SCALING VARIABLES AND STABILITY OF HYPERBOLIC FRONTS*

THIERRY GALLAY† AND GENEVIÈVE RAUGEL†

Abstract. We consider the damped hyperbolic equation

$$\varepsilon u_{tt} + u_t = u_{xx} + \mathcal{F}(u) , \quad x \in \mathbf{R} , \quad t \geq 0 , \tag{1}$$

where ε is a positive, not necessarily small parameter. We assume that $\mathcal{F}(0) = \mathcal{F}(1) = 0$ and that $\mathcal{F}$ is concave on the interval $[0, 1]$. Under these hypotheses, (1) has a family of monotone traveling wave solutions (or propagating fronts) connecting the equilibria $u = 0$ and $u = 1$. This family is indexed by a parameter $c \geq c_*$ related to the speed of the front. In the critical case $c = c_*$, we prove that the traveling wave is asymptotically stable with respect to perturbations in a weighted Sobolev space. In addition, we show that the perturbations decay to zero like $t^{-3/2}$ as $t \to +\infty$ and approach a universal self-similar profile, which is independent of ε, F, and the initial data. In particular, our solutions behave for large times like those of the parabolic equation obtained by setting $\varepsilon = 0$ in (1). The proof of our results relies on various energy estimates for (1) rewritten in self-similar variables $x/\sqrt{t}$, $\log t$.

Key words. damped wave equation, traveling wave, stability, asymptotic behavior, self-similar variables

1. Introduction.

In this paper, we study the asymptotic stability of traveling wave solutions to nonlinear damped hyperbolic equations on the real line. Besides describing the propagation of voltage along nonlinear transmission lines, these equations have been proposed as mathematical models for spreading and interacting particles [DO, Ha2, Ha3]. In the latter context, they provide an alternative to the reaction-diffusion systems which are very common in chemistry and biology, especially in genetics and population dynamics [Mu]. The two classes of models differ by the choice of the stochastic process describing the spatial spread of the individuals: instead of Brownian motion, the damped hyperbolic equations are based on a more realistic velocity jump process which takes into account the inertia of the particles [Go, Kac, Za]. Since this process is asymptotically diffusive, the long-time behavior of the solutions is expected to be essentially parabolic [GR2].

We study here the simple case of a scalar equation with a "monostable" nonlinearity. To be specific, we consider the equation

$$\varepsilon U_{TT} + U_T = U_{XX} + \mathcal{F}(U) , \tag{1.1}$$

where $X \in \mathbf{R}$, $T \geq 0$, and ε is a positive, *not necessarily small* parameter. We assume that the nonlinearity $\mathcal{F} \in \mathcal{C}^2(\mathbf{R})$ satisfies

$$\mathcal{F}(0) = \mathcal{F}(1) = 0 , \quad \mathcal{F}'(0) > 0 , \quad \mathcal{F}'(1) < 0 , \quad \mathcal{F}''(U) \leq 0 \ \text{ for } \ U \in [0, 1] . \tag{1.2}$$

In particular, $U = 1$ is a stable equilibrium of (1.1), and $U = 0$ is unstable. A typical nonlinearity satisfying (1.2) is $\mathcal{F}(U) = U - U^m$, with $m \in \mathbf{N}$, $m \geq 2$.

Under the assumptions in (1.2), equation (1.1) has monotone traveling wave solutions (or propagating fronts) connecting the equilibrium states $U = 1$ and $U = 0$ [Ha1, GR1]. Indeed, choosing $c > 0$ and setting $U(X,T) = h(\sqrt{1+\varepsilon c^2}X - cT)$, we obtain for h the ordinary differential equation

$$h''(\xi) + ch'(\xi) + \mathcal{F}(h(\xi)) \,=\, 0 \;, \quad \xi \in \mathbf{R} \;. \tag{1.3}$$

Equation (1.3) is known to have a strictly decreasing solution satisfying $h(-\infty) = 1$ and $h(+\infty) = 0$ if and only if $c \geq c_* = 2\sqrt{\mathcal{F}'(0)}$ [KPP, AW]. This solution is unique up to translations in the variable ξ. Thus, (1.1) has a family of monotone traveling waves indexed by the speed parameter $c \geq c_*$. Note that the actual speed of the wave is not c but $c/\sqrt{1+\varepsilon c^2}$, a quantity which is bounded by $1/\sqrt{\varepsilon}$ for all $c \geq c_*$.

In an earlier paper [GR1], we investigated the stability of the traveling waves of (1.1) in the case where $\mathcal{F}(U) = U - U^2$. In particular, we showed that for all $\varepsilon > 0$ and all $c \geq c_*$, the front h is asymptotically stable with respect to small perturbations in a weighted Sobolev space (with exponential weight). This local stability result holds, in fact, for all nonlinearities satisfying (1.2); see [GR3]. In addition, if $\varepsilon > 0$ is sufficiently small, we proved in [GR1] that the front h is stable with respect to large perturbations, provided some positivity conditions are fulfilled. This global stability property relies on the hyperbolic maximum principle and can also be extended to more general nonlinearities [GR3]. Finally, we showed in all cases that the perturbations converge uniformly to zero faster than $T^{-1/4}$ as $T \to +\infty$.

When $\varepsilon \to 0$, (1.1) reduces to the semilinear parabolic equation $U_T = U_{XX} + \mathcal{F}(U)$, which has been intensively studied since the pioneering works of Fisher [Fi] and Kolmogorov, Petrovskii, and Piskunov [KPP]. In particular, the parabolic maximum principle and probabilistic techniques have been used to show the convergence of a large class of solutions to traveling waves [AW, Br]. In the more general context of parabolic systems, a local stability analysis of the waves has been initiated by Sattinger [Sa] and extended by many authors [Ki, EW, Kap, BK1, RK], using resolvent estimates, energy functionals, and renormalization techniques. Finally, in the critical case $c = c_*$, it has been proved by one of us [Ga] that the perturbations of the front decay to zero like $T^{-3/2}$ as $T \to +\infty$ and approach a universal self-similar profile. The aim of the present paper is precisely to extend this detailed convergence result to the hyperbolic case $\varepsilon > 0$. Together with earlier results from [GR1, GR3], this will provide a fairly complete picture of the stability properties of the traveling waves of (1.1).

To study the stability of the critical front h with $c = c_*$, it is convenient to go to a moving frame using the change of variables $U(X,T) = V(\sqrt{1+\varepsilon c_*^2}X - c_*T, T)$. The equation for V is

$$\varepsilon V_{TT} + V_T - 2\varepsilon c_* V_{\xi T} \,=\, V_{\xi\xi} + c_* V_\xi + \mathcal{F}(V) \;, \tag{1.4}$$

where $\xi = \sqrt{1+\varepsilon c_*^2}X - c_*T$. By construction, h is a stationary solution of (1.4). Following [Ki, Ga], we consider perturbed solutions of the form

$$V(\xi,T) \,=\, h(\xi) + w(\xi,T) \,\equiv\, h(\xi) + h'(\xi) W\left(\xi, \frac{T}{1+\varepsilon c_*^2}\right) \;. \tag{1.5}$$

The equation satisfied by the perturbation w is

$$\varepsilon w_{TT} + w_T - 2\varepsilon c_* w_{\xi T} \,=\, w_{\xi\xi} + c_* w_\xi + \mathcal{F}'(h) w + \mathcal{N}(h,w) w^2 \;, \tag{1.6}$$

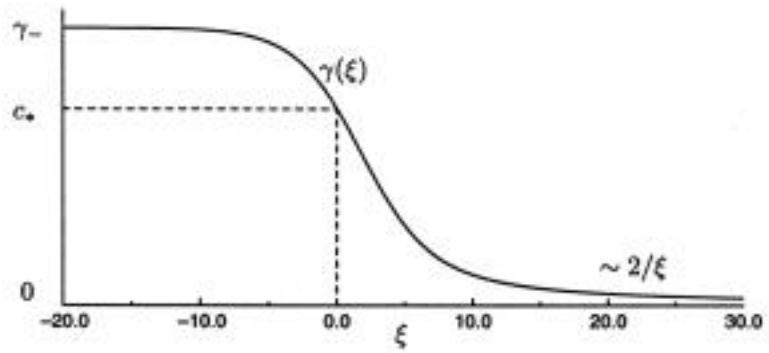

FIG. 1. *The function $\gamma(\xi)$ in the case where $\mathcal{F}(U) = U - U^2$ (hence $c_* = 2$, $\gamma_- = 2\sqrt{2}$).*

where

$$\mathcal{N}(a,b) \,=\, \int_0^1 (1-s)\mathcal{F}''(a+sb)\,\mathrm{d}s \,=\, \frac{1}{b^2}\big(\mathcal{F}(a+b) - \mathcal{F}(a) - b\mathcal{F}'(a)\big)\ . \tag{1.7}$$

The Ansatz $w(\xi,T) = h'(\xi)W(\xi,\tau)$, where $\tau = T/(1+\varepsilon c_*^2)$, is motivated by the fact that $W(\xi,\tau)$ becomes asymptotically self-similar as $T \to +\infty$, while the actual perturbation $w(\xi,T)$ does not; see Corollary 1.3 below. We remark that this definition makes sense, since $h'(\xi) < 0$ for all $\xi \in \mathbf{R}$. The equation for W reads

$$\eta W_{\tau\tau} + (1-\nu\gamma(\xi))W_\tau - 2\nu W_{\xi\tau} \,=\, W_{\xi\xi} + \gamma(\xi)W_\xi + h'(\xi)W^2\mathcal{N}(h(\xi),h'(\xi)W)\ , \tag{1.8}$$

where

$$\eta \,=\, \frac{\varepsilon}{(1+\varepsilon c_*^2)^2}\ , \quad \nu \,=\, \frac{\varepsilon c_*}{1+\varepsilon c_*^2}\ , \quad \gamma(\xi) \,=\, c_* + 2\frac{h''(\xi)}{h'(\xi)}\ . \tag{1.9}$$

Before analyzing the solutions of (1.8), we briefly comment on the definitions (1.9). We first remark that there is no loss of generality in assuming $\varepsilon = 1$ in (1.1), since $(\varepsilon,\mathcal{F})$ can be transformed into $(1,\varepsilon\mathcal{F})$ by rescaling X and T. However, we find it more convenient to fix the nonlinearity $\mathcal{F}$ and to consider ε as a free parameter. Then $c_* > 0$ is fixed, and η,ν are functions of ε only. These expressions are not independent, since $\nu^2 + \eta = \nu/c_*$. Observe also that η,ν are uniformly bounded for all $\varepsilon > 0$, and converge to zero as $\varepsilon \to 0$. We now list the properties of the "drift" $\gamma(\xi)$ which will be crucial for our analysis. From [Sa, AW], we know that the front h (with $c = c_*$) satisfies

$$h(\xi) \,=\, \begin{cases} 1 - a_3\mathrm{e}^{\kappa\xi} + \mathcal{O}(\mathrm{e}^{2\kappa\xi}) & \text{as } \xi \to -\infty\ , \\ (a_1\xi + a_2)\mathrm{e}^{-c_*\xi/2} + \mathcal{O}(\xi^2\mathrm{e}^{-c_*\xi}) & \text{as } \xi \to +\infty\ , \end{cases} \tag{1.10}$$

where $a_1, a_3 > 0$, $a_2 \in \mathbf{R}$, and $\kappa = \frac{1}{2}(-c_* + \sqrt{c_*^2 - 4\mathcal{F}'(1)}) > 0$. Using (1.10) and similar asymptotic expansions for the derivatives h', h'', we obtain

$$\gamma(\xi) \,=\, \begin{cases} \gamma_- + \mathcal{O}(\mathrm{e}^{\kappa\xi}) & \text{as } \xi \to -\infty\ , \\ 2/(\xi+\xi_0) + \mathcal{O}(\xi\mathrm{e}^{-c_*\xi/2}) & \text{as } \xi \to +\infty\ , \end{cases} \tag{1.11}$$

where $\gamma_- = c_* + 2\kappa = 2\sqrt{\mathcal{F}'(0) - \mathcal{F}'(1)}$ and $\xi_0 = (a_2/a_1 - 2/c_*)$. It also follows from (1.3), (1.9) that

$$\gamma'(\xi) \,=\, -\frac{1}{2}\gamma(\xi)^2 + 2\big(\mathcal{F}'(0) - \mathcal{F}'(h(\xi))\big)\ , \quad \xi \in \mathbf{R}\ . \tag{1.12}$$

Together with (1.2), this equation implies that $-\frac{1}{2}\gamma(\xi)^2 \le \gamma'(\xi) \le 0$ for all $\xi \in \mathbf{R}$. Indeed, the lower bound on $\gamma'(\xi)$ is obvious, and the upper bound follows from the inequality $\gamma''(\xi) + \gamma(\xi)\gamma'(\xi) \le 0$ obtained by differentiating (1.12). In fact, we even have $\gamma'(\xi) < 0$ whenever $\gamma(\xi) < \gamma_-$. Replacing $h(\xi)$ by a translate, we may (and will always) assume that $\gamma(0) = c_*$, i.e., $h''(0) = 0$; see Figure 1. This amounts to fixing the origin in the moving frame.

To study the behavior of the solutions W of (1.8), we use the *scaling variables* or *self-similar variables* defined by

$$x = \frac{\xi}{\sqrt{\tau+\tau_0}}\ , \quad t = \log(\tau+\tau_0)\ , \tag{1.13}$$

where $\tau_0 \ge 1$ will be fixed later. These variables have been widely used to investigate the long-time behavior of solutions to parabolic equations, in particular, to prove convergence to self-similar solutions [Kav, EZ, GV, EKM, BK2, Wa, GM]. Although the scaling (1.13) is parabolic in essence, we have shown in [GR2] that self-similar variables are also a powerful tool in the realm of damped hyperbolic equations. The reason is that the long-time behavior of such systems is often determined by simpler parabolic equations; see [HL, Ni, GR2] for specific examples of this phenomenon. In our case, the result of [Ga] in the parabolic limit $\varepsilon = 0$ suggests that $W(\xi,\tau)$ should behave like $\tau^{-3/2}\varphi^*(\xi/\sqrt{\tau})$ as $\tau \to +\infty$, where φ^* is given by (1.21) below. Thus, following the method developed in [GR2], we define rescaled functions u and v by

$$u(x,t) = \mathrm{e}^{3t/2}W(x\mathrm{e}^{t/2}, \mathrm{e}^t - \tau_0)\ , \quad v(x,t) = \mathrm{e}^{5t/2}W_\tau(x\mathrm{e}^{t/2}, \mathrm{e}^t - \tau_0)\ , \tag{1.14}$$

or equivalently

$$\begin{aligned} W(\xi,\tau) &= \frac{1}{(\tau+\tau_0)^{3/2}}\, u\left(\frac{\xi}{\sqrt{\tau+\tau_0}}\,, \log(\tau+\tau_0)\right)\ , \\ W_\tau(\xi,\tau) &= \frac{1}{(\tau+\tau_0)^{5/2}}\, v\left(\frac{\xi}{\sqrt{\tau+\tau_0}}\,, \log(\tau+\tau_0)\right)\ . \end{aligned} \tag{1.15}$$

Then the functions $u(x,t), v(x,t)$ satisfy the system

$$\begin{aligned} &u_t - \frac{x}{2}u_x - \frac{3}{2}u = v\ , \\ &\eta\mathrm{e}^{-t}\left(v_t - \frac{x}{2}v_x - \frac{5}{2}v\right) + (1 - \nu\gamma(x\mathrm{e}^{t/2}))v - 2\nu\mathrm{e}^{-t/2}v_x \\ &= u_{xx} + \mathrm{e}^{t/2}\gamma(x\mathrm{e}^{t/2})u_x + \mathrm{e}^{-t/2}h'(x\mathrm{e}^{t/2})u(x,t)^2N(x,t)\ , \end{aligned} \tag{1.16}$$

where $x \in \mathbf{R}$, $t \ge t_0 = \log\tau_0$, and $N(x,t) = \mathcal{N}(h(x\mathrm{e}^{t/2}), \mathrm{e}^{-3t/2}h'(x\mathrm{e}^{t/2})u(x,t))$.

We next introduce the function spaces in which we shall study the solutions of (1.16). For $t \ge 0$, $k \in \mathbf{N}$, we denote by L^2_t, H^k_t the weighted Lebesgue and Sobolev spaces defined by the norms

$$\begin{aligned} \|u\|^2_{\mathrm{L}^2_t} &= \int_{-\infty}^0 \mathrm{e}^{2\kappa x\mathrm{e}^{t/2}}u(x)^2\,\mathrm{d}x + \int_0^\infty (1+x)^6u(x)^2\,\mathrm{d}x\ , \\ \|u\|^2_{\mathrm{H}^k_t} &= \sum_{i=0}^k \|\partial_x^i u\|^2_{\mathrm{L}^2_t}\ , \end{aligned} \tag{1.17}$$

where κ appears in (1.10). Our basic space will be the product $\mathrm{Z}_t = \mathrm{H}^1_t \times \mathrm{L}^2_t$ equipped with the standard norm $\|(u,v)\|_{\mathrm{Z}_t} = (\|u\|^2_{\mathrm{H}^1_t} + \|v\|^2_{\mathrm{L}^2_t})^{1/2}$. In order to state results which are uniform in ε as $\varepsilon \to 0$, it is convenient to introduce also the quadratic form

$$\Phi_\eta(t,u,v) \,=\, \|u\|^2_{\mathrm{H}^1_t} + \eta \mathrm{e}^{-t} \|v\|^2_{\mathrm{L}^2_t} \,. \tag{1.18}$$

From (1.14), (1.15), we see that $(u,v) \in \mathrm{Z}_t$ if and only if $(W, W_\tau) \in \mathrm{Z}_0 = \mathrm{H}^1_0 \times \mathrm{L}^2_0$. Moreover, since $h', h'' = \mathcal{O}(\mathrm{e}^{\kappa\xi})$ as $\xi \to -\infty$ and $h', h'' = \mathcal{O}(\xi \mathrm{e}^{-c_*\xi/2})$ as $\xi \to +\infty$, it is easy to verify that $(W, W_\tau) \in \mathrm{Z}_0$ if and only if the actual perturbation $w = h'W$ satisfies $(w, w_T) \in Y = Y^1 \times Y^0$, where the spaces Y^0, Y^1 are defined by the norms

$$\|w\|^2_{Y^0} \,=\, \int_{-\infty}^0 w^2 \,\mathrm{d}\xi + \int_0^\infty (1+\xi)^4 \mathrm{e}^{c_*\xi} w^2 \,\mathrm{d}\xi \,, \quad \|w\|^2_{Y^1} \,=\, \|w\|^2_{Y^0} + \|w_\xi\|^2_{Y^0} \,. \tag{1.19}$$

The comparison of (1.10), (1.19) reveals that the perturbations we consider decay to zero slightly faster than the front h itself as $\xi \to +\infty$. This is a necessary condition for stability, because the equilibrium state $U = 0$ of (1.1) is linearly unstable [Sa]. In particular, small translations of the front h are *not* allowed as perturbations.

Since our function space Z_t depends on time, we have to specify what we mean by a "solution of (1.16) in Z_t." As the system (1.16) has been obtained from the simpler equation (1.8) through the change of variables (1.14), the following definition is very natural.

Definition 1.1. *Let $t_2 > t_1 \geq t_0$, and let $\tau_i = \mathrm{e}^{t_i} - \tau_0$ for $i = 1, 2$. We say that "$(u,v) \in \mathcal{C}([t_1,t_2], \mathrm{Z}_t)$ is a solution of the system* (1.16)*" if there exists a (mild) solution $(W, W_\tau) \in \mathcal{C}([\tau_1,\tau_2], \mathrm{Z}_0)$ of* (1.8) *such that the relations* (1.14), (1.15) *hold.*

We recall that a *mild* solution of a partial differential equation is a continuous solution of the associated integral equation; see [Pa, section 4.2]. According to Definition 1.1, if $(u,v) \in \mathcal{C}([t_1,t_2], \mathrm{Z}_t)$ is a solution of (1.16), then $(u(t), v(t)) \in \mathrm{Z}_t$ for all $t \in [t_1, t_2]$. However, the continuity of (u,v) with respect to t has to be understood as the continuity in Z_0 of the functions (W, W_τ) defined by (1.15). In Proposition 2.2 below, we shall show that the Cauchy problem for (1.16) in Z_t is locally well posed.

Before stating our main result, we explain its content in a heuristic way. Taking formally the limit $t \to +\infty$ in (1.16) and using (1.11), we see that u satisfies the linear parabolic equation

$$u_t \,=\, \mathcal{L}_\infty u \,\stackrel{\mathrm{def}}{=}\, u_{xx} + \left(\frac{x}{2} + \frac{2}{x}\right) u_x + \frac{3}{2} u \quad \text{if } x > 0 \,, \quad u_x \,=\, 0 \quad \text{if } x \leq 0 \,. \tag{1.20}$$

Therefore, it is reasonable to expect that the long-time behavior of the solutions of (1.16) is determined by the spectral properties of the operator $\mathcal{L}_\infty$ on $\mathbf{R}_+$, with Neumann boundary condition at $x = 0$. Now, as is easily verified, this limiting operator is just the image under the scaling (1.15) of the radially symmetric Laplace operator in three dimensions. Indeed, if u and W are related through (1.15), the equation $u_t = \mathcal{L}_\infty u$ is equivalent to $W_\tau = W_{\xi\xi} + (2/\xi) W_\xi$, $\xi > 0$. This crucial observation explains the factor $(\tau+\tau_0)^{-3/2}$ in (1.15) and allows us to compute exactly the spectrum of $\mathcal{L}_\infty$ in various function spaces; see [GR2, Appendix A]. For instance, in the space $\mathrm{H}^1(\mathbf{R}_+, (1+x)^6 \mathrm{d}x)$, the spectrum of $\mathcal{L}_\infty$ consists of one simple, isolated eigenvalue at $\lambda = 0$, and of one "continuous" spectrum filling the half-plane $\{\lambda \in \mathbf{C} \,|\, \mathrm{Re}\,\lambda \leq -1/4\}$. The eigenfunction corresponding to $\lambda = 0$ is the Gaussian $\mathrm{e}^{-x^2/4}$. Therefore, we expect that the solution $u(x,t)$ of (1.16) converges as $t \to +\infty$ to

$\alpha\varphi^*(x)$ for some $\alpha \in \mathbf{R}$, where

$$\varphi^*(x) \,=\, \frac{1}{\sqrt{4\pi}} \begin{cases} 1 & \text{if } x < 0 \ , \\ \mathrm{e}^{-x^2/4} & \text{if } x \geq 0 \ . \end{cases} \tag{1.21}$$

This function is normalized so that $\int_0^\infty x^2 \varphi^*(x)\,\mathrm{d}x = 1$. Since $v = u_t - \frac{x}{2}u_x - \frac{3}{2}u$, we also expect that $v(x,t)$ converges to $\alpha\psi^*(x)$, where

$$\psi^* \,=\, -\frac{x}{2}\varphi^*_x - \frac{3}{2}\varphi^* \ . \tag{1.22}$$

It is crucial to note that (1.20) is independent of ε: this explains why the solutions of (1.8), and hence of (1.1), behave for large times like those of the corresponding parabolic equations.

Our main result, below, shows that these heuristic considerations are indeed correct.

THEOREM 1.2. *Assume that the nonlinearity $\mathcal{F}$ satisfies (1.2), and let $\varepsilon > 0$. There exist $t_0 > 0$, $\delta_0 > 0$, and $C > 0$ such that, for all initial data $(u_0, v_0) \in \mathrm{Z}_{t_0}$ with $\Phi_\eta(t_0, u_0, v_0) \leq \delta_0^2$, the system (1.16) has a unique solution $(u, v) \in \mathcal{C}([t_0, +\infty), \mathrm{Z}_t)$ satisfying $(u(t_0), v(t_0)) = (u_0, v_0)$. In addition, there exists $\alpha^* \in \mathbf{R}$ such that, for all $t \geq t_0$,*

$$\begin{aligned} \|u(t) - \alpha^*\varphi^*\|^2_{\mathrm{H}^1_t} + \eta\mathrm{e}^{-t}\|v(t) - \alpha^*\psi^*\|^2_{\mathrm{L}^2_t} + \int_{t_0}^t \mathrm{e}^{-(t-s)/2}\|v(s) - \alpha^*\psi^*\|^2_{\mathrm{L}^2_s}\,\mathrm{d}s \\ \leq\, C(1+t)^2\mathrm{e}^{-t/2}\Phi_\eta(t_0, u_0, v_0) \ . \end{aligned} \tag{1.23}$$

Remarks.

(1) In the proof of Theorem 1.2, we shall, for the sake of convenience, take the parameter $t_0 = \log(\tau_0)$ large enough, but this choice is irrelevant since, as reflected in Corollary 1.3 below, the results for the original equation (1.1) are not affected.

(2) The estimate (1.23) shows in particular that the solution $u(t)$ converges to $\alpha^*\varphi^*$ like $t\mathrm{e}^{-t/4}$ as $t \to +\infty$. As was already mentioned, the decay rate $\mathrm{e}^{-t/4}$ corresponds to the spectral gap of the linear operator $\mathcal{L}_\infty$ in $\mathrm{H}^1(\mathbf{R}_+, (1+x)^6\,\mathrm{d}x)$ and is thus optimal in our function space. The same argument suggests that this rate could be improved up to $\mathrm{e}^{-t/2}$ at the expense of assuming a faster decay of u, v as $x \to +\infty$, as in [Ga].

(3) Theorem 1.2 does not give a satisfactory estimate of the quantity $v(t) - \alpha^*\psi^*$ in L^2_t. If ε is sufficiently small, arguing as in section 3 and using three additional pairs of functionals, one can show that $\int_0^\infty (x+x^2)|v(x,t) - \alpha^*\psi^*(x)|^2\,\mathrm{d}x$ decays at least like $(1+t)^2\mathrm{e}^{-t/2}$ and that the expression

$$\int_{-\infty}^0 \mathrm{e}^{2\kappa x \mathrm{e}^{t/2}}|v(x,t) - \alpha^*\psi^*(x)|^2\,\mathrm{d}x + \int_0^\infty |v(x,t) - \alpha^*\psi^*(x)|^2\,\mathrm{d}x$$

is bounded by a polynomial in t. Since these estimates are probably not optimal and were obtained for small ε only, the corresponding calculations will not be given here.

(4) Given $\varepsilon_0 > 0$ and a nonlinearity $\mathcal{F}$ satisfying (1.2), it is straightforward to verify that all the statements in that which follows (and their proofs) hold uniformly in ε for $\varepsilon \in (0, \varepsilon_0]$. In particular, the constants t_0, δ_0, C appearing in Theorem 1.2 are independent of ε for $\varepsilon \in (0, \varepsilon_0]$. As a consequence, taking the limit $\varepsilon \to 0$ in (1.23), we obtain a local stability result for the traveling waves of the parabolic equation

(1.1) with $\varepsilon = 0$. Except for the use of slightly different function spaces, this result coincides with Theorem 1.1 in [Ga].

Combining Theorem 1.2 and Lemma 2.4 below, we obtain in particular the following convergence result for the perturbation in the original variables.

COROLLARY 1.3. *Assume that the nonlinearity $\mathcal{F}$ satisfies* (1.2)*, and let $\varepsilon > 0$. Then there exists $\delta_1 > 0$ such that, for all initial data $(w_0, w_1) \in Y$ satisfying $\|w_0\|_{Y^1}^2 + \varepsilon\|w_1\|_{Y^0}^2 \le \delta_1^2$,* (1.6) *has a unique solution $(w, w_T) \in \mathcal{C}([0,+\infty), Y)$ such that $(w(0), w_T(0)) = (w_0, w_1)$. In addition, there exists $\alpha \in \mathbf{R}$ such that*

$$\sup_{\xi\in\mathbf{R}} \left(1 + \frac{\mathrm{e}^{c_*\xi/2}}{1+|\xi|}\right) \left| w(\xi,T) - \frac{\alpha}{T^{3/2}}\, h'(\xi)\varphi^* \left(\frac{\xi\sqrt{1+\varepsilon c_*^2}}{\sqrt{T}}\right)\right| = \mathcal{O}(T^{-7/4}\log T)$$

as $T \to +\infty$.

The rest of this paper is devoted to the proof of Theorem 1.2, which is organized as follows. First, we show that the Cauchy problem for (1.16) is locally well posed in the space Z_t, in the sense of Definition 1.1. Then, in section 2.1, we decompose the solutions (u, v) of (1.16) using a spectral projection of the time-dependent operator $\mathcal{L}_t$ defined in (2.3) below. The first term in this decomposition is one-dimensional and converges to $\alpha^*(\varphi^*, \psi^*)$ as $t \to +\infty$. The remainder (f, g) satisfies an evolution system similar to (1.16), with additional terms which are estimated in section 2.2. The core of the proof is section 3, where the evolution of (f, g) in Z_t is controlled using a hierarchy of energy functionals. As in [GR2], some of these quantities are constructed in terms of the primitives (F, G) rather than the functions (f, g) themselves. Finally, the results are summarized in the short section 4.

Although the proof we present here is certainly not simple, we believe that our approach is a systematic and very convenient way to study the long-time asymptotics in a large class of dissipative systems. As a matter of fact, the present proof follows exactly the same lines as in [GR2], although the problems considered therein are significantly different. When compared with other accurate techniques, such as the renormalization group used in [BK1, Ga], our method shows at least two advantages. First, we do not need precise estimates of the resolvent of the linearized operator around the traveling wave (although some spectral information is used to construct our energy functionals). This substantial simplification is especially interesting in the perspective of possible applications to higher-dimensional problems, where standard tools like the Evans function are not available. Next, while most of our effort is devoted to controlling the linear terms in (1.16), the nonlinearities are naturally incorporated into the scheme and do not require any extra argument. In the present case, the factor $\mathrm{e}^{-t/2}$ in front of the last term in (1.16) clearly shows that the nonlinearity is irrelevant for the long-time behavior, provided the solution $u(t)$ stays globally bounded. On the other hand, a minor drawback of our approach is the introduction of nonautonomous systems and time-dependent function spaces through the change of variables (1.14). We shall avoid this difficulty by returning to the original variables to show that the Cauchy problem for (1.16) is locally well posed and to prove that our energy functionals are differentiable in time.

Notation. In that which follows, we denote by C a generic positive constant which may differ from place to place, while numbered constants $C_i, K_i, \dots$ keep the same values throughout the paper.

2. Preliminaries. We begin with a local existence result for the solutions W of (1.8) in the function space $\mathrm{Z}_0 = \mathrm{H}_0^1 \times \mathrm{L}_0^2$. We recall that H_0^1, L_0^2 are defined by the norms (1.17) with $t = 0$.

LEMMA 2.1. *Let $\varepsilon > 0$ and $\delta > 0$. There exists $\hat\tau > 0$ such that, for all initial data $(W_0, \dot W_0) \in \mathrm{Z}_0$ with $\|(W_0, \dot W_0)\|_{\mathrm{Z}_0} \le \delta$, (1.8) has a unique (mild) solution $W \in \mathcal{C}([0,\hat\tau], \mathrm{H}^1_0) \cap \mathcal{C}^1([0,\hat\tau], \mathrm{L}^2_0)$ satisfying $(W(0), W_\tau(0)) = (W_0, \dot W_0)$. The solution (W, W_τ) depends continuously on the initial data in Z_0, uniformly in $\tau \in [0,\hat\tau]$. In addition, if $(W_0, \dot W_0) \in \mathrm{H}^2_0 \times \mathrm{H}^1_0$, then $W \in \mathcal{C}([0,\hat\tau], \mathrm{H}^2_0) \cap \mathcal{C}^1([0,\hat\tau], \mathrm{H}^1_0) \cap \mathcal{C}^2([0,\hat\tau], \mathrm{L}^2_0)$ is a classical solution of (1.8) in L^2_0.*

Proof. Let $q \in \mathcal{C}^\infty(\mathbf{R})$ be a positive function satisfying $q(\xi) = \mathrm{e}^{-\kappa\xi}$ for $\xi \le 0$ and $q(\xi) = \xi^{-3}$ for $\xi \ge 1$. Setting $W(\xi,\tau) = q(\xi)\omega(\xi,\tau)$ in (1.8), we obtain for ω the equation

$$\eta\omega_{\tau\tau} - 2\nu\omega_{\xi\tau} \,=\, \omega_{\xi\xi} + \mathcal{M}(\omega, \omega_\xi, \omega_\tau)\ , \tag{2.1}$$

where

$$\begin{aligned}\mathcal{M}(\omega, \omega_\xi, \omega_\tau) \,=\, &-\left(1 - \nu\gamma - 2\nu\frac{q'}{q}\right)\omega_\tau + \left(\gamma + \frac{2q'}{q}\right)\omega_\xi + \left(\gamma\frac{q'}{q} + \frac{q''}{q}\right)\omega \\ &+\, h'q\omega^2\mathcal{N}(h, h'q\omega)\ .\end{aligned} \tag{2.2}$$

Since the functions γ, q'/q, q''/q, and $h'q$ are all bounded, and since the nonlinearity $\mathcal{F}$ in (1.1) is $\mathcal{C}^2$, it is straightforward to verify that the map $\mathcal{M} : \mathrm{H}^1(\mathbf{R}) \times \mathrm{L}^2(\mathbf{R}) \to \mathrm{L}^2(\mathbf{R})$ defined by $(\omega, \omega_\tau) \mapsto \mathcal{M}(\omega, \omega_\xi, \omega_\tau)$ is locally Lipschitz, uniformly on bounded subsets. Therefore, by a classical result [CH], the Cauchy problem for (2.1) is locally well posed in $\mathrm{H}^1 \times \mathrm{L}^2$. More precisely, for any $r > 0$, there exists $\hat\tau > 0$ such that, for all initial data $(\omega_0, \dot\omega_0) \in \mathrm{H}^1 \times \mathrm{L}^2$ with $\|(\omega_0, \dot\omega_0)\|_{\mathrm{H}^1\times\mathrm{L}^2} \le r$, (2.1) has a unique (mild) solution $\omega \in \mathcal{C}([0,\hat\tau], \mathrm{H}^1) \cap \mathcal{C}^1([0,\hat\tau], \mathrm{L}^2)$ satisfying $(\omega(0), \omega_\tau(0)) = (\omega_0, \dot\omega_0)$. This solution depends continuously on the initial data in $\mathrm{H}^1 \times \mathrm{L}^2$, uniformly in $\tau \in [0,\hat\tau]$. Moreover, if $(\omega_0, \dot\omega_0) \in \mathrm{H}^2 \times \mathrm{H}^1$, then $\omega \in \mathcal{C}([0,\hat\tau], \mathrm{H}^2) \cap \mathcal{C}^1([0,\hat\tau], \mathrm{H}^1) \cap \mathcal{C}^2([0,\hat\tau], \mathrm{L}^2)$ is a classical solution of (2.1). Thus, returning to the original function $W = q\omega$ and using the fact that

$$C^{-1}\|(\omega, \omega_\tau)\|_{\mathrm{H}^1\times\mathrm{L}^2} \,\le\, \|(W, W_\tau)\|_{\mathrm{Z}_0} \,\le\, C\|(\omega, \omega_\tau)\|_{\mathrm{H}^1\times\mathrm{L}^2}$$

for some $C \ge 1$, we obtain the desired result, if $r = C\delta$. This concludes the proof of Lemma 2.1. □

As a consequence of Definition 1.1 and Lemma 2.1, we obtain the following existence result for the solution (u, v) of (1.16).

PROPOSITION 2.2. *Let $\varepsilon > 0$, $\delta_1 > 0$, $t_2 > t_0$. There exists $T > 0$ such that, for all $t_1 \in [t_0, t_2]$ and all $(u_1, v_1) \in \mathrm{Z}_{t_1}$ satisfying $\Phi_\eta(t_1, u_1, v_1) \le \delta_1^2$, the system (1.16) has a unique solution $(u, v) \in \mathcal{C}([t_1, t_1+T], \mathrm{Z}_t)$ with initial data $(u(t_1), v(t_1)) = (u_1, v_1)$.*

Remark. In particular, Proposition 2.2 implies that, if $(u, v) \in \mathcal{C}([t_0, t_*), \mathrm{Z}_t)$ is a maximal solution of (1.16) and if $\Phi_\eta(t, u(t), v(t)) \le \delta_1^2$ for all $t \in [t_0, t_*)$, then actually $t_* = +\infty$; i.e, the solution (u, v) is globally defined.

Proof. Given $t_1 \in [t_0, t_2]$ and $(u_1, v_1) \in \mathrm{Z}_{t_1}$ satisfying $\Phi_\eta(t_1, u_1, v_1) \le \delta_1^2$, we define

$$W_1(\xi) \,=\, \mathrm{e}^{-3t_1/2}u_1(\xi\mathrm{e}^{-t_1/2})\ , \quad \dot W_1(\xi) \,=\, \mathrm{e}^{-5t_1/2}v_1(\xi\mathrm{e}^{-t_1/2})\ , \quad \xi \in \mathbf{R}\ .$$

Then $(W_1, \dot W_1) \in \mathrm{Z}_0$, and there exists a constant $C > 0$ (depending on η and t_2) such that $\|(W_1, \dot W_1)\|_{\mathrm{Z}_0} \le C\delta_1$. Since (1.8) is autonomous, it follows from Lemma 2.1 that there exists a time $\hat\tau > 0$, depending on η, $C\delta_1$ but not on $(W_1, \dot W_1)$, such that (1.8)

has a unique (mild) solution $W \in \mathcal{C}([\mathrm{e}^{t_1}, \mathrm{e}^{t_1}+\hat\tau], \mathrm{H}^1_0) \cap \mathcal{C}^1([\mathrm{e}^{t_1}, \mathrm{e}^{t_1}+\hat\tau], \mathrm{L}^2_0)$ satisfying $W(\xi, \mathrm{e}^{t_1}) = W_1(\xi)$, $W_\tau(\xi, \mathrm{e}^{t_1}) = \dot W_1(\xi)$. Now, we set $T = \log(1+\hat\tau \mathrm{e}^{-t_2})$, and for all $t \in [t_1, t_1+T] \subset [t_1, \log(\mathrm{e}^{t_1}+\hat\tau)]$ we define

$$u(x,t) \,=\, \mathrm{e}^{3t/2} W(x\mathrm{e}^{t/2}, \mathrm{e}^t) \;, \quad v(x,t) \,=\, \mathrm{e}^{5t/2} W_\tau(x\mathrm{e}^{t/2}, \mathrm{e}^t) \;.$$

By Definition 1.1, $(u,v) \in \mathcal{C}([t_1, t_1+T], \mathrm{Z}_1)$ is a solution of (1.16) with $(u(t_1), v(t_1)) = (u_1, v_1)$, and the uniqueness of this solution follows from the uniqueness of W as a mild solution of (1.8). This concludes the proof of Proposition 2.2. □

2.1. Spectral decomposition of the solution. From now on, we assume that $(u,v) \in \mathcal{C}([t_0, t_1], \mathrm{Z}_t)$ is a solution of (1.16) in the sense of Proposition 2.2. Inspired by [Ga] and [GR2], we shall decompose this solution using a spectral projection of the (time-dependent) linear operator

$$\mathcal{L}_t \,=\, \partial_x^2 + \left(\frac{x}{2} + \mathrm{e}^{t/2} \gamma(x\mathrm{e}^{t/2}) \right) \partial_x + \frac{3}{2} \;. \tag{2.3}$$

As was already mentioned, the system (1.16) is formally equivalent to the linear equation $u_t = \mathcal{L}_t u$ in the limit $t \to +\infty$. Remark that the function φ^* defined in (1.21) is an approximate eigenfunction of $\mathcal{L}_t$, in the sense that $\|\mathcal{L}_t \varphi^*\|_{\mathrm{L}^2_t} = \mathcal{O}(\mathrm{e}^{-t/4})$ as $t \to +\infty$. The corresponding spectral projection in L^2_t is given by the formula

$$u \mapsto \left(\int_{\mathbf{R}} \mathrm{e}^{-t} p(x\mathrm{e}^{t/2}) u(x) \, \mathrm{d}x \right) \varphi^*, \tag{2.4}$$

where $p : \mathbf{R} \to \mathbf{R}$ is the (unique) solution of the differential problem

$$p'(\xi) \,=\, \gamma(\xi) p(\xi) \;, \quad \xi \in \mathbf{R} \;, \quad \lim_{\xi \to +\infty} \frac{p(\xi)}{\xi^2} \,=\, 1 \;. \tag{2.5}$$

It follows from (1.11), (2.5) that $p(\xi) > 0$ for all $\xi \in \mathbf{R}$, and $p(\xi) = \mathcal{O}(\mathrm{e}^{\gamma_- \xi})$ as $\xi \to -\infty$.

Remark. Our choice of the projection (2.4) may be understood as follows. If u and W are related through (1.15), the equation $u_t = \mathcal{L}_t u$ ($t \geq t_0$) is equivalent to $W_\tau = W_{\xi\xi} + \gamma(\xi) W_\xi$ ($\tau \geq 0$). In [Ga, section 3], it is shown that the solution W of this linear equation satisfies

$$W(\xi,\tau) \,=\, \frac{1}{(\tau+\tau_0)^{3/2}} \, \varphi^* \left(\frac{\xi}{\sqrt{\tau+\tau_0}} \right) \int_{\mathbf{R}} p(\xi') W(\xi', 0) \, \mathrm{d}\xi' + \mathcal{O}\left(\frac{1}{\tau^2} \right) \;, \quad \tau \to +\infty \;,$$

where $\tau_0 \geq 0$ is arbitrary. Choosing $\tau_0 = \mathrm{e}^{t_0}$ and returning to the scaling variables (x,t), we obtain

$$u(x,t) \,=\, \varphi^*(x) \int_{\mathbf{R}} \mathrm{e}^{-t_0} p(y\mathrm{e}^{t_0/2}) u(y, t_0) \, \mathrm{d}y + \mathcal{O}(\mathrm{e}^{-t/2}) \;, \quad t \to +\infty \;.$$

This formula clearly shows the relevance of the projection (2.4) for the long-time asymptotics of the solutions of the linear equation $u_t = \mathcal{L}_t u$.

Motivated by (2.4), we introduce the functions

$$\varphi(x,t) \,=\, \frac{\varphi^*(x)}{1+\zeta(t)} \;, \quad \psi(x,t) \,=\, \varphi_t(x,t) - \frac{x}{2} \varphi_x(x,t) - \frac{3}{2} \varphi(x,t) \;, \tag{2.6}$$

where

$$\zeta(t) \,=\, \int_{\mathbf{R}} \mathrm{e}^{-t} p(x\mathrm{e}^{t/2})\varphi^*(x)\,\mathrm{d}x - 1 \;. \tag{2.7}$$

We shall show in the proof of Lemma 2.5 below that $\zeta(t)$ and $\zeta'(t)$ converge to zero as $t \to +\infty$, so that $\varphi(x,t) \to \varphi^*(x)$ and $\psi(x,t) \to \psi^*(x)$, where ψ^* is given by (1.22). By construction, we also have

$$\int_{\mathbf{R}} \mathrm{e}^{-t} p(x\mathrm{e}^{t/2})\varphi(x,t)\,\mathrm{d}x \,=\, 1 \;, \quad \int_{\mathbf{R}} \mathrm{e}^{-t} p(x\mathrm{e}^{t/2})\psi(x,t)\,\mathrm{d}x \,=\, 0 \;, \quad t \geq 0 \;. \tag{2.8}$$

Using these notations, we decompose the solution (u,v) of (1.16) as

$$u(x,t) \,=\, \alpha(t)\varphi(x,t) + f(x,t) \;, \quad v(x,t) \,=\, \beta(t)\varphi(x,t) + \alpha(t)\psi(x,t) + g(x,t) \;, \tag{2.9}$$

where

$$\alpha(t) \,=\, \int_{\mathbf{R}} \mathrm{e}^{-t} p(x\mathrm{e}^{t/2})u(x,t)\,\mathrm{d}x \;, \quad \beta(t) \,=\, \int_{\mathbf{R}} \mathrm{e}^{-t} p(x\mathrm{e}^{t/2})v(x,t)\,\mathrm{d}x \;. \tag{2.10}$$

In view of (2.8), (2.10), the functions f, g satisfy the "orthogonality relations"

$$\int_{\mathbf{R}} \mathrm{e}^{-t} p(x\mathrm{e}^{t/2})f(x,t)\,\mathrm{d}x \,=\, 0 \;, \quad \int_{\mathbf{R}} \mathrm{e}^{-t} p(x\mathrm{e}^{t/2})g(x,t)\,\mathrm{d}x \,=\, 0 \;. \tag{2.11}$$

We now determine the evolution equations satisfied by α, β, f, g. Our first result is as follows.

LEMMA 2.3. *If $(u,v) \in \mathcal{C}([t_0,t_1],\mathrm{Z}_t)$ is a solution of (1.16), then $\alpha \in \mathcal{C}^2([t_0,t_1])$ and*

$$\frac{\mathrm{d}}{\mathrm{d}t}\alpha(t) \,=\, \beta(t) \;, \quad \frac{\mathrm{d}}{\mathrm{d}t}\big(\eta \mathrm{e}^{-t}\beta(t) + \alpha(t)\big) \,=\, m(t) \;, \tag{2.12}$$

where

$$m(t) \,=\, \int_{\mathbf{R}} \mathrm{e}^{-t} p(x\mathrm{e}^{t/2})\big(-\nu\gamma(x\mathrm{e}^{t/2})v(x,t) + \mathrm{e}^{-t/2}h'(x\mathrm{e}^{t/2})u(x,t)^2 N(x,t)\big)\,\mathrm{d}x \;.$$

Proof. Let $\tau_1 = \mathrm{e}^{t_1} - \tau_0$, and let $W(\xi,\tau)$ be given by (1.15) for $\tau \in [0,\tau_1]$. By Definition 1.1, $W \in \mathcal{C}([0,\tau_1],\mathrm{H}^1_0) \cap \mathcal{C}^1([0,\tau_1],\mathrm{L}^2_0)$ is a (mild) solution of (1.8). Since $\alpha(t) = \int_{\mathbf{R}} p(\xi)W(\xi,\mathrm{e}^t - \tau_0)\,\mathrm{d}\xi$, it follows that $\alpha \in \mathcal{C}^1([t_0,t_1])$, and

$$\frac{\mathrm{d}}{\mathrm{d}t}\alpha(t) \,=\, \mathrm{e}^t \int_{\mathbf{R}} p(\xi)W_\tau(\xi,\mathrm{e}^t - \tau_0)\,\mathrm{d}\xi \,=\, \int_{\mathbf{R}} \mathrm{e}^{-t} p(x\mathrm{e}^{t/2})v(x,t)\,\mathrm{d}x \,=\, \beta(t) \;.$$

To prove that $\alpha \in \mathcal{C}^2([t_0,t_1])$, we first assume that $(W_0,\dot{W}_0) \equiv (W(\cdot,0),W_\tau(\cdot,0)) \in \mathrm{H}^2_0 \times \mathrm{H}^1_0$. Then, by Lemma 2.1, $W \in \mathcal{C}([0,\tau_1],\mathrm{H}^2_0) \cap \mathcal{C}^1([0,\tau_1],\mathrm{H}^1_0) \cap \mathcal{C}^2([0,\tau_1],\mathrm{L}^2_0)$ is a classical solution of (1.8), hence $\alpha \in \mathcal{C}^2([t_0,t_1])$, and

$$\frac{\mathrm{d}}{\mathrm{d}t}(\eta\mathrm{e}^{-t}\beta(t) + \alpha(t)) \,=\, \mathrm{e}^t \int_{\mathbf{R}} p(\xi)(\eta W_{\tau\tau} + W_\tau)(\xi,\mathrm{e}^t - \tau_0)\,\mathrm{d}\xi \,\stackrel{\mathrm{def}}{=}\, m(t) \;.$$

Since $p(\eta W_{\tau\tau} + W_\tau) = (pW_\xi)_\xi + 2\nu(pW_\tau)_\xi - \nu p\gamma W_\tau + ph'W^2\mathcal{N}(h, h'W)$ by (1.8), (2.5), we find

$$\begin{aligned} m(t) &= \mathrm{e}^t \int_{\mathbf{R}} p(\xi) \big(-\nu\gamma W_\tau + h'W^2\mathcal{N}(h, h'W)\big)(\xi, \mathrm{e}^t - \tau_0)\,\mathrm{d}\xi \\ &= \int_{\mathbf{R}} \mathrm{e}^{-t} p(x\mathrm{e}^{t/2})\big(-\nu\gamma(x\mathrm{e}^{t/2})v(x,t) + \mathrm{e}^{-t/2}h'(x\mathrm{e}^{t/2})u(x,t)^2 N(x,t)\big)\,\mathrm{d}x\ . \end{aligned}$$

For all $t \in [t_0, t_1]$, we thus have

$$\eta\mathrm{e}^{-t}\beta(t) + \alpha(t) = \eta\mathrm{e}^{-t_0}\beta(t_0) + \alpha(t_0) + \int_{t_0}^t m(s)\,\mathrm{d}s\ . \tag{2.13}$$

By Lemma 2.1, both sides of (2.13) are continuous functions of the initial data $(W_0, \dot W_0)$ in Z_0. Since (2.13) is satisfied for all $(W_0, \dot W_0)$ in the dense subspace $\mathrm{H}^2_0 \times \mathrm{H}^1_0$, the equality must hold for all $(W_0, \dot W_0) \in \mathrm{Z}_0$. This shows that $\eta\mathrm{e}^{-t}\beta + \alpha \in \mathcal{C}^1([t_0, t_1])$ and that (2.12) holds. The proof of Lemma 2.3 is complete. □

It follows from (1.16), (2.9), and Lemma 2.3 that $(f, g) \in \mathcal{C}([t_0, t_1], \mathrm{Z}_t)$ is a solution (in the sense of Definition 1.1) of the system

$$\begin{aligned} &f_t - \frac{x}{2}f_x - \frac{3}{2}f = g\ , \\ &\eta\mathrm{e}^{-t}\left(g_t - \frac{x}{2}g_x - \frac{5}{2}g\right) + (1 - \nu\gamma(x\mathrm{e}^{t/2}))g - 2\nu\mathrm{e}^{-t/2}g_x \\ &\quad = f_{xx} + \mathrm{e}^{t/2}\gamma(x\mathrm{e}^{t/2})f_x + r(x,t)\ , \end{aligned} \tag{2.14}$$

where

$$\begin{aligned} r(x,t) &= \alpha(\varphi_{xx} + \mathrm{e}^{t/2}\gamma(x\mathrm{e}^{t/2})\varphi_x - \psi) - \eta\mathrm{e}^{-t}(2\beta\psi + \alpha(\psi_t - \tfrac{x}{2}\psi_x - \tfrac{5}{2}\psi)) \\ &\quad + \nu\gamma(x\mathrm{e}^{t/2})(\beta\varphi + \alpha\psi) + 2\nu\mathrm{e}^{-t/2}(\beta\varphi_x + \alpha\psi_x) \\ &\quad + \mathrm{e}^{-t/2}h'(x\mathrm{e}^{t/2})u(x,t)^2 N(x,t) - m(t)\varphi\ . \end{aligned} \tag{2.15}$$

Using (2.5), (2.6), (2.8), and the definition of $m(t)$ in Lemma 2.3, it is not difficult to verify that

$$\int_{\mathbf{R}} \mathrm{e}^{-t} p(x\mathrm{e}^{t/2})\big(r(x,t) - \nu\gamma(x\mathrm{e}^{t/2})g(x,t)\big)\,\mathrm{d}x = 0\ . \tag{2.16}$$

Finally, as in [GR2], it will be useful to consider also the primitives

$$F(x,t) = \int_{-\infty}^x \mathrm{e}^{-t} p(y\mathrm{e}^{t/2}) f(y,t)\,\mathrm{d}y\ , \quad G(x,t) = \int_{-\infty}^x \mathrm{e}^{-t} p(y\mathrm{e}^{t/2}) g(y,t)\,\mathrm{d}y\ . \tag{2.17}$$

Using (2.11) and standard inequalities (see Lemma 2.7 below and the remark at the end of this section), it is straightforward to verify that $(F, G) \in \mathcal{C}^1([t_0, t_1], \mathrm{H}^1 \times \mathrm{L}^2)$ is a classical solution of the system

$$\begin{aligned} &F_t - \frac{x}{2}F_x = G\ , \\ &\eta\mathrm{e}^{-t}\Big(G_t - \frac{x}{2}G_x - G\Big) + G - 2\nu\mathrm{e}^{-t/2}G_x = F_{xx} - \mathrm{e}^{t/2}\gamma(x\mathrm{e}^{t/2})F_x + R(x,t)\ , \end{aligned} \tag{2.18}$$

where

$$R(x,t) = \int_{-\infty}^x \mathrm{e}^{-t} p(y\mathrm{e}^{t/2})\big(r(y,t) - \nu\gamma(y\mathrm{e}^{t/2})g(y,t)\big)\,\mathrm{d}y\ . \tag{2.19}$$

2.2. Bounds on the nonlinear terms. In this subsection, we assume that $(u,v) \in \mathcal{C}([t_0,t_1],\mathrm{Z}_t)$ is a solution of (1.16) satisfying the bound

$$\|u(t)\|_{\mathrm{H}^1_t} \,\leq\, 1\;, \quad t \in [t_0,t_1]\;. \tag{2.20}$$

Then $u(t)$ is uniformly bounded in a weighted L^∞ space, as a consequence of the following result.

LEMMA 2.4. *There exists a constant $K_0 > 0$ such that, for all $t \geq 0$ and all $w \in \mathrm{H}^1_t$,*

$$\sup_{x\leq 0} \mathrm{e}^{\kappa x \mathrm{e}^{t/2}} |w(x)| + \sup_{x\geq 0} (1{+}x)^3 |w(x)| \,\leq\, K_0 \|w\|_{\mathrm{H}^1_t}\;. \tag{2.21}$$

Remark. Note the crucial fact that the constant K_0 in (2.21) is independent of t.

Proof. Let $t \geq 0$ and $w \in \mathrm{H}^1_t$. By a classical inequality, there exists $C > 0$ such that

$$\sup_{x\geq 0} (1{+}x)^6 w(x)^2 \,\leq\, C \int_0^\infty (1{+}x)^6 (w(x)^2 + w'(x)^2)\,\mathrm{d}x\;. \tag{2.22}$$

In particular, $w(0)^2 \leq C\|w\|^2_{\mathrm{H}^1_t}$. On the other hand, we have for all $x < 0$

$$\begin{aligned} \mathrm{e}^{2\kappa x \mathrm{e}^{t/2}} w(x)^2 \,&=\, w(0)^2 - \int_x^0 \mathrm{e}^{2\kappa y \mathrm{e}^{t/2}} \big(2w(y)w'(y) + 2\kappa \mathrm{e}^{t/2} w(y)^2\big)\,\mathrm{d}y \\ &\leq\, w(0)^2 + \int_{-\infty}^0 \mathrm{e}^{2\kappa y \mathrm{e}^{t/2}} (w(y)^2 + w'(y)^2)\,\mathrm{d}y\;. \end{aligned} \tag{2.23}$$

Combining (2.22), (2.23), we obtain (2.21). This concludes the proof of Lemma 2.4. □

In that which follows, it will be natural to control the solution (u,v) of (1.16) in terms of the functions α, β, f, g defined in (2.9), (2.10). The equivalence of the corresponding norms is the content of our next result.

LEMMA 2.5. *There exists a constant $K_1 \geq 1$ such that, for all $t \geq 0$ and all $(u,v) \in \mathrm{Z}_t$,*

$$\begin{aligned} K_1^{-1} \|u\|_{\mathrm{H}^1_t} \,&\leq\, |\alpha| + \|f\|_{\mathrm{H}^1_t} \,\leq\, K_1 \|u\|_{\mathrm{H}^1_t}\;, \\ K_1^{-1} \|v\|_{\mathrm{L}^2_t} \,&\leq\, |\alpha| + |\beta| + \|g\|_{\mathrm{L}^2_t} \,\leq\, K_1 (\|u\|_{\mathrm{H}^1_t} + \|v\|_{\mathrm{L}^2_t})\;, \end{aligned} \tag{2.24}$$

where α, β are defined in (2.10) *and f, g in* (2.9).

Proof. From (1.11), we know that $\gamma(\xi) \to \gamma_-$ as $\xi \to -\infty$ and $\gamma(\xi) \sim 2/(\xi{+}\xi_0)$ as $\xi \to +\infty$. Setting $\xi_1 = -\xi_0 + 2/\gamma_-$, we decompose $\gamma(\xi)$ as $\gamma_0(\xi) + \hat\gamma(\xi)$, where

$$\gamma_0(\xi) \,=\, \begin{cases} \gamma_- & \text{if } \xi < \xi_1\;, \\ 2/(\xi{+}\xi_0) & \text{if } \xi \geq \xi_1\;. \end{cases}$$

By (1.11), the remainder $\hat\gamma(\xi)$ decays exponentially as $|\xi| \to \infty$. Thus the solution of (2.5) can be represented as

$$p(\xi) = p_0(\xi) \exp\left(- \int_\xi^\infty \hat\gamma(s)\,\mathrm{d}s \right)\;, \quad p_0(\xi) = \begin{cases} (2/\gamma_-)^2 \mathrm{e}^{\gamma_-(\xi-\xi_1)} & \text{if } \xi < \xi_1, \\ (\xi{+}\xi_0)^2 & \text{if } \xi \geq \xi_1. \end{cases} \tag{2.25}$$

In particular, there exists $C_0 \geq 1$ such that

$$p(\xi) \leq C_0 \begin{cases} \mathrm{e}^{\gamma_- \xi} & \text{if } \xi < 0 \ , \\ (1+\xi)^2 & \text{if } \xi \geq 0 \ , \end{cases} \qquad p(\xi) \geq C_0^{-1} \begin{cases} \mathrm{e}^{\gamma_- \xi} & \text{if } \xi < 0 \ , \\ (1+\xi)^2 & \text{if } \xi \geq 0 \ . \end{cases} \tag{2.26}$$

Using (2.25) and remembering that $\int_0^\infty x^2 \varphi^*(x)\,\mathrm{d}x = 1$, we decompose the function $\zeta(t)$ defined in (2.7) as

$$\begin{aligned} \zeta(t) \ &= \int_{-\infty}^0 \mathrm{e}^{-t} p(x\mathrm{e}^{t/2}) \varphi^*(x)\,\mathrm{d}x + \int_0^\infty \mathrm{e}^{-t} \big(p(x\mathrm{e}^{t/2}) - p_0(x\mathrm{e}^{t/2})\big) \varphi^*(x)\,\mathrm{d}x \\ &\quad + \int_0^\infty \big(\mathrm{e}^{-t} p_0(x\mathrm{e}^{t/2}) - x^2\big) \varphi^*(x)\,\mathrm{d}x \ = \ \zeta_1(t) + \zeta_2(t) + \zeta_3(t) \ . \end{aligned}$$

Using (1.21), we remark that

$$\zeta_1(t) = \frac{\mathrm{e}^{-3t/2}}{\sqrt{4\pi}} \int_{-\infty}^0 p(\xi)\,\mathrm{d}\xi \ , \quad \zeta_2(t) \ = \ \mathrm{e}^{-3t/2} \int_0^\infty \big(p(\xi) - p_0(\xi)\big) \varphi^*(\xi \mathrm{e}^{-t/2})\,\mathrm{d}\xi \ ,$$

where $p(\xi) - p_0(\xi)$ decays exponentially to zero as $\xi \to +\infty$ due to (2.25). On the other hand, setting $\bar\xi = \max(0, \xi_1)$, we have

$$\zeta_3(t) \ = \ \mathrm{e}^{-3t/2} \int_0^{\bar\xi} \big(p_0(\xi) - (\xi+\xi_0)^2\big) \varphi^*(\xi \mathrm{e}^{-t/2})\,\mathrm{d}\xi + \int_0^\infty \big(2\xi_0 x \mathrm{e}^{-t/2} + \xi_0^2 \mathrm{e}^{-t}\big) \varphi^*(x)\,\mathrm{d}x \ .$$

It follows immediately from these expressions that

$$|\zeta(t)| + |\zeta'(t)| + |\zeta''(t)| \ \leq \ C_1 \mathrm{e}^{-t/2} \ , \quad (1+\zeta(t))^{-1} \ \leq \ C_1 \ , \quad t \geq 0 \ , \tag{2.27}$$

for some $C_1 > 0$. As a consequence, the functions $\varphi(x,t), \psi(x,t)$ defined by (2.6) satisfy the bounds

$$\|\varphi(t)\|_{\mathrm{H}^1_t} + \|\psi(t)\|_{\mathrm{L}^2_t} \ \leq \ C_2 \ , \quad t \geq 0 \ , \tag{2.28}$$

and

$$\|\varphi(t) - \varphi^*\|_{\mathrm{H}^1_t} + \|\psi(t) - \psi^*\|_{\mathrm{L}^2_t} \ \leq \ C_2 \mathrm{e}^{-t/2} \ , \quad t \geq 0 \ , \tag{2.29}$$

for some $C_2 > 0$.

Now, let $t \geq 0$, $(u,v) \in \mathrm{Z}_t$, and let α, β be defined as in (2.10). In view of (2.26), we have

$$\begin{aligned} |\alpha| \ &\leq \ C_0 \int_0^\infty (1+x)^2 |u|\,\mathrm{d}x + C_0 \mathrm{e}^{-t} \int_{-\infty}^0 \mathrm{e}^{\gamma_- x \mathrm{e}^{t/2}} |u|\,\mathrm{d}x \\ &\leq \ C_0 \left(\int_0^\infty (1+x)^6 u^2\,\mathrm{d}x \right)^{1/2} + \frac{C_0 \mathrm{e}^{-5t/4}}{(\gamma_- - \kappa)^{1/2}} \left(\int_{-\infty}^0 \mathrm{e}^{2\kappa x \mathrm{e}^{t/2}} u^2\,\mathrm{d}x \right)^{1/2} \ ; \end{aligned} \tag{2.30}$$

hence $|\alpha| \leq C_3 \|u\|_{\mathrm{L}^2_t}$ for some $C_3 > 0$. Similarly, we have $|\beta| \leq C_3 \|v\|_{\mathrm{L}^2_t}$. Using these bounds together with (2.9), (2.28), we obtain (2.24). This concludes the proof of Lemma 2.5. □

We now estimate the remainder terms $m(t)$ and $r(x,t)$ in (2.12), (2.14).

LEMMA 2.6. *There exists a constant $K_2 > 0$ such that, if $(u,v) \in \mathcal{C}([t_0,t_1], \mathrm{Z}_t)$ is a solution of* (1.16) *satisfying* (2.20)*, then*

$$\|r(t)\|_{\mathrm{L}^2_t} + \mathrm{e}^{t/4} |m(t)| \ \leq \ K_2 \mathrm{e}^{-t/4} \big(\alpha(t)^2 + \beta(t)^2 + \|f(t)\|^2_{\mathrm{H}^1_t} + \|g(t)\|^2_{\mathrm{L}^2_t}\big)^{1/2} \tag{2.31}$$

for all $t \in [t_0, t_1]$, where $r(x,t)$ is defined in (2.15) *and $m(t)$ in Lemma* 2.3.

Proof. We first consider the function $r_1(x,t) = \varphi_{xx} + \mathrm{e}^{t/2}\gamma(x\mathrm{e}^{t/2})\varphi_x - \psi$. It follows from (1.21), (2.6) that $r_1(x,t) = (1+\zeta(t))^{-1}(\hat r(x,t) + \zeta'(t)\varphi(x,t))$, where

$$\hat r(x,t) \,=\, \begin{cases} (\mathrm{e}^{t/2}\gamma(x\mathrm{e}^{t/2}) - 2/x)\varphi_x^* & \text{if } x > 0\ , \\ 3\varphi^*/2 & \text{if } x \le 0\ . \end{cases}$$

By (2.27), (2.28), we have $\|\zeta'(t)\varphi(t)\|_{\mathrm{L}^2_t} \le C_1C_2\mathrm{e}^{-t/2}$. To bound $\hat r(x,t)$, we observe that the function $\xi \mapsto (2-\xi\gamma(\xi))$ belongs to $\mathrm{L}^2(\mathbf{R}_+)$ by (1.11). Since $\varphi_x^* = -(x/2)\varphi^*$ for $x > 0$, we thus find

$$\int_0^\infty (1+x)^6 \hat r(x,t)^2\,\mathrm{d}x \,\le\, \frac{\mathrm{e}^{-t/2}}{4}\left(\sup_{x\ge 0}(1+x)^6\varphi^*(x)^2\right)\int_0^\infty (2-\xi\gamma(\xi))^2\,\mathrm{d}\xi\ ,$$
$$\int_{-\infty}^0 \mathrm{e}^{2\kappa x\mathrm{e}^{t/2}}\hat r(x,t)^2\,\mathrm{d}x = \frac{9}{32\pi\kappa}\,\mathrm{e}^{-t/2}\ .$$

Summarizing, we obtain $\|r_1(t)\|_{\mathrm{L}^2_t} \le C_4\mathrm{e}^{-t/4}$ for some $C_4 > 0$. Similarly, since $\gamma \in \mathrm{L}^2(\mathbf{R}_+) \cap \mathrm{L}^\infty(\mathbf{R}_-)$, we find $\|\gamma(x\mathrm{e}^{t/2})\varphi(t)\|_{\mathrm{L}^2_t} \le C_4\mathrm{e}^{-t/4}$ and $\|\gamma(x\mathrm{e}^{t/2})\psi(t)\|_{\mathrm{L}^2_t} \le C_4\mathrm{e}^{-t/4}$.

We next bound the nonlinear term $r_2(x,t) = \mathrm{e}^{-t/2}h'(x\mathrm{e}^{t/2})u(x,t)^2N(x,t)$, where $N(x,t) = \mathcal{N}(h(x\mathrm{e}^{t/2}), \mathrm{e}^{-3t/2}h'(x\mathrm{e}^{t/2})u(x,t))$. In view of (1.10), (2.20), (2.21), there exists $C_5 > 0$ such that $\sup_{x\in\mathbf{R}}|h'(x\mathrm{e}^{t/2})u(x,t)| \le C_5$ for all $t \in [t_0,t_1]$. In particular, since $\mathcal{N} : \mathbf{R}^2 \to \mathbf{R}$ is continuous, we have $\|N(\cdot,t)\|_{\mathrm{L}^\infty} \le N_0$ for some $N_0 > 0$ and all $t \in [t_0,t_1]$. It follows that $\|r_2\|_{\mathrm{L}^2_t} \le \mathrm{e}^{-t/2}C_5N_0\|u(t)\|_{\mathrm{L}^2_t}$ for $t \in [t_0,t_1]$.

Finally, the function $m(t)$ defined in Lemma 2.3 can be written as $m_1(t) + m_2(t)$, where

$$m_1(t) \,=\, -\nu\int_{\mathbf{R}} \mathrm{e}^{-t}p(x\mathrm{e}^{t/2})\gamma(x\mathrm{e}^{t/2})v(x,t)\,\mathrm{d}x\ , \quad m_2(t) \,=\, \int_{\mathbf{R}} \mathrm{e}^{-t}p(x\mathrm{e}^{t/2})r_2(x,t)\,\mathrm{d}x\ .$$

Proceeding as in (2.30), we find that $|m_2(t)| \le C_3\|r_2(t)\|_{\mathrm{L}^2_t} \le \mathrm{e}^{-t/2}C_3C_5N_0\|u(t)\|_{\mathrm{L}^2_t}$. Moreover, since $\mathrm{e}^{-t}\gamma(x\mathrm{e}^{t/2})p(x\mathrm{e}^{t/2}) \le C\mathrm{e}^{-t/2}(1+x)$ for $x \ge 0$, we obtain

$$|m_1(t)| \,\le\, C\nu\mathrm{e}^{-t/2}\int_0^\infty (1+x)|v(x,t)|\,\mathrm{d}x + C\nu\mathrm{e}^{-t}\int_{-\infty}^0 \mathrm{e}^{\gamma_- x\mathrm{e}^{t/2}}|v(x,t)|\,\mathrm{d}x\ ;$$

hence $|m_1(t)| \le C_6\nu\mathrm{e}^{-t/2}\|v(t)\|_{\mathrm{L}^2_t}$ for some $C_6 > 0$. Therefore, there exists $C_7 > 0$ such that

$$|m(t)| \le C_7\mathrm{e}^{-t/2}(\|u(t)\|_{\mathrm{L}^2_t} + \|v(t)\|_{\mathrm{L}^2_t})\ , \quad t \in [t_0,t_1]\ . \tag{2.32}$$

Summarizing our results and observing that the functions φ, φ_x, ψ, ψ_x, ψ_t, $x\psi_x$ are uniformly bounded in L^2_t by (2.6), (2.27), we see that the remainder $r(x,t)$ defined by (2.15) satisfies

$$\|r(t)\|_{\mathrm{L}^2_t} \,\le\, C_8\mathrm{e}^{-t/4}\big(|\alpha(t)| + |\beta(t)| + \|u(t)\|_{\mathrm{H}^1_t} + \|v(t)\|_{\mathrm{L}^2_t}\big)\ , \quad t \in [t_0,t_1]\ , \tag{2.33}$$

for some $C_8 > 0$. Combining (2.24), (2.32), (2.33), we obtain (2.31). This concludes the proof of Lemma 2.6. □

Finally, we bound the primitives F, G, R defined in (2.17), (2.19).

LEMMA 2.7. *There exists a constant $K_3 > 0$ such that, for all $t \geq 0$ and all $f \in \mathrm{L}^2_t$ satisfying $\int_{\mathbf{R}} p(x\mathrm{e}^{t/2})f(x)\,\mathrm{d}x = 0$, the following estimate holds:*

$$\int_{\mathbf{R}} \left(1 + \frac{\mathrm{e}^t}{p(x\mathrm{e}^{t/2})}\right) F^2\,\mathrm{d}x \leq K_3 \left(\mathrm{e}^{-2t}\int_{-\infty}^0 \mathrm{e}^{2\kappa x\mathrm{e}^{t/2}} f^2\,\mathrm{d}x + \int_0^\infty (1+x)^6 f^2\,\mathrm{d}x\right), \tag{2.34}$$

where $F(x) = \int_{-\infty}^x \mathrm{e}^{-t} p(y\mathrm{e}^{t/2})f(y)\,\mathrm{d}y$.

Proof. Let $t \geq 0$ and $f \in \mathrm{L}^2_t$. We start from the identity

$$\mathrm{e}^t \int_{-\infty}^0 \mathrm{e}^{-\gamma_- x\mathrm{e}^{t/2}} F(x)^2\,\mathrm{d}x + \frac{\mathrm{e}^{t/2}}{\gamma_-}F(0)^2 \;=\; \frac{2\mathrm{e}^{-t/2}}{\gamma_-}\int_{-\infty}^0 \mathrm{e}^{-\gamma_- x\mathrm{e}^{t/2}} p(x\mathrm{e}^{t/2})F(x)f(x)\,\mathrm{d}x\;,$$

which is a simple integration by parts. Applying Hölder's inequality to the right-hand side, we obtain

$$\mathrm{e}^t \int_{-\infty}^0 \mathrm{e}^{-\gamma_- x\mathrm{e}^{t/2}} F(x)^2\,\mathrm{d}x + \frac{\mathrm{e}^{t/2}}{\gamma_-}F(0)^2 \;\leq\; \frac{4\mathrm{e}^{-2t}}{\gamma_-^2}\int_{-\infty}^0 \mathrm{e}^{-\gamma_- x\mathrm{e}^{t/2}} p(x\mathrm{e}^{t/2})^2 f(x)^2\,\mathrm{d}x\;.$$

Using (2.26) and remembering that $\gamma_- = c + 2\kappa > 2\kappa$, we conclude that

$$\int_{-\infty}^0 \left(1 + \frac{\mathrm{e}^t}{p(x\mathrm{e}^{t/2})}\right) F(x)^2\,\mathrm{d}x + \mathrm{e}^{t/2}F(0)^2 \;\leq\; C\mathrm{e}^{-2t}\int_{-\infty}^0 \mathrm{e}^{2\kappa x\mathrm{e}^{t/2}} f(x)^2\,\mathrm{d}x \tag{2.35}$$

for some $C > 0$.

Since $\int_{\mathbf{R}} p(x\mathrm{e}^{t/2})f(x)\,\mathrm{d}x = 0$, we have $F(x) = -\int_x^\infty \mathrm{e}^{-t} p(y\mathrm{e}^{t/2})f(y)\,\mathrm{d}y$. Using (2.26) and a classical inequality of Hardy [HLP, Theorem 328], we find

$$\int_0^\infty F(x)^2\,\mathrm{d}x \;\leq\; 4\int_0^\infty \mathrm{e}^{-2t}x^2 p(x\mathrm{e}^{t/2})^2 f(x)^2\,\mathrm{d}x \;\leq\; 4C_0^2\int_0^\infty (1+x)^6 f(x)^2\,\mathrm{d}x\;. \tag{2.36}$$

On the other hand, since $F(x) = F(0) + \int_0^x \mathrm{e}^{-t} p(y\mathrm{e}^{t/2})f(y)\,\mathrm{d}y$, we have for $x > 0$

$$\frac{\mathrm{e}^{t/2}|F(x)|}{1 + x\mathrm{e}^{t/2}} \;\leq\; \frac{\mathrm{e}^{t/2}|F(0)|}{1 + x\mathrm{e}^{t/2}} + \frac{C_0}{x}\int_0^x (1+y)^2|f(y)|\,\mathrm{d}y\;. \tag{2.37}$$

Using another form of Hardy's inequality [HLP, Theorem 327], we thus obtain

$$\int_0^\infty \frac{\mathrm{e}^t F(x)^2}{(1+x\mathrm{e}^{t/2})^2}\,\mathrm{d}x \;\leq\; 2\mathrm{e}^{t/2}F(0)^2 + 8C_0^2\int_0^\infty (1+x)^4 f(x)^2\,\mathrm{d}x\;. \tag{2.38}$$

Combining (2.35), (2.36), (2.38), and using (2.26), we arrive at (2.34). This concludes the proof of Lemma 2.7. □

LEMMA 2.8. *There exists a constant $K_4 > 0$ such that, if $(u, v) \in \mathcal{C}([t_0, t_1], \mathrm{Z}_t)$ is a solution of (1.16) satisfying (2.20), then*

$$\int_{\mathbf{R}} \left(1 + \frac{\mathrm{e}^t}{p(x\mathrm{e}^{t/2})}\right) R^2\,\mathrm{d}x \;\leq\; K_4\mathrm{e}^{-t/2}\big(\alpha(t)^2 + \beta(t)^2 + \|f(t)\|^2_{\mathrm{H}^1_t} + \|g(t)\|^2_{\mathrm{L}^2_t}\big) \tag{2.39}$$

for all $t \in [t_0, t_1]$, where $R(x,t)$ is defined in (2.19).

Proof. Following the proof of Lemma 2.7, we obtain as in (2.35)

$$\int_{-\infty}^0 \left(1 + \frac{\mathrm{e}^t}{p(x\mathrm{e}^{t/2})}\right) R(x,t)^2\,\mathrm{d}x + \mathrm{e}^{t/2}R(0,t)^2 \;\leq\; C\mathrm{e}^{-2t}\int_{-\infty}^0 \mathrm{e}^{2\kappa x\mathrm{e}^{t/2}}(r^2 + \nu^2\gamma_-^2 g^2)\,\mathrm{d}x\;.$$

Next, remarking that $\mathrm{e}^{-t}p(x\mathrm{e}^{t/2})\gamma(x\mathrm{e}^{t/2}) \le C\mathrm{e}^{-t/2}(1+x)$ for $x \ge 0$, we find instead of (2.36), (2.38)

$$\int_0^\infty R(x,t)^2\,\mathrm{d}x \,\le\, C\int_0^\infty \big((1+x)^6 r(x,t)^2 + \nu^2\mathrm{e}^{-t}(1+x)^4 g(x,t)^2\big)\,\mathrm{d}x\ ,$$
$$\int_0^\infty \frac{\mathrm{e}^t R(x,t)^2}{(1+x\mathrm{e}^{t/2})^2}\,\mathrm{d}x \,\le\, 2\mathrm{e}^{t/2}R(0,t)^2 + C\int_0^\infty \big((1+x)^4 r^2 + \nu^2\mathrm{e}^{-t}(1+x)^2 g^2\big)\,\mathrm{d}x\ .$$

Combining these estimates, we obtain

$$\int_{\mathbf{R}} \left(1 + \frac{\mathrm{e}^t}{p(x\mathrm{e}^{t/2})}\right) R(x,t)^2\,\mathrm{d}x \,\le\, C\big(\|r(t)\|_{\mathrm{L}^2_t}^2 + \nu^2\mathrm{e}^{-t}\|g(t)\|_{\mathrm{L}^2_t}^2\big)\ ,$$

and (2.39) follows using Lemma 2.6. This concludes the proof of Lemma 2.8. □

Remark. For $t \ge 0$, $k \in \mathbf{N}$, let X^k_t be the weighted Sobolev space defined by the norm

$$\|u\|^2_{\mathrm{X}^0_t} \,=\, \int_{-\infty}^0 \mathrm{e}^{-\gamma_- x\mathrm{e}^{t/2}} u(x)^2\,\mathrm{d}x + \int_0^\infty u(x)^2\,\mathrm{d}x\ ,\quad \|u\|^2_{\mathrm{X}^k_t} \,=\, \sum_{i=0}^k \|\partial_x^i u\|^2_{\mathrm{X}^0_t}\ .$$

If $(u,v) \in \mathcal{C}([t_0,t_1],\mathrm{Z}_t)$ is a solution of (1.16), it follows from Lemma 2.7 and from the definition (2.17) of F,G that $(F,G) \in \mathrm{X}^2_t \times \mathrm{X}^1_t$ for all $t \in [t_0,t_1]$. Moreover, using a density argument as in the proof of Lemma 2.3, one can verify that $(F,G) \in \mathcal{C}^1([t_0,t_1],\mathrm{X}^1_t \times \mathrm{X}^0_t)$ is a classical solution of (2.18). As in Definition 1.1, this means that if

$$\tilde F(\xi,t) \,=\, F(\xi\mathrm{e}^{-t/2},t)\ ,\quad \tilde G(\xi,t) \,=\, G(\xi\mathrm{e}^{-t/2},t)\ ,$$

then $(\tilde F,\tilde G) \in \mathcal{C}^1([t_0,t_1],\mathrm{X}^1_0 \times \mathrm{X}^0_0) \cap \mathcal{C}([t_0,t_1],\mathrm{X}^2_0 \times \mathrm{X}^1_0)$. For later use, we also note that

$$\tilde F_t(\xi,t) \,=\, \Big(F_t - \frac{x}{2}F_x\Big)(\xi\mathrm{e}^{-t/2},t)\ ,\quad \tilde G_t(\xi,t) \,=\, \Big(G_t - \frac{x}{2}G_x\Big)(\xi\mathrm{e}^{-t/2},t)\ . \tag{2.40}$$

3. Energy estimates. As in the previous section, we assume that $(u,v) \in \mathcal{C}([t_0,t_1],\mathrm{Z}_t)$ is a solution of (1.16) satisfying the bound (2.20). To control the time behavior of the functions f,g defined in (2.9), we shall use five pairs of energy functionals. The construction of these functionals follows essentially the same lines as in [GR2], with additional complications due to the drift $\gamma(\xi)$ and to the nontrivial spectral projection (2.4).

We first introduce unweighted functionals for the primitives F,G defined in (2.18):

$$E_0(t) \,=\, \int_{\mathbf{R}} \left(\frac{1}{2}F^2 + \eta\mathrm{e}^{-t}FG\right)\mathrm{d}x\ ,\quad \mathcal{E}_0(t) \,=\, \frac{1}{2}\int_{\mathbf{R}} \big(F_x^2 + \eta\mathrm{e}^{-t}G^2\big)\,\mathrm{d}x\ . \tag{3.1}$$

Lemma 3.1. *Assume that $(u,v) \in \mathcal{C}([t_0,t_1],\mathrm{Z}_t)$ is a solution of (1.16). Then E_0 and $\mathcal{E}_0$ belong to $\mathcal{C}^1([t_0,t_1])$ and*

$$\dot E_0 \,=\, -\frac{E_0}{2} + \int_{\mathbf{R}} \left(-F_x^2 + \frac{\mathrm{e}^t}{2}\gamma'(x\mathrm{e}^{t/2})F^2 + \eta\mathrm{e}^{-t}G^2 - 2\nu\mathrm{e}^{-t/2}F_xG + FR\right)\mathrm{d}x\ ,$$
$$\dot{\mathcal{E}}_0 \,=\, \frac{\mathcal{E}_0}{2} + \int_{\mathbf{R}} \big(-G^2 - \mathrm{e}^{t/2}\gamma(x\mathrm{e}^{t/2})F_xG + GR\big)\,\mathrm{d}x$$

for all $t \in [t_0, t_1]$, where R is defined in (2.19).

Remark. Here and afterward, we use the notation $\dot{E} = (\mathrm{d}E/\mathrm{d}t)$, $\dot{\mathcal{E}} = (\mathrm{d}\mathcal{E}/\mathrm{d}t)$.

Proof. Since $(F, G) \in \mathcal{C}^1([t_0, t_1], \mathrm{H}^1 \times \mathrm{L}^2)$, the functions E_0 and $\mathcal{E}_0$ belong to $\mathcal{C}^1([t_0, t_1])$, and a direct calculation yields

$$\begin{aligned} \dot{E}_0(t) &= \int_{\mathbf{R}} \big(FF_t + \eta \mathrm{e}^{-t}((FG)_t - FG) \big) \, \mathrm{d}x \ , \\ \dot{\mathcal{E}}_0(t) &= \int_{\mathbf{R}} \big(-F_{xx}F_t + \eta \mathrm{e}^{-t}(GG_t - \tfrac{1}{2}G^2) \big) \, \mathrm{d}x \ . \end{aligned}$$

Using the identities

$$\begin{aligned} &FF_t + \eta \mathrm{e}^{-t}\big((FG)_t - \tfrac{x}{2}(FG)_x - FG - G^2\big) \\ &\qquad = FF_{xx} + (\tfrac{x}{2} - \mathrm{e}^{t/2}\gamma(x\mathrm{e}^{t/2}))FF_x + 2\nu \mathrm{e}^{-t/2} FG_x + FR \ , \end{aligned} \tag{3.2}$$

$$\begin{aligned} &-F_{xx}F_t + \eta \mathrm{e}^{-t}(GG_t - \tfrac{x}{2}GG_x - G^2) \\ &\qquad = -G^2 - \tfrac{x}{2}F_xF_{xx} - \mathrm{e}^{t/2}\gamma(x\mathrm{e}^{t/2})GF_x + 2\nu \mathrm{e}^{-t/2} GG_x + GR \ , \end{aligned} \tag{3.3}$$

which follow from (2.18), and integrating by parts, we obtain the desired expressions. This concludes the proof of Lemma 3.1. □

We next introduce weighted functionals for the primitives F, G:

$$\begin{aligned} E_1(t) &= \int_{\mathbf{R}} \frac{\mathrm{e}^t}{p(x\mathrm{e}^{t/2})} \left(\frac{1}{2}F^2 + \eta \mathrm{e}^{-t} FG \right) \mathrm{d}x \ , \\ \mathcal{E}_1(t) &= \frac{1}{2} \int_{\mathbf{R}} \frac{\mathrm{e}^t}{p(x\mathrm{e}^{t/2})} \left(F_x^2 + \eta \mathrm{e}^{-t} G^2 \right) \mathrm{d}x \ , \end{aligned} \tag{3.4}$$

where the weight p is defined in (2.5).

LEMMA 3.2. *Assume that $(u, v) \in \mathcal{C}([t_0, t_1], \mathrm{Z}_t)$ is a solution of* (1.16). *Then E_1 and $\mathcal{E}_1$ belong to $\mathcal{C}^1([t_0, t_1])$ and*

$$\begin{aligned} \dot{E}_1 &= \frac{E_1}{2} + \int_{\mathbf{R}} \frac{\mathrm{e}^t}{p(x\mathrm{e}^{t/2})} (-F_x^2 + \eta \mathrm{e}^{-t} G^2 + 2\nu \mathrm{e}^{-t/2} FG_x + FR) \, \mathrm{d}x \ , \\ \dot{\mathcal{E}}_1 &= \frac{3\mathcal{E}_1}{2} + \int_{\mathbf{R}} \frac{\mathrm{e}^t}{p(x\mathrm{e}^{t/2})} (-G^2 + 2\nu \mathrm{e}^{-t/2} GG_x + GR) \, \mathrm{d}x \end{aligned}$$

for all $t \in [t_0, t_1]$.

Proof. We remark that

$$E_1(t) = \int_{\mathbf{R}} \frac{\mathrm{e}^{t/2}}{p(\xi)} \left(\frac{1}{2}\tilde{F}^2 + \eta \mathrm{e}^{-t} \tilde{F}\tilde{G} \right) \mathrm{d}\xi \ , \quad \mathcal{E}_1(t) = \frac{1}{2} \int_{\mathbf{R}} \frac{\mathrm{e}^{3t/2}}{p(\xi)} (\tilde{F}_\xi^2 + \eta \mathrm{e}^{-2t} \tilde{G}^2) \, \mathrm{d}\xi \ ,$$

where $\tilde{F}(\xi, t) = F(\xi \mathrm{e}^{-t/2}, t)$, $\tilde{G}(\xi, t) = G(\xi \mathrm{e}^{-t/2}, t)$. Since $(\tilde{F}, \tilde{G}) \in \mathcal{C}^1([t_0, t_1], \mathrm{X}_0^1 \times \mathrm{X}_0^0)$ (see the remark at the end of the previous section), it follows that $E_1, \mathcal{E}_1 \in \mathcal{C}^1([t_0, t_1])$. Using (2.40), we thus find

$$\begin{aligned} \dot{E}_1 &= \frac{E_1}{2} + \int_{\mathbf{R}} \frac{\mathrm{e}^t}{p(x\mathrm{e}^{t/2})} \big(FF_t - \tfrac{x}{2}FF_x + \eta \mathrm{e}^{-t}\big((FG)_t - \tfrac{x}{2}(FG)_x - FG\big) \big) \, \mathrm{d}x \ , \\ \dot{\mathcal{E}}_1 &= \frac{3\mathcal{E}_1}{2} + \int_{\mathbf{R}} \frac{\mathrm{e}^t}{p(x\mathrm{e}^{t/2})} \big(F_xF_{xt} - \tfrac{x}{2}F_xF_{xx} - \tfrac{1}{2}F_x^2 + \eta \mathrm{e}^{-t}\big(GG_t - \tfrac{x}{2}GG_x - G^2\big) \big) \, \mathrm{d}x \ . \end{aligned}$$

Applying the identities (3.2), (3.3) and the relation $F_t = G + \frac{x}{2}F_x$, we obtain the desired result after some integrations by parts. This concludes the proof of Lemma 3.2. □

We now define positive constants A_0, B_0 by

$$A_0 \,=\, 2\left(\inf_{\xi\geq 0} p(\xi)|\gamma'(\xi)|\right)^{-1} , \quad B_0 \,=\, \left(\sup_{\xi\in\mathbf{R}} p(\xi)\gamma(\xi)^2\right)^{-1} . \tag{3.5}$$

Due to (1.11), (1.12), (2.26), these quantities are well defined. Moreover, the inequality $|\gamma'(\xi)| \leq \frac{1}{2}\gamma(\xi)^2$ implies that $A_0 \geq 4B_0 > 0$. With these notations, we introduce the functional

$$S_1(t) \,=\, A_0E_0(t) + B_0\mathcal{E}_0(t) + 2E_1(t) + \mathcal{E}_1(t) , \quad t\in[t_0,t_1] .$$

Proposition 3.3. *Assume that $\eta\mathrm{e}^{-t_0}$ is sufficiently small, and that $(u,v) \in \mathcal{C}([t_0,t_1],\mathrm{Z}_t)$ is a solution of (1.16) satisfying the bound (2.20). Then $S_1 \in \mathcal{C}^1([t_0,t_1])$, $S_1(t) \geq 0$, and there exist positive constants K_5, K_6 such that, for all $t\in[t_0,t_1]$,*

$$\dot S_1(t) + \frac{1}{2}S_1(t) \,\leq\, -K_5\int_0^\infty (x^2+x^4)f^2\,\mathrm{d}x + K_6\mathrm{e}^{-t/4}(\|f\|_{\mathrm{L}^2_t}+\|g\|_{\mathrm{L}^2_t})M(t) , \tag{3.6}$$

where $M(t)^2 \,=\, \alpha(t)^2+\beta(t)^2+\|f(t)\|^2_{\mathrm{H}^1_t}+\|g(t)\|^2_{\mathrm{L}^2_t}$.

Proof. Assuming $\eta\mathrm{e}^{-t_0} \leq \min(1/2, B_0/A_0)$, one verifies that $A_0E_0(t)+B_0\mathcal{E}_0(t) \geq 0$ and $2E_1(t)+\mathcal{E}_1(t) \geq 0$ for $t\in[t_0,t_1]$. Next, we remark that $F_x = \mathrm{e}^{-t}p(x\mathrm{e}^{t/2})f$, hence $\|F_x\|_{\mathrm{L}^2} \leq C\|f\|_{\mathrm{L}^2_t}$ by (1.17), (2.26). Thus, using Lemmas 2.7 and 2.8, we deduce from Lemma 3.1 that

$$\dot E_0(t) + \frac{E_0(t)}{2} \,\leq\, \int_{\mathbf{R}}\left(-F_x^2 + \frac{\mathrm{e}^t}{2}\gamma'(x\mathrm{e}^{t/2})F^2\right)\mathrm{d}x + C\mathrm{e}^{-t/4}(\|f\|_{\mathrm{L}^2_t}+\|g\|_{\mathrm{L}^2_t})M(t) .$$

Similarly, using the bound $|\mathrm{e}^{t/2}\gamma(x\mathrm{e}^{t/2})F_xG| \leq \frac{1}{2}(G^2+\mathrm{e}^t\gamma(x\mathrm{e}^{t/2})^2F_x^2)$, we obtain

$$\dot{\mathcal{E}}_0(t) + \frac{\mathcal{E}_0(t)}{2} \,\leq\, \frac{1}{2}\int_{\mathbf{R}}\left(-G^2+F_x^2+\mathrm{e}^t\gamma(x\mathrm{e}^{t/2})^2F_x^2\right)\mathrm{d}x + C\mathrm{e}^{-t/4}\|g\|_{\mathrm{L}^2_t}M(t) .$$

Finally, applying Lemma 2.7 and Lemma 2.8 again, we deduce from Lemma 3.2 that

$$\begin{aligned} 2\dot E_1(t) + \dot{\mathcal{E}}_1(t) + E_1(t) + \frac{1}{2}\mathcal{E}_1(t) \,&\leq\, C\mathrm{e}^{-t/4}(\|f\|_{\mathrm{L}^2_t}+\|g\|_{\mathrm{L}^2_t})M(t) \\ &+ \int_{\mathbf{R}}\frac{\mathrm{e}^t}{p(x\mathrm{e}^{t/2})}\left(-F_x^2-G^2+F^2+2\nu\mathrm{e}^{-t/2}(2F+G)G_x\right)\mathrm{d}x . \end{aligned}$$

The last term in the right-hand side is bounded with the help of (2.17), (2.26), and Lemma 2.7:

$$\begin{aligned} \int_{\mathbf{R}}\frac{\mathrm{e}^{t/2}}{p(x\mathrm{e}^{t/2})}|(2F+G)G_x|\,\mathrm{d}x &\leq C\left(\int_{\mathbf{R}}\frac{\mathrm{e}^t(F^2+G^2)}{p(x\mathrm{e}^{t/2})}\,\mathrm{d}x\right)^{1/2}\left(\int_{\mathbf{R}}\mathrm{e}^{-2t}p(x\mathrm{e}^{t/2})g^2\,\mathrm{d}x\right)^{1/2} \\ &\leq C\mathrm{e}^{-t/2}(\|f\|_{\mathrm{L}^2_t}+\|g\|_{\mathrm{L}^2_t})\|g\|_{\mathrm{L}^2_t} . \end{aligned}$$

Combining these estimates and using (2.35), (3.5) together with the bound $\gamma'(\xi)\leq 0$ for $\xi\leq 0$, we obtain

$$\begin{aligned} \dot S_1(t) + \frac{S_1(t)}{2} \,\leq\, &-\frac{B_0}{2}\int_{\mathbf{R}}(7F_x^2+G^2)\,\mathrm{d}x - \int_{\mathbf{R}}\frac{\mathrm{e}^t}{p(x\mathrm{e}^{t/2})}\left(\frac{1}{2}F_x^2+G^2\right)\mathrm{d}x \\ &+ C\mathrm{e}^{-t/4}(\|f\|_{\mathrm{L}^2_t}+\|g\|_{\mathrm{L}^2_t})M(t) \end{aligned}$$

for all $t \in [t_0, t_1]$, and (3.6) follows using (2.17), (2.26). This concludes the proof of Proposition 3.3. □

In the rest of this section, we introduce three pairs of weighted functionals $E_i, \mathcal{E}_i$ $(i = 2, 3, 4)$ to control the solutions (f, g) of (2.14) in the space Z_t. To each pair will correspond a different weight function $p_i : \mathbf{R} \to \mathbf{R}_+$. To define the weight p_2, we choose a smooth function $\chi_2 : \mathbf{R} \to (0, 1]$ satisfying $\chi_2(\xi) = 2\kappa/\gamma_- < 1$ for $\xi \le -1$ and $\chi_2(\xi) = 1$ for $\xi \ge 0$. We set $\gamma_2 = \chi_2\gamma$. The weight $p_2 : \mathbf{R} \to \mathbf{R}_+$ is then the (unique) solution of the differential problem

$$p_2'(\xi) \,=\, \gamma_2(\xi) p_2(\xi) \;, \quad \xi \in \mathbf{R} \;, \quad \lim_{\xi \to +\infty} \frac{p_2(\xi)}{\xi^2} \,=\, 1 \;. \tag{3.7}$$

Clearly, $p_2(\xi) = p(\xi)$ for $\xi \ge 0$, and there exists $C \ge 1$ such that $C^{-1}\mathrm{e}^{2\kappa\xi} \le p_2(\xi) \le C\mathrm{e}^{2\kappa\xi}$ for $\xi \le 0$. In particular, we have for all $u \in \mathrm{L}^2_t$

$$\int_{-\infty}^0 p_2(x\mathrm{e}^{t/2}) u(x)^2 \,\mathrm{d}x + \int_0^\infty \mathrm{e}^{-t} p_2(x\mathrm{e}^{t/2}) u(x)^2 \,\mathrm{d}x \,\le\, C\|u\|^2_{\mathrm{L}^2_t} \;. \tag{3.8}$$

We now define the functionals

$$\begin{aligned} E_2(t) \,&=\, \int_{\mathbf{R}} \mathrm{e}^{-t} p_2(x\mathrm{e}^{t/2}) \left(\frac{1}{2} f^2 + \eta \mathrm{e}^{-t} fg \right) \mathrm{d}x \;, \\ \mathcal{E}_2(t) \,&=\, \frac{1}{2} \int_{\mathbf{R}} \mathrm{e}^{-t} p_2(x\mathrm{e}^{t/2}) \left(f_x^2 + \eta \mathrm{e}^{-t} g^2 \right) \mathrm{d}x \end{aligned} \tag{3.9}$$

together with $S_2(t) = 2E_2(t) + \mathcal{E}_2(t)$.

