&\fint_{B_{\theta^j\rho}(x_0)} |Du - \Upsilon_{x_0}|^2\,dx \le 2\Phi(x_0,\theta^j\rho) + 2|(Du)_{x_0,\theta^j\rho} - \Upsilon_{x_0}|^2\\
&\le 2\theta^{2\beta j}\Phi(x_0,\rho) + 2c_{13}(M_0)\omega(\theta^j\rho) + 2c_{15}^2\Big(\theta^{2\beta j}\Phi(x_0,\rho) + \Omega(\theta^j\rho)\Big)\\
&\le c_{16}\Big(\theta^{2\beta j}\Phi(x_0,\rho) + \Omega(\theta^j\rho)\Big).
\end{aligned}$$

For $0 < r \le \rho$ we can find $j \in \mathbb{N}\cup\{0\}$ with $\theta^{j+1}\rho < r \le \theta^j\rho$. For this j we have

$$\begin{aligned}
&\fint_{B_r(x_0)} |Du - \Upsilon_{x_0}|^2\,dx \le \theta^{-n}\fint_{B_{\theta^j\rho}(x_0)} |Du - \Upsilon_{x_0}|^2\,dx\\
&\le c_{16}\theta^{-n}\Big(\theta^{2j\beta}\Phi(x_0,\rho) + \Omega(\theta^j\rho)\Big)\\
&= c_{16}\theta^{-n}\left(\frac{\theta^{2(j+1)\beta}}{\theta^{2\beta}}\Phi(x_0,\rho) + \Omega\left(\frac{\theta^{j+1}\rho}{\theta}\right)\right)\\
&\le c_{16}\theta^{-n}\Big(\Big(\frac{r}{\rho}\Big)^{2\beta}\theta^{-2\beta}\Phi(x_0,\rho) + \theta^{-2\alpha}\Omega(\theta^{j+1}\rho)\Big)\\
&\le c_{16}\theta^{-n-2\beta}\Big(\Big(\frac{r}{\rho}\Big)^{2\beta}\Phi(x_0,\rho) + \Omega(r)\Big);
\end{aligned} \tag{5.24}$$

here we have used (2.3) to obtain the second to last inequality. This shows (5.23) with $c_{14} = c_{16}\theta^{-n-2\beta}$ (note that c_{14} has the correct dependencies). ∎

We are now in a position to complete the partial-regularity proof.

Proof of Theorem 2.2. We give the proof of (i); the proof of (ii) is completely analogous. We assume that for some $x_0 \in U$ and $M_0 > 0$ we have

$$|(Du)_{x_0,\rho}| < M_0 \quad\text{and}\quad \Phi(x_0,\rho) < \Phi_0(M_0)$$

on $B_\rho(x_0)$, where $B_{2\rho}(x_0) \subset\subset U$ with $0 < \rho \le \rho_0(M_0)$. Such a ρ can always be found for each x_0 belonging neither to Σ_1 nor to Σ_2. Since the functions $z \mapsto (Du)_{z,\rho}$ and $z \mapsto \Phi(z,\rho)$ are continuous there exists a ball $B_\sigma(x_0) \subset\subset U$, such that for all $z \in B_\sigma(x_0)$ we have $B_\rho(z) \subset\subset U$, and further there holds

$$|(Du)_{z,\rho}| < M_0 \quad\text{and}\quad \Phi(z,\rho) < \Phi_0(M_0) \quad \text{for all } z \in B_\sigma(x_0). \tag{5.25}$$

We can thus apply Lemma 5.2 on $B_r(z)$ for any $z \in B_\sigma(x_0)$ and r with $0 < r \le \rho$ to deduce

$$\fint_{B_r(z)} |Du - \Upsilon_z|^2\,dx \le c_{14}\Big(\Big(\frac{r}{\rho}\Big)^{2\beta}\Phi(z,\rho) + \Omega(r)\Big). \tag{5.26}$$

For $z, \widetilde{z} \in B_\sigma(x_0)$ with $r = |z - \widetilde{z}| < 2\sigma$ and $a = (z + \widetilde{z})/2$ we obtain

$$\begin{aligned}
|\Upsilon_z - \Upsilon_{\widetilde{z}}|^2 &= \frac{1}{\alpha_n (r/2)^n} \int_{B_{r/2}(a)} |\Upsilon_z - \Upsilon_{\widetilde{z}}|^2 \, dx \\
&\le \frac{2^n}{\alpha_n r^n} \int_{B_r(z) \cap B_r(\widetilde{z})} |\Upsilon_z - \Upsilon_{\widetilde{z}}|^2 \, dx \\
&\le 2^{n+1} \left[\fint_{B_r(z)} |Du - \Upsilon_z|^2 \, dx + \fint_{B_r(\widetilde{z})} |Du - \Upsilon_{\widetilde{z}}|^2 \, dx \right] \\
&\le 2^{n+1} c_{14} \left[\Big(\frac{r}{\rho}\Big)^{2\beta} \Big(\Phi(z, \rho) + \Phi(\widetilde{z}, \rho) \Big) + 2\Omega(r) \right] \\
&\le 2^{2n+2} c_{14} \left[\Big(\frac{|z - \widetilde{z}|}{\rho} \Big)^{2\beta} \Phi(x_0, 2\rho) + \Omega(|z - \widetilde{z}|) \right].
\end{aligned}$$

Here we have used (5.26) in the third to last inequality, and the fact that $\Phi(z, \rho) + \Phi(\widetilde{z}, \rho) \le 2^{n+1} \Phi(x_0, 2\rho)$ in obtaining the final inequality. Since Υ_z is the Lebesgue-representative of $Du(z)$, we can conclude the desired continuity. □

As noted in section 2 we can weaken the hypotheses of the theorem by omitting (H4). This entails essentially only notational changes in the proof: in (5.1), (5.9), and (5.18) we need to replace $\nu(\,\cdot\,)$ by $\nu(M + 1, \,\cdot\,)$ for $|(Du)_{x_0,\rho}|$ (respectively, $|p_0|$) less than M and check that this is preserved in the iteration. Analogous changes also need to be made in Lemma 4.1. We thus have the following corollary.

COROLLARY 5.3. *The conclusion of Theorem* 2.2 *also follows if we omit the hypothesis* (H4).

PERIODIC STRUCTURE IN TWO-DIMENSIONAL RIEMANN PROBLEMS FOR HAMILTON–JACOBI EQUATIONS*

J. D. PINEZICH†

Abstract. This paper investigates the structure of two-dimensional Riemann problems for Hamilton–Jacobi equations. The solutions to such problems are fundamental building blocks for constructing solutions to more general problems, in particular, for numerical construction using methods such as front tracking. Here we prove the existence of a particular class of Riemann problem for which the viscosity solutions contain closed characteristic orbits, enclosing furthermore a periodic sonic structure, which in turn encloses a parabolic structure. The existence of such examples elucidates the difficulties encountered in designing construction methods for viscosity solutions to Riemann problems in dimension ≥ 2. This investigation was prompted by the discovery of numerical evidence of examples displaying an even richer internal structure.

Key words. Riemann problem, Hamilton–Jacobi equation, conservation law, sonic shock, delay differential equations, viscosity solutions

1. Introduction.

The central equation in this paper is the Hamilton–Jacobi equation

$$\mathcal{S}(v) - D\mathcal{S}(v) \cdot v + \mathcal{H}(D\mathcal{S}(v)) = 0, \tag{1}$$

$$\text{with } D\mathcal{S} \text{ specified at infinity.} \tag{2}$$

Here $D\mathcal{S}$ denotes the gradient of $\mathcal{S} : \mathbb{R}^2 \to \mathbb{R}$, and the Hamiltonian $\mathcal{H} : \mathbb{R}^2 \to \mathbb{R}$ is a supposed known function of $D\mathcal{S}$. Assuming only continuity of $\mathcal{H}$, (1), (2) has a unique viscosity solution $\mathcal{S}$ (see [9] based on [4, 5, 14]); nevertheless the construction of the solution is rarely straightforward. Exceptions occur when either $\mathcal{H}$ or data $D\mathcal{S}$ are convex, for which $\mathcal{S}$ is obtained from $\mathcal{H}$ and $D\mathcal{S}$ through the Legendre transform [3, 9]. Classification of solution types for problem (1), (2) is an open problem. We develop a geometric framework for understanding the structure of solutions and singularities arising therein. Within this framework we exhibit a class of problems for which the viscosity solution has a complex internal structure. The work here establishes tools for the construction of a variety of classes of solution types.

Solutions of (1), (2) are related to solutions of the Hamilton–Jacobi equation

$$D_t \phi + \mathcal{H}(D_z \phi) = 0 \tag{3}$$

for a function $\phi : \mathbb{R}^2 \times \mathbb{R}^+ \to \mathbb{R}$, with initial data at $t = 0$. Equation (3) occurs in many contexts as an evolution model, e.g., the propagation of wavefronts and the evolution of material interfaces as occurs under etching and deposition processes in chip manufacture [9, 10, 12, 24, 25]. Equation (3) is the integrated form of a

conservation law for $p = D_z\phi$: $D_t\, p + D_z\, \mathcal{H}(p) = 0$, and one expects discontinuities (e.g., shocks) to arise in the gradient of ϕ. Conservation laws generally suffer from a lack of uniqueness of solutions, and the notion of viscosity solutions guaranteeing uniqueness for Hamilton–Jacobi equations was introduced precisely for this reason.

A natural framework for understanding the evolution of singularities in solutions to (3) is to seek them in self-similar form: $\phi(z,t) = t\,\mathcal{S}(z/t)$. With $v = z/t$, (1) is the reduced equation for $\mathcal{S}$ [3, 9]. We refer to the boundary condition at infinity, induced by the directional derivatives of $\phi(z,0)$ at $z = 0$, as the *Riemann data*, the viscosity solution $\mathcal{S}$ as the *Riemann solution*, and (1), (2) as a *Riemann problem*.

The theory of Legendre transforms has its parallel in the construction of solutions to (3), i.e., closed forms for $\phi(z,t)$ in terms of $\mathcal{H}$ and the initial data. Such formulas were first obtained for one spatial dimension [20] with convex $\mathcal{H}$ or initial data and later under similar hypotheses extended in [2, 13, 18]. These ideas have been further extended to certain nonconvex cases [3]. Such results allow for the decomposition of an arbitrary function $\mathcal{H}$ as a sum of simpler ones and have led to Godunov-type algorithms for the numerical construction of viscosity solutions for (3) [1, 19, 21]. Such algorithms yield then, in principle, numerical algorithms for the construction of solutions to the Riemann problem (1), (2).

The front tracking [7, 8, 10, 12] approach to (3) is opposite in spirit, as it uses knowledge of Riemann solutions to propagate singularities in the solution and higher order methods for the propagation of the solution where it is smooth. Such algorithms are more efficient than regular solvers and there is considerable interest in constructing Riemann solutions and in understanding their structure. Although the local structure of Riemann solutions for Hamilton–Jacobi equations is well understood [9], a complete theory of their global structure and algorithms for their construction is lacking at the time of this writing. It is hoped that the example studied here, by providing insight to the structure of solutions, will further this goal, as in the case of Riemann problems for the related two-dimensional conservation laws [17, 26, 28].

Characteristics for (1) are straight lines and the method of characteristics constructs the proper solution to (1), (2) near infinity where characteristic velocities point radially inward. Within a compact set, piecewise characteristic closed paths can form, along which the Cauchy problem fails to be hyperbolic. The existence of such cases was conjectured earlier and in this paper we provide the first rigorous construction of this phenomenon.

A shock is called *sonic* if characteristics are tangent to it. Sonic shocks can be characteristic, and thus straight lines, or noncharacteristic, and thus curved.

DEFINITION 1. *A* sonic sequence *is a sequence V_i, $i = 0,\ldots,N-1$, of noncharacteristic sonic shocks, such that all characteristics incident upon shock V_i, $i = 1,\ldots,N-1$, leave shock V_{i-1} tangentially. If all characteristics incident upon V_0 leave shock V_{N-1} tangentially, the sonic sequence is said to be* periodic *with* period N.

The main result of this paper is the following theorem.

THEOREM 1. *There exist C^1 Hamiltonians and Riemann problems so that the associated Riemann solutions to the Hamilton–Jacobi equation* (1) *possess a period* 4 *sonic sequence.*

This theorem was motivated by the Riemann problem

$$\mathcal{H}(p) = \xi\eta + \frac{1}{2}(\eta^4 - \xi^4), \tag{4}$$

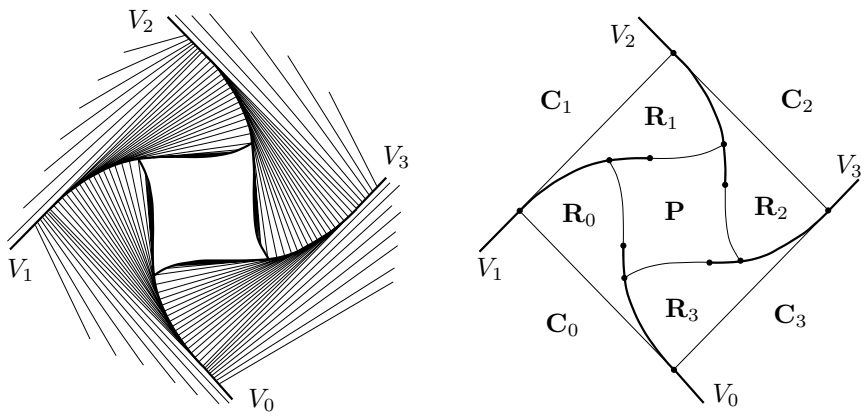

FIG. 1. *Conjectured structure of viscosity solution to* (4), (5). *Left*: *shocks* V_i *and characteristics. Right*: $\mathbf{C}_i$, $\mathbf{R}_i$, $\mathbf{P}$ *are domains of plane waves, sonic rarefactions, and a parabolic wave.*

where $p = (\xi, \eta)$, and Riemann data

$$D\mathcal{S}(\theta) = \begin{cases} \alpha_3 = (0,1) & \text{if} \quad -\pi/4 \le \theta < \pi/4, \\ \alpha_2 = (-1,0) & \text{if} \quad \pi/4 \le \theta < 3\pi/4, \\ \alpha_1 = (0,-1) & \text{if} \quad 3\pi/4 \le \theta < 5\pi/4, \\ \alpha_0 = (1,0) & \text{if} \quad -3\pi/4 \le \theta < -\pi/4 \end{cases} \tag{5}$$

posed by Tangerman and Kranzer, for which a numerical solution was found containing a period 4 sonic sequence [22, 23], shown in Figure 1. Regions $\mathbf{C}_i$ are the domains of plane waves (see below), on which the solution is linear; regions $\mathbf{R}_i$ are the domains of sonic rarefactions, on which the solution is a union of lines tangent to the curves V_i; and the region $\mathbf{P}$ is the domain of a parabolic wave, on which the solution is a saddle-type function.

To prove Theorem 1 we construct a somewhat simpler function $\mathcal{S}$ containing a period 4 sonic sequence, see Figure 2, and from it derive $\mathcal{H}$ and data $D\mathcal{S}$ such that $\mathcal{S}$ is a Riemann solution. Characteristics form two closed paths, one joining points B_i, the other joining points A_i, and the shock segments between these points form the sonic sequence. The main difficulty in the construction arises from a geometric constraint on continuity imposed by the periodicity: characteristic paths leaving a shock ultimately return to that shock. We remark that period 3 sonic sequences are trivial since a closed path of three characteristics lies on a straight line.

In section 2 we provide relevant background material. In section 3 we give an example for which the Riemann solution contains a closed characteristic path bounding a parabolic wave, later used in section 7. Section 4 describes the geometric structure of sonic rarefactions and in section 5 we derive properties of sonic sequences required for the construction of periodic sonic sequences in section 6. The proof of Theorem 1 is found in section 7, where we simultaneously construct $\mathcal{S}$, $\mathcal{H}$, and Riemann problems. The author would like to thank Tangerman for suggesting this problem and his insights toward its resolution.

2. Background. For Hamilton–Jacobi equations, Crandall, Evans, and Lions introduced the concept of a *viscosity solution* and demonstrated existence and unique-

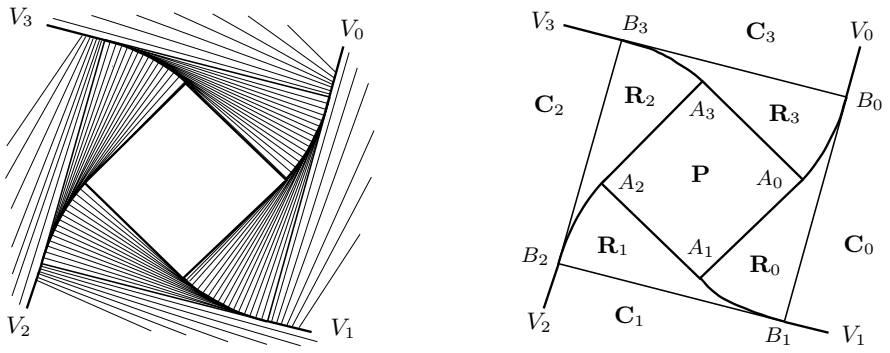

FIG. 2. *Solution with a period* 4 *sonic sequence, used in the proof of Theorem* 1. *The solution here is simpler than that in Figure* 1; *there, characteristics leave the parabolic wave.*

ness in this category [4]. $p \in \mathbb{R}^2$ is a *superderivative*, resp., *subderivative* [4, 9] of $\mathcal{S}$ at $v_0 \in \mathbb{R}^2$ if

$$\limsup_{v \to v_0} \frac{\mathcal{S}(v) - \mathcal{S}(v_0) - p \cdot (v - v_0)}{|v - v_0|} \le 0, \qquad \liminf_{v \to v_0} \frac{\mathcal{S}(v) - \mathcal{S}(v_0) - p \cdot (v - v_0)}{|v - v_0|} \ge 0.$$

Let $C^\wedge(v_0)$ be the set of superderivatives and $C^\vee(v_0)$ the set of subderivatives at v_0, and let $C^{\wedge\vee}(v_0) = C^\wedge(v_0) \cup C^\vee(v_0)$. $C^\wedge(v_0)$ and $C^\vee(v_0)$ are closed, convex, and possibly empty [9]. If $\mathcal{S}$ is differentiable at v_0, then the gradient $p = D\mathcal{S}(v_0)$ is the unique super- and subderivative. Conversely, if both $C^\wedge(v_0)$ and $C^\vee(v_0)$ are nonempty, then each consists of the same element, namely, the derivative of $\mathcal{S}$ at v_0. At a point v_0 on a shock, $C^{\wedge\vee}(v_0)$ is the convex hull of the gradients $p, q \in \mathbb{R}^2$ on each side of the shock. By continuity, $p - q \in \mathbb{R}^2$ is normal to the shock. If $p - q$ points to the side with $D\mathcal{S} = p$ (equivalently, $q - p$ points to side with $D\mathcal{S} = q$), the shock is a *convex edge* and $C^{\wedge\vee}(v_0) = C^\vee(v_0)$; otherwise it is a *concave edge* and $C^{\wedge\vee}(v_0) = C^\wedge(v_0)$.

$\mathcal{S}$ is a *viscosity solution* [4, 9] of (1) if for all $v \in \mathbb{R}^2$

$$\begin{aligned} &\mathcal{S}(v) - v \cdot p + \mathcal{H}(p) \le 0 \quad \text{for all } p \in C^\wedge(v) \\ \text{and} \quad &\mathcal{S}(v) - v \cdot p + \mathcal{H}(p) \ge 0 \quad \text{for all } p \in C^\vee(v). \end{aligned}$$

For any given Riemann data and continuous $\mathcal{H}$, (1), (2) has a unique Lipschitz continuous Riemann solution $\mathcal{S}$ [4, 9, 14].

With $p = D\mathcal{S}$ the characteristic equations for (1) are the system of ODEs [9, 15]

$$D_\tau p = 0, \qquad D_\tau v = -v + D_p \mathcal{H}(p), \qquad D_\tau \mathcal{S} = -v \cdot p + D_p \mathcal{H}(p) \cdot p.$$

Outside a compact set these equations are nonsingular and the Riemann data can be propagated inward by hyperbolic methods [9]. By the first of these equations, p, and thus $D_p\mathcal{H}(p)$, are constant along characteristics, hence characteristics are straight lines. They are directed toward points given by the *parabolic mapping* $L(p) := (v(p), \mathcal{S}(p)) : \mathbb{R}^2 \to \mathbb{R}^2 \times \mathbb{R}$ [9]:

$$v(p) = D_p \mathcal{H}(p), \qquad \mathcal{S}(p) = v(p) \cdot p - \mathcal{H}(p). \tag{6}$$

A characteristic path can terminate at a shock or, if the shock is sonic, continue along the outgoing tangential shock. By an *orbit* we mean a closed path of characteristics.

Define the graph of the mapping $p \to v_0 \cdot p - \mathcal{S}(v_0)$ over $C^{\wedge\vee}(v_0)$ as the *chord* of $C^{\wedge\vee}(v_0)$. The viscosity condition can be expressed as a generalization of the Oleĭnik condition [20].

Oleĭnik: *$\mathcal{S}$ is a Riemann solution if and only if the chord of $C^{\wedge}(v)$ lies on or above the graph of $\mathcal{H}$ and the chord of $C^{\vee}(v)$ lies on or below the graph of $\mathcal{H}$ for all $v \in \mathbb{R}^2$.*

As a consequence, characteristics satisfy the Lax condition [16] at a shock [9].

Lax: *Characteristic directions point toward the shock or are tangent to it.*

In this paper all Riemann solutions are piecewise smooth and consist of three wave-types classified by rank of the matrix $D^2\mathcal{S}(v)$ of second derivatives of $\mathcal{S}$ at a point v. Let E be an open connected set on which a Riemann solution is C^2. If $\operatorname{rank} D^2\mathcal{S}(v) = 2$ on E, the solution is called a *parabolic wave*. If $\operatorname{rank} D^2\mathcal{S}(v) = 1$ on E the solution is called a *rarefaction*. If $\operatorname{rank} D^2\mathcal{S}(v) = 0$ on E the solution is called a *plane wave*.

Throughout the paper we exploit the symmetry of (1). With $p = D\mathcal{S}$, (1) becomes

$$\mathcal{S}(v) - v \cdot p + \mathcal{H}(p) = 0,$$

and the change of notation $v \leftrightarrow p$, $\mathcal{S} \leftrightarrow \mathcal{H}$ results in the same equation. The plane on which $\mathcal{S}$ is defined is called the *v-plane*; the plane on which $\mathcal{H}$ is defined is called the *p-plane*.

3. Example with period 4 orbit. The solution to the Riemann problem with Hamiltonian $\mathcal{H}(p) = (\xi^2 - \eta^2)/2$, where $p = (\xi, \eta)$, and Riemann data $\{\zeta_i\}$ as in Figure 3 contains a period 4 orbit bounding a parabolic wave. Let $\zeta_i = (\xi_i, \eta_i)$. By (6), characteristics are directed toward points $A_i = (a_i, \mathcal{S}(a_i))$ given by $a_i = (\xi_i, -\eta_i)$, $\mathcal{S}(a_i) = (\xi_i^2 - \eta_i^2)/2$. $\mathbf{P}$ is the convex hull of the set $\{a_i\}$ and is the domain of the parabolic wave. For each i, the set $\mathbf{C}_i = a_i + \bigcup_{\kappa,\kappa' \geq 0} \kappa\,(a_{i-1} - a_i) + \kappa'\,(a_i - a_{i+1})$ is the domain of a plane wave with gradient ζ_i. These waves are joined by shocks V_i that propagate inward from infinity along straight lines.

This example furnishes us with a structure from which we can construct outward a solution containing a sonic sequence, as done in the following sections, and which is ultimately used to prove Theorem 1. The idea is to replace the plane waves with sonic rarefactions tangential to the plane waves at the parabolic boundary.

PROPOSITION 1. *The Riemann solution to the above Riemann problem is*

$$\mathcal{S}(v) = \begin{cases} (x^2 - y^2)/2, & v \in \mathbf{P}, \\ y + 1/2, & v \in \mathbf{C}_0, \\ -x - 1/2, & v \in \mathbf{C}_1, \\ -y + 1/2, & v \in \mathbf{C}_2, \\ x - 1/2, & v \in \mathbf{C}_3, \end{cases} \tag{7}$$

where $v = (x, y)$. The boundary of the parabolic wave is an orbit of period 4.

Proof. Where differentiable, $\mathcal{S}$ satisfies (1). On $\mathbf{P}$, $\mathcal{S}$ is a ruled surface with two distinct rulings that coincide with four characteristic shocks V_i from infinity which form an orbit bounding the parabolic wave. These shocks are also the boundaries of the plane waves and hence $\mathcal{S}$ is continuous. $\mathcal{H}$ is also a ruled surface and the chords of $C^{\wedge\vee}(v)$ along the shocks lie on the graph of $\mathcal{H}$ and hence the Oleĭnik condition is satisfied. □

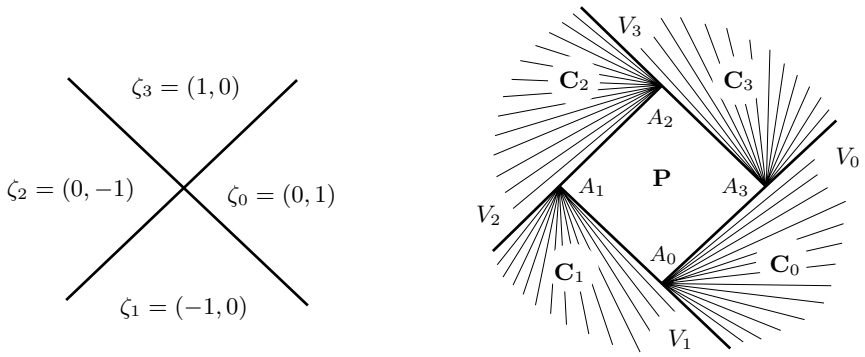

FIG. 3. *Riemann solution with orbit. Left: Riemann data* $\{\zeta_i\}$. *Right: shocks* V_i *and characteristics directed toward points* $\mathrm{A_i}$. $\mathbf{C}_i$, $\mathbf{P}$ *are domains of plane and parabolic waves, respectively.*

4. Structure of sonic rarefactions. Sonic rarefactions occur when characteristics leave a shock V tangentially. Since characteristics are straight lines, a sonic rarefaction is a type of ruled surface, called the *tangent surface* of the curve V. Given a curve V with tangent surface described by a function $\mathcal{S}$, we show that there exists a Hamiltonian $\mathcal{H}$ such that (1) is satisfied. The properties developed here, and in section 5 (sequences of sonic rarefactions), allow for the construction in section 6 of a period 4 sonic sequence, using an orbit as starting point (as from, e.g., the example in section 3). Before proceeding, we provide basic terminology.

A *parameterized curve* is a C^2 differentiable map $\Gamma : I \to \mathbb{R}^n$ $(n = 2, 3)$, where I is the unit interval $[0, 1]$. If $\dot{\Gamma}(t) \neq 0$ for all $t \in I$, the curve is *regular* (the notation $\dot{f}(t) = D_t f(t)$ indicates differentiation of f with respect to t). Two parameterized curves $\Gamma, \bar{\Gamma} : I \to \mathbb{R}^n$ are *equivalent* if there exists an orientation-preserving diffeomorphism $\phi : I \to I$ such that $\bar{\Gamma}(t) = \Gamma(\phi(t))$, $t \in I$. By the *oriented curve* Γ we mean the equivalence class of all parameterized curves equivalent to Γ. Let $v : I \to \mathbb{R}^2$ be an oriented curve which can be written in an orthogonal frame as $v(x) = (x, \varphi(x))$. If φ is strictly convex then v is called a *convex curve*.

For $z \in \mathbb{R}^2$ we denote as z^* the rotation of z about the origin by $+90°$. For vectors $w, z \in \mathbb{R}^2$ we can compute their determinant $\|w\ z\|$ as $w^* \cdot z$. For a convex curve $v : I \to \mathbb{R}^2$, the determinant $\|\dot{v}(t)\ \ddot{v}(t)\| \neq 0$ for all $t \in I$, and v lies entirely in a closed half plane which has boundary given by a tangent line of v. The interior of the intersection of all such half planes of v is called the *inside* of v. The *outside* of v is the closure of the complement of the inside of v. Note that the inside of a convex planar curve is convex.

We now describe the tangent surface to a curve; see Figure 4. Since our construction of the periodic sequence in section 6 is *outward* from an orbit, the choice of orientation in (8) is the natural one. Let $v : I \to \mathbb{R}^2$ be a regular curve and let $S : I \to \mathbb{R}$ be a C^2 function. Denote by $V : I \to \mathbb{R}^2 \times \mathbb{R}$ the curve defined by $V(t) = (v(t), S(t))$. Let $\mathbf{U} = \{(t, s) \mid 0 \leq t \leq 1, s > 0\}$ and consider the mapping $\Omega : \overline{\mathbf{U}} \to \mathbb{R}^2 \times \mathbb{R}$, where $\overline{\mathbf{U}}$ is the closure of $\mathbf{U}$, given by

$$\Omega(t, s) = V(t) - s\dot{V}(t). \tag{8}$$

DEFINITION 2. *The image* $\Omega(\overline{\mathbf{U}})$ *is called the* tangent surface *of* V. *The tangent half line given by* $\Omega(t, s)$, $s > 0$, *is called the* characteristic *at* $V(t)$.

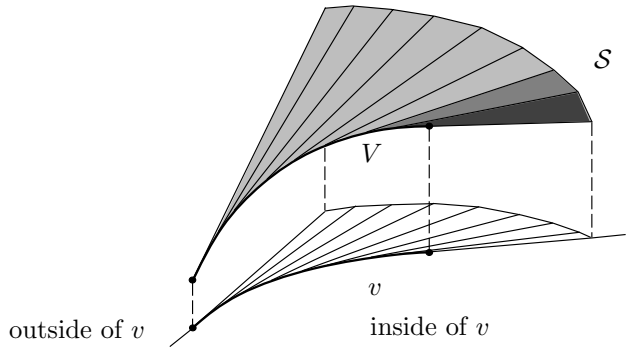

FIG. 4. *The structure of a sonic rarefaction is described by the tangent surface of a curve $V = (v, S)$. For convex v, $\mathcal{S}$ is a function representing the tangent surface. The inside of v is the intersection of half planes containing v.*

If v is convex, $\Omega(\overline{\mathbf{U}})$ is a graph of a C^1 function $\mathcal{S}$ with domain the tangent surface of v. We show in Proposition 2 that for some $\mathcal{H}$, $\mathcal{S}$ is a solution to (1). Of principal importance in the following lemma is the orthogonality of v and p, leading naturally to a notion of *duality*, and further exploited in developing properties of sonic sequences, and in the construction of our solution.

LEMMA 1. (a) *The gradient $D\mathcal{S}$ of $\mathcal{S}$ is constant along characteristics and equals*

$$D\mathcal{S}(\omega(t,s)) = \frac{-\ddot{S}(t)\dot{v}^*(t) + \dot{S}\ddot{v}^*(t)}{\|\ddot{v}(t)\ \dot{v}(t)\|} =: p(t). \tag{9}$$

(b) $\dot{p}(t) \cdot \dot{v}(t) = 0$, (c) $\dot{S}(t) = p(t) \cdot \dot{v}(t)$, $t \in I$.

Proof. (a) Write $\Omega(t,s) = (\omega(t,s), S(t,s))$, where $\omega(t,s) = v(t) - s\dot{v}(t)$ and $S(t,s) = S(t) - s\dot{S}(t)$. By the chain rule $D\mathcal{S}(\omega(t,s)) = DS(t,s)(D\omega(t,s))^{-1}$. Evaluating this we obtain (9), and since this is independent of s, the gradient is constant along characteristics. (b) Differentiate (9) and carry out the dot product. (c) Since $\omega(t,0) = v(t)$ we have $\dot{S}(t) = D_t\mathcal{S}(v(t)) = D\mathcal{S}(v(t)) \cdot \dot{v}(t) = p(t) \cdot \dot{v}(t)$. ∎

Note that (9) is well defined for equivalence classes of parameterized curves: suppose $\bar{V}(t) = V(\phi(t))$, then $\bar{p}(t) = p(\phi(t))$. If V is C^∞, then p is C^∞ and hence $\mathcal{S}$ is C^∞ for $s \neq 0$. For $s = 0$, i.e., along v, the (s, t)-coordinate system is singular and there $\mathcal{S}$ is usually only C^1.

For a given tangent surface $\mathcal{S}$ determined by a curve $V = (v, S)$, we have obtained an expression $p(t)$ for $D\mathcal{S}$ and shown that $\dot{p}(t) \perp \dot{v}(t)$. To an additive constant, the pair (v, p) is an equivalent descriptor of $\mathcal{S}$. Let $v, p : I \to \mathbb{R}^2$ satisfy Lemma 1(b), and $S : I \to \mathbb{R}$ satisfy Lemma 1(c). If $\mathcal{S}$ is the tangent surface of $V = (v, S)$, then $D\mathcal{S}(\omega(t,s)) = p(t)$. This result allows us to construct our solution in terms of pairs $(v, p) : I \to \mathbb{R}^2 \times \mathbb{R}^2$ in the v- and p-planes.

DEFINITION 3. *Let $v, p : I \to \mathbb{R}^2$ be curves such that $\dot{v}(t) \cdot \dot{p}(t) = 0$, $t \in I$. Then (v, p) is called an* orthogonal pair. *If v and p are also convex, then (v, p) is called a* dual pair. *Let $\mathcal{S}$ be a tangent surface with dual pair (v, p). Let H satisfy $\dot{H}(t) = v(t) \cdot \dot{p}(t)$ and $H(0) = v(0) \cdot p(0) - S(0)$, and let $\mathcal{H}$ be the tangent surface of $P(t) := (p(t), H(t))$. Then H, P, and $\mathcal{H}$ are said to be* dual *to S, V, and $\mathcal{S}$, respectively. Characteristics tangent to P (or p) are* dual *to those tangent to V (or v).*

PROPOSITION 2. *Let $\mathcal{H}$ be dual to $\mathcal{S}$.* (a) *The characteristics at $v(t)$ and $p(t)$ are orthogonal.* (b) *On the characteristic at $p(t)$, $D_p\mathcal{H} = v(t)$.* (c) *If $\mathcal{H}$ is dual to $\mathcal{S}$, then*

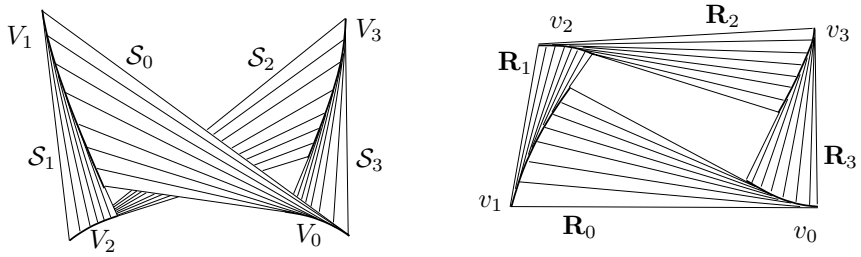

FIG. 5. *A periodic structure on the left, with annular domain on the right.*

$\mathcal{S}$ *satisfies* (1) *with Hamiltonian* $\mathcal{H}$.

Proof. (a) By Lemma 1(b).

(b) By Lemma 1(a) with $\mathcal{H}$, H, p in place of $\mathcal{S}$, S, v, respectively.

(c) Let z be on the characteristic at $v(t)$. Then $\mathcal{S}(z) = \mathcal{S}(v(t)) + p(t) \cdot (z - v(t))$. Writing $z = v(t) + (z - v(t))$, the left-hand side of (1) becomes $\mathcal{S}(z) - z \cdot D\mathcal{S}(z) + \mathcal{H}(D\mathcal{S}(z)) = \mathcal{S}(v(t)) - v(t) \cdot p(t) + \mathcal{H}(p(t))$. The derivative with respect to t of the right-hand side is zero since $D_p\mathcal{H}(p(t)) = v(t)$ by (b). By the duality of $\mathcal{S}$ and $\mathcal{H}$, $\mathcal{S}(v(0)) + \mathcal{H}(p(0)) = S(0) + H(0) = v(0) \cdot p(0)$, and thus $\mathcal{S}$ satisfies (1). ∎

5. Sequences of sonic rarefactions. If V_1 is a curve embedded in the tangent surface of a curve V_0, we can form a sequence of two tangent surfaces by truncating characteristics from V_0 along V_1. Generalizing this idea we can form sequences of length N, and if V_0 is embedded in the tangent surface of V_{N-1}, characteristic paths cycle periodically through the N curves. Here we derive properties of sequences of length $2, 3$, and 4, necessary for the construction carried out in section 6.

For $i = 0, 1, 2, 3$ let $\mathcal{S}_i$ be the tangent surfaces of curves $V_i = (v_i, S_i)$, such that characteristics tangent to V_i form an orientation-preserving diffeomorphism from V_i to V_{i+1} (here $V_{3+1} = V_0$); see Figure 5. Truncate characteristics from V_i at points on V_{i+1}; the domain of the resulting $\mathcal{S}_i$ has v_i and v_{i+1} in its boundary and is denoted by $\mathbf{R}_i$. If the interiors of the domains $\mathbf{R}_i$ and $\mathbf{R}_j$, $i \neq j$, are disjoint, the function $\mathcal{S}$ given by $\mathcal{S}(v) = \mathcal{S}_i(v)$, $v \in \mathbf{R}_i$, is called a *periodic structure*. We assume that the domain of the periodic structure is a topological annulus embedded in the plane and that the boundary curves of the annulus are orbits of the characteristic flow.

A periodic structure satisfying (1) for some $\mathcal{H}$ is a period 4 sonic sequence. However, a period 4 sonic sequence need not be a periodic structure: characteristics in a periodic sonic sequence can escape. The numerical solution [23, 22] motivating Theorem 1 contains such a sequence, joining a periodic structure to a parabolic wave.

DEFINITION 4. *Let* $\Gamma_i, \Gamma_j : I \to \mathbb{R}^n$, $i \neq j$ *be curves. By a* common parameterization *we mean that* $\Gamma_i(t)$ *and* $\Gamma_j(t)$ *are joined by a characteristic path for each* $t \in I$.

Note in the following lemma that (11) is independent of the curve v_{i+1}; this anticipates our method of construction in section 6. First construct V_0 and V_2 and from these derive V_1 and V_3 such that the sequence V_0, V_1, V_2, V_3 forms a periodic structure.

LEMMA 2. *Let* $\mathcal{S}_i, \mathcal{S}_{i+1}, \mathcal{S}_{i+2}$ *be tangent surfaces of curves* $V_i, V_{i+1}, V_{i+2} : I \to \mathbb{R}^2 \times \mathbb{R}$ *with common parameterization.* (a) $\mathcal{S}_i(v_{i+1}(t)) = \mathcal{S}_{i+1}(v_{i+1}(t))$ *if and only if*

$(p_i(t)-p_{i+1}(t))\cdot\dot v_{i+1}(t)=0$ *and* $\mathcal{S}_i(v_{i+1}(0))=\mathcal{S}_{i+1}(v_{i+1}(0))$. (b) *Suppose* $\mathcal{S}_i(v_{i+1}(t))=\mathcal{S}_{i+1}(v_{i+1}(t))$ *and* $\mathcal{S}_{i+1}(v_{i+2}(t))=\mathcal{S}_{i+2}(v_{i+2}(t))$, $t\in I$; *then*

$$p_{i+1}(t)\cdot(v_{i+2}(t)-v_{i+1}(t))=p_i(t)\cdot(v_{i+2}(t)-v_{i+1}(t)), \tag{10}$$

$$S_{i+2}(t)-S_i(t)=p_i(t)\cdot(v_{i+2}(t)-v_i(t)). \tag{11}$$

Proof. (a) This follows directly from continuity. (b) Since $\mathcal{S}_i$ and $\mathcal{S}_{i+1}$ join continuously along V_{i+1}, by (a) we have $(p_{i+1}(t)-p_i(t))\cdot\dot v_{i+1}(t)=0$, so that (10) holds. Since $\mathcal{S}_{i+1}$ and $\mathcal{S}_{i+2}$ join continuously along V_{i+2} we have $\mathcal{S}_{i+1}(v_{i+2}(t))=S_{i+2}(t)$ so that by (10) we obtain $S_{i+2}(t)-S_i(t)=p_{i+1}(t)\cdot(v_{i+2}(t)-v_{i+1}(t))+p_i(t)\cdot(v_{i+1}(t)-v_i(t))=p_i(t)\cdot(v_{i+2}(t)-v_i(t))$. □

Remark. In a period 3 orbit the three characteristics must lie in a plane, hence the gradient values on each characteristic lie along a straight line. By Lemma 2(a), the tangent vectors $\dot v_i(t)$ have direction orthogonal to this line; hence they, and therefore the characteristics, are all parallel. Thus period 3 sonic structures are trivial.

The periodic sonic sequence constructed in section 6 is bounded by orbital paths and in the following proposition we establish the geometry of such paths in the v- and p-planes.

Proposition 3. *Let periodic structure* $\mathcal{S}$ *have an orbit containing four points* $A_i=(a_i,\mathcal{S}_i(a_i))$ *with* $\{a_i\}$ *a strictly convex oriented quadrilateral. Then* $\{\alpha_i\}:=\{D\mathcal{S}_i(a_i)\}$ *is a strictly convex quadrilateral with opposite orientation.* (a) $(a_i-a_{i+1})\cdot(\alpha_i-\alpha_{i-1})=0$, (b) $(a_i-a_{i+2})\cdot(\alpha_i-\alpha_{i+2})=0$.

Proof. (a) follows from (10) of Lemma 2(b) and (b) from continuity along the orbit. An oriented quadrilateral with edges $\mathbf{e}_i$ is strictly convex if and only if $\|\mathbf{e}_i\ \mathbf{e}_{i+1}\|$ is of the same sign for all i, with sign given by orientation. Let $\mathbf{e}_i=a_i-a_{i+1}$ and $\mathbf{f}_i=\alpha_i-\alpha_{i-1}$. By (a), $\mathbf{f}_i=c_i\mathbf{e}_i^*$ for scalars c_i; thus $\alpha_{i+1}-\alpha_{i-1}=c_{i+1}\mathbf{e}_{i+1}^*+c_i\mathbf{e}_i^*$. Writing $a_{i+1}-a_{i-1}=\mathbf{e}_i+\mathbf{e}_{i-1}=-\mathbf{e}_{i+1}-\mathbf{e}_{i+2}$ and using $\mathbf{e}_{i+1}^*\cdot\mathbf{e}_i=\|\mathbf{e}_{i+1}\ \mathbf{e}_i\|$, we obtain from (b) $c_{i+1}/c_i=-\|\mathbf{e}_{i-1}\ \mathbf{e}_i\|/\|\mathbf{e}_{i+1}\ \mathbf{e}_{i+2}\|$. Since $\{a_i\}$ is strictly convex, the right-hand side is negative; hence c_{i+1} and c_i are of opposite sign. Thus $\|\mathbf{f}_i\ \mathbf{f}_{i+1}\|=c_ic_{i+1}\|\mathbf{e}_i\ \mathbf{e}_{i+1}\|$ is of sign opposite $\|\mathbf{e}_i\ \mathbf{e}_{i+1}\|$, demonstrating that $\{\alpha_i\}$ has orientation opposite that of $\{a_i\}$. □

Definition 5. *By* dual quadrilaterals *we mean strictly convex quadrilaterals* $\{a_i\}$ *and* $\{\alpha_i\}$ *of opposite orientation satisfying* (a) *and* (b) *in Proposition* 3.

Corollary 1. *The orbit of Proposition* 1 *has dual quadrilaterals* $\{a_i\}$ *and* $\{\zeta_{i+1}\}$.

Proof. The gradient of $\mathcal{S}$ on the characteristic joining A_i and A_{i+1} is ζ_{i+1}. □

Definition 6. *Let* $\mathcal{S}$ *be a periodic structure. The diffeomorphism* $\gamma: I\to I$ *defined as the first return from* v_0 *to* v_0 *by characteristic paths is called the* return map *of* $\mathcal{S}$.

We now derive a system of differential equations that the curves p_0 and p_2 in a periodic structure must satisfy. Note that these equations are independent of curves V_1 and V_3 (i.e., dual pairs (v_1,p_1) and (v_3,p_3)). Given appropriate curves v_0 and v_2 and return map γ, we can thus obtain curves p_0 and p_2, and we later show that the resulting (v_0,p_0) and (v_2,p_2) are dual pairs. These dual pairs allow for the construction of curves V_0 and V_2, and associated tangent surfaces, unique up to additive constants. From these, the curves V_1 and V_3 (hence the periodic structure) are derived.

Theorem 2. *Let characteristic paths in periodic structure* $\mathcal{S}$ *be given by the diagram*

$$\begin{pmatrix} v_0(t)\\ p_0(t)\end{pmatrix}\to\begin{pmatrix} v_1(t)\\ p_1(t)\end{pmatrix}\to\begin{pmatrix} v_2(t)\\ p_2(t)\end{pmatrix}\to\begin{pmatrix} v_3(t)\\ p_3(t)\end{pmatrix}\to\begin{pmatrix} v_0(\gamma(t))\\ p_0(\gamma(t))\end{pmatrix}. \tag{12}$$

Then p_0 and p_2 satisfy

$$\dot{p}_0(t) = \frac{(p_2(t) - p_0(t)) \cdot \dot{v}_2(t)}{\|\dot{v}_0(t)\ \ v_2(t) - v_0(t)\|} \dot{v}_0^*(t), \tag{13}$$

$$\dot{p}_2(t) = \frac{(p_2(t) - p_0(\gamma(t))) \cdot \dot{v}_0(\gamma(t))}{\|\dot{v}_2(t)\ \ v_2(t) - v_0(\gamma(t))\|} \dot{v}_2^*(t). \tag{14}$$

Proof. Applying (11) of Lemma 2(b) to $V_0(t), V_1(t), V_2(t)$ and $V_2(t), V_3(t), V_0(\gamma(t))$ yields $S_2(t) - S_0(t) = p_0(t) \cdot (v_2(t) - v_0(t))$ and $S_0(\gamma(t)) - S_2(t) = p_2(t) \cdot (v_0(\gamma(t)) - v_2(t))$. Taking derivatives and using $\dot{S}_i(t) = p_i(t) \cdot \dot{v}_i(t)$ from Lemma 1(c) gives

$$(p_2(t) - p_0(t)) \cdot \dot{v}_2(t) = (v_2(t) - v_0(t)) \cdot \dot{p}_0(t), \tag{15}$$

$$(p_2(t) - p_0(\gamma(t)) \cdot \dot{v}_0(\gamma(t)) = (v_2(t) - v_0(\gamma(t))) \cdot \dot{p}_2(t). \tag{16}$$

Since v_i is convex by assumption, $\dot{v}_i(t) \neq 0$, and Lemma 1(b) implies that $\dot{p}_i(t)$ has the form $N_i(t)\dot{v}_i^*(t)$. The coefficients $N_0(t)$ and $N_2(t)$ are found from (15) and (16) resp., and yield (13), (14). ∎

If $\gamma(t) \leq t$, (13) and (14) are known as a *delay* system with *bounded delay* and have properties similar to ordinary differential equations [6, 11]. If the denominators are nonzero, the system (13), (14) is globally Lipschitz in $p_i(t)$ and by the methods of Chapters 25 and 26 of [6] and Chapter 2 of [11] has a unique solution on I which is a C^2 function of initial conditions, parameters, and t. Suppose $\bar{v}_0(t) = v_0(\phi(t))$ (inducing $\bar{v}_2(t) = v_2(\phi(t))$), then $\bar{p}_0$, $\bar{p}_2$ satisfy $\bar{p}_i(t) = p_i(\phi(t))$, $i = 0, 2$, and therefore (13), (14) is well defined for equivalence classes of parameterized curves.

6. The periodic structure. We first construct dual pairs for $i = 0, 2$ and from these derive dual pairs for $i = 1, 3$ completing the periodic structure $\mathcal{S}$. The dual pairs generate a dual periodic structure $\mathcal{O}$ representing chords of super- and subderivatives of $\mathcal{S}$.

6.1. Construction of dual pairs. Let $\{a_i\}$ and $\{\alpha_i\}$ be square dual quadrilaterals centered at the origin and define vectors $\mathbf{e}_i = a_i - a_{i+1}$ and sectors $U_i = \bigcup_{\kappa,\kappa'>0}(\kappa\ \mathbf{e}_i + \kappa'\ \mathbf{e}_{i-1})$; see Figure 6. Each sector is of angle 90°, U_i is adjacent to U_{i+1}, and $a_i \in U_{i+1}$. Let $v_0, v_2 : I \to \mathbb{R}^2$ be C^∞ convex curves such that

(A1) $v_i(0) = a_i$ and v_i is in U_{i+1};

(A2) $\dot{v}_i(0)$ is in the direction $\mathbf{e}_i$ and $\dot{v}_i(t) \in U_i$ for $t > 0$.

Since $v_i(0) = a_i$ is in the open set U_{i+1} such curves exist. Let the correspondence between points on v_0 and v_2 through characteristic paths through v_1 be given by the orientation-preserving diffeomorphism $\phi_{012} : v_0 \to v_2$ and the correspondence between points on v_0 and v_2 through characteristic paths through v_3 be given by the orientation-preserving diffeomorphism $\phi_{230} : v_2 \to v_0$. Let v_0 and v_2 have a common parameterization given by paths of ϕ_{012}, i.e., $v_2(t) = \phi_{012}(v_0(t))$. Assume that $\gamma : I \to I$, determined by the composition $\phi_{230} \circ \phi_{012}$, satisfies $\gamma(t) \leq t$, $t \in I$.

The following lemma is implied by assumptions (A1) and (A2).

LEMMA 3. *v_0 is in the inside of v_2, and vice versa.*

Analogous to $\mathbf{e}_i$ and U_i we define vectors $\mathbf{f}_i = \alpha_i - \alpha_{i-1}$ and sectors $\Upsilon_i = \bigcup_{\kappa,\kappa'>0}(\kappa\ \mathbf{f}_{i+1} + \kappa'\ \mathbf{f}_i)$. Since $\{\alpha_i\}$ is dual to $\{a_i\}$, $\mathbf{f}_i = c_i\mathbf{e}_i^*$ with the scalars c_i alternating in sign (as in Proposition 3). Hence Υ_i is equal to either U_{i-1} or U_{i+1}.

PROPOSITION 4. *Let p_0, p_2 be the solution to the system* (13), (14) *of Theorem* 2 *with $p_0(0) = \alpha_0$ and $p_2(0) = \alpha_2$. Then $\dot{p}_0(0)$ has direction $\mathbf{f}_0$ and $\dot{p}_2(0)$ has direction*

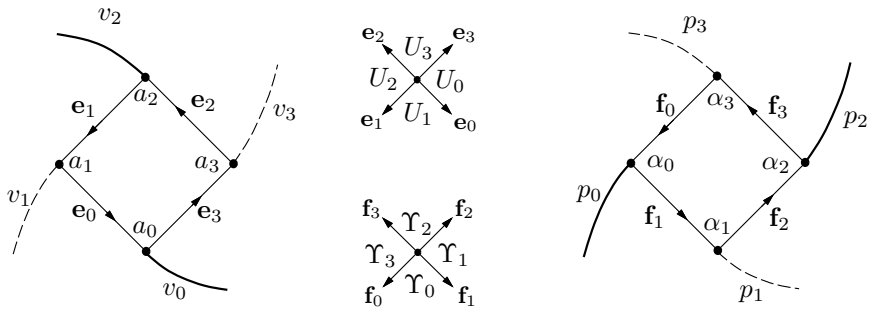

FIG. 6. *Specification of data*: *dual quadrilaterals* $\{a_i\}$, $\{\alpha_i\}$, *curves* v_0, v_2, *and diffeomorphisms* $\phi_{012} : v_0 \to v_2$, *and* $\phi_{230} : v_2 \to v_0$ *such that* $\gamma(t) \le t$. *Curve initial directions* $\mathbf{e}_i$, $\mathbf{f}_i$ *define sectors* U_i, Υ_i.

$\mathbf{f}_2$. *The curves* $V_0 = (v_0, S_0)$ *and* $V_2 = (v_2, S_2)$, *where* $\dot{S}_i(t) = p_i(t) \cdot \dot{v}_i(t)$, *satisfy*

$$S_2(t) - S_0(t) = p_0(t) \cdot (v_2(t)) - v_0(t)), \tag{17}$$

$$S_0(\gamma(t)) - S_2(t) = p_2(t) \cdot (v_0(\gamma(t)) - v_2(t)) \tag{18}$$

provided $S_2(0) - S_0(0) = \alpha_0 \cdot (a_2 - a_0) = \alpha_2 \cdot (a_2 - a_0)$.

Proof. By assumption (A2), $\dot{v}_i(0) = \epsilon_i \mathbf{e}_i$, $\epsilon_i > 0$, and hence $\dot{p}_i(0) = -\epsilon_{i+2} c_i c_{i+1} \|\mathbf{e}_{i+1}\ \mathbf{e}_{i+2}\| / \|\mathbf{e}_i\ \mathbf{e}_{i+1}\| \mathbf{f}_i$, and $\dot{p}_i(0)$ has direction $\mathbf{f}_i$. From (13) we obtain $(v_2(t) - v_0(t)) \cdot \dot{p}_0(t) = (p_2(t) - p_0(t)) \cdot \dot{v}_2(t)$. Subtracting $p_0(t) \cdot \dot{v}_0(t) = \dot{S}_0(t)$ from both sides yields $D_t[(v_2(t) - v_0(t)) \cdot p_0(t)] = D_t[S_2(t) - S_0(t)]$. Integrating from 0 to t gives (17). A similar argument establishes (18). □

Recall that if (v, p) is a dual pair, then the tangent surface of curve $V = (v, S)$, with $\dot{S}(t) = p(t) \cdot \dot{v}(t)$, has gradient $p(t)$ along the characteristic from $V(t)$ (Lemma 1). If we are given plane curves v_0, v_2, and a return map γ, by Proposition 4 we can construct curves V_0, V_2 such that the point $V_2(t)$ lies in the plane tangent to the tangent surface of V_0 at $V_0(t)$, and the point $V_0(\gamma(t))$ lies in the plane tangent to the tangent surface of V_2 at $V_2(t)$. This is precisely the geometry needed to construct curves V_1 and V_3.

Before proceeding with the construction we need to show that the curves p_0 and p_2 are regular. It is sufficient to show that the numerators in the coefficients N_0 and N_2 of (13) and (14) are nonzero. We first prove this for the special case where γ is the identity. Let $q(t) = p_2(t) - p_0(t)$. Subtracting (13) from (14) shows that q satisfies a linear equation $\dot{q}(t) = A(t)q(t)$ for some matrix $A(t)$. Since $q(0) = \alpha_2 - \alpha_0 \neq 0$, the solution q is never zero. Adding (17) to (18) in Proposition 4 shows that

$$(p_2(t) - p_0(t)) \cdot (v_2(t) - v_0(t)) = 0 \tag{19}$$

at all fixed points of γ. Thus $q(t) \perp (v_2(t) - v_0(t))$ for all $t \in I$. By assumption (A1) $v_2(t) - v_0(t) \in U_3$, and since $q(0) = \alpha_2 - \alpha_0 \in \Upsilon_1$ and $q(t) \neq 0$, the trace of q is in Υ_1. This proves that the numerators in N_0 and N_2 are never zero since by assumption (A2), $\dot{v}_i(t) \in \overline{U}_i$, and $\overline{U}_i$ is equal to either $\overline{\Upsilon}_1$ or $\overline{\Upsilon}_3$.

To prove regularity for general γ, we introduce the return map $\gamma_\mu : I \to I$, $\mu \in I$, defined by $\gamma_\mu(t) = (1 - \mu)t + \mu\gamma(t)$ which interpolates between γ and the identity γ_0. Since $\gamma_\mu(t) \le t$, Proposition 4 holds with γ_μ in place of γ; we denote the solutions as $p_i(t, \mu)$, noting that they are continuous functions of μ, and prove that they are regular for $\mu \in I$.

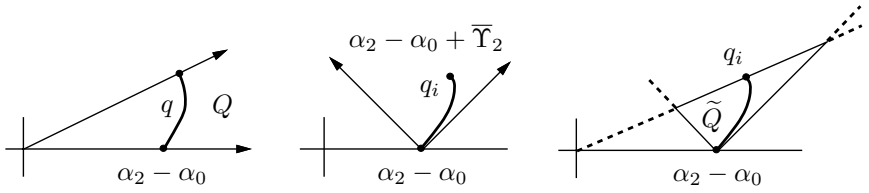

FIG. 7. *This figure pertains to the proof of Lemma* 4. *Q is the sector generated by q. The curves q_i are in Q and in $\alpha_2 - \alpha_0 + \overline{\Upsilon}_2$ and hence in their intersection, denoted $\widetilde{Q}$.*

LEMMA 4. *The curves p_0 and p_2 resulting from Proposition* 4 *are regular. p_2 is in the inside of p_0 and vice versa.*

Proof. Denote the now μ-dependent coefficients of (13) and (14) by $N_0(t,\mu)$ and $N_2(t,\mu)$, resp., and define the curves

$$q_0(t,\mu) = p_2(t,\mu) - p_0(t,\mu), \qquad q_2(t,\mu) = p_2(t,\mu) - p_0(\gamma_\mu(t),\mu).$$

It is enough to show that the numerators $q_0(t,\mu)\cdot \dot{v}_2(t)$ in N_0 and $q_2(t,\mu)\cdot \dot{v}_0(t)$ in N_2 are nonzero and we do this by proving that $q_i(t,\mu) \in \Upsilon_1$, $i = 0, 2$, for $(t,\mu) \in I \times I$.

Let $J = \{\mu \in I : q_i(t,\mu) \in \Upsilon_1; t \in I, i = 0, 2\}$. Since γ_μ is the identity for $\mu = 0$, and $q_i(t,0) = q(t) \in \Upsilon_1$ for $t \in I$, J is not empty. Since Υ_1 is open, J is open. Define

$$Q = \bigcup_{\kappa \geq 0, t \in I} \kappa\, q(t) \qquad \widetilde{Q} = Q \bigcap (\alpha_2 - \alpha_0 + \overline{\Upsilon}_2),$$

see Figure 7, and note that $\widetilde{Q}$ is a closed subset of Υ_1. We show that $\mu \in J$ implies $q_i(t,\mu) \in \widetilde{Q}$ for $t \in I$, from which it follows that J is closed; hence $J = I$.

Let $\mu \in J$. By assumption (A2), $\dot{v}_0(t) \in \overline{U}_0$ and $\dot{v}_2(t) \in \overline{U}_2$ for $t \in I$. Since $q_i(t,\mu) \in \Upsilon_1$, and Υ_1 is equal to either U_0 or U_2, the numerators in N_0 and N_2 are nonzero and of constant but opposite sign for $t \in I$. By Lemma 3, v_0 is in the inside of v_2 and vice versa; hence the denominators are also of constant but opposite sign, and therefore the coefficients $N_i(t,\mu)$ are nonzero and agree in sign on I. By Proposition 4, $\dot{p}_i(0,\mu)$ is in the direction $\alpha_i - \alpha_{i-1} = \mathbf{f}_i \in \overline{\Upsilon}_i$ and hence the signs are such that

$$\dot{p}_i(t,\mu) = N_i(t,\mu)\dot{v}_i(t) \in \overline{\Upsilon}_i. \tag{20}$$

Derivatives of q_i with respect to t are $\dot{q}_0(t,\mu) = \dot{p}_2(t,\mu) - \dot{p}_0(t,\mu)$ and $\dot{q}_2(t,\mu) = \dot{p}_2(t,\mu) - \dot{p}_0(\gamma_\mu(t),\mu)$, and therefore $\dot{q}_i(t,\mu) \in \overline{\Upsilon}_2$. From this we infer

$$q_i(t,\mu) \in q_i(\tau,\mu) + \overline{\Upsilon}_2 \tag{21}$$

for $t, \tau \in I$, $t \geq \tau$. In particular, $q_i(t,\mu) \in \alpha_2 - \alpha_0 + \overline{\Upsilon}_2$ for $t \in I$.

Now suppose there exists a point $q_i(\tau,\mu)$ not in $\widetilde{Q}$. Then by (21), $q_i(1,\mu)$ is not in $\widetilde{Q}$. But this is a contradiction: $t = 1$ is a fixed point of γ_μ, and by (19) must lie on a boundary line of Q, hence on a boundary line of $\widetilde{Q}$. Therefore $q_i(t,\mu) \in \widetilde{Q}$, $t \in I, i = 0, 2$. Thus J is closed and $J = I$. In particular, for $\mu = 1$, the numerators in N_0 and N_2 are nonzero. This proves that the curves p_0 and p_2 are regular.

By (20) we have $p_i(t) \in \alpha_i + \Upsilon_i, t \in I$. Since q_i is in Υ_1, we also have $p_i(t) \in \alpha_{i+1} + \Upsilon_{i-1}, t \in I$. Therefore p_i is in $(\alpha_i + \overline{\Upsilon}_i) \bigcap (\alpha_{i+1} + \Upsilon_{i-1})$, and it follows that p_2 is in the inside of p_0 and vice versa. ∎

THEOREM 3. *Let v_0, v_2 satisfy assumptions* (A1), (A2)*, and let p_0, p_2 be as in Proposition* 4*. Then (v_0, p_0) and (v_2, p_2) are dual pairs.*

Proof. For $i = 0, 2$, $\dot{p}_i(t) \cdot \dot{v}_i(t) = 0$, $t \in I$; thus (v_i, p_i) are orthogonal pairs. $\ddot{p}_i(t) = \dot{N}_i(t)\dot{v}_i^*(t) + N_i(t)\ddot{v}_i^*(t)$ so that $\|\dot{p}_i(t)\ \ddot{p}_i(t)\| = N_i^2(t)\|\dot{v}_i(t)\ \ddot{v}_i(t)\|$. Since p_i is regular by Lemma 4, $N_i(t) \neq 0$, and since v_i is convex the right-hand side is nonzero. Therefore p_i is convex and (v_i, p_i) are dual pairs. ∎

Remark. The assumption $\gamma(t) \leq t$ corresponds to characteristic paths that "spiral inward." The construction above has a natural dual for the case $\gamma(t) \geq t$, i.e., characteristic paths "spiral outward." Namely, we specify curves p_0, p_2 in place of v_0, v_2, and derive a system dual to (13), (14) for which v_0, v_2 are unknowns, and for which $\dot{v}_2(t)$ depends upon $v_0(\gamma^{-1}(t))$. Since $\gamma^{-1}(t) \leq t$, the dual system is a delay system and the method employed above is valid (interchanging v and p).

6.2. Completion of periodic structure. We now construct curves V_1 and V_3 which complete the periodic structure. We first obtain v_1 and v_3 as the solutions to differential equations, and then curves $V_1 = (v_1, S_1)$ and $V_3 = (v_3, S_3)$ by setting $S_1(t) = \mathcal{S}_0(v_1(t))$ and $S_3(t) = \mathcal{S}_2(v_3(t))$. The geometric relationship established in Proposition 4 provides that V_2 will lie in the tangent surface of V_1, and V_0 in the tangent surface of V_3, as shown below in Proposition 6.

In the v-plane, the periodic structure is captured by the diagram $v_0(t) \to v_1(t) \to v_2(t) \to v_3(t) \to v_0(\gamma(t))$. Since we are looking for sonic curves,

$$v_1(t) - v_0(t) = -l_0(t)\dot{v}_0(t), \tag{22}$$

$$v_2(t) - v_1(t) = -l_1(t)\dot{v}_1(t), \tag{23}$$

$$v_3(t) - v_2(t) = -l_2(t)\dot{v}_2(t), \tag{24}$$

$$v_0(\gamma(t)) - v_3(t) = -l_3(t)\dot{v}_3(t), \tag{25}$$

where l_i are positive scalar functions. From (22) we find two expressions for $l_0(t)$, one directly, the other upon differentiation:

$$\frac{\|\ddot{v}_0(t)\ \ v_1(t) - v_0(t)\|}{\|\dot{v}_0(t)\ \ddot{v}_0(t)\|} = l_0(t) = -\frac{\|\dot{v}_0(t)\ \dot{v}_1(t)\|}{\|\dot{v}_0(t)\ \ddot{v}_0(t)\|}. \tag{26}$$

From (23) we have $\dot{v}_1(t) = -(v_2(t) - v_1(t))/l_1(t)$, and inserting this to the right-hand expression for $l_0(t)$ in (26) and then using the left-hand expression yield

$$l_1(t) = -\frac{\|\dot{v}_0(t)\ \ v_2(t) - v_1(t)\|}{\|\ddot{v}_0(t)\ \ v_1(t) - v_0(t))\|}.$$

From (22), $\|\dot{v}_0(t)\ \ v_2(t) - v_1(t)\| = \|\dot{v}_0(t)\ \ v_2(t) - v_0(t)\|$; thus v_1 satisfies the differential equation

$$\dot{v}_1(t) = \frac{\|v_1(t) - v_0(t)\ \ \ddot{v}_0(t)\|}{\|\dot{v}_0(t)\ \ v_0(t) - v_2(t)\|}\ (v_1(t) - v_2(t)). \tag{27}$$

A similar equation holds for v_3:

$$\dot{v}_3(t) = \frac{\|v_3(t) - v_2(t)\ \ \ddot{v}_2(t)\|}{\|\dot{v}_2(t)\ \ v_2(t) - v_0(\gamma(t))\|}\ (v_3(t) - v_0(\gamma(t))). \tag{28}$$

PROPOSITION 5. *Let $i = 1$ (or 3) and let v_i be the unique solution of* (27) (*or* (28) *for $i = 3$) with initial condition $v_i(0) = a_i$. Then v_i is a C^∞ convex curve in $a_i + \overline{U}_i$. For $i = 0, 1, 2, 3$ the functions l_i are positive and v_i is inside v_{i+1}.*

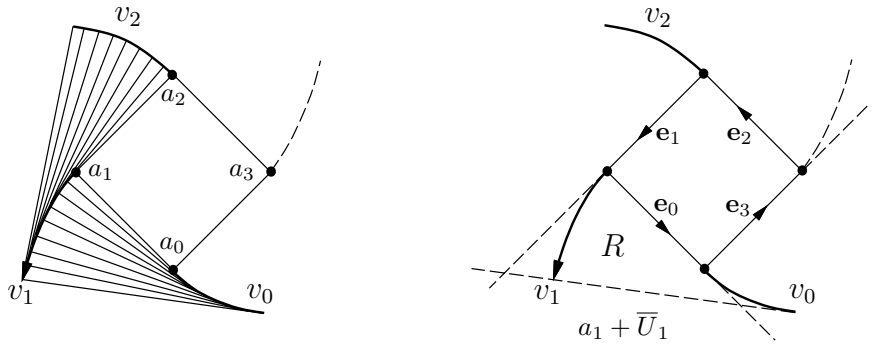

FIG. 8. *The geometrical relationship between v_0, v_1, and v_2. Left: characteristics are tangent to v_0 and v_1. Right: R is the intersection of the tangent surface of v_0 and $a_1 + \overline{U}_1$. v_1 is in R.*

Proof. Let $i = 1$ and consider the intersection R of the sector $a_1 + \overline{U}_1$ with the tangent surface of v_0; see Figure 8. R is a bounded set and since v_2 is inside v_0 (Lemma 3), (27) satisfies a Lipschitz condition on $I \times R$. The relations (22), (23) hold for the initial condition $v_1(0) = a_1 \in R$, and it follows that they hold for the unique C^∞ solution v_1 of (27); thus v_1 is in the tangent surface of v_0, and $l_0(t) > 0$. By assumptions (A1), (A2) the coefficient of $v_1(t) - v_2(t)$ in (27) is positive and thus v_1 is regular and $\dot{v}_1(t)$ has direction $v_1(t) - v_2(t) \in \overline{U}_1$. This implies v_1 is in $a_1 + \overline{U}_1$ and hence in R, and $l_1(t) > 0$. From (23) we compute $l_1(t)\|\dot{v}_1(t)\, \ddot{v}_1(t)\| = -\|\dot{v}_1(t)\, \dot{v}_2(t)\| \neq 0$ by assumptions (A1), (A2), and thus v_1 is convex. Similar results hold for $i = 3$. Finally, since $v_i \in a_i + \overline{U}_i$, v_i is inside v_{i+1} for all i. ∎

We remark that (27), (28) are well defined on equivalence classes of parameterized curves.

Since $l_i(t) > 0$, $v_{i+1}(t)$ is on the characteristic from $v_i(t)$ and we truncate characteristics from v_i along the curve v_{i+1}. Thus the closed set $\mathbf{R}_i$, defined by $\mathbf{R}_i = \bigcup_{t\in I} \bigcup_{0\le s\le l_i(t)} (v_i(t) - s\dot{v}_i(t))$, is the union of (truncated) characteristics tangent to v_i (see Figure 9). We show that the interiors of $\mathbf{R}_i$ and $\mathbf{R}_j$, $i \neq j$, are disjoint. For $j = i + 1$, $\mathbf{R}_i$ is in the inside of v_{i+1} and $\mathbf{R}_{i+1}$ is in the outside of v_{i+1}, hence their intersection is v_{i+1} and this is in the boundary of both. For $j = i + 2$, note that v_i and v_{i+1} are both in the inside of v_{i+2}. Since the inside of a curve is convex, $\mathbf{R}_i$ is inside v_{i+2} and disjoint from $\mathbf{R}_{i+2}$. Thus the union of the sets $\mathbf{R}_i$, $i = 0, 1, 2, 3$, forms a topological annulus, on which we define the periodic structure as follows.

Dual pair (v_0, p_0) generates a curve $V_0 = (v_0, S_0)$ which in turn generates a tangent surface described by a function $\mathcal{S}_0$ defined on $\mathbf{R}_0$. Similarly, dual pair (v_2, p_2) generates a curve V_2 and a tangent surface described by a function $\mathcal{S}_2$ defined on $\mathbf{R}_2$. The curves V_0, V_2, and hence the tangent surfaces, are unique up to additive constants and we fix these such that $S_2(0) - S_0(0) = \alpha_0 \cdot (a_2 - a_0)$. Curve v_1 is in the domain of $\mathcal{S}_0$ and v_3 is in the domain of $\mathcal{S}_2$, and we define $S_1(t) = \mathcal{S}_0(v_1(t))$ and $S_3(t) = \mathcal{S}_2(v_3(t))$. The curves $V_1(t) := (v_1(t), S_1(t))$ and $V_3(t) := (v_3(t), S_3(t))$ generate unique tangent surfaces given by functions $\mathcal{S}_1$ on $\mathbf{R}_1$ and $\mathcal{S}_3$ on $\mathbf{R}_3$. The four tangent surfaces define a periodic structure $\mathcal{S}$ on the topological annulus. Note that by Lemma 1(a) we obtain curves p_1, p_3 for the gradients $D\mathcal{S}_1$, $D\mathcal{S}_3$.

PROPOSITION 6. $\mathcal{S}_{i-1}(v_i(t)) = \mathcal{S}_i(v_i(t))$.

Proof. By construction the claim is true for $i = 1, 3$. Let $i = 0$, the case $i = 2$ is proved analogously. By the choice of additive constants, (17), (18) of Proposi-

tion 4 hold. From Proposition 5, $V_3(t)$ lies on the characteristic from $V_2(t)$ on which $D\mathcal{S}_2(t) = p_2(t)$. Thus $S_3(t) - S_2(t) = p_2(t) \cdot (v_3(t) - v_2(t))$. Subtracting this from (18) yields $S_0(\gamma(t)) - S_3(t) = p_2(t) \cdot (v_0(\gamma(t)) - v_3(t)) = p_3(t) \cdot (v_0(\gamma(t)) - v_3(t))$, where the second equality follows from $(p_2(t) - p_3(t)) \cdot \dot{v}_3(t) = 0$ of Lemma 2(a) and $\|\dot{v}_3(t)\ v_0(\gamma(t)) - v_3(t)\| = 0$. But then $\mathcal{S}_0(v_0(\gamma(t))) = S_0(\gamma(t)) = S_3(t) + p_3(t) \cdot (v_0(\gamma(t)) - v_3(t)) = \mathcal{S}_3(v_0(\gamma(t)))$. □

THEOREM 4. *Let $\{a_i\}$, $\{\alpha_i\}$ be square dual quadrilaterals centered at the origin, and let curves v_0, v_2 satisfy assumptions* (A1), (A2)*, and diffeomorphisms $\phi_{012} : v_0 \to v_2$, $\phi_{230} : v_2 \to v_0$ have return map $\gamma(t) \le t$. Then $\mathcal{S}$ is a periodic structure, unique up to an additive constant.*

Proof. By Proposition 6, $\mathcal{S}$ is continuous and so characteristics tangent to V_i form a map from V_i to V_{i+1}. Since the maps ϕ_{012} and ϕ_{230} are orientation-preserving diffeomorphisms and the curves V_i are regular, the characteristic maps from V_i to V_{i+1} are orientation-preserving diffeomorphisms. Hence $\mathcal{S}$ is a periodic structure. S_0 and S_2 are unique up to an additive constant and $\mathcal{S}$ is unique up to this constant also. □

Since $V_{i+1}(0)$ is on the characteristic from $V_i(0)$ for each i, these points are joined by an orbit. Algebraically we find $p_1(0) = \alpha_1$ and $p_3(0) = \alpha_3$. Characteristics joining points $V_{i+1}(1)$ also form an orbit with dual quadrilaterals $\{b_i\} := \{v_i(1)\}$ and $\{\beta_i\} := \{p_i(1)\}$.

6.3. Dual periodic structure completed. We continue our development by showing that (v_1, p_1) and (v_3, p_3) are dual pairs. This allows us to define a *dual* periodic structure $\mathcal{O}$, composed of tangent surfaces $\mathcal{H}_i$ dual to $\mathcal{S}_i$. The dual characteristics comprising the dual periodic structure correspond to the chords of super- and subderivatives $C^{\wedge\vee}(v_i)$ of the periodic structure $\mathcal{S}$. We use the dual periodic structure to show that $\mathcal{S}$ satisfies the Oleĭnik condition for the Hamiltonian $\mathcal{H}$ constructed in section 7.

Since adjacent surfaces $\mathcal{S}_i$ join continuously, from Lemma 2(a), the jump in $D\mathcal{S}$ across V_i is orthogonal to $\dot{v}_i(t)$, hence parallel to $\dot{p}_i(t)$. If $\dot{p}_i(t) \neq 0$, we have

$$p_3(t) - p_0(\gamma(t)) = -\lambda_0(\gamma(t))\dot{p}_0(\gamma(t)), \tag{29}$$

$$p_0(t) - p_1(t) = -\lambda_1(t)\dot{p}_1(t), \tag{30}$$

$$p_1(t) - p_2(t) = -\lambda_2(t)\dot{p}_2(t), \tag{31}$$

$$p_2(t) - p_3(t) = -\lambda_3(t)\dot{p}_3(t) \tag{32}$$

for scalar functions λ_i. We have not yet shown that p_1 and p_3 are regular; however by Lemma 4, *p_0 and p_2 are regular, and* (29) *and* (31) *are valid.* Using the fact that $p_1(t)$ lies on a characteristic tangent to the convex curve p_2 and has direction orthogonal to $\dot{v}_1(t)$, it follows that $\lambda_2(t) > 0$. From (31) we find that $\|\dot{p}_2(t)\, \dot{p}_1(t)\| = -\lambda_2(t)\|\dot{p}_2(t)\, \ddot{p}_2(t)\| \neq 0$; hence $\dot{p}_1(t) \neq 0$ and p_1 is regular. Since $\dot{p}_1(t) \perp \dot{v}_1(t)$ and v_1 is convex, p_1 is convex, and (v_1, p_1) is a dual pair. Moreover, $\lambda_1(t) > 0$ and p_1 is in $\alpha_1 + \overline{\Upsilon}_1$; it follows that p_1 is in the inside of p_0. Similar results hold for p_3. We summarize these results in the following lemma.

LEMMA 5. *p_i is regular and in $\alpha_i + \overline{\Upsilon}_i$. The functions λ_i are positive. (v_i, p_i) are dual pairs. p_i is in the inside of p_{i-1}.*

Let the functions $H_i : I \to \mathbb{R}$ be dual to S_i (Definition 3). Then curves $P_i := (p_i, H_i)$ are dual to $V_i = (v_i, S_i)$ and generate tangent surfaces $\mathcal{H}_i$ dual to $\mathcal{S}_i$.

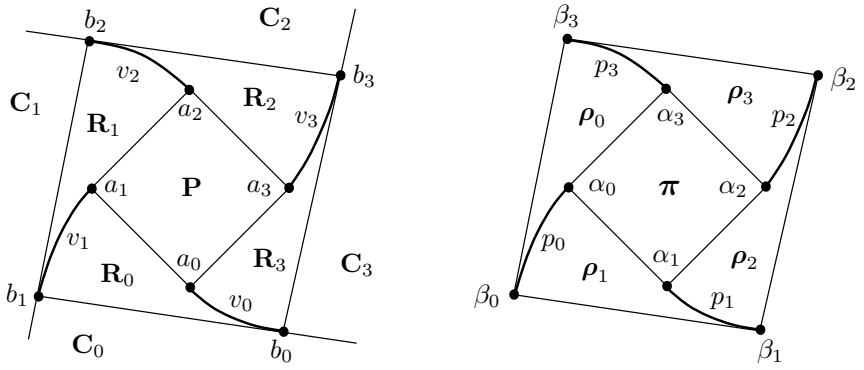

FIG. 9. *Constructed solution $\mathcal{S}$ in the v- and p-planes. Left: domains $\mathbf{C}_i$ of plane waves, $\mathbf{R}_i$ of sonic rarefactions, and $\mathbf{P}$ of a parabolic wave. $\mathcal{S}$ forms a convex edge along v_i for $i = 0, 2$ and a concave edge for $i = 1, 3$. Right: $\mathcal{H}$ is defined by $\mathcal{O}$ on $\boldsymbol{\pi}$ and curves p_i, and extended to the plane.*

PROPOSITION 7. $\mathcal{H}_{i+1}(p_i(t)) = \mathcal{H}_i(p_i(t))$.

Proof. Let $f(t) = \mathcal{H}_{i+1}(p_i(t)) - \mathcal{H}_i(p_i(t))$. From Proposition 2(b), $\dot{f}(t) = (v_{i+1}(t) - v_i(t)) \cdot \dot{p}_i(t)$ for $i = 0, 1, 2$ and $\dot{f}(t) = (v_0(\gamma(t)) - v_3(t)) \cdot \dot{p}_3(t)$ for $i = 3$. By (22)–(25), $\dot{f}(t) = 0$; hence f is a constant. Since H_i is dual to S_i, $f(0) = H_i(0) - H_{i-1}(0) - a_i \cdot (\alpha_i - \alpha_{i-1}) = 0$, thus $f \equiv 0$. ∎

Since $\lambda_i(t) > 0$, $p_{i-1}(t)$ is on the dual characteristic tangent at $p_i(t)$ and we truncate dual characteristics tangent to p_i along p_{i-1}. The union of these dual characteristics form closed sets $\boldsymbol{\rho}_i$ defined by $\boldsymbol{\rho}_i = \bigcup_{t \in I} \bigcup_{0 \le \sigma \le \lambda_i(t)} (p_i(t) - \sigma \dot{p}_i(t))$. As shown for the sets $\mathbf{R}_i$, the interiors of $\boldsymbol{\rho}_i$ and $\boldsymbol{\rho}_j$, $i \neq j$, are disjoint; hence their union is a topological annulus. We define the *dual periodic structure* $\mathcal{O}$ by $\mathcal{O}(p) = \mathcal{H}_i(p)$ for $p \in \boldsymbol{\rho}_i$. By Proposition 2(c), where it is differentiable, $\mathcal{S}$ satisfies (1) with $\mathcal{H} \equiv \mathcal{O}$.

THEOREM 5. *The dual periodic structure $\mathcal{O}$, up to a reordering of indices, is a periodic structure. The chord of $C^{\wedge\vee}(v_i(t))$ is the graph of $\mathcal{O}$ restricted to the line segment $p_{i-1}(t)p_i(t)$.*

Proof. By Proposition 7 $\mathcal{O}$ is continuous, and by Lemma 5 the curves P_i are regular, thus dual characteristics from P_i to P_{i-1} form orientation-preserving diffeomorphisms. Therefore $\mathcal{O}$ is a periodic structure with indices reversed. $C^{\wedge\vee}(v_i(t))$ is the convex hull of $p_{i-1}(t)$ and $p_i(t)$; hence the graph of $\mathcal{O}$ between these points is its chord. ∎

7. Proof of the main theorem. We now construct a function $\mathcal{S}$, Riemann data $\{\beta_i\}$, and a Hamiltonian $\mathcal{H}$ such that $\mathcal{S}$ is the Riemann solution to (1), (2). Let $\{a_i\}$, $\{\alpha_i\}$ be the dual quadrilaterals (Corollary 1) of the example of section 3. By section 6 we obtain a periodic structure composed of functions $\mathcal{S}_i$, and its dual periodic structure composed of functions $\mathcal{H}_i$, having inner orbit given by $\{a_i\}$, $\{\alpha_i\}$ and outer orbit given by $\{b_i\}$, $\{\beta_i\}$; see Figure 9. Let $\mathbf{P}$ be the convex hull of $\{a_i\}$. $\mathcal{P}$ defined by $\mathcal{P}(v) = (x^2 - y^2)/2$, $v = (x, y) \in \mathbf{P}$ is the parabolic wave of section 3. We define sets $\mathbf{C}_i = b_{i+1} + \bigcup_{\kappa, \kappa' \ge 0} \kappa(b_i - b_{i+1}) + \kappa'(b_{i+1} - b_{i+2})$, and plane waves $\mathcal{C}_i(v) = \beta_i \cdot (v - b_{i+1}) + \mathcal{S}_{i+1}(b_{i+1}), v \in \mathbf{C}_i$. $\mathbf{P}$, $\mathbf{R}_i$, and $\mathbf{C}_i$ have disjoint interiors and the solution $\mathcal{S}$ is defined by

$$\mathcal{S}(v) = \begin{cases} \mathcal{P}(v), & v \in \mathbf{P}, \\ \mathcal{S}_i(v), & v \in \mathbf{R}_i, \\ \mathcal{C}_i(v), & v \in \mathbf{C}_i. \end{cases} \tag{33}$$

This yields Riemann data $\{\beta_i\}$ by letting $v \to \infty$ in $\mathbf{C}_i$.

Let $\boldsymbol{\pi}$ be the convex hull of $\{\alpha_i\}$ and define $\boldsymbol{\pi}_0$ to be the union of $\boldsymbol{\pi}$ and the curves p_i.

PROPOSITION 8. *$\mathcal{S}$ is continuous, and at points of differentiability satisfies* (1) *with*

$$\mathcal{H}(p) = \begin{cases} (\xi^2 - \eta^2)/2, & p \text{ in } \boldsymbol{\pi}, \\ \mathcal{H}_i(p), & p \text{ on } p_i. \end{cases} \tag{34}$$

Proof. The inner orbit is the boundary of the parabolic wave and the outer orbit coincides with the plane waves, hence $\mathcal{S}$ is continuous. By Propositions 1 and 2(c), $\mathcal{S}$ satisfies (1) in $\mathbf{P}$ and $\mathbf{R}_i$, and by construction, satisfies it in $\mathbf{C}_i$. □

PROPOSITION 9. *For the given choice of dual quadrilaterals,*

$$\text{for } i = 0, 2 : \mathcal{S} \text{ satisfies Oleĭnik condition along } v_i \Leftrightarrow \mathcal{H}(p) \geq \mathcal{O}(p),\ p \in \boldsymbol{\rho}_i, \tag{35}$$

$$\text{for } i = 1, 3 : \mathcal{S} \text{ satisfies Oleĭnik condition along } v_i \Leftrightarrow \mathcal{H}(p) \leq \mathcal{O}(p),\ p \in \boldsymbol{\rho}_i. \tag{36}$$

Proof. For the choice of dual quadrilaterals, $V_i = (v_i, \mathcal{S}(v_i))$ is a convex edge for $i = 0, 2$, and is a concave edge for $i = 1, 3$. Thus $C^{\wedge\vee}(v_i(t)) = C^{\vee}(v_i(t))$ for $i = 0, 2$ and $C^{\wedge\vee}(v_i(t)) = C^{\wedge}(v_i(t))$ for $i = 1, 3$. By Theorem 5 the chord of $C^{\wedge\vee}(v_i(t))$ is given by $\mathcal{O}$ on $\boldsymbol{\rho}_i$, and the result follows (see Oleĭnik, section 2). □

Note that if we extend $\mathcal{H}$ by defining $\mathcal{H}(p) = \mathcal{O}(p)$ for $p \in \boldsymbol{\rho}_i$, and then extend further to the plane in any continuous manner, we obtain a solution with a period 4 sonic sequence for a C^0 Hamiltonian. To prove Theorem 1 we extend $\mathcal{H}$, given by (34) on $\boldsymbol{\pi}_0$, to a C^1 function such that (35), (36) hold. Equation (34) specifies derivatives of $\mathcal{H}$ on $\boldsymbol{\pi}$ and tangential derivatives on p_i. To obtain a C^1 extension we specify transverse derivatives on p_i by letting

$$D_p \mathcal{H}(p_i(t)) = v_{i+1}(t). \tag{37}$$

LEMMA 6. *$\mathcal{H}$ given by* (34), (37) *is C^1 on the closed set $\boldsymbol{\pi}_0$.*

Proof. From (34), by Proposition 2(b) and (29)–(32), $\dot{\mathcal{H}}(p_i(t)) = \dot{\mathcal{H}}_i(p_i(t)) = v_i(t) \cdot \dot{p}_i(t) = v_{i+1}(t) \cdot \dot{p}_i(t)$, agreeing with (37) and $\mathcal{H}$ is well defined on $\boldsymbol{\pi}_0$. Since $v_{i+1}(0) = a_{i+1} = D_p \mathcal{H}(\alpha_i)$ (evaluated in $\boldsymbol{\pi}$), $\mathcal{H}$ is C^1 at $p = \alpha_i$, hence C^1 on $\boldsymbol{\pi}_0$. □

For the choice (37), characteristics from v_i are directed toward v_{i+1} (see (6)) and the necessary Lax condition is satisfied. The derivatives of $\mathcal{H}$ in directions normal to the boundary of $\boldsymbol{\rho}_i$ are consistent with the Oleĭnik conditions (35), (36). Using the approximation theory of Whitney [27] there exists a C^1 extension $\mathcal{H} : \mathbb{R}^2 \to \mathbb{R}$ so that (35), (36) are satisfied.

PROPOSITION 10. *$\mathcal{S}$ is a Riemann solution to* (1) *with data $\{\beta_i\}$ and Hamiltonian $\mathcal{H} : \mathbb{R}^2 \to \mathbb{R}$.*

Proof. At infinity, $\mathcal{S}$ has gradient matching the Riemann data. By Proposition 8, $\mathcal{S}$ is continuous and a solution of (1). On the curves v_i, the Oleĭnik condition is satisfied by (35) and (36). On the boundary of $\mathbf{P}$ the one-sided gradients of $\mathcal{S}$ are the same as those in Proposition 1 and therefore the Oleĭnik condition is satisfied for $\mathcal{S}$. □

Thus the periodic structure in $\mathcal{S}$ is a period 4 sonic sequence and this proves Theorem 1.

8. Concluding remarks. We have shown that there exist C^1 Hamiltonians and Riemann data such that the corresponding Riemann problem has Riemann solution containing a period 4 sonic sequence. Our construction allows for return maps satisfying $\gamma(t) \leq t$, corresponding to inward spiraling periodic structures, and $\gamma(t) \geq t$,

corresponding to outward spiraling structures. Although the periodic sequence inner orbit was specified by square dual quadrilaterals, examination of the principal equations shows that they are well defined for arbitrary dual quadrilaterals. Thus, by using the dual quadrilaterals of the outer orbit of one periodic sequence as the inner orbit of another, the restrictions $\gamma(t) \geq t$ and $\gamma(t) \leq t$ can be relaxed, resulting in solutions with richer interval dynamics.

The C^1 Hamiltonian $\mathcal{H}$ used for the proof of Theorem 1 may be chosen to be C^∞ at points other than the four gradients α_i corresponding to the inner orbit. At these points, a convex curve joins to a straight line and thus $\mathcal{H}$ fails to be C^2. However, numerical work (discussed in [22]) suggests that solutions containing periodic sonic sequences exist for real analytic Hamiltonians, and that to prove Theorem 1 for such Hamiltonians we should consider a complex interaction between sonic rarefactions and the parabolic wave in which the parabolic wave boundary is not a straight line and characteristics leave it tangentially.

EXACT MULTIPLICITY AND S-SHAPED BIFURCATION CURVE FOR SOME SEMILINEAR ELLIPTIC PROBLEMS FROM COMBUSTION THEORY*

YIHONG DU†

Abstract. In this paper, by making use of a new limiting equation and a continuation method based on a local bifurcation theorem of Crandall and Rabinowitz, we rigorously confirm some long-standing conjectures on the exact number of positive solutions for a class of elliptic equations arising from combustion theory. This work extends that of [S.-H. Wang, *Proc. Roy. Soc. London Sect. A,* 454 (1998), pp. 1031–1048] for the 1 dimension case to cover both dimensions 1 and 2, and it extends the work of [Y. Du and Y. Lou, *J. Differential Equations,* to appear] for the special case $m = 0$ to $0 \le m < 1$. It is shown that the main results are not true if the dimension is greater than 2 or if $m \ge 1$. Therefore, our results are in a sense the best possible.

1. Introduction.

We are interested in the exact structure of the positive solution set $\{(\mu, v)\}$ of the problem

$$-\Delta v = \mu(1+\epsilon v)^m e^{v/(1+\epsilon v)} \text{ in } B,\ v = 0 \text{ on } \partial B, \tag{1.1}$$

where B is the unit open ball in R^n $(n \ge 1)$, $\epsilon > 0, m \ge 0$, are constants, and $\mu > 0$ is treated as a bifurcation parameter. By a positive solution, we mean $v > 0$ in B.

Problem (1.1) arises in combustion theory, where μ is known as the Frank–Kamenetskii parameter, v the dimensionless temperature, and ϵ the reciprocal activation energy. We refer to [4], [31], [33], and the references therein for more background.

The case that ϵ is small and $0 \le m < 1$, especially $m = 0$ (Arrhenius reaction rate) and $m = 1/2$ (bimolecular reaction rate), is of particular interest in applications and has attracted considerable amount of studies (see, e.g., [3], [4], [9], [22], [29], [31], [32], [33], and the references therein). On the basis of numerical studies, it has long been believed that the positive solution set $\{(\mu, v)\}$ of (1.1) is an S-shaped smooth curve provided that $0 \le m < 1$, ϵ is small and the space dimension $n = 1$ or 2. For dimension $n = 1$, this was rigorously proved recently by Wang [33], and for dimension $n = 2$, this was proved only for $m = 0$ by Du and Lou [9]. In this paper, among other things, we extend the result of [9] for $m = 0$ to all $0 \le m < 1$ and determine exactly how the solution curve changes once $m \ge 1$ for both dimensions 1 and 2. We also discuss briefly the higher dimension case. Our techniques can be applied to problems with more general nonlinearities, but we restrict ourselves to (1.1) for simplicity and its clear physical significance.

To explain the method we use in this paper, we must mention a closely related problem. In catalysis theory, there is an equation closely related to (1.1); under some

simple changes of variables, it reduces essentially to

$$-\Delta v = \mu(1-\epsilon v)^p e^{v/(1+\epsilon v)} \text{ in } B, \quad v = 0 \text{ on } \partial B, \tag{1.2}$$

where p is a nonnegative integer (see, e.g., Aris [2, Vol. 1, Chapter 4]). Let us note that when $p = 0$ and $m = 0$, both (1.1) and (1.2) reduce to the so-called perturbed Gelfand equation (see [3] for more details)

$$-\Delta v = \mu e^{v/(1+\epsilon v)};$$

and when $\epsilon = 0$, both (1.1) and (1.2) reduce to the well-known Gelfand equation

$$-\Delta v = \mu e^v.$$

For (1.2), it has been conjectured that for any nonnegative integer p, the positive solution set $\{(\mu, v)\}$ is S-shaped provided $\epsilon > 0$ is small and the dimension $n = 1$ or 2. The conjecture was proved to be true for $n = 1$ by Hastings and McLeod [17] (see also [32], [34], and [22] for further results). For $n = 2$, the conjecture is only rigorously proved by the above-mentioned work of Du and Lou [9] for $p = 0$.

Dancer [7] introduced a useful abstract perturbation method and used it to study (1.2) for small $\epsilon > 0$ and all dimension $n \geq 1$, taking the point of view that (1.2) is a perturbation of the Gelfand equation. Since the positive solution curve of the Gelfand equation on a ball is completely understood (see [19]), Dancer was able to show, among other things, that when $3 \leq n \leq 9$, (1.2) can have a large number of positive solutions at some particular values of μ if ϵ is sufficiently small. Dancer's method can be extended to (1.1). Therefore, the solution set of (1.1) in dimensions 3–9 is more complicated than S-shaped for small ϵ. In [20] and [21], asymptotic methods were used to study (1.2) with $p = 1$ and $1 \leq n \leq 3$. The numerical pictures of the bifurcation curves in these papers strongly support what was conjectured about (1.2) and agree very well with the results in [7].

Unfortunately, as we will explain below, our techniques in this paper work for (1.1) but do not seem to work for (1.2). One of the new ingredients in our approach is a new limiting problem. In order to see how this limiting problem arises naturally, as in [9], we take a different point of view to [7]. Let

$$u = \epsilon^2 v, \quad \lambda = (\epsilon^2 e^{1/\epsilon})\mu.$$

Then (1.1) becomes

$$-\Delta u = \lambda(u+\epsilon)^m e^{-1/(u+\epsilon)} \text{ in } B, \quad u = 0 \text{ on } \partial B. \tag{1.3}$$

We will regard (1.3) as a perturbation of

$$-\Delta u = \lambda u^m e^{-1/u} \text{ in } B, \quad u = 0 \text{ on } \partial B. \tag{1.4}$$

Clearly, for fixed $\epsilon > 0$, the shape of the positive solution curve $\{(\mu, v)\}$ of (1.1) is the same as that of the positive solution curve $\{(\lambda, u)\}$ of (1.3). From now on, we will focus on (1.3) rather than (1.1).

It turns out that the solution set $\{(\lambda, u)\}$ of (1.3) is determined completely by that of (1.4) when $n = 1, 2$, even for large ϵ. For $n \geq 3$, (1.4) determines part of the solution curve of (1.3). Therefore, we will have a detailed study of (1.4).

One might wonder whether such a change of variables trick can also be employed for (1.2). But unfortunately, since any positive solution v of (1.2) satisfies $\epsilon v \leq 1$, this trick does not seem promising for small ϵ.

We will actually obtain a complete understanding of the solution set of (1.4) for any $m \geq 0$ and in all dimensions. Let $n^* = (n+2)/(n-2)$ if $n > 2$ and $n^* = \infty$ if $n = 1, 2$, and let λ_1 denote the first eigenvalue of

$$-\Delta u = \lambda u, \quad u|_{\partial B} = 0.$$

Then our results on (1.4) can be summarized as follows:

- *If $m \geq n^*$ (hence $n > 2$), then* (1.4) *has no positive solution for any $\lambda > 0$.*
- *If $1 < m < n^*$, then* (1.4) *has a unique positive solution for any $\lambda > 0$.*
- *If $m = 1$, then* (1.4) *has no positive solution for $\lambda \leq \lambda_1$, and it has a unique positive solution for $\lambda > \lambda_1$.*
- *If $0 \leq m < 1$, then there exists $\lambda_0 > 0$ such that* (1.4) *has no positive solution for $\lambda < \lambda_0$; it has exactly one positive solution for $\lambda = \lambda_0$ and exactly two positive solutions for $\lambda > \lambda_0$.*

It is well known that when Ω is a ball centered at the origin, then any positive solution (λ, u) of $-\Delta u = \lambda f(u),\ u|_{\partial\Omega} = 0$ is uniquely determined by $(\lambda, u(0))$. Therefore, the positive solution curve $\{(\lambda, u)\}$ in $R \times C(\overline{B})$ is well represented by the curve $\{(\lambda, u(0))\}$ in R^2. We will also call $\{(\lambda, u(0))\}$ the positive solution curve. Moreover, we would say (λ, u) is above $(\tilde{\lambda}, \tilde{u})$ if $(\lambda, u(0))$ is above $(\tilde{\lambda}, \tilde{u}(0))$ in R^2, etc.

Our results in section 2 show that the shape of the positive solution curve $\{(\lambda, u(0))\}$ of (1.4) can be described by the diagrams in Figure 1 (see Theorems 2.5–2.7 for more details).

With the help of (1.4), we can obtain a very good understanding of (1.3) for $n = 1, 2$, while the case $n \geq 3$ is still incompletely understood. The results for $n = 1, 2$ are described by the diagrams in Figure 2 (see Theorems 3.3–3.6 for more details).

Central to our approach in this paper is a continuation method which we describe briefly below.

Set $X = C_0^{2,\alpha}(\overline{B})$, $Y = C^{\alpha}(\overline{B})$, and $F(\lambda, u) = \Delta u + \lambda f(u)$, where $f(u)$ is a smooth function. Clearly,

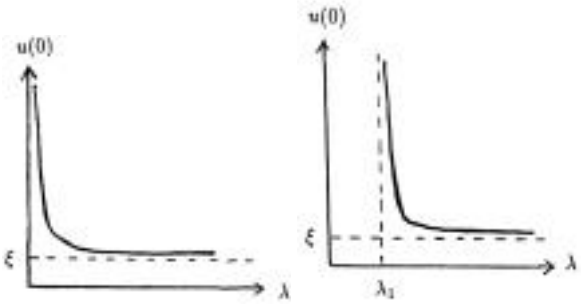
$$-\Delta u = \lambda f(u), \quad u|_{\partial B} = 0 \tag{1.5}$$

is equivalent to $F(\lambda, u) = 0$. It is easy to see that F is a smooth Fredholm mapping of index zero from $R^+ \times X$ to Y, and the partial derivative F_u at (λ, u) is given by $F_u(\lambda, u)\phi = \Delta\phi + \lambda f'(u)\phi$. If (λ_0, u_0) is not a degenerate solution, that is, if the linearization

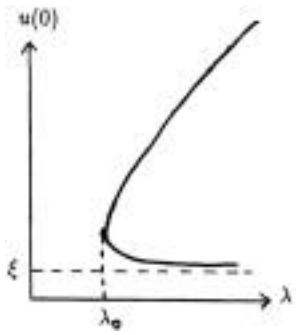
$$-\Delta\phi = \lambda_0 f'(u_0)\phi, \quad \phi|_{\partial B} = 0 \tag{1.6}$$

has no nontrivial solution ϕ, then it follows from the implicit function theorem that the solutions of (1.5) near (λ_0, u_0) form a smooth curve parametrized by λ. In other words, the solution curve can be continued from (λ_0, u_0) to both the left and the right of this point.

If (λ_0, u_0) is degenerate, i.e., (1.6) has a nontrivial solution, then the solution set of (1.5) near (λ_0, u_0) could be extremely complicated. However, if one can show that any nontrivial solution ϕ of (1.6) does not change sign in B, then the conditions of Theorem 3.2 of Crandall and Rabinowitz [5] are usually satisfied, and hence, by



(a) $1 < m < n^*$. (b) $m = 1$.



(c) $0 \le m < 1$.

FIG. 1. *Positive solution curve of* (1.4)*, where* $\xi > 0$ *when* $n > 2, \xi = 0$ *when* $n = 1, 2$.

this theorem, near the degenerate solution (λ_0, u_0), the solutions of (1.5) still form a smooth curve which is expressed in the form

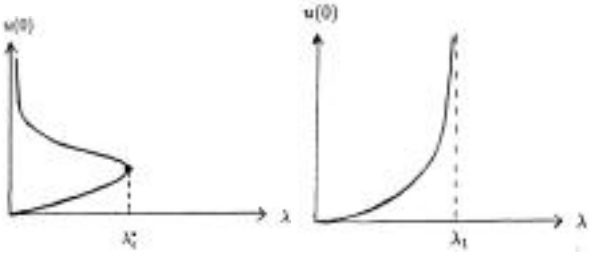
$$(\lambda(s), u(s)) = (\lambda_0 + \tau(s), u_0 + s\phi + z(s)), \tag{1.7}$$

where $s \to (\tau(s), z(s)) \in R \times Z$ is a smooth function near $s = 0$ with $\tau(0) = \tau'(0) = 0, z(0) = z'(0) = 0$, where Z is a complement of span$\{\phi\}$ in X, and ϕ is the positive solution of (1.6), which is unique if normalized.

From the expression (1.7), we see that the solution curve makes a turn to the left at (λ_0, u_0) if $\tau''(0) < 0$, and it turns to the right if $\tau''(0) > 0$. Substituting expression (1.7) to (1.5), one easily deduces that (see [1, Prop. 20.2] for a more general version of this formula)

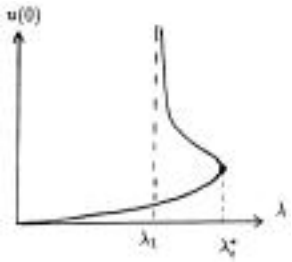
$$\tau''(0) = -\lambda_0 \frac{\int_B f''(u_0)\phi^3 dx}{\int_B f(u_0)\phi dx}. \tag{1.8}$$

Now we come to the key point of this continuation method, which allows one to determine the global shape of the bifurcation curve provided that certain information from the linearization of (1.5) can be obtained. More precisely, if one can show that whenever (1.5) has a degenerate solution, then the solutions of the linearized problem

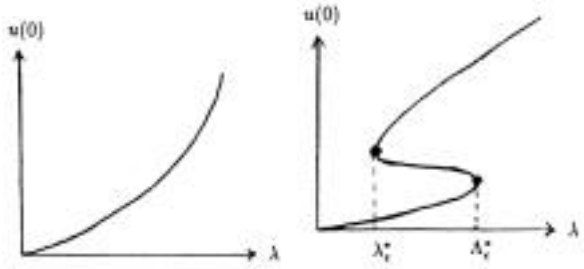


(a) $m > 1, \epsilon > 0$.
$\lim_{\epsilon \to 0} \lambda_\epsilon^* = \infty$,
$\lim_{\epsilon \to \infty} \lambda_\epsilon^* = 0$.

(b) $m = 1, \epsilon \geq 1$.



(c) $m = 1, 0 < \epsilon < 1$.
$\lim_{\epsilon \to 0} \lambda_\epsilon^* = \infty$,
$\lim_{\epsilon \to 1} \lambda_\epsilon^* = \lambda_1$.



(d) $0 \leq m < 1$,
$\epsilon \geq (1 + \sqrt{1-m})^{-2}$.

(e) $0 \leq m < 1$,
$0 < \epsilon << 1$.
$\lim_{\epsilon \to 0} \lambda_\epsilon^* = \lambda_0$,
$\lim_{\epsilon \to 0} \Lambda_\epsilon^* = \infty$.

FIG. 2. *Positive solution curve of* (1.3) *for* $n = 1, 2$.

(1.6) do not change sign, and furthermore, the corresponding $\tau''(0)$ can be proved to have the same sign by using (1.8) at any degenerate solution, then starting from any solution of (1.5), the solution curve can be continued, either by the implicit function theorem or by the Crandall–Rabinowitz theorem. More importantly, one cannot meet more than one degenerate solution in this process of continuation since the solution curve makes a turn to the same direction whenever it meets a degenerate one. Thus,

such a priori knowledge on $\tau''(0)$ determines the number of degenerate solutions on the global bifurcation curve: there is at most one degenerate solution, and hence on the whole bifurcation curve there can be at most one turning point.

The above continuation method has proved to be particularly useful in tackling bifurcation curves with exactly one turning point (see, e.g., [8], [10], [23], [28], [35], and the references therein). In section 2, we will also use this method to prove some uniqueness results. To handle S-shaped bifurcation curves in section 3, where two turning points occur on the curve, we combine this continuation method with a perturbation technique developed in [8] (see also [9], [10], and [11]).

The continuation method described above goes one step further from a well-known continuation method introduced much earlier, where the expressions (1.7) and (1.8) were used to obtain only local exact multiplicity results (see, e.g., [1], [6]). More precisely, in these earlier works, (1.7) and (1.8) were used to deal with the first turning point on the bifurcation curve which occurs when a smooth branch of stable solutions first loses stability, but the number of degenerate solutions along the global bifurcation curve is not determined, and hence the exact shape of the bifurcation curve beyond the first turning point is not determined. In this work and those mentioned in the last paragraph, the number of degenerate solutions on the bifurcation curve is determined through a priori estimates on the sign of $\tau''(0)$ at all possible degenerate solutions. This last part actually constitutes the most difficult part in the continuation method described before this paragraph and can be done only for certain nonlinear problems.

One of the referees pointed out the following recent papers, [13], [14], and [25], where the well-known continuation method is used to analyze global bifurcation branches for various nonlinear problems.

The rest of the paper is organized as follows. In section 2, we study the limiting equation (1.4). In section 3, we discuss the perturbed equation (1.3) for dimensions 1 and 2. In section 4, we discuss rather briefly the higher dimensional case for (1.3).

2. The limiting equation. In this section, we consider

$$-\Delta u = \lambda u^m e^{-1/u} \equiv \lambda f(u), \quad u|_{\partial B} = 0, \tag{2.1}$$

where $\lambda > 0,\ m \geq 0$ and $B = \{x \in R^n : |x| < 1\}, n \geq 1$. We will obtain a complete understanding for the positive solution set of (2.1). Let us note that f is C^∞ in $[0, \infty)$, including 0.

We begin with some technical but important lemmas.

LEMMA 2.1. *Suppose $0 \leq m < n^*$. If u is a degenerate positive solution of* (2.1) *and ϕ is a nontrivial solution to*

$$-\Delta\phi = \lambda f'(u)\phi, \quad \phi|_{\partial B} = 0,$$

then ϕ does not change sign in B.

The proof of Lemma 2.1 is rather long and technical. Therefore we postpone it until section 5.

LEMMA 2.2. *Suppose that u_0 is a degenerate positive solution of* (2.1) *with $\lambda = \lambda_0$. Then all positive solutions (λ, u) of* (2.1) *that are near (λ_0, u_0) in $R \times C(\overline{B})$ lie on a smooth curve represented by*

$$(\lambda, u) = (\lambda_0 + \tau(s), u_0 + s\phi + z(s)) \text{ with } s \text{ small},$$

where $z(0) = z'(0) = 0,\ \tau(0) = \tau'(0) = 0$, and ϕ is the positive eigenfunction given in Lemma 2.1. *Moreover, $\tau''(0) > 0$ if $0 \leq m < 1$, and $\tau''(0) < 0$ if $n^* > m \geq 1$.*

Proof. When $0 \le m < 1$, this follows from Lemma 2.1 and the fact that

$$f(0) = 0, \quad f''(u) > 0 \ \text{ on } (0, \alpha), \quad f''(u) < 0 \ \text{ on } (\alpha, \infty), \alpha = \frac{1}{1 - m + \sqrt{1-m}}.$$

The proof is a simple variant of [35, p. 3239] (see also [9], [23], and [28]), where the well-known formula

$$\tau''(0) = -\lambda_0 \frac{\int_B f''(u_0)\phi^3 dx}{\int_B f(u_0)\phi dx} \tag{2.2}$$

is used. We omit the details here.

When $m \ge 1$, $\tau''(0) < 0$ follows directly from (2.2) and the fact that $f''(u) > 0$ for $u > 0$. □

LEMMA 2.3. *Suppose $f \in C^1(R)$ is an arbitrary function, B is the unit ball in R^n, $n \ge 1$. Then for any given $c > 0$, the problem*

$$-\Delta u = \lambda f(u), \ u|_{\partial B} = 0$$

can have at most one solution (λ, u) satisfying $\lambda > 0, u \ge 0$ and $u(0) = c$.

Proof. This is a well-known fact. A simple proof appears in [9, Lemma 1]. □

THEOREM 2.4. *If $m \ge n^*$ and $n > 2$, then (2.1) has no positive solution for any $\lambda > 0$.*

Proof. This follows from the Pohozaev identity: If we use the notations in the proof of Lemma 2.1, then $m \ge (n+2)/(n-2)$ implies $G(u) < 0$ for $u > 0$. Thus we arrive at the contradicting inequalities before (5.3) if there is a positive solution. □

THEOREM 2.5. *Suppose $1 < m < n^*$. Then for any $\lambda > 0$, (2.1) has a unique positive solution u_λ. Moreover, $\lambda \to u_\lambda$ is a continuous (actually smooth) function from $(0, \infty)$ to $C(\overline{B})$, and $\lambda \to u_\lambda(0)$ is strictly decreasing with*

$$\lim_{\lambda \to 0^+} u_\lambda(0) = \infty, \ \lim_{\lambda \to \infty} u_\lambda(0) = \xi,$$

where $\xi > 0$ when $n > 2$ and $\xi = 0$ when $n = 1, 2$.

Proof. Clearly we have

$$\lim_{u \to 0} f(u)/u = 0, \quad \lim_{u \to \infty} f(u)/u^m = 1. \tag{2.3}$$

It follows from a standard application of the mountain pass theorem (see, e.g., [30]) that (2.1) has at least one positive solution for any $\lambda > 0$. Moreover, by the first identity in (2.3) and standard local bifurcation theory (see, e.g., [1]), any positive solution of (2.1) has its L_∞ norm bounded away from 0 for λ in any compact set of $(0, \infty)$. Due to the second identity in (2.3), the well-known blowing-up method of Gidas and Spruck [16] guarantees that any positive solution of (2.1) has its L_∞ norm bounded away from ∞ for λ in any compact set of $(0, \infty)$.

We show in the following that there is exactly one positive solution when $\lambda > 0$. Note that there is extensive literature on the uniqueness of positive solutions for various nonlinearities; see, for example, [12], [27], and the references therein. But to the best of our knowledge, our nonlinearity $f(u)$ does not seem covered by the existing results. In our proof of uniqueness below, we use a continuation argument, which seems to be new in this context.

We first prove the theorem under the assumption that any positive solution is nondegenerate. The verification of this assumption is deferred to the very end of the proof.

Under this nondegeneracy assumption, we pick up an arbitrary positive solution (λ_0, u_0) and use the implicit function theorem to continue the solution curve towards both smaller and larger values of λ and obtain a smooth solution curve $\{(\lambda, u_\lambda)\}$. As all the positive solutions are nondegenerate, this continuation procedure can be continued unless u_λ loses positivity or its L_∞ norm becomes unbounded at some finite $\lambda^* \in (0, \infty)$. However, these cases of concern cannot occur, because by Harnack inequality u_λ can lose positivity only through $\|u_\lambda\|_\infty \to 0$, which, together with the second case, is ruled out at the very beginning of the proof. Thus we obtain a smooth curve of positive solutions

$$\Gamma = \{(\lambda, u_\lambda) : 0 < \lambda < \infty\}.$$

By Lemma 2.3, the function $\lambda \to u_\lambda(0)$ must be strictly monotone. Hence

$$\lim_{\lambda \to 0^+} u_\lambda(0) = \eta \in [0, \infty].$$

From (2.3) and standard bifurcation theory we know $\eta = 0$ is impossible. If $\eta > 0$ is finite, then a simple compactness argument shows that $\lim_{\lambda \to 0^+} u_\lambda$ is a positive solution of (2.1) with $\lambda = 0$, which is evidently impossible. Therefore we must have $\eta = \infty$. It follows that $\lambda \to u_\lambda(0)$ is strictly decreasing.

Let $\xi = \lim_{\lambda \to \infty} u_\lambda(0)$. Then $\xi \in [0, \infty)$. We show that $\xi > 0$ when $n > 2$ and $\xi = 0$ when $n = 1, 2$. Indeed, when $n > 2$, $\xi > 0$ is a simple consequence of (5.3) in the proof of Lemma 2.1. When $n = 2$, we argue indirectly. Suppose that $\xi > 0$. Consider the initial value problem

$$(rz')' = -rz^m e^{-1/z}, \quad z(0) = \xi, \ z'(0) = 0.$$

It is easily seen that $z'(r) < 0$ for $r \in (0, r_0)$ as long as z is positive on $(0, r_0)$. If z remains positive on $[0, \infty)$, then $z(x) = z(|x|) = z(r)$ satisfies $\Delta z = -z^m e^{-1/z} < 0$ on R^2 and hence is a bounded subharmonic function on R^2. It is well known that in such a case, $z \equiv$ *constant*. Clearly this is impossible. Hence z has a first zero $r_0 > 0$: $z(r) > 0$ in $[0, r_0)$ and $z(r_0) = 0$. By continuous dependence of the solutions on the initial values, for λ^* large, the unique solution z^* of the initial value problem

$$(rz')' = -rz^m e^{-1/z}, \quad z(0) = u_{\lambda^*}(0), \ z'(0) = 0$$

has a first zero r^* close to r_0. But then $u^*(r) = z^*(r^* r)$ is a solution of (2.1) with $u^*(0) = u_{\lambda^*}(0)$ but $\lambda = (r^*)^2 \to r_0^2 \neq \lambda^*$ as $\lambda^* \to \infty$. This contradicts Lemma 2.3. Hence we must have $\xi = 0$.

When $n = 1$, the proof is similar but simpler. The initial value problem now is changed to

$$z'' = -z^m e^{-1/z}, \ z(0) = \xi, z'(0) = 0,$$

and the existence of a first zero of z follows from $z'' < 0$ on $[0, \infty)$.

We still need to show that Γ contains all the solutions. Suppose there is a positive solution (λ^0, u^0) not lying on Γ. Then we can repeat the above continuation argument to obtain a second solution curve $\{(\lambda, \tilde{u}_\lambda)\}$ containing (λ^0, u^0) with the property $\tilde{u}_\lambda(0) \to \infty$ as $\lambda \to 0^+$. This, however, clearly contradicts Lemma 2.3.

Finally, we verify that all the positive solutions are nondegenerate. Suppose that (λ_0, u_0) is a degenerate positive solution. It follows from Lemma 2.2 that the positive solutions near this point form a smooth curve which has a turning point at (λ_0, u_0), and the curve lies to the left of this point, i.e., all points (λ, u) on the curve have their λ values smaller than or equal to λ_0. We see that (λ_0, u_0) divides the curve into two branches. We call the branch with larger values of $u(0)$ the upper branch and denote it as $\{(\lambda, u^\lambda)\}$, while the other branch will be called the lower branch and denoted by $\{(\lambda, u_\lambda)\}$. These two branches of solutions can be continued towards smaller values of λ until we reach $\lambda = 0$ if we don't meet a degenerate solution, since, as before, this continuation cannot be stopped by loss of positivity for u or the norm of u becoming unbounded. We cannot meet a degenerate solution either, however, because by Lemma 2.2, if we meet a degenerate solution in the procedure of continuation towards smaller values of λ, then the solutions near the degenerate solution must all lie to the left of this point, which is clearly impossible.

Now we look at the lower branch

$$\{(\lambda, u_\lambda) : 0 < \lambda < \lambda_0\}.$$

By Lemma 2.3, we must have $\lambda \to u_\lambda(0)$ increasing. Therefore

$$\lim_{\lambda \to 0^+} u_\lambda(0) = \zeta \in [0, u_0(0)).$$

By (2.3) and standard bifurcation argument, we know as before $\zeta > 0$. Then a compactness argument shows $\lim_{\lambda \to 0^+} u_\lambda$ is a positive solution of (2.1) with $\lambda = 0$, a contradiction. This finishes the proof of Theorem 2.5. □

THEOREM 2.6. *If $m = 1$, then (2.1) has no positive solution for $\lambda \le \lambda_1$, and it has a unique positive solution $u = u_\lambda$ when $\lambda > \lambda_1$. Moreover, $\lambda \to u_\lambda$ is a continuous (actually smooth) function from (λ_1, ∞) to $C(\overline{B})$, and $\lambda \to u_\lambda(0)$ is strictly decreasing with*

$$\lim_{\lambda \to \lambda_1 + 0} u_\lambda(0) = \infty, \quad \lim_{\lambda \to \infty} u_\lambda(0) = \xi,$$

where $\xi > 0$ when $n > 2$ and $\xi = 0$ when $n = 1, 2$.

Proof. This is a modification of the proof for Theorem 2.5. Therefore we only point out the differences.

Since $m = 1$,

$$\lim_{u \to 0} f(u)/u = 0, \quad \lim_{u \to \infty} f(u)/u = 1. \tag{2.4}$$

It follows from Theorem 15.1 of [1] that (2.1) has at least one positive solution for $\lambda \in (\lambda_1, \infty)$. Moreover, using standard theories on local bifurcation and on asymptotically linear operators (see, e.g., [1]), one easily deduces from (2.4) that the L_∞ norm of the positive solutions are bounded away from 0 and ∞ for λ in any compact set of (λ_1, ∞).

Since

$$-\Delta u = \lambda f(u) < \lambda u,$$

one easily deduces $\lambda > \lambda_1$ whenever there is a positive solution.

The rest of the proof is exactly the same as that for Theorem 2.5 except that we replace $\lambda = 0$ there by $\lambda = \lambda_1$ now. □

THEOREM 2.7. *Suppose $0 \le m < 1$. Then there exists $\lambda_0 > 0$ such that (2.1) has no positive solution for $\lambda < \lambda_0$, exactly one positive solution for $\lambda = \lambda_0$, and exactly two positive solutions for $\lambda > \lambda_0$. Moreover, the positive solution set $\{(\lambda, u)\}$ of (2.1) forms a "$\subset$"-shaped smooth curve in the space $R \times C(\overline{B})$. Moreover, if we denote the upper and lower branches by*

$$\{(\lambda, u^\lambda) : \lambda_0 \le \lambda < \infty\} \text{ and } \{(\lambda, u_\lambda) : \lambda_0 \le \lambda < \infty\},$$

respectively, then $\lambda \to u^\lambda(x)$ is strictly increasing for any fixed $|x| < 1$, $\lambda \to u_\lambda(0)$ is strictly decreasing, and

$$\lim_{\lambda\to\infty} u^\lambda(x) = \infty \ \forall |x| < 1; \quad \lim_{\lambda\to\infty} u_\lambda(0) = \xi, \ \xi = 0 \text{ if } n = 1, 2 \text{ and } \xi > 0 \text{ if } n > 2.$$

Proof. We first show that for λ large, (2.1) has at least one positive solution. Choose $\psi \in C_0^\infty(B)$ satisfying $\psi \ge 0$ and $\max_B \psi = 1$. Let $\underline{u}$ be the unique solution of $\Delta u + \psi = 0, u|_{\partial B} = 0$, and for $\lambda > 0$ let $\overline{u}_\lambda$ be the unique positive solution of $\Delta u + \lambda u^m = 0, u|_{\partial B} = 0$. The existence here follows from a standard upper and lower solution argument since $\lim_{u\to 0} u^m/u = \infty$ and $\lim_{u\to\infty} u^m/u = 0$, while the uniqueness follows from the concavity of u^m. It is easy to check that

$$\overline{u}_\lambda = (\lambda/\lambda_0)^{1-m} \overline{u}_{\lambda_0}$$

for any positive numbers λ and λ_0. By the strong maximum principle, we see that $\overline{u}_{\lambda_0} \ge \delta \underline{u}$ for some positive constant δ. Hence $\overline{u}_\lambda \ge \underline{u}$ when λ is large. Clearly, $\Delta \overline{u}_\lambda + \lambda f(\overline{u}_\lambda) \le \Delta \overline{u}_\lambda + \lambda (\overline{u}_\lambda)^m = 0$. Thus $\overline{u}_\lambda$ is an upper solution to (2.1). On the other hand, since ψ has compact support in B while $f(\underline{u})$ is bounded away from 0 on any compact subset of the open ball B, $\lambda f(\underline{u}) \ge \psi$ on B for all large λ. It follows that $\Delta \underline{u} + \lambda f(\underline{u}) \ge \Delta \underline{u} + \psi = 0$ for large λ. Hence, for large λ, $\overline{u}_\lambda \ge \underline{u}$ and they are upper and lower solutions to (2.1), respectively. Therefore there exists $\lambda_* > 0$ such that (2.1) has at least a positive solution provided that $\lambda \ge \lambda_*$.

Now we can set

$$\lambda_0 = \inf \big\{\lambda > 0 : (2.1) \text{ has at least a positive solution}\big\}.$$

We claim that $\lambda_0 > 0$. Otherwise, there exists $\lambda_i \to 0$ and v_i positive, such that

$$\Delta v_i + \lambda_i v_i^m e^{-1/v_i} = 0, \quad v_i|_{\partial B} = 0.$$

Set $\tilde{v}_i = v_i/\|v_i\|_\infty$. Then

$$\Delta \tilde{v}_i + \lambda_i e^{-1/v_i} (v_i)^{m-1} \tilde{v}_i = 0, \quad \tilde{v}_i|_{\partial B} = 0.$$

As $e^{-1/v_i}(v_i)^{m-1}$ is uniformly bounded, by standard elliptic regularity, $\|\tilde{v}_i\|_{W^{2,p}} \to 0$. The Sobolev embedding theorem implies that $\tilde{v}_i \to 0$ uniformly. However, this is impossible as $\|\tilde{v}_i\|_\infty = 1$. This contradiction implies that $\lambda_0 > 0$.

Again by standard elliptic regularity, we can further show that (2.1) with $\lambda = \lambda_0$ has at least a positive solution. We choose one of them and denote it as u_0. We claim that u_0 must be a degenerate solution. If not, then by the implicit function theorem we can show that for λ less than but close to λ_0, (2.1) has at least one positive solution, which contradicts the definition of λ_0. Since u_0 is degenerate, our Lemma 2.2 implies that the solutions near (λ_0, u_0) form a smooth curve which turns to the right in the (λ, u) space. We may call the part of the smooth curve $\{(\lambda, u)\}$ with

$u(0) > u_0(0)$ the upper branch, and the rest the lower branch, and denote the upper and lower branches by u^λ and u_λ, respectively. As long as (λ, u^λ) and (λ, u_λ) are nondegenerate, the implicit function theorem ensures that we can continue to extend these two branches in the direction of increasing λ. To save notations, we still denote the extensions as u^λ and u_λ. This process of continuation towards larger values of λ for both branches may be stopped at some finite λ^* by one of the following three possibilities:

(i) $\|u^{\lambda_n}\|_\infty$ or $\|u_{\lambda_n}\|_\infty$ goes to infinity for some $\lambda_n \to \lambda^* - 0$;

(ii) $\|u^{\lambda_n}\|_\infty$ or $\|u_{\lambda_n}\|_\infty$ goes to 0 for some $\lambda_n \to \lambda^* - 0$ (note that by the Harnack inequality, u^λ and u_λ can only lose positivity through vanishing on the entire domain);

(iii) u^{λ^*} or u_{λ_*} is a degenerate solution.

However, (i) cannot occur since u^{λ_n} and u_{λ_n} are bounded from above by the unique positive solution of $\Delta u + (\lambda^* + 1)u^m = 0,\ u|_{\partial B} = 0$, which follows from a simple upper and lower solution argument; (ii) cannot occur either as otherwise, denoting $u_n = u^{\lambda_n}$ or u_{λ_n},

$$0 = \lambda_1(-\Delta - \lambda_n e^{-1/u_n}(u_n)^{m-1}) \to \lambda_1(-\Delta) > 0.$$

Finally, (iii) cannot occur. This is because, if, say, (λ, u^λ) becomes degenerate at $\lambda = \lambda^*$, then Lemma 2.2 tells us that all the solutions near $(\lambda^*, u^{\lambda^*})$ must lie to the right side of it, which is a contradiction. Therefore we can always extend these two branches of solutions to $\lambda = \infty$.

By Lemma 2.3, we see that the real functions $\lambda \to u^\lambda(0)$ and $\lambda \to u_\lambda(0)$ must be strictly monotone and $u^\lambda(0) > u_0(0) > u_\lambda(0)$ for any $\lambda \in (\lambda_0, \infty)$. Hence

$$\lim_{\lambda\to\infty} u_\lambda(0) = \xi \in [0, u_0(0)); \quad \lim_{\lambda\to\infty} v^\lambda(0) = \eta \in (u_0(0), \infty].$$

We show that $\eta = \infty$ always, and $\xi > 0$ when $n > 2$, $\xi = 0$ when n=1,2. By Lemma 2.3, this would imply that all the positive solutions of (2.1) are contained in these two solution branches if we can show that there is no positive solution of (2.1) satisfying $u(0) \le \xi$ when $\xi > 0$.

Let us first show that $\eta = \infty$. In fact we show a little more than that. An argument similar to but slightly simpler than that used in the proof of Lemma 3.4 in [23] shows that $\partial u^\lambda(r)/\partial\lambda > 0\ \forall r \in [0, 1)$ and $\lambda > \lambda_0$. Hence $\lambda \to u^\lambda(r)$ is strictly increasing and $u^\lambda(r) > u_0(r)$. It follows, noticing $f(u^\lambda) \ge f(u_0)$,

$$u^\lambda(r) = (-\Delta)^{-1}[\lambda f(u^\lambda)] \ge (\lambda/\lambda_0)(-\Delta)^{-1}[\lambda_0 f(u_0)] = (\lambda/\lambda_0)u_0(r) \to \infty$$

as $\lambda \to \infty$, for any $r \in [0, 1)$.

Second we show that if $\xi > 0$, then (2.1) has no positive solution with $u(0) \le \xi$. In fact, if there is such a solution, then the argument we used above can be repeated to show that there is a second smooth curve $\{(\lambda, \tilde{u})\}$ of positive solutions which is "$\subset$"-shaped and for $(\lambda, \tilde{u})$ on its upper branch, $\tilde{u}(0) \to \infty$ as $\lambda \to \infty$. This implies, however, that for any large number $C > 0$, there are at least two solutions u^λ and $\tilde{u}$ with $u^\lambda(0) = \tilde{u}(0) = C$, contradicting Lemma 2.3.

Finally, the fact that $\xi = 0$ if $n = 1, 2$ and $\xi > 0$ if $n > 2$ is proved in the same way as in the proof of Theorem 2.5.

The proof of Theorem 2.7 is now complete. □

3. The perturbed equation in dimensions 1 and 2. This section is devoted to the problem

$$-\Delta u = \lambda(u+\epsilon)^m e^{-1/(u+\epsilon)} \equiv \lambda f(u+\epsilon), \quad u|_{\partial B} = 0, \tag{3.1}$$

where $\epsilon > 0$, $m \geq 0$ and $B = \{x \in R^n : |x| < 1\}, n = 1, 2$.

Let us first observe the following simple relationship between (2.1) and (3.1).

If (λ, u) is a positive solution of (2.1), and $u(0) > \epsilon$, then we can find a unique $a \in (0,1)$ such that $u(a) = \epsilon$. Define

$$v(x) = u(ax) - \epsilon, \quad x \in B.$$

Clearly

$$-\Delta v = a^2 \lambda f(v+\epsilon), \quad v|_{\partial B} = 0.$$

That is, $(a^2\lambda, v)$ is a positive solution of (3.1).

This relationship between (2.1) and (3.1) will be frequently used in this section. Though such an exact relationship between the solutions of (2.1) and (3.1) is not essential for most of the results to be true, it simplifies the proofs substantially.

The following result will play a central role in this section.

LEMMA 3.1. *If u is a degenerate positive solution of* (3.1) *and ϕ is a nontrivial solution to*

$$-\Delta \phi = \lambda f'(u+\epsilon)\phi, \quad \phi|_{\partial B} = 0,$$

then ϕ does not change sign in B.

Proof. Before starting the proof, let us remark that our proof below requires only $\epsilon \geq 0$. Therefore, it is a simplification of the proof of Lemma 2.1 for the case $n = 1, 2$. It also simplifies the proof of Theorem 3 in [9] where only the special case $m = 0$ is considered. Let us also remark that this result is not true if $3 \leq n \leq 9$ and $\epsilon > 0$ is small (see section 4).

By [15], u is radially symmetric: $u(x) = u(r)$, $r = |x|$; moreover, $u'(r) < 0$ on (0,1]. By Proposition 3.3 of [24], ϕ is also radially symmetric: $\phi(x) = \phi(r)$. Hence

$$\phi'' + \frac{n-1}{r}\phi' + \lambda f'(u+\epsilon)\phi = 0 \text{ in } [0,1], \quad \phi'(0) = 0, \ \phi(1) = 0.$$

We may assume $\phi(0) > 0$.

As in [9], we make use of the test function

$$v(r) = ru'(r) + \mu$$

instead of the usual $v = ru' + \mu u$, where μ is a positive constant to be specified later. By a direct calculation,

$$v'' + \frac{n-1}{r}v' + \lambda f'(u+\epsilon)v = \lambda[\mu f'(u+\epsilon) - 2f(u+\epsilon)] \equiv G(r),$$

$$[r^{n-1}(v'\phi - v\phi')]' = G(r)r^{n-1}\phi, \tag{3.2}$$

where

$$G(r) = \lambda f(u+\epsilon)g(r), \quad g(r) = \mu\left[\frac{m}{u+\epsilon} + \frac{1}{(u+\epsilon)^2}\right] - 2.$$

Clearly, $g(r)$ is strictly increasing in r.

Now we suppose $\phi(r)$ changes sign in $(0,1)$ and want to deduce a contradiction from this. Let $r_0 \in (0,1)$ be the first zero of $\phi(r)$: $\phi(r_0) = 0$ and $\phi(r) > 0$ for $r \in [0, r_0)$. We choose $\mu = -r_0 u'(r_0)$ in $v = ru' + \mu$. Since

$$v' = -r\lambda f(u+\epsilon) + (2-n)u' < 0 \quad \forall r \in (0,1],$$

we have $v(r) > v(r_0) = 0$ on $[0, r_0)$ and $v(r) < 0$ on $(r_0, 1]$.

We divide our considerations below into two cases: (i) $g(r_0) \le 0$ and (ii) $g(r_0) > 0$.

In case (i), using $g(r) < g(r_0) \le 0$ on $[0, r_0)$, we obtain the following contradiction by integrating (3.2) from 0 to r_0:

$$0 > \int_0^{r_0} G(r) r^{n-1} \phi dr = [r^{n-1}(v'\phi - v\phi')]|_0^{r_0} = 0.$$

In case (ii), we consider the last zero of $\phi(r)$ before $r = 1$: $r_0 \le r^0 < 1,\ \phi(r^0) = 0, \phi(r) \ne 0$ for $r \in (r^0, 1)$. We may assume that $\phi(r) > 0$ on $(r^0, 1)$ (otherwise change the sign of ϕ). Then $\phi'(r^0) > 0 > \phi'(1)$. Now using $g(r) > 0$ and $v(r) \le 0$ on $[r^0, 1]$, we again deduce a contradiction:

$$0 < \int_{r^0}^1 G(r) r^{n-1} \phi(r) dr = [r^{n-1}(v'\phi - v\phi')]|_{r^0}^1 = (r^0)^{n-1} v(r^0)\phi'(r^0) - v(1)\phi'(1) \le 0.$$

The proof is complete. □

Using Lemma 3.1, we obtain a variant of Lemma 2.2, whose obvious proof we omit.

LEMMA 3.2. *Suppose that u_0 is a degenerate positive solution of* (3.1) *with $\lambda = \lambda_0$. Then all positive solutions (λ, u) of* (3.1) *that are near (λ_0, u_0) in $R \times C(\overline{B})$ lie on a smooth curve represented by*

$$(\lambda, u) = (\lambda_0 + \tau(s), u_0 + s\phi + z(s)) \text{ with } s \text{ small},$$

where $z(0) = z'(0) = 0,\ \tau(0) = \tau'(0) = 0$, and ϕ is the positive eigenfunction given in Lemma 3.1. *Moreover,*

$$\tau''(0) = -\lambda_0 \frac{\int_B f''(u_0+\epsilon)\phi^3 dx}{\int_B f(u_0+\epsilon)\phi dx}. \tag{3.3}$$

3.1. The case $m \ge 1$. Throughout this subsection, we assume $m \ge 1$. By Theorems 2.5 and 2.6, the solution set of (2.1) forms a smooth curve

$$\Gamma = \{(\lambda, u_\lambda) : \lambda_* < \lambda < \infty\},$$

where $\lambda_* = 0$ if $m > 1$ and $\lambda_* = \lambda_1$ if $m = 1$; moreover, $\lambda \to u_\lambda(0)$ is strictly decreasing and

$$\lim_{\lambda \to \lambda_* + 0} u_\lambda(0) = \infty, \quad \lim_{\lambda \to \infty} u_\lambda(0) = 0.$$

Therefore, given any $\epsilon > 0$, there is a unique $\lambda_\epsilon > \lambda_*$ such that

$$u_{\lambda_\epsilon}(0) = \epsilon.$$

Moreover,

$$\lim_{\epsilon\to 0}\lambda_\epsilon=\infty,\ \lim_{\epsilon\to\infty}\lambda_\epsilon\to\lambda_*,$$

and for any $\lambda\in(\lambda_*,\lambda_\epsilon)$, there is a unique $a=a_\lambda=a_\lambda(\epsilon)\in(0,1)$ such that

$$u_\lambda(a_\lambda)=\epsilon.$$

Since $u'(r)\neq 0$ on (0,1], $a_\lambda(\epsilon)$ varies smoothly with λ and ϵ. Moreover,

$$\text{for fixed } \epsilon>0,\ \lim_{\lambda\to\lambda_\epsilon-0}a_\lambda(\epsilon)=0;\quad \text{for fixed } \lambda>\lambda_*,\ \lim_{\epsilon\to 0}a_\lambda(\epsilon)=1.$$

Denote

$$v_\lambda(x)=u(a_\lambda x)-\epsilon,\ x\in B;\ \eta_\lambda=a_\lambda^2\lambda.$$

Then

$$\Gamma_\epsilon=\{(\eta_\lambda,v_\lambda):\lambda_*<\lambda<\lambda_\epsilon\}$$

is a smooth curve of positive solutions to (3.1) with

$$\lim_{\lambda\to\lambda_\epsilon-0}(\eta_\lambda,v_\lambda)\to(0,0),\ \lim_{\lambda\to\lambda_*+0}\|v_\lambda\|_\infty=\infty.$$

Hence Γ_ϵ is unbounded with one end at $(0,0)$. Since $a_\lambda\in(0,1)$, $\eta_\lambda<\lambda$ and hence Γ_ϵ lies to the left of $\lambda=\lambda_\epsilon$. Moreover, when $m>1$, it follows that

$$\eta_\lambda\to 0 \text{ as } \lambda\to 0^+.$$

If $m=1$, then it follows from $\lim_{u\to\infty}f(u+\epsilon)/u=1$ and standard analysis for asymptotically linear operators (see [1]) and $\lim_{\lambda\to\lambda_1+0}\|v_\lambda\|_\infty=\infty$ that we must have

$$\eta_\lambda\to\lambda_1 \text{ as } \lambda\to\lambda_1+0.$$

By Lemma 2.3, the fact that $\{v_\lambda(0):\lambda\in(\lambda_*,\lambda_\epsilon)\}=(0,\infty)$ implies that Γ_ϵ contains all the positive solutions of (3.1). The following result shows Γ_ϵ is exactly "$\supset$"-shaped if $m>1$.

THEOREM 3.3. *Suppose $m>1$. Then given any $\epsilon>0$, there exists $\lambda_\epsilon^*>0$ such that* (3.1) *has exactly two positive solutions for $\lambda\in(0,\lambda_\epsilon^*)$, exactly one positive solution for $\lambda=\lambda_\epsilon^*$, and no positive solution for $\lambda>\lambda_\epsilon^*$. Moreover, $\lambda_\epsilon^*\to\infty$ as $\epsilon\to 0$ and $\lambda_\epsilon^*\to 0$ as $\epsilon\to\infty$.*

Proof. Since η_λ is close to 0 when λ is close to either 0 or λ_ϵ,

$$\lambda_\epsilon^*=\max_{\lambda\in(0,\lambda_\epsilon)}\eta_\lambda$$

is achieved at some $\lambda_0\in(0,\lambda_\epsilon)$. By the implicit function theorem, $(\lambda_\epsilon^*,v_{\lambda_0})$ must be a degenerate solution of (3.1). Since $f''(u+\epsilon)>0\ \forall\ u\geq 0$, it follows from (3.3) that $\tau''(0)<0$ in Lemma 3.2 always. Thus we obtain a smooth curve of positive solutions which makes a turn to the left at $(\lambda_\epsilon^*,v_{\lambda_0})$. As before, we have an upper branch and a lower branch of the solution curve and can use the implicit function theorem to continue both branches towards smaller values of λ. Since the solutions have to go

along Γ_ϵ, the continuation procedure can only be stopped by meeting a degenerate solution. But this cannot occur because near any degenerate solution, Lemma 3.2 and the fact $\tau''(0) < 0$ imply the other solutions can only lie to the left of the degenerate one. Therefore, the upper branch continues to $(0, \infty)$ and the lower branch goes till to (0,0).

It remains to show $\lambda_\epsilon^* \to \infty$ as $\epsilon \to 0$ and $\lambda_\epsilon^* \to 0$ as $\epsilon \to \infty$. Since

$$\lambda_\epsilon^* = \eta_{\lambda_0} < \lambda_0 < \lambda_\epsilon, \text{ and } \lim_{\epsilon \to \infty} \lambda_\epsilon = 0,$$

one easily sees $\lambda_\epsilon^* \to 0$ as $\epsilon \to \infty$. On the other hand, for any fixed $\lambda > 0$,

$$\lambda_\epsilon^* \geq (a_\lambda(\epsilon))^2 \lambda \to \lambda \text{ as } \epsilon \to 0.$$

This implies $\lambda_\epsilon^* \to \infty$ as $\epsilon \to 0$. The proof is now complete. □

The case $m = 1$ is rather delicate. The following result shows the solution curve Γ_ϵ changes from "$\supset$"–shaped to a monotone curve when ϵ crosses $\epsilon = 1$ from $\epsilon < 1$.

THEOREM 3.4. *Suppose $m = 1$.*

(a) *If $\epsilon \geq 1$, then (3.1) has a unique positive solution u_λ when $\lambda \in (0, \lambda_1)$, and it has no positive solution for $\lambda \geq \lambda_1$. Moreover, $u_\lambda(0) \to \infty$ as $\lambda \to \lambda_1$.*

(b) *If $\epsilon \in (0, 1)$, then there exists $\lambda_\epsilon^* > \lambda_1$ such that (3.1) has exactly one positive solution for $\lambda \in (0, \lambda_1] \cup \{\lambda_\epsilon^*\}$, exactly two positive solutions for $\lambda \in (\lambda_1, \lambda_\epsilon^*)$, and no positive solution for $\lambda > \lambda_\epsilon^*$. Moreover, $\lambda_\epsilon^* \to \infty$ as $\epsilon \to 0$ and $\lambda_\epsilon^* \to \lambda_1$ as $\epsilon \to \infty$.*

Proof. (a) A simple calculation shows

$$[f(u+\epsilon)/u]' = e^{-1/(u+\epsilon)} \frac{u - \epsilon u - \epsilon^2}{u^2(u+\epsilon)} < 0 \quad \forall\, u > 0 \text{ if } \epsilon \geq 1.$$

By [18], this implies that (3.1) has at most one positive solution for any $\lambda > 0$. On the other hand, we have the positive solution curve Γ_ϵ connecting (0,0) and (λ_1, ∞). The conclusion of part (a) now follows from these two facts.

(b) Define

$$\lambda_\epsilon^* = \sup_{\lambda \in (\lambda_1, \lambda_\epsilon)} \eta_\lambda.$$

We show that $\lambda_\epsilon^* > \lambda_1$ when $\epsilon \in (0, 1)$. It suffices to show $\eta_\lambda > \lambda_1$ for some $\lambda \in (\lambda_1, \lambda_\epsilon)$. Choose $\lambda^n \to \lambda_1 + 0$ and denote

$$\mu_n = \eta_{\lambda^n}, \quad u_n = v_{\lambda^n}.$$

We know from the discussion before Theorem 3.3 that $\mu_n \to \lambda_1$ and $\|u_n\|_\infty \to \infty$. A simple compactness argument reveals $u_n/\|u_n\|_\infty \to \phi_1$ in C^1, where ϕ_1 is the first eigenfunction:

$$-\Delta\phi_1 = \lambda_1\phi_1, \ \phi_1|_{\partial B} = 0, \ \phi_1 > 0, \|\phi_1\|_\infty = 1.$$

Multipling $-\Delta u_n = \mu_n f(u_n + \epsilon)$ by ϕ_1, integrating over B, and using integration by parts yields

$$\lambda_1 \int_B u_n \phi_1 dx = \mu_n \int_B (u_n + \epsilon) e^{-1/(u_n+\epsilon)} \phi_1 dx.$$

Using the elementary inequality $e^{-t} \le 1 - t + t^2/2 \ \forall\ t \ge 0$, we deduce

$$\lambda_1 \int_B u_n \phi_1 dx \le \mu_n \int_B (u_n + \epsilon) \left[1 - \frac{1}{u_n + \epsilon} + \frac{1}{2(u_2 + \epsilon)^2}\right] \phi_1 dx$$

$$= \mu_n \int_B \left[u_n + \epsilon - 1 + \frac{1}{2(u_n + \epsilon)}\right] \phi_1 dx.$$

Hence, due to $u_n/\|u_n\|_\infty \to \phi_1$,

$$(\mu_n - \lambda_1) \int_B u_n \phi_1 dx \ge \mu_n \int_B \left[1 - \epsilon - \frac{1}{2(u_n + \epsilon)}\right] \phi_1 dx \to \lambda_1 (1 - \epsilon) \int_B \phi_1 dx > 0.$$

This implies that $\mu_n = \eta_{\lambda^n} > \lambda_1$ for large n. Therefore, we have proved $\lambda^*_\epsilon > \lambda_1$. Since η_λ is close to 0 for λ near λ_ϵ and it converges to λ_1 as $\lambda \to \lambda_1$, λ^*_ϵ must be achieved at some $\lambda_0 \in (\lambda_1, \lambda_\epsilon)$.

Now the argument used in the proof of Theorem 3.3 can be repeated to show that the solution curve can be continued from $(\lambda^*_\epsilon, v_{\lambda_0})$ leftwards, with the lower branch reaching (0,0) and the upper branch reaching (λ_1, ∞). Also, the fact that $\lambda^*_\epsilon \to \infty$ as $\epsilon \to 0$ follows from the same argument as that in the proof of Theorem 3.3. To show $\lambda^*_\epsilon \to \lambda_1$ as $\epsilon \to 1$, we use an indirect argument. Suppose $\lambda^*_{\epsilon_n} \to \lambda_0 > \lambda_1$ for some sequence $\epsilon_n \to 1$. Denote by u_n the positive solution of (3.1) at $\lambda = \lambda^*_{\epsilon_n}$. Then one easily sees by a compactness argument that u_n has a subsequence which converges to a positive solution of (3.1) with $\epsilon = 1$ and $\lambda = \lambda_0 > \lambda_1$. This contradicts part (a). The proof is complete. □

3.2. The case $0 \le m < 1$. In this subsection, we assume $0 \le m < 1$. By Theorem 2.7, the solution curve of (2.1) is "⊂"-shaped with exactly one turning point at (λ_0, u_0), where $u_0 = u_{\lambda_0} = u^{\lambda_0}$. Denote $\xi_0 = u_0(0)$. Then for any $\epsilon \ge \xi_0$, we can find a unique $\lambda^\epsilon \in [\lambda_0, \infty)$ such that

$$u^{\lambda^\epsilon}(0) = \epsilon.$$

By Theorem 2.7, for any $\lambda > \lambda^\epsilon$, we can find a unique $a^\lambda = a^\lambda(\epsilon) \in (0, 1)$ such that

$$u^\lambda(a^\lambda) = \epsilon.$$

Moreover, $\lambda \to a^\lambda$ is strictly increasing and

$$\lim_{\lambda \to \lambda^\epsilon - 0} a^\lambda = 0, \ \lim_{\lambda \to \infty} a^\lambda = 1.$$

As before, define

$$\eta^\lambda = (a^\lambda)^2 \lambda, \ v^\lambda(x) = u(a^\lambda x) - \epsilon, \ x \in B.$$

Then

$$\Gamma^\epsilon = \{(\eta^\lambda, v^\lambda) : \lambda^\epsilon < \lambda < \infty\}$$

gives a smooth solution curve of (3.1). Since a^λ is increasing with λ, it follows η^λ is strictly increasing with λ. Therefore, Γ^ϵ is a monotone curve connecting $(0, 0)$ (when $\lambda \to \lambda^\epsilon$) and (∞, ∞) (when $\lambda \to \infty$).

If $\epsilon \in (0, \xi_0)$, then for any $\lambda \geq \lambda_0$, we can find $a^\lambda = a^\lambda(\epsilon) \in (0,1)$ satisfying $u^\lambda(a^\lambda) = \epsilon$, and define η^λ, v^λ as above to obtain a smooth monotone solution curve of (3.1):

$$\Gamma^\epsilon = \{(\eta^\lambda, v^\lambda) : \lambda_0 \leq \lambda < \infty\}.$$

Clearly Γ^ϵ connects $(\eta^{\lambda_0}, v^{\lambda_0})$ to (∞, ∞).

Moreover, since $\epsilon < \xi_0$, we can find a unique $\lambda_\epsilon > \lambda_0$ such that

$$u_{\lambda_\epsilon}(0) = \epsilon.$$

By Theorem 2.7, we see that λ_ϵ increases as ϵ decreases and $\lambda_\epsilon \to \infty$ as $\epsilon \to 0$.

For any $\lambda \in [\lambda_0, \lambda_\epsilon)$, we can find a unique $a_\lambda = a_\lambda(\epsilon)$ such that

$$u_\lambda(a_\lambda) = \epsilon.$$

Clearly, for any fixed $\lambda \geq \lambda_0$,

$$\lim_{\epsilon \to 0} a_\lambda(\epsilon) = 1.$$

Now we define

$$\eta_\lambda = (a_\lambda)^2 \lambda, \ v_\lambda(x) = u_\lambda(a_\lambda x) - \epsilon, \ x \in B$$

and find that

$$\Gamma_\epsilon = \{(\eta_\lambda, v_\lambda) : \lambda_0 \leq \lambda < \lambda_\epsilon\}$$

gives another piece of smooth solution curve to (3.1). Moreover, Γ_ϵ connects the end point $(\eta^{\lambda_0}, v^{\lambda_0})$ of Γ^ϵ (when $\lambda = \lambda_0$) and $(0,0)$ (when $\lambda \to \lambda_\epsilon - 0$). Thus

$$\Gamma(\epsilon) = \Gamma^\epsilon \cup \Gamma_\epsilon$$

gives a piecewise smooth (in fact, smooth) curve for (3.1) connecting (0,0) and (∞, ∞). By Lemma 2.3, we know it contains all the positive solutions of (3.1). We are going to find out the shape of this curve.

A straightforward calculation gives

$$[f(u+\epsilon)/u]' = \frac{(u+\epsilon)^{m-2}}{u^2} e^{-1/(u+\epsilon)} [-(u+\epsilon)^2 + mu(u+\epsilon) + u].$$

It follows from elementary analysis that

$$[f(u+\epsilon)/u]' \leq 0 \ \text{ if } \epsilon \geq \epsilon_0 \equiv (1 + \sqrt{1-m})^{-2}.$$

Therefore, by [18], for any $\lambda > 0$, (3.1) has at most one positive solution if $\epsilon \geq \epsilon_0$. It follows that if $\xi_0 > \epsilon_0$, then $\Gamma(\epsilon)$ must be a monotone curve when $\epsilon \geq \epsilon_0$.

Summarizing the above discussions, we obtain the following result.

THEOREM 3.5. *If $0 \leq m < 1$ and $\epsilon \geq \min\{\xi_0, (1+\sqrt{1-m})^{-2}\}$, then (3.1) has a unique positive solution for any $\lambda > 0$.*

Our next result shows that $\Gamma(\epsilon)$ is exactly S-shaped if $\epsilon > 0$ is sufficiently small.

THEOREM 3.6. *Suppose $0 \leq m < 1$. Then for all sufficiently small $\epsilon > 0$, the solution curve $\Gamma(\epsilon)$ of (3.1) is exactly S-shaped: There exist λ^*_ϵ and Λ^*_ϵ satisfying*

(i) $0 < \lambda^*_\epsilon < \Lambda^*_\epsilon < \infty$;

(ii) (3.1) *has a unique positive solution for* $\lambda \in (0, \lambda^*_\epsilon) \cup (\Lambda^*_\epsilon, \infty)$*;*
(iii) (3.1) *has exactly two positive solutions for* $\lambda = \lambda^*_\epsilon$ *and* $\lambda = \Lambda^*_\epsilon$*;*
(iv) (3.1) *has exactly three positive solutions for* $\lambda \in (\lambda^*_\epsilon, \Lambda^*_\epsilon)$*;*
(v) $\lim_{\epsilon\to 0} \lambda^*_\epsilon = \lambda_0$, $\lim_{\epsilon\to 0} \Lambda^*_\epsilon = \infty$.

Proof. Recall that

$$f''(u) > 0 \text{ for } u \in (0, \alpha), \text{ where } \alpha = 1/[(1-m) + \sqrt{1-m}].$$

We fix some $\xi_1 \in (0, \alpha)$ and suppose

$$\epsilon < \epsilon_1 \equiv \alpha - \xi_1.$$

Then clearly $f''(u + \epsilon) > 0$ for $u \in (0, \xi_1)$.

Now we choose $\lambda_{\xi_1} > \lambda_0$ such that

$$u_\lambda(0) < \xi_1 \text{ when } \lambda \geq \lambda_{\xi_1},$$

where u_λ is the positive solution of (2.1) lying on the lower branch. By shrinking ϵ_1 we may assume that $\lambda_{\xi_1} < \lambda_\epsilon \ \forall\ \epsilon \in (0, \epsilon_1)$. We can now divide Γ_ϵ into two parts:

$$\Gamma^1_\epsilon = \{(\eta_\lambda, v_\lambda) : \lambda_{\xi_1} \leq \lambda < \lambda_\epsilon\};\ \Gamma^2_\epsilon = \{(\eta_\lambda, v_\lambda) : \lambda_0 \leq \lambda \leq \lambda_{\xi_1}\}.$$

We first analyze the shape of Γ^1_ϵ. Define

$$\Lambda^*_\epsilon = \sup_{\lambda\in[\lambda_{\xi_1}, \lambda_\epsilon)} \eta_\lambda.$$

One easily shows that there exists $\epsilon_2 \in (0, \epsilon_1]$ such that when $\epsilon \in (0, \epsilon_2)$,

$$\Lambda^*_\epsilon \text{ is achieved at some } \lambda_* \in (\lambda_{\xi_1}, \lambda_\epsilon) \text{ and } \lim_{\epsilon\to 0} \Lambda^*_\epsilon = \infty.$$

By the implicit function theorem, $(\eta_{\lambda_*}, v_{\lambda_*})$ must be a degenerate solution of (3.1). Then by Lemma 3.2, (3.3), and our choice of ξ_1, the solutions of (3.1) near $(\eta_{\lambda_*}, v_{\lambda_*})$ has a turn to the left. Therefore, we have an upper branch and a lower branch of positive solutions starting from this point, and both branches can be continued towards smaller values of λ. The lower branch can be continued to reach (0,0), because (a) we cannot meet a degenerate solution in the way of continuation due to Lemma 3.2 and $u(0) < \xi_1$ on Γ^1_ϵ, and (b) the branch goes along Γ^1_ϵ. For the same reason, the upper branch can be continued until it reaches $(\eta_{\lambda_{\xi_1}}, v_{\lambda_{\xi_1}})$. This implies that Γ^1_ϵ is exactly "$\supset$"-shaped.

Next we analyze the shape of Γ^2_ϵ. It is more convenient for our discussion if we consider a bigger piece of solution curve

$$\Gamma^3_\epsilon = \Gamma^2_\epsilon \cup \{(\eta^\lambda, v^\lambda) : \lambda_0 \leq \lambda \leq \lambda_{\xi_1}\},$$

which contains part of Γ^ϵ. We observe that any $(\lambda, u) \in \Gamma^3_\epsilon$ satisfies

$$0 < \lambda^*_\epsilon \leq \lambda \leq \lambda_{\xi_1},\ \ u_{\lambda_{\xi_1}}(0) - \epsilon \leq \|u\|_\infty = u(0) \leq u^{\lambda_{\xi_1}}(0) - \epsilon, \tag{3.4}$$

where

$$\lambda^*_\epsilon = \inf\{\lambda : (\lambda, u) \in \Gamma^3_\epsilon\}.$$

It is easily seen that λ_ϵ^* is achieved at some $\eta_{\lambda'}$, $\lambda' \in [\lambda_0, \lambda_{\xi_1})$. Therefore $(\lambda_\epsilon^*, v_{\lambda'})$ must be a degenerate solution of (3.1). Clearly

$$\lambda_\epsilon^* \le \eta_{\lambda_0} = (a_{\lambda_0}(\epsilon))^2 \lambda_0 < \lambda_0.$$

On the other hand, it is easy to see that $a_\lambda(\epsilon) \to 1$ as $\epsilon \to 0$ uniformly for $\lambda \in [\lambda_0, \lambda_{\xi_1}]$. Hence

$$\lim_{\epsilon \to 0} \lambda_\epsilon^* = \lim_{\epsilon \to 0} \min\{(a_\lambda(\epsilon))^2 \lambda : \lambda_0 \le \lambda \le \lambda_{\xi_1}\} = \lambda_0.$$

We know from the discussion above that Γ_ϵ^3 contains at least one degenerate solution $(\lambda_\epsilon^*, v_{\lambda'})$. If we can show that there exists $\epsilon_3 \in (0, \epsilon_2)$ such that whenever $\epsilon \in (0, \epsilon_3)$, any degenerate solution on Γ_ϵ^3 must make $\tau''(0) > 0$ in (3.3) of Lemma 3.2, then a continuation argument much as before shows Γ_ϵ^3 contains exactly one degenerate solution at $\lambda = \lambda_\epsilon^*$ and the curve makes a turn to the right at this point. Hence Γ_ϵ^3 must be "$\subset$"-shaped. This tells us that the entire solution curve $\Gamma(\epsilon)$ is exactly S-shaped with two turning points at $\lambda = \lambda_\epsilon^*$ and $\lambda = \Lambda_\epsilon^*$, respectively. Clearly, this would finish the proof of Theorem 3.6.

It remains to show that there exists $\epsilon_3 \in (0, \epsilon_2)$ such that any degenerate solution on Γ_ϵ^3 must make $\tau''(0) > 0$ in (3.3) of Lemma 3.2 as long as $\epsilon \in (0, \epsilon_3)$. We argue indirectly. Suppose for some $\epsilon_k \to 0$, we can find degenerate solutions $(\lambda^k, u^k) \in \Gamma_{\epsilon_k}^3$ such that

$$\tau_k''(0) = -\lambda^k \frac{\int_B f''(u^k + \epsilon_k)\phi_k^3 dx}{\int_B f(u^k + \epsilon)\phi_k dx} \le 0,$$

where ϕ_k is the positive eigenfunction given in Lemma 3.1 when $(\lambda, u) = (\lambda^k, u^k)$. We may assume that $\|\phi_k\|_\infty = 1$.

By (3.4), we may assume that $\lambda^k \to \lambda^0 \in [\lambda_0, \lambda_{\xi_1}]$. The second part of (3.4) implies that $\|f(u^k + \epsilon_k)\|_\infty$ is uniformly bounded. Therefore, by the equation for u^k and a standard regularity and compactness argument, $\{u^k\}$ has a convergent subsequence in C^1. We may assume $u^k \to u^0$ in C^1. Moreover, from

$$-\Delta\phi_k = \lambda^k f'(u^k + \epsilon_k)\phi_k, \ \phi_k|_{\partial B} = 0,$$

we can use a similar regularity and compactness argument to obtain a C^1 convergent subsequence of ϕ_k. We may assume $\phi_k \to \phi^0$. Then we easily deduce

$$-\Delta u^0 = \lambda^0 f(u^0), \ u^0|_{\partial B} = 0, \ u^0 \ge 0, u^0 \ne 0$$

and

$$-\Delta\phi^0 = \lambda^0 f'(u^0)\phi^0, \ \phi|_{\partial B} = 0, \phi^0 \ge 0, \|\phi^0\|_\infty = 1.$$

This is to say (λ^0, u^0) is a degenerate positive solution of (2.1) and ϕ^0 is the corresponding positive eigenfunction. By Theorem 2.7, (2.1) has a unique degenerate positive solution which is (λ_0, u_0), and by Lemma 2.2 and (2.2),

$$\tau''(0) = -\lambda_0 \frac{\int_B f''(u_0)\phi^3 dx}{\int_B f(u_0)\phi dx} > 0.$$

Therefore, we must have $\lambda^k \to \lambda_0, u^k \to u_0$ and $\phi^0 = \phi$ (note that the positive eigenfunction is unique if it is normalized). Then we deduce, however,

$$0 \ge \tau_k''(0) = -\lambda^k \frac{\int_B f''(u^k + \epsilon_k)\phi_k^3 dx}{\int_B f(u^k + \epsilon)\phi_k dx} \to -\lambda_0 \frac{\int_B f''(u_0)\phi^3 dx}{\int_B f(u_0)\phi dx} > 0.$$

This contradiction finishes our proof. □

4. Some remarks on the perturbed equation in higher dimensions. If $n \geq 3$, then the results of section 2 imply that any positive solution (λ, u) of (1.4) satisfies

$$u(0) > \xi > 0, \text{ where } \xi = \lim_{\lambda \to \infty} u_\lambda(0),$$

as in Theorems 2.5–2.7. Therefore, the trick of using positive solutions of (1.4) to obtain that for (1.3) mentioned at the beginning of section 3 can only give positive solutions (λ, u) of (1.3) with $u(0) > \xi - \epsilon$.

On the other hand, since along the positive solution curve Γ of (1.4), all the solutions are nondegenerate except at most one which, if exists, satisfies condition A of [7, p. 413] due to Lemma 2.2, we see that Theorem 2 of [7] and the results on page 412 of [7] (see also an improvement of these results in [11, Proposition A3]) can be used to conclude the following:

> *For any compact part Γ_c of Γ, there exists an $\epsilon_0 > 0$ small such that for each $\epsilon \in (0, \epsilon_0)$, there is a piece of solution curve Γ_c^ϵ of (1.3) which is close to Γ_c and has exactly the same shape as Γ_c, i.e., Γ_c^ϵ makes exactly the same number of turns as Γ_c does.*

In particular, if $0 \leq m < 1$, then Γ_c^ϵ is exactly "$\subset$"-shaped. Moreover, in this case, we can use the construction in section 3.2 to see that the upper branch of Γ_c^ϵ can be continued monotonically to (∞, ∞). Thus, when $0 \leq m < 1$ and ϵ is small, we can obtain a complete understanding of the part of positive solution curve of (1.3) where $u(0) > \xi$. Note, however, in the scale of (1.1), $v = \epsilon^{-2} u > \xi/\epsilon^2$ is large.

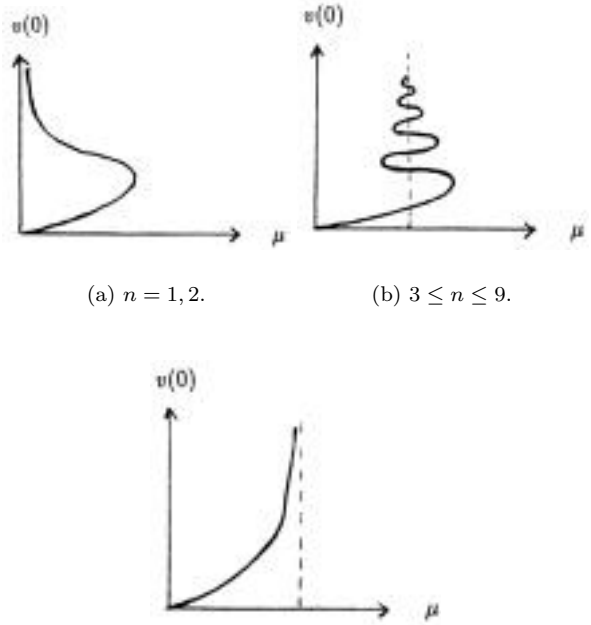
Let us now switch to (1.1) in order to understand the rest of the positive solution curve of (1.3). We now take Dancer's point of view and regard (1.1) as a perturbation of the Gelfand equation. Let Γ_0 denote the positive solution curve of the Gelfand equation on the unit ball B with Dirichlet boundary conditions. It is well known that Γ_0 can be described by the diagrams in Figure 3.

Dancer proved in [7] that solutions on Γ_0 are either nondegenerate or degenerate but satisfy his condition A. Therefore, as before, by the perturbation results in [7], for any compact part Γ_0^c of Γ_0, there exists $\epsilon_1 > 0$ small such that for each $\epsilon \in (0, \epsilon_1)$, (1.1) has a piece of positive solution curve Γ_ϵ^c which is close to Γ_0^c and makes exactly the same number of turns. In particular, in dimensions $3 \leq n \leq 9$, Γ_ϵ^c makes a large number of turns for certain μ.

Moreover, it follows from arguments in [7, p. 430] (see also Theorem 2.26 of [26]) that the eigenfunction of the linearization of the Gelfand equation at each turning point of its solution curve (except the first turning point) changes sign. Using this fact and an argument similar to that near the end of the proof of Theorem 3.6 in the present paper, one can see that the eigenfunction in Lemma 3.1 with small positive ϵ may change sign when $3 \leq n \leq 9$.

Using a phase plane argument as in [7], and employing the graph for $\{(\mu, v'(1))\}$ of the Gelfand problem, one can show as in [7] that the solution curve Γ_ϵ^c can be continued for larger values of $v(0)$ until $\mu > 0$ small (see Figure 1 in [7]), and this further continued part Γ_ϵ' has the shape similar to that of Γ_ϵ^c, but as was pointed out in [7], it is not clear if Γ_ϵ' can make extra turns besides the ones corresponding to that of Γ_ϵ^c. We illustrate these by Figure 4 (compare with Figure 1 in [21]) while omitting the rigorous proofs.

As can be seen from Figure 4, the solutions $(\mu, v) \in \Gamma_\epsilon'$ have $v'(1)$ small while that on Γ_c^ϵ obtained from (1.4) have $v'(1) = \epsilon^{-2} u_\lambda'(1)$. Therefore, there is still a gap between $\Gamma_\epsilon \cup \Gamma_\epsilon'$ and the rescaled Γ_c^ϵ.



(a) $n = 1, 2.$ (b) $3 \le n \le 9.$

(c) $n \ge 10.$

FIG. 3. *Positive solution curve of the Gelfand equation on the unit ball.*

Nevertheless, by our calculations in section 3.2, $[f(u+\epsilon)/u]' \le 0$ if $0 \le m < 1$ and $\epsilon \ge (1+\sqrt{1-m})^{-2}$. Therefore it is easy to show that (1.3) (and hence (1.1)) has a unique positive solution for any $\lambda > 0$ in this case.

5. The proof of Lemma 2.1. In this section, we give the rather long and technical proof of Lemma 2.1.

Proof of Lemma 2.1. By [15], u is radially symmetric: $u(x) = u(r)$, $r = |x|$; moreover, $u'(r) < 0$ on (0,1]. By Proposition 3.3 of [24], ϕ is also radially symmetric: $\phi(x) = \phi(r)$. Hence

$$\phi'' + \frac{n-1}{r}\phi' + \lambda f'(u)\phi = 0 \text{ in } [0,1], \quad \phi'(0) = 0, \ \phi(1) = 0.$$

By the Harnack inequality (or a well-known uniqueness result for the above singular second order ordinary differential equation), $\phi(0) \ne 0$. We may assume $\phi(0) > 0$.

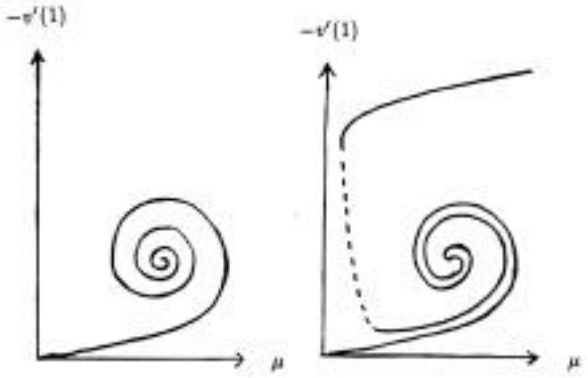
Direct calculations give

$$f'(u) = u^{m-2}e^{-1/u}(mu+1) > 0 \ \forall u > 0,$$

$$f''(u) = u^{m-4}e^{-1/u}[m(m-1)u^2 + 2(m-1)u + 1].$$

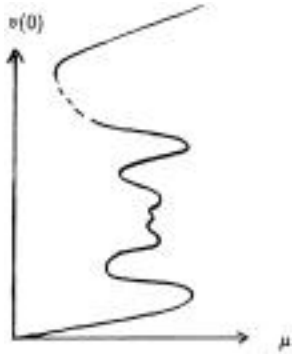
Hence

$$f''(u) > 0 \text{ for } u \in (0,\alpha); \quad f''(u) < 0 \text{ for } u \in (\alpha,\infty),$$



(a)
Gelfand equation with $3 \le n \le 9$.

(b)
(1.1) with $3 \le n \le 9$, $0 < \epsilon << 1$.



(c)
(1.1) with $3 \le n \le 9$, $0 < \epsilon << 1$.

FIG. 4.

where $\alpha = 1/[(1-m) + \sqrt{1-m}]$ if $m < 1$, and $\alpha = \infty$ if $m \ge 1$.

One easily sees

$$K(u) = uf'(u)/f(u) = m + 1/u$$

is a decreasing function of u on $(0, \infty)$ and

(a) if $m < 1$, then $K(\beta) = 1$ for $\beta = 1/(1-m) > \alpha > \rho \equiv \alpha - f(\alpha)/f'(\alpha)$;

(b) if $m \ge 1$, then $K(u) > 1 \ \forall \ u > 0$.

We define $\beta = \infty$ in case (b) and divide our discussion below into two cases:

$$\text{(i) } u(0) \le \beta \text{ and (ii) } u(0) > \beta.$$

Consider case (i) *first.* Let

$$v(r) = ru_r(r) + \mu u(r),$$

where μ is a positive constant to be specified later. Then

$$\begin{aligned} -\Delta v - \lambda f'(u)v &= \lambda[2f(u) - \mu(f'(u)u - f(u)] \\ &= \lambda f(u)[2 - \mu(K(u) - 1)]. \end{aligned} \tag{5.1}$$

Define

$$h(r) = -ru'(r)/u(r), \quad r \in [0, 1).$$

Clearly $h(0) = 0$ and $h(1) = +\infty$. We show in the following that $h'(r) > 0$ in (0,1). Indeed,

$$h'(r) = [ru_r^2 + (n-2)u_r u + \lambda r f(u)u]/u^2 = [2H(r) + \lambda r Q(u(r))]/u^2, \tag{5.2}$$

where

$$H(r) = [ru_r^2 + (n-2)u_r u]/2 + \lambda r F(u(r)), \ F(u) = \int_0^u f(s)ds,$$

$$Q(u) = uf(u) - 2F(u).$$

Here and in what follows, u_r is sometimes used for u' to avoid notations like u'^2.

If $n = 1, 2$, then it follows from the first equality in (5.2) that $h'(r) > 0$ in $(0, 1)$. Therefore, we need only consider $n > 2$ below. A simple calculation gives

$$[r^{n-1}H(r)]' = \lambda r^{n-1}G(u(r)) \text{ with } G(u) = nF(u) - \frac{n-2}{2}f(u)u.$$

Clearly $G(0) = 0$ and

$$\begin{aligned} G'(u) &= \tfrac{n+2}{2}f(u) - \tfrac{n-2}{2}f'(u)u \\ &= u^{m-1}e^{-1/u}\{[(n+2) - m(n-2)]u - (n-2)\}/2. \end{aligned}$$

It follows that

$$G'(u) < 0 \text{ on } [0, \gamma); \quad G'(u) > 0 \text{ on } (\gamma, \infty),$$

where $\gamma = (n-2)/[(n+2) - m(n-2)]$. Therefore, we have either $G(u) < 0$ on $(0, \infty)$ or $G(u) < 0$ on $(0, \gamma_0)$ and $G(u) > 0$ on (γ_0, ∞) for some $\gamma_0 > \gamma$. We show that actually only the latter alternative can occur. Indeed, if $G(u(r)) \le 0 \ \forall \ r \in [0, 1]$, then

$$0 < u_r^2(1)/2 = H(1) = \int_0^1 \lambda r^{n-1}G(u(r))dr \le 0.$$

This contradiction shows γ_0 exists and moreover

$$u(0) > \gamma_0 \tag{5.3}$$

whenever $n > 2$ and u is a positive solution of (2.1).

Let t be uniquely determined by $u(t) = \gamma_0$. We have

$$[r^{n-1}H(r)]' = \lambda r^{n-1}G(u(r)) > 0 \ \ \forall r \in (0, t),$$

which implies $H(r) > 0$ for $r \in (0,t]$. Moreover, for $r \in (t,1]$, $G(u(r)) < 0$ and therefore

$$\begin{aligned} r^{n-1}H(r) &= H(1) - \int_r^1 \lambda r^{n-1} G(u(r))dr \\ &\geq H(1) = u_r^2(1)/2 > 0. \end{aligned}$$

Thus we always have $H(r) > 0$ on $(0,1]$.

Since $Q(0) = 0$ and

$$Q'(u) = uf'(u) - f(u) = f(u)[K(u) - 1] \geq 0 \ \forall u \in [0,\beta),$$

we have $Q(u) \geq 0$ on $[0,\beta)$ and hence, by (5.2), $h'(r) > 0$ on (0,1), as required.

Denote

$$\mu(r) = 2/[K(u(r)) - 1].$$

Then $\mu(r)$ is strictly decreasing for $r \in (0,1]$, and by (5.1),

$$-\Delta v - \lambda f'(u)v = g(r), \quad g(r) = \lambda f(u)[K(u) - 1][\mu(r) - \mu].$$

With these preparations, we are now ready to show that ϕ does not change sign in B in case (i). We argue indirectly. Suppose $\phi(r)$ has a zero in (0,1). Then we can find $0 < t_1 \leq t_2 < 1$ such that

$$\phi(t_1) = 0, \phi(r) > 0 \ \forall r \in [0,t_1); \quad \phi(t_2) = 0, \phi(r) \neq 0 \ \forall r \in (t_2,1).$$

Now we choose $\mu = h(t_1)$ in $v = ru_r + \mu u$, and have two cases to consider:

$$\text{(a) } \mu(t_1) \geq \mu \text{ and (b) } \mu(t_1) < \mu.$$

We have

$$v(r) = ru_r + h(t_1)u = u[h(t_1) - h(r)] > v(t_1) = 0 \ \forall r \in [0,t_1), v(r) < 0 \ \ \forall r \in (t_1,1). \tag{5.4}$$

In case (a), we easily see $g(r) > 0$ on $(0,t_1)$, and hence, using $v(t_1) = 0$, we arrive at the following contradiction:

$$0 < \int_0^{t_1} g(r)\phi(r)r^{n-1}dr = \int_{B_{t_1}} [-\Delta v - \lambda f'(u)v]\phi = \int_{\partial B_{t_1}} v\phi_r = 0, \tag{5.5}$$

where we use $B_r = \{x \in R^n : |x| \leq r\}$.

In case (b), we may assume $\phi(r) > 0$ on $(t_2,1)$ for otherwise we can replace ϕ by $-\phi$. Moreover, one easily sees $g(r) < 0$ on $[t_1,1]$. Then by (5.4) and $\phi'(t_2) > 0 > \phi'(1)$, we also arrive at a contradiction:

$$0 > \int_{t_2}^1 g(r)\phi(r)r^{n-1}dr = \int_{B\setminus B_{t_2}} [-\Delta v - \lambda f'(u)v]\phi = \int_{\partial B_{t_2}} -v\phi_r + \int_{\partial B} v\phi_r > 0. \tag{5.6}$$

This proves the lemma for case (i).

Next we consider case (ii) where $u(0) > \beta$. Since $\beta = \infty$ when $m \geq 1$, we necessarily have $m < 1$ in this case. We can find $0 < r_1 < r_2 < 1$ uniquely determined by

$$u(r_1) = \beta,\ u(r_2) = \rho.$$

We first show $\phi(r) \neq 0$ on $(0, r_1]$. To this end, we choose $w(r) = u(r) - \rho$ as a test function. Clearly

$$-\Delta w - \lambda f'(u)w = \lambda q(u), \quad q(u) = f(u) - f'(u)(u - \rho).$$

We have

$$q'(u) = (\rho - u)f''(u),$$

which is positive on $(0, \rho)$, negative on (ρ, α), and positive on (α, ∞). Since $q(0) = \rho f'(0) = 0$, it follows that

$$q(u) \geq q(\alpha) = f(\alpha) - f'(\alpha)(\alpha - \rho) = 0\ \forall u > 0.$$

Hence

$$-\Delta w - \lambda f'(u)w = \lambda q(u) \geq 0 \text{ on } B.$$

If $\phi(r)$ has a zero in $(0, r_1]$, then we can find $t \in (0, r_1]$ such that $\phi(r) > 0$ on $[0, t)$ and $\phi(t) = 0$. Using $w(t) = u(t) - \rho > u(r_2) - \rho = 0$, we deduce

$$0 \leq \int_0^t \lambda q(u(r))\phi(r)r^{n-1}dr = \int_{B_t} [-\Delta w - \lambda f'(u)w]\phi = \int_{\partial B_t} w\phi_r < 0.$$

This contradiction finishes our proof for $\phi(r) \neq 0$ on $[0, r_1]$.

Next we suppose $\phi(r)$ changes sign in (0,1) and deduce a contradiction. Since $\phi(r) \neq 0$ in $[0, r_1]$, we can find $r_1 < t_1 \leq t_2 < 1$ such that

$$\phi(t_1) = 0, \phi(r) > 0\ \forall r \in [0, t_1); \quad \phi(t_2) = 0, \phi(r) \neq 0\ \forall r \in (t_2, 1).$$

As in case (i), we choose $\mu = h(t_1)$. Since $u(r) \leq \beta$ on $[r_1, 1]$, the above arguments for case (i) give

$$h'(r) > 0 \text{ on } (r_1, 1).$$

Hence

$$v(r) = u[h(t_1) - h(r)] > v(t_1) = 0\ \forall r \in [r_1, t_1);\ v(r) < 0\ \forall r \in (t_1, 1].$$

If $\mu(t_1) \geq \mu$, then since $\mu(r)$ is strictly decreasing on (0,1) and $K(u(r)) < 1$ on $[0, r_1)$, $K(u(r)) > 1$ on $(r_1, 1]$, we have

$$g(r) = \lambda f(u)[K(u) - 1][\mu(r) - \mu] > 0\ \forall r \in (r_1, t_1),$$

and by (5.1),

$$g(r) = \lambda f(u)[2 - \mu(K(u) - 1)] > 0\ \forall r \in [0, r_1].$$

Thus $g(r) > 0$ on $[0, t_1)$. Now we can deduce the same contradiction (5.5) as in case (i).

If $\mu(t_1) < \mu$, then

$$g(r) = \lambda f(u)[K(u) - 1][\mu(r) - \mu] < 0\ \forall r \in (t_1, 1],$$

and we arrive at the contradiction (5) as in case (i). This finishes the proof of Lemma 2.1. □

CONSTANT PRINCIPAL STRAIN MAPPINGS ON 2-MANIFOLDS*

MARTIN CHUAQUI† AND JULIAN GEVIRTZ†

Abstract. We study mappings between Riemannian 2-manifolds which have constant principal stretching factors (cps-mappings). Such mappings f can be described in terms of the relationship between the geodesic curvature of the curves of principal strain at p and that of their images at $f(p)$. In the context of local coordinates this relationship takes the form of a nonlinear hyperbolic system, the blow-up properties of which depend on the Gaussian curvatures of the two manifolds. We use the theory of such systems to study global existence when both manifolds are the hyperbolic plane $\mathbb{H}^2$ and obtain a simple description of all cps-mappings of $\mathbb{H}^2$ onto itself. We also obtain a distortion result for disks in $\mathbb{H}^2$ as well as some nonexistence results for cps-mappings of the Euclidean plane onto certain classes of manifolds. In addition, our treatment of cps-mappings in $\mathbb{H}^2$ yields, virtually as a corollary, a generalization of a theorem of Epstein to the effect that a curve in hyperbolic n-space whose geodesic curvature is bounded by 1 must be simple.

Key words. constant principal strains, hyperbolic system, hyperbolic plane

1. Introduction.

Consider a thin liquid film which upon solidification acquires a cryptocrystalline structure; that is, at each point a suitably oriented infinitesimal square of the original liquid becomes an (again, suitably oriented infinitesimal) rectangular crystal whose side lengths are constant multiples of the side length of the square. Such a process produces a deformation of the surface originally formed by the liquid, and in this paper we examine the class of deformations—those having constant principal strains—that can be realized in this manner. It turns out that the associated mappings are governed by hyperbolic systems of partial differential equations, a circumstance which in retrospect is not surprising since one would expect that singularities, in higher derivatives of the deformation, for example, propagate along the sides of the microscopic crystals, that is, along the associated curves of principal strain. This hyperbolicity in conjunction with the additional element of nonlinearity underlies most of what follows.

To give an idea of some of the relevant issues, we briefly describe the situation in the planar context (see [Ge1] for further details). Let $0 < m_1 < m_2$. A differentiable, orientation preserving mapping f of a domain $U \subset \mathbb{R}^2$ into $\mathbb{R}^2$ has constant principal stretches m_1, m_2 if there are functions $\theta, \overline{\theta}$ on U such that its Jacobian J_f satisfies

$$J_f = T(-\overline{\theta})S(m_1, m_2)T(\theta), \tag{1.1}$$

where

$$T(\theta) = \begin{bmatrix} \cos\theta & \sin\theta \\ -\sin\theta & \cos\theta \end{bmatrix} \quad \text{and} \quad S(m_1, m_2) = \begin{bmatrix} m_1 & 0 \\ 0 & m_2 \end{bmatrix}.$$

Throughout, such f will be called (m_1, m_2)-mappings, or less specifically cps-mappings ("cps" for constant principal strain). This direct manner of expressing the

condition that a mapping has constant principal stretches m_1, m_2 turns out to be rather uninformative, it being far better to work with the compatibility conditions for a matrix function to be a Jacobian; for this reason one adds the additional hypothesis that J_f be locally Lipschitz continuous on U. (See the first paragraph of section 5 for comments about this regularity assumption.) A straightforward calculation shows that a necessary and sufficient condition that locally Lipschitz functions θ and $\overline{\theta}$ give the Jacobian of an (m_1, m_2)-mapping (in a simply connected domain) via the formula (1.1) is that

$$D_1(m_1\theta - m_2\overline{\theta}) = 0 \quad \text{and} \quad D_2(m_2\theta - m_1\overline{\theta}) = 0 \tag{1.2}$$

hold almost everywhere (a.e.), where D_1 and D_2 denote differentiation in the directions $e^{i\theta}$ and $ie^{i\theta}$, respectively. These equations relate the curvatures of the curves (to be referred to henceforth as i-characteristics) along which the stretching factor is m_i and their images. Indeed, if the curvature of the former at $p \in U$ is κ_i and that of the latter at $f(p)$ is $\overline{\kappa}_i$, then (1.2) simply says that $\overline{\kappa}_i = \kappa_i/m_j$, where $\{i, j\} = \{1, 2\}$. These equations constitute a genuinely nonlinear diagonal hyperbolic system for the pair of functions θ, $\overline{\theta}$, so that, in light of a general principle established by Lax [L], one expects cps-mappings to display a marked tendency to form singularities. Specifically, the blow-up law for system (1.2) says, in the case of sufficiently differentiable mappings (and actually for all cps-mappings in the appropriate weak sense), that at each point p the derivative of κ_i in the direction of the j-characteristic through p and toward the concave side of the i-characteristic through this point is κ_i^2, from which it follows at once that the curvatures of both of the characteristics of f at p are bounded above by $1/\mathrm{dist}(p, \partial U)$. Two immediate consequences of this are (i) a cps-analogue of Liouville's theorem—the only cps-mappings of the entire plane onto itself are affine and (ii) the compactness of the class of all (m_1, m_2)-mappings of U into $\mathbb{R}^2$ with respect to the topology of uniform convergence of the first-order derivatives on compact subsets. This blow-up principle also allows one to show that the radius of the largest concentric subdisk of the unit disk Δ whose image under all (m_1, m_2)-mappings $f : \Delta \to \mathbb{R}^2$ is convex is $\left(\frac{m_1}{m_2}\right)^2$. In fact, in conjunction with (1.2) the growth law for the κ_i plays a decisive role in the analysis of other aspects of cps-mappings and of the intimately related "principal strain line inclination function" θ (whose integral curves together with their orthogonal trajectories form what is known in plasticity and optimum structure theory—see [Hil] and [He]—as Hencky–Prandtl nets), such as boundary behavior [Ge3], [Ge4], the nature and distribution of isolated singularities [Ge3], and the determination of all cps-self-homeomorphisms of certain domains [Ge4]. A number of these properties of cps-mappings are strikingly similar to their conformal analogues.

In the present paper we examine some of these issues in the context of 2-dimensional manifolds. We begin in section 2 by establishing the counterparts of (1.2) and the blow-up law, whose formal derivations are somewhat more involved than in the planar case. In section 3 we discuss the analytic details necessary to deal with questions of global existence and behavior, and in addition analyze the relationship between cps-mappings and a generalization of Hencky–Prandtl nets in the constant Gaussian curvature context; more than anything these considerations involve appropriate rewriting of the equations derived in section 2 in coordinate form so as to make manifest the exact nature of the underlying hyperbolicity. In section 4 we apply the results of section 3 first to show that in certain situations there exist no globally defined cps-mappings and then, in the special case of the hyperbolic plane $\mathbb{H}^2$, to do the

following: (i) completely describe the (wide) class of cps-mappings of $\mathbb{H}^2$ onto itself, (ii) prove a generalization of a theorem of Epstein [E1], [E2] about the curvature of self-intersecting curves in hyperbolic n-space $\mathbb{H}^n$, and (iii) derive an analogue for $\mathbb{H}^2$ of the planar radius of convexity result mentioned in the preceding paragraph.

In the planar context one could consider in addition to cps-mappings other similarly defined classes such as the one consisting of mappings with Jacobian of the form

$$J_f = T(-\overline{\theta})S(m_1(\theta,\overline{\theta}), m_2(\theta,\overline{\theta}))T(\theta)$$

for any given pair of everywhere distinct positive functions $m_1(\theta,\overline{\theta}), m_2(\theta,\overline{\theta})$ of period π in each variable (that is, mappings for which the principal strains are given functions of the directions of the principal strain lines and their images). Such a generalization is not possible in context of Riemannian 2-manifolds owing to the absence of an absolute reference direction. Indeed, since the principal stretches (and combinations of them) are the only intrinsically definable first-order parameters associated with a mapping between manifolds, in this context there are only two natural classes of mappings defined by point-independent conditions on their Jacobians: conformal mappings and (m_1, m_2)-mappings. (We are considering here only families of mappings for which, loosely speaking, the set of possible Jacobians at each point is governed by two parameters.) For this reason, cps-mappings constitute a natural object of study above and beyond their interpretation as deformations arising in certain physical situations.

2. Formal considerations. Let V and $\overline{V}$ be C^∞ Riemannian 2-manifolds, both metric tensors being denoted by $\langle\cdot,\cdot\rangle$, which we sometimes subscript with V or $\overline{V}$ for additional clarity. Let $U \subset V$ be a domain. The principal stretches (henceforth to be called principal strains in slight abuse of accepted terminology) of a mapping $f : U \to \overline{V}$ at a point $p \in V$ at which the Jacobian transformation $J_f(p)$ is nonsingular are the square roots of the eigenvalues of the transformation $J_f^*(p)J_f(p)$ of the tangent space of V at p onto itself. Let $U \subset V$ be a domain and m_1, m_2 be distinct positive constants. Then $f : U \to \overline{V}$ is an (m_1, m_2)-mapping if J_f is locally Lipschitz continuous and the principal strains of f are everywhere given by the pair (m_1, m_2). As one can imagine from what was said above about the planar case, the direct expression of this condition as a nonlinear 2×2 system of partial differential equations in terms of local coordinate systems for V and $\overline{V}$ is not very revealing, although as we shall explain in section 3 a small amount of information can be gleaned from it. Here also it is much more appropriate to consider a derived higher order system, specifically a second-order one—which has an elegant coordinate-free formulation—in which the geometric structures of V and $\overline{V}$ present themselves in a most transparent way.

In dealing with the differential geometric aspects we shall, apart from minor variations, adhere to the notation of Hicks [Hic] . In general, the counterpart for $\overline{V}$ of any object A associated with V will be denoted by $\overline{A}$. The Lie bracket of two vector fields X_1, X_2 will be denoted as usual by $[X_1, X_2]$. It is clear that if $U \subset V$ is a simply connected domain, then $f : U \to \overline{V}$ is an (m_1, m_2)-mapping if and only if its Jacobian J_f is locally Lipschitz continuous and there exist locally Lipschitz continuous fields X_1, X_2 on U such that $\langle X_i, X_j\rangle = \delta_{ij}$ and $\langle J_f X_i, J_f X_j\rangle = m_i m_j \delta_{ij}$. The fields X_1, X_2 are *principal direction fields* for f.

The unit vector $J_f X_i/m_i$ will be denoted by $\overline{X}_i$. The covariant derivative in the direction X of the vector field Y will be denoted by $D_X Y$. In addition, D_{X_i} ($D_{\overline{X}_i}$) will be abbreviated by D_i ($\overline{D_i}$), and the same symbols $D_X\alpha$, $D_i\alpha$ will be used to denote the derivative of the scalar function α in the corresponding directions. We shall use

the following facts (see [Hic]). If $f : U \to \overline{V}$ is a diffeomorphism and X, Y, and Z are vector fields on V, then

$$J_f[X, Y] = [J_f X, J_f Y], \tag{2.1}$$

$$D_X Y - D_Y X = [X, Y], \tag{2.2}$$

and

$$D_X\langle Y, Z\rangle = \langle D_X Y, Z\rangle + \langle Y, D_X Z\rangle. \tag{2.3}$$

Furthermore, if Y is a vector field and α, β are scalar functions, then

$$D_X(\alpha Y) = (D_X\alpha)Y + \alpha D_X Y \tag{2.4}$$

and

$$D_{\alpha X+\beta Z}(Y) = \alpha D_X Y + \beta D_Z Y. \tag{2.5}$$

Let $\{X_1, X_2\}$ be an orthonormal pair of locally Lipschitz vector fields on some domain U in V. The covariant derivative $D_l X_k$ exists a.e., and the equations appearing in this paragraph hold a.e. in U. As a consequence of (2.3) we have that

$$0 = D_l\langle X_j, X_k\rangle = \langle D_l X_j, X_k\rangle + \langle X_j, D_l X_k\rangle$$

so that

$$\langle D_l X_j, X_j\rangle = 0 \quad \text{and} \quad \langle D_l X_j, X_k\rangle = -\langle D_l X_k, X_j\rangle \tag{2.6}$$

and with the convention that $\{i, j\} = \{1, 2\}$, which will be in force throughout, this means that there are locally bounded measurable scalar functions κ_i such that

$$D_i X_i = \kappa_i X_j \ \text{ and } \ D_i X_j = -\kappa_i X_i. \tag{2.7}$$

At a point p at which it exists (and it does so a.e. on U), $\kappa_i(p)$ is the geodesic curvature of the integral curve through p of the field X_i. Now consider the pairs of orthonormal fields $\{X_1, X_2\}$ and $\{\overline{X}_1, \overline{X}_2\}$ associated with an (m_1, m_2)-mapping $f : U \to \overline{V}$. It follows from (2.2) and (2.7) that

$$[X_i, X_j] = D_i X_j - D_j X_i = \kappa_j X_j - \kappa_i X_i \tag{2.8}$$

so that

$$\kappa_j = \langle [X_i, X_j], X_j\rangle.$$

By (2.8) and (2.1), which may be applied since f is a local diffeomorphism,

$$\begin{aligned}
\overline{\kappa}_j &= \langle [\overline{X}_i, \overline{X}_j], \overline{X}_j\rangle = \langle [J_f X_i/m_i, J_f X_j/m_j], \overline{X_j}\,\rangle = \langle [J_f X_i, J_f X_j], \overline{X_j}\,\rangle/m_i m_j \\
&= \langle J_f[X_i, X_j], \overline{X_j}\,\rangle/m_i m_j = \langle J_f(\kappa_j X_j - \kappa_i X_i), \overline{X_j}\,\rangle/m_i m_j \\
&= \langle \kappa_j J_f X_j - \kappa_i J_f X_i, \overline{X_j}\,\rangle/m_i m_j \\
&= \langle \kappa_j m_j \overline{X}_j - \kappa_i m_i \overline{X}_i, \overline{X_j}\,\rangle/m_i m_j = \kappa_j/m_i.
\end{aligned}$$

We thus have the fundamental *curvature equations*

$$\overline{\kappa}_j = \kappa_j/m_i \text{ a.e. in } U, \qquad j = 1, 2. \tag{2.9}$$

We next consider how the curvatures change as we move along characteristics, and for the time being we shall assume that the mapping in question is of class C^3. (We shall explain in section 3—see Theorem 3.2—in what way this additional regularity requirement is in fact superfluous.) We use the fact that the Gaussian curvature of a 2-dimensional manifold V at a point p is given by $\langle R(X,Y)Y, X\rangle$ for all orthonormal pairs X, Y of vectors in the tangent space of V at p, where

$$R(X,Y)Y = D_X D_Y Y - D_Y D_X Y - D_{[X,Y]}Y.$$

In particular we have from (2.7) and (2.8)

$$\begin{aligned} R(X_1, X_2)X_2 &= D_1 D_2 X_2 - D_2 D_1 X_2 - D_{[X_1,X_2]}X_2 \\ &= D_1(\kappa_2 X_1) + D_2(\kappa_1 X_1) - D_{\kappa_2 X_2 - \kappa_1 X_1}X_2, \end{aligned}$$

so that upon taking into account (2.4), (2.5), and (2.7) again, we have

$$R(X_1, X_2)X_2 = \kappa_1\kappa_2 X_2 + (D_1\kappa_2)X_1 - \kappa_1\kappa_2 X_2 + (D_2\kappa_1)X_1 - \kappa_2^2 X_1 - \kappa_1^2 X_1.$$

Thus, if K and $\overline{K}$ denote Gaussian curvature on V and $\overline{V}$, we have

$$K = \langle R(X_1, X_2)X_2, X_1\rangle = D_1\kappa_2 + D_2\kappa_1 - \kappa_2^2 - \kappa_1^2 \tag{2.10}$$

and

$$\overline{K} = \langle R(\overline{X}_1, \overline{X}_2)\overline{X}_2, \overline{X}_1\rangle = \overline{D}_1\overline{\kappa}_2 + \overline{D}_2\overline{\kappa}_1 - \overline{\kappa}_2^2 - \overline{\kappa}_1^2. \tag{2.11}$$

In light of the fundamental relations (2.9) and the fact that $\overline{X}_i = J_f X_i/m_i$, it then follows that $\overline{D}_i\overline{\kappa}_j(f(p)) = (D_i\kappa_j(p))/m_i^2$, so that (2.11) may be written as

$$\overline{K} = (D_1\kappa_2)/m_1^2 + (D_2\kappa_1)/m_2^2 - \kappa_2^2/m_1^2 - \kappa_1^2/m_2^2. \tag{2.12}$$

Upon solving the linear system for $D_1\kappa_2$ and $D_2\kappa_1$ given by (2.10) and (2.12), we obtain

$$D_j\kappa_i = \kappa_i^2 + c_i, \qquad i = 1, 2, \tag{2.13}$$

where

$$c_i = m_j^2 \frac{m_i^2\overline{K} - K}{m_i^2 - m_j^2}. \tag{2.14}$$

We emphasize that when these *blow-up equations* (2.13) are written out fully in coordinate form the functions giving the mapping itself appear as arguments of $\overline{K}$, so that they do not in general characterize the net of principal strain lines in an intrinsic fashion. Although they purport to tell us something about how far along a characteristic from a given point a singularity—a point where the mapping fails to be locally Lipschitz—must lie, their content in this regard is meaningless unless one has information about K and $\overline{K}$. For this reason, the most interesting cases by far are those in which at least one of these curvatures is constant.

Given an orthonormal pair of fields X_1, X_2 on $U \subset V$ we refer to arcs of the integral curves of the field X_k as k-arcs. A domain $Q \subset U$ will be said to be a *characteristic quadrilateral* of X_1, X_2 (or of an associated cps-mapping) if ∂Q is a Jordan curve lying in D containing four points a, b, c, d occurring in that order when ∂D is traversed (in one direction or the other) and such that ab and cd are i-arcs, and bc and da are j-arcs. For such a Q we denote by Q_i^+ the i-side (i.e., ab or cd) along which X_j points toward the inside of Q. This i-side of Q will be referred to as the positive i-side. The other, negative, i-side will be denoted by Q_i^-. For an i-arc C we write

$$\Delta(C) = \int_C \kappa_i ds,$$

the unoriented arc length integral of κ_i along C. Let $U \subset V$ be simply connected, and let $f : U \to \overline{V}$ be an (m_1, m_2)-homeomorphism. For each characteristic quadrilateral $Q \subset U$ the positive sides of Q are mapped onto the positive sides of the image quadrilateral $\overline{Q}$. Because the exterior angles of a characteristic quadrilateral are all $\pi/2$, the Gauss–Bonnet formula says

$$\Delta(Q_1^+) - \Delta(Q_1^-) + \Delta(Q_2^+) - \Delta(Q_2^-) = -\int_Q K dA. \tag{2.15}$$

However, the cps-conditions and (2.9) together imply that

$$\Delta(\overline{Q}_i^\sigma) = \frac{m_i}{m_j}\Delta(Q_i^\sigma), \qquad i = 1, 2,\ \sigma = +, -,$$

so that application of the Gauss–Bonnet formula to $\overline{Q}$ gives

$$\frac{m_1}{m_2}\big(\Delta(Q_1^+) - \Delta(Q_1^-)\big) + \frac{m_2}{m_1}\big(\Delta(Q_2^+) - \Delta(Q_2^-)\big) = -m_1 m_2 \int_Q \overline{K}(f) dA. \tag{2.16}$$

Upon solving the system (2.15), (2.16) for the $\Delta(Q_i^+) - \Delta(Q_i^-)$, we obtain

$$\Delta(Q_i^+) - \Delta(Q_i^-) = -\int_Q c_i dA \tag{2.17}$$

for every closed characteristic quadrilateral $Q \subset U$, where c_i is given in (2.14). Although we have only shown that (2.17) holds for quadrilaterals on whose closure f is one-to-one, these equations can easily be seen to hold for any characteristic quadrilateral by the standard process of breaking them up into smaller quadrilaterals. We note that in light of (2.15) and the fact that $c_1 + c_2 = K$ the validity of (2.17) with one value of i implies it with the other one.

In the planar context a Hencky–Prandtl (HP) net on a simply connected domain D consists of two mutually orthogonal one-parameter families of curves covering D with the property that for any two fixed curves C_1, C_2 belonging to one of the families, the change in the inclination of the tangent is the same along all subarcs of curves of the other family which join a point of C_1 to a point of C_2. For simply connected domains, an orthogonal pair of curve families is an HP net if and only if it is the net of principal strain lines of a cps-mapping. This gives an intrinsic characterization of principal strain lines that, unlike one based (2.13), does not make reference to third-order derivatives. In order to obtain such an intrinsic characterization in the

nonplanar context, one needs to assume that the curvature $\overline{K}$ of the image manifold $\overline{V}$ is constant, and in order to avoid a clumsy formulation as well as to preserve the symmetry of the discussion, we shall assume that the curvature K of V is constant as well. Thus for such a V we will say that two mutually orthogonal locally Lipschitz unit vector fields X_1, X_2 on a simply connected domain $U \subset V$ are an $(m_1, m_2, \overline{K})$-HP pair if either of the equations

$$\Delta(Q_i^+) - \Delta(Q_i^-) = -c_i A(Q),$$

where $A(Q)$ is the area of Q, is satisfied for all relevant quadrilaterals; here, of course, the curvatures κ_i are defined by the first equation in (2.7). Thus we have derived the following.

THEOREM 2.1. *If V and $\overline{V}$ have constant Gaussian curvature K and $\overline{K}$, respectively, and $f : V \to \overline{V}$ is an (m_1, m_2)-mapping, then the corresponding principal fields X_1, X_2 are an $(m_1, m_2, \overline{K})$-HP pair.*

In the next section (see Theorem 3.4) we show that, conversely, given an $(m_1, m_2, \overline{K})$-HP pair on a simply connected domain U in V, there is an (m_1, m_2)-mapping f of U into a manifold $\overline{V}$ with constant Gaussian curvature $\overline{K}$, and that this mapping is unique up to rigid motions in $\overline{V}$.

3. Analytic considerations. In investigating cps-mappings two fundamental directions are to be pursued. On the one hand, one would like to say something about the global behavior of all possible cps-mappings of a given domain, that is, to develop some elements of a distortion theory for such mappings. This aspect of the theory is to be based on the three fundamental relations derived in the preceding section: the curvature equations, the blow-up equations, and the HP property, and an example will be discussed in section 4. On the other hand, one should also be able to manufacture such mappings, that is, to construct solutions to the corresponding differential equations, and this is the point we address in this section.

The most straightforward approach is that of DeTurck and Yang [DY] in which one considers the differential equations which state that the eigenvalues of the transformation $J_f^*(p)J_f(p)$ (of the tangent space at p onto itself) are the m_i^2. Specifically, we consider coordinates (u_1, u_2) and $(\overline{u}_1, \overline{u}_2)$ for neighborhoods $U, \overline{U}$ in $V, \overline{V}$, respectively. For convenience we further assume that $U = \{(u_1, u_2) \,|\, |u_1|, |u_2| < \epsilon\}$. In terms of these coordinate systems let $(f_1, f_2) = f : U \to \overline{U}$ be an (m_1, m_2)-mapping for which the length change produced by f on the arc corresponding to $u_2 = 0$ is everywhere strictly between m_1 and m_2. DeTurck and Yang showed that there are four pairs of real-analytic functions F_k^σ, $1 \le \sigma \le 4$, $k = 1, 2$, of twelve variables such that for one of the four values of σ,

$$\frac{\partial f_k}{\partial u_2}(u) = F_k^\sigma \left(\frac{\partial f}{\partial u_1}, m_1, m_2, G(u), \overline{G}(f(u)) \right), \qquad k = 1, 2,$$

where each of G and $\overline{G}$ stands for the four elements of the metric tensors of V and $\overline{V}$ evaluated as indicated. Each of these systems makes the required statement about the eigenvalues of $J_f^*(p)J_f(p)$, and that there are four of them is simply a reflection of the fact that for any given m strictly between m_1 and m_2, and any nonzero $e \in \mathbb{R}^2$, there are four distinct linear transformations $T : \mathbb{R}^2 \to \mathbb{R}^2$ with principal stretches m_1, m_2 for which $Te = me$ (two orientation preserving and two orientation reversing). Conversely, in the analytic category the Cauchy–Kowalewski theorem implies that for each of these four systems the initial value problem $f(u_1, 0) = f_0(u_1)$ has a unique local

solution provided that along the curve $u_2 = 0$ the given initial mapping f_0 changes arc length by factors lying strictly between m_1 and m_2. DeTurck and Yang made the additional very important observation that the linearizations of these four systems are diagonal hyperbolic, and this allowed them to deduce local existence in the C^∞ category. (Their work is actually considerably more general in that it deals with mappings with distinct principal strains on manifolds of arbitrary dimension.) In [Ge2] we dubbed the four Cauchy problems collectively the *DeTurck–Yang initial value problem*, a term we shall employ in what follows to refer to any one of them.

This approach to the construction of cps-mappings as solutions to first-order systems, however, throws no light on global existence because it reveals nothing about how, where, or why singularities form. Information of this nature is, on the other hand, implicit in the blow-up equations and can be put to use by basing the construction of cps-mappings either directly on them or, better still, on the analytically simpler system of curvature equations. We pursue this latter option, but because there are only two distinct characteristics and we are interested in working with the absolutely minimal condition of locally Lipschitz continuity of J_f, we do so via the method of characteristic coordinates. We begin by deriving the necessary equations.

Let U be a (small) neighborhood in V and let (u_1, u_2) be local coordinates for U; in what follows we freely identify points $p \in U$ with the corresponding $(u_1, u_2) \in \mathbb{R}^2$. We denote by $e_k = e_k(p)$ the Euclidean unit vectors at $p \in U$. A right-hand orthonormal pair (with respect to the metric of V) of vectors X_1, X_2 at $u \in U$ is completely specified by the inclination θ of X_1 to the positive u_1-axis. In other words, there are functions $\alpha_k^{(i)}(u, \theta)$ such that in terms of θ

$$X_i = \sum_{k=1}^{2} \alpha_k^{(i)}(u, \theta) e_k = F_i(u, \theta). \tag{3.1}$$

If we are dealing with a real-analytic manifold, then the $\alpha_k^{(i)}$ are, of course, real-analytic. In the discussion to follow, β will denote specific but not explicitly calculated (vector- or scalar-valued) functions of arguments to be indicated; these functions will easily be seen to be real-analytic when we are in that category and to be independent of the particular fields X_1, X_2. It is to be borne in mind that the functions denoted by this symbol may change from line to line and that the symbol D_i ($\overline{D}_i$) is used to denote both differentiation of scalar functions and covariant differentiation of vector fields in the direction X_i ($\overline{X}_i$). In the calculations to follow we use covariant differentiation rules (2.4) and (2.5). We have

$$\begin{aligned} D_i X_i = D_i \left(\sum_{k=1}^{2} \alpha_k^{(i)}(u, \theta) e_k \right) &= \sum_{k=1}^{2} (D_i \alpha_k^{(i)}(u, \theta)) e_k + \beta(u, \theta) \\ &= (D_i \theta\,) \sum_{k=1}^{2} \frac{\partial \alpha_k^{(i)}(u, \theta)}{\partial \theta} e_k + \beta(u, \theta). \end{aligned}$$

Since $\kappa_i = \langle D_i X_i, X_j \rangle$, it follows that

$$\kappa_i = \left\langle \sum_{k=1}^{2} \frac{\partial \alpha_k^{(i)}}{\partial \theta} e_k, X_j \right\rangle D_i \theta + \beta(u, \theta) = P_i(u, \theta) D_i \theta + \beta(u, \theta), \tag{3.2}$$

where $P_i(u, \theta) = \langle \frac{\partial X_i}{\partial \theta}, X_j \rangle$. Since $\frac{\partial \langle X_i, X_j \rangle}{\partial \theta} = 0$, it follows that

$$P_j(u, \theta) = -P_i(u, \theta). \tag{3.3}$$

Because X_1 is of the form $\beta(u,\theta)(\cos\theta e_1 + \sin\theta e_2)$,

$$P_1 = \left\langle \frac{\partial X_1}{\partial \theta}, X_2 \right\rangle = \left\langle \frac{\partial \beta}{\partial \theta}(u,\theta)(\cos\theta e_1 + \sin\theta e_2) + \beta(u,\theta)(-\sin\theta e_1 + \cos\theta e_2), X_2 \right\rangle$$
$$= \beta(u,\theta)\langle -\sin\theta e_1 + \cos\theta e_2, X_2\rangle \neq 0,$$

since $-\sin\theta e_1 + \cos\theta e_2$ is not a multiple of X_1. Thus, in light of (3.3) we have

$$D_i\theta = R_i(u,\theta)\kappa_i + S_i(u,\theta), \tag{3.4}$$

where $R_i(p,\theta)$ and $S_i(p,\theta)$ are functions which for given V depend only on the arguments $p \in V$ and θ.

Let X_1, X_2 be an orthonormal pair of Lipschitz continuous fields on $U \subset V$ and let $S_\epsilon = \{(t_1,t_2) : -\epsilon < t_1, t_2 < \epsilon\}$. A bi-Lipschitz homeomorphism $u : S_\epsilon \to U$ is a characteristic coordinate mapping if each segment $t_i =$ constant is carried onto a j-characteristic. The Lipschitz continuity of the X_i imply that such mappings exist locally. With reference to such a mapping, in what follows Y_i will denote the tangent field $J_u e_i$, where the e_i are the Euclidean unit vector fields on S_ϵ; more concretely, $(D_{Y_i} w)(u(t_1,t_2)) = \partial w(u(t_1,t_2))/\partial t_i$ for scalar functions w. Obviously, $[Y_i, Y_j] = 0$. Furthermore, we define $y_i(t_1,t_2)$ by

$$Y_i(u(t_1,t_2)) = y_i(t_1,t_2)X_i(u(t_1,t_2)) = y_i(t_1,t_2)F_i(u(t_1,t_2),\theta(u(t_1,t_2))), \tag{3.5}$$

where F_i is the vector-valued function appearing in (3.1). Note that Y_i and y_i only exist a.e. on $u(S_\epsilon)$ and S_ϵ, respectively.

Assuming for the moment that u has enough regularity for the calculations to make sense, we have from the rules (2.4) and (2.5) of covariant differentiation together with (2.7) that

$$D_{Y_j} Y_i = (D_{Y_j} y_i)X_i - \kappa_j y_i y_j X_j \tag{3.6a}$$

and by symmetry that

$$D_{Y_i} Y_j = (D_{Y_i} y_j)X_j - \kappa_i y_j y_i X_i. \tag{3.6b}$$

(In these formulas $y_k = y_k(u^{-1}(p))$.)

Rule (2.2) and the fact $[Y_i, Y_j] = 0$ imply equality of the right-hand sides of (3.6a) and (3.6b) from which it follows that

$$\frac{\partial y_i}{\partial t_j} = -\kappa_i\, y_i y_j. \tag{3.7}$$

For pairs of functions $\eta = (\eta_1, \eta_2)$, $y = (y_1, y_2)$ we define

$$I_1(\eta, y) = \int_0^{t_2} \eta_1(t_1,t)y_1(t_1,t)y_2(t_1,t)dt, \tag{3.8a}$$

$$I_2(\eta, y) = \int_0^{t_1} \eta_2(t,t_2)y_1(t,t_2)y_2(t,t_2)dt. \tag{3.8b}$$

We need the following lemma which says in what sense (3.7) holds in general.

LEMMA 3.1. *For almost all* $t_1 \in (-\epsilon, \epsilon)$, y_1 *as a function of* t_2 *satisfies*

$$y_1(t_1, t_2) = y_1(t_1, 0) - I_1(\kappa, y) \tag{3.9}$$

for almost all $t_2 \in (-\epsilon, \epsilon)$ *and analogously for* y_2. *(Here,*$\kappa_i = \kappa_i(u(t_1, t_2))$.*)*

Proof. It is enough to show that this is the case for sufficiently small ϵ, since one can then patch together small squares to conclude that it is so in the original square. If u is a characteristic coordinate mapping, then so is $v(t_1, t_2) = u(f_1(t_1), f_2(t_2))$ for any pair of bi-Lipschitz functions f_1, f_2. If w_k is the counterpart of y_k for v, then

$$w_k(t_1, t_2) = y_k(f_1(t_1), f_2(t_2)) f_k'(t_k),$$

from which one sees that it is sufficient to prove the statement in the case that y_1 and y_2 are identically 1 on the lines $t_2 = 0$ and $t_1 = 0$, respectively. By working with a sequence of smooth approximations to the θ which gives X_1, X_2, we can approximate the pair X_1, X_2 by sequences $X_1^{(n)}, X_2^{(n)}$of orthonormal C^∞ fields which converge uniformly to the X_i in a neighborhood U of the closure of $u(S_\epsilon)$, for which the corresponding curvatures $\kappa_i^{(n)}$ are uniformly bounded and converge to the κ_i in $L^1(S_\epsilon)$, and such that $X_i^{(n)}(u(0,0)) = X_i(u(0,0))$. We consider the corresponding characteristic coordinate mappings $u^{(n)}$ with corresponding $Y_i^{(n)}$ and $y_i^{(n)}$, where $y_i^{(n)}$ is identically 1 on the line $t_j = 0$. Since the $y_i^{(n)}$ are smooth they satisfy (3.7) and consequently

$$y_i^{(n)} = 1 - I_i(\kappa_i^{(n)}, y^{(n)}), \qquad i = 1, 2. \tag{3.10}$$

Clearly, $u^{(n)} \to u$ uniformly on S_ϵ. Since the fields $X_1^{(n)}, X_2^{(n)}$ are uniformly Lipschitz continuous it follows from elementary facts about the continuous dependence of solutions of ordinary differential equations on the initial conditions (see [Hille, Theorem 3.1.1, p. 76]) that the $u^{(n)}$ are also uniformly Lipschitz continuous, so that the $y_i^{(n)}$ are uniformly bounded on S_ϵ. Since $y_i^{(n)}$ is identically 1 on the line $t_j = 0$, (3.10) implies that for sufficiently small ϵ

$$0.9 < |Y_i^{(n)}(u(t_1, t_2))|_V < 1.1$$

on S_ϵ for all n, so that by reducing ϵ, if necessary, we may assume that the $u^{(n)}$ are uniformly bi-Lipschitz on S_ϵ. From this it follows that $\kappa_i{}^{(n)}(u^{(n)}(t_1, t_2))$ tends to $\kappa_i(u(t_1, t_2))$ in $L^1(S_\epsilon)$. For sufficiently small $\epsilon > 0$, the system made up of (3.9) and its counterpart for y_2 can easily be seen to have a unique solution in $L^\infty(S_\epsilon)$. Indeed, this solution is the L^∞ limit of the sequence generated by the iteration

$$y_0 = (1, 1),\ y_{n+1} = (1, 1) - (I_1(\kappa, y_n), I_2(\kappa, y_n)). \tag{3.11}$$

Using this we can easily estimate $\|y - z\|_{L^1} = \|y_1 - z_1\|_{L^1} + \|y_2 - z_2\|_{L^1}$, where y and z are the solutions corresponding to kernels κ and η, respectively. Let M be an upper bound for the L^∞ norms of the components of κ and η. It follows immediately from (3.11) that for appropriately small $\epsilon > 0$ the L^∞ norms of the components of the y_n and z_n are all at most 2. We have

$$\|y_{1,n+1} - z_{1,n+1}\|_{L^1} = \int_{-\epsilon}^{\epsilon} \int_{-\epsilon}^{\epsilon} \int_0^{t_2} |\kappa_1 y_{1,n} y_{2,n} - \eta_1 z_{1,n} z_{2,n}| d\tau dt_1 dt_2,$$

where all the functions in the integrands are evaluated at (t_1, τ). Thus,

$$\begin{aligned}\|y_{1,n+1} - z_{1,n+1}\|_{L^1} &\leq \int_{-\epsilon}^{\epsilon}\int_{-\epsilon}^{\epsilon}\int_{-\epsilon}^{\epsilon} |\kappa_1 y_{1,n} y_{2,n} - \eta_1 z_{1,n} z_{2,n}| d\tau dt_1 dt_2 \\ &\leq 2\epsilon \int_{-\epsilon}^{\epsilon}\int_{-\epsilon}^{\epsilon} |\kappa_1 y_{1,n} y_{2,n} - \eta_1 z_{1,n} z_{2,n}| d\tau dt_1 \\ &\leq 8\epsilon \|\kappa - \eta\|_{L^1} + 2\epsilon M \int_{-\epsilon}^{\epsilon}\int_{-\epsilon}^{\epsilon} |y_{1,n} y_{2,n} - z_{1,n} z_{2,n}| d\tau dt_1 \\ &\leq 8\epsilon \|\kappa - \eta\|_{L^1} + 4\epsilon M \|y_n - z_n\|_{L^1}.\end{aligned}$$

Obviously, the same bound holds for $\|y_2 - z_2\|_{L^1}$, so that

$$\|y_{n+1} - z_{n+1}\|_{L^1} \leq 16\epsilon \|\kappa - \eta\|_{L^1} + 8\epsilon M \|y_n - z_n\|_{L^1}.$$

Since $y_0 = z_0 = (1, 1)$, it follows from this that

$$\|y_{n+1} - z_{n+1}\|_{L^1} \leq 16\epsilon \|\kappa - \eta\|_{L^1}/(1 - 8\epsilon M),$$

so that

$$\|y - z\|_{L^1} \leq 16\epsilon \|\kappa - \eta\|_{L^1}/(1 - 8\epsilon M). \tag{3.12}$$

Because, as we have explained, $\kappa^{(n)} = \kappa^{(n)}(u^{(n)}(t_1, t_2))$ tends to $\kappa = \kappa(u(t_1, t_2))$ in $L^1(S_\epsilon)$, it follows from (3.12) that $y^{(n)}$ tends in the $L^1(S_\epsilon)$ norm to the (unique) solution $\overline{y}$ in $L^\infty(S_\epsilon)$ of the system (3.9) with the original κ_i's. But then, by replacing the $\kappa^{(n)}$ by an appropriate subsequence, we can assume that for almost all fixed $T \in (-\epsilon, \epsilon)$, $y^{(n)}(T, t_2)$ and $\kappa^{(n)}(T, t_2)$ converge to $\overline{y}(T, t_2)$ and $\kappa(T, t_2)$, respectively, in $L^1(-\epsilon, \epsilon)$. Thus, for such T it follows from (3.8a) and (3.10) that

$$\overline{y}_1(T, t_2) = 1 - \int_0^{t_2} \kappa_1(T, t)\overline{y}_1(T, t)\overline{y}_2(T, t) dt,$$

for almost all $t_2 \in (-\epsilon, \epsilon)$ and analogously for $\overline{y}_2$. Finally, we must show that these $\overline{y}_i$ are our original y_i, defined by $Y_i = y_i X_i$. In other words, we have to show that the $y_i^{(n)}$ converge to the y_i. As we have seen, $u^{(n)} \to u$ and $X_k^{(n)}(u^{(n)}(t_1, t_2)) \to X_k(u(t_1, t_2))$ uniformly on S_ϵ, so that if we denote by $\theta^{(n)}$ the θ corresponding to $X_1^{(n)}$, $\theta^{(n)}(u^{(n)}(t_1, t_2))$ converges uniformly to $\theta(u(t_1, t_2))$ on S_ϵ. We have by (3.5)

$$u^{(n)}(t_1, b) - u^{(n)}(t_1, a) = \int_a^b y_2^{(n)}(t_1, \tau) F_2(u^{(n)}(t_1, \tau), \theta^{(n)}(u^{(n)}(t_1, \tau))) d\tau.$$

But, as we saw, on almost all of the lines $t_1 = T$, $y^{(n)}(T, t_2)$ tends to $\overline{y}(T, t_2)$ in $L^1(-\epsilon, \epsilon)$, so that for such T we have by letting $n \to \infty$ that

$$\begin{aligned}\int_a^b y_2(T, \tau) F_2(u(T, \tau), \theta(u(T, \tau))) d\tau &= u(T, b) - u(T, a) \\ &= \int_a^b \overline{y}_2(T, \tau) F_2(u(T, \tau), \theta(u(T, \tau))) d\tau,\end{aligned}$$

from which we conclude that $\overline{y}_2(T,t_2) = y_2(T,t_2)$ for almost all $t_2 \in (-\epsilon,\epsilon)$ and analogously for y_1. This yields the desired conclusion. □

Let U and $\overline{U}$ be (small) neighborhoods in V and $\overline{V}$, and let $f : U \to \overline{U}$ be an (m_1,m_2)-mapping. Let (u_1,u_2) and $(\overline{u}_1,\overline{u}_2)$ be corresponding local coordinates, so that f is given by $\overline{u} = f(u) = (f_1(u), f_2(u))$. We consider a characteristic coordinate mapping u of S_ϵ into U for the pair X_1, X_2 of principal direction fields. Obviously, $f \circ u$ is a characteristic coordinate mapping for the pair $\overline{X}_1, \overline{X}_2$. Without loss of generality we can assume that the y_k as well as the corresponding $\overline{y}_k$ for $f \circ u$ are all positive. Clearly, $\overline{y}_k = m_k y_k$. Let θ and $\overline{\theta}$ be the inclination functions for these pairs of fields. We derive equations satisfied by the ten functions

$$u_k,\ y_k, \lambda_k = \kappa_k y_k,\ \overline{u}_k, \theta, \overline{\theta} \tag{3.13}$$

of (t_1,t_2), $k = 1,2$. Note that by the curvature (2.9) the counterpart $\overline{\lambda}_k = \overline{\kappa}_k \overline{y}_k$ of λ_k is equal to $m_i\lambda_i/m_j$. In what follows, when we say that $\partial w/\partial t_i = w'$ for some functions w, w' defined a.e. on S_ϵ we mean that there is a function v equal to w a.e. on S_ϵ such that for almost all $T \in (-\epsilon,\epsilon)$, v is absolutely continuous on the line $t_j = T$ and $\partial v/\partial t_i = w'$ holds in the strict sense a.e. on it. In particular, the preceding lemma says that (3.7) holds in this sense.

Consider a rectangle $\alpha_k \le t_k \le \beta_k, k = 1,2$, in S_ϵ. Then since the arc length element $ds = y_1 dt_1$ (a.e. along 1-characteristics) and $dA = y_1 y_2 dt_1 dt_2$, (2.17) says that

$$\int_{\alpha_1}^{\beta_1} \kappa_1(t_1,\alpha_2) y_1(t_1,\alpha_2) dt_1 - \int_{\alpha_1}^{\beta_1} \kappa_1(t_1,\beta_2) y_1(t_1,\beta_2) dt_1 = -\int_{\alpha_2}^{\beta_2}\int_{\alpha_1}^{\beta_1} c_1 y_1 y_2 dt_1 dt_2$$

and

$$\int_{\alpha_2}^{\beta_2} \kappa_2(\alpha_1,t_2) y_2(\alpha_1,t_2) dt_2 - \int_{\alpha_2}^{\beta_2} \kappa_2(\beta_1,t_2) y_2(\beta_1,t_2) dt_2 = -\int_{\alpha_2}^{\beta_2}\int_{\alpha_1}^{\beta_1} c_2 y_1 y_2 dt_1 dt_2,$$

where

$$c_i(t_1,t_2) = c_i(u,\overline{u}) = m_j^2 \frac{m_i^2 \overline{K}(\overline{u}) - K(u)}{m_i^2 - m_j^2}.$$

Thus, the following equations hold a.e. on S_ϵ:

$$\lambda_1(t_1,t_2) = \lambda_1(t_1,0) + \int_0^{t_2} c_1(t_1,\tau) y_1(t_1,\tau) y_2(t_1,\tau) d\tau$$

and

$$\lambda_2(t_1,t_2) = \lambda_2(0,t_2) + \int_0^{t_1} c_2(\tau,t_2) y_1(\tau,t_2) y_2(\tau,t_2) d\tau$$

or in derivative form

$$\frac{\partial \lambda_i}{\partial t_j} = c_i y_1 y_2. \tag{3.14}$$

We also have that

$$\frac{\partial u}{\partial t_1} = y_1 F_1(u,\theta) \tag{3.15}$$

and since $\overline{y}_1 = m_1 y_1$

$$\frac{\partial \overline{u}}{\partial t_1} = m_1 y_1 \overline{F}_1(\overline{u}, \overline{\theta}), \tag{3.16}$$

where $F_i(u, \theta)$ is defined in (3.1).

As an immediate consequence of Lemma 3.1 we also have

$$\frac{\partial y_i}{\partial t_j} = -\lambda_i y_j \tag{3.17}$$

(in the sense explained above, of course). Finally, in light of (3.4), we have $D_1\theta = R_1(u, \theta)\kappa_1 + S_1(u, \theta)$, so that since $D_1\theta = \frac{\partial \theta}{\partial t_1}/y_1$ we conclude

$$\frac{\partial \theta}{\partial t_1} = \lambda_1 R_1(u, \theta) + y_1 S_1(u, \theta), \tag{3.18}$$

and analogously, using the fact that $\overline{\lambda}_k = m_i \lambda_i / m_j$,

$$\frac{\partial \overline{\theta}}{\partial t_1} = \frac{m_i \lambda_i}{m_j} \overline{R}_1(\overline{u}, \overline{\theta}) + \overline{y}_1 \overline{S}_1(\overline{u}, \overline{\theta}). \tag{3.19}$$

We are now able to analyze the sense in which the blow-up equations are satisfied for cps-mappings which are not necessarily C^3. (The argument to follow contains an alternate derivation of these equations based on the Gauss–Bonnet formula.) Let w be a finite valued measurable function on an open set $D \subset \mathbb{R}^2$. Then for almost all $p \in D$ it is true that for all $\eta > 0$

$$\frac{1}{\pi \delta^2} \lim_{\delta \to 0} A(\{\xi : |w(\xi) - w(p)| > \eta\} \cap \Delta(p, \delta)) = 0, \tag{3.20}$$

where A denotes 2-dimensional measure, and $\Delta(p, \delta)$ is the disk of radius δ about p. A point p for which (3.20) holds will be called a *point of approximate continuity* of w. For an orthonormal pair X_1, X_2 of Lipschitz continuous fields on U we denote by $E_i = E_i(X_1, X_2)$ the image under u of the set of points of approximate continuity of $\kappa_i \circ u$, and it is immediate that this definition is independent of the coordinate system used. It is easy to see that if $\kappa = \kappa_i$ a.e. in U and p is a point of approximate continuity of κ, then $\kappa_i(p)$ exists and is equal to $\kappa(p)$.

THEOREM 3.2. *Let $f : U \to \overline{U}$ be an (m_1, m_2)-mapping. Then for almost all $p \in U$, κ_i (as defined by (2.7)) exists on the entire j-characteristic C through p, and the restriction of κ_i to C is differentiable and satisfies the blow-up equation $D_j \kappa_i = \kappa_i^2 + c_i$ along it, where D_j is to be interpreted as arc length differentiation along C.*

Proof. It is clearly enough to establish the conclusion in $u(S_\epsilon)$ for any characteristic coordinate mapping u. For convenience let $i = 1$. There is a set $B \subset (-\epsilon, \epsilon)$ of measure 2ϵ and functions κ and y which coincide with $\kappa_1 \circ u$ and y_1 a.e. on each line $t_1 = T \in B$ and are such that y and $\lambda = \kappa y$ are absolutely continuous on each of these lines and satisfy $\frac{\partial \lambda}{\partial t_2} = c_1 y y_2$ and $\frac{\partial y}{\partial t_2} = -\lambda y_2$ in the strict sense a.e. on them. We can assume in addition that for all $T \in B$ almost all points of the 2-arc C_T corresponding to $t_1 = T$ are in E_1. Then at all points (T, t_2) at which the equations are satisfied, we have

$$\frac{\partial \kappa}{\partial t_2} = \frac{\partial(\lambda/y)}{\partial t_2} = \frac{y^2 c_1 y_2 + \lambda^2 y_2}{y^2} = (c_1 + \kappa^2) y_2,$$

or, in other words,

$$D_2(\kappa \circ u^{-1}) = c_1 + (\kappa \circ u^{-1})^2, \tag{3.21}$$

where D_2 is interpreted as arc length differentiation. Since κ is absolutely continuous (3.21) holds everywhere on C_T. It follows easily from this and the fact that almost all points of C_T are of points of approximate continuity of $\kappa \circ u^{-1}$ that in fact *all* points of C_T are points of approximate continuity of $\kappa \circ u^{-1}$(since the same equation holds on almost all nearby 2-characteristics). But then from the comment contained in the last sentence immediately preceding the statement of the theorem we conclude that (3.21) holds everywhere on C_T with $\kappa \circ u^{-1}$ replaced with κ_i, as desired. □

Theorem 3.2 has the following important corollary.

COROLLARY (COMPACTNESS PRINCIPLE). *Let U be a domain in V and let $P \subset \overline{V}$ be compact. Then the class of all (m_1, m_2)-mappings of U into $\overline{V}$ for which $f(U) \subset P$ is compact in the topology of uniform convergence of first derivatives on compact sets.*

Proof. It is enough to see that any $p \in V$ and $\overline{p} \in \overline{V}$ have (small) coordinate neighborhoods U_1 and $\overline{U}_1$ such that the (m_1, m_2)-mappings $f : U \to P$ for which $f(U_1) \subset \overline{U}_1$ have, when expressed in coordinate form, uniformly Lipschitz first derivatives on U_1. For sufficiently small U_1 Theorem 3.2 implies that κ_1 and κ_2 must be uniformly bounded and the curvature equations then say that the same must be true for $\overline{\kappa}_1$ and $\overline{\kappa}_2$. But then (3.4) and its counterpart for the $\overline{\kappa}_k$ and $\overline{\theta}$ imply that the first derivatives of θ and $\overline{\theta}$ are uniformly bounded on U_1 and $\overline{U}_1$ and in light of (3.1) and the fact that the Jacobian of f is completely determined by the X_k and $\overline{X}_k$ it follows that the first derivatives of the $f \in \mathcal{C}$ are indeed uniformly Lipschitz. □

We now examine the DeTurck–Yang initial value problem from the point of view of (3.14)–(3.19). Let C be a curve in U with Lipschitz continuous unit tangent and let $(g_1, g_2) = g : C \to \overline{U}$ have locally Lipschitz continuous derivative. We assume that the factor by which g changes arc length (when calculated with respect to the metrics in U and $\overline{U}$) is everywhere strictly between m_1 and m_2. We want to find the (m_1, m_2)-mappings of a neighborhood of C onto a neighborhood of $g(C)$ which coincide with g on C. We limit consideration to mappings which are orientation preserving with respect to the coordinate systems u and $\overline{u}$; trivial modifications cover the orientation-reversing mappings. Let T be a unit tangent field to C and let $\overline{T}$ be the corresponding unit tangent field $J_g T/|J_g T|$ to $\overline{C} = g(C)$. Let X_1, X_2 and $\overline{X}_1, \overline{X}_2$ be the fields associated with an (m_1, m_2)-extension f of g. Let ϕ denote the angle, calculated with respect to the metric of V, between X_1 and T; without loss of generality we can assume that $0 < \phi < \pi$. Let $\overline{\phi} \in (0, \pi)$ be the angle between $\overline{X}_1$ and $\overline{T}$. Then

$$m_1^2 \cos^2 \phi + m_2^2 \sin^2 \phi = |J_g T|_{\overline{V}} \quad \text{and} \quad \tan \overline{\phi} = \frac{m_2}{m_1} \tan \phi, \tag{3.22}$$

so that there are two possible choices for continuous X_1 along C, that is, two possibilities for θ corresponding to an (m_1, m_2)-mapping of a neighborhood of C onto a neighborhood of $g(C)$ and coinciding with g on C. The second equation in (3.22) means that $\overline{X}_1$ (i.e., $\overline{\theta}$) is determined once one of these θ is selected. It follows from the first of these equations that θ is a Lipschitz continuous function of arc length along C, and then from the second equation that $\overline{\theta}$ is also.

In order to proceed with the present discussion as well as to carry out some of the derivations in section 4 it is necessary to examine the relationship between the curvature of the curve C, that of its image under the (m_1, m_2)-mapping f, and the values along C of the κ_i associated with f, which by Theorem 3.2 exist a.e. on C. For

the moment we assume that J_f is differentiable (as a function of two variables) at almost all points of C. The following calculation will be valid a.e. on C. By reversing the direction of some of the vectors $X_1, X_2, \overline{X}_1, \overline{X}_2$, if necessary, we can assume that

$$T = \cos\phi X_1 + \sin\phi X_2 \quad \text{and} \quad \overline{T} = \cos\overline{\phi}\,\overline{X}_1 + \sin\overline{\phi}\,\overline{X}_2. \tag{3.23}$$

Let $N = -\sin\phi X_1 + \cos\phi X_2$ be the unit normal to C and let $\kappa = \kappa(p)$ denote the geodesic curvature of C defined by $\kappa N = D_T T$. Applying (2.4), (2.5), and (2.7) we see that a.e. on C there holds

$$\begin{aligned}\kappa N = D_T T &= D_T\phi(-\sin\phi X_1 + \cos\phi X_2) + \cos\phi D_T X_1 + \sin\phi D_T X_2 \\ &= D_T\phi N + \cos\phi(\cos\phi D_1 X_1 + \sin\phi D_2 X_1) + \sin\phi(\cos\phi D_1 X_2 + \sin\phi D_2 X_2) \\ &= D_T\phi N + \kappa_1\cos^2\phi X_2 - \kappa_2\cos\phi\sin\phi X_2 - \kappa_1\sin\phi\cos\phi X_1 + \kappa_2\sin^2\phi X_1 \\ &= D_T\phi N + (\kappa_1\cos\phi - \kappa_2\sin\phi)N,\end{aligned}$$

so that

$$\kappa_1\cos\phi - \kappa_2\sin\phi = \kappa - D_T\phi. \tag{3.24}$$

If $\overline{\kappa}$ and $\overline{N}$ are the analogous entities on $\overline{V}$, then we also have

$$\overline{\kappa}_1\cos\overline{\phi} - \overline{\kappa}_2\sin\overline{\phi} = \overline{\kappa} - D_{\overline{T}}\overline{\phi},$$

so that in light of the curvature (2.9)

$$\frac{\kappa_1}{m_2}\cos\overline{\phi} - \frac{\kappa_2}{m_1}\sin\overline{\phi} = \overline{\kappa} - D_{\overline{T}}\overline{\phi}.$$

In addition, it follows from the second equation in (3.22) that

$$\cos\overline{\phi} = \frac{m_1\cos\phi}{\sqrt{m_1^2\cos^2\phi + m_2^2\sin^2\phi}}$$

and

$$\sin\overline{\phi} = \frac{m_2\sin\phi}{\sqrt{m_1^2\cos^2\phi + m_2^2\sin^2\phi}}.$$

Since we also have

$$D_{\overline{T}}\overline{\phi} = \frac{1}{\sqrt{m_1^2\cos^2\phi + m_2^2\sin^2\phi}} D_T\overline{\phi}(f(p)),$$

it therefore follows that

$$\frac{m_1}{m_2}\kappa_1\cos\phi - \frac{m_2}{m_1}\kappa_2\sin\phi = \sqrt{m_1^2\cos^2\phi + m_2^2\sin^2\phi}\,\overline{\kappa} - D_T\tan^{-1}\left(\frac{m_2}{m_1}\tan\phi\right). \tag{3.25}$$

Finally, we point out that this holds for all curves C with Lipschitz continuous tangent, as can be seen by a simple approximation argument using Theorem 3.2.

It is now easy to cast the DeTurck–Yang initial value problem in a characteristic coordinate setting. Let C be a curve in U with Lipschitz continuous unit tangent and let $(g_1, g_2) = g : C \to \overline{U}$ have locally Lipschitz continuous derivative. We associate (a small piece) of C with the diagonal $L_\epsilon = \{(t, -t) : -\epsilon < t < \epsilon\}$ of S_ϵ via a one-to-one bi-Lipschitz function $u(t, -t)$ of L_ϵ into C having Lipschitz continuous derivative. The functions $\phi, \overline{\phi}$ and consequently $\theta, \overline{\theta}$ also are determined on C via (3.22) and then κ_1 and κ_2 are determined uniquely a.e. on C as the solution of the system (3.24), (3.25), so that in effect these six functions, as well as $u = (u_1, u_2)$ and $\overline{u} = (\overline{u}_1, \overline{u}_2)$, are determined on L_ϵ. By interchanging the roles of m_1 and m_2 and/or reversing the orientations of the corresponding X_i's as necessary, we can assume that $0 < \phi < \pi/2$, so that on the initial line $y_1, y_2 > 0$. Simple geometry implies that on the initial line

$$y_1(t, -t) = \left| \frac{du(t, -t)}{dt} \right|_V \cos\phi, \qquad y_1(t, -t) = \left| \frac{du(t, -t)}{dt} \right|_V \sin\phi.$$

Thus, all of the functions (3.13) are given on the initial line; these initial values for u_k, y_k, $\overline{u}_k$, $k = 1, 2$, and $\theta, \overline{\theta}$ are continuous; but for $\lambda_k = \kappa_k y_k$, they are merely bounded measurable functions. It is well known that for a system of equations of the form

$$\frac{\partial v}{\partial t_1} = A(v, w), \qquad \frac{\partial w}{\partial t_2} = B(v, w), \tag{3.26}$$

where $v = (v_1, \ldots, v_r)$ and $w = (w_1, \ldots, w_s)$ are functions of (t_1, t_2), and where A and B are Lipschitz continuous, the initial value problem with bounded measurable initial data $v(t, -t) = v_0(t), w(t, -t) = w_0(t)$, $|t| < \epsilon$, is locally well posed. Here the solutions are bounded measurable functions. The neighborhood of L_ϵ in which the solution is guaranteed to exist depends, for a given system (3.26), on the range of the initial functions $\{(v_0(t), w_0(t)) : -\epsilon < t < \epsilon\}$. Furthermore, if we are in the C^∞ or analytic category (i.e., A, B, and the initial data belong to one of these categories) then the solutions belong to the same category in any domain in which they exist.

The only thing one must do to complete this treatment of the DeTurck–Yang initial value problem is to show that the function $f = \overline{u} \circ u^{-1}$ which maps a neighborhood of the piece $u(L_\epsilon)$ of C onto a neighborhood of $g(u(L_\epsilon))$ is an (m_1, m_2)-mapping. One would expect such to be the case, but this has in fact been substantially obscured by the calculations used to arrive at the system. It is, however, not necessary to show directly that for a solution of this system, with initial data arising from a mapping g of C into $\overline{V}$ in the way described above, f is necessarily an (m_1, m_2)-mapping. Indeed, for C^∞ data (i.e., C and g) one can conclude this solely from the basic principles governing hyperbolic systems, as is explained fully in [Ge2, section 3]. (It is because this argument is based on polynomial approximation and the principle of permanence of functional equations for analytic functions that we have pointed out in several places that certain functions arising in the calculations were analytic.) One can conclude in general that f is an (m_1, m_2)-mapping simply by approximating the initial data by data in the C^∞ category and using the compactness principle together with the uniqueness of the solution of the initial value problem.

Theorem 3.2 tells us that a solution to a DeTurck–Yang initial value problem will exist in the entire (two-sided) domain of dependence unless the solution of one of the ordinary differential equations $D_j\kappa_i = \kappa_i^2 + c_i$ blows up along one of the characteristics along which this equation is valid; with obvious modifications, an analogous statement holds for the characteristic initial value problem (see discussion immediately following

Lemma 3.3 below). In particular, we will have such global existence if the initial values of the κ_i and the values of m_1, m_2, K, and $\overline{K}$ are such that the solutions of these equations never blow up.

We will need the following.

LEMMA 3.3. *Let $C \subset V$ be an arc with Lipschitz continuous tangent and let $p \in C$. Let κ_1 and κ_2 be any two bounded measurable functions on C. Let $\overline{p} \in \overline{V}$ and let $\overline{S}$ be any tangent vector to $\overline{V}$ at $\overline{p}$ with $|\overline{S}| \in (m_1, m_2)$. Then there is an open subarc C' containing p on which there are exactly two $f : C' \to \overline{V}$ with Lipschitz continuous derivative for which $f(p) = \overline{p}$ and $J_f(p)T = \overline{S}$ and such that along C the solutions to the corresponding DeTurck–Yang initial value problems have these κ_i as the curvatures of the corresponding curves of principal strain.*

Proof. Let $z = z(s)$, $-\epsilon < s < \epsilon$, be an arc length parametrization of a subarc of C with $z(0) = p$. If $\phi(s) = \phi(z(s))$, then (3.24) is simply the differential equation

$$\phi' = \kappa - \kappa_1 \cos\phi(s) + \kappa_2 \sin\phi(s).$$

If we add the initial condition $\phi(0) = \phi_0$, where $\phi_0 \in (0, \pi)$ is either of the solutions of

$$m_1^2 \cos^2\phi_0 + m_2^2 \sin^2\phi_0 = |\overline{S}|,$$

then there is a unique Lipschitz continuous solution of the corresponding initial value problem on some interval $(-\delta, \delta)$. Let $C' = z((-\delta, \delta))$. Then it is easy to see that there is an $f : C' \to \overline{V}$ with $f(p) = \overline{p}$ and $J_f(p)T = \overline{S}$ such that the geodesic curvature $\overline{\kappa}(s)$ at $f(z(s))$ as stipulated above is determined by (3.25), that is,

$$\overline{\kappa}(s) = \left(\frac{m_1}{m_2}\kappa_1 \cos\phi - \frac{m_2}{m_1}\kappa_2 \sin\phi + D_T \tan^{-1}\left(\frac{m_2}{m_1}\tan\phi\right)\right) / \sqrt{m_1^2\cos^2\phi + m_2^2\sin^2\phi}.$$

But since (3.24) and (3.25) uniquely define κ_1 and κ_2 once ϕ, κ, and $\overline{\kappa}$ are given, the solution of the DeTurck–Yang problem corresponding to initial mapping f (with the $X_k, \overline{X}_k$ chosen in accordance with the normalizing stipulations implicit in (3.23)) will have principal strain line curvatures coinciding along C' with the given κ_1 and κ_2. ∎

We now discuss the characteristic initial value problem for (m_1, m_2)-mappings, which is often easier to apply and more appropriate for the description of certain classes of such mappings as well as of individual ones. Let $C_k, k = 1, 2$, be curves on V with arc length parametrizations $w_k : [\alpha_k, \beta_k] \to V$, $\alpha_k < 0 < \beta_k$, such that the unit tangent vector fields $T_k(s)$ are Lipschitz continuous, $C_1 \cap C_2 = \{p\}$, where $p = w_1(0) = w_2(0)$, and $\langle T_1(0), T_2(0)\rangle = 0$. Given $\overline{p} \in \overline{V}$ and orthonormal tangent vectors $\overline{T}_1, \overline{T}_2$ to $\overline{V}$ at $\overline{p}$, the characteristic initial value problem for (m_1, m_2)-mappings consists of finding such a mapping f for which the C_k are m_k-characteristics and such that $f(p) = \overline{p}$ and $J_f T_k(0) = \overline{T}_k$. Of course, the possibility of high curvatures of the initial curves C_k in general precludes the existence of a solution even in a neighborhood of $C_1 \cup C_2$, but it is a relatively straightforward matter to see, by formulating this problem in terms of characteristic coordinates via the system (3.14)–(3.19), that it is well posed in a neighborhood of p. As with the Cauchy problem (i.e., the DeTurck–Yang problem) the key requirement is that the initial data for the ten functions (3.13) be Lipschitz continuous, which will clearly be the case for the data we have described. Here again one must make sure that the solution corresponds to an (m_1, m_2)-mapping. However, as we have seen, one can avoid the possibly cumbersome calculations implicit

in a direct verification by appealing to the theory of hyperbolic systems. Specifically, in this case the desired conclusion is a consequence of the fact that by using the blow-up (2.13) together with Lemma 3.3 we can arrange initial data for a DeTurck–Yang initial value problem along a C^∞ curve through p whose tangent at p is orthogonal to neither of the $T_k(0)$ in such a way that its solution will have the desired characteristics.

The remainder of this section deals with the generalization of HP nets discussed at the end of section 2. Specifically, we shall prove the following.

THEOREM 3.4. *Let U be a simply connected domain on a 2-manifold with constant Gaussian curvature K, and let X_1, X_2 be an orthonormal pair of Lipschitz continuous fields on U with curvatures κ_1, κ_2 defined by* (2.7). *Let $m_1, m_2 > 0$ and $\overline{K}$ be constants. Then the following are equivalent.*

(i) *For almost all $p \in U$, κ_i is a differentiable function of arc length on the entire j-characteristic through p along which it satisfies the ordinary differential equation $D_j\kappa_i = \kappa_i^2 + c_i$, where c_i is as given in* (2.14). *(Note that we are assuming only that one of the two equations in* (2.13) *is satisfied; that the other also holds will follow as a consequence.)*

(ii) *X_1, X_2 is an $(m_1, m_2, \overline{K})$-HP pair.*

(iii) *There is an (m_1, m_2)-mapping of U into a 2-manifold $\overline{V}$ with Gaussian curvature $\overline{K}$ whose principal strain fields are X_1 and X_2.*

Proof. (i)⇒(ii). Assume that the fields X_1, X_2 satisfy (i). For notational convenience we deal with the case $i = 1$. Let $u : S_\epsilon \to U$ be a characteristic coordinate mapping for these fields corresponding a small characteristic quadrilateral for which Lemma 3.1 holds; again without loss of generality we may assume that the y_i are positive. Then for $i = 1, 2$ there exist functions z_i which are equal to y_i a.e. on S_ϵ, which are absolutely continuous on almost all lines $t_j =$ constant, and satisfy (3.7) in the strict sense a.e. on them. Let T be such that the differential equation for κ_1 holds on the 2-arc corresponding to $t_1 = T$ and z_1 satisfies (3.7) a.e. on this segment. Let $\kappa(t) = \kappa_1(u(T,t))$ and $z(t) = z_1(T,t)$. Then the equations say

$$\kappa' = y_2(T,t)(c_1 + \kappa^2)$$

and

$$z' = -\kappa z y_2(T,t)$$

a.e. on $(-\epsilon, \epsilon)$. Thus,

$$\frac{d(\kappa z)}{dt} = \kappa' z + \kappa z' = z y_2(c_1 + \kappa^2) - \kappa^2 z y_2 = c_1 z y_2,$$

a.e. on $(-\epsilon, \epsilon)$, so that since κz is Lipschitz continuous on $(-\epsilon, \epsilon)$, it follows that for almost all T, $\alpha_2, \beta_2 \in (-\epsilon, \epsilon)$ with $\alpha_2 < \beta_2$ there holds

$$\kappa_1(u(T,\beta_2))y_1(T,\beta_2) - \kappa_1(u(T,\alpha_2))y_1(T,\alpha_2) = c_1 \int_{\alpha_2}^{\beta_2} y_1(T,t)y_2(T,t)dt.$$

Since $dA = y_1 y_2 dt_1 dt_2$ and $|du/dt_1| = y_1 dt_1$, integration with respect to T tells us that for almost all $\alpha_2 < \beta_2$ and any $\alpha_1 < \beta_1$ in $(-\epsilon, \epsilon)$, (2.17) holds with $i = 1$ for the characteristic quadrilateral $u([\alpha_1, \beta_1] \times [\alpha_2, \beta_2])$. Since by hypothesis κ_1 is continuous on almost all 2-characteristics, this is then true for all $\alpha_2 < \beta_2$. This shows that (ii) is true locally; that it is true globally follows by breaking large quadrilaterals into smaller ones.

(ii)⇒(iii) Let X_1, X_2 be an $(m_1, m_2, \overline{K})$-HP pair, and again let $u : S_\epsilon \to U$ be a characteristic coordinate mapping for these fields. Equation (3.14) holds since it was shown to follow from the HP-condition (2.17), and (3.15), (3.17), and (3.18) hold since they are consequences of the definitions of the u_k, y_k, λ_k, and θ. None of these equations involves any of the barred functions $\overline{u}_k, \overline{\theta}$; indeed, the only place any of these functions could enter these equations is in the c_i appearing in (3.14), and this does not happen because of our assumption that the Gaussian curvatures are constant. Uniqueness for characteristic initial value problems tells us that the only solution of the system (3.14), (3.15), (3.17), (3.18) for the $u_k, y_k, \lambda_k, \theta$ is the one associated with the given pair X_1, X_2. If we add (3.16) and (3.19) to the system and solve the corresponding characteristic initial value problem with the same initial data, we get an (m_1, m_2)-mapping of a neighborhood of $u(0, 0)$. But the X_1, X_2 so arising are still the original fields. This shows that the desired mapping exists in a neighborhood of each point of U; that it exists in all of this simply connected domain will then follow from the monodromy principle.

(iii)⇒(i). This is a special case of Theorem 3.2. □

4. Some applications.

4.1. Nonexistence of cps-mappings. We shall use the blow-up equations to show that there is no cps-mapping f of the Euclidean plane onto certain (complete, noncompact) manifolds $\overline{V}$. First of all, one notes that the solutions of the ordinary differential equation $y' = y^2$ regular at 0 are

$$y(x) = \frac{y(0)}{1 - y(0)x},$$

so that if $y(0) \neq 0$, the solution blows up to the right or left of 0 accordingly as $y(0)$ is positive or negative. From this it easily follows that if $c(x)$ is a nonnegative continuous function on $\mathbb{R}$ which is not identically 0, then the equation $y' = y^2 + c(x)$ has no solutions on all of $\mathbb{R}$.

We begin by noting that, as indicted in the introduction, there are no cps-mappings f of all of $\mathbb{R}^2$ onto itself other than the linear ones. In this case K as well as $\overline{K}$ are identically zero, so that both blow-up equations reduce to $\kappa_i' = \kappa_i^2$. From the above comments together with Theorem 3.2, for any such f it follows that $\kappa_i = 0$ a.e. on each i-characteristic, which means that all characteristics are straight lines. The linearity easily follows from this.

More interesting, perhaps, are situations in which there exist no cps-mappings of $\mathbb{R}^2$ onto $\overline{V}$ at all. In light of the interpretation of such mappings as deformations produced by the cryptocrystalline solidification of a planar lamina, this rules out the attainment of certain configurations as the result of such a process. Since $V = \mathbb{R}^2$, K is identically 0. To facilitate the discussion we assume that $m_1 < m_2$. From (2.14) we have $c_i = \frac{m_i^2 m_j^2}{m_i^2 - m_j^2}\overline{K}$, so that

$$\operatorname{sgn}(c_1) = -\operatorname{sgn}(\overline{K}) \quad \text{and} \quad \operatorname{sgn}(c_2) = \operatorname{sgn}(\overline{K}). \tag{4.1}$$

We have the following.

(1) *If $\overline{K}$ does not change sign on $\overline{V}$ and is not identically* 0, *then there are no cps-mappings $f : \mathbb{R}^2 \to \overline{V}$.* This follows immediately from the foregoing since if such an f were to exist in the case of nonnegative $\overline{K}$, for example, then by Theorem 3.2 and (4.1) there would exist a 1-characteristic with arc length parametrization $z =$

$z(s)$, $-\infty < s < \infty$, along which $c_2(z(s))$ is nonnegative but not identically 0, and along which $d\kappa_2(z(s))/ds = (\kappa_2(z(s)))^2 + c_2(z(s))$, which is impossible, as indicated in the opening paragraph of this section.

For the next case we consider $\overline{V}$ such that there is a C^∞ homeomorphism $u : \mathbb{R}^2 \to \overline{V}$ for which there are a finite number of disjoint closed disks $\overline{\Delta}_k = \overline{\Delta}(p_k, r_k), k = 1, \ldots, n$ (where $\overline{\Delta}(a, r)$ is the disk $|p - a| \le r$), such that u is an isometry on $\mathbb{R}^2 \setminus \overline{\Delta}_1 \cup \cdots \cup \overline{\Delta}_n$ and there is some $\epsilon > 0$ for which $K(u(p)) < 0$ for $r_k - \epsilon < |p - p_k| < r_k$, $1 \le k \le n$. We regard the interiors of the $u(\overline{\Delta}_k)$ as being bumps on an otherwise planar surface. One can produce such a bump by replacing a disk of radius r by the surface obtained by rotating the graph of $y = q(x)$, $0 \le x \le r$, about the y-axis, where $q \in C^\infty(\mathbb{R})$ is even and both $q''(x) > 0$ and $q'(x) < 0$ on some (r', r). These bumps have the desired negative curvature in a vicinity of the boundary circle and any number of them can be grafted into the plane, provided the corresponding closed disks are disjoint.

(2) *There exist no cps-mappings f of $\mathbb{R}^2$ onto such a "bumpy" plane $\overline{V}$.* Again assume that such an f existed. Let $z = z_k(s), k = 1, 2$, be arc length parametrizations of the characteristics through some point p_0 lying inside the preimage of one of the bumps with $z_k(0) = p_0$ and increasing s corresponding to the direction of X_k. The curvatures of the lines of principal strain are bounded since the preimage W of the union of the bumps is compact, and from the above discussion of blow-up in the planar case $|D_i\kappa_j(p)| \le 1/\mathrm{dist}(p, W)$ a.e. in $\mathbb{R}^2 \setminus W$. From this it follows by a simple compactness argument on the family of 2-characteristics that there is a 2-characteristic C which just touches ∂W but is disjoint from W (for example, by minimizing the area of the part of W to one side of C). It then follows from Theorem 3.2 that there are 2-characteristics C' arbitrarily close to C along which κ_1 exists and satisfies the corresponding blow-up equation. However, in light of the hypothesis, along such a C' sufficiently close to C, $c_1 \ge 0$ but is not identically 0, which is impossible by the comment at the end of the first paragraph of this section.

4.2. The hyperbolic plane $\mathbb{H}^2$. We begin by examining blow-up of the solutions of the ordinary differential equations to which the equations (2.13) reduce when both of the Gaussian curvatures K and $\overline{K}$ are constant. Upon writing

$$\gamma_i^2 = |c_i| = m_j^2 \left| \frac{m_i^2 \overline{K} - K}{m_i^2 - m_j^2} \right|,$$

(2.13) becomes $D_j\kappa_i = \kappa_i^2 \pm \gamma_i^2$, so we have only to look at the solutions of the elementary equations $\kappa' = \kappa^2 + \gamma^2$ and $\kappa' = \kappa^2 - \gamma^2$, $\gamma > 0$, $\kappa = \kappa(s)$. The general solution of the first is $\kappa(s) = \gamma \tan(\gamma s + C)$, so that the longest open interval in which a regular solution can exist has length π/γ. On the other hand, the solutions of $\kappa' = \kappa^2 - \gamma^2$ are of the form

$$\kappa(s) = \gamma \frac{1 + C\, e^{2\gamma s}}{1 - C\, e^{2\gamma s}}, \tag{4.2}$$

which is regular on the entire s-axis with range $(-\gamma, \gamma)$ when $C < 0$, reduces to the constant γ when $C = 0$, and has singularity at $s_0 = -(1/2\gamma) \log C$ when $C > 0$, in which case the range consists of the intervals $(-\infty, -\gamma)$ for $s > s_0$ and (γ, ∞) for $s < s_0$. In particular, the solution exists on all of $\mathbb{R}$ if and only if $|\kappa(0)| \le \gamma$.

Henceforth $V = \overline{V} = \mathbb{H}^2$, so that $K = \overline{K} = -1$. For convenience we also assume that $m_1 < m_2$, which of course constitutes no loss of generality. We have

$$c_i = \frac{m_j^2(1 - m_i^2)}{m_i^2 - m_j^2},$$

so that both of the equations (2.13) will be of the form $\kappa' = \kappa^2 - \gamma^2$ $(\gamma \geq 0)$ if and only if

$$m_1 \leq 1 \leq m_2. \tag{4.3}$$

Specifically, for such m_1, m_2 they are

$$D_j \kappa_i = \kappa_i^2 - \gamma_i^2, \text{ where } \gamma_i = \sqrt{\frac{m_j^2(m_i^2 - 1)}{m_i^2 - m_j^2}}. \tag{4.4}$$

Consider the characteristic initial value problem with initial m_k-characteristic $C_k, k = 1, 2$. Let C_k have the arc length parametrization $w = w_k(s)$, $\alpha_k < s < \beta_k$, where $0 \in (\alpha_k, \beta_k)$ and where $p = w_1(0) = w_2(0)$. As was pointed out in the discussion of this problem in section 3, we are in general guaranteed a solution only in a neighborhood of p. However, if we assume (4.3) and that the curvatures κ_k of the initial curves satisfy

$$|\kappa_k(s)| \leq \gamma_k \text{ a.e. on } (\alpha_k, \beta_k), k = 1, 2,$$

then the comment in the paragraph immediately preceding the statement of Lemma 3.3 implies that the solution exists in the entire characteristic quadrilateral determined by the C_k. Among other things this means that C_1 and C_2 are simple curves and $C_1 \cap C_2 = \{p\}$. Thus, in light of the facts that $\gamma_1^2 + \gamma_2^2 = 1$ and that γ_1 can take any value in $[0, 1]$ with appropriate m_1 and m_2 satisfying (4.3), we have established the following.

THEOREM 4.1. *Let C_1 and C_2 be curves in $\mathbb{H}^2$ whose arc length parametrizations have locally Lipschitz derivatives and which meet orthogonally at p. Let $\lambda_1, \lambda_2 > 0$ satisfy $\lambda_1^2 + \lambda_2^2 \leq 1$. If the (unsigned) geodesic curvature of C_k is bounded above by λ_k, $k = 1, 2$, then these curves are both simple and p is their only common point.*

With exactly the same hypotheses on the curves this theorem holds in the n-dimensional hyperbolic space $\mathbb{H}^n$ as well. To prove this, it suffices to show that p is the only common point when C_1 and C_2 are both simple curves. Indeed, if we have established this and C_1 and C_2 satisfy the hypotheses but C_1 is not simple, then we can replace C_2 by a geodesic E_2 which joins two points of a simple subarc E_1 of C_1 and thereby obtain a contradiction since the curvature of E_2 is everywhere 0 and that of E_1 is bounded by λ_1. Thus we shall assume that C_1 and C_2 are both simple. Assume that $n \geq 3$ and that they have a second point of intersection q. Let $w = w_k(s)$ be corresponding arc length parametrizations with $w_k(0) = p$ and $w_k(a_k) = q$, $k = 1, 2$. A simple compactness argument allows us to assume that the pair C_1, C_2 minimizes $a_1 + a_2$, i.e., the sum of the lengths of the two arcs pq. Henceforth $\operatorname{dist}(z_1, z_2)$ will denote the geodesic distance between points $z_1, z_2 \in \mathbb{H}^n$. Then $\frac{d}{ds}\operatorname{dist}(p, w_k(s)) > 0$ on $(0, a_k)$, since if it were equal to 0 for some $b \in (0, a_k)$, then C_k would be orthogonal to the geodesic joining p to $w_k(b)$, and this would give us a new pair of simple curves for which the sum of lengths of the two arcs joining the two intersection points is smaller than $a_1 + a_2$. Let $\epsilon > 0$. Then there exists a new pair of simple curves C_1'

and C_2' with C^∞ arc length parametrizations v_k on $(-1, l_k + 1)$ for which

(i) $l_k \le a_1 + a_2 + \epsilon$;
(ii) the corresponding curvatures $\kappa_k(s)$ satisfy $\kappa_k(s) \le \lambda_k + \epsilon$ on $(-1, l_k + 1)$, $k = 1, 2$;
(iii) $v_k(0) = p$, $k = 1, 2$;
(iv) $v_k(l_k) = q, k = 1, 2$;
(v) $\operatorname{dist}(p, v_k(s))$ increases on $(0, l_k)$;
(vi) C_1' and C_2' are orthogonal at their common initial point p;
(vii) for no $s \in (0, l_k]$ is the geodesic which joins p to $v_k(s)$ tangent to C_k' at $v_k(s)$.

Let $V_k(s), s \in (0, l_k]$ be the unit tangent vector at O to the geodesic ray emanating from p and passing through $v_k(s)$. It follows from (vii) that $|V_k'(s)| > 0$ on $(0, l_k]$. It is also easy to see that $\lim_{s\to 0^+} |V_k'(s)|$ exists. We claim that there exist $s_k \in (0, l_k]$ such that

$$A(s_1, s_2) = \int_0^{s_1} |V_1'(s)|\, ds + \int_0^{s_2} |V_2'(s)|\, ds = \pi/2 \tag{4.5}$$

and

$$\operatorname{dist}(p, v_1(s_1)) = \operatorname{dist}(p, v_2(s_2)). \tag{4.6}$$

To see this, consider $A(t_1, t_2)$ for $(t_1, t_2) \in Q = [0, l_1] \times [0, l_2]$. Then $A(0, 0) = 0$ and, because C_1' and C_2' are orthogonal at p, $A(l_1, l_2) \ge \pi/2$. Furthermore, since $|V_k'(s)| > 0$ on $(0, l_k]$, $A(t_1, t_2)$ is strictly increasing in each of its arguments. Thus the set $S = \{(t_1, t_2) \big| A(t_1, t_2) = \pi/2\}$ is a curve which joins the union of the left-hand side and bottom of Q to the union of its right-hand side and top. (This curve could degenerate to the point (l_1, l_2).) But (v) implies that there are increasing continuous functions $\tau_k, k = 1, 2$, which map $[0, 1]$ onto $[0, l_k]$ such that $\operatorname{dist}(p, v_1(\tau_1(t))) = \operatorname{dist}(p, v_2(\tau_2(t)))$, $t \in [0, 1]$. This means that there must be a $t \in (0, 1]$ such that $(\tau_1(t), \tau_2(t)) \in S$, so that (4.5) and (4.6) hold with $(s_1, s_2) = (\tau_1(t), \tau_2(t))$.

We consider the following mappings from a domain in $\mathbb{H}^2$ into $\mathbb{H}^n$. Let $O \in \mathbb{H}^2$ and T^* be a fixed unit vector in the tangent space of $\mathbb{H}^2$ at O. We define the continuous function T_k from the interval $[0, t_k]$ to the set of unit tangent vectors to $\mathbb{H}^2$ at O by $T(0) = T^*$ and $|T_k'(s)| = |V_k'(s)|$, where $T_k(s)$ moves in the positive sense as s increases when $k = 1$, and in the negative sense when $k = 2$. Let $G_k(s)$ be the geodesic ray emanating from O in the direction $T_k(s)$ and let $G_k(s, \sigma)$ be the point on $G_k(s)$ at distance σ from O, $0 \le s \le s_k$, $0 < \sigma$. Let F_k map the sector of $\mathbb{H}^2$ made up of the $G_k(s)$, $0 \le s \le s_k$, into $\mathbb{H}^n$ in such a way that $F_k(G_k(s, \sigma))$ is the point on the geodesic ray emanating from p through $v_k(s)$ whose distance from p is σ. One easily sees that F_k is an isometry (as a mapping between surfaces) and that it is locally one-to-one, so that F_k^{-1} is well defined. Let $\overline{C}_k$ be the preimage of C_k' under F_k. Since F_k is an isometry, the curvature of $\overline{C}_k$ at $F_k(v_k(s))$ is the curvature of C_k at $v_k(s)$ when calculated from the point of view of C_k' as a curve in the submanifold made up of the geodesics joining its points to p; this curvature is at most $\kappa_k(s)$. Thus, the curvature of $\overline{C}_k$ is bounded above by $\lambda_k + \epsilon$. Let $\overline{C}_2'$ be the curve onto which $\overline{C}_2$ is carried when $\mathbb{H}^2$ is rotated about O through a positive angle of $\pi/2$. Then from our construction $\overline{C}_1$ and $\overline{C}_2'$ are simple arcs in $\mathbb{H}^2$ which meet orthogonally at O, intersect again at their other endpoint, have lengths bounded by $a_1 + a_2 + \epsilon$, and have curvatures bounded, respectively, by $\lambda_1 + \epsilon$ and $\lambda_2 + \epsilon$. If we allow ϵ to tend to 0, then a simple compactness argument will provide curves in $\mathbb{H}^2$ which satisfy the hypotheses of Theorem 4.1 in $\mathbb{H}^2$ but not the conclusion. This contradiction proves

that the theorem is indeed true in $\mathbb{H}^n$. As an immediate consequence we obtain the following result due to Epstein [E1], [E2].

COROLLARY. *A curve in $\mathbb{H}^n$ whose curvature is everywhere bounded by 1 cannot intersect itself.*

We now give a very simple and quite explicit description of all of the cps-mappings of the entire space $\mathbb{H}^2$ into itself. Actually, it is easy to see that if $f : \mathbb{H}^2 \to \mathbb{H}^2$ is an (m_1, m_2)-mapping, then f is one-to-one and onto, so that we shall speak of the cps-self-homeomorphisms of $\mathbb{H}^2$. Fix a point $O \in \mathbb{H}^2$, and consider any (m_1, m_2)-mapping $f : \mathbb{H}^2 \to \mathbb{H}^2$, again with the nonrestrictive assumption that $m_1 < m_2$. Let C_k be the k-characteristic passing through O parametrized with respect to arc length by w_k, where $w_1(0) = w_2(0) = O$. Since all characteristics of f have infinite length in both directions, it follows from the above discussion that (4.3) holds. It furthermore follows from the initial comments that we must have $|\kappa_k| \leq \gamma_k$ a.e. on C_k, and conversely, the discussion of existence and blow-up of the preceding section shows that if these bounds are satisfied then there exists a corresponding (m_1, m_2)-mapping, which, moreover, is uniquely determined by the two functions κ_1, κ_2 once we assign the image of O and directions corresponding in the image to the tangent directions of the C_k at O. (Note that by Theorem 4.1 the conditions $|\kappa_k| \leq \gamma_k$ automatically imply that C_1 and C_2 are simple and only cross at O.) Thus we have the following.

THEOREM 4.2. *Let $O \in \mathbb{H}^2$ be fixed. There is a one-to-one correspondence between cps-self-homeomorphisms of $\mathbb{H}^2$ and 6-tuples $(m_1, m_2, C_1, C_2, \overline{O}, T)$, such that*

(i) *$m_1 \leq 1 \leq m_2$;*
(ii) *C_1 and C_2 are curves, of infinite length in both directions, with Lipschitz continuous unit tangent vectors and whose (unsigned) geodesic curvatures κ_k are bounded by the numbers γ_k defined in* (4.4)*;*
(iii) *$\overline{O} \in \mathbb{H}^2$;*
(iv) *T is an orthogonal transformation of the tangent space at O onto the tangent space at $\overline{O}$.*

For each such 6-tuple the mapping is the solution of the corresponding characteristic initial value problem.

Before continuing we point out that the blow-up conditions allow one to completely answer the following question: Given simple curves C and $\overline{C}$ on $\mathbb{H}^2$, of infinite length in both directions, and whose arc length parametrizations have locally Lipschitz continuous derivatives, give necessary and sufficient conditions on a mapping $f : C \to \overline{C}$ for which $|df/ds|$ is locally Lipschitz continuous and satisfies $m_1 < |df/ds| < m_2$ a.e. on C, such that the corresponding DeTurck–Yang initial value problems have global solutions. To do this we proceed as follows. Let $m_1 \leq 1 \leq m_2$, since otherwise there are no global (m_1, m_2)-mappings of $\mathbb{H}^2$ onto itself by Theorem 4.2. Let $z(s)$, $-\infty < s < \infty$, be an arc length parametrization of a simple curve C in V and let $\overline{z}(s) = f(z(s))$. Let $T = T(s)$ be the corresponding unit tangent vector to C at $z(s)$, $\overline{S} = \overline{S}(s) = J_f T(s)$, and $\overline{T} = \overline{S}/|\overline{S}|$. We assume that $|\overline{S}(s)|$ lies everywhere between m_1 and m_2 and shall apply the notation, normalizations, and calculations of the paragraph immediately following the proof of the corollary to Theorem 3.2 in section 3. Rewriting (3.24) and (3.25) slightly we have

$$\kappa_1 \cos\phi - \kappa_2 \sin\phi = \kappa - \phi' \tag{4.7}$$

and

$$\begin{aligned} \frac{m_1}{m_2}\kappa_1 \cos\phi - \frac{m_2}{m_1}\kappa_2 \sin\phi &= |\overline{S}|\overline{\kappa} - D_T \tan^{-1}\left(\frac{m_2}{m_1}\tan\phi\right) \\ &= |\overline{S}|\overline{\kappa} - m_1 m_2 \phi'/|\overline{S}|^2, \end{aligned} \tag{4.8}$$

so that solving for κ_1 and κ_2 we find

$$\begin{bmatrix}\kappa_1\\ \kappa_2\end{bmatrix} = \frac{1}{D}\begin{bmatrix}-\frac{m_2\sin\phi}{m_1} & \sin\phi\\ -\frac{m_1\cos\phi}{m_2} & \cos\phi\end{bmatrix}\begin{bmatrix}\kappa-\phi'\\ |\overline{S}|\overline{\kappa}-m_1m_2\phi'/|\overline{S}|^2\end{bmatrix},$$

where $D=(m_1^2-m_2^2)\frac{\sin\phi\cos\phi}{m_1m_2}$. Thus we find from our analysis of the blow-up of the κ_i that a necessary and sufficient condition for the solution of the DeTurck–Yang initial value problem to exist in all of $\mathbb{H}^2$ is that the following hold a.e. for $-\infty<s<\infty$:

$$|(\kappa-\phi')\frac{m_2\sin\phi}{m_1}-(|\overline{S}|\overline{\kappa}-m_1m_2\phi'/|\overline{S}|^2)\sin\phi|\le m_2|D|\left(\frac{(1-m_1^2)}{m_2^2-m_1^2}\right)^{\frac{1}{2}},$$

$$|(\kappa-\phi')\frac{m_1\cos\phi}{m_2}-(|\overline{S}|\overline{\kappa}-m_1m_2\phi'/|\overline{S}|^2)\cos\phi|\le m_1|D|\left(\frac{(m_2^2-1)}{m_2^2-m_1^2}\right)^{\frac{1}{2}}.$$

These bounds are, admittedly, not particularly revealing but they become considerably more so when we limit ourselves to the case in which ϕ is constant, that is, when the initial mapping of the curve C onto $\overline{C}$ has length change $|\overline{S}|=\sigma$, a constant. Since in this case we have $\phi'=0$, the conditions simplify to

$$|m_2\kappa-m_1\overline{\kappa}\sigma|\le\sqrt{(m_2^2-m_1^2)(1-m_1^2)}\,|\cos\phi|,$$

$$|m_1\kappa-m_2\overline{\kappa}\sigma|\le\sqrt{(m_2^2-m_1^2)(m_2^2-1)}\sin\phi.$$

Finally, we derive some sharp values for the radius of convexity for cps-mappings in $\mathbb{H}^2$. Returning to (4.7) and (4.8) above, we see that

$$\overline{\kappa}=\frac{1}{|\overline{S}|}\Big(\frac{m_1}{m_2}\kappa_1\cos\phi-\frac{m_2}{m_1}\kappa_2\sin\phi+m_1m_2\phi'/|\overline{S}|^2\Big),$$

so that, since $|\overline{S}|^2=m_1^2\cos^2\phi+m_2^2\sin^2\phi$, we have by (4.7) that

$$|\overline{S}|^3\overline{\kappa}=m_1m_2(\kappa_2\sin^3\phi-\kappa_1\cos^3\phi+\kappa)+\frac{m_1^3}{m_2}\kappa_1\cos^3\phi-\frac{m_2^3}{m_1}\kappa_2\sin^3\phi.$$

Thus, writing $\mu=(\frac{m_2}{m_1})^2$ we have

$$\frac{|\overline{S}|^3\overline{\kappa}}{m_1m_2}=\kappa-(\mu-1)\left(\frac{\kappa_1}{\mu}\cos^3\phi+\kappa_2\sin^3\phi\right)\text{ a.e. on }C.$$

Let $\Delta=\Delta(R,a)$ denote the disk of radius R and centered at a in $\mathbb{H}^2$ and let $f:\Delta\to\mathbb{H}^2$ be an (m_1,m_2)-mapping, which, without loss of generality we assume to be orientation preserving. We apply the above calculations to the curve $\partial\Delta$ with positive orientation so that N and $\overline{N}$ are inward pointing normals (see (3.23) and the sentence which follows it). The curve $\partial f(\Delta)$ is convex if and only if $\overline{\kappa}=\langle D_{\overline{T}}\overline{T},\overline{N}\rangle\ge 0$ a.e. on $\partial\Delta$, that is, if and only if

$$\kappa\ge(\mu-1)\left(\frac{\kappa_1}{\mu}\cos^3\phi+\kappa_2\sin^3\phi\right). \tag{4.9}$$

If p is a point of Δ at distance d from $\partial\Delta$, then it follows from (4.2) that the greatest value that $\kappa_i(p)$ can have is

$$\kappa_i^{\max} = \gamma_i \frac{e^{2\gamma_i d}+1}{e^{2\gamma_i d}-1} = \gamma_i \coth(\gamma_i d), \tag{4.10}$$

since otherwise f would have to have a singularity inside Δ. It is well known and easily calculated that the hyperbolic geodesic curvature $k(r)$ of a circle of hyperbolic radius r is given by

$$k(r) = \frac{1+\tanh^2(r/2)}{2\tanh(r/2)}.$$

It then follows from (4.9) that $f(\Delta(r,a))$ is convex provided that

$$k(r) \geq (\mu-1)\max\left\{\frac{\gamma_1}{\mu}\coth(\gamma_1(R-r)), \gamma_2\coth(\gamma_2(R-r))\right\}. \tag{4.11}$$

For fixed $m_1 \leq 1 \leq m_2$, $R>0$ the right-hand side is increasing, so that since the left-hand side is decreasing, there is a unique $\rho = \rho(m_1, m_2, R)$ for which they coincide.

THEOREM 4.3. *Let $m_1 \leq 1 \leq m_2$, $R>0$. Then $\rho(m_1,m_2,R)$ is the largest r such that all (m_1,m_2)-mappings of $\Delta(R,a)$ into $\mathbb{H}^2$ map $\Delta(r,a)$ onto simply covered convex domains.*

Proof. That the images of the concentric disk of radius $\rho(m_1,m_2,r)$ are all convex follows from the preceding discussion. Thus we have only to show that this ρ cannot be replaced by any larger number. Let i be the index corresponding to the maximum in (4.11). Let C_j be a geodesic through a and let $q \in C_j$ be at distance ρ from a. Let $d > R-\rho$, and let C_i be a curve orthogonal to C_j at q whose geodesic curvature is 0 everywhere except on a small neighborhood N of q along which it is given by the expression in (4.10), with the "concave side" of N towards the shorter of the two arcs into which q divides C_j. It is clear then that for sufficiently small N the solution f to the characteristic initial value problem for (m_1,m_2)-mappings with these characteristics exists in all of $\Delta(R,a)$. But given any $r > \rho$, for a $d > R-\rho$ sufficiently close to $R-\rho$, (4.9) will be violated for the circle centered at a and of radius r, that is, the image of the interior of this circle will not be a convex domain. ∎

5. Comments. In closing we touch on a few of the many questions about cps-mappings that naturally suggest themselves. First of all, there are reasons to believe that the Jacobian of a C^1-mapping between 2-manifolds having constant principal strains is necessarily locally Lipschitz continuous. A partial result in this direction was given in [Ge1], where it was shown that in the planar case this conclusion is valid under the stronger assumption that the derivatives of the mapping satisfy a Hölder condition with exponent $\alpha > (\sqrt{5}-1)/2$, and the arguments given there can be strengthened to extend this result to the general manifold context with the lower bound decreased to $1/2$.

In section 4 we considered only the radius of convexity problem in $\mathbb{H}^2$ under the assumption that $m_1 \leq 1 \leq m_2$ because for other values of the principal stretches there are no (m_1,m_2)-mappings of $\Delta(R,a)$ into $\mathbb{H}^2$ when R is sufficiently large. This leads us to the problem of determining the radius of the largest disk on a complete manifold of constant Gaussian curvature K on which there exist (m_1,m_2)-mappings into a manifold of constant Gaussian curvature $\overline{K}$. In light of the opening sentences

of section 1 the answer to this question, and more generally the determination of maximal domains of existence for cps-mappings on manifolds, would have an obvious bearing on the appearance of flaws in cryptocrystalline films.

Theorem 4.2 gives a complete description of all cps-mappings of $\mathbb{H}^2$ onto itself, and we have done the same [Ge4] for two planar domains (the half-plane and the exterior of a disk), but it would appear that the nonlinear hyperbolic nature of the underlying equations precludes such a description in any appreciable generality. Moreover, it is most likely that even for many "nice" domains in $\mathbb{R}^2$ there are no such mappings at all. (Although we believe this to be the case for disks, we have as yet been unable to come up with a proof.) These circumstances suggest two problems: (1) Find other manifolds for which it is possible to describe all the cps-self-homeomorphisms. (2) Find some simple conditions on a manifold which imply that this class is vacuous.

We end with a few words about cps-mappings in higher dimensions, that is, about mappings with distinct constant principal stretches between n-dimensional manifolds. The treatment of section 2 can be carried over to this more general context, but the equations that result are vastly more complicated. In the first place, the higher dimensional counterpart of the system (2.9) of curvature equations, although hyperbolic, is not diagonal, and in the second place the analogues of the blow-up equations (2.13) involve not only the principal strain line curvatures but functions that give the rate of rotation of the frames of principal strain directions as well (see [Ge2]). An example of Yin [Y] shows that there are nonaffine cps-self-homeomorphisms of $\mathbb{R}^3$, and it would be of interest to determine all such mappings. Indeed, most of the questions we have touched on in this paper can be examined in the higher dimensional context as well.

GLOBAL NONNEGATIVE SOLUTIONS OF A NONLINEAR FOURTH-ORDER PARABOLIC EQUATION FOR QUANTUM SYSTEMS*

ANSGAR JÜNGEL† AND RENÉ PINNAU‡

Abstract. The existence of nonnegative weak solutions globally in time of a nonlinear fourth-order parabolic equation in one space dimension is shown. This equation arises in the study of interface fluctuations in spin systems and in quantum semiconductor modeling. The problem is considered on a bounded interval subject to initial and Dirichlet and Neumann boundary conditions. Further, the initial datum is assumed only to be nonnegative and to satisfy a weak integrability condition. The main difficulty of the existence proof is to ensure that the solutions stay *nonnegative* and exist *globally* in time. The first property is obtained by an exponential transformation of variables. Moreover, entropy-type estimates allow for the proof of the second property. Results concerning the regularity and long-time behavior are given. Finally, numerical experiments underlining the preservation of positivity are presented.

Key words. higher order parabolic PDE, global solution, existence, uniqueness, positivity, entropy

1. Introduction.

In the last years, the study of *nonnegative* or *positive* solutions to parabolic fourth-order equations has attracted a lot of attention in the mathematical literature (see [Ber98], [BP98], [dPGG98], [Grü95], and the references therein). In particular, it was shown that certain degenerate equations of the form

$$h_t = -(f(h)h_{xxx})_x + (g(h)h_x)_x \tag{1.1}$$

allow for positive solutions if the functions f and g satisfy certain growth conditions [dPGG98]. Equation (1.1) appears in the context of surface dominated motion of thin viscous films and spreading droplets or plasticity (for an overview see [Ber98] and the references therein). When $f(h) = h,\ g(h) \equiv 0$, this equation especially arises in the modeling of droplet breakup in a Hele–Shaw cell, where the variable h describes the thickness of a neck between two masses of fluid.

Clearly, maximum principles are in general not available for fourth-order equations such that the positivity or nonnegativity property has to be proved by other techniques. The main ingredient is to exploit the special nonlinear structure of (1.1) introduced by the degenerate mobility $f(h)$, i.e., $f(h) = h^\alpha$ as $h \to 0$ for some $\alpha > 0$. This allows for nonlinear entropy dissipation, which is essential for the positivity of solutions [dPGG98].

In this paper we show that the fourth-order equation

$$n_t = -(n(\log(n))_{xx})_{xx} \tag{1.2a}$$

for $t > 0$ subject to the initial condition

$$n(0,x) = n_0(x) \tag{1.2b}$$

allows for nonnegative solutions.

This equation, which can be equivalently written as

$$n_t = -n_{xxxx} + \left(\frac{n_x^2}{n}\right)_{xx}, \tag{1.2c}$$

arises as a scaling limit in the study of interface fluctuations in a certain spin system [DLSS91]. The variable n describes the scaling limit of probabilities for a random variable. Problem (1.2a)–(1.2b) with periodic boundary conditions was first studied by Bleher, Lebowitz, and Speer in [BLS94]. Assuming (strictly) positive $H^1(\Omega)$-data, they showed that there exists a unique positive classical solution locally in time. For "small" initial data, the solution is even global in time. However, the problem of whether nonnegative solutions for general (nonnegative) initial data exist *globally* in time remained open. In this paper we solve this problem. Note that the equivalent formulation of (1.2a) is not degenerate such that the concept of nonlinear entropy dissipation is not applicable.

More specifically, we consider (1.2a) in the bounded domain $\Omega = (0,1)$ subject to the boundary conditions

$$n(0) = n(1) = 1, \quad n_x(0) = n_x(1) = 0. \tag{1.2d}$$

Our results extend to Dirichlet boundary conditions $n(0) \neq n(1)$, but we use (1.2d) for the sake of a smoother presentation. Although (1.2a) is (formally) derived for $\Omega = \mathbb{R}$, we study the problem in a bounded domain subject to the conditions (1.2d) for the following reason.

Equation (1.2a) also arises in the modeling of quantum semiconductor devices [Pin99a]. More precisely, the so-called quantum drift diffusion model ([PU99], [AI89]) simplifies to (1.2a) in the case of zero temperature and zero (or negligible) electric field (see also [GJ99a], [Jün98], [Jün97]). In several space dimensions the simplified and scaled equation reads

$$n_t = -2 \operatorname{div}\left(n\nabla\left(\frac{\Delta\sqrt{n}}{\sqrt{n}}\right)\right)$$

or, equivalently (assuming smooth nonvacuum solutions),

$$n_t = -\sum_{i,j} \partial_i\partial_j \left(n\,\partial_i\partial_j \log(n)\right).$$

In this context, n denotes the density of electrons in the semiconductor crystal. The expression $\Delta\sqrt{n}/\sqrt{n}$ is the so-called quantum Bohm potential. Now, in quantum semiconductor modeling, usually the boundary conditions (1.2d) are used (see [Gar94], [Pin99b]). Note that our arguments also apply to the case of periodic boundary conditions.

We show that for nonnegative initial data satisfying a certain integrability condition, there exists a generalized nonnegative solution globally in time. We stress the fact that we do not assume (strictly) positive initial data. As we impose only weak assumptions on the data, we can a priori not expect that our solutions have $L^2_{loc}(0,\infty;H^2(\Omega))$-regularity (see Proposition 3.2). On account of this fact we have to weaken our solution concept. Our main result is as follows.

THEOREM 1.1. *Assume that the initial datum n_0 is measurable and satisfies the condition*

$$\int_\Omega n_0 - \log(n_0)\,dx < +\infty. \tag{1.3}$$

Then there exists a solution n of (1.2a)–(1.2d) *satisfying*

$$n(x,t) \geq 0 \quad \text{a.e. in } (0,\infty)\times\Omega, \tag{1.4a}$$

$$n \in L^2_{loc}(0,\infty;W^{1,1}(\Omega)), \quad n_t \in L^1_{loc}(0,\infty;H^{-2}(\Omega)), \tag{1.4b}$$

$$\log(n) \in L^2_{loc}(0,\infty;H^2(\Omega)) \cap L^\infty(0,\infty;L^1(\Omega)). \tag{1.4c}$$

Further, $n(\cdot,0) = n_0$ in the sense of $H^{-2}(\Omega)$ and it holds for any $T > 0$ and any smooth test function $\phi \in C_c^\infty((0,\infty)\times\Omega)$,

$$\int_0^T \langle n_t,\phi\rangle_{H^{-2},H^2_0}\,dt = -\int_0^T\int_\Omega n\,(\log(n))_{xx}\,\phi_{xx}\,dxdt.$$

REMARK 1.1.

(a) *From condition* (1.3) *one can readily deduce that $n_0 \in L^1(\Omega)$ (see Corollary* 2.5*). Thus we only impose very weak regularity assumptions on the initial data.*

(b) *Starting from smooth, positive initial data Bleher, Lebowitz, and Speer* [BLS94] *used the stronger concept of mild solutions, employing results from semigroup theory.*

(c) *The regularity of the solutions provided by Theorem* 1.1 *is quite weak. In particular, it is not clear whether uniqueness of solutions holds in the class of functions satisfying* (1.4)*. Bleher, Lebowitz, and Speer proved in* [BLS94] *the uniqueness of solutions to* (1.2a)–(1.2b) *with periodic boundary conditions, assuming (strictly) positive $H^1(\Omega)$ initial data. These results can be easily extended to our set of boundary data.*

(d) *Considering* (1.1) *with $g(h) \equiv 0$, Bernis and Friedman* [BF90] *established a very weak solution concept, basically saying that h is a solution if for all $\phi \in L^2(0,T;H^1(\Omega))$ it holds that*

$$\int_0^T \langle h_t,\phi\rangle\,dt - \int_{\{|h|>0\}} f(h)\,h_{xxx}\,\phi_x\,dxdt = 0.$$

The proof of Theorem 1.1 is based on two ideas. The first one is to perform an exponential transformation of variables. Setting $n = e^{2u}$, (1.2a) reads in the new variable

$$\left(e^{2u}\right)_t = -2\left(e^{2u}\,u_{xx}\right)_{xx}. \tag{1.5}$$

Hence, the existence of a (generalized) solution u of (1.5) implies the existence of a nonnegative solution n of (1.2a). Exponential transformations were already successfully employed in the study of the stationary quantum hydrodynamic equations [GJ99b], [BGMS95].

Clearly, a solution $u \in L^\infty((0,\infty)\times\Omega)$ to (1.5) provides a *positive* solution n to (1.2a). However, we get only the regularity $u \in L^2_{loc}(0,\infty;L^\infty(\Omega))$ (see (1.4)) such that we can only conclude the existence of nonnegative solutions to (1.2a). This is in contrast to the stationary problem, where the positivity property immediately follows from an $H^s(\Omega)$ bound for the corresponding stationary variable u and the Sobolev embedding $H^s(\Omega) \hookrightarrow L^\infty(\Omega)$ when $s > d/2$, d being the space dimension (see [GJ99b]).

This observation motivated us to discretize (1.5) in time, which is the second main idea for the proof, yielding a sequence of elliptic problems. We show the existence of solutions $u(t_k,\cdot)$ in $H^2(\Omega)$ to the resulting elliptic problems. Hence, the approximate solutions $u(t_k,\cdot)$ are in $L^\infty(\Omega)$ and expressions like $e^{u(t_k,x)}$ are well defined.

It is worth noting that (1.2a) possesses several Lyapunov functionals which provide a priori estimates in the existence proof. It can be easily seen that the *entropy*

$$S(t) = \int_\Omega n(t)\,(\log(n(t)) - 1) + 1\,dx$$

is (formally) nonincreasing in time. This has also been observed in [BLS94]. In the case of periodic boundary conditions, also the *Fisher information*

$$\int_\Omega \left|(\sqrt{n})_x\right|^2\,dx$$

is nonincreasing in time. In addition we prove that the quantity

$$\int_\Omega n(t) - \log(n(t))\,dx$$

is nonincreasing in time. More precisely, we show that

$$\int_\Omega n(t) - \log(n(t))\,dx + \int_0^t \int_\Omega |(\log(n(t)))_{xx}|^2\,dx\,dt \le \int_\Omega n_0 - \log(n_0)\,dx$$

(in a sense to be made precise later).

For the unique solvability of the resulting elliptic systems the following monotonicity property is essential. The idea is the following: First, divide (1.2a) by $\sqrt{n}$. Then we obtain (formally)

$$(\sqrt{n})_t = A(\sqrt{n}) \stackrel{\text{def}}{=} -\frac{1}{2\sqrt{n}}(n(\log(n))_{xx})_{xx}.$$

A formal computation shows that the operator $-A(\sqrt{n})$ is monotone:

$$-\langle A(\sqrt{n_1}) - A(\sqrt{n_2}), \sqrt{n_1} - \sqrt{n_2}\rangle \ge 0 \quad \text{for suitable } \sqrt{n_1}, \sqrt{n_2}.$$

This property will be made precise in section 2. We notice that the monotonicity of the operator $-A(\sqrt{n})$ was already used in the analysis of the stationary quantum drift diffusion equations [PU99], as well as for the investigation of stability properties of the linearized transient model [Pin99a].

The paper is organized as follows. Section 2 is devoted to the proof of Theorem 1.1. In section 3 we give a result on the long-time behavior of solutions and consider regularity questions. Further, we present some numerical experiments underlining the preservation of positivity for $t > 0$.

1.1. Notation and auxiliary results. We use the standard notation for Sobolev spaces (see [Ada75]), denoting the norm of $W^{m,p}(\Omega)$ ($m \in \mathbb{N}, p \in [1,\infty]$) by $\|\cdot\|_{W^{m,p}(\Omega)}$. In the special case $p = 2$ we use $H^m(\Omega)$ instead of $W^{m,2}(\Omega)$. Further, let $H_0^m(\Omega)$ be the closure of $C_c^\infty(\Omega)$ with respect to the $H^m(\Omega)$-norm. Its dual space $(H_0^m(\Omega))^*$ is denoted by $H^{-m}(\Omega)$ and the duality pairing of $H_0^m(\Omega)$ with its dual space is given by $\langle\cdot,\cdot\rangle_{H^{-m},H_0^m}$. Moreover, for any Banach space B we define the space $L^p(0,T;B)$ with $p \in [1,\infty]$ consisting of all measurable functions $\varphi : (0,T) \to B$ for which the norm

$$\|\varphi\|_{L^p(0,T;B)} \stackrel{\text{def}}{=} \left(\int_0^T \|\varphi\|_B^p \, dt\right)^{1/p}, \quad p \in [1,\infty),$$
$$\|\varphi\|_{L^\infty(0,T;B)} \stackrel{\text{def}}{=} \sup_{t\in(0,T)} \|\varphi(t)\|_B, \quad p = \infty$$

is finite. If the time interval is clear we shortly write $\|\cdot\|_{L^p(B)}$.

In the forthcoming analysis we make frequent use of the Gagliardo–Nirenberg inequality [GT83].

LEMMA 1.2. *Let $\Omega \in \mathbb{R}$ be a bounded domain and $m \geq 1$. Furthermore, let $1 \leq p,q,r \leq \infty$, $j \in \mathbb{N}_0$ with $j < m$ and $\theta \in [j/m, 1]$ such that*

$$\frac{1}{p} = j + \theta\left(\frac{1}{r} - m\right) + (1-\theta)\frac{1}{q}$$

provided that $m - j - 1/r$ is a nonnegative integer (or else take $\theta = j/m$). Then there exists a constant $C = C(\Omega, m, j, \theta, p, q, r) > 0$ such that for all $\varphi \in W^{m,r}(\Omega) \cap L^q(\Omega)$

$$\left\|D^j\varphi\right\|_{L^p(\Omega)} \leq C\,\|\varphi\|_{W^{m,r}(\Omega)}^\theta\,\|\varphi\|_{L^q(\Omega)}^{1-\theta}.$$

2. Existence. In this section we provide the proof of Theorem 1.1, which is done in several steps. First, we introduce an exponential transformation of variables. Setting $n = e^{2u}$ we get (1.5), which will be investigated in the following. Instead of Theorem 1.1, we prove the following result, which yields Theorem 1.1 by back transforming the variables.

PROPOSITION 2.1. *Assume that the initial datum u_0 is measurable and satisfies*

$$\int_\Omega e^{2u_0} - 2u_0\,dx < \infty. \tag{2.1}$$

Then there exists a solution $u \in H_0^2(\Omega)$ of

$$\left(e^{2u}\right)_t = -2\left(e^{2u}u_{xx}\right)_{xx}$$

satisfying $e^{2u(\cdot,0)} = n_0$ in the sense of $H^{-2}(\Omega)$ and

$$u \in L^2_{loc}(0,\infty;H_0^2(\Omega)) \cap L^\infty(0,\infty;L^1(\Omega)), \tag{2.2a}$$
$$e^{2u} \in L^2_{loc}(0,\infty;W^{1,1}(\Omega)), \quad \left(e^{2u}\right)_t \in L^r_{loc}(0,\infty;H^{-2}(\Omega)) \tag{2.2b}$$

for $r \in [1, 10/9)$. Further, it holds for each $T > 0$ and each $\phi \in C_c^\infty((0,\infty)\times\Omega)$

$$\int_0^T \left\langle\left(e^{2u}\right)_t, \phi\right\rangle_{H^{-2},H_0^2} dt + 2\int_0^T\int_\Omega e^{2u}\,u_{xx}\,\phi_{xx}\,dx\,dt = 0. \tag{2.3}$$

REMARK 2.1. *Note that this result is even stronger than Theorem* 1.1*, since it implies* $n_t \in L^r_{loc}(0,\infty;H^{-2}(\Omega))$ *for* $r \in [1,10/9)$*. This gain of regularity is significantly simplifying the proof due to the reflexivity of* $L^r_{loc}(0,\infty;H^{-2}(\Omega))$ *for* $r>1$.

Second, to prove Proposition 2.1 we employ a vertical line method [Rek82], i.e., we use a semidiscretization in time. This yields a sequence of elliptic problems, for which we show that each possesses a unique positive solution.

Third, we derive a priori estimates on the sequence of approximating solutions, which allow us to perform the limit in the weak formulation. They are of energy type and of entropy type as well.

2.1. Semidiscretization. We divide the interval $[0,T]$ into N subintervals by introducing the partition $0=t_0<t_1<\cdots<t_N=T$. Setting $\tau_k \stackrel{\text{def}}{=} t_k - t_{k-1}$ we define the maximal subinterval length $\tau \stackrel{\text{def}}{=} \max_{k=1,\dots,N}\tau_k$. We assume that the partition fulfills

$$\tau \to 0 \quad \text{as } N\to\infty. \tag{2.4}$$

REMARK 2.2. *Certainly, uniform partitions satisfy* (2.4) *and are sufficient for the analytical investigations. However, as the method is also of great numerical interest as it provides a positivity preserving scheme, we allow for variable timesteps, which increases the flexibility of the method* [JP99].

For any Banach space B we define

$$PC_N(0,T;B) \stackrel{\text{def}}{=} \left\{u^{(N)}:(0,T]\to B : u^{(N)}|_{(t_{k-1},t_k]} \equiv \text{const. for } k=1,\dots,N\right\}$$

and introduce the abbreviation $u_k = u^{(N)}(t)$ for $t\in(t_{k-1},t_k]$ and $k=1,\dots,N$. Further, let $\tilde{u}^{(N)}$ denote the linear interpolant of $u^{(N)}\in PC_N(0,T;L^2(\Omega))$ given by

$$\tilde{u}^{(N)}(t,x) = \frac{t-t_{k-1}}{\tau_k}\,(u_k-u_{k-1}) + u_{k-1} \quad \text{for } x\in\Omega,\quad t\in(t_{k-1},t_k].$$

Now we discretize (1.5) in the following way.

For $k=1,\dots,N$, solve recursively the elliptic equations

$$\frac{1}{\tau_k}\left(e^{2\,u_k}-e^{2\,u_{k-1}}\right) = -2\left(e^{2\,u_k}\,u_{k,xx}\right)_{xx} \tag{2.5}$$

subject to $u_k\in H^2_0(\Omega)$ and get an approximate solution $u^{(N)}\in PC_N(0,T;H^2_0(\Omega))$. We set $e^{2\,u_0}=n_0$. Then problem (2.5) possesses a unique solution, which is the content of the following result.

PROPOSITION 2.2. *Let* u_0 *satisfy* (2.1)*. For each* $k=1,\dots,N$*, there exists a unique weak solution* $u_k\in H^2_0(\Omega)$ *of* (2.5) *fulfilling*

$$2\int_\Omega e^{2\,u_k}\,u_{k,xx}\,\phi_{xx}\,dx + \frac{1}{\tau_k}\int_\Omega e^{2\,u_k}\,\phi\,dx = \frac{1}{\tau_k}\int_\Omega e^{2\,u_{k-1}}\,\phi\,dx \tag{2.6}$$

for all $\phi\in H^2_0(\Omega)$.

For the proof of Proposition 2.2, especially for the uniqueness part, we need the following result. It states the monotonicity of the nonlinear elliptic operator, which

has already been successfully employed for the investigation of stability properties of stationary states [Pin99a].

LEMMA 2.3. *Let $u, v \in H_0^2(\Omega)$. Then the operator $A : H_0^2(\Omega) \to H^{-2}(\Omega)$ given by*

$$A(u) = -e^{-u}\left(e^{2\,u}\,u_{xx}\right)_{xx}$$

is well defined and $-A$ is monotone in the following sense:

$$-\langle A(u) - A(v), e^u - e^v\rangle_{H^{-2},H_0^2} \geq 0. \tag{2.7}$$

Proof. Since $u \in H_0^2(\Omega)$ we have by Sobolev's embedding theorems [Ada75] that $u \in C^{1,\alpha}(\bar{\Omega})$ for $0 \leq \alpha \leq 1/2$, which implies $e^u > 0$ in $\bar{\Omega}$. For $\phi \in H_0^2(\Omega)$ it holds that

$$\begin{aligned}
\langle A(u), \phi\rangle_{H^{-2},H_0^2} &= -\int_\Omega e^{2\,u}\,u_{xx}\,\left(e^{-u}\,\phi\right)_{xx}\,dx \\
&= -\int_\Omega e^{2\,u}\,u_{xx}\,\left(-u_{xx}\,\phi + u_x^2\,\phi - 2\,u_x\,\phi_x + \phi_{xx}\right)\,dx \\
&\leq \left\|e^{2\,u}\right\|_{L^\infty(\Omega)}\,\|u_{xx}\|_{L^2(\Omega)}\,\Big(\|u_{xx}\|_{L^2(\Omega)}\,\|\phi\|_{L^\infty(\Omega)} \\
&\quad + \|u_x\|_{L^4(\Omega)}^2\,\|\phi\|_{L^\infty(\Omega)} + 2\,\|u_x\|_{L^2(\Omega)}\,\|\phi_x\|_{L^\infty(\Omega)} + \|\phi_{xx}\|_{L^2(\Omega)}\Big) \\
&\leq c\left(\Omega, \|u\|_{H^2(\Omega)}\right)\,\|\phi\|_{H^2(\Omega)},
\end{aligned}$$

where we used the embedding $H^2(\Omega) \hookrightarrow W^{1,\infty}(\Omega)$ in one space dimension. Hence, A is well defined.

Now, we prove the monotonicity of A. Let $u, v \in H_0^2(\Omega)$ be given. Then $e^u \in H^2(\Omega)$ since

$$\begin{aligned}
\|(e^u)_{xx}\|_{L^2(\Omega)} &\leq \|e^u\|_{L^\infty(\Omega)}\left(\|u_{xx}\|_{L^2(\Omega)} + \|u_x\|_{L^4(\Omega)}^2\right) \\
&\leq c(\Omega)\,e^{\|u\|_{L^\infty(\Omega)}}\,\|u\|_{H^2(\Omega)}\left(1 + \|u\|_{H^2(\Omega)}\right)
\end{aligned}$$

for some positive constant $c(\Omega)$, depending only on Ω by Sobolev's embedding theorems. Now consider

$$\begin{aligned}
-\langle A(u) &- A(v), e^u - e^v\rangle_{H^{-2},H_0^2} \\
&= \left\langle\left(e^{-u}\left(e^{2\,u}\,u_{xx}\right) - e^{-v}\left(e^{2\,v}\,v_{xx}\right)\right)_{xx}, e^u - e^v\right\rangle_{H^{-2},H_0^2} \\
&= \left\langle (e^u)_{xxxx} - e^{-u}\,(e^u)_{xx}^2 - (e^v)_{xxxx} + e^{-v}\,(e^v)_{xx}^2, e^u - e^v\right\rangle_{H^{-2},H_0^2} \\
&= \int_\Omega (e^u - e^v)_{xx}^2 - (e^u)_{xx}^2 - (e^v)_{xx}^2 + e^{v-u}\,(e^u)_{xx}^2 + e^{u-v}\,(e^v)_{xx}^2\,dx \\
&= \int_\Omega \left(e^{\frac{v-u}{2}}\,(e^u)_{xx} - e^{\frac{u-v}{2}}\,(e^v)_{xx}\right)^2\,dx \\
&\geq 0,
\end{aligned}$$

which yields the assertion. ∎

Now we are in position to prove the existence and uniqueness result for the elliptic problem (2.6).

Proof of Proposition 2.2. We employ Leray–Schauder's fixed point theorem to show that there exists at least one solution. Let $k \in \{1, \dots, N\}$ be fixed and assume that $e^{2\,u_{k-1}} \in L^1(\Omega)$. Further, let $w \in H^1(\Omega)$ and $\sigma \in [0,1]$ be given and consider the following problem:
Find $u \in H_0^2(\Omega)$ with

$$2 \int_\Omega e^{2\,w}\, u_{xx}\, \phi_{xx}\, dx + \frac{\sigma}{\tau_k} \int_\Omega e^{2\,u}\, \phi\, dx = \frac{\sigma}{\tau_k} \int_\Omega e^{2\,u_{k-1}}\, \phi\, dx \tag{2.8}$$

for all $\phi \in H_0^2(\Omega)$.

On account of standard results from the theory of monotone operators [Zei90], there exists a unique weak solution $u \in H_0^2(\Omega)$ of (2.8). Thus the fixed point map $T : H^1(\Omega) \times [0,1] \to H^1(\Omega)$, given by $T(w,\sigma) = u$, is well defined.

Now let $u \in H_0^2(\Omega)$ be a fixed point of T. Then, using the test function $\phi = 1 - e^{-2\,u} \in H_0^2(\Omega)$ in (2.8) gives after integration by parts,

$$\frac{\sigma}{\tau_k} \int_\Omega e^{2\,u} - e^{2\,u_{k-1}} + e^{2(u_{k-1}-u)} - 1\, dx + 4 \int_\Omega u_{xx}^2\, dx = 8 \int_\Omega u_{xx} u_x^2\, dx.$$

With

$$\int_\Omega u_{xx} u_x^2\, dx = \frac{1}{3} \int_\Omega (u_x^3)_x\, dx = \frac{1}{3} \left(u_x(1)^3 - u_x(0)^3 \right) = 0$$

and the inequality $e^x \geq 1 + x$ for all $x \in \mathbb{R}$ we obtain

$$\frac{\sigma}{\tau_k} \int_\Omega e^{2\,u} - 2u\, dx + 4 \int_\Omega u_{xx}^2\, dx \leq \frac{\sigma}{\tau_k} \int_\Omega e^{2\,u_{k-1}} - 2u_{k-1}\, dx.$$

Therefore, using the inequality $e^x - x \geq 1$ for $x \in \mathbb{R}$ and Poincaré's inequality, there exists a constant $c > 0$ independent of u and σ such that

$$\|u\|_{H^2(\Omega)} \leq c.$$

It is easy to verify that the operator T is continuous. Hence, since the embedding $H^2(\Omega) \hookrightarrow H^1(\Omega)$ is compact, we conclude the compactness of the operator T. Furthermore, $T(w,0) = 0$ for all $w \in H^1(\Omega)$. Now the existence of at least one solution follows from Leray–Schauder's fixed point theorem.

To prove uniqueness of solutions we make use of Lemma 2.3. Assume that there exist two solutions $u, v \in H_0^2(\Omega)$ of

$$2 \left(e^{2\,u}\, u_{xx} \right)_{xx} + \frac{1}{\tau_k}\, e^{2\,u} = \frac{1}{\tau_k}\, e^{2\,u_k}.$$

Since u and v are bounded in $L^\infty(\Omega)$ we can divide the corresponding equations for u and v by e^u and e^v, respectively. Using $\phi = e^u - e^v \in H_0^2(\Omega)$ (see the proof of Lemma 2.3) as test function for the difference of the equations yields

$$\begin{aligned} -2\, \langle A(u) - A(v), e^u - e^v \rangle_{H^{-2}, H_0^2} + \frac{1}{\tau_k} \int_\Omega \left(e^u - e^v \right)^2\, dx \\ = \frac{1}{\tau_k} \int_\Omega e^{2\,u_k} \left(e^{-u} - e^{-v} \right) \left(e^u - e^v \right)\, dx \\ \leq 0, \end{aligned}$$

due to $(1/x-1/y)(x-y)\le 0$ for $x,y\in\mathbb{R}^+$. Further, the monotonicity property (2.7) implies the nonnegativity of the first term on the left-hand side. Hence, we obtain

$$\int_\Omega (e^u-e^v)^2\ dx\le 0.$$

Thus, $e^u=e^v$ in $L^2(\Omega)$ and finally $u\equiv v$, which settles the uniqueness of solutions. ∎

2.2. A priori estimates. In this section we derive a priori estimates on the sequence of approximate solutions $\big(u^{(N)}\big)_{N\in\mathbb{N}}$, which is generated by the semidiscretization. First, we show an energy type inequality and some bound on the entropy.

LEMMA 2.4. *Let u_0 satisfy (2.1). For $k=1,\ldots,N$ let $u_k\in H_0^2(\Omega)$ be the recursively defined solution of (2.6) and $u^{(N)}\in PC_N(0,T;H_0^2(\Omega))$. Then $u^{(N)}\in L^2(0,T;H_0^2(\Omega))$ and there exists a positive constant c, independent of k and N, such that*

$$\int_\Omega e^{2\,u_k}-2\,u_k\,dx+4\,\tau_k\,\|u_{k,xx}\|_{L^2(\Omega)}^2\le c, \tag{2.9a}$$

$$\sup_{t\in[0,T]}\int_\Omega e^{2\,u^{(N)}(t,x)}-2\,u^{(N)}(t,x)\,dx+4\,\Big\|u^{(N)}\Big\|_{L^2(H^2)}^2\le c. \tag{2.9b}$$

Additionally, let u_0 satisfy $\int_\Omega e^{2\,u_0}\,(2\,u_0-1)+1\,dx<+\infty$. Then it also holds that

$$\int_\Omega e^{2\,u_k}\,(2\,u_k-1)+1\,dx\le\int_\Omega e^{2\,u_{k-1}}\,(2\,u_{k-1}-1)+1\,dx, \tag{2.9c}$$

for $k=1,\ldots,N$.

Proof. Let $k\in\{1,\ldots,N\}$ be fixed and use $\phi=1-e^{-2\,u_k}$ as a test function in (2.5). Note that ϕ is an admissible test function, since $u_k\in L^\infty(\Omega)$. Integration by parts yields

$$\frac{1}{\tau_k}\int_\Omega e^{2\,u_k}-e^{2\,u_{k-1}}+e^{2(u_{k-1}-u_k)}-1\,dx=2\int_\Omega e^{2\,u_k}\,u_{k,xx}\,\big(e^{-2\,u_k}\big)_{xx}\,dx.$$

Using the well-known inequality $e^x\ge 1+x$, for $x\in\mathbb{R}$, we get

$$\frac{1}{\tau_k}\int_\Omega 2\,u_{k-1}-2\,u_k+e^{2\,u_k}-e^{2\,u_{k-1}}\,dx \le -4\int_\Omega |u_{k,xx}|^2\,dx+8\int_\Omega u_{k,xx}\,u_{k,x}^2\,dx.$$

By Young's inequality and the fact that

$$\int_\Omega u_{k,xx}\,u_{k,x}^2\,dx=\frac{1}{3}\int_\Omega\big(u_{k,x}^3\big)_x\,dx=\frac{1}{3}\big(u_{k,x}^3(1)-u_{k,x}^3(0)\big)=0$$

we derive

$$\int_\Omega e^{2\,u_k}-2\,u_k\,dx+4\,\tau_k\int_\Omega |u_{k,xx}|^2\,dx\le\int_\Omega e^{2\,u_{k-1}}-2\,u_{k-1}\,dx.$$

Thus consecutively we get

$$\int_\Omega e^{2\,u_k}-2\,u_k\,dx\le\int_\Omega e^{2\,u_{k-1}}-2\,u_{k-1}\,dx\le\cdots\le\int_\Omega e^{2\,u_0}-2\,u_0\,dx,$$

from which (2.10a) follows. Furthermore, summation with respect to k yields

$$\int_\Omega e^{2\,u_k} - 2\,u_k\,dx + 4\sum_{l=1}^{k}\tau_l\int_\Omega |u_{l,xx}|^2\,dx \le \int_\Omega e^{2\,u_0} - 2\,u_0\,dx,$$

which gives the desired estimate on $u^{(N)}$.

Now choosing $\phi = u_k$ as test function in (2.6) we obtain

$$\frac{1}{\tau_k}\int_\Omega \left(e^{2\,u_k} - e^{2\,u_{k-1}}\right) u_k\,dx = -2\int_\Omega e^{2\,u_k}\,u_{k,xx}^2\,dx. \tag{2.10}$$

Again, employing $e^x \ge 1 + x$ for $x \in \mathbb{R}$, we deduce

$$\begin{aligned}\frac{2}{\tau_k}\int_\Omega \left(e^{2\,u_k} - e^{2\,u_{k-1}}\right) u_k\,dx &= \frac{2}{\tau_k}\int_\Omega e^{2\,u_k}\left(u_k - \frac{1}{2}\right) - e^{2\,u_{k-1}}\left(u_{k-1} - \frac{1}{2}\right)dx\\ &\quad + \frac{1}{\tau_k}\int_\Omega e^{2\,u_{k-1}}\underbrace{\left(e^{2\,(u_k - u_{k-1})} - 1 - 2\,(u_k - u_{k-1})\right)}_{\ge 0}dx\\ &\ge \frac{2}{\tau_k}\int_\Omega e^{2\,u_k}\left(u_k - \frac{1}{2}\right) - e^{2\,u_{k-1}}\left(u_{k-1} - \frac{1}{2}\right)dx.\end{aligned}$$

This inequality together with (2.10) immediately implies

$$\int_\Omega e^{2\,u_k}\,(2\,u_k - 1)\,dx \le \int_\Omega e^{2\,u_{k-1}}\,(2\,u_{k-1} - 1)\,dx,$$

from which we obtain (2.9c). ∎

As a consequence of interpolation theory we derive the following estimates.

COROLLARY 2.5. *Let u_0 satisfy (2.1) and for $N \in \mathbb{N}$ let $u^{(N)} \in PC_N(0,T;H_0^2(\Omega))$ be the approximate solution. Then*

$$u^{(N)} \in L^\infty(0,T;L^1(\Omega)) \cap L^{5/2}(0,T;W^{1,\infty}(\Omega)), \quad e^{2\,u^{(N)}} \in L^{5/2}(0,T,W^{1,1}(\Omega))$$

and there exists a constant $c > 0$, independent of N, such that

$$\left\|u^{(N)}\right\|_{L^\infty(L^1)} \le c, \quad \left\|u^{(N)}\right\|_{L^{5/2}(W^{1,\infty})} \le c, \quad \left\|e^{2\,u^{(N)}}\right\|_{L^{5/2}(W^{1,1})} \le c.$$

Proof. Using Taylor's expansion we have $e^x \ge 1 + x + x^2$ for $x \ge 0$, which yields

$$\begin{aligned}\int_\Omega e^{2\,u^{(N)}} - 2\,u^{(N)}\,dx &\ge \int_\Omega e^{2\left(u^{(N)}\right)^+} - 2\left(u^{(N)}\right)^+ + 2\left(u^{(N)}\right)^-\,dx\\ &= \int_\Omega 4\left(\left(u^{(N)}\right)^+\right)^2 + 2\left(u^{(N)}\right)^- + 1\,dx,\end{aligned}$$

where $u^+ = \max(0,u)$ and $u^- = -\min(0,u)$. This estimate immediately implies $(u^{(N)})^-(t) \in L^1(\Omega)$ and $(u^{(N)})^+(t) \in L^2(\Omega)$ for any $t > 0$. Thus $u^{(N)}(t) \in L^1(\Omega)$ and it holds

$$\left\|u^{(N)}\right\|_{L^\infty(L^1)} \le c,$$

where $c = c(\Omega, u_0) > 0$ is independent of N.

To show the second inequality we use Lemma 1.2 with $m = r = 2$, $j = 1$, $p = \infty$, and $q = 1$, yielding

$$\left\|u_x^{(N)}\right\|_{L^\infty(\Omega)} \le c \left\|u^{(N)}\right\|_{H^2(\Omega)}^{4/5} \left\|u^{(N)}\right\|_{L^1(\Omega)}^{1/5},$$

which gives

$$\left\|u_x^{(N)}\right\|_{L^{5/2}(L^\infty)} \le c \left\|u^{(N)}\right\|_{L^2(H^2)}^{4/5} \left\|u^{(N)}\right\|_{L^\infty(L^1)}^{1/5}.$$

Now the assertion follows from Lemma 2.4 and the previous inequality.

From Lemma 2.4 and the first inequality we get

$$\left\|e^{2\,u^{(N)}}\right\|_{L^\infty(L^1)} \le c.$$

Hence,

$$\left\|\left(e^{2\,u^{(N)}}\right)_x\right\|_{L^{5/2}(L^1)} \le \left\|e^{2\,u^{(N)}}\right\|_{L^\infty(L^1)} \|u_x\|_{L^{5/2}(L^\infty)}$$

and the third inequality follows from the second one. ∎

The next two lemmas provide the estimates, which are necessary for the compactness arguments.

LEMMA 2.6. *Let u_0 satisfy (2.1) and for $N \in \mathbb{N}$ let $u^{(N)} \in PC_N(0,T;H_0^2(\Omega))$ be the approximate solution. Choose $p \in (1,4/3)$ and fix $q \in (2,5/2)$ such that $1/q = 2(2-1/p)/5$. Then $e^{2\,u^{(N)}} \in L^q(0,T;W^{1,p}(\Omega))$ and there exists a constant $c > 0$, independent of N, such that*

$$\left\|e^{2\,u^{(N)}}\right\|_{L^q(W^{1,p})} \le c.$$

Proof. Again, employing Lemma 1.2 we derive

$$\left\|e^{2\,u^{(N)}}\right\|_{L^p(\Omega)} \le c \left\|e^{2\,u^{(N)}}\right\|_{W^{1,1}(\Omega)}^{\frac{p-1}{p}} \left\|e^{2\,u^{(N)}}\right\|_{L^1(\Omega)}^{\frac{1}{p}}.$$

Furthermore, it holds that

$$\frac{1}{q} = \frac{2\,(p-1)}{5\,p} + \frac{2}{5}$$

and thus Hölder's inequality implies

$$\left\|\left(e^{2\,u^{(N)}}\right)_x\right\|_{L^q(L^p)} \le c \left\|e^{2\,u^{(N)}}\right\|_{L^\infty(L^1)}^{\frac{1}{p}} \left\|e^{2\,u^{(N)}}\right\|_{L^{5/2}(W^{1,1})}^{\frac{p-1}{p}} \left\|u_x^{(N)}\right\|_{L^{5/2}(L^\infty)}.$$

Hence, the assertion follows from Corollary 2.5 and (2.9c). ∎

As we want to employ compactness results, we also need some regularity on the time derivative. We introduce the linear interpolant of $e^{2\,u^{(N)}} \in PC_N(0,T,L^2(\Omega))$, defined by

$$\tilde{e}^{(N)}(t,x) \stackrel{\text{def}}{=} \frac{t-t_{k-1}}{\tau_k}\left(e^{2\,u_k(x)} - e^{2\,u_{k-1}(x)}\right) + e^{2\,u_{k-1}(x)}, \quad x \in \Omega, \quad t \in (t_{k-1}, t_k].$$

LEMMA 2.7. *Let the assumptions of Lemma* 2.6 *hold. Choose* $r \in (1, 10/9)$ *such that* $1/r = 1/2 + 1/q$. *Then*

$$\tilde{e}_t^{(N)} \in L^r(0,T;H^{-2}(\Omega)), \quad \tilde{e}^{(N)} \in L^q(0,T;W^{1,p}(\Omega))$$

and there exists a constant $c > 0$, *independent of* N, *such that*

$$\left\|\tilde{e}_t^{(N)}\right\|_{L^r(H^{-2})} + \left\|\tilde{e}^{(N)}\right\|_{L^q(W^{1,p})} \le c.$$

Proof. We introduce the solution operator $\Phi : H^{-2}(\Omega) \to H_0^2(\Omega)$, $f \mapsto \Phi[f]$ by $\Phi[f]_{xxxx} = f$. Then $\|\Phi[f]_{xx}\|_{L^2(\Omega)}$ defines a norm on $H^{-2}(\Omega)$ [Zei90]. Further, $\Phi\left[\frac{e^{2u_k} - e^{2u_{k-1}}}{\tau_k}\right]$ is an appropriate test function in (2.6), which yields

$$\int_\Omega \frac{e^{2u_k} - e^{2u_{k-1}}}{\tau_k} \Phi\left[\frac{e^{2u_k} - e^{2u_{k-1}}}{\tau_k}\right] dx = -2\int_\Omega e^{2u_k} u_{k,xx} \Phi\left[\frac{e^{2u_k} - e^{2u_{k-1}}}{\tau_k}\right]_{xx} dx$$

and using integration by parts

$$\int_\Omega \left|\Phi\left[\frac{e^{2u_k} - e^{2u_{k-1}}}{\tau_k}\right]_{xx}\right|^2 dx \le 2\left\|e^{2u_k}\right\|_{L^\infty(\Omega)} \|u_{k,xx}\|_{L^2(\Omega)} \left\|\Phi\left[\frac{e^{2u_k} - e^{2u_{k-1}}}{\tau_k}\right]_{xx}\right\|_{L^2(\Omega)}.$$

Thus we finally can estimate

$$\left\|\Phi\left[\frac{e^{2u_k} - e^{2u_{k-1}}}{\tau_k}\right]_{xx}\right\|_{L^2(\Omega)} \le 2\left\|e^{2u_k}\right\|_{L^\infty(\Omega)} \|u_k\|_{H^2(\Omega)}.$$

Now we deduce from Hölder's inequality

$$\begin{aligned}\left\|\tilde{e}_t^{(N)}\right\|_{L^r(H^{-2})}^r &= \sum_{k=1}^N \tau_k \left\|\frac{e^{2u_k} - e^{2u_{k-1}}}{\tau_k}\right\|_{H^{-2}(\Omega)}^r \\ &\le 2^r \sum_{k=1}^N \tau_k \left\|e^{2u_k}\right\|_{L^\infty(\Omega)}^r \|u_k\|_{H^2(\Omega)}^r \\ &\le 2^r \left\|e^{2u^{(N)}}\right\|_{L^q(L^\infty)}^r \left\|u^{(N)}\right\|_{L^2(H^2)}^r,\end{aligned}$$

from which we easily get the uniform boundedness of $\tilde{e}_t^{(N)}$ in $L^r(0,T;H^{-2}(\Omega))$ by Lemma 2.6 together with the embedding $W^{1,p}(\Omega) \hookrightarrow L^\infty(\Omega)$ and Lemma 2.4.

Further, we note that for arbitrary $t \in (t_{k-1}, t_k]$ it holds

$$0 \le \frac{t - t_{k-1}}{\tau_k} \le 1$$

such that (see Lemma 2.6)

$$\begin{aligned}\left\|\tilde{e}^{(N)}(t)\right\|_{W^{1,p}(\Omega)} &\le \left(1 - \frac{t - t_{k-1}}{\tau_k}\right)\left\|e^{2u_{k-1}}\right\|_{W^{1,p}(\Omega)} + \frac{t - t_{k-1}}{\tau_k}\left\|e^{2u_k}\right\|_{W^{1,p}(\Omega)} \\ &\le c.\end{aligned}$$

Thus we obtain

$$\int_0^T \left\|\tilde{e}^{(N)}(t)\right\|_{W^{1,p}(\Omega)}^q \, dt \le T\, c^q,$$

finishing the proof. ∎

2.3. Proof of the existence result. Now we are in the position to prove Proposition 2.1.

Proof. We choose a sequence of partitions of $[0,T]$ satisfying (2.4). Taking into account Lemma 2.4, it follows immediately that the sequence $\left(u^{(N)}\right)_{N\in\mathbb{N}}$ is bounded in $L^2(0,T;H^2(\Omega))$. Thus there exists a subsequence, again denoted by $\left(u^{(N)}\right)_{N\in\mathbb{N}}$, such that

$$u^{(N)} \rightharpoonup u \quad \text{weakly in } L^2(0,T;H^2(\Omega)) \text{ as } N\to\infty.$$

Furthermore, from Lemmas 2.6 and 2.7 we deduce the boundedness of $\left(\tilde{e}^{(N)}\right)_N$ in $L^q(0,T;W^{1,p}(\Omega))\cap W^{1,r}(0,T;H^{-2}(\Omega))$, where p,q,r are specified therein. Since the embedding $W^{1,p}(\Omega)\hookrightarrow L^\infty(\Omega)$ is compact for $p\in(1,4/3)$, it follows from Aubin's lemma [Sim87] that

$$L^q(0,T;W^{1,p}(\Omega))\cap W^{1,r}(0,T;H^{-2}(\Omega)) \hookrightarrow L^q(0,T;L^\infty(\Omega)) \quad \text{compactly.}$$

Hence, there exists a subsequence, not relabeled, such that

$$\tilde{e}^{(N)} \to \rho \quad \text{strongly in } L^q(0,T;L^\infty(\Omega)) \text{ for } N\to\infty.$$

As $q>2$ it also holds that $\tilde{e}^{(N)}\to\rho$ in $L^2(0,T;L^2(\Omega))$ for $N\to\infty$. Note that $\tilde{e}^{(N)}\to\rho$ in $L^2(0,T;L^2(\Omega))$ implies $e^{2\,u^{(N)}}\to\rho$ in $L^2(0,T;L^2(\Omega))$ as $N\to\infty$ (see [Rek82, p. 205]). Due to the monotonicity of the exponential function we have for all $v\in L^\infty((0,\infty)\times\Omega)$

$$\int_\Omega \left(e^{2\,u^{(N)}} - e^{2\,v}\right)\left(u^{(N)} - v\right)\, dx \ge 0.$$

The derived convergence properties are by far sufficient to pass to the limit in this inequality, which yields

$$\int_\Omega \left(\rho - e^{2\,v}\right)(u-v)\, dx \ge 0$$

for all $v\in L^\infty((0,\infty)\times\Omega)$. Again, the monotonicity of the exponential implies $\rho = e^{2\,u}$.

After this identification we can perform the limit in the weak formulation, which reads

$$\int_0^T \left\langle \tilde{e}_t^{(N)}, \phi\right\rangle_{H^{-2},H_0^2} dt = -2\int_0^T\int_\Omega e^{2\,u^{(N)}}\, u_{xx}^{(N)}\, \phi_{xx}\, dx\, dt \tag{2.11}$$

for all $\phi\in L^{r'}(0,T;H_0^2(\Omega))$ with $1/r+1/r'=1$. One easily verifies that the following convergence properties are sufficient to pass to the limit in (2.11):

$$\begin{aligned}
\tilde{e}_t^{(N)} &\rightharpoonup \left(e^{2\,u}\right)_t \quad && \text{weakly in } L^r(0,T;H^{-2}(\Omega)),\\
e^{2\,u^{(N)}} &\to e^{2\,u} && \text{strongly in } L^q(0,T;L^\infty(\Omega)),\\
u_{xx}^{(N)} &\rightharpoonup u_{xx} && \text{weakly in } L^2(0,T;L^2(\Omega)),
\end{aligned}$$

as $N\to\infty$, which proves our main result. ∎

3. Additional results and discussion. In this section we present some additional results, concerning the long-time behavior of solutions and regularity properties. Further, we give some numerical examples.

3.1. Long-time behavior. The next result states that the solution converges for $t \to \infty$ to the stationary state $n_\infty \equiv 1$ in some weak sense.

PROPOSITION 3.1. *Assume* (1.3) *and let* $n \in L^2_{loc}(0,\infty,W^{1,1}(\Omega))$ *be a solution to* (1.2). *Then it holds*

$$\|\log(n(t))\|_{L^2(\Omega)} \to 0 \quad \text{as } t \to \infty.$$

Proof. Let $n = e^{2u}$. From the proof of Lemma 2.4 it follows that

$$\int_0^\infty \int_\Omega u_{xx}^2 \, dx dt \le \int_\Omega e^{2u_0} - 2u_0 \, dx.$$

Therefore, using Poincaré's inequality, there exists a sequence $(t_m)_{m\in\mathbb{N}}$ with $t_m \to \infty$ such that

$$\|u(t_m)\|_{H^2(\Omega)} \to 0 \quad \text{as } t_m \to \infty. \tag{3.1}$$

We introduce the new entropy

$$E(t) = \int_\Omega e^{2u(t)} - 2u(t) - 1 \, dx.$$

The proof of Lemma 2.4 shows that $E(t)$ is nonincreasing:

$$E(t) \le E(s) \qquad \text{for } 0 \le s \le t < \infty.$$

The result (3.1) implies $u(t_m) \to 0$ in $L^\infty(\Omega)$, by Sobolev's embedding. Hence

$$0 \le E(t_m) \to 0 \qquad \text{as } t_m \to \infty.$$

Since E is nonincreasing, $E(t) \to 0$ for all sequences $t \to \infty$. The proof of Corollary 2.5 shows that

$$E(t) \ge \int_\Omega 4u^+(t)^2 - 2u^-(t) \, dx,$$

and thus,

$$\|u(t)\|_{L^1(\Omega)} \to 0 \qquad \text{as } t \to \infty,$$

which proves the proposition. □

3.2. Regularity. Now we investigate the regularity of solutions.

PROPOSITION 3.2. *Assume* (1.3). *If it holds*

$$\int_\Omega n_0 (\log(n_0) - 1) + 1 \, dx < +\infty,$$

then any solution $n \in L^2_{loc}(0,\infty;W^{1,1}(\Omega))$ *to* (1.2) *with*

$$\log(n) \in L^2_{loc}(0,\infty;H^2_0(\Omega)) \cap L^\infty(0,\infty;L^2(\Omega))$$

even fulfills

$$n \in L^{16/15}_{loc}(0,\infty;H^2(\Omega)).$$

REMARK 3.1. *Notice that Theorem* 1.1 *and Proposition* 3.1 *ensure the existence of a solution to* (1.2) *with the desired regularity properties.*

Proof. The proof is an easy consequence of the results derived so far combined with the Gagliardo–Nirenberg inequality. Let $n = e^{2u}$. In the following c denotes positive, but not necessarily identical, constants. We estimate

$$\begin{aligned}\left\|\left(e^{2u}\right)_{xx}\right\|_{L^2(\Omega)} &\le c\left(\left\|e^{2u}\right\|_{L^\infty(\Omega)}\|u\|_{H^2(\Omega)} + \left\|e^{2u}u_x^2\right\|_{L^2(\Omega)}\right)\\ &= c\left(\left\|e^{2u}\right\|_{L^\infty(\Omega)}\|u\|_{H^2(\Omega)} + \|(e^u)_x\|^2_{L^4(\Omega)}\right).\end{aligned}$$

Due to $u \in L^2_{loc}(0,\infty;H^2_0(\Omega)) \cap L^\infty(0,\infty;L^2(\Omega))$ and $e^{2u} \in L^2_{loc}(0,\infty;W^{1,1}(\Omega))$ it holds that (compare Lemma 2.5)

$$\left\|e^{2u}\right\|_{L^{8/3}(L^\infty)} \le c \quad \text{and} \quad \|u\|_{L^{8/3}(W^{1,\infty})} \le c.$$

Further, we have $e^u \in L^{4/3}_{loc}(0,\infty;H^2(\Omega))$, since

$$\|(e^u)_{xx}\|_{L^2(\Omega)} \le \|e^u\|_{L^\infty(\Omega)}\|u_{xx}\|_{L^2(\Omega)} + \|e^u\|_{L^2(\Omega)}\|u_x\|^2_{L^\infty(\Omega)}$$

and by multiple use of Hölder's inequality

$$\|(e^u)_{xx}\|_{L^{4/3}(L^2)} \le \|e^u\|_{L^4(L^\infty)}\|u_{xx}\|_{L^2(L^2)} + \|e^u\|_{L^\infty(L^2)}\|u_x\|^2_{L^{8/3}(L^\infty)},$$

which is finite. Now we deduce by

$$\|e^u\|_{W^{1,4}(\Omega)} \le c\,\|e^u\|^{3/8}_{L^2(\Omega)}\|e^u\|^{5/8}_{H^2(\Omega)}$$

that $e^u \in L^{32/15}_{loc}(0,\infty;W^{1,4}(\Omega))$. Hence, we get finally

$$\left\|e^{2u}\right\|_{L^{16/15}(H^2)} \le c\left(\left\|e^{2u}\right\|_{L^{16/7}(L^\infty)}\|u\|_{L^2(H^2)} + \|e^u\|^2_{L^{32/15}(W^{1,4})}\right). \qquad \square$$

3.3. Numerical examples. After the analytical discussion of problem (1.2) we present some numerical results that do not only underline the preservation of nonnegativity by the solution n. They are also indicating that the solution is *positive* for $t > 0$, even for initial data, which vanishes at some point $x_0 \in \Omega = (0,1)$. This behavior was already pointed out in [BLS94] but only for strictly positive initial data.

For the numerical experiments we choose the initial datum

$$n_0(x) = \cos^{2m}(\pi x), \quad x \in (0,1), \tag{3.2}$$

with $m = 1$ or 8 and which is compatible with the boundary data. Note that n_0 vanishes at $x_0 = 1/2$ such that $\log(n_0)$ has a singularity there. However, it still holds that $\log(n_0) \in L^1(\Omega)$.

