. By the same argument we obtain from formulas (14) and (15) that φ and ψ have an equal Sobolev regularity. Furthermore, using (14) and (15) we have

$$\widehat{\psi}(\xi) = \widehat{\varphi}(\xi/2)p(\xi/2) = \widehat{\psi}(\xi/2)p(\xi/2)(1-e^{i(\alpha-\xi/2)})$$

$$= \frac{\widehat{\psi}(\xi/2)m_0(\xi/2)(1-e^{i(\alpha-\xi/2)})}{1-e^{i(\alpha-\xi)}} = \widehat{\psi}(\xi/2)\tilde{m}_0(\xi/2).$$

Now taking the inverse Fourier transform we obtain

$$\psi(x) = \sum_{k\in\mathbb{Z}} \tilde{c}_k \psi(2x-k).$$

So the function ψ satisfies the refinement equation with the coefficients $\{\tilde{c}_k\}$. Lemma 3 is proved. This completes the proof of Theorem 2. □

Now to conclude the proof of Theorem 1 it remains to establish the additional properties of the function ψ for the case of finitely many terms (see (1)). Since in this case the mask $m_0(\xi)$ is a polynomial of degree N, we see that $p(\xi)$ and $\tilde{m}_0(\xi)$ are polynomials of degree $N-2$ and $N-1$, respectively. Therefore formula (13) can be rewritten for this case as follows:

$$\psi(x) = \sum_{k=0}^{N-2} p_k \varphi(2x-k). \tag{17}$$

We also rewrite the refinement equation for ψ:

$$\psi(x) = \sum_{k=0}^{N-1} \tilde{c}_k \psi(2x-k).$$

Since supp $\varphi = [0, N]$ (see the introduction) it immediately follows from (17) that supp $\psi = [0, N-1]$. Thus in the case of finitely many terms, passing from φ to ψ decreases the order of equation and the support of function. Further, it follows from formula (16) that $\mathcal{V}_\psi \subset \mathcal{V}_\varphi$. On the other hand the inverse transform to (16) is

$$\psi(x) = \sum_{k=0}^{+\infty} e^{i\alpha k} \varphi(x-k).$$

This implies that $\mathcal{V}_\varphi \subset \mathcal{V}_\psi$. Thus $\mathcal{V}_\varphi = \mathcal{V}_\psi$, which completes the proof of Theorem 1. □

Remark 1. Let us note that we actually used the condition $\varphi \in L^1(\mathbb{R})$ only in the proof of formula (11). So it is possible to formulate Theorem 2 in another way, without the assumption $\varphi \in L^1(\mathbb{R})$. Namely, we can define a solution φ of (6) (as in the works [He2] and [CD2]) from equality (11). If the inverse Fourier transform of (11) is a regular reducible function, then Theorem 2 still holds.

Remark 2. The passage from refinement equation with mask $m_0(\xi)$ to the equation with mask $\tilde{m}_0(\xi) = \frac{m_0(\xi)(1-e^{i(\alpha-\xi)})}{1-e^{i(\alpha-2\xi)}}$ is said to be the *transfer to the previous level.* This operation is defined for a mask m_0 if and only if $m_0(\frac{\alpha}{2}) = m_0(\frac{\alpha}{2}+\pi) = 0$. The inverse passage, which is defined for a mask $\tilde{m}_0$ satisfying $\tilde{m}_0(\alpha) = 0$, is said to be correspondingly the *transfer to the next level.* It follows from Lemma 3 that the smoothness of refinable function is stable with respect to both these operations. If α is a vertex of the tree, then the transfer to the next level is, in fact, the passage from α to the next level vertices $\frac{\alpha}{2}$ and $\frac{\alpha}{2}+\pi$. This justifies our terminology. In particular, the decomposition of a reducible function by Theorem 2 is actually a transfer to the previous level.

4. Some conclusions.

Corollary 1 (a necessary condition in terms of roots of the mask). *If refinement equation* (6) *has an L^1-solution that belongs to the space W_1^L , $L \geq 0$, then condition of order L is satisfied.*

Proof. This follows from Lemmas 1 and 2. □

Remark 3. In the case of finitely many terms it is quite easy to verify this necessary condition for a given refinement equation. It is sufficient to look over all the numbers of form $\pi q 2^{-l}$, $q \in \{1, \dots, 2^{l+1}-1\}$, $0 \leq l \leq N-L-1$ (N is the order of the equation), and put those of them that are roots of the polynomial $m_0(\xi)$ onto the tree. Here the multiplicity of any vertex is said to be equal to the multiplicity of the corresponding root of m_0. If this family of vertices has at least $L+1$ common elements (counting with multiplicity) with each infinite path from the root then the condition of order L is satisfied.

Corollary 2 (unimprovability of the necessary condition). *For every family of minimal cut sets $\mathcal{A}_0, \dots, \mathcal{A}_L$, refinement equation* (1) *of order $N = \sum_{k=0}^{L} Card\ \mathcal{A}_k$ having the mask*

$$m_0(\xi) = \frac{1}{2^L} \prod_{k=0}^{L} \prod_{\alpha \in \mathcal{A}_k} (1 - e^{i(\alpha - \xi)})$$

has a compactly supported W_∞^L-solution.

Proof. Applying the transfer to the previous level (Remark 2) we can pass from the mask m_0 to the mask

$$\tilde{m}_0(\xi) = \left(\frac{1 - e^{i(\pi - \xi)}}{2} \right)^{L+1}$$

after several steps. The solution of the corresponding refinement equation is the cardinal B-spline that belongs to W_∞^L (see, for instance, [Sc] or [DL1]). □

Example 1. A necessary condition for the existence of L_1-solution of a refinement equation is the following:

There is a minimal cut set $\mathcal{A}_0$ that consists of roots of the mask.

Remark 4. It is quite surprising that for refinement equations with nonnegative coefficients the necessary condition from Example 1 is sufficient as well. This fact was proved in [W2] (for the case $\mathcal{A}_0 = \{\pi\}$) and in [P] (for the case of arbitrary minimal cut set $\mathcal{A}_0$). Nevertheless, for $L \geq 1$ the condition of order L is not sufficient for the existence of W_1^L-solutions even if all the coefficients of (1) are positive.

Remark 5. It follows from Lemmas 1 and 2 that the condition of order L is also necessary for the property $s_p(\varphi) > L$, where φ is an L^1-solution of corresponding refinement equation.

The next two corollaries concern the Riesz basis property and linear independence of integer translates of refinable functions.

The solution φ of (1) is said to be *l_p-stable* ($1 \leq p \leq \infty$) if $\varphi \in L_p(\mathbb{R})$ and there exist positive constants A_p, B_p such that for any sequence $a = \{a_k\} \in l_p$,

$$A_p \|a\|_p \leq \left\| \sum_{k \in \mathbb{Z}} a_k \varphi(x - k) \right\|_p \leq B_p \|a\|_p; \tag{18}$$

in other words, the integer translates $\{\varphi(x - k),\ k \in \mathbb{Z}\}$ form a Riesz basis of the closure of their linear span in $L_p(\mathbb{R})$. This property is also called the *Riesz basis property* of the function φ.

The l_p-stability of solutions of refinement equations plays an essential role in the study of wavelets (see [Hu], [V], [C], [JW]). This property is also used in problems concerning the convergence of subdivision algorithms [CDM], [DM] and in the study of stability of refinable functions for small perturbations of the coefficients [H]. Several important results on l_p-stability were obtained in [V], [Z], [JW], [He3]. It is a well-known fact that the first sum rule (equality (5)) is a necessary condition for l_p-stability in the case $p = 2$ (see [V]). The following statement generalizes this result to the sum rules of arbitrary order and to arbitrary $p \in [1, \infty]$.

Corollary 3. *Every reducible refinable function is not l_p-stable for any $p \in [1, \infty]$.*

Proof. Theorem 1 implies that for any reducible equation there exists a number $\theta \in \mathbb{R}$ such that $m_0(\frac{\theta}{2}) = m_0(\frac{\theta}{2} + \pi) = 0$. This equality contradicts the Riesz basis property [JW, Theorem 1].

Another important question in the study of refinable functions is linear independence of their integer translates (see [CDM], [C], [JW], [Z]). Theorem 1 yields the following result.

COROLLARY 4. *Integer translates of any reducible function are linearly dependent.*

Proof. We could again use the results of work [JW], but it is simpler to prove this corollary in another way. By Theorem 1 a reducible function $\varphi(x)$ can be decomposed into the sum $\varphi(x) = \psi(x) - e^{i\theta}\psi(x-1)$ for suitable θ and ψ. Whence,

$$\sum_{k\in\mathbb{Z}} e^{ik\theta}\varphi(x-k) = \sum_{k\in\mathbb{Z}} (e^{ik\theta}\psi(x-k) - e^{i(k+1)\theta}\psi(x-k-1)) = 0. \qquad \square$$

As we mentioned in section 2, a lot of previous results on the refinement equations, obtained for the case of complete sum rules, can be transferred by Theorem 1 to the general case without any change. We present one example.

COROLLARY 5. *Any W_1^L-refinable function possesses the following property:*

$$\sum_{k\in\mathbb{Z}} (x-k)^r \varphi(x-k) = \text{const}, \quad r = 0, \dots, L. \tag{19}$$

Remark 6. In the case $L = 0$ this statement was proved independently in [W1] and [CDM] (in that work the case of multivariate continuous refinable functions was considered).

Proof. This statement holds for equations that satisfy the sum rules (see [D]). Since the reduction by Theorem 1 preserves property (19) then this property holds for all refinable functions. $\square$

Corollaries 1 and 5 make it possible to obtain some information about a polynomial space which is spanned by integer translates of a refinable function. The problem is to construct necessary and sufficient conditions on a refinable function φ, which ensure that the space $\mathcal{V}_\varphi$ contains a given polynomial space. This problem has been studied in connection with subdivision algorithms (see [DyL] or [CDM] for many references). The work [CDM] contains a detailed multivariate discussion of this question. In particular it was shown that in the case when the integer translates $\{\varphi(x-k),\ k \in \mathbb{Z}\}$ are linearly independent, $\mathcal{V}_\varphi$ contains the space Π_L if and only if the sum rules of order L are satisfied. (Let us remember that we denote by Π_L the space of polynomials of degree at most L.) In the general case (without the independence assumption) Theorem 9.1 in [CDM] yields several criteria for the inclusion $\Pi_L \subset \mathcal{V}_\varphi$ to hold. Now let us formulate another criterion (for the univariate case) that is simpler to apply. We claim that the condition $\Pi_L \subset \mathcal{V}_\varphi$ is equivalent to the condition of order L (see Definition 1).

THEOREM 3. *For any refinable function $\varphi(x)$ and for any integer $L \geq 0$ the following properties are equivalent:*

(i) *The mask of the corresponding refinement equation* (1) *satisfies the condition of order L;*

(ii) *equality* (19) *holds for every $r = 0, \dots, L$;*

(iii) *for every $r = 0, \dots, L$ the function $\sum_{k\in\mathbb{Z}} k^r \varphi(x-k)$ is a polynomial of degree r. The leading coefficient of this polynomial is equal to* 1*;*

(iv) $\Pi_L \subset \mathcal{V}_\varphi$.

Proof. (i) ⇒ (ii). The proof is the same as that of Corollary 5.

(ii) ⇒ (iii). In the case $L = 0$ equality (19) yields $\sum \varphi(x-k) = \int \varphi(x)dx = 1$. Now property (iii) can be easily established by induction with respect to the parameter L.

(iii) ⇒ (iv). This is obvious.

(iv) ⇒ (i). The property $\Pi_L \subset \mathcal{V}_\varphi$ implies that $\widehat{\varphi}^{(r)}(2\pi n) = 0$ for every $n \in \mathbb{Z} \setminus \{0\}$, $r = 0, \dots, L$ ([CDM, Theorem 9.1]). Now we apply Lemma 2. This concludes the proof of Theorem 3. □

Remark 7. It was shown in [HC] (Proposition 4.13 of that work) that the sum rules of order L are sufficient for a refinable function to possess property (iii). Theorem 3 generalizes this result.

Remark 8. Theorem 3 and Corollary 1 imply in particular that every C^L-refinable function possesses property (iv). This fact was first established in Theorem 8.3 of [CDM].

Remark 9. Note that the fast decay assumption (7) in the statement of Theorem 2 is essential. In general the second theorem of reduction does not hold for refinement equations with infinitely many terms. Namely, there is a refinement equation

$$\varphi(x) = \sum_{k \in \mathbb{Z}} c_k \varphi(2x - k) \tag{20}$$

that is reducible (it has a unique, up to normalization, L_1-solution φ and does not satisfy the first sum rule (5)) and that possesses the following property:

If for some $\theta \in \mathbb{R}$ and $\psi \in L_1$ the decomposition

$$\varphi(x) = \psi(x) - e^{i\theta}\psi(x-1)$$

holds, then the function ψ does not satisfy any refinement equation.

Moreover, the coefficients $\{c_k\}$ of (20) decrease faster than polynomially, i.e., $\sup_{k \in \mathbb{Z}} |c_k k^l| < \infty$ for all $l > 0$. This example was constructed in [P]. Thus the assumption of exponential decay in the statement of Theorem 2 cannot be replaced by one of polynomial decay.

5. The reducibility property on time domain. In this section we restrict ourselves to the case of finitely many terms (refer to (1)). Throughout this paper we use the Fourier transform technique on frequency domain. However, there is another approach in the study of refinement equations with finitely many terms. This approach is based on the use of finite-dimensional linear operators on the time domain. This leads in many aspects to sharper results on refinable functions than the Fourier transform method (see the introduction for references). The question arises whether anything special can be said about reducible refinement equations in terms of the time domain approach. Before we formulate the main result of this section let us recall some notation.

For a given refinement equation (1) consider the two linear operators T_0 and T_1 acting on $\mathbb{C}^N$ and defined by matrices as follows:

$$(T_0)_{ks} = c_{2k-s-1}, \qquad (T_1)_{ks} = c_{2k-s}, \tag{21}$$

where c_l is the coefficient of (1) if $l \in \{0, 1, \dots, N\}$ and $c_l = 0$ otherwise.

Suppose (1) has an L^1-solution $\varphi(x)$. Then this solution is supported in the segment $[0, N]$ (see the introduction). Further, let us define a vector-function v_φ :

$[0,1] \longrightarrow \mathbb{C}^N$ by equality

$$v_\varphi(x) = \Big(\varphi(x), \varphi(x+1), \dots, \varphi(x+N-1)\Big)^T.$$

If φ is a continuous function on $\mathbb{R}$, then for any dyadic $x \in [0,1]$ we have the formula

$$v_\varphi(x) = T_{d_1} \cdots T_{d_q} v_\varphi(0). \tag{22}$$

Here $x = 0.d_1 \cdots d_q$, the index $d_j(x)$ is the jth digit in the binary expansion for x, and $v_\varphi(0)$ is an eigenvector of T_0 with the eigenvalue 1 (see [DL1], [CH]).

Otherwise, if $\varphi(x)$ is not continuous, we can use another formula

$$\int\limits_x^{x+2^{-q}} v_\varphi(x)dx = 2^{-q} T_{d_1} \cdots T_{d_q} \left(\int\limits_0^1 v_\varphi(x)dx \right) \tag{23}$$

instead of equality (22) (see [LW]). Now we are going to establish some special properties of the operators T_0 and T_1 in the case of reducible refinement equations.

First let us introduce some further notation. For a refinement equation denote by $\mathcal{B}$ the set of vertices of the tree that are roots of the mask of this equation. Further, denote by $\tilde{\mathcal{B}}$ the set of the vertices that are blocked by $\mathcal{B}$, i.e.,

$$\alpha \in \tilde{\mathcal{B}} \Longleftrightarrow \text{every infinite path from } \alpha \text{ intersects } \mathcal{B}.$$

For example, the set $\mathcal{B}$ of (8) is $\{\frac{\pi}{2}, \ \frac{3\pi}{2}\}$; consequently $\tilde{\mathcal{B}} = \{\pi\}$. It follows from Lemmas 1 and 2 that the set $\mathcal{B}$ of a reducible equation contains at least one nontrivial (other than $\{\pi\}$) minimal cut set. Hence for any reducible refinement equation the set $\tilde{\mathcal{B}}$ is nonempty.

For any $\beta \in \mathbb{R}$ let us define the vector $u(\beta) = (1, e^{i\beta}, e^{2i\beta}, \dots, e^{i(N-1)\beta})^T \in \mathbb{C}^N$.

As usual we shall denote by $\langle x, y \rangle = \sum_{j=1}^N x_j \overline{y_j}$ the scalar product in $\mathbb{C}^N$, by $Span(M)$ the linear span of a given set M in $\mathbb{C}^N$, by A^* the conjugate operator for a given operator A.

Proposition 1.

(1) Matrices T_0 and T_1 of every reducible refinement equation are degenerate. Moreover, T_0^* and T_1^* have a nontrivial common kernel.

(2) The family of operators $\{T_0^*, T_1^*\}$ is nilpotent on the nontrivial invariant subspace $Span\{u(\alpha), \ \alpha \in \tilde{\mathcal{B}}\}$.

(3) $Span\{v_\varphi(x), \ \ x \in [0,1]\} \perp Span\{u(\alpha), \ \alpha \in \tilde{\mathcal{B}}\}$.

Proof. Item (1) obviously follows from (2). To prove item (2) observe the following property of operators T_0 and T_1, which can be verified by direct calculation:

$$\begin{aligned} T_0^* u(\beta) &= \overline{m_0\Big(\frac{\beta}{2}\Big)} u\Big(\frac{\beta}{2}\Big) + \overline{m_0\Big(\frac{\beta}{2}+\pi\Big)} u\Big(\frac{\beta}{2}+\pi\Big), \\ T_1^* u(\beta) &= e^{-\frac{i\beta}{2}} \overline{m_0\Big(\frac{\beta}{2}\Big)} u\Big(\frac{\beta}{2}\Big) + e^{-i(\frac{\beta}{2}+\pi)} \overline{m_0\Big(\frac{\beta}{2}+\pi\Big)} u\Big(\frac{\beta}{2}+\pi\Big). \end{aligned} \tag{24}$$

These equalities immediately imply that

$$T_{d_1}^* \cdots T_{d_q}^* u(\alpha) = 0 \qquad \text{for every } \alpha \in \tilde{\mathcal{B}} \text{ and } (d_1, \dots, d_q) \in \{0,1\}^q, \tag{25}$$

where q is the type of the set $\mathcal{B}$. So the family $\{T_0^*, T_1^*\}$ is nilpotent on the subspace $Span\{u(\alpha),\ \alpha \in \tilde{\mathcal{B}}\}$. It remains to note that for any reducible equation this subspace is nontrivial, since the set $\tilde{\mathcal{B}}$ is nonempty. This proves item (2).

To prove item (3) assume first that φ is a continuous function on $\mathbb{R}$. It follows from (25) that the equality

$$\Big\langle T_{d_1} \cdots T_{d_q} b,\ u(\alpha) \Big\rangle = 0$$

holds for any $b \in \mathbb{C}^N$. Applying (22) we conclude that equality $\langle v_\varphi(x), u(\alpha) \rangle = 0$ holds for every dyadic x, and consequently, since $v_\varphi(x)$ is continuous, it holds for every $x \in [0, 1]$. So the proof is completed for a continuous φ.

In the other case, when $\varphi \in L^1(\mathbb{R})$ is not continuous, we have to repeat the proof stated above, but we must apply formula (23) instead of (22). □

COROLLARY 6. *If at least one of the matrices T_0, T_1 of* (1) *is nondegenerate then the sum rules of order L are necessary for the existence of a W_1^L-solution.*

Remark 10. Formulas (24) can also be obtained from general properties of the transfer operator (see [E], [CD2] for details). In particular a very similar expression was used in [CD2, formula 7.3].

6. On convergence of the cascade algorithm. In this section we consider equations with finitely many terms (see (1)). In the paper [D] Daubechies introduced the *cascade algorithm* for finding solutions of refinement equations. The one iteration of that algorithm is

$$f_n = T f_{n-1},$$

where

$$Tf(x) = \sum_k c_k f(2x - k). \tag{26}$$

If f_n converges uniformly to a continuous function φ for some initial function f_0, then φ is a continuous solution of corresponding refinement equation (1), and moreover, f_0 possesses the property

$$\sum_k f_0(x - k) \equiv \text{ const} \tag{27}$$

(see [CDM], [Du1]). The cascade algorithm *converges* if f_n converges uniformly to φ for any compactly supported continuous function f_0 satisfying (27). Properties of the cascade algorithm have been studied by many authors in various contexts. The cascade algorithm gives a simple way to approximate refinable functions. In particular this yields applications to the study of wavelets [D], [DL1], [Du1], [Du2]. On the other hand the convergence of the cascade algorithm is equivalent to the convergence of the associated subdivision scheme (see [DM] for many references). It is clear that convergence of the cascade algorithm implies the existence of a continuous solution for the corresponding refinement equation. In general the converse does not hold. (See [DL1] for corresponding examples. The correlation between the existence of continuous solution of a refinement equation and the convergence of the associated subdivision scheme is a rather complicated question. See [CDM], [DM] for general multivariate discussions of this aspect. Some interesting results of the papers [HC] and [CH] actually concern this question, although subdivision schemes were not mentioned explicitly in those works.) It is a well-known fact that the first sum rule (5) is a necessary condition for the cascade algorithm to converge [DGL2], [DyL]. Nevertheless, the sum rules of order $L \geq 1$ are not necessary for that, even if the limit refinable function is in C^L. Corollary 7 of this section yields necessary conditions to the convergence of the cascade algorithm to a smooth function. These conditions are sharp in some sense (Corollary 8). Another problem is to obtain a similar result to that of Theorem 1 for cascade algorithms, i.e., to reduce the general case to the well-studied case of complete sum rules. In general, the convergence property of the cascade algorithm is not stable with respect to the operation of transfer to the next level, unlike the existence and smoothness of refinable functions. This is one example.

Example 2. The cascade algorithm associated to (8) does not converge, since the first sum rule does not hold. Applying the reduction by Theorem 1 we obtain the irreducible equation

$$\varphi(x) = \frac{1}{3}\varphi(2x) + \varphi(2x-1) + \frac{2}{3}\varphi(2x-2). \tag{28}$$

The cascade algorithm associated to this equation converges (this follows directly from Theorem 3.3 of [CDM]). So the convergence property fails with the transfer to the next level from (28) to (8).

Thus the reduction by Theorem 1 can change the convergence property of the cascade algorithm. Before we formulate the main result of this section let us introduce some notation. Consider the space $C_0(\mathbb{R})$ of compactly supported continuous functions on $\mathbb{R}$. A sequence $\{f_n\} \subset C_0$ tends to zero in this space if $f_n \to 0$ uniformly on $\mathbb{R}$ and the supports of the functions f_n are uniformly bounded. Define the subspace $\mathcal{L} \subset C_0$ as follows:

$$\mathcal{L} = \left\{ f \in C_0 \Big| \ \sum_k f(x-k) \equiv 0 \right\}.$$

Note that by the Poisson summation formula the equality $\sum_k f(x-k) \equiv 0$ is equivalent to $\widehat{f}(2\pi n) = 0,\ n \in \mathbb{Z}$. It easily can be proved that the operator T defined by (26) preserves the subspace $\mathcal{L}$ if and only if the first sum rule holds, i.e., $m_0(\pi) = 0$. Moreover, the cascade algorithm converges if and only if the operator T^n restricted to $\mathcal{L}$ tends to zero (in the topology of C_0) as $n \to \infty$.

We shall also need the notion of the transfer to the next (previous) level defined in Remark 2.

LEMMA 4. *Let m_0 be a mask satisfying $m_0(\pi) = 0$. Suppose $\tilde{m}_0$ is obtained from m_0 by a transfer to the previous level; then the cascade algorithm associated to the mask m_0 converges if and only if the algorithm associated to $\tilde{m}_0$ does.*

Proof. Let us define the function $p(\xi)$ and the sequence $\{p_k\}$ as in the proof of Lemma 3:

$$p(\xi) = \sum_{k=0}^{N-2} p_k e^{-ik\xi} = \frac{m_0(\xi)}{1 - e^{i(\alpha - 2\xi)}}.$$

Define also two operators P and S acting in the space C_0:

$$\left(P\psi\right)(x) = \sum_{k=0}^{N-2} p_k \psi(2x-k),$$

$$(S\psi)\,(x) = \psi(x) - e^{i\alpha}\psi(x-1).$$

In the frequency domain these operators have the following form:

$$\widehat{P\psi}(\xi) = \widehat{\psi}(\xi/2)p(\xi/2); \quad \widehat{S\psi}(\xi) = \widehat{\psi}(\xi)(1-e^{i(\alpha-\xi)}). \tag{29}$$

Now observe the following relations:

$$PS = \tilde{T}, \quad SP = T, \tag{30}$$

where T and $\tilde{T}$ are operators of the cascade algorithms associated to m_0 and $\tilde{m}_0$, respectively. To prove this we apply (29) and get

$$\widehat{PS\psi}(\xi) = p(\xi/2)(1-e^{i(\alpha-\xi/2)})\widehat{\psi}(\xi/2) = \tilde{m}_0(\xi/2)\widehat{\psi}(\xi/2) = \widehat{\tilde{T}\psi}(\xi).$$

The equality $SP = T$ can be established in the same way. [It is clear that both P and S are continuous operators on $C_0(\mathbb{R})$.] Furthermore, both P and S preserve the subspace $\mathcal{L}$. To see this take any $\psi \in \mathcal{L}$ and apply formulas (29)

$$\widehat{P\psi}(2\pi n) = \widehat{\psi}(\pi n)p(\pi n) = 0.$$

Let us clarify the last equality. If n is even, then $\widehat{\psi}(\pi n) = 0$, since $\psi \in \mathcal{L}$. If n is odd then by the assumption $p(\pi n) = 0$. For the operator S we have

$$\widehat{S\psi}(2\pi n) = \widehat{\psi}(2\pi n)(1-e^{i(\alpha-2\pi n)}) = 0.$$

It follows from (30) that $T^k = S\tilde{T}^{k-1}P$ for every $k \geq 1$. Therefore, since P and S are continuous and preserve the subspace $\mathcal{L}$, the convergence $\tilde{T}^{k-1} \to 0$ on $\mathcal{L}$ implies the convergence $T^k \to 0$ on $\mathcal{L}$. Conversely, from the equality $\tilde{T}^k = PT^{k-1}S$ it follows that the convergence $T^{k-1} \to 0$ it implies that $\tilde{T}^k \to 0$. The lemma is proved. ∎

As a corollary we obtain the following proposition that reduces the problem of convergence of the cascade algorithms to the case of complete sum rules.

PROPOSITION 2. Let us have a reducible refinement equation satisfying the first sum rule. Suppose we pass to an irreducible equation by Theorem 1 after several steps; then the cascade algorithm associated to the first equation converges if and only if the algorithm associated to the second equation does.

Another corollary yields a necessary condition for the cascade algorithm to converge to a function from $W_1^L(\mathbb{R})$.

COROLLARY 7. *If the cascade algorithm associated to a mask m_0 converges to a compactly supported function from W_1^L $(L \geq 1)$ then the condition of order L is satisfied and $m_0(\pi) = 0$, i.e., there are $L+1$ minimal cut sets of the tree consisting of roots of the mask (counting with multiplicity), and one of them is trivial (coincides with $\{\pi\}$).*

This condition is sharp in the sense that every possible case is realized. The proof of the following corollary is the same as that of Corollary 2.

COROLLARY 8 (unimprovability of the necessary condition). *For every family of minimal cut sets $\mathcal{A}_0, \dots, \mathcal{A}_L$, where $L \geq 1$ and $\mathcal{A}_0 = \{\pi\}$, the cascade algorithm associated to the mask*

$$m_0(\xi) = \frac{1}{2^L}\prod_{k=0}^{L}\prod_{\alpha\in\mathcal{A}_k}(1-e^{i(\alpha-\xi)})$$

converges to a compactly supported function from W_∞^L.

Acknowledgments. I would like to sincerely thank Professors I. Daubechies, S. Konyagin, and J. Lagarias for helpful discussions and Professor Yu. Farkov for useful remarks.

This paper was written when I was visiting the Institute for Advanced Study. I am very grateful to the Institute for its warm hospitality.

THE MECHANISM OF THE POLARIZATIONAL MODE INSTABILITY IN BIREFRINGENT FIBER OPTICS*

YI A. LI† AND KEITH PROMISLOW‡

Abstract. We show that the soliton solutions of the integrable Manakov equation exhibit an instability under arbitrarily small Hamiltonian perturbations. The instability arises from eigenvalues embedded in the essential spectrum of the associated linearized operators; these eigenvalues are dislodged by smooth perturbations. Specifically we consider perturbations which arise in fiber optics as a result of birefringence, including the so-called four-wave mixing term. Employing the Evans function and a Dirichlet expansion on the stable manifold of the linearized system, we obtain rigorous perturbation results and compute the stability diagram of the fast wave for all physical values of the birefringent parameters, using a novel numerical scheme derived from the Dirichlet expansion.

Key words. traveling waves, Evans function, polarization mode instability, Dirichlet expansion

1. Introduction.

Soliton pulses form the backbone of high speed fiber-optic telecommunication systems and hold great potential for all optical switching devices. Attempts to further increase bit rates exploit the robust elastic collision properties of solitons, in particular, novel soliton packing schemes propose to subdivide information streams into different wavelengths—wavelength division multiplexing (WDM), or into orthogonal polarizations—polarization division multiplexing (PDM) [9]. However, a proper modeling of these schemes, especially to address stability properties, requires careful attention to the various perturbations which are present in optical systems.