Proposition 3.4. *Assume that $\eta \mathrm{e}^{-t_0} \le 1/8$ and that $(u, v) \in \mathcal{C}([t_0, t_1], \mathrm{Z}_t)$ is a solution of (1.16) satisfying the bound (2.20). Then $S_2 \in \mathcal{C}^1([t_0, t_1])$ and there exist positive constants K_7, K_8 such that, for all $t \in [t_0, t_1]$,*

$$S_2(t) \,\ge\, \frac{1}{4} \int_{\mathbf{R}} \mathrm{e}^{-t} p_2(x\mathrm{e}^{t/2}) (f^2 + f_x^2 + \eta \mathrm{e}^{-t} g^2) \,\mathrm{d}x \;, \tag{3.10}$$

and

$$\begin{aligned} \dot{S}_2 + \frac{1}{2} S_2 \,\le\, &- K_7 \left(\int_0^\infty x^2 \big(f_x^2 + g^2 \big) \,\mathrm{d}x + \int_{-\infty}^0 \mathrm{e}^{2\kappa x \mathrm{e}^{t/2}} f^2 \,\mathrm{d}x \right) \\ &+ K_8 \left(\int_0^\infty x^2 f^2 \,\mathrm{d}x + \mathrm{e}^{-t/4} (\|f\|_{\mathrm{L}^2_t} + \|g\|_{\mathrm{L}^2_t}) M(t) \right) \;. \end{aligned} \tag{3.11}$$

Proof. Since $2\eta \mathrm{e}^{-t}|fg| \le 4\eta \mathrm{e}^{-t} f^2 + \frac{1}{4}\eta \mathrm{e}^{-t} g^2$ and $\eta \mathrm{e}^{-t} \le 1/8$, the lower bound (3.10) is obvious. To compute the time derivative of E_2, we note that

$$E_2(t) \,=\, \int_{\mathbf{R}} \mathrm{e}^{-3t/2} p_2(\xi) \left(\frac{1}{2} \tilde{f}^2 + \eta \mathrm{e}^{-t} \tilde{f} \tilde{g} \right) \mathrm{d}\xi \;,$$

where $\tilde{f}(\xi, t) = f(\xi \mathrm{e}^{-t/2}, t)$, $\tilde{g}(\xi, t) = g(\xi \mathrm{e}^{-t/2}, t)$. If we assume that $(u(t_0), v(t_0)) \in \mathrm{H}^2_{t_0} \times \mathrm{H}^1_{t_0}$, then (as in Lemma 2.1) $(\tilde{f}, \tilde{g}) \in \mathcal{C}([t_0, t_1], \mathrm{H}^2_0 \times \mathrm{H}^1_0) \cap \mathcal{C}^1([t_0, t_1], \mathrm{H}^1_0 \times \mathrm{L}^2_0)$ and $\tilde{f}_t(\xi, t) = (f_t - \frac{x}{2} f_x)(\xi \mathrm{e}^{-t/2}, t)$, $\tilde{g}_t(\xi, t) = (g_t - \frac{x}{2} g_x)(\xi \mathrm{e}^{-t/2}, t)$. A direct calculation then yields

$$\dot{E}_2(t) \,=\, \int_{\mathbf{R}} \mathrm{e}^{-t} p_2(x\mathrm{e}^{t/2}) \left(f f_t - \frac{x}{2} f f_x - \frac{3}{4} f^2 + \eta \mathrm{e}^{-t} \left((fg)_t - \frac{x}{2} (fg)_x - \frac{5}{2} fg \right) \right) \mathrm{d}x \;.$$

Applying the identity

$$\begin{aligned} &ff_t + \eta \mathrm{e}^{-t}\big((fg)_t - \tfrac{x}{2}(fg)_x - 4fg - g^2\big) \\ &\quad = ff_{xx} + (\tfrac{x}{2} + \mathrm{e}^{t/2}\gamma(x\mathrm{e}^{t/2}))ff_x + \tfrac{3}{2}f^2 + \nu\gamma(x\mathrm{e}^{t/2})fg + 2\nu\mathrm{e}^{-t/2}fg_x + fr \ , \end{aligned} \tag{3.12}$$

which follows from (2.14), and integrating by parts, we obtain

$$\begin{aligned} \dot{E}_2 \ = \ \frac{3E_2}{2} + \int_{\mathbf{R}} \mathrm{e}^{-t} p_2(x\mathrm{e}^{t/2}) \bigg(&-f_x^2 + \frac{1}{2}\mathrm{e}^t \Gamma_2(x\mathrm{e}^{t/2}) f^2 + \eta \mathrm{e}^{-t} g^2 \\ &+ \nu(\gamma - 2\gamma_2)(x\mathrm{e}^{t/2})fg - 2\nu\mathrm{e}^{-t/2} f_x g + fr \bigg) \, \mathrm{d}x \ , \end{aligned} \tag{3.13}$$

where $\Gamma_2 = \gamma_2' - \gamma' - \gamma_2(\gamma - \gamma_2)$. As is easily verified, the right-hand side of (3.13) is a continuous function of the initial data $(u(t_0), v(t_0))$ in the topology of Z_{t_0}, uniformly in $t \in [t_0, t_1]$. Therefore, using a density argument as in the proof of Lemma 2.3, we conclude that $E_2 \in \mathcal{C}^1([t_0, t_1])$ and that (3.13) holds in the general case where $(u(t_0), v(t_0)) \in \mathrm{Z}_{t_0}$ only.

In a similar way, we obtain for regular data

$$\dot{\mathcal{E}}_2 \ = \ \int_{\mathbf{R}} \mathrm{e}^{-t} p_2(x\mathrm{e}^{t/2}) \left(f_x f_{xt} - \frac{x}{2} f_x f_{xx} - \frac{3}{4} f_x^2 + \eta \mathrm{e}^{-t} \left(g g_t - \frac{x}{2} g g_x - \frac{5}{4} g^2 \right) \right) \mathrm{d}x \ .$$

Using the relation $f_t = g + \frac{x}{2} f_x + \frac{3}{2} f$ as well as the identity

$$\begin{aligned} -f_{xx} f_t + \eta \mathrm{e}^{-t}\big(g g_t - \tfrac{x}{2} g g_x - \tfrac{5}{2} g^2 \big) \ &= \ -(1 - \nu\gamma(x\mathrm{e}^{t/2}))g^2 + 2\nu\mathrm{e}^{-t/2} g g_x \\ &\quad - \tfrac{x}{2} f_x f_{xx} - \tfrac{3}{2} f f_{xx} + \mathrm{e}^{t/2}\gamma(x\mathrm{e}^{t/2}) f_x g + gr \ , \end{aligned} \tag{3.14}$$

which follows from (2.14), we obtain after integrating by parts

$$\dot{\mathcal{E}}_2 \ = \ \frac{5\mathcal{E}_2}{2} + \int_{\mathbf{R}} \mathrm{e}^{-t} p_2(x\mathrm{e}^{t/2}) \big(-g^2 + (\nu g^2 + \mathrm{e}^{t/2} f_x g)(\gamma - \gamma_2)(x\mathrm{e}^{t/2}) + gr \big) \, \mathrm{d}x \ . \tag{3.15}$$

By the same density argument, $\mathcal{E}_2 \in \mathcal{C}^1([t_0, t_1])$ and (3.15) holds for all solutions (u, v) of (1.16) in Z_t.

We now estimate the right-hand side of (3.13). Since $|(\gamma - 2\gamma_2)(\xi)| \le \gamma(\xi)$ for $\xi \in \mathbf{R}$ and $\mathrm{e}^{-t} p_2(x\mathrm{e}^{t/2})\gamma(x\mathrm{e}^{t/2}) \le C\mathrm{e}^{-t/2}(1+x)$ for $x \ge 0$, we obtain with the help of (3.8)

$$\int_{\mathbf{R}} \mathrm{e}^{-t} p_2(x\mathrm{e}^{t/2}) |(\gamma - 2\gamma_2)(x\mathrm{e}^{t/2}) fg| \, \mathrm{d}x \ \le \ C\mathrm{e}^{-t/2} \|f\|_{\mathrm{L}^2_t} \|g\|_{\mathrm{L}^2_t} \ . \tag{3.16}$$

Remarking that $\Gamma_2(\xi) = 0$ for $\xi \ge 0$, we deduce from (3.8), (3.13), (3.16), and Lemma 2.6 that

$$\begin{aligned} \dot{E}_2 + \frac{1}{2} E_2 \le \int_0^\infty \mathrm{e}^{-t} p_2(x\mathrm{e}^{t/2})(f^2 - f_x^2) \, \mathrm{d}x + \frac{1}{2} \int_{-\infty}^0 p_2(x\mathrm{e}^{t/2}) \Gamma_2(x\mathrm{e}^{t/2}) f^2 \, \mathrm{d}x \\ + C\mathrm{e}^{-t/4}(\|f\|_{\mathrm{L}^2_t} + \|g\|_{\mathrm{L}^2_t}) M(t) \ . \end{aligned} \tag{3.17}$$

Since $\Gamma_2(\xi) \to -2\kappa(\gamma_- - 2\kappa) = -2\kappa c_*$ as $\xi \to -\infty$, we can write $\Gamma_2(\xi) \le -\kappa c_* + \Gamma_2^*(\xi)$ for all $\xi \le 0$, where Γ_2^* is a bounded nonnegative function with support in a compact

interval $[-A,0]$. Applying Lemma 2.4, we thus obtain

$$\begin{aligned}(3.18)\qquad &\int_{-\infty}^0 p_2(x\mathrm{e}^{t/2})\Gamma_2(x\mathrm{e}^{t/2})f^2\,\mathrm{d}x+\kappa c_*\int_{-\infty}^0 p_2(x\mathrm{e}^{t/2})f^2\,\mathrm{d}x\\ &\qquad\le \mathrm{e}^{-t/2}\sup_{x\ge -A\mathrm{e}^{-t/2}} f(x,t)^2\int_{-A}^0 p_2(\xi)\Gamma_2^*(\xi)\,\mathrm{d}\xi \,\le\, C\mathrm{e}^{-t/2}\|f\|_{\mathrm{H}^1_t}^2\ .\end{aligned}$$

Similarly, remarking that $\gamma_2(\xi)=\gamma(\xi)$ for $\xi\ge 0$, we deduce from (3.8), (3.15), and Lemma 2.6 that

$$(3.19)\quad \dot{\mathcal{E}}_2+\frac{1}{2}\mathcal{E}_2\,\le\,\int_0^\infty \mathrm{e}^{-t}p_2(x\mathrm{e}^{t/2})(\tfrac{3}{2}f_x^2-g^2)\,\mathrm{d}x+C\mathrm{e}^{-t/4}(\|f\|_{\mathrm{L}^2_t}+\|g\|_{\mathrm{L}^2_t})M(t)\ .$$

Combining (3.17), (3.18), (3.19), and using (2.26), (3.7), we obtain (3.11). This concludes the proof of Proposition 3.4. □

The construction of our next functionals E_3, $\mathcal{E}_3$ is one of the main difficulties in the proof of Theorem 1.2. The aim is to control the quantity

$$\int_{-\infty}^0 \mathrm{e}^{2\kappa x\mathrm{e}^{t/2}}\left(f^2+f_x^2+\eta\mathrm{e}^{-t}g^2\right)\,\mathrm{d}x+\int_0^\infty\left(f^2+f_x^2+\eta\mathrm{e}^{-t}g^2\right)\,\mathrm{d}x\ ,$$

which is part of the norm of (f,g) in Z_t. A natural idea is to define E_3, $\mathcal{E}_3$ by the formulas (3.9) with $\mathrm{e}^{-t}p_2(x\mathrm{e}^{t/2})$ replaced by $p_3(x\mathrm{e}^{t/2})$, where $p_3(\xi)=\mathcal{O}(\mathrm{e}^{2\kappa\xi})$ as $\xi\to-\infty$ and $p_3(\xi)\to 1$ as $\xi\to+\infty$. However, we are not able to estimate properly the time derivative of these functionals without including in $\mathcal{E}_3$ an additional term of the form

$$\int_{\mathbf{R}} p_3(x\mathrm{e}^{t/2})\lambda(x\mathrm{e}^{t/2})\gamma(x\mathrm{e}^{t/2})(\nu f_x^2-\eta\mathrm{e}^{-t/2}f_xg)\,\mathrm{d}x\ ;$$

see (3.25) below. With this modification, the derivative of $\mathcal{E}_3$ contains a quadratic form $Q(x,t)$ depending on the functions λ and p_3; see (3.30). As we shall show, the evolution of $E_3,\mathcal{E}_3$ can then be controlled provided $Q(x,t)$ is positive definite.

We now construct positive functions λ, p_3 so that the quadratic form $Q(x,t)$ in (3.30) is positive definite. First of all, since $\gamma_-=c_*+2\kappa>c_*$ and $\nu c_*<1$ by (1.9), we can define

$$(3.20)\qquad \lambda_-\,=\,\left(\frac{\gamma_-^2}{c_*^2}-\nu\gamma_-\right)^{-1}\,>\,0\ .$$

For later use, we remark that

$$(3.21)\qquad \lambda_-(1-\nu c_*)\,<\,(c_*/\gamma_-)^2<1\ ,\quad\text{and}\quad \lambda_-\gamma_-\,<\,\nu/\eta\ .$$

Next, in view of (1.11), (1.12), we can choose $\xi_3>0$ sufficiently large so that

$$(3.22)\qquad \gamma(\xi_3)\,<\,c_*\lambda_-\ ,\quad \nu\gamma(\xi_3)\,\le\,\frac{1}{2}\ ,\quad \gamma'(\xi)\,\le\,-\frac{1}{4}\gamma(\xi)^2\quad\text{for all}\quad \xi\ge\xi_3\ .$$

Remark that the first inequality in (3.22) is automatically satisfied if $\lambda_-\ge 1$, since $\gamma(0)=c_*$ and γ is nonincreasing. The conditions (3.21), (3.22) imply that there exists a smooth function $\lambda:\mathbf{R}\to\mathbf{R}_+$ satisfying $\lambda(\xi)=\lambda_-$ if $\xi\le 0$, $\lambda(\xi)=1$ if $\xi\ge\xi_3$, $(\lambda\gamma)'(\xi)\le 0$ for all $\xi\in\mathbf{R}$, and

$$(3.23)\qquad \lambda(\xi)\big((1-\nu\gamma(\xi))^2+\eta\gamma(\xi)^2\big)\,\le\,1\ ,\quad \xi\in[0,\xi_3]\ .$$

Indeed, assume first that $\lambda_- < 1$. Then the first inequality in (3.22) ensures that λ can be constructed so that $\lambda'(\xi) \geq 0$ and $(\lambda\gamma)'(\xi) \leq 0$ for $\xi \in [0, \xi_3]$. In particular, $\lambda(\xi) \leq 1$ for all $\xi \in \mathbf{R}$. On the other hand, we observe that the function

$$\Omega(\gamma) \,=\, (1-\nu\gamma)^2 + \eta\gamma^2 \,\equiv\, 1 - 2\nu\gamma + \frac{\nu\gamma^2}{c_*}$$

is nonincreasing for $\gamma \leq c_*$, with $\Omega(0) = 1$ and $\Omega(c_*) = 1 - \nu c_* > 0$. Since $\gamma(\xi) \leq c_*$ for $\xi \geq 0$, we have $\lambda(\xi)\Omega(\gamma(\xi)) \leq \Omega(0) = 1$ for $\xi \in [0, \xi_3]$, which is (3.23). Assume now that $\lambda_- \geq 1$, and choose λ so that $\lambda'(\xi) \leq 0$ for all $\xi \in \mathbf{R}$. Then the condition $(\lambda\gamma)'(\xi) \leq 0$ is automatically satisfied. Morevover, since $\lambda_-\Omega(\gamma(0)) < (c_*/\gamma_-)^2 < 1$ by (3.21), it is sufficient to assume that $\lambda(\xi)$ decays rapidly enough from λ_- to 1 (as ξ varies from 0 to ξ_3) so that (3.23) is satisfied.

We next define the weight function p_3. Let $\chi_3 : \mathbf{R} \to (0, 1]$ be a smooth function satisfying $\chi_3(\xi) = 2\kappa/\gamma_- < 1$ for $\xi \leq -1$, $\chi_3(\xi) = 1$ for $\xi \in [0, \xi_3]$, and $\chi_3(\xi) = 0$ for $\xi \geq \xi_3 + 1$. We also assume that $\xi\chi_3'(\xi) \leq 0$ for all $\xi \in \mathbf{R}$. We set $\gamma_3 = \chi_3\gamma$, and define the weight function $p_3 : \mathbf{R} \to \mathbf{R}_+$ as the (unique) solution of the differential problem

$$p_3'(\xi) \,=\, \gamma_3(\xi)p_3(\xi)\,, \quad \xi \in \mathbf{R}\,, \quad \lim_{\xi\to+\infty} p_3(\xi) \,=\, 1\,. \tag{3.24}$$

Clearly, there exists $C \geq 1$ such that $C^{-1} \leq p_3(\xi) \leq C$ for $\xi \geq 0$ and $C^{-1}\mathrm{e}^{2\kappa\xi} \leq p_3(\xi) \leq C\mathrm{e}^{2\kappa\xi}$ for $\xi \leq 0$.

With these definitions, we now introduce the functionals

$$\begin{aligned} E_3(t) \,&=\, \int_{\mathbf{R}} p_3(x\mathrm{e}^{t/2}) \left(\frac{1}{2}f^2 + \eta\mathrm{e}^{-t}fg\right) \mathrm{d}x\,, \\ \mathcal{E}_3(t) \,&=\, \frac{1}{2}\int_{\mathbf{R}} p_3(x\mathrm{e}^{t/2})\big(f_x^2 + \eta\mathrm{e}^{-t}g^2 + 2(\lambda\gamma)(x\mathrm{e}^{t/2})(\nu f_x^2 - \eta\mathrm{e}^{-t/2}f_xg)\big)\,\mathrm{d}x\,, \end{aligned} \tag{3.25}$$

together with $S_3(t) = KE_3(t) + \mathcal{E}_3(t)$, where $K = 3 + 4\nu\|\lambda\gamma\|_{\mathrm{L}^\infty}$.

Proposition 3.5. *Assume that $\eta\mathrm{e}^{-t_0}$ is sufficiently small, and that $(u, v) \in \mathcal{C}([t_0, t_1], \mathrm{Z}_t)$ is a solution of (1.16) satisfying the bound (2.20). Then $S_3 \in \mathcal{C}^1([t_0, t_1])$, and there exist positive constants K_9, K_{10} such that, for all $t \in [t_0, t_1]$,*

$$S_3(t) \,\geq\, \frac{1}{8}\int_{\mathbf{R}} p_3(x\mathrm{e}^{t/2})(f^2 + f_x^2 + \eta\mathrm{e}^{-t}g^2)\,\mathrm{d}x\,, \tag{3.26}$$

and

$$\begin{aligned} \dot{S}_3(t) + \frac{1}{2}S_3(t) \,\leq\, &- K_9\int_{\mathbf{R}} p_3(x\mathrm{e}^{t/2})(g^2 + f_x^2 + \mathrm{e}^t\gamma(x\mathrm{e}^{t/2})^2 f_x^2)\,\mathrm{d}x \\ &+ K_{10}\left(\int_{-\infty}^0 \mathrm{e}^{2\kappa x\mathrm{e}^{t/2}} f^2\,\mathrm{d}x + \int_0^\infty x^2 f_x^2\,\mathrm{d}x\right) \\ &+ K_{10}\big(\mathrm{e}^{-t/4}(\|f\|_{\mathrm{H}^1_t} + \|g\|_{\mathrm{L}^2_t})M(t) + \mathrm{e}^{-t/2}M(t)^2\big)\,. \end{aligned} \tag{3.27}$$

Proof. Since $|Kfg| \leq \frac{1}{8}g^2 + 2K^2f^2$ and $|\mathrm{e}^{-t/2}\lambda\gamma f_xg| \leq \frac{1}{4}\mathrm{e}^{-t}g^2 + (\lambda\gamma)^2 f_x^2$, we have

$$S_3 \geq \int_{\mathbf{R}} p_3(x\mathrm{e}^{t/2}) \left(\left(\frac{K}{2} - 2K^2\eta \mathrm{e}^{-t} \right) f^2 + \frac{1}{8}\eta \mathrm{e}^{-t} g^2 + \frac{1}{2} f_x^2 \big(1 + 2\nu\lambda\gamma - 2\eta\lambda^2\gamma^2\big)(x\mathrm{e}^{t/2}) \right) \mathrm{d}x \ .$$

Assuming that $\eta \mathrm{e}^{-t_0} \leq (8K)^{-1}$ and noting that $\nu - \eta\lambda\gamma \geq \nu - \eta\lambda_-\gamma_- > 0$ by (3.21), we obtain (3.26).

Next, proceeding as in the proof of Proposition 3.4, we show that $E_3 \in \mathcal{C}^1([t_0, t_1])$ and that

$$\dot{E}_3 = \frac{5E_3}{2} + \int_{\mathbf{R}} p_3(x\mathrm{e}^{t/2}) \big(-f_x^2 + \mathrm{e}^{t/2}(\gamma - \gamma_3)(x\mathrm{e}^{t/2}) f f_x + \eta \mathrm{e}^{-t} g^2 + \nu(\gamma - 2\gamma_3)(x\mathrm{e}^{t/2}) fg - 2\nu \mathrm{e}^{-t/2} f_x g + fr \big) \mathrm{d}x \tag{3.28}$$

for $t \in [t_0, t_1]$. The analysis of $\mathcal{E}_3$ is more complicated due to the additional term $2\lambda\gamma(\nu f_x^2 - \eta \mathrm{e}^{-t/2} f_x g)$. First, assuming that the initial data are regular, we obtain by a direct calculation

$$\dot{\mathcal{E}}_3 = \int_{\mathbf{R}} p_3(x\mathrm{e}^{t/2}) \big((1 + 2\nu(\lambda\gamma)(x\mathrm{e}^{t/2}))(f_x f_{xt} - \tfrac{x}{2} f_x f_{xx} - \tfrac{1}{4} f_x^2) + \eta \mathrm{e}^{-t}(g g_t - \tfrac{x}{2} g g_x - \tfrac{3}{4} g^2) - \eta \mathrm{e}^{-t/2}(\lambda\gamma)(x\mathrm{e}^{t/2})((f_x g)_t - \tfrac{x}{2}(f_x g)_x - f_x g) \big) \mathrm{d}x \ .$$

Using the relation $f_t = g + \frac{x}{2} f_x + \frac{3}{2} f$ together with the identities (3.14) and

$$\begin{aligned} 2\nu f_x f_{xt} - \eta \mathrm{e}^{-t/2} \big((f_x g)_t - \tfrac{x}{2}(f_x g)_x - \tfrac{9}{2} f_x g - g g_x \big) &= \mathrm{e}^{t/2}(1 - \nu\gamma(x\mathrm{e}^{t/2})) f_x g \\ &\quad - \mathrm{e}^{t/2} f_x f_{xx} - \mathrm{e}^{t} \gamma(x\mathrm{e}^{t/2}) f_x^2 + \nu x f_x f_{xx} + 4\nu f_x^2 - \mathrm{e}^{t/2} f_x r \ , \end{aligned} \tag{3.29}$$

which follow from (2.14), we obtain after integrating by parts

$$\dot{\mathcal{E}}_3 = \frac{7\mathcal{E}_3}{2} + \int_{\mathbf{R}} p_3(x\mathrm{e}^{t/2}) \big((g - \mathrm{e}^{t/2}(\lambda\gamma)(x\mathrm{e}^{t/2}) f_x) r - Q(x,t)[\mathrm{e}^{t/2}\gamma(x\mathrm{e}^{t/2}) f_x, g] \big) \mathrm{d}x \ , \tag{3.30}$$

where $Q(x,t)$ is the quadratic form defined by

$$\begin{aligned} Q(x,t)[z_1, z_2] = {} & z_1^2 \big(\lambda - \tfrac{1}{2}\lambda\gamma^{-1}(\gamma_3 + \mu) \big)(x\mathrm{e}^{t/2}) - z_1 z_2 \big(1 - \chi_3 + \lambda(1 - \nu\gamma) \big)(x\mathrm{e}^{t/2}) \\ & + z_2^2 \big(1 + \nu(\gamma_3 - \gamma) - \tfrac{1}{2}\eta\lambda\gamma(\gamma_3 + \mu) \big)(x\mathrm{e}^{t/2}) \ , \quad (z_1, z_2) \in \mathbf{R}^2 \ , \end{aligned}$$

and $\mu = (\lambda\gamma)'/(\lambda\gamma) \leq 0$. By density, (3.30) holds for all solutions (u, v) of (1.16) in Z_t.

Applying Lemma 2.6 and recalling that $K = 3 + 4\nu\|\lambda\gamma\|_{\mathrm{L}^\infty}$, we deduce from (3.28), (3.30) that

$$\begin{aligned} \dot{S}_3(t) + \frac{1}{2} S_3(t) \leq {} & \int_{\mathbf{R}} p_3(x\mathrm{e}^{t/2}) \big(-f_x^2 + \tfrac{3}{2} K f^2 - Q(x,t)[\mathrm{e}^{t/2}\gamma(x\mathrm{e}^{t/2}) f_x, g] \\ & - \mathrm{e}^{t/2}(\lambda\gamma)(x\mathrm{e}^{t/2}) f_x r + \nu K(\gamma - 2\gamma_3)(x\mathrm{e}^{t/2}) fg + K\mathrm{e}^{t/2}(\gamma - \gamma_3)(x\mathrm{e}^{t/2}) f f_x \big) \mathrm{d}x \\ & + C\mathrm{e}^{-t/4}(\|f\|_{\mathrm{H}^1_t} + \|g\|_{\mathrm{L}^2_t}) M(t) \ . \end{aligned} \tag{3.31}$$

We shall prove below that there exists $Q_0 > 0$ such that, for all $(x,t) \in \mathbf{R} \times \mathbf{R}_+$,

$$Q(x,t)[z_1, z_2] \geq Q_0(z_1^2 + z_2^2) \ , \quad (z_1, z_2) \in \mathbf{R}^2 \ . \tag{3.32}$$

Assuming for a while that (3.32) holds, and using Lemma 2.6 together with the inequalities

$$K\mathrm{e}^{t/2}\gamma(1-\chi_3)ff_x - \mathrm{e}^{t/2}\lambda\gamma f_x r \,\le\, \frac{Q_0}{2}\mathrm{e}^t\gamma^2 f_x^2 + \frac{K^2}{Q_0}f^2 + \frac{1}{Q_0}\lambda^2 r^2 \,,$$
$$\nu K\gamma(1-2\chi_3)fg \,\le\, \frac{Q_0}{2}g^2 + \frac{\nu^2K^2}{2Q_0}\gamma^2 f^2 \,,$$

we deduce from (3.31) that

(3.33)
$$\dot S_3(t) + \frac12 S_3(t) \,\le\, \int_{\mathbf{R}} p_3(x\mathrm{e}^{t/2})\left(-f_x^2 - \frac{Q_0}{2}(g^2 + \mathrm{e}^t\gamma(x\mathrm{e}^{t/2})^2 f_x^2)\right)\mathrm{d}x$$
$$+ C\left(\int_{\mathbf{R}} p_3(x\mathrm{e}^{t/2})f^2\,\mathrm{d}x + \mathrm{e}^{-t/2}M(t)^2 + \mathrm{e}^{-t/4}(\|f\|_{\mathrm{H}^1_t} + \|g\|_{\mathrm{L}^2_t})M(t)\right) \,.$$

The estimate (3.27) is then a straightforward consequence of (3.33) and of the Hardy-type inequality

$$\int_{\mathbf{R}} p_3(x\mathrm{e}^{t/2})f^2\,\mathrm{d}x \,\le\, C\left(\int_{-\infty}^0 \mathrm{e}^{2\kappa x\mathrm{e}^{t/2}}f^2\,\mathrm{d}x + \int_0^\infty x^2 f_x^2\,\mathrm{d}x\right) \,.$$

It remains to prove the property (3.32), namely,

$$\big(1-\chi_3+\lambda(1-\nu\gamma)\big)^2 \,<\, 4\big(\lambda - \tfrac12\lambda\gamma^{-1}(\gamma_3+\mu)\big)\big(1+\nu(\gamma_3-\gamma) - \tfrac12\eta\lambda\gamma(\gamma_3+\mu)\big)$$

for all $\xi\in[-\infty,+\infty]$. Expanding the products in both sides, we rewrite this condition in the equivalent form

$$(1-\chi_3)^2(1+2\nu\lambda\gamma-\eta\lambda^2\gamma^2) - 2\lambda + \lambda^2\big((1-\nu\gamma)^2+\eta\gamma^2\big)$$
$$< \eta\lambda^2\mu^2 - 2\lambda^2\eta\mu(\gamma-\gamma_3) - 2\lambda\gamma^{-1}\mu(1-\nu(\gamma-\gamma_3)) \,. \tag{3.34}$$

To prove (3.34), we first remark that the right-hand side is positive, since $\mu\le 0$, $\gamma-\gamma_3\ge 0$, and $1-\nu(\gamma-\gamma_3)\ge 1-\nu c_*>0$. We also recall that $1+2\nu\lambda\gamma-\eta\lambda^2\gamma^2\ge 1$, since $\nu-\eta\lambda\gamma>0$ (the last inequality follows from (3.21) and the fact that $(\lambda\gamma)'\le 0$). We now distinguish three cases according to whether $\xi\le 0$, $\xi\in[0,\xi_3]$, or $\xi\ge\xi_3$.

(1) If $\xi\le 0$, then $\lambda=\lambda_-$ and $1-\chi_3\le c_*/\gamma_-$; hence it is sufficient to verify the stronger condition

$$\frac{c_*^2}{\gamma_-^2}(1+2\nu\lambda_-\gamma-\eta\lambda_-^2\gamma^2) - 2\lambda_- + \lambda_-^2\big((1-\nu\gamma)^2+\eta\gamma^2\big) \,<\, 0 \tag{3.35}$$

for all $\gamma\in[c_*,\gamma_-]$. Let $\Psi(\gamma)$ denote the left-hand side of (3.35), considered as a function of γ. Using (3.21) and the relation $\nu^2+\eta=\nu/c_*$, it is not difficult to verify that Ψ is convex and that

$$\Psi(\gamma_-) \,=\, -\lambda_-^2(1-\nu c_*)\left(\frac{\gamma_-^2}{c_*^2}-1\right) \,<\, 0 \,, \quad \Psi'(c_*) \,=\, \frac{2c_*^2\lambda_-}{\gamma_-^2}(\nu-\eta c_*\lambda_-) \,>\, 0 \,.$$

Since $\Psi''>0$, it follows that $\Psi'(\gamma)\ge\Psi'(c_*)>0$ for all $\gamma\ge c_*$, hence $\Psi(\gamma)\le\Psi(\gamma_-)<0$ for all $\gamma\in[c_*,\gamma_-]$, which is the desired inequality.

(2) If $\xi\in[0,\xi_3]$, then $\chi_3=1$; hence the left-hand side of (3.34) is negative by (3.23).

(3) If $\xi \geq \xi_3$, then $\lambda = 1$, $1-\chi_3 \leq 1$, hence the left-hand side of (3.34) is bounded from above by $\nu^2\gamma^2$. Neglecting the first two terms in the right-hand side (which are positive) and noting that $\mu = \gamma'/\gamma \leq 0$, we arrive at the stronger condition

$$\nu^2\gamma(\xi)^2 \;\leq\; -2\frac{\gamma'(\xi)}{\gamma(\xi)^2}\big(1-\nu\gamma(\xi)\big)\;, \quad \xi \geq \xi_3\;,$$

which is satisfied by assumption on ξ_3; see (3.22). This concludes the proof of Proposition 3.5. □

Finally, we introduce our last pair of functionals

$$\begin{aligned} E_4(t) \;&=\; \int_{\mathbf{R}} \mathrm{e}^{-3t} p_4(x\mathrm{e}^{t/2}) \left(\frac{1}{2}f^2 + \eta \mathrm{e}^{-t} fg\right) \mathrm{d}x\;, \\ \mathcal{E}_4(t) \;&=\; \frac{1}{2}\int_{\mathbf{R}} \mathrm{e}^{-3t} p_4(x\mathrm{e}^{t/2})(f_x^2 + \eta \mathrm{e}^{-t} g^2)\,\mathrm{d}x\;, \end{aligned} \tag{3.36}$$

where $p_4(\xi) = p(\xi)^3$. We set $S_4 = 2E_4 + \mathcal{E}_4$.

Proposition 3.6. *Assume that $\eta \mathrm{e}^{-t_0} \leq 1/8$ and that $(u,v) \in \mathcal{C}([t_0,t_1],\mathrm{Z}_t)$ is a solution of (1.16) satisfying the bound (2.20). Then $S_4 \in \mathcal{C}^1([t_0,t_1])$ and there exist positive constants K_{11}, K_{12}, such that for $t \in [t_0,t_1]$,*

$$S_4(t) \;\geq\; \frac{1}{4}\int_{\mathbf{R}} \mathrm{e}^{-3t} p_4(x\mathrm{e}^{t/2})(f^2 + f_x^2 + \eta \mathrm{e}^{-t} g^2)\,\mathrm{d}x \tag{3.37}$$

and

$$\begin{aligned} \dot S_4(t) + \frac{1}{2}S_4(t) \;&\leq\; -K_{11}\int_0^\infty x^6(f_x^2+g^2)\,\mathrm{d}x \\ &\quad + K_{12}\left(\int_0^\infty (x^4f^2 + x^2 f_x^2)\,\mathrm{d}x + \mathrm{e}^{-t/4}(\|f\|_{\mathrm{H}^1_t} + \|g\|_{\mathrm{L}^2_t})M(t)\right)\;. \end{aligned} \tag{3.38}$$

Proof. The lower bound (3.37) is proved as in (3.10). Arguing as the preceding propositions, we show that $E_4, \mathcal{E}_4 \in \mathcal{C}^1([t_0,t_1])$ and that

$$\begin{aligned} \dot E_4 \;=\; -\frac{E_4}{2} + \int_{\mathbf{R}} \mathrm{e}^{-3t} p_4(x\mathrm{e}^{t/2})\big(&- f_x^2 - 2\mathrm{e}^{t/2}\gamma(x\mathrm{e}^{t/2}) f f_x + \eta \mathrm{e}^{-t} g^2 \\ &- 5\nu\gamma(x\mathrm{e}^{t/2}) fg - 2\nu \mathrm{e}^{-t/2} f_x g + fr\big)\,\mathrm{d}x\;, \end{aligned}$$

$$\dot{\mathcal{E}}_4 \;= \frac{\mathcal{E}_4}{2} + \int_{\mathbf{R}} \mathrm{e}^{-3t} p_4(x\mathrm{e}^{t/2})\big(-g^2 - 2\gamma(x\mathrm{e}^{t/2})(\nu g^2 + \mathrm{e}^{t/2} f_x g) + gr\big)\,\mathrm{d}x\;.$$

Proceeding as in (3.16) and applying Lemma 2.6, we deduce that, for $t \in [t_0,t_1]$,

$$\begin{aligned} \dot S_4(t) + \frac{1}{2}S_4(t) \;&\leq\; C\mathrm{e}^{-t/4}(\|f\|_{\mathrm{H}^1_t} + \|g\|_{\mathrm{L}^2_t})M(t) \\ &\quad + \int_0^\infty \mathrm{e}^{-3t} p_4(x\mathrm{e}^{t/2})\big(-\tfrac{3}{2}f_x^2 - g^2 - 2\mathrm{e}^{t/2}\gamma(x\mathrm{e}^{t/2})(f_x g + 2f f_x)\big)\,\mathrm{d}x\;. \end{aligned} \tag{3.39}$$

Since $p_4(\xi) = p(\xi)^3 \leq C_0^3(1+\xi)^6$ for $\xi \geq 0$, we have

$$
\begin{aligned}
&\mathrm{e}^{-3t}(\gamma p_4)(x\mathrm{e}^{t/2})|2\mathrm{e}^{t/2}f_x g + 4\mathrm{e}^{t/2}f f_x| \\
&\qquad \le \mathrm{e}^{-3t}p_4(x\mathrm{e}^{t/2})\big(\tfrac{1}{2}g^2 + f_x^2 + 2\mathrm{e}^{2t}\gamma(x\mathrm{e}^{t/2})^4 f_x^2 + 8\mathrm{e}^{t}\gamma(x\mathrm{e}^{t/2})^2 f^2\big) \\
&\qquad \le \mathrm{e}^{-3t}p_4(x\mathrm{e}^{t/2})\big(\tfrac{1}{2}g^2 + f_x^2\big) + C\big(\mathrm{e}^{-t}(1+x\mathrm{e}^{t/2})^2 f_x^2 + \mathrm{e}^{-2t}(1+x\mathrm{e}^{t/2})^4 f^2\big)
\end{aligned}
$$

for $x \ge 0$, and the estimate (3.38) follows from (3.39). This concludes the proof of Proposition 3.6. □

We now summarize the decay properties of the four auxiliary functionals S_1, S_2, S_3, and S_4. To this end, we define

$$
S_5(t) \,=\, B_1 S_1(t) + B_2 S_2(t) + S_3(t) + S_4(t) + \frac{1}{2}\eta \mathrm{e}^{-t}\beta(t)^2 \,,
$$

where $B_2 = 1 + K_7^{-1}(K_{10} + K_{12})$, $B_1 = 1 + K_5^{-1}(K_8 B_2 + K_{12})$, and β is as in (2.10). In the proof of Theorem 1.2, we shall use the following properties of $S_5(t)$.

PROPOSITION 3.7. *There exist constants $A_1, A_3, A_4 > 0$ and $A_2 \ge 1$ such that, if $\eta \mathrm{e}^{-t_0} \le A_1$ and if $(u,v) \in \mathcal{C}([t_0,t_1],\mathrm{Z}_t)$ is a solution of (1.16) satisfying the bound (2.20), then, for all $t \in [t_0,t_1]$,*

$$
A_2^{-1} S_5(t) \,\le\, \|f(t)\|_{\mathrm{H}^1_t}^2 + \eta \mathrm{e}^{-t}\big(\beta(t)^2 + \|g(t)\|_{\mathrm{L}^2_t}^2\big) \,\le\, A_2 S_5(t) \,, \tag{3.40}
$$

and

$$
\begin{aligned}
\dot S_5(t) + \frac{1}{2}S_5(t) \,\le\, &- A_3\big(\beta(t)^2 + \|g(t)\|_{\mathrm{L}^2_t}^2 + \|f_x(t)\|_{\mathrm{L}^2_t}^2\big) \\
&+ A_4 \mathrm{e}^{-t/4}\big(\|f(t)\|_{\mathrm{H}^1_t} + \|g(t)\|_{\mathrm{L}^2_t} + \mathrm{e}^{-t/4}M(t)\big)M(t) \,,
\end{aligned} \tag{3.41}
$$

where $M(t)^2 = \alpha(t)^2 + \beta(t)^2 + \|f(t)\|_{\mathrm{H}^1_t}^2 + \|g(t)\|_{\mathrm{L}^2_t}^2$.

Proof. Since $S_1(t) \ge 0$ by Proposition 3.3, the lower bound on S_5 in (3.40) follows immediately from (3.10), (3.26), (3.37), and the properties of the weights p_2, p_3, p_4. The upper bound is proved in a similar way by using, in addition, Lemma 2.7 applied to F and G. On the other hand, we have, by Lemmas 2.3 and 2.6,

$$
\begin{aligned}
\frac{\mathrm{d}}{\mathrm{d}t}\left(\frac{1}{2}\eta \mathrm{e}^{-t}\beta(t)^2\right) + \frac{1}{4}\eta \mathrm{e}^{-t}\beta(t)^2 \,&=\, -\beta(t)^2 + \frac{3}{4}\eta \mathrm{e}^{-t}\beta(t)^2 + m(t)\beta(t) \\
&\le\, -\beta(t)^2 + C\mathrm{e}^{-t/2}M(t)^2 \,.
\end{aligned} \tag{3.42}
$$

Combining the estimates (3.6), (3.11), (3.27), (3.38), and (3.42), we thus obtain

$$
\begin{aligned}
\dot S_5(t) + \frac{1}{2}S_5(t) \,\le\, &-K_5\int_0^\infty (x^2+x^4) f^2 \,\mathrm{d}x - K_7 \int_{-\infty}^0 \mathrm{e}^{2\kappa x \mathrm{e}^{t/2}} f^2 \,\mathrm{d}x \\
&- \int_0^\infty (K_7 x^2 + K_{11} x^6)(f_x^2 + g^2)\,\mathrm{d}x - K_9 \int_{\mathbf{R}} p_3(x\mathrm{e}^{t/2})(g^2 + f_x^2)\,\mathrm{d}x - \beta(t)^2 \\
&+ C\mathrm{e}^{-t/4}\big(\|f(t)\|_{\mathrm{H}^1_t} + \|g(t)\|_{\mathrm{L}^2_t} + \mathrm{e}^{-t/4}M(t)\big)M(t) \,,
\end{aligned}
$$

from which (3.41) follows using the properties of the weight p_3. This concludes the proof of Proposition 3.7. □

A useful consequence of Proposition 3.7 is the following.

COROLLARY 3.8. *There exist constants $A_5 > 0$ and $A_6 \geq 1$ such that, if $t_0 \geq A_5$ and if $(u, v) \in \mathcal{C}([t_0, t_1], \mathrm{Z}_t)$ is a solution of (1.16) satisfying the bound (2.20), then*

$$\Phi_\eta(t, u(t), v(t)) \equiv \|u(t)\|^2_{\mathrm{H}^1_t} + \eta \mathrm{e}^{-t}\|v(t)\|^2_{\mathrm{L}^2_t} \leq A_6 \Phi_\eta(t_0, u(t_0), v(t_0)) \tag{3.43}$$

for all $t \in [t_0, t_1]$.

Proof. We introduce our last functional:

$$S_6(t) = \frac{1}{2}\alpha(t)^2 + \eta \mathrm{e}^{-t}\alpha(t)\beta(t) + S_5(t) \ , \quad t \in [t_0, t_1] \ .$$

In view of (3.40), if $\eta \mathrm{e}^{-t_0} \leq \min(A_1, A_2^{-1})$, there exists a constant $\tilde{C}_1 \geq 1$ such that, for $t \in [t_0, t_1]$,

$$\tilde{C}_1^{-1} S_6(t) \leq \alpha(t)^2 + \|f(t)\|^2_{\mathrm{H}^1_t} + \eta \mathrm{e}^{-t}\big(\beta(t)^2 + \|g(t)\|^2_{\mathrm{L}^2_t}\big) \leq \tilde{C}_1 S_6(t) \ . \tag{3.44}$$

By Lemma 2.5, it follows that

$$\tilde{C}_2^{-1} S_6(t) \leq \Phi_\eta(t, u(t), v(t)) \leq \tilde{C}_2 S_6(t) \ , \quad t \in [t_0, t_1] \ , \tag{3.45}$$

for some $\tilde{C}_2 \geq 1$. Now, since $\dot{S}_6(t) = \alpha(t)m(t) + \eta \mathrm{e}^{-t}\beta(t)^2 + \dot{S}_5(t)$ by (2.12), we deduce from (2.31) and (3.41) that

$$\dot{S}_6(t) \leq -A_3(\beta(t)^2 + \|g(t)\|^2_{\mathrm{L}^2_t}) + \tilde{C}_3 \mathrm{e}^{-t/4} M(t)^2 \ , \quad t \in [t_0, t_1] \ ,$$

for some $\tilde{C}_3 > 0$. Assuming that $\tilde{C}_3 \mathrm{e}^{-t_0/4} \leq A_3$ and using (3.44), we thus find $\dot{S}_6(t) \leq \tilde{C}_1 \tilde{C}_3 \mathrm{e}^{-t/4} S_6(t)$ for $t \in [t_0, t_1]$, hence $S_6(t) \leq \tilde{C}_4 S_6(t_0)$ for $t \in [t_0, t_1]$, where $\tilde{C}_4 = \exp(4\tilde{C}_1\tilde{C}_3)$. Combining this estimate with (3.45), we obtain (3.43). This concludes the proof of Corollary 3.8. □

4. End of the proof of Theorem 1.2. Let $t_0 \geq A_5$ and $\delta_0 \leq (2A_6)^{-1/2}$, where A_5, A_6 are as in Corollary 3.8. If $(u_0, v_0) \in \mathrm{Z}_{t_0}$ satisfies $\Phi_\eta(t_0, u_0, v_0) \leq \delta_0^2$, then the system (1.16) has a unique global solution $(u, v) \in \mathcal{C}([t_0, +\infty), \mathrm{Z}_t)$ with $(u(t_0), v(t_0)) = (u_0, v_0)$. Indeed, the local existence and uniqueness follow from Proposition 2.2, and Corollary 3.8 shows that $\Phi_\eta(t, u(t), v(t)) \leq 1/2$ as long as the solution $(u(t), v(t))$ exists. Then Proposition 2.2, with $\delta_1 = 1/\sqrt{2}$, implies that the solution $(u(t), v(t))$ is globally defined.

It remains to prove the decay estimate (1.23). Since

$$\begin{aligned}
A_4 \mathrm{e}^{-t/4}\|g\|_{\mathrm{L}^2_t} M &\leq \frac{A_3}{4}\|g\|^2_{\mathrm{L}^2_t} + C\mathrm{e}^{-t/2}M^2 \ , \\
A_4 \mathrm{e}^{-t/4}\|f\|_{\mathrm{H}^1_t} M &\leq \frac{A_3}{4}(\beta^2 + \|g\|^2_{\mathrm{L}^2_t}) + A_4 \mathrm{e}^{-t/4}\|f\|_{\mathrm{H}^1_t}(|\alpha| + \|f\|_{\mathrm{H}^1_t}) + C\mathrm{e}^{-t/2}M^2 \ ,
\end{aligned}$$

it follows from (3.41) that

$$\dot{S}_5 + \frac{1}{2}S_5 \leq -\frac{A_3}{2}(\beta^2 + \|g\|^2_{\mathrm{L}^2_t}) + A_4 \mathrm{e}^{-t/4}\|f\|_{\mathrm{H}^1_t}(|\alpha| + \|f\|_{\mathrm{H}^1_t}) + \tilde{C}_5 \mathrm{e}^{-t/2} M^2$$

for some $\tilde{C}_5 > 0$. Setting $\rho_0^2 = \tilde{C}_1\tilde{C}_2 A_6 \Phi_\eta(t_0, u_0, v_0)$, we have $\alpha(t)^2 + \|f(t)\|^2_{\mathrm{H}^1_t} \leq \rho_0^2$ by (3.43), (3.44), (3.45) and $\|f(t)\|^2_{\mathrm{H}^1_t} \leq A_2 S_5(t)$ by (3.40). Therefore, assuming that $\tilde{C}_5 \mathrm{e}^{-t_0/4} \leq A_3/4$, we find

$$\dot{S}_5 + \frac{1}{2}S_5 \leq -\frac{A_3}{4}(\beta^2 + \|g\|^2_{\mathrm{L}^2_t}) + \tilde{C}_6\rho_0 \mathrm{e}^{-t/4} S_5^{1/2} + \tilde{C}_5 \rho_0^2 \mathrm{e}^{-t/2} \ , \quad t \geq t_0 \ ,$$

for some $\tilde{C}_6 > 0$. Integrating this differential inequality and using the bound $S_5(t_0) \leq A_2\rho_0^2$, we obtain after a short computation

$$S_5(t) + \int_{t_0}^{t} \mathrm{e}^{-(t-s)/2}(\beta(s)^2 + \|g(s)\|_{\mathrm{L}^2_s}^2)\,\mathrm{d}s \;\leq\; \tilde{C}_7\rho_0^2(1+(t-t_0)^2)\mathrm{e}^{-(t-t_0)/2} \tag{4.1}$$

for $t \geq t_0$, where $\tilde{C}_7 > 0$ is independent of t_0 and ρ_0. In view of (3.40), this implies, in particular,

$$\|f(t)\|_{\mathrm{H}^1_t}^2 + \eta\mathrm{e}^{-t}(\beta(t)^2 + \|g(t)\|_{\mathrm{L}^2_t}^2) \;\leq\; A_2\tilde{C}_7\rho_0^2(1+(t-t_0)^2)\mathrm{e}^{-(t-t_0)/2}, \quad t \geq t_0\ . \tag{4.2}$$

Since $\dot{\alpha}(t) = \beta(t)$, we also deduce from (4.1), by a simple argument, that $\alpha(t)$ converges to some real number α^* as $t \to +\infty$ and that

$$|\alpha(t)-\alpha^*|^2 + \int_{t_0}^{t} \mathrm{e}^{-(t-s)/2}|\alpha(s)-\alpha^*|^2\,\mathrm{d}s \;\leq\; \tilde{C}_8\rho_0^2(1+(t-t_0)^2)\mathrm{e}^{-(t-t_0)/2} \tag{4.3}$$

for some $\tilde{C}_8 > 0$ and all $t \geq t_0$. Finally, it follows from (2.9) that

$$\begin{aligned}
&\|u(t) - \alpha^*\varphi^*\|_{\mathrm{H}^1_t} \leq \|f(t)\|_{\mathrm{H}^1_t} + |\alpha(t)-\alpha^*|\,\|\varphi(t)\|_{\mathrm{H}^1_t} + |\alpha^*|\,\|\varphi(t)-\varphi^*\|_{\mathrm{H}^1_t}\ ,\\
&\|v(t) - \alpha^*\psi^*\|_{\mathrm{L}^2_t} \leq \|g(t)\|_{\mathrm{L}^2_t} + |\beta(t)|\,\|\varphi\|_{\mathrm{L}^2_t} + |\alpha(t)-\alpha^*|\,\|\psi\|_{\mathrm{L}^2_t} + |\alpha^*|\,\|\psi(t)-\psi^*\|_{\mathrm{L}^2_t};
\end{aligned}$$

hence the estimate (1.23) is a direct consequence of (2.28), (2.29), (4.1), (4.2), and (4.3). This concludes the proof of Theorem 1.2. □

RADIATION REACTION AND CENTER MANIFOLDS*

MARKUS KUNZE† AND HERBERT SPOHN‡

Abstract. We study the effective dynamics of a mechanical particle coupled to a wave field and subject to the slowly varying potential $V(\varepsilon q)$ with ε small. To lowest order in ε the motion of the particle is governed by an effective Hamiltonian. In the next order one obtains "dissipative" terms which describe the radiation reaction. We establish that this dissipative dynamics has a center manifold which is repulsive in the normal direction and which is global, in the sense that for given data and sufficiently small ε the solution stays on the center manifold forever. We prove that the solution of the full system is well approximated by the effective dissipative dynamics on its center manifold.

Key words. wave equation, adiabatic limit, effective friction

1. Introduction.

At the beginning of this century, in the context of the Maxwell–Lorentz equations, radiation reaction was one of the most outstanding problems in theoretical physics. It was left more or less unfinished when theoreticians turned to quantum electrodynamics. In this paper we study radiation reaction in the mathematically somewhat more accessible case of a scalar wave field. We believe that our results provide good indications on the effective dynamics for a charge coupled to the Maxwell field [14].

To explain in more detail the physical context we have to set up the model first. We consider a particle with position $q(t) \in \mathbb{R}^3$, momentum $p(t) \in \mathbb{R}^3$, and "charge" distribution ρ of total charge

$$\mathsf{e} = \int d^3x \rho(x).$$

We require that ρ be smooth, radial, and supported in a ball of radius R_ρ,

$$\text{(C)} \qquad \rho \in C_0^\infty(\mathbb{R}^3), \quad \rho(x) = \rho_r(|x|), \quad \rho(x) = 0 \quad \text{for} \quad |x| \geq R_\rho.$$

The particle is coupled to the scalar wave field $\phi(x,t)$ with the canonically conjugate momentum field $\pi(x,t)$, $x \in \mathbb{R}^3$. In addition the particle is subject to an external potential, V, whose properties will be listed below. We assume that the potential is *slowly varying* on the scale of the charge distribution, i.e., on the scale set by R_ρ. We formally introduce the dimensionless parameter ε, $\varepsilon \ll 1$, and consider the scale of potentials $V(\varepsilon q)$, $\varepsilon \to 0$. The equations of motion for the coupled system are

$$\begin{aligned} &\dot\phi(x,t) = \pi(x,t), \qquad \dot\pi(x,t) = \Delta\phi(x,t) - \rho(x - q(t)), \\ &\dot q(t) = \frac{p(t)}{\sqrt{1+p(t)^2}}, \quad \dot p(t) = -\varepsilon \nabla V(\varepsilon q(t)) + \int d^3x\, \phi(x,t) \nabla\rho(x - q(t)). \end{aligned} \tag{1.1}$$

The dynamics governed by (1.1) has three distinct time scales, well separated as $\varepsilon \to 0$. On the *microscopic* time scale, $t = \mathcal{O}(1)$, the particle moves along an essentially straight line and the field adjusts itself stationarily. On a time scale $\mathcal{O}(\varepsilon^{-1})$, which we call the *macroscopic* scale, the particle feels the potential and responds to it with an effective kinetic energy which incorporates the coupling to the field. This scale was studied in [5]. The particle loses energy through radiation at a rate roughly proportional to $\ddot{q}(t)^2$. Thus on the macroscopic time scale, friction through radiation is of order ε. To resolve such an effect we have to go to an even longer time scale or must look with higher precision. The *friction* time scale is the subject of our paper.

The dynamics of (1.1) is of Hamiltonian form. We need a few facts in case the external potential vanishes, i.e., $V = 0$. Then (1.1) has the energy

$$\mathcal{H}_0(\phi, \pi, q, p) = (1 + p^2)^{1/2} + \frac{1}{2} \int d^3x \, (|\pi(x)|^2 + |\nabla\phi(x)|^2) + \int d^3x \, \phi(x)\rho(x - q)$$

and the conserved total momentum

$$\mathcal{P}(\phi, \pi, q, p) = p + \int d^3x \, \phi(x) \nabla\pi(x).$$

The minimum of $\mathcal{H}_0$, at fixed $\mathcal{P}$, is attained at

$$S_{q,v} = (\phi_v(x - q), \pi_v(x - q), q, p_v), \tag{1.2}$$

where $v \in \mathcal{V} = \{v : |v| < 1\}$, $p_v = v/\sqrt{1 - v^2}$, $\pi_v = -v \cdot \nabla\phi_v$, and $\hat{\phi}_v(k) = -\hat{\rho}(k)/[k^2 - (v \cdot k)^2]$; the hat denotes Fourier transform. We call $S_{q,v}$ the soliton centered at q, v. It has the normalized energy

$$\begin{aligned} \mathcal{E}_s(v) &= \mathcal{H}_0(S_{q,v}) - \mathcal{H}_0(S_{q,0}) \\ &= (1 - v^2)^{-1/2} - 1 + 3m_e \left[\frac{2 - v^2}{2(1 - v^2)} - \frac{1}{2|v|} \log \frac{1 + |v|}{1 - |v|} \right] \end{aligned}$$

and the total momentum

$$\begin{aligned} \mathcal{P}_s(v) &= \mathcal{P}(S_{q,v}) \\ &= v(1 - v^2)^{-1/2} + 3m_e v \left[\frac{1}{2v^2(1 - v^2)} - \frac{1}{4|v|^3} \log \frac{1 + |v|}{1 - |v|} \right]. \end{aligned} \tag{1.3}$$

Here $m_e = \frac{1}{3} \int d^3k \, |\hat{\rho}(k)|^2 k^{-2}$ is the mass of the particle due to the coupling to the field. We note that because of the Hamiltonian structure we have the identity $v(d\mathcal{P}_s/dv) = (d\mathcal{E}_s/dv)$.

Taking $S_{q,v}$ as initial conditions for (1.1) with $V = 0$ we obtain a solution travelling at constant velocity v,

$$S_{q,v}(t) = (\phi_v(x - q - vt), \pi_v(x - q - vt), q + vt, p_v), \quad v \in \mathcal{V}.$$

Let us call $\{S_{q,v} : q \in \mathbb{R}^3, v \in \mathcal{V}\}$ the six-dimensional soliton manifold, $\mathcal{S}$. Thus, for $V = 0$, if we start initially on $\mathcal{S}$ the solution remains on $\mathcal{S}$ and moves along the straight line $t \mapsto q^0 + v^0 t$. In fact, if we start close to $\mathcal{S}$, then $\mathcal{S}$ is approached asymptotically [6]. When the particle is subject to a slowly varying external potential, then the rough picture is that the solution will remain close to $\mathcal{S}$ in the course of time. For simplicity we assume throughout that the initial datum for (1.1) lies exactly on $\mathcal{S}$, i.e.,

$$(\phi(0), \pi(0), q(0), p(0)) = S_{q^0, v^0}. \tag{1.4}$$

Possible generalizations are discussed below.

At this point it is instructive to transform (1.1) to the macroscopic space-time scale in such a way that the field energy remains constant. Then the macroscopic variables, denoted by a $'$, are

$$t = \varepsilon^{-1}t', \quad x = \varepsilon^{-1}x', \quad q(t) = \varepsilon^{-1}q'(t'), \quad \text{and} \quad \phi(x,t) = \sqrt{\varepsilon}\phi'(x',t').$$

We also set

$$\rho_\varepsilon(x) = \varepsilon^{-3}\rho(\varepsilon^{-1}x).$$

In particular, $\rho_\varepsilon(x) = 0$ for $|x| \geq \varepsilon R_\rho$ and $\int d^3x \rho_\varepsilon(x) = \int d^3x \rho(x)$. With this convention, omitting the primes and indicating explicitly only the ε-dependence of $q'(t')$, we arrive at

$$\begin{aligned} \ddot{\phi}(x,t) &= \Delta\phi(x,t) - \sqrt{\varepsilon}\rho_\varepsilon(x - q^\varepsilon(t)), \\ \dot{q}^\varepsilon(t) &= v^\varepsilon(t), \\ m_0(v^\varepsilon(t))\dot{v}^\varepsilon(t) &= -\nabla V(q^\varepsilon(t)) + \sqrt{\varepsilon}\int d^3x\, \phi(x,t)\nabla\rho_\varepsilon(x - q^\varepsilon(t)). \end{aligned} \tag{1.5}$$

Here $m_0(v)$ is the 3×3 matrix defined through $m_0(v)\dot{v} = \gamma\dot{v} + \gamma^3(v \cdot \dot{v})v$ with $\gamma(v) = 1/\sqrt{1-v^2}$. Rather than momenta as in (1.1) we use velocities, which turns out to be more convenient in our context. The initial soliton (1.4) transforms to

$$S^\varepsilon_{q^0,v^0} = (\phi^\varepsilon_{v^0}(x - q^0), \pi^\varepsilon_{v^0}(x - q^0), q^0, v^0), \tag{1.6}$$

where $\hat{\phi}^\varepsilon_v(k) = -\sqrt{\varepsilon}\hat{\rho}(\varepsilon k)/[k^2 - (v \cdot k)^2]$ and $\pi^\varepsilon_v = -v \cdot \nabla\phi^\varepsilon_v$. Thus, on the macroscopic scale, the total charge is $\sqrt{\varepsilon}\int d^3x\rho(x)$, whereas

$$m_e = \frac{1}{3}\varepsilon\int d^3k |\hat{\rho}_\varepsilon(k)|^2 k^{-2}$$

is independent of ε. Equations (1.5) are again of Hamiltonian form. The energy

$$\begin{aligned} \mathcal{H}_{mac}(\phi,\pi,q,v) &= \gamma(v) + V(q) + \frac{1}{2}\int d^3x\, (|\pi(x)|^2 + |\nabla\phi(x)|^2) \\ &\quad + \sqrt{\varepsilon}\int d^3x\, \phi(x)\rho_\varepsilon(x - q) \end{aligned} \tag{1.7}$$

is conserved under (1.5). It is bounded from below, as $\mathcal{H}_{mac}(\phi,\pi,q,v) \geq V(q) - 3m_e$ independently of ε.

There is another, very instructive way to think about the initial value problem (1.5), (1.6). We prescribe initial data at $t = -\tau$, $\tau > 0$, which have finite energy and some smoothness. We refer to [6] for the precise conditions. We solve (1.5) for $V = 0$ up to time $t = 0$. Then in the limit $\tau \to \infty$ the data at $t = 0$ are exactly of the form (1.6). For $t > 0$ the external forces are acting on the particle. Clearly this causes some mismatch, which is reflected by a nonsmoothness of the fields (ϕ, π) at the light cone $\{x : |x| = t, t > 0\}$ in the limit $\varepsilon \to 0$.

Under suitable assumptions on V and for $|\rho|_{L^2}$ sufficiently small we prove in [5] that

$$|\dot{q}^\varepsilon(t)| \leq \bar{v} < 1\,, \quad |\ddot{q}^\varepsilon(t)| \leq C\,, \quad \text{and} \quad |\dddot{q}^\varepsilon(t)| \leq C \tag{1.8}$$

uniformly in ε and $t \in \mathbb{R}$ and that the limit

$$\lim_{\varepsilon \to 0^+} q^\varepsilon(t) = r(t) \tag{1.9}$$

exists. Here $r(t)$ is the solution of Hamilton's equations of motion with the effective Hamiltonian $E(p) + V(q)$ (cf. the definition of $E(p)$ below (1.3)), which in terms of velocities reads

$$\dot r = u\,, \quad m(u)\dot u = -\nabla V(r), \tag{1.10}$$

with initial data $r(0) = q^0$, $u(0) = v^0$. Here $m(u) = m_0(u) + m_f(u)$, where $m_f(u)$ is the additional "mass" due to the coupling to the field defined by

$$m_f(u)\dot u = 3m_e \left(\varphi(|u|)\dot u + |u|^{-1}\varphi'(|u|)(u\cdot \dot u)u\right) \tag{1.11}$$

as a 3×3 matrix, where $\varphi(|v|)$ is the function appearing in the square brackets of (1.3). Note that the energy

$$H(r,u) = \mathcal{E}_s(u) + V(r) \tag{1.12}$$

is conserved by the solutions to (1.10).

With this background information let us return to the radiation reaction as discussed by Abraham, Lorentz, Schott, and Dirac; cf. [16] for an excellent account. Of course, these theoretical physicists were interested in the electrodynamics of moving charges. We take here the liberty to transcribe their arguments to the case of a scalar wave equation. For the sake of discussion, we reintroduce the bare mass m_0 and state the equations for small velocities only. In our proof below, however, we will handle all $v \in \mathcal{V}$.

At the beginning of this century, the hope was to define a structureless elementary charge through a point charge limit. For this program, one had to model the charge distribution phenomenologically with the understanding that finer details should become irrelevant in the limit. In (1.1) we adopted the Abraham model of a rigid charge distribution. The point charge limit then corresponds to taking in (1.1) a fixed ε-independent potential and to let the diameter of the charge distribution tend to zero. If this diameter is set proportional to ε and if we compare with (1.5), then in the point charge limit the charge distribution $\sqrt{\varepsilon}\rho_\varepsilon$ is to be replaced by ρ_ε, which in particular shows that the adiabatic limit of a slowly varying external potential is distinct from the point charge limit, where $\mathsf{e} = \int d^3x \rho_\varepsilon(x) = \int d^3x \rho(x)$ is independent of ε and the electromagnetic mass diverges as $\frac{1}{3}\int d^3k |\hat\rho_\varepsilon(k)|^2 k^{-2} = \varepsilon^{-1} m_e$. A formal Taylor expansion leads to the effective equation of motion

$$m_0 \ddot r = -\nabla V(r) - \varepsilon^{-1} m_e \ddot r + a\mathsf{e}^2\, \dddot r, \tag{1.13}$$

valid for small velocities $\dot r$, with some constant $a > 0$. Equation (1.13) is the nonrelativistic limit of the Lorentz–Dirac equation [10]. The standard argument, reproduced in many textbooks, such as [3] (with the notable exception of Landau and Lifshitz [9]), is to lump m_0 and $\varepsilon^{-1} m_e$ together and to take the limits $\varepsilon \to 0$ and $m_0 \to -\infty$ at constant $m_0 + \varepsilon^{-1} m_e = m_{exp}$, the experimentally observed mass of the particle. Then (1.13) reads as

$$m_{exp} \ddot r = -\nabla V(r) + a\mathsf{e}^2\, \dddot r\,. \tag{1.14}$$

Since this equation is of third order, one needs besides q^0, v^0 also $\dot{u}(0)$ as an initial condition which has to be extracted somehow from the initial data of the full system. Even worse, (1.14) has solutions which are exponentially unbounded in time, the famous run-away solutions. Thus one needs an additional criterion to single out the solutions of physical relevance. Dirac [1], and later Haag [2], argued that physical solutions have to satisfy the asymptotic condition

$$\lim_{t\to\infty} \ddot{r}(t) = 0, \tag{1.15}$$

as a substitute for the missing initial condition $\ddot{r}(0)$. The validity of the asymptotic condition has been checked only in trivial cases; see [10]. For general V one should expect the solutions to (1.13) to be chaotic. Physical and unphysical solutions might become badly mixed up. On a more practical level, the physical solutions are unstable and therefore difficult to compute numerically. To put it in the words of Thirring [15]: "...(1.14) *has not only crazy solutions and there are attempts to separate sense from nonsense through special initial conditions. But one hopes that the true solution to the problem will look differently and that the nature of the equations of motion is not so highly unstable that the act of balance can be achieved only through a stroke of good fortune in the initial conditions.*"

This is indeed the case, as we are going to show in this paper, and our resolution requires just a little twist. If instead of the point charge limit we consider a slowly varying external potential, then on the macroscopic time scale, according to (1.5), equation (1.13) reads

$$(m_0 + m_e)\ddot{r} = -\nabla V(r) + \varepsilon a \mathsf{e}^2 \dddot{r}, \tag{1.16}$$

which reflects that radiation reaction is a small correction to the Hamiltonian motion. In (1.16) the highest derivative appears with a small prefactor. Such differential equations are studied in geometric singular perturbation theory. From there we know that (1.16) has a six-dimensional invariant center manifold $\mathcal{I}_\varepsilon$, which is only $\mathcal{O}(\varepsilon)$ away from the Hamiltonian manifold $\mathcal{I}_0 = \{(q, \dot{q}, \ddot{q}) : (m_0 + m_e)\ddot{q} = -\nabla V(q)\}$. For initial conditions slightly off $\mathcal{I}_\varepsilon$ the solution moves away from $\mathcal{I}_\varepsilon$ exponentially fast. On $\mathcal{I}_\varepsilon$, $\dot{q}$ is bounded away from 1, $\ddot{q}$ is bounded, and the motion is governed by an effective second order equation (cf. (4.9) below), which gives *precisely* the physical solutions. To establish such a result we have to prove that the solution to (1.5) indeed stays close to $\mathcal{I}_\varepsilon$.

In our paper we carry out this program, essentially under the same conditions as in [5], namely, a sufficiently differentiable V and $|\rho|_{L^2}$ small. Our main additional estimate is

$$|\dddot{v}^{\,\varepsilon}(t)| \leq C \tag{1.17}$$

uniformly in ε and $t \in \mathbb{R}$. Thereby we can bound one further order in the rigorous Taylor expansion and obtain, setting $\dot{q}^\varepsilon = v^\varepsilon$,

$$m(v^\varepsilon)\dot{v}^\varepsilon = -\nabla V(q^\varepsilon) + \varepsilon a(v^\varepsilon)\ddot{v}^\varepsilon + \varepsilon b(v^\varepsilon, \dot{v}^\varepsilon) + \varepsilon^2 f^\varepsilon(t), \quad t \geq \varepsilon t_1, \tag{1.18}$$

with $|f^\varepsilon(t)| \leq C$ and coefficient functions a, b that will be defined below. Clearly (1.18) should be compared with

$$\dot{r} = u\,, \quad m(u)\dot{u} = -\nabla V(r) + \varepsilon a(u)\ddot{u} + \varepsilon b(u, \dot{u}). \tag{1.19}$$

Our crucial observation is that the condition $|u(t)| \leq \text{const.} < 1$ for all t holds only on the center manifold $\mathcal{I}_\varepsilon$. Thus the a priori estimate $|\dot{q}^\varepsilon(t)| \leq \bar{v} < 1$ (see (1.8)), together with the initial conditions $r(0) = q^0$, $u(0) = v^0$, *uniquely* singles out that solution of (1.19) which is to be compared with the true solution.

The coefficient functions a, b are proportional to e^2. If the total charge $\mathsf{e} = 0$, then the friction term in (1.18) vanishes identically and radiation reaction appears at a higher level of approximation.

Since on the error term $f^\varepsilon(t)$ in (1.18) we know only that it is uniformly bounded, the difference $|q^\varepsilon(t) - r(t)|$, with $r(t)$ having initial conditions on $\mathcal{I}_\varepsilon$, can be bounded at best as εe^{ct}. Thus on the time scale $t = \mathcal{O}(1)$ we seem to be back to the result (1.9) already proved in [5]. To distinguish, from this point of view, between (1.19) and (1.10) we would have to control the difference with a precision of order ε^2. At present we do not know whether this is possible, but nevertheless we can prove the weaker statement

$$|H(q^\varepsilon(t), v^\varepsilon(t)) - H(r(t), u(t))| \leq \text{const.}\, \varepsilon^2, \tag{1.20}$$

where H is the energy from (1.12). Thus, on a surface of constant energy the difference $|q^\varepsilon(t) - r(t)|$ could be of order ε, whereas along ∇H it must be of order ε^2. In addition to (1.20) it may also be shown that in fact $|q^\varepsilon(t) - r(t)| \sim \varepsilon^3$ on the short time scale $t = \mathcal{O}(\varepsilon)$, a result that is quite natural from the viewpoint of singularly perturbed ODEs. On the original time scale of (1.1) this amounts at least to an estimate with precision ε^2 over time intervals of length $\mathcal{O}(1)$, a result that could not have been obtained from the bounds in [5].

Taking a somewhat broader perspective, the problem discussed here may be viewed as an infinite-dimensional Hamiltonian system which relaxes to a stationary solution through the emission of radiation. This phenomenon is fairly common and has been studied in the context of linear and nonlinear wave equations. We refer to [12, 13] for recent work, which also contain more references to prior studies. For such problems one typically has a stationary eigenmode which turns into a resonance by coupling to propagating modes. In comparison, a simplifying feature in the present paper is that the localized and propagating degrees of freedom are already well separated on the level of the equations of motion. On the other hand, we provide a quantitative estimate on the relaxation process and not just a power law decay in time.

2. Main results. We give some more details and state our main results precisely. First we have to establish the bound (1.17).

LEMMA 2.1. *For $|\rho|_{L^2}$ sufficiently small we have*

$$\sup_{t \in \mathbb{R}} |\dddot{v}^\varepsilon(t)| \leq C$$

for every solution of (1.5) *which starts on the soliton manifold $\mathcal{S}$. Both the constant C and the bound for $|\rho|_{L^2}$ depend only on the initial data.*

The bound of Lemma 2.1 may be used to Taylor expand the self-force

$$F_s^\varepsilon(t) = \sqrt{\varepsilon} \int d^3x\, \phi(x,t) \nabla \rho_\varepsilon(x - q^\varepsilon(t)) \tag{2.1}$$

in (1.5) as

$$F_s^\varepsilon(t) = -m_f(v^\varepsilon(t))\dot{v}^\varepsilon(t) + \varepsilon a(v^\varepsilon(t))\ddot{v}^\varepsilon(t) + \varepsilon b(v^\varepsilon(t), \dot{v}^\varepsilon(t)) + \mathcal{O}(\varepsilon^2)\,, \quad t \geq \varepsilon t_1\,, \tag{2.2}$$

which together with the second equation in (1.5) yields (1.18). Here m_f is defined in (1.11). $t_1 = 2R_\rho/(1-\bar{v})$ is the microscopic time for the wave equation to forget its initial data through the compact support of ρ and the velocity bound; cf. assumption (C) and (1.8). The coefficient functions are given by

$$a(v)\ddot{v} = (\mathsf{e}^2/24\pi)(\ddot{v}\cdot\nabla_v)\nabla_v\gamma^2 = (\mathsf{e}^2/12\pi)[\gamma^4\ddot{v} + 4\gamma^6(v\cdot\ddot{v})v]\,, \tag{2.3}$$

$$\begin{aligned} b(v,\dot{v}) &= (\mathsf{e}^2/32\pi)(\dot{v}\cdot\nabla_v)^2\nabla_v\gamma^2 \\ &= (\mathsf{e}^2/4\pi)[2\gamma^6(v\cdot\dot{v})\dot{v} + \gamma^6\dot{v}^2v + 6\gamma^8(v\cdot\dot{v})^2v], \end{aligned} \tag{2.4}$$

$\dot{v}, \ddot{v} \in \mathbb{R}^3$, with $\gamma = 1/\sqrt{1-v^2}$, $|v| < 1$.

Next we explain the existence and the role of the center-like manifolds $\mathcal{I}_\varepsilon$ in greater detail. We refer to [11, 4] for further background on geometric singular perturbation theory. To rewrite (1.19) as a singular perturbation problem, let

$$x = (r,u) \in \mathbb{R}^3\times\mathcal{V}\,, \quad y = \dot{u} \in \mathbb{R}^3\,, \quad f(x,y) = (x_2,y) \in \mathcal{V}\times\mathbb{R}^3\,, \quad \text{and}$$
$$g(x,y,\varepsilon) = a(x_2)^{-1}[m(x_2)y + \nabla V(x_1) - \varepsilon b(x_2,y)]\,.$$

Then (1.19) reads as

$$\dot{x} = f(x,y)\,, \quad \varepsilon\dot{y} = g(x,y,\varepsilon)\,. \tag{2.5}$$

We intend to apply the results from [11] to (2.5) in order to find a center-like manifold for the perturbed problem near the corresponding manifold for the $(\varepsilon = 0)$-problem. With $h(x) = -m(x_2)^{-1}\nabla V(x_1)$, let

$$\begin{aligned} \mathcal{I}_0 &= \{(x,y) : g(x,y,0) = 0\} = \{(r,u,\dot{u}) : m(u)\dot{u} = -\nabla V(r)\} \\ &= \{(x,h(x)) : x \in \mathbb{R}^3\times\mathcal{V}\} \end{aligned} \tag{2.6}$$

be this invariant manifold for (2.5) with $\varepsilon = 0$. The flow on $\mathcal{I}_0$ is governed by the equation $\dot{x} = f(x,h(x))$, or stated differently, $m(\dot{r})\ddot{r} = -\nabla V(r)$, the familiar Hamiltonian flow.

To see that $\mathcal{I}_0$ is perturbed to some $\mathcal{I}_\varepsilon$ with ε small, we have to modify the functions $a(u)$, $m(u)$, and $b(u,\dot{u})$ for $|u|$ close to 1 due to the singularity at $|u| = 1$. This will cause no problems later on, since we already have the a priori bound $|v^\varepsilon(t)| \le \bar{v} < 1$ for the velocity of the true system. In (4.4) below, we will fix a small $\bar{\delta} = \bar{\delta}(\bar{v}) > 0$ satisfying some estimates; $\bar{\delta}$ depends only on bounds for the initial data, since $\bar{v}$ does so. Let

$$\mathcal{K}_{1-\bar{\delta}} = \mathbb{R}^3\times\{u\in\mathbb{R}^3 : |u| \le 1-\bar{\delta}\}.$$

We continue $a(u)$, $m(u)$, and $b(u,\dot{u})$ with their values at $|u| = 1-\bar{\delta}$ to the missing infinite strip $1-\bar{\delta} < |u| < 1$. Then the basic assumptions (I), (II) from [11, p. 45] are satisfied, since $\mathcal{I}_0$ is also what is called normally hyperbolic, i.e., repulsive in the direction normal to $\mathcal{I}_0$ at an ε-independent rate; see Lemma 4.1 below. Hence we find $\varepsilon_0 = \varepsilon_0(\bar{\delta}) > 0$ and a C^1-function $h(x,\varepsilon) = h_\varepsilon(x) : \mathbb{R}^3\times\mathcal{V}\times]0,\varepsilon_0] \to \mathbb{R}^3$ such that for $\varepsilon \le \varepsilon_0$,

$$\mathcal{I}_\varepsilon = \{(x,h_\varepsilon(x)) : x\in\mathbb{R}^3\times\mathcal{V}\}$$

is forward invariant for the flow (1.19) with the modified functions a, m, b. Since the modified equation agrees with (1.19) in the interior of $\mathcal{K}_{1-\bar{\delta}}$, we conclude that $\mathcal{I}_\varepsilon$

is locally invariant for the flow (1.19); i.e., the solution of the modified equation is the solution to the original equation as long as it does not reach the boundary set $\{(x, h_\varepsilon(x)) = (r, u, h_\varepsilon(r,u)) : |u| = 1 - \bar{\delta}\}$. The flow for $\varepsilon = 0$ is then perturbed to $\dot{x} = f(x, h_\varepsilon(x))$ for $\varepsilon \le \varepsilon_0$.

We will show in Theorem 4.4 below that for $\varepsilon \in]0, \varepsilon_1]$, with $\varepsilon_1 > 0$ sufficiently small, all solutions of (1.19) starting at points $(r, u, h_\varepsilon(r,u)) \in \mathcal{I}_\varepsilon$ with $|u| \le \bar{v}$ will indeed stay away from the boundary $\{(r, u, h_\varepsilon(r,u)) : |u| = 1 - \bar{\delta}\}$ for all future times. In addition, $\nabla V(r(t)) \to 0$ and $\ddot{r}(t) \to 0$ as $t \to \infty$, which is just the asymptotic condition (1.15) postulated by Dirac [1] and Haag [2]. If the potential is sufficiently confining, then the solution trajectory on $\mathcal{I}_\varepsilon$ not only approaches the set of critical points for V in the long time limit, but it converges to some definite critical point. Moreover, we will show that for all solutions on the center manifold, $\dot{u}(t)$ and $\ddot{u}(t)$ are bounded, and $u(t)$ is bounded away from 1, uniformly in ε and t. Conversely, every such solution to (1.19) has to lie on $\mathcal{I}_\varepsilon$. Thus $\mathcal{I}_\varepsilon$ indeed characterizes the physical solutions.

To summarize, we have established now the existence of a center manifold $\mathcal{I}_\varepsilon$ with a well-defined (semi-) flow on it that gives a unique solution to (1.19) for initial velocities bounded by $\bar{v}$.

For the potential $V \in C^3(\mathbb{R}^3)$ we assume that it is bounded in the sense that

$$\text{(U)} \qquad \sup_{q \in \mathbb{R}^3} \Big(|V(q)| + |\nabla V(q)| + |\nabla\nabla V(q)| + |\nabla\nabla\nabla V(q)| \Big) < \infty \,.$$

The method works equally well for $V \in C^3(\mathbb{R}^3)$ which is confining, i.e.,

$$\text{(U}') \qquad V(q) \to \infty \quad \text{as} \quad |q| \to \infty \,,$$

as will be made more precise in section 4; cf. Theorem 4.8.

Our main result is the following.

THEOREM 2.2. *Assume* (U) *or* (U′) *for the potential, and let the initial data* $(\phi^0(x), \pi^0(x), q^0, v^0)$ *for* (1.5) *be given by* (1.6). *Let* $|\rho|_{L^2}$ *and* $\varepsilon \le \varepsilon_1$ *be sufficiently small, and introduce the center manifolds* $\mathcal{I}_\varepsilon$ *for the comparison dynamics* (1.19) *as explained above. At time* $\varepsilon t_1 = \varepsilon 2R_\rho/(1-\bar{v})$ *we match the initial values* $r(\varepsilon t_1) = q^\varepsilon(\varepsilon t_1)$, $u(\varepsilon t_1) = v^\varepsilon(\varepsilon t_1)$ *for the motion on the center manifold; i.e., the initial data for the comparison dynamics are*

$$(q^\varepsilon(\varepsilon t_1), v^\varepsilon(\varepsilon t_1), h_\varepsilon(q^\varepsilon(\varepsilon t_1), v^\varepsilon(\varepsilon t_1))) \in \mathcal{I}_\varepsilon \,.$$

Then for every $\tau > 0$ *there exists* $c(\tau) > 0$ *such that for all* $t \in [\varepsilon t_1, \varepsilon t_1 + \tau]$

$$(2.7) \quad |q^\varepsilon(t) - r(t)| \le c(\tau)\varepsilon \,, \quad |v^\varepsilon(t) - u(t)| \le c(\tau)\varepsilon \,, \quad \textit{and} \quad |\dot{v}^\varepsilon(t) - \dot{u}(t)| \le c(\tau)\varepsilon.$$

In addition we have the bound

$$(2.8) \qquad |H(q^\varepsilon(t), v^\varepsilon(t)) - H(r(t), u(t))| \le c(\tau)\varepsilon^2.$$

Remark 2.3. (i) As already mentioned at the end of the introduction, we can also show

$$(2.9) \qquad |q^\varepsilon(t) - r(t)| \le c(\tau)\varepsilon^3 \quad \text{and} \quad |v^\varepsilon(t) - u(t)| \le c(\tau)\varepsilon^2$$

for $t \in [\varepsilon t_1, \varepsilon t_1 + \varepsilon\tau]$, i.e., $t = \mathcal{O}(\varepsilon)$; cf. Proposition 5.1.

(ii) The construction of the center manifolds and the upper bound for $|\rho|_{L^2}$ rely only on bounds for the data, but not on properties of a particularly chosen solution. Our main technical assumption is a sufficiently small $|\rho|_{L^2}$ which is presumably not necessary.

(iii) In [5] we did not require the true solution to start on the soliton manifold, but instead to start close to it. We refer to the criterion [5, Thm. 2.6] for an "adiabatic" family of solutions. The same generality could be achieved in the present context, using an appropriately modified version of [5, Thm. 2.6]. In section 8 we derive the relevant estimates, in particular (8.8), in full generality containing a nonzero initial difference $Z(0)$. The corresponding generalization of Theorem 2.2 is then straightforward. However, since we did not want to obscure our main achievement through technicalities, we decided to elaborate here the more accessible case of a trajectory starting right on the soliton manifold. In the same spirit we do not consider arbitrary time intervals of length τ, but only the particular $[\varepsilon t_1, \varepsilon t_1 + \tau]$.

(iv) The existence of solutions to (1.1) is discussed in [5, Lem. 2.2]. For every initial value $Y^0 = (\phi^0(x), \pi^0(x), q^0, p^0) \in \mathcal{E}$ we find a unique (weak) solution $Y(\cdot) \in C(\mathbb{R}, \mathcal{E})$ such that $Y(0) = Y^0$. Here the state space is $\mathcal{E} = D^{1,2}(\mathbb{R}^3) \oplus L^2(\mathbb{R}^3) \oplus \mathbb{R}^3 \oplus \mathbb{R}^3$ (where $D^{1,2}(\mathbb{R}^3) = \{\phi \in L^6(\mathbb{R}^3) : |\nabla\phi| \in L^2(\mathbb{R}^3)\}$) with norm $|Y|_{\mathcal{E}} = |\nabla\phi|_{L^2} + |\pi|_{L^2} + |q| + |p|$.

Having such fairly precise information on the particle trajectory, we can also determine the adiabatic limit $\varepsilon \to 0$ of the fields (ϕ, π) in (1.5) through the solution of the inhomogeneous wave equation. We generate the initial data as explained in the introduction. On the level of the comparison dynamics this means to extend $r(t)$ and $u(t)$ to negative times $t \leq 0$ by $r(t) = q^0 + tv^0$, resp., $u(t) = v^0$. Let the retarded time t_{ret}, depending on x and t, be the unique solution of $t_{\mathrm{ret}} = t - |x - r(t_{\mathrm{ret}})|$, and let $\hat{n}(x,t) = (x - r(t_{\mathrm{ret}}))/|x - r(t_{\mathrm{ret}})|$.

THEOREM 2.4. *Under the conditions of Theorem* 2.2 *and for the fields* (ϕ, π) *from* (1.5) *we have for* $x \neq r(t)$ *the pointwise limits*

$$\lim_{\varepsilon\to 0} \frac{1}{\sqrt{\varepsilon}}\, \phi(x,t) = -\frac{\mathsf{e}}{4\pi|x - r(t_{\mathrm{ret}})|}\, (1 - \hat{n}(x,t)\cdot u(t_{\mathrm{ret}}))^{-1} \tag{2.10}$$

and, except for the light cone $\{x : |x| = t > 0\}$,

$$\begin{aligned} &\lim_{\varepsilon\to 0} \frac{1}{\sqrt{\varepsilon}}\, \pi(x,t) \\ &= -\frac{\mathsf{e}}{4\pi|x - r(t_{\mathrm{ret}})|}\, (1 - \hat{n}(x,t)\cdot u(t_{\mathrm{ret}}))^{-3}\, \hat{n}(x,t)\cdot \dot{u}(t_{\mathrm{ret}}) \\ &\quad -\frac{\mathsf{e}}{4\pi|x - r(t_{\mathrm{ret}})|^2}\, (1 - \hat{n}(x,t)\cdot u(t_{\mathrm{ret}}))^{-3}\, (\hat{n}(x,t)\cdot u(t_{\mathrm{ret}}) - u(t_{\mathrm{ret}})^2). \end{aligned} \tag{2.11}$$

The paper is organized as follows. Since the proof of Lemma 2.1 is rather technical, we moved it to an appendix, section 8. The derivation of the representation (2.2) of the self-force term is the contents of section 3. In section 4 we give supplementary remarks on the behavior of solutions on the center manifold, whereas in section 5 we carry out the proofs of Theorem 2.2 and Proposition 5.1. Section 6 contains the proof of Theorem 2.4, and finally in section 7 we determine the amount of energy radiated to infinity.

3. Representation of the self-force. In this section we show that the self-force $F_s^\varepsilon(t)$ from (2.1) can be written in the form (2.2). We carry out this computation

on the original fast time scale corresponding to (1.1) since we will need some of the arguments from [5]. Thus we consider

$$F_s(t) = \int d^3x\, \phi(x,t)\nabla\rho(x-q(t)).$$

Since $\phi(x,t) = \phi_r(x,t) + \phi_0(x,t)$, where $\ddot{\phi}_0 = \Delta\phi_0$ with the initial values $\phi_0(x,0) = \phi^0(x)$ and $\pi_0(x,0) = \pi^0(x)$, and since

$$\phi_r(x,t) = -\frac{1}{4\pi}\int_0^t \frac{ds}{t-s}\int_{|y-x|=t-s} d^2y\,\rho(y-q(s))$$

is the retarded potential, we can decompose accordingly,

$$F_s(t) = F_0(t) + F_r(t) = \langle\phi_0(\cdot,t), \nabla\rho(\cdot - q(t))\rangle + \langle\phi_r(\cdot,t), \nabla\rho(\cdot - q(t))\rangle\,.$$

LEMMA 3.1. *The function $F_0(t)$ vanishes for $t \geq t_1 = 2R_\rho/(1-\bar{v})$.*

Proof. Let $U(t)$ denote the group generated by the free wave equation in $D^{1,2}(\mathbb{R}^3)\oplus L^2(\mathbb{R}^3)$. Then (1.4) and Fourier transformation implies

$$(\phi^0(x), \pi^0(x)) = -\int_{-\infty}^0 ds\,[U(-s)\bar{\rho}(\cdot - q^0 - v^0 s)](x)$$

with $\bar{\rho}(x) = (0, \rho(x))$. Thus Kirchhoff's formula yields, as a consequence of $|v^0| < 1$, that $\phi_0(x,t) = 0$ for $|x - q^0| \leq t - R_\rho$. Since $|q(t) - q^0| \leq \bar{v}t$, the claim follows. ∎

Hence to show (2.2) it is enough to prove the following.

LEMMA 3.2. *For $t \geq t_1$,*

$$F_r(t) = -m_f(v(t))\dot{v}(t) + a(v(t))\ddot{v}(t) + b(v(t), \dot{v}(t)) + \mathcal{O}(\varepsilon^3);$$

cf. (1.11), (2.3), *and* (2.4).