For the computations we employ a fully implicit discretization of (1.2c) with a uniform time step $\tau = 10^{-8}$. Moreover, we choose a uniform space discretization

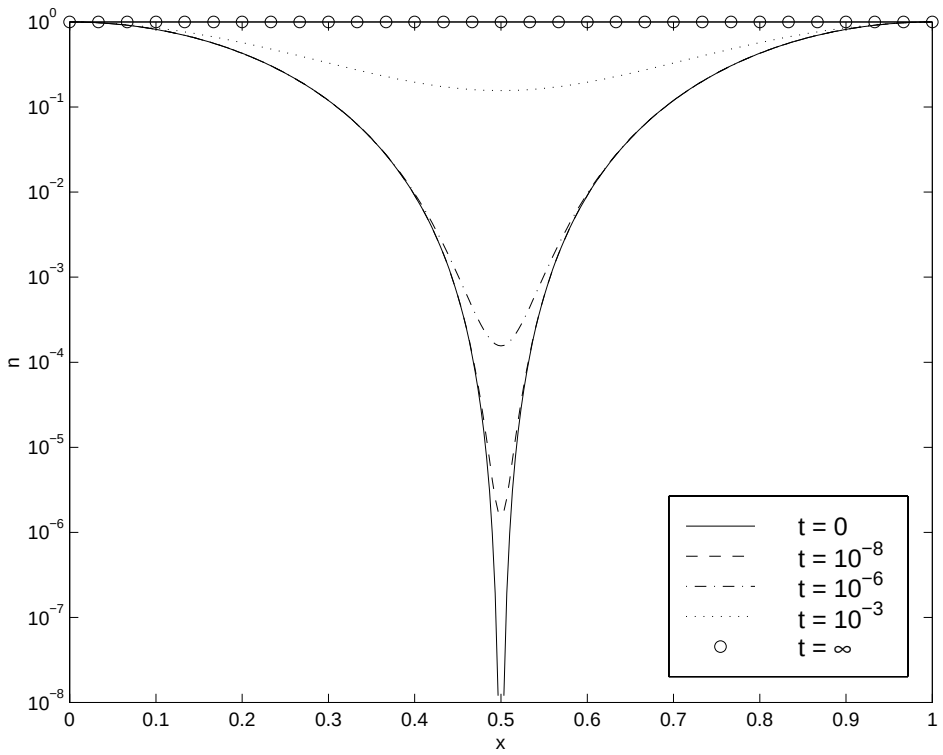

FIG. 3.1. *Evolution for* $m = 1$.

$x_l = l/M$, $l \in \{0, \dots, M\}$, $M = 300$, such that $x = 1/2$ is included in the set of nodes. Let D^+, D^- denote the standard forward, backward difference operators on this grid, respectively. Then for $l \in \{0, \dots, M\}$ and $k \in \{1, \dots, M\}$ the discrete version of (1.2c) reads

$$n_0^l = n_0(x_l),$$
$$\frac{n_k^l - n_{k-1}^l}{\tau} + D^+D^-D^+D^-n_k^l - D^+D^-\left(\frac{\left(D^+n_k^l\right)^2}{n_k^l}\right) = 0,$$

where the boundary data can be eliminated in a standard manner. These nonlinear systems are solved on each time level by a Newton-iteration, where the initial guess is chosen as the solution on the previous time level. This iteration proves to be very robust such that no damping is necessary.

REMARK 3.2. *Note that due to the fully implicit scheme, we are able to allow also for vanishing initial data. In a forthcoming paper* [JP99] *the authors investigate this approach for the so-called quantum drift diffusion model in the multidimensional case with positive initial data.*

Figure 3.1 shows the evolution of the initial datum with $m = 1$. Note that we use a logarithmic scale for the ordinate such that we cut-off all values less than 10^{-8}. Here the solution moves very fast away from zero and converges monotonically to the stationary state $n_\infty \equiv 1$. To contrast this behavior we refer to Figure 3.2, which shows the evolution for $m = 8$. Starting with *one* higher order extremum the

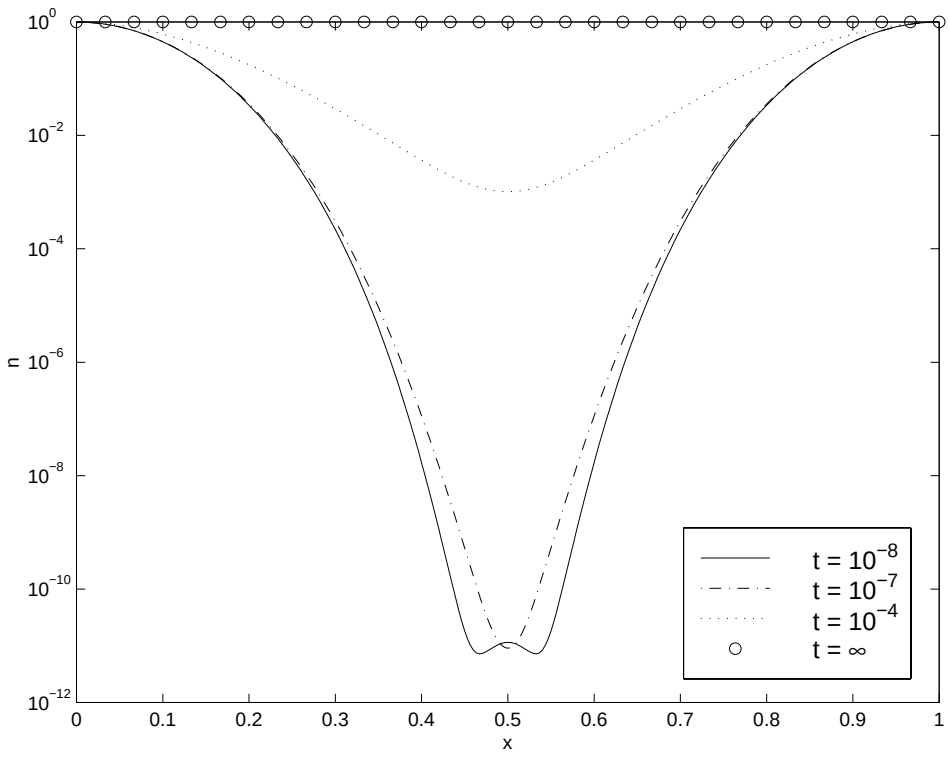

FIG. 3.2. *Evolution for* $m = 8$.

minimum bifurcates and reduces to one extremum again. We emphasize that also in this case the solution stays strictly positive for $t > 0$, although the evolution is not monotone anymore. Again, analogous results are reported in [BLS94] for strictly positive initial data.

A FREE BOUNDARY PROBLEM ARISING IN A MODEL OF WOUND HEALING*

XINFU CHEN† AND AVNER FRIEDMAN‡

Abstract. In this paper we consider a system of two semilinear parabolic reaction-diffusion equations with a free boundary, which arises in a model of corneal epithelial wound healing. We prove that the initial-boundary value problem has a unique solution and that complete healing is achieved in finite time. We then proceed to consider travelling wave solutions of the same system and establish the existence of such a solution.

Key words. free boundary, reaction-diffusion equations, travelling wave solutions, wound healing

Introduction. The mathematical modeling of wound healing has received increased attention in recent years. One area of investigation is dermal wound healing, where complex biological processes are interacting [4, 7]. Two of these processes are the invasion of fibroblasts into the wound space and their alignment there [5], and the sprouting of blood vessels into the wound space (angiogenesis) [6]. Another area of investigation is corneal epithelial wound healing, which was modelled by Dale, Maini, and Sheratt [1]. The modeling framework involves two concentrations: the generic corneal epithelial cell density N (also referred to as the corneal stimulus) in the healed region, and a chemical stimulus concentration C (also called the epidermal growth factor) both in the healed and the wound regions. The epithelial cells are assumed to migrate as a diffusing substance. The chemical stimulus also diffuses, by mechanisms such as tear fluid convection and mixing arising from blinking. Thus the model involves a system of two parabolic partial differential equations (semilinear reaction-diffusion equations) for the concentration N, in the healed region, and the concentration C, both in the healed and the wound regions. The model developed in [1] is one-dimensional and it exhibits, after a short time, a travelling wave character with speed approximately 20 μmh^{-1}; the actual observed healing rate in corneal wounds is approximately 60 μmh^{-1}.

This model was recently improved by Gaffney et al. [2] in two ways. First, they include the presence of a physiological electric field and, second, they introduce a free boundary into the model. The free boundary is the receding boundary of the wound region. The physiological electric field arises from transcornea potential difference near the boundary of the healed region: whereas the cells in the healed region maintain normal potential, in the wound region the potential is short-circuited. The physiological electric field is most significant near the free boundary. It increases the transport of epithelial cells into the wound, thus increasing the speed of the healing

process. The computations in [2] show that the average speed of the free boundary varies linearly with the electric field over a large range, and that this linear relation is robust under variations of some parameters which are difficult to estimate precisely.

The purpose of this paper is to study the model introduced in [2] by rigorous mathematical analysis. Our study consists of two parts, which are, technically, quite different. In the first part (Part I) we study the evolution of the free boundary problem for the system of the two reaction-diffusion equations for N and C and prove that the problem is well posed, and that complete healing is achieved in finite time. In the second part (Part II) we consider the speed of the healing process. As mentioned above, numerical computations in [1, 2] show that healing proceeds (after a short initial time) with constant speed, as a travelling wave. We prove, by rigorous analysis, that a travelling wave solution indeed exists.

In order to make the paper more readable, we shall deal with a general system of reaction-diffusion equations, for concentrations c and n, subject to some general assumptions. In the concluding section of the paper we write down the explicit system developed in [2], and show that it satisfies the general assumptions made throughout Parts I and II.

Part I: The evolution problem.

1. The model. Consider the following system for $n(x,t)$, $c(x,t)$, $s(t)$:

$$n_t = (d(n,c)n_x)_x + f(n,c), \quad 0 < x < s(t),\ t > 0, \tag{1.1}$$

$$ac_t = c_{xx} + g(n,c), \quad 0 < x < 1,\ t > 0 \quad (a \text{ a positive constant}), \tag{1.2}$$

$$n \equiv 0 \quad \text{if } s(t) < x < 1,\ t > 0, \tag{1.3}$$

$$n(s(t),t) = n_*, \quad t > 0 \quad (n_* \text{ constant}), \tag{1.4}$$

$$\dot{s}(t) = -\frac{1}{n_*} d(n_*,c)n_x \quad \text{at } x = s(t),\ t > 0, \tag{1.5}$$

with boundary conditions

$$n_x(0,t) = 0, \quad c_x(0,t) = 0, \quad c_x(1,t) = 0 \quad \text{for } t > 0 \tag{1.6}$$

and initial conditions

$$\begin{aligned} s(0) &= s_0, & 0 < s_0 < 1, \\ n(x,0) &= n_0(x), & 0 < x < s_0, \\ c(x,t) &= c_0(x), & 0 < x < 1. \end{aligned} \tag{1.7}$$

Here n represents the corneal stimulus cell density in the healed region $0 \le x < s(t)$, and c represents the chemical stimulus concentration in both the wound and the healed regions.

In the condition (1.4), n_* is the equilibrium cell density at the boundary of the wound. The condition (1.5) is a conservation law of cell mass; it says that the rate of increase in the cell mass at the free boundary, namely, $n_*\dot{s}(t)$, is equal to the flux of cells, $d(n_*,c)n_x$. This condition is the same as the classical Stefan condition in the model of melting of solids. As will be shown in section 9, the term $d(n,c)n_x$ in (1.1) includes the effect of diffusion due to the physiological electric field mentioned in the introduction, and the functions $f(n,c)$, $g(n,c)$ account for chemical effects and sources for c and n.

We assume that

$$0 < n_* < 1 \tag{1.8}$$

and set

$$G = \{(n, c); \quad n^* \le n \le 2, \quad 0 \le c \le 1\}.$$

We also make the following assumptions:

$$\begin{aligned} &d(n,c) \text{ is in } C^1(G) \quad \text{and} \quad \partial d/\partial n \le 0, \\ &d(n,c) \ge d_0 > 0 \quad (d_0 \text{ constant}); \end{aligned} \tag{1.9}$$

$$\begin{aligned} &f(n,c) \text{ is in } C^1(G) \quad \text{and} \\ &f(n_*, c) > 0, \quad f(2,c) \le 0 \quad \text{if } 0 \le c \le 1; \end{aligned} \tag{1.10}$$

$$\begin{aligned} &g(n,c) \text{ is in } C^1(G) \quad \text{and} \quad \partial g/\partial c < 0 \text{ in } G, \\ &g(n,0) \ge 0, \quad g(n,1) \le 0 \quad \text{for } n_* \le n \le 2; \end{aligned} \tag{1.11}$$

$$\begin{aligned} &n_0 \in C^2[0, s_0], \quad n_* < n_0(x) < 2 \quad \text{if } 0 \le x < s_0, \\ &n_0'(0) = 0, \quad n_0(s_0) = n_*, \quad n_0'(s_0) < 0; \end{aligned} \tag{1.12}$$

$$c_0 \in C^2[0,1] \quad \text{and} \quad 0 \le c_0(x) \le 1. \tag{1.13}$$

We may clearly extend the definitions of the functions d, f, g in such a way that

$$\begin{aligned} &(1.9), (1.10), (1.11) \text{ hold for } -\infty < n, \ c < \infty, \text{ and} \\ &f(n,c) > 0 \quad \text{if } n \le n_*, \quad f(n,c) \le 0 \quad \text{if } n \ge 2 \quad \text{for all } c, \\ &g(n,c) \ge 0 \quad \text{if } c \le 0, \quad g(n,c) \le 0 \quad \text{if } c \ge 1 \quad \text{for all } n. \end{aligned} \tag{1.14}$$

In the future, we shall assume such an extension has already been made.

In sections 2 and 3, we shall prove the following theorem.

THEOREM 1.1. *Assume that* (1.8)–(1.13) *hold. Then there exists a unique solution* (n, c, s) *of* (1.1)–(1.7) *for* $0 \le t < T_*$, *where* $T_* < \infty$, *and*

$$s'(t) > 0 \quad \textit{if } 0 \le t < T_*, \tag{1.15}$$

$$s(t) \to 1 \quad \textit{if } t \to T_*; \tag{1.16}$$

furthermore,

$$n_* < n(x,t) \le 2 \quad \textit{if } 0 \le x < s(t), \quad 0 \le t < T_*, \tag{1.17}$$

$$0 \le c(x,t) \le 1 \quad \textit{if } 0 \le x \le 1, \qquad 0 \le t < T_*. \tag{1.18}$$

Note that (1.16) means that the wound region $\{s(t) \le x \le 1\}$ disappears as $t \to T_*$.

In section 2, we shall prove local existence and uniqueness. In section 3, we shall derive a priori estimates that will enable us to complete the proof of Theorem 1.1.

2. Local existence and uniqueness. In this section, we prove the following lemma.

LEMMA 2.1. *Under the assumptions of Theorem* 1.1, *there exists a unique solution of* (1.1)–(1.7) *for a small time interval* $0 \le t \le T$ $(T > 0)$.

Proof. Set

$$\delta = \min\{s_0, 1 - s_0\}$$

and let $\zeta(y)$ be a function in $C^3[0,1]$ satisfying

$$\zeta(y) = 1 \quad \text{if } |y - s_0| < \frac{\delta}{4}, \qquad \zeta(y) = 0 \quad \text{if } |y - s_0| > \delta, \qquad |\zeta'(y)| < \frac{2}{\delta}.$$

We introduce a transformation that will straighten the free boundary:

$$(x,t) \to (y,t), \quad \text{where } x = y + \zeta(y)(s(t) - s_0), \quad 0 \le y \le 1. \tag{2.1}$$

Notice that as long as

$$|s(t) - s_0| < \frac{\delta}{4} \tag{2.2}$$

the transformation (2.1) is a diffeomorphism from $[0,1]$ onto $[0,1]$ (since $\partial x/\partial y > \frac{1}{2}$), and

$$\begin{aligned} 0 \le x \le s(t) &\iff 0 \le y \le s_0, \\ s(t) \le x \le 1 &\iff s_0 \le y \le 1, \\ x = s(t) &\iff y = s_0. \end{aligned}$$

One easily computes that

$$\begin{aligned} \frac{\partial y}{\partial x} &= \frac{1}{1 + \zeta'(y)(s(t) - s_0)} \equiv \sqrt{A(s(t), y)}, \\ \frac{\partial^2 y}{\partial x^2} &= \frac{\zeta''(y)(s(t) - s_0)}{[1 + \zeta'(y)(s(t) - s_0)]^3} \equiv B(s(t), y), \\ -\frac{1}{\dot{s}(t)} \frac{\partial y}{\partial t} &= \frac{\zeta(y)}{1 + \zeta'(y)(s(t) - s_0)} \equiv C(s(t), y). \end{aligned}$$

Defining

$$\varphi(y,t) = n(x,t), \qquad \psi(y,t) = c(x,t)$$

and setting

$$D(\varphi,\psi) = d(n,c), \qquad F(\varphi,\psi) = f(n,c), \qquad G(\varphi,\psi) = g(n,c),$$

the system (1.1)–(1.7) takes the form

$$\varphi_t = AD(\varphi,\psi)\varphi_{yy} + (BD(\varphi,\psi) + \dot{s}C)\varphi_y + AD_\varphi \varphi_y^2 + AD_\psi \varphi_y \psi_y + F(\varphi,\psi) \quad \text{for } 0 < y < s_0,\ t > 0, \tag{2.3}$$

$$a\psi_t = A\psi_{yy} + (B + a\dot{s}C)\psi_y + G(\varphi,\psi) \quad \text{for } 0 < y < 1,\ t > 0, \tag{2.4}$$

$$\varphi \equiv 0 \quad \text{if } s_0 < y < 1, \tag{2.5}$$

with $A = A(s,y)$, $B = B(s,y)$, $C = C(s,y)$,

$$\varphi(s_0,t) = n_*, \tag{2.6}$$

$$\dot{s}(t) = -\frac{1}{n_*} D(n_*, \psi(s_0,t))\varphi_y(s_0,t), \tag{2.7}$$

and

$$\varphi_y(0,t) = \psi_y(0,t) = \psi_y(1,t) = 0, \tag{2.8}$$

$$\begin{cases} \varphi(y,0) = \varphi_0(y), & 0 \le y < s_0, \\ \psi(y,0) = \psi_0(y), & 0 \le y \le 1, \end{cases} \tag{2.9}$$

where $\varphi_0(y) = n_0(x)$, $\psi_0(y) = c_0(x)$.

We introduce the quantity

$$s_1 = -\frac{1}{n_*} D(n_*, \psi_0(s_0))\varphi_0'(s_0) \quad (s_1 > 0), \tag{2.10}$$

which should be the derivative $\dot{s}(0)$ if a solution exists.

We shall prove existence by invoking the Schauder fixed point theorem. Toward this purpose, we introduce spaces

$$X_T = \{s \in C^1[0,T], \quad s(0) = 0, \quad \dot{s}(0) = s_1, \quad |\dot{s}(t) - s_1| \le 1 \quad \text{for } 0 \le t \le T\},$$
$$Y_T = \{\varphi \in C^0([0,s_0] \times [0,T]), \quad \varphi(y,0) = \varphi_0, \quad |\varphi - \varphi_0|_{C^0([0,s_0]\times[0,T])} \le 1\},$$

where T is such that

$$0 < T < \frac{\delta}{4(1+s_1)}.$$

For any $(\tilde{s}, \tilde{\varphi}) \in X_T \times Y_T$ we then have

$$|\tilde{s}(t) - s_0| < \frac{\delta}{4},$$

so that the mapping $(x,y) \to (y,t)$ defined by

$$x = y + \zeta(y)(\tilde{s}(t) - s_0)$$

is a diffeomorphism, and we define ψ to be the solution of

$$a\psi_t = A(\tilde{s},y)\psi_{yy} + (B(\tilde{s},y) + a\dot{\tilde{s}}C(\tilde{s},y))\psi_y + G(\tilde{\varphi},\psi) \quad \text{for } 0 < y < 1,\ 0 < t < T$$

with $\tilde{\varphi} \equiv 0$ in $[s_0,1] \times [0,T]$,

$$\psi_x(0,t) = \psi_x(1,t) = 0, \quad 0 < t < T,$$
$$\psi(y,0) = \psi_0(y).$$

Using L^p estimates for parabolic equations and Sobolev's inequalities, one can show that this system has a unique solution ψ with finite norm

$$||\psi||_{C^{1+\beta,(1+\beta)/2}([0,1]\times[0,T])} \le K \tag{2.11}$$

for any $0 < \beta < 1$, where K will be used to denote constants depending only on s_0, s_1, and on

$$|\psi_0|_{C^2[0,s_0]}, \quad |\psi_0|_{C^2[0,1]}.$$

In fact, results of this type, for more general nonlinear parabolic equations, are proved in [3].

Next, we define a function φ as the solution of the parabolic problem

$$\begin{aligned}
\varphi_t &= A(\tilde{s},y)D(\tilde{\varphi},\psi)\varphi_{yy} + [B(\tilde{s},y)D(\tilde{\varphi},\psi) + \dot{\tilde{s}}C(\tilde{s},y)]\varphi_y + A(\tilde{s},y)D_\varphi(\tilde{\varphi},\psi)\varphi_y^2 \\
&\quad + A(\tilde{s},y)D_\psi(\tilde{\varphi},\psi)\varphi_y\psi_y + f(\varphi,\psi) \quad \text{for } 0 \le y \le s_0,\ 0 \le t \le T, \\
\varphi_y(0,t) &= 0, \quad \varphi(s_0,t) = n_* \quad \text{for } 0 < t < T, \\
\varphi(y,0) &= \varphi_0(y) \quad \text{for } 0 < y < s_0.
\end{aligned}$$

As before, this system has a unique solution φ with finite norm

$$||\varphi||_{C^{1+\beta,(1+\beta)/2}([0,s_0]\times[0,T])} \le K. \tag{2.12}$$

Finally, we define

$$s(t) = s_0 - \int_0^t \frac{1}{n_*} D(n_*,\psi(s_0,\tau))\varphi_y(s_0,\tau)d\tau \tag{2.13}$$

and introduce the mapping W by

$$(s,\varphi) = W(\tilde{s},\tilde{\varphi}).$$

We want to show that W has a fixed point (s,φ), which will then imply that, together with the corresponding ψ, it forms a solution to the system (2.3)–(2.9).

Observe that

$$\dot{s}(t) - s_1 = \frac{1}{n_*}\left\{D(n_*,\psi_0(s_0))\frac{\partial\varphi_0(s_0)}{\partial y} - D(n_*,\psi(s_0,t))\varphi_y(s_0,t)\right\}$$

and the right-hand side is in $C^{\beta/2}[0,T]$. Hence

$$||\dot{s} - s_1||_{C^{\beta/2}[0,T]} \le K. \tag{2.14}$$

By (2.12), we also have

$$||\varphi - \varphi_0||_{C^{1+\beta,(1+\beta)/2}([0,s_0]\times[0,T])} \le K.$$

Hence, if T is small enough,

$$\begin{aligned}
||\dot{s} - s_1||_{C^0[0,T]} &\le ||\dot{s} - s_1||_{C^{\beta/2}[0,T]} T^{\beta/2} \le 1, \\
||\varphi - \varphi_0||_{C^0[0,s_0]} &\le ||\varphi - \varphi_0||_{C^{0,(1+\beta)/2}([0,s_0]\times[0,T])} T^{\frac{1+\beta}{2}} \le 1,
\end{aligned}$$

so that W maps $X_T \times Y_T$ into itself.

From the estimates above, it follows that the image of W lies in a compact subset of $X_T \times Y_T$, and a standard argument then also shows that W is continuous. Invoking the Schauder fixed point theorem we conclude that W has a fixed point in $X_T \times Y_T$.

We can further use the Schauder estimates to obtain additional regularity of the solution, such as the Hölder continuity of $\dot{s}(t)$, and of the second spatial derivatives of φ and ψ. It remains to prove uniqueness.

Let (s_i, φ_i, ψ_i) $(i = 1, 2)$ be two solutions. Then

$$||s_i||_{C^{1+\beta/2}[0,T]} + ||\varphi_i||_{C^{1+\beta,(1+\beta)/2}([0,s_0]\times[0,T])} + ||\psi_i||_{C^{1+\beta,(1+\beta)/2}([0,1]\times[0,T])} \le K.$$

Setting $\psi = \psi_1 - \psi_2$ and taking the difference of the equations for ψ_1, ψ_2, we get

$$\begin{aligned} a\psi_t = {} & A(s_2, y)\psi_{yy} + [B(s_2, y) + a\dot{s}_2 C(s_2, y)]\psi_y + G_1\varphi + G_2\psi \\ & + [A(s_1, y) - A(s_2, y)]\psi_{1,yy} + [B(s_1, y) - B(s_2, y)]\psi_{1,y} \\ & + a[\dot{s}_1 C(s_1, y) - \dot{s}_2 C(s_2, y)]\psi_{1,y}, \end{aligned}$$

where G_1, G_2 are the partial derivatives of G with respect to the first and second variables evaluated at an intermediate point.

Using $W^{2,p}$ estimates for parabolic equations of the form $u_t - au_{yy} - bu_y + cu = g$ and Sobolev's imbedding, we get

$$||\psi_1 - \psi_2||_{C^{1+\beta,(1+\beta)/2}} \le K\{||\varphi_1 - \varphi_2||_{C^0} + ||s_1 - s_2||_{C^1}\}. \tag{2.15}$$

Similarly, we derive the inequality

$$||\varphi_1 - \varphi_2||_{C^{1+\beta,(1+\beta)/2}} \le K\{||\psi_1 - \psi_2||_{C^{1,0}} + ||s_1 - s_2||_{C^1}\}. \tag{2.16}$$

Furthermore, taking the difference of the equations for s_1, s_2 in (2.7), we get

$$||s_1 - s_2||_{C^{1+\beta/2}} \le K||\psi_1 - \psi_2||_{C^{0,\beta/2}} + ||\varphi_{1,y} - \varphi_{2,y}||_{C^{0,\beta/2}}. \tag{2.17}$$

It then follows, upon using (2.16), (2.15), that

$$\begin{aligned} & ||s_1 - s_2||_{C^{1+\beta/2}} + ||\varphi_1 - \varphi_2||_{C^{1+\beta,(1+\beta)/2}} + ||\psi_1 - \psi_2||_{C^{1+\beta,(1+\beta)/2}} \\ & \quad \le K\{||\varphi_1 - \varphi_2||_{C^0} + ||s_1 - s_2||_{C^1}\} \\ & \quad \le KT^{\beta/2}\{||\varphi_1 - \varphi_2||_{C^{1+\beta,(1+\beta)/2}} + ||s_1 - s_2||_{C^{1+\beta/2}}\}. \end{aligned}$$

Taking T such that also $KT^{\beta/2} < 1$, we conclude that $s_1 \equiv s_2$, $\varphi_1 \equiv \varphi_2$, $\psi_1 \equiv \psi_2$. □

3. Completion of the proof of Theorem 1.1. We first derive a priori estimates for any solution of (1.1)–(1.7), assuming that it exists in some interval $0 < t < T$; these bounds will be independent of T.

LEMMA 3.1. *The solution satisfies:*

$$n_* < n(x, t) < 2 \quad \textit{if } 0 \le x < s(t),\ 0 \le t \le T, \tag{3.1}$$

$$0 \le c(x, t) \le 1 \quad \textit{if } 0 \le x \le 1,\ 0 \le t \le T, \tag{3.2}$$

and

$$n_x(s(t), t) < 0 \quad \textit{if } 0 \le t \le T. \tag{3.3}$$

Proof. By (1.14),

$$n_t - (dn_x)_x \ge 0 \quad \text{if } n \le n_*.$$

Hence the maximum principle yields the inequality $n > n_*$ if $0 < x < s(t)$, $0 < t < T$. Similarly, we have from (1.14) that

$$n_t - (dn_x)_x \le 0 \quad \text{if } n \ge 2$$

so that, by the maximum principle, $n < 2$ if $0 \le x \le s(t)$, $0 \le t \le T$. The proof of (3.2) is similar. Finally, noting that, since $f(n_*, c) > 0$,

$$n_t - (dn_x)_x = f(n, c) > 0$$

near the free boundary, the (strict) inequality (3.3) follows by the maximum principle. □

From (3.3) and (1.5), we deduce that

$$\dot{s}(t) > 0 \quad \text{for } 0 \le t \le T \tag{3.4}$$

so that $s(t)$ is strictly monotone increasing.

Also, a standard parabolic estimate shows that c_x is bounded independently of T.

LEMMA 3.2. *There exists a constant M independent of T such that*

$$\dot{s}(t) \le M \quad \textit{for } 0 < t < T. \tag{3.5}$$

Proof. Let

$$Q = \{(x, t); \quad 0 < x < s(t), \quad 0 < t < T\}$$

and introduce the operator

$$\mathcal{L}u = u_t - d(u, c)u_{xx} - d_u(u, c)u_x^2 - d_c(u, c)u_x c_x - f(u, c),$$

where c is the component of the solution (s, n, c) of (1.1)–(1.7). We shall construct a supersolution in the form

$$\bar{n}(x, t) = \begin{cases} 2, & 0 < x < s(t) - \dfrac{1}{M}, \\ n_* + (2 - n_*)\{2M(s(t) - x) - M^2(s(t) - x)^2\}, & s(t) - \dfrac{1}{M} < x < s(t). \end{cases}$$

Notice that $\bar{n} \in W_\infty^{2,1}(Q)$ and

$$\bar{n}_x \le 0, \qquad \bar{n}(s(t), t) = n_*.$$

In the interval $[0, s(t) - \frac{1}{M})$

$$\mathcal{L}\bar{n} = -f(2, c) \ge 0.$$

In the interval $(s(t) - \frac{1}{M}, s(t))$

$$\begin{aligned} \bar{n}_t &= (2 - n_*)2M\dot{s}\{1 - M(s - x)\} \ge 0 \quad \text{since } \dot{s}(t) > 0, \\ -d(\bar{n}, c)\bar{n}_{xx} &= (2 - n_*)2M^2 d(\bar{n}, c) \ge c_0 M^2, \end{aligned}$$

where $c_0 = (2 - n_*)2d_0 > 0$ (see (1.9)),

$$\begin{aligned} -d_n(\bar{n}, c)\bar{n}_x^2 &\ge 0 \qquad \text{(by (1.9))}, \\ |-d_c(\bar{n}, c)c_x\bar{n}_x| &\le c_1 M, \end{aligned}$$

and

$$|f(\bar{n}, c)| \le c_2,$$

where c_1, c_2 are constants independent of M and T. It follows that

$$\mathcal{L}\bar{n} \ge c_0 M^2 - c_1 M - c_2 > 0$$

if M is large enough. Furthermore,

$$\bar{n}_x = 0 = n_x \quad \text{at } x = 0, \qquad \bar{n} = n_* = n \quad \text{at } x = s(t),$$

and $\bar{n}(x, 0) \ge n_0(x)$ for large M. Hence by comparison, $n(x, t) \le \bar{n}(x, t)$ in Q and, consequently,

$$n_x(s(t), t) \ge \bar{n}_x(s(t), t) = -2M(2 - n_*).$$

The assertion (3.5) (with another M) now follows by recalling (1.5).

From (3.5) and (3.4), we get

$$|\dot{s}(t)| \le M. \qquad \square \tag{3.6}$$

LEMMA 3.3. *The solution to* (1.1)–(1.7) *exists and is unique, and it can be extended up to a time* T^* *satisfying* $\lim_{t \nearrow T^*} s(t) = 1$.

Proof. The assertion means that if the solution exists for $0 < t < T_0$, and if $s(T_0) < 1$, then the solution can be continued, uniquely, to a larger interval $0 < t < T_0 + \tau$ ($\tau > 0$). To prove this we observe that in the proof of Lemma 2.1 the size T of the time interval depends on a lower bound on $\min\{s, 1 - s\}$ at the initial time and on the L^∞ bound of the first two derivatives of the initial data. From (3.6) and L^p estimates applied to the system with "straightened" free boundary, (2.3)–(2.9), we deduce a priori bounds on the first two derivatives of $n(x, t)$, $c(x, t)$ at $t = T_0$ (in fact, even $C^{2+\alpha}$ bounds if we use a bootstrap argument and Schauder's estimate). Since, further, $0 < 1 - s(T_0) < 1$, we can extend the solution, and uniquely so, to a larger interval $0 < t < T_0 + \tau$, as claimed. $\square$

We next improve inequality (3.4).

LEMMA 3.4. *There exists a positive constant* γ *independent of* T *such that*

$$\dot{s}(t) \ge \gamma \quad \textit{for } 0 \le t < T. \tag{3.7}$$

Proof. We shall construct a subsolution in the form

$$\underline{n}(x, t) = n_* + \begin{cases} \dfrac{\gamma}{2} s_0^2, & 0 < x < s(t) - s_0, \\ \gamma \left[s_0(s(t) - x) - \dfrac{1}{2}(x - s(t))^2 \right], & s(t) - s_0 < x < s(t). \end{cases}$$

Notice that $\underline{n} \in W^{2,1}_\infty(G)$.

In the interval $(0, s(t) - s_0)$,

$$\mathcal{L}\underline{n} = -f\left(n_* + \frac{\gamma}{2} s_0^2, c\right) < 0$$

by (1.10) if γ is sufficiently small. In the interval $(s(t) - s_0, s(t))$,

$$\underline{n}_t = \gamma[s_0 - (s(t) - x)]\dot{s}(t) \le \gamma M \qquad \text{(by (3.6))},$$
$$f(\underline{n}, c) \ge f(n_*, c) - C_1 \gamma,$$

and all the other terms in $\mathcal{L}\underline{n}$ are bounded by $C_2\gamma$, where C_1, C_2 are positive constants independent of γ and T. Since by (1.10), $f(n_*, c) \geq \mu > 0$ for all c, we conclude that

$$\mathcal{L}\underline{n} \leq -\mu + \gamma(M + C_1 + C_2) < 0$$

if γ is sufficiently small. We also have

$$\underline{n}_x = 0 = n_* \quad \text{at } x = 0, \qquad \underline{n} = n_* = n \quad \text{at } x = s(t)$$

and $\underline{n}(x, 0) < n_0(x)$ if $0 \leq x < s_0$ provided γ is small enough; here we used the assumption $n_0'(s_0) < 0$.

By comparison we then have $\underline{n} \leq n$ in G and

$$n_x(s(t), t) \leq \underline{n}_x(s(t), t) = -\gamma s_0$$

so that (3.7) holds (with another γ).

Combining Lemma 3.3 with Lemma 3.4, we see that there exists a finite number T_* such that the solution exists for all $0 < t < T_*$, and $s(T_*) = 1$. This completes the proof of Theorem 1.1. □

Part II: Travelling wave solutions.

4. Setting up the problem. We seek a solution to (1.1)–(1.5) in the form of a travelling wave with constant speed c ($c > 0$):

$$n(x, t) = u(z), \qquad c(x, t) = v(z), \qquad z = ct - x \in \mathbb{R}^1.$$

The free boundary is given by $x = ct$, i.e., $z = 0$. Then

$$(d(u, v)u')' - cu' + f(u, v) = 0, \quad z > 0, \tag{4.1}$$

$$v'' - acv' + g(u, v) = 0, \quad -\infty < z < \infty, \tag{4.2}$$

$$u(z) \equiv 0, \quad z < 0. \tag{4.3}$$

Motivated by numerical results from [2], we wish to consider only solutions such that

$$u'(z) > 0, \quad z > 0. \tag{4.4}$$

We impose the boundary conditions

$$u(0) = u_* \quad (u_* = n_*), \tag{4.5}$$

$$d(u(0), v(0))u'(0) = cu_*, \tag{4.6}$$

$$u(\infty) = 1, \tag{4.7}$$

and

$$v(-\infty) = 1, \tag{4.8}$$

$$v(+\infty) = 0. \tag{4.9}$$

As a first step, we shall simplify the problem by reducing it to a system in the interval $\{z > 0\}$ only.

Set

$$g_0(v) = g(0, v), \qquad \beta = ac \tag{4.10}$$

so that

$$v'' - \beta v' + g_0(v) = 0 \quad \text{for } -\infty < z < 0. \tag{4.11}$$

LEMMA 4.1. *Assume that $g_0(v)$ satisfies*

$$g_0(1) = 0, \qquad \frac{d}{dv} g_0(v) < 0 \quad \textit{for all } v \in \mathbb{R}^1.$$

Then there exists a smooth function $\Psi(\beta, v)$ such that for every $\beta \in (0, \infty)$, the problem

$$v'' - \beta v' + g_0(v) = 0 \quad \textit{in } (-\infty, 0), \qquad v(0) = v_0, \qquad v'(0) = v_1 \tag{4.12}$$

has a bounded solution if and only if

$$v_1 = \Psi(\beta, v_0); \tag{4.13}$$

furthermore, the bounded solution satisfies $\lim_{z \to -\infty} v(z) = 1$. The function $\Psi(\beta, v)$ has the following properties:

$$\begin{aligned} \frac{d\Psi}{dv} &= \beta - \tfrac{g_0(v)}{\Psi} \quad \textit{in } \mathbb{R}^1 \backslash \{1\}, \\ \Psi(\beta, 1) &= 0, \end{aligned} \tag{4.14}$$

and

$$\Psi_v > 0 \quad \textit{in } \mathbb{R}^1. \tag{4.15}$$

Proof. We write (4.11) as an autonomous system

$$v' = p, \qquad p' = \beta p - g_0(v).$$

In the $v - p$ phase plane there is only one stationary point, namely, (1,0). It is a saddle point since the characteristic equation

$$\lambda^2 - \beta\lambda + g_0'(1) = 0$$

has two real roots, one positive and one negative. Hence there are only two trajectories leaving (1,0), which we shall denote by γ^+ and γ^-. The velocity field of the autonomous system is shown in Figure 1. Note that every trajectory can intersect the v-axis at most once. Hence $p = v'$ can change sign at most once and, consequently, $v(-\infty)$ exists. Since there is only one stationary point, we conclude that either $|v(-\infty)| = \infty$ or $v(-\infty) = 0$. Hence a solution is bounded if and only if (v_0, v_1) lies on the curve $\gamma^+ \cup \{(1,0)\} \cup \gamma^- \equiv \Gamma$.

Along γ^+, $p > 0$ and $v > 1$ so that $p' = \beta p - g_0(v) > 0$, whereas along γ^-, $p < 0$ and $v < 1$ so that $p' < 0$. It follows that Γ can be written as a curve $p = \Psi(\beta, v)$ and, then, a solution is bounded if and only if $v_1 = \Psi(\beta, v_0)$. It is clear that $\Psi(\beta, 1) = 0$, and the equation in (4.14) follows from

$$\frac{dp}{dv} = \beta - \frac{g_0}{p}.$$

From the last equation we get

$$\frac{d}{dv}\left(p \frac{dp}{dv}\right) = \beta \frac{dp}{dv} - \frac{dg_0}{dv} > \beta \frac{dp}{dv}. \tag{4.16}$$

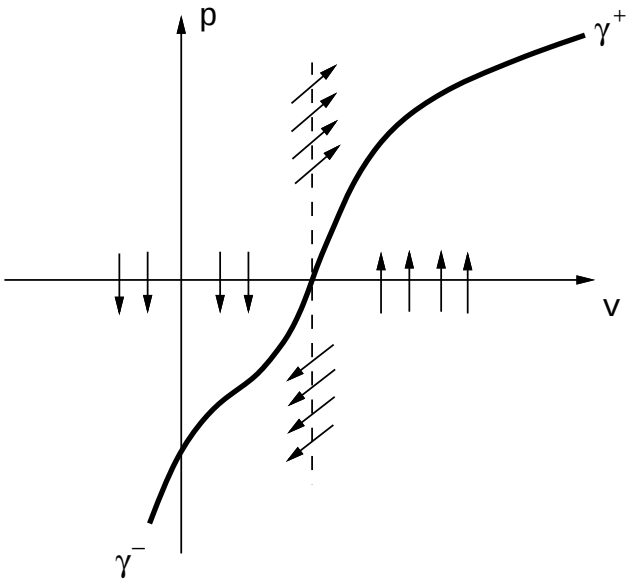

FIG. 1.

To prove (4.15) notice that the inequality holds in a neighborhood of the origin. If the inequality does not hold for all $v \neq 0$ then there is a smallest positive v^* (or a largest negative value v^{**}) at which $\Psi_v(\beta, v)$ vanishes. It follows that $\Psi_{vv} \leq 0$ at v^* (or $\Psi_{vv} \geq 0$ at v^{**}). We also have, however, $p = p(v^*) > 0$ ($p = p(v^{**}) < 0$); cf. Figure 1. Therefore, the left-hand side of (4.16) (with $p = \Psi(\beta, v)$) is negative, whereas the right-hand side vanishes at v^* (or v^{**}), which is a contradiction. □

Remark 4.1. In the special case $g_0(v) = k(1 - v)$ for some $k > 0$,

$$v = 1 - Ce^{\lambda z},$$

where

$$\lambda = \frac{1}{2}(\beta + \sqrt{\beta^2 + 4k}),$$

and $\Psi(\beta, v) = \lambda(v - 1)$.

Lemma 4.1 allows us to reformulate problem (4.1)–(4.9) as follows.

Problem (P_0). Find (c, u, v) with $c > 0$ such that

$$(d(u,v)u')' - cu' + f(u,v) = 0, \qquad z > 0, \tag{4.17}$$

$$v'' - acv' + g(u,v) = 0, \qquad z > 0, \tag{4.18}$$

$$u(0) = u_*, \quad d(u_*, v(0))u'(0) = cu_*, \quad u(\infty) = 1, \tag{4.19}$$

$$-v'(0) + \Psi(ac, v(0)) = 0, \qquad v(\infty) = 0, \tag{4.20}$$

$$u'(z) > 0, \qquad z > 0. \tag{4.21}$$

From (4.21) and (4.19), we see that as z varies from 0 to ∞, $u = u(z)$ varies from u_* to 1. We can therefore try to use u as an independent variable, i.e., set $z = z(u)$ as the inverse function of $u = u(z)$; u will vary in the interval

$$\Omega = \{u_* < u < 1\}.$$

We introduce new dependent functions by

$$Q(u) = d(u,v)u'(z)|_{z=z(u)}, \qquad V(u) = v(z)|_{z=z(u)}. \tag{4.22}$$

Using the rule

$$\frac{d}{dz} = u'\frac{d}{du} = \frac{Q(u)}{d(u,v)}\frac{d}{du},$$

we can transform problem (P_0) into the following problem.

Problem (P_1). Find (c, Q, V) with $c > 0$ such that

$$QQ_u - cQ + d(u,V)f(u,V) = 0 \quad \text{in } \Omega, \tag{4.23}$$

$$\frac{Q}{d(u,V)}\left(\frac{Q}{d(u,V)}V_u\right)_u - ac\frac{Q}{d(u,V)}V_u + g(u,V) = 0 \quad \text{in } \Omega, \tag{4.24}$$

$$Q(u_*) = cu_*, \quad Q(1) = 0, \tag{4.25}$$

$$-\frac{Q(u_*)}{d(u_*, V(u_*))}V_u + \Psi(ac, V(u_*)) = 0, \quad V(1) = 0, \tag{4.26}$$

$$Q > 0 \quad \text{in } \Omega, \tag{4.27}$$

$$\int_{u_*}^{1} \frac{d(s,V(s))}{Q(s)}\,ds = \infty. \tag{4.28}$$

Indeed, we have the following lemma.

LEMMA 4.2. *Problems* (P_0) *and* (P_1) *are equivalent.*

Proof. Given a solution to problem (P_0), define $z = z(u)$ as the inverse of $u = u(z)$ and define Q, V by (4.22). Then (4.23), (4.24), (4.26), (4.27), and the first boundary condition in (4.25) hold. Since

$$z = \int_{u_*}^{u} \frac{d(s,V(s))}{Q(s)}\,ds \tag{4.29}$$

and $u(\infty) = 1$, we also have (4.28). Finally, to prove that $Q(1) = 0$, note that the existence of $u(\infty)$ and $v(\infty)$ implies by standard ODE theory that u'', v'' are bounded, and then, by a simple argument in real analysis, $u'(\infty), v'(\infty)$ must exist and be equal to zero. Taking $u \to 1$ in the first relation of (4.22), we then deduce that $Q(1) = 0$.

Conversely, consider a solution to problem (P_1) and define $u = u(z)$ by

$$u'(z) = \frac{Q(u)}{d(u,V(u))}, \quad u(0) = u_* \tag{4.30}$$

and $v(z) = V(u(z))$. Then (4.29) holds, and one can easily show that all the equations in problem (P_0) are satisfied. ∎

5. Statement of the main result. In what follows, we shall work primarily (but not exclusively) with problem (P_1). We shall need some assumptions that include all those made in (1.9)–(1.11) (except for the condition $f(2,c) \le 0$, which will not be needed). Using the variables (u,v) instead of (n,c), we introduce the set (which coincides with G)

$$S = \{(u,v); \quad u_* \le u \le 1, \quad 0 \le v \le 1\}.$$

We assume that

$$\begin{aligned}&\text{the function } d(u,v) \text{ is in } C^1(S), \quad \text{and}\\ &0 < d_0 \le d(u,v) \le d_1 < \infty, \quad d_u \le 0, \quad d_v \ge 0, \quad ad \le 1,\end{aligned} \tag{5.1}$$

where a is the constant appearing in (4.2) and (4.18);

$$\begin{aligned}&\text{the function } f(u,v) \text{ is in } C^1(S) \quad \text{and}\\ &f(1,0) = 0, \quad f_u(1,0) < 0, \quad f(u,0) > 0 \quad \text{for } u_* \le u < 1,\\ &f_v(u,v) > 0 \quad \text{in } S;\end{aligned} \tag{5.2}$$

$$\begin{aligned}&\text{the function } g(u,v) \text{ is in } C^1(S) \quad \text{and}\\ &g(1,0) = 0, \quad g(u,0) \ge 0, \quad \text{and} \quad g(u,1) \le 0 \quad \text{for } u_* \le u \le 1,\\ &g_u(u,v) < 0, \quad g_v(u,v) < 0 \quad \text{in } S;\end{aligned} \tag{5.3}$$

$$\begin{aligned}&\text{there exists a positive number } \ell \text{ such that } \ell(1-u_*) > 1 \quad \text{and}\\ &\max_{0\le v\le \ell(1-u)} \frac{f(u,v)}{d(u,v)} + \frac{1}{\ell} g(u, \ell(1-u)) \le 0 \quad \text{for } 1 - \frac{1}{\ell} \le u \le 1.\end{aligned} \tag{5.4}$$

Note that $1 - \frac{1}{\ell} > u_*$.

THEOREM 5.1. *If the conditions* (5.1)–(5.4) *hold then problem* (P_0) *has at least one solution* (c,u,v) *and* $v'(z) < 0$ *for* $0 < z < \infty$.

The proof is given in the next three sections. In section 6, we solve, for a given $V = V(u)$, (4.23) for (c,Q) under the conditions $Q(u_*) = cu_*$, $Q(1) = 0$. Substituting this solution into (4.24), we solve the resulting equation in section 7 and denote the solution by W; this defines a mapping $T : V \to W$. For technical reasons we shall actually consider the V-equation only in the interval $u_* \le u < 1 - \varepsilon$ ($\varepsilon > 0$), in order to avoid the degeneracy of the leading coefficient at $u = 1$. Thus the mapping T depends on ε (and will be denoted by T_ε), and we shall prove that it has at least one fixed point. In section 8, we let $\varepsilon \to 0$ and, invoking the equivalence established in Lemma 4.2, prove that the solution $(c_\varepsilon, Q_\varepsilon, V_\varepsilon)$ of the fixed point of T_ε converges to a solution of problem (P_1).

6. Solution for (c,Q), given $V(u)$. For any small $\varepsilon > 0$, we introduce the space

$$X_\varepsilon = \{V \in C^0[u_*, 1], \quad 0 \le V \le 1, \quad V \equiv 0 \quad \text{on } [1-\varepsilon, 1]\}.$$

Given $V(u)$ in X_ε, consider the following problem.

Problem (P_2). Find (c,Q) with $c > 0$ such that

$$QQ_u - cQ + d(u, V(u)) f(u, V(u)) = 0 \quad \text{in } \Omega, \tag{6.1}$$

$$Q(u_*) = cu_*, \quad Q(1) = 0, \quad Q > 0 \quad \text{in } \Omega. \tag{6.2}$$

THEOREM 6.1. *Under the assumptions* (5.1), (5.2), *there exists a unique solution to* (6.1), (6.2); *furthermore, the following estimates hold:*

$$\begin{aligned}&c_1 \le c \le c_2, \quad \textit{where}\\ &c_1 = \sqrt{d_0} \max_{\bar\Omega} \left\{ \frac{1}{u} \int_{u_*}^{u} \frac{f(s,0)}{s}\, ds \right\}^{1/2}, \qquad c_2 = 2\sqrt{d_1} \max_{\bar\Omega} \left\{ \frac{1}{u} \int_{u_*}^{u} \frac{f(s,1)}{s}\, ds \right\}^{1/2},\end{aligned} \tag{6.3}$$

$$c_3(1-u) \le Q(u) \le c_2 u \quad \text{in } \Omega, \quad \text{where}$$

$$c_3 = \frac{1}{2}\left\{-c_2 + \left[c_2^2 + 4d_0 \min_{\bar\Omega} \frac{f(s,0)}{1-s}\right]^{1/2}\right\}, \tag{6.4}$$

and

$$Q(u) \le \sqrt{2d_1}\left[\int_u^1 f(s,V(s))ds\right]^{1/2} \le \sqrt{2d_1}||f||_{L^\infty}\sqrt{1-u}. \tag{6.5}$$

Note that by (5.2), $0 < c_1 < c_2$ and $c_3 > 0$.

To prove the theorem, we first consider the following more general problem.

Problem (P_3). Find (c, Q) with $c > 0$ such that

$$QQ_u - cQ + F(u) = 0 \quad \text{in } \Omega = (u_*, 1), \tag{6.6}$$

$$Q(u_*) = cu_*, \quad Q(1) = 0, \quad Q(u) > 0 \quad \text{in } \Omega, \tag{6.7}$$

where

$$F \in C^0[u_*, 1], \quad F(1) = 0, \quad F(u) > 0 \quad \text{in } (u_*, 1). \tag{6.8}$$

LEMMA 6.2. *Problem* (P_3) *admits a unique solution* (c, Q). *The solution has the following properties:*

$$c_F < c \le 2c_F, \quad \text{where } c_F = \max_{\bar\Omega}\left\{\frac{1}{u}\int_{u_*}^u \frac{F(s)}{s}\,ds\right\}^{1/2}, \tag{6.9}$$

$$0 < Q(u) < cu \quad \text{in } \Omega, \tag{6.10}$$

$$\lambda(u)(1-u) \le Q(u) \le \Lambda(u)(1-u) \quad \text{in } \Omega, \tag{6.11}$$

where

$$\lambda(u) = \frac{1}{2}\left\{-c + \left[c^2 + 4\min_{[u,1]} \frac{F(s)}{1-s}\right]^{1/2}\right\} \in (0, \infty),$$

$$\Lambda(u) = \frac{1}{2}\left\{-c + \left[c^2 + 4\max_{[u,1]} \frac{F(s)}{1-s}\right]^{1/2}\right\} \in (0, \infty) \cup \{\infty\},$$

$$Q(u) < \left\{2\int_u^1 F(s)\,ds\right\}^{1/2} \le \left\{2|F|_{L^\infty(\Omega)}\right\}^{1/2}(1-u)^{1/2} \quad \text{in } \Omega \tag{6.12}$$

and

$$c = \int_{u_*}^1 \frac{F(s)}{Q(s)}\,ds > 0. \tag{6.13}$$

Note that if $F_u(1,0) = -\infty$, then $\Lambda(u) = \infty$.

Proof. We first prove uniqueness. Suppose (c_1, Q_1) and (c_2, Q_2) are two solutions. It suffices to show that $c_1 = c_2$. We proceed by contradiction, assuming that $c_1 > c_2$. Then $Q_1(u_*) > Q_2(u_*)$, and we introduce

$$\bar u = \sup\{u \in [u_*, 1], \quad Q_1 > Q_2 \quad \text{in } [u_*, u]\}.$$

If $\bar{u} < 1$, then $Q_1(\bar{u}) = Q_2(\bar{u})$ and $\frac{d}{du}(Q_1 - Q_2) \le 0$ at $\bar{u}$. However, from (6.6), we get

$$\frac{d}{du}(Q_1 - Q_2)|_{u=\bar{u}} = c_1 - c_2 - F(\bar{u})\left[\frac{1}{Q_1(\bar{u})} - \frac{1}{Q_2(\bar{u})}\right] = c_1 - c_2 > 0,$$

a contradiction. We conclude that $\bar{u} = 1$, i.e., $Q_1 > Q_2$ in $[u_*, 1)$. Integrating (6.6) over $[u_*, 1]$ for (c_1, Q_1) and (c_2, Q_2) and taking the difference, we get, after using (6.7),

$$\begin{aligned} 0 > \frac{1}{2}(c_2^2 - c_1^2)u_*^2 &= \left[\frac{1}{2}Q_1^2 - \frac{1}{2}Q_2^2\right]_{u=u_*}^{u=1} = \int_{u_*}^1 \left(Q_1\frac{\partial Q_1}{\partial u} - Q_2\frac{\partial Q_2}{\partial u}\right) du \\ &= \int_{u_*}^1 (c_1 Q_1 - c_2 Q_2)\, du > 0, \end{aligned}$$

a contradiction.

To prove existence we extend $F(u)$ by 0 to $u > 1$. Denote by $Q(c, u)$ $(c > 0)$ the solution to

$$Q_u = c - \frac{F}{Q}\,, \qquad Q(u_*) = cu_* \tag{6.14}$$

and denote by $[u_*, \gamma(c))$ the maximal existence interval where $Q > 0$. The set

$$\mathcal{A} = \{c > 0\,; \quad \gamma(c) > 1\}$$

is clearly an open set. We claim that

$$[0, c_F) \cap \mathcal{A} = \emptyset. \tag{6.15}$$

Indeed, since $F > 0$ in Ω, (6.14) gives $Q_u < c$ so that, by integration, $Q < cu$ and, consequently,

$$Q_u < c - \frac{F}{cu}.$$

Again, by integration,

$$Q < cu - \int_{u_*}^u \frac{F(s)}{cs}\, ds = \frac{u}{c}\left\{c^2 - \frac{1}{u}\int_{u_*}^u \frac{F(s)}{s}\, ds\right\}.$$

It follows that if $c < c_F$, then $\gamma(c) < 1$, i.e., (6.15) holds.

We next prove that

$$(2c_F, \infty) \subset \mathcal{A}. \tag{6.16}$$

Indeed, denote by $\gamma_1(c)$ the smallest value of u in $[u_*, \gamma(c)]$ such that $Q = \frac{1}{2}cu$, i.e.,

$$\gamma_1(c) = \sup\left\{s \le \gamma(c), \quad Q(u) > \frac{1}{2}\, cu \quad \text{in } [u_*, s]\right\}.$$

If $\gamma_1 = \gamma_1(c) \le 1$, then integrating (6.14) over $[u_*, \gamma_1(c)]$, we obtain

$$\begin{aligned} Q(\gamma_1(c)) &= c\gamma_1 - \int_{u_*}^{\gamma_1} \frac{F}{Q} > c\gamma_1 - \int_{u_*}^{\gamma_1} \frac{2F(s)}{cs}\, ds \\ &= \frac{c\gamma_1}{2}\left\{2 - \frac{4}{c^2}\frac{1}{\gamma_1}\int_{u_*}^{\gamma_1} \frac{F(s)}{s}\, ds\right\} > \frac{c\gamma_1}{2} \quad \text{if } c > 2c_F, \end{aligned}$$

which is a contradiction. Hence $\gamma(c) \geq \gamma_1(c) > 1$ if $c \geq 2c_F$ and (6.16) is proved.

Now define $c_0 = \inf\{c;\ c \in \mathcal{A}\}$. By continuity, $\gamma(c_0) \geq 1$ and, from (6.16) and the proof of (6.15), $c_F < c_0 \leq 2c_F$. If $Q(c_0, 1) > 0$, then as $\mathcal{A}$ is open, there are values of c smaller than c_0 (and near c_0) for which $Q(c, u) > 0$ if $u_* \leq u \leq 1$, which contradicts the definition of c_0. We conclude that $Q(c_0, 1) = 0$ and thus $(c_0, Q(c_0, u))$ is a solution to problem (P_3). For simplicity, we shall denote this solution by (c, Q).

Integrating (6.6) over $[u, 1]$, we have

$$\frac{1}{2}[Q^2]_u^1 > -\int_u^1 F(s)\, ds,$$

so that

$$Q^2(u) < 2\int_u^1 F(s)\, ds,$$

and (6.12) follows. Integrating (6.14) over $[u_*, 1]$ and using (6.7), the relation (6.13) also follows.

It remains to prove (6.11). We first derive the upper bound on Q. If we define

$$\delta = \inf\{\tilde{s} > 0; \quad Q(u) < \tilde{s} + \Lambda(u)(1-u) \quad \text{in } [u_*, 1]\},$$

then it suffices to show that $\delta = 0$. Without loss of generality, here we may assume that $\Lambda(1-) < \infty$. Then $\Lambda(u)$ is continuous and, if $\delta > 0$, there exists a point $u_1 \in [u_*, 1)$ such that $Q(u_1) = \delta + \Lambda(u_1)(1 - u_1)$ and

$$\left.\frac{dQ}{du}\right|_{u=u_1} \leq \left.\frac{d}{du}\left[\Lambda(u)(1-u)\right]\right|_{u=u_1} \leq -\Lambda(u_1)$$

since $\Lambda(u)$ is monotone decreasing; the first inequality is actually an equality if $u^* < u_1 < 1$. Using (6.14), we get

$$-\Lambda(u_1) \geq c - \frac{F(u_1)}{\delta + \Lambda(u_1)(1-u_1)} \geq c - \frac{F(u_1)}{\Lambda(u_1)(1-u_1)},$$

that is,

$$-\Lambda^2(u_1) > c\Lambda(u_1) - \frac{F(u_1)}{1-u_1} \geq c\Lambda(u_1) - \max_{[u_1,1]} \frac{F(s)}{1-s}.$$

However, by definition of $\Lambda(u)$,

$$\Lambda^2(u) + c\Lambda(u) - \max_{[u,1]} \frac{F(s)}{1-s} = 0,$$

which is a contradiction.

Similarly, we define

$$\delta = \inf\{s > 0; \quad Q(u) > \lambda(u)(1-u) - s\}$$

and show that $\delta = 0$. □

Proof of Theorem 6.1. Applying Lemma 6.2 with $F(u) = d(u, V(u))f(u, V(u))$ and using (5.1), (5.2), and the fact that $V(u)$ is in X_ε, the assertions of Theorem 6.1 immediately follow. (The assumptions $d_u \leq 0$, $d_v \geq 0$, $ad \leq 1$ are not needed for Theorem 6.1.)

7. A fixed point $(c_\varepsilon, Q_\varepsilon, V_\varepsilon)$. Given $V \in X_\varepsilon$, let (c, Q) denote the solution of (6.1), (6.2) and consider the following problem.

Problem (P_4). Find $W(u)$ such that

$$\frac{Q}{d}\left(\frac{Q}{d}W_u\right)_u - ac\frac{Q}{d}W_u + g(u,W) = 0 \quad \text{in } \Omega_\varepsilon = [u_*, 1-\varepsilon], \tag{7.1}$$

$$-\frac{Q}{d}W_u + \Psi(ac, W) = 0 \quad \text{at } u = u_*, \tag{7.2}$$

$$W(u) = 0 \quad \text{in } [1-\varepsilon, 1], \tag{7.3}$$

where $d = d(u, V(u))$.

LEMMA 7.1. *Under the assumptions* (5.1)–(5.3) *there exists a unique solution* W *to problem* (P_4)*, and the following inequalities hold:*

$$0 \le W \le 1 \quad \textit{in } \Omega_\varepsilon, \tag{7.4}$$

$$-M_\varepsilon \le W_u \le 0 \quad \textit{in } \Omega_\varepsilon, \tag{7.5}$$

$$|W_u(u_*)| \le c_4, \tag{7.6}$$

where M_ε *is a constant which depends on* ε *but not on* $V \in X_\varepsilon$*, and* c_4 *is independent of* ε *and* V*.*

Proof. Extend the definition of $g(u,w)$ to all $w \in \mathbb{R}^1$ such that $g_w < 0$. By Theorem 6.1

$$c_3\varepsilon \le Q < c_2 \quad \text{in } [u_*, 1-\varepsilon] \tag{7.7}$$

so that the differential equation (7.1) is nondegenerate in Ω_ε. The inequalities $g_w < 0$ and $\Psi_w > 0$ will enable us to use the comparison principle for the system (7.1)–(7.3). For any function $\tilde{W}(u)$ satisfying $0 \le \tilde{W}(u) \le 1$, we set $g = g(u, \tilde{W}(u))$, $\Psi = \Psi(ac, \tilde{W}(u))$, and denote the corresponding solution of (7.1)–(7.3) by $W(u)$. Since

$$g(u,0) \ge g(u, \tilde{W}(u)) \ge g(u,1),$$
$$\Psi(ac,0) \le \Psi(ac, \tilde{W}(u)) \le \Psi(ac,1),$$

the comparison principle shows that $0 \le W(u) \le 1$. We can therefore apply the Schauder fixed point argument to the mapping $\tilde{W} \to W$ to deduce the existence of a solution to (7.1)–(7.3). Uniqueness of the solution of (7.1)–(7.3) follows again by a comparison argument.

Next, differentiating (7.1) and setting $Z = \frac{Q}{d}W_u$, we get

$$\left(\frac{Q}{d}Z_u\right)_u - acZ_u + g_v\frac{d}{Q}Z + g_u = 0.$$

Also

$$Z|_{u=u_*} = \Psi(ac, W(u_*)) < 0, \quad Z|_{u=1-\varepsilon} \le 0.$$

Since $g_v < 0$ and $g_u < 0$, the maximum principle yields $Z \le 0$, i.e., $W_u \le 0$. Finally, (7.6) and the first inequality in (7.5) follow from the fact that (7.1) is nondegenerate (i.e., from (7.7)). ∎

We shall now combine Lemma 7.1 with Theorem 6.1. For every $V \in X_\varepsilon$ we define (c, Q) by Theorem 6.1 and W by Lemma 7.1, and introduce the mapping T_ε by

$$T_\varepsilon V = W.$$

Clearly, T_ε maps X_ε into itself, and its image lies in a compact subset of X_ε (since $|W_u| \le M_\varepsilon$). By the uniqueness parts of Theorem 6.1 and Lemma 7.1, it also easily follows that T_ε is continuous. Invoking the Schauder fixed point theorem, we conclude that there exists at least one fixed point for T_ε. We shall denote it by $(c_\varepsilon, Q_\varepsilon, V_\varepsilon)$.

We define a function $u_\varepsilon(z)$ by

$$z = \int_{u_*}^{u_\varepsilon(z)} \frac{d(s, V_\varepsilon(s))}{Q_\varepsilon(s)}\, ds, \quad z \in [0, Z_\varepsilon], \tag{7.8}$$

where

$$Z_\varepsilon = \int_{u_*}^{1-\varepsilon} \frac{d(s, V_\varepsilon(s))}{Q_\varepsilon(s)}\, ds, \tag{7.9}$$

and introduce also the function

$$v_\varepsilon(z) = V_\varepsilon(u_\varepsilon(z)).$$

Then $(c_\varepsilon, u_\varepsilon(z), v_\varepsilon(z))$ form a solution of the system (4.17)–(4.21) in $[0, Z_\varepsilon]$ but without the conditions $u(\infty) = 1$, $v(\infty) = 0$.

By (6.9)–(6.11), the functions $Q_\varepsilon(u)$ are uniformly bounded from above and below by two positive constants, for $u_* \le u \le 1 - \delta$ (for any $\delta > 0$), and the same is true for the constants c_ε. Using also the estimates of Lemma 7.1, we deduce that $u_\varepsilon(0), u'_\varepsilon(0), v_\varepsilon(0), v'_\varepsilon(0)$, are uniformly bounded. Hence we can choose a subsequence $\varepsilon \downarrow 0$ such that

$$(c_\varepsilon, u_\varepsilon, v_\varepsilon) \to (c, u, v), \tag{7.10}$$

where (c, u, v) is a solution of (4.17)–(4.21) for $0 < z < z_0$, where

$$z_0 = \lim_{\varepsilon \downarrow 0} Z_\varepsilon. \tag{7.11}$$

The corresponding limits (Q, V) of $(Q_\varepsilon, V_\varepsilon)$ also exist, and $Q(u) > 0$ if $u_* < u < 1$, $Q(1) = 0$.

LEMMA 7.2. *If $z_0 = \infty$, then (c, u, v) is a solution to problem (P_0).*

Proof. The only assertions that still need to be proved are

$$u(\infty) = 1, \qquad v(\infty) = 0. \tag{7.12}$$

We know that $u(\infty)$, $v(\infty)$ exist. Consequently (by ODE theory) u'' and v'' are bounded and then $u'(\infty)$, $v'(\infty)$ must exist and be equal to zero. The relation (4.30) holds for $0 < z < \infty$, and taking $z \to \infty$, we get $Q(u(\infty)) = 0$ so that $u(\infty) = 1$. Finally, from (4.17), we deduce that

$$d(1, v(\infty))u'' + f(1, v(\infty)) \to 0 \quad \text{if } z \to \infty.$$

From this it follows that $f(1, v(\infty)) = 0$ (otherwise, $u'(z)$ will not converge to zero as $z \to \infty$) so that by (5.2), $v(\infty) = 0$. ∎

8. Proof of Theorem 5.1. In section 7, we established the existence of a fixed point $(c_\varepsilon, u_\varepsilon, v_\varepsilon)$, or $(c_\varepsilon, Q_\varepsilon, V_\varepsilon)$, for the mapping $T_\varepsilon : X_\varepsilon \to X_\varepsilon$ and also proved that $\partial V_\varepsilon/\partial u \le 0$. In this section, we shall replace X_ε by the subset

$$Y_\varepsilon = \Bigg\{ V \in C^0[u_*, 1]; \quad 0 \le V \le 1, \quad V_u \le 0, \\ V \equiv 0 \quad \text{on } [1-\varepsilon, 1], \quad \text{and} \quad V(u) \le \ell(1-u) \quad \text{in } \left[1 - \frac{1}{\ell}, 1\right] \Bigg\}, \tag{8.1}$$

where ℓ is the positive number appearing in condition (5.4).

LEMMA 8.1. *Under the assumptions* (5.1)–(5.4), T_ε *has a fixed point in* Y_ε.

Proof. We need only to show that T_ε maps Y_ε into itself; the rest of the analysis is as before. If we set $T_\varepsilon V = W$, then as before, $W_u \le 0$, and so all we need to show is that

$$W(u) \le \ell(1-u) \quad \text{in } \left[1 - \frac{1}{\ell}, 1 - \varepsilon\right]. \tag{8.2}$$

Consider the function $\bar{W}(u) = \ell(1-u)$ in $[1 - \frac{1}{\ell}, 1 - \varepsilon]$. It satisfies

$$\bar{W}\left(1 - \frac{1}{\ell}\right) = 1 \ge W\left(1 - \frac{1}{\ell}\right), \qquad \bar{W}(1-\varepsilon) = \ell\varepsilon > 0 = W(1-\varepsilon).$$

Also

$$\begin{aligned} \mathcal{L}W &\equiv \frac{Q}{d}\left(\frac{Q}{d}\bar{W}_u\right)_u - \alpha c \frac{Q}{d}\bar{W}_u + g(u, \bar{W}) \\ &= -\ell\left\{\frac{Q}{d}\frac{Q_u}{d} - \frac{Q^2}{d}\frac{d_u + d_v V_u}{d^2}\right\} + \ell a c \frac{Q}{d} + g(u, \bar{W}) \\ &= -\frac{\ell}{d^2}\left\{(c - acd)Q - df\right\} + \frac{Q^2\ell}{d^3}(d_u + d_v V_u) + g(u, \bar{W}) \quad \text{by (6.1)}. \end{aligned}$$

Since $d_u \le 0$, $d_v \ge 0$, $V_u \le 0$, $1 - ad \ge 0$, $Q > 0$, we get

$$\mathcal{L}W \le \ell\left\{\frac{f(u, V(u))}{d(u, V(u))} + \frac{1}{\ell}g(u, \ell(1-u))\right\} \le 0 \quad \text{in } \left[1 - \frac{1}{\ell}, 1 - \varepsilon\right],$$

by (5.4); here we used the inequality $V(u) \le \ell(1-u)$ in $[1 - \frac{1}{\ell}, 1]$. Thus $\bar{W}$ is a supersolution, and (8.2) follows by comparison. ∎

We shall henceforth work with the solution $(c_\varepsilon, u_\varepsilon, v_\varepsilon)$, or $(c_\varepsilon, Q_\varepsilon, V_\varepsilon)$, corresponding to the space Y_ε and with the corresponding limits (c, u, v) (see (7.10)) and (c, Q, V). We shall prove that (c, u, v) is a solution to problem (P_0). In view of Lemma 7.2, all we need to prove is the following.

LEMMA 8.2. *Under the assumptions* (5.1)–(5.4) *the following relations hold:*

$$z_0 = \int_{u_*}^{1} \frac{d(s, V(s))}{Q(s)}\, ds = \infty. \tag{8.3}$$

Proof. Recalling that $f(1, 0) = 0$ and using Lemma 8.1, we have

$$f(u, V_\varepsilon(u)) \le ||f_u||_{L^\infty}(1-u) + ||f_v||_{L^\infty} V_\varepsilon(u) \le M(1-u)$$

for $u \in [1-\frac{1}{\ell}, 1-\varepsilon]$. Using this in (6.5) we get $Q_\varepsilon(u) \le M(1-u)$ with another constant M, independent of ε. It follows that

$$Q(u) \le M(1-u) \quad \text{in } \left[1-\frac{1}{\ell}, 1\right]$$

and, since $d(u, V(u)) \ge d_0 > 0$, the assertion (8.3) follows. □

9. Application to corneal epithelial wound healing. In the model that appears in [2] (see also [1]), after nondimensionalization,

$$\frac{\partial N}{\partial t} = \frac{\partial}{\partial X}\left[(\alpha + 0.1\alpha C)\frac{\partial N}{\partial X}\right] + \frac{\partial}{\partial X}(e(X,t)N) + F(N,C), \tag{9.1}$$

$$\frac{\partial C}{\partial t} = D_C \frac{\partial^2 C}{\partial X^2} + G(N,C), \tag{9.2}$$

where

$$\begin{aligned} F(N,C) &= +(0.9+0.1C)(2N-N^2) - N, \\ G(N,C) &= A + B(N) - \mu N h(C) - \delta C, \\ h(C) &= \frac{C}{\hat{C}+C}, \quad \delta = 242, \\ B(N) &= B(0)\chi_{\{N=0\}}, \quad B(0) > 0, \quad \alpha = 0.012, \quad D_C = 6, \quad \mu = 2\times 10^4. \end{aligned}$$

Here the first term in $F(N,C)$ represents the reduction of the chemical level to equilibrium, and $-N$ is due to the natural death of cells. The function $B(N)$ in $G(N,C)$ is a wound bed source term. The term $h(C)$ in $G(N,C)$ represents chemical reaction between N and C, and $-\delta C$ is a loss due to decay of the chemical stimulus. Finally, $e(X,t)$ accounts for the physiological electric field. This choice is phenomenological, and it is not clear to us what is the physical motivation for a choice of the function $e(X,t)$. On the other hand, if we consider the *effect* of the electric field on the diffusion process, then it is reasonable to assume that it takes the form of a flux $k(N)N_X$, where

$$\begin{aligned} &k(n_*) > 0, \quad k'(N) \le 0 \quad \text{if } N > n_*, \\ &k(N) = 0 \quad \text{if } N > n_* + \varepsilon_0 \end{aligned}$$

for some $\varepsilon_0 > 0$. Indeed, the expression $k(N)N_X$ represents flux, which increases as we get closer to the moving boundary of the healed region, and it becomes negligible at some "distance" away from this boundary (i.e., when $N > n_* + \varepsilon_0$).

In what follows, we replace $e(X,t)N$ by $k(N)N_X$, with $k(N)$ as above, and write

$$k(N) = e_0 E(N), \quad e_0 > 0$$

so that $E'(N) \le 0$; it will be convenient to set $e_0 = \alpha e,\ e > 0$.

Let $X = \sqrt{\alpha}x$, $N = n(x,t)$, $C = 1 + C^* c(x,t)$, where, by [2], $C^* \sim 5$–50. Writing the system (9.1), (9.2) (with $e(X,t)N$ replaced by $\alpha e E(N) N_X$) in the form (1.1), (1.2), we then have

$$d(n,c) = 1.1 + bc + eE(n), \tag{9.3}$$

where $a = \alpha/D_C = 2\times 10^{-3},\ b = 0.1C^*$,

$$f(n,c) = (1+bc)n(1-n) + bnc, \tag{9.4}$$

and

$$g(n,c) = \frac{a}{C^*} G(n, 1 + C^* c).$$

It is easily seen that all the assumptions made in Theorem 1.1 are satisfied.

In order to verify the assumptions of Theorem 5.1, we observe that the numerical results obtained in [1, 2], which exhibit a travelling wave solution, imply that

$$G(1,1) = 0, \qquad G(0, 1 + C^*) = 0$$

so that

$$A = \delta + \mu h(1), \qquad C^* = \frac{1}{\delta}(\mu h(1) + B(0)). \tag{9.5}$$

Setting

$$\theta = \frac{\mu h(1)}{\mu h(1) + B(0)}, \quad 0 < \theta < 1,$$

we get

$$g(n,c) = a\delta \left\{ -c + \theta(1-n) + \theta n \left(1 - \frac{h(1 + C^* c)}{h(1)} \right) + (1-\theta)\chi_{\{n=0\}} \right\}. \tag{9.6}$$

We easily check that the functions d, f, g then satisfy all the assumptions in (5.1)–(5.3). Thus it remains to show that condition (5.4) also holds; this is more dedicate. We note that whereas in [1] (and also in [2]) $\hat{C}$ is taken as 3 so that $h(1) = \frac{1}{4}$, the numerical graph in [1, Figure 2] shows that actually $1 + C^* = 5$ in case $B(0) = 0$ so that, from the second relation in (9.5),

$$h(1) = \frac{\delta C^*}{\mu} \sim \frac{1}{20}.$$

We shall take an intermediate value, $h(1) = \frac{1}{10}$, so that $\hat{C} = 9$. Then

$$g(u,v) = 0.4 \left\{ -v + \theta(1-u) - \theta C^* \frac{uv}{1+bv} \right\}$$

in the healed region. Clearly,

$$\max_{0 \le v \le w} \frac{f(u,v)}{d(u,v)} \le u(1-u) + \frac{buw}{1+bw}$$

and, with $v = \ell(1-u)$,

$$\frac{g(u,v)}{\ell}\Big|_{v=\ell(1-u)} \le -4\theta b \frac{u(1-u)}{1+bw} \quad \text{if } \ell > 1 \ge \theta.$$

Hence the condition (5.4) holds if

$$1 + \frac{\ell b}{1+bw} - \frac{4\theta b}{1+bw} \le 0 \quad \text{for } 0 \le w \le 1. \tag{9.7}$$

This inequality is satisfied for some ℓ, θ near 1 provided $2b > 1$, which is indeed the case since $b = 0.1C^*$ and $C^* > 8$ by (9.5).

We conclude that for the relevant range of parameters that occur in [1, 2] the functions d, f, g satisfy all the assumptions made in Theorem 1.1 and all the assumptions (5.1)–(5.3) made in Theorem 5.1. As for the last assumption, (5.4), made in Theorem 5.1, it does hold for *some* range of relevant parameters.

Acknowledgments. We would like to thank Philip Maini for providing us with the manuscript [2]. We also wish to thank him and E. A. Gaffrey for useful discussions during the preparation of the present paper.

INVERSE PROBLEM FOR THE STURM–LIOUVILLE EQUATION ON A SIMPLE GRAPH*

VYACHESLAV PIVOVARCHIK†

Abstract. The spectrum of small vibrations of a graph consisting of three joint smooth strings with the free ends fixed can be reduced to the Sturm–Liouville boundary problem on a graph. This problem occurs also in quantum mechanics. The spectrum of such a problem is investigated in comparison with the union of spectra of Dirichlet problems on the rays of the graph. It is shown that the eigenvalues of the spectra interlace in some sense; thus an analogue of Sturm theorem is established. If the four spectra (the spectrum of the boundary problem on the graph and the three spectra of the mentioned Dirichlet problems) do not intersect, then the inverse problem of recovering the potentials on the rays from the four spectra is uniquely solvable. The procedure of construction of the potentials is presented.

Key words. sinus-type function, function of Hermite–Biehler type, quadratic operator pencil, interpolation series, Dirichlet boundary conditions

1. Direct problem.

It is well known [5] that if a string is smooth enough (if its density belongs to the Sobolev space W_2^2), then the equation of small transverse vibrations of the string can be reduced by means of Liouville transformation to the Sturm–Liouville equation. We consider the Sturm–Liouville boundary problem on a simple graph that consists of three intervals joined at a common point. The scattering problems on graphs of different forms were considered in many publications in connection with quantum waveguides [1], [2], [4], [7], [8], [14], [16]. The following papers are devoted to inverse problems on graphs: [13], [23], [24]. By inverse problem, we mean recovering the potentials from the known spectra of corresponding boundary problems.

Consider the following boundary problem:

$$y_j'' + \lambda^2 y_j - q_j(x) y_j = 0, \tag{1.1j}$$

$$y_j(\lambda, 0) = 0 \quad (j = 1, 2, 3), \tag{1.2j}$$

$$y_1(\lambda, a) = y_2(\lambda, a) = y_3(\lambda, a), \tag{1.3}$$

$$y_1'(\lambda, a) + y_2'(\lambda, a) + y_3'(\lambda, a) = 0. \tag{1.4}$$

This problem occurs in the following situations: (1) small vibrations of a graph of three inhomogeneous smooth strings each having one end joint and the other one fixed; (2) a quantum particle moving in a quasi-one-dimensional graph domain.

We assume that real-valued functions $q_j(x) \in L_2(0, a)$ $(j = 1, 2, 3)$. For the sake of simplicity let $q_j(x) \geq 0$. Otherwise, we can shift the spectral parameter. We denote by $s_j(\lambda, x)$ $(j = 1, 2, 3)$ the solution of $(1.1j)$ that satisfies the conditions

$$s_j(\lambda, 0) = s_j'(\lambda, 0) - 1 = 0. \tag{1.5j}$$

†Department of Higher Mathematics, Odessa State Academy of Civil Engineering and Architecture, Didrihson Street 4, 65029 Odessa, Ukraine (v.pivorakchik@paco.net).

Then the solutions of equations (1.1j) that satisfy the conditions (1.2j) are

$$y_j(\lambda,x)=C_j s_j(\lambda,x), \tag{1.6j}$$

where C_j are constants. Substituting (1.6j) into (1.3) and (1.4), we obtain the following equation for the eigenvalues of problem (1.1j), (1.2j), (1.3), (1.4):

$$\varphi_1(\lambda)=:\begin{vmatrix} s_1(\lambda,a) & -s_2(\lambda,a) & 0\\ s_1(\lambda,a) & 0 & -s_3(\lambda,a)\\ s_1'(\lambda,a) & s_2'(\lambda,a) & s_3'(\lambda,a)\end{vmatrix}=0$$

or

$$\varphi_1(\lambda)=\psi_1(\lambda)s_3(\lambda,a)+\psi_2(\lambda)s_3'(\lambda,a)=0, \tag{1.7}$$

where

$$\psi_1(\lambda)=:s_1(\lambda,a)s_2'(\lambda,a)+s_2(\lambda,a)s_1'(\lambda,a), \tag{1.8}$$

$$\psi_2(\lambda)=:s_1(\lambda,a)s_2(\lambda,a). \tag{1.9}$$

Let us denote by

$$\varphi_2(\lambda)=:s_1(\lambda,a)s_2(\lambda,a)s_3(\lambda,a), \tag{1.10}$$

by $\{\zeta_k\}_{-\infty,k\ne0}^{\infty}$, the set of zeroes of $\psi_1(\lambda)$, and by $\{\xi_k\}_{-\infty,k\ne0}^{\infty}$ the set of zeroes of $\psi_2(\lambda)$.

LEMMA 1.1. *Under proper enumeration, the following inequalities are valid:*

$$0<\zeta_1<\zeta_2<\cdots<\zeta_k<\cdots,\quad \zeta_{-k}=-\zeta_k.$$

Proof. The set $\{\zeta_k\}_{-\infty,k\ne0}^{\infty}$ coincides with the spectrum of the problem

$$\begin{aligned} y_1''+\lambda^2y_1-q_1(x)y_1&=0,\\ y_2''+\lambda^2y_2-q_2(x)y_2&=0,\\ y_1(\lambda,0)&=y_2(\lambda,0)=0,\\ y_1(\lambda,a)&=y_2(\lambda,a),\\ y_1'(\lambda,a)+y_2'(\lambda,a)&=0,\end{aligned}$$

or, what is the same, with the spectrum of the problem

$$\widetilde{y}''+\lambda^2\widetilde{y}-\widetilde{q}(x)\widetilde{y}=0, \tag{1.11}$$

$$\widetilde{y}(\lambda,0)=\widetilde{y}(\lambda,2a)=0, \tag{1.12}$$

where

$$\widetilde{y}=\begin{cases} y_1(\lambda,x) & \text{if } x\in[0,a],\\ y_2(\lambda,2a-x) & \text{if } x\in(a,2a],\end{cases}$$

$$\widetilde{q}(x)=\begin{cases} q_1(x) & \text{if } x\in[0,a],\\ q_2(2a-x) & \text{if } x\in(a,2a].\end{cases}$$

Thus the set $\{\zeta_k\}_{-\infty,k\ne0}^{\infty}$ coincides with the spectrum of Dirichlet problem (1.11)–(1.12) for the Sturm–Liouville equation with nonnegative potential. The assertion of Lemma 1.1 follows. □

The set $\{\xi_k\}_{-\infty,k\neq 0}^{\infty}$ is the union of the sets of zeroes of the functions $s_1(\lambda,a)$ and $s_2(\lambda,a)$, i.e., the union of the spectra of the following two Dirichlet problems:

$$\begin{aligned} &y_1''+\lambda^2 y_1-q_1(x)y_1=0,\\ &y_1(\lambda,0)=y_1(\lambda,a)=0 \end{aligned} \tag{1.13}$$

and

$$\begin{aligned} &y_2''+\lambda^2 y_2-q_2(x)y_2=0,\\ &y_2(\lambda,0)=y_2(\lambda,a)=0. \end{aligned} \tag{1.14}$$

As usual, we enumerate the zeroes in such a way that $\zeta_{-k}=-\zeta_k$, $\zeta_{k+1}>\zeta_k$, $\xi_{-k}=-\xi_k$, $\xi_{k+1}\geq\xi_k$. Let us introduce the function

$$\Xi(\lambda)=\psi_1(\lambda)+i\alpha\lambda\psi_2(\lambda), \tag{1.15}$$

where an arbitrary constant $\alpha\in(2,\infty)$.

LEMMA 1.2. *The function $\Xi(\lambda)$ can be presented as follows:*

$$\begin{aligned} \Xi(\lambda)&=\frac{\sin 2\lambda a}{\lambda}-\int_0^a (q_1(x)+q_2(x))dx\frac{\cos 2\lambda a}{\lambda^2}+\frac{\upsilon_1(\lambda)}{\lambda^2}\\ &+i\alpha\left(\frac{\sin^2\lambda a}{\lambda}-\int_0^a (q_1(x)+q_2(x))dx\frac{\sin 2\lambda a}{2\lambda^2}+\frac{\sin\lambda a}{\lambda^2}\upsilon_2(\lambda)+\frac{\upsilon_3(\lambda)}{\lambda^3}\right), \end{aligned} \tag{1.16}$$

where $\upsilon_1(\lambda)=-\upsilon_1(-\lambda)\in L_{2a}$, $\upsilon_2(\lambda)=-\upsilon_2(-\lambda)\in L_a$, $\upsilon_3(\lambda)=-\upsilon_3(-\lambda)\in L_{2a}$, and L_a is the class (introduced in [18]) *of entire functions of exponential type $\leq a$ that belong to $L_2(-\infty,\infty)$ for $\lambda\in\mathbb{R}$.*

Proof. We make use of the formulas of [22, section 1.2]:

$$s_j(\lambda,a)=\frac{\sin\lambda a}{\lambda}-\int_0^a q_j(x)dx\frac{\cos\lambda a}{\lambda^2}+\frac{\omega_j(\lambda)}{\lambda^2}\quad(j=1,2,3), \tag{1.17}$$

$$s_j'(\lambda,a)=\cos\lambda a+\int_0^a q_j(x)dx\frac{\sin\lambda a}{\lambda}+\frac{\varrho_j(\lambda)}{\lambda}\quad(j=1,2,3), \tag{1.18}$$

where $\omega_j(\lambda)\in L_a$, $\varrho_j(\lambda)\in L_a$. Substituting (1.17) and (1.18) into (1.8) and (1.9), we obtain

$$\psi_1(\lambda)=\frac{\sin 2\lambda a}{\lambda}-\int_0^a (q_1(x)+q_2(x))dx\frac{\cos 2\lambda a}{\lambda^2}+\frac{\upsilon_1(\lambda)}{\lambda^2}, \tag{1.19}$$

$$\psi_2(\lambda)=\frac{\sin^2\lambda a}{\lambda^2}-\int_0^a (q_1(x)+q_2(x))dx\frac{\sin 2\lambda a}{2\lambda^3}+\frac{\sin\lambda a}{\lambda^3}\upsilon_2(\lambda)+\frac{\upsilon_3(\lambda)}{\lambda^4}, \tag{1.20}$$

where $\upsilon_j(\lambda)$ for $j=1,2,3$ are as described in the statement of Lemma 1.2.

Substituting (1.19) and (1.20) into (1.15), we obtain (1.16). □

Let us denote by $\{\kappa_k\}_{-\infty}^{\infty}$ the set of zeroes of $\Xi(\lambda)$. We enumerate the zeroes in the following way: (1) $\kappa_{-k}=-\overline{\kappa_k}$ for all not pure imaginary κ_k; (2) $\operatorname{Re}\kappa_{k+1}\geq\operatorname{Re}\kappa_k$; (3) the multiplicities are taken into account. We call *proper* this way of enumeration (arbitrary in other respects).

Let us set

$$\Xi_0(\lambda)=:\frac{\sin 2\lambda a}{\lambda}+i\alpha\frac{\sin^2\lambda a}{\lambda}. \tag{1.21}$$

The following enumeration of zeroes $\kappa_k^{(0)}$ of the function $\Xi_0(\lambda)$ is proper:

$$\kappa_{2k-1}^{(0)} = \frac{2\pi k}{a} \quad (k \in N), \tag{1.22}$$

$$\kappa_{2k}^{(0)} = \frac{2\pi k}{a} + \frac{i}{2a}\ln\frac{\alpha+2}{\alpha-2} \quad (k \in N \cup \{0\}), \quad \kappa_k^{(0)} = -\overline{\kappa_k^{(0)}}. \tag{1.23}$$

LEMMA 1.3. *The zeroes of* $\Xi(\lambda)$ *enumerated in the appropriate way behave asymptotically as follows:*

$$\kappa_k = \kappa_k^{(0)} + o(1). \tag{1.24}$$

Proof. Suppose there exists a subsequence $\{\kappa_{k_m}\}_{m=1}^{\infty}$ of the sequence $\{\kappa_k\}_{-\infty}^{\infty}$ such that $\operatorname{Im}\kappa_{k_m} \underset{m\to\infty}{\longrightarrow} \infty$. Then (1.16) implies that

$$\Xi(\kappa_{k_m}) - \frac{e^{-2i\kappa_{k_m}a}}{2i\kappa_{k_m}}\left(1-\frac{\alpha}{2}\right) = o\left(\frac{e^{2|\operatorname{Im}\kappa_{k_m}|a}}{|\kappa_{k_m}|}\right), \tag{1.25}$$

which contradicts the identity $\Xi(\kappa_{k_m}) = 0$. Hence there exists a number $M > 0$ such that $\operatorname{Im}\kappa_k \le M$. In the same way, it can be proved that $\operatorname{Im}\kappa_k$ is bounded below. Hence there exists a constant $M_1 > 0$ such that

$$|\operatorname{Im}\kappa_k| \le M_1.$$

Now it follows from (1.16) and (1.21) that there exists a constant $C > 0$ such that

$$|\Xi(\lambda) - \Xi_0(\lambda)| < \frac{C}{|\lambda|^2}$$

for all $\lambda \in \Pi$, where $\{\lambda : |\operatorname{Im}\lambda| < M + \epsilon\}$. Since the function $\lambda\Xi(\lambda) = \sin 2\lambda a + i\alpha\sin^2\lambda a$ is periodic, for every $r \in (0,\epsilon)$, it is possible to find $d > 0$ such that

$$|\sin 2\lambda a + i\alpha\sin^2\lambda a| > d$$

for all $\lambda \in \Pi\backslash\bigcup_k C_k$, where C_k are circles of radii r with the centers at the points $\kappa_k^{(0)}$. Consequently, for all $\lambda = \{\lambda : \lambda \in \Pi\backslash\bigcup_k C_k, |\lambda| > \frac{C}{d}\}$, the following inequalities are valid:

$$|\Xi_0(\lambda)| > \frac{d}{|\lambda|} > \frac{C}{|\lambda^2|} > |\Xi(\lambda) - \Xi_0(\lambda)|.$$

Since $r > 0$ can be chosen arbitrarily small, we apply the Rouché theorem and obtain the assertion of Lemma 1.3. □

The class of sinus-type functions was introduced in [20].

DEFINITION 1.4. *An entire function* $\omega(\lambda)$ *of exponential type* $\sigma > 0$ *is said to be a function of sinus-type if*

1. *all the zeroes of* $\omega(\lambda)$ *lie in a strip* $|\operatorname{Im}\lambda| < h < \infty$;
2. *for some* h_1 *and all* $\lambda \in \{\lambda : \operatorname{Im}\lambda = h_1\}$, *the following inequalities hold:* $0 < m \le |\omega(\lambda)| \le M < \infty$;
3. *the type of* $\omega(\lambda)$ *in the lower half-plane coincides with that in the upper half-plane.*

LEMMA 1.5.

1. *The function* $\lambda\Xi(\lambda)$ *is of sinus-type.*
2. *The following formula is valid:*

$$\Xi(\lambda) = C\prod_{-\infty}^{\infty}\left(1-\frac{\lambda}{\kappa_k}\right). \tag{1.26}$$

Proof. It follows from Lemma 1.3 that $\lambda\Xi(\lambda)$ satisfies condition (1) of Definition 1.4. This function satisfies condition (2) of Definition 1.4 due to Lemma 1.2. Using (1.16), it is easy to check up that the types of $\lambda\Xi(\lambda)$ in the lower and in the upper half-planes are both equal to $2a$. Assertion (1) of Lemma 1.5 is proved. Now assertion (2) follows [18]. □

The set $\{\kappa_k\}_{-\infty}^{\infty}$ coincides with the spectrum of the problem generated by equations $(1.1j)$ $(j=1,2)$ and boundary conditions $(1.2j)$ $(j=1,2)$ and the following conditions at $x=a$:

$$y_1(\lambda,a) = y_2(\lambda,a), \tag{1.27}$$

$$y_1'(\lambda,a) + y_2'(\lambda,a) + i\alpha\lambda y_2(\lambda,a) = 0. \tag{1.28}$$

This problem admits the following operator interpretation. Denote by A the operator acting in the Hilbert space $H = L_2(0,a)\bigoplus L_2(0,a)\bigoplus\mathbb{C}$ according to the formulas

$$A\begin{pmatrix} y_1(x)\\ y_2(x)\\ y_1(a)\end{pmatrix} = \begin{pmatrix} -y_1''(x)+q_1(x)y_1(x)\\ -y_2''(x)+q_2(x)y_2(x)\\ y_1'(a)+y_2'(a)\end{pmatrix},$$

$$D(A) = \left\{\begin{pmatrix} y_1(x)\\ y_2(x)\\ y_1(a)\end{pmatrix}:\ \begin{matrix} y_1(x)\in W_2^2(0,a), & y_2(x)\in W_2^2(0,a), & y_1(0)=y_2(0)=0,\\ & y_1(a)=y_2(a) & \end{matrix}\right\}.$$

Let us denote by K and P the following operators on the same space:

$$K = \begin{pmatrix} 0&0&0\\ 0&0&0\\ 0&0&\alpha\end{pmatrix}, \qquad P = \begin{pmatrix} I&0&0\\ 0&I&0\\ 0&0&0\end{pmatrix}.$$

We introduce a nonmonic quadratic operator pencil acting in H:

$$L(\lambda) = \lambda^2 P - i\lambda K - A$$

with the domain $D(L(\lambda)) = D(A)$ independent of λ and dense in H.

THEOREM 1.6.

1. *The spectrum* $\{\kappa_k\}_{-\infty}^{\infty}$ *of* $L(\lambda)$ *consists of normal* (*see* [9] *for the definition*) *eigenvalues.*
2. *The geometric multiplicity of each eigenvalue is equal to* 1.
3. *The spectrum is symmetric with respect to the imaginary axis and symmetric eigenvalues possess the same multiplicities.*
4. $\operatorname{Im}\kappa_k \geq 0$ *for all* k.
5. *The point* $\lambda = 0$ *belongs to the resolvent set of* $L(\lambda)$.
6. *All (if any) real eigenvalues are simple.*

Proof. To prove assertion 1, let us notice that the pencil $L(\lambda)$ is a bounded perturbation of the quasi-linear pencil $\lambda^2 I - A$, which has normal spectrum only and it is possible to apply [10, Chapter XI, Theorem 4.2] to the pencil $-A^{-\frac{1}{2}}L(\lambda)A^{-\frac{1}{2}} = I + iA^{-\frac{1}{2}}KA^{-\frac{1}{2}} - \lambda^2 A^{-\frac{1}{2}}PA^{-\frac{1}{2}}$, which has the same spectrum as $L(\lambda)$. Assertion 2 follows from the fact that the problem (1.1j), (1.2j) (j=1,2), (1.27) possesses only one linearly independent solution. Assertion 3 is a consequence of the symmetry of the problem, i.e., of the identity $\Xi(-\bar{\lambda}) = \overline{\Xi(\lambda)}$. We obtain assertion 4 by applying the results of [17] to the pencil $L(-i\lambda)$. Assertion 5 follows from the identity $L(0) = -A$ and from the inequality $A \gg 0$.

Now let us prove assertion 6. Let $\kappa_k \neq 0$ be a real multiple eigenvalue of $L(\lambda)$ and let Y_k and $\dot{Y}_k$ be the corresponding eigen- and associated vectors. Then

$$\kappa_k^2 PY_k - i\kappa_k KY_k - AY_k = 0, \tag{1.29}$$

$$\kappa_k^2 P\dot{Y}_k - i\kappa_k K\dot{Y}_k - A\dot{Y}_k + 2\kappa_k PY_k - iKY_k = 0, \tag{1.30}$$

and consequently (1.29) implies that

$$\kappa_k^2 (PY_k, Y_k) - (AY_k, Y_k) = 0$$

and

$$(KY_k, Y_k) = 0. \tag{1.31}$$

The operator K is nonnegative, and hence

$$KY_k = 0. \tag{1.32}$$

Substituting (1.32) into (1.29), we obtain

$$(\kappa_k^2 P - A)Y_k = 0. \tag{1.33}$$

Equation (1.32) implies that

$$\big(K\dot{Y}_k, Y_k\big) = \big(\dot{Y}_k, KY_k\big) = 0. \tag{1.34}$$

Multiplying (1.30) by Y_k and using (1.31), (1.33), and (1.34), we obtain

$$\begin{aligned} &\kappa_k^2\big(P\dot{Y}_k, Y_k\big) - \big(A\dot{Y}_k, Y_k\big) + 2\kappa_k(PY_k, Y_k) \\ &\quad = \big(\dot{Y}_k, \kappa_k^2 PY_k - AY_k\big) + 2\kappa_k(PY_k, Y_k) = 2\kappa_k(PY_k, Y_k) = 0. \end{aligned} \tag{1.35}$$

The operator P is nonnegative, and therefore (1.35) yields

$$PY_k = 0. \tag{1.36}$$

Equations (1.29), (1.32), and (1.36) imply that

$$AY_k = 0,$$

a contradiction. □

LEMMA 1.7. *A real number κ_k is a zero of $\Xi(\lambda)$ if and only if it is a simple zero of $\psi_1(\lambda)$ and a double zero of $\psi_2(\lambda)$.*

Proof. If κ_k is a real zero of $\Xi(\lambda)$, then definitions (1.8) and (1.9) imply that $\operatorname{Im}\psi_1(\kappa_k) = \operatorname{Im}(\kappa_k\psi_2(\kappa_k)) = 0$. Thus from (1.15), we obtain $\psi_1(\kappa_k) = \kappa_k\psi_2(\kappa_k) = 0$.

Assertion 5 of Theorem 1.6 implies that $\kappa_k \neq 0$. This means that either $s_1(\kappa_k, a) = 0$, or $s_2(\kappa_k, a) = 0$. Let $s_1(\kappa_k, a) = 0$. Then from (1.8), we obtain $s_2(\kappa_k, a)s_1'(\kappa_k, a) = 0$. Since $s_1(\kappa_k, a)$ and $s_1'(\kappa_k, a)$ cannot be equal to zero simultaneous we conclude that $s_2(\kappa_k, a) = 0$. In the same way, $s_2(\kappa_k, a) = 0$ implies that $s_1(\kappa_k, a) = 0$. Also, it is clear from (1.15) that if $\psi_1(\kappa_k) = \psi_2(\kappa_k) = 0$, then $\Xi(\kappa_k) = 0$. □

Remark 1.1. The direct and inverse problems for the operator pencil $L(\lambda)$ are considered in details in [26].

DEFINITION 1.8. *An entire function $\omega(\lambda)$ is said to be of Hermite–Biehler (HB) class if it has no zeroes in the closed lower half-plane* $\operatorname{Im}\lambda \leq 0$ *and*

$$\left|\frac{\omega(\lambda)}{\bar{\omega}(\lambda)}\right| < 1 \quad \textit{for } \operatorname{Im}\lambda > 0.$$

Here by $\bar{\omega}(\lambda)$, we mean the entire function obtained from $\omega(\lambda)$ by replacing the coefficients in its Taylor series by their complex-conjugates.

DEFINITION 1.9 (see [18, p. 313]). *An entire function $\omega(\lambda)$ that has no zeroes in the open lower half-plane and satisfies the condition*

$$\left|\frac{\omega(\lambda)}{\bar{\omega}(\lambda)}\right| \leq 1 \quad \textit{for } \operatorname{Im}\lambda > 0 \tag{1.37}$$

is said to be a function of generalized Hermite–Biehler ($\overline{HB}$) class.

Let us arrange the sequence $\{\kappa_k\}_{-\infty}^{\infty}$ into two subsequences $\{\kappa_{k_p}\}_{p=-\infty}^{\infty}$ and $\{\kappa_{k_j}\}_{j=-n,j\neq 0}^{n}$ ($k_{-j} = -k_j$ and $k_{-p} = -k_p$ and, consequently, $\kappa_{k_{-j}} = -\bar{\kappa}_{k_j}$ and $\kappa_{k_{-p}} = -\bar{\kappa}_{k_p}$) such that $\{\kappa_{k_p}\}_{p=-\infty}^{\infty} \bigcup \{\kappa_{k_j}\}_{j=-n,j\neq 0}^{n} = \{\kappa_k\}_{-\infty}^{\infty}$, $n \leq \infty$, $\operatorname{Im}\kappa_{k_j} = 0$ for all j and $\operatorname{Im}\kappa_{k_p} > 0$ for all p. Now we can rewrite (1.26) as follows:

$$\Xi(\lambda) = C \prod_{j=-n,j\neq 0}^{n} \left(1 - \frac{\lambda}{\kappa_{k_j}}\right) \tilde{\Xi}(\lambda), \tag{1.38}$$

where

$$\tilde{\Xi}(\lambda) =: \prod_{p=-\infty}^{\infty} \left(1 - \frac{\lambda}{\kappa_{k_p}}\right). \tag{1.39}$$

LEMMA 1.10.

$$\tilde{\Xi}(\lambda) \in HB. \tag{1.40}$$

Proof. The following inequality is a consequence of (1.22)–(1.24):

$$\sum_{p=-\infty}^{\infty} \left|\operatorname{Im}\frac{1}{\kappa_{k_p}}\right| < \infty.$$

Now the assertion of the lemma follows from M.G. Krein's theorem [18, section VII.3, Theorem 6]. □

COROLLARY 1.11.

$$\Xi(\lambda) \in \overline{HB}. \tag{1.41}$$

Proof. Evidently,

$$\left|1-\frac{\lambda}{\kappa_{k_p}}\right| \le \left|1-\frac{\lambda}{\bar\kappa_{k_p}}\right|$$

for all $p=0,\pm1,\pm2,\dots$ and all λ from the open upper half-plane. This implies that

$$\left|\frac{\Xi(\lambda)}{\bar\Xi(\lambda)}\right| = \prod_{-\infty}^{\infty}\left|1-\frac{\lambda}{\kappa_{k_p}}\right|\left|1-\frac{\lambda}{\bar\kappa_{k_p}}\right|^{-1} \le 1,$$

and (1.41) follows. □

COROLLARY 1.12. *The sequences* $\{\zeta_k\}_{-\infty,k\ne0}^{\infty}$ *and* $\{\xi_k\}_{-\infty,k\ne0}^{\infty}\cup\{0\}$ *interlace in the usual sense:*

$$0\le\zeta_1\le\xi_1\le\cdots\le\zeta_k\le\xi_k\le\cdots\quad(\zeta_{-k}=-\zeta_k)\quad(\xi_{-k}=-\xi_k).$$

Proof. This corollary follows from [18, Chapter 7.2, Theorem 3′]. □

THEOREM 1.13. *The sequences* $\{\zeta_k\}_{-\infty,k\ne0}^{\infty}$ *and* $\{\xi_k\}_{-\infty,k\ne0}^{\infty}\cup\{0\}$ *interlace in the following sense:*

1. $0<\zeta_1<\xi_1$;
2. *for every* $n>1$ *the following alternative is valid: either the interval* (ζ_1,ζ_n) *contains exactly* $n-1$ *(counting multiplicities) elements of the set* $\{\xi_k\}_1^{\infty}$*, and then* $\zeta_n\notin\{\xi_k\}_1^{\infty}$*, or the interval* (ζ_1,ζ_n) *contains exactly* $n-2$ *(counting multiplicities) elements of the set* $\{\xi_k\}_1^{\infty}$*, and then* $\zeta_n\in\{\xi_k\}_1^{\infty}$*. Here* $\zeta_{-k}=-\zeta_k$ *and* $\xi_{-k}=-\xi_k$.

Proof. Since the function $\tilde\Xi(\lambda)\in HB$, the zeroes $\{\zeta_{k_p}\}_{-\infty,p\ne0}^{\infty}$ of the function $\frac{\tilde\Xi(\lambda)+\tilde\Xi(-\lambda)}{2}$ and the zeroes $\{\xi_{k_p}\}_{-\infty,p\ne0}^{\infty}$ of the function $\frac{\tilde\Xi(\lambda)-\tilde\Xi(-\lambda)}{2i\lambda}$ interlace in the strict sense due to N. Meiman's theorem (see [18, Chapter 7.2, Theorem 3]):

$$0<\zeta_{k_1}<\xi_{k_1}<\cdots<\zeta_{k_j}<\xi_{k_j}<\cdots\quad(\zeta_{k_{-1}}=-\zeta_{k_1})\quad(\xi_{k_{-1}}=-\xi_{k_1}).\tag{1.42}$$

Combining (1.42) with Lemma 1.7 and taking into account Corollary 1.12, we finish the proof. □

Let us denote by $\{\tau_k\}$ the set of zeroes of the function $\varphi_1(\lambda)$ (see (1.7) for the definition) and by $\{\theta_k\}$ the set of zeroes of the function $\varphi_2(\lambda)$ (see (1.10) for the definition).

LEMMA 1.14. *All* τ_k *and* θ_k *are real and nonzero.*

Proof. Consider the operator $\tilde A$ acting in $L_2(0,a)\bigoplus L_2(0,a)\bigoplus L_2(0,a)\bigoplus\mathbb{C}$:

$$\tilde A\begin{pmatrix}y_1(x)\\y_2(x)\\y_3(x)\\y_1(a)\end{pmatrix}=\begin{pmatrix}-y_1''(x)+q_1(x)y_1(x)\\-y_2''(x)+q_2(x)y_2(x)\\-y_3''(x)+q_3(x)y_3(x)\\y_1'(a)+y_2'(a)+y_3'(a)\end{pmatrix},$$

$$D(\tilde A)=\left\{\begin{pmatrix}y_1(x)\\y_2(x)\\y_3(x)\\y_1(a)\end{pmatrix}:\ \begin{array}{c}y_j(x)\in W_2^2(0,a),\quad y_j(0)=0\quad\text{for }(j=1,2,3),\\ y_1(a)=y_2(a)=y_3(a)\end{array}\right\}.$$

It is easy to check up that this operator is self-adjoint, and due to $q_j(x)\ge0$ for $j=1,2,3$, we obtain $\tilde A\gg0$, i.e., $\tilde A\ge\epsilon I$, where $\epsilon>0$. The set $\{\tau_k^2\}_1^{\infty}$ coincides with

the spectrum of $\tilde{A}$, and consequently $\tau_k^2 > 0$ for all k. Here we enumerate τ_k and θ_k in such a way that $\tau_{-k} = -\tau_k$ and $\theta_{-k} = -\theta_k$. The set $\{\theta_k\}_{-\infty,k\neq 0}^{\infty}$ coincides with the union of the spectra of the following three Dirichlet problems:

$$y_j'' + \lambda^2 y_j - q_j(x) y_j = 0, \tag{1.1j}$$

$$y_j(\lambda, 0) = y_j(\lambda, a) = 0 \quad (j = 1, 2, 3). \tag{1.43j}$$

The assertions of the lemma follow. □

Now it is possible to enumerate the sets $\{\tau_k\}_{-\infty,k\neq 0}^{\infty}$ and $\{\theta_k\}_{-\infty,k\neq 0}^{\infty}$ in the usual way: $\tau_{-k} = -\tau_k$, $\tau_k \le \tau_{k+1}$, and $\theta_{-k} = -\theta_k$, $\theta_k \le \theta_{k+1}$.

LEMMA 1.15.

1. *If $\tau_k = \theta_n$ for some k and n, then $\frac{d\varphi_2(\lambda)}{d\lambda}|_{\lambda=\theta_n} = 0$, i.e., at least two of the three functions $s_1(\lambda, a)$, $s_2(\lambda, a)$, $s_3(\lambda, a)$ have (simple) zeroes at $\lambda = \theta_n = \tau_k$.*
2. *If $\tau_k = \theta_n$ and $\frac{d\varphi_1(\lambda)}{d\lambda}|_{\lambda=\theta_n} = 0$, then $s_1(\theta_n, a) = s_2(\theta_n, a) = s_3(\theta_n, a) = 0$ and $\frac{d^2\varphi_1(\lambda)}{d\lambda^2}|_{\lambda=\theta_n} \neq 0$.*

Proof. By definition of θ_n we have $\varphi_2(\theta_n) = 0$ and hence definition (1.10) implies that $s_j(\theta_n, a) = 0$ for at least one j $(j = 1, 2, 3)$, say, $s_3(\theta_n, a) = 0$. Then equations $\varphi_1(\theta_n) = \varphi_1(\tau_k) = 0$ and (1.7) imply that $\psi_2(\theta_n) = 0$ and assertion 1 of Lemma 1.15 follows. If we assume not $s_3(\theta_n, a) = 0$ but $s_2(\theta_n, a) = 0$ or $s_1(\theta_n, a) = 0$, then the proof is analogous.

Now let $\frac{d\varphi_1(\lambda)}{d\lambda}|_{\lambda=\theta_n} = 0$; then

$$\begin{aligned} \left.\frac{d\varphi_1(\lambda)}{d\lambda}\right|_{\lambda=\theta_n} &= \left.\frac{d\psi_1(\lambda)}{d\lambda}\right|_{\lambda=\theta_n} s_3(\theta_n, a) + \psi_1(\theta_n) \left.\frac{\partial s_3(\lambda, a)}{\partial\lambda}\right|_{\lambda=\theta_n} \\ &\quad + \left.\frac{d\psi_2(\lambda)}{d\lambda}\right|_{\lambda=\theta_n} s_3'(\theta_n, a) + \psi_2(\theta_n) \left.\frac{\partial s_3'(\lambda, a)}{\partial\lambda}\right|_{\lambda=\theta_n} = 0. \end{aligned} \tag{1.44}$$

According to assertion 1, at least two of the functions $s_j(\lambda, a)$ have simple zeros at $\lambda = \theta_n$. Let $s_1(\theta_n, a) = s_2(\theta_n, a) = 0$ and, consequently, $\frac{\partial s_1(\lambda,a)}{\partial\lambda}|_{\lambda=\theta_n} \neq 0$ and $\frac{\partial s_2(\lambda,a)}{\partial\lambda}|_{\lambda=\theta_n} \neq 0$. Then from (1.44), we obtain

$$\begin{aligned} &s_3(\theta_n, a) \left(s_2'(\theta_n, a) \left.\frac{ds_1(\lambda, a)}{d\lambda}\right|_{\lambda=\theta_n} + s_1'(\theta_n, a) \left.\frac{ds_2(\lambda, a)}{d\lambda}\right|_{\lambda=\theta_n} \right) \\ &\quad = s_3(\theta_n, a) \left.\frac{d}{d\lambda}(s_2(\lambda, a) s_1'(\lambda, a) + s_1(\lambda, a) s_2'(\lambda, a))\right|_{\lambda=\theta_n} \\ &\quad = s_3(\theta, a) \left.\frac{d\psi_1(\lambda)}{d\lambda}\right|_{\lambda=\theta_n} = 0. \end{aligned} \tag{1.45}$$

Since all zeroes of the function $\psi_1(\lambda)$ are simple (see Lemma 1.1), (1.45) implies that $s_3(\theta_n) = 0$. It is clear that the geometric multiplicity of each eigenvalue of problem (1.1j), (1.2j), (1.3), (1.4) is not more then 2, which means that $\frac{d^2\varphi_1(\lambda)}{d\lambda^2}|_{\lambda=\theta_n} \neq 0$. If we assume that $s_1(\theta_n, a) = s_2(\theta_n, a) = 0$, then the proof is analogous. □

LEMMA 1.16. *The function $\varphi_1(\lambda)$ can be presented as follows:*

$$\begin{aligned} \varphi_1(\lambda) &= 3\frac{\sin^2\lambda a}{\lambda^2}\cos\lambda a - 2\frac{\sin\lambda a\cos^2\lambda a}{\lambda^3}(B_1 + B_2 + B_3) \\ &\quad + \frac{\sin^3\lambda a}{\lambda^3}(B_1 + B_2 + B_3) + (B_1B_2 + B_2B_3 + B_1B_3)\frac{\cos^3\lambda a}{\lambda^4} \\ &\quad + \omega_1(\lambda)\frac{\sin\lambda a}{\lambda^3} + \frac{\omega_2(\lambda)}{\lambda^4}, \end{aligned} \tag{1.46}$$

where $\omega_1(\lambda) \in L_{2a}$, $\omega_2(\lambda) \in L_{3a}$ *and* $B_j = \int_0^a q_j(x)dx$.

Proof. To prove this lemma it is sufficient to substitute (1.17) and (1.18) into (1.7) and to make use of (1.8) and (1.9). □

LEMMA 1.17. *The set* $\{\tau_k\}_{-\infty,k\neq0}^{\infty}$ *of zeroes of* $\varphi_1(\lambda)$ *can be presented as the union of three subsequences* $\{\rho_k^{(1)}\}_{-\infty,k\neq0}^{\infty} \cup \{\rho_k^{(2)}\}_{-\infty,k\neq0}^{\infty} \cup \{\rho_k^{(3)}\}_{-\infty,k\neq0}^{\infty}$, *which, being enumerated in the usual way* ($\rho_k^{(j)} = -\rho_{-k}^{(j)}$, $\rho_k \le \rho_{k+1}$), *behave asymptotically as follows:*

$$\rho_k^{(1)} \underset{k\to\infty}{=} \frac{\pi k}{a} + \frac{M_1}{k} + \frac{\beta_k^{(1)}}{k}, \tag{1.47}$$

$$\rho_k^{(2)} \underset{k\to\infty}{=} \frac{\pi k}{a} + \frac{M_2}{k} + \frac{\beta_k^{(2)}}{k}, \tag{1.48}$$

$$\rho_k^{(3)} \underset{k\to\infty}{=} \frac{\pi(k-\frac{1}{2})}{a} + \frac{1}{3k}(B_1+B_2+B_3) + \frac{\beta_k^{(3)}}{k}, \tag{1.49}$$

where $\{\beta_k^{(j)}\}_{-\infty,k\neq0}^{\infty} \in l_2$ *for* $j = 1,2,3$ *and* M_1 *and* M_2 *are the solutions (both real and may be equal) of the equation*

$$3M^2 - 2\pi^{-1}(B_1+B_2+B_3)M + \pi^{-2}(B_1B_2+B_1B_3+B_2B_3) = 0. \tag{1.50}$$

Proof. It can be proved in the same way as Lemma 1.3 that the set of zeroes $\{\tau_k\}_{-\infty,k\neq0}^{\infty}$ can be arranged in the following way: $\{\tau_k\}_{-\infty,k\neq0}^{\infty} = \{\rho_k^{(1)}\}_{-\infty,k\neq0}^{\infty} \cup \{\rho_k^{(2)}\}_{-\infty,k\neq0}^{\infty} \cup \{\rho_k^{(3)}\}_{-\infty,k\neq0}^{\infty}$, where

$$\rho_k^{(1)} \underset{k\to\infty}{=} \frac{\pi k}{a} + o(1), \tag{1.51}$$

$$\rho_k^{(2)} \underset{k\to\infty}{=} \frac{\pi k}{a} + o(1), \tag{1.52}$$

$$\rho_k^{(3)} \underset{k\to\infty}{=} \frac{\pi(k-\frac{1}{2})}{a} + o(1). \tag{1.53}$$

Substituting (1.51)–(1.53) into the equation

$$\varphi_1(\rho_k^{(j)}) = 0,$$

where $\varphi_1(\lambda)$ is given by (1.46) we expand the right-hand side of the resulting equation in power series. Then using the formulas $\{\omega_j(\rho_k^{(i)})\}_{-\infty,k\neq0}^{\infty} \in l_2$ for $j = 1,2; i = 1,2,3$ (see [22, Lemma 1.4.3]), we obtain (1.47)–(1.49). □

Let us introduce the function

$$\Upsilon(\lambda) = \varphi_1(\lambda) + i\beta\lambda\varphi_2(\lambda), \tag{1.54}$$

where $\beta \in (3,\infty)$ is an arbitrary constant.

LEMMA 1.18. *The function* $\Upsilon(\lambda)$ *can be presented as follows:*

$$\Upsilon(\lambda) = 3\frac{\sin^2\lambda a}{\lambda^2}\cos\lambda a + i\beta\frac{\sin^3\lambda a}{\lambda^2} - \frac{\sin\lambda a\cos 2\lambda a}{\lambda^3}\int_0^a (q_1(x)+q_2(x)+q_3(x))\,dx$$
$$+ -i\beta\frac{\sin^2\lambda a\cos\lambda a}{\lambda^3}\int_0^a (q_1(x)+q_2(x)+q_3(x))dx + \frac{\upsilon_3(\lambda)}{\lambda^3}, \tag{1.55}$$

where $v_3(\lambda) \in L_{3a}$.

Proof. To prove this statement it is enough to substitute (1.7)–(1.10) into (1.54) and to make use of (1.17)–(1.20). □

Let us introduce the following function:

$$\Upsilon^{(0)}(\lambda) = 3\frac{\sin^2 \lambda a}{\lambda^2}\cos \lambda a + i\beta\frac{\sin^3 \lambda a}{\lambda^2}. \tag{1.56}$$

Let us denote by $\{\lambda_k\}_{-\infty}^{\infty}$ the set of zeroes of $\Upsilon(\lambda)$ and by $\{\lambda_k^{(0)}\}_{-\infty}^{\infty}$ that of $\Upsilon_0(\lambda)$. Under proper enumeration the zeroes $\{\lambda_k^{(0)}\}_{-\infty}^{\infty}$ can be arranged into three subsequences:

$$\lambda_{3k}^{(0)} = \frac{\pi k}{a} + \frac{i}{a}\log\left(\frac{\beta+3}{\beta-3}\right), \quad k \in \mathbb{N} \cup \{0\}, \tag{1.57}$$

$$\lambda_{3k-1}^{(0)} = \lambda_{3k-2}^{(0)} = \frac{\pi k}{a}, \quad k \in \mathbb{N}. \tag{1.58}$$

Here $\lambda_{-k}^{(0)} = -\overline{\lambda_k^{(0)}}$ for all $k \neq 0$.

LEMMA 1.19. *The zeroes* $\{\lambda_k\}_{-\infty}^{\infty}$ *behave asymptotically as follows:*

$$\lambda_k \underset{k\to\infty}{=} \lambda_k^{(0)} + o(1). \tag{1.59}$$

Proof. The proof of this lemma is analogous to that of Lemma 1.3. □

LEMMA 1.20.

1. *The function* $\lambda^2\Upsilon(\lambda)$ *is of sinus-type.*
2. *The following formula is valid:*

$$\Upsilon(\lambda) = C\prod_{-\infty}^{\infty}\left(1 - \frac{\lambda}{\lambda_k}\right), \tag{1.60}$$

where C *is a constant.*

Proof. It follows from Lemma 1.19 and from formulas (1.57), (1.58) that $\lambda^2\Upsilon(\lambda)$ satisfies condition (1) of Definition 1.4. This function satisfies also condition (2) of Definition 1.4 due to Lemma 1.18. Using (1.55) it is easy to check up that the types of $\lambda^2\Upsilon(\lambda)$ in the lower and in the upper half-planes are equal to $3a$ both. Assertion (1) of Lemma 1.20 is proved. Now the assertion (2) follows [20]. □

Let us introduce the operators acting in $L_2(0,a) \bigoplus L_2(0,a) \bigoplus L_2(0,a) \bigoplus \mathbb{C}$:

$$\tilde{K} = \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & \beta \end{pmatrix}, \qquad \tilde{P} = \begin{pmatrix} I & 0 & 0 & 0 \\ 0 & I & 0 & 0 \\ 0 & 0 & I & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}.$$

It is clear that $\tilde{A} = \tilde{A}^* \gg 0$, $\tilde{P} \geq 0$, $\tilde{K} \geq 0$. We consider a nonmonic quadratic operator pencil of the form

$$\tilde{L}(\lambda) = \lambda^2\tilde{P} - i\lambda\tilde{K} - \tilde{A}$$

with the domain $D(\tilde{L}(\lambda)) = D(\tilde{A})$. We identify the spectrum $\{\lambda_k\}_{-\infty}^{\infty}$ of $\tilde{L}(\lambda)$ with the spectrum of the problem generated by (1.1j), (1.2j) (j=1,2,3), (1.3) and by the following boundary condition:

$$y_1'(\lambda,a) + y_2'(\lambda,a) + y_3'(\lambda,a) + i\beta\lambda y_1(\lambda,a) = 0. \tag{1.61}$$

This problem has the following physical sense. It describes small vibration of the mentioned graph of three strings damped at the point of connection.

THEOREM 1.21.

1. *The spectrum* $\{\lambda_k\}_{-\infty}^{\infty}$ *consists of normal eigenvalues.*
2. *The geometric multiplicity of each eigenvalue is* ≤ 2.
3. *The spectrum is symmetric with respect to the imaginary axis and symmetric points have the same multiplicities.*
4. $\operatorname{Im}\lambda_k \ge 0$.
5. *The point* $\lambda = 0$ *belongs to the resolvent set of* $\tilde{L}(\lambda)$.
6. *All (if any) real eigenvalues do not possess associated eigenvectors.*

Proof. Assertion 1 is true because the spectrum of $\tilde{L}(\lambda)$ coincides with the set of zeroes of $\Upsilon(\lambda)$, which is an entire function. Assertion 2 follows from the fact that problem (1.1j), (1.2j), ($j = 1, 2, 3$), (1.3) possesses exactly two linearly independent solutions. Assertion 3 is a consequence of the symmetry of the problem. We obtain assertion 4 if we apply the results of [17] to the pencil $\tilde{A}^{-\frac{1}{2}}\tilde{L}(-i\lambda)\tilde{A}^{-\frac{1}{2}}$. Assertion 5 follows from the inequality $\tilde{A} \gg 0$. The proof of assertion 6 is quite the same as that of assertion 6 of Theorem 1.6. □

Let us rearrange the sequence $\{\lambda_k\}_{-\infty}^{\infty}$ into two subsequences $\{\lambda_{k_p}\}_{p=-\infty}^{\infty}$ and $\{\lambda_{k_j}\}_{j=-n,j\ne 0}^{n}$, ($k_{-j} = -k_j$ and $k_{-p} = -k_p$ and, consequently, $\lambda_{k_{-j}} = -\bar{\lambda}_{k_j}$ and $\lambda_{k_{-p}} = -\bar{\lambda}_{k_p}$) such that $\{\lambda_{k_p}\}_{p=-\infty}^{\infty} \bigcup \{\lambda_{k_j}\}_{j=-n,j\ne 0}^{n} = \{\lambda_k\}_{-\infty}^{\infty}$, $n \le \infty$, $\operatorname{Im}\lambda_{k_j} = 0$ for all j and $\operatorname{Im}\lambda_{k_p} > 0$ for all p. Now we can rewrite (1.60) as follows:

$$\Upsilon(\lambda) = C\prod_{j=-n,j\ne 0}^{n}\left(1-\frac{\lambda}{\lambda_{k_j}}\right)\tilde{\Upsilon}(\lambda), \tag{1.62}$$

where

$$\tilde{\Upsilon}(\lambda) =: \prod_{p=-\infty}^{\infty}\left(1-\frac{\lambda}{\lambda_{k_p}}\right). \tag{1.63}$$

LEMMA 1.22.

$$\tilde{\Upsilon}(\lambda) \in HB. \tag{1.64}$$

The proof of this lemma is quite the same as that of Lemma 1.10.

COROLLARY 1.23.

$$\Upsilon(\lambda) \in \overline{HB}. \tag{1.65}$$

The proof of this corollary is quite the same as that of Corollary 1.11.

COROLLARY 1.24. *The sequences* $\{\tau_k\}_{-\infty,k\ne 0}^{\infty}$ *and* $\{\theta_k\}_{-\infty,k\ne 0}^{\infty} \cup \{0\}$ *interlace in the usual sense:*

$$0 \le \tau_1 \le \theta_1 \le \cdots \le \tau_k \le \theta_k \le \cdots \quad (\tau_{-k} = -\tau_k) \quad (\theta_{-k} = -\theta_k).$$

Proof. This corollary follows from [18, Chapter 7.2, Theorem 3′]. □

THEOREM 1.25. *The sets* $\{\tau_k\}_{-\infty,k\ne 0}^{\infty}$ *and* $\{\theta_k\}_{-\infty}^{\infty}$ *(we set* $\theta_0 = 0$*) interlace in the following sense:*

1. $\theta_0 < \tau_1 < \theta_1$.

2. *For each simple* τ_n $(n > 1)$, *either*

$$\theta_{n-1} < \tau_n < \theta_n$$

or

$$\tau_{n-1} < \theta_{n-1} = \tau_n = \theta_n < \tau_{n+1}.$$

3. *For each double* $\tau_n = \tau_{n+1}$ $(n > 1)$,

$$\tau_{n-1} < \theta_{n-1} = \tau_n = \theta_n = \tau_{n+1} = \theta_{n+1} < \tau_{n+2}.$$

4. *The multiplicity of each* τ_n *is* ≤ 2.

Proof. The function $\tilde{\Upsilon}(\lambda) \in HB$, and consequently the zeroes $\{\tau_{k_p}\}_{-\infty, p\neq 0}^{\infty}$ of the function $\frac{\tilde{\Upsilon}(\lambda)+\tilde{\Upsilon}(-\lambda)}{2}$ and the zeroes $\{\theta_{k_p}\}_{-\infty, p\neq 0}^{\infty}$ of the function $\frac{\tilde{\Xi}(\lambda)-\tilde{\Xi}(-\lambda)}{2i\lambda}$ interlace in the usual sense due to N. Meiman's theorem (see [18, Chapter 7.2, Theorem 3]:

$$0 < \tau_{k_1} < \theta_{k_1} < \cdots < \tau_{k_j} < \theta_{k_j} < \cdots \quad (\tau_{k_{-1}} = -\tau_{k_1}) \quad (\theta_{k_{-1}} = -\theta_{k_1}). \tag{1.66}$$

Combining (1.66) with Lemma 1.15 and taking into account Corollary 1.24, we finish the proof. □

2. Inverse problem. Here we deal with the problem of recovering of the potentials $\{q_1(x), q_2(x), q_3(x)\}$ from the spectral data. Denote by Q the set of triplets $\{q_1(x), q_2(x), q_3(x)\}$, which satisfy the following conditions: the real-valued functions $q_j(x) \in L_2(0, a)$ $(j = 1, 2, 3)$.

THEOREM 2.1. *Let the following conditions be valid:*

1. *Three sequences* $\{\nu_k^{(j)}\}_{-\infty, k\neq 0}^{\infty}$ $(j = 1, 2, 3)$ *of real numbers are such that*
   (i) $\nu_{-k}^{(j)} = -\nu_k^{(j)}$, $\nu_k^{(j)} \neq 0$ *for all* k *and* j;
   (ii) $\{\nu_k^{(1)}\}_{-\infty, k\neq 0}^{\infty} \bigcap \{\nu_k^{(2)}\}_{-\infty, k\neq 0}^{\infty} = \emptyset$; $\{\nu_k^{(2)}\}_{-\infty, k\neq 0}^{\infty} \bigcap \{\nu_k^{(3)}\}_{-\infty, k\neq 0}^{\infty} = \emptyset$; $\{\nu_k^{(1)}\}_{-\infty, k\neq 0}^{\infty} \bigcap \{\nu_k^{(3)}\}_{-\infty, k\neq 0}^{\infty} = \emptyset$;
   (iii)

$$\nu_k^{(j)} \underset{k\to\infty}{=} \frac{\pi k}{a} + \frac{B_j}{k} + \frac{\delta_k^{(j)}}{k^2}, \tag{2.1}$$

   where B_j *are real constants,* $B_1 \neq B_2$, $B_2 \neq B_3$, $B_1 \neq B_3$, $\{\delta_k^{(j)}\}_{-\infty, k\neq 0} \in l_2$ *for* $(j = 1, 2, 3)$.
2. *A sequence* $\{\tau_k\}_{-\infty, k\neq 0}^{\infty}$ *of real numbers* $(\tau_{-k} = -\tau_k,\ \tau_k \le \tau_{k+1})$ *can be presented as a union of three subsequences* $\{\tau_k\}_{-\infty, k\neq 0}^{\infty} = \{\rho_k^{(1)}\}_{-\infty, k\neq 0}^{\infty} \cup \{\rho_k^{(2)}\}_{-\infty, k\neq 0}^{\infty} \cup \{\rho_k^{(3)}\}_{-\infty, k\neq 0}^{\infty}$ $(\rho_{-k}^{(j)} = -\rho_k^{(j)}$ *and* $\rho_k^{(j)} < \rho_{k+1}^{(j)})$ *that behave asymptotically as follows:*

$$\rho_k^{(j)} \underset{k\to\infty}{=} \frac{\pi k}{a} - \frac{M_j}{k} + \frac{\beta_k^{(j)}}{k^2}, \quad k \in \mathbb{N}, \quad j = 1, 2; \tag{2.2}$$

$$\rho_k^{(3)} \underset{k\to\infty}{=} \frac{\pi(k - \frac{1}{2})}{a} + \frac{B_0}{3k} + \frac{\beta_k^{(3)}}{k^2}, \quad k \in \mathbb{N}, \tag{2.3}$$

   where $\{\beta_k^{(j)}\}_{-\infty, k\neq 0}^{\infty} \in l_2$ *for* $j = 1, 2, 3$, $B_0 = B_1 + B_2 + B_3$, *and* M_1 *and* M_2 *are the solutions (both real and not equal due to the inequalities* $B_j \neq B_p$ *for* $j \neq p$*) of equation* (1.50).

3. *The sequences* $\{\tau_k\}_{-\infty,k\ne0}^{\infty}$ *and* $\{\theta_k\}_{-\infty}^{\infty}\stackrel{\rm def}{=}\{0\}\bigcup\{\nu_k^{(1)}\}_{-\infty,k\ne0}^{\infty}\bigcup\{\nu_k^{(2)}\}_{-\infty,k\ne0}^{\infty}\bigcup\{\nu_k^{(3)}\}_{-\infty,k\ne0}^{\infty}$ *($\theta_{-k}=-\theta_k$, $\theta_k<\theta_{k+1}$) interlace in the following strict sense:*

$$\cdots<\theta_{-1}<\tau_{-1}<\theta_0=0<\tau_1<\theta_1<\tau_2<\cdots. \tag{2.4}$$

Then there exists a unique triplet $\{q_1(x),q_2(x),q_3(x)\}\in Q$ *such that the sequence* $\{\tau_k\}_{-\infty,k\ne0}^{\infty}$ *coincides with the spectrum of problem* (1.1j), (1.2j), (1.3), (1.4) *and the sequences* $\{\nu_k^{(j)}\}_{-\infty,k\ne0}^{\infty}$ ($j=1,2,3$) *coincide with the spectra of problems* (1.1j), (1.43j) *for* $j=1,2,3$, *respectively.*

Proof. Let us construct the following entire functions:

$$\tilde s_j(\lambda)=:\prod_1^{\infty}\left(1-\frac{\lambda^2}{\nu_k^{(j)2}}\right), \tag{2.5}$$

$$\phi_j(\lambda)=:\prod_1^{\infty}\left(1-\frac{\lambda^2}{\rho_k^{(j)2}}\right). \tag{2.6}$$

Due to [25, Lemma 2.1],

$$\tilde s_j(\lambda)=\frac{\sin\lambda a}{\lambda}-\frac{\pi B_j\cos\lambda a}{\lambda^2}+C^{(j)}\frac{\sin\lambda a}{\lambda^3}+\frac{f_j(\lambda)}{\lambda^3}, \tag{2.7}$$

$$\phi_1(\lambda)=\frac{\sin\lambda a}{\lambda}-\frac{\pi M_1\cos\lambda a}{\lambda^2}+E^{(1)}\frac{\sin\lambda a}{\lambda^3}+\frac{g_1(\lambda)}{\lambda^3}, \tag{2.8}$$

$$\phi_2(\lambda)=\frac{\sin\lambda a}{\lambda}-\frac{\pi M_2\cos\lambda a}{\lambda^2}+E^{(2)}\frac{\sin\lambda a}{\lambda^3}+\frac{g_2(\lambda)}{\lambda^3}, \tag{2.9}$$

where $C^{(j)}\in\mathbb{R}$, $f_j(\lambda)\in L_a$ for $j=1,2,3$, $E^{(j)}\in\mathbb{R}$, $g_j(\lambda)\in L_a$ for $j=1,2$. The following representation can be proved in the same way as Lemma 2.1 of [25]:

$$\phi_3(\lambda)=\cos\lambda a+\frac{\pi B_0\sin\lambda a}{3\lambda}+E^{(3)}\frac{\cos\lambda a}{\lambda^2}+\frac{g_3(\lambda)}{\lambda^2}, \tag{2.10}$$

where $E^{(3)}\in\mathbb{R}$ and $g_3(\lambda)\in L_a$.

Substituting (2.1) into (2.8)–(2.10), we obtain

$$\phi_1(\nu_k^{(1)})=(-1)^k\frac{a^2(B_1-M_1)}{\pi k^2}+\frac{\delta_k^{(4)}}{k^3}, \tag{2.11}$$

$$\phi_2(\nu_k^{(1)})=(-1)^k\frac{a^2(B_1-M_2)}{\pi k^2}+\frac{\delta_k^{(5)}}{k^3}, \tag{2.12}$$

$$\phi_3(\nu_k^{(1)})=(-1)^k\left(1-\frac{a^2B_1^2}{2k^2}+\frac{a^2B_0B_1}{3k^2}\right)+\frac{\delta_k^{(6)}}{k^3}, \tag{2.13}$$

$$\tilde s_2(\nu_k^{(1)})=(-1)^k\frac{a^2(B_1-B_2)}{\pi k^2}+\frac{\delta_k^{(7)}}{k^3}, \tag{2.14}$$

$$\tilde s_3(\nu_k^{(1)})=(-1)^k\frac{a^2(B_1-B_3)}{\pi k^2}+\frac{\delta_k^{(8)}}{k^3}, \tag{2.15}$$

where $\{\delta_k^{(j)}\}_{k=-\infty,k\ne0}^{\infty}\in l_2$ for $j=\overline{4,8}$.

Let us set

$$X_k^{(1)}=:\nu_k^{(1)}\left(\frac{3\phi_1(\nu_k^{(1)})\phi_2(\nu_k^{(1)})\phi_3(\nu_k^{(1)})}{\tilde s_2(\nu_k^{(1)})\tilde s_3(\nu_k^{(1)})}-\cos\nu_k^{(1)}a-\frac{\pi B_1\sin\nu_k^{(1)}a}{\nu_k^{(1)}}\right). \tag{2.16}$$

It is clear that $X_{-k} = -X_k$. To continue the proof we need the following lemma.

LEMMA 2.2.

$$\{X_k\}_{-\infty, k\neq 0}^{\infty} \in l_2. \tag{2.17}$$

Proof. To prove this lemma, it is enough to substitute (2.11)–(2.15) and the evident equality,

$$\cos \nu_k^{(1)} a + \frac{\pi B_1 \sin \nu_k^{(1)} a}{\nu_k^{(1)}} \underset{k\to\infty}{=} (-1)^k + O(k^{-2}),$$

into (2.16) and to take into account that M_1 and M_2 are the roots of (1.50). □

Now it follows from [19] that the series

$$\tilde{s}_1(\lambda) \sum_{\substack{k\neq 0 \\ -\infty}}^{\infty} \frac{X_k}{\frac{d\tilde{s}_1(\lambda)}{d\lambda}\Big|_{\lambda=\nu_k^{(1)}} (\lambda - \nu_k^{(1)})} \tag{2.18}$$

converges uniformly on any compact of the complex plane (and in the norm of $L_2(-\infty, \infty)$ for real λ) to a function $\varepsilon(\lambda)$, which belongs to L_a.

Introduce the function

$$R_1(\lambda) \stackrel{\text{def}}{=} \cos \lambda a + \frac{\pi B_1 \sin \lambda a}{\lambda} + \frac{\varepsilon(\lambda)}{\lambda}. \tag{2.19}$$

Since $\epsilon(\nu_k^{(1)}) = X_k^{(1)}$, (2.16) implies that

$$R_1(\nu_k^{(1)}) = \frac{3\phi_1(\nu_k^{(1)})\phi_2(\nu_k^{(1)})\phi_3(\nu_k^{(1)})}{\tilde{s}_2(\nu_k^{(1)})\tilde{s}_3(\nu_k^{(1)})}. \tag{2.20}$$

Let us denote the set of zeroes of the function $R_1(\lambda)$ by $\{\mu_k\}_{-\infty, k\neq 0}^{\infty}$. We number these zeroes as usual: $\mu_{-k} = -\mu_k$ and $\mu_k \leq \mu_{k+1}$. It follows from (2.19) (see [22, Lemma 3.4.2]) that

$$\mu_k^{(1)} \underset{k\to\infty}{=} \frac{\pi(2k-1)}{2a} + \frac{B_1}{k} + \frac{\gamma_k}{k}, \tag{2.21}$$

where $\{\gamma_k\}_{-\infty, k\neq 0}^{\infty} \in l_2$.

PROPOSITION 2.3.

$$\frac{3\phi_1(0)\phi_2(0)\phi_3(0)}{\tilde{s}_2(0)\tilde{s}_3(0)} > 0, \qquad (-1)^k \frac{3\phi_1(\nu_k^{(1)})\phi_2(\nu_k^{(1)})\phi_3(\nu_k^{(1)})}{\tilde{s}_2(\nu_k^{(1)})\tilde{s}_3(\nu_k^{(1)})} > 0. \tag{2.22}$$

Proof. The following inequalities can be obtained from (2.7)–(2.10) taking into account that all zeroes of $\phi_j(\lambda)$ (j=1,2,3) and all zeroes of $\tilde{s}_j(\lambda)$ are real:

$$\phi_j(0) > 0, \qquad \tilde{s}_j(0) > 0. \tag{2.23}$$

Hence the first of inequalities (2.22) follows. Let $\nu_k^{(1)} = \theta_p$, $(p \geq k > 0)$. Then it is clear from (2.4) and from the first of inequalities (2.22) that the function

$$\frac{3\phi_1(\lambda)\phi_2(\lambda)\phi_3(\lambda)}{\tilde{s}_1(\lambda)\tilde{s}_2(\lambda)\tilde{s}_3(\lambda)}$$

is positive (negative) on intervals (θ_k, τ_{k+1}) (on intervals (τ_k, θ_k)). Hence

$$\frac{3\phi_1(\theta_p)\phi_2(\theta_p)\phi_3(\theta_p)}{\tilde{s}_2(\theta_p)\tilde{s}_3(\theta_p)} \lim_{\lambda\to\theta_p} \frac{(\lambda-\theta_p)}{\tilde{s}_1(\lambda)} = \lim_{\lambda\to\theta_p} \frac{3\phi_1(\lambda)\phi_2(\lambda)\phi_3(\lambda)(\lambda-\theta_p)}{\tilde{s}_2(\lambda)\tilde{s}_3(\lambda)\tilde{s}_1(\lambda)} > 0. \tag{2.24}$$

From the other hand,

$$\lim_{\lambda\to\theta_p} \frac{(\lambda-\theta_p)}{\tilde{s}_1(\lambda)}(-1)^k = \lim_{\lambda\to\nu_k^{(1)}} \frac{(\lambda-\nu_k^{(1)})}{\tilde{s}_1(\lambda)}(-1)^k > 0. \tag{2.25}$$

The second of inequalities (2.22) follows from (2.24) and (2.25). □

Using (2.19), (2.20), and (2.22), we obtain

$$R_1(0) > 0, \quad (-1)^k R_1(\nu_k^{(1)}) > 0. \tag{2.26}$$

These inequalities imply the following proposition.

PROPOSITION 2.4.

$$\cdots < \nu_{-1}^{(1)} < \mu_{-1}^{(1)} < 0 < \mu_1^{(1)} < \nu_1^{(1)} < \mu_2^{(1)} < \nu_2^{(1)} < \cdots . \tag{2.27}$$

Now the two sequences $\{\nu_k^{(1)}\}_{-\infty,k\neq0}^{\infty}$ *and* $\{\mu_k^{(1)}t\}_{-\infty,k\neq0}^{\infty}$ *satisfy (due to* (2.1), (2.21)*, and Proposition* 2.4*) the conditions of* [22, *Theorem* 3.4.1]. *Thus it is possible to construct (via the well-known procedure* [21], [22, *section* 3.4]*) a unique real* $q_1(x) \in L_2(0,a)$ *such that* $\{\nu_k^{(1)}\}_{-\infty,k\neq0}^{\infty}$ *is the spectrum of problem* (1.1_1), (1.13) *and* $\{\mu_k^{(1)}\}_{-\infty,k\neq0}^{\infty}$ *is the spectrum of the problem*

$$\begin{aligned} y_1'' + \lambda^2 y_1 - q_1(x)y_1 = 0, \\ y_1(\lambda,0) = y_1'(\lambda,a) = 0. \end{aligned} \tag{2.28}$$

In the same way we can construct $q_2(x)$ *and* $q_3(x)$ *(each of them is unique real and belongs to* $L_2(0,a)$*). It is clear that the obtained triplet* $\{q_1(x), q_2(x), q_3(x)\}$ *generates the spectra of problems* $(1.1j)$, $(1.43j)$*, which coincide with* $\{\nu_k^{(j)}\}_{-\infty,k\neq0}^{\infty}$ *for* $j = 1,2,3$*, respectively, and the functions* $s_j(\lambda,a)$ *which coincide with* $\tilde{s}_j(\lambda)$ *defined by* (2.5)*. The sets of zeroes of values of the derivatives* $s_j'(\lambda,a)$ *coincide with* $\{\mu_k^{(j)}\}_{-\infty,k\neq0}^{\infty}$*, and consequently* $s_j'(\lambda,a)$ *coincide with* $R_j(\lambda)$*, where* $R_1(\lambda)$ *is defined by* (2.19)*. (The expressions for* $R_2(\lambda)$ *and* $R_3(\lambda)$ *are analogous.) Thus the values of the function*

$$\tilde{\varphi}_1(\lambda) \stackrel{\text{def}}{=} s_1(\lambda,a)s_2(\lambda,a)s_3'(\lambda,a) + s_2(\lambda,a)s_3(\lambda,a)s_1'(\lambda,a) + s_1(\lambda,a)s_3(\lambda,a)s_2'(\lambda,a)$$

at $\lambda = \nu_k^{(j)}$ *coincide with* $3\phi_1(\nu_k^{(j)})\phi_2(\nu_k^{(j)})\phi_3(\nu_k^{(j)})$ *for all* $k = \pm1, \pm2, \ldots$ *and all* $j = 1,2,3$*, i.e., with the corresponding values of the function* $3\phi_1(\lambda)\phi_2(\lambda)\phi_3(\lambda)$*. This means that the spectrum of problem* $(1.1j)$, $(1.2j)$, (1.3), (1.4) *generated by obtained triplet* $\{q_1(x), q_2(x), q_3(x)\}$ *coincides with* $\{\tau_k\}_{-\infty,k\neq0}^{\infty}$.

The uniqueness of the solution of the inverse problem follows from the fact that formula (2.18) *establishes one-to-one correspondence between* l_2 *and* L_a *(see* [19]).

Remark 2.1. If the spectra intersect, i.e., condition 1(ii) of Theorem 2.1 is violated (and consequently condition 3 is, too), then the solution of the inverse problem is not unique because of the same reasons as in the case of three spectral problem (see [11], [25]).

Let us now consider Hochstadt–Lieberman type (see [15], [12], [6]) inverse problem, i.e., inverse problem with partial information on the potential.

THEOREM 2.5. *The two potentials $q_1(x)$ and $q_2(x)$ (both real-valued and belonging to $L_2(0,a)$) and the spectrum $\{\tau_k\}_{-\infty,k\neq 0}^{\infty}$ of the problem (1.1j), (1.2j) ($j=1,2,3$), (1.3), (1.4) determine uniquely the (real-valued and belonging to $L_2(0,a)$) potential $q_3(x)$.*

Proof. Let us suppose there exist two potentials $q_3(x)$ and $\tilde{q}_3(x)$ (both real-valued and $\in L_2(0,a)$) such that problems (1.1j), (1.2j), (j=1,2,3), (1.3), (1.4) generated by the triplets $\{q_1(x),q_2(x),q_3(x)\}$ and $\{q_1(x),q_2(x),\tilde{q}_3(x)\}$ possess the same spectrum $\{\tau_k\}_{-\infty,k\neq 0}^{\infty}$. Then using (1.7)–(1.9), we obtain

$$\varphi_1(\lambda)=s_1(\lambda,a)s_2(\lambda,a)s_3'(\lambda,a)+s_1(\lambda,a)s_3(\lambda,a)s_2'(\lambda,a)+s_2(\lambda,a)s_3(\lambda,a)s_1'(\lambda,a), \tag{2.29}$$

$$\varphi_1(\lambda)=s_1(\lambda,a)s_2(\lambda,a)\tilde{s}_3'(\lambda,a)+s_1(\lambda,a)\tilde{s}_3(\lambda,a)s_2'(\lambda,a)+s_2(\lambda,a)\tilde{s}_3(\lambda,a)s_1'(\lambda,a), \tag{2.30}$$

where $\varphi_1(\lambda)$ is determined uniquely by the spectrum $\{\tau_k\}_{-\infty,k\neq 0}^{\infty}$ via the formulas $\varphi_1(\lambda)=3\phi_1(\lambda)\phi_2(\lambda)\phi_3(\lambda)$ and (2.6). The functions $s_1(\lambda,a)$, $s_2(\lambda,a)$, $s_1'(\lambda,a)$ and $s_2'(\lambda,a)$ are determined by $q_1(x)$ and $q_2(x)$. (They can be found by solving the corresponding Dirichlet and Dirichlet–Neumann problems.) Now we can find the values $s_3(\nu_k^{(1)},a)$ and $\tilde{s}_3(\nu_k^{(1)},a)$, where $\nu_k^{(1)}$ are the zeroes of $s_1(\lambda,a)$ via the formula

$$\tilde{s}_3(\nu_k^{(1)},a)=s_3(\nu_k^{(1)},a)=\frac{\varphi_1(\nu_k^{(1)})}{s_2(\nu_k^{(1)},a)s_1'(\nu_k^{(1)},a)} \tag{2.31}$$

if $s_2(\nu_k^{(1)},a)\neq 0$. In the opposite case (if $s_2(\nu_k^{(1)},a)=0$), formula (2.31) should be replaced by the following:

$$\tilde{s}_3(\nu_k^{(1)},a)=s_3(\nu_k^{(1)},a)=\lim_{\lambda\to\nu_k^{(1)}}\frac{\varphi_1(\lambda)}{s_2(\lambda,a)s_1'(\lambda,a)+s_1(\lambda,a)s_2'(\lambda,a)}. \tag{2.32}$$

The limit exists because: (1) all zeroes of $s_j(\lambda,a)$ are simple; (2) if $s_j(\lambda,a)=0$, then $s_j'(\lambda,a)\neq 0$; (3) according to Theorem 1.13, the equation $s_1(\lambda,a)=s_2(\lambda,a)=0$ implies $\varphi_1(\lambda)=0$; (4) all zeroes of the function $\psi_1(\lambda)=s_2(\lambda,a)s_1'(\lambda,a)+s_1(\lambda,a)s_2'(\lambda,a)$ are simple due to Lemma 1.1; and (5) if $\psi_1(\nu_k^{(1)})=0$, then due to Lemma 1.15, $\varphi_1(\nu_k^{(1)})=0$. Equations (2.29) and (2.30) imply that

$$\begin{aligned}&\nu_k^{(1)2}\left(\tilde{s}_3(\nu_k^{(1)},a)-\frac{\sin\nu_k^{(1)}a}{\nu_k^{(1)}}+\frac{\pi B_1\cos\nu_k^{(1)}a}{\nu_k^{(1)2}}\right)\\ &\quad=\nu_k^{(1)2}\left(s_3(\nu_k^{(1)},a)-\frac{\sin\nu_k^{(1)}a}{\nu_k^{(1)}}+\frac{\pi B_1\cos\nu_k^{(1)}a}{\nu_k^{(1)2}}\right)\overset{\text{def}}{=}d_k\end{aligned} \tag{2.33}$$

for all k. Using (1.17) and [22, Lemma 1.4.3], we obtain $\{d_k\}_{-\infty,k\neq 0}^{\infty}\in l_2$. This means that

$$\begin{aligned}\lambda^2\left(\tilde{s}_3(\lambda,a)-\frac{\sin\lambda a}{\lambda}+\frac{\pi B_1\cos\lambda a}{\lambda^2}\right)&=\lambda^2\left(s_3(\lambda,a)-\frac{\sin\lambda a}{\lambda}+\frac{\pi B_1\cos\lambda a}{\lambda^2}\right)\\ &=s_1(\lambda,a)\sum_{\substack{k\neq 0\\ -\infty}}^{\infty}\frac{d_k}{\frac{ds_1(\lambda,a)}{d\lambda}\Big|_{\lambda=\nu_k^{(1)}}(\lambda-\nu_k^{(1)})},\end{aligned} \tag{2.34}$$

and consequently $s_3(\lambda,a)=\tilde{s}_3(\lambda,a)$. Substituting this equation into (2.29) and (2.30), we obtain the identity $s_3'(\lambda,a)=\tilde{s}_3'(\lambda,a)$. The sets of zeroes of the functions $s_3(\lambda,a)$ and $s_3'(\lambda,a)$ uniquely determine $q_3(x)$ ([3], [21], [22]). □

The following theorem can be proved in the same way.

THEOREM 2.6. *Let the following data be given:* (1) *a (real-valued belonging to* $L_2(0,a)$*) potential* $q_1(x)$, (2) *the spectrum* $\{\tau_k\}_{-\infty,k\neq0}^{\infty}$ *of problem* (1.1j), (1.2j), (1.3), (1.4), *and* (3) *the spectrum* $\{\nu_k^{(2)}\}_{-\infty,k\neq0}^{\infty}$ *of problem* (1.1$_2$), (1.14).

If $\{\nu_k^{(2)}\}_{-\infty,k\neq0}^{\infty}\bigcap\{\nu_k^{(1)}\}_{-\infty,k\neq0}^{\infty}=\emptyset$, $\{\nu_k^{(2)}\}_{-\infty,k\neq0}^{\infty}\bigcap\{\tau_k\}_{-\infty,k\neq0}^{\infty}=\emptyset$, *and* $\{\nu_k^{(1)}\}_{-\infty,k\neq0}^{\infty}\bigcap\{\tau_k\}_{-\infty,k\neq0}^{\infty}=\emptyset$, *then these data determine uniquely the potentials* $q_2(x)$ *and* $q_3(x)$ (*in the class of real-valued* $L_2(0,a)$ *functions*).

Proof. Since given $q_1(x)$ uniquely determine the functions $s_1(\lambda,a)$ and $s_1'(\lambda,a)$ and the spectrum $\{\nu_k^{(2)}\}_{-\infty,k\neq0}^{\infty}$ uniquely determine the function $s_2(\lambda,a)$, formula (2.32) uniquely determine the set $\{s_3(\nu_k^{(1)},a)\}_{-\infty,k\neq0}^{\infty}$. Thus formula (2.33) uniquely determine the set $\{d_k\}_{-\infty,k\neq0}^{\infty}$. Consequently, formula (2.34) uniquely determine $s_3(\lambda,a)$ and the set of its zeroes $\{\nu_k^{(3)}\}_{-\infty,k\neq0}^{\infty}$. Now it is sufficient to apply Theorem 2.1 to finish the proof. □

UNFOLDING SINGULARLY PERTURBED BOGDANOV POINTS*

MATTHIAS STIEFENHOFER†

Abstract. Bogdanov points that occur in the fast dynamics of singular perturbation problems are often encountered in applications; e.g., in the van der Pol–Duffing oscillator [M. Koper, *Phys. D*, 80 (1995), pp. 64–88] or in the FitzHugh–Nagumo equation [W.-J. Beyn and M. Stiefenhofer, *J. Dynam. Differential Equations*, 11 (1997), pp. 671–709]. A parameter of the normal form is taken to be a dynamic variable with slow dynamics of speed ϵ. We analyze these points using a generic unfolding which ensures that the typical phenomena near a regularly perturbed Bogdanov point (saddle-nodes, Hopf points, periodic orbits, homoclinic orbits) carry over to Bogdanov points viewed in the context of singular perturbations. We combine analytical and numerical results to study the relations between these structures in the 3-dimensional unfolding space. In particular, the singularly perturbed homoclinic orbits can be analyzed after an appropriate blow-up of the singularly perturbed Bogdanov point using a technique from [W.-J. Beyn and M. Stiefenhofer, *J. Dynam. Differential Equations*, 11 (1997), pp. 671–709]. As indicated by numerical calculations the homoclinic orbits turn into homoclinic orbits of Shilnikov type that vanish presumably by a canard like explosion process [M. Diener, *Étude générique des canards*, IRMA, 1981], [W. Eckhaus, Lecture Notes in Math. 985, Springer, 1983, pp. 449–494], [V. I. Arnold, V. S. Afrajmovich, Y. S. Il'yashenko, and L. P. Shil'nikov, *Dynamical Systems* V: *Bifurcation Theory*, Springer, 1994], [F. Dumortier and R. Roussarie, Mem. Amer. Math. Soc. 121, AMS, 1996].

Key words. Bogdanov points, homoclinic orbits, singular perturbations

1. Introduction.

Singular perturbation problems of the form

$$\begin{aligned} \dot{u} &= F(u,v) \in \mathbb{R}^n, \\ \dot{v} &= \epsilon \cdot G(u,v) \in \mathbb{R}, \qquad -1 \ll \epsilon \ll 1 \end{aligned} \tag{1.1}$$

represent one possibility of including the real parameter v of the u-system $\dot{u} = F(u,v)$ into the dynamics of the model. We investigate this perturbation process from $\epsilon = 0$ to $\epsilon \neq 0$ when the central u-system $\dot{u} = F(u,0)$ has a Bogdanov point, i.e., a stationary point with an algebraically double and geometrically simple eigenvalue zero [15]. We refer to a point of this kind as a singularly perturbed Bogdanov point of the fast-slow system (1.1) if it additionally satisfies $G(u,0) = 0$. In this situation the well-known technique of reducing to the 1-dimensional slow manifold defined by $F(u,v) = 0$ is impossible (cf. [12], [29]) and instead of enslaving the fast u-variables by the slow v-variable (cf. [17]) we may obtain new phenomena due to the equal coupling of all variables.

The standard examples of singularly perturbed Bogdanov points are given by the van der Pol–Duffing oscillator [19]

$$\begin{aligned} \dot{u}_1 &= p_2 u_2 - u_1^3 + 3u_1 - p_1, \\ \dot{u}_2 &= u_1 - 2u_2 + v, \\ \dot{v} &= \epsilon \cdot (u_2 - v), \end{aligned} \tag{1.2}$$

and the travelling wave problem for the FitzHugh–Nagumo equation [5], [16], [21]

$$\begin{aligned} \dot{u}_1 &= u_2, \\ \dot{u}_2 &= cu_2 + u_1(u_1 - a)(u_1 - 1) + v, \\ \dot{v} &= \frac{\bar{\epsilon}}{c} \cdot (u_1 - \gamma v). \end{aligned} \tag{1.3}$$

The van der Pol–Duffing oscillator has two singularly perturbed Bogdanov points

$$(u_1, u_2, v, p_1, p_2, \epsilon) = \left(\pm\frac{1}{\sqrt{3}}, \pm\frac{1}{\sqrt{3}}, \pm\frac{1}{\sqrt{3}}, \mp\frac{4}{3\sqrt{3}}, -4, 0 \right), \tag{1.4}$$

whereas the travelling wave problem (1.3) (with $\epsilon = \bar{\epsilon}/c$) has one singularly perturbed Bogdanov point at $(u, v, a, c, \epsilon) = 0$. In [4] we examined the travelling wave problem (1.3) with respect to homoclinic orbits near the singularly perturbed Bogdanov point.

In the current paper we perform two extensions. First, we extend the results from [4] to general systems of the form (1.1). For this purpose the notion of a generic unfolding of a singularly perturbed Bogdanov point is introduced. In that framework we do not restrict ourselves to homoclinic orbits but investigate to a certain extent the unfolding structure of stationary points, periodic orbits, homoclinic orbits, and invariant tori. We use analytical results from [11], [10], [4], [26], [27], numerical results from [19], and heuristic results from [25] that are mainly obtained from the model equation

$$\begin{aligned} \dot{u}_1 &= u_2, \\ \dot{u}_2 &= u_1^2 + u_1 u_2 + k u_2 + v, \\ \dot{v} &= \epsilon \cdot (\lambda - u_1) \end{aligned} \tag{1.5}$$

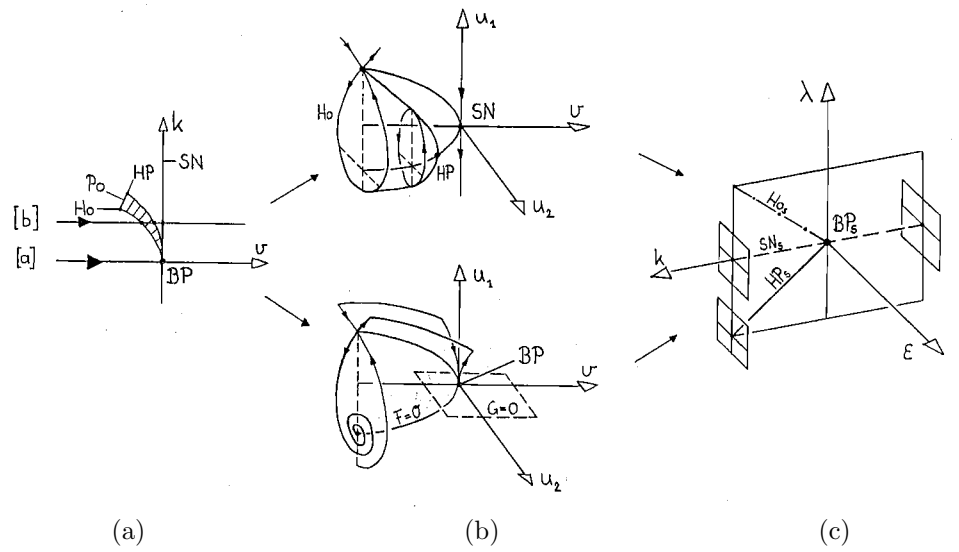
which represents a generic (λ, k)-unfolding of the singularly perturbed Bogdanov point $(u, v, \lambda, k, \epsilon) = 0$. Other examples of singularly perturbed Bogdanov points appear in the context of cell communication problems [14], [25].

The model equation (1.5) indicates our aim; for $\epsilon = 0$ we have a family of fast u-systems $\dot{u} = F(u, v, k)$ that depends on the two parameters v and k. The well-known (v, k)-unfolding diagram with corresponding bifurcation diagrams along sections [a], [b] is shown in the left and middle diagram of Figure 1 (cf. [15]).

The parameters v and k are of different nature in the sense that the v-axis in diagram (a) transversally intersects the curve of saddle-nodes SN; i.e., the v-axis represents a generic parameter direction in the 2-dimensional (v, k)-unfolding space of the Bogdanov point BP. Note also that diagram (a) shows the universal unfolding of a finitely determined Bogdanov point that occurs in the fast u-system; therefore Figure 1 shows the standard case [15]. The fast u-system of the van der Pol–Duffing oscillator (1.2) corresponds to the standard case.

By the equation $\dot{v} = \epsilon(\lambda - u_1) = \epsilon G(u, \lambda)$ the generic parameter direction v is slowly included into the dynamics of the system (1.5). Graphically, we perturb the fast dynamics shown in diagram (b) of Figure 1 by a slow dynamics in the direction of v.

This perturbation is not done in an arbitrary way; it is controlled with the help of the additional parameter λ which ensures that at $\lambda = 0$ the nullclines of the u- and v-equations meet transversally in the Bogdanov point. Compare $F = 0$ and $G = 0$ in the lower half of diagram (b) in Figure 1.



(a) (b) (c)

FIG. 1. (a) *The (v,k)-unfolding space of the fast u-system, BP = Bogdanov point, SN = saddle-node, HP = Hopf point, Po = periodic orbit, Ho = homoclinic orbit;* (b) *the bifurcation diagrams along sections* [a] *and* [b]*;* (c) *the* 3*-dimensional (λ,k,ϵ)-unfolding space of the fast-slow system* (1.5) *(BP_s, SN_s, HP_s, Ho_s explained in text).*

Note also that the curve $F=0$ can either be interpreted as a branch of stationary points of the fast u-system $\dot{u}=F(u,v,k)$ or as a continuum of stationary points in the (u,v)-phase space of the fast-slow system $\dot{u}=F(u,v,k)$, $\dot{v}=0$. The continuum of stationary points represents the singular character of our perturbation process.

With these assumptions we try to understand the structures in the 3-dimensional (λ,k,ϵ)-unfolding space of a singularly perturbed Bogdanov point (cf. (c) in Figure 1).

The paper is organized as follows. In section 2 the definitions of singularly perturbed saddle-nodes SN_s, singularly perturbed Hopf points HP_s, singularly perturbed homoclinic orbits Ho_s, and singularly perturbed Bogdanov points BP_s are introduced together with the notion of a generic unfolding. The relations between these points are summarized in a theorem and indicated in the (λ,k)-plane of Figure 1(c).

At this stage the first differences between the standard case and the FitzHugh–Nagumo equation (1.3) occur. The Bogdanov point $(u,v,a,c)=0$ of the fast u-system in (1.3) is not finitely determined; i.e., one of the two normal form coefficients vanishes which results from the fact that the central u-system $\dot{u}_1=u_2$, $\dot{u}_2=-u_1^2+u_1^3$ of the FitzHugh–Nagumo equation is Hamiltonian. The theorem applies for the standard case and the FitzHugh–Nagumo equation as well.

Next we perform the actual singular perturbation; i.e., we perturb the points SN_s, HP_s, Ho_s, and BP_s from the (λ,k)-plane in Figure 1(c) to $\epsilon\neq 0$. Here we combine analytical, numerical, and heuristical results for deriving a rough version of the complete (λ,k,ϵ)-unfolding diagram. The underlying analytical results from [8], [11], [1], [10], [26], [27] and [4] are summarized in three theorems in sections 4 and 5.

More precisely, in section 4 the unfolding structures of singularly perturbed saddle-nodes SN_s and singularly perturbed Hopf points HP_s are investigated. These unfolding diagrams represent 2-dimensional sections through the 3-dimensional unfolding space of a singularly perturbed Bogdanov point BP_s. Some of the sections

are indicated in Figure 1(c). Section 5 deals with singularly perturbed homoclinic orbits Ho_s obtained by blowing up the singularly perturbed Bogdanov point BP_s appropriately; i.e., here we do not restrict ourselves to 2-dimensional sections, but we start from the center of the (λ, k, ϵ)-unfolding diagram. Section 5 contains the most technical part of the paper.

We conclude the paper with some strange results and conjectures concerning a canard like behavior [8], [11], [1], [10] of homoclinic orbits of Shilnikov type motivated by numerical calculations.

2. The setting and the unfolding diagram. Consider a system of the form

$$\begin{aligned} \dot{u} &= F(u, v, \epsilon) \in \mathbb{R}^2, \\ \dot{v} &= \epsilon \cdot G(u, v, \epsilon) \in \mathbb{R}. \end{aligned} \tag{2.1}$$

Concerning the fast u-system $\dot{u} = F(u, 0, 0)$ at $v = 0$ assume

$$F^0 = 0, \qquad \operatorname{tr}(F_u)^0 = 0, \qquad \det(F_u)^0 = 0, \qquad F_u^0 \neq 0 \in \mathbb{R}^{2,2}, \tag{2.2}$$

where tr, det denote the trace, determinant of a matrix and the upper index "0" denotes evaluation at $(u, v, \epsilon) = (0, 0, 0)$. Concerning the regular v-perturbation $\dot{u} = F(u, v, 0)$ assume

$$F_v^0 \notin \mathrm{R}[F_u^0], \qquad F_{uu}^0 \varphi_1^2 \notin \mathrm{R}[F_u^0] \qquad \text{with} \qquad \mathrm{N}[F_u^0] = \operatorname{span}\{\varphi_1\}, \tag{2.3}$$

where R and N denote the range and kernel of a matrix, respectively. Finally, concerning the singular v-perturbation $\dot{v} = \epsilon G(u, v, \epsilon)$ assume

$$G^0 = 0, \qquad \begin{pmatrix} F_u & F_v \\ G_u & G_v \end{pmatrix}^0 \quad \text{nonsingular .} \tag{2.4}$$

We interpret these assumptions. According to (2.2) the central u-system $\dot{u} = F(u, 0)$ has a Bogdanov point in the sense defined in the introduction. According to (2.3) the regular v-perturbation $\dot{u} = F(u, v, 0)$ of this system has a quadratic limit point with respect to v; i.e., from a stationary point of view the Bogdanov point is generically perturbed by the parameter v. In the next step, the parameter v of the u-system $\dot{u} = F(u, v, 0)$ is included into the dynamics of the (u, v)-system (2.1) according to $\dot{v} = \epsilon G(u, v, \epsilon)$ where this dynamical unfolding is characterized by (2.4); i.e., the F-nullcline defined by $F(u, v, 0) = 0 \in \mathbb{R}^2$ and the surface defined by $G(u, v, 0) = 0 \in \mathbb{R}$ intersect transversally in the Bogdanov point $(u, v) = 0$. Typically, we arrive at a configuration as depicted in the lower part of Figure 1(b).

Definition 2.1. *A point $(u, v, \epsilon) = 0$ which satisfies (2.2)–(2.4) is called a singularly perturbed Bogdanov point of the system (2.1).*

Summing up we investigate a certain dynamical unfolding of a Bogdanov point of the fast u-system which satisfies $G = 0$ and some additional nondegeneracy conditions.

Next we turn to the assumptions concerning the parameter unfolding of system (2.1). Apart from the basic condition $(F, G)^0 = 0$ the central point $(u, v, \epsilon) = 0$ satisfies the two degeneracy conditions $\operatorname{tr}(F_u)^0 = 0$ and $\det(F_u)^0 = 0$. Hence it seems appropriate to examine a singularly perturbed Bogdanov point within a parameter unfolding of two parameters $p = (p_1, p_2)$:

$$\begin{aligned} \dot{u} &= F(u, v, p_1, p_2, \epsilon) \in \mathbb{R}^2, \\ \dot{v} &= \epsilon \cdot G(u, v, p_1, p_2, \epsilon) \in \mathbb{R}. \end{aligned} \tag{2.5}$$

The corresponding nondegeneracy condition of this parameter unfolding is determined with the help of the defining equation

$$H(u,v,p_1,p_2) := \begin{pmatrix} F(u,v,p_1,p_2,0) \\ G(u,v,p_1,p_2,0) \\ \det(F_u)(u,v,p_1,p_2,0) \\ \operatorname{tr}(F_u)(u,v,p_1,p_2,0) \end{pmatrix} = 0, \qquad H:\ \mathbb{R}^5 \to \mathbb{R}^5. \tag{2.6}$$

DEFINITION 2.2. *The (p_1,p_2)-unfolding* (2.5) *of system* (2.1) *is a generic unfolding of a singularly perturbed Bogdanov point if $H'(0) \in \mathbb{R}^{5,5}$ is nonsingular.* In detail, the linearization $H'(0)$ is given by

$$H'(0) = \begin{pmatrix} F_u & F_v & F_{p_1} & F_{p_2} \\ G_u & G_v & G_{p_1} & G_{p_2} \\ \det_u(F_u) & \det_v(F_u) & \det_{p_1}(F_u) & \det_{p_2}(F_u) \\ \operatorname{tr}_u(F_u) & \operatorname{tr}_v(F_u) & \operatorname{tr}_{p_1}(F_u) & \operatorname{tr}_{p_2}(F_u) \end{pmatrix}^0 \in \mathbb{R}^{5,5}. \tag{2.7}$$

Hence, the point $(u,v,p_1,p_2) = 0$ must be a regular solution of the defining equation (2.6). This condition simply ensures that the singularly perturbed Bogdanov point $(u,v,\epsilon) = 0$ of system (2.1) is unique within the unfolded system (2.5).

The van der Pol–Duffing oscillator (1.2), the travelling wave problem (1.3) (with $(p_1,p_2) = (a,c)$), and the model equation (1.5) (with $(p_1,p_2) = (\lambda,k)$) satisfy the conditions (2.2)–(2.4) and (2.7) at the Bogdanov points. Further examples can be found in [25] where cell communication problems from [14] are studied.

Our aim is to determine the unfolding structure of the general system (2.5) in the (p_1,p_2,ϵ)-parameter space. For this purpose we first determine the unfolding structure of the u-system $\dot u = F(u,v,p_1,p_2,0)$ and then we perform the singular perturbation from $\epsilon = 0$ to $\epsilon \neq 0$; i.e., we include the generic parameter v into the dynamics of the system according to $\dot v = \epsilon G(u,v,p_1,p_2,\epsilon)$.

Now the regularity of $H'(0)$ ensures that the singularly perturbed Bogdanov point lies at the intersection of the curves defined by

$$[F,G,\det(F_u)](u,v,p_1,p_2,0) = 0 \quad \text{and} \quad [F,G,\operatorname{tr}(F_u)](u,v,p_1,p_2,0) = 0. \tag{2.8}$$

In section 4 it is shown that these curves give rise to saddle-node and Hopf points of the u-system $\dot u = F(u,v,p_1,p_2,0)$ which satisfy $G(u,v,p_1,p_2,0) = 0$. Moreover, we shall see that a curve of homoclinic base points (the steady states to which the homoclinic orbits converge) of the system $\dot u = F(u,v,p_1,p_2,0)$ with $G(u,v,p_1,p_2,0) = 0$ emanates from the singularly perturbed Bogdanov point.

Analogous to the definition of a singularly perturbed Bogdanov point, we refer to these phenomena as *singularly perturbed saddle-nodes, Hopf points, and homoclinic base points*, respectively. In this sense the assumptions (2.2)–(2.4) and (2.7) guarantee that the typical phenomena near a regularly perturbed Bogdanov point carry over to Bogdanov points viewed in the context of singular perturbations. The precise definitions of singularly perturbed saddle-node and Hopf points (which are of lower degeneracy than singularly perturbed Bogdanov points) are given in section 4. Singularly perturbed homoclinic orbits are precisely defined in section 5.

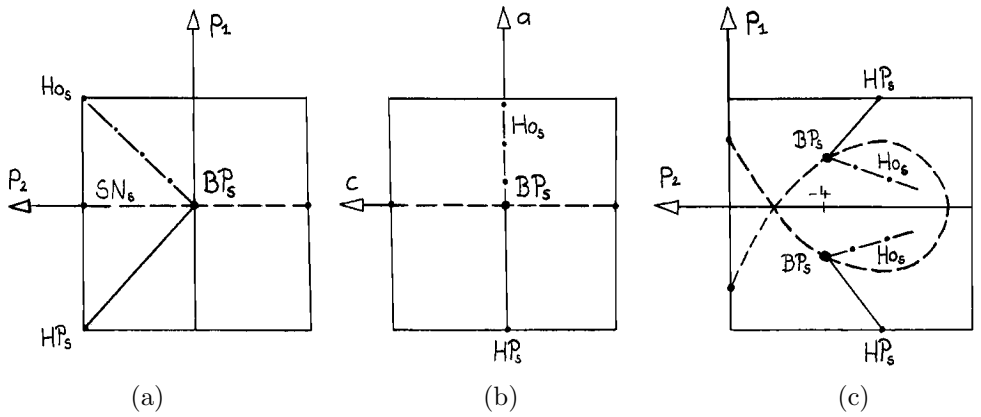


FIG. 2. *The singularly perturbed points at* $\epsilon = 0$: (a) *Standard,* (b) *FitzHugh–Nagumo,* (c) *van der Pol–Duffing.*

In the following theorem we collect the different types of singularly perturbed points that appear near a singularly perturbed and generically unfolded Bogdanov point.

THEOREM 2.3. *At* $\epsilon = 0$ *there exist in* (p_1, p_2)*-space of system* (2.5) *a two-sided curve* $SN_s(z)$, $-1 \ll z \ll 1$, $z \neq 0$ *of singularly perturbed saddle-nodes and two one-sided curves* $HP_s(z)$, $Ho_s(z)$, $0 < z \ll 1$ *of singularly perturbed Hopf points and singularly perturbed homoclinic base points, respectively. The curves can be smoothly continued to* $z = 0$. *At* $z = 0$ *the curves* $SN_s(z)$, $HP_s(z)$ *and* $SN_s(z)$, $Ho_s(z)$ *meet transversally in the singularly perturbed Bogdanov point at* $(p_1, p_2) = 0$. *The curves* $HP_s(z)$, $Ho_s(z)$ *exist on different sides of the curve* $SN_s(z)$ *and they meet transversally iff the Bogdanov point* $u = 0$ *of the system* $\dot{u} = F(u, 0)$ *is nondegenerate, i.e., if a certain normal form coefficient is different from zero.*

The theorem is proved in sections 4 and 5. We derive explicit formulas for the derivatives $SN_s{}'(0)$, $HP_s{}'(0)$, and $Ho_s{}'(0)$ in terms of derivatives of the right-hand side F and G.

In diagram (a) of Figure 2 we show the general location of the singularly perturbed points in the (p_1, p_2)-plane as they occur for the system (2.5) in generic cases.

The singularly perturbed Hopf points HP_s and the singularly perturbed homoclinic base points Ho_s terminate at the singularly perturbed Bogdanov point BP_s, whereas the singularly perturbed saddle-nodes SN_s pass through this point. The points HP_s and Ho_s occur on different sides of the curve of SN_s points. For graphical reasons the points SN_s are drawn along the p_2-axis.

In the case of the FitzHugh–Nagumo equation (1.3) we obtain diagram (b) in Figure 2; i.e., the singularly perturbed homoclinic orbits and the singularly perturbed Hopf points are positioned on the a-axis. In particular they do not meet transversally at the origin. This is a degenerate situation which results from the fact that one of the normal form coefficients of the central u-system $\dot{u}_1 = u_2$, $\dot{u}_2 = -u_1^2 + u_1^3$ vanishes.

Diagram (c) in Figure 2 shows the singularly perturbed points of the van der Pol–Duffing oscillator (1.2) which represents an example of two times the standard case. Further examples of the standard case are given by the model equation (1.5) and the cell communication problems studied in [25].

The singularly perturbed saddle-node and Hopf points in the three systems (1.5),

(1.3), and (1.2) can be given explicitly. In general it is only possible to calculate the derivatives $SN_s'(0)$, $HP_s'(0)$, and $Ho_s'(0)$ of the curves at the singularly perturbed Bogdanov point. The following are the parameter values of the singularly perturbed points. In the case of the model equation (1.5) we obtain

$$\begin{aligned} SN_s: &\quad (\lambda\ ,k) = (0\ ,k)\ , &&\quad k \neq 0,\\ HP_s: &\quad (\lambda,k)\ = (\lambda,-\lambda), &&\quad \lambda < 0,\\ Ho_s: &\quad (\lambda,k)\ = (\lambda,k(\lambda)), &&\quad \lambda > 0 \quad \text{with} \quad \tfrac{d}{d\lambda}k(\lambda) \to \tfrac{5}{7} \quad \text{as} \quad \lambda \to 0 \end{aligned}$$

(cf. diagram (a) in Figure 2 with $p_1 = \lambda$, $p_2 = k$). In the case of the FitzHugh–Nagumo equation (1.3) the singularly perturbed points occur at

$$\begin{aligned} SN_s: &\quad (a,c) = (0,c), &&\quad c \neq 0,\\ HP_s: &\quad (a,c) = (a,0), &&\quad a < 0,\\ Ho_s: &\quad (a,c) = (a,0), &&\quad a > 0 \end{aligned}$$

(cf. diagram (b) in Figure 2) and, finally, for the van der Pol–Duffing oscillator (1.2) we have

$$\begin{aligned} SN_s: &\quad (p_1,p_2) = (5z^3 - 3z, 6z^2 - 6), &&\quad z \in (-1,1) \setminus \{\pm\tfrac{1}{\sqrt{3}}\},\\ HP_s: &\quad (p_1,p_2) = (\pm(p_2 + \tfrac{8}{3})/\sqrt{3}, p_2), &&\quad p_2 < -4,\\ Ho_s: &\quad (p_1,p_2) = (p_1^{\mp}(p_2), p_2) &&\quad \text{with} \quad \tfrac{d}{dp_2}p_1^{\mp}(p_2) \to \mp\tfrac{1}{5\sqrt{3}} \quad \text{as} \quad p_2 \to -4 \end{aligned}$$

(cf. diagram (c) in Figure 2). The curve SN_s is globally parametrized by the external parameter z such that the singularly perturbed Bogdanov points BP_s occur at $z = \pm 1/\sqrt{3}$.

Next we perturb these basic structures from $\epsilon = 0$ to $\epsilon \neq 0$; i.e., we perform the actual singular perturbation. Concerning this process note that the (u,v)-linearization of the system (2.5) at the singularly perturbed Bogdanov point $(u,v,p,\epsilon) = 0$ reads

$$\begin{pmatrix} F_u^0 & F_v^0 \\ 0\cdot G_u^0 & 0\cdot G_v^0 \end{pmatrix} \in \mathbb{R}^{3,3} \quad \text{with} \quad \operatorname{tr}(F_u)^0 = 0 \quad \text{and} \quad \det(F_u)^0 = 0 \tag{2.9}$$

implying an eigenvalue zero of multiplicity three. The multiplicity three results from multiplicity two of the Bogdanov point and the degeneracy caused by the continuum of stationary points that exists in the (u,v)-phase space of system (2.5) at $\epsilon = 0$ (cf. Figure 1(b)). Hence without considering the singular perturbation character of the system (2.5) we are confronted with a highly degenerate situation. On the other hand, the assumption (2.4) implies

$$\det\left(\begin{pmatrix} F_u & F_v \\ \epsilon\cdot G_u & \epsilon\cdot G_v \end{pmatrix}\right)(u,v,p_1,p_2,\epsilon) = \epsilon \cdot \det\left(\begin{pmatrix} F_u & F_v \\ G_u & G_v \end{pmatrix}\right)(u,v,p_1,p_2,\epsilon) \neq 0 \tag{2.10}$$

for $\epsilon \neq 0$; i.e., the threefold eigenvalue zero splits completely into eigenvalues different from zero during variation from $\epsilon = 0$ to $\epsilon \neq 0$. In particular there exist no saddle-node or Bogdanov points for $\epsilon \neq 0$ which simplifies the unfolding problem considerably.

Our aim is to extend the (p_1, p_2)-unfolding diagrams of Figure 2 in the direction of ϵ. We use results [8], [11], [1], [10], [26], and [27] that are valid on 2-dimensional sections in the 3-dimensional (p_1, p_2, ϵ)-unfolding space. These sections are indicated in diagram (c) of Figure 1. The theorems describe (to some extent) the unfolding structure near the singularly perturbed saddle-node and Hopf points. As usual these 2-dimensional diagrams shrink to zero when approaching the more degenerate situation of a singularly perturbed Bogdanov point at $p = 0$.

On the contrary, the homoclinic orbits are investigated by blowing up the singularly perturbed Bogdanov point BP_s appropriately; i.e., here we do not restrict ourselves to 2-dimensional sections, but we start from the center of the 3-dimensional (p_1, p_2, ϵ)-unfolding space. Concerning this process we apply a theorem from [4]. It should be noted though that we could also use blow-up transformations for the investigation of the singularly perturbed saddle-node and Hopf points. However, these scaling transformations hardly showed further information, so we restricted ourselves to the theorems from [26], [27] that were applicable in a direct way.

A lot of gaps remain for a complete understanding of the (p_1, p_2, ϵ)-unfolding diagram. Some of these gaps are examined by a combination of numerical results and heuristical considerations mainly obtained from the model equation (1.5).

In this case we arrive at the unfolding structures depicted in diagram (a) of Figure 3 (use $p_1 = \lambda$, $p_2 = k$). The numerical calculations were performed with [9] and programs from [22].

Roughly speaking, the diagram is characterized by three surfaces: A surface of Hopf points HP, a surface of Naimark–Sacker points NP (hatched), and a surface of homoclinic orbits (or homoclinic base points) Ho. The surface of Hopf points connects the singularly perturbed saddle-nodes SN_s and the singularly perturbed Hopf points HP_s that exist at $\epsilon = 0$. In addition the points HP_s give rise to the surface NP of Naimark–Sacker points; i.e., we obtain a surface of periodic orbits with a pair of complex-conjugate Floquet multipliers on the unit circle which implies generically the existence of a 3-dimensional domain of invariant tori near the surface of Naimark–Sacker points (cf. [15]).

The surface NP terminates at the curve NP_{-1} of periodic orbits with double Floquet multiplier -1. On the other hand we obtain the threefold Floquet multiplier 1 along the curve of HP_s-points at $\epsilon = 0$. Hence during variation along the dotted line [a] the two Floquet multipliers different from 1 pass along the unit circle from 1 to -1 as indicated in diagram (b). This leads to curves of NP-points in diagram (a) with fixed Floquet multipliers on the unit circle. These curves approach the central point $(p_1, p_2, \epsilon) = 0$. As an example, the curve of NP-points with fixed Floquet multipliers $\pm i$ is indicated by NP_i.

Passing to the study of maps via a Poincaré section the points NP_{-1} and NP_i are known as $1:2$ and $1:4$ resonances, respectively (see [20] for their unfolding). We conclude that the central (u, v)-system

$$\begin{aligned} \dot{u} &= F(u, v, 0, 0, 0), \\ \dot{v} &= 0 \end{aligned} \tag{2.11}$$

at $(p_1, p_2, \epsilon) = 0$ gives rise to completely different kinds of periodic orbits. The

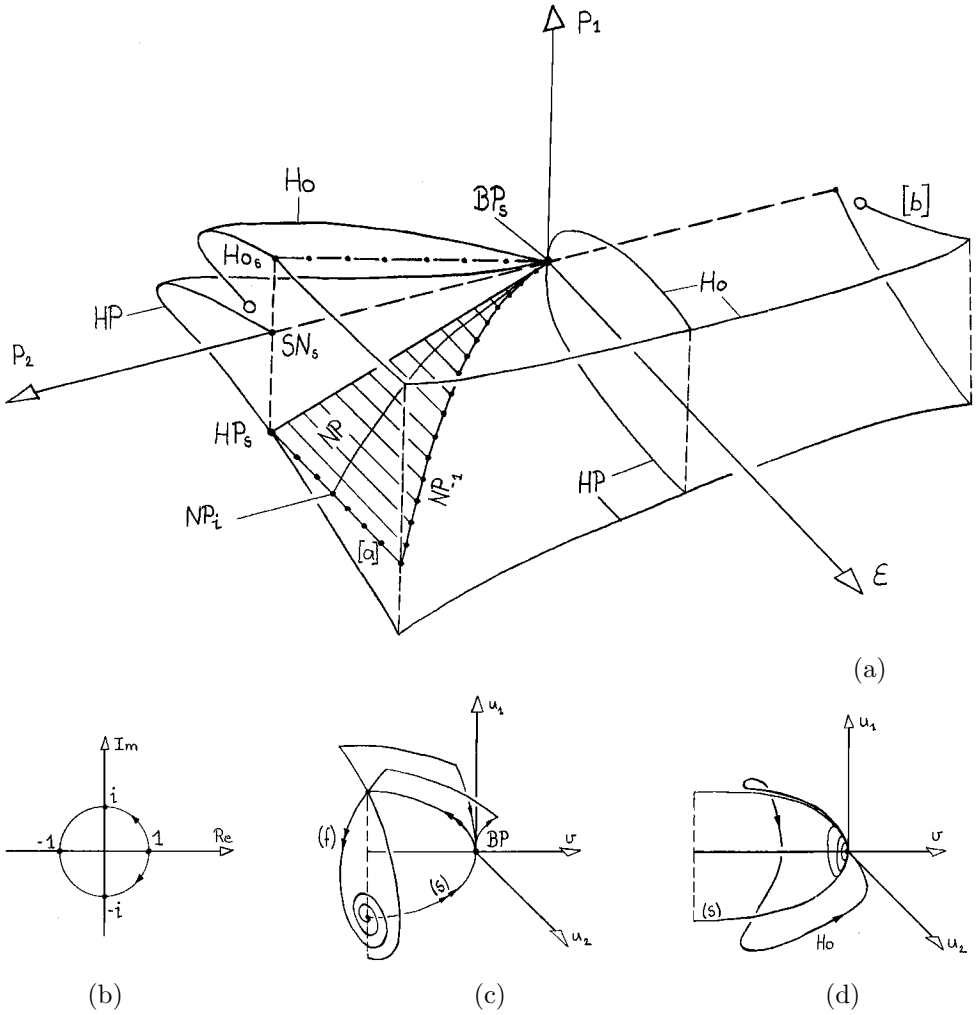

FIG. 3. (a) (p_1, p_2, ϵ)-*unfolding diagram;* (b) *Floquet multipliers along* [a]*;* (c) *a singular periodic orbit in the* (u, v)*-phase space of the central system* (2.11)*;* (d) *a typical homoclinic orbit of Shilnikov type near the border line of open circles.*

complete picture is unknown. Our suggestion is that the periodic orbits along NP_i or NP_{-1} start in a canard like manner from a singular periodic orbit (cf. [10]) of the system (2.11) composed of fast (f) and slow motions (s) as indicated by double arrows in the (u, v)-phase diagram (c). Note that the central (u, v)-system (2.11) inherits the continuum of stationary points (s) which consists of saddles and oscillating sinks (with respect to the fast u-dynamics) separated by a Bogdanov point BP at $v = 0$. Note also that diagram (c) is identical to the bifurcation diagram of the fast u-system shown in the lower half of diagram (b) in Figure 1.

Next we turn to the surface of homoclinic orbits Ho in diagram (a) that bifurcates from the singularly perturbed homoclinic base points Ho_s at $\epsilon = 0$. In general this bifurcation is not smooth in ϵ, i.e., the surface has an edge along the curve of Ho_s-points at $\epsilon = 0$ (cf. section 5).

Further, as indicated by the open circles the surface Ho is bordered by a curve

through the central point BP_s along which the homoclinic orbits vanish presumably by a canard like blow-up. More precisely, along the curve [b] we expect that the homoclinic orbits turn first into homoclinic orbits of Shilnikov type [15] and finally blow-up along the continuum of stationary points (s) of the central system (2.11) as indicated in diagram (d). Some additional features of this explosion process are described in section 5.6.

Now we return to the general system (2.5) under the assumptions (2.2)–(2.4) and (2.7). We expect that the structures in Figure 3 of the model equation (1.5) represent a typical unfolding diagram of singularly perturbed Bogdanov points in a generic situation. Some aspects of this claim are verified analytically in the next sections. Moreover, numerical calculations for the van der Pol–Duffing oscillator (1.2) (cf. [19]) and the cell communication problems in [25] confirm this conjecture.

We notice, however, that the Hamiltonian case (1.3) of the FitzHugh–Nagumo equation exhibits some special features (cf. diagram (b) in Figure 2). Therefore, we close this section with some remarks on deformations of the unfolding picture that might occur in specific examples.

First, the surfaces in Figure 3 diagram (a) may be bended diffeomorphically as usual; i.e., we are only interested in structures that are not destroyed by diffeomorphic parameter transformations. For example, the folds of Hopf and homoclinic base points shown in diagram (a) may vanish under an appropriate change of the parameters. On the other hand the transversal intersections of manifolds of singularly perturbed points represent diffeomorphic invariants.

Second, a singular perturbation problem of the form (2.5) contains at $(p_1, p_2, \epsilon) = 0$ a continuum of stationary points in the (u, v)-phase space defined by $F(u, v, 0) = 0$ (cf. (s) in diagram (c) of Figure 3). Even in the weak sense of algebraic singularity theory [13] this leads to a completely degenerate situation, i.e., a codim $= \infty$ situation occurs, so that we cannot hope to grasp all possible phenomena near a singularly perturbed Bogdanov point with the help of a certain normal form. In this sense singular perturbation problems do not fit into the framework of universal unfoldings which are based on the fact that higher order derivatives do not change the qualitative behavior of the system.

Nevertheless, every singularly perturbed Bogdanov point with a generic unfolding will show the properties that are completely determined by the derivatives involved in (2.2)–(2.4) and (2.7). But the phenomena which depend on higher derivatives will change for different singularly perturbed Bogdanov points. In spite of this principal lack of completeness which occurs in singular perturbation problems we hope that our results grasp the essential features of singularly perturbed Bogdanov points.

3. A pretransformation. First we perform a pretransformation of the system (2.5) under the slightly weaker assumption (cf. (2.7))

$$\text{rank} \left(\begin{pmatrix} F_u & F_v & F_{p_1} & F_{p_2} \\ G_u & G_v & G_{p_1} & G_{p_2} \\ \det_u(F_u) & \det_v(F_u) & \det_{p_1}(F_u) & \det_{p_2}(F_u) \end{pmatrix}^0 \right) = 4. \tag{3.1}$$

The transformed system will represent a certain normal form of a singularly perturbed Bogdanov point within a generic unfolding.

According to the assumption (2.2) the point $u = 0$ is a Bogdanov point of the system $\dot{u} = F(u, 0)$. Hence there exist $\varphi_2, \psi_1, \psi_2 \in \mathbb{R}^2 \setminus \{0\}$ with

$$F_u^0 \varphi_2 = \varphi_1, \qquad \psi_2^T F_u^0 = 0, \qquad \psi_1^T F_u^0 = \psi_2^T, \qquad \psi_i^T \varphi_j = \delta_{ij}. \tag{3.2}$$

Further, the system $\dot{u} = F(u, v, 0)$ has a quadratic limit point with respect to v (cf. (2.3)). Thus, there exist a surface of quadratic limit points $(u, v)^L(p_1, p_2, \epsilon)$ of $\dot{u} = F(u, v, p_1, p_2, \epsilon)$ and smooth tangent vectors $\phi_1(p_1, p_2, \epsilon)$ such that $(u, v)^L(0) = 0$, $\phi_1(0) = \varphi_1$. This follows from the implicit function theorem applied to the equation $[F, \det(F_u)][u, v, p_1, p_2, \epsilon] = 0$. We obtain the identity $[F, \det(F_u)^0][(u, v)^L(p_1, p_2, \epsilon), p_1, p_2, \epsilon] = 0$ and differentiation with respect to $p = (p_1, p_2)$ yields

$$\begin{pmatrix} u_p^L \\ v_p^L \end{pmatrix}(0) = -\begin{pmatrix} F_u^0 & F_v^0 \\ \det_u(F_u)^0 & \det_v(F_u)^0 \end{pmatrix}^{-1} \cdot \begin{pmatrix} F_p^0 \\ \det_p(F_u)^0 \end{pmatrix}, \tag{3.3}$$

where the regularity of the matrix follows from (2.2), (2.3). Next we substitute the limit points into the equation $G = 0$; i.e., we analyze $G[(u, v)^L(p, \epsilon), p, \epsilon] = 0$. At $(p, \epsilon) = 0$ we have $G[(u, v)^L(0), 0] = G^0 = 0$ and (3.1), (3.3) imply

$$\frac{d}{dp} G[(u, v)^L(0), 0] = (G_u^0, G_v^0) \cdot \begin{pmatrix} u_p^L \\ v_p^L \end{pmatrix}(0) + G_p^0 \neq (0, 0). \tag{3.4}$$

Without loss of generality we may assume $\frac{d}{dp_1} G[(u, v)^L(0), 0] \neq 0$. Hence there exists a unique smooth function $p_1(p_2)$ satisfying $p_1(0) = 0$ and

$$G[(u, v)^L(p_1(p_2), p_2, 0), p_1(p_2), p_2, 0] = 0; \tag{3.5}$$

i.e., within the 2-dimensional surface of limit points $(u, v)^L(p, 0)$ of the u-system $\dot{u} = F(u, v, p, 0)$ we obtain a curve of limit points which satisfies $G = 0$. Now we define the matrices $\phi(p, \epsilon) := [\phi_1(p, \epsilon), \varphi_2] \in \mathbb{R}^{2,2}$ and consider the transformation

$$\begin{aligned} p_1 &= p_1(k) + \lambda, \\ p_2 &= k, \\ u &= u^L[p_1(k) + \lambda, k, \epsilon] + \phi[p_1(k) + \lambda, k, \epsilon] \cdot x =: u(x, \lambda, k, \epsilon), \\ v &= v^L[p_1(k) + \lambda, k, \epsilon] + y =: v(y, \lambda, k, \epsilon); \end{aligned} \tag{3.6}$$

i.e., the limit points are moved to the origin of phase space, the limit points which satisfy $G = 0$ at $\epsilon = 0$ are positioned on the k-axis, and a linear normalization of the u-components is performed. We arrive at the system

$$\begin{aligned} \dot{x} &= \phi^{-1}[p_1(k) + \lambda, k, \epsilon] \cdot F[u(x, \lambda, k, \epsilon), v(y, \lambda, k, \epsilon), p_1(k) + \lambda, k, \epsilon] \\ &=: f(x, y, \lambda, k, \epsilon), \\ \dot{y} &= \epsilon \cdot G[u(x, \lambda, k, \epsilon), v(y, \lambda, k, \epsilon), p_1(k) + \lambda, k, \epsilon] \\ &=: \epsilon \cdot g(x, y, \lambda, k, \epsilon) \end{aligned} \tag{3.7}$$

which satisfies

$$f(0, 0, \lambda, k, \epsilon) \equiv 0, \qquad f_{x_1}(0, 0, \lambda, k, \epsilon) \equiv 0, \qquad g(0, 0, 0, k, 0) \equiv 0,$$

$$\begin{pmatrix} f_x & f_y \\ g_x & g_y \end{pmatrix}^0 = \begin{pmatrix} 0 & 1 & \psi_1^T F_v^0 \\ 0 & 0 & \psi_2^T F_v^0 \\ G_u^0 \varphi_1 & G_u^0 \varphi_2 & G_v^0 \end{pmatrix} \quad \text{nonsingular,}$$

$$g_\lambda^0 = (G_u \quad G_v \quad G_{p_1})^0 \cdot \begin{pmatrix} u_{p_1}^L \\ v_{p_1}^L \\ 1 \end{pmatrix}(0) \neq 0,$$

(3.8)

$$p_1'(0) = -\frac{1}{g_\lambda^0}(G_u \quad G_v \quad G_{p_2})^0 \cdot \begin{pmatrix} u_{p_2}^L \\ v_{p_2}^L \\ 1 \end{pmatrix}(0),$$

$$(f_{x_1x_1} \quad f_{x_1x_2})^0 = \begin{pmatrix} \psi_1^T \\ \psi_2^T \end{pmatrix} \cdot (F_{uu}^0\varphi_1^2 \quad F_{uu}^0\varphi_1\varphi_2) \qquad \text{with} \qquad f_{2x_1x_1}^0 \neq 0,$$

$$(f_{2x_2\lambda} \quad f_{2x_2k})^0 = (\mathrm{tr}_u(F_u) \quad \mathrm{tr}_v(F_u) \quad \mathrm{tr}_p(F_u))^0 \cdot \begin{pmatrix} u_p^L \\ v_p^L \\ I_2 \end{pmatrix}(0) \cdot \begin{pmatrix} 1 & p_1'(0) \\ 0 & 1 \end{pmatrix}.$$

The last identity follows after a lengthy but straightforward calculation using (3.2) and

$$F_u[(u,v)^L(p,0),p,0]\cdot\phi_1(p,0) = 0,$$

(3.9)

$$\mathrm{tr}_a(F_u)^0 = \psi_1^T F_{ua}^0\varphi_1 + \psi_2^T F_{ua}^0\varphi_2 \qquad \text{for} \qquad a = u_1, u_2, v, p_1, p_2.$$

Moreover we obtain from (3.3) and (3.8) after some calculations

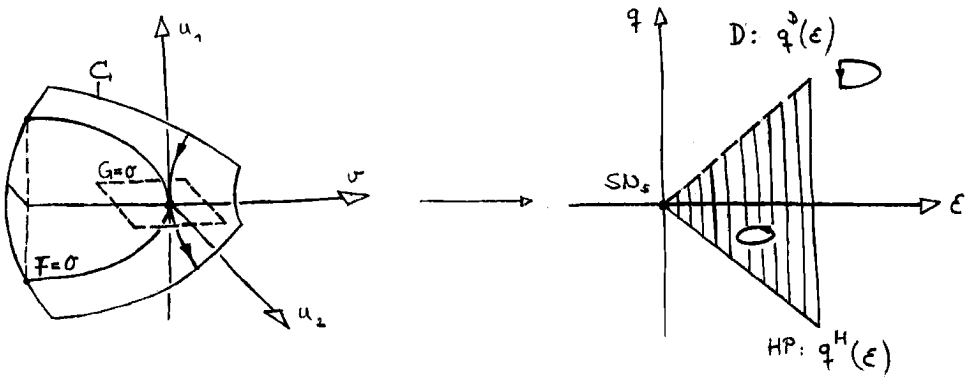
(3.10)

$$\begin{aligned} f_{2x_2k}^0 &= -\frac{1}{g_\lambda^0}\cdot\det\left(\begin{pmatrix}\mathrm{tr}_u(F_u) & \mathrm{tr}_v(F_u)\\ G_u & G_v\end{pmatrix}^0\cdot\begin{pmatrix}u_p^L\\ v_p^L\end{pmatrix}(0) + \begin{pmatrix}\mathrm{tr}_p(F_u)\\ G_p\end{pmatrix}^0\right)\\ &= \frac{1}{g_\lambda^0}\cdot\det\left(\begin{pmatrix}\mathrm{tr}_u(F_u) & \mathrm{tr}_v(F_u)\\ G_u & G_v\end{pmatrix}\begin{pmatrix}F_u & F_v\\ \det_u(F_u) & \det_v(F_u)\end{pmatrix}^{-1}\begin{pmatrix}F_p\\ \det_p(F_u)\end{pmatrix}\right.\\ &\quad \left. - \begin{pmatrix}\mathrm{tr}_p(F_u)\\ G_p\end{pmatrix}\right)^0. \end{aligned}$$

Note that the defining condition (2.7) of a generic unfolding implies $f_{2x_2k}^0 \neq 0$, whereas the weaker assumption (3.1) of this section does not exclude the case $f_{2x_2k}^0 = 0$. The homoclinic orbits of the systems (2.5) and (3.7) depend heavily on this coefficient. In the analysis of singularly perturbed saddle-node and Hopf points (cf. section 4) we restrict to $f_{2x_2k}^0 \neq 0$, whereas the singularly perturbed homoclinic orbits are investigated for $f_{2x_2k}^0 = 0$ as well (cf. section 5). In the case of $f_{2x_2k}^0 = 0$ we require further coefficients to be different from zero.

4. Unfolding singularly perturbed saddle-node and Hopf points. First we state the necessary definitions. This is done completely analogous to Definitions 2.1 and 2.2 of a singularly perturbed Bogdanov point and its generic unfolding. For definiteness the singularly perturbed points are assumed to lie in the origin.

DEFINITION 4.1. *A point* $(u,v,\epsilon) = 0$ *which satisfies* $tr(F_u)^0 \neq 0$ *and the remaining conditions in* (2.2)–(2.4) *is called a singularly perturbed saddle-node of the system* (2.1).



(a) (b)

FIG. 4. (a) *The basic configuration for the fast subsystem* $\dot{u} = F(u, v, 0, 0)$ *and the surface defined by* $G(u, v, 0, 0) = 0$, *C=center manifold;* (b) *the corresponding* (q, ϵ)*-unfolding diagram of the singularly perturbed saddle-node* SN_s.

DEFINITION 4.2. *A point* $(u, v, \epsilon) = 0$ *which satisfies* $det(F_u)^0 > 0$ *and the remaining conditions in* (2.2) *and* (2.4) *is called a singularly perturbed Hopf point of the system* (2.1).

Apart from the basic condition $(F, G)^0 = 0$ singularly perturbed saddle-node and Hopf points satisfy the degeneracy condition $\det(F_u)^0 = 0$ and $\mathrm{tr}(F_u)^0 = 0$, respectively. Hence we are led to investigate these points within a parameter unfolding of one parameter $q \in \mathbb{R}$

$$\begin{aligned} \dot{u} &= F(u, v, q, \epsilon) \in \mathbb{R}^2, \\ \dot{v} &= \epsilon \cdot G(u, v, q, \epsilon) \in \mathbb{R}. \end{aligned} \tag{4.1}$$

The corresponding nondegeneracy condition of the parameter unfolding (4.1) is again determined with the help of the defining equations

$$H_{SN_s}(u, v, q) := \begin{pmatrix} F(u, v, q, 0) \\ G(u, v, q, 0) \\ \det(F_u)(u, v, q, 0) \end{pmatrix} = 0, \qquad H_{SN_s} : \mathbb{R}^4 \to \mathbb{R}^4 \tag{4.2}$$

and

$$H_{HP_s}(u, v, q) := \begin{pmatrix} F(u, v, q, 0) \\ G(u, v, q, 0) \\ \mathrm{tr}(F_u)(u, v, q, 0) \end{pmatrix} = 0, \qquad H_{HP_s} : \mathbb{R}^4 \to \mathbb{R}^4, \tag{4.3}$$

respectively.

DEFINITION 4.3. *The q-unfolding* (4.1) *of system* (2.1) *is a generic unfolding of a singularly perturbed saddle-node (singularly perturbed Hopf point) if* $H'_{SN_s}(0) \in \mathbb{R}^{4,4}$ *is nonsingular (*$H'_{HP_s}(0) \in \mathbb{R}^{4,4}$ *is nonsingular).*

Singularly perturbed saddle-nodes have been examined in many papers; see, for example, [8], [11], [1], [10], [26]. We collect some results that are valid for a singularly perturbed saddle-node within a generic unfolding in the following theorem.

THEOREM 4.4. *There exists a* (q,ϵ)*-unfolding diagram of system* (4.1) *as depicted in diagram* (b) *of Figure* 4.

There exists a one-sided curve of Hopf points $q^H(\epsilon)$ *from which small periodic orbits bifurcate in the direction of* q*. The periodic orbits exist in the hatched region and they blow-up to some global object within an exponentially small strip of canard orbits indicated by the line* $q^D(\epsilon)$*.*

In diagram (a) we show the basic configuration for the fast subsystem $\dot{u} = F(u,v,0,0)$, $\dot{v} = 0$ with the saddle-node at $v = 0$. Here we indicate also an invariant center manifold C that comprises the continuum of stationary points (defined by $F(u,v,0,0) = 0$) and the saddle-node dynamics at $v = 0$. In [26] the precise location of $(q^H, q^D)(\epsilon)$ and the stability of the periodic orbits are expressed in terms of the reduced system on the center manifold. In the next section we repeat these calculations (to some extent) for the singularly perturbed saddle-nodes of the pretransformed system (3.7). Using the center manifold C Theorem 4.4 can be extended to $(n+1)$-dimensional systems of the form $\dot{x} = F(u,v,q,\epsilon) \in \mathbb{R}^n$, $\dot{v} = \epsilon G(u,v,q,\epsilon) \in \mathbb{R}$.

Next we turn to singularly perturbed Hopf points within a generic unfolding. In [27] points of this type are investigated under the additional nondegeneracy condition

$$\operatorname{tr}_u(F_u)^0 \cdot (F_u^0)^{-1} \cdot F_v^0 - \operatorname{tr}_v(F_u)^0 \neq 0 \ . \tag{4.4}$$

Comparing Definitions 4.1 and 4.2 of singularly perturbed saddle-node and Hopf points we see that condition (2.3) is skipped in definition 4.2 of a singularly perturbed Hopf point. Instead we assume now the nondegeneracy condition (4.4).

Both of the conditions (2.3) and (4.4) ensure that an eigenvalue of the fast u-system $\dot{u} = F(u,v,0,0)$ passes the imaginary axis with nonvanishing velocity along the branch of stationary points given by $F(u,v,0,0) = 0$. In the case of a singularly perturbed saddle-node the imaginary axis is passed at zero yielding a quadratic limit point with respect to v (cf. Figure 4 (a)). In case of a singularly perturbed Hopf point with (4.4) the imaginary axis is passed at $\pm i\sqrt{\det(F_u)^0}$ and we obtain the well-known Hopf bifurcation of periodic orbits for the fast u-system as indicated in diagram (a) of Figure 5 below. Before turning to the corresponding (q,ϵ)-unfolding diagram shown in Figure 5(b) we add some remarks concerning the necessity of the conditions (2.3) and (4.4).

In [26] the velocity condition (2.3) is ignored and we require further coefficients to be different from zero. We obtain singularly perturbed points of higher degeneracy, e.g., *singularly perturbed cusp points*. We believe that we could also relax the velocity condition (4.4) of a singularly perturbed Hopf point. This is motivated by numerical calculations and the fact that also the singularly perturbed homoclinic orbits treated in section 5 do not require a velocity condition with respect to v (intersection of stable and unstable manifold with nonvanishing velocity).

The condition (4.4) prevents the investigation of the singularly perturbed Hopf points of the FitzHugh–Nagumo equation (1.3). They occur at $c = 0$, $a < 0$ (cf. Figure 2(b)) within the family of Hamiltonian systems $\dot{u}_1 = u_2$, $\dot{u}_2 = u_1(u_1 - a)(u_1 - 1) + v$. We obtain for fixed $a < 0$ a v-dependent system that possesses a branch of stationary points which is completely filled up with Hopf points. Hence the eigenvalues remain on the imaginary axis along $F = 0$ and the results of this paper about singularly perturbed Hopf points (see Theorem 4.5 below) are not applicable in a direct way. However, note that the parameter values $a < 0$ are of no biological relevance. The results of this paper about singularly perturbed saddle-nodes and singularly perturbed homoclinic orbits are applicable to the FitzHugh–Nagumo equation as well. These phenomena occur for the biological relevant parameter values $a \geq 0$.

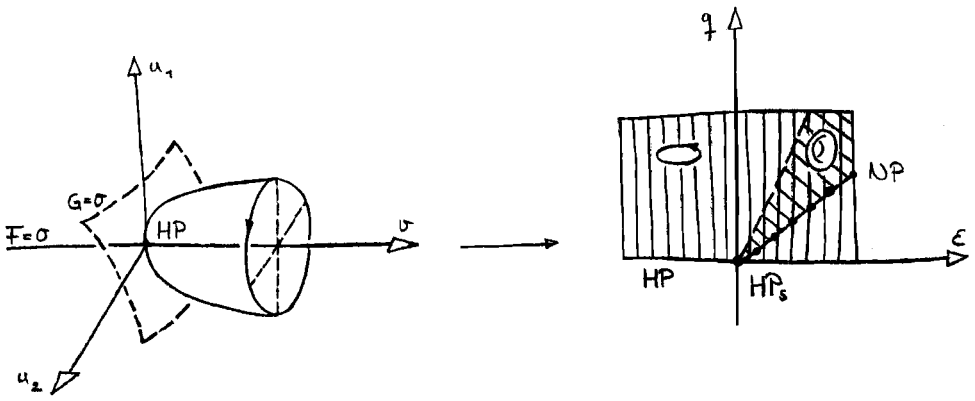


FIG. 5. (a) *The basic configuration for the fast subsystem* $\dot{u} = F(u, v, 0, 0)$ *and the surface defined by* $G(u, v, 0, 0) = 0$*;* (b) *a typical* (q, ϵ)*-unfolding diagram of a singularly perturbed Hopf point* HP_s*.*

We collect some results from [27] that are valid for a singularly perturbed Hopf point within a generic unfolding in the following theorem.

THEOREM 4.5. *Under the nondegeneracy condition* (4.4) *there exists a* (q, ϵ)*-unfolding diagram of system* (4.1) *as depicted in diagram* (b) *of Figure* 5*.*

There exists a curve of Hopf points HP through the origin (transversal to the q-axis) from which periodic orbits bifurcate in the direction of q. The periodic orbits exist in the weakly hatched region which represents a 2*-dimensional surface of periodic orbits. Depending on the sign of a characteristic constant* κ*, the surface contains a curve NP of periodic orbits with a conjugate-complex pair of Floquet multipliers on the unit circle. Typically these orbits give rise to invariant tori that are indicated in the cross hatched region.*

In the case of the van der Pol–Duffing oscillator the singularly perturbed Hopf points occur at $p_1 = \pm(p_2 + \frac{8}{3})/\sqrt{3}$, $p_2 < -4$. A corresponding unfolding diagram can be found in [19, Figure 12(a)] .

The rather technical derivation and an explicit formula of the characteristic constant κ can be found in [25], [27]. Figure 5(b) represents the case $\kappa < 0$. The precise properties of the cross hatched region with invariant tori are not known and its border is indicated by a broken line and drawn in an arbitrary fashion.

Note that at $\epsilon = 0$ not any invariant torus can survive in the resulting 2-dimensional system $\dot{u} = F(u, v, q, 0)$, $\dot{v} = 0$. This is a typical feature of singular perturbation problems, where the lower dimensional $\epsilon = 0$ system cannot show the higher dimensional phenomena that may exist in the full system. Note also that the invariant tori appear as a consequence of coupling effects between the fast x-variables and the slow y-variable. Analogous to singularly perturbed saddle-nodes we can extend Theorem 4.5 to $(n + 1)$-dimensional systems of the form $\dot{u} = F(u, v, q, \epsilon) \in \mathbb{R}^n$, $\dot{v} = \epsilon \cdot G(u, v, q, \epsilon) \in \mathbb{R}$ with the help of a reduction to a center manifold.

In concrete examples it is often rather cumbersome to calculate explicitly all the characteristic coefficients that determine quantitatively the unfolding structure depicted in diagrams (b) of Figures 4 and 5 (stability, bifurcation direction, ...). In particular at a singularly perturbed Hopf point higher order variational equations

must be solved which suggests using computeralgebraic programs. In the case of singularly perturbed Hopf points we shall mainly restrict to numerical results.

In [25], [26] we extend our unfolding scheme of singularly perturbed points to singularly perturbed periodic orbits using an averaging procedure. Additionally, we relax in [25] the transversality condition (2.4) for the nullclines of F and G. In a certain sense we obtain a hierarchical structure of singular perturbation problems in case the slow manifold loses its hyperbolicity which means that the well-known reduction to the slow manifold [12] is not possible.

In the next section we prove first the existence and location of the curves of singularly perturbed saddle-nodes SN_s and Hopf points HP_s as depicted in Figure 2. Then we shall see that these points are generically unfolded and we can apply Theorems 4.4 and 4.5 on appropriate sections in the (p_1, p_2, ϵ)-unfolding space of a singularly perturbed Bogdanov point.

This is done for the pretransformed (x, y)-system (3.7). It is always obvious how to transfer the results from the (λ, k, ϵ)-space into the (p_1, p_2, ϵ)-parameter space of the original system (2.5). The p_1-axis and the p_2-axis in Figures 2 and 3 are often referred to as λ-axis and k-axis, respectively.

4.1. Singularly perturbed saddle-nodes. Recalling (3.8), (3.10) and Definitions 4.1 and 4.3 it is straightforward to see that the points $(x, y, \lambda, k, \epsilon) = (0, 0, 0, k, 0)$ represent for fixed $k \neq 0$ singularly perturbed saddle-nodes of system (3.7) within a generic $(q, \epsilon) = (\lambda, \epsilon)$-unfolding. Note that the linearization at these points is given by

$$\begin{pmatrix} f_x & f_y \\ 0 \cdot g_x & 0 \cdot g_y \end{pmatrix}(0, k, 0) = \begin{pmatrix} 0 & f_{1x_2} & f_{1y} \\ 0 & f_{2x_2} & f_{2y} \\ 0 & 0 & 0 \end{pmatrix}(0, k, 0) \tag{4.5}$$

with $f_{1x_2}(0, k, 0) = 1 + O(k)$, $f_{2x_2}(0, k, 0) = f^0_{2x_2k} \cdot k + O(k^2)$, $f_{2y}(0, k, 0) \neq 0$, and $f^0_{2x_2k} \neq 0$ due to the assumption of a generic unfolding of a singularly perturbed Bogdanov point.

We obtain for every $k \neq 0$ the algebraically double and geometrically simple eigenvalue zero with generalized eigenspace $\operatorname{span}\{(1, 0, 0)^T, (0, f_{2y}(0, k, 0), -f_{2x_2}(0, k, 0))^T\}$ and hence there exists for every $k \neq 0$ a local center manifold which can be parametrized by the coordinates (x_1, y) and the parameters (λ, k, ϵ) (cf. [24] and Figure 4 (a)). Strictly speaking there exists a smooth function $x_2(x_1, y, \lambda, k, \epsilon)$, $k \neq 0$ such that the surface

$$(x_1, x_2, y) = (x_1, x_2(x_1, y, \lambda, k, \epsilon), y), \qquad k \neq 0 \tag{4.6}$$

remains invariant under the flow of system (3.7) in the (x_1, x_2, y)-phase space. Graphically, we obtain for fixed $k \neq 0$ and $(\lambda, \epsilon) = 0$ an invariant manifold C as indicated in diagram (a) of Figure 4. The x_1-expansion at $(y, \lambda, \epsilon) = 0$ is given by

$$x_2(x_1, 0, 0, k, 0) = -\frac{1}{2}\frac{f_{2x_1x_1}}{f_{2x_2}}(0, k, 0) \cdot x_1^2 + O(x_1^3), \qquad k \neq 0. \tag{4.7}$$

The dynamics on the invariant surface reads

$$\begin{aligned} \dot{x}_1 &= f_1(x_1, x_2(x_1, y, \lambda, k, \epsilon), y, \lambda, k, \epsilon) =: \bar{f}(x_1, y, \lambda, k, \epsilon), \\ \dot{y} &= \epsilon \cdot g(x_1, x_2(x_1, y, \lambda, k, \epsilon), y, \lambda, k, \epsilon) =: \epsilon \cdot \bar{g}(x_1, y, \lambda, k, \epsilon) \end{aligned} \tag{4.8}$$

and we again have the ordinary singular perturbation form (1.1). At $(x_1, y, \lambda, k) = (0, 0, 0, k)$ we obtain quadratic limit points with respect to y of the x_1-system $\dot{x}_1 = \bar{f}(x_1, y, 0, k, 0)$ satisfying $\bar{g}(0, 0, 0, k, 0) = 0$. Along the section $y = 0$ the fast x_1-dynamics on the center manifold is given by

$$\begin{aligned} \dot{x}_1 &= \bar{f}(x_1, 0, 0, k, 0) \\ &= -\frac{1}{2f_{2x_2}(0,k,0)} \cdot \det\left(\begin{pmatrix} f_{1x_2} & f_{1x_1x_1} \\ f_{2x_2} & f_{2x_1x_1} \end{pmatrix}\right)(0,k,0) \cdot x_1^2 + O(x_1^3) \end{aligned} \tag{4.9}$$

as can be seen by direct calculation. Recalling (3.8) the leading coefficient in (4.9) is well defined and different from zero for $k \neq 0$ which implies a saddle-node dynamics on the center manifold [15]. Qualitatively, this saddle-node dynamics is depicted in Figure 4(a) along the section $v = 0$. As expected the leading coefficient in (4.9) tends to infinity if we approach the Bogdanov point at $k = 0$.

We can apply Theorem 4.4 to the singularly perturbed saddle-nodes $(x, y, \lambda, k, \epsilon) = (0, 0, 0, k, 0)$, $k \neq 0$ of system (3.7), and obtain (λ, ϵ)-unfolding diagrams as depicted in diagram (b) of Figure 4.

The precise location of $(q^H, q^D)(\epsilon, k) = (\lambda^H, \lambda^D)(\epsilon, k)$ and the stability of the periodic orbits depend on certain derivatives of $\bar{f}$ and $\bar{g}$ at the singularly perturbed saddle-nodes. With the setting $(\bar{f}, \bar{g})^0 := (\bar{f}, \bar{g})(0, k, 0)$, $k \neq 0$ and with $-\bar{g}^0_{x_1}\bar{f}^0_y > 0$, it is shown in [25], [26] that the hatched region of periodic orbits exists for $\epsilon > 0$ and we obtain

$$\lambda^H_\epsilon(0,k) = -\frac{A+G}{B} \qquad \text{and} \qquad \lambda^D_\epsilon(0,k) = -\frac{(C+F)E+3D}{BE^2}, \tag{4.10}$$

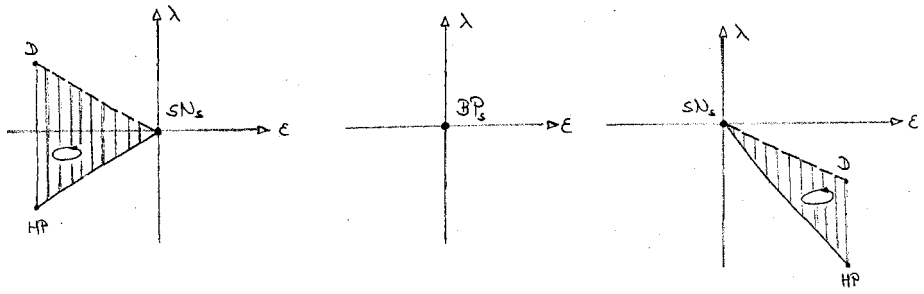
where

$$\begin{aligned} d &:= \sqrt{-\bar{g}^0_{x_1}\bar{f}^0_y} > 0, \\ A &:= \tfrac{1}{d^3}\cdot(\bar{f}_{x_1x_1}(\bar{f}_y\bar{g}_\epsilon - \bar{g}_y\bar{f}_\epsilon) - \bar{g}_{x_1}(\bar{f}_{\epsilon x_1}\bar{f}_y - \bar{f}_{yx_1}\bar{f}_\epsilon))^0, \\ B &:= \tfrac{1}{d^3}\cdot(\bar{f}_{x_1x_1}(\bar{f}_y\bar{g}_\lambda - \bar{g}_y\bar{f}_\lambda) - \bar{g}_{x_1}(\bar{f}_{\lambda x_1}\bar{f}_y - \bar{f}_{yx_1}\bar{f}_\lambda))^0 \neq 0, \\ C &:= \bar{f}^0_{x_1y}, \\ D &:= \tfrac{1}{6d}\cdot(\bar{f}_{x_1x_1x_1}\bar{f}^2_y - 3\bar{f}_{x_1y}\bar{f}_{x_1x_1}\bar{f}_y)^0, \\ E &:= \tfrac{1}{d}\cdot(\bar{f}_{x_1x_1}\bar{f}_y)^0 \neq 0, \\ F &:= \tfrac{1}{2d^2}\cdot(\bar{g}_{x_1x_1}\bar{f}^2_y - \bar{g}_y\bar{f}_{x_1x_1}\bar{f}_y)^0, \\ G &:= \tfrac{1}{d}\cdot\bar{g}^0_y\ . \end{aligned} \tag{4.11}$$

The inequalities $-\bar{g}^0_{x_1}$, $\bar{f}^0_y \neq 0$ and B, $E \neq 0$ follow by direct calculation from (3.8). In the case of $-\bar{g}^0_{x_1}\bar{f}^0_y < 0$ the periodic orbits exist for $\epsilon < 0$ and the formulas (4.10), (4.11) can be applied after performing the trivial transformation $\epsilon \to -\epsilon$.

Now the model equation (1.5) yields for $k > 0$ and $k < 0$ the left and right diagram in Figure 6, respectively.

For $k > (<)\ 0$ the periodic orbits exist locally for $\epsilon < (>)\ 0$. The derivative of the curve of Hopf points at $\epsilon = 0$ reads $\lambda^H_\epsilon(0,k) = \frac{1}{2k}$ whereas the canard orbits satisfy $\lambda^D_\epsilon(0,k) \equiv -\frac{1}{4}$. Note that our center manifold approach breaks down as



$k > 0$ $k = 0$ $k < 0$

FIG. 6. *The (λ, ϵ)-unfolding diagrams near the singularly perturbed saddle-nodes of the model equation* (1.5).

k tends to zero and we obtain no information in the middle diagram at $k = 0$. The diagrams represent incomplete (λ, ϵ)-sections through the $(p_1, p_2, \epsilon) = (\lambda, k, \epsilon)$-unfolding diagram in Figure 3(a) near the singularly perturbed saddle-nodes SN_s. Similar results are valid for the general system (2.5) and hence for the FitzHugh–Nagumo equation (1.3) and the van der Pol–Duffing oscillator (1.2). The formulas become much more involved and we do not state them here. Note that the derivatives in (4.11) are calculated after the center manifold reduction is performed.

4.2. Singularly perturbed Hopf points. In this section we are looking for Hopf points of the fast x-system $\dot{x} = f(x, y, \lambda, k, 0)$ from (3.7) which satisfy $g(x, y, \lambda, k, 0) = 0$. The corresponding defining equation reads

$$\begin{pmatrix} f \\ g \\ \operatorname{tr}(f_x) \end{pmatrix} (x, y, \lambda, k, 0) =: H(x, y, k, \lambda) = 0, \qquad H : \mathbb{R}^5 \to \mathbb{R}^4. \tag{4.12}$$

From (3.8) we obtain $H(0) = 0$ and $H_{x,y,k}(0)$ regular. Hence there exists a unique function $(x, y, k)^H(\lambda)$ with $(x, y, k)^H(0) = 0$ and $H[(x, y, k)^H(\lambda), \lambda] = 0$. Moreover, with the setting $\bar{H}(\lambda) := \det(f_x)[(x, y)^H(\lambda), \lambda, k^H(\lambda), 0]$ a simple calculation yields $\bar{H}'(0) = f^0_{2x_1x_1} g^0_\lambda / g^0_{x_1} \neq 0$; i.e., in the case of $\bar{H}'(0) > (<)\ 0$ the curve $(x, y, k)^H(\lambda)$ represents for $\lambda > (<)\ 0$ a curve of Hopf points in the family of x-systems $\dot{x} = f(x, y, \lambda, k, 0)$. Moreover we have $g = 0$ along this curve and hence a curve of singularly perturbed Hopf points within a generic $(q, \epsilon) = (k, \epsilon)$-unfolding occurs. The derivative of the k-component at $\lambda = 0$ reads

$$k^H_\lambda(0) = \frac{\operatorname{tr}_{x_1}(f_x)^0 \cdot g^0_\lambda - f^0_{2x_2\lambda} \cdot g^0_{x_1}}{f^0_{2x_2k} \cdot g^0_{x_1}}. \tag{4.13}$$

We can apply Theorem 4.5 at the singularly perturbed Hopf points if the nondegeneracy condition (4.4) is satisfied which ensures that the pair of conjugate-complex eigenvalues passes the imaginary axis with nonvanishing velocity. It is not difficult to see that the velocity condition is satisfied if the Bogdanov point of the fast system gives rise to an unfolding diagram as shown in diagram (a) of Figure 1. This diagram shows the standard case.

Concerning the model equation (1.5) (which represents the standard case) the singularly perturbed Hopf points occur at $k^H(\lambda) = -\lambda$, $\lambda < 0$. In particular we

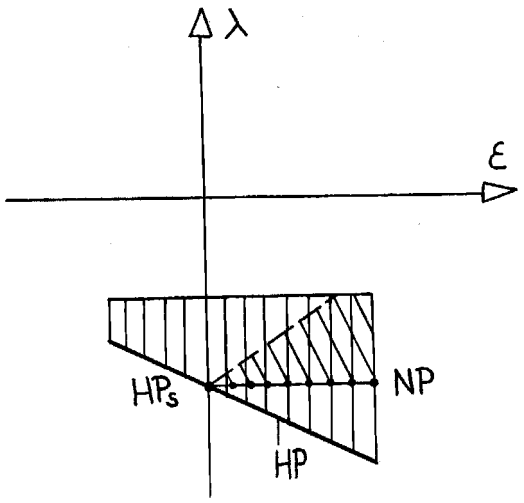


FIG. 7. *The (λ, ϵ)-unfolding diagram near the singularly perturbed Hopf points of the model equation.*

have $k^H(\lambda) \neq 0$ and it is also possible to parametrize the singularly perturbed Hopf points by k. Then Theorem 4.5 can be also applied to $(q, \epsilon) = (\lambda, \epsilon)$-sections for fixed $k > 0$ and we obtain the (λ, ϵ)-unfolding diagram as depicted in Figure 7. The Hopf points HP occur at $\epsilon = 2\lambda(\lambda + k)$, $\lambda < 0$ and the Naimark–Sacker points NP at $(\lambda, \epsilon) = (-k, \epsilon)$, $\epsilon > 0$.

Remember that Figures 6 and 7 show the local (λ, ϵ)-unfoldings of the model equation (1.5) near the singularly perturbed saddle-node and Hopf points. These local diagrams are connected by the parabolic Hopf curve $\epsilon = 2\lambda(\lambda + k)$, $\lambda < 0$ and we obtain for fixed $k > 0$ the global (λ, ϵ)-diagram as indicated in Figure 8. Moreover, the dotted NP-points terminate at the point NP_{-1} that represents a periodic orbit with double Floquet multiplier -1. Hence the two Floquet multipliers different from zero are moving along the unit circle from 1 to -1 during variation along the curve of NP-points (cf. diagram (b) in Figure 3).

Figure 8 shows a detailed (λ, ϵ)-section through the (λ, k, ϵ)-unfolding diagram (a) in Figure 3 for fixed $k > 0$. The homoclinic orbits Ho are not taken into consideration in Figure 8. This will be done in the next section.

5. Homoclinic orbits obtained by a blow-up transformation. In Figure 9 we redraw in detail the numerically calculated surface of homoclinic orbits Ho of the model equation (1.5) from Figure 3(a).

For graphical reasons we changed the direction of the ϵ-axis. Our aim is to verify analytically the hatched upper part of the surface which includes the singularly perturbed homoclinic orbits Ho_s in the $(p_1, p_2) = (\lambda, k)$-plane (dotted curve at $\epsilon = 0$). This is done for the general system (3.7) which was derived from system (2.5) under the assumptions (2.2)–(2.4). In addition we investigate more closely by numerical calculations the lower part of the surface; i.e., we investigate the approach to the border line of open circles where a canard like behavior of the homoclinic orbits seems to occur.

We state the necessary definitions. Consider a system of the form (2.1), but with

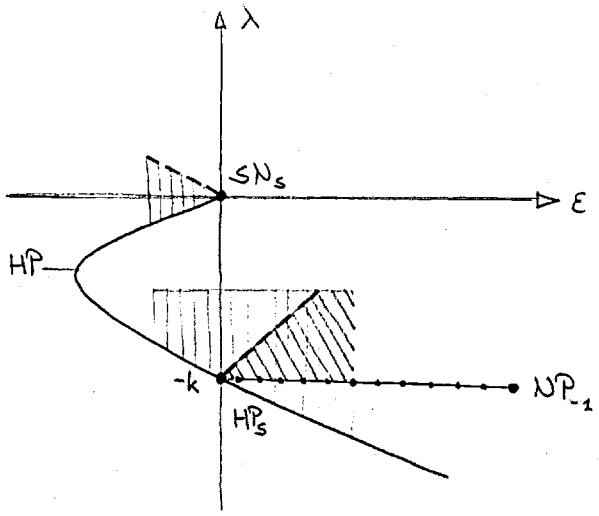

FIG. 8. *The global* (λ, ϵ)*-section through Figure* 3(a) *near the points* SN_s *and* HP_s *for fixed* $k > 0$.

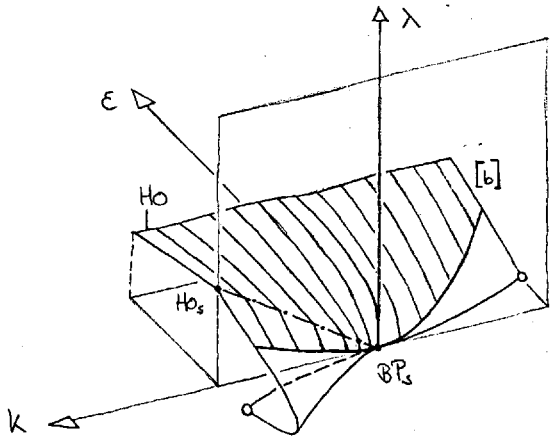

FIG. 9. *The surface of homoclinic orbits for the model equation.*

$u \in \mathbb{R}^n$, $n \geq 2$. Remember that singularly perturbed saddle-node and Hopf points can be also defined for $u \in \mathbb{R}^n$ with the help of center manifold theory (cf. (a) in Figure 4). Here we deal directly with $u \in \mathbb{R}^n$.

Concerning the fast u-system $\dot{u} = F(u, 0, 0)$ at $v = 0$ assume

$$F^0 = 0 \qquad \text{and} \qquad F_u^0 \quad \text{hyperbolic} . \tag{5.1}$$

In addition, assume the existence of a homoclinic orbit $\bar{u}(\tau)$ with base point $u = 0$ such that the only bounded solutions of the homogenous equation

$$\dot{u} = F_u(\bar{u}(\tau), 0, 0, 0) \cdot u \qquad \text{are} \qquad u = c\dot{\bar{u}}, \quad c \in \mathbb{R} . \tag{5.2}$$

Concerning the slow v-perturbation $\dot{v} = \epsilon G(u, v, \epsilon)$ assume as usual the transversality condition (2.4) of the F and G nullclines in the base point $(u, v) = 0$.

DEFINITION 5.1. *A point* $(u,v,\epsilon)=0$ *which satisfies* (5.1), (5.2), *and* (2.4) *is called a singularly perturbed homoclinic base point of the system* (2.1). *The corresponding homoclinic orbit* $(u,v,\epsilon)=(\bar{u}(\tau),0,0)$ *is referred to as singularly perturbed homoclinic orbit.*

Analogous to singularly perturbed saddle-node and Hopf points we investigate singularly perturbed homoclinic orbits within the q-parameter unfolding (4.1). Concerning the corresponding nondegeneracy condition note first that the hyperbolicity of F_u^0 ensures a unique function $(u,v)^s(q,\epsilon)$ such that

$$
\begin{aligned}
&(F,G)((u,v)^s(q,\epsilon),q,\epsilon)=0, \qquad (u,v)^s(0,0)=0,\\
&\begin{pmatrix} u_q^s & u_\epsilon^s \\ v_q^s & v_\epsilon^s \end{pmatrix}(0,0) = -\begin{pmatrix} F_u^0 & F_v^0 \\ G_u^0 & G_v^0 \end{pmatrix}^{-1} \cdot \begin{pmatrix} F_q^0 & F_\epsilon^0 \\ G_q^0 & G_\epsilon^0 \end{pmatrix}.
\end{aligned} \tag{5.3}
$$

DEFINITION 5.2. *The* q*-unfolding* (4.1) *of system* (2.1) *is a generic unfolding of a singularly perturbed homoclinic orbit if*

$$
M := -\int_{-\infty}^{\infty} \Psi^T(\tau)\cdot[F_u,F_v,F_q](\bar{u}(\tau),0,0,0)\cdot \begin{pmatrix} u_q^s(0,0) \\ v_q^s(0,0) \\ 1 \end{pmatrix} d\tau \neq 0, \tag{5.4}
$$

where $\Psi(\tau)$ *denotes the unique bounded solution (up to a constant multiple) of the adjoint equation* $\dot{u}=-F_u^T(\bar{u}(\tau),0,0,0)u$.

The condition (5.4) can be interpreted as a transversality or Melnikov condition along the branch $(u,v)^s(q,0)$ (cf. [23]). We can also interpret it as the regularity condition of an appropriate defining equation in Banach spaces of exponentially weighted functions [2].

Finally, assume for definiteness $(G_u\cdot F_u^{-1}\cdot F_v-G_v)^0<0$ which can always be achieved by time reversal. Then we obtained in [4] the following result with respect to singularly perturbed homoclinic orbits with a generic unfolding.

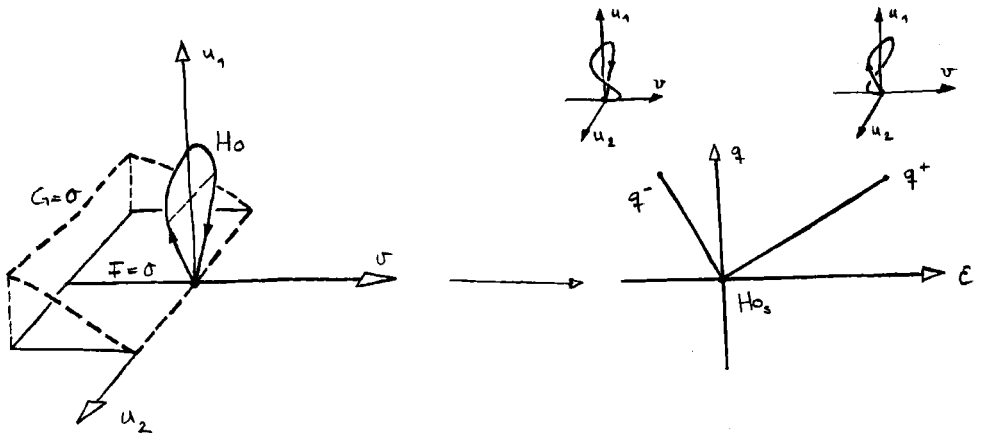
THEOREM 5.3. *There exists a* (q,ϵ)*-unfolding diagram of system* (4.1) *as depicted in diagram* (b) *of Figure* 10.

There exist $\epsilon_0>0$ *and differentiable functions*

$$
\begin{aligned}
q^+(\epsilon) &= q_1^+\cdot\epsilon+O(\epsilon^2), \qquad 0\le\epsilon\le\epsilon_0,\\
q^-(\epsilon) &= q_1^-\cdot\epsilon+O(\epsilon^2), \qquad -\epsilon_0\le\epsilon\le 0
\end{aligned} \tag{5.5}
$$

such that the system (4.1) *has homoclinic orbits* $(u^\pm,v^\pm)(\tau,\epsilon)$ *at* $(q,\epsilon)=(q^\pm(\epsilon),\epsilon)$ *with* $(u^\pm,v^\pm)(\tau,0)=(\bar{u}(\tau),0)$ *and* $q^\pm(0)=0$. *The right and left derivative* q_1^+ *and* q_1^- *can be expressed as*

$$
\begin{aligned}
q_1^+ = \frac{1}{M}\cdot\int_{-\infty}^{\infty}\Psi^T(\tau)\cdot\Bigg\{&-[F_u,F_v](\bar{u}(\tau),0,0,0)\cdot\begin{pmatrix}-(F_u^{-1}F_v)^0\\ 1\end{pmatrix}\cdot\int_\tau^\infty G(\bar{u}(s),0,0,0)ds\\
&+[F_u,F_v,F_\epsilon](\bar{u}(\tau),0,0,0)\cdot\begin{pmatrix}u_\epsilon^s(0,0)\\ v_\epsilon^s(0,0)\\ 1\end{pmatrix}+(F_u^{-1}F_v)^0\cdot G(\bar{u}(\tau),0,0,0)\Bigg\}\,d\tau
\end{aligned} \tag{5.6}
$$



(a) (b)

FIG. 10. (a) *The basic configuration for the fast subsystem* $\dot{u} = F(u, v, 0, 0)$ *and the surface defined by* $G(u, v, 0, 0) = 0$*;* (b) *the* (q, ϵ)*-unfolding diagram of the singularly perturbed homoclinic orbit* Ho_s *and the qualitative shape of the homoclinic orbits that arise for* $\epsilon < 0$ *and* $\epsilon > 0$.

and

$$q_1^- = \frac{1}{M} \cdot \int_{-\infty}^{\infty} \Psi^T(\tau) \cdot \left\{ [F_u, F_v](\bar{u}(\tau), 0, 0, 0) \cdot \begin{pmatrix} -(F_u^{-1} F_v)^0 \\ 1 \end{pmatrix} \cdot \int_{-\infty}^{\tau} G(\bar{u}(s), 0, 0, 0) ds \right.$$

$$\left. + [F_u, F_v, F_\epsilon](\bar{u}(\tau), 0, 0, 0) \cdot \begin{pmatrix} u_\epsilon^s(0,0) \\ v_\epsilon^s(0,0) \\ 1 \end{pmatrix} + (F_u^{-1} F_v)^0 \cdot G(\bar{u}(\tau), 0, 0, 0) \right\} d\tau. \tag{5.7}$$

Concerning the derivatives $(u^s, v^s)_\epsilon(0,0)$ see (5.3). We obtain two nontrivial curves of homoclinic orbits $q^+(\epsilon)$ and $q^-(\epsilon)$ for $\epsilon > 0$ and $\epsilon < 0$, respectively, both of which emanate from $(q, \epsilon) = 0$. Generically, these curves meet transversally at $\epsilon = 0$ due to $q_1^+ \neq q_1^-$. The qualitative shape of the homoclinic orbits along $q^+(\epsilon)$ and $q^-(\epsilon)$ is also indicated in diagram (b).

As usual we indicate in diagram (a) of Figure 10 the basic configuration for the fast subsystem $\dot{u} = F(u, v, 0, 0)$, $\dot{v} = 0$. In contrast to singularly perturbed saddle-node and Hopf points we do not require a velocity condition with respect to v (cf. (2.3) and (4.4)); i.e., we do not assume that the stable and unstable manifold pass each other in the homoclinic orbit Ho with nonvanishing velocity along the branch of stationary points $F(u, v, 0, 0) = 0$. The branch of stationary points (parametrized by v) of the system $\dot{u} = F(u, v, 0, 0)$ is ensured by the condition that F_u^0 is hyperbolic.

The fact that we can omit the velocity condition allows us to treat the singularly perturbed homoclinic orbits of the FitzHugh–Nagumo equation (1.3) which occur again at $c = 0$ within the family of Hamiltonian systems $\dot{u}_1 = u_2$, $\dot{u}_2 = u_1(u_1 - a)(u_1 - 1) + v$, but for now $a > 0$. In that special case every stationary point in diagram (a) of Figure 10 is a homoclinic base point of the fast u-system and we obtain a continuum of homoclinic orbits. Theorem 5.3 shows us that this degeneracy represents no special difficulties. From the continuum of homoclinic orbits only the homoclinic orbit whose base point satisfies $G = 0$ is continued to $\epsilon \neq 0$. This orbit

just represents the singularly perturbed homoclinic orbit within the continuum of homoclinic orbits. The remaining homoclinic orbits are destroyed.

Similar results as stated in Theorem 5.3 appear in [28], [18] where general transversality arguments are used to prove the pure existence of homoclinic orbits for $\epsilon \neq 0$. The precise quantitative behavior of the homoclinic solutions, for example the ϵ-expansions or the asymptotic time estimates of $(u^{\pm}, v^{\pm})(\tau, \epsilon)$ can be found in [4].

We return to the investigation of singularly perturbed Bogdanov points. In the last section we determined the unfolding diagrams of singularly perturbed saddle-node and Hopf points. We obtained some information on 2-dimensional sections through the 3-dimensional unfolding space of a singularly perturbed Bogdanov point. We could also follow this way when dealing with singularly perturbed homoclinic orbits. However, we get additional insight if we start from the center of the unfolding diagram, i.e., from the singularly perturbed Bogdanov point at $(p_1, p_2, \epsilon) = (\lambda, k, \epsilon) = 0$. This is done by an appropriate blow-up.

5.1. The blow-up. We start again from the pretransformed (x, y)-system (3.7). The blow-up transformation between the old variables $(x_1, x_2, y, \epsilon, \lambda, k, t)$ and the new variables $(u_1, u_2, v, \bar{\epsilon}, \bar{\lambda}, \bar{k}, \tau)$ reads

$$
\begin{array}{lll}
\text{coordinates :} & (x_1\ ,\ x_2\ ,\ y) = (c_1 \cdot \bar{\lambda}^2 \cdot u_1\ ,\ c_2 \cdot \bar{\lambda}^3 \cdot u_2\ ,\ c_3 \cdot \bar{\lambda}^4 \cdot v), \\
\text{parameters :} & (\epsilon\ ,\ \ \lambda\ ,\ \ k) = (c_4 \cdot \bar{\lambda}^3 \cdot \bar{\epsilon}\ ,\ \ c_5 \cdot \bar{\lambda}^2\ ,\ \ \ \ c_6 \cdot \bar{\lambda}^2 \cdot \bar{k}), \\
\text{time :} & t \qquad\qquad\quad = c_7 \cdot \bar{\lambda}^{-1} \cdot \tau,
\end{array}
\tag{5.8}
$$

where we used u and v again to denote the new coordinates. The constants $c_1, \ldots, c_7$ will be chosen later on. Essentially this $\bar{\lambda}$-scaling is a direct extension of the well-known scaling near a regularly perturbed Bogdanov point [15]. However, note that we maintain a linear dependence between the variables y and v. This seems appropriate because v represents a dynamic variable for $\bar{\epsilon} \neq 0$ and it is convenient to decouple the parameter transformation between (ϵ, λ, k) and $(\bar{\epsilon}, \bar{\lambda}, \bar{k})$ from the coordinate transformation between (x_1, x_2, y) and (u_1, u_2, v). Then a straightforward calculation yields the transformed system

$$
\begin{aligned}
\dot{u}_1 &= u_2 + \bar{\lambda} \cdot (a_1 u_1^2 + a_2 v) + O(\bar{\lambda}^2) \\
&=: F_1(u_1, u_2, v, \bar{\lambda}, \bar{k}, \bar{\epsilon}), \\
\dot{u}_2 &= u_1^2 - v + \bar{\lambda} \cdot (b_1 u_1 u_2 + b_2 \bar{k} u_2 + b_3 u_2) + O(\bar{\lambda}^2) \\
&=: F_2(u_1, u_2, v, \bar{\lambda}, \bar{k}, \bar{\epsilon}), \\
\dot{v} &= \bar{\epsilon} \cdot [u_1 - 2 + O(\bar{\lambda})] \\
&=: \bar{\epsilon} \cdot G(u_1, u_2, v, \bar{\lambda}, \bar{k}, \bar{\epsilon})
\end{aligned}
\tag{5.9}
$$

which maintains the ordinary singular perturbation form. The constants in (5.8) are chosen according to

$$
\begin{array}{lllll}
\text{coordinates :} & c_1 = \frac{1}{2}\ f^0_{2x_1x_1}, & c_2 = c_1^2, & c_3 = -c_1^3/f^0_{2y}, \\
\text{parameters :} & c_4 = -c_1^3/(f^0_{2y} \cdot g^0_{x_1}), & c_5 = -2\ c_1\ g^0_{x_1}/g^0_{\lambda}, & c_6 = c_1, \\
\text{time :} & c_7 = 1/c_1.
\end{array}
\tag{5.10}
$$

This yields the following coefficients for the linear $\bar\lambda$-terms in (5.9):

$$\begin{aligned} &a_1 = \tfrac{1}{2}\, f^0_{1x_1x_1}, \quad a_2 = -\tfrac{1}{2}\, f^0_{2x_1x_1}\cdot f^0_{1y}/f^0_{2y}, \\ &b_1 = f^0_{2x_1x_2}, \qquad b_2 = f^0_{2x_2k}, \qquad\qquad b_3 = -2\, f^0_{2x_2\lambda}\cdot g^0_{x_1}/g^0_\lambda. \end{aligned} \tag{5.11}$$

According to (3.3) and (3.8), (3.10) these coefficients are completely expressed in terms of derivatives of the original system (2.5) evaluated at the singularly perturbed Bogdanov point. Under the assumptions (2.2)–(2.4) and (3.1) the coefficients may assume arbitrary values. In the next step we shall impose conditions on the coefficients which ensure the existence of homoclinic orbits of the system (5.9) for $\bar\epsilon \neq 0$. In particular the difference between the assumption (3.1) and the stronger assumption (2.7) of a generic unfolding is analyzed.

First we are looking for homoclinic orbits of the fast u-system $\dot u = F(u, v, \bar\lambda, \bar k, 0)$ at $\bar\epsilon = 0$. Second we identify among these orbits the homoclinic orbits whose base points satisfy $G = 0$; i.e., we are looking for singularly perturbed homoclinic orbits of the blown-up system (5.9). Third we perform the actual singular perturbation; i.e., we continue the singularly perturbed homoclinic orbits to $\bar\epsilon \neq 0$. This is done with the help of the Melnikov condition (5.4) which represents the nondegeneracy condition of the unfolding.

5.2. Homoclinic orbits at $\bar\epsilon = 0$. At $\bar\epsilon = 0$, $\bar\lambda = 0$, and $\bar k \in \mathbb{R}$, the fast u-system $\dot u_1 = u_2,\ \dot u_2 = u_1^2 - v$ in (5.9) represents a well-known v-dependent family of Hamiltonian systems [15] with corresponding family of homoclinic orbits

$$\begin{aligned} \bar u_1(\tau, v) &= v^{\frac12}\cdot\left[1 - 3\ \mathrm{sech}^2\left(2^{-\frac12} v^{\frac14}\tau\right)\right], \\ \bar u_2(\tau, v) &= 3\sqrt{2} v^{\frac34}\cdot \mathrm{sech}^2\left(2^{-\frac12} v^{\frac14}\tau\right)\cdot \tanh\left(2^{-\frac12} v^{\frac14}\tau\right) \end{aligned} \tag{5.12}$$

for $v > 0$. Note that the base points $\bar u(\infty, v)$ of the homoclinic orbits are

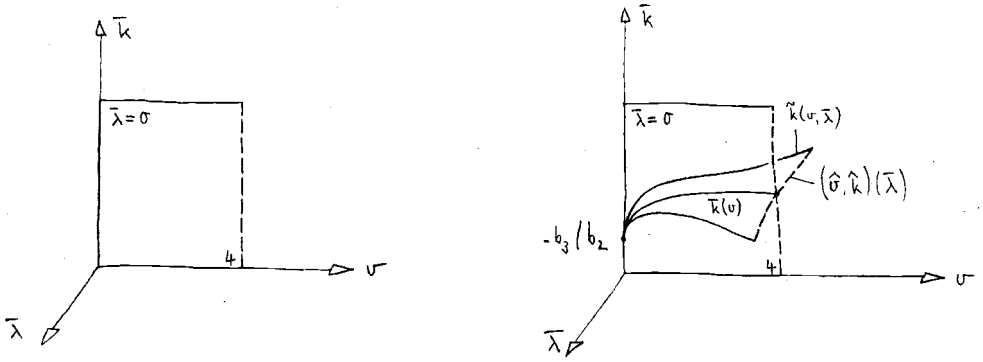
$$\bar u_1(\infty, v) = \sqrt{v}, \qquad \bar u_2(\infty, v) = 0, \qquad v > 0. \tag{5.13}$$

Hence in the 3-dimensional $(v, \bar\lambda, \bar k)$-parameter space of the u-system $\dot u = F(u, v, \bar\lambda, \bar k, 0)$ we obtain a surface of homoclinic orbits at $\bar\lambda = 0$ as indicated in diagram (a) of Figure 11. Obviously this trivial surface exists for arbitrary values of the coefficient b_2.

Next we continue some of these homoclinic orbits to $\bar\lambda \neq 0$. This leads to diagram (b) in Figure 11 under the additional restriction $b_2 = f^0_{2x_2k} \neq 0$ which is satisfied for a generic unfolding of a singularly perturbed Bogdanov point (cf. (3.10)). Without the extra v-parameter, bifurcation results of this type are derived in [7], [15], and [3]; therefore we restrict ourselves to the special features of our situation.

First the bifurcation condition which is equivalent to a vanishing Melnikov function with respect to $\bar\lambda$ reads

$$\begin{aligned} 0 &= -\int_{-\infty}^{\infty} [-\dot{\bar u}_2,\ \dot{\bar u}_1]\cdot F_{\bar\lambda}(\bar u, v, 0, \bar k, 0)\ d\tau \\ &= -\int_{-\infty}^{\infty} -\ddot{\bar u}_1\cdot(a_1\bar u_1^2 + a_2 v) + \dot{\bar u}_1^2\cdot(b_1\bar u_1 + b_2\bar k + b_3)\ d\tau \\ &= -(2a_1 + b_1)\cdot\int_{-\infty}^{\infty} \dot{\bar u}_1^2\bar u_1\ d\tau - (b_2\bar k + b_3)\cdot\int_{-\infty}^{\infty}\dot{\bar u}_1^2\ d\tau \\ &= \sqrt{2}\tfrac{24}{35} v^{\frac54}\cdot[5(2a_1 + b_1)\sqrt{v} - 7(b_2\bar k + b_3)] =: M(v, \bar k). \end{aligned} \tag{5.14}$$



$b_2\in\mathbb{R}$ (a) $b_2\neq 0$ (b)

FIG. 11. *The system* (5.9) *at* $\bar{\epsilon}=0$: (a) *The trivial surface of homoclinic orbits obtained by the blow-up;* (b) *the nontrivial surface of homoclinic orbits in case of a generic unfolding.*

In the case of $b_2 \neq 0$ we obtain $M(v,\bar{k})=0$, $v>0$ iff

$$\bar{k} = \frac{5(2a_1+b_1)\sqrt{v}-7b_3}{7b_2} =: \bar{k}(v). \tag{5.15}$$

Finally the nondegeneracy condition for bifurcations along $\bar{k}(v)$ reads

$$0 \neq \int_{-\infty}^{\infty} [-\dot{\bar{u}}_2,\ \dot{\bar{u}}_1]\cdot F_{\bar{\lambda}\bar{k}}(\bar{u},v,0,\bar{k}(v),0)\ d\tau = b_2\cdot\int_{-\infty}^{\infty}\dot{\bar{u}}_1^2\ d\tau \tag{5.16}$$

which is true according to $b_2\neq 0$. Hence we obtain a nontrivial surface of homoclinic orbits

$$[u,v,\bar{\lambda},\bar{k}] = [\tilde{u}(\tau,v,\bar{\lambda}),v,\bar{\lambda},\tilde{k}(v,\bar{\lambda})], \qquad v>0, \qquad |\bar{\lambda}|\ll 1 \tag{5.17}$$

with $\tilde{u}(\tau,v,0)=\bar{u}(\tau,v)$ and $\tilde{k}(v,0)=\bar{k}(v)$ (cf. diagram (b) in Figure 11). Summarizing, the fast u-system $\dot{u}=F(u,v,\bar{\lambda},\bar{k},0)$ has the trivial surface (5.12) of homoclinic orbits at $\bar{\lambda}=0$ which is intersected at $(v,\bar{\lambda},\bar{k})=(v,0,\bar{k}(v))$ by the nontrivial surface (5.17) in case of $b_2\neq 0$.

Up to now we performed a well-known bifurcation analysis of homoclinic orbits. In the next section we extend this bifurcation analysis to the full (x,y)-system (5.9) with respect to the singular perturbation parameter $\bar{\epsilon}$; i.e., we determine in Figure 11 the homoclinic orbits that can be continued to $\bar{\epsilon}\neq 0$.

A generic unfolding of a singularly perturbed Bogdanov point implies $b_2 = f^0_{2x_2k}\neq 0$ and diagram (b) in Figure 11 occurs. However, our approach allows us to treat the degenerate case $b_2=0$ almost without extra effort; therefore we include this case.

5.3. The bifurcation analysis with respect to $\bar{\epsilon}$. Our aim is to apply Theorem 5.3 to the blown-up system (5.9). This is done twice with respect to $(q,\epsilon)=(\bar{\lambda},\bar{\epsilon})$ and $(q,\epsilon)=(\bar{k},\bar{\epsilon})$, respectively. In section 5.2 we determined the homoclinic orbits at $\bar{\epsilon}=0$. Next we identify the homoclinic orbits whose base points satisfy $G(u,v,\bar{\lambda},\bar{k},0)=0$ in addition. This simple condition represents the bifurcation equation.

Recalling that $(u_1,u_2,v,\bar{\lambda},\bar{k})=(\sqrt{v},0,v,0,\bar{k})$ are homoclinic base points of the trivial surface (cf. (5.13)) we obtain

$$G[\sqrt{v},0,v,0,\bar{k},0]=\sqrt{v}-2=0 \qquad \text{iff} \qquad v=4, \qquad \bar{k}\in\mathbb{R}. \tag{5.18}$$

This leads to the vertical broken lines in the diagrams of Figure 11 at $v = 4$, $\bar\lambda = 0$. Concerning the nontrivial homoclinic orbits in the case of $b_2 \neq 0$ we consider (cf. (5.17))

$$\begin{aligned} G[\tilde u(\infty, v, \bar\lambda), v, \bar\lambda, \tilde k(v, \bar\lambda), 0] &= \tilde u_1(\infty, v, 0) - 2 + O(\bar\lambda) \\ &= \sqrt{v} - 2 + O(\bar\lambda) = 0 \end{aligned} \tag{5.19}$$

and obtain a locally unique function $\hat v(\bar\lambda)$ with $\hat v(0) = 4$ satisfying

$$G[\tilde u(\infty, \hat v(\bar\lambda), \bar\lambda), \hat v(\bar\lambda), \bar\lambda, \tilde k(\hat v(\bar\lambda), \bar\lambda), 0] = 0. \tag{5.20}$$

We define $(\hat u, \hat k)(\bar\lambda) := [\tilde u(\infty, \hat v(\bar\lambda), \bar\lambda), \tilde k(\hat v(\bar\lambda), \bar\lambda)]$ and denote the corresponding homoclinic orbits by $\hat u(\tau, \bar\lambda)$.

Summarizing, broken lines in Figure 11 indicate the homoclinic orbits at $\bar\epsilon = 0$ which satisfy the bifurcation equation $G = 0$ and it remains to verify the nondegeneracy conditions in (5.1), (5.2), (2.4), and (5.4) for proving bifurcation with respect to $\bar\epsilon$ with the help of Theorem 5.3.

First we obtain from (5.9) the regularity of the matrix

$$\begin{pmatrix} F_u & F_v \\ G_u & G_v \end{pmatrix} (\sqrt{v}, 0, v, 0, \bar k, 0) = \begin{pmatrix} 0 & 1 & 0 \\ 2\sqrt{v} & 0 & -1 \\ 1 & 0 & 0 \end{pmatrix}$$

as desired (cf. (2.4)). Thus we have a unique surface of steady states $(u, v)^s(\bar\lambda, \bar k, \bar\epsilon)$ with

$$\begin{aligned} &(F, G)[(u, v)^s(\bar\lambda, \bar k, \bar\epsilon), \bar\lambda, \bar k, \bar\epsilon] = 0 \qquad \text{and} \\ &(u, v)^s(0, \bar k, 0) \equiv (2, 0, 4), \qquad (u, v)^s(\bar\lambda, \hat k(\bar\lambda), 0) = (\hat u, \hat v)(\bar\lambda) \end{aligned} \tag{5.21}$$

(cf. (5.3)). Second, the condition (5.2) is satisfied along the broken lines in Figure 11 at $\bar\lambda = 0$ as can be seen from the behavior of the Wronski-determinant of the system $\dot u = F_u(\bar u(\tau, 4), 4, 0, \bar k, 0)u$ as τ tends to infinity. Concerning the nontrivial homoclinic orbits in Figure 11 this property follows locally from a perturbation argument.

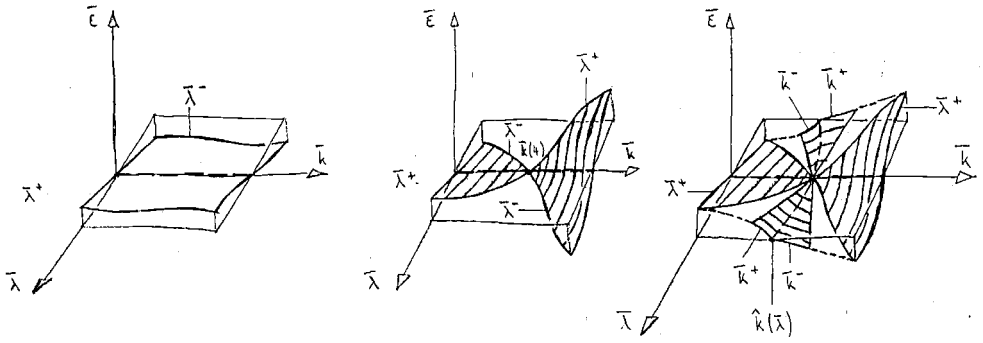
Finally, we verify the Melnikov condition (5.4) separately along $[u, v, \bar\lambda, \bar k, \bar\epsilon] = [\bar u(\tau, 4), 4, 0, \bar k, 0]$ with respect to $(q, \epsilon) = (\bar\lambda, \bar\epsilon)$ and along $[u, v, \bar\lambda, \bar k, \bar\epsilon] = [\hat u(\tau, \bar\lambda), \hat v(\bar\lambda), \bar\lambda, \hat k(\bar\lambda), 0]$ with respect to $(q, \epsilon) = (\bar k, \bar\epsilon)$.

First we continue the homoclinic orbits $[u, v, \bar\lambda, \bar k, \bar\epsilon] = [\bar u(\tau, 4), 4, 0, \bar k, 0]$ in the $(\bar\lambda, \bar\epsilon)$-plane. In this case the Melnikov condition reads

$$\begin{aligned} 0 \neq &- \int_{-\infty}^{\infty} [-\dot{\bar u}_2,\ \dot{\bar u}_1](\tau, 4) \cdot [F_u, F_v, F_{\bar\lambda}](\bar u(\tau, 4), 4, 0, \bar k, 0) \cdot \begin{pmatrix} u^s_{\bar\lambda}(0, \bar k, 0) \\ v^s_{\bar\lambda}(0, \bar k, 0) \\ 1 \end{pmatrix} d\tau \\ &= - \int_{-\infty}^{\infty} [-\dot{\bar u}_2,\ \dot{\bar u}_1](\tau, 4) \cdot F_{\bar\lambda}(\bar u(\tau, 4), 4, 0, \bar k, 0)\ d\tau = M(4, \bar k) \end{aligned} \tag{5.22}$$

(cf. (5.14)). Note that $\int_{-\infty}^{\infty} \dot{\bar u}_1\ d\tau = \int_{-\infty}^{\infty} \dot{\bar u}_2\ d\tau = \int_{-\infty}^{\infty} \dot{\bar u}_1 \bar u_1\ d\tau = 0$. According to (5.14), (5.15) this nondegeneracy condition is satisfied for

$$\bar k \in \mathbb{R} \qquad \text{in the case of} \qquad b_2 = 0, \qquad 10(2a_1 + b_1) - 7b_3 =: \gamma \neq 0 \tag{5.23}$$



(a) (b) (c)

FIG. 12. *The surfaces of homoclinic orbits of the blown-up system* (5.9): (a) $b_2 = 0$, $\gamma \neq 0$, (b) *and* (c) $b_2 \neq 0$.

and for

$$\bar{k} \neq \bar{k}(4) = \frac{\gamma}{7b_2} \qquad \text{in the case of} \qquad b_2 \neq 0. \tag{5.24}$$

Thus, we can apply Theorem 5.3. In the $(\bar{\lambda}, \bar{k}, \bar{\epsilon})$-parameter space of the system (5.9) we obtain smooth $\bar{k}$-dependent surfaces

$$\bar{\lambda} = \bar{\lambda}^+(\bar{k}, \bar{\epsilon}), \quad 0 \leq \bar{\epsilon} \leq \bar{\epsilon}_0(\bar{k}) \qquad \text{and} \qquad \bar{\lambda} = \bar{\lambda}^-(\bar{k}, \bar{\epsilon}), \quad -\bar{\epsilon}_0(\bar{k}) \leq \bar{\epsilon} \leq 0 \tag{5.25}$$

of homoclinic orbits which branch off from the $\bar{k}$-axis for $\bar{k} \in \mathbb{R}$ in the case of $b_2 = 0$, $\gamma \neq 0$ (cf. diagram (a) in Figure 12), and for $\bar{k} \in \mathbb{R} \setminus \{\bar{k}(4)\}$ in the case of $b_2 \neq 0$ (cf. diagram (b) in Figure 12). It should be noted that the proof in [4] does not describe in detail the limiting behavior of $\bar{\epsilon}_0(\bar{k})$ as $\bar{k}$ tends to $\pm\infty$ or as $\bar{k}$ tends to $\bar{k}(4)$ in the case of $b_2 \neq 0$. We only know $\bar{\epsilon}_0(\bar{k}) \to 0$ in these situations.

Further it is not difficult to see the antisymmetry $\bar{\lambda}^+(\bar{k}, \bar{\epsilon}) = -\bar{\lambda}^-(\bar{k}, -\bar{\epsilon})$ which results from a certain symmetry of the scaling transformation (5.8) and a uniqueness argument (cf. [3]). In particular the surfaces are smooth along the $\bar{k}$-axis, i.e., the derivatives at $\bar{\epsilon} = 0$ satisfy $\bar{\lambda}_1^-(\bar{k}) = \bar{\lambda}_1^+(\bar{k})$ (cf. (5.5)) and the homoclinic orbits which correspond to $\bar{\lambda} = \bar{\lambda}^+(\bar{k}, \bar{\epsilon})$ and $\bar{\lambda} = -\bar{\lambda}^-(\bar{k}, -\bar{\epsilon})$ represent the same homoclinic orbit of the unscaled system (3.7). Hence we can restrict ourselves to

$$\bar{\lambda}^+(\bar{k}, \bar{\epsilon}) = \bar{\lambda}_1^+(\bar{k}) \cdot \bar{\epsilon} + O(\bar{\epsilon}^2), \quad 0 \leq \bar{\epsilon} \leq \bar{\epsilon}_0(\bar{k}). \tag{5.26}$$

The derivative $\bar{\lambda}_1^+(\bar{k})$ at $\bar{\epsilon} = 0$ follows after some calculations from (5.6) according to

$$\bar{\lambda}_1^+(\bar{k}) = \frac{1}{M(4, \bar{k})} \cdot \int_{-\infty}^{\infty} [\bar{u}_1(\tau, 4) - 2]^2 \, d\tau = \frac{35}{4} \cdot \frac{1}{\gamma - 7b_2\bar{k}}. \tag{5.27}$$

In the case of $b_2 \neq 0$ this derivative has a pole at $\bar{k} = \bar{k}(4)$ and converges to zero as $\bar{k} \to \pm\infty$. In the case of $b_2 = 0$ we obtain the identity $\bar{\lambda}_1^+(\bar{k}) \equiv 35/(4\gamma)$.

It remains to verify in the case of $b_2 \neq 0$ the Melnikov condition (5.4) along the homoclinic orbits $[u, v, \bar{\lambda}, \bar{k}, \bar{\epsilon}] = [\hat{u}(\tau, \bar{\lambda}), \hat{v}(\bar{\lambda}), \bar{\lambda}, \hat{k}(\bar{\lambda}), 0]$ with respect to $(q, \epsilon) = (\bar{k}, \bar{\epsilon})$. Let $\psi(\tau, \bar{\lambda})$ denote the unique bounded solution (up to a scalar multiple) of the corresponding adjoint equation $\dot{u} = -F_u^T[\hat{u}(\tau, \bar{\lambda}), \hat{v}(\bar{\lambda}), \bar{\lambda}, \hat{k}(\bar{\lambda}), 0]u$. $\psi(\tau, \bar{\lambda})$ can be

chosen to vary smoothly in $(\tau, \bar{\lambda})$ and to satisfy $\psi^T(\tau, 0) = [-\dot{\hat{u}}_2, \dot{\hat{u}}_1](\tau, 4)$. Then the nondegeneracy condition reads

$$0 \neq -\int_{-\infty}^{\infty} \psi^T(\tau, \bar{\lambda}) \cdot [F_u, F_v, F_{\bar{k}}][\hat{u}(\tau, \bar{\lambda}), \hat{v}(\bar{\lambda}), \bar{\lambda}, \hat{k}(\bar{\lambda}), 0] \cdot \begin{pmatrix} u_{\bar{k}}^s(\bar{\lambda}, \hat{k}(\bar{\lambda}), 0) \\ v_{\bar{k}}^s(\bar{\lambda}, \hat{k}(\bar{\lambda}), 0) \\ 1 \end{pmatrix} d\tau \tag{5.28}$$

$$=: \hat{M}(\bar{\lambda}).$$

At $\bar{\lambda} = 0$ we have the identities $\hat{M}(0) = 0$ due to $(u_{\bar{k}}^s, v_{\bar{k}}^s)(0, 0, 0) = 0$ (cf. (5.21)) and $F_{\bar{k}}[\hat{u}(\tau, 0), 4, 0, \hat{k}(0), 0] = 0$ due to (5.9). Further, differentiation at $\bar{\lambda} = 0$ shows after some calculations

$$\begin{aligned} \hat{M}'(0) &= -\int_{-\infty}^{\infty} \psi^T(\tau, 0) \cdot \frac{d}{d\bar{\lambda}} F_{\bar{k}}[\hat{u}(\tau, \bar{\lambda}), \hat{v}(\bar{\lambda}), \bar{\lambda}, \hat{k}(\bar{\lambda}), 0]_{|\bar{\lambda}=0} \, d\tau \\ &= -b_2 \cdot \int_{-\infty}^{\infty} \dot{\hat{u}}_1^2(\tau, 4) \, d\tau \neq 0 \end{aligned} \tag{5.29}$$

and we can apply again Theorem 5.3. According to (5.5) this yields the surfaces

$$\bar{k} = \bar{k}^+(\bar{\lambda}, \bar{\epsilon}), \quad 0 \leq \bar{\epsilon} \leq \bar{\epsilon}_0(\bar{\lambda}) \qquad \text{and} \qquad \bar{k} = \bar{k}^-(\bar{\lambda}, \bar{\epsilon}), \quad -\bar{\epsilon}_0(\bar{\lambda}) \leq \bar{\epsilon} \leq 0 \tag{5.30}$$

of homoclinic orbits which branch off from the curve $[u, v, \bar{\lambda}, \bar{k}, \bar{\epsilon}] = [\hat{u}(\tau, \bar{\lambda}), \hat{v}(\bar{\lambda}), \bar{\lambda}, \hat{k}(\bar{\lambda}), 0]$ for $0 < |\bar{\lambda}| \ll 1$. Hence we can extend diagram (b) in Figure 12 as depicted in diagram (c). Note that in general we cannot expect $\bar{k}^+(\bar{\lambda}, \bar{\epsilon})$ and $\bar{k}^-(\bar{\lambda}, \bar{\epsilon})$ to form a smooth surface along $\hat{k}(\bar{\lambda})$. The precise behavior of $\bar{\epsilon}_0(\bar{\lambda})$ remains unknown as $\bar{\lambda}$ tends to zero. The surfaces show again a symmetry given by $\bar{k}^+(\bar{\lambda}, \bar{\epsilon}) = \bar{k}^-(-\bar{\lambda}, -\bar{\epsilon})$ and we can restrict to $\bar{k}^+(\bar{\lambda}, \bar{\epsilon})$.

The different surfaces $\bar{\lambda}^{\pm}(\bar{k}, \bar{\epsilon})$ and $\bar{k}^{\pm}(\bar{\lambda}, \bar{\epsilon})$ of homoclinic orbits in diagram (c) of Figure 12 are presumably parts of a common surface of homoclinic orbits as indicated by broken lines. Numerical calculations strongly confirm this conjecture.

For closing analytically the gaps between the different surfaces it would be necessary to generalize the bifurcation result in [4] which concentrates on singularly perturbed homoclinic orbits with a generic unfolding. Remember that points of this type occur in Figure 12 at $\bar{\epsilon} = 0$ along the $\bar{k}$-axis for $\bar{k} \neq \bar{k}(4)$ and along $\hat{k}(\bar{\lambda})$ for $\bar{\lambda} \neq 0$. The singularly perturbed homoclinic orbit at the bifurcation point of the two curves is not generically unfolded and the theory is not applicable.

5.4. The back transformation. In this section we transform the results obtained for the blown-up system (5.9) back to the system (3.7); i.e., we interpret the surfaces from Figure 12 within the (λ, k, ϵ)-unfolding space of our singularly perturbed Bogdanov point using the scaling transformation (5.8). Essentially this yields the hatched upper part of the surface of homoclinic orbits in Figure 9.

First we indicate the transformation of $\bar{\lambda}^+(\bar{k}, \bar{\epsilon})$ in the case of $b_2 \neq 0$. This inequality occurs at a singularly perturbed Bogdanov point with a generic unfolding. According to (5.25)–(5.27) we obtain

$$\bar{\lambda}^+(\bar{k}, \bar{\epsilon}) = \frac{35}{4} \cdot \frac{1}{\gamma - 7b_2\bar{k}} \cdot \bar{\epsilon} + O(\bar{\epsilon}^2), \qquad \bar{\epsilon} \in [0, \bar{\epsilon}_0(\bar{k})], \qquad \bar{k} \neq \bar{k}(4) \tag{5.31}$$

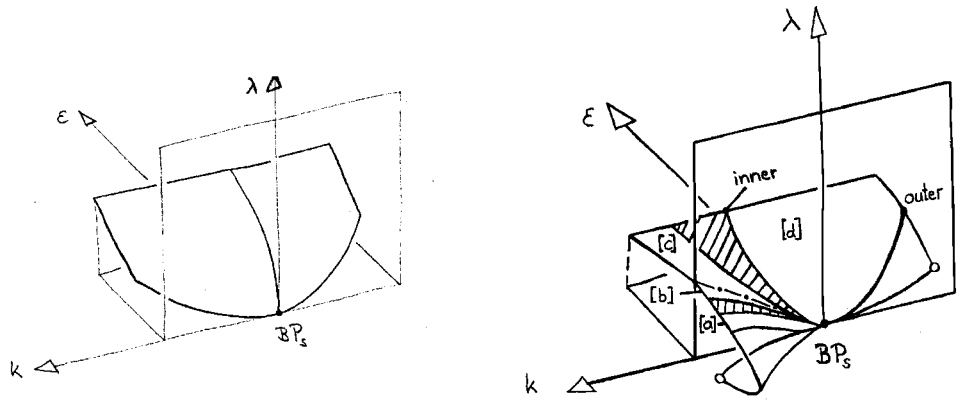


FIG. 13. *The different surfaces* [a]–[d] *(see text) of homoclinic orbits of the pretransformed system* (3.7)*;* (a) $b_2 = 0$, $\gamma \neq 0$*;* (b) $b_2 \neq 0$.

or equivalently

$$\bar{\epsilon}^+(\bar{k}, \bar{\lambda}) = \tfrac{4}{35}(\gamma - 7b_2\bar{k}) \cdot \bar{\lambda} + O(\bar{\lambda}^2), \qquad \bar{k} \neq \bar{k}(4), \tag{5.32}$$

where $\bar{\epsilon}^+(\bar{k}, \cdot)$ denotes the inverse function of $\bar{\lambda}^+(\bar{k}, \cdot)$ and $\bar{\lambda}$ is chosen according to

$$\bar{\lambda} \in \begin{cases} [0,\ \bar{\lambda}_0(\bar{k})] & \text{in the case of} \quad \gamma - 7b_2\bar{k} > 0, \\ [-\bar{\lambda}_0(\bar{k}),\ 0] & \text{in the case of} \quad \gamma - 7b_2\bar{k} < 0 \end{cases} \tag{5.33}$$

with $0 < \bar{\lambda}_0(\bar{k}) \ll 1$ and $\bar{\lambda}_0(\bar{k}) \to 0$ as $\bar{k} \to \pm\infty$ or as $\bar{k} \to \bar{k}(4)$. Then recalling the scaling transformation (5.8), the system (3.7) has homoclinic orbits at parameter values

$$(\epsilon, \lambda, k) = (\tfrac{4}{35}c_4(\gamma - 7b_2\bar{k}) \cdot \bar{\lambda}^4 + O(\bar{\lambda}^5), \quad c_5 \cdot \bar{\lambda}^2, \quad c_6\bar{k} \cdot \bar{\lambda}^2) \tag{5.34}$$

with $\bar{k} \in \mathbb{R} \setminus \{\bar{k}(4)\}$ and $\bar{\lambda}$ chosen according to (5.33). For fixed $\bar{k}$ we obtain a curve in the (λ, k, ϵ)-space parametrized by $\bar{\lambda}$. The projection of this curve onto the (λ, k)-plane forms the straight line

$$k = \frac{c_6}{c_5}\bar{k} \cdot \lambda, \qquad \lambda \in \begin{cases} [0, c_5\bar{\lambda}_0^2(\bar{k})] & \text{in the case of} \quad c_5 > 0 \\ [c_5\bar{\lambda}_0^2(\bar{k}), 0] & \text{in the case of} \quad c_5 < 0 \end{cases}. \tag{5.35}$$

In contrast to this the projection of the curve onto the (λ, ϵ)-plane yields the parabola

$$\epsilon = \frac{4}{35}\frac{c_4}{c_5^2}(\gamma - 7b_2\bar{k}) \cdot \lambda^2 + O(\lambda^2\sqrt{\lambda}). \tag{5.36}$$

During variation of $\bar{k} \in (-\infty, \bar{k}(4))$ and $\bar{k} \in (\bar{k}(4), \infty)$ we obtain the surfaces [a] and [d] as indicated in diagram (b) of Figure 13. These two surfaces represent parts of the hatched upper part in Figure 9. Remember that Figures 9 and 13 show the (λ, k, ϵ)-unfolding space of a singularly perturbed Bogdanov point with a generic unfolding.

The outer and inner border lines of the surfaces [a] and [d] show the limiting behavior

$$\frac{\lambda}{k} = \frac{c_5\bar{\lambda}_0^2(\bar{k})}{c_6\bar{\lambda}_0^2(\bar{k})\cdot\bar{k}} = \frac{c_5}{c_6}\cdot\frac{1}{\bar{k}} \to \begin{cases} 0 & \text{as} \quad \bar{k}\to\pm\infty, \\ \dfrac{c_5}{c_6}\cdot\dfrac{1}{\bar{k}(4)} & \text{as} \quad \bar{k}\to\bar{k}(4) \end{cases}. \tag{5.37}$$

In particular we have $\lambda/k = o(1)$ if we approach the origin along the outer border lines. In the case of $\bar{k}(4) = 0$ the inner border lines are tangentially touching the λ-axis. This situation occurs in the FitzHugh–Nagumo equation that is treated in detail in [4].

Next we consider $\bar{\lambda}^+(\bar{k},\bar{\epsilon})$ in the case of $b_2 = 0$, $\gamma \neq 0$ (cf. diagram (a) in Figure 12). In this situation we can choose $\bar{k}\in\mathbb{R}$ and obtain a unique surface in the (λ,k,ϵ)-parameter space as indicated in diagram (a) of Figure 13. More precisely there exist homoclinic orbits at parameter values

$$(\epsilon,\ \lambda,\ k) = (\tfrac{4}{35}c_4\gamma\cdot\bar{\lambda}^4 + O(\bar{\lambda}^5),\quad c_5\cdot\bar{\lambda}^2,\quad c_6\bar{k}\cdot\bar{\lambda}^2) \tag{5.38}$$

with $\bar{k}\in\mathbb{R}$ and $\bar{\lambda}$ chosen according to

$$\bar{\lambda} \in \begin{cases} [0,\ \bar{\lambda}_0(\bar{k})] & \text{in the case of} \quad \gamma > 0, \\ [-\bar{\lambda}_0(\bar{k}),\ 0] & \text{in the case of} \quad \gamma < 0 \end{cases}$$

with $\bar{\lambda}_0(\bar{k}) \to 0$ as $\bar{k}\to\pm\infty$.

In principle the back transformation of the two surfaces $\bar{k}^+(\bar{\lambda},\bar{\epsilon})$, $0 < \bar{\lambda} \ll 1$ and $\bar{k}^+(\bar{\lambda},\bar{\epsilon})$, $-1 \ll \bar{\lambda} < 0$ from diagram (c) in Figure 12 works along the same lines as the back transformation of $\bar{\lambda}^+(\bar{k},\bar{\epsilon})$; therefore we omit the details. We obtain the surfaces [b] and [c] in diagram (b) of Figure 13.

It is straightforward to see (cf. [4]) that the dotted curve at $\epsilon = 0$ represents a curve of singularly perturbed homoclinic orbits with a generic unfolding. Note that this curve results from the back transformation of the curve $\hat{k}(\bar{\lambda})$ (cf. (c) in Figure 12) which represents points of this type for the blown-up system (5.9). The transformation (5.8) shows that the dotted curve of singularly perturbed homoclinic orbits of the system (3.7) is given by

$$k = \frac{c_6}{c_5}\lambda\cdot\hat{k}(\sqrt{\lambda/c_5}) =: k^{Ho}(\lambda) \qquad \text{with} \qquad k_\lambda^{Ho}(0) = \frac{c_6}{c_5}\cdot\bar{k}(4) = \frac{c_6}{c_5}\cdot\frac{\gamma}{7b_2}. \tag{5.39}$$

Comparing (5.39) and (5.37) we see that the inner border lines of the surfaces [a] and [d] are tangentially touching $k^{Ho}(\lambda)$ at the singularly perturbed Bogdanov point BP_s.

According to the theory we can only guarantee the surfaces [a], [b] and [c], [d] separated by the hatched gaps. But these gaps can be closed and there is one common surface according to numerical calculations. This surface intersects the (λ,k)-plane along the dotted curve $k^{Ho}(\lambda)$ of singularly perturbed homoclinic base points. In general we cannot expect the surface to be smooth with respect to ϵ along this curve. Note that during variation of $b_2 \to 0$ the curve tends to the k-axis and we approximate diagram (a).

5.5. Proof of Theorem 2.3. Using the derivatives in (5.39), (4.13) and the transformations (3.6), (5.8), (5.11) it is now possible to draw a complete picture of the singularly perturbed points of the pretransformed system (3.7) and the original system (2.5). Thus we can prove Theorem 2.3.

We obtain from (5.39) singularly perturbed homoclinic base points Ho_s at $[\lambda, k] = [\lambda, k^{Ho}(\lambda)]$ with $0 < \lambda \ll 1$ in the case of $c_5 = -f^0_{2x_1x_1} g^0_{x_1}/g^0_\lambda > 0$ and with $-1 \ll \lambda < 0$ in the case of $c_5 < 0$. The derivative at $\lambda = 0$ is given by $k^{Ho}_\lambda(0) = c_6\gamma/(c_5 7 b_2)$. The singularly perturbed saddle-nodes SN_s occur at $[\lambda, k] = [0, k]$, $0 < |k| \ll 1$ and finally we obtain singularly perturbed Hopf points HP_s at $k^H(\lambda)$ with $0 < \lambda \ll 1$ in the case of $\bar{H}'(0) = f^0_{2x_1x_1} g^0_\lambda/g^0_{x_1} > 0$ and with $-1 \ll \lambda < 0$ in the case of $\bar{H}'(0) < 0$. The corresponding derivative $k^H_\lambda(0)$ at $\lambda = 0$ is given by (4.13). Note that $\bar{H}'(0) \cdot c_5 = -(f^0_{2x_1x_1})^2 < 0$ so that the singularly perturbed Hopf points and the singularly perturbed homoclinic orbits exist on different sides of the k-axis which represents the singularly perturbed saddle-nodes.

The assumption of a generic unfolding of the singularly perturbed Bogdanov point ensures that the singularly perturbed points of lower degeneracy (saddle-nodes, Hopf points, homoclinic base points) are also generically unfolded with respect to (λ, ϵ) or (k, ϵ).

Qualitatively we obtain diagram (a) in Figure 2 with $(p_1, p_2) = (\lambda, k)$. Here we chose $c_5 > 0$, $k^{Ho}_\lambda(0) > 0$ and $k^H_\lambda(0) < 0$ which occurs in case of the model equation (1.5). The singularly perturbed points in the (p_1, p_2)-parameter space of the original system (2.5) are obtained by diffeomorphically deforming the curves according to the transformation (3.6).

In case of the Fitzhugh–Nagumo equation (1.3) we obtain diagram (b) in Figure 2; i.e., the singularly perturbed homoclinic orbits and the singularly perturbed Hopf points are both located on the a-axis. In particular they form a smooth curve at the singularly perturbed Bogdanov point at $a = 0$. This is a degenerate situation which results from the fact that the central u-system $\dot{u}_1 = u_2$, $\dot{u}_2 = -u_1^2 + u_1^3$ has a Bogdanov point in a Hamiltonian system.

In general we obtain this degenerate case if a certain normal form coefficient of the central system vanishes, as can be seen by the following argument. At $(\lambda, k, \epsilon) = 0$ the x-part of the system (3.7) assumes the following form after performing a standard normal form transformation:

$$\begin{aligned} \dot{x}_1 &= x_2 + O(|x|^3), \\ \dot{x}_2 &= \tfrac{1}{2} f^0_{2x_1x_1} \cdot x_1^2 + \mathrm{tr}_{x_1}(f_x)^0 \cdot x_1 x_2 + O(|x|^3). \end{aligned} \tag{5.40}$$

Hence the Bogdanov point is nondegenerate iff $f^0_{2x_1x_1} \neq 0$ and $\mathrm{tr}_{x_1}(f_x)^0 \neq 0$ (cf. [15]). The first inequality is valid according to (3.8). Concerning the second inequality the equations (5.39) and (4.13) yield the equivalence

$$k^{Ho}_\lambda(0) \neq k^H_\lambda(0) \qquad \Longleftrightarrow \qquad \mathrm{tr}_{x_1}(f_x)^0 \neq 0; \tag{5.41}$$

i.e., generically we have $\mathrm{tr}_{x_1}(f_x)^0 \neq 0$ and the singularly perturbed Bogdanov point causes curves of singularly perturbed homoclinic orbits, singularly perturbed saddle-nodes and singularly perturbed Hopf points which meet transversally at the origin. The corresponding (λ, k, ϵ)-unfolding diagram is depicted in diagram (a) of Figure 3. When approaching the degenerate case $\mathrm{tr}_{x_1}(f_x)^0 = 0$ of a nontransversal intersection the precise behavior of the surfaces in Figure 3 diagram (a) is not clear.

5.6. Numerical results. We close the paper by numerically continuing the surface of homoclinic orbits to the border line indicated by the open circles in Figure 3(a), Figure 9, and Figure 13(b). This is done for the model equation (1.5). With $(p_1, p_2) = (\lambda, k)$ and for fixed $-1 \ll k < 0$ the (λ, ϵ)-section through Figure 3(a) yields the structures depicted in Figure 14.

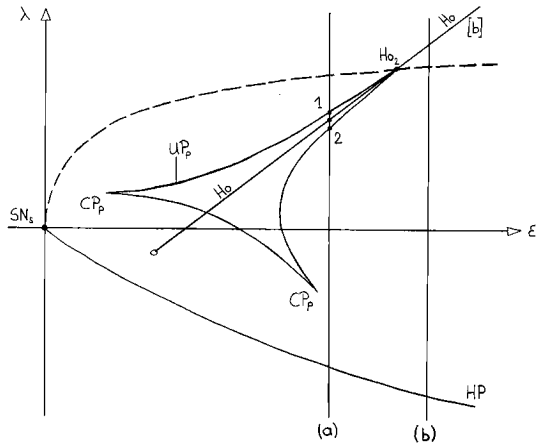

FIG. 14. *The* (λ, ϵ)*-section through Figure* 3(a) *for fixed* $-1 \ll k < 0$.

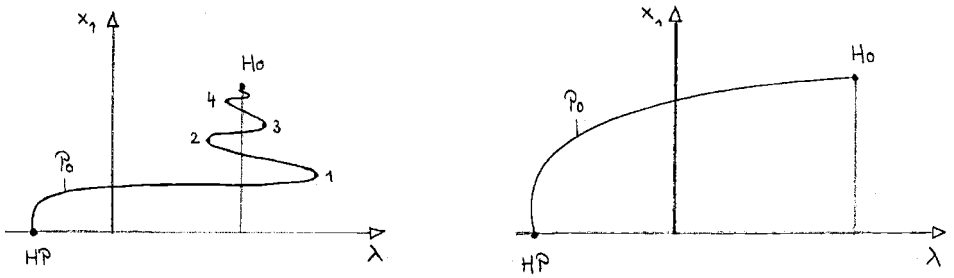

(a) (b)

FIG. 15. *The bifurcation diagrams along the* λ*-sections* (a) *and* (b) *in Figure* 14.

On the left side of the broken line we obtain three real eigenvalues at the stationary point $(u_1, u_2, v) = (\lambda, 0, -\lambda^2)$, whereas on the right side a conjugate-complex pair of eigenvalues $(\rho \pm i\omega) \in \mathbb{C}$ coexists with one real eigenvalue $\kappa \in \mathbb{R}$ with $|\kappa| > |\rho|$. Consequently, the homoclinic orbits Ho turn into homoclinic orbits of Shilnikov type [15] when crossing the broken line at the degenerate homoclinic orbit Ho_2 during variation of ϵ towards zero. Ho_2 is a well-known codimension-two homoclinic bifurcation (see [6] for numerical and theoretical results). Figure 15 shows the corresponding bifurcation diagrams along the λ-sections (a) and (b) in Figure 14.

In particular we obtain in the left diagram an infinite sequence 1,2,3,4, ... of periodic limit points with respect to λ. The first two limit points 1 and 2 are also marked along the line (a) in Figure 14. Now the numerical continuation of these points within the (λ, ϵ)-space of Figure 14 yields the closed curve UP_p of periodic limit points; i.e., the limit points 1 and 2 are connected by a curve that emanates from the degenerate homoclinic orbit Ho_2 and which contains additionally the two cusp points CP_p of periodic orbits. These cusp points arise by the coalescence of two limit points.

An analogous connection exists between the next two limit points 3 and 4 in Figure 15 and so forth. We conjecture that the (λ, ϵ)-unfolding diagram in Figure 14

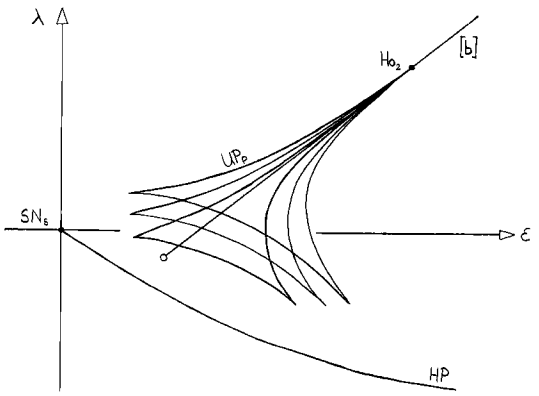

FIG. 16. *Closed curves of periodic limit points in the* (λ, ϵ)*-plane.*

can be extended by an infinite sequence of closed curves which approach the curve of homoclinic orbits Ho as indicated in Figure 16. Each of the closed curves represents a surface of periodic orbits that are connected in a rather complicated manner by limit points of periodic orbits.

Unfortunately, this observation does not clarify the behavior of the homoclinic orbits near the open circle. However, numerical calculations suggest that a canard like blow-up occurs as indicated in diagram (d) of Figure 3; i.e., the homoclinic orbits of Shilnikov type blow-up along the continuum of stationary points $v = -u_1^2$ which exists at $\epsilon = 0$. These blow-up phenomena typically occur in an exponentially small strip that is hardly accessible to numerical calculations.

Note that within the complete (λ, k, ϵ)-unfolding space of the model equation (1.5) we obtain a curve of open circles that passes through the singularly perturbed Bogdanov point at $k = 0$ (cf. Figure 3(a)). The (k, ϵ)-dependence seems to be of cubic order; i.e., we expect $k(\epsilon) = O(\epsilon^3)$ near the singularly perturbed Bogdanov point. This observation is purely motivated by numerical experiments. We did not succeed to predict it from formal asymptotic expansions.

Acknowledgment. This paper represents an extended part of the authors thesis. It was supported by the DFG–Schwerpunktprogramm "Ergodentheorie, Analysis und effiziente Simulation dynamischer Systeme" and was carried out during a four-month visit at the University of Bielefeld and a seven-month visit at the University of Tübingen. The author wishes to express his thanks to Prof. W.-J. Beyn, Prof. E. Bohl, and Prof. K. P. Hadeler.

OPTIMAL DESIGN AND CONSTRAINED QUASICONVEXITY*

PABLO PEDREGAL†

Abstract. We propose an alternative formulation for a typical optimal design problem in dimension two that allows for dependence on derivatives of the state. By means of a local formulation, we relate the optimal design problem to an equivalent vector variational problem. Relaxation in this framework involves the notion of constrained quasiconvexity.

Key words. optimal design, vector variational problems, quasiconvexity

1. Introduction.

We would like to consider the following typical optimal design problem where the cost functional has the form

$$\overline{I}(g) = \int_\Omega W(x, g(x), w(x), \nabla w(x))\, dx,$$

the design variable g is constrained in some way and is related to w through the diffusion equation

$$-\operatorname{div}(g\nabla w) = f \quad \text{in} \quad H^{-1}(\Omega), \tag{1.1}$$

where $w \in H_0^1(\Omega)$, and $f \in H^{-1}(\Omega)$ is known. Ω is assumed to be a domain in $\mathbf{R}^2$ and the density $W : \Omega \times \mathbf{R} \times \mathbf{R} \times \mathbf{R}^2 \to \mathbf{R}^*$ is supposed to enjoy typical regularity properties, essentially continuity with respect to g, w, and ∇w and measurability with respect to x. $\mathbf{R}^*$ stands for $\mathbf{R} \cup \{+\infty\}$. No convexity whatsoever is assumed on W. Typical optimal design problems ask for constraints on g of the type $g(x) \in \{a, b\}$ for each $x \in \Omega$, where $0 < a < b$ and

$$\frac{1}{|\Omega|}\int_\Omega g(x)\, dx = \lambda a + (1-\lambda)b \tag{1.2}$$

for some fixed $\lambda \in (0, 1)$. We will focus in this work on this case as well, although other situations can also be treated. In precise terms, we will be concerned with the problem

$$\text{Minimize} \quad \overline{I}(g) = \int_\Omega W(x, g(x), w(x), \nabla w(x))\, dx,$$

subject to

$$g(x) \in \{a, b\} \text{ for almost everywhere (a.e.) } x \in \Omega, \quad \frac{1}{|\Omega|}\int_\Omega g(x)\, dx = \lambda a + (1-\lambda)b,$$
$$-\operatorname{div}(g\nabla w) = f, \quad w \in H_0^1(\Omega),$$

where $0 < a < b$, $\lambda \in (0,1)$, $f \in H^{-1}(\Omega)$, and $W : \Omega \times \mathbf{R} \times \mathbf{R} \times \mathbf{R}^2 \to \mathbf{R}^*$ are given.

We would like in our analysis to link these optimal design problems to questions about vector variational problems, quasiconvexity, gradient Young measures, etc., just as in the pioneering work [9]. See also [1]. We will actually use some basic, important tools that played a role in these works. The main point in our paper is to examine and identify the underlying variational structure of this class of structural design problems, particularly what relates to relaxation. The novelty lies in the explicit dependence of the cost functional with respect to the gradient variable ∇w. Obviously, the analysis we are about to carry out for this situation can also be applied to the particular case of no dependence on this variable. For some particular choices of W, these problems have been considered in [17], although treated from a different perspective.

For the convenience of the reader, and in order to stress the main point we would like to convey, let us consider a simplified, one-dimensional situation [14]

$$\text{Minimize} \quad \overline{I}(g) = \int_0^1 W(x, g(x), w(x), w'(x))\, dx,$$

subject to

$$g(x) \in \{a, b\} \text{ for a.e. } x \in (0,1), \quad \int_0^1 g(x)\, dx = \lambda a + (1-\lambda) b,$$
$$-(g(x)w'(x))' = f, \quad w(0) = w(1) = 0,$$

where $0 < a < b$, $\lambda \in (0,1)$, $f \in H^{-1}(0,1)$ and $W : (0,1) \times \mathbf{R}^3 \to \mathbf{R}^*$ are given. Because of the restrictions on g we can write, for a suitable characteristic function χ,

$$g(x) = \chi(x) a + (1 - \chi(x))\, b, \quad \int_0^1 \chi(x)\, dx = \lambda.$$

Moreover, if

$$W_t(x, u, v) = W(x, t, u, v), \quad t = a, b,$$

the cost functional can be thought of as depending on χ:

$$I(\chi) = \int_0^1 \left[\chi(x) W_a(x, w(x), w'(x)) + (1 - \chi(x))\, W_b(x, w(x), w'(x))\right] dx.$$

On the other hand, if $-U'' = f$, $U \in H_0^1(0,1)$, then $-(gw' + U')' = 0$ and thus $g(x)w'(x) + U(x)$ must be constant throughout $(0,1)$. If we define a density $\varphi : (0,1) \times \mathbf{R}^3 \to \mathbf{R}^*$ by putting

$$\varphi(x, w, w', k) = \begin{cases} W_a(x, w, w'), & aw'(x) + U'(x) = k, \\ W_b(x, w, w'), & bw'(x) + U'(x) = k, \\ +\infty & \text{else}, \end{cases}$$

then our optimal design criterion can be written in terms of φ by minimizing the integral

$$J(w, k) = \int_0^1 \varphi(x, w(x), w'(x), k)\, dx,$$

where $w \in H_0^1(0,1)$ and k must be constant in $(0,1)$. The whole point of this formulation is that w and k in the pairs (w,k) are not related to each other in any way because the differential, nonlocal constraint has been recorded in the fact that k must be constant. The analysis would proceed by examining this equivalent variational problem. This is the type of analysis we would like to carry out for the two-dimensional situation.

It is by now a well-established fact that these optimal design problems lack classical solutions [12]. If we call χ, as in the previous one-dimensional example, the characteristic function of the set where $g = a$, then the cost functional $\overline{I}$ can also be interpreted in terms of χ. Optimizing sequences of such characteristic functions behave in such a way that there is no hope to obtain a new characteristic function as a limit in any sense, so that there will be no solution in the class of characteristic functions. This sort of behavior is typical of nonconvex variational problems. The main goal of the paper is to examine the relationship between these optimal design problems and nonconvex vector variational problems. In this regard, our point of view is similar to the one in [9], [10], [11] as pointed out in the previous paragraph.

The main feature of this type of optimization problems is the nonlocality expressed through the differential constraint (1.1). The difficulties associated with this issue can be in part overcome by the observation that in dimension two divergence-free fields and curl-free fields are essentially the same when the domain Ω is simply connected, which is an assumption we impose in our domain. Hence if $U \in H_0^1(\Omega)$ is the solution of the problem

$$-\Delta U = f \quad \text{in} \quad H^{-1}(\Omega),$$

then

$$\operatorname{div}(-g\nabla w + \nabla U) = 0.$$

Therefore if T is a $\pi/2$-rotation, there exists a stream function $v \in H^1(\Omega)$ such that

$$\nabla U = g\nabla w + T\nabla v, \tag{1.3}$$

provided Ω is simply connected [7]. This identity ties g, w, and v with U, a data of the problem. Thus we can think of the pair $u = (w, v)$, a vector field in $\mathbf{R}^2$, as our "independent" variable and of g, our design variable, as determined by (1.3). The idea is to rewrite our original cost functional $\overline{I}$ as a local functional in terms of u and carry out an analysis of the problem in this new formulation. Obviously, we have to pay close attention to the fact that (1.3) must force g to take on the values a and b exclusively, and at the same time we also have to enforce the volume constraint (1.2). This same approach was used in [15] for an analysis of magnetostriction.

In the present case, we show the equivalence of the above design problem and the following vector variational problem:

$$\inf\left\{\int_\Omega \varphi(x,u(x),\nabla u(x))\,dx : u \in H^1(\Omega;\mathbf{R}^2), u^{(1)} \in H_0^1(\Omega),\right.$$
$$\left.\int_\Omega \psi(x,u(x),\nabla u(x))\,dx = \lambda\right\}$$

for appropriate densities φ and ψ. See section 2 in order to understand the relationship between φ, ψ and W. $u^{(1)}$ indicates the first component of u. We analyze relaxation under this new formulation and show the existence of an energy density

$$\Psi(x,u,F,t) : \Omega \times \mathbf{R}^2 \times \mathbf{M}^{2\times 2} \times \mathbf{R} \to \mathbf{R}^*$$

which is continuous with respect to (u, F, t) whenever it is finite, and measurable with respect to x, that enjoys the joint convexity property with respect to the pairs (F, t) [5], [6]

$$\Psi(x, u, F, t) \leq \frac{1}{|\Omega|} \int_\Omega \Psi(x, u, F + \nabla V(y), t + \theta(y))\, dy$$

for any $V \in W_0^{1,\infty}(\Omega; \mathbf{R}^2)$, and $\theta \in L^\infty(\Omega)$ with $\int_\Omega \theta(y)\, dy = 0$. This is in fact the key constitutive assumption on Ψ to ensure an optimal solution of the problem

$$\inf \left\{ \int_\Omega \Psi(x, u(x), \nabla u(x), t(x))\, dx : u \in H^1(\Omega; \mathbf{R}^2), u^{(1)} \in H_0^1(\Omega), \right.$$
$$\left. 0 \leq t(x) \leq 1, \int_\Omega t(x)\, dx = \lambda\, |\Omega| \right\}.$$

This optimal solution encodes minimizing sequences for the optimal design problem. The relaxed energy density Ψ yields, for fixed (x, u), the optimal design corresponding to volume fraction t with respect to the value a, when the gradient of the state takes on the affine boundary values given by F. The vector nature of the problem reflects the nonlocality of the differential restriction (1.1).

In section 2, we precisely explain and show the equivalence of the initial optimal design problem and the associated vector variational principle as well as the relevant, relaxed integrand. Section 3 focuses on the analysis of this relaxed integrand, and in particular, we prove its joint convexity property which is the essential ingredient in order to have existence of solutions for the relaxed formulation. The last section deals with a typical relaxation result for the equivalent vector variational problem and incorporates a short discussion on the difficulties attached to the computation on explicit examples.

2. An alternative formulation. We describe how an equivalent, alternative formulation for our optimal design problem can be set up. This involves a vector variational principle to which all the typical ideas and techniques of the calculus of variations can be applied. The volume constraint, however, forces us to introduce the concept of constrained quasiconvexity and constrained quasiconvexification. The resulting envelope depends upon a gradient variable and a volume fraction.

In order to enforce the unique values a and b in the range of g from the outset, we write

$$g(x) = \chi(x)a + (1 - \chi(x))\, b,$$

χ being the characteristic function of a subset of Ω with

$$\int_\Omega \chi(x)\, dx = \lambda\, |\Omega|\,.$$

In this way, the cost functional can be thought of as depending on χ:

$$\bar{I}(\chi) = \int_\Omega \left[\chi(x) W_a(x, w(x), \nabla w(x)) + (1 - \chi(x)) W_b(x, w(x), \nabla w(x))\right]\, dx, \tag{2.1}$$

where W_a and W_b are appropriate, finite-everywhere energy densities and

$$\operatorname{div}(-\left[\chi a + (1 - \chi)b\right] \nabla w + \nabla U) = 0. \tag{2.2}$$

Indeed, $W_a(x,w,F) = W(x,a,w,F)$ and the analogous for b. Notice that χ is the characteristic function of the set where $\varphi = W_a$. U is taken as before: the solution of the problem

$$-\Delta U = f \quad \text{in } H^{-1}(\Omega), \quad U \in H_0^1(\Omega).$$

We have used the same letter $\overline{I}$ to designate the cost functional.

We have already pointed out in the introduction that

$$\nabla U = [\chi a + (1-\chi)b]\,\nabla w + T\nabla v \tag{2.3}$$

can be regarded as a substitute for the differential equation (2.2) if the domain Ω is simply connected. This equation is the clue for trying to recover the integral in (2.1) by means of a single cost density depending on the vector gradient $(\nabla w, \nabla v)$. In fact, we define a new energy density $\varphi : \Omega \times \mathbf{R}^2 \times \mathbf{M}^{2\times 2} \to \mathbf{R}^*$ by putting

$$\varphi(x,u,F) = \begin{cases} W_a(x,u^{(1)},F^{(1)}) & \text{if } aF^{(1)} + TF^{(2)} = \nabla U(x), \\ W_b(x,u^{(1)},F^{(1)}) & \text{if } bF^{(1)} + TF^{(2)} = \nabla U(x), \\ +\infty & \text{else.} \end{cases} \tag{2.4}$$

$F^{(i)}$, $i = 1,2$, designates the ith-row of F, and $u^{(i)}$ the ith component of u. For notational convenience, set for a real $t \in \mathbf{R}$ and a vector $B \in \mathbf{R}^2$

$$\Lambda(t,B) = \left\{ F \in \mathbf{M}^{2\times 2} : tF^{(1)} + TF^{(2)} = B \right\},$$

a two-dimensional linear manifold in the space of 2×2 matrices, $\mathbf{M}^{2\times 2}$, so that

$$\{\varphi < +\infty\} = \left\{ (x,u,F) \in \Omega \times \mathbf{R}^2 \times \mathbf{M}^{2\times 2} : F \in \Lambda(a,\nabla U(x)) \cup \Lambda(b,\nabla U(x)) \right\}.$$

There is, however, the ambiguity of how φ is defined on the intersection

$$\Lambda(a,\nabla U(x)) \cap \Lambda(b,\nabla U(x)) = \begin{pmatrix} 0 \\ T^{-1}\nabla U(x) \end{pmatrix}.$$

It is quite clear that in the set E where ∇w in (2.3) vanishes, we are free to choose a or b (i.e., $\chi = 1$ or $\chi = 0$, respectively) so as to minimize $W_a(x,w,0)$ or $W_b(x,w,0)$. Notice that w is constant a.e. in E. In this case, we would have to make the optimal choice

$$\min\left\{W_a(x,w,0), W_b(x,w,0)\right\}.$$

Hence, the definition of φ must incorporate this feature, and we redefine φ as

$$\varphi(x,u,F) = \begin{cases} W_a(x,u^{(1)},F^{(1)}) & \text{if } F \in \Lambda(a,\nabla U(x)) \setminus \Lambda(b,\nabla U(x)), \\ W_b(x,u^{(1)},F^{(1)}) & \text{if } F \in \Lambda(b,\nabla U(x)) \setminus \Lambda(a,\nabla U(x)), \\ \min\left\{W_a(x,u^{(1)},0), W_b(x,u^{(1)},0)\right\} & \text{if } F \in \Lambda(a,\nabla U(x)) \cap \Lambda(b,\nabla U(x)), \\ +\infty & \text{else.} \end{cases} \tag{2.5}$$

On the other hand, the volume constraint

$$\int_\Omega \chi(x)\,dx = \lambda\,|\Omega|$$

will also play an important role and needs to be taken into account in our new variational principle. If we let

$$\psi(x,u,F)=\begin{cases}1/|\Omega| & \text{if } F\in\Lambda(a,\nabla U(x)),\\ +\infty & \text{else,}\end{cases} \tag{2.6}$$

we must ask for the condition

$$\int_\Omega \psi(x,u(x),\nabla u(x))\,dx=\lambda.$$

Set

$$I(u)=\int_\Omega \varphi(x,u(x),\nabla u(x))\,dx,$$
$$J(u)=\int_\Omega \psi(x,u(x),\nabla u(x))\,dx.$$

We can summarize the previous discussion in the following proposition.

PROPOSITION 2.1. *Let $u\in H^1(\Omega;\mathbf{R}^2)$ such that $u^{(1)}\in H^1_0(\Omega)$ and $I(u)<+\infty$. There exists a subset of Ω whose characteristic function χ verifies*

$$\int_\Omega \chi(x)\,dx=\lambda\,|\Omega|\,,\quad \overline{I}(\chi)=I(u).$$

Conversely, if χ is the characteristic function of a subset of Ω such that

$$\int_\Omega \chi(x)\,dx=\lambda\,|\Omega|\,,$$

there exists $u\in H^1(\Omega;\mathbf{R}^2)$ such that $u^{(1)}\in H^1_0(\Omega)$ and

$$I(u)=\overline{I}(\chi),\quad J(u)=\lambda.$$

We pretend to examine the variational problem

$$\inf\left\{I(u):u\in H^1(\Omega),u^{(1)}\in H^1_0(\Omega),J(u)=\lambda\right\}. \tag{2.7}$$

It is quite apparent that in defining φ as in (2.5), we have destroyed all the nice properties (φ is no longer a Carathéodory function, not even upper semicontinuous) that allow a treatment in the context of the calculus of variations. ψ is not a Carathéodory function either. They are still weak lower semicontinuous with respect to the gradient variable. We could introduce a multiplier to take care of the integral constraint $J(u)=\lambda$. But instead we propose to consider and analyze the envelope

$$\begin{aligned}\Psi(x,u,F,t)=\frac{1}{|\Omega|}\inf\Big\{&\int_\Omega \varphi(x,u,F+\nabla V(y))\,dy : V\in W^{1,\infty}_0(\Omega),\\ &\int_\Omega \psi(x,u,F+\nabla V(y))\,dy=t\Big\}.\end{aligned} \tag{2.8}$$

This is some kind of constrained quasiconvexification. In fact, the definition of Ψ in terms of an infimum over gradients is too rigid when the integrand may take the value $+\infty$ abruptly. We are willing to allow gradient Young measures to take the

place of the gradients ∇V in the definition of Ψ [8]. The next result specifies the main properties enjoyed by Young measures associated with minimizing sequences for the optimal design problem.

LEMMA 2.2. *If the coercivity*

$$c\left(|\nabla w|^2 - 1\right) \le W_t(x, w, \nabla w), \quad c > 0 \tag{2.9}$$

holds for $t = a$ and $t = b$, then the gradients $\{\nabla u_j\}$ of every minimizing sequence $\{u_j\}$ for (2.7) generate a H^1-Young measure $\nu = \{\nu_x\}_{x\in\Omega}$ such that

$$\operatorname{supp}(\nu_x) \subset \Lambda(a, \nabla U(x)) \cup \Lambda(b, \nabla U(x)),$$
$$\int_\Omega \nu_x \left(\Lambda(a, \nabla U(x))\right)\, dx = \lambda\, |\Omega|\,.$$

Proof. If $\{u_j\}$ is minimizing for I, then for a.e. $x \in \Omega$ we should have

$$(x, u_j(x), \nabla u_j(x)) \in \{\varphi < +\infty\}\,. \tag{2.10}$$

This is equivalent to saying

$$\nabla u_j(x) \in \Lambda(a, \nabla U(x)) \cup \Lambda(b, \nabla U(x))$$

for a.e. $x \in \Omega$.

On the one hand, the coercivity assumed in (2.9) implies that the sequence $\{\nabla u_j^{(1)}\}$ is bounded in $L^2(\Omega)$. Since U is a single function in $H^1(\Omega)$, the previous fact on the support of ∇u_j says that $\{\nabla u_j\}$ is truly bounded in $L^2(\Omega)$. By the fundamental existence theorem for Young measures [2], [13], this sequence (or rather an appropriate subsequence) generates a Young measure $\nu = \{\nu_x\}_{x\in\Omega}$. By subtracting suitable constants to $u_j^{(2)}$ (note that this does not change the value of the functional I) and noticing that $u_j^{(1)} \in H_0^1(\Omega)$, we can assume without loss of generality that $\{u_j\}$ is bounded in $H^1(\Omega)$ so that ν is a H^1-Young measure.

On the other hand, if $G(x, A)$ is any nonnegative, Carathéodory function such that $\{G(x, \nabla u_j(x))\}$ is weakly convergent in $L^1(\Omega)$ and

$$G(x, \cdot)|_{\Lambda(a,\nabla U(x))\cup\Lambda(b,\nabla U(x))} \equiv 0,$$

then clearly

$$0 = \lim_{j\to\infty} \int_\Omega G(x, \nabla u_j(x))\, dx = \int_\Omega \int_{\mathbf{M}^{2\times 2}} G(x, A)\, d\nu_x(A)\, dx.$$

The arbitrariness of G indicates the conclusion on the support of ν.

The same kind of argument for a function G such that

$$G(x, \cdot)|_{\Lambda(a,\nabla U(x))} \equiv 1$$

permits us to conclude that

$$\int_\Omega \nu_x \left(\Lambda(a, \nabla U(x))\right)\, dx = \lambda\, |\Omega|\,. \qquad \square$$

We then redefine the envelope in (2.8) by putting

$$\Psi(x,u,F,t)=\inf\left\{\int_{\mathbf{M}^{2\times 2}}\varphi(x,u,F+A)\,d\nu(A):\nu \text{ is a homogeneous } H^1\text{-Young measure}, \int_{\mathbf{M}^{2\times 2}}A\,d\nu(A)=0, \int_{\mathbf{M}^{2\times 2}}\psi(x,u,F+A)\,d\nu(A)=t\right\}. \tag{2.11}$$

In so doing, we are accepting sequences of gradients that might take on values off the admissible set $\Lambda(a,\nabla U(x))\cup\Lambda(b,\nabla U(x))$ in small parts of Ω. Strictly speaking the cost of such designs would be infinite despite the fact that the cost in terms of its underlying Young measure would be finite. However, the new definition of Ψ in terms of Young measures is, if anything, a lower bound for Ψ in (2.8). We find it quite reasonable to allow these generalized designs if we can lower the cost when looking at its associated Young measure. In those small sets, g would not take either of the two values a or b, but rather it would have to be interpreted as a matrix-valued function. A more precise way of expressing these ideas is to say that the associated generalized problem in terms of Young measures

$$\inf\left\{\int_\Omega\int_{\mathbf{M}^{2\times 2}}\varphi(x,u(x),A)\,d\nu_x(A)\,dx:\nu=\{\nu_x\}_{x\in\Omega} \text{ is a } H^1\text{-Young measure}, \int_{\mathbf{M}^{2\times 2}}A\,d\nu_x(A)=\nabla u(x), u\in H^1(\Omega;\mathbf{R}^2), u^{(1)}\in H_0^1(\Omega), \int_\Omega\int_{\mathbf{M}^{2\times 2}}\psi(x,u(x),A)\,d\nu_x(A)\,dx=\lambda\,|\Omega|\right\}, \tag{2.12}$$

might not have as a solution the Young measure associated with a minimizing sequence for the original optimal design problem. Our claim is that minimizers for this optimization problem are, if anything, better if we are willing to allow "small errors" in the design in the sense explained above. More precisely we can state the following proposition.

PROPOSITION 2.3. *Let m and $\tilde{m}$ be the infima in* (2.7) *and* (2.12)*, respectively. Under the coercivity on W_t assumed in Lemma* 2.2*, $\tilde{m}\le m$.*

This proposition is a direct consequence, for instance, of Theorem 6.11 in [13]. Notice that even though ψ is not globally continuous with respect to F, it is indeed continuous restricted to the support of ν by Lemma 2.2. φ, however, is not continuous, not even when restricted to the support of ν. The integrals of φ in the above infimum should be understood in the following sense:

$$\begin{aligned}\int_{\mathbf{M}^{2\times 2}}\varphi(x,u,F+A)\,d\nu(A)=&\int_{\Lambda(a,\nabla U(x))\setminus\Lambda(b,\nabla U(x))}\varphi(x,u,F+A)\,d\nu(A)\\&+\int_{\Lambda(b,\nabla U(x))\setminus\Lambda(a,\nabla U(x))}\varphi(x,u,F+A)\,d\nu(A)\\&+\varphi\left(x,u,\begin{pmatrix}0\\T^{-1}\nabla U(x)\end{pmatrix}\right)\nu\left(\begin{pmatrix}0\\T^{-1}\nabla U(x)\end{pmatrix}\right).\end{aligned}$$

The idea of "small errors" brought to mind above admits a more formal, rigorous treatment in the context of [17], [16], and [19]. We will not insist on this issue, since our aim is to examine a vector variational problem with integrand Ψ. From now on, we stick to the functions φ, ψ, and Ψ as defined in (2.5), (2.6), and (2.11), respectively.

3. Relaxed integrand. The main property of the envelope Ψ is its jointly convex nature [5], [6] on the pairs (F,t) under which we can show existence of optimal solutions. This jointly convex property can be formulated in a standard way by requiring

$$\Psi(x,u,F,t) \le \frac{1}{|\Omega|}\int_\Omega \Psi(x,u,F+\nabla V(y), t+\theta(y))\,dy \tag{3.1}$$

whenever $V \in W_0^{1,\infty}(\Omega)$, and $\theta \in L^\infty(\Omega)$ with $\int_\Omega \theta(y)\,dy = 0$.

THEOREM 3.1. *The envelope Ψ is jointly convex in (F,t) for fixed (x,u) in the sense of* (3.1).

Proof. We divide the proof in several steps.

Step 1. V is piecewise affine and θ is piecewise constant. Let $V \in W_0^{1,\infty}(\Omega)$ be a piecewise affine function, so that we can write

$$\nabla V = \sum_i F_i \chi_{\Omega_i},$$

where $\{\Omega_i\}$ are pairwise disjoint open subdomains with

$$|\Omega - \cup_i \Omega_i| = 0.$$

Let

$$\theta(y) = \sum_i t_i \chi_{\Omega_i}, \quad \sum_i t_i\,|\Omega_i| = 0.$$

If $\nu^{(i)} = \left\{\nu_y^{(i)}\right\}_{y\in\Omega_i}$ is admissible in (2.11) for $(F+F_i, t+t_i)$ and we define $\nu = \{\nu_y\}_{y\in\Omega}$ by

$$\int_{\mathbf{M}^{2\times 2}} G(A)\,d\nu_y(A) = \int_{\mathbf{M}^{2\times 2}} G(F_i+A)\,d\nu_y^{(i)}(A),$$

whenever G is continuous and $y \in \Omega_i$, then ν is a H^1-Young measure (see the characterization of gradient Young measures in [8]). Because its underlying deformation is

$$\begin{aligned}\int_{\mathbf{M}^{2\times 2}} A\,d\nu_y(A) =& \sum_i \chi_{\Omega_i}(y)\int_{\mathbf{M}^{2\times 2}} (F_i+A)\,d\nu_y^{(i)}(A)\\ =& \sum_i \chi_{\Omega_i}(y) F_i\\ =& \nabla V(y),\end{aligned}$$

and V vanishes on the boundary (in particular it has affine boundary values), we may consider its homogenized version $\overline{\nu}$ [13]. Then

$$\begin{aligned}\int_{\mathbf{M}^{2\times 2}} \psi(x,u,F+A)\,d\overline{\nu}(A) =& \frac{1}{|\Omega|}\int_\Omega\int_{\mathbf{M}^{2\times 2}} \psi(x,u,F+A)\,d\nu_y(A)\,dy\\ =& \frac{1}{|\Omega|}\sum_i \int_{\Omega_i}\int_{\mathbf{M}^{2\times 2}} \psi(x,y,F+F_i+A)\,d\nu_y^{(i)}(A)\,dy\\ =& \frac{1}{|\Omega|}\sum_i (t_i+t)\,|\Omega_i|\\ =& t.\end{aligned}$$

Therefore $\overline{\nu}$ is admissible in the optimization problem that defines $\Psi(x,y,F,t)$ and

$$\begin{aligned}|\Omega|\,\Psi(x,u,F,t) &\le \int_\Omega \int_{\mathbf{M}^{2\times 2}} \varphi(x,u,F+A)\,d\nu_y(A)\,dy \\ &= \sum_i \int_{\Omega_i} \int_{\mathbf{M}^{2\times 2}} \varphi(x,u,F+F_i+A)\,d\nu_y^{(i)}(A)\,dy.\end{aligned}$$

Due to the arbitrariness of each admissible $\nu^{(i)}$ in (2.11) for $(F+F_i,t+t_i)$, and the independence among themselves, we can conclude

$$|\Omega|\,\Psi(x,u,F,t) \le \sum_i \Psi(x,u,F+F_i,t+t_i)\,|\Omega_i|\,,$$

which is the joint convexity for (V,θ).

Step 2. $\Psi(x,u,F,\cdot)$ is convex as a function of t, and $\Psi(x,u,\cdot,t)$ is rank-one convex as a function of F. The first fact is a direct consequence of Step 1 by taking $V\equiv 0$. For the rank-one convexity, notice that $\nu = s\nu_1 + (1-s)\nu_2$ is admissible in (2.11) for the pair (F,t) if ν_i is admissible for (F_i,t), $i=1,2$, and $\operatorname{rank}(F_1-F_2)\le 1$ (see again [8]). As a direct consequence, the dependence of Ψ with respect to (F,t) is continuous wherever it is finite.

Step 3. If $\mathcal{F}(A)$ (for fixed (x,u)) designates the multifunction

$$\mathcal{F}(A) = \{t\in[0,1] : \Psi(x,u,A,t) < +\infty\}\,,$$

then

$$\begin{aligned}\mathcal{F}(A) &= (0,1) \quad \text{if } A\notin \Lambda(a,\nabla U(x))\cup\Lambda(b,\nabla U(x)),\\ \mathcal{F}(A) &= (0,1] \quad \text{if } A\in \Lambda(a,\nabla U(x)),\\ \mathcal{F}(A) &= [0,1) \quad \text{if } A\in \Lambda(b,\nabla U(x))\setminus\Lambda(a,\nabla U(x)).\end{aligned}$$

In particular, $\mathcal{F}$, as a multifunction, is lower semicontinuous: if $t\in\mathcal{F}(A)$ and $A_j\to A$, we can find $t_j\in\mathcal{F}(A_j)$ such that $t_j\to t$.

The interesting part of the previous statement concerns the computation of $\mathcal{F}(A)$ when A does not belong to either of the sets $\Lambda(a,\nabla U(x))$, $\Lambda(b,\nabla U(x))$. We will show that for any such matrix, and for any $t\in(0,1)$ there exists a laminate μ_A supported on $\Lambda(a,\nabla U(x))\cup\Lambda(b,\nabla U(x))$ with barycenter A and such that $\mu_A(\Lambda(a,\nabla U(x))) = t$. Since the structure of laminates is preserved by translation, and the sets $\Lambda(s,B)$ are two-dimensional linear manifolds of matrices, we can show our claim, without loss of generality, replacing $\nabla U(x)$ by 0.

We will proceed in two steps.

LEMMA 3.2. *If we denote by $A^{(i)}$, $i=1,2$, the rows of A, and*

$$(3.2)\quad \Big[\Big(aA^{(1)}+TA^{(2)}\Big)\cdot\Big(bA^{(1)}+TA^{(2)}\Big)\Big]^2 - 4ab\Big(A^{(1)}\cdot A^{(2)}\Big)^2 > 0, \quad A^{(1)}\cdot A^{(2)} < 0,$$

there exists a vector $Y\in\mathbf{R}^2$, and scalars $t>0$, $s\in\mathbf{R}$, such that

$$(3.3)\qquad A + \begin{pmatrix} Y \\ sY\end{pmatrix} \in \Lambda(a,0), \quad A - t\begin{pmatrix} Y \\ sY\end{pmatrix} \in \Lambda(b,0).$$

Proof. The conditions in (3.3) can be explicitly written as

$$-aA^{(1)} - TA^{(2)} = (a\mathbf{1} + sT)\, Y,$$
$$bA^{(1)} + TA^{(2)} = t\,(b\mathbf{1} + sT)\, Y,$$

where $\mathbf{1}$ is the identity matrix. After eliminating the vector Y, we obtain

$$(a\mathbf{1} + sT)(bA^{(1)} + TA^{(2)}) + t(b\mathbf{1} + sT)(aA^{(1)} + TA^{(2)}) = 0.$$

This identity will be possible if and only if

$$\begin{vmatrix} (a\mathbf{1} + sT)(bA^{(1)} + TA^{(2)}) \\ (b\mathbf{1} + sT)(aA^{(1)} + TA^{(2)}) \end{vmatrix} = 0. \tag{3.4}$$

Moreover, the fact that we should have $t > 0$ implies

$$(a\mathbf{1} + sT)(bA^{(1)} + TA^{(2)}) \cdot (b\mathbf{1} + sT)(aA^{(1)} + TA^{(2)}) < 0. \tag{3.5}$$

If we keep in mind that

$$\det \begin{vmatrix} x \\ Ty \end{vmatrix} = x \cdot y,$$

then, after a few elementary manipulations, we get that (3.4) can be written explicitly

$$A^{(1)} \cdot A^{(2)} s^2 - \left(aA^{(1)} + TA^{(2)}\right) \cdot \left(bA^{(1)} + TA^{(2)}\right) s + abA^{(1)} \cdot A^{(2)} = 0.$$

This quadratic equation will have two real solutions if and only if (3.2) holds. We claim that one of those two solutions is such that the additional requirement (3.5) is fulfilled. Checking this explicitly is almost impossible by hand.

To this aim we introduce two scalar functions $f(s)$ and $g(s)$ determined by

$$\begin{vmatrix} (a\mathbf{1} + sT)(bA^{(1)} + TA^{(2)}) \\ (b\mathbf{1} + f(s)T)(aA^{(1)} + TA^{(2)}) \end{vmatrix} = 0,$$

and

$$g(s) = (a\mathbf{1} + sT)(bA^{(1)} + TA^{(2)}) \cdot (b\mathbf{1} + f(s)T)(aA^{(1)} + TA^{(2)}).$$

The following properties of f and g are easy to show.

1. Under (3.2), f is a quotient of two nondegenerate linear functions. Notice that the fixed points of f are the solutions of our quadratic equation above (3.4).

2. $f(s) \to f_\infty$ as $s \to \pm\infty$, where f_∞ is such that

$$\begin{vmatrix} T(bA^{(1)} + TA^{(2)}) \\ (b\mathbf{1} + f_\infty T)(aA^{(1)} + TA^{(2)}) \end{vmatrix} = 0.$$

3. g never vanishes: $g(s) = 0$ requires $A \in \Lambda(a, 0)$ or $A \in \Lambda(b, 0)$ which is impossible by (3.2) (keep in mind the definition of $f(s)$).

4. g takes on positive and negative values: notice that

$$\frac{g(s)}{s} \to T(bA^{(1)} + TA^{(2)}) \cdot (b\mathbf{1} + f_\infty T)(aA^{(1)} + TA^{(2)}),$$

as $s \to \pm\infty$.

5. Since g is continuous whenever f is continuous, g changes signs when f is not defined (note that f being a quotient of two linear functions has one vertical asymptote).

6. It is elementary to check that the two fixed points of f lie in the right branch of its graph. Therefore, we must make sure that g is negative on this branch. Because of property 4 above, it suffices to enforce

$$T(bA^{(1)} + TA^{(2)}) \cdot (b\mathbf{1} + f_\infty T)(aA^{(1)} + TA^{(2)}) < 0.$$

After a few careful computations this inequality reduces to

$$(b-a)^2 A^{(1)} \cdot A^{(2)} + \frac{\left(aA^{(1)} + TA^{(2)}\right) \cdot \left(bA^{(1)} + TA^{(2)}\right)^2}{A^{(1)} \cdot A^{(2)}} < 0.$$

This is equivalent to requiring

$$A^{(1)} \cdot A^{(2)} < 0.$$

This proves our claim. □

An interesting way of expressing the conclusion of this result is by saying that for each matrix A verifying (3.2) there exists a gradient Young measure (a laminate) of the simple form

$$\mu_A = t(A)\delta_{A_a} + (1 - t(A))\delta_{A_b} \tag{3.6}$$

such that $A_a \in \Lambda(a, 0)$, $A_b \in \Lambda(b, 0)$, $t(A) \in [0, 1]$. Let us denote by Γ the set of matrices A satisfying (3.2).

We go back to the proof of Step 3. Let A be any matrix not belonging to either of the sets $\Lambda(a, 0)$ or $\Lambda(b, 0)$. We claim that there exists a vector Y such that

$$A + \begin{pmatrix} Y \\ -Y \end{pmatrix} \in \Lambda(a, 0), \quad A - t \begin{pmatrix} Y \\ -Y \end{pmatrix} \in \Gamma$$

for arbitrarily large values of $t > 0$.

The first condition forces us to take

$$Y = -(a\mathbf{1} - T)^{-1} \left(aA^{(1)} + TA^{(2)}\right).$$

Notice that $a\mathbf{1} - T$ is nonsingular and Y is a nonvanishing vector. Then

$$\frac{1}{t}\left(A - t\begin{pmatrix} Y \\ -Y \end{pmatrix}\right) \to \begin{pmatrix} Y \\ -Y \end{pmatrix}$$

as $t \to +\infty$, and this limit belongs to Γ trivially. This proves our claim. Replacing a by b we also have the same conclusion.

This remark enables us to consider the laminates

$$\nu_a = \frac{t}{1+t}\delta_{A+Y\otimes -Y} + \frac{1}{1+t}\mu_{A-tY\otimes -Y},$$
$$\nu_b = \frac{t}{1+t}\delta_{A+X\otimes -X} + \frac{1}{1+t}\mu_{A-tX\otimes -X},$$

according to (3.1), for appropriate vectors Y and X where,

$$A + Y \otimes \ -Y = A + \begin{pmatrix} Y \\ -Y \end{pmatrix} \in \Lambda(a,0),$$
$$A + X \otimes \ -X = A + \begin{pmatrix} X \\ -X \end{pmatrix} \in \Lambda(b,0).$$

Notice that both ν_a and ν_b have barycenter A. Since these two laminates are admissible in (2.11) and

$$\nu_a\left(\Lambda(a,0)\right) \geq \frac{t}{1+t}, \quad \nu_b\left(\Lambda(b,0)\right) \geq \frac{t}{1+t},$$

for arbitrarily large t, the computation of $\mathcal{F}(A)$ is finished in this case, keeping in mind that because $\Psi(x,u,A,\cdot)$ is convex, $\mathcal{F}(A)$ must be a subinterval of $[0,1]$.

What remains to be proved in Step 3 can be derived by exploiting the rank-one convexity of $\Psi(x,u,\cdot,t)$ shown in Step 2. Indeed, if A is a matrix in the union $\Lambda(a,0) \cup \Lambda(b,0)$ and F is a rank-one matrix such that $A+F$ and $A-F$ do not lie in the union of those two subspaces (nearly any such F is valid), then for $t \in (0,1)$

$$\Psi(x,u,A,t) \leq \frac{1}{2}\Psi(x,u,A+F,t) + \frac{1}{2}\Psi(x,u,A-F,t) < +\infty.$$

Finally, it is interesting to notice that

$$0 \notin \mathcal{F}(A)$$

when $A \in \Lambda(a,\nabla U(x)) \cap \Lambda(b,\nabla U(x))$. If $0 \in \mathcal{F}(A)$ for such A, then that would imply the existence of a nontrivial gradient Young measure supported entirely in $\Lambda(b,\nabla U(x)) \setminus \Lambda(a,\nabla U(x))$. By Theorem 4.1 in [3], the linear manifold $\Lambda(b,\nabla U(x))$ would contain at least one rank-one direction, which is not trivially the case.