To model the interaction of the orthogonal polarizations of a pulse, the widely studied nonlinear Schrödinger equation (NLS) is extended to the integrable Manakov system. However, fiber-optic systems exhibit birefringence, differing phase and group velocities for different polarizations, as well as nonlinear interactions between polarizations dependent upon amplitude—cross-phase modulation (XPM) and upon complex phase—four-wave mixing (FWM). The nonlinear terms break the integrability of the Manakov equation and numerical simulations including these nonlinearities have demonstrated pulse splitting and inelastic collisions, [32, 38]. We consider the case of weak birefringence, neglecting group velocity birefringence and higher order dispersions.

Many applications of single-mode fibers require transmission of a stable state of polarization. In PDM, to reduce tail-tail interactions and increase soliton packing, solitons are sent in sequences with polarizations alternating between the fast and slow polarization axes. While the slow wave enjoys all the stability properties of the NLS soliton, in the nonintegrable case it was discovered numerically [6] that the fast wave can experience what is termed the polarization mode instability, which leads to loss of linear polarization. It has been common to neglect the FWM, arguing that the polarization axes change rapidly or even stochastically with propagation distance.

However, for soliton collisions and applications where polarization holding is desired, the polarization axes can be assumed constant with distance. Moreover, we show rigorously that the FWM produces sensitive, leading-order effects on the stability of the fast wave.

The linearization of the perturbed equations about the fast wave yields a two-parameter family of non-self-adjoint operators with a rich structure. In the integrable case there are eigenvalues embedded in the essential spectrum, and the stability of the fast wave depends upon the fate of these embedded eigenvalues under the continuous perturbations of XPM and FWM. In a beautiful construction, Grillakis [12] showed that arbitrarily small, relatively compact perturbations could eject embedded eigenvalues and produce instability. However, the construction is in a sense unnatural, involving delta functions in the spectral projection, and it has been open to speculation whether such eigenvalues could be ejected by continuous terms. We show that this is exactly the case—arbitrarily small perturbations do eject the embedded eigenvalues, whose distance to the essential spectrum initially grows quadratically in the coefficient of FWM. This is the mechanism of the polarizational mode instability, and it is in this sense that PDM is structurally unstable. We also find edge bifurcations, a special case in which the branch points of the essential spectrum eject eigenvalues.

Our analysis combines two analytical tools in a novel way—the Evans function for the linearization and a Dirichlet expansion on the stable manifold of the associated first order eigenvalue problem. The Evans function is an analytic function whose zeros coincide with the eigenvalues of the operator up to algebraic multiplicity. It has recently been the focus of considerable attention, having proven its effectiveness as an analytical tool for eigenvalue problems; see [16, 18] and the references therein. The works just cited, and particularly [16], develop techniques to calculate the first nonzero derivative of the eigenvalues with respect to the bifurcation parameters. In the analysis at hand we require the second nonzero derivative, and this is the first such computation known to the authors. Indeed, the detailed description of the motion of the eigenvalues, provided in that which follows, is testimony to efficacy of the Evans function. In previous work [22], we investigated the issues of structural stability of these waves, but the functional analytic techniques employed failed to shed light upon the fate of the embedded eigenvalues.

The Evans function and Dirichlet expansion are a particularly effective combination in the near-integrable regime; it also admits analysis when the perturbations are not small. Indeed, even far from the integrable case, the Dirichlet expansion gives a constructive formulation of the Evans function, rendering a transparent analytic extension into the essential spectrum. We exploit this construction to develop a hybrid numerical scheme which efficiently yields an accurate computation of the Evans function, making possible a detailed resolution of the eigenvalue problem. Indeed, we present a sequence of bifurcations common to several families of operators arising as linearizations about traveling waves of integrable systems under Hamiltonian perturbations [2, 26, 31]. Consider a linear operator whose spectrum is symmetric about the real and imaginary axes, and whose essential spectrum, of positive Krein sign (see [12]) takes the form $\{\pm i\mu | \mu > \mu_0\}$ with branch points at $\pm i\mu_0$, leaving uncovered a neck $(-i\mu_0, i\mu_0)$ of the imaginary axis containing the origin. Negative Krein sign eigenvalues embedded in the essential spectrum may bifurcate out under the influence of the perturbative terms. Symmetric groups of four eigenvalues, $\{\lambda, \lambda^*, -\lambda, -\lambda^*\}$, are ejected from the essential spectrum and pass through the complex plane with increasing values of the bifurcation parameter. Depending upon the length of the exposed neck, the eigenvalues may recombine in pairs either upon the real axis or upon the exposed neck of the imaginary axis, or, in a critical case, all four may arrive at the origin simultaneously. We call this phenomena a *neck bifurcation*; see Figures 1 and 2 and the discussion in section 5 for a detailed description. For the underlying equation, this bifurcation may manifest itself as an oscillatory instability under small perturbation, stability under moderate perturbations, and with yet larger perturbations leading to nonoscillatory instability.

This paper is organized as follows. In section 2 we introduce the coupled nonlinear Schrödinger systems (CNLS), the traveling waves, and their associated linearized operators, recalling the previously obtained results. In section 3 the eigenvalue problem is set up and the Dirichlet expansion solutions are constructed. The essence of our analysis lies in section 4, where we introduce the Evans function and obtain the main results, Theorems 4.3 and 4.5, which describe the asymptotic motion of the embedded eigenvalues under small perturbations. In section 5 we address the far from integrable case and provide new, rigorous-numerical results on the stability in this case; in particular, we trace the parameter dependence of the unstable eigenvalues, find the structurally stable regimes, and introduce the *neck bifurcation*.

Remark. Recently, Kapitula and Rubin [17] independently and simultaneously developed an expansion of the Evans function at its branch points similar to the expansion used herein to prove Proposition 4.6. They apply the expansion to detect edge bifurcations undergone by dark soliton solutions of NLS and complex Ginzburg–Landau under a wide class of pertubations.

2. The CNLS equations and notation.

Pulse propagation in linearly birefringent, lossless fibers is described by the CNLS equations [9]

$$\begin{aligned} i(u_t+\delta u_x)+\tfrac{1}{2}u_{xx}-\kappa u+(|u|^2+A|v|^2)u+Bv^2u^* &= 0,\\ i(v_t-\delta v_x)+\tfrac{1}{2}v_{xx}+\kappa v+(A|u|^2+|v|^2)v+Bu^2v^* &= 0, \end{aligned} \tag{2.1}$$

where the coefficient $\kappa>0$ is the phase velocity differential between the two polarizations, the XPM and FWM coefficients, respectively A and B, are positive and satisfy $A+B=1$. The complex valued solution $(u,v)^T$ represents the two orthogonal polarizations of the electromagnetic field, * denotes complex conjugation, and a superscript ^{T} denotes a transpose. Following the optics convention, t connotes scaled distance of propagation and x connotes scaled time. In that which follows, we eliminate the XPM coefficient by the substitution $A=1-B$ and employ the FWM coefficient, B, as the bifurcation parameter.

In what is termed the weak birefringence limit we neglect the group velocity birefringence δ and assume that κ is relatively small. In this form the CNLS equations possess a Hamiltonian $\mathcal{H}=\mathcal{H}_0+\mathcal{H}_1$ where $\mathcal{H}_0$ is the Hamiltonian of the integrable Manakov equation,

$$\mathcal{H}_0=\frac{1}{4}\int_{-\infty}^{\infty}\left[\left(|u_x|^2+|v_x|^2\right)-\left(|u|^2+|v|^2\right)^2+2\kappa\left(|u|^2-|v|^2\right)\right]dx,$$

and $\mathcal{H}_1$ is the birefringent perturbation,

$$\mathcal{H}_1=-\frac{B}{4}\int_{-\infty}^{\infty}\left(vu^*-uv^*\right)^2dx.$$

Large classes of solitary wave solutions of (2.1) have been found explicitly; they are the bound n-soliton solutions of the integrable Manakov equation with n-identical speeds c. We focus attention on the one-soliton. For the Manakov equation the general one-soliton is

$$\begin{pmatrix} u \\ v \end{pmatrix}(x,t) = e^{ic(x-ct)}\eta \begin{pmatrix} e^{i\omega_1 t}\cos\alpha \\ e^{i\omega_2 t}\sin\alpha \end{pmatrix} \phi\left(\eta(x-ct)\right) \tag{2.2}$$

with $\phi(x) = \operatorname{sech} x$, $\eta \geq 0$, and ω_1 and ω_2: related through η, κ, and speed c:

$$\begin{aligned} \omega_1 &= \frac{\eta^2+c^2}{2} - \kappa, \\ \omega_2 &= \frac{\eta^2+c^2}{2} + \kappa. \end{aligned}$$

Due to the Galilean invariance, it is sufficient to consider standing waves with speed $c = 0$. When $B \neq 0$ the CNLS equation does not support the traveling waves with differing phase velocity, and the persistent solutions are $(u,v)^T = e^{i\omega_j t}\Phi_j(x)$, where

$$\begin{aligned} \Phi_1 &= \eta \begin{pmatrix} 1 \\ 0 \end{pmatrix} \phi(\eta x), \\ \Phi_2 &= \eta \begin{pmatrix} 0 \\ 1 \end{pmatrix} \phi(\eta x). \end{aligned}$$

We call these the "up" and "down" waves, respectively, in analogy to the "up" and "down" states of a pendulum. It is well known that the down wave, or slow wave as it is called in the optics community, is the ground state of the Hamiltonian system and is orbitally stable; see [13]. The up wave, or fast wave, is not a ground state and may be linearly unstable. Our goal is to lay transparent the mechanism which leads to the instability of the up wave as B changes from zero.

Addressing the linear stability of the up wave, we rescale as $\tilde{x} = \eta x$ and drop the $\tilde{}$ and the subscript from the phase velocity $\omega = \omega_1$. We consider solutions W to (2.1) which are perturbations of the up wave of the form

$$W = e^{i\omega t}\left(\Phi_1 + e^{\lambda t}U\right),$$

where $U = (u,v)^T$ is small. The rescaling introduces a dimensionless parameter $\rho = \sqrt{\frac{\omega-\kappa}{\omega+\kappa}}$, which takes values in $(0,1)$; ρ expresses the relative strength of the phase velocity differential κ to the phase velocity ω. Keeping terms first order in U, we obtain two uncoupled eigenvalue problems, one each for the two components $u = u_1 + iu_2$ and $v = v_1 + iv_2$, of U.

$$\begin{aligned} J\mathcal{L}_1 \begin{pmatrix} u_1 \\ u_2 \end{pmatrix} &= \lambda \begin{pmatrix} u_1 \\ u_2 \end{pmatrix}, && \text{(a)} \\ J\mathcal{L}_2 \begin{pmatrix} v_1 \\ v_2 \end{pmatrix} &= \lambda \begin{pmatrix} v_1 \\ v_2 \end{pmatrix}, && \text{(b)} \end{aligned} \tag{2.3}$$

where

$$\begin{aligned} \mathcal{L}_1 &= \begin{pmatrix} -\frac{1}{2}\frac{d^2}{dx^2} + \frac{1}{2} - 3\phi^2 & 0 \\ 0 & -\frac{1}{2}\frac{d^2}{dx^2} + \frac{1}{2} - \phi^2 \end{pmatrix}, \\ \mathcal{L}_2 &= \begin{pmatrix} -\frac{1}{2}\frac{d^2}{dx^2} + \frac{\rho^2}{2} - \phi^2 & 0 \\ 0 & -\frac{1}{2}\frac{d^2}{dx^2} + \frac{\rho^2}{2} - (1-2B)\phi^2 \end{pmatrix}, \end{aligned}$$

and $J = \left(\begin{smallmatrix} 0 & 1 \\ -1 & 0 \end{smallmatrix}\right)$. The non-self-adjoint operators $L_1 = J\mathcal{L}_1$ and $L_2 = J\mathcal{L}_2$ are disjoint parts of the linearized operator

$$L = \begin{pmatrix} L_1 & 0 \\ 0 & L_2 \end{pmatrix};$$

the spectrum of L is the union of the spectra of L_1 and L_2. The operator L_1 is well known as it arises in the linearization of the cubic nonlinear Schrödinger equation,

$$iu_t + \frac{1}{2}u_{xx} - \kappa u + |u|^2 u = 0,$$

about the solitary wave solution $u = \eta e^{i\omega t}\operatorname{sech}\eta x$. It has only one discrete eigenvalue $\lambda = 0$, with algebraic multiplicity four and a continuous spectrum composed of the line segment $\{\Re z = 0, |\Im z| \geq \frac{1}{2}\}$. To determine if the spectrum of L is purely imaginary it suffices to study the two-parameter family of operators $L_2(\rho, B)$; we consider values $(\rho, B) \in (0,1) \times \mathbf{R}$.

The operator L_2 was studied by the authors in [22]; in particular, it was shown that the spectrum of L_2 is symmetric about both the real and the imaginary axes and the essential spectrum consists of the set $\{\Re z = 0, |\Im z| \geq \frac{\rho^2}{2}\}$. For $B \geq 0$, the point spectrum of L_2 consists of at most four eigenvalues, also symmetric about the real and the imaginary axes. For the integrable case, $B = 0$, L_2 has eigenvalues $\lambda_\pm = \pm i\frac{1-\rho^2}{2}$ with associated eigenvectors $(\phi, \mp i\phi)^T$. For $\rho \leq \frac{1}{\sqrt{2}}$, these eigenvalues are embedded in the essential spectrum. Moreover (see Theorem 6 of [22]) L_2 has no kernel except for critical values $B = B_c(\rho) = \frac{1}{4}(2+\rho)(1-\rho)$ for which zero is an eigenvalue of L_2 of multiplicity two or four. For fixed ρ small enough, and $B = B_c$, the multiplicity is two and the eigenvalues arrive at zero from the real axis as B increases to $B_c(\rho)$. For ρ close enough to 1, the multiplicity is again two but the eigenvalues arrive at zero along the imaginary axis as B increases to B_c, and for at least one value of ρ, the multiplicity is four and the eigenvalues $\{\lambda, \lambda^*, -\lambda, -\lambda^*\}$ arrive symmetrically, one from each quadrant of the complex plane.

In the next two sections we extend these results significantly, localizing the point spectrum of L_2 by computing leading order asymptotics of its eigenvalues for B small, in particular at the embedded eigenvalue and the branch points. The first step is the development of a Dirichlet expansion, given by Theorem 3.2, which constructs solutions of the linearized eigenvalue problem (2b) satisfying one-sided boundary conditions.

3. The reduced system.

We begin by writing the eigenvalue problem for L_2 as a system of first order differential equations

$$Y' = A(\lambda, x)Y, \tag{3.1}$$

where $'$ denotes differentiation with respect to x, $Y = (y_1, y_2, y_3, y_4)^T = (v_1, v_2, v_{1x}, v_{2x})^T$, and

$$A(\lambda, x) = \begin{pmatrix} 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ \rho^2 - 2\phi^2 & 2\lambda & 0 & 0 \\ -2\lambda & \rho^2 - 2(1-2B)\phi^2 & 0 & 0 \end{pmatrix}.$$

Since ϕ decays to 0 as $x \to \pm\infty$, the matrix A has asymptotic form A_0 given by

$$A_0(\lambda) = \lim_{|x|\to\infty} A(\lambda, x) = \begin{pmatrix} 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ \rho^2 & 2\lambda & 0 & 0 \\ -2\lambda & \rho^2 & 0 & 0 \end{pmatrix},$$

which has eigenvalues $\{\mu_1, -\mu_1, \mu_2, -\mu_2\}$ given by

$$\begin{array}{rcl} \mu_1(\lambda) & = & \sqrt{\rho^2 + 2i\lambda}, \\ \mu_2(\lambda) & = & \sqrt{\rho^2 - 2i\lambda}. \end{array} \tag{3.2}$$

The branch cuts for μ_1 and μ_2 are taken as $-\pi < \arg(\lambda - i\frac{\rho^2}{2}) < \pi$ and $-\pi < \arg(\lambda + i\frac{\rho^2}{2}) < \pi$, respectively. Consequently, for $\lambda \in \Omega = \{z | \Re z > 0 \text{ or } |\Im z| < \frac{\rho^2}{2}\}$ the eigenvalues μ_1 and μ_2 have positive real part. To each of the eigenvalues $\mu_1, \mu_2, \mu_3 = -\mu_1$, and $\mu_4 = -\mu_2$ we associate, respectively, the vector $\vec{\eta}_1 = (1, i, -\mu_1, -i\mu_1)^T$, $\vec{\eta}_2 = (1, -i, -\mu_2, i\mu_2)^T, \vec{\eta}_3 = (1, i, \mu_1, i\mu_1)^T$, $\vec{\eta}_4 = (1, -i, \mu_2, -i\mu_2)^T$ and solutions Y_j of (3.1) for $j = 1, 2, 3, 4$ which satisfy the asymptotic boundary conditions

$$\lim_{x\to x_j} e^{\mu_j x} Y_j(x) = \vec{\eta}_j, \tag{3.3}$$

where $x_j = \infty$ for $j = 1, 2$ and $x_j = -\infty$ for $j = 3, 4$. In particular, for $\lambda \in \Omega$, Y_j decays exponentially as $x \to \infty$ for $j = 1, 2$ and Y_j decays exponentially as $x \to -\infty$ for $j = 3, 4$. We also exploit a symmetry of the family of matrices $A(\lambda)$ which relates the Y_j to each other in a simple way. Define

$$S_1 = \begin{pmatrix} I_{2\times2} & 0 \\ 0 & -I_{2\times2} \end{pmatrix} \text{ and } S_2 = \begin{pmatrix} \sigma_3 & 0 \\ 0 & \sigma_3 \end{pmatrix},$$

where $I_{2\times2}$ is the 2×2 identity matrix and

$$\sigma_3 = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}$$

is the third Pauli spin matrix. The following lemma then holds.

Lemma 3.1. *If for each λ and B, $Y(x, \lambda, B)$ solves* (3.1)*, then $S_1 Y(-x, \lambda, B)$ $S_2 Y(x, -\lambda, B)$, and $S_1 S_2 Y(-x, -\lambda, B)$ are also solutions of* (3.1) *for the same values of λ and B. In particular*

$$\begin{array}{rcl} S_1 Y_1(-x, \lambda, B) & = & Y_3(x, \lambda, B), \\ S_1 Y_2(-x, \lambda, B) & = & Y_4(x, \lambda, B), \end{array}$$

and

$$\begin{array}{rcl} S_2 Y_1(x, -\lambda, B) & = & \left\{ \begin{array}{ll} Y_2(x, \lambda, B) & \text{if } \Im\lambda > -\frac{\rho^2}{2}, \\ Y_4(x, \lambda, B) & \text{if } \Im\lambda < -\frac{\rho^2}{2}, \end{array} \right. \\ S_1 S_2 Y_1(-x, -\lambda, B) & = & \left\{ \begin{array}{ll} Y_4(x, \lambda, B) & \text{if } \Im\lambda > -\frac{\rho^2}{2}, \\ Y_2(x, \lambda, B) & \text{if } \Im\lambda < -\frac{\rho^2}{2}. \end{array} \right. \end{array}$$

Proof. These relations follow from the fact that the matrix $A(\lambda)$ verifies the equalities

$$S_1^{-1} A(\lambda) S_1 = -A(\lambda) \text{ and } S_2^{-1} A(\lambda) S_2 = A(-\lambda)$$

from the fact that $S_1\vec{\eta}_j = \vec{\eta}_{j+2}$ for $j = 1, 2$, $S_2\vec{\eta}_j(\lambda) = \vec{\eta}_{j+1}(-\lambda)$ for $j = 1, 3$, and from the relation

$$\mu_1(-\lambda) = \begin{cases} \mu_2(\lambda) & \text{if } \Im\lambda > -\frac{\rho^2}{2}, \\ -\mu_2(\lambda) & \text{if } \Im\lambda < -\frac{\rho^2}{2}. \end{cases} \qquad \square$$

In the following theorem we construct solutions of (3.1) with the prescribed asymptotic behavior.

THEOREM 3.2. *Let λ and B be given. There exists a solution $Y_1(x; \lambda, B)$ of* (3.1) *satisfying*

$$\lim_{x\to\infty} e^{\mu_1 x} Y_1 = \vec{\eta}_1.$$

Moreover $Y_1 = (v_1, v_2, v_{1x}, v_{2x})$, where $V = (v_1, v_2)^T$ is given by the Dirichlet expansion

$$V = e^{-\mu_1 x} \sum_{k=0}^{\infty} \vec{\xi}_k e^{-2kx}, \tag{3.4}$$

uniformly convergent for $x \geq x_0$ for any $x_0 > 0$. The vectors $\vec{\xi}_k$ are defined recursively below. In particular, when $B = 0$ we have the explicit solution

$$V = \frac{\mu_1 + \tanh x}{1 + \mu_1} e^{-\mu_1 x} \begin{pmatrix} 1 \\ i \end{pmatrix}. \tag{3.5}$$

Proof. We rewrite the Dirichlet expansion (3.4) in terms of $z = e^{-x}$, expand $\phi^2(x) = \text{sech}^2 x$ as

$$\phi^2(z) = -4 \sum_{k=1}^{\infty} (-1)^k k z^{2k},$$

and substitute the expansion into (2.3b), resulting in the system of equations

$$\sum_{n=0}^{\infty} \mathcal{A}_n \vec{\xi}_n z^{2n} = -4 \begin{pmatrix} 1 & 0 \\ 0 & (1-2B) \end{pmatrix} \sum_{n=0}^{\infty} \sum_{k=1}^{n} (-1)^k k \vec{\xi}_{n-k} z^{2n}, \tag{3.6}$$

where the matrices $\mathcal{A}_n$ are given by

$$\mathcal{A}_n = \begin{pmatrix} \frac{1}{2}(\rho^2 - (\mu_1 + 2n)^2) & \lambda \\ -\lambda & \frac{1}{2}(\rho^2 - (\mu_1 + 2n)^2) \end{pmatrix}.$$

The matrix $\mathcal{A}_0$ is singular, while

$$\det\, \mathcal{A}_n = n(\mu_1 + n)(2n + \mu_1 + \mu_2)(2n + \mu_1 - \mu_2),$$

and a routine calculation shows that for the branch cuts of μ_1 and μ_2 chosen as above, $\det\mathcal{A}_n$ is nonzero for all complex λ and all $n \geq 1$.

Equating the coefficients of z^0 on both sides of relation (3.6) above, there obtains the equation

$$\mathcal{A}_0 \vec{\xi}_0 = \vec{0},$$

for which we choose the solution

$$\vec{\xi}_0 = \begin{pmatrix} 1 \\ i \end{pmatrix}, \tag{3.7}$$

while equating coefficients of z^n for $n = 1, 2, \ldots$ leads to the following recursive formula for $\vec{\xi}_n$:

$$\vec{\xi}_n = -4\mathcal{A}_n^{-1} \begin{pmatrix} 1 & 0 \\ 0 & (1-2B) \end{pmatrix} \sum_{k=1}^{n} (-1)^k k \vec{\xi}_{n-k}. \tag{3.8}$$

For fixed λ and large n, the matrix $\mathcal{A}_n$ is diagonally dominant with diagonal elements $O(n^2)$ so that

$$\|\mathcal{A}_n^{-1}\| \leq \frac{C}{n^2},$$

for all $n > 0$ and some constant $C = C(\lambda)$. We assume that $|\vec{\xi}_k| \leq Mk^p$ for some $p > 0$ and all positive integers $k < n$ and show that $|\vec{\xi}_n| \leq Mn^p$ if p is large enough, independent of n. This establishes the polynomial growth of the $\vec{\xi}_n$ in n and the uniform convergence of the Dirichlet expansion for $x \geq x_0$ for any $x_0 > 0$. Apply the triangle inequality, the bound on $\|\mathcal{A}_n^{-1}\|$, and the inductive hypothesis to (3.8) to obtain

$$\begin{aligned} \frac{|\vec{\xi}_n|}{n^p} &\leq \frac{4CM}{n^{2+p}} \sum_{k=1}^{n} k(n-k)^p, \\ &\leq 4CM \sum_{k=1}^{n} \tfrac{k}{n} \left(\tfrac{n-k}{n}\right)^p \tfrac{1}{n}, \\ &\leq 8CM \int_0^1 x(1-x)^p dx = \frac{8CM}{(p+1)(p+2)}; \end{aligned}$$

hence for p so large that $\dfrac{8C}{(p+1)(p+2)} \leq 1$ we have

$$|\vec{\xi}_n| \leq Mn^p.$$

The Dirichlet expansion converges uniformly and the limit V is analytic in both $x > 0$ and B; from classic results [8], Y_1 has an analytic extension to the whole line. The asymptotic behavior of Y_1 as $x \to \infty$ follows readily from the form of the Dirichlet expansion. For $B = 0$ an induction argument shows that the formula (3.8) for $\vec{\xi}_n$ is solved by

$$\vec{\xi}_n = \frac{2(-1)^n}{1+\mu_1} \vec{\xi}_0 \qquad \text{for } n = 1, 2, 3, \ldots,$$

and summing the Dirichlet expansion in closed form yields the solution (3.5).

4. The Evans function. The Evans function detects the intersection of the stable and unstable manifolds of (3.1). From the Dirichlet expansion, Theorem 3.2, and the symmetries of Lemma 3.1, we have explicitly constructed the functions $Y_j = (y_{j1}, y_{j2}, y_{j3}, y_{j4})^T$, which span these manifolds. Placed as columns in a matrix $\mathcal{Y} = [Y_1, Y_2, Y_3, Y_4]$ they form a matrix solution of the first order system (3.1). The Evans function can be written in several equivalent forms; see [4, 30, 15, 16] and the references therein. In the case at hand the trace of the matrix $A(\lambda)$ is zero, and the Evans function reduces to the following normalized determinate of $\mathcal{Y}$, which depends upon λ, B, and ρ but not upon x :

$$E(\lambda, B; \rho) = \frac{-1}{16\mu_1\mu_2}|\mathcal{Y}|. \tag{4.1}$$

The properties of the Evans function are given in the following theorem.

THEOREM 4.1. *The Evans function is analytic for all values of* B, $\rho \in (0,1)$, *and all* $\lambda \notin \{z|\Re z \leq 0 \text{ and } \Im z = \pm\frac{\rho^2}{2}\}$. *For fixed* B, *the zeros* λ *of the Evans function which lie in* $\Omega = \{z|\Re z > 0 \text{ or } |\Im z| < \frac{\rho^2}{2}\}$ *coincide with the eigenvalues of the linear operator* L_2, *and the order of such a zero equals the algebraic multiplicity of the eigenvalue of* L_2. *For all* $\lambda \in \overline{\Omega}$, $E(\lambda^*) = E(\lambda)^*$, *and* $E(\lambda) = E(-\lambda)$ *if* $-\lambda \in \Omega$. *As* $|\lambda| \to \infty, E(\lambda) \to 1$.

Proof. The analyticity of the Evans function follows from that of the constituent solutions Y_j afforded by Theorem 3.2, and from the choice of branch cuts of $\mu_j(\lambda)$. The analytic extension of the Evans function through the essential spectrum is transparent from the Dirichlet expansion construction; there is no need for an application of the Gap lemma; see [11, 18]. The coincidence of zeros of the Evans function in Ω and the eigenvalues of the associated operator, up to multiplicity, is a well known result which can be found in [4]. Since L_2 is a real operator, $L_2V = \lambda V$ if and only if $L_2V^* = \lambda^*V^*$, and the symmetry of the Evans function, for λ in Ω, follows. The asymptotic property of E as $|\lambda| \to \infty$ is a consequence of the normalization and Corollary 1.18 of [30]. □

Remark. The zeros of the extended Evans function which lie outside the domain Ω do not necessarily correspond to eigenvalues of L_2. Also, the symmetries $E(\lambda^*) = E(\lambda)^*$ and $E(\lambda) = E(-\lambda)$ do *not* hold for λ outside of $\overline{\Omega}$.

In that which follows we will view ρ as fixed, and write $E = E(\lambda, B)$. For $B = 0$ the matrix solution $\mathcal{Y}$ takes the simple form

$$\mathcal{Y} = \begin{pmatrix} y_1 & y_2 & y_3 & y_4 \\ iy_1 & -iy_2 & iy_3 & -iy_4 \\ y_{1x} & y_{2x} & y_{3x} & y_{4x} \\ iy_{1x} & -iy_{2x} & iy_{3x} & -iy_{4x} \end{pmatrix}, \tag{4.2}$$

where y_j are given explicitly by (3.5) and the symmetries of Lemma 3.1. We may directly evaluate the Wronskian in (4.2) to obtain the following corollary.

COROLLARY 4.2. *For* $B = 0$ *the Evans function is given by*

$$E = \frac{(1-\mu_1)(1-\mu_2)}{(1+\mu_1)(1+\mu_2)}. \tag{4.3}$$

The operator L_2 *has exactly two eigenvalues* $\lambda_\pm = \pm i\frac{1-\rho^2}{2}$ *which correspond to the localized eigenvectors given by* (3.5).