Proof. We follow the proof of [5, Lem. 5.1] but expand

$$q(s) = q(t) - v(t)(t-s) + \frac{1}{2}\dot{v}(t)(t-s)^2 - \frac{1}{6}\ddot{v}(t)(t-s)^3 + \mathcal{O}(\varepsilon^3)$$

up to third order, which is allowed by Lemma 2.1. Through Fourier transformation we arrive at

$$F_r(t) = (-i)\int_0^t ds \int d^3k\,|\hat{\rho}(k)|^2 \frac{k}{|k|}\,\sin|k|(t-s)\,e^{-i(k\cdot v)(t-s)} \times e^{-i[-\frac{1}{2}(k\cdot\dot{v})(t-s)^2 + \frac{1}{6}(k\cdot\ddot{v})(t-s)^3]} + \mathcal{O}(\varepsilon^3)\,,$$

with $v = v(t)$, etc. As in [5, Lem. 5.1], here and in the following $\int_0^t ds(\ldots)$ can be changed forth and back to $\int_{t-T}^t ds(\ldots)$ for all $t, T \geq t_1$. Because

$$e^{-i[-\frac{1}{2}(k\cdot\dot{v})(t-s)^2 + \frac{1}{6}(k\cdot\ddot{v})(t-s)^3]} = 1 + \frac{i}{2}(k\cdot\dot{v})(t-s)^2 - \frac{i}{6}(k\cdot\ddot{v})(t-s)^3 - \frac{1}{8}(k\cdot\dot{v})^2(t-s)^4 + \mathcal{O}(\varepsilon^3)$$

for $t - s = \mathcal{O}(1)$ by (8.1) below, we obtain, for $t, T \geq t_1$,

$$F_r(t) = (-i)\int_0^T d\tau \int d^3k\,|\hat{\rho}(k)|^2 \frac{k}{|k|}\,\sin|k|\tau\,e^{-i(k\cdot v)\tau} \times \left[1 + \frac{i}{2}(k\cdot\dot{v})\tau^2 - \frac{i}{6}(k\cdot\ddot{v})\tau^3 - \frac{1}{8}(k\cdot\dot{v})^2\tau^4\right] + \mathcal{O}(\varepsilon^3)\,.$$

Let

$$I_p = \int_0^T d\tau \, \frac{\sin|k|\tau}{|k|} \, e^{-i(k\cdot v)\tau} \tau^p \,, \quad p = 0, \dots, 4 \,.$$

Then

$$(\ddot{v}\cdot\nabla_v)\nabla_v I_1 = -k(k\cdot\ddot{v})I_3 \quad \text{and} \quad (\dot{v}\cdot\nabla_v)^2\nabla_v I_1 = ik(k\cdot\dot{v})^2 I_4 \,.$$

Our claim now follows from Lemma 3.3 shown below, $\int d^3k \, |\hat{\rho}(k)|^2 k I_0 \to 0$, and $(1/2)\int d^3k \, |\hat{\rho}(k)|^2 k(k\cdot\dot{v})I_2 \to -m_f(v(t))\dot{v}(t)$ for $T \to \infty$; see [5, Appendix A]. □

LEMMA 3.3. *We have the identity*

$$\int_0^\infty dt \, t \int d^3k |\hat{\rho}(k)|^2 \frac{\sin|k|t}{|k|} \, e^{-i(k\cdot v)t} = (\mathsf{e}^2/4\pi)\gamma^2 \,.$$

Proof. Since $\hat{\rho}(k) = \hat{\rho}_r(|k|)$ is radial, and by transformation to polar coordinates,

$$\int d^3k |\hat{\rho}(k)|^2 \frac{\sin|k|t}{|k|} \, e^{-i(k\cdot v)t} = \frac{4\pi}{t|v|} \int_0^\infty dR \, |\hat{\rho}_r(R)|^2 \sin(Rt)\sin(Rt|v|) \,.$$

Thus for fixed $T > 0$,

$$\begin{aligned} &\int_0^T dt \, t \int d^3k |\hat{\rho}(k)|^2 \frac{\sin|k|t}{|k|} \, e^{-i(k\cdot v)t} \\ &= \frac{2\pi}{|v|} \int_0^\infty \frac{dR}{R} |\hat{\rho}_r(R)|^2 \left(\frac{\sin(R(1-|v|)T)}{1-|v|} - \frac{\sin(R(1+|v|)T)}{1+|v|} \right) . \end{aligned}$$

To complete the proof we need only to verify that $\int d^3k |\hat{\rho}(k)|^2 \, |k|^{-3} \sin|k|T \to \mathsf{e}^2/4\pi$ as $T \to \infty$. To see this, let $\hat{\psi}(k) = |k|^{-3}\sin(|k|T)$. Then

$$\int d^3k |\hat{\rho}(k)|^2 \, \hat{\psi}(k) = (2\pi)^{-3/2} \int d^3x \rho(x) \int d^3y \, \rho(y)\psi(x-y),$$

and we are going to show $\psi(x) \to \sqrt{\pi/2}$ as $T \to \infty$. We have, by transformation to polar coordinates,

$$(2\pi)^{3/2}\psi(x) = \int d^3k \, \hat{\psi}(k) e^{-ik\cdot x} = 4\pi \int_0^\infty ds \, \frac{\sin(s)}{s} \, \frac{\sin(s|x|/T)}{s|x|/T} \to 2\pi^2$$

for $T \to \infty$. This completes the proof. □

4. More about the center manifold. In this section we explain the behavior of solutions on the center manifold. First we show that the unperturbed manifold $\mathcal{I}_0$ from (2.6) is hyperbolic in normal direction.

LEMMA 4.1. *The eigenvalues of $D_y g(x,y,0) = a(x_2)^{-1}m(x_2)$ are bounded below by a positive constant, uniformly in $x = (r,u)$ with $r \in \mathbb{R}^3$ and $|u| \le 1-\delta$ for all prescribed $\delta \in]0,1]$.*

Proof. By [8, Thm. 2, p. 185], $a(u)$ and $m(u)$ can be simultaneously transformed to diagonal form through a single nonsingular matrix B. In addition, denoting by $b_j \neq 0$ the jth column of B and by λ_j the jth eigenvalue of $a(u)^{-1}m(u)$, one has $\lambda_j a(u)b_j = m(u)b_j$, $j = 1,2,3$. Multiplication by b_j leads to $\lambda_j(\mathsf{e}^2/12\pi)\gamma^3[\gamma b_j^2 + 4\gamma^3(v\cdot b_j)^2] \ge \gamma b_j^2 + \gamma^3(v\cdot b_j)^2$, and thus $\lambda_j \ge (3\pi/\mathsf{e}^2)\gamma^{-3}$. □

Since $a(u)$, $m(u)$ are modified to be constant outside $|u| \le 1-\bar\delta$, their corresponding eigenvalues are uniformly bounded below for $|u|<1$. As a consequence of Lemma 4.1 the manifolds $\mathcal{I}_\varepsilon$ are unstable at some exponential rate $e^{\mu t}$ for solutions in the normal direction.

We note that, by [11, Thm. 2.1],

$$\sup\{|h_\varepsilon(r,u)| : (r,u)\in \mathbb{R}^3\times\mathcal{V}, \varepsilon\in]0,\varepsilon_0]\} \le c = c(\bar\delta). \tag{4.1}$$

Our next aim is to prove global existence of solutions to (1.19) forward in time which start over $\mathcal{K}_{\bar v} = \mathbb{R}^3\times\{u\in\mathbb{R}^3 : |u|\le \bar v\}$ on the center manifold, provided $\varepsilon\le\varepsilon_1$ with $\varepsilon_1>0$ sufficiently small. For this purpose we introduce a suitable Lyapunov function.

LEMMA 4.2. *Let*

$$G_\varepsilon(r,u,\dot u) = H(r,u) - \varepsilon(a(u)\dot u)\cdot u = \mathcal{E}_s(u) + V(r) - \varepsilon(a(u)\dot u)\cdot u\,.$$

Then along solutions $(r(t),u(t),\dot u(t))$ *of* (1.19) *we have*

$$\frac{d}{dt}G_\varepsilon(r,u,\dot u) = -\varepsilon(\mathsf{e}^2/12\pi)\,[6\gamma^8(u\cdot\dot u)^2 + \gamma^6\dot u^2]. \tag{4.2}$$

Proof. Observing that

$$(a(u)\dot u)\cdot u = (\mathsf{e}^2/12\pi)\gamma^6\,(1+3u^2)(u\cdot\dot u),$$

this is a straightforward calculation. □

Through the Lyapunov function G_ε we can control the long time behavior.

THEOREM 4.3. *Let* (U) *or* (U′) *hold and let any global solution* $(r(t),u(t))$ *of* (1.19) *be given such that* $\sup_{t\ge0}|u(t)|\le\bar u(\varepsilon)<1$ *and* $\sup_{t\ge0}|\dot u(t)|\le c(\varepsilon)$, *for possibly* ε*-dependent constants* $\bar u(\varepsilon)$ *and* $c(\varepsilon)$. *Then*

$$\dot u(t)\to 0,\quad \ddot u(t)\to 0,\quad \textit{and}\quad \nabla V(r(t))\to 0\quad \textit{as}\quad t\to\infty.$$

Proof. Denoting by $c(\varepsilon)$ or $C(\varepsilon)$ general ε-dependent constants, by Lemma 4.2 we have along a trajectory

$$\begin{aligned} c(\varepsilon)\int_0^T \dot u^2\,dt &\le -\int_0^T \frac{d}{dt}G_\varepsilon\,dt \\ &= -\mathcal{E}_s(u(T)) - V(r(T)) + \varepsilon(a(u(T))\dot u(T))\cdot u(T) \\ &\quad +\mathcal{E}_s(u^0) + V(r^0) - \varepsilon(a(u^0)\dot u^0)\cdot u^0 \\ &\le C(\varepsilon,\mathrm{data}). \end{aligned}$$

For the last estimate observe $\inf_{r\in\mathbb{R}^3}V(r)>-\infty$ in both cases (U) and (U′). Thus $\int_0^\infty \dot u^2\,dt \le C(\varepsilon,\mathrm{data})$ and, by (1.19), also $\sup_{t\ge0}|\ddot u(t)|\le C(\varepsilon,\mathrm{data})$. Hence we conclude $\dot u(t)\to0$ as $t\to\infty$. Next, differentiation of (1.19) yields $\sup_{t\ge0}|\dddot u\ (t)|\le C(\varepsilon,\mathrm{data})$, and thus from $\dot u(t)\to0$ we find $\ddot u(t)\to0$. Therefore $\nabla V(r(t))\to0$ follows from (1.19). □

In the demonstration of the following theorem we use the sublevel sets $\{G_\varepsilon\le c\} = \{(r,u,\dot u) : G_\varepsilon(r,u,\dot u)\le c\}$ and $\{H\le c\} = \{(r,u) : H(r,u)\le c\}$ for $c\in\mathbb{R}$. However, before proceeding, we first have to introduce an appropriate $\bar\delta = \bar\delta(\bar v)>0$ small to modify the functions $a(u)$, $m(u)$, and $b(u,\dot u)$ outside $|u|\le 1-\bar\delta$; cf. section

2. To do this, we assume (U) from now on. The case (U′) is discussed in the remarks below. Since V is bounded and $\bar{v} < 1$, we can find $c_0 \in \mathbb{R}$ such that $\mathcal{K}_{\bar{v}} \subset \{H \leq c_0\}$. Then as a consequence of $\mathcal{E}_s(u) \to \infty$ for $|u| \to 1$, we have

$$s_0 = \sup\big\{|u| : (r,u) \in \{H \leq c_0 + 1\} \text{ for some } r \in \mathbb{R}^3\big\} < 1\,. \tag{4.3}$$

Let us define

$$\bar{\delta} = \min\{(1-\bar{v})/2, (1-s_0)/2\} > 0. \tag{4.4}$$

THEOREM 4.4. *Assume the potential V to satisfy the condition* (U). *Then there exists $\varepsilon_1 > 0$ depending only upon $\bar{v}$ such that for $\varepsilon \in]0,\varepsilon_1]$ all solutions of* (1.19) *starting at points $(r,u,h_\varepsilon(r,u)) \in \mathcal{I}_\varepsilon$, $|u| \leq \bar{v}$, stay away from the boundary $\{(r,u,h_\varepsilon(r,u)) : |u| = 1-\bar{\delta}\}$ for all future times. In particular, solutions exist globally.*

Proof. Let us denote the bound $c(\bar{\delta})$ from (4.1) by c_1 and let us fix $c_a > 0$ such that $|a(u)| \leq c_a$ for all $|u| < 1$. We recall that $a(u)$ was modified to be constant outside $|u| \leq 1-\bar{\delta}$. We define $\varepsilon_1 = \min\{\varepsilon_0, (2c_ac_1)^{-1}\} > 0$.

Let $(r,u) \in \mathcal{K}_{\bar{v}}$. Then $G_\varepsilon(r,u,h_\varepsilon(r,u)) = H(r,u) - \varepsilon(a(u)h_\varepsilon(r,u))\cdot u \leq c_0 + c_ac_1\varepsilon$. Because of Lemma 4.2 the set $\{G_\varepsilon \leq c_0 + c_ac_1\varepsilon\}$ is forward invariant and the solution remains in this set for all future times. On the other hand, since $\bar{v} \leq 1 - 2\bar{\delta} < 1 - \bar{\delta}$, the solution of the modified problem is a solution to (1.19) and stays on $\mathcal{I}_\varepsilon$, at least for a short time. For the fixed time span where this holds the solution is of the form $(r_1,u_1,h_\varepsilon(r_1,u_1))$ and we have $H(r_1,u_1) = G_\varepsilon(r_1,u_1,h_\varepsilon(r_1,u_1)) + \varepsilon(a(u_1)h_\varepsilon(r_1,u_1))\cdot u_1 \leq c_0 + c_ac_1\varepsilon + c_ac_1\varepsilon = c_0 + 2c_ac_1\varepsilon \leq c_0 + 1$ for $\varepsilon \leq \varepsilon_1$. Therefore by (4.3), $|u_1| \leq s_0 \leq 1 - 2\bar{\delta} < 1 - \bar{\delta}$. This argument shows that in fact the solution is confined to $\{(r,u,\dot{u}) : |u| \leq 1 - 2\bar{\delta}\}$. Hence the solution of the modified problem exists, is a solution to (1.19), and stays on $\mathcal{I}_\varepsilon$ for all future times. □

COROLLARY 4.5. *In the setting of Theorem* 4.4, *for solutions of* (1.19) *starting on $\mathcal{I}_\varepsilon$,*

$$\begin{aligned} &\sup\{|u(t)| : t \in \mathbb{R}, \varepsilon \in]0,\varepsilon_1]\} \leq 1 - 2\bar{\delta} < 1\,, \quad \textit{and} \\ &\sup\{|\dot{u}(t)| : t \in \mathbb{R}, \varepsilon \in]0,\varepsilon_1]\} + \sup\{|\ddot{u}(t)| : t \in \mathbb{R}, \varepsilon \in]0,\varepsilon_1]\} \leq c(\bar{\delta}). \end{aligned} \tag{4.5}$$

In particular by Theorem 4.3

$$\dot{u}(t) \to 0, \quad \ddot{u}(t) \to 0, \quad \textit{and} \quad \nabla V(r(t)) \to 0 \quad \textit{as} \quad t \to \infty.$$

Proof. The first estimate was mentioned already in the preceding proof. For the second we note that (4.1) applies, since the trajectory stays on the center manifold, $\dot{u}(t) = h_\varepsilon(r(t),u(t))$. Concerning the last bound, we may write

$$h_\varepsilon(r,u) = -m(u)^{-1}\nabla V(r) + h_{1,\varepsilon}(r,u) \quad \text{with} \quad |h_{1,\varepsilon}(r,u)| \leq c(\bar{\delta})\varepsilon \tag{4.6}$$

for $(r,u) \in \mathbb{R}^3 \times \mathcal{V}$; see [11, Thm. 2.9]. By (1.19),

$$|\varepsilon\ddot{u}| \leq |a(u)^{-1}||m(u)h_{1,\varepsilon}(r,u) - \varepsilon b(u,\dot{u})| \leq c(\bar{\delta})\varepsilon,$$

so we are done. □

Solutions on $\mathcal{I}_\varepsilon$ are uniformly bounded, in the sense of the corollary; in general a bound on $r(t)$ cannot be expected, e.g., in a scattering situation. Conversely, as to

be shown next, solutions with uniformly bounded $u(t)$, $\dot{u}(t)$, and $\ddot{u}(t)$ are confined to the center manifolds.

PROPOSITION 4.6. *Suppose we have a family* $(r^\varepsilon(t), u^\varepsilon(t))$, $\varepsilon \in]0, \varepsilon_2]$, *of solutions to* (1.19) *such that*

$$\sup\{|u^\varepsilon(t)| : t \in \mathbb{R}, \varepsilon \in]0, \varepsilon_2]\} \leq \bar{u} < 1\,, \quad \textit{and}$$
$$\sup\{|\dot{u}^\varepsilon(t)| : t \in \mathbb{R}, \varepsilon \in]0, \varepsilon_2]\} + \sup\{|\ddot{u}^\varepsilon(t)| : t \in \mathbb{R}, \varepsilon \in]0, \varepsilon_2]\} \leq c_2.$$

Then for sufficiently small ε *the solutions have to lie on* $\mathcal{I}_\varepsilon$.

Proof. Note that we can construct $\mathcal{I}_\varepsilon$ here by modifying $a(u), m(u)$, and $b(u, \dot{u})$ to be constant outside, say, $\{u : |u| \leq (1 + \bar{u})/2\}$. According to [11, Thm. 2.1 (ii)] there exists $\delta > 0$ such that for all ε small and solutions $(x(t), y(t))$ to (2.5) the condition $\sup_{t\in\mathbb{R}} |y(t) - h(x(t))| \leq \delta$ implies that the solution has to lie on $\mathcal{I}_\varepsilon$. With $x(t) = (r^\varepsilon(t), u^\varepsilon(t))$ and $y(t) = \dot{u}^\varepsilon(t)$, this condition is verified since we obtain from (1.19) and the assumed bounds $|\dot{u}^\varepsilon(t) + m(u^\varepsilon(t))^{-1}\nabla V(r^\varepsilon(t))| \leq c\varepsilon \leq \delta$, the latter for ε small. □

The asymptotic condition, $\ddot{r}(t) \to 0$, of Dirac [1] and Haag [2] is also sufficient for a solution to lie on $\mathcal{I}_\varepsilon$, in the following sense.

PROPOSITION 4.7. *Suppose a family* $(r^\varepsilon(t), u^\varepsilon(t))$, $\varepsilon \in]0, \varepsilon_2]$, *of solutions to* (1.19) *is given such that*

$$\sup\{|u^\varepsilon(t)| : t \in \mathbb{R}, \varepsilon \in]0, \varepsilon_2]\} \leq \bar{u} < 1$$

and $\ddot{r}^\varepsilon(t) = \dot{u}^\varepsilon(t) \to 0$ *as* $t \to \infty$ *for each* $\varepsilon \in]0, \varepsilon_2]$. *Then for sufficient small* ε *the solutions have to lie on* $\mathcal{I}_\varepsilon$.

Proof. Fix $\delta > 0$. Since Theorem 4.3 applies, we find in the notation of Proposition 4.6

$$|y(t) - h(x(t))| = |\dot{u}^\varepsilon(t) + m(u^\varepsilon(t))^{-1}\nabla V(r^\varepsilon(t))| \leq \delta/2$$

for $t \geq t(\varepsilon)$, with some $t(\varepsilon)$. Thus the solution remains $(\delta/2)$-close to $\mathcal{I}_0$ after time $t(\varepsilon)$, and hence by (4.6) also δ-close to $\mathcal{I}_\varepsilon$ for ε small. Since $\mathcal{I}_\varepsilon$ is normally hyperbolic (repulsive) at an ε-independent rate and since $\delta > 0$ was arbitrary, this can happen only if the solution was already contained in $\mathcal{I}_\varepsilon$. □

Corollary 4.5 provides partial information on the long time behavior of the solutions to (2.5) on the center manifold. Roughly, one can distinguish two classes.

(i) (scattering): The particle enters a domain where $-\nabla V = 0$ at r_1 with velocity u_∞. If the straight line trajectory $r_1 + u_\infty t$, $t \geq 0$ is contained in this domain, then the particle travels freely to infinity. Physically this is a scattering trajectory. In this case $\lim_{t\to\infty} u(t) = u_\infty \neq 0$, whereas the position has no limit.

(ii) (bounded motion): We assume that $|r(t)| \leq$ const. and that within this ball the critical points of V form a discrete set. Then by Corollary 4.5 and by continuity we have $\lim_{t\to\infty} u(t) = 0$ and $\lim_{t\to\infty} r(t) = r_\infty$, where r_∞ is one of the critical points of V. If r_∞ is a stable critical point, then the relaxation is exponentially fast, as can be seen from linearization around the fixed point.

Clearly (i) and (ii) do not exhaust all possibilities. The critical points of V could lie on a sphere. If V is confining, one would still expect convergence to a definite r_∞. Moreover, V could vanish inside a ball. If $-\nabla V$ is pointing towards the ball, then close to each turning point the particle loses energy. Thus $\lim_{t\to\infty} u(t) = 0$, whereas the position has no limit. The potential could decrease so slowly at infinity that no definite velocity is approached. All these cases have to be studied separately.

Up to now we discussed bounded potentials satisfying (U). In the introduction we claimed that our results remain valid also for confining potentials satisfying (U′). In this case, since V is unbounded, we no longer have $\mathcal{K}_{\bar{v}} \subset \{H \leq c_0\}$ for some $c_0 \in \mathbb{R}$ as in Theorem 4.4 above. However, by energy conservation, one can derive the a priori bound $\sup_{t\in\mathbb{R}} |q^\varepsilon(t)| \leq \bar{M}$ for solutions to the true system (1.5) on the macroscopic time scale. Thus the motion is bounded also in the q-direction and it suffices to build the center manifold for the effective equation (1.19) over the bounded domain

$$\mathcal{K}_{\bar{M},\bar{v}} = \{r \in \mathbb{R}^3 : |r| \leq \bar{M}\} \times \{u \in \mathbb{R}^3 : |u| \leq \bar{v}\},$$

enlarged to a suitable $\mathcal{K}_{\bar{M}+1,1-\bar{\delta}}$ such that solutions starting over $\mathcal{K}_{\bar{M},\bar{v}}$ stay away from the boundary of $\mathcal{K}_{\bar{M}+1,1-\bar{\delta}}$ for $\varepsilon > 0$ sufficiently small. In this manner we obtain

THEOREM 4.8. *Assume* (U′) *holds for the potential, and let* $\mathcal{K}_{\bar{M},\bar{\delta}}$ *be defined as above. Then there exists* $\varepsilon_1 > 0$ *depending only on the initial data such that for* $\varepsilon \in]0, \varepsilon_1]$ *all solutions of* (1.19) *starting at points* $(r, u, h_\varepsilon(r, u)) \in \mathcal{I}_\varepsilon$, $(r, u) \in \mathcal{K}_{\bar{M},\bar{\delta}}$, *exist globally. Moreover, these solutions are uniformly bounded:*

$$\begin{aligned} \sup\{|r(t)| : t \in \mathbb{R}, \varepsilon \in]0, \varepsilon_1]\} &\leq c(\bar{\delta}), \\ \sup\{|u(t)| : t \in \mathbb{R}, \varepsilon \in]0, \varepsilon_1]\} &\leq 1 - 2\bar{\delta} < 1, \quad \textit{and} \\ \sup\{|\dot{u}(t)| : t \in \mathbb{R}, \varepsilon \in]0, \varepsilon_1]\} + \sup\{|\ddot{u}(t)| : t \in \mathbb{R}, \varepsilon \in]0, \varepsilon_1]\} &\leq c(\bar{\delta}). \end{aligned} \tag{4.7}$$

In addition,

$$\dot{u}(t) \to 0, \quad \ddot{u}(t) \to 0, \quad \textit{and} \quad \nabla V(r(t)) \to 0 \quad \textit{as} \quad t \to \infty.$$

Proof. The proof is similar to the one of Theorem 4.4. Concerning the boundedness, note that again for some $c_0 \in \mathbb{R}$ and $\varepsilon > 0$ small,

$$\mathcal{K}_{\bar{M},\bar{\delta}} \subset \{H \leq c_0\} \subset \{(r, u) : G_\varepsilon(r, u, h_\varepsilon(r, u)) \leq c_0 + c_a c_1 \varepsilon\} \subset \{H \leq c_0 + 1\}.$$

Thus all solutions starting over $\mathcal{K}_{\bar{M},\bar{\delta}}$ will remain on the manifolds over $\{H \leq c_0 + 1\}$. Since this set is independent of ε and compact by (U′), the solutions must be uniformly bounded, because h_ε is uniformly bounded. □

On the center manifold the motion is governed by the (second order) equation

$$\dot{x} = f(x, h_\varepsilon(x)). \tag{4.8}$$

Since the existence of h_ε is established only abstractly, (4.8) is somewhat implicit. From [11, (2.9-1) and Thm. 2.9] we know that h_ε depends smoothly on ε. Thus (4.8) can be expanded in ε. Including the first Taylor term we pick up an error of order ε^2, which is of the same order as the error between the true and the comparison dynamics on the center manifold. For consistency we should stop then at this order. We make the ansatz

$$h_\varepsilon(r, u) = h_0(r, u) + \varepsilon h_1(r, u) + h_{2,\varepsilon}(r, u), \quad |h_{2,\varepsilon}(r, u)| \leq c(\bar{\delta})\varepsilon^2.$$

for $(r, u) \in \mathbb{R}^3 \times \mathcal{V}$. Then

$$m(u)h_0(r, u) = -\nabla V(r),$$

and $h_1(r, u)$ is determined through

$$D_x h_0(r, u) f(r, u, h_0(r, u)) = D_y g(r, u, h_0(r, u), 0) h_1(r, u) + D_\varepsilon g(r, u, h(r, u), 0);$$

see [11, (2.9-1) and Thm. 2.9]. Computing the respective derivatives one arrives at

$$\begin{aligned} m(u)h_1(r,u) = a(u)\Big[&- m(u)^{-1}\nabla^2 V(r)u \\ &+\Big(\frac{d}{du}m(u)\Big)^{-1}\big(\nabla V(r), m(u)^{-1}\nabla V(r)\big) \\ &+ b(u, m(u)^{-1}\nabla V(r))\Big] \end{aligned}$$

and the effective second order equation

$$\dot r = u\,, \quad m(u)\dot u = -\nabla V(r) + \varepsilon m(u)h_1(r,u) \tag{4.9}$$

of the particle motion on the center manifold.

5. Comparison of the true and the effective system. In this section we prove Theorem 2.2. Since we have $|u(t_1)| = |v^\varepsilon(t_1)| \le \bar v$ by (1.8), Theorem 4.4, resp., Theorem 4.8, implies that the solution trajectory of the system with the modified functions $a(u)$, $m(u)$, and $b(u,\dot u)$ is indeed a solution trajectory to (1.19). Recall that, by (1.18) and (1.19),

$$m(v^\varepsilon)\dot v^\varepsilon = -\nabla V(q^\varepsilon) + \varepsilon a(v^\varepsilon)\ddot v^\varepsilon + \varepsilon b(v^\varepsilon,\dot v^\varepsilon) + \varepsilon^2 f^\varepsilon(t), \quad t \ge \varepsilon t_1, \tag{5.1}$$

$$m(u)\dot u = -\nabla V(r) + \varepsilon a(u)\ddot u + \varepsilon b(u,\dot u), \tag{5.2}$$

with $|f^\varepsilon(t)| \le C$. Using the bounds (1.8) and (4.5), resp., (4.7), we infer the weaker estimate

$$\begin{aligned} m(v^\varepsilon)\dot v^\varepsilon &= -\nabla V(q^\varepsilon) + \mathcal{O}(\varepsilon), \quad t \ge t_1, \\ m(u)\dot u &= -\nabla V(r) + \mathcal{O}(\varepsilon), \end{aligned}$$

which has been proved already in [5]. Hence (2.7) follows by the argument therein.

To show (2.8) we compute as in Lemma 4.2, using (5.1),

$$\begin{aligned} &\frac{d}{dt}G_\varepsilon(q^\varepsilon(t), v^\varepsilon(t), \dot v^\varepsilon(t)) \\ &= \varepsilon^2 f^\varepsilon(t)v^\varepsilon(t) \\ &\quad -\varepsilon(\mathsf{e}^2/12\pi)\Big[\gamma(\dot v^\varepsilon(t))^6\dot v^\varepsilon(t)^2 + 6\gamma(\dot v^\varepsilon(t))^8(v^\varepsilon(t)\cdot\dot v^\varepsilon(t))^2\Big], \quad t \ge \varepsilon t_1. \end{aligned}$$

Since $r(\varepsilon t_1) = q^\varepsilon(\varepsilon t_1)$ and $u(\varepsilon t_1) = v^\varepsilon(\varepsilon t_1)$, using the uniform bounds, we have for $t \ge \varepsilon t_1$

$$\begin{aligned} &|H(q^\varepsilon(t), v^\varepsilon(t)) - H(r(t),u(t))| \\ &\le \varepsilon\big|(a(v^\varepsilon(t))\dot v^\varepsilon(t))\cdot v^\varepsilon(t) - (a(u(t))\dot u(t))\cdot u(t)\big| \\ &\quad + \int_{\varepsilon t_1}^t ds\,\Big[\varepsilon^2|f^\varepsilon(s)v^\varepsilon(s)| + \varepsilon(\mathsf{e}^2/12\pi)\big(\big|\gamma(\dot v^\varepsilon(s))^6\dot v^\varepsilon(s)^2 - \gamma(\dot u(s))^6\dot u^\varepsilon(s)^2\big| \\ &\qquad\qquad +6\,\big|\gamma(\dot v^\varepsilon(s))^8(v^\varepsilon(s)\cdot\dot v^\varepsilon(s))^2 - \gamma(\dot u(s))^8(u(s)\cdot\dot u(s))^2\big|\big)\Big] \\ &\le C\varepsilon\big[|v^\varepsilon(t) - u(t)| + |\dot v^\varepsilon(t) - \dot u(t)|\big] + C\varepsilon^2 t \\ &\quad + C\varepsilon\int_{\varepsilon t_1}^t ds\,\big[|v^\varepsilon(s) - u(s)| + |\dot v^\varepsilon(s) - \dot u(s)|\big] \\ &\le C\varepsilon^2(1+t) \le C\varepsilon^2, \end{aligned}$$

by (2.7) for $t = \mathcal{O}(1)$. This concludes the proof of Theorem 2.2. ∎

Finally we show that on a microscopic time scale our results track the true trajectory with a higher precision; cf. (2.9), Remark 2.3(i).

PROPOSITION 5.1. *We have*

$$|q^\varepsilon(t) - r(t)| \le c\varepsilon^3 \quad \textit{and} \quad |v^\varepsilon(t) - u(t)| \le c\varepsilon^2, \quad t = \mathcal{O}(\varepsilon),$$

i.e., (2.9) *holds.*

Proof. Define $\Psi(s) = \big(\varepsilon^{-1}q^\varepsilon(\varepsilon s) - \varepsilon^{-1}r(\varepsilon s), v^\varepsilon(\varepsilon s) - u(\varepsilon s), \varepsilon\dot v^\varepsilon(\varepsilon s) - \varepsilon\dot u(\varepsilon s)\big)$ for $s \ge t_1$. Then $\dot\Psi(s) = A\Psi(s) + \theta(s)$, where

$$A = \begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & 0 & 0 \end{pmatrix}$$

and $\theta(s) = \varepsilon^2(0, 0, \ddot v^\varepsilon(\varepsilon s) - \ddot u(\varepsilon s))$, from which

$$\begin{aligned} |\theta(s)| &\le c\varepsilon \, \big(|q^\varepsilon(\varepsilon s) - r(\varepsilon s)| + |v^\varepsilon(\varepsilon s) - u(\varepsilon s)| + |\dot v^\varepsilon(\varepsilon s) - \dot u(\varepsilon s)| + \varepsilon^2\big) \\ &\le c(|\Psi(s)| + \varepsilon^3), \quad s \ge t_1, \end{aligned}$$

by (5.1), (5.2), and the uniform bounds. Therefore by the variation of constants formula and Gronwall's inequality for $s \in [t_1, t_1 + \tau]$, $|\Psi(s)| \le c(\tau)(|\Psi(s_1)| + \varepsilon^3)$. Consequently, $q^\varepsilon(\varepsilon t_1) = r(\varepsilon t_1)$ and $v^\varepsilon(\varepsilon t_1) = u(\varepsilon t_1)$ yields

$$\varepsilon^{-1}|q^\varepsilon(t) - r(t)| + |v^\varepsilon(t) - u(t)| \le c(\tau)\, \big(\varepsilon|\dot v^\varepsilon(\varepsilon t_1) - \dot u(\varepsilon t_1)| + \varepsilon^3\big)$$

for $t \in [\varepsilon t_1, \varepsilon t_1 + \varepsilon\tau]$. By (5.1) and (5.2), $|\dot v^\varepsilon(\varepsilon t_1) - \dot u(\varepsilon t_1)| \le c\varepsilon$, and therefore (2.9) follows. ∎

6. Adiabatic limit of the fields. We prove Theorem 2.4. Let $U(t)$ again denote the fundamental solution of the wave equation in $D^{1,2}(\mathbb{R}^3) \oplus L^2(\mathbb{R}^3)$. We set $Z(x,t) = (\phi(x,t), \pi(x,t))$ as well as $\bar\rho_\varepsilon = (0, \rho_\varepsilon)$. Then the inhomogeneous wave equation in (1.5) is solved as

$$Z(x,t) = [U(t)Z(\cdot,0)](x) - \sqrt{\varepsilon} \int_0^t ds\, [U(t-s)\bar\rho_\varepsilon(\cdot - q^\varepsilon(s))](x).$$

Since

$$Z(x,0) = -\sqrt{\varepsilon} \int_{-\infty}^0 ds\, [U(-s)\bar\rho_\varepsilon(\cdot - q^0 - v^0 s)](x)$$

(cf. Lemma 3.1), we have for $t > 0$

$$Z(x,t) = -\sqrt{\varepsilon} \int_{-\infty}^t ds\, [U(t-s)\bar\rho_\varepsilon(\cdot - q^\varepsilon(s))](x),$$

where we extended the position to negative times $t \le 0$ by $q^\varepsilon(t) = q^0 + v^0 t$. Thus by the solution formula for the wave equation

$$\frac{1}{\sqrt{\varepsilon}}\, \phi(x,t) = -\int \frac{d^3y}{4\pi|x-y|}\, \rho_\varepsilon(y - q^\varepsilon(t - |x-y|)) \tag{6.1}$$

and $\pi(x,t) = \dot\phi(x,t)$. For $\varepsilon \to 0$, $q^\varepsilon(t) \to r(t)$ (cf. (1.9)), with $r(t)$ extended to negative times by $r(t) = q^0 + v^0 t$. Moreover, $\rho_\varepsilon(x) = \varepsilon^{-3}\rho(\varepsilon^{-1}x) \to \mathsf{e}\delta_0$ in the sense of distributions. Hence the transformation $z = y - q^\varepsilon(t - |x-y|)$, $\det(dy/dz) = [1 - v^\varepsilon(t-|x-y|)\cdot(x-y)/|x-y|]^{-1}$, in (6.1) yields the pointwise convergence (2.10), except on the worldline of the particle, since the integrand in (6.1) is singular at $y = x$, i.e., for $x = r(t)$ which corresponds to $t_{\rm ret} = t$.

The analogous argument works for $\pi(x,t)$. In the limit $\varepsilon \to 0$, π is discontinuous at the light cone $\{x : |x| = t\}$, which we avoided due to our assumption. □

7. Radiated energy. Let $E_{R,q^\varepsilon(t)}(t+R)$ be the energy, particle plus field, at time $t+R$ in a ball of radius R centered at $q^\varepsilon(t)$. For $R > \varepsilon R_\rho$ this energy changes as

$$\begin{aligned}
&\frac{d}{dt}\,\big(E_{R,q^\varepsilon(t)}(t+R)\big)\\
&= \frac{d}{dt}\bigg(\mathcal{H}_{mac}(t=0) - \frac{1}{2}\int_{\{|x-q^\varepsilon(t)|>R\}} d^3x\,\big[|\pi(x,t+R)|^2 + |\nabla\phi(x,t+R)|^2\big]\bigg)\\
&= R^2\int_{|\omega|=1} d^2\omega\,\pi(q^\varepsilon(t)+R\omega,t+R)\,\omega\cdot\nabla\phi(q^\varepsilon(t)+R\omega,t+R)\\
&\quad + \frac{R^2}{2}\int_{|\omega|=1} d\omega\,(\omega\cdot v^\varepsilon(t))\big[|\pi(q^\varepsilon(t)+R\omega,t+R)|^2\\
&\qquad\qquad + |\nabla\phi(q^\varepsilon(t)+R\omega,t+R)|^2\big], \qquad (7.1)
\end{aligned}$$

where we used that the total energy is conserved.

E_R changes because there is energy flowing back and forth between particle and field, and because energy is lost irreversibly to infinity. To separate both contributions we take the limit $R \to \infty$. Using (6.1) and the relation $t + R - |q^\varepsilon(t) + R\omega - y| = t + \omega\cdot(y - q^\varepsilon(t)) + \mathcal{O}(1/R)$ for bounded $|y|$, we arrive at

$$\begin{aligned}
I^\varepsilon(t) &= \lim_{R\to\infty}\frac{d}{dt}\,\big(E_{R,q^\varepsilon(t)}(t+R)\big)\\
&= -\varepsilon(4\pi)^{-2}\int_{|\omega|=1} d^2\omega\,(1-\omega\cdot v^\varepsilon(t))\,\bigg[\int d^3y\,\rho_\varepsilon(y - q^\varepsilon(t+\omega\cdot[y-q^\varepsilon(t)]))\\
&\qquad\qquad \times\frac{\omega\cdot\dot v^\varepsilon(t+\omega\cdot[y-q^\varepsilon(t)])}{(1-\omega\cdot v^\varepsilon(t+\omega\cdot[y-q^\varepsilon(t)]))^2}\bigg]^2;
\end{aligned}$$

cf. [7, sec. 3] for details on a similar calculation. In fact, in [7] the ball of radius R was centered at the origin and the second summand in (7.1) is absent. To let $\varepsilon \to 0$, we again transform to $z = y - q^\varepsilon(t+\omega\cdot[y-q^\varepsilon(t)])$, $\det(dy/dz) = [1 - \omega\cdot v^\varepsilon(t+\omega\cdot[y-q^\varepsilon(t)])]^{-1}$, use $\rho_\varepsilon(x) \to \mathsf{e}\delta_0$ in the sense of distributions, and insert the identity $y = q^\varepsilon(t)$ for $z = 0$ to obtain

$$\begin{aligned}
\lim_{\varepsilon\to 0}\varepsilon^{-1}\,I^\varepsilon(t) &= -\mathsf{e}^2(4\pi)^{-2}\int_{|\omega|=1} d^2\omega\,(1-\omega\cdot u(t))^{-5}\,(\omega\cdot\dot u(t))^2\\
&= -(\mathsf{e}^2/12\pi)\,[6\gamma^8(u(t)\cdot\dot u(t))^2 + \gamma^6\dot u(t)^2],
\end{aligned}$$

in agreement with (4.2).

Alternatively, we could first take the limit $\varepsilon \to 0$ in (7.1). Using Theorem 2.4 we find, with $(\overline\phi, \overline\pi)$ denoting the limit fields from (2.10), (2.11),

$$
\begin{aligned}
I_R(t) &= \lim_{\varepsilon\to 0} \varepsilon^{-1} \frac{d}{dt}\left(E_{R,q^\varepsilon(t)}(t+R)\right) \\
&= R^2 \int_{|\omega|=1} d^2\omega\, \overline{\pi}(r(t)+R\omega, t+R)\, \omega\cdot\nabla\overline{\phi}(r(t)+R\omega, t+R) \\
&\quad + \frac{R^2}{2}\int_{|\omega|=1} d^2\omega\, (\omega\cdot u(t))\left[|\overline{\pi}(r(t)+R\omega,t+R)|^2\right. \\
&\qquad\qquad \left. +|\nabla\overline{\phi}(r(t)+R\omega,t+R)|^2\right].
\end{aligned}
$$

Since both $\overline{\pi}$ and $\nabla\overline{\phi}$ have one term proportional to R^{-1} and other contributions of order R^{-2}, in the limit $R\to\infty$ only the product of the two leading terms survives, and it follows that

$$
\lim_{R\to\infty} I_R(t) = -\mathsf{e}^2(4\pi)^{-2}\int_{|\omega|=1} d^2\omega\, (1-\omega\cdot u(t))^{-5}\,(\omega\cdot\dot{u}(t))^2,
$$

as before. We note that the radiated energy is of order ε and it therefore suffices to use the effective dynamics to order one, i.e., ignoring the radiation reaction.

8. Appendix: Proof of Lemma 2.1. In this appendix we prove Lemma 2.1. Since we need to use some identities from [5], we switch back to the original time scale of (1.1). Hence we have to show the following.

LEMMA 2.1 *For solutions of* (1.1) *with initial values satisfying* (1.4)*, i.e., starting on the soliton manifold, and for* $|\rho|_{L^2}$ *sufficiently small we have*

$$
\sup_{t\in\mathbb{R}} |\ddot{v}\ (t)| \le C\varepsilon^3\,.
$$

The constant C *and the bound on* $|\rho|_{L^2}$ *depend only on the data.*

Proof. From [5, Lem. 2.2 and Prop. 4.1] we already know the bounds

$$
\begin{aligned}
&\sup_{t\in\mathbb{R}}|v(t)| \le \bar{v} < 1\,, \quad \sup_{t\in\mathbb{R}}|\dot{v}(t)| + \sup_{t\in\mathbb{R}}|\dot{p}(t)| \le C\varepsilon, \\
&\qquad\text{and}\quad \sup_{t\in\mathbb{R}}|\ddot{v}(t)| + \sup_{t\in\mathbb{R}}|\ddot{p}(t)| \le C\varepsilon^2
\end{aligned}
\tag{8.1}
$$

for $|\rho|_{L^2}$ sufficiently small. The constants $\bar{v}$ and C appearing in (8.1) do not depend on the particular solution, but only on bounds for the initial values.

Denote

$$
Z(x,t) = \begin{pmatrix} \varphi(x,t) \\ \psi(x,t)\end{pmatrix} = \begin{pmatrix} \phi(x,t) - \phi_{v(t)}(x-q(t)) \\ \pi(x,t) - \pi_{v(t)}(x-q(t))\end{pmatrix}.
$$

Then (cf. [5]), with $L(t)\phi = \nabla\phi\cdot v(t) + \dot{\phi}$,

$$
\begin{aligned}
\ddot{p}(t) &= -\varepsilon^2\nabla^2 V(\varepsilon q(t))\cdot v(t) + \int d^3x\,(L(t)\varphi)(x+q(t),t)\nabla\rho(x) \\
&=: -\varepsilon^2\nabla^2 V(\varepsilon q(t))\cdot v(t) + M(t).
\end{aligned}
$$

Therefore

$$
\dddot{p}\ (t) = -\varepsilon^2\nabla^2 V(\varepsilon q(t))\cdot\dot{v}(t) - \varepsilon^3\nabla^3 V(\varepsilon q(t))(v(t),v(t)) + \dot{M}(t)\,. \tag{8.2}
$$

Below we will show the following.

LEMMA 8.1. *The estimate*

$$|\dot{M}(t)| \le C\left(\varepsilon^3 + |\rho|_{L^2}\int_0^t \frac{|\ \dddot{v}\ (s)|}{1+(t-s)^2}\,ds\right)$$

holds.

Then according to (8.2), (8.1), and assumption (U) on the potential,

$$|\ \ddot{p}\ (t)| \le C\left(\varepsilon^3 + |\rho|_{L^2}\int_0^t \frac{|\ \dddot{v}\ (s)|}{1+(t-s)^2}\,ds\right). \tag{8.3}$$

Since

$$\begin{aligned}|\ \ddot{v}\ | &= \left|\frac{d}{dp}\left(\frac{p}{\sqrt{1+p^2}}\right)\ddot{p} + 3\,\frac{d^2}{dp^2}\left(\frac{p}{\sqrt{1+p^2}}\right)(\dot{p},\ddot{p}) + \frac{d^3}{dp^3}\left(\frac{p}{\sqrt{1+p^2}}\right)(\dot{p},\dot{p},\dot{p})\right| \\ &\le C(|\ \dddot{p}\ | + \varepsilon^3),\end{aligned}$$

the claim of Lemma 2.1 is obtained from (8.3) by taking $|\rho|_{L^2}$ small enough. □

Thus it remains to give the following.

Proof of Lemma 8.1. First note

$$\dot{M}(t) = \int d^3x\,\langle(\mathcal{L}(t)Z(\cdot,t))(x),\,\nabla\rho_*(x-q(t))\rangle_{\mathbb{R}^2}\,,\quad \rho_*(x) = (\rho(x),0),$$

where $\mathcal{L}(t)Z = \nabla Z\cdot\dot{v}(t) + (\nabla^2 Z)(v(t),v(t)) + 2\nabla\dot{Z}\cdot v(t) + \ddot{Z}$. Because $\dot{Z} = AZ - B$, with

$$A(\phi,\pi) = (\pi,\Delta\phi)\quad\text{and}\quad B(x,t) = \begin{pmatrix}\nabla_v\phi_{v(t)}(x-q(t))\cdot\dot{v}(t)\\ \nabla_v\pi_{v(t)}(x-q(t))\cdot\dot{v}(t)\end{pmatrix}, \tag{8.4}$$

we obtain

$$\frac{d}{dt}(\mathcal{L}(t)Z) = A(\mathcal{L}(t)Z) - \mathcal{L}(t)B + 2\left[(\nabla^2 Z)(v,\dot{v}) + \nabla\dot{Z}\cdot\dot{v}\right] + \nabla Z\cdot\ddot{v}\,.$$

Let $U(t)$ again denote the group generated by the free wave equation on $D^{1,2}(\mathbb{R}^3)\oplus L^2(\mathbb{R}^3)$. Then

$$\begin{aligned}\dot{M}(t) \;=\;& \langle U(t)[\mathcal{L}(0)Z(\cdot,0)],\,\nabla\rho_*(\cdot-q(t))\rangle_{L^2(\mathbb{R}^2)} \\ &+\int_0^t ds\,\Big[\,-\langle U(t-s)[\mathcal{L}(s)B(\cdot,s)],\,\nabla\rho_*(\cdot-q(t))\rangle_{L^2(\mathbb{R}^2)} \\ &\qquad+2\,\langle U(t-s)[(\nabla^2 Z(\cdot,s))(v(s),\dot{v}(s)) + \nabla\dot{Z}(\cdot,s)\cdot\dot{v}(s)], \\ &\qquad\qquad\nabla\rho_*(\cdot-q(t))\rangle_{L^2(\mathbb{R}^2)} \\ &\qquad+\langle U(t-s)[\nabla Z(\cdot,s)\cdot\ddot{v}(s)],\,\nabla\rho_*(\cdot-q(t))\rangle_{L^2(\mathbb{R}^2)}\,\Big] \\ =:\;& T_0+T_1+T_2+T_3\,.\end{aligned}$$

We estimate each term T_j separately, keeping all parts which contain only initial values. Note that here according to (1.4) we have $Z(x,0)=0$, so all these terms vanish. Nevertheless, we wanted to derive the general form of the estimate; see Remark 2.3(iii).

Estimate of T_3: Since $\dot{Z} = AZ - B$, we find

$$Z(t) = U(t)Z(0) - \int_0^t ds\,U(t-s)B(\cdot,s), \tag{8.5}$$

and hence

$$\begin{aligned} T_3 &= \int_0^t ds\, \langle U(t)[\nabla Z(\cdot,0)\cdot \ddot{v}(s)],\, \nabla\rho_*(\cdot - q(t))\rangle_{L^2(\mathbb{R}^2)} \\ &\quad - \int_0^t ds \int_0^s d\tau\, \langle U(t-\tau)[\nabla B(\cdot,\tau)\cdot \ddot{v}(s)],\, \nabla\rho_*(\cdot - q(t))\rangle_{L^2(\mathbb{R}^2)} \\ &=: T_{3,0} + T_{3,1}\,. \end{aligned}$$

Then Lemma 8.2 below and (8.1) imply through integration by parts in the d^3x-integral

$$T_{3,1} \le C\varepsilon^2 \int_0^t ds \int_0^s d\tau\, \frac{\varepsilon}{1+(t-\tau)^3} \le C\varepsilon^3\,.$$

Estimate of T_0: This term is determined solely through the data.

Estimate of T_1: If we calculate the form of $\mathcal{L}(t)B = \nabla B\cdot \dot{v} + (\nabla^2 B)(v,v) + 2\nabla\dot{B}\cdot v + \ddot{B}$ explicitly from (8.4), many terms cancel, fortunately, and we find with $\Phi_v = \binom{\phi_v}{\pi_v}$,

$$\mathcal{L}(t)B = \nabla_v\Phi_v(x-q)\cdot\, \dddot{v} + 3\nabla_v^2\Phi_v(x-q)(\dot{v},\ddot{v}) + \nabla_v^3\Phi_v(x-q)(\dot{v},\dot{v},\dot{v})\,.$$

Now we may argue analogously to the estimate of T_3 and Lemma 8.2 to obtain with

$$\begin{pmatrix} \tilde{\phi}(x) \\ \tilde{\pi}(x) \end{pmatrix} = [U(t-s)\mathcal{L}(s)B(\cdot,s)](x)$$

the estimate

$$|\nabla\tilde{\phi}(x+q(t))| \le \frac{C}{1+(t-s)^2}\left(\varepsilon^3 + |\,\dddot{v}\,(s)|\right), \quad |x|\le R_\rho\,, \quad t\ge s\,. \tag{8.6}$$

Here we have used (8.1) and some of the estimates

$$\begin{aligned} |\nabla\nabla_v\phi_v(x)| + |\nabla\nabla_v^2\phi_v(x)| + |\nabla\nabla_v^3\phi_v(x)| &\le C(1+|x|)^{-2}\,, \\ |\nabla^2\nabla_v\phi_v(x)| + |\nabla^2\nabla_v^2\phi_v(x)| + |\nabla^2\nabla_v^3\phi_v(x)| &\le C(1+|x|)^{-3}\,, \\ |\nabla^3\nabla_v\phi_v(x)| + |\nabla^3\nabla_v^2\phi_v(x)| + |\nabla^3\nabla_v^3\phi_v(x)| &\le C(1+|x|)^{-4}\,, \\ |\nabla^4\nabla_v\phi_v(x)| + |\nabla^4\nabla_v^2\phi_v(x)| + |\nabla^4\nabla_v^3\phi_v(x)| &\le C(1+|x|)^{-5}\,, \\ |\nabla\nabla_v\pi_v(x)| + |\nabla\nabla_v^2\pi_v(x)| + |\nabla\nabla_v^3\pi_v(x)| &\le C(1+|x|)^{-3}\,, \\ |\nabla^2\nabla_v\pi_v(x)| + |\nabla^2\nabla_v^2\pi_v(x)| + |\nabla^2\nabla_v^3\pi_v(x)| &\le C(1+|x|)^{-4}\,, \\ |\nabla^3\nabla_v\pi_v(x)| + |\nabla^3\nabla_v^2\pi_v(x)| + |\nabla^3\nabla_v^3\pi_v(x)| &\le C(1+|x|)^{-5} \end{aligned} \tag{8.7}$$

for $x\in\mathbb{R}^3$ and $|v|\le\bar{v}$. From (8.6) we conclude

$$T_1 = -\int_0^t ds \int_{|x|\le R_\rho} d^3x\, \nabla\tilde{\phi}(x+q(t))\rho(x) \le C\left(\varepsilon^3 + |\rho|_{L^2}\int_0^t \frac{|\,\dddot{v}\,(s)|}{1+(t-s)^2}\,ds\right).$$

Estimate of T_2: Let $P(t)Z = \nabla^2 Z(\cdot,t)v(t) + \nabla\dot{Z}(\cdot,t)$. Then

$$\frac{d}{dt}(P(t)Z) = P(t)\dot{Z} + (\nabla^2 Z)\dot{v} = A(P(t)Z) - P(t)B + (\nabla^2 Z)\dot{v}\,.$$

Therefore by the definition of T_2,

$$\begin{aligned} T_2 \;=\; & 2\int_0^t ds\,\langle U(t)[(P(0)Z(\cdot,0))\cdot\dot v(s)],\,\nabla\rho_*(\cdot-q(t))\rangle_{L^2(\mathbb{R}^2)} \\ & +2\int_0^t ds\int_0^s d\tau\,\langle U(t-\tau)\left[-P(\tau)B(\cdot,\tau)+(\nabla^2 Z(\cdot,\tau))\dot v(\tau)\right]\cdot\dot v(s), \\ & \qquad\qquad \nabla\rho_*(\cdot-q(t))\rangle_{L^2(\mathbb{R}^2)} \\ =:\; & T_{2,0}+T_{2,1}+T_{2,2}\,. \end{aligned}$$

To estimate $T_{2,1}$, observe

$$P(t)B=\nabla\nabla_v\Phi_v(x-q)\cdot\ddot v+\nabla\nabla_v^2\Phi_v(x-q)(\dot v,\dot v)\,.$$

Hence we may argue as before to find $|T_{2,1}|\le C\varepsilon^3$. In order to bound $T_{2,2}$, similarly to the estimate of T_3, we again use (8.5) to get

$$\begin{aligned} & T_{2,2} \\ & \quad = 2\int_0^t ds\int_0^s d\tau\,\langle U(t)[\nabla^2 Z(0)(\dot v(\tau),\dot v(s))],\,\nabla\rho_*(\cdot-q(t))\rangle_{L^2(\mathbb{R}^2)} \\ & \qquad -2\int_0^t ds\int_0^s d\tau\int_0^\tau d\sigma\,\langle U(t-\sigma)[\nabla^2 B(\cdot,\sigma)(\dot v(\tau),\dot v(s))], \\ & \qquad\qquad\qquad \nabla\rho_*(\cdot-q(t))\rangle_{L^2(\mathbb{R}^2)} \\ & \quad =: T_{2,2,0}+T_{2,2,1}\,. \end{aligned}$$

By (8.7) and the argument of Lemma 8.2 then

$$T_{2,2,1}\le\int_0^t ds\int_0^s d\tau\int_0^\tau d\sigma\,\frac{C\varepsilon^3}{1+(t-\sigma)^4}\le C\varepsilon^3\,.$$

Summarizing all above estimates for T_0–T_3, we hence arrive at

$$\begin{aligned} |\dot M(t)|\le\; & C\left(\varepsilon^3+|\rho|_{L^2}\int_0^t\frac{|\;\ddot v\;(s)|}{1+(t-s)^2}\,ds\right) \\ & +\langle U(t)[\mathcal{L}(0)Z(\cdot,0)],\,\nabla\rho_*(\cdot-q(t))\rangle_{L^2(\mathbb{R}^2)} \\ & +2\int_0^t ds\,\langle U(t)[(P(0)Z(\cdot,0))\cdot\dot v(s)],\,\nabla\rho_*(\cdot-q(t))\rangle_{L^2(\mathbb{R}^2)} \\ & +2\int_0^t ds\int_0^s d\tau\,\langle U(t)[\nabla^2 Z(0)(\dot v(\tau),\dot v(s))],\,\nabla\rho_*(\cdot-q(t))\rangle_{L^2(\mathbb{R}^2)} \\ & +\int_0^t ds\,\langle U(t)[\nabla Z(\cdot,0)\cdot\ddot v(s)],\,\nabla\rho_*(\cdot-q(t))\rangle_{L^2(\mathbb{R}^2)}\,. \end{aligned} \tag{8.8}$$

Concerning the terms that contain data, these vanish here since $Z(x,0)=0$ as a consequence of (1.4). This completes the proof of Lemma 8.1. □

In case of solutions starting close to but not on the soliton manifold as discussed in Remark 2.3(iii), conditions on the data have to be imposed to ensure the last four terms in (8.8) can also be estimated by $C\varepsilon^3$. In [5, Thm. 2.6 and sect. 4] details are carried out for derivatives of one order less.

We used the following lemma above.

LEMMA 8.2. *The estimate*

$$\|\nabla[U(t-\tau)\nabla B(\cdot,\tau)](\cdot+q(t))\|_{R_\rho} \leq C\,\frac{\varepsilon}{1+(t-\tau)^3}\,, \quad t\geq\tau\,, \tag{8.9}$$

holds.

Proof. Such estimates have already been used in [5], but we nevertheless include some details of the argument. Let

$$\begin{pmatrix} \tilde\phi(x) \\ \tilde\pi(x) \end{pmatrix} = [U(t-\tau)\nabla B(\cdot,\tau)](x)$$

for fixed t,τ. By Kirchhoff's formula for the solution to the wave equation and by (8.4),

$$\begin{aligned} &\nabla\tilde\phi(x+q(t)) \\ &= \frac{1}{4\pi(t-\tau)^2}\int_{|y-x-q(t)|=(t-\tau)} d^2y\,\big[(t-\tau)\nabla^2\nabla_v\pi_{v(\tau)}(y-q(\tau))\cdot\dot v(\tau) \\ &\qquad +\nabla^2\nabla_v\phi_{v(\tau)}(y-q(\tau))\cdot\dot v(\tau) \\ &\qquad +\nabla^3\nabla_v\phi_{v(\tau)}(y-q(\tau))(\dot v(\tau),y-x-q(t))\,\big]. \end{aligned} \tag{8.10}$$

Now $|x|\leq R_\rho$ and $|y-x-q(t)|=(t-\tau)$ yield $|y-q(\tau)|\geq(t-\tau)-\bar v(t-\tau)-R_\rho = (1-\bar v)(t-\tau)-R_\rho$ by (8.1). As a consequence of (8.7), (8.9) therefore follows from (8.10). □

Acknowledgment. We thank A. Komech for useful discussions.

CLOSURE OF THE MANAKOV SYSTEM*

R. G. DOCKSEY† AND J. N. ELGIN†

Abstract. We discuss the closure of the product eigenstate for the Manakov system. Although the analysis is similar in principle to that for the Zakharov–Shabat system published elsewhere, two additional features arise which require careful attention.

First, in addition to the direct (or forward) scattering problem, an adjoint scattering problem is necessary. In the Zakharov–Shabat system, the adjoint problem is trivially related to the direct problem, leading to the formation of "squared" eigenstates rather than the product eigenstates which we derive.

Second, the system is not diagonal in the sense that both parts of the potential q_1 and q_2 contribute to each element S_{ij} of the scattering data, while—reciprocally—all (relevant) elements of the scattering data contribute in the reconstruction of both q_1 and q_2.

Key words. completeness, nonlinear Schrödinger equation, Manakov system

1. Introduction.

The vector nonlinear Schrödinger (NLS) equation is

$$i\mathbf{q_x} - \mathbf{q_{tt}} - \mathbf{2qq^\dagger q} = \mathbf{0}, \tag{1}$$

where a suffix denotes a partial derivative and † denotes Hermitian conjugation [1]. The most useful application of (1) is to studies on ultrashort pulse propagation down birefringent optical fibers [2], [3], [4], [5], [6]. In keeping with the notation now used in such studies, the roles of the independent variables x and t are such that *time* x is the distance propagated by the pulse down the fiber, while *spatial coordinate* t is a retarded time variable indicating position along the pulse. The Cauchy problem associated with (1) corresponds to specifying $\mathbf{q}(0,t)$, i.e., the profile of the pulse at input to the fiber. The vector nature of the dependant variable $\mathbf{q} = (q_1, q_2)^T$—where T denotes the transpose—is directly linked with the polarization state of the optical pulse.

Equation (1) is the lowest order nontrivial amplitude equation obtained from a multiple scales analysis of Maxwell's equations as appropriate to the fiber optic problem [2]. Both dispersion and nonlinearity are present, where the latter is the Kerr nonlinearity which corresponds to the intensity dependence of the refractive index of the host medium. The scalar form of (1) is obtained from the simple replacement of $\mathbf{q}$ with q and $\mathbf{q}^\dagger$ with q^*, where $*$ denotes complex conjugate; we will refer to this reduced form of (1) as the scalar problem.

Manakov [1] first demonstrated integrability of the vector NLS equation using the techniques of inverse scattering theory [7]. The Lax pair for the vector problem is a direct extension of that for the scalar problem first quoted by Zakharov and Shabat [8]. Kaup [9] investigated the closure of the squared Zakharov–Shabat eigenstates and motivated his work with the observation that it is precisely these squared eigenstates (and their closure) which are intrinsic to relating small changes in the potential q

to small changes in the set of scattering data associated with the Zakharov–Shabat system, and vice versa. The corresponding statement for the Manakov system is made in (2) and (3) below.

In this article we extend Kaup's analysis to derive the closure for a set of product eigenstates associated with the Manakov system. In constructing this closure we need to take into account two features which do not arise in the scalar problem: First, an adjoint scattering problem is required in addition to the direct (or forward) scattering problem. With the Zakharov–Shabat system the adjoint problem is trivially related to the direct problem, leading to formation of squared eigenstates rather than the product states encountered here. Second, the system is not diagonal in the sense that both q_1 and q_2 contribute to each element S_{ij} of the scattering data, while—reciprocally—all (relevant) elements of the scattering data contribute in the reconstruction of both q_1 and q_2.

The spectral transform is a mapping from a potential $\mathbf{q}(x,t)$ into a set of scattering data $S_{ij}(\zeta,x)$ $(i,j=1,2,3)$, where ζ is an eigenparameter. The inverse map permits construction of the potential $\mathbf{q}$ from the set S_{ij}. Formally, we have (as will be proven in the later sections)

$$S_{ij}=\int_{-\infty}^{\infty}\phi^{(i)}\wedge\hat{\psi}^{(j)}\begin{pmatrix}\mathbf{q},\\ -\mathbf{q}^*\end{pmatrix}dt, \tag{2}$$

$$\begin{aligned}\begin{pmatrix}\mathbf{q}\\ \mathbf{q}^*\end{pmatrix}&=\frac{1}{\pi}\int_c\left(\frac{S_{21}}{S_{11}}\psi^{(2)}\vee\hat{\psi}^{(1)}+\frac{S_{31}}{S_{11}}\psi^{(3)}\vee\hat{\psi}^{(1)}\right)d\zeta\\ &\quad-\frac{1}{\pi}\int_{\bar{c}}\left(\frac{\Delta_{21}}{\Delta_{11}}\psi^{(1)}\vee\hat{\psi}^{(2)}+\frac{\Delta_{31}}{\Delta_{11}}\psi^{(1)}\vee\hat{\psi}^{(3)}\right)d\zeta.\end{aligned} \tag{3}$$

Here, $\phi^{(i)}\wedge\hat{\psi}^{(j)}$ and $\psi^{(i)}\vee\hat{\psi}^{(j)}$ are four component row and column vectors, respectively, whose components are made up of products between Jost function components for the forward and adjoint scattering problems (as discussed in section 3). It is the closure of those product states that is the main concern in this article.

The quantities Δ_{ij} are cofactors of S_{ij}, while the contours c and $\bar{c}$ are discussed later. For the moment, only one feature of (2) and (3) need be emphasized; namely, that the product states are intrinsic to the relationship between the potential $\mathbf{q}$ and the scattering data S_{ij}. A small change in $\mathbf{q}$ results in a change in S_{ij}, and vice versa.

Now suppose that the potential $\mathbf{q}(x,t)$ at time x changes to $\mathbf{q}(x+\delta x,t)$ at a later time $x+\delta x$ in accordance with (1). Then it follows from (2) that

$$\frac{d}{dx}S_{ij}=\int_{-\infty}^{\infty}\phi^{(i)}\wedge\hat{\psi}^{(j)}\begin{pmatrix}\mathbf{q}_x\\ -\mathbf{q}_x^*\end{pmatrix}dt. \tag{4}$$

For $(i,j)=(1,1)$, it can be shown independently that dS_{11}/dx is zero, so that $(\mathbf{q}_x,-\mathbf{q}_x^*)$ is orthogonal to the basis $\phi^{(i)}\wedge\hat{\psi}^{(j)}(\zeta;x,t)$. In other words, these product states are necessarily incomplete.

It is our intention here to find the closure of the product states of the Manakov system, and hence derive the completeness statement equation (78).

The article is arranged as follows: In section 2, we discuss the direct and adjoint scattering problems, and introduce the Jost function solutions of these equations, together with the scattering data. In the next section we introduce the product eigenstates—four component vectors which are bilinear products of an element from the Jost functions in each of the direct and adjoint scattering problems—and discuss

their closure. The statement of closure made in section 3 is proved in section 4 by redress to a set of Marchenko equations.

Some final comments are made in section 5; in particular, the completeness relation is used to express **q** in terms of integrals over the product states ((3) above), and we show how the family of vector NLS equations are generated using an integro-differential operator, introduced in section 3. The consequences of adding additional terms to (1) is then examined. Such terms may model the weak and strong birefringence properties of the fiber, the effects of higher order dispersion, loss in the fiber, and so on. Their effects on soliton propagation is examined: the vector soliton is a localized pulse which propagates without change of shape or polarization state. When any—or all—of these additional terms are included, the initial soliton state becomes modified in two ways: first, the soliton parameters and the polarization state of the pulse may change adiabatically with distance down the fiber. Second, the soliton may now shed radiation. Equation (3) is required to investigate the latter, which in turn follows from the closure of the product states. This application was the initial motivation behind this study.

2. The scattering problem. The scattering problem associated with (1) is [1], [10]

$$v_t + i\zeta E v = Q v, \tag{5}$$

where $v = [v_1, v_2, v_3]^T$ is a spinor eigenstate, (complex) ζ is an eigenparameter, the suffix t denotes the derivative $\partial/\partial t$, and the matrices E and Q are defined by

$$E = \begin{pmatrix} 1 & 0 & 0 \\ 0 & -1 & 0 \\ 0 & 0 & -1 \end{pmatrix}, \qquad Q = \begin{pmatrix} 0 & q_1 & q_2 \\ -q_1^* & 0 & 0 \\ -q_2^* & 0 & 0 \end{pmatrix}. \tag{6}$$

In this article, (5) is considered on the infinite interval $-\infty < t < \infty$, while the potentials q_1 and $q_2 \in L_1$, i.e., they satisfy

$$\begin{aligned} &\int_{-\infty}^{\infty} |q_1(x,t)|dt < \infty, \\ &\int_{-\infty}^{\infty} |q_2(x,t)|dt < \infty. \end{aligned} \tag{7}$$

We define the fundamental (or Jost) solutions $\phi^{(i)}$ and $\psi^{(i)}$, and $i = 1, 2, 3$, for real $\zeta = \xi$ by the requirements that

$$\phi^{(1)} \sim \begin{pmatrix} e^{-i\xi t} \\ 0 \\ 0 \end{pmatrix}, \quad \phi^{(2)} \sim \begin{pmatrix} 0 \\ e^{i\xi t} \\ 0 \end{pmatrix}, \quad \phi^{(3)} \sim \begin{pmatrix} 0 \\ 0 \\ e^{i\xi t} \end{pmatrix}, \quad t \to -\infty,$$

$$\psi^{(1)} \sim \begin{pmatrix} e^{-i\xi t} \\ 0 \\ 0 \end{pmatrix}, \quad \psi^{(2)} \sim \begin{pmatrix} 0 \\ e^{i\xi t} \\ 0 \end{pmatrix}, \quad \psi^{(3)} \sim \begin{pmatrix} 0 \\ 0 \\ e^{i\xi t} \end{pmatrix}, \quad t \to \infty.$$

Throughout this article, a superscript will be used to denote one of the Jost function solutions, and a subscript will denote a particular component of that solution, so that $\phi_1^{(2)}$ is the first component of the Jost function, $\phi^{(2)}$.

Since $\phi^{(i)}$ and $\psi^{(j)}$ are independent sets of solutions, we can write

$$\phi^{(i)} = \sum_{j=1}^{3} S_{ji}(\zeta)\psi^{(j)}, \tag{8}$$

which defines the scattering data $S_{ij}(\zeta)$. For $\zeta = \xi$ real, S is a 3×3 unitary unimodular matrix [10].

We also require an adjoint scattering problem which is taken to be

$$\hat{v}_t - i\zeta E\hat{v} = Q^*\hat{v}, \tag{9}$$

where the $\hat{}$ symbol will be used to denote solutions of the adjoint problem. As with the direct problem, we define the fundamental solutions $\hat{\phi}^{(i)}$ and $\hat{\psi}^{(i)}$ of the adjoint problem by the requirement that

$$\hat{\phi}^{(1)} \sim \begin{pmatrix} e^{i\xi t} \\ 0 \\ 0 \end{pmatrix}, \quad \hat{\phi}^{(2)} \sim \begin{pmatrix} 0 \\ e^{-i\xi t} \\ 0 \end{pmatrix}, \quad \hat{\phi}^{(3)} \sim \begin{pmatrix} 0 \\ 0 \\ e^{-i\xi t} \end{pmatrix}, \quad t \to -\infty,$$

$$\hat{\psi}^{(1)} \sim \begin{pmatrix} e^{i\xi t} \\ 0 \\ 0 \end{pmatrix}, \quad \hat{\psi}^{(2)} \sim \begin{pmatrix} 0 \\ e^{-i\xi t} \\ 0 \end{pmatrix}, \quad \hat{\psi}^{(3)} \sim \begin{pmatrix} 0 \\ 0 \\ e^{-i\xi t} \end{pmatrix}, \quad t \to \infty.$$

Note that for the scattering problem associated with the scalar NLS equation, the two component adjoint Jost functions are related in a simple way to the direct functions by $\hat{\phi}^{(1)} = \sigma_1\phi^{(2)}$, $\hat{\phi}^{(2)} = \sigma_1\phi^{(1)}$, where σ_1 is the Pauli matrix. In view of this, no explicit statement of an adjoint problem is required.

Since by construction $(\hat{\psi}^{(i)})^T\psi^{(j)} = \delta_{ij}$, it follows that $S_{ij} = (\hat{\psi}^{(i)})^T\phi^{(j)}$. The scattering data Δ_{ij} for the adjoint scattering problem are introduced in a manner analogous to (8) by

$$\hat{\phi}^{(i)} = \sum_{j=1}^{3} \Delta_{ji}(\zeta)\hat{\psi}^{(j)}. \tag{10}$$

By virtue of the unitary nature of S, it is easily demonstrated that $\Delta_{ji}(\zeta)$ is the cofactor of the element $S_{ij}(\zeta)$ and that

$$\Delta_{ij}(\zeta) = S_{ij}^*(\zeta), \tag{11}$$

where $*$ denotes complex conjugate.

A simple consideration of the analytic properties of $\phi^{(1)}(\zeta)$, etc., reveals the following [10]:

- $\phi^{(1)}, \psi^{(2)}, \psi^{(3)}, \hat{\phi}^{(2)}, \hat{\phi}^{(3)}, \hat{\psi}^{(1)}$ are analytic in the upper half of the complex ζ-plane, as are $S_{11}, \Delta_{22}, \Delta_{33}, \Delta_{23}$, and Δ_{32};
- $\phi^{(2)}, \phi^{(3)}, \psi^{(1)}, \hat{\phi}^{(1)}, \hat{\psi}^{(2)}, \hat{\psi}^{(3)}$ are analytic in the lower half of the complex ζ-plane, as are $S_{22}, S_{33}, S_{23}, S_{32}$, and Δ_{11};
- $S_{12}, S_{13}, S_{21}, S_{31}, \Delta_{12}, \Delta_{13}, \Delta_{21}, \Delta_{31}$ are defined only for $\zeta = \xi$ real, with possible continuation into the ζ-plane dependant on the manner in which $|q_1|$ and $|q_2|$ decrease as $|t| \to \infty$. For example, if $q_1,\ q_2 < Ce^{-2K|t|}$ as $t \to \infty$, these quantities are analytic in the strip $K > \Im\zeta > -K$.

The zeros of $S_{11}(\zeta)$ in the upper half plane, $S_{11}(\zeta_k) = 0$, $k = 1, \ldots, N$, give the bound states of (5). We will assume throughout that such zeros are simple, though our results will continue to hold for cases where this is not so. With $S_{11}(\zeta_k) = 0$, (8) gives

$$\phi^{(1)}(\zeta_k, t) = c_k \psi^{(2)}(\zeta_k, t) + d_k \psi^{(3)}(\zeta_k, t), \tag{12}$$

with suitably chosen weights c_k and d_k. To construct similar bound state eigenfunctions $\phi^{(2)}$ and $\phi^{(3)}$, it would appear that we require the (overrestrictive) conditions that S_{22}, S_{23}, S_{32}, and S_{33} all vanish at some $\zeta = \bar{\zeta}_k$, $\Im\bar{\zeta}_k < 0$ in order to eliminate the exponentially growing terms at $t \to \infty$. These requirements can be relaxed by introducing a new pair of eigenfunctions $\phi^{(\pm)}$, analytic in the lower half plane, to replace $\phi^{(2)}$ and $\phi^{(3)}$. Define

$$\phi^{(+)}(\zeta, t) = S_{33}(\zeta)\phi^{(2)}(\zeta, t) - S_{32}(\zeta)\phi^{(3)}(\zeta, t) \tag{13}$$

$$= \Delta_{11}(\zeta)\psi^{(2)}(\zeta, t) - \Delta_{21}(\zeta)\psi^{(1)}(\zeta, t), \tag{14}$$

$$\phi^{(-)}(\zeta, t) = S_{22}(\zeta)\phi^{(3)}(\zeta, t) - S_{23}(\zeta)\phi^{(2)}(\zeta, t) \tag{15}$$

$$= \Delta_{11}(\zeta)\psi^{(3)}(\zeta, t) - \Delta_{31}(\zeta)\psi^{(1)}(\zeta, t), \tag{16}$$

where the second forms of each set follow from using (8).

At $\bar{\zeta}_k = \zeta_k^*$, $\Delta_{11}(\bar{\zeta}_k) = 0$, and hence we have the bound states

$$\phi^{(+)}(\bar{\zeta}_k, t) = \bar{c}_k \psi^{(1)}(\bar{\zeta}_k, t), \tag{17}$$

$$\phi^{(-)}(\bar{\zeta}_k, t) = \bar{d}_k \psi^{(1)}(\bar{\zeta}_k, t), \tag{18}$$

with suitably chosen weights $\bar{c}_k$ and $\bar{d}_k$. In Appendix A, similar definitions are given for the functions $\psi^{(\pm)}$, $\hat{\phi}^{(\pm)}$, and $\hat{\psi}^{(\pm)}$.

3. The product Manakov eigenstates and their closure. In this section we will discuss the product eigenstates of the Manakov system. These are four component vectors whose components are bilinear products of an element from each of the direct and adjoint scattering problems, such as $\psi_k^{(i)}\hat{\psi}_l^{(j)}$ for some i, j, k, l. From the scattering problem and its adjoint, we find that such product states satisfy a ninth order system of equations, which can be reduced to a smaller set of four equations by formal integration of five of the set. This procedure results in the introduction of a 4×4 integro-differential matrix operator $\mathcal{L}$,

$$\mathcal{L} = \frac{1}{2i} \begin{pmatrix} -\partial_t + J^{(1)}_{\mathbf{q}\mathbf{q}^*} & -J^{(2)}_{\mathbf{q}\mathbf{q}} \\ J^{(2)}_{\mathbf{q}^*\mathbf{q}^*} & \partial_t - J^{(1)}_{\mathbf{q}^*\mathbf{q}} \end{pmatrix}. \tag{19}$$

The integral operators $J^{(1)}$ and $J^{(2)}$ are defined by their action on an arbitrary vector function $\mathbf{f}$,

$$J^{(1)}_{\mathbf{u}\mathbf{v}}[\mathbf{f}] = \int_t^\infty \left(\mathbf{u}(t)\mathbf{v}^T(t') + \mathbf{v}^T(t')\mathbf{u}(t)\right)\mathbf{f}(t')dt', \tag{20}$$

$$J^{(2)}_{\mathbf{u}\mathbf{v}}[\mathbf{f}] = \int_t^\infty \left(\mathbf{u}(t)\mathbf{v}^T(t') + \mathbf{v}(t')\mathbf{u}^T(t)\right)\mathbf{f}(t')dt', \tag{21}$$

where $\mathbf{u}$ and $\mathbf{v}$ are (arbitrary) vector suffixes. The suffixes $\mathbf{q}$ and $\mathbf{q}^*$ which appear in (19) correspond to the potential $\mathbf{q}$ and its conjugate $\mathbf{q}^*$.

On reducing the ninth order system to a set of four coupled equations, the remaining set of four product variables can be written as the components of a four vector, which we now introduce with the following notation. For any u and $\hat{v}$, three component vector solutions of the scattering problem and its adjoint, respectively, define

$$u \vee \hat{v} = (u_1\hat{v}_2, u_1\hat{v}_3, -u_2\hat{v}_1, -u_3\hat{v}_1)^T. \tag{22}$$

Hence, for example,

$$\psi^{(i)} \vee \hat{\psi}^{(j)} = \left(\psi_1^{(i)}\hat{\psi}_2^{(j)}, \psi_1^{(i)}\hat{\psi}_3^{(j)}, -\psi_2^{(i)}\hat{\psi}_1^{(j)}, -\psi_3^{(i)}\hat{\psi}_1^{(j)}\right)^T. \tag{23}$$

One can easily show that $\psi^{(1)} \vee \hat{\psi}^{(2)}$, $\psi^{(1)} \vee \hat{\psi}^{(3)}$, $\psi^{(2)} \vee \hat{\psi}^{(1)}$, and $\psi^{(3)} \vee \hat{\psi}^{(1)}$ are all eigenfunctions of the operator $\mathcal{L}$, with eigenvalue ζ, i.e.,

$$\left.\begin{array}{l} \mathcal{L}\psi^{(1)} \vee \hat{\psi}^{(2)} = \zeta\psi^{(1)} \vee \hat{\psi}^{(2)} \\ \mathcal{L}\psi^{(1)} \vee \hat{\psi}^{(3)} = \zeta\psi^{(1)} \vee \hat{\psi}^{(3)} \end{array}\right\} \Im\zeta \le 0, \tag{24}$$

and

$$\left.\begin{array}{l} \mathcal{L}\psi^{(2)} \vee \hat{\psi}^{(1)} = \zeta\psi^{(2)} \vee \hat{\psi}^{(1)} \\ \mathcal{L}\psi^{(3)} \vee \hat{\psi}^{(1)} = \zeta\psi^{(3)} \vee \hat{\psi}^{(1)} \end{array}\right\} \Im\zeta \ge 0. \tag{25}$$

Other choices of i, j produce product states which are not eigenstates of $\mathcal{L}$; we will refer to these states as "cross states." These satisfy the relationship

$$\mathcal{L}\psi^{(i)} \vee \hat{\psi}^{(j)} = \zeta\psi^{(i)} \vee \hat{\psi}^{(j)} - \frac{1}{2i}\gamma_{ij}\begin{pmatrix} \mathbf{q} \\ \mathbf{q}^* \end{pmatrix}, \tag{26}$$

where the matrices γ_{ij} are given by

$$\begin{aligned} \gamma_{11} &= -\mathbf{I}_4, \\ \gamma_{22} &= \tfrac{1}{2}\begin{pmatrix} \mathbf{I}_2 + \sigma_3 & 0 \\ 0 & \mathbf{I}_2 + \sigma_3 \end{pmatrix}, \\ \gamma_{23} &= \begin{pmatrix} \sigma_- & 0 \\ 0 & \sigma_+ \end{pmatrix}, \\ \gamma_{32} &= \begin{pmatrix} \sigma_+ & 0 \\ 0 & \sigma_- \end{pmatrix}, \\ \gamma_{33} &= \tfrac{1}{2}\begin{pmatrix} \mathbf{I}_2 - \sigma_3 & 0 \\ 0 & \mathbf{I}_2 - \sigma_3 \end{pmatrix}, \end{aligned} \tag{27}$$

with

$$\sigma_+ = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}, \qquad \sigma_- = \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix}, \qquad \sigma_3 = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}. \tag{28}$$

The remaining $\gamma_{12}, \gamma_{13}, \gamma_{21}$, and γ_{31} matrices are zero, leading to (24) and (25).

Vectors such as $\psi^{(1)} \vee \hat{\psi}^{(2)}$ will form the basis states in our vector space. To define and evaluate inner products between such vectors, we will require an adjoint problem associated with (26) above. The adjoint operator $\mathcal{L}_A$ is now defined to be

$$\mathcal{L}_A = \frac{1}{2i} \begin{pmatrix} \partial_t + I^{(1)}_{\mathbf{q}^*\mathbf{q}} & I^{(2)}_{\mathbf{q}^*\mathbf{q}^*} \\ -I^{(2)}_{\mathbf{qq}} & -\partial_t - I^{(1)}_{\mathbf{qq}^*} \end{pmatrix}, \tag{29}$$

where the integral operators $I^{(1)}_{\mathbf{uv}}$ and $I^{(2)}_{\mathbf{uv}}$ are defined by the actions

$$I^{(1)}_{\mathbf{uv}}[\mathbf{f}] = \int_{-\infty}^{t} \left(\mathbf{u}(t)\mathbf{v}^T(t') + \mathbf{v}^T(t')\mathbf{u}(t)\right) \mathbf{f}(t')dt', \tag{30}$$

$$I^{(2)}_{\mathbf{uv}}[\mathbf{f}] = \int_{-\infty}^{t} \left(\mathbf{u}(t)\mathbf{v}^T(t') + \mathbf{v}(t')\mathbf{u}^T(t)\right) \mathbf{f}(t')dt'. \tag{31}$$

Here $\mathbf{u}$ and $\mathbf{v}$ are (arbitrary) vector suffixes, and $\mathbf{f}$ is an arbitrary vector function as before.

By analogy with (22), the adjoint product states are introduced as

$$u \wedge \hat{v} = (u_2\hat{v}_1, u_3\hat{v}_1, u_1\hat{v}_2, u_1\hat{v}_3) \tag{32}$$

so that, for example,

$$\phi^{(i)} \wedge \hat{\phi}^{(j)} = \left(\phi^{(i)}_2\hat{\phi}^{(j)}_1, \phi^{(i)}_3\hat{\phi}^{(j)}_1, \phi^{(i)}_1\hat{\phi}^{(j)}_2, \phi^{(i)}_1\hat{\phi}^{(j)}_3\right). \tag{33}$$

Note that $u \wedge \hat{v}$ is to be interpreted as a row vector, whereas $u \vee \hat{v}$ is a column vector.

It can be shown that $\phi^{(1)} \wedge \hat{\phi}^{(2)}$, $\phi^{(1)} \wedge \hat{\phi}^{(3)}$, $\phi^{(2)} \wedge \hat{\phi}^{(1)}$, and $\phi^{(3)} \wedge \hat{\phi}^{(1)}$ are eigenstates of $\mathcal{L}_A$, while the cross states satisfy

$$\mathcal{L}_A \left(\phi^{(i)} \wedge \hat{\phi}^{(j)}\right)^T = \zeta \left(\phi^{(i)} \wedge \hat{\phi}^{(j)}\right)^T + \frac{1}{2i}\gamma_{ji} \begin{pmatrix} \mathbf{q}^* \\ -\mathbf{q} \end{pmatrix}, \tag{34}$$

where the matrices γ_{ji} are as defined previously. Note the transposition of the suffixes in γ_{ij} in (34).

We will now proceed to define an inner product between the product states and the adjoint product states. It will be shown that the inner product between any bound product eigenstate (such as $\psi^{(1)} \vee \hat{\psi}^{(2)}$ evaluated at $\zeta = \bar{\zeta}_k = \zeta_k^*$) with any other eigenstate vanishes. Consequently, when the scattering problem supports bound eigenstates, the product eigenstates cannot be complete. As with the Zakharov–Shabat scattering problem, the remedy to finding closure is with the cross terms. We show that the inner product between any bound eigenstate with a cross term is nonzero. This leads us to construct a basis consisting of the product eigenstates together with the cross terms. Investigation of the linear independence of this basis reveals that the cross terms are linearly independent only when evaluated at the bound state eigenvalues, and that the linearly independent component of the cross states is the derivative of the product eigenstates with respect to the eigenvalue parameter, evaluated at the bound state eigenvalue. Following Kaup, we will refer to these derivative states as "P-states." The new basis is then taken to be the product eigenstates, together with the P-states. Finally, we construct a resolution of the identity operator.

A formal proof of completeness is deferred until the next section.

To simplify notation, we will use the Dirac bra- and ket- notation. Let $|t\rangle$ and $\langle t|$ be complete sets of eigenstates of the position vector, and define

$$\langle t|ij,\zeta\rangle = \psi^{(i)} \vee \hat{\psi}^{(j)}(\zeta,t), \tag{35}$$

$$\langle ij,\zeta|t\rangle = \phi^{(i)} \wedge \hat{\phi}^{(j)}(\zeta,t) \tag{36}$$

for $\zeta = \xi$ real and for continuation into the appropriate half space. Note that, consistent with our previous definitions, we interpret $\psi^{(i)} \vee \hat{\psi}^{(j)}(\zeta,t)$ as a column vector and $\phi^{(i)} \wedge \hat{\phi}^{(j)}(\zeta,t)$ as a row vector.

Suppose now that U^T is an arbitrary row vector and V is an arbitrary column vector. Then, the formal adjoint operator $\mathcal{L}_A$ was constructed such that the following relationship is true:

$$U^T\mathcal{L}V = V^T\mathcal{L}_A U - \frac{1}{2i}\partial_t f \tag{37}$$

with $f = f_1 - f_2$, where

$$f_1 = V^T\Sigma_3 U, \tag{38}$$

$$f_2 = \left\{ I_+ U^T \begin{pmatrix} \mathbf{q}^* \\ -\mathbf{q} \end{pmatrix} \right\} \cdot \left\{ I_- V^T \begin{pmatrix} \mathbf{q} \\ \mathbf{q}^* \end{pmatrix} \right\} + I_+ \left(U^T I_-(MV) \right). \tag{39}$$

Here,

$$\Sigma_3 = \begin{pmatrix} \mathbf{I}_2 & 0 \\ 0 & -\mathbf{I}_2 \end{pmatrix} \tag{40}$$

and M is the 4×4 matrix

$$M = \begin{pmatrix} \mathbf{q}^\dagger\mathbf{q}\mathbf{I}_2 & \mathbf{q}^*\mathbf{q}^\dagger \\ -\mathbf{q}\mathbf{q}^T & -\mathbf{q}^\dagger\mathbf{q}\mathbf{I}_2 \end{pmatrix}. \tag{41}$$

The integral operator $I_+(I_-)$ denotes integration from t to $+\infty$ ($-\infty$ to t), and it is understood that in matrix M, the first $\mathbf{q}$ variable is to appear in the integral I_+ and the second in I_- (so that, if t' and t'' are the integration variables in I_+ and I_-, respectively, $\mathbf{q}^\dagger\mathbf{q}\mathbf{I}_2 = \mathbf{q}^\dagger(t')\mathbf{q}(t'')\mathbf{I}_2$). For the simpler Zakharov–Shabat system, $\mathbf{q}$ becomes scalar q and the matrix M simplifies to

$$M = \begin{pmatrix} q^*(t') \\ -q(t') \end{pmatrix} \cdot \left(q(t''), q^*(t'') \right) \tag{42}$$

so that the second contribution to f_2 is then the same as the first, leading to results published by Kaup [9].

Note that, by virtue of the imposed conditions, (7), f_2 will vanish as $t \to \pm\infty$, while f_1 may remain finite, depending on choices for the vectors U and V.

In terms of Dirac notation, (26) and (34) read

$$\begin{aligned} \mathcal{L}|ij,\zeta\rangle &= \zeta|ij,\zeta\rangle - \frac{1}{2i}\gamma_{ij}|p\rangle, \\ \langle ij,\zeta|\mathcal{L}_A &= \zeta\langle ij,\zeta| + \frac{1}{2i}\gamma_{ji}\langle p|, \end{aligned} \tag{43}$$

where the vectors $|p\rangle$ and $\langle p|$ are defined by

$$\langle t|p\rangle = \begin{pmatrix} \mathbf{q}(t,x) \\ \mathbf{q}^*(t,x) \end{pmatrix}, \tag{44}$$

$$\langle p|t\rangle = \begin{pmatrix} \mathbf{q}^*(t,x) \\ -\mathbf{q}(t,x) \end{pmatrix}, \tag{45}$$

and it is understood that $\mathcal{L}_A$ always operates backwards on the preceeding bra. We are now in a position to define and evaluate inner products.

We define the inner product between product states by

$$\langle ij,\zeta'|kl,\zeta\rangle = \lim_{T\to\infty}\int_{-T}^{T}\left(\phi^{(i)}\wedge\hat{\phi}^{(j)}(\zeta',t)\right)\psi^{(k)}\vee\hat{\psi}^{(l)}(\zeta,t)dt. \tag{46}$$

To evaluate the integrals, and hence find the inner products, we use (43) and (37) together with the definitions of the Jost functions, and the scattering data equations (8) and (10) inserted as appropriate into the expression for f_1, (38), taken in the limit $t\to\pm\infty$. When $\zeta=\xi$ real, it is then straightforward to derive the inner products for the continuum states; these are quoted in Table 1 (we do not show results for all inner products since not all are necessary for our proof of completeness). For the bound product states, the inner products between eigenstates of the operators $\mathcal{L}$ and $\mathcal{L}_A$ are shown in Table 2. Contrary to corresponding results quoted for the Zakharov–Shabat system, these are not all equal to zero. However, the results quoted in Table 2 make use of eigenstates like $\phi^{(2)}$ and $\phi^{(3)}$ in the construction of product states and, as discussed previously, these are not suitable candidates for the bound state solutions of (5); rather, one should use $\phi^{(+)}$ and $\phi^{(-)}$. Hence, we now introduce a new set of product states $\psi^{(1)}\vee\hat{\psi}^{(+)}$, etc., defined as before in (23), but now the superfix $\pm$ replaces $j=2,3$ as appropriate. Matrix elements between members of this new set of product eigenstates can then be evaluated readily from results quoted in Table 2. All such inner products are found to be identically zero, i.e., $\langle 1+,\zeta_k|1+,\bar{\zeta}_l\rangle = \langle 1+,\zeta_k|+1,\zeta_l\rangle = \langle +1,\bar{\zeta}_k|1-,\bar{\zeta}_l\rangle = \cdots = 0$. The reason for this vanishing of the bound state inner products is made apparent by returning to the results for the continuum states in Table 1; in the new basis, the inner products are as listed in Table 3. All such products between eigenstates contain either S_{11}^2 or Δ_{11}^2, corresponding to double zeros (since S_{11} and Δ_{11} have simple zeros) on continuation away from the real ζ axis to a zero of S_{11} (or Δ_{11}).

The inner product between any bound state and any continuum state is identically zero.

Clearly, the new set of product eigenstates is incomplete. To see how to complete them we return again to the observation that all matrix elements between continuum product eigenstates are proportional either to $S_{11}^2(\xi)$ or $\Delta_{11}^2(\xi)$ $(=S_{11}^*(\xi)^2)$. As we will show, this requires that the continuum contribution to the completeness statement is an integral where coefficients appear which are proportional to $S_{11}^{-2}(\xi)$ (or $\Delta_{11}^{-2}(\xi)$). If, for temporary convenience, an assumption is made that the potentials q_1 and q_2 have compact support, then extending this integral contribution into the complex plane would result in a contribution from the double poles of $S_{11}^{-2}(\zeta)$ at $\zeta=\zeta_k$ or from $\Delta_{11}^{-2}(\zeta)$ at $\zeta=\bar{\zeta}_k$. Consequently, the residual contributions from these poles will result not only in derivatives (with respect to ζ) of other coefficients, but also derivatives of the bra- and ket-vectors which appear in the completeness statement. Such vectors are the product eigenstates $|1+,\zeta\rangle$, etc., of $\mathcal{L}$ (similarly, $\mathcal{L}_A$) discussed above.

Inner products between bound product eigenstates. The elements in the first two columns are functions of $\bar{\zeta}_k$ *and those in the last two columns are functions of* ζ. *Here,* S'_{11} *means* $dS_{11}(\zeta)/d\zeta$ *evaluated at* $\zeta = \zeta_k$, *and similarly for* $\Delta'_{11}(\bar{\zeta}_k)$

	$\|12,\bar{\zeta}_l\rangle$	$\|13,\bar{\zeta}_l\rangle$	$\|21,\bar{\zeta}_l\rangle$	$\|31,\bar{\zeta}_l\rangle$
$\langle 12,\zeta_k\|$	0	0	$\frac{1}{2i}S'_{11}\Delta_{22}\delta_{kl}$	$\frac{1}{2i}S'_{11}\Delta_{32}\delta_{kl}$
$\langle 13,\zeta_k\|$	0	0	$\frac{1}{2i}S'_{11}\Delta_{23}\delta_{kl}$	$\frac{1}{2i}S'_{11}\Delta_{33}\delta_{kl}$
$\langle 21,\bar{\zeta}_k\|$	$\frac{1}{2i}\Delta'_{11}S_{22}\delta_{kl}$	$\frac{1}{2i}\Delta'_{11}S_{32}\delta_{kl}$	0	0
$\langle 31,\bar{\zeta}_k\|$	$\frac{1}{2i}\Delta'_{11}S_{23}\delta_{kl}$	$\frac{1}{2i}\Delta'_{11}S_{33}\delta_{kl}$	0	0

This leads us to propose that the following set of states will complete our space:

$$|(+1)P,\zeta_k\rangle = \frac{\partial}{\partial\zeta}|+1,\zeta\rangle_{\zeta=\zeta_k}, \tag{47}$$

$$|(-1)P,\zeta_k\rangle = \frac{\partial}{\partial\zeta}|-1,\zeta\rangle_{\zeta=\zeta_k}, \tag{48}$$

$$|(1+)P,\bar{\zeta}_k\rangle = \frac{\partial}{\partial\zeta}|1+,\zeta\rangle_{\zeta=\bar{\zeta}_k}, \tag{49}$$

$$|(1-)P,\bar{\zeta}_k\rangle = \frac{\partial}{\partial\zeta}|1-,\zeta\rangle_{\zeta=\bar{\zeta}_k}. \tag{50}$$

A similar definition applies to the bra-states. We follow Kaup's terminology and refer to these as "P-states."