Step 4. Approximation and conclusion. Let $V \in W_0^{1,\infty}(\Omega)$, and $\theta \in L^\infty(\Omega)$ with null average such that

$$\int_\Omega \Psi(x,u,F+\nabla V(y), t+\theta(y))\,dy < \infty.$$

Hence $t+\theta(y) \in \mathcal{F}(F+\nabla V(y))$ for a.e. $y \in \Omega$. It is well known that there exists a uniformly bounded sequence of piecewise affine functions V_j such that $V_j \to V$ strongly in every $W^{1,p}(\Omega)$, $p < \infty$ [4]. Let

$$\nabla V_j = \sum_i F_i^{(j)} \chi_{\Omega_i^{(j)}}.$$

By Step 3, and the a.e. convergence $F+\nabla V_j(y) \to F+\nabla V(y)$, we can find functions θ_j such that $t+\theta_j(y) \in \mathcal{F}(F+\nabla V_j(y))$ and $t+\theta_j(y) \to t+\theta(y)$ for a.e. $y \in \Omega$. Moreover, because of the structure of ∇V_j we can always choose

$$\theta_j = \sum_i \theta_i^{(j)} \chi_{\Omega_i^{(j)}}, \quad \sum_i \theta_i^{(j)} \left|\Omega_i^{(j)}\right| = 0,$$

where $t+\theta_i^{(j)} \in \mathcal{F}(F+F_i^{(j)})$. By Step 1,

$$\Psi(x,u,F,t) \leq \lim_{j\to\infty} \int_\Omega \Psi(x,u,F+\nabla V_j(y), t+\theta_j(y))\,dy.$$

The choice of the pairs $(\nabla V_j, \theta_j)$, which are uniformly bounded, has been made within the region where Ψ is continuous, so that by pointwise convergence and dominated convergence we can conclude the joint convexity property. □

4. Relaxation. Based on the joint convexity property for the integrand Ψ, we can now prove the following existence theorem.

THEOREM 4.1. *Assume*

$$c\left(|\nabla w|^2 - 1\right) \le W_t(x, w, \nabla w) \le C\left(|\nabla w|^2 + 1\right), \quad 0 < c < C \tag{4.1}$$

for $t = a$ and $t = b$. Then

1. *the functional*

$$J(u,t) = \int_\Omega \Psi(x, u(x), \nabla u(x), t(x))\, dx$$

is weak lower semicontinuous in $H^1(\Omega; \mathbf{R}^2) \times L^\infty(\Omega)$;

2. *the variational problem*

$$\inf\left\{\int_\Omega \Psi(x, u(x), \nabla u(x), t(x))\, dx : u - u_0 \in H_0^1(\Omega; \mathbf{R}^2), \right.$$
$$\left. \|t\|_{L^\infty(\Omega)} \le M_0, \int_\Omega t(x)\, dx = t_0\, |\Omega| \right\}$$

admits a solution for any $u_0 \in H^1(\Omega; \mathbf{R}^2)$, $M_0 > 0$, and $t_0 \in [-M_0, M_0]$.

Proof. Notice that the bounds assumed on W_t imply the upper bound

$$\Psi(x, u, F, t) \le C\left(1 + |F|^2\right)$$

whenever Ψ is finite. The conclusion of the theorem is a direct consequence of Theorems 4.4 and 5.1 in [5]. The dependence of the integrand on u can be dealt with easily as in [13]. □

We finally show existence of solutions of our relaxed functional directly related to the original optimal design problem as stated at the end of the introduction. The only change with respect to Theorem 4.1 refers to the additional constraints coming from the restrictions on our optimal design problem.

THEOREM 4.2. *Under the same assumptions as in Theorem* 4.1*, the variational problem*

$$\inf\left\{\int_\Omega \Psi(x, u(x), \nabla u(x), t(x))\, dx : u \in H^1(\Omega; \mathbf{R}^2), u^{(1)} \in H_0^1(\Omega), \right.$$
$$\left. 0 \le t(x) \le 1, \int_\Omega t(x)\, dx = \lambda\, |\Omega| \right\}$$

admits an optimal solution for any $\lambda \in (0,1)$.

The proof is a simple application of the direct method. Observe that the constraints

$$u^{(1)} \in H_0^1(\Omega), \quad \int_\Omega t(x)\, dx = \lambda\, |\Omega|, \quad 0 \le t(x) \le 1$$

are preserved under weak convergence.

It is now standard to produce a nonhomogeneous Young measure minimizer by finding optimal solutions of the problem defining the envelope $\Psi(x, u(x), \nabla u(x), t(x))$ for a.e. $x \in \Omega$ [13].

The reader may feel a little bit disappointed to discover that the relaxed energy density Ψ is not computable analytically, not even for the simplest examples one can think of. At least such computation would require a deeper and a more quantitative analysis related to gradient Young measures supported in prescribed sets that must also meet the additional requirement of having a certain amount of its mass supported in a particular subset. As we know, this may be a hard question [3]. For instance, if

$$W(x,g,w,\nabla w)=|\nabla w|^2,$$

then

$$\varphi(x,F)=\begin{cases}\left|F^{(1)}\right|^2 & \text{if } F\in\Lambda(a,\nabla U(x))\cup\Lambda(b,\nabla U(x)),\\ +\infty & \text{else,}\end{cases}$$

and

$$\Psi(x,F,t)=\inf\left\{\int_{\mathbf{M}^{2\times 2}}|A|^2\,d\nu(A):\nu\in\mathcal{A}_{(x,F,t)}\right\},$$

where $\mathcal{A}_{(x,F,t)}$ consists of the set of homogeneous H^1-Young measures supported in $\Lambda(a,\nabla U(x))\cup\Lambda(b,\nabla U(x))$, with first moment F and such that $\nu(\Lambda(a,\nabla U(x)))=t$. The difficulty in computing Ψ is not in the form of φ but rather in the structure of the set of admissible Young measures $\mathcal{A}_{(x,F,t)}$. It would be interesting to analyze computationally this procedure, at least replacing gradient Young measures by laminates. We plan to do this in a subsequent paper. For this particular example important conclusions were derived in [18] by using different techniques.

The only example where further information can be drawn is the case of no dependence on derivatives, because in this case the qualitative analysis carried out in section 3 is enough to compute the density Ψ. Indeed, if we assume for simplicity that

$$W_a(x,w)\le W_b(x,w)\quad\text{for all } (x,w),\tag{4.2}$$

then it is elementary to obtain explicit expressions for φ and Ψ, namely,

$$\begin{gathered}\varphi\,(x,u,F)=W_a(x,u^{(1)}),\quad F\in\Lambda(a,\nabla U(x)),\\ \varphi\,(x,u,F)=W_b(x,u^{(1)}),\quad F\in\Lambda(b,\nabla U(x))\setminus\Lambda(a,\nabla U(x)),\\ \varphi=+\infty\quad\text{else.}\end{gathered}$$

Consequently, keeping in mind the conclusions of Step 3 in section 3, it is straightforward to arrive at

$$\begin{gathered}\Psi(x,u,F,t)=tW_a(x,u^{(1)})+(1-t)W_b(x,u^{(1)}),\quad t\in(0,1),\\ \Psi(x,u,F,t)=W_a(x,u^{(1)}),\quad F\in\Lambda(a,\nabla U(x)),t=1,\\ \Psi(x,u,F,t)=W_b(x,u^{(1)}),\quad F\in\Lambda(b,\nabla U(x))\setminus\Lambda(a,\nabla U(x)),t=0,\\ \Psi(x,u,F,t)=+\infty\quad\text{else.}\end{gathered}$$

Thus under (4.2) the optimal design problem would be "equivalent" to the variational problem

$$\text{Minimize}\quad\int_\Omega\left[t(x)W_a(x,u^{(1)}(x))+(1-t(x))W_b(x,u^{(1)}(x))\right]dx$$

subject to the constraints

$$u \in H^1(\Omega;\mathbf{R}^2), \quad u^{(1)} \in H^1_0(\Omega),$$
$$0 \le t(x) \le 1, \quad \int_\Omega t(x)\,dx = \lambda\,|\Omega|\,,$$
$$\{t=0\} \subset \{\nabla u \in \Lambda(b,\nabla U)) \setminus \Lambda(a,\nabla U))\}\,, \quad \{t=1\} \subset \{\nabla u \in \Lambda(a,\nabla U))\}\,.$$

Notice, however, that this variational problem may not have optimal solutions because coercivity assumptions on the gradient ∇u are not guaranteed.

Acknowledgments. I want to thank several referees for their criticism in improving this paper, and R. Lipton for some interesting suggestions.

POINTWISE ERROR ESTIMATES FOR RELAXATION APPROXIMATIONS TO CONSERVATION LAWS*

EITAN TADMOR† AND TAO TANG‡

Abstract. We obtain sharp *pointwise* error estimates for relaxation approximation to scalar conservation laws with piecewise smooth solutions. We first prove that the first-order partial derivatives for the perturbation solutions are uniformly upper bounded (the so-called Lip^+ stability). A one-sided interpolation inequality between classical L^1 error estimates and Lip^+ stability bounds enables us to convert a global L^1 result into a (nonoptimal) local estimate. Optimal error bounds on the weighted error then follow from the maximum principle for weakly coupled hyperbolic systems. The main difficulties in obtaining the Lip^+ stability and the optimal pointwise errors are how to construct appropriate "difference functions" so that the maximum principle can be applied.

Key words. conservation laws, error estimates, relaxation method, optimal convergence rate, one-sided interpolation inequality, maximum principle

1. Introduction.

Consider the following stiff relaxation system:

$$\begin{cases} u_t^\epsilon + v_x^\epsilon = 0, \\ \\ v_t^\epsilon + \alpha u_x^\epsilon = -\frac{1}{\epsilon}\Big(v^\epsilon - f(u^\epsilon)\Big), \qquad \epsilon > 0, \end{cases} \tag{1.1}$$

for $(x,t) \in \mathbf{R} \times (0,\infty)$. The initial conditions associated with the above system are

$$u^\epsilon(x,0) = u_0(x), \qquad v^\epsilon(x,0) = f(u_0(x)). \tag{1.2}$$

The system (1.1) can be regarded as a singular perturbation problem, and the solutions are expected to converge, as ϵ tends to zero, to the entropy solutions of the equilibrium equation

$$\begin{cases} u_t + f(u)_x = 0, \qquad v = f(u), \\ \\ u(x,0) = u_0(x), \qquad v(x,0) = f(u_0(x)). \end{cases} \tag{1.3}$$

The relaxation limit for 2×2 nonlinear systems of conservation laws was first studied by Liu [11], who justified some nonlinear stability criteria for diffusion waves, expansion waves, and traveling waves. A general mathematical framework was analyzed for the nonlinear systems by Chen, Levermore, and Liu [1]. Consult [12] for a bird's eye view of recent results in this direction.

The presence of relaxation mechanisms is widespread in both the continuum mechanics as well as the kinetic theory contexts. Relaxation is known to provide a subtle

dissipative mechanism for discontinuities against the destabilizing effect of nonlinear response [11]. The relaxation models can be loosely interpreted as discrete velocity kinetic equations. The relaxation parameter, ϵ, plays the role of the mean free path and the system models the macroscopic conservation law. In that sense they are a discrete velocity analogue of the kinetic equations introduced by Perthame and Tadmor [15] and Lions, Perthame, and Tadmor [10].

The relaxation approximation can also be used to construct numerical approximations to the equilibrium conservation laws. In [6], Jin and Xin developed a class of first- and second-order nonoscillatory numerical schemes for the conservation law (1.3), based on the relaxation approximation (1.1). Since the relaxation approximation (1.1) is formally an $\mathcal{O}(\epsilon)$ perturbation to (1.3), they can compute (1.1) without resolving the computational grid to $\mathcal{O}(\epsilon)$. Indeed, in their final form, it is seen that the relaxation parameter in these relaxation schemes plays no role. In particular, their $\epsilon = 0$-limit in the first-order case coincides with the central Lax–Friedrichs scheme, and their $\epsilon = 0$-limit in the second-order version corresponds to the central scheme of Nessyahu and Tadmor [13]. The nonoscillatory central schemes introduced in [13] are based on staggered evolution of the reconstructed averages—a high-order sequel to the celebrated first-order Lax–Friedrichs (staggered) scheme. An extension of the high-resolution central scheme to multidimensional problems can be found in [5]. The central schemes are simple, efficient, stable, and enjoy the main advantage of avoiding costly (upwind) Riemann solvers. In this context, relaxation schemes offer yet another way to derive a whole class of high-resolution Riemann-solvers-free central schemes. The key is how to discretize the relaxation, as outlined in [6].

There have been many recent studies concerning the asymptotic convergence of the relaxation systems to the corresponding equilibrium conservation laws as the rate of the relaxation tends to zero. Most of these results deal with either large-time, nonlinear asymptotic stability or the zero relaxation limit for Cauchy problems. Tveito and Winther [18, 26] provided an $\mathcal{O}(\epsilon^{1/3})$-rate of convergence for some relaxation systems with nonlinear convection arising in chromatography. Katsoulakis and Tzavaras [7] introduced a class of relaxation systems, the contractive relaxation systems, and established an $\mathcal{O}(\sqrt{\epsilon})$ error bound in the case that the equilibrium equation is a scalar multidimensional one. The approaches in [7, 18, 26] are based on the extensions of Kruzhkov and Kuznetzov-type error estimates [9]. Kurganov and Tadmor [8] studied convergence and error estimates for a class of relaxation systems, including (1.1) and the one arising in chromatography, and concluded an $\mathcal{O}(\epsilon)$ order of convergence for scalar convex conservation laws. The novelty of their approach is the use of a weak Lip'-measure of the error, which allows them to obtain sharp error estimates.[1] For the relaxation system (1.1), Natalini [12] proved that the solutions to the relaxation system converges strongly to the unique entropy solution of (1.2) as $\epsilon \to 0$. Based on a general framework developed in [23, 25], the first-order rate of convergence for (1.1) is established in the case when its equilibrium solutions are piecewise smooth [24], which is an improvement on the $\mathcal{O}(\sqrt{\epsilon})$ error bounds [7, 8]. The boundary layer effect in the small relaxation limit to the equilibrium scalar conservation laws was investigated in [27]. The existence and uniqueness for the initial-boundary value problems are established.

The convergence and the rate of convergence mentioned above are mostly in the L^1 sense. It is understood that the L^1 error estimate is a global one, while in many practical cases we are interested in the *local* behavior of $u(x,t)$. Consequently, when

[1] Here and below, Lip' stands for the dual of Lip topology.

the error is measured by the L^1-norm, there is a loss of information due to the poor resolution of shock waves in $u(x,t)$. Several authors have investigated pointwise error estimates: For a system of conservation laws, Goodman and Xin [4] proved that the viscosity methods approximating piecewise smooth solutions with finitely many *noninteracting* shocks have a local $\mathcal{O}(\epsilon)$ error bound away from the shocks. A general convergence theory for one dimensional (1D) scalar convex conservation laws was developed by Tadmor and coauthors; see, e.g., [13, 19]. They proved that when measured in the weak Lip'-topology, the convergence rate of the viscous solution is of order $\mathcal{O}(\epsilon)$ in the case of rarefaction-free initial data and is of order $\mathcal{O}(\epsilon|\ln\epsilon|)$ in the general case. These weak Lip'-estimates are then converted into the usual L^1 error bounds of order one-half, and moreover, pointwise error estimates of order one-third, $\mathcal{O}(\epsilon^{1/3})$, are derived. Pointwise error analysis for finite difference methods to scalar and system of conservation laws is given recently by Engquist and Yu [3], Engquist and Sjogreen [2]. In [20], the authors provided the *optimal* pointwise convergence rate for the viscosity approximation. They used an innovative idea which enables them to convert a *global* L^1-error estimate into a *local* error estimate. Using this local error estimate and a bootstrap argument they proved that the viscosity approximation satisfies a *pointwise* error estimate of order $\mathcal{O}(\epsilon)$ for all but finitely many neighborhoods of shock discontinuities, each of width $\mathcal{O}(\epsilon)$. The previous results for the optimal order one convergence rates, in both L^1 and L^∞ spaces, are all based on a matching method and traveling wave solutions; see, e.g., [3, 4, 23]. The approach introduced in [20] does not follow the characteristics but instead makes use of the energy method, and hence can be extended to other types of approximate solutions, e.g., [21].

The question that we address in this paper is concerned with the rate of pointwise convergence for the relaxation approximation (1.1). The main purpose is to establish the *optimal* pointwise convergence. The proof of our results is based on two ingredients:

- a one-sided interpolation inequality between the L^1 error estimates and Lip^+ stability bounds; and
- a comparison theorem (the maximum principle) for weakly coupled hyperbolic systems.

In section 2, we review the preliminary results required for obtaining our error bounds. As mentioned earlier, the L^1 error bounds for the relaxation approximation have been established by several authors. A rigorous Lip^+ stability bounds for the relaxation approximation will be established in section 3. In section 4 we first consider the case when there is only one shock in the solutions of the equilibrium equation (1.3); i.e., the set of shock S consists of only one smooth curve. In this case, we show that

$$\operatorname{dist}(x,S)|u(x,t)-u^\epsilon(x,t)|\le C\epsilon. \tag{1.4}$$

It implies that $|u(x,t)-u^\epsilon(x,t)|\le C(h)\epsilon$ for (x,t) which are at least $\mathcal{O}(h)$ away from the set of shocks. The result (1.4) can be generalized to finitely many shocks with *possible collisions*. In the final section, we discuss the possible extensions of the results obtained in this work.

2. Preliminaries. Several useful results for the relaxation approximation will be reviewed in this section. We begin by introducing the subcharacteristic condition.

2.1. Subcharacteristic condition. The main stability criterion can be (formally) derived by using the Chapman–Enskog expansion for the stiff relaxation

system (1.1)

$$u_t^\epsilon + f(u^\epsilon)_x = \epsilon\Big((\alpha - f'(u^\epsilon)^2)u_x^\epsilon\Big)_x + \mathcal{O}(\epsilon^2). \tag{2.1}$$

The above equation will be of parabolic type under the following stability condition, i.e., the subcharacteristic condition [28]:

$$\alpha > f'(u^\epsilon)^2. \tag{2.2}$$

In a recent paper, Natalini [12] provided a rigorous analysis for (1.1) that leads to the subcharacteristic condition (2.2) under some assumptions on α and the initial data u_0. More precisely, we state his results as follows.

LEMMA 2.1. *If α in the relaxation equation* (1.1) *and the initial data u_0 in* (1.2) *satisfy*

$$\sqrt{\alpha} > M(N_0), \tag{2.3}$$

where N_0 and M_0 are defined by

$$\begin{cases} N_0 := \max\left(\|u_0\|_{L^\infty},\ \|f(u_0)\|_{L^\infty}\right), M(N_0) := \sup_{|\zeta|\le B(N_0)} |f'(\zeta)|, \textit{with} \\ \\ B(N_0) := 2N_0 + F(2N_0), F(N_0) := \sup_{|\zeta|\le N_0} |f(\zeta)|, \end{cases} \tag{2.4}$$

then the relaxation system (1.1) *with initial condition* (1.2) *satisfies the subcharacteristic inequality* (2.2). *Moreover, the solution (u^ϵ, v^ϵ) for* (1.1) *is uniformly bounded with respect to ϵ:*

$$|u^\epsilon(x,t)| \le B(N_0), |v^\epsilon(x,t)| \le \sqrt{\alpha}B(N_0), \textit{for} (x,t) \in \mathbf{R}\times(0,\infty). \tag{2.5}$$ ∎

Throughout this paper, we will assume that the condition (2.3) is satisfied. Under this assumption, the subcharacteristic inequality is guaranteed and will be used to establish the Lip^+ stability and the pointwise error bounds.

2.2. Global L^1 error bounds. The L^1-error analysis for the relaxation approximation method has been presented by several authors. For general data, an optimal L^1-rate can be found in [7, 8], for example. This optimal $\mathcal{O}(\sqrt{\epsilon})$ L^1-rate is overviewed in section 3.2, based on the Lip' approach taken in [8] (for a more general class of relaxation models). For piecewise-smooth data, the *optimal* $\sim \mathcal{O}(\epsilon)$ L^1-convergence rate was recently obtained by Teng [24]. We state his results as follows.

LEMMA 2.2. *Assume α in the relaxation equation* (1.1) *and the initial data u_0 in* (1.2) *satisfy the conditions stated in Lemma* 2.1. *Assume that the solutions to the scalar convex conservation law* (1.3) *are piecewise smooth. Let (u^ϵ, v^ϵ) be the solutions of the relaxation problems* (1.1)–(1.2). *Then the following error estimate holds:*

$$\sup_{0\le t\le T}\Big(\|u^\epsilon(\cdot,t) - u(\cdot,t)\|_{L^1(\mathbf{R})} + \|v^\epsilon(\cdot,t) - v(\cdot,t)\|_{L^1(\mathbf{R})}\Big) \le C(T)\epsilon\,|\ln\epsilon|, \tag{2.6}$$

where $v = f(u)$. If there is no initial central rarefaction wave and no new generated shocks, then the error bound is improved to

$$\sup_{0\le t\le T}\Big(\|u^\epsilon(\cdot,t) - u(\cdot,t)\|_{L^1(\mathbf{R})} + \|v^\epsilon(\cdot,t) - v(\cdot,t)\|_{L^1(\mathbf{R})}\Big) \le C(T)\epsilon. \tag{2.7}$$ ∎

We shall utilize these L^1 global error bounds to derive the pointwise error estimate (1.4). The order of the global L^1 error bounds will not affect the general $\mathcal{O}(\epsilon)$-pointwise result (1.4), but it will affect the choice of the distance function—see [20] for details. Thus improved L^1-error bounds lead to sharper description of the shock layer, with an optimal shock layer of size $\sim \mathcal{O}(\epsilon)$ corresponding to the piecewise-smooth cases (2.6) and (2.7).

2.3. An interpolation inequality. We let $\|\bullet\|_{Lip^+}$ denote the Lip^+-seminorm

$$\|w\|_{Lip^+} := \operatorname{ess\,sup}_{x\neq y}\left[\frac{w(x)-w(y)}{x-y}\right]^+,$$

where $[w]^+ = H(w)w$, with $H(\bullet)$ the Heaviside function. The following lemma is due to Nessyahu and Tadmor [14, section 2]; its proof can be found in [20].

LEMMA 2.3. *Assume that $z \in L^1 \cap Lip^+(\mathcal{I})$, and $w \in C^1_{loc}(x-\delta, x+\delta)$ for an interior x such that $(x-\delta, x+\delta) \subset \mathcal{I}$. Then the following estimate holds:*

(2.8)
$$|z(x)-w(x)| \le \text{Const}\cdot\left[\frac{1}{\delta}\|z-w\|_{L^1} + \delta\{\|z\|_{Lip^+(x-\delta,x+\delta)} + |w|_{C^1_{loc}(x-\delta,x+\delta)}\}\right].$$

In particular, if the size of the smoothness neighborhood for w can be chosen so that

$$\delta \sim \|z-w\|^{1/2}_{L^1(\mathcal{I})}\cdot(\|z\|_{Lip^+} + |w|_{C^1_{loc}})^{-1/2} \le \frac{1}{2}|\mathcal{I}|, \tag{2.9}$$

then the following estimate holds:

$$|z(x)-w(x)| \le \text{Const}\cdot\|z-w\|^{1/2}_{L^1(\mathcal{I})}\cdot\left[\|z\|_{Lip^+} + |w|_{C^1_{loc}(x-\delta,x+\delta)}\right]^{1/2}. \tag{2.10}$$

□

Thus (2.10) tells us that if the global L^1-error $\|z-w\|_{L^1}$ is small, then the pointwise error $|z(x)-w(x)|$ is also small wherever w_x is bounded. This does not require the C^1-boundedness of z—the weaker one-sided Lip^+ bound of z will suffice.

2.4. A comparison lemma. The following maximum principle for weakly coupled hyperbolic systems plays an important role in this work. Consider the following system:

$$\begin{cases} \partial_t u_1 + \lambda_1(x,t)\partial_x u_1 = \alpha_{11}(x,t)u_1 + \alpha_{12}(x,t)u_2 + \beta_1(x,t), \\ \\ \partial_t u_2 + \lambda_2(x,t)\partial_x u_2 = \alpha_{21}(x,t)u_1 + \alpha_{22}(x,t)u_2 + \beta_2(x,t), \end{cases} \tag{2.11}$$

with C^1 local speeds, $\lambda_i(\cdot)$, and low-order terms on the right involving bounded coefficients, $\alpha_{ij}(\cdot), \beta_i(\cdot)$, $1 \le i,j \le 2$. The following lemma (see, e.g., [16, Theorem 13]), provides sufficient conditions which guarantee that if the initial and boundary data prescribed for (2.11) is nonpositive, the solution remains nonpositive.

LEMMA 2.4. *Consider the Cauchy problem for the weakly coupled hyperbolic systems* (2.11) *in a domain $E := \mathbf{D}\times(0,T)$, subject to nonpositive initial and boundary conditions*

$$\begin{aligned} &u_1(x,0) \le 0, \quad u_2(x,0) \le 0, && x \in \mathbf{D}, \\ &u_1(x,t) \le 0, \quad u_2(x,t) \le 0, && (x,t) \in \partial\mathbf{D}\times(0,T). \end{aligned} \tag{2.12}$$

Assume that the coefficient functions in (2.11) *satisfy*

$$\begin{aligned} &\alpha_{12}(x,t) \geq 0, \quad \alpha_{21}(x,t) \geq 0, (x,t) \in E, \\ &\beta_1(x,t) \leq 0, \quad \beta_2(x,t) \leq 0, (x,t) \in E. \end{aligned} \tag{2.13}$$

Then the solution of (2.11) *remains nonpositive in later time:*

$$u_1(x,t) \leq 0, \qquad u_2(x,t) \leq 0 \qquad \textit{for} \quad (x,t) \in E. \qquad \square \tag{2.14}$$

For the proof, we note that thanks to (2.13), the nonpositive maximal values, $U_i(t) := \sup_x u_i(x,t)$ are majorized by the ODEs, $\dot{U}_i = \alpha_{ii} U_i(t) + \alpha_{ij} u_j(t) + \beta_i(t) \leq \alpha_{ii} U_i(t)$, and hence these maximal values cannot increase in time.

The two important results, the Lip^+ stability and the optimal pointwise error bounds are all based on the above lemma. The main difficulty is how to construct appropriate object functions u_1, u_2 so that above lemma can be suitably applied.

3. Lip^+ stability and local error bounds. In this section, we assume that f is strictly convex, i.e.,

$$f''(u) \geq \beta > 0 \qquad \text{for} \quad u \in \mathbf{R}, \tag{3.1}$$

and that u_0 is Lip^+-bounded,

$$\|u_0\|_{Lip^+} < \infty. \tag{3.2}$$

DEFINITION 3.1. *We say that* $\{u^\epsilon(x,t)\}_{\epsilon>0}$ *are* Lip^+*-stable if the following estimate is fulfilled:*

$$\|u^\epsilon(\cdot,t)\|_{Lip^+} \leq \|u_0\|_{Lip^+}, \qquad t \geq 0. \tag{3.3}$$

3.1. Lip^+ stability. We will show that the family $\{u^\epsilon(x,t)\}_{\epsilon>0}$ is Lip^+-stable. Assume first that $u_0 \in C_0^1(\mathbf{R})$. This implies, by the standard regularity theory for the semilinear hyperbolic problems, that $(u^\epsilon, v^\epsilon) \in C^1(\mathbf{R} \times (0,T))$ for some $T > 0$. Differentiating the equations (1.1) with respect to x gives

$$(u^\epsilon_x)_t + (v^\epsilon_x)_x = 0, \tag{3.4}$$

$$(v^\epsilon_x)_t + \alpha (u^\epsilon_x)_x = -\frac{1}{\epsilon}(v^\epsilon_x - f'(u^\epsilon) u^\epsilon_x). \tag{3.5}$$

By doing $\sqrt{\alpha} \times (3.4) + (3.5)$ and $\sqrt{\alpha} \times (3.4) - (3.5)$, the above system can be put in the following diagonal form:

$$\begin{aligned} &(\sqrt{\alpha} u^\epsilon_x + v^\epsilon_x)_t + \sqrt{\alpha}(\sqrt{\alpha} u^\epsilon_x + v^\epsilon_x)_x = -\frac{1}{\epsilon}(v^\epsilon_x - f'(u^\epsilon) u^\epsilon_x), \\ &(\sqrt{\alpha} u^\epsilon_x - v^\epsilon_x)_t - \sqrt{\alpha}(\sqrt{\alpha} u^\epsilon_x - v^\epsilon_x)_x = \frac{1}{\epsilon}(v^\epsilon_x - f'(u^\epsilon) u^\epsilon_x). \end{aligned}$$

Letting

$$\bar{p} = \sqrt{\alpha} u^\epsilon_x + v^\epsilon_x, \qquad \bar{q} = \sqrt{\alpha} u^\epsilon_x - v^\epsilon_x$$

and by using the above results yield

$$\begin{cases} \bar{p}_t + \sqrt{\alpha}\bar{p}_x = \frac{1}{2\epsilon}\left(\frac{f'(u^\epsilon)}{\sqrt{\alpha}} - 1\right)\bar{p} + \frac{1}{2\epsilon}\left(\frac{f'(u^\epsilon)}{\sqrt{\alpha}} + 1\right)\bar{q}, \\ \bar{q}_t - \sqrt{\alpha}\bar{q}_x = -\frac{1}{2\epsilon}\left(\frac{f'(u^\epsilon)}{\sqrt{\alpha}} - 1\right)\bar{p} - \frac{1}{2\epsilon}\left(\frac{f'(u^\epsilon)}{\sqrt{\alpha}} + 1\right)\bar{q}. \end{cases} \tag{3.6}$$

We further introduce the transformations

$$\begin{cases} p = \bar{p} - \Big(\sqrt{\alpha} + f'(u^\epsilon)\Big)\|u_0\|_{Lip^+}, \\ \\ q = \bar{q} - \Big(\sqrt{\alpha} - f'(u^\epsilon)\Big)\|u_0\|_{Lip^+}. \end{cases} \tag{3.7}$$

Applying the above transformations to (3.6) gives

$$\begin{aligned} p_t + \sqrt{\alpha}p_x = {} & \frac{1}{2\epsilon}\left(\frac{f'(u^\epsilon)}{\sqrt{\alpha}} - 1\right)p + \frac{1}{2\epsilon}\left(\frac{f'(u^\epsilon)}{\sqrt{\alpha}} + 1\right)q \\ & -f''(u^\epsilon)\Big(u_t^\epsilon + \sqrt{\alpha}u_x^\epsilon\Big)\|u_0\|_{Lip^+}, \end{aligned} \tag{3.8}$$

$$\begin{aligned} q_t - \sqrt{\alpha}q_x = {} & -\frac{1}{2\epsilon}\left(\frac{f'(u^\epsilon)}{\sqrt{\alpha}} - 1\right)p - \frac{1}{2\epsilon}\left(\frac{f'(u^\epsilon)}{\sqrt{\alpha}} + 1\right)q \\ & +f''(u^\epsilon)\Big(u_t^\epsilon - \sqrt{\alpha}u_x^\epsilon\Big)\|u_0\|_{Lip^+}. \end{aligned} \tag{3.9}$$

It follows from (1.1), $u_t^\epsilon + v_x^\epsilon = 0$, that

$$\begin{aligned} u_t^\epsilon + \sqrt{\alpha}u_x^\epsilon &= -v_x^\epsilon + \sqrt{\alpha}u_x^\epsilon = q + \Big(\sqrt{\alpha} - f'(u^\epsilon)\Big)\|u_0\|_{Lip^+}, \\ u_t^\epsilon - \sqrt{\alpha}u_x^\epsilon &= -v_x^\epsilon - \sqrt{\alpha}u_x^\epsilon = -p - \Big(\sqrt{\alpha} + f'(u^\epsilon)\Big)\|u_0\|_{Lip^+}. \end{aligned}$$

The above observation, together with (3.8) and (3.9), lead to

$$\begin{aligned} p_t + \sqrt{\alpha}p_x = {} & \frac{1}{2\epsilon}\left(\frac{f'(u^\epsilon)}{\sqrt{\alpha}} - 1\right)p + \frac{1}{2\epsilon}\left(\frac{f'(u^\epsilon)}{\sqrt{\alpha}} + 1 - 2\epsilon f''(u^\epsilon)\|u_0\|_{Lip^+}\right)q \\ & -f''(u^\epsilon)\Big(\sqrt{\alpha} - f'(u^\epsilon)\Big)\|u_0\|_{Lip^+}^2, \end{aligned} \tag{3.10}$$

$$\begin{aligned} q_t - \sqrt{\alpha}q_x = {} & -\frac{1}{2\epsilon}\left(\frac{f'(u^\epsilon)}{\sqrt{\alpha}} - 1 + 2\epsilon f''(u^\epsilon)\|u_0\|_{Lip^+}\right)p - \frac{1}{2\epsilon}\left(\frac{f'(u^\epsilon)}{\sqrt{\alpha}} + 1\right)q \\ & -f''(u^\epsilon)\Big(\sqrt{\alpha} + f'(u^\epsilon)\Big)\|u_0\|_{Lip^+}^2. \end{aligned} \tag{3.11}$$

It follows from the subcharacteristic condition (2.2) that (3.10)–(3.11) is a weakly coupled hyperbolic system and its coefficients satisfy the requirements in (2.12) provided that ϵ is sufficiently small. We now check the initial conditions. First checking $p(x,0)$,

$$\begin{aligned} p(x,0) &= \sqrt{\alpha}u_0' + f'(u_0)u_0' - (\sqrt{\alpha} + f'(u_0))\|u_0\|_{Lip^+} \\ &= (\sqrt{\alpha} + f'(u_0))(u_0' - \|u_0\|_{Lip^+}) \le 0. \end{aligned}$$

Similarly, we have

$$q(x,0) = (\sqrt{\alpha} - f'(u_0))(u_0' - \|u_0\|_{Lip^+}) \le 0.$$

Using Lemma 2.4, we obtain

$$p(x,t) \le 0, \qquad q(x,t) \le 0 \qquad \text{for} \quad (x,t) \in \mathbf{R} \times (0,T). \tag{3.12}$$

It follows from (3.7) that

$$u_x^\epsilon = \frac{1}{2\sqrt{\alpha}}(p+q) + \|u_0\|_{Lip^+}.$$

This identity, together with (3.12), yields

$$u_x^\epsilon \le \|u_0\|_{Lip^+},$$

which is the Lip^+ stability (3.3) for u^ϵ when it is smooth. Finally, we extend our result to general initial data by the following standard procedure:

$$u_0^\delta(x) := \int \psi_\delta(x-y)u_0(y)dy,$$

where ψ_δ is a compactly supported nonnegative unit mass mollifier,

$$\psi_\delta(x) = \frac{1}{\delta}\psi\left(\frac{x}{\delta}\right), \qquad \int_{-\infty}^{\infty} \psi_\delta(x)dx = 1.$$

It is obvious that if $\|u_0\|_{Lip^+} < \infty$, then $\|u_0^\delta\|_{Lip^+}$ is also bounded. Consider the 2×2 stiff relaxation system (1.1) with the smooth initial data

$$u^\epsilon(x,0) = u_0^\delta(x), \qquad v^\epsilon(x,0) = f(u_0^\delta(x)). \tag{3.13}$$

Using the above proof we know that there exists a $T > 0$ such that

$$\|u^{\epsilon,\delta}(\bullet,t)\|_{Lip^+} \le \|u_0^\delta\|_{Lip^+} \quad \text{for} \quad t \in (0,T), \tag{3.14}$$

where $u^{\epsilon,\delta}$ is one component of the solution to (1.1) and (3.13). Letting $\delta \to 0+$ in (3.14) gives

$$\|u^\epsilon(\bullet,t)\|_{Lip^+} \le \|u_0\|_{Lip^+} \qquad \text{for} \quad t \in (0,T).$$

By standard continuation arguments for time, we can extend the desired Lip^+ stability result (3.3) for u^ϵ to any finite time interval.

We summarize what we have shown by stating the following.

THEOREM 3.1. *Assume α in the relaxation equation* (1.1) *and the initial data u_0 in* (1.2) *satisfy the conditions stated in Lemma* 2.1. *Assume $f'' > 0$. Then the family of solutions $\{u^\epsilon(x,t)\}_{\epsilon>0}$, given by the relaxation system* (1.1) *and initial data* (1.2), *are Lip^+-stable. Moreover, the functions $\{\sqrt{\alpha}u^\epsilon + v^\epsilon\}_{\epsilon>0}$ and $\{\sqrt{\alpha}u^\epsilon - v^\epsilon\}_{\epsilon>0}$ are also Lip^+-stable.* □

3.2. Error estimates based on *Lip′* theory. Equipped with the Lip^+-stability, one can derive $O(\sqrt{\epsilon})$ L^1- and local error bounds using the Lip' theory presented in [19]. The case for a general family of relaxation models was outlined in [8]; here is a brief overview for the particular case of the relaxation model (1.1).

To begin with, we derive the modified equation satisfied by u^ϵ. Consider the second equation in (1.1),

$$v_t^\epsilon + \alpha u_x^\epsilon = -\frac{1}{\epsilon}(v^\epsilon - f(u^\epsilon)). \tag{3.15}$$

We differentiate with respect to x and use the first equation of (1.1), $v_x^\epsilon = -u_t^\epsilon$, to find

$$u_t^\epsilon + f(u^\epsilon)_x = \epsilon(v_t^\epsilon + \alpha u_x^\epsilon)_x. \tag{3.16}$$

The term on the right is the *truncation error*. The main result in [19, 14] shows that when measured in the Lip'-norm, the global error, $u^\epsilon - u$, is governed by the truncation+initial errors

$$\|u^\epsilon - u\|_{Lip'} \le \text{Const}\,[\epsilon\|(v_t^\epsilon + \alpha u_x^\epsilon)_x\|_{Lip'} + \|u_0^\epsilon - u_0\|_{Lip'}]\,. \tag{3.17}$$

In our case of (1.2), there is no initial error. To measure the Lip'-size of the truncation error, we proceed along the lines of [8, Example 3]: we differentiate (1.1) with respect to t, obtaining

$$(u_t^\epsilon)_t + (v_t^\epsilon)_x = 0, \tag{3.18}$$

$$(v_t^\epsilon)_t + \alpha(u_t^\epsilon)_x = -\frac{1}{\epsilon}\Big(v_t^\epsilon - f'(u^\epsilon)u_t^\epsilon\Big). \tag{3.19}$$

Performing $\sqrt{\alpha}\times$ (3.18) + (3.19) and $\sqrt{\alpha}\times$ (3.18) − (3.19), then the above system can be put in the following diagonal form in terms of the characteristic variables, $\bar r := \sqrt{\alpha}u_t^\epsilon + v_t^\epsilon$ and $\bar s := \sqrt{\alpha}u_t^\epsilon - v_t^\epsilon$,

$$\begin{cases} \bar r_t + \sqrt{\alpha}\bar r_x = \frac{1}{2\epsilon}\left(\frac{f'(u^\epsilon)}{\sqrt{\alpha}} - 1\right)\bar r + \frac{1}{2\epsilon}\left(\frac{f'(u^\epsilon)}{\sqrt{\alpha}} + 1\right)\bar s, \\ \bar s_t - \sqrt{\alpha}\bar s_x = -\frac{1}{2\epsilon}\left(\frac{f'(u^\epsilon)}{\sqrt{\alpha}} - 1\right)\bar r - \frac{1}{2\epsilon}\left(\frac{f'(u^\epsilon)}{\sqrt{\alpha}} + 1\right)\bar s. \end{cases} \tag{3.20}$$

Integrate the first equation against $sgn(\bar r)$, the second against $sgn(\bar s)$, and add; in view of the subcharacteristic condition (2.2) we find (compare [8, equation (4.10)])

$$\|\bar r\|_{L^1} + \|\bar s\|_{L^1} \le \|\bar r_0\|_{L^1} + \|\bar s_0\|_{L^1}. \tag{3.21}$$

If the initial data are prepared in the sense that $\|v_0^\epsilon - f(u_0^\epsilon)\|_{L^1} = \mathcal{O}(\epsilon)$ (and in fact, in our case we ignore initial errors by restricting attention to (1.2)), then initial time derivatives

$$\|v_t^\epsilon(\cdot, t=0)\|_{L^1} + \|u_t^\epsilon(\cdot, t=0)\|_{L^1}$$

are bounded, and by (3.21), they remain bounded in later time. In particular, $\|v_t^\epsilon(\cdot,t)\|_{L^1} \le \text{Const}$. This, together with the BV bound of u^ϵ (which follows from the Lip^+ stability), imply that the Lip'-size of the local truncation error is of order ϵ

$$\|\epsilon(v_t^\epsilon + \alpha u_x^\epsilon)_x\|_{Lip'} \le \epsilon(\|v_t^\epsilon\|_{L^1} + \alpha\|u_x^\epsilon\|_{L^1}) \le \mathcal{O}(\epsilon), \tag{3.22}$$

and consequently, (3.17) implies that the Lip' size of the global error, $u^\epsilon - u$, is of the same order of $\mathcal{O}(\epsilon)$. If we interpolate between this Lip' bound and the BV boundedness of $u^\epsilon - u$, we arrive at an L^1 convergence rate estimate of order $\mathcal{O}(\sqrt{\epsilon})$,

$$\|u^\epsilon - u\|_{L^1} \le \text{Const}\|u^\epsilon - u\|_{Lip'}^{1/2} \cdot \|u^\epsilon - u\|_{BV}^{1/2} \le \text{Const}\sqrt{\epsilon}.$$

The Lip^+ stability of u^ϵ enables us to convert this global estimate into a local one: using Lemma 2.3 with $(z,w) = (u^\epsilon, u)$ we find (see (2.10))

$$|u^\epsilon(x,t) - u(x,t)| \le \text{Const}\,\delta \cdot |u|_{C^1_{loc}(x-\delta,x+\delta)}, \quad \delta \sim \epsilon^{1/4}. \tag{3.23}$$

There are several possible improvements.

- If one utilizes the $\mathcal{O}(\epsilon)$-Lip' error estimate (instead of the L^1 estimate of order $\mathcal{O}(\sqrt{\epsilon})$), then this pointwise error estimate can be further improved outside a smaller shock region of size $\delta \sim \epsilon^{1/3}$ (see [14, Corollary 2.4]).
- Moreover, for piecewise smooth data one has an L^1-error estimate of order ϵ, [24], and the above arguments yield pointwise error estimate of order $\delta \sim \|u^\epsilon - u\|_{L^1}^{1/2} = \mathcal{O}(\sqrt{\epsilon})$; this will be outlined in section 3.3.
- Finally, in section 4 we will present a bootstrap argument for a further improvement of this pointwise error estimate; we prove an pointwise error of order δ outside a shock zone of optimal size $\delta \sim \epsilon$.

Remark. In (1.3) we restrict our attention to initial data which are *exactly* matched with their assumed limit, $v_0^\epsilon = f(u_0^\epsilon)$. It is clear from the above discussion that Lip' error bound of order $\mathcal{O}(\epsilon)$ holds for more general initial data, which are only required to be prepared so that $\|u_0^\epsilon - u_0\|_{Lip'} + \|v_0^\epsilon - f(u_0^\epsilon)\|_{L^1} = \mathcal{O}(\epsilon)$.

3.3. A nonoptimal pointwise error estimate. In the following section, we will consider the case that the entropy solution for (1.3) is piecewise smooth, with finitely many shock discontinuities. Thus, if we let $S(t)$ denote the singular support of $u(\bullet, t)$, then it consists of finitely many shocks, $S(t) := \{(x,t) \,|\, x = X_k(t)\}$, each of which satisfies the Rankine–Hugoniot and the Lax conditions:

$$X_k' = \frac{[f(u(X_k,t)]}{[u(X_k,t)]}, \tag{3.24}$$

$$f'(u(X_k(t)-,t)) > X_k'(t) > f'(u(X_k(t)+,t)). \tag{3.25}$$

We note in passing that many practical initial data lead to finite number of shocks (see, e.g., [17, 22]), and in this case one has a global L^1-error bound of order ϵ, (2.7). Next we consider the characteristic variables, $\sqrt{\alpha}u^\epsilon \pm v^\epsilon$: It follows that their L^1 convergence rate from their limiting value $\sqrt{\alpha}u \pm v$ with $v = f(u)$ is also order (ϵ). Moreover, Theorem 3.1 implies the Lip^+ boundedness

$$\sqrt{\alpha}u_x^\epsilon + v_x^\epsilon \le C, \qquad \sqrt{\alpha}u_x^\epsilon - v_x^\epsilon \le C.$$

We can now apply the interpolation inequality (2.10), with $(z,w) = (\sqrt{\alpha}u^\epsilon \pm v^\epsilon, \sqrt{\alpha}u \pm f(u))$. We obtain the following pointwise error bound (see also [20]):

$$\begin{cases} |\sqrt{\alpha}u^\epsilon + v^\epsilon - (\sqrt{\alpha}u + f(u))| \le C\sqrt{\epsilon}, \\ \\ |\sqrt{\alpha}u^\epsilon - v^\epsilon - (\sqrt{\alpha}u - f(u))| \le C\sqrt{\epsilon} \quad \text{for} \quad \operatorname{dist}(x, S(t)) \ge \sqrt{\epsilon}. \end{cases} \tag{3.26}$$

It follows from the above results that

$$\begin{cases} |u^\epsilon(x,t) - u(x,t)| \le C\sqrt{\epsilon}, \\ \\ |v^\epsilon(x,t) - f(u(x,t))| \le C\sqrt{\epsilon} \quad \text{for} \quad \operatorname{dist}(x, S(t)) \ge \sqrt{\epsilon}. \end{cases} \tag{3.27}$$

Although the above pointwise local estimate is not optimal, it will suffice to derive the optimal error bound by a bootstrap argument which employs the comparison Lemma 2.4.

4. Pointwise error estimate. The key tool in obtaining the optimal pointwise error estimate is to use Lemma 2.4. In order to use it, we need to construct appropriate functions u_1 and u_2 (in this section they are error functions) such that they satisfy (2.11) and those conditions listed in the lemma. To illustrate the main idea of our proof, we first concentrate on the case that there is only one shock curve.

4.1. The case of a single shock. We assume that there is a smooth curve, $S(t) := \{(x,t)\,|\,x = X(t)\}$, so that $u(x,t)$ is C^2-smooth at any point $x \neq X(t)$. There are two smooth regions $x > X(t)$ and $x < X(t)$. We consider the pointwise error estimate in the region $x > X(t)$; the results for $x < X(t)$ can be obtained in a similar way. The function $\phi(x) \in C^2([0,\infty))$ satisfies

$$\phi(x) \sim \begin{cases} x & \text{if} \quad 0 \le x \ll 1, \\ 1 & \text{if} \quad x \gg 1. \end{cases}$$

More precisely, the function ϕ satisfies

$$\begin{cases} \phi(0) = 0, \qquad \phi'(x) > 0, \quad \phi(x) \le x \quad \text{for} \quad x > 0; \\ x\phi'(x) \le \phi(x) \quad \text{for} \quad x \ge 0; \\ |\phi^{(k)}(x)| \le 1, \quad x \ge 0, \end{cases} \tag{4.1}$$

e.g., $\phi(x) = 1 - e^{-x}$. Roughly speaking, the weighted function behaves like $\phi(x) \sim \min(|x|, 1)$.

We define two functions, which roughly speaking are the errors for u^ϵ and v^ϵ, in the following form:

$$U = u^\epsilon - u - \sigma(x,t), \qquad V = v^\epsilon - f(u+\sigma) + \epsilon\Psi(x,t), \tag{4.2}$$

where

$$\begin{cases} \sigma = \epsilon d e^{\gamma t}/\phi(x - X(t)), \\ \Psi = \Big(\alpha - f'(u+\sigma)f'(u)\Big)u_x - \Big(\sqrt{\alpha} + f'(u+\sigma)\Big)\Big(\sqrt{\alpha} - \dot{X}(t)\Big)\sigma\phi'/\phi. \end{cases} \tag{4.3}$$

In the above definitions, $\phi = \phi(x - X(t))$ is the so-called weighted distance to the shock set.[2] Also, in the above definitions, d and γ are two positive numbers to be determined.

Remark. It is seen from (4.2) and (4.3) that U is the error function for u^ϵ with first-order correction $O(\epsilon)$, while V is the error function for v^ϵ with first- and second-order corrections.

4.1.1. The basic idea. In order to put the error functions U and V to the framework of Lemma 2.4, we further let

$$p = \sqrt{\alpha}U + V, \qquad q = \sqrt{\alpha}U - V \tag{4.4}$$

and will verify the following estimates:

- (C1): for $x \ge X(0) + \sqrt{\epsilon}$,

$$p(x,0) \le 0, \qquad q(x,0) \le 0.$$

- (C2): for all $t \ge 0$,

$$p(X(t) + \sqrt{\epsilon}, t) \le 0, \qquad q(X(t) + \sqrt{\epsilon}, t) \le 0.$$

[2] In the case $x < X(t)$, the weighted distance is $\phi(X(t) - x)$. In other words, the weighted distance for any choice of x is $\phi(|x - X(t)|)$ in the single shock case.

- (C3): The functions p and q satisfies the following equations:

$$\begin{cases} p_t + \sqrt{\alpha} p_x = \alpha_{11} p + \alpha_{12} q + \beta_1(x,t), \\ \\ q_t - \sqrt{\alpha} q_x = \alpha_{21} p + \alpha_{22} q + \beta_2(x,t), \end{cases} \tag{4.5}$$

  where for $x \geq X(t) + \sqrt{\epsilon}$ the coefficients α_{12} and α_{21} are nonnegative, and the source terms β_1 and β_2 are nonpositive.

The idea is to choose d and γ sufficiently large so that Lemma 2.4 can be applied. The estimates (C1) and (C2) are satisfied by choosing sufficiently large d. Then for the time interval $0 < t \leq T_1 := \gamma^{-1}$, i.e.,

$$e^{\gamma t} \leq e, \tag{4.6}$$

we show that (C3) is satisfied by choosing sufficiently large γ.

After showing that (C1)–(C3) are verified for $t \in [0, T_1]$, we know that the error bounds for u^ϵ and v^ϵ can be established for $0 \leq t \leq T_1$. We can then use $u^\epsilon(x, T_1)$ and $u(x, T_1)$ as new initial data and repeat the same procedure to obtain the local error bounds for $T_1 < t \leq T_2$. By this standard continuation arguments, we can obtain the error bounds up to $t = T$.

4.1.2. The verification for (C1). Observe that for $x \geq X(t) + \sqrt{\epsilon}$

$$|\Psi(x,t)| \leq C + C\epsilon^{-1/2}\sigma, \qquad \sigma \geq \epsilon d. \tag{4.7}$$

Since $u^\epsilon(x,0) = u(x,0) = u_0(x)$ and $v^\epsilon(x,0) = f(u_0)$, we have, for $x \geq X(0)+ \geq \sqrt{\epsilon}$,

$$\begin{aligned} p(x,0) &= -\sqrt{\alpha}\sigma(x,0) + f(u_0) - f(u_0 + \sigma) + \epsilon\Psi \\ &= \Big(-\sqrt{\alpha} + f'(\bullet)\Big)\sigma(x,0) + \epsilon\,\Psi \\ &\leq -C_1\sigma + C\epsilon + C\sqrt{\epsilon}\sigma \\ &\leq \Big(-C_1 + C/d + C\sqrt{\epsilon}\Big)\,\sigma \leq 0 \end{aligned}$$

provided that d is sufficiently large and ϵ sufficiently small. Similarly, we can show that $q(x,0) < 0$ for $x > X(0) + \sqrt{\epsilon}$ with sufficiently large d and small ϵ.

4.1.3. The verification for (C2). It follows from the nonoptimized local error estimates (3.27) that

$$u^\epsilon - u = \mathcal{O}(\sqrt{\epsilon}), \qquad v^\epsilon - f(u) = \mathcal{O}(\sqrt{\epsilon}) \quad \text{for} \quad x \geq X(t) + \sqrt{\epsilon}.$$

It is also observed that $\sigma(x,t) \geq Cd\sqrt{\epsilon}$ for $x = X(t) + \sqrt{\epsilon}$. From the definition of p we obtain

$$\begin{aligned} p(X(t) + \sqrt{\epsilon}, t) &= \sqrt{\alpha} \times \mathcal{O}(\sqrt{\epsilon}) - \sqrt{\alpha}\sigma(x,t) + \mathcal{O}(\sqrt{\epsilon}) + f(u) - f(u+\sigma) + \mathcal{O}(\epsilon) + \mathcal{O}(\epsilon\sigma) \\ &= \mathcal{O}(\sqrt{\epsilon}) + (-\sqrt{\alpha} - f'(\bullet))\sigma(X(t) + \sqrt{\epsilon}, t) + \mathcal{O}(\epsilon) + \mathcal{O}(\epsilon\sigma) \\ &\leq C\sqrt{\epsilon} - C_1\, C\sqrt{\epsilon}\, d + C\epsilon \leq 0 \end{aligned}$$

provided that d is sufficiently large. Similarly, we can show that $q(X(t) + \sqrt{\epsilon}, t) \leq 0$.

4.1.4. The verification for (C3). By the definitions of U and V, as well as the relaxation equations (1.1) and its equilibrium equation (1.3), we have

$$
\begin{aligned}
U_t + V_x &= \underbrace{u_t^\epsilon + v_x^\epsilon}_{=0} - \underbrace{(u_t + f(u)_x)}_{=0} + (f(u)_x - f(u+\sigma)_x) - \sigma_t + \epsilon\Psi_x \\
&= \Big(f'(u) - f'(u+\sigma)\Big)u_x - f'(u+\sigma)\sigma_x - \sigma_t + \epsilon\Psi_x \\
&= -f''(\bullet)u_x\sigma - f'(u+\sigma)\sigma_x - \sigma_t + \epsilon\Psi_x.
\end{aligned} \tag{4.8}
$$

Similarly, we calculate $V_t + \alpha U_x$ and obtain

$$
\begin{aligned}
V_t + \alpha U_x &= v_t^\epsilon + \alpha u_x^\epsilon - f(u+\sigma)_t - \alpha u_x + \epsilon\Psi_t - \alpha\sigma_x \\
&= \frac{1}{\epsilon}\Big(f(u^\epsilon) - v^\epsilon\Big) - f'(u+\sigma)(u_t + \sigma_t) - \alpha u_x + \epsilon\Psi_t - \alpha\sigma_x \\
&= \frac{1}{\epsilon}\Big(f(u^\epsilon) - f(u+\sigma)\Big) - \frac{1}{\epsilon}\Big(v^\epsilon - f(u+\sigma) + \epsilon\Psi\Big) \\
&\qquad -f'(u+\sigma)\sigma_t + \epsilon\Psi_t - \alpha\sigma_x + \Psi + \Big(f'(u+\sigma)f'(u) - \alpha\Big)u_x \\
&= \frac{1}{\epsilon}f'(\bullet)U - \frac{1}{\epsilon}V - f'(u+\sigma)\sigma_t + \epsilon\Psi_t - \alpha\sigma_x \\
&\qquad -\Big(\sqrt{\alpha} + f'(u+\sigma)\Big)\Big(\sqrt{\alpha} - \dot{X}(t)\Big)\frac{\sigma\phi'}{\phi}.
\end{aligned} \tag{4.9}
$$

By the definition of p, $p = \sqrt{\alpha}U + V$, we obtain from (4.8) and (4.9) that p satisfies the first equation in (4.5) with

$$
\begin{cases}
\alpha_{11} = \frac{1}{2\epsilon}\Big(\frac{f'(\bullet)}{\sqrt{\alpha}} - 1\Big), \qquad \alpha_{12} = \frac{1}{2\epsilon}\Big(\frac{f'(\bullet)}{\sqrt{\alpha}} + 1\Big), \\
\beta_1(x,t) = -\sqrt{\alpha}f''(\bullet)u_x\sigma - \Big(\sqrt{\alpha} + f'(u+\sigma)\Big)(\sqrt{\alpha}\sigma_x + \sigma_t) \\
\qquad\qquad +\epsilon\Big(\sqrt{\alpha}\Psi_x + \Psi_t\Big) - \Big(\sqrt{\alpha} + f'(u+\sigma)\Big)(\sqrt{\alpha} - \dot{X}(t))\frac{\sigma\phi'}{\phi}.
\end{cases} \tag{4.10}
$$

We observe that $\alpha_{12} \geq 0$. Now we need to verify that $\beta_1(x,t) \leq 0$ for $x \geq X(t) + \sqrt{\epsilon}$ provided that γ is sufficiently large. It follows from the definitions of σ that

$$
\sigma_x = -\frac{\sigma\phi'}{\phi}, \quad \sigma_t = \gamma\sigma + \frac{\sigma\phi'}{\phi}\dot{X}. \tag{4.11}
$$

Using the above results and the definition of Ψ gives

$$
\begin{aligned}
\Psi_x &= \mathcal{O}(1) + \mathcal{O}\left(\frac{\sigma^2}{\phi^2}\right) + \mathcal{O}\left(\frac{\sigma}{\phi^2}\right) \\
&\leq C + C\epsilon^{-1}\sigma^2 + C\epsilon^{-1}\sigma \leq C + C\epsilon^{-1}\sigma \qquad \Big(\text{using (4.6)}\Big); \\
\Psi_t &= \mathcal{O}(1) + \mathcal{O}\left(\frac{\sigma^2}{\phi^2}\right) + \mathcal{O}\left(\frac{\sigma}{\phi^2}\right) + \mathcal{O}\left(\frac{\sigma^2}{\phi}\right) \\
&\leq C + C\epsilon^{-1}\sigma + C\sigma.
\end{aligned}
$$

The above estimates, together with (4.11) and the definition of $\beta_1(x,t)$, yield

$$
\begin{aligned}
\beta_1(x,t) &= -\sqrt{\alpha}f''(\bullet)u_x\sigma - \Big(\sqrt{\alpha} + f'(u+\sigma)\Big)\gamma\sigma + \epsilon\Big(\sqrt{\alpha}\Psi_x + \Psi_t\Big) \\
&\leq C\sigma - C_1\gamma\sigma + C\epsilon.
\end{aligned} \tag{4.12}
$$

From the definition of ψ we have $\epsilon = \phi e^{-\gamma t}\sigma/d \le C\sigma/d$. This, together with (4.12), gives

$$\beta_1(x,t) \le \Big(C - C_1\gamma + C/d\Big)\sigma \le 0 \qquad \text{for} \quad x \ge X(t) + \sqrt{\epsilon} \tag{4.13}$$

provided that γ is sufficiently large.

It follows from (4.8)–(4.9) and the definition of q, $q\sqrt{\alpha}U - V$, that q satisfies the second equation in (4.5) with

$$\begin{cases} \alpha_{21} = \frac{1}{2\epsilon}\left(1 - \frac{f'(\bullet)}{\sqrt{\alpha}}\right), \qquad \alpha_{22} = -\frac{1}{2\epsilon}\left(1 + \frac{f'(\bullet)}{\sqrt{\alpha}}\right), \\ \beta_2(x,t) = -\sqrt{\alpha}f''(\bullet)u_x\sigma + \Big(\sqrt{\alpha} - f'(u+\sigma)\Big)\Big(\sqrt{\alpha}\sigma_x - \sigma_t\Big) + \epsilon\Big(\sqrt{\alpha}\Psi_x - \Psi_t\Big) \\ \qquad\qquad + \Big(\sqrt{\alpha} + f'(u+\sigma)\Big)(\sqrt{\alpha} - \dot{X})\frac{\sigma\phi'}{\phi}. \end{cases} \tag{4.14}$$

It is seen that $\alpha_{21} \ge 0$. Moreover, it follows from (4.11) that

$$\beta_2(x,t) = -\sqrt{\alpha}f''(\bullet)u_x\sigma - \Big(\sqrt{\alpha} - f'(u+\sigma)\Big)\gamma\sigma + \epsilon\Big(\sqrt{\alpha}\Psi_x + \Psi_t\Big) + J, \tag{4.15}$$

where the last term J is defined by

$$J = 2\sqrt{\alpha}\Big(f'(u+\sigma) - \dot{X}\Big)\frac{\sigma\phi'}{\phi}. \tag{4.16}$$

Let $u_+ := u(X(t)+0,t)$. Using Lax geometrical entropy condition $\dot{X}(t) \ge f'(u_+)$ gives

$$\begin{aligned} &f'(u+\sigma) - \dot{X}(t) \le f'(u+\sigma) - f'(u_+) \\ &= f''(\bullet)(u(x,t) - u(X(t)+0,t)) + f''(\bullet)\sigma \\ &= f''(\bullet)u_x(\bullet,t)(x - X(t)) + f''(\bullet)\sigma. \end{aligned}$$

Using the fact that $x\phi'(x) \le \phi(x)$ gives

$$(x - X(t))\phi'(x - X(t)) \le C\,\phi(x - X(t)).$$

By the definition of J and the above observations, we have

$$J \le C\sigma + C\frac{\sigma^2}{\phi} \le C\sigma,$$

where in the last step we have used the fact $\sigma/\phi \le Cd$. It follows from the above results and the equation for β_2, (4.15), that $\beta_2 \le 0$ provided that γ is sufficiently large.

In summary, if d and $\gamma = \gamma(d)$ are sufficiently large, then the comparison lemma, Lemma 2.4, gives

$$p(x,t) \le 0, \qquad q(x,t) \le 0 \qquad \text{for} \quad x \ge X(t) + \sqrt{\epsilon}. \tag{4.17}$$

Similarly, changing $\phi(x - X(t))$ in (4.3) to $\phi(X(t) - x)$ will handle the case for $x \le X(t) - \sqrt{\epsilon}$. We will then obtain the following results:

$$p(x,t) \le 0, \qquad q(x,t) \le 0 \qquad \text{for} \quad x \le X(t) - \sqrt{\epsilon}. \tag{4.18}$$

Since

$$u^\epsilon - u - \epsilon d e^{\gamma t}/\phi = \frac{1}{2\sqrt{\alpha}}(p+q),$$

the estimates (4.17) and (4.18) yield

$$u^\epsilon - u \le \epsilon\, d e^{\gamma t}/\phi \qquad \text{for} \quad |x - X(t)| \ge \sqrt{\epsilon}. \tag{4.19}$$

By letting $U = u - u^\epsilon - \sigma$ and $V = f(u-\sigma) - v^\epsilon + \epsilon\tilde{\Psi}$, where $\tilde{\Psi}$ is of a similar form for Ψ, we can again using the comparison lemma obtain

$$u - u^\epsilon \le \epsilon\, d e^{\gamma t}/\phi \qquad \text{for} \quad |x - X(t)| \ge \sqrt{\epsilon}. \tag{4.20}$$

We summarize what we have shown by stating the following.

ASSERTION 4.1. *Let $u^\epsilon(x,t)$ be the relaxation solutions of* (1.1)–(1.2) *and $u(x,t)$ be the entropy solution of* (1.3). *If the entropy solution has* only one *shock discontinuity $S(t) = \{(x,t)|x = X(t)\}$, then the following error estimates hold:*

- *For a weighted distance function ϕ, $\phi(x) \sim \min(|x|, 1)$,*

$$|(u^\epsilon - u)(x,t)|\phi(|x - X(t)|) = \mathcal{O}(\epsilon), \quad |x - X(t)| \ge \sqrt{\epsilon}. \tag{4.21}$$

- *In particular, if (x,t) is away from the singular support, then*

$$|(u^\epsilon - u)(x,t)| \le C(h)\epsilon, \qquad \mathrm{dist}(x, S(t)) \ge h. \tag{4.22}$$ ∎

4.2. Finitely many shocks. In the case that the entropy solutions for the conservation law (1.3) have two shocks, our analysis in section 4.1 can be extended to cover this case easily. The main difference is to change the weighted distance function ϕ to the product of two weighted distance functions, i.e., $\phi(|x - X_1(t)|) \cdot \phi(|x - X_2(t)|)$. This idea was used in [20].

In a more general case when there are finitely many shocks, we replace the weighted distance function by

$$\rho(x,t) = \prod_{k=1}^{K} \phi\Big(|x - X_k(t)|\Big). \tag{4.23}$$

Then we consider the error functions similar to (4.3). We can apply the same techniques as used in the last subsection to obtain the optimal error bounds. We omit the detail procedure but state our main result as follows.

THEOREM 4.1. *Let $u^\epsilon(x,t)$ be the relaxation solutions of* (1.1)–(1.2) *and $u(x,t)$ be the entropy solution of* (1.3). *If the entropy solution has* finitely *many shock discontinuities, $S(t) = \{(x,t)|x = X_k(t)\}_{k=1}^K$, then the following error estimates hold:*

- *For a weighted distance function ϕ, $\phi(x) \sim \min(|x|, 1)$,*

$$|(u^\epsilon - u)(x,t)| \prod_{k=1}^{K} \phi\Big(|x - X_k(t)|\Big) = \mathcal{O}(\epsilon), \quad |x - X(t)| \ge \sqrt{\epsilon}. \tag{4.24}$$

- *In particular, if (x,t) is away from the singular support, then*

$$|(u^\epsilon - u)(x,t)| \le C(h)\epsilon, \qquad \mathrm{dist}(x, S(t)) \ge h. \tag{4.25}$$ ∎

It is noted that the above results cover the case when there are finitely many shocks with *possible collisions*.

5. Concluding remarks. In this work, we have obtained the pointwise error bounds for relaxation approximations to scalar conservation laws with piecewise smooth solutions. The proof of our results is based on two ingredients: a one-sided interpolation inequality (interpolating the L^1 error estimates and Lip^+ stability bounds), and a comparison theorem for weakly coupled hyperbolic systems. Here, we only investigated the case of entropy solutions of the equilibrium equation (1.3) which consist of finitely many shocks. The techniques used in this paper can be extended, however, in several directions:

- *Finitely many rarefaction waves.* Combining the techniques presented in [20], sharp pointwise error bounds can be obtained for entropy solutions of the equilibrium equation (1.3) which consist of finitely many rarefactions.
- *Finite difference approximations.* Sharp pointwise error bounds can be obtained for difference approximations of the equilibrium equation (1.3). A convergence study based on Lip' arguments was presented in [14]. Augmented with one-sided interpolation together with appropriate comparison techniques along the lines of our discussion in section 4, one can convert the global Lip' error estimates into sharp pointwise error estimates. The example of Lax–Friedrichs central scheme, corresponding to the first-order relaxation scheme of [6], was worked out by the authors in [21]. The second-order schemes based on the relaxation approximation (1.1) correspond to the central scheme in [13], and like most high-resolution schemes, the main difficulty lies with the question of their Lip^+ stability.

LONG TIME ASYMPTOTICS OF SOLUTIONS TO THE ANHARMONIC OSCILLATOR MODEL FROM NONLINEAR OPTICS*

FRANK JOCHMANN†

Abstract. The anharmonic oscillator model describing the propagation of electromagnetic waves in an exterior domain containing a nonlinear dielectric medium is investigated. The system under consideration consists of a generally nonlinear second order differential equation for the dielectrical polarization coupled with Maxwell's equations for the electromagnetic field. Local decay of the electromagnetic field for $t \to \infty$ in the charge free case is shown for a large class of potentials.

Key words. nonlinear optics, Maxwell's equations, exterior boundary value problem, asymptotic behavior

1. Introduction.

The subject of this paper is the anharmonic oscillator model from nonlinear optics consisting of Maxwell's equations

$$\partial_t \mathbf{E} = \operatorname{curl} \mathbf{H} - \partial_t \tilde{\mathbf{P}} - \mathbf{j}, \quad \partial_t \mathbf{H} = -\operatorname{curl} \mathbf{E} \tag{1.1}$$

on $\mathbb{R}^+ \times \Omega$ coupled with the equation

$$\alpha \partial_t^2 \mathbf{P} + \partial_t \mathbf{P} + \nabla_P V(x, \mathbf{P}) = \gamma \mathbf{E} \tag{1.2}$$

on $\mathbb{R}^+ \times G$. The initial boundary conditions

$$\vec{n} \wedge \mathbf{E} = 0 \text{ on } (0,\infty) \times \Gamma_1 \text{ and } \vec{n} \wedge \mathbf{H} = 0 \text{ on } (0,\infty) \times \Gamma_2, \tag{1.3}$$

$$\mathbf{E}(0,x) = \mathbf{E}_0(x), \mathbf{H}(0,x) = \mathbf{H}_0(x), \tag{1.4}$$

and

$$\mathbf{P}(0,x) = \mathbf{P}_0(x), \quad \partial_t \mathbf{P}(0,x) = \mathbf{P}_1(x) \text{ on } G \tag{1.5}$$

are imposed. This system describes the propagation of electromagnetic waves in a dielectric medium occupying the set G; see [3], [12]. Here $\Omega \subset \mathbb{R}^3$ is an exterior domain, $G \subset \Omega$ a certain subset, and $\Gamma_1 \subset \partial\Omega$, $\Gamma_2 \stackrel{\text{def}}{=} \partial\Omega \setminus \Gamma_1$. The unknown functions are the electric and magnetic field $\mathbf{E}, \mathbf{H}$, which depend on the time $t \geq 0$ and the space-variable $x \in \Omega$ and the dielectric polarization $\mathbf{P}$ defined on $\mathbb{R}^+ \times G$. In (1.1) the function $\tilde{\mathbf{P}}$ is the extension of $\mathbf{P}$ on $\mathbb{R}^+ \times \Omega$ defined by zero on the set $\mathbb{R}^+ \times (\Omega \setminus G)$. The physical meaning of the boundary condition (1.3) is that Γ_1 is perfectly conducting, such that the tangential component of the electric field must vanish.

†Institut für Angewandte Mathematik, Sitz: Rudower Chaussee 25, Humboldt Universität Berlin, 10099 Berlin, Germany (jochmann@mathematik.hu-berlin.de).

The coefficients $\alpha, \gamma \in L^\infty(G)$ depending on the space variables take into account the possibly variable mass, electrical charge, and density of the oscillating charged particles. An external current $\mathbf{j} \in L^1((0,\infty), L^2(\Omega))$ is included also. The potential energy function $V : G \times \mathbb{R}^3 \to [0,\infty)$ causes a spring force $\nabla_P V(x, \mathbf{P})$, which may depend nonlinearly on $\mathbf{P}$. It is assumed that the potential V satisfies the attraction condition

$$0 \le V(x,y) \le Ky(\nabla_P V)(x,y) \text{ for all } x \in G, y \in \mathbb{R}^3 \tag{1.6}$$

with some constant $K > 0$.

In particular it is allowed that $|(\nabla_P V)(x,y)|$ tends to zero for $|y| \to \infty$ as in [12]. The linear case $(\nabla_P V)(x,y) = ay$ with some $a > 0$ is included also.

In [12], where $G = \Omega = \mathbb{R}^3$ and the coefficients and the potential do not depend on x, it is shown that (1.1)–(1.2) admits a unique strong solution in $C([0,\infty), H^s(\mathbb{R}^3))$ for $s \ge 2$. Note that in our case system (1.1) does not admit classical solutions on all of $(0,\infty) \times \Omega$ due to the discontinuity of $\tilde{\mathbf{P}}$ on $\Sigma \stackrel{\text{def}}{=} (\partial G) \cap \Omega$, the interface between the polarizable medium and the vacuum-region $\Omega \setminus G$. But if the solution is smooth on $(0,\infty) \times G$ and on $(0,\infty) \times (\Omega \setminus G)$, then (1.1) involves a transmission condition, which requires the continuity of the tangential components of $\mathbf{E}$ and $\mathbf{H}$, as well as a linking condition for the normal components of $\mathbf{D} = \mathbf{E} + \tilde{\mathbf{P}}$ and $\mathbf{H}$ on Σ. Therefore a suitable weak formulation of (1.1)–(1.2) will be given in section 2, which admits discontinuous solutions. In [4] the Landau–Lifschitz equation for the magnetic moment coupled with Maxwell's equations is handled analogously. The magnetic moment is located in a bounded domain, whereas Maxwell's equations are posed on the whole space. It is shown in [4] that all points of the weak ω-limit set are solutions of the corresponding stationary equations.

The main topic of this paper is the investigation of the long time asymptotic behavior of the solutions. For this purpose it is assumed that

$$\gamma \in L^{3/2}(G) \text{ and } (1+|x|)\gamma \in L^{r_0}(G) \text{ with some } r_0 \in (3/2, \infty).$$

Since $\gamma \in L^\infty(G)$, this assumption is fulfilled, for example, if $\int_G (1+|x|)^{r_0} dx < \infty$, in particular if the set G is bounded.

Let X_0 denote the set of all $(\mathbf{f}, \mathbf{g}) \in X \stackrel{\text{def}}{=} L^2(\Omega, \mathbb{R}^6)$ which satisfy

$$\text{curl } \mathbf{f} = \text{ curl } \mathbf{g} = 0 \text{ on } \Omega, \quad \vec{n} \wedge \mathbf{f} = 0 \text{ on } \Gamma_1, \vec{n} \wedge \mathbf{g} = 0 \text{ on } \Gamma_2.$$

The basic goal is to prove the decay property

$$\int_{\{x \in \Omega : |x| \le \alpha t\}} |\mathbf{E}|^2 + |\mathbf{H}|^2 dx \stackrel{t \to \infty}{\longrightarrow} 0 \text{ for all } \alpha < 1, \tag{1.7}$$

in particular local energy decay, provided that the initial data satisfy

$$\int_\Omega (\mathbf{D}_1 \mathbf{f} + \mathbf{H}_0 \mathbf{g}) dx = 0 \text{ for all } (\mathbf{f}, \mathbf{g}) \in X_0. \tag{1.8}$$

Here $\mathbf{D}_1 \stackrel{\text{def}}{=} \mathbf{E}_0 + \tilde{\mathbf{P}}_0 - \int_0^\infty \mathbf{j}(s) ds$, where $\tilde{\mathbf{P}}_0$ denotes the extension of $\mathbf{P}_0$ by zero on $\Omega \setminus G$. (Note that the propagation speed of electromagnetic waves in a vacuum is normalized to 1 in (1.1).) Furthermore it is shown that

$$\int_\Omega |\mathbf{E}(t,x) + |x|^{-1} x \wedge \mathbf{H}(t,x)|^2 + |\mathbf{H}(t,x) - |x|^{-1} x \wedge \mathbf{E}(t,x)|^2 dx \stackrel{t \to \infty}{\longrightarrow} 0. \tag{1.9}$$

The physical meaning of (1.7) is that the wave-packet $(\mathbf{E}(t), \mathbf{H}(t))$ is concentrated near the sphere $|x| = t$ for large times. In section 4 it is also shown that the solution $(\mathbf{E}(t), \mathbf{H}(t))$ behaves asymptotically like a solution of the linear homogeneous Maxwell equations in $\mathbb{R}^3$ as $t \to \infty$.

Condition (1.8) includes

$$\text{div } \mathbf{D}_1 = 0 \text{ and } \text{ div } \mathbf{H}_0 = 0 \text{ on } \Omega$$

and the boundary conditions

$$\vec{n}\mathbf{D}_1 = 0 \text{ on } \Gamma_2 \text{ and } \vec{n}\mathbf{H}_0 = 0 \text{ on } \Gamma_1.$$

By (1.1) the function $\mathbf{D} \stackrel{\text{def}}{=} \mathbf{E} + \tilde{\mathbf{P}}$ and $\mathbf{H}$ obey $\text{ div } \mathbf{H}(t) = \text{ div } \mathbf{H}_0 = 0$ and

$$\text{div } \mathbf{D}(t) = \text{ div } \left[\mathbf{E}_0 + \tilde{\mathbf{P}}_0 - \int_0^t \mathbf{j}(s)ds\right] \stackrel{t\to\infty}{\longrightarrow} \text{ div } \mathbf{D}_1 = 0 \text{ in } \mathcal{D}'(\Omega)$$

if condition (1.8) is fulfilled. Physically this means that the space charge $\rho \stackrel{\text{def}}{=} \text{ div } \mathbf{D}$ determined by the initial-state $(\mathbf{E}_0, \mathbf{H}_0)$ and the prescribed current $\mathbf{j}$ vanishes as $t \to \infty$.

The proof of the decay property (1.7) uses a result in [11]. In particular it is shown in section 3 that for arbitrary initial states $(\mathbf{E}_0, \mathbf{H}_0)$, $\mathbf{P}_0$ and $\mathbf{P}_1$ not necessarily satisfying (1.8), the weak ω-limit set of $(\mathbf{E}, \mathbf{H})$ is contained in X_0.

2. Basic definitions, assumptions, and preliminaries. For an arbitrary open set $K \subset \mathbb{R}^3$ the space of all infinitely differentiable functions with compact support contained in K is denoted by $C_0^\infty(K)$. For $p \in [1, \infty)$ the dual exponent p^* is given by $p^{-1} + (p^*)^{-1} = 1$.

Let $\Omega \subset \mathbb{R}^3$ be a (connected) domain with bounded complement such that $\mathbb{R}^3 \backslash \overline{\Omega}$ is a Lipschitz domain and $G \subset \Omega$ a measurable set with nonempty interior. Throughout this paper the following assumptions are imposed on $V : G \times \mathbb{R}^3 \to [0, \infty)$. First $V(\cdot, y) \in L^\infty(G)$ for all $y \in \mathbb{R}^3$,

$$V(x, \cdot) \in C^2(\mathbb{R}^3, \mathbb{R}), \quad V(x, 0) = 0, \text{ and } (\nabla_P V)(x, 0) = 0 \tag{2.1}$$

for all $x \in G$. It is assumed that $(\nabla_P V)$ is Lipschitz-continuous with respect to y, i.e., there exits some $L_0 \in (0, \infty)$, such that

$$|(\nabla_P V)(x, y) - (\nabla_P V)(x, z)| \leq L_0|y - z| \text{ for all } x \in G, y, z \in \mathbb{R}^3. \tag{2.2}$$

This condition is also required in [12], since the second and third order derivatives of V are assumed to be globally bounded there.

Next, let $\alpha \in L^\infty(G)$ be a uniformly positive and $\gamma \in L^\infty(G)$ be a positive, but not necessarily uniformly positive, function on G. Now $\mathcal{G} \subset L^2(G)$ is the weighted $L^2(G)$-space consisting of all measurable functions $\mathbf{f} : G \to \mathbb{R}^3$ with $\int_G \gamma^{-1}(x)|\mathbf{f}(x)|^2 dx < \infty$ endowed with the norm

$$\|\mathbf{f}\|_{\mathcal{G}}^2 \stackrel{\text{def}}{=} \int_G \gamma^{-1}(x)|\mathbf{f}(x)|^2 dx.$$

In what follows we denote by $\underline{\mathbf{w}}_1 \in \mathbb{C}^3$ the first three and by $\underline{\mathbf{w}}_2 \in \mathbb{C}^3$ the last three components of a vector $\mathbf{w} \in \mathbb{C}^6$ and $S\mathbf{w} \stackrel{\text{def}}{=} (-x \wedge \underline{\mathbf{w}}_2, x \wedge \underline{\mathbf{w}}_1)$.

Next, some function-spaces related to Maxwell's equations with mixed boundary conditions are introduced.

First W_H denotes the closure of $C_0^\infty(\mathbb{R}^3 \setminus \overline{\Gamma_2}, \mathbb{C}^3)$ in $H_{curl}(\Omega)$, where $H_{curl}(\Omega)$ is the space of all $\mathbf{E} \in L^2(\Omega, \mathbb{C}^3)$ with $\operatorname{curl} \mathbf{E} \in L^2(\Omega)$ in the sense of distributions.

Next, W_E denotes the set of all $\mathbf{E} \in H_{curl}(\Omega)$ such that

$$\int_\Omega \mathbf{E} \operatorname{curl} \mathbf{F} - \mathbf{F} \operatorname{curl} \mathbf{E} dx = 0 \text{ for all } \mathbf{F} \in W_H,$$

which includes a weak formulation of the boundary condition $\vec{n} \wedge \mathbf{E} = 0$ on Γ_1; see [7].

Now, the following operators are defined.

Let $D(B) \stackrel{\text{def}}{=} W_E \times W_H$ and

$$B(\mathbf{E}, \mathbf{H}) \stackrel{\text{def}}{=} (\operatorname{curl} \mathbf{H}, -\operatorname{curl} \mathbf{E}) \text{ for } (\mathbf{E}, \mathbf{H}) \in D(B).$$

Then B is a densely defined skew self-adjoint operator in the Hilbert-space $X \stackrel{\text{def}}{=} L^2(\Omega, \mathbb{C}^6)$ endowed with the usual scalar product. The space X_0 in (1.8) is defined as the kernel of B, i.e.,

$$X_0 \stackrel{\text{def}}{=} \{(\mathbf{E}, \mathbf{H}) \in D(B) : B(\mathbf{E}, \mathbf{H}) = 0\}$$

$$= \{(\mathbf{E}, \mathbf{H}) \in W_E \times W_H : \operatorname{curl} \mathbf{E} = \operatorname{curl} \mathbf{H} = 0\}.$$

Let Q be the orthogonal projector on $X_0^\perp = (\ker B)^\perp = \overline{\operatorname{ran} B}$.

For $\mathbf{f} \in L^1_{loc}([0, \infty), X)$ a function $\mathbf{u} \in C([0, \infty), X)$ is called a weak solution to the initial boundary value problem

$$\partial_t \underline{\mathbf{u}}_1 = \operatorname{curl} \underline{\mathbf{u}}_2 + \underline{\mathbf{f}}_1, \quad \partial_t \underline{\mathbf{u}}_2 = -\operatorname{curl} \underline{\mathbf{u}}_1 + \underline{\mathbf{f}}_2, \tag{2.3}$$

supplemented by the initial-boundary conditions

$$\vec{n} \wedge \underline{\mathbf{u}}_1 = 0 \text{ on } (0, \infty) \times \Gamma_1 \text{ and } \vec{n} \wedge \underline{\mathbf{u}}_2 = 0 \text{ on } (0, \infty) \times \Gamma_2 \tag{2.4}$$

if

$$\frac{d}{dt} \langle \mathbf{u}(t), \mathbf{a} \rangle_X = -\langle \mathbf{u}(t), B\mathbf{a} \rangle_X + \langle \mathbf{f}(t), \mathbf{a} \rangle_X \text{ for all } \mathbf{a} \in D(B). \tag{2.5}$$

This means that (2.3) is fulfilled in the sense of distributions, whereas the boundary conditions (2.4) are satisfied in the sense that $\int_0^t \mathbf{u}(s) ds \in D(B) = W_E \times W_H$ for all $t \geq 0$. It is well known that (2.5) is equivalent to the variation of constant formula

$$\mathbf{u}(t) = \exp(tB)\mathbf{u}(0) + \int_0^t \exp((t-s)B)\mathbf{f}(s) ds \tag{2.6}$$

where $(\exp(tB))_{t \in \mathbb{R}}$ is the unitary group generated by B; see [13]. (2.6) yields the energy estimate

$$\frac{1}{2} \frac{d}{dt} \|\mathbf{u}(t)\|_X^2 = \langle \mathbf{f}(t), \mathbf{u}(t) \rangle_X . \tag{2.7}$$

Next $\mathcal{R} : L^2(G) \to X$ is defined by

$$(\mathcal{R}\mathbf{p})(x) \stackrel{\text{def}}{=} (\mathbf{p}(x), 0) \text{ if } x \in G \text{ and } (\mathcal{R}\mathbf{p})(x) \stackrel{\text{def}}{=} 0 \text{ if } x \in \Omega \setminus G.$$

Let

$$\mathbf{j} \in L^1((0,\infty), L^2(\Omega, \mathbb{R}^3)), \quad (\mathbf{E}_0, \mathbf{H}_0) \in X, \quad \mathbf{P}_0 \in \mathcal{G} \text{ and } \mathbf{P}_1 \in \mathcal{G}. \tag{2.8}$$

By (2.1) and (2.2) the nonlinear composition operator $\mathbf{p} \in \mathcal{G} \to (\nabla_y V)(\cdot, \mathbf{p}(\cdot))$ is globally Lipschitz-continuous as a map from $\mathcal{G}$ to $\mathcal{G}$. Therefore the initial value problem

$$\alpha \partial_t^2 \mathbf{P} + \partial_t \mathbf{P} + (\nabla_y V)(x, \mathbf{P}) = \gamma \mathbf{E} \text{ on } (0,\infty) \times G \tag{2.9}$$

supplemented by the initial-conditions

$$\mathbf{P}(0) = \mathbf{P}_0, \quad \partial_t \mathbf{P}(0) = \mathbf{P}_1 \tag{2.10}$$

admits for all $\mathbf{E} \in C([0,\infty), L^2(\Omega, \mathbb{R}^3))$ a unique weak solution $\mathbf{P} \in C^2([0,\infty), \mathcal{G}) \subset C^2([0,\infty), L^2(G))$. If $\mathbf{E} \in C([0,\infty), L^2(\Omega, \mathbb{R}^3))$ and $\mathbf{F} \in C([0,\infty), L^2(\Omega, \mathbb{R}^3))$, then the Lipschitz continuity of $\nabla_y V$ yields the estimate

$$\frac{1}{2}\frac{d}{dt}\left[\|\alpha^{1/2}(\partial_t \mathbf{P}(t) - \partial_t \mathbf{Q}(t))\|_{\mathcal{G}}^2 + \|\mathbf{P}(t) - \mathbf{Q}(t)\|_{\mathcal{G}}^2\right] = \int_G \gamma^{-1}(\partial_t \mathbf{P} - \partial_t \mathbf{Q})$$

$$\times [\gamma \mathbf{E} - \partial_t \mathbf{P} - \nabla_P V(x, \mathbf{P}) - \gamma \mathbf{F} + \partial_t \mathbf{Q} + \nabla_P V(x, \mathbf{Q}) + \mathbf{P} - \mathbf{Q}]\, dx$$

$$\leq C_1 \|\alpha^{1/2}(\partial_t \mathbf{P}(t) - \partial_t \mathbf{Q}(t))\|_{\mathcal{G}} \left(\|\mathbf{E}(t) - \mathbf{F}(t)\|_{L^2(\Omega)} + \|\mathbf{P}(t) - \mathbf{Q}(t)\|_{\mathcal{G}}\right)$$

$$\leq C_2 \left[\|\alpha^{1/2}(\partial_t \mathbf{P}(t) - \partial_t \mathbf{Q}(t))\|_{\mathcal{G}}^2 + \|\mathbf{P}(t) - \mathbf{Q}(t)\|_{\mathcal{G}}^2 + \|\mathbf{E}(t) - \mathbf{F}(t)\|_{L^2(\Omega)}^2\right]$$

with constants C_1, C_2 independent of $\mathbf{E}, \mathbf{F}$, and t. Here $\mathbf{Q} \in C^2([0,\infty), \mathcal{G})$ is the solution of (2.9) and (2.10) with $\mathbf{E}$ replaced by $\mathbf{F}$. By Gronwall's lemma one obtains

$$\|\partial_t(\mathbf{P}(t) - \mathbf{Q}(t))\|_{L^2(G)} \leq \|\gamma^{1/2}\|_{L^\infty(G)} \|\partial_t(\mathbf{P}(t) - \mathbf{Q}(t))\|_{\mathcal{G}} \tag{2.11}$$

$$\leq C_3 \int_0^t \exp\left(L(t-s)\right) \|\gamma(\mathbf{E}(t) - \mathbf{F}(s))\|_{L^2(\Omega)} ds$$

with some $L, C_3 > 0$ independent of $\mathbf{E}$, $\mathbf{F}$, and t.

Let $\mathcal{A} : C([0,\infty), X) \to C([0,\infty), X)$ be defined by

$$\left(\mathcal{A}(\mathbf{E}, \mathbf{H})\right)(t) \stackrel{\text{def}}{=} \exp(tB)(\mathbf{E}_0, \mathbf{H}_0) - \int_0^t \exp\left((t-s)B\right) \left[\mathcal{R}\partial_t \mathbf{P}(s) + (\mathbf{j}(s), 0)\right] ds,$$

where $\mathbf{P}$ solves (2.9) and (2.10).

Now $(\mathbf{E}, \mathbf{H}) \in C([0,\infty), X)$ and $\mathbf{P} \in C^2([0,\infty), \mathcal{G})$ solve (1.1)–(1.5) (in the sense of (2.5)) if

$$(\mathbf{E}(t), \mathbf{H}(t)) = \exp(tB)(\mathbf{E}_0, \mathbf{H}_0) \tag{2.12}$$

$$-\int_0^t \exp\left((t-s)B\right)\left[\mathcal{R}\partial_t \mathbf{P}(s) + (\mathbf{j}(s),0)\right] ds,$$

i.e.,

$$\mathcal{A}(\mathbf{E},\mathbf{H}) = (\mathbf{E},\mathbf{H}), \tag{2.13}$$

and $\mathbf{P}$ solves (2.9) and (2.10). It follows from the estimates (2.7) and (2.11) and the contraction mapping principle in the space $C([0,T],X)$ with arbitrary large $T > 0$ that the fixed point problem (2.13) has a unique solution on each finite time interval $(0,T)$ and hence a unique global solution on $(0,\infty)$.

THEOREM 2.1. *Problem* (1.1)–(1.5) *has a unique weak solution* $(\mathbf{E},\mathbf{H},\mathbf{P})$ *with the properties* $(\mathbf{E},\mathbf{H}) \in C([0,\infty),X)$ *and* $\mathbf{P} \in C^2([0,\infty),\mathcal{G})$.

Further regularity of the solution can be obtained under the additional regularity assumption

$$(\mathbf{E}_0,\mathbf{H}_0) \in D(B) \text{ and } \mathbf{j} \in W^{1,1}((0,\infty),L^2(\Omega)). \tag{2.14}$$

Then $\mathcal{R}\partial_t \mathbf{P}(\cdot) + (\mathbf{j},0) \in W^{1,1}_{loc}([0,\infty),X)$. By the result in [13, Corollary 2.5, sect. 4.2] it follows that

$$(\mathbf{E},\mathbf{H}) \in C^1([0,\infty),X) \cap C([0,\infty),D(B)) \tag{2.15}$$

is a strong solution of

$$\partial_t(\mathbf{E}(t),\mathbf{H}(t)) = B(\mathbf{E}(t),\mathbf{H}(t)) - \mathcal{R}\partial_t \mathbf{P}(t) - (\mathbf{j}(t),0).$$

REMARK 1. *It follows from* (2.15) *that all partial derivatives occurring in* (1.1) *and* (1.2) *belong to the space* $L^\infty_{loc}([0,\infty),L^2(\Omega))$. *In this sense the solution is strong. As described in the introduction* $(\mathbf{E}(t),\mathbf{H}(t))$ *is not in* $H^1(\Omega)$, *in general due to the mixed boundary conditions and the possible discontinuity of the polarization. However, the divergence-free part of the electromagnetic field satisfies by equation* (2.15) *curl* $\underline{[Q(\mathbf{E}(\cdot),\mathbf{H}(\cdot))]}_k \in L^\infty_{loc}([0,\infty),L^2(\Omega))$ *and* div $\underline{[Q(\mathbf{E}(\cdot),\mathbf{H}(\cdot))]}_k = 0$ *for* $k \in \{1,2\}$. *Hence* $Q(\mathbf{E}(\cdot),\mathbf{H}(\cdot)) \in L^\infty_{loc}([0,\infty),H^1(\mathcal{U}))$ *for all subdomains* $\mathcal{U} \subset \Omega$ *which have positive distance to* $\partial\Omega$.

It follows from (2.12) and the energy estimate (2.7) that

$$\frac{1}{2}\frac{d}{dt}\|(\mathbf{E}(t),\mathbf{H}(t))\|_X^2 = -\langle \mathcal{R}\partial_t \mathbf{P}(t) + (\mathbf{j}(t),0)), (\mathbf{E}(t),\mathbf{H}(t))\rangle_X \tag{2.16}$$

$$= -\int_G \mathbf{E}\partial_t \mathbf{P} dx - \int_\Omega \mathbf{E}\mathbf{j} dx,$$

whereas (2.9) yields

$$\frac{d}{dt}\left(1/2\|\alpha^{1/2}\partial_t \mathbf{P}(t)\|_{\mathcal{G}}^2 + \int_G \gamma^{-1} V(x,\mathbf{P}) dx\right) \tag{2.17}$$

$$= -\int_G \gamma^{-1}|\partial_t \mathbf{P}|^2 dx + \int_G \mathbf{E}\partial_t \mathbf{P} dx.$$

By (2.16) and (2.17) one obtains the energy estimate

$$\frac{1}{2}\frac{d}{dt}\left(\|(\mathbf{E}(t),\mathbf{H}(t))\|_X^2+\|\alpha^{1/2}\partial_t\mathbf{P}(t)\|_{\mathcal{G}}^2+2\int_G\gamma^{-1}V(x,\mathbf{P})dx\right) \tag{2.18}$$

$$=-\int_G\gamma^{-1}|\,\partial\mathbf{P}|^2dx-\int_\Omega\mathbf{E}\mathbf{j}dx\le\|(\mathbf{E}(t),\mathbf{H}(t))\|_X\|\mathbf{j}(t)\|_{L^2(\Omega)}-\|\partial_t\mathbf{P}(t)\|_{\mathcal{G}}^2.$$

In the next lemma elementary properties of the solution are shown.

LEMMA 2.2. (i)

$$(\mathbf{E},\mathbf{H})\in L^\infty((0,\infty),X),\quad \partial_t\mathbf{P}\in L^\infty((0,\infty),\mathcal{G})\cap L^2((0,\infty),\mathcal{G})$$

and

$$\gamma^{-1}V(x,\mathbf{P}(\cdot))\in L^\infty((0,\infty),L^1(G)).$$

(ii) *If* (2.14) *holds, one has*

$$(\mathbf{E},\mathbf{H})\in W^{1,\infty}((0,\infty),X)\cap L^\infty((0,\infty),D(B)).$$

Proof. Let

$$\mathcal{E}_t\overset{\text{def}}{=}\left(\|(\mathbf{E}(t),\mathbf{H}(t))\|_X^2+\|\alpha^{1/2}\partial_t\mathbf{P}(t)\|_{\mathcal{G}}^2+2\int_G\gamma^{-1}V(x,\mathbf{P})dx\right). \tag{2.19}$$

By (2.18) one has

$$\frac{1}{2}\frac{d}{dt}\mathcal{E}_t\le\mathcal{E}_t(\mathbf{w})^{1/2}\|\mathbf{j}(t)\|_{L^2(\Omega)}-\|\partial_t\mathbf{P}(t)\|_{\mathcal{G}}^2.$$

Since $\|\mathbf{j}(\cdot)\|_{L^2(\Omega)}\in L^1(0,\infty)$, this inequality yields (i).

If (2.14) holds it follows from (2.15) that

$$\partial_t^2(\mathbf{E}(t),\mathbf{H}(t))=B\partial_t(\mathbf{E}(t),\mathbf{H}(t))-\mathcal{R}\partial_t^2\mathbf{P}(t)-\partial_t(\mathbf{j}(t),0) \tag{2.20}$$

is satisfied weakly in the sense of (2.5). With a similar estimate as before one obtains using the global boundedness of (D_P^2V) by (2.2)

$$\frac{1}{2}\frac{d}{dt}\left(\|\partial_t(\mathbf{E}(t),\mathbf{H}(t))\|_X^2+\|\alpha^{1/2}\partial_t^2\mathbf{P}(t)\|_{\mathcal{G}}^2\right) \tag{2.21}$$

$$=-\int_\Omega\partial_t\mathbf{E}\partial_t\mathbf{j}dx-\int_G\gamma^{-1}|\partial_t^2\mathbf{P}|^2dx-\int_G\gamma^{-1}\partial_t^2\mathbf{P}\cdot(D_P^2V)(x,\mathbf{P})\cdot\partial_t\mathbf{P}dx$$

$$\le\|\partial_t(\mathbf{E}(t),\mathbf{H}(t))\|_X\|\partial_t\mathbf{j}(t)\|_{L^2(\Omega)}+C_1\|\partial_t\mathbf{P}\|_{\mathcal{G}}^2-b_0/2\|\partial_t^2\mathbf{P}\|_{\mathcal{G}}^2.$$

With part (i) and $\|\partial_t\mathbf{j}(\cdot)\|_{L^2(\Omega)}\in L^1(0,\infty)$ it follows that

$$\partial_t(\mathbf{E},\mathbf{H})\in L^\infty((0,\infty),X). \tag{2.22}$$

By part (i) one has $\partial_t \mathbf{P} \in L^\infty((0,\infty),\mathcal{G}) \subset L^\infty((0,\infty),L^2(G))$, in particular $\mathcal{R}\partial_t\mathbf{P} \in L^\infty((0,\infty),X)$. Since also $(\mathbf{j},0) \in L^\infty((0,\infty),X)$ by (2.14) and $(\mathbf{E},\mathbf{H}) \in C^1([0,\infty),X) \cap C([0,\infty),D(B))$ solves

$$\partial_t(\mathbf{E}(t),\mathbf{H}(t)) = B(\mathbf{E}(t),\mathbf{H}(t)) - \mathcal{R}\partial_t\mathbf{P}(t) - (\mathbf{j}(t),0),$$

one obtains $(\mathbf{E},\mathbf{H}) \in L^\infty([0,\infty),D(B))$. This completes the proof of part (ii). ∎

By (2.18), (2.19), the previous lemma, and $\|\mathbf{j}(\cdot)\|_{L^2(\Omega)} \in L^1(0,\infty)$ one has $\frac{d}{dt}\mathcal{E}(t) \in L^1(0,\infty)$, which implies the existence of the limit

$$\mathcal{E}_\infty \stackrel{\text{def}}{=} \lim_{t\to\infty} \mathcal{E}(t) \tag{2.23}$$

$$= \lim_{t\to\infty} \left(\|(\mathbf{E}(t),\mathbf{H}(t))\|_X^2 + \|\alpha^{1/2}\partial_t\mathbf{P}(t)\|_{\mathcal{G}}^2 + 2\int_G \gamma^{-1} V(x,\mathbf{P})dx \right).$$

The physical meaning of $\mathcal{E}(t)$ is the total energy of the system, i.e., the sum of the potential and kinetic energy of the oscillating particles and the energy of the electromagnetic field. The dissipation term $-\|\partial_t\mathbf{P}(t)\|_{\mathcal{G}}^2 = -\int_G \gamma^{-1}|\partial_t\mathbf{P}|^2 dx$ in the energy estimate (2.18) describes the dielectric losses of the medium. This energy dissipation does not result from an electrical conductivity. It also occurs in insulating materials if they are exposed to a rapidly oscillating electric field.

3. A weak convergence property of the solutions. In what follows the additional regularity assumption (2.14) will be imposed on the data for convenience. The following "unique continuation" principle is proved in [11], which holds even for arbitrary, not necessarily bounded, spatial domains. As in [11] it will be used in the investigation of the weak ω-limit set of the solution of (1.1)–(1.5).

THEOREM 3.1. *Suppose that* $\mathbf{g} \in X$ *obeys*

$$\underline{(\exp(tB)\mathbf{g})}_1 = 0 \text{ on } G \text{ for all } t \in \mathbb{R}. \tag{3.1}$$

Then $\mathbf{g} \in \ker B$.

This is a generalization of the unique continuation principle for the scalar wave equation in bounded domains, which is used in [5], [6], and [15]; see also [2].

Theorem 3.1 says that each solution $(\mathbf{e},\mathbf{f}) \in C(\mathbb{R},L^2(\Omega,\mathbb{R}^{M+N}))$ of the evolution equation $\partial_t(\mathbf{e},\mathbf{f}) = B(\mathbf{e},\mathbf{f})$ with the property that $\mathbf{e}(t,x) = 0$ for all $t \in \mathbb{R}$ and $x \in G$ satisfies $(\mathbf{e}(0),\mathbf{f}(0)) \in \ker B$. In contrast to the unique continuation principle for bounded domains it is necessary to require the condition $\mathbf{e}(t,x) = 0$ on G for all $t \in \mathbb{R}$ and not only for positive times. The basic idea of the proof of Theorem 3.1 is to show that for each $f \in C_0^\infty(\mathbb{R}\setminus\{0\})$ the function $f(iB)\mathbf{g}$ is real-analytic and vanishes on G. This implies $f(iB)\mathbf{g} = 0$ for all $f \in C_0^\infty(\mathbb{R}\setminus\{0\})$ and hence $\mathbf{g} \in \ker B$. Here the operator $f(iB)$ can be defined by the spectral theorem, since iB is self-adjoint in $L^2(\Omega,\mathbb{C}^6)$. If $f \in C_0^\infty(\mathbb{R})$, then bounded operator $f(iB)$ has the representation

$$f(iB)\mathbf{u} = (2\pi)^{-1/2}\int_{\mathbb{R}} \hat{f}(t)\exp(-tB)\mathbf{u}dt \text{ for all } \mathbf{u} \in X. \tag{3.2}$$

Here $\hat{f}$ denotes the Fourier-transform of f.

In what follows let ω_0 denote the ω-limit-set of the trajectory $(\mathbf{E},\mathbf{H})$ with respect to the weak topology of X, i.e., the set of all $\mathbf{g} \in X$, such that there exists a sequence $t_n \stackrel{n\to\infty}{\longrightarrow} \infty$ with $(\mathbf{E}(t_n),\mathbf{H}(t_n)) \stackrel{n\to\infty}{\longrightarrow} \mathbf{g}$ in X weakly.

THEOREM 3.2. *$Q(\mathbf{E}(t),\mathbf{H}(t)) \overset{t\to\infty}{\longrightarrow} 0$ in X weakly.*

Proof. Suppose $\mathbf{g} \in \omega_0$ and $t_n \overset{n\to\infty}{\longrightarrow} \infty$ with

$$(\mathbf{E}(t_n),\mathbf{H}(t_n)) \overset{n\to\infty}{\longrightarrow} \mathbf{g} \quad \text{in } X \text{ weakly.} \tag{3.3}$$

Let $\mathbf{u}_n(t) \overset{\text{def}}{=} (\mathbf{E}(t_n+t),\mathbf{H}(t_n+t)) \in X$ and $\mathbf{f}_n(t) \overset{\text{def}}{=} (\nabla_P V)(x,\mathbf{P}(t_n+t)) \in \mathcal{G}$ for $n \in \mathbb{N}$. First, we have by (2.6)

$$\mathbf{u}_n(t) = \exp(tB)\mathbf{u}_n(0) - \int_{t_n}^{t_n+t} \exp((t_n+t-s)B)\,(\partial_s \mathcal{R}\mathbf{P}(s) + (\mathbf{j}(s),0))\,ds,$$

which implies by Lemma 2.2(i) that

$$\|\mathbf{u}_n(t) - \exp(tB)\mathbf{u}_n(0)\|_X \le \int_{t_n}^{t_n+t} \|\mathcal{R}\partial_s \mathbf{P}(s)\|_X + \|\mathbf{j}(s)\|_{L^2(\Omega)} ds \overset{n\to\infty}{\longrightarrow} 0$$

for all $t \in \mathbb{R}$ and hence by (3.3) with $\mathbf{u}_n(0) = (\mathbf{E}(t_n),\mathbf{H}(t_n))$

$$\mathbf{u}_n(t) \overset{n\to\infty}{\longrightarrow} \mathbf{u}_\infty(t) \overset{\text{def}}{=} \exp(tB)\mathbf{g} \text{ in } X \text{ weakly for all } t \in \mathbb{R}. \tag{3.4}$$

Lemma 2.2 yields

$$\|\mathbf{f}_n(t) - \mathbf{f}_n(0)\|_{\mathcal{G}} \le C_1 \int_{[t_n,t_n+t]} \|\partial_t \mathbf{P}(s)\|_{\mathcal{G}} ds \overset{n\to\infty}{\longrightarrow} 0 \text{ for all } t \in \mathbb{R}. \tag{3.5}$$

Suppose $T > 0$. Then (3.5) implies for all $\varphi \in C_0^\infty((-T,T),\mathcal{G})$

$$\lim_{n\to\infty} \int_{-T}^{T} \langle \mathbf{f}_n(t), \partial_t \varphi(t)\rangle_{\mathcal{G}} dt = \lim_{n\to\infty} \int_{-T}^{T} \langle \mathbf{f}_n(0), \partial_t \varphi(t)\rangle_{\mathcal{G}} dt = 0. \tag{3.6}$$

Using $\partial_t \mathbf{P} \in L^2((0,\infty),\mathcal{G})$ again one obtains from (2.9), (3.4), and (3.6) that

$$\begin{aligned} \int_{-T}^{T}\int_G \underline{(\mathbf{u}_\infty)}_1 \partial_t \varphi dx dt &= \lim_{n\to\infty} \int_{-T}^{T}\int_G \underline{(\mathbf{u}_n)}_1 \partial_t \varphi dx dt \\ &= \lim_{n\to\infty} \int_{-T}^{T} \langle \gamma \mathbf{E}(t_n+t), \partial_t \varphi(t)\rangle_{\mathcal{G}} dt \\ &= \lim_{n\to\infty} \int_{-T}^{T} \langle \alpha \partial_t^2 \mathbf{P}(t_n+t) + \partial_t \mathbf{P}(t_n+t) + \mathbf{f}_n(t), \partial_t \varphi(t)\rangle_{\mathcal{G}} dt = 0 \end{aligned} \tag{3.7}$$

for all $\varphi \in C_0^\infty((-T,T),\mathcal{G})$, in particular

$$\partial_t \underline{(\mathbf{u}_\infty)}_1(t,x) = 0 \text{ for all } x \in G, t \in (-T,T). \tag{3.8}$$

Since $T > 0$ is chosen arbitrarily, (3.8) holds for all $t \in \mathbb{R}$.

With $(\mathbf{E},\mathbf{H}) \in L^\infty((0,\infty),D(B))$ by Lemma 2.2(ii), it follows that $\mathbf{g} \in D(B)$ and

$$\underline{(\exp(tB)B\mathbf{g})}_1(x) = \partial_t \underline{(\mathbf{u}_\infty)}_1(t,x) = 0 \text{ for all } t \in \mathbb{R} \text{ and } x \in G$$

by (3.8). Invoking Theorem 3.1 one obtains $B\mathbf{g} \in \ker B$, and hence $\|B\mathbf{g}\|_X^2 = -\langle \mathbf{g}, B^2\mathbf{g}\rangle_X = 0$, whence $\mathbf{g} \in \ker B$. Hence

$$\omega_0 \subset \ker B. \tag{3.9}$$

Since $(\mathbf{E}(t),\mathbf{H}(t))$ is bounded in X as $t \to \infty$ by Lemma 2.2(i) and zero is the only possible accumulation point of $Q(\mathbf{E}(\cdot),\mathbf{H}(\cdot))$ by (3.9), the assertion follows. ∎

4. Decay of the electromagnetic field. For all $\mathbf{a} \in \ker B$ one has by (2.12)

$$\langle (\mathbf{E}(t), \mathbf{H}(t)), \mathbf{a} \rangle_X$$

$$= \left\langle \exp(tB)(\mathbf{E}_0, \mathbf{H}_0) - \int_0^t \exp((t-s)B) \left(\mathcal{R}\partial_s \mathbf{P}(s) + (\mathbf{j}(t), 0)\right) ds, \mathbf{a} \right\rangle_X$$

$$= \left\langle (\mathbf{E}_0, \mathbf{H}_0) + \mathcal{R}\mathbf{P}(0) - \mathcal{R}\mathbf{P}(t) - \int_0^t (\mathbf{j}(s), 0) ds, \mathbf{a} \right\rangle_X$$

and hence

$$(1-Q)\left((\mathbf{E}(t), \mathbf{H}(t)) + \mathcal{R}\mathbf{P}(t) + \int_0^t (\mathbf{j}(s), 0) ds - (\mathbf{E}_0, \mathbf{H}_0) - \mathcal{R}\mathbf{P}(0)\right) = 0. \tag{4.1}$$

Recall that $1-Q$ is the orthogonal projector on $X_0 = \ker B$.

Throughout this section it is assumed that the initial-state $(\mathbf{E}_0, \mathbf{H}_0) \in X$ satisfies

$$(\mathbf{D}_1, \mathbf{H}_0) = (\mathbf{E}_0, \mathbf{H}_0) + \mathcal{R}\mathbf{P}_0 - \int_0^\infty (\mathbf{j}(s), 0) ds \in X_0^\perp,$$

i.e.,

$$(1-Q)\left((\mathbf{E}_0, \mathbf{H}_0) + \mathcal{R}\mathbf{P}_0 - \int_0^\infty (\mathbf{j}(s), 0) ds\right) = 0. \tag{4.2}$$

This is condition (1.8) on the initial states. It follows from (4.1) and (4.2) that

$$(1-Q)(\mathbf{E}(t), \mathbf{H}(t)) = (1-Q)(\mathbf{J}(t) - \mathcal{R}\mathbf{P}(t)) \tag{4.3}$$

with $\mathbf{J}(t) \stackrel{\text{def}}{=} \int_t^\infty (\mathbf{j}(s), 0) ds$.

The main goal of this section is the proof of the decay property (1.7). The main steps are summarized now. By a standard energy estimate it follows that, roughly speaking, the asymptotic propagation speed of the wave-packet $(\mathbf{E}(t), \mathbf{H}(t))$ does not exceed 1 as $t \to \infty$, i.e.,

$$\int_{\{|x| \geq bt\}} |(\mathbf{E}(t), \mathbf{H}(t))|^2 dx \stackrel{t\to\infty}{\longrightarrow} 0 \text{ for all } b > 1. \tag{4.4}$$

Next it is shown that the potential energy and the energy of the curl-free part of the electromagnetic field decay in time mean, i.e.,

$$t^{-1} \int_0^t \left(\int_G \gamma^{-1} V(x, \mathbf{P}(s)) dx + \|(1-Q)(\mathbf{E}(s), \mathbf{H}(s))\|_X^2 \right) ds \stackrel{t\to\infty}{\longrightarrow} 0. \tag{4.5}$$

Here assumption (1.6), condition (1.8) and an $L^2 - L^6$-estimate for a vector potential are used. Theorem 3.2 and (4.5) yield the local decay of the electromagnetic field at least in time mean, i.e.,

$$t^{-1} \int_0^t \|(\mathbf{E}(s), \mathbf{H}(s))\|_{L^2(\Omega \cap B_R)}^2 ds \stackrel{t\to\infty}{\longrightarrow} 0 \text{ for all } R > 0. \tag{4.6}$$

The main step of the proof of (1.7) is a description of the asymptotic energy $\mathcal{E}_\infty$ in (2.23). Due to the fact that Ω is an exterior domain one has $\mathcal{E}_\infty > 0$ in general, even if condition (1.8) is satisfied. It is shown that for all $b > 1$

$$t^{-1} \int_{\{|x| \le bt\}} [SQ_0\chi_0(\mathbf{E}(t), \mathbf{H}(t))] \cdot Q_0\chi_0(\mathbf{E}(t), \mathbf{H}(t))dx \overset{t\to\infty}{\longrightarrow} \mathcal{E}_\infty, \tag{4.7}$$

where $S\mathbf{u} \overset{\text{def}}{=} (-x \wedge \underline{\mathbf{u}}_2, x \wedge \underline{\mathbf{u}}_1)$, $\chi_0 \in C^\infty(\mathbb{R}^3)$ is a cut-off function with supp $\chi_0 \subset \Omega$ and $\chi_0(x) = 1$ outside some bounded set. Furthermore, Q_0 denotes the orthogonal projector on the space of all $\mathbf{u} \in L^2(\mathbb{R}^3)$ with $\text{div } \underline{\mathbf{u}}_j = 0$. The proof of (4.7) relies on (4.4), (4.5), (4.6), and some weighted L^p-estimates for Q_0.

For this purpose the following additional assumptions are imposed on V, the set G and γ in what follows:

$$V(x, \mathbf{y}) \le K_2\mathbf{y}(\nabla_y V)(x, \mathbf{y}) \text{ for all } x \in G, \mathbf{y} \in \mathbb{R}^3 \tag{4.8}$$

with some $K_2 \in (0, \infty)$ independent of $x, \mathbf{y}$, and

$$\gamma \in L^{3/2}(G) \text{ and } (1 + |x|)\gamma \in L^{r_0}(G) \text{ with some } r_0 \in (3/2, \infty). \tag{4.9}$$

Finally it is assumed that the external current $\mathbf{j}$ is located in a fixed finite ball, i.e., there is some $R_1 > 0$ with

$$\mathbf{j}(t, x) = 0 \text{ for all } t \in (0, \infty), x \in \mathbb{R}^3 \setminus B_{R_1}. \tag{4.10}$$

First it is shown that the convergence in Theorem 3.2 is strong on bounded subsets of Ω.

LEMMA 4.1. *For all $R > 0$ one has*

$$\|Q(\mathbf{E}(t), \mathbf{H}(t))\|_{L^2(\Omega \cap B_R)} \overset{t\to\infty}{\longrightarrow} 0.$$

Proof. Each $\mathbf{u} \in (\ker B)^\perp$ satisfies

$$\text{div } (\underline{\mathbf{u}}_1) = 0, \quad \text{div } (\underline{\mathbf{u}}_2) = 0 \tag{4.11}$$

$$\text{with } \vec{n}\underline{\mathbf{u}}_1 = 0 \text{ on } \Gamma_2 \text{ and } \vec{n}\underline{\mathbf{u}}_2 = 0 \text{ on } \Gamma_1$$

in the sense that

$$\int_\Omega (\underline{\mathbf{u}}_1 \nabla\varphi + \underline{\mathbf{u}}_2 \nabla\psi)\, dx = 0 \text{ for all } \varphi \in C_0^\infty(\mathbb{R}^3 \setminus \overline{\Gamma_1}) \text{ and } \psi \in C_0^\infty(\mathbb{R}^3 \setminus \overline{\Gamma_2}).$$

This follows from the fact that $(\nabla\varphi, \nabla\psi) \in \ker B$ for all $\varphi \in C_0^\infty(\mathbb{R}^3 \setminus \overline{\Gamma_1})$ and $\psi \in C_0^\infty(\mathbb{R}^3 \setminus \overline{\Gamma_2})$.

Suppose $\mathbf{u} \in (\ker B)^\perp \cap D(B)$. Then $\underline{\mathbf{u}}_1 \in W_E$, whereas $\underline{\mathbf{u}}_2 \in W_H$. Therefore (4.11) and the compactness theorem in [7], a generalization of the result in [16] (see also [10] and [14]) implies that

$$(\ker B)^\perp \cap D(B) \text{ is compactly embedded in } L^2(\Omega \cap B_R) \text{ for all } R > 0. \tag{4.12}$$

Now, the result follows from Lemma 2.2(ii), Theorem 3.2, and (4.12). ∎

THEOREM 4.2. *Suppose $b > 1$. Then*

$$\int_{\{|x|\geq bt\}} |(\mathbf{E}(t), \mathbf{H}(t))|^2 dx \overset{t\to\infty}{\longrightarrow} 0.$$

Proof. The proof is based on an energy estimate. Let $g \in C^\infty(\mathbb{R})$ with $g(u) = 1$ for $u \geq (1+b)/2$ and $g(u) = 0$ for $u \leq 1$. For $R > R_1$ define

$$\mathcal{E}^{(R)}(t) \overset{\text{def}}{=} \int_\Omega g((t+R)^{-1}|x|) \left[|\mathbf{E}(t)|^2 + |\mathbf{H}(t)|^2\right] dx$$

$$+ \int_G \gamma^{-1} g((t+R)^{-1}|x|) \left(\alpha|\partial_t \mathbf{P}|^2 + 2V(x, \mathbf{P})\right) dx.$$

Then one obtains from the basic equations using (2.15) and assumption (4.10) for all $t \geq 0$

$$\frac{d}{dt}\mathcal{E}^{(R)}(t) = 2\left\langle g((t+R)^{-1}|x|)(\mathbf{E}(t), \mathbf{H}(t)), B(\mathbf{E}(t), \mathbf{H}(t)) - \mathcal{R}\partial_t \mathbf{P}(t) - (\mathbf{j}(t), 0)\right\rangle_X$$

$$-(t+R)^{-2} \int_\Omega |x| g'((t+R)^{-1}|x|) \left[|\mathbf{E}(t)|^2 + |\mathbf{H}(t)|^2\right] dx$$

$$+ \int_G 2g((t+R)^{-1}|x|) \left(\mathbf{E}\partial_t \mathbf{P} - \gamma^{-1}|\partial_t \mathbf{P}|^2\right) dx$$

$$-(t+R)^{-2} \int_G \gamma^{-1}|x| g'((t+R)^{-1}|x|) \left(\alpha|\partial_t \mathbf{P}|^2 + 2V(x, \mathbf{P})\right) dx$$

$$\leq 2\left\langle g((t+R)^{-1}|x|)(\mathbf{E}(t), \mathbf{H}(t)), B(\mathbf{E}(t), \mathbf{H}(t))\right\rangle_X$$

$$-(t+R)^{-2} \int_\Omega |x| g'((t+R)^{-1}|x|) \left[|\mathbf{E}(t)|^2 + |\mathbf{H}(t)|^2\right] dx$$

$$\leq 2(t+R)^{-1} \int_\Omega |x|^{-1} g'((t+R)^{-1}|x|) \mathbf{E}(t) \cdot (x \wedge \mathbf{H}(t)) dx$$

$$-(t+R)^{-2} \int_\Omega |x| g'((t+R)^{-1}|x|) \left[|\mathbf{E}(t)|^2 + |\mathbf{H}(t)|^2\right] dx.$$

Since $g(u) = 0$ for $u \leq 1$ and $g'(u) \geq 0$, it follows that $\frac{d}{dt}\mathcal{E}^{(R)}(t) \leq 0$ and hence

$$\mathcal{E}^{(R)}(t) \leq \mathcal{E}^{(R)}(0) \text{ for all } R > R_1. \tag{4.13}$$

Since $b > 1$, one has by (4.13) for all $R > R_1$

$$\limsup_{t\to\infty} \int_{\{|x|\geq bt\}} |(\mathbf{E}(t), \mathbf{H}(t))|^2 dx \leq \limsup_{t\to\infty} \int_{\{|x|\geq (b+1)(t+R)/2\}} |(\mathbf{E}(t), \mathbf{H}(t))|^2 dx$$

$$\leq \limsup_{t\to\infty} \mathcal{E}^{(R)}(t) \leq \mathcal{E}^{(R)}(0).$$

Since $g(0) = 0$, it follows that $\mathcal{E}^{(R)}(0) \overset{R\to\infty}{\longrightarrow} 0$. Hence the assertion follows from the previous estimate letting $R \to \infty$. □

In what follows let $R_0 > 0$ such that $\mathbb{R}^3 \setminus \Omega \subset B_{R_0} \overset{\text{def}}{=} \{x \in \mathbb{R}^3 : |x| < R_0\}$ and choose $\chi_0 \in C^\infty(\mathbb{R}^3)$ with

$$\text{supp } \chi_0 \subset \Omega \quad \text{and } \chi_0(x) = 1 \text{ on } \mathbb{R}^3 \setminus B_{R_0}. \tag{4.14}$$

For $\mathbf{w} \in X$ or $\mathbf{w} \in L^2(\mathbb{R}^3)$ define

$$\mathcal{C}_0\mathbf{w} \overset{\text{def}}{=} \left((\nabla\chi_0) \wedge \underline{\mathbf{w}}_2, -(\nabla\chi_0) \wedge \underline{\mathbf{w}}_1\right). \tag{4.15}$$

For convenience $\chi_0\mathbf{w}$ and $\mathcal{C}_0\mathbf{w}$ will be regarded as elements of $L^2(\mathbb{R}^3)$ by extending them by zero outside supp χ_0 if $\mathbf{w} \in X$.

In what follows $W_{E,0}$ denotes the space of all $\mathbf{F} \in W_E$ with curl $\mathbf{F} = 0$. Since $\nabla\varphi \in W_{E,0}$ for all $\varphi \in C_0^\infty(\Omega)$, one has

$$\text{div } \mathbf{A} = 0 \text{ for all } \mathbf{A} \in W_{E,0}^\perp. \tag{4.16}$$

By the boundedness of supp $\nabla\chi_0$ it follows from (4.16) that curl $(\chi_0\mathbf{A}) = (\nabla\chi_0) \wedge \mathbf{A} + \chi_0$ curl $\mathbf{A} \in L^2(\mathbb{R}^3)$ and div $(\chi_0\mathbf{A}) = (\nabla\chi_0)\cdot\mathbf{A} \in L^2(\mathbb{R}^3)$ for all $\mathbf{A} \in W_{E,0}^\perp \cap W_E$. Here $\chi_0\mathbf{A}$ is extended by zero on $\mathbb{R}^3\setminus$ supp χ_0 and χ_0 as in (4.14). From Sobolev's inequality [1] one obtains $\chi_0\mathbf{A} \in L^6(\mathbb{R}^3)$ and hence $\mathbf{A} \in L^6(\mathbb{R}^3 \setminus B_{R_0})$.

The aim of the following considerations is to prove the following estimate.

LEMMA 4.3. *There exists a constant $K_3 \in (0,\infty)$, such that for all $\mathbf{A} \in W_E \cap W_{E,0}^\perp$ the estimate*

$$\|\mathbf{A}\|_{L^2(\Omega\cap B_{R_0})} + \|\mathbf{A}\|_{L^6(\mathbb{R}^3\setminus B_{R_0})} \leq K_3 \|\ \textit{curl}\ \mathbf{A}\|_{L^2(\Omega)}$$

holds.

LEMMA 4.4. (i) *The set of all $\mathbf{F} \in W_{E,0}$ with bounded support is dense in $W_{E,0}$ (with respect to the $L^2(\Omega)$-norm).*

(ii) *Let $\mathbf{A} \in L^2(\Omega \cap B_{R_0}) \cap L^6(\mathbb{R}^3 \setminus B_{R_0})$ with*

$$\int_\Omega \mathbf{A}\ \textit{curl}\ \mathbf{h} dx = 0 \textit{ for all } \mathbf{h} \in C_0^\infty(\mathbb{R}^3 \setminus \overline{\Gamma_2}, \mathbb{C}^3) \tag{4.17}$$

and

$$\int_\Omega \mathbf{A}\mathbf{F} dx = 0 \textit{ for all } \mathbf{F} \in W_{E,0} \textit{ with bounded support.} \tag{4.18}$$

Then $\mathbf{A} = 0$.

Proof. (i) Suppose $\mathbf{F} \in W_{E,0}$. Since curl $\mathbf{F} = 0$, there exists some $\varphi \in L^6(\mathbb{R}^3 \setminus B_{R_0})$ with

$$\mathbf{F} = \nabla\varphi \text{ on } \mathbb{R}^3 \setminus B_{R_0}. \tag{4.19}$$

Let $\psi_1 \in C_0^\infty(B_2)$ with $\psi_1 = 1$ on B_1 and $\psi_n \overset{\text{def}}{=} \psi_1(x/n)$. Now define $\mathbf{F}_n(x) \overset{\text{def}}{=} \psi_n(x)\mathbf{F}(x)$ if $x \in \Omega \cap B_n$ and $\mathbf{F}_n(x) \overset{\text{def}}{=} \psi_n(x)\mathbf{F}(x) + \varphi(x)\nabla\psi_n(x)$ if $|x| \geq n$. Then $\mathbf{F}_n$ has bounded support and curl $\mathbf{F}_n = (\nabla\psi_n) \wedge \mathbf{F} + (\nabla\varphi) \wedge \nabla\psi_n = 0$ by (4.19). Since

also $\mathbf{F}_n = \mathbf{F}$ near $\partial\Omega$ it follows easily that $\mathbf{F}_n \in W_{E,0}$. Next it follows from Hölder's inequality that

$$\|\mathbf{F}_n - \mathbf{F}\|_{L^2(\Omega)} \leq \|(1-\psi_n)\mathbf{F}\|_{L^2(\Omega)} + \|\varphi\nabla\psi_n\|_{L^2(\Omega)}$$

$$\leq \|(1-\psi_n)\mathbf{F}\|_{L^2(\Omega)} + \|\varphi\|_{L^6(\{|x|>n\})}\|\nabla\psi_n\|_{L^3(\mathbb{R}^3)}$$

$$\leq \|(1-\psi_n)\mathbf{F}\|_{L^2(\Omega)} + \|\varphi\|_{L^6(\{|x|>n\})}\|\nabla\psi_n\|_{L^\infty(\mathbb{R}^3)}|B_{2n}|^{1/3}$$

$$\leq \|(1-\psi_n)\mathbf{F}\|_{L^2(\Omega)} + C_1\|\varphi\|_{L^6(\{|x|>n\})} \overset{n\to\infty}{\longrightarrow} 0$$

with some C_1 independent of n. This completes the proof of (i).

Next let $\mathbf{A} \in L^2(\Omega\cap B_{R_0}) \cap L^6(\mathbb{R}^3 \setminus B_{R_0})$ satisfy (4.17) and (4.18). Then one has in analogy to (4.16)

$$\text{curl } \mathbf{A} = 0 \text{ and } \text{ div } \mathbf{A} = 0 \text{ on } \Omega. \tag{4.20}$$

Since supp $\nabla\chi_0$ is bounded, it follows from (4.20) that curl $(\chi_0\mathbf{A}) = (\nabla\chi_0) \wedge \mathbf{A} \in L^{6/5}(\mathbb{R}^3)$ and div $(\chi_0\mathbf{A}) = (\nabla\chi_0)\cdot\mathbf{A} \in L^{6/5}(\mathbb{R}^3)$, where $\chi_0\mathbf{A}$ is extended by zero on $\mathbb{R}^3\setminus$ supp χ_0. From Lemma 1 in [8] one obtains $\chi_0\mathbf{A} \in L^2(\mathbb{R}^3)$ and hence $\mathbf{A} \in L^2(\Omega)$. By the definition of W_E and (4.17) we have $\mathbf{A} \in W_{E,0}$. Since $\mathbf{A} \in L^2(\Omega)$, (4.18) holds for all $\mathbf{F} \in W_{E,0}$ by assertion (i). But this means $\mathbf{A} \in W_{E,0}^{\perp}$ and therefore $\mathbf{A} = 0$. □

LEMMA 4.5. *Let $\{\mathbf{A}_n\}_{n\in\mathbb{N}}$ be a sequence in $W_E \cap W_{E,0}^{\perp}$ which is bounded in $L^2(\Omega\cap B_{R_0}) \cap L^6(\mathbb{R}^3 \setminus B_{R_0})$ such that $\{curl\ \mathbf{A}_n\}_{n\in\mathbb{N}}$ is precompact in $L^2(\Omega)$. Then $\{\mathbf{A}_n\}_{n\in\mathbb{N}}$ is precompact in $L^2(\Omega\cap B_{R_0}) \cap L^6(\mathbb{R}^3 \setminus B_{R_0})$.*

Proof. Let $\tilde{\Omega} \overset{\text{def}}{=} B_{2R_0} \cap \Omega$ and choose $\chi_1 \in C_0^\infty(B_{2R_0})$ with $\chi_1(x) = 1$ on B_{R_0}, in particular

$$\chi_1(x) = 1 \text{ on supp } (\nabla\chi_0). \tag{4.21}$$

Let $S_1 \overset{\text{def}}{=} \Gamma_1 \cup \partial B_{2R_0}$ and $S_2 \overset{\text{def}}{=} \Gamma_2 = \partial\tilde{\Omega} \setminus S_1$. Recall that $\mathbb{R}^3 \setminus \Omega \subset B_{R_0} \subset B_{2R_0}$. In analogy to the definition of W_E let $\mathcal{W}_E$ be the space of all $\mathbf{e} \in H_{curl}(\tilde{\Omega})$ with $\vec{n}\wedge\mathbf{e} = 0$ on S_1 in the sense that

$$\int_{\tilde{\Omega}} \mathbf{e} \text{ curl } \mathbf{f} - \mathbf{f} \text{ curl } \mathbf{e} dx = 0 \text{ for all } \mathbf{f} \in C_0^\infty(\mathbb{R}^3 \setminus \overline{S_2}, \mathbb{C}^3).$$

Now, it follows from the assumptions that

$$\{\chi_1\mathbf{A}_n\}_{n\in\mathbb{N}} \text{ is bounded in } \mathcal{W}_E. \tag{4.22}$$

Since $\mathbf{A}_n \in W_{E,0}^{\perp}$, one has also

$$\{\text{div } [\chi_1\mathbf{A}_n]\}_{n\in\mathbb{N}} = \{\mathbf{A}_n\nabla\chi_1\}_{n\in\mathbb{N}} \text{ is bounded in } L^2(\tilde{\Omega}) \tag{4.23}$$

and $\chi_1\vec{n}\mathbf{A} = 0$ on S_2, in the sense that

$$-\int_{\tilde{\Omega}} \chi_1\mathbf{A}_n\nabla\varphi dx = \int_{\tilde{\Omega}} (\text{div } [\chi_1\mathbf{A}_n])\varphi dx = \int_{\tilde{\Omega}} (\mathbf{A}_n\nabla\chi_1)\varphi dx$$

for all $\varphi \in C_0^\infty(\mathbb{R}^3 \setminus \overline{S_1})$.

Since the Lipschitz domain $\tilde{\Omega} = B_{2R_0} \cap \Omega$ and the decomposition of its boundary $\partial\tilde{\Omega} = S_1 \cup S_2$ satisfy the assumptions in [7], it follows from (4.22), (4.23), and the result in [7] that the sequence

$$\{\chi_1 \mathbf{A}_n\}_{n\in\mathbb{N}} \text{ is precompact in } L^2(\tilde{\Omega}) = L^2(B_{2R_0} \cap \Omega). \tag{4.24}$$

Let $\mathbf{f}_n(x) \overset{\text{def}}{=} \chi_0 \mathbf{A}_n(x)$ if $x \in \Omega$ and $\mathbf{f}_n(x) \overset{\text{def}}{=} 0$ if $x \in \mathbb{R}^3 \setminus \Omega$.

Next, (4.21), (4.24), and the compactness assumption on $\{\text{curl } \mathbf{A}_n\}_{n\in\mathbb{N}}$ imply that the sequences

$$\{\text{curl } \mathbf{f}_n\}_{n\in\mathbb{N}} = \{(\nabla\chi_0) \wedge \mathbf{A}_n + \chi_0 \text{ curl } \mathbf{A}_n\}_{n\in\mathbb{N}} \tag{4.25}$$

and

$$\{\text{div } \mathbf{f}_n\}_{n\in\mathbb{N}} = \{\mathbf{A}_n \nabla\chi_0\}_{n\in\mathbb{N}} \text{ are precompact in } L^2(\mathbb{R}^3). \tag{4.26}$$

Recall that supp $\chi_0 \subset \Omega$. By (4.25) and (4.26) it follows from Sobolev's inequality or directly from Lemma 1 in [8] that the sequence $(\mathbf{f}_n)_{n\in\mathbb{N}}$ is precompact in $L^6(\mathbb{R}^3)$ and hence

$$(\mathbf{A}_n)_{n\in\mathbb{N}} \text{ is precompact in } L^6(\Omega \setminus B_{R_0}) \tag{4.27}$$

since $\chi_0(x) = 1$ for $|x| > R_0$. □

Proof of Lemma 4.3. Suppose that the estimate was not correct, i.e., there exists a sequence $\mathbf{A}_n \in W_E \cap W_{E,0}^\perp, n \in \mathbb{N}$, with

$$1 = \|\mathbf{A}_n\|_{L^2(\Omega\cap B_{R_0})} + \|\mathbf{A}_n\|_{L^6(\mathbb{R}^3\setminus B_{R_0})} \geq n\| \text{ curl } \mathbf{A}_n\|_{L^2} \text{ for all } n \in \mathbb{N}. \tag{4.28}$$

By Lemma 4.5 the sequence $\{\mathbf{A}_n\}_{n\in\mathbb{N}}$ is precompact in $L^2(\Omega \cap B_{R_0}) \cap L^6(\mathbb{R}^3 \setminus B_{R_0})$, i.e., there exist $\mathbf{A} \in L^2(\Omega \cap B_{R_0}) \cap L^6(\mathbb{R}^3 \setminus B_{R_0})$ and a subsequence $\mathbf{A}_{n_k}, k \in \mathbb{N}$, with

$$\|\mathbf{A}_{n_k} - \mathbf{A}\|_{L^2(\Omega\cap B_{R_0})} + \|\mathbf{A}_{n_k} - \mathbf{A}\|_{L^6(\mathbb{R}^3\setminus B_{R_0})} \overset{k\to\infty}{\longrightarrow} 0, \tag{4.29}$$

in particular

$$\|\mathbf{A}\|_{L^2(\Omega\cap B_{R_0})} + \|\mathbf{A}\|_{L^6(\mathbb{R}^3\setminus B_{R_0})} = 1. \tag{4.30}$$

From (4.28) and (4.29) it follows that

$$\int_\Omega \mathbf{A} \text{ curl } \mathbf{h} dx = \lim_{k\to\infty} \int_\Omega \mathbf{A}_{n_k} \text{ curl } \mathbf{h} dx \tag{4.31}$$

$$= \lim_{k\to\infty} \int_\Omega \mathbf{h} \text{ curl } \mathbf{A}_{n_k} dx = 0 \text{ for all } \mathbf{h} \in C_0^\infty(\mathbb{R}^3 \setminus \overline{\Gamma_2}, \mathbb{C}^3).$$

Furthermore

$$\int_\Omega \mathbf{A}\mathbf{F} dx = \lim_{k\to\infty} \int_\Omega \mathbf{A}_{n_k} \mathbf{F} dx = 0 \tag{4.32}$$

for all $\mathbf{F} \in W_{E,0}$ with bounded support. Now (4.31), (4.32), and Lemma 4.4(ii) would imply $\mathbf{A} = 0$. This contradicts (4.30). □

The aim of the following considerations is to show decay of the potential energy and the local electromagnetic energy at least in time mean, i.e., for all $R > 0$

$$t^{-1} \int_0^t \left(\int_G \gamma^{-1} V(x, \mathbf{P}(s)) dx + \|(\mathbf{E}(s), \mathbf{H}(s))\|^2_{L^2(\Omega \cap B_R)} \right) ds \stackrel{t \to \infty}{\longrightarrow} 0.$$

LEMMA 4.6. *There holds*

$$t^{-1} \int_0^t \langle Q(\mathbf{E}(s), \mathbf{H}(s)), \mathcal{R}\mathbf{P}(s) \rangle_X ds \stackrel{t \to \infty}{\longrightarrow} 0.$$

Proof. Let $\mathbf{u}(t) \stackrel{\text{def}}{=} Q(\mathbf{E}(t), \mathbf{H}(t))$ and $\mathbf{A}(t) \stackrel{\text{def}}{=} \int_0^t \underline{\mathbf{u}}_1(s) ds$. Since $\mathbf{u}(t) \in (\ker B)^\perp$ one has $\mathbf{A}(t) \in W^\perp_{E,0}$. With

$$\text{curl } \underline{\mathbf{u}}_1(s) = -\underline{(B\mathbf{u}(s))}_2 = -\underline{[B(\mathbf{E}(t), \mathbf{H}(t))]}_2 = \text{ curl } \mathbf{E}(s) = -\partial_t \mathbf{H}(s)$$

one gets by using Lemma 4.3

$$\|\mathbf{A}(t)\|_{L^2(\Omega \cap B_{R_0})} + \|\mathbf{A}(t)\|_{L^6(\mathbb{R}^3 \setminus B_{R_0})} \leq K_3 \| \text{ curl } \mathbf{A}(t)\|_{L^2(\Omega)}$$

$$= K_3 \| \int_0^t \text{ curl } \underline{\mathbf{u}}_1(s) ds \|_{L^2(\Omega)} = K_3 \|\mathbf{H}(0) - \mathbf{H}(t)\|_{L^2(\Omega)}.$$

Now, it follows from Lemma 2.2 and the previous estimate that

$$\|\mathbf{A}(t)\|_{L^2(\Omega \cap B_{R_0})} + \|\mathbf{A}(t)\|_{L^6(\mathbb{R}^3 \setminus B_{R_0})} \leq C_1 \text{ for all } t \in (0, \infty) \tag{4.33}$$

with some constant C_1 independent of t. Next,

$$t^{-1} \int_0^t \langle Q(\mathbf{E}(s), \mathbf{H}(s)), \mathcal{R}\mathbf{P}(s) \rangle_X ds = t^{-1} \int_0^t \int_G \underline{\mathbf{u}}_1(s) \mathbf{P}(s) dx ds \tag{4.34}$$

$$= t^{-1} \int_0^t \int_G \partial_t \mathbf{A}(s) \mathbf{P}(s) dx ds = t^{-1} \int_G \mathbf{A}(t) \mathbf{P}(t) dx - t^{-1} \int_0^t \int_G \mathbf{A}(s) \partial_t \mathbf{P}(s) dx ds$$

$$\leq C_1 t^{-1} \left(\|\mathbf{P}(t)\|_{L^2(G)} + \|\mathbf{P}(t)\|_{L^{6/5}(G)} \right)$$

$$+ C_1 t^{-1} \int_0^t \left(\|\partial_t \mathbf{P}(s)\|_{L^2(G)} + \|\partial_t \mathbf{P}(s)\|_{L^{6/5}(G)} \right) ds$$

$$\leq C_1 t^{-1} \left(\|\gamma^{1/2}\|_{L^\infty(G)} + \|\gamma^{1/2}\|_{L^3(G)} \right) \|\mathbf{P}(t)\|_{\mathcal{G}}$$

$$+ C_1 t^{-1} \int_0^t \left(\|\gamma^{1/2}\|_{L^\infty(G)} + \|\gamma^{1/2}\|_{L^3(G)} \right) \|\partial_t \mathbf{P}(s)\|_{\mathcal{G}} ds$$

by assumption (4.9) and Hölder's inequality. Next Lemma 2.2 yields

$$\|\mathbf{P}(t)\|_{\mathcal{G}} \leq \|\mathbf{P}_0\|_{\mathcal{G}} + \int_0^t \|\partial_s \mathbf{P}(s)\|_{\mathcal{G}} ds$$

$$\leq C_2 + C_2 t^{1/2} \|\partial_s \mathbf{P}\|_{L^2((0,\infty),\mathcal{G})} \leq C_3 + C_3 t^{1/2}.$$

With (4.34) and Lemma 2.2 again one obtains

$$t^{-1} \int_0^t \langle Q(\mathbf{E}(s), \mathbf{H}(s)), \mathcal{R}\mathbf{P}(s) \rangle_X ds$$

$$\leq C_4(t^{-1} + t^{-1/2}) + C_4 t^{-1/2} \|\partial_s \mathbf{P}\|_{L^2((0,\infty),\mathcal{G})} \stackrel{t\to\infty}{\longrightarrow} 0. \qquad \square$$

LEMMA 4.7. *There holds*

$$t^{-1} \int_0^t \left(\int_G \gamma^{-1} V(x, \mathbf{P}(s)) dx + \|(1-Q)(\mathbf{E}(t), \mathbf{H}(t))\|_X^2 \right) ds \stackrel{t\to\infty}{\longrightarrow} 0,$$

in particular

$$\lim_{t\to\infty} t^{-1} \int_0^t \|(\mathbf{E}(s), \mathbf{H}(s))\|_X^2 ds = \lim_{t\to\infty} t^{-1} \int_0^t \|Q(\mathbf{E}(s), \mathbf{H}(s))\|_X^2 ds = \mathcal{E}_\infty,$$

where $\mathcal{E}_\infty$ *as in* (2.23).

Proof. It follows from Lemma 2.2 and (4.3) that

$$\|(1-Q)(\mathbf{E}(t), \mathbf{H}(t))\|_X^2 = \langle (\mathbf{E}(t), \mathbf{H}(t)), (1-Q)[(\mathbf{J}(t), 0) - \mathcal{R}\mathbf{P}(t)] \rangle_X$$

$$= \langle Q(\mathbf{E}(t), \mathbf{H}(t)), \mathcal{R}\mathbf{P}(t) \rangle_X + \langle (\mathbf{E}(t), \mathbf{H}(t)), (1-Q)(\mathbf{J}(t), 0) \rangle_X - \int_G \mathbf{E}(t)\mathbf{P}(t) dx$$

$$\leq \langle Q(\mathbf{E}(t), \mathbf{H}(t)), \mathcal{R}\mathbf{P}(t) \rangle_X + C_1 \|\mathbf{J}(t)\|_{L^2(\Omega)}$$

$$- \int_G \gamma^{-1} \left[\alpha \partial_t^2 \mathbf{P}(t) + \partial_t \mathbf{P}(t) + (\nabla_y V)(x, \mathbf{P}(t)) \right] \mathbf{P} dx$$

$$\leq \langle Q(\mathbf{E}(t), \mathbf{H}(t)), \mathcal{R}\mathbf{P}(t) \rangle_X + C_1 \|\mathbf{J}(t)\|_{L^2(\Omega)}$$

$$- \int_G \gamma^{-1} \left(\alpha \partial_t^2 \mathbf{P}(t) + \partial_t \mathbf{P}(t) \right) \mathbf{P}(t) dx - K_2^{-1} \int_G \gamma^{-1} V(x, \mathbf{P}(t)) dx$$

by assumption (4.8). Now,

$$t^{-1} \int_0^t \left(\|(1-Q)(\mathbf{E}(s), \mathbf{H}(s))\|_X^2 + K_2^{-1} \int_G \gamma^{-1} V(x, \mathbf{P}(s)) dx \right) ds \tag{4.35}$$

$$\leq t^{-1} \int_0^t \left(\langle Q(\mathbf{E}(s), \mathbf{H}(s)), \mathcal{R}\mathbf{P}(s) \rangle_X + C_1 \|\mathbf{J}(s)\|_{L^2(\Omega)} \right) ds$$

$$+ C_2/t - 1/2 t^{-1} \int_G \gamma^{-1} |\mathbf{P}(t)|^2 dx - t^{-1} \int_G \alpha \gamma^{-1} \partial_t \mathbf{P}(t) \mathbf{P}(t) dx$$

$$+t^{-1}\int_0^t\int_G \alpha\gamma^{-1}|\partial_t\mathbf{P}(s)|^2dxds$$

$$\leq t^{-1}\int_0^t \left(\langle Q(\mathbf{E}(s),\mathbf{H}(s)),\mathcal{R}\mathbf{P}(s)\rangle_X + C_1\|\mathbf{J}(s)\|_{L^2(\Omega)}\right)ds$$

$$+C_3/t + C_3t^{-1}\|\partial_t\mathbf{P}(t)\|^2_{\mathcal{G}} + t^{-1}\|\alpha^{1/2}\partial_t\mathbf{P}\|^2_{L^2((0,\infty),\mathcal{G})}$$

$$\leq t^{-1}\int_0^t \left(\langle Q(\mathbf{E}(s),\mathbf{H}(s)),\mathcal{R}\mathbf{P}(s)\rangle_X + C_1\|\mathbf{J}(s)\|_{L^2(\Omega)}\right)ds + C_4/t$$

by Lemma 2.2(i) again.

In the previous estimates C_j are constants independent of t. Now, it follows from Lemma 4.6 and (4.35) that

$$t^{-1}\int_0^t \left(\int_G \gamma^{-1}V(x,\mathbf{P}(s))dx + \|(1-Q)(\mathbf{E}(t),\mathbf{H}(t))\|^2_X\right)ds \stackrel{t\to\infty}{\longrightarrow} 0. \tag{4.36}$$

Since

$$t^{-1}\int_0^t \|\alpha^{1/2}\partial_t\mathbf{P}(s)\|^2_{\mathcal{G}}ds \leq t^{-1}\|\alpha^{1/2}\partial_t\mathbf{P}\|^2_{L^2((0,\infty),\mathcal{G})}dxds \stackrel{t\to\infty}{\longrightarrow} 0$$

by Lemma 2.2(i), (2.23) and (4.36) yield

$$\lim_{t\to\infty} t^{-1}\int_0^t \|Q(\mathbf{E}(s),\mathbf{H}(s))\|^2_X ds = \lim_{t\to\infty} t^{-1}\int_0^t \|(\mathbf{E}(s),\mathbf{H}(s))\|^2_X ds = \mathcal{E}_\infty,$$

which completes the proof. □

From Lemma 4.1 and the previous lemma one now easily obtains the following.

COROLLARY 4.8. *For all $R>0$ one has*

$$t^{-1}\int_0^t \|(\mathbf{E}(s),\mathbf{H}(s))\|_{L^2(\Omega\cap B_R)}ds \stackrel{t\to\infty}{\longrightarrow} 0.$$

In what follows let

$$D(B_0) \stackrel{\text{def}}{=} H_{curl}(\mathbb{R}^3)\times H_{curl}(\mathbb{R}^3) \text{ and } B_0(\mathbf{e},\mathbf{h}) \stackrel{\text{def}}{=} (\operatorname{curl}\mathbf{h}, -\operatorname{curl}\mathbf{e}).$$

Furthermore, let Q_0 be the orthogonal projector on $(\ker B_0)^\perp$, which consists of all $\mathbf{u}\in L^2(\mathbb{R}^3)$ with $\operatorname{div}\underline{\mathbf{u}}_j = 0$. The following estimate will be used in the proof of (4.7).

LEMMA 4.9. *Let $s\in[0,1]$. Then there exists a constant $K_1\in(0,\infty)$ such that*

$$|\langle(1+|x|)^s\mathbf{f}, Q_0\mathbf{g}\rangle_{L^2(\mathbb{R}^3)}| \leq K_1\|\mathbf{f}\|_{H^1(\mathbb{R}^3)}\|(1+|x|)^s\mathbf{g}\|_{L^{q_0}(\mathbb{R}^3)}$$

for all $\mathbf{f}\in H^1(\mathbb{R}^3)$ and $\mathbf{g}\in L^2(\mathbb{R}^3)$ with $(1+|x|)^s\mathbf{f}\in L^2(\mathbb{R}^3)$ and $(1+|x|)^s\mathbf{g}\in L^{q_0}(\mathbb{R}^3)$. Here $1/q_0 = 1/(2r_0)+1/2$, where r_0 is as in assumption (4.9).

Proof. By a standard density argument it suffices to consider $\mathbf{f}, \mathbf{g} \in C_0^\infty(\mathbb{R}^3)$. Recall that $2r_0 > 3$. Let $p_1 \stackrel{\text{def}}{=} (\frac{1-s}{3} - \frac{1-s}{2r_0})^{-1} \in (\frac{3}{1-s}, \infty]$ ($p_1 = \infty$ for $s = 1$) and $p_2 \stackrel{\text{def}}{=} (\frac{s}{3} - \frac{s}{2r_0})^{-1}$. Since $(s-1)p_1 < -3$ and $sp_2 > 3$ one has

$$(1+|x|)^{s-1} \in L^{p_1}(\mathbb{R}^3) \text{ and } (1+|x|)^{-s} \in L^{p_2}(\mathbb{R}^3). \tag{4.37}$$

Now $\mathbf{F} \stackrel{\text{def}}{=} (1+|x|)^s Q_0 \mathbf{f} - Q_0\left((1+|x|)^s \mathbf{f}\right)$ obeys

$$B_0\mathbf{F} = -s(1+|x|)^{s-1}|x|^{-1} S Q_0 \mathbf{f} + (1+|x|)^s B_0 \mathbf{f} - B_0\left((1+|x|)^s \mathbf{f}\right)$$

$$= -s(1+|x|)^{s-1}|x|^{-1} S[Q_0\mathbf{f} - \mathbf{f}],$$

where $S\mathbf{w} \stackrel{\text{def}}{=} (-x \wedge \underline{\mathbf{w}}_2, x \wedge \underline{\mathbf{w}}_1)$. Hence

$$\|(1+|x|)^{1-s} B_0\mathbf{F}\|_{L^2(\mathbb{R}^3)} \le s\|(Q_0 - 1)\mathbf{f}\|_{L^2(\mathbb{R}^3)} \le s\|\mathbf{f}\|_{L^2(\mathbb{R}^3)}.$$

A similar estimate using $\text{div } \underline{(Q_0\mathbf{f})}_j = 0$ yields

$$\|(1+|x|)^{1-s} \text{ div } \underline{\mathbf{F}}_j\|_{L^2(\mathbb{R}^3)} \le s\|\underline{(Q_0\mathbf{f})}_j\|_{L^2(\mathbb{R}^3)} \le s\|\mathbf{f}\|_{L^2(\mathbb{R}^3)}.$$

With $1/q \stackrel{\text{def}}{=} 1/p_1 + 1/2$ we obtain by (4.37) and Hölder's inequality

$$\| \text{ curl } \underline{\mathbf{F}}_j\|_{L^q(\mathbb{R}^3)} \le C_1\|B_0\mathbf{F}\|_{L^q(\mathbb{R}^3)}$$

$$\le C_1\|(1+|x|)^{s-1}\|_{L^{p_1}(\mathbb{R}^3)}\|(1+|x|)^{1-s} B_0\mathbf{F}\|_{L^2(\mathbb{R}^3)} \le C_2\|\mathbf{f}\|_{L^2(\mathbb{R}^3)}$$

and

$$\| \text{ div } \underline{\mathbf{F}}_j\|_{L^q(\mathbb{R}^3)} \le C_2\|\mathbf{f}\|_{L^2(\mathbb{R}^3)}.$$

By Sobolev's inequality [1] or directly by Lemma 1 in [8] one obtains

$$\|\mathbf{F}\|_{L^r(\mathbb{R}^3)} \le C_3\|D\mathbf{F}\|_{L^q(\mathbb{R}^3)} \tag{4.38}$$

$$\le C_4\left(\|\text{curl } \underline{\mathbf{F}}_j\|_{L^q(\mathbb{R}^3)} + \| \text{ div } \underline{\mathbf{F}}_j\|_{L^q(\mathbb{R}^3)}\right) \le C_3\|\mathbf{f}\|_{L^2(\mathbb{R}^3)}.$$

Here $r \stackrel{\text{def}}{=} (\frac{1}{q} - \frac{1}{3})^{-1} = (1/6 + \frac{1-s}{3} - \frac{1-s}{2r_0})^{-1} \in (2, 6)$. Now, $\frac{1}{r} + \frac{1}{p_2} + \frac{1}{q_0} = 1$. Therefore (4.37), (4.38), and Hölder's inequality yield

$$|\langle \mathbf{F}, \mathbf{g}\rangle_{L^2(\mathbb{R}^3)}| \le \|\mathbf{F}\|_{L^r(\mathbb{R}^3)}\|(1+|x|)^{-s}\|_{L^{p_2}(\mathbb{R}^3)}\|(1+|x|)^s \mathbf{g}\|_{L^{q_0}(\mathbb{R}^3)} \tag{4.39}$$

$$\le C_5\|\mathbf{f}\|_{L^2(\mathbb{R}^3)}\|(1+|x|)^s \mathbf{g}\|_{L^{q_0}(\mathbb{R}^3)}.$$

Since $q_0 \ge 6/5$ one has $q_0^* \le 6$. Therefore, it follows from Hölder's inequality, (4.39), and the embedding $H^1(\mathbb{R}^3) \hookrightarrow L^{q_0^*}(\mathbb{R}^3)$ that

$$|\langle (1+|x|)^s \mathbf{f}, Q_0\mathbf{g}\rangle_{L^2(\mathbb{R}^3)}| \le |\langle Q_0\mathbf{f}, (1+|x|)^s \mathbf{g}\rangle_{L^2(\mathbb{R}^3)}| + |\langle \mathbf{F}, \mathbf{g}\rangle_{L^2(\mathbb{R}^3)}| \tag{4.40}$$

$$\leq C_5\|Q_0\mathbf{f}\|_{H^1(\mathbb{R}^3)}\|(1+|x|)^s\mathbf{g}\|_{L^{q_0}(\mathbb{R}^3)} + |\langle\mathbf{F},\mathbf{g}\rangle_{L^2(\mathbb{R}^3)}|$$

$$\leq C_6\|\mathbf{f}\|_{H^1(\mathbb{R}^3)}\|(1+|x|)^s\mathbf{g}\|_{L^{q_0}(\mathbb{R}^3)} \qquad \square$$

Since supp $\chi_0 \subset \Omega$, Lemma 2.2 yields $\chi_0(\mathbf{E}(\cdot),\mathbf{H}(\cdot)) \in L^\infty((0,\infty), D(B_0))$ and hence

$$Q_0\chi_0(\mathbf{E}(\cdot),\mathbf{H}(\cdot)) \in L^\infty((0,\infty), D(B_0)\cap(\ker\, B_0)^\perp) \tag{4.41}$$

$$\subset L^\infty((0,\infty), H^1(\mathbb{R}^3)),$$

where $\chi_0 \in C^\infty(\mathbb{R}^3)$ as in (4.14).

LEMMA 4.10. *There holds* (i)

$$t^{-1}\int_0^t \|(1-Q_0)\chi_0(\mathbf{E}(s),\mathbf{H}(s))\|_{L^2(\mathbb{R}^3)}ds \overset{t\to\infty}{\longrightarrow} 0.$$

(ii)

$$t^{-1}\int_0^t \|Q_0\chi_0(\mathbf{E}(s),\mathbf{H}(s))\|^2_{L^2(\mathbb{R}^3)}ds \overset{t\to\infty}{\longrightarrow} \mathcal{E}_\infty, \textit{ and}$$

(iii)

$$t^{-1}\int_0^t \|Q_0\chi_0(\mathbf{E}(s),\mathbf{H}(s))\|_{L^2(\{|x|\geq as\})}ds \overset{t\to\infty}{\longrightarrow} 0 \textit{ for all } a\in(1,\infty).$$

Proof. First the following estimate is proved:

$$\|(1-Q_0)\chi_0\mathbf{u}\|_{L^2(\mathbb{R}^3)} \leq K_1\left(\|(1-Q)\mathbf{u}\|_X + \|\mathbf{u}\|_{L^2(\Omega\cap B_{R_0})}\right) \tag{4.42}$$

for all $\mathbf{u}\in X$ with some constant independent of $\mathbf{u}$. For this purpose let $\mathbf{u}\in X$ and define $\mathbf{f} \overset{\text{def}}{=} (1-Q_0)\chi_0\mathbf{u} \in \ker\, B_0$, i.e., curl $\underline{\mathbf{f}}_j = 0$ on $\mathbb{R}^3$. Hence there exist $\varphi_j \in L^6(\mathbb{R}^3)$ with $\nabla\varphi_j \in L^2(\mathbb{R}^3)$ such that

$$\underline{\mathbf{f}}_j = \nabla\varphi_j. \tag{4.43}$$

Hence

$$\|\mathbf{f}\|^2_{L^2(\mathbb{R}^3)} = \langle\chi_0\mathbf{u},\mathbf{f}\rangle_{L^2(\mathbb{R}^3)} = \int_{\mathbb{R}^3}\chi_0\cdot(\underline{\mathbf{u}}_1\nabla\varphi_1 + \underline{\mathbf{u}}_2\nabla\varphi_2)\,dx$$

$$= \langle\mathbf{u},(\nabla[\chi_0\varphi_1],\nabla[\chi_0\varphi_2])\rangle_X - \int_{\mathbb{R}^3}(\underline{\mathbf{u}}_1(\nabla\chi_0)\varphi_1 - \underline{\mathbf{u}}_2(\nabla\chi_0)\varphi_2)\,dx.$$

Since $(\nabla[\chi_0\varphi_1],\nabla[\chi_0\varphi_2]) \in \ker B$ and supp $(\nabla\chi_0)$ is bounded, it follows that

$$\|(1-Q_0)\chi_0\mathbf{u}\|^2_{L^2(\mathbb{R}^3)} = \|\mathbf{f}\|^2_{L^2(\mathbb{R}^3)} \tag{4.44}$$

$$\leq C_1\|(1-Q)\mathbf{u}\|_X\left(\|\nabla(\chi_0\varphi_1)\|_{L^2(\mathbb{R}^3)} + \|\nabla(\chi_0\varphi_2)\|_{L^2(\mathbb{R}^3)}\right)$$

$$+C_1\|\mathbf{u}\|_{L^2(\Omega\cap B_{R_0})}\left(\|\varphi_1\|_{L^2(B_{R_0})}+\|\varphi_2\|_{L^2(B_{R_0})}\right)$$

$$\leq C_1\left(\|(1-Q)\mathbf{u}\|_X+\|\mathbf{u}\|_{L^2(\Omega\cap B_{R_0})}\right)$$

$$\left(\|\nabla\varphi_1\|_{L^2(\mathbb{R}^3)}+\|\varphi_1\|_{L^6(\mathbb{R}^3)}+\|\nabla\varphi_2\|_{L^2(\mathbb{R}^3)}+\|\varphi_1\|_{L^6(\mathbb{R}^3)}\right)$$

$$\leq C_2\left(\|(1-Q)\mathbf{u}\|_X+\|\mathbf{u}\|_{L^2(\Omega\cap B_{R_0})}\right)\|\mathbf{f}\|_{L^2(\mathbb{R}^3)}.$$

This completes the proof of (4.42). Now, assertion (i) follows immediately from Lemma 4.7, Corollary 4.8, and inequality (4.42).

Next, part (i), Corollary 4.8, and Lemma 4.7 yield by the boundedness of supp $(1-\chi_0)$

$$\lim_{t\to\infty}t^{-1}\int_0^t\|Q_0\chi_0(\mathbf{E}(s),\mathbf{H}(s))\|^2_{L^2(\mathbb{R}^3)}ds=\lim_{t\to\infty}t^{-1}\int_0^t\|\chi_0(\mathbf{E}(s),\mathbf{H}(s))\|^2_{L^2(\mathbb{R}^3)}ds$$

$$=\lim_{t\to\infty}t^{-1}\int_0^t\|(\mathbf{E}(s),\mathbf{H}(s))\|^2_X ds=\mathcal{E}_\infty,$$

whence (ii). Finally, part (iii) follows from (i) and Theorem 4.2. □

Next (4.7) is proved.

THEOREM 4.11. *Suppose $g\in C_0^\infty(\mathbb{R})$ with $g(u)=1$ on a neighborhood of $[0,1]$. Then*

$$t^{-1}\langle Sg(|x|/t)Q_0\chi_0(\mathbf{E}(t),\mathbf{H}(t)),Q_0\chi_0(\mathbf{E}(t),\mathbf{H}(t))\rangle_{L^2(\mathbb{R}^3)}\overset{t\to\infty}{\longrightarrow}\mathcal{E}_\infty,$$

where $\mathcal{E}_\infty$ is as in (2.23) *and $S\mathbf{u}\overset{\text{def}}{=}(-x\wedge\underline{\mathbf{u}}_2,x\wedge\underline{\mathbf{u}}_1)$.*

Proof. Define

$$F(t)\overset{\text{def}}{=}\langle Sg(|x|/t)Q_0\chi_0(\mathbf{E}(t),\mathbf{H}(t)),Q_0\chi_0(\mathbf{E}(t),\mathbf{H}(t))\rangle_{L^2(\mathbb{R}^3)}.$$

Then

$$F'(t)=2\,\langle Sg(|x|/t)Q_0\chi_0(\mathbf{E}(t),\mathbf{H}(t)),\tag{4.45}$$

$$Q_0\chi_0\left(B(\mathbf{E}(t),\mathbf{H}(t))-(\mathbf{j}(t),0)-\mathcal{R}\partial_t\mathbf{P}(t)\right)\rangle_{L^2(\mathbb{R}^3)}$$

$$-t^{-2}\,\langle S|x|g'(|x|/t)Q_0\chi_0(\mathbf{E}(t),\mathbf{H}(t)),Q_0\chi_0(\mathbf{E}(t),\mathbf{H}(t))\rangle_{L^2(\mathbb{R}^3)}$$

$$=\sum_{j=0}^2 h_j(t)+2\,\langle Sg(|x|/t)Q_0\chi_0(\mathbf{E}(t),\mathbf{H}(t)),B_0Q_0\chi_0(\mathbf{E}(t),\mathbf{H}(t))\rangle_{L^2(\mathbb{R}^3)}$$

$$-t^{-2}\,\langle S|x|g'(|x|/t)Q_0\chi_0(\mathbf{E}(t),\mathbf{H}(t)),Q_0\chi_0(\mathbf{E}(t),\mathbf{H}(t))\rangle_{L^2(\mathbb{R}^3)}$$

by (2.15). Here

$$h_0(t) \stackrel{\text{def}}{=} -2\,\langle Sg(|x|/t)Q_0\chi_0(\mathbf{E}(t),\mathbf{H}(t)), Q_0\chi_0(\mathbf{j}(t),0)\rangle_{L^2(\mathbb{R}^3)}\,, \tag{4.46}$$

$$h_1(t) \stackrel{\text{def}}{=} -2\,\langle Sg(|x|/t)Q_0\chi_0(\mathbf{E}(t),\mathbf{H}(t)), Q_0\chi_0\mathcal{R}\partial_t\mathbf{P}(t)\rangle_{L^2(\mathbb{R}^3)}\,, \tag{4.47}$$

$$h_2(t) \stackrel{\text{def}}{=} -2\,\langle Sg(|x|/t)Q_0\chi_0(\mathbf{E}(t),\mathbf{H}(t)), Q_0\mathcal{C}_0(\mathbf{E}(t),\mathbf{H}(t))\rangle_{L^2(\mathbb{R}^3)}\,, \tag{4.48}$$

where $\mathcal{C}_0$ is as in (4.15).

For $\mathbf{u} \in (\ker B_0)^\perp \cap D(B_0) \subset H^1(\mathbb{R}^3)$ one has $\operatorname{div} \underline{\mathbf{u}}_j = 0$. Therefore, it follows from the identity $x \wedge \operatorname{curl} \mathbf{a} = \nabla(x\mathbf{a}) - \mathbf{a} - (x\nabla)\mathbf{a}$ that

$$\begin{aligned}
&\langle Sg(|x|/t)\mathbf{u}, B_0\mathbf{v}\rangle_{L^2(\mathbb{R}^3)} + \langle Sg(|x|/t)B_0\mathbf{u}, \mathbf{v}\rangle_{L^2(\mathbb{R}^3)} \\
&= \int_{\mathbb{R}^3} g(|x|/t)\mathbf{u}\cdot(x\wedge \operatorname{curl}\underline{\mathbf{v}}_1, x\wedge \operatorname{curl}\underline{\mathbf{v}}_2)dx \\
&\quad + \int_{\mathbb{R}^3} g(|x|/t)(x\wedge \operatorname{curl}\underline{\mathbf{u}}_1, x\wedge \operatorname{curl}\underline{\mathbf{u}}_2)\cdot\mathbf{v}dx \\
&= \int_{\mathbb{R}^3} g(|x|/t)\mathbf{u}\cdot(\nabla[x\underline{\mathbf{v}}_1], \nabla[x\underline{\mathbf{v}}_2])\,dx + \int_{\mathbb{R}^3} g(|x|/t)\,(\nabla[x\underline{\mathbf{u}}_1], \nabla[x\underline{\mathbf{u}}_2])\cdot\mathbf{v}dx \\
&\quad -2\int_{\mathbb{R}^3} g(|x|/t)\mathbf{u}\cdot\mathbf{v}dx - \int_{\mathbb{R}^3} g(|x|/t)(x\nabla)[\mathbf{u}\mathbf{v}]dx \\
&= -2t^{-1}\left\langle \tilde{S}g'(|x|/t)\mathbf{u}, \mathbf{v}\right\rangle_{L^2(\mathbb{R}^3)} + \left\langle [g(|x|/t) + t^{-1}|x|g'(|x|/t)]\mathbf{u}, \mathbf{v}\right\rangle_{L^2(\mathbb{R}^3)}
\end{aligned}$$

with $\tilde{S}\mathbf{u} \stackrel{\text{def}}{=} |x|^{-1}\,([x\underline{\mathbf{u}}_1]x, [x\underline{\mathbf{u}}_2]x)$.
Hence

$$\begin{aligned}
&2\,\langle Sg(|x|/t)Q_0\chi_0(\mathbf{E}(t),\mathbf{H}(t)), B_0Q_0\chi_0(\mathbf{E}(t),\mathbf{H}(t))\rangle_{L^2(\mathbb{R}^3)} \\
&= \left\langle [g(|x|/t) + t^{-1}|x|g'(|x|/t)]Q_0\chi_0(\mathbf{E}(t),\mathbf{H}(t)), Q_0\chi_0(\mathbf{E}(t),\mathbf{H}(t))\right\rangle_{L^2(\mathbb{R}^3)} \\
&\quad -2t^{-1}\left\langle \tilde{S}g'(|x|/t)Q_0\chi_0(\mathbf{E}(t),\mathbf{H}(t)), Q_0\chi_0(\mathbf{E}(t),\mathbf{H}(t))\right\rangle_{L^2(\mathbb{R}^3)}.
\end{aligned}$$

With (4.45)–(4.48) it follows that

$$F'(t) = \|Q_0\chi_0(\mathbf{E}(t),\mathbf{H}(t))\|^2_{L^2(\mathbb{R}^3)} + \sum_{j=0}^{3} h_j(t), \tag{4.49}$$

where

$$h_3(t) \tag{4.50}$$

$$\stackrel{\text{def}}{=} \left\langle [g(|x|/t) - 1 + t^{-1}|x|g'(|x|/t)]Q_0\chi_0(\mathbf{E}(t),\mathbf{H}(t)), Q_0\chi_0(\mathbf{E}(t),\mathbf{H}(t))\right\rangle_{L^2(\mathbb{R}^3)}$$

$$-t^{-1}\left\langle (2\tilde{S} + t^{-1}|x|S)g'(|x|/t)Q_0\chi_0(\mathbf{E}(t),\mathbf{H}(t)), Q_0\chi_0(\mathbf{E}(t),\mathbf{H}(t))\right\rangle_{L^2(\mathbb{R}^3)}.$$

In the following estimates C_j are constants independent of s. Lemma 4.9 and (4.41) yield by Hölder's inequality and assumption (4.9)

$$|h_1(s)| \le C_1\|(1+|x|)^{-1/2}Sg(|x|/s)Q_0\chi_0(\mathbf{E}(s),\mathbf{H}(s))\|_{H^1(\mathbb{R}^3)}$$

$$\|(1+|x|)^{1/2}\chi_0\mathcal{R}\partial_s\mathbf{P}(s)\|_{L^{q_0}(\mathbb{R}^3)}$$

$$\le C_1\|(1+|x|)^{-1/2}Sg(|x|/s)Q_0\chi_0(\mathbf{E}(s),\mathbf{H}(s))\|_{H^1(\mathbb{R}^3)}$$

$$\|(1+|x|)^{1/2}\gamma^{1/2}\|_{L^{2r_0}(\mathbb{R}^3)}\|\gamma^{-1/2}\partial_s\mathbf{P}(s)\|_{L^2(G)}$$

$$\le C_2 s^{1/2}\|\partial_s\mathbf{P}(s)\|_{\mathcal{G}}.$$

For all $T > 0$ one obtains

$$t^{-1}\int_1^t |h_1(s)|ds \le t^{-1}\int_1^T |h_1(s)|ds + C_2 t^{-1}\int_T^t s^{1/2}\|\partial_s\mathbf{P}(s)\|_{\mathcal{G}}ds$$

$$\le t^{-1}\int_1^T |h_1(s)|ds + C_2\left(\int_T^t \|\partial_s\mathbf{P}(s)\|_{\mathcal{G}}^2 ds\right)^{1/2}$$

and hence by Lemma 2.2

$$\limsup_{t\to\infty} t^{-1}\int_1^t |h_1(s)|ds \le C_2\left(\int_T^\infty \|\partial_s\mathbf{P}(s)\|_{\mathcal{G}}^2 ds\right)^{1/2}$$

for all $T > 0$, which implies that

$$t^{-1}\int_1^t |h_1(s)|ds \stackrel{t\to\infty}{\longrightarrow} 0. \tag{4.51}$$

Next

$$|h_0(t)| \le C_3\|(1+|x|)^{-1}Sg(|x|/t)Q_0\chi_0(\mathbf{E}(t),\mathbf{H}(t))\|_{H^1}\|(1+|x|)\chi_0(\mathbf{j}(t),0)\|_{L^{q_0}}$$

$$\le C_4\|\mathbf{j}(t)\|_{L^2(B_{R_1})} \le C_4\|\mathbf{j}(t)\|_{L^2(\Omega)}$$

by assumption (4.10) which implies that

$$t^{-1}\int_0^t |h_0(s)|ds \overset{t\to\infty}{\longrightarrow} 0. \tag{4.52}$$

Similarly

$$|h_2(t)| \leq C_5\|(1+|x|)^{-1}Sg(|x|/t)Q_0\chi_0(\mathbf{E}(t),\mathbf{H}(t))\|_{H^1}\|(1+|x|)\mathcal{C}_0(\mathbf{E}(t),\mathbf{H}(t))\|_{L^{q_0}}$$

$$\leq C_6\|(\mathbf{E}(t),\mathbf{H}(t))\|_{L^2(B_{R_0})}$$

and hence by Corollary 4.8

$$t^{-1}\int_0^t |h_2(s)|ds \overset{t\to\infty}{\longrightarrow} 0. \tag{4.53}$$

Since $g'(|x|/t) = 0$ and $g(|x|/t) = 1$ if $|x| \leq at$ with some $a > 1$, Lemma 4.10(iii) yields

$$t^{-1}\int_0^t |h_3(s)|ds \leq C_7 t^{-1}\int_0^t \|Q_0\chi_0(\mathbf{E}(s),\mathbf{H}(s))\|_{L^2(\{|x|\geq as\})}ds \overset{t\to\infty}{\longrightarrow} 0. \tag{4.54}$$

Now, it follows from (4.49)–(4.54) and Lemma 4.10 that

$$\lim_{t\to\infty} t^{-1}F(t) = \lim_{t\to\infty} t^{-1}\int_1^t F'(s)ds$$

$$= \lim_{t\to\infty} t^{-1}\int_1^t \|Q_0\chi_0(\mathbf{E}(s),\mathbf{H}(s))\|^2_{L^2(\mathbb{R}^3)}ds = \mathcal{E}_\infty.$$

This completes the proof. □

Now the main results of this section, (1.7) and (1.9), can be proved.

THEOREM 4.12. *For all $a < 1$ and $b > 1$ one has*

$$\|(\mathbf{E}(t),\mathbf{H}(t))\|_{L^2(\Omega\cap B_{at})} \overset{t\to\infty}{\longrightarrow} 0 \tag{4.55}$$

and

$$\|(\mathbf{E}(t),\mathbf{H}(t)) - t^{-1}S\chi_{\{at\leq|x|\leq bt\}}(\mathbf{E}(t),\mathbf{H}(t))\|_X \overset{t\to\infty}{\longrightarrow} 0.$$

Furthermore

$$\|(1-Q_0)\chi_0(\mathbf{E}(t),\mathbf{H}(t))\|_{L^2(\mathbb{R}^3)} \overset{t\to\infty}{\longrightarrow} 0.$$

Proof. Suppose $\delta > 0$. Choose $g \in C_0^\infty(\mathbb{R},[0,\infty))$ with $g(y) = 1$ on $[0,1+\delta/2]$ and $g(u) = 0$ for all $u > 1+\delta$. Then

$$\|(1-Q_0)\chi_0(\mathbf{E}(t),\mathbf{H}(t))\|^2_{L^2(\mathbb{R}^3)}$$

$$= \|\chi_0(\mathbf{E}(t),\mathbf{H}(t))\|^2_{L^2(\mathbb{R}^3)} - \|Q_0\chi_0(\mathbf{E}(t),\mathbf{H}(t))\|^2_{L^2(\mathbb{R}^3)}$$

$$\leq \|(\mathbf{E}(t),\mathbf{H}(t))\|_X^2 - \|Q_0\chi_0(\mathbf{E}(t),\mathbf{H}(t))\|_{L^2(\mathbb{R}^3)}^2$$

$$\leq \|(\mathbf{E}(t),\mathbf{H}(t))\|_X^2 - (1+\delta)^{-1}t^{-1}$$

$$\langle Sg(|x|/t)Q_0\chi_0(\mathbf{E}(t),\mathbf{H}(t)), Q_0\chi_0(\mathbf{E}(t),\mathbf{H}(t))\rangle_{L^2(\mathbb{R}^3)}.$$

Theorem 4.11 yields

$$\limsup_{t\to\infty} \|(1-Q_0)\chi_0(\mathbf{E}(t),\mathbf{H}(t))\|_{L^2(\mathbb{R}^3)}^2 \leq \left(1-(1+\delta)^{-1}\right)\mathcal{E}_\infty,$$

since $\limsup_{t\to\infty} \|(\mathbf{E}(t),\mathbf{H}(t))\|_X^2 \leq \mathcal{E}_\infty$ by (2.23). By letting $\delta \to 0$ this implies

$$\lim_{t\to\infty} \|(1-Q_0)\chi_0(\mathbf{E}(t),\mathbf{H}(t))\|_{L^2(\mathbb{R}^3)}^2 = 0. \tag{4.56}$$

This improves assertion (i) of Lemma 4.10. Next, one obtains from Theorem 4.2, the boundedness of supp $(1-\chi_0)$, Lemma 2.2(i), (4.56), and Theorem 4.11 that for all $\beta > 1$

$$\lim_{t\to\infty} t^{-1}\langle S\chi_{\{|x|\leq\beta t\}}(\mathbf{E}(t),\mathbf{H}(t)), (\mathbf{E}(t),\mathbf{H}(t))\rangle_X \tag{4.57}$$

$$= \lim_{t\to\infty} t^{-1}\langle Sg(|x|/t)(\mathbf{E}(t),\mathbf{H}(t)), (\mathbf{E}(t),\mathbf{H}(t))\rangle_X$$

$$= \lim_{t\to\infty} t^{-1}\langle Sg(|x|/t)\chi_0(\mathbf{E}(t),\mathbf{H}(t)), \chi_0(\mathbf{E}(t),\mathbf{H}(t))\rangle_{L^2(\mathbb{R}^3)}$$

$$= \lim_{t\to\infty} t^{-1}\langle Sg(|x|/t)Q_0\chi_0(\mathbf{E}(t),\mathbf{H}(t)), Q_0\chi_0(\mathbf{E}(t),\mathbf{H}(t))\rangle_{L^2(\mathbb{R}^3)} = \mathcal{E}_\infty.$$

Here a function $g \in C_0^\infty(\mathbb{R},[0,\infty))$ with the properties $g(y) = 1$ on $[0,\beta]$ and $g(u) = 0$ for all $u > 2\beta$ is chosen.

Let $\beta > 1$. Then one obtains from (4.57)

$$\int_{\Omega\cap B_{at}} |(\mathbf{E}(t),\mathbf{H}(t))|^2 dx \leq \int_{\Omega\cap B_{\beta t}} |(\mathbf{E}(t),\mathbf{H}(t))|^2 dx$$

$$-\beta^{-1}t^{-1}\int_{\{at\leq|x|\leq\beta t\}} |x| \quad |(\mathbf{E}(t),\mathbf{H}(t))|^2 dx$$

$$\leq \|(\mathbf{E}(t),\mathbf{H}(t))\|_X^2 - \beta^{-1}t^{-1}\int_{\Omega\cap B_{\beta t}} |x| \quad |(\mathbf{E}(t),\mathbf{H}(t))|^2 dx$$

$$+\beta^{-1}a\int_{\Omega\cap B_{at}} |(\mathbf{E}(t),\mathbf{H}(t))|^2 dx$$

$$\leq \|(\mathbf{E}(t),\mathbf{H}(t))\|_X^2 - \beta^{-1}t^{-1}\langle S\chi_{\{|x|\leq\beta t\}}(\mathbf{E}(t),\mathbf{H}(t)), (\mathbf{E}(t),\mathbf{H}(t))\rangle_X$$

$$+a\int_{\Omega\cap B_{at}}|(\mathbf{E}(t),\mathbf{H}(t))|^2dx.$$

Hence

$$(1-a)\int_{\Omega\cap B_{at}}|(\mathbf{E}(t),\mathbf{H}(t))|^2dx\le\|(\mathbf{E}(t),\mathbf{H}(t))\|_X^2$$

$$-\beta^{-1}t^{-1}\langle S\chi_{\{|x|\le\beta t\}}(\mathbf{E}(t),\mathbf{H}(t)),(\mathbf{E}(t),\mathbf{H}(t))\rangle_X.$$

Invoking (4.57) one gets

$$(1-a)\limsup_{t\to\infty}\int_{\Omega\cap B_{at}}|(\mathbf{E}(t),\mathbf{H}(t))|^2dx\le(1-\beta^{-1})\mathcal{E}_\infty\text{ for all }\beta>1.$$

By letting $\beta\to1$ this impliess

$$\|(\mathbf{E}(t),\mathbf{H}(t))\|_{L^2(\Omega\cap B_{at})}\overset{t\to\infty}{\longrightarrow}0. \tag{4.58}$$

This completes the proof of the first assertion (4.55).

Suppose $\beta>1$. Then it follows from Theorem 4.2 that

$$\limsup_{t\to\infty}t^{-1}\|S\chi_{\{|x|\le bt\}}(\mathbf{E}(t),\mathbf{H}(t))\|_X\le\limsup_{t\to\infty}t^{-1}\|S\chi_{\{|x|\le\beta t\}}(\mathbf{E}(t),\mathbf{H}(t))\|_X$$

$$\le\beta\limsup_{t\to\infty}\|(\mathbf{E}(t),\mathbf{H}(t))\|_X\le\beta\mathcal{E}_\infty^{1/2}.$$

Letting $\beta\to1$ this yields

$$\limsup_{t\to\infty}t^{-1}\|S\chi_{\{|x|\le bt\}}(\mathbf{E}(t),\mathbf{H}(t))\|_X\le\mathcal{E}_\infty^{1/2}.$$

By (4.57) one obtains

$$\limsup_{t\to\infty}\|t^{-1}S\chi_{\{|x|\le bt\}}(\mathbf{E}(t),\mathbf{H}(t))-(\mathbf{E}(t),\mathbf{H}(t))\|_X^2$$

$$=\limsup_{t\to\infty}\big(t^{-2}\|S\chi_{\{|x|\le bt\}}(\mathbf{E}(t),\mathbf{H}(t))\|_X^2$$

$$-2t^{-1}\left\langle S\chi_{\{|x|\le bt\}}(\mathbf{E}(t),\mathbf{H}(t)),(\mathbf{E}(t),\mathbf{H}(t))\right\rangle_X+\|(\mathbf{E}(t),\mathbf{H}(t))\|_X^2)\le0,$$

which completes the proof. □

REMARK 2. *The above theorem does not provide any information on the asymptotic behavior of* $\mathbf{P}$. *But if the potential is quadratically coercive in the sense that*

$$\mathbf{p}(\nabla_PV)(x,\mathbf{p})\ge a_0|\mathbf{p}|^2\text{ for all }\mathbf{p}\in\mathbb{R}^3$$

with some $a_0>0$, *it follows easily from a similar estimate as* (2.17) *that*

$$\|\mathbf{P}(t)\|_{L^2(G\cap B_R)}\overset{t\to\infty}{\longrightarrow}0\text{ for all }R>0 \tag{4.59}$$

provided that $\mathbf{E}$ *satisfies*

$$\|\mathbf{E}(t)\|_{L^2(\Omega\cap B_R)} \overset{t\to\infty}{\longrightarrow} 0 \text{ for all } R>0. \tag{4.60}$$

In particular, (4.59) *holds if condition* (1.8) *is fulfilled by Theorem* 4.12. *Furthermore, it turns out that condition* (1.8) *is also necessary for the local decay of the electromagnetic field in this case. This can be seen as follows. If* $\|(\mathbf{E}(t),\mathbf{H}(t))\|_{L^2(\Omega\cap B_R)} \overset{t\to\infty}{\longrightarrow} 0$ *for all* $R>0$, *then also* (4.59) *holds and therefore*

$$(\mathbf{E}(t),\mathbf{H}(t)) \overset{t\to\infty}{\longrightarrow} 0 \text{ in } X \text{ weakly} \tag{4.61}$$

and

$$\mathbf{P}(t) \overset{t\to\infty}{\longrightarrow} 0 \text{ in } L^2(G) \text{ weakly.} \tag{4.62}$$

Hence one obtains from (4.1), (4.61), *and* (4.62) *by letting* $t\to\infty$ *that*

$$(1-Q)(\mathbf{D}_1,\mathbf{H}_0) = (1-Q)\left((\mathbf{E}_0,\mathbf{H}_0)+\mathcal{R}\mathbf{P}(0)-\int_0^\infty(\mathbf{j}(s),0)ds\right)$$

$$= w-\lim_{t\to\infty}(1-Q)\left((\mathbf{E}(t),\mathbf{H}(t))+\mathcal{R}\mathbf{P}(t)\right)=0,$$

whence (1.8).

Invoking a result in [9] concerning the linear inhomogeneous Maxwell equations without polarization it can be shown that the solution $(\mathbf{E},\mathbf{H})$ of (1.1)–(1.5) is asymptotically free in the sense that there exists a uniquely determined pair of functions $(\mathbf{F}_0,\mathbf{G}_0)\in L^2(\mathbb{R}^3)$ with $\operatorname{div}\mathbf{F}_0 = \operatorname{div}\mathbf{G}_0 = 0$ such that

$$\|(\mathbf{E}(t),\mathbf{H}(t))-(\mathbf{F}(t),\mathbf{G}(t))\|_{L^2(\Omega)} \overset{t\to\infty}{\longrightarrow} 0. \tag{4.63}$$

Here $(\mathbf{F},\mathbf{G})\in C(\mathbb{R},L^2(\mathbb{R}^3,\mathbb{C}^6))$ denotes the solution to Maxwell's equations in the whole space, that is

$$\partial_t\mathbf{F} = \operatorname{curl}\mathbf{G},\quad \partial_t\mathbf{G} = -\operatorname{curl}\mathbf{F}, \tag{4.64}$$

supplemented by the initial-condition

$$\mathbf{F}(0,x)=\mathbf{F}_0(x),\mathbf{G}(0,x)=\mathbf{G}_0(x). \tag{4.65}$$

This means that the solution to (1.1)–(1.4) behaves asymptotically like a free space solution to (4.64), (4.65) as $t\to\infty$. In what follows suppose that in addition

$$(1+|x|)^{1+\alpha_0}\gamma^{1/2}\in L^{r_1}(G) \tag{4.66}$$

for some $\alpha_0>0$ and $r_1\in(3,\infty)$. This condition is obviously fulfilled in the case where the set G is bounded.

THEOREM 4.13. *The strong limit*

$$\mathbf{U}\overset{\text{def}}{=}\lim_{t\to\infty}\exp(-tB_0)J^*(\mathbf{E}(t),\mathbf{H}(t))$$

exists in $L^2(\mathbb{R}^3)$ *and* $\mathbf{U}\in(\ker B_0)^\perp$. *Here* $J^*:L^2(\Omega)\to L^2(\mathbb{R}^3)$ *provides the extension by zero on* $\mathbb{R}^3\setminus\Omega$.

Proof. It follows from Theorem 4.12 that for all $a < 1 < b$

$$\lim_{t\to\infty} \|t^{-1} S\chi_{\{at\le|x|\le bt\}} Q_0\chi_0(\mathbf{E}(t),\mathbf{H}(t)) - J^*(\mathbf{E}(t),\mathbf{H}(t))\|_{L^2} = 0. \tag{4.67}$$

Let g be defined as in [9, Theorem 8] by $g(t,u) \stackrel{\text{def}}{=} c_\alpha t^{-1-\alpha} u^\alpha$ for $u \le (1+\alpha)^{-1}\alpha t$ and $g(t,u) \stackrel{\text{def}}{=} u^{-1}$ for $u \ge (1+\alpha)^{-1}\alpha t$. Here $\alpha \stackrel{\text{def}}{=} \alpha_0/2 > 0$ with α_0 as in assumption (4.66) and $c_\alpha \stackrel{\text{def}}{=} (1+\alpha^{-1})^{1+\alpha}$.

Since $g(t,t) = t^{-1}$, it follows easily from (4.67), Theorem 4.2, and Theorem 4.12 that

$$\lim_{t\to\infty} \|Sg(t,|x|) Q_0\chi_0(\mathbf{E}(t),\mathbf{H}(t)) - J^*(\mathbf{E}(t),\mathbf{H}(t))\|_{L^2} = 0. \tag{4.68}$$

Next Theorem 4.12 yields further $\lim_{t\to\infty} \|(1-Q_0)J^*(\mathbf{E}(t),\mathbf{H}(t))\|_{L^2} = 0$, and hence by (4.68)

$$\lim_{t\to\infty} \|L(t)\chi_0(\mathbf{E}(t),\mathbf{H}(t)) - J^*(\mathbf{E}(t),\mathbf{H}(t))\|_{L^2} = 0, \tag{4.69}$$

where $L(t) \stackrel{\text{def}}{=} Q_0 Sg(t,|x|)Q_0 \in B(L^2,L^2)$ with g defined as above.

The following result concerning the inhomogeneous linear Maxwell equations can be found in [9, Theorem 8].

THEOREM 4.14. *Suppose that* $\mathbf{u} \in L^\infty((0,\infty),D(B)) \cap C([0,\infty),X)$ *solves* $\partial_t\mathbf{u} = B\mathbf{u} + \mathbf{f}$, *where* $\mathbf{f} \in L^1_{loc}([0,\infty),X)$ *obeys* $(1+|x|)^{1+\alpha_0}\mathbf{f} \in L^1((0,\infty),L^{q_1}(\Omega)) + L^\infty((0,\infty),L^{q_1}(\Omega))$.

Then the strong limit

$$\lim_{t\to\infty} \exp(-tB_0)L(t)\chi_0\mathbf{u}(t)$$

with respect to the $L^2(\mathbb{R}^3)$*-topology exists.*

Here $q_1 \in [6/5,2)$ is defined by $1/q_1 = 1/2 + 1/r_1$, where $\alpha_0 > 0$ and $r_1 \in [3,\infty)$ are as in assumption (4.66).

In order to apply Theorem 4.14, let $\mathbf{u}(t) \stackrel{\text{def}}{=} (\mathbf{E}(t),\mathbf{H}(t))$ and $\mathbf{f}(t) \stackrel{\text{def}}{=} \partial_t\mathcal{R}\mathbf{P}(t) + (\mathbf{j}(t),0)$. With the assumptions (4.66), (4.10), and Lemma 2.2 one has $(1+|x|)^{1+\alpha_0}\mathbf{f} \in L^\infty((0,\infty),L^{q_1}(\Omega))$. Hence $\mathbf{u}$ satisfies the conditions of Theorem 4.14, which implies the existence of the limit

$$\lim_{t\to\infty} \exp(-tB_0)L(t)\chi_0(\mathbf{E}(t),\mathbf{H}(t)). \tag{4.70}$$

By (4.69) one obtains the existence of the limit

$$\mathbf{U} \stackrel{\text{def}}{=} \lim_{t\to\infty} \exp(-tB_0)J^*(\mathbf{E}(t),\mathbf{H}(t)) \text{ in } L^2(\mathbb{R}^3). \tag{4.71}$$

Since ran $L(t) \subset$ ran Q_0, it follows from (4.69) and (4.71) that $\mathbf{U} \in \overline{\text{ran } B_0} = (\ker B_0)^\perp$, i.e., div $(\underline{\mathbf{U}}_j) = 0$ on $\mathbb{R}^3$. Now, it follows easily that $(\mathbf{F},\mathbf{G}) \stackrel{\text{def}}{=} \exp(tB_0)\mathbf{U}$ satisfies (4.63). ∎

Acknowledgments. The author thanks the anonymous referees for reading the manuscript carefully and for their comments, which were helpful in improving the presentation of the results.

ON A SINGULAR NONLINEAR DIRICHLET PROBLEM WITH A CONVECTION TERM*

ZHIJUN ZHANG† AND JIANNING YU‡

Abstract. We consider a singular nonlinear Dirichlet problem with a convection term. The approach is based on existence regularity theory and a subsolution-supersolution method. Nonexistence and regularity results are also given.

Key words. semilinear elliptic equation, singular nonlinearity, Dirichlet problem, positive solution, subsolution-supersolution method

1. Introduction and main results.

Let Ω be a bounded domain in R^N ($2 \leq N$) with $C^{2+\beta}$ boundary $\partial\Omega$ for some $\beta \in (0,1)$. Consider the boundary value problem

$$\begin{cases} -\Delta u = \dfrac{1}{u^\alpha} + \lambda |\nabla u|^p + \sigma, \quad 0 < u \quad \text{in } \Omega, \\ u|_{\partial\Omega} = 0, \end{cases} \tag{1.1}$$

where $0 < \alpha$, $0 < p \leq 2$, $0 \leq \lambda$, and $0 \leq \sigma$. This problem arises in certain problems in fluid mechanics and pseudoplastic flow (see [2, 16]).

As is well known, the model problem

$$\begin{cases} -\Delta u = \dfrac{1}{u^\alpha} + \lambda u^q, \quad 0 < u \quad \text{in } \Omega, \\ u|_{\partial\Omega} = 0, \end{cases} \tag{1.2}$$

was discussed and extended to the cases of more general problems in a number of works; see, for instance, [1, 2, 3, 4, 5, 6, 7, 8, 9, 10]. It is shown that if $0 < q < 1$, then (1.2) has at least one classical solution in $C^{2+\beta}(\Omega) \bigcap C(\overline{\Omega})$ for all $\lambda \geq 0$, and if $q \geq 1$, then there exists $\overline{\lambda} \in (0, \infty)$ such that (1.2) has at least one classical solution for $\lambda \in [0, \overline{\lambda})$, and (1.2) has no classical solution for $\lambda > \overline{\lambda}$. In particular, if $\lambda = 0$, it is shown that (1.2) has a unique classical solution u. Moreover, u has the following properties (see [3, 7]):

$(1)^0$ if $\alpha > 1$, then u is not in $C^1(\overline{\Omega})$;

$(2)^0$ if $\alpha < 3$, then $u \in H_0^1(\Omega)$;

$(3)^0$ if $\alpha \geq 3$, then u is not in $H_0^1(\Omega)$.

It is worth noting that the classical solution of (1.2) with $\lambda = 0$ is not a weak solution for $\alpha \geq 3$. This is very different from that in the case of nonsingular Dirichlet problems; see, for instance, [13, 14, 15, 18].

For the problem (1.1), only partial results are known. In [8], it is shown that (1.1) has just one classical solution for $0 < \alpha$, $0 < p < 1$, $0 \le \lambda$, and $0 \le \sigma$. Other results are not known for the problem (1.1).

In this paper, among other things, we have studied the problem (1.1) for $0 < p \le 2$, $0 \le \lambda$, and $0 \le \sigma$. Our main results are the following.

THEOREM 1.1. *If $p = 2$, then (1.1) has a unique classical solution for $\lambda\sigma < \lambda_1$ and no solution in $H_0^1(\Omega)$ for $\lambda\sigma \ge \lambda_1$, where λ_1 is the first eigenvalue for the Laplacian with Dirichlet boundary condition.*

THEOREM 1.2. *If $0 < p < 2$, then there exists $\overline{\lambda}(p, \sigma) \in (0, \infty]$ such that (1.1) has a unique classical solution for $\lambda \in [0, \overline{\lambda})$ and no classical solution for $\lambda > \overline{\lambda}$. In addition,*

(i) *if $1 < p < 2$ and $0 < \sigma$, then $\overline{\lambda} < \infty$;*

(ii) *if $1 < p < 2$ and $\sigma = 0$ or $0 < p < 1$, then $\overline{\lambda} = \infty$.*

THEOREM 1.3. *The unique classical solution u of (1.1) has the following properties:*

1^0 *if $\alpha > 1$, then u is not in $C^1(\overline{\Omega})$.*

2^0 *if $\alpha < 3$, then $u \in H_0^1(\Omega)$.*

3^0 *if $\alpha \ge 3$ and one of the following conditions is satisfied*

$$(c_1)\ p = 2, \quad (c_2)\ 0 < p < 1, \quad (c_3)\ 1 < p < 2 \text{ and } \sigma = 0,$$

then u is not in $H_0^1(\Omega)$.

Remark 1.4. It is not known, if $p = 1$, whether $\overline{\lambda}$ in Theorem 1.2 is finite or not, and if $1 < p < 2$ and $0 < \sigma$, or $p = 1$, whether u in Theorem 1.3 has the property 3^0 or not.

Remark 1.5. It is obvious that (1.1) has no solution in $C^2(\overline{\Omega})$.

Remark 1.6. The problem (1.1) or (1.2) is significantly different from that problem which has been studied in [11, 12, 20, 21, 22].

The outline of this article is as follows. In section 2 we first make an attempt to develop the famous existence theorem of Amann in [13] into the more general singular boundary value problem and give some preliminary conditions. Then we give the proof of our main results. Our proof is based on the results in [3, 5, 7, 8, 9, 22, 23] and is made possible by the choice of supersolutions and subsolutions.

By a solution of (1.1) we mean, until further notice, a classical solution, i.e., a function belonging to $C^{2+\beta}(\Omega) \bigcap C(\overline{\Omega})$ and satisfying (1.1).

2. Preliminaries. First we give some preliminary considerations and lemmas.

Let ϕ_1 denote a positive eigenfunction corresponding to the first eigenvalue λ_1, and e denote the unique solution of the problem (see [14, 15])

$$\begin{cases} -\Delta u = 1 & \text{in } \Omega, \\ u|_{\partial\Omega} = 0. \end{cases} \tag{2.1}$$

As is well known, $e, \phi_1 \in C^{2+\beta}(\overline{\Omega})$, $0 < e$, $0 < \phi_1$ in Ω, and $\frac{\partial e(x)}{\partial \vec{n}} < 0$, $\frac{\partial \phi_1(x)}{\partial \vec{n}} < 0$ for all $x \in \partial\Omega$, where $\vec{n}$ denotes the outward normal to $\partial\Omega$.

Put

$$|u|_\infty = \max\{|u(x)| \,|\, x \in \overline{\Omega},\ u \in C(\overline{\Omega})\}.$$

We can obtain the following.

LEMMA 2.1. *There exist positive constants C_1 and C_2 such that*

$$C_1\phi_1 \le e \le C_2\phi_1 \qquad \text{on } \overline{\Omega}.$$

LEMMA 2.2. $\int_\Omega [\frac{1}{\phi_1(x)}]^s\,dx < \infty$ *if and only if* $s < 1$.

LEMMA 2.3 (see [7]). *Let ω be the unique solution of the problem*

$$\begin{cases} -\Delta u = \dfrac{1}{u^\alpha}, \quad 0 < u \quad \text{in } \Omega, \\ u|_{\partial\Omega} = 0. \end{cases} \tag{2.2}$$

Then if $\alpha > 1$, there exist positive constants C_3 and C_4 such that

$$C_3\phi_1^{2/(1+\alpha)} \le \omega \le C_4\phi_1^{2/(1+\alpha)} \qquad \text{on } \overline{\Omega}.$$

LEMMA 2.4 (see [17, Theorem 2.1]). *There exists $\lambda^* < \infty$ such that the following problem has a solution neither in $W^{1,1}(\Omega)$ nor in $C(\overline{\Omega})\bigcap C^2(\Omega)$ for $\lambda > \lambda^*$*

$$\begin{cases} -\Delta u = |\nabla u|^p + \lambda \quad \text{in } \Omega, \\ u|_{\partial\Omega} = 0, \end{cases} \tag{2.3}$$

where $1 < p$ and $0 < \lambda$.

Now we consider the more general problem

$$\begin{cases} -\Delta u = g(u) + h(u) + k(\nabla u), \quad 0 < u \quad \text{in } \Omega, \\ u|_{\partial\Omega} = 0, \end{cases} \tag{2.4}$$

where the functions $g(s)$, $h(s)$, and $k(\eta)$ satisfy the following conditions:

(I_1) $h \in C^1([0,\infty), [0,\infty))$;
(I_2) $g \in C^1((0,\infty), [0,\infty))$;
(I_3) $\lim_{s\to 0+} g(s) = \infty$;
(I_4) $g'(s) \le 0\ \forall s > 0$, i.e., g is nonincreasing in $(0,\infty)$;
(I_5) $k \in C^1(R^N, [0,\infty))$;
(I_6) there exists a positive constant C_5 such that

$$k(\eta) \le C_5(1 + |\eta|^2) \qquad \forall \eta \in R^N.$$

DEFINITION 2.5. *A function $\underline{u}$ is called a subsolution of* (2.4) *if $\underline{u} \in C(\overline{\Omega})\bigcap C^2(\Omega)$ and*

$$\begin{cases} -\Delta \underline{u} \le g(\underline{u}) + h(\underline{u}) + k(\nabla \underline{u}), \quad 0 < \underline{u} \quad \text{in } \Omega, \\ \underline{u}|_{\partial\Omega} = 0. \end{cases} \tag{2.5}$$

DEFINITION 2.6. *A function $\overline{u}$ is called a supersolution of* (2.4) *if $\overline{u} \in C(\overline{\Omega})\bigcap C^2(\Omega)$ and*

$$\begin{cases} -\Delta \overline{u} \ge g(\overline{u}) + h(\overline{u}) + k(\nabla \overline{u}), \quad 0 < \overline{u} \quad \text{in } \Omega, \\ \overline{u}|_{\partial\Omega} = 0. \end{cases} \tag{2.6}$$

LEMMA 2.7 (see [3]). *Under the conditions (I_2)–(I_4), the problem*

$$\begin{cases} -\Delta u = g(u + \varepsilon), \quad 0 < u \quad \text{in } \Omega, \\ u|_{\partial\Omega} = 0 \end{cases} \tag{2.7}$$

has a unique solution $\omega_\varepsilon \in C^{2+\beta}(\overline{\Omega})$ *for any sufficiently small positive number* ε. *Moreover, for any* $C^{2+\beta}$*-smooth domain* $\Omega' \subset\subset \Omega$, $\{\omega_\varepsilon\}$ *has a subsequence which converges uniformly in the* $C^2(\overline{\Omega'})$ *norm to the unique solution* $\omega \in C^{2+\beta}(\Omega) \bigcap C(\overline{\Omega})$ *of the following problem:*

$$\begin{cases} -\Delta u = g(u), \quad 0 < u \quad \text{in } \Omega, \\ u|_{\partial\Omega} = 0, \end{cases} \tag{2.8}$$

and $\omega_\varepsilon \le \omega \le \omega_\varepsilon + \varepsilon$ *on* $\overline{\Omega}$.

Obviously, under the conditions (I_2)–(I_6), ω is a subsolution of (2.4).

Basic to our subsequent discussions is the following theorem which is formulated in terms of supersolution and subsolution.

LEMMA 2.8. *If* (2.4) *has a supersolution* $\overline{u}$ *such that* $\omega \le \overline{u}$ *in* Ω, *then* (2.4) *has at least one solution* $u \in C^{2+\beta}(\Omega) \bigcap C(\overline{\Omega})$ *satisfying*

$$\omega \le u \le \overline{u} \qquad \text{on } \overline{\Omega}.$$

Proof. Consider the perturbed problem of (2.4)

$$\begin{cases} -\Delta u = g(u+\varepsilon) + h(u) + k(\nabla u), \quad 0 < u \quad \text{in } \Omega, \\ u|_{\partial\Omega} = 0, \end{cases} \tag{2.9}$$

where ε is a sufficiently small positive number.

Clearly ω_ε is a subsolution of (2.9) and $\overline{u}$ is supersolution of (2.9).

In order to prove the existence of solutions of (2.9), we can easily prove that there exists a function $f_\varepsilon(s,\eta) \in C^1(R \times R^N)$ such that

(I_7) $f_\varepsilon(s,\eta) = g(s+\varepsilon) + h(s) + k(\eta)$ $\forall (s,\eta) \in [0,\infty) \times R^N$,

(I_8) $|f_\varepsilon(s,\eta)| \le C_\varepsilon(|s|)(1+|\eta|^2)$ $\forall (s,\eta) \in R \times R^N$,

where $C_\varepsilon \in C^1([0,\infty), [0,\infty))$ and is a nondecreasing function.

Now we consider the following perturbed problem:

$$\begin{cases} -\Delta u = f_\varepsilon(u, \nabla u), \quad 0 < u \quad \text{in } \Omega, \\ u|_{\partial\Omega} = 0. \end{cases} \tag{2.10}$$

Since $\overline{u} \ge \omega \ge \omega_\varepsilon > 0$ in Ω, we know that ω_ε is also a subsolution of (2.10). It follows by the first theorem of Amann [13] that (2.10) has a maximal solution $u_\varepsilon \in C^{2+\beta}(\overline{\Omega})$ in order interval $[\omega_\varepsilon, \overline{u}]$. Thus u_ε is also a solution of (2.9).

Now we need to estimate $\{u_\varepsilon\}$. For any $C^{2+\beta}$-smooth domain $\Omega' \subset\subset \Omega$, take Ω_i, $i = 1,2,3$, with $C^{2+\beta}$-smooth boundaries such that

$$\Omega' \subset\subset \Omega_1 \subset\subset \Omega_2 \subset\subset \Omega_3 \subset\subset \Omega.$$

Let

$$\overline{f}_\varepsilon(x) = f_\varepsilon(u_\varepsilon(x), \nabla u_\varepsilon(x)), \qquad x \in \overline{\Omega}_3.$$

Since $-\Delta u_\varepsilon = \overline{f}_\varepsilon(x)$ on $\overline{\Omega}_3$, by the interior estimate theorem of Ladyzenskaya and Ural'ceva (see [14, Theorem 3.1, p. 266]), we get a positive constant C_6 independent of ε such that

$$\max_{x \in \overline{\Omega}_2} |\nabla u_\varepsilon(x)| \le C_6 \max_{x \in \overline{\Omega}_3} u_\varepsilon(x) \le C_6 \max_{x \in \overline{\Omega}} \overline{u}(x). \tag{2.11}$$

From (2.11) we see that $|\nabla u_\varepsilon(x)|$ is uniformly bounded on $\overline{\Omega}_2$. It follows that $|\overline{f}_\varepsilon(x)|$ is uniformly bounded on $\overline{\Omega}_2$, and hence $\overline{f}_\varepsilon \in L^p(\Omega_2)$ for any $p > 1$. Since $-\Delta u_\varepsilon = \overline{f}_\varepsilon(x)$, $x \in \Omega_2$, it follows by Theorem 9.11 of [15] that there exists a positive constant C_7 independent of ε such that

$$||u_\varepsilon||_{W^{2,p}(\Omega_1)} \le C_7(||\overline{f}_\varepsilon||_{L^p(\Omega_2)} + ||u_\varepsilon||_{L^p(\Omega_2)}), \tag{2.12}$$

i.e., $||u_\varepsilon||_{W^{2,p}(\Omega_1)}$ is uniformly bounded. Taking $p > N$ such that $\beta < 1 - N/p$ and applying Sobolev's embedding inequality, we see that $||u_\varepsilon||_{C^{1,\beta}(\overline{\Omega}_1)}$ is uniformly bounded. Therefore $\overline{f}_\varepsilon \in C^\beta(\overline{\Omega}_1)$ and $||\overline{f}_\varepsilon||_{C^\beta(\overline{\Omega}_1)}$ is uniformly bounded. By Schauder's interior estimate theorem (see [15, Chapter 1, p. 2]), we see that there exists a positive constant C_8 independent of ε such that

$$||u_\varepsilon||_{C^{2,\beta}(\overline{\Omega'})} \le C_8(||u_\varepsilon||_{C(\overline{\Omega}_1)} + ||\overline{f}_\varepsilon||_{C^\beta(\overline{\Omega}_1)}). \tag{2.13}$$

It follows that $||u_\varepsilon||_{C^{2,\beta}(\overline{\Omega'})}$ is uniformly bounded.

From the above proof, we see that $||u_\varepsilon||_{C^{2,\beta}(\overline{\Omega'})}$ is uniformly bounded for arbitrary $\Omega' \subset\subset \Omega$. Using Ascoli–Arzela's theorem and the diagonal sequential process, we see that $\{u_\varepsilon\}$ has a subsequence that converges uniformly in the $C^2(\overline{\Omega'})$ norm to function $u \in C^2(\Omega)$ and u satisfies the equation of (2.4). From the fact $u_\varepsilon \in [\omega_\varepsilon, \overline{u}]$ and Lemma 2.7, we get $\omega(x) \le u(x) \le \overline{u}(x)$ for any $x \in \Omega$, which implies that $\lim_{x\to\partial\Omega} u(x) = 0$. Let $u|_{\partial\Omega} = 0$; thus, we get a solution $u \in C^2(\Omega)\bigcap C(\overline{\Omega})$. Applying Shauder's interior regularity theorem we see that $u \in C^{2+\beta}(\Omega)\bigcap C(\overline{\Omega})$ and thus, Lemma 2.8 is proved.

3. Proof of theorems.

3.1. Proof of Theorem 1.1. Since $p = 2$, the change of variable $\nu = e^{\lambda u} - 1$ transforms the problem (1.1) into the equivalent one

$$\begin{cases} -\Delta\nu = \dfrac{\lambda^{1+\alpha}}{\ln^{\alpha}(\nu+1)} + \lambda^{1+\alpha}h(\nu) + \lambda\sigma\nu + \lambda\sigma, \quad 0 < \nu \quad \text{in } \Omega, \\ \nu|_{\partial\Omega} = 0, \end{cases} \tag{3.1}$$

where $h(\nu) = \frac{\nu}{\ln^{\alpha}(\nu+1)}$.

If $\lambda\sigma \ge \lambda_1$, we prove that (3.1) has no solution in $H_0^1(\Omega)$, i.e., (1.1) has no solution in $H_0^1(\Omega)$. We assume the contrary; thus (3.1) has one solution in $H_0^1(\Omega)$. Since $-\Delta\nu > \lambda\sigma\nu + \lambda\sigma$ in Ω, we obtain

$$\int_\Omega (-\Delta\nu)\phi_1\,dx \ge \lambda\sigma\int_\Omega \nu\phi_1\,dx + \lambda\sigma\int_\Omega \phi_1. \tag{3.2}$$

Note that

$$\int_\Omega (-\Delta\nu)\phi_1\,dx = \lambda_1\int_\Omega \nu\phi_1\,dx.$$

From (3.2) we deduce that $\lambda\sigma < \lambda_1$. This is a contradiction. Therefore (1.1) has no solution in $H_0^1(\Omega)$ for $\lambda\sigma \ge \lambda_1$.

If $\lambda\sigma < \lambda_1$, we next prove that (3.1) has a unique classical solution. Since the function $g(s) = \frac{\lambda^{1+\alpha}}{\ln^{\alpha}(s+1)}$ satisfies the hypotheses (I_2)–(I_4), it follows from Lemma 2.7 that the singular boundary value problem

$$\begin{cases} -\Delta\nu = \dfrac{\lambda^{1+\alpha}}{\ln^{\alpha}(\nu+1)}, \quad 0 < \nu \quad \text{in } \Omega, \\ \nu|_{\partial\Omega} = 0 \end{cases} \tag{3.3}$$

has a unique solution $\omega_1 \in C(\overline{\Omega}) \bigcap C^{2+\beta}(\Omega)$ which is a subsolution of (3.1).

Now we construct a supersolution. For $0 < \alpha \leq 1$, note that

$$\lim_{s \to 0+} h(s) = \begin{cases} 1, & \alpha = 1, \\ 0, & 0 < \alpha < 1. \end{cases}$$

Then there exists a positive constant C_9 such that

$$\lambda^{1+\alpha} h(s) \leq C_9 + \frac{\lambda_1 - \lambda\sigma}{2} s \qquad \forall s > 0.$$

Then $\overline{\nu}_1 = \omega_1 + \frac{1}{2}(\lambda_1 + \lambda\sigma)\nu_1 + (C_9 + \lambda\sigma)e$ is a supersolution of (3.1) for $0 < \alpha \leq 1$, where e is the solution of (2.1) and ν_1 is the unique solution in $C^{2+\beta}(\overline{\Omega})$ of the problem (see [14, Theorem 3.2, p. 128])

$$\begin{cases} -\Delta u = \dfrac{1}{2}(\lambda_1 + \lambda\alpha)u + |\omega_1|_\infty + (C_9 + \lambda\sigma)|e|_\infty & \text{in } \Omega, \\ u|_{\partial\Omega} = 0. \end{cases} \tag{3.4}$$

From the positive lemma of Keller and Cohen [19, p. 1363], it follows that $0 < \nu_1$ in Ω.

For $\alpha > 1$, we rewrite (3.1) in the following form:

$$\begin{cases} -\Delta \nu = \dfrac{\lambda^{1+\alpha}}{\nu^\alpha} + \dfrac{\lambda^{1+\alpha}}{\ln^\alpha(\nu+1)} + \lambda^{1+\alpha}\overline{h}(\nu) + \lambda\sigma\nu + \lambda\sigma, \quad 0 < \nu \quad \text{in } \Omega, \\ \nu|_{\partial\Omega} = 0, \end{cases} \tag{3.5}$$

where $\overline{h}(\nu) = \frac{\nu}{\ln^\alpha(\nu+1)} - \frac{1}{\nu^\alpha}$.

Since $\alpha > 1$, we have $\lim_{s \to 0+} \overline{h}(s) = -\infty$. Then there exists a positive constant C_{10} such that

$$\lambda^{1+\alpha}\overline{h}(s) \leq C_{10} + \frac{\lambda_1 - \lambda\sigma}{2} s \qquad \forall s > 0. \tag{3.6}$$

Then $\overline{\nu}_2 = \omega_2 + \frac{1}{2}(\lambda_1 + \lambda\sigma)\nu_2 + (C_{10} + \lambda\sigma)e$ is a supersolution of (3.1), where ω_2 is the unique classical solution of the problem (Lemma 2.7)

$$\begin{cases} -\Delta u = \lambda^{1+\alpha}\left(\dfrac{1}{u^\alpha} + \dfrac{1}{\ln^\alpha(u+1)}\right), \quad 0 < u \quad \text{in } \Omega, \\ u|_{\partial\Omega} = 0, \end{cases} \tag{3.7}$$

and ν_2 is the unique solution in $C^{2+\beta}(\overline{\Omega})$ of the problem (see [14, 19])

$$\begin{cases} -\Delta u = \dfrac{1}{2}(\lambda_1 + \lambda\sigma)u + |\omega_2|_\infty + (C_{10} + \lambda\sigma)|e|_\infty, \quad 0 < u \quad \text{in } \Omega, \\ u|_{\partial\Omega} = 0. \end{cases} \tag{3.8}$$

Obviously, $\omega_1 \leq \overline{\nu}_1$, $\omega_1 \leq \omega_2 \leq \overline{\nu}_2$ on $\overline{\Omega}$.

Since

$$h(s) = \frac{\lambda^{1+\alpha} s}{\ln^\alpha(s+1)} \notin C^1([0,\infty),\, [0,\infty)),$$

we consider the perturbed problem of (3.1)

$$\begin{cases} -\Delta\nu = \dfrac{\lambda^{1+\alpha}}{\ln^{\alpha}(\nu+\varepsilon+1)} + \dfrac{\lambda^{1+\alpha}\nu}{\ln^{\alpha}(\nu+\varepsilon+1)} + \lambda\sigma\nu + \lambda\sigma, \quad 0 < \nu \quad \text{in } \Omega, \\ \nu|_{\partial\Omega} = 0. \end{cases} \tag{3.9}$$

By the same proof as in Lemma 2.8, we can obtain that (3.1) has a solution $\nu \in C(\overline{\Omega}) \bigcap C^{2+\beta}(\Omega)$, i.e., (1.1) has at least one solution $u = \frac{1}{\lambda}\ln(\nu+1)$.

Finally we prove that (1.1) has a unique classical solution (in $C(\overline{\Omega}) \bigcap C^{2+\beta}(\Omega)$). We assume on the contrary that (1.1) has two classical solutions u_1 and u_2, and $\{x|\, u_1(x) > u_2(x)\} \neq \emptyset$. Let $w = u_1 - u_2$, then there exists $x_0 \in \Omega$ such that $0 < w(x_0) = \max_{x\in\Omega} w(x)$. By the basic facts (see [15]) $\nabla w(x_0) = 0$, $\Delta w(x_0) \leq 0$. But this is impossible because

$$-\Delta w(x_0) = \frac{1}{u_1^{\alpha}(x_0)} - \frac{1}{u_2^{\alpha}(x_0)} < 0.$$

This contradiction implies that the problem (1.1) has a unique classical solution. The proof is complete. □

3.2. Proof of Theorem 1.2. To apply Lemma 2.8, note that the unique solution ω of the problem (2.2) is a subsolution of (1.1). For an arbitrary positive constant C, since $0 < p < 2$, by the basic facts

$$\frac{s^p}{s^2+C} \leq \frac{p^{p/2}(2-p)^{(2-p)/2}}{2C^{1-p/2}} \qquad \forall s \geq 0$$

and

$$p^{p/2}(2-p)^{(2-p)/2} < 2,$$

we have

$$s^p \leq \frac{s^2}{C^{1-p/2}} + C^{p/2} \qquad \forall s \geq 0. \tag{3.10}$$

Now we consider the problem

$$\begin{cases} -\Delta u = \dfrac{1}{u^{\alpha}} + \lambda C^{p/2-1}|\nabla u|^2 + \lambda C^{p/2} + \sigma, \quad 0 < u \quad \text{in } \Omega, \\ u|_{\partial\Omega} = 0. \end{cases} \tag{3.11}$$

Let

$$\lambda(\lambda C^{p-1} + \sigma C^{p/2-1}) < \lambda_1. \tag{3.12}$$

It follows from Theorem 1.1 that (3.11) has a unique classical solution $\overline{u}$ which is a supersolution of the problem (1.1) for $0 < p < 2$. Moreover, we can easily prove that $\omega \leq \overline{u}$ on $\overline{\Omega}$. From Lemma 2.8, we know that the problem (1.1) has at least one solution. Using the same proof as that in Theorem 1.1, we can obtain that the problem (1.1) has just one classical solution for $0 < p < 2$.

Now we analyze the inequality (3.12). For $0 < p < 1$, given every $\lambda > 0$ and every $\sigma \geq 0$, we can choose C large enough such that (3.12) holds. Thus the problem has a unique classical solution for all $\lambda \geq 0$ and $\sigma \geq 0$, i.e., $\overline{\lambda} = \infty$.

For $p = 1$, if $\lambda^2 < \lambda_1$, then given every $\sigma \geq 0$, we can choose C large enough such that (3.12) holds. For $1 < p < 2$, if $\sigma = 0$, then given every $\lambda > 0$, we can choose C satisfying $C^{p-1} < \lambda_1/\lambda^2$ such that (3.12) holds, and if $\sigma > 0$, let

$$C = \left(\frac{(2-p)\sigma}{2\lambda(p-1)}\right)^{p/2}, \tag{3.13}$$

then we can choose λ sufficiently small enough such that (3.12) holds.

To complete the proof of Theorem 1.2 for $1 \leq p < 2$ and $0 < \sigma$, let

$$A = \{\lambda > 0 | \text{ (1.1) has a unique solution } u_\lambda\}, \qquad \overline{\lambda} = \sup A.$$

By the above proof, we see $A \neq \emptyset$. It suffices to prove that if $\widetilde{\lambda} \in A$, then $(0, \widetilde{\lambda}) \subset A$. Let $u_{\widetilde{\lambda}}$ be a unique solution of (1.1) for $\lambda = \widetilde{\lambda}$. Obviously, $u_{\widetilde{\lambda}}$ is a supersolution of (1.1) for $\lambda < \widetilde{\lambda}$, and ω is a subsolution of (1.1) for $\lambda < \widetilde{\lambda}$. Moreover, we can easily obtain $\omega \leq u_{\widetilde{\lambda}}$ in Ω. By Lemma 2.8, (1.1) has at least one classical solution for $0 < \lambda < \widetilde{\lambda}$. By the proof of Theorem 1.1, (1.1) has a unique classical solution $u_{\widetilde{\lambda}}$ for $0 < \lambda < \widetilde{\lambda}$. By the definition of $\overline{\lambda}$, we know that (1.1) has no classical solution for $\lambda > \overline{\lambda}$. We assert that $\overline{\lambda} < \infty$. In fact, since $1 < p < 2$, $0 < \sigma$ and

$$\begin{cases} -\Delta u > \lambda |\nabla u|^p + \sigma & \text{in } \Omega, \\ u|_{\partial\Omega} = 0. \end{cases} \tag{3.14}$$

Using Lemma 2.4 there exists $\lambda^* < \infty$ such that problem (3.11) has no solution in $C^2(\Omega) \bigcap C(\overline{\Omega})$ for $\sigma\lambda^{\frac{1}{p-1}} > \lambda^*$. It is following that $\overline{\lambda}$ is finite for $1 < p < 2$ and $0 < \sigma$. The proof is complete. □

3.3. Proof of Theorem 1.3. Let u be a classical solution of (1.1). Obviously the unique solution ω of (2.2) is a subsolution of (1.1), $u \geq \omega$ in Ω. By Lemma 2.3, there exists a positive constant C_3 such that if $\alpha > 1$, then $C_3\phi^{2/(1+\alpha)} \leq u$ on Ω.

First we prove 1^0, i.e., if $\alpha > 1$, then u is not in $C^1(\overline{\Omega})$.

This proof is the same as the one in [7, Theorem 2]. For every $x_0 \in \partial\Omega$,

$$\frac{\partial u(x_0)}{\partial \vec{n}} = \lim_{s\to 0+} \frac{u(x_0 + s\vec{n}) - u(x_0)}{s} \leq C_3 \frac{\partial \phi_1(x_0)}{\partial \vec{n}} \left(\frac{1}{\lim_{s\to 0+} \phi_1(x_0 + s\vec{n})}\right)^{\frac{\alpha-1}{\alpha+1}} = -\infty.$$

So u is not in $C^1(\overline{\Omega})$.

Secondly, we prove 2^0, i.e., if $\alpha < 3$, then $u \in H_0^1(\Omega)$. By the proof of Lemma 2.8 and Theorems 1.1 and 1.2, it follows that $\{u_\varepsilon\}$ has a subsequence which we may assume is the sequence itself, which converges uniformly in the $C^2(\overline{\Omega}')$ norm to u for an arbitrary $C^{2+\beta}$-smooth domain $\Omega' \subset\subset \Omega$, where u_ε satisfies

$$\begin{cases} -\Delta u_\varepsilon = \dfrac{1}{(u_\varepsilon + \varepsilon)^\alpha} + \lambda |\nabla u_\varepsilon|^p + \sigma, \quad 0 < u_\varepsilon \quad \text{in } \Omega, \\ u_\varepsilon|_{\partial\Omega} = 0 \end{cases} \tag{3.15}$$

and $u_\varepsilon \in C^{2+\beta}(\overline{\Omega})$. Moreover, it follows by Lemmas 2.3 and 2.7 that $\omega_\varepsilon \leq u_\varepsilon \leq u$ on $\overline{\Omega}$, where ω_ε is the unique solution of the problem

$$\begin{cases} -\Delta u = \dfrac{1}{(u + \varepsilon)^\alpha}, \quad 0 < u \quad \text{in } \Omega, \\ u|_{\partial\Omega} = 0. \end{cases} \tag{3.16}$$

Since

$$\int_\Omega |\nabla u_\varepsilon|^2\,dx \le \int_\Omega \frac{u_\varepsilon}{(u_\varepsilon+\varepsilon)^\alpha}\,dx + \lambda\int_\Omega u_\varepsilon|\nabla u_\varepsilon|^p\,dx + \sigma|\Omega||u|\infty, \tag{3.17}$$

and $u \in C(\overline{\Omega})$, $u|_{\partial\Omega} = 0$, Ω is a bounded domain with $C^{2+\beta}$ boundary, and given $\lambda > 0$ and $\sigma \ge 0$, we know that there exists a neighborhood U of $\partial\Omega$ such that if $\Sigma = U \bigcap \Omega$, then

$$\lambda u_\varepsilon \le \lambda u \le \frac{1}{2} \quad \text{in } \Sigma. \tag{3.18}$$

Furthermore, by Lemma 2.7 we have

$$\omega_\varepsilon + \varepsilon \ge \omega \quad \text{on } \overline{\Omega}. \tag{3.19}$$

Consequently,

$$\int_\Omega \frac{u_\varepsilon}{(u_\varepsilon+\varepsilon)^\alpha}\,dx < \int_\Omega u_\varepsilon^{1-\alpha}\,dx < \int_\Omega u^{1-\alpha}\,dx \quad \text{for } \alpha \in (0,1], \tag{3.20}$$

and for $\alpha \in (1,3)$,

$$\int_\Omega \frac{u_\varepsilon}{(u_\varepsilon+\varepsilon)^\alpha}\,dx < \int_\Omega \frac{1}{(u_\varepsilon+\varepsilon)^{\alpha-1}}\,dx < \int_\Omega \frac{1}{(\omega_\varepsilon+\varepsilon)^{\alpha-1}}\,dx < \int_\Omega \frac{1}{\omega^{\alpha-1}}\,dx. \tag{3.21}$$

So, by Lemmas 2.3 and 2.2, we have

$$\int_\Omega \frac{1}{\omega^{\alpha-1}}\,dx \le \frac{1}{C_3^{\alpha-1}}\int_\Omega \left(\frac{1}{\phi_1}\right)^{\frac{2(\alpha-1)}{1+\alpha}}\,dx < \infty. \tag{3.22}$$

It follows by (3.17)–(3.22) that

$$\int_\Omega |\nabla u_\varepsilon|^2\,dx \text{ is bounded independently of } \varepsilon. \tag{3.23}$$

Thus $u \in H_0^1(\Omega)$.

Finally we prove 3^0. We assume on the contrary that $\alpha \ge 3$, $u \in H_0^1(\Omega)$. It follows by Green's identity that

$$\int_\Omega |\nabla u|^2\,dx = \int_\Omega \frac{1}{u^{\alpha-1}}\,dx + \lambda\int_\Omega u|\nabla u|^p\,dx + \sigma\int_\Omega u\,dx. \tag{3.24}$$

Consequently

$$\int_\Omega \frac{1}{u^{\alpha-1}}\,dx \text{ is bounded.} \tag{3.25}$$

But this is impossible, because under the assumptive conditions of 3^0 we will obtain (in the following proof)

$$u \le C_{11}\phi_1^{2/(1+\alpha)} \quad \text{on } \overline{\Sigma}, \tag{3.26}$$

where $\Sigma \subset \Omega$ is a neighborhood of $\partial\Omega$ and C_{11} is a positive constant and $\alpha > 1$. By the proof of Lemma 2.2 in [7] and (3.26), we obtain

$$\int_\Omega \frac{1}{u^{\alpha-1}}\,dx = \infty \quad \text{for } \alpha \ge 3. \tag{3.27}$$

This contradiction implies that 3^0 is true.

In the remainder of this paper, we prove the inequality (3.26). Let us return to the proof of Theorems 1.1 and 1.2. We have known that (1.1) has just one classical solution for all $\lambda \geq 0$ when the condition (c_2) or (c_3) is satisfied, and the proof of Theorem 1.2 is the same as that of Theorem 1.1 because of (3.10)–(3.12). Thus it suffices to prove (3.26) when $p = 2$ in (1.1) and (3.1). Using $p = 2$ and (3.5)–(3.9), we have known that $\overline{\nu}_2 = \omega_2 + (\lambda\sigma + C_6)e + \frac{1}{2}(\lambda_1 + \lambda\sigma)\nu_2$ is a supersolution of (3.1) for $\alpha > 1$, and

$$u \leq \frac{1}{\lambda}\ln(\overline{\nu}_2 + 1) \leq \frac{1}{\lambda}\overline{\nu}_2 \quad \text{on } \overline{\Omega}. \tag{3.28}$$

Since ν_2 is the unique solution of the problem (3.8), using Hopf's maximum principle (see [15]), we have

$$\frac{\partial \nu_2(x)}{\partial \vec{n}} < 0 \quad \forall\, x \in \partial\Omega. \tag{3.29}$$

Thus we obtain that there exist two positive constants C_{12} and C_{13} such that

$$C_{12}\phi_1 \leq \nu_2 \leq C_{13}\phi_1 \quad \text{on } \overline{\Omega}. \tag{3.30}$$

Now we estimate ω_2. Since ω_2 is the unique solution of the problem (3.7), let

$$\overline{\omega}_2 = M\phi_1^{2/(1+\alpha)},$$

where M is a large positive constant to be chosen. Then we have

$$-\Delta\overline{\omega}_2 = \frac{2M(\alpha-1)|\nabla\phi_1|^2}{(1+\alpha)^2\phi_1^{2\alpha/(1+\alpha)}} + \frac{2\lambda_1 M}{1+\alpha}\phi_1^{2/(1+\alpha)} \quad \text{on } \Omega.$$

We need for the following inequality

$$-\Delta\overline{\omega}_2 \geq \frac{\lambda^{1+\alpha}}{\overline{\omega}_2^{\alpha}} + \frac{\lambda^{1+\alpha}}{\ln^{\alpha}(1+\overline{\omega}_2)} \quad \text{in } \Omega. \tag{3.31}$$

That is

$$M^{1+\alpha}\left(\frac{2(\alpha-1)|\nabla\phi_1|^2}{(1+\alpha)^2} + \frac{2\lambda_1}{1+\alpha}\phi_1^2\right) \geq \lambda^{1+\alpha} + \lambda^{1+\alpha}\left(\frac{M\phi_1^{2/(1+\alpha)}}{\ln(1+M\phi_1^{2/(1+\alpha)})}\right)^{\alpha} \quad \text{in } \Omega. \tag{3.32}$$

Since $\alpha > 1$, $\nabla\phi_1(x) \neq 0$ for all $x \in \partial\Omega$, and the function $h(s) = \frac{s^{\alpha}}{\ln^{\alpha}(1+s)}$ has the properties that $h \in C^1(0,\infty)$ is strictly increasing and $\lim_{s\to 0+} h(s) = 1$. Thus we have

$$\min_{x\in\overline{\Omega}}\left(\frac{2(\alpha-1)}{(1+\alpha)^2}|\nabla\phi_1(x)|^2 + \frac{2\lambda_1}{1+\alpha}\phi_1^2(x)\right) = C_0 > 0,$$

and there exists $C_{14} > 0$ such that

$$h(s) \leq C_{14} + \frac{C_0 s^{\alpha}}{2|\phi_1|_{\infty}^{2/(1+\alpha)}} \quad \forall\, s > 0. \tag{3.33}$$

It follows that

$$h(M\phi_1^{2/(1+\alpha)}) \le h(M|\phi_1|_\infty^{2/(1+\alpha)}) \le C_{14} + \frac{1}{2}C_0 M^\alpha \quad \text{on } \overline{\Omega}.$$

Thus, there exists a M_0 such that for all $M \ge M_0$, $\overline{\omega}_2 = M\phi_1^{2/(1+\alpha)}$ satisfying (3.32), i.e., $\overline{\omega}_2$ is a supersolution of the problem (3.7). We can obtain

$$\omega_2 \le \overline{\omega}_2 = M_0\phi_1^{2/(1+\alpha)} \quad \text{on } \overline{\Omega}. \tag{3.34}$$

By Lemma 2.1 and (3.34), (3.30), we know that there exists a positive constant C_{15} such that

$$\overline{\nu}_2 \le C_{15}(\phi_1^{2/(1+\alpha)} + \phi_1) \quad \text{on } \Omega. \tag{3.35}$$

Since $2/(1+\alpha) < 1$ and $s \le s^{2/(1+\alpha)}$ for all $s \in (0,1)$, then we obtain (3.26). The proof of Theorem 1.3 is complete. □

ALTERNATE EVANS FUNCTIONS AND VISCOUS SHOCK WAVES*

SYLVIE BENZONI-GAVAGE†, DENIS SERRE‡, AND KEVIN ZUMBRUN§

Abstract. The Evans function is known as a helpful tool for locating the spectrum of some variational differential operators. This is of special interest regarding the stability analysis of traveling waves, such as reaction-diffusion waves, solitary waves, viscous shock waves, etc., and has been used in numerous contexts. The first aim of this paper is to present an overview of the various ways to define an Evans function for an abstract differential operator. Not all of these alternatives are new, but we show consistent connections between them. Subsequently, we focus on viscous shock waves, extending the work of Gardner and Zumbrun in several directions. In particular, we (i) show some advantages of alternate Evans functions in practical computations, (ii) carry out a refined analysis in case of neutral stability, and (iii) show how to treat systems of size $n > 2$, thus resolving a problem left open by Gardner and Zumbrun.

Key words. traveling waves, asymptotic stability, viscous conservation laws

1. Introduction.

The Evans function is a tool that extends the notion of characteristic polynomial to infinite-dimensional operators, such as variational differential operators. It was first introduced in a special case by Evans [5, 6, 7, 8]. In its present generality it is due to [1]. Given an operator L, an Evans function D is a function of the frequency λ, which is analytic away from the essential spectrum of L and vanishes only on the point spectrum of L. Though not explicitly evaluable in any but very simple cases, it can nonetheless yield a great deal of information through various topological considerations. It has been successfully applied to the analysis of stability of traveling waves; see, e.g., [14, 1, 20, 2, 15, 12, 17], etc.

In the first part of this paper, we propose various ways to define an Evans function in a rather abstract framework. A special effort is made to clarify the relations between these alternatives. In view of the application to viscous shock waves, we consider a second order differential operator L (attaining exponentially fast some limits $L_\pm$ at $\pm\infty$), but the basic principles can be applied to other kinds of operators. The essential spectrum of L can be localized through standard arguments. In most generality, it should lie to the left of the spectra of $L_\pm$, which can be determined by Fourier transform. An Evans function is aimed at localizing eigenvalues of L away from its essential spectrum, in particular in the right half-plane. The starting point of the construction is well known. It consists in formulating the eigenvalue equations $Lw = \lambda w$ as a (variational) dynamical system, depending on the parameter λ, $W' = \mathbb{A}(x;\lambda)\, W$. In our case, the eigenfunctions w are searched in $H^2(\mathbb{R};\mathbb{C}^n)$, W is valued in $\mathbb{C}^{2n}$, and $\mathbb{A}(x;\lambda)$ is a square matrix of size $2n$. The basic assumption is that the dimensions of the stable and unstable manifolds of the dynamical system are complementary (for a certain range of the parameter λ). In particular, this requires

that the limit matrices $\mathbb{A}_\pm(\lambda)$ do not have a null space. This is true away from the essential spectrum of L. Then by choosing a parametrization of these manifolds, we see that they intersect in a nontrivial way if and only if a certain Wronskian $D(\lambda)$ vanishes. This is the classical way to define an Evans function. It is clear that $\lambda \notin \sigma_{\mathrm{ess}}(L)$ is an eigenvalue of L if and only if $D(\lambda) = 0$. Further refinements show that the order of vanishing of D equals the multiplicity of the eigenvalue (see [1]). An alternative way of defining an Evans function is rather to consider the *adjoint operator* L^*, using the fact that L and L^*, which are real-valued, have the same eigenvalues. This idea yields a "dual" Evans function, which we shall denote by D_*. It will appear to be of simpler use than the classical one, at least for viscous conservation laws. Another approach is of "mixed" type. It consists in characterizing the stable (or the unstable) manifold of $W' = \mathbb{A}(x;\lambda)\, W$ as the orthogonal of the stable (or the unstable) manifold of the *adjoint dynamical system* $Z' = -\mathbb{A}(x;\lambda)^*\, Z$. By choosing a parametrization of these manifolds, we obtain two alternate Evans functions, defined as "Gramian determinants" (instead of a Wronskian), which we shall denote by $D_\pm$ (the subscripts $\pm$ here do not refer to any limit at $\pm\infty$ but only to the way the basis of the manifolds are numbered). By convention of our notations, the size of D_- (respectively, D_+) is the dimension of the stable (respectively, unstable) manifold. It is well suited when this number is small. In our case, this number is equal to n. We shall nevertheless show that the use of such D_- of D_+ simplifies the calculation in some respects. It also makes possible the extension to situations in which the standard construction is not possible, for example, as in the case when the dynamical system is infinite-dimensional. (See the treatment of semidiscrete difference schemes in [3].) It is to be noted that this kind of Evans function generalizes the one used in [20]. It was first introduced by Swinton [23], and was used (in a different) form in [2]. The construction of Swinton, which holds away from branch points of the asymptotic matrices $\mathbb{A}_\pm(\lambda)$, has been related to the classical one in [4]. We attempt here to give a unified presentation, which does not preclude branch points and can be useful in various contexts.

The remaining part of the paper is devoted to viscous shock waves, but some general ideas can be translated to other contexts. Motivating problems concerning viscous shock waves come from gas dynamics, MHD, and also from the numerics of hyperbolic systems of conservation laws. The application of an Evans function method to viscous shock waves was first carried out in [12]. Gardner and Zumbrun used it to determine necessary conditions for stability in 2×2 systems. An important aspect of this analysis, which we shall not discuss much here, was the extension of the analytic framework of [1] to situations, such as occurs for viscous shock waves, in which the essential spectrum of the operator L accumulates at the imaginary axis and hence there is no spectral gap between essential spectrum and the unstable half-plane $\{\mathrm{Re}\,\lambda > 0\}$. This necessitates a refined analysis justifying analytic extension to the boundary, specifically, the "gap lemma" established independently in [12, 17]. A second aspect of the analysis in [12] was the actual calculation of stability conditions, following the model of [14, 20]; it is primarily this aspect that will concern us here. The basic approach is a natural one: observing that $D(0) = 0$, corresponding to a translational eigenvalue at $\lambda = 0$, one determines the sign of $D'(0)$ by appropriate low-frequency analysis. One then determines the sign of $D(\cdot)$ as $\lambda \to +\infty$ along the real axis (note: $D(\lambda)$ can be chosen to be real for real λ by symmetry) by separate, high-frequency analysis and compares the two. This gives a parity for the number of unstable zeros of D/eigenvalues of L; if the parity is odd, one can conclude instability.

We extend the approach of [12] in several directions.[1] First, we carry out the above calculation for the alternate Evans functions D_* and D_+. We point out that these rather specialized computations can be helpful to a reader working in a different field. In particular, they have been helpful with the work of the first author concerning semidiscrete profiles [3]. Along the way, we give a simplified treatment of the high-frequency limit, based on *homotopy* rather than rescaling/invariant sets as in [1, 12]. Next, we consider the case of neutral instability $D'(0) = 0$. We give a formula for $D''(0)$, which has similarities with Kapitula's formulas in [16]. This yields interesting examples of instability despite even parity of unstable roots. Finally, we prove a key linear algebraic result conjectured in [12], allowing the extension from 2×2 to $n \times n$ systems, also carrying out one or two calculations in this general setting (notably, the under-compressive case).

The paper is organized as follows. In section 2, we recall the definition of the standard Evans function D and we introduce the alternate ones, namely, D_* and $D_\pm$. In section 3, we recall the material necessary to the stability analysis of viscous shocks waves by means of these Evans functions. In section 4, we apply the dual Evans function D_* to viscous shock waves. First we present the computation of $D'_*(0)$, which differs significantly from the one of $D'(0)$. Then we use a homotopy method, instead of the rescaling method in [12], to derive the sign of $D_*(\lambda)$ for large real λ. In section 5, we consider the mixed Evans function D_+. We also compute the sign of $D_+(+\infty)$ by a means of a homotopy method. The main novelty lies in the computation of $D'_+(0)$, which uses the relation between the adjoint ODE and the adjoint PDE. This emphasizes the importance of this relation, which has already been used for different purposes in the literature (see [16, 24]). In section 6, we study the transition occurring when $D'(0) = 0$. In section 7, we complete the work of Gardner and Zumbrun [12] for $n \times n$ systems. This extension is important in view of the applications.

2. Definition of various Evans functions.

2.1. The classical Evans function. We consider a second order differential operator

$$Lw = Bw'' + Cw' + Dw,$$

acting on vector fields $w : \mathbb{R} \to \mathbb{R}^n$. The real-valued $n \times n$ matrices B, C, D are assumed to depend smoothly on x. Moreover, they are supposed to have limits $B_\pm$, $C_\pm$, $D_\pm$, at $\pm\infty$, with exponential rate of decay $\alpha > 0$, that is,

$$\begin{aligned} \|B(x) - B_+\| + \|C(x) - C_+\| + \|D(x) - D_+\| &\le k\, e^{-\alpha x}, \quad x > 0, \\ \|B(x) - B_-\| + \|C(x) - C_-\| + \|D(x) - D_-\| &\le k\, e^{\alpha x}, \quad x < 0. \end{aligned}$$

We denote by $L_\pm$ the limit operators

$$L_\pm := B_\pm \frac{d^2}{dx^2} + C_\pm \frac{d}{dx} + D_\pm.$$

We assume that L is uniformly elliptic, that is, there exists a positive number β such that

$$(B(x)v \,|\, v) \ge \beta\, |v|^2 \quad \forall (x, v) \in \mathbb{R} \times \mathbb{R}^n. \tag{2.1}$$

[1] For further extensions, in the multidimensional case, see [25].

We point out that this assumption forces the eigenvalues of $B(x)$ to be of positive real part.

The essential spectrum of L then lies in some left half-plane $\{\operatorname{Re}\lambda < \rho\}$. As a matter of fact, this holds true for $L_\pm$, as we can easily see by Fourier transform, using the estimate (2.1) at $x = \pm\infty$. Furthermore, we can use (2.1) in a rough energy estimate to show that, for $\operatorname{Re}\lambda$ large enough, λ cannot be an eigenvalue of L. Therefore, by a classical argument due to Henry [13], we find that $\sigma_{ess}(L)$ lies on the left of $\sigma(L_+) \cup \sigma(L_-)$, and thus it lies in a left half-plane. In most applications, $\sigma_{ess}(L)$ lies in $\{\operatorname{Re}\lambda < 0\}$, apart from the origin. In this case, stability properties are linked to possible eigenvalues of L of positive real part.

Since $B_\pm$ have eigenvalues of positive real part we find that, for $\operatorname{Re}\lambda \gg 1$, the solutions of $(L-\lambda)w = 0$ decaying to zero at $+\infty$ span an n-dimensional vector space, $\mathcal{E}_+(\lambda)$, as well as the solutions decaying to zero at $-\infty$, $\mathcal{E}_-(\lambda)$. This is still true by a continuity argument for $\operatorname{Re}\lambda > \rho$. Then the Evans function $\lambda \mapsto D(\lambda)$ is defined for $\operatorname{Re}\lambda > \rho$ by two (locally) analytic maps $\lambda \mapsto \mathcal{B}_\pm(\lambda)$, where $\mathcal{B}_\pm(\lambda)$ are bases of $\mathcal{E}_\pm(\lambda)$. Let us denote by $\phi_{j\pm}(\lambda)$ the elements of the bases. These are vector fields, belonging to $\ker(L-\lambda)$. The definition of the Evans function is

$$D(\lambda) := \left| \begin{array}{cccccc} \phi_{1-} & \cdots & \phi_{n-} & \phi_{1+} & \cdots & \phi_{n+} \\ \phi'_{1-} & \cdots & \phi'_{n-} & \phi'_{1+} & \cdots & \phi'_{n+} \end{array} \right|_{x=0}, \tag{2.2}$$

where the primes denote x-derivatives. The function D is locally analytic and vanishes at λ if and only if λ is an ordinary eigenvalue of L, that is, there exists a nontrivial $w \in L^2(\mathbb{R})$ such that $Lw = \lambda w$. Actually, by working in the exterior product $\Lambda^n(\mathbb{C}^{2n})$, it is possible to construct a function that is globally analytic and vanishes at the same points; see [1, 12]. Furthermore, it vanishes at λ with order m if and only if the generalized eigenspace (that is, the union of kernels of $(L-\lambda)^k$ in $L^2(\mathbb{R})$) is of dimension m [11, 10, 24]. Additionally, the spaces $\mathcal{E}_\pm(\lambda)$ are real when λ is real, in the sense that they are stable by complex conjugation. It turns out that their bases may be chosen in such a way that $D(\lambda)$ is real for real λ; see, e.g., [12] for further details.

This definition extends in a straightforward way to the connected component Ω of the point $\rho+1$ (i.e., the rightmost component) in the complement of the essential spectrum, where $L-\lambda : H^2 \to L^2$ is a Fredholm operator with index zero.

It is often useful to extend D to a neighborhood of Ω, especially in the case when $\rho = 0$. Such an extension, when available, does not obey the above definition, but relies instead on the "gap lemma" of Gardner and Zumbrun [12], which was proved simultaneously by Kapitula and Sandstede [17]. To discuss this point, we first rewrite the equation $Lw = \lambda w$ as a first order ODE,

$$W' = \mathbb{A}(x;\lambda)W. \tag{2.3}$$

Then $\mathbb{A}(x;\lambda)$ admits limits as $x \to \pm\infty$, denoted by $\mathbb{A}_\pm(\lambda)$. When $\lambda \in \Omega$, these are hyperbolic matrices, with n-dimensional stable/unstable subspaces denoted by $S_\pm(\lambda)$, $U_\pm(\lambda)$. Introducing

$$\Phi_{j\pm} := \begin{pmatrix} \phi_{j\pm} \\ \phi'_{j\pm} \end{pmatrix}, \quad j = 1, \dots, n,$$

these are solutions of (2.3) such that

$$U_-(\lambda) = \lim_{x\to-\infty} \operatorname{Span}\{\Phi_{1-}(x;\lambda), \dots, \Phi_{n-}(x;\lambda)\}, \tag{2.4}$$

$$S_+(\lambda) = \lim_{x\to+\infty} \operatorname{Span}\{\Phi_{1+}(x;\lambda), \dots, \Phi_{n+}(x;\lambda)\}. \tag{2.5}$$

The gap lemma shows that, whenever the spaces $S_\pm(\lambda)$ and $U_\pm(\lambda)$ have analytic extensions in some neighborhoods $\mathcal{N}_\pm$ of the origin with

$$\mathbb{C}^{2n} = S_\pm(\lambda) \oplus U_\pm(\lambda)$$

(this assumption is called "geometric separation"), the spaces $\mathcal{E}_\pm(\lambda)$ also extend analytically to a neighborhood $\mathcal{N} \subset \mathcal{N}_\pm$, the size of which depends on the decay rate $\alpha > 0$. This allows us to define $D(\lambda)$ by the above determinant (2.2) in $\mathcal{N}$. However, zeros of D in this extra domain may not be eigenvalues of L in the usual sense, since the fields $\phi_{j\pm}$ need not vanish at $\pm\infty$. They are sometimes called "effective eigenvalues" [24].

Once D is properly defined on $[0, +\infty)$, we may apply the procedure described in the introduction to find a parity for the number of unstable eigenvalues of L. It relies on the computation of $D'(0)$ (in case of translational invariance, that is, $D(0) = 0$) and of the limit $D(+\infty)$. These computations were carried out in [12], in the case when L comes from the linearization about a shock wave of a 2×2 system of viscous conservation laws. They are completed for larger systems in section 7 of this paper. We are now going to propose alternative Evans functions, which may simplify some of these computations, as we shall see in the examples of sections 4 and 5.

2.2. The dual Evans function. We consider the adjoint operator L^*, acting on co-vector fields and defined by

$$L^* z = (zB)'' - (zC)' + zD.$$

We shall assume the additional decay estimates

$$\|B''(x)\| + \|C'(x)\| \le k\, e^{-\alpha|x|}, \quad x \in \mathbb{R}.$$

We now use the well-known fact that complex conjugate of eigenvalues of L in Ω are eigenvalues of the adjoint operator L^*. However, since L has real coefficients, its spectrum is invariant by complex conjugation. Therefore, L and L^* share the same eigenvalues in Ω, and the stability properties of L may be studied through the Evans function D_* of L^*, instead of D. These both vanish at the same points, with the same order.

We can especially take advantage of using D_* instead of D when L is *conservative*, that is, when it reads

$$Lw := (Bw' - Aw)'. \tag{2.6}$$

(Here the notations differ slightly from above.) Then the adjoint operator reads

$$L^* z := (z'B)' + z'A. \tag{2.7}$$

Under natural assumptions that we shall specify later, the dual Evans function D_* can be analytically defined in a neighborhood of the origin by

$$D_*(\lambda) := \begin{vmatrix} \chi_{1-}(\lambda) & \chi'_{1-}(\lambda) \\ \vdots & \vdots \\ \chi_{n-}(\lambda) & \chi'_{n-}(\lambda) \\ \chi_{1+}(\lambda) & \chi'_{1+}(\lambda) \\ \vdots & \vdots \\ \chi_{n+}(\lambda) & \chi'_{n+}(\lambda) \end{vmatrix}_{x=0}. \tag{2.8}$$

In particular at $\lambda = 0$, the basis functions $\chi_{j\pm}$ are bounded solutions of $L^*\chi = 0$. The special form (2.7) of L^* shows that some of these functions are just constants!

The assumptions that we need are the following. Again the matrices B, A and their derivatives are assumed to converge exponentially fast at $\pm\infty$. By Fourier transform we find that $\sigma(L_\pm)$ is the set of eigenvalues of all the matrices $-\xi^2 B_\pm - i\xi A_\pm$ as $\xi \in \mathbb{R}$. We assume that the matrices

$$\mathbb{A}_\pm(\lambda) := \begin{pmatrix} 0_n & I_n \\ \lambda B_\pm^{-1} & B_\pm^{-1} A_\pm \end{pmatrix} \tag{2.9}$$

do not admit pure imaginary eigenvalues for $\operatorname{Re}\lambda > 0$. Then $\sigma_{ess}(L)$ lies within the half-space $\operatorname{Re}\lambda \le 0$. This is nothing but requiring the L^2-stability of the operator $\partial_t - L$. A local analysis at the origin shows that this implies that the eigenvalues of $A_\pm$ are real. Assuming that these eigenvalues are simple and nonzero, one obtains the geometric separation (see [12]), which in turn allows us to extend either D or D_* analytically in the vicinity of the origin. At $\lambda = 0$, the basis functions $\phi_{j\pm}$ are bounded solutions of $L\phi = 0$, that is, $B\phi' = A\phi +$ constant. They are not as simple as the (constant) $\chi_{j\pm}$.

Remark 1. The dual function D_* can be related to the classical one, D, through the following procedure. Let us denote by $\mathcal{E}(\lambda)$ and $\mathcal{F}(\lambda)$ the $2n$-dimensional spaces of solutions to $(L-\lambda)v = 0$ and $(L^*-\lambda)z = 0$, respectively. Then for all $v \in \mathcal{E}(\lambda)$ and $z \in \mathcal{F}(\lambda)$, the quantity $zBv' - z'Bv - zAv$ does not depend on x. (We use this fact elsewhere to treat mixed Evans functions; see Lemma 5.1 below.) Hence we have a bilinear form

$$\begin{aligned} \mathcal{E}(\lambda) \times \mathcal{F}(\lambda) &\to \mathbb{C}, \\ (v, z) &\mapsto \langle v, z\rangle := zBv' - z'Bv - zAv, \end{aligned}$$

which is nondegenerate. The perp map with respect to $\langle\cdot,\cdot\rangle$ thus transforms n-dimensional subspaces of $\mathcal{E}(\lambda)$ into n-dimensional subspaces of $\mathcal{F}(\lambda)$. In particular, $\mathcal{E}_\pm(\lambda)$ are transformed into $\mathcal{F}_\pm(\lambda)$, the subspaces of solutions to $(L^*-\lambda)z = 0$ decaying at $\pm\infty$.

2.3. "Mixed" Evans functions. We here consider the *adjoint ODE*

$$Z' = -\mathbb{A}(x;\lambda)^* \cdot Z, \tag{2.10}$$

where $\mathbb{A}(x;\lambda)^*$ denotes the adjoint operator of $\mathbb{A}(x;\lambda)$, thus acting on co-vectors. By definition we have

$$\mathbb{A}(x;\lambda)^* \cdot Z = Z\,\mathbb{A}(x;\bar\lambda).$$

For $\lambda \in \Omega$, the adjoint matrices $\mathbb{A}_\pm(\lambda)^*$ also have n-dimensional stable/unstable subspaces, which we denote by $S_\pm^*(\lambda)$ and $U_\pm^*(\lambda)$, and we have

$$S_+(\lambda) = U_+^*(\lambda)^\perp, \tag{2.11}$$

$$U_-(\lambda) = S_-^*(\lambda)^\perp. \tag{2.12}$$

We may choose decaying solutions to (2.10), $(\Psi_{j\pm})_{1\le j\le n}$, such that

$$U_+^*(\lambda) = \lim_{x\to+\infty} \operatorname{Span}\{\Psi_{1+}^T(x;\lambda), \dots, \Psi_{n+}^T(x;\lambda)\}, \tag{2.13}$$

$$S_-^*(\lambda) = \lim_{x\to-\infty} \operatorname{Span}\{\Psi_{1-}^T(x;\lambda), \dots, \Psi_{n-}^T(x;\lambda)\}. \tag{2.14}$$

By (2.3) and (2.10), we have that the dot products $(\Psi_i(x;\lambda)\cdot\Phi_j(x;\lambda))$ are *independent of* $\boldsymbol{x}$. Thus we see from (2.5), (2.11), and (2.13) that

$$\text{Span}\{\Phi_{1+}(x;\lambda),\dots,\Phi_{n+}(x;\lambda)\} = \text{Span}\{\Psi_{1+}(x;\lambda),\dots,\Psi_{n+}(x;\lambda)\}^{\perp} \tag{2.15}$$

and from (2.4), (2.12), and (2.14) that

$$\text{Span}\{\Phi_{1-}(x;\lambda),\dots,\Phi_{n-}(x;\lambda)\} = \text{Span}\{\Psi_{1-}(x;\lambda),\dots,\Psi_{n-}(x;\lambda)\}^{\perp}. \tag{2.16}$$

Therefore, we may define alternate Evans functions in Ω by

$$D_+(\lambda) := \det(\Psi_{i+}\cdot\Phi_{j-})_{1\le i,j\le n}, \tag{2.17}$$

$$D_-(\lambda) := \det(\Psi_{i-}\cdot\Phi_{j+})_{1\le i,j\le n}. \tag{2.18}$$

In particular D_- is nothing but the generalization of the Evans function considered by Pego and Weinstein [20] in the case when the stable manifold is 1-dimensional. It is less obvious here that $D_\pm$ are globally analytic, since individual eigenvectors are not smoothly defined in case of crossing eigenvalues. However, the complete stable/unstable manifolds, which may be represented by means of wedge products, vary analytically even where individual eigenvalues may coincide. More precisely, from the standard theory on the Evans function [1, 12], we may choose $\Phi_{j\pm}$ and $\Psi_{i\pm}$, satisfying (2.4), (2.5) and (2.13), (2.14), respectively, such that the wedge products

$$\Phi_{1\pm}\wedge\cdots\wedge\Phi_{n\pm},\quad \Psi_{1\pm}\wedge\cdots\wedge\Psi_{n\pm}$$

define analytic functions from $\Omega\cup\mathcal{N}$ to $P(\Lambda^n(\mathbb{C}^{2n}))$, the manifold of projectivized n-powers of $\mathbb{C}^{2n}$. Therefore, the analytic dependence of $D_\pm$ (up to a scalar nonvanishing function) will follow from the formula (see also Proposition 2.2 below)

$$D_\pm(\lambda) = (\Psi_{1\pm}\wedge\cdots\wedge\Psi_{n\pm})\cdot(\Phi_{1\mp}\wedge\cdots\wedge\Phi_{n\mp}), \tag{2.19}$$

which is a consequence of the following simple algebraic lemma.

LEMMA 2.1. *For all n-tuple of vectors $(W_1,\dots,W_n)$ in $\mathbb{C}^{2n}$ and for all n-tuple of co-vectors $(Z_1,\dots,Z_n)$, we have*

$$\det(Z_i\cdot W_j) = (Z_1\wedge\cdots\wedge Z_n)\cdot(W_1\wedge\cdots\wedge W_n). \tag{2.20}$$

Proof. The proof is immediate since both quantities are $2n$-linear and coincide on the basis of $(\mathbb{C}^{2n*})^n\times(\mathbb{C}^{2n})^n$. ∎

Actually a particular form of (2.19) has already been used by Alexander et al. in [2]. In their simpler forms of (2.17) and (2.18), $D_\pm$ only involve a $n\times n$ determinant instead of a $2n\times 2n$ determinant for the original or dual one. This may simplify the computations, as we shall see below. Moreover, they are likely to generalize to an infinite-dimensional setting. Assume, for example, that the dynamical system (2.3) is infinite-dimensional but that the invariant subspaces $U_\pm(\lambda)$ are finite-dimensional. Then we may define D_+ as in (2.17). This has been used to study the stability of semidiscrete shock profiles (see [3]). Returning to the finite-dimensional framework, the functions $D_\pm$ are closely related to the standard Evans function. More precisely, we have the following result, which generalizes [20, Proposition 1.15].

PROPOSITION 2.2. *There exist analytic functions, $\beta^\pm$, which do not vanish in $\Omega\cup\mathcal{N}$, such that*

$$D(\lambda) = \beta^+(\lambda)D_+(\lambda) = \beta^-(\lambda)D_-(\lambda). \tag{2.21}$$

Proof. We give it only for D_+ since the treatment of D_- is similar. We recall that the standard Evans function is given by

$$D(\lambda) = \det(\Phi_{1-}(0;\lambda), \dots, \Phi_{n-}(0;\lambda), \Phi_{1+}(0;\lambda), \dots, \Phi_{n+}(0;\lambda)). \tag{2.22}$$

There is an analytic choice of solutions $\Phi_{+1}, \dots, \Phi_{+n}$, extending $\{\Phi_{1+}, \dots, \Phi_{n+}\}$, to a basis of solutions to (2.3). Let us define

$$\beta^+(\lambda) := \det(\Phi_{+1}(0;\lambda), \dots, \Phi_{+n}(0;\lambda), \Phi_{1+}(0;\lambda), \dots, \Phi_{n+}(0;\lambda)). \tag{2.23}$$

By construction β^+ does not vanish. There is also a choice of solutions to (2.10), $\Psi_{+1}, \dots, \Psi_{+n}$, such that

$$(\Psi_{1+}, \dots, \Psi_{n+}, \Psi_{+1}, \dots, \Psi_{+n})$$

is a dual basis of

$$(\Phi_{+1}, \dots, \Phi_{+n}, \Phi_{1+}, \dots, \Phi_{n+}),$$

that is to say,

$$\begin{aligned} \Psi_{i+} \cdot \Phi_{j+} = \Psi_{+i} \cdot \Phi_{+j} = 0, \\ \Psi_{+i} \cdot \Phi_{j+} = \Psi_{i+} \cdot \Phi_{+j} = \delta_{ij}. \end{aligned} \tag{2.24}$$

Then the result follows from the definitions (2.17), (2.22), (2.23) and these matrix identities:

$$\begin{pmatrix} \Psi_{1+} \\ \vdots \\ \Psi_{n+} \\ \Psi_{+1} \\ \vdots \\ \Psi_{+n} \end{pmatrix} \begin{pmatrix} \Phi_{+1}, \dots, \Phi_{+n}, \Phi_{1+}, \dots, \Phi_{n+} \end{pmatrix} = I_{2n},$$

which is equivalent to (2.24), and

$$\begin{pmatrix} \Psi_{1+} \\ \vdots \\ \Psi_{n+} \\ \Psi_{+1} \\ \vdots \\ \Psi_{+n} \end{pmatrix} \begin{pmatrix} \Phi_{1-}, \dots, \Phi_{n-}, \Phi_{1+}, \dots, \Phi_{n+} \end{pmatrix} = \begin{pmatrix} \Psi_{i+} \cdot \Phi_{j-} & 0 \\ * & I_n \end{pmatrix}.$$

In particular, we note that the order of vanishing of D and $D_\pm$ at an eigenvalue λ is the same. ∎

3. The framework of viscous shock waves. We now consider a system of viscous conservation laws

$$u_t + f(u)_x = (B(u)u_x)_x, \tag{3.1}$$

and a traveling wave $u(x,t) = U(x-ct)$, tending to asymptotic values $u_\pm$ at $\pm\infty$. Assuming that $B(v)$ is invertible for every $v \in \mathbb{R}^n$, we obtain the ODE satisfied by U,

$$U' = G(U) := B(U)^{-1}(f(U) - f(u_-) - c(U-u_-)), \tag{3.2}$$

as well as the consistency property (Rankine–Hugoniot condition)

$$f(u_+) - f(u_-) = c(u_+ - u_-).$$

Performing a change of variable $(x,t) \mapsto (x-ct,t)$, one may view U as a steady solution of the equation

$$u_t + (f(u) - cu)_y = (B(u)u_y)_y.$$

To study its linear stability, we introduce the linearized equation

$$w_t = Lw := (B(U)w_y + (dB(U)w)U' - (df(U) - cI_n)w)_y. \tag{3.3}$$

The operator L is of the form (2.6) with

$$A(x)\cdot w := (df(U(x)) - cI_n)\cdot w - (dB(U(x))\cdot w)\cdot U'(x), \tag{3.4}$$

and with the abuse of notation

$$B(x) := B(U(x)). \tag{3.5}$$

In particular, A and B have limits at $\pm\infty$, which we shall denote by

$$A_\pm := df(u_\pm) - cI, \quad B_\pm := B(u_\pm).$$

Assuming that the states $u_\pm$ are hyperbolic rest points of G, that is, $dG(u_\pm) = B(u_\pm)^{-1}A_\pm$ do not have pure imaginary eigenvalues, we know that U' converges exponentially fast to zero. Therefore, the linear operator has the same structure as in section 2. We now make standard hypotheses which allow us to apply the gap lemma (see [12]).

(H1) The matrices $A_\pm$ have distinct, nonzero real eigenvalues;
(H2) the eigenvalues of $B(v)$ are of (strictly) positive real part;
(H3) the matrices $B(u_\pm)^{-1}A_\pm$ do not have purely imaginary eigenvalues;
(H4) there exists $\varepsilon > 0$, such that

$$\text{for all } \xi \in \mathbb{R}, \quad \operatorname{Re}\sigma(i\xi A_\pm - \xi^2 B_\pm) \le -\varepsilon\xi^2.$$

Hypothesis (H1) means the strict hyperbolicity of the reduced system

$$u_t + f(u)_x = 0 \tag{3.6}$$

and that the shock wave is noncharacteristic.

The assumption (H4) is known as the Majda–Pego stability condition [19]. It implies that, for $\operatorname{Re}\lambda > 0$, the roots of

$$P^\pm(X;\lambda) := \det(X^2 B_\pm + XA_\pm - \lambda I_n)$$

have a nonzero real part, which is equivalent to the fact that the matrices $\mathbb{A}_\pm(\lambda)$ as defined in (2.9) have no purely imaginary eigenvalues.

Let us point out that (H2)–(H4) are fulfilled whenever

(H5) in the neighborhood of the constant states $u_\pm$, the system of conservation laws (3.1) is consistent with an energy inequality of the form

$$E(u)_t + F(u, u_x)_x + \omega \|u_x\|^2 \leq 0,$$

where $D^2E(u_\pm) > 0_n$ and $\omega > 0$.

Actually, (H5) also implies the hyperbolicity of the reduced system (3.6), though not the strict hyperbolicity.

Remark 2. Most "physical" systems satisfy an energy inequality as stated in (H5) [18, 21].

DEFINITION 3.1. *The viscous shock U is said to be* linearly (spectrally) stable *if* $\sigma(L)$ *lies entirely in the left half-space* $\operatorname{Re}\lambda \leq 0$.

From the above assumptions, this is certainly true regarding the essential part of the spectrum. Therefore, it remains to analyze the possible eigenvalues of positive real part. This is the role of the Evans functions.

We point out that spectral stability is clearly necessary for bounded linearized stability. In fact, the results of [24] give a sufficient condition for linearized (and nonlinear) asymptotic orbital stability in terms of the Evans function, as well, namely, that the only zero on $\{\operatorname{Re}\lambda \geq 0\}$ should lie at $\lambda = 0$, with multiplicity agreeing with the dimension of the manifold of possible viscous profiles; for a complete discussion, see [24].

Regarding $\lambda = 0$, let us note that, by derivation of the profile equation (3.2), one has

$$LU' = 0. \tag{3.7}$$

Since $U' \in L^2$, this means that $\lambda = 0$ is a genuine eigenvalue, and hence

$$D(0) = 0.$$

It has been proved by Zumbrun and Howard [24] that $D_*(0)$ vanishes, too, but we shall give an alternate proof of this fact in section 4.

The strategy of Gardner and Zumbrun in [12] was the following. Pointing out that $D(\lambda)$ is real on $(0, +\infty)$, one may derive an *instability condition* by writing that the sign of D changes between 0^+ and $+\infty$. The sign of D for large real λ comes straightforwardly and involves only the elliptic nature of L, because the first order terms are negligible for high-frequency oscillations; however, it depends on the choice of bases at $\pm\infty$ in the definition of $D(\cdot)$ given in section 2.1. The important contribution of [12], besides the gap lemma, consists in showing that (i) $D'(0)$ may be computed in terms of the hyperbolic structure (see also [25] for a multi-d version of this fact), again up to normalization by choice of bases at $x \to \pm\infty$, and (ii) the choice of bases at $x \to \pm\infty$ made for $\lambda = 0$ can be tracked to $\lambda = +\infty$ to yield a definite sign for $D(\cdot)$; the latter had previously only been carried out in the trivial case of scalar diffusion. Therefore, as soon as $D'(0)$ and $D(\lambda)$ for $\lambda \gg 1$ are of opposite sign, the intermediate value theorem ensures the existence of a positive real eigenvalue for L, which in turn means that U is unstable. We shall show in sections 4 and 5 that a similar approach can be used concerning the alternate Evans functions defined in section 2. A notable limitation in [12] was that (ii) was carried out only for $n = 2$, though the procedure used was conjectured to remain valid in the general case; the resolution of this issue was emphasized as a key open problem in the theory. In section 7, we verify the conjecture of [12], thus completing the theory for $n > 2$.

Let us fix some notations. The eigenvalues of $A_\pm$ are denoted by $a_j^\pm$ $(1 \le j \le n)$. These are distinct nonzero real numbers, that we order by

$$a_1^\pm < \cdots < a_n^\pm.$$

Let us remark that the existence of the viscous shock U implies that $a_1^+ < 0 < a_n^-$. We shall denote by $(r_1^\pm, \dots, r_n^\pm)$ a corresponding basis of right eigenvectors and by $(\ell_1^+, \dots, \ell_n^+)$ a basis of left eigenvectors. We shall feel free to choose their orientations, in particular, according to the profile. By assumption (H3), the eigenvalues $\gamma_j^\pm$ $(1 \le j \le n$, counting with multiplicities) of $B_\pm^{-1}A_\pm$ have a nonzero real part. Furthermore, a continuation argument shows the following (see [12, Lemma 3.8]).

LEMMA 3.2. *Assuming* (H1) *through* (H4)*, the unstable/stable manifolds of* $A_\pm$ *and* $B_\pm^{-1}A_\pm$ *have equal dimensions.*

Therefore, we may assume that $\operatorname{Re}\gamma_j^\pm$ has the same sign as $a_j^\pm$.

Remark 3. Lemma 3.2 does not require the strict hyperbolicity of $A_\pm$. It also holds with (H1) replaced by

(H1′) the matrices $A_\pm$ are invertible and diagonalizable on $\mathbb{R}$.

This will be used in section 7.

4. Viscous shock waves via the dual Evans function. The main purpose of this section is to present a computation of $D_*'(0)$, which differs significantly from the one of $D'(0)$. In addition, we perform the analysis of D_* near $+\infty$ by means of a homotopy argument, which differs from the rescaling method used in [12]. As expected, we shall find the same instability criterion as in [12], since they both tell that the number of positive real eigenvalues of L (respectively, L^*) are odd, and we already know that these numbers are equal to each other.

Let us recall that, when $\operatorname{Re}\lambda > 0$, the assumption (H4) ensures that the roots of

$$P^\pm(X;\lambda) = \det(X^2B_\pm + XA_\pm - \lambda I_n)$$

have a nonzero real part. By a continuity argument, we find that n of them have a positive real part, while the n others have a negative real part. We select those of $P^+(\cdot;\lambda)$ which have a negative real part, and call them $\mu_j^+(\lambda)$ $(j = 1, \dots, n)$; we make the opposite choice for P^-. In short,

$$\det\left((\mu_j^\pm)^2B_\pm + \mu_j^\pm A_\pm - \lambda I_n\right) = 0, \quad \pm\operatorname{Re}\mu_j^\pm < 0.$$

We shall denote by $y_{j\pm}$ a corresponding left "eigenvector" such that

$$y_{j\pm}(\lambda)\left((\mu_j^\pm)^2B_\pm + \mu_j^\pm A_\pm - \lambda I_n\right) = 0.$$

By standard matrix theory, these vectors can be chosen analytically in regions where the $\mu_j^\pm$ do not "cross" each other.

Let us first concentrate on the long wave analysis, that is, the limit $\lambda \to 0^+$. We first describe the behavior of the $\mu_j^\pm$. Clearly, the limits of all the roots of $P^\pm$ are on one hand the eigenvalues of $-A_\pm B_\pm^{-1}$, which provide n roots, counting with multiplicities, and on the other hand $\mu = 0$, with multiplicity n. Actually, the small roots are equivalent to $\lambda/a_j^\pm$. We conclude that

$$\mu_j^+(\lambda) \sim \begin{cases} -\gamma_j^+ & \text{if } a_j^+ > 0, \\ \lambda/a_j^+ & \text{if } a_j^+ < 0. \end{cases}$$

Similarly,

$$\mu_j^-(\lambda) \sim \begin{cases} \lambda/a_j^- & \text{if } a_j^- > 0, \\ -\gamma_j^- & \text{if } a_j^- < 0. \end{cases}$$

As for the operator L, we choose bases of decaying solutions of the ODE $L^*\chi = \lambda\chi$, as $\operatorname{Re}\lambda > 0$. These bases are chosen holomorphically. They consist of n functions denoted by $\{\chi_{1\pm}(x;\lambda), \dots, \chi_{n\pm}(x;\lambda)\}$. These bases are analytically extended to a neighborhood of the origin, but then $\chi_{j\pm}(\lambda)$ need not decay as $x \to \pm\infty$. However, they satisfy

$$\chi_{j\pm}(x;\lambda) \underset{x \to \pm\infty}{\sim} e^{\mu_j^\pm(\lambda)x}\, y_{j\pm}(\lambda), \tag{4.1}$$

when λ is close enough to 0 (see [12, Proposition 3.2]). More precisely, the behavior of the basis functions at $\lambda = 0$ can be summarized as follows.

- When $\pm a_j^\pm > 0$, then
$$\mu_j^\pm(0) = -\gamma_j^\pm$$
and we still have $\pm\operatorname{Re}\mu_j^\pm < 0$. Thus
$$\chi_{j\pm}(\pm\infty;0) = 0,$$
with exponential decay towards the direction
$$y_{j\pm}(0) = k_j^\pm,$$
where $k_j^\pm$ is a left eigenvector of $A_\pm B_\pm^{-1}$ associated to $\gamma_j^\pm$, provided that this matrix is diagonalizable.
- When $\pm a_j^\pm < 0$, then
$$\mu_j^\pm(0) = 0$$
and by a standard bifurcation argument we find that
$$y_{j\pm}(0) = \ell_j^\pm,$$
where $\ell_j^\pm$ is a left eigenvector of $A_\pm$ associated to $a_j^\pm$. Actually, $\chi_{j\pm}$ is then *constant*:
$$\chi_{j\pm}(\cdot;0) \equiv \ell_j^\pm.$$
In particular, (4.1) trivially holds.

We shall also be concerned with the λ-derivatives

$$\theta_{j\pm}(x) := \frac{\partial\chi_{j\pm}}{\partial\lambda}(x;0).$$

These functions satisfy a nonhomogeneous equation $L^*\theta = \chi$. Moreover, when $\pm a_j^\pm > 0$ we should have

$$\theta_{j\pm}(\pm\infty;0) = 0.$$

The dual Evans function is defined by (2.8).

In the remainder of this section, we shall restrict our discussion to 2×2 systems. We investigate the three possible cases: a Lax shock, an under-compressive shock, and an over-compressive shock. In the latter, we have $D'(0) = D(0) = 0$, so that the sign of $D(0^+)$ is determined through $D''(0)$, and similarly for D_*. These cases are characterized according to the signs of the $a_j^\pm$:

- a 1-Lax shock:

$$a_1^+ < 0 < a_1^-, a_2^+, a_2^-;$$

- a 2-Lax shock:

$$a_1^+, a_1^-, a_2^+ < 0 < a_2^-;$$

- an under-compressive shock:

$$a_1^+, a_1^- < 0 < a_2^+, a_2^-;$$

- an over-compressive shock:

$$a_1^+, a_2^+ < 0 < a_1^-, a_2^-.$$

4.1. The Lax shock case. By symmetry we need only to investigate a 2-Lax shock. We have $a_1^\pm, a_2^+ < 0 < a_2^-$ and similarly for the $\gamma_j^\pm$. It follows that, for $\lambda = 0$, we have

$$\chi_{1-}(-\infty) = 0, \quad \chi_{2-} \equiv \ell_2^-, \quad \chi_{1+} \equiv \ell_1^+, \quad \chi_{2+} \equiv \ell_2^+. \tag{4.2}$$

We easily conclude that

$$D_* = \left| \begin{array}{cc} \chi_{1-} & \chi'_{1-} \\ \chi_{2-} & \chi'_{2-} \\ \chi_{1+} & \chi'_{1+} \\ \chi_{2+} & \chi'_{2+} \end{array} \right|_{x=0}$$

vanishes at $\lambda = 0$, since the two last columns of the determinant are linearly dependent, each being of the form $(\cdot, 0, 0, 0)^T$.

We now compute[2] $D'_*(0)$. It is the sum of four determinants, each one obtained from the former by replacing a row (χ, χ') by the corresponding co-vector (θ, θ'). The first one vanishes for the same reason as before, while the three others are block-triangular. For instance,

$$\left| \begin{array}{cc} \chi_{1-} & \chi'_{1-} \\ \theta_{2-} & \theta'_{2-} \\ \chi_{1+} & \chi'_{1+} \\ \chi_{2+} & \chi'_{2+} \end{array} \right| = \left| \begin{array}{cc} \chi_{1-} & \chi'_{1-} \\ \theta_{2-} & \theta'_{2-} \\ \ell_1^+ & 0 \\ \ell_2^+ & 0 \end{array} \right| = (\chi'_{1-} \wedge \theta'_{2-})(\ell_1^+ \wedge \ell_2^+), \tag{4.3}$$

where the wedge products are identified to their component on the canonical 2-form, that is,

$$\chi \wedge \kappa = \left| \begin{array}{c} \chi \\ \kappa \end{array} \right|.$$

Thus we obtain the formula

$$D'_*(0) = (\chi'_{1-} \wedge \theta'_{2-})(\ell_1^+ \wedge \ell_2^+) + (\chi'_{1-} \wedge \theta'_{1+})(\ell_2^+ \wedge \ell_2^-) + (\chi'_{1-} \wedge \theta'_{2+})(\ell_2^- \wedge \ell_1^+), \tag{4.4}$$

[2]We hope that the prime, which sometimes denotes a λ-derivative and elsewhere denotes an x-derivative, will not give rise to confusion.

all terms being taken at $x = 0$.

Now let us give another form of the wedge products $(\chi'_{1-} \wedge X)$. We have the following result.

LEMMA 4.1. *There exists a smooth scalar function c on $\mathbb{R}$ such that, for all co-vector X, for all $x \in \mathbb{R}$*

$$\chi'_{1-}(x) \wedge X = c(x) X B(x) U'(x). \tag{4.5}$$

Moreover, c satisfies the differential equation

$$c' + \operatorname{tr}\left((B' + A)B^{-1}\right)c = 0. \tag{4.6}$$

Proof. Since by (3.7) and decay assumptions the profile U is such that

$$BU'' - A \cdot U' \equiv 0, \tag{4.7}$$

we have, for any solution z to $L^* z = (z'B)' + z'A = 0$, that

$$(z'BU')' \equiv 0.$$

Hence, in particular, $\chi'_{1-} BU'$ is a constant. This constant is zero because χ'_{1-} (as well as U') vanishes at $-\infty$. Since U' does not vanish in $\mathbb{R}$, there must exist a function c such that $\chi'_{1-} \wedge X = cXBU'$. We now differentiate this identity

$$c'XBU' + cX(BU')' = \chi''_{1-} \wedge X.$$

On one hand, we have from (4.7) that

$$(BU')' = (B' + A)U',$$

and on the other hand, we have

$$\begin{aligned} \chi''_{1-} \wedge X &= -\chi'_{1-}(B' + A)B^{-1} \wedge X \\ &= -\operatorname{tr}((B' + A)B^{-1})(\chi'_{1-} \wedge X) + \chi'_{1-} \wedge X(B' + A)B^{-1} \\ &= -\operatorname{tr}((B' + A)B^{-1})(\chi'_{1-} \wedge X) + cX(B' + A)U', \end{aligned}$$

by the definition (4.5). Thus we find that for all X

$$\left(c' + \operatorname{tr}((B' + A)B^{-1})c\right) XBU' = 0.$$

This proves the formula, because U' does not vanish. ∎

Let us put the identity (4.5) into (4.4):

$$\begin{aligned} c(0)^{-1} D'_*(0) = {} & (\theta'_{2-} BU')(\ell_1^+ \wedge \ell_2^+) + (\theta'_{1+} BU')(\ell_2^+ \wedge \ell_2^-) \\ & + (\theta'_{2+} BU')(\ell_2^- \wedge \ell_1^+). \end{aligned} \tag{4.8}$$

Now we compute the terms of the form $\theta' BU'$. Since in all three cases we have $L^* \theta_{j\pm} = \chi_{j\pm} \equiv \ell_j^\pm$, we find using (4.7) that

$$(\theta'_{j\pm} BU')' = \ell_j^\pm U'.$$

This yields $\theta'_{j\pm} BU' = \ell_j^\pm (U - \text{constant})$. The constant is computed by letting $x \to \pm\infty$, since $\theta_{j\pm}$ is at most algebraically growing near $\pm\infty$, whereas U' decays

exponentially to zero on both sides. Therefore, the right-hand side must vanish at $\pm\infty$, which provides

$$\theta'_{j\pm} B U' = \ell_j^{\pm}(U - u_{\pm}).$$

This leads to

$$\begin{aligned} c(0)^{-1} D'_*(0) = {} & \ell_2^-(U-u_-)(\ell_1^+ \wedge \ell_2^+) + \ell_1^+(U-u_+)(\ell_2^+ \wedge \ell_2^-) \\ & + \ell_2^+(U-u_+)(\ell_2^- \wedge \ell_1^+). \end{aligned} \tag{4.9}$$

However, we have for all co-vectors X, Y, Z the identity

$$(X \wedge Y)\, Z + (Z \wedge X)\, Y + (Y \wedge Z)\, X = 0.$$

Therefore, (4.9) simplifies into

$$\begin{aligned} c(0)^{-1} D'_*(0) &= -\ell_2^- u_-(\ell_1^+ \wedge \ell_2^+) - \ell_1^+ u_+(\ell_2^+ \wedge \ell_2^-) - \ell_2^+ u_+(\ell_2^- \wedge \ell_1^+) \\ &= \ell_2^-[u](\ell_1^+ \wedge \ell_2^+). \end{aligned}$$

At this stage, it remains to compute the sign of $c(0)$. Actually, c has a constant sign, so that it is sufficient to evaluate it as $x \to -\infty$. We recall that

$$U'(x) \underset{x \to -\infty}{\sim} e^{\gamma_2^- x}\, s_2^-, \tag{4.10}$$

where $s_j^{\pm}$ is a right eigenvector of $B_{\pm}^{-1} A_{\pm}$ corresponding to the eigenvalue $\gamma_j^{\pm}$. (Let us point out that γ_1^- and γ_2^- cannot be conjugate to each other and thus must be real; they are simple eigenvalues of $A_- B_-^{-1}$ as well as of $B_-^{-1} A_-$.) Similarly,

$$\chi'_{1-}(x) \underset{x \to -\infty}{\sim} e^{-\gamma_1^- x}\, k_1^-, \tag{4.11}$$

where k_j^- is a left eigenvector of $A_- B_-^{-1}$ associated to γ_j^-. We point out that

$$k_j^- A_- s_k^- = k_j^- B_- s_k^- = 0$$

when $j \neq k$, whereas

$$k_j^- B_- s_j^- \neq 0.$$

We obtain from the definition (4.5) and the asymptotic behaviors (4.10) and (4.11) that

$$c(x) \underset{x \to -\infty}{\sim} \frac{(k_1^- \wedge X)}{X B_- s_2^-}\, e^{-\mathrm{tr}(A_- B_-^{-1})x}$$

for every co-vector X not parallel to k_1^-. For instance,

$$c(x) \underset{x \to -\infty}{\sim} \frac{(k_1^- \wedge k_2^-)}{k_2^- B_- s_2^-}\, e^{-\mathrm{tr}(A_- B_-^{-1})x}.$$

Finally,

$$\mathrm{sgn}\ D'_*(0) = \mathrm{sgn}\ (\ell_1^+ \wedge \ell_2^+)(k_1^- \wedge k_2^-)(k_2^- B_- s_2^-)\ \ell_2^-[u]. \tag{4.12}$$

In the above formula, several vectors are known up to a real factor and might be reversed by a new choice of the basis functions $k_1^-, \ell_2^-, \ell_j^+$. We do not worry with the orientation of k_2^-, which occurs twice. Besides, s_2^- may not be reversed, because it is entirely determined by the profile itself. Changes in the four vectors induce a possible change of the sign of the Evans function, which reflects in a change of the signs of $D_*'(0)$ and of $D_*(+\infty)$ simultaneously. Therefore, we have to express the sign of $D_*(+\infty)$ in terms of these vectors in order to know modulo 2 the number of positive real eigenvalues of L^*.

4.2. The sign of $D_*(\lambda)$ for large real λ. We present here a method that differs from the one employed in [12] and which may be simpler. It is versatile and can be used even in the evaluation of the direct Evans function. We first build a *homotopy*, for $\lambda > \Lambda$, between $\lambda \mapsto L^* - \lambda$ and $d^2/dx^2 - \lambda$:

$$L_\theta^* := \theta L^* + (1-\theta)\frac{d^2}{dx^2}, \quad \theta \in [0,1].$$

Here Λ is a real number, large enough to ensure that $L_\theta^* - \lambda$ is invertible for $\lambda > \Lambda$ and $\theta \in [0,1]$. Such a number exists because of the Gårding inequality: there exist two numbers $\omega > 0$ and Λ such that

$$(L^* z | z) + \omega \|z_x\|_{L^2} \le \Lambda \|z\|_{L^2}.$$

As in [12], but adding θ to the parameter λ, we may choose the basis functions $\chi_j^\pm$ depending analytically both on λ and θ. Thus we define a two-parameters Evans function $D_*(\lambda,\theta)$, which is real-valued if λ is real. When $\lambda > \Lambda$ and $\theta \in [0,1]$, D_* does not vanish. Therefore, the sign of $D_*(\lambda) = D_*(\lambda,1)$, for large λ, is the same as the sign of $D_*(\lambda,0)$. The latter may be computed easily. When $\theta = 0$, the eigenfunctions have the form

$$\chi_j^\pm(x;\lambda,0) = e^{\mp x\sqrt{\lambda}}\, V_j^\pm,$$

where $V_j^\pm$ are some real co-vectors. Thus

$$D_*(\lambda,0) = \begin{vmatrix} V_1^- & \sqrt{\lambda}V_1^- \\ V_2^- & \sqrt{\lambda}V_2^- \\ V_1^+ & -\sqrt{\lambda}V_1^+ \\ V_2^+ & -\sqrt{\lambda}V_2^+ \end{vmatrix} = 4\lambda (V_1^- \wedge V_2^-)(V_1^+ \wedge V_2^+).$$

Now it follows from a generalized version of Lemma 3.5 in [12], involving the additional parameter θ, that by continuity

$$\begin{array}{rcl} \operatorname{sgn}\,(V_1^- \wedge V_2^-) & = & \operatorname{sgn}\,(y_1^-(0) \wedge y_2^-(0)), \\ \operatorname{sgn}\,(V_1^+ \wedge V_2^+) & = & \operatorname{sgn}\,(y_1^+(0) \wedge y_2^+(0)). \end{array} \tag{4.13}$$

Since we have

$$y_j^+(0) = \ell_j^+,\ y_2^-(0) = \ell_2^-,$$

and, in view of (4.1) and (4.11),

$$y_1^-(0) = -k_1^-/\gamma_1^-,$$

with $-\gamma_1^- > 0$, (4.13) yield

$$\operatorname{sgn} D_*(\lambda) = \operatorname{sgn} (k_1^- \wedge \ell_2^-)(\ell_1^+ \wedge \ell_2^+) \tag{4.14}$$

for large real λ. Finally, we find that

$$\operatorname{sgn} D_*'(0)\, D_*(+\infty) = \operatorname{sgn} (k_1^- \wedge \ell_2^-)(k_1^- \wedge k_2^-)(k_2^- B_- s_2^-)\, \ell_2^-[u]. \tag{4.15}$$

Let us recall from [12] that the result for the standard Evans function is

$$\operatorname{sgn} D'(0)\, D(+\infty) = \operatorname{sgn} (r_1^- \wedge s_2^-)(r_1^- \wedge [u]). \tag{4.16}$$

It is not difficult to check from (4.15) and (4.16) that

$$\operatorname{sgn} D_*'(0)\, D_*(+\infty) = \operatorname{sgn} D'(0)\, D(+\infty).$$

As a matter of fact, let us assume for simplicity that the ℓ_i and k_i are normalized by

$$\ell_i r_j = \delta_{ij}$$

and

$$k_i B s_j = \delta_{ij}.$$

Then we have

$$\begin{aligned} r_1^- \wedge [u] &= \ell_2^-[u](r_1^- \wedge r_2^-), \\ r_1^- \wedge s_2^- &= \ell_2^- s_2^-(r_1^- \wedge r_2^-). \end{aligned}$$

Moreover, we have

$$\begin{pmatrix} k_1^- \\ k_2^- \end{pmatrix} B_- \begin{pmatrix} s_1^- & s_2^- \end{pmatrix} = I_2,$$

and thus

$$\operatorname{sgn} (k_1^- \wedge k_2^-) = \operatorname{sgn} (s_1^- \wedge s_2^-),$$

since $\det B_- > 0$. Similarly, the identity

$$\begin{pmatrix} k_1^- \\ \ell_2^- \end{pmatrix} A_- \begin{pmatrix} s_1^- & s_2^- \end{pmatrix} = \begin{pmatrix} \gamma_1^- & 0 \\ * & a_2^- \ell_2^- s_2^- \end{pmatrix}$$

implies

$$\operatorname{sgn} (k_1^- \wedge \ell_2^-) = \operatorname{sgn} (s_1^- \wedge s_2^-)\, \ell_2^- s_2^-.$$

4.3. The case of an under-compressive shock. In this paragraph, as well as in the next one, we focus only on the computation of $D_*'(0)$ (or $D_*''(0)$ if needed) once arbitrary choices of the eigenforms $\ell_j^\pm$ are made. The computation of the sign of D_* near infinity follows the same lines as in the Lax shock case. It splits into terms associated to the unstable/stable manifold only. Each term can be followed from large real λ to $\lambda = 0$ in the same way as in [12] (if $n = 2$) or in section 7 below (for general n).

We have here $a_1^\pm < 0 < a_2^\pm$ and similarly for the $\gamma_j^\pm$. It follows that, for $\lambda = 0$, we have

$$\chi_{1-}(-\infty) = 0, \quad \chi_{2-} \equiv \ell_2^-, \quad \chi_{1+} \equiv \ell_1^+, \quad \chi_{2+}(+\infty) = 0. \tag{4.17}$$

From this, we see that $D_*(\lambda = 0)$ is block-triangular, so that

$$D_*(0) = -(\ell_1^+ \wedge \ell_2^-)(\chi_{1-}' \wedge \chi_{2+}').$$

Using Lemma 4.1, which is still valid with our assumptions, we obtain

$$\chi_{1-}' \wedge \chi_{2+}' = c\chi_{2+}' BU'.$$

However, the same argument as the one in the proof of the lemma gives $\chi_{2+}' BU' \equiv 0$. Therefore, D_* vanishes at the origin, as expected, and we need to calculate $D_*'(0)$. Before doing so, we remark that we proved $\chi_{1-}' \wedge \chi_{2+}' = 0$. Since they both solve the same first order ODE $(\xi B)' + \xi A = 0$, this means (by uniqueness for the Cauchy problem) that $\chi_{2+}' = C\chi_{1-}'$, where C is a constant. There is no loss of generality to fix $C = 1$. We assume from now on that $\ell_1^+ \wedge \ell_2^- \neq 0$, so that $\chi_{2+} - \chi_{1-}$, being constant, is a linear combination of χ_{1+} and χ_{2-}.

Again $D_*'(0)$ is the sum of four determinants, each one obtained from $D_*(0)$ by replacing a row (χ, χ') by the corresponding (θ, θ'). Two of them vanish because the last row is a combination of the first three. The two others are block-triangular. Therefore, denoting χ_{1-} by χ, which equals χ_{2+} modulo constants,

$$D_*'(0) = -(\ell_1^+ \wedge \ell_2^-)\left(\chi' \wedge (\theta_{2+}' - \theta_{1-}')\right).$$

Using Lemma 4.1, this reduces to

$$D_*'(0) = -c(\ell_1^+ \wedge \ell_2^-)(\theta_{2+}' - \theta_{1-}')BU',$$

with everything being computed at $x = 0$.

However, $(\theta_{1-}' BU')' = \chi \cdot U'$ and $\theta_{1-}' BU'(-\infty) = 0$ give

$$\theta_{1-}' BU'(0) = \int_{-\infty}^0 \chi \cdot U' dx,$$

and similarly

$$\theta_{2+}' BU'(0) = -\int_0^{+\infty} \chi \cdot U' dx.$$

Finally,

$$D_*'(0) = c(0)(\ell_1^+ \wedge \ell_2^-) \int_{-\infty}^{+\infty} \chi \cdot U' dx. \tag{4.18}$$

Remarks.

- We recognize the Melnikov integral (see (3.18) in [12]) of Gardner and Zumbrun in the second factor of the right-hand side.
- The formula (4.18) shows that the assumption $\ell_1^+ \wedge \ell_2^- \neq 0$ is essential in the analysis, equivalent to assumption $r_1^- \wedge r_2^+ \neq 0$ in [12]. When this condition fails, a different calculation (in similar spirit) must be carried out; see [12].

- The last factor in the right-hand side of (4.18) does not depend on the choice of χ, modulo constants. In other words, one might have chosen $\chi = \chi_{2+}$.
- For larger systems ($n \geq 2$), with assumption $a_p(u_\pm) < 0 < a_{p+1}(u_\pm)$, we obtain the similar formula

$$D'_*(0) = c(\ell_1^+ \wedge \cdots \wedge \ell_p^+ \wedge \ell_{p+1}^- \wedge \cdots \wedge \ell_n^-) \int_{-\infty}^{+\infty} \chi \cdot U' dx,$$

where χ is a nonconstant bounded solution of $L^*\chi = 0$. The vector space of bounded solutions is generically of dimension $n+1$ and contains the constants. Besides, c is a nonvanishing function such that

$$\chi' \wedge \chi'_{2-} \wedge \cdots \wedge \chi'_{n-1,+} \wedge X = cXBU'.$$

As usual, c solves the ODE (4.6). Here, we have assumed, similarly as in the case $n = 2$, that

$$\ell_1^+ \wedge \cdots \wedge \ell_p^+ \wedge \ell_{p+1}^- \wedge \cdots \wedge \ell_n^- \neq 0.$$

4.4. The case of an over-compressive shock. Here $a_{1,2}^+ < 0 < a_{1,2}^-$. It follows that, for $\lambda = 0$, we have $\gamma_j^\pm(0) = 0$, so that $\chi_{j\pm} \equiv \ell_j^\pm$. Therefore, $D_*(0) = D'_*(0) = 0$ come trivially. Now, $\frac{1}{2}D''_*(0)$ is the sum of six determinants, each one obtained from D_* by replacing two rows (χ, χ') by the corresponding (θ, θ'). They all are block-triangular. Therefore, we obtain

$$\begin{aligned}\frac{1}{2}D''_*(0) = {} & (\theta'_{1-} \wedge \theta'_{2-})(\ell_1^+ \wedge \ell_2^+) - (\theta'_{1-} \wedge \theta'_{1+})(\ell_2^- \wedge \ell_2^+) \\ & + (\theta'_{1-} \wedge \theta'_{2+})(\ell_2^- \wedge \ell_1^+) + (\theta'_{2-} \wedge \theta'_{1+})(\ell_1^- \wedge \ell_2^+) \\ & - (\theta'_{2-} \wedge \theta'_{2+})(\ell_1^- \wedge \ell_1^+) + (\theta'_{1+} \wedge \theta'_{2+})(\ell_1^- \wedge \ell_2^-).\end{aligned}$$

Now let us notice that our viscous shock U is one among a one-parameter family $\delta \mapsto u^\delta$, since u_- is a repeller and u_+ is an attractor for the dynamical system (3.2). The operator L, therefore, has a double eigenvalue $\lambda = 0$, corresponding to the eigenfunctions U' and

$$v := \left.\frac{du^\delta}{d\delta}\right|_{\delta=0}.$$

Let us multiply $D''_*(0)$ by the nonzero determinant $Bv \wedge BU'$, using the formula

$$(\alpha \wedge \beta)(X \wedge Y) = (\alpha \cdot X)(\beta \cdot Y) - (\alpha \cdot Y)(\beta \cdot X).$$

We obtain a formula such as

$$\frac{\det B}{2}(v \wedge U')D''_*(0) = \text{a sum of 12 products.}$$

Each such term is a product of the form $\pm(\ell \wedge \ell)(\theta' BU')(\theta' Bv)$, with various indices. Let us have a look at the coefficient of $\theta'_{1-}Bv$, for instance. It appears as

$$\begin{aligned}& (\ell_1^+ \wedge \ell_2^+)(\theta'_{2-}BU') + (\ell_2^+ \wedge \ell_2^-)(\theta'_{1+}BU') + (\ell_2^- \wedge \ell_1^+)(\theta'_{2+}BU') \\ &= (\ell_1^+ \wedge \ell_2^+)\ell_2^- \cdot (U - u_-) + (\ell_2^+ \wedge \ell_2^-)\ell_1^+ \cdot (U - u_+) + (\ell_2^- \wedge \ell_1^+)\ell_2^+ \cdot (U - u_+) \\ &= (\ell_1^+ \wedge \ell_2^+)\ell_2^- \cdot [u].\end{aligned}$$

Finally,

$$\frac{\det B}{2}(v\wedge U')D_*''(0) = \theta_{1-}'Bv(\ell_1^+\wedge\ell_2^+)\ell_2^-\cdot[u] + \theta_{2-}'Bv(\ell_2^+\wedge\ell_1^+)\ell_1^-\cdot[u] + \theta_{1+}'Bv(\ell_2^-\wedge\ell_1^-)\ell_2^+\cdot[u] + \theta_{2+}'Bv(\ell_1^-\wedge\ell_2^-)\ell_1^+\cdot[u],$$

where everything is computed at $x=0$. Now we point out that $(\theta_{j\pm}'Bv)' = \ell_j^\pm\cdot v$, and that $\theta_{j\pm}'$ is bounded by a polynomial near $\pm\infty$ while v decays exponentially fast to zero. This ensures

$$\theta_{j\pm}'Bv(\pm\infty) = 0,$$

so that

$$\theta_{j\pm}'Bv(0) = \ell_j^\pm\cdot m_\pm,\quad m_\pm := \int_{\pm\infty}^0 v(x)dx.$$

Therefore,

$$\begin{aligned}\frac{\det B}{2}(v\wedge U')D_*''(0) &= (\ell_1^+\wedge\ell_2^+)(\ell_1^-\cdot m_-\ell_2^-\cdot[u]-\ell_2^-\cdot m_-\ell_1^-\cdot[u])\\ &\quad-(\ell_1^-\wedge\ell_2^-)(\ell_1^+\cdot m_+\ell_2^+\cdot[u]-\ell_2^+\cdot m_+\ell_1^+\cdot[u])\\ &= (\ell_1^-\wedge\ell_2^-)(\ell_1^+\wedge\ell_2^+)(m\wedge[u]),\end{aligned}$$

where

$$m := m_- - m_+ = \int_{-\infty}^{+\infty} v(x)dx.$$

Thus we have recovered the result of [12] in this case, too. Let us remark that the sign of $D_*''(0)$ is completely determined by those of $v\wedge U'$ (constant sign along the real line) and of $m\wedge[u] = \int v\wedge\int U'$. Let us emphasize that these need not be the same. Examples with distinct signs are given in [9].

5. Viscous shock waves via the mixed Evans function. In this section, we show how to derive a stability condition by means of the mixed Evans functions introduced in section 2.3. Our main purpose is to compute the signs of $D_\pm{}'(0)$ and $D_\pm(+\infty)$ in the Lax shock case. We choose to deal with D_+, the treatment of D_- being symmetric.

5.1. The general *p*-shock case. We recall that under the assumption (H1), the stationary discontinuity (u_-,u_+) is a p-shock for some $p\in\{1,\dots,n\}$, if the following inequalities hold:

$$a_1^1 < \cdots < a_{p-1}^- < 0 < a_p^- < \cdots < a_n^-, \tag{5.1}$$

$$a_1^+ < \cdots < a_p^+ < 0 < a_{p+1}^+ < \cdots < a_n^+. \tag{5.2}$$

Assuming the discontinuity is a p-shock, we want to evaluate $D_+{}'(0)$. From the right-hand inequalities in (5.1), it is not difficult to show that for $\lambda=0$ there are still $n-p+1$ independent solutions of (2.3), say, $\Phi_{p-},\dots,\Phi_{n-}$, decaying exponentially at $-\infty$. On the other hand, from the left-hand inequalities in (5.1), we see that $p-1$

decaying solutions for $\operatorname{Re}\lambda > 0$ bifurcate to asymptotically constant solutions for $\lambda = 0$. More precisely, we may choose $\Phi_{1-}, \dots, \Phi_{p-1-}$ such that

$$\Phi_{j-}(x;0) \underset{x \to -\infty}{\longrightarrow} \begin{pmatrix} r_j^- \\ 0 \end{pmatrix}, \quad j = 1, \dots, p-1.$$

In a similar way, we find from the inequalities in (5.2) that there are p independent solutions of (2.3), say, $\Phi_{1+}, \dots, \Phi_{p+}$, decaying exponentially at $+\infty$, and $n-p$ asymptotically constant solutions

$$\Phi_{j+}(x;0) \underset{x \to +\infty}{\longrightarrow} \begin{pmatrix} r_j^+ \\ 0 \end{pmatrix}, \quad j = p+1, \dots, n.$$

In particular, we may choose in view of (3.7)

$$\Phi_{p-} = \Phi_{p+} = \begin{pmatrix} U' \\ U'' \end{pmatrix} \quad \text{at } \lambda = 0.$$

Now, concerning the adjoint equation, the inequalities (5.2) show that there are $n-p$ independent solutions of (2.10), say, $\Psi_{p+1+}, \dots, \Psi_{n+}$, decaying exponentially at $+\infty$, and p asymptotically constant solutions, $\Psi_{1+}, \dots, \Psi_{p+}$. The point is that we can choose the Ψ_{i+} in a very simple way. This is due to the following classical result (see [24, Lemma 4.4], for instance), which relates the adjoint ODE (2.10) to the adjoint operator L^*.

LEMMA 5.1. *Equation* (2.10) *is equivalent to*

$$Z = (z, z')S, \tag{5.3}$$

$$L^* z = \bar{\lambda} z, \tag{5.4}$$

where S is the (variable coefficients) invertible matrix defined by

$$S = \begin{pmatrix} -A & B \\ -B & 0 \end{pmatrix}. \tag{5.5}$$

We recall from (2.15) that we must have

$$\Psi_{i+} \cdot \Phi_{j+} = 0, \quad i, j \in \{1, \dots, n\}. \tag{5.6}$$

This is trivial for the decaying solutions $\Psi_{p+1+}, \dots, \Psi_{n+}$ since the Φ_{j+} are bounded at $+\infty$. But we have to choose $\Psi_{1+}, \dots, \Psi_{p+}$ in order to satisfy (5.6). This is done in the following proposition.

PROPOSITION 5.2. *We assume the transversality condition*

$$\operatorname{Span}\{\ell_1^+, \dots, \ell_p^+, \ell_p^-, \dots, \ell_n^-\} = \mathbb{R}^n. \tag{5.7}$$

We take p independent co-vectors h_i such that

$$h_p \in \operatorname{Span}\{\ell_1^+, \dots, \ell_p^+\} \cap \operatorname{Span}\{\ell_p^-, \dots, \ell_n^-\}, \tag{5.8}$$

$$h_1, \dots, h_{p-1} \in \operatorname{Span}\{\ell_1^+, \dots, \ell_p^+\}. \tag{5.9}$$

Then the bounded functions

$$\Psi_{i+} := (h_i, 0)S = (-h_i A, h_i B), \quad i \in \{1, \dots, p\}, \tag{5.10}$$

are independent solutions of (2.10) *for* $\lambda = 0$ *which satisfy* (5.6).

Proof. The existence of h_p as in (5.8) follows from the condition (5.7) and the independence of $\ell_1^+, \dots, \ell_p^+$, as well as of the independence of $\ell_p^-, \dots, \ell_n^-$. Since the constants belong to the kernel of L^*, the fact that the Ψ_{i+} as defined in (5.10) are solution to (2.10) for $\lambda = 0$ is a straightforward consequence of Lemma 5.1. Furthermore, we have for all $j \in \{1, \dots, p\}$

$$\Psi_{i+} \cdot \Phi_{j+} = 0,$$

since Φ_{j+} vanishes at $+\infty$, and for all $j \in \{p+1, \dots, n\}$

$$\Psi_{i+} \cdot \Phi_{j+} = -h_i A_+ r_j^+ = -a_j^+ h_i r_j^+ = 0,$$

by evaluating the (constant) dot product at $+\infty$ and using the fact that $h_i \in \mathrm{Span}\{\ell_1^+, \dots, \ell_p^+\}$. ∎

The particular choice of Ψ_{p+} is meant to cancel as many terms as possible in $D_+{}'(0)$. As a matter of fact, it implies that

$$\Psi_{p+} \cdot \Phi_{j-} = 0, \quad j \in \{1, \dots, n\}. \tag{5.11}$$

It is straightforward if $j \in \{p, \dots, n\}$ since the Φ_{j-} vanish at $-\infty$, and if $j \in \{1, \dots, p-1\}$, we have

$$\Psi_{p+} \cdot \Phi_{j-} = -h_p A_- r_j^- = -a_j^- h_p r_j^- = 0,$$

since $h_p \in \mathrm{Span}\{\ell_p^-, \dots, \ell_n^-\}$. Moreover, we recall from the choice of Φ_{p-} that

$$\Psi_{i+} \cdot \Phi_{p-} = 0, \quad i \in \{1, \dots, n\}. \tag{5.12}$$

Consequently, we find using (5.11) and (5.12) and by elementary manipulations that $D_+{}'(0)$ breaks into

$$D_+{}'(0) = \left(\frac{\partial(\Psi_{p+} \cdot \Phi_{p-})}{\partial \lambda} \det(\Psi_{i+} \cdot \Phi_{j-})_{1 \le i,j \le p-1} \det(\Psi_{i+} \cdot \Phi_{j-})_{p+1 \le i,j \le n} \right)_{|\lambda=0}. \tag{5.13}$$

The last determinant in (5.13) cannot be evaluated explicitly since the Ψ_{i+}, $i \in \{p+1, \dots, n\}$, are only known to vanish at $+\infty$, whereas the Φ_{j-}, $j \in \{p+1, \dots, n\}$, are known to vanish at $-\infty$. It is actually the counterpart of the transversality coefficient γ that appears in the derivative of the standard Evans function $D'(0)$ (see (6.1) below). On the other hand, the first two terms in (5.13) are related to the Majda–Liu determinant

$$M = (r_1^- \wedge \cdots \wedge r_{p-1}^- \wedge [u] \wedge r_{p+1}^+ \wedge \cdots \wedge r_n^+).$$

As a matter of fact, from the definition (5.10) of the Ψ_{i+}, we have

$$\begin{aligned} \det(\Psi_{i+} \cdot \Phi_{j-})_{1 \le i,j \le p-1} &= \det(-h_i A_- r_j^-)_{1 \le i,j \le p-1} \\ &= (-a_1^-) \cdots (-a_{p-1}^-) \det(h_i r_j^-)_{1 \le i,j \le p-1}. \end{aligned}$$

It remains to compute $\partial(\Psi_{p+} \cdot \Phi_{p-})/\partial\lambda|_{\lambda=0}$. Since $\partial\Psi_{p+}/\partial\lambda|_{\lambda=0}$ is at most algebraically growing and Φ_{p-} is exponentially decaying at $+\infty$, we have

$$\frac{\partial}{\partial \lambda}(\Psi_{p+} \cdot \Phi_{p-})_{|\lambda=0} = \lim_{+\infty} \left(\Psi_{p+} \cdot \frac{\partial \Phi_{p-}}{\partial \lambda} \right)_{|\lambda=0}.$$

Now by a standard computation (see [12]) we have

$$\frac{\partial \Phi_{p-}}{\partial \lambda}|_{\lambda=0} = \begin{pmatrix} \dfrac{\partial \phi_{p-}}{\partial \lambda}|_{\lambda=0} \\ B^{-1}A\dfrac{\partial \phi_{p-}}{\partial \lambda}|_{\lambda=0} + B^{-1}(U-u_-) \end{pmatrix}.$$

Hence, in view of (5.10) we have

$$\lim_{+\infty}\left(\Psi_{p+}\cdot\frac{\partial \Phi_{p-}}{\partial \lambda}\right)|_{\lambda=0} = h_p\,[u].$$

Finally, we obtain

$$\begin{aligned}&\left(\frac{\partial(\Psi_{p+}\cdot\Phi_{p-})}{\partial\lambda}\ \det(\Psi_{i+}\cdot\Phi_{j-})_{1\le i,j\le p-1}\right)_{|\lambda=0}\\ &\qquad = h_p\,[u]\ (-a_1^-)\cdots(-a_{p-1}^-)\ \det(h_i r_j^-)_{1\le i,j\le p-1}.\end{aligned}$$

This is related to M through the matrix identity

$$\begin{pmatrix} h_1 \\ \vdots \\ h_p \\ \ell_{p+1}^+ \\ \vdots \\ \ell_n^+ \end{pmatrix}\begin{pmatrix} r_1^-,\dots,r_{p-1}^-,[u],r_{p+1}^+,\dots,r_n^+ \end{pmatrix}$$

$$= \begin{pmatrix} h_1r_1^- & \cdots & h_1r_{p-1}^- & h_1[u] & \\ \vdots & \ddots & \vdots & \vdots & 0 \\ h_{p-1}r_1^- & \cdots & h_{p-1}r_{p-1}^- & h_{p-1}[u] & \\ 0 & \cdots & 0 & h_p[u] & \\ & & * & & I_{n-p} \end{pmatrix}.$$

Indeed we have

$$h_p\,[u]\ \det(h_i r_j^-)_{1\le i,j\le p-1} = (h_1\wedge\cdots\wedge h_p\wedge\ell_{p+1}^+\wedge\cdots\wedge\ell_n^+)\ M.$$

5.2. The extreme shock case. From now on, we consider an n-shock, that is, $p=n$. Of course, the case of 1-shock can be treated symmetrically by means of the mixed function D_- instead of D_+. Then the "undetermined determinant" in (5.13) does not appear. In view of Proposition 5.2 with $p=n$, we may choose

$$h_i = \ell_i^-,\quad i\in\{1,\dots,n\}.$$

Consequently, (5.13) reduces to

$$D_+{}'(0) = \ell_n^-\,[u]\ (-a_1^-)\cdots(-a_{n-1}^-),$$

if we normalize the eigenvectors by $\ell_i r_j = \delta_{ij}$. In particular, since the a_j^-, $j\in\{1,\dots,n-1\}$, are negative, we have the very simple result

$$\operatorname{sgn} D_+{}'(0) = \operatorname{sgn}\ \ell_n^-\,[u]. \tag{5.14}$$

Now let us determine the sign of $D_+(\lambda)$ for large real λ. We adapt the homotopy method developed in section 4.2, using the operator

$$L_\theta := \theta L + (1-\theta)\frac{d^2}{dx^2}, \quad \theta \in [0,1].$$

For large real λ and $\theta = 0$, i.e., when the viscosity matrix is the identity, the unstable manifold of

$$W' = \mathbb{A}(x;\lambda,0)W = \begin{pmatrix} 0 & I_n \\ \lambda & 0 \end{pmatrix} W$$

is spanned by

$$\Phi_{j-}(x;\lambda,0) = \begin{pmatrix} e^{x\sqrt{\lambda}}p_j^- \\ \sqrt{\lambda}e^{x\sqrt{\lambda}}p_j^- \end{pmatrix}$$

for some vectors p_j^-. Similarly, the stable manifold of

$$Z' = -Z\mathbb{A}(x;\lambda,0)$$

is spanned by

$$\Psi_{i+}(x;\lambda,0) = \left(\sqrt{\lambda}e^{-x\sqrt{\lambda}}q_i^+, e^{-x\sqrt{\lambda}}q_i^+\right)$$

for some co-vectors q_i^+. This implies that

$$D_+(\lambda,0) = (2\sqrt{\lambda})^n \det(q_i^+\, p_j^-) = (2\sqrt{\lambda})^n (q_1^+ \wedge \cdots \wedge q_n^+)(p_1^- \wedge \cdots \wedge p_n^-).$$

On one hand, we know from Lemma 7.3 in section 7 and a continuity argument that

$$\operatorname{sgn}\,(p_1^- \wedge \cdots \wedge p_n^-) = \operatorname{sgn}\,(r_1^- \wedge \cdots \wedge r_{n-1}^- \wedge s_n^-). \tag{5.15}$$

As a matter of fact, we recall that, for $\theta = 1$ and $\lambda = 0$, the unstable manifold of $\mathbb{A}_-$ is spanned by $(r_j^-, 0)^T$, $j \in \{1,\dots,n-1\}$, and $(s_n^-, \gamma_n^- s_n^-)^T$, where s_n^- is a right eigenvector of $B_-^{-1}A_-$ associated to γ_n^-. On the other hand, we have the following dual version of Lemma 7.2.

LEMMA 5.3. *Assuming* (H1) *and* (H5), *for all* $\theta \in [0,1]$, *for* $\lambda \in [0,+\infty[$, *the projection* $(\zeta, q) \mapsto q$ *is one-to-one from* $U_+^*(\lambda,\theta)$ *to* $\mathbb{R}^n$.

Note that for $\lambda = 0$, this can be viewed as a consequence of Proposition 5.2. Therefore, by Lemma 5.3 and a continuity argument, we have

$$\operatorname{sgn}\,(q_1^+ \wedge \cdots \wedge q_n^+) = \operatorname{sgn}\,(\ell_1^- B \wedge \cdots \wedge \ell_n^- B). \tag{5.16}$$

Since $\det B > 0$, we deduce from (5.15) and (5.16) that

$$\operatorname{sgn}\, D_+(\lambda,0) = \operatorname{sgn}\,(\ell_1^- \wedge \cdots \wedge \ell_n^-)(r_1^- \wedge \cdots \wedge r_{n-1}^- \wedge s_n^-),$$

and thus also by continuity

$$\operatorname{sgn}\, D_+(\lambda) = \operatorname{sgn}\,(\ell_1^- \wedge \cdots \wedge \ell_n^-)(r_1^- \wedge \cdots \wedge r_{n-1}^- \wedge s_n^-) \tag{5.17}$$

for large real λ. Finally, in view of (5.14) and (5.17), we have

$$\operatorname{sgn}\, D'_+(0)\; D_+(+\infty) = \operatorname{sgn}\,(r_1^- \wedge \cdots \wedge r_{n-1}^- \wedge s_n^-)(\ell_1^- \wedge \cdots \wedge \ell_n^-)\; \ell_n^-\,[u].$$

It is easy to check, by using the relations $\ell_i r_j = \delta_{ij}$, that this sign is the same as the standard one (see (4.16) in the case $n = 2$, and (7.7) below in the general case).

6. Cases of neutral instability. In this section, we focus on the case of a Lax shock for which $D'(0)$ vanishes. This is a borderline case, where neighboring shocks may have an odd or an even index.

6.1. An interesting consequence of neutral instability. Let us first recall the mechanism for this "neutral" instability to occur. (We refer to [25] for a multidimensional version.) We use here the standard Evans function (2.2), which equivalently reads

$$D(\lambda) = e^{-\int_0^x \operatorname{tr}\mathbb{A}(s;\lambda)ds}\,(\Phi_{1-}(x;\lambda)\wedge\cdots\wedge\Phi_{n-}(x;\lambda)\wedge\Phi_{1+}(x;\lambda)\wedge\cdots\wedge\Phi_{n+}(x;\lambda)).$$

We recall that the Φ_j are solutions of the variable coefficient ODE (2.3), where

$$\mathbb{A}(\cdot;\lambda) = \begin{pmatrix} 0_n & I_n \\ B^{-1}(\lambda + A') & B^{-1}(A - B') \end{pmatrix},$$

with $A(x)$ and $B(x)$ defined by (3.4) and (3.5), respectively. We have the following lemma.

LEMMA 6.1. *Assuming* (H1) *and* (H5) *and that the discontinuity* (u_-, u_+) *is a p-shock, that is,* (5.1) *and* (5.2) *hold, we can choose the* Φ_j *such that, for* $\lambda = 0$,

$$\begin{aligned} \Phi_{p-} = \Phi_{p+} &= \begin{pmatrix} U' \\ U'' \end{pmatrix}, \\ \Phi_{j-}(-\infty) &= \begin{pmatrix} r_j^- \\ 0 \end{pmatrix}, \quad j \in \{1,\dots,p-1\}, \\ \Phi_{j+}(+\infty) &= \begin{pmatrix} r_j^+ \\ 0 \end{pmatrix}, \quad j \in \{p+1,\dots,n\}, \end{aligned}$$

where the $r_j^\pm$ *are right eigenvectors of* $A_\pm$ *associated with* $a_j^\pm$. *Then we have*

$$D'(0) = (-1)^n \det B(0)^{-1}(-a_1^-)\cdots(-a_{p-1}^-)(a_{p+1}^+)\cdots(a_n^+)\,\gamma\, M, \tag{6.1}$$

where M *is the Majda–Liu determinant*

$$M := (r_1^- \wedge\cdots\wedge r_{p-1}^- \wedge [u] \wedge r_{p+1}^+ \wedge\cdots\wedge r_n^+) \tag{6.2}$$

and γ *is given by*

$$\gamma := e^{-\int_0^x \operatorname{tr}(B^{-1}A)}\,(\phi_{1+}(x;0)\wedge\cdots\wedge\phi_{(p-1)+}(x;0)\wedge\phi_{p-}(x;0)\wedge\cdots\wedge\phi_{n-}(x;0)). \tag{6.3}$$

Furthermore, provided that the family $\{a_1^- r_1^-,\dots,a_{p-1}^- r_{p-1}^-, a_{p+1}^+ r_{p+1}^+,\dots,a_n^+ r_n^+\}$ *is independent, we have* $D'(0) = 0$ *if and only if there exist coefficients* $b_j^\pm$ *such that*

$$[u] = \sum_{j=1}^{p-1} b_j^-\, a_j^- r_j^- + \sum_{j=p+1}^{n} b_j^+\, a_j^+ r_j^+, \tag{6.4}$$

and, denoting $\psi_{p\pm} = \partial\phi_{p\pm}/\partial\lambda$,

$$\psi_{p+} - \psi_{p-} = b_p\, U' + \sum_{j\neq p} b_j^-\,\phi_{j-} + \sum_{j\neq p} b_j^+\,\phi_{j+} \tag{6.5}$$

at $\lambda = 0$.

Proof. The special choice of Φ_j is similar as in section 5.1 (see also [12]). Let us briefly recall the computation of $D'(0)$. Since $\Phi_{p-} = \Phi_{p+}$, we have just

$$\begin{aligned} D'(0) = e^{-\int_0^x \operatorname{tr}\mathbb{A}(s;0)ds}(&\Phi_{1-}(x;0)\wedge\cdots\wedge\Phi_{n-}(x;0)\wedge\Phi_{1+}(x;0)\wedge\cdots\wedge\Phi_{(p-1)+}(x;0)\\ &\wedge\Psi_{p+}(x;0) - \Psi_{p-}(x;0)\wedge\Phi_{(p+1)+}(x;0)\wedge\cdots\wedge\Phi_{n+}(x;0)), \end{aligned} \tag{6.6}$$

where $\Psi_{p\pm} := \partial\Phi_{p\pm}/\partial\lambda$. By construction, $\phi_{j+}(\cdot;0)$, $j \in \{1,\dots,p\}$, as well as the $\phi_{j-}(\cdot;0)$, $j \in \{p,\dots,n\}$, are solutions of the variable coefficient ODE

$$\phi' = B^{-1}A\phi.$$

On the other hand, we have

$$B\,\phi'_{j\pm} - A\,\phi_{j\pm} \equiv -a_j^{\pm}\,r_j^{\pm}$$

for $j \in \{1,\dots,p-1\}$ (with the sign $-$) or $j \in \{p+1,\dots,n\}$ (with the sign $+$) at $\lambda = 0$, and

$$B\,\psi'_{p\pm} - A\,\psi_{p\pm} = U - u_{\pm}.$$

Using these relations we obtain a block-triangular matrix by multiplying the matrix in (6.6) by

$$\begin{pmatrix} I_n & 0_n \\ -A(x) & B(x) \end{pmatrix}.$$

More precisely, using the remark that

$$e^{-\int_0^x \operatorname{tr}\mathbb{A}(s;0)ds} = e^{-\int_0^x \operatorname{tr}(B^{-1}(A-B'))} = \frac{\det B(x)}{\det B(0)}\, e^{-\int_0^x \operatorname{tr}(B^{-1}A)}$$

and permuting $(p-1)$ columns we obtain

$$D'(0) = \frac{e^{-\int_0^x \operatorname{tr}(B^{-1}A)}}{\det B(0)}\,(-1)^{p-1}\,\det\begin{pmatrix} \Gamma & * \\ 0_n & \Delta \end{pmatrix},$$

where

$$\Gamma := \left(\phi_{1+}(x;0),\dots,\phi_{(p-1)+}(x;0),\phi_{p-}(x;0),\dots,\phi_{n-}(x;0)\right),$$

and

$$\Delta := \left(-a_1^- r_1^-,\dots,-a_{p-1}^- r_{p-1}^-,-[u],-a_{p+1}^+ r_{p+1}^+,\dots,-a_n^+ r_n^+\right).$$

Then the result in (6.1) follows immediately, and the end of the proof comes from a pure algebraic argument. ∎

Note that if the eigenvalues $a_j^{\pm}$ are nonzero, the independence of the family $\{a_1^- r_1^-,\dots,a_{p-1}^- r_{p-1}^-, a_{p+1}^+ r_{p+1}^+,\dots,a_n^+ r_n^+\}$ is ensured by the transversality condition (5.7). Also note that γ itself is a Wronskian. Actually, γ measures transversality of the stable/unstable manifolds of the traveling wave ODE at u_+/u_-.

Now, let us examine the situation when we have such decompositions as (6.4) and (6.5). If the eigenvalues $a_j^{\pm}$ are nonzero and the transversality condition (5.7) holds,

(6.4) implies that the Majda–Liu determinant M is equal to 0. Shocks that satisfy this property cannot be of small amplitude, at least in regions where the system is strictly hyperbolic. However, weak shocks of this kind occur in MHD near states with crossing eigenvalues. When zero is a regular value of M, viewed as a function of the right state u_+, for instance, its zeros form a hypersurface which may be viewed as a transition locus between multidimensionally stable and unstable shock waves (see [22]). Here stability refers to the hyperbolic system $u_t + \operatorname{div} F = 0$, with $F_1 = f$.

Assuming that a given shock satisfies $M = 0$ and that it admits a profile U, we have $D'(0) = 0$ and we still know how to calculate the sign of $D(\lambda)$ for large real λ (see section 7). Therefore, we face the calculation of $D''(0)$. If $D''(0)D(+\infty) < 0$, we shall be able to conclude to the linear instability of the profile (more precisely, the "strong instability" of the profile: the double root of $D(\cdot)$ at $\lambda = 0$ already provides a "neutral instability"; see [12]). An interesting consequence will then happen: the linear operator admits a real positive eigenvalue λ_0, where the sign of D changes (because of analyticity, since one of the real roots of D must have an odd multiplicity). Let us move the right state u_+ slightly along the Hugoniot curve of u_-, denoted by $H_p(u_-)$. When z moves along $H_p(u_-)$, in a neighborhood of u_+, the above determinant vanishes only if $z = u_+$ and its sign changes across u_-. Therefore, we are free to choose z in such a way that, for the perturbed shock (u_-, z), the sign of $D'(0; z)D(+\infty; z)$ is positive. Then the number of real positive eigenvalues of $D(\cdot; z)$ is even, counting with multiplicity, but the eigenvalue λ_0 persists, with a small perturbation, if z is close enough to u_+. This construction provides examples where we are able to conclude to linear instability, although the index of the linearized operator is even.

6.2. Computation of $D''(0)$ when $D'(0) = 0$. We propose a method for computing $D''(0)$ when we have (6.4) and (6.5). The outcome will be an integral formula, which is (at least numerically) plainly computable.

A useful trick consists in noting that D is unchanged by adding to $\Phi_{p\pm}$ a linear combination of the other Φs. More precisely, defining

$$\tilde{\Phi}_{p+} := \Phi_{p+} + \lambda \left(b_p \, \Phi_{p+} + \sum_{j \neq p} b_j^+ \, \Phi_{j+} \right),$$

$$\tilde{\Phi}_{p-} := \Phi_{p-} - \lambda \left(\sum_{j \neq p} b_j^- \, \Phi_{j-} \right),$$

we have

$$D(\lambda) = (\Phi_{1-} \wedge \cdots \wedge \tilde{\Phi}_{p-} \wedge \cdots \wedge \Phi_{n-} \wedge \Phi_{1+} \wedge \cdots \wedge \tilde{\Phi}_{p+} \wedge \cdots \wedge \Phi_{n+})|_{x=0}.$$

Denoting naturally $\tilde{\psi}_{p\pm} := \partial \tilde{\phi}_{p\pm}/\partial\lambda$, we have because of (6.5), $\tilde{\psi}_{p+} = \tilde{\psi}_{p-}$ at $\lambda = 0$. This is the function that will appear in the final integral formula. We simply denote it by $\tilde{\Psi}$. Now, denoting

$$\tilde{\zeta}_{p\pm} := \frac{1}{2} \left. \frac{\partial^2 \tilde{\phi}_{p\pm}}{\partial \lambda^2} \right|_{\lambda=0},$$

we have

$$\left(B \, \tilde{\zeta}'_{p\pm} - A \, \tilde{\zeta}_{p\pm} \right)' = \tilde{\psi}. \tag{6.7}$$

This implies in particular that

$$B\,(\tilde\zeta'_{p+}-\tilde\zeta'_{p-})-A\,(\tilde\zeta_{p+}-\tilde\zeta_{p-})\equiv C, \tag{6.8}$$

a constant. By similar operations as in the computation of $D'(0)$, thus we find that

$$\frac12\,D''(0)=(-1)^{n-1}\,\det B(0)^{-1}(-a_1^-)\cdots(-a_{p-1}^-)(a_{p+1}^+)\cdots(a_n^+)\,\gamma\,I, \tag{6.9}$$

where

$$I:=(r_1^-\wedge\cdots\wedge r_{p-1}^-\wedge C\wedge r_{p+1}^+\wedge\cdots\wedge r_n^+). \tag{6.10}$$

The problem in evaluating I is that we do not have access to the constant C. However, we shall see that I can be written as an integral in terms of $\tilde\psi$, plus boundary terms that are explicit at least in the case of an extreme shock ($p=1$ or $p=n$).

Assuming the transversality condition (5.7), we can preferably write $I=\ell\cdot C$, where ℓ is a co-vector such that

$$\ell\cdot r_1^-=0,\dots,\ell\cdot r_{p-1}^-=0,\quad \ell\cdot r_{p+1}^+=0,\dots,\ell\cdot r_n^+=0. \tag{6.11}$$

With the notations of section 5.1, we have

$$\ell=h_p\,(r_1^-\wedge\cdots\wedge r_{p-1}^-\wedge r_p^\pm\wedge r_{p+1}^+\wedge\cdots\wedge r_n^+)/(h_p\cdot r_p^\pm).$$

Then (6.7) and (6.8) show that

$$\begin{aligned} I=\ell\cdot C=&-\int_{-\infty}^{+\infty}\ell\cdot\tilde\psi(x)\,dx\\ &+\Big(\ell\cdot(B\,\tilde\zeta'_{p+}-A\,\tilde\zeta_{p+})\Big)(+\infty)-\Big(\ell\cdot(B\,\tilde\zeta'_{p-}-A\,\tilde\zeta_{p-})\Big)(-\infty). \end{aligned} \tag{6.12}$$

Let us comment on this formula. The first part is similar to a formula obtained by Kapitula in [16]. However, there are no boundary terms in Kapitula's formula. Here they come from the fact that 0 is embedded in the essential spectrum (by the translational invariance). The integral in (6.12) is computable provided that $\tilde\psi$ is, which is at least possible numerically. Indeed, $\tilde\psi$ is the solution of the "boundary value problem"

$$(B\tilde\psi'-A\,\tilde\psi)'=U',\quad \tilde\psi(-\infty)=-\sum_{j=1}^{p-1}b_j^-\,r_j^-,\quad \tilde\psi(+\infty)=\sum_{j=p+1}^{n}b_j^+\,r_j^+.$$

Note that these boundary conditions and equations in (6.11) ensure that $\ell\cdot\tilde\psi$ is integrable (whereas $\tilde\psi$ is not!). Concerning the boundary terms in (6.12), we can give more explicit formulas. As a matter of fact, we have

$$\tilde\zeta_{p+}=\zeta_{p+}+b_p\;\psi_{p+}+\sum_{j\neq p}b_j^+\,\psi_{j+},\quad \tilde\zeta_{p-}=\zeta_{p-}-\sum_{j\neq p}b_j^-\,\psi_{j-},$$

where

$$\zeta_{p\pm}:=\frac12\,\frac{\partial^2\tilde\phi_{p\pm}}{\partial\lambda^2}\bigg|_{\lambda=0},\quad \psi_{j\pm}:=\frac{\partial\phi_{j\pm}}{\partial\lambda}\bigg|_{\lambda=0}.$$

Hence, we have

$$\begin{aligned}\tilde{\zeta}_{p+}(x) &\sim \sum_{j=p+1}^{n} b_j^+\,\psi_{j+}(x), \quad x \to +\infty \quad (\text{if } p \le n-1),\\ \tilde{\zeta}_{p-} &\sim -\sum_{j=1}^{p-1} b_j^-\,\psi_{j-}(x), \quad x \to -\infty \quad (\text{if } p \ge 2).\end{aligned} \tag{6.13}$$

Thus the boundary terms in (6.12) depend on the asymptotic behaviors of $\psi_{j\pm}$. Recalling that

$$\phi_{j\pm}(x;\lambda) \sim e^{\nu_j^\pm(\lambda)x}\, v_j^\pm(\lambda), \quad x \to \pm\infty,$$

with $(\nu_j^\pm(\lambda), v_j^\pm(\lambda))$ such that

$$\nu_j^\pm(\lambda) = -\frac{\lambda}{a_j^\pm} + \mathcal{O}(\lambda^2), \quad v_j^\pm(\lambda) = r_j^\pm$$

for $j \in \{1,\dots,p-1\}$ (with the sign $-$) or $j \in \{p+1,\dots,n\}$ (with the sign $+$), we have

$$\psi_{j\pm}(x) \sim -\frac{x}{a_j^\pm}\, r_j^\pm + \left.\frac{dv_j^\pm}{d\lambda}\right|_{\lambda=0}, \quad x \to \pm\infty.$$

Therefore, we have using (6.11)

$$\left(\ell \cdot (B\,\psi'_{j\pm} - A\,\psi_{j\pm})\right)(\pm\infty) = \ell \cdot \left(-\frac{1}{a_j^\pm}\, B_\pm\, r_j^\pm - A_\pm \left.\frac{dv_j^\pm}{d\lambda}\right|_{\lambda=0}\right) \tag{6.14}$$

for $j \in \{1,\dots,p-1\}$ (with the sign $-$) or $j \in \{p+1,\dots,n\}$ (with the sign $+$). Using (6.13) and (6.14) we obtain by linearity the value of the boundary terms in (6.12). It is not very simple but it is "explicit." Indeed, the vectors

$$\left.\frac{dv_j^\pm}{d\lambda}\right|_{\lambda=0}$$

can be computed by differentiating twice the relation satisfied by $(\nu_j^-(\lambda), v_j^-(\lambda))$,

$$(\nu^2\, B_\pm - \nu\, A_\pm - \lambda)\, v = 0.$$

Actually, the formula is much simpler for extreme shocks. Assume, for instance, that $p = n$. Then there is only the boundary term at $-\infty$ in (6.12). Furthermore, ℓ is necessarily colinear to ℓ_n^-. This implies by the double differentiation mentioned above that

$$\ell \cdot \left(-\frac{1}{a_j^-}\, B_-\, r_j^-\right) = (a_n^- - a_j^-)\, \ell \cdot \left.\frac{dv_j^\pm}{d\lambda}\right|_{\lambda=0}$$

for all $j \in \{1,\dots,n-1\}$. Substituting this equality in (6.14) we find that

$$\left(\ell \cdot (B\,\psi'_{j-} - A\,\psi_{j-})\right)(-\infty) = \frac{(\ell \cdot B_-\, r_j^-)}{a_n^- - a_j^-}.$$

Finally, we can summarize our result in the following theorem.