Proof. We use the explicit formula (3.5) for the functions $Y_j, j = 1, \dots, 4$. The Evans function has exactly two zeros, which lie on the boundary of Ω. As such they may not correspond to localized eigenvalues, but for $\lambda = \lambda_\pm$ inspection of the formula (3.5) shows that the eigenvector is localized in space. □

Each of the eigenvalues $\lambda_\pm$ moves with changes in B. From the symmetry of the spectrum of L_2, it is sufficient to study the path of the eigenvalues bifurcating from λ_+. We will focus on the eigenvalue in the closed first quadrant of the complex plain, denoting it as $\lambda(B)=\lambda(B,\rho)$. Recall that $\lambda(0,\rho)=\lambda_+$ is embedded in the essential spectrum of L_2 for $0<\rho\leq\frac{1}{\sqrt{2}}$. We calculate the derivatives of $\lambda(B)$, for fixed ρ, via the implicit function theorem. First we evaluate the partial derivatives of the Evans function at $\lambda=\lambda_+$. Let $'$ denote differentiation with respect to x and a subscript B denote differentiation with respect to B. Each function Y_j satisfies (3.1), taking the B derivative

$$Y'_{jB}=AY_{jB}+A_BY_j,$$

and since $\mathcal{Y}$ is a matrix solution of the corresponding homogeneous equation, variation of parameters yields

$$Y_{jB}(x)-\mathcal{Y}(x)\mathcal{Y}^{-1}(x_j)Y_{jB}(x_j)=\mathcal{Y}(x)\int_{x_j}^{x}\mathcal{Y}^{-1}(s)A_B(s)Y_j(s)ds.$$

From the Dirichlet expansion formulas we know that $|Y_{jB}(x)|$ decays as $e^{-(\mu_j+2)x}$ as $x\to\infty$ for $j=1,2$, and similarly $|Y_{jB}|$ decays as $x\to-\infty$ for $j=3,4$. We let $x_j\to\infty$ for $j=1,2$ and $x_j\to-\infty$ for $j=3,4$. The second term on the left-hand side converges to zero in each case as $|x|\to\infty$. Defining the matrix Φ as

$$\Phi=\left[\int_{\infty}^{x}\mathcal{Y}^{-1}A_BY_1ds,\ \int_{\infty}^{x}\mathcal{Y}^{-1}A_BY_2ds,\ \int_{-\infty}^{x}\mathcal{Y}^{-1}A_BY_3ds,\ \int_{-\infty}^{x}\mathcal{Y}^{-1}A_BY_4ds\right], \tag{4.4}$$

we can rewrite the four equations as a matrix differential equation in B,

$$\mathcal{Y}_B(x,B)=\mathcal{Y}(x,B)\Phi(x,B). \tag{4.5}$$

Applying Abel's formula [8] we obtain a differential equation for the Wronskian $W=|\mathcal{Y}|$ as

$$W_B=(\operatorname{tr}\Phi)W. \tag{4.6}$$

Since $\operatorname{tr}\Phi'=\operatorname{tr}(\mathcal{Y}^{-1}A_B\mathcal{Y})=\operatorname{tr}A_B=0$ it follows that $\operatorname{tr}\Phi$ is independent of x. We let $x\to\infty$ in (4.4) obtaining

$$\operatorname{tr}\Phi=\operatorname{tr}\int_{-\infty}^{\infty}\left[0,\ 0,\ \mathcal{Y}^{-1}A_BY_3,\ \mathcal{Y}^{-1}A_BY_4\right]dx.$$

Using the notation $y_j=y_{j1}$, we observe that $y_{j2}=(-1)^{j+1}iy_j$ for $j=1,2,3,4$. To invert $\mathcal{Y}$ we expand by cofactors

$$[\mathcal{Y}^{-1}]_{jk}=\frac{(-1)^{j+k}W_{kj}}{W},$$

where W_{kj} is the determinant of the kj-minor of $\mathcal{Y}$. For $B=0$, the minors may be evaluated directly, yielding

$$W_{43}=-4i\beta_2y_1 \text{ and } W_{44}=-4i\beta_1y_2,$$

where $\beta_j=\frac{\mu_j(\mu_j-1)}{1+\mu_j}$ for $j=1,2$. The matrix A_B has all zero entries except for $[A_B]_{4,2}=4\phi^2$. The nonzero diagonal entries of Φ are

$$\Phi_{33}=\int_{-\infty}^{\infty}\frac{-W_{43}}{W}4\phi^2y_{32}ds=-\frac{16\beta_2}{W}\int_{-\infty}^{\infty}\phi^2y_1y_3ds$$

and

$$\Phi_{44} = \int_{-\infty}^{\infty} \frac{W_{44}}{W} 4\phi^2 y_{22} ds = -\frac{16\beta_1}{W} \int_{-\infty}^{\infty} \phi^2 y_2 y_4 ds.$$

Finally we see that

$$\operatorname{tr}\Phi = -\frac{16}{W} \int_{-\infty}^{\infty} \phi^2 \left(\beta_1 y_2 y_4 + \beta_2 y_1 y_3\right) ds = -\frac{32}{W} \left(\beta_1 \gamma_2 + \beta_2 \gamma_1\right),$$

where $\gamma_j = \frac{\mu_j^2 - \frac{1}{3}}{(1+\mu_j)^2}$ for $j = 1, 2$.

Since $E = -\frac{W}{16\mu_1\mu_2}$ we have $E_B(\lambda, 0) = -\frac{W}{16\mu_1\mu_2} \operatorname{tr}\Phi(\lambda, 0)$, and substituting the formulas above,

$$E_B(\lambda, 0) = \frac{2}{\mu_1\mu_2} \left(\beta_1\gamma_2 + \beta_2\gamma_1\right). \tag{4.7}$$

In particular, at the eigenvalue $\lambda_+ = i\frac{1-\rho^2}{2}$, we have $\mu_2 = 1$ and $\mu_1 = i\alpha$ with $\alpha = \sqrt{1-2\rho^2}$, for $0 < \rho < \frac{1}{\sqrt{2}}$; consequently

$$E_B(\lambda_+, 0) = \frac{i\alpha - 1}{3(1+i\alpha)}.$$

Taking the λ partial derivative of (4.3) we calculate

$$E_\lambda(\lambda_+, 0) = \frac{i}{2} \frac{1-i\alpha}{1+i\alpha}.$$

By the implicit function theorem, the function $\lambda(B)$ which satisfies $E(\lambda(B), B) = 0$ and $\lambda(0) = \lambda_+$ has derivative

$$\lambda_B(0) = -\frac{E_B(\lambda_+, 0)}{E_\lambda(\lambda_+, 0)} = -\frac{2}{3}i. \tag{4.8}$$

To leading order in B, the embedded eigenvalue moves along the imaginary axis as B increases from zero. This result is in fact a consequence of the method developed in [16, Theorem 1.1 and Lemma 4.3] to compute the leading order motion of eigenvalues. To determine if the eigenvalue remains in the essential spectrum and on the imaginary axis, it is necessary to compute the second derivative of $\lambda(B)$ with respect to B at $B = 0$. The implicit function theorem yields

$$\lambda_{BB}(0) = -\frac{E_{\lambda\lambda}\lambda_B^2 + 2E_{\lambda B}\lambda_B + E_{BB}}{E_\lambda}.$$

Taking partial derivatives with respect to λ of (4.3) and (4.7) we obtain

$$E_{\lambda\lambda}(\lambda_+, 0) = \frac{2 - i\alpha - i\alpha^3}{i\alpha(i\alpha+1)^2} \tag{4.9}$$

and

$$E_{\lambda B}(\lambda_+, 0) = -\frac{1}{3} \frac{(i\alpha - 1)(i\alpha + 3)}{\alpha(i\alpha + 1)}. \tag{4.10}$$

It remains to calculate $E_{BB}(\lambda_+,0)$. This can be done directly by differentiating (4.6) with respect to B, obtaining $W_{BB}=\left(\operatorname{tr}\Phi_B+(\operatorname{tr}\Phi)^2\right)W$, for $B=0$ and $\lambda\neq\lambda_\pm$, taking the limit $\lambda\to\lambda_+$, and expanding in terms of $\epsilon=\mu_2-1$ as $\mathcal{Y}^{-1}$ becomes singular. However, it is easier to avoid the singularity altogether and compute W_{BB} from the vectors Y_{jB} and Y_{jBB}. Since $y_2=y_4=\frac{1}{2}\mathrm{sech}x$ at $\lambda=\lambda_+$ and $B=0$, after cancelation we obtain

$$\begin{aligned}W_{BB}=&\Big|[Y_1,Y_2,Y_3,Y_{4BB}-Y_{2BB}]\Big|+2\Big|[Y_1,Y_{2B},Y_3,Y_{4B}]\Big|\\&+2\Big|[Y_{1B},Y_2,Y_3,Y_{4B}-Y_{2B}]\Big|+2\Big|[Y_1,Y_2,Y_{3B},Y_{4B}-Y_{2B}]\Big|.\end{aligned}\tag{4.11}$$

The matrix $\mathcal{Y}$ is singular at the eigenvalue and there is a solution of (3.1), Y_5, which is linearly independent of $\{Y_1,Y_2,Y_3\}$. Using reduction of order it is straightforward to find $Y_5=(y_5,-iy_5,y_{5x},-iy_{5x})^T$, where

$$y_5=\frac{1}{2}\mathrm{sech}x\left(x+\frac{\sinh 2x}{2}\right).$$

We form the matrix solution $\mathcal{Y}_0=[Y_1,Y_2,Y_3,Y_5]$, and as before, we solve for $\mathcal{Y}_B$ via variation of parameters at $\lambda=\lambda_+$, viz.

$$\mathcal{Y}_B=\mathcal{Y}_0\Phi_0,\tag{4.12}$$

where

$$\Phi_0=\left[\int_\infty^x\mathcal{Y}_0^{-1}A_BY_1ds,\int_\infty^x\mathcal{Y}_0^{-1}A_BY_2ds,\int_{-\infty}^x\mathcal{Y}_0^{-1}A_BY_3ds,\int_{-\infty}^x\mathcal{Y}_0^{-1}A_BY_4ds\right].\tag{4.13}$$

Similarly, for $j=1,2,3,4$, the second derivatives Y_{jBB} satisfy the system of differential equations

$$Y'_{jBB}=AY_{jBB}+2A_BY_{jB}.$$

Variation of parameters again yields

$$Y_{jBB}=2\mathcal{Y}_0\int_{x_j}^x\mathcal{Y}_0^{-1}A_BY_{jB}ds,\tag{4.14}$$

where $x_j=\infty$ for $j=1,2$ and $x_j=-\infty$ for $j=3,4$. Substituting the expressions from (4.12) and (4.14) into the formula (4.11) leads to, after some computation given in the appendix, the following equality:

$$\Re\left(\frac{E_{BB}(\lambda_+,0)}{E_\lambda(\lambda_+,0)}\right)=\frac{8(2-3\rho^2)}{9\alpha(1-\rho^2)}-\frac{2\alpha(1-\rho^2)\pi^2}{9}\mathrm{sech}^2\frac{\alpha\pi}{2}.\tag{4.15}$$

We separate the other terms in the expression for $\lambda_{BB}(0)$,

$$\Re\left(\frac{2E_{\lambda B}\lambda_B}{E_\lambda}\right)=-\frac{8}{3\alpha}$$

and

$$\Re\left(\frac{E_{\lambda\lambda}\lambda_B^2}{E_\lambda}\right)=\frac{8}{9\alpha(1-\rho^2)}.$$

Combining these results we obtain the leading order expression for the motion of the real part of the embedded eigenvalue with respect to B,

$$\Re\left(\lambda_{BB}(0)\right) = \frac{2\alpha(1-\rho^2)\pi^2}{9}\operatorname{sech}^2\frac{\alpha\pi}{2}. \tag{4.16}$$

We summarize and extend the results above in the following theorem.

THEOREM 4.3. *For $B = 0$, the eigenvalue problem has two simple eigenvalues $\lambda = \pm i\frac{1-\rho^2}{2}$. For fixed ρ satisfying $\rho \in (0, \frac{1}{\sqrt{2}})$, the eigenvalues depend analytically upon B. They are embedded in the essential spectrum for $B = 0$ and leave the imaginary axis as B increases from zero, forming two complex pairs of eigenvalues. To leading order in real and imaginary parts, the unique eigenvalue in the open first quadrant of the complex plans satisfies*

$$\begin{aligned}\lambda(B) = \quad & i\left(\tfrac{1-\rho^2}{2} - \tfrac{2}{3}B + O(B^2)\right)\\ & + \left(\tfrac{2\pi^2(1-\rho^2)\sqrt{1-2\rho^2}}{9}\operatorname{sech}^2\left(\tfrac{\pi\sqrt{1-2\rho^2}}{2}\right)\right)B^2 + O(B^3).\end{aligned} \tag{4.17}$$

In particular the up wave is structurally unstable for $\rho \in (0, \frac{1}{\sqrt{2}})$. For $B = 0$ and $\rho \in (\frac{1}{\sqrt{2}}, 1)$, the eigenvalues are simple and isolated and remain upon the imaginary axis for B small enough; moreover, the unique eigenvalue of positive imaginary part satisfies

$$\lambda(B) = i\left(\frac{1-\rho^2}{2} - \frac{2}{3}B + O(B^2)\right). \tag{4.18}$$

Proof. The asymptotic formula for B small and $\rho \in (0, \frac{1}{\sqrt{2}})$ follow from the preceding discussion. The uniqueness of the eigenvalue in the open first quadrant follows from the fact that there is at most one set of four strictly complex eigenvalues, as observed in section 2. For $\rho \in (\frac{1}{\sqrt{2}}, 1)$, Corollary 4.2 indicates that the eigenvalues are isolated and simple. Since the spectrum is symmetric with respect to the imaginary axis, the eigenvalues can only leave the imaginary axis in pairs, which necessitates collision with another eigenvalue, or the essential spectrum. Thus the eigenvalues are trapped upon the imaginary axis for B small enough, all the derivatives of λ with respect to B have zero real part at $B = 0$, and the formula (4.8) holds. □

We now address the case when the embedded eigenvalues $\lambda_\pm = \pm i\frac{1-\rho^2}{2}$ of the operator L_2 coincide with the branch points $\pm i\frac{\rho^2}{2}$; i.e., $\rho = \frac{1}{\sqrt{2}}$. In this case the Evans function is not analytic at the eigenvalue, and we must unfold the Riemann surface to investigate the behavior of its zeros as B is perturbed from zero. Indeed, the Evans function in the new independent variable $\nu = \sqrt{\rho^2 + 2i\lambda}$ has a simple pole in ν at $\nu = 0$, which we eliminate and study the zeros of the function

$$D(\nu, B) = 16\nu\sqrt{2\rho^2 - \nu^2}E\left(i\frac{\rho^2 - \nu^2}{2}, B\right) \tag{4.19}$$

in a neighborhood of $\nu = 0$. Note that when $-\frac{\pi}{4} < \arg\nu < \frac{3\pi}{4}$, there is a unique λ with $-\pi < \arg(\lambda - i\rho^2/2) < \pi$ such that $\nu = \sqrt{\rho^2 + 2i\lambda}$. In particular, a zero $\nu = \nu_0$ of D corresponds to a zero $\lambda_0 = i\frac{\rho^2 - \nu_0^2}{2}$ of E if and only if $-\frac{\pi}{4} < \arg\nu_0 < \frac{3\pi}{4}$. A zero of D which does not satisfy this condition will be termed *spurious.*

Lemma 4.4. *In the new independent variable $\nu = \sqrt{\rho^2 + 2i\lambda}$, there is a neighborhood of the point $(\nu = 0, \rho = \frac{1}{\sqrt{2}})$ for which the function D is analytic with respect to ν, ρ, and B.*

Proof. The function D defined above is the Wronskian (4.2); its analyticity follows directly from that of the functions $Z_j(x, \nu, \rho, B) = Y_j(x, i\frac{\rho^2-\nu^2}{2}, B)$ for $j = 1, \dots, 4$. Each Z_j is given as a Dirichlet expansion, as in Theorem 1 for Y_j, whose terms are analytic with respect to ν, ρ, and B when $|\nu|^2 < 1 - 2\delta$ and $|\rho - \frac{1}{\sqrt{2}}| < \delta$ for any fixed constant δ with $0 < \delta < 1/4$. From the uniform convergence of the derivatives of the Dirichlet expansion with respect to these parameters, we conclude that Z_j is analytic whenever the expansion is defined, and the analytic expansion of the derivatives to the entire x-axis leads to the conclusion. □

When $\rho = \frac{1}{\sqrt{2}}$, the function

$$D(\nu, B) = 16\nu\sqrt{1-\nu^2}E\left(i\frac{\rho^2 - \nu^2}{2}, B\right) = -|\mathcal{Y}|_{\lambda = i\frac{1/2-\nu^2}{2}} \tag{4.20}$$

is analytic with respect to ν and B in the open set $\{|\nu| < 1\} \times \{|B| < \infty\}$, and from formula (4.3) of Corollary 4.2 we obtain the expression

$$D(\nu, 0) = \frac{16\nu^3(1-\nu^2)^{3/2}}{(1+\sqrt{1-\nu^2})^2(1+\nu)^2}. \tag{4.21}$$

In particular, D has a zero of the multiplicity three at $\nu = 0$ for $\rho = \frac{1}{\sqrt{2}}$. When $B > 0$ three zeros move away from the origin, but only one corresponds to a zero of the Evans function.

Theorem 4.5. *Let $\rho = \frac{1}{\sqrt{2}}$. There exists an $\epsilon > 0$ such that for all B satisfying $0 < B < \epsilon$, the operator L_2 has exactly one pair $\pm\lambda$ of eigenvalues where λ lies on the imaginary axis between 0 and $\frac{i}{4}$, and satisfies*

$$\lambda(B) = i\left(\frac{1}{4} - \frac{2}{3}B + o(B)\right). \tag{4.22}$$

Proof. On the circle $|\nu| = \frac{1}{\sqrt{2}}$ we may use the formula (4.21) to obtain the lower bound

$$|D(\nu, 0)| \geq \frac{1}{8};$$

thus for $|B|$ sufficiently small, $|D(\nu, B)| > 0$ on $|\nu| = 1/\sqrt{2}$, and since D is analytic in $V_1 = \{|\nu| \leq \frac{1}{\sqrt{2}}\}$ the number of zeros of D in V_1 is constantly 3 for B small enough. To follow the motion of these zeros with respect to B we expand D as

$$D(\nu, B) = D(\nu, 0) + D_B(\nu, 0)B + g(\nu, B)B^2,$$

where $g(\nu, B)$ is an analytic function with respect to both B and ν. Rewriting (4.7) in the new variable ν, we find from (4.20) that

$$D_B(\nu, 0) = \frac{32\nu\sqrt{1-\nu^2}\left[\nu(1/3 - \nu^2) + \sqrt{1-\nu^2}\,(\nu^2 - 2/3)\right]}{(1+\nu)^2(1+\sqrt{1-\nu^2}\,)^2} = -\frac{16}{3}\nu + O(\nu^2). \tag{4.23}$$

The function $f(\nu, B) = D(\nu, 0) + D_B(\nu, 0)B$ has, by arguments similar to those above, exactly three zeros in V_1 for B small enough. Writing

$$f(\nu, B) = D_B(\nu, 0)\left[B + \frac{D(\nu, 0)}{D_B(\nu, 0)}\right],$$

where

$$\frac{D(\nu, 0)}{D_B(\nu, 0)} = \frac{\nu^2(1-\nu^2)}{2[\nu(1/3-\nu^2) + \sqrt{1-\nu^2}\,(\nu^2 - 2/3)]} = -\frac{3}{4}\nu^2 + O(\nu^3), \tag{4.24}$$

it is easy to see that $B + \frac{D(\nu,0)}{D_B(\nu,0)}$ has two real zeros, $\nu_{-1} = -\sqrt{\frac{4}{3}B} + O(B)$ and $\nu_1 = \sqrt{\frac{4}{3}B} + O(B)$ for $B > 0$ and small enough, while $\nu_0 = 0$ is always a zero of f.

To localize the zeros of D we apply Rouche's theorem. Fixing $\alpha > 0$ small we show that the bound $|f| > B^2|g|$ holds on each of the two circles $\mathcal{U}_{\pm 1} = \{\nu : |\nu - \nu_{\pm 1}| = |\nu_{\pm 1}|^{2-\alpha}\}$. We examine only the case $\nu = \nu_1$. Substituting $B = -\frac{D(\nu_1,0)}{D_B(\nu_1,0)} = -\frac{3}{4}\nu_1^2 + O(\nu_1^3)$ into f and writing $\nu = \nu_1 + z$ where $|z| = |\nu_1|^{2-\alpha}$, computation leads to the asymptotic relation

$$\begin{aligned} |f(\nu_1 + z, B)| &= |D_B(\nu_1, 0)| \left| -\frac{D(\nu_1, 0)}{D_B(\nu_1, 0)} + \frac{D(\nu_1 + z, 0)}{D_B(\nu_1 + z, 0)} \right| \\ &= \tfrac{16}{3}|\nu_1| \left| -\tfrac{3}{2}\nu_1 z - \tfrac{3}{4}z^2 \right| + O(|\nu_1|^3, |z|^2|\nu_1|), \end{aligned}$$

from which we deduce $|f| > c_1|\nu_1|^{4-\alpha}$ for some positive constant c_1 and for $B > 0$ small enough. However, since $|B| = O(|\nu_1|^2)$ it follows that $|B^2 g| < c_2|\nu_1|^4$ for some positive c_2 and small $B > 0$. We deduce from Rouche's theorem that $D = f + B^2 g$ has exactly one zero inside $\mathcal{U}_{\pm 1}$ for $B > 0$ small enough. The circle $\mathcal{U}_{-1}$ lies inside the spurious region and zero of D inside $\mathcal{U}_{-1}$ is spurious. On the other hand, all $\nu \in \mathcal{U}_1$ satisfy $-\frac{\pi}{4} < \arg\nu < \frac{3\pi}{4}$ and hence $\nu = \sqrt{\frac{1}{2} + 2i\lambda}$ for some λ in a neighborhood of the branch point $\frac{i}{4}$. The zero of D in $\mathcal{U}_1$ corresponds to a zero of E.

The localization of the third, smallest zero of D requires a slightly different analysis. Since $D(0,0) = D_B(0,0) = D_\nu(0,0) = D_{\nu\nu}(0,0) = 0$, the Taylor expansion of D about $(0,0)$ takes the form

$$D(\nu, B) = (\nu B)D_{\nu B}(0,0) + \left(\frac{1}{2}B^2\right) D_{BB}(0,0) + R(\nu, B), \tag{4.25}$$

where R is analytic and satisfies $|R(\nu, B)| \le K_1(|B|^3 + |\nu|^3)$ for some constant $K_1 > 0$ and B and ν small enough. We may calculate directly from (4.19) that

$$D_{\nu B}(0,0) = 16E_B\left(\frac{i}{4}, 0\right) - \lim_{\nu \to 0} 16i\nu^2\sqrt{1-\nu^2}E_{B\lambda}\left(i\frac{\frac{1}{2} - \nu^2}{2}, 0\right),$$

and from (4.7) we easily deduce that the limit term is zero while $E_B(\frac{i}{4}, 0) = -\frac{1}{3}$, yielding $D_{\nu B}(0,0) = -\frac{16}{3}$. Since D is analytic in ρ we may compute from (6.5)

$$D_{BB}(0,0) = \lim_{\rho \to \frac{1}{\sqrt{2}}} 16\mu_1(\lambda_+(\rho))\mu_2(\lambda_+(\rho))E_{BB}\left(i\frac{1-\rho^2}{2}, 0\right) = -\frac{64}{9}.$$

Defining

$$f_0(\nu, B) = -\frac{16}{3}B\left(\nu + \frac{4}{3}B\right),$$

we have $D(\nu, B) = f_0(\nu, B) + R(\nu, B)$, where f_0 has a zero at $\nu_0 = -\frac{4}{3}B$. On the ball $|\nu - \nu_0| = \frac{2}{3}|B|$, we have $|f_0(\nu, B)| = \frac{64}{27}B^2$, but $|R(\nu, B)| \leq K_1(B^3 + |\nu|^3) \leq K_1(B^3 + \frac{5}{3}B^3)$. It follows from Rouche's theorem that for B small enough, D has exactly one zero inside $\mathcal{U}_0 = \{\nu : |\nu - \nu_0| = \frac{2}{3}|B|\}$. In particular if $B > 0$ this zero is spurious and does not correspond to a zero of the Evans function E.

We have shown that for $B > 0$, but small enough, D has exactly one zero in V_1, $\nu_1 = \sqrt{\frac{4}{3}B} + O(B)$ satisfying $-\frac{\pi}{4} < \arg \nu_1 < \frac{3\pi}{4}$. Indeed we show that this zero lies on the real axis. From Lemma 4.4, $D(\nu, B) = 16\nu\sqrt{1-\nu^2}E(i\frac{1/2-\nu^2}{2}, B)$ is a real valued function when $0 \leq \nu \leq 1$. The equalities $D(0, 0) = D_B(0, 0) = 0$ and $D_{BB}(0, 0) = -\frac{64}{9}$ imply that $D(0, B) < 0$ when $B > 0$ is sufficiently small. In addition, since $D(\frac{1}{\sqrt{2}}, 0) > 0$ and D is continuous in B, it follows that $D(\frac{1}{\sqrt{2}}, B) > 0$ for any $B > 0$ sufficiently small. Therefore, D has at least one zero for ν in the interval $(0, \frac{1}{\sqrt{2}})$. But D has only three zeros in V_1, two of which do not lie on $(0, \frac{1}{\sqrt{2}})$, and from the analysis above this zero must be ν_1. The asymptotic formula (4.22) for $\lambda(B)$ follows from the relation $\lambda(B) = i\frac{\frac{1}{2}-\nu_1^2}{2}$ and the expansion for ν_1. □

While the case $B < 0$ is not directly relevant to the birefringence modeled by the coupled nonlinear Schrödinger equations studied here, it has mathematical interest. Recalling the new variable $\nu = \sqrt{\rho^2 + 2i\lambda}$, the point $\lambda = 0$ corresponds to $\nu = \frac{1}{\sqrt{2}}$ and as observed above $D(\frac{1}{\sqrt{2}}, B) > 0$ for $|B|$ sufficiently small, while $D(0, 0) = 0$. Moreover, D is real when $\nu \in [0, \frac{1}{\sqrt{2}}]$, and whenever $D(0, B)$ is negative for small $|B|$, there will be a zero of D in $(0, \frac{1}{\sqrt{2}})$ which corresponds to an imaginary zero of E between the branch point and the origin. For $\rho = \frac{1}{\sqrt{2}}$ we have shown that

$$D(0, B) = D_{BB}(0, 0)\frac{B^2}{2} + O(|B|^3) = -\frac{32B^2}{9} + O(|B|^3),$$

and for $\rho \neq \frac{1}{\sqrt{2}}$ we have

$$D(0, B) = D_B(0, 0)B + O(B^2) = \frac{32\sqrt{2}\rho(1-\sqrt{2}\rho)}{3(1+\sqrt{2}\rho)^2}B + O(B^2).$$

Clearly for $\rho \in (0, \frac{1}{\sqrt{2}}]$, $D(0, B) < 0$ for $B < 0$ small enough, and as B decreases from 0, the branch points $\pm i\frac{\rho^2}{2}$ shed eigenvalues which travel along the imaginary axis toward the origin. We state this result in the following proposition.

PROPOSITION 4.6. *For $\rho \in (0, \frac{1}{\sqrt{2}}]$, as B decreases from zero, the branch points $\pm i\frac{\rho^2}{2}$ of the essential spectrum of L_2 exhibit an edge bifurcation, each shedding an eigenvalue along the imaginary axis towards the origin.*

5. Numerical computation of the stability diagram. In the far from integrable case, B not small, we no longer have explicit forms for the solutions $Y_j, j = 1, \ldots, 4$, of the linearized system (3.1). The Dirichlet expansions for the Y_j are unwieldy for an exact analysis of the eigenvalue problem. For B not small we turn to a numerical evaluation of the Evans function; however, the asymptotic boundary conditions (3.3) of the special solutions render their direct numerical computation inefficient. The Dirichlet expansion provides a fast and rigorous mechanism for their computation.

From the symmetries of the Y_j given in Lemma 3.1, the Evans function takes a particularly simple form when evaluated at $x = 0$. Recalling the notation $Y_1 = (v_1, v_2, v_{1x}, v_{2x})^T$, the following result holds.

LEMMA 5.1. *The Evans function may be expressed as*

$$E = -\frac{1}{4\mu_1\mu_2}\left(v_1(0,\lambda,B)v_1(0,-\lambda,B) + v_1(0,-\lambda,B)v_2(0,\lambda,B)\right) \times \left(v_{1x}(0,\lambda,B)v_{2x}(0,-\lambda,B) + v_{1x}(0,-\lambda,B)v_{2x}(0,\lambda,B)\right). \tag{5.1}$$

Proof. At $x = 0$ we have $Y_3(0,\lambda,B) = S_1Y_1(0,\lambda,B)$ and $Y_4(0,\lambda,B) = S_1Y_2(0,\lambda,B)$, while $Y_2(0,\lambda,B) = S_2Y_1(0,-\lambda,B)$. Evaluating the determinate leads to the formula above. □

From the uniform convergence for the Dirichlet expansion it may be efficiently summed for values of $x = x_0 > 0$. We may then take $Y_1(x_0,\lambda,B)$ as initial data for the linear system (3.1) and numerically integrate it from $x \in [0, x_0]$, an interval upon which the system is not stiff, thereby obtaining an accurate and efficient approximation to $Y_1(0,\lambda,B)$. In particular, it is straightforward to rigorously bound the numerical error in such an approximation.

We present the numerical results obtained by fixing $\rho \in (0,1)$ and increasing B from 0 to $1.05B_c(\rho)$, where at $B = B_c(\rho) = \frac{2-\rho-\rho^2}{4}$ there is an eigenvalue at 0 whose multiplicity is either two or four. We find five distinct cases:

(1) $\rho \in (0, \rho_c)$ where $\rho_c \approx 0.3242\ldots$,
(2) $\rho = \rho_c$,
(3) $\rho \in (\rho_c, \rho_b)$ where $\rho_b = \frac{1}{\sqrt{2}}$,
(4) $\rho = \rho_b$,
(5) $\rho \in (\rho_b, 1)$.