The P-states satisfy the equations

$$\mathcal{L}|(+1)P,\zeta_k\rangle = \zeta_k|(+1)P,\zeta_k\rangle + |+1,\zeta_k\rangle, \tag{51}$$

$$\langle(1+)P,\zeta_k|\mathcal{L}_A = \zeta_k\langle(1+)P,\zeta_k| + \langle 1+,\zeta_k|, \tag{52}$$

and similarly for the other states. Note that the P-states are not eigenstates of $\mathcal{L}$ (nor of $\mathcal{L}_A$). Equations (51) and (52) follow from straightforward differentiation of (24), (25), and (34) with respect to ζ.

To use the P-states, we need first to evaluate the inner products between these and the product eigenstates $|1+,\zeta\rangle$, etc., as well as between the P-states themselves. For inner products between bound states, the only nonzero inner products between a

TABLE 3

Inner products between dressed continuum eigenstates. Also shown are matrix elements between dressed eigenstates and the product cross states $|11,\xi\rangle$ and $\langle 11,\xi'|$. α and β are defined in the caption to Table 1. Note that all matrix elements in the last row are functions of ξ while all elements in the last column are functions of ξ'.

	$\|1+,\xi\rangle$	$\|1-,\xi\rangle$	$\|+1,\xi\rangle$	$\|-1,\xi\rangle$	$\|11,\xi\rangle$
$\langle 1+,\xi'\|$	0	0	$-\alpha S_{11}^2\Delta_{33}$	$\alpha S_{11}^2\Delta_{32}$	$\beta S_{11}S_{21}$
$\langle 1-,\xi'\|$	0	0	$\alpha S_{11}^2\Delta_{23}$	$-\alpha S_{11}^2\Delta_{22}$	$\beta S_{11}S_{31}$
$\langle +1,\xi'\|$	$\alpha\Delta_{11}^2 S_{33}$	$-\alpha\Delta_{11}^2 S_{32}$	0	0	$-\beta^*\Delta_{11}\Delta_{21}$
$\langle -1,\xi'\|$	$-\alpha\Delta_{11}^2 S_{23}$	$\alpha\Delta_{11}^2 S_{22}$	0	0	$-\beta^*\Delta_{11}\Delta_{31}$

P-state and an eigenstate are

$$\langle (1+)P,\zeta_k|+1,\zeta_l\rangle = \langle 1+,\zeta_k|(+1)P,\zeta_l\rangle = -i\Delta_{33}(\zeta_k)\left(S'_{11}(\zeta_l)\right)^2\delta_{kl}, \tag{53}$$

$$\langle (1-)P,\zeta_k|-1,\zeta_l\rangle = \langle 1-,\zeta_k|(-1)P,\zeta_l\rangle = -i\Delta_{22}(\zeta_k)\left(S'_{11}(\zeta_l)\right)^2\delta_{kl}, \tag{54}$$

$$\langle (1+)P,\zeta_k|-1,\zeta_l\rangle = \langle 1+,\zeta_k|(-1)P,\zeta_l\rangle = i\Delta_{32}(\zeta_k)\left(S'_{11}(\zeta_l)\right)^2\delta_{kl}, \tag{55}$$

$$\langle (1-)P,\zeta_k|+1,\zeta_l\rangle = \langle 1-,\zeta_k|(+1)P,\zeta_l\rangle = i\Delta_{23}(\zeta_k)\left(S'_{11}(\zeta_l)\right)^2\delta_{kl}, \tag{56}$$

$$\langle (+1)P,\bar\zeta_k|1+,\bar\zeta_l\rangle = \langle +1,\bar\zeta_k|(1+)P,\bar\zeta_l\rangle = -iS_{33}(\bar\zeta_k)\left(\Delta'_{11}(\bar\zeta_l)\right)^2\delta_{kl}, \tag{57}$$

$$\langle (-1)P,\bar\zeta_k|1-,\bar\zeta_l\rangle = \langle -1,\bar\zeta_k|(1-)P,\bar\zeta_l\rangle = -iS_{22}(\bar\zeta_k)\left(\Delta'_{11}(\bar\zeta_l)\right)^2\delta_{kl}, \tag{58}$$

$$\langle (+1)P,\bar\zeta_k|1-,\bar\zeta_l\rangle = \langle +1,\bar\zeta_k|(1-)P,\bar\zeta_l\rangle = iS_{32}(\bar\zeta_k)\left(\Delta'_{11}(\bar\zeta_l)\right)^2\delta_{kl}, \tag{59}$$

$$\langle (-1)P,\bar\zeta_k|1+,\bar\zeta_l\rangle = \langle -1,\bar\zeta_k|(1+)P,\bar\zeta_l\rangle = iS_{23}(\bar\zeta_k)\left(\Delta'_{11}(\bar\zeta_l)\right)^2\delta_{kl}, \tag{60}$$

where $S'_{11}(\zeta_l)$ means $dS_{11}/d\zeta|_{\zeta=\zeta_l}$, and similarly for $\Delta'_{11}(\bar\zeta_l)$.

To complete the set, we require inner products between pairs of P-states. It is found that $\langle (1\mu)P,\zeta_k|(\nu 1)P,\zeta_l\rangle$, with μ and ν equal to $\pm$ in turn, is zero unless $k=l$. With $k=l$ it is found that

$$\langle (1\mu)P,\zeta_k|(\nu 1)P,\zeta_k\rangle = \frac{\partial}{\partial\zeta}\langle(\mu 1)P,\zeta|\nu 1,\zeta\rangle_{\zeta=\zeta_k} \tag{61}$$

and, similarly,

$$\langle (\mu 1)P,\bar\zeta_k|(1\nu)P,\bar\zeta_k\rangle = \frac{\partial}{\partial\zeta}\langle(1\mu)P,\zeta|1\nu,\zeta\rangle_{\zeta=\bar\zeta_k}. \tag{62}$$

So, for example,

$$\langle (1+)P,\zeta_k|(+1)P,\zeta_l\rangle = -i\left(\Delta_{33}(\zeta)S'_{11}(\zeta)^2\right)'_{\zeta=\zeta_k}\delta_{kl}. \tag{63}$$

We will demonstrate below that the full basis constructed from the continuum eigenstates, the bound eigenstates, and these P-states is complete with respect to the $L_2(-\infty,\infty)$ norm. In consequence, any ket $|u\rangle$, say, can be expressed in terms of this set of basis functions as

$$
\begin{aligned}
|u\rangle = \frac{1}{\pi}\int_{-\infty}^{\infty} d\xi \left(f(\xi)|+1,\xi\rangle + g(\xi)|-1,\xi\rangle + \bar{f}(\xi)|1+,\xi\rangle + \bar{g}(\xi)|1-,\xi\rangle \right) \\
+ \sum_{k=1}^{N} \left(f_k|+1,\zeta_k\rangle + g_k|-1,\zeta_k\rangle + h_k|(+1)P,\zeta_k\rangle + l_k|(-1)P,\zeta_k\rangle \right) \\
+ \sum_{k=1}^{N} \left(\bar{f}_k|1+,\bar{\zeta}_k\rangle + \bar{g}_k|1-,\bar{\zeta}_k\rangle + \bar{h}_k|(1+)P,\zeta_k\rangle + \bar{l}_k|(1-)P,\bar{\zeta}_k\rangle \right). \qquad (64)
\end{aligned}
$$

Using the values for the various inner products reported above, together with some simplifying algebra, we find the following expressions for the coefficients $f(\xi)$, etc.:

$$f(\xi) = -\frac{\langle 12,\xi|u\rangle}{S_{11}(\xi)^2}, \qquad (65)$$

$$g(\xi) = -\frac{\langle 13,\xi|u\rangle}{S_{11}(\xi)^2}, \qquad (66)$$

$$\bar{f}(\xi) = \frac{\langle 21,\xi|u\rangle}{\Delta_{11}(\xi)^2}, \qquad (67)$$

$$\bar{f}(\xi) = \frac{\langle 31,\xi|u\rangle}{\Delta_{11}(\xi)^2}, \qquad (68)$$

$$f_k = \frac{i}{S'_{11}(\zeta_k)^2}\langle (12)P,\zeta_k|u\rangle - \frac{2iS''_{11}(\zeta_k)}{S'_{11}(\zeta_k)^3}\langle 12,\zeta_k|u\rangle, \qquad (69)$$

$$g_k = \frac{i}{S'_{11}(\zeta_k)^2}\langle (13)P,\zeta_k|u\rangle - \frac{2iS''_{11}(\zeta_k)}{S'_{11}(\zeta_k)^3}\langle 13,\zeta_k|u\rangle, \qquad (70)$$

$$h_k = i\frac{\langle 12,\zeta_k|u\rangle}{S'_{11}(\zeta_k)^2}, \qquad (71)$$

$$l_k = i\frac{\langle 13,\zeta_k|u\rangle}{S'_{11}(\zeta_k)^2}, \qquad (72)$$

$$\bar{f}_k = \frac{i}{\Delta'_{11}(\zeta_k)^2}\langle (21)P,\bar{\zeta}_k|u\rangle - \frac{2i\Delta''_{11}(\zeta_k)}{\Delta'_{11}(\zeta_k)^3}\langle 21,\bar{\zeta}_k|u\rangle, \qquad (73)$$

$$\bar{g}_k = \frac{i}{\Delta'_{11}(\zeta_k)^2}\langle (31)P,\bar{\zeta}_k|u\rangle - \frac{2i\Delta''_{11}(\zeta_k)}{\Delta'_{11}(\zeta_k)^3}\langle 31,\bar{\zeta}_k|u\rangle, \qquad (74)$$

$$\bar{h}_k = i\frac{\langle 21,\bar{\zeta}_k|u\rangle}{\Delta'_{11}(\bar{\zeta}_k)^2}, \qquad (75)$$

$$\bar{l}_k = i\frac{\langle 31,\bar{\zeta}_k|u\rangle}{\Delta'_{11}(\bar{\zeta}_k)^2}. \qquad (76)$$

Here $S''_{11}(\zeta_k)$ means $d^2S_{11}/d\zeta^2|_{\zeta=\zeta_k}$, and similarly for $\Delta''_{11}(\bar{\zeta}_k)$.

Note that although we have expanded $|u\rangle$ in a basis containing $|\pm 1,\xi\rangle$, etc., the matrix elements which appear in the above expressions all contain an inner product of $|u\rangle$ with the "undressed" states $\langle 21,\xi|$, $\langle 31,\xi|$, etc.; in this form the expressions for these coefficients are most succinct. Since $|u\rangle$ is arbitrary, and if this basis is complete, we may use the above results to deduce an expression for the identity operator. This

is as follows:

$$
\begin{aligned}
\mathbf{I}_4 = &-\frac{1}{\pi}\int_{-\infty}^{\infty}\frac{d\xi}{\Delta_{11}^2(\xi)}\left(|+1,\xi\rangle\langle 12,\xi| + |-1,\xi\rangle\langle 13,\xi|\right)\\
&+\frac{1}{\pi}\int_{-\infty}^{\infty}\frac{d\xi}{S_{11}^2(\xi)}\left(|1+,\xi\rangle\langle 21,\xi| + |-1,\xi\rangle\langle 31,\xi|\right)\\
&+\sum_{k=1}^{N}\left(\frac{-4iS_{11}''(\zeta_k)}{S_{11}''(\zeta_k)^3}\,|+1,\zeta_k\rangle\langle 12,\zeta_k| + \frac{2i}{S_{11}'(\zeta_k)^2}|+1,\zeta_k\rangle\langle (12)P,\zeta_k|\right.\\
&\qquad -\frac{4iS_{11}''(\zeta_k)}{S_{11}'(\zeta_k)^3}|-1,\zeta_k\rangle\langle 13,\zeta_k| + \frac{2i}{S_{11}'(\zeta_k)^2}|-1,\zeta_k\rangle\langle (13)P,\zeta_k|\\
&\qquad \left.+\frac{2i}{S_{11}'(\zeta_k)^2}|(+1)P,\zeta_k\rangle\langle 12,\zeta_k| + \frac{2i}{S_{11}'(\zeta_k)^2}|(-1)P,\zeta_k\rangle\langle 13,\zeta_k|\right)\\
&+\sum_{k=1}^{N}\left(\frac{-4i\Delta_{11}''(\bar\zeta_k)}{\Delta_{11}''(\bar\zeta_k)^3}\,|1+,\bar\zeta_k\rangle\langle 21,\bar\zeta_k| + \frac{2i}{\Delta_{11}'(\bar\zeta_k)^2}|1+,\bar\zeta_k\rangle\langle (21)P,\bar\zeta_k|\right.\\
&\qquad -\frac{4i\Delta_{11}''(\bar\zeta_k)}{\Delta_{11}'(\bar\zeta_k)^3}|1-,\bar\zeta_k\rangle\langle 31,\bar\zeta_k| + \frac{2i}{\Delta_{11}'(\bar\zeta_k)^2}|1-,\bar\zeta_k\rangle\langle (31)P,\bar\zeta_k|\\
&\qquad \left.+\frac{2i}{\Delta_{11}'(\bar\zeta_k)^2}|(1+)P,\bar\zeta_k\rangle\langle 21,\bar\zeta_k| + \frac{2i}{\Delta_{11}'(\bar\zeta_k)^2}|(1-)P,\bar\zeta_k\rangle\langle 31,\bar\zeta_k|\right). \qquad (77)
\end{aligned}
$$

The above statement for the identity operator is a consequence of the development of our analysis this far, with a mixing of dressed and undressed states, and is not the final form for this operator.

The structure of (77) can be simplified on noting that quantities which appear in the first integral (i.e., S_{11}, $|+1,\xi\rangle$, etc.) are analytic in the upper half of the complex ζ plane, while all quantities in the second integral are analytic in the lower half plane. Then, (77) can be written in terms of two contour integrals,

$$
\begin{aligned}
\mathbf{I}_4 = &\frac{1}{\pi}\int_{\bar c}\left(|1+,\zeta\rangle\frac{1}{\Delta_{11}^2(\zeta)}\langle 21,\zeta| + |1-,\zeta\rangle\frac{1}{\Delta_{11}^2(\zeta)}\langle 31,\zeta|\right)d\zeta\\
&-\frac{1}{\pi}\int_{c}\left(|+1,\zeta\rangle\frac{1}{S_{11}^2(\zeta)}\langle 12,\zeta| + |-1,\zeta\rangle\frac{1}{S_{11}^2(\zeta)}\langle 13,\zeta|\right)d\zeta. \qquad (78)
\end{aligned}
$$

Here, $\bar c$ is the contour from $-\infty - i\epsilon$ to $+\infty - i\epsilon$ passing below all zeros of $\Delta_{11}(\zeta)$, whereas c is the contour from $-\infty + i\epsilon$ to $+\infty + i\epsilon$ passing above all zeros of $S_{11}(\zeta)$.

Equation (77) is recovered when the contours c and $\bar c$ are continued down to the real ζ axis, capturing contributions from the double poles from S_{11}^{-2} and Δ_{11}^{-2} in the process.

In the next section, we will prove that (78) is the correct identity operator for the space $L_2(-\infty,\infty)$. To simplify the structure of many of the resulting expressions, it remains expedient to continue with the use of contour integrals with contours c and $\bar c$ as defined above. However, we must first question whether or not it will always be possible to do this. In (85), for example, $S_{k1}(\zeta)$, $k = 2, 3$, only have the required analytic properties when the potentials q_1 and q_2 are on compact support. More generally, with $q_1,\ q_2 \in L_1$, $S_{k1}(\zeta)$ may have meaning only when ζ is real. The appropriate result for the latter case is obtained from (85) by first assuming that q_1 and q_2 are on compact support (so that S_{k1}, $k = 2, 3$, are analytic everywhere), then continuing the contour c to the real ζ axis, picking up residue contributions from the

poles of $S_{11}^{-1}(\zeta)$ in the process, and then relaxing the assumption of compact support. The final statement in the form of an integral along the real ζ axis together with a contribution from a discrete sum is the correct one for general q_1, q_2, ϵL_1.

All contour integrals over contours c and $\bar{c}$ written in the next section are to be interpreted in this manner.

4. Proof of completeness. To prove that (78) is indeed a statement of the identity operator, we will extend the approach used by Kaup in his discussion of the Zakharov–Shabat system, and use an appropriate form of a set of Marchenko equations for the problem to evaluate independently the right-hand side of (78).

Since the algebra can become quite horrendous—as witnessed by (64) to (78)—we will simplify the working by assuming that the potentials q_1 and q_2 are on compact support, but we stress that the final result is not dependent upon this assumption.

The basic idea is to construct a Riemann–Hilbert problem for the product states, which will be solved by recourse to an appropriate set of Marchenko equations. Results from this will then be used to evaluate the right-hand side of (78). The assumption of compact support permits a succinct formulation of the Riemann–Hilbert problem, enabling us to use it in (78). To illustrate this approach, we digress a little and first examine the corresponding Riemann–Hilbert problem for the simpler system described by (5). Each step here will correspond to a similar step in the more complicated problem, and will serve as a useful point of comparison.

The independent sets of Jost function solutions to (5) are related as stated in (8). With $i = 1$, this can be written as

$$\frac{\phi^{(1)}}{S_{11}} = \psi^{(1)} + \frac{S_{21}}{S_{11}}\psi^{(2)} + \frac{S_{31}}{S_{11}}\psi^{(3)}. \tag{79}$$

This is a Riemann–Hilbert problem, where the function on the left-hand side is analytic in the upper half plane $\Im\zeta \geq 0$, $\psi^{(1)}$ is analytic for $\Im\zeta < 0$, and the other two terms are analytic nowhere. To solve (79), we reformulate it as a Marchenko equation, following the standard procedure:

- Multiply (79) by $e^{i\xi t}/2\pi i(\xi - \bar{\zeta}_0)$, $\Im\bar{\zeta}_0 < 0$, and then integrate according to $\int_{-\infty}^{\infty} d\xi$, where $\xi = \Re\zeta$.
- Next, we follow references [8], [10] and argue that $\psi^{(i)}, i = 1, 2, 3$, can be written in the form

$$\psi^{(1)}(\zeta, t) = e^{-i\zeta t}\mathbf{e}_1 + \int_t^{\infty} e^{-i\zeta p}K^{(1)}(p, t)dp, \tag{80}$$

$$\psi^{(2)}(\zeta, t) = e^{i\zeta t}\mathbf{e}_2 + \int_t^{\infty} e^{i\zeta p}K^{(2)}(p, t)dp, \tag{81}$$

$$\psi^{(3)}(\zeta, t) = e^{i\zeta t}\mathbf{e}_3 + \int_t^{\infty} e^{i\zeta p}K^{(3)}(p, t)dp, \tag{82}$$

where the unit vectors $\mathbf{e}_i = (\delta_{i1}, \delta_{i2}, \delta_{i3})^T$, and the column vectors $K^{(i)}$ are independent of ζ. These are now substituted into (79) following application of the first step described above.

- Finally, we perform the integrals

$$\lim_{\epsilon\to 0}\int_{-\infty-i\epsilon}^{\infty-i\epsilon} e^{i\bar{\zeta}_0(\tau-t)}d\bar{\zeta}_0, \qquad \tau > t. \tag{83}$$

Then, (79) is cast into an equivalent equation relating the kernels $K^{(i)}, i = 1, 2, 3$,

$$K^{(1)}(\tau, t) = -F_2(t+\tau)\mathbf{e}_2 - F_3(t+\tau)\mathbf{e}_3 - \int_t^\infty F_2(p+\tau)K^{(2)}(p,t)dp - \int_t^\infty F_3(p+\tau)K^{(3)}(p,t)dp. \tag{84}$$

Here,

$$F_k(x) = \frac{1}{2\pi}\int_c \frac{S_{k1}(\zeta)}{S_{11}(\zeta)}e^{i\zeta x}d\zeta, \qquad k = 2, 3, \tag{85}$$

where the contour c is as defined in the previous section.

Alternatively, beginning with the equations

$$\frac{\phi^{(+)}}{\Delta_{11}} = \psi^{(2)} - \frac{\Delta_{21}}{\Delta_{11}}\psi^{(1)}, \tag{86}$$

$$\frac{\phi^{(-)}}{\Delta_{11}} = \psi^{(3)} - \frac{\Delta_{31}}{\Delta_{11}}\psi^{(1)}, \tag{87}$$

and following the same set of steps above, but now with $\bar{\zeta}_0$ replaced by ζ_0, where $\Im\zeta_0 > 0$, and with the limits of integration in the final step replaced by $-\infty + i\epsilon$ to $\infty + i\epsilon$, gives the required additional equations for $K^{(2)}$ and $K^{(3)}$,

$$K^{(2)}(\tau, t) = \bar{F}_2(\tau + t)\mathbf{e}_1 + \int_t^\infty \bar{F}_2(p+\tau)K^{(1)}(p,t)dp,$$

$$K^{(3)}(\tau, t) = \bar{F}_3(\tau + t)\mathbf{e}_1 + \int_t^\infty \bar{F}_3(p+\tau)K^{(1)}(p,t)dp, \tag{88}$$

where

$$\bar{F}_k = \frac{1}{2\pi}\int_{\bar{c}} \frac{\Delta_{k1}(\zeta)}{\Delta_{11}(\zeta)}e^{-i\zeta x}d\zeta, \qquad k = 2, 3. \tag{89}$$

Equations (84) and (88) are the Marchenko equations; one can show these have a unique solution using arguments similar to those used by Zakharov and Shabat elsewhere [7], [8]. The point we wish to emphasise here is that the existence of a unique solution to these equations is equivalent to the statement that (for $k = 2, 3$ and $\tau > t$)

$$\int_c \left(\psi^{(1)}(\zeta, t) + \frac{S_{21}(\zeta)}{S_{11}(\zeta)}\psi^{(2)}(\zeta, t) + \frac{S_{31}(\zeta)}{S_{11}(\zeta)}\psi^{(3)}(\zeta, t)\right)e^{i\zeta\tau}d\zeta = 0, \tag{90}$$

$$\int_{\bar{c}} \left(\psi^{(k)}(\zeta, t) - \frac{\Delta_{k1}(\zeta)}{\Delta_{11}(\zeta)}\psi^{(1)}(\zeta, t)\right)e^{-i\zeta\tau}d\zeta = 0 \tag{91}$$

or, more succinctly, that

$$\int_c \frac{1}{S_{11}(\zeta)}\phi^{(1)}(\zeta, t)e^{i\zeta\tau}d\zeta = 0, \qquad \tau > t, \tag{92}$$

$$\int_{\bar{c}} \frac{1}{\Delta_{11}(\zeta)}\phi^{(\pm)}(\zeta, t)e^{-i\zeta\tau}d\zeta = 0, \qquad \tau > t. \tag{93}$$

Now consider the product states, where the intention is again to link the existence and uniqueness of a set of Marchenko equations to a statement like (92) and (93) above. Using (8), (10) together with the definitions of $\hat{\phi}^{(\pm)}$ given in Appendix A, we have

$$\frac{\Gamma}{S_{11}^2}\left(\phi^{(1)}\wedge\hat{\phi}^{(+)}\right)^T = \psi^{(1)}\vee\hat{\psi}^{(2)} - \frac{S_{21}^2}{S_{11}^2}\psi^{(2)}\vee\hat{\psi}^{(1)} - \frac{S_{21}S_{31}}{S_{11}^2}\psi^{(3)}\vee\hat{\psi}^{(1)}$$

$$- \frac{S_{21}}{S_{11}}\psi^{(1)}\vee\hat{\psi}^{(1)} + \frac{S_{21}}{S_{11}}\psi^{(2)}\vee\hat{\psi}^{(2)} + \frac{S_{31}}{S_{11}}\psi^{(3)}\vee\hat{\psi}^{(2)}, \tag{94}$$

where the "metric" Γ—which converts vectors with $u\wedge\hat{v}$ structure into those with $u\vee\hat{v}$ structure—is the 4×4 matrix

$$\Gamma = \begin{pmatrix} 0 & \mathbf{I}_2 \\ -\mathbf{I}_2 & 0 \end{pmatrix}. \tag{95}$$

The term on the left-hand side of (94) is analytic in the half plane $\Im\zeta > 0$, while the first term on the right-hand side is analytic in the lower half plane; other terms (in the absence of compact support) are nowhere analytic. Equation (94) is a Riemann–Hilbert problem, and as such, will be studied following the outlined procedure. Step (i) requires multiplication of both sides by $e^{2i\xi t}/\left(\xi-\bar{\zeta}_0\right)$ for $\Im\bar{\zeta}_0 < 0$, then integration according to $(2\pi i)^{-1}\int_{-\infty}^{\infty} d\xi$, giving (after some rearrangement)

$$\begin{aligned}
&\psi^{(1)}\vee\hat{\psi}^{(2)}(\bar{\zeta}_0,t) = \mathbf{e}_1 e^{-2i\bar{\zeta}_0 t} \\
&-\frac{1}{2\pi i}\int_c\left(\frac{S_{21}^2}{S_{11}^2}\psi^{(2)}\vee\hat{\psi}^{(1)} + \frac{S_{21}S_{31}}{S_{11}^2}\psi^{(3)}\vee\hat{\psi}^{(1)}\right)\frac{e^{2i\left(\zeta-\bar{\zeta}_0\right)t}}{\zeta-\bar{\zeta}_0}d\zeta \\
&-\frac{1}{2\pi i}\int_c\left(\frac{S_{21}}{S_{11}}\psi^{(1)}\vee\hat{\psi}^{(1)} - \frac{S_{21}}{S_{11}}\psi^{(2)}\vee\hat{\psi}^{(2)} - \frac{S_{31}}{S_{11}}\psi^{(3)}\vee\hat{\psi}^{(2)}\right)\frac{e^{2i\left(\zeta-\bar{\zeta}_0\right)t}}{\zeta-\bar{\zeta}_0}d\zeta,
\end{aligned} \tag{96}$$

where $\mathbf{e}_i$ are now the four component unit vectors $\mathbf{e}_i = (\delta_{i1},\delta_{i2},\delta_{i3},\delta_{i4})^T$.

Here, of course, an assumption of compact support has been used to express (96) in the relatively compact form shown. Also, for clarity, all explicit reference to the ζ-dependence of the different terms in the integrals has been suppressed. The product states $\psi^{(1)}\vee\hat{\psi}^{(2)}$, $\psi^{(1)}\vee\hat{\psi}^{(3)}$,$\psi^{(2)}\vee\hat{\psi}^{(1)}$, and $\psi^{(3)}\vee\hat{\psi}^{(1)}$ will play the same role here as $\psi^{(1)}$, $\psi^{(2)}$, and $\psi^{(3)}$ played in the previous example. Consequently, we seek a set of coupled integral equations linking these vectors, which will then be turned into a set of Marchenko equations. First, however, we note the appearance of cross terms, such as $\psi^{(1)}\vee\hat{\psi}^{(1)}$, which need to be eliminated by relating them to the product eigenstates.

Consider the cross term $\psi^{(1)}\vee\hat{\psi}^{(1)}$. Substituting first for $\psi^{(1)}$ in terms of $\phi^{(i)}$, then for $\hat{\psi}^{(1)}$ in terms of $\hat{\phi}^{(i)}$, allows us to express $\psi^{(1)}\vee\hat{\psi}^{(1)}$ in two equivalent ways:

$$\psi^{(1)}\vee\hat{\psi}^{(1)} = \frac{\psi^{(1)}\vee\hat{\phi}^{(1)}}{\Delta_{11}} - \frac{\Delta_{21}}{\Delta_{11}}\psi^{(1)}\vee\hat{\psi}^{(2)} - \frac{\Delta_{31}}{\Delta_{11}}\psi^{(1)}\vee\hat{\psi}^{(3)} \tag{97}$$

$$= \frac{\phi^{(1)}\vee\hat{\psi}^{(1)}}{S_{11}} - \frac{S_{21}}{S_{11}}\psi^{(2)}\vee\hat{\psi}^{(1)} - \frac{S_{31}}{S_{11}}\psi^{(3)}\vee\hat{\psi}^{(1)}. \tag{98}$$

Note that the first term on each of the right sides is meromorphic in one or other half plane, with simple poles at the zeros of Δ_{11} or S_{11}. Note also that all remaining terms contain one or the other of the product eigenstates.

To proceed further, we now follow an argument used by Kaup; write

$$\psi^{(1)} \vee \hat{\psi}^{(1)}(\xi,t) = \frac{1}{2\pi i}\int_{\sigma} \frac{\psi^{(1)} \vee \hat{\psi}^{(1)}}{\zeta - \xi} d\zeta, \tag{99}$$

where σ denotes a small circular path centered at real ξ taken in the positive sense. Now substitute from (98) into the right-hand side of (99), using the first statement on that part of σ where $\Im\zeta > 0$, and the second where $\Im\zeta > 0$. Evaluating explicitly the integral of the first term in either case, and rearranging, then gives

$$\begin{aligned}\psi^{(1)} \vee \hat{\psi}^{(1)}(\zeta,t) &= \frac{1}{2\pi i}\int_{c}\left(\frac{S_{21}}{S_{11}}\psi^{(2)} \vee \hat{\psi}^{(1)} + \frac{S_{31}}{S_{11}}\psi^{(3)} \vee \hat{\psi}^{(1)}\right)\frac{d\zeta'}{\zeta' - \zeta} \\ &\quad - \frac{1}{2\pi i}\int_{\bar{c}}\left(\frac{\Delta_{21}}{\Delta_{11}}\psi^{(1)} \vee \hat{\psi}^{(2)} + \frac{\Delta_{31}}{\Delta_{11}}\psi^{(1)} \vee \hat{\psi}^{(3)}\right)\frac{d\zeta'}{\zeta' - \zeta}.\end{aligned} \tag{100}$$

A similar set of results relating the remaining cross product states in terms of the product eigenstates is quoted in Appendix B. Those can now be substituted into (96) giving our first integral statement linking the four product eigenstates. We do not show the explicit form for this first equation (i.e., that obtained by substituting for $\psi^{(1)} \vee \hat{\psi}^{(1)}$, $\psi^{(2)} \vee \hat{\psi}^{(2)}$, and $\psi^{(3)} \vee \hat{\psi}^{(2)}$) since it is rather cumbersome.

To complete the set of coupled integral equations for the product eigenstates, we require similar expressions for $\psi^{(1)} \vee \hat{\psi}^{(3)}$, $\psi^{(2)} \vee \hat{\psi}^{(1)}$, and $\psi^{(3)} \vee \hat{\psi}^{(1)}$, and these are

$$\begin{aligned}&\psi^{(1)} \vee \hat{\psi}^{(3)}(\bar{\zeta}_0,t) = \mathbf{e}_2 e^{-2i\bar{\zeta}_0 t} \\ &-\frac{1}{2\pi i}\int_{c}\left(\frac{S_{31}^2}{S_{11}^2}\psi^{(3)} \vee \hat{\psi}^{(1)} + \frac{S_{31}S_{21}}{S_{11}^2}\psi^{(2)} \vee \hat{\psi}^{(1)}\right)\frac{e^{2i(\zeta-\bar{\zeta}_0)t}}{\zeta - \bar{\zeta}_0}d\zeta \\ &-\frac{1}{2\pi i}\int_{c}\left(\frac{S_{31}}{S_{11}}\psi^{(1)} \vee \hat{\psi}^{(1)} - \frac{S_{21}}{S_{11}}\psi^{(2)} \vee \hat{\psi}^{(3)} - \frac{S_{31}}{S_{11}}\psi^{(3)} \vee \hat{\psi}^{(3)}\right)\frac{e^{2i(\zeta-\bar{\zeta}_0)t}}{\zeta - \bar{\zeta}_0}d\zeta,\end{aligned} \tag{101}$$

$$\begin{aligned}&\psi^{(2)} \vee \hat{\psi}^{(1)}(\zeta_0,t) = -\mathbf{e}_3 e^{2i\zeta_0 t} \\ &+\frac{1}{2\pi i}\int_{\bar{c}}\left(\frac{\Delta_{21}^2}{\Delta_{11}^2}\psi^{(1)} \vee \hat{\psi}^{(2)} + \frac{\Delta_{21}\Delta_{31}}{\Delta_{11}^2}\psi^{(1)} \vee \hat{\psi}^{(3)}\right)\frac{e^{-2i(\zeta-\zeta_0)t}}{\zeta - \zeta_0}d\zeta \\ &+\frac{1}{2\pi i}\int_{\bar{c}}\left(\frac{\Delta_{21}}{\Delta_{11}}\psi^{(1)} \vee \hat{\psi}^{(1)} - \frac{\Delta_{21}}{\Delta_{11}}\psi^{(2)} \vee \hat{\psi}^{(2)} - \frac{\Delta_{31}}{\Delta_{11}}\psi^{(2)} \vee \hat{\psi}^{(3)}\right)\frac{e^{-2i(\zeta-\zeta_0)t}}{\zeta - \zeta_0}d\zeta,\end{aligned} \tag{102}$$

$$\begin{aligned}&\psi^{(3)} \vee \hat{\psi}^{(1)}(\zeta_0,t) = -\mathbf{e}_4 e^{2i\zeta_0 t} \\ &+\frac{1}{2\pi i}\int_{\bar{c}}\left(\frac{\Delta_{31}^2}{\Delta_{11}^2}\psi^{(1)} \vee \hat{\psi}^{(3)} + \frac{\Delta_{21}\Delta_{31}}{\Delta_{11}^2}\psi^{(1)} \vee \hat{\psi}^{(2)}\right)\frac{e^{-2i(\zeta-\zeta_0)t}}{\zeta - \zeta_0}d\zeta \\ &+\frac{1}{2\pi i}\int_{\bar{c}}\left(\frac{\Delta_{31}}{\Delta_{11}}\psi^{(1)} \vee \hat{\psi}^{(1)} - \frac{\Delta_{31}}{\Delta_{11}}\psi^{(3)} \vee \hat{\psi}^{(3)} - \frac{\Delta_{21}}{\Delta_{11}}\psi^{(3)} \vee \hat{\psi}^{(2)}\right)\frac{e^{-2i(\zeta-\zeta_0)t}}{\zeta - \zeta_0}d\zeta.\end{aligned} \tag{103}$$

In each case, appropriate expressions are to be substituted for the cross states $\psi^{(1)} \vee \hat{\psi}^{(1)}$, $\psi^{(2)} \vee \hat{\psi}^{(2)}$, $\psi^{(3)} \vee \hat{\psi}^{(3)}$, $\psi^{(2)} \vee \hat{\psi}^{(3)}$, and $\psi^{(3)} \vee \hat{\psi}^{(2)}$ as required; the latter are listed in Appendix B.

These three equations, together with (96) then become four coupled integral equations relating the product eigenstates $\psi^{(2)} \vee \hat{\psi}^{(1)}$, etc.

To proceed further, we follow the argument that permitted the $\psi^{(i)}$ considered previously to be written in the form of (80)–(82). A similar reasoning shows that the product eigenstates can be written in the form

$$\psi^{(1)} \vee \hat{\psi}^{(2)}(\zeta,t) = \mathbf{e}_1 e^{-2i\zeta t} + \int_t^\infty e^{-2i\zeta p} M^{(1)}(t,p)dp, \tag{104}$$

$$\psi^{(1)} \vee \hat{\psi}^{(3)}(\zeta,t) = \mathbf{e}_2 e^{-2i\zeta t} + \int_t^\infty e^{-2i\zeta p} M^{(2)}(t,p)dp, \tag{105}$$

$$\psi^{(2)} \vee \hat{\psi}^{(1)}(\zeta,t) = -\mathbf{e}_3 e^{2i\zeta t} + \int_t^\infty e^{2i\zeta p} M^{(3)}(t,p)dp, \tag{106}$$

$$\psi^{(3)} \vee \hat{\psi}^{(1)}(\zeta,t) = -\mathbf{e}_4 e^{2i\zeta t} + \int_t^\infty e^{2i\zeta p} M^{(4)}(t,p)dp, \tag{107}$$

where the four-vectors $M^{(i)}$ exist, are unique, and are independent of the eigenparameter ζ.

These expressions are substituted into the integral equations (96), (101), and (103), as appropriate.

We now follow the final step of the procedure outlined at the beginning of this section and perform the integrals

$$\lim_{\epsilon\to 0} \int_{-\infty-i\epsilon}^{\infty-i\epsilon} e^{2i\bar{\zeta}_0(\tau-t)} d\bar{\zeta}_0, \qquad \tau > t, \tag{108}$$

on (96) and (101) and

$$\lim_{\epsilon\to 0} \int_{-\infty+i\epsilon}^{\infty+i\epsilon} e^{-2i\zeta_0(\tau-t)} d\zeta_0, \qquad \tau > t, \tag{109}$$

on (102) and (103), leading to the Marchenko equations

$$M^{(1)}(t,\tau) + \sum_{i=1}^4 F_i(t,\tau)\mathbf{e}_i + \sum_{i=1}^4 \int_t^\infty F_i(t,p)\Gamma_3 M^{(i)}(p,\tau)dp = 0, \tag{110}$$

$$M^{(2)}(t,\tau) + \sum_{i=1}^4 G_i(t,\tau)\mathbf{e}_i + \sum_{i=1}^4 \int_t^\infty G_i(t,p)\Gamma_3 M^{(i)}(p,\tau)dp = 0, \tag{111}$$

$$M^{(3)}(t,\tau) - \sum_{i=1}^4 \bar{F}_{i+2}(t,\tau)\mathbf{e}_i - \sum_{i=1}^4 \int_t^\infty \bar{F}_{i+2}(t,p)\Gamma_3 M^{(i)}(p,\tau)dp = 0, \tag{112}$$

$$M^{(4)}(t,\tau) - \sum_{i=1}^4 \bar{G}_{i+2}(t,\tau)\mathbf{e}_i - \sum_{i=1}^4 \int_t^\infty \bar{G}_{i+2}(t,p)\Gamma_3 M^{(i)}(p,\tau)dp = 0. \tag{113}$$

Here, Γ_3 is the 4×4 matrix

$$\Gamma_3 = \begin{pmatrix} \mathbf{I}_2 & 0 \\ 0 & -\mathbf{I}_2 \end{pmatrix} \tag{114}$$

and (scalar)

$$\begin{aligned} F_1(t,\tau) &= 2\nu_{22}(t,\tau) + \nu_{33}(t,\tau), \\ F_2(t,\tau) &= \nu_{23}(t,\tau), \\ F_3(t,\tau) &= 2\mu_{22}(t,\tau) + \gamma_2(t+\tau), \\ F_4(t,\tau) &= \mu_{23}(t,\tau) + \mu_{32}(t,\tau) + \lambda(t+\tau), \end{aligned} \tag{115}$$

$$
\begin{aligned}
G_1(t,\tau) &= \nu_{32}(t,\tau),\\
G_2(t,\tau) &= \nu_{22}(t,\tau) + 2\nu_{33}(t,\tau),\\
G_3(t,\tau) &= \mu_{23}(t,\tau) + \mu_{32}(t,\tau) + \lambda(t+\tau),\\
G_4(t,\tau) &= 2\mu_{33}(t,\tau) + \gamma_3(t+\tau).
\end{aligned} \tag{116}
$$

The scalar quantities $\bar{F}_i$ and $\bar{G}_i$ are defined similarly, but with all elements ν_{ij}, γ_i, etc., replaced with $\bar{\nu}_{ij}$, $\bar{\gamma}_i$, where these elements are defined as follows:

$$\mu_{ij}(x,y) = \frac{1}{2\pi^2 i}\int_c \frac{S_{i1}(\zeta)}{S_{11}(\zeta)} e^{2i\zeta x}\int_c \frac{S_{j1}(\zeta')}{S_{11}(\zeta')} e^{2i\zeta' y}\frac{d\zeta'}{\zeta'-\zeta-i\epsilon}d\zeta, \tag{117}$$

$$\nu_{ij}(x,y) = \frac{1}{2\pi^2 i}\int_c \frac{S_{i1}(\zeta)}{S_{11}(\zeta)} e^{2i\zeta x}\int_{\bar{c}} \frac{\Delta_{j1}(\zeta')}{\Delta_{11}(\zeta')} e^{-2i\zeta' y}\frac{d\zeta'}{\zeta'-\zeta}d\zeta, \tag{118}$$

$$\bar{\mu}_{ij}(x,y) = \frac{-1}{2\pi^2 i}\int_{\bar{c}} \frac{\Delta_{i1}(\zeta)}{\Delta_{11}(\zeta)} e^{-2i\zeta x}\int_{\bar{c}} \frac{\Delta_{j1}(\zeta')}{\Delta_{11}(\zeta')} e^{-2i\zeta' y}\frac{d\zeta'}{\zeta'-\zeta+i\epsilon}d\zeta, \tag{119}$$

$$\bar{\nu}_{ij}(x,y) = \frac{-1}{2\pi^2 i}\int_{\bar{c}} \frac{\Delta_{i1}(\zeta)}{\Delta_{11}(\zeta)} e^{-2i\zeta x}\int_c \frac{S_{j1}(\zeta')}{S_{11}(\zeta')} e^{2i\zeta' y}\frac{d\zeta'}{\zeta'-\zeta}d\zeta, \tag{120}$$

$$\gamma_j(x) = \frac{1}{\pi}\int_c \left(\frac{S_{j1}(\zeta)}{S_{11}(\zeta)}\right)^2 e^{2i\zeta x}d\zeta, \tag{121}$$

$$\bar{\gamma}_j(x) = \frac{1}{\pi}\int_{\bar{c}} \left(\frac{\Delta_{j1}(\zeta)}{\Delta_{11}(\zeta)}\right)^2 e^{-2i\zeta x}d\zeta, \tag{122}$$

$$\lambda(x) = \frac{1}{\pi}\int_c \frac{S_{21}(\zeta)S_{31}(\zeta)}{S_{11}^2(\zeta)} e^{2i\zeta x}d\zeta, \tag{123}$$

$$\bar{\lambda}(x) = \frac{1}{\pi}\int_{\bar{c}} \frac{\Delta_{21}(\zeta)\Delta_{31}(\zeta)}{\Delta_{11}^2(\zeta)} e^{-2i\zeta x}d\zeta. \tag{124}$$

The suffixes on $\bar{F}$ and $\bar{G}$ in (110)–(113) are defined modulo 4, so that $\bar{F}_5 \equiv \bar{F}_1$.

Equations (110)–(113) are the analogue of the Marchenko equations associated with the inverse to the scattering problem, (5), discussed previously. One can then argue (as before) that (110)–(113) have a unique solution. The point we now wish to emphasise is that the existence of a unique solution to this coupled system is equivalent to the statements that (cf. (92) and (93))

$$\int_c \frac{\phi^{(1)} \wedge \hat{\phi}^{(\pm)}(\zeta,t)}{S_{11}^2(\zeta)} e^{2i\zeta\tau}d\zeta = 0, \qquad \tau > t, \tag{125}$$

$$\int_{\bar{c}} \frac{\phi^{(\pm)} \wedge \hat{\phi}^{(1)}(\zeta,t)}{\Delta_{11}^2(\zeta)} e^{-2i\zeta\tau}d\zeta = 0, \qquad \tau > t. \tag{126}$$

These results will be used to evaluate the right-hand side of (78).

Return now to consider our statement of completeness, (78), which we write in the equivalent form

$$\mathbf{I}_4 = -\frac{1}{\pi}\int_c \left(\frac{\Delta_{22}}{S_{11}^3}|+1,\zeta\rangle\langle 1+,\zeta| + \frac{\Delta_{32}}{S_{11}^3}|+1,\zeta\rangle\langle 1-,\zeta| \right.$$
$$\left. + \frac{\Delta_{23}}{S_{11}^3}|-1,\zeta\rangle\langle 1+,\zeta| + \frac{\Delta_{33}}{S_{11}^3}|-1,\zeta\rangle\langle 1-,\zeta| \right) d\zeta$$
$$+\frac{1}{\pi}\int_{\bar{c}} \left(\frac{S_{22}}{\Delta_{11}^3}|1+,\zeta\rangle\langle +1,\zeta| + \frac{S_{32}}{\Delta_{11}^3}|1+\zeta\rangle\langle -1,\zeta| \right.$$
$$\left. + \frac{S_{23}}{\Delta_{11}^3}|1-,\zeta\rangle\langle +1,\zeta| + \frac{S_{33}}{\Delta_{11}^3}|1-\zeta\rangle\langle -1,\zeta| \right) d\zeta. \tag{127}$$

To simplify the notation, explicit reference to the ζ dependence of the parameters S_{ij} and Δ_{ij} has been suppressed.

Consider the matrix element $\langle\tau|\mathbf{I}|t\rangle$ of this equation. Using (35) and (36), the right-hand side of (127) becomes

$$\frac{1}{\pi}\int_c \frac{\Delta_{22}(\zeta)}{S_{11}^3(\zeta)}\psi^{(+)} \vee \hat{\psi}^{(1)}(\zeta,\tau)\left(\phi^{(1)} \wedge \hat{\phi}^{(+)}(\zeta,t)\right)^T d\zeta, \tag{128}$$

together with seven other terms corresponding to each of the entries in (127). We now substitute for $\phi^{(1)} \wedge \hat{\phi}^{(+)}$ from (94) and use (100), etc., to remove the cross terms. Finally, appealing to the Marchenko equations (110)–(113) and simplifying the ensuing expression gives

$$\langle\tau|\mathbf{I}|t\rangle = \mathbf{I}\delta\left(t-\tau\right). \tag{129}$$

Equivalently, in the last step of this proof we may appeal directly to (125) and (126) to deduce this result.

We have therefore shown that our statement (78) is indeed the required identity operator and that the basis discussed in connection with (64) is complete, provided that S_{11} and Δ_{11} have only simple zeros in their respective half planes. We now state without proof that (78) continues to be the identity operator for the more general case when the zeros of S_{11} and Δ_{11} are not necessarily simple. This may be shown to be true by retracing the derivation of the Marchenko equations for this latter case. If, for example, S_{11} has a double zero in the upper half ζ plane, the resolution of (78) into its continuum and discrete basis states would give additional basis elements corresponding to second and third derivatives of $|12,\zeta\rangle$, evaluated at the bound state eigenvalues. These extra contributions would then close the set.

Finally, we note that (127) applies for any potentials q_1, $q_2 \in L_1$; each integrand is meromorphic in the half space appropriate to the contours c and $\bar{c}$. Equation (127) can be expressed in terms of an integral along the real ζ axis together with a discrete sum of residues by continuing the contours c and $\bar{c}$ to the real ζ axis, as discussed at the end of section 3.

5. The potentials q_1 and q_2. We now use our completeness results to express the potentials q_1 and q_2 as appropriate linear combinations of the product states. Introduce $|Q\rangle$ such that

$$\langle t|Q\rangle = \begin{pmatrix} \mathbf{q} \\ \mathbf{q}^* \end{pmatrix}, \tag{130}$$

where $\mathbf{q} = (q_1, q_2)^T$. Using evolution equations for the components of the product states together with the known asymptotic forms of the product states as $t \to \pm\infty$,

we can show that

$$\langle 12,\zeta|Q\rangle = S_{11}(\zeta)\Delta_{12}(\zeta), \tag{131}$$

$$\langle 13,\zeta|Q\rangle = S_{11}(\zeta)\Delta_{13}(\zeta), \tag{132}$$

$$\langle 21,\zeta|Q\rangle = S_{12}(\zeta)\Delta_{11}(\zeta), \tag{133}$$

$$\langle 31,\zeta|Q\rangle = S_{13}(\zeta)\Delta_{11}(\zeta). \tag{134}$$

Then, using (78) to form $\langle t|\mathbf{I}_4|Q\rangle$ and expressing $\psi^{(\pm)}$ in terms of $\psi^{(1)}$ and $\psi^{(2)}$, we find

$$\begin{aligned}\begin{pmatrix} \mathbf{q} \\ \mathbf{q}^* \end{pmatrix} &= \frac{1}{\pi}\int_c \left(\frac{S_{21}}{S_{11}}\psi^{(2)} \vee \hat{\psi}^{(1)} + \frac{S_{31}}{S_{11}}\psi^{(3)} \vee \hat{\psi}^{(1)}\right) d\zeta \\ &\quad - \frac{1}{\pi}\int_{\bar{c}} \left(\frac{\Delta_{21}}{\Delta_{11}}\psi^{(1)} \vee \hat{\psi}^{(2)} + \frac{\Delta_{31}}{\Delta_{11}}\psi^{(1)} \vee \hat{\psi}^{(3)}\right) d\zeta.\end{aligned} \tag{135}$$

Writing these two integrals in terms of their discrete and continuum contributions gives the final expressions for q_1 and q_2 of $\mathbf{q}$:

$$\begin{aligned}\begin{pmatrix} q_1 \\ q_2 \end{pmatrix} &= \frac{1}{\pi}\int_{-\infty}^{\infty} \left(\frac{S_{21}}{S_{11}}\begin{pmatrix} \psi_1^{(2)}\hat{\psi}_2^{(1)} \\ \psi_1^{(2)}\hat{\psi}_3^{(1)} \end{pmatrix} + \frac{S_{31}}{S_{11}}\begin{pmatrix} \psi_1^{(3)}\hat{\psi}_2^{(1)} \\ \psi_1^{(3)}\hat{\psi}_3^{(1)} \end{pmatrix}\right) d\xi \\ &\quad - \frac{1}{\pi}\int_{-\infty}^{\infty} \left(\frac{\Delta_{21}}{\Delta_{11}}\begin{pmatrix} \psi_1^{(1)}\hat{\psi}_2^{(2)} \\ \psi_1^{(1)}\hat{\psi}_3^{(2)} \end{pmatrix} + \frac{\Delta_{31}}{\Delta_{11}}\begin{pmatrix} \psi_1^{(1)}\hat{\psi}_2^{(3)} \\ \psi_1^{(1)}\hat{\psi}_3^{(3)} \end{pmatrix}\right) d\xi \\ &\quad - 2i\sum_{k=1}^{N}\begin{pmatrix} \phi_1^{(1)}(\zeta_k)\hat{\psi}_2^{(1)}(\zeta_k) \\ \phi_1^{(1)}(\zeta_k)\hat{\psi}_3^{(1)}(\zeta_k) \end{pmatrix} \\ &\quad - 2i\sum_{k=1}^{\bar{N}=N}\begin{pmatrix} \psi_1^{(1)}(\bar{\zeta}_k)\hat{\phi}_2^{(1)}(\bar{\zeta}_k) \\ \psi_1^{(1)}(\bar{\zeta}_k)\hat{\phi}_3^{(1)}(\bar{\zeta}_k) \end{pmatrix},\end{aligned} \tag{136}$$

where the components $\phi_1^{(1)}(\zeta_k)$, etc., are the bound state Jost functions discussed previously.

Note that the system is not *diagonal* in the sense that both S_{21} and S_{31} (and Δ_{21} and Δ_{31}) contribute to both q_1 and q_2. However, in the linear limit, where both q_1 and q_2 are deemed to be small, we have $S_{11}(\xi) = \Delta_{11}(\xi) \sim 1$, while $\psi^{(2)} \sim \left(0, e^{i\xi t}, 0\right)^T$, etc., so that $\psi_1^{(1)}\hat{\psi}_2^{(2)} \sim e^{-2i\xi t}$ and $\psi_1^{(1)}\hat{\psi}_3^{(3)} \sim e^{-2i\xi t}$, with all other products negligible. Then (136) does uncouple, giving

$$q_1 = -\frac{1}{\pi}\int_{-\infty}^{\infty} e^{(-2i\xi t)}\Delta_{21}(\xi)d\xi, \tag{137}$$

$$q_2 = -\frac{1}{\pi}\int_{-\infty}^{\infty} e^{(-2i\xi t)}\Delta_{31}(\xi)d\xi, \tag{138}$$

as expected. Nonlinearity causes each of Δ_{21} and Δ_{31} to contribute to both q_1 and q_2. This will have interesting and tractable consequences for the (interesting) case when $\mathbf{q}$ corresponds to a vector soliton $\mathbf{q}_s$ accompanied by a small amount of radiation $\delta\mathbf{q}$; this is not pursued further here.

6. Final comments. We conclude this article with a few comments on the vector NLS equation (1). First we state the explicit forms for the conserved densities associated with (1). Though it is well known that such a set of conserved densities will be associated with this (integrable) equation, no explicit statement of this seems to have appeared in the literature. Second, we indicate how the matrix integro-differential operator (19) can be used to generate all other (monomial) members of the vector NLS equation. In particular, this should find useful application in studies on pulse propagation in birefringent fibers operated near the zero dispersion point, where the effects of third order dispersion become important. Kodama and Hasegawa [11] have shown that the scalar NLS equation with the effects of third order dispersion present at order $O(\epsilon)$ can be transformed into a higher order NLS equation in which a new perturbation on the integrable system now appears at order $O(\epsilon^2)$. It is anticipated that a similar transformation will exist for the vector system. Third, and finally, we show how the conserved densities, and the spectral data S_{ij}, evolve when an arbitrary perturbing term $i\mathbf{F}$ (which may correspond to weak and/or strong birefringence effects in the fiber, damping, third order dispersion, soliton self-frequency shift, etc.) is added to the right-hand side of (1).

The conserved densities are obtained by examining the asymptotics of $\phi_1^{(1)}$ as $t \to \infty$, together with the result that S_{11} does not vary with x. Denoting the conserved densities by C_n, $n = 0, 1, 2, \ldots$, it is thus found that

$$C_n = \int_{-\infty}^{\infty} \left(\mathbf{q}^T \rho_n\right) dt, \tag{139}$$

where

$$\rho_0 = \mathbf{q}^*,$$
$$\rho_1 = \mathbf{q}_t,$$

and

$$\rho_{n+1} = \rho_{n,t} + \sum_{i=0}^{n-1} \rho_i \mathbf{q}^T \rho_{n-i-1}. \tag{140}$$

Note that ρ_i are 2-component vectors.

In particular,

$$C_2 = \int_{-\infty}^{\infty} \left(\mathbf{q}^T \mathbf{q}_{tt}^* + \left(\mathbf{q}^\dagger \mathbf{q}\right)^2\right) dt \tag{141}$$

is the Hamiltonian functional for (1).

A general evolution equation for the vector NLS family can be expressed in the form

$$i\partial_x \begin{pmatrix} \mathbf{q} \\ -\mathbf{q}^* \end{pmatrix} - k(-2\mathcal{L}) \begin{pmatrix} \mathbf{q} \\ \mathbf{q}^* \end{pmatrix} = 0, \tag{142}$$

where $\mathcal{L}$ is the integro-differential operator from (19) and $k(\omega)$ is the dispersion function derived from the linearized problem with $\mathbf{q} \sim e^{i(\omega t - kx)}$.

For example, with

$$k(\omega) = -\omega^2 + \epsilon\omega^3$$

we get the integrable form of the vector NLS incorporating third order dispersion to be

$$i\mathbf{q}_x - \mathbf{q}_{tt} - 2\mathbf{q}^\dagger\mathbf{q}\mathbf{q} - i\epsilon\left(\mathbf{q}_{ttt} + 3\{\mathbf{q},\mathbf{q}^\dagger\}\mathbf{q}_t\right) = 0, \tag{143}$$

where $\{\mathbf{q},\mathbf{q}^\dagger\} = \mathbf{q}\mathbf{q}^\dagger + \mathbf{q}^\dagger\mathbf{q}$ denotes the anticommutator.

Finally, we note that for the perturbed form of the vector NLS equation

$$i\mathbf{q}_x - \mathbf{q}_{tt} - 2\mathbf{q}^\dagger\mathbf{q}\mathbf{q} = i\mathbf{F} \tag{144}$$

with $\mathbf{F} = (F_1, F_2)^T$, the conserved quantities C_n evolve according to the equations (cf. [12] for the scalar case)

$$\frac{d}{dx}C_n = \int_{-\infty}^{\infty}\left(\mathbf{F}^T, -\mathbf{F}\right)\left(\mathcal{L}_A\right)^n\begin{pmatrix}\mathbf{q}^*\\ -\mathbf{q}\end{pmatrix}dt, \tag{145}$$

where $\mathcal{L}_A$ is the adjoint integro-differential operator from (29). Similarly, the spectral data now evolve in accordance with [13],

$$S_{ij,x} = S^0_{ij,x} + \int_{-\infty}^{\infty}\phi^{(j)}\wedge\hat{\psi}^{(i)}\begin{pmatrix}\mathbf{F}\\ -\mathbf{F}^*\end{pmatrix}dt, \tag{146}$$

where the term $S^0_{ij,x}$ represents the usual evolution for the unperturbed system. In particular, $S^0_{i1,x} = -4i\zeta^2 S^0_{i1}$, $i = 2, 3$, while $S^0_{11,x} = 0$.

Specific forms for the perturbation include the following:

- $\beta\sigma_3\mathbf{q}$, where β is a scalar and σ_3 is a Pauli matrix; cf. (28). This term models the weak birefringence properties of the fiber and results in a difference in phase velocity between pulse components in the two polarization eigenmodes by an amount 2β.
- $i\beta'\sigma_3\mathbf{q}_t$, where β' is a constant. This term models the strong birefringence properties of the fiber, where now the group velocities of the two modes differ by $\pm\beta'$.
- $\Gamma\mathbf{q}$, where Γ is a (real) constant. This term models loss on the fiber.
- $i\epsilon\mathbf{q}_{ttt}$. This corresponds to higher order dispersive effects in the fiber.

Other terms corresponding to different interactive, optical processes could similarly be quoted.

Suppose now that a soliton is inserted into the fiber at $x = 0$. Then, $S_{ij}(\zeta, x = 0) = 0$ for all $i \neq j$. Under the action of any of the above perturbing influences, radiation will be shed by the soliton on propagating down the fiber so that the pulse acquires a structure $\mathbf{q}(x,t) = \mathbf{q}_s(x,t) + \delta\mathbf{q}(x,t)$, say, where the suffix s denotes the soliton contribution.

Using (146), $S_{ij}(\zeta, x)$ can be computed for some specific form for $\mathbf{F}$, assuming that $\phi^{(j)}\wedge\hat{\psi}^i$ is known. If the perturbing influence is weak, the product states can be approximated by their soliton expressions; the integral on the right-hand side of (146) is then evaluated and $S_{ij}(\zeta, x)$ obtained.

On continuing the contours c and $\bar{c}$ to the real axis, the continuum contribution is identified as yielding $\delta\mathbf{q}(x,t)$, so that

$$\begin{aligned}\begin{pmatrix}\delta q_1\\ \delta q_2\end{pmatrix} &= \frac{1}{\pi}\int_{-\infty}^{\infty}\left(\frac{S_{21}}{S_{11}}\begin{pmatrix}\psi_1^{(2)}\hat{\psi}_2^{(1)}\\ \psi_1^{(2)}\hat{\psi}_3^{(1)}\end{pmatrix} + \frac{S_{31}}{S_{11}}\begin{pmatrix}\psi_1^{(3)}\hat{\psi}_2^{(1)}\\ \psi_1^{(3)}\hat{\psi}_3^{(1)}\end{pmatrix}\right)d\xi\\ &\quad - \frac{1}{\pi}\int_{-\infty}^{\infty}\left(\frac{S^*_{21}}{S^*_{11}}\begin{pmatrix}\psi_1^{(1)}\hat{\psi}_2^{(2)}\\ \psi_1^{(1)}\hat{\psi}_3^{(2)}\end{pmatrix} + \frac{S^*_{31}}{S^*_{11}}\begin{pmatrix}\psi_1^{(1)}\hat{\psi}_2^{(3)}\\ \psi_1^{(1)}\hat{\psi}_3^{(3)}\end{pmatrix}\right)d\xi.\end{aligned} \tag{147}$$

Inserting the derived expressions for S_{21}, etc., and approximating the components $\psi_j^{(i)}$, $\hat{\psi}_j^i$ in these integrals with their solitonic expressions as before then leads to the required expressions for δq_1 and δq_2—at least in principle.

In fiber optical communication systems utilizing solitons, it is important to know how radiation is shed by a soliton in a birefringent fiber and how this radiation propagates away from the main pulse, since it can then interact with other solitons in the fiber. The mathematical formalism developed here resulting in (147) should find useful application to that end.

Appendix A. The dressed Jost functions $\phi^{(\pm)}$etc. In each pair of equations below, the first equation defines the corresponding quantity while the second follows from substitution from (8) and (10) as appropriate.

We define

$$\begin{aligned}
\phi^{(+)} &= S_{33}\phi^{(2)} - S_{32}\phi^{(3)} \\
&= \Delta_{11}\psi^{(2)} - \Delta_{21}\psi^{(1)}, && \text{(A1)} \\
\phi^{(-)} &= S_{22}\phi^{(3)} - S_{23}\phi^{(2)} \\
&= \Delta_{11}\psi^{(2)} - \Delta_{31}\psi^{(1)}, && \text{(A2)} \\
\hat{\phi}^{(+)} &= \Delta_{33}\hat{\phi}^{(2)} - \Delta_{32}\hat{\phi}^{(3)} \\
&= S_{11}\hat{\psi}^{(2)} - S_{21}\hat{\psi}^{(1)}, && \text{(A3)} \\
\hat{\phi}^{(-)} &= \Delta_{22}\hat{\phi}^{(3)} - \Delta_{23}\hat{\phi}^{(2)} \\
&= S_{11}\hat{\psi}^{(3)} - S_{31}\hat{\psi}^{(1)}, && \text{(A4)} \\
\psi^{(+)} &= \Delta_{33}\psi^{(2)} - \Delta_{23}\psi^{(3)} \\
&= S_{11}\phi^{(2)} - S_{12}\phi^{(1)}, && \text{(A5)} \\
\psi^{(-)} &= \Delta_{22}\psi^{(3)} - \Delta_{32}\psi^{(2)} \\
&= S_{11}\phi^{(3)} - S_{13}\phi^{(1)}, && \text{(A6)} \\
\hat{\psi}^{(+)} &= S_{33}\hat{\psi}^{(2)} - S_{23}\hat{\psi}^{(3)} \\
&= \Delta_{11}\hat{\phi}^{(2)} - \Delta_{12}\hat{\phi}^{(1)}, && \text{(A7)} \\
\hat{\psi}^{(-)} &= S_{22}\hat{\psi}^{(3)} - S_{32}\hat{\psi}^{(2)} \\
&= \Delta_{11}\hat{\phi}^{(3)} - \Delta_{13}\hat{\phi}^{(1)}. && \text{(A8)}
\end{aligned}$$

Appendix B. Expressions for the product cross states in terms of the product eigenstates. For each case, we follow the working for $\psi^{(1)} \vee \hat{\psi}^{(1)}$ discussed in the text.

(i) $\psi^{(2)} \vee \hat{\psi}^{(2)}$. Substituting in turn for $\psi^{(2)}$ and $\hat{\psi}^{(2)}$ by using expressions given in Appendix A allows us to write $\psi^{(2)} \vee \hat{\psi}^{(2)}$ in two equivalent ways:

$$\begin{aligned}
\psi^{(2)} \vee \hat{\psi}^{(2)} &= \frac{\phi^{(+)} \vee \hat{\psi}^{(2)}}{\Delta_{11}} - \frac{\Delta_{21}}{\Delta_{11}}\psi^{(1)} \vee \hat{\psi}^{(2)} \\
&= \frac{\psi^{(2)} \vee \hat{\phi}^{(+)}}{S_{11}} - \frac{S_{21}}{S_{11}}\psi^{(2)} \vee \hat{\psi}^{(1)}. && \text{(B1)}
\end{aligned}$$

Here again, we observe that the first terms on the right-hand sides are meromorphic in one or the other half place, with simple poles at the zeros of Δ_{11} or S_{11}. Note also that the remaining terms contain one or other of the product eigenstates.

Following (99), we write

$$\psi^{(2)} \vee \hat{\psi}^{(2)}(\xi) = \frac{1}{2\pi i} \int_{\sigma} \frac{\psi^{(2)} \vee \hat{\psi}^{(2)}}{\zeta - \xi} d\zeta, \tag{B2}$$

where σ denotes a small circular path centered at (real) ξ, taken in the positive sense. Now substitute (B1) into (B2), using the first statement in (B1) on the semicircular path with $\Im\zeta < 0$ and the second on $\Im\zeta > 0$. Evaluating explicitly the first integral in either case and rearranging give

$$\psi^{(2)} \vee \hat{\psi}^{(2)}(\zeta) = \frac{1}{2\pi i} \int_{c} \frac{S_{21}}{S_{11}} \psi^{(2)} \vee \hat{\psi}^{(1)} \frac{d\zeta'}{\zeta' - \zeta} - \frac{1}{2\pi i} \int_{\bar{c}} \frac{\Delta_{21}}{\Delta_{11}} \psi^{(1)} \vee \hat{\psi}^{(2)} \frac{d\zeta'}{\zeta' - \zeta}. \tag{B3}$$

Similarly, for each of the other cross product states, the corresponding statements read as follows:

(ii) $\psi^{(3)} \vee \hat{\psi}^{(2)}$:

$$\begin{aligned} \psi^{(3)} \vee \hat{\psi}^{(2)}(\zeta) &= \frac{\psi^{(3)} \vee \hat{\phi}^{(+)}}{S_{11}} - \frac{S_{21}}{S_{11}} \psi^{(3)} \vee \hat{\psi}^{(1)} \\ &= \frac{\phi^{(-)} \vee \hat{\psi}^{(2)}}{\Delta_{11}} - \frac{\Delta_{31}}{\Delta_{11}} \psi^{(1)} \vee \hat{\psi}^{(2)} \end{aligned} \tag{B4}$$

leading to

$$\psi^{(3)} \vee \hat{\psi}^{(2)}(\zeta) = \frac{1}{2\pi i} \int_{c} \frac{S_{21}}{S_{11}} \psi^{(3)} \vee \hat{\psi}^{(1)} \frac{d\zeta'}{\zeta' - \zeta} - \frac{1}{2\pi i} \int_{\bar{c}} \frac{\Delta_{31}}{\Delta_{11}} \psi^{(1)} \vee \hat{\psi}^{(2)} \frac{d\zeta'}{\zeta' - \zeta}; \tag{B5}$$

(iii) $\psi^{(2)} \vee \hat{\psi}^{(3)}$:

$$\begin{aligned} \psi^{(2)} \vee \hat{\psi}^{(3)}(\zeta) &= \frac{\phi^{(+)} \vee \hat{\psi}^{(3)}}{\Delta_{11}} - \frac{\Delta_{21}}{\Delta_{11}} \psi^{(1)} \vee \hat{\psi}^{(3)} \\ &= \frac{\psi^{(2)} \vee \hat{\phi}^{(-)}}{S_{11}} - \frac{S_{31}}{S_{11}} \psi^{(2)} \vee \hat{\psi}^{(1)} \end{aligned} \tag{B6}$$

leading to

$$\psi^{(2)} \vee \hat{\psi}^{(3)}(\zeta) = \frac{1}{2\pi i} \int_{c} \frac{S_{31}}{S_{11}} \psi^{(2)} \vee \hat{\psi}^{(1)} \frac{d\zeta'}{\zeta' - \zeta} - \frac{1}{2\pi i} \int_{\bar{c}} \frac{\Delta_{21}}{\Delta_{11}} \psi^{(1)} \vee \hat{\psi}^{(3)} \frac{d\zeta'}{\zeta' - \zeta}; \tag{B7}$$

(iv) $\psi^{(3)} \vee \hat{\psi}^{(3)}$:

$$\begin{aligned} \psi^{(3)} \vee \hat{\psi}^{(3)}(\zeta) &= \frac{\psi^{(3)} \vee \hat{\phi}^{(-)}}{S_{11}} - \frac{S_{31}}{S_{11}} \psi^{(3)} \vee \hat{\psi}^{(1)} \\ &= \frac{\phi^{(-)} \vee \hat{\psi}^{(3)}}{\Delta_{11}} - \frac{\Delta_{31}}{\Delta_{11}} \psi^{(1)} \vee \hat{\psi}^{(3)} \end{aligned} \tag{B8}$$

leading to

$$\psi^{(3)} \vee \hat{\psi}^{(3)}(\zeta) = \frac{1}{2\pi i} \int_{c} \frac{S_{31}}{S_{11}} \psi^{(3)} \vee \hat{\psi}^{(1)} \frac{d\zeta'}{\zeta' - \zeta} - \frac{1}{2\pi i} \int_{\bar{c}} \frac{\Delta_{31}}{\Delta_{11}} \psi^{(1)} \vee \hat{\psi}^{(3)} \frac{d\zeta'}{\zeta' - \zeta}. \tag{B9}$$

In each of the above integrals, the explicit ζ' dependence of each term in the integrand has been suppressed for clarity.

When the expressions for the different cross product states (together with (100) for $\psi^{(1)} \vee \hat{\psi}^{(1)}$) are substituted into (96) and (101)–(103), the resulting equations will be a set of four integral equations coupling the product eigenstates $\psi^{(1)} \vee \hat{\psi}^{(2)}$, etc.

ANGULAR CHANNELS IN A MULTIDIMENSIONAL WAVELET TRANSFORM*

ERIC CLARKSON†

Abstract. Given a subgroup S of $GL(n)$, let G be the semidirect product of S with $\mathbb{R}^n$. The wavelet transform is defined for functions in $L^2(\mathbb{R}^n)$ by using the action of G on this space. The standard properties of the wavelet transform and its inverse are quickly and easily derived in this formalism. In particular, the admissibility condition for the wavelet is expressed in terms of an integral over S. The notion of orthogonal wavelet channels is defined, and the wavelet transform is decomposed in terms of them. Other operators on $L^2(\mathbb{R}^n)$ can also be analyzed in terms of their mixing of wavelet channels. For $n = 2$ and $n = 3$, details are given for the expansion of an arbitrary wavelet transform in terms of angular wavelet channels. An example is provided for $n = 2$. The correspondence between angular channels and the spherical harmonic decomposition of the Fourier transform of the wavelet transform is also outlined.

Key words. wavelet transform, unitary representations of locally compact groups, orthogonal functions, spherical harmonics, signal reconstruction, channel models

1. Introduction.

Wavelet transforms for functions of more than one variable have been approached from various directions. One method has been to use the theory of square integrable representations for nonunimodular, locally compact groups (see [4, 5, 7, 12]), which is very general, and apply it to a given symmetry group acting on $\mathbb{R}^n$. This has been done for the euclidean symmetry group in [2, 11]. Another method is to restrict the point symmetry group to be n-dimensional and use elementary arguments, as in [3]. This is good for $n = 2$, but for $n = 3$ the rotation-dilation group, an important example, is four-dimensional. Elementary arguments are also possible if the group contains only scale and shift operations. Optical realizations of this type of transform for $n = 2$ are carried out in [1, 10, 14, 15, 16]. In image analysis applications, however, orientation is a useful parameter. The wavelet transform derivations given below fall in the midrange. Since integration on the group is used, the arguments are not exactly elementary. On the other hand, the symmetry groups considered are all semidirect products of a translation groups $T = \mathbb{R}^n$ with a subgroup S of $GL(n)$. This is a small subclass of the set of all locally compact, nonunimodular groups, but it does cover all of the special cases mentioned above.

The decomposing of a wavelet transform into orthogonal channels in the second half of this article seems to be new, although there are hints of it in [9, 13]. For an actual image analysis system that uses the wavelet transform, it would be advantageous to have a variety of wavelets available. By using orthogonal wavelet channels, an infinite collection of wavelet transforms could be synthesized by varying some parameters, or one wavelet transform can be computed and then others derived from it by projection. In the special case of angular wavelet channels, the parameters can be

varied to emphasize certain angular features of the object. If reconstruction is also necessary, angular channels can be used to eliminate the integration over the rotation group that is normally necessary when rotations are included in the symmetry operations. Sampling can also be simplified by using a finite number of angular channels of a particular wavelet and sampling each of them in scale and translation only. Finally, in the Fourier domain, angular channels correspond to an expansion of the Fourier transform of the wavelet transform in spherical harmonics in the angular variables.

2. The one-dimensional wavelet transform. As is well known the one-dimensional wavelet transform may be formulated in terms of the one-dimensional affine group (see [6, 8]). This is reviewed in this section in order to establish notation and provide a pattern for generalizing to higher dimensions. In particular, the reformulation of the admissibility condition in terms of the scale group, while trivial in one dimension, leads to a convenient condition for admissibility in higher dimensions.

The wavelet transform of $f \in L^2(\mathbb{R})$ with respect to $h \in L^2(\mathbb{R})$ is given by

$$w(s,t) = \int_{\mathbb{R}} f(x) \frac{1}{\sqrt{|s|}} h^* \left(\frac{x-t}{s} \right) dx.$$

If h is admissible, f may be recovered via

$$f(x) = \frac{1}{C_h} \int_{\mathbb{R}^2} w(s,t) \frac{1}{\sqrt{|s|}} h \left(\frac{x-t}{s} \right) \frac{1}{s^2} ds dt.$$

The admissibility condition is

$$C_h = \int_{\mathbb{R}} |H(k)|^2 \frac{1}{|k|} dk < \infty.$$

$H(k)$ is the Fourier transform of $h(x)$. This convention will be used for other functions also. For our purposes, this can be rewritten trivially as

$$C_h = \int_{\mathbb{R}} |H(sk)|^2 \frac{1}{|s|} ds < \infty.$$

Let S be the multiplicative group of nonzero real numbers and T the additive group of real numbers. The one-dimensional affine group G is the semidirect product of S with T. An element of G is $g = (s,t)$, with $s \in S$ and $t \in T$, and if $g' = (s',t')$, then $gg' = (ss', st' + t)$. The standard action of G on $\mathbb{R}$ is given by

$$\Phi_g(x) = sx + t,$$

giving $\Phi_g \Phi_{g'} = \Phi_{gg'}$ and $\Phi_g^{-1}(x) = \Phi_{g^{-1}}(x) = \frac{x-t}{s}$. Using this action, elements of G may also act on functions such as $h(x)$ above:

$$\overline{\Phi}_g h(x) = \frac{1}{\sqrt{|s|}} h\left(\Phi_g^{-1}(x)\right) = \frac{1}{\sqrt{|s|}} h\left(\frac{x-t}{s} \right).$$

Again $\overline{\Phi}_g \overline{\Phi}_{g'} = \overline{\Phi}_{gg'}$, making $\overline{\Phi}$ an irreducible unitary representation of G on $L^2(\mathbb{R})$.

The left invariant measure (left Haar measure) on G will be denoted by dg_L. If w is a function on G, integrable with respect to this measure, and $g_0 \in G$, then the defining property of the left invariant measure for any group is

$$\int_G w(g_0 g) dg_L = \int_G w(g) dg_L.$$

If G is the one-dimensional affine group, then

$$\frac{dsdt}{s^2} = dg_L.$$

If ds_L is the left invariant measure on S, then

$$\frac{ds}{|s|} = ds_L.$$

Now the wavelet transform formulae may be written

$$w(g) = \int_{\mathbb{R}} f(x)\overline{\Phi}_g h^*(x)dx, \tag{1}$$

$$f(x) = \frac{1}{C_h}\int_G w(g)\overline{\Phi}_g h(x)dg_L, \tag{2}$$

$$C_h = \int_S |H(sk)|^2 \, ds_L < \infty. \tag{3}$$

3. A multidimensional wavelet transform. These last three formulae are easily scaled up to higher dimensions. However, there are now two questions that must be addressed. What group should be used for S? Is C_h independent of $\mathbf{k}$ for a particular choice for S? The answer to the second question is yes if the chosen group S satisfies an orbit condition in $\mathbb{R}^n$. The answer to the first question depends upon the application.

T is now the n-dimensional translation group (isomorphic to $\mathbb{R}^n$) and S is a subgroup of $GL(n)$. As before $G = \{(s, \mathbf{t}) : s \in S, \mathbf{t} \in T\}$ with multiplication rule $(s, \mathbf{t})(s', \mathbf{t}') = (ss', s\mathbf{t} + \mathbf{t}')$. Let $J(s) = |\det(s)|$. Again for each $g \in G$ we have operators on $\mathbb{R}^n$ and $L^2(\mathbb{R}^n)$

$$\Phi_g \mathbf{x} = s\mathbf{x} + \mathbf{t},$$

$$\overline{\Phi}_g h(\mathbf{x}) = \frac{1}{\sqrt{J(s)}} h\left(\Phi_g^{-1}\mathbf{x}\right) = \frac{1}{\sqrt{J(s)}} h\left(s^{-1}(\mathbf{x} - \mathbf{t})\right).$$

PROPOSITION 1. *Given $f, h \in L^2(\mathbb{R}^n)$ let*

$$w(g) = \int_{\mathbb{R}^n} f(\mathbf{x})\overline{\Phi}_g h^*(\mathbf{x})d^n x \tag{4}$$

and, for $\mathbf{k} \neq 0$,

$$C_h(\mathbf{k}) = \int_S \left|H\left(s^t\mathbf{k}\right)\right|^2 ds_L. \tag{5}$$

If $C_h(\mathbf{k})$ is finite and independent of $\mathbf{k}$, then

$$f(\mathbf{x}) = \frac{1}{C_h}\int_G w(g)\overline{\Phi}_g h(\mathbf{x})dg_L. \tag{6}$$

Proof. Let $g = (s, \mathbf{t})$ as above. Then

$$dg_L = \left(\frac{d^n t}{J(s)} \right) ds_L,$$

and the forward transform is

$$w(s, \mathbf{t}) = \int_{\mathbb{R}^n} f(\mathbf{x}) \frac{1}{\sqrt{J(s)}} h^* \left(s^{-1}(\mathbf{x} - \mathbf{t}) \right) d^n x. \tag{7}$$

As will be seen below, this wavelet transform maps $L^2(\mathbb{R}^n)$ to $L^2(G)$, the Hilbert space of functions on G square integrable with respect to dg_L. Let $\widetilde{f}$ be given by the adjoint of this transform applied to w:

$$\begin{aligned} \widetilde{f}(\mathbf{x}) &= \int_G w(g) \overline{\Phi}_g h(\mathbf{x}) dg_L \\ &= \int_S \int_{\mathbb{R}^n} w(s, \mathbf{t}) \frac{1}{\sqrt{J(s)}} h\left(s^{-1}(\mathbf{x} - \mathbf{t}) \right) \frac{d^n t}{J(s)} ds_L, \end{aligned} \tag{8}$$

and define $h_s(\mathbf{x}) = \frac{1}{\sqrt{J(s)}} h\left(s^{-1}\mathbf{x} \right)$ and $w_s(\mathbf{t}) = w(s, \mathbf{t})$. Taking the Fourier transform of (7) with respect to $\mathbf{t}$ gives

$$W_s(\mathbf{k}) = F(\mathbf{k}) H_s^*(\mathbf{k}) = F(\mathbf{k}) H^*(s^t \mathbf{k}) \sqrt{J(s)}.$$

Now let $\mathcal{F}$ denote the Fourier transform operator on $L^2(\mathbb{R}^n)$. Then (8) may be rewritten as

$$\widetilde{f}(\mathbf{x}) = \int_S \mathcal{F}^{-1} \{ W_s H_s \} \frac{ds_L}{J(s)} = \int_S \mathcal{F}^{-1} \{ F H_s^* H_s \} \frac{ds_L}{J(s)},$$

which gives

$$\begin{aligned} \widetilde{f}(\mathbf{x}) &= \int_S \int_{\mathbb{R}^n} F(\mathbf{k}) H^* \left(s^t \mathbf{k} \right) H \left(s^t \mathbf{k} \right) e^{2\pi i \mathbf{k} \cdot \mathbf{x}} d^n k ds_L \\ &= \int_{\mathbb{R}^n} F(\mathbf{k}) e^{2\pi i \mathbf{k} \cdot \mathbf{x}} \left[\int_S H^* \left(s^t \mathbf{k} \right) H \left(s^t \mathbf{k} \right) ds_L \right] d^n k. \end{aligned}$$

Therefore, if the inner integral is essentially bounded as a function of $\mathbf{k}$,

$$\widetilde{F}(\mathbf{k}) = F(\mathbf{k}) \int_S \left| H \left(s^t \mathbf{k} \right) \right|^2 ds_L = F(\mathbf{k}) C_h(\mathbf{k}). \tag{9}$$

Since, by assumption, $C_h(\mathbf{k})$ is in fact a finite constant, the result now follows. ∎

If $C_h(\mathbf{k})$ is essentially bounded, the function h will be said to be S-admissible and the vector space of S-admissible functions will be called $L^2(\mathbb{R}^n, S)$. Note that for a given S it is possible that $C_h(\mathbf{k})$ is infinite for all nonzero $h \in L^2(\mathbb{R}^n)$ and $\mathbf{k} \in \mathbb{R}^n$. In other words, $L^2(\mathbb{R}^n, S)$ may contain only the zero function. Also note that if $C_{h_1}(\mathbf{k})$ and $C_{h_2}(\mathbf{k})$ are constant and $h_3 = h_1 + h_2$, this does not necessarily imply that $C_{h_3}(\mathbf{k})$ is constant. In other words, the set of h such that $C_h(\mathbf{k})$ is a finite constant is not necessarily a vector space. The next proposition shows, however, that it can be, under the right conditions.

PROPOSITION 2. *If the S^t-orbit of a nonzero $\mathbf{k}$ in $\mathbb{R}^n$ is $\mathbb{R}^n \backslash \{0\}$, then $C_h(\mathbf{k})$ is independent of $\mathbf{k}$ for any h and (6) is true when C_h is finite.*

Proof. Suppose $\mathbf{k}_1 \neq \mathbf{k}$ and there is an $s_1 \in S$ such that $s_1^t \mathbf{k} = \mathbf{k}_1$. Then

$$C_h(\mathbf{k}_1) = \int_S \left| H\left(s^t \mathbf{k}_1\right)\right|^2 ds_L = \int_S \left| H\left(s^t s_1^t \mathbf{k}\right)\right|^2 ds_L$$
$$= \int_S \left| H\left(\left(s_1 s\right)^t \mathbf{k}\right)\right|^2 ds_L = C_h(\mathbf{k}).$$

The last equality uses the left invariance of ds_L. In other words, for all $s \in S$,

$$C_h(s^t \mathbf{k}) = C_h(\mathbf{k}).$$

If the S^t-orbit of a nonzero $\mathbf{k}$ in $\mathbb{R}^n$ is $\mathbb{R}^n \backslash \{0\}$, then such an s_1 may be found for any $\mathbf{k}_1 \neq 0$, and therefore $C_h(\mathbf{k})$ is a constant C_h. □

Note that in this case $c_h(\mathbf{x}) = C_h \delta(\mathbf{x})$. It is of course possible for $C_h(\mathbf{k})$ to be a constant for a specific function h even when S^t is not transitive on $\mathbb{R}^n \backslash \{0\}$. In general, however, if h is S-admissible, then $\widetilde{F}(\mathbf{k})$ is the product of $F(\mathbf{k})$ with an S^t-invariant bounded function $C_h(\mathbf{k})$. If $*$ denotes n-dimensional convolution, then this means that

$$\widetilde{f}(\mathbf{x}) = \left(c_h * f\right)(\mathbf{x}), \tag{10}$$

where the distribution c_h satisfies

$$J(s) c_h(s\mathbf{x}) = c_h(\mathbf{x}).$$

In this case the integral in (6) must be followed by a deconvolution to retrieve f from w.

4. Properties of the wavelet transform. The properties of the generalized wavelet transform and its adjoint listed in the next theorem will be useful in discussing the concept of angular wavelet channels. All of them are well known in the more general setting of the theory of square integrable representations of locally compact, nonunimodular groups. The advantage in the presentation below is that all derivations are elementary and the inner product $(h_1, h_2)_S$ is easily computed.

If S^t is transitive on $\mathbb{R}^n \backslash \{0\}$, then we may define an inner product of $h_1, h_2 \in L^2(\mathbb{R}^n, S)$ as

$$(h_1, h_2)_S = \int_S H_1^*\left(s^t \mathbf{k}\right) H_2\left(s^t \mathbf{k}\right) ds_L,$$

which makes this vector space into a Hilbert space. Note that the integral is independent of $\mathbf{k}$. If w is given by (4), write $w = \mathcal{W}\{f, h\}$ and let $\mathcal{W}^\top\{w, h\}$ be the adjoint transform given in (8). If $w_1, w_2 \in L^2(G)$, then let $(w_1, w_2)_G = \int_G w_1^*(g) w_2(g) dg_L$. Let $(f_1, f_2) = \int_{R^n} f_1^*(\mathbf{x}) f_2(\mathbf{x}) d^n x$ be the usual inner product of $f_1, f_2 \in L^2(\mathbb{R}^n)$. Define convolution for group functions in the standard way via $(w_1 * w_2)(g_0) = \int_G w_1(g) w_2(g^{-1} g_0) dg_L$ and let $p_{h_1 h_2} = \mathcal{W}\{h_1, h_2\}$.

PROPOSITION 3. *Suppose that S^t is transitive on $\mathbb{R}^n \backslash \{0\}$; $f, f_1, f_2 \in L^2(\mathbb{R}^n)$ and $h, h_1, h_2 \in L^2(\mathbb{R}^n, S)$. Let $w = \mathcal{W}\{f, h\}, w_1 = \mathcal{W}\{f_1, h_1\}$, and $w_2 = \mathcal{W}\{f_2, h_2\}$. Then $w, w_1, w_2 \in L^2(G)$ and*

$$(w_1, w_2)_G = (f_1, f_2)(h_2, h_1)_S,$$

$$\mathcal{W}^\top\{\mathcal{W}\{f, h_1\}, h_2\} = (h_1, h_2)_S f,$$

$$w * p_{h_1 h_2} = (h, h_1)_S \, \mathcal{W}\{f, h_2\}.$$

Proof. Note that for $g = (s, \mathbf{t})$,

$$w(g) = w_s(\mathbf{t}) = \int_{\mathbb{R}^n} F(\mathbf{k}) H_s^*(\mathbf{k}) e^{-2\pi i \mathbf{k}\cdot\mathbf{t}} d^n k.$$

Then

$$\begin{aligned}
(11) \qquad \int_G w_1^*(g) w_2(g) dg_L &= \int_S \left[\int_{\mathbb{R}^n} w_{1s}^*(\mathbf{t}) w_{2s}(\mathbf{t}) d^n t \right] \frac{1}{J(s)} ds_L \\
&= \int_S \left[\int_{\mathbb{R}^n} F_1^*(\mathbf{k}) H_{1s}(\mathbf{k}) F_2(\mathbf{k}) H_{2s}^*(\mathbf{k}) d^n k \right] \frac{1}{J(s)} ds_L \\
&= \int_{\mathbb{R}^n} F_1^*(\mathbf{k}) F_2(\mathbf{k}) \left[\int_S H_{1s}(\mathbf{k}) H_{2s}^*(\mathbf{k}) \frac{1}{J(s)} ds_L \right] d^n k \\
&= \int_{\mathbb{R}^n} F_1^*(\mathbf{k}) F_2(\mathbf{k}) \left[\int_S H_1\left(s^t \mathbf{k}\right) H_2^*\left(s^t \mathbf{k}\right) ds_L \right] d^n k.
\end{aligned}$$

Setting $w_2 = w_1 = w$ shows that $w \in L^2(G)$. This equation also gives the first relation. For the second, merely repeat the proof of Proposition 1 using h_1 and h_2 instead of h. For the third, let $w'(g) = p_{h_1 h_2}^*(g^{-1} g_0)$ and note that $w' = \mathcal{W}\{\Phi_{g_0} h_2, h_1\}$. If $w'' = W\{f, h_2\}$, then

$$(w * p_{h_1 h_2})(g_0) = (w', w)_G = (\Phi_{g_0} h_2, f)(h, h_1)_S = (h, h_1)_S \, w''(g_0).$$

This gives the result. □

Let $C_{h_1 h_2}(\mathbf{k})$ be the inner integral in (11). In the general case, since h_1 and h_2 are S-admissible, this is a bounded function of $\mathbf{k}$. Therefore the last integral is finite. Then without the orbit condition on S the relations in this proposition are

$$(w_1, w_2)_G = (F_1, C_{h_1 h_2} F_2),$$

$$\mathcal{W}^\top \{\mathcal{W}\{f, h_1\}, h_2\} = c_{h_1 h_2} * f,$$

$$w * p_{h_1 h_2} = \mathcal{W}\{c_{h h_1} * f, h_2\}.$$

5. Orthogonal channels in the wavelet transform. Obviously everything is nicer when S^t is transitive on $\mathbb{R}^n \backslash \{0\}$, which will be the assumption from here on. Let U be the closed subspace of $L^2(G)$ spanned by the set $\{\mathcal{W}\{f, h\} : f \in L^2(\mathbb{R}^n), h \in L^2(\mathbb{R}^n, S)\}$. The left regular representation of G on $L^2(G)$ is given by $L_g w(g_0) = w(g^{-1} g_0)$. It is easy to show that

$$\mathcal{W}\left\{\overline{\Phi}_g f, h\right\} = L_g \mathcal{W}\{f, h\}.$$

Therefore U is a left invariant subspace. Now suppose that $\{h_i\}$ is an orthonormal set in $L^2(\mathbb{R}^n, S)$, i.e., $(h_i, h_j)_S = \delta_{ij}$. If $U_i = \left\{\mathcal{W}\{f, h_i\} : f \in L^2(\mathbb{R}^n)\right\}$, then the U_i are left invariant, mutually orthogonal subspaces of U and $U = \bigoplus U_i$. If $p_{ij} = p_{h_i h_j}$ and $w_i = \mathcal{W}\{f, h_i\}$, then Proposition 3 gives

$$w_i * p_{jk} = \delta_{ij} w_k,$$

$$\mathcal{W}^{\top}\{w_i, h_j\} = \delta_{ij} f.$$

Now let $h = \sum_i a_i h_i$ be an admissible function, and $w = \mathcal{W}\{f, h\}$. Then $w = \sum_i a_i^* w_i$ expresses w as an orthogonal sum in $L^2(G)$. Each w_i is f filtered through the channel h_i. Any w_i may be recovered from w via $w * p_{ii} = a_i^* w_i$. The original function f may be recovered from any w_i via $f = \mathcal{W}^{\top}\{w_i, h_i\} = \frac{1}{a_i}\mathcal{W}^{\top}\{w_i, h\}$. Therefore each w_i contains all of the information about f, but this information may be contained in subtle variations in $w_i(g)$ as g varies in G. If there is noise present these subtle variations may be indiscernible. But, because of the orthogonality conditions, it is possible to compute all of the w_i simultaneously by computing w and then examining them separately by convolving w with functions p_{ii}. If each w_i produces strong responses to different features of f, this could be an efficient way to analyze the function in the presence of noise. Note that $C_h = \sum_i |a_i|^2$.

Operators on $L^2(\mathbb{R}^n)$ may also be analyzed for their effect on the channels. Let $\mathcal{Q}$ be an integral operator on $L^2(\mathbb{R}^n)$ given by $\mathcal{Q}f(\mathbf{x}) = \int_{\mathbb{R}^n} q(\mathbf{x}, \mathbf{y}) f(\mathbf{y}) d^n y$. If $w = \mathcal{W}\{f, h\}$ and $\mathcal{Q}_h w = \mathcal{W}\{\mathcal{Q}f, h\}$, then

$$\mathcal{Q}_h w(g_0) = \int_G q_h(g_0, g) w(g) dg_L,$$

where

$$q_h(g_0, g) = \frac{1}{C_h} \int_{\mathbb{R}^n} \left[\int_{\mathbb{R}^n} q(\mathbf{x}, \mathbf{y}) \overline{\Phi}_{g_0} h^*(\mathbf{x}) d^n x \right] \overline{\Phi}_g h(\mathbf{y}) d^n y. \tag{12}$$

Now let

$$q_{ij}(g_0, g) = \int_{\mathbb{R}^n} \left[\int_{\mathbb{R}^n} q(\mathbf{x}, \mathbf{y}) \overline{\Phi}_{g_0} h_i^*(\mathbf{x}) d^n x \right] \overline{\Phi}_g h_j(\mathbf{y}) d^n y$$

and notice that, for fixed g_0, this is a function in U_j^*. Also

$$q_h(g_0, g) = \frac{1}{C_h} \sum_i \sum_j a_i^* a_j q_{ij}(g_0, g).$$

As above, $w = \sum_k a_k^* w_k$ with $w_k = \mathcal{W}\{f, h_k\}$ and, using the fact that U_j and U_k are orthogonal subspaces when $k \neq j$,

$$\mathcal{Q}_h w(g_0) = \sum_i a_i^* \left[\frac{1}{C_h} \sum_j |a_j|^2 \int_G q_{ij}(g_0, g) w_j(g) dg_L \right].$$

For a fixed g, $q_{ij}(g_0, g)$ is a function in U_i. Since this is a closed subspace, the expression in brackets is also a function in U_i. Therefore $\mathcal{Q}_h w = \sum_i a_i^* \mathcal{W}\{\mathcal{Q}f, h_i\} = \sum_i a_i^* (\mathcal{Q}_h w)_i$ and

$$(\mathcal{Q}_h w)_i(g_0) = \frac{1}{C_h} \sum_j |a_j|^2 \int_G q_{ij}(g_0, g) w_j(g) dg_L.$$

The function q_{ij} then measures how much the operator mixes channel h_j with channel h_i.