THEOREM 6.2. *We assume that* (H1) *and* (H5) *hold true and that the discontinuity* (u_-, u_+) *is a* n*-shock, that is,* (5.1) *and* (5.2) *hold with* $p = n$*. We also assume that the family* $\{a_1^- r_1^-, \dots, a_{n-1}^- r_{n-1}^-\}$ *is independent and that the functions* $\Phi_j^\pm$ *are chosen as in Lemma* 6.1*. If* $D'(0) = 0$*, then there exist a unique family* $\{b_1, \dots, b_n\}$ *such that*

$$[u] = \sum_{j=1}^{n-1} b_j\, a_j^- r_j^-. \tag{6.15}$$

Furthermore, we have

$$\frac{1}{2}\, D''(0) = (-1)^{n-1}\, \det B(0)^{-1} (-a_1^-) \cdots (-a_{p-1}^-)(a_{p+1}^+) \cdots (a_n^+)\, \gamma\, I, \tag{6.16}$$

where γ *is defined by* (6.3) *and*

$$\begin{aligned} I = \; & -\int_{-\infty}^{+\infty} (r_1^- \wedge \cdots \wedge r_{n-1}^- \wedge \tilde\psi(x))\, dx \\ & + \left(r_1^- \wedge \cdots \wedge r_{n-1}^- \wedge \sum_{j=1}^{n-1} \frac{b_j}{a_n^- - a_j^-}\, B_-\, r_j^- \right) \end{aligned} \tag{6.17}$$

with $\tilde\psi$ *a function such that*

$$(B\tilde\psi' - A\,\tilde\psi)' = U', \quad \tilde\psi(-\infty) = -\sum_{j=1}^{n-1} b_j\, r_j^-,\ \tilde\psi(+\infty) = 0.$$

Note that $(U', \tilde\psi)$ form a Jordan chain for the operator L, since we have

$$L \cdot U' = 0, \quad L \cdot \tilde\psi = U'.$$

7. The case of $n \times n$ systems. In this section, we are interested in the question left open by Gardner and Zumbrun (see [12, p. 837]), concerning $n \times n$ systems. More precisely, there was missing an n-dimensional version of their "algebraic" Lemma 3.5, needed to complete the theory for $n > 2$. We shall prove such a lemma under the following hypotheses.

(h1) The $n \times n$ matrix A is real-valued, invertible, and there exists a positive definite symmetric matrix S_0 such that $S_0 A$ is symmetric;

(h2) the $n \times n$ matrix B is real-valued and there exists $\beta > 0$ such that

$$\text{for all } X \in \mathbb{C}^n, \quad \text{Re}\, \langle BX, X\rangle \geq \beta\, \langle X, X\rangle\,, \tag{7.1}$$

where $\langle ., . \rangle$ is the inner product associated to S_0.

In particular, (h1) and (h2) hold if $A = df(u)$, $B = B(u)$, and (H5) of section 3 holds in the neighborhood of the constant state u. Let us recall from Remark 2 that this is the case for most physical systems of conservation laws.

We shall denote by $\mathcal{U}(A)$ the unstable manifold of A and by $\mathcal{S}(B^{-1}A)$ the stable manifold of $B^{-1}A$. These are a priori subspaces of $\mathbb{C}^n$. However, since A and B are real-valued, we may also consider them as subspaces of $\mathbb{R}^n$. Let us first show the following lemma.

LEMMA 7.1. *Assuming* (h1) *and* (h2), *the subspaces* $\mathcal{U}(A)$ *and* $\mathcal{S}(B^{-1}A)$ *are complementary.*

Proof. The assumptions (h1) and (h2) imply that A, B satisfy the properties required in (H2), (H3), and (H4). Moreover, A satisfies the weakened assumption (H1′). Hence, by Lemma 3.2 and Remark 3, we have

$$n = \dim \mathcal{U}(A) + \dim \mathcal{S}(B^{-1}A).$$

It remains to show that these subspaces have their intersection reduced to 0. Let $X_0 \neq 0$ belong to the stable manifold of $B^{-1}A$. By definition, there exists φ such that

$$\varphi' = B^{-1}A\varphi$$

and

$$\begin{cases} \varphi(+\infty) = 0, \\ \varphi(0) = X_0. \end{cases}$$

By the symmetry of A, we have

$$\langle A\varphi, \varphi\rangle' = 2\mathrm{Re}\,\langle A\varphi, B^{-1}A\varphi\rangle \geq 2\beta|B^{-1}A\varphi|^2.$$

Since $X_0 \neq 0$ and A is invertible, we conclude that $\langle A\varphi, \varphi\rangle < 0$ on $[0, +\infty[$. In particular,

$$\langle AX_0, X_0\rangle < 0.$$

On the other hand, if X belongs to the unstable manifold of A, which is diagonalizable in an orthogonal basis, then we must have $\langle AX, X\rangle \geq 0$. ∎

For $\lambda \in \mathbb{C}$, we take the usual notation

$$\mathbb{A}(\lambda) = \begin{pmatrix} 0_n & I_n \\ \lambda B^{-1} & B^{-1}A \end{pmatrix}.$$

For $\mathrm{Re}\,\lambda > 0$, we denote by $S(\lambda)$, respectively, $U(\lambda)$, the stable/unstable manifold of $\mathbb{A}(\lambda)$. They are then extended by continuity to $\lambda = 0$.

LEMMA 7.2. *Assuming* (h1) *and* (h2), *for all* $\lambda \in [0, +\infty[$, *the projection* $(v, w)^T \mapsto v$ *is one-to-one from* $S(\lambda)$ *to* $\mathbb{R}^n$.

Proof. Since (h1) and (h2) imply the Majda–Pego condition (H4), we know that $\mathbb{A}(\lambda)$ does not have a center manifold for $\mathrm{Re}\,\lambda > 0$. The far field behavior and a continuity argument then show that for $\mathrm{Re}\,\lambda > 0$

$$\dim S(\lambda) = \dim U(\lambda) = n.$$

By continuity, it also holds for $\lambda = 0$. Thus it is sufficient to show that the projection $(v, w)^T \mapsto v$ has zero kernel in $S(\lambda)$ for $\mathrm{Re}\,\lambda > 0$ or $\lambda = 0$.

First let us treat the case $\lambda = 0$. It is known from standard computations (see [12]) that $S(0)$ consists of a center part and a genuine stable part. The stable part is spanned by the generalized eigenvectors associated to the eigenvalues of negative real part of $\mathbb{A}(0)$, which coincide with the eigenvalues of negative real part of $B^{-1}A$. The v-component as well as the w-component of these generalized eigenvectors belong to $\mathcal{S}(B^{-1}A)$. The center part is derived through a bifurcation analysis. It is spanned by

the vectors $(r,0)^T$, with $r \in \mathcal{U}(A)$. Let us consider any vector $(v_s + r, w_s)^T \in S(0)$, with $v_s, w_s \in \mathcal{S}(B^{-1}A)$ and $r \in \mathcal{U}(A)$. If $v_s + r = 0$, then by Lemma 7.1, we have necessarily $v_s = 0$ and $r = 0$. Since $(v_s = 0, w_s)^T$ belongs to the stable manifold of $\mathbb{A}(0)$, there should exist (ϕ, φ) such that

$$\begin{cases} \phi' = \varphi, & \varphi' = B^{-1}A\varphi, \\ \phi(0) = 0, & \varphi(0) = w_s, \\ \phi(+\infty) = 0, & \varphi(+\infty) = 0. \end{cases}$$

By integration, this implies $w_s = 0$. This proves the lemma in the case $\lambda = 0$.

We now assume $\operatorname{Re}\lambda > 0$. We shall use a *Lyapunov function* to show the following preliminary result.

- If $(v,0)^T \in S(\lambda)$, then $v = 0$.

As a matter of fact, let us define

$$H(v,w) := \frac{1}{2}\langle Aw, w\rangle + \operatorname{Re}\langle w, \lambda v\rangle.$$

If one has

$$\begin{pmatrix} \phi' \\ \varphi' \end{pmatrix} = \mathbb{A}(\lambda)\begin{pmatrix} \phi \\ \varphi \end{pmatrix}, \tag{7.2}$$

then by the symmetry of A

$$H(\phi,\varphi)' = \operatorname{Re}\left\langle \lambda\phi + A\varphi, B^{-1}(\lambda\phi + A\varphi)\right\rangle + \operatorname{Re}\lambda|\varphi|^2.$$

Hence, by (h2), we have $H(\phi,\varphi)' \geq 0$ with equality if and only if

$$\begin{cases} \lambda\phi + A\varphi = 0, \\ \operatorname{Re}\lambda\,|\varphi| = 0, \end{cases}$$

which is equivalent to $(\phi,\varphi) = (0,0)$. Suppose that $(v_0,0)^T \in S(\lambda)$. Then there exists (ϕ,φ) solution to (7.2) such that

$$\begin{cases} \phi(0) = v_0, & \varphi(0) = 0, \\ \phi(+\infty) = 0, & \varphi(+\infty) = 0. \end{cases}$$

Since

$$H(v_0,0) = H(0,0) = 0,$$

and H is nondecreasing along solutions of (7.2), we must have $H(\phi,\varphi) \equiv 0$ on $[0,+\infty[$. Thus we also have $H(\phi,\varphi)' \equiv 0$ on $[0,+\infty[$, which implies that $(\phi,\varphi) \equiv (0,0)$ on $[0,+\infty[$. In particular, this shows that $v_0 = 0$.

We are now in a position to show that

- if $(0,w)^T \in S(\lambda)$, then $w = 0$.

Since $S(\lambda)$ is invariant under $\mathbb{A}(\lambda)$, which is invertible, if $(0,w)^T \in S(\lambda)$, there exists $(v_1,w_1)^T \in S(\lambda)$ such that

$$\begin{pmatrix} 0 \\ w \end{pmatrix} = \mathbb{A}(\lambda)\begin{pmatrix} v_1 \\ w_1 \end{pmatrix}.$$

We actually have $0 = w_1$. From the previous result, this implies $v_1 = 0$, and thus also $w = 0$. This concludes the proof. ∎

Of course, we have symmetrically the following lemma.

LEMMA 7.3. *Assuming* (h1) *and* (h2), *for all* $\lambda \in [0, +\infty[$, *the projection* $(v, w)^T \mapsto v$ *is one-to-one from* $U(\lambda)$ *to* $\mathbb{R}^n$.

Lemmas 7.2 and 7.3 prove, in particular, that the stability conditions stated in [12, p. 837], do hold. More generally, we have the following theorem.

THEOREM 7.4. *Assuming* (H1) *and* (H5), *a necessary condition for linearized stability of a viscous n-shock wave* U *is*

$$(r_1^- \wedge \cdots \wedge r_{n-1}^- \wedge s_n^-)\ (r_1^- \wedge \cdots \wedge r_{n-1}^- \wedge [u]) \geq 0,$$

where s_n^- *denotes the asymptotic direction of* U' *at* $-\infty$.

Proof. We use the standard Evans function (2.2) and apply Lemma 6.1 regarding the long wave analysis. In the case $p = n$, γ reduces to

$$\gamma = e^{-\int_0^x \operatorname{tr}(B^{-1}A)}\ (\phi_{1+}(x;0) \wedge \cdots \wedge \phi_{n+}(x;0)).$$

Since it is a Wronskian, and the $\Phi_{j+}(\cdot;0)$ are asymptotic to the stable manifold, $S_+(0)$, of $\mathbb{A}_+(0)$ at $+\infty$, we may evaluate sgn γ at $+\infty$. Therefore, we have

$$\operatorname{sgn}\ \gamma = \operatorname{sgn}\ (s_1^+ \wedge \cdots \wedge s_n^+),$$

where the s_j^+ span $\mathcal{S}(B_+^{-1}A_+) = \mathbb{R}^n$. Since the (a_j^-), $j \in \{1, \ldots, n-1\}$, are negative, and

$$M = (r_1^- \wedge \cdots \wedge r_{n-1}^- \wedge [u]),$$

thus we infer that

$$\operatorname{sgn}\ D'(0) = \operatorname{sgn}\ (-1)^n\ (r_1^- \wedge \cdots \wedge r_{n-1}^- \wedge [u])\ (s_1^+ \wedge \cdots \wedge s_n^+). \tag{7.3}$$

On the other hand, applying either a homotopy (as in sections 4 and 5) or a rescaling method [12], we find that, for large real λ,

$$\operatorname{sgn}\ D(\lambda) = \operatorname{sgn}\ (-1)^n (v_1^- \wedge \cdots \wedge v_n^-)\ (v_1^+ \wedge \cdots \wedge v_n^+). \tag{7.4}$$

Here the $v_j^\pm$ are the projections onto the v-components of the bases of $U_-(\lambda)$ and $S_+(\lambda)$ provided by the asymptotic behavior of the Φ_{j-} and of the Φ_{j+}, respectively. From Lemma 7.2, a continuity argument and the asymptotics of the $\Phi_{j+}(\cdot;0)$, we have

$$\operatorname{sgn}\ (v_1^+ \wedge \cdots \wedge v_n^+) = \operatorname{sgn}\ (s_1^+ \wedge \cdots \wedge s_n^+). \tag{7.5}$$

Similarly, we can use Lemma 7.3 to find sgn $(v_1^- \wedge \cdots \wedge v_n^-)$. We recall that

$$\Phi_{j-}(-\infty;0) = \begin{pmatrix} r_j^- \\ 0 \end{pmatrix}, \quad j \in \{1, \ldots, n-1\}.$$

Therefore, if s_n^- denotes the asymptotic direction of $U' = \phi_{n-}(\cdot;0)$ at $-\infty$, which spans $\mathcal{S}(B_-^{-1}A_-)$, we have

$$\operatorname{sgn}\ (v_1^- \wedge \cdots \wedge v_n^-) = \operatorname{sgn}\ (r_1^- \wedge \cdots \wedge r_{n-1}^- \wedge s_n^-). \tag{7.6}$$

In view of (7.3), (7.4), (7.5), and(7.6), we have

$$\operatorname{sgn}\ D'(0)\ D(+\infty) = (r_1^- \wedge \cdots \wedge r_{n-1}^- \wedge [u])\ (r_1^- \wedge \cdots \wedge r_{n-1}^- \wedge s_n^-). \tag{7.7}$$

This concludes the proof of Theorem 7.4 by using the intermediate value theorem. ∎

DETERMINING COEFFICIENTS IN A CLASS OF HEAT EQUATIONS VIA BOUNDARY MEASUREMENTS*

B. CANUTO† AND O. KAVIAN†

Abstract. When $\Omega \subset \mathbb{R}^N$ is a bounded domain, we consider the problem of identifiability of the coefficients ρ, A, q in the equation $\rho(x)\partial_t u - \operatorname{div}(A(x)\nabla u) + q(x)u = 0$ from boundary measurements on two pieces Γ_{in} and Γ_{out} of $\partial\Omega$. Provided that $\Gamma_{\text{in}} \cap \Gamma_{\text{out}}$ has a nonempty interior, and assuming that $f(t,\sigma)$ is the given input datum for $(t,\sigma) \in (0,T) \times \Gamma_{\text{in}}$ and that the corresponding output datum is the thermal flux $A(\sigma)\nabla u(T_0,\sigma)\cdot \mathbf{n}(\sigma)$ measured at a given time T_0 for $\sigma \in \Gamma_{\text{out}}$, we prove that knowledge of all possible pairs of input-output data

$$(f, A\nabla u(T_0)\cdot \mathbf{n}_{|\Gamma_{\text{out}}})$$

determines uniquely the boundary spectral data of the underlying elliptic operator. Under suitable hypothesis on ρ, A, q, their identifiability is then proved. The same results hold when a mean value of the thermal flux is measured over a small interval of time.

1. Introduction and main results. We denote by $u(t,x)$ the temperature of a sufficiently smooth body Ω in $\mathbb{R}^N, N \geq 2$, at the time t and at the point $x \in \Omega, u_0$ is the initial temperature, f the temperature on $(0,T) \times \partial\Omega, \rho(x)$ the density, $q(x)$ the potential, and $A(x)$ the anisotropic thermal diffusion coefficient. We make the following regularity assumptions on the functions ρ, A, q:

$$\rho \in L^\infty(\Omega) \text{ and } \rho(x) \geq \beta \text{ for some constant } \beta > 0; \tag{1.1}$$

$A(x) = (a_{i\ell}(x))_{1\leq i,\ell\leq N}$ is a symmetric $N \times N$ matrix valued function in Ω satisfying the following conditions:

(i) $(a_{i\ell})_{1\leq i,\ell\leq N} \in C^{0,1}(\overline{\Omega})$, that is, there exists a constant $C > 0$ such that for every $x, y \in \overline{\Omega}$

$$|a_{i\ell}(x) - a_{i\ell}(y)| \leq C\,|x-y|\,, \quad i,\ell = 1,\ldots,N; \tag{1.2}$$

(ii) there exists a constant $\alpha > 0$ such that for every $x \in \overline{\Omega}$ and $\xi \in \mathbb{R}^N$

$$A(x)\xi\cdot\xi \geq \alpha\,|\xi|^2\,, \tag{1.3}$$

where $x \cdot y$ denotes the euclidean scalar product of two elements $x, y \in \mathbb{R}^N$;

$$q \in L^p(\Omega) \text{ for some } p > \frac{N}{2}. \tag{1.4}$$

Supposing ρ, A, q, u_0, and f assigned, then u solves the following heat equation, which we call the *direct problem*:

$$\left\{\begin{array}{rcll} \rho(x)\partial_t u - \operatorname{div}(A(x)\nabla u) + q(x)u &=& 0 & \text{in } (0,T)\times\Omega, \\ u(0) &=& u_0 & \text{in } \Omega, \\ u(t,\sigma) &=& f(t,\sigma) & \text{on } (0,T)\times\partial\Omega. \end{array}\right. \tag{1.5}$$

It is well known that, under reasonable assumptions on the data, (1.5) has a unique solution, and that the thermal flux

$$A(\sigma)\nabla u(t,\sigma)\cdot\mathbf{n}(\sigma)$$

is well defined for $(t,\sigma)\in(0,T)\times\partial\Omega$.

In the present paper we are interested in the study of identifiability of the coefficients ρ, A, q in (1.5), when, assigning the temperature f on $(0,T)\times\partial\Omega$, one measures the corresponding thermal flux $A\nabla u(T_0)\cdot\mathbf{n}_{|\Gamma_{\rm out}}$ at a given time T_0 on a piece $\Gamma_{\rm out}$ of the boundary of Ω. More generally we may impose the input f on $(0,T)\times\Gamma_{\rm in}$, where $\Gamma_{\rm in}$ is a piece of the boundary of Ω, and we ask the following question: if we denote by Λ the so-called input-output map, that is,

$$\Lambda : f \longmapsto A\nabla u(T_0)\cdot\mathbf{n}_{|\Gamma_{\rm out}}, \tag{1.6}$$

where $T_0\in(0,T]$ is a given fixed time, and by Φ the nonlinear operator

$$\Phi : (\rho, A, q) \longmapsto \Lambda, \tag{1.7}$$

is Φ *injective*? We point out that to prove the injectivity of the operator Φ in (1.7), it is equivalent to show the uniqueness of the coefficients ρ, A, q in Ω from knowledge of all possible pairs of input-output data

$$(f, A\nabla u(T_0)\cdot\mathbf{n}_{|\Gamma_{\rm out}})$$

of the solution u of (1.5), that is, from an infinite number of measurements of the thermal flux $A\nabla u(T_0)\cdot\mathbf{n}_{|\Gamma_{\rm out}}$ at a given time T_0 on $\Gamma_{\rm out}$. We observe moreover that the thermal fluxes are measured at a given time T_0 *only*, instead of measuring it over a whole interval of time such as $[0,T_0]$. We study also the problem in which a *mean* value (over a small interval of time) of the thermal flux is measured.

Similar problems have been studied by many authors. Kravaris and Seinfeld [18] consider the problem of identifiability of the coefficient $a(x)\in C^1[0,\ell]$ in the one dimensional heat equation

$$\left\{\begin{array}{rcll} \partial_t u-\partial_x(a(x)\partial_x u) &=& 0 & \text{in } (0,\ell)\times(0,T),\\ u(0) &=& u_0 & \text{in } (0,\ell),\\ a(0)\partial_x u(t,0) &=& f(t) & \text{in } (0,T),\\ a(\ell)\partial_x u(t,\ell) &=& 0 & \text{in } (0,T)\end{array}\right. \tag{1.8}$$

from the additional measurement of the temperature $u(t,x_*)$ on $[0,T]$ at one end-point x_* of the interval $[0,\ell]$ when a single input f is assigned in (1.8). More precisely, they prove that if the temperature $u(t,x_*)$ is measured at the end-point $x_*=0$, where the rod is supposedly heated, then the coefficient $a(x)$ is uniquely determined in $[0,\ell]$ provided that the input f satisfies the following condition: for some $\varepsilon>0$, $f(t)$ is not identically zero in $(0,\varepsilon)$. On the other hand, if the temperature is measured at the other end-point $x_*=\ell$, where the rod is supposedly insulated, then in general $a(x)$ is not uniquely determined, except for symmetric coefficients, i.e., $a(\ell-x)=a(x)$, in which case uniqueness holds. These uniqueness results are obtained as an implication of identifiability of the coefficient $a(x)$ in the Sturm–Liouville problem

$$\left\{\begin{array}{rcll} -(a\varphi_k')' &=& \lambda_k\varphi_k & \text{in } (0,\ell),\\ \varphi_k'(0)=\varphi_k'(\ell) &=& 0,\\ \displaystyle\int_0^\ell |\varphi_k|^2\,dx &=& 1\end{array}\right.$$

when the sequence of eigenvalues $(\lambda_k)_{k=1}^{\infty}$ and eigenfunctions $(|\varphi_k(0)|)_{k=1}^{\infty}$ is known.

For $N \geq 2$, Isakov [14] proves the unique determination of the scalar coefficients $a(x)$ and $q(x), a \in W^{2,\infty}(\Omega)$ and $q \in L^{\infty}(\Omega)$, in the equation

$$\left\{\begin{array}{rcll} \partial_t u - \operatorname{div}(a(x)\nabla u) + q(x)u &=& 0 & \text{in } (0,T)\times\Omega, \\ u(0) &=& 0 & \text{in } \Omega, \\ u(t,\sigma) &=& f(t,\sigma) & \text{on } (0,T)\times\partial\Omega \end{array}\right. \tag{1.9}$$

from the measurement of the flux $\frac{\partial}{\partial \mathbf{n}} u$ on $[0,T]\times\partial\Omega$ when all possible input data f are assigned in (1.9). We note that in this case the flux is measured on a whole interval of time and on the whole boundary of Ω.

The first step in order to prove the injectivity of the operator Φ defined in (1.7) is to study the identifiability of the boundary spectral data for the underlying elliptic operator from the input-output map Λ. More precisely, let us denote by $(\lambda_k)_{k=1}^{\infty}$ and $(\varphi_k)_{k=1}^{\infty}$, respectively, the nondecreasing sequence of eigenvalues and the corresponding eigenfunctions of the Dirichlet problem

$$\left\{\begin{array}{rcll} -\operatorname{div}(A\nabla\varphi_k) + q\varphi_k &=& \lambda_k\rho\varphi_k & \text{in } \Omega, \\ \varphi_k &=& 0 & \text{on } \partial\Omega, \\ \displaystyle\int_{\Omega} |\varphi_k|^2 \rho dx &=& 1 & \end{array}\right.$$

and by $\mathrm{BSD}(\rho, A, q)$ the *boundary spectral data*, i.e.,

$$\mathrm{BSD}(\rho, A, q) := (\lambda_k, A\nabla\varphi_k \cdot \mathbf{n}_{|\Gamma_{\mathrm{in}}\cup\Gamma_{\mathrm{out}}})_{k=1}^{\infty}.$$

The question we ask is the following: does the input-output map Λ defined in (1.6) determine the boundary spectral data $\mathrm{BSD}(\rho, A, q)$ uniquely? The first result of the present paper is the following.

THEOREM 1.1. *Let $N \geq 2$ be an integer, Ω be a bounded domain in $\mathbb{R}^N$ of class $C^{1,1}$, and let $\Gamma_{\mathrm{in}}, \Gamma_{\mathrm{out}}$ be two relatively open pieces of $\partial\Omega$ such that $\Gamma_{\mathrm{in}} \cap \Gamma_{\mathrm{out}}$ has a nonempty interior. For $j \in \{0,1\}$, consider two sets of functions (ρ_j, A_j, q_j) satisfying conditions* (1.1)–(1.4). *For some fixed $u_{0j} \in L^2(\Omega)$, and $\varphi_j \in C([0,T]; H^{\frac{3}{2}}(\partial\Omega\backslash\Gamma_{\mathrm{in}}))$, let $u_j \in C^1([O,T], L^2(\Omega)) \cap C((O,T], H^2(\Omega))$ solve*

$$\left\{\begin{array}{rcll} \rho_j(x)\partial_t u_j - \operatorname{div}(A_j(x)\nabla u_j) + q_j(x)u_j &=& 0 & \textit{in } (0,T)\times\Omega, \\ u_j(0) &=& u_{0j} & \textit{in } \Omega, \\ u_j &=& \varphi_j & \textit{on } (0,T)\times\partial\Omega\backslash\Gamma_{\mathrm{in}}, \\ u_j &=& f & \textit{on } (0,T)\times\Gamma_{\mathrm{in}}. \end{array}\right. \tag{1.10}$$

We denote by

$$\Lambda_j(f) := A_j\nabla u_j(T_0)\cdot\mathbf{n}_{|\Gamma_{\mathrm{out}}} \tag{1.11}$$

the thermal fluxes measured at a given time $T_0 \in (0,T]$ on Γ_{out}. Suppose that one has

$$\Lambda_0(f) = \Lambda_1(f) \quad \textit{in } H^{\frac{1}{2}}(\Gamma_{\mathrm{out}}) \tag{1.12}$$

for all $f \in C([0,T]; H^{\frac{3}{2}}(\Gamma_{\mathrm{in}}))$ such that the $\operatorname{supp}(f(t,\cdot)) \subset \Gamma_{\mathrm{in}}$ for $t \in [0,T]$. Then the boundary spectral data $\mathrm{BSD}(\rho_j, A_j, q_j), j \in \{0,1\}$, coincide, that is, up to an appropriate choice of the eigenfunctions φ_{0k}, for all $k \geq 1$, one has

$$\lambda_{0k} = \lambda_{1k}, \quad \textit{and} \quad A_0\nabla\varphi_{0k}\cdot\mathbf{n}_{|\Gamma_{\mathrm{in}}\cup\Gamma_{\mathrm{out}}} = A_1\nabla\varphi_{1k}\cdot\mathbf{n}_{|\Gamma_{\mathrm{in}}\cup\Gamma_{\mathrm{out}}} \quad \textit{on } \Gamma_{\mathrm{in}}\cup\Gamma_{\mathrm{out}}.$$

(Here $\mathbf{n}(\sigma)$ denotes the outer unit normal at $\sigma \in \partial\Omega$.) We observe that the initial data u_{0j} and the boundary data φ_j in (1.10) are assigned arbitrarily. In fact this assumption corresponds to a realistic situation in which the data u_{0j}, φ_j are a priori unknown.

We point out that the conclusion of Theorem 1.1 remains valid if we replace hypothesis (1.12) by equality of the mean values of the thermal fluxes in the interval $[\tau_0 - T_0, T_0]$, that is, the following theorem holds.

THEOREM 1.2. *Let $0 < \tau_0 < T_0$ be given. Under the assumptions of Theorem* 1.1 *we suppose that*

$$\int_{T_0-\tau_0}^{T_0} A_0 \nabla u_0(t) \mathbf{n}_{|\Gamma_{\text{out}}} dt = \int_{T_0-\tau_0}^{T_0} A_1 \nabla u_1(t) \mathbf{n}_{|\Gamma_{\text{out}}} dt \quad \text{in } H^{\frac{1}{2}}(\Gamma_{\text{out}})$$

for all $f \in C([0,T]; H^{\frac{3}{2}}(\Gamma_{\text{in}}))$ such that the $\text{supp}(f(t,\cdot)) \subset \Gamma_{\text{in}}$ *for $t \in [0,T]$. Then the boundary spectral data* $\text{BSD}(\rho_j, A_j, q_j), j \in \{0,1\}$, *coincide, that is, up to an appropriate choice of the eigenfunctions φ_{0k}, for all $k \geq 1$, one has*

$$\lambda_{0k} = \lambda_{1k}, \quad \text{and} \quad A_0 \nabla \varphi_{0k} \cdot \mathbf{n}_{|\Gamma_{\text{in}} \cup \Gamma_{\text{out}}} = A_1 \nabla \varphi_{1k} \cdot \mathbf{n}_{|\Gamma_{\text{in}} \cup \Gamma_{\text{out}}} \quad \text{on } \Gamma_{\text{in}} \cup \Gamma_{\text{out}}.$$

Once the result of Theorem 1.1 is at hand, we can prove the injectivity of the operator Φ defined in (1.7) in the following three cases:

(i) given $q(x)$ and $A(x)$ of the form $A(x) = a(x) I_N$, where $a(x)$ is a scalar-valued function and I_N is the identity matrix, we identify $\rho(x)$ and $a(x)$ by supposing that $\Gamma_{\text{in}} = \Gamma_{\text{out}} = \partial\Omega$;

(ii) given $A(x) = a(x) I_N$, we identify $\rho(x)$ and $q(x)$ by supposing that $\Gamma_{\text{in}} = \Gamma_{\text{out}} = \partial\Omega$;

(iii) given $\rho(x)$ and $A(x) = a(x) I_N$, we identify $q(x)$ by supposing that $\Gamma_{\text{in}} \cup \Gamma_{\text{out}} = \partial\Omega$.

In what follows we suppose that the coefficients ρ, a, q satisfy the following regularity assumptions:

$$\rho \in L^\infty(\Omega) \text{ and } \rho \geq \beta > 0 \text{ for some constant } \beta; \tag{1.13}$$

$$a \geq \alpha > 0 \text{ for some constant } \alpha, \tag{1.14}$$

when $N = 2$

$$a \in W^{1,p}(\Omega) \text{ for some } p > 2, \tag{1.15}$$

when $N \geq 3$

$$a \in C^{1,\frac{1}{2}+\varepsilon}(\overline{\Omega}); \tag{1.16}$$

when $N = 2$

$$q \in L^p(\Omega) \text{ for some } p > 1 \text{ and } q \geq -\mu_1, \tag{1.17}$$

when $N \geq 3$

$$q \in L^p(\Omega) \text{ for some } p > \frac{N}{2}. \tag{1.18}$$

Here μ_1 denotes the first eigenvalue of $-\Delta$ with Dirichlet boundary condition.

In the following theorems we prove the identifiability of the coefficients ρ, a, q in cases (i)–(iii) mentioned above, under hypothesis (1.13)–(1.18). We begin by proving case (i), that is, given q, we prove the identifiability of ρ and a.

THEOREM 1.3. *Under the assumptions of Theorem* 1.1, *let* $\Gamma_{\text{in}} = \Gamma_{\text{out}} = \partial\Omega$, *and, for* $j \in \{0,1\}$, *let* (ρ_j, a_j, q) *be two sets of functions satisfying conditions* (1.13)–(1.18) *such that, when* $N = 2, q \equiv 0$ *in* Ω. *We denote by* u_j *the solutions of problems* (1.10) *when* $(\rho_j, A_j, q_j) := (\rho_j, a_j, q)$. *Suppose that*

$$\Lambda_0(f) = \Lambda_1(f) \quad \text{in } H^{\frac{1}{2}}(\partial\Omega) \tag{1.19}$$

for all $f \in C([0,T]; H^{\frac{3}{2}}(\partial\Omega))$, *where* $\Lambda_j(f)$ *are defined in* (1.11). *Then* $\rho_0 = \rho_1$ *in* Ω *and* $a_0 = a_1$ *in* $\overline{\Omega}$.

We point out that in this case the measurements are global, since Γ_{in} and Γ_{out} coincide with the whole boundary of Ω. In the following theorem, given a, we prove the identifiability of ρ and q.

THEOREM 1.4. *Under the assumptions of Theorem* 1.1, *let* $\Gamma_{\text{in}} = \Gamma_{\text{out}} = \partial\Omega$, *and, for* $j \in \{0,1\}$, *let* (ρ_j, a, q_j) *be two sets of functions satisfying conditions* (1.13)–(1.18) *such that, when* $N = 2, a \equiv 1$ *in* $\overline{\Omega}$. *We denote by* u_j *the solutions of problems* (1.10) *when* $(\rho_j, A_j, q_j) := (\rho_j, a, q_j)$. *Suppose that*

$$\Lambda_0(f) = \Lambda_1(f) \quad \text{in } H^{\frac{1}{2}}(\partial\Omega) \tag{1.20}$$

for all $f \in C([0,T]; H^{\frac{3}{2}}(\partial\Omega))$, *where* $\Lambda_j(f)$ *are defined in* (1.11). *Then* $\rho_0 = \rho_1$ *and* $q_0 = q_1$ *in* Ω.

In the following theorem we give a simplified proof of a result of Nachman, Sylvester, and Uhlmann [22] concerning an N-dimensional Borg–Levinson theorem, which we will use below to prove the identifiability of q in case (iii).

THEOREM 1.5. *Let* $N \geq 2$ *be an integer,* Ω *be a bounded domain in* $\mathbb{R}^N$ *of class* $C^{1,1}$, *and, for* $j \in \{0,1\}$, *let* (ρ, a, q_j) *be a set of functions satisfying conditions* (1.13)–(1.18) *such that, when* $N = 2, a \equiv 1$ *in* $\overline{\Omega}$. *We denote by* $(\lambda_{jk})_{k=1}^{\infty}$ *and* $(\varphi_{jk})_{k=1}^{\infty}$, *respectively, the eigenvalues and the corresponding eigenfunctions of the following problems:*

$$\begin{cases} -\operatorname{div}(a\nabla\varphi_{jk}) + q_j\varphi_{jk} = \lambda_{jk}\rho\varphi_{jk} & \text{in } \Omega, \\ \varphi_{jk} = 0 & \text{on } \partial\Omega, \\ \displaystyle\int_\Omega |\varphi_{jk}|^2 \rho dx = 1. \end{cases} \tag{1.21}$$

Suppose that, for all $k \geq 1$,

$$\lambda_{0k} = \lambda_{1k} \quad \text{and} \quad \psi_{0k} = \psi_{1k} \quad \text{on } \partial\Omega,$$

where $\psi_{jk} := a\frac{\partial}{\partial \mathbf{n}}\varphi_{jk|\partial\Omega}$. *Then* $q_0 = q_1$ *in* Ω.

(Note that the above result is slightly more general than the one given in [21], although the idea of its proof is essentially the same.) As a consequence of Theorems 1.1 and 1.5, given ρ and a, we prove the identifiability of q in case (iii).

THEOREM 1.6. *Under the assumptions of Theorem* 1.1, *let* $\Gamma_{\text{in}} \cup \Gamma_{\text{out}} = \partial\Omega$, *and, for* $j \in \{0,1\}$, *let* (ρ, a, q_j) *be a set of functions satisfying conditions* (1.13)–(1.18) *such that, when* $N = 2, a \equiv 1$ *in* $\overline{\Omega}$. *We denote by* u_j *the solutions of problems* (1.10) *when* $(\rho_j, A_j, q_j) := (\rho, a, q_j)$. *Suppose that*

$$\Lambda_0(f) = \Lambda_1(f) \quad \text{in } H^{\frac{1}{2}}(\Gamma_{\text{out}}) \tag{1.22}$$

for all $f \in C([0,T]\,; H^{\frac{3}{2}}(\Gamma_{\rm in}))$ *such that the* $\mathrm{supp}(f(t,\cdot)) \subset \Gamma_{\rm in}$ *for* $t \in [0,T]$*, where* $\Lambda_j(f)$ *are defined in* (1.11)*. Then* $q_0 = q_1$ *in* Ω.

We point out that in this case the measurements are local, since $\Gamma_{\rm in}$ and $\Gamma_{\rm out}$ are two relatively open pieces of the boundary of Ω.

REMARK 1.7. We emphasize that, as in Theorem 1.1, the conclusions of Theorems 1.3, 1.4, and 1.6 remain valid if we replace hypotheses (1.19), (1.20), (1.22), respectively, by equality of the mean values of the thermal fluxes in the interval $[\tau_0 - T_0, T_0]$. □

The remainder of the paper is organized as follows: in section 2 we gather some preliminary results and the notations used throughout; in section 3 we prove the main results, that is, Theorem 1.1 and Theorem 1.2; in section 4 we prove Theorem 1.5; in section 5 we prove Theorems 1.3, 1.4, and 1.6; finally in section 6 we consider the same problem in the one dimensional setting.

2. Preliminary results and notations. We give now a list of notations which are used throughout the paper.

We denote by Ω a bounded domain in $\mathbb{R}^N, N \geq 2$, with boundary $\partial\Omega$ of class $C^{1,1}$. The functions ρ, A, q satisfy assumptions (1.1)–(1.4).

The thermal flux of the solution u to (1.5) at a point $\sigma \in \partial\Omega$ is denoted by

$$\psi(t,\sigma) := A(\sigma)\nabla u(t,\sigma)\cdot \mathbf{n}(\sigma),$$

where $x \cdot y$ denotes the euclidean scalar product in $\mathbb{R}^N$ and $\mathbf{n}(\sigma)$ is the outer unit normal at $\sigma \in \partial\Omega$.

We denote by $(L, \mathcal{D}(L))$ the elliptic operator

$$Lu := -\mathrm{div}(A\,(x)\,\nabla u) + q(x)u, \tag{2.1}$$

with domain $\mathcal{D}(L) := \left\{u \in H_0^1(\Omega);\ Lu \in L^2_\rho(\Omega)\right\}$, where

$$L^2_\rho(\Omega) := \left\{ f \in L^2(\Omega);\ \int_\Omega |f|^2\,\rho dx < \infty \right\},$$

equipped with the scalar product

$$(f \mid g) := \int_\Omega fg\rho dx.$$

Note that $L^2(\Omega) = L^2_\rho(\Omega)$ with equivalent norms. Actually, when $A \in C^{0,1}(\overline{\Omega})$ and $\partial\Omega$ is of class $C^{1,1}$, then

$$\mathcal{D}(L) = H^2(\Omega) \cap H_0^1(\Omega).$$

The operator L possesses a sequence of eigenvalues $(\lambda_k)_{k=1}^\infty$ (which we suppose in a nondecreasing order) and of corresponding eigenfunctions $(\varphi_k)_{k=1}^\infty$ satisfying

$$\left\{ \begin{array}{rcll} -\mathrm{div}(A\nabla\varphi_k) + q\varphi_k & = & \lambda_k\rho\varphi_k & \text{in } \Omega, \\ \varphi_k & = & 0 & \text{on } \partial\Omega, \\ \int_\Omega |\varphi_k|^2\,\rho dx & = & 1 & \end{array} \right. \tag{2.2}$$

which form a Hilbert basis of $L^2_\rho(\Omega)$. It is also known that the domain $\mathcal{D}(L)$ can be characterized by

$$\mathcal{D}(L) = \left\{ u \in L^2(\Omega);\ \sum_{k=1}^\infty \lambda_k^2\,|(u \mid \varphi_k)|^2 < +\infty \right\}, \tag{2.3}$$

where $(\cdot \mid \cdot)$ is the scalar product in $L^2_\rho(\Omega)$. The flux of the eigenfunction φ_k on $\partial\Omega$ will be denoted by ψ_k, that is,

$$\psi_k := A\nabla\varphi_k \cdot \mathbf{n}_{|\partial\Omega}. \tag{2.4}$$

We denote by m_k the geometric multiplicity of λ_k. We recall also the asymptotic behavior of the eigenvalues λ_k:

$$\lambda_k \sim C_0 k^{\frac{2}{N}} \quad \text{as } k \to +\infty,$$

where the constant C_0 depends on ρ, A, Ω, N (see Courant and Hilbert [10, pp. 442–443]). Moreover there exist two positive constants C_1, C_2 such that, for all $k \geq 1$, one has

$$C_1\lambda_k^2 \leq \|\varphi_k\|^2_{H^2(\Omega)} \leq C_2\lambda_k^2. \tag{2.5}$$

We shall need the following result concerning the linear independence, or linear dependence, of the family $(\psi_k)_{k\geq 1}$ defined above in (2.4). In general these functions are not linearly independent. However, one can show that the normal derivatives of the eigenfunctions corresponding to a given eigenvalue λ_{k_0} are actually independent. More precisely, if λ_k is an eigenvalue of L having multiplicity $m_k \geq 1$, let us denote by $\varphi_{k,i}$ for $1 \leq i \leq m_k$ the eigenfunctions corresponding to the eigenvalue λ_k which form a Hilbert basis of the kernel $N(L - \lambda_k I)$. We may state the following lemma.

LEMMA 2.1. *Under the above conditions* (1.1)–(1.4) *on the coefficients* ρ, A, q, *let* $k \geq 1$ *be fixed. If* λ_k *is an eigenvalue of multiplicity* $m_k \geq 1$ *and* Γ *is a relatively open piece of* $\partial\Omega$, *then the dimension of the subspace spanned in* $L^2(\Gamma)$ *by* $(\psi_{k,i})_{1\leq i\leq m_k}$ *is exactly* m_k.

Proof of Lemma 2.1. Indeed if there exists $(c_i)_{i=1}^{m_k} \in \mathbb{R}^{m_k}$ such that

$$\sum_{i=1}^{m_k} c_i\psi_{k,i} = 0 \qquad \text{on } \Gamma,$$

then setting $\varphi := \sum_{i=1}^{m_k} c_i\varphi_{k,i}$, one checks that

$$L\varphi = \lambda_k\varphi \quad \text{in } \Omega, \qquad \varphi = 0 \quad \text{on } \partial\Omega, \quad A\nabla\varphi \cdot \mathbf{n}_{|\Gamma} = 0 \quad \text{on } \Gamma.$$

So the unique continuation principle at the boundary implies that $\varphi \equiv 0$ in Ω (see Adolfsson and Escauriaza [1]). Due to the fact that the functions $\varphi_{k,i}$ are linearly independent, we conclude that $c_i = 0$ for $1 \leq i \leq m_k$. The proof is complete. ∎

From this we conclude the following.

LEMMA 2.2. *Under the assumptions of Lemma* 2.1, *let* Γ_{in} *and* Γ_{out} *be two relatively open pieces of* $\partial\Omega$. *For a fixed* $k \geq 1$, *consider the function* Θ_k *defined by*

$$\Theta_k(\sigma', \sigma) := \sum_{i=1}^{m_k} \psi_{k,i}(\sigma')\psi_{k,i}(\sigma) \quad \text{on } \Gamma_{\text{in}} \times \Gamma_{\text{out}}.$$

Then $\Theta_k(\sigma', \sigma)$ *is not identically zero on any relatively open subset of* $\Gamma_{\text{in}} \times \Gamma_{\text{out}}$.

Proof of Lemma 2.2. By contradiction, let Γ_1 be a relatively open piece of Γ_{in}, Γ_2 a relatively open piece of Γ_{out}, and

$$\Theta_k(\sigma', \sigma) \equiv 0 \quad \text{on } \Gamma_1 \times \Gamma_2. \tag{2.6}$$

By the previous Lemma 2.1, (2.6) implies that $\psi_{k,i} \equiv 0$ on Γ_1 for $i = 1, \dots, m_k$, and so by the unique continuation result it follows that $\varphi_{k,i} \equiv 0$ on Ω, which leads to a contradiction. □

We shall also need the following algebraic lemma.

LEMMA 2.3. *Let $m \geq 1$ and $n \geq 1$ be two arbitrary integers, Z a nonempty set, X, Y two subsets of Z, $f_i : X \cup Y \to \mathbb{R}$ (for $1 \leq i \leq m$) and $g_\ell : X \cup Y \to \mathbb{R}$ (for $1 \leq \ell \leq n$) functions such that*

$$\sum_{i=1}^{m} f_i(x) f_i(y) = \sum_{\ell=1}^{n} g_\ell(x) g_\ell(y) \quad \text{for } x, y \in X \times Y. \tag{2.7}$$

Assume moreover that

(i) *$\{f_1, \dots, f_m\}$ (resp., $\{g_1, \dots, g_n\}$) are linearly independent in $X \cup Y$;*

(ii) *$X \cap Y$ contains infinitely many points;*

(iii) *f_i, for $1 \leq i \leq m$, (resp., g_ℓ, for $1 \leq \ell \leq n$) are not identically zero in $X \cap Y$.*

Then $m = n$, and denoting

$$F(x) := \begin{pmatrix} f_1(x) \\ \vdots \\ f_m(x) \end{pmatrix} \quad \text{and} \quad G(x) := \begin{pmatrix} g_1(x) \\ \vdots \\ g_n(x) \end{pmatrix},$$

there exists an $m \times m$ orthogonal matrix M such that for all $z \in X \cup Y$ one has $F(z) = MG(z)$.

(Recall that by an orthogonal matrix M we mean $MM^* = M^*M = I_m$.)

Proof of Lemma 2.3. Let us denote by V_0 (resp., V_1) the space spanned by $\{f_1, \dots, f_m\}$ (resp., $\{g_1, \dots, g_n\}$). As f_1 is not identically zero in $X \cap Y$, there exists $x_1 \in X \cap Y$ such that $f_1(x_1) \neq 0$. Then, f_2 being independent of f_1, and $X \cap Y$ containing infinitely many points, there exists $x_2 \in X \cap Y$ such that

$$\det \begin{pmatrix} f_1(x_1) & f_2(x_1) \\ f_1(x_2) & f_2(x_2) \end{pmatrix} \neq 0.$$

By induction one sees that we may find points $x_1, x_2, \dots, x_m$ in $X \cap Y$ such that the $m \times m$ matrix

$$P := \begin{pmatrix} f_1(x_1) & f_2(x_1) & \cdots & f_m(x_1) \\ f_1(x_2) & f_2(x_2) & \cdots & f_m(x_2) \\ \vdots & \vdots & \vdots & \vdots \\ f_1(x_m) & f_2(x_m) & \cdots & f_m(x_m) \end{pmatrix}$$

is invertible. So, setting $x = x_j$ in (2.7), it follows that $PF(y) = \widetilde{P}G(y)$ in Y, where $\widetilde{P}$ is the following $m \times n$ matrix:

$$\widetilde{P} := \begin{pmatrix} g_1(x_1) & g_2(x_1) & \cdots & g_n(x_1) \\ g_1(x_2) & g_2(x_2) & \cdots & g_n(x_2) \\ \vdots & \vdots & \vdots & \vdots \\ g_1(x_m) & g_2(x_m) & \cdots & g_n(x_m) \end{pmatrix}.$$

From this it follows that $F(y) = P^{-1}\widetilde{P}G(y)$ for all $y \in Y$, where P^{-1} is the inverse matrix of P.

Similarly, changing the role of the variables x and y, we obtain that $F(x) = P^{-1}\widetilde{P}G(x)$ in X, that is,

$$F(z) = MG(z) \quad \text{in } X \cup Y,$$

where $M := P^{-1}\widetilde{P}$. Therefore, recalling that the functions $\{f_1, \dots, f_m\}$ and $\{g_1, \dots, g_n\}$ are linearly independent in $X \cup Y$, it follows that $V_0 \subseteq V_1$, that is, $m \leq n$. In the same way one may prove that $n \leq m$, and so we conclude that $m = n$.

Finally we prove that the matrix $M = P^{-1}\widetilde{P}$ is orthogonal. Indeed, recalling that $F(z) = MG(z)$ for all $z \in X \cup Y$ and using (2.7), we obtain

$$(M^*M - I_m)G(x) \cdot G(y) = 0 \quad \text{in } X \times Y,$$

where $a \cdot b$ denotes the euclidean scalar product in $\mathbb{R}^m$, M^* is the transpose matrix of M, and I_m is the $m \times m$ identity matrix. Since the functions $\{g_1, \dots, g_m\}$ are linearly independent in $X \cup Y$ it follows that $M^*M = MM^* = I_m$, that is, M is orthogonal. The proof is complete. ∎

3. Proof of Theorems 1.1 and 1.2. We begin this section with two lemmas which will be needed later on. First we give a representation formula for the solution u of problem (1.5).

LEMMA 3.1. *Let Ω be a $C^{1,1}$ bounded domain in $\mathbb{R}^N$, (ρ, A, q) be a set of functions satisfying assumptions* (1.1)–(1.4)*, and $f \in C([0,T]\,; H^{\frac{3}{2}}(\partial\Omega))$. Then the problem*

$$\text{(3.1)} \qquad \begin{cases} \rho(x)\partial_t u - \operatorname{div}(A(x)\nabla u) + q(x)u &= 0 & \text{in } (0,T)\times\Omega, \\ u(0) &= 0 & \text{in } \Omega, \\ u(t,\sigma) &= f(t,\sigma) & \text{on } (0,T)\times\partial\Omega \end{cases}$$

has a unique solution $u \in C((0,T]; H^2(\Omega)) \cap C^1([0,T]\,; L^2(\Omega))$. Moreover, u can be written in the following Fourier expansion:

$$\text{(3.2)} \qquad u(t) = \sum_{k=1}^{\infty} \alpha_k(t)\varphi_k \quad \text{in } L^2_\rho(\Omega),$$

where $\alpha_k(t)$ are the Fourier coefficients of $u(t)$.

Proof of Lemma 3.1. By the classical theory of semigroups (see, for example, Cazenave and Haraux [7]) we know that there exists a unique solution of (3.1) such that $u \in C((0,T]; H^2(\Omega)) \cap C^1([0,T]\,; L^2(\Omega))$. Now, since $(\varphi_k)_{k=1}^{\infty}$ defined in (2.2) is a Hilbert basis in $L^2_\rho(\Omega)$, we can write the solution u in the following Fourier expansion:

$$u(t) = \sum_{k=1}^{\infty} \alpha_k(t)\varphi_k \quad \text{in } L^2_\rho(\Omega),$$

where the coefficient $\alpha_k(t) := (u(t) \mid \varphi_k)$ solves

$$\text{(3.3)} \qquad \begin{cases} \frac{d}{dt}\alpha_k(t) + \lambda_k\alpha_k(t) &= -\int_{\partial\Omega} \psi_k(\sigma')f(t,\sigma')d\sigma' \quad \text{in } (0,T), \\ \alpha_k(0) &= 0. \end{cases}$$

Here $\frac{d}{dt}\alpha_k(t)$ denotes the derivative of $\alpha_k(t)$, and $\psi_k(\sigma') := A(\sigma')\nabla\varphi_k(\sigma') \cdot \mathbf{n}(\sigma')$. A direct calculation gives

$$\text{(3.4)} \qquad \alpha_k(t) = -\int_0^t \int_{\partial\Omega} \psi_k(\sigma')e^{-\lambda_k(t-\tau)}f(\tau,\sigma')d\sigma'd\tau.$$

Lemma 3.1 is proved. □

In the following lemma we give, under a suitable choice of the Dirichlet boundary datum f, a representation formula for the thermal flux $A\nabla u(T_0)\cdot\mathbf{n}_{|\partial\Omega}$ at a given time T_0 on $\partial\Omega$.

LEMMA 3.2. *Under the assumptions of Lemma* 3.1*, we suppose that the Dirichlet boundary datum f in* (3.1) *satisfies the following condition:*

$$f \equiv 0 \quad \text{on } [T_0-\varepsilon_0, T_0]\times\partial\Omega,$$

where $T_0 \in (0,T]$ and $0<\varepsilon_0<T_0$. Then the thermal flux $A\nabla u(T_0)\cdot\mathbf{n}_{|\partial\Omega}$ at a given time T_0 on $\partial\Omega$ can be written in the following form:

$$A(\sigma)\nabla u(T_0,\sigma)\cdot\mathbf{n}(\sigma) = -\int_0^{T_0-\varepsilon_0}\int_{\partial\Omega}\sum_{k=1}^{\infty}\Psi_k(\sigma',\sigma,T_0-\tau)f(\tau,\sigma')d\sigma' d\tau$$

for almost everywhere (a.e.) $\sigma\in\partial\Omega$, where $\Psi_k(\sigma',\sigma,\tau) := \psi_k(\sigma')\,\psi_k(\sigma)e^{-\lambda_k\tau}$.

Proof of Lemma 3.2. We divide the proof into three steps.

Step 1. In this step we prove that, under a suitable choice of the Dirichlet datum f in (3.1), the series (3.2) converges at the time T_0, say, for instance, in $H^2(\Omega)$, so that we can take the trace of $\nabla u(T_0)_{|\partial\Omega}$ on $\partial\Omega$. In fact, by Lemma 3.1 we know that $u\in C((0,T];H^2(\Omega))\cap C^1([0,T];L^2(\Omega))$. In particular, choosing the Dirichlet datum f in such a way that $f\equiv 0$ on $[T_0-\varepsilon_0,T_0]\times\partial\Omega$, it follows that $u(T_0)\in\mathcal{D}(L)$, where $\mathcal{D}(L) := H^2(\Omega)\cap H_0^1(\Omega)$. Then, using the characterization (2.3) of the domain $\mathcal{D}(L)$, it follows that

$$\sum_{k=1}^{\infty}\lambda_k^2\,|\alpha_k(T_0)|^2 < \infty,$$

where $\alpha_k(T_0) = (u(T_0)\mid\varphi_k)$. Now, setting $u_m(T_0) := \sum_{k=1}^m \alpha_k(T_0)\varphi_k$, then $u_m(T_0)\to u(T_0)$ in $L^2_\rho(\Omega)$ as $m\to+\infty$; moreover, it is easy to verify that

$$Lu_m(T_0) - Lu(T_0) \to 0 \quad \text{in } L^2_\rho(\Omega).$$

So, by the estimate $\|u_m(T_0)\|_{H^2(\Omega)} \le C\,\|Lu_m(T_0)\|_{L^2_\rho(\Omega)}$, it follows that $(u_m(T_0))_{m=1}^\infty$ is a Cauchy sequences in $H^2(\Omega)$, and therefore

$$u(T_0) = \sum_{k=1}^{\infty}\alpha_k(T_0)\,\varphi_k \quad \text{in } H^2(\Omega). \tag{3.5}$$

Step 2. In this step we prove that the conormal derivative of the series (3.5) coincides with the series of the conormal derivative in $H^{\frac12}(\partial\Omega)$. In fact, it is well known that the trace operator $\gamma : u\to\frac{\partial}{\partial\mathbf{n}}u_{|\partial\Omega}$ is continuous from $H^2(\Omega)$ to $H^{\frac12}(\partial\Omega)$ (see, for example, Lions and Magenes [20]). Then one has, in the sense of $H^{\frac12}(\partial\Omega)$,

$$\frac{\partial}{\partial\mathbf{n}}u(T_0)_{|\partial\Omega} = -\sum_{k=1}^{\infty}\left(\int_0^{T_0-\varepsilon_0}\int_{\partial\Omega}\psi_k(\sigma')e^{-\lambda_k(T_0-\tau)}f(\tau,\sigma')d\sigma' d\tau\right)\frac{\partial}{\partial\mathbf{n}}\varphi_{k|\partial\Omega}$$

and

$$A(\sigma)\nabla u(T_0,\sigma)\cdot\mathbf{n}(\sigma) = -\sum_{k=1}^{\infty}\int_0^{T_0-\varepsilon_0}\int_{\partial\Omega}\Psi_k(\sigma',\sigma,T_0-\tau)f(\tau,\sigma')d\sigma' d\tau \tag{3.6}$$

for a.e. $\sigma \in \partial\Omega$, where $\Psi_k(\sigma', \sigma, \tau) := \psi_k(\sigma')\,\psi_k(\sigma)e^{-\lambda_k \tau}$.

Step 3. In this step we prove that we can commute the series sign with the integral signs in the right-hand side of (3.6).

By Fubini's theorem it is sufficient, for example, to show that

$$\mathcal{I} := \int_0^{T_0-\varepsilon_0} \sum_{k=1}^{\infty} \int_{\partial\Omega} \left|\psi_k(\sigma') e^{-\lambda_k(T_0-\tau)} f(\tau,\sigma')\right| \, \|\psi_k\|_{H^{\frac{1}{2}}(\partial\Omega)} d\sigma' d\tau < \infty.$$

In fact, denoting by $\langle\cdot,\cdot\rangle$ the duality $H^{-\frac{3}{2}}(\partial\Omega), H^{\frac{3}{2}}(\partial\Omega)$, we derive that

$$\begin{aligned}
\mathcal{I} &\le \int_0^{T_0-\varepsilon_0} \sum_{k=1}^{\infty} |\langle \psi_k, f(\tau)\rangle| \, \|\psi_k\|_{H^{\frac{1}{2}}(\partial\Omega)} \, e^{-\lambda_k \varepsilon_0} d\tau \\
&\le \int_0^{T_0-\varepsilon_0} \|f(\tau)\|_{H^{\frac{3}{2}}(\partial\Omega)} \, d\tau \sum_{k=1}^{\infty} \|\psi_k\|_{H^{-\frac{3}{2}}(\partial\Omega)} \, \|\psi_k\|_{H^{\frac{1}{2}}(\partial\Omega)} \, e^{-\lambda_k \varepsilon_0} \\
&\le C \sum_{k=1}^{\infty} \lambda_k^2 e^{-\lambda_k \varepsilon_0},
\end{aligned}$$

where the last inequality is obtained upon using the fact that, by the trace theorem and (2.5), we have

$$\begin{aligned}
\|\psi_k\|_{H^{-\frac{3}{2}}(\partial\Omega)} &\le \|\psi_k\|_{H^{\frac{1}{2}}(\partial\Omega)} \\
&\le C \, \|\varphi_k\|_{H^2(\Omega)} \le C\lambda_k.
\end{aligned}$$

Note that $\sum_{k=1}^{\infty} \lambda_k^2 e^{-\lambda_k \varepsilon_0} < \infty$ since we know that $\lambda_k \sim k^{\frac{2}{N}}$, as $k \to +\infty$. Therefore we may write (3.6) as

$$A(\sigma)\nabla u(T_0,\sigma)\cdot \mathbf{n}(\sigma) = -\int_0^{T_0-\varepsilon_0} \int_{\partial\Omega} \sum_{k=1}^{\infty} \Psi_k(\sigma', \sigma, T_0-\tau) f(\tau,\sigma') d\sigma' d\tau. \tag{3.7}$$

The proof of Lemma 3.2 is complete. □

LEMMA 3.3. *Under the assumptions of Theorem* 1.1, *let* $\overline{u_j}, j \in \{0,1\}$, *be solutions of* (1.10), *with initial data* $\overline{u_{0j}} \equiv 0$ *in* Ω, *and boundary data* $\overline{\varphi_j} \equiv 0$ *on* $(0,T)\times\partial\Omega\backslash\Gamma_{\text{in}}$. *If we denote by* $\overline{\Lambda_j}(f) := A_j\nabla\overline{u_j}(T_0)\cdot\mathbf{n}_{|\Gamma_{\text{out}}}$ *the output data of the solutions* $\overline{u_j}$, *then*

$$\overline{\Lambda_0}(f) = \overline{\Lambda_1}(f)$$

for all $f \in C([0,T]; H^{\frac{3}{2}}(\Gamma_{\text{in}}))$ *such that the* $\text{supp}(f(t,\cdot)) \subset \Gamma_{\text{in}}$ *for* $t \in [0,T]$.

Proof of Lemma 3.3. Indeed, following Rakesh and Symes [25], setting $\overline{u_j}(t,x) := u_j(t,x) - v_j(t,x)$, where v_j are solutions of (1.10) with data $v_j(0) = u_{0j}$ in $\Omega, v_j = \varphi_j$ on $(0,T)\times\partial\Omega\backslash\Gamma_{\text{in}}$, and $v_j \equiv 0$ on $(0,T)\times\Gamma_{\text{in}}$, one checks that $\overline{u_j}$ are solutions of (1.10) with initial data $\overline{u_{0j}} \equiv 0$ in Ω and boundary data $\overline{\varphi_j} \equiv 0$ on $(0,T)\times\partial\Omega\backslash\Gamma_{\text{in}}$. So, if we denote by $\overline{\Lambda_j}(f) := A_j\nabla\overline{u_j}(T_0)\cdot\mathbf{n}_{|\Gamma_{\text{out}}}$ the output data of the solutions $\overline{u_j}$, it follows that

$$\overline{\Lambda_j}(f) = \Lambda_j(f) - \Lambda_j(0),$$

and therefore $\overline{\Lambda_0}(f) = \overline{\Lambda_1}(f)$ for all $f \in C([0,T]\,; H^{\frac{3}{2}}(\Gamma_{\text{in}}))$ such that the support $\text{supp}(f(t,\cdot)) \subset \Gamma_{\text{in}}$ for $t \in [0,T]$.

The proof is complete. □

In what follows we will suppose that in (1.10) the initial data $u_{0j} \equiv 0$ in Ω and the boundary data $\varphi_j \equiv 0$ on $(0,T) \times \partial\Omega \backslash \Gamma_{\rm in}$.

LEMMA 3.4. *Under the assumptions of Theorem* 1.1, *for all* $k \geq 1$, *we have*

$$\lambda_{0k} = \lambda_{1k},$$

and

$$\sum_{i=1}^{m_{0k}} \psi_{0k,i}(\sigma')\,\psi_{0k,i}(\sigma) = \sum_{\ell=1}^{m_{1k}} \psi_{1k,\ell}(\sigma')\,\psi_{1k,\ell}(\sigma) \quad \text{on } \Gamma_{\rm in} \times \Gamma_{\rm out}.$$

(As we have mentioned in section 2, m_{jk} is the multiplicity of the eigenvalue λ_{jk}.)

Proof of Lemma 3.4. We recall that by hypothesis we have

$$A_0 \nabla u_0(T_0) \cdot \mathbf{n}_{|\Gamma_{\rm out}} = A_1 \nabla u_1(T_0) \cdot \mathbf{n}_{|\Gamma_{\rm out}} \quad \text{in } H^{\frac{1}{2}}(\Gamma_{\rm out}) \tag{3.8}$$

for all $f \in C([0,T]; H^{\frac{3}{2}}(\Gamma_{\rm in}))$ such that the support $\mathrm{supp}(f(t,\cdot)) \subset \Gamma_{\rm in}$ for $t \in [0,T]$. By Lemma 3.2, when $u := u_j, j \in \{0,1\}$, we know that if the input f is chosen in such a way that $f \equiv 0$ on $[T_0 - \varepsilon_0, T_0] \times \Gamma_{\rm in}$, then the fluxes $A_j \nabla u_j(T_0) \cdot \mathbf{n}_{|\Gamma_{\rm out}}$ on $\Gamma_{\rm out}$ can be written in the following form:

$$A_j(\sigma) u(T_0,\sigma) \cdot \mathbf{n}(\sigma) = -\int_0^{T_0-\varepsilon_0} \int_{\Gamma_{\rm in}} \sum_{k=1}^{\infty} \Psi_{jk}(\sigma',\sigma,T_0-\tau) f(\tau,\sigma') d\sigma' d\tau$$

for a.e. $\sigma \in \Gamma_{\rm out}$, where

$$\Psi_{jk}(\sigma',\sigma,\tau) := \psi_{jk}(\sigma')\,\psi_{jk}(\sigma)\,e^{-\lambda_{jk}\tau}. \tag{3.9}$$

Then, from (3.8), it follows that

$$\int_0^{T_0-\varepsilon_0} \int_{\Gamma_{\rm in}} \sum_{k=1}^{\infty} (\Psi_{0k}(\sigma',\sigma,T_0-\tau) - \Psi_{1k}(\sigma',\sigma,T_0-\tau)) f(\tau,\sigma') d\sigma' d\tau = 0 \tag{3.10}$$

for a.e. $\sigma \in \Gamma_{\rm out}$. In particular we may assume that the input $f(\tau,\sigma') \equiv 0$ for $\tau \neq [T' - \varepsilon', T' + \varepsilon']$ and $\sigma' \in \Gamma_{\rm in}$, where T' is a fixed time, $T' \in (0, T_0 - \varepsilon_0)$, and $0 < \varepsilon' < T'$. Then (3.10) becomes

$$\int_{T'-\varepsilon'}^{T'+\varepsilon'} \int_{\Gamma_{\rm in}} \sum_{k=1}^{\infty} (\Psi_{0k}(\sigma',\sigma,T_0-\tau) - \Psi_{1k}(\sigma',\sigma,T_0-\tau)) f(\tau,\sigma') d\sigma' d\tau = 0$$

for all such functions f. Hence it follows that

$$\sum_{k=1}^{\infty} \Psi_{0k}(\sigma',\sigma,\tau) = \sum_{k=1}^{\infty} \Psi_{1k}(\sigma',\sigma,\tau) \quad \text{on } \Gamma_{\rm in} \times \Gamma_{\rm out}$$

for all $\tau \in [T' - \varepsilon', T' + \varepsilon']$. Therefore, by the unique continuation principle for analytic functions of the variable τ, we obtain that

$$\sum_{k=1}^{\infty} \Theta_{0k}(\sigma',\sigma) e^{-\lambda_{0k}\tau} = \sum_{k=1}^{\infty} \Theta_{1k}(\sigma',\sigma) e^{-\lambda_{1k}\tau} \quad \text{on } \Gamma_{\rm in} \times \Gamma_{\rm out} \tag{3.11}$$

for all $\tau \in (0,\infty)$, where $\Theta_{jk}(\sigma',\sigma) := \sum_{i=1}^{m_{jk}} \psi_{jk,i}(\sigma')\,\psi_{jk,i}(\sigma)$. Now, by Lemma 2.2, we know that $\Theta_{jk}(\sigma',\sigma)$ is not identically zero on any relatively open subset of $\Gamma_{\rm in}\times\Gamma_{\rm out}$. So, using the classical results on Dirichlet's series, (3.11) yields that, for all $k \geq 1$,

$$\lambda_{0k} = \lambda_{1k} \tag{3.12}$$

and

$$\Theta_{0k}(\sigma',\sigma) = \Theta_{1k}(\sigma',\sigma) \quad \text{on } \Gamma_{\rm in}\times\Gamma_{\rm out},$$

that is,

$$\sum_{i=1}^{m_{0k}} \psi_{0k,i}(\sigma')\,\psi_{0k,i}(\sigma) = \sum_{i=1}^{m_{1k}} \psi_{1k,i}(\sigma')\,\psi_{1k,i}(\sigma) \quad \text{on } \Gamma_{\rm in}\times\Gamma_{\rm out}. \tag{3.13}$$

The proof of Lemma 3.4 is complete. □

We are now in a position to prove Theorem 1.1.

Proof of Theorem 1.1. We prove that (3.13) implies that, for all $k \geq 1, m_{0k} = m_{1k}$ and, up to an appropriate choice of the eigenfunctions $\varphi_{0k}, \psi_{0k} = \psi_{1k}$ on $\Gamma_{\rm in}\cup\Gamma_{\rm out}$.

For a fixed $k \geq 1$, let us note that, by Lemma 2.1, $\psi_{jk,i}$, for $i = 1,\dots,m_{jk}$ and $j \in \{0,1\}$, are linearly independent in $L^2(\Gamma_{\rm in}\cup\Gamma_{\rm out})$. Now, applying the algebraic Lemma 2.3 with $m := m_{0k}, n := m_{1k}, Z := \Gamma_{\rm in}\cup\Gamma_{\rm out}, X := \Gamma_{\rm in}, Y := \Gamma_{\rm out}$, and F and G, respectively, the vectors

$$F := \begin{pmatrix} \psi_{0k,1|Z} \\ \vdots \\ \psi_{0k,m_{0k}|Z} \end{pmatrix} \quad \text{and} \quad G := \begin{pmatrix} \psi_{1k,1|Z} \\ \vdots \\ \psi_{1k,m_{1k}|Z} \end{pmatrix},$$

we derive that $m_{0k} = m_{1k}$, and there exists an $m\times m$ orthogonal matrix M, where $m := m_{0k} = m_{1k}$, such that

$$F(z) = MG(z) \quad \text{for } z \in \Gamma_{\rm in}\cup\Gamma_{\rm out}. \tag{3.14}$$

We prove now that $\psi_{0k,i} = \psi_{1k,i}$ on $\Gamma_{\rm in}\cup\Gamma_{\rm out}$, for $i = 1,\dots,m$, up to an appropriate choice of the eigenfunctions $\varphi_{0k,i}$. To prove this, let us define the vector

$$\widetilde{\varphi_0} := M^*\varphi_0^*,$$

where M^* is the transpose matrix of M, that is, $M^*_{ir} = M_{ri}$, and φ_0^* is the transpose vector of $\varphi_0 = (\varphi_{0k,1},\dots,\varphi_{0k,m})$. First let us note that

$$(\widetilde{\varphi_{0k,i}} \mid \widetilde{\varphi_{0k,\ell}}) = \delta_{i\ell} \quad \text{for } 1 \leq i,\ell \leq m,$$

where $(\cdot\mid\cdot)$ denotes the scalar product in $L^2_\rho(\Omega)$, and $\delta_{i\ell}$ is the Kronecker's symbol. In fact, $\widetilde{\varphi_{0k,i}} = \sum_{r=1}^m M^*_{ir}\varphi_{0k,r}$, and $\widetilde{\varphi_{0k,\ell}} = \sum_{s=1}^m M^*_{\ell s}\varphi_{0k,s} = \sum_{s=1}^m \varphi_{0k,s}M_{s\ell}$, so

$$\begin{aligned}(\widetilde{\varphi_{0k,i}} \mid \widetilde{\varphi_{0k,\ell}}) &= \sum_{r=1}^m\sum_{s=1}^m M^*_{ir}M_{s\ell}\delta_{rs} \\ &= \sum_{r=1}^m M^*_{ir}M_{r\ell} = \delta_{i\ell},\end{aligned}$$

where the last equality follows since the matrix M is orthogonal.

Now

$$\widetilde{\psi_{0k,i}} = A_0 \nabla \widetilde{\varphi_{0k,i}} \cdot \mathbf{n} = \sum_{\kappa=1}^{N} \sum_{\iota=1}^{N} a_{0,\kappa\iota} \frac{\partial}{\partial x_\iota} \widetilde{\varphi_{0k,i}} \mathbf{n}_\kappa$$

and

$$\frac{\partial}{\partial x_\iota} \widetilde{\varphi_{0k,i}} = \sum_{\ell=1}^{m} M^*_{i\ell} \frac{\partial}{\partial x_\iota} \varphi_{0k,\ell}.$$

So, substituting in $\widetilde{\psi_{0k,i}}$, we obtain that

$$\begin{aligned} \widetilde{\psi_{0k,i}} &= \sum_{\kappa=1}^{N} \sum_{\iota=1}^{N} a_{0,\kappa\iota} \sum_{\ell=1}^{m} M^*_{i\ell} \frac{\partial}{\partial x_\iota} \varphi_{0k,\ell} \mathbf{n}_\kappa \\ &= \sum_{\ell=1}^{m} M^*_{i\ell} \sum_{\kappa=1}^{N} \sum_{\iota=1}^{N} a_{0,\kappa\iota} \frac{\partial}{\partial x_\iota} \varphi_{0k,\ell} \mathbf{n}_\kappa \\ &= \sum_{\ell=1}^{m} M^*_{i\ell} \psi_{0k,\ell}. \end{aligned}$$

Now, by (3.14), we know that $\psi_{0k,\ell} = \sum_{j=1}^{m} M_{\ell j} \psi_{1k,j}$. Then, substituting in the last equality, it follows that

$$\begin{aligned} \widetilde{\psi_{0k,i}} &= \sum_{\ell=1}^{m} M^*_{i\ell} \sum_{j=1}^{m} M_{\ell j} \psi_{1k,j} \\ &= \sum_{j=1}^{m} \psi_{1k,j} \sum_{\ell=1}^{m} M^*_{i\ell} M_{\ell j} = \psi_{1k,i} \end{aligned}$$

on $\Gamma_{\text{in}} \cup \Gamma_{\text{out}}$, for $1 \le i \le m$, where the last equality follows since the matrix M is orthogonal. The proof of Theorem 1.1 is complete. □

We end this section by proving Theorem 1.2, that is, we show that Theorem 1.1 remains valid if hypothesis (1.12) is replaced by equality of the mean values of the fluxes in the interval $[T_0 - \tau_0, T_0]$, i.e., we suppose that

$$\int_{T_0-\tau_0}^{T_0} A_0 \nabla u_0(t) \cdot \mathbf{n}_{|\Gamma_{\text{out}}} dt = \int_{T_0-\tau_0}^{T_0} A_1 \nabla u_1(t) \cdot \mathbf{n}_{|\Gamma_{\text{out}}} dt \quad \text{in } H^{\frac{1}{2}}(\Gamma_{\text{out}}) \tag{3.15}$$

for all $f \in C([0,T]; H^{\frac{3}{2}}(\Gamma_{\text{in}}))$ such that the support $\text{supp}(f(t,\cdot)) \subset \Gamma_{\text{in}}$ for $t \in [0,T]$.

Proof of Theorem 1.2. First of all, using Lemma 3.3, we can always reduce to the case where in (1.10) the initial data $u_{0j} \equiv 0$ in Ω and the boundary data $\varphi_j \equiv 0$ on $(0,T) \times \partial\Omega \backslash \Gamma_{\text{in}}$. Now, choosing the Dirichlet data f in such a way that $f \equiv 0$ on $[T_0 - \varepsilon_0, T_0] \times \Gamma_{\text{in}}$, where ε_0 is such that $\tau_0 < \varepsilon_0 < T_0$, we write the solutions u_j in the Fourier expansion (3.2), i.e.,

$$u_j(t) = -\sum_{k=1}^{\infty} \int_0^{T_0-\varepsilon_0} \int_{\Gamma_{\text{in}}} \psi_{jk}(\sigma') e^{-\lambda_{jk}(t-\tau)} f(\tau,\sigma') d\sigma' d\tau \varphi_{jk} \quad \text{in } L^2_\rho(\Omega)$$

for $t \in [T_0 - \tau_0, T_0]$. In particular, by Lemma 3.2, we derive that

$$A_j(\sigma)\nabla u_j(t,\sigma)\cdot \mathbf{n}(\sigma) = \int_0^{T_0-\varepsilon_0} \int_{\Gamma_{\rm in}} \sum_{k=1}^{\infty} \Psi_{jk}(\sigma',\sigma,t-\tau) f(\tau,\sigma') d\sigma' d\tau \tag{3.16}$$

for $t \in [T_0 - \tau_0, T_0]$ and a.e. $\sigma \in \partial\Omega$, where Ψ_{jk} are defined in (3.9). Now, (3.15) and the change of variable $t - \tau = s$ in the right-hand side of (3.16) imply that

$$\int_{T_0-\tau_0}^{T_0} \int_{t-T_0+\varepsilon_0}^{t} \int_{\Gamma_{\rm in}} \sum_{k=1}^{\infty} (\Psi_{0k}(\sigma',\sigma,s) - \Psi_{1k}(\sigma',\sigma,s)) f(t-s,\sigma') d\sigma' ds dt = 0. \tag{3.17}$$

We may assume that the input $f(s,\sigma') \equiv 0$ for $s \notin [T' - \varepsilon', T' + \varepsilon']$ and $\sigma' \in \Gamma_{\rm in}$, where $T' \in (\frac{T_0-\tau_0}{2}, \frac{T_0}{2})$ is a fixed time, and $0 < \varepsilon' < T'$. Then (3.17) becomes

$$\int_{T_0-\tau_0}^{T_0} \int_{t-T'-\varepsilon'}^{t-T'+\varepsilon'} \int_{\Gamma_{\rm in}} \sum_{k=1}^{\infty} (\Psi_{0k}(\sigma',\sigma,s) - \Psi_{1k}(\sigma',\sigma,s)) f(t-s,\sigma') d\sigma' ds dt = 0$$

for all such functions f. Hence it follows that

$$\sum_{k=1}^{\infty} \Psi_{0k}(\sigma',\sigma,s) = \sum_{k=1}^{\infty} \Psi_{1k}(\sigma',\sigma,s) \quad \text{on } \Gamma_{\rm in} \times \Gamma_{\rm out}$$

for all $s \in [T' - \varepsilon', T' + \varepsilon']$. Therefore, by the unique continuation principle for analytic functions of the variable s, we obtain that

$$\sum_{k=1}^{\infty} \Theta_{0k}(\sigma',\sigma) e^{-\lambda_{0k} s} = \sum_{k=1}^{\infty} \Theta_{1k}(\sigma',\sigma) e^{-\lambda_{1k} s} \quad \text{on } \Gamma_{\rm in} \times \Gamma_{\rm out} \tag{3.18}$$

for all $s \in (0,\infty)$, where $\Theta_{jk}(\sigma',\sigma) := \sum_{i=1}^{m_{jk}} \psi_{jk,i}(\sigma') \psi_{jk,i}(\sigma)$. Now, using the classical results on Dirichlet series, (3.18) yields that, for all $k \geq 1$,

$$\lambda_{0k} = \lambda_{1k}$$

and

$$\sum_{i=1}^{m_{0k}} \psi_{0k,i}(\sigma') \psi_{0k,i}(\sigma) = \sum_{i=1}^{m_{1k}} \psi_{1k,i}(\sigma') \psi_{1k,i}(\sigma) \quad \text{on } \Gamma_{\rm in} \times \Gamma_{\rm out}.$$

Finally, following the proof of Theorem 1.1, we derive that, for all $k \geq 1, \lambda_{0k} = \lambda_{1k}$ and $\psi_{0k} = \psi_{1k}$ on $\Gamma_{\rm in} \cup \Gamma_{\rm out}$.

The proof of Theorem 1.2 is complete. □

4. Recovering coefficients via BSD. In this section we prove the result stated in Theorem 1.5.

In the last decade many authors have devoted considerable attention to the problem of identifiability of the coefficients in elliptic equations; see, for example, Calderón [6]; Kohn and Vogelius [16, 17]; Sylvester and Uhlmann [26]; Nachman, Sylvester, and Uhlmann [22]; Nachman [23, 24]; Isakov [13]; Alessandrini [2]; Chanillo [9]; Brown [4]; Brown and Uhlmann [5]. More precisely, let us recall the following uniqueness result

(for the proof see Isakov [15, Corollary 5.4.2, p. 119], for $N = 2$, and, for example, Sylvester and Uhlmann [26] for $N \geq 3$; see also the survey paper by Uhlmann [27]).

THEOREM 4.1. *Let $N \geq 2$ be an integer, Ω a bounded domain in $\mathbb{R}^N$ of class $C^{0,1}$, and, for $j \in \{0,1\}$, let (a_j, q_j) be two pairs of functions satisfying conditions (1.14)–(1.18). Let w_j solve*

$$\left\{ \begin{array}{rcl} -\mathrm{div}(a_j \nabla w_j) + q_j w_j &=& 0 \quad \text{in } \Omega, \\ w_j &=& \varphi \quad \text{on } \partial\Omega. \end{array} \right. \tag{4.1}$$

Suppose that, when $N = 2$, either $q_0 = q_1 \equiv 0$ in Ω or $a_0 = a_1 \equiv 1$ in $\overline{\Omega}$ while, when $N \geq 3$, either $q := q_0 = q_1$ or $a := a_0 = a_1$ and

$$\gamma_0(\varphi) = \gamma_1(\varphi) \quad \text{in } H^{-\frac{1}{2}}(\partial\Omega)$$

for all $\varphi \in H^{\frac{1}{2}}(\partial\Omega)$, where $\gamma_j(\varphi) := a_j \frac{\partial}{\partial \mathbf{n}} w_{j|\partial\Omega}$ denote the fluxes of w_j on $\partial\Omega$. Then one has that $a_0 = a_1$ in $\overline{\Omega}$ and $q_0 = q_1$ in Ω.

In 1946 Borg [3] and Levinson [19] asked the following question: does knowledge of the eigenvalues $(\lambda_k)_{k=1}^{\infty}$ of the Sturm–Liouville problem

$$\left\{ \begin{array}{rcll} -v_k'' + q v_k &=& \mu_k v_k & \text{in } (0,\ell), \\ v_k(0) &=& 0, & \\ v_k(\ell) &=& 0 & \end{array} \right.$$

determine q uniquely? It is clear that if $q_0(x) := q(x)$ and $q_1(x) := q(\ell - x)$, the operators A_j, defined by $A_j u := -u'' + q_j u$, have the same eigenvalues: therefore, the spectrum alone in general is not sufficient to determine the potential q uniquely. Later Gel'fand and Levitan [11] proved that knowledge of the eigenvalues $(\lambda_k)_{k=1}^{\infty}$ and of the normalizing constants

$$c_k := \int_0^{\ell} |v_k|^2 \, dx,$$

by supposing $v_k'(0) = 1$, determines q uniquely. In Theorem 1.5 we consider a similar problem in the N-dimensional setting. More precisely, we give a simplified proof of an N-dimensional Borg–Levinson result of Nachman, Sylvester, and Uhlmann [22]. To be in a position to prove Theorem 1.5 we need the following two auxiliary lemmas.

LEMMA 4.2. *Under the assumptions of Theorem 1.5, for $j \in \{0,1\}$, let $w_{j\mu}, \mu \geq 0$, solve*

$$\left\{ \begin{array}{rcl} -\mathrm{div}(a \nabla w_{j\mu}) + (q_j + \mu\rho) w_{j\mu} &=& 0 \quad \text{in } \Omega, \\ w_{j\mu} &=& \varphi \quad \text{on } \partial\Omega. \end{array} \right. \tag{4.2}$$

Then one has that

$$\|w_{j\mu}\|_{L^2_\rho(\Omega)} \to 0 \quad \text{as } \mu \to +\infty.$$

Proof of Lemma 4.2. Since $(\varphi_{jk})_{k=1}^{\infty}$ defined in (1.21) are a Hilbert basis in $L^2_\rho(\Omega)$, we can write $w_{j\mu}$ in the following Fourier expansion:

$$w_{j\mu} = \sum_{k=1}^{\infty} (w_{j\mu} \mid \varphi_{jk}) \varphi_{jk} \quad \text{in } L^2_\rho(\Omega), \tag{4.3}$$

where $(\cdot \mid \cdot)$ denotes the scalar product in $L^2_\rho(\Omega)$. After multiplying (4.2) by φ_{jk}, a direct calculation gives

$$(w_{j\mu} \mid \varphi_{jk}) = \frac{\alpha_{jk}}{\lambda_{jk}+\mu}, \tag{4.4}$$

where $\alpha_{jk} := -\int_{\partial\Omega} \psi_{jk}\varphi d\sigma$ (recall that $\psi_{jk} := a\frac{\partial}{\partial \mathbf{n}}\varphi_{jk|\partial\Omega}$). So, by (4.3) and (4.4), it is easy to verify that

$$\|w_{j\mu}\|_{L^2_\rho(\Omega)} \to 0 \quad \text{as } \mu \to +\infty.$$

The proof is complete. □

LEMMA 4.3. *Under the assumptions of Lemma* 4.2, *let us define* $w_j := w_{j0}$. *Then, for all* $\mu \geq 0$, *one has*

$$\gamma_0(\varphi) - \gamma_1(\varphi) = \gamma_{0\mu}(\varphi) - \gamma_{1\mu}(\varphi) \quad \textit{in } H^{-\frac{1}{2}}(\partial\Omega)$$

for all $\varphi \in H^{\frac{1}{2}}(\partial\Omega)$.

(Recall that $\gamma_j(\varphi) := a\frac{\partial}{\partial \mathbf{n}} w_{j|\partial\Omega}$ and $\gamma_{j\mu}(\varphi) := a\frac{\partial}{\partial \mathbf{n}} w_{j\mu|\partial\Omega}$.)

Proof of Lemma 4.3. Let $w_{j\mu}$ be solutions of (4.2) for $\varphi \in H^{\frac{3}{2}}(\partial\Omega)$. Putting $z_{j\mu} := w_{j\mu} - w_j$, then $z_{j\mu}$ solve

$$\left\{ \begin{array}{rcll} -\mathrm{div}(a\nabla z_{j\mu}) + q_j z_{j\mu} + \mu\rho z_{j\mu} & = & -(\mu-\mu_0)\rho w_j & \text{in } \Omega, \\ z_{j\mu} & = & 0 & \text{on } \partial\Omega \end{array} \right. \tag{4.5}$$

and

$$z_{j\mu} = \sum_{k=1}^{\infty} (z_{j\mu} \mid \varphi_{jk})\varphi_{jk} \quad \text{in } L^2_\rho(\Omega), \tag{4.6}$$

where $(\cdot \mid \cdot)$ denotes the scalar product in $L^2_\rho(\Omega)$. After multiplying (4.5) by φ_{jk}, a direct calculation gives

$$(z_{j\mu} \mid \varphi_{jk}) = -\frac{(\mu-\mu_0)\alpha_k}{(\lambda_k+\mu)^2},$$

where $\alpha_k := -\int_{\partial\Omega} \psi_k\varphi d\sigma, \psi_k := \psi_{0k} = \psi_{1k}, \psi_{jk} := a\frac{\partial}{\partial \mathbf{n}}\varphi_{jk|\partial\Omega}$, and $\lambda_k := \lambda_{0k} = \lambda_{1k}$. Moreover, one can verify that the series (4.6) converge to $z_{j\mu}$ in $H^2(\Omega)$. Now, since the trace operator $\gamma : u \to \frac{\partial}{\partial \mathbf{n}} u_{|\partial\Omega}$ is continuous from $H^2(\Omega)$ to $H^{\frac{1}{2}}(\partial\Omega)$, it follows that

$$a\frac{\partial}{\partial \mathbf{n}} z_{j\mu|\partial\Omega} = -\sum_{k=1}^{\infty} \frac{(\mu-\mu_0)\alpha_k}{(\lambda_k+\mu)^2}\psi_{jk} = -\sum_{k=1}^{\infty} \frac{(\mu-\mu_0)\alpha_k}{(\lambda_k+\mu)^2}\psi_k \quad \text{in } H^{\frac{1}{2}}(\partial\Omega).$$

So, in the sense of $H^{\frac{1}{2}}(\partial\Omega)$, one has

$$a\frac{\partial}{\partial \mathbf{n}} z_{0\mu|\partial\Omega} - a\frac{\partial}{\partial \mathbf{n}} z_{1\mu|\partial\Omega} = 0,$$

that is,

$$\gamma_0(\varphi) - \gamma_1(\varphi) = \gamma_{0\mu}(\varphi) - \gamma_{1\mu}(\varphi) \quad \text{in } H^{\frac{1}{2}}(\partial\Omega) \tag{4.7}$$

for all $\varphi \in H^{\frac{3}{2}}(\partial\Omega)$ and for all $\mu \geq 0$. Finally, by a density argument, (4.7) holds in $H^{-\frac{1}{2}}(\partial\Omega)$ for all $\varphi \in H^{\frac{1}{2}}(\partial\Omega)$.

The proof is complete. □

Now we can prove Theorem 1.5.

Proof of Theorem 1.5. Let $w_{j\mu}$ solve (4.2) for $\varphi \in H^{\frac{3}{2}}(\partial\Omega), \mu \geq 0$. Multiplying (4.2), for $j = 0$, by $w_{1\mu}$ and integrating by parts over Ω we obtain

$$\int_\Omega a\nabla w_{0\mu} \cdot \nabla w_{1\mu} dx - \int_{\partial\Omega} a\frac{\partial}{\partial \mathbf{n}} w_{0\mu}\varphi d\sigma + \int_\Omega q_0 w_{0\mu} w_{1\mu} dx = -\mu \int_\Omega \rho w_{0\mu} w_{1\mu} dx. \tag{4.8}$$

Similarly, multiplying (4.2), for $j = 1$, by $w_{0\mu}$ and integrating by parts over Ω we obtain

$$\int_\Omega a\nabla w_{0\mu} \cdot \nabla w_{1\mu} dx - \int_{\partial\Omega} a\frac{\partial}{\partial \mathbf{n}} w_{1\mu}\varphi d\sigma + \int_\Omega q_1 w_{0\mu} w_{1\mu} dx = -\mu \int_\Omega \rho w_{0\mu} w_{1\mu} dx. \tag{4.9}$$

Then, subtracting (4.8) from (4.9), it follows that

$$\int_{\partial\Omega} (\gamma_{0\mu}(\varphi) - \gamma_{1\mu}(\varphi))\varphi d\sigma + \int_\Omega (q_1 - q_0) w_{0\mu} w_{1\mu} dx = 0 \tag{4.10}$$

for all $\mu \geq 0$. Thus, letting $\mu \to +\infty$ in (4.10), recalling that $\|w_{j\mu}\|_{L^2_\rho(\Omega)} \to 0$ as $\mu \to +\infty$ and that $\gamma_0(\varphi) - \gamma_1(\varphi) = \gamma_{0\mu}(\varphi) - \gamma_{1\mu}(\varphi)$, for all $\mu \geq 0$, we derive that

$$\int_{\partial\Omega} (\gamma_0(\varphi) - \gamma_1(\varphi))\varphi d\sigma = 0 \tag{4.11}$$

for all $\varphi \in H^{\frac{3}{2}}(\partial\Omega)$. In particular, by a density argument, (4.11) holds for all $\varphi \in H^{\frac{1}{2}}(\partial\Omega)$, which implies

$$\gamma_0(\varphi) - \gamma_1(\varphi) = 0 \quad \text{in } H^{-\frac{1}{2}}(\partial\Omega)$$

for all $\varphi \in H^{\frac{1}{2}}(\partial\Omega)$. Finally, by Theorem 4.1, it follows that $q_0 = q_1$ in Ω.
The proof of Theorem 1.5 is complete. □

5. Uniqueness results for some classes of heat equations. In this section we prove the injectivity of the operator Φ defined in (1.7) in the following three cases:

(i) given $q(x)$, and $A(x)$ of the form $A(x) = a(x)I_N$, where $a(x)$ is a scalar-valued function and I_N is the identity matrix, we identify $\rho(x)$ and $a(x)$ by supposing that $\Gamma_{\text{in}} = \Gamma_{\text{out}} = \partial\Omega$;

(ii) given $A(x) = a(x)I_N$, we identify $\rho(x)$ and $q(x)$ by supposing that $\Gamma_{\text{in}} = \Gamma_{\text{out}} = \partial\Omega$;

(iii) given $\rho(x)$ and $A(x) = a(x)I_N$, we identify $q(x)$ by supposing that $\Gamma_{\text{in}} \cup \Gamma_{\text{out}} = \partial\Omega$.

We begin by proving case (i), that is, Theorem 1.3: given q, we prove the identifiability of ρ and a.

Proof of Theorem 1.3. First let us note that, without loss of generality, we can suppose that in (1.10) the initial data $u_{0j} \equiv 0$ in $\Omega, j \in \{0, 1\}$ (see Lemma 3.3). As usual we denote by $(\lambda_{jk})_{k=1}^\infty$ and $(\varphi_{jk})_{k=1}^\infty$, respectively, the eigenvalues and the corresponding eigenfunctions of the underlying elliptic operators with Dirichlet boundary conditions, that is,

$$\left\{ \begin{array}{rcll} -\text{div}(a_j \nabla \varphi_{jk}) + q\varphi_{jk} & = & \lambda_{jk}\rho_j\varphi_{jk} & \text{in } \Omega, \\ \varphi_{jk} & = & 0 & \text{on } \partial\Omega, \\ \int_\Omega |\varphi_{jk}|^2 \rho_j dx & = & 1. & \end{array} \right. \tag{5.1}$$

By Theorem 1.1 we know that the boundary spectral data $\mathrm{BSD}(\rho_j, a_j, q)$ coincide, that is, for all $k \geq 1$,

$$\lambda_{0k} = \lambda_{1k} =: \lambda_k \quad \text{and} \quad \psi_{0k} = \psi_{1k} =: \psi_k \quad \text{on } \partial\Omega. \tag{5.2}$$

(We recall that $\psi_{jk} := a_j \frac{\partial}{\partial \mathbf{n}} \varphi_{jk|\partial\Omega}$.) Set $u_j(t,x) = v_j(t,x) + w_j(x)$, where v_j solve

$$\begin{cases} \rho_j(x)\partial_t v_j - \mathrm{div}(a_j(x)\nabla v_j) + q(x)v_j &= 0 & \text{in } (0,T)\times\Omega, \\ v_j(0) &= -w_j & \text{in } \Omega, \\ v_j(t,\sigma) &= 0 & \text{on } (0,T)\times\partial\Omega, \end{cases}$$

and w_j solve (4.1) for $\varphi \in H^{\frac{3}{2}}(\partial\Omega)$. Since $(\varphi_{jk})_{k=1}^{\infty}$ are a Hilbert basis in $L^2_\rho(\Omega)$, we can write $v_j(t)$ in the following Fourier expansion:

$$v_j(t) = \sum_{k=1}^{\infty} \alpha_{jk}(t)\varphi_{jk} \quad \text{in } L^2_\rho(\Omega), \tag{5.3}$$

where the coefficients $\alpha_{jk}(t) := (v_j(t) \mid \varphi_{jk})$ solve

$$\begin{cases} \frac{d}{dt}\alpha_{jk}(t) + \lambda_{jk}\alpha_{jk}(t) &= 0 & \text{in } (0,T), \\ \alpha_{jk}(0) &= -(w_j \mid \varphi_{jk}), \end{cases}$$

and $(\cdot \mid \cdot)$ denotes the scalar product in $L^2_\rho(\Omega)$. Then

$$\alpha_{jk}(t) = -(w_j \mid \varphi_{jk})e^{-\lambda_{jk}t}.$$

After multiplying (4.1) by φ_{jk}, a simple calculation gives

$$(w_j \mid \varphi_{jk}) = -\frac{1}{\lambda_{jk}} \int_{\partial\Omega} \psi_{jk}\varphi d\sigma.$$

Hence, from (5.2), we deduce that $\alpha_{0k}(t) = \alpha_{1k}(t) =: \alpha_k(t)$ on $[0,T]$ for all $k \geq 1$.

Moreover, one can verify that the series (5.3), at $t = T_0$, converge to $v_j(T_0)$ in $H^2(\Omega)$. Thus, since the trace operator $\gamma : u \to \frac{\partial}{\partial \mathbf{n}} u_{|\partial\Omega}$ is continuous from $H^2(\Omega)$ to $H^{\frac{1}{2}}(\partial\Omega)$, it follows that

$$a_j \frac{\partial}{\partial \mathbf{n}} v_j(T_0)_{|\partial\Omega} = \sum_{k=1}^{\infty} \alpha_k(T_0)\psi_{jk} = \sum_{k=1}^{\infty} \alpha_k(T_0)\psi_k \quad \text{in } H^{\frac{1}{2}}(\partial\Omega),$$

and therefore

$$a_j \frac{\partial}{\partial \mathbf{n}} u_j(T_0)_{|\partial\Omega} = \sum_{k=1}^{\infty} \alpha_k(T_0)\psi_k + a_j \frac{\partial}{\partial \mathbf{n}} w_{j|\partial\Omega} \quad \text{in } H^{\frac{1}{2}}(\partial\Omega). \tag{5.4}$$

Now, recalling that $a_0 \frac{\partial}{\partial \mathbf{n}} u_0(T_0)_{|\partial\Omega} = a_1 \frac{\partial}{\partial \mathbf{n}} u_1(T_0)_{|\partial\Omega}$, from (5.4) we derive that

$$a_0 \frac{\partial}{\partial \mathbf{n}} w_{0|\partial\Omega} = a_1 \frac{\partial}{\partial \mathbf{n}} w_{1|\partial\Omega} \quad \text{in } H^{\frac{1}{2}}(\partial\Omega) \tag{5.5}$$

for all $\varphi \in H^{\frac{3}{2}}(\partial\Omega)$. In particular, by a density argument, (5.5) holds in $H^{-\frac{1}{2}}(\partial\Omega)$ for all $\varphi \in H^{\frac{1}{2}}(\partial\Omega)$. Finally, by Theorem 4.1, it follows that $a_0 = a_1$ in $\overline{\Omega}$.

Now we denote by $a(x) := a_0(x) = a_1(x)$. Set $u_j(t,x) = \widetilde{v_j}(t,x) + \widetilde{w_j}(x)$, where $\widetilde{v_j}$ solve

$$\left\{\begin{array}{rcll} \rho_j(x)\partial_t\widetilde{v_j} - \mathrm{div}(a(x)\nabla\widetilde{v_j}) + q(x)\widetilde{v_j} &=& -\rho_j(x)\widetilde{w_j} & \text{in } (0,T)\times\Omega, \\ \widetilde{v_j}(0) &=& -\widetilde{w_j} & \text{in } \Omega, \\ \widetilde{v_j}(t,\sigma) &=& 0 & \text{on } (0,T)\times\partial\Omega, \end{array}\right.$$

and $\widetilde{w_j}$ solve

$$\left\{\begin{array}{rcll} -\mathrm{div}(a\nabla\widetilde{w_j}) + (q+\rho_j)\widetilde{w_j} &=& 0 & \text{in } \Omega, \\ \widetilde{w_j} &=& \varphi & \text{on } \partial\Omega. \end{array}\right.$$

By following the above arguments, again we derive that

$$a\frac{\partial}{\partial\mathbf{n}}\widetilde{w_0}_{|\partial\Omega} = a\frac{\partial}{\partial\mathbf{n}}\widetilde{w_1}_{|\partial\Omega} \quad \text{in } H^{-\frac{1}{2}}(\partial\Omega)$$

for all $\varphi \in H^{\frac{1}{2}}(\partial\Omega)$. Then Theorem 4.1 implies that $\rho_0 = \rho_1$ in Ω.

The proof of Theorem 1.3 is complete. □

Now we prove case (ii), that is, Theorem 1.4: given a, we prove the identifiability of ρ and q.

Proof of Theorem 1.4. Repeating arguments, with the obvious changes, in the proof of Theorem 1.3 one obtains, in a first step, that $q_0 = q_1$ in Ω, and in a second step, that $\rho_0 = \rho_1$ in Ω. □

As a direct consequence of Theorems 1.1 and 1.5, we can prove case (iii), that is, Theorem 1.6: given ρ and a, we prove the identifiability of q by supposing that $\Gamma_{\mathrm{in}} \cup \Gamma_{\mathrm{out}} = \partial\Omega$.

Proof of Theorem 1.6. As usual, without loss of generality, we can suppose that in (1.10) the initial data $u_{0j} \equiv 0$ in Ω and the boundary data $\varphi_j \equiv 0$ on $(0,T)\times\partial\Omega\backslash\Gamma_{\mathrm{in}}$. We denote by $(\lambda_{jk})_{k=1}^{\infty}$ and $(\varphi_{jk})_{k=1}^{\infty}$, respectively, the eigenvalues and the corresponding eigenfunctions of the underlying elliptic operators with Dirichlet boundary conditions, that is,

$$\left\{\begin{array}{rcll} -\mathrm{div}(a\nabla\varphi_{jk}) + q_j\varphi_{jk} &=& \lambda_{jk}\rho\varphi_{jk} & \text{in } \Omega, \\ \varphi_{jk} &=& 0 & \text{on } \partial\Omega, \\ \int_\Omega |\varphi_{jk}|^2 \rho dx &=& 1. & \end{array}\right.$$

By Theorem 1.1 we know that the boundary spectral data $\mathrm{BSD}(\rho, a, q_j)$ coincide, that is, for all $k \geq 1$,

$$\lambda_{0k} = \lambda_{1k} \quad \text{and} \quad \psi_{0k} = \psi_{1k} \quad \text{on} \quad \partial\Omega.$$

So, by Theorem 1.5, it follows that $q_0 = q_1$ in Ω.

The proof is complete. □

6. The one dimensional case. In this section we investigate the problem of determining the coefficients $\rho(x), a(x), q(x)$ in the one dimensional heat equation

$$\left\{\begin{array}{rcll} \rho(x)\partial_t u - \partial_x(a(x)\partial_x u) + q(x)u &=& 0 & \text{in } (0,T)\times(0,\ell), \\ u(0) &=& u_0 & \text{in } (0,\ell), \\ u(t,0) &=& f(t) & \text{in } (0,T), \\ u(t,\ell) &=& g(t) & \text{in } (0,T) \end{array}\right. \tag{6.1}$$

from the additional measurement of the thermal flux $a(x_*)\partial_x u(T_0, x_*)$ at a given time $T_0 \in (0, T]$, at one end-point x_* of the interval $[0, \ell]$, when all input $f \in C[0, T]$ are assigned in (6.1) (the temperature $u(t, \ell) = g(t)$ at the other end-point $x = \ell$ is given arbitrarily). We study two different cases. In the first one we prove that knowledge of the additional data $a(0)\partial_x u(T_0, 0)$ at the end-point $x_* = 0$, where the input f is assigned, uniquely determines *one* of the coefficients ρ, a, q. In the second case we prove that knowledge of the additional data $a(\ell)\partial_x u(T_0, \ell)$ at the other end-point $x_* = \ell$ (where the temperature $u(t, \ell)$ is a priori unknown) in general does not determine uniquely ρ, a, q, except for symmetric coefficients, in which case uniqueness holds.

We make the following regularity assumptions on the coefficients ρ, a, q:

$$\rho \in C^{1,1}[0, \ell] \text{ and } \rho \geq \beta \text{ for some constant } \beta > 0; \tag{6.2}$$

$$a \in C^{1,1}[0, \ell] \text{ and } a \geq \alpha \text{ for some constant } \alpha > 0; \tag{6.3}$$

$$q \in L^p(0, \ell) \text{ for some } p > 1. \tag{6.4}$$

In this section we prove the following uniqueness result.

THEOREM 6.1. *Let $N = 1, \ell < +\infty$ and, for $j \in \{0, 1\}$, let (ρ_j, a_j, q_j) be two sets of functions satisfying conditions* (6.2)–(6.4). *For some fixed $u_{0j} \in C[0, \ell]$ and $g_j \in C[0, T]$, let u_j be solutions of* (6.1) *when $(\rho, a, q) := (\rho_j, a_j, q_j), u_0 := u_{0j}$ and $g := g_j$. We denote by*

$$\Lambda_j(f) := a_j(0)\partial_x u_j(T_0, 0)$$

the thermal fluxes measured at a given time $T_0 \in (0, T]$ at the end-point $x_* = 0$. Suppose that one has

$$\Lambda_0(f) = \Lambda_1(f)$$

for all $f \in C[0, T]$ such that $f \equiv 0$ in $[T_0 - \varepsilon_0, T_0]$, where ε_0 is such that $0 < \varepsilon_0 < T_0$. Then, given $\rho := \rho_0 = \rho_1$ and $q := q_0 = q_1$, one has that $a_0 = a_1$ in $[0, \ell]$.

REMARK 6.2. We observe that one can prove that either, given $\rho := \rho_0 = \rho_1$ and $a := a_0 = a_1$, that $q_0 = q_1$ in $(0, \ell)$, or given $a := a_0 = a_1$ and $q := q_0 = q_1$, that $\rho_0 = \rho_1$ in $[0, \ell]$. □

Proof of Theorem 6.1. First of all, without loss of generality, we can suppose that the initial data $u_{0j} \equiv 0$ in $(0, \ell)$ and the boundary data $g_j \equiv 0$ in $(0, T)$ (see Lemma 3.3). Now, let us denote by $(\lambda_{jk})_{k=1}^{\infty}$ and $(\varphi_{jk})_{k=1}^{\infty}$, respectively, the eigenvalues and the corresponding eigenfunctions of the following problems (with Dirichlet boundary conditions):

$$\begin{cases} -(a_j\varphi'_{jk})' + q_j\varphi_{jk} &= \lambda_{jk}\rho_j\varphi_{jk} \quad \text{in } (0, \ell), \\ \varphi_{jk}(0) = \varphi_{jk}(\ell) &= 0, \\ \int_0^\ell |\varphi_{jk}|^2 \rho_j dx &= 1. \end{cases} \tag{6.5}$$

By Theorem 1.1 we know that the boundary spectral data $\mathrm{BSD}(\rho_j, a_j, q_j) := (\lambda_{jk}, a_j(0)\varphi'_{jk}(0))$ coincide, i.e., for all $k \geq 1$, one has that

$$\lambda_{0k} = \lambda_{1k} =: \lambda_k \tag{6.6}$$

and

$$a_0(0)\varphi'_{0k}(0) = a_1(0)\varphi'_{1k}(0). \tag{6.7}$$

Now, supposing in (6.5) that $\rho := \rho_0 = \rho_1$ in $[0,\ell]$ and $q := q_0 = q_1$ in $(0,\ell)$, we prove that (6.6) and (6.7) imply that $a_0 = a_1$ in $[0,\ell]$. Since the proof of this result is reasonably well known, for the reader's convenience we give only an outline of it (one may refer to McLaughlin [21], Gladwell [12], Chadan, Colton, Päivärinta, and Rundell [8]. We thank one of the referees for having suggested these references). First, recalling the asymptotic behavior of the eigenvalues of (6.5) (see, for example, Courant and Hilbert [10, p. 414]), and (6.6), one can derive that

$$\int_0^\ell \left(\frac{\rho}{a_0}\right)^{\frac{1}{2}} ds = \int_0^\ell \left(\frac{\rho}{a_1}\right)^{\frac{1}{2}} ds =: \ell_*.$$

Then, we consider the so-called Liouville transform of the eigenfunctions φ_{jk} (see, for example, Courant and Hilbert [10, p. 292]), i.e., setting

$$y := \alpha_j(x) = \int_0^x \left(\frac{\rho}{a_j}\right)^{\frac{1}{2}} ds, \tag{6.8}$$

we define

$$v_{jk}(y) := (\widetilde{a_j}(y)\widetilde{\rho}(y))^{\frac{1}{4}}\widetilde{\varphi_{jk}}(y), \tag{6.9}$$

where $\widetilde{a_j}(y) := a_j(\alpha_j^{-1}(y)), \widetilde{\rho}(y) := \rho(\alpha_j^{-1}(y))$ and $\widetilde{\varphi_{jk}}(y) := \varphi_{jk}(\alpha_j^{-1}(y))$. One can verify that the functions v_{jk} satisfy the following problems (the so-called Sturm–Liouville problem in normal form):

$$\left\{\begin{array}{rcl} v''_{jk} - p_j v_{jk} &=& \lambda_{jk} v_{jk} \quad \text{in } (0,\ell_*), \\ v_{jk}(0) = v_{jk}(\ell_*) &=& 0, \\ \int_0^{\ell^*} |v_{jk}|^2\, dy &=& 1, \end{array}\right. \tag{6.10}$$

where

$$p_j(y) := \frac{f''_j(y)}{f_j(y)} + \frac{\widetilde{q}(y)}{\widetilde{\rho}(y)}, \tag{6.11}$$

$$f_j(y) := (\widetilde{a_j}(y)\widetilde{\rho}(y))^{\frac{1}{4}}, \tag{6.12}$$

and $\widetilde{q}(y) := q(\alpha_j^{-1}(y))$. Recalling the asymptotic behavior of the eigenfunctions of (6.10) (see, for example, Courant and Hilbert [10, p. 338]), and (6.7) it is easy to obtain that

$$a_0(0) = a_1(0)$$

and then, for all $k \geq 1$,

$$v'_{0k}(0) = v'_{1k}(0).$$

Thus, following Gel'fand and Levitan [11], the coefficients p_j in (6.10) can be computed via

$$p_j(y) = \frac{1}{2}\frac{d}{dy}K(y,y),$$

where $K(t,y)$ is the unique solution of the linear integral equation

$$F(t,y)+K(t,y)+\int_0^y K(s,y)F(t,s)ds=0,\quad 0\le t\le y\le \ell_*,$$

where

$$F(t,y)=\frac{1}{\xi_1}\sin(\sqrt{\lambda_1}y)(\sqrt{\lambda_1}t)-\frac{1}{\ell_*}+\sum_{k=2}^{\infty}\left[\frac{\sin(\sqrt{\lambda_k}y)\sin(\sqrt{\lambda_k}t)}{\xi_k}-\frac{2}{\ell_*}\sin\left(\frac{k\pi}{\ell_*}y\right)\sin\left(\frac{k\pi}{\ell_*}t\right)\right]$$

and $\xi_k:=v_k'(0)^{-2}$, where $v_k'(0):=v_{0k}'(0)=v_{1k}'(0)$. Thus we derive that $p_0=p_1$ in $[0,\ell]$.

The proof of Theorem 6.1 is completed by going back to the coefficients a_j of (6.5). □

We conclude this section with an example in which we prove that knowledge, for all possible input f assigned in $x=0$, of the additional data $a(\ell)\partial_x u(T_0,\ell)$ at the end-point $x_*=\ell$ of the interval $[0,\ell]$, where the datum g is supposed to be identically zero, in general does not determine uniquely the coefficients ρ,a,q. This example is contained in the following proposition.

PROPOSITION 6.3. *Under the assumptions of Theorem* 6.1, *let* $\rho:=\rho_0=\rho_1, q:=q_0=q_1$ *be given, and let* $\rho,q\in C[0,\ell]$ *be symmetric functions, that is,* $\rho(x)=\rho(\ell-x)$ *and* $q(x)=q(\ell-x)$. *For* $a\in C^1[0,\ell]$, *let* $a_0(x):=a(x)$, *and let* $a_1(x):=a(\ell-x)$. *Suppose that* $u_j, j\in\{0,1\}$, *solve* (6.1) *when* $(\rho,a,q):=(\rho,a_j,q), u_0\equiv 0$ *in* $(0,\ell)$ *and* $g\equiv 0$ *in* $(0,T)$. *Then, for a given* $T_0\in(0,T]$, *and for all* $f\in C(0,T)$ *such that* $f\equiv 0$ *in* $[T_0-\varepsilon_0,T_0]$, *where* $0<\varepsilon_0<T_0$, *one has*

$$a_0(\ell)\partial_x u_0(T_0,\ell)=a_1(\ell)\partial_x u_1(T_0,\ell).$$

Proof of Proposition 6.3. First let us note that, since the coefficients ρ,q are symmetric and $a_0(x)=a_1(\ell-x)$, it follows that the eigenvalues and the eigenfunctions of problems (6.5) verify the following identities:

$$\lambda_{0k}=\lambda_{1k}\quad\text{and}\quad\varphi_{1k}(x)=\varphi_{0k}(\ell-x)\tag{6.13}$$

for all $k\ge 1$. By Lemma 3.2 we know that

$$a_j(\ell)\partial_x u_j(T_0,\ell)=-\sum_{k=1}^{\infty}\int_0^{T_0-\varepsilon_0}e^{-\lambda_{jk}(T_0-\tau)}a_j(0)a_j(l)\varphi_{jk}'(0)\varphi_{jk}'(\ell)f(\tau)d\tau.$$

Thus (6.13) yields that $a_0(\ell)\partial_x u_0(T_0,\ell)=a_1(\ell)\partial_x u_1(T_0,\ell)$. □

REMARK 6.4. Under the assumptions of Theorem 6.1, let $\rho:=\rho_0=\rho_1, q:=q_0=q_1$ be given, and, for $j\in\{0,1\}$, let ρ,a_j,q be symmetric functions, that is, $\rho(x)=\rho(\ell-x), a_j(x)=a_j(\ell-x), q(x)=q(\ell-x)$. Suppose that the fluxes of the solutions u_j of (6.1), when $(\rho,a,q):=(\rho,a_j,q), u_0:=u_{0j}$, and $g:=g_j$, coincide at the end-point $x_*=\ell$, i.e.,

$$a_0(\ell)\partial_x u_0(T_0,\ell)=a_1(\ell)\partial_x u_1(T_0,\ell)$$

for all $f\in C[0,T]$ such that $f=0$ in $[T_0-\varepsilon_0,T_0]$. Then $a_0=a_1$ in $[0,\ell]$. □

UNIFORM ASYMPTOTIC EXPANSIONS FOR THE REVERSE GENERALIZED BESSEL POLYNOMIALS, AND RELATED FUNCTIONS*

T. M. DUNSTER†

Abstract. The generalized Bessel polynomials $y_n(z;a)$ are generalizations of the well-known modified Bessel functions $K_\nu(z)$. In this paper a study is undertaken of the reverse generalized Bessel polynomials, which are defined by $\theta_n(z;a) = z^n y_n(z^{-1};a)$, and their asymptotic behavior as the degree $n \to \infty$ is comprehensively determined. This is achieved by an application of two general asymptotic theories, due to F. W. J. Olver, to an ordinary differential equation satisfied by $\theta_n(z;a)$: one for the case of complex domains which are free of turning points (yielding Liouville–Green expansions), and the other for complex domains containing a simple turning point (yielding Airy function expansions). The approximations are uniformly valid for z lying in certain unbounded subdomains of the complex plane and are complete with explicit error bounds. Together the domains of validity cover the whole complex plane. Moreover, all the results are uniformly valid for real or complex a, the only restrictions being that $a = O(n)$ as $n \to \infty$ and that a must not be close to the values $-n$ or $-2n$. Two companion solutions to $\theta_n(z;a)$ are defined, which are solutions of the same differential equation and are recessive at certain singularities of the equation. Similar Liouville–Green and Airy function expansions, with accompanying error bounds, are also derived for these functions.

Key words. Bessel polynomials, Liouville–Green expansions, turning point problems

1. Introduction.

The generalized Bessel polynomials are defined by

$$y_n(z;a) = \sum_{k=0}^{n} \binom{n}{k} (n+a-1)_k \left(\frac{1}{2}z\right)^k, \tag{1.1}$$

where $(\alpha)_k = \Gamma(\alpha+k)/\Gamma(\alpha)$ is Pochhammer's symbol. In terms of the hypergeometric function they can be represented by

$$y_n(z;a) = {}_2F_0\left(-n, a+n-1; -\frac{1}{2}z\right). \tag{1.2}$$

These polynomials satisfy the linear second order differential equation

$$z^2 \frac{\mathrm{d}^2 y}{\mathrm{d}z^2} + (az+2)\frac{\mathrm{d}y}{\mathrm{d}z} - n(n+a-1)y = 0, \tag{1.3}$$

which has an irregular singularity at $z = 0$ and a regular singularity at infinity. We find it preferable to have the location of these types of singularities interchanged, and therefore, we shall study the so-called reverse generalized Bessel polynomials, which are defined by

$$\theta_n(z;a) = z^n y_n(z^{-1};a). \tag{1.4}$$

†Department of Mathematical Sciences, San Diego State University, San Diego, CA 92182-7720 (dunster@math.sdsu.edu).

The purpose of this paper is to investigate the asymptotic behavior of the polynomials $\theta_n(z;a)$ as $n \to \infty$. Clearly, from the relationship (1.4), any asymptotic results concerning $\theta_n(z;a)$, or their zeros, trivially lead to corresponding results for the generalized Bessel polynomials $y_n(z;a)$: the domain of validity of any asymptotic results for $\theta_n(z;a)$ must, of course, be transformed under the map $z \to 1/z$ to give the domain of validity of the corresponding asymptotic results for $y_n(z;a)$. However, our asymptotic results for $\theta_n(z;a)$, when taken together, will be valid for all (unbounded) complex values of z, and consequently, the same is true when these results are converted for the generalized Bessel polynomials $y_n(z;a)$.

An early appearance of the generalized Bessel polynomials was in the 1929 papers by Bochner [1] and Romanovsky [10], and they have appeared after that in papers by many other authors. The importance of these polynomials was seen in 1949 by Krall and Frink [7] (who introduced the name Bessel polynomials) in their connection with the wave equation in spherical coordinates, and also in 1949 by Thompson [11] in his study of electrical networks.

To this day, the asymptotic behavior of $y_n(z;a)$ for large degree n and real or complex z has not been fully determined, due to lack of error bounds and restrictive regions of validity. Perhaps the reason for this is that even for real positive a, the problem involves turning points which are neither real nor purely imaginary: the only exception being when $a = 2$ (leading to purely imaginary turning points), in which case well-known asymptotic results for unmodified and modified Bessel functions are applicable (see (1.12) below, [8, Chap. 10, sect. 7], and [8, Chap. 11, sect. 10]). The position of the turning points in the complex plane makes the analysis more complicated, both for integral and for differential equation methods. In the latter method, which we shall use in this paper, the primary difficulty of having complex turning points is that they lead to a more complicated Liouville transformation (details of which are given in section 3 of this paper).

The most recent, and comprehensive, asymptotic work on generalized Bessel polynomials is that of Wong and Zhang [12], who used an integral representation and the method of Chester, Friedman, and Ursel [4] to obtain asymptotic expansions for $y_n(z;a)$ involving Airy functions. In this paper we obtain similar (but not identical) Airy function expansions: our results are more extensive than those of [12] since they are valid for a larger range of variable z (in particular, in domains which contain both the origin and infinity), as well as a larger range of the parameter a, and also include explicit (computable) error bounds. Since the results of this paper, when taken together, are valid for all (unbounded) complex values of z, they can be used to obtain uniform asymptotic approximations of the zeros of $\theta_n(z;a)$ (or $y_n(z;a)$). For each n and a, these zeros lie on a certain curve in the complex plane (which we briefly discuss in section 5), and for earlier results concerning these zeros, see [3], [5], [6], and [11].

Before proceeding, we present some important properties of the reverse Bessel polynomials. Many of these results can be found by perusing the literature, most notably the comprehensive monograph of Grosswald [6].

First, the polynomials are related to the confluent hypergeometric function

$$U(a,c,z) = \frac{1}{\Gamma(a)} \int_0^\infty t^{a-1}(1+t)^{c-a-1}e^{-zt}dt \quad \left(|\arg(z)| < \frac{1}{2}\pi, \quad \operatorname{Re} a > 0 \right) \tag{1.5}$$

by the relation

$$\theta_n(z;a) = 2^{n+a-1}z^{2n+a-1}U(n+a-1, 2n+a, 2z). \tag{1.6}$$

Also, in terms of the Laguerre polynomials $L_n^{(\alpha)}(x)$ they are expressible as

$$\theta_n(z;a) = (-1)^n n! 2^{-n} L_n^{(-2n-a+1)}(2z). \tag{1.7}$$

A Rodrigues formula is given by

$$\theta_n(z;a) = (-1)^n 2^{-n} e^{2z} z^{2n+a-1} \frac{\mathrm{d}^n}{\mathrm{d}z^n}(z^{-n-a+1} e^{-2z}). \tag{1.8}$$

The following provides a generating function expansion:

$$\left\{\frac{1+(1-2t)^{1/2}}{2}\right\}^{2-a} \frac{\exp\{z(1-(1-2t)^{1/2})\}}{(1-2t)^{1/2}} = \sum_{k=0}^{\infty} \frac{t^k \theta_k(z;a)}{k!}. \tag{1.9}$$

A recurrence relation (in the order n) is given by the relation

$$(n+a-1)(2n+a-2)\theta_{n+1}(z;a) \tag{1.10}$$

$$= \left\{(2n+a)\left(n-1+\frac{1}{2}a\right)+(a-2)z\right\}(2n+a-1)\theta_n(z;a)+n(2n+a)z^2\theta_{n-1}(z;a).$$

Special values worth noting are

$$\theta_n(0;a) = \frac{\Gamma(2n+a-1)}{2^n \Gamma(n+a-1)} \tag{1.11}$$

and

$$\theta_n(z;2) \equiv \theta_n(z) = \sqrt{\frac{2}{\pi}} z^{n+1/2} e^z K_{n+1/2}(z). \tag{1.12}$$

In the latter equation, $K_\nu(z)$ denotes the modified Bessel function, and the polynomials $\theta_n(z)$ in this equation are known as Bessel polynomials; indeed, it is from the relation (1.12) that the terminology *generalized Bessel polynomial* arises.

Finally, the reverse generalized Bessel polynomials $\theta_n(z;a)$ satisfy the following second order linear differential equation:

$$z\frac{\mathrm{d}^2\theta}{\mathrm{d}z^2} - (2n-2+a+2z)\frac{\mathrm{d}\theta}{\mathrm{d}z} + 2n\theta = 0. \tag{1.13}$$

It is from this equation, suitably transformed, that we shall derive our asymptotic results.

The plan of this paper is as follows. In section 2 we define two companion functions to $\theta_n(z;a)$, which are also solutions of (1.13). These are characterized as being recessive at $z=\infty$ in the left half plane ($\frac{1}{2}\pi \le \arg(z) \le \frac{3}{2}\pi$), and at $z=0$, respectively. Since $\theta_n(z;a)$ is the solution of (1.13) that is recessive at $z=\infty$ in the right half plane, the three solutions form a numerically satisfactory set for the whole complex z plane (see [8, Chap. 5, sect. 7]). In section 3 of this paper a Liouville transformation is given which transforms the differential equation (1.13) into a canonical form from which Airy function expansions can be derived. These expansions are given in section 4 and are then identified with $\theta_n(z;a)$, and the two other solutions as defined in section 2. The main result for $\theta_n(z;a)$ is given by Theorem 4.1 in section 4. Simpler expansions, involving elementary (exponential) functions are given by applying the

well-known Liouville–Green theory for ordinary differential equations in the complex plane. In section 5 such expansions are given which are valid for complex z (but in more restricted domains than those of section 4). The results of section 5 are then simplified even further in sections 6 and 7, where z is assumed to be real (positive in section 6, and negative in section 7).

When $a = 2$ the results of section 4 are equivalent to the special case of the asymptotic expansion of Bessel functions in the complex plane given by Olver [8, Chap. 11, sect. 10]. The reader may find it helpful to compare the results of Olver to those of section 4 of the present paper.

Throughout this paper z and a take real or complex values (as specified), but we assume that n (which is large) is a positive integer. It is straightforward to extend the following results to noninteger positive values of n (with $\theta_n(z;a)$, no longer a polynomial, defined by (1.6)), but we do not pursue this.

2. Companion solutions of the differential equation. The first step in obtaining asymptotic solutions to (1.13) is to remove the first derivative. To this end, it is straightforward to show that if $\theta(z)$ is any solution of (1.13), then

$$w(z) = z^{1-n-a/2}e^{-z}\theta(z) \tag{2.1}$$

satisfies the differential equation

$$\frac{\mathrm{d}^2w}{\mathrm{d}z^2} = \left\{1 + \frac{a-2}{z} + \frac{(2n+a)(2n+a-2)}{4z^2}\right\} w. \tag{2.2}$$

We shall define three fundamental solutions of the differential equation (2.2), which will be characterized as being recessive at certain points in the complex plane, and indeed will form a numerically satisfactory set for the whole complex plane (subject to appropriate restrictions on $\arg(z)$).

By introducing (for convenience) a normalizing constant 2^{-n-a+1}, we have from (2.1) as the first of these three solutions

$$w_n^{(0)}(z;a) = 2^{-n-a+1}z^{1-n-a/2}e^{-z}\theta_n(z;a), \tag{2.3}$$

or alternatively, from (1.6),

$$w_n^{(0)}(z;a) = e^{-z}z^{n+a/2}U(n+a-1, 2n+a, 2z). \tag{2.4}$$

Now from (1.1), (1.4), and (2.3) we observe that as $z \to \infty$

$$w_n^{(0)}(z;a) = 2^{-n-a+1}z^{1-a/2}e^{-z}\{1 + O(z^{-1})\}. \tag{2.5}$$

The significance of (2.5) is that $w_n^{(0)}(z;a)$ is seen to be recessive in the right half plane. To obtain a solution which is recessive in the left half plane we replace U by V in (2.4), where V denotes the confluent hypergeometric function defined by [8, Chap. 7, (10.03)]. Thus we have as our second fundamental solution

$$w_n^{(1)}(z;a) = (-1)^{n+1}e^{-z}z^{n+a/2}V(n+a-1, 2n+a, 2z), \tag{2.6}$$

where again for convenience we have introduced a constant (this time the factor $(-1)^{n+1}$). A branch of V in the definition given by [8, Chap. 7, (10.03)] must be specified, and we choose it so that $\arg(-z) = \pi$ when $\arg(z) = 0$. Thus we have in effect defined V by the relation

$$V(a,c,z) = e^zU(c-a, c, ze^{-\pi i}). \tag{2.7}$$

Next, from (2.6) and (2.7), we see that

$$w_n^{(1)}(z;a) = (-1)^{n+1} e^z z^{n+a/2} U(n+1, 2n+a, 2ze^{-\pi i}), \tag{2.8}$$

and hence from [8, Chap. 7, (10.01)]

$$w_n^{(1)}(z;a) = 2^{-n-1} z^{a/2-1} e^z \{1 + O(z^{-1})\} \tag{2.9}$$
$$\left(z \to \infty \text{ with } -\frac{1}{2}\pi + \delta \le \arg(z) \le \frac{5}{2}\pi - \delta\right).$$

This confirms that $w_n^{(1)}(z;a)$ is recessive in the left half plane $\frac{1}{2}\pi \le \arg(z) \le \frac{3}{2}\pi$.

Our third of the numerically satisfactory set of solutions is to be recessive at the regular singularity at $z = 0$. We define it by

$$w_n^{(-1)}(z;a) = e^{-z} z^{n+a/2} \mathbf{M}(n+a-1, 2n+a, 2z), \tag{2.10}$$

where $\mathbf{M}$ is the confluent hypergeometric function defined by [8, Chap. 7, (9.04)], that is,

$$\mathbf{M}(a,c,z) = \frac{1}{\Gamma(c)} {}_1F_1(a;c;z) = \sum_{s=0}^{\infty} \frac{(a)_s}{s!\Gamma(c+s)} z^s. \tag{2.11}$$

It is then seen from (2.10) and (2.11) that

$$w_n^{(-1)}(z;a) = \frac{z^{n+a/2}}{\Gamma(2n+a)}\{1 + O(z)\} \quad (z \to 0). \tag{2.12}$$

An important connection formula relating the three solutions can be derived from well-known results concerning confluent hypergeometric functions (see [8, Chap. 7, (10.10)]), and for the case where n is an integer (as is assumed throughout this paper), we arrive at

$$w_n^{(-1)}(z;a) = (-1)^{n+1} \frac{e^{a\pi i}}{n!} w_n^{(0)}(z;a) + \frac{1}{\Gamma(n+a-1)} w_n^{(1)}(z;a). \tag{2.13}$$

We finally remark that all three solutions can be regarded as generalizations of the standard modified Bessel functions, since, on setting $a = 2$ in (2.4), (2.8), and (2.10) and referring to [8, Chap. 7, Exercises 9.1 and 10.1], we find that

$$w_n^{(-1)}(z;2) = \sqrt{\frac{\pi}{2}}\ \frac{z^{1/2}}{2^n \Gamma(n+1)} I_{n+1/2}(z), \tag{2.14}$$

$$w_n^{(0)}(z;2) = \frac{z^{1/2}}{\sqrt{2\pi} 2^n} K_{n+1/2}(z), \tag{2.15}$$

and

$$w_n^{(1)}(z;2) = -i \frac{z^{1/2}}{\sqrt{2\pi} 2^n} K_{n+1/2}(ze^{-\pi i}). \tag{2.16}$$

The relation (2.15), of course, could also have been deduced from (1.12) and (2.3).

3. Preliminary transformations for the turning point case. It is easy to see that the right-hand side of (2.2) has two zeros, which as $n \to \infty$ are located at points given by $z = \pm in + O(1)$. These zeros are the so-called turning points of the equation, and we wish for them to be bounded. With this in mind we shall rescale the independent variable. Before doing so, we define as our large parameter

$$u = n + \frac{1}{2}, \tag{3.1}$$

and, for convenience, we introduce a parameter α by the relation $a = 2 + u\alpha$, i.e.,

$$\alpha = \frac{a-2}{u}. \tag{3.2}$$

We shall assume throughout this paper that α is bounded and not close to -1. Some of the subsequent results also break down when α is close to -2. The reason for these two values being exceptional will become clear shortly. Thus the original parameter a can range from 0 to the same magnitude as u in absolute value, but it must be bounded away from $-u$ (and for the most part $-2u$): more precisely, we require that

$$|a| = O(u), \quad |a+u| \geq \delta u > 0, \text{ and } |a+2u| \geq \delta u > 0. \tag{3.3}$$

Now, on replacing z by uz in (2.2), we are led to the following equation which will be the focus of our attention, and which is satisfied by each function $w_n^{(j)}(uz; a)$ $(j = 0, \pm 1)$:

$$\frac{\mathrm{d}^2 w}{\mathrm{d}z^2} = \{u^2 f(\alpha, z) + g(z)\} w, \tag{3.4}$$

where

$$f(\alpha, z) = 1 + \frac{\alpha}{z} + \frac{(2+\alpha)^2}{4z^2} \tag{3.5}$$

and

$$g(z) = -\frac{1}{4z^2}. \tag{3.6}$$

This particular partitioning was chosen so that the subsequent expansions will be uniformly valid at both $z = 0$ and $z = \infty$. To see why this is so, we refer the reader to [8, Chap. 6, sect.s 4.3 and 5.3].

We are considering the case where $u \to \infty$, and as such the dominant term is $u^2\ f(\alpha, z)$, except near the zeros of $f(\alpha, z)$. The function $f(\alpha, z)$ has two zeros, say, at $z_1(\alpha)$ and $z_2(\alpha)$, where

$$z_{1,2}(\alpha) = \pm i\sqrt{1+\alpha} - \frac{1}{2}\alpha, \tag{3.7}$$

and consequently, $f(\alpha, z)$ can be expressed in the form

$$f(\alpha, z) = \frac{(z - z_1)(z - z_2)}{z^2}. \tag{3.8}$$

The zeros $z_1(\alpha)$ and $z_2(\alpha)$ are the turning points of (3.4). The principal branch of the square root in (3.7) is taken for both, so that when α is real and greater than -1

the turning point $z_1(\alpha)$ lies in the upper half plane (second quadrant when $\alpha > 0$), and the turning point $z_2(\alpha)$ lies in the lower half plane (third quadrant when $\alpha > 0$), with both being continuous functions of α in the complex plane having a cut from $\alpha = -1$ to $\alpha = -\infty$. When α is real and greater than -1 we observe that

$$|z_{1,2}(\alpha)| = 1 + \frac{1}{2}\alpha. \tag{3.9}$$

Note that as $\alpha \to 0$ (for example, when $n \to \infty$ with a fixed),

$$z_{1,2}(\alpha) = \pm i - \frac{1}{2}(1 \mp i)\alpha \mp \frac{1}{8}i\alpha^2 + O(\alpha^3). \tag{3.10}$$

Thus from (3.1), (3.2), (3.3), (3.7), and (3.10) we perceive that these turning points are bounded, and if a is fixed, they approach the points $z = \pm i$, respectively, when $u \to \infty$. Also, in the special case $-1 < \alpha < \infty$ these turning points are complex conjugates, located on the line $\operatorname{Re} z = -\frac{1}{2}\alpha$. At the end of this section we discuss in more detail the position of the two turning points in the complex plane.

Our aim is to obtain asymptotic solutions which are valid in domains which contain the turning point $z = z_1(\alpha)$ (as well as $z = 0$ and $z = \infty$). The domains will be specified precisely later and will be seen to depend on the value of the parameter α. If α lies in the interval $-1 < \alpha < \infty$ the domains of validity will be shown to contain the whole upper half plane (as well as parts of the lower half plane).

To obtain the desired asymptotic expansions we shall use a Liouville transformation (see [8, Chap. 6, (1.03) and (1.04)]) to transform (3.4) into the form

$$\frac{\mathrm{d}^2 W}{\mathrm{d}\zeta^2} = \{u^2\zeta + \psi(\zeta)\}W, \tag{3.11}$$

where W and ζ are, respectively, new dependent and independent variables. The new differential equation (3.11) has a turning point at $\zeta = 0$, which must correspond to the original turning point at $z = z_1$. The nondominant term, the so-called Schwarzian derivative $\psi(\zeta)$ (given by (3.13) and (3.14) below), will then be analytic at $\zeta = 0$. A general asymptotic theory for differential equations of the form (3.11), for the case ζ complex, is then supplied by Olver [8, Chap. 11, Thm. 9.1].

The appropriate Liouville transformation is given by [8, Chap. 11, (3.02)]

$$\zeta\left(\frac{\mathrm{d}\zeta}{\mathrm{d}z}\right)^2 = f(\alpha, z), \qquad W = (f/\zeta)^{1/4}w, \tag{3.12}$$

and this leads to

$$\psi(\zeta) = \frac{5}{16\zeta^2} + \frac{\zeta\{4ff'' - 5f'^2\}}{16f^3} + \frac{\zeta g}{f}, \tag{3.13}$$

or, equivalently (from (3.5) and (3.6)),

$$\psi(\zeta) = \frac{5}{16\zeta^2} - \frac{\zeta z}{16(z - z_1)^3(z - z_2)^3}[4z^3 - (4 + 3\alpha)(4 + \alpha)z - \alpha(2 + \alpha)^2]. \tag{3.14}$$

Integration of the first equation of (3.12) yields the relationship

$$\frac{2}{3}\zeta^{3/2} = \int_{z_1}^{z} f^{1/2}(\alpha, t)\,\mathrm{d}t = \int_{z_1}^{z} \frac{(t - z_1)^{1/2}(t - z_2)^{1/2}}{t}\mathrm{d}t, \tag{3.15}$$

where the lower integration limit is chosen to ensure that $\zeta = 0$ corresponds to $z = z_1(\alpha)$. As a result ζ, regarded as a function of z, is analytic at $z = z_1$ but has branch points at $z = 0$ and $z = z_2$. Explicit integration of the right-hand side of (3.15) yields

$$\begin{aligned}\frac{2}{3}\zeta^{3/2} &= [(z-z_1)(z-z_2)]^{1/2} \\ &\quad - \frac{1}{2}(z_1+z_2)\ln\left\{\frac{z-\frac{1}{2}(z_1+z_2)+[(z-z_1)(z-z_2)]^{1/2}}{(z_1-z_2)/(2i)}\right\} \\ &\quad + \sqrt{z_1z_2}\ln\left\{\frac{[z_1z_2(z-z_1)(z-z_2)]^{1/2}+\frac{1}{2}z(z_1+z_2)-z_1z_2}{z(z_1-z_2)/(2i)}\right\} - \frac{1}{2}(1+\alpha)\pi i.\end{aligned} \tag{3.16}$$

In this relationship it is helpful to note from (3.7) that

$$z_1z_2 = \left(1+\frac{1}{2}\alpha\right)^2, \quad z_1+z_2 = -\alpha, \quad \frac{z_1-z_2}{2i} = \sqrt{1+\alpha}. \tag{3.17}$$

The $z-\zeta$ transformation (3.16) is quite complicated. In order to understand it more fully, and to specify the branches precisely, it is convenient to introduce an intermediate variable ω by

$$\frac{2}{3}\zeta^{3/2} = \omega = \int_{z_1}^{z}\frac{(t-z_1)^{1/2}(t-z_2)^{1/2}}{t}\mathrm{d}t. \tag{3.18}$$

We then introduce a branch cut along the ray emanating from $z = 0$ and passing through $z = z_2$. In addition, since ω (regarded as a function of z) has a branch point at $z = z_1$, we introduce (temporarily) a branch cut from $z = z_1$ to $z = \infty$ along the ray $\arg(z) = \arg(z_1)$; see Figure 1. Then ω is defined as being a continuous function of z in this cut plane, with branches specified so that $\operatorname{Im}\omega = -\frac{1}{2}(1+\alpha)\pi$ when $\alpha \in (-1,\infty)$ and z is real. Assuming for the moment that α is real and lying in the interval $-1 < \alpha < \infty$, we find that (on utilizing (3.16))

$$\omega = z + \frac{1}{2}\alpha\ln(2z) + \frac{1}{2}\alpha - \frac{1}{2}(1+\alpha)\ln(1+\alpha) - \frac{1}{2}(1+\alpha)\pi i + O(z^{-1}) \tag{3.19}$$

as $z \to \infty$ in the right half plane, where $\ln(2z)$ is real when z is positive. For each fixed z in the cut plane, we also specify that ω depends continuously on α in the complex plane having a cut from $\alpha = -1$ to $\alpha = -\infty$.

From these definitions we observe that as $\operatorname{Re} z \to -\infty$ (to the left of the rays ABC and DEF in Figure 1)

$$\omega = -z - \frac{1}{2}\alpha\ln(2z) + \frac{1}{2}(1+\alpha)\ln(1+\alpha) - \frac{1}{2}\alpha + \frac{1}{2}(1+\alpha)\pi i + O(z^{-1}). \tag{3.20}$$

With our choice of branches the effect of the $z-\omega$ transformation is depicted in Figures 1, 2(a), and 2(b) (for the case $\alpha > 0$). Figure 2(a) depicts the region mapped to the right of the rays $\arg z = \arg z_1$ and $\arg z = \arg z_2$, and Figure 2(b) depicts the region mapped to the left of these rays. In these (and subsequent figures) corresponding points are labeled by the same capital letters. For example, the point $\omega = -(1+\alpha)\pi i$ corresponds to $z = z_2$ on the right-hand side of the cut, and is labeled

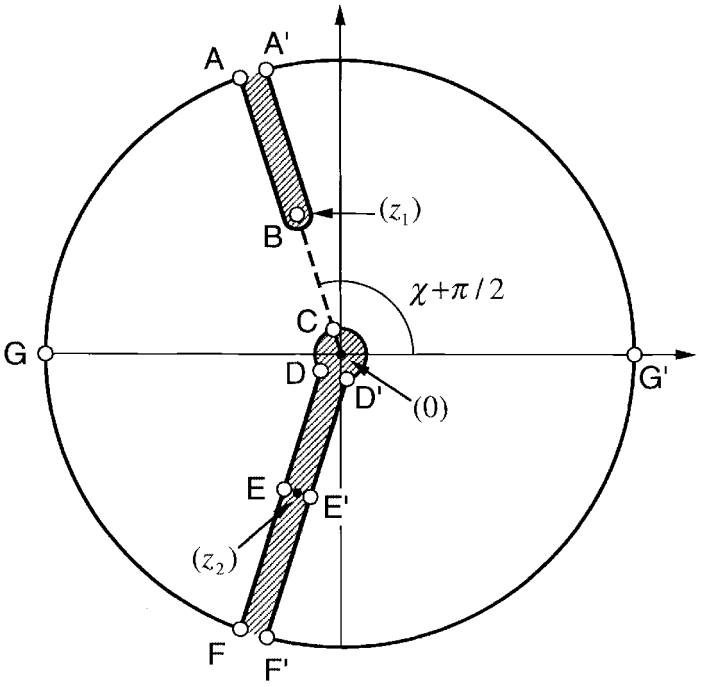

FIG. 1. *z plane.*

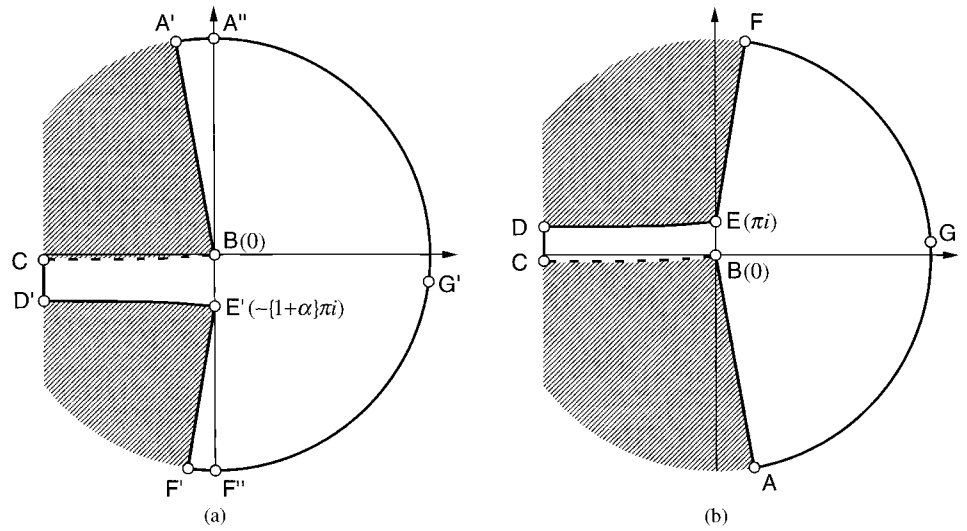

FIG. 2. (a) *ω plane,* (b) *ω plane.*

E′ in Figures 1 and 2(a). Likewise, $z = z_2$ on the other side of the cut is mapped to $\omega = \pi i$ (labeled E in Figures 1 and 2(b)).

Finally, from the relationship $\omega = \frac{2}{3}\zeta^{3/2}$, the domain, say, Δ, corresponding to the cut z plane of Figure 3 (the cut emanating from $z = z_1$ now being removed) can be determined via Figures 2(a) and 2(b). This domain is shown in Figure 4, with

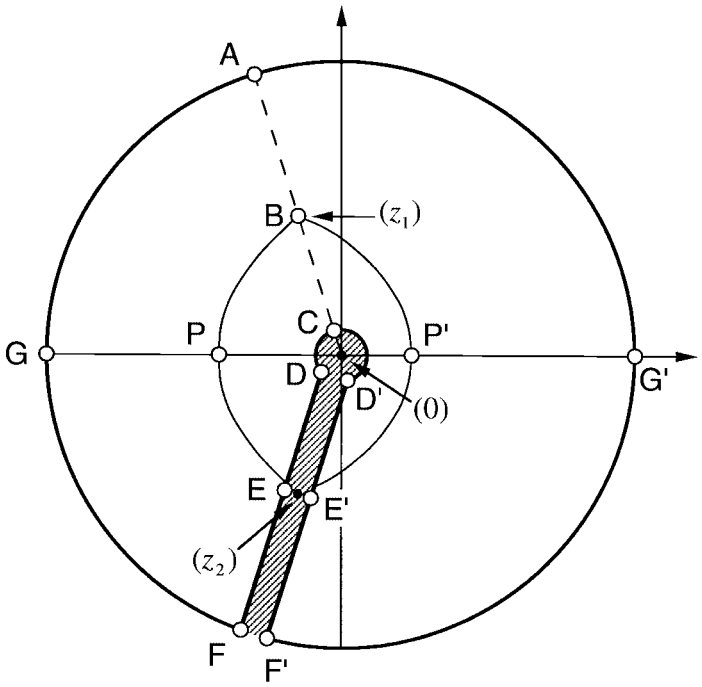

FIG. 3. *z plane.*

the points E and E′, which correspond to the turning point $z = z_2$ on either side of the cut, being mapped to the points $\zeta = e^{-\pi i/3}[\frac{3}{2}(1+\alpha)\pi]^{2/3}$ and $\zeta = -(\frac{3}{2}\pi)^{2/3}$, respectively. The origin in the ζ plane, labeled B, corresponds to the turning point $z = z_1$, and is, of course, a regular point of the $z - \zeta$ transformation.

We shall require the following asymptotic results for the cases $z \to \infty$ and $z \to 0$. First, exponentiation of (3.19) yields

$$\exp\left\{\frac{2}{3}u\zeta^{3/2}\right\} = e^{-u(1+\alpha)\pi i/2}(1+\alpha)^{-u(1+\alpha)/2}e^{u\alpha/2}e^{uz}(2z)^{u\alpha/2}\{1+O(z^{-1})\} \tag{3.21}$$

as $z \to \infty$: here and in section 4, this means that $z \to \infty$ in *any* direction in the cut plane depicted in Figure 3. However, when $z \to \infty$ it is understood that ζ approaches infinity in the part of Δ, containing the positive real axis, which is bounded by the curves BEF and BE′F′ (see Figure 4). In (3.21) $\exp\{\frac{2}{3}u\zeta^{3/2}\}$ takes its principle value in the right half plane is continuous elsewhere in the stated subdomain.

Next, we can show from (3.16) that

$$\begin{aligned}\frac{2}{3}\zeta^{3/2} &= \frac{1}{2}(2+\alpha)\ln\{2(2+\alpha)^{-2}z\} + 1 + \frac{1}{2}\alpha \\ &\quad + \frac{1}{2}(1+\alpha)\ln(1+\alpha) - \frac{1}{2}(1+\alpha)\pi i + O(z)\end{aligned} \tag{3.22}$$

as $z \to 0$. Note that $\zeta \to \infty e^{-2\pi i/3}$ in this case. In both (3.21) and (3.22) the O terms are real when z is positive and α is lying in the interval $-1 < \alpha < \infty$.

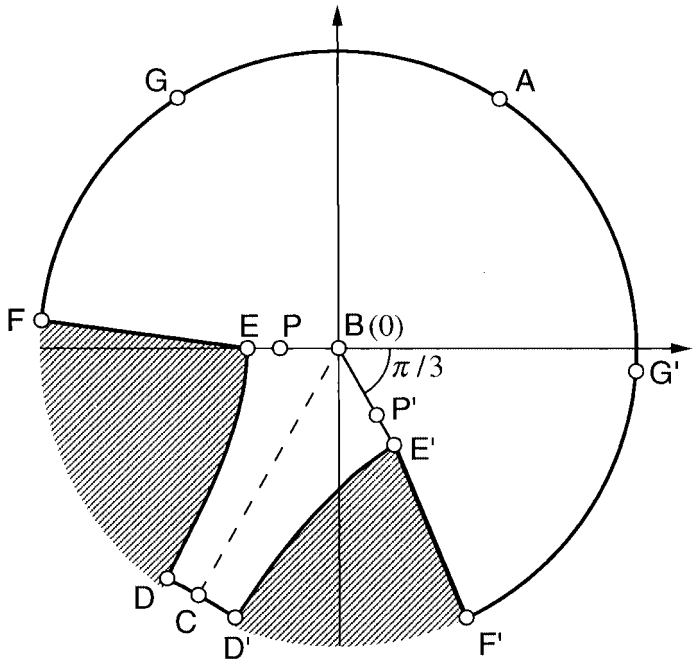

FIG. 4. ζ *plane.*

It is also worth noting that when $-1 < \alpha < \infty$

$$\zeta = \frac{2e^{-\pi i/6-2i\chi(\alpha)/3}(1+\alpha)^{1/6}}{(2+\alpha)^{2/3}}(z-z_1) + O\{(z-z_1)^2\}, \tag{3.23}$$

as $z \to z_1$, where (see Figure 1)

$$\chi(\alpha) = \arg(z_1(\alpha)) - \frac{1}{2}\pi = \sin^{-1}\left(\frac{\alpha}{2+\alpha}\right). \tag{3.24}$$

The principal value of the inverse sine applies here, so that as $\alpha \to 0$

$$\chi(\alpha) = \frac{1}{2}\alpha + O(\alpha^2). \tag{3.25}$$

We conclude this section by examining the location of the two turning points in the z plane when α is complex. First, let us write

$$\alpha = -1 + r^2 e^{i\theta}, \tag{3.26}$$

where $r > 0$ and $-\pi \le \theta \le \pi$. Then, from (3.7) and (3.26) one finds that

$$\text{Im } z_1(\alpha) = r\cos\left(\frac{1}{2}\theta\right)\left\{1 - r\sin\left(\frac{1}{2}\theta\right)\right\} \tag{3.27}$$

and

$$\text{Im } z_2(\alpha) = -r\cos\left(\frac{1}{2}\theta\right)\left\{1 + r\sin\left(\frac{1}{2}\theta\right)\right\}. \tag{3.28}$$

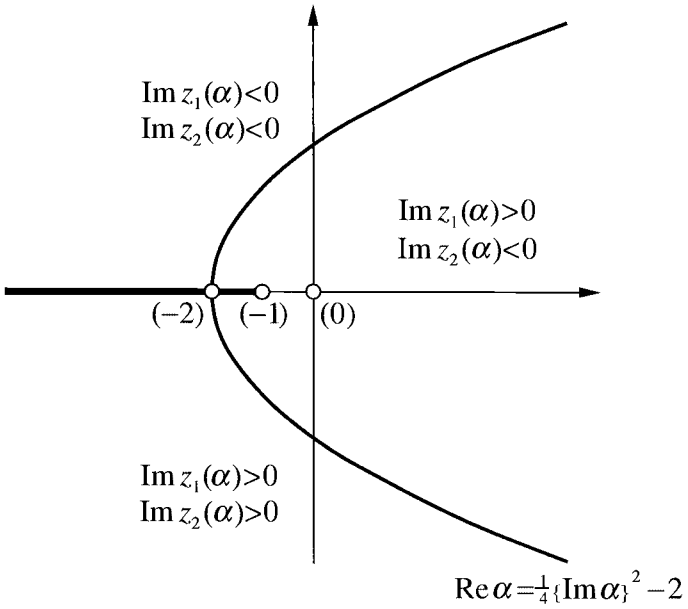

FIG. 5. α *plane.*

Hence, Im $z_1(\alpha) > 0$ when $-\pi < \theta \leq 0$ (α in lower half plane), and Im $z_2(\alpha) < 0$ when $0 \leq \theta < \pi$ (α in upper half plane). On the other hand $z_1(\alpha)$ passes from the upper to lower half planes as α passes across the curve $r\sin(\frac{1}{2}\theta) = 1$, $0 < \theta < \pi$; from (3.26) we see that this is the curve Im $\sqrt{\alpha+1} = 1$, i.e., the half-parabola Re $\alpha = \frac{1}{4}\{\text{Im}\,\alpha\}^2 - 2$, Im $\alpha > 0$. On this half-parabola $z_1(\alpha)$ is real and negative, taking the value $z_1 = -\frac{1}{8}\{\text{Im}\,\alpha\}^2$. Likewise, $z_2(\alpha)$ passes from the lower to upper half planes as α passes across the half-parabola Re $\alpha = \frac{1}{4}\{\text{Im}\,\alpha\}^2 - 2$, Im $\alpha < 0$ (taking the value $z_2 = -\frac{1}{8}\{\text{Im}\,\alpha\}^2$ on this curve). All these situations are depicted in Figure 5.

Consider now the case when α lies on the interval $-\infty < \alpha \leq -1$, say, below the cut. We set $e^{i\theta} = -1$ in (3.26), so that $\alpha = -1 - r^2$ ($0 \leq r < \infty$). Then, it follows that $z_1(\alpha) = \frac{1}{2}(1+r)^2$ and $z_2(\alpha) = \frac{1}{2}(1-r)^2$ (or vice versa if α lies above the cut). Thus, both turning points lie on the nonnegative real z axis, with $r = 0$ ($\alpha = -1$) and $r = 1$ ($\alpha = -2$) being critical values: in the former case the two turning points coalesce with one another at the point $z = \frac{1}{2}$, and in the latter case the turning point $z_2(\alpha)$ coalesces with the pole $z = 0$ (or alternatively, $z_1(\alpha)$ coalesces with the pole when $\alpha \to -2$ above the cut). Both the cases $\alpha = -1$ and $\alpha = -2$ are beyond the scope of this paper, although they can be tackled using established results. A general theory for two coalescing turning points (in the real variable case) is provided by [9], and a general theory for a coalescing turning point and double pole (in both real and complex variable cases) is provided by [2]. We remark, however, that some of the Airy function results that follow in section 4 will still be valid when $\alpha \to -2$, since the turning point $z_1(\alpha)$ (defined as $z_1(\alpha) = \frac{1}{2}(1+r)^2$ when $\alpha = -1-r^2$) will be bounded away from both the pole at $z = 0$ and the other turning point $z_2(\alpha)$. However, when $\alpha \to -2$ none of the subsequent expansions will be valid in the vicinity of the pole $z = 0$.

4. Uniform asymptotic expansions involving Airy functions. We now focus on the transformed differential equation (3.11). We apply Theorem 9.1 of [8, Chap. 11] (with n replaced by N) to this equation to obtain the following three solutions ($j = 0, \pm 1$):

$$W_{2N+1,j}(u,\zeta) = \mathrm{Ai}_j(u^{2/3}\zeta)\sum_{s=0}^{N}\frac{A_s(\zeta)}{u^{2s}} + \frac{1}{u^2}\frac{\mathrm{d}\ \mathrm{Ai}_j(u^{2/3}\zeta)}{\mathrm{d}\zeta}\sum_{s=0}^{N-1}\frac{B_s(\zeta)}{u^{2s}} + \varepsilon_{2N+1,j}(u,\zeta), \tag{4.1}$$

where $\mathrm{Ai}(z)$ is the standard Airy function and

$$\mathrm{Ai}_j(u^{2/3}\zeta) = \mathrm{Ai}(u^{2/3}\zeta e^{-2\pi i j/3}). \tag{4.2}$$

The significance of each Airy function $\mathrm{Ai}_j(u^{2/3}\zeta)$ ($j = 0, \pm 1$) is that it is recessive (exponentially small) inside the sector $|\arg(\zeta e^{-2\pi j i/3})| \leq \frac{1}{3}\pi$, and dominant (exponentially large) outside this sector (except on the boundaries of the three sectors). Following [8, Chap. 11, sect. 8.1] we denote these three sectors by $\mathbf{S}_j$ ($j = 0, \pm 1$).

The coefficients in the asymptotic expansions (4.1) are defined recursively by $A_0(\zeta) = 1$,

$$A_{s+1}(\zeta) = -\frac{1}{2}B_s'(\zeta) + \frac{1}{2}\int_{\infty}^{\zeta}\psi(\nu)B_s(\nu)\mathrm{d}\nu \quad (s = 0, 1, 2, \ldots) \tag{4.3}$$

and

$$B_s(\zeta) = \frac{1}{2\zeta^{1/2}}\int_0^{\zeta}\{\psi(\nu)A_s(\nu) - A_s''(\nu)\}\frac{\mathrm{d}\nu}{\nu^{1/2}} \quad (s = 0, 1, 2, \ldots). \tag{4.4}$$

The lower integration limits in (4.3) are taken at a point of infinity in the part of Δ which is bounded by the curves BEF and $\mathsf{BE'F'}$ (see Figure 4), i.e., corresponding to $z = \infty$. As a result, from (3.14) and (3.19) and induction on (4.3) and (4.4), it can be shown that for $s = 0, 1, 2 \ldots$

$$\lim_{\substack{\zeta\to\infty\\(z\to\infty)}} A_{s+1}(\zeta) = 0 \tag{4.5}$$

and

$$\lim_{\substack{\zeta\to\infty\\(z\to\infty)}} \zeta^{1/2}B_s(\zeta) = l_s \tag{4.6}$$

for some constants $\{l_s\}_{s=0}^{\infty}$ (which will be discussed later).

The error terms $\varepsilon_{2N+1,j}(u,\zeta)$ ($j = 0, \pm 1$) are $O(u^{-2N-1})$ as $u \to \infty$, uniformly for ζ lying in certain (unbounded) subdomains of Δ, which we denote by $\mathbf{Z}_j(\alpha)$, since these regions of asymptotic validity will depend on α. The domains $\mathbf{Z}_j$ are described in a general setting by Olver in [8, Chap. 11, sect. 9] and are denoted by $\mathbf{Z}_j(u,\alpha_j)$ in that reference: they consist of all points in Δ which can be linked by a certain path $\mathcal{L}_j$ to a so-called reference point in $\Delta \cap \mathbf{S}_j$ (which in [8, Chap. 11, sect. 9] is denoted by $\zeta = \alpha_j$). For our purposes we choose the reference points to be at $\zeta = +\infty$, $\infty e^{2\pi i/3}$, $\infty e^{-2\pi i/3}$ for $j = 0, 1, -1$, respectively. We are permitted to take these points at

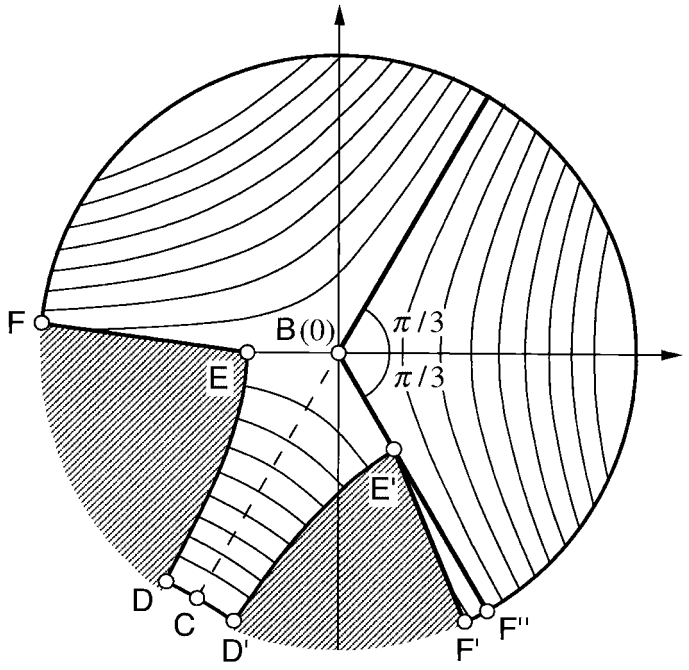

FIG. 6. ζ *plane.*

infinity by virtue of the fact that $\psi^{(s)}(\zeta) = O(\zeta^{-2-s})$ as $\zeta \to \infty$ (for both the cases $z \to 0$ and $z \to \infty$): see (3.14), (3.21), and (3.22), and [8, sect. 9.3].

Each path $\mathcal{L}_j$ must consist of a finite chain of R_2 arcs which lie inside Δ, avoid neighborhoods of the finite singularities $\zeta = e^{-\pi i/3}[\frac{3}{2}(1+\alpha)\pi]^{2/3}$ and $\zeta = -(\frac{3}{2}\pi)^{2/3}$ (labeled E and E' in the figures), and be such that Re $\nu^{3/2}$ is monotonic as ν passes along $\mathcal{L}_j$ from $\infty e^{2\pi i j/3}$ to ζ. In this definition the branch of Re $\nu^{3/2}$, for each $j = 0, \pm 1$, is defined to be continuous with Re $\nu^{3/2} \geq 0$ in $\mathbf{S}_j$ and Re $\nu^{3/2} \leq 0$ in $\mathbf{S}_{j-1} \cup \mathbf{S}_{j+1}$. (Here and elsewhere the suffixes are enumerated modulo 3.)

Although the above descriptions of the domains of validity $\mathbf{Z}_j(\alpha)$ appear quite complicated, the idea is quite straightforward. As an example, suppose that α is real and positive, so that the turning points are located as in Figure 4, with the boundary of the domain Δ also being depicted in this figure. Now, let us first determine the domain $\mathbf{Z}_0(\alpha)$. In Figure 6 the so-called level curves Re $\zeta^{3/2}$ = constant are superimposed on the domain Δ, with Re $\zeta^{3/2} \geq 0$ in $\mathbf{S}_0$ and Re $\zeta^{3/2} \leq 0$ in $\mathbf{S}_1 \cup \mathbf{S}_{-1}$: thus the value of the associated constant for each of these curves is zero on the boundaries of $\mathbf{S}_j$, increases to infinity as $\zeta \to +\infty$, and decreases to minus infinity as $\zeta \to \infty e^{\pm 2\pi i/3}$. It is then readily seen from this figure that all points in Δ (excluding neighborhoods of the singularities at E and E') lie in $\mathbf{Z}_0(\alpha)$, since each point ζ can be linked to the reference point $\zeta = +\infty$ by a path $\mathcal{L}_0$ on which Re $\nu^{3/2}$ is nonincreasing (as ν passes along $\mathcal{L}_0$ from $+\infty$ to ζ).

On the other hand the domains $\mathbf{Z}_1(\alpha)$ and $\mathbf{Z}_{-1}(\alpha)$ differ from $\mathbf{Z}_0(\alpha)$ in the following way. They consist of all points in Δ with neighborhoods of E and E' excluded, but all points on or near the ray $\mathsf{E}'\mathsf{F}''$ must also be excluded. The reason is that any path $\mathcal{L}_1$ (or $\mathcal{L}_{-1}$) linking a point on the ray $\mathsf{E}'\mathsf{F}''$ to $\zeta = \infty e^{2\pi i/3}$ (or $\zeta = \infty e^{-2\pi i/3}$) must necessarily pass through (or close to) the singularity at E', due to the requirement

that Re $\nu^{3/2}$ be monotonic along the path. (Recall that the branch of Re $\nu^{3/2}$, as described above, is chosen differently for the cases $j=1$ and $j=-1$.)

Having described the regions of validity, we apply Olver's theorem to obtain the following error bounds, these being uniformly valid for $\zeta \in \mathbf{Z}_j(\alpha)$:

$$|\varepsilon_{2N+1,j}(u,\zeta)| \le \frac{4v_2 M_{j\pm1}(u^{2/3}\zeta)}{E_j(u^{2/3}\zeta)} \times \exp\left\{\frac{4v_1}{u}\mathcal{V}_{\mathcal{L}_j}(\zeta^{1/2}B_0)\right\}\frac{\mathcal{V}_{\mathcal{L}_j}(\zeta^{1/2}B_n)}{u^{2N+1}} \quad (j=0,\pm1). \tag{4.7}$$

In these bounds

$$E_0(z) = \left|\exp\left(\frac{2}{3}z^{3/2}\right)\right|, \tag{4.8}$$

$$E_j(z) = E_0(ze^{-2\pi ij/3}) \quad (j=\pm1), \tag{4.9}$$

$$M_j(z) = \{E_{j+1}^2(z)|\mathrm{Ai}_{j+1}^2(z)| + E_{j-1}^2(z)|\mathrm{Ai}_{j-1}^2(z)|\}^{1/2}, \tag{4.10}$$

$$v_1 = \sup_{\text{all } z}\{\pi|z|^{1/2}M_j^2(z)\}, \tag{4.11}$$

and

$$v_2 = \sup_{\text{all } z}\{\pi E_{j-1}(z)M_j(z)|z^{1/2}\mathrm{Ai}_{j-1}(z)|\}. \tag{4.12}$$

The branches in (4.8) are chosen so that $E_0(u\zeta^{3/2}) \ge 1$ in $\mathbf{S}_0$ and $E_0(u\zeta^{3/2}) \le 1$ in $\mathbf{S}_1 \cup \mathbf{S}_{-1}$. Hence for $j=\pm1$, from the definition (4.9), $E_j(u\zeta^{3/2}) \ge 1$ in $\mathbf{S}_j$ and $E_j(u\zeta^{3/2}) \le 1$ in $\mathbf{S}_{j-1} \cup \mathbf{S}_{j+1}$. Since $\psi(\zeta) = O(\zeta^{-2})$ as $\zeta \to \infty$ (for both the cases $z \to 0$ and $z \to \infty$) it follows from the bound (4.7), and from section 9.3 of [8], that $\varepsilon_{2N+1,j}(u,\zeta) = E_j^{-1}(u^{2/3}\zeta)M_{j\pm1}(u^{2/3}\zeta)O(\zeta^{-3/2})$ as $\zeta \to \infty e^{2\pi ij/3}$ $(j=0,1,-1)$.

Having derived asymptotic solutions, we match them with the standard solutions of (3.4). On account of uniqueness of recessive solutions, we assert that for $j=0,1,-1$

$$\Lambda_{2N+1,j}w_n^{(j)}(uz;a) = \left\{\frac{z^2\zeta}{(z-z_1)(z-z_2)}\right\}^{1/4} W_{2N+1,j}(u,\zeta), \tag{4.13}$$

where $\Lambda_{2N+1,j}$ are constants.

Let us first determine $\Lambda_{2N+1,0}$. To do this we shall use the well-known behavior of Airy functions of large argument (see, for example, [8, Chap. 11, (1.07)])

$$\mathrm{Ai}(w) = \frac{\exp\{-\frac{2}{3}w^{3/2}\}}{2\sqrt{\pi}w^{1/4}}\{1+O(w^{-1})\}, \tag{4.14}$$

$$\mathrm{Ai}'(w) = -\frac{w^{1/4}\exp\{-\frac{2}{3}w^{3/2}\}}{2\sqrt{\pi}}\{1+O(w^{-1})\} \tag{4.15}$$

as $w \to \infty$ with $|\arg(w)| \le \pi - \delta$. Now using these, while letting $z \to \infty$ in (4.1), and referring to (4.5) and (4.6), we find that

$$\left\{\frac{z^2\zeta}{(z-z_1)(z-z_2)}\right\}^{1/4} W_{2N+1,0}(u,\zeta) = \frac{\exp\{-\frac{2}{3}u\zeta^{3/2}\}}{2\sqrt{\pi}u^{1/6}}\left[1-\sum_{s=0}^{N-1}\frac{l_s}{u^{2s+1}}\right]\{1+O(\zeta^{-3/2})\}. \tag{4.16}$$

On the other hand, from (2.5)

$$w_n^{(0)}(uz;a) = 2^{-u-u\alpha-1/2}u^{-u\alpha/2}z^{-u\alpha/2}e^{-uz}\{1+O(z^{-1})\}, \tag{4.17}$$

as $z \to \infty$. Therefore, from (4.13), (4.16), and (4.17) we find that

$$\Lambda_{2N+1,0} = \frac{2^{u+u\alpha-1/2}u^{u\alpha/2-1/6}}{\sqrt{\pi}}\left[1-\sum_{s=0}^{N-1}\frac{l_s}{u^{2s+1}}\right]\lim_{z\to\infty} z^{u\alpha/2}\exp\left\{uz-\frac{2}{3}u\zeta^{3/2}\right\}, \tag{4.18}$$

which, on referring to (3.21), yields our desired formula

$$\Lambda_{2N+1,0} = \frac{e^{u(1+\alpha)\pi i/2}2^{u+u\alpha/2-1/2}u^{u\alpha/2-1/6}(1+\alpha)^{u(1+\alpha)/2}e^{-u\alpha/2}}{\sqrt{\pi}}\left[1-\sum_{s=0}^{N-1}\frac{l_s}{u^{2s+1}}\right]. \tag{4.19}$$

We find $\Lambda_{2N+1,1}$ similarly. When $j=1$ the left-hand side of (4.13) has the form

$$\begin{aligned}&\left\{\frac{z^2\zeta}{(z-z_1)(z-z_2)}\right\}^{1/4} W_{2N+1,1}(u,\zeta)\\ &\quad= \frac{e^{\pi i/6}\exp\{\frac{2}{3}u\zeta^{3/2}\}}{2\sqrt{\pi}u^{1/6}}\left[1+\sum_{s=0}^{N-1}\frac{l_s}{u^{2s+1}}\right]\{1+O(\zeta^{-3/2})\}\end{aligned} \tag{4.20}$$

when $z \to \infty$. Next, from (2.9) we see that

$$w_n^{(1)}(uz;a) = 2^{-u-1/2}u^{u\alpha/2}z^{u\alpha/2}e^{uz}\{1+O(z^{-1})\} \tag{4.21}$$

as $z \to \infty$ (with $-\frac{1}{2}\pi+\delta \le \arg(z) \le \frac{5}{2}\pi-\delta$), and hence, using these in (4.13) (with $j=1$), and again referring to (3.21), we find that

$$\Lambda_{2N+1,1} = \frac{e^{\pi i/6}e^{-(1+\alpha)\pi i/2}2^{u+u\alpha/2-1/2}e^{u\alpha/2}}{\sqrt{\pi}u^{u\alpha/2+1/6}(1+\alpha)^{u(1+\alpha)/2}}\left[1+\sum_{s=0}^{N-1}\frac{l_s}{u^{2s+1}}\right]. \tag{4.22}$$

We finally find $\Lambda_{2N+1,-1}$ by setting $j=-1$ in (4.13) and again letting $z \to \infty$. Thus, we find that

$$\begin{aligned}&\left\{\frac{z^2\zeta}{(z-z_1)(z-z_2)}\right\}^{1/4} W_{2N+1,-1}(u,\zeta)\\ &\quad= \frac{e^{-\pi i/6}\exp\{\frac{2}{3}u\zeta^{3/2}\}}{2\sqrt{\pi}u^{1/6}}\left[1+\sum_{s=0}^{N-1}\frac{l_s}{u^{2s+1}}+\delta_{2N+1}\right]\{1+O(\zeta^{-3/2})\},\end{aligned} \tag{4.23}$$

where

$$\delta_{2N+1} = e^{\pi i/6}2\sqrt{\pi}u^{1/6}\lim_{\zeta\to+\infty}\exp\left\{-\frac{2}{3}u\zeta^{3/2}\right\}\zeta^{1/4}\varepsilon_{2N+1,-1}(u,\zeta). \tag{4.24}$$

Explicit bounds for this constant are available via (4.7), and we note that $\delta_{2N+1} = O(u^{-2N-1})$ as $u \to \infty$. On the other hand, on utilizing (2.5), (2.9), (2.13), (3.1),

(3.2), and (3.21), we find that as $z \to \infty$ with $-\frac{1}{2}\pi+\delta \le \arg(z) \le \frac{3}{2}\pi-\delta$ (i.e., $\zeta \to \infty$ with $|\arg(\zeta e^{-\pi i/3})| \le \frac{2}{3}\pi-\delta$)

$$w_n^{(-1)}(uz;a) = i\,\frac{e^{u(1+\alpha)\pi i/2}e^{u\alpha/2}\exp\{-\frac{2}{3}u\zeta^{3/2}\}}{2^{u+u\alpha/2+1/2}u^{u\alpha/2}(1+\alpha)^{u(1+\alpha)/2}\Gamma(u+\frac{1}{2})}\{1+O(\zeta^{-3/2})\} \tag{4.25}$$
$$+\,\frac{e^{u(1+\alpha)\pi/2}u^{u\alpha/2}(1+\alpha)^{u(1+\alpha)/2}\exp\{\frac{2}{3}u\zeta^{3/2}\}}{2^{u+u\alpha/2+1/2}e^{u\alpha/2}\Gamma(u+u\alpha+\frac{1}{2})}\{1+O(\zeta^{-3/2})\}.$$

In particular, if $\zeta \to +\infty$ the first term on the right-hand side is negligible, and hence from (4.13) and (4.23) we obtain the desired expression

$$\Lambda_{2N+1,-1} = \frac{e^{-\pi i/6}e^{-u(1+\alpha)\pi i/2}2^{u+u\alpha/2-1/2}\Gamma(u+u\alpha+\frac{1}{2})e^{u\alpha/2}}{\sqrt{\pi}u^{1/6}u^{u\alpha/2}(1+\alpha)^{u(1+\alpha)/2}} \tag{4.26}$$
$$\times\left[1+\sum_{s=0}^{N-1}\frac{l_s}{u^{2s+1}}+\delta_{2N+1}\right].$$

Although it is possible to find $\Lambda_{2N+1,-1}$ without the unknown constant δ_{2N+1} by instead letting $\zeta \to \infty e^{-2\pi i/3}$ (i.e., $z \to 0$), we prefer to again let $\zeta \to +\infty$ (i.e., $z \to \infty$) so as to obtain an expression for $\Lambda_{2N+1,-1}$ which involves the same constants $\{l_s\}_{s=0}^{\infty}$ as in (4.19) and (4.22) above. Moreover, from (4.26) we are able to obtain as a byproduct a method for easily calculating these constants, as we now demonstrate. First, from (4.1), (4.2), (4.5), (4.6), and [8, Chap. 11, (1.08) and (1.09)] it can be seen that

$$\left\{\frac{z^2\zeta}{(z-z_1)(z-z_2)}\right\}^{1/4} W_{2N+1,-1}(u,\zeta) \tag{4.27}$$
$$= \frac{e^{\pi i/12}}{\sqrt{\pi}u^{1/6}}\left[\cos\left(i\frac{2}{3}u\zeta^{3/2}+\frac{1}{4}\pi\right)-i\sin\left(i\frac{2}{3}u\zeta^{3/2}+\frac{1}{4}\pi\right)\sum_{s=0}^{N-1}\frac{l_s}{u^{2s+1}}\right]$$
$$+\left\{\frac{z^2\zeta}{(z-z_1)(z-z_2)}\right\}^{1/4}\varepsilon_{2N+1,-1}(u,\zeta)+O(\zeta^{-3/2})$$

as $\zeta e^{2\pi i/3} \to -\infty$. (Note that (4.14) and (4.15) cannot be used here.) Now in (4.27) let $\zeta = \zeta_p$, where $\frac{2}{3}u\zeta_p^{3/2} = 2p\pi i + \frac{1}{4}\pi i$, where p is a positive integer (and the branch is such that $\arg(\zeta) = \frac{1}{3}\pi$). Then $\cos(i\frac{2}{3}u\zeta_p^{3/2}+\frac{1}{4}\pi) = 1$, $\sin(i\frac{2}{3}u\zeta_p^{3/2}+\frac{1}{4}\pi) = 0$, and $\zeta_p \to \infty e^{\pi i/3}$ as $p \to \infty$. Hence, we see that

$$\lim_{\substack{\zeta=\zeta_p\\ p\to\infty}}\left\{\frac{z^2\zeta}{(z-z_1)(z-z_2)}\right\}^{1/4} W_{2N+1,-1}(u,\zeta) = \frac{e^{\pi i/12}}{\sqrt{\pi}u^{1/6}}\{1+O(u^{-2N-1})\}, \tag{4.28}$$

in which

$$O(u^{-2N-1}) = e^{-\pi i/12}\sqrt{\pi}u^{1/6}\lim_{p\to\infty}\zeta_p^{1/4}\varepsilon_{2N+1,-1}(u,\zeta_p). \tag{4.29}$$

Likewise, from (4.25)

$$\lim_{\substack{\zeta=\zeta_p\\ p\to\infty}} w_n^{(-1)}(uz;a) = \frac{e^{\pi i/4}e^{u(1+\alpha)\pi i/2}e^{u\alpha/2}}{2^{u+u\alpha/2+1/2}u^{u\alpha/2}(1+\alpha)^{u(1+\alpha)/2}\Gamma(u+\frac{1}{2})} \tag{4.30}$$

$$+\frac{e^{\pi i/4}e^{u(1+\alpha)\pi i/2}u^{u\alpha/2}e^{-u\alpha/2}(1+\alpha)^{u(1+\alpha)/2}}{2^{n+u\alpha/2+1}\Gamma(u+u\alpha+\frac{1}{2})}.$$

Thus, inserting (4.28) and (4.30) into (4.13) we find that

$$\Lambda_{2N+1,-1}=\frac{e^{-\pi i/6}e^{-u(1+\alpha)\pi i/2}2^{u+u\alpha/2+1/2}}{\sqrt{\pi}u^{1/6}}\{1+O(u^{-2N-1})\} \tag{4.31}$$
$$\times\left[\frac{e^{u\alpha/2}}{u^{u\alpha/2}(1+\alpha)^{u(1+\alpha)/2}\Gamma(u+\frac{1}{2})}+\frac{u^{u\alpha/2}(1+\alpha)^{u(1+\alpha)/2}}{e^{u\alpha/2}\Gamma(u+u\alpha+\frac{1}{2})}\right]^{-1}.$$

If we now compare (4.26) and (4.31) and note that N is arbitrary, we deduce that (at least formally)

$$1+\sum_{s=0}^{\infty}\frac{l_s}{u^{2s+1}}=2\left[1+\frac{e^{u\alpha}\Gamma(u+u\alpha+\frac{1}{2})}{u^{u\alpha}(1+\alpha)^{u(1+\alpha)}\Gamma(u+\frac{1}{2})}\right]^{-1}. \tag{4.32}$$

We first notice that when $\alpha=0$ the right-hand side reduces identically to 1, and hence, it follows that $l_s=0$ for all s. This is in agreement with the well-known case for Bessel functions (see [8, Chap. 11, (10.23)]). For other fixed values of α (real or complex, subject to $|\arg(\alpha+1)|\le\pi-\delta$ and $\alpha\ne-1$) we can utilize a symbolic algebra program (such as MAPLE) to expand the right-hand side, via Stirling's formula, in inverse powers of u, thereby determining the coefficients l_s. For example, we find that the first two are given by

$$l_1=-\frac{\alpha}{48(1+\alpha)} \tag{4.33}$$

and

$$l_2=\frac{\alpha(6048+6048\alpha+2021\alpha^2)}{1658880(1+\alpha)^3}. \tag{4.34}$$

Let us summarize our main result.

THEOREM 4.1. *Denote new parameters by*

$$u=n+\frac{1}{2},\quad \alpha=\frac{a-2}{u}, \tag{4.35}$$

let turning points $z_{1,2}$ be defined by (3.7)*, and define a new dependent variable ζ by* (3.16)*. Then if $\alpha=O(1)$, $|\alpha+1|\ge\delta>0$, and $|\alpha+2|\ge\delta>0$, the reverse generalized Bessel polynomial has the uniform asymptotic expansion*

$$\theta_n(uz;a)=\frac{e^{-u(1+\alpha)\pi i/2}\sqrt{\pi}2^{1+u\alpha/2}u^{u-1/3}e^{u\alpha/2}}{(1+\alpha)^{u(1+\alpha)/2}}\left[1+\sum_{s=0}^{N-1}\frac{l_s}{u^{2s+1}}\right]^{-1} \tag{4.36}$$
$$\times\left\{\frac{\zeta}{(z-z_1)(z-z_2)}\right\}^{1/4}z^{u+u\alpha/2}e^{uz}W_{2N+1,0}(u,\zeta),$$

where the constants $\{l_s\}_{s=0}^{\infty}$ are implicitly defined via the asymptotic expansion (4.32)*. In the expansion* (4.36)

$$W_{2N+1,0}(u,\zeta)=\mathrm{Ai}(u^{2/3}\zeta)\sum_{s=0}^{N}\frac{A_s(\zeta)}{u^{2s}}+\frac{1}{u^2}\frac{\mathrm{d}\ \mathrm{Ai}(u^{2/3}\zeta)}{\mathrm{d}\zeta}\sum_{s=0}^{N-1}\frac{B_s(\zeta)}{u^{2s}}+\varepsilon_{2N+1,0}(u,\zeta), \tag{4.37}$$

where the coefficients $A_s(\zeta)$ *and* $B_s(\zeta)$ *are defined by* (4.3) *and* (4.4), *and the error term* $\varepsilon_{2N+1,0}(u,\zeta)$ *is bounded by* (4.7), *uniformly for* $\zeta \in \mathbf{Z}_0(\alpha)$ *(this domain of validity being described above). The corresponding region of validity in the* z *plane, for the case* α *real and lying in the interval* $-1 < \alpha < \infty$, *consists of all points in the cut plane depicted in Figure* 3, *with the exception of a neighborhood of* $z = z_2$ *(which is a singularity of the* $z - \zeta$ *transformation). In particular, when* $-1 < \alpha < \infty$ *the asymptotic expansion* (4.36) *and* (4.37) *is uniformly valid for* $\mathrm{Im}(z) \geq 0$.

Remark. For a corresponding asymptotic expansion which is valid in the lower half plane (and in particular in a neighborhood of the turning point at $z = z_2(\alpha)$) one can use (4.36) and (4.37) with α replaced by $\overline{\alpha}$ (so that ζ is suitably redefined), and the reflection formula

$$\theta_n(z;a) = \overline{\theta_n(\bar{z};\bar{a})}. \tag{4.38}$$

In deriving (4.36) we used the behavior of both sides as $z \to \infty$. Therefore, as a powerful check on the correctness of this approximation (which is supposed to be valid at the singularity at $z = 0$), we compare both sides as $uz \to 0$ (with $u \to \infty$). Now since $u^{2/3}\zeta \to \infty e^{-2\pi i/3}$ as $z \to 0$ and $u \to \infty$, we use (3.7), (3.22), (4.14), and (4.37) to find that in this case the right-hand side of (4.36) (for the case $N = 0$) takes the form

$$\sqrt{\frac{2}{u(2+\alpha)}}\left(\frac{2+\alpha}{1+\alpha}\right)^{u\alpha}\left\{\frac{u(2+\alpha)^2}{2e(1+\alpha)}\right\}^u \{1+O(u^{-1})\}\{1+O(uz)\}. \tag{4.39}$$

As a comparison, from (1.11) we observe that

$$\theta_n(uz;a) = \frac{\Gamma(2n+a-1)}{2^n\Gamma(n+a-1)}\{1+O(uz)\} \tag{4.40}$$

as $uz \to 0$. Now from (4.35), and with the aid of Stirling's formula (with $u \to \infty$ and α fixed), it follows that

$$\begin{aligned}\frac{\Gamma(2n+a-1)}{2^n\Gamma(n+a-1)} &= \frac{\Gamma(2u+u\alpha)}{2^{u-1/2}\Gamma(u+u\alpha+\frac{1}{2})} \\ &= \sqrt{\frac{2}{u(2+\alpha)}}\left(\frac{2+\alpha}{1+\alpha}\right)^{u\alpha}\left\{\frac{u(2+\alpha)^2}{2e(1+\alpha)}\right\}^u \{1+O(u^{-1})\}.\end{aligned} \tag{4.41}$$

Thus, we have verified that (4.39) and (4.40) are indeed equivalent.

5. Expansions involving elementary functions: Complex *z*. We now obtain asymptotic expansions for the three solutions in terms of elementary (exponential) functions. These will be even simpler than the Airy function expansions of the previous section, but they will not be valid in the neighborhood of either turning point, although they will still be valid at $z = 0$ and $z = \infty$. Moreover, the (complex) domains of validity will contain the entire real z axis. Although the results will be valid for certain complex values of α, for simplicity we shall assume in what follows that α is real and lying in the interval $-1 < \alpha < \infty$.

The relevant asymptotic theory, the Liouville–Green approximation in the complex plane, is given by Olver in [8, Chap. 10, sects. 1–5]. From (2.02) of [8] we first introduce a new independent variable by

$$\xi = \int f^{1/2}(\alpha,z)\mathrm{d}z = \int \frac{\{z^2+\alpha z+(1+\frac{1}{2}\alpha)^2\}^{1/2}}{z}\mathrm{d}z. \tag{5.1}$$

Upon integration we find that

$$\xi = Z + \frac{1}{2}(2+\alpha)\ln\left\{\frac{2(2+\alpha)Z - 2\alpha z - (2+\alpha)^2}{z}\right\} + \frac{1}{2}\alpha\ln\{2Z + 2z + \alpha\}, \tag{5.2}$$

where

$$Z = \{(z-z_1)(z-z_2)\}^{1/2} = \left\{z^2 + \alpha z + \left(1 + \frac{1}{2}\alpha\right)^2\right\}^{1/2}. \tag{5.3}$$

The branches associated with (5.2) are as specified in section 3, so that in terms of the variable ω defined by (3.18) we have

$$\xi = \omega + \frac{1}{2}(1+\alpha)\ln(1+\alpha) + \frac{1}{2}(4+3\alpha)\ln(2) + \frac{1}{2}(1+\alpha)\pi i. \tag{5.4}$$

For identification purposes we shall require knowledge of the behavior of ξ as z approaches the singularities of the differential equation (3.4). First, from (3.19) and (5.4) we see that as $\mathrm{Re}\ z \to \infty$

$$\xi = z + \frac{1}{2}\alpha\ln(z) + 2(1+\alpha)\ln(2) + \frac{1}{2}\alpha + O(z^{-1}), \tag{5.5}$$

and as $\mathrm{Re}\ z \to -\infty$

$$\xi = -z - \frac{1}{2}\alpha\ln(z) + (2+\alpha)\ln(2) + (1+\alpha)\ln(1+\alpha) - \frac{1}{2}\alpha + (1+\alpha)\pi i + O(z^{-1}). \tag{5.6}$$

Likewise, as $z \to 0$ we find that

$$\begin{aligned}\xi = {} & \frac{1}{2}(2+\alpha)\ln(z) + (1+\alpha)\ln(1+\alpha) + (3+2\alpha)\ln(2) \\ & - (2+\alpha)\ln(2+\alpha) + \frac{1}{2}\alpha + 1 + O(z).\end{aligned} \tag{5.7}$$

Next, we define a new dependent variable, say, $\tilde{W}$, in the usual manner

$$\tilde{W} = f^{1/4}w. \tag{5.8}$$

From the Liouville transformations (5.1) and (5.8) we then obtain our desired equation

$$\frac{\mathrm{d}^2\tilde{W}}{\mathrm{d}\xi^2} = \{u^2 + \tilde{\psi}(\xi)\}\tilde{W}, \tag{5.9}$$

which is of the same form as (2.01) of [8, Chap. 10]. The Schwarzian derivative this time is given by

$$\tilde{\psi}(\xi) = \frac{4ff'' - 5f'^2}{16f^3} + \frac{g}{f}, \tag{5.10}$$

and so after some calculation, and referring to (3.5) and (3.6), we find explicitly that

$$\tilde{\psi}(\xi) = \frac{z\{(4+3\alpha)(4+\alpha)z + \alpha(2+\alpha)^2 - 4z^3\}}{32\{z^2 + \alpha z + (1+\frac{1}{2}\alpha)^2\}^3}. \tag{5.11}$$

Note that $\tilde{\psi}(\xi)$ is analytic at $z = 0$, but unlike $\psi(\zeta)$ given by (3.14) above, has a singularity at the turning point $z = z_1(\alpha)$.

Next, using (2.09) of [8, Chap. 10] we recursively define the coefficients

$$\mathsf{A}_{s+1}(z) = -\frac{z}{2\{z^2 + \alpha z + (1 + \frac{1}{2}\alpha)^2\}^{1/2}}\mathsf{A}_s'(z) \tag{5.12}$$

$$+ \frac{1}{32}\int_{\infty}^{z} \frac{\alpha(2+\alpha)^2 + (3\alpha+4)(4+\alpha)t - 4t^3}{\{t^2 + \alpha t + (1+\frac{1}{2}\alpha)^2\}^{5/2}}\mathsf{A}_s(t)\mathrm{d}t \quad (s = 0, 1, 2, \ldots)$$

with $\mathsf{A}_0(z) = 1$. We now can apply Theorem 3.1 of Olver [8, Chap. 10] to our equation (5.9). We express the first asymptotic solution, given by (3.02) of Olver's theorem, in the form

$$W_N^{(-1)}(u,\xi) = e^{u\xi}\sum_{s=0}^{N-1}\frac{\mathsf{A}_s(z)}{u^s} + \varepsilon_N^{(-1)}(u,\xi). \tag{5.13}$$

In order to bound the error term we specify a reference point, and the natural choice is $\xi = -\infty$: this corresponds to $z = 0$ (see (5.4), and Figures 1, 2(a), and 2(b)). Setting $j = 1$ in (3.04) of [8, Chap. 10] we obtain the bounds

$$|\varepsilon_N^{(-1)}(u,\xi)|, \left|\frac{\partial\varepsilon_N^{(-1)}(u,\xi)}{u\partial\xi}\right| \le 2|e^{u\xi}|\exp\left\{\frac{2}{u}\mathcal{V}_{\mathcal{L}^{(-1)}}(\mathsf{A}_1)\right\}\frac{\mathcal{V}_{\mathcal{L}^{(-1)}}(\mathsf{A}_N)}{u^N}. \tag{5.14}$$

The path $\mathcal{L}^{(-1)}$ connects $-\infty$ to ξ and must meet the following two requirements:

(i) it consists of a finite chain of R_2 arcs, and

(ii) as ν runs from $-\infty$ to ξ along this path, Re ν is nondecreasing.

The domain of validity of the expansion consists of all points that can be accessed by such a path. For the case α real and lying in the interval $-1 < \alpha < \infty$ this domain is depicted in Figure 7(a).

The second solution, given by (3.03) of Theorem 3.1 of [8, Chap. 10], actually supplies two more solutions. One is recessive at $z = +\infty$ and the other at $z = -\infty$. These are of the same form, but the reference point is different for each: one is at $\xi = +\infty$ corresponding to $z = -\infty$ (see Figure 2(a)), and the other is at $\xi = +\infty$ corresponding to $z = +\infty$ (see Figure 2(b)). Using the suffix $j = 1$ for the former, and $j = 0$ for the latter, we thus have the following two independent asymptotic solutions:

$$W_N^{(j)}(u,\xi) = e^{-u\xi}\sum_{s=0}^{N-1}(-1)^s\frac{\mathsf{A}_s(z)}{u^s} + \varepsilon_N^{(j)}(u,\xi), \tag{5.15}$$

where

$$|\varepsilon_N^{(j)}(u,\xi)|, \left|\frac{\partial\varepsilon_N^{(j)}(u,\xi)}{u\partial\xi}\right| \le 2|e^{-u\xi}|\exp\left\{\frac{2}{u}\mathcal{V}_{\mathcal{L}^{(j)}}(\mathsf{A}_1)\right\}\frac{\mathcal{V}_{\mathcal{L}^{(j)}}(\mathsf{A}_N)}{u^N}. \tag{5.16}$$

The paths of integration run from the respective reference points at infinity to the point ξ, and this time Re ν must be nonincreasing as ν runs from ∞ to the point ξ. The z domains of validity of the bounds (5.16) are depicted in Figures 7(b) ($j = 0$) and 7(c) ($j = 1$) (for the case α real and lying in the interval $-1 < \alpha < \infty$).

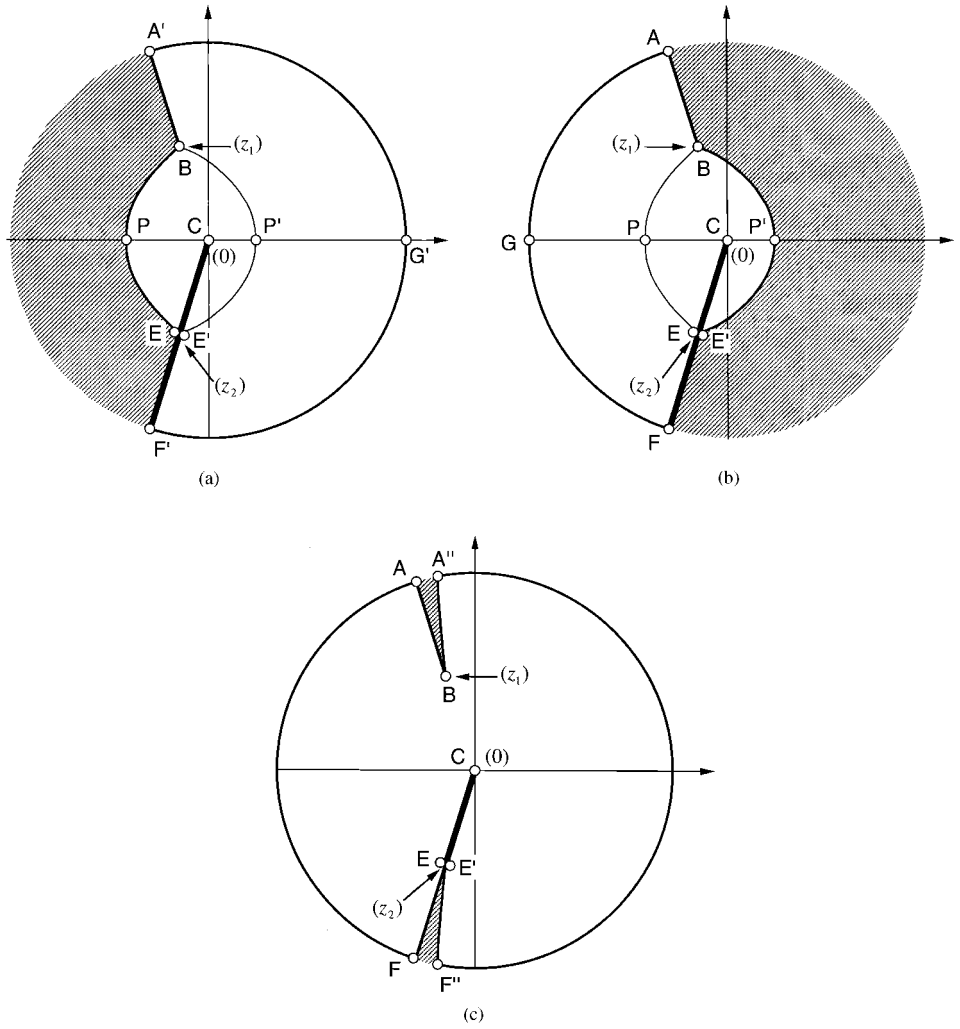

FIG. 7. *z plane.*

We now identify the asymptotic solutions with the standard solutions in the manner of section 4. On employing (5.5) we find that

$$\theta_n(uz;a) = \frac{4^{u(1+\alpha)}u^{u-1/2}e^{u\alpha/2}z^{u(2+\alpha)/2}e^{uz}}{\{z^2+\alpha z+(1+\frac{1}{2}\alpha)^2\}^{1/4}}W_N^{(0)}(u,\xi), \tag{5.17}$$

both being solutions which are recessive at $z=+\infty$.

Next, we identify solutions which are recessive at $z=0$, and using (5.7) we find that

$$w_n^{(-1)}(uz;a) = \frac{(2+\alpha)^{2u+u\alpha+1/2}u^{u+u\alpha/2+1/2}}{2^{3u+2u\alpha+1/2}e^{u(2+\alpha)/2}(1+\alpha)^{u(1+\alpha)}\Gamma(2u+u\alpha+1)} \tag{5.18}$$

$$\times\left\{1+\sum_{s=1}^{N-1}\frac{\mathsf{A}_s(0)}{u^s}\right\}^{-1}\frac{z^{1/2}}{\{z^2+\alpha z+(1+\frac{1}{2}\alpha)^2\}^{1/4}}W_N^{(-1)}(u,\xi).$$

Finally, for the solutions recessive at $z=-\infty$ we use (5.6) to obtain

$$w_n^{(1)}(uz;a)=(-1)^n e^{u\alpha\pi i}2^{u+u\alpha-1/2}e^{-u\alpha/2}u^{u\alpha/2}(1+\alpha)^{u+u\alpha} \tag{5.19}$$

$$\times\left\{1+\sum_{s=1}^{N-1}(-1)^s\frac{\mathsf{A}_s(-\infty)}{u^s}\right\}^{-1}\frac{z^{1/2}}{\{z^2+\alpha z+(1+\frac{1}{2}\alpha)^2\}^{1/4}}W_N^{(1)}(u,\xi),$$

where

$$\mathsf{A}_s(-\infty)=\lim_{z\to-\infty}\mathsf{A}_s(z). \tag{5.20}$$

A compound asymptotic expansion for $\theta_n(uz;a)$, which is valid in a part of the left half plane (as depicted in Figure 7(b) when $-1<\alpha<\infty$), is easily obtained by inserting the expansions (5.18) and (5.19) into the connection formula (2.13) (and referring to (2.3)). Such an expansion is valid along the curve PBE (except near the turning points at the ends of this curve). The significance of this is that the zeros of $\theta_n(uz;a)$ are located near this curve when n is large.

In the next two sections we consider the case z real, and we also give a particularly simple procedure for calculating the coefficients $\{\mathsf{A}_s(z)\}_{s=1}^{\infty}$, as well as the limiting constants given by (5.20).

6. Expansions involving elementary functions: Positive *z*. We continue to assume that $-1<\alpha<\infty$ but now restrict z to $0<z<\infty$. Let us first introduce the positive parameter

$$p=1/Z=\left\{z^2+\alpha z+\left(1+\frac{1}{2}\alpha\right)^2\right\}^{-1/2}. \tag{6.1}$$

Then, as z decreases from ∞ to $-\infty$, p increases from 0 to a maximum value of $\{1+\alpha\}^{-1/2}$ (corresponding to $z=-\frac{1}{2}\alpha$), and then decreases back to 0. In terms of this variable we can express the recursion formula (5.12) for the coefficients in the form

$$\mathsf{A}_{s+1}(z(p))=\frac{1}{4}p^2[2-2(1+\alpha)p^2-\alpha p\{1-(1+\alpha)p^2\}^{1/2}]\frac{\mathrm{d}}{\mathrm{d}p}\mathsf{A}_s(z(p)) \tag{6.2}$$

$$+\frac{1}{16}\int_0^p\left[\frac{\alpha q\{5(1+\alpha)q^2-3\}}{\{1-(1+\alpha)q^2\}^{1/2}}-10(1+\alpha)q^2+2\right]\mathsf{A}_s(z(q))\mathrm{d}q.$$

A further simplification in this comes from introducing a variable t by

$$t=\sin^{-1}(\sqrt{1+\alpha}p). \tag{6.3}$$

The branch of the inverse sine is chosen so that t depends continuously on z for $-\infty<z<\infty$, with $t=0$ corresponding to $z=\infty$, $t=\frac{1}{2}\pi$ corresponding to $z=-\frac{1}{2}\alpha$ (i.e., $p=1/\sqrt{1+\alpha}$), and $t=\pi$ corresponding to $z=-\infty$.

Remark. t is real for $-1<\alpha<\infty$ and $-\infty<z<\infty$. To see this we use (6.1) and (6.3) to obtain

$$\sin^2(t)=(1+\alpha)p^2=\frac{1+\alpha}{1+\alpha+(z+\frac{1}{2}\alpha)^2}. \tag{6.4}$$

Thus,

$$0 < \sin(t) \leq 1 \tag{6.5}$$

with $\sin(t) \to 0$ as $z \to \pm\infty$, and $t = t_0$ when $z = 0$, where

$$t_0 = \cos^{-1}\left\{\frac{\alpha}{2+\alpha}\right\}, \tag{6.6}$$

the branch of the inverse cosine being such that $0 < t_0 < \pi$ when $-1 < \alpha < \infty$. In summary, for fixed α in $(-1, \infty)$, the z interval $-\infty < z < \infty$ is mapped one to one by (6.3) to the t interval $0 < t < \pi$.

We now consider the coefficients defined by (6.2) as functions of t. If we write

$$\mathsf{A}_s(z) = V_s(t), \tag{6.7}$$

we obtain the recursion formula

$$V_{s+1}(t) = \frac{1}{4}\sin^2(t)\left[\frac{2\cos(t)}{\sqrt{1+\alpha}} - \frac{\alpha\sin(t)}{1+\alpha}\right]\frac{\mathrm{d}}{\mathrm{d}t}V_s(t) \tag{6.8}$$

$$+\frac{1}{16}\int_0^t \left[\frac{2\cos(\tau)\{1-5\sin^2(\tau)\}}{\sqrt{1+\alpha}} + \frac{\alpha\sin(\tau)\{5\sin^2(\tau)-3\}}{1+\alpha}\right] V_s(\tau)\mathrm{d}\tau \quad (s = 0, 1, 2, \ldots)$$

with $V_0(t) = 1$. Note that the lower limit $t = 0$ in this integral corresponds to $z = \infty$, but *not* to $z = -\infty$. In other words, each coefficient vanishes as $z \to \infty$ but not necessarily as $z \to -\infty$. In fact, for $z = -\infty$ the coefficients are given by

(6.9)

$$\begin{aligned}\mathsf{A}_s(-\infty) &= V_s(\pi)\\ &= \frac{1}{16}\int_0^\pi \left[\frac{2\cos(\tau)\{1-5\sin^2(\tau)\}}{\sqrt{1+\alpha}} + \frac{\alpha\sin(\tau)\{5\sin^2(\tau)-3\}}{1+\alpha}\right] V_{s-1}(\tau)\mathrm{d}\tau.\end{aligned}$$

From (6.8) we observe that each $V_s(t)$ is a multivariate polynomial of the two variables $\cos(t)$ and $\sin(t)$. The recursion (6.8) is therefore easily handled by a symbolic algebra program, and, for example, we find that

$$V_1(t) = \frac{\sin(t)(5\sin^2(t)-3)}{24\sqrt{1+\alpha}} + \frac{\alpha(\cos(t)-1)(5\cos^2(t)+5\cos(t)-1)}{48(1+\alpha)} \tag{6.10}$$

and

(6.11)

$$\begin{aligned}V_2(t) = {}& \frac{\sin^2(t)}{1152(1+\alpha)}(81 - 462\sin^2(t) + 385\sin^4(t)) - \frac{\alpha^2(\cos(t)-1)^2 P(\cos(t))}{4608(1+\alpha)^2}\\ &+ \frac{\alpha\sin(t)(\cos(t)-1)(385\cos^4(t)+385\cos^3(t)-231\cos^2(t)-226\cos(t)+2)}{1152(1+\alpha)^{3/2}},\end{aligned}$$

where

$$\begin{aligned}P(x) = {}& 145x^{10} + 290x^9 - 435x^8 - 1160x^7 + 290x^6\\ &+ 1740x^5 + 50x^4 - 1640x^3 - 666x^2 + 298x + 143.\end{aligned} \tag{6.12}$$

The Liouville transformation, for $0 < z < \infty$, is the same as in section 5, and in terms of t we find that

$$\xi = \frac{\sqrt{1+\alpha}}{\sin(t)} - \frac{\alpha}{2}\ln\left\{\tan\left(\frac{1}{2}t\right)\right\} - (2+\alpha)\tanh^{-1}\left\{\frac{2\sqrt{1+\alpha}\tan(\frac{1}{2}t)+\alpha}{2+\alpha}\right\}. \tag{6.13}$$

The interval $0 < z < \infty$ is mapped to $-\infty < \xi < \infty$, with $\xi = -\infty$ corresponding to $z = 0$, and $\xi = \infty$ corresponding to $z = \infty$.

The identification of solutions (recessive at $z = \infty$ and $z = 0$) proceeds as before, and we merely state the results:

(6.14)

$$\theta_n(uz;a) = 4^{u(1+\alpha)}u^{u-1/2}e^{u\alpha/2}p^{1/2}z^{u(2+\alpha)/2}e^{uz-u\xi}\left\{\sum_{s=0}^{N-1}(-1)^s\frac{V_s(t)}{u^s} + \eta_N^-(u,t)\right\},$$

where

$$|\eta_N^-(u,t)| \le 2\exp\left\{\frac{2}{u}\mathcal{V}_{0,t}(V_1)\right\}\frac{\mathcal{V}_{0,t}(V_N)}{u^N} \tag{6.15}$$

uniformly for $0 < z < \infty$, and

(6.16)

$$\mathbf{M}(n+a-1,2n+a,2uz) = \frac{(2+\alpha)^{2u+u\alpha+1/2}}{2^{3u+2u\alpha+1/2}e^{u(2+\alpha)/2}(1+\alpha)^{u(1+\alpha)}\Gamma(2u+u\alpha+1)}$$
$$\times \left\{1+\sum_{s=1}^{N-1}\frac{V_s(t_0)}{u^s}\right\}^{-1} p^{1/2}z^{-u(2+\alpha)/2}e^{uz+u\xi}\left\{\sum_{s=0}^{N-1}\frac{V_s(t)}{u^s} + \eta_N^+(u,t)\right\},$$

where

$$|\eta_N^+(u,t)| \le 2\exp\left\{\frac{2}{u}\mathcal{V}_{t,t_0}(V_1)\right\}\frac{\mathcal{V}_{t,t_0}(V_N)}{u^N} \tag{6.17}$$

uniformly for $0 < z < \infty$.

7. Expansions involving elementary functions: Negative *z*. The variable ξ is not real when $-\infty < z < 0$, so we introduce the following real variable instead:

$$\tilde{\xi} = Z + \frac{1}{2}(2+\alpha)\ln\left\{\frac{2(2+\alpha)Z - 2\alpha z - (2+\alpha)^2}{|z|}\right\} + \frac{1}{2}\alpha\ln\{2Z+2z+\alpha\}. \tag{7.1}$$

When $-\infty < z < 0$ this differs from ξ, as given by (5.2) (with $\arg(z) = \pi$), by a constant: that is,

$$\tilde{\xi} = \xi - \frac{1}{2}(2+\alpha)\pi i. \tag{7.2}$$

Hence, the transformed equation is still of the form (5.9) (with ξ replaced by $\tilde{\xi}$). In order to identify recessive solutions we require the following asymptotic forms:

$$\tilde{\xi} = \frac{1}{2}(2+\alpha)\ln|z| + (1+\alpha)\ln(1+\alpha) + (3+2\alpha)\ln(2) \tag{7.3}$$
$$- (2+\alpha)\ln(2+\alpha) + \frac{1}{2}\alpha + 1 + O(z)$$

as $z \to 0$ and

$$\tilde{\xi} = |z| - \frac{1}{2}\alpha \ln|z| + (2+\alpha)\ln(2) + (1+\alpha)\ln(1+\alpha) - \frac{1}{2}\alpha + O(z^{-1}) \tag{7.4}$$

as $z \to -\infty$.

Now for z negative a real solution of (3.4) which is recessive at $z = -\infty$ is given by $U(n+1, 2n+a, 2u|z|)$, where the confluent hypergeometric function U is defined by (1.5). The behavior of this function at $z = -\infty$ follows from [8, Chap. 7, (10.01)], and using this and (7.4) we arrive at the asymptotic expansion

$$U(n+1, 2n+a, 2u|z|) = 2^{u+u\alpha-1/2}(1+\alpha)^{u(1+\alpha)}u^{-u-1/2}e^{-u\alpha/2} \tag{7.5}$$
$$\times \left\{1 + \sum_{s=1}^{N-1}(-1)^s \frac{V_s(\pi)}{u^s}\right\}^{-1} p^{1/2}|z|^{-u(2+\alpha)/2}e^{u|z|-u\tilde{\xi}} \left\{\sum_{s=0}^{N-1}(-1)^s \frac{V_s(t)}{u^s} + \tilde{\eta}_N^-(u,t)\right\}.$$

Here $\tilde{\eta}_N^-(u,t)$ is bounded by

$$|\tilde{\eta}_N^-(u,t)| \le 2\exp\left\{\frac{2}{u}\mathcal{V}_{t,\pi}(V_1)\right\}\frac{\mathcal{V}_{t,\pi}(V_N)}{u^N} \tag{7.6}$$

uniformly for $t_0 < t < \pi$ (i.e., $-\infty < z < 0$).

The corresponding expansion for the solution recessive at $z = 0$ is found to be

$$\mathbf{M}(n+a-1, 2n+a, 2uz) = \frac{(2+\alpha)^{2u+u\alpha+1/2}}{2^{3u+2u\alpha+1/2}e^{u(2+\alpha)/2}(1+\alpha)^{u(1+\alpha)}\Gamma(2u+u\alpha+1)} \tag{7.7}$$
$$\times \left\{1 + \sum_{s=1}^{N-1}\frac{V_s(t_0)}{u^s}\right\}^{-1} p^{1/2}|z|^{-u(2+\alpha)/2}e^{uz+u\tilde{\xi}} \left\{\sum_{s=0}^{N-1}\frac{V_s(t)}{u^s} + \tilde{\eta}_N^+(u,t)\right\}.$$

The bound on $\tilde{\eta}_N^+(u,t)$ is the same as that given by (6.17) for $\eta_N^+(u,t)$.

The Bessel polynomial $\theta_n(uz;a)$ is of most interest, but it is not recessive in $-\infty < z < 0$, and hence cannot be identified directly with a Liouville–Green asymptotic solution. However, we obtain a compound asymptotic expansion which is uniformly valid in this interval via the connection formula

$$\theta_n(uz;a) = 2^{n+a-1}u^{2n+a-1}n!|z|^{2n+a-1} \tag{7.8}$$
$$\times \left[\frac{e^{2uz}U(n+1, 2n+a, 2u|z|)}{\Gamma(n+a-1)} + (-1)^n\mathbf{M}(n+a-1, 2n+a, 2uz)\right].$$

Thus, we substitute (7.5) and (7.7) into this to obtain the uniform asymptotic expansion

$$\theta_n(uz;a) = n!e^{-u\alpha/2}p^{1/2}|z|^{u(2+\alpha)/2}e^{uz} \tag{7.9}$$
$$\times \left[C_N^-e^{-u\tilde{\xi}}\left\{\sum_{s=0}^{N-1}(-1)^s\frac{V_s(t)}{u^s} + \tilde{\eta}_N^-(u,t)\right\} + (-1)^nC_N^+e^{u\tilde{\xi}}\left\{\sum_{s=0}^{N-1}\frac{V_s(t)}{u^s} + \tilde{\eta}_N^+(u,t)\right\}\right],$$

where

$$C_N^- = \frac{2^{2u(1+\alpha)}(1+\alpha)^{u(1+\alpha)}u^{u+u\alpha-1/2}}{\Gamma(u+u\alpha+\frac{1}{2})}\left\{1+\sum_{s=1}^{N-1}(-1)^s\frac{V_s(\pi)}{u^s}\right\}^{-1} \tag{7.10}$$

and

$$C_N^+ = \frac{(2+\alpha)^{2u+u\alpha+1/2}u^{u(2+\alpha)}}{2^{u(2+\alpha)}(1+\alpha)^{u(1+\alpha)}e^u\Gamma(2u+u\alpha+1)}\left\{1+\sum_{s=1}^{N-1}\frac{V_s(t_0)}{u^s}\right\}^{-1}. \tag{7.11}$$

EXISTENCE OF LARGE AMPLITUDE PERIODIC WAVES IN TWO-FLUID FLOWS OF INFINITE DEPTH*

S. M. SUN†

Abstract. Two-dimensional periodic traveling gravity waves in a two-fluid flow are considered, where the flow has no rigid boundaries. Each fluid is inviscid, incompressible, and irrotational and the density ratio of the upper fluid to the lower fluid is between zero and one. The governing equations are first transformed into a single nonlinear integral equation using the Hilbert transform and the corresponding integral operator is compact in certain Banach spaces after a cut-off function is introduced. By a global bifurcation theorem, it is shown that there exist periodic waves of large amplitude on the interface until either the bifurcation parameter goes to infinity or the function of the wave profile and its first-order derivative are not in the classical Hölder space. It is also noted that the nonlinear integral equation is very general and can be used to study the waves of large amplitude numerically.

1. Introduction.

Mathematical investigation of two-dimensional propagating gravity waves in fluids has attracted a great deal of attention in the last several decades. The fluids are assumed to be inviscid, incompressible, and irrotational and waves are moving with a uniform speed in the fluids without changing its form. There are two types of waves that we consider, single-hump waves, called solitary waves, and periodic waves. Although such waves have been observed in experiments and derived formally from the exact equations using the asymptotic method, it is of interest to study these waves mathematically and show rigorously the existence of such waves from the exact nonlinear governing equations.

For waves in a one-layered fluid with free surface, there are many theoretical works in the literature focusing on the existence of periodic and solitary waves of small amplitude (for example, Levi-Civita [1], Struik [2], Nekrasov [3], Friedrichs and Hyers [4], and Beale [5]). Krasovskii [6] first studied existence of large amplitude periodic waves using a similar integral formulation by Nekrasov [3] and found a global existence of periodic waves. Keady and Norbury [7] extended the Krasovskii set of periodic waves using a global bifurcation theorem. Amick and Toland [8] proved existence of solitary waves of all amplitudes from zero up to and including that of solitary wave of greatest height. Further study on the largest amplitude solution can be found in [9, 10, 11] and the references therein. Recently, Buffoni, Dancer, and Toland [12] gave a significant new contribution on this problem and showed a very complicated structure of secondary bifurcation near the solution of largest amplitude using a variational method.

For interfacial waves between two fluids of different densities without boundaries, Holyer [13] performed extensive numerical computations and found interfacial waves

for which the interface profile is vertical at some points if amplitude of waves becomes large. Meiron and Saffman [14] computed the solutions again and established the existence of overhanging waves, for which some portions of the heavier fluid lie above the lighter fluid. Subsequently, Turner and VandenBroeck [15] and Grimshaw and Pullin [16] carried out extensive numerical computations and found that the situations are quite complicated. The large amplitude waves can oscillate alternating between an overhanging wave and a single-valued wave indefinitely [15] or approach to a mushroom-like limiting configuration [16]. Similar wave profiles can be calculated for interfacial waves in two-fluid flows of finite depth [17, 18], while Amick and Turner [19] proved the existence of large-amplitude waves with wave profiles having no vertical tangent lines. By contrast, there is almost no theoretical work to show the existence of large amplitude periodic waves in two-layered fluids of infinite depth. To study overhanging waves, a formulation similar to the one by Nekrasov [3] for one-layered fluids must be obtained, which was an open problem and given to the author by Benjamin [20].

In this paper, we shall derive an integral formulation for two-dimensional periodic traveling gravity waves in two fluids without boundaries and then give a mathematical proof of the existence of such waves of small and large amplitude using the global bifurcation theory. The result can be stated as follows. Let the wave be symmetric with respect to its crest and periodic. The interface of two fluids is determined by Φ, which measures the angle between the tangent line of the interfacial curve and horizontal direction. It is shown that if the wave speed is near its first critical value, nonuniform waves of small amplitude will bifurcate from the uniform state and the solutions in this branch always satisfy $\Phi \in [0, \pi]$. When amplitude of the waves in this branch becomes large, the bifurcation branch can be extended infinitely until either the bifurcation parameter goes to infinity or the function Φ and its first-order derivative are no longer Hölder continuous. Our formulation of the problem is quite general and can also be used for numerical calculations of the wave profiles.

The idea to prove the result can be summarized as follows. The exact equations are first transformed into several integral equations using the Hilbert transform. Then some tricky algebraic manipulations are used to transform the integral equations into one integral equation of Φ so that the corresponding integral operator is compact in a Banach space under some restrictions on Φ. To have an equation valid for all functions Φ, the integral equation is further transformed into another integral equation using a cut-off function. Therefore, finding the solutions of the exact governing equations becomes finding fixed points of a compact operator. Then we view the problem as a global bifurcation problem with a bifurcation parameter related to the amplitude of the wave, which was first proposed by Keady and Norbury [7] for one-layered fluids. By a global bifurcation theorem [21, 22], the existence of global bifurcation branch of solutions is obtained. Finally, using some properties of solutions derived from governing equations, we show that the solution branch cannot be bounded. Therefore, the bifurcation branch must be extended to infinity. A similar idea can be applied to derive an integral equation for a two-fluid system with either one or two horizontal rigid boundaries.

The paper is organized as follows. In section 2, the governing equations are given and some properties of the solutions are stated. Section 3 gives the integral representation of solutions for the problem. In section 4, the integral equation is modified using a cut-off function so that the equation is valid for any functions without any artificial restriction. In section 5, the global bifurcation theorem is used to obtain

a global branch of solutions for the problem. The proofs of some properties of solutions and compactness of the operators are given in Appendices A and B, respectively.

2. Formulation of the problem. Consider a two-dimensional periodic progressing wave moving with a constant speed $-c$ at the interface of two fluids. In reference to a rectangular coordinate (x, y) system moving with the wave, the flow is steady, where the x-axis is the horizontal direction with the velocity $(c, 0)$ as the positive direction and the y-axis is the vertical direction upwards through the crest of the wave so that the gravity acts in the negative y direction. The interface is symmetric with respect to the y-axis and the period of the wave is τ so that the tangent lines of the interface at $x = -\tau/2$ and $x = \tau/2$ are horizontal. In the following, we use f^+ and f^- to denote a quantity f in upper and lower fluids, respectively. The densities of the fluids are ρ^+ and ρ^- with $\rho^- > \rho^+$.

Since the fluids are incompressible and irrotational, the velocity potentials $\varphi^\pm$ and stream functions $\psi^\pm$ are well defined and the velocity vectors are given by $(\varphi^\pm_x, \varphi^\pm_y)$. It is well known that the functions $w^\pm(x, y) = w^\pm(z) = \varphi^\pm(x, y) + i\psi^\pm(x, y)$ are analytic in the upper and lower fluids with respect to $z = x + iy$. Without loss of generality, we choose $\varphi^\pm = 0$ at the crest $x = 0$ and $\psi^\pm = 0$ at the interface. In addition, there are Bernoulli equations at the interface,

$$(p^\pm/\rho^\pm) + (1/2)((u^\pm)^2 + (v^\pm)^2) + gy^\pm = H^\pm\,,$$

where $p(x, y)$ is the pressure, g is the gravitational acceleration constant, $H^\pm$ are constants called the Bernoulli heads, and $y^+ = y^-$ at the interface. By choosing the origin of the y-axis so that $H^\pm = c^2/2$, the continuity of the pressure across the interface is

$$\begin{aligned}\rho^+((1/2)((u^+)^2 + (v^+)^2) + gy^+ - (c^2/2)) \\ = \rho^-((1/2)((u^-)^2 + (v^-)^2) + gy^- - (c^2/2))\end{aligned} \tag{1}$$

at $\psi^\pm = 0$. Here, all functions are periodic in x with period τ and the choice of the origin for the y-axis makes the interface of undisturbed state at $y = 0$.

Because the form of the interface is unknown, we resort to conformal mappings to overcome this difficulty. We try to find a conformal mapping which maps two infinite regions in the z-plane occupied by two fluids onto two regions in another complex plane $U = \xi + i\eta = re^{i\theta}$ with the unit circle deleted so that the interface is mapped to the circumference of the unit circle. The upper fluid is mapped onto $r = |U| < 1$ with the infinity corresponding to the center of the circle and the lower fluid is mapped onto $r > 1$. By the symmetry and periodicity of the interface, two points at $x = -\tau/2$ and $x = \tau/2$ on the interface are mapped to $\theta = -\pi, \pi$, and $x = 0$ is mapped to $\theta = 0$. The circumference of the unit circle is parametrized by $\theta^\pm$ from $-\pi$ to π.

Now we let the conformal mapping from the z-plane to the U-plane have the following form:

$$\frac{dz}{dU} = -\frac{\tau i f^+(U)}{2\pi U}, \quad r = |U| < 1\,, \quad \frac{dz}{dU} = -\frac{\tau i f^-(U)}{2\pi U}, \quad r > 1\,, \tag{2}$$

where $f^\pm$ are analytic functions in $r < 1$ and $r > 1$, respectively, as will be determined later. More detailed discussion of (2) for single-layered fluids (i.e., $\rho^+ = 0$) can be found in [23]. Let $f^\pm(U) = R^\pm(r, \theta)e^{i\Phi^\pm(r,\theta)}$. From the symmetry and the positions

of crests and troughs of the wave, we have

$$R^{\pm}(r,\theta) = R^{\pm}(r,-\theta)\,, \quad \Phi^{\pm}(r,\theta) = -\Phi^{\pm}(r,-\theta)\,, \tag{3}$$
$$\Phi^{\pm}(r,0) = \Phi^{\pm}(r,-\pi) = 0\,.$$

For the sake of convenience, we denote $f^{\pm}(e^{i\theta}) \stackrel{\text{def}}{=} R^{\pm}(\theta)e^{i\Phi^{\pm}(\theta)}$ on $r = 1$. From (2), we can see that $\Phi^{\pm}(\theta)$ gives the angle between the x-axis and the tangent of the interface and $R^{\pm}(\theta)$ is the length of the tangent vector at the interface.

Now we find w in terms of U. From the interfacial conditions and the conditions at infinity, we have that

$$\psi = +\infty \quad \text{at } r = 0\,, \tag{4}$$
$$\psi = -\infty \quad \text{at } r = +\infty\,, \tag{5}$$
$$\psi = 0 \quad \text{at } r = 1\,, \tag{6}$$
$$u - iv = c \quad \text{at } r = 0, \infty. \tag{7}$$

Equations (4)–(6) are satisfied if

$$w = -\frac{\tau c i}{2\pi}\log U\,. \tag{8}$$

The definition of φ implies

$$u - iv = \varphi_x - i\varphi_y = \frac{dw}{dz} = \frac{dw}{dU}\frac{dU}{dz} = \frac{c}{f(U)}\,, \tag{9}$$

and $f^{+}(0) = f^{-}(\infty) = 1$ if condition (7) is satisfied. This fits the fact that $f^{\pm} = 1$ is the appropriate choice for the undisturbed flow.

If $R^{\pm}(\theta^{\pm})$ is never zero, then $\log f^{\pm} = \log R^{\pm} + i\Phi^{\pm}$ is analytic. By using the Poisson integral [25], we can have the following relation between real and imaginary parts of an analytic function on the unit circle (see the detailed discussion in [3] and [24]):

$$\Phi^{\pm}(\theta^{\pm}) = \mp\frac{1}{\pi}\int_{-\pi}^{\pi}\left(\sum_{n=1}^{+\infty}\frac{\sin n\theta^{\pm}\sin ns}{n}\right)\left(\frac{d}{ds}\log R^{\pm}(s)\right)ds\,, \tag{10}$$

where the kernel can also be written as

$$\sum_{n=1}^{+\infty}\frac{\sin n\theta\sin ns}{n} = \frac{1}{2}\log\left|\frac{\sin((s+\theta)/2)}{\sin((s-\theta)/2)}\right|\,. \tag{11}$$

Here, we note that the interface is parametrized by two parameters θ^{+} and θ^{-} and a value of z may not correspond to same $\theta^{\pm}$. By using z at the interface, we can consider θ^{-} as a function of θ^{+} on the unit circle. Therefore, the interfacial conditions are

$$z^{+}(\theta^{+}) = x^{+}(\theta^{+}) + iy^{+}(\theta^{+}) = z^{-}(\theta^{-}(\theta^{+})) = x^{-}(\theta^{-}(\theta^{+})) + iy^{-}(\theta^{-}(\theta^{+})),$$

which implies

$$\frac{dz^{-}}{d\theta^{-}} = \frac{dz^{+}}{d\theta^{-}} = \frac{dz^{+}}{d\theta^{+}}\frac{d\theta^{+}}{d\theta^{-}}\,. \tag{12}$$

To have periodic solutions in $\theta^{\pm}$, we need $\theta^+ = \theta^-$ at $\theta^- = 0$, π and $-\pi$. From (2) and (12), we have

$$(d\theta^+/d\theta^-) = (R^-/R^+)\exp(i(\Phi^- - \Phi^+))\,,$$

which gives

$$\Phi^+(\theta^+) = \Phi^-(\theta^-)\,, \qquad \frac{d\theta^-}{d\theta^+} = \frac{R^+(\theta^+)}{R^-(\theta^-)} \stackrel{\text{def}}{=} V(\theta^+)\,, \tag{13}$$

where θ^- is considered as a function of θ^+ on the circle and

$$\theta^- = \theta^-(\theta^+) = \int_0^{\theta^+} V(s)ds \stackrel{\text{def}}{=} L(\theta^+) \qquad \text{with} \quad \int_0^{-\pi} V(s)ds = -\pi\,. \tag{14}$$

By (1), (2), and (9), the Bernoulli equations can be rewritten as

$$\frac{1}{2}\left[\frac{1}{(R^-(\theta^-))^2} - \frac{\rho}{(R^+(\theta^+))^2}\right] + \frac{g(1-\rho)}{c^2}y^+(\theta^+) = \frac{1}{2}(1-\rho)\,, \tag{15}$$

where $\rho = \rho^+/\rho^- < 1$. By using (2) again and $u = e^{i\theta}$ on the circle,

$$\frac{dy^+}{d\theta^+} = \frac{\tau R^+ \sin\Phi^+}{2\pi}\,.$$

Then we take the derivative on both sides of (15) with respect to θ^+ to obtain

$$\begin{aligned}\frac{1}{2R^+(\theta^+)}&\left[\frac{\partial}{\partial\theta^+}\left(\frac{1}{(R^-(\theta^-))^2}\right) - \frac{\partial}{\partial\theta^+}\left(\frac{\rho}{(R^+(\theta^+))^2}\right)\right]\\ &+\frac{\tau g(1-\rho)}{2\pi c^2}\sin\Phi^+(\theta^+) = 0\,.\end{aligned} \tag{16}$$

We state a theorem which gives some properties of solution satisfying (3), (13), (14), and (16).

THEOREM 1. *Assume that there are analytic functions $f^{\pm}(u) = R^{\pm}(r,\theta)e^{i\Phi(r,\theta)} \neq 0$ for $|u| = r < 1$ and $|u| = r > 1$, where $R^{\pm}(\theta) = R^{\pm}(1,\theta)$ and $\Phi^{\pm}(\theta) = \Phi^{\pm}(1,\theta)$ are C^1 functions for $\theta \in [-\pi,\pi]$ satisfying (3), (13), (14), and (16). If $\Phi^+(\theta^+) = \Phi^-(\theta^-) \in [0,\pi]$ for $\theta^{\pm} \in [-\pi,0]$ with $\Phi^{\pm}(r,0) = \Phi^{\pm}(r,-\pi) = 0$ and $\Phi^-(r,\theta) \to 0$ as $r \to +\infty$, then $\Phi^{\pm}(\theta^{\pm}) \in (0,\pi)$ for $\theta^{\pm} \in (-\pi,0)$ and $\Phi^{\pm}_{\theta}(-\pi) > 0, \Phi^{\pm}_{\theta}(0) < 0$.*

The proof is quite technical and will be given in Appendix A. This theorem will be used to obtain the global existence of the solutions. Geometrically, the theorem gives us that if the variation of the angle between the horizontal direction and the tangent of the interface is in $[0,\pi]$ for the negative half of the wave, then tangent lines will never be horizontal except at the crests and troughs.

3. Integral representation of the solutions. In this section, we shall express the solutions of (10), (13), (13), (14), and (16) as solutions of some integral equations. From (13), we rewrite (16) as

$$\begin{aligned}\frac{1}{2}&\left[\frac{1}{R^+(\theta^+)}\frac{\partial}{\partial\theta^+}\left(\frac{V^2(\theta^+)}{(R^+(\theta^+))^2}\right) - \frac{2\rho}{3}\frac{\partial}{\partial\theta^+}\left(\frac{1}{(R^+(\theta^+))^3}\right)\right]\\ &+\frac{\tau g(1-\rho)}{2\pi c^2}\sin\Phi^+(\theta^+) = 0\,,\end{aligned}$$

which can be simplified to

$$\frac{1}{2}\left[\frac{2}{3}(V^2(\theta^+)-\rho)\frac{\partial}{\partial\theta^+}\left(\frac{1}{(R^+(\theta^+))^3}\right)+\frac{1}{(R^+(\theta^+))^3}\frac{\partial V^2(\theta^+)}{\partial\theta^+}\right] = -\frac{\tau g(1-\rho)}{2\pi c^2}\sin\Phi^+(\theta^+)\,. \tag{17}$$

If we assume that $V(\theta^+)$ and $R^+(\theta^+)$ are given, $(R^+(\theta^+))^{-3}$ in (17) is solved by

$$\left(\frac{1}{R^+(\theta^+)}\right)^3 = (V^2(\theta^+)-\rho)^{-3/2}I(\theta^+)\,, \tag{18}$$

where

$$I(\theta^+) \stackrel{\text{def}}{=} C\left(\frac{1}{\mu}-\int_0^{\theta^+}\sin\Phi^+(s)(V^2(s)-\rho)^{1/2}ds\right), \qquad C \stackrel{\text{def}}{=} \frac{3g(1-\rho)\tau}{2\pi c^2}\,, \qquad \lambda \stackrel{\text{def}}{=} \frac{(1-\rho)^{3/2}\mu}{3(1+\rho)}\,, \tag{19}$$

$\mu>0$ is an integration constant, and λ is the bifurcation parameter to be used later. We note that from (13) and (18)

$$\left(\frac{C}{\mu}\right)^{2/3} = \frac{1}{(R^-(0))^2}-\frac{\rho}{(R^+(0))^2} = c^2\left((u^-)^2+(v^-)^2-\rho((u^-)^2+(v^-)^2)\right)\big|_{\theta^\pm=0}\,. \tag{20}$$

Thus μ and λ are related to the velocity of the particle at the crest of the wave and relevant to the amplitude of the interface $y(0)$ by using (15). By (10), (11), and (18),

$$\Phi^+(\theta^+) = -\frac{1}{2\pi}\int_{-\pi}^{\pi}\log\left|\frac{\sin((\theta^++s)/2)}{\sin((\theta^+-s)/2)}\right|\left[\frac{1}{2}\frac{d}{ds}\log(V^2(s)-\rho)-\frac{I'(s)}{3I(s)}\right]ds\,. \tag{21}$$

Also from (13) and (18), we have

$$R^-(\theta^-) = \frac{(V^2(\theta^+)-\rho)^{1/2}}{V(\theta^+)I^{1/3}(\theta^+)}\,. \tag{22}$$

By (10) and (22),

$$\Phi^-(\theta^-) = \frac{1}{2\pi}\int_{-\pi}^{\pi}\log\left|\frac{\sin((\theta^-+s^-)/2)}{\sin((\theta^--s^-)/2)}\right|\left[\frac{d}{ds^-}\log\frac{(V^2(s^+)-\rho)^{1/2}}{V(s^+)I^{1/3}(s^+)}\right]ds^-\,, \tag{23}$$

where $s^+ = L^{-1}(s^-)$. From (13) and (14), we have that $\Phi^+(\theta^+) = \Phi^-(\theta^-) = \Phi^-(L(\theta^+))$. Therefore, (21) and (23) determine the solutions $\Phi^+(\theta^+)$ and $V(\theta^+)$. In the following, it is convenient to let $\theta \stackrel{\text{def}}{=} \theta^+$ and $\Phi(\theta) \stackrel{\text{def}}{=} \Phi^+(\theta^+)$.

Since (13) and (14) imply that $L(\theta^+)$ is odd for $\theta\in[-\pi,\pi]$, by (3) we consider only the solution $\Phi(\theta)\in[0,\pi]$ for $\theta\in[-\pi,0]$. Thus $I(\theta)$ in (19) is well defined and it is straightforward to see that finding $\varphi^\pm(x,y)$ and $\psi^\pm(x,y)$ is equivalent to finding $\Phi(\theta)$ and $V(\theta)$ satisfying (21) and (23). It is noted that if $\rho=0$, then (23) with $V=1, \theta^-=\theta$ is reduced to the integral equation obtained by Nekrasov [3]. In the

following, we assume $0 < \rho < 1$. Under this condition, we can solve $V(\theta)$ in terms of $\Phi(\theta)$ from (21).

Define an integral operator $H[f]$, called the Hilbert transform (see more discussion in [26]), by

$$H[f] = \frac{1}{2\pi}\int_{-\pi}^{\pi} \frac{f(s)}{\tan((\theta-s)/2)} ds\,,$$

where $f(x) \in C^{\kappa}$ with $0 < \kappa < 1$ and $C^{n,\kappa}$ is the classical Hölder space [26] with $C^{0,\kappa} = C^{\kappa}$. The transform has the following properties:

$$H[H[f]] = -f + \frac{1}{2\pi}\int_{-\pi}^{\pi} f(s)ds, \tag{24}$$

and if $f(x), f'(x)$ are continuous for $x \in [-\pi, \pi]$ and $f(x) = f(-x)$, then

$$\begin{aligned} &\frac{1}{2\pi}\int_{-\pi}^{\pi} \log\left|\frac{\sin((\theta+s)/2)}{\sin((\theta-s)/2)}\right| f_s(s)ds \\ &\qquad = -\frac{1}{\pi}\int_{-\pi}^{\pi} \log|\sin((\theta-s)/2)| f_s(s)ds = H[f]\,. \end{aligned} \tag{25}$$

Applying H on both sides of (21) and using (24), we obtain

$$H[\Phi](\theta) = \log\frac{(V^2-\rho)^{1/2}(C\mu^{-1})^{1/3}}{(1-\rho)^{1/2}I^{1/3}} - \frac{1}{2\pi}\int_{-\pi}^{\pi} \log\frac{(V^2-\rho)^{1/2}(C\mu^{-1})^{1/3}}{(1-\rho)^{1/2}I^{1/3}} ds\,. \tag{26}$$

If we let

$$\alpha = \frac{1}{2\pi}\int_{-\pi}^{\pi} \log\frac{(1-\rho V^2)^{1/2}(C\mu^{-1})^{1/3}}{(1-\rho)^{1/2}I^{1/3}} ds\,,$$

then (26) becomes

$$W(\theta) = (1-\rho)^{1/2}(C\mu^{-1})^{-1/3} I^{1/3} \exp(\alpha + H[\Phi])\,,$$

where $W(\theta) = (V^2(\theta) - \rho)^{1/2}$. Thus by the definition of I in (19),

$$W^3(\theta) = (1-\rho)^{3/2}\mu\left(\mu^{-1} - \int_0^{\theta} \sin\Phi(s)W(s)ds\right)\exp\Big(3\alpha + 3H[\Phi](\theta)\Big)\,. \tag{27}$$

Multiplying both sides of (27) by $\exp(-3H[\Phi](\theta))$ and differentiating it with respect to θ, we get

$$(W^2(\theta))' - 2W^2(\theta)H'[\Phi](\theta) = -(2(1-\rho)^{3/2}\mu/3)\Big(\sin\Phi(\theta)\Big)\exp\Big(3\alpha + 3H[\Phi](\theta)\Big)\,,$$

which implies

$$W^2(\theta) = e^{2H[\Phi](\theta)}\left(D - (2(1-\rho)^{3/2}\mu/3)\int_0^{\theta} (\sin\Phi(s))e^{3\alpha + H[\Phi](s)}ds\right)\,,$$

where $D = (V^2(0)-\rho)^2 e^{-2H[\Phi](0)}$. From (26), we let $\theta = 0$ and obtain that $D = (1-\rho)e^{2\alpha}$. Therefore,

$$V^2(\theta) - \rho = e^{2H[\Phi](\theta)}A(\theta)\,, \tag{28}$$

where $A(\theta)$ is defined as follows:

$$A(\theta) \stackrel{\text{def}}{=} (1-\rho)e^{2\alpha} - (2(1-\rho)^{3/2}\mu/3)\int_0^\theta (\sin\Phi(s))e^{3\alpha+H[\Phi](s)}ds\,. \tag{29}$$

$V(\theta)$ and $I(\theta)$ are then solved in terms of $\Phi(\theta)$:

$$V(\theta) = \left(\rho + e^{2H[\Phi](\theta)}A(\theta)\right)^{1/2}, \tag{30}$$

$$I(\theta) = C\left(\mu^{-1} - \int_0^\theta \sin\Phi(s)e^{H[\Phi](s)}A^{1/2}(s)ds\right). \tag{31}$$

Here α is determined by the condition that $\theta^+ = -\pi$ at $\theta^- = -\pi$, i.e.,

$$\int_0^{-\pi} V(s)ds = -\pi = \int_0^{-\pi}\left(\rho + e^{2H[\Phi](\theta)}A(\theta)\right)^{1/2}d\theta\,. \tag{32}$$

There is a unique $\alpha \in (-\infty, +\infty)$ such that (32) is satisfied since the right-hand side of (30) is a strictly increasing function of α and goes to $\sqrt{\rho} < 1$ or $+\infty$ as $\alpha \to -\infty$ or $+\infty$.

(10) and (25) give

$$\Phi^-(\theta^-) = \frac{1}{2\pi}\int_{-\pi}^{\pi}\frac{\log R^-(s^-)}{\tan((\theta^- - s^-)/2)}ds^-\,.$$

By taking the Hilbert transform on both sides of the equation, we obtain

$$\frac{1}{2\pi}\int_{-\pi}^{\pi}\frac{\Phi^-(s^-)}{\tan((\theta^- - s^-)/2)}ds^- = -\log R^-(\theta^-) + \frac{1}{2\pi}\int_{-\pi}^{\pi}\log R^-(s^-)ds^-\,,$$

which yields

$$R^-(\theta^-) = \exp\left(\gamma - \frac{1}{2\pi}\int_{-\pi}^{\pi}\frac{\Phi(s)V(s)}{\tan((L(\theta)-L(s))/2)}ds\right), \tag{33}$$

where $\gamma = \frac{1}{2\pi}\int_{-\pi}^{\pi}\log R^-(s^-)ds^-$.

Next we need to rewrite the equation of $V(\theta)$ in (30). From (21), (23), and (25),

$$\Phi^+(\theta^+) = -H\left[\log R^+(\theta^+)\right], \tag{34}$$

$$\Phi^-(\theta^-) = -\frac{1}{\pi}\int_{-\pi}^{\pi}\left(\log\left|\sin((\theta^- - s^-)/2)\right|\right)\left(\frac{d}{ds^-}\log\frac{R^+(s^+)}{V(s^+)}\right)ds^-\,. \tag{35}$$

By the relations between $\theta^+, \theta^-, \Phi^+$, and Φ^-, (35) can be transformed into

$$\begin{aligned}\Phi(\theta) &= -\frac{1}{\pi}\int_{-\pi}^{\pi}\log\left|\sin\frac{L(\theta)-L(s)}{2}\right|\left(\frac{d}{ds}\log\frac{R^+(s)}{V(s)}\right)ds\\ &= H\left[\log\frac{R^+(s)}{V(s)}\right] + P[V,\Phi]\,,\end{aligned} \tag{36}$$

where by (33)

$$\begin{aligned}P[V,\Phi] &= -\frac{1}{\pi}\int_{-\pi}^{\pi}\log\left|\frac{\sin((L(\theta)-L(s))/2)}{\sin((\theta-s)/2)}\right|\left(\frac{d}{ds}\log R^-(s^-)\right)ds\\ &= \frac{1}{\pi}\int_{-\pi}^{\pi}\log\left|\frac{\sin((L(\theta)-L(s))/2)}{\sin((\theta-s)/2)}\right|\left(\frac{d}{ds}\left(\frac{1}{2\pi}\int_{-\pi}^{\pi}\frac{\Phi(t)V(t)}{\tan((L(s)-L(t))/2)}dt\right)\right)ds\,.\end{aligned}$$

Adding (34) to (36), we obtain $2\Phi(\theta) = -H[\log V(\theta)] + P[V,\Phi]$ or

$$2H[\Phi](\theta) = \log V(\theta) - \frac{1}{2\pi}\int_{-\pi}^{\pi} \log V(\theta)d\theta + H[P[V,\Phi]]\,,$$

which yields $V(\theta) = \exp(2H[\Phi] - H[P[V,\Phi]] + \beta)$ with $\beta = (1/2\pi)\int_{-\pi}^{\pi}\log V(\theta)d\theta$. By the condition (32), β is obtained as follows:

$$e^{\beta} = \pi\left(\int_{-\pi}^{0} e^{2H[\Phi]-H[P[V,\Phi]]}d\theta\right)^{-1}. \tag{37}$$

Also from (28), we have $e^{4H[\Phi]-2H[P[V,\Phi]]+2\beta} - \rho - e^{2H[\Phi]}A(\theta) = 0$, which can be transformed into

$$e^{2H[\Phi]} = \frac{A(\theta) + \sqrt{A^2(\theta) + 4\rho e^{2\beta-2H[P[V,\Phi]]}}}{2e^{2\beta-2H[P[V,\Phi]]}}$$

or

$$\Phi(\theta) = -\frac{1}{2}H\left[\log\left(\frac{A(\theta) + \sqrt{A^2(\theta) + 4\rho e^{2\beta-2H[P[V,\Phi]]}}}{2e^{2\beta-2H[P[V,\Phi]]}}\right)\right] \stackrel{\text{def}}{=} \mathcal{W}[\Phi]\,, \tag{38}$$

where β is determined in (37).

Note that the function $V(\theta)$ in $P[V,\Phi]$ can be expressed in terms of $\Phi(\theta)$ using (30). On one hand, for (30) to be valid, the term inside the square root must not be negative. Also from (18), $I(\theta)$ in (31) cannot be zero. By checking $A(\theta)$ in (29) and $I(\theta)$, we have that $A(\theta)$ is always positive and $I(\theta)$ is never zero if $\Phi(\theta) \in [0,\pi]$ for $\theta \in [-\pi, 0]$, which is true in our case (see Lemma 2 below). On the other hand, in order to apply the global bifurcation theory, we need to define operators with no restriction $\Phi \in [0,\pi]$. Therefore, we need cut-off functions to modify our operator so that $V(\theta)$ in (30) is well-defined and $I(\theta)$ in (31) is not equal to zero for any $\Phi(\theta) \in C^{1,\kappa}$.

4. Modified equations using a cut-off function. We rewrite $A(\theta)$ and $I(\theta)$ in (29) and (31) as follows:

$$\tilde{A}_0(\theta) \stackrel{\text{def}}{=} e^{2\alpha}(1-\rho)\left[1 + \left(2(1-\rho)^{1/2}/3\right)E\left(\int_{\theta}^{0}\mu\sin(\Phi(s))e^{\alpha+H[\Phi](s)}\,ds\right)\right], \tag{39}$$

$$\tilde{I}_0(\theta) \stackrel{\text{def}}{=} (C/\mu)\left(1 + E\left(\int_{\theta}^{0}\mu\sin\Phi(s)e^{H[\Phi](s)}\tilde{A}_0^{1/2}(s)\,ds\right)\right), \tag{40}$$

where $E(y)$ is an infinitely differentiable function on $\mathbf{R}$ with $E(y) = y$ for $y \geq -\delta$ and $E(y) = -2\delta$ for $y \leq -2\delta$ such that $0 \leq E'(y) \leq 1$ and $|E^{(n+1)}(y)| \leq K\delta^{-n}$ for $n \geq 1$. Here $\delta > 0$ is chosen so that $4\delta = \min((3/2)(1-\rho)^{-1/2}, 1)$. Thus, $\tilde{A}_0(\theta) \geq (1/2)(1-\rho)e^{2\alpha}$ and $\tilde{I}_0(\theta) \geq (C/2\mu)$ for any Hölder continuous function $\Phi(\theta)$. Obviously, if $\pi \geq \Phi(\theta) \geq 0$, then $\tilde{A}_0(\theta) = A(\theta)$ and $\tilde{I}_0(\theta) = I(\theta)$.

By (30), we define $\tilde{V}_0(\theta) \stackrel{\text{def}}{=} (\rho + e^{2H[\Phi](\theta)}\tilde{A}_0(\theta))^{1/2}$. Then $\tilde{V}_0(\theta) > \rho^{1/2}$. Here α in (39) is determined by the condition

$$\int_{-\pi}^{0}\left(\rho + e^{2H[\Phi](\theta)}\tilde{A}_0(\theta)\right)^{1/2}d\theta = \pi\,.$$

If $y = e^{\alpha}$, $\tilde{A}_0(\theta)$ is a strictly increasing function of y since for any fixed θ and $y > 0$ by the definition of $E(y)$

$$\begin{aligned}(d\tilde{A}_0/dy) &= 2y(1-\rho)\left[1+\left(2(1-\rho)^{1/2}/3\right)E\left(\int_\theta^0 \mu\sin(\Phi(s))ye^{H[\Phi](s)}\,ds\right)\right]\\ &\quad +y^2(1-\rho)\left(2(1-\rho)^{1/2}/3\right)E'\left(\int_\theta^0 \mu\sin(\Phi(s))ye^{H[\Phi](s)}\,ds\right)\\ &\quad \times\int_\theta^0 \mu\sin(\Phi(s))e^{H[\Phi](s)}ds\\ &\geq 2y(1-\rho)(1/2)-y(1-\rho)^{3/2}(2/3)2\delta\\ &> y(1-\rho)(1-(4/3)(1-\rho)^{1/2}\delta\pi)\geq y(1-\rho)(1/2)>0\,.\end{aligned}$$

When $y\to 0$, $\int_{-\pi}^0(\rho+e^{2H[\Phi](\theta)}\tilde{A}_0(\theta))^{1/2}d\theta\to\rho^{1/2}\pi<\pi$. As $y\to+\infty$, $\int_{-\pi}^0(\rho+e^{2H[\Phi](\theta)}\tilde{A}_0(\theta))^{1/2}d\theta\to+\infty$. Thus, there must be a unique $y\in(0,\infty)$ and hence a unique $\alpha\in(-\infty,+\infty)$ with $y=e^{\alpha}$ such that

$$\int_{-\pi}^0\left(\rho+e^{2H[\Phi](\theta)}\tilde{A}_0(\theta)\right)^{1/2}d\theta=\pi\,.$$

Let this unique α be $\Lambda(\Phi)$. By using the implicit function theorem, we have that $\Lambda(\Phi)$ is Frechet differentiable with respect to Φ. Thus, if we let $\alpha=\Lambda(\Phi)$ in (39) and (40),

$$A_0(\theta)\stackrel{\text{def}}{=}e^{2\Lambda}(1-\rho)\left[1+\left(2(1-\rho)^{1/2}/3\right)E\left(\int_\theta^0\mu\sin(\Phi(s))e^{\Lambda+H[\Phi](s)}\,ds\right)\right],\tag{41}$$

$$I_0(\theta)\stackrel{\text{def}}{=}(C/\mu)\left(1+E\left(\int_\theta^0\mu\sin\Phi(s)e^{H[\Phi](s)}A_0^{1/2}(s)\,ds\right)\right),\tag{42}$$

then

$$V_0(\theta)\stackrel{\text{def}}{=}\left(\rho+e^{2H[\Phi](\theta)}A_0(\theta)\right)^{1/2}\tag{43}$$

always satisfies $\int_{-\pi}^0 V_0(\theta)d\theta=\pi$ for any $\Phi\in C^{1,\kappa}$ and $V_0(\theta)$ is a function of Φ only. We note that $(\min_{-\pi\leq\theta\leq\pi}V_0(\theta))^{-1}\leq\rho^{-1/2}$. Hence, if $\|\Phi\|_{C^{1,\kappa}}\leq K_0$, then $V_0(\theta)\in C^{1,\kappa}$ with $\|V_0(\theta)\|_{C^{1,\kappa}}\leq K$. We summarize this in the following theorem.

THEOREM 2. *For a given $\Phi(\theta)\in C^{1,\kappa}$ with $\|\Phi(\theta)\|_{C^{1,\kappa}}\leq K_0$, then $V_0(\theta)\in C^{1,\kappa}$ with $\|V_0(\theta)\|_{C^{1,\kappa}}\leq K$ and $\min_{-\pi\leq\theta\leq\pi}V_0(\theta)\geq\rho^{1/2}$, where K is a constant that is independent of Φ but may depend on K_0. If $0\leq\Phi\leq\pi$, then $V_0(\theta)\equiv V(\theta)$.*

Finally, using (41)–(43), we rewrite $P[\Phi]$ in (36) by

$$\begin{aligned}P_0[\Phi]=\frac{1}{2\pi^2}\int_{-\pi}^{\pi}\log\left|\frac{\sin((L_0(\theta)-L_0(s))/2)}{\sin((\theta-s)/2)}\right|\\ \times\frac{d}{ds}\left(\int_{-\pi}^{\pi}\frac{\Phi(t)V_0(t)dt}{\tan((L_0(s)-L_0(t))/2)}\right)ds\,,\end{aligned}\tag{44}$$

where $L_0(\theta)=\int_0^\theta V_0(s)ds$ and $V_0(\theta)$ in (43) depends only upon Φ. Then (38) is changed to

$$\Phi(\theta)=-\frac{1}{2}H\left[\log\left(\frac{A_0(\theta)+\sqrt{A_0^2(\theta)+4\rho e^{2\beta-2H[P_0]}}}{2e^{2\beta-2H[P_0]}}\right)\right]\stackrel{\text{def}}{=}\mathcal{W}_0[\Phi]\,,\tag{45}$$

where β is defined by

$$e^{\beta} = \pi \left(\int_{-\pi}^{0} e^{2H[\Phi]-H[P_0]} d\theta \right)^{-1}.$$

If the condition for $\Phi(\theta)$ in Theorem 2 is satisfied, then $\mathcal{W}_0[\Phi](\theta) = \mathcal{W}[\Phi](\theta)$, as defined in (38).

5. Existence proof. First we try to find the corresponding linear operator for $\mathcal{W}_0$ for small Φ. From (41), (42), and (44), (45) can then be rewritten as

$$\begin{aligned} \Phi(\theta) &= H\left[(1-\rho)^{3/2}\mu(3(1+\rho))^{-1}\int_0^{\theta}\Phi(s)ds\right] + N_1[\mu,\Phi] \\ &= \lambda\left(\frac{1}{2\pi}\int_{-\pi}^{\pi}\log\left|\frac{\sin((\theta+s)/2)}{\sin((\theta-s)/2)}\right|\Phi(s)ds + \mathcal{N}[\lambda,\Phi]\right) \\ &= \lambda\left(\mathcal{L}[\Phi] + \mathcal{N}[\lambda,\Phi]\right) = \lambda\mathcal{T}[\lambda,\Phi] \end{aligned} \tag{46}$$

where λ is defined as in (19), $\mathcal{N}[\lambda,\Phi]$ is nonlinear in Φ with $\mathcal{N}(\lambda,0)=0$ and

$$\lim_{\|\Phi\|_{C^{1,\kappa}}\to 0}\left(\frac{\|\mathcal{N}[\lambda,\Phi]\|_{C^{1,\kappa}}}{\|\Phi\|_{C^{1,\kappa}}}\right) = 0.$$

Here we note that $\mathcal{T}$ in (46) may not be a positive operator. Define Banach spaces as follows.

$$\begin{aligned} B_e^{n,\kappa} = \{&f(\theta)\in C^{n,\kappa}[-\pi,\pi] \mid f(\theta)=f(-\theta) \text{ for } \theta\in[-\pi,\pi] \text{ and periodic in } \theta \\ &\text{with period } 2\pi \text{ with } f'(0)=f'(-\pi)=0\,,\ \ \|f\|_{B_e^{n,\kappa}} = \|f\|_{C^{n,\kappa}[-\pi,\pi]} < +\infty\}\,, \\ B_o^{n,\kappa} = \{&f(\theta)\in C^{n,\kappa}[-\pi,\pi] \mid f(\theta)=-f(-\theta) \text{ for } \theta\in[-\pi,\pi] \text{ and periodic in } \theta \\ &\text{with period } 2\pi \text{ with } f(0)=f(-\pi)=0\,,\ \ \|f\|_{B_o^{n,\kappa}} = \|f\|_{C^{n,\kappa}[-\pi,\pi]} < +\infty\}\,, \end{aligned}$$

where $0<\kappa<1$. For $n=1$, we denote $B_e^{n,\kappa}=B_e$ and $B_o^{n,\kappa}=B_o$.

The fact that $\mathcal{T}$ is compact in B_o can be obtained in the following lemma, whose proof will be given in Appendix B.

LEMMA 1. *$\mathcal{T}$ and $\mathcal{N}$ in* (46) *are compact operators in the Banach space B_o. Moreover, for any Φ with $\|\Phi\|_{C^{1,\kappa}} \le K_0$, then $\|\mathcal{T}[\lambda,\Phi]\|_{C^{1,\kappa_1}} + \|\mathcal{N}[\lambda,\Phi]\|_{C^{1,\kappa_1}} \le K$, where $\kappa<\kappa_1\le 1$ and K is a constant only dependent of K_0 and λ with $|\lambda|<+\infty$.*

The integral operator $\mathcal{L}[\Phi]$ has been studied by Nekrasov [3] and Keady and Norbury [7]. It can be easily shown that $\mathcal{L}[\Phi]$ has eigenvalue $\lambda_n = n$ and the corresponding eigenfunction $e_n(\theta) = -\sin(n\theta)$ for $n=1,2,3,\ldots$, and the multiplicity of each eigenvalue is one.

For the nonlinear equation (46), we have small amplitude solutions by applying a local bifurcation theory [22].

THEOREM 3. *There is a constant $h>0$ such that* (46) *has exactly one solution $\Phi(\theta)$ with $\|\Phi(\theta)\|_{C^{1,\kappa}} \le h$ for each $\lambda>1$ but near 1 and $\Phi(\theta)>0$ for $\theta\in(-\pi,0)$, and the branch of solutions (λ,Φ) bifurcates from $(1,0)$. Also, the solution can be expanded into a power series in terms of $\lambda-1$.*

Remark. In fact, each $\lambda_n = n$ is a bifurcation point and for $\lambda-\lambda_n$ small, the solution Φ on the bifurcation branch can be written as $\Phi(\theta) = \epsilon e_n(\theta) + O(\epsilon^2), \Phi'(\theta) = \epsilon e_n'(\theta) + O(\epsilon^2)$, where $\epsilon = O(\lambda-\lambda_n)$. Therefore, for λ sufficiently close to λ_n with

$n \geq 2$, the solutions on the bifurcation branch change sign if $\theta \in [-\pi, 0]$, while for λ sufficiently close to $\lambda_0 = 1$, the solutions are in $(0, \pi)$ if $\theta \in (-\pi, 0)$.

We note that the corresponding result for the solutions of a one-layered fluid was obtained by Nekrasov [3] using integral equations and Levi-Civita [1] using differential equations. Also by the definition of λ in (see [19]) and the relation (see [20]), the wave speed c must be near some critical value in order to have such a bifurcation.

To study the global bifurcation for the solution of (46), we need to use the following global bifurcation theory [21, 22]. Consider the global solution behavior of the bifurcating branches of the equation

$$X = \lambda(\mathcal{L}[X] + \mathcal{N}[X]) \qquad \text{for} \quad \lambda \in \mathbf{R} \quad \text{and} \quad X \in \mathbf{B}\,,$$

where $\mathbf{B}$ is a Banach space over $\mathbf{R}$.

THEOREM 4. *Assume that the operators $\mathcal{L}$ and $\mathcal{N}$ from $\mathbf{B}$ to $\mathbf{B}$ are compact where $\mathcal{L}$ is linear and $\|\mathcal{N}[X]\|/\|X\| \to 0$ as $X \to 0$, and a real number λ_0^{-1} is an eigenvalue of $\mathcal{L}$ with odd algebraic multiplicity. Let $\mathcal{C}(\lambda_0)$ be a solution component in $\mathbf{R} \times \mathbf{B}$ which begins at $(\lambda, X) = (\lambda_0, 0)$. Then there are exactly two possibilities:* (i) *$\mathcal{C}(\lambda_0)$ is unbounded;* (ii) *$\mathcal{C}(\lambda_0)$ is compact and also contains a further point of the trivial solution branch in addition to $(\lambda_0, 0)$.*

Now we consider (46). Let $\mathbf{B} = B_o$ be the Banach space and $\mathcal{L}$ be defined in (46). Since $\mathcal{L}$ is a compact operator in B_o [3, 7], by Lemma 1, $\mathcal{N}$ in (46) is a compact operator in B_o. Therefore, we can apply Theorem 4 to (46) and obtain a global bifurcation branch for each eigenvalue of $\mathcal{L}$. Let us denote the bifurcation branch for the first eigenvalue by $\mathcal{C}(1)$. It is obvious that $\mathcal{C}(1)$ starts from the solutions obtained in Theorem 3 and is connected and closed. By Theorem 4, $\mathcal{C}(1)$ is either unbounded in $\mathbf{R} \times C^{1,\kappa}$ or compact with $(1/n, 0)$ in $\mathcal{C}(1)$ for some $n \geq 2$.

LEMMA 2. *If $(\lambda, \Phi) \in \mathcal{C}(1)$, then $0 < \Phi(\theta) < \pi$ for $\theta \in (-\pi, 0)$.*

Proof. Let $\mathcal{S}_1 = \{(\lambda, \Phi) \in \mathcal{C}(1) \mid 0 \leq \Phi(\theta) \leq \pi \text{ for all } \theta \in [-\pi, 0]\}$ and $\mathcal{S}_2 = \{(\lambda, \Phi) \in \mathcal{C}(1) \mid \Phi(\theta) \notin [0, \pi] \text{ for some } \theta \in [-\pi, 0]\}$. Obviously, $\mathcal{C}(1) = \mathcal{S}_1 \cup \mathcal{S}_2$, $\mathcal{S}_1$ is closed, and $\mathcal{S}_1, \mathcal{S}_2$ are disjoint. By Theorem 1, $\mathcal{S}_1 = \{(\lambda, \Phi) \in \mathcal{C}(1) \mid 0 < \Phi(\theta) < \pi \text{ for all } \theta \in (-\pi, 0) \text{ and } \Phi'(-\pi) > 0, \Phi'(0) < 0\}$, which is an open set in $\mathcal{C}(1)$. By Theorem 3, $\mathcal{S}_1$ is not empty. Therefore, $\mathcal{C}(1) = \mathcal{S}_1$ since $\mathcal{C}(1)$ is connected. This proves the lemma. □

By Lemma 2 and the remark after Theorem 3, $\mathcal{C}(1)$ cannot include $(1/n, 0)$ for any $n \geq 2$ since the solutions near such point will change sign for $-\pi \leq \theta \leq 0$. Therefore, $\mathcal{C}(1)$ is unbounded in $\mathbf{R} \times C^{1,\kappa}$ and we have the existence of large amplitude solutions (λ, Φ) of (46) until either $\lambda \to +\infty$ or $\|\Phi\|_{C^{1,\kappa}} \to +\infty$ or both. By Lemma 2, the solutions on $\mathcal{C}(1)$ satisfy that $0 < \Phi(\theta) < \pi$ for $-\pi < \theta < 0$. Hence, solutions on $\mathcal{C}(1)$ also satisfy (38), which implies that there is an unbounded branch of solutions in $\mathbf{R} \times C^{1,\kappa}$ for (38) bifurcating from the steady state $(\lambda, \Phi(\theta)) = (1, 0)$.

After $\Phi(\theta) = \Phi^+(\theta^+)$ is determined for the corresponding λ in (38), the function $V(\theta^+)$ can be found in (30) with α determined by (32) and $\theta^- = \int_0^{\theta^+} V(s)ds = L(\theta^+)$ transforms θ^+ to θ^-. Hence, at $\theta^- = L(\theta^+)$, $\Phi^-(\theta^-) = \Phi^+(\theta^+)$ is obtained. Finally, $R^-(\theta^-)$ and $R^+(\theta^+)$ are determined by (18) and (22) and the solutions for (13), (14), and (16) are obtained. We summarize the result as follows.

THEOREM 5. *There exists a branch of solutions $(\lambda, \Phi^\pm(\theta^\pm), R^\pm(\theta^\pm))$ satisfying* (3), (13), (15), *and* (16) *with $\lambda \geq 1$ and $0 < \Phi^-(\theta^-) < \pi$ for $-\pi < \theta^- < 0$, where $\lambda = (1-\rho)^{3/2}\mu(3(1+\rho))^{-1}$, μ satisfies*

$$\frac{1}{2}\left(\frac{3g(1-\rho)\tau}{2\pi c^2 \mu}\right)^{2/3} + \frac{g(1-\rho)}{c^2} y(0) = \frac{1-\rho}{2}\,,$$

and $y(0)$ is the height of the interface at $x = 0$. The branch bifurcates from steady state $(\lambda,\ \Phi^{\pm}(\theta^{\pm}),\ R^{\pm}(\theta^{\pm})) = (1, 0, 0)$ when c is near its critical value. The solution branch exists until $|\lambda| + \|\Phi^{+}(\theta^{+})\|_{C^{1,\kappa}}$ becomes infinity.

It should be noted that two limiting cases, $|\lambda| \to +\infty$ and $\|\Phi^{+}(\theta^{+})\|_{C^{1,\kappa}} \to +\infty$, can happen separately (see numerical computations by Turner and VandenBroeck [15] and Grimshaw and Pullin [16]). For a one-layered fluid (i.e., $\rho^{+} = 0$), these limiting cases occur simultaneously, i.e., as $|\lambda| \to +\infty$, $\|\Phi^{-}(\theta^{-})\|_{C^{1,\theta}} \to +\infty$. Also we have that $\Phi^{-}(\theta^{-})$ is always finite in $C^{1,\kappa}$ as long as $\Phi^{+}(\theta^{+}) \in C^{1,\kappa}$, which implies that the break-up of $\Phi^{-}(\theta^{-})$ in $C^{1,\kappa}$ cannot happen before the break-up of $\Phi^{+}(\theta^{+})$. The numerical evidence shows that they break up at the same time [16].

Appendix A. First let us state two lemmas [27].

LEMMA A.1 (the Hopf lemma). *Let $S \subseteq \mathbf{R}^2$ be a domain in which a nonconstant function $\Phi(x, y) \in C^1(\bar{S})$ satisfies $\Delta\Phi = 0, \Phi \geq 0$. If $(\xi, \eta) \in \partial S$ is a boundary point at which the boundary has a well-defined tangent line, and if $\Phi(\xi, \eta) = 0$, then $\partial_n \Phi(\xi, \eta) < 0$ for n, the exterior normal vector at (ξ, η) to ∂S.*

LEMMA A.2 (the Hopf "corner-point" lemma). *Consider $S \subseteq \mathbf{R}^2$ and $\Phi(x, y) \in C^1(\bar{S})$ as above, and let $(\xi, \eta) \in \partial S$ be a boundary point at which the boundary curve is not smooth but consists of two C^1 arcs meeting with an interior angle $\alpha \geq \pi/2$. (That is, interior tangent vectors t_1, t_2 to the two arcs have $t_1 \cdot t_2 \leq 0$). Let $\nu = at_1 + bt_2$ for some $a, b > 0$; the vector ν points into S. If $\Phi(\xi, \eta) = 0$, then either $\partial_\nu \Phi(\xi, \eta) > 0$ or else $\partial_\nu \Phi(\xi, \eta) = 0$ for all such ν, $t_1 \cdot t_2 = 0$, and $\partial_\nu^2 \Phi(\xi, \eta) > 0$.*

Now we can use these two lemmas to prove Theorem 1. Assume that $u = \xi + i\eta = re^{i\theta}$. Since $f^{\pm}(u) = R^{\pm}(r, \theta)e^{i\Phi^{\pm}(r,\theta)}$ are analytic and $R^{\pm} \neq 0$ for $|u| < 1$ and $|u| > 1$, $\log R^{\pm}(\xi, \eta) + i\Phi^{\pm}(\xi, \eta)$ is analytic in $\eta < 0$ except at $\xi^2 + \eta^2 = 1$ and the Cauchy–Riemann equations hold for $\log R^{\pm}$ and $\Phi^{\pm}$. Let $D^{+} = \{(\xi, \eta) = re^{i\theta} : r < 1 \text{ and } \eta < 0\}$ and $D^{-} = \{(\xi, \eta) = re^{i\theta} : r > 1 \text{ and } \eta < 0\}$. On the boundary ∂D^{+} of D^{+}, we know that $0 \leq \Phi^{+}(\theta^{+}) \leq \pi$ and $\Phi^{+}(\theta^{+}) \not\equiv 0$ for $\theta^{+} \in [-\pi, 0]$, which implies $\Phi^{+} \geq 0$ in D^{+}. If there is a $\theta_0^{+} \in (-\pi, 0)$ such that $\Phi(\theta_0^{+}) = 0$, then Φ^{+} has a minimum at θ_0^{+} with $(d\Phi^{+}(\theta_0^{+})/d\theta) = 0$. By Lemma A.1, $\Phi_r^{+}(\theta_0^{+}) < 0$. Similarly, by the condition that $\Phi^{+}(\theta^{+}) = \Phi^{-}(\theta^{-})$ on $r = 1$ and $\Phi^{-} \to 0$ as $r \to +\infty$, we have $\Phi_r^{-}(\theta_0^{-}) > 0$, where θ_0^{+} and θ_0^{-} correspond to a single point on $r = 1$. By using $r^2 = \xi^2 + \eta^2$, $\theta = \arctan(\eta/\xi)$, and the Cauchy–Riemann equations for $\log R^{\pm}$ and $\Phi^{\pm}$, we obtain that

$$(\log R)_\theta = -\Phi_\eta r \sin\theta - \Phi_\xi r \cos\theta\,,$$

$$\Phi_\xi = (-1/r)(\Phi_\theta \sin\theta - \Phi_r r \cos\theta)\,, \quad \Phi_\eta = (1/r)(\Phi_r r \sin\theta + \Phi_\theta \cos\theta)\,,$$

which implies $(\log R)_\theta = -r\Phi_r$. Thus, at $r = 1, \theta = \theta_0^{\pm}$, we have

$$\frac{R_{\theta^+}^{+}(\theta_0^{+})}{R^{+}(\theta_0^{+})} = -\Phi_r^{+}(\theta_0^{+}) > 0\,, \qquad \frac{R_{\theta^-}^{-}(\theta_0^{-})}{R^{-}(\theta_0^{-})} = -\Phi_r^{-}(\theta_0^{-}) < 0\,.$$

Then by (16), we obtain that the left-hand side of (16) is strictly positive, which contradicts (16). Therefore, there is no $\theta_0^{\pm}$ with $0 < \theta_0^{\pm} < \pi$ such that $\Phi^{\pm}(\theta_0^{\pm}) = 0$. By a similar proof, we can show that there is no $\theta_0^{\pm}$ with $0 < \theta_0^{\pm} < \pi$ such that $\Phi^{\pm}(\theta_0^{\pm}) = \pi$. Hence, $\Phi^{\pm}(\theta^{\pm})$ cannot reach its minimum 0 or maximum π at $0 < \theta^{\pm} < \pi$.

At $\theta^{\pm} = 0$, $\Phi^{\pm}(0) = 0$ and $\Phi^{\pm}$ take their minima in $D^{\pm}$ at $\theta^{\pm} = 0$. Thus $\Phi_{\theta^{\pm}}^{\pm}(0-) \leq 0$. Asusume that $\Phi_{\theta^{\pm}}^{\pm}(0-) = 0$. First let us consider $\Phi^{+}(r, \theta^{+})$ in D^{+}.

Obviously, $\Phi^+(r,\theta^+)$ is harmonic in D^+ with $\Phi^+_r(1,0)=\Phi^+_{\theta^+}(1,0)=0$. The point $(\xi,\eta)=(1,0)$ is a corner of D^+ and two interior tangent vectors $t_1=(0,-1), t_2=(-1,0)$ at this point have the properties that $t_1\cdot t_2=0$ and $\partial_\nu\Phi^+(\xi,\eta)|_{1,0}=0$ for any $\nu=at_1+bt_2$ with $a,b>0$. Therefore, by Lemma A.2, we have $\partial^2_\nu\Phi^+(\xi,\eta)|_{(1,0)}>0$. If we let $\nu=(-1,-1)$, then $\partial^2_\nu\Phi^+(\xi,\eta)|_{(1,0)}=\Phi^+_{\xi\eta}(1,0)>0$. At $\theta^+=0$, $\Phi^+_{\xi\eta}(1,0)=\Phi^+_{r\theta^+}(1,0)>0$. Similarly, we have that $\Phi^-_{r\theta^-}(1,0)<0$. But we know that $R^\pm_{\theta^\pm}=-rR^\pm\Phi^\pm_r$, which implies that $R^\pm_{\theta^\pm}(\xi,\eta)|_{(1,0)}=0$. From (16),

$$\frac{V(\theta^+)\Phi^-_r(1,\theta^-)}{(R^-(\theta^-))^2}-\frac{\rho\Phi^+_r(1,\theta^+)}{(R^+(\theta^+))^2}+\frac{\tau g(1-\rho)}{2\pi c^2}R^+(\theta^+)\sin\Phi^+(\theta^+)=0. \tag{A.1}$$

By taking the derivative of both sides of (A.1) with respect to θ^+ and using the fact that $R^\pm_{\theta^\pm}=\Phi^\pm_r=\Phi^\pm_{\theta^\pm}=\Phi^\pm=0$ at $(\xi,\eta)=(1,0)$, we obtain that at $(\xi,\eta)=(1,0)$,

$$\frac{V^2(\theta^+)\Phi^-_{r\theta^-}(\theta^-)}{(R^-(\theta^-))^2}-\frac{\rho\Phi^+_{r\theta^+}(\theta^+)}{(R^+(\theta^+))^2}=0\,,$$

which contradicts the inequalities $\Phi^+_{r\theta^+}>0$ and $\Phi^-_{r\theta^-}<0$ at $(\xi,\eta)=(1,0)$. Thus, $\Phi^\pm_\theta(0)<0$. Similarly, we can show that $\Phi^\pm_\theta(-\pi)>0$. The proof is complete.

Appendix B. Let a set $S\subset B_o$ such that $\Phi\in S$ if $\|\Phi\|_{B_o}\le K_0<+\infty$. It is obvious that $I_0(\theta)\in B^{1,\kappa_1}_e, A_0(\theta)\in B^{1,\kappa_1}_e$ for $1\ge\kappa_1>\kappa$ with bounded norms and $\mathcal{W}_0[\Phi]$ is odd and periodic with period 2π if $\Phi\in S$. Therefore, we need only show $P_0[\Phi]\in B^{1,\kappa_1}_e$ for any $1\ge\kappa_1>\kappa$. Consider integral

$$H_1[\Phi,V_0](\theta)=H_1(\theta)\stackrel{\text{def}}{=}\frac{1}{2\pi}\int_0^\pi\frac{\Phi(s)V_0(s)}{\tan((L_0(\theta)-L_0(s))/2)}ds\,. \tag{B.1}$$

If we let $t=u(s)=\int_0^s V_0(s)ds$ and $w=u(\theta)=\int_0^\theta V_0(s)ds$, then

$$H_1[\Phi,V_0]=\frac{1}{2\pi}\int_{-\pi}^\pi\frac{\Phi(u^{-1}(t))}{\tan((w-t)/2)}dt\stackrel{\text{def}}{=}W(w)\,.$$

The Hölder norm of W with respect to w is

$$\frac{|W(w_1)-W(w_2)|}{|w_1-w_2|^\kappa}\le K\|\Phi(u^{-1}(w))\|_{C^{0,\kappa}}\,,$$

which yields

$$\begin{aligned}\frac{|W(u(\theta_1))-W(u(\theta_2))|}{|\theta_1-\theta_2|^\kappa}&=\frac{|W(u(\theta_1))-W(u(\theta_2))|}{|u(\theta_1)-u(\theta_2)|^\kappa}\times\frac{|u(\theta_1)-u(\theta_2)|^\kappa}{|\theta_1-\theta_2|^\kappa}\\&\le K\left\|\Phi(u^{-1}(s))\right\|_{C^{0,\kappa}}\left|(\theta_1-\theta_2)^{-1}\int_{\theta_1}^{\theta_2}V_0(s)ds\right|^\kappa\le K\|\Phi(u^{-1}(s))\|_{C^{0,\kappa}}\|V_0\|^\kappa_{C^0}\,.\end{aligned}$$

The Hölder norm of $\Phi(u^{-1}(s))$ with respect to s is

$$\begin{aligned}\frac{|\Phi(u^{-1}(s_1))-\Phi(u^{-1}(s_2))|}{|s_1-s_2|^\kappa}&=\frac{|\Phi(u^{-1}(s_1))-\Phi(u^{-1}(s_2))|}{|u^{-1}(s_1)-u^{-1}(s_2)|^\kappa}\times\frac{|u^{-1}(s_1)-u^{-1}(s_2)|^\kappa}{|s_1-s_2|^\kappa}\\&\le K\|\Phi(\theta)\|_{C^{0,\kappa}}\,,\end{aligned}$$

where Theorem 2 has be used. Therefore, $\|H_1[\Phi, V_\epsilon]\|_{C^{0,\kappa}} \le K\|V_0\|^\kappa_{C^0}\|\Phi\|_{C^{0,\kappa}}$. The derivative of W with respect to w is

$$W'(w) = \frac{1}{2\pi}\int_{-\pi}^{\pi} \frac{\Phi'(u^{-1}(t))}{V_0(u^{-1}(t))\tan((w-t)/2)}dt\,,$$

whose Hölder norm can be estimated as

$$\frac{|W'(w_1) - W'(w_2)|}{|w_1 - w_2|^\kappa} \le K\left\|\Phi'\left(u^{-1}(t)\right)\left(V_0(u^{-1}(t))\right)^{-1}\right\|_{C^{0,\kappa}}.$$

Hence,

$$\|H_1[\Phi, V_0]\|_{C^{1,\kappa}}$$
$$\le K\left(\|V_0\|^\kappa_{C^{0,\kappa}} + \left\|\Phi'(u^{-1}(t))\left(V_0(u^{-1}(t))\right)^{-1}\right\|_{C^{0,\kappa}}\|V_0\|^\kappa_{C^0}\right).$$

But $|\Phi'(u^{-1}(t))(V_0(u^{-1}(t)))^{-1}| \le K\|\Phi'\|_{C^{0,\kappa}}$ and

$$\left|\Phi'(u^{-1}(t_1))\left(V_0(u^{-1}(t_1))\right)^{-1} - \Phi'(u^{-1}(t_2))\left(V_0(u^{-1}(t_2))\right)^{-1}\right||t_1 - t_2|^{-\kappa}$$
$$\le K\left\|\Phi'(\theta)\left(V_0(\theta)\right)^{-1}\right\|_{C^{0,\kappa}} \le K\left(\|V_0\|_{C^0}\|\Phi'\|_{C^{0,\kappa}} + \|\Phi'\|_{C^0}\|V_0\|_{C^{0,\kappa}}\right),$$

which gives

$$\|H_1[\Phi, V_0]\|_{C^{1,\kappa}} \le K\left(\|V_0\|_{C^0}\|\Phi\|_{C^{1,\kappa}} + \|\Phi\|_{C^{1,0}}\|V_0\|_{C^\kappa}\right).$$

Using Theorem 2, we can obtain

$$\|H_1[\Phi, V_0]\|_{C^{1,\kappa}} \le K\|\Phi\|_{C^{1,\kappa}}. \tag{B.2}$$

Next, we study

$$P_0[\Phi] = -\frac{1}{\pi}\int_{-\pi}^{\pi}\log\left|\frac{\sin((L_0(\theta) - L_0(s))/2)}{\sin((\theta - s)/2)}\right|\left(\frac{d}{ds}H_1(s)\right)ds\,. \tag{B.3}$$

First, we let $-\pi/2 \le \theta \le \pi/2$. Since $L_0(-\pi) = -\pi$ and $L_0(\pi) = \pi$, we have $-3\pi/4 \le (\theta - s)/2 \le 3\pi/4$ if $s \in [-\pi, \pi]$. Then there is a $\delta_0 > 0$ such that $-\pi + \delta_0 \le (L_0(\theta) - L_0(s))/2 \le \pi - \delta_0$. We rewrite (B.3) by

$$\int_{-\pi}^{\pi}\log\left|\frac{L_0(\theta) - L_0(s)}{\theta - s}\right|\left(\frac{d}{ds}H_1(s)\right)ds$$
$$+\int_{-\pi}^{\pi}\log\left|\frac{\sin((L_0(\theta) - L_0(s))/2)}{L_0(\theta) - L_0(s)}\frac{(\theta - s)}{\sin((\theta - s)/2)}\right|\left(\frac{d}{ds}H_1(s)\right)ds \stackrel{\text{def}}{=} I_1(\theta) + I_2(\theta)\,.$$

The estimates for $I_2(\theta)$ are obtained as follows:

$$\left|\frac{d\,I_2(\theta)}{d\theta}\right| \le \int_{-\pi}^{\pi}\left(\frac{d}{d\theta}\left(\log\left|\frac{\sin((L_0(\theta) - L_0(s))/2)}{L_0(\theta) - L_0(s)}\frac{\theta - s}{\sin((\theta - s)/2)}\right|\right)\right)\left(\frac{d}{ds}H_1(s)\right)ds$$
$$\le K\big(1 + \|V_0(\theta)\|_{C^0}\big)\|(dH_1(s)/ds)\|_{C^0}$$

$$\left|\frac{d^2\,I_2(\theta)}{d\theta^2}\right| \le K\big(1 + \|V_0(\theta)\|_{C^{1,0}}\big)\|(dH_1(s)/ds)\|_{C^0}.$$

The derivative of $I_1(\theta)$ can be rewritten as

$$\begin{aligned}\frac{d\,I_1(\theta)}{d\theta} &= \int_{-\pi}^{\pi} \left(\frac{V_0(\theta)}{L_0(\theta)-L_0(s)} - \frac{1}{\theta-s}\right)\left(\frac{d}{ds}H_1(s)\right) ds \\ &= \int_{-\pi}^{\pi} \frac{\int_0^1 (V_0(t\theta+(1-t)s)-V_0(\theta))\,dt}{(\theta-s)\int_0^1 V_0(t\theta+(1-t)s)dt}\left(\frac{d}{ds}H_1(s)\right) ds\,.\end{aligned}$$

Note that $|V_0(t\theta+(1-t)s)-V_0(\theta)| \le K\|V_0'\|_{C^0}|\theta-s|(1-t)$ and $|\int_0^1 V_0(t\theta+(1-t)s)ds|^{-1} \le K$, which implies

$$\left|\frac{d\,I_1(\theta)}{d\theta}\right| \le K\|V_0'\|_{C^0}\|H_1'(s)\|_{C^0}\,.$$

The estimate of the second-order derivative of $I_1(\theta)$ is

$$\begin{aligned}\left|\frac{d^2\,I_1(\theta)}{d\theta^2}\right| \le \Bigg| &\int_{-\pi}^{\pi} \frac{1}{\theta-s}\left(\frac{d}{d\theta}\frac{\int_0^1 (V_0(t\theta+(1-t)s)-V_0(\theta))\,dt}{\int_0^1 V_0(t\theta+(1-t)s)dt}\right)\left(\frac{d}{ds}H_1(s)\right) ds \\ &- \int_{-\pi}^{\pi} \frac{1}{(\theta-s)^2}\left(\frac{\int_0^1 (V_0(t\theta+(1-t)s)-V_0(\theta))\,dt}{\int_0^1 V_0(t\theta+(1-t)s)dt}\right)\left(\frac{d}{ds}H_1(s)\right) ds\Bigg| \\ = &\left|\int_{-\pi}^{\pi} \frac{g_1(\theta,s)}{\theta-s}ds\right|,\end{aligned}$$

where

$$\begin{aligned}g_1(\theta,s) \stackrel{\text{def}}{=} &\left[\left(\frac{d}{d\theta}\frac{\int_0^1 (V_0(t\theta+(1-t)s)-V_0(\theta))\,dt}{\int_0^1 V_0(t\theta+(1-t)s)dt}\right)\right. \\ &\left.-\left(\frac{\int_0^1\int_0^1 (1-t)V_0'((1-\omega)(t\theta+(1-t)s)+\theta\omega)d\omega dt}{\int_0^1 V_0(t\theta+(1-t)s)dt}\right)\right]\left(\frac{d}{ds}H_1(s)\right).\end{aligned}$$

Since $V_0(\theta)$ and $H_1(\theta)$ are in $C^{1,\kappa}$, $g_1(\theta,s)$ is in C^κ with respect to s and θ for $-\pi/2 \le \theta \le \pi/2$ and $-\pi \le s \le \pi$. If $v = \theta - s$, then $\theta+\pi \ge \pi/2$ and $\theta-\pi \le -\pi/2$ and

$$\begin{aligned}\int_{-\pi}^{\pi} \frac{g_1(\theta,s)}{\theta-s}ds &= \int_{\theta-\pi}^{\theta+\pi} \frac{g_1(\theta,\theta-v)}{v}\,dv \\ &= \left(\int_{\theta-\pi}^{-\pi/2} + \int_{-\pi/2}^{\pi/2} + \int_{\pi/2}^{\theta+\pi}\right)\frac{g_1(\theta,\theta-v)}{v}dv\,.\end{aligned}$$

By a similar argument as the proof of Lemma 3 in [28], for $-\pi/2 \le \theta \le \pi/2$, we have

$$\left\|\frac{d^2\,I_1}{d\theta^2}\right\|_{C^{0,\kappa}[-\pi/2,\pi/2]} \le K\left(1+\|V_0(\theta)\|_{C^{1,\kappa}}\right)\|dH_1(s)/ds\|_{C^{0,\kappa}}\,.$$

For $-\pi \le \theta \le -(\pi/2)$ or $\pi/2 \le \theta \le \pi$, we can use the periodic property of (B.3). If $\pi/2 \le \theta \le (3\pi/2)$, which implies $-\pi/2 \le \theta-\pi \le \pi/2$, then by $L_0(\pi) = \pi$ and

$L_0(2\pi) = 2\pi$

$$\int_{-\pi}^{\pi} \log \left| \frac{\sin((L_0(\theta) - L_0(s))/2)}{\sin((\theta - s)/2)} \right| \left(\frac{d}{ds} H_1(s) \right) ds$$
$$= \int_{-\pi}^{\pi} \log \left| \frac{\sin\left((\int_s^{\theta-\pi} V_0(t+\pi) ds)/2 \right)}{\sin((\theta - \pi - s)/2)} \right| \left(\frac{d}{ds} H_1(s+\pi) \right) ds \,.$$

Let $\theta_0 = \theta - \pi$ and $V_{0,0}(t) = V_0(t+\pi)$. We have $-\pi/2 \le \theta_0 \le \pi/2$ and $V_{0,0}(\theta) \in C^{1,\kappa}$. By the proof for the estimates of I_1 with $\theta \in [-\pi/2, \pi/2]$, we have

$$\left\| \frac{d^2 I_1}{d\theta_0^2} \right\|_{C^{0,\kappa}[-\pi/2,\pi/2]} \le K \left(1 + \|V_0(\theta)\|_{C^{1,\kappa}}\right) \left\| \frac{d}{ds} H_1(s) \right\|_{C^{0,\kappa}} .$$

Hence, we obtain

$$\left\| \frac{d^2 I_1}{d\theta^2} \right\|_{C^{\kappa}[-\pi,\pi]} \le K \left(1 + \|V_0(\theta)\|_{C^{1,\kappa}}\right) \left\| \frac{d}{ds} H_1(s) \right\|_{C^{0,\kappa}} .$$

Combining the estimates for I_1 and I_2 together, we have shown that

$$\|P_0[\Phi]\|_{C^{2,\kappa}} \le K \left(1 + \|V_0(\theta)\|_{C^{1,\kappa}}\right) \|(dH_1(s)/ds)\|_{C^{0,\kappa}} .$$

Therefore, Theorem 2, (B.1), and (B.2) yield

$$\|P_0[\Phi]\|_{C^{2,0}} \le K \left(1 + \|V_0(\theta)\|_{C^{1,\kappa}}\right) \|\Phi\|_{C^{1,\kappa}}$$
$$\le K \|\Phi\|_{C^{1,\kappa}} ,$$

where K is a constant independent of Φ, κ but may depend on K_0. Hence, $P_0[\Phi] \in B_e^{1,\kappa_1}$ for any $1 \ge \kappa_1 > \kappa$ and $\mathcal{T}$ is compact in B_o since any bounded set in C^{1,κ_1} is a compact set of $C^{1,\kappa}$ if $1 \ge \kappa_1 > \kappa$.

Acknowledgment. The author wishes to thank Professor T. B. Benjamin for introducing this problem to him.

RAISING MULTIWAVELET APPROXIMATION ORDER THROUGH LIFTING*

FRITZ KEINERT†

Abstract. Given a pair of biorthogonal, compactly supported multiwavelets, we present an algorithm for raising their approximation orders to any desired level, using one lifting step and one dual lifting step. Free parameters in the algorithm are explicitly identified, and can be used to optimize the result with respect to other criteria.

Key words. wavelets, multiwavelets, lifting, approximation order

1. Introduction.

A *refinable function vector of multiplicity* r *and dilation factor* m is a vector $\boldsymbol{\phi}^{(0)}$ of r real-valued functions

$$\boldsymbol{\phi}^{(0)}(x) = \begin{pmatrix} \phi_1^{(0)}(x) \\ \vdots \\ \phi_r^{(0)}(x) \end{pmatrix}, \qquad x \in \boldsymbol{R}, \tag{1.1}$$

which satisfies a *matrix refinement equation*

$$\boldsymbol{\phi}^{(0)}(x) = \sqrt{m} \sum_{k \in \boldsymbol{Z}} h_k^{(0)} \boldsymbol{\phi}^{(0)}(mx - k). \tag{1.2}$$

The sequence $\mathcal{H}^{(0)} = \{h_k^{(0)}\}_{k \in \boldsymbol{Z}}$ of coefficient matrices is called the *mask* of the function. We assume that only finitely many $h_k^{(0)}$ are nonzero and that all $\phi_j^{(0)}$ have compact support.

We call $\boldsymbol{\phi}^{(0)}$ a *multiscaling function* if it generates a *multiresolution approximation* (MRA) [21] of $L^2(\boldsymbol{R})$. This means that there exists a sequence of subspaces V_j, $j \in \boldsymbol{Z}$, of $L^2(\boldsymbol{R})$ with the following properties:

1. $V_j \subset V_{j+1}$,
2. $\bigcap_j V_j = \{0\}, \quad \overline{\bigcup_j V_j} = L^2(\boldsymbol{R})$,
3. $f(x) \in V_j \Leftrightarrow f(x - m^{-j}k) \in V_j, \quad k \in \boldsymbol{Z}$,
4. $f(x) \in V_j \Leftrightarrow f(mx) \in V_{j+1}$,
5. $\{\phi_j^{(0)}(x - k) : j, k \in \boldsymbol{Z}\}$ forms a Riesz basis of V_0.

In detail, property 5 means that there exist constants $0 < A \le B$ so that

$$A \sum_j \|\boldsymbol{c}_j\|_2^2 \le \Big\| \sum_j \boldsymbol{c}_j^* \boldsymbol{\phi}^{(0)}(x - j) \Big\|_2^2 \le B \sum_j \|\boldsymbol{c}_j\|_2^2 \tag{1.3}$$

for any sequence of coefficient vectors $\{\boldsymbol{c}_j\}$ with $\sum_j \|\boldsymbol{c}_j\|_2^2 < \infty$. The superscript $*$ denotes the transpose.

Other function vectors $\boldsymbol{\phi}^{(\nu)}$, $\nu = 1, \ldots, m-1$, are called *multiwavelet functions* if $\{\phi_j^{(\nu)}(x-k) : j,k \in \boldsymbol{Z}\}$ form Riesz bases of other spaces $W_0^{(\nu)}$ so that

$$V_0 \oplus W_0^{(1)} \oplus \cdots \oplus W_0^{(m-1)} = V_1$$

and

$$\{m^{\ell/2}\phi_j^{(\nu)}(m^\ell x - k) : j,k,\ell \in \boldsymbol{Z}, \nu = 1, \ldots, m-1\}$$

forms a Riesz basis of $L^2(\boldsymbol{R})$.

These multiwavelet functions satisfy refinement equations

$$\boldsymbol{\phi}^{(\nu)}(x) = \sqrt{m} \sum_k h_k^{(\nu)} \boldsymbol{\phi}^{(0)}(mx - k). \tag{1.4}$$

We again assume that all coefficient sequences are finite and all multiwavelet functions have compact support.

In the standard literature, the word "wavelet" sometimes means an individual wavelet function, sometimes scaling function and wavelets together. To avoid ambiguity, we refer to the entire collection $\boldsymbol{\phi} = \{\boldsymbol{\phi}^{(\nu)} : \nu = 0, \ldots, m-1\}$ as a multiwavelet and to the individual $\boldsymbol{\phi}^{(\nu)}$ as multiscaling functions or multiwavelet functions.

The properties of refinable function vectors, multiscaling functions, and multiwavelet functions with dilation factor $m = 2$ are discussed in many papers. Some of the earliest occurrences are [1], [9], [11], [12]; more recent treatments include [4], [6], [14], [18], [25], [26], [28]. It is straightforward to extend these results to the case of general m, following the one-dimensional case which is discussed, for example, in [16], [27], [35].

Two multiwavelets $\boldsymbol{\phi}$, $\tilde{\boldsymbol{\phi}}$ form a biorthogonal pair if they satisfy the *biorthogonality conditions*

$$\int \phi_k^{(\mu)}(x) \tilde{\phi}_\ell^{(\nu)}(x-j)\, dx = \delta_{\mu\nu}\delta_{0j}\delta_{k\ell}, \tag{1.5}$$

where δ is the Kronecker delta.

One of the properties of a multiscaling function which has great practical interest is the *approximation order* [15], [17], [22], [23]. $\boldsymbol{\phi}^{(0)}$ has approximation order $p \geq 1$ if all powers of x up to $p-1$ can be locally written as linear combinations of its integer translates. That is, there exist vectors $\boldsymbol{y}_k^{(j)} \in \boldsymbol{R}^r$ such that for $j = 0, \ldots, p-1$

$$x^j = \sum_k \boldsymbol{y}_k^{(j)*} \boldsymbol{\phi}^{(0)}(x-k). \tag{1.6}$$

Since we assume compact support, the sum is finite for each fixed x, and there are no convergence problems.

This paper considers the following problem: Given a biorthogonal multiwavelet pair $\boldsymbol{\phi}$, $\tilde{\boldsymbol{\phi}}$ and integers $p \geq 1$, $\tilde{p} \geq 1$, find an algorithm to generate from them new multiwavelets $\boldsymbol{\phi}_{\text{new}}$, $\tilde{\boldsymbol{\phi}}_{\text{new}}$ with approximation orders p, $\tilde{p}$, respectively.

One known way to raise approximation order is through the use of two-scale similarity transforms (TSTs) [24], [25], [28], [29], [30]. Our approach uses *lifting*. As a systematic strategy for creating new multiwavelet functions, this approach dates back to [5], and in the more general context of stable multiscale representations to [2]. Under the name "lifting," these techniques were later applied in [3], [7], [8], [20], [33], [34]. Details can be found in section 3.

Compared to TSTs, the lifting approach has the following advantages:

1. lifting produces a complete new multiwavelet pair; TST produces only a new multiscaling function;
2. lifting uses no matrix division or singular matrices;
3. lifting generally produces shorter new masks than the TST algorithm.

The outline of this paper is as follows.

Sections 2, 3 introduce notation and summarize needed results from the literature. The main result can be found in Theorem 4.1 at the end of section 4. The proof is constructive, and forms the basis for a numerical algorithm. An alternative approach, based on a suggestion in [34], is presented in section 5. Implementation details for both algorithms are stated in section 6. Section 7 contains some examples.

2. Representations of multiwavelet masks. The results in this section are well known. Proofs or appropriate references can be found, e.g., in [2], [5], [6], or [25].

Throughout this paper, all calculations are based on the masks $\mathcal{H}$, $\tilde{\mathcal{H}}$ alone. In terms of masks, the biorthogonality conditions (1.5) are represented as

$$\sum_k h_k^{(\mu)} \tilde{h}_{k+mj}^{(\nu)T} = \delta_{\mu\nu}\delta_{0j} I. \tag{2.1}$$

Here and in the remainder of this paper, I denotes an identity matrix of appropriate size.

The existence of a biorthogonal pair of masks does not automatically guarantee the existence of a corresponding pair of MRAs. This raises the question of whether the new masks produced by our algorithm actually represent multiwavelets in the sense described in the introduction, or merely the coefficients of filter banks for signal processing applications. We will address this question in section 6.3.3, using the notation of [2], [5], which we briefly introduce at this point. (The multiscale representations discussed in [2] actually cover more general cases than described here.)

There are various conditions given in the literature (see, for example, [4], [10], [14], [19], [25]) which can be checked to see whether a given $\mathcal{H}^{(0)}$ gives rise to a refinable function vector $\boldsymbol{\phi}^{(0)}$ and an MRA. This corresponds to the concept of a (uniformly) *stable basis* in [2].

Given $\boldsymbol{\phi}^{(0)}$, the multiwavelet functions $\boldsymbol{\phi}^{(\nu)}$, $\nu = 1, \dots, m-1$, always exist by (1.4). They form a *stable completion* of $\boldsymbol{\phi}^{(0)}$ if

$$\{\phi_j^{(\nu)}(x-k) : \nu = 0, \dots, m-1, j, k \in \boldsymbol{Z}\}$$

forms a Riesz basis of V_1.

If

$$\{m^{\ell/2}\phi_j^{(\nu)}(m^\ell x - k) : j, k, \ell \in \boldsymbol{Z}, \nu = 1, \dots, m-1\}$$

forms a Riesz basis of $L^2(\boldsymbol{R})$, this is called *stability over all levels*.

In section 6.3.3, we will refer to these concepts as stability of $\boldsymbol{\phi}^{(0)}$, stability of $\boldsymbol{\phi}$, and stability over all levels, respectively.

The information contained in a mask $\mathcal{H}$ can be represented in various forms. We present here the two forms used in this paper.

The *symbol* of a function mask $\mathcal{H}^{(\nu)}$ is defined as

$$H^{(\nu)}(\xi) = \frac{1}{\sqrt{m}} \sum_k h_k^{(\nu)} e^{-ik\xi}, \qquad \xi \in \boldsymbol{R}. \tag{2.2}$$

In terms of symbols, the biorthogonality conditions (2.1) can be expressed as either

$$\sum_{k=0}^{m-1} H^{(\nu)}\left(\xi+\frac{2\pi}{m}k\right)\tilde{H}^{(\mu)*}\left(\xi+\frac{2\pi}{m}k\right)=\delta_{\nu\mu}I \tag{2.3}$$

or

$$\sum_{\nu=0}^{m-1} \tilde{H}^{(\nu)*}\left(\xi+\frac{2\pi}{m}k\right)H^{(\nu)}\left(\xi+\frac{2\pi}{m}\ell\right)=\delta_{k\ell}I, \tag{2.4}$$

where for complex-valued functions the superscript $*$ stands for the complex conjugate transpose.

A mask $\mathcal{H}$ satisfies *condition E* if $H^{(0)}(0)$ has a simple eigenvalue of 1, with all other eigenvalues less than 1 in modulus. Condition E is automatically satisfied if the mask generates an MRA of $L^2(\boldsymbol{R})$ with compactly supported basis functions [19], [25].

The *polyphase representation* $P(\xi)$ is the block matrix

$$P(\xi)=\begin{pmatrix} H_0^{(0)}(\xi) & H_1^{(0)}(\xi) & \dots & H_{m-1}^{(0)}(\xi)\\ H_0^{(1)}(\xi) & H_1^{(1)}(\xi) & \dots & H_{m-1}^{(1)}(\xi)\\ \vdots & \vdots & \ddots & \vdots\\ H_0^{(m-1)}(\xi) & H_1^{(m-1)}(\xi) & \dots & H_{m-1}^{(m-1)}(\xi)\end{pmatrix}, \tag{2.5}$$

where the *polyphase symbols* $H_\mu^{(\nu)}(\xi)$ are defined by

$$H_\mu^{(\nu)}(\xi)=\sum_k h_{mk+\mu}^{(\nu)}e^{-ik\xi}. \tag{2.6}$$

The normalization is chosen so that biorthogonality is equivalent to

$$P(\xi)\tilde{P}(\xi)^*=I. \tag{2.7}$$

The determinants of $P(\xi)$, $\tilde{P}(\xi)$ are trigonometric polynomials. If $\mathcal{H}$, $\tilde{\mathcal{H}}$ both have finite length, the determinants must be monomials.

If a multiwavelet has approximation order p, as defined in (1.6), then necessarily (see [15], [22], [23])

$$\boldsymbol{y}_k^{(j)}=\sum_{\ell=0}^{j}\binom{j}{\ell}k^{j-\ell}\boldsymbol{y}^{(\ell)} \tag{2.8}$$

for some vectors $\boldsymbol{y}^{(j)}\in\boldsymbol{R}^r$, $\boldsymbol{y}^{(0)}\neq\boldsymbol{0}$, and

$$\sum_{\ell=0}^{j}\binom{j}{\ell}(-i)^{j-\ell}m^\ell\boldsymbol{y}^{(\ell)*}D^{j-\ell}H^{(0)}\left(\frac{2\pi}{m}k\right)=\delta_{0k}\boldsymbol{y}^{(j)*} \tag{2.9}$$

for $j=0,\dots,p-1$ and $k=0,\dots,m-1$. D denotes the differentiation operator. We take (2.9) as the definition of approximation order for masks.

If $Y(\xi)$ is any vector of trigonometric polynomials with

$$D^jY(0)=i^{-j}\boldsymbol{y}^{(j)},\qquad j=0,\dots,p-1, \tag{2.10}$$

then another way to express (2.9) is

$$D^j \left[H^{(0)*}(\xi + \frac{2\pi}{m}k) Y(m\xi) \right] \Big|_{\xi=0} = \delta_{0k} D^j Y(0) = \delta_{0k} i^{-j} y^{(j)}. \tag{2.11}$$

The following theorem states that the approximation order of $\tilde{\mathcal{H}}$ can be determined by examining $\mathcal{H}$. It is a crucial step for the development in section 4. A partial result (the "only if" part for $\nu = 0$) was earlier derived in [32]. A similar result for multivariate wavelets can also be found in [13].

THEOREM 2.1. *Assume $\mathcal{H}$, $\tilde{\mathcal{H}}$ are biorthogonal masks. Then $\tilde{\mathcal{H}}$ has approximation order $\tilde{p}$ with vectors $\tilde{\boldsymbol{y}}^{(j)}$ if and only if*

$$\sum_{s=0}^{j} \binom{j}{s} i^{j-s} D^{j-s} H^{(\nu)}(0) \tilde{\boldsymbol{y}}^{(s)} = \delta_{0\nu} m^j \tilde{\boldsymbol{y}}^{(j)} \tag{2.12}$$

for $j = 0, \dots, \tilde{p} - 1$, $\nu = 0, \dots, m - 1$.

Proof. Assume $\tilde{Y}(\xi)$ satisfies (2.11) for the dual mask:

$$D^j \left[\tilde{H}^{(0)*}(\xi + \frac{2\pi}{m}k) \tilde{Y}(m\xi) \right] \Big|_{\xi=0} = \delta_{0k} D^j \tilde{Y}(0). \tag{2.13}$$

Take $\mu = 0$ in (2.3) and multiply by $\tilde{Y}(m\xi)$:

$$\sum_{k=0}^{m-1} H^{(\nu)} \left(\xi + \frac{2\pi}{m}k \right) \tilde{H}^{(0)*} \left(\xi + \frac{2\pi}{m}k \right) \tilde{Y}(m\xi) = \delta_{0\nu} \tilde{Y}(m\xi). \tag{2.14}$$

Differentiate j times and evaluate at $\xi = 0$:

$$\begin{aligned} \delta_{0\nu} m^j D^j \tilde{Y}(0) &= \sum_{s=0}^{j} \sum_{k=1}^{m-1} \binom{j}{s} D^{j-s} H^{(\nu)}(\frac{2\pi}{m}k) D^s \left[H^{(0)*}(\xi + \frac{2\pi}{m}k) \tilde{Y}(m\xi) \right] \Big|_{\xi=0} \\ &= \sum_{s=0}^{j} \sum_{k=1}^{m-1} \binom{j}{s} D^{j-s} H^{(\nu)}(0) D^s \tilde{Y}(0), \end{aligned} \tag{2.15}$$

which simplifies to (2.12). ∎

Remark. If the dual multiscaling function $\tilde{\boldsymbol{\phi}}^{(0)}$ has approximation order $\tilde{p}$, this implies that the multiwavelet functions have $\tilde{p}$ vanishing continuous moments, that is,

$$\int x^j \phi_k^{(\nu)}(x)\, dx = 0 \tag{2.16}$$

for $j = 0, \dots, \tilde{p} - 1$, $k = 1, \dots, r$, and $\nu = 1, \dots, m - 1$.

Equation (2.12) for $\nu = 1, \dots, m - 1$ can also be derived from the vanishing moment condition (2.16). Thus, Theorem 2.1 is a strictly algebraic version of the statement "the dual multiscaling function has approximation order $\tilde{p}$ if and only if the multiwavelet functions have $\tilde{p}$ vanishing moments."

3. Lifting. The following theorem forms the basis for the lifting procedure.

THEOREM 3.1. *If P_1, P_2 are polyphase matrices for two multiwavelets with the same multiscaling function, they are related by*

$$P_2(\xi) = \begin{pmatrix} I & 0 \\ L(\xi) & M(\xi) \end{pmatrix} P_1(\xi), \tag{3.1}$$

where L is of size $(m-1)r \times r$, M is of size $(m-1)r \times (m-1)r$. If both masks have finite length, $\det(M(\xi))$ is a monomial.

For wavelets of multiplicity 1 and dilation factor 2, this theorem dates back to [36].

As a general technique for creating stable refinable bases, the theorem was first used (in a periodic setting) in [5]. The most general version is given in [2], in the context of stable multiscale representations. A multiscale representation generalizes the concept of MRA by allowing each of the nested subspaces V_j to have its own basis Φ_j, not necessarily generated by translates and dilations from a small number of scaling functions. It is shown that any two stable completions of the same Φ_j are related in a manner similar to (3.1). (Polyphase matrices are not available in the general multiscale case, so the notation is different).

In the scalar case, Sweldens called (3.1) with $M = 1$ a *lifting step* [7], [33], [34], and showed that any wavelet can be built from the trivial polyphase matrix $P(\xi) = I$ by a finite combination of lifting steps and dual lifting steps:

$$P_{\text{new}}(\xi) = \begin{pmatrix} 1 & L(\xi) \\ 0 & 1 \end{pmatrix} P(\xi). \tag{3.2}$$

We also ignore M, since it has no effect on the scaling functions or dual scaling functions and their approximation orders. Thus, we define a multiwavelet lifting step as

$$P_{\text{new}}(\xi) = \begin{pmatrix} I & 0 \\ L(\xi) & I \end{pmatrix} P(\xi) = \begin{pmatrix} I & 0 & \dots & 0 \\ L^{(1)}(\xi) & I & & \\ \vdots & & \ddots & \\ L^{(m-1)}(\xi) & & & I \end{pmatrix} P(\xi), \tag{3.3}$$

where each $L^{(\nu)}(\xi)$ is an $r \times r$ matrix trigonometric polynomial. The effect on the dual is

$$\tilde{P}_{\text{new}}(\xi) = \begin{pmatrix} I & -L(\xi)^* \\ 0 & I \end{pmatrix} \tilde{P}(\xi). \tag{3.4}$$

In terms of the function symbols, our definition of multiwavelet lifting is equivalent to

$$\begin{aligned} &H^{(0)}_{\text{new}}(\xi) = H^{(0)}(\xi), \\ &H^{(\nu)}_{\text{new}}(\xi) = H^{(\nu)}(\xi) + L^{(\nu)}(m\xi)H^{(0)}(\xi), && \nu = 1, \dots, m-1, \\ &\tilde{H}^{(0)}_{\text{new}}(\xi) = \tilde{H}^{(0)}(\xi) - \textstyle\sum_{\nu=1}^{m-1} L^{(\nu)*}(m\xi)\tilde{H}^{(\nu)}(\xi), \\ &\tilde{H}^{(\nu)}_{\text{new}}(\xi) = \tilde{H}^{(\nu)}(\xi), && \nu = 1, \dots, m-1. \end{aligned} \tag{3.5}$$

In terms of multiscaling and multiwavelet functions, we have

$$\begin{aligned} &\boldsymbol{\phi}^{(0)}_{\text{new}}(x) = \boldsymbol{\phi}^{(0)}(x), \\ &\boldsymbol{\phi}^{(\nu)}_{\text{new}}(x) = \boldsymbol{\phi}^{(\nu)}(x) + \textstyle\sum_k L^{(\nu)}_k \boldsymbol{\phi}^{(0)}(x-k), && \nu = 1, \dots, m-1, \\ &\tilde{\boldsymbol{\phi}}^{(0)}_{\text{new}}(x) = \tilde{\boldsymbol{\phi}}^{(0)}(\xi) - \textstyle\sum_{\nu=1}^{m-1} \sum_k L^{(\nu)*}_{-k} \tilde{\boldsymbol{\phi}}^{(\nu)}(x-k), \\ &\tilde{\boldsymbol{\phi}}^{(\nu)}_{\text{new}}(x) = \tilde{\boldsymbol{\phi}}^{(\nu)}(x), && \nu = 1, \dots, m-1. \end{aligned} \tag{3.6}$$

Different but related multiwavelet lifting procedures are described in [8], [32]. Lifting for multivariate wavelets is discussed in [3] and [20].

4. Raising approximation order by lifting. In this section, we show how a single lifting step can be used to raise the approximation order of the dual multiscaling function to any desired level, while leaving the multiscaling function and its approximation order invariant.

In the scalar case, the idea of using lifting to raise the dual approximation order goes back to Sweldens' original papers [33], [34]. In the multiwavelet setting, different implementations appear in [8], [32]. Similar ideas can also be found in [13] (for multivariate wavelets) and [2] (for general multiscale approximations).

Let $\mathcal{H}$, $\tilde{\mathcal{H}}$ be a biorthogonal pair of masks, with $\mathcal{H}$ satisfying condition E.

Remark. As pointed out above, condition E is automatically satisfied for compactly supported stable $\boldsymbol{\phi}^{(0)}$, so it is a desirable property anyway. This is the reason why we impose condition E instead of the slightly weaker conditions we actually need.

Given any trigonometric matrix polynomial

$$L(\xi) = \sum_k L_k\, e^{-ik\xi}, \tag{4.1}$$

we define its *discrete moments* as

$$\Lambda_j = \sum_k k^j L_k = i^j D^j L(0), \qquad j = 0, 1, \ldots. \tag{4.2}$$

If the coefficients L_k are nonzero only for $k = k_0, \ldots, k_0 + n - 1$, and $N \geq 1$ is arbitrary, then L_k and Λ_k are related by

$$(\Lambda_0, \ldots, \Lambda_{N-1}) = (L_{k_0}, \ldots, L_{k_0+n-1})\, A, \tag{4.3}$$

where A is a block Vandermonde matrix with blocks of size $r \times r$

$$A = \begin{pmatrix} k_0^0 I & k_0^1 I & \cdots & k_0^{N-1} I \\ (k_0+1)^0 I & (k_0+1)^1 I & \cdots & (k_0+1)^{N-1} I \\ \vdots & \vdots & \ddots & \vdots \\ (k_0+n-1)^0 I & (k_0+n-1)^1 I & \cdots & (k_0+n-1)^{N-1} I \end{pmatrix}. \tag{4.4}$$

Let $M_j^{(\nu)}$ denote the jth discrete moment of $H^{(\nu)}$. It follows from differentiating (3.5) and evaluating at $\xi = 0$ that the new moments after lifting are given by

$$\begin{aligned} M_{\mathrm{new},j}^{(0)} &= M_j^{(0)}, \\ M_{\mathrm{new},j}^{(\nu)} &= M_j^{(\nu)} + \sum_{s=0}^{j} \binom{j}{s} m^s \Lambda_s^{(\nu)} M_{j-s}^{(0)}. \end{aligned} \tag{4.5}$$

We want to satisfy the dual approximation order conditions (2.12) of order $\tilde{p}$. We do this first for $\nu = 0$, where the conditions are

$$\sum_{s=0}^{j} \binom{j}{s} M_{j-s}^{(0)} \tilde{\boldsymbol{y}}^{(s)} = m^j \tilde{\boldsymbol{y}}^{(j)}, \qquad j = 0, \ldots, \tilde{p} - 1. \tag{4.6}$$

We can rewrite this in the form

$$\begin{aligned}\tilde{\boldsymbol{y}}^{(0)} &= M_0^{(0)}\tilde{\boldsymbol{y}}^{(0)},\\ \tilde{\boldsymbol{y}}^{(j)} &= \left(m^j I - M_0^{(0)}\right)^{-1}\sum_{s=0}^{j-1}\binom{j}{s}M_{j-s}^{(0)}\tilde{\boldsymbol{y}}^{(s)}, \qquad j=1,2,\ldots,\tilde{p}-1.\end{aligned} \tag{4.7}$$

Condition E is sufficient to guarantee solvability.

After the $\tilde{\boldsymbol{y}}^{(j)}$ have been determined, define

$$\boldsymbol{z}_j^{(\nu)} = m^{-j}\sum_{s=0}^{j}\binom{j}{s}M_{j-s}^{(\nu)}\tilde{\boldsymbol{y}}^{(s)}. \tag{4.8}$$

By (4.6),

$$\boldsymbol{z}_j^{(0)} = \tilde{\boldsymbol{y}}^{(j)} \tag{4.9}$$

for $j=0,\ldots,\tilde{p}-1$. By (2.12), $\tilde{\mathcal{H}}$ has existing approximation order $\tilde{q}$ if and only if

$$\boldsymbol{z}_j^{(\nu)} = \boldsymbol{0} \tag{4.10}$$

for $\nu=1,\ldots,m-1$ and $j=0,\ldots,\tilde{q}-1$.

Next, we satisfy the remaining conditions (2.12) for $\nu=1,\ldots,m-1$, which are

$$\sum_{s=0}^{j}\binom{j}{s}M_{\mathrm{new},j-s}^{(\nu)}\tilde{\boldsymbol{y}}^{(s)} = \boldsymbol{0}. \tag{4.11}$$

Substitute (4.5) to obtain

$$\begin{aligned}-\sum_{s=0}^{j}\binom{j}{s}M_{j-s}^{(\nu)}\tilde{\boldsymbol{y}}^{(s)} &= \sum_{s=0}^{j}\sum_{\ell=0}^{j-s}\binom{j}{s}\binom{j-s}{\ell}m^\ell\Lambda_\ell^{(\nu)}M_{j-s-\ell}^{(0)}\tilde{\boldsymbol{y}}^{(s)}\\ &= \sum_{\ell=0}^{j}\sum_{s=0}^{j-\ell}\binom{j}{\ell}\binom{j-\ell}{s}m^\ell\Lambda_\ell^{(\nu)}M_{j-s-\ell}^{(0)}\tilde{\boldsymbol{y}}^{(s)}\\ &= \sum_{\ell=0}^{j}\binom{j}{\ell}m^\ell\Lambda_\ell^{(\nu)}\sum_{s=0}^{j-\ell}\binom{j-\ell}{s}M_{j-s-\ell}^{(0)}\tilde{\boldsymbol{y}}^{(s)}\\ &= m^j\sum_{\ell=0}^{j}\binom{j}{\ell}\Lambda_\ell^{(\nu)}\tilde{\boldsymbol{y}}^{(j-\ell)},\end{aligned} \tag{4.12}$$

or

$$\sum_{\ell=0}^{j}\binom{j}{\ell}\Lambda_\ell^{(\nu)}\tilde{\boldsymbol{y}}^{(j-\ell)} = -\boldsymbol{z}_j^{(\nu)}. \tag{4.13}$$

For each fixed ν, this can be solved by choosing $\Lambda_j^{(\nu)}$ successively for $j=0,\ldots,\tilde{p}-1$ to satisfy

$$\Lambda_j^{(\nu)}\tilde{\boldsymbol{y}}^{(0)} = -\boldsymbol{z}_j^{(\nu)} - \sum_{\ell=0}^{j-1}\binom{j}{\ell}\Lambda_\ell^{(\nu)}\tilde{\boldsymbol{y}}^{(j-\ell)}. \tag{4.14}$$

The solution is not unique, except in the scalar case.

The matrix A in (4.3) is nonsingular for $N = n = \tilde{p}$, so we can always find a trigonometric polynomial $L^{(\nu)}(\xi)$ of length $\tilde{p}$ or less with an arbitrary starting index k_0 and prescribed moments $\Lambda_j^{(\nu)}$, $j = 0, \dots, \tilde{p} - 1$.

We summarize the results of this section in the following theorem.

THEOREM 4.1. *Assume $\mathcal{H}$, $\tilde{\mathcal{H}}$ are biorthogonal masks with approximation orders q, $\tilde{q}$, respectively, with $\mathcal{H}$ satisfying condition E. Then for any $\tilde{p} \geq 1$ it is possible to find trigonometric polynomials $L^{(\nu)}(\xi)$ of length at most $\tilde{p}$, so that the new masks $\mathcal{H}_{new}$, $\tilde{\mathcal{H}}_{new}$ produced by the lifting process* (3.3) *have approximation orders q, $\tilde{p}$, respectively.*

If $\tilde{\mathcal{H}}_{new}$ satisfies condition E, we can follow the first lifting step with a dual lifting step that produces new masks with approximation orders p, $\tilde{p}$, respectively, for any $p \geq 1$.

It is shown in section 6.3.3 below that if $\tilde{\mathcal{H}}$ satisfies condition E, it is always possible to preserve it during the lifting step.

5. A modified approach. In the procedure in the previous section, it is necessary to impose all $\tilde{p}$ conditions, even if the original $\tilde{\mathcal{H}}$ already has some approximation order $\tilde{q}$. A modified algorithm, suggested in the scalar case in [34], can be adapted to the multiwavelet case.

The motivation is the following. As stated in (3.6) above, the effect of lifting on the multiwavelet functions is described by

$$\boldsymbol{\phi}_{\text{new}}^{(\nu)}(x) = \boldsymbol{\phi}^{(\nu)}(x) + \sum_k L_k^{(\nu)} \boldsymbol{\phi}^{(0)}(x - k). \tag{5.1}$$

Sweldens [34] proposes to replace this by

$$\boldsymbol{\phi}_{\text{new}}^{(\nu)}(x) = \boldsymbol{\phi}^{(\nu)}(x) + \sum_k T_k^{(\nu)} \boldsymbol{\phi}^{(\nu)} \left(\frac{x}{m} - k \right), \tag{5.2}$$

since this preserves existing vanishing moment conditions (2.16).

In our setting, this suggestion amounts to choosing

$$L^{(\nu)}(\xi) = T^{(\nu)}(\xi) H^{(\nu)}(\xi) \tag{5.3}$$

for some shorter trigonometric polynomials $T^{(\nu)}$. It is easy to verify directly that this approach will preserve the existing approximation orders for masks.

THEOREM 5.1. *If $\mathcal{H}$, $\tilde{\mathcal{H}}$ are biorthogonal masks, and $\mathcal{H}_{new}$, $\tilde{\mathcal{H}}_{new}$ are produced by lifting with*

$$L^{(\nu)}(\xi) = T^{(\nu)}(\xi) H^{(\nu)}(\xi), \tag{5.4}$$

then $\tilde{\mathcal{H}}_{new}$ has at least the same approximation order as $\tilde{\mathcal{H}}$.

Proof. Assume that $\tilde{\mathcal{H}}$ has approximation order $\tilde{q}$ or, equivalently (see (4.10))

$$\boldsymbol{z}_j^{(\nu)} = \mathbf{0} \tag{5.5}$$

for $\nu = 1, \dots, m - 1$ and $j = 0, \dots, \tilde{q} - 1$.

Differentiate (5.3) and evaluate at $\xi = 0$ to get

$$\Lambda_\ell^{(\nu)} = \sum_{s=0}^{\ell} \binom{\ell}{s} \Upsilon_s^{(\nu)} M_{\ell - s}^{(\nu)}, \tag{5.6}$$

where $\Upsilon_s^{(\nu)}$ are the moments of $T^{(\nu)}(\xi)$. Thus, for $\nu = 1, \ldots, m-1$ and $j = 0, \ldots, \tilde{q}-1$,

$$\begin{aligned}\sum_{\ell=0}^{j} \binom{j}{\ell} \Lambda_{j-\ell}^{(\nu)} \tilde{\boldsymbol{y}}^{(\ell)} &= \sum_{\ell=0}^{j} \sum_{s=0}^{j-\ell} \binom{j}{\ell} \binom{j-\ell}{s} \Upsilon_s^{(\nu)} M_{j-\ell-s}^{(\nu)} \tilde{\boldsymbol{y}}^{(\ell)} \\ &= \sum_{s=0}^{j} \sum_{\ell=0}^{j-s} \binom{j}{s} \binom{j-s}{\ell} \Upsilon_s^{(\nu)} M_{j-s-\ell}^{(\nu)} \tilde{\boldsymbol{y}}^{(\ell)} \\ &= \sum_{s=0}^{j} \binom{j}{s} m^{j-s} \Upsilon_s^{(\nu)} \boldsymbol{z}_{j-s}^{(\nu)} = \mathbf{0} = -\boldsymbol{z}_j^{(\nu)},\end{aligned} \tag{5.7}$$

so (4.13) is satisfied. ∎

The calculations in (5.7) also provide the equations for determining $\Upsilon_j^{(\nu)}$. As in (4.13), we need

$$\begin{aligned}-\boldsymbol{z}_j^{(\nu)} &= \sum_{\ell=0}^{j} \binom{j}{\ell} \Lambda_{j-\ell}^{(\nu)} \tilde{\boldsymbol{y}}^{(\ell)} \\ &= \sum_{s=0}^{j} \binom{j}{s} m^{j-s} \Upsilon_s^{(\nu)} \boldsymbol{z}_{j-s}^{(\nu)} \\ &= \sum_{s=0}^{j-\tilde{q}} \binom{j}{s} m^{j-s} \Upsilon_s^{(\nu)} \boldsymbol{z}_{j-s}^{(\nu)}\end{aligned} \tag{5.8}$$

for $j = \tilde{q}, \ldots, \tilde{p}-1$. These equations can again be solved successively for $\Upsilon_j^{(\nu)}$ and then $T_{k_0+j}^{(\nu)}$, $j = 0, \ldots, \tilde{p}-\tilde{q}$.

The modified algorithm is faster than the original one. However, it frequently results in longer new masks than the original algorithm. This is illustrated by the examples in section 7.

6. Algorithms. The following algorithms are implementations of the procedures outlined in the previous two sections. They can be used to find suitable lifting factors of any desired length, with free parameters explicitly identified.

Assume that $\mathcal{H}$, $\tilde{\mathcal{H}}$ are biorthogonal masks, with $\mathcal{H}$ satisfying condition E.

6.1. Algorithm 1. Given integers $\tilde{p} \geq 1$, $n \geq 1$, k_0 arbitrary, we want to find matrix trigonometric polynomials of length n with starting index k_0

$$L^{(\nu)}(\xi) = \sum_{k=k_0}^{k_0+n-1} L_k^{(\nu)} e^{-ik\xi} \tag{6.1}$$

so that the new dual mask $\tilde{\mathcal{H}}_{\text{new}}$ produced by the lifting process (3.3) has approximation order $\tilde{p}$.

Step 1. Compute the moments

$$M_j^{(\nu)} = \frac{1}{\sqrt{m}} \sum_k k^j h_k^{(\nu)} \tag{6.2}$$

for $\nu = 0, \ldots, m-1$ and $j = 0, \ldots, \tilde{p}-1$.

Step 2. Compute the vectors $\tilde{\boldsymbol{y}}^{(j)}$, $\boldsymbol{z}_j^{(\nu)}$ for $\nu = 1, \dots, m-1$ and $j = 0, \dots, \tilde{p}-1$ from

$$\begin{aligned} \tilde{\boldsymbol{y}}^{(0)} &= M_0^{(0)} \tilde{\boldsymbol{y}}^{(0)}, \\ \tilde{\boldsymbol{y}}^{(j)} &= \left(m^j I - M_0^{(0)} \right)^{-1} \sum_{s=0}^{j-1} \binom{j}{s} M_{j-s}^{(0)} \tilde{\boldsymbol{y}}^{(s)}, \\ \boldsymbol{z}_j^{(\nu)} &= m^{-j} \sum_{\ell=0}^{j} \binom{j}{\ell} M_\ell^{(\nu)} \tilde{\boldsymbol{y}}^{(j-\ell)}. \end{aligned} \tag{6.3}$$

Step 3. Form the matrices

$$A = \begin{pmatrix} k_0^0 I & k_0^1 I & \cdots & k_0^{\tilde{p}-1} I \\ (k_0+1)^0 I & (k_0+1)^1 I & \cdots & (k_0+1)^{\tilde{p}-1} I \\ \vdots & \vdots & \ddots & \vdots \\ (k_0+n-1)^0 I & (k_0+n-1)^1 I & \cdots & (k_0+n-1)^{\tilde{p}-1} I \end{pmatrix}, \tag{6.4}$$

$$Y = \begin{pmatrix} \binom{0}{0} \tilde{\boldsymbol{y}}^{(0)} & \binom{1}{0} \tilde{\boldsymbol{y}}^{(1)} & \binom{2}{0} \tilde{\boldsymbol{y}}^{(2)} & \cdots & \binom{\tilde{p}-1}{0} \tilde{\boldsymbol{y}}^{(\tilde{p}-1)} \\ & \binom{1}{1} \tilde{\boldsymbol{y}}^{(0)} & \binom{2}{1} \tilde{\boldsymbol{y}}^{(1)} & \cdots & \binom{\tilde{p}-1}{1} \tilde{\boldsymbol{y}}^{(\tilde{p}-2)} \\ & & \binom{2}{2} \tilde{\boldsymbol{y}}^{(0)} & \cdots & \binom{\tilde{p}-1}{2} \tilde{\boldsymbol{y}}^{(\tilde{p}-3)} \\ & & & \ddots & \vdots \\ & & & & \binom{\tilde{p}-1}{\tilde{p}-1} \tilde{\boldsymbol{y}}^{(0)} \end{pmatrix}, \tag{6.5}$$

and

$$Z = \begin{pmatrix} \boldsymbol{z}_0^{(1)} & \cdots & \boldsymbol{z}_{\tilde{p}-1}^{(1)} \\ \vdots & \ddots & \vdots \\ \boldsymbol{z}_0^{(m-1)} & \cdots & \boldsymbol{z}_{\tilde{p}-1}^{(m-1)} \end{pmatrix}. \tag{6.6}$$

The equations (4.13) are equivalent to

$$LAY = -Z, \tag{6.7}$$

where L contains the desired coefficients of $L^{(\nu)}(\xi)$

$$L = \begin{pmatrix} L_{k_0}^{(1)} & \cdots & L_{k_0+\tilde{p}-1}^{(1)} \\ \vdots & \ddots & \vdots \\ L_{k_0}^{(m-1)} & \cdots & L_{k_0+\tilde{p}-1}^{(m-1)} \end{pmatrix}. \tag{6.8}$$

Step 4. Perform a singular value decomposition (SVD)

$$AY = U \Sigma V^*. \tag{6.9}$$

Here U is of size $nr \times nr$, Σ is of size $nr \times \tilde{p}$, and V is of size $\tilde{p} \times \tilde{p}$. Let s be the rank of Σ, then

$$\Sigma = \begin{pmatrix} \Sigma_{11} & 0 \\ 0 & 0 \end{pmatrix} \tag{6.10}$$

with Σ_{11} nonsingular and of size $s \times s$.

Substitute the SVD into (6.7), multiply by V on the right, and partition all matrices corresponding to the partitioning of Σ

$$((LU)_1, (LU)_2) \begin{pmatrix} \Sigma_{11} & 0 \\ 0 & 0 \end{pmatrix} = -((ZV)_1, (ZV)_2), \tag{6.11}$$

or

$$\begin{aligned} (LU)_1 \Sigma_{11} &= -(ZV)_1, \\ 0 &= (ZV)_2. \end{aligned} \tag{6.12}$$

If $(ZV)_2 \neq 0$, the system is unsolvable. Go back to the start and increase n. Otherwise, the solution is

$$\begin{aligned} (LU)_1 &= -(ZV)_1 \Sigma_{11}^{-1}, \\ (LU)_2 &= \text{arbitrary}. \end{aligned} \tag{6.13}$$

The general solution is then

$$L = ((LU)_1, (LU)_2) U^*. \tag{6.14}$$

The free parameters are the elements of $(LU)_2$, of which there are $r(nr - s)(m - 1)$.

Step 5. Assemble the $L^{(\nu)}(\xi)$ and perform the lifting.

Step 6. If required, verify that $\tilde{\mathcal{H}}_{\text{new}}$ satisfies condition E or other properties. If necessary, use optimization on the free parameters to satisfy these conditions.

6.2. Algorithm 2. Given integers $\tilde{p} \geq 1$, $n \geq 1$, k_0 arbitrary, we want to find matrix trigonometric polynomials of length n and starting index k_0

$$T^{(\nu)}(\xi) = \sum_{k=k_0}^{k_0+n-1} T_k^{(\nu)} e^{-ik\xi} \tag{6.15}$$

so that the new dual mask $\tilde{\mathcal{H}}_{\text{new}}$ produced by the lifting process (3.3) performed with $L^{(\nu)}(\xi) = T^{(\nu)}(\xi) H^{(\nu)}(\xi)$ has approximation order $\tilde{p}$.

Steps 1 and 2 are the same as in Algorithm 1.

The existing approximation order $\tilde{q}$ of $\tilde{\mathcal{H}}$ is the largest number $\tilde{q}$ for which $\boldsymbol{z}_j^{(\nu)} = \mathbf{0}$ for all $\nu = 1, \ldots, m$ and $j = 0, \ldots, \tilde{q} - 1$.

Step 3. Form the matrices

$$A = \begin{pmatrix} k_0^0 I & k_0^1 I & \cdots & k_0^{\tilde{p}-\tilde{q}-1} I \\ (k_0+1)^0 I & (k_0+1)^1 I & \cdots & (k_0+1)^{\tilde{p}-\tilde{q}-1} I \\ \vdots & \vdots & \ddots & \vdots \\ (k_0+n-1)^0 I & (k_0+n-1)^1 I & \cdots & (k_0+n-1)^{\tilde{p}-\tilde{q}-1} I \end{pmatrix}, \tag{6.16}$$

$$Y^{(\nu)} = \begin{pmatrix} \binom{\tilde{q}}{0} m^{\tilde{q}} \tilde{\boldsymbol{z}}_{\tilde{q}}^{(\nu)} & \binom{\tilde{q}+1}{0} m^{\tilde{q}+1} \tilde{\boldsymbol{z}}_{\tilde{q}+1}^{(\nu)} & \cdots & \binom{\tilde{p}-1}{0} m^{\tilde{p}-1} \tilde{\boldsymbol{z}}_{\tilde{p}-1}^{(\nu)} \\ & \binom{\tilde{q}+1}{1} m^{\tilde{q}} \tilde{\boldsymbol{z}}_{\tilde{q}}^{(\nu)} & \cdots & \binom{\tilde{p}-1}{1} m^{\tilde{p}-2} \tilde{\boldsymbol{z}}_{\tilde{p}-2}^{(\nu)} \\ & & \ddots & \vdots \\ & & & \binom{\tilde{p}-1}{\tilde{p}-\tilde{q}-1} m^{\tilde{q}} \tilde{\boldsymbol{z}}_{\tilde{q}}^{(\nu)} \end{pmatrix}, \tag{6.17}$$

and

$$Z^{(\nu)} = \left(\boldsymbol{z}_{\tilde{q}}^{(\nu)}, \ldots, \boldsymbol{z}_{\tilde{p}-1}^{(\nu)} \right). \tag{6.18}$$

The equations (5.8) are equivalent to the sequence of equations

$$T^{(\nu)} A Y^{(\nu)} = -Z^{(\nu)} \tag{6.19}$$

for $\nu = 1, \ldots, m-1$, where $T^{(\nu)}$ contains the desired coefficients of $T^{(\nu)}(\xi)$

$$T^{(\nu)} = \left(T_{k_0}^{(\nu)}, \ldots, T_{k_0+n-1}^{(\nu)} \right). \tag{6.20}$$

Step 4. This step is repeated for each $\nu = 1, \ldots, m-1$.