Of the four eigenvalues of the point spectrum, we denote by $\lambda_1(B,\rho)$ the eigenvalue of largest real part, and when two have the same real part, the one with smallest positive imaginary part. An eigenvalue which is not a symmetry of λ_1 will be denoted λ_2. When λ_1 is purely real or imaginary it is also the eigenvalue of L_2 of negative Krein sign.

For case (1) (see Figure 1(a)) with $B = 0$, the eigenvalue $\lambda_1(0,\rho) = \lambda_+ = i\frac{1-\rho^2}{2}$ is embedded in the essential spectrum and by Theorem 4.3 it leaves the imaginary axis quadratically in B. From the numerical computation we find that as B increases the eigenvalue moves toward the real axis, forming a Jordan pair on the real axis with its complex conjugate when $B = B_1(\rho) < B_c(\rho)$. As B increases further the pair split with λ_2 moving toward and reaching the origin at $B = B_c$, and λ_1 moving outward from the origin along the real axis with increasing B. When λ_2 reaches the origin, it combines with its negative, and this pair splits into complex conjugates which move outward along the imaginary axis until they vanish at the branch points of the essential spectrum.

In the critical case, $\rho_c \approx 0.3242\ldots$ (see Figure 1(b)), the path traced by λ_1 and its symmetries "pinches" at the origin. Specifically, the embedded eigenvalue leaves the essential spectrum quadratically in B as it increases from $B = 0$, moving through the complex plane toward the origin, where the four recombine, forming a Jordan chain of multiplicity four at the origin as $B = B_c(\rho_c)$. For $B > B_c$, λ_1 and its negative move outward from the origin along the real axis and λ_2 and its negative move outward along the imaginary axis until they hit the branch point at $\pm i\frac{\rho^2}{2}$, becoming spurious.

For case (3), the complex eigenvalues ejected from the essential spectrum at $B = 0$

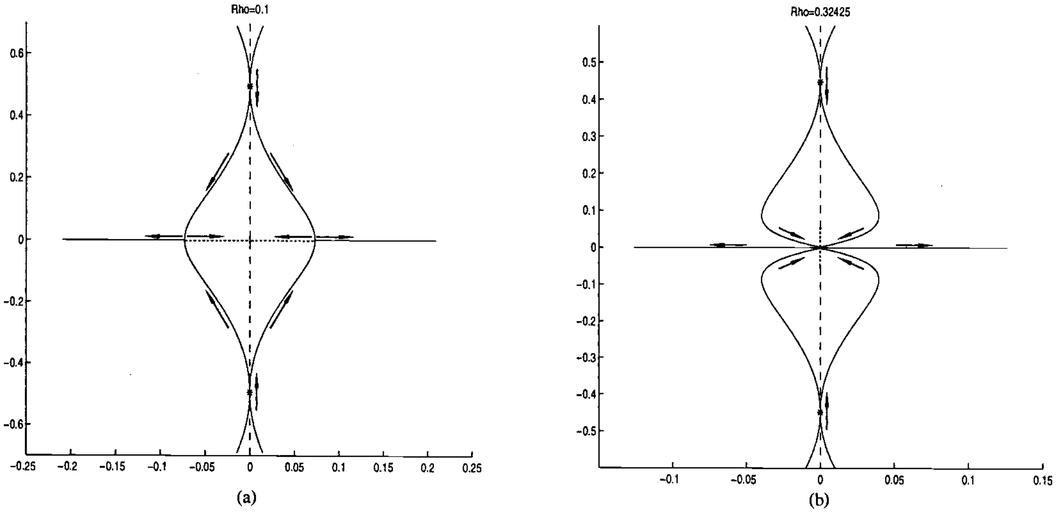

FIG. 1. *The spectrum of* $L_2(\rho, B)$ *for* (a) $\rho = 0.1$ *and* (b) $\rho = 0.32425$. *Solid line: location of negative Krein sign eigenvalue; dashed line: essential spectrum; dot: branch point; dotted line: positive Krein sign eigenvalue; arrows: direction of motion with increasing* B. *The* $*$ *indicates location of eigenvalue at* $B = 0$. *In both figures,* B *ranges from* $-0.75B_c(\rho)$ *to* $1.05B_c(\rho)$. *In figure* (a) *the branch points almost touch the real axis. In figure* (b) *the four complex eigenvalues meet at the origin.*

land upon the exposed neck of the imaginary axis; viewing Figures 1(a)–(b) and 2(a)–(b) sequentially, as ρ increases, the essential spectrum recedes from the origin until at the critical value the corresponding path of the complex eigenvalues pinches down to a point at the origin, and for values of $\rho > \rho_c$ the path of the complex eigenvalues "pulls up" on the imaginary axis. It is this sequence of events which we term a *neck bifurcation.* Figure 2(a) shows that as B increases from $B = 0$, the embedded eigenvalue λ_1 leaves the imaginary axis quadratically in B, and at $B = B_2(\rho) < B_c(\rho)$ it returns to the imaginary axis, forming a Jordan pair with $-\lambda_1^*$ at some point below the branch point $i\frac{\rho^2}{2}$. This pair splits, λ_1 moves down the imaginary axis, forming a Jordan pair at the origin with its complex conjugate for $B = B_c(\rho)$, and λ_2 moves up the imaginary axis, hits the branch point, and becomes spurious. This motion of λ_2 is not shown on Figure 2 due to smallness of scale. For $B > B_c$ the Jordan pair at the origin splits, forming a pair $\pm\lambda_1$, which move outward from the origin along the real axis.

For case (4), with $\rho = \frac{1}{\sqrt{2}}$ pictured in Figure 2(b), the eigenvalue λ_1 coincides with the branch point $\frac{i}{4}$ as $B = 0$, arriving there from off the imaginary axis. For clarity of presentation the eigenvalues on the imaginary axis for $B < 0$ are not shown. For $B > 0$ the eigenvalue λ_1 travels along the imaginary axis toward the origin, arriving there at $B = B_c(\rho_b)$ where it forms a Jordan pair with its complex conjugate, splitting into a real pair $\pm\lambda_1$ as $B > B_c(\rho_b)$. For case (5), not pictured, when $B = 0$ the eigenvalue λ_1 is on the imaginary axis between the branch point of the essential spectrum and the origin; as B increases it moves along the imaginary axis toward the origin, forming a Jordan pair with its complex conjugate at the origin as $B = B_c(\rho)$, again splitting into a real pair as B increases further. In case (5) there are only two eigenvalues for $B > 0$.

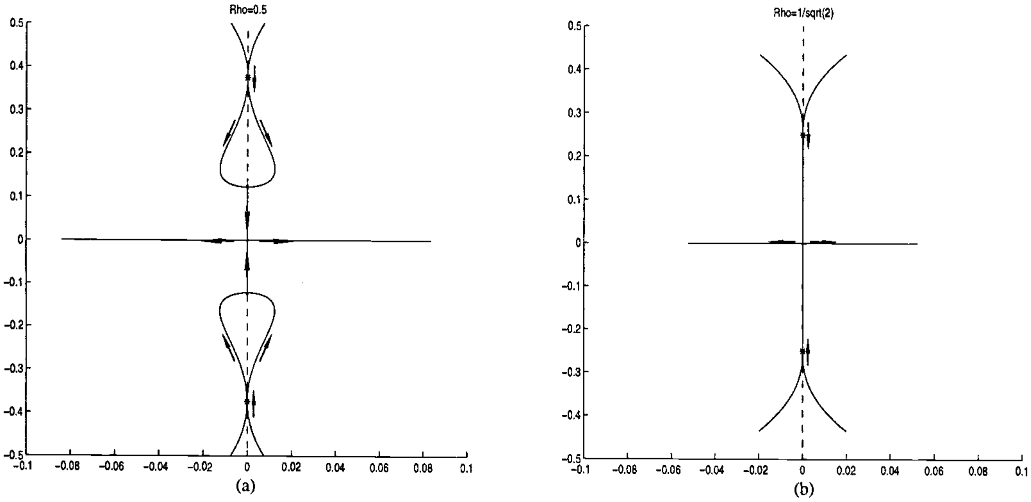

FIG. 2. *The spectrum of* $L_2(\rho, B)$ *for* (a) $\rho = 0.5$ *and* (b) $\rho = \frac{1}{\sqrt{2}}$. *The legend is the same as Figure* 1. B *varies from* $-0.75B_c$ *to* $1.05B_c$. *In* (b) *the embedded eigenvalues coincide with the branch points for* $B = 0$.

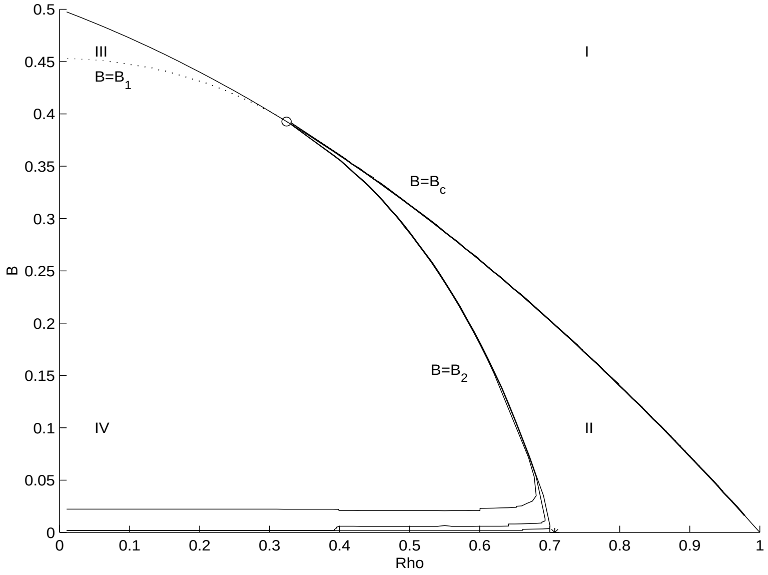

FIG. 3. *The stability diagram of the eigenvalue problem, showing the line* $B = B_c(\rho)$ *(solid), and contours of* $\Re\lambda_1$ *(solid) and* $\Im\lambda_1$ *(dotted) at* $10^{-4}, 10^{-6}$, *and* 10^{-7}.

In Figure 3 we plot the stability diagram comprised of contours of $\Re\lambda_+(B, \rho)$ and $\Im\lambda_+(B, \rho)$ for $(\rho, B) \in [0, 1] \times [0, 1]$. The curves $B = B_c(\rho)$, $B = B_1(\rho)$, and $B = B_2(\rho)$ meet at a common point, indicated with a circle, and divide the square into four regions, labeled I-IV. In region I the eigenvalue λ_1 is real and positive. In region II it is on the imaginary neck between the branch points of the essential spectrum.

This is the region of structural stability of the operator $L_2(\rho, B)$. In region III both λ_1 and λ_2 are real. In the remainder of the bifurcation state space, region IV, there is a set of four complex eigenvalues, symmetric about the real and imaginary axis. The point indicated with the circle in Figure 3 identifies the values $\rho = \rho_c, B = B_c(\rho_c)$ at which the kernel of L_2 has dimension four.

6. Appendix. We calculate here the result given in (4.15). Recalling the definition (4.13) of Φ_0, we substitute the values of A_B and Y_j from (4.2) to obtain

$$\Phi_0 = 4i\left[\int_{\infty}^{x}\phi^2 y_1\mathcal{Y}_0^{-1}\vec{e}_4, \int_{\infty}^{x}-\phi^2 y_2\mathcal{Y}_0^{-1}\vec{e}_4, \int_{-\infty}^{x}\phi^2 y_3\mathcal{Y}_0^{-1}\vec{e}_4, \int_{-\infty}^{x}-\phi^2 y_4\mathcal{Y}_0^{-1}\vec{e}_4\right],$$

where $\vec{e}_4 = (0,0,0,1)^T$. The determinate $W_0 = |\mathcal{Y}_0| = \frac{4i\alpha(1-i\alpha)}{1+i\alpha}$ and from the cofactors of $\mathcal{Y}_0$ we calculate

$$\mathcal{Y}_0^{-1}\vec{e}_4 = \frac{1}{W_0}(-iy_3, -iW_0y_5, iy_1, iW_0y_2)^T.$$

For notational convenience we write Φ_0 in terms of its column vectors as $\Phi_0 = [\vec{\gamma}, \vec{\delta}, \vec{\sigma}, \vec{\nu}]$, and consequently (4.12) implies $Y_{1B} = \mathcal{Y}_0\vec{\gamma}$, $Y_{2B} = \mathcal{Y}_0\vec{\delta}, \ldots$, etc. The second derivative terms (4.14) have a similar form; specifically we denote $\vec{\alpha} = \int_{\infty}^{x}\mathcal{Y}_0^{-1}A_B\mathcal{Y}_0\vec{\delta}ds$ and $\vec{\beta} = \int_{-\infty}^{x}\mathcal{Y}_0^{-1}A_B\mathcal{Y}_0\vec{\nu}ds$, and hence $Y_{2BB} = 2\mathcal{Y}_0\vec{\alpha}$ and $Y_{4BB} = 2\mathcal{Y}_0\vec{\beta}$. In this notation we may expand the determinates in (4.11), finding many zero terms. After simplification we obtain

$$\Big|[Y_1, Y_2, Y_3, Y_{4BB} - Y_{2BB}]\Big| = 2(\beta_4 - \alpha_4)W_0,$$

$$\Big|[Y_1, Y_{2B}, Y_3, Y_{4B}]\Big| = (\delta_2\nu_4 - \delta_4\nu_2)W_0,$$

$$\Big|[Y_{1B}, Y_2, Y_3, Y_{4B} - Y_{2B}]\Big| = \big(\gamma_1(\nu_4 - \delta_4) - \gamma_4(\nu_1 - \delta_1)\big)W_0,$$

and

$$\Big|[Y_1, Y_2, Y_{3B}, Y_{4B} - Y_{2B}]\Big| = \big(\sigma_3(\nu_4 - \delta_4) - \sigma_4(\nu_3 - \delta_3)\big)W_0.$$

The Wronskian W is independent of x and the equalities

$$\text{(6.1)}\ \vec{\delta}(x) = \begin{pmatrix}\delta_1(x)\\ \delta_2(x)\\ \delta_3(x)\\ \delta_4(x)\end{pmatrix} = \begin{pmatrix}\nu_3(-x)\\ \nu_2(-x)\\ \nu_1(-x)\\ -\nu_4(-x)\end{pmatrix}, \qquad \vec{\gamma}(x) = \begin{pmatrix}\gamma_1(x)\\ \gamma_2(x)\\ \gamma_3(x)\\ \gamma_4(x)\end{pmatrix} = \begin{pmatrix}\sigma_3(-x)\\ \sigma_2(-x)\\ \sigma_1(-x)\\ -\sigma_4(-x)\end{pmatrix}$$

hold for any $x \in \mathbb{R}$; we use them to simplify (4.11) as

$$W_{BB} = 2W_0\ \ (\beta_4 - \alpha_4 - 2\delta_2\delta_4 - 4\gamma_1\delta_4 + 2\gamma_4(\delta_1 - \delta_3))\big|_{x=0}.$$

Recalling the equality $E_{BB} = \frac{i}{16\alpha}W_{BB}$ and the relation $E_\lambda = \frac{W_0}{8\alpha}$ valid at $\lambda = \lambda_+$ and $B = 0$, we arrive at the expression

$$\text{(6.2)}\qquad \frac{E_{BB}}{E_\lambda} = i\ \ (\beta_4 - \alpha_4 - 2\delta_2\delta_4 - 4\gamma_1\delta_4 + 2\gamma_4(\delta_1 - \delta_3))\big|_{x=0}.$$

From the definition of $\vec{\delta}$ and $\vec{\gamma}$ we have

$$-2\delta_2(0)\delta_4(0) = 32\int_0^\infty \phi^2 y_2 y_5\,dx \int_0^\infty \phi^2 y_2^2\,dx = \frac{4}{9}(1+2\ln 2),$$

$$-4\gamma_1(0)\delta_4(0) = -\frac{64}{W_0}\int_0^\infty \phi^2 y_1 y_3\,dx \int_0^\infty \phi^2 y_2^2\,dx = -i\frac{8(2-3\rho^2)}{9\alpha\,(1-\rho^2)}, \tag{6.3}$$

and

$$2\gamma_4(0)(\delta_1(0)-\delta_3(0)) = \frac{32}{W_0}\int_0^\infty \phi^2 y_1 y_2\,dx \int_0^\infty \phi^2 (y_1+y_3)\,dx$$

$$= \frac{2\pi \operatorname{sech}\frac{\alpha\pi}{2}}{9}\left[1+2\alpha\int_0^\infty \operatorname{sech}^3(x)\,\sin(\alpha\,x)\,dx + i(\alpha(1-\rho^2)\pi)\operatorname{sech}\frac{\alpha\pi}{2}\right].$$

It remains to evaluate the quantity $\beta_4(0)-\alpha_4(0)$. From the definition of $\vec{\alpha}$ and $\vec{\beta}$ and the equalities (6.1) we have $\beta_4(0) = -\alpha_4(0)$. Moreover

$$\beta_4(0) = 4\left(\int_0^\infty (\delta_2 y_2 + \delta_4 y_5)\phi^2 y_2\,dx - \int_0^\infty (\delta_1 y_1 + \delta_3 y_3)\phi^2 y_2\,dx\right) = 4(I_1 - I_2). \tag{6.4}$$

We evaluate I_1 as

$$I_1 = 4\Bigg(\int_0^\infty \phi^2(x)\,y_2^2(x)\,dx \int_x^\infty \phi^2(s)\,y_2(s)\,y_5(s)\,ds \\ - \int_0^\infty \phi^2(x)\,y_2(x)\,y_5(x)\,dx \int_x^\infty \phi^2(s)\,y_2^2(s)\,ds\Bigg) = \frac{1}{27}(4-3\ln 2).$$

The integral I_2 takes the form

$$I_2 = \frac{4}{W_0}\Bigg(\int_0^\infty \phi^2(x)\,y_1(x)\,y_2(x)\,dx \int_x^\infty \phi^2(s)\,y_2(s)\,y_3(s)\,ds \\ - \int_0^\infty \phi^2(x)\,y_2(x)\,y_3(x)\,dx \int_x^\infty \phi^2(s)\,y_1(s)\,y_2(s)\,ds\Bigg) = \frac{\Im(\mathcal{G})}{4\alpha\,(1-\rho^2)},$$

where $\Im(\mathcal{G})$ is the imaginary part of the integral $\mathcal{G}$ defined by

$$\mathcal{G} = \int_0^\infty \operatorname{sech}^3(x)\big(i\alpha + \tanh x\big)e^{-i\alpha x}dx \int_x^\infty \operatorname{sech}^3(s)\big(i\alpha - \tanh s\big)e^{i\alpha s}ds.$$

Substituting these values into (6.2) yields

$$\begin{aligned} E_{BB}(\lambda_+,0) = \quad & E_\lambda(\lambda_+,0)\Bigg[\left(\tfrac{8(2-3\rho^2)}{9\alpha\,(1-\rho^2)} - \tfrac{2\alpha(1-\rho^2)\pi^2}{9}\operatorname{sech}^2\tfrac{\alpha\pi}{2}\right) \\ & + i\left(\tfrac{44}{27} - 2\tfrac{\Im(\mathcal{G})}{\alpha\,(1-\rho^2)} + \tfrac{2\pi\operatorname{sech}\frac{\alpha\pi}{2}}{9}\big(1+2\alpha\textstyle\int_0^\infty \operatorname{sech}^3(x)\,\sin(\alpha\,x)\,dx\big)\right)\Bigg]. \end{aligned} \tag{6.5}$$

Taking the real part of $\frac{E_{BB}}{E_\lambda}$, we arrive at the aforementioned result (4.15).

7. Discussion. We have described in detail the sequence of bifurcations characterizing the polarizational mode instability in the limit of weak birefringence. These occur in several families of NLS systems where nonlinear coupling occurs not only through amplitude via cross phase modulation but also through complex phase via the FWM. We find parameter regimes in which both the fast and the slow waves are linearly stable. The instability of the fast wave manifests itself as a rotation of polarization angle, the parameter α in (2.2), leading to a subsequent chaotic wobble. The impact of this instability on soliton collision, or more generally the modulational stability of the two soliton, is a subject of further study.

The Dirichlet expansion and the Evans function have shown themselves to be an efficient pair of analytical tools. The sharp resolution of the fourth root manifested in the eigenpath pinching of Figure 1(b) at the origin required many accurate evaluations of the Evans function. Moreover, the detailed resolution of the stability diagram (Figure 3) would have been impractical by more direct methods. Although the integrability of the unperturbed Manakov equation was reflected in the closed form expression of the Dirichlet expansion in that case, the integrability was not directly exploited, and the Dirichlet expansion may well find useful application to Evans function calculations for nonintegrable problems where significant information is available about the stable and unstable manifolds of the traveling wave forms.

Acknowledgments. We are thankful to T. Kapitula and B. Sandstede for many helpful discussions.

CONVERGENCE OF MEISSNER MINIMIZERS OF THE GINZBURG–LANDAU ENERGY OF SUPERCONDUCTIVITY AS $\kappa \to +\infty$[*]

A. BONNET[†], S. J. CHAPMAN[‡], AND R. MONNEAU[§]

Abstract. The Meissner solution of a smooth cylindrical superconducting domain subject to a uniform applied axial magnetic field is examined. Under an additional convexity condition the uniqueness of the Meissner solution is proved. It is then shown that it is a local minimizer of the Ginzburg–Landau energy $\mathcal{E}_\kappa$, For applied fields less than a critical value, the existence of the Meissner solution is proved for large enough Ginzburg–Landau parameter κ. Moreover it is proved that the Meissner solution converges to a local minimizer of a certain energy $\mathcal{E}_\infty$ in the limit as $\kappa \to \infty$. Finally, it is proved that for κ large enough the Meissner solution is not a global minimizer of $\mathcal{E}_\kappa$.

1. Introduction.

At temperatures below their critical temperature, type II superconductors can exist in one of three different states, depending on the strength of the applied magnetic field. For low magnetic fields they are in what is known as the Meissner state, in which the magnetic field is excluded from the interior except in thin boundary layers whose thickness is known as the penetration depth, denoted by λ. At intermediate applied magnetic fields the magnetic field penetrates the sample in the form of quantized flux tubes, usually known as vortices, since they are each circled by a vortex of superconducting current. The cores of these tubes comprise nonsuperconducting (normal) material, and are of a radius ξ, which is known as the coherence length. An important physical parameter is the ratio of these two lengthscales, $\kappa = \lambda/\xi$, which is known as the Ginzburg–Landau parameter. For type II superconductors $\kappa > 1/\sqrt{2}$, but κ is typically much larger than this, especially in superconducting alloys. We note that all the high-temperature superconducting materials discovered to date have very large (typically 50 to 100) values of κ.

As the applied magnetic field increases further, the density of vortices increases. For large applied magnetic fields the material becomes completely normal.

The transition from the vortex state to the normal state occurs at the upper critical field, H_{c_2}, and is second order and therefore reversible. On the other hand, the transition from the Meissner state to the vortex state is first order and exhibits hysteresis. The magnetic field at which the vortex state becomes theoretically energetically favorable is known as the lower critical field, H_{c_1}, but there is both "superheating" and "supercooling" around this field. The superheating of the Meissner state is the subject of this paper.

We study the Meissner state for finite κ and in the limit as $\kappa \to \infty$, in which case the model is substantially simplified. The layout of the paper is as follows. In the remainder of the introduction we introduce the Ginzburg–Landau theory of superconductivity and state our main results. We also establish the convergence of the Meissner solution to the solution of the simplified problem as $\kappa \to \infty$.

In section 3 we prove the uniqueness of the Meissner solution, while in section 4 we establish its existence for magnetic fields less than a critical value and for large enough κ. In section 5 we consider global and local minimizers of the Ginzburg–Landau (GL) free energy. We show that the Meissner solution is a local minimizer for magnetic fields below a (second) critical value, but that for large κ and nonzero applied magnetic field it is not the global minimizer. Finally, we present our conclusions.

2. The Ginzburg–Landau model.

We consider a superconductor material occupying a domain $\Sigma \subset \mathbb{R}^3$ in a uniform exterior magnetic field $H_0\boldsymbol{e_3}$. The state of the superconductor is characterized by a complex order parameter Ψ (defined on Σ) such that $|\Psi|^2$ represents the number density of superconducting electrons, which may be thought of as a kind of "macroscopic wavefunction," and the magnetic vector potential $\boldsymbol{A}$, which is such that the magnetic field is given by

$$\boldsymbol{H} = \mathrm{curl}\ \boldsymbol{A}.$$

In the theory introduced by Ginzburg and Landau [9] the equilibrium state of the superconductor is given by the minimizer of the Ginzburg–Landau energy (for a review of the theory the reader may consult [4, 6, 7]):

$$\mathcal{E} = \int_\Sigma \left|\left(\frac{1}{\kappa}\nabla - i\boldsymbol{A}\right)\Psi\right|^2 + \frac{(|\Psi|^2-1)^2}{2} + |\,\mathbf{curl}\ \boldsymbol{A} - H_0\boldsymbol{e_3}|^2\,dV + \int_{\mathbb{R}^3\setminus\Sigma} |\,\mathbf{curl}\ \boldsymbol{A} - H_0\boldsymbol{e_3}|^2\,dV. \tag{2.1}$$

Here κ is the Ginzburg–Landau parameter of the introduction. The energy (2.1) is in the usual nondimensional form in which $|\Psi| = 1$ represents wholly superconducting material, $|\Psi| = 0$ represents wholly normal material, and lengths have been scaled with the penetration depth λ, which is the typical lengthscale for variations in the magnetic potential. The vortex core radius is then given by $1/\kappa$.

The Euler–Lagrange equations corresponding to (2.1) are the celebrated Ginzburg–Landau equations

$$\left(\frac{1}{\kappa}\nabla - i\boldsymbol{A}\right)^2\Psi = \left(|\Psi|^2-1\right)\Psi \qquad \text{in } \Sigma, \tag{2.2}$$

$$(\mathrm{curl})^2\boldsymbol{A} = \frac{i}{2\kappa}\left(\Psi\nabla\Psi^* - \Psi^*\nabla\Psi\right) - |\Psi|^2\boldsymbol{A} \qquad \text{in } \Sigma, \tag{2.3}$$

$$(\mathrm{curl})^2\boldsymbol{A} = \boldsymbol{0} \qquad \text{in } \mathbb{R}^3\setminus\Sigma, \tag{2.4}$$

$$\boldsymbol{n}\cdot\left(\frac{1}{\kappa}\nabla - i\boldsymbol{A}\right)\Psi = 0 \qquad \text{on } \partial\Sigma, \tag{2.5}$$

$$[\boldsymbol{n}\wedge\boldsymbol{A}] = \boldsymbol{0}, \tag{2.6}$$

$$[\boldsymbol{n}\wedge\mathrm{curl}\ \boldsymbol{A}] = \boldsymbol{0}, \tag{2.7}$$

$$\mathrm{curl}\ \boldsymbol{A} \to H_0\boldsymbol{e_3} \qquad \text{as } |\boldsymbol{x}| \to \infty, \tag{2.8}$$

where [ ] represents the jump in the enclosed quantity across $\partial\Sigma$, and $\boldsymbol{n}$ is the unit outward normal to Σ. We consider the case where the superconductor has the shape of a long cylinder, mathematically idealized by $\Sigma = \Omega \times \mathbb{R}$ where the section of the cylinder $\Omega \subset \mathbb{R}^2$ is a bounded smooth open set, and the axis of the cylinder is parallel to $\boldsymbol{e_3}$. Then the energy (2.1) makes no sense, but assuming that the problem is invariant by translation in the direction $\boldsymbol{e_3}$ of the axis of the cylinder, we can simply redefine the energy as an integral over the cross-section $\mathbb{R}^2$. If we assume also that the magnetic field lies only in the $\boldsymbol{e}_3$ direction, then (2.4) and (2.8) imply that the magnetic field is constant and equal to $H_0\boldsymbol{e}_3$ in $\mathbb{R}^2\backslash\Omega$. Then the continuity conditions on $\partial\Omega$ can be replaced by $\boldsymbol{H} = H_0\boldsymbol{e}_3$ there.

Vortices correspond to zeros of the order parameter Ψ, while the Meissner solution is a solution in which $|\Psi| > 0$ on $\overline{\Omega}$. In this case we can make the change of gauge

$$\begin{cases} \Psi = fe^{i\chi}, f > 0 \\ \mathbf{Q} = \boldsymbol{A} - \frac{1}{\kappa}\nabla\chi, \end{cases}$$

where χ is uniquely defined (up to $2k\pi$, $k \in \mathbf{Z}$) if, for example, Ψ is smooth. Then we define the new energy for $\kappa \in (0, +\infty]$:

$$\mathcal{E}_\kappa(f, \mathbf{Q}) = \int_\Omega \frac{|\nabla f|^2}{\kappa^2} + |\text{curl } \mathbf{Q} - H_0|^2 + G(f, \mathbf{Q}),$$

where

$$G(f, \mathbf{Q}) = f^2|\mathbf{Q}|^2 + \frac{(f^2 - 1)^2}{2}$$

and curl $\mathbf{Q} = \partial_1 Q_2 - \partial_2 Q_1$ with $\mathbf{Q} = \begin{pmatrix} Q_1 \\ Q_2 \end{pmatrix}$. For $\kappa = +\infty$, we take

$$\mathcal{E}_\infty(f, \mathbf{Q}) = \int_\Omega |\text{curl } \mathbf{Q} - H_0|^2 + G(f, \mathbf{Q}).$$

Let us remark that $\frac{1}{2}G''(f, \mathbf{Q}) \cdot (g, \boldsymbol{q})^2 = (f\boldsymbol{q} + 2g\mathbf{Q})^2 + 3g^2(f^2 - |\mathbf{Q}|^2 - \frac{1}{3})$, so that G is convex if $f^2 - |\mathbf{Q}|^2 \geq \frac{1}{3}$.