6. Angular channels in a two-dimensional wavelet transform. As an example of a channel decomposition consider the $n = 2$ case. An element f of $L^2\left(\mathbb{R}^2\right)$ may be thought of as an image and the wavelet transform could be used for image analysis or modification. Let the point group S be $\mathbb{R}^+ \times SO(2)$, where $\mathbb{R}^+$ is the multiplicative group of positive real numbers. If $s \in S$, then $s = aR(\phi)$, indicating a scale transformation by a factor of a and a rotation by an angle ϕ about the origin. Here $R(\phi)$ is the usual 2×2 rotation matrix associated with ϕ,

$$R(\phi) = \begin{pmatrix} \cos\phi & -\sin\phi \\ \sin\phi & \cos\phi \end{pmatrix}.$$

If $s' = a'R(\phi')$, then $ss' = aa'R(\phi + \phi')$. The invariant measures are

$$ds_L = \left(\frac{da}{a}\right) d\phi,$$

$$dg_L = \left(\frac{d^2t}{J(s)}\right) ds_L = \frac{da}{a^3} d\phi d^2t.$$

Let J be the interval $[0, 2\pi)$. The detailed wavelet formulae for this case are

$$w(a, \phi, \mathbf{t}) = \int_{\mathbb{R}^2} f(\mathbf{x}) \frac{1}{a} h^* \left(\frac{1}{a} R(-\phi)(\mathbf{x} - \mathbf{t})\right) d^2x,$$

$$f(\mathbf{x}) = \frac{1}{C_h} \int_{\mathbb{R}^2} \int_J \int_{\mathbb{R}^+} w(a, \phi, \mathbf{t}) \frac{1}{a} h \left(\frac{1}{a} R(-\phi)(\mathbf{x} - \mathbf{t})\right) \frac{da}{a^3} d\phi d^2t,$$

$$C_h = \int_J \int_{\mathbb{R}^+} \left|H\left(aR(-\phi)\mathbf{k}\right)\right|^2 \frac{da d\phi}{a} < \infty.$$

This admissibility condition is equivalent to

$$C_h = \int_{\mathbb{R}^2} \left|H\left(\mathbf{k}\right)\right|^2 \frac{d^2k}{\left|\mathbf{k}\right|^2} < \infty.$$

Similarly, the wavelet inner product is given by

$$\left(h_1, h_2\right)_S = \int_{\mathbb{R}^2} H_1^*\left(\mathbf{k}\right) H_2\left(\mathbf{k}\right) \frac{d^2k}{\left|\mathbf{k}\right|^2}.$$

The channel expansion for h will be the Fourier expansion in the angular coordinate. This is also the expansion of h into basis functions for irreducible representations of $SO(2)$. Let $\theta(\widehat{\mathbf{x}})$ be the polar angle of the vector $\mathbf{x}$. Then

$$h(\mathbf{x}) = \sum_{n=-\infty}^{\infty} a_n \overline{h}_n\left(|\mathbf{x}|\right) \exp[in\theta\left(\widehat{\mathbf{x}}\right)] = \sum_{n=-\infty}^{\infty} a_n h_n\left(\mathbf{x}\right),$$

where

$$\overline{h}_n\left(r\right) = \frac{1}{2\pi a_n} \int_J h(r, \theta) e^{-in\theta} d\theta,$$

and a_n is chosen so that $(h_n, h_n)_S = 1$. If we let

$$\overline{H}_n(k) = 2\pi \int_{\mathbb{R}^+} J_n(2\pi kr)\overline{h}_n(r) r dr,$$

where J_n is the nth order Bessel function of the first kind, then

$$H_n(\mathbf{k}) = \overline{H}_n\left(|\mathbf{k}|\right) \exp\left[in\theta\left(\widehat{\mathbf{k}}\right)\right].$$

This implies that $(h_n, h_m)_S = \delta_{nm.}$ The normalization condition on h_n is equivalent to

$$2\pi \int_{\mathbb{R}^+} \left|\overline{H}_n\left(a\,|\mathbf{k}|\right)\right|^2 \frac{da}{a} = 2\pi \int_{\mathbb{R}^+} \left|\overline{H}_n(a)\right|^2 \frac{da}{a} = 1.$$

Scaling and rotating h_n gives

$$\begin{aligned} h_n\left(\frac{1}{a}R(-\phi)\mathbf{x}\right) &= \overline{h}_n\left(\frac{1}{a}\,|\mathbf{x}|\right) \exp\left[in(\theta\left(\widehat{\mathbf{x}}\right) - \phi)\right] \\ &= \exp(-in\phi) h_n\left(\frac{1}{a}\mathbf{x}\right). \end{aligned}$$

The forward transform now has the form

$$w(a, \phi, \mathbf{t}) = \sum_{n=-\infty}^{\infty} a_n^* \exp(in\phi)\overline{w}_n\left(a, \mathbf{t}\right), \tag{13}$$

with

$$\overline{w}_n\left(a, \mathbf{t}\right) = \int_{\mathbb{R}^2} f(\mathbf{x}) \frac{1}{a} h_n^*\left(\frac{1}{a}(\mathbf{x} - \mathbf{t})\right) d^2x.$$

Therefore the order n wavelet channel is given by

$$w_n\left(a, \phi, \mathbf{t}\right) = \exp(in\phi)\overline{w}_n\left(a, \mathbf{t}\right).$$

Using w_n and h_n to recover f results in

$$f(\mathbf{x}) = 2\pi \int_{\mathbb{R}^2} \int_{\mathbb{R}^+} \overline{w}_n\left(a, \mathbf{t}\right) \frac{1}{a} h_n\left(\frac{1}{a}(\mathbf{x} - \mathbf{t})\right) \frac{da}{a^3} d^2t. \tag{14}$$

Notice that each $\overline{w}_n\left(a, \mathbf{t}\right)$ is a wavelet transform with point group $\{aI : a > 0\}$ and wavelet h_n and that (14) is the corresponding inversion formula. This point group, in contrast to $\mathbb{R}^+ \times SO(2)$, is not transitive on $\mathbb{R}^2 \backslash \{0\}$ but $C_{h_n}(\mathbf{k})$ is still a constant due to the particular angular dependence of h_n. Thus each angular channel h_n gives rise via scaling and translations to a wavelet transform $w_n(a, \phi, \mathbf{t})$ and each transform contains all of the information about f. But each channel will have strong responses to different local angular features of the image. To examine these features the projection functions may be convolved with w. They are given by

$$p_{nm}\left(a, \phi, \mathbf{t}\right) = e^{im\phi}\overline{p}_{nm}\left(a, \mathbf{t}\right),$$

with

$$\overline{p}_{nm}\left(a, \mathbf{t}\right) = \int_{\mathbb{R}^2} h_n\left(\mathbf{x}\right) \frac{1}{a} h_m^*\left(\frac{1}{a}\left(\mathbf{x} - \mathbf{t}\right)\right) d^2x.$$

From $w_n = w_m * p_{mn}$, we have

$$\overline{w}_n(a_0, \mathbf{t}_0) = \int_{\mathbb{R}^2} \int_{\mathbb{R}^+} \overline{w}_m(a, \mathbf{t}) \widehat{p}_{mn}(a, \mathbf{t}; a_0, \mathbf{t}_0) \frac{1}{a^3} da d^2t,$$

with

$$\widehat{p}_{mn}(a, \mathbf{t}; a_0, \mathbf{t}_0) = \int_J \overline{p}_{mn} \left(\frac{a_0}{a}, \frac{1}{a} R(-\phi)\mathbf{t}_0 - \mathbf{t} \right) e^{i(m-n)\phi} d\phi.$$

This looks rather complicated. Fortunately there is an easier way:

$$\overline{w}_n(a, \mathbf{t}) = \frac{1}{2\pi} \int_J w(a, \phi, \mathbf{t}) e^{-in\phi} d\phi,$$

which is actually more useful since this operation could be performed numerically with the fast Fourier transform. The prescription then is to compute w for a given f, and to Fourier transform the angular variable in w to pick out the response w_n of each channel.

For operators, we have

$$q_{nm}(a_0, \phi_0, \mathbf{t}_0; a, \phi, \mathbf{t}) = e^{i(n\phi_0 - m\phi)} \overline{q}_{nm}(a_0, \mathbf{t}_0; a, \mathbf{t}),$$

with

$$\overline{q}_{nm}(a_0, \mathbf{t}_0; a, \mathbf{t}) = \int_{\mathbb{R}^2} \int_{\mathbb{R}^2} q(\mathbf{x}, \mathbf{y}) \frac{1}{a_0} h_n^* \left(\frac{1}{a_0} (\mathbf{x} - \mathbf{t}_0) \right) \frac{1}{a} h_m \left(\frac{1}{a} (\mathbf{x} - \mathbf{t}) \right) d^2x d^2y$$

and

$$(\mathcal{Q}_h w)_n(a_0, \phi_0, \mathbf{t}_0) = e^{in\phi_0} \sum_{m=-\infty}^{\infty} |a_m|^2 \int_{\mathbb{R}^2} \int_{\mathbb{R}^+} \overline{q}_{nm}(a_0, \mathbf{t}_0; a, \mathbf{t}) \overline{w}_m(a, \mathbf{t}) \frac{da}{a^3} d^2t.$$

7. An example. Let $\overline{h}_0(r) = 0$, and for $n \neq 0$ let $\overline{h}_n(r) = b_n$ when $r < 1$ and zero otherwise. Also let $a_n = \frac{\lambda^n}{b_n}$ with $0 < \lambda < 1$. In other words, $h(r, \theta) = \mathrm{Re}[\sum_{n=1}^{\infty} \lambda^n e^{in\theta}]$ for $r < 1$. The following function $\overline{H}_n(k)$ may be calculated in this case:

$$\overline{H}_n(k) = \frac{2b_n}{\pi k^2} \left[\pi k \sum_{j=0}^{\infty} J_{n+2j+1}(2\pi k) - \sum_{j=0}^{\infty} (j+1) J_{n+2j+2}(2\pi k) \right].$$

For small k, $J_n(2\pi k) \sim \frac{(\pi k)^n}{(n+1)!}$ and

$$\overline{H}_n(k) \sim 2\pi b_n (\pi k)^n.$$

Thus each h_n is admissible. Explicitly, for $r < 1$,

$$h(r, \theta) = \frac{2\lambda [\cos(\theta) - \lambda]}{(1 + \lambda^2) - 2\lambda \cos(\theta)}.$$

For a real image f, the function $\mathrm{Re}[w_1]$ will have a strong peak when $(a_0, \phi_0, \mathbf{t}_0)$ localizes h_1 with its center on an edge oriented in direction $\phi_0 + \frac{\pi}{2}$ and longer than $2a_0$. The function $\mathrm{Re}[w_2]$ will have a strong peak when $(a_0, \phi_0, \mathbf{t}_0)$ places the center

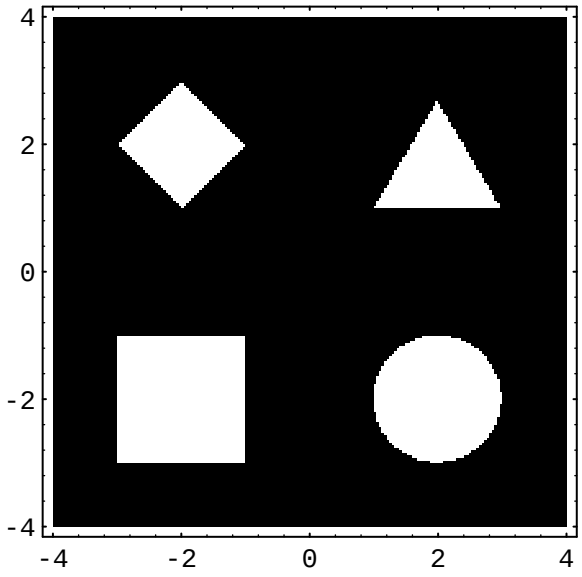

FIG. 1. *The function f.*

of h_2 on a right angled corner oriented with an edge at angle $\phi_0 + \frac{\pi}{4}$. Other orders in h have a similar behavior. In a noisy system these strong peaks are desirable for analyzing an image.

To illustrate some of these points Figure 1 shows a binary function f. In Figures 2–6 the functions $\mathrm{Re}[w_1(a,\phi,\mathbf{t})]$ are shown as functions of $\mathbf{t} = (t_1, t_2)$ with $a = .25$ and $\phi = 0,\ \frac{\pi}{6},\ \frac{\pi}{4},\ \frac{\pi}{3},\ \frac{\pi}{2}$, respectively. As expected this channel responds strongly to edges oriented perpendicular to ϕ and gives zero response when an edge is oriented parallel to ϕ. In Figures 7–10 are similar plots of $\mathrm{Re}[w_2(a,\phi,\mathbf{t})]$ for $\phi = 0,\ \frac{\pi}{6},\ \frac{\pi}{4},\ \frac{\pi}{3}$. This channel has extreme points at locations where there is a right angle oriented with its bisector perpendicular or parallel to ϕ. On edges parallel or perpendicular to ϕ it produces a peak and a trough next to each other. For Figures 11–13 $\mathrm{Re}[w_3(a,\phi,\mathbf{t})]$ is shown for $\phi = 0,\ \frac{\pi}{6},\ \frac{\pi}{4}$. Finally in Figures 14–18 $\mathrm{Re}[w(a,\phi,t)]$ is plotted for $\phi = 0,\ \frac{\pi}{6},\ \frac{\pi}{4},\ \frac{\pi}{3},\ \frac{\pi}{2}$ and $\lambda = \frac{1}{2}$. This function is the sum of $\mathrm{Re}[\lambda^n w_n]$ for $n = 1, 2, 3, \ldots$. Notice that the corner detecting ability of w_2 is hidden when the sum is taken. Of course any w_n can be retrieved from w by Fourier transforming in the ϕ variable and evaluating at frequency n.

8. Angular channels in a three-dimensional wavelet transform. Now let $n = 3$ so that f may be considered to be some three-dimensional distribution of intensity or other interesting quantity. Take $S = \mathbb{R}^+ \times SO(3)$ and $T = \mathbb{R}^3$. For $\sigma \in SO(3)$, the wavelet formulae now look like

$$w(a,\sigma,\mathbf{t}) = \int_{\mathbb{R}^3} f(\mathbf{x}) \frac{1}{\sqrt{a^3}} h^* \left(\frac{1}{a} \sigma^{-1}(\mathbf{x} - \mathbf{t}) \right) d^2x,$$

$$f(\mathbf{x}) = \frac{1}{C_h} \int_{\mathbb{R}^3} \int_{SO(3)} \int_{\mathbb{R}^+} w(a,\sigma,\mathbf{t}) \frac{1}{\sqrt{a^3}} h \left(\frac{1}{a} \sigma^{-1}(\mathbf{x} - \mathbf{t}) \right) \frac{da}{a^4} d\sigma_L d^3t,$$

$$C_h = \int_{SO(3)} \int_{\mathbb{R}^+} \left| H\left(a\sigma^t \mathbf{k}\right) \right|^2 \frac{da}{a} d\sigma_L < \infty.$$

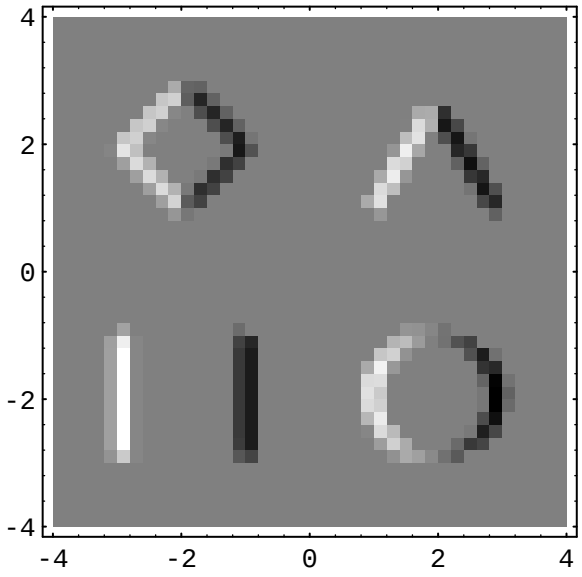

FIG. 2. *Real part of $n = 1$ component of w at angle 0 degrees.*

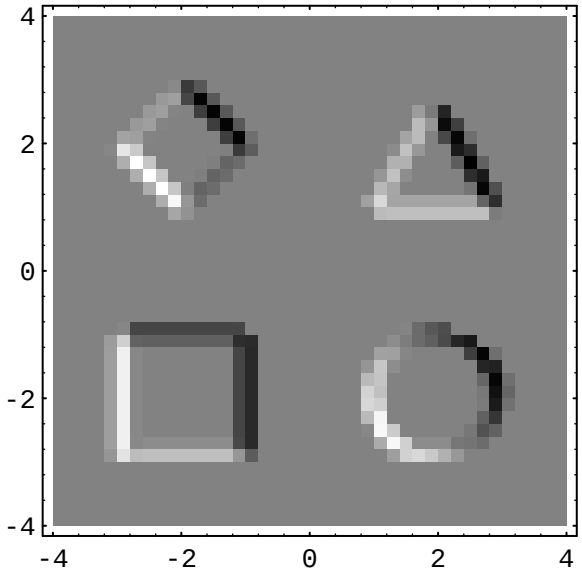

FIG. 3. *Real part of $n = 1$ component of w at angle 30 degrees.*

If $d\sigma_L$ is suitably normalized, it can be shown that the admissibility condition is

$$C_h = \int_{\mathbb{R}^3} |H(\mathbf{k})|^2 \frac{d^3k}{|\mathbf{k}|^3} < \infty.$$

Similarly, the wavelet inner product is

$$(h_1, h_2)_S = \int_{\mathbb{R}^3} H_1^*(\mathbf{k}) H_2(\mathbf{k}) \frac{d^3k}{|\mathbf{k}|^3}.$$

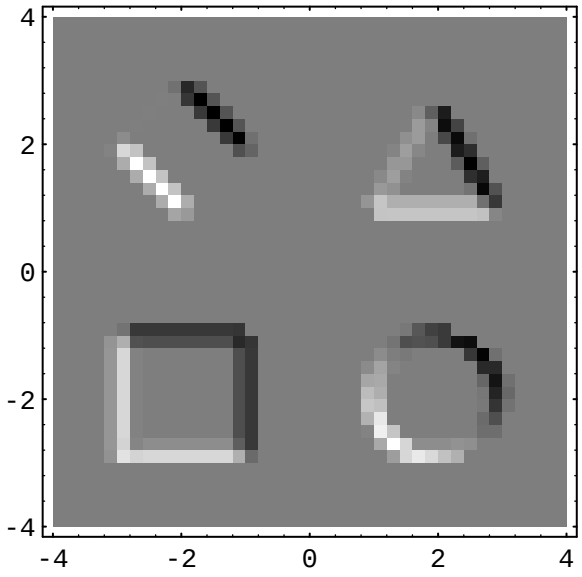

FIG. 4. *Real part of $n = 1$ component of w at angle 45 degrees.*

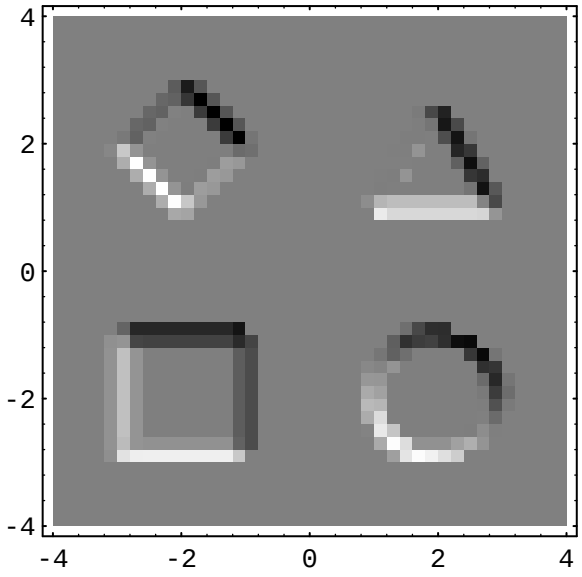

FIG. 5. *Real part of $n = 1$ component of w at angle 60 degrees.*

The channel situation is more complicated. The angular decomposition of h is given by

$$h(\mathbf{x}) = \sum_{l=0}^{\infty} \sum_{m=-l}^{l} a_m^l \overline{h}_m^l \left(|\mathbf{x}|\right) \Psi_m^l \left(\widehat{\mathbf{x}}\right) = \sum_{l=0}^{\infty} \sum_{m=-l}^{l} a_m^l h_m^l(\mathbf{x}),$$

where the functions Ψ_m^l are the spherical harmonics. For a given l, they form a basis for an irreducible unitary representation of $SO(3)$ of dimension $2l + 1$. This means

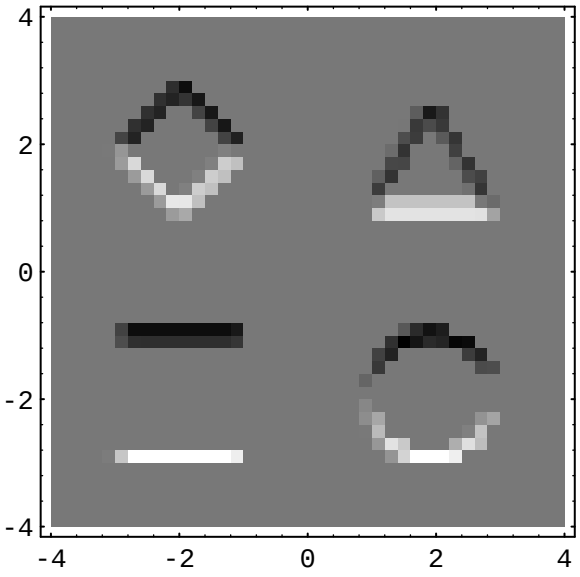

FIG. 6. *Real part of $n = 1$ component of w at angle 90 degrees.*

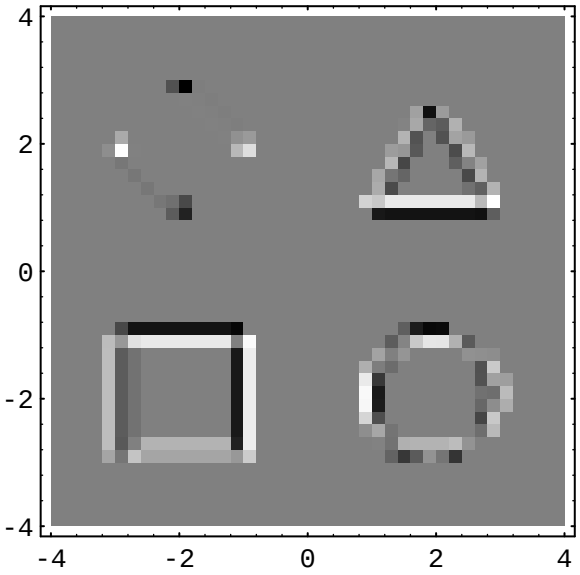

FIG. 7. *Real part of $n = 2$ component of w at angle 0 degrees.*

that

$$\Psi_m^l\left(\sigma^{-1}\widehat{\mathbf{x}}\right) = \sum_{n=-l}^{l} U_{nm}^l(\sigma)\,\Psi_n^l(\widehat{\mathbf{x}}),$$

with the matrices $U^l(\sigma)$ determined by the corresponding representation. In Fourier space

$$H_m^l(\mathbf{k}) = \overline{H}_m^l(|\mathbf{k}|)\,\Psi_m^l\left(\widehat{\mathbf{k}}\right),$$

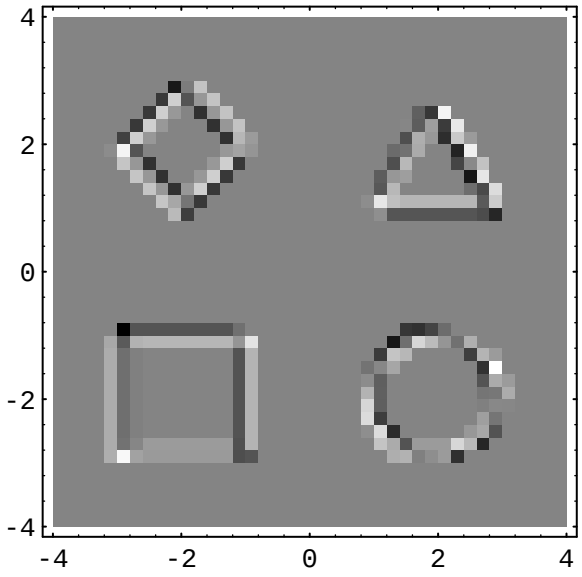

FIG. 8. *Real part of $n = 2$ component of w at angle 30 degrees.*

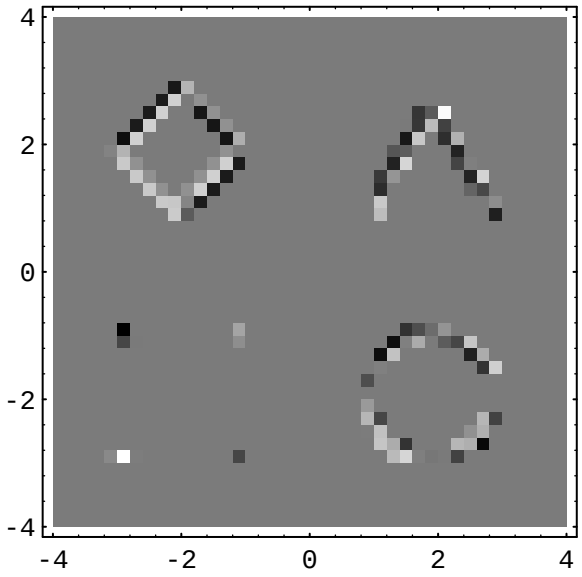

FIG. 9. *Real part of $n = 2$ component of w at angle 45 degrees.*

where

$$\overline{H}_m^l(k) = 4\pi i^l \int_{\mathbb{R}^+} \overline{h}_m^l(r) j_l(2\pi kr) r^2 dr$$

and j_l is the degree l spherical Bessel function of the first kind. Therefore if $l \neq l'$ or $m \neq m'$, then $\left(h_m^l, h_{m'}^{l'}\right)_S = 0$. As before, choose the a_m^l so that $\left(h_m^l, h_m^l\right)_S = 1$.

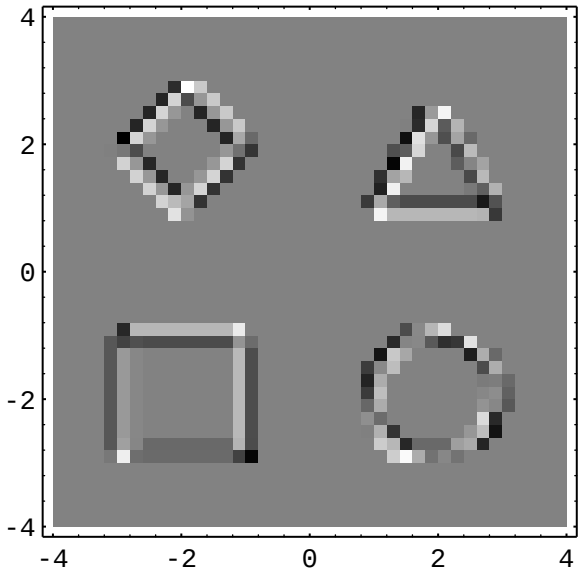

FIG. 10. *Real part of $n = 2$ component of w at angle 60 degrees.*

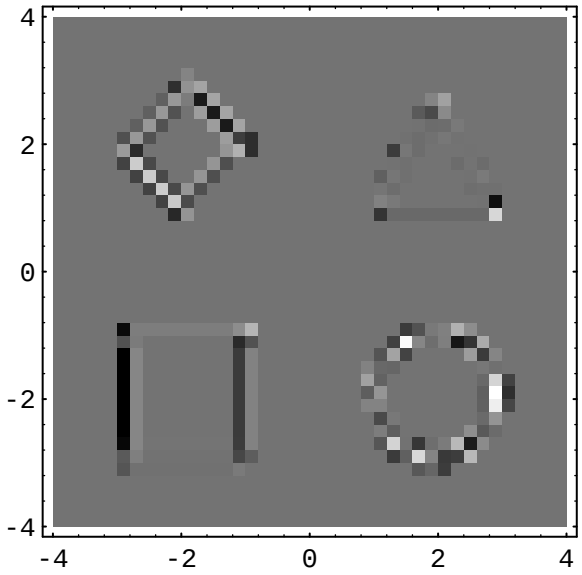

FIG. 11. *Real part of $n = 3$ component of w at angle 0 degrees.*

For the wavelet transform, let $h^l_{mn}(\mathbf{x}) = \overline{h}^l_m(|\mathbf{x}|)\,\Psi^l_n(\widehat{\mathbf{x}})$. Then rotating and scaling h^l_m gives

$$h^l_m\left(\frac{1}{a}\sigma^{-1}\mathbf{x}\right) = \overline{h}^l_m\left(\frac{1}{a}|\mathbf{x}|\right)\Psi^l_m\left(\sigma^{-1}\widehat{\mathbf{x}}\right) = \sum_{n=-l}^{l} U^l_{nm}(\sigma)\,h^l_{mn}(\mathbf{x}).$$

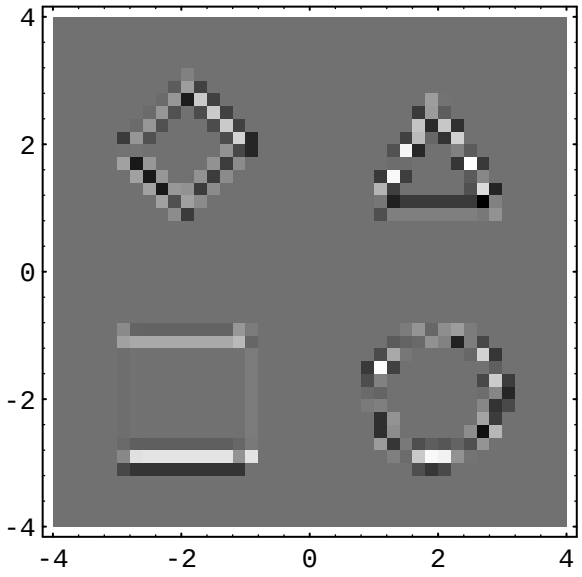

FIG. 12. *Real part of $n = 3$ component of w at angle 30 degrees.*

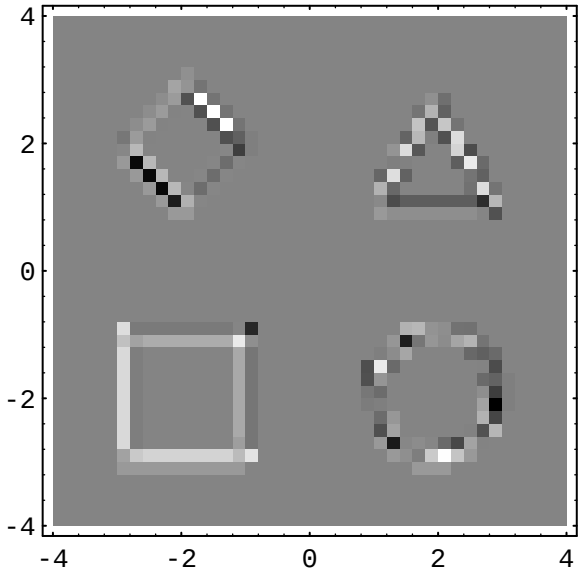

FIG. 13. *Real part of $n = 3$ component of w at angle 60 degrees.*

Putting this into the forward transform gives the response in the angular channel h_m^l:

$$w_m^l(a, \sigma, \mathbf{t}) = \sum_{n=-l}^{l} \left[U_{nm}^l(\sigma)\right]^* \overline{w}_{mn}^l(a, \mathbf{t}),$$

with

$$\overline{w}_{mn}^l(a, \mathbf{t}) = \int_{\mathbb{R}^3} f(\mathbf{x}) \frac{1}{\sqrt{a^3}} \left[h_{mn}^l\left(\frac{1}{a}(\mathbf{x} - \mathbf{t})\right)\right]^* d^3x.$$

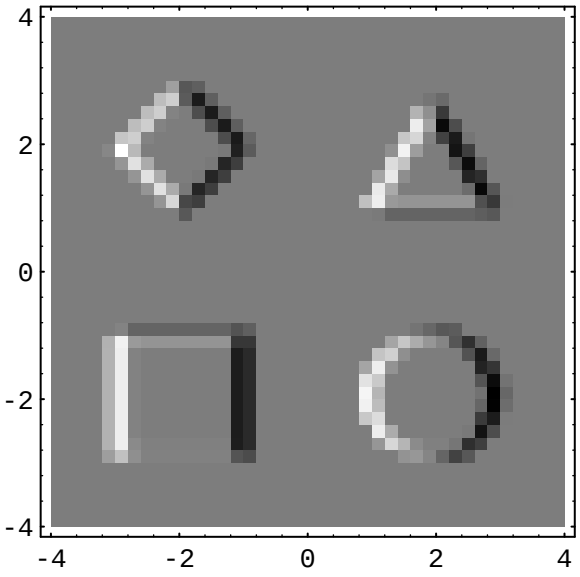

FIG. 14. *Real part of w at angle* 0 *degrees.*

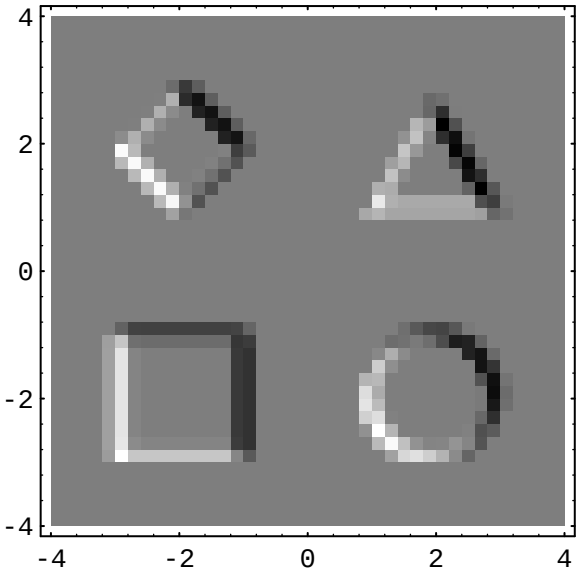

FIG. 15. *Real part of w at angle* 30 *degrees.*

Notice again that this is a scale only wavelet transform of f. This suggests the definition

$$w^l_{mn}(a,\sigma,\mathbf{t}) = \left[U^l_{nm}(\sigma)\right]^* \overline{w}^l_{mn}(a,\mathbf{t}),$$

which could be called the nth angular subchannel of w^l_m.

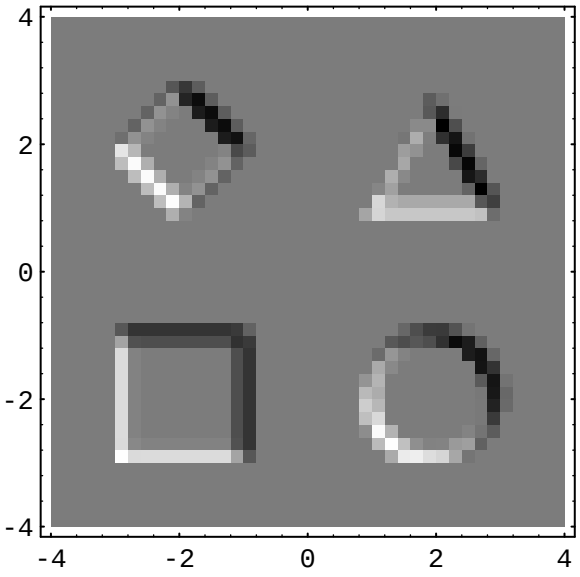

FIG. 16. *Real part of w at angle 45 degrees.*

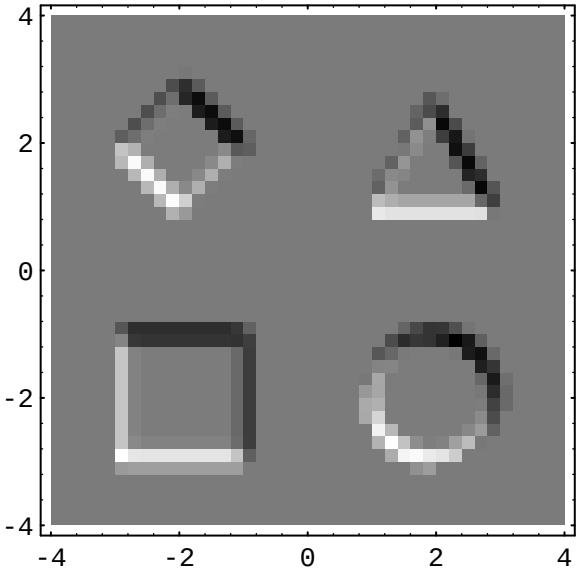

FIG. 17. *Real part of w at angle 60 degrees.*

When f is recovered from w_m^l and h_m^l, the result is

$$\begin{aligned} f(\mathbf{x}) &= \int_{\mathbb{R}^3}\int_{SO(3)}\int_{\mathbb{R}^+} w_m^l(a,\sigma,\mathbf{t})\frac{1}{\sqrt{a^3}}h_m^l\left(\frac{1}{a}\sigma^{-1}\left(\mathbf{x}-\mathbf{t}\right)\right)\frac{da}{a^4}d\sigma_L d^3t \\ &= \int_{\mathbb{R}^3}\int_{SO(3)}\int_{\mathbb{R}^+}\sum_{n=-l}^{l}\left[U_{nm}^l\left(\sigma\right)\right]^*\overline{w}_{mn}^l(a,\mathbf{t})\frac{1}{\sqrt{a^3}} \end{aligned}$$

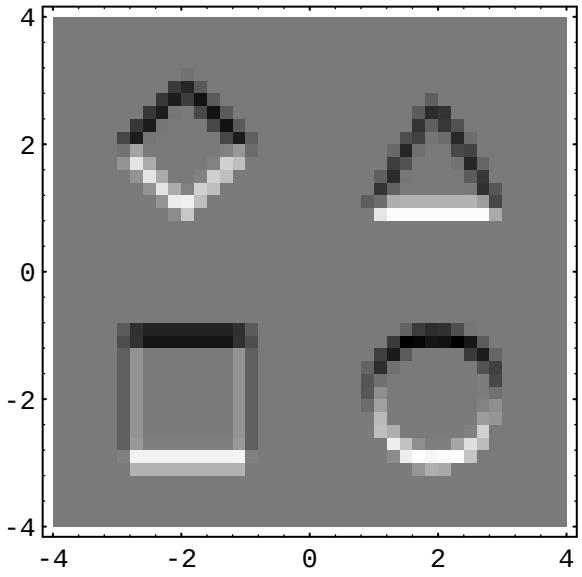

FIG. 18. *Real part of w at angle 90 degrees.*

$$\cdot \left[\sum_{n'=-l}^{l} U^l_{n'm}(\sigma)\, h^l_{mn'} \left(\frac{1}{a}(\mathbf{x}-\mathbf{t}) \right) \right] \frac{da}{a^4} d\sigma_L d^3t.$$

However, a fact from representation theory is that

$$\int_{SO(3)} \left[U^l_{nm}(\sigma) \right]^* U^{l'}_{n'm'}(\sigma) d\sigma_L = \frac{\omega}{2l+1} \delta_{ll'} \delta_{mm'} \delta_{nn'}, \tag{15}$$

where $\int_{SO(3)} d\sigma_L = \omega$. With the present normalization for $d\sigma_L$, $\omega = 4\pi$, so

$$f(\mathbf{x}) = \frac{4\pi}{2l+1} \sum_{n=-l}^{l} \int_{\mathbb{R}^3} \int_{\mathbb{R}^+} \overline{w}^l_{mn}(a,\mathbf{t}) \frac{1}{\sqrt{a^3}} h^l_{mn} \left(\frac{1}{a}(\mathbf{x}-\mathbf{t}) \right) \frac{da}{a^4} d^3t.$$

Notice that the subchannels h^l_{mn} do not interfere when reconstructing f from w^l_m. Normally, in a data compression or filtering operation, w would be sampled on some discrete set in G, which is eight dimensional, and these samples would be modified in some way. Then f would be reconstructed by discretizing the inverse transform on the same subset of G. However, if the harmonic expansion of h is known, then the $\overline{w}^l_{mn}$ could be sampled on $\mathbb{R}^+ \times \mathbb{R}^3$, a four-dimensional space, for a finite set of (l,m,n). After the samples are modified, this last integral could be discretized on the same set for reconstruction. If h is well approximated by a small number of its angular components, this could be a more efficient process.

Equation (15) also implies that

$$\left(w^l_{mn}, w^{l'}_{m'n'} \right)_G = 0$$

when $l \neq l'$, $m \neq m'$, or $n \neq n'$. Thus the subchannels may be projected from w:

$$\overline{w}^l_{mn}(a,\mathbf{t}) = \frac{(2l+1)}{\omega} \int_{SO(3)} U^l_{nm}(\sigma)\, w(a,\sigma,\mathbf{t}) d\sigma_L.$$

However, f cannot in general be reconstructed from one subchannel transform without a deconvolution step. Again, each channel and subchannel provides different local angular information about f.

For projection functions, we have

$$p_{mm'}^{ll'}(a,\sigma,\mathbf{t}) = \sum_{n'=-l}^{l} U_{n'm'}^{l'}(\sigma)^* \, \overline{p}_{mm',nn'}^{ll'}(a,\mathbf{t}),$$

with

$$\overline{p}_{mm',nn'}^{ll'}(a,\mathbf{t}) = \int_{\mathbb{R}^3} h_{mn}^{l}(\mathbf{x}) \frac{1}{\sqrt{a^3}} \left[h_{m'n'}^{l'}\left(\frac{1}{a}(\mathbf{x}-\mathbf{t})\right)\right]^* d^3x.$$

For an operator,

$$q_{mm'}^{ll'}(a_0,\sigma_0,\mathbf{t}_0;a,\sigma,\mathbf{t}) = \sum_{n=-l}^{l}\sum_{n'=-l}^{l} U_{nm}^{l}(\sigma_0)^* \, U_{n'm'}^{l'}(\sigma) \, \overline{q}_{mm',nn'}^{ll'}(a_0\mathbf{t}_0;a,\mathbf{t}),$$

with

$$\begin{aligned}\overline{q}_{mm',nn'}^{ll'}(a_0\mathbf{t}_0;a,\mathbf{t}) = \int_{\mathbb{R}^3}\int_{\mathbb{R}^3} q(\mathbf{x},\mathbf{y}) \frac{1}{\sqrt{a_0^3}} \left[h_{mn}^{l}\left(\frac{1}{a_0}(\mathbf{x}-\mathbf{t}_0)\right)\right]^* \\ \cdot \frac{1}{\sqrt{a^3}} h_{m'n'}^{l'}\left(\frac{1}{a}(\mathbf{y}-\mathbf{t})\right) d^3x d^3y.\end{aligned}$$

Notice that, as in the two-dimensional case, all angular integrations, i.e., those over $SO(3)$, can be removed if the angular decomposition of h is known.

9. Angular channels in higher dimensions and in the Fourier domain. The generalization to a wavelet transform for $L^2(\mathbb{R}^n)$ using $S = \mathbb{R}^+ \times SO(n)$ is straightforward. As before, if $d\sigma_L$ is suitably normalized,

$$(h_1,h_2)_S = \int_{\mathbb{R}^n} H_1^*(\mathbf{k}) \, H_2(\mathbf{k}) \, \frac{d^n k}{|\mathbf{k}|^n}.$$

No new complications arise when decomposing a particular wavelet into angular channels using the appropriate spherical harmonics. Again, integration over $SO(n)$ can be eliminated in the reconstruction of f by using angular subchannels as in the three-dimensional case. Since the dimension of $SO(n)$ is $\frac{n(n-1)}{2}$, sampling advantages increase with dimension if the angular components of h are known.

Another way to avoid integration over $SO(n)$ is to go into Fourier space. In general,

$$W(s,\mathbf{k}) = W_s(\mathbf{k}) = F(\mathbf{k}) H^*(s^t\mathbf{k}) \sqrt{J(s)}.$$

Let $\mathbf{k}_0 = s^t\mathbf{k}$. If $s_1^t\mathbf{k} = s_2^t\mathbf{k}$, then $(s_1^t)^{-1} s_2^t\mathbf{k} = \mathbf{k}$. This implies that $(s_1^t)^{-1} s_2^t \in SO(n)$ and therefore $J(s_1) = J(s_2)$. Then there is a well-defined function $\widehat{W}(\mathbf{k}_0,\mathbf{k})$ satisfying

$$W(s,\mathbf{k}) = \widehat{W}\left(s^t\mathbf{k},\mathbf{k}\right)$$

and since $J(s) = \left(\frac{|\mathbf{k}_0|}{|\mathbf{k}|}\right)^n$,

$$\widehat{W}(\mathbf{k}_0, \mathbf{k}) = F(\mathbf{k}) \left(\frac{|\mathbf{k}_0|}{|\mathbf{k}|}\right)^{\frac{n}{2}} H(\mathbf{k}_0).$$

The forward transform may now be described as follows:

1. Fourier transform $f(\mathbf{x})$ to get $F(\mathbf{k})$.
2. Multiply $F(\mathbf{k})$ by $(\frac{|\mathbf{k}_0|}{|\mathbf{k}|})^{\frac{n}{2}} H(\mathbf{k}_0)$ to get $\widehat{W}(\mathbf{k}_0, \mathbf{k})$.
3. Evaluate $\widehat{W}(\mathbf{k}_0, \mathbf{k})$ on the twisted diagonal $\mathbf{k}_0 = s^t \mathbf{k}$ to get $W(s, \mathbf{k})$.
4. Inverse Fourier transform $W(s, \mathbf{k})$ to get $w(s, \mathbf{t})$.

Let $s^t_{\mathbf{k}_0\mathbf{k}}$ be the element of S corresponding to a rotation and dilation in the plane spanned by $\mathbf{k}$ and $\mathbf{k}_0$ which takes $\mathbf{k}$ to $\mathbf{k}_0$. For a normalized wavelet, the inverse transform can be arrived at via the following:

1. Fourier transform $w(s, \mathbf{t})$ to get $W(s, \mathbf{k})$.
2. Let $\widehat{W}(\mathbf{k}_0, \mathbf{k}) = W(s_{\mathbf{k}_0\mathbf{k}}, \mathbf{k})$.
3. Multiply $\widehat{W}(\mathbf{k}_0, \mathbf{k})$ by $|\mathbf{k}|^{\frac{n}{2}} |\mathbf{k}_0|^{-\frac{3n}{2}} H(\mathbf{k}_0)$ and integrate over $\mathbf{k}_0$ to get $F(\mathbf{k})$.
4. Inverse Fourier transform $F(\mathbf{k})$ to get $f(\mathbf{x})$.

The integration over $SO(n)$ has been replaced by the integration over $\mathbb{R}^n$ in step 3. The spherical harmonic expansion of h gives rise to one for H as before. This corresponds now to the spherical harmonic expansion for $\widehat{W}$ in the first variable. Therefore each w^l_m corresponds to a $\widehat{W}^l_m$. If we expanded f also, this would give the expansion for $\widehat{W}$ in the second variable.

10. Conclusion. Multidimensional wavelet transforms and inverse transforms have been developed which can be used with a wide variety of point symmetry groups. The admissibility condition of a particular wavelet is the boundedness of a certain integral over the point group. The decomposition of a wavelet transform into orthogonal channels has been described and the expression of integral operators in terms of these channels has been given. As an example, angular wavelet channels in two and three dimensions have been developed in detail. In three dimensions, results from the theory of group representations came into play in the notion of angular subchannels. The generalization of angular channels to higher dimensions has been indicated and the implications in the Fourier domain have been outlined.

Acknowledgments. I would like to thank Harry Barrett and Jack Denny for their help and encouragement.

NONLINEAR ELLIPTIC PROBLEMS UNDER MIXED BOUNDARY VALUE CONDITIONS IN NONSMOOTH DOMAINS*

CARSTEN EBMEYER†

Abstract. Strongly nonlinear elliptic equations and systems are investigated under mixed boundary value conditions. It is supposed that the domain is a multidimensional polyhedral domain. Global regularity results of $|\nabla u|^\sigma$ ($\sigma \geq 1$) are proven, in particular, $W^{s,p}(\Omega)$-regularity ($s < \frac{1}{2}$) of $|\nabla u|$ and $|\nabla u|^2$.

Key words. mixed boundary value problem, piecewise smooth boundary, difference quotient, Nikolskii space.

1. Introduction.

Let $\Omega \subset \mathbb{R}^n$ ($n \geq 2$) be a bounded polyhedral domain, let $\partial\Omega = \Gamma_D \cup \Gamma_N$, and let ν be the outward normal of $\partial\Omega$. We consider the mixed boundary value problem

$$\begin{aligned} -\sum_{i=1}^n \partial_i F_i(x, \nabla u) &= f(x) + \sum_{i=1}^n \partial_i f_i(x) && \text{in } \Omega, \\ u(x) &= 0 && \text{on } \Gamma_D, \\ -\sum_{i=1}^n F_i(x, \nabla u)\nu_i &= \sum_{i=1}^n f_i \nu_i && \text{on } \Gamma_N, \end{aligned} \tag{1.1}$$

where Γ_D is the Dirichlet and Γ_N the Neumann boundary.

We treat elliptic equations and systems. The aim of this paper is to investigate the regularity of $|\nabla u|^\sigma$ for $\sigma \geq 1$. We prove $W^{s,p}(\Omega)$-regularity results of $|\nabla u|^\sigma$ up to the boundary for $s = \frac{1}{2} - \varepsilon$.

It is known that solutions of mixed boundary value problems may have singularities on the boundary at points where the boundary condition changes or where the boundary is not smooth. In the case of linear elliptic equations various regularity results in Sobolev spaces of fractional order have been proven. In the case when the domain Ω is two-dimensional, detailed information about the behavior of u near singular points is known (see, eg., [1, 6, 10, 11]). In higher dimensions (i.e., $\Omega \subset \mathbb{R}^n$ and $n > 2$) there are still open questions even if the equation is linear. Three-dimensional problems are investigated in [2, 3, 15, 16, 20, 21]. In the case when the equation is nonlinear the literature is very rare. Quasi-linear equations and problems with p-structure are considered in [4, 5, 17, 22], where barrier functions are constructed. Asymptotic expansions of solutions are given in [7, 18].

In [8, 9] problem (1.1) is studied. A new technique is developed in order to treat strongly nonlinear problems. The regularity of a weak solution u is investigated. It is shown that $u \in W^{\frac{3}{2}-\varepsilon,2}(\Omega)$ and $\nabla u \in L^{3+\varepsilon}(\Omega)$.

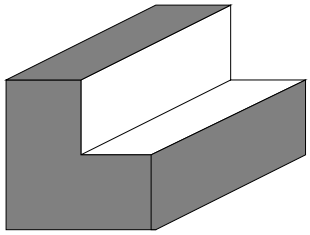

FIG. 1. *An admissible nonconvex domain where angle*$(\Gamma_N, \Gamma_D) \leq \pi$.

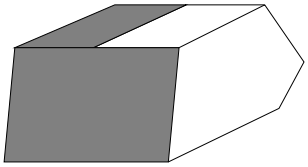

FIG. 2. *An admissible domain in the case when angle*$(\Gamma_N, \Gamma_D) = \pi$.

In this paper, we prove regularity results of $|\nabla u|^\sigma$. Therefore, we have refined and simplified the technique of [8, 9]. The method of proof is a difference quotient technique. Let us emphasize that we do not use Fourier series as in [8, 9]. Further, following the proof given below we could obtain all results of [8, 9] without using Fourier series.

This paper is organized as follows. In the next section we give the assumptions on the data and state the main results. In section 4 we investigate the regularity of certain difference quotients of ∇u. Section 5 contains the proofs of the main theorems.

2. Assumptions on the data and the main results. The domain $\Omega \subset \mathbb{R}^n$ ($n \geq 2$) is a bounded polyhedral domain. We assume that $N \geq 1$, $u : \Omega \to \mathbb{R}^N$, $f, f_i : \Omega \to \mathbb{R}^N$, and $F_i : \Omega \times \mathbb{R}^{nN} \to \mathbb{R}^N$ for $1 \leq i \leq n$.

In order to state our first theorem we give the assumptions on the functions F_i, f_i, and f in the case when $N = 1$. First of all, we suppose that

(i) $\partial\Omega = \bigcup_{1 \leq i \leq M} \overline{\Gamma^i}$, where each Γ^i is an open subset of a hyperplane, and $\partial\Gamma^i$ is polyhedral.

(ii) $\Gamma^i \cap \Gamma^j = \emptyset$ for $i \neq j$.

(iii) $\Gamma^i \subset \Gamma_D$ or $\Gamma^i \subset \Gamma_N$ for each $1 \leq i \leq M$.

(iv) $\bigcap_{i \in \Lambda} \partial\Gamma^i = \emptyset$ if $\Lambda \subset \{1, \ldots, M\}$ and $|\Lambda| > n$.

(v) angle$(\Gamma^i, \Gamma^j) \leq \pi$ if $\Gamma^i \subset \Gamma_D$, $\Gamma^j \subset \Gamma_N$, and $\partial\Gamma^i \cap \partial\Gamma^j \neq \emptyset$.

(vi) There is at most one pair of boundary manifolds Γ^i, Γ^j $(1 \leq i, j \leq M)$ satisfying $\Gamma^i \subset \Gamma_D$, $\Gamma^j \subset \Gamma_N$, $\partial\Gamma^i \cap \partial\Gamma^j \neq \emptyset$, and angle$(\Gamma^i, \Gamma^j) = \pi$.

Remark. (i) By angle(Γ^i, Γ^j) we denote the inner angle between a pair of boundary manifolds Γ^i, Γ^j satisfying $\partial\Gamma^i \cap \partial\Gamma^j \neq \emptyset$.

(ii) Let $\partial\Gamma^i \cap \partial\Gamma^j \neq \emptyset$. We assume that angle$(\Gamma^i, \Gamma^j) \leq \pi$, if $\Gamma^i \subset \Gamma_D$ and $\Gamma^j \subset \Gamma_N$. But if the boundary condition does not change (i.e., either $\Gamma^i, \Gamma^j \subset \Gamma_D$ or $\Gamma^i, \Gamma^j \subset \Gamma_N$) we admit $0 <$ angle$(\Gamma^i, \Gamma^j) < 2\pi$.

(iii) In Figure 1 and Figure 2 examples of admissible domains are given, where Γ_N and Γ_D are marked grey and white, respectively. Figure 1 shows a nonconvex domain. In Figure 2 a domain is given where the angle between a Dirichlet and a Neumann boundary manifold is equal to π.

Let $x \in \overline{\Omega}$, $r \in \mathbb{R}^n$, and $x = (x_1, \ldots, x_n)^T$. We suppose there is a C^2-function $F(x, r)$ such that $\frac{\partial}{\partial r_i} F(x, r) = F_i(x, r)$ for $1 \leq i \leq n$. We set $F_{x_i}(x, r) = \frac{\partial}{\partial x_i} F(x, r)$, $F_{i,x_k}(x, r) = \frac{\partial}{\partial x_k} F_i(x, r)$, and $F_{i,k}(x, r) = \frac{\partial}{\partial r_k} F_i(x, r)$ for $1 \leq i, k \leq n$. Furthermore, we suppose there are functions g_0, g_{x_i}, g_i, and g_{i,x_k} $(1 \leq i, k \leq n)$ (here the indices do not denote derivatives) such that

(H1) $c_0 + c_0'|r|^2 \leq F(x, r) \leq g_0(x) + c|r|^2$ for $g_0 \in L^\infty(\Omega)$ and $c_0' > 0$,

(H2) $|F_{x_i}(x, r)| \leq g_{x_i}(x) + c|r|^2$ for $g_{x_i} \in L^1(\Omega)$,

(H3) $|F_i(x,r)| \le g_i(x) + c|r|$ for $g_i \in L^2(\Omega)$,
(H4) $|F_{i,x_k}(x,r)| \le g_{i,x_k}(x) + c|r|$ for $g_{i,x_k} \in L^2(\Omega)$,
(H5) $|F_{i,k}(x,r)| \le c$,
(H6) there is a constant $k_0 > 0$ independent of x and r such that

$$k_0|\xi|^2 \le \sum_{i,k=1}^{n} F_{i,k}(x,r)\xi_i\xi_k \qquad \text{for all } \xi \in \mathbb{R}^n,$$

(H7) $f(x) \in L^2(\Omega)$ and $f_i(x) \in W^{1,2}(\Omega) \cap L^\infty(\Omega)$ for $1 \le i \le n$.

Remark. We assume there is a function $F(x,r)$ such that $F_i(x,r)$ is the partial derivative of F with respect to the ith component of r. Thus, our proof is restricted to the variational case.

Let $u : \Omega \to \mathbb{R}$ and $V = \{v \in W^{1,2}(\Omega) : v = 0 \text{ on } \Gamma_D\}$. It is well known that under the above hypotheses there exists a unique weak solution $u(x) \in W^{1,2}(\Omega)$ satisfying

$$\sum_{i=1}^{n} \int_\Omega F_i(x, \nabla u)\partial_i v = \int_\Omega fv - \sum_{i=1}^{n} \int_\Omega f_i \partial_i v \qquad \text{for all } v \in V. \tag{2.1}$$

We prove the following result for $N = 1$.

THEOREM 2.1. *Let $u : \Omega \to \mathbb{R}$ be a scalar function and $1 \le \sigma \le \frac{5}{2}$. Let the functions g_{x_i}, g_i, g_{i,x_k}, f, and f_k, given in* (H1)–(H7), *satisfy*

$$g_i \in L^{\frac{n}{1-\delta}}(\Omega), \text{ and } g_{x_i},\ g_{i,x_k},\ f,\ \partial_i f_k \in L^{\frac{2n}{3-\delta}}(\Omega) \tag{2.2}$$

for $1 \le i,k \le n$ and some small $\delta > 0$. Then it holds that

$$|\nabla u|^\sigma \in W^{s,p}(\Omega) \qquad \text{for all } s < \frac{1}{2} \text{ and } p = \frac{6}{2\sigma+1} + \varepsilon_0, \tag{2.3}$$

where $\varepsilon_0 = 0$ for $\sigma = 1$ and $\varepsilon_0 > 0$ for $\sigma > 1$.

Remark. (i) In the case when $n = 2$ and $\sigma > 1$, a better result than (2.3) can be proven; cf. Theorem 2.2 below.

(ii) In the proof of Theorem 2.1 we use the fact that $u \in C^{0,\alpha}(\Omega)$ for some $\alpha > 0$. In particular, if $\sigma > 1$ it holds that $\varepsilon_0 > 0$, where the value of ε_0 depends on α.

(iii) Clearly, it holds that $\nabla u \in W^{\frac{1}{2}-\varepsilon,2}(\Omega)$. This is proven in [8, 9]. Further, (2.3) implies that $|\nabla u|^2 \in W^{\frac{1}{2}-\varepsilon,p}(\Omega)$ for $p = \frac{6}{5}$ and $|\nabla u|^{\frac{5}{2}} \in W^{\frac{1}{2}-\varepsilon,1}(\Omega)$.

Our method of proof can also be applied to elliptic systems, i.e., $u : \Omega \to \mathbb{R}^N$ and $N > 1$. Let $x \in \Omega \subset \mathbb{R}^n$, $r \in \mathbb{R}^{nN}$, and let $F(x,r)$ satisfy the above growth conditions. Let us note that then the ellipticity condition reads as follows:

$$k_0|\xi|^2 \le \sum_{s,t=1}^{N} \sum_{i,k=1}^{n} F_{i,k}^{st}(x,r)\xi_i^s\xi_k^t \qquad \text{for all } \xi \in \mathbb{R}^{nN},$$

where $F_{i,k}^{st}(x,r) = \frac{\partial}{\partial r_k^t} F_i^s(x,r)$, and F_i^s is the sth component of F_i.

The proof of Theorem 2.1 employs the fact that u is Hölder continuous. But it is well known that this may not be satisfied if $N > 1$.

For solutions $u : \Omega \to \mathbb{R}^N$ $(N > 1)$ which are Hölder continuous, the proof of Theorem 2.1 provides (2.3). In the general case there holds the following result.

THEOREM 2.2. *Let $u : \Omega \to \mathbb{R}^N$, $N \ge 1$, and $1 \le \sigma < \frac{2n-1}{n-1}$. Then it holds that*

$$|\nabla u|^\sigma \in W^{s,p}(\Omega) \qquad \text{for all } s < \frac{1}{2} \text{ and } p = \frac{2}{1 + (\sigma-1)\frac{n-1}{n}}. \tag{2.4}$$

Remark. (i) We can also prove Theorems 2.1 and 2.2 for domains with a piecewise smooth boundary. Then we locally map the domain onto a polyhedron. Therefore we need that $\partial\Omega$ is $W^{2,\infty}$-piecewise. Details about this technique can be found in [8, 9]. Further, we can treat domains with a slit.

(ii) Let $n = 2$. In the case when the problem is linear it is known that $|u| \le cr^\alpha$ for some $\alpha \ge \frac{1}{2}$, where r denotes the distance to the corner point. This result holds for equations and systems as well; cf. the survey [12]. In particular, the function $u(r,\varphi) = r^{\frac{1}{2}} \sin\frac{1}{2}\varphi$ is a weak solution of

$$\Delta u(x,y) = 0 \text{ in } \mathbb{R}\times\mathbb{R}^+, \quad u(x,0) = 0 \text{ for } x \ge 0, \quad -\partial_y u(x,0) = 0 \text{ for } x < 0.$$

If $\Omega \subset \mathbb{R}\times\mathbb{R}^+$ is an appropriate bounded domain, u satisfies $|\nabla u|^\sigma \in W^{s,\frac{4}{\sigma+1}}(\Omega)$ for $s < \frac{1}{2}$, but $|\nabla u|^\sigma \notin W^{s,\frac{4}{\sigma+1}}(\Omega)$ for $s = \frac{1}{2}$. Thus, Theorem 2.2 is sharp for $n = 2$.

(iii) Let $n = 3$ and $N \ge 1$. If the domain has a slit and the boundary condition does not change, there holds $|u| \le cr^{\frac{1}{2}}$ where r is the distant to the edge; cf. [12]. Then, in general, $|\nabla u|^\sigma \in W^{s,\frac{4}{\sigma+1}}(\Omega)$ if and only if $s < \frac{1}{2}$. This implies that (2.3) and (2.4) are sharp for $\sigma = 1$.

(iv) If $n \ge 3$ and $\sigma > 1$, our results are possibly not sharp. Let us note that (2.3) yields a better result for Hölder continuous solutions than (2.4). Then the value of p depends on the size of the Hölder exponent.

3. Notations. Let $P \in \partial\Omega$, $R > 0$, $B_R(P) = \{x \in \mathbb{R}^n : |P - x| < R\}$, $B(R) = B_R(P) \cap \Omega$, and $B_R = B_R(P)$. We assume P and R are fixed such that P is the only vertex of $B_{3R} \cap \partial\Omega$ or that there is no vertex of $\partial\Omega$ in B_{3R}. Further, $B_{3R} \cap \partial\Omega$ is simply connected, and $\partial\Gamma^i \cap \partial\Gamma^j \ne \emptyset$ holds if $\Gamma^i \cap B_{3R} \ne \emptyset$ and $\Gamma^j \cap B_{3R} \ne \emptyset$.

For convenience, we set $B = B(2R)$ and $B_0 = B(R)$. In the case when $\Gamma^k \cap B_{3R} \ne \emptyset$ we often write Γ^k_* instead of $\Gamma^k \cap B_{3R}$.

The function τ_0 is a cut-off function satisfying $\tau_0 \equiv 1$ in $B_R(P)$, supp $\tau_0 = B_{2R}(P)$, and $|\nabla\tau_0| \le \frac{c}{R}$. By τ we denote the restriction of τ_0 onto $\overline{\Omega}$.

Let $\zeta^1, \dots, \zeta^n$ be a basis of $\mathbb{R}^n$. We assume $|\zeta^i| = 1$ for each $1 \le i \le n$ and $x + s\zeta^i \subset \overline{\Omega}$ for $x \in \overline{B}$ and $s \in (0,R)$. Below, we use the shift operator $E_i^\sigma x = x + \sigma\zeta^i$. We will write $E_i^\sigma f(x)$ instead of $f(E_i^\sigma x)$ and $E_i^\sigma f(x)g(x)$ instead of $(E_i^\sigma f(x))g(x)$. In what follows, we assume $h > 0$. Let us set

$$\Delta_i^h f(x) = E_i^h f(x) - f(x) \quad \text{and} \quad \Delta_i^{-h} f(x) = E_i^{-h} f(x) - f(x).$$

Moreover, we define the Sobolev spaces $W^{s,p}(\Omega)$ and the Nikolskii spaces $\mathcal{H}^{s,p}(\Omega)$; cf. [13]. Let m be an integer, $0 < \sigma < 1$, $s = m + \sigma$, $1 \le p < \infty$, $z \in \mathbb{R}^n$, and $\Omega_\eta = \{x \in \Omega : \operatorname{dist}(x,\partial\Omega) \ge \eta\}$. The spaces $W^{s,p}(\Omega)$ and $\mathcal{H}^{s,p}(\Omega)$ consist of all functions $f : \Omega \to \mathbb{R}$ for which the norms

$$\|f\|_{W^{s,p}(\Omega)} = \left(\|f\|^p_{W^{m,p}(\Omega)} + \sum_{|\alpha|=m} \int_\Omega \int_\Omega \frac{|\partial^\alpha f(x) - \partial^\alpha f(y)|^p}{|x-y|^{n+p\sigma}}\, dxdy \right)^{\frac{1}{p}}$$

and

$$\|f\|_{\mathcal{H}^{s,p}(\Omega)} = \left(\|f\|^p_{L^p(\Omega)} + \sum_{|\alpha|=m} \sup_{\substack{\eta>0 \\ 0<|z|<\eta}} \int_{\Omega_\eta} \frac{|\partial^\alpha f(x+z) - \partial^\alpha f(x)|^p}{|z|^{\sigma p}}\, dx \right)^{\frac{1}{p}}$$

are finite.

We write $\partial_i = \frac{\partial}{\partial x_i}$ and $\sum_i$ instead of $\sum_{i=1}^n$. Further, c denotes a constant which will be allowed to vary from equation to equation.

4. The basic estimate. In this section we prove $h^{-\frac{1}{2}+\varepsilon}\Delta_k^h \nabla u \in L^2(B_0)$ for all $\varepsilon > 0$; see Proposition 4.1 below. First, let us give some notations. Let ζ^1 be a basis vector. By definition, $x + h\zeta^1 \in \overline{\Omega}$ holds for all $x \in \overline{\Omega \cap B_{2R}}$. We define

$$\Omega_1^h = \{z \in B(3R) : z \neq x + h\zeta^1,\ x \in B(3R)\} \tag{4.1}$$

and

$$\Omega_1^{-h} = \{z \in B_{3R}(P) \setminus \Omega : z = x - h\zeta^1,\ x \in B(3R)\}. \tag{4.2}$$

Let $z_0 \in \partial\Omega \cap \partial\Omega_1^{-h}$, $0 < \lambda \leq h$, and $z_0 - \lambda\zeta^1 \in \Omega_1^{-h}$. For some function f_1 we define an even extension into Ω_1^{-h} by setting

$$f_1(z_0 - \lambda\zeta^1) = f_1(z_0 + \lambda\zeta^1). \tag{4.3}$$

Next, let f_2 be a function satisfying $f_2(z_0) = 0$ for all $z_0 \in \partial\Omega \cap \partial\Omega_1^{-h}$. We extend f_2 into Ω_1^{-h} by setting

$$f_2(z_0 - \lambda\zeta^1) = 0. \tag{4.4}$$

Let us note that this is an $W^{1,2}$-extension and, in fact, an $\mathcal{H}^{\frac{3}{2},2}$-extension.

Now we state the main result of this section.

PROPOSITION 4.1. *Let $\varepsilon > 0$. There is a basis $\zeta^1, \ldots, \zeta^n$ of $\mathbb{R}^n$ such that*

$$\sup_{0<h<R} \int_{B_0} \left| h^{-\frac{1}{2}+\varepsilon} \Delta_k^h \nabla u \right|^2 dx \leq c \qquad \text{for } 1 \leq k \leq n, \tag{4.5}$$

where the constant c depends only on R, ε, and the data.

In order to prove the proposition we proceed in several steps. Let $\Gamma_*^i = \Gamma^i \cap B_{3R}$. We set

$$\omega = \max\{\text{angle}(\Gamma_*^i, \Gamma_*^j) : \Gamma_*^i \subset \Gamma_N, \Gamma_*^j \subset \Gamma_D\}$$

if $\Gamma_N \cap B_{3R} \neq \emptyset$ and $\Gamma_D \cap B_{3R} \neq \emptyset$. Otherwise, we set $\omega = 0$. (By $\text{angle}(\Gamma_*^i, \Gamma_*^j)$ we denote the inner angle between Γ_*^i and Γ_*^j.) In what follows, we distinguish the cases when $\omega < \pi$ or when $\omega = \pi$.

LEMMA 4.2. *Let $\omega < \pi$. Let ζ^1 be parallel to $\Gamma_N \cap B_{3R}$ and angle$(\zeta^1, \Gamma_D \cap B_{3R}) \geq \alpha > 0$. Then there holds that*

$$\sup_{0<h<R} \int_{B_0} \left| h^{-\frac{1}{2}} \Delta_1^h \nabla u \right|^2 dx \leq c, \tag{4.6}$$

where the constant c depends only on R, α, and the data.

Proof. Let $0 < h < R$. We define extensions of the functions $\tau(\cdot)$ and $F(\cdot, r)$ into Ω_1^{-h} using (4.3), and we extend u using (4.4).

We choose the test function $v = \tau^2 h^{-1} \Delta_1^{-h} u \equiv \tau^2 h^{-1}(E_1^{-h}u - u)$ in (2.1). Notice that this is an admissible test function, for there holds $E_1^{-h}x \in \Omega_1^{-h}$ for $x \in \Gamma_D \cap B$, thus $E_1^{-h}u(x) = u(x) = 0$ on $\Gamma_D \cap B$.

Taking $v = \tau^2 h^{-1}\Delta_1^{-h}u$ in (2.1) we obtain

$$\begin{aligned}\sum_i \int_B F_i(x,\nabla u)\tau^2 h^{-1}\partial_i\Delta_1^{-h}u = &-\sum_i \int_B F_i(x,\nabla u)\partial_i\tau^2 h^{-1}\Delta_1^{-h}u\\ &+\int_B f\tau^2 h^{-1}\Delta_1^{-h}u\\ &-\sum_i \int_B f_i\partial_i\left(\tau^2 h^{-1}\Delta_1^{-h}u\right).\end{aligned} \tag{4.7}$$

Let $r \in \mathbb{R}^n$. The Taylor expansion of $F(x,r)$ and the ellipticity condition (H6) entail

$$\begin{aligned}F(x,r') - F(x,r) &= \sum_i (r'-r)_i F_i(x,r)\\ &\quad+\sum_{i,k}(r'-r)_i(r'-r)_k\int_0^1 (1-t)F_{i,k}(x,tr'+(1-t)r)\,dt\\ &\geq \sum_i (r'-r)_i F_i(x,r) + \frac{k_0}{2}|r'-r|^2.\end{aligned} \tag{4.8}$$

We put $r = \nabla u$ and $r' = E_1^{-h}\nabla u$. This yields

$$-\sum_i F_i(x,\nabla u)h^{-1}\Delta_1^{-h}\partial_i u \geq -h^{-1}[F(x,E_1^{-h}\nabla u) - F(x,\nabla u)] + \frac{k_0}{2h}\left|\Delta_1^{-h}\nabla u\right|^2.$$

In view of (4.7), we obtain

$$\begin{aligned}&\frac{k_0}{2}\int_B \tau^2 h^{-1}\left|\Delta_1^{-h}\nabla u\right|^2\\ &\leq \int_B \tau^2 h^{-1}\Delta_1^{-h}F(x,\nabla u)\\ &\quad+\int_B \tau^2 h^{-1}\left[F\left(x,E_1^{-h}\nabla u\right) - F\left(E_1^{-h}x,E_1^{-h}\nabla u\right)\right]\\ &\quad+\sum_i\int_B F_i(x,\nabla u)\partial_i\tau^2 h^{-1}\Delta_1^{-h}u\\ &\quad-\int_B f\tau^2 h^{-1}\Delta_1^{-h}u + \sum_i\int_B f_i\partial_i\left(\tau^2 h^{-1}\Delta_1^{-h}u\right)\\ &= J_1+\cdots+J_5.\end{aligned}$$

Now we estimate the integrals $J_1,\dots,J_5$. Let us define

$$B_h = \{x \in B(3R) : x = y + \lambda\zeta^1,\ y \in B,\ 0 \leq \lambda \leq h\}. \tag{4.9}$$

The Leibniz rule $\Delta_1^{-h}fg = \Delta_1^{-h}(fg) - E_1^{-h}f\Delta_1^{-h}g$ implies that

$$\begin{aligned}J_1 &= \int_{B_h}\tau^2 h^{-1}\Delta_1^{-h}F(x,\nabla u)\\ &= \int_{B_h} h^{-1}\Delta_1^{-h}\left(\tau^2 F(x,\nabla u)\right) - \int_{B_h} h^{-1}\Delta_1^{-h}\tau^2 E_1^{-h}F(x,\nabla u)\\ &= J_{11}+J_{12}.\end{aligned}$$

The extension (4.4) yields $\nabla u = 0$ in Ω_1^{-h}, where Ω_1^{-h} is introduced in (4.2). Due to (H1) it follows that

$$\begin{aligned} J_{11} &= h^{-1} \int_{\Omega_1^{-h}} \tau^2 F(x, \nabla u) \le h^{-1} \int_{\Omega_1^{-h}} |g_0| \\ &\le \|g_0\|_{L^\infty(\Omega_1^{-h})}\, h^{-1} |\Omega_1^{-h}| \le c. \end{aligned}$$

Using (H1) again and the fact that $\tau^2 \in W^{1,\infty}(\Omega)$ we get

$$|J_{12}| \le c \left(\left\| E_1^{-h} g_0 \right\|_{L^1(B_h)} + \left\| E_1^{-h} \nabla u \right\|^2_{L^2(B_h)} \right) \le c.$$

Let $\zeta^1 = (\zeta_1^1, \dots, \zeta_n^1)^T$. Hypothesis (H2) and the Taylor expansion yield

$$\begin{aligned} |J_2| &\le \int_B \tau^2 \sum_k \left|\zeta_k^1\right| \int_0^1 \left| F_{x_k} \left(x - (1-t) h \zeta^1, E_1^{-h} \nabla u \right) \right| \, dt dx \\ &\le c \left(\sum_k \sup_{0 \le t \le 1} \left\| g_{x_k}(x - th\zeta^1) \right\|_{L^1(B)} + \left\| E_1^{-h} \nabla u \right\|^2_{L^2(B)} \right) \\ &\le c. \end{aligned}$$

In view of (H3) and (H7), we obtain

$$|J_3| \le c \left(\sum_i \|g_i\|^2_{L^2(B)} + \|\nabla u\|^2_{L^2(B)} + \left\| h^{-1} \Delta_1^{-h} u \right\|^2_{L^2(B)} \right) \le c$$

and

$$|J_4| \le c \left(\|f\|^2_{L^2(B)} + \left\| h^{-1} \Delta_1^{-h} u \right\|^2_{L^2(B)} \right) \le c.$$

Further, let B_h be the set introduced in (4.9). We find

$$J_5 = \sum_i \int_{B_h} f_i \partial_i \tau^2 h^{-1} \Delta_1^{-h} u + \sum_i \int_{B_h} f_i \tau^2 h^{-1} \Delta_1^{-h} \partial_i u = J_{51} + J_{52}.$$

Hypothesis (H7) yields

$$|J_{51}| \le c \left(\|f_i\|^2_{L^2(B_h)} + \left\| h^{-1} \Delta_1^{-h} u \right\|^2_{L^2(B_h)} \right) \le c.$$

Applying the Leibniz rule we get

$$\begin{aligned} J_{52} &= \sum_i \int_{B_h} h^{-1} \Delta_1^{-h} (f_i \tau^2 \partial_i u) - \sum_i \int_{B_h} h^{-1} \Delta_1^{-h} (f_i \tau^2) E_1^{-h} \partial_i u \\ &= J_{53} + J_{54}. \end{aligned}$$

Let us note that $\partial_i u = 0$ in Ω_1^{-h}, thus,

$$J_{53} = h^{-1} \sum_i \int_{\Omega_1^{-h}} \tau^2 f_i \partial_i u = 0.$$

Moreover, noting that $\tau \in W^{1,\infty}(\Omega)$ we get

$$|J_{54}| \le c \left(\|f_i\|^2_{W^{1,2}(B_h)} + \|\nabla u\|^2_{L^2(B_h)} \right) \le c.$$

Altogether we obtain

$$\int_B \tau^2 \left| h^{-\frac{1}{2}} \Delta_1^{-h} \nabla u \right|^2 \leq c$$

and the constant c is independent of h. Notice that $\tau \equiv 1$ in B_0. Thus the assertion follows. □

LEMMA 4.3. *Let $\omega < \pi$. Let ζ^1 be parallel to $\Gamma_D \cap B_{3R}$ and angle$(\zeta^1, \Gamma_N \cap B_{3R}) \geq \alpha > 0$. Then there holds that*

$$\sup_{0<h<R} \int_{B_0} \left| h^{-\frac{1}{2}} \Delta_1^h \nabla u \right|^2 dx \leq c, \tag{4.10}$$

where the constant c depends only on R, α, and the data.

Proof. Let $0 < h < R$. Notice that

$$x + \lambda \zeta^1 \in \Gamma_D \qquad \text{for all } x \in \Gamma_D \cap B_{2R} \text{ and } 0 < \lambda < R.$$

Thus the function $v = \tau^2 h^{-1} \Delta_1^h u$ is an admissible test function in (2.1). Testing the equation we obtain

$$\begin{aligned} \sum_i \int_B F_i(x, \nabla u) \tau^2 h^{-1} \partial_i \Delta_1^h u = &- \sum_i \int_B F_i(x, \nabla u) \partial_i \tau^2 h^{-1} \Delta_1^h u \\ &+ \int_B f \tau^2 h^{-1} \Delta_1^h u - \sum_i \int_B f_i \partial_i \left(\tau^2 h^{-1} \Delta_1^h u \right). \end{aligned}$$

Next, let us put $r = \nabla u$ and $r' = E_1^h \nabla u$ in the Taylor expansion (4.8). This entails

$$- \sum_i F_i(x, \nabla u) h^{-1} \Delta_1^h \partial_i u \geq -h^{-1} [F(x, E_1^h \nabla u) - F(x, \nabla u)] + \frac{k_0}{2h} \left| \Delta_1^h \nabla u \right|^2.$$

Thus we get

$$\begin{aligned} \frac{k_0}{2} \int_B \tau^2 h^{-1} \left| \Delta_1^h \nabla u \right|^2 \leq &\int_B \tau^2 h^{-1} \Delta_1^h F(x, \nabla u) \\ &+ \int_B \tau^2 h^{-1} \left[F\left(x, E_1^h \nabla u\right) - F\left(E_1^h x, E_1^h \nabla u\right) \right] \\ &+ \sum_i \int_B F_i(x, \nabla u) \partial_i \tau^2 h^{-1} \Delta_1^h u \\ &- \int_B f \tau^2 h^{-1} \Delta_1^h u + \sum_i \int_B f_i \partial_i \left(\tau^2 h^{-1} \Delta_1^h u \right) \\ = &\, J_1 + \cdots + J_5. \end{aligned}$$

The Leibniz rule $f \Delta_1^h g = \Delta_1^h (fg) - \Delta_1^h f E_1^h g$ yields

$$\begin{aligned} J_1 &= \int_B h^{-1} \Delta_1^h \left(\tau^2 F(x, \nabla u) \right) - \int_B h^{-1} \Delta_1^h \tau^2 E_1^h F(x, \nabla u) \\ &= J_{11} + J_{12} \end{aligned}$$

and it holds that

$$J_{11} = -h^{-1} \int_{\Omega_1^h} \tau^2 F(x, \nabla u).$$

Further, let us consider J_5. Using the notations from above we find

$$\begin{aligned}|J_{53}| &\equiv \left|\sum_i \int_B h^{-1}\Delta_1^h(f_i\tau^2\partial_i u)\right| = \left|\sum_i h^{-1}\int_{\Omega_1^h} f_i\tau^2\partial_i u\right| \\ &\le \frac{c}{\delta h}|\Omega_1^h|\sum_i \|\tau f_i\|^2_{L^\infty(\Omega_1^h)} + \frac{\delta}{h}\int_{\Omega_1^h}\tau^2|\nabla u|^2 \\ &\le c - \frac{\delta}{c_0'}J_{11}.\end{aligned}$$

Choosing $\delta = \frac{c_0'}{2}$ and using (H1) we obtain

$$J_{11} + |J_{53}| = c - \frac{1}{2h}\int_{\Omega_1^h}\tau^2 F(x,\nabla u) \le c - \frac{1}{2h}\int_{\Omega_1^h} c_0 \le c.$$

Now, following the proof of Lemma 4.2, we are able to estimate the integrals $J_1,\dots,J_5$. We may conclude that

$$\int_B \tau^2 h^{-1}\left|\Delta_1^h\nabla u\right|^2 \le c.$$

This yields the assertion. ∎

Next we investigate the regularity in the case when $\omega = \pi$. Let $\Gamma_*^i \subset \Gamma_N$, $\Gamma_*^j \subset \Gamma_D$, and $\operatorname{angle}(\Gamma_*^i,\Gamma_*^j) = \pi$. To begin with, let us assume

$$(\Gamma_*^i \cup \Gamma_*^j) \subset \{x\in\mathbb{R}^n : x_n = 0\} \quad\text{and}\quad \Omega\cap B_{3R} \subset \{x\in\mathbb{R}^n : x_n > 0\}. \tag{4.11}$$

In general, (4.11) is not satisfied. Then we make a rotation of the domain. This will be discussed later.

Further, let $\zeta^1,\dots,\zeta^n$ be a suitable basis of $\mathbb{R}^n$ such that $\zeta^n = e_n$ and $\zeta^i\cdot e_n = 0$ for $1\le i\le n-1$. We proceed in several steps.

LEMMA 4.4. *Let $\omega = \pi$ and let (4.11) be satisfied. There are basis vectors $\zeta^1,\dots,\zeta^n$ of $\mathbb{R}^n$ such that $\zeta^n = e_n$, $\zeta^i\cdot e_n = 0$ for $1\le i\le n-1$, and*

$$\sup_{0<h<R}\int_{B_0}\left|h^{-\frac12}\Delta_j^h\nabla u\right|^2 dx \le c \qquad \text{for } 1\le j\le n-1. \tag{4.12}$$

Further, the constant c depends only on R and the data.

Proof. Let $0<h<R$. Notice that $\operatorname{angle}(\Gamma_*^i,\Gamma_*^j) = \pi$. Let $\Gamma_1 = \overline{\Gamma_*^i\cup\Gamma_*^j}$ and $\Gamma_2 = (\partial\Omega\cap B_{3R})\setminus\Gamma_1$. We can find basis vectors ζ^i $(1\le i\le n-1)$ parallel to $\{x\in\mathbb{R}^n : x_n = 0\}$ such that

(1) $x + s\zeta^i \in \Gamma_D$ for $x\in\Gamma_1\cap\Gamma_D$ and $0<s<R$.
(2) $x + s\zeta^i \in \overline{\Omega}$ for $x\in\Gamma_2$ and $0<s<R$.
(3) At least one of the following conditions holds:
  (i) ζ^i is parallel to $\partial\Omega\cap B_{3R}$.
  (ii) There is just one Γ^k such that $\Gamma^k\cap B_{3R}\ne\emptyset$ and $\operatorname{angle}(\zeta^i,\Gamma^k)\ge\alpha$.
(4) $\operatorname{Angle}(\zeta^i,\zeta^j)\ge\alpha>0$ for $1\le i<j\le n-1$.
(5) α depends only on the geometry of $\partial\Omega$.

In order to prove (4.12) we distinguish three cases.

Case 1: ζ^i satisfies (3)(i). Then the function $v = \tau^2 h^{-1}\Delta_i^h u$ is an admissible test function in (2.1).

Case 2: ζ^i satisfies (3)(ii) where $\Gamma^k \subset \Gamma_N$. Then $v = \tau^2 h^{-1} \Delta_i^h u$ is an admissible test function.

Case 3: ζ^i satisfies (3)(ii) where $\Gamma^k \subset \Gamma_D$. Then $v = \tau^2 h^{-1} \Delta_i^{-h} u$ is an admissible test function.

Proceeding as in the proof of either Lemma 4.2 or Lemma 4.3 yields the assertion. ∎

LEMMA 4.5. *Let $\omega = \pi$, let (4.11) be satisfied, and $\varepsilon > 0$. Then there is a constant c depending only on R, ε, and the data such that*

$$\sup_{0<h<R} \int_{B_0} \left| h^{-\frac{1}{2}+\varepsilon} \Delta_n^h \partial_j u \right|^2 dx \le c \qquad \text{for } 1 \le j \le n-1. \tag{4.13}$$

Proof. Let $0 < h < R$ and $1 \le j \le n-1$. Estimate (4.12) entails

$$h^{-\frac{1}{2}} \Delta_j^h (\tau^2 u) \in W^{1,2}(\Omega).$$

The imbedding $W^{1,2}(\Omega) \to \mathcal{H}^{1,2}(\Omega)$ implies that $h^{-\frac{1}{2}} \Delta_j^h (\tau^2 u) \in \mathcal{H}^{1,2}(\Omega)$, thus,

$$h^{-\frac{1}{2}-\varepsilon} \Delta_i^h \left(h^{-\frac{1}{2}} \Delta_j^h (\tau^2 u) \right) \in \mathcal{H}^{\frac{1}{2}-\varepsilon,2}(\Omega) \qquad \text{for } 1 \le i \le n$$

and

$$h^{-\frac{1}{2}+\varepsilon} \Delta_l^h \left(\bar{h}^{-\frac{1}{2}-\varepsilon} \Delta_i^{\bar{h}} \left(\bar{h}^{-\frac{1}{2}} \Delta_j^{\bar{h}} (\tau^2 u) \right) \right) \in L^2(\Omega) \qquad \text{for } 1 \le i,l \le n,\ 0 < h, \bar{h} < R.$$

Choosing $i = j$ and $l = n$, we obtain

$$\bar{h}^{-1-\varepsilon} \Delta_j^{\bar{h}} \Delta_j^{\bar{h}} \left(h^{-\frac{1}{2}+\varepsilon} \Delta_n^h (\tau^2 u) \right) \in L^2(\Omega).$$

It follows that $\partial_{\zeta^j} (h^{-\frac{1}{2}+\varepsilon} \Delta_n^h u) \in L^2(B_0)$ for $0 < h < R$ and each $\varepsilon > 0$. This holds for all $j \in \{1, \dots, n-1\}$. Due to the fact that $\zeta^j \cdot e_n = 0$, the assertion follows. ∎

LEMMA 4.6. *Let $\omega = \pi$ and let (4.11) be satisfied. Further, let $\zeta^1, \dots, \zeta^n$ be the basis chosen in Lemma 4.4. Then there holds that*

$$\sup_{0<h<R} \int_{B_0} \left| h^{-\frac{1}{2}} \Delta_j^h F_n(x, \nabla u) \right|^2 dx \le c \qquad \text{for } 1 \le j \le n-1, \tag{4.14}$$

where the constant c depends only on R and the data.

Proof. Let $0 < h < R$, $1 \le j \le n-1$, and $\zeta^j = (\zeta_1^j, \dots, \zeta_n^j)^T$. The Taylor expansion, (H4), and (H5) entail

$$\begin{aligned}
&\int_{B_0} \left| h^{-\frac{1}{2}} \Delta_j^h F_n(x, \nabla u) \right|^2 \\
&\le \int_{B_0} \sum_k \left| h^{\frac{1}{2}} \zeta_k^j \int_0^1 F_{n,x_k}(x + th\zeta^j, \nabla u)\ dt \right|^2 \\
&\quad + \int_{B_0} \left(\sum_k \left| \int_0^1 F_{n,k}(E_j^h x, t E_j^h \nabla u + (1-t)\nabla u)\ dt \right| \left| h^{-\frac{1}{2}} \Delta_j^h \partial_k u \right| \right)^2 \\
&\le ch \left(\sum_k \sup_{0 \le t \le 1} \left\| g_{n,x_k}(x + th\zeta^j) \right\|_{L^2(B_0)}^2 + \|\nabla u\|_{L^2(B_0)}^2 \right) \\
&\quad + c \left\| h^{-\frac{1}{2}} \Delta_j^h \nabla u \right\|_{L^2(B_0)}^2.
\end{aligned}$$

Note that $g_{n,x_k} \in L^2(B)$. Further, due to (4.12), the last term on the right-hand side is bounded. Thus the assertion follows. ∎

LEMMA 4.7. *Let $\omega = \pi$, let (4.11) be satisfied, and let $\varepsilon > 0$. Then there holds that*

$$\sup_{0<h<R} \int_{B_0} \left| h^{-\frac{1}{2}+\varepsilon} \Delta_n^h F_n(x, \nabla u) \right|^2 dx \le c, \tag{4.15}$$

where the constant c depends only on R, ε, and the data.

Proof. Let $0 < h < R$ and $\varepsilon > 0$. Below we prove

$$\partial_j \left(h^{-\frac{1}{2}+\varepsilon} \Delta_n^h F_n(x, \nabla u) \right) \in W^{-1,2}(B_0) \qquad \text{for } 1 \le j \le n. \tag{4.16}$$

Further, let us note that $h^{-\frac{1}{2}+\varepsilon} \Delta_n^h F_n(x, \nabla u) \in W^{-1,2}(B_0)$. Now we apply the well-known estimate (cf. [19])

$$\|w\|_{L^2(\Omega)} \le c \left(\sum_i |\partial_i w|_{W^{-1,2}(\Omega)} + |w|_{W^{-1,2}(\Omega)} \right)$$

and obtain $h^{-\frac{1}{2}+\varepsilon} \Delta_n^h F_n(x, \nabla u) \in L^2(B_0)$ for $0 < h < R$. Thus the assertion follows.

In order to show (4.16), we distinguish two cases.