Perform the SVD

$$AY^{(\nu)} = U^{(\nu)} \Sigma^{(\nu)} V^{(\nu)*}. \tag{6.21}$$

and proceed as in Step 4 of Algorithm 1.

The free parameters are the elements of $(T^{(\nu)} U^{(\nu)})_2$. Their total number is

$$r \sum_{\nu} (nr - s^{(\nu)}) = nr^2(m-1) - r \sum_{\nu} s^{(\nu)}. \tag{6.22}$$

Steps 5 and 6 are the same as in Algorithm 1.

6.3. Further comments.

6.3.1. About the implementation. In Algorithm 1, it is possible in Step 3 to solve the equations for all ν simultaneously, since Y is independent of ν. This is not possible in Algorithm 2. As Example 2 in section 7 illustrates, the ranks $s^{(\nu)}$ may vary with ν.

In order to obtain dual approximation order $\tilde{p}$, we need to impose conditions on $\Lambda_j^{(\nu)}$, $j = 1, \ldots, \tilde{p}-1$. We can always find a suitable $L^{(\nu)}$ of length $\tilde{p}$, but we want $L^{(\nu)}$ of length n, with $n < \tilde{p}$ in general. Setting the higher moments to 0 does not result in shorter $L^{(\nu)}$. Instead, we incorporate the matrix A into the algorithms, and solve for $L_j^{(\nu)}$ directly.

6.3.2. Choosing n, k_0. Choosing n as small as possible results in the shortest possible new wavelets, which is usually desirable. Since each approximation order condition amounts to r scalar equations, and each $L_j^{(\nu)}$ contains r^2 coefficients, dual approximation order $\tilde{p}$ should require a smallest possible n of

$$n = \operatorname{ceil}(\tilde{p}/r). \tag{6.23}$$

This cannot be guaranteed (there are counterexamples), but (6.23) gives a good estimate. In particular, constant $L^{(\nu)}$, which does not increase the support lengths of the functions, will in general be able to achieve approximation order r already.

Larger n could be used if extra free parameters are desired.

The starting subscript k_0 of $L^{(\nu)}$ affects both the support length and the centering of the new multiwavelet (see formulas (3.6)). Numerical experiments indicate that the new dual wavelets tend to be smoother if k_0 is chosen so that the scaling function and new dual scaling function are approximately centered around the same point (see Example 1(c) in section 7).

The algorithms could easily be generalized to allow different n, k_0 for each ν.

6.3.3. Stability. We now address the question raised in section 2, regarding the stability properties of the new masks $\mathcal{H}_{\text{new}}$, $\tilde{\mathcal{H}}_{\text{new}}$ (see section 2). The complete answer is not known, but we offer some observations.

1. *Stability of $\boldsymbol{\phi}^{(0)}$ is preserved. Stability of $\tilde{\boldsymbol{\phi}}^{(0)}$ is not preserved in general, but we may be able to preserve it by choosing a suitable L (possibly of higher degree).*

The first part is obvious, since $\boldsymbol{\phi}^{(0)}_{\text{new}} = \boldsymbol{\phi}^{(0)}$.

It is shown in [7] (for scalar wavelets) that any polyphase matrix can be completely factored into lifting steps. Since lifting steps are reversible, this means that any polyphase matrix can be converted into any other by multiple lifting and dual lifting steps. Obviously, stability can get lost in the process.

However, we can always preserve condition E for $\tilde{\boldsymbol{\phi}}^{(0)}$, which is a prerequisite for stability. By (3.5), line 3,

$$\tilde{M}^{(0)}_{\text{new},0} = \tilde{M}^{(0)}_0 - \sum_{\nu=1}^{m-1} \Lambda^{(\nu)*}_0 \tilde{M}^{(\nu)}_0. \tag{6.24}$$

If we choose $\Lambda^{(\nu)}(0) = 0$, then $\tilde{M}^{(0)}_0 = \tilde{M}^{(0)}_{\text{new},0}$, and condition E remains valid. This approach may require increasing n.

In most of the numerical examples we tried, condition E was preserved automatically. In the remaining cases, a simple change in the free parameters was sufficient, with no increase in n needed.

We conjecture that stability of $\tilde{\boldsymbol{\phi}}^{(0)}$ can also be preserved, but the necessary additional conditions on L are not known.

2. *Stability of $\boldsymbol{\phi}$ is preserved.*

If L has finite degree, and $\{\boldsymbol{\phi}^{(\nu)}\}$ form a stable completion of $\boldsymbol{\phi}^{(0)}$, so do $\{\boldsymbol{\phi}^{(\nu)}_{\text{new}}\}$. This follows from Proposition 3.1 in [2].

3. *It is not known whether stability of $\tilde{\boldsymbol{\phi}}$ or stability over all levels for $\boldsymbol{\phi}$ and $\tilde{\boldsymbol{\phi}}$ can be preserved.*

6.3.4. Free parameters. Free parameters that occur during the lifting process can be used for numerical optimization. One defines a function that takes the free parameters as input, calculates the new masks produced by a lifting step with these parameters, and then calculates some objective function which is to be maximized or minimized.

In Example 1(c) in section 7, we used the Sobolev smoothness estimate from [18] as the objective function, to produce the smoothest possible new dual scaling functions for given n and k_0.

7. Examples. We illustrate our algorithms with some numerical examples.

Example 1. This example has dilation factor $m = 2$, multiplicity $r = 2$. We start with cubic Hermite splines as the original scaling function [31]. A basic completion to a biorthogonal pair of masks has the symbols

$$H(z) = \frac{1}{16}\begin{pmatrix} 4+8z+4z^2 & 6-6z^2 \\ -1+z^2 & -1+4z-z^2 \\ 8 & 0 \\ 0 & 8 \end{pmatrix},$$
$$\tilde{H}(z) = \frac{1}{4z}\begin{pmatrix} 4z^2 & 0 \\ 0 & 8z^2 \\ -2+4-2z^2 & -1+z^2 \\ 3-3z^2 & 1+4z+z^2 \end{pmatrix}, \tag{7.1}$$

where $z = \exp(-i\xi)$. The original dual approximation order is 0. $\mathcal{H}$ satisfies condition E, $\tilde{\mathcal{H}}$ does not.

(a) Raise the dual approximation order from 0 to 2.

Algorithm 1 can achieve this with $n = 1$, and no free parameters. For $k_0 = 0$, the result is

$$L(z) = \frac{1}{4}\begin{pmatrix} -2 & 15 \\ 0 & -1 \end{pmatrix}, \tag{7.2}$$

$$\begin{aligned} H_{\text{new}}(z) &= \frac{1}{64}\begin{pmatrix} 16+32z+16z^2 & 24-24z^2 \\ -4+4z^2 & -4+16z-4z^2 \\ 9-16z+7z^2 & -27+60z-3z^2 \\ 1-z^2 & 33-4z+z^2 \end{pmatrix}, \\ \tilde{H}_{\text{new}}(z) &= \frac{1}{16z}\begin{pmatrix} -4+8z+12z^2 & -2+2z^2 \\ 33-60z+27z^2 & 16+4z+18z^2 \\ -8+16z-8z^2 & -4+4z^2 \\ 12-12z^2 & 4+16z+4z^2 \end{pmatrix}. \end{aligned} \tag{7.3}$$

The new masks have length 3. Any other choice of k_0 results in longer masks.

Algorithm 2 gives identical results, since $H^{(1)}(z)$ is a multiple of the identity.

(b) Raise the dual approximation order from 2 to 4, starting with the H_{new} from (a).

Algorithm 1 can achieve this with $n = 2$, and no free parameters. The shortest new masks have length 5, for $k_0 = -1$, and are generated by lifting using

$$L(z) = \frac{1}{48z}\begin{pmatrix} -12+12z & -63-117z \\ 2-2z & 9+21z \end{pmatrix}. \tag{7.4}$$

Algorithm 2 requires only $n = 1$, with no free parameters, but the shortest new masks (also for $k_0 = -1$) have length 7. The lifting factor is

$$L(z) = \frac{1}{13824z}\begin{pmatrix} -729+1152z-423z^2 & -729-3996z+135z^2 \\ 81-160z+79z^2 & -567+636z-39z^2 \end{pmatrix}, \tag{7.5}$$

which is produced from

$$T(z) = \frac{1}{216z}\begin{pmatrix} -72 & -81 \\ 10 & -9 \end{pmatrix}. \tag{7.6}$$

(c) Raise the dual approximation order from 0 to 2 (starting again with the original $\mathcal{H}$, $\tilde{\mathcal{H}}$) with free parameters, and optimize for smoothness.

The algorithm described in [18] can be used to determine a lower bound on the Sobolev exponent s of a multiscaling function. The shortest dual scaling function with approximation order 2 derived in (a) is in the Sobolev space $W^{-1.2294}$, so it is not even an L^2-function.

If we apply Algorithm 1 with $n = 2$, there are 4 free parameters. The shortest new scaling function symbols have length 5 for $k_0 = -1$ or $k_0 = 0$.

For $k_0 = 0$, the coefficients of H_{new} and $\tilde{H}_{\text{new}}$ are centered at 2 and -1, respectively. Numerical optimization of the Sobolev exponent yields a smoothest $\tilde{H}_{\text{new}}$ in $W^{-0.7877}$.

For $k_0 = -1$, the centers are 0 and 1, which is a better fit. The smoothest $\tilde{H}_{\text{new}}$ is in $W^{0.8289}$, which matches the result of [30], [32]. This $\tilde{H}_{\text{new}}$ satisfies condition E, and could be used as the basis for a further dual lifting step.

Example 2. This example has dilation factor $m = 3$, multiplicity $r = 1$. We take $\phi^{(0)}$ to be the characteristic function of $[0, 1]$, i.e., the Haar scaling function, with approximation order 1. A completion with dual approximation order 1 is

$$H(z) = \frac{1}{9}\begin{pmatrix} 3 + 3z + 3z^2 \\ \sqrt{3}\left(-1 + 2z - z^2\right) \\ \sqrt{3}\left(-1 - z + 2z^2\right) \end{pmatrix},$$
$$\tilde{H}(z) = \frac{1}{3}\begin{pmatrix} 1 + z + z^2 \\ \sqrt{3}\left(-1 + z\right) \\ \sqrt{3}\left(-1 + z^2\right) \end{pmatrix}. \tag{7.7}$$

Condition E is satisfied by the original masks. Since $r = 1$, it is automatically preserved.

We want to raise the dual approximation order to 3.

Algorithm 1 requires $n = 3$, with no free parameters. The choice $k_0 = -1$ produces the shortest new masks of length 9

$$H_{\text{new}}(z) = \frac{1}{243z^3}\begin{pmatrix} 81z^3 + 81z^4 + 81z^5 \\ \sqrt{3}\left(1 + z + z^2 - 29z^3 + 52z^4 - 29z^5 + z^6 + z^7 + z^8\right) \\ \sqrt{3}\left(4 + 4z + 4z^2 - 26z^3 - 26z^4 + 55z^5 - 5z^6 - 5z^7 - 5z^8\right) \end{pmatrix},$$
$$\tilde{H}_{\text{new}}(z) = \frac{1}{81z^3}\begin{pmatrix} -4 - z + 5z^2 + 26z^3 + 29z^4 + 26z^5 + 5z^6 - z^7 - 4z^8 \\ \sqrt{3}\left(-27z^3 + 27z^4\right) \\ \sqrt{3}\left(-27z^3 + 27z^5\right) \end{pmatrix}, \tag{7.8}$$

using

$$L(z) = \frac{1}{27\sqrt{3}z}\begin{pmatrix} 1 - 2z + z^2 \\ 4 + z - 5z^2 \end{pmatrix}. \tag{7.9}$$

Algorithm 2 requires at least $n = 2$, and produces new masks of length 12. There is one free parameter, in $T^{(1)}$ only.

Acknowledgments. This article was written during the author's sabbatical leave at Flinders University, Adelaide, South Australia. It is part of a long-term research project involving the design of wavelets with prescribed properties, directed by Prof. Jaroslav Kautsky. I would like to thank Profs. Kautsky and Bill Moran for their hospitality and support during this time, and to thank them and other group members (notably Radka Turcajová and Vasily Strela) for inspiration and helpful discussions.

I would also like to thank the anonymous referees for helpful suggestions, in particular for a simplified proof of Theorem 2.1 and clarifications on stability questions.

LARGE TIME ASYMPTOTICS OF SOLUTIONS AROUND SOLITARY WAVES TO THE GENERALIZED KORTEWEG–DE VRIES EQUATIONS*

TETSU MIZUMACHI†

Abstract. We consider the long time asymptotics of solutions that are close to a solitary wave solution to the generalized Korteweg–de Vries equation

$$u_t + u^p u_x + u_{xxx} = 0 \quad \text{for } x \in \mathbb{R},\ t > 0.$$

If $1 \le p < 4$ and the spectrum of the linearized equation around the initial solitary wave has the simplest possible structure, the solitary wave turns out to be asymptotically stable with respect to finite energy perturbations with polynomial decay as $x \to \infty$. Furthermore, we show that the asymptotics of the solution for large time is given by a sum of a solitary wave with slightly displaced parameters and a small dispersion if $2 < p < 4$.

Key words. generalized Korteweg–de Vries equation, solitary waves, nonlinear scattering

1. Introduction.

In the present paper, we study the large time behavior of solutions around solitary waves to the generalized Korteweg–de Vries (GKdV) equation

$$u_t + f(u)_x + u_{xxx} = 0 \quad \text{for } x \in \mathbb{R},\ t > 0, \tag{1.1}$$

$$u(x,0) = u_0(x) \quad \text{for } x \in \mathbb{R}, \tag{1.2}$$

where

$$f(u) = u^{p+1}/(p+1).$$

For $p = 1$, the equation was derived by Korteweg and de Vries in [23] as a model for long waves propagating in a canal.

Solitary wave solutions are a class of spatially localized solutions with finite energy. The GKdV equation has a two-parameter family of solitary wave solutions of the form $u(x,t) = \varphi_c(x - ct + \gamma)$, where c is a positive number, $\gamma \in \mathbb{R}$, and $\varphi_c(y)$ is a positive symmetric function to

$$\varphi_c'' - c\varphi_c + f(\varphi_c) = 0 \quad \text{for } y \in \mathbb{R}.$$

Now, let

$$u_0(x) = \varphi_{c_0}(x + \gamma_0) + v_0(x), \tag{1.3}$$

where $c_0 > 0$, $\gamma_0 \in \mathbb{R}$, and $v_0 \in H^1(\mathbb{R})$. The orbital stability of the solitary wave solutions has been studied by Benjamin [3], Bona [4], Bona, Souganidis, and Strauss [8], and Weinstein [37] (see also Bona and Soyeur [9]). They proved that the solitary

wave solutions are stable if $0 < p < 4$ and unstable if $p \geq 4$. That is to say, the solution u to (1.1)–(1.3) with small v_0 remains close to the set $\{\varphi_{c_0}(x - c_0 t + \gamma) \,|\, \gamma \in \mathbb{R}\}$ for all the time if $0 < p < 4$.

If $p = 1$ or 2, the inverse scattering theory is available. It informs us that the solution to (1.1) with well-localized initial data resolves into a train of solitary waves moving to the right and dispersive radiation which moves to the left (see [1], [12], [13], [14], [31]). Although the inverse scattering theory does not apply to (1.1) with more general p, there is some numerical evidence that shows that this type of asymptotic resolution extends to equations with more general nonlinearities (see [5], [6], [7]).

Pego and Weinstein [28] proved the asymptotic stability of solitary waves with an exponential spatial weight e^{ay} $(a > 0)$ in the case where $p = 1$, 2 or $3 \leq p < 4$ and the linearized operator around solitary waves has no eigenvalue in L^2 other than 0.

However, exponential localization seems to be a strong constraint. Indeed, if there exists a small soliton other than the main wave, their results cannot be applied because solitons are not small in $H^1 \cap H^1_a$, where $H^1_a = \{v \,|\, e^{ay} v \in H^1\}$ with $\|v\|_{H^1_a} = \|e^{ay} v\|_{H^1}$ (see [28, p. 337]).

To deal with a more general class of perturbations, it is natural to use the algebraically weighted space. Recently, Miller [24] has shown some estimates of the solutions to the linearized equation in algebraically weighted spaces following the lines of Jensen and Kato [18].

One of the purposes of the present paper is to show the asymptotic stability of solitary waves in algebraically weighted spaces. Making use of the weighted L^p-L^q estimate, which is a generalization of the linear estimates in [24], we prove the asymptotic stability of solitary waves in H^1 with a weight function growing polynomially as $x \to \infty$ and decaying exponentially as $x \to -\infty$ (see Theorem 2.2 in section 2). Our result can deal with the case where the small soliton is behind and well apart from the dominant soliton. Furthermore, our result covers the case where $1 < p < 3$, which was left open in [28].

The other purpose of the present paper is to show the existence of scattering states around solitary wave solutions of the GKdV equation. There is extensive literature on the nonlinear scattering of solutions to (1.1)–(1.2) if $u_0(x)$ is small (see [11], [16], [20], [21], [22], [29], [30], [32], [35], and the references therein). They tell us that small solutions to (1.1) decay at the same rate as solutions to the linear problem

$$u_t + u_{xxx} = 0 \quad \text{for } x \in \mathbb{R} \text{ and } t > 0 \tag{1.4}$$

and are asymptotically free if $p > 2$. There is also a conjecture in [30] that the small solutions are not asymptotically free for $1 < p \leq 2$.

On the other hand, the existence of scattering states around standing wave solutions has been studied for some classes of nonlinear Schrödinger equation (see [10], [33], [34]). To the best of our knowledge, however, the corresponding result for the GKdV equation remains unknown. We prove that the dispersive wave part of the solution around the solitary wave also behaves like the free dispersion wave as $t \to \infty$ if $p > 2$ (see Theorem 2.4 in section 2).

To prove the result, we show that the interaction of the dispersive part and the solitary wave becomes small in various norms as $t \to \infty$, and we apply the method due to Hayashi and Naumkin [16], which shows nonlinear scattering of solutions to the GKdV equation in the case where $p > 2$ and the initial data are small.

The plan of the present paper is as follows. In section 2, we introduce our main results and several lemmas which shall be used in the sections that follow. In section 3,

we will show that the solution u to (1.1)–(1.3) which is close to solitary waves in an algebraically weighted space can be expressed in the form

$$u(x,t) = \varphi_{c(t)}(y,t) + v(y,t) \quad \text{with } y = x - \int_0^t c(s)ds + \gamma(t),$$

following the lines of [28], [10], [33], and [34]. Here the parameters of speed $c(t)$ and phase shift $\gamma(t)$ vary in time so that $\varphi_{c(t)}(y)$ describes the motion of the solitary wave part for each t. In section 4, we will derive some a priori estimates of (v, c, γ) and show that the solution which is initially close to a solitary wave tends to a nearby solitary wave as $t \to \infty$ in a local sense relative to a frame moving with the solitary wave. In section 5, we show that solutions which are close to a solitary wave in some weighted space can be resolved into a solitary wave and a purely dispersive wave. In the appendix, we estimate the rate of decay of solutions to the linearized equation in some weighted spaces (see Lemma 2.7 and Corollaries 2.9 and 2.10).

Finally, let us introduce several notations, which shall be used later. Let $x_+ = \max(x, 0)$, $x_- = \max(-x, 0)$, $\langle x \rangle = (1 + x^2)^{1/2}$ for $x \in \mathbb{R}$. We use the notations $\|\cdot\|_p$ for the $L^p(\mathbb{R})$-norm and $\|\cdot\|_{m,s}$ for the norms defined by $\|v\|_{m,s} = \|\langle x \rangle^s (1-\partial^2)^{m/2} v\|_2$. For simplicity, we denote by $\|\cdot\|$ and $(\cdot,\cdot)$ the norm and the inner product of $L^2(\mathbb{R})$, respectively. For $\alpha > 0$ and $b > 0$, let $h_{\alpha,b}(x)$ be a smooth function that satisfies $h_{\alpha,b}(x) > 0$, $h'_{\alpha,b} > 0$ for $x \in \mathbb{R}$, $\sup_{x\in\mathbb{R}} |h^{(k)}_{\alpha,b}(x)/h_{\alpha,b}(x)| < \infty$ for $k \in \mathbb{N} \cup \{0\}$, and

$$h^{(k)}_{\alpha,b}(x) = \begin{cases} O(|x|^{\alpha-k}) & \text{as } x \to \infty, \\ O(e^{bx}) & \text{as } x \to -\infty \end{cases}$$

for $0 \le k \le [\alpha]$, where $h^{(k)}_{\alpha,b}(x)$ denotes the kth derivative of $h_{\alpha,b}(x)$. For the definiteness, we choose a nonnegative C^∞-function $\varphi(x) \in C_0^\infty[-1, 1]$ with $\|\varphi\|_1 = 1$ and define $h_{\alpha,b}$ by $h_{\alpha,b}(x) = \exp\left\{\int_0^x \omega_{\alpha,b} * \varphi(y)dy\right\}$ for $\alpha > 0$, $b > 0$, where

$$\omega_{\alpha,b}(x) = \begin{cases} \alpha & \text{for } x \le 1, \\ b(x - 1 + b/\alpha)^{-1} & \text{for } x \ge 1. \end{cases}$$

This family of functions meets all our requirements and will be used without further comments. For $\alpha < 0$ and $b < 0$, we define $h_{\alpha,b}(x)$ by $h_{\alpha,b}(x) = h_{-\alpha,-b}(x)^{-1}$. We denote by $L^p(\alpha, b)$, $W^{k,p}(\alpha, b)$, and $L^{s,p}(\alpha, b)$ the weighted spaces with the norms defined by

$$\|v\|_{L^p(\alpha,b)} = \|h_{\alpha,b} v\|_p, \quad \|v\|_{W^{k,p}(\alpha,b)} = \left(\sum_{|\beta|\le k} \|h_{\alpha,b} \partial_x^\beta v\|_p^p \right)^{1/p},$$

$$\|v\|_{L^{s,p}(\alpha,b)} = \|(1 - \partial_x^2)^{s/2} h_{\alpha,b} v\|_p,$$

where $k \in \mathbb{N} \cup \{0\}$, $p \in [1, \infty]$, $s \in \mathbb{R}$. Note that $W^{k,p}(\alpha, b)$ and $L^{k,p}(\alpha, b)$ are equivalent if $1 < p < \infty$ and that the space $L^{-s,p'}(-\alpha, -b)$ is the dual space of $L^{s,p}(\alpha, b)$ for $1 < p < \infty$, where $1/p + 1/p' = 1$.

We define D^α as

$$D^\alpha f \equiv \mathcal{F}^{-1} \xi^\alpha e^{-i\pi(1+\alpha)/2} \mathcal{F} f$$

$$= \frac{2\pi}{\Gamma(1-\alpha)} \int_0^\infty (f(x+y) - f(x)) \frac{dy}{y^{\alpha+1}}$$

for $\alpha \in (0,1)$, where $\mathcal{F}f(\xi) = \int e^{-ix\xi} f(x)dx$ and $\mathcal{F}^{-1}g(x) = \frac{1}{2\pi}\int e^{ix\xi} g(\xi)d\xi$. In the course of calculations, various constants will be denoted simply by C and C_i, which are possibly different from one line to the next.

2. Assumptions and results. First, we recall the spectral properties of the linearized operator of (1.1) around the solitary wave solutions. Let $A_{[c]}$ be the operator defined by

$$A_{[c]}u \equiv -\partial_y\{\partial_y^2 - c + f'(\varphi_c(y))\}u. \tag{2.1}$$

Obviously, the essential spectrum of the linearized operator $A_{[c]}$ consists of $i\mathbb{R}$ and it holds that $A_{[c]}\partial_y\varphi_c = 0$, $A_{[c]}\partial_c\varphi_c = -\partial_y\varphi_c$. So $\lambda = 0$ is always an eigenvalue of $A_{[c]}$ embedded in the essential spectrum. Put

$$\xi_1(y,\, c) = \partial_y\varphi_c(y), \quad \xi_2(y,\, c) = \partial_c\varphi_c(y),$$
$$\eta_1(y,c) = \theta_1\int_{-\infty}^{y}\partial_c\varphi_c + \theta_2\varphi_c(y), \quad \eta_2(y,c) = \theta_3\varphi_c(y),$$

where

$$\theta_3 = -\theta_1 = 2\left(\frac{d}{dc}\|\varphi_c\|^2\right)^{-1} \quad \text{and} \quad \theta_2 = 2\left(\frac{d}{dc}\int_{\mathbb{R}}\varphi_c\right)^2\left(\frac{d}{dc}\|\varphi_c\|^2\right)^{-2}. \tag{2.2}$$

The functions $\xi_1(y,c)$, $\xi_2(y,c)$, and $\eta_2(y,c)$ decay exponentially as $|y| \to \infty$. The function $\eta_1(y)$ also decays exponentially as $y \to -\infty$, but it is merely bounded as $y \to \infty$. In addition, it holds that

$$A_{[c]}\xi_1(y,c) = 0, \quad A_{[c]}\xi_2(y,c) = -\xi_1(y,c), \tag{2.3}$$
$$A_{[c]}^*\eta_1(y,c) = -\eta_2(y,c), \quad A_{[c]}^*\eta_2(y,c) = 0, \tag{2.4}$$
$$\langle\xi_i(\cdot,\, c),\, \eta_j(\cdot,\, c)\rangle = \delta_{ij} \quad \text{for } i,j = 1,2, \tag{2.5}$$

where $\langle\cdot,\cdot\rangle$ is defined by $\langle f,g\rangle = \int f\bar{g}dx$.

Let P_c and Q_c be the projections defined by

$$P_cu = \sum_{i=1}^{2}\langle u,\, \eta_i(\cdot,c)\rangle\xi_i(\cdot,c) \quad \text{and} \quad Q_cu = (1-P_c)u \tag{2.6}$$

in $W^{k,p}(\alpha,b)$. The operators P_c and Q_c are well defined if $1 \le p \le \infty$, $\alpha > 1 - 1/p$, and $b > 0$ is a sufficiently small number.

For the operator $A_{[c]}$ defined in L^2, put

$$\mathrm{Ker}(A_{[c]}) = \{w \in D(A_{[c]}) \mid A_{[c]}u = 0\}, \quad \mathrm{Ker}_g(A_{[c]}) = \bigcup_{k=0}^{\infty}\mathrm{Ker}(A_{[c]}^k).$$

The following proposition due to Pego and Weinstein [27], [28] tells us that $A_{[c]}$ generically has no eigenvalue in $L^2(\mathbb{R})$ other than 0.

PROPOSITION 2.1 (see Pego and Weinstein [27], [28]).

(i) *Assume $0 < p \le 4$. Then $A_{[c]}$ has no isolated eigenvalues. Its spectrum coincides with the imaginary axis.*

(ii) *Assume* $\frac{d}{dc}\|\varphi_c\|_{L^2}^2 \neq 0$ $(p \neq 4)$. *Then* $\lambda = 0$ *is an eigenvalue for* $A_{[c]}$ *with algebraic multiplicity two. More precisely, it holds that*

$$\mathrm{Ker}_g(A_{[c]}) = \mathrm{Ker}(A_{[c]}^2) = \mathrm{span}\{\xi_1(\cdot, c), \xi_2(\cdot, c)\},$$
$$\mathrm{Ker}_g(A_{[c]}^*) = \mathrm{Ker}(A_{[c]}^{*2}) = \mathrm{span}\{\eta_1(\cdot, c), \eta_2(\cdot, c)\},$$

where $\mathrm{span}\{w_1, w_2\}$ *denotes the linear subspace* $\{\alpha w_1 + \beta w_2 \,|\, \alpha, \beta \in \mathbb{C}\}$.

(iii) *The set* $\mathbf{E}$*, of values* p *with* $p > 0$*, where* $A_{[c]}$ *has a nonzero eigenvalue on the imaginary axis, is a discrete set. In particular,* $\mathbf{E} \cap [1, 4]$ *is a finite set, which does not include the values* $p = 1$ *and* $p = 2$.

We will assume the absence of nonzero eigenvalues of $A_{[c]}$ in the closed right half plane of $\mathbb{C}$ throughout the paper.

Now, we are in position to state our main results.

THEOREM 2.2 (asymptotic stability). *Assume* $1 \leq p < 4$ *and* $p \notin \mathbf{E}$*, where* $\mathbf{E}$ *is a set defined in Proposition* 2.1. *Let* u *be the solution to* (1.1)–(1.3). *Let* α_1, α_2 *be positive numbers such that* $\alpha_1 = \alpha_2 + r + 1$, $\alpha_2 = r + 1/2$, *and* $r \geq 2$. *Let* b *be a sufficiently small positive number. Then, there exist some* $\varepsilon_0 > 0$ *and* $C > 0$ *satisfying the following. If*

$$\|v_0\|_{1,0} + \|v_0\|_{L^2(\alpha_1, b)} = \varepsilon$$

for $0 < \varepsilon < \varepsilon_0$*, there exists* $(c_+, \gamma_+) \in \mathbb{R}_+ \times \mathbb{R}$ *such that*

$$|c_+ - c_0| + |\gamma_+ - \gamma_0| < C\varepsilon, \tag{2.7}$$
$$\sup_{t \geq 0} \|u(\cdot, t) - \varphi_{c_+}(\cdot - c_+ t + \gamma_+)\|_{1,0} \leq C\varepsilon, \tag{2.8}$$
$$\sup_{t \geq 0} t^r \|u(\cdot + c_+ t - \gamma_+, t) - \varphi_{c_+}(\cdot)\|_{W^{1,2}(\alpha_2, b)} \leq C\varepsilon. \tag{2.9}$$

Remark 2.3. It is expected that more or less initial data u_0 evolve, in a fairly short time, into a train of solitary waves plus a dispersive trail. If $p = 1$ or 2, the phenomenon is understood analytically as a consequence of inverse scattering transform. Although the inverse scattering theory is not available in the nonintegrable case, there is some numerical evidence which suggests that the phenomenon extends for more general p (see, for example, [5], [6], [7]).

Pego and Weinstein [28] proved the asymptotic stability of the main wave in an exponentially weighted space. That is, if $u_0(x) = \varphi_{c_0}(x + \gamma_0) + v_0(x)$ and $\|v_0\|_{H^1} + \|e^{ax} v_0\|_{H^1}$ is sufficiently small for an $a > 0$, the solution arising from such initial data tends toward a nearby solitary wave in the weighted space. Although their method is broadly useful to investigate the large time asymptotics of nonintegrable equations, their result does not apply to multipulse solutions for the following reason. Let c_1, c_2, γ_1, and γ_2 be numbers satisfying $c_1 > c_2 > 0$ and $\gamma_1 < \gamma_2$. Suppose that u is a 2-soliton solution to the KdV equation that approaches $\varphi_{c_1}(x - c_1 t + \gamma_1) + \varphi_{c_2}(x - c_2 t + \gamma_2)$ as $t \to \infty$. Then the solution $u(x, t)$ spatially decays at the same rate as $e^{-\sqrt{c_2} x}$ as $x \to \infty$. So the assumption $e^{ax} v_0 \in H^1$ imposes the minimum size on the amplitude of solitary wave in the combination, since we must have $\sqrt{c_2} > a$. On the other hand, since $\varphi_c(x) = c^{1/p} \varphi_1(c^{1/2} x)$, we have $c \to 0$ as $\|\varphi_c\|_{H^1} \to 0$. But there is no guarantee that the H^1 norm of φ_{c_2} with $\sqrt{c_2} > a$ is enough to regard u as a small perturbation to $\varphi_{c_1}(x - c_1 t + \gamma_1)$ and apply their argument.

To deal with more general classes of perturbations from which solitary waves arise, we make use of the weight function that grows polynomially as $x \to \infty$. Since

$\|\varphi_c(\cdot+\gamma)\|_{L^2(\alpha_1,b)} \to 0$ as $c \to 0$ and $\gamma \to 0$, we can regard an N-soliton solution as a perturbation to the dominant solitary wave if the $N-1$ of the waves are small and far behind the main wave.

The following theorem shows that the initial data which is close to a solitary wave (in a certain weighted space) resolves into a solitary wave with shifted parameters plus the linear evolution.

THEOREM 2.4 (scattering). *Let $2 < p < 4$, $p \notin \mathbf{E}$, and $\alpha > 11/2$. Suppose that*

$$\|(1+x_+)^\alpha v_0\| + \|v_0\|_{1,1} = \varepsilon$$

is sufficiently small. Then, there exists $V \in L^2(\mathbb{R})$ and (c_+, γ_+) satisfying (2.7)–(2.9) *with $\alpha_2 = \alpha/2 - 1/4$ and*

$$\|u(\cdot,t) - \varphi_{c_+}(\cdot - c_+t + \gamma_+) - e^{-t\partial_x^3}V\| = o(1) \tag{2.10}$$

as $t \to \infty$.

Remark 2.5. Noting that $\varphi_c(x) = c^{1/p}\varphi_1(c^{1/2}x)$, we see that $\|\varphi_c\|_{1,1}$ does not tend to 0 as $c \to 0$. So the smallness of v_0 in $H^{1,1}$ precludes the possibility of the emergence of small solitons ahead or behind the main wave.

Remark 2.6. The solitary wave solutions are unstable if $p \geq 4$ (see [8]). There are some numerical experiments that show that solutions near the solitary wave blow up in a finite time (see [6], [7]).

On the other hand, if $p \leq 2$, the dispersive wave part is expected not to be asymptotically free as $t \to \infty$ (see [30]).

To prove the above theorems, we need some results on the local decay of solutions to the linearized equation. Let $u(t,x)$ be the solution to

$$\begin{cases} \partial_t u - A_{[c]}u = 0, \\ u(0,x) = u_0(x), \end{cases}$$

and let $U_c(t)u_0 := u(t,x)$. Then we have the following lemma.

LEMMA 2.7. *Assume that $1 \leq p < 4$ and that $p \notin \mathbf{E}$. Let $1 \leq q_1 \leq q_2 < \infty$ and let b be a sufficiently small number. Let $k \in \mathbb{N} \cup \{0\}$, $m = 0,1,2,3$, and let r be a real number with $r \geq [(m+1)/2] + 1$. Suppose that $\alpha_1 \geq \alpha_2 + r + 1 + 1/q_2 - 1/q_1$, $\alpha_2 > 1 - 1/q_2$. Then there exists a $C_1 > 0$ such that*

$$\|U_c(t)Q_cu_0\|_{W^{k+m,q_2}(\alpha_2,b)} \leq C_1 t^{-r}\|Q_cu_0\|_{W^{k,q_1}(\alpha_1,b)}$$

for every $u_0 \in W^{k,q_1}(\alpha_1,b)$ and $t > 0$. Especially, there exists a $C_2 > 0$ such that

$$\|U_c(t)Q_cu_0\|_{W^{k,2}(\alpha_2,b)} \leq C_2(1+t)^{-r}\|Q_cu_0\|_{W^{k,2}(\alpha_1,b)}$$

for every $u_0 \in W^{k,2}(\alpha_1,b)$ and $t \geq 0$. Furthermore, if I is a compact subset of $(0,\infty)$, the constants C_1 and C_2 can be chosen uniformly for all $c \in I$.

Remark 2.8. Lemma 2.7 of this paper is a generalization of Theorem 1.1 in [24]. The difference between our Lemma 2.7 and Theorem 1.1 of [24] is that q_1 need not be equal to q_2, which enables us to prove the asymptotic stability in the algebraically weighted space.

COROLLARY 2.9. *Let $1 \leq q_1 \leq q_2 \leq \infty$ and $q_1 \neq \infty$. Let p, α_1, α_2, and b be as in Lemma* 2.7. *Let θ be a number satisfying*

$$\theta = \begin{cases} 1/4 & \text{if } 1/q_1 - 1/q_2 < 3/4, \\ 1/3 & \text{if } 1/q_1 - 1/q_2 \geq 3/4. \end{cases}$$

If $r \geq 1$, there exists a $C_1 > 0$ such that

$$\|U_c(t)Q_c u_0\|_{L^{q_2}(\alpha_2,b)} \leq C_1 t^{-\theta}(1+t)^{-r+\theta}\|Q_c u_0\|_{L^{q_1}(\alpha_1,b)}$$

for every $t > 0$ and $u_0 \in L^{q_1}(\alpha_1, b)$. If $r \geq 2$, there exists a $C_2 > 0$ such that

$$\|\partial_x U_c(t)Q_c u_0\|_{L^{q_2}(\alpha_2,b)} \leq C_2 t^{-3/4}(1+t)^{-r+3/4}\|Q_c u_0\|_{L^{q_1}(\alpha_1,b)}$$

for every $t > 0$ and $u_0 \in L^{q_1}(\alpha_1, b)$. Moreover, if I is a compact subset of $(0, \infty)$, the constants C_1 and C_2 can be chosen uniformly for all $c \in I$.

COROLLARY 2.10. *Let p, α_1, α_2, and b be as in Lemma 2.7. Assume that $1 < q_1 \leq q_2 < \infty$ and that $r \geq 2$. Then, there exists a $C > 0$ such that*

$$\|U_c(t)Q_c u_0\|_{L^{q_2}(\alpha_2,b)} \leq Ct^{-3/4}(1+t)^{-r+3/4}\|Q_c u_0\|_{L^{-1,q_1}(\alpha_1,b)}$$

for every $t > 0$ and $u_0 \in L^{-1,q_1}(\alpha_1, b)$. Moreover, if I is a compact subset of $(0, \infty)$, the constant C can be chosen uniformly for all $c \in I$.

The proofs of Lemma 2.7 and Corollaries 2.9 and 2.10 will be given in the appendix.

3. Separation of the motions. Let us represent the solution u to the Cauchy problem (1.1)–(1.3) as

$$u(x,t) = \varphi_{c(t)}(y) + v(y,t) \tag{3.1}$$

with $y = x - \int_0^t c(s)ds + \gamma(t)$.

In order to distinguish the motion of the solitary wave part and that of the residual part, we impose the constraint that

$$v(y,t) \in \text{Range}\left(Q_{c(t)}(t)\right).$$

This requirement corresponds to

$$\langle v(\cdot,t),\, \eta_i(\cdot,\, c(t))\rangle = 0 \quad \text{for } i = 1,\, 2, \tag{3.2}$$

which can be satisfied by modulating $c(t)$ and $\gamma(t)$. In this section, we show that the decomposition exists locally in time, and we derive an evolution equation which arises from (3.2).

PROPOSITION 3.1. *Let $p \geq 1$, $\alpha > 3/4$, and $t_0 \geq 0$. Suppose $u_0 \in H^1 \cap L^2(\alpha, b)$. Then there exist positive numbers δ_0 and δ_1 such that, for any real γ_0, if the solution u to (1.1) satisfies*

$$\sup_{0\leq t\leq t_0} \|u(\cdot - \gamma_0, t) - \varphi_{c_0}(\cdot - c_0 t)\|_{L^2(\alpha,b)} < \delta_0,$$

there exists a unique function $(c(t), \gamma(t)) \in C([0,t_0];\mathbb{R}^2) \cap C^1((0,t_0);\mathbb{R}^2)$ satisfying

$$\sup_{0\leq t\leq t_0} (|c(t) - c_0| + |\gamma(t) - \gamma_0|) < \delta_1, \tag{3.3}$$

$$F_i[u,c,\gamma] := \left\langle u\left(\cdot + \int_0^t c(s)ds - \gamma(t), t\right) - \varphi_{c(t)}(\cdot),\, \eta_i(\cdot, c(t))\right\rangle = 0 \tag{3.4}$$

for $i = 1,\, 2$ and $0 \leq t \leq t_0$. The number δ_0 may be chosen as the decreasing function of t_0.

Before we prove the proposition, we will show the continuity of the solutions in $L^2(\alpha, b)$.

LEMMA 3.2. *Let $p \geq 1$, $\alpha > 3/4$, and $b > 0$. If $u_0 \in H^1 \cap L^2(\alpha, b)$, the solution u to (1.1)–(1.2) satisfies*

$$u \in C([0,\infty); L^2(\alpha, b)) \cap C([0,\infty); H^1(\mathbb{R})).$$

Furthermore, if $\alpha > 2$ and $u_0 \in H^1 \cap L^2(\alpha, b)$, it holds that

$$u \in C((0,\infty); W^{1,2}(\alpha, b)).$$

Proof. As one easily sees, there exist σ and λ_0 with $\lambda_0 > \sigma > 0$ such that $-\partial_x^3 - \sigma$ is dissipative on $L^2(\alpha, b)$ and λ_0 belongs to the resolvent set $\rho(-\partial_x^3)$. So, the operator $-\partial_x^3$ generates a C_0-semigroup $T_0(t)$ on $L^2(\alpha, b)$ (see [24, p. 119] and [26]).

By the variation of constants formula, the solution u to (1.1) satisfies

$$u(t) = T_0(t)u_0 + \int_0^t T_0(t-s)\partial_x f(u(s))ds, \tag{3.5}$$

where $T_0(t) = \exp(-t\partial_x^3)$. To prove the former part of the proposition, we will show that each term of (3.5) belongs to $C([0,\infty); L^2(\alpha, b))$. Since $T_0(t)$ is a C^0-semigroup defined on $L^2(\alpha, b)$, it holds that $T_0(t)u_0 \in C([0,\infty); L^2(\alpha, b))$.

Next, we show that the second term of (3.5) belongs to $C([0,\infty); L^2(\alpha, b))$. For each t, the operator $T_0(t)$ can be represented as the convolution with the function

$$S_t(x) = (3t)^{-1/3}\,\mathrm{Ai}(x(3t)^{-1/3}),$$

where

$$\mathrm{Ai}(x) = (2\pi)^{-1}\int \exp(i\xi^3/3 + ix\xi)d\xi.$$

Let α_1 be a number with $\alpha_1 > \alpha + 1/4$. Since the Airy function $\mathrm{Ai}(x)$ satisfies

$$|\mathrm{Ai}^{(i)}(x)| \leq C_i(1+x_-)^{(2i-1)/4}e^{-Cx_+^{3/2}} \quad \text{for } i = 0, 1 \tag{3.6}$$

(see [17, p. 213]) and

$$|h_{\alpha,b}(x)h_{\alpha_1,b}(y)^{-1}| \leq \begin{cases} Ce^{b(x-y)} & \text{if } x \geq y, \\ C\langle x-y\rangle^{\alpha-\alpha_1} & \text{if } x \leq y \end{cases} \tag{3.7}$$

follows, then

$$\big\|\|h_{\alpha,b}(x)S_t(x-y)h_{\alpha_1,b}(y)^{-1}\|_{L^2(\mathbb{R}_x)}\big\|_{L^\infty(\mathbb{R}_y)} \leq Ct^{-1/3} \quad \text{for } t \in [0,T].$$

Combining this with Minkowski's inequality, we have

$$\|T_0(t)v\|_{L^2(\alpha,b)} \leq C_T t^{-1/3}\|v\|_{L^1(\alpha_1,b)} \quad \text{for } t \in [0,T], \tag{3.8}$$

where $\alpha_1 > \alpha + 1/4$, $T > 0$ is arbitrary, and C_T is a positive number depending on T. Since the solution u to (1.1)–(1.2) with $u_0 \in H^1 \cap L^2(\alpha_1, b)$ satisfies

$$u \in C(\mathbb{R}; H^1) \cap L^\infty_{loc}([0,\infty); L^2(\alpha, b)),$$
$$u_x \in L^2_{loc}([0,\infty); L^2(\alpha - 1/2, b))$$

(see [15], [20], and the references therein), we have

$$f(u)_x \in L^q_{loc}([0,\infty); L^1(\alpha_*, b)) \quad \text{for } \alpha_* = \alpha + (2\alpha - 1)/q \text{ and } 2 \le q \le \infty. \tag{3.9}$$

Combining (3.8) and (3.9) with $q = 2$ and the fact that $T_0(t)$ is the C^0-semigroup on $L^2(\alpha, b)$, we have

$$\begin{aligned}
&\left\| \int_0^{t+h} T_0(t+h-s)\partial_x f(u(s))ds - \int_0^t T_0(t-s)\partial_x f(u(s))ds \right\|_{L^2(\alpha,b)} \\
&\le \left\| \int_t^{t+h} T_0(t+h-s)\partial_x f(u(s))ds \right\|_{L^2(\alpha,b)} \\
&\quad + \left\| (T_0(h)-1) \int_0^t T_0(t-s)\partial_x f(u(s))ds \right\|_{L^2(\alpha,b)} = o(1) \quad \text{as } h \downarrow 0,
\end{aligned}$$

which implies the right continuity of the second term in $L^2(\alpha, b)$. The left continuity can be shown exactly in the same way.

Now, we prove the latter part of the proposition. Using (3.6) and (3.7), one can see that

$$\|\partial_x T_0(t)v\|_{L^2(\alpha,b)} \le Ct^{-3/4}\|v\|_{L^1(\alpha_1,b)} \quad \text{for } t \in [0,T]$$

with $0 < T < \infty$ if $\alpha_1 > \alpha + 3/4$. Combining this with (3.5) and (3.9) with $q > 4$, we can prove that $u(t) \in C((0,\infty); W^{1,2}(\alpha, b))$ in the same way. Thus we complete the proof. □

Proof of Proposition 3.1. The proof follows the line of Proposition 5.1 in [28]. Let $F[u, c, \gamma] = (F_1[u, c, \gamma], F_2[u, c, \gamma])$ be the functional defined by (3.4) that maps $C([0, t_0); L^{-3,2}(\alpha, b)) \times C([0, t_0); \mathbb{R}^2)$ to $C([0, t_0); \mathbb{R}^2)$. We remark that $F \in C^1$ and that

$$u \in C^1([0,\infty); L^{-3,2}(\alpha, b))$$

follows from Lemma 3.2 and (1.1).

Put $U_0 = (\varphi_{c_0}(\cdot - c_0 t), c_0, \gamma_0)$. Then it follows that $F[U_0] = 0$ and

$$D_{(c,\gamma)}F[U_0] = \begin{pmatrix} B & -1 \\ -1 & 0 \end{pmatrix},$$

where B is a functional given by $B[c](t) = \int_0^t c(s)ds$. Applying the implicit function theorem, we see that there exists a unique function $(c(t), \gamma(t))$ satisfying (3.3) and (3.4) and that $u \mapsto (\gamma(\cdot), c(\cdot))$ is a C^1-mapping from $C([0, t_0]; L^{-3,2}(\alpha, b))$ to $C([0, t_0]; \mathbb{R}^2)$. Since $u \in C^1([0,\infty); L^{-3,2}(\alpha, b))$, we conclude that $(c(t), \gamma(t)) \in C^1([0, t_0); \mathbb{R}^2)$. Thus we have proved Proposition 3.1. □

Let δ_0 be a positive number. Then, there is an $\varepsilon > 0$ such that if $\|v_0\|_{1,0} + \|v_0\|_{L^2(\alpha_2,b)} < \varepsilon$, we have $u \in C([0, t_1]; L^2(\alpha_2, b))$ with

$$\sup_{0 \le t \le t_1} \|u(\cdot - \gamma_0, t) - \varphi_{c_0}(\cdot - c_0 t)\|_{L^2(\alpha_2,b)} \le \delta_0$$

for some $t_1 > 0$. If δ_0 is a sufficiently small number, Proposition 3.1 implies the existence of decomposition (3.1)–(3.2) on the time interval $[0, t_1]$.

Next, we will derive the evolution equations of (v, c, γ), which are valid for $0 < t < t_1$. Substituting (3.1) into (1.1), we have

$$\partial_t v - A_{[c(t)]}v + \dot{\gamma}(t)\partial_y v + \partial_y N(t, v) + (\dot{c}(t)\partial_c + \dot{\gamma}(t)\partial_y)\varphi_{c(t)} = 0, \tag{3.10}$$

where

$$N(t, v) = f(\varphi_{c(t)} + v) - f(\varphi_{c(t)}) - f'(\varphi_{c(t)})v.$$

Let $\psi(t)$ be an arbitrary smooth function with $\psi(0) = \psi(t_1) = 0$, and let $\chi_j(x)$ $(j \in \mathbb{N})$ be nonnegative smooth functions satisfying

$$\chi_j(x) = \begin{cases} 0 & \text{for } x \geq j + 1, \\ 1 & \text{for } x \leq j. \end{cases}$$

Then

$$-\int_0^{t_1} \langle v(t),\, \chi_j \eta_i(\cdot, c(t))\rangle \psi' dt = \int_0^{t_1} \{\langle v_t,\, \chi_j \eta_i(\cdot, c(t))\rangle + \dot{c}\langle v,\, \chi_j \partial_c \eta_i(\cdot, c(t))\rangle\}\, \psi(t) dt. \tag{3.11}$$

Substituting (3.10) into the integrand of the right-hand side of (3.11), integrating the resulting equation by parts, sending $j \to \infty$, and using (2.4) and (3.2), we have

$$\mathcal{A}(t)\begin{pmatrix} \dot{\gamma} \\ \dot{c} \end{pmatrix} = -\begin{pmatrix} \langle N(t, v), \partial_y \eta_1(\cdot, c(t))\rangle \\ \langle N(t, v), \partial_y \eta_2(\cdot, c(t))\rangle \end{pmatrix}, \tag{3.12}$$

where

$$\mathcal{A}(t) = \begin{pmatrix} 1 - \langle v,\, \partial_y \eta_1(\cdot, c(t))\rangle & -\langle v,\, \partial_c \eta_1(\cdot, c(t))\rangle \\ -\langle v,\, \partial_y \eta_2(\cdot, c(t))\rangle & 1 - \langle v,\, \partial_c \eta_2(\cdot, c(t))\rangle \end{pmatrix}. \tag{3.13}$$

Thus we obtain a triplet of equations (3.10) and (3.12), which describes the motion of the solitary wave part and the residual part. We remark that the system (3.10) and (3.12) with $\langle v(0), \eta_i\rangle = 0$ $(i = 1, 2)$ is valid and equivalent to (1.1)–(1.3) as long as the decomposition (3.1) with (3.2) persists.

4. A priori estimates and asymptotic stability. In this section, we aim to prove Theorem 2.2. Let t_1 be a positive number such that the decomposition (3.1) with (3.2) persists for $0 < t < t_1$. In order to prove the theorem, we first derive from (3.10) and (3.12) a priori estimates of (v, c, γ) on $[0, t_1]$, which do not depend on t_1. The estimates will ensure the persistence of the decomposition (3.1) with (3.2) for all the time and imply that the residual part v locally decays to 0 as $t \to \infty$.

Let $c_1 = c(t_1)$ and $\gamma_1 = \gamma(t_1) - \int_0^{t_1}(c(s) - c_1)ds$. Using the change of variables

$$\tilde{v}(z, t) = v(y, t), \quad z = x - c_1 t + \gamma_1, \tag{4.1}$$

we can rewrite (3.10) into

$$\partial_t \tilde{v} - A_{[c_1]}\tilde{v} + \partial_z \widetilde{N}(t, \tilde{v}) + (\dot{c}\partial_c + \dot{\gamma}\partial_z)\varphi_{c(t)}(y) = 0, \tag{4.2}$$

where

$$\begin{aligned} \widetilde{N}(t, \tilde{v}) &= f(\varphi_{c(t)}(y) + \tilde{v}) - f(\varphi_{c(t)}(y)) - f'(\varphi_{c_1}(z))\tilde{v} \\ &= \int_0^1 \{f'(\varphi_{c(t)}(y) + \theta\tilde{v}) - f'(\varphi_{c_1}(z))\} d\theta \tilde{v}. \end{aligned}$$

To obtain the local energy decay estimate of $\tilde{v}$, we make use of the spectral properties of the linearized operator around $\varphi_{c_1}(z)$. Let us decompose $\tilde{v}$ into the contribution of the generalized eigenfunctions of $A_{[c_1]}$ and the other part. Let $g = P_{c_1}\tilde{v}$ and $h = Q_{c_1}\tilde{v}$. Then by (3.2) and (4.2),

$$h(t) = U_{c_1}(t)h(0) - \int_0^t U_{c_1}(t-s)Q_{c_1}\partial_z \widetilde{N}(s,\tilde{v})ds$$
$$- \int_0^t U_{c_1}(t-s)Q_{c_1}(\dot{c}\partial_c + \dot{\gamma}\partial_z)\varphi_{c(s)}(y)ds, \tag{4.3}$$

$$\mathcal{B}(t)\begin{pmatrix}\kappa_1\\ \kappa_2\end{pmatrix} + \begin{pmatrix}\int h(z,t)\eta_1(y,c(t))dz\\ \int h(z,t)\eta_2(y,c(t))dz\end{pmatrix} = 0, \tag{4.4}$$

and $\kappa_i(t) = \langle g(\cdot), \eta_i(\cdot, c_1)\rangle$ for $i = 1, 2$ and

$$\mathcal{B}(t) = \begin{pmatrix}\int \xi_1(z,c_1)\eta_1(y,c(t))dz & \int \xi_2(z,c_1)\eta_1(y,c(t))dz\\ \int \xi_1(z,c_1)\eta_2(y,c(t))dz & \int \xi_2(z,c_1)\eta_2(y,c(t))dz\end{pmatrix}.$$

From the orthogonality conditions (2.5), we see that $\mathcal{B}(t)$ satisfies

$$\mathcal{B}(t) = \begin{pmatrix}1 & 0\\ 0 & 1\end{pmatrix} + O(|c(t)-c_1| + |y(t)-z(t)|). \tag{4.5}$$

Now, let us introduce several functions:

$$M_0(t) = \sup_{0\le\tau\le t}\langle\tau\rangle^{2r-2}|y(\tau)-z(\tau)|, \qquad M_1(t) = \sup_{0\le\tau\le t}\langle\tau\rangle^{2r-1}|c(\tau)-c_1|,$$
$$M_2(t) = \sup_{0\le\tau\le t}\langle\tau\rangle^{r}\left(|\kappa_1(\tau)| + |\kappa_2(\tau)|\right), \qquad M_3(t) = \sup_{0\le\tau\le t}\|\tilde{v}(\cdot,\tau)\|_{1,0},$$
$$M_4(t) = \sup_{0\le\tau\le t}\langle\tau\rangle^{r}\|h(\cdot,\tau)\|_{L^2(\alpha_2,b)},$$
$$M_5(t) = \sup_{0\le\tau\le t}\tau^{3/4+\eta}\langle\tau\rangle^{r-3/4-\eta}\|\partial_z h(\cdot,\tau)\|_{L^2(\alpha_2,b)},$$

where η is a sufficiently small positive number.

Our strategy to prove Theorem 2.2 is to estimate the above system of functions and derive the closed system of inequalities that does not depend on t_1. Hereafter, we denote by $C(M)$ various functions of M_i $(0 \le i \le 5)$ which are bounded in some neighborhood of the origin.

PROPOSITION 4.1. *Let p, α_1, α_2, b, and r be positive numbers as in Theorem 2.2. Assume that $v_0 \in H^1 \cap L^2(\alpha_1, b)$. Then, for $t \in [0, t_1]$,*

$$M_0 + M_1 \le C(M)(M_2^2 + M_4^2), \tag{4.6}$$
$$M_2 \le C(M)M_4(M_0 + M_1), \tag{4.7}$$
$$M_3 \le C(\|v_0\|_{1,0} + \|v_0\|_{L^2(\alpha_2,b)}) + C(M)(M_2 + M_4), \tag{4.8}$$
$$\begin{aligned} M_4 + M_5 \le{}& \|\tilde{v}(0)\|_{L^2(\alpha_1,b)} + \delta(M_2 + M_4)\\ &+ C(M)(M_2 + M_4)(M_2 + M_3 + M_5)\\ &+ C(M)\{(M_0 + M_1)(M_2 + M_4 + M_5) + M_2^2 + M_4^2\}, \end{aligned} \tag{4.9}$$

where C is a positive constant and $\delta = \delta(M_0, M_1, M_2, M_3) \to 0$ as $\sum_{0\le i\le 3} M_i \to 0$. Moreover, the constants C, $C(M)$, and δ do not depend on t_1.

Proof. To begin with, we estimate $M_0(t)$ and $M_1(t)$. By (3.13), we have

$$\mathcal{A}(t) = I + O(\|v\|).$$

Since

$$\|v\|_{L^2_y(\alpha_2,b)} \le C(\|h\|_{L^2_z(\alpha_2,b)} + |\kappa_1| + |\kappa_2|)e^{bM_0},$$

it follows from (3.12) that

$$|\dot\gamma(\tau)| + |\dot c(\tau)| \le C(M)\|v\|^2_{L^2_y(\alpha_2,b)} \le C(M)(M_2^2 + M_4^2)\langle\tau\rangle^{-2r}. \tag{4.10}$$

So, we see that (4.6) follows from (4.10) and the definition of M_0 and M_1.

Using the orthogonality conditions $\langle h(\cdot,\tau), \eta_i(\cdot, c_1)\rangle = 0$ $(i = 1, 2)$, we have

$$\begin{aligned}\left|\int h(z,\tau)\eta_i(y,c(\tau))dz\right| &= \left|\int h(z,\tau)(\eta_i(y,c(\tau)) - \eta_i(z,c_1))dz\right| \\ &\le C(M)M_4(M_0+M_1)(1+\tau)^{-r}.\end{aligned}$$

Combining this with (4.4) and (4.5), we obtain (4.7).

We now turn to the estimate of $M_4(t)$ and $M_5(t)$. Let $0 < \beta \le 2\alpha_2$, and let χ_+ and χ_- be the characteristic functions of the intervals $[0,\infty)$ and $(-\infty, 0]$. Noting that

$$\begin{aligned}|\varphi^{(i)}_{c(\tau)}(y) - \varphi^{(i)}_{c_1}(z)| &\le C(M)(|y-z| + |c(\tau)-c_1|)(e^{-c(\tau)|y|} + e^{-c_1|z|}) \\ &\le C(M)(M_0+M_1)(e^{-c(\tau)|y|} + e^{-c_1|z|})\end{aligned}$$

for $i = 0$, 1 and that

$$\begin{aligned}\|\tilde v\tilde v_z\|_{L^1(\beta,b)} &\le C\|\chi_+\tilde v\|_{L^2(\alpha_2,b)}\|\chi_+\tilde v_z\|_{L^2(\alpha_2,b)} + C\|\chi_-\tilde v\|_{L^2(\alpha_2,b)}\|\chi_-\tilde v_z\| \\ &\le Cs^{-3/4-\eta}\langle s\rangle^{-r+3/4+\eta}(M_2+M_4)(M_2+M_3+M_5),\end{aligned}$$

we compute

$$\begin{aligned}&\|\partial_z \widetilde N(s,\tilde v)\|_{L^1(\beta,b)} \\ &\quad\le \left\|\int_0^1 \{f'(\varphi_{c(s)}(y)+\theta\tilde v) - f'(\varphi_{c_1}(z))\}d\theta\tilde v_z\right\|_{L^1(\beta,b)} \\ &\qquad + \left\|\int_0^1 f''(\varphi_{c(s)}(y)+\theta\tilde v)(\varphi'_{c(s)}(y) - \varphi'_{c_1}(z) + \theta\tilde v_z)d\theta\tilde v\right\|_{L^1(\beta,b)} \\ &\qquad + \left\|\int_0^1 \{f''(\varphi_{c(s)}(y)+\theta\tilde v) - f''(\varphi_{c_1}(z))\}\varphi'_{c_1}(z)d\theta\tilde v\right\|_{L^1(\beta,b)} \\ &\quad\le C(M)\{\|\tilde v\tilde v_z\|_{L^1(\beta,b)} + (|c(s)-c_1| + |y(s)-z(s)|)\|\tilde v\|_{W^{1,2}(\alpha_2,b)}\} + \delta\|\tilde v\|_{L^2(\alpha_2,b)} \\ &\quad\le s^{-3/4-\eta}\langle s\rangle^{-r+3/4+\eta}C(M)(M_2+M_4)(M_2+M_3+M_5) \\ &\qquad + s^{-3/4-\eta}\langle s\rangle^{-r+3/4+\eta}C(M)(M_0+M_1)(M_2+M_4+M_5) + \langle s\rangle^{-r}\delta(M_2+M_4),\end{aligned} \tag{4.11}$$

where $\delta = \sup_{0\le\theta\le1}|f''(\varphi_{c(s)}(y)+\theta\tilde v) - f''(\varphi_{c_1}(z))|$. We see that $\delta = 0$ if $f(u) = u^2$ and that δ is a positive number that tends to 0 as $\sum_{0\le i\le 3} M_i \to 0$ if $p > 1$.

Let $\alpha_1 = \alpha_2 + r + 1$. Applying Corollary 2.9 to (4.3) and using (4.10) and (4.11), we have

$$\begin{aligned}
&\|h\|_{L^2(\alpha_2,b)}\\
&\le C\langle t\rangle^{-r}\|Q_{c_1}\tilde{v}(0)\|_{L^2(\alpha_1,b)}\\
&\quad + C\int_0^t \langle t-s\rangle^{-r+1/4}|t-s|^{-1/4}\|Q_{c_1}\partial_z\widetilde{N}(s,\tilde{v})\|_{L^1(\alpha_1-1/2,b)}\\
&\quad + C\int_0^t \langle t-s\rangle^{-r}\|Q_{c_1}(\dot{c}\partial_c + \dot{\gamma}\partial_z)\varphi_{c(s)}(y)\|_{L^2(\alpha_1,b)}\\
&\le C\langle t\rangle^{-r}\|Q_{c_1}\tilde{v}(0)\|_{L^2(\alpha_1,b)} + \langle t\rangle^{-r}(M_2+M_4)\{\delta + C(M)(M_2+M_3+M_5)\}\\
&\quad + \langle t\rangle^{-r}C(M)\{(M_0+M_1)(M_2+M_4+M_5) + (M_2^2+M_4^2)\}
\end{aligned}$$

and

$$\begin{aligned}
&\|\partial_z h\|_{L^2(\alpha_2,b)}\\
&\le Ct^{-3/4}\langle t\rangle^{-r+3/4}\|Q_{c_1}\tilde{v}(0)\|_{L^2(\alpha_1,b)}\\
&\quad + C\int_0^t \langle t-s\rangle^{-r+3/4}|t-s|^{-3/4}\|Q_{c_1}\partial_z\widetilde{N}(s,\tilde{v})\|_{L^1(\alpha_1-1/2,b)}\\
&\quad + C\int_0^t \langle t-s\rangle^{-r+3/4}|t-s|^{-3/4}\|Q_{c_1}(\dot{c}\partial_c + \dot{\gamma}\partial_z)\varphi_{c(s)}(y)\|_{L^2(\alpha_1,b)}\\
&\le Ct^{-3/4}\langle t\rangle^{-r+3/4}\|Q_{c_1}\tilde{v}(0)\|_{L^2(\alpha_1,b)}\\
&\quad + t^{-1/2-\eta}\langle t\rangle^{-r+1/2+\eta}(M_2+M_4)\{\delta + C(M)(M_2+M_3+M_5)\}\\
&\quad + C(M)t^{-1/2-\eta}\langle t\rangle^{-r+1/2+\eta}(M_0+M_1)(M_2+M_4+M_5)\\
&\quad + C(M)\langle t\rangle^{-r}(M_2^2+M_4^2).
\end{aligned}$$

Thus we have (4.9). Furthermore, we get $\lim_{t\downarrow 0} M_5(t) = 0$.

Finally, we estimate the H^1-norm of the residual part. As in [28, p. 335], the H^1-estimate can be obtained by using the Lyapunov stability analysis and the local energy decay of v. Let E be the functional defined by

$$E[u] = \int \left(\frac{1}{2}u_x^2 + \frac{c_0}{2}u^2 - F(u)\right) dx,$$

where $F' = f$ with $F(0) = 0$. Put $k = u(x,t) - \varphi_{c_0}(y) = v(y,t) + \varphi_{c(t)}(y) - \varphi_{c_0}(y)$. Since φ_{c_0} is a critical point of the functional E,

$$E[u] - E[\varphi_{c_0}] = \frac{1}{2}\int \left(k_y^2 + c_0k^2 - 2f'(\varphi_{c_0})k^2\right) dy + O(\|k\|_{1,0}^3). \tag{4.12}$$

Note that $\delta E := E[u] - E[\varphi_{c_0}]$ is constant in time and that

$$|\delta E| = |E[\varphi_{c_0} + v_0] - E[\varphi_{c_0}]| \le C\|v_0\|_{1,0}^2.$$

As can be easily seen,

$$|\|k\|_{1,0} - \|v\|_{1,0}| \le C|c(t) - c_0|,$$

$$\int f'(\varphi_{c_0})k^2 dy \le C(\|v\|_{L^2(\alpha_2,b)} + |c(t) - c_0|)^2.$$

Combining these inequalities with (4.12), we have

$$\|v\|_{1,0}^2 \le C(\delta E + |c(t) - c_0|^2 + \|v\|_{L^2(\alpha_2,b)}^2). \tag{4.13}$$

By (4.10),

$$|c(t) - c_0| + |\gamma(t) - \gamma_0| \le |c(0) - c_0| + |\gamma(0) - \gamma_0| + C(M)(M_2^2 + M_4^2). \tag{4.14}$$

Applying Proposition 3.1 with $t_1 = 0$, we see that the map $v_0 \mapsto (c(0), \gamma(0))$ is C^1 in a small neighborhood of the origin. In particular, the map is locally Lipschitz continuous and

$$|c(0) - c_0| + |\gamma(0) - \gamma_0| \le C\|v_0\|_{L^2(\alpha_2,b)}. \tag{4.15}$$

Combining (4.13)–(4.15), we have (4.8). □

COROLLARY 4.2. *Let p, α_1, α_2, and b be positive numbers as in Theorem* 2.2. *Then, there exist $\varepsilon_0 > 0$ and $C > 0$ such that*

$$\|v_0\|_{1,0} + \|v_0\|_{L^2(\alpha_1,b)} = \varepsilon < \varepsilon_0$$

implies

$$\sum_{i=0}^{5} M_i(t) \le C\varepsilon \quad \textit{for every } t \ge 0.$$

Proof. In view of (4.15) and $\tilde{v}(z,0) = v_0(x) + \varphi_{c_0}(x + \gamma_0) - \varphi_{c(0)}(x + \gamma(0))$, we have

$$\|\tilde{v}(0)\|_{L^2_z(\alpha_1,b)} \le C(M)\|v_0\|_{L^2(\alpha_1,b)}. \tag{4.16}$$

By Proposition 4.1 and (4.16),

$$\sum_{i=0}^{5} M_i(t) \le C(M)\varepsilon + \delta(M_2(t) + M_4(t)) + W(M_0(t), \dots, M_5(t)), \tag{4.17}$$

where $W = O(\sum_{i=0}^{5} M_i^2)$ and $\delta = o(1)$ as $\sum_{i=0}^{5} M_i \to 0$. So, if ε is sufficiently small, the solution of (4.17) can belong either to a small neighborhood of 0 or to a domain whose distance from 0 is bounded from below uniformly with respect to ε. Since $M_i(t) \in C([0,t_1];\mathbb{R})$ $(0 \le i \le 5)$ follows Proposition 3.1, Lemma 3.2, and the fact that $\lim_{t\downarrow 0} M_5(t) = 0$, there exists a $C > 0$ such that

$$\sum_{i=0}^{5} M_i(t) \le C\varepsilon \quad \text{for } t \in [0,t_1]. \tag{4.18}$$

Let T be the supremum of the set of all positive numbers t_1, for which the solution $u(x,t)$ has a decomposition (3.1)–(3.2) for $t \in [0,t_1]$. The proof of Corollary 4.2 will be complete if we obtain $T=\infty$. Suppose that $T<\infty$ and put $c_*=c(T-t_0/2)$, $\gamma_*=-\int_0^{T-t_0/2}c(s)ds+\gamma(T-t_0/2)$, and $\tilde{u}(x,t)=u(x-\gamma_*,t+T-t_0/2)$, where t_0 is a positive number to be fixed later. By (4.6), (4.9), (4.15), and (4.18), we obtain

$$\begin{aligned}\|\tilde{u}(x,0)-\varphi_{c_0}(x)\|_{L^2(\alpha_2,b)} &\le \|v(x,T-t_0/2)\|_{L^2(\alpha_2,b)}+\|\varphi_{c_*}-\varphi_{c_0}\|_{L^2(\alpha_2,b)}\\ &\le C\varepsilon,\end{aligned}$$

where C is a positive number which does not depend on ε and t_0. Therefore, if ε_0 is sufficiently small, there exists a $t_0>0$ such that $\tilde{u}(x,t)$ satisfies the hypothesis of Proposition 3.1. (Note that δ_0 in Proposition 3.1 can be chosen as a decreasing function of t_0.) From $\tilde{u}$, we get $(\tilde{\gamma}(t),\tilde{c}(t))$ that satisfies $(\tilde{\gamma}(0),\tilde{c}(0))=(\gamma_*,c_*)$. Then the extension can be defined by $(\gamma(t),c(t))=(\tilde{\gamma}(t-T+t_0/2)-\gamma_*+\gamma(T-t_0/2),\tilde{c}(t+T-T_{\tilde{0}}/2))$ for $T-T_0/2\le t\le T+t_0/2$, which contradicts the definition of T. Thus we have $T=\infty$. □

Now, we are in position to prove Theorem 2.2.

Proof of Theorem 2.2. Corollary 4.2 and (4.10) imply that there exists a $C>0$ such that

$$|\dot{\gamma}(t)|+|\dot{c}(t)|\le C\varepsilon(1+t)^{-2r}\quad\text{for every } t\ge 0.$$

Hence,

$$c_+=\lim_{t\to\infty}c(t)\quad\text{and}\quad\gamma_+=\lim_{t\to\infty}\left(\gamma(t)-\int_0^t(c(s)-c_+)ds\right)$$

exist and satisfy $|c(t)-c_+|\le C\varepsilon(1+t)^{-2r+1}$ and $|y(t)-z(t)|\le C\varepsilon(1+t)^{-2r+2}$, where $z(t)=x-c_+t+\gamma_+$. Using Corollary 4.2 and the above estimates, we have

$$\begin{aligned}&\|u(\cdot+c_+t-\gamma_+,t)-\varphi_{c_+}(\cdot)\|_{W^{1,2}(\alpha_2,b)}\\ \le&\|\tilde{v}(x,t)\|_{W^{1,2}(\alpha_2,b)}+\|\varphi_{c(t)}(\cdot+y(t)-z(t))-\varphi_{c_+}\|_{W^{1,2}(\alpha_2,b)}\\ \le&C\varepsilon t^{-r}\end{aligned}$$

and

$$\|u(\cdot+c_+t-\gamma_+,t)-\varphi_{c_+}(\cdot)\|_{1,0}\le\|\tilde{v}(x,t)\|_{1,0}+\|\varphi_{c(t)}(\cdot+y(t)-z(t))-\varphi_{c_+}\|_{1,0}\le C\varepsilon.$$

In view of (4.10), (4.15), and Corollary 4.2, we have (2.7). Thus we complete the proof of Theorem 2.2. □

Finally, we will show the boundedness of

$$\begin{aligned}M_6&=\sup_{\tau\ge0}\langle\tau\rangle^{r-1/4}\tau^{1/4}\|h(\cdot,\tau)\|_{L^q(\alpha_3,b)},\\ M_7&=\sup_{\tau\ge0}\tau^{3/4}\langle\tau\rangle^{r-3/4}\|h_z(\cdot,\tau)\|_{L^q(\alpha_3,b)}\end{aligned}$$

for $2\le q\le\infty$, which shall be used in the next section.

LEMMA 4.3. *Let p, α_1, α_2, r, and b be positive numbers as in Theorem* 2.2. *Assume that $2\le q\le\infty$ and $1<\alpha_3\le r+1-1/q$. Then, there exist $C>0$ and $\varepsilon_0>0$ such that*

$$\|v_0\|_{1,0}+\|v_0\|_{L^2(\alpha_1,b)}=\varepsilon<\varepsilon_0$$

implies

$$M_6 + M_7 \le C\varepsilon.$$

Proof. Applying Corollary 2.9 to (4.3), we have

$$\begin{aligned}\|h\|_{L^q(\alpha_3,b)} &\le C\langle t\rangle^{-r+1/4}t^{-1/4}\|Q_{c_+}\tilde{v}(0)\|_{L^2(\alpha_1,b)}\\ &\quad + C\int_0^t \langle t-s\rangle^{-r+1/3}|t-s|^{-1/3}\|Q_{c_+}\partial_z\widetilde{N}(s,\tilde{v})\|_{L^1(\alpha_3+r+1/q,b)}\\ &\quad + C\int_0^t \langle t-s\rangle^{-r+1/4}|t-s|^{-1/4}\|Q_{c_1}(\dot{c}\partial_c+\dot{\gamma}\partial_z)\varphi_{c(s)}(y)\|_{L^2(\alpha_1,b)}\end{aligned}$$

and

$$\begin{aligned}\|h_z\|_{L^q(\alpha_3,b)} &\le C\langle t\rangle^{-r+3/4}t^{-3/4}\|Q_{c_+}\tilde{v}(0)\|_{L^2(\alpha_1,b)}\\ &\quad + C\int_0^t \langle t-s\rangle^{-r+3/4}|t-s|^{-3/4}\|Q_{c_+}\partial_z\widetilde{N}(s,\tilde{v})\|_{L^1(\alpha_3+r+1/q,b)}\\ &\quad + C\int_0^t \langle t-s\rangle^{-r+3/4}|t-s|^{-3/4}\|Q_{c_1}(\dot{c}\partial_c+\dot{\gamma}\partial_z)\varphi_{c(s)}(y)\|_{L^2(\alpha_1,b)}.\end{aligned}$$

Substituting (4.10) and (4.11) into the above inequalities and applying Corollary 4.2, we have $M_6 + M_7 \le C\varepsilon$. Thus we have proved Lemma 4.3. □

5. Scattering. In this section, we will prove Theorem 2.4. Let

$$u(x,t) = \varphi_{c_+}(z) + w(x,t) \quad \text{and} \quad z = x - c_+t + \gamma_+.$$

Then

$$w_t + w_{xxx} + f(\varphi_{c_+}+w)_x - f(\varphi_{c_+})_x = 0 \quad \text{for } x\in\mathbb{R} \text{ and } t>0. \tag{5.1}$$

The ingredient to prove the existence of scattering states is to show

$$\sup_{x\in\mathbb{R}}|w(x,t)| \le C(1+t)^{-1/3}. \tag{5.2}$$

Our strategy to obtain (5.2) is to combine the method due to Hayashi and Naumkin [16] with the local energy decay estimate obtained in section 4.

Let L and I be the operators defined by

$$L\phi = \partial_t\phi + \partial_x^3\phi, \quad I\phi = x\phi + 3t\int_{-\infty}^x \partial_t\phi dx', \quad J\phi = (x - 3t\partial_x^2)\phi \tag{5.3}$$

for $\phi\in C_0^\infty(\mathbb{R}^2)$. Note that

$$[L,J]=0, \quad [L,I] = 3\int_{-\infty}^x L\phi dx', \quad [I,\partial_x]\phi = [J,\partial_x]\phi = -\phi. \tag{5.4}$$

To prove (5.2), we need the following lemma.

LEMMA 5.1 (see Hayashi and Naumkin [16]). *Let*

$$N[u](t) := \|u(t)\|_{1,0} + \|D_x^\alpha Ju(t)\| + \|D_xJu(t)\| + |\overline{u}(t)|, \quad \overline{u}(t) = \int_{\mathbb{R}} u(x,t)dx.$$

If $q \in (4,\infty]$ and $u(x,t)$ is a smooth function with $\sup_{t\geq 0} N[u](t) < \infty$ for an $\alpha \in (0,1/2)$, then there exists a $C>0$ such that

$$\|u\|_{L^q} \leq C(1+t)^{-1/3+1/(3q)} N[u](t),$$
$$\|uu_x\|_{L^\infty} \leq Ct^{-2/3}(1+t)^{-1/3} N[u]^2(t)$$

for every $t \geq 0$.

Now, we will show the boundedness of $N[w]$.

PROPOSITION 5.2. *Let p, α be as in Theorem 2.4, and let β be a number with $\beta = 1/2-\gamma$ and $0<\gamma<\min\{1/2,(p-2)/3\}$. Then, there exist positive numbers ε_0 and C such that, for every $0<\varepsilon<\varepsilon_0$ and $t\geq 0$,*

$$\|(1+x_+)^\alpha v_0\| + \|v_0\|_{1,1} = \varepsilon < \varepsilon_0$$

implies

$$N[w](t) = \|w(t)\|_{1,0} + \|D^\beta Jw(t)\| + \|\partial_x Jw(t)\| + |\overline{w}(t)| \leq C\varepsilon. \tag{5.5}$$

Proof. To begin with, we remark that the solution u to (1.1)–(1.2) with $p>2$ and $u_0 \in H^{1,1}$ locally exists in time and satisfies $N[u](t)<\infty$ (see [16] and the references therein).

Now, we estimate each term of $N[w]$. Noting that

$$w(x,t) = \tilde{v}(z,t) + \varphi_{c(t)}(y) - \varphi_{c_+}(z), \tag{5.6}$$

and using Corollary 4.2 and (5.1), we have

$$\begin{aligned} \|w\|_{1,0} &\leq \|\tilde{v}(z,t)\|_{1,0} + \|\varphi_{c(t)}(y) - \varphi_{c_+}(z)\|_{1,0} \\ &\leq C(\|v_0\|_{1,0} + \|v_0\|_{L^2(\alpha_1,b)}) \end{aligned} \tag{5.7}$$

and

$$\begin{aligned} |\overline{w}(t)| = |\overline{w}(0)| &\leq C\|w(0)\|_{1,1} \\ &\leq C(\|v_0\|_{1,1} + \|v_0\|_{L^2(\alpha_1,b)}). \end{aligned} \tag{5.8}$$

By (5.1), (5.3), and (5.4),

$$\begin{aligned} LIw &= ILw + 3\int_{-\infty}^x Lw dx' \\ &= (x\partial_x + 3t\partial_t + 3)\{f(\varphi_{c+}) - f(\varphi_{c+}+w)\} \\ &= f'(\varphi_{c_+})I\varphi_{c_+,x} - f'(\varphi_{c_+}+w)I(\varphi_{c_+}+w)_x \\ &\quad + 3(f(\varphi_{c+}) - f(\varphi_{c+}+w)). \end{aligned} \tag{5.9}$$

Applying D^β to (5.9), taking an inner product of the resulting equation and $D^\beta Iw$ in L^2, and using (5.4), we have

$$\frac{d}{dt}\|D^\beta Iw\|^2 = -2(K_1+K_2+K_3+K_4+K_5), \tag{5.10}$$

where

$$
\begin{aligned}
K_1 &= (D^\beta Iw, D^\beta\{(f'(\varphi_{c_+}+w)-f'(\varphi_{c_+}))(I\varphi_{c_+})_x\}),\\
K_2 &= (D^\beta Iw, D^\beta\{f'(w)(Iw)_x\}),\\
K_3 &= (D^\beta Iw, D^\beta\{(f'(\varphi_{c_+}+w)-f'(w))(Iw)_x\}),\\
K_4 &= (D^\beta Iw, D^\beta\{g(\varphi_{c_+}+w)-g(\varphi_{c_+})-g(w)\}),\\
K_5 &= (D^\beta Iw, D^\beta g(w)),
\end{aligned}
$$

where $g(v)=3f(v)-f'(v)v$.

Multiplying (5.9) by $(Iw)_{xx}$ and integrating the resulting equation by parts, we have

$$
\frac{d}{dt}\|(Iw)_x\|^2 = -2(K_6+K_7+K_8+K_9), \tag{5.11}
$$

where

$$
\begin{aligned}
K_6 &= ((Iw)_x, \{(f'(\varphi_{c_+}+w)-f'(\varphi_{c_+}))(I\varphi_{c_+})_x\}_x),\\
K_7 &= \frac{1}{2}\int |(Iw)_x|^2 f''(w)w_x dx + \int (Iw)_x g'(w)w_x dx,\\
K_8 &= \frac{1}{2}\int |(Iw)_x|^2\{(f'(\varphi_{c_+}+w)-f'(w))\}_x dx,\\
K_9 &= ((Iw)_x, \{g(\varphi_{c_+}+w)-g(\varphi_{c_+})-g(w)\}_x).
\end{aligned}
$$

Using (5.6), $(I\varphi_{c_+})_x = (z-2c_+t-\gamma_+)\varphi'_{c_+}(z)+\varphi_{c_+}(z)$, and Corollary 4.2, we have

$$
\begin{aligned}
|K_1| &\le C\|D^\beta Iw\|\left\|\int_0^1 f''(\varphi_{c_+}+\theta w)d\theta w(I\varphi_{c_+})_x\right\|_{1,0}\\
&\le C(1+t)\|D^\beta Iw\|(\|\tilde v\|_{W^{1,2}(\alpha_1,b)}+|c(t)-c_+|+|y(t)-z(t)|)\\
&\le Ct^{-3/4}(1+t)^{-r+7/4}\|D^\beta Iw\|(M_0+M_1+M_4+M_5)\\
&\le C\varepsilon t^{-3/4}(1+t)^{-r+7/4}\|D^\beta Iw\|,
\end{aligned}
$$

$$
\begin{aligned}
|K_4| &\le C\|D^\beta Iw\|\left\|\int_0^1 g''(\theta_1\varphi_{c_+}+\theta_2 w)d\theta_1 d\theta_2\varphi_{c_+}w\right\|_{1,0}\\
&\le Ct^{-3/4}(1+t)^{-r+3/4}\|D^\beta Iw\|(M_0+M_1+M_4+M_5)\\
&\le C\varepsilon t^{-3/4}(1+t)^{-r+3/4}\|D^\beta Iw\|
\end{aligned}
$$

for $r\ge 2$. Here we used the fact that $\min\{r,2r-2\}=r$ for $r\ge 2$. Similarly, we have

$$
\begin{aligned}
|K_6| &\le C\varepsilon t^{-3/4}(1+t)^{-r+7/4}\|(Iw)_x\|,\\
|K_9| &\le C\varepsilon t^{-3/4}(1+t)^{-r+3/4}\|(Iw)_x\|.
\end{aligned}
$$

By Lemma 2.3 of [16], we have

$$\begin{aligned}|K_2| &\le C\|D^\beta Iw\|(\|D^\beta Iw\| + \|(Iw)_x\|)(\|w\|_\infty^{p-2}\|ww_x\|_\infty + \|w\|_\infty^{p-2-2\gamma}\|w\|^{2\gamma}\|ww_x\|_\infty \\ &\qquad + \|w\|_\infty^{p-2+2\gamma}\|ww_x\|_\infty^{1-\gamma}) \\ &\le C(N[w])^p t^{-2/3}\langle t\rangle^{-(p-1-2\gamma)/3}\|D^\beta Iw\|(\|D^\beta Iw\| + \|(Iw)_x\|), \\ |K_5| &\le C\|D^\beta Iw\|\|w\|_{2p}^p(\|ww_x\|_\infty^{1/2} + \|w\|_\infty^{3\gamma}\|ww_x\|_\infty^{(1-3\gamma)/2}) \\ &\le C(N[w])^{p+1}t^{-1/3}\langle t\rangle^{-p/3+\gamma/2}\|D^\beta Iw\|, \\ |K_7| &\le C\|w\|_\infty^{p-2}\|ww_x\|_\infty\|(Iw)_x\|(\|(Iw)_x\| + \|w\|) \\ &\le C(N[w])^p t^{-2/3}\langle t\rangle^{-(p-1)/3}(N[w] + \|(Iw)_x\|)\|(Iw)_x\|.\end{aligned}$$

To estimate K_3 and K_8, we will show the boundedness of

$$M_8(t) = \sup_{0\le\tau\le t} \tau^{-3/4}\langle\tau\rangle^{-r+7/4}\|(Iw)_x\|_{L^2(\alpha_4,b)},$$

where $\alpha_4 = \alpha_2 - 1$. Differentiating (5.9) by x, we have

$$L(Iw)_x + \partial_x(f'(\varphi_{c_+})(Iw)_x) = -\partial_x(I_1 + I_2), \tag{5.12}$$

where

$$\begin{aligned}I_1 &= \{f'(\varphi_{c_+} + w) - f'(\varphi_{c_+})\}(Iw)_x, \\ I_2 &= g(\varphi_{c_+} + w) - g(\varphi_{c_+}) + \{f'(\varphi_{c_+} + w) - f'(\varphi_{c_+})\}(I\varphi_{c_+})_x.\end{aligned}$$

Making use of the change of variables $z = x - c_+t + \gamma_+$ and the variation of constants formula, we can rewrite (5.12) into

$$\psi(t) = U_{c_+}(t)\psi(0) - \int_0^t U_{c_+}(t-s)\partial_z(I_1 + I_2)ds,$$

where $\psi(z,t) = (Iw)_x(x,t)$. Applying Corollary 2.10 to the equation above, we have

$$\begin{aligned}&\|Q_{c_+}\psi(t)\|_{L^2(\alpha_4,b)} \\ &\le \|U_{c_+}(t)Q_{c_+}\psi(0)\|_{L^2(\alpha_4,b)} + \int_0^t \|U_{c_+}(t-s)Q_{c_+}\partial_z(I_1+I_2)\|_{L^2(\alpha_4,b)}ds \\ &\le Ct^{-3/4}\langle t\rangle^{-r+3/4}\|\psi(0)\|_{L^{-1,2}(\alpha_1-1,b)} \\ &\quad + C\int_0^t |t-s|^{-3/4}\langle t-s\rangle^{-r+3/4}\|\partial_z(I_1+I_2)\|_{L^{-1,2}(\alpha_1-1,b)}.\end{aligned} \tag{5.13}$$

Clearly,

$$\|\psi(0)\|_{L^{-1,2}(\alpha_1-1,b)} \le \|xw(0)\|_{L^2(\alpha_1-1,b)} \le C\|(1+x_+)^{\alpha_1}w(0)\|. \tag{5.14}$$

Since $\|\partial_z I_2\|_{L^{-1,2}(\alpha_1-1,b)} \le C(1+s)\|w\|_{L^2(\alpha_2,b)}$ and

$$\begin{aligned}\|\partial_z I_1\|_{L^{-1,2}(\alpha_1-1,b)} &\le C\|(|\varphi_{c_+}| + |w|)^{p-1}w(Iw)_x\|_{L^2(\alpha_1-1,b)} \\ &\le C\|(Iw)_x\|\|w\|_{L^\infty(\alpha_3,b)}(1 + \|w\|_{L^\infty(\alpha_3,b)}\|w\|_\infty^{p-2})\end{aligned}$$

for $\alpha_3 = (\alpha_1 - 1)/2 = r + 1/4$, it follows from (5.13), (5.14), Corollary 4.2, and Lemma 4.3 that

$$\begin{aligned}\|Q_{c_+}\psi(t)\|_{L^2(\alpha_4,b)} &\le Ct^{-3/4}\langle t\rangle^{-r+3/4}\|(1+x_+)^{\alpha_1}w(0)\| \\ &\quad + C\left\{M_4 + \sup_{0\le s\le t}\|(Iw)_x\|(M_0+M_1+M_2+M_6)\right\} \\ &\quad \times \int_0^t |t-s|^{-3/4}\langle t-s\rangle^{-r+3/4}s^{-2/3}\langle s\rangle^{-r+5/3}ds \\ &\le C\varepsilon t^{-3/4}\langle t\rangle^{-r+7/4}\left(1+\sup_{0\le s\le t}\|(Iw)_x\|\right).\end{aligned} \tag{5.15}$$

On the other hand, by (2.6), (5.1), and (5.3),

$$\begin{aligned}\|P_{c_+}\psi(t)\|_{L^2(\alpha_4,b)} &\le \sum_{i=1}^{2}\|\langle (xw)_x + 3tw_t, \eta_i\rangle\xi_i\|_{L^2(\alpha_4,b)} \\ &\le C(1+t)\|w\|_{L^2(\alpha_2,b)}.\end{aligned} \tag{5.16}$$

Hence, it follows from (5.15) and (5.16) that

$$M_8(t) \le C\varepsilon\left(1+\sup_{0\le s\le t}\|(Iw)_x\|\right) \quad \text{for } t \ge 0.$$

Now, we turn to the estimate of K_3 and K_8. It follows that

$$\begin{aligned}|K_3| &\le (\|D^\beta Iw\| + \|(Iw)_x\|)\left\|\int_0^1 f''(\theta\varphi_{c_+}+w)d\theta\varphi_{c_+}(Iw)_x\right\| \\ &\le C(\|D^\beta Iw\| + \|(Iw)_x\|)\|\varphi_{c_+}(Iw)_x\| \\ &\le C\varepsilon t^{-3/4}\langle t\rangle^{-r+7/4}(\|D^\beta Iw\| + \|(Iw)_x\|)\left(1+\sup_{0\le s\le t}\|(Iw)_x\|\right).\end{aligned}$$

Furthermore, we have

$$\begin{aligned}|K_8| &\le C\int |(Iw)_x|^2|\left\{\int_0^1 f''(\theta\varphi_{c_+}+w)d\theta\varphi_{c_+}\right\}_x|dx \\ &\le C\|(Iw)_x\|(\|(Iw)_x\|_{L^2(\alpha_4,b)} + \|(Iw)_x\|\|w_x\|_{L^\infty(\alpha_3,b)}) \\ &\le Ct^{-3/4}\langle t\rangle^{-r+7/4}(M_8 + M_7\|(Iw)_x\|)\|(Iw)_x\| \\ &\le C\varepsilon t^{-3/4}\langle t\rangle^{-r+7/4}\left(1+\sup_{0\le s\le t}\|(Iw)_x\|\right)\|(Iw)_x\|.\end{aligned}$$

Substituting the above estimates of K_i $(6 \le i \le 9)$ into (5.11), we have

$$\begin{aligned}\frac{d}{dt}\|(Iw)_x\| \le& C\{\varepsilon t^{-3/4}\langle t\rangle^{-r+7/4} + (N[w])^{p+1}t^{-2/3}\langle t\rangle^{-(p-1)/3}\} \\ &+ C\{\varepsilon t^{-3/4}\langle t\rangle^{-r+7/4} + t^{-2/3}\langle t\rangle^{-(p-1)/3}(N[w])^p\}\sup_{0\le s\le t}\|(Iw)_x\|.\end{aligned}$$

Applying the Gronwall inequality, we have

$$\sup_{0\le s\le t}\|(Iw)_x\| \le C\sup_{0\le s\le t}\left\{(\varepsilon + (N[w])^p)\exp\left(\varepsilon + (N[w])^p\right)\right\}.$$

Substituting the estimates of K_i $(1 \le i \le 5)$ and that of $\|(Iw)_x\|$ into (5.10) and applying the Gronwall inequality, we have

$$\sup_{0\le s\le t} \|D^\beta Iw\| \le C\left(\sup_{0\le s\le t} N[w], \varepsilon\right) \sup_{0\le s\le t} \{\varepsilon + (N[w])^p\},$$

where C is bounded in some neighborhood of $(0,0)$. Combining these with (5.3) and Corollary 4.2, we have

(5.17)
$$\begin{aligned}\|D^\beta Jw\| + \|(Jw)_x\| &\le \|D^\beta Iw\| + \|(Iw)_x\| + 3t\|D^\beta\{f(\varphi_{c_+}+w) - f(\varphi_{c_+})\}\| \\ &\quad + 3t\|\{f(\varphi_{c_+}+w) - f(\varphi_{c_+})\}_x\| \\ &\le C\left(\sup_{0\le s\le t} N[w], \varepsilon\right) \sup_{0\le s\le t} (\varepsilon + (N[w])^p).\end{aligned}$$

Hence, if ε is sufficiently small, the inequality (5.5) follows from (5.7), (5.8), and (5.17). Thus we complete the proof. □

We are now in position to prove our main result.

Proof of Theorem 2.4. It follows from (5.1), Corollary 4.2, and Proposition 5.2 that

$$\begin{aligned}\|T(-t)w(t) - T(-s)w(s)\| &\le \int_s^t \|\{f(\varphi_{c_+}+w) - f(\varphi_{c_+})\}_x\| d\tau \\ &\le C\int_s^t (\|w\|_{W^{1,2}(\alpha_1,b)} + \|w\|_\infty^{p-2}\|ww_x\|_\infty\|w\|) d\tau \\ &\le C\varepsilon s^{-(p-2)/3}\end{aligned}$$

for $1 \le s \le t$. Therefore, there exists a $V \in L^2$ satisfying (2.10). This completes the proof of Theorem 2.4. □

Appendix A. In this section, we give the proofs of Lemma 2.7 and Corollaries 2.9 and 2.10, which is a generalization of Theorem 1.1 in [24]. The main difference between the weighted L^p-L^q estimate stated in section 2 and that of Miller [24] is that the indices p and q need not be equal in our case.

To start, let us introduce several notations. For Banach spaces X and Y, we denote the space of linear continuous operator by $\mathcal{L}(X,Y)$ and the space of linear compact operator by $\mathcal{L}_C(X,Y)$. We abbreviate $\mathcal{L}(X,X)$ and $\mathcal{L}_C(X,X)$ as $\mathcal{L}(X)$ and $\mathcal{L}_C(X)$, respectively. Let $A_{0,c} = -\partial_x^3 + c\partial_x$ and $T_c = A_{[c]} - A_{0,c}$. We define the resolvent operator of $A_{0,c}$ and $A_{[c]}$ as $R_0(\lambda;c) = (\lambda - A_{0,c})^{-1}$ and $R(\lambda;c) = (\lambda - A_{[c]})^{-1}$, respectively. For a linear subspace W of X, we denote by ${}^\perp W$ the subspace $\{g \in X^* \,|\, \langle g, u\rangle = 0 \text{ for every } u \in W\}$.

The proof of Lemma 2.7 basically follows the lines of Miller [24]. However, there is a mistake to be fixed in [24], although it is not so serious. In fact, she claims that $(1 - R_0(0;c)T_c)^{-1} \in \mathcal{L}(L^p(\alpha,b), Q_c L^p(\alpha,b))$ in Proposition 3.7 and Lemma 3.6 of [24]. But the Fredholm alternative theorem tells us that

$$(1 - R_0(0;c)T_c)u = A_{0,c}\varphi_c$$

does not have any solution in $L^p(\alpha,b)$ because $\mathrm{Ker}(1 - R_0(0;c)T_c)^* = \{\alpha A_{0,c}\varphi_c \,|\, \alpha \in \mathbb{C}\}$. For the sake of the reader's convenience, we shall give the complete proof of the resolvent expansion of $R(\lambda;c)$ around $\lambda = 0$ following the lines of Murata [25].

The first step is an examination of the free resolvent $R_0(\lambda;c)$ on $\Sigma := \{\lambda \,|\, \mathrm{Re}\,\lambda > 0\}$.

LEMMA A.1.

(i) *Let $m = 0,\ 1,\ 2,\ 3,\ k,\ r \in \mathbb{N} \cup \{0\}$, and $1 \le q_1 \le q_2 \le \infty$. Let $\alpha_1 \ge \alpha_2 + r + 1 + 1/q_2 - 1/q_1$, $\alpha_2 > 0$, and $b > 0$ be a small number. Then $R_0^{(i)}(\lambda;c) \in C\left(\overline{\Sigma} \times (0,\infty); \mathcal{L}(W^{k,q_1}(\alpha_1,b), W^{k+3,q_2}(\alpha_2,b))\right)$ for $0 \le i \le r$ and there exists a $C > 0$ such that*

$$\|R_0^{(i)}(\lambda;c)\|_{\mathcal{L}(W^{k,q_1}(\alpha_1,b);W^{k+m,q_2}(\alpha_2,b))} \le C\langle\lambda\rangle^{-2(i+1)/3+m/3} \tag{A.1}$$

for $\lambda \in \overline{\Sigma}$. For every compact subset I of $(0,\infty)$, the constant C in (A.1) *can be chosen uniformly for all $c \in I$.*

(ii) *Let r, m, α_1, α_2, and b be as in* (i). *Let $k \in \mathbb{Z}$ and $1 < q_1 \le q_2 < \infty$. Then there exists a $C > 0$ such that*

$$\|R_0^{(i)}(\lambda;c)\|_{\mathcal{L}(L^{k,q_1}(\alpha_1,b);L^{k+m,q_2}(\alpha_2,b))} \le C\langle\lambda\rangle^{-2(i+1)/3+m/3}. \tag{A.2}$$

For every compact subset I of $(0,\infty)$, the constant C in (A.2) *can be chosen uniformly for all $c \in I$.*

Proof. The equation

$$\mu^3 - c\mu + \lambda = 0$$

has roots $\mu_i(\lambda;c)$ $(i = 1,2,3)$ which satisfy

$$\mathrm{Re}\,\mu_1(\lambda;c) < 0 < \mathrm{Re}\,\mu_2(\lambda;c) \le \mathrm{Re}\,\mu_3(\lambda;c)$$

for $\lambda \in \Sigma$ and

$$\mathrm{Re}\,\mu_1(\lambda;c) < 0 = \mathrm{Re}\,\mu_2(\lambda;c) < \mathrm{Re}\,\mu_3(\lambda;c)$$

for $\lambda \in \partial\Sigma$. The roots $\mu_i(\lambda;c)$ $(i = 1,2,3)$ are continuous in λ and c. Moreover, they satisfy

$$\mu_1(\lambda;c) = -\sqrt{c} + O(\lambda), \quad \mu_2(\lambda;c) = \lambda/c + O(\lambda^3), \quad \mu_3(\lambda;c) = \sqrt{c} + O(\lambda)$$

around $\lambda = 0$ and

$$\mu_i(\lambda;c) = (-\lambda)^{1/3} + O(|\lambda|^{-1/3}) \tag{A.3}$$

uniformly as $\lambda \to \infty$ in Σ (see [27], [28]). So if I is a compact subset of $(0,\infty)$, we have $\mu_* = \sup_{c\in I} \sup_{\lambda\in\Sigma} \mathrm{Re}\,\mu_1(\lambda;c) < 0$.

Let $K_0(x,\lambda;c)$ be the kernel of $R_0(\lambda;c)$. Then, for $\lambda \in \overline{\Sigma}$ with $\lambda \ne 2(c/3)^{3/2}$ (i.e., $\mu_2 \ne \mu_3$), the kernel of $R_0(\lambda;c)$ is given by

$$K_0(x,\lambda;c) = \begin{cases} a_1(\lambda;c)e^{\mu_1(\lambda;c)x} & \text{for } x \ge 0, \\ -a_2(\lambda;c)e^{\mu_2(\lambda;c)x} - a_3(\lambda;c)e^{\mu_3(\lambda;c)x} & \text{for } x \le 0, \end{cases} \tag{A.4}$$

where $a_i(\lambda;c) = \prod_{j\ne i}(\mu_i(\lambda;c) - \mu_j(\lambda;c))^{-1}$. Put

$$\widetilde{K}_{r,m}(x,y,\lambda;c) = |h_{\alpha_2,b}(x)\partial_\lambda^r \partial_x^m K_0(x-y,\lambda;c) h_{\alpha_1,b}(y)^{-1}|.$$

From the definition of $h_{\alpha,b}$, (A.4), and the fact that

$$\frac{d^r}{d\lambda^r}(\mu_i^m a_i) = O(\langle\lambda\rangle^{(m-2r-2)/3}),$$

it follows that

$$\widetilde{K}_{r,m}(x,y,\lambda;c) \le \begin{cases} C\langle\lambda\rangle^{(m-2r-2)/3}\langle x\rangle^{\alpha_2}\langle y\rangle^{-\alpha_1+r} & \text{if } 0 \le x \le y, \\ C\langle\lambda\rangle^{(m-2r-2)/3}e^{bx/2}\langle y\rangle^{-\alpha_1+r} & \text{if } x \le 0 \text{ and } y \ge 0, \\ C\langle\lambda\rangle^{(m-2r-2)/3}e^{b(x-y)}\langle x-y\rangle^{r} & \text{if } x \le y \le 0, \\ C\langle\lambda\rangle^{(m-2r-2)/3}\langle x-y\rangle^{r}e^{(\mu_*+b)(x-y)} & \text{if } x \ge y, \end{cases}$$

where C is a positive number that does not depend on λ, x, and y. Moreover, since μ_i and its derivatives are continuous in λ and c and (A.3) holds uniformly with respect to $c \in I$, the constant C can be chosen uniformly for some neighborhood of $c \in (0,\infty)$. Hence, we have

$$\sup_{x\in\mathbb{R}}\|\widetilde{K}_{r,m}(x,\cdot,\lambda;c)\|_{L^{q_3}} + \sup_{y\in\mathbb{R}}\|\widetilde{K}_{r,m}(\cdot,y,\lambda;c)\|_{L^{q_3}} \le C\langle\lambda\rangle^{\{m-2(r+1)\}/3} \tag{A.5}$$

for $m = 0,1,2$, where $1/q_3 = 1 + 1/q_2 - 1/q_1$ and C is a positive number that can be chosen uniformly in some neighborhood of c. Furthermore, we have

$$\lim_{(c_1,\lambda_1)\to(c,\lambda)} |||\widetilde{K}_{r,m}(\cdot,\cdot,\lambda_1;c_1) - \widetilde{K}_{r,m}(\cdot,\cdot,\lambda;c)||| \to 0,$$

where $|||f(\cdot,\cdot)||| = \sup_{x\in\mathbb{R}}\|f(x,\cdot)\|_{L^{q_3}} + \sup_{y\in\mathbb{R}}\|f(\cdot,y)\|_{L^{q_3}}$. Using Young's inequality, we see that (A.5) implies (A.1) and that $\partial_x^m R_0(i)(\lambda;c)$ $(0 \le i \le r)$ is continuous in $\lambda \in \overline{\Sigma}$ and $c > 0$ if $k \in \mathbb{N}\cup\{0\}$ and $m = 0,1,2$. The case where $m = 3$ follows by using $\partial_x^3 R_0(\lambda;c) = 1 - (\lambda - c\partial_x)R_0(\lambda;c)$.

Next, we show (A.2). Using

$$(R_0^{(r)}(\lambda;c))^* u = \int_{\mathbb{R}} \partial_\lambda^r K_0(y-x,\bar{\lambda};c)u(y)dy,$$

we have

$$\|(R_0^{(r)}(\lambda;c))^*\|_{\mathcal{L}(L^{-k-m,q_2'}(-\alpha_2,-b);L^{-k,q_1'}(-\alpha_1,-b))} \le C\langle\lambda\rangle^{\{m-2(r+1)\}/3}$$

for $k \le -m$, where $1/q_1 + 1/q_1' = 1/q_2 + 1/q_2' = 1$ and C is a positive number. Hence, we have (A.2) with $k \le -m$ by using the standard duality argument. For $k \ge 0$, (A.2) immediately follows from (A.1) and the equivalence of $L^{k_i,q_i}(\alpha_i,b)$ and $W^{k_i,q_i}(\alpha_i,b)$ for $i = 0,1$. Combining these, we obtain (A.2).

Looking at the above proof, we see that $R_0^{(i)}(\lambda;c)$ is continuous in λ and c and the constant C in (A.1) and (A.2) can be chosen uniformly for some neighborhood of $c \in (0,\infty)$. □

The next step is to estimate the resolvent operator $R(\lambda;c)$ by using the resolvent identity

$$R(\lambda;c) = (1 - R_0(\lambda;c)T_c)^{-1}R_0(\lambda;c) \tag{A.6}$$

around $\lambda = 0$. The proof of the next lemma follows the lines of Murata [25].

LEMMA A.2. *Assume that $p \neq 4$. Let b, r, and m be as in Lemma* A.1, *and let $\alpha_1 \geq \alpha_2 + r + 1 + 1/q_2 - 1/q_1$, $\alpha_2 > 1 - 1/q_2$. Let I be a compact subset I of $(0, \infty)$.*

(i) *Suppose that $k \in \mathbb{N} \cup \{0\}$ and that $1 \leq q_1 \leq q_2 < \infty$ and $0 \leq i \leq r$. Then, there exists a neighborhood U of 0 in $\mathbb{C}$ such that*

$$\sup_{c \in I} \sup_{\lambda \in U \cap \overline{\Sigma}} \|Q_c R^{(i)}(\lambda; c)\|_{\mathcal{L}(W^{k,q_1}(\alpha_1,b); W^{k+m,q_2}(\alpha_2,b))} < \infty.$$

(ii) *Suppose that k is an integer with $k \geq -m$ and that $1 < q_1 \leq q_2 < \infty$. Then, there exists a neighborhood U of 0 in $\mathbb{C}$ such that*

$$\sup_{c \in I} \sup_{\lambda \in U \cap \overline{\Sigma}} \|Q_c R^{(i)}(\lambda; c)\|_{\mathcal{L}(L^{k,q_1}(\alpha_1,b); L^{k+m,q_2}(\alpha_2,b))} < \infty.$$

Proof. Let $X = W^{k,q_1}(\alpha_1, b)$ ($X = L^{k,q_1}(\alpha_1, b)$) and $Y = W^{k+m,q_2}(\alpha_2, b)$ ($Y = L^{k+m,q_2}(\alpha_2, b)$), respectively. Put $G_j = \frac{1}{j!} \frac{d^j}{d\lambda^j} R_0(0; c) = (-1)^j G_0^{j+1}$ for $j \in \mathbb{N} \cup \{0\}$. Because $f'(\varphi_c)$ is an exponentially decaying function and $\mu_i(\lambda; c)$ ($i = 0, 1, 2, 3$) are analytic in λ, it follows from (A.4) that

$$R_0(\lambda; c) T_c : \{\lambda \in \mathbb{C} \,|\, \operatorname{Re} \lambda > -\epsilon\} \to \mathcal{L}(Y)$$

is an analytic operator-valued function for an $\epsilon > 0$. By Lemma A.1, we see that $1 - R_0(\lambda; c) T_c$ is invertible in $\mathcal{L}(Y)$ for some $\lambda \in \Sigma$ with $|\lambda|$ sufficiently large. Hence, the analytic Fredholm theorem implies that $(1 - R_0(\lambda; c) T_c)^{-1}$ is a meromorphic function in $\mathcal{L}(Y)$ and has a Laurent series expansion

$$(1 - R_0(\lambda; c) T_c)^{-1}(\lambda) = \sum_{j=k}^{\infty} \lambda^j S_j$$

on $\{\lambda \in \mathbb{C} \,|\, 0 < |\lambda| < \delta\}$ for some $k \in \mathbb{Z}$ and $\delta > 0$. By Propositions 1.15 and 1.16 in [27], the singularity of $R(\lambda; c)$ is the same as the order of zero of the Evans function $D(\lambda)$. Hence, from (2.7) in [27],

$$\|R(\lambda; c)\|_{\mathcal{L}(X,Y)} = O(\lambda^{-2}) \quad \text{as } \lambda \to 0 \text{ in } \overline{\Sigma}. \tag{A.7}$$

In view of (A.7) and the identity

$$(1 + R(\lambda; c) T_c)(1 - R_0(\lambda; c) T_c) = 1,$$

we have $k \geq -2$. Thus we have

$$(1 - R_0(\lambda; c) T_c)^{-1} = S_{-2} \lambda^{-2} + S_{-1} \lambda^{-1} + r(\lambda; c), \tag{A.8}$$

where $r(\lambda; c)$ is an analytic function from $\{\lambda \in \mathbb{C} \,|\, \operatorname{Re} \lambda > -\epsilon\}$ to $\mathcal{L}(Y)$.

Since $(1 - R_0(\lambda; c) T_c)(1 - R_0(\lambda; c) T_c)^{-1} = (1 - R_0(\lambda; c) T_c)^{-1}(1 - R_0(\lambda; c) T_c) = 1$, it follows that, for $j = 0, -1, -2$,

$$(1 - G_0 T_c) S_j - G_1 T_c S_{j-1} - G_2 T_c S_{j-2} = \delta_j, \tag{A.9}$$

$$S_j (1 - G_0 T_c) - S_{j-1} G_1 T_c - S_{j-2} G_2 T_c = \delta_j, \tag{A.10}$$

where $S_j = 0$ for $j \leq -3$. By (2.3) and Proposition 2.1(ii),

$$\operatorname{Ker}(1 - G_0 T_c) = \operatorname{span}\{\partial_y \varphi_c\} \quad \text{and} \quad \operatorname{Ker}(1 - G_0 T_c)^* = \operatorname{span}\{A_{0,c} \varphi_c\}.$$

So (A.9) and (A.10) with $j=-2$ imply

$$\mathrm{Range} S_{-2} \subset \mathrm{Ker}(1-G_0T_c) = \mathrm{span}\{\partial_y\varphi_c\}, \tag{A.11}$$

$$\mathrm{Ker} S_{-2} \supset \mathrm{Range}(1-G_0T_c) = {}^{\perp}\mathrm{span}\{A_{0,c}\varphi_c\}. \tag{A.12}$$

Thus we have

$$S_{-2}v = \alpha\langle v, A_{0,c}\varphi_c\rangle\partial_y\varphi_c \tag{A.13}$$

for an $\alpha\in\mathbb{C}$. Applying $A_{0,c}$ to (A.9) with $j=-1$ and using $(1-G_0T_c)S_{-2}=0$, we have $A_{[c]}S_{-1}=S_{-2}$. Hence (A.13), (2.3), and Proposition 2.1(ii) yield

$$S_{-1}v = -\alpha\langle v, A_{0,c}\varphi_c\rangle\partial_c\varphi_c + \langle g, v\rangle\partial_y\varphi_c \tag{A.14}$$

for some $g\in Y^*$.

Since $Q_cS_{-2}=Q_cS_{-1}=0$, it follows from (A.8) that the operator $Q_c(1-R_0(\lambda;c)T_c)^{-1}$ is analytic in some neighborhood of $\lambda=0$.

Suppose that $c\in I$ and that $|\lambda|\le\varepsilon/4$. Then,

$$Q_c(1-R_0(\lambda;c)T_c)^{-1} = \frac{1}{2\pi i}\int_{|\zeta|=\frac{\varepsilon}{2}} \frac{Q_c(1-R_0(\zeta;c)T_c)^{-1}}{\zeta-\lambda}.$$

Since the integrand is continuous in c and λ and uniformly bounded on $\{\zeta\,|\,|\zeta|=\varepsilon/2\}$, we have $\sup_{c\in I}\sup_{|\lambda|\le\varepsilon/4}\|Q_c(1-R_0(\lambda;c)T_c)^{-1}\|_{\mathcal{L}(Y)}<\infty$. Combining the above with Lemma A.1 and (A.6), we have $\sup_{c\in I}\sup_{|\lambda|\le\varepsilon/4}\|Q_cR^{(r)}\|_{\mathcal{L}(X,Y)}<\infty$. Thus we have proved the lemma. □

LEMMA A.3. *Let p, m, r, α_1, α_2, and b be as in Lemma* A.2.

(i) *Let $1\le q_1\le q_2<\infty$ and $k\in\mathbb{N}\cup\{0\}$. Then, there exists a positive number C such that*

$$\|Q_cR^{(r)}(\lambda;c)\|_{\mathcal{L}(W^{k,q_1}(\alpha_1,b),W^{k+m,q_2}(\alpha_2,b))}\le C\langle\lambda\rangle^{-2(r+1)/3+m/3}$$

for every $\lambda\in\overline{\Sigma}$. Furthermore, if I is a compact subset of $(0,\infty)$, the constant C can be chosen uniformly for all $c\in I$.

(ii) *Let $1<q_1\le q_2<\infty$, and let k be an integer with $k\ge -m$. Then, there exists a positive number C such that*

$$\|Q_cR^{(r)}(\lambda;c)\|_{\mathcal{L}(L^{k,q_1}(\alpha_1,b),L^{k+m,q_2}(\alpha_2,b))}\le C\langle\lambda\rangle^{-2(r+1)/3+m/3}$$

for every $\lambda\in\overline{\Sigma}$. Furthermore, if I is a compact subset of $(0,\infty)$, the constant C can be chosen uniformly for all $c\in I$.

Proof. Let X and Y be as in the proof of Lemma A.2. First, we show that $(1-R_0(\lambda;c)T_c)^{-1}\in\mathcal{L}(Y)$ for every $\lambda\in\overline{\Sigma}\setminus\{0\}$. Let $\lambda\in\overline{\Sigma}$ be a point so that $1-R_0(\lambda;c)T_c$ is not invertible. Since $R_0(\lambda;c)T_c$ is a compact operator, it then follows that there exists a nontrivial solution $u\in Y$ to

$$u - R_0(\lambda;c)T_cu = 0. \tag{A.15}$$

It follows from Lemma A.1 and (A.15) that u is a classical solution to (2.1) and satisfies $u(x)=O((1+x)^{-\alpha_2})$ as $x\to\infty$ and $u(x)=O(e^{bx})$ as $x\to-\infty$. If $b>0$ is sufficiently small, [27, Proposition 1.6 and Theorem 3.6] tells us that the solution u actually decays exponentially as $|x|\to\infty$ and λ is also an eigenvalue of the operator

$A_{[c]}$ in L^2. Since 0 is the only eigenvalue of $A_{[c]}$ in L^2, it follows that $\lambda = 0$ and that $(1 - R_0(\lambda; c)T_c)^{-1} \in \mathcal{L}(Y)$ for $\lambda \in \overline{\Sigma} \setminus \{0\}$.

Now, let I be a compact subset of $(0, \infty)$. Then by Lemma A.1, there exists an $M > 0$ such that $\sup_{c\in I} \sup_{|\lambda|\le M} \|R_0(\lambda; c)T_c\|_{\mathcal{L}(Y)} \le 1/2$. For such an $M > 0$, we have

$$\sup_{c\in I} \sup_{|\lambda|\ge M} \|Q_c R^{(i)}(\lambda; c)T_c\|_{\mathcal{L}(X,Y)} < \infty \quad \text{for } 0 \le i \le r.$$

By Lemma A.1, the definitions of Q_c and T_c, and (A.6), $Q_c R^{(i)}(\lambda; c) \in \mathcal{L}(X, Y)$ $(0 \le i \le r)$ is continuous in $\lambda \in \overline{\Sigma} \setminus \{0\}$ and $c > 0$. The continuity of $Q_c R^{(i)}(\lambda; c)$ $(0 \le i \le r)$ and Lemma A.2 imply

$$\sup_{c\in I} \sup_{|\lambda|\le M} \|Q_c R^{(i)}(\lambda; c)T_c\|_{\mathcal{L}(X,Y)} < \infty \quad \text{for } 0 \le i \le r.$$

Thus we complete the proof. □

We are now in position to prove Lemma 2.7 and Corollaries 2.9 and 2.10 stated in section 2.

Proof of Lemma 2.7. The standard semigroup theory (see [26]) tells us that there exists a $\gamma > 0$ such that

$$e^{tA}u_0 = \frac{1}{2\pi} \int_{-\infty}^{\infty} e^{(\gamma+i\lambda)t} R(\gamma + i\lambda; c) d\lambda u_0$$

for $u_0 \in D(A^2) = H^6$. Let X and Y be as in the proof of Lemma A.2, and let $r > (m+1)/2$. Then Lemma A.3 implies that $\|R^{(r)}(\gamma + i\lambda)\|_{\mathcal{L}(X,Y)}$ decays uniformly at the rate $\langle\lambda\rangle^{-1-\varepsilon}$ as $\lambda \to \infty$, where $\varepsilon = (2r - m - 1)/3 > 0$. Let u, $v \in C_0^\infty(\mathbb{R})$. Since $R^{(r)}(\gamma + i\lambda) \in L^1(\mathbb{R}_\lambda; \mathcal{L}(X, Y))$ for every $\gamma > 0$, we may shift the contour of the integration and obtain

$$(e^{tA}Q_c u, v) = \frac{1}{2\pi(it)^r} \int_{-\infty}^{\infty} e^{it\lambda} (R^{(r)}(i\lambda + 0; c)Q_c u, v) d\lambda.$$

This implies that

$$\|U_c(t)Q_c\|_{\mathcal{L}(X,Y)} \le Ct^{-r}$$

for every $t > 0$. Thus we prove Lemma 2.7 for $r \in \mathbb{N}$ satisfying $r \ge [(m+1)/2] + 1$.

Let $\psi(x)$ be a smooth function with $\operatorname{supp}\psi = [1, 4]$, $\psi(x) > 0$ for $x \in (1, 4)$, and let

$$\psi_j(x) = \begin{cases} \psi(2^{-j}x) & \text{for } j \ge 0, \\ \psi\Big(\frac{3bx}{2\alpha \log 2} - \frac{3j}{2}\Big) & \text{for } j \le -1, \end{cases} \qquad \varphi_j(x) = \frac{\psi_j(x)}{\sum_{k=-\infty}^{\infty} \psi_k(x)}.$$

Then, $\varphi_j(x)$ $(j \in \mathbb{Z})$ are nonnegative functions satisfying the following:

(i) $$\operatorname{supp}\varphi_j = \begin{cases} [2^j, 2^{j+2}] & \text{for } j \ge 0, \\ [\alpha(j + 2/3) \log 2/b, \alpha(j + 8/3) \log 2/b] & \text{for } j \le -1, \end{cases}$$

(ii) $$\sum_{j=-\infty}^{\infty} \varphi_j(x) = 1,$$

(iii) $$\sup_{j\in\mathbb{Z}} \sup_{x\in\mathbb{R}} |\phi_j^{(i)}(x)| < \infty \quad \text{for every } i \in \mathbb{N} \cup \{0\}.$$

Put $\tilde{\varphi}_j = \sum_{k=-l}^{l} \varphi_{j+k}$. Let l be an integer such that $\varphi_j = \tilde{\varphi}_j \varphi_j$ for every $j \in Z$. We denote by A_j ($j \in \mathbb{Z}$) the Banach space $W^{k,p}(\alpha, b)$ equipped with the norm $\|\cdot\|_{A_j} = 2^{\alpha j}\|\cdot\|_{W^{k,p}}$. Set $Sf = \{\varphi_j(x)f(x)\}_{j=-\infty}^{\infty}$ and $R\{f_j\} = \sum_{j=-\infty}^{\infty} \tilde{\varphi}_j f_j$. Then by definition, $RS = E$ (the identity map), S is a bounded linear operator from $W^{k,p}(\alpha, b)$ to $\dot{l}_p(A_j)$, and R is a bounded linear operator from $\dot{l}_p(A_j)$ to $W^{k,p}(\alpha, b)$. Indeed,

$$\sum_{j\in\mathbb{Z}} \|\varphi_j f\|_{A_j}^p \le C \sum_{j\in\mathbb{Z}} \sum_{|\alpha|\le k} 2^{\alpha j p} \int_{\operatorname{supp}\varphi_j} |D^\alpha u|^p dx \le C\|u\|_{W^{k,p}(\alpha,b)}^p$$

and

$$\left\| \sum_{j\in\mathbb{Z}} \tilde{\varphi}_j f_j \right\|_{W^{k,p}(\alpha,b)}^p \le \sum_{j\in\mathbb{Z}} (6l+1)\|\tilde{\varphi}_j f_j\|_{W^{k,p}(\alpha,b)}^p \le C \sum_{j\in\mathbb{Z}} \|f_j\|_{A_j}^p.$$

Hence, R is a retraction. Combining the above with [2, Theorems 6.4.2 and 3.1.2] and the proof of [2, Theorem 5.6.1], we have Lemma 2.7. □

Proof of Corollaries 2.9 *and* 2.10. Let $T(t)$ denote the evolution operator corresponding to $-\partial_x^3 + c\partial_x$. Then it holds that

$$(T(t)f)(x) = \int_{\mathbb{R}} S_t(x - y + ct) f(y) dy \quad \text{for } t > 0. \tag{A.16}$$

Let

$$I^i(t, x, y) = |h_{\alpha_2,b}(x) D_x^i S_t(x - y + ct) h_{\alpha_1,b}(y)^{-1}|$$

and let $z = x - y$. By (3.6) and (3.7),

$$I^i(t,x,y) \le \begin{cases} C_1 t^{-(i+1)/3} \exp\left(bz - C_2 t^{-1/2}(z+ct)^{3/2}\right) & \text{if } z \ge 0, \\ C_1 t^{-(i+1)/3} \exp\left(-C_2 t^{-1/2}(z+ct)^{3/2}\right) \langle z\rangle^{\alpha_2-\alpha_1} & \text{if } -ct \le z \le 0, \\ C_1 t^{-(i+1)/3} \left(1 + t^{-1/3}|z+ct|\right)^{(2i-1)/4} \langle z\rangle^{\alpha_2-\alpha_1} & \text{if } z \le -ct, \end{cases}$$

where $i = 0, 1$ and C_i ($i = 1, 2$) are positive numbers. Let $1 \le q_1 \le q_2 \le \infty$. By the assumption, it holds that $q_3(\alpha_2 - \alpha_1) \le -1 - rq_3$, where $1/q_3 = 1 + 1/q_2 - 1/q_1$. Furthermore, if $x \ge y$ and b is sufficiently small, there exist positive numbers c_1 and c_2 such that

$$bz - C_2 t^{-1/2}(z+ct)^{3/2} \le -c_1 z^{3/2} t^{-1/2} - c_2 t.$$

Hence, there exists a $C > 0$ such that

$$\|I^0(t,x,y)\|_{L_y^\infty L_x^{q_3}} + \|I^0(t,x,y)\|_{L_x^\infty L_y^{q_3}} \le \begin{cases} C\langle t\rangle^{-r} t^{-1/4} \text{ if } 1 \le q_3 < 4, \\ C\langle t\rangle^{-r} t^{-1/3} \text{ if } q_3 \ge 4. \end{cases}$$

So applying Young's inequality to (A.16), we have

$$\|T(t)\|_{\mathcal{L}(L^{q_1}(\alpha_1,b), L^{q_2}(\alpha_2,b))} \le C\langle t\rangle^{-r} t^{-\theta} \quad \text{for } t > 0, \tag{A.17}$$

where $\theta = 1/3$ if $1/q_1 - 1/q_2 \le 3/4$ and $\theta = 1/4$ if $1/q_1 - 1/q_2 > 3/4$. Analogously, we have

$$\|I^1(t,x,y)\|_{L^\infty_y L^{q_3}_x} + \|I^1(t,x,y)\|_{L^\infty_x L^{q_3}_y} \le C\langle t\rangle^{-r+1/4} t^{-3/4}$$

for $t > 0$. Hence, it holds that

$$\|\partial_x T(t)\|_{\mathcal{L}(L^{q_1}(\alpha_1,b),L^{q_2}(\alpha_2,b))} \le C\langle t\rangle^{-r+1/4} t^{-3/4}. \tag{A.18}$$

Using that

$$\frac{d}{dt}\big(T(-t)U_c(t)Q_c\big) = T(-t)\partial_x\{f'(\varphi_c)U_c(t)Q_c u\}$$

for $u \in H^3$, and the fundamental theorem of the calculus, we compute

$$U_c(t)Q_c = T(t)Q_c - \int_0^t T(t-s)\partial_x\{f'(\varphi_c)U_c(s)Q_c\}ds. \tag{A.19}$$

Let

$$\begin{aligned} L_1(t) &= \sup_{0<s\le t}\left(s^\theta \|U_c(s)Q_c u_0\|_{L^{q_2}(\alpha_2,b)}\right), \\ L_2(t) &= \sup_{0<s\le t}\left(s^{3/4}\|\partial_x U_c(s)Q_c u_0\|_{L^{q_2}(\alpha_2,b)}\right). \end{aligned}$$

Combining (A.17)–(A.19), we have

$$\begin{aligned} &\|U_c(t)Q_c u_0\|_{L^{q_2}(\alpha_2,b)} \\ &\le \|T(t)Q_c u_0\|_{L^{q_2}(\alpha_2,b)} + \int_0^t \|\partial_x T(t-s)f'(\varphi_c)U_c(s)Q_c u_0\|_{L^{q_2}(\alpha_2,b)} \\ &\le Ct^{-\theta}\|u_0\|_{L^{q_1}(\alpha_1,b)} + CL_1(t)\int_0^t (t-s)^{-3/4}s^{-\theta}ds \\ &\le Ct^{-\theta}\|u_0\|_{L^{q_1}(\alpha_1,b)} + Ct^{1/4-\theta}L_1(t) \end{aligned}$$

and

$$\begin{aligned} &\|\partial_x U_c(t)Q_c u_0\|_{L^{q_2}(\alpha_2,b)} \\ &\le \|\partial_x T(t)Q_c u_0\|_{L^{q_2}(\alpha_2,b)} + \int_0^t \|\partial_x T(t-s)\partial_x\{f'(\varphi_c)U_c(s)Q_c u_0\}\|_{L^{q_2}(\alpha_2,b)} \\ &\le Ct^{-3/4}\|u_0\|_{L^{q_1}(\alpha_1,b)} + CL_2(t)\int_0^t (t-s)^{-3/4}s^{-3/4}ds \\ &\le Ct^{-3/4}\|u_0\|_{L^{q_1}(\alpha_1,b)} + Ct^{-1/2}L_2(t). \end{aligned}$$

Hence, there exist positive numbers t_1 and C such that

$$L_1(t_1) + L_2(t_1) \le C\|u_0\|_{L^{q_1}(\alpha_1,b)}. \tag{A.20}$$

Combining these with Lemma 2.7, we obtain Corollary 2.9 with $q_2 \ne \infty$.

Now, let $q_2 = \infty$. From Lemma 2.7 and (A.20), we have

$$\|U_c(t)Q_c u_0\|_{L^{q_1}(\alpha_1-r-1,b)} \le Ct^{-1/4}\langle t\rangle^{-r+1/4}\|u_0\|_{L^{q_1}(\alpha_1,b)}.$$

Using (A.18) and the above, we have

$$\begin{aligned}
&\|U_c(t)Q_cu_0\|_{L^\infty(\alpha_2,b)}\\
&\le \|T(t)Q_cu_0\|_{L^\infty(\alpha_2,b)} + \int_0^t \|\partial_x T(t-s)f'(\varphi_c)U_c(s)Q_cu_0\|_{L^\infty(\alpha_2,b)}\\
&\le Ct^{-\theta}\langle t\rangle^{-r}\|u_0\|_{L^{q_1}(\alpha_1,b)}\\
&\quad + C\int_0^t (t-s)^{-3/4}\langle t-s\rangle^{-r+1/4}\|f'(\varphi_c)U_c(s)Q_cu_0\|_{L^{q_1}(\alpha_1,b)}ds\\
&\le C\|u_0\|_{L^{q_1}(\alpha_1,b)}\left(\langle t\rangle^{-r}t^{-\theta} + \int_0^t (t-s)^{-3/4}\langle t-s\rangle^{-r+1/4}\langle s\rangle^{-r+1/4}s^{-1/4}ds\right)\\
&\le Ct^{-\theta}\langle t\rangle^{-r+\theta}\|u_0\|_{L^{q_1}(\alpha_1,b)}.
\end{aligned}$$

We can show

$$\|\partial_x U_c(t)Q_cu_0\|_{L^\infty(\alpha_2,b)} \le Ct^{-3/4}\langle t\rangle^{-r+3/4}\|u_0\|_{L^{q_1}(\alpha_1,b)}$$

in the same way.

Now, we turn to the proof of Corollary 2.10. Analogously to (A.18), we see that there exists a $C>0$ such that

$$\|T^*(t)u_0\|_{L^{1,q_1'}(-\alpha_1,-b)} \le Ct^{-3/4}\|u_0\|_{L^{q_2'}(-\alpha_2,-b)} \quad \text{for } t>0,$$

which is equivalent to

$$\|T(t)u_0\|_{L^{q_2}(\alpha_2,b)} \le Ct^{-3/4}\|u_0\|_{L^{-1,q_1}(\alpha_1,b)} \quad \text{for } t>0.$$

Using the above and (A.19), we see that there exist a $t_1>0$ and a $C>0$ such that

$$\sup_{0<s\le t_1} s^{3/4}\|U_c(s)Q_cu_0\|_{L^{q_2}(\alpha_2,b)} \le C\|u_0\|_{L^{-1,q_1}(\alpha_1,b)}$$

for every $u_0 \in L^{-1,q_1}(\alpha_1,b)$. On the other hand, in view of Lemma A.3 and the proof of Lemma 2.7, we get

$$\|U_c(t)Q_cu_0\|_{L^{q_2}(\alpha_2,b)} \le Ct^{-r}\|u_0\|_{L^{-1,q_1}(\alpha_1,b)} \quad \text{for } t>0.$$

Combining these, we obtain Corollary 2.10.

Looking at the proof, we see that constants C and C_i $(i=1,2)$, which appear in the right-hand side of the estimates, can be taken uniformly if the parameter c belongs to some compact subset of $(0,\infty)$. Thus we have completed the proof. □

Acknowledgments. The author would like to express his gratitude to Professor Hiroshi Matano for his encouragement and to Professor Yoshio Tsutsumi for stimulating discussions and valuable suggestions.

OPTIMAL INEQUALITIES FOR GRADIENTS OF SOLUTIONS OF ELLIPTIC EQUATIONS OCCURRING IN TWO-PHASE HEAT CONDUCTORS*

ROBERT LIPTON†

Abstract. We consider solutions to divergence form partial differential equations that model steady state heat conduction in random two-phase composites. The coefficient representing the conductivity takes two scalar values. Optimal bounds on the L^2 norm of the gradient of the solution are found. The optimal upper bound is given in terms of the volume fraction occupied by each conducting phase. The optimal lower bound is independent of the volume fractions of the component conductors. The bounds follow from a Stieltjes integral representation for the L^2 norm of the gradient. Maximizing sequences of configurations are found using the corrector theory of homogenization.

1. Introduction.

Consider a bounded region Ω of R^N with a sufficiently regular boundary containing two isotropic conductors subjected to a constant applied temperature gradient $\mathbf{E}$ in R^N. Here we consider any dimension N greater than or equal to 2. The conductivities of the two materials are written as α and β, and the indicator function of the β phase is denoted by χ, where $\chi = 1$ inside the β phase and 0 otherwise. We suppose that the set occupied by the β phase is Lebesgue measurable and that $\beta > \alpha$. The local conductivity of the two-phase conductor is described by $a(\chi) = \alpha(1-\chi) + \beta\chi$. The temperature T inside the two-phase conductor is the solution of

$$-\text{div } (a(\chi)\nabla T) = 0 \tag{1.1}$$

subject to the boundary condition $T = \mathbf{E}\cdot\mathbf{x}$. Since the coefficient $a(\chi)$ is bounded and measurable, the equilibrium equation (1.1) is interpreted in the weak sense. Here we recall that the weak solution of (1.1) is defined to be the function T in $W^{1,2}(\Omega)$ that satisfies

$$\int_\Omega a(\chi)\nabla T\cdot\nabla\varphi\, dx = 0 \tag{1.2}$$

for all functions φ in $W_0^{1,2}(\Omega)$.

We suppose that the composite is random in that we specify only the volume fraction θ of the β phase and consider the ensemble of configurations that satisfy

this isoperimetric constraint. The set of conductivities associated with this class is denoted by ad_θ and is written

$$ad_\theta = \left\{ a(\chi), \text{ where } \chi \text{ satisfies } \int_\Omega \chi \, dx = \theta \times meas(\Omega),\ 0 \le \theta \le 1 \right\}. \tag{1.3}$$

In this paper we address the problem of extremizing

$$\|\nabla T\|_2^2 \triangleq \int_\Omega |\nabla T|^2 \, dx \tag{1.4}$$

over the class ad_θ. We provide optimal upper and lower bounds on the quantity $\|\nabla T\|_2^2$. The upper bound depends explicitly upon the volume fraction occupied by the β phase. In order to state the bounds we set $\lambda = \frac{\beta}{\alpha}$ and introduce the function $f(z)$ defined by

$$f(z) = \frac{z}{\left(\frac{1}{1-\lambda} - z\right)^2} \tag{1.5}$$

and we give the following optimal inequality.

THEOREM 1.1 (optimal inequality for the L^2 norm of the gradient). *For any admissible conductivity $a(\chi)$ in ad_θ the associated temperature gradient ∇T satisfies*

$$meas(\Omega) \times |\mathbf{E}|^2 \le \|\nabla T\|_2^2 \le U(\theta, \mathbf{E}), \tag{1.6}$$

where $U(\theta, \mathbf{E})$ depends upon the contrast λ and is given by

$$U(\theta, \mathbf{E}) = meas(\Omega) \times (1 + \theta f(1-\theta)) \, |\mathbf{E}|^2 \quad \text{for } \lambda \le 2, \tag{1.7}$$

and for $\lambda \ge 2$

$$U(\theta, \mathbf{E}) = meas(\Omega) \times \begin{cases} (1 + \theta f(1/(\lambda-1))) \, |\mathbf{E}|^2 & \text{if } \theta \le 1 - 1/(\lambda-1), \\ (1 + \theta f(1-\theta)) \, |\mathbf{E}|^2 & \text{if } \theta \ge 1 - 1/(\lambda-1). \end{cases} \tag{1.8}$$

The upper bound is attained by a suitable extremal sequence of configurations in ad_θ. The lower bound is attained by a configuration made up of parallel layers of the β conductor with layer normals orthogonal to $\mathbf{E}$. These results hold for all bounded domains Ω of R^N, $N \ge 2$ with Lipschitz boundary.

Extremal sequences of configurations that attain the upper bound are found to be given by the well-known finite rank laminar microstructures. This class of configurations is known to give extremal effective conductivity properties; see [7] and [9]. They also arise in the study of minimization problems for integral functionals of the form $\int_\Omega W(\nabla \phi) \, dx$ with nonconvex energy densities W; see [1], [3], [4], and [6].

It is shown here that only laminates of the first and second rank appear in extremal sequences of configurations. In order to describe a second rank laminate we introduce two characteristic functions, one for each scale of oscillation. We consider the periodic function $\chi^1(t)$ defined on the real line with period $0 \le t \le 1$ such that $\chi^1 = 1$ for $0 \le t \le \theta_1$ and $\chi^1 = 0$ elsewhere. Similarly we introduce the unit periodic function χ^2 such that $\chi^2 = 1$ for $0 \le t \le \theta_2$ and $\chi^2 = 0$ elsewhere. We introduce unit vectors $\mathbf{n}^1$ and $\mathbf{n}^2$ representing layer directions and put

$$\chi_L^\varepsilon(x) = \left(1 - \chi^1\left(\frac{\mathbf{n}^1 \cdot x}{\varepsilon}\right)\right)\left(1 - \chi^2\left(\frac{\mathbf{n}^2 \cdot x}{\varepsilon^2}\right)\right). \tag{1.9}$$

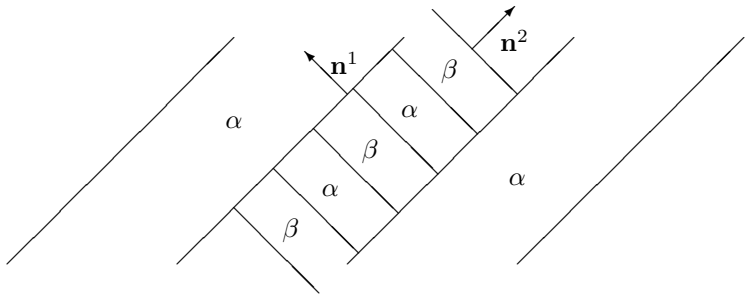

FIG. 1. *A laminate of second rank.*

The configurations associated with the sequence of characteristic functions $\{\chi_L^\varepsilon\}_{\varepsilon>0}$ are referred to as a laminate of the second rank. The conductivities for this sequence of configurations are given by $a(\chi_L^\varepsilon)$; see Figure 1. The laminate of first rank has one less scale of oscillation and is given by

$$\chi_L^\varepsilon(x) = \left(1 - \chi^1\left(\frac{\mathbf{n}^1 \cdot x}{\varepsilon}\right)\right). \tag{1.10}$$

The sequence of temperature gradients associated with laminates of rank one or two is written as $\{\nabla T_L^\varepsilon\}_{\varepsilon>0}$, where

$$-\text{div } (a(\chi_L^\varepsilon)\nabla T_L^\varepsilon) = 0 \tag{1.11}$$

and $T_L^\varepsilon = \mathbf{E}\cdot\mathbf{x}$ on the boundary of Ω.

In general, we may consider any sequence of configurations $\{\chi^\varepsilon\}_{\varepsilon>0}$ indexed by ε and the associated sequence of temperature gradients $\{\nabla T^\varepsilon\}_{\varepsilon>0}$ satisfying $-\text{div } (a(\chi^\varepsilon)\nabla T^\varepsilon) = 0$ and $T^\varepsilon = \mathbf{E}\cdot\mathbf{x}$ on the boundary of Ω. A sequence of configurations $\{\chi^\varepsilon\}_{\varepsilon>0}$ is said to be a maximizing sequence if

$$\lim_{\varepsilon\to 0} \|\nabla T^\varepsilon\|^2 = U(\theta, \mathbf{E}). \tag{1.12}$$

A configuration is said to be minimizing if the associated temperature T satisfies

$$\|\nabla T\|^2 = meas(\Omega) \times |\mathbf{E}|^2. \tag{1.13}$$

The next result identifies configurations that minimize the L^2 norm of the gradient.

THEOREM 1.2 (minimizing configurations for the L^2 norm). *Given* $\mathbf{E}$ *in* R^N, *a minimizing configuration is obtained by placing the* β *conductor in layers oriented so that the layer normals are orthogonal to* $\mathbf{E}$. *The number and thickness of the layers is constrained only by the requirement that the configuration be in* ad_θ.

It is easily shown that the temperature for this configuration is given by $T = \mathbf{E}\cdot\mathbf{x}$ everywhere in Ω; see section 4.

We now identify maximizing sequences of configurations.

THEOREM 1.3 (maximizing sequences of configurations for the L^2 norm). *Given* $\mathbf{E}$ *in* R^N

1. *If $\lambda \leq 2$, then a maximizing sequence of configurations is given by a laminate of the first rank in ad_θ with layer normal $\mathbf{n}^1$ parallel to $\mathbf{E}$ and $\theta^1 = 1 - \theta$.*
2. *If $\lambda > 2$, then*
   (a) *if $\theta \leq 1 - 1/(\lambda - 1)$, then a maximizing sequence of configurations is given by a laminate of the second rank in ad_θ with layer normal $\mathbf{n}^1$ parallel to $\mathbf{E}$, layer normal $\mathbf{n}^2$ orthogonal to $\mathbf{E}$, $\theta_1 = \frac{1}{1+\theta(\lambda-1)}$, and $\theta_2 = 1 - \theta - (\frac{1}{\lambda-1})$;*
   (b) *if $\theta \geq 1 - 1/(\lambda - 1)$, then a maximizing sequence of configurations is given by a laminate of the first rank in ad_θ with layer normal $\mathbf{n}^1$ parallel to $\mathbf{E}$ and $\theta_1 = 1 - \theta$.*

The geometry for minimizing configurations is independent of the volume fraction of the β phase and the contrast λ. On the other hand, for $\lambda > 2$, we see that the maximizing sequences of configurations change from laminates of rank one to laminates of rank two when the volume fraction of the β phase drops below $1 - \frac{1}{\lambda-1}$. When this happens the extremal configuration of α and β phases changes topology and the α phase occupies a connected set, while the β phase is in the form of thin rectangular inclusions.

In view of the applications, it is important to control the temperature gradient, as regions containing large temperature gradients are most often the first to suffer damage during service. Theorem 1.2 provides rigorous rules of thumb for the design of configurations for minimizing the L^2 norm of the temperature gradient, i.e., minimizing configurations are given by layering the two conductors in strips parallel to the applied field $\mathbf{E}$. On the other hand, the upper bound given in Theorem 1.1 provides the best possible upper bound on the L^2 norm of the temperature gradient when only the volume fraction of the β phase is known. We point out that the upper bound goes to infinity with the contrast λ.

The basic idea behind our approach is to encode the constraint given by the equilibrium condition (1.1) directly into the cost functional $\|\nabla T\|_2^2$. To do this we follow Golden and Papanicolaou [5] and introduce a scattering theory formalism to express ∇T in terms of the solution operator for (1.1). We then substitute the representation for ∇T into the L^2 norm to obtain the desired Stieltjes representation for $\|\nabla T\|_2^2$ in terms of a matrix valued measure. Using perturbation theory we see as in [5] that there are an infinite number of constraints on the matrix valued measure. We judiciously choose a subset of these constraints associated with the first and second moments of the measure. Our choice is motivated by the corrector theory of homogenization for laminates of finite rank given by Briane [2]. Subject to these constraints we extremize the Stietljes representation formula over all associated matrix valued measures to obtain the bounds given in Theorem 1.1. The attainability of the upper bound is established by comparing it to the limits of the L^2 norms associated with laminates of rank one or two. The comparison is facilitated using an explicit Stieltjes integral representation formula for these limits. We are confident that the approach developed here will be successful for investigating analogous problems in the elasticity setting.

The paper is organized as follows. In section 2 we review the recent results of Briane [2] that give the explicit form of corrector matrices for laminates of finite rank. We apply this theory to write the limit of the L^2 norms for finite rank laminates as Stieltjes functions. In section 3 we develop a Stieltjes representation formula for the L^2 norm of the gradient for any admissible configuration. In section 4 we use the representation formula to obtain the bounds stated in Theorem 1.1 and to establish their optimality.

2. Correctors and the L^2 norm for layered materials. In this section we obtain an explicit formula for

$$\lim_{\varepsilon\to 0}\|\nabla T_L^\varepsilon\|_2^2.$$

We start by reviewing the notion of H convergence due to Spagnolo [10] and Murat and Tartar [8]. We consider the sequence of conductivities $\{a(\chi^\varepsilon)\}_{\varepsilon>0}$ associated with the sequence of configurations $\{\chi^\varepsilon\}_{\varepsilon>0}$. The sequence $\{a(\chi^\varepsilon)\}_{\varepsilon>0}$ is said to H converge to A if for any function f of $H^{-1}(\Omega)$ the solutions $u^\varepsilon \in W_0^{1,2}(\Omega)$ of

$$-\text{div }(a(\chi^\varepsilon)\nabla u^\varepsilon) = f$$

satisfy $u^\varepsilon \to u^0$ weakly in $W^{1,2}(\Omega)$ and $a(\chi^\varepsilon)\nabla u^\varepsilon \to A\nabla u^0$ weakly in $L^2(\Omega; R^N)$, where u^0 is the solution of $-\text{div }\left(A\nabla u^0\right) = f$ and $u^0 \in W_0^{1,2}(\Omega)$. In fact more can be said about the convergence of the sequence $\{\nabla u^\varepsilon\}_{\varepsilon>0}$. There exists a matrix field $\mathbf{P}^\varepsilon$, called a corrector, for which

$$\nabla u^\varepsilon = \mathbf{P}^\varepsilon \nabla u^0 + z^\varepsilon,$$

where $z^\varepsilon \to 0$ strongly in $L^1(\Omega; R^N)$. Tartar [11] and Murat and Tartar [8] prove there always exists such a sequence of correctors $\mathbf{P}^\varepsilon$.

We choose layering directions $\mathbf{n}^1$ and $\mathbf{n}^2$ so that they are orthogonal to each other and put $\chi_1^\varepsilon = \chi^1(\frac{\mathbf{n}^1\cdot\mathbf{x}}{\varepsilon})$ and $\chi_2^\varepsilon = \chi^2(\frac{\mathbf{n}^2\cdot\mathbf{x}}{\varepsilon^2})$. We invoke Theorem 2.1 of Briane [2], and a straightforward calculation shows that the correctors are of the form

$$\mathbf{P}^\varepsilon = \chi_1^\varepsilon \mathbf{P}^1 + (1-\chi_1^\varepsilon)\left[\chi_2^\varepsilon \mathbf{P}^2 + (1-\chi_2^\varepsilon)\mathbf{P}^3\right], \tag{2.1}$$

where the constant matrices $\mathbf{P}^1$, $\mathbf{P}^2$, and $\mathbf{P}^3$ are given by

$$\mathbf{P}^1 = \mathbf{I} + (1-\theta_1)\left(\frac{(1-\theta_2)(\lambda-1)}{1-\theta_1(1-\theta_2)+\theta_1(1-\theta_2)\lambda}\right)\mathbf{n}^1\otimes\mathbf{n}^1, \tag{2.2}$$

$$\mathbf{P}^2 = \mathbf{I} - \theta_1\left(\frac{(1-\theta_2)(\lambda-1)}{1-\theta_1(1-\theta_2)+\theta_1(1-\theta_2)\lambda}\right)\mathbf{n}^1\otimes\mathbf{n}^1 + (1-\theta_2)\left(\frac{\lambda-1}{(1-\theta_2)+\theta_2\lambda}\right)\mathbf{n}^2\otimes\mathbf{n}^2, \tag{2.3}$$

and

$$\mathbf{P}^3 = \mathbf{I} - \theta_1\left(\frac{(1-\theta_2)(\lambda-1)}{1-\theta_1(1-\theta_2)+\theta_1(1-\theta_2)\lambda}\right)\mathbf{n}^1\otimes\mathbf{n}^1 - \theta_2\left(\frac{\lambda-1}{(1-\theta_2)+\theta_2\lambda}\right)\mathbf{n}^2\otimes\mathbf{n}^2, \tag{2.4}$$

where $\mathbf{I}$ is the $N\times N$ identity and $\mathbf{n}^1\otimes\mathbf{n}^1$ and $\mathbf{n}^2\otimes\mathbf{n}^2$ are the rank one matrices $\mathbf{n}_i^1\mathbf{n}_j^1$ and $\mathbf{n}_i^2\mathbf{n}_j^2$, respectively. The H limit for the sequence $\{a(\chi_L^\varepsilon)\}_{\varepsilon>0}$ is a constant $N\times N$ matrix denoted by A^L [7], [8]. For the boundary value problem treated here we have that

$$\begin{aligned} T^\varepsilon &\to \mathbf{E}\cdot\mathbf{x} \quad \text{weakly in } W^{1,2}(\Omega) \text{ and} \\ a(\chi^\varepsilon)\nabla T^\varepsilon &\to A^L\mathbf{E} \quad \text{weakly in } L^2(\Omega; R^N). \end{aligned} \tag{2.5}$$

From the corrector theory we have

$$\nabla T_L^\varepsilon = \mathbf{P}^\varepsilon\mathbf{E} + z^\varepsilon. \tag{2.6}$$

It is evident from the formulas describing $\mathbf{P}^\varepsilon$ that the sequence $\{\mathbf{P}^\varepsilon\}_{\varepsilon>0}$ is uniformly bounded in $L^\infty(\Omega;\, R^{N\times N})$. Thus we appeal to Theorem 3 of Murat and Tartar [8] to find that $z^\varepsilon \to 0$ strongly in $L^2(\Omega;\, R^N)$. We note that because of the separation of scales, the sequence of products $\{\chi_1^\varepsilon \chi_2^\varepsilon\}_{\varepsilon>0}$ converges in a weak L^∞ *star* to the product $\theta_1\theta_2$. Collecting our results and taking limits we find that

$$\lim_{\varepsilon\to 0} \|\nabla T_L^\varepsilon\|_2^2 = \mathbf{C}_{ij}^L \mathbf{E}_i \mathbf{E}_j, \tag{2.7}$$

where the matrix $\mathbf{C}^L$ is given by

$$\begin{aligned}\mathbf{C}^L &= meas(\Omega)\mathbf{I} \\ &\quad + meas(\Omega)(1-\theta_1)(1-\theta_2)\left(\frac{\theta_1(1-\theta_2)}{(\frac{1}{1-\lambda}-\theta_1(1-\theta_2))^2}\right)\mathbf{n}^1\otimes\mathbf{n}^1 \\ &\quad + meas(\Omega)(1-\theta_1)(1-\theta_2)\left(\frac{\theta_2}{(\frac{1}{1-\lambda}-\theta_2)^2}\right)\mathbf{n}^2\otimes\mathbf{n}^2. \end{aligned}\tag{2.8}$$

Here we note that the total volume fraction of the β phase is given by $\theta = (1-\theta_1)(1-\theta_2)$, and we can rewrite (2.8) as

$$\mathbf{C}^L = \mathbf{C}(\boldsymbol{\mu}^L) = meas(\Omega)\times\left(\mathbf{I} + \int_0^{1-\theta} f(z)\boldsymbol{\mu}^L(dz)\right), \tag{2.9}$$

where the matrix valued measure $\boldsymbol{\mu}$ is given by

$$\boldsymbol{\mu}^L(dz) = \left(\theta\delta(z-\theta_1(1-\theta_2))\mathbf{n}^1\otimes\mathbf{n}^1 + \theta\delta(z-\theta_2)\mathbf{n}^2\otimes\mathbf{n}^2\right)dz. \tag{2.10}$$

Equations (2.9) and (2.10) provide the desired Stieltjes integral formula for the limit given in (2.7).

3. Stieltjes integral representation formula for the L^2 norm. In this section we develop a representation formula for $\|\nabla T\|_2^2$, where T is the solution of (1.1) and $T = \mathbf{E}\cdot\mathbf{x}$ on the boundary of Ω. Motivated by perturbation theory we shall first rewrite the constraint given by (1.1). To this end we introduce the solution operator $(-\Delta)^{-1}$ mapping $H^{-1}(\Omega)$ onto $W_0^{1,2}(\Omega)$ for the problem given by $w \in W_0^{1,2}(\Omega)$ and

$$-\Delta w = f \quad \text{on } \Omega. \tag{3.1}$$

Next we introduce the subspace $\mathcal{E}$ of $L^2(\Omega;\, R^N)$ defined by

$$\mathcal{E} = \{\eta \in L^2(\Omega;\, R^N) \mid \eta = \nabla\varphi,\ \varphi \in W_0^{1,2}(\Omega)\},$$

and we introduce the operator P defined by $P = \partial_{x_i}(\Delta)^{-1}\partial_{x_j}$. It is easily checked that the operator P is a projection from $L^2(\Omega;\, R^N)$ into the subspace $\mathcal{E}$. We introduce the field perturbation $\phi = T - \mathbf{E}\cdot\mathbf{x}$ and rewrite the conductivity $a(\chi)$ as a positive perturbation from the uniform state α, i.e., $a(\chi) = \alpha + (\beta-\alpha)\chi$. Expanding T and $a(\chi)$ in (1.1) gives

$$-\alpha\Delta\phi = \text{div}\,\left((\beta-\alpha)\chi(\nabla\phi + \mathbf{E})\right). \tag{3.2}$$

Dividing both sides by α, applying $(-\Delta)^{-1}$ to both sides, and manipulating gives

$$\nabla\phi + \mathbf{E} + P\left[\,(\lambda-1)\chi\,(\nabla\phi+\mathbf{E})\,\right] = \mathbf{E} \tag{3.3}$$

or

$$[\,\mathbf{I} + (\lambda - 1)\,\Lambda\,]\,\nabla T = \mathbf{E}, \tag{3.4}$$

where $\Lambda = P\chi$. From this we obtain the desired expression

$$\nabla T = [\,\mathbf{I} + (\lambda - 1)\,\Lambda\,]^{-1}\,\mathbf{E}. \tag{3.5}$$

It is clear that the equilibrium constraint (1.1) is now explicitly encoded in the formula for ∇T as given by (3.5). The next step is to rewrite $\|\nabla T\|_2^2$ in a way that exploits the spectral properties of the operator Λ. To do this we expand the energy dissipation denoted by Q in two different ways. Here

$$Q = \frac{1}{meas(\Omega)} \int_\Omega a(\chi)\,\nabla T \cdot \nabla T\,dx. \tag{3.6}$$

Expanding $a(\chi)$ as $a(\chi) = \alpha + \chi(\beta - \alpha)$ and substitution into (3.6) gives

$$Q = \frac{1}{meas(\Omega)} \int_\Omega \alpha |\nabla T|^2\,dx + \frac{(\beta - \alpha)}{meas(\Omega)} \int_\Omega \chi\,|\nabla T|^2\,dx. \tag{3.7}$$

We expand ∇T as $\nabla T = \nabla\phi + \mathbf{E}$ in (3.6) to obtain

$$\begin{aligned} Q &= \frac{1}{meas(\Omega)} \int_\Omega a(\chi)\,\nabla T \cdot \mathbf{E}\,dx \\ &= \alpha |\mathbf{E}|^2 + \frac{(\beta - \alpha)}{meas(\Omega)} \int_\Omega \chi\,\nabla T \cdot \mathbf{E}\,dx. \end{aligned} \tag{3.8}$$

Here the first equality in (3.8) follows from (1.2), and the second follows from expansion of $a(\chi)$ and $\int_\Omega \nabla\phi \cdot \mathbf{E}\,dx = 0$. Eliminating Q using (3.7) and (3.8) gives

$$\|\nabla T\|_2^2 = meas(\Omega)\left(|\mathbf{E}|^2 + \frac{(\lambda - 1)}{meas(\Omega)} \int_\Omega \chi\,(\nabla T \cdot \mathbf{E})\,dx - \frac{(\lambda - 1)}{meas(\Omega)} \int_\Omega \chi\,|\nabla T|^2\,dx\right). \tag{3.9}$$

For vector fields η and ψ in $L^2(\Omega;\, R^N)$ we introduce the bilinear form $\langle \eta, \psi \rangle$ defined by

$$\langle \eta, \psi \rangle = \frac{1}{meas(\Omega)} \int_\Omega \chi\,(\eta \cdot \psi)\,dx,$$

and $\langle \eta, \psi \rangle$ is an inner product for the Hilbert space $\mathcal{H}$ defined by

$$\mathcal{H} = \left\{ \psi \in L^2(\Omega;\, R^N) \text{ modulo the equivalence class of elements } \psi \right.$$
$$\left. \text{such that } \int_\Omega \chi\psi\,dx = 0 \right\}.$$

Substitution of (3.5) into (3.9) gives

$$\begin{aligned} \|\nabla T\|_2^2 &= meas(\Omega)|\mathbf{E}|^2 \\ &\quad + meas(\Omega)(\lambda - 1)\left\langle [\,\mathbf{I} + (\lambda - 1)\,\Lambda\,]^{-1}\,\mathbf{E}, \mathbf{E} \right\rangle \\ &\quad - meas(\Omega)(\lambda - 1)\left\langle [\,\mathbf{I} + (\lambda - 1)\,\Lambda\,]^{-1}\,\mathbf{E}, [\,\mathbf{I} + (\lambda - 1)\,\Lambda\,]^{-1}\,\mathbf{E} \right\rangle. \end{aligned} \tag{3.10}$$

It is easily seen that Λ is a positive symmetric operator on $\mathcal{H}$ with norm less than or equal to 1. From spectral theory we immediately obtain the existence of a projection valued measure $R(dz)$ with support on $[0,1]$ for which

$$\left\langle [\,\mathbf{I} + (\lambda-1)\,\Lambda\,]^{-1}\,\mathbf{E},\mathbf{E}\right\rangle = \left\langle \int_0^1 \frac{1}{1+z(\lambda-1)}\,R(dz)\mathbf{E},\mathbf{E}\right\rangle \tag{3.11}$$

and

$$\left\langle [\,\mathbf{I} + (\lambda-1)\,\Lambda\,]^{-1}\,\mathbf{E},[\,\mathbf{I} + (\lambda-1)\,\Lambda\,]^{-1}\,\mathbf{E}\right\rangle = \left\langle \int_0^1 \frac{1}{(1+z(\lambda-1))^2}\,R(dz)\mathbf{E},\mathbf{E}\right\rangle. \tag{3.12}$$

Collecting our results we arrive at the Stieltjes integral representation formula given by the following theorem.

THEOREM 3.1 (Stieltjes integral representation formula).

$$\|\nabla T\|_2^2 = \mathbf{C}_{ij}(\boldsymbol{\mu})\mathbf{E}_i\mathbf{E}_j, \tag{3.13}$$

where

$$\mathbf{C}(\boldsymbol{\mu}) = meas(\Omega)\left(\mathbf{I} + \int_0^1 f(z)\,\boldsymbol{\mu}(dz)\right) \tag{3.14}$$

and

$$\boldsymbol{\mu}_{ij}(dz) = \langle R(dz)\,\mathbf{e}^i,\mathbf{e}^j\rangle. \tag{3.15}$$

Here $\mathbf{e}^i$, $i=1,2\ldots,N$ *is an orthonormal basis for* R^N. *Moreover,* $\boldsymbol{\mu}_{ij}=\boldsymbol{\mu}_{ji}$, *since* $R(dz)$ *is symmetric and for all* $\mathbf{E}$ *in* R^N *we have that the measures* $\boldsymbol{\mu}(dz)\mathbf{E}\cdot\mathbf{E}$ *are positive.*

It is evident from Theorem 3.1 that the geometric information is stored in the measure $\boldsymbol{\mu}$ while the ratio of conductivities is contained in $f(z)$. The extremal behavior of $\|\nabla T\|_2^2$ is governed by the global maxima and minima of f on $[0,1]$.

4. Derivation of the isoperimetric inequalities. In view of the Stieltjes formula for the gradient we can replace the extremal problems

$$\mathrm{A} = \inf_{a(\chi)\in ad_\theta}\left\{\|\nabla T\|_2^2\,;\,-\mathrm{div}\,(a(\chi)\nabla T)=0,\ T=\mathbf{E}\cdot\mathbf{x}\ \text{on}\ \partial\Omega\right\} \tag{4.1}$$

and

$$\mathrm{B} = \sup_{a(\chi)\in ad_\theta}\left\{\|\nabla T\|_2^2\,;\,-\mathrm{div}\,(a(\chi)\nabla T)=0,\ T=\mathbf{E}\cdot\mathbf{x}\ \text{on}\ \partial\Omega\right\} \tag{4.2}$$

with the equivalent problems given by

$$\mathrm{A} = \inf_{\boldsymbol{\mu}\in\mathcal{A}_\theta}\{\mathbf{C}(\boldsymbol{\mu})\mathbf{E}\cdot\mathbf{E}\} \tag{4.3}$$

and

$$\mathrm{B} = \sup_{\boldsymbol{\mu}\in\mathcal{A}_\theta}\{\mathbf{C}(\boldsymbol{\mu})\mathbf{E}\cdot\mathbf{E}\}. \tag{4.4}$$

Here the set $\mathcal{A}_\theta$ is the set of measures $\boldsymbol{\mu}$ given by (3.15) associated with any configuration of the β phase described by a characteristic function χ subject to the isoperimetric

constraint $\int_\Omega \chi\, dx = \theta\, meas(\Omega)$. Instead of attempting an explicit characterization of $\mathcal{A}_\theta$ we introduce a larger set of measures $\overline{\mathcal{A}_\theta}$ and compute the lower and upper bounds

$$\underline{\mathrm{A}} = \inf_{\boldsymbol{\mu}\in\overline{\mathcal{A}_\theta}} \{\mathbf{C}(\boldsymbol{\mu})\mathbf{E}\cdot\mathbf{E}\} \tag{4.5}$$

and

$$\overline{\mathrm{B}} = \sup_{\boldsymbol{\mu}\in\overline{\mathcal{A}_\theta}} \{\mathbf{C}(\boldsymbol{\mu})\mathbf{E}\cdot\mathbf{E}\}\,. \tag{4.6}$$

The goal here is to find a suitable choice for $\overline{\mathcal{A}_\theta}$ that delivers optimal bounds. We start by examining constraints on the measure $\boldsymbol{\mu}^L(dz)$ associated with laminates of the second rank defined in (2.10). One readily sees that

$$\int_0^1 \boldsymbol{\mu}^L(dz) = \theta\mathbf{I}, \tag{4.7}$$

and since $1-\theta = \theta_2 + \theta_1(1-\theta_2)$ we have

$$\mathbf{T}^L \triangleq \int_0^1 z\,\boldsymbol{\mu}^L(dz) \le (\max\{\theta\theta_1(1-\theta_2), \theta\theta_2\}) \times \mathbf{I} \le \theta(1-\theta)\mathbf{I}. \tag{4.8}$$

Next, for comparison, we apply perturbation expansions to look for constraints on $\boldsymbol{\mu}(dz)$. Expansion about $\lambda = 1$ gives

$$[\,\mathbf{I} + (\lambda-1)\,\Lambda\,]^{-1} = \mathbf{I} + (1-\lambda)\,\Lambda + (1-\lambda)^2\,\Lambda^2 + (1-\lambda)^3\,\Lambda^3 + \cdots \tag{4.9}$$

and

$$\frac{1}{1+z(\lambda-1)} = 1 + (1-\lambda)\,z + (1-\lambda)^2\,z^2 + (1-\lambda)^3\,z^3 + \cdots. \tag{4.10}$$

Substituting these expansions into (3.11) and equating like powers of $\lambda - 1$ gives

$$\int_0^1 z^n\,\boldsymbol{\mu}_{ij}(dz) = \langle \Lambda^n \mathbf{e}^i, \mathbf{e}^j\rangle, \quad n = 0, 1\ldots. \tag{4.11}$$

Focusing on the cases $n = 0$ and $n = 1$ we have

$$\int_0^1 \boldsymbol{\mu}_{ij}(dz) = \theta\,\mathbf{I}_{ij} \tag{4.12}$$

and

$$\int_0^1 z\,\boldsymbol{\mu}_{ij}(dz) = \langle \Lambda\mathbf{e}^i, \mathbf{e}^j\rangle. \tag{4.13}$$

We estimate the largest and smallest eigenvalues for the tensor $\mathbf{T}_{ij} \triangleq \langle \Lambda\mathbf{e}^i, \mathbf{e}^j\rangle$. We note that constant vectors lie in the null space of the operator P, and we introduce $\overline{\chi} = \chi - \theta$ to find that

$$\begin{aligned} 0 \le \mathbf{T}_{ij}\mathbf{E}_i\mathbf{E}_j &= \frac{1}{meas(\Omega)}\int_\Omega (P\chi)\mathbf{E}\cdot\chi\mathbf{E}\,dx \\ &= \frac{1}{meas(\Omega)}\int_\Omega (P\overline{\chi})\mathbf{E}\cdot\overline{\chi}\mathbf{E}\,dx \\ &\le \frac{1}{meas(\Omega)}\int_\Omega (\overline{\chi})^2\,dx|\mathbf{E}|^2 = \theta(1-\theta)|\mathbf{E}|^2. \end{aligned} \tag{4.14}$$

Thus the spectrum of the tensor $\mathbf{T}$ lies in the interval $[0, \theta(1-\theta)]$. Motivated by (4.7), (4.8), (4.12), and (4.14) we define $\overline{\mathcal{A}_\theta}$ to be given by all $N \times N$ symmetric matrices with elements given by finite Borel measures such that for any vector $\mathbf{v}$ the measure given by $\boldsymbol{\mu}(dz)\mathbf{v}\cdot\mathbf{v}$ is positive and the matrix of measures satisfies the moment constraints

$$\int_0^1 \boldsymbol{\mu}(dz) = \theta\,\mathbf{I} \tag{4.15}$$

and

$$\int_0^1 z\,\boldsymbol{\mu}(dz) = \mathbf{T}, \tag{4.16}$$

where $\mathbf{T}$ is a symmetric $N \times N$ matrix with eigenvalues contained in the interval $[0, \theta(1-\theta)]$. Its clear from the definition of $\overline{\mathcal{A}_\theta}$ that this set of measures contains $\mathcal{A}_\theta$.

For the purpose of computing the bounds $\underline{\mathrm{A}}$ and $\overline{\mathrm{B}}$ we characterize the range of the map $\mathbf{H}(\boldsymbol{\mu})$ given by

$$\mathbf{H}(\boldsymbol{\mu}) = \int_0^1 f(z)\,\boldsymbol{\mu}(dz) \tag{4.17}$$

for $\boldsymbol{\mu}$ in $\overline{\mathcal{A}_\theta}$. We introduce the set $\overline{\mathcal{V}}_\theta$ of vectors $(\nu_1, \nu_2, \ldots, \nu_N)$ whose elements are positive finite Borel measures supported on $[0,1]$ that satisfy the constraints

$$\int_0^1 \nu_i(dz) = \theta, \quad i = 1, \ldots, N, \tag{4.18}$$

and

$$\int_0^1 z\,\nu_i(dz) = m_i, \quad \text{where } 0 \le m_i \le \theta(1-\theta), \quad i = 1, \ldots, N. \tag{4.19}$$

We now state the following theorem.

THEOREM 4.1 (the matrix range of $\mathbf{H}(\boldsymbol{\mu})$). *Let* R *be the image of* $\overline{\mathcal{A}_\theta}$ *under the map* $\mathbf{H} : \overline{\mathcal{A}_\theta} \to R^{N\times N}$. *Then* R *is given by*

$$\mathrm{R} = \left\{ \begin{array}{c} M \in R^{N\times N}\,;\ M = \Sigma_{i=1}^N \lambda_i \mathbf{e}^i \otimes \mathbf{e}^i, \\ \textit{where } \lambda_i = \int_0^1 f(z)\,\nu_i(dz), \textit{and } (\nu_1, \nu_2\ \ldots \nu_N) \textit{ in } \overline{\mathcal{V}}_\theta, \\ \textit{and } \mathbf{e}^i,\ i = 1, \ldots, N, \quad \textit{is any orthonormal basis for } R^N. \end{array} \right\}. \tag{4.20}$$

Proof. We denote the right-hand side of (4.20) by S and show $R = S$. One sees that $S \subset R$ by writing $M = \int_0^1 f(z)\,P(dz)$, where $P(dz) = \Sigma_i \nu_i(dz)\mathbf{e}^i \otimes \mathbf{e}^i$, and checking (4.15) and (4.16). To show $R \subset S$ we consider the matrix M given by $M = \int_0^1 f(z)\boldsymbol{\mu}(dz)$. Since M is symmetric it has an orthonormal system of eigenvectors $\mathbf{v}^i$, $i = 1 \ldots, N$, and $M = \Sigma_i \lambda_i \mathbf{v}^i \otimes \mathbf{v}^i$. From this one deduces that $\lambda_i = \int_0^1 f(z)\mu_i(dz)$, where μ_i are the positive measures given by $\mu_i(dz) = \boldsymbol{\mu}(dz)\mathbf{v}^i \cdot \mathbf{v}^i$. Next we observe that

$$\int_0^1 \mu_i(dz) = \int_0^1 \boldsymbol{\mu}(dz)\mathbf{v}^i \cdot \mathbf{v}^i = \theta \tag{4.21}$$

and

$$m_i = \int_0^1 z\,\mu_i(dz) = \int_0^1 z\,\boldsymbol{\mu}(dz)\mathbf{v}^i \cdot \mathbf{v}^i \le \theta(1-\theta) \tag{4.22}$$

to discover that $(\mu_1, \dots \mu_N)$ lies in $\overline{\mathcal{V}}_\theta$, and the theorem is proved. ∎

We now establish the explicit formulas for the bounds given by the following theorem.

THEOREM 4.2 (bounds on the L^2 norm of the gradient).

$$\underline{\mathrm{A}} = meas(\Omega)|\mathbf{E}|^2 \le \|\nabla T\|_2^2 \le \overline{\mathrm{B}} = U(\theta, \mathbf{E}). \tag{4.23}$$

Before establishing the theorem we note that the lower bound $meas(\Omega)|\mathbf{E}|^2$ can be found directly. Indeed, we can write $T = \phi + \mathbf{E}\cdot\mathbf{x}$, where $\phi = 0$ on the boundary of Ω. Then expanding $\|\nabla T\|_2^2$ and noting that $\int_\Omega \nabla\phi\cdot\mathbf{E}\,dx = 0$, we have

$$\|\nabla T\|_2^2 = meas(\Omega)|\mathbf{E}|^2 + \int_\Omega |\nabla\phi|^2\,dx, \tag{4.24}$$

and the lower bound follows immediately.

Proof of Theorem 4.2. We start by proving $\underline{\mathrm{A}} = meas(\Omega)|\mathbf{E}|^2$. From Theorem 4.1 it follows that

$$\underline{\mathrm{A}} = \inf_{M\in R} \left\{ meas(\Omega)(\mathbf{I}+M)\,\mathbf{E}\cdot\mathbf{E}\right\}. \tag{4.25}$$

It is evident from (4.25) that for $(\nu_1, \dots, \nu_N)$ fixed the minimum occurs when $\mathbf{E}$ lies in the eigenspace of the smallest eigenvalue of M. Without loss of generality we assume that $\lambda_1 = \int_0^1 f(z)\,\nu_1(dz)$ is the smallest eigenvalue of M, and we choose $\mathbf{e}^1 = \mathbf{E}/|\mathbf{E}|$ to find that

$$\underline{\mathrm{A}} = \inf_{\substack{\nu_1\ge 0,\\ \int_0^1 \nu_1(dz)=\theta, \int_0^1 z\nu_1(dz)\le\theta(1-\theta)}} \left\{ meas(\Omega)\left(1+\int_0^1 f(z)\,\nu_1(dz)\right)|\mathbf{E}|^2\right\}. \tag{4.26}$$

To finish the minimization we note that for $\lambda > 1$ the function $f(z)$ is strictly positive on $0 < z < \infty$ with $f(0) = 0$ and $\lim_{z\to\infty} f(z) = 0$. Moreover, $f(z)$ has a global maximum over $[0,\infty)$ at $z = 1/(\lambda-1)$ with $\acute{f}(z) \ge 0$ for $z \le 1/(\lambda-1)$ and $\acute{f}(z) \le 0$ for $z \ge 1/(\lambda-1)$. With this in mind we choose $\nu_1(dz) = \theta\delta(z)dz$. Since this choice is admissible we have established that $\underline{\mathrm{A}} = meas(\Omega)|\mathbf{E}|^2$.

Next we establish the upper bound. From Theorem 4.1 it follows that

$$\overline{\mathrm{B}} = \sup_{M\in R} \left\{ meas(\Omega)(\mathbf{I}+M)\,\mathbf{E}\cdot\mathbf{E}\right\}. \tag{4.27}$$

Here it is evident that for $(\nu_1, \dots, \nu_N)$ fixed the maximum occurs when $\mathbf{E}$ lies in the eigenspace of the largest eigenvalue of M. Without loss of generality we assume that $\lambda_1 = \int_0^1 f(z)\,\nu_1(dz)$ is the largest eigenvalue of M, and we choose $\mathbf{e}^1 = \mathbf{E}/|\mathbf{E}|$ to find that

$$\overline{\mathrm{B}} = \sup_{\substack{\nu_1\ge 0,\\ \int_0^1 \nu_1(dz)=\theta, \int_0^1 z\nu_1(dz)\le\theta(1-\theta)}} \left\{ meas(\Omega)\left(1+\int_0^1 f(z)\,\nu_1(dz)\right)|\mathbf{E}|^2\right\}. \tag{4.28}$$

To proceed we normalize and write $\nu_1(dz) = \theta p(dz)$. The extremal problem becomes

$$\overline{\mathrm{B}} = meas(\Omega)\left(|\mathbf{E}|^2 + \theta\sup_{p\in\mathcal{C}}\left(\int_0^1 f(z)\,p(dz)\right)|\mathbf{E}|^2\right), \tag{4.29}$$

where $\mathcal{C}$ is the set of probability measures for which $0 \leq \bar{z} = \int_0^1 z\, p(dz) \leq (1-\theta)$. Noting that the function $f(z)$ is strictly concave over an interval that includes $[0, 1/(\lambda-1)]$, strictly increasing on $[0, 1/(\lambda-1)]$, and strictly decreasing on $(1/(\lambda-1), \infty)$, we have for $(1-\theta) \leq 1/(\lambda-1)$ that

$$\int_0^1 f(z)\, p(dz) < f(\bar{z}) \leq f(1-\theta). \tag{4.30}$$

It is evident that the best choice is $p(dz) = \delta(z-(1-\theta))$, and we find that

$$\overline{\mathrm{B}} = meas(\Omega) \times (1 + \theta f(1-\theta))\, |\mathbf{E}|^2. \tag{4.31}$$

We observe that for $1 < \lambda \leq 2$ we have $1/(\lambda-1) \geq 1$ and for $0 \leq \theta \leq 1$ we always have $(1-\theta) \leq 1/(\lambda-1)$. On the other hand, when $(1-\theta) \geq 1/(\lambda-1)$ it is evident that the best choice corresponds to the global maximum of f, i.e., $p(dz) = \delta(z - 1/(\lambda-1))$, and we find that

$$\overline{\mathrm{B}} = meas(\Omega) \times (1 + \theta f(1/(\lambda-1)))\, |\mathbf{E}|^2, \tag{4.32}$$

and the theorem follows. □

We conclude by proving Theorems 1.2 and 1.3. To prove Theorem 1.2 we show that the lower bound $\underline{\mathrm{A}}$ is attained by configurations made up of layers of the β phase with layer normals orthogonal to $\mathbf{E}$. We recall (1.2) and write it in the equivalent form

$$\begin{aligned} \alpha \Delta T &= 0 \quad \text{in the } \alpha \text{ phase,} \\ \beta \Delta T &= 0 \quad \text{in the } \beta \text{ phase, and} \\ \beta \nabla T \cdot \mathbf{n} &= \alpha \nabla T \cdot \mathbf{n} \quad \text{on the layer interface.} \end{aligned} \tag{4.33}$$

When $\mathbf{n}$ is perpendicular to $\mathbf{E}$ we easily see that the affine function $T = \mathbf{E} \cdot \mathbf{x}$ is a solution of (4.33) and optimality follows. To prove Theorem 1.3 we first suppose that that $1-\theta \leq 1/(\lambda-1)$ and show that the upper bound $\overline{\mathrm{B}}$ is saturated by a laminate of rank one. We refer to formulas (2.7), (2.9), and (2.10) and choose $\mathbf{n}^1$ parallel to $\mathbf{E}$ and set $\theta_1 = 1-\theta$ and $\theta_2 = 0$ to obtain

$$\lim_{\varepsilon \to 0} \|\nabla T_L^\varepsilon\|_2^2 = \overline{\mathrm{B}}. \tag{4.34}$$

Last we suppose that $1-\theta \geq 1/(\lambda-1)$. Here we choose $\mathbf{n}^1$ parallel to $\mathbf{E}$ and $\mathbf{n}^2$ orthogonal to $\mathbf{E}$ and choose $\theta_1 = \frac{1}{1+\theta(\lambda-1)}$ and $\theta_2 = 1-\theta-(\frac{1}{\lambda-1})$. This choice gives $\theta_1(1-\theta_2) = 1/(\lambda-1), (1-\theta_1)(1-\theta_2) = \theta$, and

$$\lim_{\varepsilon \to 0} \|\nabla T_L^\varepsilon\|_2^2 = \overline{\mathrm{B}} \tag{4.35}$$

follows from (2.7), (2.9), and (2.10).

STABILITY CONDITIONS FOR PATTERNS OF NONINTERACTING LARGE SHOCK WAVES*

MARTA LEWICKA†

Abstract. In this paper we study different conditions whose presence is required for

A. the admissibility and stability of large shocks present in solutions of a strictly hyperbolic $n \times n$ system of conservation laws in one space dimension

$$u_t + f(u)_x = 0,$$

B. the solvability and L^1 well posedness of the Cauchy problem for the above equation, near solutions containing large and stable, but noninteracting shock waves.

We compare the corresponding conditions of type A and B appearing in the literature; in particular, we show that the finiteness and stability conditions used in our most recent works generalize and/or unify these conditions in appropriate ways.

Key words. conservation laws, shock waves, stability conditions, large BV data

1. Introduction.

Consider the Cauchy problem for an $n \times n$ system of conservation laws in one space dimension:

$$u_t + f(u)_x = 0, \tag{1.1}$$

$$u(0, \cdot) = \bar{u}. \tag{1.2}$$

In the study of local existence and stability of solutions to (1.1), (1.2), due to the finite speed of propagation one is led to consider the special case where the initial data $\bar{u}$ is a small perturbation of a Riemann data:

$$\bar{u}(x) = \begin{cases} u^-, & x < 0, \\ u^+, & x > 0. \end{cases} \tag{1.3}$$

In this case, several results in the literature have shown that existence and stability of solutions can be obtained under a suitable linearized stability condition for the solutions of (1.1), (1.2), (1.3). (For a general theory of conservation laws in one space dimension, cf. [B], [D], [Sm].)

The main purpose of this paper is to compare the various assumptions of this kind and to prove their equivalence. We shall restrict ourselves to the case where the solution of (1.1), (1.2), (1.3) consists of $m + 1$ constant states, $m \in \{2, \dots, n\}$, separated by (possibly large) admissible shocks, say, in the characteristic families

$i_1 < \cdots < i_m$. Calling these intermediate states $u_0^0 = u^-, u_0^1, u_0^2, \dots, u_0^m = u^+$, and Λ^q the speed of the i_q shock, the linearized system has the form

$$v_t + Df(u_0^q) \cdot v_x = 0, \qquad x/t \in (\Lambda^q, \Lambda^{q+1}). \tag{1.4}$$

Along shock lines we have the boundary equations obtained by linearizing the Rankine–Hugoniot equations that yield the linear dependence of the strengths of the outgoing waves on the components of the incoming wave vector interacting with the i_q large shock under consideration:

$$\epsilon_k^{out} = \sum_{\substack{s:1\dots n \\ incoming}} W_q^{k,s} \cdot \epsilon_s^{in} \tag{1.5}$$

(see Figure 1.1).

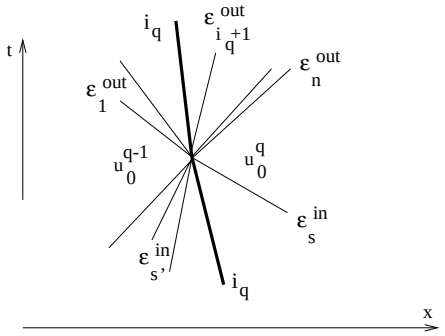

FIG. 1.1.

As we have mentioned, under some classical assumptions on the flux f in (1.1), which are recalled below, a variety of results concerning the (global) existence and uniqueness of admissible solutions to (1.1), (1.2) and their L^1 stability have been recently established [BC], [BM], [Le], [LT], [Scho], [W].

In all of these works, the conditions of two different natures are necessarily introduced:

A. conditions yielding the admissibility and stability of each of the large shocks in the reference solution of (1.1), (1.2), (1.3),

B. conditions guaranteeing the BV *stability* of the linearized system (1.4) [Scho], [BM], [Le], [W]. In [Scho], it is proved that they imply the local existence of solutions to the Cauchy problem, for data $\bar{u}$ suitably close to (1.3), and conditions providing the L^1 *stability* of the system (1.4) [BM], [BC], [Le]. It was proved that these in turn imply the L^1 stability of the nonlinear system (1.1), on a domain $\mathcal{D}$ of small BV perturbations of the data (1.3).

Our paper is organized as follows. In section 2 we focus on the conditions of type A, in particular, the well-known Majda stability condition [M].

Section 3 discusses different conditions of type B. In [Le], [LT], the stability conditions are formulated in terms of the existence of a suitable family of weights $w_s^q > 0$ such that the corresponding BV or L^1 norm of any solution of the linearized system (1.4) is nonincreasing in time. The main result of section 3 (Theorem 3.2) will show that the Schochet BV stability assumptions [Scho] are equivalent to BV stability assumptions in [Le]. Also, the L^1 stability condition in [BM], [Le], will appear to imply the mentioned BV stability (Theorem 3.1).

In the last section we treat the case of systems of $n = 2$ equations, with the presence of $m = 2$ large shocks and deal with the corresponding conditions introduced in [BC], [W], [LT].

We end this section by recalling the setting of the Cauchy problem (1.1), (1.2) (compare [Le]). In the n-dimensional state space $m+1$ distinct states $\{u_0^q\}_{q=0}^m$ are fixed, with their corresponding open disjoint neighborhoods $\{\Omega^q\}_{q=0}^m$ such that

- $f : \Omega \longrightarrow \mathbf{R}^n$ is smooth and defined on $\Omega = \bigcup_{q=0}^{m} \Omega^q \subset \mathbf{R}^n$.
- f is strictly hyperbolic in Ω, that is, at each point $u \in \Omega$, the matrix $Df(u)$ has n real and simple eigenvalues $\lambda_1(u) < \cdots < \lambda_n(u)$.
- Each characteristic field of (1.1) is either linearly degenerate or genuinely nonlinear, that is, with a basis $\{r_k(u)\}_{k=1}^n$ of corresponding right eigenvectors of $Df(u)$, $Df(u)r_k(u) = \lambda_k(u)r_k(u)$, each of the n directional derivatives $r_k \nabla \lambda_k$ vanishes either identically or nowhere.

The solution to (1.1), (1.2) with the initial data

$$\bar{u}(x) = \begin{cases} u_0^0, & x < 0, \\ u_0^m, & x > 0 \end{cases} \tag{1.6}$$

is given by m shocks (u_0^{q-1}, u_0^q), $q : 1 \dots m$, belonging to respective characteristic families i_q and travelling with respective speeds Λ^q:

$$u(t,x) = \begin{cases} u_0^0, & x < \Lambda^1 t, \\ u_0^q, & \Lambda^q t < x < \Lambda^{q+1} t, \quad q : 1 \dots m-1, \\ u_0^m, & x > \Lambda^m t, \end{cases} \tag{1.7}$$

as in Figure 1.2.

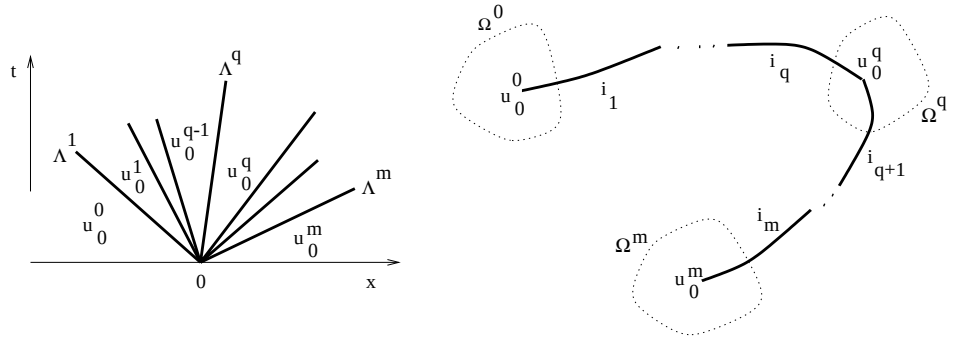

FIG. 1.2.

2. Stability of large shocks revisited. In this section we discuss the conditions of type A. Since every shock (u_0^{q-1}, u_0^q) has to be treated separately, it is not restrictive to assume that $m = 1$ and simplify the notation $u_0^0 = u^-, u_0^1 = u^+, \Omega^0 = \Omega^-, \Omega^1 = \Omega^m = \Omega^+, i_1 = i, \Lambda^1 = \Lambda$.

In this setting, for (1.7) to be a distributional solution of (1.1), (1.2), (1.3), the Rankine–Hugoniot conditions must be satisfied:

$$f(u^-) - f(u^+) = \Lambda(u^- - u^+). \tag{2.1}$$

Second, our i-shock is assumed to be compressive in the sense of Lax [L], that is,

$$\lambda_i(u^-) > \Lambda > \lambda_i(u^+). \tag{2.2}$$

Finally, in order to treat the Cauchy problem (1.1), (1.2), with $\bar{u}$ in (1.2) being a perturbation of (1.3), one must guarantee the so-called stability of the shock (u^-, u^+). This condition, introduced and justified in [LT], [Le], [BC] is the following:

(2.3)
There exists a smooth function $\Psi : \Omega^- \times \Omega^+ \longrightarrow \mathbf{R}^{n-1}$ such that

(i) $\Psi(u^0, u^1) = 0$ iff the states u^0 and u^1 can be connected by a (large) shock of the ith characteristic family, with the speed $\Lambda(u^0, u^1)$. The Rankine–Hugoniot condition holds: $f(u^0) - f(u^1) = \Lambda(u^0, u^1)(u^0 - u^1)$. In particular, $\Psi(u^-, u^+) = 0$ and $\Lambda(u^-, u^+) = \Lambda$.

(ii)
$$\operatorname{rank} \frac{\partial \Psi}{\partial u^0}(u^-, u^+) = \operatorname{rank} \frac{\partial \Psi}{\partial u^1}(u^-, u^+) = n - 1.$$

(iii) The $n - 1$ vectors
$$\left\{ \frac{\partial \Psi}{\partial u^0}(u^-, u^+) \cdot r_k(u^-) \right\}_{k=1}^{i-1} \cup \left\{ \frac{\partial \Psi}{\partial u^1}(u^-, u^+) \cdot r_k(u^+) \right\}_{k=i+1}^{n}$$
are linearly independent.

Under these hypotheses one can see that if only the sets Ω^-, Ω^+ are small enough, then any Riemann problem $(u^0, u^1) \in \Omega^- \times \Omega^+$ for (1.1) has a unique self-similar solution composed of n shocks or rarefaction waves. The ith wave is a large i compressive Lax shock, connecting some states in the domains Ω^- and Ω^+.

In [Scho], the stability of the large shock (u^-, u^+) satisfying (2.1), (2.2) is understood in the classical sense of Majda:

(2.4)
The n vectors
$$r_1(u^-), \dots, r_{i-1}(u^-), u^- - u^+, r_{i+1}(u^+), \dots, r_n(u^+)$$
are linearly independent.

Obviously for weak shocks (2.4) is always satisfied, and equivalent to (2.3)(iii). The main result of this section discusses this same situation in the general case.

THEOREM 2.1. *Let (u^-, u^+) be a Rankine–Hugoniot shock such that its speed Λ in* (2.1) *is not an eigenvalue of $Df(u^-)$ nor of $Df(u^+)$. Then the conditions* (2.3) *and* (2.4) *are equivalent.*

The proof of Theorem 2.1 relies on the construction of a particular function Ψ_0, whose zero level set consists of those pairs of states $(u^0, u^1) \in \Omega^- \times \Omega^+$ that can be connected by an admissible i-shock as in (2.3)(i).

We define Ψ_0 as follows:

$$\Psi_0(u^0, u^1) = \left\{ \left\langle f(u^1) - f(u^0),\ V_k(u^1 - u^0) \right\rangle \right\}_{k=1}^{n-1}, \tag{2.5}$$

where V_k are any smooth functions defined on a neighborhood of the vector $u_0 = u^+ - u^- \neq 0$ with values in $\mathbf{R}^n$, and such that for every u the space

$$\text{span}\{V_1(u), \dots, V_{n-1}(u)\}$$

is the orthogonal complement of the vector u.

LEMMA 2.2. *$\{V_k\}_{k=1}^{n-1}$ can be taken so that*

$$V_k(u_0) = -[DV_k(u_0)]^T \cdot u_0 \quad \forall k : 1 \dots n-1. \tag{2.6}$$

Proof. By $e_1, \dots, e_n$ we denote the standard Euclidean base of $\mathbf{R}^n$.

For u close to e_n define the vectors $\{\widetilde{V}_k(u)\}_{k=1}^{n-1}$ applying the Gramm–Schmidt orthogonalization process to n linearly independent vectors $u, e_1, \dots, e_{n-1}$. Namely, set

$$\begin{aligned} \widetilde{V}_1(u) &= e_1 - \langle e_1, u\rangle \cdot \tfrac{u}{|u|^2}, \\ \widetilde{V}_k(u) &= e_k - \left[\langle e_k, u\rangle \cdot \tfrac{u}{|u|^2} + \sum_{s=1}^{k-1} \langle e_k, \widetilde{V}_s(u)\rangle \cdot \widetilde{V}_s(u)\right] \quad \forall k : 2 \dots n-1. \end{aligned} \tag{2.7}$$

Note that

$$\widetilde{V}_k(e_n) = e_n \quad \forall k : 1 \dots n-1 \tag{2.8}$$

and

- $\langle \widetilde{V}_k(u), u\rangle = 0 \quad \forall k : 1 \dots n-1$,
- $\{\widetilde{V}_k\}_{k=1}^{n-1}$ are smooth functions of u.

Thus, $\text{span}\{\widetilde{V}_1(u), \dots, \widetilde{V}_{n-1}(u)\}$ always complements orthogonally the vector u.

Moreover, using (2.8) and the fact that $\widetilde{V}_k \in \text{span}(e_1, \dots, e_k, u)$, by the explicit formulas (2.7) one proves inductively that

$$D\widetilde{V}_k(e_n) = [d_{sl}]_{s,l:1\dots n}, \quad d_{sl} = \begin{cases} -1 & \text{for } (s,l) = (n,k), \\ 0 & \text{otherwise.} \end{cases} \tag{2.9}$$

Now for u close to u_0 define

$$V_k(u) = A^{-1} \cdot \widetilde{V}_k(Au), \tag{2.10}$$

where A is an orthogonal transformation composed with an appropriate dilation such that $Au_0 = e_n$. Consequently

$$A^{-1} = |u_0|^2 A^T. \tag{2.11}$$

Obviously $\{V_k\}_{k=1}^{n-1}$ are smooth functions, and by the corresponding property of $\{\widetilde{V}_k\}_{k=1}^{n-1}$ they span the orthogonal complement of its argument vector.

By (2.10), (2.11), (2.9), and (2.8) we get

$$\begin{aligned} [DV_k(u_0)]^T \cdot u_0 =& A^T \cdot [D\widetilde{V}_k(e_n)]^T \cdot (A^T)^{-1} \cdot u_0 = A^{-1} \cdot [D\widetilde{V}_k(e_n)]^T \cdot Au_0 \\ =& -A^{-1} e_k = -A^{-1} \cdot \widetilde{V}_k(Au_0) = -V_k(u_0), \end{aligned}$$

which proves (2.6). ∎

Using the above lemma one finds a convenient formula for the derivatives of Ψ_0:

$$\frac{\partial \Psi_0}{\partial u^0}(u^-, u^+) = -V \cdot [Df(u^-) - \Lambda Id], \tag{2.12}$$

$$\frac{\partial \Psi_0}{\partial u^1}(u^-, u^+) = V \cdot [Df(u^+) - \Lambda Id], \tag{2.13}$$

where V is the $(n-1) \times n$ matrix, whose rows are the vectors $V_1(u_0), \dots, V_{n-1}(u_0)$. Note that since rank $V = n-1$, then Λ is neither an eigenvalue of $Df(u^-)$ nor $Df(u^+)$, which in view of (2.12), (2.13) implies

$$\operatorname{rank} \frac{\partial \Psi_0}{\partial u^0}(u^-, u^+) = \operatorname{rank} \frac{\partial \Psi_0}{\partial u^1}(u^-, u^+) = n-1. \tag{2.14}$$

Proof of Theorem 2.1.

Step 1. By (2.12), (2.13) we get

$$\frac{\partial \Psi_0}{\partial u^0}(u^-, u^+) \cdot r_k(u^-) = -(\lambda_k(u^-) - \Lambda) \cdot V \cdot r_k(u^-) \quad \forall k : 1 \dots i-1,$$

$$\frac{\partial \Psi_0}{\partial u^1}(u^-, u^+) \cdot r_k(u^+) = (\lambda_k(u^+) - \Lambda) \cdot V \cdot r_k(u^+) \quad \forall k : i+1 \dots n.$$

Since $\Lambda \notin \{\lambda_k(u^-)\}_{k=1}^{i-1} \cup \{\lambda_k(u^+)\}_{k=i+1}^{n}$ we see that the condition (2.3)(iii) for our function Ψ_0 is satisfied iff the vectors $\{V \cdot r_k(u^-)\}_{k=1}^{i-1} \cup \{V \cdot r_k(u^+)\}_{k=i+1}^{n}$ are linearly independent, which is in turn equivalent to Majda's condition (2.4), as $\ker\ V = \operatorname{span}(u_0)$. We have thus shown that (2.4) is equivalent to (2.3)(iii) for the function Ψ_0.

Recalling (2.14), one sees this way that (2.4) implies (2.3).

Step 2. Now we turn toward proving the converse implication. Let Ψ be any function satisfying (2.3). In particular, by (2.3)(ii), $\operatorname{rank}\ D\Psi(u^-, u^+)$ is maximal and equal to $n-1$. The same is true for $D\Psi_0(u^-, u^+)$, by (2.14), so

$$\operatorname{rank}\ D\Psi(u^-, u^+) = \operatorname{rank}\ D\Psi_0(u^-, u^+). \tag{2.15}$$

Another important remark is that

$$\ker\ D\Psi(u^-, u^+) = \ker\ D\Psi_0(u^-, u^+). \tag{2.16}$$

The spaces in (2.16) both coincide with the tangent space of the manifold $(\Psi_0)^{-1}(0)$ at point (u^-, u^+).

The following simple fact of linear algebra will be used in what follows.

LEMMA 2.3. *Let $A, B : \mathbf{R}^n \longrightarrow \mathbf{R}^s$ be two linear operators, $s < n$. Assume that* $\operatorname{rank}\ A = \operatorname{rank}\ B = s$ *and* $\ker\ A = \ker\ B$. *Then for any s vectors $v_1, \dots, v_s \in \mathbf{R}^n$ it holds that the vectors $\{Av_k\}_{k=1}^s$ are linearly independent iff $\{Bv_k\}_{k=1}^s$ are linearly independent.*

In view of (2.15), (2.16), we can apply Lemma 2.2 to the linear operators

$$D\Psi(u^-, u^+),\ D\Psi_0(u^-, u^+) : \mathbf{R}^{2n} \longrightarrow \mathbf{R}^{n-1}$$

and the following set of $n-1$ test vectors in $\mathbf{R}^{2n}$:

$$\{[r_k(u^-)^T, 0 \dots 0]^T\}_{k=1}^{i-1} \cup \{[0 \dots 0, r_k(u^+)^T]^T\}_{k=i+1}^{n}.$$

By (2.3)(iii) we receive that the same condition is satisfied by our function Ψ_0. This in turn, is equivalent to (2.4), as shown in Step 1. □

The proof of Theorem 2.1 shows that if the function Ψ as in (2.3) exists, then it can be replaced by the function Ψ_0, in this case necessarily enjoying the properties (2.3)(i)–(2.3)(iii).

3. *BV* and L^1 stability conditions compared. In this and the next sections we discuss different stability conditions of type B, used in [BC], [W], [Scho], and [Le]. Recall that these conditions guarantee the well posedness of the problem (1.1), (1.2) and the existence of the Lipschitz continuous semigroup of solutions, whose domain contains all the small $L^1 \cap BV$ perturbations of the initial data $\bar{u}$ in (1.6) (compare [Le]).

We show the equivalence of the Schochet BV stability condition (called in [Scho] the finiteness condition) with the BV stability condition used in [Le], as well as with the Wang BV stability condition [W], and the equivalence of L^1 stability condition from [BM], [Le] with the one introduced in [BC] for 2×2 systems.

Also (see Remark 3.8), we position our work to some of the results found in [LY].

We start by recalling the mentioned conditions.

3.1. *BV* stability condition. There exist positive weights $w_1^q, \dots, w_n^q$ (for every $q : 0 \dots m$) such that the following holds. Consider a small wave of a family $k \leq i_q$, hitting from the right the large initial i_q-shock (u_0^{q-1}, u_0^q), as in Figure 3.1. Then

$$\sum_{s=1}^{i_q-1} \frac{w_s^{q-1}}{w_k^q} \cdot \left| \frac{\partial}{\partial \epsilon_k^{in}} \, \epsilon_s^{out} \right| + \sum_{s=i_q+1}^{n} \frac{w_s^q}{w_k^q} \cdot \left| \frac{\partial}{\partial \epsilon_k^{in}} \, \epsilon_s^{out} \right| < 1 \tag{3.1}$$

at $\epsilon_1^{in} = \cdots = \epsilon_k^{in} = \cdots = \epsilon_n^{in} = 0$.

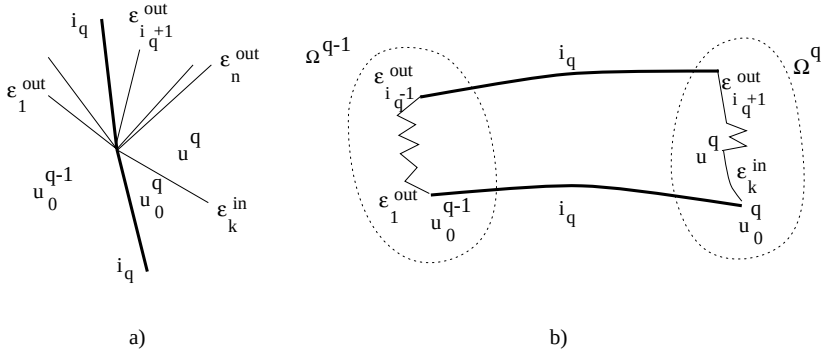

FIG. 3.1.

Symmetrically, in the case when a small k-wave with $k \geq i_q$ hits the shock (u_0^{q-1}, u_0^q) from the left (compare Figure 3.2), there holds

$$\sum_{s=1}^{i_q-1} \frac{w_s^{q-1}}{w_k^{q-1}} \cdot \left| \frac{\partial}{\partial \epsilon_k^{in}} \, \epsilon_s^{out} \right| + \sum_{s=i_q+1}^{n} \frac{w_s^q}{w_k^{q-1}} \cdot \left| \frac{\partial}{\partial \epsilon_k^{in}} \, \epsilon_s^{out} \right| < 1 \tag{3.2}$$

at $\epsilon_1^{in} = \cdots = \epsilon_k^{in} = \cdots = \epsilon_n^{in} = 0$.

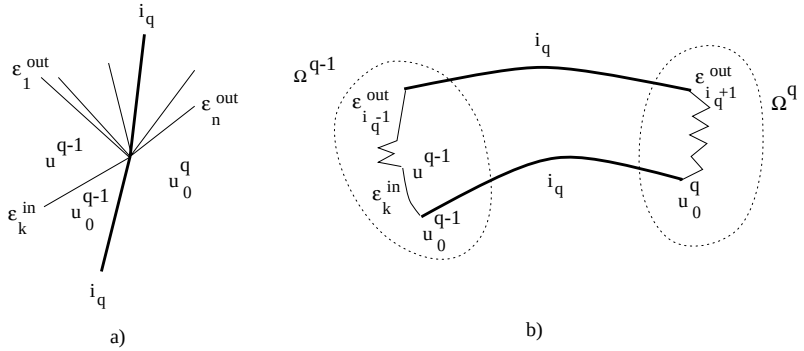

FIG. 3.2.

Regarding w_s^q as the weight given to an s-wave located in the region between the $q-1$ and the qth large shock, conditions (3.1), (3.2) simply say that every time a small wave hits a large shock, the total weighted strength of the outgoing small waves is smaller than the weighted strength of the incoming wave.

3.2. L^1 stability condition [Le], [BM]. There exist positive weights $w_1^q, \dots, w_n^q$ (for every $q : 0 \dots m$) such that in the setting of Figure 3.1

$$\begin{aligned}\sum_{s=1}^{i_q-1} \frac{w_s^{q-1}}{w_k^q} \cdot \left| \frac{\partial}{\partial \epsilon_k^{in}} \left(\frac{\epsilon_s^{out} \cdot (\lambda_s^{out} - \Lambda^q)}{(\lambda_k^{in} - \Lambda^q)} \right) \right| \\ + \sum_{s=i_q+1}^{n} \frac{w_s^q}{w_k^q} \cdot \left| \frac{\partial}{\partial \epsilon_k^{in}} \left(\frac{\epsilon_s^{out} \cdot (\lambda_s^{out} - \Lambda^q)}{(\lambda_k^{in} - \Lambda^q)} \right) \right| < 1\end{aligned} \tag{3.3}$$

at $\epsilon_1^{in} = \cdots = \epsilon_k^{in} = \cdots = \epsilon_n^{in} = 0$, while in the setting of Figure 3.2

$$\begin{aligned}\sum_{s=1}^{i_q-1} \frac{w_s^{q-1}}{w_k^{q-1}} \cdot \left| \frac{\partial}{\partial \epsilon_k^{in}} \left(\frac{\epsilon_s^{out} \cdot (\lambda_s^{out} - \Lambda^q)}{(\lambda_k^{in} - \Lambda^q)} \right) \right| \\ + \sum_{s=i_q+1}^{n} \frac{w_s^q}{w_k^{q-1}} \cdot \left| \frac{\partial}{\partial \epsilon_k^{in}} \left(\frac{\epsilon_s^{out} \cdot (\lambda_s^{out} - \Lambda^q)}{(\lambda_k^{in} - \Lambda^q)} \right) \right| < 1\end{aligned} \tag{3.4}$$

at $\epsilon_1^{in} = \cdots = \epsilon_k^{in} = \cdots = \epsilon_n^{in} = 0$.

Note that since the weights $\{w_i^0\}_{i=1}^n$ and $\{w_i^m\}_{i=1}^n$ appear only in one inequality (3.1) or (3.2), then the corresponding BV stability estimates for the leftmost large shock (u_0^0, u_0^1) and the rightmost (u_0^{m-1}, u_0^m) may take the following, simplified form:

$$\sum_{s=i_2}^{n} \frac{w_s^1}{w_k^1} \cdot \left| \frac{\partial}{\partial \epsilon_k^{in}} \, \epsilon_s^{out} \right| < 1 \tag{3.1a}$$

for all small waves of families $k \le i_1$, hitting the first shock i_1 from the right, and

$$\sum_{s=1}^{i_{m-1}} \frac{w_s^{m-1}}{w_k^{m-1}} \cdot \left| \frac{\partial}{\partial \epsilon_k^{in}} \, \epsilon_s^{out} \right| < 1 \tag{3.2a}$$

for all small waves of families $k \ge i_m$, hitting the last shock i_m from the left.

The analogous simplifications may be easily done for the L^1 stability estimates (3.3) and (3.4).

Also, for $q \notin \{1, m\}$, (3.1) and (3.2) can be rewritten as follows:

$$\sum_{s=1}^{i_{q-1}} \frac{w_s^{q-1}}{w_k^q} \cdot \left| \frac{\partial}{\partial \epsilon_k^{in}} \, \epsilon_s^{out} \right| + \sum_{s=i_{q+1}}^{n} \frac{w_s^q}{w_k^q} \cdot \left| \frac{\partial}{\partial \epsilon_k^{in}} \, \epsilon_s^{out} \right| < 1, \tag{3.1a}$$

$$\sum_{s=1}^{i_{q-1}} \frac{w_s^{q-1}}{w_k^{q-1}} \cdot \left| \frac{\partial}{\partial \epsilon_k^{in}} \, \epsilon_s^{out} \right| + \sum_{s=i_{q+1}}^{n} \frac{w_s^q}{w_k^{q-1}} \cdot \left| \frac{\partial}{\partial \epsilon_k^{in}} \, \epsilon_s^{out} \right| < 1. \tag{3.2a}$$

Analogously, the L^1 stability condition (3.3) and (3.4) for $q \notin \{1, m\}$ may be formulated with the correspondingly changed summation ranges.

THEOREM 3.1. *The L^1 stability condition* (3.3), (3.4) *implies the BV stability condition* (3.1), (3.2).

Proof. In view of the preceding remarks, assume that the L^1 stability condition (3.3a) and (3.4a) holds, with weights $\{w_s^q\}$. For $q : 1 \dots m-1$ and $s : 1 \dots n$ define

$$\widetilde{w}_s^q = \left| \lambda_s(u_0^q) - \Lambda^{q+1} \right| \cdot w_s^q.$$

We will show that the BV stability condition (3.1), (3.2) is satisfied for all $q : 1 \dots m$.

Indeed, to prove (3.1), compute

$$\begin{aligned}
&\sum_{s=1}^{i_{q-1}} \frac{\widetilde{w}_s^{q-1}}{\widetilde{w}_k^q} \cdot \left| \frac{\partial}{\partial \epsilon_k^{in}} \, \epsilon_s^{out} \right| + \sum_{s=i_{q+1}}^{n} \frac{\widetilde{w}_s^q}{\widetilde{w}_k^q} \cdot \left| \frac{\partial}{\partial \epsilon_k^{in}} \, \epsilon_s^{out} \right| \\
&\qquad = \sum_{s=1}^{i_{q-1}} \frac{w_s^{q-1}}{w_k^q} \cdot \left| \frac{\partial}{\partial \epsilon_k^{in}} \, \epsilon_s^{out} \right| \cdot \frac{|\lambda_s(u_0^{q-1}) - \Lambda^q|}{|\lambda_k(u_0^q) - \Lambda^{q+1}|} \\
&\qquad\quad + \sum_{s=i_{q+1}}^{n} \frac{w_s^q}{w_k^q} \cdot \left| \frac{\partial}{\partial \epsilon_k^{in}} \, \epsilon_s^{out} \right| \cdot \frac{|\lambda_s(u_0^q) - \Lambda^{q+1}|}{|\lambda_k(u_0^q) - \Lambda^{q+1}|} < 1
\end{aligned}$$

by (3.3a) and the following easily received inequalities:

$$\begin{aligned}
&\left| \lambda_k(u_0^q) - \Lambda^{q+1} \right| > |\lambda_k(u_0^q) - \Lambda^q| \quad \forall k \le i_q, \\
&\left| \lambda_k(u_0^q) - \Lambda^{q+1} \right| < |\lambda_k(u_0^q) - \Lambda^q| \quad \forall k \ge i_{q+1}.
\end{aligned}$$

The estimate (3.2) is justified in a similar way. ∎

3.3. The Schochet BV stability condition [Scho]. In connection with (3.1) and (3.2), for every $q : 1 \dots m$ define four nonnegative matrices, expressing the strengths of outgoing waves in terms of the strengths of the incoming small waves,

interacting with the large initial i_q-shock:

- interaction from the right, waves outgoing to the right

$$M_q^{rr} = [a_{sk}^q], \quad s : i_{q+1} \dots n, \ k : 1 \dots i_q,$$

- interaction from the right, waves outgoing to the left

$$M_q^{rl} = [a_{sk}^q], \quad s : 1 \dots i_{q-1}, \ k : 1 \dots i_q,$$

(3.5)

- interaction from the left, waves outgoing to the right

$$M_q^{lr} = [a_{sk}^q], \quad s : i_{q+1} \dots n, \ k : i_q \dots n,$$

- interaction from the left, waves outgoing to the left

$$M_q^{ll} = [a_{sk}^q], \quad s : 1 \dots i_{q-1}, \ k : i_q \dots n.$$

In all of the above definitions

$$a_{sk}^q = \left| \frac{\partial \epsilon_s^{out}}{\partial \epsilon_k^{in}} \right|$$

at $\epsilon_1^{in} = \cdots = \epsilon_k^{in} = \cdots = \epsilon_n^{in} = 0$.

Note that in (3.5) the range of s (indexing the outgoing small waves) depends on the neighboring large shock (of the family i_{q-1} or i_{q+1}). Indeed, it is relevant to keep track of only these newborn waves that in the future may possibly interact with large shocks, thus changing the global wave pattern.

Keeping the above comment in mind, we also remark that the notation for the matrices $M_1^{rl}, M_1^{lr}, M_1^{ll}, M_m^{rr}, M_m^{lr}, M_m^{rl}$ is ambiguous, however, in view of what we have said, the precise form of these matrices is irrelevant in the following analysis.

Consider the first pair of large shocks (u_0^0, u_0^1) and (u_0^1, u_0^2) and a tuple $\gamma = [\gamma_k]_{k:i_2 \dots n}$ of small waves travelling in the region between these shocks, and approaching the second one. By interaction of γ with (u_0^1, u_0^2), then, interaction of the newborn "reflected" waves with (u_0^0, u_0^1) and so on, further waves travelling in the region between the two large shocks are produced. Call

$$R^1 = M_1^{rr}. \tag{3.6}$$

The total strength of such waves, belonging to the characteristic families $k \geq i_2$, is then seen to be

$$\left[Id + R^1 M_2^{ll} + \left(R^1 M_2^{ll} \right)^2 + \cdots \right] |\gamma| = \left(Id - R^1 M_2^{ll} \right)^{-1} |\gamma| \doteq P^{1-2} |\gamma|$$

(where $|\gamma| = [|\gamma_k|]_{k:i_2 \dots n}$), provided that the first finiteness requirement

$$\text{all eigenvalues of } R^1 \cdot M_2^{ll} \text{ are } < 1 \text{ in absolute value} \tag{3.7}$$

is satisfied.

Now, view the pair of the first two large shocks as a single entity. The reflection matrix R^{1-2}, expressing the strengths of the outgoing small waves of families $k \geq i_3$, exiting the region between the first and the second large waves to the right of the

latter one, in terms of the incoming waves of the families $k \leq i_2$, possibly interacting with the $(i_1 - i_2)$ couple of large shocks from the right, has the form

$$R^{1-2} = M_2^{rr} + M_2^{lr} P^{1-2} R^1 M_2^{rl}.$$

The natural finiteness requirement for the triple $(i_1 - i_2 - i_3)$ of large shocks, analogous to (3.7) is then

$$\text{all eigenvalues of } R^{1-2} \cdot M_3^{ll} \text{ are } < 1 \text{ in absolute value.}$$

Proceeding in the same manner and viewing any fixed combination $(i_1 - \cdots - i_q)$ of consecutive large shocks as a single entity, influencing its succeeding large wave i_{q+1}, we obtain the following $(m-1)$ assertions that constitute the announced Schochet BV stability condition:

$$\begin{aligned} &\text{spRad}(F^{1-2}) < 1, \\ &\text{spRad}(F^{1-2-3}) < 1, \\ &\quad \vdots \\ &\text{spRad}(F^{1-\cdots-m}) < 1 \end{aligned} \tag{3.8}$$

(spRad stands here for the spectral radius of the reference matrix). The finiteness matrices F are defined inductively, together with the corresponding reflection and production matrices R, P, by recalling (3.6) and setting

$$F^{1-\cdots-q} \doteq R^{1-\cdots-(q-1)} \cdot M_q^{ll} \qquad \text{for } q : 2 \dots m, \tag{3.9}$$

$$P^{1-\cdots-q} \doteq \left(Id - F^{1-\cdots-q}\right)^{-1} \qquad \text{for } q : 2 \dots m, \tag{3.10}$$

$$R^{1-\cdots-q} \doteq M_q^{rr} + M_q^{lr} P^{1-\cdots-q} R^{1-\cdots-(q-1)} M_q^{rl} \qquad \text{for } q : 2 \dots m-1. \tag{3.11}$$

3.4. *BV* stability condition. The main theorem of this subsection is the following.

THEOREM 3.2. *The BV stability condition* (3.1), (3.2) *is equivalent to the Schochet BV stability condition* (3.8).

To prove Theorem 3.2, we need two abstract results on matrix theory.

LEMMA 3.3. *Let $Q = [q_{sk}]_{s,k:1\dots n}$ be an $n \times n$ matrix with nonnegative entries: $q_{sk} \geq 0$. The following conditions are equivalent:*

(i) $\text{spRad}(Q) < 1$.

(ii) *There exists a diagonal matrix $W = \text{diag}(w_1, \dots, w_n)$ with positive diagonal entries $w_s > 0$ such that $\| WQW^{-1} \|_1 < 1$.*
Here the norm of an $n \times n$ matrix $P = [p_{sk}]_{s,k:1\dots n}$ is defined by

$$\| P \|_1 \ = \max_{k:1\dots n} \sum_{s=1}^{n} |p_{sk}|.$$

The above lemma, which came up independently in the investigations leading to this paper, follows also from the results in [LY, Theorem 1 in Appendix 1]; thus for brevity we omit its proof.

LEMMA 3.4. *Let A, B be two $n \times n$ matrices with nonnegative entries:*

$$A = [a_{sk}]_{s,k:1\dots n}, \quad B = [b_{sk}]_{s,k:1\dots n}.$$

Assume that there exist two sets of indices $col, ver \subset \{1 \dots n\}$ *with the properties*

- $col \cap ver = \emptyset$,
- $\forall k \notin col\ \forall s : 1 \dots n, \quad a_{sk} = b_{ks} = 0$,
- $\forall s \notin ver\ \forall k : 1 \dots n, \quad a_{sk} = b_{ks} = 0$.

Then the following two statements are equivalent:

(i) *There exists* $W = \mathrm{diag}(w_1, \dots, w_n)$ *with all* $w_k > 0$ *such that* $\| WAW^{-1} \|_1 < 1$ *and* $\| WBW^{-1} \|_1 < 1$.

(ii) *There exists* $W = \mathrm{diag}(w_1, \dots, w_n)$ *with all* $w_k > 0$ *such that* $\| WABW^{-1} \|_1 < 1$.

The matrix norm $\| \cdot \|_1$ *is defined as in Lemma* 3.3.

Proof. (i) $\Rightarrow$ (ii). This implication is an obvious consequence of the fact that $\| \cdot \|_1$ is a matrix norm.

(ii) $\Rightarrow$ (i). Since $WABW^{-1} = (WAW^{-1})(WBW^{-1})$, we may without loss of generality assume that $\| AB \|_1 < 1$ and prove the existence of a diagonal matrix W satisfying (i). By (ii) we have

$$\sum_{s \in col} \left[b_{sk} \cdot \sum_{r \in ver} a_{rs} \right] < 1 \quad \forall k \in ver.$$

For a fixed $\epsilon > 0$ define

$$w_k = \begin{cases} \displaystyle\sum_{s \in ver} a_{sk} + \epsilon & \text{for } k \in col, \\ 1 & \text{otherwise.} \end{cases}$$

Then

$$\sum_{s \in ver} w_s a_{sk} = \sum_{s \in ver} a_{sk} < w_k \quad \forall k \in col,$$

$$\sum_{s \in col} w_s b_{sk} = \sum_{s \in col} \left(\sum_{r \in ver} a_{rs} \right) b_{sk} + \sum_{s \in col} \epsilon b_{sk} < 1 = w_k \quad \forall k \in ver,$$

provided that ϵ is small enough.

We have thus proved that $\| WAW^{-1} \|_1 < 1$ and $\| WBW^{-1} \|_1 < 1$. ∎

For every matrix $M_q^{xy},\ x, y \in \{l, r\}$, define the corresponding square $n \times n$ matrix $\widetilde{M}_q^{xy}$ by completing all the "missing" entries with zeros. For example, in view of (3.5)

$$\widetilde{M}_1^{rr} = [\widetilde{a}_{sk}]_{s,k:1\dots n}, \qquad \widetilde{a}_{sk} = \begin{cases} a_{sk} & \text{for } s : i_2 \dots n,\ k : 1 \dots i_1, \\ 0 & \text{otherwise.} \end{cases}$$

The next lemma shows some possible reformulations of our BV stability condition (3.1), (3.2).

LEMMA 3.5. *The following conditions are equivalent to the* BV *stability condition* (3.1), (3.2) :

(i) *There exist $m-1$ diagonal matrices $\{W^q\}_{q=1}^{m-1}$ with positive diagonal entries such that*

(3.12)
$$\| W^1 \widetilde{M}_1^{rr} (W^1)^{-1} \|_1 < 1,$$

(3.13)
$$\begin{array}{l} \| W^{q-1} \widetilde{M}_q^{ll} (W^{q-1})^{-1} + W^q \widetilde{M}_q^{lr} (W^{q-1})^{-1} \|_1 < 1 \\ \| W^q \widetilde{M}_q^{rr} (W^q)^{-1} + W^{q-1} \widetilde{M}_q^{rl} (W^q)^{-1} \|_1 < 1 \end{array} \qquad \forall q : 2 \dots m-1,$$

(3.14)
$$\| W^{m-1} \widetilde{M}_m^{ll} (W^{m-1})^{-1} \|_1 < 1.$$

(ii) *Define two block square matrices of the dimension $(m-1)\cdot n$:*

$$Odd_m = \begin{bmatrix} \widetilde{M}_1^{rr} & 0 & \dots & \dots & 0 \\ 0 & \widetilde{M}_3^{ll} & \widetilde{M}_3^{rl} & 0 & \vdots \\ \vdots & \widetilde{M}_3^{lr} & \widetilde{M}_3^{rr} & 0 & \\ \vdots & 0 & 0 & \widetilde{M}_5^{ll} & \\ 0 & \dots & & & \ddots \end{bmatrix},$$

$$Even_m = \begin{bmatrix} \widetilde{M}_2^{ll} & \widetilde{M}_2^{rl} & 0 & \dots & 0 \\ \widetilde{M}_2^{lr} & \widetilde{M}_2^{rr} & 0 & \dots & \\ 0 & 0 & \widetilde{M}_4^{ll} & \widetilde{M}_4^{rl} & \\ \vdots & \vdots & \widetilde{M}_4^{lr} & \widetilde{M}_4^{rr} & \\ 0 & & & & \ddots \end{bmatrix}.$$

Then

(3.15)
$$\mathrm{spRad}(Odd_m \cdot Even_m) < 1.$$

Proof. The condition (i) is obviously equivalent to (3.1), (3.2) if we define $W^q = \mathrm{diag}(w_1^q, \dots, w_n^q)$ for all $q : 1 \dots m-1$.

Note that (3.12), (3.13), (3.14) are equivalent to

(3.16)
$$\| W \cdot Odd_m \cdot W^{-1} \| < 1, \qquad \| W \cdot Even_m \cdot W^{-1} \| < 1,$$

where W is the block diagonal matrix of the dimension $(m-1)\cdot n$ given by

$$W = \mathrm{diag}(W^1, \dots, W^{m-1}).$$

By Lemma 3.3 and Lemma 3.4, (3.16) is in turn equivalent to (3.15), which proves (ii). ∎

Before we give the proof of Theorem 3.2, we need one more result of a technical nature.

LEMMA 3.6. *Let A, B be two $n \times n$ matrices with nonnegative entries such that $\| A + B \|_1 < 1$. Then $\| B \cdot (Id - A)^{-1} \|_1 < 1$.*

Proof. Note first that since $\| A \|_1 < 1$, then the matrix $Id - A$ is invertible and its inverse

$$(Id - A)^{-1} = Id + A + A^2 + \cdots$$

has nonnegative entries. From the assumption it follows moreover that

$$\sum_{i=1}^{n} [B]_{ik} < 1 - \sum_{i=1}^{n} [A]_{ik} = \sum_{i=1}^{n} [Id - A]_{ik},$$

for every $k : 1 \dots n$, and thus

$$\begin{aligned}
\sum_{i=1}^{n} [B \cdot (Id - A)^{-1}]_{ik} &= \sum_{s=1}^{n} \left(\sum_{i=1}^{n} [B]_{is} \right) \cdot [(Id - A)^{-1}]_{sk} \\
&< \sum_{s=1}^{n} \left(\sum_{i=1}^{n} [Id - A]_{is} \right) \cdot [(Id - A)^{-1}]_{sk} \\
&= \sum_{i=1}^{n} [(Id - A) \cdot (Id - A)^{-1}]_{ik} = 1,
\end{aligned}$$

for every $k : 1 \dots n$, which proves our lemma. □

Now we are ready to give the following proof.

Proof of Theorem 3.2.

Step 1. (3.1), (3.2) ⇒ (3.8). We use the equivalent form of the BV stability condition (3.1), (3.2) given in Lemma 3.5(i).

We first show that

$$\forall q : 1 \dots m-1 \quad \| W^q \cdot \widetilde{R}^{1-\cdots-q} \cdot (W^q)^{-1} \|_1 < 1. \tag{3.17}$$

We proceed by induction on q. For $q = 1$, (3.17) is equivalent to (3.12) in view of (3.6). For $q : 2 \dots m-1$, by (3.11) we have

$$\begin{aligned}
W^q \cdot \widetilde{R}^{1-\cdots-q} \cdot (W^q)^{-1} &= W^q \widetilde{M}_q^{rr} (W^q)^{-1} \\
&\quad + \left[W^q \widetilde{M}_q^{lr} \widetilde{P}^{1-\cdots-q} \widetilde{R}^{1-\cdots-(q-1)} (W^{q-1})^{-1} \right] \\
&\quad \cdot \left[W^{q-1} \widetilde{M}_q^{rl} (W^q)^{-1} \right].
\end{aligned}$$

The desired conclusion (3.17) will thus follow from the second inequality in (3.13) provided that

$$\| W^q \widetilde{M}_q^{lr} \widetilde{P}^{1-\cdots-q} \widetilde{R}^{1-\cdots-(q-1)} (W^{q-1})^{-1} \|_1 < 1. \tag{3.18}$$

Note that

$$
\begin{aligned}
&W^q\widetilde{M}_q^{lr}\widetilde{P}^{1-\cdots-q}\widetilde{R}^{1-\cdots-(q-1)}(W^{q-1})^{-1}\\
&\quad= W^q\widetilde{M}_q^{lr}\cdot\Big(Id-\widetilde{R}^{1-\cdots-(q-1)}\widetilde{M}_q^{ll}\Big)^{-1}\cdot\widetilde{R}^{1-\cdots-(q-1)}(W^{q-1})^{-1}\\
&\quad= \Big[W^q\widetilde{M}_q^{lr}(W^{q-1})^{-1}\Big]\\
&\qquad\cdot\Big\{Id-\Big[W^{q-1}\widetilde{R}^{1-\cdots-(q-1)}(W^{q-1})^{-1}\Big]\cdot\Big[W^{q-1}\widetilde{M}_q^{ll}(W^{q-1})^{-1}\Big]\Big\}^{-1}\\
&\qquad\cdot\Big[W^{q-1}\widetilde{R}^{1-\cdots-(q-1)}(W^{q-1})^{-1}\Big].
\end{aligned}
\tag{3.19}
$$

Setting

$$A=W^{q-1}\widetilde{M}_q^{ll}(W^{q-1})^{-1},\qquad B=W^q\widetilde{M}_q^{lr}(W^{q-1})^{-1}$$

and combining Lemma 3.6 with the inductive assumption

$$\|\ W^{q-1}\cdot\widetilde{R}^{1-\cdots-(q-1)}\cdot(W^{q-1})^{-1}\ \|_1<1,$$

we get (3.18) by (3.19) and thus complete the proof of (3.17).

We now prove inductively that the BV stability condition (3.1), (3.2) implies (3.8). For $m=2$, the conditions (3.12) and (3.14) are by Lemmas 3.3 and 3.4 equivalent to

$$\text{all eigenvalues of } \widetilde{M}_1^{rr}\cdot\widetilde{M}_2^{ll} \text{ are } <1 \text{ in absolute value.} \tag{3.20}$$

However,

$$\text{Spec } M_1^{rr}M_2^{ll}\subset\text{Spec }\widetilde{M}_1^{rr}\widetilde{M}_2^{ll}\subset\big(\text{Spec }M_1^{rr}M_2^{ll}\big)\cup\{0\},$$

thus (3.20) is equivalent to

$$\text{spRad}(F^{1-2})<1,$$

which is in turn precisely the condition (3.8).

Note that we proved above even more than we need to at this point—we proved the equivalence of (3.1), (3.2), and (3.8) in case $m=2$ of only two large shocks present.

Let now $m>2$. Since (3.13) for $q=m-1$ implies

$$\|\ W^{q-2}\widetilde{M}_{q-1}^{ll}(W^{q-1})^{-1}\ \|_1<1,$$

by the inductive assumption we get

$$\text{spRad}(F^{1-\cdots-q})<1\quad\forall q:2\dots m-1.$$

However, by (3.14) and (3.17) for $q=m-1$, in view of Lemma 3.4 and definition (3.9)

$$\|\ W^{m-1}\widetilde{F}^{1-\cdots-m}(W^{m-1})^{-1}\ \|_1<1,$$

which by Lemma 3.3 implies finally

$$\mathrm{spRad}(F^{1-\cdots-m}) < 1.$$

This finishes the proof of (3.1), (3.2) $\Rightarrow$ (3.8). □

Step 2. (3.8) $\Rightarrow$ (3.1), (3.2). We use the equivalent form of the BV stability condition (3.1), (3.2) given in Lemma 3.5(ii).

We proceed by induction on m. For $m = 2$ the assertion has already been established in Step 1. Let $m > 2$ and fix $\lambda \geq 1$. We will show that

$$\det(Odd_m \cdot Even_m - \lambda Id) \neq 0, \tag{3.21}$$

which by the property of nonnegative matrices mentioned in the proof of Lemma 3.3 will prove the theorem.

Assume first that m is an odd number. By known formulae on the determinant of block matrices (see [G]) and a few easy computations one gets

$$\begin{aligned}
&\det(Odd_m \cdot Even_m - \lambda Id)\\
&\quad = \det(Odd_{m-1} \cdot Even_{m-1} - \lambda Id)\\
&\qquad \cdot \det\Big(\widetilde{M}_m^{ll}\widetilde{M}_{m-1}^{rr} + \widetilde{M}_m^{ll} \cdot A_m \cdot (\lambda Id - Odd_{m-1} \cdot Even_{m-1})^{-1}\\
&\qquad\qquad \cdot B_m \cdot \widetilde{M}_{m-1}^{rl} - \lambda Id\Big),
\end{aligned} \tag{3.22}$$

where A_m is an $n \times ((m-2)\cdot n)$ block matrix of the form

$$A_m = \begin{bmatrix} 0 & \dots & \dots & 0 & \widetilde{M}_{m-1}^{lr} \end{bmatrix},$$

and B_m is an $((m-2)\cdot n) \times n$ block matrix

$$B_m = \begin{bmatrix} 0 & \dots & 0 & \widetilde{M}_{m-2}^{rl} & \widetilde{M}_{m-2}^{rr} \end{bmatrix}^T,$$

while Odd_{m-1} and $Even_{m-1}$ are defined analogously to Odd_m and $Even_m$ as in Lemma 3.5(ii).

Note that the Schochet condition (3.8) implies (by the inductive assumption)

$$\det\left(Odd_{m-1} \cdot Even_{m-1} - \lambda Id\right) \neq 0, \tag{3.23}$$

$$\mathrm{spRad}(F^{1-\cdots-m}) < 1. \tag{3.24}$$

By the definitions (3.9)–(3.11)

$$F^{1-\cdots-m} = M_m^{ll} \cdot \Big[M_{m-1}^{rr} + M_{m-1}^{lr}\big(Id - F^{1-\cdots-(m-1)}\big)^{-1} \cdot R^{1-\cdots-(m-2)} M_{m-1}^{rl}\Big].$$

Thus, in view of (3.23) and (3.24), the needed (3.21) will follow from (3.22) provided that

$$\begin{aligned}
&A_m \cdot (Id - Odd_{m-1} \cdot Even_{m-1})^{-1} \cdot B_m\\
&\qquad = \widetilde{M}_{m-1}^{lr} \cdot \big(Id - \widetilde{F}^{1-\cdots-(m-1)}\big)^{-1} \cdot \widetilde{R}^{1-\cdots-(m-2)}.
\end{aligned} \tag{3.25}$$

By the same kind of reasoning it is possible to prove that for m even, (3.21) is a consequence of the formula

$$\begin{aligned} C_m \cdot (Id - Odd_{m-1} \cdot Even_{m-1})^{-1} \cdot D_m \\ = \left(Id - \widetilde{F}^{1-\cdots-(m-1)}\right)^{-1} \cdot \widetilde{R}^{1-\cdots-(m-2)} \cdot \widetilde{M}^{rl}_{m-1}, \end{aligned} \tag{3.26}$$

where C_m is an $n \times ((m-2)\cdot n)$ block matrix of the form

$$C_m = \left[\begin{array}{ccccc} 0 & \dots & 0 & \widetilde{M}^{lr}_{m-2} & \widetilde{M}^{rr}_{m-2} \end{array} \right],$$

and D_m is an $((m-2)\cdot n) \times n$ block matrix

$$D_m = \left[\begin{array}{ccccc} 0 & \dots & \dots & 0 & \widetilde{M}^{rl}_{m-1} \end{array} \right]^T.$$

In the remaining part of the proof we will concentrate on showing that (3.25) holds for every odd number m. The proof of (3.26) is entirely the same, so we leave it to the careful reader.

We are going to prove (3.25) by induction on odd numbers m. For $m = 3$, the left-hand side of (3.25) reduces to

$$\widetilde{M}^{lr}_2 \cdot (Id - \widetilde{M}^{rr}_1 \cdot \widetilde{M}^{ll}_2)^{-1} \cdot \widetilde{M}^{rr}_1,$$

which is precisely equal to $\widetilde{M}^{lr}_2 \cdot \left(Id - \widetilde{F}^{1-2}\right)^{-1} \cdot \widetilde{R}^1$ by (3.6) and (3.9).

For $m > 3$ and odd, computing $(Id - Odd_{m-1} \cdot Even_{m-1})^{-1}$ in terms of the matrices $Odd_{m-3}, Even_{m-3}$, and the basic block-interaction matrices M^{xy}_q, we receive the equivalent form of the left-hand side of the formula (3.25):

$$\begin{aligned} A_m \cdot (Id - Odd_{m-1} \cdot Even_{m-1})^{-1} \cdot B_m \\ = \left[\begin{array}{cc} 0 & \widetilde{M}^{lr}_{m-1} \end{array} \right] \\ \cdot \left\{ Id - \left[\begin{array}{cc} \widetilde{M}^{ll}_{m-2} & \widetilde{M}^{rl}_{m-2} \\ \widetilde{M}^{lr}_{m-2} & \widetilde{M}^{rr}_{m-2} \end{array} \right] \cdot \left[\begin{array}{cc} \widetilde{M}^{rr}_{m-3} & 0 \\ 0 & \widetilde{M}^{ll}_{m-1} \end{array} \right] \right. \\ - \left[\begin{array}{c} \widetilde{M}^{ll}_{m-2} \\ \widetilde{M}^{lr}_{m-2} \end{array} \right] \cdot A_{m-2} \cdot (Id - Odd_{m-3} \cdot Even_{m-3})^{-1} \\ \left. \cdot B_{m-2} \cdot \left[\begin{array}{cc} \widetilde{M}^{rl}_{m-3} & 0 \end{array} \right] \right\}^{-1} \cdot \left[\begin{array}{c} \widetilde{M}^{rl}_{m-2} \\ \widetilde{M}^{rr}_{m-2} \end{array} \right]. \end{aligned} \tag{3.27}$$

Using the inductive assumption and the definition (3.11) we reformulate the right-hand side of (3.27):

$$
\begin{aligned}
&A_m \cdot (Id - Odd_{m-1} \cdot Even_{m-1})^{-1} \cdot B_m \\
&\quad = \begin{bmatrix} 0 & \widetilde{M}^{lr}_{m-1} \end{bmatrix} \\
&\qquad \cdot \Bigg\{ Id - \begin{bmatrix} \widetilde{M}^{ll}_{m-2} & \widetilde{M}^{rl}_{m-2} \\ \widetilde{M}^{lr}_{m-2} & \widetilde{M}^{rr}_{m-2} \end{bmatrix} \cdot \begin{bmatrix} \widetilde{M}^{rr}_{m-3} & 0 \\ 0 & \widetilde{M}^{ll}_{m-1} \end{bmatrix} \\
&\qquad\qquad - \begin{bmatrix} \widetilde{M}^{ll}_{m-2} \\ \widetilde{M}^{lr}_{m-2} \end{bmatrix} \cdot \widetilde{M}^{lr}_{m-3} \cdot (Id - \widetilde{F}^{1-\cdots-(m-3)})^{-1} \\
&\qquad\qquad\qquad \cdot \widetilde{R}^{1-\cdots-(m-4)} \begin{bmatrix} \widetilde{M}^{rl}_{m-3} & 0 \end{bmatrix} \Bigg\}^{-1} \cdot \begin{bmatrix} \widetilde{M}^{rl}_{m-2} \\ \widetilde{M}^{rr}_{m-2} \end{bmatrix} \\
&\quad = \begin{bmatrix} 0 & \widetilde{M}^{lr}_{m-1} \end{bmatrix} \cdot \Bigg\{ Id - \begin{bmatrix} \widetilde{M}^{ll}_{m-2} & \widetilde{M}^{rl}_{m-2} \\ \widetilde{M}^{lr}_{m-2} & \widetilde{M}^{rr}_{m-2} \end{bmatrix} \\
&\qquad \cdot \begin{bmatrix} \widetilde{M}^{rr}_{m-3} + & \\ \widetilde{M}^{lr}_{m-3}(Id - \widetilde{F}^{1-\cdots-(m-3)})^{-1} \cdot & 0 \\ \cdot \widetilde{R}^{1-\cdots-(m-4)} \widetilde{M}^{rl}_{m-3} & \\ 0 & \widetilde{M}^{ll}_{m-1} \end{bmatrix} \Bigg\}^{-1} \cdot \begin{bmatrix} \widetilde{M}^{rl}_{m-2} \\ \widetilde{M}^{rr}_{m-2} \end{bmatrix} \\
&\quad = \begin{bmatrix} 0 & \widetilde{M}^{lr}_{m-1} \end{bmatrix} \cdot \Bigg\{ Id - \begin{bmatrix} \widetilde{M}^{ll}_{m-2} & \widetilde{M}^{rl}_{m-2} \\ \widetilde{M}^{lr}_{m-2} & \widetilde{M}^{rr}_{m-2} \end{bmatrix} \\
&\qquad\qquad \cdot \begin{bmatrix} \widetilde{R}^{1-\cdots-(m-3)} & 0 \\ 0 & \widetilde{M}^{ll}_{m-1} \end{bmatrix} \Bigg\}^{-1} \cdot \begin{bmatrix} \widetilde{M}^{rl}_{m-2} \\ \widetilde{M}^{rr}_{m-2} \end{bmatrix}.
\end{aligned} \tag{3.28}
$$

Calling

$$
\begin{aligned}
X &= Id - \widetilde{M}^{ll}_{m-2} \widetilde{R}^{1-\cdots-(m-3)}, \\
Y &= -\widetilde{M}^{rl}_{m-2} \widetilde{M}^{ll}_{m-1}, \\
Z &= -\widetilde{M}^{lr}_{m-2} \widetilde{R}^{1-\cdots-(m-3)}, \\
W &= Id - \widetilde{M}^{lr}_{m-2} \widetilde{M}^{ll}_{m-1},
\end{aligned}
$$

we rewrite the right-hand side of (3.28):

$$
\begin{aligned}
&\begin{bmatrix} 0 & \widetilde{M}^{lr}_{m-1} \end{bmatrix} \cdot \begin{bmatrix} X & Y \\ Z & W \end{bmatrix}^{-1} \cdot \begin{bmatrix} \widetilde{M}^{rl}_{m-2} \\ \widetilde{M}^{rr}_{m-2} \end{bmatrix} \\
&\qquad = \widetilde{M}^{lr}_{m-1} \cdot \Big(-(W - ZX^{-1}Y)^{-1} ZX^{-1} \cdot \widetilde{M}^{rl}_{m-2} \\
&\qquad\qquad + (W - ZX^{-1}Y)^{-1} \cdot \widetilde{M}^{rr}_{m-2} \Big) \\
&\qquad = \widetilde{M}^{lr}_{m-1} \cdot (W - ZX^{-1}Y)^{-1} \cdot \big(\widetilde{M}^{rr}_{m-2} - ZX^{-1} \cdot \widetilde{M}^{rl}_{m-2} \big) \\
&\qquad = \widetilde{M}^{lr}_{m-1} \cdot (Id - \widetilde{R}^{1-\cdots-(m-2)} \widetilde{M}^{ll}_{m-1})^{-1} \cdot \widetilde{R}^{1-\cdots-(m-2)},
\end{aligned} \tag{3.29}
$$

because, by definitions (3.9)–(3.11)

$$W - ZX^{-1}Y = Id - \widetilde{R}^{1-\cdots-(m-2)}\widetilde{M}^{ll}_{m-1},$$
$$\widetilde{M}^{rr}_{m-2} - ZX^{-1}\cdot\widetilde{M}^{rl}_{m-2} = \widetilde{R}^{1-\cdots-(m-2)}.$$

The equality (3.29) together with (3.28) prove (3.25). The proof of Step 2 and thus also the proof of Theorem 3.2 is complete. □

3.5. L^1 stability condition. In connection with (3.3) and (3.4), we define the matrices $N^{rr}_q, N^{rl}_q, N^{lr}_q$, and N^{ll}_q $(q : 1\dots m)$, having the same dimensions as their corresponding matrices M^{xy}_q in (3.5), and with their (nonnegative) entries given by

$$b_{sk} = a_{sk}\cdot\left|\frac{\lambda_s(u^q_0)-\Lambda^q}{\lambda_k(u^q_0)-\Lambda^q}\right| \quad \text{in } N^{rr}_q,$$
$$b_{sk} = a_{sk}\cdot\left|\frac{\lambda_s(u^{q-1}_0)-\Lambda^q}{\lambda_k(u^q_0)-\Lambda^q}\right| \quad \text{in } N^{rl}_q,$$
$$b_{sk} = a_{sk}\cdot\left|\frac{\lambda_s(u^q_0)-\Lambda^q}{\lambda_k(u^{q-1}_0)-\Lambda^q}\right| \quad \text{in } N^{lr}_q,$$
$$b_{sk} = a_{sk}\cdot\left|\frac{\lambda_s(u^{q-1}_0)-\Lambda^q}{\lambda_k(u^{q-1}_0)-\Lambda^q}\right| \quad \text{in } N^{ll}_q.$$

Using the analysis of the previous subsection, we can now state the following.

PROPOSITION 3.7. *The L^1 stability condition* (3.3), (3.4) *is equivalent to the condition* (3.8)*, where the matrices $F^{1-\cdots-q}$ are defined as in* (3.9)–(3.11)*, with every matrix M^{xy}_q replaced by the corresponding one N^{xy}_q. In particular, for $m = 2$,* (3.8) *reduces to*

$$\begin{aligned}&\textit{the spectral radius of an } n\times n \textit{ matrix}\\ &|\mathcal{S}-\Lambda^1 Id|\cdot\widetilde{M}^{rr}_1\cdot|\mathcal{S}-\Lambda^1 Id|^{-1}\cdot|\mathcal{S}-\Lambda^2 Id|\cdot\widetilde{M}^{ll}_2\cdot|\mathcal{S}-\Lambda^2 Id|^{-1}\\ &\textit{is smaller than } 1,\end{aligned}\tag{3.30}$$

where

$$|\mathcal{S}-\Lambda Id| = \operatorname{diag}(|\lambda_1(u^1_0)-\Lambda|,\dots,|\lambda_n(u^1_0)-\Lambda|).$$

Remark 3.8. It has recently been brought to our attention that conditions similar to our BV and L^1 stability conditions, though expressed in the language of matrix analysis, can be found in the book [LY].

The authors investigate the (short time) existence and regularity of classical solutions to the so-called typical boundary value problems on fan-shaped domains for quasi-linear hyperbolic systems with smooth coefficients. In particular, they show the existence of a unique C^1 solution to this problem, provided that the so-called minimal characterizing number of the characterizing matrix for the typical boundary value problem is smaller than 1 (Theorem 1.1 in Chapter 4). If the same holds for the second characterizing matrix (see paragraph 4 in Chapter 7), then the corresponding solution is C^2 regular (Theorem 1.1 in Chapter 7).

These results can well be applied to the quasi-linear system (1.4) with the boundary conditions (1.5) along the boundaries of the angular domains given by the large

shocks in the solution of (1.1), (1.2), (1.3). The boundary conditions (1.5) appear already in the solvable form (see Lemma 5.10 in Chapter 2), that is, some of the components of u at the vertex $x = 0, t = 0$ (namely, the components corresponding to the outgoing modes) are explicitly expressed as functions of the others (corresponding to the incoming modes). It is not hard to notice that the characterizing matrix of this problem is made up of the quantities $\{\frac{\partial}{\partial \epsilon_k^{in}}\ \epsilon_s^{out}\}$ in such a way that its minimal characterizing number is smaller than 1 iff our BV stability condition holds. In a similar manner, the mentioned solvability condition for the second characterizing matrix, containing the numbers $\{\frac{\partial}{\partial \epsilon_k^{in}}\left(\frac{\epsilon_s^{out}\cdot(\lambda_s^{out}-\Lambda^q)}{(\lambda_k^{in}-\Lambda^q)}\right)\}$, is equivalent to our L^1 stability condition.

The results in [LY] thus imply the local in time existence of the piecewise C^1 (respectively, C^2) solution to the problem (1.1), (1.2) with $\bar{u}$ smooth except at the point $x = 0$, where it induces the Riemann problem "close" to (u^-, u^+).

4. Systems of two equations. In the particular case $n = m = 2,\ i_1 = 1,\ i_2 = 2$, the matrices M_1^{rr} and M_2^{ll} reduce to single numbers, and the L^1 stability condition (3.30) appears in a simple form:

$$\left|\frac{\partial \epsilon_2^{out}}{\partial \epsilon_1^{in}}\ |\epsilon_1^{in}=0\right| \cdot \left|\frac{\partial \epsilon_1^{out}}{\partial \epsilon_2^{in}}\ |\epsilon_2^{in}=0\right| \cdot \frac{\lambda_1(u_0^1)-\Lambda^2}{\lambda_1(u_0^1)-\Lambda^1}\cdot\frac{\lambda_2(u_0^1)-\Lambda^1}{\lambda_2(u_0^1)-\Lambda^2} < 1. \tag{4.1}$$

Similarily, the BV stability condition (3.1), (3.2) is equivalent to

$$\left|\frac{\partial \epsilon_2^{out}}{\partial \epsilon_1^{in}}\ |\epsilon_1^{in}=0\right| \cdot \left|\frac{\partial \epsilon_1^{out}}{\partial \epsilon_2^{in}}\ |\epsilon_2^{in}=0\right| < 1. \tag{4.2}$$

In both (4.1) and (4.2) the first derivative corresponds to the right interaction with the large shock of the first family, while the second derivative corresponds to the left interaction with the large shock of the second characteristic family.

In what follows we show that (4.1) and (4.2) are equivalent, respectively, to the appropriate conditions providing stability results in [BC] and [W].

4.1. The Bressan–Colombo L^1 stability condition [BC]. In the setting of [BC],

$$\kappa_1 = \frac{\partial \epsilon_2^{out}}{\partial \epsilon_1^{in}}\ |\epsilon_1^{in}=0 = -\frac{\left\langle \frac{\partial \Psi^2(u_0^0,u_0^1)}{\partial u^1}, r_1(u_0^1)\right\rangle}{\left\langle \frac{\partial \Psi^2(u_0^0,u_0^1)}{\partial u^1}, r_2(u_0^1)\right\rangle}$$

and

$$\kappa_2 = \frac{\partial \epsilon_1^{out}}{\partial \epsilon_2^{in}}\ |\epsilon_2^{in}=0 = -\frac{\left\langle \frac{\partial \Psi^1(u_0^1,u_0^2)}{\partial u^1}, r_2(u_0^1)\right\rangle}{\left\langle \frac{\partial \Psi^1(u_0^1,u_0^2)}{\partial u^1}, r_1(u_0^1)\right\rangle},$$

where

$$\Psi^1(u^1,u^2) = \langle l_1(u^1,u^2), u^1-u^2\rangle,$$

$$\Psi^2(u^0,u^1) = \langle l_2(u^0,u^1), u^0-u^1\rangle,$$

l_1 and l_2 being the left eigenvectors of the averaged flux gradient matrix between the reference points u.

One sees that the Bressan–Colombo stability condition

$$\left|\kappa_1 \cdot \frac{\lambda_1(u_0^1) - \Lambda^2}{\lambda_1(u_0^1) - \Lambda^1}\right| \cdot \left|\kappa_2 \cdot \frac{\lambda_2(u_0^1) - \Lambda^1}{\lambda_2(u_0^1) - \Lambda^2}\right| < 1$$

is precisely (4.1).

4.2. The Wang BV stability condition [W]. In [W], (1.1), (1.7) is assumed to satisfy the following finiteness condition:

Let

$$\begin{aligned} \left(\Lambda^1 Id - Df(u_0^1)\right)^{-1}(u_0^1 - u_0^0) &= \alpha r_1(u_0^1) + \beta r_2(u_0^1), \\ \left(Df(u_0^1) - \Lambda^2 Id\right)^{-1}(u_0^2 - u_0^1) &= \gamma r_1(u_0^1) + \delta r_2(u_0^1). \end{aligned} \tag{4.3}$$

Then

$$|\beta\gamma| < |\alpha\delta|. \tag{4.4}$$

The above condition is a reduction of a multidimensional BV stability condition (to be found in [Me]) to the case of one space dimension.

THEOREM 4.1. *Assume that both shocks in the reference solution* (1.7) *(recall that* $m = 2$*) are Majda stable and Lax admissible. Then the condition* (4.4) *is equivalent to the BV stability condition* (4.2).

Proof. It is enough to show that in the context of (4.3), (4.4), (4.2), there hold

$$\left|\frac{\beta}{\alpha}\right| = \left|\frac{\partial \epsilon_2^{out}}{\partial \epsilon_1^{in}} \; |\epsilon_1^{in} = 0\right|, \tag{4.5}$$

$$\left|\frac{\gamma}{\delta}\right| = \left|\frac{\partial \epsilon_1^{out}}{\partial \epsilon_2^{in}} \; |\epsilon_2^{in} = 0\right|. \tag{4.6}$$

We focus on (4.5) and thus the case when the large shock (u_0^0, u_0^1) is hit from the right by a small wave of the first characteristic family and strength ϵ_1^{in}. The proof of (4.6) is entirely similar, so we omit it.

Let $F : \Omega^0 \times \Omega^1 \times I \longrightarrow \mathbf{R}$ be defined as follows (I is here a small neighborhood of $0 \in \mathbf{R}$):

$$F(u^-, u^+, \epsilon) = \Psi_0(u^-, \widetilde{\Phi}_2(u^+, \epsilon)),$$

where Ψ_0 is as in (2.5), (2.6) (its existence is implied by the proof of Theorem 2.1, in view of the Majda stability of the first large shock). The functions $\widetilde{\Phi}_i : \Omega^1 \times I \longrightarrow \Omega^1$ for $i = 1, 2$ are such that

$$\widetilde{\Phi}_i(u^+, \epsilon) = u^- \quad \text{iff} \quad \Phi_i(u^-, \epsilon) = u^+,$$

where $\Phi_i : \Omega^1 \times I \longrightarrow \Omega^1$ for a fixed u^- coincides with the ith rarefaction curve in the positive part of I, and for $\epsilon \in I$ negative follows the ith shock curve through the argument point u (compare [L]). It is not hard to notice that $\frac{\partial}{\partial \epsilon}\widetilde{\Phi}_i(u, 0) = -r_i(u)$.

The fundamental equation relating the strengths ϵ_1^{in} and ϵ_2^{out} in (4.5) has by (2.6) the form

$$F(u_0^0, \Phi_1(u_0^1, \epsilon_1^{in}), \epsilon_2^{out}) = 0. \tag{4.7}$$

Differentiating (4.7) with respect to ϵ_1^{in} at $\epsilon_1^{in} = 0$ and using (2.13), we receive

$$\begin{aligned} 0 &= \frac{\partial \Phi_0}{\partial u^1}(u_0^0, u_0^1) \cdot r_1(u_0^1) - \frac{\partial \Phi_0}{\partial u^1}(u_0^0, u_0^1) \cdot r_2(u_0^1) \cdot \frac{\partial \epsilon_2^{out}}{\partial \epsilon_1^{in}} \ |\epsilon_1^{in} = 0 \\ &= V_1(u_0^1 - u_0^0)^T \cdot \big[Df(u_0^1) - \Lambda^1 Id\big] \cdot \left(r_1(u_0^1) - r_2(u_0^1) \cdot \frac{\partial \epsilon_2^{out}}{\partial \epsilon_1^{in}} \ |\epsilon_1^{in} = 0 \right). \end{aligned} \tag{4.8}$$

Since $V_1(u_0^1 - u_0^0)$ is orthogonal to $u_0^1 - u_0^0$, (4.8) is equivalent to

$$\big[Df(u_0^1) - \Lambda^1 Id\big] \cdot \left(r_1(u_0^1) - r_2(u_0^1) \cdot \frac{\partial \epsilon_2^{out}}{\partial \epsilon_1^{in}} \ |\epsilon_1^{in} = 0 \right) = s \cdot (u_0^1 - u_0^0), \tag{4.9}$$

with some $s \neq 0$, as Λ^1 is not an eigenvalue of $Df(u_0^1)$. The first formula in (4.3) is equivalent to

$$\big[Df(u_0^1) - \Lambda^1 Id\big] \cdot \big(-\alpha r_1(u_0^1) - \beta r_2(u_0^1)\big) = (u_0^1 - u_0^0),$$

and thus by (4.9) we get (4.5). □

THE HEAT EQUATION IN $L_q((0,T),L_p)$-SPACES WITH WEIGHTS*

N. V. KRYLOV†

Abstract. Existence and uniqueness theorems are presented for the heat equation in L_p-spaces with or without weights allowing derivatives of solutions to blow up near the boundary. It is allowed for the powers of summability with respect to space and time variables to be different.

Key words. Sobolev spaces with weights, parabolic equations

AMS subject classification. 35K20

PII. S0036141000372039

We are going to investigate the equation

$$u_t(t,x) = a^{ij}(t)u_{x^ix^j}(t,x) + f(t,x) \tag{0.1}$$

in several subdomains of $\mathsf{R}\times\mathsf{R}^d = \{(t,x) : t \in \mathsf{R}, x \in \mathsf{R}^d\}$ with a^{ij} being only bounded measurable functions of $t \in \mathsf{R}$ satisfying the uniform ellipticity condition. In (0.1) and throughout the article Einstein's summation convention is enforced. We assume that $a(t) := (a^{ij}(t))$ is a symmetric matrix-valued function depending only on t and, for some constants $K, \delta > 0$ and all $t \in \mathsf{R}$ and $\lambda \in \mathsf{R}^d$, we have

$$K|\lambda|^2 \geq a^{ij}(t)\lambda^i\lambda^j \geq \delta|\lambda|^2. \tag{0.2}$$

Equation (0.1) is understood in the sense of generalized functions only with respect to x. In other words, say, in the case of the whole $\mathsf{R}\times\mathsf{R}^d$ by a solution of (0.1), we mean a function $u(t)$, $t \in \mathsf{R}$, taking values in the set of generalized functions on R^d such that, for any $t, s \in \mathsf{R}$ satisfying $t \geq s$ and test function $\varphi \in C_0^\infty(\mathsf{R}^d)$, we have

$$(u(t),\varphi) = (u(s),\varphi) + \int_s^t [a^{ij}(r)(u(r),\varphi_{x^ix^j}) + (f(r),\varphi)]\,dr.$$

The emphasis is on proving solvability in function spaces of Sobolev type with different powers of summability p and q with respect to x and t. This issue arose from the theory of stochastic partial differential equations in domains in Sobolev spaces with weights and it turns out that, in this theory, the spaces with weights are the only reasonable ones where one can look for solutions to equations in domains.

Surprisingly enough, to the best of our knowledge, the case $q \neq p$ was never addressed before even for the heat equation in $\mathsf{R}\times\mathsf{R}^d$ without weights. We could only find references [1] and [12], where different powers of summability can be related to the Cauchy problem in $\{t > 0\}$ for $f = 0$. It turns out that in $\mathsf{R}\times\mathsf{R}^d$ the result we need can be obtained quite easily on the basis of a Banach space version of the Calderón–Zygmund theorem (see section 1), which allows one to pass from $q = p$ to $q \neq p$.

†School of Mathematics, 127 Vincent Hall, University of Minnesota, Minneapolis, MN 55455 (krylov@math.umn.edu).

For (0.1) in $\mathsf{R}\times\mathsf{R}^d_+$ with $\mathsf{R}^d_+=\{x=(x^1,x'):x^1>0,x'\in\mathsf{R}^{d-1}\}$ we impose the zero boundary condition and look for solutions in weighted Sobolev spaces with weights allowing the spatial derivatives of solutions to blow up near the boundary $x^1=0$. Our results in this setting extend the corresponding results in [5], where $q=p$.

This time we use again the Calderón–Zygmund theorem starting with the results valid for $q=p$. However, in order to check the conditions of this theorem, we need some nontrivial properties of the heat semigroup in weighted spaces, which we prove in section 2. In section 3, this allows us to get the result for $\mathsf{R}\times\mathsf{R}^d_+$, but only if $a^{1j}\equiv 0$ for $j\geq 2$. Usually, if one proves a sufficiently strong result for the heat equation, the same or very close result can be proved for equations with variable *continuous* coefficients. However, in the main application, which we have in mind, to stochastic partial differential equations from filtering theory, the regularity of a^{ij} in time is hard to control. Therefore, we always deal only with measurable coefficients and, in section 4 after some additional work, we prove our main result for equations in $\mathsf{R}\times\mathsf{R}^d_+$ in full generality.

The arguments of section 4 are based on Lemma 1.5, which also allows us to give a different proof of the result in $\mathsf{R}\times\mathsf{R}^d$ by using the Marcinkiewicz interpolation theorem rather than the Calderón–Zygmund theorem.

In section 5 we prove a general theorem used in section 2 saying, roughly speaking, that whatever estimate is true for the heat equation, is also true for parabolic equations with coefficients depending only on time. This theorem is equally applicable to Sobolev and Hölder spaces.

Finally, it is worth noting that we also give results for the initial value problems. To give the reader a flavor of our results in $\mathsf{R}\times\mathsf{R}^d_+$, we state a particular case of Theorem 3.2.

THEOREM 0.1. *Let $p,q\in(1,\infty)$, $-1<\alpha<p-1$, $T\in(0,\infty)$, and assume that we are given a function $f(t,x)$ defined for $t>0,x\in\mathsf{R}^d_+$ and such that*

$$\int_0^T\left(\int_{\mathsf{R}^d_+}(x^1)^{\alpha+p}|f(t,x)|^p\,dx\right)^{q/p}dt<\infty.$$

Then on $[0,T]\times\bar{\mathsf{R}}^d_+$ there is a unique function u satisfying the heat equation

$$u_t=\Delta u+f\quad in\quad (0,T)\times\mathsf{R}^d_+,$$

vanishing for $t=0$ and for $x^1=0$ in a natural sense and such that

$$\int_0^T\left(\int_{\mathsf{R}^d_+}(x^1)^{\alpha}[|u(t,x)/x^1|^p+|u_x(t,x)|^p+|x^1u_{xx}(t,x)|^p]\,dx\right)^{q/p}dt<\infty.$$

Throughout the paper we fix $a^{ij}(t)$ and the constants $K,\delta>0$, assume (0.2), and use the following notation:

$$u_{x^i}=\frac{\partial u}{\partial x^i}=D_iu,\quad u_x=(u_{x^1},\dots,u_{x^d})=Du,$$

$$u_{x^ix^j}=\frac{\partial^2u}{\partial x^i\partial x^j}=D_{ij}u,\quad u_{xx}=(u_{x^ix^j})_{i,j=1}^d=D^2u,\quad u_t=\frac{\partial u}{\partial t}.$$

1. Main results without weights. Here we consider (0.1) in usual Sobolev spaces. The following theorems may be well known to specialists. However, the author could not find their proofs in the literature and since the proofs will be later used with some modification in a more complicated situation, they are presented here.

Theorem 1.1 is the main result. We give it three proofs. One of them is based on the Calderón–Zygmund theorem. It seems impossible to carry over this approach to the case of stochastic partial differential equations. The second proof uses the fact that $||u||_p^{np}$ can be written as the integral of $|u(x_1)\cdot\ldots\cdot u(x_n)|^p$ over R^{nd}. This allows us to reduce estimating the $L_{np}(L_p)$-norm of $u(t,x)$ to estimating the L_p-norm of the function $u(t,x_1)\cdot\ldots\cdot u(t,x_n)$. It turns out that this device works equally well for stochastic partial differential equations. Finally, the third proof, given in section 3, uses our result for spaces with weights and is designed to show that in a sense the case with weights is more general than the one without weights.

Define

$$Lu = a^{ij}u_{x^ix^j} - u_t, \tag{1.1}$$

$$L_p = L_p(\mathsf{R}^d), \quad H_p^\gamma = (1-\Delta)^{-\gamma/2}L_p, \quad \mathbb{H}_p^{\gamma,q} = L_q(\mathsf{R}, H_p^\gamma),$$

$$\mathbb{H}_p^{\gamma,q}(T) = L_q((0,T), H_p^\gamma), \quad \mathbb{L}_p^q = \mathbb{H}_p^{0,q}, \quad \mathbb{L}_p^q(T) = \mathbb{H}_p^{0,q}(T).$$

It is important to emphasize that for simplicity of notation we also use the same symbols L_p and H_p^γ for spaces of real-valued, vector-valued, and matrix-valued functions defined on R^d. It is well known that, for any $s\in\mathsf{R}$ and $f\in C_0^\infty(\mathsf{R}^d)$, there exists a unique bounded continuous function $u(t,x)$ on $[s,\infty)\times\mathsf{R}^d$ satisfying $Lu(t)=0$ for $t>s$ with initial condition $u(s)=f$. We denote $u(t)=T_{s,t}f$ and recall that, for each s and t, the operator $T_{s,t}$ is written as the convolution of f with a Gaussian density. In particular, $T_{s,t}f$ is infinitely differentiable in x. Finally, for $f\in C_0^\infty(\mathsf{R}\times\mathsf{R}^d)$, let

$$Rf(t) := \int_{-\infty}^t T_{s,t}f(s)\,ds, \quad Af := D^2Rf.$$

Also remember that, for $f\in C_0^\infty(\mathsf{R}\times\mathsf{R}^d)$, the function Rf satisfies $LRf=-f$.

THEOREM 1.1. *Let $q,p\in(1,\infty)$, $\gamma\in\mathsf{R}$. Then the operator A is uniquely extendable to a bounded operator acting in $\mathbb{H}_p^{\gamma,q}$. If we keep the same notation for the extension, then*

$$||D^2Rf||_{\mathbb{H}_p^{\gamma,q}} \le N(\delta,d,q,p)||f||_{\mathbb{H}_p^{\gamma,q}}. \tag{1.2}$$

Let us make precise that in this theorem the statement that A is an operator acting in $\mathbb{H}_p^{\gamma,q}$ means that it maps the space of real-valued functions of class $\mathbb{H}_p^{\gamma,q}$ into the space of matrix-valued functions of class $\mathbb{H}_p^{\gamma,q}$. We allow ourselves such an abuse of language on some occasions in the future as well. Another comment is that the constant N in (1.2) is independent of K (see (0.2)).

Before proving Theorem 1.1 we derive from it the following theorem.

THEOREM 1.2. *Let $q,p\in(1,\infty)$, $T\in(0,\infty)$, and $\gamma\in\mathsf{R}$. Take $\varepsilon>0$, $f\in\mathbb{H}_p^{\gamma,q}(T)$, and $u_0\in H_p^{\gamma+2-2/q+\varepsilon}$. Then in $\mathbb{H}_p^{\gamma+2,q}(T)$ there is a unique solution of (0.1) with the initial condition $u(0)=u_0$. For this solution*

$$||u_{xx}||_{\mathbb{H}_p^{\gamma,q}(T)} \le N(||f||_{\mathbb{H}_p^{\gamma,q}(T)} + ||u_0||_{H_p^{\gamma+2-2/q+\varepsilon}}), \tag{1.3}$$

where $N = N(\delta, d, q, p, T, \varepsilon)$, and if $u_0 = 0$, then N is independent of T. Finally, if $q = p$, one can take $\varepsilon = 0$.

Proof. Since we can apply the operator $(1-\Delta)^{\gamma/2}$ to both sides of (0.1), we need to prove the theorem only for $\gamma = 0$. After that the independence of N of T if $u_0 = 0$ is derived by using self similarity.

Now, we reduce the general situation to the one in which $u_0 = 0$. To do this we have to show only that there is a continuation of u_0 to a function $\bar{u}$ such that the norms of $\bar{u}_{xx}$ and $\bar{u}_t$ in $\mathbb{L}_p^q(T)$ are controlled by $||u_0||_{H_p^{2-2/q+\varepsilon}}$.

Let $T_t, t \geq 0$, be the semigroup associated with Δ in R^d and let $\bar{u}(t) = T_t u_0$. The semigroup $e^{-t}T_t$ has generator $\Delta - 1$, which also generates the scale of spaces H_p^γ. It follows by Theorem 14.11 of [2] that, for $\theta \in [0,1]$, $t > 0$, and $f \in L_p$, we have

$$||T_t f||_{L_p} \leq N e^t t^{-\theta} ||f||_{H_p^{-2\theta}},$$

where $N = N(d, p, \theta)$. By replacing f with $(1-\Delta)u_0$, taking $\theta = 1/q - \varepsilon/2$, and assuming without losing generality that $\varepsilon < 2/q$, we conclude

$$||\bar{u}(t)||_{H_p^2} \leq N e^t t^{-1/q+\varepsilon/2} ||u_0||_{H_p^{2-2/q+\varepsilon}},$$

$$\int_0^T ||\bar{u}(t)||_{H_p^2}^q \, dt \leq N ||u_0||_{H_p^{2-2/q+\varepsilon}}^q.$$

Since $\bar{u}_t = \Delta \bar{u}$, we see that the function $\bar{u}(t)$ possesses the desired properties. If $q = p$, the same holds for $\varepsilon = 0$ as is shown in section 4.3 of [8]. Therefore, in the rest of the proof we take $u_0 = 0$.

Take $f \in C_0^\infty(\mathsf{R}_+ \times \mathsf{R}^d)$ and let $u = Rf$. As we have mentioned before, u is a classical solution of $Lu = -f$ for $t > 0$ and obviously $u(0) = 0$. Owing to Theorem 1.1 and the fact that $u(t)$ for $t \in [0,T]$ is independent of the values of $f(s)$ for $s \geq T$, we get (1.3) and from the equation $Lu = -f$ that $||u_t||_{\mathbb{L}_p^q(T)} \leq N||f||_{\mathbb{L}_p^q(T)}$. In particular, for any $T < \infty$,

$$\sup_{t \leq T} ||u(t,\cdot)||_{L_p} \leq N||f||_{\mathbb{L}_p^q(T)} \tag{1.4}$$

with N independent of f. It follows that, if f is in a bounded set in $\mathbb{L}_p^q(T)$, then u is in a bounded set in $\mathbb{H}_p^{2,q}(T) \cap C([0,T], L_p)$. Using obvious approximations proves our assertion about the existence of solutions.

To prove uniqueness, let $u \in \mathbb{H}_p^{2,q}(T)$ satisfy $Lu = 0$ in $(0,T) \times \mathsf{R}^d$ and $u(0) = 0$. (Remember that $u(t)$ is weakly continuous in t by the definition of solution.) Then, of course, $u_t = a^{ij} u_{x^i x^j} \in \mathbb{L}_p^q(T)$ and one can find a sequence of infinitely differentiable functions $u_n(t,x)$ vanishing for large $|x|$ and for $t = 0$ such that

$$||u - u_n||_{\mathbb{H}_p^{2,q}(T)} + ||u - u_{nt}||_{\mathbb{L}_p^q(T)} \to 0.$$

In that case, $Lu_n \to Lu = 0$ in $\mathbb{L}_p^q(T)$. Since $u_n = -RLu_n$, (1.4) implies that

$$\sup_{t \leq T} ||u_n(t,\cdot)||_{L_p} \to 0, \quad \sup_{t \leq T} ||u(t,\cdot)||_{L_p} = 0.$$

The theorem is proved. □

The following corollary of Theorem 1.2 is obtained by odd continuation of the functions involved.

COROLLARY 1.3. *All assertions of Theorem* 1.2 *hold true for* $\gamma = 0$ *if we replace* R^d *with* R^d_+ *everywhere, assume that* $a^{1j} \equiv 0$ *for* $j = 2, \dots, d$, *and supplement* (0.1) *with zero boundary condition at* $x^1 = 0$.

To prove Theorem 1.1, we use the following Banach space version of the Calderón–Zygmund theorem. This is a standard result which is discussed, for instance, in Chapter 1 of [10] and can be extracted from more general results of [1]. For a Hilbert space version of this theorem in the form of multipliers along with a version of Theorem 1.1 for $q = p$ and different operators L, we refer the reader to [9].

THEOREM 1.4. *Let* F *and* G *be Banach spaces, let* $p \in (1, \infty)$, *and let* $A : L_p(\mathsf{R}^n, F) \to L_p(\mathsf{R}^n, G)$ *be a linear bounded operator. Assume that if a bounded strongly measurable* F*-valued function* f *has compact support* Γ, *then, for almost any* $x \notin \Gamma$, *we have*

$$Af(x) = \int_{\mathsf{R}^n} K(x,y) f(y)\, dy,$$

where $K(x,y)$ *is a bounded operator from* F *into* G, *defined for* $x \neq y$, *strongly measurable with respect to* y *with norm bounded in* y *outside any neighborhood of* x. *Also assume that* $K(x,y)$ *is strongly measurable with respect to* x *and there exists a constant* N *such that*

$$\int_{|x-y|>2|y-z|} |K(x,y) - K(x,z)|\, dx \leq N$$

for any y *and* z, *which holds, for instance, if* $K(x,y)$ *is weakly differentiable in* y *and* $|\nabla_y K(x,y)| \leq N|x-y|^{-d-1}$.

Then the operator A *is uniquely extendable to a bounded operator from* $L_q(\mathsf{R}^n, F)$ *to* $L_q(\mathsf{R}^n, G)$ *for any* $q \in (1, p]$ *and* A *is of weak-type* $(1,1)$ *on bounded functions with compact support.*

The first proof of Theorem 1.1. In [3] a general theorem is proved which, roughly speaking, says that whatever estimate is true for the heat equation in translation invariant spaces is also true with the same constant for (0.1) with the coefficients depending only on t provided $(a^{ij}(t)) \geq (\delta^{ij})$. (We prove a similar result for equations in half spaces in Theorem 5.1 and show how to use it in the proof of Theorem 2.5.) Of course, we can achieve the inequality $(a^{ij}(t)) \geq (\delta^{ij})$ by using dilations once we are given (0.2). Therefore, we may and will assume that $a^{ij} \equiv \delta^{ij}$. Also as in the proof of Theorem 1.2, assuming $\gamma = 0$ does not restrict generality.

Now we are ready to use Theorem 1.4. From section 4.3 of [8] we know that A is uniquely defined and is bounded as an operator acting in $L_p(\mathsf{R}, L_p)$. We are going to check that A satisfies the assumptions of Theorem 1.4 with $F = G = L_p$.

Observe the simple fact that, for $t > 0$, $k = 1, 2, \dots$, and $f \in L_p$, we have $\partial T_t f/\partial t = \Delta T_t f$ and $||\partial^k T_t f/\partial t^k||_{L_p} \leq N t^{-k} ||f||_{L_p}$, where N depends only on d and k. For $t > 0$ introduce the operator $K(t) = \Delta T_t$ acting from L_p into L_p with norm bounded by Nt^{-1}, where N is independent of t. For $t \leq 0$, let $K(t) = 0$.

Since $a^{ij} = \delta^{ij}$, we have

$$Rf(t,x) = \int_{-\infty}^{t} T_{t-s} f(s,\cdot)(x)\, ds.$$

In addition, if t is at a distance from the support of f, then differentiating the above formula presents no difficulties and we find

$$Af(t,x) = \int_{-\infty}^{t} \Delta T_{t-s} f(s,\cdot)\, dx = \int_{\mathsf{R}} K(t-s) f(s)(x)\, ds.$$

In order to prove that the assumptions of Theorem 1.4 are satisfied, it remains only to use

$$||\partial K(t-s)f/\partial s||_{L_p} = ||\partial^2 T_{t-s}f/\partial s^2||_{L_p} I_{t>s} \leq N|t-s|^{-2}||f||_{L_p}.$$

By Theorem 1.4, A is well defined and bounded as an operator from $L_q(\mathsf{R}, L_p)$ into itself for $1 < q \leq p$. By considering the adjoint to A, we conclude that A is bounded in $L_q(\mathsf{R}, L_p)$ for any $q, p \in (1, \infty)$. The theorem is proved.

To give a different proof of Theorem 1.1 we prepare two auxiliary results. The first one is an equivalent restatement of the same basic a priori estimate used in the above proof of Theorem 1.1.

LEMMA 1.5. *Let $T \leq \infty$, $p \in (1, \infty)$, and let $u \in L_p((0,T) \times \mathsf{R}^d) = \mathbb{L}_p^p(T)$ be a solution of the equation $Lu = f^{ij}_{x^i x^j}$ with zero initial data and with $f^{ij} \in L_p((0,T) \times \mathsf{R}^d)$. Then*

$$||u||_{\mathbb{L}_p^p(T)} \leq N(d, \delta, p) \sum_{ij} ||f^{ij}||_{\mathbb{L}_p^p(T)}.$$

This lemma follows, for instance, from the results of section 4.3 in [8] up to the fact that there the results are stated for the heat equation or from Theorem 5.1 of [4] up to the assertion that N is independent of T. The latter is obtained in a standard way by using self similarity. In almost the same form as stated, this lemma is proved in the appendix of [11].

In the next lemma we do the first step toward considering the power of summability in t equal to multiples of p. This lemma is also crucial for our investigation of equations in R^d_+ in section 4.

LEMMA 1.6. *Let $T \leq \infty$, $p \in (1, \infty)$, and $n = 1, 2, \ldots$. For $k = 1, \ldots, n$, let $\lambda_k \in (0, \infty)$, $\gamma_k \in \mathsf{R}$, and $u^k \in \mathbb{H}_p^{\gamma_k+2,p}(T)$ be solutions of the equation*

$$u^k_t = a^{ij} u^k_{x^i x^j} + f^k$$

with zero initial data and with $f^k \in \mathbb{H}_p^{\gamma_k,p}(T)$. Denote $\Lambda_k = (\lambda_k - \Delta)^{\gamma_k/2}$. Then

$$\int_0^T \prod_{k=1}^n ||\Lambda_k \Delta u^k(t)||^p_{L_p} \, dt \tag{1.5}$$

$$\leq N \sum_{k=1}^n \int_0^T ||\Lambda_k f^k(t)||^p_{L_p} \prod_{j \neq k} ||\Lambda_j \Delta u^j(t)||^p_{L_p} \, dt,$$

where $N = N(n, d, p, \delta)$.

Proof. By considering $\Lambda_k u^k$ instead of u^k, we see that without loss of generality we may assume $\gamma_k = 0$. In this case define $v^k = \Delta u^k$. For $X = (x_1, \ldots, x_n) \in \mathsf{R}^{nd}$ with $x_i \in \mathsf{R}^d$, define

$$V(t, X) = v^1(t, x_1) \cdot \ldots \cdot v^n(t, x_n).$$

Observe that

$$V_t(t, X) = \mathbb{M} V(t, X) + F(t, X),$$

where $\mathbb{M}V = a^{rs}(V_{x_1^r x_1^s} + \cdots + V_{x_n^r x_n^s})$,

$$F(t,X) = \Delta_{x_i} G^i(t,X), \quad G^i(t,X) = f^i(t,x_i)\prod_{j\neq i} v^j(t,x_j).$$

Hence, by Lemma 1.5

$$||V||_{L_p((0,T)\times \mathsf{R}^{nd})} \leq N\sum_i ||G^i||_{L_p((0,T)\times \mathsf{R}^{nd})},$$

and this is exactly (1.5). The lemma is proved. □

The second proof of Theorem 1.1. As in the first proof, we have only to consider the case $a^{ij} \equiv \delta^{ij}$ and $\gamma = 0$. Also, obviously it suffices to prove (1.2) for $f \in C_0^\infty(\mathsf{R}\times\mathsf{R}^d)$. Without loss of generality we assume that $f(t) = 0$ for $t \leq 0$.

Let $u = Rf$. Then u is a classical solution of $u_t = \Delta u + f$ for $t > 0$ with zero initial condition and, even more than that, $u(s) = 0$ for $s \leq 0$. In addition, it is easy to check that $u \in L_p((0,T), H_p^2)$ for each $T < \infty$.

Next we take $q = np$, where $n = 1, 2, \ldots$. By Lemma 1.6 applied to $u^k = u$ we have

$$||u_{xx}||^{np}_{L_{np}((0,T),L_p)} \leq N\int_0^T ||f(t)||^p_{L_p} ||u_{xx}(t)||^{(n-1)p}_{L_p}\, dt,$$

which by Hölder's inequality yields $||u_{xx}||_{L_{np}((0,T),L_p)} \leq N||f||_{L_{np}((0,T),L_p)}$. By letting $T \to \infty$ we obtain (1.2).

To treat general $q \geq p$, it suffices to use the Marcinkiewicz interpolation theorem. As in the first proof, the case $q \leq p$ is considered by duality. The theorem is proved.

2. Some smoothing properties of the heat semigroup in spaces $H^\gamma_{p,\theta}$. In this section we investigate smoothing properties of solutions to (0.1) in $\mathsf{R}_+ \times \mathsf{R}^d_+$ for $f \equiv 0$. Throughout this section we assume

$$a^{1j}(t) \equiv 0, \quad j = 2, \ldots, d. \tag{2.1}$$

The smoothing is measured in terms of $H^\gamma_{p,\theta}$ spaces introduced in [5] and [6] and recalled briefly below. We fix a function $\zeta \in C_0^\infty(\mathsf{R}_+)$ such that

$$\sum_{n=-\infty}^{\infty} \zeta(e^{n-x}) \geq 1,$$

and for $\theta, \gamma \in \mathsf{R}$, and $p \in (1,\infty)$ we define $H^\gamma_{p,\theta}$ as the space of all distributions u on R^d_+ with finite norm given by

$$||u||^p_{H^\gamma_{p,\theta}} = \sum_{n=-\infty}^{\infty} e^{n\theta} ||u(e^n\cdot)\zeta||^p_{H^\gamma_p}.$$

We write $L_{p,\theta} = H^0_{p,\theta}$. By M^β we denote the operator of multiplying by $(x^1)^\beta$, $M = M^1$. It turns out that for integral γ

$$H^\gamma_{p,\theta} = \{u : M^n D^n u \in L_p(\mathsf{R}^d_+, (x^1)^{\theta-d}\, dx) \quad n = 0, 1, \ldots, \gamma\},$$

where $D^n u$ is the collection of all nth derivatives of u. For other γ one can have an idea about the spaces $H^\gamma_{p,\theta}$ by observing that they are complex interpolation spaces

and the dual to $H^\gamma_{p,\theta}$ is $H^{\gamma'}_{p',\theta'}$ with $\gamma' = -\gamma$, $1/p + 1/p' = 1$, and $\theta/p + \theta'/p' = d$. From other properties of $H^\gamma_{p,\theta}$ which are most often used in this article we point out that the operators MD and DM are bounded operators from $H^\gamma_{p,\theta}$ to $H^{\gamma-1}_{p,\theta}$ and, if $M^{-1}u \in H^\gamma_{p,\theta}$ and $\theta \neq d-1, d-1+p$, then

$$||MD^2u||_{H^{\gamma-2}_{p,\theta}} \leq N||M^{-1}u||_{H^\gamma_{p,\theta}} \leq N||MD^2u||_{H^{\gamma-2}_{p,\theta}}. \tag{2.2}$$

We start with the following general lemma from [7]. We give its proof here for the sake of completeness.

LEMMA 2.1. *Let $g(x,y)$ be a function on $\mathsf{R}^d_+ \times \mathsf{R}^d_+$ satisfying*

$$|g(x,y)| \leq (1+x^1)^\alpha (1+y^1)^\beta e^{-\varepsilon|x-y|^2},$$

where $\varepsilon > 0$, $\alpha, \beta \in \mathsf{R}$ are some constants. Let $1 < p \leq q < \infty$, $\theta \in \mathsf{R}$, and $\delta := (\theta - d)q/p - q(\alpha+\beta)$. Assume

$$d - p/q + p(\alpha+\beta) < \theta < d - 1 + p$$

(so that automatically $\delta > -1$ and $\alpha + \beta < 1 - 1/p + 1/q$). Then, for any $u \in L_{p,\theta}$,

$$\int_{\mathsf{R}^d_+} (x^1)^\delta \left| \int_{\mathsf{R}^d_+} g(x,y)u(y)\,dy \right|^q dx \leq N||u||^q_{L_{p,\theta}}, \tag{2.3}$$

where N is independent of u.

Proof. By using Hölder's inequality we see that

$$\left| \int_{\mathsf{R}^d_+} g(x,y)u(y)\,dy \right| \leq (1+x^1)^\alpha I_1^{1/p}(x) I_2^{(p-1)/p}(x),$$

where

$$\begin{aligned} I_1(x) &= \int_{\mathsf{R}^d_+} |y^1|^{\theta-d}|u(y)|^p e^{-\varepsilon|x-y|^2}\,dy \\ &\leq \int_{\mathsf{R}^{d-1}} \left(\int_0^\infty |y^1|^{\theta-d}|u(y)|^p\,dy^1 \right) e^{-\varepsilon|x'-y'|^2}\,dy' = J(x'), \\ I_2(x) &= I_2(x^1) = \int_{\mathsf{R}^d_+} |y^1|^{(d-\theta)/(p-1)} (1+y^1)^{\beta p/(p-1)} e^{-\varepsilon|x-y|^2}\,dy \\ &= N\int_0^\infty |y^1|^{(d-\theta)/(p-1)} (1+y^1)^{\beta p/(p-1)} e^{-\varepsilon|x^1-y^1|^2}\,dy^1, \end{aligned}$$

where the last integral converges due to $(d-\theta)/(p-1) > -1$. Also, as it is easy to see, this integral behaves like $(x^1)^{(d-\theta+\beta p)/(p-1)}$ when $x^1 \to \infty$. Therefore,

$$\begin{aligned} (1+x^1)^\alpha I_2^{(p-1)/p}(x) &\leq N(1+x^1)^{\alpha+\beta+(d-\theta)/p}, \\ (x^1)^\delta \left| \int_{\mathsf{R}^d_+} g(x,y)u(y)\,dy \right|^q &\leq N(x^1 \wedge 1)^\delta I_1^{q/p}(x). \end{aligned}$$

Thus the left-hand side of (2.3) is less than

$$\int_{\mathsf{R}^{d-1}} J^{q/p}(x')\,dx' + \int_{\mathsf{R}^d} I_1^{q/p}(x)\,dx.$$

To estimate these integrals we notice that I_1 and J are convolutions and the $L_{q/p}$-norm of a convolution is less than the L_1-norm of one function times the $L_{q/p}$-norm of the other. Then we obviously come to (2.3). The lemma is proved. □

LEMMA 2.2. *Let $m \in \{0,1,2,\dots\}$ and $D^m = D_{x^1}^{2l} D_{x'}^{m-2l}$ be an mth derivative operator, where $l \in \{0,1,2,\dots\}$, $D_{x^1}^{2l}$ is the operator of taking $2l$ derivatives in x^1, and $D_{x'}^{m-2l}$ is an $(m-2l)$th derivative with respect to x'. Define*

$$p(t,x) = \frac{1}{(4\pi t)^{d/2}} e^{-|x|^2/(4t)}, \quad Ax = (-x^1, x^2, \dots, x^d),$$

$$p(t,x,y) = p(t,x-y) - p(t,x-Ay), \quad p^{(m)}(t,x,y) = D^m p(t,x,y).$$

Then

$$p^{(m)}(t,x,y) = 0 \quad \text{for} \quad x^1 y^1 = 0, t > 0, \tag{2.4}$$

$$p^{(m)}(t,x,y) = (-1)^m p^{(m)}(t,y,x) \quad \text{for} \quad x, y \in \mathsf{R}_+^d, t > 0. \tag{2.5}$$

Proof. If $l = 0$, (2.4) follows from the equality $p(t,x,y) = 0$ for $x^1 y^1 = 0$. If $l \geq 1$, it suffices to use the induction on l after noticing that, for $x^1 y^1 = 0$, we have

$$\begin{aligned} D_{x^1}^{2l} D_{x'}^{m-2l} p(t,x,y) &= D_{x^1}^{2(l-1)} D_{x'}^{m-2l} \Delta_x p(t,x,y) \\ &= D_t D_{x^1}^{2(l-1)} D_{x'}^{m-2l} p(t,x,y). \end{aligned}$$

To prove (2.5), notice that both sides satisfy the heat equation in x with zero boundary condition on $x^1 = 0$ due to (2.4). Their initial values also coincide since $D_x^m \delta(x-y) = (-1)^m D_x^m \delta(y-x)$. The lemma is proved. □

Denote by $\tilde{T}_t$ the semigroup associated with the operator Δ in R_+^d with zero boundary condition on $\{x^1 = 0\}$. In the following two lemmas we present some properties of the operator

$$S_t^{(m)} = M^{-1} D^m \tilde{T}_t M^{-1},$$

where D^m is taken from Lemma 2.2.

LEMMA 2.3. *Let $1 < p \leq q < \infty$, $\tau, \theta \in \mathsf{R}$, $\sigma := d + (\theta - d)q/p + q\tau$. Assume*

$$d - p/q - p\tau < \theta < d - 1 + p, \quad \tau \leq 2, \quad n \in \{0,1,2,\dots\}.$$

Then, for any $u \in H_{p,\theta}^n$,

$$||S_1^{(m)} u||_{H_{q,\sigma}^n} \leq N ||u||_{H_{p,\theta}^n}, \tag{2.6}$$

where N is independent of u.

Proof. It is well known that

$$\tilde{T}_t u(x) = \int_{\mathsf{R}_+^d} p(t,x,y) u(y)\, dy.$$

Therefore, for $g(x,y) := (x^1 y^1)^{-1} D_x^m p(1,x,y)$, we have

$$S_1^{(m)} u(x) = \int_{\mathsf{R}_+^d} g(x,y) u(y)\, dy.$$

We split the last integral into two parts. Let $\zeta(x^1)$ be an infinitely differentiable function on R such that $\zeta(x^1)=0$ if $0\leq x^1\leq 1$ and $\zeta(x^1)=1$ if $x^1\geq 2$. Denote $\eta=1-\zeta$. Then, for $g_1(x,y):=g(x,y)\zeta(y)$ and $g_2(x,y):=g(x,y)\eta(y)$, we have

$$S_1^{(m)}u(x)=\int_{\mathsf{R}^d_+}g_1(x,y)u(y)\,dy+\int_{\mathsf{R}^d_+}g_2(x,y)u(y)\,dy$$

$$=:S_{11}^{(m)}u(x)+S_{12}^{(m)}u(x)$$

and we estimate each term separately by using Lemma 2.1. Observe that almost obviously, for any derivative D^k with respect to (x,y), we have

$$|D^kp(1,x,y)|\leq Ne^{-|x-y|^2/8},\quad x,y\in\mathsf{R}^d_+. \tag{2.7}$$

Hence, for $x^1\geq 1$, by noticing that the only values of y^1 for which g_1 does not vanish satisfy $y^1\geq 1$, we get

$$|g_1(x,y)|\leq N(1+x^1)^\alpha(1+y^1)^\beta e^{-|x-y|^2/8} \tag{2.8}$$

if $\alpha\geq -1$ and $\beta\geq -1$. Furthermore, (2.8) holds for $x^1\leq 1$ (and all y) as well, since owing to (2.4) we have

$$|g_1(x,y)|=\left|\zeta(y)(y^1)^{-1}\int_0^1 D_{x^1}D_x^mp(1,rx^1,x',y)\,dr\right|$$

and, in addition, $|rx^1-y^1|\geq|x^1-y^1|$ if $x^1\leq 1\leq y^1$. By letting $\tau=-\alpha-\beta$, from Lemma 2.1 we conclude that (2.6) holds with $n=0$ and $S_{11}^{(m)}$ in place of $S_1^{(m)}$.

As long as $S_{12}^{(m)}$ is concerned, notice that

$$\begin{aligned}g_2(x,y)&=\eta(y)(x^1)^{-1}\int_0^1 D_{y^1}D_x^mp(1,x,ry^1,y')\,dr\\&=\eta(y)\int_0^1\int_0^1 D_{y^1}D_{x^1}D_x^mp(1,sx^1,x',ry^1,y')\,drds.\end{aligned} \tag{2.9}$$

The first equality and (2.7) show that, if $x^1\geq 2$ and $y^1\leq 2$,

$$|g_2(x,y)|\leq N(1+x^1)^\alpha(1+y^1)^\beta e^{-|x-y|^2/8} \tag{2.10}$$

with $\alpha\geq -1$ and any β. Inequality (2.10) also holds if $x^1\geq 2$ and $y^1\geq 2$ since in this case $g_2(x,y)=0$.

The second equality in (2.9) shows that (2.10) holds if $0<x^1,y^1<2$. Again trivially it also holds if $x^1\leq 2$ and $y^1\geq 2$. Thus, (2.10) is true for all $x,y\in\mathsf{R}^d_+$ with no restriction on $\tau=-\alpha-\beta$, and Lemma 2.1 allows us to conclude that (2.6) holds with $n=0$ and $S_{12}^{(m)}$ in place of $S_1^{(m)}$. This proves (2.6) for $n=0$.

Now we pass to the case of general $n\geq 1$. Observe that in order to prove that a function f belongs to $H^n_{p,\theta}$, we have to prove that $M^kD^kf\in L_{p,\theta}$ for all $k=0,1,\dots,n$. By using the fact that, for $k\geq 1$,

$$M^kD^kf=M^{k-1}D^kMf+h, \tag{2.11}$$

where h is a linear combination of M^rD^rf with $r \le k-1$, and bearing in mind the induction on n we see that it suffices to consider only terms $M^{k-1}D^kMf$.

Thus, we need only to prove that

$$||M^{n-1}D^nMS_1^{(m)}u||_{L_{q,\sigma}} \le N||u||_{H^n_{p,\theta}}. \tag{2.12}$$

We take the functions ζ and η from above and for any function f on R^d_+ denote $\bar{f}$ its even with respect to x^1 extension to R^d.

Then

$$\begin{aligned} M^{n-1}D^nMS_1^{(m)}u =& M^{n-1}D^mT_1D^n(M^{-1}\bar{\zeta}\bar{u}) \\ &+ M^{n-1}D^{n+m}\tilde{T}_1M^{-1}\eta u = Iu + Ju. \end{aligned} \tag{2.13}$$

First, we estimate J. The kernel of J is

$$\tilde{g}_2(x,y) := \eta(y^1)(x^1)^{n-1}(y^1)^{-1}D_x^{n+m}p(1,x,y).$$

Here, owing to $p(t,x,y) = 0$ for $y^1 = 0$, we have $D_x^{n+m}p(1,x,y) = 0$ if $y^1 = 0$. Upon remembering that $n \ge 1$, we easily derive that $\tilde{g}_2$ satisfies (2.10) with $\alpha \ge n-1$ and any β. Hence, for $\tau = -\alpha - \beta$, by Lemma 2.1 we obtain

$$||Ju||_{L_{q,\sigma}} \le N||u||_{L_{p,\theta}} \le N||u||_{H^n_{p,\theta}}. \tag{2.14}$$

Next, we notice that by Corollary 2.4 of [5], for $v = \zeta u$, we have $||v||_{H^n_{p,\theta}} \le N||u||_{H^n_{p,\theta}}$. Also by Leibnitz's rule, $D^nM^{-1}v$ is written as a linear combination of $M^{-1-k}D^{n-k}v = M^{-1-n}M^{n-k}D^{n-k}v$. It follows that

$$D^n(M^{-1}\zeta u) = M^{-1-n}h, \quad ||h||_{L_{p,\theta}} \le N||u||_{H^n_{p,\theta}},$$

and, in addition, $h(y) = 0$ for $0 \le y^1 \le 1$. Furthermore,

$$\begin{aligned} |Iu(x)| &\le N(x^1)^{n-1}\int_{\mathsf{R}^d_+}(e^{-|x-y|^2/8} + e^{-|x-Ay|^2/8})I_{y^1\ge 1}(y^1)^{-1-n}|h(y)|\,dy \\ &\le N(x^1)^{n-1}\int_{\mathsf{R}^d_+} e^{-|x-y|^2/8}(1+y^1)^{-1-n}|h(y)|\,dy. \end{aligned}$$

We observe that

$$(x^1)^{n-1}(1+y^1)^{-1-n}e^{-|x-y|^2/8} \le N(1+x^1)^{\alpha}(1+y^1)^{\beta}e^{-|x-y|^2/8}$$

if $\alpha = n-1$ and $\beta \ge -n-1$, and by Lemma 2.1 after denoting $\tau = -\alpha - \beta$ we conclude

$$||Iu||_{L_{q,\sigma}} \le N||h||_{L_{p,\theta}} \le N||u||_{H^n_{p,\theta}}.$$

By combining this with (2.13) and (2.14), we finally arrive at (2.12). The lemma is proved. □

LEMMA 2.4. *Let $1 < p \le q < \infty$, $\tau, \theta \in \mathsf{R}$, $\sigma := d + (\theta - d)q/p + q\tau$, and*

$$d - p/q - p\tau < \theta < d - 1 + p.$$

(i) *If* $\tau \leq 1$ *and* $n \in \{1,2,3,\ldots\}$, *then, for any* $u \in H^{n-1}_{p,\theta}$,

$$||S_1^{(m)}u||_{H^n_{q,\sigma}} \leq N||u||_{H^{n-1}_{p,\theta}};$$

(ii) *if* $\tau \leq 0$ *and* $n \in \{2,3,\ldots\}$, *then, for any* $u \in H^{n-2}_{p,\theta}$,

$$||S_1^{(m)}u||_{H^n_{q,\sigma}} \leq N||u||_{H^{n-2}_{p,\theta}},$$

where N *is independent of* u.

Proof. (i) For $k = 0,1,\ldots,n$, we have to estimate the $L_{q,\sigma}$-norm of $M^kD^kS_1^{(m)}u$ through $||u||_{H^{n-1}_{p,\theta}}$. For $k \leq n-1$, we have the desired estimate from Lemma 2.3. Formula (2.11) shows that we need only prove that

$$||M^{n-1}D^nMS_1^{(m)}u||_{L_{q,\sigma}} \leq N||u||_{H^{n-1}_{p,\theta}}. \tag{2.15}$$

We again use the functions ζ and η from the proof of Lemma 2.3 and rewrite (2.13) as follows:

$$\begin{aligned} M^{n-1}D^nMS_1^{(m)}u =& M^{n-1}D^{m+1}T_1D^{n-1}(M^{-1}\bar{\zeta}\bar{u}) \\ &+ M^{n-1}D^{n+m}\tilde{T}_1M^{-1}\eta u. \end{aligned}$$

Then an obvious modification of the argument ending the proof of Lemma 2.3 immediately leads to (2.15).

(ii) As in (i), but now due to (i) instead of Lemma 2.3, we need only prove that

$$||M^{n-1}D^nMS_1^{(m)}u||_{L_{q,\sigma}} \leq N||u||_{H^{n-2}_{p,\theta}}. \tag{2.16}$$

This time we rewrite (2.13) as follows:

$$\begin{aligned} M^{n-1}D^nMS_1^{(m)}u =& M^{n-1}D^{2+m}T_1D^{n-2}(M^{-1}\bar{\zeta}\bar{u}) \\ &+ M^{n-1}D^{n+m}\tilde{T}_1M^{-1}\eta u \end{aligned}$$

and get (2.16) in the same way as above. The lemma is proved. □

The following theorem is the main result of this section. It shows that the solutions of the Cauchy problem for (0.1) are "naturally smoother" than the initial data. This result, interesting in its own right, plays a central role in section 3 in proving the solvability of parabolic equations in weighted spaces.

For $t \geq s$ introduce the operator $\tilde{T}_{s,t}$ so that, for $f \in C_0^\infty(\mathsf{R}^d_+)$, $\tilde{T}_{s,t}f$ is the solution of the equation $u_t(t,x) = a^{ij}(t)u_{x^ix^j}(t,x)$ for $t > s$ and $x \in \mathsf{R}^d_+$ satisfying $u(s,x) = f(x)$ with zero boundary condition at $x^1 = 0$. Due to (2.1), one has a very well-known representation of the kernel of $\tilde{T}_{s,t}$ as the difference of certain Gaussian densities. In the following theorem we use the operator D^m from Lemma 2.2.

THEOREM 2.5. *Assume* $a^{1j}(t) \equiv 0$ *for* $j = 2,\ldots,d$. *Let* $1 < p \leq q < \infty$, $\alpha,\theta,\gamma \in \mathsf{R}$,

$$\alpha \leq 2, \quad d - p/q - p\alpha < \theta < d - 1 + p.$$

Then, for $\alpha_+ = \max(0,\alpha)$, *generalized function* v *given on* R^d_+,

$$\hat{\alpha} = \alpha - (1/p - 1/q)d, \quad (\hat{\theta} - d)/q = (\theta - d)/p,$$

we have

$$||M^{\alpha-1}D^m\tilde{T}_{0,t}v||_{H^{\gamma}_{q,\hat{\theta}}} \le Nt^{(\hat{\alpha}-m)/2-1}||Mv||_{H^{\bar{\gamma}}_{p,\theta}}, \tag{2.17}$$

where $\bar{\gamma} := \gamma + \alpha_+ - 2$ *and* N *depends only on* $d, p, q, \alpha, \theta, \gamma, m,$ *and* δ.

Proof. We give the proof in several steps. In Steps 1 through 3 we assume that $a^{ij} \equiv \delta^{ij}$.

Step 1. Denote $u = Mv$, $\sigma = d + (\theta - d)q/p + q\alpha$. Then it is easy to see (2.17) becomes

$$||S_t^{(m)}u||_{H^{\gamma}_{q,\sigma}} \le Nt^{(\hat{\alpha}-m)/2-1}||u||_{H^{\bar{\gamma}}_{p,\theta}}. \tag{2.18}$$

Now, remember that if $u(t,x)$ is a solution of the heat equation, then for any constant $c > 0$ the function $u(c^2t, cx)$ is also a solution of the same equation. It follows that $\tilde{T}_t u(c\,\cdot)(x) = \tilde{T}_{c^2t}u(cx)$,

$$\begin{aligned} S_t[u(c\,\cdot)](x) &= cM^{-1}\tilde{T}_t[(M^{-1}u)(c\,\cdot)](x) \\ &= cM^{-1}[(\tilde{T}_{c^2t}M^{-1}u)(c\,\cdot)](x) = c^2[M^{-1}\tilde{T}_{c^2t}M^{-1}u](cx), \\ S_t u(x) &= c^2 S_{c^2t}[u(c^{-1}\cdot)](cx). \end{aligned}$$

By adding to this the homogeneity property of $H^{\gamma}_{p,\theta}$-norms, taking $c = t^{-1/2}$, and denoting $v(x) = u(t^{1/2}x)$, we get that, if (2.18) is true for $t = 1$, then

$$\begin{aligned} ||S_t^{(m)}u||_{H^{\gamma}_{q,\sigma}} &= t^{-1-m/2}||[S_1^{(m)}v](t^{-1/2}\cdot)||_{H^{\gamma}_{q,\sigma}} \le Nt^{\sigma/(2q)-1-m/2}||S_1 v||_{H^{\gamma}_{q,\sigma}} \\ &\le Nt^{\sigma/(2q)-1-m/2}||u(t^{1/2}\cdot)||_{H^{\bar{\gamma}}_{p,\theta}} = Nt^{\sigma/(2q)-1-m/2-\theta/(2p)}||u||_{H^{\bar{\gamma}}_{p,\theta}}. \end{aligned}$$

Upon noticing that $\sigma/q - \theta/p = \hat{\alpha}$, we see that we need concentrate only on the case $t = 1$ and prove

$$||S_1^{(m)}u||_{H^{\gamma}_{q,\sigma}} \le N||u||_{H^{\bar{\gamma}}_{p,\theta}}. \tag{2.19}$$

Step 2. By Lemma 2.4, inequality (2.19) holds if $\gamma = 2, 3, \ldots$ and $\alpha \le 0$, so that $\bar{\gamma} = \gamma - 2$. By an interpolation theorem (see Corollary 3.3 of [6]), (2.19) holds if $\gamma \ge 2$ and $\alpha \le 0$. We also observe that, by Lemma 2.2, the kernel of $S_1^{(m)}$ is either symmetric or antisymmetric; hence using duality leads us to

$$||S_1^{(m)}u||_{H^{2-\gamma}_{p',\theta'}} \le N||u||_{H^{-\gamma}_{q',\sigma'}} \tag{2.20}$$

if

$$\gamma \ge 2, \quad p' = p/(p-1), \quad q' = q/(q-1),$$

$$\theta'/p' + \theta/p = d, \quad \sigma'/q' + \sigma/q = d, \tag{2.21}$$

$$\sigma = d + (\theta - d)q/p + q\alpha, \quad \alpha \le 0,$$

$$d - p/q - p\alpha < \theta < d - 1 + p.$$

It turns out that (2.20) implies

$$||S_1^{(m)}u||_{H^{\gamma_1}_{q_1,\sigma_1}} \leq N||u||_{H^{\gamma_1-2}_{p_1,\theta_1}} \tag{2.22}$$

whenever $\gamma_1 \leq 0$,

$$q_1 \geq p_1 > 0, \quad \alpha_1 \leq 0,$$

$$\sigma_1 = d + (\theta_1 - d)q_1/p_1 + q_1\alpha_1, \tag{2.23}$$

$$d - p_1/q_1 - p_1\alpha_1 < \theta_1 < d - 1 + p_1.$$

To derive (2.22) from (2.20), take in (2.20)

$$\gamma = 2 - \gamma_1, \quad p = q_1/(q_1 - 1), \quad q = p_1/(p_1 - 1), \quad \alpha = \alpha_1,$$

$$\theta = pd - \sigma_1(p - 1), \quad \sigma = qd - \theta_1(q - 1).$$

Notice that

$$p' = q_1, \quad q' = p_1, \quad q \geq p,$$

and from the second line in (2.21) we infer that

$$\theta' := p'd - \theta p'/p = \sigma_1(p - 1)p'/p = \sigma_1,$$

$$\sigma' := q'd - \sigma q'/q = \theta_1(q - 1)q'/q = \theta_1.$$

This identifies the subscripts in (2.20) and (2.22). Next, from the second line in (2.23) and from the definition of θ we get

$$\begin{aligned}\theta_1 &= (\sigma_1 - d)p_1/q_1 + d - \alpha_1 p_1 = (\sigma_1 - d)q'/p' + d - \alpha q' \\ &= ((pd - \theta)/(p - 1) - d)q'/p' + d - \alpha q' = (pd - \theta)q'/p - q'd/p' + d - \alpha q'.\end{aligned}$$

We can now check that the third line in (2.21) is consistent with our definitions. We have

$$\begin{aligned}\sigma &:= qd - \theta_1(q - 1) = qd - (pd - \theta)q/p + qd/p' - (q - 1)d + \alpha q \\ &= \theta q/p + qd(p - 1)/p - (q - 1)d + \alpha q = d + (\theta - d)q/p + \alpha q.\end{aligned}$$

Finally, to take care of the inequalities imposed on θ in (2.21), notice that

$$\begin{aligned}\theta &:= q_1 d/(q_1 - 1) - (d + (\theta_1 - d)q_1/p_1 + q_1\alpha_1)/(q_1 - 1) \\ &< q_1 d/(q_1 - 1) - (d + (-p_1/q_1 - p_1\alpha_1)q_1/p_1 + q_1\alpha_1)/(q_1 - 1) = d - 1 + p, \\ \theta &> q_1 d/(q_1 - 1) - (d + (-1 + p_1)q_1/p_1 + q_1\alpha_1)/(q_1 - 1) = d - p/q - p\alpha.\end{aligned}$$

Thus, (2.22) holds, indeed, if conditions (2.23) are satisfied and $\gamma_1 \leq 0$. As mentioned in the beginning of Step 2, this is also true if $\gamma_1 \geq 2$. Interpolation in γ_1 shows that (2.22) holds if conditions (2.23) are satisfied without any restriction on γ_1. This proves our theorem for $\alpha \leq 0$.

Step 3. For $0 \le \alpha \le 2$ we again use interpolation. As in Step 2 one can use Lemma 2.3 and the arguments based on interpolation and duality. Then by combining the result with (2.22), we get that

$$||S_1^{(m)}u||_{H^\gamma_{q,\sigma_0}} \le N||u||_{H^\gamma_{p,\theta_0}}, \quad ||S_1^{(m)}u||_{H^\gamma_{q,\sigma_1}} \le N||u||_{H^{\gamma-2}_{p,\theta_1}}$$

whenever

$$\sigma_0 = d + (\theta_0 - d)q/p + 2q, \quad d - p/q - 2p < \theta_0 < d - 1 + p,$$

$$\sigma_1 = d + (\theta_1 - d)q/p, \quad d - p/q < \theta_1 < d - 1 + p.$$

It follows by interpolation that (2.19) holds if we can find $\kappa \in [0,1]$ and θ_i as above so that

$$\gamma + \alpha - 2 = \kappa(\gamma - 2) + (1-\kappa)\gamma,$$

$$\theta = \kappa\theta_1 + (1-\kappa)\theta_0, \quad \sigma = \kappa\sigma_1 + (1-\kappa)\sigma_0. \tag{2.24}$$

Of course, we take $\kappa = 1 - \alpha/2$. With this choice, the last equation in (2.24) follows from the first one. (Remember that σ is defined in the beginning of Step 1.) It remains only to notice that $\kappa\theta_1 + (1-\kappa)\theta_0$ spans the interval $(d - p/q - p\alpha, d - 1 + p)$ as θ_1 and θ_0 run through $(d - p/q, d - 1 + p)$ and $(d - p/q - 2p, d - 1 + p)$, respectively. This proves the theorem if $a^{ij} \equiv \delta^{ij}$.

Step 4. To consider general a^{ij} with $a^{1j} \equiv 0$ for $j \ge 2$, we apply Theorem 5.1 from the last section. First, by using an obvious time change, one reduces the general situation to the one with $a^{11} \equiv 1$. Bearing in mind an appropriate dilation with respect to $x^2, \dots, x^d$ we may further assume that $(a^{ij}(t)) \ge (\delta^{ij})$.

In Theorem 5.1 take $H = \mathsf{R}$, $\mathcal{U} = \{(u,0)\}$, where $u = u(s,t,x)$ is an arbitrary function defined on $(\mathsf{R}^2 \cap \{s \le t\}) \times \mathsf{R}^d_+$ such that the "norm"

$$||(u,0)||_{\mathcal{U}} := ||M^{\alpha-1}D^m u(0,t_0,\cdot)||_{H^\gamma_{q,\hat\theta}}$$

is finite, where $t_0 > 0$ is a fixed number. Also, let $\mathcal{F} = \{(f,0)\}$, where f is an arbitrary function on $\mathsf{R} \times \mathsf{R}^d_+$ such that $f(0,\cdot) \in M^{-1}H^{\bar\gamma}_{q,\theta}$, with "norm" in $\mathcal{F}$ defined by

$$||(f,0)||_{\mathcal{F}} := ||Mf(0,\cdot)||_{H^{\bar\gamma}_{q,\theta}}.$$

Define $\mathcal{A} = C_0^\infty(\mathsf{R} \times \mathsf{R}^d_+) \times \{0\}$ and $\mathcal{B} = \mathcal{B}_1 \times \{0\}$, where $\mathcal{B}_1$ is the set of all functions u of $(s,t,x) \in (\mathsf{R}^2 \cap \{s \le t\}) \times \mathsf{R}^d_+$, which are bounded and continuous in (s,t,x) along with each their derivative with respect to x and such that $||(u,0)||_{\mathcal{U}} < \infty$.

Then all the assumptions of Theorem 5.1 are satisfied due to obvious properties of the spaces $H^\gamma_{p,\theta}$ and the above treatment of the case $a^{ij} \equiv \delta^{ij}$. By this theorem, (2.17) holds with $t = t_0$ and $v \in C_0^\infty(\mathsf{R}^d_+)$. This yields the result due to denseness of $C_0^\infty(\mathsf{R}^d_+)$ in spaces $H^\nu_{p,\tau}$. The theorem is proved. □

REMARK 2.6. *Obviously, this theorem also holds for complex and Hilbert-space-valued functions* v.

COROLLARY 2.7. *Under the assumptions of Theorem* 2.5*, let* $a^{ij}(t)$ *be infinitely differentiable in* t. *Then, for any* $t > s$, *we have*

$$||M^{\alpha-1}D_s D^m \tilde T_{s,t} v||_{H^\gamma_{q,\hat\theta}} \le N(t-s)^{(\hat\alpha - m)/2 - 2}||Mv||_{H^{\bar\gamma}_{p,\theta}},$$

with N depending only on $d, p, q, \alpha, \theta, \gamma, m, K$, and δ.

To prove this, it suffices to notice that, for $v \in C_0^\infty(\mathsf{R}^d_+)$,

$$\frac{\partial}{\partial s}\tilde{T}_{s,t}v = -a^{11}(s)\frac{\partial^2}{(\partial x^1)^2}\tilde{T}_{s,t}v - \sum_{i,j\geq 2} a^{ij}(s)\frac{\partial^2}{\partial x^i \partial x^j}\tilde{T}_{s,t}v.$$

COROLLARY 2.8. *Under the assumptions of Theorem* 2.5 *let $\hat{\alpha} > 0$ and $M^{-1}u \in H^{\gamma+\alpha}_{p,\theta}$. Then*

$$||M^{\alpha-1}(\tilde{T}_t - 1)u||_{H^\gamma_{q,\hat{\theta}}} \leq Nt^{\hat{\alpha}/2}||M\Delta u||_{H^{\gamma+\alpha-2}_{p,\theta}}.$$

Indeed, if $u \in C_0^\infty(\mathsf{R}^d_+)$,

$$(\tilde{T}_t - 1)u = \int_0^t \tilde{T}_r \Delta u \, dr.$$

Hence,

$$\begin{aligned}||M^{\alpha-1}(\tilde{T}_t - 1)u||_{H^\gamma_{q,\hat{\theta}}} &\leq \int_0^t ||M^{\alpha-1}\tilde{T}_r\Delta u||_{H^\gamma_{q,\hat{\theta}}}\, dr \\ &\leq N\int_0^t r^{\hat{\alpha}/2-1}\, dr||M\Delta u||_{H^{\gamma+\alpha-2}_{p,\theta}} = Nt^{\hat{\alpha}/2}||M\Delta u||_{H^{\gamma+\alpha-2}_{p,\theta}}.\end{aligned}$$

Our assertion follows since $C_0^\infty(\mathsf{R}^d_+)$ is dense in the spaces $H^\gamma_{p,\theta}$ and $||M\Delta u||_{H^\nu_{p,\theta}} \leq N||M^{-1}u||_{H^{\nu+2}_{p,\theta}}$.

3. Equation (0.1) in R^d_+ in spaces with weights. Recall that the spaces $H^\gamma_{p,\theta}$ and the operators $\tilde{T}_{s,t}$ are introduced in the beginning of section 2 and before Theorem 2.5, respectively. Define

$$\tilde{R}f(t) = \int_{-\infty}^t \tilde{T}_{s,t}f(s)\, ds, \quad \tilde{A} = MD^2\tilde{R}M^{-1}f.$$

Existence and uniqueness results for (0.1) in $(0,T)\times\mathsf{R}^d_+$ are based on the following counterpart of Theorem 1.1. In this section we prove Theorem 3.1 under additional assumption (2.1), postponing consideration of the general case until section 4.

THEOREM 3.1. *Let*

$$p, q \in (1,\infty), \quad \gamma \in \mathsf{R}, \quad d - 1 < \theta < d - 1 + p.$$

Then the operator $\tilde{A}$ is uniquely extendable to a bounded operator acting in $L_q(\mathsf{R}, H^\gamma_{p,\theta})$. If we keep the same notation for the extension, then

$$||MD^2\tilde{R}M^{-1}f||_{L_q(\mathsf{R},H^\gamma_{p,\theta})} \leq N(\delta, d, q, p, \gamma)||f||_{L_q(\mathsf{R},H^\gamma_{p,\theta})}. \tag{3.1}$$

Proof. First we prove (3.1) for $q = p$ and $f \in C_0^\infty(\mathsf{R}\times\mathsf{R}^d)$. Without losing generality we assume that $f(s) = 0$ for $s \leq 0$. Then $\tilde{R}M^{-1}f$ is a classical solution of $Lu = -M^{-1}f$ vanishing for $t \leq 0$ and on $x^1 = 0$. Due to our restriction on θ and Theorem 5.6 of [5] we have that (3.1) indeed holds for $q = p$ and $f \in C_0^\infty(\mathsf{R}\times\mathsf{R}^d)$. By

using the fact that $C_0^\infty(\mathsf{R}\times\mathsf{R}^d)$ is dense in $L_q(\mathsf{R},H^\gamma_{p,\theta})$, we conclude that (3.1) holds for $q=p$ and any $f\in L_q(\mathsf{R},H^\gamma_{p,\theta})$.

Below we also use Theorem 4.1 of [5], which says that $||M\Delta\cdot||_{H^\gamma_{p,\theta}}\sim||MD^2\cdot||_{H^\gamma_{p,\theta}}$ in our range of θ. Therefore, instead of considering $\tilde A$ we may and will prove the theorem for

$$\bar A=M\Delta\tilde RM^{-1}f.$$

Notice that, if $f\in C_0^\infty(\mathsf{R}\times\mathsf{R}^d)$ and t is not in the support of $f(s)$ as a function of s, then $\tilde T_{s,t}M^{-1}f(s)$ is infinitely differentiable in x and

$$\bar Af(t)=M\Delta\tilde RM^{-1}f(t)=\int_{-\infty}^t M\Delta\tilde T_{s,t}M^{-1}f(s)\,ds. \tag{3.2}$$

Moreover, estimates (2.2), Theorem 2.5 (with $q=p$ and $\alpha=m=2$), and the boundedness of $\bar A$ as an operator from $L_p(\mathsf{R},H^\gamma_{p,\theta})$ to $L_p(\mathsf{R},H^\gamma_{p,\theta})$ show that (3.2) holds for almost all t outside the support of f if f is a bounded $H^\gamma_{p,\theta}$-valued function with compact support. In other words, for those t,

$$\bar Af(t)=\int_{\mathsf{R}}K(t,s)f(s)\,ds,$$

where the operator $K(t,s)$ is defined by the formula

$$K(t,s)h=I_{t>s}M\Delta\tilde T_{s,t}M^{-1}h.$$

Observe that by Theorem 2.5, $K(t,s)$ is a bounded operator from $H^\gamma_{p,\theta}$ into itself with norm less than $N|t-s|^{-1}$.

Now we claim that $\bar A$ is a bounded operator from $L_q(\mathsf{R},H^\gamma_{p,\theta})$ to $L_q(\mathsf{R},H^\gamma_{p,\theta})$ for $1<q\le p$. Here we prove this under the additional assumption that (2.1) holds. Clearly, we may assume that the coefficients a^{ij} are infinitely differentiable as long as we can prove that the estimates on $\bar A$ are independent of smoothness of a^{ij}. Then, owing to Theorem 1.4, to prove the claim, it suffices to show that the norm of $D_sK(t,s)$ as an operator in $H^\gamma_{p,\theta}$ is less than $N|t-s|^{-2}$ with N depending only on d,p,q,θ,γ,K, and δ. However, this is just the statement of Corollary 2.7 for $\alpha=m=2$.

Thus, $\bar A$ is a bounded operator in $L_q(\mathsf{R},H^\gamma_{p,\theta})$ for $1<q\le p$. The same is true for $1<p\le q$, which is proved by using duality and the fact that the dual to $H^\gamma_{p,\theta}$ is $H^{-\gamma}_{p',\theta'}$, with $1/p+1/p'=1$ and $\theta/p+\theta'/p'=d$, where θ' runs through $(d-1,d-1+p')$ as θ runs through $(d-1,d-1+p)$. The theorem is proved. □

Now we can investigate the solvability of (0.1) in $(0,T)\times\mathsf{R}^d_+$ in weighted spaces. Denote

$$\mathbb{H}^{\gamma,q}_{p,\theta}(T)=L_q((0,T),H^\gamma_{p,\theta}),\quad \mathbb{H}^{\gamma,q}_{p,\theta}=L_q(\mathsf{R},H^\gamma_{p,\theta}),$$

$$\mathbb{L}^q_{p,\theta}(T)=\mathbb{H}^{0,q}_{p,\theta}(T),\quad \mathbb{L}^q_{p,\theta}=\mathbb{H}^{0,q}_{p,\theta}.$$

Remember that the operator L is introduced in (1.1).

THEOREM 3.2. *Let $p,q\in(1,\infty)$, $T\in(0,\infty)$, $\gamma\in\mathsf{R}$,*

$$d-1<\theta<d-1+p,\quad \varepsilon>0.$$

$Mf \in \mathbb{H}^{\gamma,q}_{p,\theta}(T)$, and $M^{2/q-1-\varepsilon}u_0 \in H^{\gamma+2-2/q+\varepsilon}_{p,\theta}$. Then in $M\mathbb{H}^{\gamma+2,q}_{p,\theta}(T)$ there is a unique solution of (0.1) on $(0,T)$ with initial data u_0. For this solution

$$||M^{-1}u||_{\mathbb{H}^{\gamma+2,q}_{p,\theta}(T)} \leq N_1||MLu||_{\mathbb{H}^{\gamma,q}_{p,\theta}(T)} + N_2||M^{2/q-1-\varepsilon}u(0)||_{H^{\gamma+2-2/q+\varepsilon}_{p,\theta}}, \tag{3.3}$$

where $N_1 = N(d,p,q,\delta,K,\theta,\gamma)$ and $N_2 = N(d,p,q,\delta,K,\theta,\gamma,T)$. In addition, if $q = p$, one can allow $\varepsilon = 0$, and then N_2 is independent of T.

Proof. First we reduce the general situation to the one with $u_0 = 0$. From [7] we know that there is a continuation operator P mapping $u_0 \in M^{1+\varepsilon-2/q}H^{\gamma+2-2/q+\varepsilon}_{p,\theta}$ into a function of $(t,x) \in [0,\infty) \times \mathsf{R}^d_+$ which is weakly continuous in t and satisfies $Pu|_{t=0} = u_0$,

$$||M^{-1}Pu_0||_{\mathbb{H}^{\gamma+2,q}_{p,\theta}(T)} + ||M(Pu_0)_t||_{\mathbb{H}^{\gamma,q}_{p,\theta}(T)} \leq N||M^{2/q-1-\varepsilon}u_0||_{H^{\gamma+2-2/q+\varepsilon}_{p,\theta}}.$$

It is also proved that if $q = p$, then the result holds for $\varepsilon = 0$ with N independent of T. By using (2.2) again, we see that indeed everything is reduced to the case $u_0 = 0$.

Now take $f \in C_0^\infty(\mathsf{R}_+ \times \mathsf{R}^d_+)$ and let $u = \tilde{R}f$. Then u is a classical solution of $Lu = -f$ for $t > 0$, $x^1 > 0$ satisfying $u(0) = 0$ and $u = 0$ on $x^1 = 0$. Owing to Theorem 3.1, (2.2), and the fact that $u(t)$ for $t \in [0,T]$ is independent of the values of $f(s)$ for $s \geq T$, we get (3.3) and, from the equation $Lu = -f$, that $||Mu_t||_{\mathbb{H}^{\gamma,q}_{p,\theta}(T)} \leq N||Mf||_{\mathbb{H}^{\gamma,q}_{p,\theta}(T)}$. In particular, for any $T < \infty$,

$$\sup_{t\leq T}||Mu(t,\cdot)||_{H^\gamma_{p,\theta}} \leq N||Mf||_{\mathbb{H}^{\gamma,q}_{p,\theta}(T)}$$

with N independent of f. It follows that if f is in a bounded set in $M^{-1}\mathbb{H}^{\gamma,q}_{p,\theta}(T)$, then u is in a bounded set in

$$M\mathbb{H}^{\gamma+2,q}_{p,\theta}(T) \cap M^{-1}C([0,T],H^\gamma_{p,\theta}).$$

Using obvious approximations proves our assertion about the existence of solutions.

To prove uniqueness, observe that it suffices to prove the a priori estimate (3.3) for any function $M^{-1}u \in \mathbb{H}^{\gamma+2,q}_{p,\theta}(T)$ which is weakly continuous in t and satisfies $u(0) = 0$ and $MLu \in \mathbb{H}^{\gamma,q}_{p,\theta}(T)$. The latter along with (2.2) implies that $Mu_t \in \mathbb{H}^{\gamma,q}_{p,\theta}(T)$. Any such function u belongs to the class $H^{\gamma+2,q}_{p,\theta}(T)$ introduced in [7], where it is also proved that there exists a sequence of functions $u_n(t,x)$ which are infinitely differentiable in x, have support in $[0,T] \times G_n$, where $G_n = \bar{G}_n \subset \mathsf{R}^d_+$, vanish at $t = 0$, have bounded derivative in t, and

$$||M^{-1}(u-u_n)||_{\mathbb{H}^{\gamma+2,q}_{p,\theta}(T)} + ||M(u-u_n)_t||_{\mathbb{H}^{\gamma,q}_{p,\theta}(T)} \to 0.$$

Then, of course, $u_n = -\tilde{R}f_n$ with $f_n(t) = I_{t\in(0,T)}Lu_n(t)$, and

$$||M(Lu-f_n)||_{\mathbb{H}^{\gamma,q}_{p,\theta}(T)} \leq N(||MD^2(u-u_n)||_{\mathbb{H}^{\gamma,q}_{p,\theta}(T)} + ||M(u-u_n)_t||_{\mathbb{H}^{\gamma,q}_{p,\theta}(T)}) \to 0.$$

It remains only to notice that by the first part of the proof

$$||M^{-1}u_n||_{\mathbb{H}^{\gamma+2,q}_{p,\theta}(T)} \leq N_1||Mf_n||_{\mathbb{H}^{\gamma,q}_{p,\theta}(T)}.$$

The theorem is proved. □

The third proof of Theorem 1.1. As in section 1, we may assume that $\gamma = 0$. Also, obviously we need only to prove (1.2) for $f \in C_0^\infty(\mathsf{R} \times \mathsf{R}^d)$. Now comes the crucial observation that, due to self similarity of (1.2) for $\gamma = 0$, we can assume that $f = 0$ for $x^1 \notin (1,2)$ and prove only that

$$||\zeta D^2 R\zeta f||_{\mathbb{L}_p^q} \le N||f||_{\mathbb{L}_p^q} \tag{3.4}$$

for a function $\zeta \in C_0^\infty(\mathsf{R}_+)$ such that $\zeta(r) = 1$ on $[1,2]$.

Next, for $n > 1$ define $f_n(t,x) = f(t,x^1 - n, x')$, $\zeta_n(r) = \zeta(r-n)$. Then it is easily seen that

$$R\zeta f = \lim_{n\to\infty} v_n \quad \text{with} \quad v_n(t,x) = u_n(t,x^1+n,x'), \quad u_n = \tilde{R}(\zeta_n f_n). \tag{3.5}$$

Upon noticing that on the support of ζ_n it holds that $\zeta_n(r) \sim \zeta_n(r)r/n$, by Theorem 3.1 with $\theta = d$ we have

$$\begin{aligned}
||\zeta D^2 v_n||_{\mathbb{L}_p^q}^q = ||\zeta_n D^2 u_n||_{\mathbb{L}_p^q}^q &\le N\int_{\mathsf{R}} \left(\int_{\mathsf{R}^d} |(x^1/n)D^2 u_n(t,x)|^p\,dx\right)^{q/p} dt \\
&\le Nn^{-q}\int_{\mathsf{R}} \left(\int_{\mathsf{R}^d} |x^1\zeta_n f_n(t,x)|^p\,dx\right)^{q/p} dt \\
&\le N\int_{\mathsf{R}} \left(\int_{\mathsf{R}^d} |f_n(t,x)|^p\,dx\right)^{q/p} = N\int_{\mathsf{R}} \left(\int_{\mathsf{R}^d} |f(t,x)|^p\,dx\right)^{q/p}.
\end{aligned}$$

This along with (3.5) yields (3.4) and brings our third proof to an end.

4. Proof of Theorem 3.1 in the general case. We need two lemmas, in the first of which no restriction on θ is imposed. Remember that $Lu = a^{ij}u_{x^ix^j} - u_t$.

LEMMA 4.1. *Let $p \in (1,\infty)$, $n \in \{1,2,\dots\}$, $\gamma \ge \nu$, $\theta \in \mathsf{R}$, $M^{-1}u \in \mathbb{H}_{p,\theta}^{\nu,np}$, and $Mf \in \mathbb{H}_{p,\theta}^{\gamma-2,np}$. Assume u is a solution of $Lu = f$ in $\mathsf{R}\times\mathsf{R}_+^d$. Then $M^{-1}u \in \mathbb{H}_{p,\theta}^{\gamma,np}$ and*

$$||M^{-1}u||_{\mathbb{H}_{p,\theta}^{\gamma,np}} \le N(||MLu||_{\mathbb{H}_{p,\theta}^{\gamma-2,np}} + ||M^{-1}u||_{\mathbb{H}_{p,\theta}^{\nu,np}}), \tag{4.1}$$

where $N = N(d,n,p,\theta,\gamma,\nu,\delta)$.

Proof. Clearly (4.1) becomes stronger if ν decreases. Therefore, we may assume that $\nu = \gamma - k$, where k is an integer, and bearing in mind an obvious induction, we see that, without loss of generality, we may let $\nu = \gamma - 1$.

Now notice that

$$\begin{aligned}
||M^{-1}u||_{\mathbb{H}_{p,\theta}^{\gamma,np}}^{np} &= \int_{\mathsf{R}} ||M^{-1}u(t)||_{H_{p,\theta}^{\gamma}}^{np}\,dt \le N\int_{\mathsf{R}} ||u(t)||_{H_{p,\theta-p}^{\gamma}}^{np}\,dt \\
&= N\sum_{m_1,\dots,m_n=-\infty}^{\infty} e^{(\theta-p)\bar{m}} \int_{\mathsf{R}} \prod_{i=1}^{n} ||u(t,e^{m_i}\cdot)\zeta||_{H_p^\gamma}^p\,dt
\end{aligned} \tag{4.2}$$

with $\bar{m} := m_1 + \cdots + m_n$. Here

$$\begin{aligned}
||u(t,e^m\cdot)\zeta||_{H_p^\gamma}^p &\le N||\Delta[u(t,e^m\cdot)\zeta]||_{H_p^{\gamma-2}}^p \\
&= ||(1-\Delta)^{\gamma/2-1}\Delta[u(t,e^m\cdot)\zeta]||_{L_p}^p \\
&= e^{m(p\gamma-d)}||(\lambda_m - \Delta)^{\gamma/2-1}\Delta[u(t)\zeta_m]||_{L_p}^p,
\end{aligned}$$

where $\lambda_m = e^{-2m}$ and $\zeta_m(x) = \zeta(e^{-m}x)$. Furthermore, $L(u\zeta_m) = \bar{f}_m$, where,

$$\bar{f}_m = f\zeta_m + 2a^{ij}\zeta_{mx^i}u_{x^j} + ua^{11}\zeta_{mx^1x^1},$$

and similarly to the above computation

$$||(\lambda_m - \Delta)^{\gamma/2-1}\bar{f}_m(t)||^p_{L_p} = e^{-m(p\gamma-2p-d)}||\bar{f}_m(t,e^m\cdot)||^p_{H_p^{\gamma-2}}.$$

Therefore, by Lemma 1.6, which is obviously valid for R in place of $(0,T)$, for any $m_1,\dots,m_n$, we have

$$\int_{\mathsf{R}}\prod_{i=1}^n ||u(t,e^{m_i}\cdot)\zeta||^p_{H_p^\gamma}\,dt$$
$$\leq N\int_{\mathsf{R}}\sum_{i=1}^n e^{2m_ip}||\bar{f}_{m_i}(t,e^{m_i}\cdot)||^p_{H_p^{\gamma-2}}\prod_{j\neq i}||u(t,e^{m_j}\cdot)\zeta||^p_{H_p^\gamma}\,dt.$$

Coming back to (4.2), we conclude

$$||M^{-1}u||^{np}_{\mathbb{H}^{\gamma,np}_{p,\theta}} \leq N\int_{\mathsf{R}} F(t)||u(t)||^{(n-1)p}_{H^\gamma_{p,\theta-p}}\,dt,$$

where

$$F(t) := \sum_{m=-\infty}^{\infty} e^{m(\theta+p)}||\bar{f}_m(t,e^m\cdot)||^p_{H_p^{\gamma-2}}.$$

Next we use (see [5]) that the operator M^β is a bounded operator from $H^\gamma_{p,\theta}$ to $H^\gamma_{p,\theta+\beta p}$ and that $M\nabla$ is a bounded operator from $H^\gamma_{p,\theta}$ to $H^{\gamma-1}_{p,\theta}$. Then we find

$$F(t) \leq N\sum_{m=-\infty}^{\infty} e^{m(\theta+p)}||f(t,e^m\cdot)\zeta||^p_{H_p^{\gamma-2}}$$
$$+N\sum_{m=-\infty}^{\infty} e^{m\theta}||u_x(t,e^m\cdot)\zeta'||^p_{H_p^{\gamma-2}} + N\sum_{m=-\infty}^{\infty} e^{m(\theta-p)}||u(t,e^m\cdot)\zeta''||^p_{H_p^{\gamma-2}}$$
$$\leq N\left(||Mf(t)||^p_{H^{\gamma-2}_{p,\theta}} + ||Mu_x(t)||^p_{H^{\gamma-2}_{p,\theta-p}} + ||M^{-1}u(t)||^p_{H^{\gamma-2}_{p,\theta}}\right)$$
$$\leq N\left(||Mf(t)||^p_{H^{\gamma-2}_{p,\theta}} + ||u(t)||^p_{H^{\gamma-1}_{p,\theta-p}}\right) \leq N\left(||Mf(t)||^p_{H^{\gamma-2}_{p,\theta}} + ||M^{-1}u(t)||^p_{H^{\gamma-1}_{p,\theta}}\right).$$

Thus,

$$||M^{-1}u||^{np}_{\mathbb{H}^{\gamma,np}_{p,\theta}}$$
$$\leq NE\int_{\mathsf{R}}\left(||Mf(t)||^p_{H^{\gamma-2}_{p,\theta}} + ||M^{-1}u(t)||^p_{H^{\gamma-1}_{p,\theta}}\right)||M^{-1}u(t)||^{(n-1)p}_{H^\gamma_{p,\theta}}\,dt,$$

and, to get (4.1) for $\nu = \gamma - 1$, it remains only to use Hölder's inequality. The lemma is proved. □

LEMMA 4.2. *Let $p,q \in (1,\infty)$, $d-1 < \theta < d-1+p$, $M^{-1}u \in \mathbb{H}^{2,q}_{p,\theta}$, and $Mf \in \mathbb{L}^q_{p,\theta}$. Assume u is a solution of $Lu = f$ in $\mathsf{R}\times\mathsf{R}^d_+$. Then*

$$||M^{-1}u||_{\mathbb{L}^q_{p,\theta}} \leq N||MLu||_{\mathbb{L}^q_{p,\theta}}, \tag{4.3}$$

where $N = N(d,p,q,\theta)$.