2.1. A classical difficulty and the mathematical framework. Let V be the space (to be defined) on which we want to study the energy $\mathcal{E}_\kappa$. Let us remark that the functional $\mathcal{E}_\kappa$ is convex on the convex set $K_0 = \{(f, \mathbf{Q}) \in V,\ f^2 - |\mathbf{Q}|^2 \geq \frac{1}{3}\}$.

We are interested in the solutions $(f_\kappa, \mathbf{Q}_\kappa)$ such that

$$\inf_{(f,\mathbf{Q})\in K_0} \mathcal{E}_\kappa(f, \mathbf{Q}) \tag{2.9}$$

is attained by $(f_\kappa, \mathbf{Q}_\kappa)$ and $(f_\kappa, \mathbf{Q}_\kappa)$ belongs to $\text{Int}(K_0)$, the interior of K_0. For the value H_0 of the exterior magnetic field, we will denote by $u_\kappa^{H_0}$ such a minimizing point $(f_\kappa, \mathbf{Q}_\kappa)$.

Then at least two choices seem natural:

(a) $V = V_4$, where $V_4 = \{(f, \mathbf{Q}) \in L^4 \times L^4,\ \nabla f \in L^2,\ \text{curl } \mathbf{Q} \in L^2\}$, with the norm $|(f, \mathbf{Q})|_{V_4} = |f|_{L^4} + |\mathbf{Q}|_{L^4} + |\nabla f|_{L^2} + |\text{curl } \mathbf{Q}|_{L^2}$, the space on which the energy $\mathcal{E}_\kappa$ is naturally defined.

(b) The constraint which defines K_0 requires an L^∞ control on f and $\mathbf{Q}$. Then it is natural to define $V = V_\infty$ where $V_\infty = \{(f, \mathbf{Q}) \in L^\infty \times L^\infty,\ \nabla f \in L^2,\ \text{curl } \mathbf{Q} \in L^2\}$, with the norm $|(f, \mathbf{Q})|_{V_\infty} = |f|_{L^\infty} + |\mathbf{Q}|_{L^\infty} + |\nabla f|_{L^2} + |\text{curl } \mathbf{Q}|_{L^2}$.

Let us remark that in each case, (a) or (b), the energy $\mathcal{E}_\kappa$ is defined and continuous on V. Generally the existence of a minimizer $u_\kappa^{H_0}$ is a consequence of the fact that

$\mathcal{E}_\kappa(f,\mathbf{Q}) \to +\infty$ as $|(f,\mathbf{Q})|_V \to +\infty$; but here in both cases, (a) and (b), this property is not clear. A second difficulty is that if $u_\kappa^{H_0}$ is a minimizer on K_0, how can we know that $u_\kappa^{H_0} \notin \partial K_0$ (and then $u_\kappa^{H_0} \in \mathrm{Int}(K_0)$)? A great difficulty in the case (a) is that if $u_\kappa^{H_0} \in \mathrm{Int}(K_0)$, then for a perturbation of applied fields h in a neighborhood of H_0, it is not possible to claim that u_κ^h stays in $\mathrm{Int}(K_0)$; on the contrary this is possible in the case (b). This difficulty is associated with the fact that K_0 is not closed when $V = V_4$, but is closed if $V = V_\infty$.

Then we chose $V = V_\infty$ and we define the convex closed sets

$$K_{\delta_0} = \Big\{(f,\mathbf{Q}) \in V,\ f^2 - |\mathbf{Q}|^2 \geq \frac{1}{3} + \delta_0\Big\},\ \delta_0 \geq 0.$$

Then $\mathrm{Int}(K_0) = \cup_{\delta_0>0} K_{\delta_0}$. In particular $\mathcal{E}_\kappa$ is strictly convex on K_{δ_0}. Moreover there exists $c = c(\delta_0) > 0$ such that if $(f,\mathbf{Q})$ is a critical point of $\mathcal{E}_\kappa$ and $(f,\mathbf{Q}), (f+\overline{f}, \mathbf{Q}+\overline{\mathbf{Q}}) \in K_{\delta_0}$, then

$$\mathcal{E}_\kappa(f+\overline{f}, \mathbf{Q}+\overline{\mathbf{Q}}) \geq \mathcal{E}_\kappa(f,\mathbf{Q}) + \int_\Omega \frac{|\nabla \overline{f}|^2}{\kappa^2} + |\mathrm{curl}\ \overline{\mathbf{Q}}|^2 + c(|\overline{f}|^2 + |\overline{\mathbf{Q}}|^2).$$

2.2. Main results.

Definition 2.1. *We say that $(f,\mathbf{Q}) \in V$ is a local minimizer of $\mathcal{E}_\kappa$ on V if $\exists \epsilon = \epsilon(f,\mathbf{Q}) > 0$ such that if $|(\overline{f},\overline{\mathbf{Q}})|_V < \epsilon$, then $\mathcal{E}_\kappa(f+\overline{f}, \mathbf{Q}+\overline{\mathbf{Q}}) \geq \mathcal{E}_\kappa(f,\mathbf{Q})$. The function $(f,\mathbf{Q})$ is said to be a strict local minimizer if, moreover, $\mathcal{E}_\kappa(f+\overline{f}, \mathbf{Q}+\overline{\mathbf{Q}}) > \mathcal{E}_\kappa(f,\mathbf{Q})$ for $(\overline{f},\overline{\mathbf{Q}}) \neq 0$. Finally, $(f,\mathbf{Q})$ is a global minimizer if we can take $\epsilon = +\infty$ in the definition of a local minimizer.*

An element $(f,\mathbf{Q}) \in V$ is said to be a critical point of $\mathcal{E}_\kappa$ on V if it satisfies the Euler–Lagrange equations

$$\left\{ \begin{array}{l} \frac{1}{\kappa^2}\Delta f = \frac{1}{2}G'_f \\ -\ \mathbf{curl}\ (\mathrm{curl}\ \mathbf{Q}) = \frac{1}{2}G'_{\mathbf{Q}} \end{array} \right| \text{ on } \Omega \tag{2.10}$$

with the boundary conditions (that we obtain formally)

$$\left\{ \begin{array}{l} \frac{\partial_n f}{\kappa^2} = 0 \\ \mathrm{curl}\ \mathbf{Q} = H_0 \end{array} \right| \text{ on } \partial\Omega. \tag{2.11}$$

We assume that $\partial\Omega \in C^{2,\alpha}$ for some $\alpha \in (0,1)$. Let us remark that we can deduce (2.11) rigorously as weak boundary conditions (see (3.2)). Then we have (see [13, 14, 15] for similar uniqueness results for the Meissner solution).

Theorem 2.2. *If $(f,\mathbf{Q})$ is a critical point of $\mathcal{E}_\kappa$ on V (a weak solution of* (2.10)–(2.11)*), and $(f,\mathbf{Q}) \in \mathrm{Int}(K_0)$, then $(f,\mathbf{Q})$ is unique. Moreover $(f,\mathbf{Q})$ is a strict local minimizer of $\mathcal{E}_\kappa$.*

In what follows we denote by $(f_\kappa, \mathbf{Q}_\kappa)$ this local minimizer when it exists. We will use the more precise and compact notation $u_\kappa^{H_0}$ to denote this solution under an exterior magnetic field H_0.

Let us recall that in [1], Berestycki, Bonnet, and Chapman have proved with help of an inverse function theorem that there exists a critical magnetic field H_0^* which only depends on Ω such that $\forall H_0 \in [0, H_0^*)$, $u_\infty^{H_0}$ exists; $u_\infty^{H_0^*} \in \partial K_0$; and $\forall H_0 > H_0^*$, $u_\infty^{H_0}$ does not exist. Then we have the following theorem.

Theorem 2.3. *There exists a positive continuous and nondecreasing function γ defined on $(0,+\infty]$ such that $\gamma(+\infty) = H_0^*$ and such that $\forall(\kappa, H_0) \in \mathcal{P} := \{(\kappa, H_0),\ \kappa \in$*

$(0,+\infty],\ 0 \leq H_0 < \gamma(\kappa)\}$, $u_\kappa^{H_0} \in \mathrm{Int}(K_0)$ exists. Moreover $(\kappa, H_0) \to u_\kappa^{H_0} \in V$ is continuous on $\mathcal{P}$. In particular this implies that for $0 \leq H_0 < H_0^*$: $u_\kappa^{H_0} \to u_\infty^{H_0}$ in V as $\kappa \to +\infty$.

Now we give a result which proves that for κ large enough, $u_\kappa^{H_0}$ is only a local minimizer and not a global minimizer.

Theorem 2.4. *$\forall H_0 \geq 0, \exists C = C(H_0) > 0$ such that*

$$\inf_{(f,\mathbf{Q})\in V} \mathcal{E}_\kappa(f,\mathbf{Q}) \leq \frac{C}{\sqrt{\kappa}}.$$

In particular for $\kappa = +\infty$, $\mathcal{E}_\infty$ has no global minimizer if $H_0 > 0$.

2.3. Proof of Theorem 2.3. We give here the proof of Theorem 2.3, because it is very short and shows the main idea of this article. The proof of Theorem 2.3 uses the following two propositions.

Proposition 2.5 (case $\kappa \in (0,+\infty)$). *For $\kappa_0 \in (0,+\infty)$ and $H_0 \geq 0$, if $u_{\kappa_0}^{H_0} \in \mathrm{Int}(K_0)$, then $\exists \epsilon = \epsilon(\kappa_0, H_0) > 0$, such that if $|h - H_0|, |\kappa - \kappa_0| < \epsilon$, then u_κ^h exists and $u_\kappa^h \in \mathrm{Int}(K_0)$. Moreover the map $(\kappa, h) \longmapsto u_\kappa^h \in V$ is continuous.*

We denote curl $\mathbf{Q}_\infty$ by H_∞ where $(f_\infty, \mathbf{Q}_\infty)$ is the solution $u_\infty^{H_0}$. In [10] it is proved that the map $H_0 \longmapsto \sup_{\overline{\Omega}} |\nabla H_\infty|$ is nondecreasing. Then $\forall \delta_0 > 0$, there exists a unique $H_{\delta_0}^* \in (0, H_0^*)$ such that $\forall h \in [0, H_{\delta_0}^*]$, $u_\infty^h \in K_{\delta_0}$, and $\forall h > H_{\delta_0}^*$, $u_\infty^h \notin K_{\delta_0}$.

We need to have an a priori L^∞-control on f and $\mathbf{Q}$, so we define for $M > 1$ the set

$$K_{\delta_0}^M = \left\{ (f,\mathbf{Q}) \in K_{\delta_0},\ f, |\mathbf{Q}| \leq M \text{ and } f \geq \frac{1}{M} \right\}.$$

Then we have the following proposition.

Proposition 2.6 (case κ close to $+\infty$). *For $\delta_0 > 0$, $\exists \kappa_0 = \kappa_0(\delta_0) > 0$ such that $\forall M > 1\ \forall \theta \in (0,1)$, $\exists C_\theta = C_\theta(\delta_0, M) > 0$ such that $\forall H_0 \in [0, H_{\delta_0}^*]\ \forall \kappa \geq \kappa_0$, then if $u_\kappa^{H_0}$ exists and $u_\kappa^{H_0} \in K_{\delta_0}^M$, then*

$$|u_\kappa^{H_0} - u_\infty^{H_0}|_V \leq \frac{C_\theta(\delta_0, M)}{\kappa^{\frac{1}{2}-\theta}}.$$

Given these two propositions, the proof of Theorem 2.3 can be made in three steps:

Step 1. Fix some $\theta \in (0, \frac{1}{2})$. Let $\delta_0 > 0$ be given. Choose $M_0 = M_0(\delta_0) > 1$ such that $\forall H_0 \in [0, H_{\delta_0}^*]$, $u_\infty^{H_0} \in K_{\delta_0}^{M_0}$. Then choose $\kappa_1 = \kappa_1(\delta_0) > 0$, large enough such that $\forall H_0 \in [0, H_{\delta_0}^*]$, then

$$\forall u \in V,\ \left(|u - u_\infty^{H_0}|_V \leq \frac{C_\theta(\frac{\delta_0}{4}, 4M_0)}{\kappa_1^{\frac{1}{2}-\theta}} \right) \Longrightarrow \left(u \in K_{\frac{\delta_0}{2}}^{2M_0} \right). \tag{2.12}$$

Step 2. Let $\kappa \geq \kappa_1$. We have $u_\kappa^0 = (1,0) \in \mathrm{Int}(K_0)$ and Proposition 2.5 allows us to build a u_κ^h for h in a neighborhood of 0, and with help of the control given by Proposition 2.6 and (2.12), u_κ^h stays in $K_{\frac{\delta_0}{2}}^{2M_0}$, and then we have existence of u_κ^h until $h = H_{\delta_0}^*$.

Step 3. For $H_0 \in [0, H_0^*)$, from Proposition 2.5, the map $\kappa \longmapsto u_\kappa^{H_0} \in V$ is continuous, and from Proposition 2.6, $u_\kappa^{H_0}$ admits the limit $u_\infty^{H_0}$ as $\kappa \to +\infty$. Consequently we can always choose a positive continuous and nondecreasing function γ as described in Theorem 2.3.

Theorem 2.3 is then proved. □

3. Uniqueness of Meissner solutions in an infinite cylinder under a convexity condition. Here we are interested in the uniqueness of Meissner solutions of the Ginzburg–Landau equations in infinite cylinder $\Sigma_\infty = \Omega \times \mathbb{R}$. The problem is invariant by translation, and we usually restrict the study to solutions which have this symmetry (which is the case in Theorem 2.2):

$$f = f(x_1, x_2), \qquad \mathbf{Q} = \begin{pmatrix} Q_1(x_1, x_2) \\ Q_2(x_1, x_2) \\ 0 \end{pmatrix}, \qquad (x_1, x_2) \in \partial\Omega.$$

Here we relax these conditions somewhat but not completely. We still suppose that the magnetic field outside the superconductor lies in the $\boldsymbol{e}_3$ direction, so that it is constant and equal to $H_0\boldsymbol{e}_3$, and the energy density in $\mathbb{R}^3\backslash\Sigma_\infty$ vanishes. However, we relax the symmetry assumption inside the superconductor, so that we prove the uniqueness (under a certain convexity condition) of solutions $(f, \mathbf{Q})$ defined in all the cylinder Σ_∞ of the form

$$f = f(x_1, x_2, x_3), \qquad \mathbf{Q} = \begin{pmatrix} Q_1(x_1, x_2, x_3) \\ Q_2(x_1, x_2, x_3) \\ Q_3(x_1, x_2, x_3) \end{pmatrix};$$

Theorem 2.2 will be a particular case of Theorem 3.1. As we have already mentioned, we cannot derive the Ginzburg–Landau equations on an infinite cylinder from an energy. Let us then take as a model the case of a periodic cylinder and derive rigorously the Euler–Lagrange equations. In this way we will find the minimal regularity assumption to impose on our solution to the infinite cylinder.

Then for $\Lambda > 0$, let the periodic cylinder $\Sigma_\Lambda = \Omega \times \Lambda\mathbf{S}^1$ where $\mathbf{S}^1 = \mathbf{Z}/(2\pi\mathbf{Z})$, and let f, $\mathbf{Q}$ be functions defined on $\overline{\Sigma}_\Lambda$. Then for $\kappa \in (0, +\infty]$, the Ginzburg–Landau energy is

$$\mathcal{E}_\kappa^\Lambda(f, \mathbf{Q}) = \int_{\Sigma_\Lambda} \frac{|\nabla f|^2}{\kappa^2} + |\ \mathbf{curl}\ \mathbf{Q} - H_0\boldsymbol{e}_\mathbf{3}|^2 + G(f, \mathbf{Q}).$$

Let us recall that $V = \{(f, \mathbf{Q}) \in L^\infty \times L^\infty,\ \nabla f \in L^2,\ \ \mathbf{curl}\ \mathbf{Q} \in L^2\}$. Then $\mathcal{E}_\kappa$ is defined on V. In particular, if $(f, \mathbf{Q})$ is an extremum of $\mathcal{E}_\kappa^\Lambda$, then we get the Euler–Lagrange equations in the distributional sense inside Σ_λ:

$$\left\{ \begin{array}{l} \frac{1}{\kappa^2}\Delta f = \frac{1}{2}G'_f \in L^\infty \\ -(\ \mathbf{curl}\ )^2\mathbf{Q} = \frac{1}{2}G'_\mathbf{Q} \in L^\infty \end{array} \right| \text{ in } \mathcal{D}'(\Sigma_\Lambda) \tag{3.1}$$

and the boundary conditions in $H^{-\frac{1}{2}}(\partial\Sigma_\Lambda)$:

$$\left\{ \begin{array}{l} \partial_n f = 0 \\ (\ \mathbf{curl}\ \mathbf{Q} - H_0\boldsymbol{e}_\mathbf{3}) \wedge n = 0. \end{array} \right. \tag{3.2}$$

The only difficulty is to justify the weak sense of the boundary conditions. It is possible to define these conditions by duality (for example $\langle \partial_n f, \phi \rangle_{H^{-\frac{1}{2}}(\partial\Sigma_\Lambda) \times H^{\frac{1}{2}}(\partial\Sigma_\Lambda)} = \int_{\Sigma_\Lambda} \Delta f \phi + \nabla f \cdot \nabla\phi$ for $\phi \in H^1(\Sigma_\Lambda)$). In particular see [8] for the definition of the tangential trace of a vector field $\boldsymbol{A} \in L^2$ with $\mathbf{curl}\ \boldsymbol{A} \in L^2$.

Minimal regularity assumption. In the following we assume at least the minimal regularity $f, \mathbf{Q} \in L^\infty(\Sigma_\infty)$, ∇f, $\mathbf{curl}\ \mathbf{Q} \in L^2_{loc}(\Sigma_\infty)$ (and $\mathbf{curl}\ ^2\mathbf{Q} \in L^2_{loc}(\Sigma_\infty)$ which is a consequence of the Ginzburg–Landau equations).

Then we have in the case of the infinite cylinder the following theorem.

Theorem 3.1. *For $\kappa \in (0, +\infty]$, if $(f, \mathbf{Q})$ satisfies* (3.1)–(3.2) *on $\Sigma_\infty = \Omega \times \mathbb{R}$, with the minimal regularity assumption and $(f, \mathbf{Q}) \in K_{\delta_0} = \{(f, \mathbf{Q}) \in V,\ f^2 - |\mathbf{Q}|^2 \geq \frac{1}{3} + \delta_0\}, \delta_0 > 0$, then $(f, \mathbf{Q})$ is unique and*

$$\begin{cases} Q_3 \equiv 0, \\ f \textit{ and } \mathbf{Q} \textit{ are independent on } x_3. \end{cases}$$

In particular $\boldsymbol{H} = H(x_1, x_2)\boldsymbol{e_3}$ where $\boldsymbol{H} = \mathbf{curl}\ \mathbf{Q}$, $(x_1, x_2) \in \Omega$.

Now we can identify the solutions $(f, \mathbf{Q})$ on Σ_∞ as functions defined on Ω, and we have the following proposition.

Proposition 3.2. *The solutions $(f, \mathbf{Q})$ of Theorem* 3.1 *are analytic in Ω. On $\overline{\Omega}$, the solutions $(f, \mathbf{Q})$ have at least the regularity $C^{1+m,\alpha}$ if $\partial\Omega \in C^{2+m,\alpha}$, $m \geq 0$.*

Proof of Proposition 3.2. If $f, \mathbf{Q} \in L^\infty(\Omega)$, ∇f, $\mathbf{curl}\ \mathbf{Q} \in L^2(\Omega)$, then for finite κ

$$\begin{cases} \frac{1}{\kappa^2}\Delta f = \frac{1}{2}G'_f \in L^\infty \text{ in } \mathcal{D}'(\Omega), \\ \partial_n f = 0 \text{ in } H^{-\frac{1}{2}}(\partial\Omega). \end{cases}$$

Then (see [2] for the regularity of weak solutions) $f \in H^2(\Omega)$, and by the standard L^p-elliptic theory, $f \in W^{2,p}$ and therefore $f \in C^{1,\theta}$ (Schauder theory). Let us remark that the equation on $\mathbf{Q}$ is elliptic in dimension 1 but is not elliptic in dimension $n \geq 2$. So it is interesting to obtain an elliptic formulation, and it was done in [1] introducing the magnetic field $H = \text{curl}\ \mathbf{Q} = \partial_1 Q_2 - \partial_2 Q_1$. Using the explicit form of G it is easy to obtain an elliptic equation satisfied by H. Writing $-\ \mathbf{curl}$ (curl $\mathbf{Q}$) $= \frac{1}{2}G'_{\mathbf{Q}}$ as $-\ \mathbf{curl}\ H = f^2\mathbf{Q}$ where $\mathbf{curl}\ H = \left(\begin{smallmatrix} \partial_2 H \\ -\partial_1 H \end{smallmatrix}\right)$, we see that $H = \text{curl}\ \mathbf{Q} = \text{curl}\ (-\frac{\mathbf{curl}\ H}{f^2}) = \nabla \cdot (\frac{\nabla H}{f^2})$. Thus

$$\begin{cases} \nabla \cdot (\frac{\nabla H}{f^2}) - H = 0 \text{ in } \mathcal{D}'(\Omega), \\ H = H_0 \text{ in } H^{-\frac{1}{2}}(\partial\Omega); \end{cases} \tag{3.3}$$

$\mathbf{Q}$ may be found by the inverse formula $\mathbf{Q} = -\frac{\mathbf{curl}\ H}{f^2}$. Then $H \in C^{2,\theta}$ (see [2]). Consider the elliptic system

$$\begin{cases} \frac{1}{\kappa^2}\Delta f = \frac{1}{2}G'_f(f, -\frac{\mathbf{curl}\ H}{f^2}), \\ \partial_n f = 0, \\ \nabla(\frac{\nabla H}{f^2}) - H = 0, \\ H = H_0. \end{cases} \tag{3.4}$$

A classical bootstrap argument permits us to see that if $(f, H) \in C^{m,\alpha} \times C^{m+1,\alpha}$ with $m \geq 1$, then $(f, H) \in C^{m+1,\alpha} \times C^{m+2,\alpha}$, and then $f, H \in C^\infty(\Omega)$. Moreover because the elliptic (nonlinear) system is analytic, the solutions (f, H) are analytic on Ω (result of Morrey; see [11]). In particular if $\partial\Omega$ is analytic, then (f, H) is analytic on $\overline{\Omega}$. Finally we find the regularity on $\mathbf{Q}$, taking $\mathbf{Q} = -\frac{\mathbf{curl}\ H}{f^2}$. For infinite κ, the proof can be found in [1]. This ends the proof.

Proof of Theorem 3.1. Let $(f_j, \mathbf{Q}_j)$, $j = 1, 2$, be two solutions in K_{δ_0} of (3.1)–(3.2) on $\Sigma_\infty = \Omega \times \mathbb{R}$. Let $\psi(x_3)$ be a function with compact support. We multiply the equation $\frac{1}{\kappa^2}\Delta(f_2-f_1)=\frac{1}{2}[G'_f]^{f_2,\mathbf{Q}_2}_{f_1,\mathbf{Q}_1}$ by $\psi(f_2-f_1)$, and the equation $-(\textbf{ curl })^2(\mathbf{Q}_2-\mathbf{Q}_1)=\frac{1}{2}[G'_{\mathbf{Q}}]^{f_2,\mathbf{Q}_2}_{f_1,\mathbf{Q}_1}$ by $\psi(\mathbf{Q}_2-\mathbf{Q}_1)$. Then by integration on $\Sigma=\Sigma_\infty$ we obtain

$$\int_\Sigma\left(\frac{1}{\kappa^2}\nabla(\psi(f_2-f_1))\cdot\nabla(f_2-f_1)+\textbf{ curl }(\psi(\mathbf{Q}_2-\mathbf{Q}_1))\cdot\textbf{ curl }(\mathbf{Q}_2-\mathbf{Q}_1)\right.$$
$$\left.+\frac{1}{2}[G']^{f_2,\mathbf{Q}_2}_{f_1,\mathbf{Q}_1}\cdot\psi\begin{pmatrix} f_2-f_1\\ \mathbf{Q}_2-\mathbf{Q}_1\end{pmatrix}\right)=0.$$

Here we have integrated by parts one time in f, and one time in $\mathbf{Q}$, using the equality $\int_\Sigma(\textbf{ curl }\boldsymbol{A})\cdot\boldsymbol{B}=\int_\Sigma\boldsymbol{A}\cdot(\textbf{ curl }\boldsymbol{B})+\int_{\partial\Sigma}(\boldsymbol{A}\wedge\boldsymbol{B})\cdot\boldsymbol{n}$. Moreover the boundary terms obtained for f and for $\mathbf{Q}$ are zero because of (3.2). Then we obtain (using $\textbf{curl }(f\boldsymbol{A})=\nabla f\wedge\boldsymbol{A}+f\textbf{ curl }\boldsymbol{A}$)

$$\int_\Sigma\psi\left\{\frac{1}{\kappa^2}|\nabla(f_2-f_1)|^2+|\textbf{ curl }(\mathbf{Q}_2-\mathbf{Q}_1)|^2+\frac{1}{2}[G']^{f_2,\mathbf{Q}_2}_{f_1,\mathbf{Q}_1}\cdot\begin{pmatrix} f_2-f_1\\ \mathbf{Q}_2-\mathbf{Q}_1\end{pmatrix}\right\}$$
$$=\int_\Sigma\left(-\frac{f_2-f_1}{\kappa}\right)\cdot\left(\frac{\nabla\psi}{\sqrt{\psi}}\right)\cdot\left(\sqrt{\psi}\frac{\nabla(f_2-f_1)}{\kappa}\right)$$
$$-\left(\frac{\nabla\psi}{\sqrt{\psi}}\wedge(\mathbf{Q}_2-\mathbf{Q}_1)\right)\cdot\left(\sqrt{\psi}\textbf{ curl }(\mathbf{Q}_2-\mathbf{Q}_1)\right).\tag{3.5}$$

But G is strictly convex on K_{δ_0}, and from the inequality of convexity we deduce that

$$\exists c=c(\delta_0)>0\text{ such that }\frac{1}{2}[G']^{f_2,\mathbf{Q}_2}_{f_1,\mathbf{Q}_1}\cdot\begin{pmatrix} f_2-f_1\\ \mathbf{Q}_2-\mathbf{Q}_1\end{pmatrix}\geq c((f_2-f_1)^2+(\mathbf{Q}_2-\mathbf{Q}_1)^2).$$

On the other hand we have the L^∞-estimates on the right-hand side of (3.5): $|f_2-f_1|\leq C$, $|\mathbf{Q}_2-\mathbf{Q}_1|\leq C$. Then from the Cauchy–Schwarz inequality we have

$$\int_\Sigma\psi\left\{\frac{|\nabla(f_2-f_1)|^2}{\kappa^2}+|\textbf{ curl }(\mathbf{Q}_2-\mathbf{Q}_1)|^2+\delta((f_2-f_1)^2+(\mathbf{Q}_2-\mathbf{Q}_1)^2)\right\}$$
$$\leq C\left(\int_\Sigma\frac{|\nabla\psi|^2}{\psi}\right)^{\frac{1}{2}}\left\{\left(\int_\Sigma\psi\frac{|\nabla(f_2-f_1)|^2}{\kappa^2}\right)^{\frac{1}{2}}+\left(\int_\Sigma\psi|\textbf{ curl }(\mathbf{Q}_2-\mathbf{Q}_1)|^2\right)^{\frac{1}{2}}\right\}.$$

But if we take $\psi(x)=\psi_0(\lambda x_3)$, where $\psi_0\geq 0$ has a support in $[-2,2]$, is equal to 1 on $[-1,1]$, then using the fact that $\int_\Sigma\frac{|\nabla\psi|^2}{\psi}=\lambda\int_\Sigma\frac{|\nabla\psi_0|^2}{\psi_0}$, we deduce as $\lambda\to 0$ that

$$\int_\Sigma\frac{|\nabla(f_1-f_2)|^2}{\kappa^2}+|\textbf{ curl }(\mathbf{Q}_2-\mathbf{Q}_1)|^2+c((f_2-f_1)^2+(\mathbf{Q}_2-\mathbf{Q}_1)^2)=0.$$

Consequently $f_2=f_1$ and $\mathbf{Q}_2=\mathbf{Q}_1$.

Now if $(f,\mathbf{Q})$ is a solution, for $t\in\mathbb{R}$ let $f^t(x_1,x_2,x_3)=f(x_1,x_2,x_3+t)$, and $\mathbf{Q}^t(x_1,x_2,x_3)=\mathbf{Q}(x_1,x_2,x_3+t)$. It is clear that $(f^t,\mathbf{Q}^t)$ is a solution, and from the uniqueness result we deduce that f and $\mathbf{Q}$ do not depend on the coordinate x_3.

Now let $\tilde{\mathbf{Q}}=\begin{pmatrix} Q_1(x_1,x_2)\\ Q_2(x_1,x_2)\\ 0\end{pmatrix}$. Then (for every fixed Λ) we have by construction

$$\mathcal{E}^\Lambda_\kappa(f,\mathbf{Q}+\overline{\mathbf{Q}})\leq\mathcal{E}^\Lambda_\kappa(f,\mathbf{Q})\text{ where }\overline{\mathbf{Q}}=\tilde{\mathbf{Q}}-\mathbf{Q}.\tag{3.6}$$

We conclude with the help of the following lemma.