Case 1: *Let* $1 \le j \le n-1$. Estimate (4.14) yields $h^{-\frac{1}{2}} \Delta_j^h \left(\tau^2 F_n(x, \nabla u) \right) \in L^2(\Omega)$. It follows that

$$h^{-\frac{1}{2}+\varepsilon} \Delta_n^h \left(\bar{h}^{-\frac{1}{2}-\varepsilon} \Delta_j^{\bar{h}} \left(\bar{h}^{-\frac{1}{2}} \Delta_j^{\bar{h}} (\tau^2 F_n(x, \nabla u)) \right) \right) \in W^{-1,2}(\Omega)$$

for $0 < \bar{h} < R$, thus,

$$\partial_{\zeta^j} \left(h^{-\frac{1}{2}+\varepsilon} \Delta_n^h F_n(x, \nabla u) \right) \in W^{-1,2}(B_0).$$

Due to the fact that $\zeta^j \cdot e_n = 0$ for each $j \in \{1, \dots, n-1\}$ we get

$$\partial_j \left(h^{-\frac{1}{2}+\varepsilon} \Delta_n^h F_n(x, \nabla u) \right) \in W^{-1,2}(B_0) \qquad \text{for } 1 \le j \le n-1. \tag{4.17}$$

Case 2: *Let* $j = n$. Equation (1.1) yields

$$\begin{aligned} &h^{-\frac{1}{2}+\varepsilon} \Delta_n^h \left(\partial_n F_n(x, \nabla u) \right) \\ &= h^{-\frac{1}{2}+\varepsilon} \Delta_n^h \left(- \sum_{k=1}^{n-1} \partial_k F_k(x, \nabla u) - f(x) - \sum_i \partial_i f_i(x) \right). \end{aligned} \tag{4.18}$$

As in the proof of Lemma 4.6 it follows that

$$h^{-\frac{1}{2}} \Delta_k^h (\tau^2 F_k(x, \nabla u)) \in L^2(\Omega) \qquad \text{for } 1 \le k \le n-1.$$

This implies that

$$h^{-\frac{1}{2}+\varepsilon} \Delta_n^h \left(\bar{h}^{-1-\varepsilon} \Delta_k^{\bar{h}} \Delta_k^{\bar{h}} \left(\tau^2 F_k(x, \nabla u) \right) \right) \in W^{-1,2}(\Omega) \qquad \text{for } 1 \le k \le n-1,$$

thus,

$$h^{-\frac{1}{2}+\varepsilon} \Delta_n^h \partial_k F_k(x, \nabla u) \in W^{-1,2}(B_0) \qquad \text{for } 1 \le k \le n-1.$$

Hence, the right-hand side of (4.18) is a $W^{-1,2}(B_0)$-function. This entails

$$\partial_n \left(h^{-\frac{1}{2}+\varepsilon} \Delta_n^h F_n(x, \nabla u) \right) \in W^{-1,2}(B_0). \tag{4.19}$$

Altogether, (4.17) and (4.19) provide (4.16). This yields the assertion. □

LEMMA 4.8. *Let $\omega = \pi$, let (4.11) be satisfied, and let $\varepsilon > 0$. Then there is a constant c depending only on R, ε, and the data such that*

$$\sup_{0<h<R} \int_{B_0} \left| h^{-\frac{1}{2}+\varepsilon} \Delta_n^h \nabla u \right|^2 dx \leq c. \tag{4.20}$$

Proof. The Taylor expansion yields

$$\begin{aligned} J_1 &= h^{-\frac{1}{2}+\varepsilon} \Delta_n^h \partial_n u \int_0^1 F_{n,n}(x, tE_n^h \nabla u + (1-t)\nabla u)\, dt \\ &= h^{-\frac{1}{2}+\varepsilon} \Delta_n^h F_n(x, \nabla u) - h^{\frac{1}{2}+\varepsilon} \int_0^1 F_{n,x_n}(x + the_n, E_n^h \nabla u)\, dt \\ &\quad - \sum_{k=1}^{n-1} h^{-\frac{1}{2}+\varepsilon} \Delta_n^h \partial_k u \int_0^1 F_{n,k}(x, tE_n^h \nabla u + (1-t)\nabla u)\, dt \\ &= J_2 + J_3 + J_4. \end{aligned} \tag{4.21}$$

Estimate (4.15) entails

$$\sup_{0<h<R} \int_{B_0} |J_2|^2 = \sup_{0<h<R} \int_{B_0} \left| h^{-\frac{1}{2}+\varepsilon} \Delta_n^h F_n(x, \nabla u) \right|^2 \leq c.$$

Hypothesis (H4) implies that

$$\begin{aligned} &\sup_{0<h<R} \int_{B_0} |J_3|^2 \\ &\leq \sup_{0<h<R} ch^{1+2\varepsilon} \left(\sup_{0\leq t\leq 1} \|g_{n,x_n}(x + the_n)\|^2_{L^2(B_0)} + c \left\| E_n^h \nabla u \right\|^2_{L^2(B_0)} \right) \leq c. \end{aligned}$$

Using (4.13) and (H5) we get

$$\sup_{0<h<R} \int_{B_0} |J_4|^2 \leq \sup_{0<h<R} c \sum_{k=1}^{n-1} \int_{B_0} \left| h^{-\frac{1}{2}+\varepsilon} \Delta_n^h \partial_k u \right|^2 \leq c.$$

Thus from (4.21) we may conclude that

$$\sup_{0<h<R} \int_{B_0} |J_1|^2 = \sup_{0<h<R} \int_{B_0} \left| h^{-\frac{1}{2}+\varepsilon} \Delta_n^h \partial_n u F_{nn} \right|^2 \leq c,$$

where $F_{nn} = \int_0^1 F_{n,n}(x, tE_n^h \nabla u + (1-t)\nabla u)\, dt$. In view of the ellipticity condition (H6) we have

$$\int_{B_0} |J_1|^2 \geq k_0^2 \int_{B_0} \left| h^{-\frac{1}{2}+\varepsilon} \Delta_n^h \partial_n u \right|^2.$$

It follows that

$$\sup_{0<h<R}\int_{B_0}\left|h^{-\frac{1}{2}+\varepsilon}\Delta_n^h\partial_n u\right|^2\le c. \tag{4.22}$$

Altogether, (4.13) and (4.22) entail the assertion. □

Proof of Proposition 4.1. If $\Gamma_*^j\subset\Gamma_D$, $\Gamma_*^k\subset\Gamma_N$, and $\operatorname{angle}(\Gamma_*^j,\Gamma_*^k)=\pi$ we set $\Gamma_1=\overline{\Gamma_*^j\cup\Gamma_*^k}$ and $\Gamma_2=(\partial\Omega\cap B_{3R})\setminus\Gamma_1$. We choose appropriate basis vectors ζ^i $(1\le i\le n)$ such that $|\zeta^i|=1$ and there hold

(1) $\operatorname{angle}(\zeta^i,\zeta^j)\ge\alpha>0$ for $1\le i<j\le n$.

(2) $x+s\zeta^i\in\overline{\Omega}$ for $x\in\overline{\Omega}\cap B_{2R}$ and $0<s<R$.

(3) If $\Gamma_*^k\subset\Gamma_D$ and ζ^i is parallel to Γ_*^k, then $y+s\zeta^i\in\Gamma_*^k$ for $y\in\Gamma_*^k\cap B_{2R}$ and $0<s<R$.

(4) If $\Gamma^k\cap B_{3R}\ne\emptyset$ and ζ^i is not parallel to Γ^k, then $\operatorname{angle}(\zeta^i,\Gamma^k)\ge\alpha>0$.

(5) If $\operatorname{angle}(\zeta^i,\Gamma_*^k)\ge\alpha>0$, then $x-s\zeta^i\notin\overline{\Omega}$ for all $x\in\Gamma_*^k$ and $0<s<R$.

(6) There holds at least one of the following conditions:

(i) ζ^i is parallel to $\partial\Omega\cap B_{3R}$,

(ii) $\operatorname{angle}(\zeta^i,\Gamma_D\cap B_{3R})\ge\alpha$ and either $\Gamma_N\cap B_{3R}=\emptyset$ or ζ^i is parallel to $\Gamma_N\cap B_{3R}$,

(iii) $\operatorname{angle}(\zeta^i,\Gamma_N\cap B_{3R})\ge\alpha$ and either $\Gamma_D\cap B_{3R}=\emptyset$ or ζ^i is parallel to $\Gamma_D\cap B_{3R}$,

(iv) $\operatorname{angle}(\zeta^i,\Gamma_1\cap B_{3R})\ge\alpha$ and either $\Gamma_2\cap B_{3R}=\emptyset$ or ζ^i is parallel to $\Gamma_2\cap B_{3R}$,

(v) $\operatorname{angle}(\zeta^i,\Gamma_*^k\cap B_{3R})\ge\alpha$ for just one Γ_*^k and ζ^i is parallel to $\Gamma_1\cap B_{3R}$.

(7) α depends only on the geometry of $\partial\Omega$.

Clearly we can find such a basis satisfying (1)–(7). Let us note that, due to the conditions (1)–(7), we can proceed as in the above proofs. Therefore, we must extend u across Γ_D in some direction ζ^i. Due to (6), however, we need no extension of u across Γ_N.

Following the proofs of Lemmas 4.2, 4.3, 4.4, and 4.8 yields the assertion in the case when (i) $\omega<\pi$ or when (ii) $\omega=\pi$ and (4.11) is satisfied.

Next, let us consider the case when $\omega=\pi$ and (4.11) is not satisfied. Then there are Γ_*^i, Γ_*^j such that $\Gamma_*^i\subset\Gamma_N$, $\Gamma_*^j\subset\Gamma_D$, and $\operatorname{angle}(\Gamma_*^i,\Gamma_*^j)=\pi$. Let $\zeta^1,\dots,\zeta^{n-1}$ be tangential to $\Gamma_*^i\cup\Gamma_*^j$ and ζ^n be parallel to $\Gamma_2\cap B_{3R}$. For simplicity, we asume ζ^n is the inner normal of $\Gamma_*^i\cup\Gamma_*^j$. We rotate the domain Ω such that ζ^n is mapped onto e_n. Let A be the matrix describing the rotation. Let $\hat{x}=Ax$, $\hat{u}(\hat{x})=u(A^{-1}\hat{x})$, etc., and $\widetilde{\partial}_i=\sum_k a_{ik}\partial_k$. Then there holds the equation

$$-\sum_{i=1}^n\widetilde{\partial}_i\hat{F}_i(\hat{x},\widetilde{\nabla}\hat{u})=\hat{f}(\hat{x})+\sum_{i=1}^n\widetilde{\partial}_i\hat{f}_i(\hat{x})\qquad\text{in }\hat{\Omega}.$$

Let us note that $\widetilde{\partial}_1,\dots,\widetilde{\partial}_{n-1}$ are derivatives in directions tangential to the boundary and $\widetilde{\partial}_n$ is the normal derivative. Thus (4.12) yields

$$\sup_{0<h<R}\int_{\hat{B}_0}\left|h^{-\frac{1}{2}+\varepsilon}\widetilde{\Delta}_j^h\widetilde{\nabla}\hat{u}\right|^2\le c \tag{4.23}$$

for $1\le j\le n-1$ (and $\varepsilon=0$). Further, following the proof of Lemma 4.8 we obtain (4.23) for $j=n$ and $\varepsilon>0$. Due to

$$\left|\widetilde{\Delta}_j^h\widetilde{\nabla}\hat{u}\right|^2=\left|A\widetilde{\Delta}_j^h\nabla\hat{u}\right|^2=\left|\widetilde{\Delta}_j^h\nabla\hat{u}\right|^2$$

and the substitution rule for integrals we get

$$\sup_{0<h<R}\int_{B_0}\left|h^{-\frac{1}{2}+\varepsilon}\Delta_j^h\nabla u\right|^2\le c\qquad\text{for } 1\le j\le n,$$

where the constant c depends on R, $\varepsilon>0$, and the data. □

5. The proofs of Theorems 2.1 and 2.2. In this section we prove the main results.

Let us note that $f\in L^q(\Omega)$ and $f_i\in L^{2q}(\Omega)$ for some $q>\frac{n}{2}$ and $1\le i\le n$. Thus it holds that $u\in C^{0,\alpha}\left(\overline{\Omega}\right)$ for some $\alpha>0$. This can be proven as in [14], where quasi-linear problems are treated.

From the Hölder continuity of u and the assumption (2.2) it follows that

$$\nabla u\in L^{3+\varepsilon}(\Omega)\qquad\text{for some }\varepsilon>0; \tag{5.1}$$

cf. [9]. We use this result in order to prove Theorem 2.1.

Proof of Theorem 2.1. Let $r\in\mathbb{R}^n$. The Taylor expansion of $G(r)=|r|^\sigma$ entails

$$G(r')-G(r)=\sum_i(r'-r)_i\int_0^1 G_i(tr'+(1-t)r)\,dt,$$

where $G_i(r)=\frac{\partial}{\partial r_i}G(r)=\sigma|r|^{\sigma-2}r_i$. Let $j\in\{1,\dots,n\}$ be fixed. Setting $r=\nabla u$ and $r'=E_j^hr$ we get

$$\Delta_j^h|\nabla u|^\sigma=\sum_i\Delta_j^h\partial_iu\int_0^1 G_i(tr'+(1-t)r)\,dt.$$

Let $\varepsilon>0$ be small. We find

$$\left|h^{-\frac{1}{2}+\varepsilon}\Delta_j^h|\nabla u|^\sigma\right|\le\sigma\left|h^{-\frac{1}{2}+\varepsilon}\Delta_j^h\nabla u\right|\int_0^1\left|tE_j^h\nabla u+(1-t)\nabla u\right|^{\sigma-1}dt. \tag{5.2}$$

Let $\sigma>1$. Proposition 4.1 yields $h^{-\frac{1}{2}+\varepsilon}\Delta_j^h\nabla u\in L^2(B_0)$. Further, (5.1) implies that $|tE_j^h\nabla u+(1-t)\nabla u|^{\sigma-1}\in L^s(\Omega)$ for $s=\frac{3+\varepsilon}{\sigma-1}$. It follows that

$$\left|h^{-\frac{1}{2}+\varepsilon}\Delta_j^h\nabla u\right|\int_0^1\left|tE_j^h\nabla u+(1-t)\nabla u\right|^{\sigma-1}dt\in L^q(B_0) \tag{5.3}$$

for $q=\frac{2s}{2+s}=\frac{6+\delta}{2\sigma+1}$ and some $\delta>0$. Let us note that $\frac{6+\delta}{2\sigma+1}>1$ holds for $1<\sigma\le\frac{5}{2}$. Thus, in view of (5.2) and (5.3), we have

$$\sup_{0<h<R}\int_{B_0}\left|h^{-\frac{1}{2}+\varepsilon}\Delta_j^h|\nabla u|^\sigma\right|^{\frac{6+\delta}{2\sigma+1}}\le c\qquad\text{for } 1\le j\le n\text{ and }\sigma>1. \tag{5.4}$$

Next, estimate (5.2) and Proposition 4.1 entail

$$\sup_{0<h<R}\int_{B_0}\left|h^{-\frac{1}{2}+\varepsilon}\Delta_j^h|\nabla u|\right|^2\le c\qquad\text{for } 1\le j\le n. \tag{5.5}$$

Let $p=\frac{6+\delta}{2\sigma+1}$ for $\sigma>1$ and $p=2$ for $\sigma=1$. Then (5.4) and (5.5) imply (for $\sigma>1$ and $\sigma=1$, respectively) that

$$\sup_{\substack{\eta>0\\0<|z|<\eta}}\int_{B_\eta}\left|\frac{|\nabla u(x+z)|^\sigma-|\nabla u(x)|^\sigma}{|z|^{\frac{1}{2}-\varepsilon}}\right|^p dx\le c\qquad\text{for } 1\le\sigma\le\frac{5}{2}, \tag{5.6}$$

where $B_\eta = \{x \in B_0 : \operatorname{dist}(x, \partial\Omega) \geq \eta\}$. Further, the constant c depends only on ε, the data, and R.

We can find finite sets of numbers $\{R_1, \dots, R_k\}$ and of points $\{P_1, \dots, P_k\}$ depending only on the geometry of $\partial\Omega$ such that $\overline{\Omega} \subset \bigcup_{i=1}^k B_{R_i}(P_i)$, and each ball $B_{R_i}(P_i)$ satisfies: If $B_{R_i}(P_i) \cap \partial\Omega \neq \emptyset$, then $B_{R_i}(P_i) \cap \partial\Omega$ is simply connected, and $\partial\Gamma^i \cap \partial\Gamma^j \neq \emptyset$ holds if $\Gamma^i \cap B_{R_i}(P_i) \neq \emptyset$ and $\Gamma^j \cap B_{R_i}(P_i) \neq \emptyset$. Further, P_i is the only vertex of $B_{R_i}(P_i) \cap \partial\Omega$ or there is no vertex of $\partial\Omega$ in $B_{R_i}(P_i)$. Thus it follows that

$$|\nabla u|^\sigma \in \mathcal{H}^{\frac{1}{2}-\varepsilon,p}(\Omega).$$

The imbedding theorem of Nikolskii spaces into Sobolev spaces (cf. [13])

$$\mathcal{H}^{s,p}(\Omega) \to W^{s-\varepsilon,p}(\Omega) \qquad \text{for all } \varepsilon > 0$$

entails $|\nabla u|^\sigma \in W^{\frac{1}{2}-2\varepsilon,p}(\Omega)$ for all $\varepsilon > 0$. This yields the assertion. □

Proof of Theorem 2.2. We proceed as in the proof of Proposition 4.1. Let us remark that now, $u, F_i, f, f_i \in \mathbb{R}^N$ and $\nabla u \in \mathbb{R}^{nN}$ for some $N > 1$. The changes to be made in the proof are obvious. Hence Proposition 4.1 yields

$$\sup_{\substack{\eta>0 \\ 0<|z|<\eta}} \int_{B_\eta} \left| \frac{\nabla u(x+z) - \nabla u(x)}{|z|^{\frac{1}{2}-\varepsilon}} \right|^2 dx \leq c,$$

where $B_\eta = \{x \in B_0 : \operatorname{dist}(x, \partial\Omega) \geq \eta\}$. Applying the same cover argument as in the proof of Theorem 2.1 we get

$$\nabla u \in \mathcal{H}^{\frac{1}{2}-\varepsilon,2}(\Omega; \mathbb{R}^{nN}). \tag{5.7}$$

The imbedding theorem of Nikolskii spaces into Sobolev spaces yields

$$\nabla u \in W^{\frac{1}{2}-\varepsilon,2}(\Omega; \mathbb{R}^{nN}) \qquad \text{for all } \varepsilon > 0. \tag{5.8}$$

Let $\sigma > 1$. From the Sobolev imbedding theorem it follows that

$$|\nabla u|^{\sigma-1} \in L^s(\Omega) \qquad \text{for } 1 \leq s < \frac{2n}{(\sigma-1)(n-1)}. \tag{5.9}$$

Let $1 \leq j \leq n$. Due to (5.7) and (5.9) it holds that

$$\left| h^{-\frac{1}{2}+\varepsilon} \Delta_j^h \nabla u \right| \int_0^1 \left| t E_j^h \nabla u + (1-t)\nabla u \right|^{\sigma-1} dt \in L^q(\Omega) \quad \text{for } q = \frac{2s}{2+s}. \tag{5.10}$$

Thus, (5.10) holds for all $q < p$, where $p = \frac{2}{1+(\sigma-1)\frac{n-1}{n}}$. Using estimate (5.2) we get

$$h^{-\frac{1}{2}+\varepsilon} \Delta_j^h |\nabla u|^\sigma \in L^q(\Omega) \qquad \text{for } 1 \leq q < p \text{ and } 1 \leq j \leq n. \tag{5.11}$$

This implies that $|\nabla u|^\sigma \in \mathcal{H}^{\frac{1}{2}-\varepsilon,q}(\Omega)$ for $1 \leq q < p$, thus,

$$|\nabla u|^\sigma \in \mathcal{H}^{\frac{1}{2}-2\varepsilon,p}(\Omega) \qquad \text{for all } \varepsilon > 0 \text{ and } \sigma > 1. \tag{5.12}$$

Next, in the case when $\sigma = 1$, estimate (5.2) and Proposition 4.1 yield

$$|\nabla u| \in \mathcal{H}^{\frac{1}{2}-\varepsilon,2}(\Omega) \qquad \text{for all } \varepsilon > 0. \tag{5.13}$$

From (5.12), (5.13), and the imbedding theorem of Nikolskii spaces into Sobolev spaces the assertion follows. □

NONSYMMETRIC LORENZ ATTRACTORS FROM A HOMOCLINIC BIFURCATION*

CLARK ROBINSON†

Abstract. We consider a bifurcation of a flow in three dimensions from a double homoclinic connection to a fixed point satisfying a resonance condition between the eigenvalues. For correctly chosen parameters in the unfolding, we prove that there is a transitive attractor of Lorenz type. In particular we show the existence of a bifurcation to an attractor of Lorenz type which is semiorientable, i.e., orientable on one half and nonorientable on the other half. We do not assume any symmetry condition, so we need to discuss nonsymmetric one-dimensional Poincaré maps with one discontinuity and absolute value of the derivative always greater than one. We also apply these results to a specific set of degree four polynomial differential equations. The results do not apply to the actual Lorenz equations because they do not have enough parameters to adjust to make them satisfy the hypothesis.

1. Introduction.

In previous papers, [12] and [13], we proved that there is a bifurcation for differential equations in three dimensions with a symmetry from a double homoclinic connection for a fixed point to an attractor of Lorenz type. This attractor could be either untwisted or twisted on both sides. In this paper we consider the situation without a symmetry: in particular, we show that there can be a bifurcation from a double homoclinic connection to an attractor which is twisted on one side but untwisted on the other side. We give basic assumptions which are sufficient for this to take place. We also verify that specific polynomial differential equations in three dimensions can realize this bifurcation.

The mathematical results of this paper give a framework for analyzing the computational and experimental output exhibiting an attractor of Lorenz type. The analysis of the one-dimensional maps given in section 2 shows what type of structures can occur for attractors of flows in three dimensions even in cases not covered by the bifurcation theorem given in this paper. In particular, one-dimensional maps for attractors can occur that are either transitive on a single interval or transitive on multiple intervals. Also, typical trajectories outside the attractor can approach the attractor in different ways depending on the existence or lack of a trapping region. The codimension three bifurcation itself can occur as the unfolding of a degenerate singularity in systems for which there are many parameters which can be adjusted. Finally, the main theorem shows that attractors which are twisted on one or both sides can occur for actual polynomial differential equations. These twists relate to the type of knotted orbits which occur on the attractor. For an introduction to knots and templates for three-dimensional flows see [5] or [17].

In this paper, a transversality assumption and the dominance of the strong stable eigenvalue are used with standard stable manifold theory to reduce the problem to a

*Received by the editors August 17, 1998; accepted for publication (in revised form) June 10, 1999; published electronically June 22, 2000.

†Department of Mathematics, Northwestern University, Evanston, IL 60208 (clark@math.northwestern.edu).

one-dimensional map just as in the previous papers. The problem of the unfolding of the bifurcation is thus reduced to a question of understanding the unfolding of a certain type of one-dimensional map. In all the cases of the homoclinic bifurcation of the three-dimensional flow satisfying a set of assumptions, the resulting one-dimensional map can be shown to have a transitive invariant set for correctly chosen parameter values.

The standard symmetric untwisted situation leads to a symmetric one-dimensional problem which is monotonically increasing on both sides. In this paper, we consider one-dimensional maps which are not symmetric; in one case, the map is increasing on one side and decreasing on the other side. We present the results of the thesis of Byers [2], which show how to carry through the result of Williams [18] to show that the one-dimensional map is transitive in these nonsymmetric cases when the absolute value of the derivative is greater than square root of 2. We also refer to the recent result of Morales and Pujals [9], a previous work of Li and Yorke [8], and the thesis of Choi [3], which show that if the absolute value of the derivative is greater than one, then the map has a transitive invariant set which is not always the whole original interval. One example of these transitive invariant sets has a stable set which forms a dense open subset of a neighborhood, but the invariant set does not have a trapping region. We are interesting in verifying that the corresponding flow on $\mathbb{R}^3$ does have a trapping region so we give some conditions in section 2 which imply its existence.

A *trapping region* for a map f is a nonempty open set U such that the closure of the image of U is contained in the interior of U, $\mathrm{cl}(f(U)) \subset \mathrm{int}(U)$. A set Λ is called an *attracting set* provided there is a trapping region U such that $\Lambda = \bigcap_{k\geq 0} f^k(U)$. A set Λ is called an *attractor* provided it is an attracting set and $f|\Lambda$ is chain transitive. These definitions follow those given in [11].

For an attracting set Λ, there is a neighborhood U such that for any point $x \in U$ the ω-limit set of x is contained in Λ (i.e., the distance from $f^i(x)$ to Λ goes to zero as i goes to infinity); however, this condition is not equivalent to the existence of a trapping region. The simplest example is the map

$$f(x) = x + \frac{1}{2}x^2(1-x)^2 \qquad \text{for } x \bmod 1.$$

The ω-limit set of any point x_0 is 0, but there is no trapping region for $x = 0$. The problem is that the orbit of a small positive x_0 needs to go far away (near 0.5) before it returns near 1, which is equal to 0 mod 1.

There are other definitions of attractors, including Milnor's, which would call 0 an attractor for the map above. He only requires that there be a set B of positive measure such that the ω-limit sets of points in B are contained in Λ; i.e., B is contained in the stable set of Λ.

In this paper we consider another concept between our definition of an attractor and Milnor's: we call a set Λ a *weak attractor* provided (i) there is a neighborhood U of Λ and a dense open subset U' of U such that for all $x_0 \in U'$ the ω-limit set of x_0 is contained in Λ, and (ii) $f|\Lambda$ is chain transitive.

A weak attractor can have a 1-cycle in the terminology of Palis; i.e., there can be points $x_0 \in U \setminus \Lambda$ which are on both the stable and unstable set of Λ. If the map is f is one to one, then it has a 1-cycle provided there is a point $x_0 \notin \Lambda$ for which $\omega(x_0) \subset \Lambda$ and $\alpha(x_0) \subset \Lambda$; if f is not invertible, then it has a 1-cycle provided there is a point $x_0 \notin \Lambda$ for which $\omega(x_0) \subset \Lambda$ and there is some choice of preimages $\{x_i\}_{i\leq 0}$ with $f(x_{i-1}) = x_i$ for $i \leq 0$ and the distance from x_i to Λ goes to zero as i goes to $-\infty$. In the example given above, $x = 0$ is a weak attractor with a 1-cycle: for any

point $x_0 \in (0,1)$, $\alpha(x_0) = 0$ and $\omega(x_0) = 1 = 0 \bmod 1$. In section 2, we given another type of example of a map with a weak attractor but not an attractor in our sense of the term.

In this paper, as in [12] and [13], we consider a homoclinic bifurcation from the situation where there is a resonance between the eigenvalues together with transversality conditions. There are two other results by Rychlik [16] and Dumortier, Kokubu, and Oka [4] and Oka [10] which give different homoclinic bifurcations to Lorenz attractors than the one we analyze. These other authors assume there is no resonance of the eigenvalues, but each also assumes that there is a type of nontransversality along the homoclinic orbit (which is different in the two papers), while we assume there is transversality.

In section 2, we present the results on the one-dimensional maps. The main theorem about the homoclinic bifurcation of flows is given in section 3 together with the assumptions that are needed for this result. Section 4 contains the proof of the homoclinic bifurcation theorem. Section 5 contains some further comments about the unfolding of the bifurcation. Finally, section 6 proves that the assumptions for the bifurcation can be satisfied for specific polynomial differential equations in $\mathbb{R}^3$.

2. One-dimensional results. We are interested in conditions which imply that a one-dimensional map with a single discontinuity is topologically transitive.

We consider a map $f : J \to \mathbb{R}$ where $J \subset \mathbb{R}$ is an open interval and which we assume satisfies the following conditions:

(a) The map f has a discontinuity at a single point $c \in J$.

(b) The map f is continuously differentiable on $J \setminus \{c\}$, with

$$\lambda = \inf_{x \in J \setminus \{c\}} |f'(x)| > 1.$$

(c) The right and left limits of f exist at c: let

$$a^+ = \lim_{x \to c+} f(x) \quad \text{and} \quad a^- = \lim_{x \to c-} f(x).$$

Often we act as if f is not defined at c, but we could always take $f(c) = a^+$, $f(c) = a^-$, or $f(c) = c$.

We state the last two assumptions separately for the cases when f has the same monotonicity for x less than c and x greater than c. First, we consider the case when f is either monotonically increasing on both sides of c or monotonically decreasing on both sides.

(d1) Let $a = \max\{a^-, a^+\}$ and $b = \min\{a^-, a^+\}$. We assume that $b < c < a$, so that c is in the interior of the interval $[b, a]$.

(e1) Finally, we assume that $b < f(a)$, $f(b) < a$, so that the interval $[b, a]$ is invariant, $f([b, a]) \subset [b, a]$.

Next, we consider the case when f is monotonically increasing on one side of c and monotonically decreasing on the other side.

(d2) Let $a = \max\{a^-, a^+\}$ and $b = f(a)$. We assume that $b = f(a) < c < a$, so that c is in the interior of the interval $[b, a]$. (If $a = \min\{a^-, a^+\} < c$ and $b = f(a) > c$, then a reversal of orientation changes this case into the one considered here.)

(e2) Finally, we assume that $b < f(b) < a$, so that the interval $[b, a]$ is invariant.

It is not very hard to check that if f satisfies assumptions (a)–(e), then there is a small $\epsilon > 0$ such that the slightly larger interval $[b - \epsilon, a + \epsilon]$ is a trapping region. See Figure 2.1 for graphs of maps satisfying (a)–(e).

According to a theorem of Williams [18], if a map f satisfies conditions (a)–(e) and has the same monotonicities on both the subintervals $[b, c)$ and $(c, a]$, and $\lambda > \sqrt{2}$, then f is topologically transitive on $[a, b]$. Theorem 2.6 below gives a generalization of this result to other cases when f is increasing on one of the subintervals and is decreasing on the other.

There are other results that extend the results to the case of a map that satisfies conditions (a)–(e) for any $\lambda > 1$. Li and Yorke [8] proved that such maps have an ergodic measure whose support can be a subset of the original interval. More recently, Morales and Pujals [9] proved a different generalization of the result of Williams: they proved that if the map f satisfies conditions (a)–(e) for any $\lambda > 1$, then there is a closed subset $L_f \subset [b, a]$ which contains c in its interior such that f is topologically transitive on L_f and a dense open subset of points of $[b, a]$ have forward orbits which eventually are contained in L_f (the stable manifold of L_f is dense and open in $[b, a]$). In fact, L_f contains an interval I with c in its interior and L_f is the forward orbit of I. In general, the set L_f is the support of the measure found earlier by Li and Yorke.

In [3], Choi made more explicit the properties of L_f. In particular, (i) L_f is the finite union of closed intervals; (ii) the maximal invariant set in $\mathrm{cl}(J \setminus L_f)$ is a hyperbolic repeller R_f; (iii) L_f is always a weak attractor as defined in the introduction, but [3] gives an example where there is no trapping region for L_f so L_f is not an attractor in our strong sense of the term. The repeller R_f can be a set of periodic orbits and their preimages. (There are cases when R_f contains wandering points which have an α-limit set in one periodic orbit in R_f and an ω-limit set in another periodic orbit in R_f.) It is also possible for R_f to be a subshift of finite type as an example below shows. Choi has also shown that there are examples for which the set L_f does not have a trapping region (so L_f is not an attractor); such examples have a repelling periodic point on the boundary of L_f, i.e., a periodic orbit in $R_f \cap L_f$. For this example, the set L_f has a 1-cycle of the type discussed in the introduction. We give a different example below for which L_f does not have a trapping region, but without a 1-cycle. Choi also showed that the map can always be perturbed to a new map g without periodic points on the boundary of L_g, so L_g has a trapping region and so is an attractor for the new map g. We give a different example where L_h is not an attractor below.

We summarize these results in the following theorem.

THEOREM 2.1. *Assume that $f : J \to \mathbb{R}$ satisfies the assumptions* (a)–(e) *above with $\lambda > 1$.*

(a) *(Morales and Pujals) There is a $\delta_f > 0$ such that f is topologically transitive on*

$$L_f \equiv \mathrm{cl}\{\mathcal{O}^+((c - \delta_f, c + \delta_f), f)\},$$

and

$$W^s(L_f, f) \equiv \{x \in J : f^i(x) \in L_f \text{ for some } i \geq 0\}$$

is dense and open in J.

(b) *(Choi)* (i) *The set L_f is the finite union of closed intervals $\bigcup_{i=1}^n [x_i, y_i]$ and the endpoints*

$$\{x_i, y_i\}_{i=1}^n \subset \mathcal{O}^+(a^+, f) \cup \mathcal{O}^+(a^-, f).$$

(ii) *The maximal invariant set in $\mathrm{cl}(J \setminus L_f)$ is a closed hyperbolic repelling set R_f. (Some of the points in R_f can be wandering.)* (iii) *The set L_f has a trapping region*

for f if and only if

$$R_f \cap L_f = \emptyset, \quad \textit{i.e.},$$
$$\mathrm{Per}(f) \cap \partial(L_f) = \emptyset.$$

(iv) *Assume* $\mathrm{Per}(f) \cap \partial(L_f) \neq \emptyset$*, so f does not have a trapping region. There is a point $z_0 \in \mathrm{Per}(f) \cap \partial(L_f)$ with $f^j(z_0) = z_0$ and $f^k(a^\sigma) = z_0$, where σ is either $+$ or $-$. If g is near enough to f and $g^k(a_g^\sigma)$ does not have period j for g, $g^{j+k}(a_g^\sigma) \neq g^k(a_g^\sigma)$, then L_g will have a trapping region for g.*

We give some examples to clarify the theorem. When $L_f \neq J$, the maximal invariant set in the gaps R_f is often a collection of repelling periodic orbits and orbits whose α-limit set is one of these orbits and whose ω-limit set is another orbit. The first example gives an example where R_f is a single repelling fixed point; the second example shows that the set R_f can be a subshift of finite type.

Example 2.2. A simple example of a function f for which L_f is not the whole interval $[a, b]$ is given by

$$f(x) = \begin{cases} \dfrac{4}{3}\,x + 10 & \text{for } -6 \le x \le 0, \\ -1.3x + 10 & \text{for } 0 \le x \le 11. \end{cases}$$

Note that f is not differentiable at 0 so $c = 0$, $f(0) = 10$, $f(10) = -3$, $f(-3) = 6$, $f(6) = 2.2$, and $f(2.2) = 7.14 > 6$. Therefore $[a, b] = [-3, 10]$, and the transitive set $L_f = [-3, 2.2] \cup [6, 10]$. The set R_f is the single fixed point $10/2.3 \approx 4.35$.

Example 2.3. An example of a function g for which R_g is a subshift of finite type is given by

$$g(x) = \begin{cases} \dfrac{4}{3}\,x + 18 & \text{for } -21 \le x \le 0, \\ -\dfrac{7}{6}\,x + 18 & \text{for } 0 \le x \le 6, \\ -5\,(x - 6) + 11 & \text{for } 6 \le x \le 10, \\ -\dfrac{9}{8}\,(x - 10) - 9 & \text{for } 10 \le x \le 20. \end{cases}$$

The orbit of the nondifferentiable point 0 is not eventually periodic: $g(0) = 18$, $g(18) = -18$, $g(-18) = -6$, $g(-6) = 10$, $g(10) = -9$, $g(-9) = 6$, and $g(6) = 11 > 10$. The transitive set is $L_g = [-18, -9] \cup [-6, 6] \cup [10, 18]$. The repeller R_g is determined by the images of the gaps and is a subshift of finite type: $g([-9, -6]) = [6, 10]$, and $g([6, 10]) = [-9, 11] \supset [-9, -6] \cup [6, 10]$. Since none of the endpoints of L_g are periodic, $R_g \cap L_g = \emptyset$ and L_g has a trapping region.

Example 2.4. If we change the function g above so that $h(6) = 10$ but keep h piecewise linear with images of -18, -9, -6, 0, 10, and 18 unchanged, then $L_h = [-18, -9] \cup [-6, 6] \cup [10, 18]$ is the same as the last example but has a period three orbit on its boundary: $h^3(10) = h^2(-9) = h(6) = 10$. The repeller R_h is still a subshift of finite type, but $R_h \cap L_h = \{-9, 6, 10\} \neq \emptyset$ is a periodic orbit. The set L_h does not have a trapping region for h since it is accumulated upon by points in R_h outside of L_h. The stable set of L_h will include $[-19, 20] \setminus R_h$, which is dense and open in $[-19, 20]$ but is not a neighborhood of L_h. Therefore, L_h is a weak attractor but not an attractor (in terms of our terminology).

By approximating h by k with $k(6) = 10 + \epsilon > 10$, we can assure that L_k has a trapping region. Notice that we still have that $k^4(0) = 10$ but this is no longer a

periodic point and $L_k \cap \mathrm{Per}(k) = \emptyset$. Theorem 2.1(iv) states if this type of perturbation is possible for any map without a trapping region, then it can be approximated by a map with a trapping region. In terms of the application to homoclinic bifurcations of differential equations, this means that the differential equation needs to be able to be perturbed in such a way that the unstable manifold of the fixed point is not in the stable manifold of the given periodic orbit which gives the boundary orbit.

In the rest of this section, we give conditions from the thesis of Byers [2] which imply that L_f is the whole interval $[b, a]$. As stated above, Williams [18] proved this in the case when f has the same monotonicities. In the general results about a "Lorenz attractor" from a homoclinic bifurcation in Theorem 3.1, we only verify the weaker conditions of Theorem 2.1. In the "nearly symmetric" case where $C^+_{\eta_0} \approx C^-_{\eta_0}$, the results of Theorem 2.6 apply to show that there is a "Lorenz attractor" that has a one-dimensional return map with a single transitive interval.

Rather than prove directly that the map f is topologically transitive, we verify another condition called weakly locally eventually onto; Williams called a map $f : [b, a] \to [b, a]$ *locally eventually onto* (LEO) provided that for any nonempty open subinterval K there is an $n > 0$ such that $f^n(K) = [b, a]$. A map $f : [b, a] \to [b, a]$ is said to be *weakly locally eventually onto* (WLEO) provided that for any nonempty open interval $K \subset [b, a]$ there are an $n > 0$ and a finite set of points A such that $\bigcup_{i=0}^{n} f^i(K) = [b, a] \setminus A$; i.e., the forward orbit of K misses at most a finite set of points. It is easier to verify that a map is WLEO than LEO, and it still implies that the map is topologically transitive on $[b, a]$ by the Birkhoff transitivity theorem.

In proving that these maps f are WLEO, there are several cases depending on whether f is increasing or decreasing on the two subintervals $[b, c)$ and $(c, a]$. Graphs of these cases are given in Figure 2.1.

Case (i) (the original Lorenz map). The map f is increasing on both subintervals $[b, c)$ and $(c, a]$, $a = a^- > c$, $b = a^+ < c$, $b \le f(b)$, and $f(a) \le a$.

Case (ii) (the twisted Lorenz map). The map f is decreasing on both subintervals $[b, c)$ and $(c, a]$, $a = a^+ > c$, $b = a^- < c$, $f(b) \le a$, and $b \le f(a)$.

Case (iii) (variation of case (ii): the left endpoint is not a^- but is the image of a^+). The function f is decreasing on both subintervals $[b, c)$ and $(c, a]$, $a = a^+ > c$, $b = f(a) < c$, $b < a^-$, and $f(b) < a$.

Case (iv). The function f is increasing on $[b, c)$ and decreasing on $(c, a]$, $a = a^+ \ge a^- > c$, $b = f(a) < c$, and $b \le f(b)$.

Case (v). The function f is increasing for $[b, c)$ and decreasing on $(c, a]$, $a = a^- > a^+ > c$, $b = f(a) < c$, and $b \le f(b)$.

There are other cases with $a^+, a^- < c$ which are equivalent to Cases (iv) and (v) by a change of orientation which we do not list.

The proof of Williams [18] shows that in Cases (i)–(ii), if $\lambda > \sqrt{2}$ then f is LEO and transitive on all of $[b, a]$. As was shown in [2], for Cases (iv) and (v) this is not true: f is not always transitive on all of $[b, a]$ even when $\lambda > \sqrt{2}$. We state this in the following theorem.

THEOREM 2.5 (Byers). *Assume that $f : J \to \mathbb{R}$ satisfies the assumptions* (a)–(e) *above.*

In Case (iv) *above, there is a fixed point $p \in (c, a)$. Assume that $f(x) < p$ for all $x \in [b, c)$. Then f is not transitive on $[b, a]$.*

In Case (v) *above, there is an orbit of period two, $\{q^-, q^+\}$ with $q^- \in (b, c)$ and $q^+ \in (c, a)$. Assume that $c < a^+ < q^+$ and $q^- = f(q^+) < f(b) = f^2(a^-)$. Then f is not topologically transitive on $[b, a]$.*

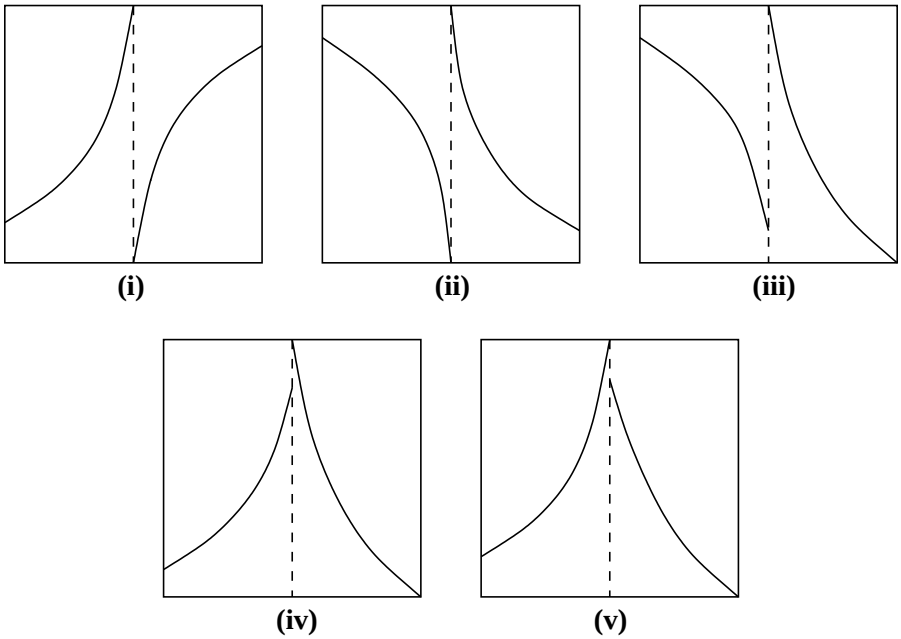

FIG. 2.1. *Graphs of Cases* (i)–(v).

Proof (idea of the proof).

Case (iv): Since $f'(x) > 1$ and $f[c, a] = [f(a), a]$, it follows that $f(a) < c$ and $f[c, a] \supset [c, a]$. Because the interval covers itself, there is a fixed point $p \in (c, a)$. (Notice that the fixed point cannot be either of the endpoints.)

This fixed point p must be repelling because $f'(x) > 1$ everywhere. There is an interval K about p which covers itself but is not in the image of any other points in $[b, a] \setminus K$. Therefore K is not contained in the transitive attractor L and f is not topologically transitive on all of $[b, a]$. See [2] for details.

An example of such a function given in [2] is

$$f(x) = \begin{cases} 1.6x + 0.35 & \text{for } -0.5 \le x < 0, \\ -1.5x + 1 & \text{for } 0 \le x \le 1. \end{cases}$$

Case (v): Let $\ell(K)$ be the length of an interval K. If $f(b) \ge c$, then $f[b, c] = [f(b), a] \subset [c, a]$ and $\ell(f[b, c]) \ge \lambda\ell([b, c])$. Then $f^2[b, c] = [b, f^2(b)]$ and $\ell(f^2[b, c]) \ge \lambda\ell(f[b, c]) \ge \lambda^2\ell([b, c])$, so this interval covers itself, $f^2[b, c] \supset [b, c]$. Thus there is a point of period two with $q^- \in [b, c]$, $q^+ = f(q^-) \in f[b, c] \subset [c, a]$. This proves the existence of a point of period two under the assumption that $f(b) \ge c$.

Otherwise, $f(b) < c$. We also have that $a^- > a^+ > c$. Then $f[b, c] \supset [c, a]$ and $f^2[b, c] \supset f[c, a] = [b, a^+] \supset [b, c]$. Again, there is a point of period two as desired.

With the assumptions of the theorem for f in Case (v), $q^+ > a^+$ and $q^- < f(b)$. Therefore there is a neighborhood K of $\{q^-, q^+\}$ made up of two intervals, which covers itself but is not in the image of any other points in $[b, a] \setminus K$. Therefore K is not contained in the transitive attractor L and f is not topologically transitive on all of $[b, a]$. See [2] for details.

An example of such a function given in [2] is

$$f(x) = \begin{cases} 1.415\,x + 1 & \text{for } -0.815 \le x \le 0, \\ -1.415\,x + 0.6 & \text{for } 0 \le x \le 1. \end{cases} \qquad \square$$

Notice that the examples given of the above theorem satisfy $\lambda > \sqrt{2}$ and are still not WLEO or topologically transitive. Therefore it is necessary to add further assumptions in order to insure that the map f is topologically transitive.

We now combine the various results in [2] into a single theorem.

THEOREM 2.6 (Byers). *Assume f satisfies assumptions* (a)–(e) *above and $\lambda > \sqrt{2}$. With the following added assumptions in each of the cases, $f|[a,b]$ is WLEO and so topologically transitive.*

In Cases (i) *or* (ii) *no added assumption is needed.*

In Case (iii), *further assume that $f(a^-) \ge p$, where $p \in (c,a)$ is the fixed point.*

In Case (iv), *where $a^+ \ge a^-$, further assume that $a^- \ge p$, where $p \in (c,a)$ is the fixed point.*

In Case (v), *where $a^- > a^+$, further assume that $a^+ \ge q^+$, where $q^+ \in (c,a]$ is the point of period two.*

Remark 2.7. Byers proved in [2] that in Case (iv) it is sufficient to assume that $(1+\sqrt{2})a^- \ge a^+$: this condition implies that $a^- \ge p$. Similarly, in Case (v) it is sufficient to assume that $(3-\sqrt{2})a^+ \ge a^-$; this condition implies that $a^+ \ge q^+$.

The proofs for all of the cases use the same basic construction due to Williams. Given an open interval $K \subset [b,a]$, we define inductively a sequence of intervals $K_i \subset [b,a]$ for $i \ge 0$. Define K_0 to be the longer component of $K \setminus \{c\}$. (Note that if $c \notin K$, then $K_0 = K$.) If K_j is defined for $0 \le j < i$, then let K_i be the longer component of $f(K_{i-1}) \setminus \{c\}$. Since $f(K_{i-1})$ is an open interval at each stage, it follows that all the K_i are open intervals.

Let $\ell(K)$ be the length of an open interval K.

LEMMA 2.8. *If $\lambda > \sqrt{2}$, then there exists an $n > 0$ such that $c \in f(K_{n-1})$ and $c \in f(K_n)$, so $c \in \partial(K_n) \cap f(K_n)$.*

Proof. If $c \notin f(K_i)$, then $\ell(K_{i+1}) \ge \lambda \ell(K_i)$. On the other hand, if $c \in f(K_i)$, then $c \in \partial(K_{i+1})$ and $\ell(K_{i+1}) \ge \frac{\lambda}{2}\ell(K_i)$. So if $c \notin f(K_{i-1}) \cap f(K_i)$ we get that

$$\ell(K_{i+1}) \ge \frac{\lambda^2}{2}\,\ell(K_{i-1}).$$

Since $\frac{\lambda^2}{2} > 1$, this cannot go on indefinitely, and there must be an $n > 0$ such that $c \in f(K_{n-1}) \cap f(K_n)$. $\square$

In the proofs below, we take n as given in the above lemma for which $c \in \partial(K_n) \cap f(K_n)$.

Proof (Case (i)). This is the case considered by Williams in [18]. We do not assume that $f(b) < c$ or $f(a) > c$. However, by modifying the argument in [18] or [11] in ways similar to the cases below, it still follows that f is WLEO. $\square$

Proof (Case (ii)). Because f expands lengths by a factor of $\lambda > 1$, it follows that $f(b) > c$ and $f(a) < c$. Therefore the proof is exactly as given before. $\square$

Proof (Case (iii)). If $K_n \subset (c,a]$, then $c \in \partial(K_n) \cap f(K_n)$ implies that

$$f(K_n) \supset [c,a) \quad \text{and} \quad f^2(K_n) \supset (b,a).$$

On the other hand, if $K_n \subset [b,c)$, then

$$
\begin{aligned}
&f(K_n) \supset (a^-, c],\\
&f^2(K_n) \supset (a^-, p] \supset [c, p],\\
&f^3(K_n) \supset [p, a^+) = [p, a), \quad \text{and}\\
&f^4(K_n) \supset (b, p].
\end{aligned}
$$

Therefore $f^3(K_n) \cup f^4(K_n) \supset (b, p] \cup [p, a) = (b, a)$. This completes the proof of this case. □

Proof (Case (iv)). This case is very similar to Case (iii). We leave the details to the reader. Also see [2]. □

Proof (Case (v)). If $K_n \subset [b, c)$, then

$$f(K_n) \supset [c, a^-) = [c, a), \quad \textit{and} \quad f^2(K_n) \supset (b, a^+) \supset (b, c].$$

Therefore $f(K_n) \cup f^2(K_n) \supset (b, a)$.

On the other hand, suppose $K_n \subset (c, a]$. Then

$$
\begin{aligned}
&f(K_n) \supset [c, a^+) \supset (c, q^+),\\
&f^2(K_n) \supset (f(a^+), a^+) \supset (q^-, c),\\
&f^3(K_n) \supset (q^+, a), \quad \textit{and}\\
&f^4(K_n) \supset (b, q^-).
\end{aligned}
$$

Therefore

$$f(K_n) \cup f^2(K_n) \cup f^3(K_n) \cup f^4(K_n) \supset (b, a) \setminus \{q^-, q^+\}.$$

This completes the proof of this case and the theorem. □

3. Statement of results for a homoclinic bifurcation. In this section we give the assumptions on flows in three dimensions which insure that a homoclinic bifurcation to a Lorenz attractor can take place. The first six assumptions, (A1)–(A6), on the parameterized differential equations concern the properties at the bifurcation value, η_0. The last assumption, (A7), is on the unfolding of the parameter η which ensures that there are parameter values that possess an attractor. The parameter space needs to be big enough to verify the assumptions of the one-dimensional map given in the last section.

(A1) We consider a C^2 vector field X_η on $\mathbb{R}^3$ which depends on the parameter η and which has a fixed point $\mathbf{Q}_\eta$ for all parameter values near η_0. We assume that the eigenvalues of $DX_\eta(\mathbf{Q}_\eta)$ are all real with $\lambda_{ss}(\eta) < \lambda_s(\eta) < 0 < \lambda_u(\eta)$ and with respective eigenvectors $\mathbf{v}^{ss}$, $\mathbf{v}^s$, and $\mathbf{v}^u$,

With this assumption, there are several invariant manifolds for the fixed point at the origin. We denote the one-dimensional unstable manifold tangent to $\mathbf{v}^u$ by $W^u(\mathbf{Q}_\eta, \eta)$ and the two-dimensional stable manifold tangent to the $\mathbf{v}^s$ and $\mathbf{v}^{ss}$ by $W^s(\mathbf{Q}_\eta, \eta)$. Next, there is a one-dimensional strong stable manifold tangent to $\mathbf{v}^{ss}$ which we denote by $W^{ss}(\mathbf{Q}_\eta, \eta)$. This latter manifold is made up of points which converge to $\mathbf{Q}_\eta$ at an asymptotic rate determined by the eigenvalue λ_{ss}. All of these manifolds are C^r if the vector field is C^r and are even real analytic if the vector field is real analytic. Finally, there is a two-dimensional manifold tangent to the two most expanding directions, $\mathbf{v}^u$ and $\mathbf{v}^s$, which we denote by $W^{eu}(\mathbf{Q}_\eta, \eta)$. This manifold

is local in the stable direction but can be extended along the unstable manifold by flowing forward in time. We call this the *extended unstable manifold* even though it is not expanding in all directions. (Some people call this the center unstable manifold.) This manifold is at least C^1 (and C^2 with assumption (A4) on the dominance of the contraction toward $W^{eu}(\mathbf{Q}_\eta, \eta)$ given by $e^{\lambda_{ss}}$ in comparison with the greatest contraction within $W^{eu}(\mathbf{Q}_\eta, \eta)$ given by e^{λ_s}.) With this notation we can make the second assumption about the existence of a homoclinic orbit. Without a symmetry assumption on the differential equations it is a codimension two condition to have a double homoclinic connection.

(A2) For the bifurcation value η_0, there is a *double homoclinic connection* with the unstable manifold of $\mathbf{Q}_{\eta_0}$ contained in the stable manifold but outside the strong stable manifold,

$$\Gamma \equiv W^u(\mathbf{Q}_{\eta_0}, \eta_0) \subset W^s(\mathbf{Q}_{\eta_0}, \eta_0) \setminus W^{ss}(\mathbf{Q}_{\eta_0}, \eta_0).$$

(The fact that Γ misses the strong stable manifold can be expressed as a transversality condition by stating that $W^u(\mathbf{Q}_{\eta_0}, \eta_0)$ is transverse to $W^{ss}(\mathbf{Q}_{\eta_0}, \eta_0)$.) In fact, we assume that the two branches $\Gamma^{\pm}$ of $\Gamma \setminus \{\mathbf{Q}_{\eta_0}\}$ are contained in the same component of $W^s(\mathbf{Q}_{\eta_0}, \eta_0) \setminus W^{ss}(\mathbf{Q}_{\eta_0}, \eta_0)$: $\Gamma = \{\mathbf{Q}_{\eta_0}\} \cup \Gamma^+ \cup \Gamma^-$.

(A3) For η_0, the two-dimensional extended unstable manifold $W^{eu}(\mathbf{Q}_{\eta_0}, \eta_0)$ is transverse to the two-dimensional stable manifold $W^s(\mathbf{Q}_{\eta_0}, \eta_0)$ along Γ.

The transversality condition in (A3) is generically satisfied and so does not add a codimension to the bifurcation. Let

$$P(\mathbf{q}) \equiv T_{\mathbf{q}} W^{eu}(\mathbf{Q}_{\eta_0}, \eta_0) \qquad \text{for } \mathbf{q} \in \Gamma.$$

Note that $P(\mathbf{Q}_{\eta_0})$ is spanned by $\mathbf{v}^u$ and $\mathbf{v}^s$. The transversality condition in (A3) together with the condition $W^u(\mathbf{Q}_{\eta_0}, \eta_0) \cap W^{ss}(\mathbf{Q}_{\eta_0}, \eta_0) = \emptyset$ in assumption (A2) implies that $P(\mathbf{q})$ converges to $P(\mathbf{Q}_{\eta_0})$ as $\mathbf{q}$ converges to $\mathbf{Q}_{\eta_0}$ along Γ by the inclination lemma (lambda lemma). Therefore $\{P(\mathbf{q}) : \mathbf{q} \in \Gamma\}$ is a continuous bundle over Γ. Considering one half of the homoclinic connection $\Gamma^+ \cup \mathbf{Q}_{\eta_0}$, let $\nu^+ = 1$ if the bundle $\{P(\mathbf{q}) : \mathbf{q} \in \Gamma^+ \cup \mathbf{Q}_{\eta_0}\}$ is orientable (not twisted) and $\nu^+ = -1$ if this bundle is nonorientable (twisted). In the same way considering the other half of the homoclinic connection $\Gamma^- \cup \mathbf{Q}_{\eta_0}$, let $\nu^- = \pm 1$ whenever the bundle $\{P(\mathbf{q}) : \mathbf{q} \in \Gamma^- \cup \mathbf{Q}_{\eta_0}\}$ is orientable or nonorientable, respectively. If the bundle is orientable, then the resulting one-dimensional map (which is discussed in the next section) is increasing on the corresponding subinterval; if the bundle is nonorientable then the resulting one-dimensional map is decreasing on the corresponding subinterval.

(A4) We assume that for η_0 the strong stable eigenvalue dominates the other two eigenvalues in the sense that

$$\lambda_{ss}(\eta_0) + [\lambda_u(\eta_0) - \lambda_s(\eta_0)] < 0 \quad \textit{and} \quad \lambda_{ss}(\eta_0) < 2\,\lambda_s(\eta_0).$$

This is an open condition and so does not add a codimension to the bifurcation. The second inequality in (A4) is what ensures that the manifold $W^{eu}(\mathbf{Q}_{\eta_0}, \eta_0)$ is C^2. See Theorem 5.1 in [6]. It is also redundant with the resonance assumption (A6) (although sometimes we want to assume (A4) but not necessarily assume (A6)). These conditions are used to prove that the one-dimensional Poincaré map is differentiable.

The next assumption on the equations is a restriction on the total change in area within the $P(q)$ directions ("within the attractor directions") when a solution travels the whole length of one of the loops Γ^+ or Γ^-.

(A5) Let $\mathbf{q}^{\pm}(t)$ be a parameterization of the solution along $\Gamma^{\pm}$. An initial vector $\mathbf{v}_0$ can be translated along the trajectory by the linearized equations (called the first variation equations in differential equations)

$$\dot{\mathbf{v}}(t) = DX_{\mathbf{q}^{\pm}(t)}\,\mathbf{v}(t)$$

to give a vector solution $\mathbf{v}(t)$ with $\mathbf{v}(0) = \mathbf{v}_0$. (If $\phi^t(\mathbf{x}_0)$ is the flow for the initial condition $\mathbf{x}_0$, then $\mathbf{v}(t) = D(\phi^t)_{\mathbf{x}_0}\mathbf{v}_0$.) One such solution is $X_\eta(\mathbf{q}^{\pm}(t))$. Let $\mathbf{v}^{\pm}(t)$ be such a solution of the linearized equations along $\mathbf{q}^{\pm}(t)$ so that $P(\mathbf{q}^{\pm}(t))$ is spanned by $\mathbf{v}^{\pm}(t)$ and $X_\eta(\mathbf{q}^{\pm}(t))$ for each t. Let $A^{\pm}(t)$ be the area of the parallelogram in $P(\mathbf{q}^{\pm}(t))$ spanned by $\mathbf{v}^{\pm}(t)$ and $X_\eta(\mathbf{q}^{\pm}(t))$. Define $C^{\pm}_{\eta_0}$ by

$$C^{\pm}_{\eta_0} = \lim_{t\to\infty} \frac{A^{\pm}(t)}{A^{\pm}(-t)}.$$

The quantity $C^{\pm}_{\eta_0}$ is the change in area within the planes $P(\mathbf{q}^{\pm})$ along the whole length of $\Gamma^{\pm}$. We assume that the limit exists and $0 < C^{\pm}_{\eta_0} < 1$. If $C^{+}_{\eta_0} \approx C^{-}_{\eta_0}$, then the interval $[b_\eta, a_\eta]$ in Lemma 4.2 is nearly symmetric about c_η and we only need $0 < C^{\pm}_{\eta_0} < 2$.

Assumption (A5) is an open condition.

Lemma 4.1 in the next section shows that $C^{\pm}_{\eta_0}$ has meaning in terms of a one-dimensional Poincaré map, f_{η_0}, as the coefficient of the lowest order nonconstant term. Therefore, $f'_{\eta_0}(c_{\eta_0}\pm) = \nu^{\pm}\,C^{\pm}_{\eta_0}$ in the sense of the one-sided limit of f' from above and below c_{η_0}. The fact that $C^{\pm}_{\eta_0} < 2$ means that f_{η_0} stretches lengths by a factor less than 2 and there is a hope that for η near η_0, f_η will map the appropriate interval $[b_\eta, a_\eta]$ inside itself (since there is one discontinuity). We restrict to $C^{\pm}_{\eta_0} < 1$ because in the proof this allows us to verify the necessary inequalities for $E_\eta = |\lambda_s(\eta)|/\lambda_u(\eta) < 1$. The fact that $C^{\pm}_{\eta} > 0$ makes it is possible for the derivative of the one-dimensional map to have absolute value greater than 1 in the desired interval for $\eta \neq \eta_0$. Lemma 4.2 gives conditions on unfolding parameters a^{+}_{η}, a^{-}_{η}, and $e_\eta = 1 - E_\eta = 1 - |\lambda_s(\eta)|/\lambda_u(\eta)$, which ensures that this interval is invariant and that the absolute value of the derivative is always bigger than 1.

In order to understand why the limit defining $C^{\pm}_{\eta_0}$ exists and to motivate the next assumption, we remember that in two dimensions the divergence gives the infinitesimal change of area. Let $\mathrm{div}_2(\mathbf{q}^{\pm}(t)) = A'(t)$ be the infinitesimal change of area within the two-dimensional planes $P(\mathbf{q}^{\pm}(t))$ as the solution $\mathbf{q}^{\pm}(t)$ moves along Γ, i.e., the "two-dimensional divergence in $P(\mathbf{q})$" along Γ. In terms of this quantity,

$$C^{\pm}_{\eta_0} = \exp\left(\int_{-\infty}^{\infty} \mathrm{div}_2(\mathbf{q}^{\pm}(t))\,dt\right).$$

The plane $P(\mathbf{q}^{\pm}(t))$ converges exponentially to the plane spanned by the eigenvectors $\mathbf{v}^s$ and $\mathbf{v}^u$ for the eigenvalues $\lambda_s(\eta_0)$ and $\lambda_u(\eta_0)$, so the quantity $\mathrm{div}_2(\mathbf{q}^{\pm}(t))$ converges exponentially to $\lambda_u(\eta_0) + \lambda_s(\eta_0)$. If $\lambda_u(\eta_0) + \lambda_s(\eta_0) \neq 0$, then $\mathrm{div}_2(\mathbf{q}^{\pm}(t)) \neq 0$ for $|t|$ large, the integral in expressing $C^{\pm}_{\eta_0}$ in terms of $\mathrm{div}_2(\mathbf{q}^{\pm}(t))$ would be $\pm\infty$, $C^{\pm}_{\eta_0}$ would be ∞ or 0, and the total change of area along $\Gamma^{\pm}$ would be ∞ or 0. On the other hand, if $\lambda_u(\eta_0) + \lambda_s(\eta_0) = 0$, then $\mathrm{div}_2(\mathbf{q}^{\pm}(t))$ converges exponentially to 0, the integral converges to a finite limit, and $C^{\pm}_{\eta_0}$ is a positive, nonzero quantity. Therefore, the final resonance assumption for η_0 makes assumption (A5) possible. This resonance condition is a codimension one condition; in total, the conditions of η_0

are codimension three. (Two codimensions are from the double homoclinic connection, and the resonance condition gives the third and final codimension.)

(A6) There is a one-to-one resonance between the unstable and weak stable eigenvalues for η_0:

$$\lambda_u(\eta_0) + \lambda_s(\eta_0) = 0.$$

Letting $E_\eta = |\lambda_s(\eta)|/\lambda_u(\eta)$ and $e_\eta = 1 - E_\eta$, this condition can be expressed by saying that $E_{\eta_0} = 1$ or $e_{\eta_0} = 0$.

The final assumption relates to the unfolding of the bifurcation.

(A7) We need to assume that the parameter space is big enough so that a_η^+, a_η^-, and $E_\eta = |\lambda_s(\eta)|/\lambda_u(\eta)$ can be varied independently for η near η_0. (If the equations are symmetric, as was the case in [12] and [13], then we need only assume that a_η^+ and E_η can be varied independently for η near η_0.)

It is now possible to state the main theorem.

THEOREM 3.1. *Assume that the vector field in $\mathbb{R}^3$, depending on a parameter η, is C^2 and satisfies assumptions* (A1)–(A7). *Let $\mathcal{N}$ be a small neighborhood of η_0 in parameter space. Then, there exists a subset $\mathcal{N}' \subset \mathcal{N}$ with nonempty interior such that $\eta_0 \in \mathrm{cl}(\mathcal{N}')$ and such that for $\eta \in \mathcal{N}'$ the flow for η has a topologically transitive weak attractor which contains the fixed point $\mathbf{Q}_\eta$. In fact, the weak attractor is determined by a one-dimensional Poincaré map f_η which is WLEO on a finite union of closed intervals L_η containing a single point of discontinuity in its interior. The values of $\nu^\pm$ determine whether the attractor is orientable or not on the two branches. If the vector field is C^3, then the resulting one-dimensional Poincaré map f_η for $\eta \in \mathcal{N}'$ has an ergodic invariant measure with support equal to the whole invariant set L_η and equivalent to Lebesgue on L_η.*

The proof of the theorem is contained in the next section.

Remark 3.2. The fact that the flow satisfies assumptions (A1)–(A4) means that standard stable manifold theory applies to show that the problem can be reduced to a one-dimensional Poincaré map. Thus, with the given assumptions, the proof of the theorem reduces to analyzing the unfolding of the one-dimensional map and showing that we can get the situation discussed in Theorem 2.1. The three unfolding parameters of the one-dimensional map are e_η and the two constant terms $a_\eta^\pm$ which are defined in Lemma 4.1. The proof indicates more fully what part of the parameter space yields an attractor. This is discussed more fully in section 5.

Remark 3.3. Although we call these Lorenz attractors for the differential equations, if the equations are very nonsymmetric (C_η^+ and C_η^- have very different values) then the one-dimensional Poincaré map will be transitive on a set made up of a finite number of intervals and not just one. In other words, the results of Morales–Pujals and Choi apply rather than Byers' extension of the result of Williams. Therefore all we verify is that the invariant set is a weak attractor. We believe that for a dense and open set of values $\eta \in \mathcal{N}'$, the invariant set is an attractor and not just a weak attractor. To prove this would require showing that by changing the parameters e_η and $a_\eta^\pm$, it is possible to realize the type of perturbations of the one-dimensional map f_η indicated in Theorem 2.1(b)(iv).

Remark 3.4. If the equations are nearly symmetric in the sense that

$$\sqrt{2} - 1 < \frac{C_{\eta_0}^+}{C_{\eta_0}^-} < \frac{1}{\sqrt{2} - 1},$$

then it is possible to insure that the derivative is greater than $\sqrt{2}$ in absolute value. For these parameters the equations have an attractor and the one-dimensional map is topologically transitive on a single interval I_η. Theorem 2.6 is only used to show that this remark is true and not in the proof of Theorem 3.1 as stated.

Remark 3.5. The existence of an ergodic invariant measure follows as in [13], using the result of Keller [7].

4. Proof of the theorem from the assumptions. We begin the proof by discussing the construction of the Poincaré map from the homoclinic connection and its form as given in [13].

Let Σ be a transversal to both $\Gamma^{\pm}$ out a short distance along the local stable manifold of $\mathbf{Q}_{\eta_0}$. The section can be taken with one component since we are assuming both branches of $\Gamma^{\pm}$ are in the same component of $W^s(\mathbf{Q}_{\eta_0}) \setminus W^{ss}(\mathbf{Q}_{\eta_0})$. There is a neighborhood $V \subset \Sigma$ of $\Gamma \cap \Sigma$ such that points in $V \setminus W^s(\mathbf{Q}_{\eta_0})$ return to Σ for $\eta = \eta_0$, defining a Poincaré map

$$F_{\eta_0} : V \setminus W^s(\mathbf{Q}_{\eta_0}, \eta_0) \subset \Sigma \to \Sigma.$$

Since the flow varies continuously with the parameter, the Poincaré map is defined for η near enough to η_0,

$$F_\eta : V \setminus W^s(\mathbf{Q}_\eta, \eta) \subset \Sigma \to \Sigma.$$

In [13], it was shown that assumption (A4) implies that the flow has an invariant continuous bundle of strong stable directions over Γ, $\{E^{ss}(\mathbf{q}) : \mathbf{q} \in \Gamma\}$, with $E^{ss}(\mathbf{Q}_{\eta_0}, \eta_0) = \langle \mathbf{v}^{ss} \rangle$. These conditions are open, so this bundle exists not only over Γ for η_0 but also over a neighborhood of Γ for nearby η. Then the stable manifold theory implies that there is a $C^{1+\mu}$ (C^1 plus μ-Hölder for some $\mu > 0$) invariant strong stable foliation in a neighborhood of Γ for η near η_0. If we take the union of these locally along an orbit and then intersect these with Σ, we get a one-dimensional foliation of Σ which is invariant by F_η. The projection along the leaves of the strong stable manifolds of orbits defines a map $\pi_\eta : \Sigma \to \Sigma^1$. By changing the orientation of Σ^1 if necessary, we can insure that we do not have $\nu^- = -1$ and $\nu^+ = 1$. (This last case can be changed into $\nu^- = 1$ and $\nu^+ = -1$.) The projection π_η can be used to define a one-dimensional map

$$f_\eta : V^1 \setminus \{c_\eta\} \subset \Sigma^1 \to \Sigma^1$$

by $f_\eta(\pi_\eta \mathbf{q}) = \pi_\eta F_\eta(\mathbf{q})$, where $V^1 = \pi_\eta(V)$ and $c_\eta = \pi_\eta(W^s(\mathbf{Q}_\eta, \eta) \cap V)$ is the point of discontinuity.

We need to analyze the one-dimensional map well enough to show that for correctly chosen parameter values it has a transitive invariant set containing the point of discontinuity. The next lemma, which was proved in [12] and [13], gives an expansion of the map which is used to prove the existence of such a set. First we label the constant terms of the expansion of f_η; let

$$a_\eta^{\pm} = \limsup_{\tau \to c_\eta \pm} f_\eta(\tau).$$

This quantity corresponds to the signed distance of $\Gamma_\eta^{\pm} \subset W^u(\mathbf{Q}_\eta, \eta)$ from $W^s(\mathbf{Q}_\eta, \eta)$ as measured in Σ^1.

LEMMA 4.1. *Assume assumptions* (A1)–(A4) *are satisfied. Let* E_η *and* $C_{\eta_0}^{\pm}$ *be defined as in assumptions* (A6) *and* (A5). *Let* $c_\eta = \pi(W^s(\mathbf{Q}_\eta, \eta) \cap V)$. *Let* $J \subset \Sigma^1$

be a fixed small interval about c_{η_0}. For η in a small neighborhood of η_0, the induced one-dimensional Poincaré map $f_\eta : J \setminus \{c_\eta\} \subset \Sigma^1 \to \Sigma^1$ has continuous derivative on $J \setminus \{c_\eta\}$, and f_η and f'_η have the following form:

$$f_\eta(\tau) = \begin{cases} a_\eta^+ + \nu^+ C_\eta^+ |\tau - c_\eta|^{E_\eta} + o(|\tau - c_\eta|^{E_\eta}) & \text{for } \tau > c_\eta, \\ a_\eta^- - \nu^- C_\eta^- |\tau - c_\eta|^{E_\eta} + o(|\tau - c_\eta|^{E_\eta}) & \text{for } \tau < c_\eta, \end{cases}$$

$$f'_\eta(\tau) = \begin{cases} \nu^+ E_\eta C_\eta^+ |\tau - c_\eta|^{E_\eta - 1} + o(|\tau - c_\eta|^{E_\eta - 1}) & \text{for } \tau > c_\eta, \\ \nu^- E_\eta C_\eta^- |\tau - c_\eta|^{E_\eta - 1} + o(|\tau - c_\eta|^{E_\eta - 1}) & \text{for } \tau < c_\eta. \end{cases}$$

The constants $C_\eta^\pm$ depend continuously on η.

See [13] for the lemma's proof. The proof uses either (i) linearization near the fixed point or (ii) the analysis of the flow past the fixed point using a normal form of the vector field. Also see [14].

Let $a_\eta = \max\{a_\eta^-, a_\eta^+\}$ and $b_\eta = \min\{a_\eta^-, a_\eta^+, f(a_\eta)\}$. We are interested in parameter values η for which $b_\eta < c_\eta < a_\eta$. In order to have an expanding attractor for these parameter values, we also need f_η to preserve the interval $[b_\eta, a_\eta]$ and the absolute value of the derivative to be greater than 1 for points in the interval.

The three unfolding parameters that we use are $a_\eta^\pm$ and e_η. The parameters $a_\eta^\pm$ measure the extent to which the homoclinic connections are broken (and to which sides). The quantity $e_\eta = 1 - E_\eta = 1 - |\lambda_s(\eta)|/\lambda_u(\eta)$ measures the extent to which the two eigenvalues are no longer in resonance.

For the three allowable cases of $\nu^\pm$, if we take parameter values η for which $\nu^+(a_\eta^+ - c_\eta) < 0$ and $\nu^-(a_\eta^- - c_\eta) > 0$, then $a_\eta > c_\eta$.

Lemma 4.2 proves that η_0 can be approximated by parameter values η for which $f_\eta([b_\eta, c_\eta)) \subset [b_\eta, a_\eta]$, $f_\eta((c_\eta, a_\eta]) \subset [b_\eta, a_\eta]$, $|f'_\eta(a_\eta)| > 1$, and $|f'_\eta(b_\eta)| > 1$. Since $|f'_\eta(a_\eta)| > 1$ and $|f'_\eta(b_\eta)| > 1$, the form of f'_η given in Lemma 4.1 implies that there is a $\lambda > 1$ such that $|f'_\eta(\tau)| \geq \lambda$ for all $\tau \in [b_\eta, a_\eta]$. By the result of Morales and Pujals [9] summarized in Theorem 2.1(a), this implies that there is a transitive invariant set L_{f_η} containing c_η which is a weak attractor. Because the one-dimensional map can be varied by changing the flow, if there is a periodic point on the boundary of L_{f_η} then it seems likely that it can be perturbed away. If this is indeed the case, then by the results of [3] summarized in Theorem 2.1(b), either L_η is an attractor for f_η or η can be perturbed to η' for which $L_{\eta'}$ is an attractor for $f_{\eta'}$. Because of the relationship between the flow and the one-dimensional Poincaré map, this shows that the flow for η has a transitive weak attractor as claimed in the theorem. Most likely it can be approximated by a parameter η' which has a transitive attractor as discussed in Remark 3.3. The claim about the ergodic measure for the one-dimensional map follows just as in [13] using the result of Keller [7]. Thus we only need to prove the following lemma.

LEMMA 4.2. *Let*

$$\begin{aligned} \mathcal{N}' = \{\eta \in \mathcal{N} : e_\eta > 0,\ \nu^+(a_\eta^+ - c_\eta) < 0,\ \nu^-(a_\eta^- - c_\eta) > 0, \\ f([b_\eta, c_\eta)) \subset [b_\eta, a_\eta],\ f((c_\eta, a_\eta]) \subset [b_\eta, a_\eta], \\ |f'_\eta(a_\eta)| > 1,\ |f'_\eta(b_\eta)| > 1\ \}. \end{aligned}$$

Then $\mathcal{N}' \neq \emptyset$ and $\eta_0 \in \mathrm{cl}(\mathcal{N}')$. The conditions on e_η and $a_\eta^\pm$ which ensure that $\eta \in \mathcal{N}'$ are given by inequality (4.1) *below when $\nu^+ = \nu^- = 1$ and by inequality* (4.3) *when $\nu^+ = \nu^- = -1$.*

Remark 4.3. When $\nu^+ = \nu^- = \pm 1$, the interval found for $\eta \in \mathcal{N}'$ extends from a_η^- to a_η^+ and satisfies

$$\frac{\log|a_\eta^+ - c_\eta|}{\log|a_\eta^- - c_\eta|} \approx \frac{\log(C_\eta^+)}{\log(C_\eta^-)}.$$

Note that for $C_\eta^- \neq C_\eta^+$, the interval is not symmetric about c_η.

When $\nu^- = -\nu^+ = 1$, the parameters found for $\eta \in \mathcal{N}'$ satisfy $a_\eta^+ \approx a_\eta^-$. One end of the interval is $a_\eta = \max\{a_\eta^+, a_\eta^-\}$, and the other end is $b_\eta = f_\eta(a_\eta)$. In the proof below we show that

$$\max\left\{0, \frac{C_\eta^+}{C_\eta^-} - 1\right\} < \frac{c_\eta - b_\eta}{a_\eta - c_\eta} < \frac{C_\eta^+}{C_\eta^-}.$$

Again, the interval is not symmetric about c_η when $C_\eta^- \neq C_\eta^+$.

Proof. First consider the case when $\nu^+ = \nu^- = 1$. These maps fall into Case (i). To get a transitive attractor, we take parameter values such that $a_\eta = a_\eta^- > c_\eta$ and $b_\eta = a_\eta^+ < c_\eta$. If $C_\eta^+ = C_\eta^-$ (as in the symmetric case), we can take $a_\eta^+ - c_\eta \approx -(a_\eta^- - c_\eta)$; this is the situation considered in Lemma 2 of [13]. We need to allow C_η^+ to have a value very different from C_η^- even though both are in the interval $(0, 2)$. We want the derivative to be greater than 1:

$$\begin{aligned} &1 < |f_\eta'(a_\eta)| \approx E_\eta C_\eta^+ |a_\eta^- - c_\eta|^{E_\eta - 1} \quad \textit{and} \\ &1 < |f_\eta'(b_\eta)| \approx E_\eta C_\eta^- |a_\eta^+ - c_\eta|^{E_\eta - 1}. \end{aligned}$$

Also, we need the interval $[b_\eta, a_\eta]$ to be invariant, so

$$\begin{aligned} &|a_\eta^- - c_\eta| + |c_\eta - a_\eta^+| \geq |f_\eta(a_\eta^-) - a_\eta^+| \approx C_\eta^+ |a_\eta^- - c_\eta|^{E_\eta} \quad \textit{and} \\ &|a_\eta^- - c_\eta| + |c_\eta - a_\eta^+| \geq |f_\eta(a_\eta^+) - a_\eta^-| \approx C_\eta^- |a_\eta^+ - c_\eta|^{E_\eta}. \end{aligned}$$

Thus the conditions on a_η^+, a_η^-, and e_η are approximately the following:

$$\begin{aligned} -\log(E_\eta C_\eta^-) < &e_\eta \log(|a_\eta^+ - c_\eta|^{-1}) < \log\left(1 + \left|\frac{a_\eta^- - c_\eta}{a_\eta^+ - c_\eta}\right|\right) - \log(C_\eta^-), \\ -\log(E_\eta C_\eta^+) < &e_\eta \log(|a_\eta^- - c_\eta|^{-1}) < \log\left(1 + \left|\frac{a_\eta^+ - c_\eta}{a_\eta^- - c_\eta}\right|\right) - \log(C_\eta^+). \end{aligned} \tag{4.1}$$

Since E_η goes to 1 as η goes to η_0, these conditions can be solved at the same time, with

$$\frac{\log(|a_\eta^+ - c_\eta|^{-1})}{\log(|a_\eta^- - c_\eta|^{-1})} \approx \frac{\log(C_\eta^-)}{\log(C_\eta^+)}. \tag{4.2}$$

When both $C_{\eta_0}^+, C_{\eta_0}^- < 1$, the resulting value of e_η can be made positive. If $C_{\eta_0}^+ \approx C_{\eta_0}^-$, then the interval is nearly symmetric, $\log\left(1 + \left|\frac{a_\eta^- - c_\eta}{a_\eta^+ - c_\eta}\right|\right) \approx \log(2)$, and we need only $C_{\eta_0}^\pm < 2$.

Next consider the case when $\nu^+ = \nu^- = -1$. These maps could fall into Cases (ii) or (iii), but we just use Case (ii) to show that parameter values exist. Again the

symmetric case was considered in [13]. In the general (possibly nonsymmetric) case, we choose parameter values so that $a_\eta = a_\eta^+ > c_\eta$ and $b_\eta = a_\eta^- < c_\eta$. We want

$$\begin{aligned} 1 < |f'_\eta(a_\eta)| &\approx E_\eta C_\eta^+ |a_\eta^+ - c_\eta|^{E_\eta - 1} \quad \textit{and} \\ 1 < |f'_\eta(b_\eta)| &\approx E_\eta C_\eta^- |a_\eta^- - c_\eta|^{E_\eta - 1}. \end{aligned}$$

Also, we need the interval $[b_\eta, a_\eta]$ to be invariant, so

$$\begin{aligned} |a_\eta^- - c_\eta| + |c_\eta - a_\eta^+| \geq |f_\eta(a_\eta^+) - a_\eta^+| &\approx C_\eta^+ |a_\eta^+ - c_\eta|^{E_\eta} \quad \textit{and} \\ |a_\eta^- - c_\eta| + |c_\eta - a_\eta^+| \geq |f_\eta(a_\eta^-) - a_\eta^-| &\approx C_\eta^- |a_\eta^- - c_\eta|^{E_\eta}. \end{aligned}$$

Thus the conditions on a_η^+, a_η^-, and e_η are approximately the following:

$$\begin{aligned} -\log(E_\eta C_\eta^+) < & e_\eta \log(|a_\eta^+ - c_\eta|^{-1}) < \log\left(1 + \left|\frac{a_\eta^- - c_\eta}{a_\eta^+ - c_\eta}\right|\right) - \log(C_\eta^+), \\ -\log(E_\eta C_\eta^-) < & e_\eta \log(|a_\eta^- - c_\eta|^{-1}) < \log\left(1 + \left|\frac{a_\eta^+ - c_\eta}{a_\eta^- - c_\eta}\right|\right) - \log(C_\eta^-). \end{aligned} \tag{4.3}$$

Again when both $C_\eta^+, C_\eta^- < 1$, these conditions can be solved at the same time with $e_\eta > 0$ and

$$\frac{\log(|a_\eta^+ - c_\eta|^{-1})}{\log(|a_\eta^- - c_\eta|^{-1})} \approx \frac{\log(C_\eta^+)}{\log(C_\eta^-)}. \tag{4.4}$$

We could enlarge the set of allowable parameter values to include those which give one-dimensional maps that fall into Case (iii) as long as $a_\eta^- - f_\eta(a_\eta^+)$ is small enough.

Finally, we consider the case when $\nu^+ = -1$ and $\nu^- = 1$. (The case with $\nu^+ = 1$ and $\nu^- = -1$ can be reduced to this case by reversing orientation of Σ^1.) These maps fall into Cases (iv) or (v). We first take parameter values η so that $a_\eta = a_\eta^- = a_\eta^+ > c_\eta$. After we obtain the result in this case, the interval remains invariant with absolute value of the derivative greater than 1 for $|a_\eta^+ - a_\eta^-|$ small and $a_\eta = \max\{a_\eta^-, a_\eta^+\}$.

Set $b_\eta = f_\eta(a_\eta)$. Thus $f_\eta[c_\eta, a_\eta] = [b_\eta, a_\eta]$ maps inside the relevant interval. We need to check that $|f'_\eta(a_\eta)| > 1$, $|f'_\eta(b_\eta)| > 1$, and $f_\eta(b_\eta) > b_\eta$. The last condition ensures that $f_\eta[b_\eta, a_\eta] \subset [b_\eta, a_\eta]$.

The derivative at a_η must satisfy

$$1 < |f'_\eta(a_\eta)| \approx E_\eta C_\eta^+ |a_\eta - c_\eta|^{-e_\eta}$$

or

$$-\log(C_\eta^+ E_\eta) < e_\eta \log(|a_\eta - c_\eta|^{-1}).$$

Next, we need $f_\eta(b_\eta) > b_\eta$. Since

$$\begin{aligned} f_\eta(b_\eta) - b_\eta &\approx f_\eta(a_\eta - C_\eta^+ (a_\eta - c_\eta)^{E_\eta}) - a_\eta + C_\eta^+ (a_\eta - c_\eta)^{E_\eta} \\ &\approx a_\eta - C_\eta^- [-a_\eta + C_\eta^+ (a_\eta - c_\eta)^{E_\eta} + c_\eta]^{E_\eta} - a_\eta + C_\eta^+ (a_\eta - c_\eta)^{E_\eta} \\ &= (a_\eta - c_\eta)^{E_\eta} \{C_\eta^+ - C_\eta^- [C_\eta^+ (a_\eta - c_\eta)^{-e_\eta} - 1]^{E_\eta}\}, \end{aligned}$$

$f_\eta(b_\eta) - b_\eta > 0$ provided

$$\frac{C_\eta^+}{C_\eta^-} > [C_\eta^+(a_\eta - c_\eta)^{-e_\eta} - 1]^{E_\eta}.$$

Since E_η converges to 1, this is approximately the inequality

$$\frac{C_\eta^+}{C_\eta^-} > C_\eta^+(a_\eta - c_\eta)^{-e_\eta} - 1 \quad or \quad \frac{1}{C_\eta^-} + \frac{1}{C_\eta^+} > (a_\eta - c_\eta)^{-e_\eta}.$$

This is the second inequality we need to satisfy. Thus these two conditions are satisfied provided (approximately)

$$\log\left(\frac{1}{C_\eta^+ E_\eta}\right) < e_\eta \log(|a_\eta - c_\eta|^{-1}) < \log\left(\frac{1}{C_\eta^-} + \frac{1}{C_\eta^+}\right). \tag{4.5}$$

These two inequalities can be satisfied at the same time.

To check that $|f'_\eta(b_\eta)| > 1$, we need to consider two subcases: (i) $1 > C_{\eta_0}^- > C_{\eta_0}^+ > 0$ and (ii) $1 > C_{\eta_0}^+ \geq C_{\eta_0}^- > 0$. First, define the comparison of the lengths of the two sides of the interval $[b_\eta, a_\eta]$ by

$$\gamma_\eta = \frac{c_\eta - f_\eta(a_\eta)}{a_\eta - c_\eta} = \frac{c_\eta - b_\eta}{a_\eta - c_\eta}.$$

We see below that $0 < \gamma_\eta < 1$ for subcase (i) and $\gamma_\eta > -1 + C_\eta^+/C_\eta^-$ for subcase (ii), which can often be greater than 1. Using Lemma 4.1 and the definition of γ_η,

$$\begin{aligned} a_\eta - b_\eta &\approx C_\eta^+(a_\eta - c_\eta)^{E_\eta}, \\ a_\eta - b_\eta &= a_\eta - c_\eta + c_\eta - b_\eta \\ &= (1 + \gamma_\eta)(a_\eta - c_\eta), \quad \text{so} \\ (1 + \gamma_\eta) &\approx C_\eta^+(a_\eta - c_\eta)^{-e_\eta}. \end{aligned}$$

For the first subcase (i) when $1 > C_{\eta_0}^- > C_{\eta_0}^+ > 0$, using (4.5),

$$\begin{aligned} 1 + \gamma_\eta &\approx C_\eta^+(a_\eta - c_\eta)^{-e_\eta}, \\ 1 < C_\eta^+(a_\eta - c_\eta)^{-e_\eta} &< 1 + \frac{C_\eta^+}{C_\eta^-}, \quad \text{so} \\ 0 < \gamma_\eta &< \frac{C_\eta^+}{C_\eta^-} < 1. \end{aligned}$$

Therefore, for parameters satisfying (4.5),

$$\begin{aligned} |f'_\eta(b_\eta)| &\approx E_\eta C_\eta^- |b_\eta - c_\eta|^{-e_\eta} \\ &\approx E_\eta C_\eta^- \gamma_\eta^{-e_\eta} |a_\eta - c_\eta|^{-e_\eta} \\ &> \frac{C_\eta^-}{C_\eta^+} \gamma_\eta^{-e_\eta} \\ &> \frac{C_\eta^-}{C_\eta^+} > 1, \end{aligned}$$

since $\gamma_\eta^{-1} > 1$. Thus for this subcase all three conditions are satisfied for parameters satisfying (4.5).

Now consider subcase (ii) when $1 > C^+_{\eta_0} \geq C^-_{\eta_0} > 0$. Again

$$|f'_\eta(b_\eta)| \approx E_\eta C^-_\eta \gamma_\eta^{-e_\eta} |a_\eta - c_\eta|^{-e_\eta}.$$

Inequality (4.5) together with the fact that $1 + \gamma_\eta \approx C^+_\eta (a_\eta - c_\eta)^{-e_\eta}$ imply that γ_η is bounded as η converges to η_0 in $\mathcal{N}'$. Therefore $E_\eta \gamma_\eta^{-e_\eta}$ converges to 1 as η converges to η_0 in $\mathcal{N}'$. Therefore the inequality $|f'_\eta(b_\eta)| > 1$ is (essentially) equivalent to

$$-\log(C^-_\eta) < e_\eta \log(|a_\eta - c_\eta|^{-1}).$$

Since $-\log(C^+_\eta) < -\log(C^-_\eta)$, this implies that all three conditions are satisfied in this subcase provided

$$\log\left(\frac{1}{C^-_\eta}\right) < e_\eta \log(|a_\eta - c_\eta|^{-1}) < \log\left(\frac{1}{C^-_\eta} + \frac{1}{C^+_\eta}\right). \tag{4.6}$$

Notice that for these parameters

$$\frac{C^+_\eta}{C^-_\eta} < C^+_\eta (a_\eta - c_\eta)^{-e_\eta} \approx 1 + \gamma_\eta < 1 + \frac{C^+_\eta}{C^-_\eta}, \quad \text{so}$$
$$0 \leq \frac{C^+_\eta}{C^-_\eta} - 1 < \gamma_\eta < \frac{C^+_\eta}{C^-_\eta},$$

which can be quite large if the system is very asymmetrical. This completes the proof of the lemma and theorem. □

5. Unfolding of the bifurcation. To make the discussion simpler, we assume that $c_\eta \equiv 0$. We assume that $0 < C^\pm_{\eta_0} < 1$ since this is the situation that leads to an attractor of Lorenz type. In fact, the situation we verify for specific equations in this paper and the papers [12], [13] has $0 < C^\pm_{\eta_0} << 1$. We discuss the cases $\nu^+ = \nu^- = \pm 1$ and $\nu^- = -\nu^+$ separately. In each case we take the relationship between a^+_η and a^-_η found in the proof of Lemma 4.2 so there are only two parameters, $e_\eta = 1 - E_\eta$ and either a^+_η or a^-_η

First consider $\nu^+ = \nu^- = 1$. By (4.2), $a^+_\eta \approx -|a^-_\eta|^\kappa$, where $\kappa = \log(C^-_\eta)/\log(C^+_\eta)$. So, we can use the two parameters $a_\eta = a^-_\eta$ and $e_\eta = 1 - E_\eta$.

The region of parameters labeled (ii) in Figure 5.1 is the region $\mathcal{N}'$ found in Theorem 3.1, which corresponds to systems with an attractor of Lorenz type. As a consequence of inequality (4.1) in the proof of Lemma 4.2, the boundary of $\mathcal{N}'$ is contained in $\partial\mathcal{N}$, γ_1, and γ_2, where the latter two are given approximately by

$$\gamma_1 : \quad e_\eta \log(|a^-_\eta|^{-1}) \approx \log\left(\frac{1}{C^+_\eta}\right), \quad a^-_\eta > 0,$$
$$\gamma_2 : \quad e_\eta \log(|a^-_\eta|^{-1}) \approx \log\left(\frac{1}{C^+_\eta}\right) + \log(1 + |a^-_\eta|^{\kappa-1}), \quad a^-_\eta > 0.$$

Notice that in the symmetric case $\kappa = 1$ and

$$\gamma_2 : \quad e_\eta \log(|a^-_\eta|^{-1}) \approx \log\left(\frac{2}{C^+_\eta}\right),$$

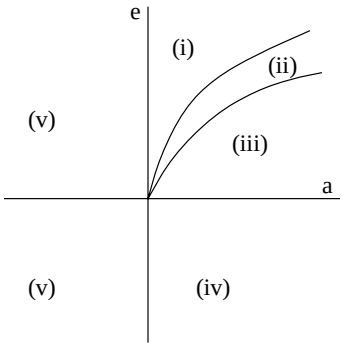

FIG. 5.1. *Bifurcation diagram.*

which is the form of the boundary given in [12] and [13].

Region (iii) in Figure 5.1: In this case the absolute value of the derivative is not greater than 1 at all points in $[a_\eta^+, a_\eta^-]$. However, for many of these parameters, the map is still eventually expanding and there is a transitive attractor. We do not attempt to analyze these cases more thoroughly.

Region (i) in Figure 5.1: In this region $a_\eta^- > 0$ and e_η is above γ_2. It follows that (a) $|f(a_\eta^-)| > a_\eta^-$, (b) the interval $[a_\eta^+, a_\eta^-]$ is not invariant, and (c) there is a horseshoe that is separated from the fixed point of the flow.

Region (iv) in Figure 5.1: In this case there is an attracting periodic orbit. See Remark 5.1 below.

Region (v) in Figure 5.1: Because $a_{\eta_0}^- < 0$, the discontinuity 0 is not in the image of the map, so there is no invariant set that bifurcates off near the homoclinic orbit.

The case for $\nu^- = \nu^+ = -1$ is very similar. By (4.4), $a_\eta^- \approx -|a_\eta^+|^\kappa$, where the exponent $\kappa = \log(C_\eta^-)/\log(C_\eta^+)$. So, we can use the two parameters $a_\eta = a_\eta^+$ and $e_\eta = 1 - E_\eta$. The interval is $[a_\eta^-, a_\eta^+]$.

Again the region of parameters labeled (ii) in Figure 5.1 is the region $\mathcal{N}'$ found in Theorem 3.1, which corresponds to systems with an attractor of Lorenz type. As a consequence of inequality (4.3) in the proof of Lemma 4.2, the boundary of $\mathcal{N}'$ is contained in $\partial\mathcal{N}$, γ_1, and γ_2, where the latter two are given approximately by

$$\gamma_1 : \quad e_\eta \log(|a_\eta^+|^{-1}) \approx \log\left(\frac{1}{C_\eta^+}\right), \quad a_\eta^+ > 0,$$

$$\gamma_2 : \quad e_\eta \log(|a_\eta^+|^{-1}) \approx \log\left(\frac{1}{C_\eta^+}\right) + \log(1 + |a_\eta^+|^{\kappa-1}), \quad a_\eta^+ > 0.$$

The other regions are similar to the previous case.

Finally we consider the case when $\nu^- = -\nu^+ = 1$. In this case we take $a_\eta = a_\eta^+ = a_\eta^-$. By inequalities (4.5) and (4.6), the two boundary components of region (ii) are now given approximately by

$$\gamma_1 : \quad e_\eta \log(|a_\eta^+|^{-1}) \approx \max\left\{\log\left(\frac{1}{C_\eta^+}\right), \log\left(\frac{1}{C_\eta^-}\right)\right\}, \quad a_\eta > 0,$$

$$\gamma_2 : \quad e_\eta \log(|a_\eta^+|^{-1}) \approx \log\left(\frac{1}{C_\eta^+} + \frac{1}{C_\eta^-}\right), \quad a_\eta^+ > 0, \quad a_\eta > 0.$$

The other regions are very similar to the situation of the previous cases.