Proof. Our assertion means that the a priori estimate (4.3) holds for any weakly continuous $u(t)$ defined on R and satisfying $M^{-1}u \in \mathbb{H}^{2,q}_{p,\theta}$, which implies $MD^2u \in \mathbb{L}^q_{p,\theta}$ (see (2.2)), and such that the right-hand side of (4.3) is finite, which adds that $Mu_t \in \mathbb{L}^q_{p,\theta}$. This interpretation allows us to use approximations and shows that we may assume $u \in C_0^\infty(\mathsf{R} \times \mathsf{R}^d_+)$.

Denote $Lu = -f$ and let $\tilde{p}(s,t,x,y)$ be the kernel of $\tilde{T}_{s,t}$. It is well known that $\tilde{p}(s,t,x,y)$ can be written as $\tilde{p}(s,t,x^1,y^1,x'-y')$. Then $u(t,x)$ is written as

$$\int_{-\infty}^t \tilde{T}_{t,s} f(s,x)\,ds = \int_{-\infty}^t \int_{\mathsf{R}^d_+} \tilde{p}(s,t,x^1,y^1,y') f(s,y^1,x'-y')\,dyds.$$

Hence by Minkowski's inequality, for any $x^1 > 0$ and t, the norm $||u(t,x^1,\cdot)||_{L_p(\mathsf{R}^{d-1})} =: \bar{u}(t,x^1)$ is less than

$$\int_{-\infty}^t \int_{\mathsf{R}^d_+} \tilde{p}(s,t,x^1,y^1,y') ||f(s,y^1,\cdot - y')||_{L_p(\mathsf{R}^{d-1})}\,dyds$$

$$= \int_{-\infty}^t \int_{\mathsf{R}_+} \tilde{p}(s,t,x^1,y^1) \tilde{f}(s,y^1)\,dy^1 ds =: \tilde{u}(t,x^1),$$

where

$$\tilde{p}(s,t,x^1,y^1) = \int_{\mathsf{R}^{d-1}} \tilde{p}(s,t,x^1,y^1,y')\,dy',$$

$$\tilde{f}(s,y^1) = ||f(s,y^1,\cdot)||_{L_p(\mathsf{R}^{d-1})}.$$

Obviously $\tilde{p}(s,t,x^1,y^1)$ is the fundamental solution of the equation $a^{11}u_{x^1x^1} - u_t = 0$. Hence, by (2.2) and Theorem 3.1 applied for $d = 1$ and $\sigma = \theta - d + 1$, we get

$$||M^{-1}\tilde{u}||_{\mathbb{L}^q_{p,\sigma}} \le ||M^{-1}\tilde{u}||_{\mathbb{H}^{2,q}_{p,\sigma}} \le N||M\tilde{f}||_{\mathbb{L}^q_{p,\sigma}}.$$

It remains only to notice that

$$||M\tilde{f}||^q_{\mathbb{L}^q_{p,\sigma}} = \int_{\mathsf{R}} \left(\int_{\mathsf{R}_+} (x^1)^{\sigma-1+p} |\tilde{f}(t,x^1)|^p\,dx^1 \right)^{q/p} dt = ||Mf||^q_{\mathbb{L}^q_{p,\theta}},$$

$$||M^{-1}u||_{\mathbb{L}^q_{p,\theta}} = ||M^{-1}\bar{u}||_{\mathbb{L}^q_{p,\sigma}} \le ||M^{-1}\tilde{u}||_{\mathbb{L}^q_{p,\sigma}}.$$

The lemma is proved. □

Now we can finish proving Theorem 3.1 in the general case. Remember that the operator $\tilde{A}$ is introduced before Theorem 3.1. As we had mentioned in the proof of Theorem 3.1 in section 3, if $f \in C_0^\infty(\mathsf{R} \times \mathsf{R}^d_+)$, then $\tilde{R}M^{-1}f$ is a classical solution of $Lu = -M^{-1}f$ vanishing for $x^1 = 0$ and for all t sufficiently large negative. It follows quite easily that $M^{-1}\tilde{R}M^{-1}f \in \mathbb{H}^{\gamma,q}_{p,\theta}$ for all γ and q. Therefore, from (2.2) and Lemmas 4.1 and 4.2 we get that $\tilde{A}$ is a bounded operator in $L_{np}(\mathsf{R}, H^\gamma_{p,\theta})$ for $n = 1,2,\ldots$ and $\gamma \ge 0$. By the Marcinkiewicz interpolation theorem we can replace np with any $q \ge p$.

Next we claim that, for $q \geq p$, $\tilde{A}$ is a bounded operator in $L_q(\mathsf{R}, H^\gamma_{p,\theta})$ for any $\gamma \in \mathsf{R}$. As we have seen before, this is equivalent to saying that $M^{-1}\tilde{R}M^{-1}$ is a bounded operator from $\mathbb{H}^{\gamma,q}_{p,\theta}$ to $\mathbb{H}^{\gamma+2,q}_{p,\theta}$ for any γ.

To prove this property of $\tilde{R}M^{-1}$, we introduce the operator

$$\mathcal{L}_b = M^2\Delta + bMD_1, \quad \mathcal{L} = \mathcal{L}_2.$$

We are going to use Theorem 2.16 of [5], which asserts that $\mathcal{L}$ is a bounded one-to-one operator from $H^\gamma_{p,\theta}$ onto $H^{\gamma-2}_{p,\theta}$ and its inverse is also bounded. We are also using the fact (see [5]) that DM and $M^{-\beta}\mathcal{L}_b M^\beta$ are bounded operators from $H^\gamma_{p,\theta}$ into $H^{\gamma-1}_{p,\theta}$ and $H^\gamma_{p,\theta}$ into $H^{\gamma-2}_{p,\theta}$, respectively. Define

$$\bar{R}M^{-1} := \mathcal{L}\tilde{R}M^{-1}\mathcal{L}^{-1} + 2\tilde{R}M^{-1}S = M(M^{-1}\mathcal{L}M)T\mathcal{L}^{-1} + 2MTS,$$

where $T := M^{-1}\tilde{R}M^{-1}$ and S is a "smoothing" operator defined by

$$\begin{aligned} S &= a^{1j}M(D_jM^{-1}\mathcal{L}_1 + M^{-1}\mathcal{L}_1D_j)\tilde{R}M^{-1}\mathcal{L}^{-1} + MD_1\mathcal{L}^{-1} \\ &= a^{1j}MD_j(M^{-1}\mathcal{L}_1M)T\mathcal{L}^{-1} + a^{1j}\mathcal{L}_1(D_jM)T\mathcal{L}^{-1} + MD_1\mathcal{L}^{-1}. \end{aligned}$$

Fix an integer $n \geq 0$ and assume that $M^{-1}\tilde{R}M^{-1}$ is a bounded operator from $\mathbb{H}^{\gamma,q}_{p,\theta}$ to $\mathbb{H}^{\gamma+2,q}_{p,\theta}$ for any $\gamma \geq -n$. By the above result this is true if $n = 0$. Fix a $\gamma \geq -n$. Then T is a bounded operator from $\mathbb{H}^{\gamma,q}_{p,\theta}$ to $\mathbb{H}^{\gamma+2,q}_{p,\theta}$. This and the abovementioned properties of $M^{-\beta}\mathcal{L}_bM^\beta$, D_1M, and MD_1 imply that the operator S is a bounded operator from $\mathbb{H}^{\gamma-1,q}_{p,\theta}$ to $\mathbb{H}^{\gamma,q}_{p,\theta}$. It follows that $M^{-1}\bar{R}M^{-1}$ is a bounded operator from $\mathbb{H}^{\gamma-1,q}_{p,\theta}$ to $\mathbb{H}^{\gamma+1,q}_{p,\theta}$:

$$||M^{-1}\bar{R}M^{-1}f||_{\mathbb{H}^{\gamma+1,q}_{p,\theta}} \leq N||f||_{\mathbb{H}^{\gamma-1,q}_{p,\theta}}. \tag{4.4}$$

Furthermore, it turns out that

$$\bar{R}M^{-1}f = \tilde{R}M^{-1}f \tag{4.5}$$

if $f \in C_0^\infty(\mathsf{R} \times \mathsf{R}^d_+)$. Indeed, the function $v := \tilde{R}M^{-1}\mathcal{L}^{-1}f$ belongs to $M\mathbb{H}^{\gamma+4,q}_{p,\theta}$ (for any γ) and satisfies

$$Lv = -M^{-1}\mathcal{L}^{-1}f.$$

We apply $\mathcal{L}$ to both parts of this equality and, for $u := \mathcal{L}v \in M\mathbb{H}^{\gamma+2,q}_{p,\theta}$, get that

$$Lu = -M^{-1}f + \bar{f},$$

where

$$\bar{f} = 2a^{1j}D_jM^{-1}\mathcal{L}_1v + 2a^{1j}M^{-1}\mathcal{L}_1D_jv + 2D_1\mathcal{L}^{-1}f.$$

Since $u \in M\mathbb{H}^{\gamma+2,q}_{p,\theta}$, it follows that

$$\mathcal{L}\tilde{R}M^{-1}\mathcal{L}^{-1}f =: u = \tilde{R}M^{-1}f - \tilde{R}\bar{f},$$

which is exactly (4.5). Hence, $\bar{R}M^{-1}$ is indeed an extension of $\tilde{R}M^{-1}$.

Thus, (4.4) means that

$$||M^{-1}\tilde{R}M^{-1}f||_{\mathbb{H}^{\gamma+1,q}_{p,\theta}} \le N||f||_{\mathbb{H}^{\gamma-1,q}_{p,\theta}}.$$

We conclude that the assumption that $M^{-1}\tilde{R}M^{-1}$ is a bounded operator from $\mathbb{H}^{\gamma,q}_{p,\theta}$ to $\mathbb{H}^{\gamma+2,q}_{p,\theta}$ for any $\gamma \ge -n$ leads to the conclusion that $M^{-1}\tilde{R}M^{-1}$ is a bounded operator from $\mathbb{H}^{\gamma,q}_{p,\theta}$ to $\mathbb{H}^{\gamma+2,q}_{p,\theta}$ for any $\gamma \ge -(n+1)$.

It follows by induction that the operator A is a bounded operator in $L_q(\mathsf{R}, H^{\gamma}_{p,\theta})$ for any $\gamma \in \mathsf{R}$ if $q \ge p > 1$. After that, repeating literally the corresponding argument from section 3 brings the proof of Theorem 3.1 to an end.

5. A general theorem on equations with coefficients depending only on time. Here we prove a version of Theorem 2.2 of [3]. Let H be a separable Hilbert space. Let $\mathcal{U}$ be a set of couples of H-valued functions $u = (u_1, u_2)$ of $(s,t,x) \in (\mathsf{R}^2 \cap \{s \le t\}) \times \mathsf{R}^d_+$ and $\mathcal{F}$ be a set of couples of H-valued functions $f = (f_1, f_2)$ of (t,x) defined on $\mathsf{R} \times \mathsf{R}^d_+$. We consider couples of functions in order to be able to treat the Cauchy problem and inhomogeneous equations at the same time. Assume that on $\mathcal{U}$ and $\mathcal{F}$ we are given some finite real-valued functions $||\cdot||_{\mathcal{U}}, ||\cdot||_{\mathcal{F}}$ interpreted as "norms."

Assumption 5.1. (i) The "norms" on $\mathcal{U}$ and $\mathcal{F}$ are tangentially translation invariant: for any continuous R^d-valued function $b(t)$ with $b^1(t) \equiv 0$ defined on R and $u \in \mathcal{U}$ and $f \in \mathcal{F}$, we have $u^b \in \mathcal{U}$, $f^b \in \mathcal{F}$, and

$$||u^b||_{\mathcal{U}} = ||u||_{\mathcal{U}}, \quad ||f^b||_{\mathcal{F}} = ||f||_{\mathcal{F}},$$

where $u^b(s,t,x) = u(s,t,x+b(t))$ and $f^b(t,x) = f(t,x+b(t))$.

Assumption 5.2. The set $\mathcal{F}$ contains $\mathcal{A} = \mathcal{A}_1 \times \mathcal{A}_2$, where $\mathcal{A}_i$ are some tangentially translation invariant sets of functions $g(t,x)$ with compact support $\subset \mathsf{R} \times \mathsf{R}^d_+$ which are continuous in (t,x) together with each their derivative in x.

Assumption 5.3. The set $\mathcal{U}$ contains the set $\mathcal{B} = \mathcal{B}_1 \times \mathcal{B}_2$, where $\mathcal{B}_i$ are some tangentially translation invariant sets of functions $v(s,t,x)$ which are bounded and continuous in (s,t,x) together with each their derivative with respect to x.

Assumption 5.4. If (Ω, Σ, P) is a probability space and (i) $u(\omega,s,t,x)$ is a bounded function such that $u(\omega,\cdot,\cdot,\cdot) \in \mathcal{B}$ for any $\omega \in \Omega$, (ii) $u(\omega,s,t,x)$ is measurable in ω for any (s,t,x), and (iii) $\mathsf{E}\,||u||_{\mathcal{U}} < \infty$, then $\mathsf{E}\,u \in \mathcal{U}$ and $||\mathsf{E}\,u||_{\mathcal{U}} \le \mathsf{E}\,||u||_{\mathcal{U}}$.

Remember that $\tilde{T}_t$ is the semigroup associated with operator Δ with zero boundary condition on $x^1 = 0$ and $\tilde{T}_{s,t}$ is the operator such that, for $f \in C_0^\infty(\mathsf{R}^d_+)$, $\tilde{T}_{s,t}f$ is the solution of the equation $u_t(t,x) = a^{ij}(t)u_{x^ix^j}(t,x)$ for $t > s$ and $x \in \mathsf{R}^d_+$ satisfying $u(s,x) = f(x)$ with zero boundary condition on $x^1 = 0$.

THEOREM 5.1. *Under the above assumptions define the following operators on* $\mathcal{A}$*:*

$$\begin{aligned} R_0 : f = (f_1, f_2) &\to R_0(f_1, f_2)(s,t,x) \\ &= \left(\tilde{T}_{t-s}f_1(s,\cdot)(x), \int_s^t \tilde{T}_{t-r}f_2(r,\cdot)(x)\,dr\right), \\ R : f = (f_1, f_2) &\to R(f_1, f_2)(s,t,x) \\ &= \left(\tilde{T}_{s,t}f_1(s,\cdot)(x), \int_s^t \tilde{T}_{r,t}f_2(r,\cdot)(x)\,dr\right), \end{aligned}$$

and assume that for any $f \in \mathcal{A}$ *we have* $R_0 f \in \mathcal{B}$ *and*

$$||R_0 f||_{\mathcal{U}} \le N_0||f||_{\mathcal{F}},$$

where N_0 is a finite constant. Let $a(t) := (a^{ij}(t)) \geq (\delta^{ij})$ for any t, $a^{1j} \equiv 0$ for $j \geq 2$, and $a^{11} \equiv 1$. Then, for any $f \in \mathcal{A}$, we have $Rf \in \mathcal{U}$ and

$$||Rf||_{\mathcal{U}} \leq N_0 ||f||_{\mathcal{F}}.$$

Proof. Take a probability space (Ω, Σ, P) carrying a d-dimensional Wiener process w_t defined for all $t \in \mathsf{R}$. On R define the following random process:

$$b(t) = \int_0^t \sqrt{a(r) - 1}\, dw_r.$$

Observe that $b^1(t) = 0$ since $a^{11} = 1$ and $a^{1j} = 0$ if $j \geq 2$. Also take a d-dimensional Wiener process B_t independent of w_t. It is well known that for any $s < t$ the random vectors $\eta_{s,t} := b(t) - b(s) + B_t - B_s$ and

$$\zeta_{s,t} := \left(B_t^1 - B_s^1, \int_s^t \left(\sqrt{a(r)}\right)^{2j}\, dw_r^j, \dots, \int_s^t \left(\sqrt{a(r)}\right)^{dj}\, dw_r^j \right)$$

have the same Gaussian distribution and that, for bounded nonrandom functions h and $x^1 > 0$, we have

$$\tilde{T}_{t-s} h(s,\cdot)(x) = \mathsf{E}\, h(s, x + B_t - B_s) I_{\tau(s,x)>t},$$
$$\tilde{T}_{s,t} h(s,\cdot)(x) = \mathsf{E}\, h(s, x + \zeta_{s,t}) I_{\tau(s,x)>t},$$

where

$$\tau(s,x) = \inf\{t : t \geq s, x^1 + B_t^1 - B_s^1 \leq 0\}.$$

Next, for $f \in \mathcal{A}$ we have

$$\begin{aligned} ||\mathsf{E}\left([R_0(f^{-b})]^b\right)||_{\mathcal{U}} &\leq \mathsf{E}||\, [R_0(f^{-b})]^b||_{\mathcal{U}} = \mathsf{E}\, ||R_0(f^{-b})||_{\mathcal{U}} \\ &\leq N_0 \mathsf{E}\, ||f^{-b}||_{\mathcal{F}} = N_0 \mathsf{E}\, ||f||_{\mathcal{F}} = M||f||_{\mathcal{F}}. \end{aligned}$$

It remains only to check that

$$\mathsf{E}\left([R_0(f^{-b})]^b\right) = Rf. \tag{5.1}$$

However, for any bounded Borel h,

$$\begin{aligned} \mathsf{E}\left([\tilde{T}_{t-s}(h^{-b})(s,\cdot)(x)]^b\right) &= \mathsf{E}\, \tilde{T}_{t-s}(h^{-b})(s,\cdot)(x + b(t)) \\ &= \mathsf{E}\, h(s, x + b(t) - b(s) + B_t - B_s) I_{\tau(s,x)>t} \\ &= \mathsf{E}\, h(s, x + \eta_{s,t}) I_{\tau(s,x)>t} = \mathsf{E}\, h(s, x + \zeta_{s,t}) I_{\tau(s,x)>t}, \end{aligned}$$

and the last expression coincides with $\tilde{T}_{s,t} h(s,\cdot)(x)$. This certainly proves (5.1) and with it the theorem. □

Acknowledgments. The author is sincerely grateful to W. Littman for discussing certain issues related to this article and to the referee and I. Gyöngy for several useful comments.

SEQUENTIAL BUCKLING: A VARIATIONAL ANALYSIS*

MARK A. PELETIER†

Abstract. We examine a variational problem from elastic stability theory: a thin elastic strut on an elastic foundation. The strut has infinite length, and its lateral deflection is represented by $u : \mathbb{R} \to \mathbb{R}$. Deformation takes place under conditions of prescribed total shortening, leading to the variational problem

$$\inf \left\{ \frac{1}{2} \int u''^2 + \int F(u) : \frac{1}{2} \int u'^2 = \lambda \right\}. \tag{0.1}$$

Solutions of this minimization problem solve the Euler–Lagrange equation

$$u'''' + pu'' + F'(u) = 0, \qquad -\infty < x < \infty. \tag{0.2}$$

The foundation has a nonlinear stress-strain relationship F', combining a *destiffening* character for small deformation with subsequent *stiffening* for large deformation. We prove that for every value of the shortening $\lambda > 0$ the minimization problem has at least one solution. In the limit $\lambda \to \infty$ these solutions converge on bounded intervals to a periodic profile that is characterized by a related variational problem.

We also examine the relationship with a bifurcation branch of solutions of (0.2), and show numerically that all minimizers of (0.1) lie on this branch This information provides an interesting insight into the structure of the solution set of (0.1).

1. Introduction.

1.1. Localized buckling. Long elastic structures that are loaded in the longitudinal direction can buckle in a localized manner. By this we mean that the lateral deflection is concentrated on a small section of the total length of the structure. A well-known example of this localization phenomenon is the axially loaded cylinder, which buckles in a localized diamond-like pattern [28, 14, 8]. Another example, one which will be the subject of this paper, is the strut on a foundation: a thin elastic layer confined laterally by a different elastic material.

One area of application in which the model of a strut on a foundation has received extensive attention is that of structural geology. In this context the strut represents a thin layer of rock that is embedded in a different type of rock, and the longitudinal compression is the result, directly or indirectly, of tectonic plate movement. In the geological context the most common constitutive assumptions are those of viscous, or visco-elastic, materials; however, there is a case to be made for the importance of elastic effects in the deformation process [21, p. 302], and this is the situation we consider here. An introduction to this field can be found in [21, Chapters 10–15].

Observed geological folds commonly display a certain degree of periodicity. Much of the initial work in this area, initiated by Biot in the late 1950's [1], centered on using the observed period to determine—by doing a parameter fit on the strut model—some of the material properties involved. In the 1970s, with the coming of powerful computational techniques, a consensus arose that folds can be formed in a sequential manner, as depicted by Figure 1.1 [5, 6]. The fold initiates around an imperfection, and as the applied shortening increases, the initial folds lock up and cease to grow, while new folds spawn at neighboring locations. At a given time the resulting profile shows a periodic section flanked by decaying tails; as the shortening increases the periodic section widens. Similar examples of localization followed by spreading are found in axially loaded cylinders [14, 8], in sandwich structures [9], and in kink banding in layered materials [10]. The survey paper [9] discusses these examples from a common perspective.

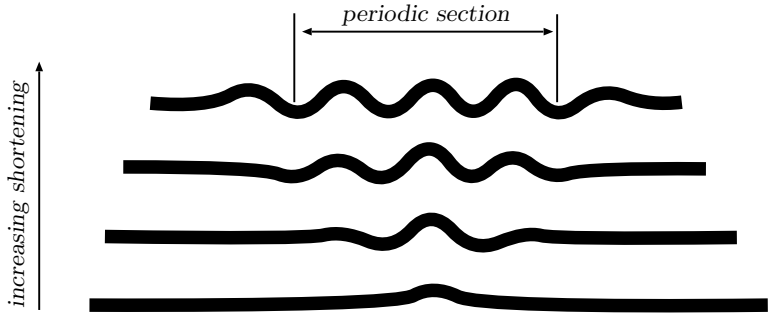

FIG. 1.1. *Folds can form in a sequential manner, driven by increasing shortening (schematic).*

1.2. The modelling. In this paper we investigate the issues of localization and subsequent spreading of deformation for a model of an elastic strut confined by an elastic foundation. We will make a number of important simplifications, and therefore we now discuss the derivation of the equations in some detail.

Our starting point is a thin Euler strut (a strut whose cross-sections remain planar and orthogonal to the center line) of infinite length. Throughout the paper we assume a two-dimensional setting. The independent variable x measures arc length, and we characterize the configuration of the strut by the center-line angle $\theta = \theta(x)$. The strain energy associated with the bending of the strut is equal to $(EI/2)\int \theta'^2(x)dx$. E is Young's modulus and I is the moment of inertia of the cross-section.

The strut is assumed to rest on a foundation of Winkler type, as shown in Figure 1.2. The force response q of this foundation is a function of the local vertical displacement $u(x)$ only, i.e., $q(x) = f(u(x))$. Because of the local character of this response, the strain energy associated with the foundation is equal to $\int F(u(x))dx$, where $F' = f$, $F(0) = 0$. The vertical displacement u and the angle θ are related by $u'(x) = \sin\theta(x)$.

After nondimensionalization the total strain energy for the strut and its foundation is therefore given by

$$\mathcal{W}(\theta) = \frac{1}{2}\int_{-\infty}^{\infty} \theta'^2(x)\,dx + \int_{-\infty}^{\infty} F(u(x))\,dx,$$

where it is understood that $u' = \sin\theta$, $u(-\infty) = 0$. We also define the shortening

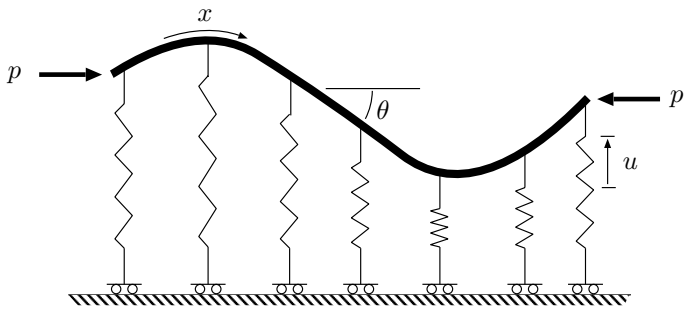

FIG. 1.2. *A strut on an elastic Winkler foundation.*

of the strut, the amount the end-points approach each other because of the deformation $\theta(\cdot)$:

$$\mathcal{J}(\theta) := \int_{-\infty}^{\infty} (1 - \cos\theta(x))\, dx.$$

In engineering it is common to differentiate between dead and rigid loading. In dead loading the external force acting on the structure (in Figure 1.2 the in-plane load p) is prescribed ("controlled" is the usual word, reflecting the possibility of a varying load). In rigid loading a load is applied, but the controlled parameter is the displacement (or some other measure of the deformation). Here the load plays the role of an implied quantity. The two forms of loading share the same equilibria, but the stability properties of these equilibria depend on the form of loading: as a general rule, localized buckles are unstable under dead loading, and stable under rigid loading. (An example of dead loading from daily life is a human being standing on a beer can. As soon as the buckle appears the can collapses completely, showing the instability of the localized buckle under dead loading. However, under rigid loading conditions a variety of localized buckles are witnessed [28]).

With this in mind, we minimize the strain energy $\mathcal{W}$ under a prescribed value λ of the total shortening, i.e., under the condition $\mathcal{J} = \lambda$. While this is a well-posed problem, and one that we intend to return to in subsequent publications, the nonlinearities present render the analysis difficult. We therefore consider a partial linearization of this problem instead, by assuming that u' is small and replacing

$$\theta' = \frac{u''}{\sqrt{1 - u'^2}} \qquad \text{by} \qquad u'' \tag{1.1}$$

and

$$1 - \cos\theta = 1 - \sqrt{1 - u'^2} \qquad \text{by} \qquad \frac{1}{2}u'^2. \tag{1.2}$$

(Note that in doing so we eliminate nonlinearities of a geometrical nature, but retain the nonlinearity in the function F, which is more of a material kind. We discuss this issue further in section 7.) The resulting problem, the central problem in this paper, is

Find a function $u \in H^2(\mathbb{R})$ that solves the minimization problem

$$\inf\{W(u) : J(u) = \lambda\}, \tag{1.3a}$$

where the strain energy W and total shortening J are given by

$$W(u) = \frac{1}{2}\int u'^2 + \int F(u) \qquad \text{and} \qquad J(u) = \frac{1}{2}\int u'^2. \tag{1.3b}$$

A solution u satisfies the Euler–Lagrange equation

$$W'(u) - pJ'(u) = 0, \tag{1.4}$$

for some $p \in \mathbb{R}$, where primes denote Fréchet derivatives, which is equivalent to

$$u'''' + pu'' + f(u) = 0 \qquad \text{on } \mathbb{R}. \tag{1.5}$$

The Lagrange multiplier p is physically interpreted as the in-plane load that is required to enforce the prescribed amount of shortening. Without this load, i.e., when minimizing W without constraint, the sole minimizer would be the trivial state $u \equiv 0$.

Equation (1.5), for various forms of the nonlinearity f, has a history too lengthy to discuss in detail here. Suffice it to mention that it is known, among other names, as the stationary Swift–Hohenberg equation or the stationary extended Fisher–Kolmogorov equation, and that it appears in a host of different applications. We refer the interested reader to the survey articles [2, 3, 18].

1.3. The nonlinearity *F*. The results of this paper depend in a very sensitive manner on the properties of F. In order to describe this we introduce some terminology. Recall that F itself is the potential energy associated with the foundation springs, $F'(u) = f(u)$ is the force associated with a deflection u, and F'' is the *marginal stiffness*.

In the engineering literature *destiffening* refers to a decrease in marginal stiffness, or in everyday language, a weakening of the material. For this model, destiffening refers to a decrease of $F''(u)$ as u moves away from zero (in either positive or negative direction).

The opposite of destiffening is stiffening, which applies to an increase in marginal stiffness as $|u|$ moves away from zero. Although we briefly dwell on such functions in the next section, a more interesting property is what we call *de/restiffening*, or *restiffening* for short: $F''(u)$ decreases for small $|u|$ and becomes increasing for large $|u|$. Throughout this paper we assume a fixed function of restiffening type:

$$F(u) = \frac{1}{2}u^2 - \frac{1}{4}u^4 + \frac{\alpha}{6}u^6, \qquad \alpha \geq \frac{1}{4}. \tag{1.6}$$

Besides the restiffening property this function also has some other desirable qualities, such as

- F is even;
- $F(u) > 0$ if $u \neq 0$;
- $uF'(u) \geq 0$.

We will return to these issues in section 7, where we discuss in some detail the relationship between the results and the function F.

1.4. Results. In this paper we bring together a number of results concerning the minimization problem (1.3), (1.6).

The existence of solutions of the minimization problem (1.3) is not immediate, since the domain is unbounded and therefore minimizing sequences need not be compact. The nonlinearity F is crucial to this issue. To illustrate this, we mention that in the next section we show that a stiffening function F leads to nonexistence:

if $2F(u)/u^2 > F''(0)$ for all $u \neq 0$, then minimizing sequences are never compact, and the infimum is not achieved.

In the parlance of the beginning of this paper, minimizing sequences *delocalize* and spread out. In section 2 we show how the restiffening property of (1.6) guarantees the existence of a minimizer.

The role of λ in problem (1.3) is that of a pure parameter: properties of problem (1.3) for one value of λ are completely decoupled from those for a different value. In addition, minimizers need not be unique. If we choose a minimizer for each value of λ, and denote it by u_λ, then these observations imply that the map $\lambda \mapsto u_\lambda$ may have no continuity properties whatsoever.

In fact, however, the situation is different. The numerical results in section 5 indicate that there is a strong evolutionary aspect, in that the map $\lambda \mapsto u_\lambda$ is "mostly" continuous. In addition, we prove in section 3 that the evolution suggested by Figure 1.1 is essentially correct:

THEOREM. *For any sequence $\lambda_n \to \infty$, a subsequence $u_{\lambda_{n'}}$ converges, after an appropriate translation, to a periodic function $u_\#$. This convergence is uniform on bounded sets.*

The periodic function $u_\#$ solves a related variational problem (see section 3). In section 4 we discuss some symmetry properties of this function.

In section 5 we introduce a numerical method to search for minimizers of (1.3), based on a constrained gradient flow. Figure 1.3 shows some of the results of this calculation. While the form of this curve is unusual at first sight, in section 6 we present an interpretation of this curve in terms of a bifurcation diagram of a related problem ((1.5) for prescribed p). This interpretation, while nonrigorous, gives a satisfactory explanation and raises a few interesting questions as well. We conclude, in section 7, with some comments on the choice of the nonlinearity F.

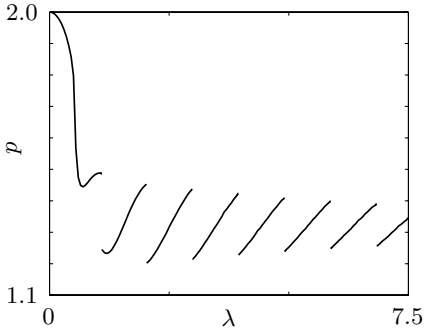

FIG. 1.3. *Plot of the load p_λ associated with a minimizer against λ.*

2. Existence of minimizers. The existence of minimizers of problem (1.3) is a nontrivial problem because of the potential lack of compactness on the unbounded domain $\mathbb{R}$. To illustrate this we consider the case of a completely stiffening function F, one for which $F''(u) > F''(0)$ if $u \neq 0$, or slightly more generally, one for which $2F(u)/u^2 > F''(0)$ if $u \neq 0$. We then have for any $u \in H^2(\mathbb{R})$,

$$W(u) = \frac{1}{2}\int u''^2 + \int F(u) > \frac{1}{2}\int u''^2 + \frac{1}{2}\int u^2 \geq 2J(u), \tag{2.1}$$

where the final inequality follows from the observation that

$$\int u'^2 = -\int u''u \le \frac{1}{2}\int u''^2 + \frac{1}{2}\int u^2.$$

We infer that for any $\lambda > 0$, we have $\inf\{W(u) : J(u) = \lambda\} \ge 2\lambda$, and for any given u this inequality is strict: $W(u) > 2J(u)$.

We now construct an explicit minimizing sequence u_n of problem (1.3) for this potential F. Set

$$u_n(x) = a_n e^{-x^2/n} \sin x, \qquad x \in \mathbb{R}, \tag{2.2}$$

where $a_n \in \mathbb{R}$ is chosen so that $J(u_n) = \lambda$. Note that $a_n \to 0$ as $n \to \infty$. An explicit calculation shows that $W(u_n) \to 2\lambda$; therefore, with the remarks made above in mind, we conclude that $\inf\{W(u) : J(u) = \lambda\} = 2\lambda$ and that the infimum is not attained.

Contained in the argument above is a snippet of information that we will use several times in the proofs that follow. For easy reference we make it a lemma.

LEMMA 2.1. *Let $I \subset \mathbb{R}$ be an interval, bounded or otherwise, and let $u \in H^2(I)$ be such that $uu' = 0$ on ∂I. Then*

$$2\int_I u'^2 \le \int_I u''^2 + \int_I u^2.$$

As above, the proof follows by partial integration.

The theorem below shows that, in contrast to the example above, the infimum is attained if F is not of completely stiffening type, but has a destiffening character for small u (i.e., $F''(u) < F''(0)$ for small $u \ne 0$). We can interpret the situation in the following way. A destiffening quality ($F'' < F''(0)$) favors localized deformation, therefore causing minimizing sequences to be compact, resulting in the existence of minimizers on unbounded domains. A stiffening potential favors delocalization, spreading, of the deformation, as illustrated by the minimizing sequence (2.2). If the two characters are combined, as in the potential (1.6), then the destiffening character for small u is sufficient to guarantee the existence of minimizers, regardless of the behavior for large u. On the other hand, the restiffening character in F becomes noticeable for larger values of λ, in which an equilibrium between localizing and spreading effects creates a periodic structure. We will return to this issue in the next section.

Note that on a bounded interval, given appropriate boundary conditions, a minimizer always exists. One might wonder whether the problem would not be simplified by working on a bounded interval instead of on $\mathbb{R}$. In fact, we expect a strong correspondence between the (non-)existence of minimizers on $\mathbb{R}$ and the form of the minimizers on large but bounded intervals: if existence holds on $\mathbb{R}$, then minimizers on intervals will be localized and largely independent of the size of the interval; but if there is nonexistence on $\mathbb{R}$, then minimizers on the interval will be spread out, with a small amplitude, similar to the sequence u_n above. (See [7] for a discussion of the purely stiffening nonlinearity on a bounded interval). From the point of view of the developments later in this paper, the current problem, with a restiffening foundation, is fundamentally different from the purely stiffening case. In addition, we will use the unbounded domain in the convergence result of Theorem 3.1 and in the comparison with a bifurcation diagram on $\mathbb{R}$ in section 6. With this in mind we choose to consider the problem on the unbounded domain $\mathbb{R}$.

Throughout this paper we define

$$W_\lambda = \inf_{u\in C_\lambda} W(u), \qquad C_\lambda = \{u \in H^2(\mathbb{R}) : J(u) = \lambda\}.$$

THEOREM 2.2. *Let F be as given in* (1.6). *Then for each $\lambda > 0$ there exists $u \in C_\lambda$ that minimizes* (1.3).

Before we prove this theorem we derive some auxiliary properties.

LEMMA 2.3. *For all $\lambda > 0$,*

1. *$W_\lambda < 2\lambda$.*
2. *If $u_n \in \mathcal{C}_\lambda$ is a minimizing sequence of W, then*

$$\limsup_{n\to\infty} \|u_n\|_{L^\infty(\mathbb{R})} \le M\lambda$$

for some constant M.

Proof. Define the explicit sequence

$$u_\varepsilon(x) = a_\varepsilon \varepsilon^{1/2} \operatorname{sech}(\varepsilon x)\cos x,$$

where a_ε is chosen such that $J(u_\varepsilon) = \lambda$ (note that $a_\varepsilon = O(1)$ as $\varepsilon \to 0$). This sequence satisfies $W(u_\varepsilon) \to 2\lambda$, implying $W_\lambda \le 2\lambda$. For the strict inequality we compute

$$\begin{aligned}\lambda &= \frac{1}{2}\int u_\varepsilon'(x)^2\,dx \\ &= \frac{1}{2}a_\varepsilon^2\left\{\varepsilon\int \operatorname{sech}^2(\varepsilon x)\sin^2 x\,dx - 2\varepsilon^2\int \operatorname{sech}(\varepsilon x)\operatorname{sech}'(\varepsilon x)\cos x\sin x\,dx\right. \\ &\qquad \left. + \varepsilon^3\int (\operatorname{sech}'(\varepsilon x))^2\cos^2 x\,dx\right\}. \end{aligned} \tag{2.3}$$

Note that

$$\begin{aligned}\int \operatorname{sech}(\varepsilon x)\operatorname{sech}'(\varepsilon x)\cos x\sin x\,dx& \\ &= \frac{1}{4\varepsilon}\int (\operatorname{sech}^2(\varepsilon x))'\sin 2x\,dx = \frac{1}{2\varepsilon}\int \operatorname{sech}^2(\varepsilon x)\cos 2x\,dx \\ &= \frac{1}{\varepsilon^2}\sqrt{\frac{\pi}{2}}\,\widehat{(\operatorname{sech}^2)}\left(\frac{2}{\varepsilon}\right),\end{aligned}$$

where $\hat{}$ denotes the Fourier transform

$$\hat v(\omega) = \frac{1}{\sqrt{2\pi}}\int_{\mathbb{R}} v(x)e^{-i\omega x}dx.$$

Since $\operatorname{sech}^2 \in \mathcal{S}$, the set of smooth rapidly decreasing functions, we have $\widehat{(\operatorname{sech}^2)} \in \mathcal{S}$, and therefore

$$\int \operatorname{sech}(\varepsilon x)\operatorname{sech}'(\varepsilon x)\cos x\sin x\,dx = o(\varepsilon^k) \qquad \text{for all } k \in \mathbb{N}.$$

Using the same ideas to estimate the first and third terms in (2.3) we find

$$\begin{aligned}\int \operatorname{sech}^2(\varepsilon x)\sin^2 x\,dx &= \frac{1}{2}\int \operatorname{sech}^2(\varepsilon x)\,dx + o(\varepsilon^k), \\ \int (\operatorname{sech}'(\varepsilon x))^2\cos^2 x\,dx &= \frac{1}{2}\int (\operatorname{sech}'(\varepsilon x))^2\,dx + o(\varepsilon^k)\end{aligned}$$

for all $k \in \mathbb{N}$. Consequently (2.3) implies

$$a_\varepsilon^2 = 4\lambda(1 + O(\varepsilon^2)) \left(\int_{\mathbb{R}} \operatorname{sech}^2(y)\, dy \right)^{-1}.$$

Using this we compute

$$\frac{1}{2} \int u_\varepsilon^2 = \lambda(1 + O(\varepsilon^2)), \tag{2.4}$$

$$\int u_\varepsilon^4 = c_1 \varepsilon (1 + O(\varepsilon^2)), \tag{2.5}$$

$$\int u_\varepsilon^6 = c_2 \varepsilon^2 (1 + O(\varepsilon^2)), \tag{2.6}$$

$$\frac{1}{2} \int u_\varepsilon''^2 = \lambda(1 + O(\varepsilon^2)) \tag{2.7}$$

for some constants $c_1, c_2 > 0$. For the last equality above we apply the same argument as for $\int u_\varepsilon'^2$ to eliminate the cross-product terms. Uniting these estimates we conclude that

$$W(u_\varepsilon) = \lambda(2 + O(\varepsilon^2)) - c_1 \varepsilon,$$

and hence

$$\inf_{\mathcal{C}_\lambda} W(u) < 2\lambda.$$

For part 2 we first note that since $\alpha > 3/16$, there exists $\beta > 0$ such that

$$F(u) \geq \frac{\beta}{2} u^2 \qquad \text{for} \qquad u \in \mathbb{R}. \tag{2.8}$$

By part 1 we can restrict our attention to minimizing sequences that satisfy $W(u_n) \leq 2\lambda$; we have

$$\|u_n\|_{L^\infty(\mathbb{R})}^2 \leq C \|u_n\|_{H^1(\mathbb{R})}^2 \leq 2C \max\{1, 1/\beta\}\, W(u_n) \leq 4C\lambda \max\{1, 1/\beta\}. \qquad \square$$

Remark 2.1. The proof of part 1 of the lemma above uses the relative importance of the destiffening quartic term: the destiffening is of order ϵ, while the "noise" associated with the nonconstant amplitude in u_n is of order ϵ^2 (as shown by the estimates (2.4) and (2.7)). It follows that for a destiffening character of higher order, e.g., a function F of the type $u^2/2 - u^8/8 + \alpha u^{10}/10$, this method of proof does not apply, since the destiffening will be dwarfed by the noise. However, numerical tests have shown that for such functions F the minimization problem still admits solutions, and that the assertion of the lemma still holds.

COROLLARY 2.4. *Let u_n be a minimizing sequence for problem* (1.3). *Then*

$$\liminf_{n\to\infty} \|u_n\|_{L^\infty(\mathbb{R})} = m(\lambda) > 0.$$

Proof. If $\|u_n\|_{L^\infty(\mathbb{R})} \to 0$, then

$$\frac{\frac{1}{2}\int u_n''^2 + \frac{1}{2}\int u_n^2}{W(u_n)} \to 1 \qquad \text{as} \quad n \to \infty. \tag{2.9}$$

Since

$$2\lambda = \int {u_n'}^2 = -\int u_n'' u_n \leq \frac{1}{2}\int u_n''^2 + \frac{1}{2}\int u_n^2,$$

we infer from (2.9) that $\liminf W(u_n) \geq 2\lambda$, which contradicts part 1 of Lemma 2.3. □

In addition, we need an a priori result on minimizers, which is proved in the appendix, as shown below.

LEMMA 2.5. *Let $u \in H^2(\mathbb{R})$ be a solution of (1.3). Then $p < 2$.*

We now continue with the proof of the main theorem of this section.

Proof of Theorem 2.2. The proof follows quite closely the outline of the examples given in [12, 13]. Let u_n be a minimizing sequence, and consider $\rho_n = {u_n'}^2/2$, so that $\rho_n \geq 0$ and $\int \rho_n = 1$. Of the three possibilities for this sequence, vanishing, dichotomy, and compactness, we show that neither vanishing nor dichotomy can occur, leaving compactness as the only possibility.

Vanishing cannot occur. Suppose that

$$\sup_x \int_{x-R}^{x+R} {u_n'}^2 \to 0 \qquad \text{for all} \qquad R > 0.$$

We can choose $x = 0$ as the location of a maximum of each $|u_n|$, and by Corollary 2.4 we then have $u_n(0) \geq m(\lambda) > 0$ (changing u_n into $-u_n$ if necessary). Consequently

$$\liminf_{n\to\infty} \int_{\mathbb{R}} F(u_n) \geq \liminf_{n\to\infty} \frac{\beta}{2}\int_{-R}^{R} u_n^2 \geq \beta m(\lambda)^2 R,$$

which is unbounded as $R \to \infty$. This contradicts $\limsup W(u_n) < 2\lambda$.

Dichotomy cannot occur. For any given $\lambda > 0$, dichotomy is contradicted, proving compactness of the minimizing sequence and therefore existence of a minimizer, if

$$W_\lambda < W_{\theta\lambda} + W_{(1-\theta)\lambda} \tag{2.10}$$

for all $\theta \in (0,1)$ (see [12, 13]). We shall show that (2.10) holds for all $\lambda > 0$ and $\theta \in (0,1)$.

Define

$$A = \{\mu > 0 : (1.3) \text{ has a solution for all } 0 < \lambda \leq \mu\}.$$

First we show that A is nonempty. There exist $\bar{u}, \delta > 0$ such that $2F(u) - uf(u) \geq \delta u^4$ for all $|u| \leq \bar{u}$. Choose λ_0 small enough to ensure that $2M\lambda \leq \bar{u}$ for all $0 < \lambda < \lambda_0$, and pick $0 < \lambda < \lambda_0$. Let v_n be a minimizing sequence such that $J(v_n) = \lambda$; without loss of generality we suppose that $\|v_n\|_{L^\infty(\mathbb{R})} \leq \bar{u}$. Then

$$\begin{aligned}
\frac{d}{d\mu}\frac{W(\mu v_n)}{J(\mu v_n)}\bigg|_{\mu=1} &= \frac{1}{J(v_n)^2}\left(J(v_n)W'(v_n)v_n - W(v_n)J'(v_n)v_n\right) \\
&= \frac{1}{J(v_n)}\left(\int v_n f(v_n) - 2\int F(v_n)\right) \\
&\leq -\frac{\delta}{\lambda}\int v_n^4. \qquad (2.11)
\end{aligned}$$

Since $\|v_n'\|^2_{L^2(\mathbb{R})} = 2\lambda$ is bounded and $\|v_n\|_{L^\infty(\mathbb{R})} > m(\lambda)$, the last term above is bounded away from zero as $n \to \infty$. Therefore W_λ/λ is a strictly decreasing function of λ for $0 < \lambda < \lambda_0$; this shows that $(0, \lambda_0) \subset A$, since we have for any $\theta \in (0,1)$

$$\begin{aligned} W_\lambda = \lambda \frac{W_\lambda}{\lambda} &< \lambda \left(\theta \frac{W_{\theta\lambda}}{\theta\lambda} + (1-\theta) \frac{W_{(1-\theta)\lambda}}{(1-\theta)\lambda} \right) \\ &= W_{\theta\lambda} + W_{(1-\theta)\lambda}. \end{aligned}$$

To show that A is open, suppose that there exists a sequence $\lambda_n + \varepsilon_n \notin A$, $\lambda_n + \varepsilon_n \downarrow \lambda$, $\lambda \in A$, and $\varepsilon_n \to 0$, such that

$$W_{\lambda_n + \varepsilon_n} = W_{\lambda_n} + W_{\varepsilon_n}.$$

Since $\liminf W_{\varepsilon_n}/\varepsilon_n = 2$—by an argument similar to that of Corollary 2.4—this implies

$$\limsup_{\varepsilon \to 0} \frac{1}{\varepsilon} (W_{\lambda+\varepsilon} - W_\lambda) \geq 2. \tag{2.12}$$

However, since $\lambda \in A$, there exists $u \in \mathcal{C}_\lambda$ with $W(u) = W_\lambda$, and by Lemma 2.5 the associated load satisfies $p < 2$. Then

$$\frac{d}{d_\mu} W(\mu u)\bigg|_{\mu=1} = W'(u)u = pJ'(u)u = p \, \frac{d}{d_\mu} J(\mu u)\bigg|_{\mu=1}.$$

Consequently

$$\limsup_{\varepsilon \to 0} \frac{1}{\varepsilon} (W_{\lambda+\varepsilon} - W_\lambda) \leq p < 2,$$

contradicting (2.12).

Finally, we show that A is closed by the following claim: If u and v are minimizers of W at the respective values of λ, then

$$\inf\{W(z) : J(z) = J(u) + J(v)\} < W(u) + W(v). \tag{2.13}$$

This proves that A is closed by the following argument. Suppose $A \supset (0, \lambda_0)$; for all $\theta \in (0,1)$ we have functions u and v that minimize W under the constraints $J(u) = \theta\lambda_0$ and $J(v) = (1-\theta)\lambda_0$. Inequality (2.13) then reduces to (2.10), implying that problem (1.3) also has a solution for $\lambda = \lambda_0$.

To prove (2.13) we choose two sequences $x_n \geq 0$, $y_n \leq 0$, with $x_n \to \infty$ and $y_n \to -\infty$ with certain properties detailed below. We introduce a notation for integrals over a part of $\mathbb{R}$:

$$W_{[a,b]}(u) = \frac{1}{2} \int_a^b u''^2 + \int_a^b F(u) \qquad \text{and} \qquad J_{[a,b]}(u) = \frac{1}{2} \int_a^b u'^2.$$

Setting $p = \max\{p_u, p_v\}$ (the maximum of the two values of the load associated with u and v) we require of the sequences x_n, y_n that there exists an $\varepsilon > 0$ such that

$$p \leq \min \left\{ \frac{W_{[x_n,\infty)}(u)}{J_{[x_n,\infty)}(u)}, \frac{W_{(-\infty,y_n]}(v)}{J_{(-\infty,y_n]}(v)} \right\} - \varepsilon \qquad \text{for all } n.$$

This is possible since u and v are small at infinity, and therefore

$$\limsup W_{[x_n,\infty)}(u)/J_{[x_n,\infty)}(u) \geq 2.$$

In addition we assume that $(u,u')(x_n) = (v,v')(y_n)$ for all n. This is also possible since for large K the set $\{(u,u')(x) : x > K\} \subset \mathbb{R}^2$ is a spiral around the origin. The same is true for $\{(v,v')(x) : x < -K\}$ but for v the spiral rotates in the opposite direction. It follows that there is a countably infinite set of intersections of the two spirals, corresponding to pairs (x_n, y_n) with $x_n \to \infty$, $y_n \to -\infty$.

Now pick $\hat{u}, \hat{v} \in H^2(\mathbb{R})$ such that $\operatorname{supp}\hat{u} \subset (-\infty, 0)$ and $\operatorname{supp}\hat{v} \subset (0,\infty)$ and that in addition $J'(u)\hat{u} = J'(v)\hat{v} = 1$. Define

$$z_n(x) = \begin{cases} u(x_n + x) + \gamma_n \hat{u}(x_n + x) & \text{for } x < 0, \\ v(y_n + x) + \gamma_n \hat{v}(y_n + x) & \text{for } x > 0. \end{cases}$$

Here γ_n is fixed by the requirement $J(z_n) = J(u) + J(v)$:

$$J(z_n) = \frac{1}{2}\int_{-\infty}^{x_n} u'^2 + \gamma_n \int_{-\infty}^{x_n} u'\hat{u}' + \frac{\gamma_n^2}{2}\int_{-\infty}^{x_n} \hat{u}'^2 + \frac{1}{2}\int_{y_n}^{\infty} v'^2 + \gamma_n \int_{y_n}^{\infty} v'\hat{v}' + \frac{\gamma_n^2}{2}\int_{y_n}^{\infty} \hat{v}'^2.$$

Since $\operatorname{supp}\hat{u} \cap [x_n, \infty) = \emptyset$,

$$\gamma_n \int_{-\infty}^{x_n} u'\hat{u}' = \gamma_n \int_{-\infty}^{\infty} u'\hat{u}' = \gamma_n J'(u)\hat{u} = \gamma_n,$$

so that

$$\begin{aligned} J(z_n) &= \frac{1}{2}\int_{-\infty}^{x_n} u'^2 + \frac{1}{2}\int_{y_n}^{\infty} v'^2 + 2\gamma_n + C\gamma_n^2 \\ &= J(u) + J(v) - J_{[x_n,\infty)}(u) - J_{(-\infty,y_n]}(v) + 2\gamma_n + C\gamma_n^2, \end{aligned}$$

where $C = (1/2)\int(\hat{u}'^2 + \hat{v}'^2)$. It follows that γ_n satisfies

$$\gamma_n = \frac{1}{2}J_{[x_n,\infty)}(u) + \frac{1}{2}J_{(-\infty,y_n]}(v) - \frac{C}{2}\gamma_n^2$$

as $n \to \infty$. Note that $\gamma_n \to 0$.

Putting it all together,

$$\begin{aligned} W(z_n) &= W_{(-\infty,x_n]}(u + \gamma_n\hat{u}) + W_{[y_n,\infty)}(v + \gamma_n\hat{v}) \\ &= W(u + \gamma_n\hat{u}) + W(v + \gamma_n\hat{v}) - W_{[x_n,\infty)}(u + \gamma_n\hat{u}) - W_{(-\infty,y_n]}(v + \gamma_n\hat{v}) \\ &= W(u) + W(v) + \gamma_n(W'(u)\hat{u} + W'(v)\hat{v}) + O(\gamma_n^2) - W_{[x_n,\infty)}(u) \\ &\qquad - W_{(-\infty,y_n]}(v) \\ &= W(u) + W(v) + \gamma_n(p_u + p_v) + O(\gamma_n^2) - W_{[x_n,\infty)}(u) - W_{(-\infty,y_n]}(v) \\ &\leq W(u) + W(v) + 2\gamma_n p - (p+\varepsilon)(J_{[x_n,\infty)}(u) + J_{(-\infty,y_n]}(v)) + O(\gamma_n^2) \\ &\leq W(u) + W(v) - 2\varepsilon\gamma_n + O(\gamma_n^2). \end{aligned}$$

This last inequality proves the claim (2.13) and therefore Theorem 2.2. ∎

The definition of W_λ provides no explicit continuity properties with respect to variation of λ. However, the variational character can be exploited to derive an interesting semiconvexity property.

LEMMA 2.6. *There exists $C > 0$ such that*

$$\frac{d^2}{d\lambda^2} W_\lambda \le \frac{C}{\lambda} \qquad \text{for all} \qquad \lambda > 0,$$

in the sense of distributions.

Proof. Note that $u^2 f'(u) - uf(u) \le 24F(u)$ for all $u \in \mathbb{R}$. Choose $\lambda > 0$, and let u achieve W_λ. Setting $v_h = u\sqrt{1 + h/\lambda}$, we have $J(v_h) = \lambda + h$ and

$$\begin{aligned} \frac{d^2}{dh^2} W(v_h)\Big|_{h=0} &= \frac{1}{4\lambda^2} \left\{ W''(u) \cdot u \cdot u - W'(u) \cdot u \right\} \\ &= \frac{1}{4\lambda^2} \int (u^2 f'(u) - uf(u)) \\ &\le \frac{6W(u)}{\lambda^2} \le \frac{12}{\lambda}. \end{aligned}$$

This implies the result. ∎

Lemma 2.6 implies that the left and right derivatives of W_λ with respect to λ are well defined. Note that the Euler–Lagrange equation (1.4) implies that if W_λ is achieved at $\lambda = \lambda_0$ by u_{λ_0}, with load p_{λ_0}, then $\partial W_\lambda / \partial \lambda(\lambda_0 -) \ge p_{\lambda_0} \ge \partial W_\lambda / \partial \lambda(\lambda_0 +)$. It follows that any jumps in p_λ must be downward (for increasing λ).

3. Appearance of a periodic section. In the introduction we mentioned the locking-up and spreading of the deformation as the shortening increases. If this process is continued, we expect a periodic section to build up, flanked by spreading tails. The following theorem makes this precise for the model considered in this paper.

THEOREM 3.1. *For any sequence $\lambda_n \to \infty$, a subsequence $u_{\lambda_{n'}}$ converges, after an appropriate translation, to a periodic function $u_\#$. This convergence is in $C^k(K)$ for all $k \ge 0$ and for all compact sets $K \subset \mathbb{R}$. The periodic function $u_\#$ solves the minimization problem*

$$M_\# = \inf \left\{ \frac{W(u)}{J(u)} : u \in H^2_{\mathrm{loc}}(\mathbb{R}) \text{ periodic} \right\}. \tag{3.1}$$

In addition, as $\lambda_{n'} \to \infty$, $p_{\lambda_{n'}} \to M_\#$.

In the formulation of this theorem, as in the rest of this paper, the functionals W and J will be defined on periodic functions $u \in H^2_{\mathrm{loc}}(\mathbb{R})$ by restricting the integrals to a period and normalizing, i.e., if u has period T, then

$$W(u) = \frac{1}{2T} \int_0^T u''^2 + \frac{1}{T} \int_0^T F(u).$$

Before entering the details of the proof, we should briefly comment on the appearance of the new minimization problem (3.1). If u minimizes W/J among all periodic functions, then by choosing periodic test functions $\phi \in H^2_{\mathrm{loc}}(\mathbb{R})$ with the same period and considering the perturbations $u + \varepsilon\phi$ we derive the Euler–Lagrange equation

$$0 = \frac{1}{J(u)} \left\{ W'(u) \cdot \phi - \frac{W(u)}{J(u)} J'(u) \cdot \phi \right\}.$$

Comparison with (1.4) shows that u solves the same ODE as u_λ, and the load is numerically equal to the optimal quotient $W(u)/J(u) = M_\#$.

We conjecture that the solution of (3.1) is unique for the function F that we consider in this paper. However, it is not difficult to construct a different function F for which uniqueness does not hold. (One could construct a function F which is identical to (1.6) over the range of $u_\#$, but is different for (much) larger values of $|u|$. Then $u_\#$ remains a local minimum for the minimization problem (3.1), but an additional minimum may exist with a much larger amplitude. By adjusting F this function can be given the same value of the ratio W/J as $u_\#$).

Proof. The proof falls apart in five steps.

Step 1. $\limsup_{\lambda\to\infty} W_\lambda/\lambda \le M_\#$. Indeed, if v is a periodic function, then $v_\lambda(x) = \eta(|x| - \mu)v(x)$ belongs to C_λ for some $\mu = \mu(\lambda)$. Here η is a smooth cut-off function satisfying

$$\eta(x) = \begin{cases} 1 & x \le 0, \\ 0 & x \ge 1. \end{cases}$$

Then $W(v_\lambda)/\lambda = W(v_\lambda)/J(v_\lambda) \to W(v)/J(v)$ as $\lambda \to \infty$; therefore

$$\limsup_{\lambda\to\infty} \frac{W_\lambda}{\lambda} \le \limsup_{\lambda\to\infty} \frac{W(v_\lambda)}{\lambda} = \frac{W(v)}{J(v)},$$

from which it follows that $\limsup_{\lambda\to\infty} W_\lambda/\lambda \le M_\#$.

Step 2. Translation of u_λ and construction of a periodic function w_λ.

We first note that by the assumption $\alpha \ge 1/4$ the nonlinearity F is increasing in $|u|$. This implies that $p \ge 0$ by the equation (obtained by multiplying (1.5) by u and integrating)

$$p\int u'^2 = \int u''^2 + \int uf(u). \tag{3.2}$$

As a result the origin is a saddle-focus for (1.5) (when viewed as a dynamical system in x), and orbits in the stable and unstable manifold oscillate around zero.

For a given λ we divide $\mathbb{R}$ into intervals $[x_i, x_{i+1})$ delimited by the stationary points x_i of u_λ. Note that the oscillation mentioned above implies that none of the intervals $[x_i, x_{i+1})$ is unbounded. We calculate the ratio r_i of the local values of W and J for each of these intervals,

$$r_i = \frac{\frac12 \int_{x_i}^{x_{i+1}} u_\lambda''^2 + \int_{x_i}^{x_{i+1}} F(u_\lambda)}{\frac12 \int_{x_i}^{x_{i+1}} u_\lambda'^2}.$$

For large $|x|$, $F(u_\lambda) \sim u_\lambda^2/2$, and therefore $\liminf_{i\to\pm\infty} r_i \ge 2$. Since $W(u_\lambda)/\lambda$ is a convex combination of $\{r_i\}$,

$$\frac{W(u_\lambda)}{\lambda} = \sum_{i\in\mathbb{Z}} \frac{r_i}{2\lambda} \int_{x_i}^{x_{i+1}} u_\lambda'^2, \qquad \sum_{i\in\mathbb{Z}} \frac{1}{2\lambda} \int_{x_i}^{x_{i+1}} u_\lambda'^2 = \frac{J(u_\lambda)}{\lambda} = 1,$$

and since $W(u_\lambda)/\lambda < 2$, there exists $i \in \mathbb{Z}$ such that r_i is minimal among all r_i, and for this i we have $r_i < 2$. Fixing i we translate u_λ such that the interval $[x_i, x_{i+1})$ becomes $[0, T/2)$. The periodic function w_λ, with period T, is now defined to be equal

to u_λ on $[0, T/2)$, and to be even around 0 and around $T/2$, as shown in Figure 3.1. Note that by the choice of i we have

$$\frac{W(w_\lambda)}{J(w_\lambda)} = r_i < \frac{W(u_\lambda)}{\lambda}. \tag{3.3}$$

Remark also that this inequality implies that any localized function has a ratio W/J that is strictly larger than $M_\#$. To indicate the dependence of T on λ we write T_λ.

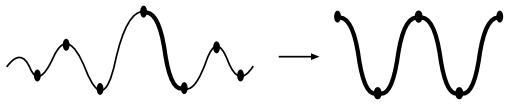

FIG. 3.1. *A section between two stationary points is replicated.*

Step 3. $\lim_{\lambda\to\infty} W(w_\lambda)/J(w_\lambda) = M_\#$. This follows from the sequence of inequalities

$$\begin{aligned} M_\# &\le \liminf_{\lambda\to\infty} \frac{W(w_\lambda)}{J(w_\lambda)} \le \limsup_{\lambda\to\infty} \frac{W(w_\lambda)}{J(w_\lambda)} \\ &\le \limsup_{\lambda\to\infty} \frac{W(u_\lambda)}{\lambda} \le M_\#. \end{aligned}$$

Step 4. The sequence $\{u_\lambda\}$ is bounded in $H^4_{\mathrm{loc}}(\mathbb{R})$, and the sequence $\{w_\lambda\}$ is bounded in $H^2_{\mathrm{loc}}(\mathbb{R})$. This result depends crucially on the destiffening-restiffening character of F via the lemma below.

LEMMA 3.2. *Fix $K \in \mathbb{R}$. There exists $M > 0$ such that if $p \le K$ and $u \in L^\infty(\mathbb{R})$ solves* (1.5)*, then $\|u\|_{L^\infty(\mathbb{R})} \le M$.*

Note that the order of the quantifiers is important: the lemma states that if u is bounded, then it is bounded by a constant independent of u and p (subject to $p \le K$). We defer the proof of this lemma to the end of this section.

Since the functions u_λ satisfy (1.5) and $p_\lambda < 2$, the sequence $\{u_\lambda\}$ is bounded in $L^\infty(\mathbb{R})$. Standard elliptic estimates (e.g. [23, Theorem 11.1]) then give the boundedness of $\{u_\lambda\}$ in H^4 on compact sets. Since the cut-and-paste operation by which w_λ is constructed does not conserve H^4-regularity, the functions w_λ only enjoy the same regularity properties up to H^2-regularity.

As a consequence of the H^4-boundedness, u'_λ, u''_λ, and u'''_λ are all bounded in $L^\infty(\mathbb{R})$ independently of λ; additionally T_λ is bounded from below, since if $T_\lambda \to 0$, then by the bound on u'_λ, $\|u_\lambda\|_{L^\infty(0,T_\lambda)} = \|w_\lambda\|_{L^\infty(\mathbb{R})} \to 0$, so that we have $\liminf W(w_\lambda)/J(w_\lambda) \ge 2$. This contradicts (3.3).

Step 5. Convergence. Since w_λ is bounded in H^2_{loc} uniformly in λ, we can choose a sequence that converges weakly in $H^2_{\mathrm{loc}}(\mathbb{R})$ to a limit function w_∞.

1. If T_λ is bounded along this sequence, then—possibly after extracting a subsequence—T_λ and $J(w_\lambda)$ converge, and w_∞ is periodic with a finite period. The weak convergence implies that $W(w_\infty) \le \liminf W(w_\lambda)$, so that w_∞ is a solution of the minimization problem (3.1).

2. If T_λ is unbounded, then note that w_λ and u_λ have the same weak limit w_∞. We choose a subsequence such that p_λ, which is bounded between 0 and 2, converges. The weak convergence of u_λ in H^4_{loc} implies that w_λ satisfies (1.5) with limit load p_∞. This load lies necessarily between 0 and 2; this implies, as above, that solutions tending to zero oscillate around zero, contradicting the monotonicity of w_λ.

We conclude that case 2 does not occur.

If we pick $\delta > 0$ such that $(0,\delta)$ is included in $(0,T_\lambda/2)$ for all λ, and $\phi \in C_c^\infty((0,\delta))$, then

$$p_\lambda = \frac{W'(u_\lambda)\cdot\phi}{J'(u_\lambda)\cdot\phi} = \frac{W'(w_\lambda)\cdot\phi}{J'(w_\lambda)\cdot\phi} \to \frac{W'(w_\infty)\cdot\phi}{J'(w_\infty)\cdot\phi}$$

by the weak convergence of w_λ. By the remark made before the beginning of the proof, the fact that w_∞ minimizes the ratio W/J among all periodic functions implies that w_∞ also satisfies (1.5) with $p = M_\#$. Therefore $p_\lambda \to M_\#$.

Step 6. Conclusion. The functions u_λ and w_∞ solve the same differential equation (1.5) for loads p_λ and $M_\#$ that satisfy $p_\lambda \to M_\#$. We have $u_\lambda \rightharpoonup w_\infty$ in $H^2(0,\delta)$; using standard elliptic theory it follows that u_λ converges to w_∞ in $C^k(0,\delta)$ for all $k \in \mathbb{N}$. The classical result of continuous dependence on initial data then extends this to any compact set K. This concludes the proof of the theorem. ∎

We end this section with the proof of Lemma 3.2.

Proof. We first prove the lemma under the condition $|p| \le K$. Suppose that $p_n \in [-K,K]$ and u_n satisfy (1.5), with $\|u_n\|_{L^\infty(\mathbb{R})} \to \infty$. Set $\gamma_n = \|u_n\|^{-1}_{L^\infty(\mathbb{R})}$, so that $\gamma_n \to 0$, and define

$$v_n(x) = \gamma_n u_n(\gamma_n x).$$

Then

$$v_n'''' + p_n\gamma_n^2 v_n'' + \gamma_n^4 v_n - \gamma_n^2 v_n^3 + \alpha v_n^5 = 0.$$

Since v_n is uniformly bounded, classical elliptic estimates (e.g., [23]) imply that $v_n \rightharpoonup v_\infty$ in $H^4_{\mathrm{loc}}(\mathbb{R})$, after extraction of a subsequence. The limit v_∞ therefore satisfies the equation

$$v_\infty'''' + \alpha v_\infty^5 = 0 \qquad \text{on } \mathbb{R}, \tag{3.4}$$

which has no nonzero bounded solution (see, e.g., [19]). This contradicts the fact that $\|v_n\|_{L^\infty(\mathbb{R})} = 1$.

If we release the lower bound on p, and assume that $p_n \to -\infty$, then we define in addition

$$\delta_n = \max\{\gamma_n, |p_n|^{1/2}\gamma_n^2\}$$

and

$$v_n(x) = \gamma_n u_n(\delta_n x).$$

Since v'''' and pv'' are both positive operators if $p < 0$, the unboundedness of p is irrelevant for the elliptic estimates. The limit equation is

$$\overline{\gamma} v_\infty'''' - \overline{\delta} v_\infty'' + v_\infty^5 = 0 \qquad \text{on } \mathbb{R},$$

where $\overline{\gamma}, \overline{\delta} \in [0,1]$ and $\overline{\gamma} + \overline{\delta} \neq 0$. For none of the possible combinations of $\overline{\gamma}$ and $\overline{\delta}$ does this equation have a bounded nonzero solution. ∎

4. The periodic function $u_\#$. In the previous section we showed that there exists a solution $u_\#$ to the variational problem

$$M_\# = \inf\left\{\frac{W(u)}{J(u)} : u \in H^2_{\mathrm{loc}}(\mathbb{R}) \text{ periodic}\right\}$$

and that it is the limit, on compact sets, of solutions u_λ of problem (1.3). In this section we discuss a number of issues concerning this periodic function $u_\#$.

4.1. Critical buckling load. Going back to the model of an axially loaded strut, let us briefly examine the behavior under dead loading, rather than rigid loading; i.e., we fix the load p and seek an associated response. The appropriate energy for this loading situation is [24, p. 50]

$$\mathcal{L}(u) = W(u) - pJ(u), \tag{4.1}$$

which is often called the total potential or the Lagrangian. Note that equilibria of $\mathcal{L}$ again satisfy (1.4); both dead and rigid loading lead to the same equilibria, but the stability properties differ.

For small values of p, $\mathcal{L}$ is a positive definite function of u, and the trivial response, $u \equiv 0$, is the unique global minimizer. When p passes a threshold value there will be profiles with a negative Lagrangian, so that the zero response is no longer optimal, and can be improved upon by a nonzero deflection. Thus we can define a critical load p_c, such that

$$\begin{aligned} \inf_{u\in H^2(\mathbb{R})} \mathcal{L}(u) &= 0 \qquad \text{if } p < p_c, \\ \inf_{u\in H^2(\mathbb{R})} \mathcal{L}(u) &< 0 \qquad \text{if } p > p_c. \end{aligned}$$

Note that if $\inf \mathcal{L}(u) < 0$, then in fact $\inf \mathcal{L}(u) = -\infty$, by replication of an appropriate function u.

An alternative, but equivalent, way of representing the statements above is

$$p_c = \inf_{u\in H^2(\mathbb{R})} \frac{W(u)}{J(u)}.$$

Here the connection with the previous section becomes clear.

4.2. Symmetry of the minimizer. Variational problems very similar to that of $\inf \mathcal{L}$ arise in the study of polymeric materials under tension [11, 16]. It is interesting to note that the concept of a critical load (p_c), that has its origin in a mechanical viewpoint, is mirrored very closely by the ideas presented in [11], notably Theorem 6.1.

While the settings of [11, 16] are slightly different from the current one, some of the proofs carry over immediately. By adapting Lemmas 3.3 and 3.6 of [16] we find the following.

LEMMA 4.1 (see [16]).

1. *$u_\#$ is even about any critical point;*
2. *if $u_\#$ has a zero, then it is odd about this zero.*

As for the condition that $u_\#$ have zeros, this is easily proved as follows.

LEMMA 4.2. *$u_\#$ has a zero.*

Proof. Suppose that $u_\# > 0$ on $\mathbb{R}$. For $\mu > 1$, define $v_\mu = \max u_\# - \mu((\max u_\#) - u_\#)$. Then $\int v_\mu''^2 = \mu^2 \int u_\#''^2$, $\int v_\mu'^2 = \mu^2 \int u_\#'^2$, and $\int F(v_\mu) \le \int F(u_\#)$ provided

$v_\mu \geq 0$ (recall that $F'(u) \geq 0$ if $u \geq 0$). Therefore

$$\frac{W(v_\mu)}{J(v_\mu)} \leq \frac{\frac{\mu^2}{2}\int u_\#''^{\,2} + \int F(u_\#)}{\frac{\mu^2}{2}\int u_\#'^{\,2}} < \frac{W(u_\#)}{J(u_\#)},$$

which contradicts the minimality of $u_\#$. □

In summary, $u_\#$ is both odd and even.

5. Numerical computation of minimizers.

5.1. Procedure. The computation of global minimizers in a nonconvex setting suffers from the potential existence of a large number of local minimizers. The problem at hand—that of minimizing W for prescribed values of J—appears to be particularly demanding from this point of view, since the associated Euler–Lagrange equation (1.5) is expected to have a large number of homoclinic solutions. Champneys and Toland [4] showed the existence of a multitude of homoclinic orbits bifurcating from $p = -2$ for a related problem ($\alpha = 0$), which they numerically tracked into the $p > 0$ domain. These orbits are "multimodal," "repeated" versions of a primary orbit. In addition the existence of many "multibump" homoclinics has been shown, which consist of N copies of a given homoclinic, separated by large distances.

However, there is evidence that many of these homoclinic orbits are not constrained minimizers. There is a folk theorem, which received some backup in [22], that local stability under rigid loading is related to the change of J along an equilibrium path: if J decreases, then the solution is stable, and it is unstable otherwise. This would disqualify many equilibria off-hand. For the multibump homoclinics an additional argument suggests that they can never be stable (see again [22]). Based on this circumstantial evidence, we conjecture that the number of constrained local minimizers is in fact very limited. The numerical evidence of this section supports this conjecture, and we shall return to a further discussion of the issue in section 6.

We therefore adopt the following procedure to seek a global minimizer of problem (1.3) for given λ. Starting from quasi-random initial data (satisfying $J = \lambda$) we solve the constrained gradient flow problem

$$u_t = -u_{xxxx} - pu_{xx} - f(u), \qquad x \in \mathbb{R},\ t > 0, \tag{5.1}$$

$$J(u(\cdot, t)) = \lambda, \qquad t > 0. \tag{5.2}$$

Here $p = p(t)$ is a priori unknown, and is determined as part of the solution. This problem has a strictly decreasing Lyapunov function (the functional W), and converges rapidly to a stationary solution, which we assume to be a local minimizer. By repeating this process for a "large" number of different random initial data we collect a number of local minimizers. We select the solution with the lowest value of W as the global minimizer of W under the condition $J = \lambda$.

For the computation of solutions of the constrained dynamical system (5.1)–(5.2) we restrict the problem to a finite domain $(-L, L)$, with L suitably large, and impose the boundary conditions of a simply supported beam ($u(\pm L) = u_{xx}(\pm L) = 0$). An equivalent variational formulation follows by multiplying the equation by a test function v with $v(\pm L) = 0$ and integrating:

$$\int_{-L}^{L} u_t v\,dx + \int_{-L}^{L} u_{xx}v_{xx}\,dx - p\int_{-L}^{L} u_x v_x\,dx + \int_{-L}^{L} f(u)v\,dx = 0. \tag{5.3}$$

We now determine an approximation to $u(x,t)$ by using the finite-element method to give a semidiscretization of (5.3) [25]. To do this we approximate $u(x,t)$ by the function $U_h(x,t) = \sum U_i(t)\phi_i(x) + \sum U_{xi}(t)\psi_i(x)$. Here ϕ_i and ψ_i are piecewise cubic functions defined on a uniform mesh of spacing $h := 2L/N$ so that

$$\phi_i(-L+jh) = \psi_i'(-L+jh) = \delta_{ij} \qquad \text{and} \qquad \psi_i(-L+jh) = \phi'(-L+jh) = 0 \quad \text{for } i,j = 0,\dots,N.$$

The space S_h is the span of the functions ϕ_i $(i = 1,\dots,N-1)$ and ψ_i $(i = 0,\dots,N)$ (such that the imposed boundary condition $u = 0$ is incorporated into the solution space). We set $U \in \mathbb{R}^{2N}$ equal to $U = U(t) = (U_1,\dots,U_{N-1},U_{x0},\dots,U_{xN})$. Now we require that U_h should satisfy (5.3) for all functions $V \in S_h$. Setting $V = \phi_i$ or $V = \psi_i$ leads to the following system of ODEs for U and P:

$$AU_t + BU - PCU + D = 0, \tag{5.4}$$

where the $2N \times 2N$ matrices A, B, and C are given by

$$A_{ij} = \int \phi_i\phi_j, \qquad 1 \le i,j \le N-1,$$
$$B_{ij} = \int \phi_i''\phi_j'', \qquad 1 \le i,j \le N-1,$$
$$C_{ij} = \int \phi_i'\phi_j', \qquad 1 \le i,j \le N-1,$$

with similar entries for other ranges of i and j. The components D_i of the zero-order term D in (5.4) are numerical approximations, using Simpson's rule, of the integral

$$\int f(U_h)\phi_i, \qquad 1 \le i \le N-1,$$
$$\int f(U_h)\psi_{i-N}, \qquad N \le i \le 2N.$$

The in-plane load $p(t)$ is determined as part of the solution and the necessary and sufficient condition comes from the integral constraint (5.2), which reads in discretized form

$$\frac{1}{2}U^TCU = \lambda. \tag{5.5}$$

The system (5.4)–(5.5) is then an index-2 differential-algebraic equation. Differentiating (5.5) with respect to time we find

$$U^TCU_t = 0. \tag{5.6}$$

We solved (5.4) and (5.6) using `DDASSL`, a backward-difference form differential-algebraic equation solver [20]. We choose to replace the constraint (5.5) by (5.6) since the latter provides a DAE system of index one, which `DDASSL` is designed to handle. It is verified after calculation that the deviation from (5.5) due to accumulation of numerical error is acceptably small (relative error less than 0.01).

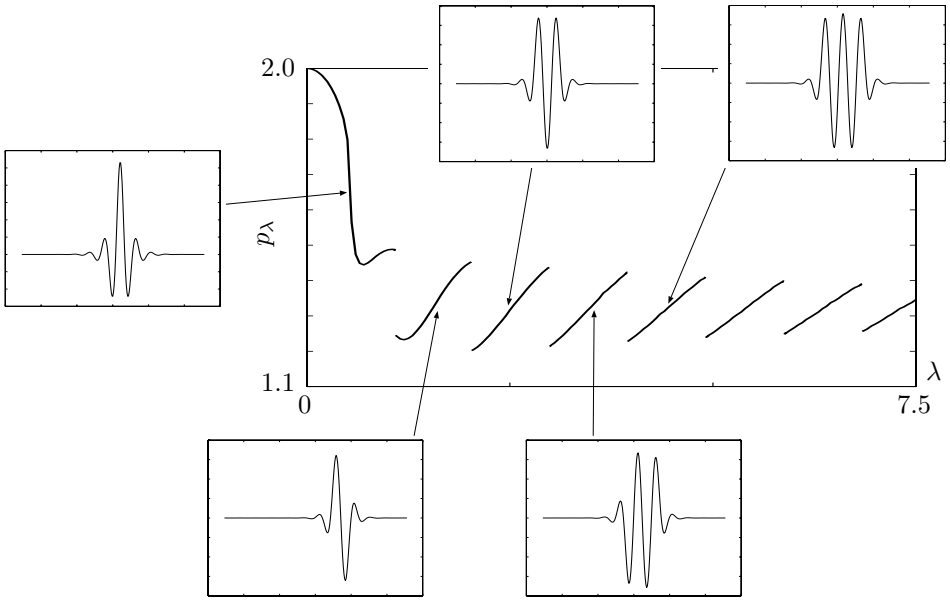

FIG. 5.1. *Results of the numerical minimization ($\alpha = 0.3$).*

5.2. Results. Figure 5.1 shows a plot of the load p_λ as a function of λ. The initial data sample size is 25.

A number of features of this graph merit special mention.

1. The graph decomposes into a collection of continuous curves. The apparent discontinuities in this figure are actual discontinuities; the change in λ causes local minima to move relative to each other, and at these discontinuities the global minimum jumps from one local minimum to another. Also, it appears that the continuous curves are projections of continua of solutions in state space (note that comparison is not trivial because of the interference of the discretization; also, we do not want to impose any symmetry).

2. Theorem 3.1 states that for any sequence $\lambda_n \to \infty$, $p_{\lambda_n} \to M_\#$. In Figure 5.1 we recognize this convergence in the decrease of the vertical extent of the graph as λ increases.

3. On the continuous parts of the curve, the solution has either odd or even symmetry. At the jumps the solution switches from one to the other.

4. The load is not a continuous function of λ; but all jumps are downward. Compare this to Lemma 2.6.

In the next section we give an interpretation of the form of Figure 5.1.

6. Correspondence with the bifurcation diagram. In this section we briefly change our perspective: instead of problem (1.3) we consider the ODE (1.5),

$$u'''' + pu'' + f(u) = 0 \qquad \text{on } \mathbb{R}, \tag{1.5}$$

where p is a prescribed parameter. A solution of (1.3) also solves (1.5), but the opposite is not true. As we mentioned in the previous section, there are many solutions of (1.5) that are strongly suspected of not even being local constrained minimizers.

Figure 6.1 shows a bifurcation plot of (1.5). At $p = 2$, at zero J, a Hamiltonian–Hopf bifurcation creates four homoclinic orbits. Two of these are even, and each the

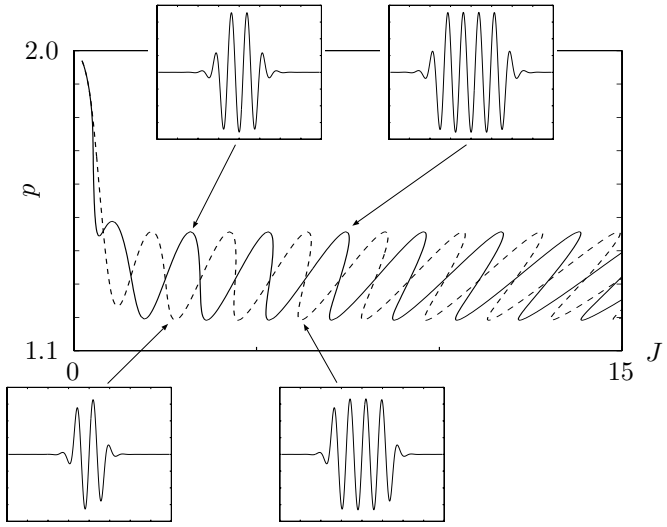

FIG. 6.1. *Bifurcation diagram for* (1.5) *showing curves of even (continuous line) and odd (dashed line) solutions bifurcating from* $p = 2$. *Here* $\alpha = 0.3$.

opposite of the other ($u_2 = -u_1$); the other two are odd, and again each other's opposite. In Figure 6.1 we identify the two even and the two odd solutions and thus draw two curves in total.

The initial part of the figure, near $p = 2$, is typical for a destiffening nonlinearity. The oscillating behavior for larger values of J, however, is related to the competing destiffening and restiffening qualities. It is shown in [19] how the restiffening nature (more specifically, the fact that $F(u) > F(0)$ for $u \neq 0$) implies that along the curve p must be bounded from below. Woods [26] and Woods and Champneys [27] show that the snaking behavior can be explained as the result of a collision of the unstable manifold of zero with the stable manifold of a family of periodic orbits parametrized by p. When $p = M_{\#}$, this periodic orbit is exactly the function $u_{\#}$ of Theorem 3.1.

When we combine this figure and Figure 5.1 into one diagram (Figure 6.2) there is a strong suggestion that all minimizers lie on the bifurcation curve. If we elevate this numerical suggestion to the status of hypothesis, that is, if we suppose that all minimizers of problem (1.3) lie on this bifurcation diagram, then the jumps from one curve to the other result from a simple energy argument. In a graph of load against deflection, strain energy is represented by area under the graph. More precisely, if we have a continuum of solutions v_s of (1.4), parametrized by s, with associated load p_s, then

$$\begin{aligned} W(v_{s_2}) - W(v_{s_1}) &= \int_{s_1}^{s_2} W'(v_s) \cdot \frac{dv_s}{ds}\, ds \\ &= \int_{s_1}^{s_2} p_s J'(v_s) \cdot \frac{dv_s}{ds}\, ds \\ &= \int_{s_1}^{s_2} p_s\, dJ(v_s), \end{aligned}$$

with a slight abuse of notation in the last integral.

To explain the jumps, let us assume, to start with, that for some interval of

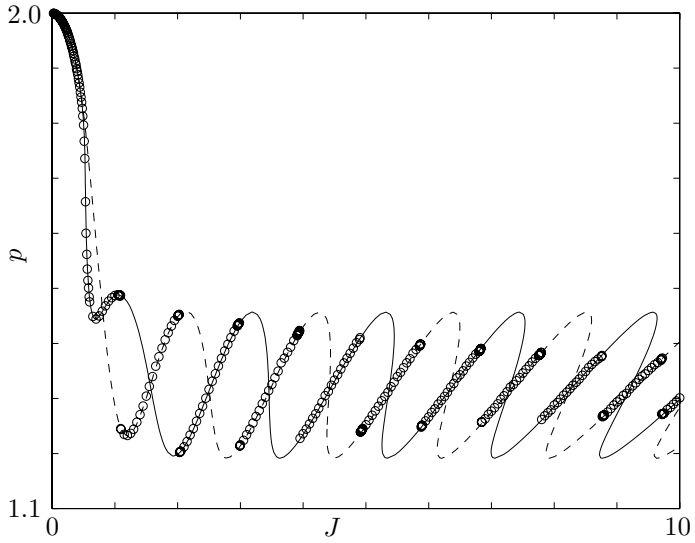

FIG. 6.2. *Combination of Figures* 5.1 *and* 6.1.

values of λ all minimizers lie on a given continuum of solutions v_s. This is shown schematically in Figure 6.3. At the critical value λ_c the two areas E_1 and E_2 are equal, implying that the strain energies at **A** and **B** are equal. As λ passes through the critical value, the minimum in the strain energy jumps from the top to the bottom curve.

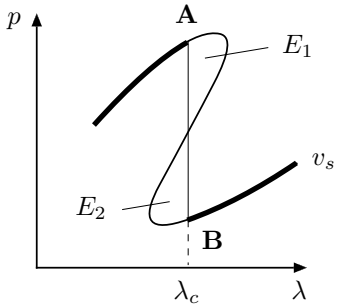

FIG. 6.3. *The thick line indicates the minimizer under constrained* λ.

In the case of the problem as stated in (1.3), the numerical results clearly indicate that both the branches of solutions in Figure 6.1 contain minimizers. We therefore need to take both curves into account when searching for jumps. As an example, Figure 6.4 shows a blow-up of the first jump in Figure 5.1, where the minimum passes from the even to the odd branch. Again the jump corresponds to an equal-area condition. The other jumps arise in the same manner.

In summary, if we make the assumption that all global minimizers of (1.3) lie on the bifurcation diagram of Figure 6.1, then the form of Figure 5.1 follows readily from energy comparison.

The assumption that all global minimizers lie on the bifurcation diagram is a strong one. As of yet there is no conclusive argument why this might be the case. For some specific classes of solutions of (1.5) it has been shown that they are or are not locally minimal (see above) but these results depend in a critical manner on the

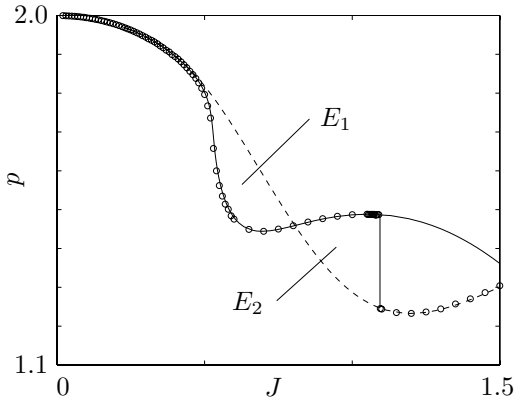

FIG. 6.4.

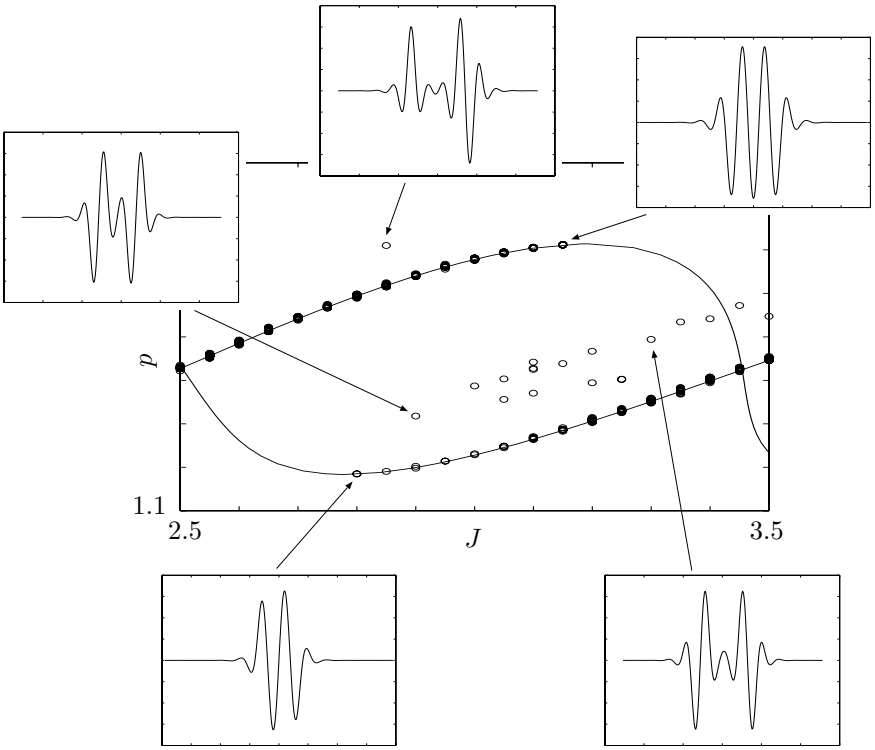

FIG. 6.5. *Every circle represents a "local minimizer" that was found numerically (see text).*

structure of the solutions involved. A complete classification of all solutions of (1.5) is still a distant goal, and therefore doing an exhaustive search is not an option.

To complicate matters, the numerical results suggest that local optimality does not guarantee membership of the bifurcation diagram in Figure 6.1. As mentioned before, the algorithm used for finding the global minimizer runs a constrained gradient flow algorithm starting from random initial data; the function that the algorithm stabilizes at for large time is assumed to represent a local minimum. This procedure is repeated a number of times, and the local minimum with least strain energy is

tagged as the global minimum. This is the solution that appears in Figures 5.1 and 6.2.

In Figure 6.5 we show an excerpt of Figure 6.2, but this time we plot not only the global minimum but all of the local minima that were found along the way. In addition to the solutions that we would expect, those that lie on the two bifurcation curves, other solutions appear with a different structure. Of course, "local optimality" has been established in a crude manner, so this could well be a numerical artifact. The question of the relationship between the minimization problem (1.3) and Figure 6.1 remains an interesting one, however, that merits being studied in more detail.

7. The nonlinearity F. In this paper we concentrate entirely on functions F of the form (1.6). Of course the class of functions for which one can derive the same results is much larger, and in this section we give some indication as to which properties of F enter into play. In addition, the existence result (Theorem 2.2) and the convergence result (Theorem 3.1) differ in their requirements, and we shall also comment on this issue.

The term destiffening was defined in the introduction as a decrease in the marginal stiffness $F''(u)$ as u moves away from zero. The actual property used in the proofs, however, is the combination "$F'''(0) = 0$ and $F''''(0) < 0$" (in Lemma 2.3, part 1). The function (1.6) satisfies both of these formulations of the destiffening character, but the function $F(u) = u^2/2 - u^6/6 + \alpha u^8/8$, for instance, satisfies only the first of the two. As remarked on page 1149, the proof of lemma 2.3 does not apply to this latter function, but numerical results suggest that the assertion of the Lemma ($W_\lambda < 2\lambda$) holds nonetheless. At this stage we must conclude that there is a grey area between these two formulations of "destiffening."

If we tolerate this lack of accuracy for the moment, we can assert that the destiffening nature is crucial for the existence proof, via the same property $W_\lambda < 2\lambda$ and the estimate (2.11). However, destiffening alone is not sufficient to guarantee existence for all $\lambda > 0$. If F takes negative values (assuming $F(0) = 0$), say $F(\bar{u}) < 0$, then for sufficiently large values of λ we can create admissible profiles with large *negative* strain energy. As an example, consider

$$u_k(x) = \bar{u}\,\eta(|x| - k),$$

where η is a smooth cut-off function such that $\eta \equiv 1$ on $(-\infty, -1]$ and $\eta \equiv 0$ on $[1, \infty)$. If $k > 1$, then $J(u_k)$ is independent of k, but $W(u_k)$ takes arbitrarily large negative values as $k \to \infty$. Since we therefore have $\inf_{\mathcal{C}_\lambda} W = -\infty$, the existence question is absurd. In order to avoid this degeneracy, we need to assume $F(u) \geq 0$ (the possibility $F(\bar{u}) = 0$, $\bar{u} \neq 0$ leads to noncompactness of minimizing sequences; however, such sequences can be adapted to regain compactness, so that the existence of a minimizer is not compromised).

To summarize, the main characteristics of F that lead to existence are the destiffening nature and this positivity property. The function (1.6) meets these constraints if and only if $\alpha \geq 3/16$.

Turning to the convergence of minimizers as the end-shortening λ tends to infinity (Theorem 3.1), simple positivity of F is not sufficient. One can construct counter-examples where $F(u)$ is small, but positive, for large $|u|$; minimizers for such nonlinearities are unbounded in the L^∞-norm and therefore do not converge. Some form of stiffening for larger u is necessary to prevent this runaway. As before, no sharp condition is known, but Lemma 3.2, which provides the all-important L^∞ bound, can

be proved for all F with

$$F'(s) \sim s^{q-1} \qquad \text{as } |s| \to \infty, \qquad \text{with } q > 2,$$

without any change in the proof. For such functions F the statement of Theorem 3.1 should hold unchanged.

In addition, for the convergence result we assume that $\alpha \geq 1/4$, so that $p \geq 0$ (see (3.2)), and solutions necessarily oscillate at infinity. This property is used twice in the proof of Theorem 3.1. We conjecture that $\alpha \geq 1/4$ is unnecessarily restrictive, however, and that $\alpha \geq 3/16$ should suffice for both existence of minimizers and the convergence for large λ.

While dwelling on the subject of the nonlinearity F, we might also comment on the requirement of restiffening itself, i.e., the fact that we assume a relatively complex structure in the response of the elastic foundation. It is true that the combination of initial destiffening and subsequent stiffening appears artificial. However, there is good reason to assume that both the destiffening and the subsequent stiffening characters are present in actual examples of elastic struts on foundations—not in the foundation response, but in other elements in the model. For instance, in linearizing the higher-order terms in the equation—that is, by replacing $\mathcal{W}$ and $\mathcal{J}$ by W and J—a destiffening property that is present in the original formulation has been discarded. Mühlhaus [17] gives a heuristic argument for this fact, and it can be verified by doing a small-amplitude development of the appropriate nonlinear terms.

Similarly, a foundation that does not have the local response of the Winkler foundation that we consider here, but "feels" the proximity of the layer at adjoining sites, has a strongly stiffening character for large deformations. This is illustrated by Figure 7.1, where the material indicated by the hashing, being squashed by the bends in the strut, will exert a large force on the strut in the opposite direction. This is an inherently nonlocal effect that cannot be captured with a Winkler foundation. In summary, the various simplifying assumptions that we have made during the modelling process have removed the destiffening and subsequent stiffening characteristics from the formulation, forcing us to reintroduce them via the foundation response.

With these arguments in mind we chose to consider a mathematical model that has the nature, if not the exact form, of the mechanical problem. We hope that the ideas of this paper will be amenable to future extension.

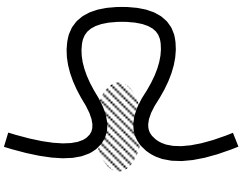

FIG. 7.1. *Squashed material exerts a nonlocal force on the strut.*

Appendix. Proof of Lemma 2.5. It is relatively simple to prove that for any minimizer u the load necessarily satisfies $p \leq 2$. If u minimizes W at constant J, with associated load p, then u is a stationary point of the functional

$$\mathcal{L}(u) = W(u) - pJ(u).$$

Since the constraint is one-dimensional, the second derivative of $\mathcal{L}$ at u cannot have more than one unstable eigenmode.

On the other hand, suppose that $p > 2$ and let $\phi \in C_c^\infty(\mathbb{R})$ satisfy

$$\int \left(\phi''^2 - p\phi'^2 + \phi^2\right) < 0.$$

If $|x|$ is sufficiently large, then $F''(u(x)) \leq 1$ and therefore, setting $\psi_K(x) = \phi(x-K)$,

$$\mathcal{L}''(u)\cdot\phi_K\cdot\phi_K = \int \left({\phi_K''}^2 - p{\phi_K'}^2 + F''(u){\phi_K}^2\right) < 0,$$

both for large and for small K. It follows that $\mathcal{L}$ has at least two unstable directions, and this contradicts the assumption that u is a minimum.

When we write (1.5), for $p = 2$, as a four-dimensional dynamical (Hamiltonian) system, then the linear part of this system is given by a matrix which is not diagonizable. Using normal form theory, for every $k \in \mathbb{N}$ we can transform the system to a system given by the Hamiltonian

$$H = \frac{1}{2}|p|^2 + \langle p, Jq\rangle + P(|q|^2, \langle p, Jq\rangle) + O(|p|^{2k}, |q|^{2k}) \tag{A.1}$$

(see, e.g., [15, Chapter VII]). Here P is a polynomial in its two arguments, whose lowest-order terms are quadratic. For our purposes the only important term in $P(u,v)$ is au^2, or equivalently $a|q|^4$. The calculations done by Woods [26] show that $a > 0$.

By hypothesis, the orbit represented by $(p(t), q(t))$ converges to the origin as $t \to \infty$. Since the system is linear in the limit of small amplitude, it follows that (p,q) must converge to solutions of the linear problem. More accurately, if we choose $t_n \to \infty$, and rescale by setting

$$(p_n, q_n)(t) = \frac{1}{|(p,q)(t_n)|}(p,q)(t - t_n),$$

then the functions (p_n, q_n) converge on compact subsets to bounded solutions of the linear problem. Since all such solutions satisfy $p \equiv 0$, it follows that $p = o(|q|)$ as $t \to \infty$.

We next transform (p,q) to polar coordinates (r, R, θ, Θ), given by

$$\begin{aligned} q_1 &= r\cos\theta, & q_2 &= r\sin\theta,\\ p_1 &= R\cos\theta - \left(\frac{\Theta}{r}\right)\sin\theta, & p_2 &= R\sin\theta + \left(\frac{\Theta}{r}\right)\cos\theta. \end{aligned}$$

The Hamiltonian then takes the form

$$H(r,R,\theta,\Theta) = \frac{1}{2}\left(R^2 + \left(\frac{\Theta}{r}\right)^2\right) - \Theta + P(r^2,\Theta) + O\left(\left|R^2 + \left(\frac{\Theta}{r}\right)^2\right|^k + r^{2k}\right).$$

The result $p = o(|q|)$ translates to $R/r, \Theta/r^2 \to 0$, which implies, together with $H = 0$, that

$$\Theta \sim \frac{1}{2}R^2 + ar^4.$$

We can then calculate an estimate of the rate of decay of Θ:

$$\dot{\Theta} = -\frac{\partial H}{\partial \theta} = O(R^{2k} + r^{2k}) = O(\Theta^{k/2}).$$

It follows that for $k \geq 4$ the rate of decay of Θ is too small to be compatible with the condition that $u \in H^2(\mathbb{R})$, or

$$\int^{\infty} \left(|p|^2 + |q|^2\right) < \infty,$$

since

$$|p|^2 + |q|^2 \geq R^2 + r^2 \geq c\Theta$$

for some $c > 0$, in the limit $t \to \infty$.

Acknowledgments. Many of the ideas presented in this paper arose in discussions at the Centre for Nonlinear Mechanics, Bath, and the author is grateful to Chris Budd and Giles Hunt for providing such a stimulating environment. In addition, the author is indebted to Boris Buffoni for the idea of Lemma 2.5.

ERRATUM TO "WEIGHTED ZERO DISTRIBUTION FOR POLYNOMIALS ORTHOGONAL ON AN INFINITE INTERVAL"*

WALTER VAN ASSCHE†

Abstract. In [W. Van Assche, *SIAM J. Math. Anal.*, 16 (1985), pp. 1317–1334] the second term in the asymptotic expansion of Laguerre polynomials (Perron's formula) was computed and used to obtain some information about the rate of convergence of weighted zero distributions for Laguerre and Hermite polynomials. This second term in Theorem 2.3 and in the appendix of [W. Van Assche, *SIAM J. Math. Anal.*, 16 (1985), pp. 1317–1334] is in error. In this note we give the correct expression for this second term and indicate how this affects the results on the rate of convergence for the weighted zero distributions.

Key words. Laguerre polynomials, Perron's formula, asymptotic expansion

AMS subject classification. 33C25

PII. S0036141099359871

1. Perron's formula for Laguerre polynomials. Thomas Müller [1, pp. 548–549] recently expressed doubt about the correctness of the second term in the asymptotic expansion for Laguerre polynomials (Perron's formula) as given in Theorem 2.3 in [3]. Perron's formula for Laguerre polynomials is for $\alpha > -1$

$$L_n^{(\alpha)}(z) = \frac{1}{2\sqrt{\pi}} e^{z/2} (-z)^{-(2\alpha+1)/4} n^{(2\alpha-1)/4} \exp(2\sqrt{-nz}) \times \left(\sum_{j=0}^{p-1} C_j(\alpha; z) n^{-j/2} + \mathcal{O}(n^{-p/2}) \right), \tag{1.1}$$

where the bound for the remainder holds uniformly on every compact subset of $\mathbb{C} \setminus [0, \infty)$, $(-z)^{-(2\alpha+1)/4}$ and $\sqrt{-z}$ must be taken to be real and positive if $z < 0$. It is known that $C_0(\alpha; z) = 1$. The second term $C_1(\alpha; z)$ was worked out in the appendix of [3], but unfortunately an error was made in working out the expansion of the term $A_0(z)$ on page 1333. The correct expansion for $A_0(z)$ should read

$$A_0(z) = \frac{1}{2} (-z)^{-1/4} (-1)^{\alpha/2} n^{(2\alpha-1)/4} \exp(2\sqrt{-nz}) e^{-z/2} \times \left\{ 1 + \frac{\sqrt{-z}}{2\sqrt{n}} \left(\alpha + 1 - \frac{z}{6} \right) + \mathcal{O}\left(\frac{1}{n} \right) \right\}. \tag{1.2}$$

The resulting expression for $C_1(\alpha; z)$ then becomes

$$C_1(\alpha; z) = \frac{1}{4\sqrt{-z}} \left(\frac{1}{4} - \alpha^2 - 2(\alpha + 1)z + \frac{z^2}{3} \right). \tag{1.3}$$

2. Weighted zero distributions for Laguerre and Hermite polynomials. The explicit expression of the term $C_1(\alpha;z)$ was only used in section 4 of [3], in particular in Theorems 4.1, 4.3, and 4.4. The proofs of these three theorems remain valid and Theorems 4.1 and 4.3 are correct as formulated. The formulation of Theorem 4.4 needs to be changed to the following.

THEOREM 4.4.

(i) *Let $Z_n^+(x)$ and $Z^+(x)$ be as in the case of generalized Laguerre polynomials and put $R_n^+(x)=\sqrt{n}\{Z_n^+(x)-Z^+(x)\}$. Let $f(x)$ be such that $f((1+y)/(1-y))$ is analytic in some open set containing $[-1,1]$; then as $n\to\infty$*

$$\sum_{j=1}^{n}\frac{f(x_{j,n}^+)}{1+x_{j,n}^+}-\frac{\sqrt{n}}{\pi}\int_0^\infty\frac{f(x)}{\sqrt{x}(1+x)}\,dx=\int_0^\infty f(x)\,dR_n^+(x)$$
$$\to-\frac{2\alpha+1}{4}f(0)-\frac{1}{2}f(\infty).$$

(ii) *Let $Z_n(x)$ and $Z(x)$ be as in the case of generalized Hermite polynomials and put $R_n^+(x)=\sqrt{2n}\{Z_n(x)-Z(x)\}$. Let $f(x)$ be a function such that $f(\pm((1+y)/(1-y))^{1/2})$ is analytic in some open set containing $[-1,1]$; then as $n\to\infty$*

$$\sum_{j=1}^{n}\frac{f(x_{j,n})}{1+x_{j,n}^2}-\frac{\sqrt{2n}}{\pi}\int_{-\infty}^\infty\frac{f(x)}{1+x^2}\,dx=\int_{-\infty}^\infty f(x)\,dR_n(x)$$
$$\to-\alpha f(0)-\frac{1}{2}f(\infty)-\frac{1}{2}f(-\infty).$$

Acknowledgments. The author thanks Thomas Müller (Queen Mary and Westfield College, London) for pointing out the error and Frank Olver (University of Maryland) for providing two alternative ways to compute the required term $C_1(\alpha,z)$ using the techniques from his book [2].

VARIATIONAL APPROXIMATION OF A SECOND ORDER FREE DISCONTINUITY PROBLEM IN COMPUTER VISION*

LUIGI AMBROSIO†, LORIS FAINA‡, AND RICCARDO MARCH§

Abstract. We consider a functional, proposed by Blake and Zisserman for computer vision problems, which depends on free discontinuities, free gradient discontinuities, and second order derivatives. We show how this functional can be approximated by elliptic functionals defined on Sobolev spaces. The approximation takes place in a variational sense, the De Giorgi Γ-convergence, and extends to this second order model an approximation of the Mumford–Shah functional obtained by Ambrosio and Tortorelli. For the purpose of illustration an algorithm based on the Γ-convergent approximation is applied to the problem of computing depth from stereo images and some numerical examples are presented.

1. Introduction.

In recent years, variational principles with a free discontinuity set have been introduced to solve reconstruction problems in computer vision theory (see, for instance, [4, 26, 31]). The variational approach to the image segmentation problem proposed by Mumford and Shah [27] consists of minimizing the functional

$$E(u,K)=\int_{\Omega\setminus K}\left(|\nabla u|^2+\mu|u-g|^2\right)\,dx+\alpha\mathcal{H}^{n-1}(K\cap\Omega)\ , \tag{1.1}$$

where $\Omega\subset\mathbf{R}^n$ is a bounded open set, $\mathcal{H}^{n-1}$ is the Hausdorff $(n-1)$-dimensional measure, $g\in L^\infty(\Omega)$, and α, $\mu>0$ are fixed positive parameters. The functional has to be minimized over all closed sets $K\subset\overline{\Omega}$ and all $u\in C^1(\Omega\setminus K)$. In the case $n=2$ the function g represents the image to be segmented. By minimizing the functional one tries to detect the discontinuities of g due to the edges of the objects in the image, and to cancel the discontinuities due to noise and small irregularities. The set K contains the jump points of u and represents the edges of the objects. The functional penalizes large sets K, and outside K the function u is required to be close to g and C^1.

The Mumford and Shah variational principle can be extended to several reconstruction problems of computer vision [25]: stereo reconstruction [32], computation of optical flow [28], shape from shading [33]. Variational problems involving functionals of this form are usually called free discontinuity problems, after a terminology introduced by De Giorgi [18].

The Mumford and Shah model has some drawbacks: it is unable to reconstruct crease discontinuities and yields the over-segmentation of steep gradients (the so-called ramp effect). To overcome these defects of the first order model, Blake and Zisserman [9] introduced a second order functional which can be written in the form

$$F(u,K_0,K_1)=\int_{\Omega\setminus(K_0\cup K_1)}\left(|\nabla^2 u|^2+\Phi(x,u)\right)\,dx + \alpha\mathcal{H}^{n-1}(K_0\cap\Omega)+\beta\mathcal{H}^{n-1}((K_1\setminus K_0)\cap\Omega)\ , \tag{1.2}$$

with $\alpha,\,\beta>0$ positive parameters. The functional has to be minimized over the unknown sets K_0, K_1, with $K_0\cup K_1$ closed and $u\in C^2(\Omega\setminus(K_0\cup K_1))$ approximately continuous on $\Omega\setminus K_0$. If $\Phi(x,u)=\mu|u-g|^2$ and $n=2$, the functional (1.2) is just that one introduced in [9] (the thin plate surface under tension). In the second order model, K_0 represents the set of jump points for u, and $K_1\setminus K_0$ is the set of crease points. Since the reconstruction of crease discontinuities is particularly relevant in those computer vision problems which require the reconstruction of visible surfaces from two-dimensional images, we have then introduced in (1.2) the function $\Phi(x,u)$. A suitable choice of this function will allow us to apply this variational method to computer vision problems as, for instance, the computation of depth from pairs of stereo images (see [25]).

If the conditions (see [9])

$$\beta\le\alpha\le 2\beta \tag{1.3}$$

are satisfied, the existence of minimizers for the functional $F(u,K_0,K_1)$ has been proved, in the case $n=2$ and $\Phi(x,u)=\mu|u-g|^2$, by Carriero, Leaci, and Tomarelli [13] (notice that (1.3) are necessary and sufficient for the lower semicontinuity of $\overline{F}$ with respect to the L^1 convergence). The proof is based on a weak formulation of the problem by setting

$$\overline{F}(u)=\int_\Omega\left(|\nabla^2 u|^2+\Phi(x,u)\right)\,dx+\alpha\mathcal{H}^{n-1}(S_u)+\beta\mathcal{H}^{n-1}(S_{\nabla u}\setminus S_u)\ , \tag{1.4}$$

where ∇u denotes an approximate differential, S_u is the discontinuity set of u in an approximate sense, and $S_{\nabla u}$ is the discontinuity set of ∇u. In [12] the existence of minimizers for the functional $\overline{F}$ over the space

$$\left\{u:\Omega\to\mathbf{R}:\ u\in L^2(\Omega),\ u\in GSBV(\Omega),\ \nabla u\in[GSBV(\Omega)]^n\right\}\ , \tag{1.5}$$

has been proved in any space dimension n, $GSBV(\Omega)$ being the space of generalized special functions of bounded variation introduced in [17]. A regularity theorem in [13] then shows that, for $n=2$, any weak minimizer actually provides a minimizing triplet (u,K_0,K_1) of F by taking a suitable representative of the function and the closure of S_u and $S_{\nabla u}$.

Ambrosio and Tortorelli [5, 6] approximated the Mumford and Shah functional (1.1) by a family of elliptic functionals defined on Sobolev spaces. The approximation takes place in a variational sense, the De Giorgi Γ-convergence. The approximating elliptic functionals proposed in [6] are defined by

$$E_\epsilon(u,s)=\int_\Omega(s^2+\lambda_\epsilon)|\nabla u|^2\,dx+\mu\int_\Omega|u-g|^2\,dx+\alpha\mathcal{G}_\epsilon(s)\ , \tag{1.6}$$

where the approximation takes place as $\epsilon \to 0^+$, $\lambda_\epsilon \to 0^+$, and

$$\mathcal{G}_\epsilon(s) = \int_\Omega \left[\epsilon |\nabla s|^2 + \frac{(s-1)^2}{4\epsilon} \right] dx \ . \tag{1.7}$$

The variable $s \in [0,1]$ is related to the set of jumps K. The minimizing s_ϵ are near to 0 in a neighborhood of the set K, and far from the neighborhood they are close to 1. The neighborhood shrinks as $\epsilon \to 0$. The Ambrosio and Tortorelli approximation can be used to find an effective algorithm for computing the minimizers of E [25, 29, 30]. The approximation has been applied to several computer vision problems in [28, 32, 33], and further improvements have been proposed and experimented in [34].

In the present paper we consider the following family of functionals:

$$\begin{aligned} F_\epsilon(u,s,\sigma) = &\int_\Omega (\sigma^2 + \kappa_\epsilon) |\nabla^2 u|^2 \, dx + \int_\Omega \Phi(x,u) \, dx + (\alpha - \beta) \mathcal{G}_\epsilon(s) \\ &+ \beta \mathcal{G}_\epsilon(\sigma) + \xi_\epsilon \int_\Omega (s^2 + \zeta_\epsilon) |\nabla u|^\gamma \, dx \end{aligned} \tag{1.8}$$

for suitable infinitesimals κ_ϵ, ξ_ϵ, ζ_ϵ, and $\gamma \geq 2$. A slight variant of these functionals has been proposed by Bellettini and Coscia [7] in the case $n = 1$ and in that case the Γ-convergence of F_ϵ to $\overline{F}$ has been proved (see also the discussion in the beginning of section 6). We extend their Γ-convergence result in the following way: we prove the lower inequality of Γ-convergence in any space dimension n, and we prove the upper inequality when u is bounded and $|\nabla u| \in L^\gamma(\Omega)$, under a very mild regularity assumption on the sets S_u and $S_{\nabla u}$, which is fulfilled in computer vision applications. In the particular case when $\alpha = \beta$ and $n = 2$, we obtain a full Γ-convergence theorem.

The extension of the Ambrosio and Tortorelli approximation to the second order problem presents several difficulties. The lower inequality cannot be obtained by means of the slicing technique and consequent reduction to a one-dimensional problem used in [5, 6]. Such a reduction yields the operator norm of the Hessian matrix in the Γ-limit instead of the euclidean norm. The second derivatives are then estimated by adapting a global technique proposed by Ambrosio in [3] and relying on a compactness theorem in the space (1.5) due to Carriero, Leaci, and Tomarelli [12]. Conversely, the jump part of the functional is estimated by using a slicing argument, taking into account that the space $GSBV$ is a vector space under a suitable energy condition (Proposition 4.3).

The major difficulty in the proof of the upper inequality consists in obtaining a suitable estimate on $\int |\nabla u|^\gamma dx$ from the finiteness of (1.4). Such an estimate would permit us to adapt the constructive part of Ambrosio and Tortorelli's proof [6] to the second order problem. In the case $\alpha = \beta$, $n = \gamma = 2$, an estimate which yields a full Γ-convergence result is obtained by means of a suitable interpolation inequality in $W^{2,2}$ (Proposition 4.6). If $\alpha \neq \beta$, we obtain only a partial result, proving the upper inequality under some mild regularity assumptions on u.

The discretization of the functional (1.2) is not straightforward and it is difficult to apply gradient descent with respect to the unknown sets K_0 and K_1. Conversely, the Γ-convergent approximation yields a sequence of functionals (1.8) which are numerically much more tractable, so that discretization and gradient descent may be applied in a straightforward way. In particular, a simple discretization method, commonly used for computer vision problems [35], may be applied to the functionals (1.8). We then apply the Γ-convergence result to the problem of computation of depth from stereo images, and we present some computer experiments on synthetic images to illustrate the feasibility of the approximation.

2. Notations and preliminary results. Let $\Omega \subset \mathbf{R}^n$ be a bounded open set. We denote by $\mathcal{B}(\Omega)$ the σ-algebra of all the Borel subsets of Ω; for any $C \in \mathcal{B}(\Omega)$ we denote by $\mathrm{meas}(C)$ the Lebesgue n-dimensional measure of C and by $\mathcal{H}^{n-1}(C)$ the Hausdorff $(n-1)$-dimensional measure of C. We denote by $B_\rho(x)$ the open ball $\{y \in \mathbf{R}^n : |y-x| < \rho\}$. We denote by $\mathbf{M}^{n\times n}$ the space of $n \times n$ matrices endowed with the euclidean norm. We introduce the following notations: $s \wedge t = \min\{s,t\}$, $s \vee t = \max\{s,t\}$ for every $s,t \in \mathbf{R}$; given two vectors a, b, we set $\langle a,b\rangle = a \cdot b = \sum_i a_i b_i$ and $(a \otimes b)_{ij} = a_i b_j$.

For any Borel function $u : \Omega \to \mathbf{R}$ we define the approximate upper and lower limits $u^+(x)$, $u^-(x)$ by

$$u^+(x) = \inf\left\{ t \in [-\infty,+\infty] : \lim_{\rho\to 0^+} \frac{\mathrm{meas}(\{y \in B_\rho(x) : u(y) > t\})}{\rho^n} = 0 \right\},$$

$$u^-(x) = \sup\left\{ t \in [-\infty,+\infty] : \lim_{\rho\to 0^+} \frac{\mathrm{meas}(\{y \in B_\rho(x) : u(y) < t\})}{\rho^n} = 0 \right\}.$$

The set

$$S_u = \{x \in \Omega :\ u^-(x) < u^+(x)\}$$

is the discontinuity set of u in an approximate sense and it is negligible with respect to Lebesgue measure (see [20, section 2.9.13]). Suppose $z = u^+(x) = u^-(x) \in \mathbf{R}$; we say that $\nabla u(x) \in \mathbf{R}^n$ is the approximate differential of u at x if $v^+(x) = 0$, where

$$v(y) = \frac{|u(y) - z - \langle \nabla u(x), y-x\rangle|}{|y-x|} \qquad \forall y \in \Omega \setminus \{x\}\ .$$

If u is differentiable at x, then $\nabla u(x)$ is the classical gradient. In the one-dimensional case we shall use the notation u' in place of ∇u. An important property of the approximate differential is the fact that

$$\nabla u(x) = 0 \qquad \text{almost everywhere (a.e.) on} \quad \{y \in \Omega : u(y) = c\} \qquad \forall c \in \mathbf{R}\ . \tag{2.1}$$

We denote by $BV(\Omega)$ the space of functions of bounded variation in Ω, i.e., the functions $u \in L^1(\Omega)$ such that the distributional derivative of u is representable by means of a vector measure $Du = (D_1u, \dots, D_nu)$ with finite total variation. We denote by $|Du|$ the measure total variation of Du. If $u \in BV(\Omega)$, then ∇u exists a.e. in Ω and coincides a.e. with the Radon–Nikodym derivative of Du with respect to the Lebesgue measure [11]. Moreover, the set S_u is countably $(n-1)$-rectifiable, i.e., representable as a disjoint union $\cup_{i=1}^\infty K_i \cup N$, where $\mathcal{H}^{n-1}(N) = 0$ and K_i are compact sets, each contained in a C^1 hypersurface $\Gamma_i \subset \mathbf{R}^n$ [16].

Let $E \subset \mathcal{B}(\Omega)$; we define

$$P(E,\Omega) = \sup\left\{ \int_E \mathrm{div}\ \phi\, dx : \phi \in C_0^1(\Omega;\mathbf{R}^n), |\phi| \le 1 \right\}.$$

We say that E is a set of finite perimeter in Ω if $P(E,\Omega) < +\infty$. By Riesz's theorem (see [21]), E is a set of finite perimeter if and only if $1_E \in BV(\Omega)$, and $P(E,\Omega) = |D1_E|(\Omega)$.

The following Fleming–Rishel coarea formula (see [21]) establishes an important connection between BV functions and sets of finite perimeter:

$$|Du|(\Omega) = \int_{-\infty}^{+\infty} P(\{x \in \Omega : u(x) > t\}, \Omega)\, dt. \tag{2.2}$$

We say that $u \in BV(\Omega)$ belongs to the space of special functions of bounded variation $SBV(\Omega)$ if

$$|Du|(\Omega) = \int_\Omega |\nabla u|\, dx + \int_{S_u} |u^+ - u^-|\, d\mathcal{H}^{n-1} .$$

Functions like the Cantor–Vitali function, whose derivative is concentrated on Cantor's middle third set, are then excluded by $SBV(\Omega)$ (see [1, 17]).

Given a Borel function $u : \Omega \to \mathbf{R}$ we say that $u \in GSBV(\Omega)$ if (see [2, 17])

$$-N \vee u \wedge N \in SBV_{\rm loc}(\Omega) \qquad \forall N \in \mathbf{N}. \tag{2.3}$$

The jump set of u is given by

$$S_u = \bigcup_{N=1}^{\infty} S_{-N\vee u\wedge N}.$$

Furthermore, if $u \in GSBV(\Omega)$, then S_u is countably $(n-1)$-rectifiable, ∇u exists a.e. in Ω and is given by (see [2])

$$\nabla u = \nabla(-N \vee u \wedge N) \quad \text{a.e. on} \quad \{x \in \Omega : |u| \le N\} \qquad \forall N \in \mathbf{N}.$$

We also set

$$GSBV^2(\Omega) = \{u \in GSBV(\Omega) :\ \nabla u \in [GSBV(\Omega)]^n\} .$$

Given $u \in GSBV^2(\Omega)$, we use the notation $\nabla^2_{i,j} u = \nabla_j(\nabla_i u)$ and, in the one-dimensional case, $u'' = (u')'$. Moreover we set

$$S_{\nabla u} = \bigcup_{i=1}^{n} S_{\nabla_i u}.$$

The following compactness result has been proved by Carriero, Leaci, and Tomarelli in [12].

THEOREM 2.1. *Let $(u_h) \subset GSBV^2(\Omega)$ be a sequence such that*

$$\|u_h\|_{L^2} , \qquad \mathcal{H}^{n-1}(S_{u_h} \cup S_{\nabla u_h}) , \qquad \int_\Omega |\nabla^2 u_h|^2\, dx$$

are uniformly bounded in h. Then there exist a subsequence (u_{h_k}) and $u \in GSBV^2(\Omega) \cap L^2(\Omega)$ such that, as $k \to +\infty$,

$$\begin{aligned} &u_{h_k} \to u \qquad \textit{strongly in } L^1(\Omega),\\ &\nabla u_{h_k} \to \nabla u \qquad \textit{a.e. in } \Omega,\\ &\nabla^2 u_{h_k} \rightharpoonup \nabla^2 u \qquad \textit{weakly in } L^2(\Omega; \mathbf{M}^{n\times n}) . \end{aligned}$$

Finally, we recall the following lemma (see [10]).

LEMMA 2.2. *Let $\mu : \mathcal{B}(\Omega) \to [0, +\infty]$ be a σ-finite measure, and let $(f_i) \subset L^1(\Omega)$ be a sequence of nonnegative functions. Then,*

$$\begin{aligned} &\int_\Omega \sup_{i\in\mathbf{N}} f_i(x)\, d\mu(x)\\ &\quad = \sup\left\{ \sum_{i=1}^{k} \int_{A_i} f_i(x)\, d\mu(x) : A_i \subset \Omega \textit{ open and mutually disjoint, } k \in \mathbf{N} \right\}. \end{aligned}$$

We now recall the definition and some properties of Γ-convergence (see [15]). Let X be a metric space and let $f_\epsilon : X \to [0, +\infty]$ be a family of functions indexed by $\epsilon > 0$. We say that f_ϵ Γ-converge as $\epsilon \to 0^+$ to $f : X \to [0, +\infty]$ if the following two conditions

$$\forall x_\epsilon \to x \quad \liminf_{\epsilon \to 0^+} f_\epsilon(x_\epsilon) \geq f(x) \tag{2.4}$$

and

$$\exists x_\epsilon \to x \quad \limsup_{\epsilon \to 0^+} f_\epsilon(x_\epsilon) \leq f(x) \tag{2.5}$$

are fulfilled for every $x \in X$. The Γ-limit, if it exists, is unique and lower semicontinuous. The Γ-convergence is stable under continuous perturbations, that is, $f_\epsilon + g$ Γ-converge to $f + g$ if f_ϵ Γ-converge to f and g is continuous. The most important property of Γ-convergence is the following: if (x_ϵ) is asymptotically minimizing, i.e.,

$$\lim_{\epsilon \to 0^+} \left(f_\epsilon(x_\epsilon) - \inf_X f_\epsilon \right) = 0, \tag{2.6}$$

and if x_{ϵ_h} converge to x for some sequence $\epsilon_h \to 0$, then x minimizes f.

3. Statement of main results. Let $\Phi(x, u) = \mu|u - g|^2$, $\mu > 0$, and $0 < \beta \leq \alpha \leq 2\beta$. For every $u \in GSBV^2(\Omega) \cap L^2(\Omega)$ and every $g \in L^\infty(\Omega)$, we write (1.4) as

$$\overline{F}(u) = \int_\Omega \left(|\nabla^2 u|^2 + \mu|u - g|^2 \right) dx + (\alpha - \beta)\mathcal{H}^{n-1}(S_u) + \beta\mathcal{H}^{n-1}(S_u \cup S_{\nabla u}).$$

In [12], using Theorem 2.1 and a suitable lower semicontinuity theorem in $GSBV^2(\Omega)$, Carriero, Leaci, and Tomarelli proved that the problem

$$(\mathcal{P}) \qquad \min \left\{ \overline{F}(u) : \ u \in GSBV^2(\Omega) \cap L^2(\Omega) \right\}$$

has at least one solution.

For every $\epsilon > 0$ and any function $v \in W^{1,2}(\Omega; [0, 1])$, let us define

$$\mathcal{G}_\epsilon(v) = \int_\Omega \left(\epsilon|\nabla v|^2 + \frac{(v-1)^2}{4\epsilon} \right) dx.$$

Our aim is to approximate $\overline{F}$, in the sense of Γ-convergence, by a family of elliptic functionals F_ϵ which are formally defined by

$$\begin{aligned} F_\epsilon(u, s, \sigma) = &\int_\Omega (\sigma^2 + \kappa_\epsilon)|\nabla^2 u|^2 \, dx + \mu \int_\Omega |u - g|^2 \, dx + (\alpha - \beta)\mathcal{G}_\epsilon(s) \\ &+ \beta\mathcal{G}_\epsilon(\sigma) + \xi_\epsilon \int_\Omega (s^2 + \zeta_\epsilon)|\nabla u|^\gamma \, dx \end{aligned} \tag{3.1}$$

for suitable nonnegative infinitesimals κ_ϵ, ξ_ϵ, ζ_ϵ (in some cases they are allowed to vanish; see the statements below). This formula makes sense if $u \in W^{2,2}(\Omega)$ and s, $\sigma \in W^{1,2}(\Omega)$; however, in the case $\kappa_\epsilon = 0$, because of the coefficient σ^2 multiplying the second derivatives, the functionals F_ϵ are not coercive in these spaces. In section 5 we identify a domain $\mathcal{D}(\Omega)$ of the functionals F_ϵ such that the problem

$$(\mathcal{P}_\epsilon) \qquad \min\{F_\epsilon(u,s,\sigma) : \ (u,s,\sigma) \in \mathcal{D}(\Omega)\}$$

has at least one solution, provided $\gamma > 2$ and $\kappa_\epsilon + \zeta_\epsilon > 0$.

We define

$$X(\Omega) = L^2(\Omega) \times L^\infty(\Omega;[0,1]) \times L^\infty(\Omega;[0,1]) \supset \mathcal{D}(\Omega)$$

and we denote by $\mathcal{F} : X(\Omega) \to [0,+\infty]$ the functional defined by

$$\mathcal{F}(u,s,\sigma) = \begin{cases} \overline{F}(u) & \text{if } u \in GSBV^2(\Omega),\ s \equiv 1,\ \sigma \equiv 1, \\ +\infty & \text{otherwise.} \end{cases}$$

Analogously, we denote by $\mathcal{F}_\epsilon : X(\Omega) \to [0,+\infty]$ the functional defined by

$$\mathcal{F}_\epsilon(u,s,\sigma) = \begin{cases} F_\epsilon(u,s,\sigma) & \text{if } (u,s,\sigma) \in \mathcal{D}(\Omega), \\ +\infty & \text{otherwise.} \end{cases}$$

We first prove the lower inequality of Γ-convergence.

THEOREM 3.1. *Assume that $\gamma \geq 2$, that*

$$\lim_{\epsilon \to 0^+} \frac{\xi_\epsilon}{\epsilon^{\gamma-1}} = +\infty, \tag{3.2}$$

and that either $\kappa_\epsilon > 0$ for ϵ small enough or $\zeta_\epsilon > 0$ for ϵ small enough. Then, for every triple $(u,s,\sigma) \in X(\Omega)$ and for every family $(u_\epsilon, s_\epsilon, \sigma_\epsilon) \in \mathcal{D}(\Omega)$ converging to (u,s,σ) in $[L^1(\Omega)]^3$ as $\epsilon \to 0^+$, we have

$$\liminf_{\epsilon \to 0^+} \mathcal{F}_\epsilon(u_\epsilon, s_\epsilon, \sigma_\epsilon) \geq \mathcal{F}(u,s,\sigma) \ .$$

Moreover, (3.2) can be replaced by the condition $\xi_\epsilon \geq 0$ in the case $\alpha = \beta$.

Then we prove the equicoercivity of the family $(\mathcal{F}_\epsilon)$ under the same assumptions on γ and on the infinitesimals κ_ϵ, ξ_ϵ, ζ_ϵ made in Theorem 3.1.

THEOREM 3.2. *Let $(u_\epsilon, s_\epsilon, \sigma_\epsilon) \in \mathcal{D}(\Omega)$ be such that*

$$\sup_{\epsilon > 0} \mathcal{F}_\epsilon(u_\epsilon, s_\epsilon, \sigma_\epsilon) < +\infty.$$

Then the family $(u_\epsilon, s_\epsilon, \sigma_\epsilon)$ is relatively compact in the $[L^1(\Omega)]^3$ topology as $\epsilon \to 0^+$ and any limit point is of the form $(u,1,1)$ with $u \in GSBV^2(\Omega) \cap L^2(\Omega)$.

We now consider the upper inequality of Γ-convergence. We first state our full Γ-convergence result in the special case when $n = 2$, $\gamma = 2$ and $\alpha = \beta$. We recall that a domain Ω is strictly star-shaped if there exists $x_0 \in \Omega$ such that $t(\Omega - x_0) + x_0 \subset\subset \Omega$ for any $t \in [0,1)$.

THEOREM 3.3. *Assume that $n = \gamma = 2$, $\alpha = \beta$, and Ω is strictly star-shaped. Assume that $\kappa_\epsilon > 0$ and $\kappa_\epsilon = o(\epsilon^4)$, while $\xi_\epsilon = \zeta_\epsilon = 0$. Then the family $(\mathcal{F}_\epsilon)$ Γ-converges to $\mathcal{F}$ in the $[L^1(\Omega)]^3$ topology as $\epsilon \to 0^+$.*

Then from the properties of Γ-convergence and Theorem 3.2, if $(\bar{u}_\epsilon, \bar{s}_\epsilon, \bar{\sigma}_\epsilon)$ minimizes $\mathcal{F}_\epsilon$, then the family $(\bar{u}_\epsilon, \bar{s}_\epsilon, \bar{\sigma}_\epsilon)$ is relatively compact in $[L^1(\Omega)]^3$ as $\epsilon \to 0^+$ and any limit point corresponds to a triple $(u,1,1)$ with u minimizer of $\overline{F}$.

Notice that in the case $\alpha = \beta$, $\xi_\epsilon = 0$, the functionals $\mathcal{F}_\epsilon$ do not depend on s; hence we can write them in the much simpler form

$$F_\epsilon(u,\sigma) = \int_\Omega (\sigma^2 + \kappa_\epsilon)|\nabla^2 u|^2 \, dx + \mu \int_\Omega |u - g|^2 \, dx + \beta \mathcal{G}_\epsilon(\sigma) \ .$$

Now we consider a more general situation. For every set $A \subset \mathbf{R}^n$ and every positive real number ρ, we denote by $(A)_\rho$ the open tubular neighborhood of A with radius ρ, that is, $(A)_\rho = \{x \in \mathbf{R}^n : \ \mathrm{dist}(x, A) < \rho\}$. We define the Minkowski $(n-1)$-dimensional upper and lower content of the set A, respectively, by

$$\mathcal{M}^*(A) = \limsup_{\rho \to 0^+} \frac{\mathrm{meas}((A)_\rho)}{2\rho} \ , \qquad \mathcal{M}_*(A) = \liminf_{\rho \to 0^+} \frac{\mathrm{meas}((A)_\rho)}{2\rho} \ .$$

It can be shown (see [20, section 3.2.39]) that $\mathrm{meas}((A)_\rho)/\rho$ converges to $2\mathcal{H}^{n-1}(A)$ as $\rho \to 0^+$ for any compact subset A of a C^1 hypersurface. In particular, by inner approximation this implies

$$\mathcal{M}_*(A) \geq \mathcal{H}^{n-1}(A)$$

for any $u \in BV(\Omega)$ and any Borel set $A \subset S_u$, because $\mathcal{H}^{n-1}$-almost all of S_u can be covered by C^1 hypersurfaces. The inequality $\mathcal{M}^*(A) \leq \mathcal{H}^{n-1}(A)$, which implies

$$\lim_{\rho \to 0^+} \frac{\mathrm{meas}((A)_\rho)}{2\rho} = \mathcal{H}^{n-1}(A) \ ,$$

holds under very mild regularity assumptions on the set A [5].

We are able to prove the upper inequality of Γ-convergence under the assumption that $u \in L^\infty(\Omega)$, $|\nabla u| \in L^\gamma(\Omega)$ and that, for the sets S_u and $S_u \cup S_{\nabla u}$, Hausdorff measure and Minkowski content coincide.

THEOREM 3.4. *Assume that $\gamma \geq 2$, $\kappa_\epsilon = 0$, $\zeta_\epsilon > 0$, ξ_ϵ satisfies* (3.2) *and $\xi_\epsilon \zeta_\epsilon = o(\epsilon^{\gamma-1})$. Then, for every triple $(u, s, \sigma) \in X(\Omega)$ such that $u \in L^\infty(\Omega)$, $|\nabla u| \in L^\gamma(\Omega)$, and*

$$\mathcal{M}^*(S_u) \leq \mathcal{H}^{n-1}(S_u) \ , \qquad \mathcal{M}^*(S_u \cup S_{\nabla u}) \leq \mathcal{H}^{n-1}(S_u \cup S_{\nabla u}) \ ,$$

there exist $(u_\epsilon, s_\epsilon, \sigma_\epsilon) \in \mathcal{D}(\Omega)$ converging to (u, s, σ) in $[L^1(\Omega)]^3$ as $\epsilon \to 0^+$ such that

$$\limsup_{\epsilon \to 0^+} \mathcal{F}_\epsilon(u_\epsilon, s_\epsilon, \sigma_\epsilon) \leq \mathcal{F}(u, s, \sigma). \tag{3.3}$$

Remark 3.5. The Γ-convergence result still holds if the term $\mu|u - g|^2$ in the functional $\mathcal{F}$ is replaced by $\Phi(x, u)$ in such a way that the functional $u \to \int_\Omega \Phi(x, u)\, dx$ is lower semicontinuous with respect to the strong $L^1(\Omega)$ topology and continuous with respect to the strong $L^2(\Omega)$ topology (see section 7). Let Φ be a Carathéodory function on $\Omega \times \mathbf{R}$, i.e., $\Phi(\cdot, p)$ is measurable for any $p \in \mathbf{R}$ and $\Phi(x, \cdot)$ is continuous for almost every $x \in \Omega$. Then a sufficient condition for Γ-convergence is the following [19]:

$$\begin{cases} \Phi : \Omega \times \mathbf{R} \to \mathbf{R} \quad \textit{is Carathéodory} \ , \\ 0 \leq \Phi(x, u) \leq a(x) + b|u|^2 \ , \end{cases}$$

with $a \in L^1(\Omega)$ and $b \geq 0$.

4. Basic properties of $GSBV^2$ functions. In this section we give some technical results concerning the one-dimensional sections of functions $u \in GSBV(\Omega)$. Let $\nu \in \mathbf{S}^{n-1} = \{x \in \mathbf{R}^n : |x| = 1\}$ be a fixed direction. We set

$$\begin{aligned} &\Pi_\nu = \{x \in \mathbf{R}^n : \langle x, \nu \rangle = 0\}, \\ &\Omega_x = \{t \in \mathbf{R} : x + t\nu \in \Omega\} \quad (x \in \Pi_\nu), \\ &\Omega_\nu = \{x \in \Pi_\nu : \Omega_x \neq \emptyset\}. \end{aligned}$$

The sets Ω_x are the 1-dimensional slices of Ω indexed by $x \in \Pi_\nu$, and Ω_ν is the projection of Ω on Π_ν. Given $u \in GSBV(\Omega)$, we define for $\mathcal{H}^{n-1}$-a.e. $x \in \Omega_\nu$ the restriction

$$u_x(t) = u(x + t\nu) \quad \text{for a.e. } t \in \Omega_x.$$

The following slicing result can be obtained from [1, Theorem 3.3] and [2, section 1].

LEMMA 4.1. *Let $u : \Omega \to \mathbf{R}$ be a measurable function. Then $u \in GSBV(\Omega)$ if and only if, for any $\nu \in \mathbf{S}^{n-1}$, $u_x \in GSBV(\Omega_x)$ for $\mathcal{H}^{n-1}$-a.e. $x \in \Omega_\nu$ and*

$$\int_{A_\nu} |D(-N \vee u_x \wedge N)|(A_x)\, d\mathcal{H}^{n-1} < +\infty \tag{4.1}$$

for any open set $A \subset\subset \Omega$ and any $N \in \mathbf{N}$.

Moreover, if $u \in GSBV(\Omega)$ and $\nu \in \mathbf{S}^{n-1}$, then for $\mathcal{H}^{n-1}$-a.e. $x \in \Omega_\nu$ we have

(a) *$u_x'(t) = \langle \nabla u(x + t\nu), \nu \rangle$ for a.e. $t \in \Omega_x$;*

(b) *$S_{u_x} = (S_u)_x$.*

The proof of the following lemma can be found in Federer [20, section 3.2.22].

LEMMA 4.2. *For every countably $\mathcal{H}^{n-1}$-rectifiable set $E \subset \mathbf{R}^n$ there exists a Borel function $\nu_E : E \to \mathbf{S}^{n-1}$ such that*

$$\int_E |\langle \nu, \nu_E(x) \rangle|\, d\mathcal{H}^{n-1}(x) = \int_{E_\nu} \mathcal{H}^0(E_x)\, d\mathcal{H}^{n-1}(x) \qquad \forall \nu \in \mathbf{S}^{n-1}.$$

The function $\nu_E(x)$ is a normal unit vector to E at x in an approximate sense (see [20, section 3.2.16]).

Although $GSBV(\Omega)$ is not a vector space, we can prove that the natural energy spaces for our problems do have a vector structure.

PROPOSITION 4.3. *The set*

$$Y = \left\{ u \in GSBV(\Omega) : \int_\Omega |\nabla u|\, dx + \mathcal{H}^{n-1}(S_u) < +\infty \right\}$$

is a vector space.

Proof. Let u_1, $u_2 \in Y$, and $\nu \in \mathbf{S}^{n-1}$ be fixed. By Lemma 4.1(a), (b) and Lemma 4.2 we have

$$\int_{\Omega_x} |u_{ix}'|\, dt + \mathcal{H}^0(S_{u_{ix}}) < +\infty \qquad \text{for } i = 1, 2$$

for $\mathcal{H}^{n-1}$-a.e. $x \in \Omega_\nu$, because

$$\int_{\Omega_\nu} \left[\int_{\Omega_x} |u_{ix}'|\, dt + \mathcal{H}^0(S_{u_{ix}}) \right] d\mathcal{H}^{n-1} \le \int_\Omega |\nabla u_i|\, dx + \mathcal{H}^{n-1}(S_{u_i}) < +\infty.$$

In particular, $u_{ix} \in L^\infty_{\mathrm{loc}}(\Omega_x)$, and since $SBV_{\mathrm{loc}}(\Omega_x)$ is a vector space $u_{1x} + u_{2x}$ belongs to $SBV_{\mathrm{loc}}(\Omega_x)$ for $\mathcal{H}^{n-1}$-a.e. $x \in \Omega_\nu$. Since the condition (4.1) is easily verified the conclusion follows by using Lemma 4.1. □

Finally, we show how in $GSBV^2(\Omega)$ second order derivatives and jump set of the derivative can be recovered as well by a slicing method.

LEMMA 4.4. *Let $u \in GSBV^2(\Omega)$ be such that*

$$\int_\Omega |\nabla^2 u|\, dx + \mathcal{H}^{n-1}(S_{\nabla u}) < +\infty.$$

Then, for any $\nu \in \mathbf{S}^{n-1}$ the function $\langle \nabla u, \nu \rangle$ belongs to $GSBV(\Omega)$ and for $\mathcal{H}^{n-1}$-a.e. $x \in \Omega_\nu$ we have

(a) $u'_x \in GSBV(\Omega_x)$;

(b) $u''_x(t) = \langle \nabla \langle \nabla u, \nu \rangle (x + t\nu), \nu \rangle$ *for a.e.* $t \in \Omega_x$;

(c) $S_{u'_x} = (S_{\nabla u \cdot \nu})_x$.

Proof. By Proposition 4.3 it follows that $\langle \nabla u, \nu \rangle \in GSBV(\Omega)$ whenever $\nabla_i u \in GSBV(\Omega)$ for $i = 1, \dots, n$. By Lemma 4.1(a) it follows that $u'_x = \langle \nabla u, \nu \rangle_x$ a.e. in Ω_x for $\mathcal{H}^{n-1}$-a.e. $x \in \Omega_\nu$; in particular, $u'_x \in GSBV(\Omega_x)$ for $\mathcal{H}^{n-1}$-a.e. $x \in \Omega_\nu$. Then, statements (b), (c) follow by applying Lemma 4.1(a,b) to $\langle \nabla u, \nu \rangle$. ∎

COROLLARY 4.5. *The set*

$$\left\{ u \in GSBV^2(\Omega) : \int_\Omega |\nabla^2 u| \, dx + \mathcal{H}^{n-1}(S_u \cup S_{\nabla u}) < +\infty \right\}$$

is a vector space.

Proof. The proof is the same as for Proposition 4.3 using Lemma 4.4 instead of Lemma 4.1. ∎

We conclude this section with an interpolation inequality in $W^{2,2}$ which provides a mild estimate of $\int |\nabla u|^2 \, dx$ with the Blake–Zisserman energy (see also [12]).

PROPOSITION 4.6. *Let A, $B \subset \mathbf{R}^n$ be open sets with $(A)_{2r} \subset\subset B$. Then*

$$\int_A |\nabla u|^2 \, dx \le 16n \left[r^{-2} \int_B u^2 \, dx + 2r^2 \int_B |\nabla^2 u|^2 \, dx \right] \qquad \forall u \in W^{2,2}_{\mathrm{loc}}(B) \ . \tag{4.2}$$

Proof. We prove the inequality only in the case $n = 1$; the general case can be achieved by a slicing argument, taking into account Lemma 4.4(b).

Let x be such that the interval $[x - 2r, x + 2r] \subset B$ and choose $x_1 \in [x + r, x + 2r]$, $x_2 \in [x - 2r, x - r]$ such that

$$r u(x_1) = \int_{x+r}^{x+2r} u(s) \, ds, \qquad r u(x_2) = \int_{x-2r}^{x-r} u(s) \, ds$$

and $x_3 \in [x_2, x_1]$ such that $u'(x_3) = [u(x_1) - u(x_2)]/(x_1 - x_2)$. Then, for any $y \in [x - 2r, x + 2r]$, using twice Hölder inequality we estimate

$$\begin{aligned} |u'(y)|^2 &\le 2|u'(x_3)|^2 + 2 \left(\int_{x_3}^y u''(s) \, ds \right)^2 \\ &\le \frac{4(u^2(x_1) + u^2(x_2))}{r^2} + 2|x_3 - y| \left| \int_{x_3}^y |u''(s)|^2 \, ds \right| \\ &\le \frac{4}{r^3} \int_{x-2r}^{x+2r} u^2(s) \, ds + 8r \int_{x-2r}^{x+2r} |u''(s)|^2 \, ds. \end{aligned}$$

By integration we obtain

$$\int_{x-2r}^{x+2r} |u'|^2 \, dy \le \frac{16}{r^2} \int_{x-2r}^{x+2r} u^2 \, dy + 32r^2 \int_{x-2r}^{x+2r} |u''|^2 \, dy \ .$$

Covering A by a finite number of intervals of length $4r$ contained in B the conclusion follows. ∎

5. The approximation framework. In this section we find a domain suitable for coercivity and lower semicontinuity of the functionals F_ϵ formally defined by (3.1).

We often set $w = (u, s, \sigma)$ and we always assume that $0 \le s \le 1$, $0 \le \sigma \le 1$ almost everywhere. If $\kappa_\epsilon = 0$, we define $p = 2\gamma/(\gamma+2)$ and

$$\mathcal{D}(\Omega) = \left\{(u,s,\sigma) \in X(\Omega) :\ u,\ s,\ \sigma \in W^{1,2}(\Omega),\ \ \sigma\nabla u \in W^{1,p}(\Omega;\mathbf{R}^n)\right\}\ ,$$

if $\kappa_\epsilon > 0$ we define

$$\mathcal{D}(\Omega) = W^{2,2}_{\rm loc}(\Omega) \times W^{1,2}(\Omega;[0,1]) \times W^{1,2}(\Omega;[0,1])\ .$$

If $u \in \mathcal{D}(\Omega)$ and $\kappa_\epsilon = 0$, the approximate differentiability of u and of $\sigma\nabla u$ imply that $\nabla^2 u$ exists a.e. in $\{\sigma > 0\}$ and is given by

$$\nabla^2 u = \frac{\nabla(\sigma\nabla u) - \nabla\sigma \otimes \nabla u}{\sigma}\ . \tag{5.1}$$

We also set $\nabla^2 u = 0$ in $\{\sigma = 0\}$.

In the following we do not need to consider the function s in the case $\alpha = \beta$. We now prove a compactness theorem for the sublevels of F_ϵ.

THEOREM 5.1. *Assume that $\gamma > 2$, $\kappa_\epsilon + \zeta_\epsilon > 0$ and let $(w_h) = (u_h, s_h, \sigma_h) \subset \mathcal{D}(\Omega)$ be a sequence such that*

$$\sup_h F_\epsilon(w_h) < +\infty.$$

Then there exist a subsequence (w_{h_k}) and $w = (u, s, \sigma) \in \mathcal{D}(\Omega)$ such that (w_{h_k}) converge in $[L^1(\Omega)]^3$ to w and (∇u_{h_k}) converge a.e. to ∇u in $\{\sigma > 0\}$.

Proof. From (4.2), in the case $\kappa_\epsilon > 0$, we have that (u_h) is bounded in $W^{2,2}(A)$ for any open set $A \subset\subset \Omega$. The statement then follows from Rellich theorem. Hence, in the following we consider the more delicate case when $\kappa_\epsilon = 0$ and $\zeta_\epsilon > 0$.

From the definition of F_ϵ the sequences (s_h) and (σ_h) are bounded in $W^{1,2}(\Omega)$. Moreover, since $(|\nabla u_h|)$ is bounded in $L^\gamma(\Omega)$ and

$$\nabla(\sigma_h \nabla u_h) = \sigma_h \nabla^2 u_h + \nabla\sigma_h \otimes \nabla u_h,$$

$v_h = \sigma_h \nabla u_h$ are also bounded in $W^{1,p}(\Omega;\mathbf{R}^n)$. Hence, possibly extracting a further subsequence we can assume that (v_{h_k}) is converging a.e. in Ω. It easily follows that $\nabla u_{h_k} = v_{h_k}/\sigma_{h_k}$ converge a.e. to ∇u in $\{\sigma > 0\}$.

In order to prove that $\sigma\nabla u \in W^{1,p}(\Omega;\mathbf{R}^n)$ (hence $w \in \mathcal{D}(\Omega)$), we notice that by Hölder inequality, we have

$$\lim_{h\to+\infty} \int_{\{\sigma=0\}} |\sigma_h \nabla u_h|\, dx = 0$$

hence (possibly extracting a subsequence) $\sigma_h\nabla u_h$ converge a.e. to $\sigma\nabla u$ in the whole of Ω. Since $(\sigma_h\nabla u_h)$ is also bounded in $W^{1,p}(\Omega;\mathbf{R}^n)$, it follows that $\sigma\nabla u \in W^{1,p}(\Omega;\mathbf{R}^n)$ and that $\sigma_{h_k}\nabla u_{h_k}$ weakly converge in $W^{1,p}(\Omega;\mathbf{R}^n)$ to $\sigma\nabla u$. □

Now we prove the lower semicontinuity of F_ϵ.

THEOREM 5.2. *Assume that $\gamma > 2$, $\kappa_\epsilon + \zeta_\epsilon > 0$ and let $(w_h) = (u_h, s_h, \sigma_h) \subset \mathcal{D}(\Omega)$ be converging in $[L^1(\Omega)]^3$ to $w = (u, s, \sigma) \in \mathcal{D}(\Omega)$. Then*

$$\liminf_{h\to+\infty} F_\epsilon(w_h) \ge F_\epsilon(w)\ .$$

Proof. In this case we also consider only the more difficult case when $\kappa_\epsilon = 0$ and $\zeta_\epsilon > 0$. It is not restrictive to assume that $(F_\epsilon(w_h))$ is converging to a finite limit and, by Theorem 5.1 and its proof, we can also assume that ∇u_h converge to ∇u a.e. in $\{\sigma > 0\}$ and $\sigma_h \nabla u_h$ weakly converge in $W^{1,p}(\Omega; \mathbf{R}^n)$ to $\sigma \nabla u$.

Since the sequences (s_h) and (σ_h) are bounded in $W^{1,2}(\Omega)$, they weakly converge, respectively, to s, σ and therefore the terms $\mathcal{G}_\epsilon(s)$ and $\mathcal{G}_\epsilon(\sigma)$ are lower semicontinuous. The lower semicontinuity of $\int_\Omega (s^2 + \zeta_\epsilon)|\nabla u|^\gamma \, dx$ directly follows by Ioffe lower semicontinuity theorem (see [10, Theorem 4.1.1]).

Finally, the identity

$$\nabla(\sigma_h \nabla u_h) = \sigma_h \nabla^2 u_h + \nabla \sigma_h \otimes \nabla u_h$$

and the weak convergence of $\nabla(\sigma_h \nabla u_h)$ to $\nabla(\sigma \nabla u)$ easily imply that $\nabla^2 u_h$ weakly converge to $\nabla^2 u$ in $L^2(K; \mathbf{M}^{n\times n})$ on any compact set $K \subset \Omega$ on which (σ_h) uniformly converges to σ, (∇u_h) uniformly converges to ∇u, and $\inf_K \sigma > 0$. Then, Ioffe lower semicontinuity theorem again gives

$$\int_K \sigma^2 |\nabla^2 u|^2 \, dx \le \liminf_{h\to+\infty} \int_K \sigma_h^2 |\nabla^2 u_h|^2 \, dx.$$

Let $\delta > 0$; by Egorov theorem we can cover almost all of $\{\sigma \ge \delta\}$ by an increasing sequence of compact sets on which (σ_h) and (∇u_h) are uniformly converging. As a consequence, the inequality above holds with $\{\sigma \ge \delta\}$ in place of K, and letting $\delta \downarrow 0$ we obtain the lower semicontinuity of the term $\int_\Omega \sigma^2 |\nabla^2 u|^2 \, dx$. □

From the compactness and the lower semicontinuity properties of the functional F_ϵ it follows that for any $\epsilon > 0$ the problem

$$(\mathcal{P}_\epsilon) \qquad \min \{F_\epsilon(u, s, \sigma) : \ (u, s, \sigma) \in \mathcal{D}(\Omega)\}$$

has at least one solution, provided $\gamma > 2$ and $\kappa_\epsilon + \zeta_\epsilon > 0$. Finally, if $\kappa_\epsilon > 0$, the problem $(\mathcal{P}_\epsilon)$ has a solution also in the case $\gamma = 2$.

6. The lower inequality. In this section we prove the lower inequality of Γ-convergence (2.4) and the equicoercivity of the family $(\mathcal{F}_\epsilon)$. In the following it will be convenient also to consider functionals depending on the domain of integration.

The following lower bound for the jump terms in the one-dimensional case has been shown by Bellettini and Coscia in [7, Theorem 3.1].

LEMMA 6.1. *Assume that κ_ϵ, ξ_ϵ, ζ_ϵ are as in Theorem* 3.1 *and $\gamma \ge 2$. Let $I \subset \mathbf{R}$ be a bounded open set and $\epsilon_h \to 0^+$. Then, for every sequence (w_h) converging to w in $[L^1(I)]^3$ as $h \to +\infty$ such that $\mathcal{F}_{\epsilon_h}(w_h)$ is bounded, we have*

$$\begin{aligned} \liminf_{h\to+\infty} [(\alpha - \beta)\mathcal{G}_{\epsilon_h}(s_h, I) + \beta \mathcal{G}_{\epsilon_h}(\sigma_h, I)] &\ge (\alpha - \beta)\mathcal{H}^0(S_u \cap I) \\ &\quad + \beta \mathcal{H}^0\left((S_u \cup S_{u'}) \cap I\right) \ . \end{aligned} \tag{6.1}$$

The condition (3.2) *on ξ_ϵ can be dropped in the case $\alpha = \beta$.*

Since our functionals are slightly different from those in [7], some remarks are necessary. Indeed, the functionals in [7] are given by

$$\begin{aligned} F_\epsilon(u, s, \sigma) = &\int_\Omega (\sigma^2 + \kappa_\epsilon)|\nabla^2 u|^2 \, dx + \mu \int_\Omega |u - g|^2 \, dx + (\alpha - \beta)\mathcal{G}_\epsilon(s) \\ &+ \beta \mathcal{G}_\epsilon(\sigma) + \xi_\epsilon \int_\Omega s^2 |\nabla u|^2 \, dx \ , \end{aligned}$$

hence the differences with respect to ours are two: first they assume that $\zeta_\epsilon = 0$ and $\gamma = 2$ and then they prove the lower bound only in the case when $\kappa_\epsilon > 0$ (hence $u_h \in W^{2,2}(I)$). The assumption that $\zeta_\epsilon = 0$ is not a problem, since smaller functionals are considered, and also a general exponent γ can be considered, provided (3.2) holds. However, for technical reasons related to the proof of the Γ-limsup inequality, in particular, the difficulty in estimating the second derivatives of $u_\epsilon = \psi_\epsilon u$ in the proof of Theorem 3.4 (this can be avoided in the case $n = 1$ using suitable interpolating cubic polynomials), we have preferred a different formulation of the energy in the larger class $\mathcal{D}(\Omega)$, which still provides compactness of minimizing sequences and lower semicontinuity of the energy. Moreover, the proof of the Γ-liminf inequality of Bellettini and Coscia works, essentially with no modification, also for our more general functionals. Notice also that our full Γ-convergence result Theorem 3.3 fits exactly in the Bellettini and Coscia framework.

The reason why no condition on ξ_ϵ (besides $\xi_\epsilon \geq 0$) is necessary in the case $\alpha = \beta$ is that the term $\xi_\epsilon \int s^2 |\nabla u|^\gamma \, dx$ has been added to the energy to force σ_h to tend to zero at least *twice* (paying asymptotically at least $2\beta \geq \alpha$) close to jumps of u if s_h is far away from 0 (if this does not happen and (3.2) holds, then the additional term diverges; see Lemma 3.2(i) of [7]); in the case when $\alpha = \beta$ it is not necessary to force this behavior of σ_h, since σ_h is already forced by the other terms of F_ϵ to tend to zero at least *once* (paying asymptotically at least β) close to jumps of u or of u', regardless of the values of s_h.

Finally, we notice that we can restate (6.1) as follows:

$$\begin{aligned} &\liminf_{h\to+\infty} \left[t\mathcal{F}_{\epsilon_h}(w_h) + (\alpha-\beta)\mathcal{G}_{\epsilon_h}(s_h, I) + \beta \mathcal{G}_{\epsilon_h}(\sigma_h, I) \right] \\ &\geq (\alpha-\beta)\mathcal{H}^0(S_u \cap I) + \beta \mathcal{H}^0\left((S_u \cup S_{u'}) \cap I \right) \qquad \forall t > 0 \, . \end{aligned} \tag{6.2}$$

The advantage of this new formulation is that the a priori assumption that $\mathcal{F}_{\epsilon_h}(w_h)$ is bounded can be dropped.

6.1. Proof of Theorem 3.1. Let $(w_\epsilon) \in \mathcal{D}(\Omega)$, $w \in X(\Omega)$, be such that $w_\epsilon \to w$ in $[L^1(\Omega)]^3$ as $\epsilon \to 0^+$. We assume that

$$+\infty > L = \liminf_{\epsilon\to 0} \mathcal{F}_\epsilon(w_\epsilon, \Omega) = \lim_{h\to+\infty} \mathcal{F}_{\epsilon_h}(w_{\epsilon_h}, \Omega) \, , \tag{6.3}$$

otherwise the result is trivial. For notational simplicity we set $w_{\epsilon_h} = (u_h, s_h, \sigma_h)$ and we assume that w_{ϵ_h} converge a.e. to (u, s, σ) as $h \to +\infty$.

We also assume that (w_h) converges to w fast enough, i.e., $\sum_h \|w_h - w\|_{L^1} < +\infty$. This assumption and Fubini theorem imply (with the notation of section 4)

$$\lim_{h\to\infty} w_{hx} = w_x \quad \text{a.e. in } \Omega_x \qquad\qquad \text{for } \mathcal{H}^{n-1}\text{-a.e. } x \in \Omega_\nu$$

for any direction $\nu \in \mathbf{S}^{n-1}$, and this will be useful in what follows.

If either s or σ were not identically equal to 1, then by the Fatou's lemma we would get

$$L \geq \liminf_{h\to+\infty} \left[(\alpha-\beta) \int_{\{s\neq 1\}} \frac{(s_h-1)^2}{4\epsilon_h} \, dx + \beta \int_{\{\sigma\neq 1\}} \frac{(\sigma_h-1)^2}{4\epsilon_h} \, dx \right] \geq +\infty,$$

which contradicts the assumption that $L < +\infty$. Therefore, we will assume that $s \equiv 1$ and $\sigma \equiv 1$. As before we do not need to consider the function s in the case $\alpha = \beta$.

The proof now follows by proving separately the following inequalities:

$$\liminf_{h\to+\infty} \int_\Omega {\sigma_h}^2 |\nabla^2 u_h|^2 \, dx \geq \int_\Omega |\nabla^2 u|^2 \, dx \ , \tag{6.4}$$

$$\begin{aligned} \liminf_{h\to+\infty} [(\alpha-\beta)\mathcal{G}_{\epsilon_h}(s_h,\Omega) + \beta \mathcal{G}_{\epsilon_h}(\sigma_h,\Omega)] &\geq (\alpha-\beta)\mathcal{H}^{n-1}(S_u) \\ &\quad + \beta \mathcal{H}^{n-1}(S_u \cup S_{\nabla u}) \ . \end{aligned} \tag{6.5}$$

The lower semicontinuity of the term $\int |u-g|^2 \, dx$ with respect to the strong $L^1(\Omega)$ topology then completes the proof.

Possibly extracting a subsequence (this is allowed, since we are assuming that $\mathcal{F}_{\epsilon_h}(w_{\epsilon_h})$ is converging) we can assume that both lim inf in (6.4) and (6.5) are finite limits, denoted by L_1 and L_2, respectively.

We first prove (6.4). Let $\psi(t) = \int_0^t (1-\tau)\, d\tau$; using (6.3) we have

$$\int_\Omega |\nabla \psi(\sigma_h)| \, dx = \int_\Omega |\nabla \sigma_h| (1-\sigma_h) \, dx \leq \int_\Omega \left[\epsilon_h |\nabla \sigma_h|^2 + \frac{(1-\sigma_h)^2}{4\epsilon_h} \right] dx \leq \frac{L+1}{\beta}$$

for h large enough. Then, by the coarea formula (2.2), we have

$$\int_0^{\psi(1)} P(\{\psi(\sigma_h) > t\}, \Omega) \, dt = \int_\Omega |\nabla \psi(\sigma_h)| \, dx \leq \frac{L+1}{\beta}$$

for h large enough. By the Fatou lemma we then get

$$\int_{\psi(a)}^{\psi(1)} \liminf_{h\to+\infty} P(\{\psi(\sigma_h) > t\}, \Omega) \, dt \leq \liminf_{h\to+\infty} \int_\Omega |\nabla \psi(\sigma_h)| \, dx \leq \frac{L+1}{\beta}$$

for any $a \in (0,1)$. Therefore there exists $t_0 = \psi(\theta) \in (\psi(a), \psi(1))$ for some $\theta \in (a,1)$ such that

$$\liminf_{h\to+\infty} P(\{\psi(\sigma_h) > t_0\}, \Omega) \leq l < +\infty \tag{6.6}$$

with $l = (L+1)/[\beta(\psi(1)-\psi(a))]$.

Then, if we set $E_h = \{\sigma_h > \theta\}$, by (6.6) we get $P(E_h, \Omega) \leq l+1$ for infinitely many h; for notational simplicity we will assume in the following that the inequality is true for any h (in the general case a further subsequence must be extracted). By the L^1 convergence of (σ_h) to 1 we obtain

$$\mathrm{meas}(\Omega \setminus E_h) \leq \frac{1}{1-\theta} \int_\Omega (1-\sigma_h) \, dx \to 0 \ .$$

Then we define

$$v_h = u_h 1_{E_h} \ . \tag{6.7}$$

By the locality property (2.1) we get

$$\nabla v_h = 1_{E_h} \nabla u_h \ , \qquad \nabla^2 v_h = 1_{E_h} \nabla^2 u_h$$

for a.e. $x \in \Omega$. Since

$$-N \vee v_h \wedge N = 1_{E_h} [-N \vee u_h \wedge N] \qquad \forall N \in \mathbf{N} \ ,$$

and taking into account that E_h has finite perimeter, from [36, Chapter 4, section 6.4] it follows that $v_h \in GSBV(\Omega)$. Analogously,

$$-N \vee (\nabla_i v_h) \wedge N = 1_{E_h}[-N \vee (\nabla_i u_h) \wedge N] \in SBV_{\rm loc}(\Omega)$$

for any $N \in \mathbf{N}$ and any $i = 1, \dots, n$. Then $v_h \in GSBV^2(\Omega)$ and we have

$$\mathcal{H}^{n-1}(S_{v_h} \cup S_{\nabla v_h}) \le P(E_h, \Omega) \le l + 1 \quad \text{for every } h \in \mathbf{N} \ .$$

Then, since $\sigma_h \ge \theta$ on E_h, the sequence (v_h) satisfies all the assumptions of the compactness Theorem 2.1, hence we can assume (again, possibly passing to a subsequence) that (v_h) converges in $L^1(\Omega)$ to some function $v \in GSBV^2(\Omega)$ with $\nabla v_h \to \nabla v$ a.e. in Ω and $\nabla^2 v_h$ weakly converging to $\nabla^2 v$ in $L^2(\Omega; \mathbf{M}^{n\times n})$. Since (u_h) converges to u in $L^1(\Omega)$ and $\mathrm{meas}(\Omega \setminus E_h) \to 0$, we obtain that $u = v \in GSBV^2(\Omega)$; moreover, by the lower semicontinuity of quadratic forms with respect to weak convergence in L^2 we get

$$L_1 \ge \liminf_{h\to+\infty} \int_{E_h} \theta^2 |\nabla^2 u_h|^2 \, dx = \liminf_{h\to+\infty} \int_\Omega \theta^2 |\nabla^2 v_h|^2 \, dx \ge \int_\Omega \theta^2 |\nabla^2 u|^2 \, dx \ .$$

By letting $a \uparrow 1$ (hence $\theta \to 1$) we obtain (6.4).

The relation (6.5) will be proved using (6.2) and a slicing argument. Let $A \subset \Omega$ be open and $\nu \in \mathbf{S}^{n-1}$ be fixed. By using the notation of section 4 we have

$$\begin{aligned}
\mathcal{G}_{\epsilon_h}(s_h, A) &\ge \int_A \left(\epsilon_h |\langle \nabla s_h, \nu \rangle|^2 + \frac{(s_h - 1)^2}{4\epsilon_h} \right) dx \\
&= \int_{A_\nu} d\mathcal{H}^{n-1}(x) \int_{A_x} \left(\epsilon_h |s'_{hx}|^2 + \frac{(s_{hx} - 1)^2}{4\epsilon_h} \right) dt \\
&= \int_{A_\nu} \mathcal{G}_{\epsilon_h}(s_{hx}, A_x) \, d\mathcal{H}^{n-1}(x) \ .
\end{aligned}$$

An analogous relation holds for $\mathcal{G}_{\epsilon_h}(\sigma_h, A)$ and, taking into account Lemma 4.4, for $\mathcal{F}_{\epsilon_h}(w_h, A)$.

Since w_{hx} converge to w_x in $[L^1(\Omega_x)]^3$ for $\mathcal{H}^{n-1}$-almost every $x \in \Omega_\nu$, by using Fatou's lemma, (6.2), Lemmas 4.1 and 4.4, and eventually Lemma 4.2, we get

$$\begin{aligned}
&\liminf_{h\to+\infty} [t\mathcal{F}_{\epsilon_h}(w_h) + (\alpha - \beta)\mathcal{G}_{\epsilon_h}(s_h, A) + \beta \mathcal{G}_{\epsilon_h}(\sigma_h, A)] \\
&\ge \int_{A_\nu} \liminf_{h\to+\infty} [t\mathcal{F}_{\epsilon_h}(w_{hx}) + (\alpha - \beta)\mathcal{G}_{\epsilon_h}(s_{hx}, A_x) + \beta \mathcal{G}_{\epsilon_h}(\sigma_{hx}, A_x)] \, d\mathcal{H}^{n-1}(x) \\
&\ge (\alpha - \beta) \int_{A_\nu} \mathcal{H}^0(S_{u_x} \cap A_x) \, d\mathcal{H}^{n-1}(x) + \beta \int_{A_\nu} \mathcal{H}^0((S_{u_x} \cup S_{u'_x}) \cap A_x) \, d\mathcal{H}^{n-1}(x) \\
&= (\alpha - \beta) \int_{A_\nu} \mathcal{H}^0((S_u \cap A)_x) \, d\mathcal{H}^{n-1}(x) + \beta \int_{A_\nu} \mathcal{H}^0(((S_u \cup S_{\nabla u \cdot \nu}) \cap A)_x) \, d\mathcal{H}^{n-1}(x) \\
&= \alpha \int_{S_u \cap A} |\langle \nu, \nu_u(x) \rangle| \, d\mathcal{H}^{n-1}(x) + \beta \int_{(S_{\nabla u \cdot \nu} \setminus S_u) \cap A} |\langle \nu, \nu_{\nabla u}(x) \rangle| \, d\mathcal{H}^{n-1}(x)
\end{aligned}$$

for any $t > 0$, where $\nu_u(x)$ and $\nu_{\nabla u}(x)$ are approximate unit normals to S_u and $S_{\nabla u}$, respectively. Since $\mathcal{F}_{\epsilon_h}(w_{\epsilon_h}, \Omega)$ converges to L, then by letting $t \downarrow 0$ we obtain

$$\begin{aligned}
&\liminf_{h\to+\infty} [(\alpha - \beta)\mathcal{G}_{\epsilon_h}(s_h, A) + \beta \mathcal{G}_{\epsilon_h}(\sigma_h, A)] \\
&\quad \ge \alpha \int_{S_u \cap A} |\langle \nu, \nu_u(x) \rangle| \, d\mathcal{H}^{n-1}(x) + \beta \int_{(S_{\nabla u \cdot \nu} \setminus S_u) \cap A} |\langle \nu, \nu_{\nabla u}(x) \rangle| \, d\mathcal{H}^{n-1}(x) \ .
\end{aligned} \tag{6.8}$$

We now apply Lemma 2.2 in the following framework:

- $f_\nu(x) = \alpha|\langle \nu, \nu_u(x)\rangle| 1_{S_u} + \beta|\langle \nu, \nu_{\nabla u}(x)\rangle| 1_{S_{\nabla u\cdot\nu}\setminus S_u}$,
- $\mu = \mathcal{H}^{n-1}\lfloor(S_u \cup S_{\nabla u})$,

with ν varying in a countable dense subset D of $\mathbf{S}^{n-1}$. Since $\sup_{\nu\in D} f_\nu = \alpha 1_{S_u} + \beta 1_{S_{\nabla u}\setminus S_u}$ (because any $x \in S_{\nabla u}$ belongs to $S_{\nabla u\cdot\nu}$ provided $\langle \nu, \nabla^+ u(x) - \nabla^- u(x)\rangle \neq 0$), by Lemma 2.2 we have that

$$(\alpha-\beta)\mathcal{H}^{n-1}(S_u) + \beta\mathcal{H}^{n-1}(S_u \cup S_{\nabla u})$$

is equal to the supremum of

$$\sum_{i=1}^k \left\{ \alpha \int_{S_u\cap A_i} |\langle \nu_i, \nu_u(x)\rangle|\, d\mathcal{H}^{n-1}(x) + \beta \int_{(S_{\nabla u\cdot\nu_i}\setminus S_u)\cap A_i} |\langle \nu_i, \nu_{\nabla u}(x)\rangle|\, d\mathcal{H}^{n-1}(x) \right\}$$

among all finite families (A_i, ν_i) with $\nu_i \in D$ and $A_i \subset \Omega$ open and pairwise disjoint. By (6.8) and the superadditivity of the lim inf operator, any of these sums is less than L_2, whence the inequality (6.5) follows (see also [5]). □

6.2. Proof of Theorem 3.2. By the equiboundedness of $\mathcal{F}_\epsilon(w_\epsilon)$ it follows as before that $(s_\epsilon, \sigma_\epsilon) \to (1,1)$ in $[L^1(\Omega)]^2$ as $\epsilon \to 0^+$.

Reasoning as in the proof of (6.4) of Theorem 3.1 we can find a sequence $\epsilon_h \to 0^+$ and measurable sets E_h such that $\mathrm{meas}(\Omega \setminus E_h) \to 0$ and $v_{\epsilon_h} = u_{\epsilon_h} 1_{E_h}$ converge in $L^1(\Omega)$ to $u \in GSBV^2(\Omega) \cap L^2(\Omega)$. Since (u_ϵ) is equibounded in $L^2(\Omega)$, by Hölder inequality $\|u_{\epsilon_h} - v_{\epsilon_h}\|_{L^1} \to 0$ as $h \to +\infty$, hence $u_{\epsilon_h} \to u$ in $L^1(\Omega)$. □

7. The upper inequality.

7.1. Proof of Theorem 3.3. We can assume without losing generality that $u \in GSBV^2(\Omega) \cap L^2(\Omega)$, $|\nabla^2 u| \in L^2(\Omega)$, and $\sigma \equiv 1$. Since we are assuming that $\alpha = \beta$ we simply set $s_\epsilon \equiv 1$ for any $\epsilon > 0$. We construct a family u_ϵ converging to u in $L^2(\Omega)$, so that we can neglect the term $\mu \int |u-g|^2\, dx$, which is continuous with respect to the strong $L^2(\Omega)$ topology, and we then assume $\mu = 0$.

Assuming that Ω is star-shaped with respect to the origin, we set $\Omega_t = t\Omega$ with $t \in (0,1)$ and construct a family $w_\epsilon = (u_\epsilon, s_\epsilon, \sigma_\epsilon) \in \mathcal{D}(\Omega_t)$ such that (as in the previous section we emphasize the dependence on the domain of integration)

$$\limsup_{\epsilon\to 0^+} \mathcal{F}_\epsilon(w_\epsilon, \Omega_t) \le \mathcal{F}(w, \Omega)\ . \tag{7.1}$$

Then, the functions $w_{\epsilon,t}(x) = w_\epsilon(tx)$ belong to $\mathcal{D}(\Omega)$ and satisfy

$$\limsup_{\epsilon\to 0^+} \mathcal{F}_\epsilon(w_{\epsilon,t}, \Omega) \le t^{-n}\mathcal{F}(w, \Omega)\ ,$$

hence the desired family of the Γ-limsup inequality can be constructed by a diagonal argument by letting $t \uparrow 1$.

In order to construct the family (w_ϵ) satisfying (7.1) we follow the outline of [6], assuming first that

$$\mathcal{M}^*\left((S_u \cup S_{\nabla u}) \cap K\right) = \mathcal{H}^{n-1}\left((S_u \cup S_{\nabla u}) \cap K\right) \text{ for any } K \subset \Omega \text{ compact}\ . \tag{7.2}$$

We restrict our choice to the functions u_ϵ and σ_ϵ that, outside a tubular neighborhood of $S_u \cup S_{\nabla u}$, with radius depending on ϵ, are, respectively, equal to u and 1.

Setting $\tilde{S}_u = S_u \cup S_{\nabla u}$ and $\tau(x) = \operatorname{dist}(x, \tilde{S}_u)$, by the interpolation inequality (4.2) we obtain a constant C depending only on u such that

$$\int_{\Omega_t \setminus (\tilde{S}_u)_r} |\nabla u|^2 \, dx \le C r^{-2} \tag{7.3}$$

for any r sufficiently small. In view of our assumption on κ_ϵ, we can find an infinitesimal b_ϵ faster than ϵ such that $\kappa_\epsilon = o(b_\epsilon^4)$ (for instance, $b_\epsilon = (\epsilon \kappa_\epsilon^{1/4})^{1/2}$), and an infinitesimal η_ϵ faster than $\sqrt{\epsilon}$ such that $a_\epsilon = -2\epsilon \ln \eta_\epsilon$ is infinitesimal (for instance, $\eta_\epsilon = \epsilon$).

With this choice of infinitesimals, we then define

$$\sigma_\epsilon(x) = \begin{cases} 0 & \text{if } x \in (\tilde{S}_u)_{b_\epsilon}, \\ 1 - \eta_\epsilon & \text{if } x \in \Omega_t \setminus (\tilde{S}_u)_{a_\epsilon + b_\epsilon} \ . \end{cases}$$

Let now y_ϵ be the solution of the Cauchy problem

$$\dot{y}(t) = \frac{1 - y}{2\epsilon}, \qquad y(b_\epsilon) = 0,$$

that is, $y_\epsilon(t) = 1 - \exp\left[(b_\epsilon - t)/(2\epsilon)\right]$. We complete the definition of σ_ϵ by setting

$$\sigma_\epsilon(x) = y_\epsilon \circ \tau(x) \qquad \text{if } x \in (\tilde{S}_u)_{a_\epsilon + b_\epsilon} \setminus (\tilde{S}_u)_{b_\epsilon} \ .$$

Now we turn to the choice of u_ϵ. To this aim, we build a smooth function $\psi_\epsilon : \Omega \to [0,1]$ such that $\psi_\epsilon = 0$ in $\{\tau \le b_\epsilon/2\}$, $\psi_\epsilon = 1$ in $\{\tau \ge b_\epsilon\}$, and $|\nabla \psi_\epsilon| = O(1/b_\epsilon)$, $|\nabla^2 \psi_\epsilon| = O(1/b_\epsilon^2)$. Taking into account that $|\nabla \tau| = 1$ a.e., a function ψ_ϵ with the required properties can be built as $(\chi \circ \tau) * \rho$, where ρ is a convolution kernel with diameter $b_\epsilon/3$ and $\chi(s) = [0 \vee (6s/b_\epsilon - 4) \wedge 1]$. The assumptions on u and the interpolation inequality (4.2) yield

$$u \in W^{2,2}_{\mathrm{loc}}(\Omega \setminus \overline{\tilde{S}_u}) \ ,$$

so that, if we set $u_\epsilon = u\psi_\epsilon$, we have $u_\epsilon \in W^{2,2}(\Omega_t)$.

With these choices, we get

$$\mathcal{F}_\epsilon(w_\epsilon, \Omega_t) = \int_{\Omega_t} (\sigma_\epsilon^2 + \kappa_\epsilon) |\nabla^2 u_\epsilon|^2 \, dx \tag{7.4}$$

$$+\beta \mathcal{G}_\epsilon(\sigma_\epsilon, \Omega_t \cap ((\tilde{S}_u)_{a_\epsilon + b_\epsilon} \setminus (\tilde{S}_u)_{b_\epsilon})) \tag{7.5}$$

$$+\beta \frac{\operatorname{meas}(\Omega_t \cap (\tilde{S}_u)_{b_\epsilon})}{4\epsilon} \tag{7.6}$$

$$+\beta \frac{\eta_\epsilon^2}{4\epsilon} \operatorname{meas}(\Omega_t \setminus (\tilde{S}_u)_{a_\epsilon + b_\epsilon}) \ . \tag{7.7}$$

Since $u_\epsilon \equiv u$ on $\{\sigma_\epsilon > 0\}$ (because $\psi_\epsilon \equiv 1$ on $\{\tau \ge b_\epsilon\} \supset \{\sigma_\epsilon > 0\}$), the upper limit of the term in (7.4) does not exceed

$$\int_\Omega |\nabla^2 u|^2 \, dx + \limsup_{\epsilon \to 0^+} \kappa_\epsilon \int_{\Omega_t \cap \{b_\epsilon/2 \le \tau \le b_\epsilon\}} |\nabla^2 u_\epsilon|^2 \, dx \ .$$

Taking into account (7.3), the identity

$$\nabla^2 u_\epsilon = \psi_\epsilon \nabla^2 u + 2\nabla\psi_\epsilon \otimes \nabla u + u\nabla^2\psi_\epsilon \ ,$$

and our choice of b_ϵ we obtain that the lim sup above is zero.

Concerning the term in (7.5), from the proof of Theorem 3.1 of [6] it follows that its upper limit does not exceed $\beta\mathcal{M}^*(\tilde{S}_u \cap \overline{\Omega}_t)$; by (7.2) we obtain that the upper limit is less than $\beta\mathcal{H}^{n-1}(\tilde{S}_u)$.

The term in (7.6) is infinitesimal because the Minkowski content is finite and $b_\epsilon = o(\epsilon)$, and similarly the term in (7.7) is infinitesimal because $\eta_\epsilon^2 = o(\epsilon)$.

This proves, under the additional assumption (7.2), the existence of a family (w_ϵ) satisfying (7.1). The assumption can be removed as follows. Consider for any $\lambda > 0$ the penalized problem

$$\min\left\{\int_\Omega \left(|\nabla^2 v|^2 + \lambda|v-u|^2\right)\, dx + \beta\mathcal{H}^{n-1}\left(S_v \cup S_{\nabla v}\right) :\ v \in GSBV^2(\Omega) \cap L^2(\Omega)\right\}\ ,$$

and let u_λ be a minimizer (see [12]). Notice that $\overline{F}(u_\lambda) \le \overline{F}(u) < +\infty$, hence $u_\lambda \to u$ as $\lambda \to +\infty$. Then, it has been proved in [14] that any function u_λ fulfills (7.2), and therefore a family (w_ϵ) satisfying (7.1) for $(u,1,1)$ can be obtained from those already constructed for $(u_\lambda,1,1)$ by a diagonal argument. □

7.2. Proof of Theorem 3.4. Since the proof is similar to that of Theorem 3.3 we sketch only the relevant differences. The function σ_ϵ is defined in the same way and s_ϵ is constructed analogously in a tubular neighborhood of S_u. Let $\tau_1(x) = \mathrm{dist}(x, S_u)$. In order to construct u_ϵ we fix some smooth function ψ_ϵ such that $\psi_\epsilon = 0$ in $\{\tau_1 \le b_\epsilon/2\}$, $\psi_\epsilon = 1$ in $\{\tau_1 \ge b_\epsilon\}$, and $|\nabla\psi_\epsilon| = O(1/b_\epsilon)$. The assumptions on u yield $u \in W^{1,\gamma}(\Omega \setminus \overline{S}_u)$, so that setting $u_\epsilon = u\psi_\epsilon$ we have $u_\epsilon \in W^{1,\gamma}(\Omega)$ and $\sigma_\epsilon \nabla u_\epsilon \in W^{1,p}(\Omega;\mathbf{R}^n)$.

The cut-off function ψ_ϵ is built only in the tubular neighborhood of S_u, otherwise the term $\xi_\epsilon \int (s_\epsilon^2 + \zeta_\epsilon)|\nabla u_\epsilon|^\gamma dx$ cannot be controlled in the neighborhood of $S_{\nabla u} \setminus S_u$. Then we must set $\kappa_\epsilon = 0$ otherwise $\mathcal{F}_\epsilon(w_\epsilon)$ is not finite.

With these choices the estimates proceed in the same way as in the proof of Theorem 3.3 taking into account that the upper limit of the term $\xi_\epsilon \int (s_\epsilon^2+\zeta_\epsilon)|\nabla u_\epsilon|^\gamma dx$ does not exceed

$$\xi_\epsilon \int_\Omega |\nabla u|^\gamma\, dx + \limsup_{\epsilon\to 0^+} \xi_\epsilon\zeta_\epsilon \int_{\Omega\cap\{b_\epsilon/2 \le \tau_1 \le b_\epsilon\}} |\nabla u_\epsilon|^\gamma\, dx\ .$$

In view of the assumption on $\xi_\epsilon\zeta_\epsilon$, we can find an infinitesimal b_ϵ faster than ϵ such that $\xi_\epsilon\zeta_\epsilon = o(b_\epsilon^{\gamma-1})$, for instance, $b_\epsilon = (\epsilon(\xi_\epsilon\zeta_\epsilon)^{\frac{1}{\gamma-1}})^{1/2}$, so that the lim sup above is zero. □

8. An application to the computation of depth from stereo images. The Γ-convergent approximation has been experimented on the problem of computation of depth from a pair of stereo images for the purpose of illustration. In the following Ω denotes the open set $(0,1)\times(0,1)$ of $\mathbf{R}^2$, and $x = (x_1, x_2)$. In the case of parallel camera geometry [22] we choose the expression of the function $\Phi(x,u)$ used in [23, 24, 25]:

$$\Phi(x,u) = \mu\left[L(x_1,x_2) - R(x_1+u,x_2)\right]^2\ ,$$

where u is the disparity function, $\mu > 0$ is a parameter, and R, L are bounded continuous functions corresponding to the right and left image intensities. Depth is

inversely proportional to disparity. The Γ-convergence theorem may be applied if the functions R and L satisfy the conditions of the Remark 3.5, which can be fulfilled, for instance, by means of a convolution of the image intensities with a smooth kernel having a suitably small diameter. For the purpose of illustration we set $\gamma = 2$.

A simple discretization method, commonly used for computer vision problems [35], may be applied to the functionals $\mathcal{F}_\epsilon$ in a straightforward way. Discrete versions of u, s, and σ are defined on a square lattice of coordinates (ih, jh), where $h = 1/(N-1)$, $0 \le i \le N-1$, $0 \le j \le N-1$. We denote by $u^h_{i,j}$, $s^h_{i,j}$, and $\sigma^h_{i,j}$, an approximation of $u(ih, jh)$, $s(ih, jh)$, and $\sigma(ih, jh)$, respectively. We denote by $u^h, s^h, \sigma^h \in \mathbf{R}^{N^2}$ the vectors of the discrete variables. Then we set $\kappa_\epsilon = 0$, $\zeta_\epsilon > 0$, and we discretize

$$\mathcal{F}^1_\epsilon(u, s, \sigma) = \int_\Omega \sigma^2 |\nabla^2 u|^2 \, dx + \xi_\epsilon \int_\Omega (s^2 + \zeta_\epsilon) |\nabla u|^2 \, dx$$

by

$$\begin{aligned} \mathcal{F}^1_{\epsilon,h}(u^h, s^h, \sigma^h) = \sum_{i,j} \Bigg\{ & (\sigma^h_{i,j})^2 \frac{1}{h^2} \left[(u^h_{i+1,j} - 2u^h_{i,j} + u^h_{i-1,j})^2 \right. \\ & + 2(u^h_{i+1,j+1} - u^h_{i,j+1} - u^h_{i+1,j} + u^h_{i,j})^2 \\ & \left. + (u^h_{i,j+1} - 2u^h_{i,j} + u^h_{i,j-1})^2 \right] \\ & + \xi_\epsilon ((s^h_{i,j})^2 + \zeta_\epsilon) \left[(u^h_{i+1,j} - u^h_{i,j})^2 + (u^h_{i,j+1} - u^h_{i,j})^2 \right] \Bigg\}. \end{aligned} \tag{8.1}$$

We set

$$\mathcal{F}^2_\epsilon(s, \sigma) = (\alpha - \beta) \mathcal{G}_\epsilon(s) + \beta \mathcal{G}_\epsilon(\sigma) \ ,$$

and we discretize $\mathcal{G}_\epsilon(s)$ by

$$\mathcal{G}_{\epsilon,h}(s^h) = \sum_{i,j} \left\{ \epsilon \left[(s^h_{i+1,j} - s^h_{i,j})^2 + (s^h_{i,j+1} - s^h_{i,j})^2 \right] + \frac{h^2}{4\epsilon} (s^h_{i,j} - 1)^2 \right\} \ , \tag{8.2}$$

and analogously for $\mathcal{G}_\epsilon(\sigma)$. Then we set

$$\mathcal{F}^3(u) = \mu \int_\Omega \left[L(x_1, x_2) - R(x_1 + u(x_1, x_2), x_2) \right]^2 \, dx \ ,$$

which is discretized by

$$\mathcal{F}^3_h(u^h) = \mu \sum_{i,j} h^2 \left(L^h_{i,j} - R^h_{i+u^h_{i,j},j} \right)^2 \ , \tag{8.3}$$

where $R^h_{i,j}$, $L^h_{i,j}$ denote an approximation of $R(ih, jh)$, $L(ih, jh)$ and, since $u^h_{i,j}$ is generally not an integer, the discretization of R is computed by means of a linear interpolation. We set

$$\mathcal{F}_{\epsilon,h}(u^h, s^h, \sigma^h) = \mathcal{F}^1_{\epsilon,h}(u^h, s^h, \sigma^h) + \mathcal{F}^2_{\epsilon,h}(s^h, \sigma^h) + \mathcal{F}^3_h(u^h) \ .$$

In order to recover a stable solution, the grid must resolve the width of the transition region of the functions s and σ. Then the discretization step should be

at least $h = o(\epsilon)$ as it has been shown in [8] for the discretization of the Ambrosio and Tortorelli approximating functionals. A global solution of the discrete nonconvex variational problem could be computed by means of a stochastic optimization method. However, we use a faster deterministic continuation procedure in which α and β are considered as continuation variables [35]. The functional $\mathcal{F}_\epsilon^1 + \mathcal{F}_\epsilon^2$ becomes increasingly convex for larger values of these variables. Then a solution of the system of equations

$$\nabla \mathcal{F}_{\epsilon,h}(u^h, s^h, \sigma^h) = 0$$

is computed by using a nonlinear Gauss–Seidel iterative method, with α and β initially set to high values, then gradually lowered. The continuation procedure yields experimental good, although not globally optimal, solutions. The parameters α and β are lowered according to the rule

$$\alpha^{(k)} = \alpha_0 (c)^k, \qquad \beta^{(k)} = \beta_0 (c)^k, \tag{8.4}$$

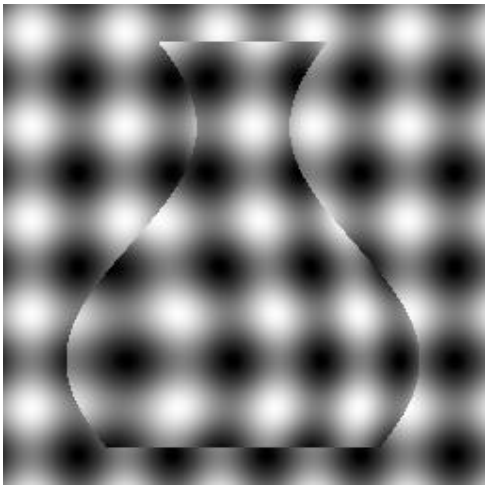
where α_0, β_0 are the initial values, $c < 1$ is a real positive number, and each step k of the continuation procedure consists of 32 nonlinear Gauss–Seidel iterations.

The Γ-convergence theorem and the continuation algorithm have been experimented on synthetic stereo pairs of images corresponding to simple patterns. The images are discretized with N=256. The brightness patterns of all the surfaces represented in the synthetic images are linear combinations of spatially orthogonal sinusoids. The spatial frequency of the sinusoids is chosen to give a reasonably strong brightness gradient such as that usually required for binocular stereo matching (see also March [23, 24, 25]). The range of brightness values for L, R is [0,255]. Depth has to be recovered from the local geometrical distortion of the brightness pattern in the left image relative to the one in the right image. The periodicity of the brightness pattern causes further difficulties to the problem of recovering disparity because of the presence of many ambiguous corresponding points in the two images.

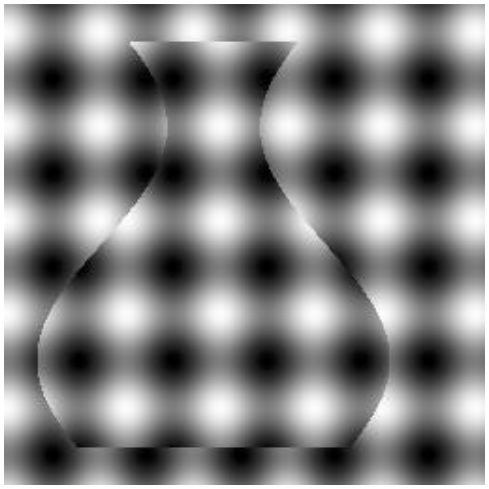
The algorithm was started with an initial estimate of the disparity function u equal to a constant value, and setting the functions σ, s equal to 1 everywhere. The values of the parameters in the functional were chosen on the basis of the results of a number of experiments.

Figures 1(a) and 1(b) show the two images L and R of a stereo pair representing an object shaped as a revolution surface and portrayed against a plane background. The value of disparity ranges from 14 to 32 pixels ($14h \le u \le 32h$). The stereo disparity u in the images of Figures 1(a) and 1(b) is discontinuous along the occluding boundary between the curved surface and the plane background. The function u has no creases in this example.

We set $\sqrt{\mu} = 26$ and $c = 0.8$ in (8.4). The continuation procedure is iterated for 43 steps (1376 total Gauss–Seidel iterations) and the final values of the parameters are $\alpha = 37$, $\beta = 32.7$. Figure 2(a) shows the function σ computed with $\epsilon = 2 \cdot 10^{-2}$, and Figure 2(b) shows the same function computed with $\epsilon = 1.3 \cdot 10^{-2}$. Figure 3(a) shows the function σ computed with $\epsilon = 6.5 \cdot 10^{-3}$: in this case σ reaches values of order 10^{-5} along the discontinuity set of u. In the figures representing the functions σ and s by means of grey values, white corresponds to 0 and black corresponds to 1. The figures show the convergence of the functions σ_ϵ towards the discontinuity set of the disparity u as ϵ decreases, thus illustrating the behavior of Γ-convergence in this specific example. Figure 3(b) shows the function s computed with $\epsilon = 6.5 \cdot 10^{-3}$. Because of the presence of the factor ξ_ϵ converging to zero, the values of the functions s_ϵ might approach zero more slowly than the functions σ_ϵ as ϵ tends to zero.



(a) L image of a synthetic stereo pair (only jumps).



(b) R image of a synthetic stereo pair (only jumps).

FIG. 1.

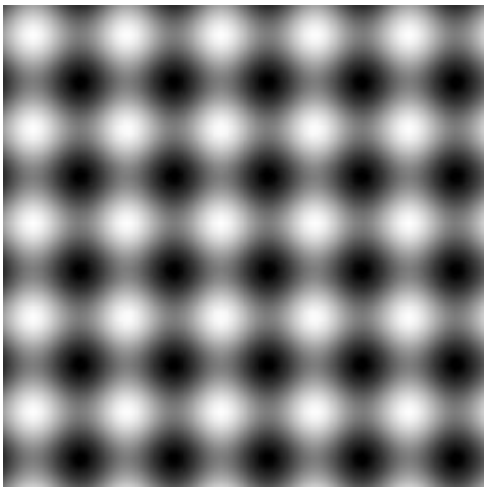
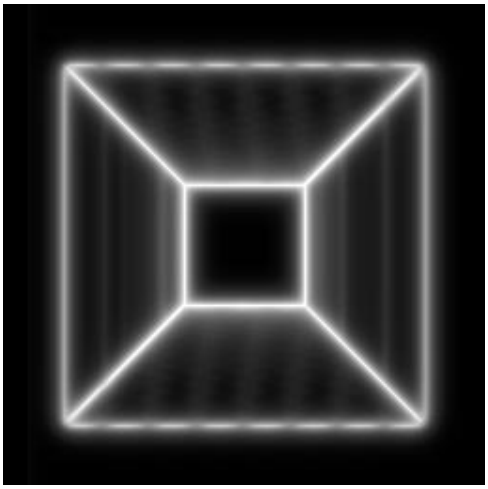
(a) L image of a synthetic stereo pair (only creases).

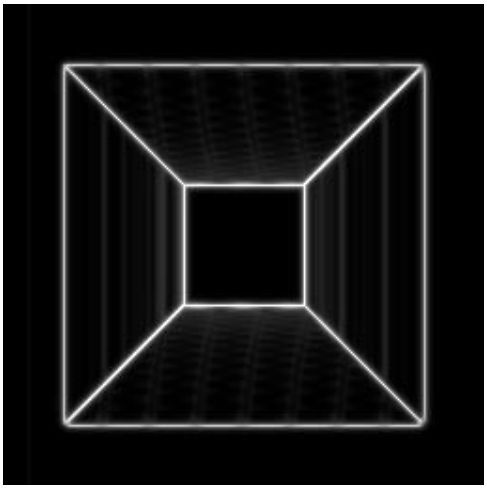


(b) R image of a synthetic stereo pair (only creases).

FIG. 5.



(a) The function σ computed with $\epsilon = 8.0 \cdot 10^{-3}$.



(b) The function σ computed with $\epsilon = 2.0 \cdot 10^{-3}$.

FIG. 6.

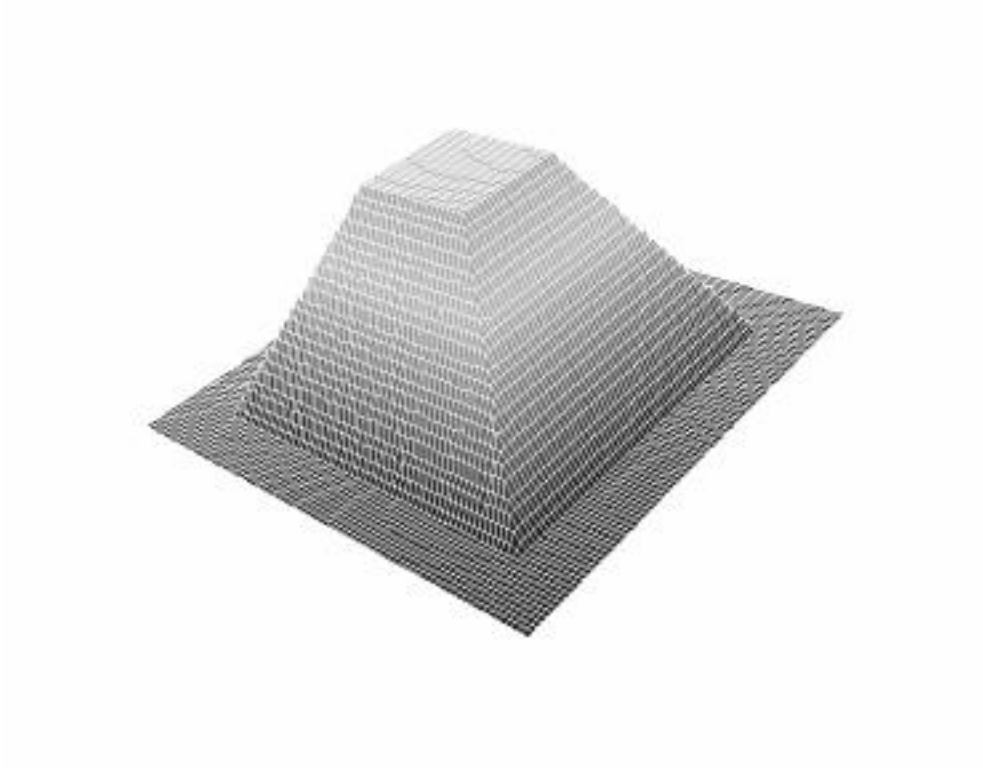


FIG. 7. *Surface with creases recovered from the stereo pair* 5(a), (b).

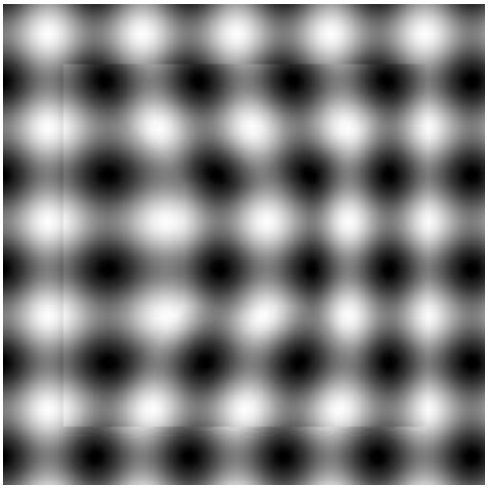
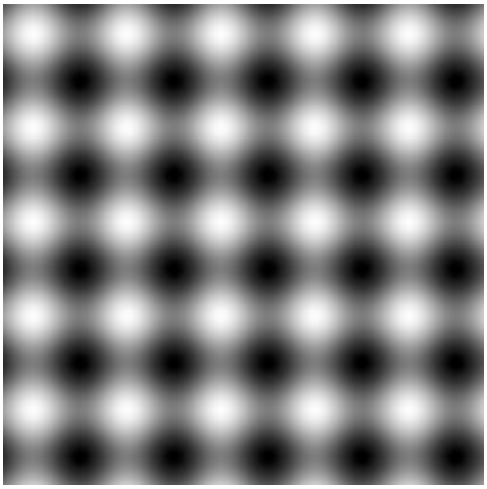
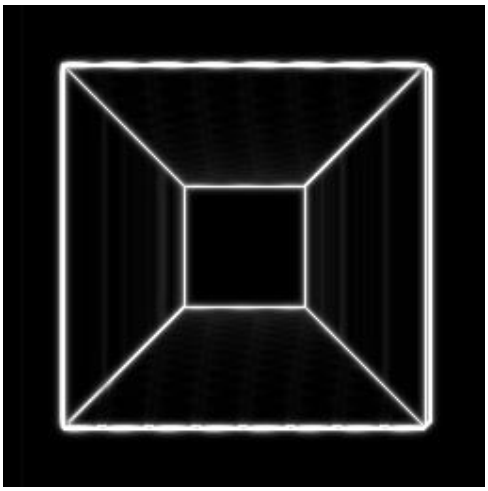


(a) L image of a synthetic stereo pair (jumps+creases).

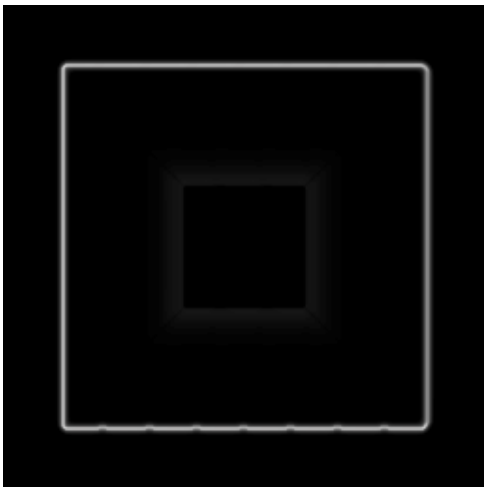


(b) R image of a synthetic stereo pair (jumps+creases).

FIG. 8.



(a) The function σ computed with $\epsilon = 2.0 \cdot 10^{-3}$.



(b) The function s computed with $\epsilon = 2.0 \cdot 10^{-3}$.

FIG. 9.

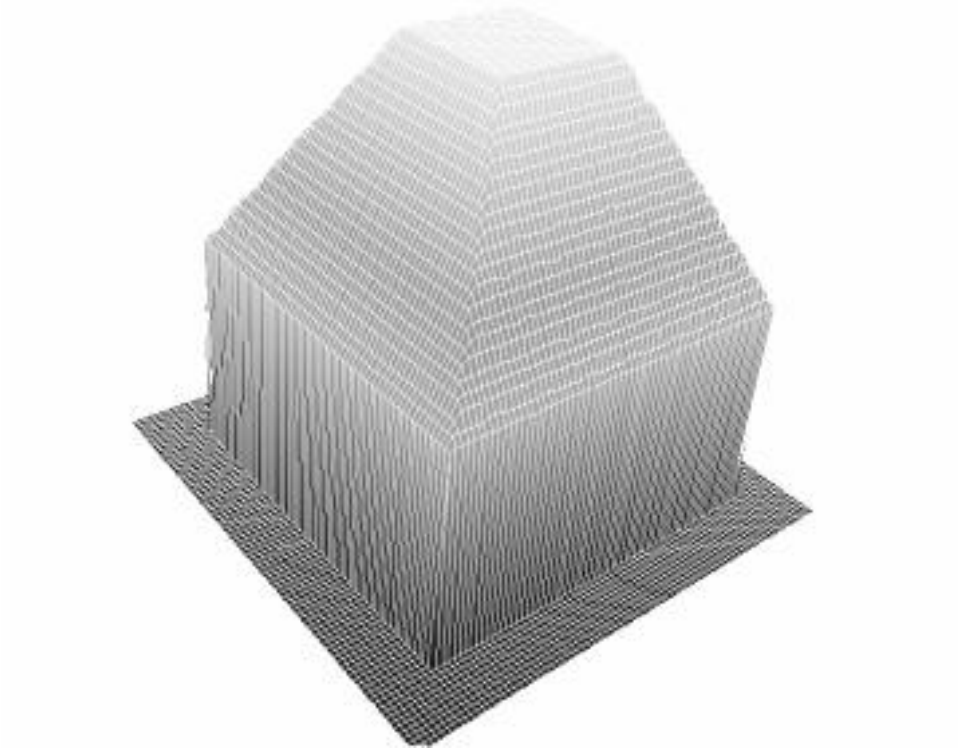


FIG. 10. *Surface with jumps and creases recovered from the stereo pair* 8(a), (b).

For instance, in the present example s reaches the value of $6 \cdot 10^{-2}$, but takes values between 0.3 and 0.7 along some portions of the discontinuity contour. Finally, Figure 4 shows the surfaces corresponding to the disparity map recovered from the stereo pair. The discontinuity set is correctly reconstructed along the occluding contour.

Figures 5(a) and 5(b) show the images L, R of a stereo pair representing a truncated pyramid laid upon a plane background. Disparity ranges from 12 to 24 pixels ($12h \le u \le 24h$) and, in this example, the function u has creases and no jumps.

We set $\sqrt{\mu} = 47$ and $c = 0.76$. The continuation procedure consists of 45 steps (1440 total Gauss–Seidel iterations) and the final values of the parameters are $\alpha = 14.6$, $\beta = 7.3$. Figure 6(a) shows the function σ computed with $\epsilon = 8 \cdot 10^{-3}$. Figure 6(b) shows σ computed with $\epsilon = 2 \cdot 10^{-3}$: in this case σ reaches values of order either 10^{-3} or 10^{-2} along the set of creases of u. The figures show the capability of Γ-convergence in the localization of the creases.

Figure 7 shows the surface recovered from the stereo pair with the creases correctly reconstructed.

Figures 8(a) and 8(b) show the last stereo pair used in the computer experiments which is obtained from the previous one by introducing a jump between the truncated pyramid and the plane background. Disparity ranges from 8 to 24 pixels ($8h \le u \le 24h$). In this example the function u has both creases and jumps.

We set $\sqrt{\mu} = 47$ and $c = 0.76$. The continuation procedure consists of 43 steps (1376 Gauss–Seidel iterations) and the final values of the parameters are $\alpha = 14.3$, $\beta = 12.6$. Figures 9(a) and 9(b) show, respectively, the functions σ and s computed with $\epsilon = 2 \cdot 10^{-3}$. The function σ reaches values of order 10^{-5} along the jumps, and of order 10^{-2} along the creases, while s is about 0.3 along the jumps. Finally, Figure 10 shows the surfaces corresponding to the disparity map recovered from the stereo pair. Both discontinuities and gradient discontinuities are reconstructed.

Acknowledgments. The authors wish to thank an anonymous referee for the careful review of the paper which improved the presentation. The third author wishes to thank Dr. Mario Rosati for many discussions.

HOMOGENIZATION OF THIN STRUCTURES BY TWO-SCALE METHOD WITH RESPECT TO MEASURES*

GUY BOUCHITTÉ† AND ILARIA FRAGALÀ‡

Abstract. To the aim of studying the homogenization of low-dimensional periodic structures, we identify each of them with a periodic positive measure μ on $\mathbb{R}^n$. We introduce a new notion of two-scale convergence for a sequence of functions $v_\varepsilon \in L^p_{\mu_\varepsilon}(\Omega;\mathbb{R}^d)$, where Ω is an open bounded subset of $\mathbb{R}^n$, and the measures μ_ε are the ε-scalings of μ, namely, $\mu_\varepsilon(B) := \varepsilon^n \mu(\varepsilon^{-1}B)$. Enforcing the concept of tangential calculus with respect to measures and related periodic Sobolev spaces, we prove a structure theorem for all the possible two-scale limits reached by the sequences $(u_\varepsilon, \nabla u_\varepsilon)$ when $\{u_\varepsilon\} \subset \mathcal{C}^1_0(\Omega)$ satisfy the boundedness condition $\sup_\varepsilon \int_\Omega |u_\varepsilon|^p + |\nabla u_\varepsilon|^p \, d\mu_\varepsilon < +\infty$ and when the measure μ satisfies suitable connectedness properties. This leads us to deduce the homogenized density of a sequence of energies of the form $\int_\Omega j(\frac{x}{\varepsilon}, \nabla u)\, d\mu_\varepsilon$, where $j(y,z)$ is a convex integrand, periodic in y, and satisfying a p-growth condition. The case of two parameter integrals is also investigated, in particular for what concerns the commutativity of the limit process.

Key words. thin structures, homogenization, two-scale convergence, tangential calculus with respect to periodic measures, connectedness

1. Introduction.

For a given periodic Radon measure μ on $\mathbb{R}^n$, we study the asymptotic behavior of a sequence of functionals of the form

$$J_\varepsilon(u) := \int_\Omega j\left(\frac{x}{\varepsilon}, \nabla u\right) d\mu_\varepsilon \ , \qquad u \in \mathcal{C}^1_0(\Omega) \ , \tag{1.1}$$

where Ω is a bounded open subset of $\mathbb{R}^n$, the integrand $j = j(y,z)$ is assumed to be periodic μ-measurable in y and convex with a p-growth condition in z, ε is a positive parameter tending to zero, and μ_ε is the rescaled measure $\mu_\varepsilon(B) := \varepsilon^n \mu\big(\frac{B}{\varepsilon}\big)$.

We think of μ as the Hausdorff measure $\mathcal{H}^k$ on a k-dimensional periodic domain of $\mathbb{R}^n$: when the small parameter ε tends to zero, we recover by this way the classical framework of homogenization on perforated domains (when $k = n$), or on reticulated thin elastic structures (when $k < n$) (see [5] for an introduction to the subject). Actually, for an assigned continuous bounded function f on Ω, the minimum problem

$$\inf\left\{ J_\varepsilon(u) - \int_\Omega f u \, d\mu_\varepsilon \ : \ u \in \mathcal{C}^1_0(\Omega) \right\} \tag{$\mathcal{P}_\varepsilon$}$$

is the variational counterpart of an elliptic equation posed, with boundary conditions, on an ε-periodic domain. For instance, in the case when μ is the Lebesgue measure on a perforated domain, the choice of a quadratic energy density $j(y,z) = \frac{1}{2}\sum_{1\le i,j\le n} a_{i,j}(y) z_i z_j$, where $\mathcal{A}(y) = a_{i,j}(y)$ is a symmetric matrix of periodic and

bounded coefficients, has been intensively studied in the literature (see [14], [25], [9]). More precisely, the classical setting corresponds to the choice $\mu = \mathcal{L}^n \llcorner A$, where A is the complement of a periodic system of holes; denoting by A_ε the set εA, occupied by the material and by T_ε the collection of holes $A \setminus A_\varepsilon$, the minimum problem $(\mathcal{P}_\varepsilon)$ corresponds in this case to the system

$$(\mathcal{S}_\varepsilon) \qquad \begin{cases} -\operatorname{div}\left(\mathcal{A}(\frac{x}{\varepsilon})\nabla u_\varepsilon\right) = f & \text{in } A_\varepsilon, \\ u_\varepsilon = 0 & \text{on } \partial\Omega, \\ \dfrac{\partial u_\varepsilon}{\partial n} = 0 & \text{on } \partial T_\varepsilon. \end{cases}$$

Under suitable geometric assumptions on T_ε , the behavior of $(\mathcal{S}_\varepsilon)$ when $\varepsilon \to 0$ is well known (see, for instance, [16]) and gives rise to a limit problem of the same type, $-\operatorname{div}(\mathcal{A}_{\text{eff}}\nabla u) = f$; the constant matrix $\mathcal{A}_{\text{eff}}$ represents the physical characteristics of a homogenized material which macroscopically behaves like the inhomogeneous perforated body as $\varepsilon \to 0$.

The same is the essence of homogenization in the case of thin periodic structures, except that another parameter δ must be considered, which corresponds to the thickness of the region occupied by the material; thus, a double passage to the limit is needed, as the small parameters ε and δ both tend to zero [17], [3], [15], [18]. For instance, the case of a one-dimensional ε-periodic structure εS, reinforced by some material distributed along bars of cross-section δ, corresponds in our framework to the choice $\mu = \mathcal{H}^1 \llcorner S$, and possibly to $\mu_\delta = |S_\delta|^{-1}\mathcal{L}^n \llcorner S_\delta$, being $S_\delta := \{x \in \mathbb{R}^n : \operatorname{dist}(x, S) \le \delta\}$.

The classical approach to this kind of problem is based on the possibility of defining a suitable extension of the solution u_ε of each elliptic problem such as $(\mathcal{S}_\varepsilon)$ to the whole $\mathbb{R}^n$ [16], [23]; this assumption strongly depends on the shape of the domain under consideration, so that the proof technique must be adapted in each case.

Here we adopt a different point of view, in order to study the Γ-convergence of the functionals J_ε defined in (1.1). This seems to be an unifying approach for structures of arbitrary dimension, as well as for structures containing junctions between parts of different dimensions (see [18]). We represent the structure by general periodic Radon measure μ and we make use of the tangential calculus with respect to μ, which has been developed in some recent papers [7], [6]. In particular, we introduce a notion of two-scale convergence with respect to measures, which generalizes the method proposed in [26], [1], [2]; we prove a structure result for the two-scale possible limits of a sequence $\{(u_\varepsilon, \nabla u_\varepsilon)\}$, when $u_\varepsilon \in \mathcal{C}_0^1(\Omega)$ satisfy the uniform estimate $\int (|u_\varepsilon|^p + |\nabla u_\varepsilon|^p)\, d\mu_\varepsilon \le M$ (see Theorem 4.2). This allows us to deduce the homogenized energy density associated with J_ε in terms of a local unit-cell problem (see Theorem 5.2); further, when fattened stuctures are considered, the limit process as the two parameters ε (of periodicity) and δ (of thickness) tend to zero, can be shown to be commutative (see Theorem 6.1 and Remark 6.2).

Our main assumptions involve some concepts of *connectedness* on the measure μ. They can be formulated by using the corresponding periodic Sobolev spaces $H^{1,p}_\mu(\mathbf{T})$ on the n-torus $\mathbf{T}$, and are related to the connectedness notions for an open domain of $\mathbb{R}^n$ discussed in [28] as an alternative to the extension operator technique.

The case when μ is "nonconnected" is not treated within; neverthless, we point out that in such a situation the two-parameter variational integrals involved in the above described case of fattened thin structures may give rise to a nonlocal limit energy. This phenomenon deserves to our advice further investigation, as it throws some light

on the nonindifference in letting first the periodicity or the thickness parameter tend to zero.

A short outline of the paper follows.

In section 2 we introduce the new notion of two-scale convergence with respect to measures, and some related results are given, which will be useful for the proof of the main homogenization theorem. In section 3 we develop the theory of the periodic Sobolev spaces associated with a measure μ; this allows us, in particular, to formulate in a natural way some different notions of connectedness for μ, which are briefly discussed in section 4 before giving the statement and proof of the main structure theorem for a two-scale limit of a sequence of gradients. The homogenization result for thin structures is then deduced in section 5 as well as a corrector result in the case of quadratic energies. Finally, section 6 is devoted to the case of a sequence of two-parameter variational integrals. We first show that, when μ is connected, the limit energy is independent of the order we let the two parameters ε and δ tend to zero. We conclude by a counterexample in the nonconnected case.

2. Two-scale convergence with respect to a measure. We fix some preliminary notation. Let Ω be an open bounded subset of $\mathbb{R}^n$ with smooth boundary and let Y be the unitary cube of $\mathbb{R}^n$. We will always assume that μ is a positive Y-periodic Radon measure on $\mathbb{R}^n$ with $\mu(\partial Y) = 0$; notice that the latter condition is not restrictive since Y may be replaced by any translated cell $y_0 + Y$. For any $\varepsilon > 0$, we denote by μ_ε the measure defined by

$$\int_\Omega \varphi(x)\, d\mu_\varepsilon(x) = \varepsilon^n \int_{\Omega/\varepsilon} \varphi(\varepsilon x)\, d\mu(x) \qquad \forall \varphi \in \mathcal{C}_0(\Omega), \tag{2.1}$$

$\mathcal{C}_0(\Omega)$ being the space of continuous and compactly supported functions on Ω.

It is easy to check, using (2.1) and the periodicity of μ, that

$$\mu_\varepsilon \rightharpoonup \mu(Y)\, \mathcal{L}^n \llcorner \Omega \tag{2.2}$$

in the vague topology of measures. To have $\mu_\varepsilon \rightharpoonup \mathcal{L}^n \llcorner \Omega$, we assume without loss of generality that $\mu(Y) = 1$. We also set for brevity $m := (\mathcal{L}^n \llcorner \Omega) \otimes (\mu \llcorner Y)$.

We call $\mathbf{T}$ the n-dimensional torus $\mathbb{R}^n/\mathbf{Z}^n$, and throughout the paper we identify functions on $\mathbf{T}$ with Y-periodic functions on $\mathbb{R}^n$. In particular, by writing $\varphi \in \mathcal{D}(\Omega; \mathcal{C}^\infty(\mathbf{T}))$, we mean that $\varphi = \varphi(x, y)$ is smooth in both its variables $(x, y) \in \Omega \times \mathbb{R}^n$, compactly supported in x and Y-periodic in y. We can now set the following.

Definition 2.1. *Let $u_\varepsilon \in L^p_{\mu_\varepsilon}(\Omega)$ and $u_0 \in L^p_m(\Omega \times \mathbf{T})$ for some $p \geq 1$. We say that $\{u_\varepsilon\}$ two-scale converges to u_0 (with respect to μ and as $\varepsilon \to 0$), and we write $u_\varepsilon \rightharpoonup\!\!\!\rightharpoonup u_0$ if*

$$\lim_{\varepsilon \to 0} \int_\Omega u_\varepsilon(x) \varphi\left(x, \frac{x}{\varepsilon}\right) d\mu_\varepsilon(x) = \int_{\Omega \times Y} u_0(x, y) \varphi(x, y)\, dm(x, y) \quad \forall \varphi \in \mathcal{D}(\Omega; \mathcal{C}^\infty(\mathbf{T}))\ .$$

Remark 2.2. Note that, if $u_\varepsilon \rightharpoonup\!\!\!\rightharpoonup u_0$, then $u_\varepsilon \mu_\varepsilon \rightharpoonup u \mathcal{L}^n \llcorner \Omega$, where $u(x) := \int_Y u_0(x, y)\, d\mu(y)$ (choose in Definition 2.1 a test function $\varphi(x, y) = \psi(x) \in \mathcal{D}(\Omega)$).

On the other hand, similarly as in the well-known case where $\mu_\varepsilon = \mathcal{L}^n \llcorner \Omega$ for every ε, Definition 2.1 retains more information on the sequence $\{u_\varepsilon \mu_\varepsilon\}$ than the pure weak convergence in the sense of measures: it also takes into account the "oscillations" which have the same frequency as the test functions $\varphi(x, \frac{x}{\varepsilon})$. For instance, in the simplest case when $u_\varepsilon(x) = u(x, \frac{x}{\varepsilon})$, with u continuous on $\Omega \times \mathbb{R}^n$ and Y-periodic in

its second variable, we have $u_\varepsilon \rightharpoonup u$. This follows from the convergence

$$v\left(x,\frac{x}{\varepsilon}\right)\mu_\varepsilon \rightharpoonup \left(\int_Y v(x,y)\,d\mu(y)\right)\mathcal{L}^n \llcorner \Omega\ , \tag{2.3}$$

holding for any function v continuous on $\Omega\times\mathbb{R}^n$ and Y-periodic in y.

In view of the following compactness property, the two-scale convergence is a good notion for a sequence $\{u_\varepsilon\}$ which satisfies a uniform bound of the type $\int_\Omega |u_\varepsilon|^p\,d\mu_\varepsilon \le M$, with $p>1$. Throughout this section, the symbols $\|\cdot\|_{p,\mu_\varepsilon}$ and $\|\cdot\|_{p,m}$ will be used, respectively, for the $L^p_{\mu_\varepsilon}(\Omega)$ and the $L^p_m(\Omega\times Y)$ norms, while $p'=\frac{p}{p-1}$ will denote the conjugate exponent of p.

PROPOSITION 2.3. *Let $p>1$, and let $u_\varepsilon\in L^p_{\mu_\varepsilon}(\Omega)$ satisfy $\int_\Omega |u_\varepsilon|^p\,d\mu_\varepsilon\le M$. Then there exists a subsequence u_{ε_k} such that $u_{\varepsilon_k}\rightharpoonup u_0$, with $u_0\in L^p_m(\Omega\times Y)$; in particular, $u_{\varepsilon_k}\mu_{\varepsilon_k}\rightharpoonup u\mathcal{L}^n$, where $u(x):=\int_Y u_0(x,y)\,d\mu(y)$.*

Proof. Let $(B\,,\,\|\cdot\|_B)$ be the Banach space of all continuous functions on $\Omega\times Y$ vanishing at the boundary of $\Omega\times Y$, endowed with the uniform norm. For any $\varphi\in B$ we have

$$\|\varphi\left(x,\frac{x}{\varepsilon}\right)\|_{p',\mu_\varepsilon}\ \le\ C\|\varphi\|_B\ , \tag{2.4}$$

$$\lim_{\varepsilon\to 0}\ \|\varphi\left(x,\frac{x}{\varepsilon}\right)\|_{p',\mu_\varepsilon}\ =\ \|\varphi(x,y)\|_{p',m}. \tag{2.5}$$

The first inequality follows from the boundedness of μ_ε (as Ω is relatively compact with $\mathcal{L}^n(\partial\Omega)=0$, we have by (2.2) $\mu_\varepsilon(\Omega)\to\mathcal{L}^n(\Omega)$ as $\varepsilon\to 0$). To prove (2.5), we simply apply (2.3) with $v(x,y)=|\varphi(x,y)|^{p'}$. Now let us consider for any $\varepsilon>0$ the linear operator T_ε defined on B by

$$\langle T_\varepsilon,\varphi\rangle := \int_\Omega u_\varepsilon(x)\varphi\left(x,\frac{x}{\varepsilon}\right)\,d\mu_\varepsilon,$$

where we think of φ as implicitly extended by Y-periodicity on $\Omega\times\mathbb{R}^n$. By the Hölder inequality, the assumption on u_ε and (2.4), we have

$$\begin{aligned}|\langle T_\varepsilon,\varphi\rangle| \le \|u_\varepsilon\|_{p,\mu_\varepsilon}\|\varphi\left(x,\frac{x}{\varepsilon}\right)\|_{p',\mu_\varepsilon} &\le M^{1/p}\|\varphi\left(x,\frac{x}{\varepsilon}\right)\|_{p',\mu_\varepsilon}\\ &\le M^{1/p}C\|\varphi\|_B.\end{aligned} \tag{2.6}$$

Thus T_ε is a bounded sequence in the space B' of finite Borel measures and, possibly passing to a subsequence, we can assume that T_ε weakly star converges to an element T_0 of B'. Then, using (2.5) to pass to the limit as $\varepsilon\to 0$ in (2.6), we get

$$|\langle T_0,\varphi\rangle|\le M^{1/p}\|\varphi(x,y)\|_{p',m}\qquad\forall\varphi\in B.$$

Hence, by the density of B in $L^{p'}_m(\Omega\times Y)$, T_0 may be represented by an element $u_0\in L^p_m(\Omega\times Y)$ satisfying

$$\lim_{\varepsilon\to 0}\int_\Omega u_\varepsilon(x)\varphi\left(x,\frac{x}{\varepsilon}\right)\,d\mu_\varepsilon=\int_{\Omega\times Y}u_0(x,y)\varphi(x,y)\,dm\qquad\forall\varphi\in B.$$

This also implies, by Remark 2.2, the second part of the statement. ∎

Remark 2.4. Under the assumptions of Proposition 2.3, the space of admissible test functions in the two-scale convergence can be considerably enlarged. Indeed,

the same proof of Proposition 2.3 works whenever the space of continuous functions vanishing at the boundary of $\Omega \times Y$ is replaced by another separable Banach space B, dense in $L^{p'}_m(\Omega \times Y)$, such that (2.4) and (2.5) hold. For instance, all these conditions are satisfied if we take $B = \mathcal{C}(\overline{\Omega}, L^p_\mu(\mathbf{T}))$ (a detailed proof can be derived with minor changes from [1, Corollary 5.4]); in particular, the convergence (2.3) holds for any $v \in \mathcal{C}(\overline{\Omega}, L^p_\mu(\mathbf{T}))$.

The two-scale convergence enjoys the following lower semicontinuity property when dealing with convex periodic integrands.

PROPOSITION 2.5. *Let $v_\varepsilon \in L^p_{\mu_\varepsilon}(\Omega; \mathbb{R}^d)$ two-scale converge (by components) to $v_0 \in L^p_m(\Omega \times Y; \mathbb{R}^d)$, $p > 1$; let $j = j(y,z)$ be a function on $\mathbb{R}^n \times \mathbb{R}^d$ μ-measurable and Y-periodic in y, convex in z, and satisfying, for some positive constants C, c, the estimate*

$$c|z|^p \le j(y,z) \le C\,(1 + |z|^p) \qquad \forall (y,z) \in \mathbb{R}^n \times \mathbb{R}^d\ .$$

Then

$$\liminf_{\varepsilon \to 0} \int_\Omega j\left(\frac{x}{\varepsilon}, v_\varepsilon\right) d\mu_\varepsilon \ge \int_{\Omega \times Y} j(y, v_0(x,y))\, dm.$$

Proof. For any function $\varphi \in \mathcal{D}(\Omega \times Y)$, the Fenchel's inequality gives

$$\int_\Omega j\left(\frac{x}{\varepsilon}, v_\varepsilon\right) d\mu_\varepsilon \ge \int_\Omega v_\varepsilon(x) \varphi\left(x, \frac{x}{\varepsilon}\right) d\mu_\varepsilon - \int_\Omega j^*\left(\frac{x}{\varepsilon}, \varphi\left(x, \frac{x}{\varepsilon}\right)\right) d\mu_\varepsilon,$$

where $j^*(y, \cdot)$ denotes the conjugate functional of $j(y, \cdot)$, and φ is extended by Y-periodicity on $\Omega \times \mathbb{R}^n$. Since $v_\varepsilon \rightharpoonup\!\!\!\!\rightharpoonup v_0$, recalling Remark 2.4, passing to the limit as $\varepsilon \to 0$ in the above inequality yields

$$\liminf_{\varepsilon \to 0} \int_\Omega j\left(\frac{x}{\varepsilon}, v_\varepsilon\right) d\mu_\varepsilon \ge \int_{\Omega \times Y} v_0(x,y) \varphi\big(x,y\big)\, dm - \int_{\Omega \times Y} j^*\Big(y, \varphi\big(x,y\big)\Big)\, dm. \tag{2.7}$$

Taking the supremum of the right-hand side of (2.7) when φ varies in $\mathcal{D}(\Omega \times Y)$, one gets, using a classical localization argument and the convexity assumption on j,

$$\liminf_{\varepsilon \to 0} \int_\Omega j\left(\frac{x}{\varepsilon}, v_\varepsilon\right) d\mu_\varepsilon \ \ge \ \int_{\Omega \times Y} j^{**}(y, v_0(x,y))\, dm \ = \int_{\Omega \times Y} j(y, v_0(x,y))\, dm. \qquad \square$$

Applying the above proposition with $j(y,z) = |z|^p$, we get

$$\liminf_{\varepsilon \to 0} \int_\Omega |u_\varepsilon|^p\, d\mu_\varepsilon \ge \int_{\Omega \times Y} |u_0|^p\, dm, \tag{2.8}$$

whenever $u_\varepsilon \in L^p_{\mu_\varepsilon}(\Omega)$ two-scale converge to $u_0 \in L^p(\Omega \times Y)$ $(p > 1)$.

DEFINITION 2.6. *Let $u_\varepsilon \in L^p_{\mu_\varepsilon}(\Omega)$ and $u_0 \in L^p_m(\Omega \times \mathbf{T})$ for some $p > 1$. We say that $\{u_\varepsilon\}$ two-scale strongly converges to u_0 (with respect to μ and as $\varepsilon \to 0$), and we write $u_\varepsilon \rightrightarrows u_0$ if*

$$u_\varepsilon \rightharpoonup\!\!\!\!\rightharpoonup u_0 \quad \text{and} \quad \limsup_{\varepsilon \to 0} \int_\Omega |u_\varepsilon|^p\, d\mu_\varepsilon \le \int_{\Omega \times Y} |u_0|^p\, dm\ .$$

In view of (2.8), when $u_\varepsilon \rightarrow\!\!\!\!\rightarrow u_0$, the $L^p_{\mu_\varepsilon}(\Omega)$-norm of u_ε converges to the $L^p_m(\Omega \times Y)$-norm of u_0. This means that all the oscillations of the sequence $\{u_\varepsilon \mu_\varepsilon\}$ are captured by the two-scale limit, namely, they are in resonance with those of the test functions $\varphi(x, \frac{x}{\varepsilon})$.

Example 2.7. Let $u_\varepsilon = u_0(x, \frac{x}{\varepsilon})$, where $u_0(x, y)$ is given by $u_0(x, y) = u(x)w(y)$, with $u \in L^p(\Omega)$ and $w \in L^\infty(\mathbf{T})$. Then it is easy to check that $u_\varepsilon \rightarrow\!\!\!\!\rightarrow u_0$. In fact this conclusion also holds for more general u_0, in particular, for $u_0 \in C(\overline{\Omega}; L^p_\mu(\mathbf{T}))$.

PROPOSITION 2.8. *Let $p > 1$, and let $u_\varepsilon \in L^p_{\mu_\varepsilon}(\Omega)$, $v_\varepsilon \in L^{p'}_{\mu_\varepsilon}(\Omega)$ satisfy*

$$u_\varepsilon \rightarrow\!\!\!\!\rightarrow u_0 \ , \quad u_0 \in L^p_m(\Omega \times Y) \ , \tag{2.9}$$

$$v_\varepsilon \rightharpoonup\!\!\!\!\rightharpoonup v_0 \ , \quad v_0 \in L^{p'}_m(\Omega \times Y) \ , \quad \int_\Omega |v_\varepsilon|^{p'} \, d\mu_\varepsilon \leq M \ . \tag{2.10}$$

Then

$$u_\varepsilon v_\varepsilon \mu_\varepsilon \rightharpoonup \left(\int_Y u_0(\cdot, y) v_0(\cdot, y) \, d\mu(y) \right) \mathcal{L}^n \llcorner \Omega, \tag{2.11}$$

$$\lim_{\varepsilon \to 0} \int_\Omega |u_\varepsilon - u_0\big(x, \frac{x}{\varepsilon}\big)|^p \, d\mu_\varepsilon = 0 \quad \textit{whenever } u_0 \in \mathcal{C}(\Omega \times \mathbf{T}). \tag{2.12}$$

Proof. Let $\{\varphi_h\} \subset \mathcal{D}(\Omega \times Y)$ be a sequence of smooth functions converging to u_0 in $L^p_m(\Omega \times Y)$ and extended by Y-periodicity on $\Omega \times \mathbb{R}^n$. For any test function $\psi \in C_0(\Omega)$, it holds that

$$\lim_{\varepsilon \to 0} \int_\Omega u_\varepsilon v_\varepsilon \psi \, d\mu_\varepsilon = \lim_{h \to +\infty} \lim_{\varepsilon \to 0} \left\{ \int_\Omega \left[u_\varepsilon - \varphi_h \left(x, \frac{x}{\varepsilon} \right) \right] v_\varepsilon \psi \, d\mu_\varepsilon + \int_\Omega \varphi_h \left(x, \frac{x}{\varepsilon} \right) v_\varepsilon \psi \, d\mu_\varepsilon \right\}.$$

By (2.10) and the choice of $\{\varphi_h\}$ we have

$$\begin{aligned} \lim_{h \to +\infty} \lim_{\varepsilon \to 0} \int_\Omega \varphi_h \left(x, \frac{x}{\varepsilon} \right) v_\varepsilon \psi \, d\mu_\varepsilon &= \lim_{h \to +\infty} \int_{\Omega \times Y} \varphi_h\big(x, y\big) v_0(x, y) \psi(x) \, dm \\ &= \int_{\Omega \times Y} u_0(x, y) v_0(x, y) \psi(x) \, dm. \end{aligned}$$

To prove (2.11), it is then enough to show that

$$\lim_{h \to +\infty} \lim_{\varepsilon \to 0} \int_\Omega \left[u_\varepsilon - \varphi_h \left(x, \frac{x}{\varepsilon} \right) \right] v_\varepsilon \psi \, d\mu_\varepsilon = 0. \tag{2.13}$$

Applying the Hölder inequality and assumption (2.10), we deduce

$$\left| \int_\Omega \left[u_\varepsilon - \varphi_h \left(x, \frac{x}{\varepsilon} \right) \right] v_\varepsilon \psi \, d\mu_\varepsilon \right| \leq M^{1/p'} \|\psi\|_\infty \left\| u_\varepsilon - \varphi_h \left(x, \frac{x}{\varepsilon} \right) \right\|_{p, \mu_\varepsilon}.$$

The Clarkson inequalities give, respectively, for $p \geq 2$ and for $p \leq 2$

$$\begin{cases} \left\| u_\varepsilon - \varphi_h\left(x, \dfrac{x}{\varepsilon}\right)\right\|^p_{p,\mu_\varepsilon} \\ \leq\ 2^p \left\{ \dfrac{1}{2}\|u_\varepsilon\|^p_{p,\mu_\varepsilon} + \dfrac{1}{2}\left\|\varphi_h\left(x, \dfrac{x}{\varepsilon}\right)\right\|^p_{p,\mu_\varepsilon} - \left\| \dfrac{u_\varepsilon + \varphi_h\big(x, \frac{x}{\varepsilon}\big)}{2}\right\|^p_{p,\mu_\varepsilon} \right\}, \\ \left\| u_\varepsilon - \varphi_h\left(x, \dfrac{x}{\varepsilon}\right)\right\|^{p'}_{p,\mu_\varepsilon} \\ \qquad \leq\ 2^{p-1} \left\{ \left[\dfrac{1}{2}\|u_\varepsilon\|^p_{p,\mu_\varepsilon} + \dfrac{1}{2}\left\|\varphi_h\left(x, \dfrac{x}{\varepsilon}\right)\right\|^p_{p,\mu_\varepsilon}\right]^{\frac{1}{p-1}} - \left\| \dfrac{u_\varepsilon + \varphi_h\big(x, \frac{x}{\varepsilon}\big)}{2}\right\|^{p'}_{p,\mu_\varepsilon} \right\}. \end{cases}$$

Using (2.9) and the smoothness of each φ_h, we infer

$$\begin{cases} \limsup\limits_{\varepsilon\to 0} \|u_\varepsilon - \varphi_h\left(x, \dfrac{x}{\varepsilon}\right)\|^p_{p,\mu_\varepsilon} \leq 2^p \left\{ \dfrac{1}{2}\|u_0\|^p_{p,m} + \dfrac{1}{2}\|\varphi_h\|^p_{p,m} - \left\| \dfrac{u_0 + \varphi_h}{2}\right\|^p_{p,m} \right\}, \\ \limsup\limits_{\varepsilon\to 0} \|u_0 - \varphi_h\|^{p'}_{p,m} \leq 2^{p-1} \left\{ \left[\dfrac{1}{2}\|u_0\|^p_{p,m} + \dfrac{1}{2}\|\varphi_h\|^p_{p,m}\right]^{\frac{1}{p-1}} - \left\| \dfrac{u_0 + \varphi_h}{2}\right\|^{p'}_{p,m} \right\}. \end{cases}$$

Passing now to the limsup as $h \to +\infty$, by the choice of the sequence $\{\varphi_h\}$, both the right-hand sides of the above inequalities tend to zero, so that (2.13) is proved.

To obtain (2.12), it is enough to write the Clarkson inequalities with φ_h replaced by u_0 and to observe that, being u_0 globally continuous and Y-periodic in its second variable, the right-hand sides converge to zero as $\varepsilon \to 0$. □

3. The periodic Sobolev spaces $\boldsymbol{H^{1,p}_\mu(\mathbf{T})}$. First, let us give a brief recall about the Sobolev spaces $H^{1,p}_\mu$ introduced in [7].

Let $\mathcal{D} := \mathcal{C}^\infty_0(\mathbb{R}^n)$ and $\mathcal{D}'$ be the space of distributions on $\mathbb{R}^n$. Let $p\,,\, p' \in [1, +\infty]$ be fixed conjugate exponents. For any $q \geq 1$, let $L^q_\mu := L^q_\mu(\mathbb{R}^n)$, $(L^q_\mu)^n := L^q_\mu(\mathbb{R}^n; \mathbb{R}^n)$, and similarly for $L^q_{\mu,\mathrm{loc}}$, $(L^q_{\mu,\mathrm{loc}})^n$. The notation $\|\cdot\|_{q,\mu}$ will be used throughout the section for the usual norms of L^q_μ and $(L^q_\mu)^n$, as well as for $L^q_\mu(\mathbf{T})$ and $(L^q_\mu(\mathbf{T}))^n$ (implicitly assuming in this case, whenever unambiguous, that the integrals are made over Y).

We recall that, for any $\sigma \in (L^1_{\mu,\mathrm{loc}})^n$, $\mathrm{div}(\sigma\mu) \in \mathcal{D}'$ is defined by

$$\langle \mathrm{div}(\sigma\mu), \psi\rangle_{(\mathcal{D}',\mathcal{D})} := -\int_{\mathbb{R}^n} \sigma \cdot \nabla\psi \, d\mu \qquad \forall \psi \in \mathcal{D}\ .$$

Whenever $\mathrm{div}(\sigma\mu)$ is a measure absolutely continuous with respect to μ with a density belonging to $L^{p'}_\mu$, we write for brevity $\mathrm{div}(\sigma\mu) \in L^{p'}_\mu$, and we denote by $\mathrm{div}_\mu\, \sigma$ the derivative $\frac{d}{d\mu}\,\mathrm{div}(\sigma\mu)$.

It will be useful in the following to notice that there holds

$$\mathrm{div}(\psi\sigma\mu) = \psi\,\mathrm{div}(\sigma\mu) + (\sigma\cdot\nabla\psi)\mu \qquad \forall \psi \in \mathcal{D},\ \forall \sigma \in (L^1_{\mu,\mathrm{loc}})^n\ . \tag{3.1}$$

As in [7], we introduce the class $X^{p'}_\mu$ of all vector fields Φ which are "tangent to μ," given by

$$X^{p'}_\mu := \left\{ \Phi \in (L^{p'}_\mu)^n \ :\ \mathrm{div}(\Phi\mu) \in L^{p'}_\mu \right\}\ ,$$

and $T_\mu^p(x)$ the tangent space of μ at x, obtained as

$$T_\mu^p(x) := \mu - \operatorname{ess} \bigcup \left\{ \Phi(x) \ : \ \Phi \in X_\mu^{p'} \right\} , \qquad x \in \mathbb{R}^n \ .$$

For details on the meaning of the μ-essential union and on the properties of the multifunction T_μ^p, we refer to [7], [21]; in particular, at least for usual measures, $T_\mu^p(x)$ does not depend on the exponent p, and it will be denoted simply by $T_\mu(x)$.

The Sobolev space $H_\mu^{1,p} = H_\mu^{1,p}(\mathbb{R}^n)$ is defined as the completion of $\mathcal{D}$ with respect to the norm $\|\psi\|_{1,p,\mu} := \|\psi\|_{p,\mu} + \|\nabla_\mu \psi\|_{p,\mu}$, where $\nabla_\mu \psi(x) := P_\mu(x)[\nabla \psi(x)]$ is the orthogonal projection $P_\mu(x)$ of $\nabla \psi(x)$ onto $T_\mu(x)$. In other words, it turns out that the linear operator $A : D(A) \subset L_\mu^p \to (L_\mu^p)^n$ defined by $D(A) = \mathcal{D}$ and $A\psi = \nabla_\mu \psi$ is closable [7, Proposition 2.1], and the domain of its unique closed extension $\overline{A}$ is called $H_\mu^{1,p}$. By definition $H_\mu^{1,p}$ is a Banach space, and it is reflexive when $p \in (1, +\infty)$. For any $u \in H_\mu^{1,p}$, we set $\nabla_\mu u := \overline{A} u$. Then a straightforward density argument gives the following useful integration by parts:

$$\int_{\mathbb{R}^n} \nabla_\mu u \cdot \Phi \, d\mu = - \int_{\mathbb{R}^n} u \, \operatorname{div}_\mu \Phi \, d\mu \qquad \forall u \in H_\mu^{1,p}, \ \forall \Phi \in X_\mu^{p'} \ .$$

Notice the adjoint operator $A^* : (L_\mu^{p'})^n \to L_\mu^{p'}$ equals $-\operatorname{div}(P_\mu \sigma \mu)$ when applied to any vector field σ belonging to its domain $D(A^*)$, given by

$$D(A^*) = \left\{ \sigma \in (L_\mu^{p'})^n \ : \ \operatorname{div}(P_\mu \sigma \mu) \in L_\mu^{p'} \right\} = \left\{ \sigma \in (L_\mu^{p'})^n \ : \ P_\mu \sigma \in X_\mu^{p'} \right\} =: Y_\mu^{p'} \ .$$

In particular, when $p > 1$, the following characterization by duality of $H_\mu^{1,p}$ can be deduced from Lemma 3.1 below:

$$H_\mu^{1,p} = \left\{ u \in L_\mu^p \text{ such that } \exists C > 0 \ : \ |\langle u, \operatorname{div}(P_\mu \sigma \mu) \rangle| \le C \|\sigma\|_{p',\mu} \quad \forall \sigma \in Y_\mu^{p'} \right\} .$$

LEMMA 3.1. *Let V, W be two Banach spaces, with W reflexive. Assume that $T : D(T) \subset V \to W$ is a linear and closable operator with dense domain. Then*

$$D(\overline{T}) = \left\{ v \in V \text{ such that } \exists C > 0 \ : \ |\langle v, T^* w' \rangle_{(V,V')}| \le C \|w'\|_{W'} \ \forall w' \in D(T^*) \right\}. \tag{3.2}$$

The proof of this lemma is an immediate consequence of the equality $\overline{T} = T^{**}$, which holds by standard arguments of functional analysis [10].

Let us turn now our attention to Y-periodic functions. Set

$$X_\mu^{p'}(\mathbf{T}) := \left\{ \Phi \in \left(L_\mu^{p'}(\mathbf{T}) \right)^n \ : \ \operatorname{div}(\Phi \mu) \in L_{\mu,\mathrm{loc}}^{p'} \right\} .$$

Notice that, since $\mu(\partial Y) = 0$, we have

$$\mu - \operatorname{ess} \bigcup \left\{ \Phi(x) \ : \ \Phi \in X_\mu^{p'}(\mathbf{T}) \right\} = T_\mu(x) \qquad \mu\text{-a.e. (almost everywhere) on } Y. \tag{3.3}$$

Let $A_\sharp : D(A_\sharp) \subset L_\mu^p(\mathbf{T}) \to (L_\mu^p(\mathbf{T}))^n$ be the linear operator given by $D(A_\sharp) = \mathcal{C}^\infty(\mathbf{T})$, $A_\sharp \psi = \nabla_\mu \psi$. In order to prove that $A_\sharp$ is closable, we need some preliminary lemmas. For any $\psi \in \mathcal{D}$, we set

$$\psi^\sharp(y) = \sum_{i \in \mathbf{Z}^n} \psi(y - i) \ , \qquad y \in Y.$$

The function $\psi^\sharp$ is well defined as soon as ψ is compactly supported, and it turns out to be Y-periodic by construction.

LEMMA 3.2. *For any $v \in L^1_\mu(\mathbf{T})$ and any $\psi \in \mathcal{D}$, there holds $\int_{\mathbb{R}^n} v\psi \, d\mu = \int_Y v\psi^\sharp \, d\mu$.*

Proof. Due to the Y-periodicity of v and μ, we have

$$\int_{\mathbb{R}^n} v\psi \, d\mu = \sum_{i\in\mathbf{Z}^n} \int_{i+Y} v\psi \, d\mu = \sum_{i\in\mathbf{Z}^n} \int_Y v(y)\psi(y-i)\, d\mu(y) \ .$$

The last sum over $i \in \mathbf{Z}^n$ may equivalently be made over the finite set of indices $I_\psi := \{i \in \mathbf{Z}^n \ : \ (Y-i) \cap \operatorname{spt}\psi \neq \emptyset\}$. Thus, it can be passed under the sign of integral and the lemma is proved. □

LEMMA 3.3. *There exists a sequence $\{\psi_h\} \subset \mathcal{D}$ such that $\psi_h^\sharp \to 1$ in $H^{1,\infty}_\mu(\mathbf{T})$.*

Proof. For any $h \in \mathbb{N}$, take $\psi_h \in \mathcal{C}^\infty_0(\mathbb{R}^n; [0, h^{-n}])$ satisfying

$$\psi_h = h^{-n} \ \text{ on } hY \ , \qquad \psi_h = 0 \ \text{ on } \mathbb{R}^n \setminus (h+1)Y \ ; \tag{3.4}$$

$$|\nabla\psi_h| \le Ch^{-n} \ \text{ on } \mathbb{R}^n. \tag{3.5}$$

For any $y \in Y$, we have

$$h^{-n}\operatorname{card} I_h(y) \le \psi_h^\sharp(y) \le h^{-n}\operatorname{card} J_h(y) \ , \tag{3.6}$$

where $I_h(y) = \{i \in \mathbf{Z}^n \ : \ \psi_h(y-i) = h^{-n}\}$, $J_h(y) = \{i \in \mathbf{Z}^n \ : \ \psi_h(y-i) \neq 0\}$.

By (3.4), $\operatorname{card} I_h(y) \ge h^n$ and $\operatorname{card} J_h(y) \le (h+1)^n$, thus (3.6) yields $1 \le \psi_h^\sharp(y) \le \big(1+\frac{1}{h}\big)^n$ and we deduce that $\psi_h^\sharp$ converge pointwise to 1 on Y.

On the other hand, by (3.5) we have

$$\sup_{y\in Y} |\nabla\psi_h^\sharp(y)| \le \sup_{y\in Y} Ch^{-n}\big[\operatorname{card} J_h(y) - \operatorname{card} I_h(y)\big] \le Ch^{-n}\big[(h+1)^n - h^n\big] \ .$$

It follows that $\psi_h^\sharp$ and $\nabla\psi_h^\sharp$ both converge uniformly to 1 and 0, respectively, on Y, hence $\psi_h^\sharp$ converge to 1 strongly in $H^{1,\infty}_\mu(\mathbf{T})$. □

LEMMA 3.4. *For any $u \in \mathcal{C}^\infty(\mathbf{T})$ and any $\Phi \in X^{p'}_\mu(\mathbf{T})$, there holds*

$$\int_Y \nabla_\mu u \cdot \Phi \, d\mu = -\int_Y u \operatorname{div}_\mu \Phi \, d\mu \ . \tag{3.7}$$

Proof. Take a sequence $\{\psi_h\} \subset \mathcal{D}$ as in Lemma 3.3. For any $u \in \mathcal{C}^\infty(\mathbf{T})$ and for every h, the product function $u\psi_h$ belongs to $\mathcal{D}$. Then, for any $\Phi \in X^{p'}_\mu(\mathbf{T})$, we are allowed to write

$$\int_{\mathbb{R}^n} \nabla_\mu(u\psi_h) \cdot \Phi \, d\mu = -\int_{\mathbb{R}^n} u\psi_h \operatorname{div}_\mu \Phi \, d\mu. \tag{3.8}$$

Using Lemma 3.2, the left-hand side of the above equation can be rewritten as

$$\int_{\mathbb{R}^n} \big(\psi_h \nabla_\mu u + u\nabla_\mu\psi_h\big) \cdot \Phi \, d\mu = \int_Y \big(\psi_h^\sharp \nabla_\mu u + u\nabla_\mu\psi_h^\sharp\big) \cdot \Phi \, d\mu \ .$$

By the choice of $\{\psi_h\}$, (3.7) thus follows from (3.8) when passing to the limit as $h \to +\infty$. □

PROPOSITION 3.5. *The operator $A_\sharp$ is closable.*

Proof. We need to show that, if $\{u_h\} \subset \mathcal{C}^\infty(\mathbf{T})$ satisfies $u_h \to 0$ in $L^p_\mu(\mathbf{T})$ and $\nabla_\mu u_h \to v$ in $(L^p_\mu(\mathbf{T}))^n$, then $v = 0$ μ-a.e. on Y. To this aim, it is enough to show that

$$\sup\left\{\int_Y v\cdot\Phi\,d\mu \;:\; \Phi\in X^{p'}_\mu(\mathbf{T})\right\}=0. \tag{3.9}$$

Indeed, $X^{p'}_\mu(\mathbf{T})$ satisfies the following locality property: whenever $\Phi \in X^{p'}_\mu(\mathbf{T})$ and $\psi \in \mathcal{D}(Y)$, the field $\psi\Phi$ (extended by periodicity out of Y) belongs to $X^{p'}_\mu(\mathbf{T})$. Then a commutation argument between supremum and integral can be applied [8, Theorem 1], and, using also (3.3), (3.9) becomes

$$\int_Y \sup\{v\cdot z \;:\; z\in T_\mu(x)\}\,d\mu=0\ .$$

This, coupled with the information that $v(x) \in T_\mu(x)$ for μ-a.e. x (recall that $v = \lim_h \nabla_\mu u_h$), implies that v vanishes μ-a.e.

It remains to prove (3.9). To this aim, we use Lemma 3.4 and the convergence of $\{u_h\}$ to zero:

$$\int_Y v\cdot\Phi\,d\mu=\lim_{h\to+\infty}\int_Y\nabla_\mu u_h\cdot\Phi\,d\mu=-\int_Y u_h\,\mathrm{div}_\mu\,\Phi\,d\mu=0. \qquad \square$$

We can now give the following definition.

DEFINITION 3.6. *Set* $H^{1,p}_\mu(\mathbf{T}) := D(\overline{A}_\sharp)$, *and* $\nabla_\mu u := \overline{A}_\sharp u$ *for any* $u \in H^{1,p}_\mu(\mathbf{T})$.

It turns out by this definition that $H^{1,p}_\mu(\mathbf{T})$ is a closed subspace of $H^{1,p}_{\mu,\mathrm{loc}} := \{u \in L^p_{\mu,\mathrm{loc}} \;:\; u\psi \in H^{1,p}_\mu\ \forall\psi\in\mathcal{D}\}$ (in particular, it is reflexive for $p \in (1+\infty)$). Moreover, the integration by parts formula (3.7) can immediately be extended to any $u \in H^{1,p}_\mu(\mathbf{T})$.

Let us consider now the adjoint operator $A^*_\sharp$. We have

$$D(A^*_\sharp)=\left\{\sigma\in\left(L^{p'}_\mu(\mathbf{T})\right)^n \;:\; \left|\int_Y\sigma\cdot\nabla_\mu u\,d\mu\right|\le C\|u\|_{p',\mu}\ \forall u\in\mathcal{C}^\infty(\mathbf{T})\right\}=:Y^{p'}_\mu(\mathbf{T}).$$

PROPOSITION 3.7. $Y^{p'}_\mu(\mathbf{T}) = \left\{\sigma \in \left(L^{p'}_\mu(\mathbf{T})\right)^n \;:\; P_\mu\sigma \in X^{p'}_\mu(\mathbf{T})\right\}$; $A^*_\sharp\sigma = -\,\mathrm{div}_\mu(P_\mu\sigma)$.

Proof. Let us prove the first assertion. The inclusion $\supseteq$ is an immediate consequence of (3.7). For the converse, let $\sigma \in Y^{p'}_\mu(\mathbf{T})$, and let us show that the restriction $\mathrm{div}(P_\mu\sigma\mu)\llcorner\Omega$ of $\mathrm{div}(P_\mu\sigma\mu)$ to any bounded open set Ω belongs to $L^{p'}_\mu(\Omega)$. Take $\psi \in \mathcal{D}$ with $\mathrm{spt}\,\psi \subset \Omega$. Using Lemma 3.2, we get

$$-\langle\mathrm{div}(P_\mu\sigma\mu)\llcorner\Omega,\psi\rangle_{(\mathcal{D},\mathcal{D}')}=\int_{\mathbb{R}^n}P_\mu\sigma\cdot\nabla\psi\,d\mu=\int_Y P_\mu\sigma\cdot\nabla\psi^\sharp\,d\mu=\int_Y\sigma\cdot\nabla_\mu\psi^\sharp\,d\mu\ .$$

Then, since $\sigma \in Y^{p'}_\mu(\mathbf{T})$, there exists $C > 0$ such that

$$|\langle\mathrm{div}(P_\mu\sigma\mu)\llcorner\Omega,\psi\rangle|\le C\|\psi^\sharp\|_{p,\mu}\qquad\forall\psi\in\mathcal{D}(\Omega)\ . \tag{3.10}$$

Now, using the boundedness of Ω, we can find a positive constant C' such that

$$\|\psi^\sharp\|_{p,\mu,Y}\le C'\|\psi\|_{p,\mu,\Omega}\qquad\forall\psi\in\mathcal{D}(\Omega)\ . \tag{3.11}$$

Indeed, setting $I_\Omega := \{i \in \mathbf{Z}^n \,:\, (Y-i)\cap\Omega \neq \emptyset\}$, we obtain

$$\int_Y |\psi^\sharp|^p\,d\mu = \int_Y \left|\sum_{i\in I_\Omega}\psi(y-i)\right|^p d\mu \le \int_Y \left\{\sum_{i\in I_\Omega}|\psi(y-i)|\right\}^p d\mu$$
$$\le (\mathrm{card} I_\Omega)^{p-1}\sum_{i\in I_\Omega}\int_Y |\psi(y-i)|^p\,d\mu = (\mathrm{card} I_\Omega)^{p-1}\int_\Omega |\psi|^p\,d\mu.$$

Combining (3.10) and (3.11), we deduce that $\mathrm{div}(P_\mu\sigma\mu)\llcorner\Omega$ can be identified with an element of $L^{p'}_\mu(\Omega)$ and the first part of the statement is proved. To obtain the second assertion, we take $u\in\mathcal{C}^\infty(\mathbf{T})$ and $\sigma\in Y^{p'}_\mu(\mathbf{T})$. Then (3.7) yields

$$\int_Y \nabla_\mu u\cdot\sigma\,d\mu = \int_Y \nabla_\mu u\cdot P_\mu\sigma\,d\mu = -\int_Y u\,\mathrm{div}_\mu(P_\mu\sigma)\,d\mu\ . \qquad \square$$

As an immediate consequence of Proposition 3.7 and of Lemma 3.1, we can equivalently define $H^{1,p}_\mu(\mathbf{T})$ as follows:

$$H^{1,p}_\mu(\mathbf{T}) = \Big\{u\in L^p_\mu(\mathbf{T}) \text{ s.t. } \exists C>0 : |\langle u, \mathrm{div}(P_\mu\sigma\mu)\rangle| \le C\|\sigma\|_{p',\mu}\ \forall\sigma\in Y^{p'}_\mu(\mathbf{T})\Big\}. \tag{3.12}$$

The next theorem is the periodic version of Theorem 3.1 in [7], to which we refer for some details omitted in the proof.

PROPOSITION 3.8. *Let J be the functional defined on $L^p_\mu(\mathbf{T})$ $(p>1)$ by*

$$J(u) = \begin{cases} \displaystyle\int_Y j(y,\nabla u)\,d\mu & \text{if } u\in\mathcal{C}^\infty(\mathbf{T}),\\ +\infty & \text{if } u\in L^p_\mu(\mathbf{T})\setminus\mathcal{C}^\infty(\mathbf{T}),\end{cases}$$

where the integrand $j=j(y,z)$ is μ-measurable in y, convex in z, and satisfies, for some positive constants C,c, the growth condition

$$c|z|^p \le j(y,z) \le C\big(1+|z|^p\big) \qquad \forall (y,z)\in Y\times\mathbb{R}^n\ .$$

Then the relaxed functional of J on L^p_μ is given by

$$\overline{J}(u) = \begin{cases} \displaystyle\int_Y j_\mu(y,\nabla_\mu u)\,d\mu & \text{if } u\in H^{1,p}_\mu(\mathbf{T}),\\ +\infty & \text{if } u\in L^p_\mu(\mathbf{T})\setminus H^{1,p}_\mu(\mathbf{T}),\end{cases}$$

where

$$j_\mu(y,z) := \inf\big\{j(y,z+\xi)\ :\ \xi\in[T_\mu(y)]^\perp\big\}. \tag{3.13}$$

Remark 3.9. We stress that $j_\mu(y,z)$ depends only on the component of z along $T_\mu(y)$.

Proof. By convexity, $\overline{J}$ coincides with the bipolar functional J^{**} in the duality $\big(L^p_\mu(\mathbf{T}), L^{p'}_\mu(\mathbf{T})\big)$. Let $B: D(B)\subset L^p_\mu(\mathbf{T})\to\big(L^p_\mu(\mathbf{T})\big)^n$ be the linear operator defined by $D(B) := \mathcal{C}^\infty(\mathbf{T})$, $Bu=\nabla u$. Set $F_j(u) := \int_Y j(y,u)\,d\mu$. An abstract convex analysis lemma for the computation of $(F_j\circ B)^*$ gives (see [7, Theorem 5.1])

$$J^*(v) = (F_j\circ B)^*(v) = \inf\left\{\int_Y j^*(y,\Phi)\ :\ B^*\Phi = v\right\}\ , \qquad v\in L^{p'}_\mu(\mathbf{T})\ .$$

Now J^{**} equals by definition

$$J^{**}(u) = \sup\left\{\langle u, v\rangle - J^*(v) \ : \ v \in L^{p'}_\mu(\mathbf{T})\right\}$$

$$= \sup\left\{\langle u, B^*\Phi\rangle - \int_Y j^*(y,\Phi)\,d\mu \ : \ \Phi \in D(B^*)\right\}$$

It can be checked, arguing as in the proof of Proposition 3.7, that $D(B^*) = X^{p'}_\mu(\mathbf{T})$ and $B^*\Phi = -\operatorname{div}_\mu \Phi$, hence

$$J^{**}(u) = \sup\left\{\int_Y \left[-u\operatorname{div}_\mu\Phi - j^*(y,\Phi)\right] d\mu \ : \ \Phi \in X^{p'}_\mu(\mathbf{T})\right\}.$$

In particular, when $u \notin H^{1,p}_\mu(\mathbf{T})$, (3.12) and the growth condition satisfied by j^* lead to $J^{**}(u) = +\infty$. On the other hand, if $u \in H^{1,p}_\mu(\mathbf{T})$, we can integrate by parts and we obtain

$$J^{**}(u) = \sup\left\{\int_Y \left[\nabla_\mu u\cdot\Phi - j^*(y,\Phi)\right] d\mu \ : \ \Phi \in X^{p'}_\mu(\mathbf{T})\right\}.$$

Applying the same argument of commutation as used in the proof of Proposition 3.5, the supremum can be passed under the sign of integral; thus, taking into account (3.3), we obtain

$$\overline{J}(u) = J^{**}(u) = \int_Y \sup_{z^*\in T_\mu(y)} [\nabla_\mu u\cdot z^* - j^*(y,z^*)]d\mu = \int_Y j_\mu(y,\nabla_\mu u)d\mu\ . \qquad \square$$

4. Connectedness assumptions and two-scale limit of gradients. In this section, we consider a sequence $\{u_\varepsilon\} \subset \mathcal{C}^1_0(\Omega)$ which satisfies, as well as the sequence of its gradients $\{\nabla u_\varepsilon\}$, a uniform boundedness estimate in $L^p_{\mu_\varepsilon}$. In light of Proposition 2.3, we may associate to the pair $(u_\varepsilon, \nabla u_\varepsilon)$ a two-scale limit (u_0, χ). The aim of the structure result below (see Theorem 4.2) is to establish a differential relation between u_0 and χ, thus generalizing the Lebesgue case already studied in [1]. Dealing with a general periodic measure μ is considerably more delicate and requires us to introduce some notions of connectedness related to the Sobolev framework developed in section 3. Such notions, whose relationships are summarized in Remark 4.1 below, are all given for a fixed exponent $p \in [1, +\infty]$ and read as follows (C, c are supposed real constants).

- μ is *weakly p-connected on* $\mathbf{T}$ if

$$(H1) \qquad u \in H^{1,p}_\mu(\mathbf{T}), \quad \nabla_\mu u = 0 \ \mu\text{-a.e.} \quad \Rightarrow \quad \exists\, c \ : \ u = c \ \mu\text{-a.e.};$$

- μ is *weakly p-connected on* $\mathbb{R}^n$ if

$$(H2) \qquad u \in H^{1,p}_{\mu,loc}, \quad \nabla_\mu u = 0 \ \mu\text{-a.e.} \quad \Rightarrow \quad \exists\, c \ : \ u = c \ \mu\text{-a.e.};$$

- μ is *strongly p-connected on* $\mathbf{T}$ if

$$(H3) \qquad \exists\, C \ : \ \int_Y |u|^p\,d\mu \le C\int_Y |\nabla_\mu u|^p\,d\mu \quad \forall u \in H^{1,p}_\mu(\mathbf{T}) \text{ with } \int_Y u\,d\mu = 0;$$

- μ is *strongly p-connected on* $\mathbb{R}^n$ if

$$(H4) \qquad \exists\, C : \int_{kY} |u|^p\,d\mu \le Ck^p\int_{kY} |\nabla_\mu u|^p\,d\mu \ \ \forall k \in \mathbb{N}, \forall u \in H^{1,p}_\mu(k\mathbf{T}) \text{ with } \int_{kY} u\,d\mu = 0.$$

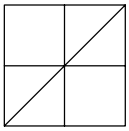

FIG. 4.1A.

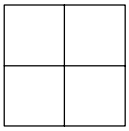

FIG. 4.1B.

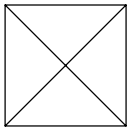

FIG. 4.1C.

Remark 4.1.

(i) We notice first that by density the properties $(H3)$–$(H4)$ need to be checked only on smooth functions. It is immediate that $(H4) \Rightarrow (H3) \Rightarrow (H1)$ and that $(H4) \Rightarrow (H2) \Rightarrow (H1)$. On the other hand we stress that $(H3) \not\Rightarrow (H2)$ (consider the case when $n = 3$ and μ is the measure $\mathcal{H}^1$ over a periodic network of e_3-parallel fibers) and that also $(H2) \not\Rightarrow (H3)$ (check by taking μ as the Lebesgue measure weighted by a suitable degenerated density).

(ii) The *assumption* $(H1)$. We stress that, in the special case when μ is the Lebesgue measure on an open periodic subset Q of $\mathbb{R}^n$, the connectedness of Q in the sense of [28, Definition 1.1] is equivalent to $(H1)$. Notice also that $(H1)$ does depend on p: in the well known-case of the Lebesgue measure concentrated on the black squares of a chess-board, it is satisfied if and only if $p > 2$. If, more drastically, the support of μ is not connected in the topological sense, then $(H1)$ is obviously false.

(iii) *The assumption* $(H4)$. Poincaré-type inequalities on manifolds or on weighted Sobolev spaces have recently received a deal of attention for their importance in different areas (see, for instance, [11], [22]). By $(H4)$ we require that the Poincaré constant on kY is finite for every $k \in \mathbb{N}$ and further that it is equal to k times the Poincaré constant on Y: by change of variables, this implies, in particular, that the Poincaré constant for each rescaled measure μ_ε on Y is independent of ε (see (5.4)). For instance, $(H4)$ is fulfilled if $n = 2$ and $\mu \llcorner Y$ is the one-dimensional Hausdorff measure over one of the sets described in Figure 4.1.

We can now prove the structure result mentioned in the opening of the section.

THEOREM 4.2. *Let $p > 1$, let Ω be an open bounded subset of $\mathbb{R}^n$ of class $\mathcal{C}^1$, and let $\{u_\varepsilon\} \subset \mathcal{C}_0^1(\Omega)$ satisfy $\int_\Omega \big(|u_\varepsilon|^p + |\nabla u_\varepsilon|^p\big)\, d\mu_\varepsilon \le M$; possibly passing to a subsequence, assume that $u_\varepsilon \rightharpoonup u_0 \in L^p_m(\Omega \times Y)$ and $\nabla u_\varepsilon \rightharpoonup \chi \in \big(L^p_m(\Omega \times Y)\big)^n$. Then*

(i) *if μ satisfies $(H1)$, $u_0(x, y) = u(x)$ (i.e. u_0 is independent of y), where the function u belongs to $W^{1,p}_0(\Omega)$ provided μ satisfies also $(H2)$ and $(H3)$;*

(ii) *under assumptions $(H2)$ and $(H3)$ on μ, there exists $u_1 \in L^p\big(\Omega, H^{1,p}_\mu(\mathbf{T})\big)$ such that $\chi(x, y) = \nabla u(x) + \nabla_{\mu,y} u_1(x, y) + \xi(y)$, with u as in* (i), *and $\xi(y) \in \big[T_\mu(y)\big]^\perp$ μ-a.e. on Y; in addition, $\nabla_{\mu_\varepsilon} u_\varepsilon \rightharpoonup \nabla u(x) + \nabla_{\mu,y} u_1(x, y)$.*

The proof of Theorem 4.2 requires some intermediate steps, which are given in the form of autonomous lemmas.

LEMMA 4.3. *Let $V := \big\{ \operatorname{div}_\mu \Phi \,:\, \Phi \in X^{p'}_\mu(\mathbf{T}) \big\}$. If μ enjoys $(H1)$, then the orthogonal space $V^\perp$ of V in $L^p_\mu(\mathbf{T})$ is given by the constant functions.*

Remark 4.4. A consequence of the above lemma is that the closure of V in $L^{p'}_\mu(\mathbf{T})$ is given by the functions with zero mean value. A similar result has been obtained in a different framework by Zhikov in the case $p = 2$ (see [28]).

Proof of Lemma 4.3. Consider the functional J on $L^p_\mu(\mathbf{T})$:

$$J(u) = \begin{cases} \dfrac{1}{p} \displaystyle\int_Y |\nabla_\mu u|^p \, d\mu & \text{if } u \in H^{1,p}_\mu(\mathbf{T}), \\ +\infty & \text{if } u \in L^p_\mu(\mathbf{T}) \setminus H^{1,p}_\mu(\mathbf{T}). \end{cases}$$

We can write J as $J = F \circ A_\sharp$, where $F(z) := \frac{1}{p}\int |z|^p \, d\mu$, and the linear operator $A_\sharp : D(A_\sharp) \subset L^p_\mu(\mathbf{T}) \to \big(L^p_\mu(\mathbf{T})\big)^n$ is defined as in section 3. For the computation of $(F \circ A_\sharp)^*$, we can apply the same lemma already used in the proof of Proposition 3.8 (see [7, Theorem 5.1]), which gives, for any $v \in L^{p'}_\mu(\mathbf{T})$,

$$\begin{aligned} J^*(v) &= \inf\left\{ \frac{1}{p'}\int_Y |\sigma|^{p'} \, d\mu \ : \ A^*_\sharp \sigma = v \right\} \\ &= \inf\left\{ \frac{1}{p'}\int_Y |\sigma|^{p'} \, d\mu \ : \ \sigma \in Y^{p'}_\mu(\mathbf{T}) \ , \ -\mathrm{div}_\mu(P_\mu \sigma) = v \right\} \\ &= \inf\left\{ \frac{1}{p'}\int_Y |\sigma|^{p'} \, d\mu \ : \ \sigma \in X^{p'}_\mu(\mathbf{T}) \ , \ -\mathrm{div}_\mu(\sigma) = v \right\}. \end{aligned}$$

Hence V coincides with $\mathrm{dom}(J^*) := \big\{ v \in L^{p'}_\mu(\mathbf{T}) \ : \ J^*(v) < +\infty \big\}$. Let J^∞ be the recession function of J. It is defined by

$$J^\infty(u) = \lim_{t\to+\infty} \frac{J(tu)}{t} = \begin{cases} +\infty & \text{if } u \notin H^{1,p}_\mu(\mathbf{T}), \\ \\ \displaystyle\lim_{t\to+\infty} \frac{t^{p-1}}{p}\int_Y |\nabla_\mu u|^p \, d\mu & \text{if } u \in H^{1,p}_\mu(\mathbf{T}). \end{cases}$$

Due to the assumption $(H1)$ on μ, we get

$$J^\infty(u) < +\infty \iff J^\infty(u) = 0 \iff \exists\, c \ : \ u = c \ \mu - \text{a.e. on } Y \ . \tag{4.1}$$

As J is convex, lower semicontinuous, and proper ($J(0) = 0$), by a well-known result in convex analysis (see, for instance, [27, Theorem 13.3]), the recession functional J^∞ of J satisfies

$$J^\infty(u) = \sup\left\{ \int_Y u\, v \, d\mu \ : \ v \in \mathrm{dom}(J^*) \right\} \ , \qquad u \in L^p_\mu(\mathbf{T}).$$

Thus u belongs to the othogonal of $V = \mathrm{dom}(J^*)$ if and only if $J^\infty(u) = 0$. The conclusion follows from (4.1). □

LEMMA 4.5. *Let j satisfy the assumptions of Proposition* 3.8*, and set*

$$j^{\mathrm{hom}}(z) := \inf\left\{ \int_Y j(y, z + \nabla u(y)) \, d\mu \ : \ u \in \mathcal{C}^\infty(\mathbf{T}) \right\}, \qquad z \in \mathbb{R}^n. \tag{4.2}$$

Then

(i) *j^{hom} is convex and satisfies a growth condition $j^{\mathrm{hom}}(z) \le \Lambda\big(1 + |z|^p\big)$ ($\Lambda \in (0, +\infty)$);*

(ii) *$\big(j^{\mathrm{hom}}\big)^*(z^*) = \inf\Big\{ \int_Y j^*(y, \Phi) \, d\mu \ : \ \Phi \in X^{p'}_\mu(\mathbf{T}),\ \mathrm{div}_\mu \Phi = 0,\ \int_Y \Phi \, d\mu = z^* \Big\}$;*

(iii) *$j^{\mathrm{hom}}(z) = \inf\Big\{ \int_Y j_\mu(y, z_\mu + \nabla_\mu u(y)) \, d\mu \ : \ u \in H^{1,p}_\mu(\mathbf{T}) \Big\}$, where $z_\mu := P_\mu(y)[z]$;*

(iv) *under the hypotheses $(H2)$ and $(H3)$ on μ, j^{hom} enjoys a coercivity property $j^{\mathrm{hom}}(z) \ge \lambda |z|^p$ ($\lambda \in (0, +\infty)$), hence in particular $(j^{\mathrm{hom}})^*$ is continuous on the whole $\mathbb{R}^n$.*

Proof. The convexity and the growth assumption on j give straightforwardly the corresponding properties for j^{hom}.

To compute $(j^{\rm hom})^*$ (in the duality $\big(\big(L^p_\mu(\mathbf{T})\big)^n, \big(L^{p'}_\mu(\mathbf{T})\big)^n\big)$), notice that $j^{\rm hom}$ can be written as

$$j^{\rm hom} = F_j \nabla\chi_G + \chi_C \ , \tag{4.3}$$

where $F_j(u) = \int_Y j(y,u)\,d\mu$, $\chi_G(u)$ and $\chi_C(u)$ are finite and equal to zero if and only if u belongs, respectively, to

$$G := \big\{\nabla\psi \ : \ \psi \in \mathcal{C}^\infty(\mathbf{T})\big\}\,, \quad C := \big\{v \in (L^p_\mu(\mathbf{T}))^n \text{ s.t. } \exists\, z \in \mathbb{R}^n \ : \ v = z \ \mu\text{-a.e. on } Y\big\}\,,$$

and $(F_j\nabla\chi_G)(u) := \inf\big\{F_j(u+v) + \chi_G(-v) \ : \ v \in \big(L^p_\mu(\mathbf{T})\big)^n\big\}$. Being F_j continuous at $0 \in \mathrm{dom}(\chi_G)$, we deduce from (4.3) (see, for instance, [27, Theorem 16.4])

$$(j^{\rm hom^*}) = (F_j\nabla\chi_G)^*\nabla\chi^*_C = \big(F^*_j + \chi^*_G\big)\nabla\chi^*_C \ .$$

We have $\chi^*_G = \chi_{G^\perp}$, $\chi^*_C = \chi_{C^\perp}$, with (recall Lemma 3.4)

$$G^\perp = \big\{\Phi \in X^{p'}_\mu(\mathbf{T}) \ : \ \mathrm{div}_\mu\,\Phi = 0\big\}\,, \qquad C^\perp = \left\{v \in \big(L^{p'}_\mu(\mathbf{T})\big)^n \ : \ \int_Y v\,d\mu = 0\right\}.$$

Thus we get, using [13, Theorem VII.14] for the computation of F^*_j,

$$\begin{aligned}
\big(j^{\rm hom}\big)^*(z^*) &= \inf\big\{F^*_j(z^*+\sigma) \ : \ z^*+\sigma \in G^\perp \ , \ \sigma \in C^\perp\big\} \\
&= \inf\left\{\int_Y j^*(y, z^*+\sigma)\,d\mu : z^*+\sigma \in X^{p'}_\mu(\mathbf{T}),\, \mathrm{div}_\mu(z^*+\sigma) = 0,\right. \\
&\qquad\qquad \left.\int_Y \sigma\,d\mu = 0\right\} \\
&= \inf\left\{\int_Y j^*(y,\Phi)\,d\mu \ : \ \Phi \in X^{p'}_\mu(\mathbf{T}),\ \mathrm{div}_\mu\,\Phi = 0,\ \int_Y \Phi\,d\mu = z^*\right\}.
\end{aligned}$$

The assertion (iii) is a consequence of Proposition 3.8 and of a well-known property of relaxation (see [12, Chapter 1]).

We finally pass to prove (iv). The growth condition from below on j implies

$$j^{\rm hom}(z) \geq c \inf\left\{\int_Y |z_\mu + \nabla_\mu u|^p\,d\mu \ : \ u \in H^{1,p}_\mu(\mathbf{T})\right\} =: c f(z).$$

In fact, by the assumption (H3) on μ, the infimum above is attained on $H^{1,p}_\mu(\mathbf{T})$. Then, we claim that $f(z) > 0$ whatever $z \neq 0$. Indeed, if $f(z) = 0$, there exists $u \in H^{1,p}_\mu(\mathbf{T})$ such that $z_\mu + \nabla_\mu u = 0$ μ-a.e. on Y, or equivalently $\nabla_\mu(z\cdot y + u) = 0$ μ-a.e. on Y. Since the function $y \mapsto z\cdot y + u\,(x)$ belongs to $H^{1,p}_{\mu,\rm loc}$, the assumption $(H2)$ on μ implies that it must be constant μ-a.e., and this is equivalent, by the periodicity of u, to requiring that z equals zero. Denoting by m_1 the (strictly positive) minimum of f on the unit ball of $\mathbb{R}^n$, and using the p-homogeneity of f, we deduce that the coercivity property (iv) holds with $\lambda = cm_1$. □

Lemma 4.6. *Let $M := \big\{\sigma \in Y^{p'}_\mu(\mathbf{T}) \ : \ \mathrm{div}_\mu(P_\mu\sigma) = 0\big\}$. If μ enjoys $(H3)$, then the orthogonal space $M^\perp$ of M in $\big(L^{p'}_\mu(\mathbf{T})\big)^n$ is given by $N := \big\{\nabla_\mu u \ : \ u \in H^{1,p}_\mu(\mathbf{T})\big\}$.*

Proof. We have $N = R(A_\sharp) :=$ image of $A_\sharp$, and $M = \ker(A^*_\sharp)$, $A^*_\sharp$ being the linear operator defined in section 3. Therefore $M = N^\perp$ [10, Corollary II.17], and so

$M^\perp = \overline{N}$. It remains to prove that N is closed in $\big(L^p_\mu(\mathbf{T})\big)^n$. To this aim, we exploit the assumption $(H3)$ on μ. Let $\{\nabla_\mu u_h\}$ be a sequence of elements of N converging in $\big(L^p_\mu(\mathbf{T})\big)^n$. Then $\big\{u_h - \int_Y u_h\,d\mu\big\}$ is a Cauchy sequence in $H^{1,p}_\mu(\mathbf{T})$, since by $(H3)$

$$\left\|u_h - \int_Y u_h\,d\mu - u_k + \int_Y u_k\,d\mu\right\|_{p,\mu} \le \big\|\nabla_\mu u_h - \nabla_\mu u_k\big\|_{p,\mu}.$$

By completeness of $H^{1,p}_\mu(\mathbf{T})$, the sequence $\big\{u_h - \int_Y u_h\,d\mu\big\}$ converges to some $u \in H^{1,p}_\mu(\mathbf{T})$, so that the limit of $\{\nabla_\mu u_h\}$ equals $\nabla_\mu u$ and in particular it belongs to N. □

We can now give the following.

Proof of Theorem 4.2. Let $\Phi \in X^{p'}_\mu(\mathbf{T})$ and $\psi \in \mathcal{D}(\overline{\Omega})$. Using (2.1), one can check that $\operatorname{div}\big(\Phi(\frac{x}{\varepsilon})\mu_\varepsilon\big) = \varepsilon^{-1}(\operatorname{div}_\mu \Phi)\big(\frac{x}{\varepsilon}\big)\mu_\varepsilon$. Then (3.1) gives

$$\operatorname{div}\left(\psi(x)\Phi\left(\frac{x}{\varepsilon}\right)\mu_\varepsilon\right) = \nabla\psi(x)\cdot\Phi\left(\frac{x}{\varepsilon}\right)\mu_\varepsilon + \varepsilon^{-1}\psi(x)(\operatorname{div}_\mu\Phi)\left(\frac{x}{\varepsilon}\right)\mu_\varepsilon. \tag{4.4}$$

Since u_ε belong to $\mathcal{D}$ (when extended to zero out of Ω), both sides of the above inequality can be applied to u_ε, and, multiplying by ε, we get

$$\begin{aligned}\varepsilon\int_\Omega \psi(x)\nabla u_\varepsilon(x)\cdot\Phi\left(\frac{x}{\varepsilon}\right)d\mu_\varepsilon \\ = \ \varepsilon\int_\Omega u_\varepsilon(x)\nabla\psi(x)\cdot\Phi\left(\frac{x}{\varepsilon}\right)d\mu_\varepsilon + \int_\Omega u_\varepsilon(x)\psi(x)(\operatorname{div}_\mu\Phi)\left(\frac{x}{\varepsilon}\right)d\mu_\varepsilon.\end{aligned}$$

If we pass to the limit as $\varepsilon\to 0$, taking into account that $\{u_\varepsilon\}$ and $\{\nabla u_\varepsilon\}$ are both uniformly bounded in $L^p_{\mu_\varepsilon}(\Omega)$, we obtain

$$\lim_{\varepsilon\to 0}\int_\Omega u_\varepsilon(x)\psi(x)(\operatorname{div}_\mu\Phi)\left(\frac{x}{\varepsilon}\right)d\mu_\varepsilon = 0.$$

Now, in view of Remark 2.4, $\varphi(x,y) := \psi(x)\operatorname{div}_\mu\Phi(y)$ is an admissible test function with respect to the two-scale convergence, and we infer

$$\int_\Omega \psi(x)\left[\int_Y u_0(x,y)\operatorname{div}_\mu\Phi(y)\,d\mu(y)\right]dx = 0.$$

By the arbitrariness of $\psi\in\mathcal{D}(\overline{\Omega})$ and of $\Phi\in X^{p'}_\mu(\mathbf{T})$, it follows that, for $\mathcal{L}^n$-a.e. $x\in\Omega$, $u_0(x,\cdot)$ belongs to $V^\perp$ with V defined as in Lemma 4.3. Then by the same lemma we deduce that, for $\mathcal{L}^n$-a.e. $x\in\Omega$, $u_0(x,\cdot)$ is constant μ-a.e. on Y.

Set $u(x) := u_0(x,y)$, and let us prove that u belongs to $W^{1,p}_0(\Omega)$ under the assumptions $(H2)$ and $(H3)$ on μ. Let ψ, Φ be as above, and assume in addition that $\operatorname{div}_\mu\Phi = 0$. Applying both sides of (4.4) to u_ε (this time without multiplying by ε), it follows that

$$-\int_\Omega \psi(x)\nabla u_\varepsilon(x)\cdot\Phi\left(\frac{x}{\varepsilon}\right)d\mu_\varepsilon = \int_\Omega u_\varepsilon(x)\nabla\psi(x)\cdot\Phi\left(\frac{x}{\varepsilon}\right)d\mu_\varepsilon.$$

Passing to the two-scale limit, we deduce

$$\begin{aligned}-\int_{\Omega\times Y}\psi(x)\chi(x,y)\cdot\Phi(y)\,dm &= \int_{\Omega\times Y} u(x)\nabla\psi(x)\cdot\Phi(y)\,dm \\ &= \left\{\int_\Omega u(x)\nabla\psi(x)\,dx\right\}\cdot\left\{\int_Y\Phi(y)\,d\mu\right\}.\end{aligned} \tag{4.5}$$

By the Hölder inequality, it follows that

$$\overline{\Phi}\cdot\int_\Omega u\nabla\psi\,dx\le\|\chi\|_{p,m,\Omega\times Y}\|\Phi\|_{p',\mu,Y}\|\psi\|_{p',\mathcal{L}^n,\Omega}\ , \tag{4.6}$$

where we have set $\overline{\Phi}:=\int_Y\Phi(y)\,d\mu(y)$. Consider now the convex subset of $\mathbb{R}^n$

$$K:=\Big\{\overline{\Phi}\ :\ \Phi\in X_\mu^{p'}\ ,\ \mathrm{div}_\mu\,\Phi=0\ ,\ \|\Phi\|_{p',\mu,Y}\le 1\Big\}\ . \tag{4.7}$$

Notice that, by Lemma 4.5 (iii) and the definition of K, we have

$$\mathrm{dom}\,\big(j^{\mathrm{hom}}\big)^*=\bigcup_{\lambda\in\mathbb{R}}\lambda K\ .$$

If μ satisfies $(H2)$ and $(H3)$, we know from Lemma 4.5(iv) that $\mathrm{dom}\,\big(j^{\mathrm{hom}}\big)^*=\mathbb{R}^n$, so K must have a nonempty interior. By the regularity assumption on Ω, it follows from (4.6) that u belongs to $W_0^{1,p}(\Omega)$ (cf. [10, Proposition IX.18]).

We can in this case integrate by parts on Ω at the right-hand side of (4.5). We get

$$\int_\Omega\psi(x)\left\{\int_Y\big[\chi(x,y)-\nabla u(x)\big]\cdot\Phi(y)\,d\mu(y)\right\}dx=0.$$

By the arbitrariness of $\psi\in\mathcal{D}(\overline{\Omega})$, it follows that, for $\mathcal{L}^n$-a.e.$x\in\Omega$ and for every vector field $\Phi\in X_\mu^{p'}(\mathbf{T})$ with $\mathrm{div}_\mu\,\Phi=0$, there holds

$$\int_Y\big[\chi(x,y)-\nabla u(x)\big]\cdot\Phi(y)\,d\mu(y)=0\ .$$

In particular, taking $\Phi=P_\mu\sigma$, with $\sigma\in Y_\mu^{p'}(\mathbf{T})$, we deduce that $P_\mu(\cdot)\big[\chi(x,\cdot)-\nabla u(x)\big]$ belongs to $M^\perp$, where M is defined as in Lemma 4.6. Using such lemma, it then follows that there exists $u_1\in L^p(\Omega,H_\mu^{1,p}(\mathbf{T}))$ such that $P_\mu(y)\big[\chi(x,y)-\nabla u(x)\big]=\nabla_{\mu,y}u_1(x,y)$. Hence $\chi(x,y)=\nabla u(x)+\nabla_{\mu,y}u_1(x,y)+\xi(y)$, with $\xi(y)\in[T_\mu(y)]^\perp$. Finally, we apply Proposition 2.8 to the sequences $P_{\mu_\varepsilon}\in L^{p'}_{\mu_\varepsilon}(\Omega;\mathbb{R}^{n^2})$ and $\nabla u_\varepsilon\in L^p_{\mu_\varepsilon}(\Omega;\mathbb{R}^n)$: we have, respectively, $P_{\mu_\varepsilon}\twoheadrightarrow P_\mu(y)$ (see Example 2.7) and $\nabla u_\varepsilon\rightharpoonup\chi(x,y)$, so that the product $P_{\mu_\varepsilon}(\nabla u_\varepsilon)=\nabla_{\mu_\varepsilon}u_\varepsilon$ two-scale converges to $P_\mu(y)\big(\chi(x,y)\big)=\nabla u(x)+\nabla_{\mu,y}u_1(x,y)$. □

Remark 4.7. When $(H2)$ does not hold, we can apply all the steps of the above proof except that in this case the convex set K defined by (4.7) has an empty interior. Thus, denoting by M the subspace of $\mathbb{R}^n$ spanned by the relative interior of K, the estimate $z\cdot\nabla u\in L^p(\Omega)$ can be obtained only for $z\in M$. Therefore, in part (i) of Theorem 4.2, the assertion $u\in W_0^{1,p}(\Omega)$ must be replaced by $u\in W^{1,p}_{0,M}(\Omega)$, where

$$W^{1,p}_{0,M}(\Omega):=\big\{u\in L^p(\Omega)\ :\ \forall z\in M\ ,\ \ z\cdot\nabla u\in L^p(\Omega)\ \text{ and }\ u\,(\nu_\Omega\cdot z)=0\ \text{on}\ \partial\Omega\big\}.$$

5. Homogenization with periodic measures. We can now consider the homogenization problem introduced at the beginning of the paper, namely, the study of the Γ-convergence in the sense of De Giorgi [19] of the sequence of functionals

$$J_\varepsilon(u)=\begin{cases}\displaystyle\int_\Omega j\big(\frac{x}{\varepsilon},\nabla u\big)\,d\mu_\varepsilon & \text{if } u\in\mathcal{C}_0^1(\Omega),\\ +\infty & \text{if } u\in L^p_\mu(\Omega)\setminus\mathcal{C}_0^1(\Omega).\end{cases} \tag{5.1}$$

Let us fix here the assumptions made on the integrand $j(y,z)$, which, however, fall into the standard setting already employed in section 3: j is μ-measurable and Y-periodic in y, convex in z, and satisfies, for suitable positive constants C, c, the p-growth condition (where $p > 1$)

$$c|z|^p \le j(y,z) \le C\big(1+|z|^p\big)\ , \qquad (y,z) \in \mathbb{R}^n \times \mathbb{R}^n. \tag{5.2}$$

Naturally, the first step to be done in the study of the asymptotic behavior of J_ε is the choice of a suitable convergence on the class of all admissible functions u. To this purpose, note that the role played by u in the expression of $J_\varepsilon(u)$ is that of a function defined μ_ε-a.e.; thus, as μ_ε varies with ε, it is convenient to see the convergence of u_ε to u as the weak star convergence of the measures μ_ε to $u\mathcal{L}^n$. Therefore we implicitly extend the definition (5.1) of J_ε to the space $\mathcal{M}$ of Radon measures on $\mathbb{R}^n$ by setting

$$J_\varepsilon(\lambda) = \begin{cases} \displaystyle\int_\Omega j\big(\frac{x}{\varepsilon}, \nabla u\big)\, d\mu_\varepsilon & \text{if } \lambda = u\mu_\varepsilon\ ,\ u \in \mathcal{C}_0^1(\Omega), \\ +\infty & \text{otherwise.} \end{cases} \tag{5.3}$$

The equicoerciveness of (J_ε) on $\mathcal{M}$ obtained in Lemma 5.1 below is related to the strong p-connectness property of μ.

LEMMA 5.1. *Let $p > 1$ and μ be a periodic Radon measure satisfying $(H4)$. Then, for any sequence $\{u_\varepsilon\} \in \mathcal{C}_0^1(\Omega)$ such that $J_\varepsilon(u_\varepsilon\mu_\varepsilon)$ is upper bounded, we have that $\sup_\varepsilon \int_\Omega |u_\varepsilon|^p\, d\mu_\varepsilon < +\infty$; therefore $\{u_\varepsilon\mu_\varepsilon\}$ is relatively compact in $\mathcal{M}$ and any of its limit points is absolutely continuous with respect to $\mathcal{L}^n$, with a density $u \in L^p(\Omega)$.*

Proof. By the coerciveness assumption on j, there exists $M' > 0$ such that $\int_\Omega |\nabla u_\varepsilon|^p\, d\mu_\varepsilon \le M'$. Notice now that, for any $\varepsilon > 0$, any integer k, and any $v \in \mathcal{C}_0^1(\varepsilon k Y)$, there holds

$$\int_{\varepsilon k Y} |v|^p\, d\mu_\varepsilon \le (\varepsilon k C)^p \int_{\varepsilon k Y} |\nabla v|^p\, d\mu_\varepsilon, \tag{5.4}$$

where C is the positive and finite constant involved in $(H4)$. Indeed, using the definition of μ_ε and the assumption $(H4)$ on μ, we get

$$\begin{aligned} \int_{\varepsilon k Y} |v|^p\, d\mu_\varepsilon &= \varepsilon^n \int_{kY} |v(\varepsilon x)|^p\, d\mu \le \varepsilon^n (kC)^p \int_{kY} \big|\nabla\big(v(\varepsilon x)\big)\big|^p\, d\mu \\ &= \varepsilon^n (\varepsilon k C)^p \int_{kY} |\nabla v(\varepsilon x)|^p\, d\mu = (\varepsilon k C)^p \int_{\varepsilon k Y} |\nabla v|^p\, d\mu_\varepsilon\ . \end{aligned}$$

Since Ω is bounded, for any $\varepsilon > 0$ there exists a positive integer k_ε, with $\varepsilon k_\varepsilon \le C' < +\infty$, such that $\Omega \subset \varepsilon k_\varepsilon Y$. Applying (5.4) to every $u_\varepsilon \in \mathcal{C}_0^1(\Omega) \subset \mathcal{C}_0^1(\varepsilon k_\varepsilon Y)$, we infer

$$\int_\Omega |u_\varepsilon|^p\, d\mu_\varepsilon = \int_{\varepsilon k_\varepsilon Y} |u_\varepsilon|^p\, d\mu_\varepsilon \le (C')^p C^p \int_{\varepsilon k_\varepsilon Y} |\nabla u_\varepsilon|^p\, d\mu_\varepsilon \le (C')^p C^p M'\ . \tag{5.5}$$

Then the weak compactness of $\{u_\varepsilon\mu_\varepsilon\}$ in $\mathcal{M}$, and the fact that any of its limit points is absolutely continuous with respect to $\mathcal{L}^n$, with a density $u \in L^p(\mathbb{R}^n)$, follows straightforward from Proposition 2.3. ∎

We can now state our main Γ-convergence theorem. It extends to general periodic measures μ the well-known result proved for the first time by Marcellini [24] in the case when μ is the Lebesgue measure over the complement of a periodic system of balls.

For the sake of completeness, we preliminarily recall that the the sequence $\{J_\varepsilon\}$ Γ-converges to $J^{\rm hom}$ if and only if both of the following inequalities hold:

(I) $\inf\Big\{ \liminf_{\varepsilon\to 0} J_\varepsilon(\lambda_\varepsilon) \ : \ \lambda_\varepsilon \rightharpoonup \lambda\Big\} \geq J^{\rm hom}(\lambda)\ , \quad \lambda\in\mathcal{M}\ ;$

(II) $\inf\Big\{ \limsup_{\varepsilon\to 0} J_\varepsilon(\lambda_\varepsilon) \ : \ \lambda_\varepsilon \rightharpoonup \lambda\Big\} \leq J^{\rm hom}(\lambda)\ , \quad \lambda\in\mathcal{M}\ .$

THEOREM 5.2. *Let μ satisfy $(H4)$ (and let $p>1$). Then the sequence $\{J_\varepsilon\}$ defined in* (5.3) *Γ-converges on $\mathcal{M}$ as $\varepsilon\to 0$ to the homogenized functional $J^{\rm hom}$ defined by*

$$J^{\rm hom}(\lambda) = \begin{cases} \displaystyle\int_\Omega j^{\rm hom}(\nabla u(x))\,dx & \text{if } \lambda = u\mathcal{L}^n\ ,\ u\in W^{1,p}_0(\Omega),\\ +\infty & \text{otherwise,}\end{cases} \tag{5.6}$$

where the integrand $j^{\rm hom}$ is defined via the unit-cell problem (4.2).

Remark 5.3. Theorem 5.2 can also be formulated replacing $(H4)$ by $(H2)$–$(H3)$: in this case we need to restrict ourselves to sequences $\{u_\varepsilon\}$ such that $\sup_\varepsilon \int |u_\varepsilon|^p\,d\mu_\varepsilon < +\infty$. One can also skip the assumption $(H2)$: in this case the integrand $j^{\rm hom}$ is still given by formula (4.2), but it degenerates in the directions $z\in M^\perp$, where M is the linear space defined in Remark 4.7; accordingly, $W^{1,p}_0(\Omega)$ has to be replaced by $W^{1,p}_{0,M}$ in the homogenization formula (5.6).

Proof of Theorem 5.2. We divide the proof into two parts, showing separately that the inequalities (I) and (II) required for the Γ-convergence hold.

Proof of (I). By Lemma 5.1, it is enough to prove (I) for $\lambda = u\mathcal{L}^n$, with $u\in W^{1,p}_0(\Omega)$. Let $u_\varepsilon\mu_\varepsilon \rightharpoonup u\mathcal{L}^n$, with $J_\varepsilon(u_\varepsilon\mu_\varepsilon)\leq M$. Then, by Lemma 5.1 and Theorem 4.2(i), we can assume that $\{u_\varepsilon\}$ two-scale converges to a function $u_0(x,y)$ independent of y, which then must be equal to $u(x)$. Moreover, we know from Theorem 4.2(ii) that $\nabla u_\varepsilon \rightharpoonup \chi$, where $\chi(x,y) = \nabla u(x) + \nabla_{\mu,y} u_1(x,y) + \xi(y)$, with $u_1\in L^p(\Omega, H^{1,p}_\mu(\mathbf{T}))$ and $\xi(y)\in \big[T_\mu(y)\big]^\perp$ μ-a.e. Applying Proposition 2.5, definition (3.13) of j_μ, and (iii) of Lemma 4.5, we obtain

$$\begin{aligned}\liminf_{\varepsilon\to 0} J_\varepsilon(u_\varepsilon\mu_\varepsilon) &\geq \int_{\Omega\times Y} j(y,\chi(x,y))\,dm = \int_{\Omega\times Y} j\big(y,\nabla u(x)+\nabla_{\mu,y}u_1(x,y)+\xi(y)\big)\,dm\\ &\geq \int_\Omega \left\{\int_Y \big[j_\mu(y,\nabla u(x)+\nabla_{\mu,y}u_1(x,y)\big]\,d\mu\right\} dx \geq \int_\Omega j^{\rm hom}\big(\nabla u(x)\big)\,dx.\end{aligned}$$

Proof of (II). Let $\lambda = u\mathcal{L}^n$, with $u\in W^{1,p}_0(\Omega)$; otherwise, there is nothing to prove. We have to find $\{u_\varepsilon\}\subset \mathcal{C}^1_0(\Omega)$ such that $\limsup_{\varepsilon\to 0} J_\varepsilon(u_\varepsilon)\leq J^{\rm hom}(\lambda)$. In view of the density of $\mathcal{D}(\Omega)$ into $W^{1,p}(\Omega)$, and of the continuity of $J^{\rm hom}$, by a standard diagonalization argument it is not restrictive to assume that $u\in\mathcal{D}(\Omega)$. For an arbitrary function $\varphi\in\mathcal{D}(\Omega;\mathcal{C}^\infty(\mathbf{T}))$, consider the sequence $\{u_\varepsilon\}\subset\mathcal{D}(\Omega)$ defined by

$$u_\varepsilon(x) = u(x) + \varepsilon\varphi\left(x,\frac{x}{\varepsilon}\right).$$

The measures $\{u_\varepsilon\mu_\varepsilon\}$ converge weakly to $u\mathcal{L}^n$, because $\varphi\big(x,\frac{x}{\varepsilon}\big)\mu_\varepsilon \rightharpoonup \{\int_Y \varphi(x,y)\,d\mu(y)\}\mathcal{L}^n$, and so $\varepsilon\varphi\big(x,\frac{x}{\varepsilon}\big)\mu_\varepsilon \rightharpoonup 0$. We have

$$\nabla u_\varepsilon(x) = \nabla u(x) + \varepsilon\nabla_x\varphi\left(x,\frac{x}{\varepsilon}\right) + \nabla_y\varphi\left(x,\frac{x}{\varepsilon}\right);$$

hence, by a well-known lemma concerning convex functions which satisfy a p-growth condition (see, for instance, [20, eq. 4.2.1]), the following inequality holds for some

positive constant C:

$$\begin{aligned}&\left|j(\nabla u_\varepsilon(x)) - j\left(\nabla u(x) + \nabla_y\varphi\left(x,\frac{x}{\varepsilon}\right)\right)\right| \\ &\qquad \le C\varepsilon\left|\nabla_x\varphi\left(x,\frac{x}{\varepsilon}\right)\right|\left\{1 + \left|\nabla u(x)\right|^{p-1} + \left|\nabla_y\varphi\big(x,\frac{x}{\varepsilon}\big)\right|^{p-1}\right\}.\end{aligned}$$

Integrating over Ω, a quite standard application of the Hölder inequality yields

$$\lim_{\varepsilon\to 0}\int_\Omega j(\nabla u_\varepsilon)\,d\mu_\varepsilon = \lim_{\varepsilon\to 0}\int_\Omega j\left(\nabla u(x) + \nabla_y\varphi\left(x,\frac{x}{\varepsilon}\right)\right)\,d\mu_\varepsilon.$$

Hence, to compute the limit of $J_\varepsilon(u_\varepsilon)$, we are reduced to having to apply convergence (2.3) to the right-hand side of the above equality choosing $v(x,y) = j\big(\nabla u(x) + \nabla_y\varphi(x,y)\big)$ as a test function. So we infer

$$\lim_{\varepsilon\to 0}\int_\Omega j\left(\frac{x}{\varepsilon},\nabla u_\varepsilon\right)\,d\mu_\varepsilon = \int_{\Omega\times Y} j\big(y,\nabla u(x) + \nabla_y\varphi(x,y)\big)\,dm.$$

In particular, we deduce that the upper Γ-limit of J_ε, defined by

$$J(u) := \inf_{u_\varepsilon\mu_\varepsilon \rightharpoonup u\mathcal{L}^n}\left\{\limsup_{\varepsilon\to 0}\int_\Omega j\left(\frac{x}{\varepsilon},\nabla u_\varepsilon\right)\,d\mu_\varepsilon\right\},$$

satisfies

$$J(u) \le \inf_{\varphi\,\in\,\mathcal{D}(\Omega;\mathcal{C}^\infty(\mathbf{T}))}\left\{\int_{\Omega\times Y} h_\varphi(x)\,dm\right\},$$

where

$$h_\varphi(x) := \int_Y j\big(y,\nabla u(x) + \nabla_y\varphi(x,y)\big)\,d\mu(y).$$

Noticing that, by a standard localization argument, we have for all $x\in\Omega$

$$\inf_{\varphi\,\in\,\mathcal{D}(\Omega;\mathcal{C}^\infty(\mathbf{T}))} h_\varphi(x) = \inf_{\varphi\,\in\,\mathcal{C}^\infty(\mathbf{T})} h_\varphi(x) = j^{hom}(\nabla u(x)),$$

the proof of the inequality $J(u)\le J^{hom}(u)$ (i.e., of (II)) is then concluded provided we show that

$$\inf_{\varphi\,\in\,\mathcal{D}(\Omega;\mathcal{C}^\infty(\mathbf{T}))}\int_\Omega h_\varphi\,dx = \int_\Omega\left\{\inf_{\varphi\,\in\,\mathcal{D}(\Omega;\mathcal{C}^\infty(\mathbf{T}))} h_\varphi(x)\right\}\,dx\ . \tag{5.7}$$

At this point we make use of the following commutation argument [8, Theorem 1]: if $\mathcal{H}\subset L^1(\Omega)$ is an *inf-stable family*, in the sense that

$$\begin{gathered}\{u_1,\dots,u_N\}\subset\mathcal{H}\ ,\quad \{\alpha_1,\dots,\alpha_N\}\subset\mathcal{C}^1(\overline{\Omega};[0,1]),\ \text{with}\ \sum_{i=1}^N\alpha_i = 1,\\ \Downarrow \\ \exists u\in\mathcal{H}\ :\ u\le\sum_{i=1}^N\alpha_i u_i\ ,\end{gathered} \tag{5.8}$$

then

$$\inf_{u\in\mathcal{H}}\int_\Omega u\,dx=\int_\Omega \operatorname*{ess\,inf}_{u\in\mathcal{H}} u\;dx\;.$$

In order to prove (5.7), we apply this principle to the the subfamily of $L^1(\Omega)$ defined by

$$\mathcal{H}:=\big\{h_\varphi\;:\;\varphi\in\mathcal{D}(\Omega;\mathcal{C}^\infty(\mathbf{T}))\big\}\;.$$

To check the inf-stability of $\mathcal{H}$, we consider $\{\varphi_1,\dots,\varphi_N\}\subset\mathcal{D}(\Omega;\mathcal{C}^\infty(\mathbf{T}))$, $\{\alpha_1,\dots,\alpha_N\}$ as in (5.8), and $\overline{\varphi}(x,y):=\sum_{i=1}^N\alpha_i(x)\varphi(x,y)$. Then $\overline{\varphi}\in\mathcal{D}(\Omega;\mathcal{C}^\infty(\mathbf{T}))$, so that $h_{\overline{\varphi}}\in\mathcal{H}$. We claim that $h_{\overline{\varphi}}\le\sum_{i=1}^N\alpha_i h_{\varphi_i}$. Indeed,

$$\begin{aligned}h_{\overline{\varphi}}(x)&:=\int_Y j\big(y,\nabla u(x)+\nabla_y\overline{\varphi}(x,y)\big)d\mu(y)\\&=\int_Y j\left(y,\sum_{i=1}^N\alpha_i(x)[\nabla u(x)+\nabla_y\varphi_i(x,y)]\right)d\mu(y)\\&\le\sum_{i=1}^N\alpha_i(x)\int_Y j\big(y,\nabla u(x)+\nabla_y\varphi_i(x,y)\big)\,d\mu(y)=\sum_{i=1}^N\alpha_i(x)h_{\varphi_i}(x),\end{aligned}$$

where we used the convexity of j in its second variable. Thus we get

$$\inf_{\varphi\,\in\,\mathcal{D}(\Omega;\mathcal{C}^\infty(\mathbf{T}))}\int_\Omega h_\varphi(x)\,dx=\int_\Omega\operatorname*{ess\,inf}_{\varphi\,\in\,\mathcal{D}(\Omega;\mathcal{C}^\infty(\mathbf{T}))}h_\varphi(x)\,dx\;.\tag{5.9}$$

On the other hand, $\mathcal{H}$ is contained in the space $\mathcal{C}_0(\Omega)$, which is separable with respect to the uniform norm; hence, we can find a sequence $\{h_n\}$ such that $\inf_{h\in\mathcal{H}}h(x)=\inf_n h_n(x)\;\forall x\in\Omega$. It follows from the definition of essential infimum that

$$\operatorname*{ess\,inf}_{h\in\mathcal{H}}h(x)=\inf_n h_n(x)=\inf_{h\in\mathcal{H}}h(x)\qquad\mathcal{L}^n\text{-a.e. on }\Omega\;.\tag{5.10}$$

By (5.9) and (5.10), (5.7) is proved and this achieves our proof. □

As a consequence of well-known properties of Γ-convergence [19, Theorem 7.8 and Corollary 7.17], we deduce from Lemma 6.1 and Theorem 6.2 the following.

COROLLARY 5.4. *Let μ satisfy $(H4)$ with $p>1$, and consider for any $\varepsilon>0$ the problem*

$$\inf\left\{J_\varepsilon(u)-\int_\Omega fu\,d\mu_\varepsilon\;,\quad u\in\mathcal{C}_0^1(\Omega)\right\},\tag{$\mathcal{P}_\varepsilon$}$$

where J_ε are defined by (5.1)*, and f is a prescribed function in $\mathcal{C}(\overline{\Omega})$. Then*

(i) $\liminf_{\varepsilon\to0}(\mathcal{P}_\varepsilon)=\min(\mathcal{P})$*;*

(ii) *if $\{u_\varepsilon\}$ is a minimizing sequence for $(\mathcal{P}_\varepsilon)$, up to subsequences it holds, that $u_\varepsilon\mu_\varepsilon\rightharpoonup u\mathcal{L}^n$, where u solves the limit problem $(\mathcal{P})$, given by*

$$\min\left\{J^{\rm hom}(u)-\int_\Omega fu\,dx\;,\quad u\in W_0^{1,p}(\Omega)\right\}.\tag{$\mathcal{P}$}$$

As usual, in the case of quadratic functionals, the unit-cell problem defined in (5.2) is completely determined in terms of n linear problems. Let us assume that the density of J_ε is given by $j(y,z) = \frac{1}{2}\sum_{i,j} a_{ij}(y) z_i\, z_j$, where the coefficients of the matrix $A(y) := a_{ij}(y)$ belong to $L^\infty(\mathbf{T})$ and are such that $\lambda|z|^2 \le j(y,z) \le \Lambda(1+|z|^2)$ for suitable positive constants λ and Λ. Then, we consider the following linear problems on the unit cell:

$$-\operatorname{div}_y \Big[A(y)\Big(e_{i,\mu}(y) + \nabla_\mu \chi_i(y)\Big)\Big] = 0\ , \qquad \chi_i \in H^{1,2}_\mu(\mathbf{T})\ , \qquad i = 1,2,\dots,n\ , \tag{5.11}$$

where we have set $e_{i,\mu}(y) := P_\mu(y) e_i$. Accordingly, the homogenized integrand takes the form $j^{\hom}(z) = \frac{1}{2} A^{\hom} z \cdot z$, where the effective matrix $A^{\hom}$ is given by

$$A^{\hom}_{i,j} = \int_Y \big(e_{i,\mu} + \nabla_{\mu,y}\chi_i\big)\cdot\big(e_{j,\mu} + \nabla_{\mu,y}\chi_j\big)\, d\mu(y)\ ; \tag{5.12}$$

consequently, the homogenized problem reads as

$$-\operatorname{div}_x\big(A^{\hom}\nabla u(x)\big) = f(x)\ , \qquad u \in W^{1,2}_0(\Omega). \tag{5.13}$$

In light of our two-scale approach we obtain the following corrector-type result.

PROPOSITION 5.5. *Under the same assumptions of Corollary* 5.4, *suppose in addition that j is quadratic as above and let $\{u_\varepsilon\}$ be a minimizing sequence for problem $(\mathcal{P}_\varepsilon)$. Then*

$$(u_\varepsilon, \nabla_{\mu_\varepsilon} u_\varepsilon) \ \rightharpoonup\ \left(u(x)\,,\ \sum_i (e_i + \nabla_{\mu,y}\chi_i(y))\,\frac{\partial u}{\partial x_i}(x)\right), \tag{5.14}$$

where $u \in W^{1,2}_0(\Omega)$ and $\chi_i \in H^{1,2}_\mu(\mathbf{T})$ are, respectively, the unique solutions to (5.13) *and to* (5.11). *Moreover, setting $u_1(x,y) := \sum_i \frac{\partial u}{\partial x_i}(x)\,\chi_i(y)$, we have*

$$\lim_{\varepsilon\to 0}\int_\Omega \big|u_\varepsilon(x) - u(x)\big|^2\, d\mu_\varepsilon = 0, \tag{5.15}$$

$$\lim_{\varepsilon\to 0}\Big\|u_\varepsilon - u - u_1\Big(x, \frac{x}{\varepsilon}\Big)\Big\|_{H^{1,2}_{\mu_\varepsilon}(\Omega)} = 0. \tag{5.16}$$

Proof. By Theorem 4.2, up to subsequences $(u_\varepsilon, \nabla_{\mu_\varepsilon} u_\varepsilon)$ two-scale converges to $(u(x), \nabla u(x) + \nabla_{\mu,y} u_1(x,y))$, where $(u,u_1) \in W^{1,2}_0(\Omega)\times L^2(\Omega, H^{1,2}_\mu(\mathbf{T}))$. Let now $(\varphi,\varphi_1) \in \mathcal{D}(\Omega)\times\mathcal{D}(\Omega;\mathcal{C}^\infty(\mathbf{T}))$, and multiply by $\varphi(x) + \varphi_1(x, \frac{x}{\varepsilon})$ the Euler equation satisfied by u_ε. Passing to the two-scale limit, we obtain that (u,u_1) satisfy the variational formulation

$$\begin{aligned}&\int_{\Omega\times Y} A(y)\,[\nabla u(x) + \nabla_{\mu,y} u_1(x,y)]\cdot[\nabla\varphi(x) + \nabla_{\mu,y}\varphi_1(x,y)]\, dm\\ &\qquad = \int_\Omega f(x)\varphi(x)\, dx \qquad \forall(\varphi,\varphi_1)\in\mathcal{D}(\Omega)\times\mathcal{D}(\Omega;\mathcal{C}^\infty(\mathbf{T}))\ .\end{aligned} \tag{5.17}$$

By Lax–Milgram's theorem, (5.17) admits a unique solution; thus (u,u_1) do not depend on the choice of the subsequence. Now it is easily seen that (5.17) is the variational formulation of the system

$$\begin{cases} -\operatorname{div}_y\Big[A(y)\Big(\nabla u(x) + \nabla_{\mu,y} u_1(x,y)\Big)\Big] = 0 & \text{in } \Omega\times Y,\\ -\operatorname{div}_x\Big[\displaystyle\int_Y A(y)\Big(\nabla u(x) + \nabla_{\mu,y} u_1(x,y)\Big)\, d\mu(y)\Big] = f & \text{in } \Omega,\end{cases}$$

which is in turn equivalent to the homogenized equations (5.13) and (5.11) via (5.12) and the relation $u_1(x,y) = \sum_i \frac{\partial u}{\partial x_i}(x)\,\chi_i(y)$. Thus (5.14) is proved. In order to prove the second part of the statement, we notice first that the corrector result (5.15) follows straightforwardly from (5.16). Indeed, by (H4), a Poincaré constant independent of ε rules as well for all the measures μ_ε (cf. (5.5)). Hence, we are done if we show (5.16). First we claim that, since u_ε is a minimizing sequence for $(\mathcal{P}_\varepsilon)$, we have

$$\lim_{\varepsilon\to 0}\left(\int_\Omega A\left(\frac{x}{\varepsilon}\right)\left\{\nabla_{\mu_\varepsilon} u_\varepsilon\right\}^2 dx - \int_\Omega f u_\varepsilon dx\right) = 0\ . \tag{5.18}$$

Indeed, setting $\alpha_\varepsilon := \int_\Omega A(\frac{x}{\varepsilon})\big\{\nabla_{\mu_\varepsilon} u_\varepsilon\big\}^2 dx$ and $\beta_\varepsilon := \int_\Omega f u_\varepsilon dx$, we have, for every real t and for a suitable sequence $\delta_\varepsilon \to 0$,

$$\frac{1}{2}\alpha_\varepsilon - \beta_\varepsilon = J_\varepsilon(u_\varepsilon) - \int_\Omega f u_\varepsilon\, d\mu_\varepsilon \;\le\; J_\varepsilon(tu_\varepsilon) - \int_\Omega f\,(tu_\varepsilon)\, d\mu_\varepsilon + \delta_\varepsilon = \frac{1}{2}t^2\alpha_e - t\beta_\varepsilon + \delta_\varepsilon\ .$$

Taking then the infimum with respect to t, we get $\frac{1}{2}\alpha_\varepsilon - \beta_\varepsilon \le -\frac{1}{2}\frac{\beta_\varepsilon^2}{\alpha_\varepsilon} + \delta_\varepsilon$; thus $\frac{(\alpha_\varepsilon-\beta_\varepsilon)^2}{\alpha_e} \to 0$, which proves the claim. Now, by (5.18),

$$\begin{aligned}
&\lim_{\varepsilon\to 0}\int_\Omega A\left(\frac{x}{\varepsilon}\right)\left\{\nabla_{\mu_\varepsilon}\left[u_\varepsilon(x) - u(x) - \varepsilon u_1\left(x,\frac{x}{\varepsilon}\right)\right]\right\}^2 d\mu_\varepsilon\\
&= \lim_{\varepsilon\to 0}\left\{\int_\Omega f(x)u_\varepsilon(x)d\mu_\varepsilon - 2\int_\Omega A\left(\frac{x}{\varepsilon}\right)\nabla_{\mu_\varepsilon}u_\varepsilon\cdot\nabla_{(\mu_\varepsilon)}\left[u(x)+\varepsilon u_1\left(x,\frac{x}{\varepsilon}\right)\right] d\mu_\varepsilon\right.\\
&\qquad\left. + \int_\Omega A\left(\frac{x}{\varepsilon}\right)\left\{\nabla_{\mu_\varepsilon}\left[u(x)+\varepsilon u_1\left(x,\frac{x}{\varepsilon}\right)\right]\right\}^2 d\mu_\varepsilon\right\}\\
&= \int_\Omega f(x)u(x)\,dx - \int_{\Omega\times Y} A(y)\left\{\nabla u(x) + \nabla_{\mu,y}u_1(x,y)\right\}^2 dm,
\end{aligned}$$

where we used the notation $Av^2 := Av\cdot v$. We now observe that, in view of the equality $u_1(x,y) = \sum_i \frac{\partial u}{\partial x_i}(x)\,\chi_i(y)$, it turns out that u_1, $\nabla_x u_1$, and $\nabla_{\mu,y}u_1$ are all "admissible" in the two-scale convergence (cf. Remark 2.4). Hence, we are allowed to take $(\varphi,\varphi_1) = (u,u_1)$ as test functions in (5.17); thus the last term in the above chain of equalities is zero, and (5.16) follows straightforward using the coercivity of A. □

Example 5.6. We conclude this section with an example of explicit computation of $j^{\hom}$ when μ is, respectively, the one-dimensional measure on a periodic grid or it has a Cantor-like structure. In the former case, our method allows us to recover in a very direct and concise way the homogenized energy density obtained in [17] through the classical fattening approach. The latter case can also be easily handled, in spite of the irregular structure of μ.

Let j be a quadratic-like energy density of the kind

$$j(z) = \frac{1}{2}\big(a_{11}z_1^2 + 2a_{12}z_1z_2 + a_{22}z_2^2\big)\ ;$$

we suppose the coefficients a_{ij} are constant and satisfy the nondegenerate ellipticity condition of Proposition 5.5 above (which, in particular, applies).

To the aim of computing $j^{\hom}$, we make use of Lemma 4.5(iii) so that we need the expression of j_μ for the measures μ under consideration. In view of the definitions of μ

specified below, only the coordinate axes e_1 and e_2 are involved as tangent directions. When $T_\mu(y) = \langle e_1 \rangle$, using definition (3.13) we find

$$j_\mu(y,z) = \inf_{\xi_2 \in \mathbb{R}} \frac{1}{2}\big(a_{11}z_1^2 + 2a_{12}z_1\xi_2 + a_{22}\xi_2^2\big) = \frac{1}{2}\left(a_{11} - \frac{a_{12}^2}{a_{22}}\right) z_1^2 =: \frac{1}{2} q_1 z_1^2.$$

Similarly, when $T_\mu(y) = \langle e_2 \rangle$, we obtain

$$j_\mu(y,z) = \frac{1}{2}\Big(a_{22} - \frac{a_{12}^2}{a_{11}}\Big) z_2^2 =: \frac{1}{2} q_2 z_2^2 \ .$$

Note that, by the uniform coercivity of the matrix (a_{ij}), the coefficients $q_1 = \frac{\det a_{i,j}}{a_{2,2}}$ and $q_2 = \frac{\det a_{i,j}}{a_{1,1}}$ are both strictly positive.

(i) Let μ be given on the unit cell $[-\frac{1}{2}, \frac{1}{2}[^2$ by $\mu := \frac{1}{2}\,(dx_1 \otimes \delta_0(dx_2) + \delta_0(dx_1) \otimes dx_2)$, δ_0 being the Dirac mass at 0. We obtain

$$\begin{aligned} j^{\hom}(z) &= \frac{1}{4} \min \left\{ \int_{-\frac{1}{2}}^{\frac{1}{2}} q_1 \big(z_1 + \nabla_1 u\,(y_1, 0)\big)^2 \, dy_1 \right. \\ &\qquad \left. + \int_{-\frac{1}{2}}^{\frac{1}{2}} q_2 \big(z_2 + \nabla_2 u\,(0, y_2)\big)^2 \, dy_2 \ : \ u \in H^{1,p}_\mu(\mathbf{T}) \right\} \\ &= \frac{1}{4}\big\{q_1 z_1^2 + q_2 z_2^2\big\}. \end{aligned}$$

(ii) Let μ be given on the unit cell $[-\frac{1}{2}, \frac{1}{2}[^2$ by $\mu := \frac{1}{2}\,(dx_1 \otimes \delta_0(dx_2) + \tau(dx_1) \otimes dx_2)$, τ being a probability measure concentrated on a Cantor subset of $(-\frac{1}{2}, \frac{1}{2})$ whose tangent space degenerates to $\{0\}$. Noticing that the condition $u \in H^{1,p}_\mu(\mathbf{T})$ implies that $\lim_{y_2 \to 0} u(y_1, y_2) = u(y_1, 0)$ for τ-a.e. y_1, it is easy to check that, as in case (i), μ satisfies assumption $(H4)$. However, the transmission condition along the segment $Y \cap \{y_1 = 0\}$ does not affect the value of the minimum problem involved in the definition of $j^{\hom}$. We actually obtain

$$\begin{aligned} j^{\hom}(z) &= \frac{1}{4} \min \left\{ \int_{-\frac{1}{2}}^{\frac{1}{2}} q_1 \big(z_1 + \nabla_1 u\,(y_1, 0)\big)^2 \, dy_1 \right. \\ &\qquad \left. + \int_{-\frac{1}{2}}^{\frac{1}{2}} \left(\int_{-\frac{1}{2}}^{\frac{1}{2}} q_2 \big(z_2 + \nabla_2 u\,(y_1, y_2)\big)^2 \, dy_2 \right) \tau(dy_1) \ : \ u \in H^{1,p}_\mu(\mathbf{T}) \right\} \\ &= \frac{1}{4}\big\{q_1 z_1^2 + q_2 z_2^2\big\}. \end{aligned}$$

6. The case of two-parameter integrals. Our framework of homogenization with periodic measures includes in a natural way the case of thin reinforced structures: they are made of identical cells periodically repeated, in which the material is concentrated along bars of thickness δ, small with respect to the period ε. Thus, the energy of the δ-thick, ε-periodic structure is given by

$$J_{\delta,\varepsilon}(u) = \int_\Omega j\big(\nabla u\big)\, d\mu_{\delta,\varepsilon} \ ; \tag{6.1}$$

here $\mu_{\delta,\varepsilon}$ is the ε-periodization of μ_δ according to (2.1), μ_δ being the Y-periodic measure associated with the structure of thickness δ. Notice that here we use a

simplified model where the density of energy in (6.1) is described by a homogeneous integrand $j(z)$ (in full generality $j(z)$ should be replaced by $j_\delta(\frac{x}{\varepsilon}, z)$).

In this section, we investigate the commutativity of the passage to the limit in (6.1) as the two parameters ε and δ tend to zero. In fact, a possible first procedure is to homogenize with respect to each μ_δ, and then let δ tend to zero; the computations required for the latter limit process can be found, in some particular cases, in [17], [15] (see also [18] for a quite recent survey about reticulated structures). A second natural procedure is to apply Theorem 5.2 taking as a measure μ the weak limit of μ_δ as $\delta \to 0$, namely, the measure associated with the skeleton of the structure. Let us emphasize that the latter method is in practice much simpler to apply, as in many cases it is easy to compute explicitly the effective energy density given by (4.2). Therefore it is worth establishing whether the two procedures are equivalent or not. Our claim is that the equivalence holds provided μ is connected. Actually, under this assumption, we can prove a much stronger statement: if we let δ depend on ε in (6.1), the Γ-limit of $J_{\delta(\varepsilon),\varepsilon}$ is the same whatever the choice of the sequence $\delta(\varepsilon)$. This is derived from Theorem 5.2 when the measures μ_δ are approximations of μ by convolution (see Theorem 6.1). Similar conclusions can be reached also in the case of δ-fattened structures (see Remark 6.2); we omit the required additional computations which are technical but straightforward.

In what follows, for any $\lambda > 0$, we let ρ_λ be a convolution kernel $\rho_\lambda(x) := \frac{1}{\lambda^n}\rho\left(\frac{x}{\lambda}\right)$, where ρ is assumed to be a smooth, positive, even function, compactly supported on the unit ball of $\mathbb{R}^n$, and such that $\int_{\mathbb{R}^n} \rho\, dx = 1$. For any measure ν, the notation $\rho_\lambda \star \nu$ will be used to denote the smooth function $\rho_\lambda \star \nu(x) := \int_{\mathbb{R}^n} \rho_\lambda(x-y)\, d\nu(y)$; we also recall that, when ν is Y-periodic, ν_ε denotes the measure defined by (2.1). In view of these definitions, it is easy to check that the measure $[(\rho_\lambda \star \nu)\mathcal{L}^n]_\varepsilon$ agrees with the measure with Lebesgue density $\rho_{\lambda\varepsilon} \star \nu_\varepsilon$.

We can now give the main result of the section. We stress that the Γ-limit of $J_{\delta,\varepsilon}$ is computed with respect to the analogous convergence as in Theorem 5.2, namely, $u_\varepsilon \mu_{\delta,\varepsilon} \rightharpoonup u\mathcal{L}^n$.

THEOREM 6.1. *Let μ satisfy $(H4)$, with $p > 1$. Let ε and $\delta = \delta(\varepsilon)$ be positive parameters tending to zero, and let $\mu_{\delta,\varepsilon} := [(\rho_{\delta(\varepsilon)} \star \mu)\mathcal{L}^n]_\varepsilon$. Then the functionals $J_{\delta,\varepsilon}$ defined by* (6.1) *Γ-converge to the functional $J^{\hom}$ defined by* (5.6).

Proof. For simplicity, throughout the proof we shall not denote the dependence of δ on ε. We begin by checking the Γ-liminf inequality for any sequence u_ε such that $u_\varepsilon \mu_{\delta,\varepsilon} \rightharpoonup u\mathcal{L}^n$. If we set $v_\varepsilon = \rho_{\delta\cdot\varepsilon} \star u_\varepsilon$, by the Jensen's inequality we have

$$\begin{aligned} J_{\delta,\varepsilon}(u_\varepsilon) &= \int j(\nabla u_\varepsilon)[\rho_{\delta\cdot\varepsilon} \star \mu_\varepsilon]\, dx = \int \rho_{\delta\cdot\varepsilon} \star j(\nabla u_\varepsilon)\, d\mu_\varepsilon \\ &\geq \int j(\rho_{\delta\cdot\varepsilon} \star \nabla u_\varepsilon)\, d\mu_\varepsilon = J_\varepsilon(v_\varepsilon). \end{aligned}$$

Hence, the Γ-liminf inequality is a straightforward consequence of Theorem 5.2, provided we prove that

$$v_\varepsilon \mu_\varepsilon \rightharpoonup u\mathcal{L}^n. \tag{6.2}$$

To show (6.2), let φ be any test function in $\mathcal{C}_0(\mathbb{R}^n)$. By Fubini's theorem, taking into account the assumption $\rho(z) = \rho(-z)$, we have

$$\begin{aligned}
&\left| \int \varphi \, (\rho_{\delta\cdot\varepsilon} \star u_\varepsilon) \, d\mu_\varepsilon - \int \varphi \, (\rho_{\delta\cdot\varepsilon} \star \mu_\varepsilon) \, u_\varepsilon \, d\mathcal{L}^n \right| \\
&\quad = \left| \int \int [\varphi(x) - \varphi(y)] \rho_{\delta\cdot\varepsilon}(x-y) \, u_\varepsilon(y) \, dy \, d\mu_\varepsilon(x) \right| \\
&\quad \leq \sup_{|s-t|<\delta\cdot\varepsilon} |\varphi(s) - \varphi(t)| \int \int |u_\varepsilon(y| \, \rho_{\delta\cdot\varepsilon}(x-y) \, d\mu_\varepsilon(x) \\
&\quad = \mathrm{o}(\delta\cdot\varepsilon) \int |u_\varepsilon| \, d\mu_{\delta,\varepsilon}.
\end{aligned}$$

Hence, $\{v_\varepsilon \mu_\varepsilon\}$ is bounded in the space of measures and actually converges weakly, as $\varepsilon \to 0$, to the same limit as the sequence $\{u_\varepsilon \mu_{\delta,\varepsilon}\}$. The claim (6.2) follows.

It remains to prove the Γ- limsup inequality. To this aim, it is enough to consider the same sequence $\{u_\varepsilon\} \subset \mathcal{D}(\Omega)$ already employed in the proof of Theorem 5.2, namely

$$u_\varepsilon(x) = u(x) + \varepsilon\varphi\left(x, \frac{x}{\varepsilon}\right)$$

for an arbitrary function $\varphi \in \mathcal{D}(\Omega; \mathcal{C}^\infty(\mathbf{T}))$. To verify that such a sequence gives the required upper bound for the Γ- limsup of $J_{\delta,\varepsilon}$, it is enough to replace μ_ε by $\mu_{\delta,\varepsilon}$ in the proof of Theorem 5.2 part (II) (accordingly, it has to be noticed that the convergence (2.3) still holds if in its left-hand member we substitute μ_ε with $\mu_{\delta,\varepsilon}$). □

Remark 6.2. A variant of Theorem 6.1 can be obtained in the case of δ-fattened stuctures. Let us consider a multijunction body $S = S_1 \cup S_2 \cup \cdots \cup S_m$, where S_k is a k-dimensional Y-periodic subset of $\mathbb{R}^n$. We assume in addition that every S_k is piecewise C^2 and satisfies $\mathcal{H}^k(S_k \cap \partial Y) = 0$, so that the normalized measures $\mu_k := \left[\mathcal{H}^k(Y \cap S_k)\right]^{-1} \mathcal{H}^k \llcorner S_k$ satisfy $\mu_k(Y) = 1$. The δ-fattened structure can be written as $S_\delta = \cup_k S_{k,\delta}$ where $S_{k,\delta} := \{x \in \mathbb{R}^n : \mathrm{dist}(x, S_k) \leq \delta\}$. Then we represent the energy on S_δ through (6.1), where $\mu_\delta := \sum_k c_k \, \mu_{k,\delta}$, being $\mu_{k,\delta} := \left[\mathcal{L}^n(Y \cap S_{k,\delta})\right]^{-1} \mathcal{L}^n \llcorner S_{k,\delta}$ and c_k is a weight on each part of the multijunction. We notice that μ_δ has a piecewise constant Lebesgue density in $\mathbb{R}^n$ and one checks easily, by using the regularity assumption on each S_k, that $\{\mu_\delta\}$ converges weakly to $\mu := \sum_k c_k \mu_k$ as δ tends to zero. The expected limit density of energy can be represented by (4.2) using this definition of measure μ. Indeed, if such μ satisfies $(H4)$ and if $J_{\delta,\varepsilon}$ is given by (6.1) with μ_δ defined above, then there holds $J_{\delta(\varepsilon),\varepsilon} \xrightarrow{\Gamma} J^{\mathrm{hom}}$ for any sequences ε and $\delta = \delta(\varepsilon)$ tending to zero. In particular, the limit processes with respect to the parameters ε and δ are actually commutative.

We conclude by emphasizing that Theorem 6.1 does not apply if μ does not enjoy the connectedness property (H1). This is illustrated by the example below, where the case of a fiber reinforced structure is considered and the exponent p represents the growth of the energy under consideration. Our method applies if and only if the choice of p ensures the connectedness of μ. In the other cases, it has been recently proved by Bellieud and Bouchitté [4] that the homogenized energy obtained as a contemporary limit, as $\varepsilon \to 0$ and $\delta = \delta(\varepsilon) \to 0$, of $J_{\delta,\varepsilon}$ may contain a nonlocal term which depends on the velocity of convergence to zero of $\delta(\varepsilon)$.

Example 6.3. Consider the sequence μ_δ of Y-periodic measures given on Y by the Lebesgue measure with a density a_δ equal, respectively, to 1 on $Y \setminus F_\delta$ and to $\frac{k}{\delta^2}$ on F_δ, being F_δ a system of cylindrical fibers of very small radius δ, parallel to the three coordinated axes (see Figure 7.1A).