LEMMA 3.3. *Assume that* $(f,\mathbf{Q})\in V$ *is a solution of* (3.1)–(3.2) *on* Σ_Λ. *Consider* $(\overline{f},\overline{\mathbf{Q}})\in V$, *and assume that* $(f,\mathbf{Q})$ *and* $(f+\overline{f},\mathbf{Q}+\overline{\mathbf{Q}})$ *are in* K_{δ_0}. *Then we have*

$$\mathcal{E}_\kappa^\Lambda(f+\overline{f},\mathbf{Q}+\overline{\mathbf{Q}})\geq\mathcal{E}_\kappa^\Lambda(f,\mathbf{Q})+\int_{\Sigma_\Lambda}\frac{|\nabla\overline{f}|^2}{\kappa^2}+|\ \mathbf{curl}\ \overline{\mathbf{Q}}|^2+c(|\overline{f}|^2+|\overline{\mathbf{Q}}|^2). \tag{3.7}$$

From (3.6), this lemma implies (with $\overline{f}=0$) that $\int_{\Sigma_\Lambda}|\ \mathbf{curl}\ \overline{\mathbf{Q}}|^2+c|\overline{\mathbf{Q}}|^2=0$, so that $\overline{\mathbf{Q}}=0$. Hence $Q_3=0$. Then $\boldsymbol{H}=\ \mathbf{curl}\ \mathbf{Q}=H(x_1,x_2)\boldsymbol{e_3}$, and Theorem 3.1 is proved.

Proof of Lemma 3.3. We have

$$\begin{aligned}\mathcal{E}_\kappa(f+\overline{f},\mathbf{Q}+\overline{\mathbf{Q}})&=\mathcal{E}_\kappa(f,\mathbf{Q})+\int_{\Sigma_\Lambda}\left\{\frac{2}{\kappa^2}\nabla f\cdot\nabla\overline{f}+\frac{1}{\kappa^2}|\nabla\overline{f}|^2\right.\\&\left.+2(\ \mathbf{curl}\ \overline{\mathbf{Q}})\cdot(\ \mathbf{curl}\ \mathbf{Q}-H_0\boldsymbol{e_3})+|\ \mathbf{curl}\ \overline{\mathbf{Q}}|^2+G(f+\overline{f},\mathbf{Q}+\overline{\mathbf{Q}})-G(f,\mathbf{Q})\right\}.\end{aligned}$$

Moreover, from Taylor's formula with integral remainder, we obtain

$$G(f+\overline{f},\mathbf{Q}+\overline{\mathbf{Q}})-G(f,\mathbf{Q})=G'_{(f,\mathbf{Q})}(f,\mathbf{Q})\cdot(\overline{f},\overline{\mathbf{Q}})+\int_0^1(1-t)(\overline{f},\overline{\mathbf{Q}})\cdot G''(f,\mathbf{Q}+t\overline{\mathbf{Q}})\cdot(\overline{f},\overline{\mathbf{Q}})dt,$$

which gives, after an integration by parts,

$$\begin{aligned}\mathcal{E}_\kappa(f+\overline{f},\mathbf{Q}+\overline{\mathbf{Q}})&=\mathcal{E}_\kappa(f,\mathbf{Q})+\int_{\Sigma_\Lambda}\frac{1}{\kappa^2}|\nabla\overline{f}|^2+|\ \mathbf{curl}\ \overline{\mathbf{Q}}|^2\\&+\int_0^1dt(1-t)\left(\int_{\Sigma_\Lambda}(\overline{f},\overline{\mathbf{Q}})\cdot G''(f+t\overline{f},\mathbf{Q}+t\overline{\mathbf{Q}})\cdot(\overline{f},\overline{\mathbf{Q}})\right)\\&+2\left\{\int_{\Sigma_\Lambda}\overline{f}\cdot\left(-\frac{1}{\kappa^2}\Delta f+\frac{1}{2}G'_f(f,\mathbf{Q})\right)+\overline{\mathbf{Q}}\cdot\left((\ \mathbf{curl}\ )^2\mathbf{Q}+\frac{1}{2}G'_{\mathbf{Q}}(f,\mathbf{Q})\right)\right.\\&\left.\qquad+\int_{\partial\Sigma_\Lambda}\frac{1}{\kappa^2}\overline{f}\cdot\frac{\partial f}{\partial n}-(\ \mathbf{curl}\ \mathbf{Q}-H_0\boldsymbol{e_3})\wedge\overline{\mathbf{Q}}\cdot n\right\}.\end{aligned}$$

The last term is zero, since $(f,\mathbf{Q})$ satisfies (3.1)–(3.2). On the other hand $(f,\tilde{\mathbf{Q}})\in K_{\delta_0}$, so from the inequality of convexity we have

$$\frac{1}{2}(\overline{f},\overline{\mathbf{Q}})\cdot G''(f+t\overline{f},\mathbf{Q}+t\overline{\mathbf{Q}})\cdot(\overline{f},\overline{\mathbf{Q}})\geq c(|\overline{f}|^2+|\overline{\mathbf{Q}}|^2).$$

This implies the lemma.

4. Existence of Meissner solutions.

4.1. A priori estimates as $\boldsymbol{\kappa\to+\infty}$. In the following we consider only the functions f and $\mathbf{Q}=(Q_1,Q_2)$ defined on Ω, with curl $\mathbf{Q}=\partial_1Q_2-\partial_2Q_1$, and the associated energy defined for $(f,\mathbf{Q})\in V$, $\kappa\in(0,+\infty]$:

$$\mathcal{E}_\kappa(f,\mathbf{Q})=\int_\Omega\frac{|\nabla f|^2}{\kappa^2}+|\mathrm{curl}\ \mathbf{Q}-H_0|^2+G(f,\mathbf{Q}).$$

We recall that a critical point $(f_\kappa, \mathbf{Q}_\kappa)$ of $\mathcal{E}_\kappa$ satisfies

$$\left\{\begin{array}{l} \left.\begin{array}{l} \frac{1}{\kappa^2}\Delta f_\kappa = \frac{1}{2}G'_f(f_\kappa, \mathbf{Q}_\kappa) \\ -\,\mathbf{curl}\ (\mathrm{curl}\ \mathbf{Q}_\kappa) = \frac{1}{2}G'_{\mathbf{Q}}(f_\kappa, \mathbf{Q}_\kappa) \end{array}\right| \text{ on } \Omega, \\ \left.\begin{array}{l} \frac{\partial_n f_\kappa}{\kappa^2} = 0 \\ \mathrm{curl}\ \mathbf{Q}_\kappa = H_0 \end{array}\right| \text{ on } \partial\Omega, \end{array}\right. \tag{4.1}$$

which implies $H_\kappa = \mathrm{curl}\ \mathbf{Q}_\kappa$ satisfies

$$\left\{\begin{array}{ll} \nabla\cdot\left(\dfrac{\nabla H_\kappa}{f_\kappa^2}\right) - H_\kappa = 0 & \text{in } \Omega, \\ H_\kappa = H_0 \qquad \text{on } \partial\Omega & \end{array}\right. \tag{4.2}$$

with $\mathbf{Q}_\kappa$ given by the inverse formula

$$\mathbf{Q}_\kappa = -\frac{\mathbf{curl}\ H_\kappa}{f_\kappa^2}.$$

We are interested in the solutions of (4.1) in $\mathrm{Int}(K_{\delta_0})$. Theorem 3.1 claims the uniqueness of these solutions (when they exist). Then we have the following a priori estimates as $\kappa \to +\infty$ (which imply Proposition 2.6).

PROPOSITION 4.1. *$\forall\delta_0 > 0$, $\exists\kappa_0 = \kappa_0(\delta_0) > 0$ such that $\forall M > 1$ $\forall\theta \in (0,1)$, $\exists C_\theta = C_\theta(\delta_0, M) > 0$ such that $\forall H_0 \in [0, H^*_{\delta_0}]$ $\forall\kappa \geq \kappa_0$ for all solutions $(f_\kappa, \mathbf{Q}_\kappa) \in K^M_{\delta_0}$ of (4.1), we have*

$$\left.\begin{array}{l} |f_\kappa - f_\infty|_{C^{0,\theta}(\overline{\Omega})} \\ |\mathbf{Q}_\kappa - \mathbf{Q}_\infty|_{C^{0,\theta}(\overline{\Omega})} \\ |H_\kappa - H_\infty|_{C^{1,\theta}(\overline{\Omega})} \end{array}\right\} \leq \frac{C_\theta}{\kappa^{\frac{1}{2}-\theta}}$$

and

$$|\nabla(f_\kappa - f_\infty)|_{L^2} = O\left(\frac{1}{\kappa^{\frac{1}{2}}}\right).$$

Remark 4.2. Here C_θ depends only on θ, Ω and on $\max(M, \frac{1}{\delta_0})$.

Motivation. The essential difficulty as $\kappa \to +\infty$ is the singular perturbation of f resulting from the highest order derivatives in the equation $\frac{1}{\kappa^2}\Delta f = \frac{1}{2}G'_f$ vanishing in the limit. The limiting solution, $f = f_\infty$, does not satisfy the boundary condition ($\partial_n f_\infty \neq 0$), and there is a boundary layer of width $1/\kappa$. If (s, n) are coordinates tangential and normal to $\partial\Omega$, respectively, then rescaling $n = \bar{n}/\kappa$ in the boundary layer we find that

$$f \sim f_\infty(s,0) + \frac{1}{\kappa}\left(\partial_n f_\infty(s,0)\bar{n} + \frac{\partial_n f_\infty(s,0)}{\sqrt{2}f_\infty(s,0)}e^{-\sqrt{2}f_\infty(s,0)\bar{n}}\right)$$

there. Thus a good approximation to f both in the bulk and in the boundary layer region is

$$f_\infty(x) + \frac{1}{\kappa}\frac{\partial_n f_\infty(y)}{\sqrt{2}f_\infty(y)}e^{-\sqrt{2}f_\infty(y)\kappa d(x,\partial\Omega)}, \tag{4.3}$$

where $y \in \partial\Omega$ is such that $d(x, \partial\Omega) = |x - y|$.

Now let f_∞^κ be any approximation to f_∞ which takes into account the boundary layer, i.e., is such that

$$\partial_n f_\infty^\kappa = 0 \text{ on } \partial\Omega. \tag{4.4}$$

Write $\overline{f} = f_\kappa - f_\infty^\kappa$, $\overline{\mathbf{Q}} = \mathbf{Q}_\kappa - \mathbf{Q}_\infty$, $\overline{H} = H_\kappa - H_\infty$. Recall that $\forall H_0 \in [0, H_{\delta_0}^*]$, $(f_\infty, \mathbf{Q}_\infty) \in K_{\delta_0}$. Then under the assumption of Proposition 4.1 and (4.4) we have the following lemma.

Lemma 4.3. *For* $1 < p < +\infty$ $\forall H_0 \in [0, H_{\delta_0}^*]$, $\exists C = C(\delta_0, M, p) > 0$ *such that if* $(f_\infty^\kappa, \mathbf{Q}_\infty) \in K_{\frac{\delta_0}{2}}$ *then for every solution* $(f_\kappa, \mathbf{Q}_\kappa) \in K_{\delta_0}^M$ *of* (4.1) *we have*

$$\left.\begin{array}{l} |\overline{f}|_{L^2} \\ \frac{1}{\kappa}|\nabla\overline{f}|_{L^2} \\ |\overline{\mathbf{Q}}|_{L^2} \\ |\mathrm{curl}\overline{\mathbf{Q}}|_{\mathrm{L}^2} \end{array}\right\} \leq C\left\{\left|\frac{\Delta f_\infty^\kappa}{\kappa^2} - \frac{1}{2}[G'_f]_{f_\infty,\mathbf{Q}_\infty}^{f_\infty^\kappa,\mathbf{Q}_\infty}\right|_{L^2} + \left|\frac{1}{2}[G'_{\mathbf{Q}}]_{f_\infty,\mathbf{Q}_\infty}^{f_\infty^\kappa,\mathbf{Q}_\infty}\right|_{L^2}\right\}, \tag{4.5}$$

$$\frac{\left|\Delta\overline{f}\right|_{L^2}}{\kappa^2} \leq \left|\frac{\Delta f_\infty^\kappa}{\kappa^2} - \frac{1}{2}[G'_f]_{f_\infty,\mathbf{Q}_\infty}^{f_\infty^\kappa,\mathbf{Q}_\infty}\right|_{L^2} + \left|\frac{1}{2}[G'_f]_{f_\infty^\kappa,\mathbf{Q}_\infty}^{f_\kappa,\mathbf{Q}_\kappa}\right|_{L^2}, \tag{4.6}$$

$$\left.\begin{array}{l} \left|D^2\overline{H}\right|_{L^p} \\ \left|\nabla\overline{H}\right|_{L^p} \\ |\overline{H}|_{L^p} \end{array}\right\} \leq C(1+|\overline{H}|_{L^\infty}+|\nabla\overline{H}|_{L^\infty})\{|\overline{f}|_{L^p}+|\nabla\overline{f}|_{L^p}+|f_\infty^\kappa-f_\infty|_{L^p}+|\nabla(f_\infty^\kappa-f_\infty)|_{L^p}\}. \tag{4.7}$$

The proof of Lemma 4.3 will follow the proof of Proposition 4.1.

Remark 4.4. We note that under the assumption of Proposition 4.1 the quantities $|\frac{1}{2}[G']_{f_\infty,\mathbf{Q}_\infty}^{f_\infty^\kappa,\mathbf{Q}_\infty}|_{L^2}$ are bounded by a constant times $|f_\infty^\kappa - f_\infty|_{L^2}$. For

$$f_\infty^\kappa - f_\infty = \frac{1}{\kappa}\frac{\partial_n f_\infty(y)}{\sqrt{2}f_\infty(y)}e^{-\sqrt{2}f_\infty(y)\kappa d(x,\partial\Omega)}$$

we have $|f_\infty^\kappa - f_\infty|_{L^2} \sim C/\kappa^{\frac{3}{2}}$ which is therefore heuristically the best estimate of $|f_\kappa - f_\infty|_{L^2}$ that we can hope for.

Rather than using the exponential correction (4.3) we choose a linear function times a cut off, which makes it easier to obtain the necessary estimates. Precisely, our choice is

$$f_\infty^\kappa = f_\infty - \chi_\kappa\psi_{f_\infty},$$

where $\psi_{f_\infty}(x) = d(x,\partial\Omega)\cdot\partial_n f_\infty(y)$ where $y \in \partial\Omega$ satisfies $d(x,\partial\Omega) = |x-y|$, and where $\chi_\kappa(x) = \chi_0(\kappa d(x,\partial\Omega))$, with χ_0 a smooth nonincreasing function which satisfies $\chi_0 \geq 0$ on $[0,+\infty[$, $\chi_0 = 1$ on $[0,\frac{1}{2}]$, $\chi_0 = 0$ on $[1,+\infty[$. We assume that $\partial\Omega \in C^{2,\alpha}$; then in particular $\chi_\kappa\psi_{f_\infty} \in C^{1,\alpha}$. With this definition we have $\partial_n f_\infty^\kappa = 0$ and (compare with Remark 4.4)

$$|f_\infty^\kappa - f_\infty|_{L^2} = O\left(\frac{1}{\kappa^{\frac{3}{2}}}\right).$$

More general estimates on $f_\infty^\kappa - f_\infty$ are put together in the following lemma.

Lemma 4.5. *For $1 \leq p < +\infty$, $\theta \in (0,1)$, we have*

$$\begin{aligned}|f_\infty^\kappa - f_\infty|_{L^p} &= O\left(\frac{1}{\kappa^{1+\frac{1}{p}}}\right),\\ |\nabla(f_\infty^\kappa - f_\infty)|_{L^p} &= O\left(\frac{1}{\kappa^{\frac{1}{p}}}\right),\\ |f_\infty^\kappa - f_\infty|_{C^{0,\theta}} &= O\left(\frac{1}{\kappa^{1-\theta}}\right).\end{aligned}$$

Proof. The calculation is straightforward.

Remark 4.6. If $\partial\Omega \in C^{3,\alpha}$, then $\chi_\kappa \psi_{f_\infty} \in C^{2,\alpha}$ in which case $\Delta(f_\infty^\kappa - f_\infty)$ makes sense and we have $|\Delta(f_\infty^\kappa - f_\infty)|_{L^2} = O(\sqrt{\kappa})$.

Then we deduce the following lemma.

Lemma 4.7. *$\exists \kappa_0 = \kappa_0(\delta_0) > 0$ such that $\forall \kappa \geq \kappa_0$, for every solution $(f_\kappa, \mathbf{Q}_\kappa) \in K_{\delta_0}^M$ of* (4.1) *we have*

$$|\overline{f}|_{L^2}, |\overline{\mathbf{Q}}|_{L^2}, |curl\, \overline{\mathbf{Q}}|_{L^2} = O\left(\frac{1}{\kappa^{\frac{3}{2}}}\right), \qquad |\nabla \overline{f}|_{L^2} = O\left(\frac{1}{\kappa^{\frac{1}{2}}}\right), \tag{4.8}$$

$$|\Delta \overline{f}|_{L^2} = O(\sqrt{\kappa}), \tag{4.9}$$

and for $1 < p < +\infty$

$$|D^2 \overline{H}|_{L^p}, |\nabla \overline{H}|_{L^p}, |\overline{H}|_{L^p} = O\left(\frac{1}{\kappa^{\frac{1}{p}}} + |\overline{f}|_{L^p} + |\nabla \overline{f}|_{L^p}\right). \tag{4.10}$$

Proof of Lemma 4.7. For κ larger than some κ_0, for every $H_0 \in [0, H_{\delta_0}^*]$, we obtain $(f_\infty^\kappa, Q_\infty) \in K_{\frac{\delta_0}{2}}$, and then Lemma 4.3 can be used. The estimates (4.8) and (4.9) are directly deduced from Lemmas 4.3 and 4.5. To deduce (4.10) it is sufficient to remark that $\mathbf{Q}_\kappa = -\frac{\mathbf{curl}\ H_\kappa}{f_\kappa^2}$ and then $|\nabla H_\kappa|_{L^\infty} \leq |\mathbf{Q}_\kappa|_{L^\infty} |f_\kappa^2|_{L^\infty} \leq C$ because $(f_\kappa, \mathbf{Q}_\kappa) \in K_{\delta_0}^M$. Moreover $|\overline{H}|_{L^2} = |\text{curl}\ \overline{\mathbf{Q}}|_{L^2} = O(1/\kappa^{\frac{3}{2}})$, and therefore $|H|_{L^\infty} \leq C$, and $|\overline{H}|_{L^\infty}, |\nabla \overline{H}|_{L^\infty} \leq C$, and we deduce (4.10), which ends the proof of the lemma. □

As we have already mentioned in the introduction, we have an L^∞ constraint on the solution, while the natural spaces and estimates are L^p. Thus we need to use Gagliardo–Nirenberg inequalities (see [12]). The proof of Proposition 4.1 uses these inequalities many times, and for the convenience of the reader we recall them here for a bounded open set $\Omega \subset \mathbb{R}^n$.

Gagliardo–Nirenberg inequalities. Let $1 \leq q, r \leq +\infty$, $0 \leq j < m$, and $q' > 0$. Then

$$|D^j u|_p \leq C\{|D^m u|_r^a\, |u|_q^{1-a} + |u|_{q'}\},$$

where

$$\frac{1}{p} = \frac{j}{n} + a\left(\frac{1}{r} - \frac{m}{n}\right) + (1-a)\frac{1}{q}$$

for $\frac{j}{m} \leq a \leq 1$, and only for $\frac{j}{m} \leq a < 1$ if $m-j-\frac{n}{r} \in \mathbb{N}$ and $1 < r < +\infty$. Here $D^s u$ symbolizes the set of all partial derivatives of total order s, and for $-\infty < 1/p < +\infty$, we use the definition

$$|v|_p = \begin{cases} (\int_\Omega |v|^p)^{\frac{1}{p}} \text{ if } 0 < \frac{1}{p} < +\infty, \\ \sup_{x\in\Omega} |v(x)| \text{ if } \frac{1}{p} = 0, \\ [D^s v]_\alpha = \sup_{x,x'\in\Omega, x\neq x'} \frac{|D^s v(x') - D^s v(x)|}{|x'-x|^\alpha} \\ \qquad\qquad \text{if } -\infty < \frac{1}{p} < 0, s = [-\frac{n}{p}], \alpha = (-\frac{n}{p}) - s. \end{cases}$$

End of the proof of Proposition 4.1. We use various inequalities of Gagliardo–Nirenberg.

From the inequality

$$|\overline{f}|_{L^\infty} \leq C\{|D^2\overline{f}|_{L^2}^{\frac{1}{2}} |\overline{f}|_{L^2}^{\frac{1}{2}} + |\overline{f}|_{L^2}\};\ n = 2$$

we deduce that

$$|\overline{f}|_{L^\infty} = O\left(\kappa^{-\frac{1}{2}}\right). \tag{4.11}$$

From the inequality

$$[\overline{f}]_{2a-1} \leq C\{|D^2\overline{f}|_{L^2}^{a} |\overline{f}|_{L^2}^{1-a} + |\overline{f}|_{L^2}\};\ n = 2, \frac{1}{2} < a < 1$$

we deduce $[\overline{f}]_{2a-1} = O(\kappa^{2(a-\frac{3}{4})})$. With $\theta = 2a-1$ this implies that $\forall \theta \in (0,1), |\overline{f}|_{C^{0,\theta}} = O(1/\kappa^{\frac{1}{2}-\theta})$, and from Lemma 4.5 we deduce that

$$\forall \theta \in (0,1), |f_\kappa - f_\infty|_{C^{0,\theta}} = O\left(\frac{1}{\kappa^{\frac{1}{2}-\theta}}\right).$$

From the inequality

$$|\nabla\overline{f}|_{L^p} \leq C\{|D^2\overline{f}|_{L^2}^{a} |\overline{f}|_{L^2}^{1-a} + |\overline{f}|_{L^2}\};\ n = 2,\ \frac{1}{p} = 1-a,\ \frac{1}{2} \leq a < 1$$

we deduce $|\nabla\overline{f}|_{L^p} = O(1/\kappa^{\frac{2}{p}-\frac{1}{2}});\ 2 \leq p < +\infty$. In particular from Lemma 4.5 we deduce

$$|\nabla(f_\kappa - f_\infty)|_{L^2} = O\left(\frac{1}{\kappa^{\frac{1}{2}}}\right).$$

Moreover, from (4.11), we get $|\overline{f}|_{L^p} = O(1/\kappa^{\frac{1}{2}})$ obviously for $2 \leq p < +\infty$; and (4.10) gives $|D^2\overline{H}|_{L^p}, |\nabla\overline{H}|_{L^p}, |\overline{H}|_{L^p} = O(1/\kappa^{\frac{2}{p}-\frac{1}{2}});\ 2 \leq p < +\infty$. From the inequality

$$|\nabla\overline{H}|_{L^{\overline{p}}} \leq C\{|D^2\overline{H}|_{L^p}^{a} |\overline{H}|_{L^2}^{1-a} + |\overline{H}|_{L^2}\};\ n = 2,\ -\frac{n}{\overline{p}} = a\left(3 - \frac{2}{p}\right) - 2;$$

$$\frac{1}{2} \leq a < 1 \text{ if } p = 2;\ \frac{1}{2} \leq a \leq 1 \text{ if } 2 < p < +\infty;$$

we deduce with $\theta = 1-\frac{2}{p},\ a = 1,\ 2 < p < +\infty$, that $\forall \theta \in (0,1),\ [\nabla\overline{H}]_\theta = O(1/\kappa^{\frac{1}{2}-\theta})$. In the limit case $\theta = 0$, we have $|\nabla\overline{H}|_{L^\infty} \leq \frac{C_\eta}{\kappa^{\frac{1}{2}-\eta}}$ where η is arbitrarily small.

Therefore $\forall\theta\in(0,1), |\nabla\overline{H}|_{C^{0,\theta}}=O(1/\kappa^{\frac{1}{2}-\theta})$. In particular because $|\overline{H}|_{L^2}=O(1/\kappa^{\frac{3}{2}})$ we deduce that $|\overline{H}|_{L^\infty}=O(1/\kappa^{\frac{1}{2}-\theta})$; thus

$$\forall\theta\in(0,1),\ |\overline{H}|_{C^{1,\theta}}=O\left(\frac{1}{\kappa^{\frac{1}{2}-\theta}}\right).$$

Moreover

$$\overline{\mathbf{Q}}=\mathbf{Q}_\kappa-\mathbf{Q}_\infty=-\frac{\mathbf{curl}\ \overline{H}}{f^2}+(\ \mathbf{curl}\ H_\infty)\left(\frac{1}{f_\infty^2}-\frac{1}{f_\kappa^2}\right).$$

Thus using $|f_\infty^\kappa-f_\infty|_{C^{0,\theta}}=O(1/\kappa^{1-\theta})$ from Lemma 4.5, we deduce that

$$\forall\theta\in(0,1),\quad |\overline{\mathbf{Q}}|_{C^{0,\theta}}=O\left(\frac{1}{\kappa^{\frac{1}{2}-\theta}}\right)$$

which ends the proof of Proposition 4.1.

Proof of Lemma 4.3. From (4.1) we get

$$(4.12)\qquad \left\{\begin{array}{l} \left.\begin{array}{l}\frac{1}{\kappa^2}\Delta\overline{f}=\frac{1}{2}\{[G'_f]_{f_\infty^\kappa,\mathbf{Q}_\infty}^{f_\kappa,\mathbf{Q}_\kappa}+[G'_f]_{f_\infty,\mathbf{Q}_\infty}^{f_\infty^\kappa,\mathbf{Q}_\infty}\}-\frac{\Delta f_\infty^\kappa}{\kappa^2}\\ -\ \mathbf{curl}\ (\mathrm{curl}\ \overline{\mathbf{Q}})=\frac{1}{2}\{[G'_\mathbf{Q}]_{f_\infty^\kappa,\mathbf{Q}_\infty}^{f_\kappa,\mathbf{Q}_\kappa}+[G'_\mathbf{Q}]_{f_\infty,\mathbf{Q}_\infty}^{f_\infty^\kappa,\mathbf{Q}_\infty}\}\end{array}\right|\ \text{on }\Omega,\\ \left.\begin{array}{l}\partial_n\overline{f}=0\\ \mathrm{curl}\ \overline{\mathbf{Q}}=0\end{array}\right|\ \text{on }\partial\Omega.\end{array}\right.$$

The first equation gives the inequality (4.6). To obtain the inequality (4.5), we multiply the first equation of (4.12) (resp., the second equation of (4.12)) by $\overline{f}$ (resp., $\overline{\mathbf{Q}}$) and integrate by parts. Then we obtain

$$\int_\Omega\frac{|\nabla\overline{f}|^2}{\kappa^2}+|\mathrm{curl}\ \overline{\mathbf{Q}}|^2+\frac{1}{2}[G']_{f^\kappa,\mathbf{Q}^*}^{f,\mathbf{Q}}\cdot\left(\begin{array}{c}\overline{f}\\ \overline{\mathbf{Q}}\end{array}\right)=\int_\Omega\left(\frac{\Delta f^\kappa}{\kappa^2}-\frac{1}{2}[G'_f]_{f^*,\mathbf{Q}^*}^{f^\kappa,\mathbf{Q}^*}\right)\overline{f}-\frac{1}{2}[G'_\mathbf{Q}]_{f^*,\mathbf{Q}^*}^{f^\kappa,\mathbf{Q}^*}\cdot\overline{\mathbf{Q}}.$$

Using the inequality of convexity because $(f_\infty^\kappa,\mathbf{Q}_\infty)\in K_{\frac{\delta_0}{2}}$, we get for $c=c(\frac{\delta_0}{2})$

$$\frac{1}{2}[G']_{f_\infty^\kappa,\mathbf{Q}_\infty}^{f_\kappa,\mathbf{Q}_\kappa}\cdot\left(\begin{array}{c}\overline{f}\\ \overline{\mathbf{Q}}\end{array}\right)\geq c(\overline{f}^2+\overline{\mathbf{Q}}^2)$$

and we find the inequality (4.5).

From (4.2) we have

$$\left\{\begin{array}{l}\nabla\cdot(\frac{\nabla\overline{H}}{f_\infty^2})-\overline{H}=-g,\\ \overline{H}=0,\end{array}\right.$$

where

$$g=\nabla\cdot\left((\nabla H_\kappa)\left(\frac{1}{f_\kappa^2}-\frac{1}{(f_\infty)^2}\right)\right)=(\Delta H_\kappa)\left(\frac{1}{f_\kappa^2}-\frac{1}{(f_\infty)^2}\right)-2(\nabla H_\kappa)\left(\frac{\nabla f_\kappa}{f_\kappa^3}-\frac{\nabla f_\infty}{(f_\infty)^3}\right),$$

but from (4.2) we obtain $\Delta H_\kappa=f_\kappa^2H_\kappa+2\nabla H_\kappa\cdot\frac{\nabla f_\kappa}{f_\kappa}$ and then

$$g=\frac{H_\kappa}{(f_\infty)^2}((f_\infty)^2-f_\kappa^2)+2\frac{\nabla H_\kappa}{(f_\infty)^2}\left(\frac{\nabla f_\infty}{f_\infty}-\frac{\nabla f_\kappa}{f_\kappa}\right).$$

Then $|g|_{L^p}\leq C(|H|_{L^\infty}+|\nabla H|_{L^\infty})(|f_\kappa-f_\infty|_{L^p}+|\nabla(f_\kappa-f_\infty)|_{L^p})$. On another hand we have the standard elliptic L^p-estimate, $|\overline{H}|_{W^{2,p}}\leq C|g|_{L^p}$. Consequently we obtain the inequality (4.7), and the lemma is proved.