Remark 5.1. Rovella [15] showed that there are flows with $E_\eta > 1$ and $\nu^\pm = 1$ that have transitive attractors. Such an attractor has a one-dimensional Poincaré map whose derivative is zero at the discontinuity. Rovella showed that the method of Benedicks and Carleson [1] could be used to show that there is a transitive attractor for a positive set of parameter values. These results should also apply when $\nu^\pm = -1$, but the case for $\nu^- = -\nu^+$ is very different and it is not clear that this argument applies.

These attractors do not occur in our unfolding for $\nu^- = \nu^+ = 1$ because (in the symmetric case) in order for $f_\eta(a_\eta^+) > c_\eta$ it is necessary for $C_\eta^+ > 1$ and we consider only $0 < C_\eta^+, C_\eta^- < 1$. On the other hand, if $C_{\eta_0}^+ = C_{\eta_0}^- > 1$ and $\nu^+ = \nu^- = \pm 1$, it seems likely that an attractor of the type found by Rovella occurs in the unfolding.

6. Specific differential equations satisfying the assumptions. In the previous papers [12] and [13] we showed that there were symmetric differential equations satisfying assumptions (A1)–(A7) with $\nu^+ = \nu^- = 1$ or $\nu^+ = \nu^- = -1$. In this section, we show that there is a polynomial differential equation satisfying (A1)–(A7) with $\nu^+ = -1$ and $\nu^- = 1$. The basic idea of the example is the same as before, but the equations need to be modified so that the twisting is different on the two sides. Because of the difference, it is no longer possible to make the equations have symmetry. Most of the verification of the assumptions is very straightforward. The two things that need to be checked more carefully are the transversality of assumption (A3) and the bound on the coefficients $C_{\eta_0}^\pm$ in assumption (A5).

The equations we consider are

$$\text{(NSE)} \qquad \begin{aligned} \dot{x} &= y, \\ \dot{y} &= x - 2\,x^3 - \alpha\,y + \beta\,x^2 y + \epsilon\,x^3 y + xyz, \\ \dot{z} &= -\gamma\,z + \delta\,x^2. \end{aligned}$$

The parameters are $\eta = (\alpha, \beta, \gamma, \delta, \epsilon)$. The changes from the equations considered in the previous papers [12] and [13] are that in the $\dot{y}$ equation we have added the term $\epsilon\,x^3 y$ and the term xyz replaces yz in [12] and xz in [13].

The fixed point $\mathbf{0}$ is always the origin. The linearization of the vector field is given by

$$DX_{(x,y,z)} = \begin{pmatrix} 0 & 1 & 0 \\ 1 - 6x^2 + 2\beta xy + 3\epsilon x^2 y + yz & -\alpha + \beta x^2 + \epsilon x^3 + xz & xy \\ 2\delta x & 0 & -\gamma \end{pmatrix}.$$

At the origin, the eigenvalues are $\lambda_{ss} = -\alpha/2 - (1 + \alpha^2/4)^{1/2}$, $\lambda_u = -\alpha/2 + (1 + \alpha^2/4)^{1/2}$, and $\lambda_s = -\gamma$, giving assumption (A1).

By picking the parameter $\gamma_0 = \lambda_u = -\alpha_0/2 + (1 + \alpha_0^2/4)^{1/2}$ at the bifurcation, we can insure that $\lambda_s(\eta_0) + \lambda_u(\eta_0) = 0$, giving assumption (A6).

To obtain (A4), we need the combination of all three eigenvalues less than zero, $\lambda_{ss}(\eta_0) - \lambda_s(\eta_0) + \lambda_u(\eta_0) < 0$:

$$\begin{aligned} 0 &> [-\alpha_0/2 - (1 + \alpha_0^2/4)^{1/2}] + 2[-\alpha_0/2 + (1 + \alpha_0^2/4)^{1/2}] \\ &> -3\alpha_0/2 + (1 + \alpha_0^2/4)^{1/2} \end{aligned}$$

or

$$\alpha_0 > 2^{-\frac{1}{2}}.$$

Thus to obtain a C^1 foliation, it is not possible to take a small perturbation of the integrable case where $\alpha = \beta = \delta = 0$. Given the resonance condition (A6), the second inequality in (A4) follows from the first.

To verify assumptions (A2), (A3), and (A5), we start with $\delta_1 = 0$. By adjusting the parameter values β_1 and ϵ_1 we can make a double homoclinic connection with $\delta_1 = 0$. For $\delta_1 = 0$ the (x, y)-plane is invariant and $W^u(\mathbf{0}, \eta_1) \subset W^{ss}(\mathbf{0}, \eta_1)$, so (A2) is not true. Just as in [13], we can perturb δ_1 to $\delta_0 > 0$ and adjust β_1 to β_0 and ϵ_1 to ϵ_0 to keep the double homoclinic connection. Because the $\delta_0 x^2$ term is positive in $\dot{z}$, the unstable manifold $W^u(\mathbf{0}, \eta_0)$ is pushed upward and $W^{ss}(\mathbf{0}, \eta_0)$ is pushed downward, giving assumption (A2), $W^u(\mathbf{0}, \eta_0) \cap W^{ss}(\mathbf{0}, \eta_0) = \emptyset$. Following the argument in [13], our Lemma 6.1 proves that after this perturbation with $\delta_0 > 0$ but small, the transversality condition of assumption (A3) is satisfied and that $0 < C_{\eta_0} < 2$ as required in assumption (A5). It also proves that $\nu^+ = -1$ and $\nu^- = -1$.

The unfolding assumption (A7) is satisfied because changing γ varies e_η while β and ϵ can adjust $a_\eta^\pm$ independently. Thus all that is left to prove is the following lemma.

LEMMA 6.1. *For $\delta_0 > 0$ but small, $W^{eu}(\mathbf{0}, \eta_0)$ is transverse to $W^s(\mathbf{0}, \eta_0)$, $0 < C_{\eta_0}^\pm << 1$, and $\nu^+ = -1$ and $\nu^- = -1$.*

Proof. A normal vector to $W^{eu}(\mathbf{0}, \eta)$, or $P(\mathbf{q}_\eta^\pm(t))$, is a covector and satisfies the adjoint differential equation

$$\dot{\mathbf{p}} = -\mathbf{p}\, DX(\mathbf{q}_\eta^\pm(t)).$$

(Note that in this equation, $\mathbf{p}$ is written as a row vector.) We denote the solution that is perpendicular to $P(\mathbf{q}_\eta^\pm(t))$ by $\mathbf{p}_\eta^\pm(t) = (p_1^\pm(t, \eta), p_2^\pm(t, \eta), p_3^\pm(t, \eta))$. Note that together, $(\mathbf{q}_\eta^\pm(t), \mathbf{p}_\eta^\pm(t))$ lies on the unstable manifold of $(\mathbf{0}, \mathbf{0})$ in the space of positions and covectors, $T^*\mathbb{R}^3$.

We start with $\delta_1 = 0$ and β_1 and ϵ_1 adjusted so that there are double homoclinic orbits. As t goes to infinity, we want to show that $p_3^\pm(t, \eta_1)$ goes to $-\infty$ and $\mathbf{p}_{\eta_1}^\pm(t)$ approaches the direction given by $-\mathbf{v}_s^*$ along the negative z-axis. The equations for $\dot{p}_1$ and $\dot{p}_2$ are independent of p_3 and so can be solved independently for a solution $(p_1^\pm(t, \eta_1), p_2^\pm(t, \eta_1))$ that is perpendicular to the homoclinic orbit in the (x, y)-plane, and so it limits on the eigendirection $\mathbf{v}_u^*$ for the eigenvalue $-\lambda_u$. Therefore $(p_1(t, \eta_1), p_2(t, \eta_1)) \to \mathbf{0}$ as t goes to infinity.

We parameterize the homoclinic connections $\mathbf{q}_\eta^\pm(t)$ so that $y^\pm(0, \eta) = 0$, so $x^\pm(t, \eta) y^\pm(t, \eta)$ is positive for $t < 0$ and negative for $t > 0$. Since

$$\begin{aligned}
\dot{p}_3^\pm(t, \eta) &= -x^\pm(t, \eta)\, y^\pm(t, \eta)\, p_2^\pm(t, \eta) + \gamma\, p_3^\pm(t, \eta), \\
p_3^\pm(t, \eta) &= e^{\gamma(t-t_0)} p_3^\pm(t_0, \eta) - \int_{t_0}^{t} x^\pm(s, \eta)\, y^\pm(s, \eta)\, p_2^\pm(s, \eta)\, e^{\gamma(t-s)}\, ds.
\end{aligned}$$

As t_0 goes to $-\infty$, since $(\mathbf{q}_\eta^\pm(t_0), \mathbf{p}_\eta^\pm(t_0))$ is in the unstable manifold in $T^*\mathbb{R}^3$, $\mathbf{p}_\eta^\pm(t_0)$ goes to zero exponentially at a rate given by λ_{ss}, $e^{-|\lambda_{ss}||t_0|}$. Since this is faster decay than the growth given by γ, we can let $t_0 \to -\infty$ and obtain

$$p_3^\pm(t, \eta) = -\int_{-\infty}^{t} x^\pm(s, \eta)\, y^\pm(s, \eta)\, p_2^\pm(s, \eta)\, e^{\gamma(t-s)}\, ds.$$

Because $X(\mathbf{q}_{\eta_1}^\pm(0))$ points in the direction of $(0, 1, 0)$, $p_2^\pm(0, \eta_1) = 0$ and we can take $p_2^\pm(t, \eta_1) > 0$ for $t < 0$ and $p_2^\pm(t, \eta_1) < 0$ for $t > 0$, so $x^\pm(t, \eta_1) y^\pm(t, \eta_1) p_2^\pm(t, \eta_1) \geq 0$

and

$$-p_3(t,\eta_1) > e^{\gamma t}\int_0^t x^{\pm}(s,\eta_1)\, y^{\pm}(s,\eta_1)\, p_2(s,\eta_1)\, e^{-\gamma s}\, ds.$$

As t goes to infinity, the integral is positive and $e^{\gamma t}$ goes to infinity, so $-p_3(t,\eta_1)$ goes to infinity. Since we showed above that $(p_1(t,\eta_1),p_2(t,\eta_1)) \to \mathbf{0}$, $\mathbf{p}^{\pm}(t,\eta_1)$ has a limiting direction along the negative z-axis, i.e., in the direction of the coeigenvector $-\mathbf{v}_s^*$ for the eigenvalue $-\lambda_s$. Therefore the limiting plane $P(\mathbf{q}^{\pm}_{\eta_1}(\infty))$ is spanned by the directions $\{\mathbf{v}^u, \mathbf{v}^{ss}\}$, and $W^{eu}(\mathbf{0},\eta_1)$ is transverse to $W^s(\mathbf{0},\eta_1)$. Since transversality is an open condition, it remains true for η_0 with $\delta_0 > 0$ small, giving assumption (A3).

We now want to show that $\nu^+ = -1$ and $\nu^- = 1$. The limiting direction of $\mathbf{p}^{\pm}_{\eta_0}(t)$ as t goes to $-\infty$ is $-\mathbf{v}^*_{ss}$, with a negative first coordinate. To understand the behavior as t goes to ∞, notice that for η_1, the limiting direction of $\mathbf{p}^{\pm}_{\eta_1}(t)$ is $-\mathbf{v}^*_s$, which is contained in the space spanned by $\{\mathbf{v}^*_{ss}, \mathbf{v}^*_s\}$. Since it is an open condition not to have a component in the $\mathbf{v}^*_u$ direction for the eigenvalue $-\lambda_u$, it will continue to be true for η_0. (This is the openness of the transverse intersection of assumption (A3).) For η_0 with $\delta_0 > 0$ but small, there is still a homoclinic connection, but now the homoclinic orbit $\mathbf{q}^{\pm}_{\eta_0}(t)$ approaches $\mathbf{0}$ along the weak stable direction. Since $\mathbf{p}^{\pm}_{\eta_0}(t)$ must remain orthogonal to X, the limiting direction of $\mathbf{p}^{\pm}_{\eta_0}(t)$ is contained in the space spanned by $\{\mathbf{v}^*_{ss}, \mathbf{v}^*_u\}$. Combining the two arguments, the limiting direction must be in the $\pm\mathbf{v}^*_{ss}$ direction. (This shows that the bundle of planes $\{P(\mathbf{q}) : \mathbf{q} \in \Gamma\}$ is continuous, and so is a second way of seeing that assumption (A3) is true.) Because the trajectory bends upward and then down asymptotic to the z-axis, the limiting direction of $\mathbf{p}^{+}_{\eta_0}(t)$ is $\mathbf{v}^*_{ss}$, while that of $\mathbf{p}^{-}_{\eta_0}(t)$ is $-\mathbf{v}^*_{ss}$. Therefore $\nu^+ = -1$ and $\nu^- = 1$.

As argued in [12], for η_1 with $\delta_1 = 0$, the integral of assumption (A5) is $-\infty$ and $C^{\pm}_{\eta_1} = 0$. By the perturbation argument given in [12], for $\delta_0 > 0$ small, the integral is still very negative but finite, so $0 < C^{\pm}_{\eta_0} << 1$. This proves assumption (A5). Notice that since we do not calculate the integrals, we have no way of knowing whether $C^{+}_{\eta_0}$ is nearly equal to $C^{-}_{\eta_0}$. □

ANALYSIS OF A FREE BOUNDARY PROBLEM ARISING IN BUBBLE DYNAMICS*

ZS. BIRO† AND J. J. L. VELAZQUEZ‡

Abstract. In this paper we study a model for the dynamics of a gas bubble immersed in a liquid. We describe the expansion of the bubble due to the decrease of the fluid pressure induced by a sound wave that traverses the fluid. The model considered here takes into account the dissipation of energy induced by the thermal conductivity. The expansion of the bubble can take place in a runaway manner in some cases. We obtain some global existence results for the model under consideration and we also describe a possible blow-up mechanism.

Key words. free boundary problems, bubble dynamics, parabolic differential equations, blow-up

1. Introduction.

In this paper we analyze a free boundary problem that arises in the study of the dynamics of gas bubbles in a liquid under the effect of an external sound field.

There exists a huge amount of literature concerning the dynamics of a gas bubble immersed in a liquid. It was predicted long time ago by Rayleigh [Ra] that, due to the interaction with an external sound wave, gas bubbles could experience in some circumstances a large expansion followed by an abrupt collapse. During the collapse of the bubble many interesting phenomena can occur, for instance, the breaking of symmetry of the bubble, sonochemistry, sonoluminiscence, and others [Le].

We are basically concerned with the analysis of the expansion stage of the process. In the models that are commonly used to describe bubble dynamics, it is usually assumed that the expansion part of the process is isothermal and that the collapse is approximately adiabatic [Le]. In any case, it is commonplace in several models to assume polytropic laws for the equation of state that relates the pressure and the density of the gas. Under these assumptions, together with the hypothesis of radial symmetry, it follows that the evolution of the bubble can be modeled by an ordinary differential equation (ODE) known as the Rayleigh–Plesset equation that will be described later. This ODE has been extensively studied using analytical and numerical methods (see [Le] and references therein).

We shall consider in this paper a model of bubble dynamics in which the effect of thermal conductivity of the gas is taken into account. This model arises in a natural way if the free boundary problem for the Navier–Stokes system that describes the evolution of the bubble in the radially symmetric case is written in nondimensional units. More precisely, we have made nondimensional the different magnitudes using the characteristic quantities that appear in some recent experimental studies of sonoluminiscence [BP1], [BP2], [BWLRP]. In the resulting model that we have derived

in this way (neglecting small nondimensional numbers) the pressure of the gas and the density are not related by a simple power law. Actually, the evolution of the gas during the expansion phase cannot be considered as either isothermal or isoentropic. It turns out, however, that both magnitudes (pressure and density) are related to the temperature by means of the usual equation of state for ideal gases, and on the other hand, the temperature satisfies a parabolic equation. The consequence of this analysis is that the whole problem for bubble evolution becomes a free boundary problem instead of an ODE problem.

The main goal of this paper is to analyze this free boundary problem during the expansion phase of the bubble. In the model that we consider a parameter Γ appears that measures the importance of inertial effects on the fluid compared with the changes of pressure induced by the external sound field. This parameter is very small during the expansion stage of the process. However, inertial effects play an essential role after the explosive growth of the radius of the bubble and are responsible for its collapse. For this reason, we have let the parameter Γ be different from zero in part of our analysis, since this quantity should become crucial after the runaway growth of the bubble.

In this article we show that the equilibrium state that corresponds to a constant radius is stable under small perturbations for the whole model with $\Gamma \neq 0$. To this end we use a suitable thermodynamic potential as a Lyapunov function. In the rest of the paper we assume $\Gamma = 0$ and we prove that all the solutions are global in time if the pressure of the liquid is always positive. On the other hand, using matched asymptotic expansions, we describe a blow-up mechanism that can take place for the model if the pressure of the liquid can become negative for some range of times. We have not attempted to describe in this paper the precise way in which inertial effects become relevant after the expansion of the bubble or the collapse of its radius.

2. Derivation of the model. In order to describe the dynamics of the bubble, we need to consider the motion of the liquid produced by the variation of size of the bubble. The dynamics of the liquid is described by the incompressible Navier–Stokes equation. We restrict our analysis to radially symmetric deformations of the bubble. The continuity equation for the liquid can then be written as

$$\frac{1}{r^2}\frac{\partial}{\partial r}(r^2 v_r) = 0, \qquad r > R(t), \tag{2.1}$$

where $v_r(r,t)$ is the radial velocity of the liquid and $R(t)$ is the radius of the bubble. Assuming that the fluid far away from the bubble is at rest, we obtain

$$v_r(r,t) = \frac{a(t)}{r^2}. \tag{2.2}$$

The momentum equation for the liquid is given under our symmetry hypothesis by

$$\frac{\partial v_r}{\partial t} = \frac{1}{\varrho_l}\Delta v_r - v_r\frac{\partial v_r}{\partial r} - \frac{1}{\varrho_l}\frac{\partial p_l}{\partial r}, \qquad r > R(t), \tag{2.3}$$

where ϱ_l, p_l are, respectively, the density and the pressure of the liquid. Plugging (2.2) into (2.3), it is readily seen that the viscous term disappears. We then have that

$$\dot{a}(t)\frac{1}{r^2} = \frac{2(a(t))^2}{r^5} - \frac{1}{\varrho_l}\frac{\partial p_l}{\partial r}, \qquad r > R(t). \tag{2.4}$$

Integrating (2.4) in the region $r > R(t)$ we obtain

$$\frac{\dot{a}(t)}{R(t)} = \frac{1}{2}\frac{(a(t))^2}{(R(t))^4} - \frac{1}{\varrho_l}p_\infty(t) + \frac{1}{\varrho_l}p_l(t), \tag{2.5}$$

where $p_l(t) = p_l(R(t), t)$ is the pressure of the liquid at the surface of the bubble and p_∞ is the liquid pressure far away from the bubble.

Taking into account the fact that the velocity of the liquid coincides with the speed of the bubble at its boundary, we deduce that

$$a(t) = (R(t))^2\dot{R}(t), \tag{2.6}$$

and using (2.6) in (2.5) we obtain the equation [Le]

$$R\ddot{R} + \frac{3}{2}(\dot{R})^2 = \frac{p_l(t) - p_\infty(t)}{\varrho_l}. \tag{2.7}$$

We have to complement (2.7) with the equations that describe the gas dynamics. These are the Navier–Stokes equations for compressible fluids that in the radially symmetric case read as

$$\frac{\partial \varrho}{\partial t} + \frac{1}{r^2}\frac{\partial}{\partial r}(\varrho r^2 v) = 0, \tag{2.8}$$

$$\varrho\left(\frac{\partial v}{\partial t} + v\frac{\partial v}{\partial r}\right) = \nu\Delta v - \frac{\partial p}{\partial r}, \tag{2.9}$$

$$\varrho T\frac{Ds}{Dt} = \nabla\cdot(\kappa\nabla T), \tag{2.10}$$

where ϱ is the density of the liquid, $p(r,t)$ is the pressure, $v(r,t)$ is the radial velocity, ν is the viscosity coefficient, κ is the thermal conductivity, T is the temperature, and s is the entropy per unit of mass. The definition of the convective derivative $\frac{D}{Dt}$ is the usual one:

$$\frac{D}{Dt} = \frac{\partial}{\partial t} + v\frac{\partial}{\partial r}.$$

We need to complement these equations with suitable equations of state. Taking into account the order of magnitude for the pressure, densities, and temperature that is reached inside the bubble during the expansion stage, it is enough to use the classical equations of state for ideal gases, namely,

$$p = R_g\varrho T, \tag{2.11}$$

$$s = c_v\log\left(\frac{p}{\varrho^\gamma}\right), \tag{2.12}$$

where $\gamma = \frac{c_p}{c_v}$ takes the well-known values $\frac{5}{3}$ for monoatomic gases and $\frac{7}{5}$ for diatomic gases.

Throughout this paper, we will assume that the temperature and density inside the bubble, as well as the remaining physical magnitudes, have the order of magnitude given by the experimental data in [BP1], [BP2], [BWLRP]. For the reader's convenience, we have included in Appendix A at the end of the paper a list of the sizes of the different quantities that are relevant for our problem. Let us denote as t_c the characteristic time associated to the frequency of oscillation, and let c be the order of magnitude of the sound speed inside the bubble. Let R_0 be the characteristic length that measures the size of the bubble. In our current situation (cf. Appendix A),

$$R_0 \ll ct_c.$$

Since the sound velocity is so large, disturbances in the fluid propagate through the bubble very quickly. In particular, writing the momentum equation (2.9) in nondimensional form we obtain to the lowest order

$$\frac{\partial p}{\partial r} = 0,$$

which implies

$$p = p(t). \tag{2.13}$$

On the other hand, the jump of the pressure at the boundary of the bubble is given by the surface tension. We are using here the fact that in our case the contributions due to viscosity terms are negligible compared with pressure forces. Then

$$p(t) = p(R(t), t) = p_l(t) + \frac{2\sigma}{R(t)}, \tag{2.14}$$

where from now on $p(t)$ denotes the pressure of the liquid. To conclude, notice that the nonslip condition on the side of the gas yields

$$v(R(t), t) = \dot{R}(t). \tag{2.15}$$

In several analyses of bubble dynamics, the gas pressure and its density are related by means of a power law. For instance, this approach can be found in [Le], where a polytropic law is assumed as an equation of state. The effect of the vapor pressure has also been taken into account there. Under these assumptions, the following relation between pressure and velocity holds:

$$p_l(t) = \left(p_0 + \frac{2\sigma}{R_0} - p_v\right)\left(\frac{R_0}{R}\right)^{3k} + p_v - \frac{2\sigma}{R(t)} \tag{2.16}$$

for some suitable k. Combining (2.7) and (2.16), the following differential equation results:

$$R\ddot{R} + \frac{3}{2}(\dot{R})^2 = \frac{1}{\varrho_l}\left\{\left(p_0 + \frac{2\sigma}{R_0} - p_v\right)\left(\frac{R_0}{R}\right)^{3k} + p_v - p_\infty(t) - \frac{2\sigma}{R(t)}\right\}. \tag{2.17}$$

Equation (2.17) is the well-known Rayleigh–Plesset equation that has been extensively studied by different authors (see [Le] for an extensive review). In this paper we will not assume a polytropic law as (2.16), but on the contrary we will relate p and ϱ

by means of (2.11) and introduce an additional equation for T. Since the thermal conductivity of the gas in nondimensional units is very high (see Appendix A), we can assume that the temperature of the liquid is a constant T_l and then coincides with the temperature of the gas at the surface of the bubble:

$$T(R(t),t) = T_l. \tag{2.18}$$

Our goal is to analyze the model (2.7), (2.8), (2.10)–(2.15). To this end we nondimensionalize the problem (see Appendix A) and plug (2.14) into (2.7). For the sake of convenience we will keep the same symbols to denote nondimensional quantities. The problem then becomes

$$R\ddot{R} + \frac{3}{2}(\dot{R})^2 = \frac{1}{\Gamma}\left(p(t) - p_\infty(t) - \frac{2\sigma}{R(t)}\right), \tag{2.19}$$

$$\frac{\partial \varrho}{\partial t} + \frac{1}{r^2}\frac{\partial}{\partial r}(\varrho r^2 v) = 0, \qquad B_{R(t)}(0) \times \mathbb{R}^+, \tag{2.20}$$

$$p = p(t), \qquad B_{R(t)}(0) \times \mathbb{R}^+, \tag{2.21}$$

$$\varrho T \frac{Ds}{Dt} = \nabla \cdot (\kappa \nabla T), \qquad B_{R(t)}(0) \times \mathbb{R}^+, \tag{2.22}$$

complemented with (2.11), (2.12), (2.14), and (2.18). The nondimensional number Γ in (2.19) is defined as

$$\Gamma = \frac{p_0 t_c^2}{R_0^2 \varrho_l},$$

where p_0 is the order of magnitude of the external pressure. In view of the data in Appendix A the parameter Γ turns out to be very small:

$$\Gamma \sim \frac{1}{400}.$$

The pressure field p_∞ that describes the variations of pressure due to the external sound field is given (in nondimensional units) by

$$p_\infty(t) = 1 + \alpha \cos(\omega t). \tag{2.23}$$

In the experiments of [BP1], [BP2], [BWLRP], α is approximately 1.2. Notice that this implies that during some time p_∞ becomes negative. In fact, these negative values of the pressure are responsible for the large expansion experienced by the bubble.

3. Some preliminary results. In this section we establish local well-posedness for the problem (2.11), (2.12), (2.15), (2.18)–(2.23) with initial data:

$$\varrho(r,0) = \varrho_0(r), \qquad 0 < r < R(0), \tag{3.1}$$

$$T(r,0) = T_0(r), \qquad 0 < r < R(0). \tag{3.2}$$

The following result holds.

THEOREM 3.1. *Let us assume that* $\varrho_0 \in C^{2+2\alpha}([0, R(0)])$, $0 < \alpha < \frac{1}{2}$. *Suppose also that for some* $\eta > 0$, $\varrho_0(r) \geq \eta$ *in the interval* $[0, R(0)]$. *Then there exists* $\delta = \delta(\|\varrho_0\|_{2+2\alpha})$ *such that the problem* (2.11), (2.12), (2.15), (2.18)–(2.23), (3.1), (3.2) *has a unique solution satisfying*

$$\varrho \in C^{2+2\alpha;1+\alpha}_{x;t}([0, R(t)] \times [0, \delta]),$$
$$R \in C^{3+\alpha}[0, \delta].$$

Proof. Using (2.11) we can eliminate T into (2.20) and deduce

$$\frac{p}{R_g}\frac{Ds}{Dt} = \kappa\Delta\left(\frac{p}{R_g\varrho}\right). \tag{3.3}$$

Taking into account (2.21) we can drop $p = p(t)$ from both sides of this equation, from which

$$\frac{Ds}{Dt} = \kappa\Delta\left(\frac{1}{\varrho}\right). \tag{3.4}$$

Plugging (2.12) in the left-hand side of this equation and using (2.19) we obtain

$$c_v\left\{\frac{p_t}{p} - \gamma\frac{D\varrho}{Dt}\right\} = \kappa\Delta\left(\frac{1}{\varrho}\right). \tag{3.5}$$

It readily follows from (2.20) that

$$\frac{1}{\varrho}\frac{D\varrho}{Dt} + \frac{1}{r^2}\frac{\partial}{\partial r}(r^2 v) = 0. \tag{3.6}$$

Plugging (3.6) into (3.5) we easily deduce

$$\frac{p_t}{p} = \frac{\kappa}{c_v}\Delta\left(\frac{1}{\varrho}\right) - \frac{\gamma}{r^2}\frac{\partial}{\partial r}(r^2 v). \tag{3.7}$$

Recalling that for radially symmetric functions $\Delta = \frac{1}{r^2}\frac{\partial}{\partial r}(r^2\frac{\partial}{\partial r})$, we multiply (3.7) by r^2 and integrate on the radial variable to obtain

$$\frac{p_t}{p}\frac{r^3}{3} = \frac{\kappa}{c_v}r^2\frac{\partial}{\partial r}\left(\frac{1}{\varrho}\right) - \gamma r^2 v + \alpha(t), \tag{3.8}$$

where $\alpha(t)$ is some suitable function depending only on t. We are interested in regular solutions at $r = 0$. Evaluating (3.8) at $r = 0$ it follows that $\alpha(t) = 0$. Equation (3.8) then becomes

$$\gamma v = \frac{\kappa}{c_v}\frac{\partial}{\partial r}\left(\frac{1}{\varrho}\right) - \frac{p_t}{p}\frac{r}{3}. \tag{3.9}$$

Eliminating v from (2.20) by means of (3.9) we deduce

$$\frac{\partial\varrho}{\partial t} + \frac{\kappa}{\gamma c_v}\frac{1}{r^2}\frac{\partial}{\partial r}\left(\varrho r^2\frac{\partial}{\partial r}\left(\frac{1}{\varrho}\right)\right) - \frac{p_t}{3\gamma p}\frac{1}{r^2}\frac{\partial}{\partial r}(\varrho r^3) = 0,$$

or, in an equivalent way,

$$\frac{\partial \varrho}{\partial t} = \frac{\kappa}{\gamma c_v}\Delta(\log(\varrho)) + \frac{p_t}{3\gamma p} r \frac{\partial \varrho}{\partial r} + \frac{p_t}{\gamma p}\varrho, \quad \text{in } B_{R(t)}(0). \tag{3.10}$$

On the other hand, the boundary condition (2.18) and the equation of state (2.11) yield

$$p(t) = R_g T_l \varrho(R(t), t). \tag{3.11}$$

Differentiating (3.11) we obtain

$$\frac{p_t}{p} = \left\{ \frac{\varrho_t}{\varrho} + \frac{\varrho_r}{\varrho}\dot{R}(t) \right\}. \tag{3.12}$$

Evaluating (3.9) at $r = R(t)$ and using the boundary condition (2.15) it follows that

$$\dot{R}(t) = -\frac{\kappa}{\gamma c_v} \frac{\varrho_r(R(t), t)}{(\varrho(R(t), t))^2} - \frac{R(t)}{3\gamma}\frac{p_t}{p}. \tag{3.13}$$

Summarizing, we have reduced the original problem to a free boundary problem for the density $\varrho(r, t)$ and the radius $R(t)$, namely (2.19), (3.10)–(3.13). To further simplify this problem we combine (2.19) and (3.12) to obtain

$$\frac{p_t}{p} = \frac{\Gamma(4\dot{R}\ddot{R} + R\dddot{R}) + p_{\infty,t} - \frac{2\sigma}{R^2}\dot{R}}{\Gamma(R\ddot{R} + \frac{3}{2}\dot{R}^2) + p_\infty + \frac{2\sigma}{R}}, \tag{3.14}$$

and substituting this formula into (3.13) we deduce a differential equation for the radius of the bubble:

$$\begin{aligned} \Gamma\dddot{R} = &-\frac{4\Gamma\dot{R}\ddot{R}}{R} - \frac{p_{\infty,t}}{R} + \frac{2\sigma\dot{R}}{R^3} \\ &-3\gamma\left(\frac{\kappa}{\gamma c_v}\frac{\varrho_r}{\varrho} + \dot{R}\right)\left[\Gamma\left(\frac{\ddot{R}}{R} + \frac{3}{2}\frac{(\dot{R})^2}{R^2}\right) + \frac{p_\infty}{R^2} + \frac{2\sigma}{R^3}\right]. \end{aligned} \tag{3.15}$$

On the other hand, eliminating $p(t)$ between (2.17) and (3.9) it follows that

$$\varrho(R(t), t) = \frac{1}{R_g T_l}\left[p_\infty + \frac{2\sigma}{R} + \Gamma\left(R\ddot{R} + \frac{3}{2}(\dot{R})^2\right)\right]. \tag{3.16}$$

We can obtain a solution of the free boundary problem (3.10), (3.14)–(3.16) by using a standard fixed point procedure in a way very similar to the one used in the analysis of the one-dimensional Stefan problem [Fr]. We transform the problem into a fixed boundary problem by means of the change of variables

$$r = R(t)y,$$

where y is the new space variable. Then problem (3.10), (3.14)–(3.16) becomes

$$\frac{\partial \varrho}{\partial t} = \frac{\kappa}{c_v}\Delta_y(\log(\varrho)) + f_1\left(y, t, \varrho(y, t), \quad \frac{\partial \varrho}{\partial y}(y, t), \varrho(1, t), R, \dot{R}, \ddot{R}, \dddot{R}\right) \quad \text{in } B_1(0), \tag{3.17}$$

$$\varrho(1,t) = f_2(R, \dot{R}, \ddot{R}, t), \tag{3.18}$$

$$\dddot{R} = f_3\left(t, R, \dot{R}, \ddot{R}, \varrho(1,t), \frac{\partial \varrho}{\partial y}(1,t)\right), \tag{3.19}$$

where the functions f_1, f_2, f_3 are analytic functions on all their variables for $R \neq 0$, and $\varrho(1,t) \neq 0$. This problem is equivalent to the original free boundary problem for smooth solutions.

The local solution of (3.17)–(3.19) with initial condition (3.1) as well as the initial conditions $R(0) = R_0, \dot{R}(0) = \dot{R}_0$ can be obtained by means of a standard fixed point argument on $R(t)$. More precisely, we introduce a functional space:

$$X = \{\bar{R}(t) : \bar{R} \in C^{3+\alpha}[0,\delta], \bar{R}(0) = R_0, \quad \dot{\bar{R}}(0) = \dot{R}_0, [\bar{R}]_{3+\alpha} < \infty\},$$

where $\delta > 0$ is some small number that will be chosen later. Given $\bar{R} \in X$ we solve (3.15), (3.16) with R replaced by $\bar{R}$ with initial data $\varrho_0(y,0) = \varrho_0(R_0 y)$. Taking into account that $\varrho_0 \geq \eta > 0$ for $0 \leq r \leq R_0$ we can apply classical regularity theory for quasi-linear parabolic equations in order to deduce the existence and uniqueness of a smooth solution $\varrho(y,t)$ for $0 \leq t \leq \delta \leq \delta_0(\eta, \|\varrho_0\|_{L^\infty(B_1(0))})$. Moreover, by standard estimates, it follows that

$$[\varrho]_{C^{2+2\alpha;1+\alpha}_{y;t}(B_1(0)\times[0,\delta])} \leq C(\|\varrho_0\|_{L^\infty(B_1(0))}, \eta),$$

where $0 < \alpha < \frac{1}{2}$. It then follows by classical embedding theory that

$$\left[\frac{\partial \varrho}{\partial y}(1,\cdot)\right]_{C^{\frac{1}{2}+\alpha}_t([0,\delta])} \leq C(\|\varrho_0\|_{L^\infty(B_1(0))}, \eta).$$

Then, given $\bar{R} \in X$ we can define the operators:

$$T_1[\bar{R}] \equiv \varrho(1,t),$$
$$T_2[\bar{R}] \equiv \frac{\partial \varrho}{\partial y}(1,t),$$

where $\varrho(y,t)$ is the corresponding solution of (3.17), (3.18) that we have just obtained. The pair $(\bar{R}, \varrho)$, where $\bar{R} \in X$, solves the problem (3.17)–(3.19) if and only if $\bar{R}$ solves the equation

$$\dddot{R} = f_3(t, R, \dot{R}, \ddot{R}, T_1[R], T_2[R]), \qquad 0 \leq t \leq \delta, \tag{3.20}$$

where $R(0) = R_0, \dot{R}(0) = \dot{R}_0$, and $\ddot{R}$ is obtained from (3.16) as

$$\ddot{R}(0) = \frac{1}{R_0}\left\{\frac{1}{\Gamma}\left(R_g T_l \varrho_0(y=1) - p_\infty(0) - \frac{2\sigma}{R_0}\right) - \frac{3}{2}(\dot{R}_0)^2\right\}.$$

Taking into account the analyticity of f_1, f_2 and classical continuous dependence of the solutions of (3.17) on the source term R it follows that for $\bar{R}_1, \bar{R}_2 \in X$

$$[T_1[\bar{R}_1] - T_1[\bar{R}_2]]_{C^{1+\alpha}[0,\delta]} + [T_2[\bar{R}_1] - T_2[\bar{R}_2]]_{C^{\frac{1}{2}+\alpha}[0,\delta]} \leq C[\bar{R}_1 - \bar{R}_2]_{C^{3+\alpha}[0,\delta]}. \tag{3.21}$$

We can write (3.20) as

$$
\begin{aligned}
&R(t) = R_0 + \dot{R}_0 t + \ddot{R}_0 \frac{t^2}{2} \\
&+ \int_0^t \int_0^{s_1} \int_0^{s_2} f_3(s_3, R(s_3), \dot{R}(s_3), \ddot{R}(s_3), T_1[R](s_3), T_2[R](s_3)) ds_3 ds_2 ds_1.
\end{aligned} \tag{3.22}
$$

Using (3.21) it easily follows that the operator on the right-hand side of (3.22) is contractive on the space X if δ is small enough. The proof of Theorem 3.1 then follows by means of a classical fixed point argument. □

4. Stability of the steady state. The goal of this section is to prove that the steady state of (2.11), (2.12), (2.15), (2.18)–(2.23) is stable under small perturbations.

4.1. Description of the steady state. We have reduced the original problem with $\Gamma > 0$ to the free boundary problem (3.10), (3.14)–(3.16). We now proceed to describe the steady state of this problem. To this end, we assume without loss of generality that the forcing term $p_\infty(t)$ is constant:

$$p_\infty \equiv 1.$$

We are interested in steady state solutions. Taking into account (3.10), (3.13), we deduce that the steady state satisfies

$$\Delta(\log(\varrho)) = 0 \qquad \text{in } B_{R_s}(0),$$

$$\frac{\partial \varrho}{\partial r}(R_s) = 0,$$

where R_s denotes the stationary radius. Taking into account that ϱ depends only on r it follows that

$$\varrho(r) = \varrho(R_s) \equiv \varrho_0 \qquad \text{for} \qquad 0 \le r \le R_s. \tag{4.1}$$

On the other hand, (4.1), (2.11), (2.13), and the boundary condition (2.16) imply

$$T(r) = T_l \qquad \text{for} \qquad 0 \le r \le R_s, \tag{4.2}$$

from which by (2.11), (2.19) it follows that

$$R_g \varrho_0 T_l = p_\infty + \frac{2\sigma}{R_s} \equiv p_0, \tag{4.3}$$

which fixes the radius R_s as a function of ϱ_0. Summarizing, for each value of ϱ_0 we have one value of R_s prescribed by (4.3) that corresponds to the stationary radius.

4.2. Helmholtz free energy. In this section we recall some classical thermodynamic expressions that will be useful in our forthcoming analysis of the stability of steady states. Notice that the gas contained in the bubble is doing mechanical work against the liquid in a process that takes place at a constant boundary temperature. It is well known [LL] that for such processes the Helmholtz free energy provides a suitable Lyapunov function for the evolution of the system. The main goal of this section is to write the evolution law for the Helmholtz free energy in our particular setting. Given a function $\varphi(x,t)$ the following formula holds:

$$\frac{d}{dt}\left(\int_{B_{R(t)}} \varrho \varphi d^3x\right) = \int_{B_{R(t)}} \varrho \frac{D\varphi}{Dt} d^3x, \tag{4.4}$$

where $\partial B_{R(t)}$ moves with the fluid. Although (4.4) is rather standard, for the reader's convenience, we recall its derivation in the radially symmetric case is given in Appendix B at the end of the paper.

On the other hand, the following well-known thermodynamic identity is satisfied:

$$du = Tds - pd\left(\frac{1}{\varrho}\right), \tag{4.5}$$

where u is the internal energy by unit of mass.

In the case of an ideal gas, the entropy per unit of gas is given by (2.12) which combined with (4.5) implies the well-known thermodynamic identity:

$$u = c_v T, \tag{4.6}$$

where we have used $\gamma = \frac{c_p}{c_v}$ as well as $c_p - c_v = R_g$.

Notice that (4.5) implies

$$\varrho \frac{Du}{Dt} = \varrho T \frac{Ds}{Dt} - \varrho p \frac{D(\frac{1}{\varrho})}{Dt} = \varrho T \frac{Ds}{Dt} + \frac{p}{\varrho}\frac{D\varrho}{Dt}. \tag{4.7}$$

Using (2.10), (4.7), as well as the continuity equation (2.8) written in the form

$$\frac{D\varrho}{Dt} + \varrho \ \mathrm{div}(\overrightarrow{v}) = 0,$$

and it readily follows that

$$\varrho \frac{Du}{Dt} = \nabla(\kappa \nabla T) - p \ \mathrm{div}(\overrightarrow{v}). \tag{4.8}$$

The Helmholtz free energy for the bubble is given by the thermodynamic expression:

$$F = U - T_l S,$$

where U and S are the total internal energy and the total entropy of the gas, respectively, and T_l is the temperature of the heat bath (in our case the liquid).

In our case the Helmholtz free energy of the gas inside the bubble is given by the expression

$$F = \int_{B_{R(t)}} \varrho u d^3x - T_l \int_{B_{R(t)}} \varrho s d^3x. \tag{4.9}$$

Taking into account (4.4), and using (2.10), (2.13), (2.15), and (4.8), it follows that

$$\begin{aligned}
\frac{dF}{dt} &= \int_{B_{R(t)}} \nabla(\kappa \nabla T) d^3x - p(t) \int_{B_{R(t)}} \mathrm{div}(\overrightarrow{v}) d^3x - \int_{B_{R(t)}} \frac{T_l}{T} \nabla(\kappa \nabla T) d^3x \\
&= \int_{\partial B_{R(t)}} \kappa \nabla T d\overrightarrow{S} - p(t) \int_{\partial B_{R(t)}} v d\overrightarrow{S} \\
&\quad - \int_{\partial B_{R(t)}} \kappa \nabla T d\overrightarrow{S} - T_l \int_{B_{R(t)}} \kappa \frac{(\nabla T)^2}{T^2} d^3x \\
&= -\kappa T_l \int_{B_{R(t)}} \frac{(\nabla T)^2}{T^2} d^3x - p(t) v(R(t), t) \int_{\partial B_{R(t)}} dS.
\end{aligned} \tag{4.10}$$

The first term on the right-hand side of (4.11) corresponds to the dissipation of energy due to thermal conductivity. The second is the total amount of work made for the bubble in its expansion. Writing

$$\frac{dW}{dt} = -p(t)v(R(t),t)\int_{\partial B_{R(t)}} dS = -4\pi p(t)(R(t))^2\dot{R}(t),$$

we obtain from (4.11) the well-known thermodynamic formula:

$$\frac{dF}{dt} \leq \frac{dW}{dt}.$$

We now use the fact that the amount of work made by the gas against the liquid is spent in the variation of the interfacial energy of the liquid-gas boundary as well as in the change of mechanical energy of the liquid. The kinetic energy of the liquid is

$$K_l = \frac{1}{2}\int_{R(t)}^{+\infty} \varrho_l 4\pi r^2 (v_r(r,t))^2 dr, \tag{4.11}$$

where $v_r(r,t)$ has to be computed using (2.2), (2.6) implying

$$K_l = 2\pi\varrho_l (R(t))^3(\dot{R}(t))^2. \tag{4.12}$$

On the other hand, the energy of the liquid-gas interface is given by

$$U_{gl} = 4\pi\sigma(R(t))^2. \tag{4.13}$$

We compute

$$\frac{d}{dt}(U_{gl}+K_l) = 6\pi\varrho_l R^2\dot{R}^3 + 4\pi\varrho_l R^3\dot{R}\ddot{R} + 8\pi\sigma R\dot{R}.$$

Using (2.7) to compute $\dot{R}\ddot{R}$ we deduce that

$$\frac{d}{dt}(U_{gl}+K_l) = 6\pi\varrho_l R^2\dot{R}^3 - 6\varrho_l R^2\dot{R}^3 + 4\pi R^2(p_l(t)-p_\infty(t))\dot{R} + 8\pi\sigma R\dot{R}.$$

With the help of the boundary condition (2.14), it then follows that

$$\frac{d}{dt}(U_{gl}+K_l) = -4\pi p_\infty(t)R^2\dot{R} + 4\pi R^2 p(t)\dot{R}. \tag{4.14}$$

Adding (4.11) and (4.14) we arrive at

$$\frac{d}{dt}(F+U_{gl}+K_l) = -4\pi p_\infty(t)R^2\dot{R} - \kappa T_l\int_{B_{R(t)}}\frac{(\nabla T)^2}{T^2}d^3x. \tag{4.15}$$

The first term on the right-hand side of (4.15) is the work made by the external sound field. The second term is the energy dissipation due to the termal conductivity of the gas.

In the particular case in which we take $\alpha = 0$ in (2.21), (4.15) may be written as

$$\frac{d}{dt}\left(F+U_{gl}+K_l+\frac{4\pi}{3}R^3\right) = -\kappa T_l\int_{B_{R(t)}}\frac{(\nabla T)^2}{T^2}d^3x. \tag{4.16}$$

Equation (4.16) is just a version of the second law of thermodynamics particularized to our actual problem. Notice that (4.16) implies that the steady state is characterized for a uniform distribution of temperature T inside the bubble. Moreover, at those points the functional $F+U_{gl}+K_l+\frac{4\pi}{3}R^3$ reaches an extremal point under our current assumptions. Notice that since $\nabla T = 0$ inside the bubble, the boundary condition (2.16) implies $T = T_l$. Taking into account that in our model the pressure is uniform and using the equation of state (2.11), it follows that ϱ is uniform. We can then write (4.9) as

$$F = \frac{4\pi R^3}{3}\varrho u - \frac{4\pi R^3}{3}\varrho s T_l,$$

whence the steady state solutions correspond to the extremal points of the function

$$\Phi \equiv \frac{4\pi R^3}{3}\varrho u - \frac{4\pi R^3}{3}\varrho s T_l + 4\pi\sigma R^2 + \frac{4\pi}{3}R^3, \tag{4.17}$$

where (p, s, u) are given, respectively, by (2.11), (2.12), and (4.6) and where the conservation of mass inside the bubble implies

$$\frac{4\pi R^3}{3}\varrho = M_0. \tag{4.18}$$

Using (2.11), (2.12) and (4.6), (4.18) we can rewrite (4.17) as

$$\Phi = c_v T_l M_0 - c_v M_0 T_l \log(T_l) + c_v(\gamma-1)T_l M_0 \log(\varrho) + 4\pi\sigma R^2 + \frac{4\pi}{3}R^3. \tag{4.19}$$

We eliminate ϱ from (4.19) using (4.18). It then follows (using also the classical formula) that

$$c_v(\gamma-1) = c_p - c_v = R_g,$$

$$\Phi = c_v T_l M_0 - c_v M_0 T_l \log(T_l) + R_g T_l M_0 \log\left(\frac{3M_0}{2\pi}\right) - 3R_g T_l M_0 \log(R) + 4\pi\sigma R^2 + \frac{4\pi}{3}R^3,$$

and computing the minimum of the function with respect to R we readily deduce that the equilibrium $R = R_s$ satisfies

$$p_0 \equiv R_g \varrho_0 T_l = 1 + \frac{2\sigma}{R_s},$$

where ϱ_0 is the density inside the gas. As it should be expected this formula coincides with (4.3).

4.3. Linearized problem near the steady state. Our next goal is to study the linearization of the problem (2.11), (2.12), (2.15), (2.18)–(2.23) near the steady state, where we take $\alpha = 0$ in (2.23). We consider the evolution equation written in the form (3.10), (3.14)–(3.16). We then set

$$p = p_0 + g, \tag{4.20a}$$

$$\varrho = \varrho_0 + \zeta, \tag{4.20b}$$

$$R = R_s + \lambda. \tag{4.20c}$$

Formally linearizing in (3.8), (3.12), (3.13), (3.14) we then obtain the following system of equations:

$$\frac{\partial \zeta}{\partial t} = \frac{\kappa}{c_v T_l}\Delta(\zeta) + \frac{1}{R_g} T_l \left(\Gamma R_s \dddot{\lambda} - \frac{2\sigma}{R_s^2}\dot{\lambda} \right), \tag{4.21}$$

$$\Gamma \dddot{\lambda} = -3\frac{p_0}{R_s^2}\left(\dot{\lambda} + \frac{\kappa}{c_v}\frac{\zeta_r(R_s,t)}{\varrho_0^2} \right) + \frac{2\sigma}{R_s^3}\dot{\lambda}, \tag{4.22}$$

$$\zeta(R_s,t) = \frac{1}{R_g T_l}\left(-\frac{2\sigma}{R_s^2}\lambda + \Gamma R_s \ddot{\lambda} \right), \tag{4.23}$$

where by assumption $\lambda(0), \dot{\lambda}(0), \zeta(r,0)$ are given and $\ddot{\lambda}(0)$ can be then obtained from (4.23).

On the other hand, if we keep in (4.15) just the quadratic terms on g, ζ, λ we obtain a formula that is satisfied for the linearized system (4.21)–(4.23). We could do this more precisely by writing (4.20) as

$$p = p_0 + \varepsilon g,$$

$$\varrho = \varrho_0 + \epsilon\zeta,$$

$$R = R_s + \varepsilon\lambda.$$

Then taking the formal limit $\varepsilon = 0$ in the linear equation and in the energy dissipation formula (4.16) written in new variables it would follow the energy formula for the linearized problem that contains just quadratic terms. More precisely, we can write

$$K_l = 2\pi\varrho_l R_s^3(\dot{\lambda})^2 + \text{cubic terms},$$

$$U_{gl} = 4\pi\sigma R_s^2 + 8\pi\sigma R_s\lambda + 4\pi\sigma\lambda^2,$$

$$\frac{4\pi}{3}R^3 = \frac{4\pi}{3}R_s^3 + 4\pi R_s^2\lambda + 4\pi R_s\lambda^2 + \text{cubic terms}.$$

We approximate F as follows:

$$\begin{aligned} F &= c_v\int_{B_R}\varrho T d^3x - c_v T_l\int_{B_R}\varrho\log(p)d^3x + c_v\gamma T_l\int_{B_R}\varrho\log(\varrho)d^3x \\ &= \frac{c_v p}{R_g}\int_{B_R} d^3x - c_v T_l M_0\log(p) + c_v\gamma T_l\int_{BR}\varrho\log(\varrho)d^3x \\ &= \frac{4\pi c_v p}{3R_g}R^3 - c_v T_l M_0\log(p) + c_v\gamma T_l\int_{B_R}\varrho\log(\varrho)d^3x, \end{aligned}$$

where

$$M_0 = \int_{B_R} \varrho d^3x$$

is the total mass of gas, and we consider perturbations of the gas that keep the pressure p homogeneous throughout volume.

We write

$$\begin{aligned}\int_{B_R} \varrho \log(\varrho) d^3x &= \int_{B_R} \varrho \log(\varrho+\zeta) d^3x \\ &= \int_{B_R} \varrho \left\{ \log(\varrho_0) + \frac{\zeta}{\varrho_0} - \frac{\zeta^2}{2\varrho_0^2} \right\} d^3x + \text{cubic terms} \\ &= \log(\varrho_0) M_0 + \int_{B_R} \frac{\varrho}{\varrho_0} \zeta d^3x - \frac{1}{2\varrho_0} \int_{B_{R_0}} \zeta^2 d^3x + \text{cubic terms} \\ &= M_0 \log(\varrho_0) + \int_{B_R} \zeta d^3x + \frac{1}{2\varrho_0} \int_{B_{R_0}} \zeta^2 d^3x + \text{cubic terms}.\end{aligned}$$

Using the fact that

$$M_0 = \int_{B_R} (\varrho_0 + \zeta) d^3x, \tag{4.24}$$

it follows that

$$\int_{B_R} \zeta d^3x = M_0 - \int_{B_R} \varrho_0 d^3x = M_0 - \varrho_0 \frac{4\pi R^3}{3},$$

from which

$$\begin{aligned}F &= \frac{4\pi c_v p R^3}{3R_g} - c_v T_l M_0 \log(p) + c_v \gamma T_l M_0 \log(\varrho_0) \\ &\quad + c_v \gamma T_l M_0 - c_v \gamma T_l \varrho_0 \frac{4\pi R^3}{3} + \frac{c_v \gamma T_l}{2\varrho_0} \int_{B_{R_0}} \zeta^2 d^3x + \text{cubic terms} \\ &= F_0 + \left(\frac{4\pi c_v p_0 R_s^2 \lambda}{R_g} - c_v \gamma T_l 4\pi R_s^2 \varrho_0 \lambda \right) \\ &\quad + \left[\frac{4\pi c_v p_0 R_s}{R_g} \lambda^2 + \frac{4\pi c_v R_s^2}{R_g} g\lambda + \frac{c_v T_l M_0}{2p_0^2} g^2 \right. \\ &\quad \left. -4\pi c_v \gamma T_l \varrho_0 R_s \lambda^2 + \frac{c_v \gamma T_l}{2\varrho_0} \int_{B_{R_s}} \zeta^2 d^3x \right] \\ &\quad + \text{cubic terms},\end{aligned}$$

where

$$F_0 = \frac{4\pi c_v p_0 R_s^3}{3R_g} - c_v T_l M_0 \log(p_0) + c_v \gamma T_l M_0 \log(\varrho_0) + c_v \gamma T_l M_0 - \gamma c_v T_l \varrho_0 \frac{4\pi}{3} R_s^3.$$

From this we derive

$$\begin{aligned}F &= F_0 - 4\pi c_v R_s^2 (\gamma - 1) T_l \varrho_0 \lambda \\ &\quad + \left[4\pi c_v \varrho_0 T_l R_s (1-\gamma) \lambda^2 + \frac{4\pi c_v R_s^2}{R_g} g\lambda + \frac{c_v T_l M_0}{2p_0^2} g^2 + \frac{c_v \gamma T_l}{2\varrho_0} \int_{B_{R_s}} \zeta^2 d^3x \right] \\ &\quad + \text{cubic terms}.\end{aligned}$$

Summarizing to quadratic order and using that $p_0 = 1 + \frac{2\sigma}{R_s}$ we deduce from (4.16) that the solution of (4.21)–(4.23) satisfies

$$\begin{aligned} &\frac{d}{dt}\left[4\pi\sigma\lambda^2 + \tfrac{4\pi c_v R_s^2}{R_g}g\lambda + \tfrac{c_v T_l M_0}{2p_0^2}g^2 + \tfrac{c_v\gamma T_l}{2\varrho_0}\int_{B_{R_s}}\zeta^2 d^3x + 2\pi\varrho_l R_s^3(\lambda_t)^2\right] \\ &= -\tfrac{\kappa T_l}{\varrho_0^2}\int_{B_{R_s}}|\nabla\zeta|^2 d^3x. \end{aligned} \tag{4.25}$$

Notice that (4.24) implies to linear order

$$\lambda = -\frac{1}{4\pi\varrho_0 R_s^2}\int_{B_{R_s}}\zeta d^3x, \tag{4.26}$$

which in turn yields

$$\begin{aligned} &4\pi\sigma\lambda^2 + \frac{4\pi c_v R_s^2}{R_g}g\lambda + \frac{c_v T_l M_0}{2p_0^2}g^2 + \frac{c_v T_l\gamma}{2\varrho_0^2}\int_{B_{R_s}}\zeta^2 d^3x \\ &= \frac{\sigma}{4\pi\varrho_0^2 R_s^4}\left(\int_{B_{R_s}}\zeta d^3x\right)^2 - \frac{c_v}{\varrho_0 R_g}g\int_{B_{R_s}}\zeta d^3x + \frac{c_v T_l M_0}{2p_0^2}g^2 + \frac{c_v\gamma T_l}{2\varrho_0}\int_{B_{R_s}}\zeta^2 d^3x \\ &= \frac{c_v T_l M_0}{2}\left(\frac{g}{p_0} - \frac{1}{M_0}\int_{B_{R_s}}\zeta d^3x\right)^2 + \frac{c_v\gamma T_l}{2\varrho_0}\int_{B_{R_s}}\zeta^2 d^3x \\ &- \left(\frac{\sigma}{4\pi\varrho_0^2 R_s^4} + \frac{c_v T_l}{2M_0}\right)\left(\int_{B_{R_s}}\zeta d^3x\right)^2 \geq \frac{c_v T_l M_0}{2}\left(\frac{g}{p_0} - \frac{1}{M_0}\int_{B_{R_s}}\zeta d^3x\right)^2 \\ &+ \left[\frac{c_v\gamma T_l}{2\varrho_0} - \left(\frac{\sigma}{4\pi\varrho_0^2 R_s^4} + \frac{c_v T_l}{2M_0}\right)\frac{4\pi R_s^3}{3}\right]\int_{B_{R_s}}\zeta^2 d^3x \\ &= \frac{c_v T_l M_0}{2}\left(\frac{g}{p_0} - \frac{1}{M_0}\int_{B_{R_s}}\zeta d^3x\right)^2 \\ &+ \frac{1}{\varrho_0}\left(\frac{c_v(\gamma-1)T_l}{2} - \frac{R_g T_l}{6} + \frac{1}{6\varrho_0}\right)\int_{B_{R_s}}\zeta^2 d^3x \\ &= \frac{c_v T_l M_0}{2}\left(\frac{g}{p_0} - \frac{1}{M_0}\int_{B_{R_s}}\zeta d^3x\right)^2 + \left(\frac{R_g T_l}{3} + \frac{1}{6\varrho_0}\right)\int_{B_{R_s}}\zeta^2 d^3x. \end{aligned} \tag{4.27}$$

Using the energy estimate (4.16) we can prove the following stability result.

THEOREM 4.1. *Let us assume that $\varrho(r,t)$, $R(t)$ is a solution of the free boundary problem* (3.10), (3.14)–(3.16) *with $p_\infty = 1$ and with initial data $\varrho(r,0)$, $R(0)$ satisfying*

$$[\varrho(\cdot,0) - \varrho_0]_{C_r^{2+2\alpha}} \leq \eta_0, \tag{4.28}$$

$$|R(0) - R_s| \leq \eta_0, \tag{4.29}$$

where $\eta_0 > 0$ is small enough and η_0, R_s are the values of the density and the radius corresponding to a steady state (cf. (4.3)*). Then the solution $(\varrho(r,t), R(t))$ is globally defined and satisfies the estimates*

$$[\varrho(\cdot,,t) - \varrho_0]_{C_r^{2+2\alpha}} \leq \varepsilon_0, \tag{4.30}$$

$$|R(t) - R_0| \leq \varepsilon_0 \tag{4.31}$$

for any $t > 0$, where ε_0 is a small number that can be made arbitrarily small if η_0 in (4.28), (4.29) *is small enough.*

Theorem 4.1 shows that steady states are Lyapunov stable. The proof of Theorem 4.1 is a standard use of the classical Lyapunov method. A key step in the proof of Theorem 4.1 is the following lemma.

LEMMA 4.2. *Let us assume that there exists a constant $\nu > 1$ such that*

$$\frac{1}{\nu} \leq \varrho(r) \leq \nu, \tag{4.32}$$

$$\frac{1}{\nu} \leq R \leq \nu, \tag{4.33}$$

$$\int_{B_R} \varrho(r) d^3x = M_0. \tag{4.34}$$

Then there exist constants $\Theta > 0$, $\delta_0 > 0$ depending only on M_0 in (4.18), *T_l in* (2.18), *and ν such that the function $Q = F + U_{gl} + \frac{4\pi}{3} R^3$ satisfies*

$$Q - Q_0 \geq \Theta \left(\int_{B_R} (\varrho(r) - \varrho_0)^2 d^3x \right), \tag{4.35}$$

provided that $|\varrho - \varrho_0| \leq \delta_0$, and where Q_0 is evaluated at the steady state (ϱ_0, R_s).

Proof. The proof of Lemma 4.2 consists essentially in retracing the steps in the proof of (4.27) and keeping track of the cubic terms that were neglected there. In this way we obtain the following estimate:

$$\begin{aligned} Q - Q_0 \geq{}& \frac{c_v T_l M_0}{2} \left(\frac{p - p_0}{p_0} - \frac{1}{M_0} \int_{B_R} (\varrho - \varrho_0) d^3x \right)^2 \\ &+ \left(\frac{R_g T_l}{3} + \frac{1}{6\varrho_0} \right) \left(\int_{B_R} (\varrho - \varrho_0)^2 d^3x \right) \\ &- C \left(\int_{B_R} |\varrho - \varrho_0|^3 d^3x + |p - p_0|^3 + |R - R_0|^3 \right), \end{aligned} \tag{4.36}$$

where the constant C depends only on ν, M_0, T_l. Notice that the integrals in (4.36) are computed in B_R instead of in B_{R_s} as in (4.27). Using (4.24) we obtain the following nonlinear version of (4.26):

$$\frac{4\pi\varrho_0}{3}(R^3 - R_s^3) = -\int_{B_R} (\varrho - \varrho_0) d^3x. \tag{4.37}$$

Taking into account (4.33) it readily follows that

$$|R - R_s| \leq C \left(\int_{B_R} |\varrho - \varrho_0|^2 d^3x \right)^{\frac{1}{2}}, \tag{4.38}$$

where C depends only on ν, M_0, T_l. On the other hand,

$$|p - p_0| \leq C \left\{ \left| \frac{p - p_0}{p_0} - \frac{1}{M_0} \int_{B_R} (\varrho - \varrho_0) d^3x \right| + \left(\int_{B_R} (\varrho - \varrho_0)^2 d^3x \right)^{\frac{1}{2}} \right\}. \tag{4.39}$$

Using (4.38), (4.39) and taking into account that $|p-p_0| = R_g T_l |\varrho - \varrho_0|$ at $r = R$, we readily obtain that for $|\varrho - \varrho_0| \leq \delta_0$ and δ_0 small enough (4.35) holds true. □

Proof of Theorem 4.1. It is easily checked using (4.4) that the total mass of gas $\int_{B_R} \varrho d^3x$ is a constant of the motion. We rewrite (4.16) as

$$\frac{d}{dt}(Q + K_l) = -KT_l \int_{B_R} \frac{(\nabla T)^2}{T^2} d^3x, \tag{4.40}$$

where Q is as in Lemma 4.2. We then obtain the following estimate:

$$Q(t) - Q_0 \leq K_l(0) + (Q(0) - Q_0). \tag{4.41}$$

Under the assumptions of Theorem 4.1, we can take $|K_l(0)|$ and $|Q(0) - Q_0|$ smaller than some number $\varepsilon_1 > 0$ if η_0 is chosen small enough. On the other hand, using Lemma 4.2, combined with (4.41) we obtain

$$\Theta\left(\int_{B_R} (\varrho(r,t) - \varrho_0)^2 d^3x\right) \leq \varepsilon_1. \tag{4.42}$$

Let us assume that

$$[\varrho(\cdot,t) - \varrho_0]^{2+2\alpha}_{C_r} \leq \nu \tag{4.43}$$

for some $\nu > 1$. Certainly this estimate holds for short times, and as far as this bound and (4.32) are satisfied we can apply Theorem 3.1 in order to define the solution $(\varrho(r,t), R(t))$ for a larger time. Our goal is to show (4.43) globally in time. To this end, we argue as follows. Using classical interpolation results we can obtain from (4.42), (4.43) the estimate

$$\left|\frac{\partial \varrho}{\partial r}\right| + |\varrho - \varrho_0| \leq \varepsilon_2, \tag{4.44}$$

where ε_2 might be made small if ε is so.

Notice that (4.44) implies, if ε_2 is small enough, that (4.32) holds as far as (4.43) is satisfied. Moreover, (4.38) and (4.44) imply (4.33). We can then combine (3.15) and the estimate for $\frac{\partial \varrho}{\partial r}$ in (4.44) to show that $|\dddot{R}|$ is uniformly small. The proof can then be concluded by means of a bootstrap argument. More precisely, the regularity of $\ddot{R}$ as well as (3.10), (3.14), (3.16) implies estimates for $[\frac{\partial \varrho}{\partial r}(r=1,\cdot)]_\delta$, $0 < \delta < \frac{1}{4}$, and this provides similar estimates for $[\dddot{R}(\cdot)]_\delta$. Iterating the procedure, we obtain bounds for $[\dddot{R}(\cdot)]_\alpha$ for any $\alpha < \frac{1}{2}$ as well as analogous estimates for ϱ. This yields (4.43) and concludes the proof of Theorem 4.1 □

5. The limit case $\Gamma = 0$. We now consider the problem (2.11), (2.12), (2.15), (2.18)–(2.23) in the case in which we formally make $\Gamma = 0$, which is rather natural since as indicated before, in nondimensional units $\Gamma \sim \frac{1}{400}$. Recalling (2.15), (2.19), (3.7), (3.8), (3.9) it follows that the problem can be written as the following free boundary problem:

$$\frac{\partial \varrho}{\partial t} = \frac{\kappa}{\gamma c_v} \Delta(\log(\varrho)) + \frac{p_t}{3\gamma p} r \frac{\partial \varrho}{\partial r} + \frac{p_t}{\gamma p} \varrho, \tag{5.1}$$

$$p(t) = R_g T_l \varrho(R(t), t), \tag{5.2}$$

$$\dot{R}(t) = \frac{\kappa}{\gamma c_v}\frac{\partial}{\partial r}\left(\frac{1}{\varrho}\right)\Big|_{r=R(t)} - \frac{p_t}{p}\frac{R}{3\gamma}, \tag{5.3}$$

$$p(t) = p_\infty(t) + \frac{2\sigma}{R(t)}. \tag{5.4}$$

Problem (5.1)–(5.4) with suitable initial data is a standard free boundary problem very similar to the classical one-dimensional Stefan problem. Local existence and uniqueness of Hölder solutions of (5.1)–(5.4) can be obtained with an argument similar to that used in the proof of Theorem 3.1. The following result holds.

THEOREM 5.1. *Assume that* $\varrho_0 \geq \eta > 0$, $\varrho_0 \in C^{2,\alpha}([0, R(0)])$, $\frac{\partial \varrho_0}{\partial r}(0) = 0$. *Then for* $\delta > 0$ *small enough there exists a unique solution of* (5.1)–(5.4) *in the class of function* $R \in C^{1+\alpha}([0,\delta])$, $0 < \alpha < \frac{1}{2}$, $\varrho \in C^{1+\frac{\alpha}{2},2+\alpha}([0,\delta] \times [0, R(t)])$.

The proof of Theorem 5.1 can be obtained exactly as the analogous result for the one-dimensional Stefan problem [Fr]. It turns out that solutions of (5.1)–(5.4) are global in time if the external pressure p_∞ remains always positive. More precisely, we have the following.

THEOREM 5.2. *If* $p_\infty > 0$, *any solution of* (5.1)–(5.4) *with initial data* $\varphi(r,0) = \varphi_0(r) > 0$ *is global, i.e., for any* $T > 0$ *there holds*

$$|\dot{R}(t)| \leq C(T), \quad 0 \leq t \leq T,$$

for some suitable function $C(T)$.

Proof. We define a new variable as

$$\varphi(r,t) = \frac{\varrho(r,t)}{R_g T_l p(t)}, \tag{5.5}$$

that transforms (5.1)–(5.4) into

$$\varphi_t = \frac{A}{p(t)}\Delta(\log(\varphi)) + \frac{p_t}{3\gamma p} r\varphi_r + \left(\frac{1}{\gamma} - 1\right)\frac{p_t}{p}\varphi, \qquad A = \frac{\kappa}{\gamma c_v R_g T_l}, \tag{5.6}$$

$$\varphi(R(t),t) = 1, \tag{5.7}$$

$$\dot{R}(t) = -\frac{A}{p(t)}\varphi_r(R,t) - \frac{p_t}{3\gamma p}R. \tag{5.8}$$

If we introduce the change of variables $\xi = \frac{r}{R(t)}$, (5.6) becomes

$$\varphi_t = \frac{A}{pR^2}\Delta_\xi(\log(\varphi)) + \left(\frac{p_t}{3\gamma p} + \frac{R_t}{R}\right)\xi\varphi_\xi + \left(\frac{1}{\gamma} - 1\right)\frac{p_t}{p}\varphi. \tag{5.9}$$

Notice that

$$\frac{R_t}{R} + \frac{p_t}{3\gamma p} = \frac{R_t}{R} + \frac{1}{3\gamma p}\left(p_{\infty,t} - \frac{2\sigma R_t}{R^2}\right) = \frac{R_t}{R}\left(1 - \frac{2\sigma}{R}\frac{1}{3\gamma p}\right) + \frac{p_{\infty,t}}{3\gamma p}. \tag{5.10}$$

On the other hand, (5.8) implies

$$R_t = -\frac{A}{p(t)}\frac{1}{R}\varphi_\xi(R,t) - \frac{R}{3\gamma p}\left(p_{\infty,t} - \frac{2\sigma R_t}{R^2}\right),$$

whence, using (5.10) it follows that

$$\frac{R_t}{R}+\frac{p_t}{3\gamma p}=-\frac{A}{pR^2}\varphi_\xi(1,t)-\frac{1}{3\gamma p}p_{\infty,t}+\frac{p_{\infty,t}}{3\gamma p}=-\frac{A}{pR^2}\varphi_\xi(1,t).$$

We then write (5.9) as

$$\varphi_t=\frac{A}{pR^2}\Delta_\xi(\log(\varphi))-\frac{A}{pR^2}\varphi_\xi(1,t)\xi\varphi_\xi+\left(\frac{1}{\gamma}-1\right)\frac{p_t}{p}\varphi, \tag{5.11}$$

which we have to complement with the boundary condition

$$\varphi(1,t)=1 \tag{5.12}$$

as well as (5.8) which we rewrite the new variables as

$$R_t=\left(1-\frac{2\sigma}{R}\frac{1}{3\gamma p}\right)^{-1}\left[-\frac{A}{pR}\varphi_\xi(1,t)-\frac{R}{3\gamma p}p_{\infty,t}\right]. \tag{5.13}$$

Notice that since $\gamma>1$ our assumptions on $p_\infty(t)$ imply that $(1-\frac{2\sigma}{R}\frac{1}{3\gamma p})^{-1}$ is a smooth function as far as the solution of (5.1)–(5.4) is defined. Before proving Theorem 5.2 we need some estimates for $\varphi(\xi,t)$. The following result holds.

LEMMA 5.3. *Let us assume that* $(\varphi(\xi,t),R(t))$ *is a solution of* (5.4), (5.11), (5.13). *Then*

$$p(t)(R(t))^3\int_0^1\varphi(\xi,t)\xi^2d\xi=C, \tag{5.14}$$

where $C>0$ *is a suitable constant that depends on the initial data.*

Proof. Let us write

$$M=\int_0^1\varphi(\xi,t)\xi^2d\xi.$$

Multiplying (5.11) by ξ^2 and integrating in the interval $[0,1]$, we obtain

$$\begin{aligned}\tfrac{dM}{dt}&=\tfrac{A}{pR^2}\varphi_\xi(1,t)-\tfrac{A}{pR^2}\varphi_\xi(1,t)\left(\varphi(1,t)-3\int_0^1\varphi(\xi,t)\xi^2d\xi\right)\\&\quad+\left(\tfrac{1}{\gamma}-1\right)\tfrac{p_t}{p}M=\left[\tfrac{3A}{pR^2}\varphi_\xi(1,t)+\left(\tfrac{1}{\gamma}-1\right)\tfrac{p_t}{p}\right]M.\end{aligned} \tag{5.15}$$

Using (5.13) and (5.4) we deduce that

$$\begin{aligned}&\frac{3A}{pR^2}\varphi_\xi(1,t)+\left(\frac{1}{\gamma}-1\right)\frac{p_t}{p}\\&=\frac{3A}{pR^2}\left[-\frac{pR}{A}\left(1-\frac{2\sigma}{R}\frac{1}{3\gamma p}\right)R_t-\frac{pR}{A}\frac{R}{3\gamma p}p_{\infty,t}\right]+\left(\frac{1}{\gamma}-1\right)\frac{p_t}{p}\\&=-\frac{3}{R}R_t-\frac{p_t}{p},\end{aligned}$$

which combined with (5.15) implies (5.14). □

Lemma 5.3 is just a restatement of the conservation of mass of gas which can be written as

$$\int_{B_R(0)}\varrho(x,t)d^3x=M_0.$$

We now continue the proof of the the theorem. Notice that (5.4) and Lemma 5.3 imply the following. If $\varphi(\xi,t) \leq 1$ for $0 \leq \xi \leq 1$, then $R(t) \geq \delta_0 > 0$, where δ_0 depends only on $p_\infty(t)$. We now argue as follows. Notice that the function

$$\tilde{\varphi}(\xi,t) = \frac{K}{(p(t))^{1-\frac{1}{\gamma}}} \tag{5.16}$$

is a solution of (5.11). Suppose that K is selected large enough so that the following inequalities hold:

$$\tilde{\varphi}(\xi,0) > \max\{\varphi_0(\xi)\},$$

$$K > \left(\sup(p_\infty) + \frac{2\sigma}{\delta_0}\right)^\beta,$$

and

$$\tilde{\varphi}(\xi,0) > 1.$$

We can use $\tilde{\varphi}(\xi,t)$ as a supersolution for (5.11), (5.12) as far as $\tilde{\varphi}(\xi,t)$ remains larger than one. Define $t^* = \inf\{t : \tilde{\varphi}(\xi,t) = 1\}$. By assumption $t^* > 0$. Suppose that $t^* < \infty$. Then by comparison $\varphi(\xi,t^*) \leq 1$ whence $R(t^*) \geq \delta_0 > 0$, but this implies $p(t^*) \leq \sup(p_\infty) + \frac{2\sigma}{\delta_0}$. However, our assumptions on K imply $\varphi(\xi,t^*) > 1$ and this yields a contradiction with the definition of t^*.

We then obtain that $t^* = \infty$ and $\tilde{\varphi}(\xi,t)$ defined in (5.16) is a global supersolution for (5.11), (5.12). It then follows that, as far as the solution of (5.4), (5.11)–(5.13) is defined, there holds $\varphi(\xi,t) \leq \tilde{\varphi}(\xi,t)$. Using (5.14) we obtain the following estimate:

$$C \leq \frac{pR^3}{3}\tilde{\varphi}(\xi,t) = \frac{K}{3}p^{1-\beta}R^3 = \frac{K}{3}p^{\frac{1}{\gamma}}R^3. \tag{5.17}$$

Taking into account (5.4) and (5.17) as well as the fact that $\gamma > 1$, it follows that $R \geq \delta > 0$ where δ depends only on p_∞, $\varphi_0(\xi)$, $R(0)$. Using again (5.4) as well as our assumption on p_∞ we arrive at

$$0 < m < p(t) < \frac{1}{m} \tag{5.18}$$

for some suitable constant m. Taking $\varepsilon_0 > 0$ small enough we deduce that the function $\tilde{\tilde{\varphi}}(\xi,t) = \frac{\varepsilon_0}{(p(t))^\beta}$ is a subsolution for (5.11), (5.12) such that $\tilde{\tilde{\varphi}}(\xi,0) \leq \varphi_0(\xi)$. By comparison, it then follows that $\tilde{\tilde{\varphi}}(\xi,t) \leq \varphi(\xi,t)$, which combined with (5.14) yields $R(t) \leq C_1$ for some constant $C_1 > 0$. Summarizing, we have obtained the estimates

$$\Theta \leq \varphi(\xi,t) \leq \frac{1}{\Theta}, \tag{5.19}$$

$$\Theta \leq R(t) \leq \frac{1}{\Theta} \tag{5.20}$$

for some suitable constant $\Theta > 0$, as far as the functions $(\varphi(\xi,t), R(t))$ are well defined.

As a next step we obtain a lower estimate of $\varphi_\xi(1,t)$. To this end, notice that (5.4), (5.11), (5.13) imply that φ solves the problem

$$\begin{aligned}\varphi_t = &\tfrac{A}{pR^2}\Delta_\xi(\log(\varphi)) - \tfrac{A}{pR^2}\varphi_\xi(1,t)\xi\varphi_\xi \\ &- \left(1-\tfrac{1}{\gamma}\right)\left(1-\tfrac{2\sigma}{3\gamma pR}\right)^{-1}\tfrac{p_{\infty,t}}{p}\varphi + \tfrac{2\sigma 1-\frac{1}{\gamma}A}{pR^3}\left(1-\tfrac{2\sigma}{3\gamma pR}\right)^{-1}\varphi_\xi(1,t)\varphi.\end{aligned} \tag{5.21}$$

For any ε, let us define a function $u(\xi,\varepsilon)$ as

$$u(\xi,\varepsilon) = v_\varepsilon\left(\frac{\xi-1}{\varepsilon}\right), \quad y = \frac{\xi-1}{\varepsilon}, \tag{5.22}$$

where $v(y)$ solves the problem

$$(\log(v))_{yy} - v_y - \Gamma\varepsilon v = 0, \tag{5.23}$$

$$v(0) = 1, \tag{5.24}$$

$$v_y(0) = 1, \tag{5.25}$$

where $\Gamma > 0$ is a positive constant that will be fixed presently and $\varepsilon > 0$ is a small number to be precised.

It is easily seen by means of the standard theory of ODEs that

$$\lim_{\varepsilon\to 0} v_\varepsilon(y) = \frac{1}{1-y},$$

uniformly on compact sets of the y-variable. Using (5.18) and (5.20) it readily follows that taking

$$\Gamma \geq 2\sup\left\{2\sigma\left(1-\frac{1}{\gamma}\right)\left(1-\frac{2\sigma}{3\gamma pR}\right)^{-1}\right\}$$

and $\varepsilon > 0$ small enough, the following inequality holds in $-(\frac{2}{\Theta}-1)\varepsilon \leq \xi - 1 \leq 0$, where $\Theta > 0$ is as in (5.20):

$$\begin{aligned}&-\frac{A}{pR^2}\Delta_\xi(\log(u)) + \frac{A}{pR^2}u_\xi(1,t)\xi u_\xi \\ &+\frac{1}{1-\gamma}\left(1-\frac{2\sigma}{3\gamma pR}\right)^{-1}\frac{p_{\infty,t}}{p}u + \frac{2\sigma A\frac{1}{1-\gamma}}{pR^2}\left(1-\frac{2\sigma}{3\gamma pR}\right)^{-1}u_\xi(1,t)u \\ &\leq -\frac{A}{pR^2}(\log(u))_{\xi\xi} - \frac{A}{pR^2}\frac{(\log(u))_\xi}{\xi} \\ &+\frac{A}{pR^2}u_\xi(1,t)u_\xi + \frac{A}{pR^2}u_\xi(1,t)(\xi-1)u_\xi + \Gamma\frac{A}{pR^2}u_\xi(1,t)u \\ &\leq \frac{A}{pR^2}[-(\log(u))_{\xi\xi} + u_\xi(1,t)u_\xi + \Gamma u_\xi(1,t)u] = 0.\end{aligned}$$

We can use $u(\xi,\varepsilon)$ as a subsolution for (5.11), (5.12) as far as the solution of this last problem is defined. Indeed, let us select ε small enough such that $u(\xi,\varepsilon) < \varphi_0(\xi)$ in $-(\frac{2}{\Theta}-1)\varepsilon \leq \xi - 1 \leq 0$. Taking into account (5.20), it readily follows that

$u(\xi,\varepsilon) \le \varphi(\xi,t)$ at $\xi = (\frac{2}{\Theta} - 1)\varepsilon$. Notice that as far as $u(\xi,\varepsilon) \le \varphi(\xi,t)$ we have $\varphi_\xi(\xi,t) \le u_\xi(\xi,\varepsilon)$. Since $u_\xi \ge 0$, it follows that for $-(\frac{2}{\Theta} - 1)\varepsilon \le \xi - 1 \le 0$

$$\begin{aligned} &u_t - \frac{A}{pR^2}\Delta_\xi(\log(u)) + \frac{A}{pR^2}\varphi_\xi(1,t)\xi u_\xi + \left(\frac{1}{\gamma} - 1\right)\frac{p_t}{p}u \\ &\le -\frac{A}{pR^2}\Delta_\xi(\log(u)) + \frac{A}{pR^2}u_\xi(1,t)\xi u_\xi + \left(\frac{1}{\gamma} - 1\right)\left(1 - \frac{2\sigma}{3\gamma pR}\right)^{-1}\frac{p_{\infty,t}}{p}u \\ &+\frac{2\sigma A^{\frac{1}{\gamma}} - 1}{pR^2}\left(1 - \frac{2\sigma}{3\gamma pR}\right)^{-1} u_\xi(1,t)u \le 0. \end{aligned}$$

Let us define as t^* the smallest time where the inequality $\varphi_\xi(\xi,t) < u_\xi(\xi,\varepsilon)$ fails. Arguing by comparison we deduce that $u(\xi,\varepsilon) < \varphi(\xi,t^*)$, whence this inequality holds as far as $\varphi(\xi,t)$ is defined. As indicated above this implies

$$\varphi_\xi(\xi,t) \le C \tag{5.26}$$

as long as the solution of (5.4), (5.11)–(5.13) is defined. The constant $C > 0$ depends only on $\varphi_0(\xi)$, $p_\infty(t)$, $R(0)$.

To conclude the proof of Theorem 5.2, it remains only to prove a lower estimate for $\varphi_\xi(1,t)$. Such a lower estimate combined with (5.26) would imply a global existence theorem for (5.4), (5.11)–(5.13). Indeed, an estimate of $|\varphi_\xi(1,t)|$ together with (5.18)–(5.20) provides estimates for higher order derivatives of φ by means of a standard bootstrap argument applied to (5.11). Using Theorem 5.1 we can then extend the time interval of definition for (5.4), (5.11)–(5.13).

In order to obtain the desired lower estimate for $\varphi_\xi(1,t)$, we define a function $U(\xi,\varepsilon)$ as the unique solution of

$$\Delta_\xi(\log(U)) - C\xi U_\xi + \frac{\tilde{\Gamma}}{\varepsilon}CU = 0, \tag{5.27}$$

$$U(\xi,\varepsilon) = 1, \tag{5.28}$$

$$U_\xi(1,\varepsilon) = -\frac{1}{\varepsilon}, \tag{5.29}$$

where C is as in (5.26) and $\tilde{\Gamma} > 0$ will be made precise later. It is not hard to check that U behaves asymptotically as

$$U(\xi,\varepsilon) \simeq w\left(\frac{\xi - 1}{\varepsilon}\right), \quad y = \frac{\xi - 1}{\varepsilon} \tag{5.30}$$

uniformly in the region $-K\varepsilon \le \xi - 1 \le 0$, where K is any fixed positive constant, and where

$$w = e^{-y}.$$

It turns out that U is a supersolution of (5.11), (5.12) if $\tilde{\Gamma}$ is chosen large enough as far as $\varphi(\xi,t) \le U(\xi)$. Indeed, under these assumptions and also using (5.26) we have

$$-\frac{1}{\varepsilon} \le \varphi_\xi(1,t) \le C,$$

from which, if $\varepsilon > 0$ is chosen small enough,

$$U_t - \frac{A}{pR^2}\Delta_\xi(\log(U)) + \frac{A}{pR^2}\varphi_\xi(1,t)\xi U_\xi$$
$$+ \left(1 - \frac{1}{\gamma}\right)\left(1 - \frac{2\sigma}{3\gamma pR}\right)^{-1}\frac{p_{\infty,t}}{p}U + \frac{2\sigma A(1-\frac{1}{\gamma})}{pR^2}\left(1 - \frac{2\sigma}{3\gamma pR}\right)^{-1}\varphi_\xi(1,t)U$$
$$\geq -\frac{A}{pR^2}\left[\Delta_\xi(\log(U)) - C\xi U_\xi + \frac{\tilde{\Gamma}}{\varepsilon}CU\right] = 0.$$

Arguing then by comparison as in the proof of (5.26) we obtain the estimate

$$\varphi_\xi(1,t) \geq C, \tag{5.31}$$

where C depends only on $\varphi_0(\xi)$, $p_\infty(t)$, $R(0)$. Combining (5.26) and (5.31) we obtain an upper estimate of $|\varphi_\xi(1,t)| \geq C$, and this concludes the proof of Theorem 5.2. □

6. Singularity formation for $\Gamma = 0$. In this section we exhibit a singularity formation mechanism for the system (5.1)–(5.4) that can take place if the assumption $p_\infty(t) > 0$ in Theorem 5.2 is dropped. The goal here is to describe in detail one possible singularity mechanism using formal techniques. We have not attempted to provide a rigorous construction of the solutions to be exhibited. Let us assume that $p_\infty(t)$ can take negative values. For the singular solution that we describe here the function $R(t)$ remains bounded but $|\dot{R}(t)|$ blows up. An analogous phenomena occurs also for the one-dimensional undercooled Stefan problem [HV]. As in this last case the derivative $\varphi_\xi(1,t)$ blows up in finite time. However, there is a major difference between the bubble model (5.1)–(5.4) and the undercooled Stefan problem, namely, the rate of blow-up for $\varphi_\xi(1,t)$ is much larger for the Stefan problem than for the system (5.1)–(5.4). To get some intuition on the blow-up mechanism described here, we just remark that it exhibits some analogies with the blow-up mechanism that can take place for (2.19) in the case $\Gamma = 0$. In this case (2.19) reduces to an algebraic equation and the blow-up can be analyzed in a straightforward manner. After the onset of the singularity, the approximation $\Gamma = 0$ ceases to be valid. In fact, as soon as $|\dot{R}(t)|$ grows sufficiently large, the inertial terms $\Gamma(R\ddot{R} + \frac{3}{2}(\dot{R})^2)$ become relevant and should be taken into account. We have not attempted to describe the effects of those terms in the singularity formation mechanism.

For convenience we will use the equivalent formulation of (5.1)–(5.4) given by (5.4), (5.11)–(5.13). Let us denote as R_0 the value of the radius for which the singularity appears, and let T be the time of formation of the singularity. We write

$$\left(1 - \frac{2\sigma}{3\gamma pR}\right) = \frac{1}{3\gamma p}\left(3\gamma p_\infty + \frac{2\sigma(3\gamma - 1)}{R}\right). \tag{6.1}$$

The singularity that we describe here will appear due to the vanishing of the left-hand side of (6.1) (see (5.13)). Taking into account (6.1) the following relation between R_0 and T easily follows:

$$\frac{3\gamma p_\infty(T)}{3\gamma - 1} + \frac{2\sigma}{R_0} = 0. \tag{6.2}$$

Notice that at the time $t = T$ we have $p(T) = p_\infty(T) + \frac{2\sigma}{R_0} > 0$. The function p that appears in (5.11), (5.13) is then of order one near the blow-up point and it does

not affect very much the form of the singularity. By assumption, as $t \to (T)^-, R$ approaches to R_0. Thus

$$3\gamma p_\infty(t) + \frac{2\sigma(3\gamma-1)}{R} = 3\gamma(p_\infty(t) - p_\infty(T) + 2\sigma(3\gamma-1)\left(\frac{1}{R} - \frac{1}{R_0}\right)$$
$$\approx 3\gamma \dot{p}_\infty(T)(t-T) + \frac{2\sigma(3\gamma-1)}{(R_0)^2}(R_0 - R).$$

It is then natural to approximate (5.13) as

$$R_t = -\frac{\frac{3\gamma A}{R_0}\varphi_\xi(1,t) + R_0 p_{\infty,t}(T)}{3\gamma\dot{p}_\infty(T)(t-T) + \frac{2\sigma(3\gamma-1)}{(R_0)^2}(R_0 - R)}. \tag{6.3}$$

On the other hand, near the point $\xi \approx 1$ the function φ will remain close to the value one (cf. (5.12)). We then introduce the function

$$\psi = \varphi - 1. \tag{6.4}$$

Approximating $\log(\varphi)$ by ψ we can write (5.11) to the lowest order in neighborhood of $\xi = 1$ as

$$\psi_t = \frac{A}{p(T)(R_0)^2}(\Delta(\psi) - \psi_\xi(1,t)\psi_\xi) - \left(\frac{1}{\gamma} - 1\right)\frac{2\sigma R_t}{p(T)(R_0)^2}, \tag{6.5}$$

where we have approximated p_t using (5.4) by

$$p_t = p_{\infty,t} - \frac{2\sigma R_t}{(R)^2} \approx -\frac{2\sigma R_t}{(R_0)^2}.$$

Taking into account (5.12), we need to complement (6.5) with

$$\psi(1,t) = 0.$$

The blow-up mechanism that we describe here is essentially driven by the ODE (6.3) with $\varphi_\xi(1,t)$ roughly of order one (although with logarithmic corrections). It is then natural to expect a behavior of the form $(R_0 - R) \approx C\sqrt{T-t}$ or, in general, the weaker assumption

$$(R_0 - R) \gg (T-t), \tag{6.6}$$

as $t \to T$. Using (6.4) and (6.6) we can write (6.3) as

$$R_t = -\frac{R_0}{2\sigma(3\gamma-1)}\frac{3\gamma A\varphi_\xi(1,t) + (R_0)^2 p_{\infty,t}(T)}{(R_0 - R)}. \tag{6.7}$$

We now proceed to describe a singularity formation mechanism for (6.5), (6.6), (6.7) in which the resulting solution is compatible with all the approximations made. Toward this end, it is convenient to introduce self-similar variables as follows:

$$\psi(\xi,t) = (T-t)^{\frac{1}{2}}G(y,\tau), \tag{6.8}$$

$$y = \frac{\xi - 1}{\sqrt{T-t}}, \tag{6.9}$$

$$\tau = -\log(T-t), \tag{6.10}$$

$$R - R_0 = (T-t)^{\frac{1}{2}}\lambda(\tau). \tag{6.11}$$

Using this new set of variables (6.5), (6.6), (6.7) becomes

$$\begin{aligned} G_\tau &= \frac{A}{p(T)(R_0)^2}G_{yy} - \frac{y}{2}G_y \\ &+\frac{1}{2}G + \frac{2Ae^{-\tau}}{p(T)(R_0)^2(1+e^{-\tau}y)}G_y \\ &-\frac{Ae^{-\tau}}{p(T)(R_0)^2}G(0,\tau)G_y + \left(1-\frac{1}{\gamma}\right)\frac{2\sigma}{p(T)(R_0)^2}\left(\lambda_\tau - \frac{1}{2}\lambda\right), \end{aligned} \tag{6.12}$$

$$G(0,\tau) = 0, \tag{6.13}$$

$$\lambda_\tau = \frac{1}{2}\lambda + \frac{R_0}{2\sigma(3\gamma-1)}\frac{3\gamma A G_y(0,\tau) + (R_0)^2 p_{\infty,t}(T)}{\lambda}. \tag{6.14}$$

Neglecting exponentially small factors in (6.12), we obtain the approximate equation:

$$G_\tau = \frac{A}{p(T)(R_0)^2}G_{yy} - \frac{y}{2}G_y + \frac{1}{2}G + \left(1-\frac{1}{\gamma}\right)\frac{2\sigma}{p(T)(R_0)^2}\left(\lambda_\tau - \frac{1}{2}\lambda\right). \tag{6.15}$$

Problem (6.13), (6.15) does not admit stationary solutions except in the case $\lambda = 0$. In order to check this, it is enough to multiply the equation of the steady state by $y\exp(-\frac{p(T)(R_0)^2y^2}{4A})$ and integrate in the interval $(-\infty, 0)$. After integration by parts, using (6.13) it follows that $\lambda = 0$. Notice, however, that $\lambda = 0$ cannot be a steady state of (6.13)–(6.15). This excludes self-similar behaviors as possible asymptotics for singular solutions of (5.1)–(5.4). We will look then for solutions of (6.13)–(6.15) with the asymptotics

$$G(y,\tau) \sim a(\tau)y, \tag{6.16}$$

as $\tau \to \infty$. Multiplying (6.15) by $y\exp(-\frac{p(T)(R_0)^2y^2}{4A})$ and integrating in the interval $(-\infty, 0)$, we obtain after some computations the differential equation

$$a_\tau = -\frac{2\sigma(\gamma-1)}{\gamma R_0\sqrt{\pi}}\frac{(\lambda_\tau - \frac{\lambda}{2})}{\sqrt{Ap(T)}}. \tag{6.17}$$

On the other hand, (6.16) yields $G_y(0,\tau) \sim a(\tau)$ as $\tau \to \infty$. Equation (6.14) can then be approximated as

$$\lambda_\tau = \frac{\lambda}{2} + \frac{R_0}{2\sigma(3\gamma-1)}\big[3\gamma A a(\tau) + (R_0)^2 p_{\infty,t}(T)\big]\lambda. \tag{6.18}$$

It is easy to check that the system of equations (6.17), (6.18) admits solutions with the asymptotics

$$a(\tau) \sim -\frac{3\sigma(\gamma-1)^2(\tau)^2}{4\gamma(3\gamma-1)\pi R_0 p(T)} \quad \tau \to \infty, \tag{6.19}$$

$$\lambda(\tau) \sim -\frac{3(\gamma-1)\sqrt{A}\tau}{2(3\gamma-1)\sqrt{\pi R_0 p(T)}} \quad \tau \to \infty. \tag{6.20}$$

The asymptotics (6.19), (6.20) combined with (6.16) provide a solution that is compatible with all the previous approximations. Notice that in the original set of variables (6.20) implies

$$R(t) \sim R_0 - \frac{3(\gamma-1)}{2(3\gamma-1)}\sqrt{\frac{A}{\pi p(T)}}(T-t)^{\frac{1}{2}}|\log(T-t)|^{\frac{1}{2}} \quad t \to T^-. \tag{6.21}$$

Finally, we can compute the final profile of $\varphi(\xi,t)$ arguing as in [HV]. Let us fix $\bar{t}$ close enough to T and $y_0 < 0$ with $|y_0|$ large enough. According to (6.16), (6.19) there holds

$$\psi(\xi,\bar{t}) \sim -\frac{3\sigma(\gamma-1)^2|\log(T-\bar{t})|^2}{4\gamma(3\gamma-1)\pi R_0 p(T)}(\xi-1) \tag{6.22}$$

for $\xi - 1 = y_0\sqrt{T-\bar{t}}$. As in [HV], the solution of (6.5) remains approximately constant in the interval $[\bar{t},T]$ if $|y_0|$ is large enough. Taking into account that $\log(1-\xi) \sim \log(\sqrt{T-\bar{t}})$ as $\bar{t} \to T^-$, from (6.4), (6.22) the following final profile for $\varphi(\xi,t)$ then follows:

$$\varphi(\xi,t) \sim 1 + \frac{3\sigma(\gamma-1)^2(1-\xi)(\log(1-\xi))^2}{\gamma(3\gamma-1)\pi R_0 p(T)}, \quad \xi \to 1^-. \tag{6.23}$$

Formulae (6.21), (6.23) provide a rather detailed description of the singular behavior of the solution of (5.1)–(5.4). We remark that such behavior is not strictly self-similar due to the onset of logarithmic corrections.