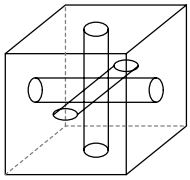

FIG. 7.1A.

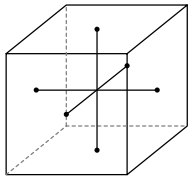

FIG. 7.1B.

Then $\mu_\delta \rightharpoonup \mu$, where $\mu = \mu' + \mu''$, being the restrictions of μ' and μ'' on Y given, respectively, by the Lebesgue measure $\mathcal{L}^3 \llcorner Y$ and by $k\pi$ times the one-dimensional measure $\mathcal{H}^1$ over the skeleton F of the fibers (see Figure 7.1B).

When $p > 2$, μ turns out to satisfy $(H4)$, so applying Theorem 5.2 with the choice $j(y,z) = \frac{1}{p}|z|^p$, we obtain that the Γ-limit of $J_{\delta,\varepsilon}$ is given by

$$J^{\rm hom}(u) := \frac{1}{p}\left\{\int_\Omega |\nabla u|^p\,dx + k\pi\int_\Omega \Big[\Big|\frac{\partial u}{\partial x_1}\Big|^p + \Big|\frac{\partial u}{\partial x_2}\Big|^p + \Big|\frac{\partial u}{\partial x_3}\Big|^p\Big]\,dx\right\},\quad u \in W^{1,p}_0(\Omega). \tag{6.3}$$

On the other hand, when $p \le 2$, μ fails to satisfy $(H1)$, so Theorem 4.2 does not apply, and the two-scale limit of a sequence $\{u_\varepsilon\}$ uniformly bounded in $L^p_{\mu_\varepsilon}(\Omega)$ takes a priori two different values on the two "connected components" of μ, i.e.

$$u_0(x,y) = \begin{cases} u(x) & \text{if } y \in Y \setminus F,\\ v(x) & \text{if } y \in F.\end{cases}$$

This kind of behavior suggests that one should consider the measures μ'_δ and μ''_δ given on Y, respectively, by $\mu_\delta \llcorner (Y \setminus F_\delta)$ and $\mu_\delta \llcorner F_\delta$, and to split the energies $J_{\delta,\varepsilon}$ into

$$J_{\delta,\varepsilon}(u) = \frac{1}{p}\int_\Omega |\nabla u|^p\,d(\mu'_\delta)_\varepsilon + \frac{1}{p}\int_\Omega |\nabla u|^p\,d(\mu''_\delta)_\varepsilon\ . \tag{6.4}$$

Since μ'_δ and μ''_δ weakly converge, respectively, to μ' and μ'', Theorem 5.2 can now be applied to each of the sequences on the right-hand side of (6.4). In this way, denoting by u and v the weak limits associated, respectively, with the sequences $\{u_\varepsilon\,\mu'_{\delta,\varepsilon}\}$ and $\{u_\varepsilon\,\mu''_{\delta,\varepsilon}\}$, we obtain the following lower bound:

$$\liminf_{\varepsilon\to 0} J_{\delta(\varepsilon),\varepsilon}(u_\varepsilon) \ge \frac{1}{p}\left\{\int_\Omega |\nabla u|^p\,dx + k\pi\int_\Omega \Big[\Big|\frac{\partial v}{\partial x_1}\Big|^p + \Big|\frac{\partial v}{\partial x_2}\Big|^p + \Big|\frac{\partial v}{\partial x_3}\Big|^p\Big]\,dx\right\}.$$

Assuming that v agrees with u would lead us to replace the right-hand member of the above inequality by the functional $J^{\rm hom}(u)$ given by (6.3), which in fact does not provide the optimal lower bound. Indeed, the crucial point is that the correct limit energy $\Phi(u,v)$ contains an additional term (depending on the gap $v-u$) which takes into account the interaction between the two "connected components" of μ. Precisely, we have (see [4])

$$\Phi(u,v) = \frac{1}{p}\left\{\int_\Omega |\nabla u|^p\,dx + k\pi\int_\Omega \Big[\Big|\frac{\partial v}{\partial x_1}\Big|^p + \Big|\frac{\partial v}{\partial x_2}\Big|^p + \Big|\frac{\partial v}{\partial x_3}\Big|^p\Big]\,dx + 6\pi\gamma\int_\Omega |u-v|^p\,dx\right\},$$

where the positive constant γ is given by

$$\gamma = \begin{cases} \lim\limits_{\varepsilon\to 0}\ \varepsilon^{-2}\big|\log\big(\varepsilon\delta(\varepsilon)\big)\big|^{-1} & \text{if } p = 2,\\ \lim\limits_{\varepsilon\to 0}\ \Big|\dfrac{2-p}{p-1}\Big|^{p-1}\varepsilon^{-p}\delta(\varepsilon)^{2-p} & \text{if } p < 2\end{cases}$$

(notice that γ does depend on the way $\delta(\varepsilon)$ tends to zero). Thus the Γ-limit of $J_{\delta,\varepsilon}$ is given by

$$J(u) := \inf\left\{\Phi(u,v) \ : \ v \in W_0^{1,p}(\Omega)\right\}, \qquad u \in W_0^{1,p}(\Omega),$$

which means to compute the infimum with respect to v of a nonlocal energy in u (whatever γ is in $(0,+\infty)$).

We address to a forthcoming paper for a systematic treatment, in our framework of measures, of nonlocal phenomenon due to the lack of connectedness.

Acknowledgment. The second author wishes to thank the hospitality and support of the University of Toulon.

THE FINITE LARMOR RADIUS APPROXIMATION*

EMMANUEL FRÉNOD† AND ERIC SONNENDRÜCKER‡

Abstract. The presence of a large external magnetic field in a plasma introduces an additional time-scale which is very constraining for the numerical simulation. Hence it is very useful to introduce averaged models which remove this time-scale. However, depending on other parameters of the plasma, different starting models for the asymptotic analysis may be considered. We introduce here a generic framework for our analysis which fits many of the possible regimes and apply it in particular to justify the finite Larmor radius approximation both in the linear case and in the nonlinear case in the plane transverse to the magnetic field.

Key words. Vlasov–Poisson equations, kinetic equations, homogenization, two-scale convergence, multiple time scales

1. Introduction.

The main goal of this paper is the investigation of an asymptotic regime taking place in the description of the behavior of charged particles under the action of a strong external magnetic field and called the finite Larmor radius approximation. This approximation has a natural field of application in tokamak physics.

This work was announced in Frénod and Sonnendrücker [9] and follows Frénod and Sonnendrücker [8, 10], where we exhibited global asymptotic behavior of plasmas. Those global behaviors have also been mathematically put in light by Golse and Saint-Raymond [12, 11] and Grenier [14]. The context of the finite Larmor radius approximation is more local. Its object is to describe the behavior of the considered plama's particles when the observation length scale is comparable with their Larmor radius.

We choose to lead our study in the framework of the Vlasov equation which writes, in this context

$$\begin{aligned} &\frac{\partial f^\epsilon}{\partial t} + \mathbf{v}_\parallel \cdot \nabla_x f^\epsilon + \frac{1}{\epsilon}\mathbf{v}_\perp \cdot \nabla_x f^\epsilon + \left(\mathbf{E} + \frac{1}{\epsilon}\mathbf{v}\times\mathbf{m}\right)\cdot \nabla_v f^\epsilon = 0, \\ &f^\epsilon_{|t=0} = f_0, \end{aligned} \tag{1.1}$$

where ϵ is a small parameter which will tend to 0. In (1.1) the distribution function $f^\epsilon \equiv f^\epsilon(t,\mathbf{x},\mathbf{v})$; $t \in [0,T)$ for some $T < \infty$ is the time, $\mathbf{x} = (x_1,x_2,x_3) \in \mathbb{R}^3_x$ is the position, and $\mathbf{v} = (v_1,v_2,v_3) \in \mathbb{R}^3_v$ is the velocity. We denote $\mathcal{O} = \mathbb{R}^3_x \times \mathbb{R}^3_v$, $\Omega = [0,T) \times \mathbb{R}^3_x$, and $\mathcal{Q} = [0,T) \times \mathcal{O}$. The magnetic field $\mathbf{m}$ is supposed to be $\mathbf{e}_1$, the first vector of the frame $(\mathbf{e}_1,\mathbf{e}_2,\mathbf{e}_3)$ of $\mathbb{R}^3$. For any vector $\mathbf{v} \in \mathbb{R}^3$, $\mathbf{v}_\parallel$ stands for $\mathbf{v}_\parallel = (\mathbf{v}\cdot\mathbf{m})\mathbf{m} = v_1\mathbf{e}_1$ and $\mathbf{v}_\perp$ for $\mathbf{v}_\perp = \mathbf{v} - \mathbf{v}_\parallel = v_2\mathbf{e}_2 + v_3\mathbf{e}_3$. The electric field $\mathbf{E} \equiv \mathbf{E}(t,\mathbf{x})$ is external and nonoscillating.

In order to make the process $\epsilon \to 0$ in (1.1), we assume

$$f_0 \geq 0, \quad f_0 \in L^1 \cap L^2(\mathcal{O}), \tag{1.2}$$

and for $\mathbf{E}$, we assume

$$\mathbf{E} \in \mathcal{C}^1(\Omega). \tag{1.3}$$

Then we have the following theorem.

THEOREM 1.1. *Under assumptions* (1.2) *and* (1.3)*, for each* $\epsilon > 0$*, there exists a unique solution* f^ϵ *of* (1.1) *in* $L^\infty(0,T,L^1 \cap L^2(\mathcal{O}))$*. As* $\epsilon \to 0$*,*

$$f^\epsilon \rightharpoonup f \text{ in } L^\infty(0,T,L^2(\mathcal{O})) \text{ weak} - *, \tag{1.4}$$

where f *is the unique solution of*

(1.5)
$$\frac{\partial f}{\partial t} + \mathbf{v}_\parallel \cdot \nabla_x f + \frac{1}{2\pi}\left(\int_0^{2\pi} \mathcal{R}(-\tau)\mathbf{E}(t, \mathbf{x} + \mathcal{R}(\tau)\mathbf{v})\, d\tau\right) \cdot \nabla_x f + \frac{1}{2\pi}\left(\int_0^{2\pi} R(-\tau)\mathbf{E}(t, \mathbf{x} + \mathcal{R}(\tau)\mathbf{v})\, d\tau\right) \cdot \nabla_v f = 0,$$

$$f_{|t=0} = \frac{1}{2\pi}\int_0^{2\pi} f_0(\mathbf{x} + \mathcal{R}(-\tau)\mathbf{v}, R(-\tau)\mathbf{v})\, d\tau,$$

where the matrices R *and* $\mathcal{R}$ *are given by*

$$R(\tau) = \begin{pmatrix} 1 & 0 & 0 \\ 0 & \cos\tau & \sin\tau \\ 0 & -\sin\tau & \cos\tau \end{pmatrix}, \quad \mathcal{R}(\tau) = \begin{pmatrix} 0 & 0 & 0 \\ 0 & \sin\tau & 1-\cos\tau \\ 0 & \cos\tau - 1 & \sin\tau \end{pmatrix}. \tag{1.6}$$

The way to prove this theorem uses the 2-scale convergence defined as follows.

THEOREM 1.2 (see Nguetseng [18] and Allaire [2]). *If a sequence* f^ϵ *is bounded in* $L^\infty(0,T;W)$*, for a Banach spaces* W *being the dual of a separable space and being compactly embedded in* $\mathcal{D}'(\mathcal{O})$*, then for every period* θ *there exists a* θ*-periodic profile* $F_\theta(t,\tau,\mathbf{x},\mathbf{v}) \in L^\infty(0,T;L^\infty_\theta(\mathbb{R}_\tau;W))$ *such that for all* $\psi_\theta(t,\tau,\mathbf{x},\mathbf{v})$ *regular, with compact support with respect to* $(t,\mathbf{x},\mathbf{v})$ *and* θ*-periodic with respect to* τ*, we have, up to a subsequence,*

$$\int_{\mathcal{Q}} f^\epsilon \psi^\epsilon_\theta\, dt\, d\mathbf{x}\, d\mathbf{v} \to \int_{\mathcal{Q}}\int_0^\theta F_\theta \psi_\theta\, d\tau\, dt\, d\mathbf{x}\, d\mathbf{v}. \tag{1.7}$$

We then say that f^ϵ *two scale converges to* F_θ*. Above,* $L^\infty_\theta(\mathbb{R}_\tau)$ *stands for the space of functions being* $L^\infty(\mathbb{R})$ *and being* θ*-periodic and* $\psi^\epsilon_\theta \equiv \psi_\theta(t, \frac{t}{\epsilon}, \mathbf{x}, \mathbf{v})$*.*

The profile F_θ *is called the* θ*-periodic two scale limit of* f^ϵ *and the link between* F_θ *and the weak–*$*$ *limit* f *of* (f^ϵ) *is given by*

$$\int_0^\theta F_\theta(t,\tau,\mathbf{x},\mathbf{v})\, d\tau = f(t,\mathbf{x},\mathbf{v}). \tag{1.8}$$

Moreover, if a sequence (g^ϵ) *strongly converges to* g *in a second Banach space* W' *(with the same assumption for* W' *as for* W*), such that the product makes sense in a third Banach space* W''*, then,*

$$f^\epsilon g^\epsilon \text{ 2-scale converges to } F_\theta g \in L^\infty(0,T;L^\infty_\theta(\mathbb{R}_\tau;W'')). \tag{1.9}$$

Remark. Our definition of the two scale convergence by (1.7) does not comply with the averaging rule usually used. Otherwise the right-hand side of (1.7) would be divided by θ.

The proof of Theorem 1.1 consists in finding a constraint equation for the two scale limit F of f^ϵ, using a weak formulation with oscillating test function of (1.1). This constraint imposes a form to F. Then using oscillating test functions satisfying the constraint equation in the previously evoked weak formulation gives the equation satisfied by F. Integrating this last equation yields finally (1.5).

As the proof of Theorem 1.1 in this paper and of Theorems 1.1 and 3.2 of Frénod and Sonnendrücker [8] are very close, we develop here a generic framework inside which all those proofs may be included. This generic framework consists in considering a conservation law linearly perturbed:

$$\begin{aligned} &\frac{\partial u^\epsilon}{\partial t} + \mathbf{A}\cdot\nabla_x u^\epsilon + \frac{1}{\epsilon}\mathbf{L}\cdot\nabla_x u^\epsilon = 0,\\ &u^\epsilon_{t=0} = u_0. \end{aligned} \tag{1.10}$$

In this system, $u^\epsilon \equiv u^\epsilon(t,\mathbf{x})$, $t\in[0,T)$ for some $T<\infty$ and $\mathbf{x}\in\mathbb{R}^n=\mathcal{O}$. Let us mention that $\mathbf{x}$ here is an abstract variable which is not connected to the position which is also denoted by $\mathbf{x}$ in the Vlasov equation. We denote $\mathcal{Q}=[0,T)\times\mathcal{O}$, and we assume $\mathbf{A}\equiv\mathbf{A}(t,\mathbf{x})\in L^\infty(0,T;L^2_{loc}(\mathcal{O}))$, with $\nabla_x\cdot\mathbf{A}=0$ and $\mathbf{L}\equiv M\mathbf{x}+N$, where M is a real $n\times n$ matrix with constant entries, satisfying $\mathrm{tr}M=0$ and where $N\in\mathrm{Im}M$. We moreover assume that $e^{\tau M}$ is θ-periodic for a given $\theta\in\mathbb{R}$. The generic theorem writes as follows.

THEOREM 1.3. *Under the assumptions above, if, moreover, the sequence (u^ϵ) of solution of* (1.10) *satisfies*

$$\|u^\epsilon\|_{L^\infty(0,T;L^2(\mathcal{O}))}\le C, \tag{1.11}$$

for some constants C independent on ϵ, then, extracting a subsequence,

$$u^\epsilon \text{ 2-scale converges to a } \theta\text{-periodic profile } U\in L^\infty(0,T;L^\infty_\theta(\mathbb{R}_\tau;L^2(\mathcal{O}))) \tag{1.12}$$

and

$$u^\epsilon \rightharpoonup u \text{ in } L^\infty(0,T;L^2(\mathcal{O})) \text{ weak}-*. \tag{1.13}$$

We have

$$U(t,\tau,\mathbf{x}) = U_0(t, e^{-\tau M}(\mathbf{x}-\overline{N})+\overline{N}), \tag{1.14}$$

where $\overline{N}$ is such that $-M\overline{N}=N$ and where $U_0\equiv U_0(t,\mathbf{y})$ is solution of

$$\begin{aligned} &\frac{\partial U_0}{\partial t} + \frac{1}{\theta}\int_0^\theta e^{-\sigma M}\mathbf{A}(t, e^{\sigma M}(\mathbf{y}-\overline{N})+\overline{N})\,d\sigma\cdot\nabla_y U_0 = 0,\\ &U_{0|t=0} = \tfrac{1}{\theta}u_0. \end{aligned} \tag{1.15}$$

Moreover, u is solution of

$$\begin{aligned} &\frac{\partial u}{\partial t} + \frac{1}{\theta}\int_0^\theta e^{-\sigma M}\mathbf{A}(t, e^{\sigma M}(\mathbf{x}-\overline{N})+\overline{N})d\sigma\cdot\nabla_x\, u = 0,\\ &u_{|t=0}(\mathbf{x}) = \frac{1}{\theta}\int_0^\theta u_0(e^{-\sigma M}(\mathbf{x}-\overline{N})+\overline{N})\,d\sigma. \end{aligned} \tag{1.16}$$

When restricting to the plane perpendicular to $\mathbf{m}$, we may extend the previous result to the Vlasov–Poisson system.

We suppose now that f^ϵ does not depend on x_1 and v_1, and we use the following notations: $t \in [0,T)$, $T < \infty$, still denotes the time, the position- and velocity-variables become $\mathbf{x} = (x_2, x_3) \in \mathbb{R}^2_x$ and $\mathbf{v} = (v_2, v_3) \in \mathbb{R}^2_v$. We set $\mathcal{O} = \mathbb{R}^2_x \times \mathbb{R}^2_v$, $\Omega = [0,T) \times \mathbb{R}^2_x$, and $\mathcal{Q} = [0,T) \times \mathcal{O}$. For clarity, we denote $\mathcal{O}' = \mathbb{R}^2_y \times \mathbb{R}^2_u$ and $\mathcal{Q} = [0,T) \times \mathcal{O}'$. The electric field $\mathbf{E}^\epsilon \equiv \mathbf{E}^\epsilon(t,\mathbf{x})$ standing in the Vlasov equation is now given by the Poisson equation, and then the system we work with writes

$$
\begin{aligned}
&\frac{\partial f^\epsilon}{\partial t} + \frac{1}{\epsilon}\mathbf{v}\cdot\nabla_x f^\epsilon + \left(\mathbf{E}^\epsilon + \frac{1}{\epsilon}\mathbf{v}\times\mathbf{m}\right)\cdot\nabla_v f^\epsilon = 0,\\
&f^\epsilon_{|t=0} = f_0,\\
&\mathbf{E}^\epsilon = -\nabla\phi^\epsilon, \quad -\Delta\phi^\epsilon = \rho^\epsilon,\\
&\rho^\epsilon = \int_{\mathbb{R}^2_v} f^\epsilon \, d\mathbf{v}.
\end{aligned}
\tag{1.17}
$$

As the first equation in (1.17) is bidimensional, we precise the sense to give to $\mathbf{v}\times\mathbf{m}$

$$
\mathbf{v}\times\mathbf{m} = \begin{pmatrix} v_3 \\ -v_2 \end{pmatrix}. \tag{1.18}
$$

We assume

$$
f_0 \geq 0, \quad f_0 \in L^1 \cap L^p(\mathcal{O}), \quad 0 < \int_{\mathcal{O}} f_0(1+|\mathbf{v}|^2)\, d\mathbf{v} < +\infty, \tag{1.19}
$$

for some $p \geq 2$, and we have the following theorem.

THEOREM 1.4. *Under assumption* (1.19)*, for each* ϵ*, there exists a solution* $(f^\epsilon, \mathbf{E}^\epsilon)$ *of* (1.17) *in* $L^\infty(0,T; L^1 \cap L^p(\mathcal{O})) \times L^\infty(0,T; W^{1,\frac{3}{2}}(\mathbb{R}^2_x))$ *for any* $T \in \mathbb{R}^+$*. Moreover, this solution is bounded in* $L^\infty(0,T; L^1 \cap L^p(\mathcal{O})) \times L^\infty(0,T; W^{1,\frac{3}{2}}(\mathbb{R}^2_x))$ *independently on* ϵ*.*

If we consider a sequence $(f^\epsilon, \mathbf{E}^\epsilon)$ *of such solutions, extracting a subsequence, we have*

$$
\begin{aligned}
&f^\epsilon \text{ 2-scale converges to } F \in L^\infty(0,T; L^\infty_{2\pi}(\mathbb{R}_\tau; L^p(\mathcal{O}))),\\
&\mathbf{E}^\epsilon \text{ 2-scale converges to } \mathcal{E} \in L^\infty(0,T; L^\infty_{2\pi}(\mathbb{R}_\tau; W^{1,\frac{3}{2}}(\mathbb{R}^2_x))),
\end{aligned}
\tag{1.20}
$$

where $F \equiv F(t,\tau,\mathbf{x},\mathbf{v})$ *and* $\mathcal{E} \equiv \mathcal{E}(t,\tau,\mathbf{x})$*.*

Moreover, there exists a function $G \equiv G(t,\mathbf{y},\mathbf{u}) \in L^\infty(0,T; L^1 \cap L^p(\mathcal{O}'))$ *such that*

$$
F(t,\tau,\mathbf{x},\mathbf{v}) = G(t, \mathbf{x} + \mathcal{R}(-\tau)\mathbf{v}, R(-\tau)\mathbf{v}), \tag{1.21}
$$

and $(G,\mathcal{E})$ *is solution of*

(1.22)
$$\frac{\partial G}{\partial t}+\frac{1}{2\pi}\left(\int_0^{2\pi}\mathcal{R}(-\tau)\mathcal{E}(t,\tau,\mathbf{y}+\mathcal{R}(\tau)\mathbf{u})\,d\tau\right)\cdot\nabla_y G + \frac{1}{2\pi}\left(\int_0^{2\pi}R(-\tau)\mathcal{E}(t,\tau,\mathbf{y}+\mathcal{R}(\tau)\mathbf{u})\,d\tau\right)\cdot\nabla_u G=0,$$

$$G_{|t=0}=\frac{1}{2\pi}f_0,$$

$$\mathcal{E}\equiv\mathcal{E}(t,\tau,\mathbf{x}),\ \textit{with}\ \mathcal{E}=-\nabla\Phi,\ \ -\Delta\Phi=\int G(t,\mathbf{x}+\mathcal{R}(-\tau)\mathbf{v},R(-\tau)\mathbf{v})\,d\mathbf{v},$$

with R *and* $\mathcal{R}$ *given by*

$$R(\tau)=\begin{pmatrix}\cos\tau & \sin\tau\\ -\sin\tau & \cos\tau\end{pmatrix},\ \ \mathcal{R}(\tau)=\begin{pmatrix}\sin\tau & 1-\cos\tau\\ \cos\tau-1 & \sin\tau\end{pmatrix}. \tag{1.23}$$

In order to prove this theorem, we modify the generic framework previously introduced. We consider here

$$\begin{aligned}&\frac{\partial u^\epsilon}{\partial t}+\mathbf{A}^\epsilon\cdot\nabla_x u^\epsilon+\frac{1}{\epsilon}\mathbf{L}\cdot\nabla_x u^\epsilon=0,\\ &u^\epsilon_{t=0}=u_0,\end{aligned} \tag{1.24}$$

where the notations are similar as for (1.10): $u^\epsilon\equiv u^\epsilon(t,\mathbf{x})$, $t\in[0,T)$, $T<\infty$; $\mathbf{x}\in\mathbb{R}^n=\mathcal{O}$, $\mathcal{Q}=[0,T)\times\mathcal{O}$. We suppose, as previously, that $\mathbf{L}\equiv M\mathbf{x}+N$, where M is a constant entry matrix satisfying $\mathrm{tr}M=0$ and $e^{\tau M}$ is θ-periodic and where $N\in\mathrm{Im}M$. The assumptions we make on $\mathbf{A}^\epsilon$ are the following: we suppose that, for all $\epsilon>0$, $\nabla_x\cdot\mathbf{A}^\epsilon=0$ and that, for some $q>1$,

$$\mathbf{A}^\epsilon\ \text{2-scale converges to}\ \mathcal{A}\in L^\infty(0,T;L^\infty_\theta(\mathbb{R}_\tau;W^{1,q}(K))) \tag{1.25}$$

for all compact sets $K\subset\mathbb{R}^n$ and where $\mathcal{A}\equiv\mathcal{A}(t,\tau,\mathbf{x})$ is θ-periodic in τ.

We have the following.

THEOREM 1.5. *Under the assumptions above, if, moreover, the sequence* (u^ϵ) *of solutions of* (1.24) *satisfies*

$$\|u^\epsilon\|_{L^\infty(0,T;L^p(\mathcal{O}))}\le C, \tag{1.26}$$

for some $p>1$ *such that* $\frac{1}{p}+\frac{1}{q'}<1$, *where* $\frac{1}{q'}=\mathrm{Max}\{\frac{1}{q}-\frac{1}{n},0\}$; *then, extracting a subsequence,*

$$u^\epsilon\ \textit{2-scale converges to a profile}\ U\in L^\infty(0,T;L^\infty_\theta(\mathbb{R}_\tau;L^p(\mathcal{O}))). \tag{1.27}$$

Moreover, we have

$$U(t,\tau,\mathbf{x})=U_0(t,e^{-\tau M}(\mathbf{x}-\overline{N})+\overline{N}), \tag{1.28}$$

where $\overline{N}$ *is such that* $-M\overline{N}=N$ *and where* $U_0\equiv U_0(t,\mathbf{y})$ *is solution of*

$$\begin{aligned}&\frac{\partial U_0}{\partial t}+\int_0^\theta e^{-\sigma M}\mathcal{A}(t,\sigma,e^{\sigma M}(\mathbf{y}-\overline{N})+\overline{N})\,d\sigma\cdot\nabla_y U_0=0,\\ &U_{0|t=0}=\tfrac{1}{\theta}u_0.\end{aligned} \tag{1.29}$$

The proof of this theorem consists in finding the constraint equation imposed on U by the $\frac{1}{\epsilon}L$ operator. This yields (1.28). Then we remove the essential oscillation of u^ϵ by defining $w^\epsilon(t,\mathbf{y}) = u^\epsilon(t, e^{\frac{t}{\epsilon}M}(\mathbf{y}-\overline{N})+\overline{N})$. Using the equation w^ϵ satisfies, denoting $(W_0^{1,r}(K))^*$ the dual of $W_0^{1,r}(K)$, we prove that $\frac{\partial w^\epsilon}{\partial t}$ is bounded in $L^\infty(0,T;(W_0^{1,r}(K))^*)$, for some $r>1$ ($\frac{1}{r^*} = \frac{1}{p}+\frac{1}{q}-\frac{1}{n}$, $\frac{1}{r}+\frac{1}{r^*}=1$), which, applying the Aubin–Lions lemma, gives that $w^\epsilon \to \theta U_0$ strongly in $L^\infty(0,T;(W_0^{1,q}(K))^*)$ for any compact set $K\subset\mathbb{R}^n$. This fact, coupled with (1.25), enables us to pass to the limit in the equation satisfied by w^ϵ and find (1.29).

Theorem 1.4 is a direct application of Theorem 1.5 once the wanted regularity of $\mathbf{E}^\epsilon$ is proved. This is done with the help of classical kinetic energy estimates and the regularization property of the Laplace operator.

The paper is organized as follows. In section 2 we present the scaling leading to the finite Larmor radius approximation. We show how to obtain (1.1) and system (1.17). The next section is devoted to the deduction of the asymptotic behavior of the linear Vlasov equation. Finally, in section 4 we prove Theorems 1.5 and 1.4 concerning the nonlinear case.

2. Scaling: The finite Larmor radius regime. Approximate models in the case of a large external magnetic field have been used by physicists for a long time and the corresponding gyrokinetic ordering is due to Taylor and Hastie [24] and Rutherford and Frieman [19]. We also refer to [6] for a further discussion. And for a physical introduction of the finite Larmor radius model, we refer to [15, 17]. Our scaling assumptions follow from those works.

We present here the scaling leading to (1.1) and system (1.17). We exhibit the important parameters playing a role when charged particles are submitted to a strong magnetic field. For this purpose we consider the following Vlasov–Poisson system

$$
\begin{aligned}
&\frac{\partial f}{\partial t} + \mathbf{v}\cdot\nabla_x f + \frac{q}{m}(\mathbf{E}(t,\mathbf{x}) + \mathbf{v}\times\mathbf{B}(t,\mathbf{x}))\cdot\nabla_v f = 0\\
&f_{|t=0} = f_0,\\
&\mathbf{E} = -\nabla\phi, \qquad -\Delta\phi = \frac{q}{\epsilon_0}\rho,\\
&\rho(t,\mathbf{x}) = \int_{\mathbb{R}^3_v} f(t,\mathbf{x},\mathbf{v})\,d\mathbf{v},
\end{aligned}
\tag{2.1}
$$

before any scaling, which can be considered as a natural model to describe the behavior of charged particles under the action of an external magnetic field $\mathbf{B}(t,\mathbf{x})$.

We define some characteristic scales: $\bar{t}$ stands for a characteristic time, $\overline{L_\parallel}$ for a characteristic length in the direction of the magnetic field, $\overline{L_\perp}$ for a characteristic length in the direction orthogonal to the magnetic field, $\overline{v}$ for a characteristic velocity. Denoting, for any vector $\mathbf{x}$, $\mathbf{x}_\parallel$ and $\mathbf{x}_\perp$ its components parallel and perpendicular to the magnetic field, we now define new variables t', $\mathbf{x}'$, and $\mathbf{v}'$, by $t = \bar{t}t'$, $\mathbf{x}_\parallel = \overline{L_\parallel}\mathbf{x}'_\parallel$, $\mathbf{x}_\perp = \overline{L_\perp}\mathbf{x}'_\perp$, and $\mathbf{v} = \overline{v}\mathbf{v}'$, making the characteristic scales the unities. In the same way, we define the scaling factors for the fields: $\overline{E}$ for the electric field and $\overline{B}$ for the magnetic field and the new fields $\mathcal{E}$ and $\mathcal{B}$ are given by $\overline{E}\mathcal{E}(t',\mathbf{x}') = \mathbf{E}(\bar{t}t', \overline{L_\parallel}\mathbf{x}'_\parallel, \overline{L_\perp}\mathbf{x}'_\perp)$ and $\overline{B}\mathcal{B}(t',\mathbf{x}') = \mathbf{B}(\bar{t}t', \overline{L_\parallel}\mathbf{x}'_\parallel, \overline{L_\perp}\mathbf{x}'_\perp)$. Lastly, defining a scaling factor $\overline{f}$ for the repartition function, noticing that f is a repartition function on the phase-space, it is natural to

define the new repartition function by

$$\overline{f} f'(t', \mathbf{x}', \mathbf{v}') = \overline{L_\parallel}\,\overline{L_\perp}^2 \overline{v}^3 f(\overline{t}t', \overline{L_\parallel}\mathbf{x}'_\parallel, \overline{L_\perp}\mathbf{x}'_\perp, \overline{v}\mathbf{v}'). \tag{2.2}$$

With those new variables and fields we deduce the scaling equations.

2.1. Scaling of the Vlasov equation. Let us begin with the Vlasov equation; we obtain that f' is solution of

$$\frac{\partial f'}{\partial t'} + \frac{\overline{v}\overline{t}}{\overline{L_\parallel}}\mathbf{v}'_\parallel \cdot \nabla_{x'} f' + \frac{\overline{v}\overline{t}}{\overline{L_\perp}}\mathbf{v}'_\perp \cdot \nabla_{x'} f' + \left(\frac{q\overline{E}\overline{t}}{m\overline{v}}\mathcal{E}(t', \mathbf{x}') + \frac{q\overline{B}\overline{t}}{m}\mathbf{v}' \times \mathcal{B}(t', \mathbf{x}')\right) \cdot \nabla_{v'} f' = 0. \tag{2.3}$$

Now, we introduce the characteristic cyclotron frequency: $\overline{\omega}_c = \frac{q\overline{B}}{m}$ and the characteristic Larmor radius: $\overline{a}_L = \frac{\overline{v}}{\overline{\omega}_c}$. Using those physical quantities, (2.3) becomes

$$\frac{\partial f'}{\partial t'} + \overline{t\omega}_c \frac{\overline{a}_L}{\overline{L_\parallel}}\mathbf{v}'_\parallel \cdot \nabla_{x'} f' + \overline{t\omega}_c \frac{\overline{a}_L}{\overline{L_\perp}}\mathbf{v}'_\perp \cdot \nabla_{x'} f' + \left(\overline{t\omega}_c \frac{\overline{E}}{\overline{v}\overline{B}}\mathcal{E}(t', \mathbf{x}') + \overline{t\omega}_c \mathbf{v}' \times \mathcal{B}(t', \mathbf{x}')\right) \cdot \nabla_{v'} f' = 0. \tag{2.4}$$

Assuming the magnetic field is strong consists essentially in setting

$$\overline{t\omega_c} = \frac{1}{\epsilon} \text{ and } \frac{\overline{E}}{\overline{v}\overline{B}} = \epsilon \tag{2.5}$$

for a small parameter ϵ, and the finite Larmor radius regime consists in choosing

$$\frac{\overline{a}_L}{\overline{L_\parallel}} = \epsilon \text{ and } \frac{\overline{a}_L}{\overline{L_\perp}} = 1. \tag{2.6}$$

Hence the rescaled Vlasov equation writes

$$\frac{\partial f'}{\partial t'} + \mathbf{v}'_\parallel \cdot \nabla_{x'} f' + \frac{1}{\epsilon}\mathbf{v}'_\perp \cdot \nabla_{x'} f' + (\mathcal{E}(t', \mathbf{x}') + \frac{1}{\epsilon}\mathbf{v} \times \mathcal{B}(t', \mathbf{x}')) \cdot \nabla_{v'} f' = 0. \tag{2.7}$$

Concerning the initial data, under the scaling (2.2), the second equation of (2.1) directly gives

$$f'_{|t'=0} = \frac{\overline{L_\parallel}\,\overline{L_\perp}^2 \overline{v}^3}{\overline{f}} f_0(\overline{L_\parallel}\mathbf{x}'_\parallel, \overline{L_\perp}\mathbf{x}'_\perp, \overline{v}\mathbf{v}'). \tag{2.8}$$

Hence, if we assume that the scales of variations of the initial data f_0 (before scaling) are of the same order as the characteristic lengths used, and that $\overline{f} = \overline{L_\parallel}\,\overline{L_\perp}^2 \overline{v}^3$, it is natural to consider (1.1) as a relevant model to understand local behavior of charged particles under the action of a strong external constant magnetic field.

This is the reason why we study (1.1) in section 3.

2.2. Scaling of the Poisson equation. We now turn to the Poisson equation given by the third and fourth equations of (2.1). For this purpose, we define the new electric potential by

$$\overline{E}\,\overline{L_\parallel}\phi'(t', \mathbf{x}') = \phi(\overline{t}t', \overline{L_\parallel}\mathbf{x}'_\parallel, \overline{L_\perp}\mathbf{x}'_\perp), \tag{2.9}$$

and the new particle density by

$$\rho'(t',\mathbf{x}') = \int f'(t',\mathbf{x}',\mathbf{v}')\,d\mathbf{v}'. \tag{2.10}$$

Direct computations give

$$\rho'(t',\mathbf{x}') = \frac{\overline{L_\parallel}\,\overline{L_\perp}^2}{\overline{f}}\rho(\bar{t}t',\overline{L_\parallel}\mathbf{x}'_\parallel,\overline{L_\perp}\mathbf{x}'_\perp), \tag{2.11}$$

$$\nabla\phi(\bar{t}t',\overline{L_\parallel}\mathbf{x}'_\parallel,\overline{L_\perp}\mathbf{x}'_\perp) = \overline{E}\begin{pmatrix}\nabla_{\mathbf{x}'_\parallel}\phi'(t',\mathbf{x}')\\ \frac{\overline{L_\parallel}}{\overline{L_\perp}}\nabla_{\mathbf{x}'_\perp}\phi'(t',\mathbf{x}')\end{pmatrix}, \tag{2.12}$$

and

$$\Delta\phi(\bar{t}t',\overline{L_\parallel}\mathbf{x}'_\parallel,\overline{L_\perp}\mathbf{x}'_\perp) = \frac{\overline{E}}{\overline{L_\parallel}}\left(\Delta_{\mathbf{x}'_\parallel}\phi'(t',\mathbf{x}') + \frac{\overline{L_\parallel}^2}{\overline{L_\perp}^2}\Delta_{\mathbf{x}'_\perp}\phi'(t',\mathbf{x}')\right). \tag{2.13}$$

Hence the Poisson equation $-\Delta\phi = \frac{q}{\epsilon_0}\rho$ becomes

$$-\left(\Delta_{\mathbf{x}'_\parallel}\phi' + \frac{\overline{L_\parallel}^2}{\overline{L_\perp}^2}\Delta_{\mathbf{x}'_\perp}\phi'\right) = \frac{q}{\epsilon_0}\frac{\overline{f}}{\overline{E}\,\overline{L_\perp}^2}\rho' \tag{2.14}$$

and the definition of the electric field $\mathbf{E} = -\nabla\phi$ yields

$$\mathcal{E} = -\begin{pmatrix}\nabla_{\mathbf{x}'_\parallel}\phi'\\ \frac{\overline{L_\parallel}}{\overline{L_\perp}}\nabla_{\mathbf{x}'_\perp}\phi'\end{pmatrix}. \tag{2.15}$$

Setting now the same ratio as in (2.5) and (2.6) and considering that the scales of variations of the initial data are of the same order as the characteristic lengths, the rescaled Vlasov–Poisson system writes

$$\begin{aligned}
&\frac{\partial f'}{\partial t'} + \mathbf{v}'_\parallel\cdot\nabla_{x'}f' + \frac{1}{\epsilon}\mathbf{v}'_\perp\cdot\nabla_{x'}f' + \left(\mathcal{E}(t',\mathbf{x}') + \frac{1}{\epsilon}\mathbf{v}\times\mathcal{B}(t',\mathbf{x}')\right)\cdot\nabla_{v'}f' = 0,\\
&f_{|t=0} = f'_0,\\
&\mathcal{E} = -\begin{pmatrix}\nabla_{\mathbf{x}'_\parallel}\phi'\\ \frac{1}{\epsilon}\nabla_{\mathbf{x}'_\perp}\phi'\end{pmatrix},\quad -\left(\Delta_{\mathbf{x}'_\parallel}\phi' + \frac{1}{\epsilon^2}\Delta_{\mathbf{x}'_\perp}\phi'\right) = \gamma\rho',\\
&\rho'(t',\mathbf{x}') = \int_{\mathbb{R}^3_v} f'(t',\mathbf{x}',\mathbf{v}')\,d\mathbf{v}',
\end{aligned} \tag{2.16}$$

with $\gamma = \frac{q}{\epsilon_0}\frac{\overline{f}}{\overline{E}\overline{L_\perp}^2}$.

For the study we lead in section 4 we consider the previous system with $\gamma = \frac{1}{\epsilon}$ and with $\mathcal{B} = \mathbf{m} = \mathbf{e}_1$. We moreover assume that none of the fields depend on the component parallel to the magnetic fields $\mathbf{x}_\parallel$ and $\mathbf{v}_\parallel$. In this case the Poisson equation from which we remove the $\mathbf{x}_\parallel-$dependency

$$\mathcal{E} = -\begin{pmatrix}0\\ \frac{1}{\epsilon}\nabla_{\mathbf{x}'_\perp}\phi'\end{pmatrix},\quad -\frac{1}{\epsilon^2}\Delta_{\mathbf{x}'_\perp}\phi' = \frac{1}{\epsilon}\rho', \tag{2.17}$$

is equivalent to, removing the magnetic field direction,

$$\mathcal{E} = -\nabla\phi^*, \quad -\Delta\phi^* = \rho^*, \tag{2.18}$$

where ϕ^* is nothing but $\frac{1}{\epsilon}\phi'$ and with

$$\rho^* = \int_{\mathbb{R}^2_v} f'\, d\mathbf{v}, \tag{2.19}$$

explaining the interest of studying system (1.17).

3. Homogenization of the Vlasov equation. In this section, we provide the homogenization of the Vlasov equation (1.1) and prove Theorem 1.1. Since the contexts of (1.1) and the equation studied in Frénod and Sonnendrücker [8] are similar, we develop a generic framework and apply it to prove Theorem 1.1. We then show that this generic framework applies also to prove Theorems 1.1 and 3.2 of Frénod and Sonnendrücker [8].

3.1. Generic framework—proof of Theorem 1.3. The framework inside which the problem we want to homogenize enters is the following conservation law singularly linearly perturbed:

$$\begin{aligned} &\frac{\partial u^\epsilon}{\partial t} + \mathbf{A}\cdot\nabla_x u^\epsilon + \frac{1}{\epsilon}\mathbf{L}\cdot\nabla_x u^\epsilon = 0,\\ &u^\epsilon_{|t=0} = u_0, \end{aligned} \tag{3.1}$$

where $u^\epsilon \equiv u^\epsilon(t,\mathbf{x})$, $t \in [0,T)$ for some $T < \infty$, and $\mathbf{x} \in \mathbb{R}^n = \mathcal{O}$. We denote $\mathcal{Q} = [0,T)\times\mathcal{O}$, and we assume $\mathbf{A} \equiv \mathbf{A}(t,\mathbf{x}) \in L^\infty(0,T;L^2_{loc}(\mathcal{O}))$, with $\nabla_x\cdot\mathbf{A} = 0$ and $\mathbf{L} \equiv M\mathbf{x} + N$, where M is a real $n\times n$ matrix with constant entries satisfying $\mathrm{tr}M = 0$ and where $N \in \mathrm{Im}M$, which implies that $\nabla_x\cdot\mathbf{L} = 0$.We moreover assume that $e^{\tau M}$ is θ-periodic for a given $\theta\in\mathbb{R}$.

The proof of Theorem 1.3, characterizing the limit of (3.1), is led in three steps. First, we look for the constraint imposed by the operator $(\frac{1}{\epsilon}\mathbf{L}\cdot\nabla_x)$ on the profile U, 2-scale limit of (u^ϵ). Studying the characteristics associated with this constraint, we obtain the form (1.14) it gives to U. In the second step, using test functions satisfying the constraint in the weak formulation of (3.1), we get the equation satisfied by U_0. In view of formula (1.8) linking the 2-scale limit to the weak$-*$ limit, in the last step, we integrate the equation satisfied by U_0 to deduce (1.16).

Under the assumption (1.11), we may apply the result of Nguetseng [18] and Allaire [2] (see Theorem 1.2). Then, for any period $\tilde\theta$ there exists a $\tilde\theta$-periodic profile $U_{\tilde\theta}(t,\tau,\mathbf{x}) \in L^\infty(0,T;L^\infty_{\tilde\theta}(\mathbb{R}_\tau;L^2(\mathcal{O})))$ such that, for any regular function $\psi_{\tilde\theta}(t,\tau,\mathbf{x})$ compactly supported in $(t,\mathbf{x})$ and $\tilde\theta$-periodic in τ, we have

$$\int_{\mathcal{Q}} u^\epsilon(t,\mathbf{x})\psi_{\tilde\theta}\left(t,\frac{t}{\epsilon},\mathbf{x}\right)\,dt\,d\mathbf{x} \to \int_{\mathcal{Q}}\int_0^{\tilde\theta} U(t,\tau,\mathbf{x})\psi_{\tilde\theta}(t,\tau,\mathbf{x})\,d\tau\,dt\,d\mathbf{x}. \tag{3.2}$$

Now, we write a weak formulation of (3.1) with oscillating test functions $(\psi_{\tilde\theta})^\epsilon = \psi_{\tilde\theta}(t,\frac{t}{\epsilon},\mathbf{x})$, with $\psi_{\tilde\theta}(t,\tau,\mathbf{x})$ previously defined. Since $\nabla_x\cdot\mathbf{A} = \nabla_x\cdot\mathbf{L} = 0$, it writes

$$\int_{\mathcal{Q}} u^\epsilon\left(\left(\frac{\partial\psi_{\tilde\theta}}{\partial t}\right)^\epsilon + \frac{1}{\epsilon}\left(\frac{\partial\psi_{\tilde\theta}}{\partial\tau}\right)^\epsilon + \mathbf{A}\cdot(\nabla_x\psi_{\tilde\theta})^\epsilon + \frac{1}{\epsilon}\mathbf{L}\cdot(\nabla_x\psi_{\tilde\theta})^\epsilon\right)dtd\mathbf{x} = -\int_{\mathcal{O}} u_0\psi_{\tilde\theta}(0,0,\mathbf{x})\,d\mathbf{x}. \tag{3.3}$$

Multiplying (3.3) by ϵ and passing to the limit gives the following constraint equation for the $\tilde{\theta}$-periodic profile $U_{\tilde{\theta}}$:

$$\frac{\partial U_{\tilde{\theta}}}{\partial \tau} + \mathbf{L} \cdot \nabla_x U_{\tilde{\theta}} = 0 \text{ in } \mathcal{D}'(\mathbb{R}_\tau \times \mathcal{O}). \tag{3.4}$$

This equation says that $U_{\tilde{\theta}}$ is constant along the characteristics of the following dynamical system:

$$\frac{d\mathbf{X}}{d\tau} = \mathbf{L}(\mathbf{X}(\tau)) = M\mathbf{X}(\tau) + N. \tag{3.5}$$

Using the assumptions made on $\mathbf{L}$, writing $\mathbf{X}(\tau; \mathbf{x}, s)$ for the solution of (3.5) satisfying $\mathbf{X}(s; \mathbf{x}, s) = \mathbf{x}$, we obtain

$$\mathbf{X}(\tau; \mathbf{x}, s) = e^{(\tau - s)M}(\mathbf{x} - \overline{N}) + \overline{N}. \tag{3.6}$$

Hence from (3.4), we deduce, on the one hand, that for any $\tilde{\theta}$ the $\tilde{\theta}$-periodic profile writes

$$U_{\tilde{\theta}}(t, \tau, \mathbf{x}) = U_0(t, e^{-\tau M}(\mathbf{x} - \overline{N}) + \overline{N}) \tag{3.7}$$

for a function $U_0 \equiv U_0(t, \mathbf{y}) \in L^\infty(0, T; L^2(\mathcal{O}'))$. On the other hand, we take the θ-periodicity of $e^{-\tau M}$ under consideration. In view of (3.7), we deduce that if $\tilde{\theta}$ and θ are incommensurable, $U_{\tilde{\theta}}$ cannot depend on τ, and then contains no information concerning the oscillations of (u^ϵ). Yet if $\tilde{\theta}$ equals (or is multiple of) θ, the profile $U_{\tilde{\theta}}$ naturally satisfies its $\tilde{\theta}$-periodicity condition once (3.7) is satisfied.

Hence, among every possible periodic profile, we are incited to work now with the θ-periodic one

$$U := U_\theta, \tag{3.8}$$

which writes

$$U(t, \tau, \mathbf{x}) = U_0(t, e^{-\tau M}(\mathbf{x} - \overline{N}) + \overline{N}) \tag{3.9}$$

for $U_0 \equiv U_0(t, \mathbf{y}) \in L^\infty(0, T; L^2(\mathcal{O}'))$, which is the equality (1.14) of Theorem 1.3.

Now, we seek the equation U_0 satisfies. For this purpose, we build oscillating test functions satisfying the constraint and use them in the weak formulation (3.3).

For any $\varphi(t, \mathbf{y})$, regular and compactly supported, we define $\psi(t, \tau, \mathbf{x}) = \varphi(t, e^{-\tau M}(\mathbf{x} - \overline{N}) + \overline{N})$ and we inject in (3.3) test function $(\psi)^\epsilon = \psi(t, \frac{t}{\epsilon}, \mathbf{x})$. Acting in such a way, the terms containing the constraint vanishes. We have then

$$\int_{\mathcal{Q}} u^\epsilon \left(\left(\frac{\partial \psi}{\partial t} \right)^\epsilon + \mathbf{A} \cdot (\nabla_x \psi)^\epsilon \right) dt d\mathbf{x} = - \int_{\mathcal{O}} u_0 \psi(0, 0, \mathbf{x})\, d\mathbf{x}, \tag{3.10}$$

which passing to the limit yields

$$\int_{\mathcal{Q}} \int_0^\theta U \left(\frac{\partial \psi}{\partial t} + \mathbf{A} \cdot \nabla \psi \right) dt d\mathbf{x} d\tau = - \int_{\mathcal{O}} u_0 \psi(0, 0, \mathbf{x})\, d\mathbf{x}. \tag{3.11}$$

In (3.11) we use the expression of U in terms of U_0, the expression of ψ in term of φ, without forgetting

$$\nabla_x \psi(t, \tau, \mathbf{x}) = (e^{-\tau M})^T \nabla_y \varphi(t, e^{-\tau M}(\mathbf{x} - \overline{N}) + \overline{N}), \tag{3.12}$$

denoting $(e^{-\tau M})^T$ the transpose of $e^{-\tau M}$; and we make the change of variable $\mathbf{x} \mapsto \mathbf{y} = e^{-\tau M}(\mathbf{x} - \overline{N}) + \overline{N}$. This gives

$$\int_{\mathcal{Q}'} \int_0^\theta U_0 \left(\frac{\partial \varphi}{\partial t} + e^{-\tau M} \mathbf{A}(t, e^{\tau M}(\mathbf{y} - \overline{N}) + \overline{N}) \cdot \nabla_y \varphi \right) dt d\mathbf{y} d\tau = - \int_{\mathcal{O}} u_0 \varphi(0, \mathbf{y})\, d\mathbf{y}. \tag{3.13}$$

An easy computation coupled with the fact that $\nabla_x \cdot \mathbf{A} = 0$ gives

$$\nabla_y \cdot (e^{-\sigma M} \mathbf{A}(t, e^{\sigma M}(\mathbf{y} - \overline{N}) + \overline{N})) = (\nabla_x \cdot \mathbf{A})(t, e^{\sigma M}(\mathbf{y} - \overline{N}) + \overline{N}) = 0. \tag{3.14}$$

Hence, knowing that neither U_0 nor φ depend on τ, we deduce that (3.13) is the weak formulation of

$$\begin{aligned} &\frac{\partial U_0}{\partial t} + \frac{1}{\theta} \int_0^\theta e^{-\sigma M} \mathbf{A}(t, e^{\sigma M}(\mathbf{y} - \overline{N}) + \overline{N})\, d\sigma \cdot \nabla_y U_0 = 0, \\ &U_{0|t=0} = \frac{1}{\theta} u_0, \end{aligned} \tag{3.15}$$

proving the second part of Theorem 1.3.

In order to get (1.16) we use the fact that

$$u(t, \mathbf{x}) = \int_0^\theta U(t, \tau, \mathbf{x})\, d\tau = \int_0^\theta U_0(t, e^{-\tau M}(\mathbf{x} - \overline{N}) + \overline{N})\, d\tau. \tag{3.16}$$

Replacing in (3.15) $\mathbf{y}$ by $e^{-\tau M}(\mathbf{x} - \overline{N}) + \overline{N}$ and integrating in τ we get

$$\begin{aligned} &\frac{\partial}{\partial t} \left(\int_0^\theta U_0(t, e^{-\tau M}(\mathbf{x} - \overline{N}) + \overline{N})\, d\tau \right) \\ &\quad + \frac{1}{\theta} \int_0^\theta \int_0^\theta e^{-\sigma M} \mathbf{A}(t, e^{(\sigma - \tau) M}(\mathbf{x} - \overline{N}) + \overline{N})\, d\sigma \cdot \nabla_y U_0(t, e^{-\tau M}(\mathbf{x} - \overline{N}) + \overline{N})\, d\tau = 0, \\ &\int_0^\theta U_0(t, e^{-\tau M}(\mathbf{x} - \overline{N}) + \overline{N}))_{|t=0}\, d\tau = \frac{1}{\theta} \int_0^\theta u_0(e^{-\tau M}(\mathbf{x} - \overline{N}) + \overline{N})\, d\tau. \end{aligned} \tag{3.17}$$

An easy computation yields

$$\nabla_x (U_0(t, e^{-\tau M}(\mathbf{x} - \overline{N}) + \overline{N})) = (e^{-\tau M})^T (\nabla_y U_0)(t, e^{-\tau M}(\mathbf{x} - \overline{N}) + \overline{N}), \tag{3.18}$$

and then replacing in the second term of the first equation in (3.17) gives

$$\begin{aligned} &\int_0^\theta \int_0^\theta e^{-\sigma M} \mathbf{A}(t, e^{(\sigma - \tau) M}(\mathbf{x} - \overline{N}) + \overline{N})\, d\sigma \cdot (e^{\tau M})^T \nabla_x (U_0(t, e^{-\tau M}(\mathbf{x} - \overline{N}) + \overline{N})\, d\tau \\ &\quad = \int_0^\theta \int_0^\theta e^{(\tau - \sigma) M} \mathbf{A}(t, e^{(\sigma - \tau) M}(\mathbf{x} - \overline{N}) + \overline{N})\, d\sigma \cdot \nabla_x (U_0(t, e^{-\tau M}(\mathbf{x} - \overline{N}) + \overline{N}))\, d\tau. \end{aligned} \tag{3.19}$$

Yet by the periodicity of $\tau \mapsto e^{\tau M}$ we deduce that

$$\int_0^\theta e^{(\tau - \sigma) M} \mathbf{A}(t, e^{(\sigma - \tau) M}(\mathbf{x} - \overline{N}) + \overline{N})\, d\sigma = \int_0^\theta e^{-\sigma M} \mathbf{A}(t, e^{\sigma M}(\mathbf{x} - \overline{N}) + \overline{N})\, d\sigma \tag{3.20}$$

does not depend on τ.

We may finally conclude that (3.17) reads

$$\begin{aligned} &\frac{\partial u}{\partial t} + \frac{1}{\theta}\int_0^\theta e^{-\sigma M}\mathbf{A}(t, e^{\sigma M}(\mathbf{x}-\overline{N})+\overline{N})d\sigma \cdot \nabla u = 0, \\ &u_{|t=0}(\mathbf{x}) = \frac{1}{\theta}\int_0^\theta u_0(e^{-\sigma M}(\mathbf{x}-\overline{N})+\overline{N})\,d\sigma. \end{aligned} \tag{3.21}$$

achieving the proof of Theorem 1.3.

3.2. Application to the Vlasov equation—proof of Theorem 1.1. Using assumption (1.2) made on f_0 and the following property of f^ϵ solution of (1.1)

$$\frac{d}{dt}\|f^\epsilon(t,\cdot,\cdot)\|_{L^2(\mathcal{O})} = 0, \tag{3.22}$$

obtained by a direct integration in $\mathbf{x}$ and $\mathbf{v}$ of the first equation in (1.1), after multiplication by f^ϵ, we deduce that

$$\|f^\epsilon\|_{L^\infty(0,T;L^2(\mathcal{O}))} \leq C \tag{3.23}$$

for some constants C.

Hence, the Vlasov equation (1.1) enters the generic framework previously built with

$$\mathbf{A}(t,\mathbf{x},\mathbf{v}) = \begin{pmatrix} \mathbf{v}_\parallel \\ \mathbf{E}(t,\mathbf{x}) \end{pmatrix} (\in \mathbb{R}^6) \text{ and } \mathbf{L}(t,\mathbf{x},\mathbf{v}) = \begin{pmatrix} \mathbf{v}_\perp \\ \mathbf{v}\times\mathbf{m} \end{pmatrix} (\in \mathbb{R}^6). \tag{3.24}$$

Then the differential system defining the characteristics $(\dot{X},\dot{V}) = \mathbf{L}(X,V)$ becomes

$$\frac{dX_\perp}{d\tau} = V_\perp, \qquad \frac{dV}{d\tau} = V\times\mathbf{m}.$$

An easy computation then yields $V(\tau;\mathbf{v},s) = R(\tau-s)\mathbf{v}$ and $X(\tau;(\mathbf{x},\mathbf{v}),s) = \mathbf{x} + \mathcal{R}(\tau-s)\mathbf{v}$, with $\mathcal{R}(\tau)$ and $R(\tau)$ given by (1.6). Hence $e^{\tau M}$ reads in this case

$$e^{\tau M} = \begin{pmatrix} I & \mathcal{R}(\tau) \\ 0 & R(\tau) \end{pmatrix}. \tag{3.25}$$

We can then deduce

$$f^\epsilon \text{ 2-scale converges to } F \in L^\infty(0,T;L^\infty_{2\pi}(\mathbb{R}_\tau;L^2(\mathcal{O}))), \tag{3.26}$$

and applying Theorem 1.3, we can deduce that there exists a function $G \equiv G(t,\mathbf{y},\mathbf{u}) \in L^\infty(0,T;L^2(\mathcal{O}'))$ such that

$$F(t,\tau,\mathbf{x},\mathbf{v}) = G(t,\mathbf{x}+\mathcal{R}(-\tau)\mathbf{v}, R(-\tau)\mathbf{v}), \tag{3.27}$$

where G is the unique solution of

$$\begin{aligned} &\frac{\partial G}{\partial t} + \mathbf{u}_\parallel\cdot\nabla_y G + \frac{1}{2\pi}\left(\int_0^{2\pi}\mathcal{R}(-\tau)\mathbf{E}(t,\mathbf{y}+\mathcal{R}(\tau)\mathbf{u})\,d\tau\right)\cdot\nabla_y G \\ &\qquad + \frac{1}{2\pi}\left(\int_0^{2\pi} R(-\tau)\mathbf{E}(t,\mathbf{y}+\mathcal{R}(\tau)\mathbf{u})\,d\tau\right)\cdot\nabla_v G = 0, \\ &G_{|t=0} = \frac{1}{2\pi}f_0. \end{aligned} \tag{3.28}$$

Always applying Theorem 1.3, we also deduce that the weak$-*$ limit f of (f^ϵ) is the unique solution of (1.5).

The fact that the whole sequence (f^ϵ) 2-scale converges to F and weak$-*$ converges to f is a direct consequence of the uniqueness of the solution of (3.28) and (1.5). This ends the proof of Theorem 1.1.

3.3. Link with physical models. In order to compare the model we obtain with the finite Larmor radius approximation used by physicists, we restrain to the plane orthogonal to the magnetic field. Denoting here $R(\tau)$ and $\mathcal{R}(\tau)$ there restrictions to this plan, we introduce the Larmor radius variable $\mathbf{r} = \mathbf{v}^\perp$ and the guiding center variable $\mathbf{x}_C = \mathbf{x} - \mathbf{r}$, where for any vector $\mathbf{v} = (v_2, v_3)$, $\mathbf{v}^\perp$ stand for $\mathbf{v}^\perp = (-v_3, v_2)$. In this new variables, (3.28) reads:

$$\frac{\partial f}{\partial t} - \frac{1}{2\pi}\left(\int_0^{2\pi} \mathbf{E}^\perp(t, \mathbf{x}_C + R(\tau)\mathbf{r})\, d\tau\right)\cdot \nabla_{x_C} f + \frac{1}{2\pi}\left(\int_0^{2\pi} R(-\tau)\mathbf{E}^\perp(t, \mathbf{x}_C + R(\tau)\mathbf{r})\, d\tau\right)\cdot \nabla_r f = 0. \tag{3.29}$$

Then, assuming that the distribution function is a Maxwellian distribution, i.e., $f \equiv n(\mathbf{x}_c, t)e^{-\mathbf{r}^2/(2\sigma^2)}/(2\pi\sigma)$, we integrate (3.29) with respect to $\mathbf{r}$. This procedure cancels the third term. Indeed

$$\int_0^{2\pi} R(-\tau)\mathbf{E}^\perp(t, \mathbf{x}_C + R(\tau)\mathbf{r})\, d\tau \tag{3.30}$$

depends only on $|\mathbf{r}|$ and then the integrand is odd. Then we get

$$\frac{\partial n}{\partial t} - \int_{\mathbb{R}^2_r} \frac{1}{2\pi}\left(\int_0^{2\pi} \mathbf{E}^\perp(t, \mathbf{x}_C + R(\tau)\mathbf{r})\, d\tau\right) e^{-\mathbf{r}^2/(2\sigma^2)}/(2\pi\sigma)\, d\mathbf{r}\cdot \nabla_{x_C} n = 0, \tag{3.31}$$

which is the model introduced by Hansen et al. [15].

3.4. About previous results. Notice that Theorem 1.1 of Frénod and Sonnendrücker [8], proving that the asymptotic behavior of

$$\begin{aligned} &\frac{\partial f^\epsilon}{\partial t} + \mathbf{v}\cdot\nabla_x f^\epsilon + \left(\mathbf{E} + \mathbf{v}\times\left(\mathbf{B} + \frac{\mathbf{m}}{\epsilon}\right)\right)\cdot\nabla_v f^\epsilon = 0, \\ &f^\epsilon_{|t=0} = f_0 \end{aligned} \tag{3.32}$$

is given by

$$\begin{aligned} &\frac{\partial f}{\partial t} + \mathbf{v}_\parallel\cdot\nabla_x f + (\mathbf{E}_\parallel + \mathbf{v}\times\mathbf{B}_\parallel)\cdot\nabla_v f = 0, \\ &f_{|t=0} = \frac{1}{2\pi}\int_0^{2\pi} f_0(\mathbf{x}, \mathbf{u}(\mathbf{v}, \tau))\, d\tau, \end{aligned} \tag{3.33}$$

is also a consequence of Theorem 1.3 by setting

$$\mathbf{A} = \begin{pmatrix} \mathbf{v} \\ \mathbf{E} + \mathbf{v}\times\mathbf{B} \end{pmatrix} \text{ and } \mathbf{L} = \begin{pmatrix} 0 \\ \mathbf{v}\times\mathbf{m} \end{pmatrix}. \tag{3.34}$$

This is the same for Theorem 3.2 of [8] with

$$\mathbf{A} = \begin{pmatrix} \mathbf{v} \\ \mathbf{E} + \mathbf{v} \times \mathbf{B} \end{pmatrix} \text{ and } \mathbf{L} = \begin{pmatrix} 0 \\ \mathbf{n} + \mathbf{v} \times \mathbf{m} \end{pmatrix}. \tag{3.35}$$

This theorem says that the weak$-*$ limit of the solution of

$$\begin{aligned} &\frac{\partial f^\epsilon}{\partial t} + \mathbf{v} \cdot \nabla_x f^\epsilon + \left(\left(\mathbf{E} + \frac{\mathbf{n}}{\epsilon} \right) + \mathbf{v} \times \left(\mathbf{B} + \frac{\mathbf{m}}{\epsilon} \right) \right) \cdot \nabla_v f^\epsilon = 0, \\ &f^\epsilon_{|t=0} = f_0, \end{aligned} \tag{3.36}$$

with $\mathbf{n} = \mathbf{e}_2$, satisfies

$$\begin{aligned} &\frac{\partial f}{\partial t} + \begin{pmatrix} v_1 \\ 0 \\ -1 \end{pmatrix} \cdot \nabla_x f + \left[\begin{pmatrix} E_1 - B_2 \\ 0 \\ 0 \end{pmatrix} + \begin{pmatrix} v_1 \\ v_2 \\ v_3 + 1 \end{pmatrix} \times \begin{pmatrix} B_1 \\ 0 \\ 0 \end{pmatrix} \right] \cdot \nabla_v f = 0, \\ &f_{|t=0} = \frac{1}{2\pi} \int_0^{2\pi} f_0(\mathbf{x}, \mathbf{u}(\mathbf{v}, \tau))\, d\tau. \end{aligned} \tag{3.37}$$

4. 2-scale limit of the 2D Vlasov–Poisson system. The aim of this section is to characterize the equation satisfied by the 2-scale limit of the sequence $(f^\epsilon, \mathbf{E}^\epsilon)$ of the Vlasov–Poisson system (1.17) For this purpose, we generalize the generic framework to the case when the operator $\mathbf{A}^\epsilon$ is oscillating. Then we apply the results obtained in this new generic framework to prove Theorem 1.4.

4.1. Generalized generic framework–proof of Theorem 1.5. We consider here

$$\begin{aligned} &\frac{\partial u^\epsilon}{\partial t} + \mathbf{A}^\epsilon \cdot \nabla_x u^\epsilon + \frac{1}{\epsilon} \mathbf{L} \cdot \nabla_x u^\epsilon = 0, \\ &u^\epsilon_{t=0} = u_0, \end{aligned} \tag{4.1}$$

where the notations are the same as for (1.10): $u^\epsilon \equiv u^\epsilon(t, \mathbf{x})$, $t \in [0, T)$, $T < \infty$; $\mathbf{x} \in \mathbb{R}^n = \mathcal{O}$, $\mathcal{Q} = [0, T) \times \mathcal{O}$. We suppose, as previously, that $\mathbf{L} \equiv M\mathbf{x} + N$, where M is a constant entry matrix satisfying $\mathrm{tr} M = 0$ and $e^{\tau M}$ is θ-periodic. The assumptions we make on $\mathbf{A}^\epsilon$ are the following: we suppose that, for all $\epsilon > 0$, $\nabla_x \cdot \mathbf{A}^\epsilon = 0$ and that, for some $q > 1$,

$$\mathbf{A}^\epsilon \text{ 2-scale converges to } \mathcal{A} \in L^\infty(0, T; L^\infty_\theta(\mathbb{R}_\tau; W^{1,q}(K))) \tag{4.2}$$

for all compact sets $K \subset \mathbb{R}^n$ and where $\mathcal{A} \equiv \mathcal{A}(t, \tau, \mathbf{x})$ is θ-periodic in τ.

The proof of Theorem 1.5 begins as the proof of Theorem 1.3 in the sense that the constraint equation and its consequences are similar. Hence relation (1.28) is obvious. In order to get the equation U_0 satisfies, we proceed as follows: we define $w^\epsilon(t, \mathbf{x}) = u^\epsilon(t, e^{\frac{t}{\epsilon} M}(\mathbf{x} - \overline{N}) + \overline{N})$, which is the function u^ϵ from which the essential oscillation is removed. This idea has also been used in Frénod and Sonnendrücker [10], Grenier [13, 14], Schochet [20], Joly, Metivier, and Rauch [16], and Colin [5]. Using the equation satisfied by w^ϵ, we show that

$$w^\epsilon \to \theta U_0 \text{ in } L^\infty(0, T; (W^{1,q}_0(K))^*), \tag{4.3}$$

where $(W_0^{1,q}(K))^*$ is the dual of $(W_0^{1,q}(K))$. This fact coupled with the assumption on $\mathbf{A}^\epsilon$ enables us to pass to the limit and find (1.29).

Under assumption (1.26) we may deduce, up to subsequences,

$$u^\epsilon \text{ 2-scale converges to } U \in L^\infty(0,T;L^\infty_\theta(\mathbb{R}_\tau;L^p(\mathcal{O}))). \tag{4.4}$$

The weak formulation of (4.1) with θ-periodic oscillating functions $(\psi)^\epsilon \equiv \psi(t,\frac{t}{\epsilon},\mathbf{x})$ writes

$$\int_{\mathcal{Q}} u^\epsilon \left(\left(\frac{\partial\psi}{\partial t}\right)^\epsilon + \frac{1}{\epsilon}\left(\frac{\partial\psi}{\partial\tau}\right)^\epsilon + \mathbf{A}^\epsilon\cdot(\nabla_x\psi)^\epsilon + \frac{1}{\epsilon}\mathbf{L}\cdot(\nabla_x\psi)^\epsilon \right) dtd\mathbf{x} = -\int_{\mathcal{O}} u_0\psi(0,0,\mathbf{x})\,d\mathbf{x}. \tag{4.5}$$

Proceeding as in subsection 3.1 we obtain that U satisfies

$$\frac{\partial U}{\partial\tau} + \mathbf{L}\cdot\nabla_x U = 0 \text{ in } \mathcal{D}'(\mathbb{R}_\tau\times\mathcal{O}) \tag{4.6}$$

and then

$$U(t,\tau,\mathbf{x}) = U_0(t, e^{-\tau M}(\mathbf{x}-\overline{N})+\overline{N}) \tag{4.7}$$

for $U_0 \equiv U_0(t,\mathbf{y}) \in L^\infty(0,T;L^2(\mathcal{O}'))$, which is (1.28) of Theorem 1.5.

Now we look for the equation U_0 satisfies. For this purpose, we define

$$w^\epsilon(t,\mathbf{y}) = u^\epsilon(t, e^{\frac{t}{\epsilon}M}(\mathbf{y}-\overline{N})+\overline{N}), \tag{4.8}$$

and we have the following lemma which characterizes the asymptotic limit of w^ϵ.

LEMMA 4.1. *The sequence (w^ϵ) satisfies*

$$w^\epsilon \to \theta U_0 \text{ in } L^\infty(0,T;(W_0^{1,q}(K))^*), \tag{4.9}$$

where U_0 is linked with the profile U by (1.28).

Proof. First, we prove that w^ϵ 2-scale converges to U_0 and w^ϵ weakly$-*$ converges to θU_0. Second, we show that $\frac{\partial w^\epsilon}{\partial t}$ is bounded in $L^\infty(0,T;(W_0^{1,r}(K))^*)$ for some $r>1$. Since w^ϵ is bounded in $L^\infty(0,T;L^p(\mathcal{O}))$, the Aubin–Lions lemma leads to the conclusion.

We take any function $\phi(t,\tau,\mathbf{y})$ regular, with compact support in t and $\mathbf{y}$ and θ-periodic with respect to τ. We have

$$\begin{aligned}\int_{\mathcal{O}'} w^\epsilon(t,\mathbf{y})\phi\left(t,\frac{t}{\epsilon},\mathbf{y}\right) dtd\mathbf{y} &= \int_{\mathcal{O}'} u^\epsilon(t,e^{\frac{t}{\epsilon}M}(\mathbf{y}-\overline{N})+\overline{N})\phi\left(t,\frac{t}{\epsilon},\mathbf{y}\right) dtd\mathbf{y}\\ &= \int_{\mathcal{O}} u^\epsilon(t,\mathbf{x})\phi\left(t,\frac{t}{\epsilon},e^{-\frac{t}{\epsilon}M}(\mathbf{x}-\overline{N})+\overline{N}\right) dtd\mathbf{x}.\end{aligned} \tag{4.10}$$

This last quantity converges to

$$\int_{\mathcal{O}}\int_0^\theta U(t,\tau,\mathbf{x})\phi(t,\tau,e^{-\tau M}(\mathbf{x}-\overline{N})+\overline{N})\,dtd\mathbf{x}d\tau = \int_{\mathcal{O}}\int_0^\theta U_0\phi\,dtd\mathbf{y}d\tau, \tag{4.11}$$

proving w^ϵ 2-scale converges to U_0. Since U_0 does not depend on τ, we immediately deduce $w^\epsilon \rightharpoonup \theta U_0$ weakly$-*$.

Now, we seek the equation w^ϵ satisfies. We have

(4.12)
$$\frac{\partial w^\epsilon}{\partial t}(t,\mathbf{y}) = \frac{\partial u^\epsilon}{\partial t}(t, e^{\frac{t}{\epsilon}M}(\mathbf{y}-\overline{N})+\overline{N}) + \frac{M}{\epsilon}e^{\frac{t}{\epsilon}M}(\mathbf{y}-\overline{N})\cdot\nabla_x u^\epsilon(t, e^{\frac{t}{\epsilon}M}(\mathbf{y}-\overline{N})+\overline{N});$$

writing this last equality in $\mathbf{y} = e^{-\frac{t}{\epsilon}M}(\mathbf{x}-\overline{N})+\overline{N}$ we obtain

$$\begin{aligned}\frac{\partial w^\epsilon}{\partial t}(t, e^{-\frac{t}{\epsilon}M}(\mathbf{x}-\overline{N})+\overline{N}) &= \frac{\partial u^\epsilon}{\partial t}(t,\mathbf{x}) + \frac{M}{\epsilon}(\mathbf{x}-\overline{N})\cdot\nabla_x u^\epsilon(t,\mathbf{x}) \\ &= \frac{\partial u^\epsilon}{\partial t}(t,\mathbf{x}) + \frac{1}{\epsilon}\mathbf{L}\cdot\nabla_x u^\epsilon(t,\mathbf{x}).\end{aligned} \tag{4.13}$$

Hence in view of the equation satisfied by u^ϵ and of

$$\nabla_y w^\epsilon(t,\mathbf{y}) = (e^{\frac{t}{\epsilon}M})^T\nabla_x u^\epsilon(t, e^{\frac{t}{\epsilon}M}(\mathbf{y}-\overline{N})+\overline{N}), \tag{4.14}$$

we obtain that w^ϵ is solution of

$$\frac{\partial w^\epsilon}{\partial t} + \mathbf{A}^\epsilon(t, e^{\frac{t}{\epsilon}M}(\mathbf{y}-\overline{N})+\overline{N})\cdot(e^{-\frac{t}{\epsilon}M})^T\nabla_y w^\epsilon = 0, \tag{4.15}$$

i.e.,

$$\frac{\partial w^\epsilon}{\partial t} + e^{-\frac{t}{\epsilon}M}\mathbf{A}^\epsilon(t, e^{\frac{t}{\epsilon}M}(\mathbf{y}-\overline{N})+\overline{N})\cdot\nabla_y w^\epsilon = 0. \tag{4.16}$$

Having (4.16) at hand we can prove that $\frac{\partial w^\epsilon}{\partial t}$ is bounded in $L^\infty(0,T;(W_0^{1,r}(K))^*)$ for some $r>1$ and any compact $K\subset\mathbb{R}^n$. It is an easy game to show

$$\nabla_y\cdot\left[e^{-\frac{t}{\epsilon}M}\mathbf{A}^\epsilon(t, e^{\frac{t}{\epsilon}M}(\mathbf{y}-\overline{N})+\overline{N})\right] = 0. \tag{4.17}$$

Hence, from (4.16) we deduce

$$\frac{\partial w^\epsilon}{\partial t} = -\nabla_y\cdot\left[e^{-\frac{t}{\epsilon}M}\mathbf{A}^\epsilon(t, e^{\frac{t}{\epsilon}M}(\mathbf{y}-\overline{N})+\overline{N})\; w^\epsilon\right], \tag{4.18}$$

and since, due to its two scale convergence, $\mathbf{A}^\epsilon$ is bounded in $W_0^{1,q}(K)$ with a bound independent on t, a Sobolev embedding theorem implies that $\mathbf{A}^\epsilon$ is bounded in $L^{q'}(K)$, where q' is defined by $\frac{1}{q'} = \mathrm{Max}(\frac{1}{q}-\frac{1}{n},0)$, and since $\tau\mapsto e^{-\tau M}$ is periodic, we deduce that $\left(e^{-\frac{t}{\epsilon}M}\mathbf{A}^\epsilon(t, e^{\frac{t}{\epsilon}M}(\mathbf{y}-\overline{N})+\overline{N})\right)$ is also bounded in $L^{q'}(K)$. Then as w^ϵ is bounded in $L^p(\mathcal{O})$, we get that $\left(e^{-\frac{t}{\epsilon}M}\mathbf{A}^\epsilon(t, e^{\frac{t}{\epsilon}M}(\mathbf{y}-\overline{N})+\overline{N})\, w^\epsilon\right)$ is bounded in $L^{r^*}(K)$ with $\frac{1}{r^*} = \frac{1}{p}+\frac{1}{q'}$. We may then conclude that

$$\frac{\partial w^\epsilon}{\partial t} \text{ is bounded in } L^\infty(0,T;(W_0^{1,r}(K))^*), \text{ with } \frac{1}{r^*}+\frac{1}{r} = 1 \tag{4.19}$$

for any compact $K\subset\mathbb{R}^n$.

In order to conclude, we treat first the case when $r^*<q^*$, where q^* is such that $\frac{1}{q^*}+\frac{1}{q} = 1$. As K is compact, we have $L^{q^*}(K)\subset L^{r^*}(K)$. Since, by considering separately the functions and their derivatives, $(W_0^{1,q}(K))^*$ and $(W_0^{1,r}(K))^*$ are, respectively, isomorphic to $(L^{q^*}(K))^{n+1}$ and $(L^{r^*}(K))^{n+1}$ we deduce, on the one hand,

$$(W_0^{1,q}(K))^* \subset (W_0^{1,r}(K))^* \tag{4.20}$$

with continuous injection. On the other hand, as a consequence of the Rellich–Kondrachov theorem, we have

$$L^p(K) \subset (W_0^{1,q}(K))^* \quad \text{compactly.} \tag{4.21}$$

Hence, applying an analogue of the Aubin–Lions lemma proved by Simon [21], we deduce

$$\mathcal{U} = \left\{ u \in L^\infty(0,T;L^p(K)), \frac{\partial u}{\partial t} \in L^\infty(0,T;(W_0^{1,r}(K))^*) \right\} \tag{4.22}$$

is compactly embedded in $L^\infty(0,T;(W_0^{1,q}(K))^*)$. Then we deduce that w^ϵ converges strongly in $L^\infty(0,T;(W_0^{1,r}(K))^*)$, giving the conclusion of the Lemma.

The case $r^* \geq q^*$ is simpler. Indeed, in this case, we directly have from (4.19)

$$\frac{\partial w^\epsilon}{\partial t} \text{ is bounded in } L^\infty(0,T;(W_0^{1,q}(K))^*), \tag{4.23}$$

yielding directly the conclusion of the lemma. ∎

Having Lemma 4.1 at hand, we want to pass to the limit in (4.16). This will give the equation for U_0. In order to realize this, we have first to prove the following.

LEMMA 4.2. *We have*

(4.24)
$\mathbf{A}^\epsilon(t, e^{\frac{t}{\epsilon}M}(\mathbf{y}-\overline{N})+\overline{N})$ *2-scale converges to* $\mathcal{A}(t,\tau,e^{\tau M}(\mathbf{y}-\overline{N})+\overline{N})$ *in* $L^\infty(0,T;L^\infty_\theta(\mathbb{R}_\tau;W_0^{1,q}(K)))$.

Proof. A direct computation gives

$$\begin{aligned}
&\int_{\mathcal{Q}'} \mathbf{A}^\epsilon(t, e^{\frac{t}{\epsilon}M}(\mathbf{y}-\overline{N})+\overline{N})\psi\left(t,\frac{t}{\epsilon},\mathbf{y}\right)\,dtd\mathbf{y} \\
&\qquad = \int_{\mathcal{Q}} \mathbf{A}^\epsilon(t,\mathbf{x})\psi\left(t,\frac{t}{\epsilon},e^{-\frac{t}{\epsilon}M}(\mathbf{x}-\overline{N})+\overline{N}\right)\,dtd\mathbf{x} \\
&\qquad \to \int_{\mathcal{Q}}\int_0^\theta \mathcal{A}(t,\tau,\mathbf{x})\psi(t,\tau,e^{-\tau M}(\mathbf{x}-\overline{N})+\overline{N}))\,dtd\mathbf{y}d\tau \\
&\qquad\qquad = \int_{\mathcal{Q}'}\int_0^\theta \mathcal{A}(t,\tau,e^{\tau M}(\mathbf{y}-\overline{N})+\overline{N}))\psi(t,\tau,\mathbf{y})\,dtd\mathbf{y}d\tau
\end{aligned} \tag{4.25}$$

for any θ-periodic test function. This proves the lemma. ∎

Now, writing a weak formulation of (4.16), we have

$$\int_{\mathcal{Q}'} w^\epsilon\left[\frac{\partial\varphi}{\partial t} + e^{-\frac{t}{\epsilon}M}\mathbf{A}^\epsilon(t,e^{\frac{t}{\epsilon}M}(\mathbf{y}-\overline{N})+\overline{N})\cdot\nabla_y\varphi\right]dtd\mathbf{y} = \int_{\mathcal{O}'} u_0\varphi(0,\cdot)\,d\mathbf{y} \tag{4.26}$$

for any $\varphi(t,\mathbf{y})$ regular and compactly supported in $\mathcal{Q}$. Let K be a compact containing the support of φ, since

(4.27)
$w^\epsilon \to \theta U_0$ in $L^\infty(0,T;(W_0^{1,q}(K))^*)$,

$\mathbf{A}^\epsilon(t, e^{\frac{t}{\epsilon}M}(\mathbf{y}-\overline{N})+\overline{N})$ 2-scale converges to $\mathcal{A}(t,e^{\tau M}(\mathbf{y}-\overline{N})+\overline{N})$ in $L^\infty(0,T;L^\infty_\theta(\mathbb{R}_\tau;W_0^{1,q}(K)))$,

we can pass to the limit in (4.26) and find

(4.28)
$$\int_{\mathcal{Q}'} \theta U_0 \left[\frac{\partial \varphi}{\partial t} + \int_0^\theta e^{-\tau M} \mathcal{A}(t, \tau, e^{\tau M}(\mathbf{y} - \overline{N}) + \overline{N}) d\tau \cdot \nabla_y \varphi \right] dt d\mathbf{y} = \int_{\mathcal{O}'} u_0 \varphi(0, \cdot)\, d\mathbf{y}.$$

Noticing at last that neither U_0 nor φ depend on τ, (4.28) is nothing but a weak formulation of (1.29), proving Theorem 1.5.

Remark. In the case when $\mathbf{A}$ does not depend on ϵ, its 2-scale limit is $\frac{\mathbf{A}}{\theta}$, so that we indeed get the same result as in Theorem 1.3.

4.2. Application to the 2D Vlasov–Poisson system—proof of Theorem 1.4. In order to deduce Theorem 1.4 from Theorem 1.5 we essentially have to show (1.20) and to pass to the limit in the Poisson equation. Indeed, once those two things are proved, the theorem follows noticing that the Vlasov equation which is the first equation of (1.17) enters the generalized generic framework with

$$\mathbf{A}^\epsilon(t, \mathbf{x}, \mathbf{v}) = \begin{pmatrix} 0 \\ \mathbf{E}^\epsilon(t, \mathbf{x}) \end{pmatrix} (\in \mathbb{R}^4) \text{ and } \mathbf{L}(t, \mathbf{x}, \mathbf{v}) = \begin{pmatrix} \mathbf{v} \\ \mathbf{v} \times \mathbf{m} \end{pmatrix} (\in \mathbb{R}^4). \tag{4.29}$$

In this case $e^{\tau M}$ becomes

$$e^{\tau M} = \begin{pmatrix} I & \mathcal{R}(\tau) \\ 0 & R(\tau) \end{pmatrix}, \tag{4.30}$$

with $\mathcal{R}(\tau)$ and $R(\tau)$ given by (1.23).

Multiplying the Vlasov equation which is the first equation of (1.17) by $(f^\epsilon)^{p-1}$ and integrating in $\mathbf{x}$ and $\mathbf{v}$ we obtain

$$\|f^\epsilon\|_{L^\infty(0,T;L^p(\mathcal{O}))} \leq C \tag{4.31}$$

for some constants C. From this estimate, we deduce the following.

LEMMA 4.3. *Under assumption* (1.19)

$$f^\epsilon \text{ 2-scale converges to } F \in L^\infty(0, T; L^\infty_{2\pi}(\mathbb{R}_\tau; L^p(\mathcal{O}))). \tag{4.32}$$

The fact that $\mathbf{E}^\epsilon$ 2-scale converges takes a bit longer to obtain. We need first to show the following lemma.

LEMMA 4.4. *Under assumption* (1.19)*, we have*

$$\|(|v|^2 f^\epsilon)\|_{L^\infty(0,T;L^1(\mathcal{O}))} \leq C \text{ and } \|\rho^\epsilon(\mathbf{x}, t)\|_{L^\infty(0,T;L^{\frac{3}{2}}(\mathbb{R}^3_x))} \leq C \tag{4.33}$$

for some constant C.

Proof. Multiplying the Vlasov equation by $|\mathbf{v}|^2$, and integrating with respect to $\mathbf{x}$ and $\mathbf{v}$, we get

$$\frac{d}{dt} \int_{\mathcal{O}} f^\epsilon |\mathbf{v}|^2 \, d\mathbf{v}\, d\mathbf{x} - 2 \int_{\mathbb{R}^2_x} \mathbf{J}^\epsilon \cdot \mathbf{E}^\epsilon \, d\mathbf{x} = 0, \tag{4.34}$$

where

$$\mathbf{J}^\epsilon(\mathbf{x}, t) = \int_{\mathbb{R}^2_v} \mathbf{v} f^\epsilon \, d\mathbf{v}. \tag{4.35}$$

Now, integrating the Vlasov equation in $\mathbf{v}$ gives the continuity equation

$$\frac{\partial \rho^\epsilon}{\partial t} + \frac{1}{\epsilon}\nabla \cdot \mathbf{J}^\epsilon = 0. \tag{4.36}$$

Using this, we obtain

$$\int_{\mathbb{R}^2_x} \mathbf{J}^\epsilon \cdot \mathbf{E}^\epsilon \, d\mathbf{x} = -\int_{\mathbb{R}^2_x} \mathbf{J}^\epsilon \cdot \nabla \phi^\epsilon \, d\mathbf{x} = \int_{\mathbb{R}^2_x} \nabla \cdot \mathbf{J}^\epsilon \, \phi^\epsilon \, d\mathbf{x} = -\epsilon \int_{\mathbb{R}^2_x} \frac{\partial \rho_\epsilon}{\partial t} \, \phi^\epsilon \, d\mathbf{x}. \tag{4.37}$$

Using now the Poisson equation, we get

$$\frac{1}{2}\frac{d}{dt}\int_{\mathbb{R}^2_x} (\nabla \phi^\epsilon)^2 \, d\mathbf{x} = -\int_{\mathbb{R}^2_x} \frac{\partial}{\partial t}\Delta \phi^\epsilon \, \phi^\epsilon \, d\mathbf{x} = \int_{\mathbb{R}^2_x} \frac{\partial \rho_\epsilon}{\partial t} \, \phi^\epsilon \, d\mathbf{x}. \tag{4.38}$$

Coupling (4.37) and (4.38) yields

$$-2\int_{\mathbb{R}^2_x} \mathbf{J}^\epsilon \cdot \mathbf{E}^\epsilon \, d\mathbf{x} = \epsilon \frac{d}{dt}\int_{\mathbb{R}^2_x} (\nabla \phi^\epsilon)^2 \, d\mathbf{x}, \tag{4.39}$$

and then (4.34) reads

$$\frac{d}{dt}\left[\int_{\mathcal{O}} f^\epsilon |\mathbf{v}|^2 \, d\mathbf{v} \, d\mathbf{x} + \epsilon \int_{\mathbb{R}^2_x} (\nabla \phi^\epsilon)^2 \, d\mathbf{x},\right] = 0, \tag{4.40}$$

and as an immediate consequence we have

$$\|(|v|^2 f^\epsilon)\|_{L^\infty(0,T;L^1(\mathcal{O}))} \le C \tag{4.41}$$

for some constant C. The first part of the lemma is then proved.

Concerning ρ^ϵ we have

$$\rho^\epsilon(\mathbf{x},t) = \int_{\mathbb{R}^2_v} f^\epsilon \, d\mathbf{v} = \int_{|v|<R} f^\epsilon \, d\mathbf{v} + \int_{|v|>R} f^\epsilon \, d\mathbf{v} \tag{4.42}$$

for any $R > 0$. Using the Cauchy–Schwartz inequality, we have

$$\int_{|v|<R} f^\epsilon \, d\mathbf{v} \le \left(\int_{|v|<R} (f^\epsilon)^2 \, d\mathbf{v}\right)^{\frac{1}{2}} \left(\int_{|v|<R} d\mathbf{v}\right)^{\frac{1}{2}} \le C_1 R \left(\int_{\mathbb{R}^2_v} (f^\epsilon)^2 \, d\mathbf{v}\right)^{\frac{1}{2}} \tag{4.43}$$

and

$$\int_{|v|>R} f^\epsilon \, d\mathbf{v} \le \int_{|v|>R} \frac{|v|^2}{R^2} f^\epsilon \, d\mathbf{v} \le \frac{1}{R^2}\int_{\mathbb{R}^2_v} |v|^2 f^\epsilon \, d\mathbf{v}. \tag{4.44}$$

Hence, we have for any $R > 0$

$$|\rho^\epsilon(\mathbf{x},t)| \le C_1 R \left(\int_{\mathbb{R}^2_v} (f^\epsilon)^2 \, d\mathbf{v}\right)^{\frac{1}{2}} + \frac{1}{R^2}\int_{\mathbb{R}^2_v} |v|^2 f^\epsilon \, d\mathbf{v}. \tag{4.45}$$

Taking the R which minimizes the right-hand side we obtain

$$|\rho^\epsilon(\mathbf{x},t)| \le C_2 \left(\int_{\mathbb{R}^2_v} (f^\epsilon)^2 \, d\mathbf{v}\right)^{\frac{1}{3}} \left(\int_{\mathbb{R}^2_v} |v|^2 f^\epsilon \, d\mathbf{v}\right)^{\frac{1}{3}} \tag{4.46}$$

and finally

$$\int_{\mathbb{R}^2_x} |\rho^\epsilon(\mathbf{x},t)|^{\frac{3}{2}}\,d\mathbf{x} \le C_3 \int_{\mathbb{R}^2_x} \left(\int_{\mathbb{R}^2_v} (f^\epsilon)^2\,d\mathbf{v}\right)^{\frac{1}{2}} \left(\int_{\mathbb{R}^2_v} |v|^2 f^\epsilon\,d\mathbf{v}\right)^{\frac{1}{2}} d\mathbf{x},$$
$$\le C_3 \left(\int_{\mathbb{R}^2_x\times\mathbb{R}^2_v} (f^\epsilon)^2\,d\mathbf{x}\,d\mathbf{v}\right)^{\frac{1}{2}} \left(\int_{\mathbb{R}^2_x\times\mathbb{R}^2_v} |v|^2 f^\epsilon\,d\mathbf{x}\,d\mathbf{v}\right)^{\frac{1}{2}},$$

thanks to the Hölder inequality. Now, knowing that the terms on the right-hand side are bounded, we have our estimate on ρ^ϵ. Hence the proof of the lemma is ended. □

As a direct consequence of Lemma 4.4, and of the regularization properties of the Laplace operator, we deduce that $\mathbf{E}^\epsilon$ is bounded in $L^\infty(0,T;W^{1,\frac{3}{2}}(\mathbb{R}^2_x))$ and the following lemma holds true.

LEMMA 4.5. *Extracting a subsequence, we have*

$$E^\epsilon \text{ 2-scale converges to } \mathcal{E} \in L^\infty(0,T;L^\infty_{2\pi}(\mathbb{R}_\tau;W^{1,\frac{3}{2}}(\mathbb{R}^2_x))). \tag{4.47}$$

Hence we proved the two facts yielding the first two equations of (1.22) with the help of Theorem 1.5.

It now remains to pass to the 2-scale limit in the Poisson equation (1.17). This can be done easily writing a weak formulation of the Poisson equation with oscillating test functions,

$$\int_{\mathbb{R}^2_x} \nabla\phi^\epsilon(t,\mathbf{x})\cdot\nabla\psi\left(t,\frac{t}{\epsilon},\mathbf{x}\right)\,dtd\mathbf{x} = \int_{\mathcal{O}} f^\epsilon(t,\mathbf{x},\mathbf{v})\psi\left(t,\frac{t}{\epsilon},\mathbf{x}\right)\,dtd\mathbf{x}d\mathbf{v}, \tag{4.48}$$

in which case we can pass to the limit and obtain, denoting Φ the 2-scale limit of ϕ^ϵ

$$\int_{\mathbb{R}^2_x}\int_0^{2\pi} \nabla\Phi\cdot\nabla\psi\,dtd\mathbf{x}d\tau = \int_{\mathcal{O}}\int_0^{2\pi} F\psi\,dtd\mathbf{x}d\mathbf{v}d\tau$$
$$= \int_{\mathcal{O}}\int_0^{2\pi} G(t,\mathbf{x}+\mathcal{R}(-\tau)\mathbf{v},R(-\tau)\mathbf{v})\psi\,dtd\mathbf{x}d\mathbf{v}d\tau,$$

which is the weak formulation of the third equation of (1.22), achieving, in view of what is said in the beginning of the subsection, the proof of Theorem 1.4.

Remark. The deduction of the equation satisfied by the weak$-*$ limit f from (1.22) is an open problem. Indeed, writing an equation for $[G(t,\mathbf{x}+\mathcal{R}(-\tau)\mathbf{v},R(-\tau)\mathbf{v})]$ from (1.22) introduces the τ-variable in the coefficients of $\nabla_x[G(t,\mathbf{x}+\mathcal{R}(-\tau)\mathbf{v},R(-\tau)\mathbf{v})]$ and $\nabla_v[G(t,\mathbf{x}+\mathcal{R}(-\tau)\mathbf{v},R(-\tau)\mathbf{v})]$. Hence we cannot proceed as in the linear case. Moreover, since those coefficients also depend on $\mathbf{x}$ and $\mathbf{v}$, the nonlocal homogenization methods (see Tartar [22, 23], Amirat, Hamdache and Ziani [3, 4] Frénod and Hamdache [7], Alexandre [1]...) do not work.

Acknowledgments. We would like to thank Pierre Bertrand for the very interesting discussions we had with him and which helped us understand the finite Larmor radius approximation. We also thank Pierre-Arnaud Raviart for his pertinent advice about this work.

ON THE TRACE APPROACH TO THE INVERSE SCATTERING PROBLEM IN DIMENSION ONE*

ALEXEI RYBKIN†

Abstract. We present an elementary procedure to derive certain trace relations for Schrödinger operators in dimension one relating potentials with some scattering data. In this way, we obtain some new trace type formulas as well as known ones previously studied by Gesztesy, Holden, Simon, and others, our a priori hypothesis on potentials being minimal. We also establish sharp conditions on absolute summability of the trace formulas.

Key words. inverse scattering, trace formulas, Krein's spectral shift function, Weyl's m-function

1. Introduction. For Schrödinger operators $H = -d^2/dx^2 + v(x)$ in $L_2(\mathbb{R})$ with short-range potentials $v(x)$, the inverse scattering problem is well developed due to the Gel'fand–Levitan–Marchenko procedure for recovering $v(x)$ from certain scattering data. (Simon [24] has recently initiated a systematic generalization of the Gel'fand–Levitan–Marchenko theory to the case of arbitrary v.) However, this technique is rather involved and it is always desirable to have some explicit formulas for computing potentials in terms of some observable scattering data. One of the few such methods is the so-called trace approach to the inverse scattering problem. Some formulas serving for short-range, periodical, and other cases were obtained by Deift and Trubowitz [6] in the late 1970s and more recently by Venakides [26] and Craig [5] (see also [12] for extended literature), though they were not identified as trace relations. A consistent approach based on Krein's trace formulas was recently put forward and systematically studied by Gesztesy et al. [8, 11], Gesztesy [9], Gesztesy and Holden [10, 15], Gesztesy, Holden, and Simon [12], Gesztesy and Simon [13, 14], and Gesztesy and Makarov [16]. Their original idea is not to compare H with the free Hamiltonian $H_0 = -d^2/dx^2$ but to compare H with the associated self-adjoint Dirichlet operator H_{x_0} obtained from H by splitting it at a point $x = x_0$ by a Dirichlet boundary condition $u(x_0 \pm 0) = 0$. In this way, one obtains a pair of operators (H_{x_0}, H) whose resolvent difference is a rank one operator. Then the required trace formulas for recovering potentials result from regularizing Krein's trace formula for $\operatorname{tr}(H_{x_0} - H)$. Specifically, if $x = x_0$ is a point of Lebesgue continuity for v, then

$$v(x_0) = E + \lim_{\varepsilon \to +0} \int_E^\infty e^{-\varepsilon k} \{1 - 2\xi(x_0, k)\}\, dk = E + \lim_{z \to i\infty} \int_E^\infty \left(\frac{z}{k - z}\right)^2 \{1 - 2\xi(x_0, k)\}\, dk, \tag{1.1}$$

where $\xi(x_0, k)$ is the Krein spectral shift function of the pair (H_{x_0}, H) and $E = \inf \sigma(H)$. (See section 2 for notation and background information.)

The proof of (1.1) combines Krein's trace formula with path integral arguments and imposes very weak a priori conditions on $v(x)$: local integrability and essential boundedness from below. Note that all the relevant results by Deift, Craig, Trubowitz, Venakides, and others appear as specific cases of (1.1).

In the present paper, we shall introduce a new way of generating trace-type formulas similar to (1.1) that is not based upon Krein's trace formula but rests on the Weyl theory for second order differential equations and asymptotics of the Weyl m-function. (See also [21] for some applications to the Korteweg–de Vries equation.) In particular, we give an elementary proof of (1.1) under the only requirement that v be locally integrable, thus allowing the case $E = -\infty$. Moreover, we show that the second formula (1.1) holds even for points of jump discontinuity (with a substitution $v(x_0)$ for $\frac{1}{2}(v(x_0-0)+v(x_0+0))$). To give this topic full consideration we shall also improve the relevant results of [12] on absolute summability of trace relations (1.1) by finding sharp conditions. Some other applications of our approach are in preparation [23].

We shall also take a look at the circle of ideas of Gesztesy, Holden, and Simon from a different point of view motivated by the Lax–Phillips scattering theory in the interpretation of Pavlov [20]. To this end, instead of putting a boundary condition at a point x_0 we "cut off" the part of the potential $v(x)$ lying to the left from x_0 and compare $H = -d^2/dx^2 + v_{x_0}(x)$ with $H_0 = -d^2/dx^2$, where $v_{x_0}(x) = 0, x < x_0; v_{x_0}(x) = v(x), x \geq x_0$. The scattering matrix for (H, H_0) does not in general exist, but one of its elements does, namely, the reflection coefficients $R(x_0,k)$ from the left defined in a certain way. The function $R(x_0,k)$ is analytic and contractive in the upper half plane $\mathbb{C}_+$, and its complex zeros $\{z_n(x_0)\}$ make clear physical sense of resonance states. We shall provide a simple procedure of recovering potentials in terms of the reflection coefficient.

The structure of the present paper is as follows. In section 2 we agree upon the terminology and provide the relevant background material. Section 3 is the central analytic part: we state and prove some propositions which will play a crucial role in our approach. Section 4 forms the main body of this text. Here we present the abovementioned way of representation of potentials via the reflection coefficient. Here we also improve one result of Klibanov and Sacks [18] on asymptotics of the reflection coefficient on the real line. Section 5 is related to section 4—it utilizes some of the results of the previous section to make some curious conclusions on resonances. Section 6 is also central. Here we demonstrate how our approach works in settings considered by others. We give simple proofs and extend already known results on trace formula (1.1) and its analog for other than Dirichlet boundary conditions. Finally, in section 7 we consider conditions providing absolute summability of the trace formula (1.1). We prove sharp results for cascade type potentials considered in [12].

2. Notation and preliminaries. Notation. We will follow standard notation: $\mathbb{R}_\pm = (\pm\infty, 0), \mathbb{C}_\pm = \{z \in \mathbb{C} : \pm \operatorname{Im} \geq 0\}$. Scripts z and k will always stand, respectively, for a complex variable and a real one; $z \to i\infty$ will mean $|z| \to \infty$ inside any cone $0 < \varepsilon \leq \arg z \leq \pi - \varepsilon$. We will also use standard spaces $(1 \leq p < \infty)$

$$L_p(\Delta, d\mu) = \left\{ f : \|f\|_p \equiv \left(\int_\Delta |f(x)|^p \, d\mu \right)^{1/p} < \infty \right\}, \quad L_p(\Delta, dx) \equiv L_p(\Delta),$$

$$L_\infty(\Delta) = \{ f : \|f\|_\infty \equiv \operatorname{ess\,sup} |f(x)| < \infty \}, \quad L_{p,\mathrm{loc}} = \{ \cap L_p(\Delta) : \Delta \text{ is compact} \}.$$

$W_m^p(\Delta)$ denotes the usual Sobolev space whose elements have up to m distributional derivatives in $L_p(\Delta)$; $\sigma_d(H), \sigma_{sc}(H)$, and $\sigma_{ac}(H)$ are, respectively, the discrete, singular continuous, and absolutely continuous spectrums of a self-adjoint operator H.

Lebesgue points. A point $x \in \Delta$ is called a right (left) Lebesgue continuity point of a function $f(x) \in L_1(\Delta)$ if (see, e.g., [7])

$$\int_0^h |f(x \pm t) - f(x)|\, dt = o(h), \quad h \to +0.$$

If also

$$\int_{-h}^h |f(x+t) - f(x)|\, dt = o(h), \quad h \to +0,$$

x is called a Lebesgue continuity point. A right (left) Lebesgue point may coincide with the left (right) endpoint of Δ as opposed to a Lebesgue point which by definition must be an inner point of Δ.

LEMMA 2.1. *Let $\phi(x), f(x) \in L_1(\Delta)$, $\|\phi\|_1 = 1$, and $\psi(x) = \sup\{|\phi(t)| : |t| \geq |x|\} \in L_1(\Delta)$. Then*

$$f(x) = \lim_{h \to 0} \frac{1}{h} \int_\Delta \phi\left(\frac{x-t}{h}\right) f(t)\, dt$$

for every Lebesgue point x of $f(x)$.

Herglotz functions. An analytic function $f(z)$ is called Herglotz if $f(z)$ maps $\mathbb{C}_+$ into $\mathbb{C}_+$ (see, e.g., [1]).

PROPOSITION 2.2. *Let $f(z)$ be a Herglotz function. Then there exist a positive measure $d\rho$ on $\mathbb{R}$ and a real-valued ξ such that*

$$f(z) = a + bz + \int_{\mathbb{R}} \left(\frac{1}{k-z} - \frac{k}{1+k^2}\right) d\rho(k) \tag{2.1}$$

$$= \exp\left\{c + \int_{\mathbb{R}} \left(\frac{1}{k-z} - \frac{k}{1+k^2}\right) \xi(k) dk\right\}, \tag{2.2}$$

where

$$a = \operatorname{Re} f(i), \quad b \geq 0, \quad c = \operatorname{Re} \ln f(i),$$
$$\int_{\mathbb{R}} \frac{d\rho(k)}{1+k^2} < \infty, \quad \int_{\mathbb{R}} \frac{\xi(k) dk}{1+k^2} < \infty, \quad 0 \leq \xi(k) \leq 1.$$

The functions $\rho(\Delta), \xi(k)$ can be computed by

$$\rho(\Delta) = \lim_{\varepsilon \to o+} \frac{1}{\pi} \int_\Delta \operatorname{Im} f(k + i\varepsilon)\, dk, \quad \xi(k) = \frac{1}{\pi} \lim_{\varepsilon \to o+} \arg f(k + i\varepsilon).$$

Schrödinger operators. Given a real-valued potential $v \in L_{1,\mathrm{loc}}$ we introduce the differential expression

$$l = -\frac{d^2}{dx^2} + v(x), \quad x \in \mathbb{R}.$$

We associate with l several self-adjoint operators:

$$Hu = lu, \quad u \in \mathrm{Dom}\,(H) = \{f \in L_2(\mathbb{R}) : lf \in L_2(\mathbb{R})\}, \tag{2.3}$$

$$\begin{aligned} H_{x_0}^{\pm} u &= lu, \quad u \in \mathrm{Dom}\left(H_{x_0}^{\pm}\right) \\ &= \{f \in L_2(x_0, \pm\infty) : lf \in L_2(x_0, \pm\infty), f(x_0 \pm 0) = 0\}, \end{aligned} \tag{2.4}$$

$$H_{x_0} = H_{x_0}^{+} \oplus H_{x_0}^{-}. \tag{2.5}$$

A more detailed description of the domains in (2.3)–(2.5) can be found, e.g., in [19]. If a potential v is in the so-called limit circle case at $\pm\infty$, then operators in (2.3)–(2.5) are no longer well defined. In this case we have to impose some self-adjoint boundary conditions at $\pm\infty$. Throughout the paper we include the limit circle case by assuming a suitable boundary condition at $\pm\infty$. For simplicity, we decided to retain the same notation for operators (2.3)–(2.5) in both cases.

Weyl's *m*-function. Let $\theta(x,z), \varphi(x,z)$ be the solutions of

$$-u'' + v(x)\,u = zu, \quad x \in \mathbb{R}_{\pm}, \quad z \in \mathbb{C}_{+}, \tag{2.6}$$

satisfying the following boundary conditions:

$$\theta(\pm 0, z) = 1, \quad \theta'(\pm 0, z) = 0; \quad \varphi(\pm 0, z) = 0, \quad \varphi'(\pm 0, z) = 1.$$

According to the Weyl theory (see, e.g., [19, 25]), there exists a unique function $m_{\pm}(z)$ analytic in $\mathbb{C} \setminus \mathbb{R}$ with $\pm \operatorname{Im} m_{\pm}(z) \geq 0, z \in \mathbb{C}_{\pm}$, such that

$$\psi_{\pm}(x,z) = \theta(x,z) + m_{\pm}(z)\,\varphi(x,z) \in L_2(\mathbb{R}_{\pm}). \tag{2.7}$$

This function $m_{\pm}$ is called the Weyl–Titchmarsh m-function (or the Weyl m-function) associated with $H_0^{\pm}$. Sometimes for simplicity we will write $m_+ = m$. For solutions $\theta(x,z), \varphi(x,z)$ we have

$$\theta(x,z) = \cos\sqrt{z}x + \frac{1}{\sqrt{z}} \int_0^x \sin\sqrt{z}\,(x-y)\,v(y)\,\theta(y,z)\,dy, \tag{2.8}$$

$$\varphi(x,z) = \frac{\sin\sqrt{z}x}{\sqrt{z}} + \frac{1}{\sqrt{z}} \int_0^x \sin\sqrt{z}\,(x-y)\,v(y)\,\varphi(y,z)\,dy,$$

$$\left|e^{i\sqrt{z}x}\theta(x,z)\right| \leq \exp\left\{\frac{1}{|\sqrt{z}|}\int_0^x |v(y)|\,dy\right\}, \tag{2.9}$$

$$\left|e^{i\sqrt{z}x}\varphi(x,z)\right| \leq \frac{1}{|\sqrt{z}|}\exp\left\{\frac{1}{|\sqrt{z}|}\int_0^x |v(y)|\,dy\right\}.$$

Recall that if v is in the limit circle case at $\pm\infty$, then any solution of (2.6) is in $L_2(\mathbb{R}_{\pm})$ and $m_{\pm}$ is not defined uniquely, and we then follow the procedure outlined above.

The next proposition is due to Atkinson [2].

PROPOSITION 2.3. *Let $v(x) \in L_1(0, \pm\delta)$ for some $\delta > 0$; then in any cone $0 < \varepsilon < \arg z < \pi - \varepsilon$*

$$m_{\pm}(z) = \pm i\sqrt{z} - \int_0^{\pm\delta} e^{\pm 2i\sqrt{z}x} v(x)\,dx + o\left(1/\sqrt{z}\right), \quad z \to \infty. \tag{2.10}$$

Note that further terms in asymptotics (2.10) (under the same conditions) were derived in [17].

Besides the Weyl m-function $m_\pm(z)$ of the Dirichlet problem we will also consider Weyl m-functions $m_{\pm,h}(z)$ corresponding to other conditions $u'(\pm 0)+hu(\pm 0)=0$, $h\in\mathbb{R}$. Weyl m-functions $m_{\pm,h}$ are related to $m_\pm$ by the formula

$$m_{\pm,h}(z)=\frac{hm_\pm(z)-1}{m_\pm(z)+h}. \tag{2.11}$$

The reflection coefficient. Let $v_0(x)=0, x<0$; $v_0(x)=v(x), x\geq 0$. Consider the equation

$$-u''+v_0(x)u=zu,\quad x\in\mathbb{R},\quad z\in\mathbb{C}_+,$$

and introduce its solution $u(x,z)$ such that

$$\begin{aligned} &u(x,z)=e^{i\sqrt{z}x}+R(z)e^{-i\sqrt{z}x},\quad x<0,\\ &u(x,z)=c(z)\psi_+(x,z),\quad x\geq 0, \end{aligned}$$

where $\sqrt{z}$ is chosen so that $\operatorname{Im}\sqrt{z}\geq 0$. The requirement of continuity of $u(x,z)$ and $u'(x,z)$ at $x=0$ implies

$$R(z)=-\frac{m_+(z)-i\sqrt{z}}{m_+(z)+i\sqrt{z}}. \tag{2.12}$$

Due to general properties of $m_+(z)$, $R(z)$ is analytic and contractive $|R(z)|\leq 1$ in $\mathbb{C}_+$, and therefore has boundary values a.e. on $\mathbb{R}$ and admits the canonical representation (see, e.g., [7])

$$\begin{aligned} &R(z)=e^{ic}B(z)S_i(z)S_e(z),\quad z\in\mathbb{C}_+,\\ &B(z)=\prod_n\left\{\frac{1+\overline{z}_n^2}{|1+z_n^2|}\frac{z-z_n}{z-\overline{z}_n}\right\},\\ &S(z)=\exp\frac{i}{\pi}\left\{\int_{\mathbb{R}}\frac{1+zk}{k-z}\frac{\log|R(k)|\,dk+d\mu(k)}{1+k^2}+\pi az\right\}, \end{aligned} \tag{2.13}$$

where $a\geq 0, c\in\mathbb{R}$, and $\mu(k)$ is a nonnegative singular measure.

The Weyl m-function has no clear physical sense, but the function $R(z)$, following Pavlov [20], can be interpreted as the reflection coefficient of plane waves $e^{i\sqrt{z}x}$ with momentum $\sqrt{z}, (\operatorname{Im}\sqrt{z}=0)$ coming from $-\infty$ and reflected by the potential $v_0(x)$. The fact that in general $\sigma_{ac}(H)=\operatorname{clos}\{k\in\mathbb{R}:\operatorname{Im}m(k+i0)>0\}\neq\emptyset$ (therefore, $|R(k)|\leq 1$ on $\sigma_{ac}(H)$) means that the waves $e^{i\sqrt{z}x}, z\in\sigma_{ac}(H)$, are not completely reflected by $v_0(x)$ and can also propagate on $(0,\infty)$. The zeros $\{z_n\}$ of $R(z)$ in $\mathbb{C}_+$ are related to so-called resonances (surface states) by $\{k_n\}$ by $k_n=\sqrt{z_n}, \operatorname{Im}\sqrt{z_n}>0$. Note that resonances are observable physical quantities, $\left(\operatorname{Im}\sqrt{z_n}\right)^{-1}$ being interpreted as lifetimes. Note also that $\{z_n\}$, being zeros of analytic contractive function, are subject to the Blaschke condition

$$\sum_n\frac{\operatorname{Im}z_n}{|z_n+i|^2}<\infty. \tag{2.14}$$

Krein's spectral shift function. Let (H, H_0) be an abstract pair of resolvent comparable Hilbert space operators (i.e., $(H - zI)^{-1} - (H_0 - zI)^{-1}$ is of trace class for a complex z). Then (see, e.g., [3]) there exists a unique (up to an additive constant) real-valued function $\xi(k) \in L_1\left(\mathbb{R}, \frac{dk}{1+k^2}\right)$ such that the Krein trace formula

$$\operatorname{tr}\{\varphi(H) - \varphi(H_0)\} = \int_{\mathbb{R}} \varphi'(k)\, \xi(k)\, dk \tag{2.15}$$

holds; φ is an arbitrary function of some suitable class. The function $\xi(k)$ is called the spectral shift function of the pair (H, H_0), and for almost all $k \in \sigma_{ac}(H_0)$ the function $\xi(k)$ is related to the scattering matrix $S(k)$ of (H, H_0) by the Birman–Krein formula

$$\det S(k) = e^{-2\pi i \xi(k)}.$$

Note that as opposed to the scattering matrix, the spectral shift function is defined on the whole line.

3. Auxiliary results. The following lemma is a well-known fact on differentiation of asymptotic expansions of analytic functions.

LEMMA 3.1. *Let $f(z)$ be an analytic function in $\mathbb{C}_+$. If $f(z)$ admits the representation*

$$f(z) = a_0 + \frac{a_1}{z} + o\left(\frac{1}{z}\right)$$

for $z \to \infty$ inside a cone $\Gamma_\varepsilon = \{z \in \mathbb{C}_+ : 0 < \varepsilon \le \arg z \le \pi - \varepsilon\}$, then

$$a_1 = -\lim z^2 f'(z), \quad z \to \infty, \quad z \in \Gamma_\varepsilon. \tag{3.1}$$

Proof. Change z for $1/z$. Then $\Gamma_\varepsilon \to \overline{\Gamma}_\varepsilon = \{z \in \mathbb{C}_- : \overline{z} \in \Gamma_\varepsilon\}$ and

$$f(1/z) = a_0 + a_1 z + o(z). \tag{3.2}$$

Fix $z \in \overline{\Gamma}_\varepsilon$, and let $C_r(z) = \{\lambda \in \mathbb{C}_- : |\lambda - z| = r\}$ be a circle with radius $r = |z| \sin \varepsilon/2$. It follows from (3.2) that

$$\frac{1}{2\pi i} \int_{C_r(z)} \frac{f(\lambda)\, d\lambda}{(\lambda - z)^2} = \sum_{m=0}^{1} a_m \frac{1}{2\pi i} \int_{C_r(z)} \frac{(\lambda - z_0)^m\, d\lambda}{(\lambda - z)^2} + \widetilde{o}(z), \tag{3.3}$$

where for the remainder $\widetilde{o}(z)$ we have

$$\begin{aligned} |\widetilde{o}(z)| &\le r^{-1} \max_{\lambda \in C_r(z)} |\lambda|\, o(1) \\ &= \frac{|z| + r}{r} \cdot o(1) = \frac{1 + \sin \varepsilon}{\sin \varepsilon} \cdot o(1). \end{aligned}$$

Therefore, $\widetilde{o}(z) \to 0$ as $z \to \infty, z \in \overline{\Gamma}_{\varepsilon/2}$, and hence by the Cauchy theorem, (3.3) implies

$$\frac{d}{dz} f(1/z) = a_1 + \widetilde{o}(z) \to a_1, \text{ as } z \to 0, \quad z \in \overline{\Gamma}_{\varepsilon/2},$$

which implies (3.1) by substituting $1/z$ back for z. □

LEMMA 3.2. *Let $f(x) \in L_1(0,\delta)$ for some $\delta > 0$, and let $x = 0$ be a right Lebesgue point of $f(x)$; then*

$$\int_0^\delta e^{izx} f(x)\,dx = \frac{if(0)}{z} + o(1/z), \quad z \to \infty, \quad \varepsilon < \arg z < \frac{\pi}{2} - \varepsilon.$$

Proof. We have

$$\int_0^\delta e^{izx} f(x)\,dx = f(0)\int_0^\delta e^{izx}dx + \int_0^\delta e^{izx}(f(x) - f(0))\,dx = f(0)\,\frac{e^{iz\delta}-1}{iz} + \widetilde{o}(1/z),$$

where $\widetilde{o}(1/z) = \int_0^\delta e^{izx}(f(x) - f(0))\,dx$. It follows from $\varepsilon < \arg z < \frac{\pi}{2} - \varepsilon$ that $|z| \le (1+\cot\varepsilon)\operatorname{Im} z$, and hence one gets $\left|f(0)\,e^{iz\delta}\right| \to 0, \operatorname{Im} z \to \infty$, and

$$\begin{aligned}|z\widetilde{o}(1/z)| &\le |z|\int_0^\delta e^{-\operatorname{Im} z\cdot x}\,|f(x) - f(0)|\,dx \\ &\le (1+\cot\varepsilon)\operatorname{Im} z\int_0^\delta e^{-\operatorname{Im} z\cdot x}\,|f(x) - f(0)|\,dx = o(1), \quad \operatorname{Im} z \to \infty,\end{aligned}$$

since the functions $\psi(x) = \sup\left\{e^{-|t|} : |t| \ge |x|\right\}$ and $|f(x) - f(0)|$ satisfy the conditions of Lemma 2.1 with $h = (\operatorname{Im} z)^{-1}$. □

PROPOSITION 3.3. *Suppose $v(x)$ is a real-valued function defined on $\mathbb{R}$ and such that*

$$\exists v_\pm \in \mathbb{R} : v(x) - v_\pm \in L_1(\mathbb{R}_\pm), \quad \int_{\mathbb{R}_\pm} (v(x) - v_\pm)\cos sx dx \in L_1(\mathbb{R}_+). \tag{3.4}$$

Set $\Omega_\pm(\lambda) \equiv \frac{m_\pm(\lambda+i0) \mp i\sqrt{\lambda - v_\pm}}{\pm i\sqrt{\lambda}}$; then for some $a > 0$

$$\operatorname{Im}\Omega_\pm, \quad \operatorname{Im}\Omega_\pm^2 \in L_1(a,\infty).$$

Proof. Consider only the right half-line. Observe once that $m(z) = \widetilde{m}(z-c)$, where $\widetilde{m}(z)$ is the Weyl m-function of H_0^+ with $v(x) = v(x) - v_+$, and hence we may simply set $v_+ = 0$.

Since now $v \in L_1(\mathbb{R}_+)$, we may use the well-known representation of the Weyl m-function [25]

$$m(z) = i\sqrt{z}\,\frac{1 - \int_0^\infty \frac{e^{i\sqrt{z}y}}{i\sqrt{z}} v(y)\,\theta(y,z)\,dy}{1 + \int_0^\infty e^{i\sqrt{z}y} v(y)\,\varphi(y,z)\,dy} \equiv i\sqrt{z}\,\frac{1 - \frac{1}{i\sqrt{z}}A_\theta(z)}{1 + \frac{1}{i\sqrt{z}}A_\varphi(z)}, \quad \operatorname{Im}\sqrt{z} \ge 0. \tag{3.5}$$

It follows from (3.5) that uniformly in $\operatorname{Im}\sqrt{z} \ge 0, |z| \to \infty$,

$$\frac{m(z) - i\sqrt{z}}{i\sqrt{z}} = -\frac{A_\theta(z) + A_\varphi(z)}{i\sqrt{z}} + \frac{(A_\theta(z) + A_\varphi(z))\,A_\varphi(z)}{(i\sqrt{z})^2} + O\left(\frac{e^{-3\operatorname{Im}\sqrt{z}}}{|z|^{3/2}}\right). \tag{3.6}$$

Set $z = \lambda + i\varepsilon$. Making use of (2.9), by Lebesgue's dominated convergence theorem as $\varepsilon \to 0$ we get

$$\begin{aligned}A_\theta \equiv A_\theta(\lambda) &= \int_0^\infty e^{i\sqrt{\lambda}x} v(x)\,\theta(x,\lambda+i0)\,dx, \\ A_\varphi \equiv A_\varphi(\lambda) &= i\sqrt{\lambda}\int_0^\infty e^{i\sqrt{\lambda}x} v(x)\,\varphi(x,\lambda+i0)\,dx.\end{aligned}$$

Set $\Omega = \Omega_+$. Now (3.6) yields ($\Omega = \Omega_+$)

$$\Omega(\lambda) = \frac{m(\lambda) - i\sqrt{\lambda}}{i\sqrt{\lambda}} = -\frac{A_\theta + A_\varphi}{i\sqrt{\lambda}} - \frac{(A_\theta + A_\varphi) A_\varphi}{\lambda} + O\left(\frac{1}{\lambda^{3/2}}\right), \quad \lambda \to \infty. \tag{3.7}$$

Let us compute A_θ, A_φ. Applying (2.8) twice and taking into account (2.9) one can get

$$\begin{aligned} A_\theta &= \int_0^\infty e^{i\sqrt{\lambda}x} v(x) \left\{ \cos\sqrt{\lambda}x + \frac{1}{k}\int_0^x \sin\sqrt{\lambda}(x-y)\, v(y)\, \theta(y, \lambda + i0)\, dy \right\} dx \\ &= \int_0^\infty e^{i\sqrt{\lambda}x} v(x) \cos\sqrt{\lambda}x \cdot dx \\ &+ \frac{1}{\sqrt{\lambda}} \int_0^\infty e^{i\sqrt{\lambda}x} v(x) \left\{ \int_0^x \sin\sqrt{\lambda}(x-y)\, v(y) \cos\sqrt{\lambda}y \cdot dy \right\} dx + O\left(\frac{1}{\lambda}\right). \end{aligned}$$

In the same way one obtains

$$\begin{aligned} A_\phi &= i\int_0^\infty e^{i\sqrt{\lambda}x} v(x) \sin\sqrt{\lambda}x \cdot dx \\ &+ \frac{i}{k} \int_0^\infty e^{i\sqrt{\lambda}x} v(x) \left\{ \int_0^x \sin\sqrt{\lambda}(x-y)\, v(y) \sin\sqrt{\lambda}y \cdot dy \right\} dx + O\left(\frac{1}{\lambda}\right), \end{aligned} \tag{3.8}$$

and hence

$$\begin{aligned} A_\theta + A_\varphi &= \int_0^\infty e^{2i\sqrt{\lambda}x} v(x)\, dx \\ &+ \frac{1}{k} \int_0^\infty e^{2i\sqrt{\lambda}x} v(x) \left\{ \int_0^x \sin\sqrt{\lambda}(x-y)\, v(y)\, e^{i\sqrt{\lambda}y} dy \right\} dx + O\left(\frac{1}{\lambda}\right). \end{aligned} \tag{3.9}$$

The second integral in (3.9) can be transformed into

$$\begin{aligned} &\frac{1}{2i\sqrt{\lambda}} \left\{ \int_0^\infty e^{i\sqrt{\lambda}x} v(x) \left(\int_0^x v(y)\, dy \right) dx - \int_0^\infty v(x) \left(\int_0^x e^{2i\sqrt{\lambda}y} v(y)\, dy \right) dx \right\} \\ &= \frac{1}{2i\sqrt{\lambda}} \left\{ 2\int_0^\infty e^{2i\sqrt{\lambda}x} v(x) \left(\int_0^x v(y)\, dy \right) dx - \int_0^\infty v(x)\, dx \cdot \int_0^\infty e^{2i\sqrt{\lambda}x} v(x)\, dx \right\}, \end{aligned}$$

and finally we have

$$A_\theta + A_\varphi = F\left(2\sqrt{\lambda}\right) + \frac{1}{2i\sqrt{\lambda}} \left\{ 2F_1\left(2\sqrt{\lambda}\right) - \int_0^\infty v(x)\, dx \cdot F\left(2\sqrt{\lambda}\right) \right\} + O\left(\frac{1}{\lambda}\right), \tag{3.10}$$

where

$$F(s) \equiv \int_0^\infty e^{isx} v(x)\, dx, \tag{3.11}$$

$$F_1(s) \equiv \int_0^\infty e^{isx} V(x)\, dx, \quad V(x) = v(x) \int_0^x v(y)\, dy. \tag{3.12}$$

Equation (3.8) yields

$$\begin{aligned} A_\varphi &= i\int_0^\infty e^{i\sqrt{\lambda}x} v(x) \sin\sqrt{\lambda}x \cdot dx + O\left(\frac{1}{\sqrt{\lambda}}\right) \\ &= \frac{1}{2}F\left(2\sqrt{\lambda}\right) - \frac{1}{2}\int_0^\infty v(x)\,dx + O\left(\frac{1}{\sqrt{\lambda}}\right). \end{aligned} \tag{3.13}$$

Combining (3.7), (3.10), and (3.13) one obtains

$$\Omega(\lambda) = -\frac{F\left(2\sqrt{\lambda}\right)}{i\sqrt{\lambda}} - \frac{F^2\left(2\sqrt{\lambda}\right) - 2F_1\left(2\sqrt{\lambda}\right)}{2\lambda} + O\left(\frac{1}{\lambda^{3/2}}\right), \tag{3.14}$$

$$\Omega^2(\lambda) = \frac{F^2\left(2\sqrt{\lambda}\right)}{\lambda} + O\left(1/\lambda^{3/2}\right),$$

and hence

$$\operatorname{Im}\Omega(\lambda) = \frac{\widehat{v}_c\left(2\sqrt{\lambda}\right)}{\sqrt{\lambda}} + \frac{\left(\widehat{V}_s - \widehat{v}_c\widehat{v}_s\right)\left(2\sqrt{\lambda}\right)}{\lambda} + O\left(\frac{1}{\lambda^{3/2}}\right), \tag{3.15}$$

$$\operatorname{Im}\Omega^2(\lambda) = \frac{2\widehat{v}_c\left(2\sqrt{\lambda}\right)\widehat{v}_s\left(2\sqrt{\lambda}\right)}{\lambda} + O\left(\frac{1}{\lambda^{3/2}}\right),$$

where $\widehat{f}_c(s)$ ($\widehat{f}_s(s)$) stands for $\cos$ ($\sin$) $-$Fourier transform of $f(x)$. The first term in (3.15) is in $L_1(\mathbb{R}_+)$ since

$$\left\|\lambda^{-1/2}\widehat{v}_c\left(2\sqrt{\lambda}\right)\right\|_1 = \|\widehat{v}_c\|_1.$$

Further, it is well known [27] that if the Fourier transform of a summable function is summable, then the function is continuous (together with its Fourier transform). By our condition $\widehat{v}_c \in L_1(\mathbb{R}_+)$, and hence $v \in C(\mathbb{R}_+)$. The latter implies $V(x) = v(x)\int_0^x v(y)\,dy \in C(\mathbb{R}_+)$, and hence $v, V \in L_2(\mathbb{R}_+)$ since $C(\mathbb{R}_+)\cap L_1(\mathbb{R}_+) \subset L_2(\mathbb{R}_+)$. However, by [27] the Fourier transform of a function from $L_2(\mathbb{R}_+)$ is again in $L_2(\mathbb{R}_+)$, and thus $\widehat{v}_c, \widehat{v}_s, \widehat{V}_c \in L_2(\mathbb{R}_+)$. Therefore,

$$\left\|\lambda^{-1}\widehat{v}_c\left(2\sqrt{\lambda}\right)\widehat{v}_s\left(2\sqrt{\lambda}\right)\right\|_1 \le \|\widehat{v}_c\|_2\,\|\widehat{v}_s\|_2 < \infty,$$

$$\left\|\lambda^{-1}\widehat{V}_s\left(2\sqrt{\lambda}\right)\right\|_1 = 2\left\|\lambda^{-1}\widehat{V}_s(\lambda)\right\|_1 \le C\left\|\widehat{V}_s\right\|_2 < \infty$$

with some constant C dependent on the choice of $a > 0$ in $L_2(a,\infty)$. Now from (3.15) we conclude that $\operatorname{Im}\Omega, \operatorname{Im}\Omega^2 \in L_1(a,\infty)$. □

Actually, as a byproduct, we obtained the asymptotics of the Weyl m-function along the real line (which is likely known to the specialists).

COROLLARY 3.4. *Let $v(x) \in L_1(\mathbb{R}_+)$. Then for $k \to \infty$ along the real line*

$$m(\lambda) = i\sqrt{\lambda} - F\left(2\sqrt{\lambda}\right) + \frac{1}{2i\sqrt{\lambda}}\left\{F^2\left(2\sqrt{\lambda}\right) - 2F_1\left(2\sqrt{\lambda}\right)\right\} + O\left(\frac{1}{\lambda}\right), \tag{3.16}$$

where F, F_1 are given by (3.11), (3.12).

4. Scattering on truncated potentials. Throughout this section we assume potentials to be real-valued, integrable in some neighborhood of a point $x = x_0$, and otherwise arbitrary. For simplicity set $x_0 = 0$.

THEOREM 4.1. *Suppose $v(x)$ is real-valued and belongs to $L_1(0,\delta)$ with some $\delta > 0$. If 0 is a right Lebesgue point of v and $R(z)$ is the reflection coefficient defined by (2.12), then $v(0)$ can be computed by any of the following formulas:*

$$v(0) = 4 \lim_{z\to i\infty} zR(z), \tag{4.1}$$

$$v(0) = -\frac{4}{\pi} \lim_{z\to i\infty} \int_{-\infty}^{\infty} \left(\frac{z}{k-z}\right)^2 \arg(1+R(k))\, dk, \tag{4.2}$$

$$v(0) = \frac{4i}{\pi} \lim_{z\to i\infty} \int_{-\infty}^{\infty} \left(\frac{z}{k-z}\right)^2 \operatorname{Re} R(k)\, dk. \tag{4.3}$$

Proof. It immediately follows from (2.10) and (2.12) that

$$R(z) = \frac{1}{2i\sqrt{z}} \int_0^{\delta} e^{2i\sqrt{z}x} v(x)\, dx + o(1/z), \quad z \to i\infty.$$

Then by Lemma 3.2

$$R(z) = \frac{1}{2i\sqrt{z}} \left(\frac{iv(0)}{2\sqrt{z}} + o\left(1/\sqrt{z}\right)\right) = \frac{v(0)}{4z} + o(1/z), \quad z \to \infty,$$

and we arrive at (4.1).

Now consider the function $i(1+R(z))$. Since $|R(z)| \le 1, \operatorname{Im} z \ge 0$, it is Herglotz and hence admits representation (2.2):

$$\begin{aligned} i(1+R(z)) &= \exp\left\{c + \int_{\mathbb{R}} \left(\frac{1}{k-z} - \frac{k}{1+k^2}\right) \frac{\arg(1+R(k))}{\pi} dk\right\} \\ &= i\left(1 + \frac{v(0)}{4z} + o\left(\frac{1}{z}\right)\right). \end{aligned}$$

Taking the logarithm of both parts we get

$$c + \int_{\mathbb{R}} \left(\frac{1}{k-z} - \frac{k}{1+k^2}\right) \frac{\arg(1+R(k))}{\pi} dk = i\pi/2 + \frac{v(0)}{4z} + o(1/z), \quad z \to i\infty.$$

Applying Lemma 3.1 then yields (4.2).

Using the very same arguments and (2.1), one easily obtains

$$v(0) = \frac{4i}{\pi} \lim_{z\to i\infty} \int_{-\infty}^{\infty} \left(\frac{z}{k-z}\right)^2 (1 + \operatorname{Re} R(k))\, dk.$$

Since by Cauchy's theorem $\int_{-\infty}^{\infty} \left(\frac{z}{k-z}\right)^2 dk = 0$, we arrive at (4.3). ∎

Remark 1. If $v(x) \ge c > 0$, then (4.2) reads

$$v(0) = -\frac{4}{\pi} \lim_{z\to i\infty} \int_{E}^{\infty} \left(\frac{z}{k-z}\right)^2 \arg(1+R(k))\, dk,$$

where $E = \inf \sigma\left(H_0^+\right)$. Indeed, in this case the spectrum of H_0^+ is bounded below. Due to (2.12) $R(k)$ is real-valued for $k < E$ and $\arg(1+R(k)) = 0$, $k < E$.

The limit in (4.2) cannot be removed in general. However, in a particular case of cascade-type potentials one can pass to the limit under the integral sign. See the following theorem.

THEOREM 4.2. *Suppose $v(x)$ is subject to*

$$\exists c : v(x) - c \in L_1(\mathbb{R}_+), \quad \int_0^\infty (v(x) - c)\cos kx \cdot dx \in L_1(\mathbb{R}_+). \tag{4.4}$$

Then

$$v(0) = -\frac{4}{\pi}\int_E^\infty \arg(1 + R(k))\, dk, \quad E = \inf\sigma\left(H_0^+\right). \tag{4.5}$$

Proof. First of all, as in the proof of Proposition 3.3 we may set $c = 0$. From (2.12) one derives

$$1 + R(k) = \frac{2i\sqrt{k}}{m(k) + i\sqrt{k}} \tag{4.6}$$

and, therefore,

$$\begin{aligned}\arg(1 + R(k)) &= \operatorname{Im}\ln(1 + R(k)) = -\operatorname{Im}\ln\frac{m(k) + i\sqrt{k}}{2i\sqrt{k}} \\ &= -\operatorname{Im}\ln\left(1 + \frac{m(k) - i\sqrt{k}}{2i\sqrt{k}}\right) \\ &= -\frac{1}{2}\operatorname{Im}\Omega(k) + \frac{1}{4k}\operatorname{Im}\Omega^2(k) + O\left(\frac{1}{k^{3/2}}\right),\end{aligned}$$

and hence, by Proposition 3.3, $\arg(1 + R(k)) \in L_1(a, \infty)$ with some $a > 0$. Since $|\arg(1 + R(k))| \le \pi$ for all k and $\left|\frac{z}{k - z}\right| \le 1, \operatorname{Re} z = 0$, by the Lebesgue dominated convergence theorem, we get (4.5). □

We do not know whether under condition (4.4) asymptotics (4.1) can be extended to the case when $k \to \infty$ along the real line, but at least the following holds.

THEOREM 4.3. *If $v(x) - c \in W_1^1(\mathbb{R}_+)$ for some c, then*

$$R(k) = \frac{v(0) - c}{4k} + o(1/k), \quad k \to \infty. \tag{4.7}$$

Proof. As before, set $c = 0$. From (4.6) and (2.10) we have

$$R(k) = \frac{1}{2i\sqrt{k}}\int_0^\infty e^{2i\sqrt{k}x} v(x)\, dx + o(1/k). \tag{4.8}$$

Let $v_\varepsilon(x)$ be a smooth function with a compact support containing $x = 0$ such that $v_\varepsilon \to v, \varepsilon \to 0$, in $W_1^1(\mathbb{R}_+)$, and $v_\varepsilon(0) = v(0)$. For the integral in (4.8) we then have

$$\begin{aligned}&\frac{1}{2i\sqrt{k}}\int_0^\infty e^{2i\sqrt{k}x} v_\varepsilon(x)\, dx + O\left(\|v - v_\varepsilon\|_1\right) = \frac{1}{4k}\left(v_\varepsilon(0) + \int_0^\infty e^{2i\sqrt{k}x} v_\varepsilon'(x)\, dx\right) \\ &\quad + O\left(\|v - v_\varepsilon\|_1\right) = \frac{1}{4k}v(0) + \frac{1}{4k}\int_0^\infty e^{2i\sqrt{k}x} v_\varepsilon'(x)\, dx + O\left(\|v - v_\varepsilon\|_{W_1^1}\right).\end{aligned}$$

Letting $\varepsilon \to 0$ yields

$$R(k) = \frac{v(0)}{4k} + \frac{1}{4k}\int_0^\infty e^{2i\sqrt{k}x} v_\varepsilon'(x)\,dx + o(1/k),$$

and by the Riemann–Lebesgue lemma, we arrive at (4.7). □

Remark 2. Under extra conditions $v \in L_1\left(\mathbb{R}_+, \left(1+x^2\right)dx\right)$ and the absence of resonances, (4.7) was also obtained in [18].

Remark 3. Summarizing the formulas of this section, we get a procedure of recovering potentials. Indeed, given point x_0 we cut off the potential to the left from x_0 and observe the plane waves reflected by the truncated potential. Knowing the reflection coefficient $R(x_0, k)$ for all energies k lets us now compute $v(x_0)$ by one of the formulas (4.1)–(4.3).

Remark 4. The setting of this section is a specific case of the abstract scheme of [22] (which also includes the three-dimensional case). In particular, it follows from [22] that $\frac{1}{\pi}\arg(1+R(k))$ appears as the spectral shift function of some self-adjoint operators.

5. Resonance states and potentials. As it follows from (2.13) the reflection coefficient $R(z), \operatorname{Im} z \geq 0$, is uniquely determined by $\left(1+k^2\right)^{-1}(\log|R(k)|dk + d\mu(k))$ on the real line and resonance states $\{k_n\}\left(k_n = z_n^2\right)$. One can easily observe from (4.1) that discarding a finite number of Blaschke factors $\frac{1+\overline{z}_j^2}{|1+z_j^2|}\frac{z-z_j}{z-\overline{z}_j}$ from $R(z)$ affects only the sign of $v(0)$. Actually, the same concerns some infinite Blaschke products. Let us say that a series of resonances $\{k_j\}$ does not contribute to computing the potential $|v|$ at $x = 0$ if

$$\left|\lim_{z\to i\infty} zR(z)\right| = \left|\lim_{z\to i\infty} zb^{-1}(z)\,R(z)\right|, \tag{5.1}$$

where $b(z)$ is the Blaschke product corresponding to $\{z_j\}$. The following proposition describes all series of resonances having property (5.1).

THEOREM 5.1. *Assume $v(x) \in L_1(0,\delta)$ for some $\delta > 0$. A series of resonances $\{k_j\}$ does not contribute to evaluating $|v(0)|$ by* (4.1) *if and only if $\{k_j\}$ satisfies*

$$\sum_j \frac{\operatorname{Im} z_j}{|z_j + i|} < \infty, \qquad \text{where } z_j^2 = k_j. \tag{5.2}$$

Proof. Assume that $\{z_j\}$ is subject to (5.2). It follows from the upper half-plane version of the Frostman theorem [4] that

$$b(z) \equiv \prod_j \frac{1+\overline{z}_j^2}{|1+z_j^2|}\frac{z-z_j}{z-\overline{z_j}}$$

has a limit as $z \to i\infty$ along the imaginary axis and $|\lim_{\tau\to\infty} b(i\tau)| = 1$ that immediately implies (5.1).

Now suppose $\{k_j\}$ do not contribute to the limit (4.1). It follows from (5.1) that $\lim_{\tau\to\infty} b(i\tau)$ exists and is equal by modulus to 1. Applying the same Frostman theorem to $\{z_j\}$ yields (5.2). □

In complex analysis, condition (5.2) is referred to as the Frostman condition at infinity [4]. Note that if $\{z_j\}$ accumulates at a finite distance, then the Blaschke condition (2.14) for $\{z_j\}$ is equivalent to (5.2). Since $\left(\operatorname{Im}\sqrt{z_j}\right)^{-1}$ defines the lifetime

of k_j, condition (5.2) also means that series of resonances subject to (5.2) are in a certain sense long living.

THEOREM 5.2. *If a potential $v(x)$ is such that $v(0) \neq 0$ and the spectrum of H is purely point, then*

$$\sum_j \frac{\operatorname{Im} z_j}{|z_j + i|} = \infty.$$

Proof. Since $\sigma(H) = \sigma_p(H)$, the reflection coefficient $|R(k)| = 1$ for almost all real k. Moreover, it follows from (2.12) that $R(z)$ is analytic on $\mathbb{R} \setminus \sigma(H)$ and at any point $k_0 \in \sigma_p(H)$ we have $\lim_{z \to k_0} R(z) = -1, z \in \mathbb{C}_+$. Therefore, by [7] the measure μ in (2.13) is 0, and hence $R(z)$ is a product of $\exp iaz$ and a Blaschke product. Since $\lim z \exp iaz = 0, z \to i\infty$, contradicts the condition $v(0) \neq 0$ we conclude that $a = 0$, and hence $R(z) = B(z)$, where $B(z)$ is a Blaschke product. However, it follows from (4.1) that $\lim_{z \to i\infty} R(z) = 0$, which implies that $B(z)$ must be an infinite Blaschke product with the property $\lim_{\tau \to \infty} B(i\tau) = 0$. By the Frostman theorem [4] this means that (5.2) fails and

$$\sum_j \frac{\operatorname{Im} z_j}{|z_j + i|} = \infty.$$

This proves the theorem. □

6. The trace formula. In this section we discuss the situation when we no longer cut off the left side of a potential and substitute it for 0. The reflection coefficient can be defined even in this setting, but we prefer to follow [8, 9, 10, 11, 12, 13, 14, 15], and as scattering data we now consider Krein's spectral shift function $\xi(x_0, k)$ of the pair (H_{x_0}, H). The main objective of this section is to extend some of the results of Gesztesy et al. [8, 11], Gesztesy [9], Gesztesy and Holden [10, 15], Gesztesy, Holden, and Simon [12], and Gesztesy and Simon [13, 14]. In the literature, formulas of type (1.1) are related to the so-called trace approach to the inverse scattering problem. Under different (but rather restrictive) conditions and various forms, they have been previously studied by many authors. A good account on the literature can be found, e.g., in [12].

THEOREM 6.1 (trace formula). *Suppose $v(x) \in L_1(x_0 - \delta, x_0 + \delta)$ for some $\delta > 0$. If x_0 is both a left and right Lebesgue point, then*

$$\frac{v(x_0 - 0) + v(x_0 + 0)}{2} = \lim_{z \to i\infty} \int_{\mathbb{R}} \left(\frac{z}{k - z} \right)^2 \{\chi(k) - 2\xi(x_0, k)\} \, dk, \tag{6.1}$$

where $\chi(k)$ is the characteristic function of $\mathbb{R}_+$.

Proof. Without loss of generality we set $x_0 = 0$. It follows from Proposition 2.3 that for $z \to i\infty$

(6.2)

$$\frac{m_+(z) - m_-(z)}{2i\sqrt{z}} = 1 - \frac{1}{2i\sqrt{z}} \left(\int_0^\delta e^{2i\sqrt{z}x} v(x) \, dx + \int_{-\delta}^0 e^{-2i\sqrt{z}x} v(x) \, dx \right) + o\left(1/\sqrt{z}\right).$$

Functions $m_+(z) - m_-(z)$ and $2i\sqrt{z}$ are clearly Herglotz, and by (2.2) we have

$$m_+(z) - m_-(z) = \exp\left\{ a + \int_{\mathbb{R}} \left(\frac{1}{k - z} - \frac{k}{1 + k^2} \right) \alpha(k) dk \right\}, \tag{6.3}$$

$$2i\sqrt{z} = \exp\left\{ \ln 2 + \int_{\mathbb{R}} \left(\frac{1}{k - z} - \frac{k}{1 + k^2} \right) \beta(k) dk \right\},$$

where a is an inessential constant and

$$\alpha(k) = \frac{1}{\pi} \lim_{\varepsilon \to o+} \arg \{m_+ (k + i\varepsilon) - m_- (k + i\varepsilon)\}, \tag{6.4}$$
$$\beta(k) = 1, k < 0; \quad \beta(k) = 1/2, k > 0.$$

Plugging (6.3) into (6.2) and passing to the logarithm, we get

$$a + \int_{\mathbb{R}} \left(\frac{1}{k - z} - \frac{k}{1 + k^2} \right) (\alpha(k) - \beta(k))\, dk \tag{6.5}$$
$$= \ln \left\{ 1 - \frac{1}{2i\sqrt{z}} \left(\int_0^\delta e^{2i\sqrt{z}x} v(x)\, dx + \int_{-\delta}^0 e^{-2i\sqrt{z}x} v(x)\, dx \right) + o\left(1/\sqrt{z}\right) \right\}$$
$$= -\frac{1}{2i\sqrt{z}} \left(\int_0^\delta e^{2i\sqrt{z}x} v(x)\, dx + \int_{-\delta}^0 e^{-2i\sqrt{z}x} v(x)\, dx \right) + o\left(1/\sqrt{z}\right).$$

Now relate $\alpha(k)$ to the Krein spectral shift function $\xi(k)$ of the pair (H_0, H). Since (see, e.g., [13])

$$\xi(k) = \frac{1}{\pi} \arg \{m_- (k + i0) - m_+ (k + i0)\}^{-1} \tag{6.6}$$

and is chosen to be $0 \le \xi(k) \le 1$, one immediately has $\alpha(k) + \xi(k) = 1$, and hence

$$\alpha(k) - \beta(k) = -\xi(k) + 1/2\chi(k).$$

Equation (6.5) now reads

$$a + \int_{\mathbb{R}} \left(\frac{1}{k - z} - \frac{k}{1 + k^2} \right) \left(\frac{\chi(k)}{2} - \xi(k) \right) dk \tag{6.7}$$
$$= -\frac{1}{2i\sqrt{z}} \int_0^\delta e^{2i\sqrt{z}x} \{v(x) + v(-x)\}\, dx + o\left(1/\sqrt{z}\right).$$

Applying Lemma 3.2 to the right-hand side of (6.7) one gets

$$a + \int_{\mathbb{R}} \left(\frac{1}{k - z} - \frac{k}{1 + k^2} \right) \left(\frac{\chi(k)}{2} - \xi(k) \right) dk = -\frac{v(+0) + v(-0)}{4z} + o\left(\frac{1}{z}\right),$$

which, due to Lemma 3.1, yields (6.1) for $x_0 = 0$. □

Remark 5. Under the additional hypothesis that $v(x) \ge c > -\infty$ and x_0 is a Lebesgue point of $v(x)$, formula (6.1) turns into

$$v(x_0) = E + \lim_{z \to i\infty} \int_E^\infty \left(\frac{z}{k - z} \right)^2 \{1 - 2\xi(x_0, k)\}\, dk, \tag{6.8}$$

which is (1.1). The original proof of (6.8) employs a different strategy based upon the Krein trace formula (2.15) for

$$\operatorname{tr}\{\exp(-tH_{x_0}) - \exp(-tH)\} \tag{6.9}$$

and the Feynman–Kac formula to derive the asymptotic expansion of (6.9) as $t \to +0$. In this way, the abovementioned authors first obtain

$$v(x_0) = E + \lim_{t \to +0} \int_E^\infty e^{-kt} \{1 - 2\xi(x_0, k)\}\, dk, \tag{6.10}$$

which is valid only if v is essentially bounded from below. Formula (6.8) then follows from (6.10) and can be clearly interpreted as a resolvent regularization of the diverging trace $\mathrm{tr}(H_{x_0}-H)$. Now it is clear why (6.1) is called a trace formula. Note that under our conditions formula (6.10) no longer holds.

Let us also note that a trace formula close to (6.1) was recently obtained in [16] as a corollary of some general results on the operator-valued version of (6.8), but the requirement of the setting imposes $v\in L_\infty(\mathbb{R})\cap C[x_0-\delta,x_0+\delta]$.

Theorem 6.1 can also be stated for other than Dirichlet boundary conditions. Let $H^h_{x_0}=H^{h,+}_{x_0}\oplus H^{h,-}_{x_0}$, where $h\in\mathbb{R}$ and

$$\begin{aligned}H^{h,\pm}_{x_0}u&=lu, u\in \mathrm{Dom}\left(H^{h,\pm}_{x_0}\right)\\ &=\left\{f\in L_2(x_0,\pm\infty): lf\in L_2(x_0,\pm\infty), f'(x_0\pm 0)+hf(x_0\pm 0)=0\right\}.\end{aligned}$$

THEOREM 6.2. *Suppose a real-valued $v(x)\in L_1(x_0-\delta,x_0+\delta)$ and x_0 is both a left and right Lebesgue point. If $\xi_h(x_0,k)$ is the spectral shift function of the pair $(H,H^h_{x_0})$, then*

$$\frac{v(x_0-0)+v(x_0+0)}{2}=2h^2+\lim_{z\to i\infty}\int_{\mathbb{R}}\left(\frac{z}{k-z}\right)^2\{\chi(k)+2\xi_h(x_0,k)\}dk. \tag{6.11}$$

Proof. As in Theorem 6.1 one can treat only the case $x_0=0$. Let $m_{h,\pm}(z)=m_{h,\pm}(z)$ be Weyl's m-functions corresponding to $\mathbb{R}_\pm$ and associated with the boundary condition $u'(\pm 0)+hu(\pm 0)=0$. By (2.11) we have

$$m_{h,+}-m_{h,-}=\frac{\left(1+h^2\right)(m_+-m_-)}{(m_++h)(m_-+h)}. \tag{6.12}$$

Rewrite (6.12) as follows:

$$\frac{-i\sqrt{z}}{2(1+h^2)}(m_{h,+}-m_{h,-})=\frac{\frac{m_+-m_-}{2i\sqrt{z}}}{\frac{m_++h}{i\sqrt{z}}\cdot\frac{m_-+h}{-i\sqrt{z}}}.$$

The function $m_{h,+}-m_{h,-}$ is Herglotz and applying the very same arguments as in the proof of Theorem 6.1 yields

$$\begin{aligned}&a(h)+\int_{\mathbb{R}}\left(\frac{1}{k-z}-\frac{k}{1+k^2}\right)(\alpha_h(k)+\beta(k))\,dk\\ &=\ln\frac{m_+-m_-}{2i\sqrt{z}}-\ln\left(\frac{m_++h}{i\sqrt{z}}\cdot\frac{m_-+h}{-i\sqrt{z}}\right)\end{aligned} \tag{6.13}$$

with some inessential complex constant $a(h)$. By (2.10) and (2.11) we have

$$\frac{m_\pm+h}{\pm i\sqrt{z}}=1\pm\frac{h}{i\sqrt{z}}\mp\frac{1}{i\sqrt{z}}\int_0^{\pm\delta}e^{\pm 2i\sqrt{z}x}v(x)\,dx+o\left(1/\sqrt{z}\right),\quad z\to i\infty. \tag{6.14}$$

In analogy to (6.8) one gets $\alpha_h(k)+\beta(k)=-\left(\xi_h(k)+(1/2)\chi(k)\right)$. It follows from (6.13), (6.14) that

$$\begin{aligned}&a(h)+\int_{\mathbb{R}}\left(\frac{1}{k-z}-\frac{k}{1+k^2}\right)\left(\xi_h(k)\ +\frac{\chi(k)}{2}\right)dk\\ &\qquad=-\frac{v(-0)+v(+0)-8h^2}{4z}+o(1/z),\quad z\to i\infty,\end{aligned}$$

and Lemma 3.2 immediately applies (6.11). □

Note that Theorem 6.2 extends some of the results of [8, 9, 10, 11], where v is assumed to be bounded from below.

7. Absolute summability of the trace formula. Now discuss conditions when we can remove the resolvent regularization in (6.1). As the following theorem shows, it can be done for certain potential with different spatial asymptotics at $\pm\infty$.

THEOREM 7.1. *Suppose $v(x)$ is subject to*

$$\exists v_\pm \in \mathbb{R} : v(x) - v_\pm \in L_1(\mathbb{R}_\pm), \quad \int_{\mathbb{R}_\pm} (v(x+x_0) - v_\pm) \cos kx \cdot dx \in L_1(\mathbb{R}). \tag{7.1}$$

If $\xi(x_0, k)$ is the spectral shift function of the pair (H_{x_0}, H), then

$$\frac{v(x_0 - 0) + v(x_0 + 0)}{2} = E + \int_E^\infty (1 - 2\xi(x_0, k))\, dk, \tag{7.2}$$

where $E = \inf \sigma(H)$.

Proof. As before, it is enough to treat the case $x_0 = 0$. Note first that under hypothesis (7.1) the spectrum of H is bounded from below by $E = \inf \sigma(H)$, and formula (6.1) then reads

$$\frac{v(-0) + v(+0)}{2} = E + \lim_{z \to i\infty} \int_E^\infty \left(\frac{z}{k - z}\right)^2 \{1 - 2\xi(k)\}\, dk.$$

It follows from (6.4) and (6.6) that

$$1 - 2\xi(k) = \frac{1}{\pi} \operatorname{Im} \ln \frac{m_+(k) - m_-(k)}{i\sqrt{k}}. \tag{7.3}$$

Let us evaluate (7.3). Setting $k_\pm = \sqrt{k - v_\pm}$ we have

$$\begin{aligned} \frac{m_+(k) - m_-(k)}{i\sqrt{k}} &= \frac{m_+(k) - ik_+}{i\sqrt{k}} + \frac{m_-(k) + ik_-}{-i\sqrt{k}} + \frac{k_+ + k_-}{\sqrt{k}} \\ &= \frac{k_+ + k_-}{\sqrt{k}} \left\{1 + \frac{\sqrt{k}}{k_+ + k_-} (\Omega_+(k) + \Omega_-(k))\right\}, \end{aligned}$$

where $\Omega_\pm(k)$ as in Proposition 3.3. It follows then from (7.3) that

$$1 - 2\xi(k) = \frac{1}{\pi} \operatorname{Im} \ln \left\{1 + \frac{\sqrt{k}}{k_+ + k_-} (\Omega_+(k) + \Omega_-(k))\right\}$$

for $k \geq k_0 = \max\{v_+, v_-\}$. In virtue of Proposition 3.3 we have $\Omega_+(k) + \Omega_-(k) \in L_1(a, \infty)$ with some $a > k_0$. On the other hand, from (6.4) and (6.6) one has $|1 - 2\xi(k)| \leq 1$ for all $k \in \mathbb{R}$. However, $\left|\frac{z}{k-z}\right| \leq 1, \operatorname{Re} z = 0$, and applying Lebesgue's dominated convergence theorem then completes the proof. ∎

Theorem 7.1 appears to be first obtained in [6] in a different form under pretty strong requirements on potentials v. Another proof was recently presented in [12] assuming v, v' are locally absolute continuous, $v - v_\pm \in L_1(\mathbb{R}_\pm)$, for some real constants $v_\pm$, and $v', v'' \in L_1(\mathbb{R})$. Let us note that our arguments allow one to conduct the proof under sharp conditions on v. Indeed, the only thing we rely on is Proposition 3.3, where the conditions on $v(x)$ are clearly sharp (and might even be necessary/sufficient). What (7.1) actually says is that besides $v - v_\pm \in L_1(\mathbb{R}_\pm)$ potentials v must be slightly better than locally continuous on $(-\infty, x_0)$ and (x_0, ∞), e.g., Dini continuous (see, e.g., [27]). Also note that we do allow for one point of jump discontinuity at x_0. Indeed, conditions of Theorem 7.1 force v to be continuous on $(-\infty, x_0)$ and (x_0, ∞), but the condition $v(x_0 + 0) = v(x_0 - 0)$ need not hold.

ASYMPTOTICALLY-FREE SOLUTIONS FOR THE SHORT-RANGE NONLINEAR SCHRÖDINGER EQUATION*

KENJI NAKANISHI†

Abstract. We consider the nonlinear Schrödinger equation (NLS) with a power nonlinearity $|u|^{p-1}u$, where $1+2/n<p$. We show that for any free solution in L^2 or H^1 there exists a solution of NLS which approaches the free solution in the same space as t tends to infinity. We also show that the wave operators exist in $\Sigma^s=H^s\cap\mathcal{F}H^s$ for the critical power $p=1+4/(n+2s)$.

1. Introduction and main result. In this note, we study asymptotic behavior of the solutions for the nonlinear Schrödinger equation (NLS):

$$i\dot{u}-\Delta u+\lambda|u|^{p-1}u=0, \tag{1.1}$$

where $u=u(t,x):\mathbb{R}^{1+n}\to\mathbb{C}$, $\dot{u}=\partial u/\partial t$, $n\in\mathbb{N}$, $\lambda\in\mathbb{R}$, and $p>1+2/n$. There is a large amount of literature on the scattering theory for the equation above. It is well known that we need $p>1+2/n$ to have the wave operators. In this short-range case, there are many results on the existence of the wave operators and the scattering operator. However, the available results on the scattering in the energy space are restricted to the case where $p\geq 1+4/n$, and those results concerned with the case $1+2/n<p<1+4/n$ rely totally on decay assumptions for initial data at the spatial infinity. Such decay conditions are not compatible with the Hamiltonian (conservative) structure of the equation and the free propagator is no longer unitary on the function spaces with the corresponding weights. When we consider the scattering theory in such spaces, the space-decay provides a priori time-decay to the solutions and enables us to use perturbative arguments at the time infinity for solutions with sufficient decay in time. Thus, our understanding so far is very limited concerning the asymptotic behavior of the solutions along the conservative structure or the unitary-free evolution if $p<1+4/n$. Here we present a first step for this question; we show that for any free solution in L^2 or H^1 there exists a solution of NLS in the same space which is asymptotic to the free solution. The uniqueness of such a solution would give us well-defined wave operators in those spaces, but we have no idea if the uniqueness holds or not. It is generally very difficult to get uniqueness only from the information that the solutions approach to a fixed free solution (as in (1.2)).

It is an advantage of our result that we do not need any restriction for higher dimensions as in the case of the scattering in weighted spaces, though we have not succeeded in treating the low dimensional case, which is easier for the weighted scattering. Our main result follows.

THEOREM 1.1. *Let $n \geq 3$ and $1 + 2/n < p < 1 + 4/n$. Define $X = L^2(\mathbb{R}^n)$ or $H^1(\mathbb{R}^n)$. Then for any solution $v \in C(\mathbb{R}; X)$ of the free Schrödinger equation, there exists a solution $u \in C(\mathbb{R}; X)$ of NLS satisfying*

$$\lim_{t\to\infty} \|u(t) - v(t)\|_X = 0. \tag{1.2}$$

Let us compare this with the known results. As for the converse correspondence, i.e., from u to v, it is known that $U(-t)u(t)$ converges weakly in H^1 for any finite energy solution of NLS, where $U(t) = e^{-it\Delta}$ [15]. A similar result for the nonlinear Klein–Gordon equation was proved in [11]. Notice that there is significant difference between the weak and the strong convergence in this problem, since the weak topology cannot even distinguish the standing waves from the 0 solution. However, if we assume additionally that $xu(0) \in L^2$ and $\lambda \geq 0$, then it is known that $U(-t)u(t)$ converges strongly in L^2 [18].

If $1 + 4/n < p < 1 + 4/(n-2)$, $\lambda \geq 0$, and $X = H^1$, then the solution u above is uniquely determined so that we have the wave operators well defined on the whole energy space for any $n \in \mathbb{N}$. Moreover, we know the asymptotic completeness, i.e., $v(0) \mapsto u(0)$ is a bijection on the energy space H^1 [10, 8, 12]. A similar result is given in [3] for radial data in the case where $p = 1 + 4/(n-2)$ and $n \geq 3$.

When $p = 1 + 4/n$, we can define the wave operators on $X = H^1$ if we restrict the nonlinear solutions to those possessing a certain global space-time integrability. It is an open problem whether every finite energy solution has that property when $\lambda \geq 0$, which would also imply the asymptotic completeness; the invertibility of the wave operators is known only for small L^2 data or in some weighted spaces [7, 8, 2].

For $p < 1 + 4/n$, most results are obtained in weighted spaces. For $0 < s < 2$, the wave operators are well defined on $\Sigma^s = H^s \cap \mathcal{F}H^s$ if $p > \max(1+2/n, 1+4/(n+2s), s)$, where $\mathcal{F}$ denotes the Fourier transform [4, 6]. Here we remark that $p = 1+4/(n+2s)$ is allowed if it is larger than $1+2/n$ and s. We will show this fact in the next section. If $p \leq 1 + 2/n$, then the wave operators cannot exist [1, 9, 15], but the modified wave operators are given in some cases [13, 5]. If $p \geq 1 + 8/(\sqrt{(n+2)^2 + 8n} + n - 2)$ and $\lambda \geq 0$, then we have the asymptotic completeness in Σ^1 [7, 16, 4].

The proof of the above theorem relies on the compactness argument. To have compatibility of the convergence and the nonlinearity, we use the local smoothing effect of the Schrödinger equation. The strong convergence follows from the weak convergence and the conservation laws. The condition $n \geq 3$ is required so that the decay order $t^{-n/2}$ of the free propagator is integrable for $t \to \infty$. This fact is used only for the weak continuity in the compactness argument. However, it might be too optimistic to regard that condition as solely technical, because the above result is indeed quite delicate, which can be seen by the following observation. Let u and v be as in the above theorem. Then, by the equation NLS we have

$$\langle iu, v\rangle(T) - \langle iu, v\rangle(S) = -\int_S^T \langle \lambda|u|^{p-1}u, v\rangle(t)dt, \tag{1.3}$$

where $\langle u, v\rangle := \Re \int u\bar{v}dx$. Since u approaches to v as $t \to \infty$, we might try to replace u by v in the right-hand side. However, it is easy to construct a free solution v with finite energy satisfying

$$\int_S^\infty \int |v|^{p+1}dxdt = \infty \tag{1.4}$$

for any $S > 0$ if $p < 1+4/n$. Nevertheless, the left-hand side of (1.3) converges to 0 as $S, T \to \infty$. Thus, u does not approximate v in such a strong sense but is even better than v itself in the meaning above. Notice that the integral is finite if $p \geq 1 + 4/n$ and also for the nonlinear solution u if $p > 1 + 4/n$, due to the Strichartz estimate and the scattering result. It is also an interesting open problem if the integral is finite for the finite energy solution u obtained in the above theorem.

Another way to observe the difficulty of this problem is to use the pseudoconformal transform. Our problem is converted by the transform into the following Cauchy problem:

$$\begin{aligned} i\dot{u} - \Delta u + \lambda t^{-\nu}|u|^{p-1}u = 0, \\ u(0) = \overline{\mathcal{F}v(0)}, \end{aligned} \tag{1.5}$$

where $\nu = n(1+4/n-p)/2$. Then the scaling argument tells us that this problem with $X = L^2$ is in the so-called "super-critical" case, as is the nonlinear wave equation on $\mathbb{R}^{1+3}$ with a power greater than 5 and the Navier–Stokes equation on $\mathbb{R}^{1+3}$. Namely, if we expand a solution by the scaling which leaves the equation invariant, then the initial norm (in L^2 for our problem) increases. This means that the Cauchy problem does not become easier at all even if we restrict the argument to a smaller time interval or small data. However, our result is better than those about the other examples above, since we have the strong continuity in time and the conservation laws for the solutions that we obtain.

Proof of Theorem 1.1. By the Strichartz estimate, for any $T > 0$ we have the unique solution w to

$$\begin{aligned} i\dot{w} - \Delta w + \lambda|w|^{p-1}w = 0, \\ w(T) = v(T), \end{aligned} \tag{1.6}$$

satisfying $w \in C(\mathbb{R}; X) \cap Y$, where Y denotes the Banach space endowed with the following norm:

$$\|w\|_Y := \sup_{\tau\in\mathbb{R}} \|w\|_{L^{2+4/n}((\tau,\tau+1)\times\mathbb{R}^n)}. \tag{1.7}$$

See [17]. In the following, the arguments about energy are concerned only with the case $X = H^1$. w satisfies the conservation laws for the charge and the energy:

$$\|w(t)\|_{L^2} = \|v(0)\|_{L^2} < \infty, \tag{1.8}$$

$$\begin{aligned} E(w;t) &:= \int |\nabla w(t)|^2 + \frac{2\lambda}{p+1}|w(t)|^{p+1}dx \\ &= \int |\nabla v(T)|^2 + \frac{2\lambda}{p+1}|v(T)|^{p+1}dx. \end{aligned} \tag{1.9}$$

Thus, the charge does not depend on T and

$$E(w;t) = E(w;0) \to \int |\nabla v(0)|^2 dx =: E(v) \tag{1.10}$$

as $T \to \infty$ because we have

$$\|v(T)\|_{L^{p+1}} \to 0 \tag{1.11}$$

for any free solution v with finite energy since $2 < p+1 < 2n/(n-2)$. By the Sobolev inequality and the interpolation, we have

$$\int |w(t)|^{p+1}dx \le C\|\nabla w(t)\|_{L^2}^{\alpha}\|w(t)\|_{L^2}^{p+1-\alpha}, \tag{1.12}$$

where $\alpha < 2$ since $p < 1 + 4/n$. Thus we have a uniform bound of $w(t)$ in X. Now we take the weak limit $T \to \infty$. Let $A \subset C_0^\infty(\mathbb{R}^n)$ be an enumerable set which is dense in L^2. We denote $U(t) = e^{-it\Delta}$. Then, for any $\psi \in A$, the L^2 coupling $(U(-t)w(t), \psi)$ is a function of t bounded uniformly for t and T. We also have the uniform equicontinuity up to $t \to \infty$ as follows:

$$\begin{aligned} |(U(-t)w(t),\psi) - (U(-s)w(s),\psi)| &= \left|\int_s^t (U(-\sigma)\lambda|w|^{p-1}w(\sigma),\psi)d\sigma\right| \\ &\le C\int_s^t \sigma^{-1-\varepsilon}\|w(\sigma)\|_{L^q}^p\|\psi\|_{L^r}d\sigma \\ &\le C\|v(0)\|_{L^2}^{(1-\theta)p}\|w\|_Y^{\theta p}\|\psi\|_{L^r}\min(s^{-\varepsilon}, |t-s|^{1-p/q}) \\ &\le C(\|v(0)\|_{L^2},\psi)\min(s^{-\varepsilon}, |t-s|^{1-p/q}), \end{aligned} \tag{1.13}$$

where $1 < s < t$, $1/r = p/q = 1/2 + (1+\varepsilon)/n$, and $\varepsilon > 0$ is a constant chosen such that $1/q = (1-\theta)/2 + \theta/(2+4/n)$ with $0 < \theta < 1$ and $p/q < 1$, which is possible since $1 + 4/n > p > 1 + 2/n$ and $n \ge 3$. Thus, $\{(U(-t)w(t),\psi)\}_{T>0}$ is uniformly bounded and equicontinuous on $t \in [-\infty, \infty]$. Now we can apply the Ascoli–Arzela theorem and by a further diagonal argument, we obtain a subsequence w such that $(U(-t)w(t),\psi)$ converges uniformly on $t \in [-\infty,\infty]$ as $T \to \infty$ for any $\psi \in A$. By the X boundedness of w and the denseness of A in the dual space X', w converges weakly in X. Denote the limit by u. The limit function $U(-t)u(t)$ is weakly continuous on $[-\infty,\infty]$ and u satisfies $U(-t)u(t) \to v(0)$ as $t \to \infty$ weakly in X. To show that u solves (1.1), we need that $f(w)$ converges to the appropriate limit $f(u)$, for which purpose the weak topology is not efficient in general. When $X = H^1$, we know the standard argument via the compactness of the Sobolev embedding to ensure such compatibility. Even if $X = L^2$, we can argue similarly in the space-time by the local smoothing effect. In fact, we have the following.

LEMMA 1.2. *Let $u_\nu \in C(\mathbb{R}; L^2) \cap Y$ be a sequence of solutions to* (1.1) *with bounded L^2 norms (Y is defined in* (1.7)*). Then, u_ν converges along some subsequence in $L^q_{loc}(\mathbb{R}^{1+n})$ for any $q < 2 + 4/n$.*

We postpone the proof of this lemma and continue the proof of the theorem. Since $p < 2 + 4/n$, the above lemma implies that $f(w)$ converges to $f(u)$ in $L^1_{loc}(\mathbb{R}^{1+n})$, so that the limit function u is a weak solution of (1.1) in Y. Since we have the uniqueness of such a solution to the Cauchy problem for NLS, this solution u satisfies the conservation laws. Because it is a weak limit as $T \to \infty$ in L^2 at each t, we have

$$\|U(-t)u(t)\|_{L^2} = \|u(t)\|_{L^2} =: C_\infty \le \|v(0)\|_{L^2}, \tag{1.14}$$

but we know that its weak limit as $t \to \infty$ is exactly $v(0)$, which implies that $C_\infty = \|v(0)\|_{L^2}$ and all the convergences in L^2 must be strong. In the case of $X = H^1$, from the L^2 convergence and the H^1 boundedness, we have the L^{p+1} convergence as $T \to \infty$. Then, from (1.9), (1.10), and (1.11) we have

$$E(u;t) =: E_\infty \le \int |\nabla v(0)|^2 dx = E(v). \tag{1.15}$$

Since $U(-t)u(t) \to v(0)$ weakly in H^1, we have

$$E(v) \le \liminf_{t\to\infty} \|\nabla U(-t)u(t)\|_{L^2}^2 \le E_\infty. \tag{1.16}$$

Therefore, $E_\infty = E(v)$ and all the convergences must be strong in H^1. Thus we obtain the desired solution $u \in C(\mathbb{R}; X)$ satisfying $U(-t)u(t) \to v(0)$ strongly in X. □

Remark 1.3. The subsequence of w chosen above converges in $C(\mathbb{R}; X)$. If we have the uniqueness of the limit, then a similar argument will also yield the continuity of the wave operators.

Proof of Lemma 1.2. We use the local smoothing effect of the Schrödinger equation [14]

$$\|\chi U(t)\varphi\|_{L_t^2 H_x^{1/2}} \le C\|\varphi\|_{L^2}, \tag{1.17}$$

where χ is an arbitrary function in $C_0^\infty(\mathbb{R}^{1+n})$ and C is a positive constant dependent only on χ. Interpolating this with the Strichartz estimate, we obtain

$$\left\|\chi \int_0^t U(t-s)F(s)ds\right\|_{L_t^\alpha H_x^s} \le C\|F\|_{L_t^\beta L_x^\gamma}, \tag{1.18}$$

for $1 \le \beta < 2$, $n/\gamma - n/2 = 2 - 2/\beta$ and $1/\alpha > 1/\beta - 1/2 > s$, where C is a positive constant dependent only on these exponents and χ. Since the L^2 bound implies the boundedness in Y, we can use the above estimates to deduce that χu_ν are also bounded in $L_t^2 H_x^s$ for some $s > 0$. By the equation NLS, $\chi \dot{u}_\nu$ are bounded in $L_t^2 H_x^{-2}$. Hence, by the interpolation, there exists some $\delta > 0$ such that χu_ν are bounded in $H^\delta(\mathbb{R}^{1+n})$. By the compactness of the Sobolev embedding, u_ν converges along some subsequence in $L^2_{loc}(\mathbb{R}^{1+n})$. Then, by the $L^{2+4/n}$ boundedness, it converges also in $L^q_{loc}(\mathbb{R}^{1+n})$ for any $q < 2 + 4/n$. □

2. Wave operators for the critical power on Σ^s. In this section we show that the wave operators are well defined on $\Sigma^s = H^s \cap \mathcal{F}H^s$ for $p = 1 + 4/(n + 2s)$ if $p > 1 + 2/n$ and $p > s > 0$.

Following [16, 4], the construction of the wave operators is converted into the Cauchy problem (1.5) with $\mathcal{F}v(0) \in \Sigma^s$. Then, the argument to solve the Cauchy problem is quite standard with the fixed point theorem and the Strichartz estimate. The main point is to derive a closed estimate for the inhomogeneous term in the integral equation

$$I := \int_0^t U(t-\sigma)\sigma^{-\nu}|u|^{p-1}u(\sigma)d\sigma, \tag{2.1}$$

starting from the Strichartz estimate for the free solution. We use the Hölder inequality and its counterpart for the Besov spaces to estimate the inhomogeneous input term $t^{-\nu}|u|^{p-1}u$. The critical power $p = 1 + 4/(n + 2s)$ was excluded in the preceding works because $t^{-\nu} \notin L^{1/\nu}(0, 1)$. However, if we use the fact $t^{-\nu} \in L^{1/\nu,\infty}$ (Lorentz space), refinements of the inequalities via the real interpolation and well-known fixed point argument in the critical case, we can obtain local wellposedness of (1.5). More specifically, we will use the Lorentz spaces $L^{q,2}$ for t instead of the Lebesgue spaces.

First, we use the real interpolation to refine Hölder's inequality and the Strichartz estimate. We have

$$\|fg\|_{L^{p,q}} \le C\|f\|_{L^{p_0,q_0}}\|g\|_{L^{p_1,q_1}}, \tag{2.2}$$

where $1/p = 1/p_0 + 1/p_1$, $1/q = 1/q_0 + 1/q_1$ and $p, p_0, p_1 < \infty$. Similarly, we have the refinement of Young's inequality (or Hardy–Littlewood–Sobolev)

$$\|f * g\|_{L^{p,q}} \le C\|f\|_{L^{p_0,q_0}} \|g\|_{L^{p_1,q_1}}, \tag{2.3}$$

where $1/p = 1/p_0 + 1/p_1 - 1$, $1/q = 1/q_0 + 1/q_1$, $1 < p, p_0, p_1 < \infty$, and $1 \le q, q_0, q_1$. For convenience, we give the following proof.

Proof. Apply the real interpolation of type (θ, ∞) to Hölder's inequality for f with varying p and p_0. Then we have

$$\|fg\|_{L^{p,\infty}} \le C\|f\|_{L^{p_0,\infty}} \|g\|_{L^{p_1}}. \tag{2.4}$$

Apply the interpolation of type (θ, q_1) to this inequality for g with varying p and p_1. Then we have

$$\|fg\|_{L^{p,q_1}} \le C\|f\|_{L^{p_0,\infty}} \|g\|_{L^{p_1,q_1}}, \tag{2.5}$$

which gives the desired estimate in the case where q_0 or q_1 is infinity. Then, by the complex interpolation for both f and g, we obtain the result for $1 \le q$. The remaining case follows from the power theorem. The proof for the generalized Young is the same. □

If we use (2.3) with $q = q_1 = 2$ and $q_0 = \infty$ instead of the Hardy–Littlewood–Sobolev to prove the Strichartz estimate, we obtain

$$\begin{aligned} \|U(t)\varphi\|_{L^{q,2}(L^r)} &\le C\|\varphi\|_{L^2} \\ \left\| \int_0^t U(t-s) f(s) ds \right\|_{L^{q,2}(L^r)\cap L^\infty(L^2)} &\le C\|f\|_{L^{q',2}(L^{r'})}, \end{aligned} \tag{2.6}$$

where $2 < q < \infty$, $2 \le r \le \infty$, $1/r = 1/2 - 2/(nq)$, and $1/q + 1/q' = 1/r + 1/r' = 1$. Variants of this estimate in the Sobolev or Besov norms for the solutions in H^s are immediate from (2.6) operated by $\mathcal{F}^{-1}\langle x\rangle^s \mathcal{F} = (1-\Delta)^{s/2}$ or the Littlewood–Paley decomposition.

Now it is easy to obtain the following.

THEOREM 2.1. *Let $n \in \mathbb{N}$ and $0 < s < p = 1 + 4/(n+2s) > 1 + 2/n$. Then, the wave operators for NLS are well defined on $\Sigma^s = H^s \cap \mathcal{F}H^s$.*

Proof. It suffices to solve the Cauchy problem (1.5) locally in time, since it is known that the solutions will be automatically global. We can use the fixed point theorem, for example, in the space $S := L^{q,2}(B^s_{r,2})$, where $1/r = 1/2 - 2/(nq)$ and $(p+1)/q + \nu = 1$. By the Sobolev embedding, we have $S \subset X := L^{q,2}(L^\rho)$, where $1/\rho = 1/r - s/n > 0$. By the generalized Hölder inequality (2.2) we have $\|t^{-\nu}|u|^{p-1}u\|_{S'} \le C\|t^{-\nu}\|_{L^{1/\nu,\infty}} \|u\|_X^{p-1} \|u\|_S \le C\|u\|_S^p$, where $S' = L^{q',2}(B^s_{r',2})$ with $1/q' = 1 - 1/q$ and $1/r' = 1 - 1/r$. Then, by the generalized Strichartz estimate (2.6), we obtain $I \in S \cap C(\mathbb{R}; H^s)$. The difference of two solutions can be estimated in the spaces without the derivative. Hence we obtain the unique local solution $u \in C(\mathbb{R}; H^s)$ to the Cauchy problem (1.5) by the standard argument. Next, following [6], we replace $\mathcal{F}^{-1}\langle x\rangle^s \mathcal{F}$ with $U(t)\langle x\rangle^s U(-t)$ in the above argument and use the corresponding Besov-type spaces and commutation properties to deduce that $\langle x\rangle^s U(-t)u(t) \in C(\mathbb{R}; L^2)$ by the same procedure as above. Thus we conclude that $u \in C(\mathbb{R}; \Sigma^s)$. □

FAST EVALUATION OF RADIAL BASIS FUNCTIONS: METHODS FOR FOUR-DIMENSIONAL POLYHARMONIC SPLINES*

R. K. BEATSON†, J. B. CHERRIE†, AND D. L. RAGOZIN‡

Abstract. As is now well known for some basic functions ϕ, hierarchical and fast multipole-like methods can greatly reduce the storage and operation counts for fitting and evaluating radial basis functions. In particular, for spline functions of the form

$$s(x) = p(x) + \sum_{k=1}^{N} d_k \phi(|x - x_k|),$$

where p is a low degree polynomial and with certain choices of ϕ, the cost of a single extra evaluation can be reduced from $\mathcal{O}(N)$ to $\mathcal{O}(\log N)$, or even $\mathcal{O}(1)$, operations and the cost of a matrix-vector product (i.e., evaluation at all centers) can be decreased from $\mathcal{O}(N^2)$ to $\mathcal{O}(N \log N)$, or even $\mathcal{O}(N)$, operations.

This paper develops the mathematics required by methods of these types for polyharmonic splines in $\mathbb{R}^4$. That is, for splines s built from a basic function from the list $\phi(r) = r^{-2}$ or $\phi(r) = r^{2n} \ln(r)$, $n = 0, 1, \ldots$. We give appropriate far and near field expansions, together with corresponding error estimates, uniqueness theorems, and translation formulae.

A significant new feature of the current work is the use of arguments based on the action of the group of nonzero quaternions, realized as 2×2 complex matrices

$$\mathbb{H}_0^1 = \left\{ x = \begin{bmatrix} z & w \\ -\overline{w} & \overline{z} \end{bmatrix} : \ |z|^2 + |w|^2 > 0 \right\},$$

acting on $\mathbb{C}^2 = \mathbb{R}^4$. Use of this perspective allows us to give a relatively efficient development of the relevant spherical harmonics and their properties.

Key words. radial basis functions, polyharmonic splines, fast multipole methods

1. Introduction.

In a large scale comparison of methods for interpolating two-dimensional scattered data Franke [10] identified radial basis functions as one of the most promising methods. These are functions of the form

$$s(\cdot) = p(\cdot) + \sum_{k=1}^{N} d_k \phi(|\cdot - x_k|), \tag{1.1}$$

where p is a low degree polynomial, and the basic function ϕ is usually of noncompact support [17]. Statisticians have also successfully employed radial basis functions fitted by generalized cross validation to smoothing noisy data, e.g., in modeling rainfall distribution across Australia [13]. However, widespread adoption of these techniques has

been delayed by their apparent extreme computational cost. For example, conventional methods for fitting by interpolation require $\mathcal{O}(N^2)$ storage and $\mathcal{O}(N^3)$ arithmetic operations, where N is the number of data points. This makes computations when N exceeds $10,000$ totally impractical.

These storage and operation counts had led many researchers to incorrectly conclude that the computations are all but impossible. Sibson and Stone [20], talking about problems with $50,000$ to $100,000$ data sites, state: "*We believe such problems will indefinitely remain beyond the scope of thin-plate splines.*" Also Flusser [9], in the context of warping digital images, comments on the computational complexity of evaluation of thin-plate splines, concluding that "*their direct use has extreme computing complexity and is not suitable for practical applications.*"

Recent algorithmic advances involving hierarchical and fast multipole-like methods have invalidated the comments noted above, at least for two- and three-dimensional data; see [3, 4, 7, 8, 11]. These algorithmic developments employ far field and near field expansions to reduce the computational cost of evaluating an N center polyharmonic radial basis function at $m \geq N$ points to $\mathcal{O}(m \log N)$ or even $\mathcal{O}(m)$ operations, at least in $\mathbb{R}^2$ and $\mathbb{R}^3$. Furthermore, interpolatory fitters have been developed which can solve the interpolation problem for such splines in $\mathcal{O}(N)$ storage and $\mathcal{O}(N \log N)$ arithmetic operations. These iterative fitters use the hierarchical evaluators as fast matrix-vector multipliers and can fit interpolatory thin-plate splines to $100,000$ data points in a few minutes on relatively inexpensive workstations.

Polyharmonic splines in $\mathbb{R}^4$ are spline functions of the form (1.1), where the basic function ϕ is a member of the list

$$\phi(r) = \begin{cases} r^{-2}, \\ r^{2n} \ln(r), \quad n = 0, 1, \dots . \end{cases} \tag{1.2}$$

Interpolatory splines of this type minimize suitable energy seminorms, as do their analogues in lower dimensions. For example, the functional

$$I(s) = \int_{\mathbb{R}^4} \sum_{|\alpha|=3} \binom{3}{\alpha} \Big(\big(D^\alpha s\big)(x) \Big)^2 dx$$

is minimized over all suitably smooth functions, satisfying the interpolation conditions

$$s(x_k) = f(x_k), \qquad k = 1, \dots , N, \tag{1.3}$$

if and only if s is the triharmonic spline

$$s(\cdot) = p_2(\cdot) + \sum_{k=1}^{N} d_k |\cdot - x_k|^2 \ln |\cdot - x_k|,$$

where $p_2 \in \pi_2^4$ (the space of quadratics in 4 variables), and the coefficients $\{d_k\}$, and those of the polynomial p_2, are determined by the interpolation conditions (1.3) along with the orthogonality conditions

$$\sum_{k=1}^{N} d_k q(x_k) = 0 \qquad \text{for all } q \in \pi_2^4.$$

Thus polyharmonic splines in $\mathbb{R}^4$ can be expected to be highly successful approximators and interpolators, as experience has shown the polyharmonic splines in lower

dimensions to be. However, meaningful data sets in $\mathbb{R}^4$ can be expected to have many points. Hence, the development of fast evaluation and fitting methods is almost a prerequisite to the use of polyharmonic splines in $\mathbb{R}^4$. Motivated by this we will develop the analytic underpinnings of a fast hierarchical and a fast multipole-like method for polyharmonic splines in $\mathbb{R}^4$. There are many potential applications of these fast methods. One possible application to data mining is estimating the probability of some attribute, such as early death due to heart attack or the filing of a fraudulent tax return, by a regression spline depending on four predictor variables. An application to environmental engineering is modeling the concentration of some chemical, or pollutant, as a function of position and time. Turk and O'Brien [21] suggest using polyharmonic splines in $\mathbb{R}^4$ for shape transformation, or morphing, of implicitly defined three-dimensional surfaces.

The core ideas underlying hierarchical, and fast multipole methods, are beautifully simple. They will be described in the next few paragraphs. First, one needs to accept that only a certain finite precision is necessary. This allows the use of approximations. Second, a suitable far field expansion about 0 must be known for the shifted basic function $\phi(|\cdot - x_<|)$. Here, a far field expansion is a series expansion in which the influence of the source point $x_<$, and the evaluation point x, separates. Furthermore, the series should converge at a geometric rate at all points x with $|x|$ sufficiently large compared to $|x_<|$. Associate with any region T in $\mathbb{R}^d$ the part of the RBF due to sources in T,

$$s_T = \sum_{k:x_k \in T} d_k \phi(|\cdot - x_k|). \tag{1.4}$$

Approximate s_T by a truncated far field expansion r_T, chosen to have appropriate accuracy at all evaluation points x sufficiently far from the center of T. If the number of centers x_k in T is large compared to the number of terms in the far field series, it will be quicker to approximately evaluate $s_T(x)$ by evaluating the series $r_T(x)$ rather than by evaluating $s_T(x)$ directly.

The idea, described above, of using an approximating series when it is faster to do so, lies at the heart of hierarchical methods. Its application is organized by using also a hierarchical subdivision of space. This subdivision determines for a given evaluation point x which parts of s, that is, which s_T's, should be approximated by the corresponding far field series r_T and which parts are to be evaluated directly. In order to be more explicit about the algorithmic organization of the evaluation process, suppose for the moment that space is subdivided into a binary tree of rectangular panels. The root panel will be chosen to contain all the centers, and the children of each parent will be formed by splitting the parent with a hyperplane. Associate with every panel T, the RBF s_T, far field approximation r_T, and a distance from the center of T at which r_T gives a sufficiently accurate approximation to s_T. Then approximate evaluation of $s(x)$ can be performed by a recursive descent of the tree. The actions to be taken when panel T is encountered during this descent are as follows:

- If x is sufficiently far from T, that is, if the distance from x to the center of T is large enough, then the approximation to $s(x)$ is incremented with the approximation $r_T(x)$ to $s_T(x)$.
- Else, if T is childless, the approximation to $s(x)$ is incremented by the directly calculated value of $s_T(x)$.
- Otherwise the process descends to the children of T.

We turn now from algorithmic matters to the analytic underpinnings of a generic

fast multipole method. Results of the following nature are required for the basic function ϕ being used:

- The existence of a rapidly converging far field expansion, centered at 0, for the shifted basic function $\phi(|\cdot - x_<|)$, e.g., Lemmas 4.1 and 4.4.
- Error bounds that determine how many terms are required in each expansion to achieve a specified accuracy, e.g., Theorems 4.2 and 4.10.
- Efficient recurrence relations for computing the coefficients of the expansions, e.g., Lemmas 3.3 and 3.4.
- Uniqueness results that justify indirect translation of expansions, thus allowing the expansions of parent panels to be calculated quickly from those of children, e.g., Lemmas 5.1 and 5.2.
- Formulae for efficiently converting a far field expansion to a rapidly convergent local expansion, e.g., Theorem 6.1.

This paper provides appropriate mathematics for polyharmonic radial basis functions on $\mathbb{R}^4$. That is, for functions of the form (1.1) where ϕ is given by (1.2).

Our discussion above outlines the analytic and algorithmic underpinnings of hierarchical and fast multipole methods. More detailed discussions may be found in the original paper of Greengard and Rokhlin [11], or the introductory short course [3]. Previous papers concerning fast multipole and related methods for fast evaluation of radial basis functions include [4, 5, 6].

A significant technique in our development in this paper is the use of a group action perspective, in particular, of arguments based on the action of the group of nonzero quaternions, realized as 2×2 complex matrices

$$\mathbb{H}_0^1 = \left\{ x = \begin{bmatrix} z & w \\ -\overline{w} & \overline{z} \end{bmatrix} : |z|^2 + |w|^2 > 0 \right\}$$

acting on $\mathbb{C}^2 = \mathbb{R}^4$. We develop almost all the (simple) details needed for these arguments without relying on other presentations of the possibly unfamiliar group representation theory. Use of this perspective allows us to give a relatively efficient development of the relevant spherical harmonics and their properties. See [18, 19] for related analyses of spherical harmonics and their approximation properties. Our work has also been influenced by the elegant and concise treatment due to Epton and Dembart [8] of the analogous expansions for the three-dimensional fast multipole method.

This paper is organized as follows. Section 2 concerns some of the properties of polyharmonic functions on $\mathbb{R}^4$—including realizations of $\mathbb{R}^4$ and representations of $\mathbb{H}_0^1$. It also introduces the inner and outer functions (spherical harmonics) that form the basis of our far field expansions. Section 3 develops a number of properties of these functions that can be applied to far field expansions. These include recurrence formulae, derivative formulae, and symmetries. Section 4 contains the main results on the far field expansions themselves and the associated error bounds. Section 5 develops the uniqueness results that allow the far field expansions to be computed indirectly and economically via the translation theory of section 6. Section 6 also contains the outer-to-inner and inner-to-inner translation formulae needed to approximate far field series by local Taylor series.

2. Polyharmonic functions on $\mathbb{R}^4$. We will represent a nonzero $x \in \mathbb{R}^4$ in three different ways:

$$x = \begin{pmatrix} x_1 \\ x_2 \\ x_3 \\ x_4 \end{pmatrix} \quad \text{or} \quad [z, w] \quad \text{or} \quad \begin{bmatrix} z & w \\ -\overline{w} & \overline{z} \end{bmatrix},$$

where $z = x_1 + \mathbf{i}x_2$, $w = x_3 + \mathbf{i}x_4$, and $x_1, \ldots, x_4 \in \mathbb{R}$. The first realization is as an element of $\mathbb{R}^4$, the second is as an element of $\mathbb{C}^2$, and the last as an element of the punctured quaternion (Hamiltonian) space

$$\mathbb{H}_0^1 = \left\{ x = \begin{bmatrix} z & w \\ -\overline{w} & \overline{z} \end{bmatrix} : |z|^2 + |w|^2 > 0 \right\}. \tag{2.1}$$

Note that for elements of $\mathbb{H}_0^1$ the classical adjoint or adjugate and the Hermitian adjoint coincide and

$$x^{-1} = x^* / \det(x).$$

We are primarily interested in $\mathbb{R}^4$ with the usual inner product,

$$\langle x, x_< \rangle = x_1 x_{<1} + x_2 x_{<2} + x_3 x_{<3} + x_4 x_{<4} = |x||x_<| \cos\theta,$$

where $|\cdot|$ is the 2-norm for $\mathbb{R}^4$. In terms of the $\mathbb{C}^2$ realization of $\mathbb{R}^4$ this becomes

$$\langle x, x_< \rangle = \Re(z\overline{z_<} + w\overline{w_<}) = \tfrac{1}{2}(z\overline{z_<} + w\overline{w_<} + z_<\overline{z} + w_<\overline{w})$$

and, in terms of the matrix realization $\mathbb{H}_0^1$,

$$\langle x, x_< \rangle = \tfrac{1}{2}\operatorname{Tr}(x^* x_<) = \tfrac{1}{2}|x|^2 \operatorname{Tr}(x^{-1} x_<) = \tfrac{1}{2}\operatorname{Tr}({x_<}^* x),$$

where Tr is the trace. Note that this inner product gives the norm

$$|x|^2 = x_1^2 + x_2^2 + x_3^2 + x_4^2 = z\overline{z} + w\overline{w} = \det(x).$$

We also require an inner product for functions on the unit ball $B = \{x \in \mathbb{R}^4 : |x| \le 1\}$. For $f, g \in L^2(B)$ we define their inner product by

$$(f, g) = \int_{|\xi| \le 1} f(\xi)\overline{g(\xi)} d\xi. \tag{2.2}$$

We will also use this pairing for other functions f and g on B with $f\overline{g} \in L^1(B)$. Furthermore, we will also require the subspaces of $C(\mathbb{R}^4)$ defined by

$$\mathcal{H}_m = \{p([z_1, z_2]) : p \text{ is a homogeneous polynomial of degree } m \text{ in } z_1, z_2\},$$

where $m \in \mathbb{N}_0$, the set of nonnegative integers.

2.1. Irreducible representations of $\mathbb{H}_0^1$-spherical harmonics. In this section we will develop irreducible representations of $\mathbb{H}_0^1$ in $\mathcal{H}_m$. Our purpose for doing so is that the coefficient functions of these representations will eventually be seen to form a very computationally convenient basis for the harmonic polynomials in $\mathbb{R}^4$. In fact, when these coefficient functions are multiplied by $|x|^{2\ell}, \ell = 0, \ldots, k$, they yield

a basis for all $(k+1)$-harmonic polynomials in $\mathbb{R}^4$. We note in particular the simple form of the addition formulae (Lemma 2.9), the recurrence relation (Lemma 3.3), and the dual basis (Lemma 3.10), to come.

Most of the relevant representation theory and mathematical physics literature is focused on rotations of $\mathcal{S}^2$ or $\mathcal{S}^3$ and therefore considers representations of

$$SU(2) = \left\{ x \in \mathbb{H}_0^1 \,:\, \det(x) = |x|^2 = 1 \right\} = \mathcal{S}^3.$$

However, in the context of far field expansions it is convenient to work instead with all of $\mathbb{H}_0^1$ to take into account both the scaling by $|x|$ and rotation by elements of $SU(2)$. This leads to some differences, most importantly the character functions now depend on the norm of x as well as the angle θ between x and the north pole $[1,0]$. Other differences include the formula for the product of two character functions and the addition formulae.

DEFINITION 2.1. *Given a group G, a* representation $T : G \to \mathrm{GL}(V)$ *of G on V is an operator valued map that satisfies $T(g \cdot h) = T(g)T(h)$. A representation T of G on V is* irreducible *if the only subspaces of V that are invariant under $T(g)$ for all $g \in G$ are $\{0\}$ and V.*

We define representations $T_m(x)$ of $\mathbb{H}_0^1$ in the spaces $\mathcal{H}_m$ given by

$$\begin{aligned} T_m(x)\; p([z_1, z_2]) &= p([z_1, z_2]x) \\ &= p([z_1 z - z_2 \overline{w},\; z_1 w + z_2 \overline{z}]). \end{aligned} \tag{2.3}$$

Note that since $\mathcal{H}_m$ is embedded in the space of functions on $\mathbb{H}^1$ (or even on $\mathbb{H}_0^1$), this representation is just the restriction of the right action defined by

$$\big(x \cdot f\big)([z_1, z_2]) = f([z_1, z_2]x), \quad x \in \mathbb{H}_0^1.$$

If we put a (Hilbert space) norm on these functions via (2.2), i.e.,

$$\|f\|^2 = (f, f) = \int_{|\xi| \le 1} |f(\xi)|^2 d\xi,$$

then the rotation invariance of Lebesgue measure implies that $\|x \cdot f\| = \|f\|$, whenever $|x| = 1$, i.e., whenever $x \in \mathcal{S}^3$. Thus

$$\big(T_m(x)f, T_m(x)f\big) = (f, f)$$

for all functions $f \in L^2(B)$, and $T_m(x)$, as an operator, is unitary if $|x| = 1$. The reader is cautioned that the matrix realization of $T_m(x)$ to come is not unitary, but can be scaled to be so (see Lemma 2.5).

LEMMA 2.2. *The representations* (2.3) *are irreducible.*

Proof. Assume there is a subspace $V \subset \mathcal{H}_m$ that is invariant under $T_m(x)$ for all $x \in \mathbb{H}_0^1$. Then V is invariant under $T_m(x)$ if we restrict attention to $x \in SU(2) \subset \mathbb{H}_0^1$. Since the representations T_m of $SU(2)$ are irreducible [16, pp. 208–211], it follows that either $V = \{0\}$ or $V = \mathcal{H}_m$ and hence that the representations T_m are irreducible. ∎

The monomials

$$e_k^m([z_1, z_2]) = z_1^{m-k} z_2^k, \qquad 0 \le k \le m,$$

form a basis for $\mathcal{H}_m$. The operators $T_m(x)$ have a matrix realization once this basis for $\mathcal{H}_m$ is chosen. The elements of these matrices will be denoted $t^m_{i,j}$ and are given by

$$\begin{aligned} t^m_{i,j}(x) &= t^m_{i,j}(z,w) \\ &= \text{coefficient of } e^m_i \text{ in } T_m(x)e^m_j \\ &= \text{coefficient of } z_1^{m-i}z_2^i \text{ in } (z_1z - z_2\overline{w})^{m-j}(z_1w + z_2\overline{z})^j. \end{aligned}$$

Equivalently,

$$\sum_{i=0}^{m} t^m_{i,j}(z,w)z_1^{m-i}z_2^i = (z_1z - z_2\overline{w})^{m-j}(z_1w + z_2\overline{z})^j. \tag{2.4}$$

For $m = 0$, $t^0_{0,0}(x) = 1$, while for $m = 1$, from (2.4)

$$\begin{aligned} t^1_{0,0}(z,w) &= z, & t^1_{0,1}(z,w) &= w, \\ t^1_{1,0}(z,w) &= -\overline{w}, & t^1_{1,1}(z,w) &= \overline{z}, \end{aligned}$$

or in matrix terms

$$[T_1(x)] = x. \tag{2.5}$$

An immediate consequence of this choice of basis is the following lemma.

LEMMA 2.3. *Treated as matrices, $T_m(z,0)$ is a diagonal matrix and $T_m(0,w)$ is an antidiagonal matrix. Specifically these matrices have entries*

$$t^m_{i,j}(z,0) = \begin{cases} 0, & i \neq j, \\ z^{m-i}\overline{z}^i, & i = j, \end{cases}$$

and

$$t^m_{i,j}(0,w) = \begin{cases} 0, & i \neq m-j, \\ w^{m-i}(-\overline{w})^i, & i = m-j. \end{cases}$$

The basis elements e^m_k for $\mathcal{H}_m$ are orthogonal with respect to the inner product (2.2). In fact the exact norms for the basis elements e^m_k and thus the row and column scalings to get unitary matrices are easily computed.

LEMMA 2.4. *The basis functions e^m_k are orthogonal with inner products given by*

$$\left(e^m_k, e^{m'}_{k'}\right) = \int_{|\xi|\leq 1} e^m_k(\xi)\overline{e^{m'}_{k'}(\xi)}d\xi = \delta_{m,m'}\delta_{k,k'}\pi^2\frac{k!(m-k)!}{(m+2)!}.$$

Proof. Introduce polar coordinates (r_1,θ_1) and (r_2,θ_2) in the z_1 and z_2 planes (where $\xi = [z_1, z_2]$).

$$\begin{aligned} \left(e^m_k, e^{m'}_{k'}\right) &= \int_{|\xi|\leq 1} e^m_k(\xi)\overline{e^{m'}_{k'}(\xi)}d\xi \\ &= \int_0^1 \int_0^{\sqrt{1-r_1^2}} \int_0^{2\pi} \int_0^{2\pi} r_1^{m-k}e^{\mathbf{i}(m-k)\theta_1}r_2^k e^{\mathbf{i}k\theta_2} \end{aligned}$$

$$\begin{aligned}
&\times r_1^{m'-k'} e^{-\mathbf{i}(m'-k')\theta_1} r_2^{k'} e^{-\mathbf{i}k'\theta_2}\, d\theta_2 d\theta_1 r_2 dr_2 r_1 dr_1 \\
&= (2\pi)^2 \delta_{k,k'}\delta_{m,m'} \int_0^1 \int_0^{\sqrt{1-r_1^2}} r_1^{2(m-k)+1} r_2^{2k+1} dr_2 dr_1 \\
&= (2\pi)^2 \delta_{k,k'}\delta_{m,m'} \int_0^1 r_1^{2(m-k)+1} \frac{(1-r_1^2)^{k+1}}{2k+2} dr_1 \\
&= \pi^2 \delta_{k,k'}\delta_{m,m'} \mathrm{B}(m-k+1,k+2)/(k+1) \\
&= \pi^2 \delta_{k,k'}\delta_{m,m'} \frac{(m-k)!(k+1)!}{(m+2)!(k+1)},
\end{aligned}$$

where B is the Beta function $\mathrm{B}(n,m) = \Gamma(n)\Gamma(m)/\Gamma(n+m)$. ∎

Since T_m restricted to $\mathcal{S}^3$ acts in a norm preserving way on $\mathcal{H}_m$, we easily obtain the following matrix representation for $T_m(x^{-1})$.

LEMMA 2.5. *There exist row and column scalings that make the matrices $T_m(x)$ unitary for $|x| = 1$. Specifically*

(i) *The inverse of $T_m(x)$ is given by*

$$T_m(x^{-1}) = \left[t_{i,j}^m(x^{-1})\right] = \left[|x|^{-2m}\overline{t_{j,i}^m(x)}\binom{m}{i}\binom{m}{j}^{-1}\right],$$

or equivalently via

$$t_{i,j}^m(x^*) = t_{i,j}^m(\overline{z},-w) = \overline{t_{j,i}^m(z,w)}\binom{m}{i}\binom{m}{j}^{-1}.$$

(ii) *For all $x \neq 0$, the inverses of the matrices*

$$U_m(x) = \left[t_{i,j}^m(x)\sqrt{\binom{m}{j}\binom{m}{i}^{-1}}\right]$$

are given by $U_m(x)^{-1} = |x|^{-2m}U_m(x)^*$ and thus these matrices are unitary when $|x| = 1$.

Proof. The definition of $t_{j,i}^m$ and the orthogonality of $\{e_k^m : k = 0,\dots,m\}$ implies

$$\left(e_j^m, T_m(x)e_i^m\right) = \left(e_j^m, t_{j,i}^m(x)e_j^m\right) = \overline{t_{j,i}^m(x)}(e_j^m, e_j^m). \tag{2.6}$$

Since $T_m\big((x/|x|)^{-1}\big)$ preserves the inner product (2.2) and is homogeneous of degree m,

$$\begin{aligned}
\left(e_j^m, T_m(x)e_i^m\right) &= \Big(T_m\big((x/|x|)^{-1}\big)e_j^m, T_m\big((x/|x|)^{-1}\big)T_m(x)e_i^m\Big) \\
&= \left(|x|^m T_m(x^{-1})e_j^m, |x|^m e_i^m\right) = |x|^{2m} t_{i,j}^m(x^{-1})(e_i^m, e_i^m).
\end{aligned} \tag{2.7}$$

Equating (2.6) to (2.7) and solving, we obtain

$$t_{i,j}^m(x^{-1}) = |x|^{-2m}\overline{t_{j,i}^m(x)}\frac{(e_j^m, e_j^m)}{(e_i^m, e_i^m)}.$$

Taking into account the previous lemma and the fact that $x^{-1} = [\overline{z},-w]/(z\overline{z}+w\overline{w})$, this gives the desired results. ∎

Since it is easy to use the definitions to show the first row of each $T_m(x)$ is given by

$$t^m_{0,j}(x) = t^m_{0,j}(z,w) = z^{m-j}w^j = e^m_j([z,w]),$$

part of Lemma 2.4 shows that $\{t^m_{0,j}\}$ is orthogonal with respect to the inner product (2.2). In fact much more general (bi-) orthogonality facts are true for $t^m_{i,j}(x)$ and $\overline{t^m_{j,i}(x^{-1})}$. These are related to the orthogonality properties of the irreducible unitary matrix representations of any compact group, such as $\mathcal{S}^3$, as in [12, (27.19)]. But we prefer to present them in a slightly more general form which is closely related to the coordinate-free proofs in Chapter 3 of [1], particularly Proposition 3.15, Schur's Lemma 3.22, and its corollary, 3.23.

LEMMA 2.6.

(i) *(Schur's lemma) For any $(m+1)\times(m+1)$ matrix A*

$$\widetilde{A} = \int_{0<|x|\le 1} T_m(x^{-1})AT_m(x)dx = cI,$$

where

$$c = \frac{\mathrm{vol}\{|x|\le 1\}}{m+1}\,\mathrm{Tr}(A) = \frac{\pi^2/2}{m+1}\,\mathrm{Tr}(A).$$

(ii) *The set*

$$\left\{ \frac{(m+1)}{(\pi^2/2)}\binom{m}{j}\binom{m}{i}^{-1} |\cdot|^{-2m} t^m_{i,j}(\cdot) = \frac{m+1}{\pi^2/2}\overline{t^m_{j,i}(\cdot^{-1})}, i,j = 0,\dots,m \right\}$$

is biorthogonally dual to $\{t^m_{i,j}(\cdot), i,j = 0,\dots,m\}$ with respect to the pairing (2.2). That is,

$$\int_{0<|x|\le 1} \frac{m+1}{\pi^2/2} t^m_{i',j'}(x)t^m_{j,i}(x^{-1})dx = \delta_{i,i'}\delta_{j,j'}.$$

(iii) *The first two parts are also true when $\{0<|x|\le 1\}$ is replaced by $\mathcal{S}^3$ and "vol" is replaced by "surface area" (so $\pi^2/2$ is replaced by $2\pi^2$).*

Proof. For (i), let $y\in\mathcal{S}^3$ be arbitrary. Then

(2.8)
$$\widetilde{A}T_m(y) = \int_{0<|x|\le 1} T_m(x^{-1})AT_m(xy)dx = \int_{0<|x|\le 1} T_m(yx^{-1})AT_m(x)dx = T_m(y)\widetilde{A},$$

since $x\mapsto xy^{-1}$ leaves Lebesgue measure invariant. Let c be any eigenvalue for $\widetilde{A}$ with v an associated eigenvector. From (2.8) $T_m(y)v$ is also an eigenvector for the same eigenvalue c. By the irreducibility of T_m, $\mathrm{span}\{T_m(y)v : y\in\mathcal{S}^3\} = \mathcal{H}_m$. Thus $\widetilde{A}v = cv$ for all vectors v and it follows that $\widetilde{A} = cI$.

To get the formula for c, take the trace of all terms. Then move the linear functional Tr inside the integral and use $\mathrm{Tr}(T_m(x^{-1})AT_m(x)) = \mathrm{Tr}(A)$ to obtain

$$\mathrm{Tr}(cI) = (m+1)c = \int_{0<|x|\le 1} \mathrm{Tr}(A)dx = \mathrm{vol}\{0<|x|\le 1\}\,\mathrm{Tr}(A).$$

For (ii) substitute $A = E_{i,i'} = [\delta_{i,j}\delta_{j',i'}]$ into (i), i.e., use the matrix A with 1 at row i, column i' and zero elsewhere and then use j, j' to index the matrix. Then

$$T_m(x^{-1})E_{i,i'}T_m(x) = [t^m_{j,i}(x^{-1})t^m_{i',j'}(x)].$$

Since $\mathrm{Tr}(E_{i,i'}) = \delta_{i,i'}$, (i) yields

$$\left[\int_{0<|x|\le 1} t^m_{j,i}(x^{-1})t^m_{i',j'}(x)dx\right] = \frac{\pi^2/2}{m+1}\delta_{i,i'}[\delta_{j,j'}].$$

For (iii) repeat the proofs with the ball replaced by the sphere. Or, more simply, just note that if $d\Omega$ denotes the standard "surface" measure on S^3, then integration in spherical coordinates is with respect to $|x|^3 d\Omega(x/|x|)d|x|$. Then, due to the homogeneity of T_m, (i) becomes

$$\int_{\mathcal{S}^3}\int_{|x|=0}^{|x|=1} T_m\big((x/|x|)^{-1}\big)AT_m(x/|x|)|x|^3 d|x|d\Omega(x/|x|)$$
$$= \frac{1}{4}\int_{\mathcal{S}^3} T_m\big((x/|x|)^{-1}\big)AT_m(x/|x|)d\Omega(x/|x|) = \frac{\pi^2/2}{m+1}\,\mathrm{Tr}(A).$$

Clearing the denominator of 4 leads to the desired formula for (i) on $\mathcal{S}^3$. Now (ii) on $\mathcal{S}^3$ follows by exactly the same reasoning. Since $|x|^{-2m} = 1$ on $\mathcal{S}^3$, the orthogonality of $\{t^m_{i,j}\}$ on $\mathcal{S}^3$ follows, as does their independence since none of these functions are zero (or have norm zero) on $\mathcal{S}^3$. □

Lemma 2.6(iii) implies that the coefficient functions are linearly independent in both $L^2(\mathcal{S}^3)$ and $C(\mathbb{R}^4)$. Indeed, they form a basis for homogeneous harmonic polynomials on $\mathbb{R}^4$ and for the spherical harmonics of degree m on $\mathcal{S}^3$ (see (3.14)). Hence, for any $p \in \mathbb{N}$, $\{t^m_{i,j} : 0 \le i, j \le m, 0 \le m \le p\}$ is linearly independent both on $\mathcal{S}^3$ and on $\mathbb{R}^4$.

Given the north pole $[1, 0]$ and some general vector $x = [z, w]$, we can find a rotation that leaves the north pole fixed and rotates x to a vector in the direction $[e^{\mathbf{i}\theta}, 0]$, where $\cos\theta = \Re(z)/|x|$. Note that θ is just the angle between x and the north pole. We could equivalently rotate to a vector in the direction $[e^{-\mathbf{i}\theta}, 0]$. Hence any function independent of rotation about the north pole must be a function of $|x|$ and θ and furthermore must be even in θ, i.e., is a function of $\cos\theta$. It is known that all rotations leaving the north pole fixed can be achieved by conjugation, $x \mapsto vxv^{-1}$, with elements of $SU(2)$. See [14, pp. 277–279] or [2, pp. 214–217] for a geometric proof.

The same result may be obtained algebraically by considering the diagonalizability of x (see, e.g., [16, pp. 209–210]). Therefore there is a $v \in SU(2)$ such that

$$x = v\gamma v^{-1},$$

where

$$\gamma = |x|\,\mathrm{diag}(e^{\mathbf{i}\theta}, e^{-\mathbf{i}\theta}).$$

Note that conjugation with $-v$ achieves the same rotation as conjugation with v, but this is the only nonuniqueness in identifying conjugations with rotations of the equatorial $\mathcal{S}^2$.

These conjugation facts lead to explicit formulae for the traces of these representations. Specifically,

$$\begin{aligned}\operatorname{Tr}\big(T_m(x)\big) = \operatorname{Tr}\big(T_m(v\gamma v^{-1})\big) &= \operatorname{Tr}\big(T_m(v)T_m(\gamma)T_m(v^{-1})\big)\\ &= \operatorname{Tr}\big(T_m(v)T_m(\gamma)T_m(v)^{-1}\big) = \operatorname{Tr}\big(T_m(\gamma)\big).\end{aligned}$$

Using Lemma 2.3,

$$t^m_{i,j}(\gamma) = t^m_{i,j}(|x|e^{\mathbf{i}\theta}) = \begin{cases} |x|^m e^{\mathbf{i}(m-2j)\theta}, & i = j,\\ 0, & i \neq j.\end{cases}$$

Hence

$$\begin{aligned}\operatorname{Tr}\big(T_m(x)\big) = \operatorname{Tr}\big(T_m(\gamma)\big) &= \sum_{j=0}^{m} t^m_{j,j}(\gamma)\\ &= \sum_{j=0}^{m} |\gamma|^m e^{\mathbf{i}(m-2j)\theta}\\ &= |\gamma|^m \frac{e^{\mathbf{i}(m+1)\theta} - e^{-\mathbf{i}(m+1)\theta}}{e^{\mathbf{i}\theta} - e^{-\mathbf{i}\theta}} \qquad \text{if } \theta \neq 0,\\ &= |x|^m \frac{\sin(m+1)\theta}{\sin\theta},\end{aligned}$$

and interpreting $\sin(m+1)\theta/\sin\theta$ in the conventional fashion (as $m+1$) at $\theta = 0$, the expression is also valid there. As usual the character of the representation is defined to be the function $\chi_m : \mathbb{H}^1_0 \to \mathbb{R}$ given by the trace

$$\chi_m(x) := \operatorname{Tr}\big(T_m(x)\big) = |x|^m \frac{\sin(m+1)\theta}{\sin\theta}. \tag{2.9}$$

In particular $\chi_0(x) = 1$ and $\chi_1(x) = \operatorname{Tr}(x) = 2|x|\cos\theta$. Since the entries in $T_m(x)$ are homogeneous polynomials of degree m in z, w, $\overline{w}$, and $\overline{z}$, the χ_m are also. We extend the definition of χ_m to $x = 0$ by continuity and define $\chi_{-1} = 0$. Note that these χ_m are multiples of the Chebyshev polynomials of the second kind as functions of $t = \cos\theta$.

LEMMA 2.7. *For $x \in \mathbb{H}^1$ and $m \in \mathbb{N}_0$,*

$$\chi_1(x)\chi_m(x) = \chi_{m+1}(x) + |x|^2\chi_{m-1}(x). \tag{2.10}$$

Proof. The result is trivially true when $m = 0$ or $x = 0$. For $m > 0$ and $x \neq 0$

$$\begin{aligned}\chi_1(x)\chi_m(x) &= \frac{|x|^{m+1}}{\sin^2\theta}\Big\{\sin(2\theta)\sin\big((m+1)\theta\big)\Big\}\\ &= \frac{|x|^{m+1}}{\sin^2\theta}\Big\{2\sin(\theta)\cos(\theta)\sin\big((m+1)\theta\big)\Big\}\\ &= \frac{|x|^{m+1}}{\sin\theta}\Big\{\sin\big((m+2)\theta\big) + \sin(m\theta)\Big\}\\ &= \chi_{m+1}(x) + |x|^2\chi_{m-1}(x). \qquad \square\end{aligned}$$

2.2. Inner and outer functions. We will refer to the functions $t^m_{i,j}$ of the previous subsection as the *inner* functions as they will be shown to be homogeneous of nonnegative degree and harmonic in $\mathbb{R}^4$. The purpose of this subsection is to introduce the *outer* functions $o^m_{i,j}$ which will be shown to be homogeneous of negative degree and harmonic in $\mathbb{R}^4\backslash\{0\}$. The subsection also contains the addition formula connecting the inner and outer functions with the character functions.

The representations T_m may be used to construct antirepresentations, O_m of $\mathbb{H}^1_0$, defined by

$$O_m(x) := |x|^{-2} T_m(x^{-1}) \tag{2.11}$$

or, in terms of the coefficient functions,

$$\begin{aligned} o^m_{i,j}(z,w) = |x|^{-2} t^m_{i,j}(x^{-1}) &= (z\overline{z} + w\overline{w})^{-1} t^m_{i,j}(\overline{z}/|x|^2, -w/|x|^2) \\ &= |x|^{-(2m+2)} t^m_{i,j}(\overline{z}, -w) \\ &= |x|^{-2(m+1)} \overline{t^m_{j,i}(z,w)} \binom{m}{i} \binom{m}{j}^{-1}. \end{aligned} \tag{2.12}$$

Thus the coefficient functions for O_m are homogeneous of degree $-(m+2)$. Together, (2.4) and (2.12) give the equivalent definition of the outer functions

$$|x|^{2(m+1)} \sum_{i=0}^{m} o^m_{i,j}(z,w) z_1^{m-i} z_2^i = (z_1\overline{z} + z_2\overline{w})^{m-j} \big(z_1(-w) + z_2 z\big)^j. \tag{2.13}$$

See the appendix for tables of low degree inner and outer functions. These O_m are antirepresentations as

$$O_m(x \cdot y) = O_m(y) \cdot O_m(x).$$

Remark 2.8. When we prove harmonicity of the inner functions, or of the outer functions, the harmonicity of the other set will follow. Indeed, definition (2.12) corresponds to an inversion of the functions $t^m_{i,j}$ in the unit sphere followed by scaling by $|x|^{-2}$, along with reflection in the $\Re(z)$ axis. This reflection $(z,w) \to (\overline{z}, -w)$ corresponds to quaternionic conjugation. Both this scaled inversion, sometimes called the Kelvin transformation, and the reflection preserve harmonicity.

Associated with the spherical harmonics in $\mathcal{S}^{d-1}$ for any integer $d \geq 2$ is an addition formula [15, pp. 3–10]. These addition formulae express the character function (sometimes called the Gengenbauer polynomial or the Legendre function) at the inner product of two points u and v on $\mathcal{S}^{d-1}$ as a sum of products, in each of which the influence of u and v is separated. Perhaps the best known example of this phenomena is the addition formula for the ordinary Legendre polynomial, $P_n(\cos\gamma)$, which is exploited in the multipole expansion of the three-dimensional potential (see, e.g., [3, 7, 8]). With our definition of the inner and outer functions, the addition formula for $\mathbb{R}^4$ takes the following forms.

LEMMA 2.9 (Addition formulae for χ_m).

(i) *If* $x, x_< \in \mathbb{H}^1$, $x \neq 0$, *then*

$$\chi_m(x^{-1}x_<) = |x|^2 \operatorname{Tr}\big(O_m(x) T_m(x_<)\big) = |x|^2 \sum_{i,j=0}^{m} t^m_{j,i}(x_<)\, o^m_{i,j}(x). \tag{2.14}$$

(ii) *If* $x, x_< \in \mathbb{H}^1$, *then*

$$\chi_m(x^* x_<) = \mathrm{Tr}\left(T_m(x_<{}^*) T_m(x)\right) = \sum_{i,j=0}^{m} t_{j,i}^m(x_<{}^*)\, t_{i,j}^m(x). \tag{2.15}$$

Proof. From the definition of the character functions χ_m,

$$\begin{aligned}
\chi_m(x^{-1}x_<) = \mathrm{Tr}\left(T_m(x^{-1}x_<)\right) &= \mathrm{Tr}\left(T_m(x^{-1})T_m(x_<)\right) \\
&= \sum_{i,j=0}^{m} t_{i,j}^m(x^{-1}) t_{j,i}^m(x_<) \\
&= |x|^2 \sum_{i,j=0}^{m} |x|^{-2} t_{i,j}^m(x^{-1}) t_{j,i}^m(x_<) \\
&= |x|^2 \sum_{i,j=0}^{m} o_{i,j}^m(x) t_{j,i}^m(x_<),
\end{aligned}$$

which proves part (i). For part (ii), notice that by (2.9),

$$\chi_m(x^*) = \chi_m(x).$$

Therefore

$$\chi_m(x^* x_<) = \chi_m(x_<{}^* x) = \mathrm{Tr}\left(T_m(x_<{}^*)T_m(x)\right) = \sum_{i,j=0}^{m} t_{j,i}^m(x_<{}^*)\, t_{i,j}^m(x). \qquad \square$$

The addition formula (2.14) essentially displays the fact that

$$\frac{m+1}{\pi^2/2}\chi_m(x^{-1}x_<)$$

is a reproducing kernel for $\mathrm{span}\{t_{i,j}^m, i,j = 0, \ldots, m\}$, the space of homogeneous harmonic polynomials of degree m. In fact the biorthogonality in Lemma 2.6(ii) immediately shows that for any

$$f_m = \sum_{i,j=0}^{m} a_{i,j} t_{i,j}^m$$

in this span,

$$\int_{0<|x|\le 1} f_m(x) \frac{m+1}{\pi^2/2} \chi_m(x^{-1}x_<) dx = f_m(x_<).$$

3. Properties of the inner and outer functions. Some fundamental properties of the inner and outer functions will be developed in this section. These properties are needed for the development of a fast multipole-like method, but are also of interest in their own right. Properties which are considered below include symmetries, recurrence relations, derivative formulae, and harmonicity.

3.1. Symmetries. In this subsection we will develop some symmetry properties of the inner and outer functions. We have already seen an example of a symmetry relation in Lemma 2.5. One application of these symmetry properties is an approximate halving of the costs of forming and evaluating the truncated far field expansions to be developed in section 4.

We will use the symbols i, j, and k for the fundamental quaternionic units and $\mathbf{i}$ for the imaginary number $\sqrt{-1}$. It will be convenient to use the 2×2 matrix realization of the quaternions. In this realization the quaternion 1 is the 2×2 identity matrix and

$$\mathsf{i} = \begin{bmatrix} \mathbf{i} & 0 \\ 0 & -\mathbf{i} \end{bmatrix}, \qquad \mathsf{j} = \begin{bmatrix} 0 & 1 \\ -1 & 0 \end{bmatrix}, \qquad \mathsf{k} = \begin{bmatrix} 0 & \mathbf{i} \\ -\mathbf{i} & 0 \end{bmatrix}.$$

Now consider conjugation of an element in $\mathbb{H}^1$ by i.

$$\begin{bmatrix} \mathbf{i} & 0 \\ 0 & -\mathbf{i} \end{bmatrix} \begin{bmatrix} z & w \\ -\overline{w} & \overline{z} \end{bmatrix} \begin{bmatrix} -\mathbf{i} & 0 \\ 0 & \mathbf{i} \end{bmatrix} = \begin{bmatrix} z & -w \\ \overline{w} & \overline{z} \end{bmatrix}.$$

Applying T_m

$$T_m(\mathbf{i}, 0) T_m(z, w) T_m(-\mathbf{i}, 0) = T_m(z, -w).$$

By Lemma 2.3 $T_m(\mathbf{i}, 0)$ and $T_m(-\mathbf{i}, 0)$ are diagonal with

$$t^m_{i,i}(\mathbf{i}, 0) = (-1)^i \mathbf{i}^m, \qquad t^m_{j,j}(-\mathbf{i}, 0) = (-1)^{m-j} \mathbf{i}^m.$$

We conclude that

$$(-1)^i \mathbf{i}^m t^m_{i,j}(z, w) (-1)^{m-j} \mathbf{i}^m = t^m_{i,j}(z, -w)$$

for $0 \le i, j \le m$. That is,

$$t^m_{i,j}(z, w) = (-1)^{i-j} t^m_{i,j}(z, -w) \tag{3.1}$$

for $0 \le i, j \le m$.

Similar results can be obtained in the same way by conjugation with j and k. These results are summarized in the following lemma.

LEMMA 3.1. *The inner functions $t^m_{i,j}$ defined by* (2.4) *satisfy*

$$t^m_{i,j}(z, w) = (-1)^{i-j} t^m_{i,j}(z, -w), \tag{3.2a}$$

$$t^m_{i,j}(z, w) = (-1)^{i+j} t^m_{m-i,m-j}(\overline{z}, \overline{w}), \tag{3.2b}$$

$$t^m_{i,j}(z, w) = t^m_{m-i,m-j}(\overline{z}, -\overline{w}) \tag{3.2c}$$

for all $x = [z, w] \in \mathbb{C}^2$.

Because each $t^m_{i,j}(z, w)$ is a polynomial with real coefficients in z, w, $\overline{z}$, and $\overline{w}$,

$$\overline{T_m(z, w)} = T_m(\overline{z}, \overline{w}).$$

Hence (3.2b) may be written

$$t^m_{i,j}(z, w) = (-1)^{i+j} \overline{t^m_{m-i,m-j}(z, w)}. \tag{3.3}$$

Using the expression (2.12) for the outer functions in terms of the inner functions, each symmetry of T_m implies a symmetry of O_m. In particular, symmetry (3.3) implies

$$\begin{aligned} o^m_{i,j}(z,w) &= |x|^{-(2m+2)} t^m_{i,j}(\overline{z},-w) \\ &= |x|^{-(2m+2)}(-1)^{i+j} t^m_{m-i,m-j}(z,-\overline{w}) \\ &= (-1)^{i+j}\overline{o^m_{m-i,m-j}(z,w)}. \end{aligned} \tag{3.4}$$

From symmetries (3.3) and (3.4)

$$o^m_{i,j}(x)t^m_{j,i}(x_<) = \overline{o^m_{m-i,m-j}(x)t^m_{m-j,m-i}(x_<)}$$

for $0 \le i,j \le m$. Hence the terms in the addition formula expression (2.14) for $\chi_m(x^{-1}x_<)$ are conjugate symmetric with respect to reflection in the middle index $(m/2, m/2)$. Thus the addition formula can be rewritten to involve a real part and approximately half the number of terms. For example, one such recasting is

$$\begin{aligned} \chi_m(x^{-1}x_<) &= |x|^2 \sum_{i,j=0}^{m} o^m_{i,j}(x)t^m_{j,i}(x_<) \\ &= |x|^2 \Re\left(\sum_{k=0}^{\left\lfloor \frac{1}{2}\left((m+1)^2-1\right)\right\rfloor} (2-\delta_{m/2,i(k)}\,\delta_{m/2,j(k)}) o^m_{i(k),j(k)}(x)t^m_{j(k),i(k)}(x_<) \right), \end{aligned} \tag{3.5}$$

where $i(k) = k \mod (m+1)$ and $j(k) = \lfloor k/(m+1)\rfloor$. This observation can and should be used to halve the storage requirements and flop counts of fast evaluators built upon the analysis of this paper. For example, the recast expression (3.5) can be substituted almost directly into the truncated far field expansion, g_p, for a sum of shifts of the potential of Theorem 4.2. This will then approximately halve the marginal operation count for evaluating $g_p(x)$ at a single extra x.

A further symmetry will be useful to recast products of powers of $|x|$ with outer functions as inner functions.

LEMMA 3.2. *For $m \in \mathbb{N}$ and $0 \le i,j \le m$*

$$\binom{m}{j}|x|^{2m+2}o^m_{i,j}(x) = (-1)^{i-j}\binom{m}{i}t^m_{m-j,m-i}(x).$$

Proof. Substitution of (3.3) into (2.12) gives the result. ∎

3.2. Recurrence relationships. In this subsection we develop recurrence relations which provide efficient methods for calculating the inner and outer functions. For a given x they allow calculation of $\{t^m_{i,j},\ 0 \le i,j \le m,\ 0 \le m \le p\}$ or $\{o^m_{i,j},\ 0 \le i,j \le m,\ 0 \le m \le p\}$ in $\mathcal{O}(p^3)$ operations, which is the same magnitude as the number of terms to be calculated.

It is convenient to extend the definitions of $t^m_{i,j}$ and $o^m_{i,j}$ by defining $t^m_{i,j} = 0 = o^m_{i,j}$ for i or $j \notin [0,m]$.

LEMMA 3.3. *The inner functions $t^m_{i,j}$ defined by* (2.4) *satisfy the overlapping recurrence relations*

$$t^{m+1}_{i,j}(z,w) = \begin{cases} z\, t^m_{i,j}(z,w) - \overline{w}\, t^m_{i-1,j}(z,w), & 0 \le j \le m, \\ w\, t^m_{i,j-1}(z,w) + \overline{z}\, t^m_{i-1,j-1}(z,w), & 1 \le j \le m+1 \end{cases} \tag{3.6}$$

for $0 \le i \le m+1$ *and also satisfy the backward recurrence relations*

$$
\begin{aligned}
|x|^2 t^m_{i,j}(z,w) &= \overline{z}\; t^{m+1}_{i,j}(z,w) + \overline{w}\; t^{m+1}_{i,j+1}(z,w) \\
&= -w\; t^{m+1}_{i+1,j}(z,w) + z\; t^{m+1}_{i+1,j+1}(z,w)
\end{aligned} \tag{3.7}
$$

for $0 \le i, j \le m$.

Proof. From (2.4), for $1 \le j \le m+1$, we obtain

$$
\begin{aligned}
&\sum_{i=0}^{m+1} t^{m+1}_{i,j}(z,w)\; z_1^{m+1-i} z_2^i \\
&\quad = (z z_1 - \overline{w} z_2)^{m+1-j} (w z_1 + \overline{z} z_2)^j \\
&\quad = \left\{ (z z_1 - \overline{w} z_2)^{m-(j-1)} (w z_1 + \overline{z} z_2)^{j-1} \right\} (w z_1 + \overline{z} z_2) \\
&\quad = \left\{ \sum_{i=0}^{m} t^m_{i,j-1}(z,w)\; z_1^{m-i} z_2^i \right\} (w z_1 + \overline{z} z_2) \\
&\quad = \sum_{i=0}^{m} t^m_{i,j-1}(z,w) \left\{ w z_1^{m+1-i} z_2^i + \overline{z} z_1^{m-i} z_2^{i+1} \right\} \\
&\quad = \sum_{i=0}^{m} t^m_{i,j-1}(z,w) w z_1^{m+1-i} z_2^i + \sum_{i=0}^{m} t^m_{i,j-1}(z,w) \overline{z} z_1^{(m+1)-(i+1)} z_2^{i+1} \\
&\quad = \sum_{i=0}^{m} w\; t^m_{i,j-1}(z,w) z_1^{m+1-i} z_2^i + \sum_{i=1}^{m+1} \overline{z}\; t^m_{i-1,j-1}(z,w) z_1^{m+1-i} z_2^i \\
&\quad = \sum_{i=0}^{m+1} \left\{ w\; t^m_{i,j-1}(z,w) + \overline{z}\; t^m_{i-1,j-1}(z,w) \right\} z_1^{m+1-i} z_2^i .
\end{aligned}
$$

Equating coefficients of $z_1^{m+1-i} z_2^i$ gives the second part of (3.6). The first part may be obtained in a similar manner, or more directly by application of the symmetry relation (3.2b) to both sides of the part just proved.

The backward recursion may be obtained directly from the forward recursion. Multiplying the first right-hand side of (3.6) by $\overline{z}$ and the second right-hand side (with j replaced by $j+1$) by $\overline{w}$ and summing gives the first right-hand side of (3.7). The second right-hand side is obtained similarly. ∎

These formulae are analogous to the addition formulae which express $\cos(m \pm 1)\theta$ and $\sin(m \pm 1)\theta$ in terms of $\cos\theta$, $\sin\theta$, $\sin m\theta$, and $\cos m\theta$.

LEMMA 3.4. *The outer functions* $o^m_{i,j}$ *defined by* (2.12) *satisfy the overlapping recurrence relations*

$$
o^{m+1}_{i,j}(z,w) = \begin{cases} \dfrac{\overline{z}}{|x|^2} o^m_{i,j}(z,w) + \dfrac{\overline{w}}{|x|^2} o^m_{i-1,j}(z,w), & 0 \le j \le m, \\ \dfrac{-w}{|x|^2} o^m_{i,j-1}(z,w) + \dfrac{z}{|x|^2} o^m_{i-1,j-1}(z,w), & 1 \le j \le m+1 \end{cases} \tag{3.8}
$$

for $0 \le i \le m+1$ *and also satisfy the backward recurrence relations*

$$
\begin{aligned}
o^m_{i,j}(z,w) &= z\; o^{m+1}_{i,j}(z,w) - \overline{w}\; o^{m+1}_{i,j+1}(z,w) \\
&= w\; o^{m+1}_{i+1,j}(z,w) + \overline{z}\; o^{m+1}_{i+1,j+1}(z,w)
\end{aligned} \tag{3.9}
$$

for $0 \le i, j \le m$.

Proof. This follows easily by substituting the expression (2.12) for $o^m_{i,j}$ into the relations (3.6) and (3.7) for the inner functions $t^m_{i,j}$. ∎

3.3. Derivatives and harmonicity. In this subsection we develop derivative formulae for the inner and outer functions. Applications include proofs of harmonicity, a dual basis for the inner functions, and an expression for the outer functions as appropriate derivatives of $1/|x|^2$. Analogous formulae in the three-dimensional case are given in Epton and Dembart [8].

We start by recalling the definitions for the complex derivative operators:

$$\begin{aligned} \frac{\partial}{\partial z} &= \frac{1}{2}\left(\frac{\partial}{\partial x_1} - \mathbf{i}\frac{\partial}{\partial x_2}\right), & \frac{\partial}{\partial \overline{z}} &= \frac{1}{2}\left(\frac{\partial}{\partial x_1} + \mathbf{i}\frac{\partial}{\partial x_2}\right), \\ \frac{\partial}{\partial w} &= \frac{1}{2}\left(\frac{\partial}{\partial x_3} - \mathbf{i}\frac{\partial}{\partial x_4}\right), & \frac{\partial}{\partial \overline{w}} &= \frac{1}{2}\left(\frac{\partial}{\partial x_3} + \mathbf{i}\frac{\partial}{\partial x_4}\right). \end{aligned} \tag{3.10}$$

By considering z, $\overline{z}$, w, and $\overline{w}$ as functions of x_1, x_2, x_3, and x_4, these operators may be applied to functions defined on $\mathbb{C}^2$ in the natural way. Indeed, immediate consequences of these definitions are the relations

$$\frac{\partial}{\partial z}\overline{z} = 0 \qquad \text{and} \qquad \frac{\partial}{\partial z} z = 1,$$

their conjugates and the similar relations with w, $\overline{w}$. More generally, if $f(x) = h(z, \overline{z}, w, \overline{w})$ is complex analytic in z, i.e., independent of $\overline{z}$ in the sense that $\partial h/\partial \overline{z} = 0$, then $\partial f/\partial z$ is given by all the usual rules for differentiation. Furthermore, armed with these operators the ordinary Laplacian may be expressed as

$$\Delta = 4\left(\frac{\partial^2}{\partial z \partial \overline{z}} + \frac{\partial^2}{\partial w \partial \overline{w}}\right). \tag{3.11}$$

LEMMA 3.5. *Any of the first partial derivatives map the inner functions of degree* m *to (multiples of) inner functions of degree* $m-1$. *Specifically, for* $0 \le i, j \le m+1$,

$$\frac{\partial}{\partial z} t^{m+1}_{i,j}(z,w) = (m+1-j)\, t^m_{i,j}(z,w), \tag{3.12a}$$

$$\frac{\partial}{\partial \overline{w}} t^{m+1}_{i,j}(z,w) = -(m+1-j)\, t^m_{i-1,j}(z,w), \tag{3.12b}$$

$$\frac{\partial}{\partial w} t^{m+1}_{i,j}(z,w) = j\, t^m_{i,j-1}(z,w), \tag{3.12c}$$

$$\frac{\partial}{\partial \overline{z}} t^{m+1}_{i,j}(z,w) = j\, t^m_{i-1,j-1}(z,w). \tag{3.12d}$$

Proof. Differentiating (2.4) with respect to z gives

$$\begin{aligned} \sum_{i=0}^{m+1} \frac{\partial}{\partial z} t^{m+1}_{i,j}(z,w) z_1^{m+1-i} z_2^i &= (m+1-j) z_1 (z_1 z - z_2 \overline{w})^{m-j} (z_1 w + z_2 \overline{z})^j \\ &= (m+1-j) z_1 \sum_{i=0}^{m} t^m_{i,j}(z,w) z_1^{m-i} z_2^i \\ &= (m+1-j) \sum_{i=0}^{m} t^m_{i,j}(z,w) z_1^{m+1-i} z_2^i. \end{aligned}$$

Equating coefficients gives (3.12a). In a similar manner, by differentiating (2.4) with respect to $\overline{w}$, w, and $\overline{z}$ we may obtain (3.12b), (3.12c), and (3.12d), respectively. ∎

LEMMA 3.6. *Any of the first partial derivatives map the outer functions of degree $-m-2$ to (multiples of) outer functions of degree $-m-3$. Specifically, for $m \geq 0$ and $0 \leq j \leq m$,*

$$\frac{\partial}{\partial z} o_{i,j}^m(z,w) = -(m+1-i)\; o_{i,j}^{m+1}(z,w), \qquad 0 \leq i \leq m+1, \tag{3.13a}$$

$$\frac{\partial}{\partial \overline{w}} o_{i,j}^m(z,w) = (m+1-i)\; o_{i,j+1}^{m+1}(z,w), \qquad 0 \leq i \leq m+1, \tag{3.13b}$$

$$\frac{\partial}{\partial w} o_{i,j}^m(z,w) = -(i+1)\; o_{i+1,j}^{m+1}(z,w), \qquad -1 \leq i \leq m, \tag{3.13c}$$

$$\frac{\partial}{\partial \overline{z}} o_{i,j}^m(z,w) = -(i+1)\; o_{i+1,j+1}^{m+1}(z,w), \qquad -1 \leq i \leq m. \tag{3.13d}$$

Proof of (3.13a). The proof is by induction on m.

Induction basis. Since

$$o_{0,0}^0(z,w) = (z\overline{z} + w\overline{w})^{-1},$$

an application of (3.8) shows

$$O_1(z,w) = |x|^{-4} \begin{bmatrix} \overline{z} & -w \\ \overline{w} & z \end{bmatrix}.$$

It follows that (3.13a) is true for $m = 0$.

Induction step. Assume that (3.13a) is true for $0 \leq m \leq M$. By the first part of (3.8),

$$o_{i,j}^{M+1}(z,w) = \frac{\overline{z}}{|x|^2} o_{i,j}^M(z,w) + \frac{\overline{w}}{|x|^2} o_{i-1,j}^M(z,w)$$

for $0 \leq i \leq M+1$ and $0 \leq j \leq M$. Using the inductive hypothesis to differentiate the outer functions,

$$\begin{aligned} \frac{\partial}{\partial z} o_{i,j}^{M+1}(x) =& \frac{\overline{z}(-\overline{z})}{|x|^4} o_{i,j}^M(x) + \frac{\overline{z}}{|x|^2} \frac{\partial}{\partial z} o_{i,j}^M(x) + \frac{\overline{w}(-\overline{z})}{|x|^4} o_{i-1,j}^M(x) + \frac{\overline{w}}{|x|^2} \frac{\partial}{\partial z} o_{i-1,j}^M(x) \\ =& \frac{-\overline{z}}{|x|^2} \left(\frac{\overline{z}}{|x|^2} o_{i,j}^M(x) + \frac{\overline{w}}{|x|^2} o_{i-1,j}^M(x) \right) - (M+1-i) \frac{\overline{z}}{|x|^2} o_{i,j}^{M+1}(x) \\ & - (M+2-i) \frac{\overline{w}}{|x|^2} o_{i-1,j}^{M+1}(x). \end{aligned}$$

Two applications of the first part of (3.8) give the result.

However, if $j = M+1$, the above does not hold. By the second part of (3.8),

$$o_{i,j}^{M+1}(z,w) = \frac{-w}{|x|^2} o_{i,j-1}^M(z,w) + \frac{z}{|x|^2} o_{i-1,j-1}^M(z,w)$$

for $0 \leq i \leq M+1$ and $1 \leq j \leq M+1$. Once again the inductive hypothesis will be used to differentiate this expression. This gives

$$\begin{aligned} \frac{\partial}{\partial z} o_{i,j}^{M+1}(x) =& \frac{(-w)(-\overline{z})}{|x|^4} o_{i,j-1}^M(x) + \frac{(-w)}{|x|^2} \frac{\partial}{\partial z} o_{i,j-1}^M(x) \\ & + \frac{z(-\overline{z})}{|x|^4} o_{i-1,j-1}^M(x) + \frac{z}{|x|^2} \frac{\partial}{\partial z} o_{i-1,j-1}^M(x) + \frac{1}{|x|^2} o_{i-1,j-1}^M(x) \end{aligned}$$

$$
\begin{aligned}
&= \frac{(-w)(-\overline{z})}{|x|^4} o^M_{i,j-1}(x) - (M+1-i)\frac{(-w)}{|x|^2} o^{M+1}_{i,j-1}(x) \\
&\quad + \frac{z(-\overline{z})}{|x|^4} o^M_{i-1,j-1}(x) - (M+2-i)\frac{z}{|x|^2} o^{M+1}_{i-1,j-1}(x) \\
&\quad + \frac{z\overline{z} + w\overline{w}}{|x|^4} o^M_{i-1,j-1}(x) \\
&= -(M+1-i)\frac{(-w)}{|x|^2} o^{M+1}_{i,j-1}(x) - (M+2-i)\frac{z}{|x|^2} o^{M+1}_{i-1,j-1}(x) \\
&\quad - \frac{(-w)}{|x|^2}\left(\frac{\overline{z}}{|x|^2} o^M_{i,j-1}(x) + \frac{\overline{w}}{|x|^2} o^M_{i-1,j-1}(x)\right).
\end{aligned}
$$

By the first part of (3.8), the term in the brackets is equal to $o^{M+1}_{i,j-1}(z,w)$ and thus the second part of (3.8) gives the required result. This proves (3.13a) by induction on m. The other three relations in (3.13) may be proven in a similar way. □

Given the above expressions for the derivatives of the inner and outer functions it is easy to show that they are harmonic functions. Since (3.11) may be used for the Laplacian, it follows that

(3.14)
$$
\frac{1}{4}\Delta o^m_{i,j} = \big(-(m+1-i)\big)\big(-(i+1)\big) o^{m+2}_{i+1,j+1} + (m+1-i)\big(-(i+1)\big) o^{m+2}_{i+1,j+1} = 0
$$

and

$$
\frac{1}{4}\Delta t^{m+2}_{i,j} = j(m+2-j)t^m_{i-1,j-1} - j(m+2-j)t^m_{i-1,j-1} = 0. \tag{3.15}
$$

Each of (3.14) and (3.15) can be inferred from the other as indicated in Remark 2.8.

From the product rule for the Laplacian,

$$
\Delta(fg) = (\Delta f)g + 2(\nabla f)\cdot(\nabla g) + f(\Delta g),
$$

and the Euler relation for a function f that is homogeneous of degree m,

$$
x\cdot\big(\nabla f\big)(x) = mf(x),
$$

we easily obtain the following.

LEMMA 3.7. *Let $|\cdot|$ be the 2-norm on $\mathbb{R}^d$, d being even. If $f:\mathbb{R}^d\setminus\{0\}\to\mathbb{R}$ is a nontrivial harmonic function that is homogeneous of degree m, then*

$$
\Delta(|\cdot|^{2\ell} f) = 4\ell\left(\frac{d}{2} + \ell + m - 1\right)|\cdot|^{2(\ell-1)} f.
$$

Hence $|\cdot|^{2\ell} f$ is polyharmonic of exact order

$$
\begin{cases} \ell+1 & \text{for } \ell \ge 0 \text{ and } m > -d/2 \text{ or } m < 1-\ell-d/2, \\ \ell+m+d/2 & \text{for } \ell < 0 \text{ and } m \ge 1-\ell-d/2. \end{cases}
$$

COROLLARY 3.8.

$$
\begin{aligned}
\Delta(|\cdot|^{2\ell} o^m_{i,j}) &= 4\ell(\ell-m-1)|\cdot|^{2(\ell-1)} o^m_{i,j}, \\
\Delta(|\cdot|^{2\ell} t^m_{i,j}) &= 4\ell(\ell+m+1)|\cdot|^{2(\ell-1)} t^m_{i,j}.
\end{aligned}
$$

All of the outer functions $o^m_{i,j}(x)$ may be written as (multiples of) derivatives of $1/|x|^2$ as in the following.

LEMMA 3.9. *Define*

$$R^m_{i,j} = \begin{cases} \dfrac{(-1)^{m-j+i}}{i!(m-i)!} \dfrac{\partial^m}{\partial \overline{w}^{j-i} \partial z^{m-j} \partial \overline{z}^i}, & i \le j, \\ \dfrac{(-1)^m}{i!(m-i)!} \dfrac{\partial^m}{\partial w^{i-j} \partial z^{m-i} \partial \overline{z}^j}, & i \ge j, \end{cases} \tag{3.16}$$

$0 \le i, j \le m$, $m \in \mathbb{N}_0$. *Then for* $x \in \mathbb{R}^4 \backslash \{0\}$,

$$o^m_{i,j}(x) = R^m_{i,j} \frac{1}{|x|^2}. \tag{3.17}$$

Furthermore, for harmonic functions f,

$$R^m_{i,j} R^{m'}_{i',j'} f = e(m, m', i)_{i',i'} R^{m+m'}_{i+i',j+j'} f, \tag{3.18}$$

where

$$e(m, m', i)_{i',i'} = \binom{i+i'}{i} \binom{m+m'-(i+i')}{m-i}. \tag{3.19}$$

Proof. The definition of the outer functions in terms of the inner functions, (2.12), and the fact that $t^0_{0,0} = 1$, imply

$$o^0_{0,0}(x) = \frac{1}{|x|^2}.$$

Then (3.17) follows by repeated use of Lemma 3.6.

Consider now (3.18). If $i \le j$ and $i' \le j'$ *or* $i \ge j$ and $i' \ge j'$, then (3.18) follows easily from (3.16). Turning to the slightly more difficult *mixed case*, assume, without loss of generality, $i \le j$ and $i' \ge j'$. Using definition (3.16),

$$R^m_{i,j} R^{m'}_{i',j'} f = \frac{(-1)^{m-j+i+m'}}{i!(m-i)!i'!(m'-i')!} \frac{\partial^{m+m'}}{\partial \overline{w}^{j-i} \partial w^{i'-j'} \partial z^{m-j+m'-i'} \partial \overline{z}^{i+j'}} f. \tag{3.20}$$

Let g be harmonic. Then from the form (3.11) for the Laplacian

$$\frac{\partial^2}{\partial z \partial \overline{z}} g = -\frac{\partial^2}{\partial w \partial \overline{w}} g.$$

Hence, if $i' - j' \ge j - i$, then

$$\frac{\partial^{i'-j'+j-i}}{\partial \overline{w}^{j-i} \partial w^{i'-j'}} f = (-1)^{j-i} \frac{\partial^{i'-j'+j-i}}{\partial w^{i+i'-(j+j')} \partial z^{j-i} \partial \overline{z}^{j-i}} f.$$

Substituting this into (3.20) gives

$$\begin{aligned} R^m_{i,j} R^{m'}_{i',j'} f &= \frac{(-1)^{m+m'}}{i!(m-i)!i'!(m'-i')!} \frac{\partial^{m+m'}}{\partial w^{i+i'-(j+j')} \partial z^{m+m'-(i+i')} \partial \overline{z}^{j+j'}} f \\ &= e(m, m', i)_{i',i'} R^{m+m'}_{i+i',j+j'} f, \end{aligned}$$

since $i' - j' \geq j - i$ implies $i + i' \geq j + j'$. The case when $i' - j' \leq j - i$ is similar. ∎

Motivated by the operators $R^m_{i,j}$ we are led to define operators

$$L^m_{i,j} = \begin{cases} \dfrac{1}{j!(m-j)!} \dfrac{\partial^m}{\partial w^{j-i} \partial \overline{z}^i \partial z^{m-j}}, & i \leq j, \\ \dfrac{(-1)^{i-j}}{j!(m-j)!} \dfrac{\partial^m}{\partial \overline{w}^{i-j} \partial \overline{z}^j \partial z^{m-i}}, & i \geq j. \end{cases} \tag{3.21}$$

Repeated use of Lemma 3.5 then shows the following.

LEMMA 3.10 (Dual basis for the inner functions). *The operators $L^m_{i,j}$ satisfy*

$$L^m_{i,j} t^m_{i,j} = t^0_{0,0},$$

and also have the more general property

$$L^{m'}_{i',j'} t^m_{i,j} = \binom{j}{j'} \binom{m-j}{m'-j'} t^{m-m'}_{i-i',j-j'}.$$

Thus the functionals

$$\lambda^m_{i,j}(f) = \big(L^m_{i,j} f\big)(0), \tag{3.22}$$

$0 \leq i, j \leq m$, $0 \leq m \leq p$, *form a dual basis for* $\big\{t^m_{i,j},\ 0 \leq i, j \leq m,\ 0 \leq m \leq p\big\}$.

4. Expansions of polyharmonic basic functions. In this section we develop far field expansions of the functions $|\cdot - x_<|^{-2}$ and $|\cdot - x_<|^{2n} \ln(|\cdot - x_<|)$, $n = 0, 1, \ldots$. These functions lead to polyharmonic splines of order 1 and $n + 2$, respectively. We also find bounds on the error in approximating the associated polyharmonic radial basis functions by truncating these far field expansions. We will truncate by dropping all terms of sufficiently negative homogeneity.

We will find it useful in this section to make use of the cosine formula in the form

$$\begin{aligned} |x - x_<|^2 &= |x|^2 + |x_<|^2 - 2\langle x, x_< \rangle \\ &= |x|^2 + |x_<|^2 - |x|^2 \operatorname{Tr}(x^{-1} x_<) \\ &= |x|^2 + |x_<|^2 - |x|^2 \chi_1(x^{-1} x_<) \qquad \text{(4.1a)} \\ &= |x|^2 + |x_<|^2 - \chi_1(x^* x_<) \\ &= |x|^2 + |x_<|^2 - \chi_1({x_<}^* x). \qquad \text{(4.1b)} \end{aligned}$$

4.1. Expansion of the potential. We start with a far field expansion of the potential function $|x - x_<|^{-2}$. This is an expansion in the character functions, which are products of powers of $|x_<|/|x|$ and the appropriate Gengenbauer polynomials—the Chebyshev polynomials of the second kind.

LEMMA 4.1. *For $x, x_< \in \mathbb{R}^4$ with $|x_<| < |x|$,*

$$\frac{1}{|x - x_<|^2} = \frac{1}{|x|^2} \sum_{m=0}^{\infty} \chi_m(x^{-1} x_<). \tag{4.2}$$

Proof. The result is trivially true when $x_< = 0$. Hence in what follows we assume that $0 < |x_<| < |x|$. Then from the definition of the character function, (2.9),

$$\chi_m(x^{-1} x_<) = \left(\frac{|x_<|}{|x|}\right)^m \frac{\sin(m+1)\theta}{\sin\theta},$$

where θ is the angle between x and $x_<$. As is well known,

$$\left|\frac{\sin(m+1)\theta}{\sin\theta}\right| \le m+1 \quad \text{for all} \quad \theta \in \mathbb{R}.$$

Therefore the series on the right of (4.2) converges absolutely.

We will prove the lemma by showing the product of the right-hand side of (4.2) with $|x-x_<|^2$ is 1. Let $y = x^{-1}x_<$, then

$$\begin{aligned}
|x-x_<|^2 \frac{1}{|x|^2}\sum_{m=0}^{\infty}\chi_m(y) &= \big\{|x|^2+|x_<|^2-|x|^2\chi_1(y)\big\}\frac{1}{|x|^2}\sum_{m=0}^{\infty}\chi_m(y)\\
&= \big\{1+|y|^2-\chi_1(y)\big\}\sum_{m=0}^{\infty}\chi_m(y)\\
&= \sum_{m=0}^{\infty}\big\{\chi_m(y)+|y|^2\chi_m(y)-\chi_1(y)\chi_m(y)\big\}\\
&= \sum_{m=0}^{\infty}\big\{\chi_m(y)+|y|^2\chi_m(y)-\chi_{m+1}(y)-|y|^2\chi_{m-1}(y)\big\}\\
&= \chi_0(y)-|y|^2\chi_{-1}(y)\\
&= 1,
\end{aligned}$$

where we have used Lemma 2.7 to expand the product $\chi_1(y)\chi_m(y)$, a telescoping argument which is valid since $\chi_m(y) \to 0$ as $m \to \infty$ and because of the fact that $\chi_{-1} = 0$. □

We will now obtain a bound on the error in approximating $\Phi_{x_<}(\cdot) = 1/|\cdot - x_<|^2$ by the truncated series

$$g_p(x) = \frac{1}{|x|^2}\sum_{m=0}^{p}\chi_m(x^{-1}x_<).$$

From the explicit formula for the character function, (2.9), $|\chi_m(y)| \le (m+1)|y|^m$ for all $y \in \mathbb{H}^1$ and therefore the error in approximating $\Phi_{x_<}(\cdot)$ by g_p is bounded by

$$\begin{aligned}
\big|\Phi_{x_<}(x)-g_p(x)\big| &\le \frac{1}{|x|^2}\sum_{m=p+1}^{\infty}\big|\chi_m(x^{-1}x_<)\big|\\
&\le \frac{1}{|x|^2}\sum_{m=p+1}^{\infty}(m+1)|y|^m\\
&= \frac{|y|^{p+1}}{|x|^2}\sum_{m=0}^{\infty}\big((p+1)+(m+1)\big)|y|^m\\
&= \frac{|y|^{p+1}}{|x|^2}\left\{(p+1)\sum_{m=0}^{\infty}|y|^m+\sum_{m=0}^{\infty}(m+1)|y|^m\right\},
\end{aligned}$$

where $y = x^{-1}x_<$. If $|x_<| < |x|$, then $|y| < 1$ and the well-known identities

$$\sum_{m=0}^{\infty}h^m = \frac{1}{1-h} \qquad \text{and} \qquad \sum_{m=0}^{\infty}(m+1)h^m = \frac{1}{(1-h)^2},$$

for $|h| < 1$, may be applied. This gives

$$\left|\Phi_{x_<}(x) - g_p(x)\right| \leq \frac{|y|^{p+1}}{|x|^2}\left\{\frac{p+1}{1-|y|} + \frac{1}{(1-|y|)^2}\right\}. \tag{4.3}$$

Denote the bound on the right of (4.3) by $e_p(|y|)$. For $|x|$ fixed, since each term on the right in (4.3) is obviously strictly increasing in $|y|$ for $0 < |y| < 1$, so is $e_p(|y|)$. Considering now the sum

$$s(x) = \sum_{k=1}^{N} \frac{d_k}{|x - x_k|^2},$$

we apply the bound above to each term and sum. The monotonicity of the bound enables us to estimate $e_p(|x_k|/|x|)$ by $e_p(d)$, where

$$d = \max_{1\leq k\leq N} \frac{|x_k|}{|x|}.$$

In combination with Lemma 4.1 and (2.14), this gives the following.

THEOREM 4.2. *Suppose $x_k \in \mathbb{R}^4$, $|x_k| \leq r$, and $d_k \in \mathbb{R}$ for each $1 \leq k \leq N$. Let*

$$s(x) = \sum_{k=1}^{N} \frac{d_k}{|x - x_k|^2},$$

and let C_m be the $(m+1)\times(m+1)$ matrix

$$\left[C^m_{i,j}\right] = \sum_{k=1}^{N} d_k\big(T_m(x_k)\big).$$

For $p \in \mathbb{N}_0$, set

$$g_p(x) = \sum_{m=0}^{p}\sum_{i,j=0}^{m} C^m_{j,i}\, o^m_{i,j}(x) = \sum_{m=0}^{p} \operatorname{Tr}\left(C_m O_m(x)\right), \tag{4.4}$$

$x \in \mathbb{R}^4\backslash\{0\}$. Then for all x with $|x| > r$

$$|s(x) - g_p(x)| \leq \frac{M}{r^2}\left(\frac{p+1}{1-1/c} + \frac{1}{(1-1/c)^2}\right)\left(\frac{1}{c}\right)^{p+3},$$

where $M = \sum_{k=1}^{N} |d_k|$ and $c = |x|/r$.

4.2. Expansion of a polyharmonic function. In this subsection our aim is to develop far field expansions for the functions $|\cdot - x_<|^{2n}\ln|\cdot - x_<|$, which are polyharmonic of order $n+2$. This will be done by induction on n with the biharmonic case $\ln|\cdot - x_<|$ being used as the induction basis.

The polyharmonic functions f of order $n+2$ that occur will be written in the form

$$f = f_0 + |\cdot|^2 f_1 + \cdots + |\cdot|^{2n+2} f_{n+1},$$

where $f_0, \ldots, f_{n+1}$ are harmonic. In this sum, $|\cdot|^{2j} f_j$ is actually a $(j+1)$-harmonic term. As a consequence the terms of a specified homogeneous order k in our expansions will no longer involve a single χ_m as in the harmonic case of Lemma 4.1. Rather, they will be a weighted sum of $\chi_m(y), |y|^2\chi_{m-2}(y), \ldots, |y|^{2n+2}\chi_{m-2n-2}(y)$, consistent with the polyharmonicity orders of Lemma 3.7. For this reason we need to know how pairs of character functions combine.

LEMMA 4.3. *For $m \in \mathbb{N}$, $m \geq 2$, and $|x_<| < |x|$,*

$$\chi_m(x^{-1}x_<) - \frac{|x_<|^2}{|x|^2}\chi_{m-2}(x^{-1}x_<) = 2\frac{|x_<|^m}{|x|^m}\cos(m\theta), \tag{4.5}$$

where θ is the angle between x and $x_<$.

Proof. The lemma is trivially true when $x_< = 0$. For $0 < |x_<| < |x|$, the explicit formula for the character function implies

$$\begin{aligned}
\chi_m(x^{-1}x_<) - \frac{|x_<|^2}{|x|^2}\chi_{m-2}(x^{-1}x_<) &= \frac{|x_<|^m}{|x|^m}\left(\frac{\sin(m+1)\theta}{\sin\theta} - \frac{\sin(m-1)\theta}{\sin\theta}\right) \\
&= \frac{|x_<|^m}{|x|^m}\left(\frac{\sin(m+1)\theta - \sin(m-1)\theta}{\sin\theta}\right) \\
&= 2\frac{|x_<|^m}{|x|^m}\frac{\sin(\theta)\cos(m\theta)}{\sin\theta} \\
&= 2\frac{|x_<|^m}{|x|^m}\cos(m\theta). \qquad \square
\end{aligned}$$

Our next goal is a far field expansion for the biharmonic function $\ln|\cdot - x_<|$. While this expansion is useful in and of itself, we will also use it as the induction basis for the expansion of the more general function $|\cdot - x_<|^{2n}\ln|\cdot - x_<|$, which is polyharmonic of order $n+2$.

LEMMA 4.4. *For $x, x_< \in \mathbb{R}^4$, and $|x_<| < |x|$,*

$$\ln|x - x_<|^2 = \ln|x|^2 - \sum_{m=1}^{\infty}\frac{1}{m}\left\{\chi_m(x^{-1}x_<) - \frac{|x_<|^2}{|x|^2}\chi_{m-2}(x^{-1}x_<)\right\}. \tag{4.6}$$

Proof. The case $x_< = 0$ is trivially true. Hence we assume $0 < |x_<| < |x|$.

We will use $\ln(\cdot)$ for the real logarithm and $\log(\cdot)$ for the principal branch of the complex logarithm. Thus $\Re(\log z) = \ln|z|$ away from the branch cut. We will represent $x = (x_1, x_2, x_3, x_4)^T \in \mathbb{R}^4$ by $x = [x_1 + \mathbf{i}x_2, x_3 + \mathbf{i}x_4] \in \mathbb{C}^2$ and similarly for $x_<$. There exists a rotation R_1 such that

$$R_1 x = [|x|, 0].$$

By the argument that precedes the introduction of the character function χ_m in (2.9), there is a rotation R_2 that fixes the north pole $[1,0]$ and rotates $R_1 x_<$ to the direction $[e^{\mathbf{i}\theta}, 0]$, where θ is the angle between $R_1 x_<$ and the north pole. Since rotations preserve angles θ is also the angle between x and $x_<$, $R = R_2 R_1$ is a rotation such that

$$Rx = [|x|, 0], \qquad Rx_< = [|x_<|e^{\mathbf{i}\theta}, 0].$$

Thus

$$|x - x_<| = |R(x - x_<)| = |Rx - Rx_<|$$
$$= \left|[|x| - |x_<|e^{\mathbf{i}\theta}, 0]\right| = |x|\left|1 - \frac{|x_<|}{|x|}e^{\mathbf{i}\theta}\right| = |x|\left|1 - |y|e^{\mathbf{i}\theta}\right|,$$

where $y = x^{-1}x_<$, and

$$\ln|x - x_<| = \Re\left\{\log\left(|x|\left(1 - |y|e^{\mathbf{i}\theta}\right)\right)\right\}$$
$$= \Re\left\{\log(|x|) + \log\left(1 - |y|e^{\mathbf{i}\theta}\right)\right\} = \ln|x| + \Re\left\{\log\left(1 - |y|e^{\mathbf{i}\theta}\right)\right\}.$$

Now

$$\log\left(1 - |y|e^{\mathbf{i}\theta}\right) = -\sum_{m=1}^{\infty}\frac{1}{m}\left(|y|e^{\mathbf{i}\theta}\right)^m = -\sum_{m=1}^{\infty}\frac{1}{m}|y|^m e^{\mathbf{i}m\theta}.$$

Taking the real part of this expression,

$$\Re\left\{\log\left(1 - \frac{|x_<|}{|x|}e^{\mathbf{i}\theta}\right)\right\} = -\sum_{m=1}^{\infty}\frac{1}{m}\frac{|x_<|^m}{|x|^m}\cos(m\theta)$$
$$= -\frac{1}{2}\sum_{m=1}^{\infty}\frac{1}{m}\left\{\chi_m(x^{-1}x_<) - \frac{|x_<|^2}{|x|^2}\chi_{m-2}(x^{-1}x_<)\right\},$$

where we have used Lemma 4.3 to express $(|x_<|^m/|x|^m)\cos(m\theta)$ in terms of the character functions χ_m. □

We now wish to obtain an expansion for the polyharmonic function

$$|x - x_<|^{2n}\ln|x - x_<|^2.$$

To simplify this procedure, we observe that

(4.7)
$$|x - x_<|^{2n}\ln|x - x_<|^2 = |x - x_<|^{2n}\ln|x|^2 + |x|^{2n}|I - x^{-1}x_<|^{2n}\ln|I - x^{-1}x_<|^2,$$

where I is the 2×2 identity in $\mathbb{H}_0^1$ or the element $[1, 0]$ in $\mathbb{C}^2$. This splits the function into a term containing the logarithmic singularity and a term amenable to "Laurent" expansion. We shall handle the two parts of the right-hand side of (4.7) separately.

The coefficient of $\ln|x|$ in the expansion. We first consider the polynomial that multiplies the $\ln|x|$ term in (4.7). We will give an expression for this polynomial in terms of the inner functions and discuss some symmetry properties.

LEMMA 4.5. *For $x, x_< \in \mathbb{R}^4$,*

$$|x - x_<|^{2n} = \sum_{m=0}^{n}|x|^{2m}\sum_{\ell=0}^{n-m}b_{m,\ell}^n|x_<|^{2\ell}\chi_{n-m-\ell}(x_<{}^*x) \tag{4.8}$$
$$= \sum_{m=0}^{n}|x|^{2m}\sum_{\ell=0}^{n-m}\sum_{i,j=0}^{n-m-\ell}D_{j,i}^{m,\ell}(x_<)t_{i,j}^{n-m-\ell}(x),$$

where the coefficients $b_{m,\ell}^n$ are given recursively by

$$b_{m,\ell}^{n+1} = b_{m-1,\ell}^n + b_{m,\ell-1}^n - b_{m,\ell}^n - b_{m-1,\ell-1}^n \tag{4.9a}$$

along with the initial conditions

$$b^0_{m,\ell} = \begin{cases} 1, & m = \ell = 0, \\ 0 & \text{otherwise}, \end{cases} \tag{4.9b}$$

$$b^n_{m,\ell} = 0 \qquad \text{if } m + \ell > n \text{ or } m, \ell \notin [0, n], \tag{4.9c}$$

and the coefficients $D^{m,\ell}_{j,i}(x_<)$ *are given by*

$$D^{m,\ell}_{j,i}(x_<) = b^n_{m,\ell} |x_<|^{2\ell} t^{n-m-\ell}_{j,i}(x_<{}^*). \tag{4.10}$$

Proof. Simple application of (4.1b), along with the product rule (2.10) for character functions χ_m, gives this first equality by induction on n. The second equality then follows by substituting (2.15) for $\chi_{n-m-\ell}(x_<{}^* x)$. ∎

Remark 4.6. Since $b^n_{m,\ell}$ is real and

$$t^{n-m-\ell}_{j,i}(x_<{}^*) = (-1)^{i+j} \overline{t^{n-m-\ell}_{n-m-\ell-j,n-m-\ell-i}(x_<{}^*)},$$

by symmetry (3.3) we see that

$$D^{m,\ell}_{j,i}(x_<) = (-1)^{i+j} \overline{D^{m,\ell}_{n-m-\ell-j,n-m-\ell-i}(x_<)}$$

for all $0 \le m \le n$, $0 \le \ell \le n - m$, $0 \le i, j \le n - m - \ell$. Provided the weights d_k are real, this symmetry is inherited by the coefficients of polynomials

$$q(x) = \sum_{k=0}^{N} d_k |x - x_k|^{2n} = \sum_{m=0}^{n} |x|^{2m} \sum_{\ell=0}^{n-m} \sum_{i,j=0}^{n-m-\ell} \widetilde{D}^{m,\ell}_{j,i} t^{n-m-\ell}_{i,j}(x) \tag{4.11}$$

occurring as the coefficient of the $\ln |x|^2$ in the truncated far field expansion of Theorem 4.10 to come.

One use of this property would be to recast the polynomial $q(x)$ as the weighted sum of approximately half as many $t^{n-m-\ell}_{i,j}(x)$'s, thereby reducing the operation count for approximate evaluation.

The nonlogarithmic part in the expansion. We now consider the infinite or far field part of (4.7). We find an explicit form for the expansion and give bounds on the error in approximation by truncation for this series.

LEMMA 4.7. *For* $n \in \mathbb{N}_0$ *and* $y \in \mathbb{R}^4$, $|y| < 1$,

$$|I - y|^{2n} \ln |I - y|^2 = \sum_{\ell=0}^{n+1} \sum_{m=\max\{1,2\ell\}}^{\infty} c^n_{m,\ell} |y|^{2\ell} \chi_{m-2\ell}(y), \tag{4.12}$$

where the series (4.12) *converges absolutely. The coefficients* $c^n_{m,\ell}$ *are given by the formulae*

$$c^0_{m,\ell} = \begin{cases} -1/m, & \ell = 0,\ m \ge 1, \\ 1/m, & \ell = 1,\ m - 2\ell \ge 0, \\ 0 & \text{otherwise} \end{cases} \tag{4.13a}$$

and the recurrence

$$c^{n+1}_{m,\ell} = c^n_{m,\ell} - c^n_{m-1,\ell} - c^n_{m-1,\ell-1} + c^n_{m-2,\ell-1}. \tag{4.13b}$$

Proof. The proof is by induction on n.

Induction basis: The case $n = 0$ of formulae (4.12) and (4.13a) is contained in Lemma 4.4.

Induction step: Assume (4.12) has been established for $n = K$. Then using the cosine formula (4.1a) and the product formula (2.10) we find

$$\begin{aligned}&|I-y|^{2K+2}\ln|I-y|^2\\&=\sum_{\ell=0}^{K+1}\sum_{m=\max\{1,2\ell\}}^{\infty}c_{m,\ell}^{K}|y|^{2\ell}\Big\{\chi_{m-2\ell}(y)-\chi_{m+1-2\ell}(y)-|y|^2\chi_{m-1-2\ell}(y)+|y|^2\chi_{m-2\ell}(y)\Big\}.\end{aligned}$$

Rearranging by collecting terms of the same homogeneity we find a series

$$|I-y|^{2K+2}\ln|I-y|^2=\sum_{\ell=0}^{K+2}\sum_{m=\max\{1,2\ell\}}^{\infty}c_{m,\ell}^{K+1}|y|^{2\ell}\chi_{m-2\ell}(y)$$

converging absolutely for $|y| < 1$ and with coefficients given by (4.13b). Thus (4.12) holds for $n = K + 1$. The result follows by induction. ∎

LEMMA 4.8. *For $m > 2n \geq 0$ and $0 \leq \ell \leq n+1$, the coefficients $c_{m,\ell}^{n}$ defined recursively in Lemma 4.7 have the explicit form*

$$c_{m,\ell}^{n}=(-1)^{n+\ell+1}n!\binom{n+1}{\ell}\Big/\prod_{\substack{k=m-\ell-n\\k\neq m-2\ell+1}}^{m-\ell+1}k. \tag{4.14}$$

Proof. The proof is by induction on n.

Induction basis: The formula for $n = 0$ is formula (4.13a) of Lemma 4.7.

Induction step: Assume that the formula holds for $n = K$ and $m > 2K$. Then for $n = K + 1$

$$c_{m,\ell}^{K+1}=c_{m,\ell}^{K}-c_{m-1,\ell}^{K}-c_{m-1,\ell-1}^{K}+c_{m-2,\ell-1}^{K}.$$

Assume now that $m > 2(K + 1)$ and $1 \leq \ell \leq K + 1$. Using the induction hypothesis,

$$\begin{aligned}c_{m,\ell}^{K+1}=&(-1)^{K+1+\ell}K!\Big\{\binom{K+1}{\ell}\Big\{\big(m-\ell-(K+1)\big)(m-2\ell+1)\\&-(m-\ell+1)(m-2\ell)\Big\}+\binom{K+1}{\ell-1}\Big\{(m-\ell-K-1)(m-2\ell+2)\\&-(m-\ell+1)(m-2\ell+1)\Big\}\Big\}\Big/\prod_{k=m-\ell-(K+1)}^{m-\ell+1}k\\=&(-1)^{K+1+\ell}\frac{K!(K+1)!}{\ell!(K+2-\ell)!}\Big\{(K+2-\ell)\Big\{(m-\ell-K-1)(m-2\ell+1)\\&-(m-\ell-1)(m-2\ell)\Big\}+\ell\Big\{(m-\ell-K-1)(m-2\ell+2)\\&-(m-\ell+1)(m-2\ell+1)\Big\}\Big\}\Big/\prod_{k=m-\ell-(K+1)}^{m-\ell+1}k\\=&(-1)^{K+2+\ell}\frac{K!(K+1)!}{\ell!(K+2-\ell)!}(K+2)(K+1)(m-2\ell+1)\Big/\prod_{k=m-\ell-(K+1)}^{m-\ell+1}k,\end{aligned}$$

agreeing with (4.14). The proof of the induction step when $\ell = 0$ or $\ell = K+2$ is similar. Hence the result follows by induction. ∎

LEMMA 4.9. *Let $n \in \mathbb{N}_0$ and $y \in \mathbb{R}^4$, $|y| < 1$. For $p \in \mathbb{N}$ let*

$$\widehat{g}_p(y) = \sum_{m=1}^{p} \sum_{\ell=0}^{\min\{\lfloor m/2 \rfloor, n+1\}} c_{m,\ell}^n |y|^{2\ell} \chi_{m-2\ell}(y). \tag{4.15}$$

If $p > 2n$, then

$$\left| |I-y|^{2n} \ln |I-y|^2 - \widehat{g}_p(y) \right| \le \frac{2^{n+1} n! (p+2)^2}{(p+1-n)\cdots(p-2n)} \frac{|y|^{p+1}}{1-|y|}.$$

Proof. By Lemma 4.7,

$$\left| |I-y|^{2n} \ln |I-y|^2 - \widehat{g}_p(y) \right| \le \left| \sum_{m=p+1}^{\infty} \sum_{\ell=0}^{n+1} c_{m,\ell}^n |y|^{2\ell} \chi_{m-2\ell}(y) \right|. \tag{4.16}$$

Then using Lemma 4.8 the magnitude of all the terms of order $|y|^m$ can be estimated by

$$\begin{aligned}
&\left| \sum_{\ell=0}^{n+1} c_{m,\ell}^n |y|^{2\ell} \chi_{m-2\ell}(y) \right| \\
&\qquad \le \sum_{\ell=0}^{n+1} \frac{(m-\ell-n-1)!}{(m-\ell+1)!} (m-2\ell+1) n! \binom{n+1}{\ell} (m-2\ell+1) |y|^m \\
&\qquad \le n! |y|^m \sum_{\ell=0}^{n+1} \frac{(m-2\ell+1)^2}{(m-\ell+1)\cdots(m-\ell-n)} \binom{n+1}{\ell}, \\
&\qquad \le n! |y|^m q_n(m) \sum_{\ell=0}^{n+1} \binom{n+1}{\ell} \\
&\qquad = n! 2^{n+1} |y|^m q_n(m),
\end{aligned}$$

where

$$q_n(m) = \frac{(m+1)^2}{\big(m-n\big)\big(m-(n+1)\big)\cdots\big(m-(2n+1)\big)}. \tag{4.17}$$

The function $q_n(m)$ is positive and decreasing in m for $m > 2n+1$. Hence the right-hand side of (4.16) can be estimated as

$$\begin{aligned}
\left| \sum_{m=p+1}^{\infty} \sum_{\ell=0}^{n+1} c_{m,\ell}^n |y|^{2\ell} \chi_{m-2\ell}(y) \right| &\le \sum_{m=p+1}^{\infty} \left| \sum_{\ell=0}^{n+1} c_{m,\ell}^n |y|^{2\ell} \chi_{m-2\ell}(y) \right| \\
&\le \sum_{m=p+1}^{\infty} n! 2^{n+1} |y|^m q_n(m) \\
&\le 2^{n+1} n! q_n(p+1) \frac{|y|^{p+1}}{1-|y|}. \qquad ∎
\end{aligned}$$

The full expansion and error bound. Combining the results from (4.7), Lemma 4.5, and Lemma 4.7, the function

$$\Phi_{x_<}(x) = |x - x_<|^{2n} \ln |x - x_<|^2$$

may be approximated by the truncated series

$$g_p(x) = \ln |x|^2 \sum_{m=0}^{n} |x|^{2m} \sum_{\ell=0}^{n-m} b_{m,\ell}^n |x_<|^{2\ell} \chi_{n-m-\ell}(x^* x_<) + |x|^{2n} \widehat{g}_p(x^{-1} x_<),$$

where $\widehat{g}_p$ is defined in (4.15). Then from Lemma 4.9 we obtain the error bound

$$\left|\Phi_{x_<}(x) - g_p(x)\right| \le |x|^{2n} \frac{2^{n+1} n! (p+2)^2}{(p+1-n)\cdots(p-2n)} \frac{|x^{-1}x_<|^{p+1}}{1 - |x^{-1}x_<|}$$

for $|x| > |x_<|$. Since $p > 2n$ this bound is increasing in $|y| = |x_<|/|x|$. We can apply the bound to each center x_k in turn and sum. This gives the following.

THEOREM 4.10. *Suppose $x_k \in \mathbb{R}^4$, $|x_k| \le r$, and $d_k \in \mathbb{R}$ for each $1 \le k \le N$. Let s be the $(n+2)$-harmonic spline*

$$s(x) = \sum_{k=1}^{N} d_k |x - x_k|^{2n} \ln |x - x_k|^2.$$

Furthermore, let $B_{m,\ell}$ be the $(n-m-\ell+1) \times (n-m-\ell+1)$ matrix

$$B_{m,\ell} = \left[B_{i,j}^{m,\ell}\right]_{i,j=0}^{n-m-\ell} = b_{m,\ell}^n \sum_{k=1}^{N} d_k |x_k|^{2\ell} \big(T_{n-m-\ell}(x_k^*)\big),$$

and let $C_{m,\ell}$ be the $(m-2\ell+1) \times (m-2\ell+1)$ matrix

$$C_{m,\ell} = \left[C_{i,j}^{m,\ell}\right]_{i,j=0}^{m-2\ell} = c_{m,\ell}^n \sum_{k=1}^{N} d_k |x_k|^{2\ell} \big(T_{m-2\ell}(x_k)\big),$$

where the coefficients $b_{m,\ell}^n$ and $c_{m,\ell}^n$ are given recursively by (4.9) *and* (4.13)*, respectively. Let $p \in \mathbb{N}$, $p > 2n$, and set*

(4.18)

$$\begin{aligned} g_p(x) &= \ln |x|^2 \sum_{m=0}^{n} \sum_{\ell=0}^{n-m} \sum_{i,j=0}^{n-m-\ell} B_{j,i}^{m,\ell} |x|^{2m} t_{i,j}^{n-m-\ell}(x) \\ &\qquad + \sum_{\ell=0}^{n+1} \sum_{m=\max\{1,2\ell\}}^{p} \sum_{i,j=0}^{m-2\ell} C_{j,i}^{m,\ell} |x|^{2(n+1-\ell)} o_{i,j}^{m-2\ell}(x) \\ &= \ln |x|^2 \sum_{m=0}^{n} |x|^{2m} \sum_{\ell=0}^{n-m} \operatorname{Tr}\big(B_{m,\ell} T_{n-m-\ell}(x)\big) \\ &\qquad + \sum_{\ell=0}^{n+1} \sum_{m=\max\{1,2\ell\}}^{p} |x|^{2(n+1-\ell)} \operatorname{Tr}\big(C_{m,\ell} O_{m-2\ell}(x)\big), \end{aligned}$$

$x \in \mathbb{R}^4 \backslash \{0\}$. Then for all x with $|x| > r$

$$\left|s(x) - g_p(x)\right| \le M r^{2n} \frac{(p+2)^2 2^{n+1} n!}{(p+1-n)\cdots(p-2n)} \left(\frac{1}{c}\right)^{p-2n+1} \frac{1}{1-1/c},$$

where $M = \sum_{k=1}^{N} |d_k|$ and $c = |x|/r$.

5. Uniqueness. In this section we will prove that the truncated expansions, g_p, appearing in (4.4) and (4.18) are the only functions of these forms achieving the stated asymptotic accuracy in approximating s as $|x| \to \infty$. These uniqueness results will allow us to form far field expansions in an inexpensive indirect manner, knowing that the expansions so obtained are identical with, and enjoy the same error estimates as, the computationally expensive directly formed expansions.

LEMMA 5.1. *Let $p \in \mathbb{N}_0$. Suppose a function $\widetilde{g}_p$ defined for $x \in \mathbb{R}^4 \backslash \{0\}$ can be written in the form*

$$\widetilde{g}_p(x) = \ln|x|^2 \sum_{m=0}^{n} \sum_{\ell=0}^{n-m} \sum_{i,j=0}^{n-m-\ell} \widetilde{B}_{j,i}^{m,\ell} |x|^{2m} t_{i,j}^{n-m-\ell}(x) + \sum_{\ell=0}^{n+1} \sum_{m=\max\{1,2\ell\}}^{p} \sum_{i,j=0}^{m-2\ell} \widetilde{C}_{j,i}^{m,\ell} |x|^{2(n+1-\ell)} o_{i,j}^{m-2\ell}(x), \tag{5.1}$$

where the various coefficients are complex numbers. Then

(i) *The coefficients $\{\widetilde{B}_{j,i}^{m,\ell}\}$ and $\{\widetilde{C}_{j,i}^{m,\ell}\}$ are uniquely determined by the function $\widetilde{g}_p$.*

(ii) *If $p > 2n$ and*

$$|\widetilde{g}_p(x)| = o(|x|^{2n-p}) \qquad \text{as } |x| \to \infty,$$

then $\widetilde{g}_p$ is identically zero.

Proof. We will need to use the fundamental properties of the inner and outer functions developed in section 3. Recall that $t_{i,j}^m$ is homogeneous of order m and $\{t_{i,j}^m : 0 \le i,j \le m,\ 0 \le m \le q\}$ is an orthogonal set of nontrivial spherical harmonics on the unit sphere $\mathcal{S}^3$. The definition of the outer functions (2.12)

$$o_{i,j}^m(z,w) = |x|^{-(2m+2)} t_{i,j}^m(\overline{z}, -w)$$

then implies that $o_{i,j}^m$ is homogeneous of order $-(m+2)$ and $\{o_{i,j}^m : 0 \le i,j \le m,\ 0 \le m \le q\}$ is linearly independent on $\mathcal{S}^3$.

Now fix $p \in \mathbb{N}_0$ and consider a function of the form (5.1). Rearrange the finite sum $\widetilde{g}_p$ by grouping together terms of the same growth at infinity, and arranging the groups in order of decreasing growth at infinity. The order of magnitude of $\widetilde{g}_p$ as $|x| \to \infty$ will be the same as that of the first nonzero group of terms.

Fix an integer k and denote the sum of the group of terms of growth $|x|^k \ln|x|$ by L_k. Thus

$$L_k(x) = \ln|x|^2 \sum_{m=0}^{n} \sum_{\ell=0}^{n-m} \sum_{i,j=0}^{n-m-\ell} \delta_{k,n+m-\ell} \widetilde{B}_{j,i}^{m,\ell} |x|^{2m} t_{i,j}^{n-m-\ell}(x).$$

Restricting attention to those terms for which the delta function is nonzero, we see that among these a particular inner function $t_{i',j'}^{k'}$ can arise only when $k' = k - 2m$ and thus can arise at most once. Hence by the linear independence of $\{t_{i,j}^m : 0 \le i,j \le m,\ 0 \le m \le n\}$ on $\mathcal{S}^3$, $L_k(x)$ is identically zero for all $x \ne 0$ if and only if

$$\delta_{k,n+m-\ell} \widetilde{B}_{j,i}^{m,\ell} = 0$$

for all $m = 0, \dots, n$; $\ell = 0, \dots, n-m$; $i, j = 0, \dots, n-m-\ell$. Similarly, the sum of the group of terms of growth $|x|^k$ at infinity is

$$G_k(x) = \sum_{\ell=0}^{n+1} \sum_{m=\max\{1,2\ell\}}^{p} \sum_{i,j=0}^{m-2\ell} \delta_{k,2n-m} \widetilde{C}_{j,i}^{m,\ell} |x|^{2(n+1-\ell)} o_{i,j}^{m-2\ell}.$$

Fix k and restrict attention to those terms for which the delta function is nonzero. A particular outer function $o_{i',j'}^{m'}$ can arise only when $m' = 2n-k-2\ell$. Since k and n are fixed this happens for at most one value of ℓ, and hence at most once. Thus by the linear independence of $\{o_{i',j'}^{m'} : 0 \le i', j' \le m',\ 0 \le m' \le q\}$ on $\mathcal{S}^3$, $G_k(x)$ is identically zero for all $x \neq 0$ if and only if

$$\delta_{k,2n-m} \widetilde{C}_{j,i}^{m,\ell} = 0$$

for all $\ell = 0, \dots, n+1$; $m = \max\{1, 2\ell\}, \dots, p$; $i, j = 0, \dots, m$.

For (ii) just note that if $p > 2n$, then $o(|x|^{2n-p}) \to 0$ so no terms can appear in the $\ln|x|^2$ summand, as each of those terms do not decay. Each term in the second summand is homogeneous of order $2n - m \ge 2n - p$. But the decay rate $o(|x|^{2n-p})$ precludes these terms from occurring, i.e., $\widetilde{g}_p = 0$. ∎

A simpler argument based on the same ideas shows the following.

LEMMA 5.2. *Let $p \in \mathbb{N}_0$. Suppose a function $\widetilde{g}_p$ defined for $x \in \mathbb{R}^4 \backslash \{0\}$ can be written in the form*

$$\widetilde{g}_p(x) = \sum_{m=0}^{p} \sum_{i,j=0}^{m} \widetilde{C}_{j,i}^{m}\, o_{i,j}^{m}(x).$$

Then

(i) *The coefficients $\{\widetilde{C}_{j,i}^{m}\}$ are uniquely determined by the function $\widetilde{g}_p$.*

(ii) *If*

$$|\widetilde{g}_p(x)| = o(|x|^{-(p+2)}) \qquad \text{as } |x| \to \infty,$$

then $\widetilde{g}_p$ is identically zero.

6. Translation of expansions. In this section we develop formulae which enable us to obtain a truncated expansion about one center indirectly from a truncated expansion about another. The operation count for this translation operation depends only on the order of the original expansion, not upon the number of centers x_k underlying it. In contrast, the operation count for direct expansion of a cluster is $\mathcal{O}(N(n+1)p^3)$, where N is the number of centers in the cluster. Thus indirect formation of expansions can be more efficient than direct expansion when the number of centers in a particular cluster is large and truncated expansions of subclusters are available.

For any matrix $A = (a_{i',j'})$, denote by $A|_{i,j}^{m}$ the $(m+1) \times (m+1)$ submatrix of A which begins at the (i, j) position, i.e.,

$$(A|_{i,j}^{m})_{i',j'} = a_{i+i',j+j'}, \qquad i', j' = 0, \dots, m.$$

THEOREM 6.1 (outer to outer or inner translation). *Let $x, x_< \in \mathbb{H}_0^1$, be such that $0 < |x_<| < |x|$. Then*

$$o_{i,j}^{m}(x - x_<) = \sum_{m'=0}^{\infty} \operatorname{Tr}\left(E(m, m', i) O_{m+m'}(x) \Big|_{i,j}^{m'} T_{m'}(x_<) \right), \tag{6.1}$$

where $E(m,m',i)$ *is the* $(m'+1)\times(m'+1)$ *diagonal matrix with entries*

$$e(m,m',i)_{i',i'} = \binom{i+i'}{i}\binom{m+m'-(i+i')}{m-i}.$$

Proof. Using Lemma 4.1, Lemma 2.9, and the relationship (3.17) between the outer functions and the operators $R^m_{i,j}$,

$$\begin{aligned}
o^m_{i,j}(x-x_<) = R^m_{i,j}\frac{1}{|x-x_<|^2} &= R^m_{i,j}\sum_{m'=0}^{\infty}\operatorname{Tr}\left(O_{m'}(x)T_{m'}(x_<)\right)\\
&= R^m_{i,j}\sum_{m'=0}^{\infty}\sum_{i',j'=0}^{m'} o^{m'}_{i',j'}(x)t^{m'}_{j',i'}(x_<)\\
&= R^m_{i,j}\sum_{m'=0}^{\infty}\sum_{i',j'=0}^{m'} t^{m'}_{j',i'}(x_<)R^{m'}_{i',j'}\frac{1}{|x|^2}\\
&= \sum_{m'=0}^{\infty}\sum_{i',j'=0}^{m'} t^{m'}_{j',i'}(x_<)R^m_{i,j}R^{m'}_{i',j'}\frac{1}{|x|^2}\\
&= \sum_{m'=0}^{\infty}\sum_{i',j'=0}^{m'} t^{m'}_{j',i'}(x_<)e(m,m',i)_{i',i'}R^{m+m'}_{i+i',j+j'}\frac{1}{|x|^2}\\
&= \sum_{m'=0}^{\infty}\sum_{i',j'=0}^{m'} e(m,m',i)_{i',i'}o^{m+m'}_{i+i',j+j'}(x)t^{m'}_{j',i'}(x_<)\\
&= \sum_{m'=0}^{\infty}\operatorname{Tr}\left(E(m,m',i)O_{m+m'}(x)\Big|^{m'}_{i,j}T_{m'}(x_<)\right),
\end{aligned}$$

where the differentiation term by term is justified by the real analyticity. ∎

This theorem is sufficient to translate a far field expansion of the type in (4.4). In particular consider an expansion like (4.4) but centered on $x_< \neq 0$. Then

$$\begin{aligned}
g_p(x-x_<) &= \sum_{m=0}^{p}\sum_{i,j=0}^{m} C^m_{j,i}\, o^m_{i,j}(x-x_<)\\
&= \sum_{m=0}^{p}\sum_{i,j=0}^{m} C^m_{j,i}\sum_{m'=0}^{\infty}\sum_{i',j'=0}^{m'} e(m,m',i)_{i',i'}o^{m+m'}_{i+i',j+j'}(x)t^{m'}_{j',i'}(x_<)\\
&= \sum_{m=0}^{p}\sum_{i,j=0}^{m} D^m_{j,i}\, o^m_{i,j}(x) + \mathcal{O}(|x|^{-(p+3)}),
\end{aligned} \tag{6.2}$$

where the coefficients $D^m_{j,i}$ are defined by the "convolution"

$$\binom{m}{i}D^m_{j,i} = \sum_{m'=0}^{m}\binom{m}{m'}\sum_{i',j'=0}^{m'}\binom{m-m'}{i-i'}t^{m-m'}_{j-j',i-i'}(x_<)\binom{m'}{i'}C^{m'}_{j',i'}. \tag{6.3}$$

Thus

$$h_p(x) = \sum_{m=0}^{p}\sum_{i,j=0}^{m} D^m_{j,i}\, o^m_{i,j}(x)$$

approximates $g_p(x)$ with error of order $\mathcal{O}(|x|^{-(p+3)})$ as $|x| \to \infty$. But by Theorem 4.2 the series formed directly, u_p, is of the same form and shares the same order of approximation. Hence the difference $u_p(x) - h_p(x)$ is $\mathcal{O}(|x|^{-(p+3)})$ as $|x| \to \infty$, and by the uniqueness theorem, Lemma 5.2, u_p and h_p are identical.

Furthermore, Theorem 6.1 is sufficient to translate an expansion of the form (6.2) into a Taylor series about 0 (a Maclaurin series). Since the functions $o^m_{i,j}$ are homogenous of degree m,

$$o^m_{i,j}(x - x_<) = (-1)^m o^m_{i,j}(x_< - x).$$

This simple observation allows the roles of x and $x_<$ to be switched in the application of Theorem 6.1. Starting with g_p defined by (6.2) and proceeding in this manner, we obtain

$$\begin{aligned} g_p(x - x_<) &= \sum_{m'=0}^{p} \sum_{i',j'=0}^{m'} C^{m'}_{j',i'} (-1)^{m'} o^{m'}_{i',j'}(x_< - x) \\ &= \sum_{m'=0}^{p} \sum_{i',j'=0}^{m'} (-1)^{m'} C^{m'}_{j',i'} \sum_{m=0}^{\infty} \sum_{i,j=0}^{m} e(m', m, i')_{i,i} o^{m+m'}_{i+i',j+j'}(x_<) t^m_{j,i}(x) \\ &= \sum_{m=0}^{p} \sum_{i,j=0}^{m} F^m_{j,i}\, t^m_{i,j}(x) + \mathcal{O}(|x|^{p+1}) \quad \text{as } |x| \to 0, \end{aligned}$$

where the coefficients $F^m_{j,i}$ are given by the "correlation"

(6.4)
$$\binom{m}{j}^{-1} F^m_{j,i} = \sum_{m'=0}^{p} \binom{m+m'}{m} \sum_{i',j'=0}^{m'} \binom{m+m'}{j+j'}^{-1} o^{m+m'}_{j+j',i+i'}(x_<)\, (-1)^{m'} \binom{m'}{j'} C^{m'}_{i',j'}.$$

Then by the characterization of the Maclaurin polynomial q of degree p for a function f as the only polynomial of total degree p with

$$|f(x) - q(x)| = o(|x|^p) \qquad \text{as } |x| \to 0,$$

it follows that

$$q(\cdot) = \sum_{m=0}^{p} \sum_{i,j=0}^{m} F^m_{j,i}\, t^m_{i,j}(\cdot). \tag{6.5}$$

THEOREM 6.2 (inner-to-inner translation formula). *For all $x, x_< \in \mathbb{R}^4$, $m \in \mathbb{N}_0$, and $0 \le i, j \le m$,*

$$t^m_{i,j}(x - x_<) = \sum_{m'=0}^{m} \sum_{\substack{i'=\max\{0,i-(m-m')\} \\ j'=\max\{0,j-(m-m')\}}}^{\substack{i'=\min\{i,m'\} \\ j'=\min\{j,m'\}}} (-1)^{m-m'} \binom{m-j}{m'-j'} \binom{j}{j'} t^{m-m'}_{i-i',j-j'}(x_<) t^{m'}_{i',j'}(x).$$

Proof. Because the functions $\left\{t^{m'}_{i',j'} : 0 \le i', j' \le m',\ 0 \le m' \le m\right\}$ form a basis for harmonic homogenous polynomials of degree at most m, and since $t^m_{i,j}(\cdot - x_<)$ is such a polynomial,

$$t^m_{i,j}(x - x_<) = \sum_{m'=0}^{m} \sum_{i',j'=0}^{m'} a^{m,m'}_{i,i',j,j'} t^{m'}_{i',j'}(x)$$

for some coefficients $a^{m,m'}_{i,i',j,j'}$ that depend on $x_<$. Applying the functionals $\lambda^{m''}_{i'',j''}$ of Lemma 3.10 to this expression gives

$$\binom{j}{j''}\binom{m-j}{m''-j''} t^{m-m''}_{i-i'',j-j''}(-x_<) = a^{m,m''}_{i,i'',j,j''}.$$

Since $(-1)^{m-m''}$ factors out by the homogeneity of $t^{m-m''}_{i-i'',j-j''}$, the result follows once we recall that the left-hand side is zero unless $j'' \le j$, $j - j'' \le m - m''$, $i'' \le i$, and $i - i'' \le m - m''$. ∎

This theorem may be used to translate a polynomial expansion such as (6.5). For example, if

$$q(x) = \sum_{m'=0}^{p} \sum_{i',j'=0}^{m'} F^{m'}_{j',i'}\, t^{m'}_{i',j'}(x - x_<), \tag{6.6}$$

then by Theorem 6.2 we get

$$\begin{aligned} q(x) &= \sum_{m'=0}^{p} \sum_{i',j'=0}^{m'} F^{m'}_{j',i'} \sum_{m=0}^{m'} \sum_{i,j=0}^{m} (-1)^{m'-m} \binom{m'-j'}{m-j} \binom{j'}{j} t^{m'-m}_{i'-i,j'-j}(x_<) t^{m}_{i,j}(x) \\ &= \sum_{m=0}^{p} \sum_{i,j=0}^{m} G^{m}_{j,i}\, t^{m}_{i,j}(x), \end{aligned}$$

where the coefficients $G^m_{j,i}$ are given by the "convolution"

$$\binom{m}{j}^{-1} G^m_{j,i} = \sum_{m'=0}^{p} \binom{m'}{m} \sum_{i',j'=0}^{m'} \binom{m'}{j'}^{-1} F^{m'}_{j',i'}\, (-1)^{m'-m} \binom{m'-m}{j'-j} t^{m'-m}_{i'-i,j'-j}(x_<). \tag{6.7}$$

It should be noted that this is an exact recentering of the polynomial q.

Just as we were able to translate expansions of the form (6.2), we want to be able to translate expansions like (4.18). One of our tools will be formulae for the products of z, w, $\overline{z}$, or $\overline{w}$ with a single inner or single outer function. These multiplication rules are contained in Lemmas 6.3 and 6.4 below.

LEMMA 6.3. *For $m \ge 0$ and $0 \le i, j \le m$,*

$$z\ o^m_{i,j}(z,w) = \frac{i+1}{m+1}\ |x|^2 o^{m+1}_{i+1,j+1}(z,w) + \frac{m-j}{m+1}\ o^{m-1}_{i,j}(z,w), \tag{6.8a}$$

$$w\ o^m_{i,j}(z,w) = -\frac{m+1-i}{m+1}\ |x|^2 o^{m+1}_{i,j+1}(z,w) + \frac{m-j}{m+1}\ o^{m-1}_{i-1,j}(z,w), \tag{6.8b}$$

$$\overline{z}\ o^m_{i,j}(z,w) = \frac{m+1-i}{m+1}\ |x|^2 o^{m+1}_{i,j}(z,w) + \frac{j}{m+1}\ o^{m-1}_{i-1,j-1}(z,w), \tag{6.8c}$$

$$\overline{w}\ o^m_{i,j}(z,w) = \frac{i+1}{m+1}\ |x|^2 o^{m+1}_{i+1,j}(z,w) - \frac{j}{m+1}\ o^{m-1}_{i,j-1}(z,w). \tag{6.8d}$$

Proof. First assume $m > 0$. Differentiate (2.13) with respect to $\overline{z}$. For the

right-hand side we obtain

$$\begin{aligned}(m-j)z_1(z_1\overline{z}+z_2\overline{w})^{m-1-j}(z_1(-w)+z_2z)^j&\\ &= (m-j)z_1|x|^{2m}\sum_{i=0}^{m-1} z_1^{m-1-i}z_2^i o_{i,j}^{m-1}(z,w)\\ &= (m-j)|x|^{2m}\sum_{i=0}^{m-1} z_1^{m-i}z_2^i o_{i,j}^{m-1}(z,w). \qquad (6.9)\end{aligned}$$

Since $|x|^2 = z\overline{z}+w\overline{w}$, for the left-hand side we have

$$\begin{aligned}&z(m+1)|x|^{2m}\sum_{i=0}^{m} z_1^{m-i}z_2^i o_{i,j}^m(z,w) + |x|^{2(m+1)}\sum_{i=0}^{m} z_1^{m-i}z_2^i\frac{\partial}{\partial\overline{z}}o_{i,j}^m(z,w) \qquad (6.10)\\ &= z(m+1)|x|^{2m}\sum_{i=0}^{m} z_1^{m-i}z_2^i o_{i,j}^m(z,w) - |x|^{2(m+1)}\sum_{i=0}^{m} z_1^{m-i}z_2^i(i+1)o_{i+1,j+1}^{m+1}(z,w),\end{aligned}$$

where we have used (3.13d) to evaluate $\frac{\partial}{\partial\overline{z}}o_{i,j}^m$. By considering the coefficient of $z_1^{m-i}z_2^i$ in (6.9) and (6.10) we see that

$$(m-j)o_{i,j}^{m-1}(z,w) = z(m+1)o_{i,j}^m(z,w) - |x|^2(i+1)o_{i+1,j+1}^{m+1}(z,w)$$

for $0\le i,j\le m$, which proves (6.8a)

By differentiating (2.13) with respect to $\overline{w}$, z, and w, in a similar manner we obtain (6.8b), (6.8c), and (6.8d), respectively, for $m>0$. The special case of $m=0$ for (6.8) follows directly from $o_{0,0}^0 = |x|^{-2}$ and the recurrence relations (3.8). □

Substituting (2.12) into (6.8) leads to a similar result for the inner functions. Specifically, we have the following.

LEMMA 6.4. *For $m\ge 0$ and $0\le i,j\le m$,*

$$z\ t_{i,j}^m(z,w) = \frac{m+1-i}{m+1}\ t_{i,j}^{m+1}(z,w) + \frac{j}{m+1}\ |x|^2 t_{i-1,j-1}^{m-1}(z,w), \qquad (6.11a)$$

$$w\ t_{i,j}^m(z,w) = \frac{m+1-i}{m+1}\ t_{i,j+1}^{m+1}(z,w) - \frac{m-j}{m+1}\ |x|^2 t_{i-1,j}^{m-1}(z,w), \qquad (6.11b)$$

$$\overline{z}\ t_{i,j}^m(z,w) = \frac{i+1}{m+1}\ t_{i+1,j+1}^{m+1}(z,w) + \frac{m-j}{m+1}\ |x|^2 t_{i,j}^{m-1}(z,w), \qquad (6.11c)$$

$$\overline{w}\ t_{i,j}^m(z,w) = -\frac{i+1}{m+1}\ t_{i+1,j}^{m+1}(z,w) + \frac{j}{m+1}\ |x|^2 t_{i,j-1}^{m-1}(z,w). \qquad (6.11d)$$

Since $t_{i,j}^m = 0$ and $o_{i,j}^m = 0$ if $m<0$, multiple applications of Lemma 6.3 and Lemma 6.4 may be used to obtain the following.

COROLLARY 6.5. *Let p be a given homogenous polynomial of degree m' in z, $\overline{z}$, w, and $\overline{w}$. Then to each inner function $t_{i,j}^m$ there correspond constants $\{F_{i',j'}^{\ell'}\}$ and to each outer function $o_{i,j}^m$ there correspond constants $\{G_{i',j'}^{\ell'}\}$ such that*

$$p(z,\overline{z},w,\overline{w})\ t_{i,j}^m(x) = \sum_{\ell'=0}^{\min\{m',\lfloor(m+m')/2\rfloor\}} |x|^{2\ell'} \sum_{i',j'=0}^{m+m'-2\ell'} F_{i',j'}^{\ell'} t_{i',j'}^{m+m'-2\ell'}(x),$$

$$p(z,\overline{z},w,\overline{w})\ o_{i,j}^m(x) = \sum_{\ell'=0}^{\min\{m',\lfloor(m+m')/2\rfloor\}} |x|^{2(m'-\ell')} \sum_{i',j'=0}^{m+m'-2\ell'} G_{i',j'}^{\ell'} o_{i',j'}^{m+m'-2\ell'}(x).$$

We now demonstrate how these results may be used to translate a truncated far field series, such as (4.18), due to a polyharmonic spline. Let g_p be such a series with center of expansion at $x_<$, i.e.,

$$g_p(x) = \ln|x-x_<|^2 \sum_{\ell=0}^{n} |x-x_<|^{2\ell} \left\{ \sum_{m=0}^{n-\ell} \sum_{i,j=0}^{n-\ell-m} B_{j,i}^{\ell,m} t_{i,j}^{n-\ell-m}(x-x_<) \right\} + \sum_{\ell=0}^{n+1} |x-x_<|^{2(n+1-\ell)} \left\{ \sum_{m=\max\{1,2\ell\}}^{p} \sum_{i,j=0}^{m-2\ell} C_{j,i}^{\ell,m} o_{i,j}^{m-2\ell}(x-x_<) \right\}. \tag{6.12}$$

The translations of objects such as those in the two sets of curly braces has been discussed already. The terms in the first set may be translated via Theorem 6.2 in much the same way as (6.6) was translated. The terms in the second set of braces may be translated using Theorem 6.1 in a similar manner to (6.2). Let $\{\widetilde{B}_{j,i}^{\ell,m}\}$ and $\{\widetilde{C}_{j,i}^{\ell,m}\}$ be the translated coefficients. Then

$$g_p(x) = \ln|x-x_<|^2 \sum_{\ell=0}^{n} |x-x_<|^{2\ell} \left\{ \sum_{m=0}^{n-\ell} \sum_{i,j=0}^{n-\ell-m} \widetilde{B}_{j,i}^{\ell,m} t_{i,j}^{n-\ell-m}(x) \right\} + \sum_{\ell=0}^{n+1} |x-x_<|^{2(n+1-\ell)} \left\{ \sum_{m=\max\{1,2\ell\}}^{p} \sum_{i,j=0}^{m-2\ell} \widetilde{C}_{j,i}^{\ell,m} o_{i,j}^{m-2\ell}(x) \right\} + \mathcal{O}(|x|^{-(p+1-2n)}). \tag{6.13}$$

Recall that

$$|x-x_<|^2 = |x|^2 - 2\langle x, x_<\rangle + |x_<|^2 = |x|^2 - (z\overline{z_<} + \overline{z}z_< + w\overline{w_<} + \overline{w}w_<) + |x_<|^2.$$

Thus we may use Lemma 6.4 to "translate" any product of the form $|x-x_<|^2 t_{i',j'}^{m'}(x)$ into a sum of at most ten terms of the form $|x|^{2\ell''} t_{i'',j''}^{m''}(x)$, where the coefficients of those terms depend on $x_<$. An analogous procedure employing Lemma 6.3 translates a product of the form $|x-x_<|^2 o_{i',j'}^{m'}(x)$ into a sum of at most ten terms of the form $|x|^{2\ell''} o_{i'',j''}^{m''}(x)$. Applying this procedure repeatedly to (6.13) viewed as a nested product

$$f_0(x) + |x-x_<|^2\Big(f_1(x) + |x-x_<|^2\Big(f_2(x) + \cdots + |x-x_<|^2\Big(f_n(x) + |x-x_<|^2 f_{n+1}(x)\Big)\cdots\Big)\Big)$$

brings g_p to the form

$$g_p(x) = \ln|x-x_<|^2 \sum_{\ell=0}^{n} |x|^{2\ell} \sum_{m=0}^{n-\ell} \sum_{i,j=0}^{n-\ell-m} \widetilde{\widetilde{B}}_{j,i}^{\ell,m}\ t_{i,j}^{n-\ell-m}(x) + \sum_{\ell=0}^{n+1} |x|^{2(n+1-\ell)} \sum_{m=\max\{1,2\ell\}}^{p} \sum_{i,j=0}^{m-2\ell} \widetilde{\widetilde{C}}_{j,i}^{\ell,m}\ o_{i,j}^{m-2\ell}(x) + \mathcal{O}(|x|^{-(p+1-2n)}) \tag{6.14}$$

with only the $\ln|x-x_<|^2$ term left untranslated. This step in the translation costs $\mathcal{O}((n+1)^2(p+1)^3)$ operations. This is acceptable since n is small, typically $n \le 2$, and the number of terms in the series to be translated is $\mathcal{O}((n+1)(p+1)^3)$.

By Theorem 4.10,

$$\ln|x-x_<|^2 = \ln|x|^2 + \sum_{\ell'=0}^{1} |x|^{2-2\ell'} \sum_{m'=\max\{1,2\ell'\}}^{p'} \sum_{i',j'=0}^{m'-2\ell'} D^{\ell',m'}_{j',i'}(x_<) o^{m'-2\ell'}_{i',j'}(x) + \mathcal{O}(|x|^{-(p'+1)}).$$

Substituting this into (6.14) gives

(6.15)
$$g_p(x) = \ln|x|^2 \sum_{\ell=0}^{n} |x|^{2\ell} \sum_{m=0}^{n-\ell} \sum_{i,j=0}^{n-\ell-m} \widetilde{\widetilde{B}}^{\ell,m}_{j,i}\ t^{n-\ell-m}_{i,j}(x) + F_{x_<}(x) + \sum_{\ell=0}^{n+1} |x|^{2(n+1-\ell)} \sum_{m=\max\{1,2\ell\}}^{p} \sum_{i,j=0}^{m-2\ell} \widetilde{\widetilde{C}}^{\ell,m}_{j,i}\ o^{m-2\ell}_{i,j}(x) + \mathcal{O}(|x|^{-(p+1-2n)}),$$

where $F_{x_<}(x)$ is given by the product

(6.16)
$$\left\{ \sum_{\ell=0}^{n} |x|^{2\ell} \sum_{m=0}^{n-\ell} \sum_{i,j=0}^{n-\ell-m} \widetilde{\widetilde{B}}^{\ell,m}_{j,i}\ t^{n-\ell-m}_{i,j}(x) \right\} \times \left\{ \sum_{\ell'=0}^{1} |x|^{2-2\ell'} \sum_{m'=\max\{1,2\ell'\}}^{p'} \sum_{i',j'=0}^{m'-2\ell'} D^{\ell',m'}_{j',i'}(x_<) o^{m'-2\ell'}_{i',j'}(x) \right\}$$

after it has been truncated by removing terms that are $\mathcal{O}(|x|^{-(p+1-2n)})$ as $|x| \to \infty$. From Corollary 6.5, (6.16) can be written in the form

$$\sum_{\ell=0}^{n+1} |x|^{2(n+1-\ell)} \sum_{m=\max\{1,2\ell\}}^{p} \sum_{i,j=0}^{m-2\ell} \widetilde{D}^{\ell,m}_{j,i} o^{m-2\ell}_{i,j}(x).$$

This completes the translation.

SPACE-TIME PERIODIC SOLUTIONS AND LONG-TIME BEHAVIOR OF SOLUTIONS TO QUASI-LINEAR PARABOLIC EQUATIONS*

G. BARLES† AND P. E. SOUGANIDIS‡

Abstract. This paper considers (i) the existence of space-time periodic solutions of quasi-linear parabolic equations and (ii) the convergence, as $t \to \infty$, of space periodic solutions of the initial value problem of quasi-linear parabolic equations to the space-time periodic solutions.

Key words. asymptotic behavior, space-time periodic solutions, quasi-linear parabolic equations, strong maximum principle, viscosity solutions

1. Introduction.

In this article, we are interested in the following two questions about space-time periodic quasi-linear parabolic equations: (i) the existence of space-time periodic solutions and (ii) the asymptotic behavior as $t \to \infty$ of the solutions of the initial value problem for quasi-linear parabolic equations in the periodic setting.

Concerning the first question, the typical result is that there exists a unique $\lambda \in \mathbb{R}$ such that the equation

$$\phi_t - \mathrm{tr}(A(x,t,D\phi)D^2\phi) + H(x,t,D\phi) + \lambda = 0 \quad \text{in } \mathbb{R}^N \times \mathbb{R} \tag{1.1}$$

has a space-time periodic solution $\phi : \mathbb{R}^N \times \mathbb{R} \to \mathbb{R}$ provided A and H are space-time periodic in (x,t). It is necessary, of course, to impose a number of conditions on A and H; these are stated later.

The second question is about the asymptotic behavior, as $t \to +\infty$, of the solution of the initial value problem

$$\begin{cases} u_t - \mathrm{tr}(A(x,t,Du)D^2u) + H(x,t,Du) = 0 & \text{in } \mathbb{R}^N \times (0,+\infty), \\ u(x,0) = u_0(x) & \text{in } \mathbb{R}^N \times \{0\} \end{cases} \tag{1.2}$$

with $u_0 \in W^{1,\infty}(\mathbb{R}^N)$ and periodic. The type of result expected here is that, as $t \to \infty$,

$$u(x,t) - \lambda t - \phi(x,t) \to 0 \quad \text{uniformly in } \mathbb{R}^N, \tag{1.3}$$

where ϕ is a space-time periodic solution of (1.1).

To explain the results we obtain here, we consider first the model case in which $A(x,t,p) \equiv$ Id, i.e., the case where (1.1) has the form

$$\phi_t - \Delta\phi + H(x,t,D\phi) + \lambda = 0 \quad \text{in } \mathbb{R}^N \times \mathbb{R} \tag{1.4}$$

with H a space-time periodic, continuous function.

A classical method for proving the existence of ϕ and λ consists in considering the problem

$$\phi_t^\epsilon - \Delta\phi^\epsilon + H(x,t,D\phi^\epsilon) + \epsilon\phi^\epsilon = 0 \quad \text{in } \mathbb{R}^N \times \mathbb{R}\,. \tag{1.5}$$

Under suitable assumptions on H, the existence of a space-time periodic solution of (1.5) follows easily from the maximum principle and the fixed point theorem for contraction maps. The problem then is to let $\epsilon \to 0$. Although the family $(\phi^\epsilon)_{\epsilon>0}$ does not converge in general, the goal is to show the existence of a constant c_ϵ such that $\phi^\epsilon(x,t) - c_\epsilon$ converges, locally uniformly, at least along a subsequence, and that ϵc_ϵ converges to the constant λ. In most cases it suffices to choose the constant $c_\epsilon = \phi^\epsilon(x_0,t_0)$ for some $(x_0,t_0) \in \mathbb{R}^N \times \mathbb{R}$, although occasionally other choices are more suitable.

In order to obtain this type of behavior for the family $(\phi^\epsilon)_{\epsilon>0}$, it is necessary to establish a gradient bound. In the case at hand, this will be a bound on $D\phi^\epsilon$ and not on ϕ_t^ϵ. This is where the properties of H play a key role. We consider two cases, which we call *sublinear* and *superlinear*, despite the fact that the terminology is not completely accurate.

In the *sublinear case* the gradient bound comes from the ellipticity of the equation, i.e., from the Δ-term in (1.4). To obtain this gradient bound, it is necessary to impose certain growth conditions on $H(x,t,p)$ with respect to p, which are, in fact, a bit more general than sublinearity. Our approach here is inspired by the method of Ishii and Lions [10] (see also Barles [2]).

On the contrary, in the *superlinear case* the gradient bound comes from the H-term. Therefore, our approach can handle cases of degenerate parabolic equations and even first-order Hamilton–Jacobi equations. The main tool here is the "weak Bernstein-type arguments" introduced in Barles [1].

It is worth mentioning that the main difficulty in obtaining gradient bounds is the fact that we cannot use any L^∞-bounds on the ϕ^ϵ. In fact the opposite is true. The gradient bounds will be used to deduce some kind of L^∞-bounds on ϕ^ϵ, namely, bounds on $\phi^\epsilon - c_\epsilon$. As a matter of fact, and this is perhaps a little bit surprising, the gradient bound in x is enough to get the full answer, i.e., the convergence of $\phi^\epsilon - c_\epsilon$ along subsequences. In particular, no bounds on ϕ_t^ϵ are needed.

The approach described above yields rather general existence results of space-time periodic solutions both for (1.4) and (1.1). Unfortunately our results on the asymptotic behavior as $t \to +\infty$ of the solutions of (1.2) are proved under far more restrictive assumptions. In fact, the key ingredient will be the strong maximum principle, which will require in the case of (1.1)–(1.2) the smoothness of solutions. It is therefore necessary to impose appropriate assumptions on A and H in order to be able to prove the needed regularity. In particular, we are able to treat only the uniformly parabolic case. It is worth remarking here that in the completely degenerate case, i.e., when $A = 0$, it is not true that solutions of (1.2) converge as $t \to \infty$ to solutions of (1.1), as was shown recently by Fathi and Mather [8] and Barles and Souganidis [3]. Of course, more classical results can be used for (1.4) and the study of the asymptotic behavior of the solution of the associated initial value problem.

The existence of space-time periodic solutions for parabolic equations has been studied in Namah and Roquejoffre [17] using different methods and, in particular, degree theory. The main assumption of [17] is that H in (1.2) depends on u, which implies that (1.3) holds with an exponential rate of convergence. Roquejoffre [18], [19]

also considered the case of first-order Hamilton–Jacobi equations with strictly convex nonlinearity and obtained asymptotic results using the approach of [16]. Finally, when $A \equiv 0$, the existence of λ and of a space-time periodic solution of (1.1) was also studied in Majda and Souganidis [15] as a step in the study of some models in turbulent combustion.

The existence of a space-time periodic solution of parabolic equations is also related to the ergodic properties of stochastic processes in space-time environments, for example, the existence of principal eigenvalues for uniformly parabolic space-time periodic operators. Such questions have been looked at in different contexts by a number of authors but not in the generality of this paper. We refer to Freidlin [9], Sinai [20], and the references therein.

The paper is organized as follows. In section 2 we consider the case of the model equation (1.4). Section 3 is devoted to the extensions to the general equation (1.1). In section 4 we provide the asymptotic results for (1.2).

2. The model equation.

2.1. The sublinear case.

The main assumption on H is

$$\text{(H1)} \qquad \begin{cases} H \in C(\mathbb{R}^N \times \mathbb{R} \times \mathbb{R}^N) \text{ is } [0,\Lambda]^N \times [0,T]\text{-space-time periodic, and} \\ \text{there exists a continuous function } \chi : [0,+\infty) \to \mathbb{R} \text{ such that} \\ \displaystyle\int^{+\infty} \chi(u)^{-1} du = +\infty \text{ and } |H(x,t,p)| \le \chi(|p|) \text{ in } \mathbb{R}^N \times \mathbb{R} \times \mathbb{R}^N. \end{cases}$$

THEOREM 2.1. *Assume* (H1). *Then there exists at least one solution* (ϕ, λ) *of* (1.4), *where* ϕ *is a continuous space-time periodic function and* $\lambda \in \mathbb{R}$. *The constant* λ *is unique. Moreover, if* H *is locally Lipschitz continuous in* p, *then* ϕ *is unique up to constants.*

Proof. 1. The uniqueness of λ, which is classical even in the context of viscosity solutions theory (see, for example, Lions, Papanicolaou, and Varadhan [14] or, in a slightly different context, Lions [13]), follows from the maximum principle. The up to constants uniqueness of ϕ is not true in general. Here it follows from the strong maximum principle.

2. The existence is based on a priori estimates on the gradient of the space-time periodic solution ϕ^ϵ of the equation

$$\phi_t^\epsilon - \Delta\phi^\epsilon + H(x,t,D\phi^\epsilon) + \epsilon\phi^\epsilon = 0 \quad \text{in } \mathbb{R}^N \times \mathbb{R}. \tag{2.1}$$

□

The key result is the following lemma.

LEMMA 2.2. *If* (H1) *holds and* ϕ^ϵ *is a continuous, space-time periodic solution of* (2.1), *then there exists* $K > 0$ *depending only on* H *such that*

$$\sup_{t \in \mathbb{R}} \|D\phi^\epsilon(\cdot,t)\|_\infty \le K.$$

Proof. 1. Consider the

$$\max_{\mathbb{R}^N \times \mathbb{R}^N \times \mathbb{R}} \left[\phi^\epsilon(x,t) - \phi^\epsilon(y,t) - \psi(|x-y|)\right]$$

for a suitable increasing concave function $\psi : [0,+\infty) \to \mathbb{R}$ such that $\psi(0) = 0$. This is indeed a maximum, since ϕ^ϵ is (x,t)-periodic and ψ is increasing. Hence the max is achieved in the set

$$Q_\Lambda = \{(x,y,t) : |x-y| \le 2\Lambda, t \in [0,T]\}.$$

It follows that ψ has to be built only on $[0, 2\Lambda]$, and then it suffices to extend it to $[0, +\infty)$ by keeping it increasing and concave. To this end, if χ is the function given by (H1), we choose ψ to be a solution of

$$2\psi'' = -\chi(\psi') \quad \text{on } (0, 2\Lambda), \quad \psi(0) = 0$$

with $\psi' > 0$ on $[0, 2\Lambda]$. Since ψ' can be defined by

$$2\int_{\psi'(s)}^{K} \chi(u)^{-1} du = s,$$

it follows from (H1) that, if K is chosen large enough, ψ satisfies all the above requirements.

2. If the max is zero—note that it is always nonnegative—then, for all x, y, t,

$$\phi^\epsilon(x,t) - \phi^\epsilon(y,t) \le \psi(|x-y|) \le K|x-y|,$$

the last inequality being a consequence of the concavity of ψ.

3. If the max is positive, let $(\overline{x}, \overline{y}, \overline{t})$ be the point where it is achieved. It follows that $\overline{x} \neq \overline{y}$. Then classical results from the theory of viscosity solutions (see the user's guide by Crandall, Ishii, and Lions [7]) yield the existence of $a \in \mathbb{R}$ and symmetric matrices X, Y such that $(a, p, X) \in D^{2,+}\phi^\epsilon(\overline{x}, \overline{t})$, $(a, p, Y) \in D^{2,-}\phi^\epsilon(\overline{y}, \overline{t})$ and

$$\begin{pmatrix} X & 0 \\ 0 & -Y \end{pmatrix} \le \psi'(|\overline{x}-\overline{y}|) \begin{pmatrix} B & -B \\ -B & B \end{pmatrix} + \psi''(\overline{x}-\overline{y}) \begin{pmatrix} q\otimes q & -q\otimes q \\ -q\otimes q & q\otimes q \end{pmatrix}, \tag{2.2}$$

where $p = |\overline{x}-\overline{y}|^{-1}\psi'(|\overline{x}-\overline{y}|)(\overline{x}-\overline{y})$, $q = |\overline{x}-\overline{y}|^{-1}(\overline{x}-\overline{y})$, and $B = |\overline{x}-\overline{y}|^{-1}(I - q\otimes q)$.

Applying (2.2) to any $\mathbb{R}^{2N}$-vector of the form (r, r) with $r \in \mathbb{R}^N$ gives

$$X \le Y.$$

To obtain the gradient bounds, we follow Ishii and Lions [10] and apply (2.2) to $(q, -q)$ using that $Bq = 0$. It follows that

$$(Xq, q) - (Yq, q) \le 4\psi''(|\overline{x}-\overline{y}|)\ .$$

Combining the above we obtain

$$\operatorname{tr}(X) - \operatorname{tr}(Y) \le 4\psi''(|\overline{x}-\overline{y}|)\ . \tag{2.3}$$

On the other hand, the viscosity inequalities for (2.1) read

$$a - \operatorname{tr}(X) + H(\overline{x}, \overline{t}, p) + \epsilon\phi^\epsilon(\overline{x}, \overline{t}) \le 0 \quad \text{and} \quad a - \operatorname{tr}(Y) + H(\overline{y}, \overline{t}, p) + \epsilon\phi^\epsilon(\overline{y}, \overline{t}) \ge 0.$$

Subtracting these last two inequalities and using (2.3) together with (H1) gives

$$-4\psi''(|\overline{x}-\overline{y}|) - 2\chi(\psi'(|\overline{x}-\overline{y}|)) + \epsilon[\phi^\epsilon(\overline{x}, \overline{t}) - \phi^\epsilon(\overline{y}, \overline{t})] \le 0.$$

Since $2\psi'' = -\chi(\psi')$ and $\phi^\epsilon(\overline{x}, \overline{t}) - \phi^\epsilon(\overline{y}, \overline{t}) > 0$ (otherwise the maximum would be negative), this is a contradiction. Hence the maximum is always zero, and the claim follows by step 2. □

Remark 2.3. The above proof does not use the L^∞-norm of ϕ^ϵ. The gradient bound is therefore independent of $\|\phi^\epsilon\|_\infty$ and will be used even to provide an L^∞-bound on $\phi^\epsilon - c_\epsilon$.

The next step is the following lemma.

LEMMA 2.4. *There exists a continuous, space-time periodic solution of* (1.4).

Proof. 1. Define the function

$$H^K(x,t,p) = \begin{cases} H(x,t,p) & \text{if } |p| \le K, \\ \\ H\Big(x,t,K|p|^{-1}p\Big) & \text{if } |p| \ge K, \end{cases}$$

where K is the constant given by Lemma 2.2. It follows that H^K satisfies (H1) with the same function χ as H.

2. Consider the problem

$$\phi_t^{\epsilon,K} - \Delta\phi^{\epsilon,K} + H^K(x,t,D\phi^{\epsilon,K}) + \epsilon\phi^{\epsilon,K} = 0 \quad \text{in } \mathbb{R}^N \times \mathbb{R}, \tag{2.4}$$

which can be seen as a stationary equation set in $\mathbb{R}^N \times \mathbb{R}$.

If $M = \|H^K(x,t,0)\|_\infty = \|H(x,t,0)\|_\infty$, then $-\epsilon^{-1}M$ and $\epsilon^{-1}M$ are, respectively, sub- and supersolutions of (2.4). Moreover, the special dependence of H^K in p allows for a comparison result between discontinuous sub- and supersolutions of (2.4). Since the supremum of space-time periodic subsolutions is itself space-time periodic, Perron's method (see the user's guide by Crandall, Ishii, and Lions [7]) leads to the existence of a space-time periodic solution of (2.4) satisfying

$$-\epsilon^{-1}M \le \phi^{\epsilon,K}(x,t) \le \epsilon^{-1}M \ \text{ in } \mathbb{R}^N \times \mathbb{R}. \tag{2.5}$$

We conclude by observing that Lemma 2.2 clearly implies that $\phi^\epsilon = \phi^{\epsilon,K}$ is a solution of (2.1) as well.

3. In order to let $\epsilon \to 0$, set $\lambda_\epsilon = \epsilon\phi^\epsilon(0,0)$ and consider the function

$$\underline{\phi}^\epsilon(x,t) = \phi^\epsilon(x,t) - \phi^\epsilon(0,0),$$

which solves the initial value problem

$$\begin{cases} \underline{\phi}_t^\epsilon - \Delta\underline{\phi}^\epsilon + H(x,t,D\underline{\phi}^\epsilon) + \epsilon\underline{\phi}^\epsilon + \lambda_\epsilon = 0 & \text{in } \mathbb{R}^N \times (0,+\infty), \\ \\ \underline{\phi}^\epsilon(x,0) = \phi^\epsilon(x,0) - \phi^\epsilon(0,0) & \text{in } \mathbb{R}^N. \end{cases} \tag{2.6}$$

The gradient bound and the space-time periodicity of ϕ^ϵ implies an independent of ϵ, L^∞-bound on $\underline{\phi}^\epsilon(x,0)$, and this together with (2.5)—which provides the boundedness of λ_ϵ—yields the existence of subsequences, which, for notational simplicity, are also denoted by ϵ such that $\lambda_\epsilon \to \lambda \in \mathbb{R}$ and $\underline{\phi}^\epsilon(x,0)$ converges uniformly in $\mathbb{R}^N$.

Since ϕ^ϵ is Lipschitz continuous in x, the comparison result for (2.6) yields, for any $\epsilon_1, \epsilon_2 > 0$,

$$\sup_{0\le t\le T} \|\underline{\phi}^{\epsilon_1}(\cdot,t) - \underline{\phi}^{\epsilon_2}(\cdot,t)\|_\infty \le \|\underline{\phi}^{\epsilon_1}(x,0) - \underline{\phi}^{\epsilon_2}(x,0)\|_\infty + T|\lambda_{\epsilon_1} - \lambda_{\epsilon_2}|.$$

Hence the family $(\underline{\phi}^\epsilon)_{\epsilon>0}$ converges uniformly in $\mathbb{R}^N \times [0,T]$ to ϕ, which, in view of the stability result for viscosity solutions, is a solution of

$$\phi_t - \Delta\phi + H(x,t,D\phi) + \lambda = 0 \ \text{ in } \mathbb{R}^N \times (0,T).$$

Moreover, ϕ is x-periodic with $\phi(x,T) = \phi(x,0)$ for any $x \in \mathbb{R}^N$. Extending ϕ for $t \in \mathbb{R}$ by periodicity provides the desired solution. ∎

2.2. The superlinear case.

The main assumption here is that

$$\text{(H2)}\quad \begin{cases} H \in C(\mathbb{R}^N \times \mathbb{R} \times \mathbb{R}^N) \text{ is } [0,\Lambda]^N \times [0,T] \text{ space-time periodic in } \mathbb{R}^N \times \mathbb{R}. \\ \text{Moreover, for all } t \in \mathbb{R},\ (x,p) \mapsto H(x,t,p) \text{ is locally Lipschitz continuous} \\ \text{on } \mathbb{R}^N \times \mathbb{R}^N, \text{ and there exists } L > 0 \text{ such that, for all } |p| \geq L, x \in \mathbb{R}^N, \\ t \in \mathbb{R}, \\ \qquad (H_p \cdot p - H - \|H(x,t,0)\|_\infty)L - |H_x| \geq 0. \end{cases}$$

Assumption (H2) is typically satisfied by a nonlinearity H of the form

$$H(x,t,p) = a(x,t)|p|^{1+\beta} + f(x,t),$$

where $\beta > 0$ (superlinear growth), $a, f \in C(\mathbb{R}^N \times \mathbb{R}) \cap L^\infty(\mathbb{R}, W^{1,\infty}(\mathbb{R}^N))$ are $[0,\Lambda]^N \times [0,T]$ space-time periodic in $\mathbb{R}^N \times \mathbb{R}$, and there exists $\eta > 0$ such that

$$a \geq \eta > 0 \quad \text{on } \mathbb{R}^N \times \mathbb{R}.$$

The result is the following theorem.

THEOREM 2.5. *The results of Theorem* 2.1 *hold if we replace* (H1) *by* (H2).

The proof of Theorem 2.5 follows the structure of the proof of Theorem 2.1. The only difference is the way that the gradient bound on the solution of (2.1) is obtained. Indeed in Theorem 2.1 the gradient bound clearly came from the Laplacian, while here it will come from the H term.

The key is the following lemma.

LEMMA 2.6. *If* (H2) *holds, ϕ^ϵ is a continuous, space-time periodic solution of* (2.1)*, and $w^\epsilon : \mathbb{R}^N \times \mathbb{R} \to \mathbb{R}$ is defined by*

$$\exp(w^\epsilon) = \phi^\epsilon - \min_{\mathbb{R}^N \times \mathbb{R}} \phi^\epsilon + 1,$$

then, for the L given in (H2)*,*

$$\sup_{t \in \mathbb{R}} \|Dw^\epsilon\|_{L^\infty(\mathbb{R}^N)} \leq L.$$

We continue with a brief sketch of the proof of Theorem 2.5 using Lemma 2.6.

Proof of Theorem 2.5. We follow the proof of Theorem 2.1 and, in particular, of Lemma 2.4 with the modifications we describe below.

Since ϕ^ϵ is continuous and space-time periodic, there exists (x_ϵ, t_ϵ) such that

$$\phi^\epsilon(x_\epsilon, t_\epsilon) = \min_{\mathbb{R}^N \times \mathbb{R}} \phi^\epsilon.$$

Set $\lambda_\epsilon = \epsilon \phi^\epsilon(x_\epsilon, t_\epsilon)$ and consider the function

$$\underline{\phi}^\epsilon(x,t) = \phi^\epsilon(x,t) - \phi^\epsilon(x_\epsilon, t_\epsilon)\ ,$$

which solves the initial value problem

$$\text{(2.7)}\quad \begin{cases} \underline{\phi}^\epsilon_t - \Delta \underline{\phi}^\epsilon + H(x,t,D\underline{\phi}^\epsilon) + \epsilon \underline{\phi}^\epsilon + \lambda_\epsilon = 0 & \text{in } \mathbb{R}^N \times (t_\epsilon, t_\epsilon + T), \\ \underline{\phi}^\epsilon(x,t_\epsilon) = \phi^\epsilon(x,t_\epsilon) - \phi^\epsilon(x_\epsilon, t_\epsilon) & \text{on } \mathbb{R}^N. \end{cases}$$

Since $w^\epsilon(x_\epsilon, t_\epsilon) = 0$, the gradient bound of Lemma 2.6 and the space periodicity of w^ϵ yield, independent of ϵ, an L^∞-bound for $w^\epsilon(\cdot, t_\epsilon)$, and, therefore, for $\underline{\phi}^\epsilon(\cdot, t_\epsilon)$.

Moreover, the comparison result for (2.7) yields

$$\sup_{t_\epsilon \le t \le t_\epsilon + T} \|\underline{\phi}(\cdot, t)\|_\infty \le \|\underline{\phi}^\epsilon(\cdot, t_\epsilon)\|_\infty + T(M + |\lambda_\epsilon|),$$

where M is defined as in the proof of Lemma 2.4.