4.2. Local existence of the Meissner solution. We aim to find by perturbation from a known solution some solutions $(f, \mathbf{Q})$ of (4.1), that is, solutions $(f, \tilde{H})$ of the system

$$\tag{4.13} \begin{cases} \frac{1}{\kappa^2}\Delta f = \frac{1}{2}G'_f(f, -\frac{\textbf{curl } \tilde{H}}{f^2}), \\ \partial_n f = 0, \\ \nabla \cdot (\frac{\nabla \tilde{H}}{f^2}) - \tilde{H} = H_0, \\ \tilde{H} = 0, \end{cases}$$

where we have introduced the notation $\tilde{H} = H - H_0$ to obtain homogeneous boundary conditions. We will perturb using H_0. On the other hand, we are interested only in the solutions $(f, \mathbf{Q}) \in \mathrm{Int}(K_0)$, i.e., $(f, \tilde{H})$ in the open set

$$\mathcal{U} = \left\{ (f, \tilde{H}) : \text{ for } \mathbf{Q} = -\frac{\textbf{curl } \tilde{H}}{f^2},\ (f, \mathbf{Q}) \in \mathrm{Int}(K_0) \right\}.$$

Then it is natural to introduce the operator

$$\mathcal{A}(f, \tilde{H}) = \begin{cases} \frac{1}{\kappa^2}\Delta f - \frac{1}{2}G'_f(f, -\frac{\textbf{curl } \tilde{H}}{f^2}), \\ \nabla \cdot (\frac{\nabla \tilde{H}}{f^2}) - \tilde{H}. \end{cases}$$

We want to apply an inverse function theorem in Hölder spaces, which is possible because the solutions $(f, \tilde{H})$ are in fact regular (see Proposition 3.2). Define the spaces

$$X_0^{m,\alpha} = \{f, \tilde{H} \in C^{m,\alpha}(\overline{\Omega}),\ \partial_n f = 0, \tilde{H} = 0 \text{ on } \partial\Omega\},$$

$$X^{m,\alpha} = \{f, \tilde{H} \in C^{m,\alpha}(\overline{\Omega})\}.$$

We will work in the space of minimal regularity $X_0^{2,\alpha}$. In particular we assume that $\partial\Omega \in C^{2,\alpha}$. Then $\mathcal{A} : \mathcal{U}_0 = \mathcal{U} \cap X_0^{2,\alpha} \to X^{0,\alpha}$ is a regular map. We want to solve

$$\mathcal{A}(f, \tilde{H}) = \begin{pmatrix} 0 \\ H_0 \end{pmatrix}.$$

We start with the particular solution

$$\mathcal{A}(1, 0) = \begin{pmatrix} 0 \\ 0 \end{pmatrix}, \text{ where } (1, 0) \in \mathcal{U}_0.$$

Proof of Proposition 2.5. We have

$$D_{(f,\tilde{H})}\mathcal{A}(f, \tilde{H}) \cdot (\phi, \tilde{h}) = \begin{cases} \frac{1}{\kappa^2}\Delta\phi - 3(f^2 - \frac{|\nabla\tilde{H}|^2}{f^4} - \frac{1}{3})\phi - 2\frac{(\textbf{ curl } \tilde{H})\cdot(\textbf{ curl } \tilde{h})}{f^3}, \\ \nabla \cdot (\frac{\nabla\tilde{h}}{f^2} - 2\frac{\nabla\tilde{H}}{f^3}\phi) - \tilde{h}. \end{cases}$$

We denote $\chi = f^2 - \frac{|\nabla\tilde{H}|^2}{f^4} - \frac{1}{3}$, and we consider the equation

$$\tag{4.14} D_{(f,\tilde{H})}\mathcal{A}(f, \tilde{H}) \cdot (\phi, \tilde{h}) = \begin{cases} \phi_0 \\ \tilde{h}_0 \end{cases} \in X^{0,\alpha}.$$

We remark that if $(\phi, \tilde{h}) \in \mathrm{Ker} D\mathcal{A}(f, \tilde{H})$, then multiplying the first equation by ϕ and the second by $\tilde{h}$, and integrating by parts we obtain (with the cancellation of two terms $\mathbf{curl}\ \tilde{H} \cdot\ \mathbf{curl}\ \tilde{h} - \nabla\tilde{H} \cdot \nabla\tilde{h} = 0$)

$$\int_\Omega \frac{|\nabla\phi|^2}{\kappa^2} + 3\chi\phi^2 + \frac{|\nabla\tilde{h}|}{f^2} + \tilde{h}^2 = 0.$$

But if $(f, \tilde{H}) \in \mathcal{U}_0$ then there exists some $\eta_0 > 0$ such that $\chi > \eta_0 > 0$. Therefore $\phi = \tilde{h} = 0$ and $\mathrm{Ker} D\mathcal{A}(f, \tilde{H}) = \{0\}$.

We establish the surjectivity of $D\mathcal{A}(f, \tilde{H})$ with the help of Fredholm theory. In fact (4.14) can be written

$$\left\{ \begin{array}{l} \frac{1}{\kappa^2}\Delta\phi - 3\chi\phi - 2\frac{\nabla\tilde{H}\cdot\nabla\tilde{h}}{f^3} = \phi_0, \\ \Delta\tilde{h} - 2\frac{\nabla f\cdot\nabla\tilde{H}}{f} - 2f^2\nabla\cdot(\frac{\nabla\tilde{H}\phi}{f^3}) - f^2\tilde{h} = f^2\tilde{h}_0. \end{array} \right.$$

Here the terms of second derivatives are decoupled in ϕ and $\tilde{h}$, and we can write these equations as a compact perturbation of the identity. If we introduce (for example) the two well-known isomorphisms

$$\begin{array}{ll} A_1: & \{\phi \in C^{2,\alpha},\ \partial_n\phi = 0\} \quad \to C^{0,\alpha} \\ & \phi \longmapsto \Delta\phi - \phi \end{array},$$

$$\begin{array}{ll} A_2: & \{\tilde{h} \in C^{2,\alpha},\ \tilde{h} = 0\} \quad \to C^{0,\alpha} \\ & \tilde{h} \longmapsto \Delta\tilde{h} - \tilde{h} \end{array},$$

then (4.14) can be written

$$(\mathrm{Id} + T)(\phi, \tilde{h}) = (\phi_1, \tilde{h}_1),$$

where

$$\begin{array}{l} \phi_1 = A_1^{-1}(\kappa^2\phi_0), \\ \tilde{h}_1 = A_2^{-1}(f^2\tilde{h}_0), \end{array}$$

and

$$T(\phi, \tilde{h}) = \left\{ \begin{array}{l} A_1^{-1}((1 - 3\kappa^2\chi)\phi - 2\kappa^2\frac{\nabla\tilde{H}\cdot\nabla\tilde{h}}{f^3}), \\ A_2^{-1}((1 - f^2)\tilde{h} - 2\frac{\nabla\cdot\nabla\tilde{h}}{f} - 2f^2\nabla\cdot(\frac{\phi\nabla\tilde{H}}{f^3})). \end{array} \right.$$

Then $T: X_0^{0,\alpha} \to X_0^{0,\alpha}$ is clearly compact, and then

$$Ind(\mathrm{Id} + T) = Ind(\mathrm{Id}).$$

However, $Ind(\mathrm{Id} + T) = \mathrm{dimKer}(\mathrm{Id} + T) - codim\mathrm{Im}(\mathrm{Id} + T)$ and $Ind(\mathrm{Id}) = 0$, $\mathrm{dimKer}(\mathrm{Id}+T) = 0$, so that $\mathrm{Id}+T$ is surjective and $D\mathcal{A}(f, \tilde{H})$ is surjective. Therefore $D\mathcal{A}(f, \tilde{H}): X_0^{2,\alpha} \to X^{0,\alpha}$ is invertible and the inverse function theorem applies, which proves Proposition 2.5.

5. Global and local minimizers.

5.1. A minimizing sequence.

We start with the existence of a minimizing sequence for $\mathcal{E}_\infty$. Recall that

$$V = \{(f, \mathbf{Q}) \in L^\infty \times L^\infty,\ \nabla f \in L^2,\ \mathbf{curl}\ \mathbf{Q} \in L^2\}.$$

PROPOSITION 5.1. (i) *For any* $H_0 \geq 0$,

$$\inf_{(f,\mathbf{Q})\in V} \mathcal{E}_\infty(f, \boldsymbol{Q}) = 0.$$

The minimizing sequence can be chosen in C^∞.

(ii) *For* $H_0 > 0$ *there is no global minimizer of* $\mathcal{E}_\infty$.

Proof of Proposition 5.1. We remark that zero is the absolute minimum of $\mathcal{E}_\infty$, whose density is nonnegative. Assuming that the first part of the theorem holds, a global minimizer should satisfy almost everywhere (a.e.)

$$f^2 \left|\boldsymbol{Q}\right|^2 + \frac{(f^2-1)^2}{2} + (\text{curl } \boldsymbol{Q} - H_0)^2 = 0.$$

Then we have a.e. in Ω: $f = 1$, $\boldsymbol{Q} = 0$ and curl $\boldsymbol{Q} = H_0$. Then the distributional derivative of $\mathbf{Q}$ is zero and therefore $H_0 = 0$.

The minimizing sequence. The problem is somewhat analogous to the problem of minimizing the functional

$$\int_{-1}^{1} ((F')^2 - 1)^2 + F^2\, dx.$$

There it is well known that a minimizing sequence is furnished by the sawtooth function

$$F_n = \begin{cases} x - \frac{2j+1/2}{n} & x \in \left[\frac{2j}{n}, \frac{2j+1}{n}\right) \\ -x + \frac{2j+3/2}{n} & x \in \left(\frac{2j+1}{n}, \frac{2j+2}{n}\right] \end{cases} \quad j \in \mathbf{Z}.$$

Thus we have that $(F')^2 - 1$ is identically zero, while the derivative F_n' switches between the values -1 and $+1$ increasingly rapidly as $n \to \infty$ so that F itself stays small.

In the present case we need to satisfy curl $\boldsymbol{Q} = H_0$ while keeping $\boldsymbol{Q}$ small. If we take the second component of $\boldsymbol{Q}$ to be a sawtooth function

$$Q_2^{(n)} = H_0\left(x - \frac{j+1/2}{n}\right) \qquad x \in \left[\frac{j}{n}, \frac{j+1}{n}\right), \quad j \in \mathbf{Z},$$

then the jumps in $Q_2^{(n)}$ will create δ-function spikes in the first component at the points $x = j/n$. However, we can neutralize the effect on the energy of these spikes by simply dropping f down to zero locally.

We now construct a C^∞ minimizing sequence which is a smooth version of that described above. Let ψ be a real C^∞ function, $0 \leq \psi \leq 1$ such that

$$\psi(x) \equiv 0 \text{ for } |x| \geq 2,$$
$$\psi(x) \equiv 1 \text{ for } |x| \leq 1.$$

We introduce

$$g_n(x,y) = 1 - \sum_{k=-\infty}^{\infty} \psi\left(n^2\left(x - \frac{k}{n}\right)\right).$$

The function g_n is a sum of C^∞ functions with compact supports $\{\frac{k}{n} - \frac{2}{n^2} \leq x \leq \frac{k}{n} + \frac{2}{n^2}\}$. Now let χ_ϵ be an approximation of the identity in $\mathbb{R}$ (a nonnegative real C^∞ function with support in $(-\epsilon,\epsilon)$ and mass $\int \chi_\epsilon = 1$). Let $[x]$ denote the integral part of x (i.e., $[x] = \max\{n \in \mathbb{N}, n \leq x\}$). We define h_n as the convolution

$$h_n(x) = \left(x - \frac{[nx]}{n}\right) * \chi_{\frac{1}{2n^2}}.$$

We then define the functional

$$\boldsymbol{P_n}(x,y) = (y(h_n'(x) - 1), h_n(x)),$$

and compute curl $\boldsymbol{P_n} = h_n'(x) - (h_n'(x) - 1) = 1$. We then construct a sequence $(f_n, \boldsymbol{Q_n})$ as

$$\left\{\begin{array}{l} f_n = g_{n|\Omega}, \\ \boldsymbol{Q_n} = H_0 \boldsymbol{P}_{\boldsymbol{n}|\Omega}. \end{array}\right. \tag{5.1}$$

Let us consider the sets $B_j^n = \Omega \bigcap \bigcup_{k=-\infty}^{+\infty}\{(x,y), \{\frac{k}{n} - \frac{j}{n^2} \leq x \leq \frac{k}{n} + \frac{j}{n^2}\}$ for $j = 1, 2$. The sequence $(f_n, \boldsymbol{Q_n})$ is such that

$$\left\{\begin{array}{ll} \text{curl } \boldsymbol{Q_n} = H_0 & \text{in } \Omega, \\ 0 \leq f_n \leq 1 & \text{in } \Omega, \\ f_n = 1 & \text{in } \Omega \backslash B_2^n, \\ |\boldsymbol{Q_n}| = H_0 h_n(x) \leq \frac{H_0}{n} & \text{in } \Omega \backslash B_1^n, \\ f_n = 0 & \text{in } B_1^n. \end{array}\right.$$

We remark that $\text{meas}(B_j^n) \leq 2\frac{j}{n}(\text{diam}(\Omega))^2$. Therefore, if we estimate the energy on $\Omega \backslash B_2^n$, $B_2^n \backslash B_1^n$ and B_1^n, we obtain

$$\mathcal{E}_\infty(f_n, \boldsymbol{Q_n}) \leq \frac{C}{n}.$$

Consequently, $\inf \mathcal{E}_\infty = 0$ and $(f_n, \boldsymbol{Q_n})$ is a minimizing sequence. This completes the proof of Proposition 5.1.

From the construction above, we notice that

$$\mathcal{E}_\kappa(f_n, \boldsymbol{Q_n}) \leq \frac{C}{n} + C'\frac{n^3}{\kappa^2}.$$

Therefore, for $n = \sqrt{\kappa}$, we deduce Theorem 2.4.

5.2. Properties of local minimizers. Here we present some properties of local minimizers (see Definition 2.1).

PROPOSITION 5.2. *For $\kappa \in (0, +\infty)$, if $(f, \mathbf{Q})$ is a local minimizer in V of $\mathcal{E}_\kappa$, then $\exists \epsilon > 0$ such that either $\epsilon \leq f \leq 1 - \epsilon$ or $f \equiv 0$ or $f \equiv 1$.*

Remark 5.3. If $f \equiv 1$, then $\mathbf{Q} \equiv 0$, but curl $\mathbf{Q} = H_0$ on $\partial\Omega$, and so $H_0 = 0$.

Proof of Proposition 5.2. Let us first remark that if $(f, \mathbf{Q})$ is a global minimizer, then $\mathcal{E}_\kappa(\min(f,1),\mathbf{Q}) \leq \mathcal{E}_\kappa(f,\mathbf{Q})$ and therefore $0 \leq f \leq 1$. If $(f,\mathbf{Q})$ is a local minimizer, then let $\overline{f} = (f - (\sup_\Omega f - \epsilon))^+$. If $\sup_\Omega f > 1$, then for ϵ small enough, $\mathcal{E}_\kappa(f-\overline{f},\mathbf{Q}) < \mathcal{E}_\kappa(f,\mathbf{Q})$, which is impossible, therefore $0 \leq f \leq 1$.
Now

$$\begin{cases} \frac{1}{\kappa^2}\Delta f = f(f^2 + |\mathbf{Q}|^2 - 1), \\ f \geq 0. \end{cases}$$

Then, by the strong maximum principle, either $f \equiv 0$ or $f > 0$ on Ω. Since $\partial_n f = 0$, by the Hopf lemma we deduce that $\inf_\Omega f > 0$, and then $\inf_{\overline{\Omega}} f > 0$.

Now let $v = 1 - f$, then

$$\begin{cases} \frac{1}{\kappa^2}\Delta v - f(f+1)v = -f|\mathbf{Q}|^2 \leq 0, \\ v \geq 0. \end{cases}$$

Then, as previously, we deduce that either $v = 0$ or $\inf_{\overline{\Omega}} v > 0$, and therefore $\sup_{\overline{\Omega}} f < 1$, and the proposition is proved.

PROPOSITION 5.4. *If $(f,\mathbf{Q})$ is a critical point and there exists $\delta_0 > 0$ such that $f^2 - |\mathbf{Q}|^2 - \frac{1}{3} > \delta_0$, then $(f,\mathbf{Q})$ is a local minimizer of $\mathcal{E}_\kappa$ (for finite or infinite κ).*

Proof of Proposition 5.4. This follows immediately from Lemma 3.3.

COROLLARY 5.5. *For $\kappa = +\infty$, if $(\mathbf{Q}_\infty)^2 < \frac{1}{3} - \delta_0$ and $f_\infty > 0$, then every critical point $(f_\infty, \mathbf{Q}_\infty)$ is a local minimizer of $\mathcal{E}_\infty$.*

PROPOSITION 5.6. *For $\kappa = +\infty$, if $(f,\mathbf{Q}) \in V$ is a critical point of $\mathcal{E}_\infty$ such that*

$$\exists x_0 \in \Omega,\ |\mathbf{Q}(x_0)|^2 > \frac{1}{3} \text{ and } f(x_0) > 0$$

and $(f,\mathbf{Q})$ is continuous at $x_0 \in \Omega$, then $(f,\mathbf{Q})$ is not a local minimizer of $\mathcal{E}_\infty$.

Proof of Proposition 5.6. Let us first consider the general case $\kappa \in (0,+\infty]$. Without loss of generality we take x_0 to be the origin, and we choose the coordinates (x,y) in $\mathbb{R}^2$ such that $\mathbf{Q}(0) = |\mathbf{Q}(0)|e_x$. We consider the following function:

$$\phi(x,y) = \chi(y)\cos(\alpha x)1_{\{\alpha x \in [-\frac{\pi}{2},\frac{\pi}{2}]\}},$$

where for $\lambda, \mu > 0$,

$$\chi(y) = \begin{cases} 0 \text{ if } |y| > \frac{\lambda+\mu}{\alpha}, \\ 1 \text{ if } |y| \leq \frac{\lambda}{\alpha}, \\ \text{continuous and linear on } [-\frac{\lambda+\mu}{\alpha}, -\frac{\lambda}{\alpha}] \cup [\frac{\lambda}{\alpha}, \frac{\lambda+\mu}{\alpha}]. \end{cases}$$

Consider

$$\begin{cases} \overline{\mathbf{Q}} = \nabla\phi, \\ \overline{f} = -\Lambda\partial_x\phi. \end{cases}$$

Then

$$\mathcal{E}_\kappa(f + t\overline{f}, \mathbf{Q} + t\overline{\mathbf{Q}}) = \mathcal{E}_\kappa(f,\mathbf{Q}) + t\mathcal{E}'_\kappa(f,\mathbf{Q})\cdot(\overline{f},\overline{\mathbf{Q}}) + \frac{t^2}{2}\mathcal{E}''_\kappa(f,\mathbf{Q})\cdot(\overline{f},\overline{\mathbf{Q}})^2 + O(t^3).$$

Suppose that $(f,\mathbf{Q})$ is a local minimizer. Then $\mathcal{E}'_\kappa(f,\mathbf{Q})\cdot(\overline{f},\overline{\mathbf{Q}}) = 0$, and it remains only to examine the sign of the quantity

$$\begin{aligned} J \quad &= \tfrac{1}{2}\mathcal{E}''_\kappa(f,\mathbf{Q})\cdot(\overline{f},\overline{\mathbf{Q}})^2 \\ &= \int_\Omega \tfrac{2}{\kappa^2}|\nabla\overline{f}|^2 + 2|\ \mathbf{curl}\ \overline{\mathbf{Q}}|^2 + (f\overline{\mathbf{Q}} + 2\overline{f}\mathbf{Q})^2 + 3\overline{f}^2(f^2 - |\mathbf{Q}|^2 - \tfrac{1}{3}) \\ &= \int_\Omega \tfrac{2\Lambda^2}{\kappa^2}|\nabla\partial_x\phi|^2 - 3\Lambda^2(\partial_x\phi)^2(\tfrac{1}{3} - f^2 + |\mathbf{Q}|^2) \\ &+(\partial_x\phi)^2(f - 2\Lambda\mathbf{Q}_1)^2 + (f\partial_y\phi - 2\Lambda\mathbf{Q}_2\partial_x\phi)^2. \end{aligned}$$

Now, if we choose

$$\Lambda = \frac{f(0)}{2|\mathbf{Q}_1(0)|},$$

let $\omega = \operatorname{supp}\,\phi$, $\delta = \inf_\omega(\frac{1}{3} - f^2 + |\mathbf{Q}|^2)$, and $R = \sup_\omega(|\mathbf{Q_2}|\Lambda, |f - 2\Lambda\mathbf{Q}_1|)$, we find (using the fact that $0 \leq f \leq 1$)

$$J \leq \frac{2\Lambda^2}{\kappa^2}|\nabla\partial_x\phi|^2_{L^2} + 2|\partial_y\phi|^2_{L^2} - |\partial_x\phi|^2_{L^2}\{3\Lambda^2\delta - C'R^2\}.$$

Moreover

$$\begin{aligned} |\partial_x\phi|^2_{L^2} &= \pi\left(\lambda + \frac{\mu}{3}\right), \\ |\partial_y\phi|^2_{L^2} &= \frac{\pi}{\mu}, \\ |\nabla\partial_x\phi|^2_{L^2} &= \alpha^2(|\partial_x\phi|^2_{L^2} + |\partial_y\phi|^2_{L^2}) = \alpha^2\pi\left(\lambda + \frac{\mu}{3} + \frac{1}{\mu}\right). \end{aligned}$$

Then if we take $\lambda = 1$, $\mu = \sqrt{\alpha}$, then $|\partial_y\phi|_{L^2} \to 0$, $|\partial_x\phi|_{L^2} \to +\infty$ and $R \to 0$ as $\alpha \to +\infty$, and in particular for $\kappa = +\infty$ we find $\delta > 0$ (because $f^2 + |\mathbf{Q}|^2 = 1$). Then we obtain $J < 0$ which gives a contradiction. Consequently $(f, \mathbf{Q})$ is not a local minimizer, and Proposition 5.6 is proved.

Remark 5.7.

Large but finite $\boldsymbol{\kappa}$. For large but finite κ we can see heuristically the condition for $(f, \mathbf{Q})$ not to be a local minimizer should be

$$\left|(f^2 - |\mathbf{Q}|^2 - \frac{1}{3})^-\right|_{L^2(\omega)} \geq O\left(\frac{1}{\kappa}\right). \tag{5.2}$$

The argument goes as follows. We first remark that for finite κ if $(f, \mathbf{Q}) \in V$ is a local minimizer with $f \not\equiv 0$ and $\mathbf{Q} \not\equiv 0$, then $(f, \mathbf{Q})$ is analytic, and then if $f(x_0) = 0$ or $\mathbf{Q}(x_0) = 0$, we can chose another point x_0 arbitrarily closed to the first one such that $f(x_0) \neq 0$ and $\mathbf{Q}(x_0) \neq 0$.

Then, in the previous calculation let $L = |(f, \mathbf{Q})|_{C^1(\omega)}$ and $r^2 = (\frac{\pi}{2\alpha})^2 + (\frac{\lambda+\mu}{\alpha})^2$. Then $R^2 \leq CL^2r^2(1 + \Lambda^2)$. Then, for $\lambda = 1$ we obtain

$$\frac{J}{\pi} \leq \frac{2\Lambda^2}{\kappa^2}\alpha^2\left(1 + \frac{\mu}{3} + \frac{1}{\mu}\right) + \frac{2}{\mu} - \left(1 + \frac{\mu}{3}\right)\left\{3\Lambda^2\delta - C''\frac{L^2}{\alpha^2}(1 + \mu^2)(1 + \Lambda^2)\right\}.$$

Heuristically, if $\delta \simeq 0$, then (for κ large enough) $\Lambda \simeq \Lambda_\infty = f_\infty/(2|\mathbf{Q}_\infty|) = 1/\sqrt{2}$ (since $f^2_\infty + \mathbf{Q}^2_\infty = 1$). Then $\Lambda^2\delta \leq 1$. Let us choose $\mu = O(1/\delta)$, $\alpha = O(\kappa\sqrt{\delta})$, and $\kappa \geq L/\delta^{\frac{5}{2}}$. Then $J < 0$, so that $(f, \mathbf{Q})$ is not a local minimizer (and (5.2) is satisfied).

5.3. On the critical field at $\boldsymbol{\kappa = +\infty}$. We consider here the field H_0^* at which (for $\kappa = +\infty$) the solution $|\boldsymbol{Q}_\infty|$ first reaches $1/\sqrt{3}$. In one dimension there is an explicit solution for the infinite-κ Ginzburg–Landau equations on a halfspace $]-\infty, a]$ (see [3]), namely $H(x) = -\sqrt{2}\sinh x/\cosh^2 x$, $H(a) = H_0$, and $H' = (1-Q^2)Q$. Then $Q(a) = 1/\sqrt{3}$ when $H_0 = \sqrt{5/18} = H_0^*$, and $Q(a) = 1$ when $H_0 = 1/\sqrt{2}$. For more general domains, we have the following comparison theorem.

Proposition 5.8. *For $1/R \in \mathbb{R}$ let $B_R = \{|x| < R\}$ if $R > 0$, $B_\infty = \{(x_1, x_2), x_1 > 0\}$ if $1/R = 0$, $B_R = \{|x| > |R|\}$ if $R < 0$. Let $K_+ = \max_{x \in \partial\Omega} curv(x)$ (with $K_+ > 0$ for a disk), $K_- = \min_{x \in \partial\Omega} curv(x)$. Then*

$$H_0^*\left(B_{\frac{1}{K_-}}\right) \leq H_0^*(\Omega) \leq H_0^*\left(B_{\frac{1}{K_+}}\right).$$

In particular if Ω is convex then $H_0^*(\Omega) \geq \sqrt{5/18}$.

Proof of Proposition 5.8. This is straightforward using sub- and supersolutions.

6. Conclusion.

We have been concerned with the Meissner solution of the Ginzburg–Landau model, that is, the superconducting solution for which there are no vortices and the modulus of the order parameter is strictly positive. We have demonstrated the existence of this solution for values of the applied field H_0 less than a critical value H_0^*, and (under an additional convexity assumption) its uniqueness. We have shown that in the limit as the Ginzburg–Landau parameter $\kappa \to \infty$ the Meissner solution approaches the solution of the limiting problem formulated in [3, 1], which is a local minimizer of the limiting Ginzburg–Landau energy $\mathcal{E}_\infty$. Moreover, we have shown that the Meissner solution is only a local minimizer of the Ginzburg–Landau energy $\mathcal{E}_\kappa$, and not a global minimizer, for large enough κ.

The minimizing sequence we constructed for the energy $\mathcal{E}_\infty$ corresponds to filling the material with vortex sheets, and is in some sense comparable to the solution of the vortex density model in [5] in which the domain contains a uniform vortex density equal to the applied magnetic field. Indeed, since

$$\boldsymbol{Q} \sim \frac{1}{r}\boldsymbol{e}_\theta$$

at a vortex, a vortex may be thought of as generating a δ-function in curl $\boldsymbol{Q}$, and thus a natural way to define the Ginzburg–Landau energy for $\kappa = +\infty$ in the presence of vortices is

$$\mathcal{E}_\infty(f, \mathbf{Q}) = \int_\Omega |\text{curl } \mathbf{Q} + \omega - H_0|^2 + G(f, \mathbf{Q}),$$

where ω is the vortex density. In this case the minimizer is clearly $\boldsymbol{Q} \equiv \mathbf{0}$, $f \equiv 1$, $\omega \equiv H_0$. It is interesting that this solution is somehow found by the minimizing sequence, even when the details of the vortex cores have been ignored completely.

GENERIC HOPF BIFURCATION FROM LINES OF EQUILIBRIA WITHOUT PARAMETERS: II. SYSTEMS OF VISCOUS HYPERBOLIC BALANCE LAWS*

BERNOLD FIEDLER† AND STEFAN LIEBSCHER†

Abstract. We investigate viscous shock profiles of the Riemann problem for systems of hyperbolic balance laws. Even strictly hyperbolic flux terms together with a nonoscillating kinetic part can lead to oscillating viscous shock profiles. They appear near a Hopf-like bifurcation point of the traveling wave equation.

Key words. viscous profiles, oscillating viscous shocks, Riemann problem, hyperbolic balance laws

1. Introduction.

Searching for viscous shock profiles of the Riemann problem, we consider systems of hyperbolic balance laws of the form

$$u_t + f(u)_x = \epsilon^{-1} g(u) + \epsilon\delta u_{xx}, \tag{1.1}$$

with $u = (u_0, u_1, \ldots, u_N) \in \mathbb{R}^{N+1}, f \in C^3, g \in C^2, \delta > 0$, and with real time t and space x. We assume strict hyperbolicity, that is, the Jacobian $A(u) = f'(u)$ possesses simple real distinct eigenvalues

$$\sigma_0, \sigma_1, \ldots, \sigma_N \in \text{spec } A(u) \tag{1.2}$$

The case of conservation laws, $g \equiv 0$, has been studied extensively. See, for example, [8] for a background. Viscous profiles are traveling wave solutions of the form

$$u = u\left(\frac{x - st}{\epsilon}\right) \tag{1.3}$$

with wave speed s. Here (1.3) provides a solution of (1.1) if

$$-s\dot{u} + A(u)\dot{u} = g(u) + \delta\ddot{u}. \tag{1.4}$$

Here $A(u) = f'(u)$ denotes the Jacobian and $\dot{} = \frac{d}{d\tau}$ with $\tau = (x - st)/\epsilon$. Note that (1.4) is independent of $\epsilon > 0$. Any solution of system (1.4) for which

$$\lim_{\tau \to \pm\infty} u(\tau) = u^{\pm} \tag{1.5}$$

exists gives rise, for $\epsilon \searrow 0$, to a solution of the Riemann problem of (1.1) with values $u = u^{\pm}$ connected by a shock traveling with shock speed s. We call solutions $u(\cdot)$ of (1.4), (1.5) *viscous profiles.*

†Institut für Mathematik I, Freie Universität Berlin, Arnimallee 2-6, 14195 Berlin, Germany (fiedler@math.fu-berlin.de, liebsch@math.fu-berlin.de).