Since $|\lambda_\epsilon| \le M$ and because $\underline{\phi}^\epsilon$ is time-periodic, the inequality above provides, independent of ϵ and t, an L^∞-bound for $\underline{\phi}^\epsilon$ and w^ϵ which, together with the bound on Dw^ϵ, also implies such a bound for $\|D\underline{\phi}^\epsilon\|_\infty$.

Finally, the existence of ϕ^ϵ and ϕ follows from the same standard approximation arguments as in the proof of Lemma 2.4. □

Proof of Lemma 2.6. 1. The function w^ϵ solves

$$w_t^\epsilon - \Delta w^\epsilon - |Dw^\epsilon|^2 + b(x, t, w^\epsilon, Dw^\epsilon) = 0 \quad \text{in } \mathbb{R}^N \times \mathbb{R},$$

where

$$b(x, t, u, p) = \exp(-u) H(x, t, \exp(u)p) + \epsilon + \epsilon(m_\epsilon - 1)\exp(-u)$$

and

$$m_\epsilon = \min_{\mathbb{R}^N \times \mathbb{R}} \phi^\epsilon.$$

2. Next consider

$$\max_{\mathbb{R}^N \times \mathbb{R}} (w^\epsilon(x, t) - w^\epsilon(y, t) - L|x - y|),$$

where L is given by (H2). By the same arguments as in the proof of Lemma 2.2, this is indeed a maximum, since w^ϵ is space-time periodic and continuous, it is achieved at $(\overline{x}, \overline{y}, \overline{t})$, and it is nonnegative. If the max is zero, the desired gradient bound follows.

3. If the max is positive, then $\overline{x} \neq \overline{y}$. As in the proof of Lemma 2.2, there exist $a \in \mathbb{R}$ and symmetric matrices X, Y such that $(a, p, X) \in D^{2,+} w^\epsilon(\overline{x}, \overline{t})$ and $(a, p, Y) \in D^{2,-} w^\epsilon(\overline{y}, \overline{t})$ with $p = |\overline{x} - \overline{y}|^{-1} L(\overline{x} - \overline{y})$.

Subtracting the viscosity inequalities

$$a - X - |p|^2 + b(\overline{x}, \overline{t}, w^\epsilon(\overline{x}, \overline{t}), p) \le 0 \quad \text{and} \quad a - Y - |p|^2 + b(\overline{y}, \overline{t}, w^\epsilon(\overline{y}, \overline{t}), p) \ge 0$$

and using that $X \le Y$ yields

$$b(\overline{x}, \overline{t}, w^\epsilon(\overline{x}, \overline{t}), p) - b(\overline{y}, \overline{t}, w^\epsilon(\overline{y}, \overline{t}), p) \le 0.$$

4. To simplify the presentation, we argue next as if H and, therefore, b were C^1 functions. A complete, rigorous proof can be made by standard regularization and approximation arguments.

For $s \in [0, 1]$, set

$$X_s = (s\overline{x} + (1 - s)\overline{y}, \overline{t}, s w^\epsilon(\overline{x}, \overline{t}) + (1 - s) w^\epsilon(\overline{y}, \overline{t}), p)$$

and rewrite the last inequality as

$$b(X_1) - b(X_0) = \int_0^1 \frac{d}{ds}[b(X_s)] ds \le 0 \,,$$

i.e.,

$$\int_0^1 [b_x(X_s)\cdot(\overline{x}-\overline{y}) + b_u(X_s)(w^\epsilon(\overline{x},\overline{t}) - w^\epsilon(\overline{y},\overline{t}))]ds \le 0\ . \tag{2.8}$$

Straightforward computations yield

$$b_x(x,t,u,p) = \exp(-u)H_x(x,t,\exp(u)p)$$

and

$$b_u(x,t,u,p) = \exp(-u)\left[H_p\cdot p - H\right](x,t,\exp(u)p) - \epsilon(m_\epsilon - 1)\exp(-u)\ .$$

5. Since $\|\epsilon\phi^\epsilon\|_{L^\infty(\mathbb{R}^N\times\mathbb{R})} \le \|H(x,t,0)\|_\infty$, it follows that $\epsilon m_\epsilon \le \|H(x,t,0)\|_\infty$ and, therefore,

$$b_u(X_s) > \exp(-u)\Big[H_p\cdot p - H - \|H(x,t,0)\|_\infty\Big](x,t,\exp(u)p).$$

6. Since by definition $w^\epsilon \ge 0$, we have

$$u = sw^\epsilon(\overline{x},\overline{t}) + (1-s)w^\epsilon(\overline{y},\overline{t}) \ge 0,$$

hence

$$\exp(u)|p| \ge L, \tag{2.9}$$

and, in view of (H2),

$$b_u(X_s) > 0.$$

Finally, the assumption that the max is positive gives

$$w^\epsilon(\overline{x},\overline{t}) - w^\epsilon(\overline{y},\overline{t}) > L|\overline{x}-\overline{y}|.$$

Combining all the above information we obtain

$$b_u(X_s)(w^\epsilon(\overline{x},\overline{t})-w^\epsilon(\overline{y},\overline{t})) > \exp(-u)\big[H_p\cdot p - H - \|H(x,t,0)\|_\infty\big](x,t,\exp(u)p)L|\overline{x}-\overline{y}|.$$

7. If

$$Q = [b_x(X_s)\cdot(\overline{x}-\overline{y}) + b_u(X_s)(w^\epsilon(\overline{x},\overline{t}) - w^\epsilon(\overline{y},\overline{t}))]\ ,$$

then

$$\begin{aligned} Q &> \exp(-u)|\overline{x}-\overline{y}|\left[H_x\cdot\frac{\overline{x}-\overline{y}}{|\overline{x}-\overline{y}|} + (H_p\cdot p - H - \|H(x,t,0)\|_\infty)L\right] \\ &> \exp(-u)|\overline{x}-\overline{y}|\left[(H_p\cdot p - H - \|H(x,t,0)\|_\infty)L - |H_x|\right]. \end{aligned}$$

Using (H2) and recalling (2.9) yields the strict positivity of the integral of (2.8), which provides the desired contradiction. □

Remark 2.7. The argument used in the proof of Lemma 2.6 follows along the lines of Barles [1], which introduced a "weak" Bernstein method to obtain gradient bounds on solutions of fully nonlinear PDEs. Here the difference is that L^∞-bounds on the w^ϵ cannot be used, and this is a nontrivial additional difficulty.

3. Extensions to quasi-linear equations. In this section we provide two existence results of continuous, space-time periodic solutions of (1.1). They correspond to the sub- and superlinear cases presented in the previous section. We omit their proofs, since they are only routine adaptations of the proofs of Theorems 2.1 and 2.5, although they involve more tedious computations. In what follows $\mathcal{M}_{N,M}$ denotes the space of $N \times M$ matrices and $\mathcal{M}_N$ denotes the space of $N \times N$ matrices.

Throughout the section we assume

$$\text{(H3)} \qquad \begin{cases} A \in C(\mathbb{R}^N \times \mathbb{R} \times \mathbb{R}^N, S^N) \text{ and } H \in C(\mathbb{R}^N \times \mathbb{R} \times \mathbb{R}^N) \\ \\ \text{are } [0,\Lambda]^N \times [0,T] \text{ space-time periodic.} \end{cases}$$

For the *sublinear case*, we introduce the following additional hypotheses:

$$\text{(H4)} \qquad \begin{cases} \text{There exists a } \mu : \mathbb{R} \to (0,\infty) \text{ and a constant } C > 0 \text{ such that, for all} \\ (x,t,p) \in \mathbb{R}^N \times \mathbb{R} \times \mathbb{R}^N, \\ \\ \qquad C^{-1}\mu(|p|)\mathrm{Id} \le A(x,t,p) \le C\mu(|p|)\mathrm{Id}, \end{cases}$$

$$\text{(H5)} \qquad \begin{cases} \text{there exist } \sigma \in C(\mathbb{R}^N \times \mathbb{R} \times \mathbb{R}^N; \mathcal{M}_N),\ \theta \in \left(\tfrac{1}{2}, 1\right], \text{ and } C > 0 \text{ such that} \\ \\ \qquad A = \sigma\sigma^T \text{ and } |\sigma(x,t,p) - \sigma(y,t,p)| \le C\mu^{1/2}(|p|)|x-y|^\theta, \end{cases}$$

and

$$\text{(H6)} \qquad \begin{cases} \text{there exists } \chi \in C(\mathbb{R}^+, \mathbb{R}^+) \text{ such that } \displaystyle\int^{+\infty} \chi(u)^{-1} du = +\infty, \text{ and} \\ \\ |H(x,t,p)| \le \mu(|p|)\chi(|p|) \text{ for all } (x,t,p) \in \mathbb{R}^N \times \mathbb{R} \times \mathbb{R}^N. \end{cases}$$

Our result is the following theorem.

THEOREM 3.1. *Assume that* (H3)–(H6) *hold. Then there exists a solution* (ϕ, λ) *of* (1.1)*, where* ϕ *is a continuous space-time periodic function. Moreover, the constant* λ *is unique.*

The proof of Theorem 3.1 follows exactly along the lines of the one of Theorem 2.1. Assumption (H5) is used both to get a gradient bound on the ϕ^ϵ and to have a comparison result available for the PDE satisfied by ϕ^ϵ. The gradient bound by itself can be obtained with weaker assumptions. We refer to Barles [2] for discussions in this direction.

For the *superlinear case* we introduce the following assumptions:

$$\text{(H7)} \qquad \begin{cases} \text{There exists a locally Lipschitz continuous function} \\ \\ \sigma : \mathbb{R}^N \times \mathbb{R} \times \mathbb{R}^N \to \mathcal{M}_{N,p} \text{ such that } A = \sigma\sigma^T, \end{cases}$$

and

$$\text{(H8)} \qquad \begin{cases} H \text{ is locally Lipschitz continuous with respect to } (x,p) \text{ for all } t \in \mathbb{R}, \\ H_p \cdot p - H \to +\infty \text{ as } |p| \to +\infty \text{ uniformly with respect to } (x,t), \\ \text{and, as } |p| \to \infty, \\ \\ \qquad A_p \cdot p|p|^2,\ (\sigma_p \cdot p)^2|p|^2 = o(H_p \cdot p - H), \\ \\ \qquad (A_x \cdot p)^2,\ (A_x \cdot p)|p|,\ H_x \cdot p = o((H_p \cdot p - H)|p|). \end{cases}$$

THEOREM 3.2. *Under assumptions* (H3), (H7), *and* (H8), *the conclusions of Theorem* 2.1 *remain valid.*

In Theorem 3.2, the gradient estimate is obtained following the method of proof (or by using directly the result) of Barles [1, Theorem 2, p. 265]) after an exponential change of variable is performed, as in the proof of Theorem 2.5. It is necessary, however, to control carefully the dependence of all the terms in w^ϵ since, again, we have no a priori L^∞-bound on w^ϵ.

4. Convergence as $t \to \infty$ to space-time periodic solutions.

Our main result is the following theorem.

THEOREM 4.1. *Under the assumptions of Theorem* 3.1 *or* 3.2, *for any* $u_0 \in W^{1,\infty}(\mathbb{R}^N)$ $[0,\Lambda]^N$*-periodic in* x, *there exists a unique solution* u *of* (1.2), *which is in* $W^{1,\infty}(\mathbb{R}^N)$ *for any* $t > 0$ *and* $[0,\Lambda]^N$*-periodic in* x. *Moreover,* $u(x,t) - \lambda t$ *is uniformly bounded. If* (1.2) *satisfies the strong maximum principle, then* (1.3) *holds for some* $[0,\Lambda]^N \times [0,T]$*-space-time periodic solution of* (1.1).

We will return to the assumption that (1.2) satisfies the strong maximum principle after the short proof of Theorem 4.1. We want, however, just to point out here that this assumption implies the uniqueness of ϕ up to constants.

Proof. 1. The existence of u relies essentially on the same arguments as the existence of the space-time periodic solution ϕ of (1.1). The uniqueness uses in an essential way the boundedness of Du.

2. Since $u(x,t) - \lambda t$ and ϕ are solutions in $\mathbb{R}^N \times (0,+\infty)$ of the same equation, a standard comparison principle yields

$$\|u(x,t) - \lambda t - \phi(x,t)\|_\infty \le \|u_0(x) - \phi(x,0)\|_\infty,$$

and, therefore, $u(x,t) - \lambda t$ remains bounded in L^∞. This also leads to an easier gradient bound for $u(x,t) - \lambda t$.

3. Setting $v(x,t) = u(x,t) - \lambda t$, applying the same comparison result on $\mathbb{R}^N \times (t,+\infty)$ instead of $\mathbb{R}^N \times (0,\infty)$, and using that ϕ is T-periodic in time yields, for $s \ge t$,

$$\max_x (v(x,s) - \phi(x,s)) \le \max_x (v(x,t) - \phi(x,t)).$$

Therefore,

$$m(t) = \max_x (v(x,t) - \phi(x,t))$$

is decreasing, and, since $m(t)$ is bounded,

$$m(t) \to \overline{m} \quad \text{as } t \to +\infty.$$

4. The sequence $(v(\cdot,kT))_k$ is compact in $C(\mathbb{R}^N)$. Therefore, using the periodicity in x, it is possible to extract a subsequence, which for notational simplicity is also denoted $(v(\cdot,kT))_k$, converging uniformly to $\overline{v} \in W^{1,\infty}(\mathbb{R}^N)$. Moreover, the comparison result for viscosity solution yields

$$\|v(\cdot,t+kT) - v(\cdot,t+\widehat{k}T)\|_\infty \le \|v(\cdot,kT) - v(\cdot,\widehat{k}T)\|_\infty \to 0 \quad \text{as } k,\widehat{k} \to +\infty.$$

Hence $v(x,t+kT) \to w(x,t)$, which is, by the stability of viscosity solution, a solution of

$$(4.1) \quad \begin{cases} w_t - \operatorname{tr}(A(x,t,Dw)D^2w) + H(x,t,Dw) + \lambda = 0 & \text{in } \mathbb{R}^N \times (0,+\infty), \\ w(x,0) = \overline{v}(x) & \text{in } \mathbb{R}^N. \end{cases}$$

5. Passing to the limit in

$$m(t+kT) = \max_x (v(x,t+kT) - \phi(x,t))$$

and using the uniform convergence of the $v(\cdot,\cdot+kT)$ yields

$$\overline{m} = \max_x (w(x,t) - \phi(x,t)) \quad \text{for any } t > 0.$$

The strong maximum principle then implies that

$$w = \phi + \overline{m}.$$

An easy argument then gives (1.3) with ϕ replaced by $\phi + \overline{m}$. Indeed, on one hand, since $\overline{v} = \phi + \overline{m}$ is the only possible limit of any subsequence of the sequence $(v(\cdot,kT))_k$, it follows that $v(\cdot,kT) \to \phi(\cdot,0) + \overline{m}$. On the other hand, for t large, we consider the integer k such that $kT \le t < (k+1)T$. A standard comparison result together with the time periodicity of ϕ yields

$$\begin{aligned} \|u(x,t) - \lambda t - [\phi(x,t) + \overline{m}]\|_\infty &= \|v(x,t) - [\phi(x,t) + \overline{m}]\|_\infty \\ &\le \|v(x,kT) - \phi(x,kT)\|_\infty \\ &= \|v(x,kT) - [\phi(x,0) + \overline{m}]\|_\infty \to 0 \\ &\quad \text{as } t \to +\infty. \qquad \square \end{aligned}$$

Next we turn to the question, When is the strong maximum principle satisfied by (4.1)? In fact there are two very different cases, depending on whether A depends on p or not.

When A *does not depend on* p, the strong maximum principle can easily be established, using rather soft arguments, in the general framework of viscosity solutions. In fact, in addition to the uniform ellipticity of the equation, it requires only the basic assumptions of a classical comparison result together with a suitable hypothesis on the Lipschitz continuity of H with respect to p. More precise assumptions will be given below. It is, however, worth pointing out that, since we deal here with solutions which are Lipschitz continuous in x, these assumptions are rather weak. In particular, in this case, no deep regularity result on the solutions is needed and as a consequence the strong maximum principle can be applied to equations where the solutions are not classical.

On the contrary, if A *depends on* p, to the best of our knowledge, the strong maximum principle holds only for classical solutions, and therefore a regularity result for the solutions of (4.1) is needed. The form of the equation and the classical parabolic theory suggest that it is enough to have solutions which are $C^{1,\alpha}$ in x. Indeed then Schauder's theory yields $C^{2,1}$ solutions for (4.1), where $C^{2,1}$ is the space of functions which are C^2 in x and C^1 in t. The strong maximum principle then follows.

There has been a substantial body of work about the question of $C^{1,\alpha}$ regularity of solutions of fully nonlinear, uniformly elliptic/parabolic PDEs (see, for example, Caffarelli [4], Caffarelli and Cabré [5], Crandall et al. [6], Krylov [11], Wang [21], [22], etc.). There are basically two approaches. The first uses difference quotients for viscosity solutions and yields $C^{1,\alpha}$ bounds. The required assumptions do not, however, cover quasi-linear equations, when A depends on Dw. The second approach deals with general fully nonlinear problems and yields $C^{1,\alpha}$ bounds for smooth, say, C^3-solutions, for which there is not, however, in general, existence.

It turns out that for (4.1) under the assumptions (H3)–(H6) or (H3), (H7), and (H8) which yield a priori Lipschitz estimates, the gap described above can be closed when (H4) holds. Indeed, as soon as one has a priori bounds on the gradient, the theory developed in Chapter VI of Ladyzenskaja, Solonnikov, and Ural'ceva [12] provides a $C^{1,\alpha}$-bound on the solutions which then yields a $C^{2,\alpha}$-bound by the classical regularity theory. The existence of a space-time periodic, classical solution then follows from a straightforward truncation of A and H. Moreover, this solution is uniformly bounded and even compact in $C^{2,1}$ equipped with the natural norm.

Now we come back to the original convergence problem. In the statement of our result below, in the case when A is independent of p, we will say that A satisfies assumptions (H′4) and (H′5) if (H4) and (H5) hold with σ being independent of p and $\mu(|p|)$ being replaced by a constant $\tilde{\mu} > 0$.

The above discussion on the strong maximum principle and the existence of $C^{2,1}$-solutions together with Theorem 4.1 leads to the following theorem.

THEOREM 4.2. *Assume that either* (i) *A is independent of p and satisfies* (H3), (H′4), (H′5) *and that H is locally Lipschitz continuous with respect to p, uniformly in x and t, or* (ii) *A and H are locally Lipschitz continuous functions satisfying* (H3) *and* (H4). *If the assumptions of Theorem* 3.1 *or* 3.2 *are satisfied, then, for any $u_0 \in W^{1,\infty}(\mathbb{R}^N)$ which is $[0,\Lambda]^N$-periodic in x, there exists a unique solution u of* (1.2), *which is in $W^{1,\infty}(\mathbb{R}^N)$ for any $t > 0$, is $[0,\Lambda]^N$-periodic in x, and* (1.3) *holds for some $[0,\Lambda]^N \times [0,T]$-space-time periodic solution of* (1.1).

A REMARK ON ISOPOLAR POTENTIALS*

MACIEJ ZWORSKI†

Abstract. We discuss the inverse problem for resonances of one-dimensional potentials.

Key words. resonances, inverse problems

AMS subject classifications. 34L25, 81U40

PII. S0036141000375585

1. In the approach to scattering by compactly supported perturbations introduced by Lax and Phillips [3], the scattering poles, or resonances, might be considered as the natural analogue of the discrete spectrum of operators on compact manifolds. One could then ask to what extent could the resonances determine the scatterer and consider the "isopolar" rather than the isospectral problem. I would like to make a simple remark concerning the Schrödinger operator on the line.

Different situations could also be considered. In hyperbolic scattering, using a modification of Sunada's construction, Zelditch [7] and Bérard [1] obtained examples of "isopolar manifolds." We recall that in the finite volume case, hyperbolic scattering can be considered as a type of scattering by a compactly supported perturbation of a half-line—see, for instance, Example 1.1 in [5] and the references given therein.

2. We consider the Schrödinger operator

$$-\frac{d^2}{dx^2}+p(x), \quad x\in\mathbb{R}.$$

We shall follow the notation from [4]. Our conclusion is a simple consequence of standard facts about inverse scattering. We shall be concerned with real even potential p in $L^1_{\rm comp}(\mathbb{R})$ which is equivalent to considering scattering on a half-line, or the lowest angular momentum scattering by a radially symmetric potential in $\mathbb{R}^3$. The scattering matrix has the form

$$S_p(\lambda)=\begin{bmatrix} i\lambda/\widehat{X}(\lambda) & \widehat{Y}(\lambda)/\widehat{X}(\lambda)\\ \widehat{Y}(-\lambda)/\widehat{X}(\lambda) & i\lambda/\widehat{X}(\lambda)\end{bmatrix}.$$

The potential p is said to have a half-bound state at 0 if $\widehat{X}(0)=0$. The scattering poles, or resonances, are given by the zeros of $\widehat{X}$ in $\Im\lambda<0$, but we will also include in that set the square roots of the negative eigenvalues of $-d^2/dx^2+p(x)$, which correspond to the zeros of $\widehat{X}$ in $\Im\lambda>0$. Other than at $\lambda=0$, $\widehat{X}$ cannot vanish on the real axis.

PROPOSITION. *Let $p\in L^1_{\rm comp}(\mathbb{R})$ be even. Then, if p does not have a half-bound state at 0, the scattering poles determine p uniquely. If p has a half-bound state, then*

*Received by the editors July 21, 2000; accepted for publication October 18, 2000; published electronically March 28, 2001.

†Department of Mathematics, The Johns Hopkins University, Baltimore, MD 21218. Current address: Mathematics Department, University of California, Berkeley, CA 94720 (zworski@math.berkeley.edu).

there exists precisely one $p_1 \in L^1_{\text{comp}}(\mathbb{R})$, $p_1 \neq p$, *with the same set of scattering poles.*

Proof. Since the scattering matrix determines a compactly supported potential uniquely (see, for instance, Proposition 8 of [8]) we need to show only that the poles determine $S_p(\lambda)$, i.e., $\widehat{X}$ and $\widehat{Y}$. Let us first assume that $\widehat{X}(0) \neq 0$. We use the facts about the properties of zeros of Fourier transforms from [6], extended to Fourier transforms of distributions as in Lemma 1 of [8]. If the support of $X \in \mathcal{E}'$ is $[-4a, 0]$ (where in fact $2a$ is the diameter of the support of p), then the Carleman formula and the bound $\mathcal{O}(r)$ on the number of poles give, as in Theorem 6 of [6],

$$\widehat{X}(\lambda) = e^{2a\lambda}\widehat{X}(0) \prod_{\text{poles}} \left(1 - \frac{\lambda}{\lambda_j}\right), \quad |\lambda_1| \leq \cdots |\lambda_j| \leq \cdots.$$

The density of the poles is given by $4a/\pi$ so the exponential factor is fully determined. Since $X - \delta' - C\delta \in L^1$, the factor $\widehat{X}(0)$ is determined uniquely—multiplication of $\widehat{X}(0)$ by a constant would destroy the property $\widehat{X}(\lambda) - i\lambda - C \to 0$, $\lambda \to \pm\infty$. It remains to construct $\widehat{Y}(\lambda)$. For that we recall the unitarity relation

$$\widehat{X}(\lambda)\widehat{X}(-\lambda) = \lambda^2 + \widehat{Y}(\lambda)^2, \tag{1}$$

where $\widehat{Y}(\lambda) = \widehat{Y}(-\lambda)$, as p is even. Thus $\widehat{Y}(\lambda) = \pm(-\lambda^2 + \widehat{X}(\lambda)\widehat{X}(-\lambda))^{\frac{1}{2}}$. To determine the branch we recall that the definition of $\widehat{X}$ and $\widehat{Y}$ (see [4] or [8]) implies $\widehat{Y}(0) = -\widehat{X}(0) \neq 0$.

When $\widehat{X}(0) = 0$, the unitarity relation (1) shows that the zero is of order one. Thus we can apply the above argument to $\widehat{X}(\lambda)/\lambda$. Now, however, there is no obstruction to the choice of either branch in the formula for $\widehat{Y}$, and we obtain two different scattering matrices. □

We conclude with a few remarks. The restriction to compactly supported potentials is natural if one wants to define resonances globally. However, if the potential decays faster than any exponential, then $\widehat{X}$ is still holomorphic in $\mathbb{C}$ and again the resonances are globally defined as its zeros. In fact, if $p \in C^\infty(\mathbb{R})$ and $p(x) = \mathcal{O}(\exp(-A|x|^{1+a}))$, then the number of resonances of p in a disc of radius r, $N_p(r)$, satisfies

$$N_p(r) = \mathcal{O}(r^{\frac{1+a}{a}}).$$

This can be seen from the methods of [4] by showing that $X(y) = \delta'(y) - \frac{1}{2}(\int p(z)dz)\delta(y) + \mathcal{O}(\exp(-2^{-2(1+a)}A|y|^{1+a}))$. But, unlike in the compactly supported case (see [8]), the existence of asymptotics and the structure of the Hadamard factorization of $\widehat{X}$ are not clear and one misses up to $[(1+a)/a] + 1$ constants needed for the recovery procedure in the proof of the proposition.

The various methods of constructing potentials with the same scattering matrix (see, for instance, [2]) certainly yield isopolar potentials if one starts with, say, a compactly supported potential (so that the scattering matrix is globally meromorphic), but they immediately destroy the compact support property or, in fact, the super-exponential decay (see Proposition 8 of [8]).

Remark 1. I wrote this paper in 1988 and revised it in 1992. I decided to publish it now in view of renewed interest in one-dimensional resonance problems [9], [11], [12], [13].

For other relevant developments in the theory of resonances I refer the reader to the bibliography of [14] and to [10].

Remark 2. Determining potentials on a half-line from their resonances was recently studied by Kargaev and Korotyaev [12]. Some results on that can also be obtained by the method above: $\hat{X}(\xi)\hat{X}(-\xi) = (-i\xi + \hat{Y}(\xi))(i\xi + \hat{Y}(\xi))$ and the poles for the Neumann and Dirichlet problems are given by zeros of the two factors on the right, respectively. Proceeding as in the proof of the proposition shows that we can determine $\hat{Y}$ from either set, and hence the zeros of $\hat{X}$, and hence $\hat{X}$ itself. The additional information of distinguishing Dirichlet and Neumann spectra now eliminates the ambiguity in the case of a zero resonance. Amusingly, when a zero resonance is present, then the two potentials in the proposition above have their Dirichlet and Neumann resonances interchanged.

Kargaev and Korotyaev also pointed out a mistake in [8, Proposition 8]: the compactness of the support of a potential cannot be concluded from the transmission coefficient alone. That can, however, be done when the potential is even, and that is all that is relevant in this note.

EXPLICIT CHARACTERIZATION OF INCLUSIONS IN ELECTRICAL IMPEDANCE TOMOGRAPHY*

MARTIN BRÜHL†

Abstract. In electrical impedance tomography one seeks to recover the spatial conductivity distribution inside a body from knowledge of the Neumann–Dirichlet map. In many practically relevant situations the conductivity is smooth apart from some inhomogeneities where the conductivity jumps to a higher or lower value. An explicit characterization of these inclusions is developed in this paper. To this end a class of dipole-like indicator functions is introduced, for which one has to check whether their boundary values are contained in the range of an operator determined by the measured Neumann–Dirichlet map. It is shown that this holds true if and only if the dipole singularity lies inside the inhomogeneity. This procedure is conceptually similar to a recent method proposed by Kirsch in inverse scattering theory.

AMS subject classifications. 35R30, 31A25, 31B20, 35R05

PII. S003614100036656X

1. Introduction.

In 1980 Calderón [4] posed the following inverse boundary value problem: is the conductivity coefficient $\sigma(x) > 0$ in the elliptic equation

$$\nabla \cdot \sigma \nabla u = 0 \qquad \text{in } B \tag{1.1}$$

uniquely determined from knowledge of the Neumann and Dirichlet boundary values of all its solutions u, and, if yes, how can σ be reconstructed from these data? Here, B denotes a two- or three-dimensional domain with smooth boundary $T = \partial B$. The first of these questions has been answered in the affirmative for broad classes of conductivities. Kohn and Vogelius [14], Sylvester and Uhlmann [20], Nachman [17], and Brown and Uhlmann [1] proved uniqueness under certain smoothness assumptions on σ. For discontinuous but piecewise smooth conductivities uniqueness has been settled by Kohn and Vogelius [15] and Isakov [12].

This work is devoted to the second question and gives an—at least partial—answer to the reconstruction problem in the case of discontinuous conductivities. For ease of exposition we restrict ourselves to the case of a constant background conductivity, $\sigma = \mathbb{1}$, where $\mathbb{1}$ is the function identically 1. We consider conductivities of the following form:

$$\sigma(x) = \begin{cases} \kappa(x), & x \in \overline{\Omega}, \\ 1, & x \in B \setminus \overline{\Omega}, \end{cases} \tag{1.2}$$

where Ω, $\overline{\Omega} \subset B$, is a collection of separated and simply connected domains with sufficiently smooth boundary $\Gamma = \partial\Omega$, and the conductivity within Ω is significantly higher or lower than the background conductivity, or more precisely

$$\kappa(x) \geq 1 + \varepsilon \qquad \text{or} \qquad \kappa(x) \leq 1 - \varepsilon \qquad \text{for } x \in \overline{\Omega} \text{ and some } \varepsilon > 0. \tag{1.3}$$

http://www.siam.org/journals/sima/32-6/36656.html

†Fachbereich Mathematik, Johannes Gutenberg–Universität Mainz, 55099 Mainz, Germany (bruehl@math.uni-mainz.de).

We will refer to the components of Ω as *inclusions*.

In this paper we give an explicit representation of the inclusions Ω in terms of the measured Neumann–Dirichlet operator Λ_σ which maps the Neumann boundary values of potentials u in (1.1) to its Dirichlet boundary values. For that we consider a Neumann function $N(z,x)$ for the Laplace equation in B and, for some direction d, its directional derivative $d\cdot\nabla_z N(z,x)$ as a function of x. Then we show that its boundary values $g_{z,d} = (d\cdot\nabla_z N(z,\cdot))|_T$ are contained in the range $\mathcal{R}(|\Lambda_\sigma - \Lambda_{\mathbb{1}}|^{1/2})$ if and only if the parameter point z lies in Ω. Here, the operators Λ_σ and $\Lambda_{\mathbb{1}}$ are regarded as operators in L^2 topology, and from their compactness it follows that $\mathcal{R}(|\Lambda_\sigma - \Lambda_{\mathbb{1}}|^{1/2})$ is a nonclosed subspace of $L^2(T)$; see section 2 for details.

It should be emphasized that the idea of characterizing the support of an obstacle by the range of some operator has been introduced by Colton and Kirsch [5] and rigorously justified by Kirsch [13] in the context of inverse scattering problems. Recently, Hähner [9] has carried over Kirsch's techniques to the impedance tomography problem for the special case of grounded perfect electrical conductors, i.e., $\kappa = \infty$ in $\overline{\Omega}$. For the general situation addressed in this paper Ikehata [11] has established a characterization of inclusions, which happens to be nonconstructive; on the other hand, in [10] he has indicated a constructive procedure to recover the convex hull of the inclusions.

This paper is organized as follows. In the next section we introduce the notions associated with the forward problem and summarize some properties of the Neumann–Dirichlet operator. In section 3 we state and prove our main result for the case of a single inclusion and piecewise constant conductivity. Generalizations of this special case are treated in section 4.

The subtle difficulties that need to be overcome to turn our constructive method of proof into a numerical algorithm are discussed in [3].

2. Forward problem. For every $f \in H^{-1/2}(T)$ with $\langle f, \mathbb{1}\rangle_{L^2(T)} = \oint_T f\,ds = 0$ the Neumann boundary value problem

$$\nabla\cdot\sigma\nabla u = 0 \quad \text{in } B, \qquad \sigma\frac{\partial u}{\partial \nu} = f \quad \text{on } T \tag{2.1}$$

has a unique weak solution $u_\sigma \in H^1(B)$ with $\oint_T u_\sigma\,ds = 0$. The expression $\langle\phi,\psi\rangle_{L^2(T)} = \oint_T \phi\psi\,ds$ will be used for both the L^2 inner product on T and the dual pairing in $\langle H^{-1/2}(T), H^{1/2}(T)\rangle$. Moreover, let us introduce the following subspaces of the usual Sobolev spaces:

$$\begin{aligned}
L^2_\diamond(T) &= \{\phi \in L^2(T) : \oint_T \phi\,ds = 0\},\\
H^{\pm1/2}_\diamond(T) &= \{\phi \in H^{\pm1/2}(T) : \oint_T \phi\,ds = 0\},\\
L^2_\diamond(\Gamma) &= \{\phi \in L^2(\Gamma) : \oint_\Gamma \phi\,ds = 0\},\\
H^{\pm1/2}_\diamond(\Gamma) &= \{\phi \in H^{\pm1/2}(\Gamma) : \oint_\Gamma \phi\,ds = 0\},\\
H^1_\diamond(B) &= \{u \in H^1(B) : \oint_T u\,ds = 0\},\\
H^1_{\diamond,T}(B\setminus\overline{\Omega}) &= \{u \in H^1(B\setminus\overline{\Omega}) : \oint_T u\,ds = 0\},\\
H^1_{\diamond,\Gamma}(B\setminus\overline{\Omega}) &= \{u \in H^1(B\setminus\overline{\Omega}) : \oint_\Gamma u\,ds = 0\}.
\end{aligned}$$

Then, the solution operator $f \mapsto u_\sigma$ of (2.1) is a well-defined bounded linear operator $H^{-1/2}_\diamond(T) \to H^1_\diamond(B)$ and by passing to the trace of u_σ we obtain the *Neumann–*

Dirichlet operator

$$\Lambda_\sigma : H_\diamond^{-1/2}(T) \longrightarrow H_\diamond^{1/2}(T), \qquad f \longmapsto u_\sigma|_T,$$

which in fact is an isomorphism between these spaces.

The following properties of Λ_σ are well known, see, e.g., [8], but we sketch the proof for convenience.

LEMMA 2.1.

(a) $\Lambda_\sigma : L_\diamond^2(T) \to L_\diamond^2(T)$ *is compact, self-adjoint, and positive.*

(b) Λ_σ *is strictly monotonically decreasing in* σ*, i.e.,*

$$\langle f, \Lambda_\sigma f\rangle_{L^2(T)} > \langle f, \Lambda_{\tilde\sigma} f\rangle_{L^2(T)} \qquad \text{for } \sigma \le \tilde\sigma, \sigma \ne \tilde\sigma, \text{ and } f \ne 0.$$

Proof. (a) Compactness is a consequence of the compactness of the embeddings $H_\diamond^{1/2}(T) \hookrightarrow L_\diamond^2(T)$ and $L_\diamond^2(T) \hookrightarrow H_\diamond^{-1/2}(T)$, and self-adjointness and positivity follow from the weak formulation of (2.1) since

$$\langle f, \Lambda_\sigma \tilde f\rangle_{L^2(T)} = \int_B \sigma \nabla u_\sigma \cdot \nabla \tilde u_\sigma \, dx = \langle \tilde f, \Lambda_\sigma f\rangle_{L^2(T)},$$

where u_σ and $\tilde u_\sigma$ are the solutions of (2.1) for f and $\tilde f$, respectively.

(b) Here we use the fact that u_σ is the unique minimizer in $H_\diamond^1(B)$ of the energy functional

$$\frac{1}{2}\int_B \sigma |\nabla u|^2 \, dx - \oint_T f u \, ds$$

with the minimum value $-\frac{1}{2}\oint_T f u_\sigma \, ds$. Therefore,

$$\begin{aligned} -\frac{1}{2}\langle f, \Lambda_\sigma f\rangle_{L^2(T)} &= \frac{1}{2}\int_B \sigma |\nabla u_\sigma|^2 \, dx - \oint_T f u_\sigma \, ds \\ &< \frac{1}{2}\int_B \sigma |\nabla u_{\tilde\sigma}|^2 \, dx - \oint_T f u_{\tilde\sigma} \, ds \\ &\le \frac{1}{2}\int_B \tilde\sigma |\nabla u_{\tilde\sigma}|^2 \, dx - \oint_T f u_{\tilde\sigma} \, ds = -\frac{1}{2}\langle f, \Lambda_{\tilde\sigma} f\rangle_{L^2(T)}, \end{aligned}$$

which establishes the monotonicity. ∎

For piecewise smooth conductivities of the form

$$\sigma(x) = \begin{cases} \kappa(x), & x \in \overline{\Omega}, \\ 1, & x \in B \setminus \overline{\Omega}, \end{cases} \tag{2.2}$$

the forward problem (2.1) can be formulated in a classical sense as a *diffraction problem* (cf. [16]);

$$\begin{aligned} \nabla \cdot \sigma \nabla u = 0 \quad \text{in } B \setminus \Gamma, \qquad & \frac{\partial u}{\partial \nu} = f \quad \text{on } T, \\ [u]_\Gamma = 0, \qquad & \Big[\sigma \frac{\partial u}{\partial \nu}\Big]_\Gamma = 0. \end{aligned} \tag{2.3}$$

Here, $[\,\cdot\,]_\Gamma$ denotes the jump of the bracketed quantity across the inner boundary $\Gamma = \partial\Omega$, i.e.,

$$[u]_\Gamma = u^+ - u^- \qquad \text{and} \qquad \Big[\sigma \frac{\partial u}{\partial \nu}\Big]_\Gamma = \frac{\partial u^+}{\partial \nu} - \kappa \frac{\partial u^-}{\partial \nu}$$

with

$$u^{\pm}(x) = \lim_{t\to 0+} u(x \pm t\nu) \qquad \text{and} \qquad \frac{\partial u^{\pm}(x)}{\partial \nu} = \lim_{t\to 0+} \nu \cdot \nabla u(x \pm t\nu)$$

for $x \in \Gamma$, where ν is the normal vector at x pointing outward Ω.

Example 2.1 (Radially symmetric case). For the unit disk $B = B_1 = \{x \in \mathbb{R}^2 : |x| < 1\}$ consider the conductivity distribution

$$\sigma(x) = \begin{cases} \kappa, & |x| \le \rho, \\ 1, & \rho < |x| < 1, \end{cases}$$

with a constant $\kappa > 0$ and $0 < \rho < 1$. Solving the forward problem explicitly using polar coordinates $x = re^{i\xi}$ yields the spectral decomposition

$$\Lambda_\sigma : \begin{Bmatrix} \frac{1}{\sqrt{\pi}} \cos k\xi \\ \frac{1}{\sqrt{\pi}} \sin k\xi \end{Bmatrix} \longmapsto \frac{1}{k} \frac{1+\mu\rho^{2k}}{1-\mu\rho^{2k}} \begin{Bmatrix} \frac{1}{\sqrt{\pi}} \cos k\xi \\ \frac{1}{\sqrt{\pi}} \sin k\xi \end{Bmatrix} \tag{2.4}$$

with $\mu = (1-\kappa)/(1+\kappa) \in (-1,1)$; cf., for instance, [18]. The asymptotic decay $\mathcal{O}(k^{-1})$ of the eigenvalues indicates the smoothing, $H_\diamond^{-1/2}(T) \to H_\diamond^{1/2}(T)$, of exactly one order in Sobolev scale of this Neumann–Dirichlet map. Later on this example will be reconsidered in order to illustrate some of our abstract results.

3. Main result (for piecewise constant conductivity). In this section we confine ourselves to the special case of a single inclusion, in which the conductivity is constant, i.e., $\kappa(x) = \kappa$ in (2.2). As will be shown in section 4, our results can be generalized to the case of multiple inclusions and less restrictive conductivity distributions.

Let $N(z,x)$ be a Neumann function for the domain B, i.e., $N(z,x) = \Phi(z-x) + n(z,x)$ for $z, x \in B$, where Φ denotes the fundamental solution for the Laplacian, and $n(z,x)$ solves the Neumann boundary value problem

$$\begin{aligned} \Delta_x n(z,x) &= 0 \quad \text{in } B, \\ \frac{\partial n(z,x)}{\partial \nu_x} &= \beta(x) - \frac{\partial \Phi(z-x)}{\partial \nu_x} \quad \text{on } T, \\ \oint_T \beta(x) n(z,x)\, ds_x &= -\oint_T \beta(x)\Phi(z-x)\, ds_x \end{aligned}$$

for some scaling function β with $\oint_T \beta(x)\, ds = 1$. In our main result we will need the boundary values of the directional derivative of $N(z,x)$ with respect to z in some fixed direction d, $|d| = 1$,

$$g_{z,d}(x) = \frac{\partial N(z,x)}{\partial_z d}\Big|_T = (d \cdot \nabla_z N(z,x))\big|_T.$$

THEOREM 3.1. *For $\kappa \neq 1$ there holds $g_{z,d} \in \mathcal{R}(|\Lambda_\sigma - \Lambda_{\mathbb{1}}|^{1/2})$ if and only if $z \in \Omega$.*

Outline of proof. The key ingredient of the proof is a factorization $\Lambda_\sigma - \Lambda_{\mathbb{1}} = LFL'$, where $L : H_\diamond^{-1/2}(\Gamma) \to H_\diamond^{1/2}(T)$ and $L' : H_\diamond^{-1/2}(T) \to H_\diamond^{1/2}(\Gamma)$ are dual to each other and $F : H_\diamond^{1/2}(\Gamma) \to H_\diamond^{-1/2}(\Gamma)$ is an isomorphism with $F = F'$. This factorization will be derived in section 3.1.

Having this factorization at our disposal, we shall be able to show equality of the ranges, $\mathcal{R}(|\Lambda_\sigma - \Lambda_{\mathbb{1}}|^{1/2}) = \mathcal{R}(L)$. Here, $\mathcal{R}(L) \subset H_\diamond^{1/2}(T)$ is understood as a subspace of $L_\diamond^2(T)$.

Then, the special choice of L allows for a characterization of $\mathcal{R}(L)$ according to the theorem; see section 3.2 for details. ∎

Note that, as a byproduct, Theorem 3.1 also provides a uniqueness result for this class of conductivities and, in contrast to the uniqueness results cited above (apart from [10]), it is proven in a constructive way.

3.1. Factorization of the Neumann–Dirichlet map. Consider the following Neumann boundary value problem:

$$\Delta v = 0 \quad \text{in } B \setminus \overline{\Omega}, \qquad \frac{\partial v}{\partial \nu} = 0 \quad \text{on } T, \qquad \frac{\partial v^+}{\partial \nu} = \phi \quad \text{on } \Gamma, \tag{3.1}$$

which for $\phi \in H_\diamond^{-1/2}(\Gamma)$ has a unique solution $v \in H^1_{\diamond,T}(B \setminus \overline{\Omega})$. Thus, we may define a bounded operator L by

$$L : H_\diamond^{-1/2}(\Gamma) \longrightarrow H_\diamond^{1/2}(T), \qquad \phi \longmapsto v|_T. \tag{3.2}$$

The dual operator L' of L is then given by the boundary value problem

$$\Delta v' = 0 \quad \text{in } B \setminus \overline{\Omega}, \qquad \frac{\partial v'}{\partial \nu} = -\phi' \quad \text{on } T, \qquad \frac{\partial {v'}^+}{\partial \nu} = 0 \quad \text{on } \Gamma, \tag{3.3}$$

with a unique solution $v' \in H^1_{\diamond,\Gamma}(B \setminus \overline{\Omega})$ via

$$L' : H_\diamond^{-1/2}(T) \longrightarrow H_\diamond^{1/2}(\Gamma), \qquad \phi' \longmapsto v'|_\Gamma. \tag{3.4}$$

This is easily seen by applying Green's formula to v and v' in the domain $B \setminus \overline{\Omega}$:

$$\begin{aligned}\langle \phi', L\phi \rangle_{L^2(T)} &= -\oint_T \frac{\partial v'}{\partial \nu} v \, ds \;=\; -\oint_\Gamma \frac{\partial {v'}^+}{\partial \nu} v \, ds - \oint_T v' \frac{\partial v}{\partial \nu} \, ds + \oint_\Gamma v' \frac{\partial v^+}{\partial \nu} \, ds \\ &= \oint_\Gamma v' \phi \, ds \;=\; \langle v', \phi \rangle_{L^2(\Gamma)}.\end{aligned}$$

As follows from uniqueness for the Cauchy problem for the Laplace equation, both L and L' are injective. Note that L and L' depend only on the inclusion Ω itself and not on the specific conductivity distribution in the interior of Ω.

Now we are prepared to formulate our result on the factorization of $\Lambda_\sigma - \Lambda_{\mathbb{1}}$.

LEMMA 3.2. *Let $\kappa \neq 1$. With L and L' defined by* (3.2) *and* (3.4)*, respectively, the difference of Neumann–Dirichlet maps can be factorized as $\Lambda_\sigma - \Lambda_{\mathbb{1}} = LFL'$, where $F : H_\diamond^{1/2}(\Gamma) \to H_\diamond^{-1/2}(\Gamma)$ is an isomorphism with $F = F'$.*

Proof. For fixed boundary current $f \in H_\diamond^{-1/2}(T)$ denote by u_σ the solution of the forward problem (2.3) and by $u_{\mathbb{1}}$ the solution of the associated homogeneous problem. The difference $u_\sigma - u_{\mathbb{1}}$ is then harmonic in $B \setminus \overline{\Omega}$ and

$$\oint_\Gamma \frac{\partial (u_\sigma - u_{\mathbb{1}})^+}{\partial \nu} \, ds = \oint_T \frac{\partial (u_\sigma - u_{\mathbb{1}})}{\partial \nu} \, ds = 0$$

by the divergence theorem. Thus, $v = u_\sigma - u_{\mathbb{1}}$ solves (3.1) for $\phi = \frac{\partial (u_\sigma - u_{\mathbb{1}})^+}{\partial \nu}\big|_\Gamma$ and by the definition (3.2) of L we have

$$L\big(\tfrac{\partial (u_\sigma - u_{\mathbb{1}})^+}{\partial \nu}\big|_\Gamma\big) = (u_\sigma - u_{\mathbb{1}})|_T = (\Lambda_\sigma - \Lambda_{\mathbb{1}}) f. \tag{3.5}$$

If we now introduce the operator $G_\sigma : f \mapsto \frac{\partial u_\sigma^+}{\partial \nu}\big|_\Gamma$ and set $G = G_\sigma - G_{\mathbb{1}}$, then we have so far derived a factorization

$$\Lambda_\sigma - \Lambda_{\mathbb{1}} = LG. \tag{3.6}$$

Note that G_σ is a well-defined bounded operator from $H_\diamond^{-1/2}(T)$ to $H_\diamond^{-1/2}(\Gamma)$. This is a consequence of the boundedness of

$$H(\mathrm{div}, B \setminus \overline{\Omega}) \longrightarrow H^{-1/2}(\Gamma), \qquad \mathbf{v} \longmapsto (\nu \cdot \mathbf{v})^+|_\Gamma, \tag{3.7}$$

the mapping of vector fields in $H(\mathrm{div}, B\setminus\overline{\Omega}) = \{\mathbf{v} \in (L^2(B\setminus\overline{\Omega}))^n : \nabla\cdot\mathbf{v} \in L^2(B\setminus\overline{\Omega})\}$ to their normal component on the boundary (cf. [7, Thm. 2.5]); we apply this result to the current field $\sigma\nabla u_\sigma$.

Next, we want to compute the dual operator G'_σ of G_σ. To this purpose, consider the following diffraction problem with inhomogeneous jump condition:

$$\begin{aligned} \Delta w = 0 \quad &\text{in } B\setminus\Gamma, & \frac{\partial w}{\partial \nu} = 0 \quad &\text{on } T, \\ \big[w\big]_\Gamma = \psi, & & \Big[\sigma\frac{\partial w}{\partial \nu}\Big]_\Gamma = 0, & \end{aligned} \tag{3.8}$$

which for $\psi \in H_\diamond^{1/2}(\Gamma)$ possesses a unique solution w_σ with $w_\sigma|_{B\setminus\overline{\Omega}} \in H^1_{\diamond,T}(B\setminus\overline{\Omega})$ and $w_\sigma|_\Omega \in H^1(\Omega)$; cf., for example, [16]. Applying Green's formula in $B\setminus\overline{\Omega}$ and in Ω, we obtain

$$\begin{aligned} \langle G_\sigma f, \psi\rangle_{L^2(\Gamma)} &= \oint_\Gamma \frac{\partial u_\sigma^+}{\partial\nu}(w_\sigma^+ - w_\sigma^-)\,ds \;=\; -\oint_\Gamma \kappa\frac{\partial u_\sigma^-}{\partial\nu}w_\sigma^-\,ds + \oint_\Gamma \frac{\partial u_\sigma^+}{\partial\nu}w_\sigma^+\,ds \\ &= \oint_\Gamma \Big(-\kappa\frac{\partial w_\sigma^-}{\partial\nu}u_\sigma^- + \frac{\partial w_\sigma^+}{\partial\nu}u_\sigma^+\Big)\,ds + \oint_T \Big(\frac{\partial u_\sigma}{\partial\nu}w_\sigma - \frac{\partial w_\sigma}{\partial\nu}u_\sigma\Big)\,ds \\ &= \oint_T f w_\sigma\,ds \;=\; \langle f, w_\sigma\rangle_{L^2(T)}, \end{aligned}$$

where the first integral in the second line vanishes according to the jump conditions $[u_\sigma]_\Gamma = 0$ and $\big[\sigma\frac{\partial w_\sigma}{\partial\nu}\big]_\Gamma = 0$. This shows that $G'_\sigma\psi = w_\sigma|_T$ and hence

$$G'\psi = (G'_\sigma - G'_{\mathbb{1}})\psi = (w_\sigma - w_{\mathbb{1}})|_T.$$

Note that the restriction of w_σ to $B\setminus\overline{\Omega}$ also solves (3.1) with $\phi = \frac{\partial w_\sigma^+}{\partial\nu}\big|_\Gamma$, which in terms of our operators can be written as $L\big(\frac{\partial w_\sigma^+}{\partial\nu}\big|_\Gamma\big) = w_\sigma|_T = G'_\sigma\psi$, and, by linearity,

$$L\big(\tfrac{\partial (w_\sigma - w_{\mathbb{1}})^+}{\partial\nu}\big|_\Gamma\big) = (w_\sigma - w_{\mathbb{1}})|_T = G'\psi. \tag{3.9}$$

Finally, we define the operator F by the mapping rule $\psi \mapsto \frac{\partial (w_\sigma - w_{\mathbb{1}})^+}{\partial\nu}\big|_\Gamma$. The proof of the asserted properties of the operator F will be deferred to the subsequent Lemma 3.3. With help of this operator (3.9) now reads $LF = G'$, and by transposition we obtain $G = F'L' = FL'$. Inserting this into (3.6) yields the desired factorization $\Lambda_\sigma - \Lambda_{\mathbb{1}} = LFL'$. ∎

LEMMA 3.3. *For $\kappa \neq 1$ the operator $F : \psi \mapsto \frac{\partial (w_\sigma - w_{\mathbb{1}})^+}{\partial\nu}\big|_\Gamma$ is an isomorphism $H_\diamond^{1/2}(\Gamma) \to H_\diamond^{-1/2}(\Gamma)$ with $F' = F$. Here w_σ and $w_{\mathbb{1}}$ are the solutions of the diffraction problem* (3.8) *with conductivities σ and $\mathbb{1}$, respectively.*

Proof. From the solution theory for diffraction problems (see [16]) and (3.7) it follows that $F : H_\diamond^{1/2}(\Gamma) \to H^{-1/2}(\Gamma)$ is well defined and bounded. Moreover, the divergence theorem applied to w_σ in $B \setminus \overline{\Omega}$ gives $\oint_\Gamma \frac{\partial w_\sigma^+}{\partial \nu}\, ds = \oint_T \frac{\partial w_\sigma}{\partial \nu}\, ds = 0$ and similarly $\oint_\Gamma \frac{\partial w_{\mathbb{1}}^+}{\partial \nu}\, ds = 0$, so that we have indeed $F\psi \in H_\diamond^{-1/2}(\Gamma)$.

In order to demonstrate the surjectivity of F we construct for arbitrarily chosen $\phi \in H_\diamond^{-1/2}(\Gamma)$ a function $\psi \in H_\diamond^{1/2}(\Gamma)$ with $F\psi = \phi$. The construction proceeds in several steps. First we take the unique solution $W \in H^1_{\diamond,T}(B \setminus \overline{\Omega})$ of the boundary value problem

$$\Delta W = 0 \quad \text{in } B \setminus \overline{\Omega}, \qquad \frac{\partial W}{\partial \nu} = 0 \quad \text{on } T, \qquad \frac{\partial W^+}{\partial \nu} = \phi \quad \text{on } \Gamma, \tag{3.10}$$

and set $\omega = W^+|_\Gamma$. In the inclusion Ω we define W to be the solution of the Dirichlet problem

$$\Delta W = 0 \quad \text{in } \Omega, \qquad W^- = \omega \quad \text{on } \Gamma, \tag{3.11}$$

and afterwards we set $\varphi = \big[\sigma \frac{\partial W}{\partial \nu}\big]_\Gamma = \phi - \kappa \frac{\partial W^-}{\partial \nu}\big|_\Gamma$; note that the Neumann boundary values $\kappa \frac{\partial W^-}{\partial \nu}\big|_\Gamma$ are well defined in $H^{-1/2}(\Gamma)$ by (3.7) with $B \setminus \overline{\Omega}$ replaced by Ω. Therefore, we have $\varphi \in H_\diamond^{-1/2}(\Gamma)$, because $\oint_\Gamma \frac{\partial W^-}{\partial \nu}\, ds = 0$ by the divergence theorem.

In the next step we define the function $w_{\mathbb{1}}$. In the exterior domain we take $w_{\mathbb{1}}$ to be the unique solution in $H^1_{\diamond,T}(B \setminus \overline{\Omega})$ of the Neumann boundary value problem

$$\Delta w_{\mathbb{1}} = 0 \quad \text{in } B \setminus \overline{\Omega}, \qquad \frac{\partial w_{\mathbb{1}}}{\partial \nu} = 0 \quad \text{on } T, \qquad \frac{\partial w_{\mathbb{1}}^+}{\partial \nu} = \frac{1}{\kappa - 1}\varphi \quad \text{on } \Gamma,$$

whereas in the interior domain we let $w_{\mathbb{1}}$ be the solution of

$$\Delta w_{\mathbb{1}} = 0 \quad \text{in } \Omega, \qquad \frac{\partial w_{\mathbb{1}}^-}{\partial \nu} = \frac{1}{\kappa - 1}\varphi \quad \text{on } \Gamma, \qquad \oint_\Gamma w_{\mathbb{1}}^-\, ds = \oint_\Gamma w_{\mathbb{1}}^+\, ds.$$

Now set $\psi = [w_{\mathbb{1}}]_\Gamma$. The special normalization condition for the last interior problem ensures that $\oint_\Gamma \psi\, ds = 0$ and hence $\psi \in H_\diamond^{1/2}(\Gamma)$.

Then it is easily checked that the so-defined functions $w_{\mathbb{1}}$ and $w_\sigma := w_{\mathbb{1}} + W$ solve the diffraction problems (3.8) for conductivities $\mathbb{1}$ and σ, respectively. Obviously we have $F\psi = \frac{\partial (w_\sigma - w_{\mathbb{1}})^+}{\partial \nu}\big|_\Gamma = \frac{\partial W^+}{\partial \nu}\big|_\Gamma = \phi$, what we intended to show.

To verify the injectivity of F let us assume that $F\psi = 0$. This means that the difference $W = w_\sigma - w_{\mathbb{1}}$ of the solutions of the diffraction problems (3.8) for σ and $\mathbb{1}$, respectively, is itself a solution of (3.10) and (3.11) for $\phi = 0$. This implies $W = 0$, i.e., $w_\sigma = w_{\mathbb{1}}$ in $B \setminus \overline{\Omega}$ and Ω. Combining this and $\big[\frac{\partial w_{\mathbb{1}}}{\partial \nu}\big]_\Gamma = \big[\sigma \frac{\partial w_\sigma}{\partial \nu}\big]_\Gamma = 0$ we obtain

$$\frac{\partial w_\sigma^-}{\partial \nu}\big|_\Gamma = \frac{\partial w_{\mathbb{1}}^-}{\partial \nu}\big|_\Gamma = \frac{\partial w_{\mathbb{1}}^+}{\partial \nu}\big|_\Gamma = \frac{\partial w_\sigma^+}{\partial \nu}\big|_\Gamma = \kappa \frac{\partial w_\sigma^-}{\partial \nu}\big|_\Gamma,$$

from which we conclude that all normal derivatives in this equation must be zero, and hence $w_\sigma = w_{\mathbb{1}}$ must be equal to constants in Ω and as well in $B \setminus \overline{\Omega}$. Thus, $\psi = [w_{\mathbb{1}}]_\Gamma = \text{const}$ and after all the normalization condition $\oint_\Gamma \psi\, ds = 0$ implies $\psi = 0$, which shows the injectivity of F.

As a consequence of the open mapping theorem the inverse of the bijective bounded linear operator $F : H_\diamond^{1/2}(\Gamma) \to H_\diamond^{-1/2}(\Gamma)$ is also bounded.

To establish the remaining assertion $F = F'$, it suffices to show that $F_\sigma = F'_\sigma$ (which encloses $F_{\mathbb{1}} = F'_{\mathbb{1}}$ as a special case). For $\psi_1, \psi_2 \in H^{1/2}_\diamond(\Gamma)$ let w_1, w_2 be the corresponding solutions of the diffraction problem (3.8). Green's formula applied to $B \setminus \overline{\Omega}$ and Ω yields

$$\begin{aligned}
\langle F_\sigma \psi_1, \psi_2 \rangle_{L^2(\Gamma)} &= \oint_\Gamma \frac{\partial w_1^+}{\partial \nu} \psi_2 \, ds \;=\; \oint_\Gamma \frac{\partial w_1^+}{\partial \nu} w_2^+ \, ds - \oint_\Gamma \kappa \frac{\partial w_1^-}{\partial \nu} w_2^- \, ds \\
&= \oint_T \Big(\frac{\partial w_1}{\partial \nu} w_2 - w_1 \frac{\partial w_2}{\partial \nu} \Big) \, ds + \oint_\Gamma \Big(w_1^+ \frac{\partial w_2^+}{\partial \nu} - w_1^- \kappa \frac{\partial w_2^-}{\partial \nu} \Big) \, ds \\
&= \oint_\Gamma (w_1^+ - w_1^-) \frac{\partial w_2^+}{\partial \nu} \, ds \;=\; \oint_\Gamma \psi_1 \frac{\partial w_2^+}{\partial \nu} \, ds \\
&= \langle F_\sigma \psi_2, \psi_1 \rangle_{L^2(\Gamma)},
\end{aligned}$$

hence F_σ is symmetric in the dual pairing $\langle H^{-1/2}_\diamond(\Gamma), H^{1/2}_\diamond(\Gamma) \rangle$, and therefore $F_\sigma = F'_\sigma$. ∎

The proof of Lemma 3.2 is now complete. Before making further use of this result, we take up again our radially symmetric example from above.

Example 3.1. For the situation in Example 2.1 we give explicit representations of the operators occurring in our factorization. Solving (3.1) by separation of variables we compute the following singular value decomposition of L:

$$L : \begin{Bmatrix} \frac{1}{\sqrt{\pi\rho}} \cos k\xi \\ \frac{1}{\sqrt{\pi\rho}} \sin k\xi \end{Bmatrix} \longmapsto \frac{1}{k} \frac{2\rho^{k+1/2}}{1-\rho^{2k}} \begin{Bmatrix} -\frac{1}{\sqrt{\pi}} \cos k\xi \\ -\frac{1}{\sqrt{\pi}} \sin k\xi \end{Bmatrix}.$$

Hence, a singular value decomposition of L' is given by

$$L' : \begin{Bmatrix} \frac{1}{\sqrt{\pi}} \cos k\xi \\ \frac{1}{\sqrt{\pi}} \sin k\xi \end{Bmatrix} \longmapsto \frac{1}{k} \frac{2\rho^{k+1/2}}{1-\rho^{2k}} \begin{Bmatrix} -\frac{1}{\sqrt{\pi\rho}} \cos k\xi \\ -\frac{1}{\sqrt{\pi\rho}} \sin k\xi \end{Bmatrix},$$

which we would have also obtained by solving (3.3) explicitly.

Analogously we derive spectral decompositions of the operators F_σ,

$$F_\sigma : \begin{Bmatrix} \frac{1}{\sqrt{\pi\rho}} \cos k\xi \\ \frac{1}{\sqrt{\pi\rho}} \sin k\xi \end{Bmatrix} \longmapsto \frac{k}{2\rho} \frac{(1-\mu)(\rho^{2k}-1)}{1-\mu\rho^{2k}} \begin{Bmatrix} \frac{1}{\sqrt{\pi\rho}} \cos k\xi \\ \frac{1}{\sqrt{\pi\rho}} \sin k\xi \end{Bmatrix},$$

and $F = F_\sigma - F_{\mathbb{1}}$,

$$F : \begin{Bmatrix} \frac{1}{\sqrt{\pi\rho}} \cos k\xi \\ \frac{1}{\sqrt{\pi\rho}} \sin k\xi \end{Bmatrix} \longmapsto \frac{k}{2\rho} \frac{\mu(\rho^{2k}-1)^2}{1-\mu\rho^{2k}} \begin{Bmatrix} \frac{1}{\sqrt{\pi\rho}} \cos k\xi \\ \frac{1}{\sqrt{\pi\rho}} \sin k\xi \end{Bmatrix}.$$

Here, the asymptotic behavior $\mathcal{O}(k)$ of the eigenvalues parallels the fact that $F : H^{1/2}_\diamond(\Gamma) \to H^{-1/2}_\diamond(\Gamma)$ is an isomorphism.

3.2. Range of L. The next building block for the proof of Theorem 3.1 is to show that the ranges of L and $|\Lambda_\sigma - \Lambda_{\mathbb{1}}|^{1/2}$ coincide.

We set $\mathcal{D}(F) = F^{-1}(L^2_\diamond(\Gamma))$ and interpret F as an operator from $\mathcal{D}(F)$ onto $L^2_\diamond(\Gamma)$; note that $\mathcal{D}(F)$ is a proper subspace of $H^{1/2}_\diamond(\Gamma)$ by Lemma 3.3. Since $F = F'$, the restriction $F^{-1} : L^2_\diamond(\Gamma) \to \mathcal{D}(F)$ is self-adjoint, and as the inverse of an injective self-adjoint operator is itself self-adjoint (see, e.g., [19, Thm. 13.11]), we obtain that $F : \mathcal{D}(F) \to L^2_\diamond(\Gamma)$ is self-adjoint; in particular, F is densely defined in $L^2_\diamond(\Gamma)$.

Next we show that $\pm F$ is positive, where the sign is chosen according to the sign of $1-\kappa$. For $0 \neq \psi \in \mathcal{R}(L') \subset H_\diamond^{1/2}(\Gamma)$, i.e., $\psi = L'\phi$ with $\phi \in H_\diamond^{-1/2}(T)$, we have

$$\begin{aligned}\langle F\psi, \psi\rangle_{L^2(\Gamma)} &= \langle FL'\phi, L'\phi\rangle_{L^2(\Gamma)} = \langle LFL'\phi, \phi\rangle_{L^2(T)} \\ &= \langle (\Lambda_\sigma - \Lambda_{\mathbb{1}})\phi, \phi\rangle_{L^2(T)} \begin{cases} > 0 & \text{for } 0 < \kappa < 1, \\ < 0 & \text{for } \kappa > 1, \end{cases}\end{aligned}$$

using the factorization of $\Lambda_\sigma - \Lambda_{\mathbb{1}}$ and Lemma 2.1(b). But since L is injective and therefore $\overline{\mathcal{R}(L')} = \mathcal{N}(L)^\perp = \{0\}^\perp = H_\diamond^{1/2}(\Gamma)$, the range of L' is dense in $H_\diamond^{1/2}(\Gamma)$; thus we conclude that for all $\psi \in H_\diamond^{1/2}(\Gamma)$

$$\langle F\psi, \psi\rangle_{L^2(\Gamma)} \begin{cases} \geq 0 & \text{for } 0 < \kappa < 1, \\ \leq 0 & \text{for } \kappa > 1. \end{cases}$$

Since F is injective and densely defined, the case $\langle \psi, F\psi\rangle_{L^2(\Gamma)} = 0$ for $0 \neq \psi \in \mathcal{D}(F)$ can be excluded, whence the positivity of $\pm F$ follows.[1]

We proceed with a functional analytic auxiliary result.

LEMMA 3.4. *Let $V \hookrightarrow H \hookrightarrow V'$ be a Gelfand triple, i.e., these injections are continuous and have dense range. Assume that the restriction of an isomorphism $K : V' \to V$ to an operator $H \to H$ is self-adjoint and positive. Then, the (self-adjoint and positive) square root $K^{1/2} : H \to H$ is an isomorphism $H \to V$ and admits an isomorphic extension $\widetilde{K}^{1/2} : V' \to H$. Furthermore, these two isomorphisms are dual to each other, and $K : V' \to V$ can be written as $K = K^{1/2}\widetilde{K}^{1/2}$.*

Proof. Since we have

$$\|K^{1/2}\phi\|_H^2 = \langle K\phi, \phi\rangle_H \leq \|K\phi\|_V \|\phi\|_{V'} \leq \|K\|_{V'\to V}\|\phi\|_{V'}^2 \qquad \text{for } \phi \in H,$$

the square root $K^{1/2}$ can be extended to a bounded operator $\widetilde{K}^{1/2} : V' \to H$. By duality, $(\widetilde{K}^{1/2})' : H \to V$ is also bounded and coincides on H with $\widetilde{K}^{1/2}|_H = K^{1/2}$ because of the self-adjointness. Hence, $K^{1/2}$ is bounded as an operator $H \to V$ and moreover we have

$$K = K^{1/2}\widetilde{K}^{1/2} : V' \to V, \tag{3.12}$$

for the operators on both sides are bounded and coincide on the dense subspace $H \subset V'$.

The operator $K^{1/2}$ is injective as a square root of an injective operator, and (3.12) and the bijectivity of K imply also its surjectivity. Finally, the bijectivity of $\widetilde{K}^{1/2}$ is now again a consequence of (3.12). ∎

Applying this lemma to $K = |F|^{-1}$ and taking inverses, we see that the square root of $|F|$ can be extended to isomorphic operators $|F|^{1/2} : H_\diamond^{1/2}(\Gamma) \to L_\diamond^2(\Gamma)$ and $(|F|^{1/2})' : L_\diamond^2(\Gamma) \to H_\diamond^{-1/2}(\Gamma)$, so that $|F| : H_\diamond^{1/2}(\Gamma) \to H_\diamond^{-1/2}(\Gamma)$ can be written as $|F| = (|F|^{1/2})'|F|^{1/2}$. The factorization derived in Lemma 3.2 of $\Lambda_\sigma - \Lambda_{\mathbb{1}}$, treated as an operator in $L_\diamond^2(T)$, then takes the form

$$|\Lambda_\sigma - \Lambda_{\mathbb{1}}| = L(|F|^{1/2})'|F|^{1/2}L'\big|_{L_\diamond^2(T)} = \big(|F|^{1/2}L'\big|_{L_\diamond^2(T)}\big)^*|F|^{1/2}L'\big|_{L_\diamond^2(T)},$$

where the star denotes the adjoint of $|F|^{1/2}L'\big|_{L_\diamond^2(T)} : L_\diamond^2(T) \to L_\diamond^2(\Gamma)$.

[1] In what follows we write $|F|$ for $\operatorname{sgn}(1-\kappa)F$.

Now, we can apply a general result to our case, namely, that for every operator A acting between Hilbert spaces there holds $\mathcal{R}((A^*A)^{1/2}) = \mathcal{R}(A^*)$; see, e.g., [6, Prop. 2.18]. This yields

$$\mathcal{R}(|\Lambda_\sigma - \Lambda_{\mathbb{1}}|^{1/2}) = \mathcal{R}((|F|^{1/2}L'\big|_{L^2_\diamond(T)})^*) = \mathcal{R}(L(|F|^{1/2})') = \mathcal{R}(L), \tag{3.13}$$

the latter equality due to the bijectivity of $(|F|^{1/2})' : L^2_\diamond(\Gamma) \to H_\diamond^{-1/2}(\Gamma)$. This is just what we wanted to show.

To complete the proof of Theorem 3.1 we have to figure out the connection between the boundary values $g_{z,d} = d \cdot \nabla_z N(z, \cdot\,)\big|_T$ and the range of L.

LEMMA 3.5. *$g_{z,d} \in \mathcal{R}(L)$ if and only if $z \in \Omega$.*

Proof. It is obvious from (3.1) and (3.2) that $g_{z,d}$ is contained in the range of the operator L if and only if the Cauchy problem

$$\begin{aligned} \Delta v &= 0 \quad \text{in } B \setminus \overline{\Omega}, \\ v &= g_{z,d} \quad \text{on } T, \qquad \frac{\partial v}{\partial \nu} = 0 \quad \text{on } T, \end{aligned} \tag{3.14}$$

has a solution $v \in H^1_{\diamond,T}(B \setminus \overline{\Omega})$. In this case we would have $\frac{\partial v^+}{\partial \nu}\big|_\Gamma \in H_\diamond^{-1/2}(\Gamma)$ and $L(\frac{\partial v^+}{\partial \nu}\big|_\Gamma) = g_{z,d}$.

Let us recall that $d \cdot \nabla_z N(z, \cdot\,)$ is harmonic away from z where this function has a dipole-like singularity. Moreover, for $z \in B$ and $x \in T$ we have

$$\frac{\partial}{\partial \nu_x} d \cdot \nabla_z N(z, \cdot\,) = d \cdot \nabla_z \frac{\partial N(z, \cdot\,)}{\partial \nu_x} = d \cdot \nabla_z \beta(x) = 0$$

and $d \cdot \nabla_z N(z, \cdot\,) = g_{z,d}$; hence $d \cdot \nabla_z N(z, \cdot\,)$ fulfills the Cauchy boundary conditions in (3.14).

From uniqueness for the Cauchy problem for the Laplace equation we can now deduce that $d \cdot \nabla_z N(z, \cdot\,)$ is the only possible candidate for a solution of the Cauchy problem (3.14). If $z \in \Omega$, then indeed $d \cdot \nabla_z N(z, \cdot\,)$ is a solution, whereas if the singularity z lies in $B \setminus \overline{\Omega}$ or on the inner boundary Γ, then $d \cdot \nabla_z N(z, \cdot\,) \notin H^1_{\diamond,T}(B \setminus \overline{\Omega})$, i.e., it is not a solution of (3.14). This proves the lemma. ∎

Example 3.2. The Neumann function for the unit disk and for the scaling function $\beta \equiv 1/2\pi$ is known explicitly, namely,

$$N(z,x) = \begin{cases} \frac{1}{2\pi}\big(\log|z-x| + \log\big|\frac{z}{|z|} - |z|x\big|\big) & \text{for } z \neq 0, \\ \frac{1}{2\pi}\log|x| & \text{for } z = 0, \end{cases}$$

and the boundary values of its directional derivative are

$$g_{z,d}(x) = d \cdot \nabla_z N(z,x)\big|_T = \frac{1}{\pi}\frac{(z-x)\cdot d}{|z-x|^2} \qquad \text{for } |x| = 1.$$

Introducing polar coordinates $z = |z|e^{i\zeta}$, $d = e^{i\vartheta}$, $x = e^{i\xi}$ we obtain for $g_{z,d}$ the Fourier series expansion

$$g_{z,d}(\xi) = \sum_{k=1}^{\infty} \frac{-|z|^{k-1}}{\pi} \cos\big(k(\xi-\zeta) - (\vartheta - \zeta)\big).$$

Then the (formal) solution of the Cauchy problem (3.14) reads

$$v(r,\xi)=\sum_{k=1}^{\infty}\frac{-|z|^{k-1}}{2\pi}\cos\big(k(\xi-\zeta)-(\vartheta-\zeta)\big)\big(r^k+r^{-k}\big),$$

and the normal derivative on the circle $\Gamma=\{z:|z|=\rho\}$ can (formally) be computed as

$$\frac{\partial v}{\partial r}(\rho,\xi)=\sum_{k=1}^{\infty}\frac{-k|z|^{k-1}}{2\pi}\frac{\cos\big(k(\xi-\zeta)-(\vartheta-\zeta)\big)}{\sqrt{\rho}}\big(\rho^{k-1/2}-\rho^{-k-1/2}\big).$$

This function belongs to $H_{\diamond}^{-1/2}(\Gamma)$ if and only if the sum

$$\sum_{k=1}^{\infty}k^{-1}\Big(\frac{-k|z|^{k-1}}{2\pi}\Big)^2\big(\rho^{k-1/2}-\rho^{-k-1/2}\big)^2 = \sum_{k=1}^{\infty}\frac{k|z|^{2k-2}(\rho^{2k-1}-2\rho^{-1})}{4\pi^2}+\frac{1}{4\pi^2\rho^3}\sum_{k=1}^{\infty}k\Big(\frac{|z|}{\rho}\Big)^{2k-2}$$

converges. While the first sum is always finite, for the second sum this is the case if and only if $\rho>|z|$, i.e., if the test point z is located in the interior of the inclusion Ω. This illustrates the evidence of Lemma 3.5.

According to Theorem 3.1 we may alternatively use the spectral decomposition of $\Lambda_\sigma-\Lambda_{\mathbb{1}}$ (cf. (2.4)),

$$\Lambda_\sigma-\Lambda_{\mathbb{1}}:\begin{Bmatrix}\frac{1}{\sqrt{\pi}}\cos k\xi\\ \frac{1}{\sqrt{\pi}}\sin k\xi\end{Bmatrix}\longmapsto\frac{2}{k}\frac{\mu\rho^{2k}}{1-\mu\rho^{2k}}\begin{Bmatrix}\frac{1}{\sqrt{\pi}}\cos k\xi\\ \frac{1}{\sqrt{\pi}}\sin k\xi\end{Bmatrix}.$$

Indeed, we can actually calculate (formally) the preimage of $g_{z,d}$ under $|\Lambda_\sigma-\Lambda_{\mathbb{1}}|^{1/2}$, namely,

$$|\Lambda_\sigma-\Lambda_{\mathbb{1}}|^{-1/2}g_{z,d}=\sum_{k=1}^{\infty}-\frac{|z|^{k-1}}{\pi}\Big|\frac{2}{k}\frac{\mu\rho^{2k}}{1-\mu\rho^{2k}}\Big|^{-1/2}\cos\big(k(\xi-\zeta)-(\vartheta-\zeta)\big),$$

which is an element of $L^2_{\diamond}(T)$ if and only if the Fourier coefficients are square summable. Obviously, this takes place if and only if $|z|<\rho$, thus leading to the same result as predicted by Theorem 3.1.

4. Generalizations.

4.1. Multiple inclusions. Our first generalization concerns the practically important case of finitely many separated inclusions. By this we mean simply connected open domains $\Omega_1,\dots,\Omega_p$ with $\overline{\Omega}_i\cap\overline{\Omega}_j=\emptyset$ for $i\neq j$. Our aim is to carry over Theorem 3.1 to the case of piecewise constant conductivities, i.e.,

$$\sigma(x)=\begin{cases}\kappa, & x\in\overline{\Omega}_j,\quad j=1,\dots,p,\\ 1, & x\in B\setminus\overline{\Omega},\end{cases}\tag{4.1}$$

where $\Omega=\Omega_1\cup\cdots\cup\Omega_p$. Basically the proof for a single inclusion can be adopted with few minor modifications on which we will comment now.

Since the inner boundary now consists of several components $\Gamma_j = \partial\Omega_j$, it is convenient to set $\Gamma = \Gamma_1 \times \cdots \times \Gamma_p$ and interpret the relevant Sobolev spaces accordingly as product spaces, e.g., $H_\diamond^{\pm 1/2}(\Gamma) = H_\diamond^{\pm 1/2}(\Gamma_1) \times \cdots \times H_\diamond^{\pm 1/2}(\Gamma_p)$.

The operator L is again defined by (3.1), (3.2), where the inner Neumann boundary condition should be understood componentwise, i.e., $\frac{\partial v^+}{\partial \nu} = \phi_j$ on Γ_j, $j = 1, \ldots, p$, for $\phi = (\phi_1, \ldots, \phi_p) \in H_\diamond^{-1/2}(\Gamma)$.

For the definition of its dual operator we consider again the boundary value problem (3.3), whose solution v' is unique up to an additive constant. Special care now has to be taken because in general no solution fulfills all normalization conditions $\oint_{\Gamma_j} v'\, ds = 0$, $j = 1, \ldots, p$, at once. It turns out that each trace component $v'|_{\Gamma_j}$ has to be normalized independently, i.e., if we fix an arbitrary solution v' and set $c_j = \big(\oint_{\Gamma_j} v'\, ds\big) \,/\, \big(\oint_{\Gamma_j} ds\big)$, then one verifies that the dual operator of L is given by

$$L' : H_\diamond^{-1/2}(T) \longrightarrow H_\diamond^{1/2}(\Gamma), \qquad \phi' \longmapsto (v'|_{\Gamma_1} - c_1, \ldots, v'|_{\Gamma_p} - c_p).$$

The proofs of the factorization in Lemma 3.2 and the range characterization in section 3.2 then remain essentially unchanged if boundary conditions on Γ are interpreted componentwise. Thus we have shown:

PROPOSITION 4.1. *Theorem* 3.1 *holds also true in the case* (4.1) *of multiple inclusions.*

4.2. Insulating and perfectly conducting inclusions. Next we extend Theorem 3.1 to the extreme cases of insulating ($\kappa = 0$) and perfectly conducting ($\kappa = \infty$) inclusions, for which the forward problems must be modeled slightly differently.

No current can flow into an insulating inclusion; this is expressed by the inner boundary condition $\frac{\partial u^+}{\partial \nu} = 0$ on Γ. Thus, the forward problem can be formulated as follows:

$$\Delta u = 0 \quad \text{in } B \setminus \overline{\Omega}, \qquad \frac{\partial u}{\partial \nu} = f \quad \text{on } T, \qquad \frac{\partial u^+}{\partial \nu} = 0 \quad \text{on } \Gamma,$$

for which a unique weak solution $u_\sigma \in H^1_{\diamond,T}(B \setminus \overline{\Omega})$ exists; here, by a weak solution we mean $u_\sigma \in H^1_{\diamond,T}(B \setminus \overline{\Omega})$ satisfying

$$\int_{B\setminus\overline{\Omega}} \nabla u_\sigma \cdot \nabla \phi \, dx = \oint_T f\phi \, ds \qquad \text{for all } \phi \in H^1_{\diamond,T}(B \setminus \overline{\Omega}).$$

In perfectly conducting inclusions potential differences would even out immediately so that there the potential must be constant. Consequently, also in this case the differential equation needs only to be considered in $B \setminus \overline{\Omega}$ if one encloses the source freedom of the inclusion as an additional condition, which implicitly determines the value of the potential constant inside of Ω. The forward problem thus may be stated as follows:

$$\begin{aligned} &\Delta u = 0 \quad \text{in } B \setminus \overline{\Omega}, && \frac{\partial u}{\partial \nu} = f \quad \text{on } T, \\ &u^+ = \text{const} \quad \text{on } \Gamma, && \oint_\Gamma \frac{\partial u^+}{\partial \nu}\, ds = 0, \end{aligned} \tag{4.2}$$

for which we seek a solution u_σ normalized according to $\oint_T \frac{\partial u^+}{\partial \nu}\, ds = 0$. By means of the subspace

$$\tilde{H}^1_{\diamond,T}(B \setminus \overline{\Omega}) = \{u \in H^1_{\diamond,T}(B \setminus \overline{\Omega}) : u|_\Gamma = \text{const}\}$$

the corresponding weak formulation then reads as follows: determine $u_\sigma \in \tilde{H}^1_{\diamond,T}(B\setminus\overline{\Omega})$ satisfying

$$\int_{B\setminus\overline{\Omega}} \nabla u_\sigma \cdot \nabla\phi \, dx = \oint_T f\phi \, ds \qquad \text{for all } \phi \in \tilde{H}^1_{\diamond,T}(B \setminus \overline{\Omega}).$$

In both the insulating and the perfectly conducting cases the solution u_σ is also given as the minimizer of

$$\frac{1}{2}\int_{B\setminus\overline{\Omega}} |\nabla u|^2 \, dx - \oint_T fu \, ds$$

in the spaces $H^1_{\diamond,T}(B\setminus\overline{\Omega})$ and $\tilde{H}^1_{\diamond,T}(B\setminus\overline{\Omega})$, respectively. This fact allows us to extend the monotonicity property of Lemma 2.1(b) to these two extreme cases.

The factorization of the Neumann–Dirichlet map, $\Lambda_\sigma - \Lambda_{\mathbb{1}} = L'FL$, follows along the lines of section 3.1. Since as stressed above the operators L and L' depend anyhow only on Ω, merely the definition of F has to be adjusted. However, the properties of F shown in Lemma 3.3 also hold in these cases; see [2] for details. The proof of the equality (3.13) relies only on these properties and on the definiteness of $\Lambda_\sigma - \Lambda_{\mathbb{1}}$, which follows from the monotonicity.

PROPOSITION 4.2. *Theorem* 3.1 *is also valid if* $\kappa = 0$ *or* $\kappa = \infty$.

It should be emphasized here that Hähner [9] recently gave a similar characterization for grounded perfectly conducting inclusions. There, the grounding is expressed by zero Dirichlet boundary conditions on the inner boundary Γ replacing the two last conditions in (4.2).

4.3. Nonconstant conductivity inside inclusions. Now we want to generalize Theorem 3.1 to our initial situation (1.2), where the conductivity is allowed to vary within Ω subject to the constraint (1.3). The idea here is to reduce this case to the already proven results by sandwiching the nonconstant conductivity distribution between piecewise constant ones.

Let us assume that $\kappa(x) \geq 1+\varepsilon$ (the case $\kappa(x) \leq 1-\varepsilon$ can be treated analogously). If we set

$$\underline{\sigma}(x) = \begin{cases} 1+\varepsilon, & x \in \Omega, \\ 1, & x \in B\setminus\overline{\Omega}, \end{cases} \qquad \text{and} \qquad \overline{\sigma}(x) = \begin{cases} \infty, & x \in \Omega, \\ 1, & x \in B\setminus\overline{\Omega}, \end{cases}$$

then we have $\underline{\sigma} \leq \sigma \leq \overline{\sigma}$ and by the monotonicity of the Neumann–Dirichlet map

$$\Lambda_{\overline{\sigma}} - \Lambda_{\mathbb{1}} \leq \Lambda_\sigma - \Lambda_{\mathbb{1}} \leq \Lambda_{\underline{\sigma}} - \Lambda_{\mathbb{1}} \leq O, \tag{4.3}$$

where the ordering of the operators is to be understood in the sense of positive semidefiniteness as in Lemma 2.1(b).

Now we utilize an auxiliary result, namely, that for a self-adjoint and injective operator A we have

$$y \in \mathcal{R}(A) \qquad \text{if and only if} \qquad \sup_{0\neq x\in\mathcal{D}(A)} \frac{\langle y, x\rangle}{\|Ax\|} < \infty. \tag{4.4}$$

This is seen as follows: first note that the inverse of an injective self-adjoint operator A is itself self-adjoint and $\mathcal{R}(A) = \mathcal{D}(A^{-1}) = \mathcal{D}(A^{-*})$. But by definition we have

$y \in \mathcal{D}(A^{-*})$ if and only if $\sup\{\frac{\langle A^{-1}z,y\rangle}{\|z\|} : 0 \neq z \in \mathcal{D}(A^{-1})\} < \infty$; see, e.g., [19, sect. 13]. Using $\mathcal{D}(A^{-1}) = \mathcal{R}(A)$ and substituting $z = Ax$ then yields (4.4).

We apply this to our situation by letting $y \in \mathcal{R}(|\Lambda_\sigma - \Lambda_{\mathbb{1}}|^{1/2})$. From (4.3) and (4.4) we obtain

$$\sup_{0\neq x\in L^2_\diamond(T)} \frac{\langle y,x\rangle_{L^2(T)}}{\||\Lambda_{\overline{\sigma}} - \Lambda_{\mathbb{1}}|^{1/2}x\|_{L^2_\diamond(T)}} \leq \sup_{0\neq x\in L^2_\diamond(T)} \frac{\langle y,x\rangle_{L^2(T)}}{\||\Lambda_\sigma - \Lambda_{\mathbb{1}}|^{1/2}x\|_{L^2_\diamond(T)}} < \infty,$$

and then it follows that $y \in \mathcal{R}(|\Lambda_{\overline{\sigma}} - \Lambda_{\mathbb{1}}|^{1/2})$ again by (4.4). Thus we have $\mathcal{R}(|\Lambda_\sigma - \Lambda_{\mathbb{1}}|^{1/2}) \subset \mathcal{R}(|\Lambda_{\overline{\sigma}} - \Lambda_{\mathbb{1}}|^{1/2})$ and correspondingly we can show that $\mathcal{R}(|\Lambda_{\underline{\sigma}} - \Lambda_{\mathbb{1}}|^{1/2}) \subset \mathcal{R}(|\Lambda_\sigma - \Lambda_{\mathbb{1}}|^{1/2})$. But since $\mathcal{R}(|\Lambda_{\underline{\sigma}} - \Lambda_{\mathbb{1}}|^{1/2}) = \mathcal{R}(|\Lambda_{\overline{\sigma}} - \Lambda_{\mathbb{1}}|^{1/2}) = \mathcal{R}(L)$ (cf. (3.13)), $\mathcal{R}(|\Lambda_\sigma - \Lambda_{\mathbb{1}}|^{1/2})$ also must coincide with $\mathcal{R}(L)$.

PROPOSITION 4.3. *Theorem* 3.1 *is also valid for conductivity distributions of the form* (1.2) *subject to the constraint* (1.3).

4.4. Nonconstant and anisotropic background. Our proofs can be adapted in a straightforward way to the case of smoothly varying background conductivities which may even be anisotropic. We emphasize that for our method the background conductivity is required to be a priori known in each of these situations, and only the support of the discontinuous perturbations to this background can be reconstructed.

Let us consider conductivity distributions of the form

$$\sigma(x) = \begin{cases} \kappa(x), & x \in \overline{\Omega}, \\ \gamma(x), & x \in B \setminus \overline{\Omega}, \end{cases} \tag{4.5}$$

where the *background conductivity* $\gamma(x) = (\gamma_{ij}(x))$ is a smooth and symmetric positive definite matrix in $\overline{B}$, and the conductivity inside the inclusion, $\kappa(x) = (\kappa_{ij}(x))$, is symmetric positive definite. The discontinuity condition now takes the form

$$\kappa(x) \geq (1+\varepsilon)\gamma(x) \quad \text{or} \quad \kappa(x) \leq (1-\varepsilon)\gamma(x) \qquad \text{for } x \in \overline{\Omega} \text{ and some } \varepsilon > 0, \tag{4.6}$$

where the matrix ordering is to be understood in the sense of positive semidefiniteness.

As test functions we utilize the boundary values $g_{z,d}(x) = (d \cdot \nabla_z N(z,x))|_T$ of a directional derivative of the Neumann function $N(z,x)$ associated with the differential operator $\nabla\cdot\gamma\nabla$ in B. The Neumann–Dirichlet operator corresponding to γ is denoted by Λ_γ.

PROPOSITION 4.4. *Under the assumption* (4.6) *we have* $g_{z,d} \in \mathcal{R}(|\Lambda_\sigma - \Lambda_\gamma|^{1/2})$ *if and only if* $z \in \Omega$.

Sketch of proof. If $\kappa(x) = \kappa\gamma(x)$ for a constant κ, then one can go step by step through the proof of section 3, replacing the Laplacian by $\nabla\cdot\gamma\nabla$ at every occurrence. The case of more general $\kappa(x)$ is treated by employing the "sandwiching technique" from section 4.3. ∎

4.5. Putting it all together. Propositions 4.1 to 4.4 generalize our findings in several directions independently. However, these extensions can be combined in a straightforward way. For instance, if the conductivity has the form

$$\sigma(x) = \begin{cases} \kappa_j(x), & x \in \overline{\Omega}_j, \quad j = 1,\dots,p, \\ \gamma(x), & x \in B \setminus \overline{\Omega}, \end{cases}$$

of section 4.4 with *several inclusions* Ω_j with $0 \leq \kappa_j(x) \leq (1-\varepsilon)\gamma(x)$ for $x \in \overline{\Omega}_j$, $j = 1,\dots,p$, then one would first sandwich κ in $\overline{\Omega}$ between 0 and $(1-\varepsilon)\gamma(x)$ as in section 4.3 and then proceed as in sections 4.1, 4.2, and 4.4.

Acknowledgements. The author is indebted to Martin Hanke for countless discussions about the subject and for many detailed hints, which improved the presentation of this paper considerably. The author is also grateful to Andreas Kirsch for the continuous readiness to share his ideas for the related inverse scattering problem, and to Michael Pidcock for inspiring and encouraging discussions.

TRAVELLING WAVES FOR FOURTH ORDER PARABOLIC EQUATIONS*

JAN BOUWE VAN DEN BERG†, JOSEPHUS HULSHOF‡, AND ROBERTUS C. VANDERVORST†§

Abstract. We study travelling wave solutions for a class of fourth order parabolic equations. Travelling wave fronts of the form $u(x,t) = U(x+ct)$, connecting homogeneous states, are proven to exist in various cases: connections between two stable states, as well as connections between an unstable and a stable state, are considered.

Key words. travelling wave, fourth order equation, nonlinear parabolic equation, bistable equation, Poincaré transformation, global analysis

1. Introduction.

Fourth order parabolic equations of the form

$$u_t = -\gamma u_{xxxx} + u_{xx} + f(u), \qquad \gamma > 0, \tag{1.1}$$

where $x \in \mathbb{R}$, $t > 0$, occur in many physical models such as the theory of phase-transitions [9], nonlinear optics [1], shallow water waves [7], etc. Usually the potential $F(u) = \int f(s)ds$ has at least two local maxima (stable state) and one local minimum (unstable state).[1] A prototypical example is $f_a(u) = (u+a)(1-u^2)$ with $-1 < a < 1$.

For a thorough understanding of (1.1), the stationary problem is of great importance. An extensive literature on this subject exists (see, e.g., [3, 29, 7, 16, 17, 18, 25, 22, 23, 24]). Typically, depending on the parameter γ, the stationary problem displays a multitude of periodic, homoclinic, and heteroclinic solutions. The stationary equation is Hamiltonian, which restricts the possible connections between the equilibrium points. As an example we mention that when the maximum of F is attained in two points, e.g., $F(u) = -\frac{1}{4}(u^2-1)^2$, a solution connecting these maxima exists for all $\gamma > 0$. One could regard this solution as a standing wave. The heteroclinic solution is unique (modulo the obvious symmetries) for small values of γ, say, $\gamma \le \gamma_1(f)$ [28, 29, 19]. On the other hand, for large γ, say, $\gamma > \gamma_2(f)$, there is a multitude of (multibump/transition) solutions connecting the two maxima [17, 18, 24]. This is due to the fact that as γ crosses the critical value $\gamma = \gamma_2(f)$, the eigenvalues of the linearized stationary equation around the two maxima of F become complex.

In the special case $f(u) = u - u^3$, corresponding to $F(u) = -\frac{1}{4}(u^2-1)^2$, it holds that $\gamma_1(f) = \gamma_2(f) = \frac{1}{8}$. Although in many simple cases equality holds, generally

[1]Sometimes the potential is denoted by $-F$ so that the stable states correspond to local minima.

there will be a gap between $\gamma_1(f)$ and $\gamma_2(f)$. The critical value γ_1 is not necessarily small, and a lower bound on γ_1 can in general be explicitly determined (see [29] for more details).

For the time-dependent problem travelling fronts of the form $u(x,t) = U(x + ct)$, connecting extrema of the potential F, play a prominent role in most models. Results on travelling waves for (1.1) have previously been obtained in [6], where nonlinearities of the form $f(u) = f_a(u) = (u + a)(1 - u^2)$, $a \approx 0$, are considered using transversality arguments and perturbing near a standing wave. Moreover, in [2] singular perturbations techniques were applied near $\gamma = 0$. In both cases travelling waves between local maxima (stable states) are studied. A recent work [27] deals with singular perturbations techniques for travelling waves connecting an unstable and a stable state; the stability of these waves for very small γ is also established. Furthermore, in the context of singular perturbation theory, travelling waves for higher order parabolic equations have been studied in [15].

The objective of this paper is to obtain existence results for a large range of parameter values. We therefore study travelling waves of (1.1) via topological arguments rather than perturbation methods. To illustrate the underlying ideas of the method, let us consider the related second order parabolic equation, i.e., $\gamma = 0$. Such equations arise as models in, for example, population genetics and combustion theory [4]. In the special case where $f(u) = f_a(u)$, (1.1) with $\gamma = 0$ admits a travelling wave solution $u(x,t) = \tanh\big(\frac{x+a\sqrt{2}t}{\sqrt{2}}\big)$. This travelling wave connects the two stable homogeneous states $u = -1$ and $u = +1$. The literature on this problem is extensive and we will not attempt to give a complete list. However, a few key references are of importance for explaining the similarities of the second and fourth order problems. In the case $\gamma = 0$ the equation for travelling waves $u(x,t) = U(x + ct)$ is given by $cU' = U'' + f(U)$. A phase plane analysis for both $0 < c \ll 1$ and $c \gg 1$ shows two topologically different phase portraits, from which the conclusion may be drawn that a global bifurcation has to take place for some intermediate c-value(s). In this way a wave speed c_0 can be found for which a travelling wave exists which connects the two local maxima of F. In this context we mention the work by Fife and McLeod [13] based on an analytic approach and Conley's more topological approach [8].

From the second order problem we learn that for the present problem it is sensible to look for topologically different phase portraits (in $\mathbb{R}^4$) for small and large values of c. A big part of our analysis will be to do just that.

In order to simplify the exposition of the main results we reformulate (1.1) as

$$u_t = -u_{xxxx} + \alpha u_{xx} + f(u), \tag{1.2}$$

via the rescaling $x \mapsto \gamma^{\frac{1}{4}} x$, with $\alpha = \frac{1}{\sqrt{\gamma}}$. Notice that (1.2) also has meaning for $\alpha \leq 0$.

Let us start now with the hypotheses on the nonlinearity:

$$(\mathrm{H}_0)\quad \begin{cases} \bullet\ F'(u) = f(u) \in C^1(\mathbb{R}); \\ \bullet\ f(u) = 0 \Leftrightarrow u \in \{\pm 1, -a\} \text{ for some } a \in (-1,1), \text{ and } f'(\pm 1) \neq 0,\ f'(-a) \neq 0; \\ \bullet\ F(-1) < F(+1); \\ \bullet\ F(u) \to -\infty \text{ as } u \to \pm\infty; \\ \bullet\ \text{for some } M > 0 \text{ it holds that } f'(u) \leq M \text{ for all } u \in \mathbb{R}.^2 \end{cases}$$

Of course, the prototypical example $f_a(u) = (u+a)(1-u^2)$ satisfies (H_0). We remark that the third condition excludes the existence of a standing wave which connects

[2]Note that $f'(u)$ may be unbounded from below.

two different equilibria. The last condition is a technical one, which we use to obtain certain a priori bounds. Without loss of generality we set

$$F(u) = \int_1^u f(s)ds,$$

so that $F(1) = 0$.

Denote the wave speed by c, and, searching for a travelling wave, we set $u(x,t) = U(x+ct)$, which, switching to lower case again, reduces (1.2) to the ordinary differential equation

$$cu' = -u'''' + \alpha u'' + f(u). \tag{1.3}$$

An important ingredient of our analysis is a conserved quantity for (1.3) when $c = 0$, which is a Lyapunov function when $c \neq 0$. Define

$$\mathcal{E}(u, u', u'', u''') \stackrel{\text{def}}{=} -u'u''' + \frac{1}{2}u''^2 + \frac{\alpha}{2}u'^2 + F(u). \tag{1.4}$$

Multiplying (1.3) by u' we find that

$$\mathcal{E}'(u, u', u'', u''') = cu'^2, \tag{1.5}$$

so that $\mathcal{E}$, which will be referred to as the *energy* of the solution, is increasing along orbits if $c > 0$, constant if $c = 0$, and decreasing if $c < 0$. When we are looking for a solution of (1.3) connecting $u = -1$ to $u = 1$, we see that we can restrict our attention to $c > 0$.

The first theorem deals with the connection between the two stable states $u = -1$ and $u = +1$. This connection is nongeneric with respect to the wave speed c. Noting that $F(u) \leq 0$ for all $u \in \mathbb{R}$ if f satisfies hypothesis (H_0), we define

$$\sigma(f) \stackrel{\text{def}}{=} \min_{-1<u<-a} \frac{-F(u)}{2f(u)^2}. \tag{1.6}$$

THEOREM 1.1. *Let f satisfy hypothesis (H_0) and let $\alpha > \frac{1}{\sqrt{\sigma(f)}}$. Then, for some wave speed $c = c_0(f) > 0$, there exists a travelling wave solution of (1.2) connecting $u = -1$ to $u = +1$.*

The analogous condition on γ for (1.1) reads $0 < \gamma < \sigma(f)$.

At the minimum in (1.6) the equality $\frac{-F(u)}{2f(u)^2} = \frac{-1}{4f'(u)}$ holds. We easily derive that for our model nonlinearity f_a we have $\sigma(f_a) > \frac{1}{8(1-a)}$ for all $0 < a < 1$. Although this estimate is sharp for $a \to 0$, it is not sharp at all for larger values of a.

For general nonlinearities $f(u)$ satisfying (H_0), a lower bound on σ is

$$\sigma \geq \min\Big\{ \frac{-1}{4f'(u)} \;\Big|\; u \in (-1,-a) \text{ and } f'(u) < 0 \Big\}. \tag{1.7}$$

This estimate is often easier to compute than σ itself, but it is in general a rather blunt estimate. Finally, we remark that the critical value σ is also encountered in the study of homoclinic orbits for $c = 0$ (see [22, Theorem B]). This originates from the similarity of that problem with the proof of Lemma 5.1, which is in fact the only instance in our analysis where γ is required to be smaller than σ.

We do not obtain much insight in the shape of the travelling wave from Theorem 1.1. Because Theorem 1.1 does not give information about the wave speed, it is not known whether the connected equilibrium points are approached monotonically or in an oscillatory manner. The linearized equation around the equilibrium points leads to the following characteristic equation for the eigenvalues: $c\lambda = -\lambda^4 + \alpha\lambda + f'(\pm 1)$. A few conclusions can be drawn from analyzing this equation. It follows that for $\alpha \geq \sqrt{-4f'(1)}$ the travelling wave tends to $+1$ monotonically as $x \to \infty$. Besides, for $\alpha \leq \sqrt{-4f'(-1)}$ the travelling wave tends to -1 in an oscillatory way as $x \to -\infty$. For other cases the behavior in the limits depends on the value of c.

The travelling wave solution found in Theorem 1.1 connects the two maxima of F. Theorem 1.1 can be extended to potentials F having many local extrema, i.e., $f(u)$ having many zeros. In that case we find a travelling wave connecting the global maximum and the second largest local maximum of F. The other conditions on F remain the same, but we also need that $f(u)u < 0$ for large values of $|u|$. The definition of σ in this case is, setting $\max_{u\in\mathbb{R}} F(u) = 0$,

$$\sigma(f) \stackrel{\text{def}}{=} \inf\left\{ \frac{-F(u)}{2f(u)^2} \;\middle|\; u \in \mathbb{R} \text{ and } f(u)f'(u) > 0 \right\}.$$

The travelling wave solution found in Theorem 1.1 connects the two stable states. The following theorems deal with travelling waves connecting the unstable state $u = -a$ to one of the stable states $u = \pm 1$. These theorems also apply to the parameter regime where $\alpha \geq 0$, but for these parameter values we need an additional condition on f:

(H_1) f satisfies (H_0) and $\lim_{|u|\to\infty} \dfrac{f(u)}{u} = -\infty$.

THEOREM 1.2. *Let $\alpha \in \mathbb{R}$ and let f satisfy hypothesis* (H_0) *if $\alpha < 0$ and* (H_1) *if $\alpha \geq 0$.*[3] *Then for every $c > 0$ there exists a travelling wave solution of* (1.2) *connecting $u = -a$ to $u = -1$.*

The limiting behavior of the travelling waves can be determined from the characteristic equations. For $\alpha \geq \sqrt{-4f'(-1)}$ the solution tends to -1 monotonically for $x \to \infty$ regardless of the speed c. On the other hand, for $\alpha < \sqrt{-4f'(-1)}$ the limit behavior is oscillatory for small c and monotonic for large c. The limit behavior near $u = -a$ as $x \to -\infty$ is more complicated. For small c the behavior is generically oscillatory, while for large c the solutions generically tends to $-a$ monotonically. We do not know whether the behavior is indeed generic. However, for $\alpha > \sqrt{12f'(-a)}$ there is an intermediate range of c-values for which the travelling wave certainly tends to $-a$ monotonically.

For general potentials F this result applies to any pair of consecutive nondegenerate extrema u_- (a minimum) and u_+ (a maximum), for which the interval $\big(F(u_-), F(u_+)\big)$ contains no critical values and either u_- or u_+ is the only critical point at level $F(u_\pm)$. The other conditions on F remain the same. The method of proof of Theorem 1.2 requires only one of the two extrema -1 or $-a$ to be nondegenerate.

The next theorem deals with the case of travelling waves from $-a$ to $+1$.

THEOREM 1.3. *Let $\alpha \in \mathbb{R}$ and let f satisfy hypothesis* (H_0) *if $\alpha < 0$ and* (H_1) *if $\alpha \geq 0$. Then there exists a constant $c^*(f) > 0$, such that for every $c > c^*$ there exists a travelling wave solution of* (1.2) *connecting $u = -a$ to $u = +1$.*

[3] The result also holds when $F(-1) = F(+1)$.

Theorem 1.3 extends to general potentials, giving travelling waves between any pair of consecutive nondegenerate extrema u_- (a minimum) and u_+ (a maximum), provided the local minimum $\tilde{u}_-$ on the other side of u_+, if it exists, satisfies $F(\tilde{u}_-) > F(u_-)$. Of course, if the opposite inequality holds then one can exchange u_- and $\tilde{u}_-$. If equality holds, i.e., $F(\tilde{u}_-) = F(u_-)$, then one obtains for every $c > c^*$ a travelling wave connecting either u_- or $\tilde{u}_-$ to u_+. Again, the other conditions on F remain the same.

In certain cases one obtains information about the constant c^* in Theorem 1.3. In that case the situation is very much analogous to the second order equation.

COROLLARY 1.4. *Let f satisfy hypothesis* (H_0) *and let $\alpha > \frac{1}{\sqrt{\sigma(f)}}$. Then there exists a $c^*(f) > 0$, such that c^* is the largest speed for which there exists a travelling wave solution of* (1.2) *connecting $u = -1$ to $u = +1$. Moreover, for all $c > c^*$ there exists a travelling wave solution of* (1.2) *connecting $u = -a$ to $u = +1$.*

Finally, we discuss nonlinearities with different behavior for $u \to \pm\infty$. Assume that f has *two* zeros and satisfies

$$(\mathrm{H}_2)\quad \begin{cases} \bullet\ F'(u) = f(u) \in C^1(\mathbb{R}); \\ \bullet\ f(u) = 0 \Leftrightarrow u \in \{0, 1\}, \text{ and } f'(0) \neq 0,\ f'(1) \neq 0; \\ \bullet\ \text{for some } D < 0 \text{ it holds that } F(u) > F(1) \text{ for all } u < D; \\ \bullet\ F(u) \to -\infty \text{ as } u \to \infty; \\ \bullet\ \text{if } \alpha \geq 0, \text{ then } \lim_{|u|\to\infty} \frac{f(u)}{u} = -\infty. \end{cases}$$

A typical example is $f(u) = u(1 - u)$. The following theorem is analogous to Theorem 1.2.

THEOREM 1.5. *Let $\alpha \in \mathbb{R}$ and let f satisfy hypothesis* (H_2). *Then for every $c > 0$ there exists a travelling wave solution of* (1.2) *connecting $u = 0$ to $u = 1$.*

This last theorem is just an example of how the methods in this paper can also be applied when $F(u)$ does not tend to $-\infty$ as $u \to \pm\infty$. The theorem holds under weaker conditions, but we leave this to the interested reader.

Of the results in this paper, the proof of Theorem 1.1 is by far the most involved. This is caused by the fact that connections between local maxima are nongeneric with respect to the wave speed c. Hence, part of the problem is to determine the wave speed c. The idea behind the proof is that one can detect a change in the phase portrait (in $\mathbb{R}^4$) of (1.3) as c goes from small values to large values. In particular, looking for a travelling wave which connects -1 to $+1$, we investigate the global behavior of the orbits in the stable manifold $W^s(1)$ of the equilibrium point $u = +1$.

The analysis for $c > 0$ large is based on a continuation argument deforming the nonlinearity $f(u)$ into a function which is linear on some interval containing $u = 1$.

For $c > 0$ small the analysis is much more involved. A crucial step is that for $c = 0$ all orbits in $W^s(1)$ are unbounded. A first result in this direction was already proved in [29]. There it was shown that, for γ not too large, the bounded stationary solutions of (1.1) correspond exactly to the bounded stationary solutions of the second order equation ($\gamma = 0$). This excludes the existence of bounded orbits in $W^s(1)$. However, since the analysis comprises *all* bounded solutions, this result is limited to a restricted parameter regime. In particular, the equilibrium points $u = \pm 1$ need to be real saddles. In the present situation we want to exclude bounded solutions in the stable manifold of $u = 1$, i.e., we can restrict the analysis to the energy level $\mathcal{E} = 0$. This allows us to cover a larger range of α-values; to be precise, $\alpha > \frac{1}{\sqrt{\sigma(f)}}$. This parameter regime includes cases where both equilibrium points $u = \pm 1$ are saddle-foci. To give an example, for our model nonlinearity $f_a = (u + a)(1 - u^2)$ with $0 < a < 1$

the result from [29] holds for $\alpha \geq \sqrt{8(1+a)}$. The equilibrium points $u = 1$ and $u = -1$ become saddle-foci for $\alpha < \sqrt{8(1+a)}$ and $\alpha < \sqrt{8(1-a)}$, respectively. One may compare this to the estimate $\sigma(f_a) > \frac{1}{8(1-a)}$. Notice that this estimate, although sharp for $a \to 0$, is very blunt for a close to 1.

For the description of unbounded orbits we use a modified Poincaré transformation which we believe is of independent interest. We investigate the unbounded orbits, and we will show that, in an appropriate compactification of the phase space, these orbits must converge to a unique periodic orbit lying at infinity in the phase space. The analysis at infinity largely relies on a global analysis of bounded and unbounded solutions of the family of equations

$$u'''' + u^s = 0 \quad \text{with the convention that} \quad u^s = |u|^{s-1}u, \ s \geq 1.$$

This equation is invariant under the scaling $u(t) \mapsto \kappa u(\kappa^{\frac{s-1}{4}}t)$ for all $\kappa > 0$. The analysis of this equation is in particular used in the proof of finite time blow-up of unbounded solutions, and, more importantly, to determine the behavior of unbounded orbits for $0 \leq c \ll 1$.

From this analysis we conclude that the phase portrait for c positive but small is different from the phase portrait for c large, which in turn is used to prove the existence of a connection between -1 and $+1$ for some intermediate wave speed c_0.

The organization of the paper is as follows. We start with some a priori bounds in section 2. In section 3 we give the proof of Theorem 1.1, and in sections 4 to 6 the details of this proof are filled in. In particular, in section 4 we perform an analysis of the flow "at infinity." Sections 5 and 6 deal with the analysis of the orbits in $W^s(1)$ for small c and large c, respectively. Section 7 discusses the existence of travelling waves connecting $u = -a$ to $u = \pm 1$; Theorems 1.2 to 1.5 are proved here. We conclude with some remarks on open problems in section 8.

2. A priori estimates. We establish a priori bounds on the wave speed c and the profile u for any travelling wave connecting -1 and $+1$. The bound on the wave speed c holds for all $\alpha \in \mathbb{R}$.

LEMMA 2.1. *Let f satisfy hypothesis* (H_0) *and let $\alpha \in \mathbb{R}$. There exists a constant c_0, depending only on α, $F(-1)$, $F(-a)$, and the upper bound M for $f'(u)$, such that when $c > 0$ is a speed for which there exists a travelling wave solution of* (1.3) *connecting -1 to $+1$, then $c \leq c_0$.*

Proof. Suppose u is a solution of (1.3) connecting -1 to $+1$. Integrating (1.5), we have

$$-F(-1) = F(1) - F(-1) = c\int_{-\infty}^{\infty} u'^2. \tag{2.1}$$

Multiplying (1.3) by u'' and integrating (by parts) we obtain

$$\int_{-\infty}^{\infty} u'''^2 + \alpha\int_{-\infty}^{\infty} u''^2 = \int_{-\infty}^{\infty} (f(u))'u' = \int_{-\infty}^{\infty} f'(u)u'^2 \leq M\int_{-\infty}^{\infty} u'^2 = M\frac{-F(-1)}{c}. \tag{2.2}$$

Let $u_1 \in (-a, 1)$ be defined by

$$F(u_1) = \frac{F(-a) + F(-1)}{2}.$$

There must be points $t_0, t_1 \in \mathbb{R}$, $t_0 < t_1$, such that $u(t_0) = -a$, $u(t_1) = u_1$, and $u(t) \in [-a, u_1]$ for $t \in [t_0, t_1]$. The length of this interval is estimated from below by

$$(u_1 + a)^2 = \left(\int_{t_0}^{t_1} u'(t) dt \right)^2 \leq (t_1 - t_0)^2 \int_{t_0}^{t_1} u'(t)^2 dt \leq (t_1 - t_0)^2 \frac{-F(-1)}{c}.$$

On the one hand, because the energy $\mathcal{E}$ increases along orbits, we have

$$\begin{aligned} \int_{t_0}^{t_1} \left(-u'''(t)u'(t) + \frac{1}{2}u''(t)^2 + \frac{\alpha}{2}u'(t)^2 \right) dt & \\ \geq \int_{t_0}^{t_1} \big(F(-1) - F(u(t)) \big) dt & \\ \geq (F(-1) - F(u_1))(t_1 - t_0) = \frac{F(-1) - F(-a)}{2}(t_1 - t_0) & \\ \geq \frac{F(-1) - F(-a)}{2}(u_1 + a)\sqrt{\frac{c}{-F(-1)}}. & \end{aligned} \tag{2.3}$$

We now first restrict to the case that $\alpha > 0$, and come back to the other case later on. Using (2.1) and (2.2), we obtain the estimate

$$\begin{aligned} \int_{t_0}^{t_1} \left(-u'''(t)u'(t) + \frac{1}{2}u''(t)^2 + \frac{\alpha}{2}u'(t)^2 \right) dt & \\ \leq \int_{t_0}^{t_1} \left(\frac{1}{2}\big(u'''(t)^2 + u''(t)^2 \big) + \frac{1+\alpha}{2}u'(t)^2 \right) dt & \\ \leq \left(M \max\left\{ \frac{1}{\alpha}, 1 \right\} + 1 + \alpha \right) \frac{-F(-1)}{2c}. & \end{aligned} \tag{2.4}$$

By combining (2.3) and (2.4) we obtain

$$\frac{F(-1) - F(-a)}{2}(u_1 + a)\sqrt{\frac{c}{-F(-1)}} \leq \left(M \max\left\{ \frac{1}{\alpha}, 1 \right\} + 1 + \alpha \right) \frac{-F(-1)}{2c}.$$

Since also

$$\frac{F(-1) - F(-a)}{2} = F(u_1) - F(-a) \leq \frac{M}{2}(u_1 + a)^2,$$

it follows that

$$c \leq M^{\frac{1}{3}} \left(M \max\left\{ \frac{1}{\alpha}, 1 \right\} + 1 + \alpha \right)^{\frac{2}{3}} \frac{-F(-1)}{F(-1) - F(-a)}.$$

This completes the proof of the lemma for the case that $\alpha > 0$.

We now deal with the case $\alpha \leq 0$. The first part of estimate 2.4 is replaced by

$$\begin{aligned} \int_{t_0}^{t_1} \left(-u'''(t)u'(t) + \frac{1}{2}u''(t)^2 + \frac{\alpha}{2}u'(t)^2 \right) dt & \\ \leq \int_{-\infty}^{\infty} \left(\frac{1}{2}u'''(t)^2 + \frac{1}{2}u''(t)^2 + \frac{1}{2}u'(t)^2 \right) dt & \end{aligned}$$

$$= \int_{-\infty}^{\infty} \left(u'''(t)^2 + \alpha u''(t)^2 + \left(\frac{1}{2} - \alpha\right) u''(t)^2 - \frac{1}{2} u'''(t)^2 + \frac{1}{2} u'(t)^2 \right) dt$$
$$\leq \int_{-\infty}^{\infty} \left(u'''(t)^2 + \alpha u''(t)^2 + \frac{4\alpha^2 - 4\alpha + 5}{8} u'(t)^2 \right) dt,$$

where we have used that $\int_{-\infty}^{\infty} u''^2 \leq \lambda \int_{-\infty}^{\infty} u'''^2 + \frac{1}{4\lambda} \int_{-\infty}^{\infty} u'^2$ for all $\lambda > 0$. The remainder of the proof is the same as above. □

The L^∞-bound on the profile u holds for $\alpha > 0$, or equivalently, for all $\gamma > 0$.

LEMMA 2.2. *Let f satisfy hypothesis* (H_0) *and let $\alpha > 0$. There exists a constant C_1, depending only on α, $F(-1)$, $F(-a)$, and the upper bound M for $f'(u)$, such that when u is, for some $c > 0$, a travelling wave solution of* (1.3) *connecting -1 to $+1$, then $F(u) \geq C_1$.*

Proof. We may suppose that there is a connection u with range not contained in the bounded interval $\{u \in \mathbb{R} \,|\, F(u) \geq F(-a)\}$, otherwise we already have our desired uniform bound. Therefore, without loss of generality we may assume that

$$F(u(0)) = \min_{t \in \mathbb{R}} F(u(t)) < F(-a). \tag{2.5}$$

We consider the case where $u(0) < -1$ (the case $u(0) > 1$ is completely analogous). Since

$$\mathcal{E}(u, u', u'', u''')(t) \in \big(F(-1), F(1)\big) = \big(F(-1), 0\big) \quad \text{for all } t \in \mathbb{R}, \tag{2.6}$$

we clearly have that

$$u(0) < -1, \quad u'(0) = 0, \quad 0 < \sqrt{2\big(F(-1) - F(u(0))\big)} < u''(0) < \sqrt{-2F(u(0))}.$$

We now consider two cases: $u'''(0) \geq 0$ and $u'''(0) < 0$. We start with the latter case. Since $u(t)$ tends to an equilibrium point as $t \to -\infty$, there exists a $t_1 < 0$ such that $u'''(t) < 0$ for $t_1 < t < 0$ and $u'''(t_1) = 0$, (1.5) implies that

$$-u'(t)u'''(t) + F(u(t)) - F(u(0)) = -\frac{1}{2}\big(u''(t)^2 - u''(0)^2\big) - \frac{\alpha}{2} u'(t)^2 + c \int_0^t u'(s)^2 ds. \tag{2.7}$$

By (2.5) we know that $F(u(t_1)) \geq F(u(0))$, so that

$$\frac{1}{2}\big(u''(t_1)^2 - u''(0)^2\big) + \frac{\alpha}{2} u'(t_1)^2 \leq -c \int_{t_1}^0 u'(s)^2 ds.$$

Since $u''(t)$ decreases on $(t_1, 0)$ and α is positive, this implies that $c < 0$, a contradiction.

We now deal with the case that $u'''(0) \geq 0$. Since $u''''(0) > 0$ by the differential equation, and since $u(t)$ tends to an equilibrium point as $t \to \infty$, there exists a $t_2 > 0$ such that $u'''(t) > 0$ for $0 < t < t_2$ and $u'''(t_2) = 0$. By (2.5) we know that $F(u(t_2)) \geq F(u(0))$. Since $\alpha > 0$, it follows from (2.7) that

$$\frac{\alpha}{2} u'(t_2)^2 \leq c \int_0^{t_2} u'(s)^2 ds \leq c \int_{-\infty}^{\infty} u'(s)^2 ds \leq -F(-1). \tag{2.8}$$

Furthermore, from the fact that $u''(t)$ increases on $(0, t_2)$ we infer that

$$u''(0)t \leq u'(t) \leq u'(t_2) \qquad \text{for } t \in [0, t_2]. \tag{2.9}$$

On the one hand it follows from (2.8) and (2.9) that $\frac{\alpha}{2}u'(t_2)^2 \le c\int_0^{t_2} u'(s)^2 ds \le cu'(t_2)^2 t_2$, hence

$$t_2 \ge \frac{\alpha}{2c}. \tag{2.10}$$

On the other hand it follows from (2.8) and (2.9) that $-F(-1) \ge c\int_0^{t_2} u'(s)^2 ds \ge \frac{1}{3}ct_2^3 u''(0)^2$. Combining with (2.10) we thus obtain that

$$u''(0)^2 \le \frac{-24c^2F(-1)}{\alpha^3}.$$

This gives a bound on $u''(0)^2$, because it follows from Lemma 2.1 that the wave speed c is bounded above by a constant $c_0\big(\alpha, M, F(-a), F(-1)\big)$.

Finally, by (2.5) and (2.6) we have

$$F(u(t)) \ge F(u(0)) \ge F(-1) - \frac{1}{2}u''(0)^2 \qquad \text{for all } t \in \mathbb{R}.$$

This completes the proof of Lemma 2.2. □

3. Proof of Theorem 1.1. In this section we give the proof of Theorem 1.1. Some of the major steps, which require a quite involved analysis, are only stated as a proposition in this section and are proved in subsequent sections.

We first use the a priori bounds of section 2 to reduce our analysis to nonlinearities $f(u)$ of the form $f(u) = -u^3 + g(u)$, where $g(u)$ has compact support. The advantage of such nonlinearities is that they behave nicely as $u \to \pm\infty$, and it will thus be possible to analyze the flow near/at infinity.

Let $f(u)$ satisfy hypothesis (H_0). Lemma 2.2 implies that there exists a constant C_0 such that any travelling wave solution u connecting -1 to $+1$ satisfies $\|u\|_\infty < C_0$. Define the cut-off function $\phi \in C_0^\infty$ with $0 \le \phi \le 1$, $\phi(y) = 1$ for $|y| \le C_0$, and $\phi(y) = 0$ for $|y| > C_0 + 1$. We now consider the modified nonlinearity $\tilde{f}(u) = \phi(u)f(u) - u^3(1-\phi(u))$. Lemma 2.2 ensures that u is a travelling wave solution for nonlinearity $f(u)$ if and only if u is a travelling wave solution for nonlinearity $\tilde{f}(u)$. Besides, $\sigma(f) = \sigma(\tilde{f})$. This shows that we may restrict our analysis to nonlinearities $f(u)$ such that

(3.1) $f(u) = -u^3 + g(u)$ *with* g *compactly supported, and* f *satisfies hypothesis* (H_0).

The purpose of the reduction to nonlinearities f which satisfy (3.1) is that it makes it possible to analyze the orbits which are unbounded. An important property of unbounded solutions, which we will need in the following, is formulated in the next lemma.

LEMMA 3.1. *Let* f *satisfy hypothesis* (3.1) *and let* $\alpha, c \in \mathbb{R}$. *Then any unbounded solution of* (1.3) *blows up in finite time.*

This lemma is proved in section 4.5, Theorem 4.8(b), and is based on the analysis of the flow near/at infinity.

As already discussed in the introduction, denote the wave speed by c. For finding a travelling wave we set $u(x,t) = U(x+ct)$, which reduces (1.1) to the ordinary differential equation (1.3). Written as a four-dimensional system, (1.3) becomes

$$u' = v; \quad v' = w; \quad w' = z; \quad z' = \alpha w - cv + f(u). \tag{3.2}$$

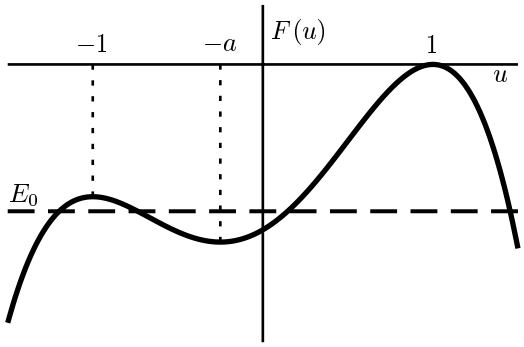

FIG. 3.1. *The potential $F(u)$ and the energy level E_0 separating $u = -a$ from $u = \pm 1$.*

The equilibria of this system are $(u, v, w, z) = (-1, 0, 0, 0)$, $(u, v, w, z) = (-a, 0, 0, 0)$, and $(u, v, w, z) = (1, 0, 0, 0)$ (for short: $u = -1$, $u = -a$, and $u = 1$). To prove Theorem 1.1 we look for a $c \neq 0$ and a corresponding heteroclinic orbit of (3.2) connecting $u = -1$ to $u = 1$. Linearizing around $u = \pm 1$ we find that, irrespective of c, both $u = -1$ and $u = 1$ have two-dimensional stable and unstable manifolds, denoted by $W^s(\pm 1)$ and $W^u(\pm 1)$. Generically $W^s(1)$ and $W^u(-1)$ will not intersect but varying c we expect to pick up a nonempty intersection.

We recall that the *energy* is defined as

$$\mathcal{E}(u, v, w, z) \stackrel{\text{def}}{=} -vz + \frac{1}{2}w^2 + \frac{\alpha}{2}v^2 + F(u),$$

where the potential $F(u) = \int_1^u f(s)ds$ is depicted in Figure 3.1. Since we are looking for a solution of (1.3) which connects $u = -1$ to $u = 1$, we see from (1.5) that we can restrict our attention to $c > 0$. The energy $\mathcal{E}$ thus increases along orbits.

To separate the equilibrium point $u = -a$ from $u = \pm 1$, we choose an energy level E_0 such that (see also Figure 3.1)

$$F(-a) < E_0 < F(-1) < 0,$$

and we define the set

$$K \stackrel{\text{def}}{=} \{(u, v, w, z) \in \mathbb{R}^4 \,|\, \mathcal{E}(u, v, w, z) \geq E_0\}. \tag{3.3}$$

This allows us to formulate the following lemma.

LEMMA 3.2. *Let f satisfy hypothesis* (3.1) *and let $\alpha \in \mathbb{R}$. If $c > 0$ is such that $W^s(1) \cap W^u(-1) = \emptyset$, then every orbit in $W^s(1)$ enters K through its boundary δK and $\hat{\Gamma} = W^s(1) \cap \delta K$ is a simple closed curve. The set of positive c for which this property holds is open and $\hat{\Gamma}$ varies continuously with c.*

Proof. In view of (1.5) the intersection of $W^s(1)$ and δK must be transversal. Assume that $W^s(1) \cap W^u(-1) = \emptyset$. We need to show that every orbit in $W^s(1)$ can be traced back to δK, for then there is bijection between $W^s(1) \cap \delta K$ and a smooth simple closed curve in $W^s_{\text{loc}}(1)$ winding around $u = 1$ (in $W^s_{\text{loc}}(1)$). Arguing by contradiction we assume that there is an orbit in $W^s(1)$ which is completely contained in K. Let $u(t)$ be a solution representing this orbit. Then $u(t)$ exists on some maximal time interval $(t_{\min}, \infty)$. Since $u(t)$ has energy larger than E_0, it follows from (1.5) and

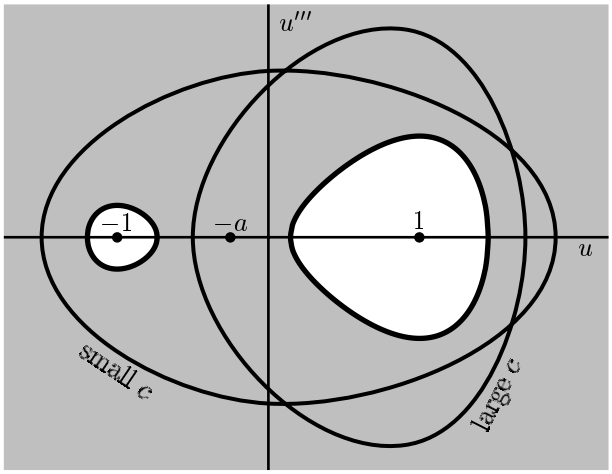

FIG. 3.2. *The projection (in grey) of δK onto the (u,z)-plane. The closed curves which form the boundary of the grey area are given by* (3.6). *The other two curves depict Γ (i.e., the projection of $W^s(1)\cap\delta K$ onto the (u,z)-plane) for small c and large c.*

(3.3) that

$$\int_{t_{\min}}^{\infty} u'^2 \le \frac{F(1)-E_0}{c} = \frac{-E_0}{c}, \tag{3.4}$$

so that $u(t)$ remains bounded on $(t_{\min},\infty)$ if $t_{\min}$ is finite. Thus $t_{\min}=-\infty$ and, by Lemma 3.1, $u(t)$ is bounded. It follows from standard arguments that the orbit converges to a limit as $t\to-\infty$. Because $u=-1$ is the only equilibrium in K with energy less than the energy of $u=1$, we infer that $u(t)\in W^u(-1)$. This contradicts the assumption that $W^s(1)\cap W^u(-1)=\emptyset$. The second statement is an immediate consequence of the (topological) transversality of $W^s(1)\cap\delta K$. □

It now suffices to show that there is a $c>0$ for which the assumption of Lemma 3.2 fails. Again arguing by contradiction, we assume that Lemma 3.2 applies to all $c>0$ and search for a topological obstruction. This requires a description of δK that allows us to form a global picture of this set. To this end we write δK as (with $\alpha>0$)

$$\delta K = \left\{ (u,v,w,z)\in\mathbb{R}^4 \;\middle|\; \frac{\alpha}{2}\left(v-\frac{1}{\alpha}z\right)^2+\frac{1}{2}w^2 = E_0-F(u)+\frac{1}{2\alpha}z^2 \right\}. \tag{3.5}$$

In Figure 3.2 we have plotted the projection of δK onto the (u,z)-plane. For (u,z) lying inside one of the two closed curves (see Figure 3.2) defined by

$$E_0-F(u)+\frac{1}{2\alpha}z^2=0, \tag{3.6}$$

every (u,v,w,z) belongs to K, hence there are no points in δK with (u,z) lying inside these two closed curves. For (u,z) lying outside the two closed curves we have that (u,v,w,z) is in K if (v,w) is outside the ellipse defined by $\frac{\alpha}{2}\big(v-\frac{1}{\alpha}z\big)^2+\frac{1}{2}w^2=0$. We conclude that the projection of δK onto the (u,z)-plane is the region outside the two closed curves defined by (3.6); see Figure 3.2.

The projection of δK onto the (u,z)-plane maps $\hat{\Gamma} = W^s(1) \cap \delta K$, which by assumption exists for all $c > 0$, to a closed but not necessarily simple curve Γ in the (u,z)-plane for which the winding numbers[4] $n(\Gamma,-1)$ and $n(\Gamma,1)$ around $(u,z) = (-1,0)$ and $(u,z) = (1,0)$, respectively, are well defined and independent of c (by continuity). However, the following proposition establishes the configuration depicted in Figure 3.2, contradicting the assumption that $W^s(1) \cap W^u(-1) = \emptyset$ for all $c > 0$, and thereby completing the proof of Theorem 1.1.

PROPOSITION 3.3. *Let f satisfy hypothesis* (3.1).

(a) *Let $\alpha > \frac{1}{\sqrt{\sigma(f)}}$. Then there exists a $c_* > 0$ such that $n(\Gamma,-1) = 1$ and $n(\Gamma,1) = 1$ for all $0 < c < c_*$.*

(b) *Let $\alpha \in \mathbb{R}$. Then there exists a $c^* > 0$ such that $n(\Gamma,-1) = 0$ and $n(\Gamma,1) = 1$ for all $c > c^*$.*

Part (a) of Proposition 3.3 will be proved in Theorem 5.3 in section 5, while part (b) is proved in section 6, Theorem 6.1.

4. Classification of unbounded solutions. In this section we investigate the behavior of unbounded solutions, or in other words, we analyze the flow at infinity. This analysis is relevant both for the proof of finite time blow-up of unbounded solutions, and to determine the behavior of unbounded orbits for $0 \le c \ll 1$. We have argued in section 3 that we may restrict our attention to nonlinearities of the form $f(u) = -u^3 + g(u)$, where $g(u)$ has compact support. It turns out that the flow for large u is governed by the *reduced* equation $u'''' + u^3 = 0$, i.e., only the highest order derivative and the highest order term in the nonlinearity play a role at infinity. In the following sections we investigate the reduced equation, and in section 4.5 we come back to the full equation.

4.1. A modified Poincaré transformation. We analyze the reduced equation

$$u'''' + u^s = 0 \quad \text{with the convention that} \quad u^s = |u|^{s-1}u, \ s \ge 1, \tag{4.1}$$

and we use this notational convention throughout. Written as a system, (4.1) reads

$$x_1' = x_2; \quad x_2' = x_3; \quad x_3' = x_4; \quad x_4' = -x_1^s, \tag{4.2}$$

where x_1, x_2, x_3, and x_4 correspond to u, u', u'', and u'''. Note that for this system the energy (or Hamiltonian)

$$H(x_1,x_2,x_3,x_4) \stackrel{\text{def}}{=} -x_2x_4 + \frac{x_3^2}{2} - \frac{|x_1|^{s+1}}{s+1} \tag{4.3}$$

is a conserved quantity.

Introduce five new dependent variables X_1, X_2, X_3, X_4, and $X_5 > 0$ by setting

$$x_i = \frac{X_i}{X_5^{a_i}} \qquad (i = 1,2,3,4), \tag{4.4}$$

where the exponents a_i are to be chosen shortly. Unbounded orbits of (4.2) will correspond to orbits in the new variables with X_5 approaching zero. By substituting

[4] We may choose the orientation of the simple closed curve in $W^s_{\text{loc}}(1)$ winding around $u = 1$ in such a way that its projection onto the (u,z)-plane has winding number equal to $+1$.

(4.4) in (4.2) we obtain the equations

$$X_5X_1' - a_1X_1X_5' = X_2X_5^{1+a_1-a_2}; \tag{4.5a}$$
$$X_5X_2' - a_2X_2X_5' = X_3X_5^{1+a_2-a_3}; \tag{4.5b}$$
$$X_5X_3' - a_3X_3X_5' = X_4X_5^{1+a_3-a_4}; \tag{4.5c}$$
$$X_5X_4' - a_4X_4X_5' = -X_1^sX_5^{1+a_4-sa_1}, \tag{4.5d}$$

with a fifth equation pending. We choose the exponents in such a way that all the exponents in the right-hand sides of (4.5) are the same, i.e.,

$$b \stackrel{\text{def}}{=} 1 + a_1 - a_2 = 1 + a_2 - a_3 = 1 + a_3 - a_4 = 1 + a_4 - sa_1.$$

Solving for a_1, a_2, a_3, a_4, and b we find

$$a_1 = 4\lambda;\ a_2 = (s+3)\lambda;\ a_3 = (2s+2)\lambda;\ a_4 = (3s+1)\lambda;\ b = 1-(s-1)\lambda, \tag{4.6}$$

where λ is still free and, for the moment, positive. We close system (4.5) by imposing as a fifth equation

$$X_1^sX_1' + X_2X_2' + X_3X_3' + X_4X_4' = 0. \tag{4.7}$$

If we multiply (4.5a)–(4.5d) by X_1^s, X_2, X_3, and X_4 respectively, and add up the resulting equations, we obtain

$$PX_5' = -\frac{1}{\lambda}QX_5^b. \tag{4.8}$$

Here we have set

$$P \stackrel{\text{def}}{=} 4|X_1|^{s+1} + (3+s)X_2^2 + (2+2s)X_3^2 + (1+3s)X_4^2, \tag{4.9}$$

which is nonnegative, and

$$Q \stackrel{\text{def}}{=} X_1^s(X_2 - X_4) + X_3(X_2 + X_4).$$

Introducing a new independent variable, we write

$$\dot{X}_5 = PX_5^{(s-1)\lambda}X_5' = -\frac{1}{\lambda}QX_5, \tag{4.10}$$

where the dot denotes derivation with respect to this new independent variable from which the old one may be recovered by integration. Thus, combining (4.10) and (4.5), we arrive at the system

$$\dot{X}_1 = X_2P - 4X_1Q\,; \tag{4.11a}$$
$$\dot{X}_2 = X_3P - (3+s)X_2Q\,; \tag{4.11b}$$
$$\dot{X}_3 = X_4P - (2+2s)X_3Q\,; \tag{4.11c}$$
$$\dot{X}_4 = -X_1^sP - (1+3s)X_4Q\,. \tag{4.11d}$$

Note that X_5 has been decoupled from the equations. By construction the system (4.11) leaves the surfaces

$$\Sigma \stackrel{\text{def}}{=} \left\{(X_1,X_2,X_3,X_4) \;\middle|\; \frac{|X_1|^{s+1}}{s+1} + \frac{X_2^2}{2} + \frac{X_3^2}{2} + \frac{X_4^2}{2} = C_0\right\} \cong S^3 \tag{4.12}$$

invariant for all $C_0 > 0$. The free parameter λ appears only in (4.10) and may be discarded.

The Poincaré transformation (4.4) is used here to blow up the flow near "infinity." As will be explained in section 4.4 this is equivalent to blowing up the flow near the equilibrium point $u = 0$. This blowing-up technique is frequently used in the study of flows in the neighborhood of nonhyperbolic equilibrium points (see, e.g., [10, 11, 21]). The transformation defined by (4.4) and (4.12) is a variant of the standard Poincaré transformation, which has $a_1 = a_2 = a_3 = a_4 = 1$ and imposes as fifth equation that $X_1^2 + X_2^2 + X_3^2 + X_4^2 + X_5^2$ be constant, so that the transformed problem is situated on the Poincaré sphere. The modification presented above, in particular the choice of exponents, is needed to obtain a nontrivial vector field at infinity from which we may derive the qualitative properties of the flow of the system (4.2) near infinity. The values of the exponents are derived from the invariance of (4.1) under the scaling $u(t) \mapsto \kappa u(\kappa^{\frac{s-1}{4}} t)$.

In (4.7) we have chosen not to include a term $X_5 X_5'$ and to modify the exponent of X_1. This simplifies the new vector field and allows the decoupling of the $\dot{X}_5$-equation. Note that instead of a Poincaré sphere we now have a Poincaré cylinder Π, namely, the topological product of the deformed sphere Σ and the positive X_5-axis:

$$\Pi \stackrel{\text{def}}{=} \{(X_1, X_2, X_3, X_4, X_5) \,|\, (X_1, X_2, X_3, X_4) \in \Sigma,\ X_5 \geq 0\} \cong S^3 \times [o, \infty).$$

The flow of (4.2) is completely determined by the flow of (4.11) on Σ. Therefore, we have a reduction from dimension 4 for (4.2) to dimension 3 for (4.11). The role of $X_5 = 0$ and $X_5 = \infty$ can be reversed by changing from positive to negative λ at the expense of a minus sign in (4.10).

Remark 4.1. The choice of $C_0 > 0$ in (4.12) is arbitrary, because the flows on all spheres Σ are C^1-conjugated (modulo the introduction of the new independent variable in (4.10)). This is in fact the very idea of Poincaré transformations, namely, that we divide out the invariance of (4.1) and focus on the resulting flow. From a more abstract point of view one can construct a flow on the quotient manifold $\big(\mathbb{R}^4 \backslash \{0\}\big)/\mathbb{R}^+ \cong S^3$ via the scaling invariance $u(t) \mapsto \kappa u(\kappa^{\frac{s-1}{4}} t)$ ($\mathbb{R}^+$-action); see [20] for more details. Our construction involves explicit choices of coordinates, for which the flows, by general theory, are all related by conjugation.

To be explicit, let X_i and Y_i be two sets of Poincaré coordinates, i.e.,

$$x_i = \frac{X_i}{X_5^{a_i}} = \frac{Y_i}{Y_5^{a_i}} \qquad \text{for } i = 1, 2, 3, 4,$$

with constraints

$$\frac{|X_1|^{s+1}}{s+1} + \frac{X_2^2}{2} + \frac{X_3^2}{2} + \frac{X_4^2}{2} = C_0, \tag{4.13a}$$

$$\frac{|Y_1|^{s+1}}{s+1} + \frac{Y_2^2}{2} + \frac{Y_3^2}{2} + \frac{Y_4^2}{2} = C_1. \tag{4.13b}$$

When we define $\mu = \frac{X_5}{Y_5}$, then the two sets of coordinates are related by

$$X_5 = \mu Y_5 \qquad \text{and} \qquad X_i = \mu^{a_i} Y_i \quad \text{for } i = 1, 2, 3, 4. \tag{4.14}$$

Substituting this into (4.13a) we obtain

$$G(Y_1, Y_2, Y_3, Y_4, \mu) \equiv \mu^{(s+1)a_1} \frac{|Y_1|^{s+1}}{s+1} + \mu^{2a_2} \frac{Y_2^2}{2} + \mu^{2a_3} \frac{Y_3^2}{2} + \mu^{2a_4} \frac{Y_4^2}{2} = C_0.$$

Since $\frac{\partial G}{\partial \mu} > 0$ for all Y_i that obey (4.13b), it follows from the implicit function theorem that $\mu(Y_1, Y_2, Y_3, Y_4)$ is a differentiable function. It is now easily seen from (4.14) that X_i and Y_i are related by a C^1-conjugacy. Therefore, we may choose the constant C_0 according to our liking to obtain a description of the flow that is most suitable to our needs.

4.2. The flow at infinity. For the analysis of (4.11) we first observe the following.

LEMMA 4.2. *System* (4.11) *has no stationary points on* Σ *for any* $C_0 > 0$.

Proof. Since $X_1 = X_2 = X_3 = X_4 = 0$ is excluded we have that P, defined by (4.9), is positive. Equating the right-hand sides of (4.11) to zero and considering the resulting equations as linear equations in P and Q, it follows that we can only have solutions if every determinant of every pair of two equations vanishes. This would give, for instance, that

$$0 \le (2+2s)X_3^2 = (3+s)X_2X_4;$$
$$0 \le 4|X_1|^{s+1} = -(1+3s)X_2X_4.$$

We conclude that $X_2X_4 = 0$ and with any of the $X_i = 0$ the others thus follow immediately. □

We next use the conserved quantity to obtain a further reduction from dimension 3 to dimension 2 for the limit sets of orbits of (4.5) which approach infinity ($X_5 \to 0$) or the origin ($X_5 \to \infty$). In the new variables the Hamiltonian is

$$H = \left(-X_2X_4 + \frac{X_3^2}{2} - \frac{|X_1|^{s+1}}{s+1} \right) X_5^{-4\lambda(s+1)}. \tag{4.15}$$

Denote the first factor of H by H_0:

$$H_0 \stackrel{\text{def}}{=} -X_2X_4 + \frac{X_3^2}{2} - \frac{|X_1|^{s+1}}{s+1}. \tag{4.16}$$

Since H is a conserved quantity, we conclude that for $\lambda > 0$

$$X_5 \to 0 \quad \Leftrightarrow \quad H_0 \to 0. \tag{4.17}$$

For the classification of unbounded orbits we have to analyze the flow restricted to the invariant set given by

$$T \stackrel{\text{def}}{=} \{(X_1, X_2, X_3, X_4) \in \Sigma \mid H_0 = 0\}$$
$$= \left\{ (X_1, X_2, X_3, X_4) \;\middle|\; \frac{|X_1|^{s+1}}{s+1} + \frac{X_2^2}{2} + \frac{X_3^2}{2} + \frac{X_4^2}{2} = C_0, \frac{X_3^2}{2} = X_2X_4 + \frac{|X_1|^{s+1}}{s+1} \right\}.$$

This set is a topological torus as can be seen by setting

$$X_1 = \xi_1; \quad X_2 = \frac{\xi_2 + \xi_4}{\sqrt{2}}; \quad X_3 = \xi_3; \quad X_4 = \frac{\xi_2 - \xi_4}{\sqrt{2}}, \tag{4.18}$$

so that, in terms of the ξ-variables,

$$T = \left\{ (\xi_1, \xi_2, \xi_3, \xi_4) \;\middle|\; \frac{2}{s+1}|\xi_1|^{s+1} + \xi_2^2 = \xi_3^2 + \xi_4^2 = C_0 \right\} \cong S^1 \times S^1. \tag{4.19}$$

Clearly we have that T is the product of two topological circles, one in the (ξ_1, ξ_2)-plane, the other in the (ξ_3, ξ_4)-plane.

LEMMA 4.3. *Let $s \geq 1$ and fix the constant $C_0 > 0$. Then there exist precisely two periodic orbits Λ_- and Λ_+ of (4.11) on the torus T.*

Proof. The proof is based on the observation that the coefficient Q in (4.10), which after transforming by (4.18) reads

$$Q = \sqrt{2}(\xi_1^s \xi_4 + \xi_2 \xi_3), \tag{4.20}$$

plays a double role. Obviously it determines which parts of infinity attract solutions toward $X_5 = 0$, in forward and in backward time. We begin by showing that Q can also be seen as minus the divergence of the vector field restricted to the invariant torus T. From (4.11) and (4.18) we derive

$$\dot{\xi}_1 = \frac{\xi_2 + \xi_4}{\sqrt{2}} P - 4\xi_1 Q\,; \tag{4.21a}$$

$$\dot{\xi}_2 = \frac{\xi_3 - \xi_1^s}{\sqrt{2}} P - ((2+2s)\xi_2 + (1-s)\xi_4) Q\,; \tag{4.21b}$$

$$\dot{\xi}_3 = \frac{\xi_2 - \xi_4}{\sqrt{2}} P - (2+2s)\xi_3 Q\,; \tag{4.21c}$$

$$\dot{\xi}_4 = \frac{\xi_3 + \xi_1^s}{\sqrt{2}} P - ((1-s)\xi_2 + (2+2s)\xi_4) Q\,. \tag{4.21d}$$

We parametrize T by "polar coordinates"

$$\xi_1 = f_1(\phi); \quad \xi_2 = g_1(\phi); \quad \xi_3 = f_2(\theta); \quad \xi_4 = g_2(\theta), \tag{4.22}$$

satisfying

$$f_1' = -g_1; \quad g_1' = f_1^s; \quad f_2' = -g_2; \quad g_2' = f_2. \tag{4.23}$$

Note that when $C_0 = 1$ and $s = 1$ we just have

$$\xi_1 = \cos\phi; \quad \xi_2 = \sin\phi; \quad \xi_3 = \cos\theta; \quad \xi_4 = \sin\theta.$$

From (4.21a), (4.21c), (4.22), and (4.23) we derive that on T the flow is given by

$$\dot{\phi} = \frac{P}{\sqrt{2}} \left(-1 - \frac{g_2}{g_1} \right) + 4Q \frac{f_1}{g_1} \equiv w_1(\phi, \theta); \tag{4.24a}$$

$$\dot{\theta} = \frac{P}{\sqrt{2}} \left(1 - \frac{g_1}{g_2} \right) + 2(s+1)Q \frac{f_2}{g_2} \equiv w_2(\phi, \theta), \tag{4.24b}$$

where in terms of f_1, g_1, f_2, g_2,

$$P = 4(s+1)C_0 + 2(1-s)g_1 g_2, \qquad \text{and} \qquad Q = \sqrt{2}(f_1^s g_2 + f_2 g_1).$$

The functions w_1 and w_2, defined in (4.24), appear to have singularities, but using (4.19) they can be written as

$$w_1(\phi, \theta) = \sqrt{2}\big[-2(s+1)C_0 - (s+3)g_1 g_2 + (s-1)g_2^2 + 4 f_1 f_2\big],$$
$$w_2(\phi, \theta) = \sqrt{2}\big[2(s+1)C_0 - (3s+1)g_1 g_2 + (s-1)g_1^2 + 2(s+1) f_1^s f_2\big].$$

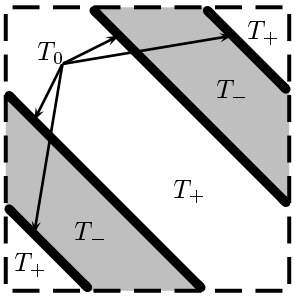

FIG. 4.1. *A fundamental domain of the torus, in which T_-, T_+, and T_0 are indicated (schematically).*

Taking the divergence of the vector field w we obtain (using (4.23),

$$\nabla \cdot w = \frac{\partial w_1}{\partial \phi} + \frac{\partial w_2}{\partial \theta} = \sqrt{2}(-5-3s)(f_1^s g_2 + f_2 g_1) = -(3s+5)Q.$$

Next, we split T into

$$T_+ = \{(X_1, X_2, X_3, X_4) \,|\, Q > 0\} \quad \text{and} \quad T_- = \{(X_1, X_2, X_3, X_4) \,|\, Q < 0\}.$$

These two sets share the boundary

$$T_0 = \{(X_1, X_2, X_3, X_4) \,|\, Q = 0\},$$

which, in view of (4.19) and (4.20), consists of two topological circles, which both wind once around the two homotopically distinct simple loops on the torus (see Figure 4.1). We will show in Lemma 4.4 that, when C_0 is chosen properly, an orbit can only pass through T_0 from T_- to T_+. It then follows from the negativity of $\nabla \cdot w$ in T_+ and the winding properties of T_0 on T that T_+ contains precisely one periodic orbit. The same statement holds for T_- with respect to the backward flow on T.

To be precise, we deduce from (4.22), (4.23), and (4.19) that we may choose $\xi_3 = f_2(\theta) = \sqrt{C_0}\cos\theta$. Define the set $S \stackrel{\text{def}}{=} \{(\theta, \phi) \in T \,|\, \theta = \frac{\pi}{2}\}$, and it follows that

$$\dot{\theta}\Big|_S = \sqrt{2}\left[2(s+1)C_0 - (3s+1)\sqrt{C_0}g_1 + (s-1)g_1^2\right].$$

Since $|g_1| \le \sqrt{C_0}$, it is easy to check that $\dot{\theta}\big|_S \ge 0$, and equality holds only when $g_1 = \sqrt{C_0}$. By continuity arguments the orbit through this point crosses S also in the direction of increasing θ. Thus S is a global section for the flow on T. Moreover, the return map is well defined, since there is no point in T for which the forward orbit is contained in $T \setminus S$. Indeed, such a forward orbit would either be contained in T_- or eventually be in T_+, because T_+ is positively invariant and orbits can only pass through T_0 from T_- to T_+. In the absence of equilibrium points (Lemma 4.2) its ω-limit set would be a periodic orbit. However, there would have to be an equilibrium point inside this periodic orbit, contradicting Lemma 4.2. Hence the return map is well defined. The intersection $S \cap (T_+ \cup T_0)$ consists of the line segment $\{(\theta, \phi) \in T \,|\, \theta = \frac{\pi}{2}, f_1(\phi) \ge 0\}$. The return map maps this line segment into itself, which implies the existence of a periodic orbit in T_+. Similarly, there exists a periodic orbit in T_-. The return map is contracting in T_+ and expanding in T_-, since the divergence

of the vector field is negative in T_+ and positive in T_-. This proves the uniqueness of the two period orbits and shows that all other orbits on the torus T have Λ_- as α-limit set and Λ_+ as ω-limit set.

We remark that the same conclusion can be reached by combining the Poincaré–Bendixson theorem for flows on the torus and the Morse theory for Morse–Smale flows.

Finally, note that, although the preceding proof needs C_0 to have a particular value (see Lemma 4.4 and (4.27)), the statement in Lemma 4.3 is true for any choice of $C_0 > 0$ (see Remark 4.1).

Another observation is that the linear case $s = 1$ may be treated by direct computation, i.e., by transforming the general solution of the then linear equation (4.1) to the X-variables. □

We still have to show that an orbit can only pass through T_0 from T_- to T_+.

LEMMA 4.4. *Let $s > 1$. There exists a $C_0 > 0$ such that orbits on T can only pass through T_0 in the direction from T_- to T_+.*

Proof. We deduce from (4.20) and (4.21) that

$$\dot{Q}\Big|_{Q=0} = P\Big(|\xi_1|^{2s} + \xi_2^2 + \xi_3^2 + \xi_4^2 + (s|\xi_1|^{s-1} - 1)(\xi_2 + \xi_4)\xi_4\Big). \tag{4.25}$$

Notice that for $s = 1$, P is positive on T (see (4.9)), thus $\dot{Q}\big|_{Q=0} > 0$ on T. For $s > 1$ we define R as the second factor in the right-hand side of (4.25) and simplify it using the expression (4.19) for T:

$$\begin{aligned} R &\stackrel{\text{def}}{=} |\xi_1|^{2s} + \xi_2^2 + \xi_3^2 + \xi_4^2 + (s|\xi_1|^{s-1} - 1)(\xi_2 + \xi_4)\xi_4 \\ &= 2C_0 + |\xi_1|^{2s} - \frac{2}{s+1}|\xi_1|^{s+1} - (1 - s|\xi_1|^{s-1})(\xi_2 + \xi_4)\xi_4. \end{aligned} \tag{4.26}$$

From (4.19) we infer that

$$(\xi_2+\xi_4)\xi_4 \le \left(\left(C_0 - \frac{2}{s+1}|\xi_1|^{s+1}\right)^{\frac{1}{2}} + C_0^{\frac{1}{2}}\right)C_0^{\frac{1}{2}} = C_0\left(1+\left(1 - \frac{2}{C_0(s+1)}|\xi_1|^{s+1}\right)^{\frac{1}{2}}\right).$$

Fix

$$C_0 = \frac{2}{s+1}\Big(\frac{1}{s}\Big)^{\frac{s+1}{s-1}}, \tag{4.27}$$

and set

$$|\xi_1| = x\left(\frac{1}{s}\right)^{\frac{1}{s-1}}, \text{ where } 0 \le x \le 1.$$

It follows that

$$\begin{aligned} R &\ge \frac{2}{s+1}\Big(\frac{1}{s}\Big)^{\frac{s+1}{s-1}}\Big(2 + \frac{s+1}{2s}x^{2s} - x^{s+1} - (1 - x^{s-1})(1 + (1 - x^{s+1})^{\frac{1}{2}})\Big) \\ &= \frac{2}{s+1}\Big(\frac{1}{s}\Big)^{\frac{s+1}{s-1}}\Big(1 + \frac{s+1}{2s}x^{2s} - x^{s+1} + x^{s-1} - (1 - x^{s-1})(1 - x^{s+1})^{\frac{1}{2}}\Big) \\ &= \frac{2}{s+1}\Big(\frac{1}{s}\Big)^{\frac{s+1}{s-1}}\Big((1 - x^{s+1})^{\frac{1}{2}}\big((1 - x^{s+1})^{\frac{1}{2}} - (1 - x^{s-1})^{\frac{1}{2}}\big) + x^{s-1} + \frac{s+1}{2}x^{2s}\Big). \end{aligned}$$

Since $0 \le x \le 1$ we see that $R > 0$ unless $x = 0$. Looking at (4.26) we infer that R can only be zero if $\xi_1 = \xi_3 = 0$ and $\xi_2 = \xi_4 = \pm\sqrt{C_0}$, or, in terms of the X_i, if

$X_1 = X_3 = X_4 = 0$. By continuity arguments it follows that also in these two points the orbits go from T_- to T_+. Thus, with the particular choice of C_0 given by (4.27) we have indeed that T_+ is positively invariant and T_- is negatively invariant. □

Having proven the existence of precisely two periodic orbits, Λ_- and Λ_+, on the torus T, we analyze some of their properties.

LEMMA 4.5. *The three nontrivial Floquet multipliers of Λ_+ are contained in the interval $(0,1)$, and the three nontrivial Floquet multipliers of Λ_- are contained in the interval $(1,\infty)$.*

Proof. Restricted to T the nontrivial Floquet multiplier of Λ_+ equals (see, e.g., [26, p. 198])

$$\exp\left(\oint_{\Lambda_+} \nabla \cdot w\right) = \exp\left(\oint_{\Lambda_+} -(3s+5)Q\right).$$

Since Q is uniformly positive on Λ_+, this Floquet multiplier is in $(0,1)$. Close to the periodic orbit Λ_+ we choose ϕ, θ, X_5, and H_0 as coordinates on the Poincaré cylinder Π, where H_0 given by (4.16). Since $H = H_0 X_5^{-4\lambda(s+1)}$ is a conserved quantity on Π, it follows from (4.10) that

$$\dot{H}_0 = -4(s+1)Q\, H_0.$$

Together with (4.10) this implies that the other Floquet multipliers are

$$\exp\left(\oint_{\Lambda_+} -4(s+1)Q\right) \quad \text{and} \quad \exp\left(\oint_{\Lambda_+} -\frac{1}{\lambda}Q\right),$$

which are in $(0,1)$ as before. Thus Λ_+ is exponentially stable. The statement for Λ_- is obtained by time reversal. □

LEMMA 4.6. *Every orbit (other than $\Lambda_\pm$) on the sphere Σ has Λ_- as α-limit set and Λ_+ as ω-limit set.*

Proof. We have already dealt with the flow on the torus T in Lemma 4.3. Orbits of the flow on the complement $\Sigma \backslash T$ of the torus T on the sphere Σ correspond to solutions with nonzero Hamiltonian H. Since X_5 does not appear in (4.10), the motion on Σ is independent of X_5. Let $X_5 \neq 0$, then the dynamics of X_5 are governed by (4.11), and the motion takes place in the part of the Poincaré cylinder Π that corresponds to the finite part of phase space in the x-variables. In other words, orbits of the flow on the set $\Sigma \setminus T$ correspond to solutions of (4.2) with nonzero Hamiltonian.

Since $H = H_0 X_5^{-4\lambda(s+1)}$ and H_0 is bounded on Σ (because Σ is compact), it follows that for such orbits X_5 remains bounded, i.e., in x-variables the solution stays away from the origin. Thus orbits in $\Sigma \setminus T$ are bounded in the X-variables and hence have nonempty invariant α- and ω-limit sets. We have to show that these limit sets can only be the two periodic orbits Λ_- and Λ_+ provided by Lemma 4.3. To this end it suffices to show that all solutions of (4.1) with $H \neq 0$ are unbounded in forward and backward time, i.e., $X_5 \to 0$ along a sequence of points in forward and backward time.

Postponing the proof of the unboundedness of solutions with $H \neq 0$, we first show how unboundedness in backward and forward time implies that Λ_- and Λ_+ are the α- and ω-limit sets. By (4.17) $X_5 \to 0$ implies that also $H_0 \to 0$. An unbounded orbit thus comes arbitrary close to the torus T. We choose an open tubular neighborhood Λ_-^ε of Λ_- in T, such that $Q < 0$ in Λ_-^ε. Clearly all orbits starting in $T \setminus \Lambda_-^\varepsilon$ tend to

Λ_+ in forward time. Note that $T_0 \cup T_+ \subset T \setminus \Lambda_-^\varepsilon$. By compactness of T and since Λ_+ is asymptotically stable (see Lemma 4.5), there exists an open neighborhood T^ε of $T \setminus \Lambda_-^\varepsilon$ in Π such that all orbits starting in T^ε tend to Λ_+ in forward time. Since an orbit which comes close to $X_5 = 0$ (and thus close to T) can only do so with nonnegative Q, it enters T^ε and hence tends to Λ_+. The statement for Λ_- follows by time reversal.

We still have to prove that any solution of (4.1) with nonzero Hamiltonian is unbounded in forward and backward time. We recall that solutions with $H \neq 0$ stay away from the origin. If an orbit would be bounded in backward or forward time, then its (nonempty) α- or ω-limit set would consist of bounded orbits, i.e., orbits which are bounded for all time. However, this is not possible, because it has been proved in [19] that (4.1) admits no bounded solutions except $u \equiv 0$. Here we present a different proof of the fact that (4.1) admits no bounded solutions except $u \equiv 0$, because we need to extend this result to more general situations (see Remark 4.7).

Assume, by contradiction, that $u \not\equiv 0$ is a bounded solution of (4.1). First observe that if u tends to a limit as $t \to \pm\infty$, then this limit can only be 0. It follows that u attains at least one positive maximum or one negative minimum. Switching from u to $-u$ if necessary, we may suppose that u attains a positive maximum at t_0:

$$u(t_0) > 0, \quad u'(t_0) = 0, \quad u''(t_0) \leq 0.$$

Changing from t to $-t$ if necessary, we may assume that $u'''(t_0) \leq 0$ and apply an oscillation argument from [29] which we repeat here for the sake of completeness. There exists a $t^* > t_0$ such that $u'''(t) < 0$ for $t_0 < t < t^*$ and $u'''(t^*) = 0$. Using the fact that

$$H = -u'u''' + \frac{1}{2}u''^2 - \frac{1}{s+1}|u|^{s+1}$$

is constant, it follows that $u(t^*) < -u(t_0)$ and that the next minimum must occur at $t_1 > t^*$ with $u(t_1) < u(t^*) < -u(t_0)$ and both $u''(t_1)$ and $u'''(t_1)$ positive. Repeating this argument we obtain a sequence $t_1 < t_2 < t_3 < \ldots$, in which $u(t)$ has nondegenerate extrema with $|u(t_1)| < |u(t_2)| < |u(t_3)| < \ldots$. By assumption these extrema remain bounded, say $\lim_{i\to\infty} |u(t_i)| = a \in \mathbb{R}^+$, and the derivatives are bounded as well. A compactness argument now shows that there must be a solution $\tilde{u}$ of (4.2) in the ω-limit set of u with

$$\tilde{u}(t_0) = a, \quad \tilde{u}'(t_0) = 0, \quad \tilde{u}''(t_0) < 0, \quad \text{and} \quad \tilde{u}'''(t_0) \leq 0 \qquad \text{at some } t_0 \in \mathbb{R},$$

and such that $|\tilde{u}(t)| \leq a$ for all $t \in \mathbb{R}$. However, when we apply the above argument to $\tilde{u}$ we obtain that $\tilde{u} < -a$ at the first minimum to the right of t_0, a contradiction. This completes the proof of Lemma 4.6. □

Remark 4.7. The oscillation argument above will be applied several times in this paper to differential equations that differ from the present one. It holds that any solution of (1.3) with $c = 0$ and $\beta \geq 0$ which does not have its range contained in

$$\{u \in \mathbb{R} \,|\, F(u) \geq F(-a)\}$$

oscillates toward infinity either in forward or in backward time in exactly the way described above (the additional second order term does not cause any difficulties). For more details we refer to [29].

4.3. The reduced system in the linear limit. We have shown in the previous section that for any $s \geq 1$ the flow of (4.1) is basically governed by two periodic orbits at infinity. For the linear equation ($s = 1$) this was already observed (in a broader setting) by Palis [21]. The analysis thus shows that the behavior for all $s > 1$ is largely analogous to the linear equation. In this section we make some observations about the limit $s \downarrow 1$.

Let us rewrite this system as

$$\dot{X} = V(X; s), \quad X = (X_1, X_2, X_3, X_4). \tag{4.28}$$

Then the vector field $V(\cdot, s)$ is continuously differentiable for every $s \geq 1$ and the first order partial derivatives are bounded on compact sets, uniformly in $s \geq 1$. We do not have that $V(\cdot, s) \to V(\cdot, 1)$ in C^1_{loc} because of the term X_1^s appearing in V, but we do have that $V(\cdot, s) \to V(\cdot, 1)$ uniformly on compact sets. Therefore the orbits of (4.28) with $s > 1$, which are bounded uniformly in s in view of (4.12), converge to orbits of (4.28) with $s = 1$ as $s \to 1$. More precisely, the solution map

$$(\tau, \xi, s) \to X(\tau; \xi, s),$$

where $X(\tau; \xi, s)$ is the solution $X(\tau)$ of (4.28) with $X(0) = \xi$, is continuous on $\mathbb{R} \times \mathbb{R}^4 \times [1, \infty)$. In particular, this implies that the two periodic orbits Λ_- and Λ_+ depend continuously on s for $s \in [1, \infty)$.

In the limit case $s = 1$ the two periodic orbits on

$$T = \{(\xi_1, \xi_2, \xi_3, \xi_4) |\, \xi_1^2 + \xi_2^2 = \xi_3^2 + \xi_4^2 = C_0\}$$

are given by

$$\xi_1 \xi_3 - \xi_2 \xi_4 = 0, \tag{4.29}$$

or in terms of (4.22), by $\phi + \theta = \pm\frac{\pi}{2}$. This can be seen from a second conservation law that exists in the linear case: multiplying $u'''' + u = 0$ by u''' we have that $\frac{1}{2}u'''^2 + uu'' - \frac{1}{2}u'^2$ is constant. In particular, after transforming to the X-variables,

$$\frac{1}{2}X_4^2 + X_1 X_3 - \frac{1}{2}X_2^2 = 0$$

is invariant, whence (4.29), which defines two circles on the torus T.

4.4. Small solutions. We observed in section 4.1 that the role of $X_5 = 0$ and $X_5 = \infty$ may be reversed. This is a direct consequence of the scaling invariance of (4.1). Thus we may also use (4.4) for the analysis of small solutions to (4.1). The situation is depicted schematically in Figure 4.2. We simply apply (4.4) with a negative λ so that $X_5 \to 0$ corresponds to $u \to 0$. This changes only the sign in (4.10) for X_5 and means that the orbit Λ_+ now lies in the part of $X_5 = 0$ which repels solutions with $X_5 > 0$. Hence the stable manifold of Λ_+ is contained in $\Pi \cap \{X_5 = 0\}$. The unstable manifold of Λ_+ is given by the direct product $\Lambda_+ \times \{X_5 \,|\, X_5 > 0\}$ and has dimension 2. In the original variables it is the unstable manifold of $u = 0$ if $s = 1$ and the center-unstable manifold if $s > 1$. Likewise, the stable manifold of Λ_- is $\Lambda_- \times \{X_5 \,|\, X_5 > 0\}$, i.e., the direct product of Λ_- and the positive X_5-axis. As we have seen in section 4.3, the limit $s \to 1$ is well behaved in the X-variables.

We will use this analysis of the behavior near the equilibrium point $u = 0$ in section 5 to perform a continuous deformation of the stable manifold for $s = 1$ to the center-stable manifold for $s > 1$. We remark that, based on the similarity of the linear and nonlinear problem, the equilibrium point $u = 0$ of (4.1) for $s > 1$ can be considered as the nonlinear equivalent of a saddle-focus.

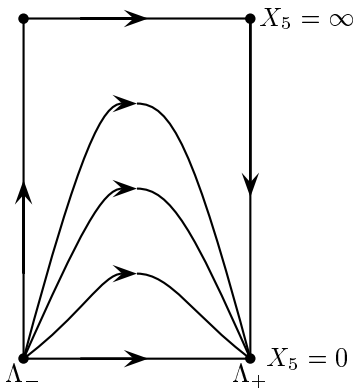

FIG. 4.2. *A schematic view of the flow on the Poincaré cylinder* Π *for the equation* $u'''' + u^s = 0$. *The role of* $X_5 = 0$ *and* $X_5 = \infty$ *is reversed when* λ *is negative.*

4.5. The full system. Applying the Poincaré transformation (4.4) with exponents (4.6) to the differential equation (1.3), or, more generally, to

$$x_1' = x_2; \quad x_2' = x_3; \quad x_3' = x_4; \quad x_4' = \Phi(x_1, x_2, x_3, x_4),$$

we arrive at

$$\dot{X}_1 = X_2 P - 4X_1 Q\,; \tag{4.30a}$$

$$\dot{X}_2 = X_3 P - (3+s) X_2 Q\,; \tag{4.30b}$$

$$\dot{X}_3 = X_4 P - (2+2s) X_3 Q\,; \tag{4.30c}$$

$$\dot{X}_4 = \Psi P - (1+3s) X_4 Q\,; \tag{4.30d}$$

$$\dot{X}_5 = -\frac{1}{\lambda} X_5 Q\,, \tag{4.30e}$$

where

$$Q = X_1^s X_2 + X_4 \Psi + X_3 (X_2 + X_4) \tag{4.31}$$

and

$$\Psi = X_5^{4\lambda s} \Phi \left(\frac{X_1}{X_5^{4\lambda}}, \frac{X_2}{X_5^{(3+s)\lambda}}, \frac{X_3}{X_5^{(2+2s)\lambda}}, \frac{X_4}{X_5^{(1+3s)\lambda}} \right). \tag{4.32}$$

In the case of (1.3) we have

$$\Phi(x_1, x_2, x_3) = \alpha x_3 - c x_2 + f(x_1),$$

where $f(x_1) = -x_1^3 + g(x_1)$ with $g(x_1)$ compactly supported. With $s = 3$ and $\lambda = \frac{1}{2}$ we thus obtain

$$\Psi = -X_1^3 + \alpha X_3 X_5^2 - c X_2 X_5^3 + g\left(\frac{X_1}{X_5^2}\right) X_5^6. \tag{4.33}$$

The last term in (4.33) is C^2 and has its derivatives up to second order vanishing in $X_5 = 0$. The extra terms are thus at least quadratic in X_5 for small X_5. Therefore

the local analysis near $X_5 = 0$ and in particular the Floquet multipliers of $\Lambda_\pm$ in the previous section are completely unaffected. The flow on the sphere Σ (at infinity) is identical to the flow for the reduced equation (4.2). Only the flow on $\Pi \setminus \Sigma$ is different. Note that in this analysis it is essential that the exponent s is larger than 1. We have the following theorem (compare Lemmas 4.3, 4.5 and 4.6).

THEOREM 4.8. *Let f satisfy hypothesis* (3.1) *and let $\alpha, c \in \mathbb{R}$.*

(a) *The stable periodic orbit Λ_+ of* (4.11) *is an asymptotically stable periodic orbit of* (4.30) *with nontrivial Floquet multipliers in* $(0,1)$. *Every solution of* (1.3) *which is unbounded in forward time corresponds to a solution of* (4.30) *having Λ_+ as ω-limit set. A similar statement holds for solutions unbounded in backward time and Λ_-.*

(b) *Unbounded solutions of* (1.3) *blow up oscillatorily in finite time.*

(c) *If $c \neq 0$, the energy $\mathcal{E}$ also blows up.*

Proof. By Lemma 4.6 all solutions of (4.30) which lie in the invariant set $\Pi \cap \{X_5 = 0\} \setminus \Lambda_- \subset \Pi$ tend to Λ_+ in forward time. Reminiscent of the proof of Lemma 4.6 we choose a small negatively invariant open tubular neighborhood Λ_-^ε of Λ_- in Π. By compactness of $\Pi \cap \{X_5 = 0\}$ there exists an open neighborhood Σ^ε of $\Pi \cap \{X_5 = 0\} \setminus \Lambda_-^\varepsilon$ in Π such that all orbits with starting point in Σ^ε tend to Λ_+ in forward time. Clearly every unbounded solution of (1.3) enters Σ^ε and thus tends to Λ_+.

For part (b) we observe that the exponent b in (4.8) is smaller than 1 so that in the old time variable X_5 can only go to zero in finite time. Finally we have that the energy $\mathcal{E}$ can remain bounded only if its derivative is integrable. For $c \neq 0$ this implies that u' is square integrable (see (1.5)) and thus u itself is (locally) bounded, which prohibits finite time blow-up, a contradiction. ∎

Remark 4.9. Theorem 4.8 establishes that large solutions of (1.3) are really described by oscillating solutions of $u'''' + u^3 = 0$. Thus large solutions do not "see" the other terms in (1.3) as they oscillate away to infinity. This is not only true for perturbations of the form $-u^3 + g(u)$ with g compactly supported and smooth, but also for global lower order perturbations. For such lower order perturbations Theorem 4.8 applies as well.

5. The winding number for small speeds. In this section we prove part (a) of Proposition 3.3. Before we can prove this theorem we first need a description of the global behavior of $W^s(1)$ for $c = 0$. In the following lemma we show that for $\alpha > \frac{1}{\sqrt{\sigma(f)}}$ all orbits in the stable manifold $W^s(1)$ are unbounded, and, after transforming to the X-variables in section 4, they all have Λ_- as α-limit set. Because all the nontrivial Floquet multipliers of Λ_- lie in $(1, \infty)$ (see Theorem 4.8(a)), this remains true for $c > 0$ sufficiently small.

LEMMA 5.1. *Let f satisfy hypothesis* (3.1), *let $\alpha > \frac{1}{\sqrt{\sigma(f)}}$, and let $c = 0$. Then $W^s(1)$ consists of unbounded orbits only, all of which connect Λ_- to $u = 1$.*

Proof. The proof is a combination of arguments also used in [25]. Any bounded solution must have its range in the set

$$V = \{u \in \mathbb{R} \mid F(u) \geq F(-a)\}$$

because a solution reaching outside this interval oscillates away toward infinity, as mentioned in Remark 4.7. Besides, any bounded solution must have at least one minimum below the line $u = -a$, again basically by the same oscillation argument as in the proof of Lemma 4.5. We now assume, arguing by contradiction, that u is a bounded orbit in $W^s(1)$. We will show that the range of u is not contained in V, so

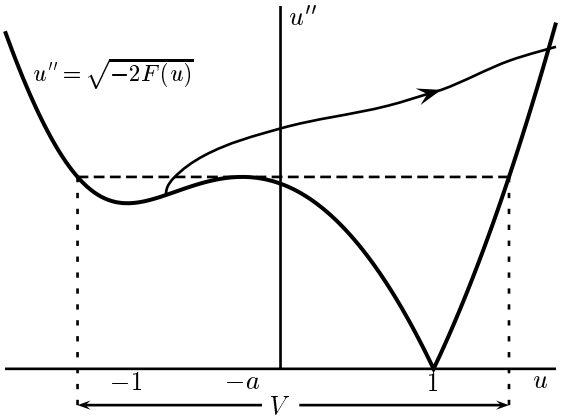

FIG. 5.1. *The (u, u'')-plane with the curve $u'' = \sqrt{-2F(u)}$. We have sketched the orbit of u for $t \geq t_0$, which is discussed in the proof of Lemma* 5.1. *We have also indicated the set V, in which every bounded solution has its range.*

that u is in fact unbounded. It then follows from Theorem 4.8 that u tends to Λ_- as $t \to -\infty$.

Thus, suppose that u is a bounded solution in $W^s(1)$. Changing from t to $-t$ if necessary we have that in such a minimum (using the fact that $\mathcal{E}(u, u', u'', u''') = 0$)

$$u(t_0) \leq -a, \quad u'(t_0) = 0, \quad u''(t_0) = \sqrt{-2F(u(t_0))} > 0, \quad u'''(t_0) \geq 0. \tag{5.1}$$

We will show that $u(t)$ increases to a value outside V for $t > t_0$, which immediately leads to a contradiction.

Define an auxiliary function

$$G(t) \stackrel{\text{def}}{=} u''(t) - \sqrt{-2F(u(t))}.$$

The following line of reasoning is depicted in Figure 5.1. First, $G(t_0) = 0$ and we show that $G(t) > 0$ in a right neighborhood of t_0. It is seen from the condition on α and the observation that $f(u) > 0$ on $(-\infty, -1) \cup (-a, 1)$ that

$$f(u) > -\sqrt{-\frac{\alpha^2}{2} F(u)} \qquad \text{for } u < 1. \tag{5.2}$$

If $u'''(t_0) > 0$, then clearly $G'(t_0) > 0$, whereas when $u'''(t_0) = 0$, then $G'(t_0) = 0$, and (since $u'(t_0) = 0$)

$$G''(t_0) = u''''(t_0) + \frac{f(u(t_0))}{\sqrt{-2F(u(t_0))}} u''(t_0) = \alpha \sqrt{-2F(u(t_0))} + 2f(u(t_0)) > 0$$

by the differential equation, and (5.1) and (5.2). Thus $G(t) > 0$ in a right neighborhood of t_0.

Second, we show that $G(t) > 0$ as long as $u(t) < 1$. We define $t_1 > t_0$ as the first maximum of $u(t)$ and $t_2 > t_0$ as the first point where $G(t_2) = 0$ (a priori, both t_1 and t_2 may be ∞). Then $t_2 < t_1$ since $u''(t) > 0$ as long as $G(t) > 0$. It now follows from the expression (1.4) for the energy and by (5.2) that

$$G'(t) = u'''(t) + \frac{f(u(t))}{\sqrt{-2F(u(t))}} u'(t)$$

$$= \frac{\frac{1}{2}u''^2(t) + F(u(t))}{u'(t)} + \left(\frac{\alpha}{2} + \frac{f(u(t))}{\sqrt{-2F(u(t))}}\right) u'(t)$$
$$> 0$$

as long as $G(t) > 0$ and $u(t) < 1$. Since $G(t) > 0$ in a right neighborhood of t_0 this implies that $G(t) > 0$ and $G'(t) > 0$ as long as $u(t) < 1$, and thus $u(t_2) \geq 1$.

Finally, we define $t_3 > t_0$ as the first point where $u(t) = -a$. It is easily seen that $t_3 < t_2$. By the energy expression we have that $u'''(t) > 0$ as long as $G(t) > 0$, thus $u''(t_2) > u''(t_3) > \sqrt{-2F(-a)}$. Combining the inequalities $u(t_2) \geq 1$ and $F(u(t_2)) = -\frac{1}{2}u''^2(t_2) < F(-a)$, we infer that $u(t_2)$ lies outside V, so that u is unbounded. By Theorem 4.8 all these unbounded orbits converge to Λ_-. □

Remark 5.2. Because all the nontrivial Floquet multipliers of Λ_- lie in $(1, \infty)$ (see Theorem 4.8(a)), Lemma 5.1 remains true for $c > 0$ sufficiently small.

The following theorem is equivalent to Proposition 3.3(a). We recall that K is defined in (3.3), and that its boundary δK is a level set of the energy.

THEOREM 5.3. *Let f satisfy hypothesis* (3.1) *and let $\alpha > \frac{1}{\sqrt{\sigma(f)}}$. For $F(-a) < E_0 < F(-1)$ let K be defined by* (3.3) *and let $W^s(1)$ be the stable manifold of the equilibrium $u = 1$. Then, provided $c > 0$ is sufficiently small, $W^s(1) \cap \delta K$ is a topological circle. Its projection Γ on the (u, u''')-plane winds exactly once around a disk containing both closed curves defined by $E_0 - F(u) + \frac{1}{2\alpha}u'''^2 = 0$ (see also Figure* 3.2*), i.e., $n(\Gamma, -1) = n(\Gamma, 1) = 1$.*

Proof. Our strategy is to deform $f(u)$ in several steps to the pure cubic $-u^3$ and let α go to zero. We have to do this in such a way that for each intermediate f the conclusion of Lemma 5.1 remains valid. All orbits in the stable manifold $W^s(1)$ thus tend to Λ_- in backward time, and this remains true during the entire deformation process. At the end of the deformation process we arrive at the reduced equation $u'''' + u^3 = 0$. We then use the analysis performed in section 4 to find a precise description of the orbits in $W^s(1)$. Finally, we obtain the results of Theorem 5.3 for the original equation (1.3) via continuation arguments.

Recall that $f(u) = -u^3 + g(u)$ with g having compact support, say, $g(u) = 0$ for all $|u| \geq C_0$. Taking C_0 sufficiently large, define the cut-off function $\phi \in C_0^\infty$ with $0 \leq \phi \leq 1$, $\phi(y) = 1$ for $|y| \leq C_0$, and $\phi(y) = 0$ for $|y| > C_0 + 1$.

Step 1. First deform $f(u)$ to a function which changes sign at $u = 1$ only. Let

$$f_\lambda(u) = f(u) - \lambda(u-1)\phi(u).$$

For λ large enough, say, $\lambda > \lambda_0$, the function $f_\lambda(u)$ has a zero at $u = 1$ only.

LEMMA 5.4. *Let $\alpha > \frac{1}{\sqrt{\sigma(f)}}$ and replace $f(u)$ by $f_\lambda(u)$. Then for all $\lambda \in [0, \lambda_0]$ the stable manifold $W^s(1)$ consists of unbounded orbits only, all of which connect Λ_- to $u = 1$.*

Proof. Let $\lambda_1 = \inf\{\lambda \mid f_\lambda(u) > 0 \text{ for all } u < 1\}$. For any $\lambda < \lambda_1$ the argument is exactly the same as in the proof of Lemma 5.1, where we use the following generalized definition of σ:

$$\sigma(f_\lambda) = \min\left\{ \frac{-F(u)}{2f(u)^2} \;\middle|\; u < 1 \text{ and } f(u) < 0 \right\}.$$

Note that $\sigma(f_\lambda) \leq \sigma(f_0)$ for $0 < \lambda < \lambda_1$ since $f_\lambda(u)$ and $-F_\lambda(u)$ are increasing in λ for all $u < 1$. For $\lambda \geq \lambda_1$ the result also holds, but by a different and less

restrictive oscillation argument, which applies to any $f(u)$ with a single zero at which it goes from positive to negative, and all $\alpha \geq 0$. We already used this in the proof of Lemma 4.6; the argument showing that every solution $u \not\equiv 1$ oscillates toward infinity is almost identical (for $\alpha \geq 0$ the second order term does not cause any difficulties). This completes the proof of the lemma. □

Continuing with the proof of Theorem 5.3, we change f to $f^1 \stackrel{\text{def}}{=} f_{\lambda_0}$ by letting λ go from 0 to λ_0. This leaves the local structure near $X_5 = 0$, and in particular near Λ_-, unaffected (see section 4.5).

Step 2. We change $f^1(u) = -u^3 + g^1(u)$ with $g^1(u) = g(u) - \lambda_0(u-1)\phi$ to $f^2(u) \stackrel{\text{def}}{=} -u^3(1-\phi) - (u-1)\phi$. Using the deformation functions

$$f_\lambda(u) = -u^3(1-\phi(u)) + (1-\lambda)(-u^3\phi(u) + g^1(u)) - \lambda(u-1)\phi(u),$$

we let λ go from 0 to 1, thus continuously deforming f^1 into f^2. All orbits in $W^s(1)$ are still unbounded and tend to Λ_- as $t \to -\infty$ during this deformation, since $f_\lambda(u)$ has a single zero at which it goes from positive to negative (see the proof of Lemma 5.4).

Step 3. It is now easy to shift the zero to the origin. Define

$$f_\lambda(u) = -u^3(1-\phi(u)) - (u - (1-\lambda))\phi(u).$$

Letting λ change from 0 to 1 deforms f^2 into $f^3 \stackrel{\text{def}}{=} -u^3(1-\phi) - u\phi$. Since we have shifted the origin we now have $W^s(0)$ instead of $W^s(1)$. All orbits in $W^s(0)$ are still unbounded and tend to Λ_- as $t \to -\infty$.

Step 4. Next we let α go to zero. The stable manifold $W^s(0)$ changes smoothly and the local structure near Λ_- again remains unaffected because α only appears in terms quadratic in X_5. For $\alpha = 0$ we have arrived at the equation

$$u'''' - f^3(u) = 0, \quad \text{with } f^3(u) = -u^3(1-\phi) - u\phi.$$

Step 5. We change f^3 using a family of functions

$$f_s(u) = -u^3(1-\phi) - u^s\phi.$$

Letting s increase from $s = 1$ to $s = 3$ we obtain a function $f^4(u) \stackrel{\text{def}}{=} u^3$. We note (see section 4.4) that for $s > 1$ the manifold W is the center-stable manifold of 0. Here we use section 4.3 to conclude that in this process W changes continuously, with the orbits in manifold $W = W^{cs}(0)$ still tending to Λ_- in backward time.

By sections 4.1 and 4.4 we have that, after going through Steps 1–5, W is the product of Λ_- and the X_5-axis. In view of the nontrivial Floquet multipliers of Λ_- being in $(1, \infty)$, it holds that for any small $\varepsilon > 0$ there exists a negatively invariant tubular neighborhood Λ_-^ε of Λ_- in Π with

$$\Lambda_-^\varepsilon \subset \{X = (X_1, X_2, X_3, X_4, X_5) \in \Pi \,|\, d(X, \Lambda_-) < \varepsilon\}.$$

We can choose this neighborhood such that

$$\overline{\Lambda_-^\varepsilon} \cap \{X_5 = \varepsilon\} \;=\; \{(X_1, X_2, X_3, X_4) \in \Lambda_-,\, X_5 = \varepsilon\}. \tag{5.3}$$

Besides, we can choose Λ_ε such that the flow for our final equation $u'''' + u^3 = 0$ is transversal to $\delta\Lambda_-^\varepsilon$. Moreover, for $\varepsilon > 0$ sufficiently small, we can choose Λ_ε such the flow is transversal to $\delta\Lambda_-^\varepsilon$ for every intermediate $f(u)$ and α in the deformation process of Steps 1–5 above, hence also for the original equation (1.3) with $c = 0$.

For any given $r > 0$ we can choose $\varepsilon > 0$ so small that the projection Γ_ε of $W \cap \delta\Lambda_-^\varepsilon$ on the (x_1, x_4)-plane (or, equivalently, on the (u, u''')-plane) is a curve with minimal distance to the origin at least r. To see this, we observe that the solution of (4.1) represented by Λ_- cannot have a point where $u = u''' = 0$, for in such a point also $u'' = 0$ in view of the energy $\mathcal{E}$ being zero. This would contradict the fact that $Q < 0$ on Λ_-. Thus in the X-variables Λ_- is uniformly bounded away from $(X_1, X_4) = (0, 0)$, so that for any $r > 0$ we can find an $\varepsilon > 0$ such that the projection of Λ_-^ε on the (u, u''')-plane has a distance larger than r from the origin. Therefore, the winding numbers around $u = \pm 1$ of the projection Γ_ε of $W \cap \delta\Lambda_-^\varepsilon$ on the (u, u''')-plane are well defined for ε sufficiently small.

It follows from (5.3) that for our final equation $u'''' + u^3 = 0$ we have

$$W \cap \delta\Lambda_-^\varepsilon = \{(X_1, X_2, X_3, X_4, X_5) \,|\, (X_1, X_2, X_3, X_4) \in \Lambda_-,\ X_5 = \varepsilon\},$$

so that, choosing r large, $n(\Gamma_\varepsilon, -1) = n(\Gamma_\varepsilon, 1) = 1$. By continuity the winding numbers of Γ_ε do not change if we reverse Steps 1–5, and again by continuity arguments and Remark 5.2 this remains true for $c > 0$ sufficiently small.

Finally, for our original equation (1.3) we know that, tracing back orbits in $W^s(1)$ until they hit $\delta\Lambda_-^\varepsilon$, their energy $\mathcal{E}$ remains close to 0, provided we keep $c > 0$ sufficiently small. Thus $W^s(1) \cap \delta K$ is contained in Λ_-^ε for small $c > 0$. Following $W^s(1) \cap \delta\Lambda_-^\varepsilon$ backwards along the flow to $W^s(1) \cap \delta K$ (which is a transversal intersection for $c > 0$), we see that the winding numbers $n(\Gamma, \pm 1)$ of the projection of $W^s(1) \cap \delta K$ are also 1. This completes the proof of Theorem 5.3. □

6. The winding number for large speeds. In this section we proof part (b) of Proposition 3.3.

THEOREM 6.1. *Let f satisfy hypothesis* (3.1) *and let $\alpha \in \mathbb{R}$. For $c > 0$ sufficiently large the intersection of the stable manifold $W^s(1)$ of $u = 1$ and the boundary δK of K is a smooth simple closed curve which projects on a closed curve Γ in the (u, z)-plane with $n(\Gamma, -1) = 0$ and $n(\Gamma, 1) = 1$.*

Proof. We first prove the theorem for a deformation of $f(u)$. We choose the nonlinearity $\tilde{f}(u)$ to satisfy

$$\tilde{f}(u) = f'(1)(u - 1) \quad \text{in a neighborhood } B_\varepsilon(1) \text{ of } u = 1.$$

For this deformed nonlinearity $\tilde{f}$ we compute the energy $\tilde{\mathcal{E}}$ on a closed curve in $\tilde{W} = W^s(1)$ winding once around $u = 1$ with u-values contained in $B_\varepsilon(1)$. The equation is now linear near $u = 1$, and the characteristic equation

$$-\mu^4 + \alpha\mu^2 + f'(1) = c\mu$$

has two eigenvalues $-\mu_1$ and $-\mu_2$ with negative real part (recall that $f'(1) < 0$). For $c > 0$ large enough μ_1 and μ_2 are real, and asymptotically

$$\mu_1 \sim c^{\frac{1}{3}} \quad \text{and} \quad \mu_2 \sim \frac{-f'(1)}{c} \qquad \text{as } c \to \infty. \tag{6.1}$$

Since the equation is linear, $\tilde{W}$ is given by (for c large enough)

$$\tilde{W} = \{(u, v, w, z) \,|\, u = u(t) = 1 + A_1 e^{-\mu_1 t} + A_2 e^{-\mu_2 t},\ v = u'(t),\ w = u''(t),\ z = u'''(t)\}. \tag{6.2}$$

We may choose a curve $S_1 \subset \tilde{W}$ around $u = 1$ parametrized by $\phi \in [0, 2\pi)$ by taking $t = 0$ and $A_1 = r\cos\phi$, $A_2 = r\sin\phi$ in (6.2) for some fixed $r > 0$. The projection of S_1 on the (u, u''')-plane is given by

$$\{(u, z) \,|\, u = 1 + r(\cos\phi + \sin\phi),\ z = -r(\mu_1^3\cos\phi + \mu_2^3\sin\phi),\ 0 \le \phi < 2\pi\}.$$

The energy on S_1 is given by

$$\begin{aligned} -\mathcal{E} &= \int_0^\infty cu'(t)^2 dt = c\int_0^\infty (A_1\mu_1 e^{-\mu_1 t} + A_2\mu_2 e^{-\mu_2 t})^2 dt \\ &= c\left(\frac{A_1^2\mu_1}{2} + \frac{2A_1A_2\mu_1\mu_2}{\mu_1+\mu_2} + \frac{A_2^2\mu_2}{2}\right) = c\mu_2\left(\frac{A_1^2\mu_1}{2\mu_2} + \frac{2A_1A_2\mu_1}{\mu_1+\mu_2} + \frac{A_2^2}{2}\right). \end{aligned} \tag{6.3}$$

Using (6.1) and estimating (6.3) from below we have, for c sufficiently large,

$$\mathcal{E} \le \frac{f'(1)}{4} r^2 < 0 \ \text{ on } S_1.$$

Thus, choosing an energy level $0 > \tilde{E}_0 > \frac{f'(1)}{4} r^2$, we have that S_1 lies in the complement of K. Let $\tilde{S} = \tilde{W} \cap \delta\tilde{K}$. Then $\tilde{S}$ lies inside S_1 and is obtained by tracing solutions in (6.2) of the linear equation forwards in time until they enter $\tilde{K}$. It follows that $\tilde{S}$ winds around $u = 1$ in $\tilde{W}$ exactly once and therefore its projection $\tilde{\Gamma}$ on the (u, z)-plane winds once around $(u, z) = (1, 0)$.

The calculations above involve only u-values between $1 - r\sqrt{2}$ and $1 + r\sqrt{2}$ so we may change the definition of $\tilde{f}(u)$ outside this range. In particular, taking r small, we may choose $\tilde{f}(u)$ such that $\tilde{F}(u)$ has a minimum $\tilde{F}(-a) < \tilde{E}_0$ and a maximum $\tilde{F}(-1) \in (\tilde{E}_0, \tilde{F}(1))$, with $-1 < -a < 1 - r\sqrt{2}$. Clearly $\tilde{\Gamma}$ does not wind around the point $(u, z) = (-1, 0)$.

We continue $\tilde{f}$ to f and $\tilde{E}_0$ to E_0, taking c large enough as to stay within a class of nonlinearities for which there does not exist a connection between $u = -1$ and $u = 1$ (see Lemma 2.1). By continuity we still have that $n(\Gamma, -1) = 0$ and $n(\Gamma, 1) = 1$. □

7. Travelling waves connecting an unstable to a stable state. In this section we focus on travelling waves that connect the unstable state $u = -a$ to one of the two stable states $u = \pm 1$. As in the proof of Theorem 1.1 in section 3 we begin by reducing to nonlinearities f which satisfy (3.1).

To obtain the necessary bound for $\alpha > 0$ we fix $c > 0$ and simply follow the argument in the proof of Lemma 2.2 with $F(-1)$ replaced by $F(-a)$ (for connections from $-a$ to $+1$), or by $F(-1) - F(-a)$ (for connections from $-a$ to -1).

By different methods it is also possible to prove a priori bounds in the case that $\alpha \le 0$. Applying a result by Gallay [14] to the present context we obtain the following. Let f satisfy (H_1), i.e., $\lim_{|u|\to\infty} \frac{f(u)}{u} = -\infty$. Then for any $\alpha \in \mathbb{R}$ there exists a constant C_0 such that any travelling wave solution $u(t, x) = U(x + ct)$ of (1.1) satisfies $\|u\|_\infty \le C_0$. The constant C_0 will thus depend only on α and $m \overset{\text{def}}{=} \sup\{|u| : \frac{f(u)}{u} \ge -D_\alpha\}$, where $D_\alpha > 0$ is a constant which depends on α only.

The idea is to consider $\Phi_y(t) = \int_{-\infty}^\infty h_y(x)u^2(t, x)dx$, where $h_y(x) = \frac{1}{1+(x-y)^2}$. Using the differential equation (1.1) one obtains an estimate of the form $\frac{d\Phi_y}{dt} \le A_0 - \Phi_y$ for some constant A_0 independent of y and t, hence $\Phi_y(t) \le A_0 + \Phi_y(0)e^{-t}$. Defining $\Psi(t) = \sup_{y\in\mathbb{R}} \Phi_y(t)$ one derives that for travelling waves, Ψ is independent of t, hence

$\Psi \leq A_0$. Combining this with the fact that $\int_{-\infty}^{\infty}(\frac{du}{dx})^2 dx = \frac{F(\pm 1)-F(-a)}{c}$, one then obtains an L^∞-bound on u.

Thus, for every $c > 0$ there exists a constant $C_0 > 0$ such that any solution of (1.3) connecting $-a$ to ± 1 satisfies $\|u\| < C_0$. This a priori estimate implies that we may replace f by $\tilde{f}(u) = \phi(u)f(u) - u^3(1-\phi(u))$, where the cut-off function $\phi \in C_0^\infty$ is such that $0 \leq \phi \leq 1$, $\phi(y) = 1$ for $|y| \leq C_0$, and $\phi(y) = 0$ for $|y| > C_0 + 1$. As in section 3 it holds that u is a travelling wave solution with speed c for nonlinearity $f(u)$ if and only if u is a travelling wave solution with speed c for nonlinearity $\tilde{f}(u)$.

The above argument shows that, looking for travelling waves, we may as well assume that f satisfies (3.1). The next theorem thus proves Theorem 1.2.

THEOREM 7.1. *Let f satisfy hypothesis* (3.1) *and let $\alpha \in \mathbb{R}$. For every $c > 0$ there exists a solution of* (1.3) *connecting $u = -a$ to $u = -1$.*

Proof. For all $c > 0$ we have that the three equilibria are hyperbolic and

$$\dim W^s(\pm 1) = \dim W^u(\pm 1) = 2, \quad \dim W^u(-a) = 3, \quad \dim W^s(-a) = 1.$$

Travelling wave solutions connecting $u = -a$ and $u = -1$ correspond to a nonempty intersection of $W^u(-a)$ and $W^s(-1)$. Recall that

$$\mathcal{E}(u, u', u'', u''') = -u'u''' + \frac{1}{2}u''^2 + \frac{\alpha}{2}u'^2 + F(u), \quad \text{where} \quad F(u) = \int_1^u f(s)ds,$$

satisfies (1.5). We take $F(-1) < E_1 < F(1)$ and consider the set

$$\tilde{K} = \left\{ (u, v, w, z) \,|\, E(u, v, w, z) = -vz + \frac{1}{2}w^2 + \frac{\alpha}{2}v^2 + F(u) \leq E_1 \right\}.$$

Now suppose that for some $c > 0$ the theorem is false. Then all orbits in $W^u(-a)$ have to leave $\tilde{K}$ through $\delta\tilde{K}$, because an orbit with bounded energy has no other choice than to converge to an equilibrium (see the proof Lemma 3.2) and $u = -1$, the only equilibrium in $\tilde{K}$ with energy larger than $E(-a)$, is excluded by assumption. Thus we have that the intersection of $W^u(-a)$ and $\delta\tilde{K}$ is homeomorphic to a 2-sphere S^2.

For the moment we consider the case that $\alpha > 0$. Since $\delta\tilde{K}$ is given by

$$\alpha\left(v - \frac{z}{\alpha}\right)^2 + w^2 = 2E_1 - 2F(u) + \frac{z^2}{\alpha}, \tag{7.1}$$

we may deform it smoothly into

$$\{(u, v, w, z) \,|\, u^2 + z^2 = 1 + v^2 + w^2\},$$

which defines a 3-manifold homeomorphic to $\mathbb{R}^2 \times S^1$. As deformations we use

$$(\lambda\alpha + 1 - \lambda)\left(v - \lambda\frac{z}{\alpha}\right)^2 + w^2 = G(u, \lambda) + \left(1 - \lambda + \frac{\lambda}{\alpha}\right)z^2,$$

with λ running from 1 to 0, and $G(u, 1) = 2E_1 - 2F(u)$ and $G(u, 0) = -1 + u^2$. Singularities can only appear in points on these manifolds where $G_u = v = w = z = 0$ and can thus be avoided by the choice of E_1.

It follows that $\delta\tilde{K}$ is homeomorphic to $\mathbb{R}^2 \times S^1$, or, equivalently, to the open solid torus. The intersection $W^u(-a) \cap \delta\tilde{K}$, being homeomorphic to S^2, divides $\delta\tilde{K}$ into two components, one bounded and homeomorphic to an open ball in $\mathbb{R}^3$, the other

unbounded. This division is in fact not completely straightforward. One needs to lift (a neighborhood of) $W^u(-a) \cap \delta\tilde{K}$ to the universal covering space $\mathbb{R}^3$ of $\tilde{K}$ and show that the unbounded part of the complement of the countable union of lifts is path-connected. Using the fact that the intersection $W^u(-a) \cap \delta\tilde{K}$ is induced by a flow, one can invoke the generalized Schoenflies theorem (see [5, Theorem 19.11]) to conclude that a lift of $W^u(-a) \cap \delta\tilde{K}$ divides $\mathbb{R}^3$ into an unbounded and a bounded component, which is homeomorphic to an open ball, in $\mathbb{R}^3$. Besides, the bounded components of the countable infinity of lifts can be contracted to points. The unbounded component (the complement of the countable union of bounded components) is thus homeomorphic to $\mathbb{R}^3 \setminus \mathbb{Z}$, hence path-connected.[5]

Now consider the piecewise smooth 3-manifold formed by the disjoint union of the point $(-a, 0, 0, 0)$, $W^u(-a) \cap \tilde{K}$ and the bounded component of $\delta\tilde{K} \setminus (W^u(-a) \cap \delta\tilde{K})$. This 3-manifold is homeomorphic to two closed balls in $\mathbb{R}^3$ sharing an S^2, namely, $W^u(-a) \cap \delta\tilde{K}$, as boundary and is therefore homeomorphic to an S^3. By the Jordan–Brouwer theorem this 3-manifold divides $\mathbb{R}^4$ to two components, one bounded, the other unbounded. We notice that the bounded component is negatively invariant. Clearly both components contain exactly one of the two orbits which together form $W^s(-a)$. Now consider the orbit in $W^s(-a)$ contained in the bounded component (which is negatively invariant). Since its energy is bounded we may, again by the argument in the proof of Lemma 3.2, conclude that, tracing it backwards, it must go to an equilibrium with energy less than the energy of $u = -a$. Since such an equilibrium does not exist, we have arrived at a contradiction.

The cases $\alpha < 0$ and $\alpha = 0$ are similar, the only changes being that we deform $\delta\tilde{K}$, given by (7.1), to $u^2 + v^2 = 1 + z^2 + w^2$ if $\alpha < 0$, and that for $\alpha = 0$ we rewrite $\delta\tilde{K}$ as $-2vz + w^2 = 2E_1 - 2F(u)$, which deforms into $-2vz + w^2 = -1 + u^2$ or $\frac{1}{2}(v+z)^2 + u^2 = \frac{1}{2}(v-z)^2 + w^2 + 1$. This completes the proof of the theorem. □

Remark 7.2. In the proof of Theorem 7.1 above we have used the nondegeneracy of the equilibrium point $u = -a$, while $u = -1$ may degenerate (i.e., $f'(-1) = 0$). The theorem also holds when $u = -a$ is degenerate but $u = -1$ is nondegenerate; in this case the argument in the proof of Theorem 7.3 below can be used. If $F(-1) = F(1)$ one also applies the proof of Theorem 7.3; see Remark 7.4.

Next we prove Theorem 1.3. Let

$$c^* \stackrel{\text{def}}{=} \inf\{\tilde{c} > 0 \,|\, \text{there is no connection from } -1 \text{ to } +1 \text{ for } c > \tilde{c}\}.$$

From Lemma 2.1 we see that c^* is well defined, and $c^* > 0$ for $\alpha > \frac{1}{\sqrt{\sigma(f)}}$ by Theorem 1.1. The argument at the beginning of this section shows that, in order to prove Theorem 1.3, we may restrict to nonlinearities f which satisfy (3.1). If $c_* > 0$, then it follows from Lemma 3.2 that for $c = c^*$ there exists a solution of (1.3) which connects -1 to $+1$. The following theorem thus proves both Theorem 1.3 and Corollary 1.4.

THEOREM 7.3. *Let f satisfy hypothesis* (3.1) *and let $\alpha \in \mathbb{R}$. For every $c > c^*$ there exists a solution of* (1.3) *connecting $u = -a$ to $u = 1$.*

Proof. We consider the stable manifold $W = W^s(1)$ of $u = 1$. We have shown in Theorem 6.1 that for $c > 0$ large enough the intersection of the stable manifold W of $u = -1$ and the boundary δK of K (defined in (3.3)) is a smooth simple closed

[5]We gratefully acknowledge several discussions with H. Geiges. He showed us that, via the Jordan–Brouwer separation theorem and an inductive Mayer–Vietoris argument, the division of $\delta\tilde{K}$ into two components can also be derived without using the extra information provided by the flow.

curve which projects on a closed curve Γ in the (u,z)-plane with $n(\Gamma,-1)=0$ and $n(\Gamma,1)=1$. It follows from the definition of c^* and Lemma 3.2 that, by continuity, this remains true for all $c>c_*$. Now fix $c>c^*$.

Let us assume by contradiction that there is no connection between $u=-a$ and $u=1$. The intersection between W and δK depends continuously on the energy level E as long as we do not encounter an equilibrium point. Assuming there is no connection between $u=-a$ and $u=1$, we let E decrease from $F(-1)>E_0>F(-a)$ to $E_2<F(-a)$. The projection Γ in the (u,z)-plane then depends continuously on E, as do the winding numbers, so that $n(\Gamma,-1)=0$ and $n(\Gamma,1)=1$ for all $E_0\le E\le E_2$. However, for the energy level E_2 we have that $(-1,0)$ and $(1,0)$ lie in the same component of the complement of the projection of δK onto the (u,z)-plane. Therefore $n(\Gamma,-1)=n(\Gamma,1)$, a contradiction. □

Remark 7.4. When $F(-1)=F(+1)$, then the same method shows that there exist travelling waves connecting $u=-a$ to $u=\pm1$ for all $c>0$ and all $\alpha\in\mathbb{R}$. Besides, as already noted in Remark 7.2, the method in the proof of Theorem 7.3 can be used to obtain an alternative proof of Theorem 7.1.

Finally, we prove Theorem 1.5 which deals with nonlinearities with two zeros (and a different behavior for $u\to\pm\infty$).

THEOREM 7.5. *Let $\alpha\in\mathbb{R}$ and let f satisfy hypothesis* (H_2). *For every $c>0$ there exists a solution of* (1.3) *connecting $u=0$ to $u=1$.*

Proof. Since the shape of the nonlinearity differs significantly from the one considered so far, we cannot invoke Lemma 3.2 directly. Besides, we find a priori bounds via a slightly different method.

Let $D\overset{\text{def}}{=}\sup\{\tilde u<0\,|\,F(u)>0 \text{ on } (-\infty,\tilde u)\}$. Travelling wave solutions connecting 0 to 1 satisfy $u\ge D$, since it follows from (1.4) and (1.5) that u can have no extremum in the range $u<D$ (at an extremum one would have $\mathcal{E}>F(1)$, which is impossible). Therefore, we may without loss of generality replace f by any function f_1 for which $f_1(u)=f(u)$ for $u\ge D$, and $f_1(u)<0$ for $u<D$. We choose f_1 such that $f_1(u)=u$ for $u<D-1$.

Now that we have a bound from below, we can also obtain a bound from above. A connecting solution of (1.3) is also a solution of (1.3) with f_1 replaced by any f_2 for which $f_2(u)=f_1(u)$ for all $u\ge D-1$. We choose $f_2(u)=-u^3$ for $u<D-2$, and argue as at the beginning of this section to conclude that there exists a uniform bound $\|u\|_\infty\le C_0$ on all travelling wave solutions. We may thus replace f_1 by a function f_3 for which $f_3(u)=f_1(u)$ for $u\le C_0$ and $f_3(u)=-u^3$ for $u\ge C_0+1$. We conclude that u is a travelling wave solution with speed c for nonlinearity $f(u)$ if and only if u is a travelling wave solution with speed c for nonlinearity $f_3(u)$.

In the following we therefore assume, without loss of generality, that $f(u)=u$ for $u\le D-1$, and $f(u)=-u^3$ for $u\ge C_0+1$.

We now follow the argument in the proof of Lemma 3.2. However, we cannot use Lemma 3.1 to show that orbits in $W^s(1)$, which are completely contained in K, are bounded. Instead, we argue as follows. Suppose, by contradiction, that an orbit $u(t)$ in $W^s(1)$ is completely contained in K and is unbounded. As in the proof of Lemma 3.2 it follows from (3.4) that $u(t)$ exists for all $t\in\mathbb{R}$. There are now two possibilities: either $u(t)\ge D-1$ for all $t\in\mathbb{R}$ or there exists some $t_0\in\mathbb{R}$ such that $u(t_0)<D-1$. First we deal with the latter case.

Since (see above) $u(t)$ cannot attain an extremum in the range $u<D$, it follows that $u(t)$ is increasing for $t\le t_0$. Hence $u(t)$ obeys, for $t\le t_0$, the linear equation $cu'=-u''''+\alpha u''+u$. Since u is unbounded as $t\to-\infty$, it follows that $u=$

$-a_0 e^{-a_1 t} + o(1)$ for some $a_0, a_1 > 0$ as $t \to -\infty$. By substituting this into (3.4) a contradiction is reached.

Next we deal with the case where $u(t) \geq D - 1$ for all $t \in \mathbb{R}$. Clearly $u(t)$ is a solution of (1.3) with f replaced by any function $\tilde{f}$ for which $\tilde{f}(u) = f(u)$ for all $u \geq D-1$. We choose $\tilde{f}(u) = -u^3$ for $u < D-2$, and it follows from Lemma 3.1 that u blows up in finite time, a contradiction.

Having circumvented the problem in the proof of Lemma 3.2 we conclude that for $F(0) < E_0 < F(-1)$ the intersection of the stable manifold W of $u = -1$ and the boundary δK of K (defined in (3.3)) is a smooth simple closed curve which projects on a closed curve Γ in the (u, z)-plane with $n(\Gamma, 1) = 1$.

The rest of the argument is analogous to the proof of Theorem 7.3. Assuming that there is no connection between $u = 0$ and $u = 1$, the final contradiction is now obtained by the fact that $n(\Gamma, 1) = 0$ for $E_2 < F(0)$. □

8. Concluding remarks. The most apparent open problem concerns the range of α-values for which a travelling wave connecting -1 to $+1$ exists. For some examples it can be shown that such a travelling wave does not exist for all $\alpha \in \mathbb{R}$. The more general question whether for any nonlinearity satisfying (H_1) a bound α_* exists such that there are no travelling waves for $\alpha < \alpha_*$ remains open.

Regarding the uniqueness of the various travelling wave solutions not much is known. For large α (i.e., $\gamma \approx 0$) the travelling wave connecting -1 to $+1$ may be expected to be unique (analogous to the limiting second order case). The results in [6] show that uniqueness does not hold for $f_a(u) = (u + a)(1 - u^2)$ with a small when $\alpha < \sqrt{8}$. Equation (1.1) with $f(u) = u - u^3$ admits an abundance of standing wave solutions for $0 \leq \alpha < \sqrt{8}$. It has been proved in [6] that these solutions can be perturbed to travelling waves for $f_a(u)$ with small a and small $c = c(a)$. Since this can be done for any standing wave, an infinite family of curves in the (a, c)-plane passing through the origin is thus obtained.

The method used in this paper does not give any information about the shape of the solution. For example, we would like to know for which values of α the solution is monotone. Since we do not know the value of c for which a traveling wave occurs, we do not in general even know whether the connected equilibrium points are approached monotonically or in an oscillatory manner.

Finally, the question arises to what extent the travelling wave solution is of importance to the dynamics of the PDE. It might be a limit profile for a broad class of initial conditions as is the case for the second order equation [13]. Since travelling waves connecting $u = -a$ to $u = \pm 1$ exist for large ranges of c, it would be interesting to know which of these waves is generally encountered. In [9, 12] the wave selection mechanism has been investigated for a propagating front which is formed from localized initial data (i.e., $u + a$ is localized). Using the physically motivated assumption that the linearized equation (around $u = -a$) drives the system, it is argued that for $\alpha > \sqrt{12 f'(-a)}$ one of the travelling waves is selected (and the wave speed is calculated), while for $\alpha < \sqrt{12 f'(-a)}$ the propagating front is argued not to have a fixed profile. However, the only rigorous stability result that we know of is of a perturbative nature [27] (i.e., α very large) and moreover it does not answer the question of the selection of the wave speed.

ISOSPECTRAL FLOWS OF THIRD ORDER OPERATORS*

L. AMOUR†

Abstract. We consider the third order linear differential operator $L_{p,q} = i\frac{d^3}{dx^3} + i\frac{d}{dx}q + iq\frac{d}{dx} + p$ on the unit interval. The associated boundary conditions are $y(0) = y(1) = 0$, $y'(0) = zy'(1)$ with $z \in \mathbf{C}$, $|z| = 1$. For all but a finite number of parameters z, the eigenvalues λ_j of $L_{p,q}$ are of multiplicity one. For fixed boundary conditions we make the formulae for isospectral flows induced by the Hamiltonian function λ_j explicit. These flows commute.

Key words. inverse spectral theory, third order operator, isospectral flows

1. Introduction and results.

In this paper we consider the third order linear differential operator

$$L_{p,q} = i\frac{d^3}{dx^3} + i\frac{d}{dx}q + iq\frac{d}{dx} + p \tag{1}$$

on the unit interval. The potentials p and q are real valued functions. It is supposed that $(p,q) \in L^2_R \times H^1_R$. We will often use the abbreviated notation $' = \partial/\partial x$.

Let us introduce the boundary conditions depending on a real parameter $\phi \in T = R|_{2\pi Z}$:

$$(BC)_\phi \qquad \begin{cases} y(0) = y(1) = 0, \\ y'(0) = e^{i\phi}y'(1). \end{cases} \tag{2}$$

Fix ϕ in T. The operator $L_{p,q}$ associated with the boundary conditions $(BC)_\phi$ is self-adjoint in $L^2_{\mathbf{C}}[0,1]$ with the scalar product $(f,g) = \int_0^1 f\bar{g}\,dx$ and has a discrete spectrum. Each eigenvalue is real and of multiplicity one or two. Let $(\lambda_j(p,q,\phi))_{j\in\mathbf{Z}}$ denote the increasing sequence of eigenvalues.

The main result is Theorem 3. Preliminary results on the spectrum of $L_{p,q}$ are given in Theorems 1 and 2. Note that the description of the spectrum is not as precise as the one in [A2]. In particular, there is no counting lemma here.

THEOREM 1. *Fix $(p,q) \in L^2_R \times H^1_R$. For all but a finite number of parameters $\phi \in T$ the eigenvalues of $L_{p,q}$ associated with the boundary conditions $(BC)_\phi$ are of multiplicity one.*

From now on, therefore, it is possible to restrict ourselves to simple spectra. The sequence $(\lambda_j(p,q,\phi))_{j\in\mathbf{Z}}$ denotes a strictly increasing sequence of eigenvalues. Let $h_j(x,p,q,\phi)$ be the eigenfunctions corresponding to $\lambda_j(p,q,\phi)$ with $\|h_j(\cdot,p,q,\phi)\|_{L^2_{\mathbf{R}}[0,1])} = 1$. Thus the function h_j is determined up to the phase. This phase is irrelevant in the following. Set $\langle q\rangle = \int_0^1 q(x)\,dx$.

THEOREM 2. *Suppose $(p,q,\phi) \in L^2_R \times H^1_R \times T$. Then*

$$\text{(i)}\quad \lambda_j(p,q,\phi) = (2j\pi)^3 + (2j\pi)^2(3\phi - \pi) + 2j\pi\left(3\left(\phi - \frac{\pi}{3}\right)^2 - 2\langle q\rangle\right) + O(1)$$

as $j \to +\infty$, *and*

$$\text{(ii)} \quad \lambda_j(p,q,\phi) = (2j\pi)^3 + (2j\pi)^2(3\phi+\pi) + 2j\pi\left(3\left(\phi+\frac{\pi}{3}\right)^2 - 2\langle q\rangle\right) + O(1)$$

as $j \to -\infty$.

In particular, $\langle q\rangle$ and ϕ are spectral invariants. We introduce the Poisson bracket

$$\{F,G\} = \int_0^1 \frac{\partial F}{\partial p}\left(\frac{\partial G}{\partial q}\right)' - \frac{\partial G}{\partial p}\left(\frac{\partial F}{\partial q}\right)' dx$$

for smooth real valued functions of (p,q). It is skew-symmetric and satisfies Jacobi's identity. In other words, the space of potentials is equipped with the symplectic structure $\omega(\mathbf{D}\xi,\mathbf{D}\eta) = \int_0^1 \xi_1\eta_2' - \xi_2'\eta_1\,dx$, where the skew-symmetric operator $\mathbf{D} = \begin{pmatrix} 0 & \frac{d}{dx} \\ \frac{d}{dx} & 0 \end{pmatrix}$.

Set $N_j = \begin{pmatrix} \frac{\partial\lambda_j}{\partial p} \\ \frac{\partial\lambda_j}{\partial q} \end{pmatrix}$. For $F = \lambda_j$, $G = \lambda_k$ one has

$$\{\lambda_j,\lambda_k\} = \int_0^1 N_j^\top \mathbf{D} N_k\,dx.$$

Set $V_k = \mathbf{D}N_k$. The bracket $\{\lambda_j,\lambda_k\}$ is, according to the chain rule, the change of λ_j under the Hamiltonian flow induced by the vector field V_k. We shall prove that $\{\lambda_j,\lambda_k\} = 0\,\forall\, j,k$. This means that all λ_j are integrals of the motion induced by the vector field V_k. Then the corresponding flow is isospectral. The flows induced by the vectors fields V_j and V_k commute. This is also a consequence of $\{\lambda_j,\lambda_k\} = 0$. The existence of these isospectral flows is given by explicit formulae. Our main result is the following.

THEOREM 3. *The solution to*

$$\frac{d}{dt}\begin{pmatrix} p(\cdot,t) \\ q(\cdot,t) \end{pmatrix} = V_j(\cdot, p(t), q(t), \phi)$$

with initial value (p_0,q_0) *with* $h_j'(0,p_0,q_0) = 0$ *exists for every* $t \in \mathbf{R}$ *and is given by*

$$p(x,t) = p_0(x) + 3(e^t-1)\frac{d}{dx}\frac{\operatorname{Im}\left(h_j(x,p_0,q_0)\bar{h}_j'(x,p_0,q_0)\right)}{\theta_j(x,t,p_0,q_0)}, \tag{3}$$

$$q(x,t) = q_0(x) + \frac{3}{2}\frac{d^2}{dx^2}\log\theta_j(x,t,p_0,q_0), \tag{4}$$

where

$$\theta_j(x,t,p_0,q_0) = 1 + (e^t-1)\int_0^x |h_j(s,p_0,q_0)|^2\,ds.$$

Theorem 3 proves that some isospectral flows, in the third order case and for fixed boundary conditions, are given by a very particular explicit formula of the following form: *initial potential* $+ G$, where G depends only on t and on one eigenfunction of the initial potential.

The proof of Theorem 3 is then carried out in a constructive way. We determine a function $G = G(t, h_j)$ *together with* the associated eigenfunctions $h_j(t)$ requiring that the flow *initial potential* $+ G$ is isospectral while knowing the expression of its associated vectors field V_j in term of $h_j(t)$. These two requests lead to a unique G. However, when the initial eigenfunction verifies $h_j'(0) \neq 0$, the formulae (3) and (4) are not valid. The reason may be one of the following two: the form *initial potential* $+ G$ is too restrictive, or the boundary conditions $(BC)_\phi$ have to be generalized by introducing one or more parameters which should change with t. Nevertheless, one should note that for third order operators and contrarily to second order ones (see [IT]) there always exist (see next paragraph) some isospectral flows in the form *initial potential* $+ G$ for various parameters ϕ and for *fixed* boundary conditions.

The assumption $h_j'(0, p_0, q_0) = 0$ in Theorem 3 is satisfied for a large class of potential (p_0, q_0). Let us give examples. Set $r_0 \in H_R^1[0,1]$ such that the Schrödinger operator $-\frac{d^2}{dx^2} + r_0(x)$ has the origin as eigenvalue with the Dirichlet boundary conditions on the unit interval, and let $y(x)$ be the associated eigenfunction. This is not restrictive since the translation of τ on the spectrum acts on the potential as $r_0 \to r_0 + \tau$. Choose ϕ_0 with Theorem 1 such that $L_{p_0=0, q_0=-2r_0}$ has a simple spectrum. Using $L_{0,-2r_0} y^2 = 2iy(y'' - r_0 y)' + 6iy'(y'' - r_0 y)$ one obtains that y^2 is an eigenfunction of $L_{0,-2r_0}$ and satisfies $(y^2)'(0) = 0$.

If the condition $h_j'(0, p_0, q_0) = 0$ was not imposed, there would be an explicit isospectral flow for each j. The number of *explicit* isospectral flows is then restricted. When $h_j'(0, p_0, q_0) \neq 0$, nonexplicit isospectral flows could exist.

Furthermore, the condition $h_j'(0, p_0, q_0) = 0$ may be not artificial since it appears again with a different method for deriving isospectral flows. Namely, the commutation method leads to Theorem 3 in the case where $p_0 = 0$ and when h_j corresponds to the eigenvalue $\mu_j = 0$ (or, equivalently, $p_0 \equiv \mu_j$). In particular, one recovers the formula (4), and (3) becomes $p(x,t) \equiv 0$. Let us briefly outline the steps. Set $D = \frac{1}{i}\frac{d}{dx}$, $A_h^+ = hD\frac{1}{h}$, and $A_h^- = \frac{1}{h}Dh$. Let $L_{p,q} h_k = \mu_k h_k \ \forall k$. Fix j and suppose first that $\frac{1}{2}(h_j')^2 - h_j h_j'' - q h_j^2 = 0$. Then it is easy to check that $A_{h_j}^- D A_{h_j}^+ = L_{p,q} - \mu_j$. Therefore, $\forall k \neq j$, $h_k^+ = D A_{h_j}^+ h_k$ and $h_j^+ = \frac{1}{h_j}(c_1(t) + c_2(t)\int_0^x h_j^2(s)ds + c_3(t)\int_0^x h_j^2(s)\int_0^s h_j(\sigma)d\sigma)$ satisfy $D A_{h_j}^+ A_{h_j}^- h_k^+ = (\mu_k - \mu_j) h_k^+ \ \forall k$. In these conditions, $D A_{h_j}^+ A_{h_j}^- = D A_{h_j^+}^- A_{h_j^+}^+$ and commuting again we find that $\forall k \neq j$, $\tilde{h}_k = A_{h_j^+}^+ h_k^+$ and $\tilde{h}_j = \frac{1}{h_j^+}$ satisfy $A_{h_j^+}^+ D A_{h_j^+}^- \tilde{h}_k = (\mu_k - \mu_j)\tilde{h}_k \ \forall k$. This proves that $A_{h_j^+}^+ D A_{h_j^+}^- + \mu_j$ is isospectral to $A_{h_j}^- D A_{h_j}^+ + \mu_j = L_{p,q}$. Turning back to the condition $\frac{1}{2}(h_j')^2 - h_j h_j'' - q h_j^2 = 0$, we have $h_j L_{0,q} h_j = D(\frac{1}{2}(h_j')^2 - h_j h_j'' - q h_j^2)$ so that $L_{0,q} h_j = \mu_j h_j$ and (2) implies $\frac{1}{2}(h_j')^2 - h_j h_j'' - q h_j^2 = \frac{1}{2}(h_j'(0))^2 - \mu_j \int_0^x h_j^2(s)ds$ which vanish if $\mu_j = 0$ and $h_j'(0) = 0$. The formulae resulting from $A_{h_j}^- D A_{h_j}^+$ are (3) with $p(x,t) \equiv 0$ and (4). The jth eigenfunction $\tilde{h}_j$ is the same as the one in section 3.

In the second order case, isospectral flows have been largely studied in various situations. For the Schrödinger operator $-\frac{d^2}{dx^2} + q(x)$, $x \in [0,1]$, $q \in L^2$ explicit formulae for isospectral flows are established for the Dirichlet boundary conditions in [PT], for the separated boundary conditions in [IT], for the periodic case in [FIT], and for the generalized periodic case in [RT]. Explicit formulae are derived in [GR] for the singular Schrödinger operator $-\frac{d^2}{dx^2} + \frac{2}{x^2} + q(x)$, $x \in [0,1]$, $q \in L^2$ with Dirichlet boundary conditions and in [CM] for the Dirichlet problem $\frac{d}{dx}(p^2 \frac{d}{dx} y) + \lambda p^2 y = 0$, $y(0) = y(1) = 0$. For each eigenvalue λ_j the explicit formula arises naturally as Hamiltonian phase flows

with the Hamiltonian function λ_j.[1] The corresponding explicit formulae are derived using commutation methods based on the Crum–Darboux method (see [PT, section 5], [GST, appendices A, B]). These Hamiltonian flows are decisive for a full description of isospectral sets. For unbounded domains, explicit formulae are obtained in [MT] for the perturbed quantum harmonic oscillator $-\frac{d^2}{dx^2}+x^2+q(x)$, $x\in\mathbf{R}$, $q\in S$ and recently for a general situation $-\frac{d^2}{dx^2}+q(x)$, $x\in\mathbf{R}$, $q\in L^2$ in [GST]. In [A1] and [AG] explicit formulae of isospectral flows are given for a first order differential operator. To the best of our knowledge, Schrödinger operators, first order systems, and now third order operators (1) are the only examples where explicit formulae are derived for the isospectral flows induced by the Hamiltonian functions λ_j.

Let us mention that in the Lax framework and in the periodic case, one step in the study of a wave equation is to introduce an auxiliary spectra (made up of simple eigenvalues), of an ordinary differential operator L, self-adjoint in most cases. The eigenvalues of L and the canonically conjugated coordinates constitute a coordinate system on the phase space for the evolution equation. The boundary conditions for L are the Dirichlet boundary conditions or are closely related. The isospectral flows are used to determine the exact image of the phase space by the coordinate system. The wave equation associated to the ordinary differential operator $L=L_{p,q}$ is the Boussinesq equation $\frac{\partial^2 q}{\partial t^2}=\frac{\partial^2}{\partial x^2}(\frac{4}{3}q^2+\frac{1}{3}\frac{\partial^2 q}{\partial x^2})$ (see [M] for more considerations). The boundary conditions in (2) are chosen so as to be close to the Dirichlet boundary conditions, to obtain a self-adjoint operator when associated with $L_{p,q}$, and to potentially give simple eigenvalues. The fact that this would provide an auxiliary spectra is beyond our purpose.

Sections 2, 3, and 4 are concerned with the proofs of Theorem 1, Theorem 2, and Theorem 3, respectively.

2. Proof of Theorem 1. This section is devoted to the proof of Theorem 1. The proof is a consequence of Lemmas 2 and 3. Lemma 2 follows from Theorem 4 and Lemma 1.

Consider $(p,q)\in L^2_R\times H^1_R$, and let $\lambda\in\mathbf{C}$. The functions $y_1(x,\lambda,p,q)$, $y_2(x,\lambda,p,q)$, $y_3(x,\lambda,p,q)$ are defined as the unique solutions to $L_{p,q}y(x)=\lambda y(x)$ for a.e. $x\in[0,1]$, satisfying the initial conditions

$$\begin{pmatrix} y_1(0,\lambda,p,q) & y_2(0,\lambda,p,q) & y_3(0,\lambda,p,q)\\ y_1'(0,\lambda,p,q) & y_2'(0,\lambda,p,q) & y_3'(0,\lambda,p,q)\\ y_1''(0,\lambda,p,q) & y_2''(0,\lambda,p,q) & y_3''(0,\lambda,p,q)\end{pmatrix}=Identity.$$

Every solution to $L_{p,q}y=\lambda y$ can be expressed as

$$y(x)=a\,y_1(x,\lambda,p,q)+b\,y_2(x,\lambda,p,q)+c\,y_3(x,\lambda,p,q), \tag{5}$$

where $(a,b,c)=(y(0),y'(0),y''(0))$.

THEOREM 4. *Fix $(p,q,\phi)\in L^2_R\times H^1_R\times T$.*

(i) *The eigenvalues of $L_{p,q}$ associated with the boundary conditions $(BC)_\phi$ are of multiplicity one or two. They are the roots of the function defined from $\mathbf{C}$ into $\mathbf{R}$*

$$\lambda\mapsto\Delta(\lambda,p,q,\phi)=\cos\left(\frac{\phi}{2}\right)\operatorname{Re}y_3(1,\lambda,p,q)-\sin\left(\frac{\phi}{2}\right)\operatorname{Im}y_3(1,\lambda,p,q). \tag{6}$$

[1] Other types of isospectral flows are induced by the Korteweg–deVries (KdV) hierarchy of Hamiltonian functions.

(ii) *Moreover, λ is an eigenvalue and of multiplicity two if and only if $\mathcal{M}(\lambda,p,q,\phi)=\left(\begin{smallmatrix}0&0\\0&0\end{smallmatrix}\right)$, where*

$$\mathcal{M}(\lambda,p,q,\phi)=\begin{pmatrix} y_2(1,\lambda,p,q) & y_3(1,\lambda,p,q)\\ y_2'(1,\lambda,p,q)-e^{i\phi} & y_3'(1,\lambda,p,q)\end{pmatrix}. \tag{7}$$

Proof of Theorem 4. Using (5) the boundary conditions $(BC)_\phi$ are

$$\mathcal{M}(\lambda,p,q,\phi)\begin{pmatrix} b\\ c\end{pmatrix}=\begin{pmatrix}0\\0\end{pmatrix},\quad (b,c)\neq(0,0).$$

Consequently, λ is an eigenvalue if and only if $\operatorname{Ker}\mathcal{M}(\lambda,p,q,\phi)\le 1$. Thus the eigenvalues are the roots of $\det\mathcal{M}(\lambda,p,q,\phi)=0$. Using $\bar{y}_3=y_3'y_2-y_3y_2'$ (see [A2, Lemma 4]) we have

$$\det\mathcal{M}(\lambda,p,q,\phi)=\bar{y_3}(1,\lambda,p,q)+e^{i\phi}y_3(1,\lambda,p,q). \tag{8}$$

From (8) it is easy to check that

$$\det\mathcal{M}(\lambda,p,q,\phi)=2e^{i\frac{\phi}{2}}\left(\cos\left(\frac{\phi}{2}\right)\operatorname{Re}y_3(1,\lambda,p,q)-\sin\left(\frac{\phi}{2}\right)\operatorname{Im}y_3(1,\lambda,p,q)\right).$$

This proves (i). The eigenvalue λ is of multiplicity two if and only if $\operatorname{Ker}\mathcal{M}(\lambda,p,q,\phi)=2$. This proves (ii). □

LEMMA 1. *Suppose $(p,q)\in L^2_R\times H^1_R$ and $\lambda\in\mathbf{R}$. Then*

$$y_3(1,\lambda,p,q)=0\Rightarrow y_3'(1,\lambda,p,q)=y_2(1,\lambda,p,q)=|y_2'(1,\lambda,p,q)|-1=0.$$

Proof of Lemma 1. We have (see [A2, Lemma 4])

$$\bar{y}_2(x,\lambda,p,q)=y_3'(x,\lambda,p,q)y_1(x,\lambda,p,q)-y_3(x,\lambda,p,q)y_1'(x,\lambda,p,q) \tag{9}$$

and

$$\bar{y}_3(x,\lambda,p,q)=y_3'(x,\lambda,p,q)y_2(x,\lambda,p,q)-y_3(x,\lambda,p,q)y_2'(x,\lambda,p,q) \tag{10}$$

for $(x,\lambda,p,q)\in[0,1]\times\mathbf{R}\times L^2_R\times H^1_R$. We omit (p,q) from the notations for brevity.

Using (10), $y_3(1,\lambda)=0\Rightarrow y_2(1,\lambda)=0$ or $y_3'(1,\lambda)=0$. From (9), $y_3(1,\lambda)=y_3'(1,\lambda)=0\Rightarrow y_2(1,\lambda)=0$. Consequently, we have

$$y_3(1,\lambda)=0\Rightarrow y_2(1,\lambda)=0. \tag{11}$$

Moreover, (10) gives $\bar{y_3'}(1,\lambda)=y_3''(1,\lambda)y_2(1,\lambda)-y_3(1,\lambda)y_2''(1,\lambda)$. Then with (11) we get

$$y_3(1,\lambda)=0\Rightarrow y_2(1,\lambda)=y_3'(1,\lambda)=0. \tag{12}$$

There is no second order derivative in $L_{p,q}$. Then the Wronskian

$$W(x,\lambda)=\begin{vmatrix} y_1(x,\lambda) & y_2(x,\lambda) & y_3(x,\lambda)\\ y_1'(x,\lambda) & y_2'(x,\lambda) & y_3'(x,\lambda)\\ y_1''(x,\lambda) & y_2''(x,\lambda) & y_3''(x,\lambda)\end{vmatrix}$$

does not depend on x and therefore is equal to 1.

Suppose $y_3(1,\lambda) = y_3'(1,\lambda) = y_2(1,\lambda) = 0$. From $W(1,\lambda) = 1$ we get

$$y_1(1,\lambda)y_2'(1,\lambda)y_3''(1,\lambda) = 1. \tag{13}$$

Differentiate (9) with respect to x to obtain

$$\bar{y}_2'(1,\lambda)y_3''(1,\lambda) = y_3''(1,\lambda)y_1(1,\lambda). \tag{14}$$

Equalities (13) and (14) show that $|y_2'(1,\lambda)| = 1$.

$$y_3(1,\lambda) = y_3'(1,\lambda) = y_2(1,\lambda) = 0 \Rightarrow |y_2'(1,\lambda)| = 1. \tag{15}$$

Therefore, (12) and (16) complete the proof. □

LEMMA 2. *Suppose $(p,q) \in L^2_R \times H^1_R$ and $\lambda \in \mathbf{R}$. Then $y_3(1,\lambda,p,q) = 0$ if and only if there exists a unique $\phi \in T$ such that λ is an eigenvalue of multiplicity two for the operator $L_{p,q}$ with the boundary conditions $(BC)_\phi$.*

Proof of Lemma 2. The proof is a direct consequence of Theorem 4 and Lemma 1. Indeed if $y_3(1,\lambda,p,q) = 0$, then from Lemma 1, there exists a unique $\phi \in T$ such that $y_3'(1,\lambda,p,q) = y_2(1,\lambda,p,q) = 0$ and $y_2'(1,\lambda,p,q) = e^{i\phi}$. Then from Theorem 4(ii), λ is a double eigenvalue for $(BC)_\phi$. Conversely, using Theorem 4(ii) again, $y_3(1,\lambda,p,q) = 0$ when λ is a double eigenvalue. □

LEMMA 3. *Suppose $(p,q) \in L^2_R \times H^1_R$. The function defined from $\mathbf{R}$ into $\mathbf{C}$*

$$X \mapsto y_3(1,X,p,q)$$

has no roots in $|X| \geq 54^3 e^{3\|(p,q)\|}$, where $\|(p,q)\| = \|p\|_{L^2_R[0,1]} + 2\|q\|_{L^2_R[0,1]} + \|q'\|_{L^2_R[0,1]}$.

Proof of Lemma 3. Set $\Xi(x,\lambda) = e^{(|\operatorname{Im} k| + |\operatorname{Im} \omega k| + |\operatorname{Im} \omega^2 k|)\frac{x}{2}}$, where $\omega = e^{2i\frac{\pi}{3}}$ and $k^3 = \lambda$. From [A2, Theorem 3] we have

$$|y_3(1,\lambda,p,q) - y_3(1,\lambda,0,0)| \leq \frac{3}{|\lambda|} e^{\|(p,q)\|} \Xi(1,\lambda) \tag{16}$$

for every $\lambda \in \mathbf{C}$. Let $k = X + iY$ with $(X,Y) \in \mathbf{R}^2$, and define the sector

$$\mathcal{S} = \left\{ k \in \mathbf{C};\ X > 0 \text{ and } |Y| < \sqrt{3}X \right\}.$$

From (16) we obtain

$$|y_3(1,\lambda,p,q) - y_3(1,\lambda,0,0)| \leq \frac{3}{|\lambda|} e^{\|(p,q)\| + \frac{\sqrt{3}}{2}X + \frac{|Y|}{2}} \tag{17}$$

for every λ with $k \in \mathcal{S}$.

Moreover, $y_3(x,\lambda,0,0) = -\frac{1}{3k^2}(e^{ikx} + \omega e^{iwkx} + \omega^2 e^{iw^2 kx})$. In the half plane $\{X \geq 0\}$ the main term of $y_3(x,\lambda,0,0)$ is $\omega^2 e^{iw^2 kx}$. Therefore, it is easy to obtain

$$|y_3(1,\lambda,0,0)| \geq \frac{e^{\frac{\sqrt{3}}{2}X + \frac{Y}{2}}}{3|k|^2} \left(1 - e^{-\sqrt{3}X} - e^{-\frac{\sqrt{3}}{2}X - \frac{3}{2}Y}\right) \tag{18}$$

in $\{X \geq 0\}$. In addition, if $Y \geq -1$ and $\frac{\sqrt{3}}{2}X \geq 2\log 2 + \frac{3}{2}$, then $e^{-\frac{\sqrt{3}}{2}X - \frac{3}{2}Y} \leq \frac{1}{4}$ and $e^{-\sqrt{3}X} \leq \frac{1}{4}$. Under these conditions (18) gives

$$|y_3(1,\lambda,0,0| \geq \frac{1}{6|k|^2} e^{\frac{\sqrt{3}}{2}X + \frac{Y}{2}}. \tag{19}$$

Combining (17) and (19) we deduce that

$$|y_3(1,\lambda,p,q)-y_3(1,\lambda,0,0)|<|y_3(1,\lambda,0,0)| \tag{20}$$

for any λ in $\mathcal{D}$, where

$$\mathcal{D}=\Big\{\lambda=k^3\in\mathbf{C};\ k\in\mathcal{S},\ \operatorname{Re}k>\frac{4\sqrt{3}}{3}\log 2+\sqrt{3},$$

$$\operatorname{Im}k>-1,\ |k|>18e^{\|(p,q)\|}\Big\}.$$

Since $y_3(1,\cdot,p,q)$ is an entire function (cf. [A2, Theorem 4]), Rouché's theorem is applied with (20) on any contours inside $\mathcal{D}$. Consequently, $y_3(1,\lambda,p,q)$ and $y_3(1,\lambda,0,0)$ have the same number of real roots greater than $18^3e^{3\|(p,q)\|}$. Using (19), $y_3(1,\lambda,0,0)$ has no root in $\mathcal{D}$. Thus $y_3(1,\lambda,p,q)$ has no real root greater than $18^3e^{3\|(p,q)\|}$. It can be proved similarly that $y_3(1,\lambda,p,q)$ has no real root smaller than $-18^3e^{3\|(p,q)\|}$. □

The proof of Theorem 1 is now a consequence of Lemmas 2 and 3.

Proof of Theorem 1. Fix (p,q) in $L^2_R\times H^1_R$. From Lemma 3 the roots of $\lambda\mapsto y_3(1,\lambda,p,q)$ belong to $\{\mu\in\mathbf{R};\ |\mu|<18^3e^{3\|(p,q)\|}\}$. By the analyticity properties of $y_3(1,\cdot,p,q)$ (see [A2, Theorem 4][2]) there is a finite number of roots of $y_3(1,\lambda,p,q)$ in $\{\mu\in\mathbf{R};\ |\mu|<18^3e^{3\|(p,q)\|}\}$. The roots of $y_3(1,\cdot,p,q)$ are necessarily real. Let $\nu_1,\nu_2,\dots,\nu_N$ be these points and using Lemma 1 we define the real numbers $\psi_1,\psi_2,\dots,\psi_N$ by $y_2'(1,\nu_j,p,q)=e^{i\psi_j}$, $j=1,2,\dots,N$.

Following Theorem 4(i) the ν_j's are eigenvalues of $L_{p,q}$ with the boundary conditions $(BC)_\phi$ and for any $\phi\in T$. In other words, the roots of $y_3(1,\cdot,p,q)$ are the particular eigenvalues that remain fixed as the boundary conditions change. The multiplicity of the ν_j's is one or two. Following Lemma 2 the ν_j's are of multiplicity one when $\phi\neq\psi_1,\psi_2,\dots,\psi_N$.

From Lemma 3 and Theorem 1(ii) all eigenvalues in $\{\mu\in\mathbf{R};\ |\mu|\geq 18^3e^{3\|(p,q)\|}\}$ are simple for the boundary conditions $(BC)_\phi$ with any $\phi\in T$. The proof is now complete. □

3. Proof of Theorem 2. Let us recall here that the eigenvalues $\lambda_j(p,q,\phi)$ are the roots of $\operatorname{Re}(e^{i\frac{\phi}{2}}y_3(1,\lambda,p,q))$ and are of multiplicity one for $|j|$ sufficiently large. Following Picard's iteration for the integral equation satisfied by $y_3(x,\lambda,p,q)$ (see [A2, section 1]) we obtain for all $\lambda\in\mathbf{C}$

$$y_3(1,\lambda,p,q)=y_3(1,\lambda,0,0)+\sum_{n\geq 1}c_n(1,\lambda,p,q), \tag{21}$$

where

$$\begin{aligned}c_0(x,\lambda,p,q)&=y_3(x,\lambda,0,0),\\ c_n(x,\lambda,p,q)&=\int_0^x\Big(-2y_3'(x-t,\lambda,0,0)q(t)+y_3(x-t,\lambda,0,0)(q'(t)\\ &\qquad +ip(t)\Big)c_{n-1}(t,\lambda,p,q)\,dt.\end{aligned} \tag{22}$$

[2]The hypothesis $q(0)=0$ in [A2, Theorem 4] is not necessary for y_3.

For all $(x,\lambda)\in[0,1]\times\mathbf{C}$

$$\begin{aligned} y_1(x,\lambda,0,0) &= \frac{1}{3}\left(e^{ikx}+e^{i\omega kx}+e^{i\omega^2 kx}\right),\\ y_2(x,\lambda,0,0) &= \frac{1}{3ik}\left(e^{ikx}+\omega^2 e^{i\omega kx}+\omega e^{i\omega^2 kx}\right),\\ y_3(x,\lambda,0,0) &= \frac{1}{3(ik)^2}\left(e^{ikx}+\omega e^{i\omega kx}+\omega^2 e^{i\omega^2 kx}\right), \end{aligned} \tag{23}$$

and

$$|y_j(x,\lambda,0,0)|\le\frac{3}{|k|^{j-1}}\Xi(x,\lambda), \tag{24}$$

where $\Xi(x,\lambda)=e^{(|\mathrm{Im}\frac{k}{2}|+|\mathrm{Im}\frac{\omega k}{2}|+|\mathrm{Im}\frac{\omega^2 k}{2}|)x}$. Therefore, (21), (22), (23), and (24) give

$$y_3(1,\lambda,p,q)=y_3(1,\lambda,0,0)+c_1(1,\lambda,p,q)+O\left(\frac{\Xi(1,\lambda)}{|k|^4}\right). \tag{25}$$

Using (22) with (24)

$$c_1(1,\lambda,p,q)=-2\int_0^1 y_3'(1-t,\lambda,0,0)y_3(t,\lambda,0,0)q(t)\,dt+O\left(\frac{\Xi(1,\lambda)}{|k|^4}\right). \tag{26}$$

The key formula is

$$\begin{aligned} y_3'(x-t,\lambda,0,0)y_3(x,\lambda,0,0) = \frac{i}{3\lambda}\Big(&y_1(x,\lambda,0,0)\\ &+\omega y_1(x+t(\omega-1),\lambda,0,0)+\omega^2 y_1(x+t(\omega^2-1),\lambda,0,0)\Big) \end{aligned} \tag{27}$$

for all $(x,\lambda)\in[0,1]\times\mathbf{C}$. This is easily checked using (23). For $\lambda\in\mathbf{R}$, $\Xi(1,\lambda)=O(e^{\frac{\sqrt{3}}{2}|k|})$, and from (26) and (27) one gets

$$\begin{aligned} c_1(1,\lambda,p,q) = -\frac{2i}{3\lambda}\Big(&y_{\ 1}(1,\lambda,0,0)\langle q\rangle+\omega I_1(\lambda,p,q)\\ &+\omega^2 I_2(\lambda,p,q)\Big)+O\left(\frac{e^{\frac{\sqrt{3}}{2}|k|}}{|k|^4}\right), \end{aligned} \tag{28}$$

where

$$I_l(\lambda,p,q)=\int_0^1 y_1(1+t(\omega^l-1),\lambda,0,0)q(t)\,dt,\quad l=1,2, \tag{29}$$

for all $\lambda\in\mathbf{R}$. From (23) we deduce

$$I_1(\lambda,p,q)=\frac{1}{3}\sum_{j=1}^{3}J_j(\lambda,p,q),$$

where

$$J_j(\lambda,p,q)=\int_0^1 e^{ik\omega^{j-1}(1-t)+ik\omega^j t}q(t)\,dt,\quad j=1,2,3, \tag{30}$$

for all $\lambda \in \mathbf{R}$. Integrating by parts J_j, $j = 1, 2, 3$, we deduce that

$$I_1(\lambda, p, q) = O\left(\frac{e^{\frac{\sqrt{3}}{2}|k|}}{|k|}\right). \tag{31}$$

Similarly, (31) is valid replacing $I_1(\lambda, p, q)$ by $I_2(\lambda, p, q)$. Consequently, (25) and (28) give for every $\lambda \in \mathbf{R}$

$$y_3(1, \lambda, p, q) = y_3(1, \lambda, 0, 0) - \frac{2i\langle q\rangle}{3\lambda} y_1(1, \lambda, 0, 0) + O\left(\frac{e^{\frac{\sqrt{3}}{2}|k|}}{|k|^4}\right). \tag{32}$$

Set $k_j^3 = \lambda_j(p, q, \phi)$. From (32) and $\operatorname{Re}\left(e^{i\frac{\phi}{2}} y_3(1, \lambda_j(p, q, \phi), p, q)\right) = 0$ we obtain

$$\operatorname{Re}\left(e^{i\frac{\phi}{2}} y_3(1, \lambda_j(p, q, \phi), 0, 0)\right) + \frac{2\langle q\rangle}{3\lambda_j} \operatorname{Re}\left(e^{i\left(\frac{\phi-\pi}{2}\right)} y_1(1, \lambda_j(p, q, \phi), 0, 0)\right)$$

$$= O\left(\frac{e^{\frac{\sqrt{3}}{2}|k_j|}}{|k_j|^4}\right). \tag{33}$$

Using (33) and (23)

$$\frac{2\langle q\rangle}{3\lambda} \operatorname{Re}\left(e^{i\left(\frac{\phi-\pi}{2}\right)} y_1(1, \lambda, 0, 0)\right) = \frac{2\langle q\rangle}{9\lambda}\left(e^{\frac{\sqrt{3}}{2}|k|} \cos\left(\frac{k - \phi + \pi}{2}\right) + O(1)\right) \tag{34}$$

as $0 \le k \to +\infty$. For $k_j \ge 0$ we set

$$k_j = 2j\pi + \phi - \frac{\pi}{3} + 2\delta_j, \tag{35}$$

where $|\delta_j| < \pi$. Then combining (33) with (34) we deduce that

$$\cos\left(\frac{\pi}{2} + \delta_j\right) = \frac{2}{3k_j}\langle q\rangle \cos\left(\frac{\pi}{3} + \delta_j\right) + O\left(\frac{1}{k_j^2}\right)$$

for $k_j \ge 0$. Consequently, $\delta_j \to 0$ as $j \to +\infty$. Then $\delta_j = -\frac{\langle q\rangle}{6j\pi} + O(\frac{1}{j^2})$ as $j \to +\infty$ and $k_j = 2j\pi + \phi - \frac{\pi}{3} - \frac{\langle q\rangle}{3j\pi} + O(\frac{1}{j^2})$ as $j \to +\infty$. This proves (i). The asymptotic (ii) $k_j = 2j\pi + \phi + \frac{\pi}{3} - \frac{\langle q\rangle}{3j\pi} + O(\frac{1}{j^2})$ as $j \to -\infty$ can be obtained similarly or by observing that λ is an eigenvalue for $L_{p,q}$ with the boundary conditions $(BC)_\phi$ if and only if $-\lambda$ is an eigenvalue for L_{p^*,q^*} with the boundary conditions $(BC)_{-\phi}$, where $p^*(x) = p(x)$ for every x in $[0, 1]$ and $q^*(x) = q(x)$ for a.e. x in $[0, 1]$. □

4. Proof of Theorem 3. Fix $(p, q) \in L^2_R \times H^1_R$. It is proved in section 2 that for all but a finite number of parameters $\phi \in T$ the eigenvalues of $L_{p,q}$ with boundary conditions $(BC)_\phi$ are of multiplicity one. In section 2 we consider such ϕ and omit it from the notations. By the simplicity of the $\lambda_j(p, q, \phi)$ and applying the implicit functions theorem with $\Delta(\lambda_j(p, q, \phi), p, q, \phi) = 0$, we obtain that each λ_j is a smooth function of (p, q). Then the computation of the $L^2_R[0, 1] \times L^2_R[0, 1]$ gradient $\nabla_{p(x),q(x)}\lambda_j(p, q, \phi)$ is given by Lemma 5. The scalar product associated with $L^2_R[0, 1] \times L^2_R[0, 1]$ is

$$\left\langle \begin{pmatrix} Y(x) \\ Z(x) \end{pmatrix}, \begin{pmatrix} \tilde{Y}(x) \\ \tilde{Z}(x) \end{pmatrix} \right\rangle = \int_0^1 Y(x)\tilde{Y}(x) + Z(x)\tilde{Z}(x)\, dx.$$

We shall prove that the flow $(p(t), q(t))$ associated with the vector field

$$\begin{pmatrix} 0 & \frac{d}{dx} \\ \frac{d}{dx} & 0 \end{pmatrix} \nabla_{p(x),q(x)} \lambda_j(p,q)$$

is isospectral. Moreover, when $h_j'(0,p,q) = 0$, this flow exists $\forall t \in \mathbf{R}$ and is given by (3) and (4). Define $[y,z](x) = y'(x)z(x) - y(x)z'(x)\ \forall x \in [0,1]$.

LEMMA 4. *Suppose* $(p,q) \in L^2_R \times H^1_R$. *For every* $j \in \mathbf{Z}$

$$\nabla_{p(x),q(x)} \lambda_j(p,q) = \begin{pmatrix} |h_j(x,p,q)|^2 \\ i[h_j, \bar{h}_j](x,p,q) \end{pmatrix} \forall\, x \in [0,1].$$

Proof of Lemma 4. For $p, q, q' \in C^0_R[0,1]$, h_j''' is continuous. Then

$$L_{p,q}\,(d_p h_j(u)) + u h_j = \lambda_j d_p h_j(u) + d_p \lambda_j(u) h_j \tag{36}$$

and

$$L_{p,q}\,(d_q h_j(v)) + i(v h_j)' + i v h_j' = \lambda_j d_q h_j(v) + d_q \lambda_j(v) h_j. \tag{37}$$

Since $L_{p,q}$ is self-adjoint, $\|h_j\| = 1$, and $h_j(0) = h_j(1) = 0$, we obtain from (36) and (37) that $d_p \lambda_j(u) = (|h_j|^2, u)_{L^2_C[0,1]}$ and $d_q \lambda_j(v) = (ih_j' \bar{h}_j - i h_j \bar{h}_j', u)_{L^2_C[0,1]}$. Therefore,

$$d_{p,q}\lambda_j(u,v) = \left\langle \begin{pmatrix} |h_j(x,p,q)|^2 \\ i[h_j, \bar{h}_j](x,p,q) \end{pmatrix}, \begin{pmatrix} u \\ v \end{pmatrix} \right\rangle_{L^2_R[0,1] \times L^2_R[0,1]}.$$

Then for $p, q, q' \in C^0_R[0,1]$ we have $\nabla_{p,q}\lambda_j = \begin{pmatrix} |h_j|^2 \\ i[h_j, \bar{h}_j] \end{pmatrix}$ and since $\nabla_{p,q}\lambda_j$, h_j and h_j' are continuous functions of (p,q) in $L^2_R \times H^1_R$, it is true for $(p,q) \in L^2_R \times H^1_R$. □

LEMMA 5. *For every* $(j,k) \in \mathbf{Z}^2$ *we have* $\{\lambda_j, \lambda_k\} = 0$.

Consequently, every λ_k is an integral of $\begin{pmatrix} \dot{p} \\ \dot{q} \end{pmatrix} = V_j(p,q)$ for fixed boundary conditions.

Proof of Lemma 5. The proof is similar to [M, section 6]. For every $(j,k) \in \mathbf{Z}^2$ we have

$$\begin{aligned} &\int_0^1 \begin{pmatrix} |h_j|^2 \\ i[h_j, \bar{h}_j] \end{pmatrix} \begin{pmatrix} 0 & \frac{d}{dx} \\ \frac{d}{dx} & 0 \end{pmatrix} \begin{pmatrix} |h_k|^2 \\ i[h_k, \bar{h}_k] \end{pmatrix} dx \\ &\quad = -\frac{i}{3} \int_0^1 2[h_j, \bar{h}_j]' |h_k|^2 - 2[h_k, \bar{h}_k]' |h_j|^2 \\ &\qquad + [h_k, \bar{h}_k](|h_j|^2)' - [h_k, \bar{h}_k](|h_j|^2)'\, dx \\ &\quad = \frac{2i}{3} \int_0^1 w(\bar{h}_j, h_k) h_j \bar{h}_k - w(\bar{h}_k, h_j) h_k \bar{h}_j\, dx, \end{aligned} \tag{38}$$

where $w(\bar{f}, g) = i(\bar{f}''g - \bar{f}'g' + \bar{f}g'' + 2q\bar{f}g)$. If $j = k$ the expression (38) vanishes. Moreover, it is easy to check that

$$\frac{d}{dx} w(\bar{f}, g) = (\lambda - \mu)\bar{f}g \tag{39}$$

when $L_{p,q} f = \lambda f$ and $L_{p,q} g = \mu g$. Then (39) and (38) give

$$\{\lambda_j, \lambda_k\} = w(\bar{h}_j, h_k) w(\bar{h}_k, h_j)|_{x=0}^{x=1},$$

which completes the proof with (2). □

We now prove Theorem 3.

Proof of Theorem 3. (p_0, q_0, ϕ_0) are fixed. Let $h_j = h_j(x, p_0, q_0, \phi_0)$ and $\lambda_j = \lambda_j(x, p_0, q_0, \phi_0)$. Observing Lemma 5, the proof is carried out by determining not only the potentials but also one eigenfunction. We look for $(h(x,t), p(x,t), q(x,t))$ satisfying

$$\|h(t)\|_{L^2_R[0,1]} = 1, \tag{40}$$

$$L_{p(t),q(t)}h(t) = \lambda_j h(t), \tag{41}$$

$$h(0,t) = h(1,t) = 0, \quad h'(0,t) = e^{i\phi}h'(1,t), \tag{42}$$

and

$$\frac{d}{dt}\begin{pmatrix} p(t) \\ q(t) \end{pmatrix} = \frac{3}{2}\begin{pmatrix} 0 & \frac{d}{dx} \\ \frac{d}{dx} & 0 \end{pmatrix}\begin{pmatrix} |h(t)|^2 \\ i[h(t), \bar{h}(t)] \end{pmatrix}. \tag{43}$$

The $(h(t), p(t), q(t))$ are expressed as

$$h(x,t) = b(t)\frac{h_j(x)}{\theta(x,t)} \tag{44}$$

and

$$p(x,t) = p_0(x) + A(x,t), \quad q(x,t) = q_0(x) + B(x,t), \tag{45}$$

where $b(t)$, $\theta(x,t)$, $A(x,t)$, and $B(x,t)$ are real valued functions. In (44) $b(t)$ is the L^2 unit normalization (40). Using

$$[h(t), \bar{h}(t)] = \frac{b^2(t)}{\theta^2(x,t)}[h_j(x), \bar{h}_j(x)]$$

and since $\frac{h_j}{\theta(t)}$ satisfies (42) under the assumption $h_j'(0) = 0$, we shall determine $b(t)$, $\theta(x,t)$, $A(x,t)$, and $B(x,t)$ satisfying

$$\left\| b(t)\frac{h_j}{\theta(t)} \right\|_{L^2_R[0,1]} = 1, \tag{46}$$

$$L_{p_0+A(t),q_0+B(t)}\left(\frac{h_j}{\theta(t)}\right) = \lambda_j \frac{h_j}{\theta(t)}, \tag{47}$$

and

$$\frac{d}{dt}\begin{pmatrix} A(t) \\ B(t) \end{pmatrix} = \frac{3}{2}b^2(t)\frac{d}{dx}\frac{1}{\theta^2(t)}\begin{pmatrix} i[h_j, \bar{h}_j] \\ |h_j|^2 \end{pmatrix}. \tag{48}$$

First we deal with (47). Combining

$$i\left(\frac{h_j}{\theta}\right)''' + 2i(q_0 + B)\left(\frac{h_j}{\theta}\right)' + (iq_0' + iB' + p + A)\left(\frac{h_j}{\theta}\right) = \lambda_j\left(\frac{h_j}{\theta}\right)$$

with $ih_j''' + 2iq_0h_j' + (iq_0' + p_0)h_j = \lambda_j h_j$ while using $(\frac{h_j}{\theta})''' = h_j'''\left(\frac{1}{\theta}\right) + 3h_j''\left(\frac{1}{\theta}\right)' + 3h_j'\left(\frac{1}{\theta}\right)'' + h_j\left(\frac{1}{\theta}\right)'''$ gives

$$\begin{aligned}(A+iB')\left(\frac{h_j}{\theta}\right) + 2iB\left(\frac{h_j}{\theta}\right)' + 2iq_0h_j\left(\frac{1}{\theta}\right)' \\ + 3ih_j''\left(\frac{1}{\theta}\right)' + 3ih_j'\left(\frac{1}{\theta}\right)'' + ih_j\left(\frac{1}{\theta}\right)''' = 0.\end{aligned} \tag{49}$$

The real part of (49) multiplied by $2\bar{h}_j$ is

$$2|h_j|^2A\left(\frac{1}{\theta}\right) + 2i[h_j,\bar{h}_j]B\left(\frac{1}{\theta}\right) + 3i[h_j,\bar{h}_j]'\left(\frac{1}{\theta}\right)' + 3i[h_j,\bar{h}_j]\left(\frac{1}{\theta}\right)'' = 0 \tag{50}$$

and the imaginary part of (49) multiplied by $2\bar{h}_j$ gives

$$\begin{aligned}2B'|h_j|^2\left(\frac{1}{\theta}\right) + 2B\left(\left(|h_j|^2\right)'\left(\frac{1}{\theta}\right) + 4B|h_j|^2\left(\frac{1}{\theta}\right)'\right) \\ + 4q_0|h_j|^2\left(\frac{1}{\theta}\right)' + 3(h_j''\bar{h}_j + h_j\bar{h}_j'')\left(\frac{1}{\theta}\right)' \\ + 3\left(|h_j|^2\right)'\left(\frac{1}{\theta}\right)'' + 2|h_j|^2\left(\frac{1}{\theta}\right)''' \\ = 0.\end{aligned} \tag{51}$$

Equation (49) is equivalent to (50) and (51). Equation (50) is also

$$2|h_j|^2A\left(\frac{1}{\theta}\right) + 2i[h_j,\bar{h}_j]B\left(\frac{1}{\theta}\right) + 3i\left([h_j,\bar{h}_j]\left(\frac{1}{\theta}\right)'\right)' = 0. \tag{52}$$

The first two terms in (52) are exact derivatives. Therefore, we set

$$A = ia\left([h_j,\bar{h}_j]\left(\frac{1}{\theta}\right)\right)', \quad B = a\left(|h_j|^2\left(\frac{1}{\theta}\right)\right)', \tag{53}$$

where $a = a(t)$ is a real valued function and does not depend on x.

Then (52) is equivalent to

$$2a\left([h_j,\bar{h}_j]|h_j|^2\left(\frac{1}{\theta^2}\right)\right)' + 3\left([h_j,\bar{h}_j]\left(\frac{1}{\theta}\right)'\right)' = 0. \tag{54}$$

Since $[h_j,\bar{h}_j] = 0$ at $x = 0$, (54) gives $\theta' = \frac{2}{3}a|h_j|^2$, then

$$\theta(x,t) = 1 + \frac{2}{3}a(t)\int_0^x |h_j(s)|^2\,ds. \tag{55}$$

Note that any other choice of $c(t)$ instead of 1 in (55) would affect only $a(t)$ and $b(t)$. Next we determine $a(t)$ in terms of $b(t)$ using (48) and (55). From (53)

$$\frac{d}{dt}\begin{pmatrix} A \\ B \end{pmatrix} = \frac{d}{dx}\left(\frac{1}{\theta}\frac{d}{dt}a - \frac{a}{\theta^2}\frac{d}{dt}\theta\right)\begin{pmatrix} i[h_j,\bar{h}_j] \\ |h_j|^2 \end{pmatrix}.$$

Then from (48) we get

$$\frac{1}{\theta}\frac{d}{dt}a - \frac{a}{\theta^2}\frac{d}{dt}\theta = \frac{3}{2}b^2. \tag{56}$$

Using (55) and (56) we obtain

$$\frac{d}{dt}a = \frac{3b^2}{2\theta^2}. \tag{57}$$

Besides it is easy to check that

$$\left|\frac{h_j}{\theta}\right|^2 = |h_j|^2 - \frac{2}{3}a\left(\frac{1}{\theta}\left(\int_0^x |h_j|^2\right)^2\right)' ds. \tag{58}$$

Then (58) gives

$$\left\|\frac{h_j}{\theta}\right\|^2_{L^2_{\mathbf{R}}[0,1]} = \frac{1}{1+\frac{2}{3}a}. \tag{59}$$

Therefore, (46) and (59) give

$$1 + \frac{2}{3}a = b^2. \tag{60}$$

Following (59), $a(0) = 0$. Combining (57) and (60) and looking for $a(t)$ with $a(0) = 0$ we get

$$\frac{2}{3}a(t) = e^t - 1, \quad b(t) = e^{\frac{t}{2}}. \tag{61}$$

Therefore, (50) is satisfied with

$$\theta(x,t) = 1 + (e^t - 1)\int_0^x |h_j(s)|^2\, ds, \tag{62}$$

$$A(x,t) = \frac{3}{2}i(e^t - 1)\frac{d}{dx}\frac{[h_j(x), \bar{h}_j(x)]}{\theta(x,t)}, \tag{63}$$

$$\begin{aligned} B(x,t) &= \frac{3}{2}(e^t - 1)\frac{d}{dx}\frac{|h_j(x)|^2}{\theta(x,t)} \\ &= \frac{3}{2}\frac{d^2}{dx^2}\log\theta(x,t). \end{aligned} \tag{64}$$

The function $\theta(x,t) > 0\ \forall\,(x,t) \in [0,1] \times \mathbf{R}$. Therefore, (50) is verified with (62), (63), and (64). It remains to check that (51) is satisfied with (62) and (64). From (53) and (55)

$$B = \frac{3}{2}\left(\frac{\theta'}{\theta}\right)'. \tag{65}$$

Using (65) and $|h_j|^2 = \frac{3}{2a}\theta'$, the left-hand side of (51) is, after expressing $\left(\frac{1}{\theta}\right)'''$, $\left(\frac{1}{\theta}\right)''$, $\left(\frac{1}{\theta}\right)'$,

$$\begin{aligned}
&\frac{9}{2a}\frac{\theta'}{\theta}\left(\frac{\theta'''}{\theta} - 3\frac{\theta''\theta'}{\theta^2} + 2\left(\frac{\theta'}{\theta}\right)^3\right) + \frac{9}{2a}\frac{\theta''}{\theta}\left(\frac{\theta''}{\theta} - \left(\frac{\theta'}{\theta}\right)^2\right)\\
&- \frac{9}{a}\left(\frac{\theta'}{\theta}\right)^2\left(\frac{\theta''}{\theta} - \left(\frac{\theta'}{\theta}\right)^2\right) - \frac{6}{a}q_0\left(\frac{\theta'}{\theta}\right)^2 - 3\frac{\theta'}{\theta^2}(\bar{h}_j''h_j + \bar{h}_j h_j'') \qquad (66)\\
&+ \frac{9}{2a}\theta''\left(2\frac{(\theta')^2}{\theta^3} - \frac{\theta''}{\theta^2}\right) + \frac{3}{a}\theta'\left(-6\frac{(\theta')^3}{\theta^4} + 6\frac{\theta'\theta''}{\theta^3} - \frac{\theta'''}{\theta^2}\right).
\end{aligned}$$

In (66) the terms $\frac{(\theta')^2\theta''}{\theta^3}$, $(\frac{\theta'}{\theta})^4$, $(\frac{\theta''}{\theta})^2$ vanish and the remaining terms are

$$\frac{3}{2a}\frac{\theta'''}{\theta^2}\theta' - \frac{6q_0}{a}\left(\frac{\theta'}{\theta}\right)^2 - 3\frac{\theta'}{\theta^2}(\bar{h}_j''h_j + \bar{h}_j h_j''). \qquad (67)$$

Using

$$\theta''' = \frac{2}{3}a(\bar{h}_j''h_j + 2\bar{h}_j'h_j' + \bar{h}_j h_j''),$$

(67) is equal to

$$\begin{aligned}
&- 2\frac{\theta'}{\theta^2}(\bar{h}_j''h_j - |h_j'|^2 + \bar{h}_j h_j'' + 2q_0|h_j|^2)\\
&= 2i\frac{\theta'}{\theta^2}w(\bar{h}_j, h_j). \qquad (68)
\end{aligned}$$

Following (39) the derivative of $w(\bar{h}_j, h_j)$ with respect to x vanishes. Then the assumption $h_j'(0) = 0$ and (2) show that (68) is zero for every $x \in [0,1]$. Then (51) is verified. □

GLOBAL EXISTENCE OF SMALL SOLUTIONS TO THE QUADRATIC NONLINEAR SCHRÖDINGER EQUATIONS IN TWO SPACE DIMENSIONS*

NAKAO HAYASHI† AND PAVEL I. NAUMKIN‡

Abstract. We study a global existence in time of small solutions to the quadratic nonlinear Schrödinger equation in two space dimensions,

$$\begin{cases} i\partial_t u + \frac{1}{2}\Delta u = \mathcal{N}(u), & (t,x) \in \mathbf{R}\times\mathbf{R}^2, \\ u(0,x) = u_0(x), & x \in \mathbf{R}^2, \end{cases} \tag{0.1}$$

where

$$\mathcal{N}(u) = \sum_{j,k=1}^{2} \left(\lambda_{jk}(\partial_{x_j} u)(\partial_{x_k} u) + \mu_{jk}(\partial_{x_j}\bar{u})(\partial_{x_k}\bar{u})\right),$$

$\lambda_{jk}, \mu_{jk} \in \mathbf{C}$. We prove that if the initial data u_0 satisfy some analyticity and smallness conditions in a suitable norm, then the solution of the Cauchy problem (0.1) exists globally in time. Furthermore we prove the existence of the usual scattering states.

1. Introduction.

In this paper we prove the global existence of small analytic solutions and the existence of the usual scattering states to the Cauchy problem for the derivative nonlinear Schrödinger equation

$$\begin{cases} i\partial_t u + \frac{1}{2}\Delta u = \mathcal{N}(u), & (t,x) \in \mathbf{R}\times\mathbf{R}^n, \\ u(0,x) = u_0(x), & x \in \mathbf{R}^n, \end{cases} \tag{1.1}$$

with quadratic nonlinearity

$$\mathcal{N}(u) = \sum_{j,k=1}^{n} \left(\lambda_{jk}\left(\partial_{x_j} u\right)\left(\partial_{x_k} u\right) + \mu_{jk}\left(\partial_{x_j}\bar{u}\right)\left(\partial_{x_k}\bar{u}\right)\right),$$

where $\lambda_{jk}, \mu_{jk} \in \mathbf{C}$ when the space dimension $n = 2$. Global existence of small solutions to nonlinear Schrödinger equations with quadratic nonlinearities was first studied in papers [12], [13], [15] under the condition

$$\frac{\partial \mathcal{N}}{\partial(\partial_{x_j} u)} \quad \text{is pure imaginary} \tag{1.2}$$

and the space dimension $n \geq 5$. Condition (1.2) was removed in [8], where the global existence of small solutions to the Cauchy problem (1.1) with general nonlinearity

‡Instituto de Física y Matemáticas, Universidad Michoacana, AP 2-82, CP 58040, Morelia, Michoacán, México (pavelni@zeus.ccu.umich.mx).

was proved for any space dimension $n \geq 5$. Note that the problem on the global existence of solutions becomes more difficult in the case of low space dimensions. In [11] a global existence theorem with the condition

$$\left|\frac{\partial \mathcal{N}}{\partial u}\right| + \left|\frac{\partial \mathcal{N}}{\partial \bar{u}}\right| \leq C\,|\nabla u| \tag{1.3}$$

was obtained for the case $n = 3, 4$. In [7] the problem was solved for the case $n = 4$ with condition (1.2). Recently, the nonlinear term

$$\mathcal{N} = \lambda u^2 + \mu \bar{u}^2, \tag{1.4}$$

where $\lambda, \mu \in \mathbf{C}$, was considered in [10] and a global existence theorem for small solutions was shown in three space dimensions. However, for low spatial dimensions there are only a few results. In the exceptional case

$$\mathcal{N} = (\nabla u)^2, \tag{1.5}$$

(1.1) can be linearized by the Hopf–Cole transformation and the solution can be written explicitly, so the global existence and the asymptotic properties of the solution can be studied; see paper [14]. If we can prove that the existence time T of solutions has a representation $T = O\left(\exp\left(\frac{C}{\varepsilon}\right)\right)$, where $\varepsilon > 0$ is the size of the initial data in a suitable norm, then we call the result an almost global existence of solutions. An almost global existence theorem was proved in [5] for the case $n = 3$. In the case of two space dimensions the almost global existence of small analytic solutions to the Cauchy problem (1.1) with the nonlinearity

$$\mathcal{N}(u) = \sum_{j,k=1}^{2} \left(\lambda_{jk} \left(\partial_{x_j} u\right) \left(\partial_{x_k} u\right) + \mu_{jk} \left(\partial_{x_j} \bar{u}\right) \left(\partial_{x_k} \bar{u}\right) + \nu_{jk} \left(\partial_{x_j} u\right) \left(\partial_{x_k} \bar{u}\right)\right)$$

was studied in paper [9]. Moreover, it was proved that the global existence of small analytic solutions to the problem (1.1) in the case of the nonlinearity is

$$\mathcal{N} = \lambda \left(\partial_{x_1} u \partial_{x_2} \bar{u} - \partial_{x_1} \bar{u} \partial_{x_2} u\right), \tag{1.6}$$

where $\lambda \in \mathbf{C}$. In order to state the result from [4] we need the condition

$$\mathcal{N}(u) = \sum_{j,k=1}^{2} \mu_{jk} \left(\partial_{x_j} \bar{u}\right) \left(\partial_{x_k} \bar{u}\right). \tag{1.7}$$

In [4] the global existence of small solutions in the usual Sobolev spaces was established for the case (1.7) by using the method of normal forms introduced in [16]. We note that the method used in [4] does not work for the case $\lambda_{jk} \neq 0$. For the reader's convenience we use Tables 1.1 and 1.2 to show the previous works on the global solvability of nonlinear Schrödinger equations with quadratic nonlinearities. To make these tables we introduce the following conditions:

$$\mathcal{N} \quad \text{does not depend on} \quad \nabla u \quad \text{and} \quad \nabla \bar{u}. \tag{1.8}$$

Note that the nonlinearity (1.4) is a particular case of (1.8). Also, we define the condition

$$\mathcal{N} \quad \text{does not depend on} \quad u \quad \text{and} \quad \bar{u}. \tag{1.9}$$

As the consequences of (1.9) we have nonlinearity (1.6) and the Hopf–Cole case (1.5).

As we see from Tables 1.1 and 1.2 there are no global existence and time decay results in the one-dimensional case (except the Hopf–Cole case (1.5)). The estimate $T = O\left(\varepsilon^{-6}\right)$ for time existence of solutions was shown in [3] in one spatial dimension, if the nonlinearity $\mathcal{N} = i(\bar{u}_x)^2$ by using the method of normal forms.

The difficulty in the study of the large time asymptotic behavior of solutions to the Cauchy problem (1.1) is that the quadratic nonlinearity in two space dimensions is critical; that is, it decays in time with the same speed as the linear terms in the equation and cannot be omitted in the first approximation of the perturbation theory. The special oscillating structure of the nonlinearity must be taken into account to show that the solution has the usual scattering properties. Another difficulty is that the structure of the quadratic nonlinearity under consideration is not self-conjugate; that is, it does not satisfy the property $\mathcal{N}\left(ue^{i\theta}\right) = e^{i\theta}\mathcal{N}(u)$ for all $\theta \in \mathbf{R}$. This fact does not allow us to estimate the operator $\mathcal{J} = x + it\nabla$ via the standard energy type methods. To overcome this obstacle and also the so-called difficulty of the derivatives loss, we apply the analytic functional spaces. The important fact is that the nonlinearity under consideration has the type (1.9). This helps us to evaluate large time asymptotics of the nonlinearity, since the remainder terms can be estimated by the operator $\mathcal{Q} = x \cdot \nabla + it\Delta = \mathcal{J} \cdot \nabla$ through the operator $\mathcal{P} = x \cdot \nabla + 2t\partial_t$.

To state our result precisely, we now give *notation and function spaces.* We denote $\partial_{x_j} = \frac{\partial}{\partial x_j}$ and $\partial^\alpha = \partial_{x_1}^{\alpha_1}\partial_{x_2}^{\alpha_2}$, where $\alpha \in (\mathbf{N} \cup \{0\})^2$. We define the differential operators $\mathcal{P} = x \cdot \nabla + 2t\partial_t$, $\mathcal{Q} = x \cdot \nabla + it\Delta$, the vector $\Omega = \left(\Omega^{(j,k)}\right)_{(j,k=1,2)}$, where the operators $\Omega^{(j,k)} = x_j\partial_k - x_k\partial_j$ act as the angular derivatives, and the vector $\mathcal{J} = (\mathcal{J}_j)_{(j=1,2)}$ with components $\mathcal{J}_j = x_j + it\partial_j$. These operators help us to obtain the time decay properties of the linear Schrödinger evolution group $\mathcal{U}(t)\phi = \frac{1}{2\pi it}\int e^{\frac{i}{2t}(x-y)^2}\phi(y)\,dy = \mathcal{F}^{-1}e^{-\frac{it}{2}\xi^2}\mathcal{F}\phi$, where $\mathcal{F}\phi \equiv \hat{\phi}(\xi) = \frac{1}{2\pi}\int e^{-i(x\cdot\xi)}\phi(x)\,dx$ denotes the Fourier transform of the function $\phi(x)$ and $\mathcal{F}^{-1}$ is the inverse Fourier transformation defined by $\mathcal{F}^{-1}\phi \equiv \check{\phi}(x) = \frac{1}{2\pi}\int e^{i(x\cdot\xi)}\phi(\xi)\,d\xi$. We also denote the extended vectors $\Gamma = (\mathcal{P}, \Omega, \nabla)$, $\widetilde{\Gamma} = (\mathcal{P} + 2, \Omega, \nabla)$, and $\Theta = (\mathcal{Q}, \Omega, \nabla)$. We have the fol-

lowing relations: $\mathcal{Q}=\mathcal{P}-2it\mathcal{L}=\mathcal{J}\cdot\nabla=\mathcal{U}(t)\,x\mathcal{U}(-t)\cdot\nabla=it\mathcal{M}(t)\,\nabla\overline{\mathcal{M}(t)}\cdot\nabla$, where $\mathcal{M}(t)=e^{ix^2/2t}$, $\mathcal{L}=i\partial_t+\frac{1}{2}\Delta$. We use freely in the paper the following commutation relations: $[\mathcal{Q},\nabla]=[\mathcal{P},\nabla]=-\nabla$, $[\mathcal{Q},\mathcal{J}]=[\mathcal{P},\mathcal{J}]=\mathcal{J}$, $[\mathcal{P},\mathcal{Q}]=[\Omega,\mathcal{P}]=[\Omega,\mathcal{Q}]=0$, $[\partial_k,\mathcal{J}_l]=\delta_l^{(k)}$, $[\Omega_x^{(j,k)},\partial_l]=\delta_l^{(k)}\partial_j-\delta_l^{(j)}\partial_k$, where $\delta_j^{(k)}=1$ if $j=k$ and $\delta_j^{(k)}=0$ if $j\neq k$. We note that the free Schrödinger evolution group $\mathcal{U}(t)$ can be represented in the following manner: $\mathcal{U}(t)=\mathcal{M}(t)\,\mathcal{D}(t)\,\mathcal{F}M(t)$, where $\mathcal{M}(t)=\exp(ix^2/2t)$; the dilation operator is $(\mathcal{D}(t)\,\varphi)(x)=\frac{i}{t}\varphi\left(\frac{x}{t}\right)$. The inverse free Schrödinger evolution group is written as $\mathcal{U}(-t)=-\mathcal{M}(-t)\,i\mathcal{F}^{-1}\mathcal{D}\left(\frac{1}{t}\right)\mathcal{M}(-t)$, where $\mathcal{D}^{-1}(t)=-i\mathcal{D}\left(\frac{1}{t}\right)$ is the inverse dilation operator. We denote the usual Lebesgue space by $\mathbf{L}^p\left(\mathbf{R}^2\right)$ with the norm $\|\phi\|_p=\left(\int_{\mathbf{R}^2}|\phi(x)|^p\,dx\right)^{1/p}$ if $1\leq p<\infty$ and $\|\phi\|_\infty=\operatorname{ess.sup}\left\{|\phi(x)|\,;x\in\mathbf{R}^2\right\}$ if $p=\infty$. For simplicity we write $\|\cdot\|=\|\cdot\|_2$. The weighted Sobolev space is defined by $\mathbf{H}_p^{m,k}\left(\mathbf{R}^2\right)=\{\phi\in\mathbf{L}^2\left(\mathbf{R}^2\right):\|\langle x\rangle^k\langle i\nabla\rangle^m\phi\|_p<\infty\}$, where $m,k\in\mathbf{R}^+$, $1\leq p\leq\infty$, $\langle x\rangle=\sqrt{1+x^2}$ are the Japanese brackets. We also denote $\mathbf{H}^{m,k}\left(\mathbf{R}^2\right)=\mathbf{H}_2^{m,k}\left(\mathbf{R}^2\right)$ and the norm $\|\phi\|_{m,k}=\|\phi\|_{m,k,2}$. We now define the analytic function space

$$\mathbf{A}^{m,p}(t)=\left\{\phi\in\mathbf{L}^p\left(\mathbf{R}^2\right);\|\phi\|_{\mathbf{A}^{m,p}}=\sum_{|\beta|\leq m}\sum_{\alpha}\frac{b^{|\alpha|}}{\alpha!}\left\|\Gamma^{\alpha+\beta}\phi\right\|_p<\infty\right\},$$

where $\Gamma=\Gamma(t)=(\mathcal{P},\Omega,\nabla)$, $b=b(t)=b_\infty+(b_0-b_\infty)\left(\log(e+t)\right)^{-\gamma}$, $0<b_\infty<b_0<1$, and $\gamma>0$ is sufficiently small. Similarly we write

$$\widetilde{\mathbf{A}}^{m,p}(t)=\left\{\phi\in\mathbf{L}^p\left(\mathbf{R}^2\right);\|\phi\|_{\widetilde{\mathbf{A}}^{m,p}}=\sum_{|\beta|\leq m}\sum_{\alpha}\frac{b^{|\alpha|}}{\alpha!}\left\|\widetilde{\Gamma}^{\alpha+\beta}\phi\right\|_p<\infty\right\}.$$

Here the summation is over all admissible multi-indices α. We often use the summations convention if it does not cause confusion. For simplicity we write $\mathbf{A}^m(t)=\mathbf{A}^{m,2}(t)$ and $\widetilde{\mathbf{A}}^m(t)=\widetilde{\mathbf{A}}^{m,2}(t)$. By $[s]$ we denote the largest integer less than or equal to s. Let $\mathbf{C}(\mathbf{I};\mathbf{B})$ be the space of continuous functions from a time interval $\mathbf{I}$ to a Banach space $\mathbf{B}$. Different positive constants we denote by the same letter C. Our basic estimates of the solution are in the functional space $\mathbf{X}=\left\{u\in\mathbf{C}\left(\mathbf{R};\mathbf{L}^2\right);\|u\|_{\mathbf{X}}<\infty\right\}$, where

$$\begin{aligned}\|u\|_{\mathbf{X}}&=\sup_{t>0}\|u(t)\|_{\mathbf{A}^3(t)}+\sup_{t>0}t^{-1-\eta}\sum_{|\gamma|\leq1}\|\mathcal{J}^\gamma u(t)\|_{\mathbf{A}^2(t)}\\&+\sum_{|\gamma|=1}\int_0^\infty\|\Theta^\gamma u\|_{\mathbf{A}^3(t)}\,|b'|\,dt+\sum_{|\gamma|=1,|\sigma|\leq1}\int_1^\infty\|\Theta^\gamma\mathcal{J}^\sigma u\|_{\mathbf{A}^3(t)}\,\frac{|b'|\,dt}{t^{1+\eta}}\\&+\sup_{t>0}t^{1-2\eta}\sum_{\alpha}\frac{b^{|\alpha|}}{\alpha!}\|\partial_t\mathcal{V}(-t)\,\mathcal{K}\Gamma^\alpha\nabla u(t)\|_\infty\\&+\sum_{|\delta|\leq3}\int_1^\infty\sum_{\alpha}\frac{b^{|\alpha|}}{\alpha!}\left\|\partial_t\mathcal{V}(-t)\,\mathcal{K}\Gamma^{\alpha+\delta}u(t)\right\|t^{2\eta-\frac{1}{2}}dt;\end{aligned}$$

here $\mathcal{K}=\mathcal{F}\mathcal{M}\mathcal{U}(-t)$ and $\eta>0$ is sufficiently small. Now we state our result.

THEOREM 1.1. *We assume that the initial data $u_0\in\mathbf{A}^3(0)$ are such that $x_ju_0\in\mathbf{A}^2(0)$ for $j=1,2$ and the norm $\|u_0\|_{\mathbf{A}^3(0)}+\|x_1u_0\|_{\mathbf{A}^2(0)}+\|x_2u_0\|_{\mathbf{A}^2(0)}=\varepsilon$ is sufficiently small. Then there exists a unique global solution of the Cauchy problem*

(1.1) *such that* $u(t,x) \in \mathbf{A}^3(t)$ *for all* $t \in \mathbf{R}$. *Moreover, there exist unique functions* $u^{\pm} \in \mathbf{L}^2(\mathbf{R}^2)$ *such that*

$$\left\| \mathcal{U}(-t)\, u(t) - u^{\pm} \right\| \le C\, |t|^{-\omega},$$

as $t \to \pm\infty$, *where* $0 < \omega < \frac{1}{2}$.

We assumed in the theorem that $0 < b_\infty < b_0 < 1$. This ensures that the function space $\mathbf{A}^3(0)$ for the initial data is not empty: as in [1], [2], we can see that our result is valid for the initial function ϕ, which has an analytic continuation Φ to the domain

$$\begin{aligned} \Pi = \big\{ z \in \mathbf{C}^2;\ & z_j = x_j + i y_j,\ x_j \in \mathbf{R}, \\ & -a - |x_j| \tan\vartheta < y_j < a + |x_j| \tan\vartheta,\ j = 1,2 \big\} \end{aligned}$$

such that

$$\int\int_{\Pi} |\Phi(z)|^2\, dxdy < \infty,$$

where $\vartheta \in \left(0, \frac{\pi}{2}\right)$, $\sin\vartheta = c$, and $a, c \in (b_0, 1)$. For example, we can take $1/\left(1+x^4\right)$, e^{-x^2} as the initial data for the Cauchy problem (1.1).

We conclude this section with the following remark. The method of the present paper can also be applied for the proof of the global existence of small solutions to the system of derivative nonlinear Schrödinger equations

$$\begin{cases} i\partial_t v + \frac{1}{2}\Delta v = \partial_{x_1} \mathcal{N}(v,w), & (t,x) \in \mathbf{R} \times \mathbf{R}^2, \\ i\partial_t w + \frac{1}{2}\Delta w = \partial_{x_2} \mathcal{N}(v,w), & (t,x) \in \mathbf{R} \times \mathbf{R}^2, \\ v(0,x) = v_0(x), w(0,x) = w_0(x) & x \in \mathbf{R}^2, \end{cases}$$

where

$$\mathcal{N}(v,w) = \lambda_1 v^2 + \lambda_2 \overline{v}^2 + \lambda_3 w^2 + \lambda_4 \overline{w}^2 + \lambda_5 vw + \lambda_6 \overline{vw},$$

where $\lambda_j \in \mathbf{C}$, $j = 1, \dots, 6$. This system can be obtained from (1.1) via differentiating with respect to x_1 and x_2 and putting $v = \partial_{x_1} u$ and $w = \partial_{x_2} u$.

The rest of the paper we organize as follows. In section 2 we give some preliminary estimates in the analytic functional spaces $\mathbf{A}^{m,p}$. Section 3 is devoted to the proof of Theorem 1.1.

2. Preliminary estimates.

LEMMA 2.1. *Let* $\phi \in \mathbf{A}^{m,p}(t)$. *Then we have*

$$\|\phi\|_{\tilde{\mathbf{A}}^{m,p}(t)} \le e^{2b} \|\phi\|_{\mathbf{A}^{m,p}(t)}.$$

Proof. We have

$$\begin{aligned} \sum_{l=0}^{\infty} \frac{b^l}{l!} \left\| (\mathcal{P}+2)^l \phi \right\|_p &\le \sum_{l=0}^{\infty} \sum_{k=0}^{l} \frac{(2b)^k}{k!} \frac{b^{l-k}}{(l-k)!} \left\| \mathcal{P}^{l-k} \phi \right\|_p \\ &\le e^{2b} \sum_{l=0}^{\infty} \frac{b^l}{l!} \left\| \mathcal{P}^l \phi \right\|_p, \end{aligned}$$

whence the result of the lemma follows. □

Denote by $C_m^k = \frac{m!}{(m-k)!k!}$ the binomial coefficients.

LEMMA 2.2. *We have the following commutation relations:*

$$\left[\partial_{x_j}^l, \mathcal{J}_{x_j}\right] = l\partial_{x_j}^{l-1}, \quad \left[\mathcal{J}_j^l, \partial_{x_j}\right] = -l\mathcal{J}_{x_j}^{l-1},$$

$$\mathcal{P}^l \mathcal{J}_{x_j} = \sum_{0\le m\le l} C_l^m \mathcal{J}_{x_j} \mathcal{P}^{l-m}, \quad \mathcal{P}^l \partial_{x_j} = \sum_{0\le m\le l} C_m^l \left(-1\right)^m \partial_{x_j} \mathcal{P}^{l-m}, \tag{2.1}$$

$$\mathcal{J}_{x_j} \mathcal{P}^l = \sum_{0\le m\le l} C_l^m \left(-1\right)^m \mathcal{P}^{l-m} \mathcal{J}_{x_j}, \quad \partial_{x_j} \mathcal{P}^l = \sum_{0\le m\le l} C_l^m \mathcal{P}^{l-m} \partial_{x_j}, \tag{2.2}$$

$$\begin{aligned} \Omega_{x_j x_k}^l \partial_{x_j} = &\sum_{0\le 2m\le l} \left(-1\right)^m C_l^{2m} \partial_{x_j} \Omega_{x_j x_k}^{l-2m} \\ &+ \sum_{0\le 2m+1\le l} \left(-1\right)^{m+1} C_l^{2m+1} \partial_{x_k} \Omega_{x_j x_k}^{l-2m-1}, \end{aligned} \tag{2.3}$$

$$\begin{aligned} \partial_{x_j} \Omega_{x_j x_k}^l = &\sum_{0\le 2m\le l} \left(-1\right)^{m+1} C_l^{2m} \Omega_{x_j x_k}^{l-2m} \partial_{x_j} \\ &+ \sum_{0\le 2m+1\le l} \left(-1\right)^m C_l^{2m+1} \Omega_{x_j x_k}^{l-2m-1} \partial_{x_k}. \end{aligned} \tag{2.4}$$

Formulas (2.1) *and* (2.2) *also hold if we replace* $\mathcal{P}$ *by* $\mathcal{Q}$*, and formulas* (2.3) *and* (2.4) *are valid if we replace* ∂_{x_j} *by* $\mathcal{J}_{x_j}$*.*

For the proof, see [9, Lemma 2.6].

The following lemma is an analytic version of Lemma 2.2 from paper [6]. It will be used in many stages of the proof of the result.

LEMMA 2.3. *We have the estimate*

$$\left\|\mathcal{J}\nabla\phi\right\|_{\mathbf{A}^{m,p}(t)} \le C \sum_{|\alpha|=1} \left\|\Theta^\alpha \phi\right\|_{\mathbf{A}^{m,p}(t)}.$$

For the proof, see [9, Lemma 2.5].

The next lemma is obtained via the application of the commutation relations of Lemma 2.2. (See [9, Lemma 2.7].)

LEMMA 2.4. *The inequalities*

$$C_1 \left\|\partial_{x_j}\phi\right\|_{\mathbf{A}^{m,p}(t)} \le \sum_{|\beta|\le m} \sum_\alpha \frac{b^{|\alpha|}}{\alpha!} \left\|\partial_{x_j} \Gamma^{\alpha+\beta}\phi\right\|_p \le C_2 \left\|\partial_{x_j}\phi\right\|_{\mathbf{A}^{m,p}(t)}$$

and

$$\begin{aligned} C_1 \left\|\mathcal{J}_{x_j}\phi\right\|_{\mathbf{A}^{m,p}(t)} &\le \sum_{|\beta|\le m} \sum \frac{b^{|\alpha|}}{\alpha!} \left\|\mathcal{J}_{x_j} \Gamma^{\alpha+\beta}\phi\right\|_p + \left\|\phi\right\|_{\mathbf{A}^{m,p}(t)} \\ &\le C_2 \left(\left\|\mathcal{J}_{x_j}\phi\right\|_{\mathbf{A}^{m,p}(t)} + \left\|\phi\right\|_{\mathbf{A}^{m,p}(t)}\right) \end{aligned}$$

are true for all $t > 0$*, where* C_1*,* $C_2 > 0$*.*

To estimate the nonlinearity in the analytic functional spaces we use the following result. (See [9, Lemma 2.8] for the proof.)

LEMMA 2.5. *We have the estimate*

$$\|\phi\psi\|_{\widetilde{\mathbf{A}}^{0,p}(t)} \le C \|\phi\|_{\mathbf{A}^{0,q}(t)} \|\psi\|_{\mathbf{A}^{0,r}(t)}$$

for all $t > 0$, *where* $\frac{1}{p} = \frac{1}{q} + \frac{1}{r}$.

Let $1 \le q, r \le \infty$, $j, m \in \mathbf{N} \cup \{0\}$ *be such that* $0 \le j \le m$. *Then the Sobolev embedding inequality is true in the analytic functional spaces*

$$\sum_{|\alpha|=j} \|\partial^\alpha \phi\|_{\mathbf{A}^{0,p}(t)} \le C \sum_{|\beta|=m} \left\|\partial^\beta \phi\right\|^a_{\mathbf{A}^{0,r}(t)} \|\phi\|^{1-a}_{\mathbf{A}^{0,q}(t)}$$

for all $t > 0$, *where* $\frac{1}{p} = \frac{j}{2} + a\left(\frac{1}{r} - \frac{m}{2}\right) + \frac{1-a}{q}$ *and* a *is such that* $\frac{j}{m} \le a < 1$ *if* $m - j - \frac{2}{r} \in \mathbf{N} \cup \{0\}$, *and* $\frac{j}{m} \le a \le 1$ *otherwise.*

We define the evolution operator

$$\mathcal{V}(t)\varphi = \mathcal{F}^{-1} e^{\frac{i\xi^2}{2t}} \mathcal{F}\varphi = \frac{t}{2i\pi} \int e^{-i\frac{t}{2}(\xi - y)^2} \varphi(y)\, dy$$

and $\mathcal{K} = \mathcal{F}\mathcal{M}\mathcal{U}(-t)$. By a direct calculation we see that

$$\mathcal{V}(-t)\left(E^{\omega-1}\varphi\right) = \mathcal{D}_\omega E^{\omega(\omega-1)} \mathcal{V}(-\omega t)\varphi \tag{2.5}$$

with $\mathcal{D}_\omega \varphi = \frac{1}{\omega}\varphi\left(\frac{\xi}{\omega}\right)$ and $E = e^{it\xi^2/2}$, where $\omega \ne 0$. We need the following lemma to get the decay estimates of the solution for large time.

LEMMA 2.6. *The estimates*

$$\left\|\mathcal{D}_\omega E^{\omega(\omega-1)} (\mathcal{V}(-\omega t) - 1)(\mathcal{K}\phi)(\mathcal{K}\psi)\right\| + \left\|\mathcal{D}_\omega E^{\omega(\omega-1)} (\mathcal{K}\psi)(\mathcal{V}(-\omega t) - 1)(\mathcal{K}\phi)\right\| \le C t^{\eta - \frac{1}{2}} \sum_{|\alpha|\le 1, |\beta| \le 1} \|\mathcal{J}^\alpha \phi\| \left\|\mathcal{J}^\beta \psi\right\|$$

and

$$\left\|\mathcal{D}_\omega E^{\omega(\omega-1)} (\mathcal{V}(-\omega t) - 1)(\mathcal{K}\phi)(\mathcal{K}\psi)\right\|_\infty + \left\|\mathcal{D}_\omega E^{\omega(\omega-1)} (\mathcal{K}\psi)(\mathcal{V}(-\omega t) - 1)(\mathcal{K}\phi)\right\|_\infty \le C \left(\sum_{|\alpha|\le 1, |\beta|\le 1} \|\mathcal{J}^\alpha \phi\|^{1-\eta} \left\|\mathcal{J}^\beta \psi\right\|^{1-\eta}\right) \sum_{|\alpha|\le 2, |\beta|\le 2} \|\mathcal{J}^\alpha \phi\|^\eta \left\|\mathcal{J}^\beta \psi\right\|^\eta$$

are valid for all $t > 0$, *where* $\omega \ne 0$, $\eta > 0$ *is sufficiently small.*

Proof. Note that $\|\mathcal{K}\phi\|_{1,0} = \|\mathcal{U}(-t)\phi\|_{0,1} \le C \sum_{|\alpha|\le 1} \|\mathcal{J}^\alpha \phi\|$. By the Sobolev embedding theorem we obtain

$$\left\|\mathcal{D}_\omega E^{\omega(\omega-1)} (\mathcal{V}(-\omega t) - 1)\mathcal{K}\phi\mathcal{K}\psi\right\| = \left\|\left(e^{-\frac{i\xi^2}{2\omega t}} - 1\right)\mathcal{F}(\mathcal{K}\phi\mathcal{K}\psi)\right\|$$

$$\le C t^{\eta - \frac{1}{2}} \|\mathcal{F}(\mathcal{K}\phi\mathcal{K}\psi)\|_{0,1-2\eta} = C t^{\eta - \frac{1}{2}} \|\mathcal{K}\phi\mathcal{K}\psi\|_{1-2\eta,0} \le C t^{\eta - \frac{1}{2}} \|\mathcal{K}\phi\|_{1,0} \|\mathcal{K}\psi\|_{1,0}$$

and

$$\left\|\mathcal{D}_\omega E^{\omega(\omega-1)} \mathcal{K}\psi (\mathcal{V}(-\omega t) - 1)\mathcal{K}\phi\right\| \le C \|\mathcal{K}\psi\|_{2+\frac{2}{\eta}} \left\|\left(e^{-\frac{i\xi^2}{2\omega t}} - 1\right)\mathcal{F}\mathcal{K}\phi\right\|_{2+2\eta}$$

$$\le C t^{\eta - \frac{1}{2}} \|\mathcal{K}\psi\|_{1,0} \|\mathcal{F}\mathcal{K}\phi\|_{0,1} = C t^{\eta - \frac{1}{2}} \|\mathcal{K}\psi\|_{1,0} \|\mathcal{K}\phi\|_{1,0},$$

whence the first estimate of the lemma follows. To prove the second estimate we apply the Hölder inequality and the Sobolev embedding theorem:

$$\left\|\mathcal{D}_\omega E^{\omega(\omega-1)}\left(\mathcal{V}\left(-\omega t\right)-1\right)\mathcal{K}\phi\mathcal{K}\psi\right\|_\infty \le C\left\|\mathcal{F}\left(\mathcal{K}\phi\mathcal{K}\psi\right)\right\|_1$$
$$\le C\left\|\mathcal{K}\phi\mathcal{K}\psi\right\|_{2,0}^{\eta}\left\|\mathcal{K}\phi\mathcal{K}\psi\right\|_{1,0}^{1-\eta} \le C\left\|\mathcal{K}\phi\right\|_{2,0}^{\eta}\left\|\mathcal{K}\psi\right\|_{2,0}^{\eta}\left\|\mathcal{K}\phi\right\|_{1,0}^{1-\eta}\left\|\mathcal{K}\psi\right\|_{1,0}^{1-\eta}.$$

In the same manner we have

$$\left\|\mathcal{D}_\omega E^{\omega(\omega-1)}\mathcal{K}\psi\left(\mathcal{V}\left(-\omega t\right)-1\right)\mathcal{K}\phi\right\|_\infty \le C\left\|\mathcal{K}\phi\right\|_{2,0}^{\eta}\left\|\mathcal{K}\psi\right\|_{2,0}^{\eta}\left\|\mathcal{K}\phi\right\|_{1,0}^{1-\eta}\left\|\mathcal{K}\psi\right\|_{1,0}^{1-\eta}.$$

Thus we have the second estimate of the lemma. Lemma 2.6 is proved. □

3. Proof of Theorem 1.1. We prove Theorem 1.1 via the contraction mapping principle in the functional space $\mathbf{X}$. For any $v \in \mathbf{X}$ with sufficiently small norm $\|v\|_{\mathbf{X}}$, we consider the linearized version of (1.1),

$$\begin{cases} i\partial_t u + \frac{1}{2}\Delta u = \mathcal{N}(v), & (t,x) \in \mathbf{R}\times\mathbf{R}^2, \\ u\left(0,x\right) = u_0(x), & x \in \mathbf{R}^2, \end{cases} \tag{3.1}$$

where $\mathcal{N}(v) = \sum_{j,k=1}^{2}\left(\lambda_{jk}\left(\partial_{x_j}v\right)\left(\partial_{x_k}v\right) + \mu_{jk}\left(\partial_{x_j}\bar{v}\right)\left(\partial_{x_k}\bar{v}\right)\right)$, $\lambda_{jk},\mu_{jk} \in \mathbf{C}$. The linear Cauchy problem (3.1) defines a mapping $u = \mathcal{B}v$. We prove that $\mathcal{B}$ is a contraction mapping from a closed ball in $\mathbf{X}$ with a center at the origin and a radius $C\varepsilon$ into itself. Multiplying both sides of (3.1) by $\mathcal{K}\Gamma^{\alpha+\delta}$, where $\mathcal{K} = \mathcal{F}\mathcal{M}\mathcal{U}\left(-t\right)$, we get

$$\mathcal{L}\mathcal{K}\Gamma^{\alpha+\delta}u = \mathcal{K}\widetilde{\Gamma}^{\alpha+\delta}\mathcal{N} = \frac{1}{it}\sum_{\beta\le\alpha}\sum_{\gamma\le\delta}C_\alpha^\beta C_\delta^\gamma\sum_{j,k=1}^{2}\left(\lambda_{jk}E\left(\mathcal{K}\widetilde{\Gamma}^{\delta-\gamma}f\right)\mathcal{K}\Gamma^\gamma g\right.$$
$$\left.+\mu_{jk}\overline{E}^3\left(\overline{\mathcal{K}\widetilde{\Gamma}^{\delta-\gamma}f}\right)\overline{\mathcal{K}\Gamma^\gamma g}\right), \tag{3.2}$$

where $\mathcal{L} = i\partial_t + \frac{1}{2t^2}\Delta_\xi$, $f = \widetilde{\Gamma}^{\alpha-\beta}\partial_{x_j}v$, $g = \Gamma^\beta\partial_{x_k}v$, $C_\alpha^\beta = \frac{\alpha!}{(\alpha-\beta)!\beta!}$, $|\delta| \le 3$. Applying operator $\mathcal{V}\left(t\right)\varphi = \mathcal{F}^{-1}\mathcal{M}\left(t\right)\mathcal{F}\varphi$ to both sides of (3.2), we obtain by virtue of identity (2.5)

$$i\partial_t\mathcal{V}\left(-t\right)\mathcal{K}\Gamma^{\alpha+\delta}u\left(t\right)$$
$$= \frac{1}{it}\sum_{\gamma\le\delta}\sum_{\beta\le\alpha}C_\delta^\gamma C_\alpha^\beta\sum_{j,k=1}^{2}\mathcal{V}\left(-t\right)\left(\lambda_{jk}E\left(\mathcal{K}\widetilde{\Gamma}^{\delta-\gamma}f\right)\mathcal{K}\Gamma^\gamma g\right.$$
$$\left.+\mu_{jk}\overline{E}^3\left(\overline{\mathcal{K}\widetilde{\Gamma}^{\delta-\gamma}f}\right)\overline{\mathcal{K}\Gamma^\gamma g}\right)$$
$$= \frac{1}{it}\sum_{\gamma\le\delta}\sum_{\beta\le\alpha}C_\delta^\gamma C_\alpha^\beta\sum_{j,k=1}^{2}\left(\lambda_{jk}\mathcal{D}_2E^2\mathcal{V}\left(-2t\right)\left(\mathcal{K}\widetilde{\Gamma}^{\delta-\gamma}f\right)\mathcal{K}\Gamma^\gamma g\right.$$
$$\left.+\mu_{jk}\mathcal{D}_{-2}E^6\mathcal{V}\left(2t\right)\left(\overline{\mathcal{K}\widetilde{\Gamma}^{\delta-\gamma}f}\right)\overline{\mathcal{K}\Gamma^\gamma g}\right). \tag{3.3}$$

Then we write the identity

$$\mathcal{V}\left(-2t\right)\left(\mathcal{K}\widetilde{\Gamma}^{\delta-\gamma}f\right)\mathcal{K}\Gamma^\gamma g$$
$$= \left(\mathcal{V}\left(-2t\right)\mathcal{K}\widetilde{\Gamma}^{\delta-\gamma}f\right)\mathcal{V}\left(-2t\right)\mathcal{K}\Gamma^\gamma g - \left(\mathcal{K}\Gamma^\gamma g\right)\left(\mathcal{V}\left(-2t\right)-1\right)\left(\mathcal{K}\widetilde{\Gamma}^{\delta-\gamma}f\right)$$
$$-\left(\mathcal{V}\left(-2t\right)\mathcal{K}\widetilde{\Gamma}^{\delta-\gamma}f\right)\left(\mathcal{V}\left(-2t\right)-1\right)\mathcal{K}\Gamma^\gamma g + \left(\mathcal{V}\left(-2t\right)-1\right)\left(\mathcal{K}\widetilde{\Gamma}^{\delta-\gamma}f\right)\mathcal{K}\Gamma^\gamma g.$$

By Lemma 2.6 we have

$$\begin{aligned}&\left\|\mathcal{D}_2E^2\left(\mathcal{V}\left(-2t\right)-1\right)\left(\mathcal{K}\widetilde{\Gamma}^{\delta-\gamma}f\right)\mathcal{K}\Gamma^{\gamma}g\right\|\\&+\left\|\mathcal{D}_2E^2\left(\mathcal{K}\Gamma^{\gamma}g\right)\left(\mathcal{V}\left(-2t\right)-1\right)\mathcal{K}\widetilde{\Gamma}^{\delta-\gamma}f\right\|\\&\le C\left|t\right|^{\eta-\frac{1}{2}}\left(\sum_{|\sigma|\le1}\left\|\mathcal{J}^{\sigma}\widetilde{\Gamma}^{\delta-\gamma}f\right\|\right)\left(\sum_{|\sigma|\le1}\left\|\mathcal{J}^{\sigma}\Gamma^{\gamma}g\right\|\right).\end{aligned}\tag{3.4}$$

Thus we may rewrite (3.3) in the form

$$\begin{aligned}&i\partial_t\mathcal{V}\left(-t\right)\mathcal{K}\Gamma^{\alpha+\delta}u\left(t\right)\\&=\frac{1}{it}\sum_{\gamma\le\delta}\sum_{\beta\le\alpha}C_{\delta}^{\gamma}C_{\alpha}^{\beta}\sum_{j,k=1}^{2}\left(\lambda_{jk}\mathcal{D}_2E^2\left(\mathcal{V}\left(-t\right)\mathcal{K}\widetilde{\Gamma}^{\delta-\gamma}f\right)\mathcal{V}\left(-t\right)\mathcal{K}\Gamma^{\gamma}g\right.\\&\left.+\mu_{jk}\mathcal{D}_{-2}E^6\left(\overline{\mathcal{V}\left(-t\right)\mathcal{K}\widetilde{\Gamma}^{\delta-\gamma}f}\right)\overline{\mathcal{V}\left(-t\right)\mathcal{K}\Gamma^{\gamma}g}\right)+R_1\left(t\right),\end{aligned}\tag{3.5}$$

where the remainder term $R_1\left(t\right)$ can be estimated by virtue of (3.4) and Lemmas 2.1–2.4 as follows:

$$\begin{aligned}&\sum_{\alpha}\frac{b^{|\alpha|}}{\alpha!}\left\|R_1\left(t\right)\right\|\\&\le C\left|t\right|^{\eta-\frac{3}{2}}\sum_{\gamma\le\delta}\sum_{\alpha}\sum_{\beta\le\alpha}C_{\delta}^{\gamma}C_{\alpha}^{\beta}\frac{b^{\alpha}}{\alpha!}\left(\sum_{|\sigma|\le1}\left\|\mathcal{J}^{\sigma}\widetilde{\Gamma}^{\delta-\gamma}f\right\|\right)\sum_{|\sigma|\le1}\left\|\mathcal{J}^{\sigma}\Gamma^{\gamma}g\right\|\\&\le C\varepsilon\left|t\right|^{\eta-\frac{3}{2}}\sum_{|\sigma|\le1}\left\|\Theta^{\sigma}v\left(t\right)\right\|_{\mathbf{A}^3(t)}.\end{aligned}\tag{3.6}$$

Similarly, we have for $|\delta|\le1$

$$\begin{aligned}&\sum_{\alpha}\frac{b^{|\alpha|}}{\alpha!}\left\|R_1\left(t\right)\right\|_{\infty}\\&\le\frac{C}{t}\sum_{\alpha}\sum_{\beta\le\alpha}\sum_{\gamma\le\delta}C_{\delta}^{\gamma}C_{\alpha}^{\beta}\frac{b^{\alpha}}{\alpha!}\left(\sum_{|\sigma|\le2}\left\|\mathcal{J}^{\sigma}\widetilde{\Gamma}^{\delta-\gamma}f\right\|^{\eta}\right)\sum_{|\sigma|\le1}\left\|\mathcal{J}^{\sigma}\widetilde{\Gamma}^{\delta-\gamma}f\right\|^{1-\eta}\\&\times\left(\sum_{|\sigma|\le1}\left\|\mathcal{J}^{\sigma}\Gamma^{\gamma}g\right\|^{1-\eta}\right)\sum_{|\sigma|\le2}\left\|\mathcal{J}^{\sigma}\Gamma^{\gamma}g\right\|^{\eta}\le C\varepsilon^2\left|t\right|^{\eta-1}.\end{aligned}\tag{3.7}$$

Since $\mathcal{V}\left(-t\right)\mathcal{K}=\overline{\mathcal{F}^{-1}\mathcal{M}\mathcal{F}}\mathcal{F}\mathcal{M}\mathcal{U}\left(-t\right)=\mathcal{F}\mathcal{U}\left(-t\right)$, we have $i\xi_j\mathcal{V}\left(-t\right)\mathcal{K}=\mathcal{V}\left(-t\right)\mathcal{K}\partial_{x_j}$. Hence by (3.5) we get

$$\begin{aligned}&i\partial_t\mathcal{V}\left(-t\right)\mathcal{K}\Gamma^{\alpha+\delta}u\left(t\right)\\&=\frac{1}{t}\sum_{\gamma\le\delta}\sum_{\beta\le\alpha}C_{\delta}^{\gamma}C_{\alpha}^{\beta}\sum_{j,k=1}^{2}\left(\lambda_{jk}\mathcal{D}_2E^2\xi_j\left(\mathcal{V}\left(-t\right)\mathcal{K}\partial_{x_j}^{-1}\widetilde{\Gamma}^{\delta-\gamma}f\right)\mathcal{V}\left(-t\right)\mathcal{K}\Gamma^{\gamma}g\right.\\&\left.-\mu_{jk}\mathcal{D}_{-2}E^6\xi_j\left(\overline{\mathcal{V}\left(-t\right)\mathcal{K}\partial_{x_j}^{-1}\widetilde{\Gamma}^{\delta-\gamma}f}\right)\overline{\mathcal{V}\left(-t\right)\mathcal{K}\Gamma^{\gamma}g}\right)+R_1\left(t\right).\end{aligned}\tag{3.8}$$

If $|\delta-\gamma|<|\gamma|$ we exchange f and g in the right-hand side of (3.8). By virtue of the equality $E^\omega=\left(1+\frac{it}{2}\omega\xi^2\right)^{-1}\partial_t\left(tE^\omega\right)$ we obtain the identity

$$\frac{\phi}{t}E^\omega=\partial_t\left(\frac{\phi E^\omega}{1+\frac{it}{2}\omega\xi^2}\right)-\frac{E^\omega\partial_t\phi}{1+\frac{it}{2}\omega\xi^2}+\frac{1+it\omega\xi^2}{t\left(1+\frac{it}{2}\omega\xi^2\right)^2}\phi E^\omega.$$

Therefore, we get from (3.8)

$$i\partial_t\Psi=R_2, \tag{3.9}$$

where

$$\begin{aligned}\Psi&=\mathcal{V}\left(-t\right)\mathcal{K}\Gamma^{\alpha+\delta}u\left(t\right)\\&\quad+\sum_{\gamma\le\delta}\sum_{\beta\le\alpha}C_\delta^\gamma C_\alpha^\beta\sum_{j,k=1}^{2}\left(\lambda_{jk}\mathcal{D}_2\frac{\xi_jE^2}{1+it\xi^2}\left(\mathcal{V}\left(-t\right)\mathcal{K}\partial_{x_j}^{-1}\widetilde{\Gamma}^{\delta-\gamma}f\right)\mathcal{V}\left(-t\right)\mathcal{K}\Gamma^\gamma g\right.\\&\qquad\left.+\mu_{jk}\mathcal{D}_{-2}\frac{\xi_jE^6}{1+3it\xi^2}\left(\overline{\mathcal{V}\left(-t\right)\mathcal{K}\partial_{x_j}^{-1}\widetilde{\Gamma}^{\delta-\gamma}f}\right)\overline{\mathcal{V}\left(-t\right)\mathcal{K}\Gamma^\gamma g}\right),\end{aligned}$$

$R_2=R_1+\sum_{j=1}^3 I_j$, and

$$\begin{aligned}I_1&=\frac{1}{it}\sum_{\gamma\le\delta}\sum_{\beta\le\alpha}C_\delta^\gamma C_\alpha^\beta\sum_{j,k=1}^{2}\left(\lambda_{jk}\mathcal{D}_2\frac{\left(1+2it\xi^2\right)E^2}{\left(1+it\xi^2\right)^2}\xi_j\left(\mathcal{V}\left(-t\right)\mathcal{K}\partial_{x_j}^{-1}\widetilde{\Gamma}^{\delta-\gamma}f\right)\right.\\&\quad\left.\times\mathcal{V}\left(-t\right)\mathcal{K}\Gamma^\gamma g-\mu_{jk}\mathcal{D}_{-2}\frac{\left(1+6it\xi^2\right)E^6}{\left(1+3it\xi^2\right)^2}\xi_j\left(\overline{\mathcal{V}\left(-t\right)\mathcal{K}\partial_{x_j}^{-1}\widetilde{\Gamma}^{\delta-\gamma}f}\right)\overline{\mathcal{V}\left(-t\right)\mathcal{K}\Gamma^\gamma g}\right),\end{aligned}$$

$$\begin{aligned}I_2&=-\frac{1}{it}\sum_{\gamma\le\delta}\sum_{\beta\le\alpha}C_\delta^\gamma C_\alpha^\beta\sum_{j,k=1}^{2}\lambda_{jk}\mathcal{D}_2\frac{\xi_jE^2}{1+it\xi^2}\left(\left(\partial_t\mathcal{V}\left(-t\right)\mathcal{K}\partial_{x_j}^{-1}\widetilde{\Gamma}^{\delta-\gamma}f\right)\times\mathcal{V}\left(-t\right)\mathcal{K}\Gamma^\gamma g\right.\\&\qquad\left.+\left(\mathcal{V}\left(-t\right)\mathcal{K}\partial_{x_j}^{-1}\widetilde{\Gamma}^{\delta-\gamma}f\right)\partial_t\mathcal{V}\left(-t\right)\mathcal{K}\Gamma^\gamma g\right),\end{aligned}$$

and

$$\begin{aligned}I_3&=-\frac{1}{it}\sum_{\gamma\le\delta}\sum_{\beta\le\alpha}C_\delta^\gamma C_\alpha^\beta\sum_{j,k=1}^{2}\mu_{jk}\mathcal{D}_{-2}\frac{\xi_jE^6}{1+3it\xi^2}\left(\left(\overline{\partial_t\mathcal{V}\left(-t\right)\mathcal{K}\partial_{x_j}^{-1}\widetilde{\Gamma}^{\delta-\gamma}f}\right)\right.\\&\quad\left.\times\overline{\mathcal{V}\left(-t\right)\mathcal{K}\Gamma^\gamma g}+\left(\overline{\mathcal{V}\left(-t\right)\mathcal{K}\partial_{x_j}^{-1}\widetilde{\Gamma}^{\delta-\gamma}f}\right)\overline{\partial_t\mathcal{V}\left(-t\right)\mathcal{K}\Gamma^\gamma g}\right).\end{aligned}$$

By the Hölder's inequality, the identities $\mathcal{V}\left(-t\right)\mathcal{K}=\mathcal{F}\mathcal{U}\left(-t\right)$, $\mathcal{J}=\mathcal{U}\left(t\right)x\mathcal{U}\left(-t\right)$, and Lemmas 2.1–2.4 we get the estimates

$$\begin{aligned}&\sum_\alpha\frac{b^{|\alpha|}}{\alpha!}\left\|I_1\left(t\right)\right\|\\&\le C\left|t\right|^{-\frac{3}{2}}\sum_\alpha\sum_{\beta\le\alpha}C_\alpha^\beta\frac{b^{|\alpha|}}{\alpha!}\sum_{j,k=1}^{2}\left(\sum_{|\delta|\le3}\left\|\partial_{x_j}^{-1}\widetilde{\Gamma}^\delta f\right\|\right)\sum_{|\gamma|\le1}\left\|\mathcal{V}\left(-t\right)\mathcal{K}\Gamma^\gamma g\right\|_\infty\end{aligned}$$

$$
\begin{aligned}
&\le C\left|t\right|^{-\frac{3}{2}}\sum_{\alpha}\sum_{\beta\le\alpha}C_{\alpha}^{\beta}\frac{b^{|\alpha|}}{\alpha!}\left(\sum_{|\delta|\le3}\left\|\partial_{x_j}^{-1}\widetilde{\Gamma}^{\delta}f\right\|\right)\\
&\times\sum_{|\gamma|\le1}\left(\sum_{|\sigma|\le1}\left\|\mathcal{J}^{\sigma}\Gamma^{\gamma}g\right\|^{1-\eta}\right)\sum_{|\sigma|\le2}\left\|\mathcal{J}^{\sigma}\Gamma^{\gamma}g\right\|^{\eta} \qquad (3.10)\\
&\le C\varepsilon^{2}\left|t\right|^{2\eta-\frac{3}{2}}
\end{aligned}
$$

for $|\delta|\le3$. In the same way we obtain

$$
\begin{aligned}
&\sum_{\alpha}\frac{b^{|\alpha|}}{\alpha!}\left(\left\|I_2\left(t\right)\right\|+\left\|I_3\left(t\right)\right\|\right)\\
&\le C\left|t\right|^{-\frac{1}{2}}\sum_{\alpha}\sum_{\beta\le\alpha}\sum_{|\gamma|\le1}C_{\delta}^{\gamma}C_{\alpha}^{\beta}\frac{b^{|\alpha|}}{\alpha!}\sum_{j,k=1}^{2}\left(\left\|\partial_t\mathcal{V}\left(-t\right)\mathcal{K}\partial_{x_j}^{-1}\widetilde{\Gamma}^{\delta-\gamma}f\right\|\times\left\|\mathcal{V}\left(-t\right)\mathcal{K}\Gamma^{\gamma}g\right\|_{\infty}\right.\\
&\qquad\left.+\left\|\partial_t\mathcal{V}\left(-t\right)\mathcal{K}\Gamma^{\gamma}g\right\|_{\infty}\left\|\mathcal{V}\left(-t\right)\mathcal{K}\partial_{x_j}^{-1}\widetilde{\Gamma}^{\delta-\gamma}f\right\|\right)\\
&\le C\varepsilon\left|t\right|^{2\eta-\frac{1}{2}}\sum_{\alpha}\frac{b^{|\alpha|}}{\alpha!}\left(\sum_{|\delta|\le3}\left\|\partial_t\mathcal{V}\left(-t\right)\mathcal{K}\widetilde{\Gamma}^{\alpha+\delta}v\right\|\right.\\
&\qquad\left.+\sum_{|\gamma|\le1}\left\|\partial_t\mathcal{V}\left(-t\right)\mathcal{K}\Gamma^{\alpha+\gamma}\nabla v\right\|_{\infty}\right). \qquad (3.11)
\end{aligned}
$$

In view of (3.6), (3.10), and (3.11) we have the estimate

$$
\begin{aligned}
&\sum_{\alpha}\frac{b^{|\alpha|}}{\alpha!}\left\|R_2\left(t\right)\right\|\\
&\le C\varepsilon\left|t\right|^{\eta-\frac{3}{2}}\left\|v\right\|_{\mathbf{A}^4(t)}+C\varepsilon^{2}\left|t\right|^{2\eta-\frac{3}{2}}\\
&\quad+C\varepsilon\left|t\right|^{2\eta-\frac{1}{2}}\sum_{|\delta|\le3}\sum_{\alpha}\frac{b^{|\alpha|}}{\alpha!}\left\|\partial_t\mathcal{V}\left(-t\right)\mathcal{K}\Gamma^{\alpha+\delta}v\right\|\\
&\quad+C\varepsilon\left|t\right|^{2\eta-\frac{1}{2}}\sum_{|\gamma|\le1}\sum_{\alpha}\frac{b^{|\alpha|}}{\alpha!}\left\|\partial_t\mathcal{V}\left(-t\right)\mathcal{K}\Gamma^{\alpha+\gamma}\nabla v\right\|_{\infty}. \qquad (3.12)
\end{aligned}
$$

Multiplying both sides of (3.9) by $\overline{\Psi\left(t\right)}$, integrating with respect to the space variables and taking the imaginary part of the result, we obtain the inequality $\frac{d}{dt}\left\|\Psi\left(t\right)\right\|\le\left\|R_2\left(t\right)\right\|$, whence

$$
\frac{d}{dt}\sum_{\alpha}\frac{b^{|\alpha|}}{\alpha!}\left\|\Psi\left(t\right)\right\|-b'\sum_{\alpha}\sum_{|\delta|=1}\frac{b^{|\alpha-\delta|}}{(\alpha-\delta)!}\left\|\Psi\left(t\right)\right\|\le\sum_{\alpha}\frac{b^{|\alpha|}}{\alpha!}\left\|R_2\left(t\right)\right\|.
$$

Then integration with respect to t in view of (3.12) yields

$$\begin{aligned}
&\|u(t)\|_{\mathbf{A}^3(t)} + C\sum_{|\sigma|=1}\int_1^t \|\Gamma^\sigma u(\tau)\|_{\mathbf{A}^3(\tau)}\,|b'|\,d\tau \\
&\le C\varepsilon + C\varepsilon^2 + \frac{C}{\sqrt{t}}\,\|v(t)\|^{2-\eta}_{\mathbf{A}^3(t)} \sum_{|\gamma|\le 1}\|\mathcal{J}^\gamma v\|^\eta_{\mathbf{A}^2(t)} \\
&\quad + C\int_1^t \|v(\tau)\|^{1-\eta}_{\mathbf{A}^3(\tau)}\,\|v(\tau)\|^{1-\eta}_{\mathbf{A}^4(\tau)} \left(\|v(\tau)\|^\eta_{\mathbf{A}^3(\tau)} \sum_{|\gamma|\le 1}\|\mathcal{J}^\gamma v\|^\eta_{\mathbf{A}^2(\tau)} \right. \\
&\qquad\qquad \left. + \|v(\tau)\|^\eta_{\mathbf{A}^4(\tau)} \sum_{|\gamma|\le 1}\|\mathcal{J}^\gamma v\|^\eta_{\mathbf{A}^3(\tau)} \right) \frac{|b'|\,d\tau}{\sqrt{\tau}} \\
&\le C\varepsilon + C\varepsilon^2, \qquad (3.13)
\end{aligned}$$

where we used the estimate

$$\|u(t)\|_{\mathbf{A}^3(t)} + C\sum_{|\alpha|=1}\int_0^t \|\Gamma^\sigma u(t)\|_{\mathbf{A}^3(t)}\,|b'|\,dt \le C\varepsilon + C\varepsilon^2$$

for $t \le 1$, which follows from the classical energy method. Applying the operator $\mathcal{J}_{x_l}$ to both sides of (3.1), we get

$$\begin{aligned}
&\left(i\partial_t + \frac{1}{2}\Delta\right)\mathcal{J}_{x_l}\Gamma^{\alpha+\delta}u \\
&= \sum_{\gamma\le\delta}\sum_{\beta\le\alpha} C^\gamma_\delta C^\beta_\alpha \sum_{j,k=1}^2 \left(\lambda_{jk}\left(\widetilde{\Gamma}^{\delta-\gamma}f\right)\mathcal{J}_{x_l}\Gamma^\gamma g + it\lambda_{jk}\left(\partial_{x_l}\widetilde{\Gamma}^{\delta-\gamma}f\right)\Gamma^\gamma g \right. \\
&\qquad \left. + \mu_{jk}\overline{\left(\widetilde{\Gamma}^{\delta-\gamma}f\right)\mathcal{J}_{x_l}\Gamma^\gamma g} - it\mu_{jk}\overline{\left(\partial_{x_l}\widetilde{\Gamma}^{\delta-\gamma}f\right)\Gamma^\gamma g}\right);
\end{aligned}$$

hence by the classical energy method and via inequality $\left\|\left(\partial_{x_j}\phi\right)\left(\partial_{x_k}\psi\right)\right\| \le \frac{C}{t}\,\|\Theta\phi\|\,\|\Theta\psi\|$, we obtain

$$\begin{aligned}
&\sum_\alpha \frac{b^{|\alpha|}}{\alpha!}\frac{d}{dt}\left\|\mathcal{J}_{x_l}\Gamma^{\alpha+\delta}u(t)\right\| \\
&\le C\left(\|v\|_{\mathbf{A}^3(t)} + \sum_{|\sigma|\le 1}\|\Theta^\sigma v\|_{\mathbf{A}^2(t)}\right)\sum_{|\gamma|\le 1}\|\Theta^\gamma v\|_{\mathbf{A}^2(t)} \le C\varepsilon^2
\end{aligned}$$

for $|\delta| \le 2$. Multiplying both sides of the last inequality by $t^{-1-\eta}$ and integrating with respect to t, we have

$$\begin{aligned}
&t^{-1-\eta}\sum_{|\gamma|=1}\|\mathcal{J}^\gamma u(t)\|_{\mathbf{A}^2(t)} + C\sum_{|\gamma|=1,|\sigma|=1}\int_1^t \|\Gamma^\sigma\mathcal{J}^\gamma u(t)\|_{\mathbf{A}^2(t)}\,\frac{|b'|\,dt}{t^{1+\eta}} \\
&\qquad\qquad \le C\varepsilon + C\varepsilon^2, \qquad (3.14)
\end{aligned}$$

where we used the estimate

$$\sum_{|\gamma|=1}\|\mathcal{J}^\gamma u(t)\|_{\mathbf{A}^2(t)} + C\sum_{|\gamma|=|\delta|=1}\int_0^t \left\|\Gamma^\delta\mathcal{J}^\gamma u(t)\right\|_{\mathbf{A}^2(t)}\,|b'|\,dt \le C\varepsilon + C\varepsilon^2$$

for $t \le 1$. By the identity $\mathcal{P}u = \mathcal{Q}u + 2it\mathcal{N}(v)$ we see that

$$\|\mathcal{Q}u\|_{\mathbf{A}^m(t)} \le \|\mathcal{P}u\|_{\mathbf{A}^m(t)} + C\|\mathcal{Q}v\|_{\mathbf{A}^m(t)}\|\mathcal{Q}v\|_{\mathbf{A}^m(t)} \le \|\mathcal{P}u\|_{\mathbf{A}^m(t)} + C\varepsilon^2,$$

where $m \ge 2$. Therefore, by virtue of (3.13) and (3.14) we get

$$\begin{aligned}
&\|u(t)\|_{\mathbf{A}^3(t)} + t^{-1-\eta}\sum_{|\gamma|=1}\|\mathcal{J}^\gamma u(t)\|_{\mathbf{A}^2(t)} \\
&+C\sum_{|\sigma|=1}\int_1^t \|\Theta^\sigma u(t)\|_{\mathbf{A}^3(t)}|b'|\,dt \\
&+C\sum_{|\sigma|=1,|\gamma|\le 1}\int_1^t \|\Theta^\sigma \mathcal{J}^\gamma u(t)\|_{\mathbf{A}^2(t)}\frac{|b'|\,dt}{t^{1+\eta}} \\
&\le C\varepsilon + C\varepsilon^2. \qquad (3.15)
\end{aligned}$$

By (3.3) via Lemma 2.6 we have

$$\sum_{|\sigma|\le 1}\sum_\alpha \frac{b^{|\alpha|}}{\alpha!}\left\|\partial_t\mathcal{V}(-t)\mathcal{K}\Gamma^{\alpha+\sigma}\nabla u(t)\right\|_\infty \le C\varepsilon^2 t^{2\eta-1}$$

and

$$\sum_{|\delta|\le 3}\sum_\alpha \int_1^\infty \frac{b^{|\alpha|}}{\alpha!}\left\|\partial_t\mathcal{V}(-t)\mathcal{K}\Gamma^{\alpha+\delta}u(t)\right\|\frac{dt}{t^{\frac{1}{2}-2\eta}} \le C\varepsilon\int_1^\infty t^{3\eta-\frac{3}{2}}\|v(t)\|_{\mathbf{A}^3(t)}\,dt \le C\varepsilon^2.$$

We also have by a classical energy method

$$\sum_{|\sigma|\le 1}\sum_\alpha \frac{b^{|\alpha|}}{\alpha!}\left\|\partial_t\mathcal{V}(-t)\mathcal{K}\Gamma^{\alpha+\sigma}\nabla u(t)\right\|_\infty \le C\varepsilon^2$$

and

$$\sum_{|\delta|\le 3}\sum_\alpha \int_0^t \frac{b^{|\alpha|}}{\alpha!}\left\|\partial_t\mathcal{V}(-t)\mathcal{K}\Gamma^{\alpha+\delta}u(t)\right\|dt \le C\varepsilon^2$$

for $t \le 1$. In the same way as in the proof of (3.15) we find that $\|\mathcal{B}v_1 - \mathcal{B}v_2\|_{\mathbf{X}} \le \frac{1}{2}\|v_1 - v_2\|_{\mathbf{X}}$. Therefore, (3.15) implies that $\mathcal{B}$ is a contraction mapping from $\mathbf{X}$ into itself. Hence there exists a unique solution u of the Cauchy problem (1.1) such that $u \in \mathbf{X}$. In particular we have $u \in \mathbf{A}^3(t)$. Next we show the existence of the usual scattering states. From (3.9) with $\alpha = 0$, $\delta = 0$ we have

$$\begin{aligned}
i\partial_t\mathcal{V}(-t)\mathcal{K}u(t) - \partial_t\sum_{\beta\le\alpha}C_\alpha^\beta\sum_{j,k=1}^2\Bigg(&\lambda_{jk}\mathcal{D}_2\frac{\xi_j E^2}{1+it\xi^2}\left(\mathcal{V}(-t)\mathcal{K}u\right)\mathcal{V}(-t)\mathcal{K}\partial_{x_k}u \\
&+\mu_{jk}\mathcal{D}_{-2}\frac{\xi_j E^6}{1+3it\xi^2}\left(\overline{\mathcal{V}(-t)\mathcal{K}u}\right)\overline{\mathcal{V}(-t)\mathcal{K}\partial_{x_k}u}\Bigg) \\
&= R_3(t),
\end{aligned}$$

where $\|R_3(t)\| \le C\varepsilon^2|t|^{4\eta-\frac{3}{2}}$. Integrating this equation with respect to t, we obtain

$$\|\mathcal{V}(-t)\mathcal{K}u(t) - \mathcal{V}(-s)\mathcal{K}u(s)\| \le C\varepsilon^2|s|^{4\eta-\frac{1}{2}} \qquad (3.16)$$

for $t > s > 0$. Here we used the estimate

$$\begin{aligned}&\left\|\mathcal{D}_2 \frac{\xi_j E^2}{1+it\xi^2}\left(\mathcal{V}(-t)\mathcal{K}u\right)\mathcal{V}(-t)\mathcal{K}\partial_{x_k}u\right\| \\ &+\left\|\mathcal{D}_{-2}\frac{\xi_j E^6}{1+3it\xi^2}\left(\overline{\mathcal{V}(-t)\mathcal{K}u}\right)\overline{\mathcal{V}(-t)\mathcal{K}\partial_{x_k}u}\right\| \\ &\le C|t|^{-\frac{1}{2}}\|u\|\sum_{|\sigma|\le 1}\|\Theta^\sigma u\|^{1-\eta}\sum_{|\sigma|\le 1,|\gamma|\le 1}\|\mathcal{J}^\gamma\Theta^\sigma u\|^\eta \le C\varepsilon^2|s|^{4\eta-\frac{1}{2}}.\end{aligned}$$

Since $\mathcal{V}(-t)\mathcal{K} = \mathcal{F}\mathcal{U}(-t)$, from the inequality (3.16) we find that there exists a unique final state $u_+ \in \mathbf{L}^2$ such that $\|u(t) - \mathcal{U}(t)u_+\| \le C\varepsilon^2|t|^{\eta-\frac{1}{2}}$. This completes the proof of Theorem 1.1.

Acknowledgment. The authors would like to thank the referee for useful suggestions.