We rewrite the viscous profile equation (1.4) as a second order system

$$\begin{aligned} \dot{u} &= v, \\ \delta\dot{v} &= -g(u) + (A(u) - s)v. \end{aligned} \tag{1.6}$$

Note that any viscous profile must satisfy

$$g(u^{\pm}) \;=\; 0. \tag{1.7}$$

In other words, the asymptotic states $u^{\pm}$ must be equilibria of the reaction term $g(u)$. In the conservation law case, $g \equiv 0$, this condition does not impose any constraint on the Riemann values $u^{\pm}$. In the other extreme of a reaction term g with unique equilibrium, we obtain $u^{+} = u^{-}$ and traveling shock profiles of Riemann type do not exist. In the case of one conservation law mixed with N balance laws, one expects curves of equilibria $g(u^{\pm}) = 0$. For example, reaction terms $g(u)$ typically depend on concentrations or temperature, but not on velocity.

Addressing a simple case, for demonstration purposes, we therefore assume that the u_0-component does not contribute to the reaction terms and still all that reaction components vanish, say at $u = 0$. Specifically, we assume throughout this paper that

$$g = g(u_1, \ldots, u_N) = \begin{pmatrix} g_0 \\ g_1 \\ \vdots \\ g_N \end{pmatrix} \tag{1.8}$$

is independent of u_0 and satisfies

$$g(0) = 0. \tag{1.9}$$

This gives rise to a line of equilibria

$$u_0 \in \mathbb{R}, \quad u_1 = \cdots = u_N = 0, \quad v = 0 \tag{1.10}$$

of our viscous profile system (1.6).

The asymptotic behavior of viscous profiles $u(\tau)$ for $\tau \to \pm\infty$ depends on the linearization L of (1.6) at $u = u_{\pm}$, $v = 0$. In block matrix notation corresponding to coordinates (u, v) we have

$$L = \begin{pmatrix} 0 & \mathrm{id} \\ -\delta^{-1} g' & \delta^{-1}(A - s). \end{pmatrix} \tag{1.11}$$

Here $A = A(u)$, and $g' = g'(u)$ describes the Jacobi matrix of the reaction term g at $u = u^{\pm}$. In (1.11) we write s rather than $s \cdot \mathrm{id}$ for brevity. In the case $g \equiv 0$ of pure conservation laws, the linearization L possesses an $(N+1)$-dimensional kernel corresponding to the then arbitrary choice of the equilibrium $u \in \mathbb{R}^{N+1}$, $v = 0$. Normal hyperbolicity of this family of equilibria, in the sense of dynamical systems [5], [2], [9], is ensured for wave speeds s not in the spectrum of the strictly hyperbolic Jacobian $A(u)$:

$$s \notin \mathrm{spec}\; A(u) = \{\sigma_0, \ldots, \sigma_N\}. \tag{1.12}$$

Indeed, (1.12) ensures that additional zeros do not arise in the real spectrum

$$\mathrm{spec}\; L = \{0\} \cup \delta^{-1}\,\mathrm{spec}\,(A(u) - s). \tag{1.13}$$

In the present paper we investigate the failure of normal hyperbolicity of L along the line of equilibria $u = (u_0, 0, \ldots, 0), v = 0$, given by (1.10). Although our method applies in complete generality, we present just a simple specific example for which purely imaginary eigenvalues of L arise when $\delta > 0$ is fixed small enough. Specifically, we consider three-dimensional systems, $N = 2$, satisfying

$$\begin{aligned} A(u_0,0,0) &= A_0 + u_0 \cdot A_1, \\ A_0 &= \begin{pmatrix} \alpha & & \\ & 1 & \\ & & -1 \end{pmatrix}, \quad \alpha \neq 0, \quad A_1 \text{ symmetric}, \\ g'(0) &= \begin{pmatrix} 0 & & \\ & \gamma & 1 \\ & 1 & \gamma \end{pmatrix}, \quad |\gamma| < 1, \end{aligned} \tag{1.14}$$

with omitted entries being zero. Note that these data can arise from flux functions f which are gradient vector fields, still giving rise to purely imaginary eigenvalues. At the end of this paper we present a specific example where the reaction terms $\dot{u} = g(u)$ *alone*, likewise, do not support even transient oscillatory behavior; see (3.12). The interaction of flux and reaction, in contrast, is able to produce purely imaginary eigenvalues of the linearization L, as follows.

PROPOSITION 1.1. *Consider the linearization $L = L(u_0)$ along the line $u_0 \in \mathbb{R}, u_1 = u_2 = 0$ of equilibria of the viscous profile system* (1.6) *in $\mathbb{R}^3$; see* (1.11). *Assume* (1.14) *holds.*

For $\delta \searrow 0$ and small $|s|, |u_0|$, the spectrum of L then decouples into two parts:

(i) *an unboundedly growing part* $\operatorname{spec}_\infty(L) = \delta^{-1}\operatorname{spec}(A - s) + O(1)$,

(ii) *a bounded part* $\operatorname{spec}_{bd}(L) = \operatorname{spec}((A-s)^{-1}g') + O(\delta)$.

Here A, g are evaluated at $u = (u_0, 0, 0)$.

For $\delta = 0, s = 0, |\gamma| < 1$, the bounded part $\operatorname{spec}_{bd}(L)$ *at $u_0 = 0$ limits onto simple eigenvalues $\mu_0 \in \{0, \pm i\omega_0\}$, $\omega_0 = \sqrt{1-\gamma^2}$ with eigenvectors $\left(\begin{smallmatrix} \tilde{u} \\ \tilde{v} \end{smallmatrix}\right)$ given by $\tilde{v} = \mu_0\tilde{u}$ and*

$$\begin{aligned} \tilde{u} &= \begin{pmatrix} 1 \\ 0 \\ 0 \end{pmatrix} \qquad \textit{for } \mu_0 = 0, \\ \tilde{u} &= \begin{pmatrix} 0 \\ -\gamma - i\omega_0 \\ 1 \end{pmatrix} \qquad \textit{for } \mu_0 = +i\omega_0. \end{aligned} \tag{1.15}$$

Proof. Regular perturbation theory applies to the scaled block matrix

$$\delta L = \begin{pmatrix} 0 & 0 \\ -g' & A - s \end{pmatrix} + \delta \begin{pmatrix} 0 & \mathrm{id} \\ 0 & 0 \end{pmatrix}, \tag{1.16}$$

which becomes lower triangular for $\delta = 0$. This provides us with the unbounded part $\operatorname{spec}_\infty(L)$ of the spectrum, generated in v-space alone with $u = 0$.

Moreover, δL possesses three-dimensional kernel, at $\delta = 0$, given by

$$g'u = (A - s)v. \tag{1.17}$$

On this kernel, the eigenvalue problem for L reduces to

$$\mu_0 u \;=\; v \;=\; (A-s)^{-1} g' u. \tag{1.18}$$

The characteristic polynomial of (1.18) at $u_0 = 0$ is given by

$$p_0(\mu) = \left(\mu^2 - \frac{2\gamma s}{1-s^2}\mu + \frac{1-\gamma^2}{1-s^2}\right)\mu. \tag{1.19}$$

Direct calculation completes the proof. □

Note that our choices of A_0 and $g'(0)$ are normalized, such that the bifurcation occurs at a shock speed $s = 0$. For more general systems the Hopf point may occur at nonzero values of the shock speed parameter.

For explicit calculations here and below, we have used and recommend assistance by symbolic packages like Mathematica, Maple, etc.

Bifurcations from lines of equilibria in absence of parameters have been investigated in [6], [3] from a theoretical view point. We briefly recall that result for convenience. Consider C^5 vector fields

$$\dot{\mathbf{u}} = F(\mathbf{u}) \tag{1.20}$$

with $\mathbf{u} = (u_0, u_1, \ldots, u_n) \in \mathbb{R}^{n+1}$. We assume a line of equilibria

$$0 = F(u_0, 0, \ldots, 0) \tag{1.21}$$

along the u_0-axis. At $u_0 = 0$, we assume the Jacobi matrix $F'(u_0, 0, \ldots, 0)$ to be hyperbolic, except for a trivial kernel vector along the u_0-axis and a complex conjugate pair of simple, purely imaginary, nonzero eigenvalues $\mu(u_0), \overline{\mu(u_0)}$ crossing the imaginary axis transversely as u_0 increases through $u_0 = 0$:

$$\begin{aligned} \mu(0) &= i\omega(0), \quad \omega(0) > 0, \\ \operatorname{Re}\mu'(0) &\neq 0. \end{aligned} \tag{1.22}$$

Let Z be the two-dimensional real eigenspace of $F'(0)$ associated to $\pm i\omega(0)$. By Δ_Z we denote the Laplacian with respect to variations of u in the eigenspace Z. Coordinates in Z are chosen as coefficients of the real and imaginary parts of the complex eigenvector associated to $i\omega(0)$. Note that the linearization acts as a rotation with respect to these not necessarily orthogonal coordinates. Let P_0 be the one-dimensional eigenprojection onto the trivial kernel along the u_0-axis. Our final nondegeneracy assumption then reads

$$\Delta_Z P_0 F(0) \neq 0. \tag{1.23}$$

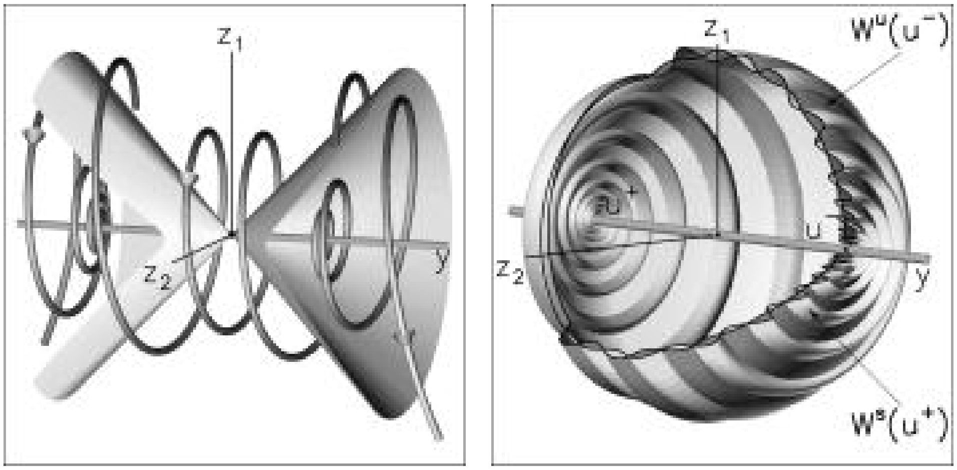
Fixing orientation along the positive u_0-axis, we can consider $\Delta_Z P_0 F(0)$ as a real number. Depending on the sign

$$\eta := \operatorname{sign}\,(\operatorname{Re}\mu'(0)) \;\cdot\; \operatorname{sign}\,(\Delta_Z P_0 F(0)), \tag{1.24}$$

we call the "bifurcation" point $u_0 = 0$ *elliptic* if $\eta = -1$ and *hyperbolic* for $\eta = +1$.

The following result from [3] investigates the qualitative behavior of solutions in a normally hyperbolic three-dimensional center manifold to $\mathbf{u} = 0$.

The results for the hyperbolic case $\eta = +1$ are based on normal form theory and a spherical blow-up construction inside the center manifold. The elliptic case $\eta = -1$



Case (a): hyperbolic, $\eta = +1$. Case (b): elliptic, $\eta = -1$.

FIG. 1.1. *Dynamics near Hopf bifurcation from lines of equilibria.*

is based on Neishtadt's theorem on exponential elimination of rapidly rotating phases [7]. For a related application to binary oscillators in discretized systems of hyperbolic balance laws see [4]. For an application to square rings of additively coupled oscillators see [1].

THEOREM 1.2. *Let assumptions* (1.21)–(1.23) *hold for the* C^5 *vector field* $\dot{\mathbf{u}} = F(\mathbf{u})$. *Then the following holds true in a neighborhood* U *of* $\mathbf{u} = 0$ *within a three-dimensional center manifold to* $\mathbf{u} = 0$.

In the hyperbolic case, $\eta = +1$, *all nonequilibrium trajectories leave the neighborhood* U *in positive or negative time direction (possibly both). The stable and unstable sets of* $\mathbf{u} = 0$, *respectively, form cones around the positive/negative* u_0-*axis, with asymptotically elliptic cross section near their tips at* $\mathbf{u} = 0$. *These cones separate regions with different convergence behavior. See Figure* 1.1 (a).

In the elliptic case all nonequilibrium trajectories starting in U *are heteroclinic between equilibria* $\mathbf{u}^{\pm} = (u_0^{\pm}, 0, \ldots, 0)$ *on opposite sides of* $u_0 = 0$. *If* $F(\mathbf{u})$ *is real analytic near* $\mathbf{u} = 0$, *then the two-dimensional strong stable and strong unstable manifolds of* $\mathbf{u}^{\pm}$ *within the center manifold intersect at an angle which possesses an exponentially small upper bound in terms of* $|\mathbf{u}^{\pm}|$. *See Figure* 1.1 (b).

In the present paper, we apply Theorem 1.2 to the problem of zero speed viscous profiles of systems of hyperbolic balance laws near Hopf points as in Proposition 1.1. Nonzero shock speeds can be treated completely analogously, absorbing them into the flux term.

THEOREM 1.3. *Consider the problem* (1.5)–(1.7) *of finding viscous profiles with shock speed* $s = 0$ *to hyperbolic balance laws* (1.1). *Let assumptions* (1.8)–(1.10), (1.14) *hold, so that a pair of purely imaginary simple eigenvalues occurs for the linearization* L, *in the limit* $\delta \to 0$.

Then there exist nonlinearities $A(u) = f'(u)$ *and* $g(u)$, *compatible with the above assumptions, such that the assumptions and conclusions of Theorem* 1.2 *are valid for the viscous profile system* (1.6). *Both the elliptic and the hyperbolic cases occur; see Figure* 1.1.

Since both conditions are open, the results persist, in particular, for small nonzero shock speeds s, *even when* f, g *remain fixed.*

Specific choices of flux $f(u)$ and reaction terms $g(u)$ are presented in Corollary 3.3; see (3.12). In the elliptic case $\eta = -1$, we nevertheless observe (at least) pairs of weak shocks with oscillatory tails, connecting u_- and u_+. In the hyperbolic case $\eta = +1$, viscous profiles leave the neighborhood U and thus represent large shocks. At $u_0 = 0$, their profiles change discontinuously and the role of the u_0-axis switches from providing the left to providing the right asymptotic state with oscillatory tail.

This paper is organized as follows. In section 2 we check transversality condition (1.22) for the purely imaginary eigenvalues. We also compute an expansion in terms of δ for the eigenprojection P_0 onto the trivial kernel along the u_0-axis. In section 3, we check nondegeneracy condition (1.23) for $\Delta_Z P_0 F(0)$, in the limit $\delta \searrow 0$, completing the proof of Theorem 1.3 by reduction to Theorem 1.2.

2. Linearization and transverse eigenvalue crossing. In this section we continue our analysis of the linearization

$$L^\delta(u_0) = \begin{pmatrix} 0 & \mathrm{id} \\ -\delta^{-1} g' & \delta^{-1} A \end{pmatrix}, \tag{2.1}$$

with $A = A(u)$, $g' = g'(u)$ evaluated along the line of equilibria $u = (u_0, 0, 0)$. See (1.11) with $s = 0$ and Proposition 1.1. In the limit $\delta \searrow 0$, we address the issue of transverse crossing of purely imaginary eigenvalues in Lemma 2.1. In Lemma 2.2, we explicitly compute the one-dimensional eigenprojection P_0^δ onto the trivial kernel of $L^\delta(0)$.

Throughout this section we fix the notation

$$A(u_0, 0, 0) = A_0 + u_0 A_1 = \begin{pmatrix} \alpha & & \\ & 1 & \\ & & -1 \end{pmatrix} + u_0 \cdot (a^1_{jk})_{0 \le j,k \le 2}, \tag{2.2}$$

with $a^1_{jk} = a^1_{kj}$ symmetric; see (1.14). We also assume that the linearized reaction term

$$g'(u_0, 0, 0) = g'(0) = \begin{pmatrix} 0 & & \\ & \gamma & 1 \\ & 1 & \gamma \end{pmatrix}, \qquad |\gamma| < 1, \tag{2.3}$$

which is independent of u_0 by assumption (1.8), possesses a vanishing g_0-component.

By Proposition 1.1, purely imaginary eigenvalues of $L^\delta(u_0)$ arise from an $O(\delta)$ perturbation of the matrix

$$A^{-1} g' = (A_0 + u_0 A_1)^{-1} g'(0) \tag{2.4}$$

with spectrum $\mathrm{spec}_{bd}(L)$. Let

$$\mu(u_0), \quad \bar\mu(u_0) \tag{2.5}$$

denote the continuation of the simple, purely imaginary eigenvalues

$$\mu(0) = i\omega_0, \quad \bar\mu(0) = -i\omega_0$$

with u_0-derivatives $\mu'(u_0), \bar\mu'(u_0)$.

Lemma 2.1. *In the above setting and notation,*

$$\mathrm{Re}\, \mu'(0) = -\frac{\gamma}{2}(a^1_{11} + a^1_{22}) + a^1_{12}. \tag{2.6}$$

Proof. Since the unit vector e_0 in u_0-direction is a trivial kernel vector of $g'(0)$ and since the remaining eigenvalues of $A^{-1}g'$ remain conjugate complex for small $|u_0|$, we have

$$\text{Re}\ \mu(u_0) = \frac{1}{2}\ \text{trace}\ (A^{-1}g'). \tag{2.7}$$

In particular, trace $A_0^{-1}g' = 0$. With the u_0-expansion

$$A^{-1} = (A_0 + u_0A_1)^{-1} = A_0^{-1} - u_0A_0^{-1}A_1A_0^{-1} + \cdots \tag{2.8}$$

we immediately obtain

$$\text{Re}\ \mu'(u_0) = -\frac{1}{2}\ \text{trace}\,(A_0^{-1}A_1A_0^{-1}g'). \tag{2.9}$$

Inserting A_0, A_1, g' proves the lemma. □

By regular perturbation of $\text{spec}_{bd}\,(L)$, the result $\text{Re}\ \mu'(0) \neq 0$ of Lemma 2.1 extends to small positive δ.

We now turn to an expansion for the eigenprojection P_0^δ onto the one-dimensional kernel of the 6×6-matrix $L^\delta(u_0)$ at $u_0 = 0$; see (2.1)–(2.3). Aligning the notations of Proposition 1.1 and of Theorem 1.2, we decompose

$$\mathbf{u} = (u, v) \in \mathbb{R}^6 = \mathbb{R}^3 \times \mathbb{R}^3.$$

Again, $e_0^T = (1, 0, 0)$ denotes the first unit vector in $\mathbb{R}^3$ and $\mathbf{e}_0^T = (e_0^T, 0)$ the first unit vector in $\mathbb{R}^6$.

Lemma 2.2. *In the above setting and notation*

$$\begin{aligned} P_0^\delta &= \mathbf{e}_0 \cdot \mathbf{e}_\delta^T, \qquad \textit{with} \\ \mathbf{e}_\delta^T &= (1 + (\tfrac{\delta}{\alpha})^2)^{-1/2}(e_0^T, -\tfrac{\delta}{\alpha}e_0^T). \end{aligned} \tag{2.10}$$

Proof. Kernel and cokernel of $L^\delta(u_0)$ are one-dimensional, corresponding to the simple zero eigenvalue of $L^\delta(u_0)$. Obviously

$$\ker L^\delta(u_0) = \mathbf{e}_0, \tag{2.11}$$

because $g'(u_0, 0, 0)e_0 = 0$. At $u_0 = 0$, the cokernel of $L^\delta(u_0)$ is given by

$$0 = \mathbf{e}_\delta^T \cdot \begin{pmatrix} 0 & \text{id} \\ -\delta^{-1}g' & \delta^{-1}A_0 \end{pmatrix}. \tag{2.12}$$

Inserting A_0 from (2.2) and g' from (2.3) proves the lemma. □

3. Higher order nondegeneracy. In this section we complete the proof of Theorem 1.3. In view of Theorem 1.2, we have already checked transverse crossing of purely imaginary eigenvalues, assumption (1.22), in Lemma 2.1. Letting

$$F(\mathbf{u}) = F(u, v) = \begin{pmatrix} v \\ -\delta^{-1}g(u) + \delta^{-1}A(u)v \end{pmatrix} \tag{3.1}$$

it remains to check the nondegeneracy assumption $\Delta_Z P_0 F \neq 0$; see (1.23). In Lemma 3.1, we check this assumption in the limit $\delta \searrow 0$. In Corollary 3.2, we provide explicit expressions for the type determining sign $\eta = \pm 1$ defined in (1.24). In particular, we show in Corollary 3.3 that both the hyperbolic case $\eta = +1$ and the elliptic case $\eta = -1$ can be realized by our nonlinear hyperbolic balance laws, even with gradient flux terms. This then completes the proof of Theorem 1.3.

To check nondegeneracy condition (1.23) on $\Delta_Z P_0 F$ in the limit $\delta \searrow 0$, we use the following notation. By transverse eigenvalue crossing at $\delta = 0$, Lemma 2.1, we also obtain purely imaginary eigenvalues $\pm i\omega^\delta$ at equilibria $\mathbf{u}^\delta = (u_0^\delta, 0, \ldots, 0) = (u^\delta, 0)$ on the u_0-axis, for small $\delta > 0$. Let Z^δ denote the corresponding eigenspace. We recall our expression for the eigenprojection P_0^δ onto the trivial kernel,

$$P_0^\delta = (1 + (\tfrac{\delta}{\alpha})^2)^{-1/2}\, \mathbf{e}_0 \cdot (e_0^T, -\tfrac{\delta}{\alpha} e_0^T) \tag{3.2}$$

with $\mathbf{e}_0 = (e_0^T, 0)^T$, see Lemma 2.2. Note that $\mathbf{u}^\delta, \omega^\delta, P_0^\delta$, and Z^δ vary differentiably with δ.

Lemma 3.1. *In the above setting and notation we have*

$$\Delta_{Z^\delta} P_0^\delta F(\mathbf{u}^\delta) = (1 + (\tfrac{\delta}{\alpha})^2)^{-1/2}\, \frac{1}{\alpha} g_0''(u^\delta)[\tilde{u}^\delta, \bar{\tilde{u}}^\delta]\, \mathbf{e}_0 \tag{3.3}$$

at the Hopf point $\mathbf{u}^\delta = (u^\delta, 0)$ with complex eigenvector $(\tilde{u}^\delta, \tilde{v}^\delta)$ of $i\omega^\delta$.

Consider, in particular, quadratic forms $g_0''(0)$, which are strictly positive/negative definite on (u_1, u_2)-space, with $\Gamma = \pm 1$ indicating the sign of definiteness. Then

$$\operatorname{sign} \Delta_{Z^\delta} P_0^\delta F(\mathbf{u}^\delta) = \Gamma \cdot \operatorname{sign} \alpha \tag{3.4}$$

for all small $\delta > 0$.

Proof. By Lemma 2.2 we have

$$(1 + (\tfrac{\delta}{\alpha})^2)^{1/2} P_0^\delta = \mathbf{e}_0 \cdot \mathbf{e}_0^T - \tfrac{\delta}{\alpha} \mathbf{e}_0 \cdot (0, e_0^T). \tag{3.5}$$

The explicit form (3.1) of the nonlinearity F implies

$$\Delta_{Z^\delta} P_0^0 F(\mathbf{u}^\delta) = \mathbf{e}_0 \Delta_{Z^\delta} v_0 = 0 \tag{3.6}$$

on any subspace Z^δ and for any $\mathbf{u}^\delta$, simply because the u-component of F is linear. With P_0^δ instead of P_0^0 we obtain more generally

$$\begin{aligned} (1 + (\tfrac{\delta}{\alpha})^2)^{1/2} \mathbf{e}_0^T \Delta_{Z^\delta} P_0^\delta F(\mathbf{u}) &= -\Delta_{Z^\delta} \left(0, -\tfrac{\delta}{\alpha} e_0^T \delta^{-1}(-g(u) + A(u)v)\right) \\ &= -\tfrac{1}{\alpha} \Delta_{Z^\delta} \left(-g_0(u) + (A(u)v)_0\right). \end{aligned} \tag{3.7}$$

Here $(A(u)v)_0$ denotes the zero-component of $A(u)v$. We treat this term first, using the notation

$$\tilde{\mathbf{u}}^\delta = \begin{pmatrix} \tilde{u}^\delta \\ \tilde{v}^\delta \end{pmatrix} \tag{3.8}$$

for the complex eigenvector of the purely imaginary Hopf eigenvalue $\mu^\delta = i\omega^\delta$ at $u = u^\delta, v = 0$. Then $Z^\delta = \operatorname{span}\{\mathrm{Re}\, \tilde{\mathbf{u}}^\delta, \mathrm{Im}\, \tilde{\mathbf{u}}^\delta\}$. Denoting by $\Delta_\beta = \partial_{\beta_1}^2 + \partial_{\beta_2}^2$ the standard Laplacian, evaluated at $\beta = 0$, and inserting $\tilde{v}^\delta = \mu^\delta \tilde{u}^\delta$ yields

$$\begin{aligned} \Delta_{Z^\delta}(A(u)v)_0 &= \Delta_\beta\big(A(u^\delta + \beta_1 \mathrm{Re}\, \tilde{u}^\delta + \beta_2 \mathrm{Im}\, \tilde{u}^\delta)\ \ (\beta_1\, \mathrm{Re}\, \tilde{v}^\delta + \beta_2 \mathrm{Im}\, \tilde{v}^\delta)\big)_0 \\ &= 2\left((A'(u^\delta)\mathrm{Re}\, \tilde{u}^\delta)\mathrm{Re}\, \tilde{v}^\delta + (A'(u^\delta)\mathrm{Im}\, \tilde{u}^\delta)\mathrm{Im}\, \tilde{v}^\delta\right)_0 \\ &= 2\, \mathrm{Re}\, \left((A'(u^\delta)\tilde{u}^\delta)\bar{\tilde{v}}^\delta\right)_0 \\ &= 2\, \mathrm{Re}\, (\bar{\mu}^\delta)\, \left(f''(u^\delta)[\tilde{u}^\delta, \bar{\tilde{u}}^\delta]\right)_0 \\ &= 2\, \mathrm{Re}\, (\mu^\delta)\, f_0''(u^\delta)[\tilde{u}^\delta, \bar{\tilde{u}}^\delta] = 0 \end{aligned} \tag{3.9}$$

all along the Hopf curve $u = u^\delta, v = 0$. Here we have used $A(u) = f'(u)$ for the flux function and the fact that the Hessian matrix $f_0^{''}(0)$ is symmetric.

Therefore, we can conclude from (3.7), (3.9) that

$$\left(1 + \left(\tfrac{\delta}{\alpha}\right)^2\right)^{1/2} \mathbf{e}_0^T \Delta_{Z^\delta} P_0^\delta F(\mathbf{u}^\delta) = \frac{1}{\alpha}\Delta_{Z^\delta} g_0(u) = \frac{1}{\alpha} g_0''(u^\delta)[\tilde{u}^\delta, \bar{\tilde{u}}^\delta]. \tag{3.10}$$

This proves (3.3) and the lemma. □

Corollary 3.2. *Combining Lemmas* 2.1 *and* 3.1*, the* sign $\eta = \pm 1$ *distinguishing elliptic from hyperbolic Hopf bifurcation along our line of equilibria is given explicitly by*

$$\begin{aligned} \eta = &\quad \text{sign Re } \mu'(0) \cdot \text{sign}\, \Delta_Z P_0 F(0) \\ = &\quad \text{sign}(a_{12}^1 - \tfrac{\gamma}{2}(a_{11}^1 + a_{22}^1)) \cdot \text{sign}\, \alpha \cdot \Gamma, \end{aligned} \tag{3.11}$$

for $\delta > 0$ small enough. Here derivatives are evaluated at $u = 0$ and are assumed to be chosen such that $\eta \neq 0$. The sign $\Gamma = \pm 1$ *indicates positive/negative definiteness of $g_0''(0)$ on (u_1, u_2)-space. Obviously, both signs of η can be realized.*

Corollary 3.3. *Theorems* 1.2, 1.3 *hold true for $\eta = \pm 1$ with the following specific choices of a gradient flux term $f(u) = \nabla\Phi(u)$ and a reaction term $g(u)$:*

$$\begin{aligned} g(u) &= \begin{pmatrix} u_1^2 & + & u_2^2 \\ -\frac{1}{2}u_1 & + & u_2 \\ u_1 & - & \frac{1}{2}u_2 \end{pmatrix}, \\ \Phi(u) &= u_0^2 + \tfrac{1}{2}(u_1^2 - u_2^2) + \eta u_0 u_1^2. \end{aligned} \tag{3.12}$$

These choices correspond to $\alpha = 2, \gamma = -\frac{1}{2}, \Gamma = +1$.

Acknowledgments. Helpful discussions with Bob Pego and Heinrich Freistühler concerning the set-up of viscous profiles for hyperbolic balance laws are gratefully acknowledged. This work was supported by the Deutsche Forschungsgemeinschaft, Schwerpunkt "Analysis und Numerik von Erhaltungsgleichungen," and was completed during a fruitful and enjoyable research visit of one of the authors at the Institute of Mathematics and Its Applications, University of Minnesota, Minneapolis, supported with funds provided by the National Science Foundation.