Appendix A. In this appendix we describe some of the physical parameters that we have used in order to obtain the model (2.7), (2.8), (2.10)–(2.15). To this end, we use the experimental values in [BP2]. In the expansion phase, the radius of the bubble described in [BP2] varies between 5×10^{-4} cm. and 4×10^{-3} cm. As the average value for the radius we will take

$$R_0 \sim 2 \times 10^{-3} \text{ cm.} \tag{A.1}$$

The frequency of the external sound wave is of order $\omega = 2\pi \times 26.5$ Khz. It is then natural to introduce a characteristic time of order

$$t_{osc} \sim 4 \times 10^{-5} s. \tag{A.2}$$

The experiments in [BP2], [BWLRP] were made at approximately constant temperature. We will take a characteristic temperature T_{char} of order:

$$T_{char} \sim 300\ K. \tag{A.3}$$

The momentum equation for the gas can be written as

$$\varrho_g \frac{Dv}{Dt} = -\frac{\partial p}{\partial r} + \frac{\partial}{\partial r}\left[2\mu\frac{\partial v}{\partial r} + \left(\mu_v - \frac{2}{3}\mu\right)\nabla\cdot(\vec{v})\right] + \frac{4\mu}{r}\frac{\partial v}{\partial r} - \frac{4\mu v}{r^2}, \tag{A.4}$$

where μ, μ_v are the viscosity coefficients and ϱ_g is the density of the gas. Taking into account that $\frac{\partial p}{\partial r} = \frac{dp}{d\varrho}\frac{\partial \varrho}{\partial r}$ and that $\frac{dp}{d\varrho}$ is of the order of magnitude of the square of the velocity of the sound (that we use to denote as c), it follows that

$$\left|\frac{\partial p}{\partial r}\right| \sim \frac{c^2 \delta \varrho_g}{R_0} = \frac{c^2 \varrho_g}{R_0}\frac{\delta \varrho}{\varrho_g}, \tag{A.5}$$

where $\delta\varrho$ denotes the order of magnitude of variations of density. The order of magnitude of the speed of sound in our particular setting is

$$c^2 \sim \frac{p}{\varrho} \sim 10^9 \text{ cm}^2 s^{-2}, \tag{A.6}$$

where we have taken as an order of magnitude for the pressure the atmospheric pressure, and as an order of magnitude for the density, $\varrho \sim 10^{-3} g \text{ cm}^{-3}$. The size of the inertial terms in (A.4) is roughly

$$\varrho_g \left|\frac{Dv}{Dt}\right| \sim \varrho_g \frac{R_0}{t_{osc}^2}. \tag{A.7}$$

Finally, the order of magnitude of viscous terms in (A.4) is

$$\frac{\mu v}{R_0^2} \sim \frac{\mu}{R_0 t_{osc}}. \tag{A.8}$$

Comparison between (A.5) and (A.8) shows that viscous terms are negligible compared with pressure terms. In fact, the order of magnitude of the variations of the radius suggests that $\frac{\delta \varrho}{\varrho_g} \sim 1$. Then

$$\frac{|\frac{\partial p}{\partial r}|}{\frac{\mu v}{R_0^2}} \sim \frac{c^2 t_{osc}}{\nu},$$

where $\nu = \frac{\mu}{\varrho_g}$ stands for kinematic viscosity. At atmospheric pressure and $T = 300\, K$, ν takes the value

$$\nu = 0.160 \text{ cm}^2 s^{-1}. \tag{A.9}$$

It then follows that

$$\frac{|\frac{\partial p}{\partial r}|}{\frac{\mu v}{R_0^2}} \sim 2.5 \times 10^5. \tag{A.10}$$

On the other hand, the relative size of pressure and inertial terms has the order of magnitude

$$\frac{|\frac{\partial p}{\partial r}|}{\varrho_g t |\frac{Dv}{Dt}|} \sim \frac{c^2 t_{osc}^2}{R_0^2}\frac{\delta \varrho}{\varrho_g} \sim \frac{c^2 t_{osc}^2}{R_0^2} \sim 4 \times 10^5. \tag{A.11}$$

It follows from (A.10) and (A.11) that the leading term in (A.4) is $\frac{\partial p}{\partial r}$. As is usual in fluid mechanics, we will then approximate (A.4) by

$$\frac{\partial p}{\partial r} = 0, \tag{A.12}$$

or, in an equivalent way,

$$p = p(t). \tag{A.13}$$

In the liquid, the Reynolds number that measures the relative size of inertial and viscous terms is of order one. In fact $Re_l \sim \frac{R_0^2}{\nu_l t_{osc}} \sim 5$, where we have used that $\nu_l \sim 1\,\mathrm{cm}^2 s^{-1}$. This means that in the liquid we have to deal with the whole Navier–Stokes system. However, this is not a serious difficulty, since in the spherically symmetric case the solution of that system (including viscous terms) is given by the explicit solution (2.2).

We need to determine the relative importance of viscous terms at the boundary of the bubble. The condition of mechanical equilibrium at the surface of the bubble is

$$-p_l + p_g - \left(2\nu_l \frac{\partial v_l}{\partial r} - 2\nu_g \frac{\partial v_g}{\partial r}\right) = \frac{2\sigma}{R}. \tag{A.14}$$

It turns out that viscous terms are completely negligible compared with the effect of surface tension. In fact, using the fact that $\nu_l \sim 10^{-2} g\, cm^{-1} s^{-1} \gg \nu_g \sim 10^{-4} g\,\mathrm{cm}^{-1} s^{-1}$, it follows that

$$\nu_l \frac{\partial v_l}{\partial r} - \nu_g \frac{\partial v_g}{\partial r} \sim \frac{\nu_l}{t_{osc}}. \tag{A.15}$$

The surface tension for the air-water interface at ambient temperature is of order

$$\sigma \sim 70\, dyn\,\mathrm{cm}^{-1}. \tag{A.16}$$

Using (A.1), (A.15), (A.16), it follows that

$$\frac{|\nu_l \frac{\partial v_l}{\partial r} - \nu_g \frac{\partial v_g}{\partial r}|}{\frac{2\sigma}{R}} \sim \frac{\nu_l R}{2\sigma t_{osc}} \sim \frac{1}{300}. \tag{A.17}$$

It is then natural to assume that viscous terms are not relevant in (A.14) and we replace that equation by

$$-p_l + p_g = \frac{2\sigma}{R}. \tag{A.18}$$

We now proceed to estimate the importance of thermal effects in the model. As a first step we consider the relative size of viscous effects in the liquid. The temperature in the liquid phase satisfies the equation:

$$\rho_l c_l \frac{DT}{Dt} = \nabla(k_l \nabla T) + \nabla v : \tau', \tag{A.19}$$

where τ' is the viscous part of the stress intensity factor, and k_l, c_l are the thermal conductivity and the specific heat of the liquid, respectively.

At ambient temperature we have the following numerical values: $\alpha = \frac{k_l}{\varrho_l c_l} \sim 1.5 \times 10^{-3}\ \mathrm{cm}^2 s^{-1}$, $c_l \sim 4 \times 10^7\, erg\, g^{-1} K^{-1}$. We then obtain the following relative sizes for the different terms in (A.19):

$$\frac{|\nabla(k_l \nabla T)|}{\rho_l c_l |\frac{DT}{Dt}|} \sim \alpha \frac{t_{osc}}{R_0^2} = 1.5 \times 10^{-2}, \tag{A.20}$$

$$\frac{|\nabla v : \tau'|}{\rho_l c_l |\frac{DT}{Dt}|} \sim \frac{\nu_l}{\rho_l c_l t_{osc} T_l} \left(\frac{\delta T}{T_l}\right)^{-1} \sim \frac{1}{4.8 \times 10^5} \left(\frac{\delta T}{T_l}\right)^{-1}. \tag{A.21}$$

Notice that (A.21) indicates that viscous terms are negligible as soon as relative changes of temperature are larger that 10^{-5}. It follows from (A.20), (A.21) that we can approximate (A.19) as

$$\frac{DT}{Dt} = 0. \tag{A.22}$$

Assuming that the initial temperature of the liquid is constant ($T = T_l$), we then deduce that T remains constant everywhere. Using the fact that the temperature is continuous across the interface, we then obtain the following boundary condition for the temperature of the gas at the surface of the bubble:

$$T = T_l \ \text{ at } \ r = R(t). \tag{A.23}$$

As a next step we proceed to determine the relevant terms in the thermal equation for the gas. The entropy equation for the gas can be written as

$$\varrho T \frac{Ds}{Dt} = \nabla(k\nabla T) + \nabla v : \tau'. \tag{A.24}$$

We can readily compare the sizes of the viscous and conduction terms:

$$\frac{|\nabla v : \tau'|}{\nabla(k\nabla T)} \sim \frac{v_g R_0^2}{\alpha c_v T} \sim 10^{-15},$$

where we have made the assumption $\frac{\delta T}{T} \sim 1$. The effect of viscous terms in (A.24) is then completely negligible. On the other hand, we need to compare convective and conductive terms in (A.24). The relative size of these terms is given by

$$\frac{|\varrho T \frac{Ds}{Dt}|}{|\nabla(k\nabla T)|} \sim \frac{R_0^2}{\alpha t_{osc}} \sim \frac{1}{2}. \tag{A.25}$$

We are thus led to assume that convective and conductive terms in (A.24) are of the same order of magnitude. We then replace (A.24) by

$$\rho T \frac{Ds}{Dt} = \nabla(k\nabla T). \tag{A.26}$$

Equation (A.26) has to be complemented with the boundary condition (A.23).

To conclude this appendix we adimensionalize the resulting model using R_0 as the unit of length, t_{osc} as the unit of time, using as characteristic units of density and pressure on the liquid, respectively, $\rho_s = 10^{-3} g\ \text{cm}^{-3}, p_0 = 1$ atm. Finally, we use as the unit of density in the liquid $\varrho_l = 1\, g\ \text{cm}^{-3}$. With the above mentioned approximations, the evolution of the bubble turns out to be described for the model (2.19)–(2.22), where we have to take into account that in (2.19) σ stands for $\frac{\sigma}{R_0 p_0}$ and in (2.22) k is the nondimensional number $\frac{\alpha t_{osc}}{R_0^2}$. It is relevant to determine the order of magnitude of the number Γ in (2.19), which is given by

$$\Gamma = \frac{R_0^2 \varrho_l}{p_0 t_c^2} \sim \frac{1}{400}.$$

Appendix B. We recall here the derivation of (4.4) in the radially symmetric case. Notice that

$$\frac{d}{dt}\left(\int_{B_{R(t)}} \varrho\Phi d^3x\right) = \frac{d}{dt}\int_0^{R(t)} 4\pi\varrho\Phi r^2 dr$$
$$= 4\pi R^2\varrho\Phi|_{R(t)}\dot{R} + \int_0^{R(t)} 4\pi(\varrho_t\Phi + \varrho\Phi_t)r^2 dr.$$

Taking into account the continuity equation (2.18) as well as the boundary condition (2.15) we obtain

$$\frac{d}{dt}\left(\int_{B_{R(t)}} \varrho\Phi d^3x\right) = 4\pi R^2(\varrho\Phi v)|_{R(t)} + 4\pi\int_0^{R(t)} \varrho\Phi_t r^2 dr$$
$$-4\pi\int_0^{R(t)} \frac{\partial}{\partial r}(r^2\varrho v)\Phi dr = 4\pi\int_0^{R(t)} \varrho\frac{D\Phi}{Dt}r^2 dr = \int_{B_{R(t)}} \varrho\frac{D\Phi}{Dt}d^3x,$$

as we wanted to prove.

Acknowledgments. The authors are very thankful to A. Liñán for several interesting discussions about the formulation of the model considered in this paper. Part of this work was made during a stay by the first author at Universidad Complutense of Madrid funded by the European Science Foundation through his FBP Scientific Programme.

A SOLUTION WITH BOUNDED EXPANSION RATE TO THE MODEL OF VISCOUS PRESSURELESS GASES*

LAURENT BOUDIN†

Abstract. We prove the existence of a global smooth solution to the equations of one-dimensional viscous pressureless gases and obtain a uniform upper estimate on the expansion rate with respect to viscosity. Then we get the convergence to the inviscid model in the duality sense of Bouchut and James.

Key words. pressureless gases, viscous solutions, entropy conditions, Oleinik entropy condition, inviscid limit, duality solutions

1. Introduction and main results. We study here the one-dimensional system describing a viscous pressureless gas. The gas density $\rho(t,x) > 0$ and the velocity $u(t,x) \in \mathbb{R}$ have to satisfy the following equations:

$$\partial_t \rho + \partial_x(\rho u) = 0 \qquad \text{in }]0,T[\times\mathbb{R}, \tag{1.1}$$

$$\partial_t u + u\partial_x u = \varepsilon \frac{\partial^2_{xx} u}{\rho} \qquad \text{in }]0,T[\times\mathbb{R}, \tag{1.2}$$

where $T > 0$, and $\varepsilon > 0$ is the viscosity coefficient. We also give initial conditions

$$u(0,.) = u_0, \qquad \rho(0,.) = \rho_0. \tag{1.3}$$

We could also study the same problem set in $]0,+\infty[\times\mathbb{R}$. All the results in this paper can be extended to that case.

Remark. Note that (1.1)–(1.2) formally imply

$$\partial_t(\rho u) + \partial_x(\rho u^2) = \varepsilon \partial^2_{xx} u \qquad \text{in }]0,T[\times\mathbb{R}. \tag{1.4}$$

This computation is justified by the smoothness of ρ and u. When $\varepsilon = 0$, (1.4) is the momentum conservation law, i.e., we find the model of inviscid pressureless gases.

The equations can be seen as a simplified model of Navier–Stokes equations of gas dynamics, where the pressure has been set to 0. They can describe either cold plasmas or galaxies' dynamics [16]. One-dimensional Navier–Stokes equations with pressure are studied, for example, in [13] or [11] and the references therein.

Several results have been obtained recently on the inviscid pressureless problem by Grenier [9], Weinan, Rykov, and Sinai [7], Brenier and Grenier [5], Bouchut [1], and Bouchut and James [2], [3], [4] (see also Poupaud and Rascle [14] for an approach in the multidimensional case). The main feature that comes out is the importance of the estimate $\partial_x u \leq 1/t$ on the expansion rate. We prove here a similar estimate on the viscous problem.

†Laboratoire de Mathématiques, Applications, et Physique Mathématiques d' Orléans, Université d' Orléans, UMR CNRS 6628, BP 6759, 45067 Orléans Cedex 2, France (boudin@labomath.univ-orleans.fr).

We assume that initial data $\rho_0 > 0$ and u_0 satisfy the following conditions:

$$\rho_0 \in L^\infty(\mathbb{R}), \frac{1}{\rho_0} \in L^\infty(\mathbb{R}), \qquad \partial_x \rho_0 \in L^1 \cap L^\infty(\mathbb{R}), \tag{1.5}$$

$$u_0 \in L^1 \cap L^2(\mathbb{R}), \qquad \partial_x u_0 \in L^1 \cap L^2(\mathbb{R}). \tag{1.6}$$

Notations. We denote by $C_0(\mathbb{R})$ the space of continuous functions of $x \in \mathbb{R}$ that tend to 0 when $|x| \to +\infty$. Then $\mathcal{D}_+(I)$ denotes the space of nonnegative functions in $\mathcal{D}(I)$, for any open interval $I \subset \mathbb{R}$. Finally, E is the Banach space

$$E = \{v \in L^2_t(C_{0_x}) \ \mid \ \partial_x v \in L^2_t(C_{0_x}) \cap L^2_t(L^1_x)\}, \tag{1.7}$$

with the norm

$$\|v\|_E = \|v\|_{L^2_t(C_{0_x})} + \|\partial_x v\|_{L^2_t(C_{0_x})} + \|\partial_x v\|_{L^2_t(L^1_x)}.$$

Our first main result follows.

THEOREM 1. *Let T, $\varepsilon > 0$ and two functions $\rho_0 > 0$ and u_0 satisfying* (1.5) *and* (1.6). *Then there exists a solution (ρ, u) in the sense of distributions to* (1.1)–(1.3) *such that $\rho > 0$,*

$$\rho \in C([0,T]; L^1_{\mathrm{loc}}(\mathbb{R})) \cap L^\infty(]0,T[\times\mathbb{R}), \qquad \frac{1}{\rho} \in L^\infty(]0,T[\times\mathbb{R}), \tag{1.8}$$

$$u \in C([0,T]; H^1(\mathbb{R})) \cap L^2(]0,T[; H^2(\mathbb{R})). \tag{1.9}$$

Moreover, the following a priori estimates hold, with $w = \partial_x u$, $w_0 = \partial_x u_0$:

$$\|w(t)\|_{L^1_x} \le \|w_0\|_{L^1}, \quad 0 \le t \le T, \qquad \text{and} \qquad \|u\|_{L^\infty_{t,x}} \le \|u_0\|_{L^\infty}.$$

We also have, in $\mathcal{D}'_{t,x}$, the following renormalized equations for any $S \in C^2(\mathbb{R})$ such that $S'' \in L^\infty$:

$$\partial_t(\rho S(u)) + \partial_x(\rho u S(u)) - \varepsilon \partial_x(S'(u)\partial_x u) = -\varepsilon S''(u)(\partial_x u)^2, \tag{1.10}$$

$$\begin{aligned} &\partial_t S(w) + \partial_x(uS(w)) - \varepsilon \partial_x\left(\frac{S'(w)\partial_x w}{\rho}\right) \\ &\qquad = w(S(w) - wS'(w)) - \varepsilon S''(w)\frac{(\partial_x w)^2}{\rho}. \end{aligned} \tag{1.11}$$

Finally, if we assume that $\operatorname{ess\,sup} \partial_x u_0 < +\infty$, *we have the uniform upper bound estimate on the expansion rate*

$$\partial_x u(t,x) \le \frac{A}{At+1} \le \frac{1}{t} \qquad \text{almost everywhere (a.e.) } (t,x) \in [0,T]\times\mathbb{R}, \tag{1.12}$$

where $A = \max(\operatorname{ess\,sup} \partial_x u_0, 0)$.

Remark. For a given u, the solution ρ to (1.1) can be obtained with the results of DiPerna and Lions [6] or Bouchut and James [2]. Note that the norms $\|\rho\|_{L^\infty_{t,x}}$ and $\|1/\rho\|_{L^\infty_{t,x}}$ can be estimated in terms of $\|\rho_0\|_{L^\infty}$, $\|1/\rho_0\|_{L^\infty}$, and $\|u\|_E$ (see formula (4.1)).

The renormalized equations (1.10)–(1.11) give entropy inequalities when S is convex, and the inequality (1.12) on $\partial_x u$ is called the Oleinik entropy condition. It has

been proved in its optimal form by Hoff [10] for the solution of a scalar conservation law.

The proof of Theorem 1 is divided into three steps. We first solve the linear equation associated to (1.2), namely,

$$\partial_t u + b\partial_x u = \sigma \partial^2_{xx} u, \tag{1.13}$$

where b and σ are fixed, by using a standard theorem of J.-L. Lions [12], [15]. Next we use Schäfer's fixed point theorem [8], applied as follows. We start with a smooth enough approximate velocity $\tilde{u}$ and get the solution $\rho > 0$ to

$$\partial_t \rho + \partial_x(\rho \tilde{u}) = 0.$$

Then we solve (1.13) with $b = \tilde{u}$ and $\sigma = \varepsilon/\rho$. Thus we build u from $\tilde{u}$. We conclude with Schäfer's result applied to the operator $Q : \tilde{u} \mapsto u$. Then we get estimate (1.12).

Finally, we prove that condition (1.12) is sufficient to justify the asymptotics $\varepsilon \to 0$, in the sense defined by Bouchut and James [2], [3], [4].

Definition 1. *A solution $p \in \mathrm{Lip}_{\mathrm{loc}}([0,T] \times \mathbb{R})$ to*

$$\partial_t p + u\partial_x p = 0 \qquad \text{in }]0,T[\times\mathbb{R} \tag{1.14}$$

is said to be reversible if there exists two solutions $p_1, p_2 \in \mathrm{Lip}_{\mathrm{loc}_{t,x}}$ to (1.14) such that

$$\partial_x p_1 \geq 0, \qquad \partial_x p_2 \geq 0, \qquad \text{and} \qquad p = p_1 - p_2.$$

Remark. The backward problem (1.14) with final Cauchy data $p_T \in \mathrm{Lip}_{\mathrm{loc}}(\mathbb{R})$ is well-posed in the class of reversible solutions if we assume that $u \in L^\infty_{t,x}$ satisfies the Oleinik entropy condition $\partial_x u \leq 1/t$.

Definition 2. *We say that $\mu \in C([0,T]; w^*\text{-}\mathcal{M}_{\mathrm{loc}_x})$ is a duality solution to*

$$\partial_t \mu + \partial_x(\mu u) = 0 \qquad \text{in }]0,T[\times\mathbb{R} \tag{1.15}$$

if, for any $0 < \tau \leq T$, and any reversible solution p, with compact support in x, to $\partial_t p + u\partial_x p = 0$ in $]0,\tau[\times\mathbb{R}$, the function

$$t \mapsto \int_{\mathbb{R}} p(t,x)\mu(t,dx)$$

is constant on $[0,\tau]$.

For our viscous system

$$\partial_t \rho^\varepsilon + \partial_x(\rho^\varepsilon u^\varepsilon) = 0, \tag{1.16}$$

$$\partial_t q^\varepsilon + \partial_x(q^\varepsilon u^\varepsilon) = \varepsilon \partial^2_{xx} u^\varepsilon, \tag{1.17}$$

with $q^\varepsilon = \rho^\varepsilon u^\varepsilon$, the notion of duality solution enables us to justify the convergence when $\varepsilon \to 0$ to

$$\partial_t \rho + \partial_x(\rho u) = 0, \tag{1.18}$$

$$\partial_t q + \partial_x(q u) = 0, \tag{1.19}$$

with $q = \rho u$, i.e., the system of inviscid pressureless gases. We have the following result.

THEOREM 2. *We assume that* ρ_0^ε *and* u_0^ε *satisfy* (1.5)–(1.6) *for each* ε *and*

$$(q_0^\varepsilon) \rightharpoonup q_0 \text{ in } w^*\text{-}\mathcal{M}_{\mathrm{loc}}, \tag{1.20}$$
$$\rho_0^\varepsilon > 0, \qquad \|1/\rho_0^\varepsilon\|_{L^\infty} \le \frac{C}{\varepsilon^{1/4}}, \qquad (\rho_0^\varepsilon) \rightharpoonup \rho_0 \ge 0 \text{ in } \mathrm{w}^*\text{-}\mathcal{M}_{\mathrm{loc}},$$
$$\|u_0^\varepsilon\|_{L^\infty} \le C, \qquad \text{ess sup}\, \partial_x u_0^\varepsilon \le \frac{C}{\sqrt{\varepsilon}},$$

where C *is a constant independent on* ε. *Then there exists a subsequence of* $(\rho^\varepsilon, q^\varepsilon)$ *solutions to* (1.16)–(1.17) *with initial data* $(\rho_0^\varepsilon, q_0^\varepsilon)$ *which converge in* $C_t(w^*\text{-}\mathcal{M}_{\mathrm{loc}_x})$ *to* (ρ,q) *solution to* (1.18)–(1.19) *in the sense of duality, in any subinterval* $]t_1, t_2[$, $0 < t_1 < t_2 \le T$, *with initial data* ρ_0 *and* q_0, *and where* u *is a limit of a subsequence of* (u^ε) *in* $w^*\text{-}L^\infty$.

This result is obtained via a backward approximate viscous problem, which solutions, up to a subsequence, converge towards the reversible solutions to the inviscid problem.

Remark. For simplicity, in this theorem and its proof, we identify u and its universal representative defined in [3].

2. Linear equation—a priori estimates. Let three functions b, σ, and u_0 be such that

$$b \in E \qquad \text{and} \qquad \|b\|_{L^\infty_{t,x}} \le b_M, \tag{2.1}$$
$$\sigma_m \le \sigma(t,x) \le \sigma_M \qquad \text{a.e. } (t,x) \in [0,T] \times \mathbb{R}, \tag{2.2}$$
$$u_0 \in L^2(\mathbb{R}), \qquad \partial_x u_0 \in L^1 \cap L^2(\mathbb{R}), \tag{2.3}$$

where b_M, σ_m, and σ_M are strictly positive constants.

In this section, we prove the existence of a solution u to

$$\partial_t u + b\partial_x u = \sigma \partial^2_{xx} u \qquad \text{in }]0,T[\times\mathbb{R}, \tag{2.4}$$
$$u(0,.) = u_0. \tag{2.5}$$

It is obtained via the equation on $\partial_x u$.

PROPOSITION 3. *If* b, σ *satisfy* (2.1)–(2.2) *and for any*

$$w_0 \in L^1 \cap L^2(\mathbb{R}), \tag{2.6}$$

there exists a unique solution in the sense of distributions

$$w \in C_t(L^2_x) \cap L^2_t(H^1_x) \tag{2.7}$$

to

$$\partial_t w + \partial_x(bw) = \partial_x(\sigma \partial_x w) \qquad \text{in }]0,T[\times\mathbb{R}, \tag{2.8}$$
$$w(0,.) = w_0. \tag{2.9}$$

The problem (2.8)–(2.9) *satisfies the following property of stability, denoted by* (S). *Let us consider* (b_n), (σ_n), *and* (w_{0_n}) *satisfying* (2.1), (2.2), (2.6) *for each* n *and such that*

$$(b_n) \to b \text{ in } E, \tag{2.10}$$
$$(\sigma_n(t,x)) \to \sigma(t,x) \text{ a.e.}, \tag{2.11}$$
$$(w_{0_n}) \to w_0 \text{ in } L^2(\mathbb{R}). \tag{2.12}$$

Then the unique sequence (w_n) *defined by*

$$\partial_t w_n + \partial_x(b_n w_n) = \partial_x(\sigma_n \partial_x w_n) \qquad \text{in }]0,T[\times\mathbb{R}, \tag{2.13}$$

$$w_n(0,.) = w_{0_n} \tag{2.14}$$

strongly converges to the solution w *to* (2.8)–(2.9) *in* $C_t(L^2_x) \cap L^2_t(H^1_x)$.

We also have the renormalized equation on w *in* $\mathcal{D}'_{t,x}$

$$\begin{aligned} &\partial_t(S(w)) + \partial_x(bS(w)) - \partial_x(\sigma S'(w)\partial_x w) \\ &\qquad = \partial_x b(S(w) - wS'(w)) - \sigma S''(w)(\partial_x w)^2 \end{aligned} \tag{2.15}$$

for any $S \in C^2(\mathbb{R})$ *such that* S'' *is bounded.*

Finally we have

$$w \in C_t(L^1_x) \qquad \text{and} \qquad \|w(t)\|_{L^1_x} \le \|w_0\|_{L^1}, \qquad 0 \le t \le T, \tag{2.16}$$

and the estimate

$$\|w\|_{L^2_t(C_{0_x})} \le C\|\partial_x w\|^{2/3}_{L^2_{t,x}} \tag{2.17}$$

holds with a constant C *only depending on* $\|w_0\|_{L^1}$.

Once Proposition 3 is proved, we can easily obtain the following proposition.

PROPOSITION 4. *If* b, σ, *and* u_0 *satisfy* (2.1)–(2.3), *it is possible to define* $u \in C_t(C_{0_x})$ *by*

$$u(t,x) = \int_{-\infty}^{x} w(t,y)dy, \tag{2.18}$$

where w *is the solution to* (2.8) *given by Proposition* 3 *with initial data* $\partial_x u_0$. *Then* u *satisfies* (2.4)–(2.5) *and the following maximum principle estimate:*

$$\|u\|_{C_t(C_{0_x})} \le \|w_0\|_{L^1}. \tag{2.19}$$

In order to prove existence and uniqueness of a solution w to (2.8), we recall the following.

THEOREM 5 (J.-L. Lions). *Let* $(H, |.|_H)$ *and* $(V, |.|_V)$ *be two Hilbert spaces such that*

$$V \subset H \subset V'$$

with continuous and dense injections.

For a.e. $t \in [0,T]$, *we consider a bilinear form* $a(t;.,.) : V^2 \to \mathbb{R}$ *satisfying*

(i) $t \mapsto a(t;w,v)$ *is measurable for any* $(w,v) \in V^2$,

(ii) $|a(t;w,v)| \le M|w|_V|v|_V$ *a.e.* $t \in [0,T]$ $\forall w,v \in V$,

(iii) $a(t;v,v) \ge \alpha|v|^2_V - C|v|^2_H$ *a.e.* $t \in [0,T]$ $\forall w,v \in V$,

where $M, C \in \mathbb{R}$ *and* $\alpha > 0$ *are constants.*

Then, for $f \in L^2(]0,T[;V')$, $w_0 \in H$, *there exists a unique* w *such that*

$$w \in C([0,T];H) \cap L^2(]0,T[;V), \qquad \partial_t w \in L^2(]0,T[;V'),$$

and

$$\left\{ \begin{array}{rcll} \langle \partial_t w, v\rangle + a(t;w,v) & = & \langle f(t), v\rangle & \text{a.e. } t \quad \forall v \in V, \\ w(0,.) & = & w_0. & \end{array} \right.$$

This result can be found in [12] or [15].

Proof of Proposition 3. We apply Theorem 5 with $H = L^2_x(\mathbb{R})$ and $V = H^1_x(\mathbb{R})$ with their usual norm, and set

$$a(t; w, v) = -\int_{\mathbb{R}} bw\partial_x v dx + \int_{\mathbb{R}} \sigma\partial_x w\partial_x v dx \qquad \text{a.e. } t \quad \forall w, v \in H^1_x.$$

Then $a(t; ., .)$ is clearly a bilinear form on H^1_x and $t \mapsto a(t; w, v)$ is measurable for any w, v, because b and σ are measurable too. Condition (ii) is clear. For condition (iii),

$$a(t; v, v) \geq \sigma_m \|v\|^2_{H^1_x} - \sigma_m \|v\|^2_{L^2_x} - b_M \|v\|_{L^2_x} \|v\|_{H^1_x}.$$

Let us choose a constant α such that $\alpha > b_M/2\sigma_m$. Then the constant $\sigma_m - b_M/2\alpha$ is strictly positive, and since, for any v,

$$a(t; v, v) \geq \left(\sigma_m - \frac{b_M}{2\alpha}\right)\|v\|^2_{H^1_x} - \left(\sigma_m + \frac{b_M\alpha}{2}\right)\|v\|^2_{L^2_x},$$

we get (iii).

Therefore Theorem 5 gives the existence and uniqueness of the solution w to (2.7)–(2.9) and

$$\langle \partial_t w, v\rangle + a(t; w, v) = 0 \qquad \text{a.e. } t \quad \forall v \in V. \tag{2.20}$$

Note that the solution to (2.20) is also a solution to (2.8) in the sense of distributions. The inverse holds too, thanks to the density of tensor products of functions of $\mathcal{D}(]0, T[)$ and $\mathcal{D}(\mathbb{R})$ in $\mathcal{D}(]0, T[\times\mathbb{R})$. This ends the proof of existence and uniqueness for Proposition 3. □

Proof of (S). Let us prove first some preliminary results.

LEMMA 1. *For any* $(t_1, t_2) \in [0, T]^2$, *we have*

$$\frac{1}{2}\left[\int_{\mathbb{R}} (w(t_2)^2 - w(t_1)^2)dx\right] = \int_{t_1}^{t_2}\int_{\mathbb{R}} (bw\partial_x w - \sigma(\partial_x w)^2)dxdt. \tag{2.21}$$

Proof. The estimate is easily obtained by considering the equation satisfied by $\theta_m * w$, where $(\theta_m(x))$ is a mollifying sequence. □

LEMMA 2. *If we set*

$$A_1 = \|w_0\|_{L^2} \ \exp\left(\frac{1}{2}\|\partial_x b\|_{L^2_t(C_{0_x})}\sqrt{T}\right), \tag{2.22}$$

$$A_2 = \left[\frac{1}{2\sigma_m}\left(\|w_0\|^2_{L^2} + A_1^2\|\partial_x b\|_{L^2_t(C_{0_x})}\sqrt{T}\right)\right]^{1/2}, \tag{2.23}$$

$$A_3 = \sqrt{2}((b_M A_1)^2 T + (\sigma_M A_2)^2)^{1/2}, \tag{2.24}$$

then we have

$$\|w(t)\|_{L^2_x} \leq A_1, \qquad 0 \leq t \leq T, \tag{2.25}$$

$$\|\partial_x w\|_{L^2_{t,x}} \leq A_2, \tag{2.26}$$

$$\|\partial_t w\|_{L^2_t(H^{-1}_x)} \leq A_3. \tag{2.27}$$

Proof. For (2.25), we use (2.21) with $t_1 = 0$ and $t_2 = t \in]0, T]$; that is,

$$\int_{\mathbb{R}} \frac{w(t)^2}{2} dx - \int_{\mathbb{R}} \frac{w_0^2}{2} dx = \int_0^t \int_{\mathbb{R}} \left[bw\partial_x w - \sigma(\partial_x w)^2 \right] dx ds. \tag{2.28}$$

This implies

$$\|w(t)\|_{L^2_x}^2 \leq \|w_0\|_{L^2_x}^2 + \int_0^t \|w(s)\|_{L^2_x}^2 \|\partial_x b(s)\|_{C_{0_x}} ds.$$

Thanks to Gronwall's lemma, we get (2.25).

For (2.26), we use (2.21) with $t_1 = 0$ and $t_2 = T$; that is,

$$\int_{\mathbb{R}} \frac{w(T)^2}{2} dx - \int_{\mathbb{R}} \frac{w_0^2}{2} dx = - \int_0^T \int_{\mathbb{R}} \left[\partial_x b \frac{w^2}{2} + \sigma(\partial_x w)^2 \right] dx dt.$$

Then

$$\int_0^T \int_{\mathbb{R}} \sigma(\partial_x w)^2 dx dt \leq \frac{1}{2} \left[\|w_0\|_{L^2}^2 - \int_0^T \int_{\mathbb{R}} \partial_x b \; w^2 dx dt \right] \tag{2.29}$$

$$\leq \frac{1}{2} \left(\|w_0\|_{L^2}^2 + A_1^2 \|\partial_x b\|_{L^2_t(C_{0_x})} \sqrt{T} \right), \tag{2.30}$$

and we get (2.26).

Let us prove (2.27). For any $\varphi \in H^1_x$ and a.e. t,

$$\langle \partial_t w(t), \varphi \rangle_{H_x^{-1}, H_x^1} = \langle b(t) w(t) - \sigma(t) \partial_x w(t), \varphi' \rangle_{L^2_x, L^2_x}.$$

Hence, by (2.25), (2.26), and after integration, we get (2.27). □

We now begin the proof of (S). We want to prove that the sequence given by the solutions w_n to (2.13)–(2.14) strongly converges to the solution w to (2.8)–(2.9) in $C_t(L^2_x) \cap L^2_t(H^1_x)$.

First, we prove that

$$(w_n) \to w \text{ in } C_t(\text{w-}L^2_x), \tag{2.31}$$

and

$$(\partial_x w_n) \rightharpoonup \partial_x w \text{ in w} - L^2_{t,x}. \tag{2.32}$$

Thanks to Lemma 2, we know for each n and any t that

$$\|w_n(t)\|_{L^2_x} \leq \|w_{0_n}\|_{L^2} \; \exp\left(\frac{1}{2} \|\partial_x b_n\|_{L^2_t(C_{0_x})} \sqrt{T} \right).$$

From (2.10) and (2.12), we can state that there exists a constant B_1 depending only on b and w_0 such that

$$\|w_n(t)\|_{L^2_x} \leq B_1, \qquad 0 \leq t \leq T, \qquad \forall n. \tag{2.33}$$

In the same way, we can find constants B_2 and B_3 such that

$$\|\partial_x w_n\|_{L^2_{t,x}} \leq B_2 \qquad \forall n, \tag{2.34}$$

$$\|\partial_t w_n\|_{L^2_t(H^{-1}_x)} \leq B_3 \qquad \forall n. \tag{2.35}$$

Thanks to Ascoli's theorem applied in the closed ball $\mathcal{K}$, which is a metric compact space for the weak topology of $L^2(\mathbb{R})$, we can state that there exists $\omega \in C_t(\text{w-}L^2_x)$ such that, up to a subsequence,

$$(w_n) \to \omega \text{ in } C_t(\text{w-}L^2_x).$$

Furthermore, by (2.34), we can state that $\omega \in L^2_t(H^1_x)$ and, up to a subsequence,

$$(\partial_x w_n) \rightharpoonup \partial_x \omega \text{ in } \text{w} - L^2_{t,x}.$$

In (2.13) and (2.14), it is then possible to let $n \to \infty$ and we find that (2.8) and (2.9) are verified by ω. We now must prove that $\omega = w$.

LEMMA 3. *If $z \in C_t(\text{w} - L^2_x) \cap L^2_t(H^1_x)$ is a solution in the sense of distributions to (2.8)–(2.9), then $z \in C_t(L^2_x)$.*

Proof. We use the same argument as in the proof of (2.21) with the mollifying sequence (θ_m) and $z_m = \theta_m *_x z$. We then prove that $t \mapsto \|z(t)\|^2_{L^2_x}$ is continuous. Since $z \in C_t(\text{w} - L^2_x)$, the proof is ended. □

Lemma 3 ensures that $\omega \in C_t(L^2_x)$. Thanks to the uniqueness of a solution to (2.8)–(2.9) in $C_t(L^2_x) \cap L^2_t(H^1_x)$ given in Theorem 5, we find that $\omega = w$ and (2.31) and (2.32) are proved.

We note here that (2.32), (2.34), and (2.35) imply that, up to a subsequence,

$$(w_n(t,x)) \to w(t,x) \qquad \text{a.e.} \tag{2.36}$$

Let us now prove that the weak convergences (2.31) and (2.32) are strong. By (2.21), we have, for any $0 \leq t \leq T$,

$$\begin{aligned}\int_{\mathbb{R}} w_n(t)^2 dx - \int_{\mathbb{R}} w(t)^2 dx &= \int_{\mathbb{R}} w^2_{0_n} dx - \int_{\mathbb{R}} w_0^2 dx \\ &+ \int_0^t \int_{\mathbb{R}} (\partial_x b w^2 - \partial_x b_n w_n^2) dx ds + 2\int_0^t \int_{\mathbb{R}} \left(\sigma(\partial_x w)^2 - \sigma_n(\partial_x w_n)^2\right) dx ds.\end{aligned} \tag{2.37}$$

Let us study the term

$$\int_0^t \int_{\mathbb{R}} (\partial_x b w^2 - \partial_x b_n w_n^2) dx ds.$$

By interpolation, with (2.33) and (2.34), we find a constant B_5 such that

$$\|w_n\|_{L^2_t(C_{0_x})} \leq B_5 \qquad \forall n, \tag{2.38}$$

and once again by interpolation, with (2.33) and (2.38), we find a constant $B_{4,p}$ such that, for any $p \in [2, \infty]$,

$$\|w_n\|_{L^{2p/p-2}_t(L^p_x)} \leq B_{4,p} \qquad \forall n. \tag{2.39}$$

The conjunction of (2.36) and (2.39) implies that, up to a subsequence,

$$(w_n^2) \to w^2 \text{ in } L^2_t(L^{p/2}_x) \tag{2.40}$$

for $2 < p < 4$.

Besides, since $(\partial_x b_n) \to \partial_x b$ in both $L^2_t(C_{0_x})$ and $L^2_t(L^1_x)$, we get

$$(\partial_x b_n) \to \partial_x b \text{ in } L^2_t(L^{p/p-2}_x). \tag{2.41}$$

From (2.40) and (2.41), we can state that

$$(\partial_x b_n w_n^2) \to \partial_x b w^2 \text{ in } L^1_{t,x}. \tag{2.42}$$

Moreover, by (2.12), $(\|w_{0_n}\|_{L^2}) \to \|w_0\|_{L^2}$, so (2.37) can be transformed, for any t, into

$$\begin{aligned} &\frac{1}{2}\left(\|w_n(t)\|^2_{L^2_x} - \|w(t)\|^2_{L^2_x}\right) \\ &\qquad = \varepsilon_n(t) + \int_0^t \int_{\mathbb{R}} \left(\sigma(\partial_x w)^2 - \sigma_n(\partial_x w_n)^2\right) dxds, \end{aligned} \tag{2.43}$$

where (ε_n) is a sequence of functions of t that uniformly tends to 0, because of (2.42).

Let $t \in [0,T]$ be fixed. We know (2.31), and by (2.29), we can state that, up to a subsequence,

$$(\sqrt{\sigma_n}\partial_x w_n) \rightharpoonup \sqrt{\sigma}\partial_x w \qquad \text{in w} - L^2_{t,x}. \tag{2.44}$$

Then we have

$$\|w(t)\|^2_{L^2_x} \leq \underline{\lim}\ \|w_n(t)\|^2_{L^2_x}$$

and

$$\int_0^t \int_{\mathbb{R}} \sigma(\partial_x w)^2 dxds \leq \underline{\lim} \int_0^t \int_{\mathbb{R}} \sigma_n(\partial_x w_n)^2 dxds.$$

Those two inequalities and (2.43) allow us to state that

$$\left(\|w_n(t)\|_{L^2_x}\right) \to \|w(t)\|_{L^2_x}$$

and

$$\left(\int_0^t \int_{\mathbb{R}} \sigma_n(\partial_x w_n)^2 dxds\right) \to \int_0^t \int_{\mathbb{R}} \sigma(\partial_x w)^2 dxds,$$

which implies, if we choose $t = T$ and with (2.44), that

$$(\sqrt{\sigma}_n \partial_x w_n) \to \sqrt{\sigma}\partial_x w \text{ in } L^2_{t,x}, \tag{2.45}$$

and then, with (2.11), $(\partial_x w_n) \to \partial_x w$ in $L^2_{t,x}$. Thanks to (2.43), for any t,

$$\begin{aligned} &\frac{1}{2}\left|\|w_n(t)\|^2_{L^2_x} - \|w(t)\|^2_{L^2_x}\right| \\ &\qquad \leq \|\varepsilon_n\|_{L^\infty} + \int_0^T \int_{\mathbb{R}} |\sigma(\partial_x w)^2 - \sigma_n(\partial_x w_n)^2| dxds, \end{aligned}$$

which does not depend on t and tends to 0 when $n \to \infty$ because of (2.45).

Thus we have the uniform convergence of $(\|w_n\|_{L^2_x})$ to $\|w\|_{L^2_x}$ in $C([0,T])$ and the convergence of (w_n) to w in $C_t(\text{w-}L^2_x)$, and we already know that $w \in C_t(L^2_x)$.

Therefore, we can state that $(w_n) \to w$ in $C_t(L^2_x)$, and the proof of the property (S) is finally completed. □

Remark. The solutions w_n to (2.13)–(2.14) are smooth when the coefficients in these two equations are smooth too [12].

Proof of (2.15). Let $S \in C^2(\mathbb{R})$ such that $S'' \in L^\infty$. We use (S) to prove the renormalized equation for any b, σ, and w. We consider (b_n), (σ_n), and (w_n) satisfying the property of stability (S) for the problem (2.8)–(2.9). We notice that (2.15) is obvious for smooth quantities.

Since S is C^2 with S'' bounded, it is clear that $(S''(w_n))$ tends to $S''(w)$ a.e., that $(S'(w_n))$ converges to $S'(w)$ in $C_t(L^2_{\mathrm{loc}_x})$ and that $(S(w_n))$ tends to $S(w)$ in $C_t(L^1_{\mathrm{loc}_x})$. It is then easy to let n go to $+\infty$ in the smooth version of (2.15). □

Proof of (2.16). We need here auxiliary functions $(\varphi_\alpha)_{\alpha>0}$ that are defined as follows for each $\alpha > 0$:

$$\varphi_\alpha(y) = \begin{cases} 0 & \text{if} \quad 0 \le y \le \alpha, \\ (y-\alpha)/2 + \alpha/2\pi \ \sin(\pi y/\alpha) & \text{if} \quad \alpha \le y \le 2\alpha, \\ y - 3\alpha/2 & \text{if} \quad y \ge 2\alpha, \end{cases}$$

and φ_α is an even function. For $\alpha > 0$, φ_α is positive, C^2, and convex, and φ''_α is bounded by 1. The sequence $(\varphi_\alpha)_{\alpha>0}$ uniformly tends to the absolute value when α goes to 0. We also notice, for $y \in \mathbb{R}$,

$$0 \le \varphi_\alpha(y) \le |y|, \tag{2.46}$$

$$0 \le \varphi_\alpha(y) \le \frac{\pi}{4}\frac{y^2}{\alpha}, \tag{2.47}$$

$$|\varphi_\alpha(y) - y\varphi'_\alpha(y)| \le (3/2 + 1/2\pi)\alpha = \kappa\alpha. \tag{2.48}$$

Since $w \in C_t(L^2_x)$, (2.46) and (2.47) ensure that $\varphi_\alpha(w) \in C_t(L^1_x) \cap C_t(L^2_x)$.

Remembering that φ_α is convex, i.e., $\varphi''_\alpha \ge 0$, the renormalized equation (2.15) for $S = \varphi_\alpha$ becomes an inequation in $\mathcal{D}'_{t,x}$; that is,

$$\partial_t\varphi_\alpha(w) + \partial_x(b\varphi_\alpha(w)) - \partial_x(\sigma\varphi'_\alpha(w)\partial_x w) \le \partial_x b(\varphi_\alpha(w) - w\varphi'_\alpha(w)). \tag{2.49}$$

Using a standard truncation result, we integrate (2.49):

$$\frac{d}{dt}\left(\int_{\mathbb{R}} \varphi_\alpha(w(t))dx\right) \le \kappa\alpha \int_{\mathbb{R}} |\partial_x b(t,x)|dx \qquad \text{in } \mathcal{D}'_t. \tag{2.50}$$

Hence, we can integrate (2.50) between 0 and $t \in]0,T]$ and get

$$\int_{\mathbb{R}} \varphi_\alpha(w(t))dx - \int_{\mathbb{R}} \varphi_\alpha(w_0)dx \le \kappa\alpha\sqrt{T}\|\partial_x b\|_{L^2_t(L^1_x)} = K\alpha, \tag{2.51}$$

where K is a constant (i.e., independent on t and α).

We use Fatou's lemma for $(\varphi_\alpha(w(t)))_{\alpha\in]0,1]}$, for any fixed t and find that $|w(t)| \in L^1_x$ and

$$\|w(t)\|_{L^1_x} \le \underline{\lim}\left(\int_{\mathbb{R}} \varphi_\alpha(w_0)dx + K\alpha\right) = \|w_0\|_{L^1}, \qquad 0 \le t \le T. \tag{2.52}$$

We must now prove that $w \in C_t(L^1_x)$.

LEMMA 4. *Let us consider $\gamma_1 : \mathbb{R} \to [0,1]$ a C^∞ even function, increasing on $[0,+\infty[$, such that*

$$0 \le x \le 1 \Rightarrow \gamma_1(x) = 0,$$
$$x \ge 2 \Rightarrow \gamma_1(x) = 1,$$

and, for $r \ge 1$, $\gamma_r : \mathbb{R} \to [0,1]$, $x \mapsto \gamma_1(x/r)$. Then

$$\int_{\mathbb{R}} |w(t,x)|\gamma_r(x)dx \le \int_{|x|\ge r} |w_0(x)|dx + \frac{K_0}{\sqrt{r}}, \qquad 0 \le t \le T, \tag{2.53}$$

where

$$K_0 = \lambda(b_M + \sigma_M \|\partial_x w\|_{L^2_{t,x}}), \tag{2.54}$$

and λ is a constant depending only on T, γ_1', and w_0.

Proof. We prove (2.53)–(2.54) by integrating the equation satisfied by $\varphi_\alpha(w)\gamma_r$ and using Fatou's lemma when $\alpha \to 0^+$. □

Finally, we prove that $w \in C_t(L^1_x)$ by using the fact that $w \in C_t(L^2_x)$ and Lemma 4. □

Proof of (2.17). We know that $w(t)$ belongs to $H^1_x(\mathbb{R}) \subset C_{0_x}(\mathbb{R})$ (continuous injection). By interpolation, and using (2.16), there exists a constant C_1 such that

$$\|w(t)\|_{L^\infty_x} \le C_1 \|w_0\|_{L^1}^{1/3} \|\partial_x w(t)\|_{L^2_x}^{2/3} \qquad \text{a.e. } t,$$

and we finally find (2.17). □

The proof of Proposition 3 is now completed.

Proof of Proposition 4. We first prove that, for any $t \in [0,T]$,

$$\int_{\mathbb{R}} w(t,x)dx = 0. \tag{2.55}$$

The solution w built in Proposition 3 satisfies (2.8). Using a standard truncation result, we get, in $\mathcal{D}'_t$,

$$\frac{d}{dt}\left(\int_{\mathbb{R}} w(t,x)dx\right) = 0. \tag{2.56}$$

Since, by (2.16), $t \mapsto \int_{\mathbb{R}} w(t)dx$ is continuous on $[0,T]$, we can state that

$$\int_{\mathbb{R}} w(t)dx = \int_{\mathbb{R}} w_0 dx = 0, \qquad 0 \le t \le T.$$

We are now able to define u by (2.18) and then (2.19) is obvious.

We still have to prove (2.4). It is clear that both bw and $\sigma\partial_x w$ belong to $L^2_{t,x}$. Moreover, $\partial_t w \in L^2_t(H^{-1}_x)$ implies that $\partial_t u \in L^2_{t,x}$. Hence $\mathcal{E}u := \partial_t u + bw - \sigma\partial_x w \in L^2_{t,x}$. But $\partial_x \mathcal{E}u = 0$. The two previous remarks imply (2.4).

That ends the proof of Proposition 4. □

3. Fixed point theorem. Let T, $\varepsilon > 0$. We consider the system

$$\partial_t \rho + \partial_x(\rho \tilde{u}) = 0 \qquad \text{in }]0,T[\times\mathbb{R}, \tag{3.1}$$

$$\partial_t u + \tilde{u}\partial_x u = \varepsilon \frac{\partial^2_{xx} u}{\rho} \qquad \text{in }]0,T[\times\mathbb{R}. \tag{3.2}$$

The solutions $\rho > 0$ and u must satisfy initial conditions

$$u(0,.) = u_0 \qquad \text{and} \qquad \rho(0,.) = \rho_0, \tag{3.3}$$

where $\rho_0 > 0$ and u_0 verify the following conditions:

$$\rho_0 \in L^\infty(\mathbb{R}), \qquad \frac{1}{\rho_0} \in L^\infty(\mathbb{R}), \qquad \partial_x \rho_0 \in L^1 \cap L^\infty(\mathbb{R}), \tag{3.4}$$

$$u_0 \in L^2(\mathbb{R}), \qquad \partial_x u_0 \in L^1 \cap L^2(\mathbb{R}). \tag{3.5}$$

The function $\tilde{u}$ is given and satisfies the same initial condition as u. It will be made more precise later.

3.1. Schäfer's fixed point. We use the following result which is a corollary of Schäfer's fixed point theorem [8, pp. 280–281].

THEOREM 6 (Schäfer). *Let E be a Banach space, L a closed convex set containing 0, and $Q : L \to L$ a continuous operator on L satisfying the following:*

(i) *for any closed ball B' of E centered at 0, $\overline{Q(B' \cap L)}$ is compact,*

(ii) *the set $\{x \in E \ \mid \ \exists\ \theta \in [0,1] \ \ x = \theta\ Q(x)\}$ is bounded.*

Then Q has a fixed point in L.

From now on, E will denote the space defined in (1.7), and we take

$$L = \{u \in E \ \mid \ \|u\|_{L^\infty_{t,x}} \le \|\partial_x u_0\|_{L^1}\},$$

which is a closed convex set containing 0, and

$$\mathcal{S} = \{v \in L \ \mid \ \exists\ \theta \in [0,1] \ \ v = \theta\ Q(v)\}.$$

The image $Q\tilde{u}$ of an element $\tilde{u}$ of L is obtained as follows. We solve (3.1) with initial condition ρ_0, and find $\rho > 0$ satisfying (1.8). The uniqueness of ρ follows from Lemma 2.4.1 in [2]. Next we solve the linear equation (3.2) with initial condition u_0 thanks to the results of section 2 (with $b = \tilde{u}$ and $\sigma = \varepsilon/\rho$). Finally, $Q\tilde{u} = u$, the solution of (3.2).

Remark. The image $u = Q\tilde{u}$ of $\tilde{u} \in L$ is also an element of L. First $u \in C_t(C_{0_x})$ implies that $u \in L^2_t(C_{0_x})$. Next, by (2.7), we obtain that $\partial_x u = w \in L^2_t(C_{0_x})$. The fact that $\partial_x u \in L^2_t(L^1_x)$ is a consequence of (2.16). Thus $u \in E$. It is an element of L thanks to estimate (2.19).

3.2. Properties of u. We suppose that some properties of the solution ρ to (3.1) with initial condition ρ_0 are well known [2], [6].

PROPOSITION 7. *Assuming that $\tilde{u} \in L$ and u_0 satisfies* (3.5)*, the solution u to* (3.2) *with initial condition u_0 belongs to $C_t(L^2_x)$.*

Proof. We notice that $\partial_t u \in L^2_{t,x}$, because of (3.2), and then the result is clear thanks to the injection $H^1_t(L^2_x) \subset C_t(L^2_x)$. □

PROPOSITION 8. *We consider $\tilde{u} \in L$, ρ_0, u_0 satisfying* (3.4)–(3.5)*, and let ρ and u be solutions to* (3.1)–(3.3)*. Then we have, for $S \in C^2(\mathbb{R})$, the renormalized equation*

$$\partial_t(\rho S(u)) + \partial_x(\rho \tilde{u} S(u)) - \varepsilon \partial_x(S'(u)\partial_x u) = -\varepsilon S''(u)(\partial_x u)^2. \tag{3.6}$$

Proof. Let us use property (S). We assume that ρ_{0_n}, u_{0_n}, and $\tilde{u}_n$ are smooth and verify the same assumptions as ρ_0, u_0, and $\tilde{u}$. It is easy to prove (3.6) for u_n solution to (3.2) with $\tilde{u}_n$ and ρ_n instead of $\tilde{u}$ and ρ. Since $(w_n) \to w$ in $C_t(L^2_x) \cap L^2_t(H^1_x)$, by (3.2), we can see that $(\partial_t u_n) \to \partial_t u$ in $L^2_{t,x}$. Then, with the convergence of (u_{0_n}) to u_0 in $L^2(\mathbb{R})$ and Proposition 7, we can state that $(u_n) \to u$ in $C_t(L^2_x)$. That property is sufficient to justify $n \to \infty$ in the renormalized equation depending on n. Hence (3.6) is proved. ∎

Remark. We can here prove that $\|u\|_{L^\infty_{t,x}} \leq \|u_0\|_{L^\infty}$ using (3.6) for adequate functions S. For more details on the proof, see section 7 where a similar proof is given. Note that u_0 necessarily belongs to L^∞ because of (2.16) and (2.18).

Remark. Propositions 7 and 8 and section 2 imply the smoothness (1.9) of the solution u to (1.1)–(1.2).

In the next three sections, we prove that Q satisfies conditions (i) and (ii) of Theorem 6.

4. Compactness of Q. In this section, we fix $R > 0$, and denote by $\tilde{u}$ any function in $L \cap B'(R)$.

First of all, we notice, thanks to [2] or [6], that a maximum principle applied to (3.1) gives, for a.e. t, x, knowing $\tilde{u} \in B'(R)$,

$$0 < a_0 \mathrm{e}^{-R\sqrt{T}} \leq \frac{1}{\rho(t,x)} \leq a_0' \mathrm{e}^{R\sqrt{T}}, \qquad \text{a.e. } (t,x), \tag{4.1}$$

where $a_0 = (\max \rho_0)^{-1}$ and $a_0' = (\min \rho_0)^{-1}$.

We immediately obtain a uniform estimate on $\|w(t)\|_{L^2_x}$, i.e., the following proposition.

PROPOSITION 9. *The following estimate holds:*

$$\|w(t)\|^2_{L^2_x} \leq \|w_0\|^2_{L^2} e^{R\sqrt{T}}, \qquad 0 \leq t \leq T. \tag{4.2}$$

Proof. From (2.22) and (2.25) with $b = \tilde{u}$ and $\sigma = \varepsilon/\rho$, we get (4.2). ∎

4.1. Compactness of $\partial_x u$ in $L^2_t(L^1_x)$.

PROPOSITION 10. *There exists a strictly positive constant C_1 only depending on R, ε, and initial data such that*

$$\|\partial_x w\|_{L^2_{t,x}} \leq C_1. \tag{4.3}$$

Proof. We use (2.23) and (2.26). ∎

PROPOSITION 11. *There exists a strictly positive constant C_2 depending only on R, ε, and initial data such that*

$$\|\partial_t w\|_{L^2_t(H^{-1}_x)} \leq C_2. \tag{4.4}$$

Proof. We use (2.24) and (2.27). ∎

A standard compactness result ensures from (4.3) and (4.4) the compactness of w in $L^2_t(L^1_{\mathrm{loc}_x})$. It only remains to prove that the compactness also holds in $L^2_t(L^1_x)$.

LEMMA 5. *With the notations of Lemma 4, there exists a strictly positive constant C_3 depending only on R, ε, and initial data such that, for any $r \geq 1$ and any $0 \leq t \leq T$,*

$$\int_{\mathbb{R}} |w(t)| \gamma_r dx \leq \int_{|x| \geq r} |w_0| dx + \frac{C_3}{\sqrt{r}}. \tag{4.5}$$

Proof. We only have to use Lemma 4. ∎

Lemma 5 ensures that $\sup_{t\in[0,T]}\int_{\mathbb{R}}|w(t)|\gamma_r dx$ tends to 0 when $r\to+\infty$ since the estimate (4.5) involves only R, ε, and initial data, and then, thanks to a standard compactness result, we can state the compactness of w in $L^2_t(L^1_x)$.

4.2. Compactness of $\partial_x u$ in $L^2_t(C_{0_\infty})$. Let $(\theta_n)_{n\in\mathbb{N}}$ a mollifying sequence of functions of $x\in\mathbb{R}$. We know that $w\in L^2_{t,x}$ and $\partial_t w\in L^2_t(H^{-1}_x)$. This implies, for each n, that $\theta_n *_x w\in H^1_t(C^\infty_x)$. Moreover, we have the locally compact injection $H^1_t(C^\infty_x)\subset L^2_t(C_{0_x})$. But we also have

$$\begin{aligned}|(\theta_n * w)(t,x)-w(t,x)| &\le \left(\int_{-1/n}^{1/n}\sqrt{|h|}\theta_n(h)dh\right)\|\partial_x w(t)\|_{L^2_x}\\ &\le \frac{\|\partial_x w(t)\|_{L^2_x}}{\sqrt{n}}.\end{aligned}$$

Hence, thanks to (4.3),

$$\|\theta_n *_x w - w\|_{L^2_t(C_{0_x})}\le\frac{C_1}{\sqrt{n}},$$

which proves that $(\theta_n *_x w)$ tends to w in $L^2_t(C_{0_x})$. We need the following lemma and a standard compactness result to end the proof.

LEMMA 6. *With the notations of Lemma* 4, *there exists a strictly positive constant* C_4 *depending only on* R, ε, *and initial data such that, for any* $r\ge 1$,

$$\|w\gamma_r\|_{L^2_t(C_{0_x})}\le C_4\ \|w\gamma_r\|^{1/3}_{L^2_t(L^1_x)}. \tag{4.6}$$

Proof. We prove (4.6) thanks to an interpolation result and (4.2)–(4.3). ∎

4.3. Compactness of u in $L^2_t(C_{0_\infty})$. The operator $L^2_t(L^1_x)\to L^2_t(C_{0_x})$ defined by $w\mapsto u$ is continuous, so it maps a compact set into another one. Thanks to subsection 4.1, we can state the compactness of u in $L^2_t(C_{0_x})$.

5. Continuity of Q. We prove that Q is sequentially continuous. Let $(\tilde u_n)_{n\in\mathbb{N}}\subset L$ converging to $\tilde u$ in E. As a converging sequence, $(\tilde u_n)$ is bounded in E. Let us denote $R=1+\sup\|\tilde u_n\|_E>0$.

The previous section ensures that there exists an element f of E such that, up to a subsequence, $(u_n)=(Q\tilde u_n)\to f$ in E. Let us prove that $g=\partial_x f$ satisfies the following properties:

$$\partial_t g+\partial_x(\tilde u g)=\varepsilon\partial_x\left(\frac{\partial_x g}{\rho}\right)\qquad\text{in }\mathcal{D}'_{t,x}, \tag{5.1}$$

$$g(0,.)=\partial_x u_0, \tag{5.2}$$

$$\partial_t g\in L^2_t(H^{-1}_x), \tag{5.3}$$

$$g\in L^2_t(H^1_x), \tag{5.4}$$

$$g\in C_t(L^2_x). \tag{5.5}$$

We then get $g=\partial_x(Q\tilde u)$, as a consequence of the uniqueness in Theorem 5. We successively check the properties (5.1)–(5.5).

Proof of (5.1). First, $(u_n)\to f$ in E, so $(\partial_t u_n)\rightharpoonup\partial_t f$ in $\mathcal{D}'$. Next, $(u_n)\to f$ in E implies that $(\partial_x u_n)\to\partial_x f=g$ in $L^2_t(L^1_x)$, and $(\tilde u_n)$ converges to $\tilde u$ in E, so the product sequence $(\tilde u_n\partial_x u_n)$ tends to $\tilde u g$ in $\mathcal{D}'$.

For the last term, we first notice that $(1/\rho_n) \to 1/\rho$ a.e. (a consequence of a result in [6]), and we still have (4.1). Besides, by (2.29) with $b = \tilde{u}_n$ and $\sigma = \varepsilon/\rho_n$, it is clear that $(\partial^2_{xx} u_n)$ is uniformly bounded in $L^2_{t,x}$ with respect to n. Since $(u_n) \to f$ in E and consequently in $\mathcal{D}'$, we can state that $(\partial^2_{xx} u_n)$ weakly converges in $L^2_{t,x}$ to $\partial^2_{xx} f = \partial_x g$ in w-$L^2_{t,x}$. Hence the product sequence $(\partial^2_{xx} u_n/\rho_n)$ tends to $\partial^2_{xx} f/\rho$ in $\mathcal{D}'$.

Since $\partial_t u_n + \tilde{u}_n \partial_x u_n = \varepsilon \partial^2_{xx} u_n/\rho_n$, $n \to \infty$ gives (5.1) after derivation. □

Proof of (5.2). It is obvious since $\partial_x(Q\tilde{u}_n)(0,.) = \partial_x u_0$. □

Proof of (5.3)–(5.4). We have only to use estimates (4.4) and (4.2) for each w_n and let $n \to +\infty$. □

Proof of (5.5). The estimate (4.2) implies that (w_n) is bounded in $L^\infty_t(L^2_x)$. Hence, up to a subsequence, (w_n) converges in w*-L^∞_t(w-L^2_x). But we already know that (w_n) goes to g in $\mathcal{D}'_{t,x}$. This implies that the whole sequence (w_n) converges to g in w*-L^∞_t(w-L^2_x) and then $g \in L^\infty_t(L^2_x)$. Since g verifies (5.1)–(5.2), $g \in C_t(\mathcal{D}'_x)$. Then we can state that $g \in C_t$(w-$L^2_{t,x}$) and we only have to apply Lemma 3 to end the proof. □

Now we can use uniqueness in Theorem 5 and obtain that $g = w$ and $f = u$. Thus u is the limit in E of the subsequence $(Q\tilde{u}_n)$. In fact, every converging subsequence tends to the same limit u. That means that the entire sequence $(Q\tilde{u}_n)$ converges to u, i.e., Q is continuous on E.

6. Boundedness of the set $\mathcal{S}$. We have to prove that there exists a constant β such that for any $\tilde{u} \in \mathcal{S}$,

$$\|\tilde{u}\|_{L^2_t(C_{0_x})} \leq \beta, \tag{6.1}$$

$$\|\partial_x \tilde{u}\|_{L^2_t(L^1_x)} \leq \beta, \tag{6.2}$$

$$\|\partial_x \tilde{u}\|_{L^2_t(C_{0_x})} \leq \beta. \tag{6.3}$$

By (2.16)–(2.19), and since $0 \leq \theta \leq 1$, (6.1) and (6.2) are satisfied for $\beta \geq \|w_0\|_{L^1}\sqrt{T}$. Let us prove (6.3).

First of all, we consider the system

$$\partial_t \rho + \partial_x(\rho b) = 0 \qquad \text{in }]0,T[\times\mathbb{R}, \tag{6.4}$$

$$\rho(0) = \rho_0, \tag{6.5}$$

where ρ_0 satisfies (1.5) and

$$b \in V = C_t(H^1_x) \cap L^2_t(H^2_x). \tag{6.6}$$

The existence and uniqueness of a solution to (6.4)–(6.5) in C_t(w-$L^1_{\mathrm{loc}_x}$) are proved in [2]. Moreover, the problem satisfies a property of stability [6]; for example, if $(b_n) \to b$ in V and $(\rho_{0_n}) \to \rho_0$ a.e. with a uniform bound on both $(\|\rho_{0_n}\|_{L^\infty})$ and $(1/\|\rho_{0_n}\|_{L^\infty})$, then the sequence (ρ_n) of the solutions to (6.4)–(6.5), with b_n and ρ_{0_n} instead of b and ρ_0, converges toward ρ a.e. with a uniform bound on both $(\|\rho_n\|_{L^\infty_{t,x}})$ and $(1/\|\rho_n\|_{L^\infty_{t,x}})$.

LEMMA 7. *If ρ is the solution to* (6.4)–(6.5), *ρ_0 and b satisfying* (1.5) *and* (6.6), *then both $\partial_x \ln\rho$ and $\partial_t \ln\rho$ are in $L^\infty_t(L^2_x)$, and we have, in $\mathcal{D}'_{t,x}$,*

$$\partial_t \ln\rho + b\partial_x \ln\rho = -\partial_x b \tag{6.7}$$

and

$$\partial_t(\partial_x \ln\rho) + \partial_x(b\partial_x \ln\rho) = -\partial^2_{xx} b. \tag{6.8}$$

Proof. Thanks to the property of stability for (6.4)–(6.5), we can consider $\rho_{0_n} \in C^\infty(\mathbb{R})$, $b_n, \rho_n \in C^\infty_{t,x}$. More precisely, b_n and ρ_{0_n} are regularized functions of b and ρ_0 and ρ_n is the solution to (6.4)–(6.5) with b_n and ρ_{0_n} instead of b and ρ_0. Let us set $z_n = \partial_x \ln \rho_n$. Equation (6.4) can be transformed into

$$\partial_t \ln \rho_n + b_n z_n = -\partial_x b_n, \tag{6.9}$$

$$\partial_t z_n + \partial_x (b_n z_n) = -\partial^2_{xx} b_n. \tag{6.10}$$

From (6.10), we can prove that $|z_n(t)| \in L^2_x(\mathbb{R})$ a.e. t and

$$\int_{\mathbb{R}} |z_n(t)|^2 dx \le \mathrm{e}^T \big(\|z_{0_n}\|^2_{L^2_x} + \|\partial^2_{xx} b_n\|^2_{L^2_{t,x}} \big) \exp\big(\|\partial_x b_n\|_{L^2_t(C_{0_x})} \sqrt{T} \big).$$

From (6.9), we get, for a.e. t,

$$\|\partial_t \ln \rho_n(t)\|^2_{L^2_x} \le 2\big(\|\partial_x b_n(t)\|^2_{L^2_x} + \|b_n\|^2_{C_t(H^1_x)} \|z_n(t)\|^2_{L^2_x} \big).$$

The convergences on (z_{0_n}) and (b_n) ensure that there exists $C > 0$ such that

$$\|\partial \ln \rho_n\|_{L^\infty_t(L^2_x)} \le C. \tag{6.11}$$

Besides, we know that $(\ln \rho_n) \to \ln \rho$ a.e., with a uniform bound on $\|\ln \rho_n\|_{L^\infty_{t,x}}$, so $(\partial \ln \rho_n) \rightharpoonup \partial \ln \rho$ in $\mathcal{D}'_{t,x}$. Since $(\partial \ln \rho_n)$ is bounded in $L^\infty_t(L^2_x)$, up to a subsequence,

$$(\partial \ln \rho_n) \rightharpoonup \partial \ln \rho \qquad \text{in w*-}L^\infty_t(\text{w-}L^2_x). \tag{6.12}$$

Then we can let $n \to \infty$ in (6.9) and find (6.7), (6.8), and the fact that $\partial \ln \rho \in L^\infty_t(L^2_x)$. □

Let us go back to our problem. Since $\tilde{u} = \theta u$, $\tilde{u}$ has the same smoothness as u, i.e., $\tilde{u} \in V$. Thanks to Lemma 7, we know that the derivatives $\partial \ln \rho$ are in $L^2_{t,x}$ and satisfy the following equation, in $\mathcal{D}'_{t,x}$,

$$\partial_t(\partial_x \ln \rho) + \partial_x(\tilde{u} \partial_x \ln \rho) = -\partial^2_{xx} \tilde{u}, \tag{6.13}$$

which implies that $\partial_x \ln \rho \in C_t(\mathcal{D}'_x)$. Since $\partial_x \ln \rho$ also belongs to $L^\infty_t(L^2_x)$, we can state that $\partial_x \ln \rho \in C_t(\text{w-}L^2_x)$.

We also have, in $\mathcal{D}'_{t,x}$,

$$\partial_t(\rho u) + \partial_x(\rho u \tilde{u}) = \varepsilon \partial^2_{xx} u, \tag{6.14}$$

where $\rho u \in C_t(\text{w-}L^2_x)$ thanks to the properties of both ρ and u. Using (6.13), (6.14), and $\tilde{u} = \theta u$, we get the equation, in $\mathcal{D}'_{t,x}$,

$$\partial_t F + \partial_x(\tilde{u} F) = 0, \tag{6.15}$$

after having set $F = \theta \rho u + \varepsilon \partial_x \ln \rho \in C_t(\text{w-}L^2_x)$.

We also notice that the initial condition $F_0 = \theta \rho_0 u_0 + \varepsilon \partial_x \rho_0 / \rho_0$ associated to (6.15) is in $L^1(\mathbb{R})$. Formally, by (3.6) with $S = |\cdot|$ convex, we can state that $\rho|u| \in L^\infty_t(L^1_x)$ and

$$\int_{\mathbb{R}} \rho(t)|u(t)| dx \le \int_{\mathbb{R}} \rho_0 |u_0|, \qquad 0 \le t \le T, \tag{6.16}$$

by (1.5) and (1.6). This formal computation can be justified with $S = \varphi_\alpha$. Besides, since $|\partial_x \rho_0/\rho_0| \in L^1$ too, we notice that $F_0 \in L^1$. Since, by [6], $F \in C_t(L^1_x)$ and $\|F(t)\|_{L^1_x} \leq \|F_0\|_{L^1}$, $0 \leq t \leq T$, consequently, for any t, $\partial_x \ln \rho(t) \in L^1_x$, and

$$\varepsilon \int_{\mathbb{R}} |\partial_x \ln \rho(t)| dx \leq 2 \big\| \rho_0 |u_0| \big\|_{L^1} + \varepsilon \|\partial_x \ln \rho_0\|_{L^1} = \varepsilon K_2'. \tag{6.17}$$

Using (2.16), (2.19), and (6.17), we get, for any t,

$$\int_{\mathbb{R}} |\partial_t \ln \rho(t)| dx \leq \|\partial_x u_0\|_{L^1}(1 + K_2') = K_1', \tag{6.18}$$

and then $\partial_t \ln \rho \in L^\infty_t(L^1_x)$. We can now write, for any t and a.e. x,

$$\ln \rho(t,x) = \ln \rho_0(x) + \int_0^t \partial_t \ln \rho(s,x) ds.$$

By (6.18), it is clear that $\int_0^t \partial_t \ln \rho(s,x) ds \in L^\infty_t(L^1_x)$. Let us fix $t \in [0,T]$. There exists a sequence $(x_m(t))$ which goes to $-\infty$ when $m \to +\infty$ such that

$$\int_0^t \partial_t \ln \rho(s, x_m(t)) ds \overset{m\infty}{\longrightarrow} 0. \tag{6.19}$$

But we can also write that

$$\ln \rho(t,x) = \lim_{x \to -\infty} \ln \rho(t,x) + \int_{-\infty}^x \partial_x \ln \rho(t,y) dy, \qquad x \in \mathbb{R}. \tag{6.20}$$

Using (6.20), (6.19), and letting $m \to \infty$, we find

$$\lim_{x \to -\infty} \ln \rho(t,x) = \lim_{m\infty} \ln \rho_0(x_m(t)).$$

Consequently, we find that, by (6.20) and (6.17),

$$\|\ln \rho\|_{L^\infty_{t,x}} \leq \|\ln \rho_0\|_{L^\infty} + K_2'.$$

Then there exists $K > 0$ which does not depend on θ such that

$$\frac{1}{\rho(t,x)} \geq K \qquad \text{a.e. } (t,x). \tag{6.21}$$

Moreover, by interpolation, we get, for a.e. t,

$$\|\partial_x \tilde{u}(t)\|_{C_{0_x}} \leq \big(C \|w_0\|^{1/3}_{L^1}\big) \|\partial_x w(t)\|^{2/3}_{L^2_x}, \tag{6.22}$$

by (2.16), and

$$\|w(t)\|_{L^2_x} \leq C \|w(t)\|^{2/3}_{L^1_x} \|\partial_x w(t)\|^{1/3}_{L^2_x} \leq \big(C \|w_0\|^{2/3}_{L^1}\big) \|\partial_x w(t)\|^{1/3}_{L^2_x}. \tag{6.23}$$

By (2.30) with $b = \tilde{u}$ and $\sigma = \varepsilon/\rho$, we have

$$2\varepsilon \int_0^T \int_{\mathbb{R}} \frac{(\partial_x w)^2}{\rho} dx dt \leq \|w_0\|^2_{L^2} + \int_0^T \|\partial_x \tilde{u}(t)\|_{C_{0_x}} \|w(t)\|^2_{L^2_x} dt. \tag{6.24}$$

With (6.21), (6.22), and (6.23), (6.24) becomes

$$2\varepsilon K\|\partial_x w\|^2_{L^2_{t,x}} \le \|w_0\|^2_{L^2} + CT^{1/3}\|\partial_x w\|^{4/3}_{L^2_{t,x}}.$$

Since $2 > 4/3$ in the previous equation, we can find an estimate on $\|\partial_x w\|_{L^2_{t,x}}$ that does not depend on θ, i.e.,

$$\exists\, C > 0 \qquad \|\partial_x w\|_{L^2_{t,x}} \le C. \tag{6.25}$$

The estimates (6.22) and (6.25) then imply (6.3) by Hölder's inequality.

We have checked all the conditions needed in Theorem 6 (the renormalized equation on u is easily obtained in the same way as that of $w = \partial_x u$). The fixed point of Q has all the properties of $\tilde{u}$ and u. Theorem 1 is proved, except (1.12). Note that the renormalized equation (1.10) on u is easily obtained in the same way as that of $w = \partial_x u$.

7. Upper estimate on $\partial_x u$. Let us set $v = (At+1)w$, which obviously has the same smoothness as w and satisfies

$$\partial_t v + \partial_x(uv) - \varepsilon\partial_x\left(\frac{\partial_x v}{\rho}\right) = \frac{Av}{At+1}.$$

First, we can easily prove that $(v-A)_+ \in L^2_t(H^1_x) \cap C_t(L^2_x)$. Next, as for (2.15), we notice that w satisfies the following renormalized equation in $\mathcal{D}'_{t,x}$:

$$\begin{aligned} &\partial_t S(v) + \partial_x(uS(v)) - \varepsilon\partial_x\left(\frac{S'(v)\partial_x v}{\rho}\right) \\ &= \frac{v}{At+1}\big[(A-v)S'(v) + S(v)\big] - \varepsilon S''(v)(\partial_x v)^2/\rho, \end{aligned} \tag{7.1}$$

where S is C^2 and S'' is bounded.

Let us consider, for $\alpha > 0$, the auxiliary function Φ_α defined as

$$\Phi_\alpha(y) = \begin{cases} 0 & \text{if} \quad y \le A, \\ \varphi_\alpha(y-A) & \text{if} \quad y \ge A, \end{cases}$$

where φ_α is the function we defined in section 2. For $\alpha > 0$, Φ_α is clearly positive, C^2, convex, and Φ''_α is bounded by 1. Moreover, $(\Phi_\alpha)_{\alpha\in]0,1]}$ uniformly tends to $(\cdot - A)_+$ in $C(\mathbb{R})$.

From the properties (2.46), (2.47), and (2.48) of φ_α, we can also state that

$$0 \le \Phi_\alpha(y) \le (y-A)_+, \tag{7.2}$$

$$0 \le \Phi_\alpha(y) \le \pi/(4\alpha)(y-A)^2_+, \tag{7.3}$$

$$|\Phi_\alpha(y) - (y-A)\Phi'_\alpha(y)| \le \kappa\alpha. \tag{7.4}$$

Since $(v-A)_+ \in C_t(L^2_x)$, (7.2) and (7.3) ensure that $\Phi_\alpha(v)$ is in both $C_t(L^1_x)$ and $C_t(L^2_x)$.

In (7.1), we take $S = \Phi_\alpha$ which is C^2 convex. Using a standard truncation result and noticing that $v_0 = w_0 \le A$ a.e., we get

$$\int_{\mathbb{R}} \Phi_\alpha(v(t))dx \le K\alpha, \qquad 0 \le t \le T,$$

where K is a constant which does not depend on α and t. We now use Fatou's lemma with fixed t for $(\Phi_\alpha(v(t)))_{\alpha\in]0,1]}$ and we obtain that $(v(t)-A)_+ \in L^1_x$ and

$$\int_{\mathbb{R}} (v(t)-A)_+ dx \leq 0.$$

Hence we have (1.12).

8. Inviscid limit. This section is concerned about the proof of Theorem 2.

8.1. The viscous backward problem. Equation (1.16) contains no viscosity term so that we can directly use Definition 2 of duality solutions. Indeed, L^∞ distributional solutions are duality solutions [2]. Next, we associate to (1.17) the following backward problem

$$\partial_t p^\varepsilon + u^\varepsilon \partial_x p^\varepsilon + \varepsilon \frac{\partial^2_{xx} p^\varepsilon}{\rho^\varepsilon} = 0, \tag{8.1}$$

$$p^\varepsilon(T,.) = p_T, \tag{8.2}$$

where $p_T \in \mathrm{Lip}(\mathbb{R})$ does not depend on ε and $\partial_x p_T \in L^1(\mathbb{R})$.

We set $\pi^\varepsilon = \partial_x p^\varepsilon$. If we write the system satisfied by $p^\varepsilon(T-t,x)$, we find a forward problem which can be solved thanks to Theorem 5. Hence, we can state that, since $\pi_T \in L^1$ and $p_T \in \mathrm{Lip}$, there exists a unique solution $\pi^\varepsilon \in C_t(L^2_x) \cap L^2_t(H^1_x)$, in the sense of distributions, to

$$\partial_t \pi^\varepsilon + \partial_x(u^\varepsilon \pi^\varepsilon) + \varepsilon \partial_x \left(\frac{\partial_x \pi^\varepsilon}{\rho^\varepsilon} \right) = 0, \tag{8.3}$$

$$\pi^\varepsilon(T,.) = \pi_T. \tag{8.4}$$

Then we can define p^ε by

$$p^\varepsilon(t,x) = \int_{-\infty}^{x} \pi^\varepsilon(t,y) dy + \lim_{-\infty} p_T, \tag{8.5}$$

because we can prove that $\pi^\varepsilon \in C_t(L^1_x)$ and $\frac{d}{dt}\int_{\mathbb{R}} \pi^\varepsilon(t) dx = 0$. Then we easily obtain that $p^\varepsilon \in L^\infty_{t,x}$.

Next we have to verify that p^ε defined by (8.5) satisfies (8.1). If we set $A(p^\varepsilon) = \partial_t p^\varepsilon + u^\varepsilon \partial_x p^\varepsilon + \varepsilon \partial^2_{xx} p^\varepsilon / \rho^\varepsilon$, we notice that $\partial_x[A(p^\varepsilon)] = 0$ in $\mathcal{D}'_{t,x}$ and that $A(p^\varepsilon) \in L^2_{t,x}$, which ensures that $A(p^\varepsilon) = 0$. Hence we have proved the first part of the following proposition.

PROPOSITION 12. *There exists a unique solution p^ε in the sense of distributions to* (8.1)–(8.2) *such that $\pi^\varepsilon \in C(]0,T]; L^2_x) \cap L^2(]0,T[; H^1_x)$ and*

$$\|p^\varepsilon\|_{L^\infty_{t,x}} \leq \|p_T\|_{L^\infty} + \|\partial_x p_T\|_{L^1}.$$

It satisfies the following a priori estimate:

$$|\partial_x p^\varepsilon(t,x)| \leq \frac{T}{t} \|\partial_x p_T\|_{L^\infty} \qquad \text{a.e. } t,x. \tag{8.6}$$

Moreover, if p_T is monotone, then p^ε has the same monotonicity in x.

Remark. This monotonicity property is compatible to the notion of reversible solutions for the inviscid problem.

Proof. In this proof, we will not use the notations with ε. Let us set $\nu(t,.) = \pi(t,.)t/T$, which satisfies the following renormalized equation, where N is an arbitrary constant and $S \in C^2(\mathbb{R})$ is such that S'' is bounded:

$$\begin{aligned}(8.7)\qquad &\partial_t S(\nu) + \partial_x(u\nu + \varepsilon\partial_x\nu/\rho)\\ &= (\nu - Nt\partial_x u)S'(\nu)/t + \partial_x u(S(\nu) - \nu S'(\nu)) + \varepsilon(\partial_x\nu)^2 S''(\nu)/\rho.\end{aligned}$$

First, we can choose $N = \max(\operatorname{ess\,sup}\pi_T, 0)$ and, at least formally, $S(y) = (y-N)_+$. Knowing the smoothness of ν, we obtain, in the same way as in section 7, that $(\nu - N)_+$ has the same smoothness as ν. Then, noticing that the chosen function S is convex, we get, in $\mathcal{D}'_{t,x}$,

$$\partial_t(\nu - N)_+ \geq (\nu - Nt\partial_x u)\frac{\mathbf{1}_{\nu>N}}{t} = 0,$$

since we know that $\nu \leq N$ and $\partial_x u \leq 1/t$. That gives us, for any $0 < t \leq T$,

$$\int_{\mathbb{R}} (\nu(t) - N)_+ dx \leq \int_{\mathbb{R}} (\nu_T - N)_+ dx = 0,$$

and finally

$$(8.8)\qquad \pi(t) \leq \frac{T}{t}N \leq \frac{T}{t}\|\pi_T\|_{L^\infty_{t,x}} \qquad \text{a.e.}$$

Remark. The previous formal computation can easily be justified with approximate functions as done in section 7.

Note that, if we choose a nonincreasing final datum p_T in (8.2), N becomes equal to 0 in (8.8) and we obtain the required monotonicity property.

To complete the proof, we can set, for example, $N = -\max(\operatorname{ess\,sup}(-\pi_T), 0)$ and choose $S(y) = (y-N)_-$. Then it is easy to prove the other side of the desired estimate and end the proof. ∎

We now want to justify the asymptotics $\varepsilon \to 0$ in the backward problem. Let us choose $\tau \in]0, T[$. We need the following lemma.

LEMMA 8. *The following a priori estimate holds:*

$$\|\pi^\varepsilon(t)\|_{L^2_x} \leq \frac{T}{t}\|\pi_T\|_{L^2} \qquad \textit{a.e. } t \in [\tau, T].$$

Proof. From (8.3), we can compute that

$$(8.9)\qquad \frac{d}{dt}\|\pi^\varepsilon(t)\|^2_{L^2_x} + \int_{\mathbb{R}} \partial_x u^\varepsilon(t)\pi^\varepsilon(t)^2 dx - 2\varepsilon\int_{\mathbb{R}} \frac{(\partial_x\pi^\varepsilon(t))^2}{\rho^\varepsilon(t)}dx = 0,$$

which implies, thanks to Gronwall's lemma and (1.12) and after having noticed that the term $\int_{\mathbb{R}} \frac{(\partial_x\pi^\varepsilon)^2}{\rho^\varepsilon}dx$ is nonnegative, the desired estimate. ∎

We are now able to prove the following asymptotics result.

PROPOSITION 13. *There exists a subsequence of the solutions (p^ε) to (8.1)–(8.2) which converges in $C([\tau, T]; C_x)$ toward the solution p to (1.14) with final data p_T, where u is the weak* limit in $L^\infty_{t,x}$ of a subsequence of (u^ε).*

Proof. Let us prove that the last term $(\varepsilon\partial_x\pi^\varepsilon/\rho^\varepsilon)$ goes to 0 when $\varepsilon \to 0$ in, say, $L^2_{t,x}$. From (8.9) integrated between τ and T, we get

$$\varepsilon\int_\tau^T\int_{\mathbb{R}} \frac{(\partial_x\pi^\varepsilon)^2}{\rho^\varepsilon}dxdt \leq \frac{1}{2}\|\pi_T\|^2_{L^2} + \int_\tau^T \frac{\|\pi^\varepsilon(t)\|^2_{L^2_x}}{2t}dt \leq C,$$

where C is a constant which does not depend on ε, because of Lemma 8.

Moreover, taking (1.12) into account and thanks to the assumptions about ρ_0^ε and u_0^ε, a maximum principle applied to (1.16) gives

$$\frac{1}{\rho^\varepsilon(t,x)} \leq \frac{(1+\max(\text{ess sup}\,\partial_x u_0^\varepsilon,0))}{\rho_0^\varepsilon(x)} \leq \frac{C}{\sqrt{\varepsilon}} \qquad \text{a.e.,}$$

where C does not depend on ε.

Hence, thanks to Cauchy–Schwartz's inequality,

$$\varepsilon^2 \int_\tau^T \int_{\mathbb{R}} \frac{(\partial_x \pi^\varepsilon)^2}{(\rho^\varepsilon)^2} dx dt \leq C\sqrt{\varepsilon}, \tag{8.10}$$

and then $(\varepsilon \partial_x \pi^\varepsilon/\rho^\varepsilon)$ tends to 0 in $L^2_{t,x}$ when $\varepsilon \to 0$. We must now prove the asymptotics on $(u^\varepsilon \partial_x p^\varepsilon)$. In fact, we study the sequences $(p^\varepsilon u^\varepsilon)$ and $(\partial_x u^\varepsilon p^\varepsilon)$.

From Lemma 8, we know that $(\partial_x p^\varepsilon)$ is uniformly bounded in $L^\infty_t(L^2_x)$, and, from (8.1), (8.10), and Lemma 8, we easily find that $(\partial_t p^\varepsilon)$ is also uniformly bounded in $L^2_{t,x}$. Consequently, we have, by interpolation, a uniform estimate on (p^ε) in both $L^\infty_t(C^{0,1/2}_x)$ and $C^{0,1/2}_t(L^2_x)$. Hence, up to a subsequence, $(p^\varepsilon) \to p$ in $C_{t,x}$. Since (u^ε) is uniformly bounded in $L^\infty_{t,x}$, there exists a subsequence of (u^ε) converging in w*-$L^\infty_{t,x}$ to a limit u, and then $(p^\varepsilon u^\varepsilon)$ converges to pu in $\mathcal{D}'_{t,x}$.

To study the term $p^\varepsilon \partial_x u^\varepsilon$, we set $\mu^\varepsilon = 1/t - \partial_x u^\varepsilon$. Thanks to (1.12), we can state that μ^ε is a nonnegative measure. We want to prove that (μ^ε) is bounded in the sense of measures. In fact, we first notice that it is bounded in the sense of distributions. More precisely, if $\varphi \in \mathcal{D}_{t,x}$,

$$|\langle \mu^\varepsilon, \varphi \rangle_{\mathcal{D}',\mathcal{D}}| \leq \frac{|K|}{\tau} \|\varphi\|_{L^\infty_{t,x}} + C|K| \|\partial_x \varphi\|_{L^\infty_{t,x}},$$

where K is the compact support of φ and $|K|$ its Lebesgue measure. Then, since μ^ε is nonnegative, we easily find that (μ^ε) is bounded in the sense of measures. This implies that $(\partial_x u^\varepsilon)$ is uniformly measure-bounded too. Then there exists a subsequence of $(\partial_x u^\varepsilon)$ that is convergent in the sense of measures. But since $(p^\varepsilon) \to p$ in $C_{t,x}$, we find that $(p^\varepsilon \partial_x u^\varepsilon) \rightharpoonup p \partial_x u$ in $\mathcal{D}'_{t,x}$.

Finally we have proved that p satisfies

$$\partial_t p + u \partial_x p = \partial_t p + \partial_x (pu) - p \partial_x u = 0.$$

The previous equation proves that $p \in C([\tau,T]; \text{w-}L^2_x)$. Consequently, the final condition is satisfied too. □

8.2. Proof of Theorem 2. Now that we know (p^ε) converges towards p, we have to justify that (q^ε) is convergent too. First of all, thanks to (1.20) and (6.16), it is clear that (q^ε) is uniformly bounded in the sense of measures; thus, up to a subsequence, (q^ε) is convergent.

Besides, knowing the smoothness of p^ε, ρ^ε, and u^ε, we have only to prove that

$$\frac{d}{dt}\left(\int_{\mathbb{R}} p^\varepsilon \rho^\varepsilon u^\varepsilon dx \right) = 0 \qquad \text{in } [\tau,T], \tag{8.11}$$

as a generalization of the notion of duality solutions.

Each term in (8.1) is in $L^2_{t,x}$, so we can multiply it by $q^\varepsilon \in L^2_{t,x}$ and get

$$q^\varepsilon \partial_t p^\varepsilon + q^\varepsilon u^\varepsilon \partial_x p^\varepsilon + \varepsilon u^\varepsilon \partial^2_{xx} p^\varepsilon = 0. \tag{8.12}$$

On the other hand, thanks to Lemma 7, we know that $\partial\rho^\varepsilon \in L^\infty_t(L^2_x)$. Since $u^\varepsilon, p^\varepsilon \in L^\infty_{t,x}$, and $\partial_t u^\varepsilon, \partial_x u^\varepsilon, \partial^2_{xx} u^\varepsilon \in L^2_{t,x}$, we can justify the multiplication of (1.17) by p^ε and get

$$p^\varepsilon \partial_t(q^\varepsilon) + p^\varepsilon \partial_x(q^\varepsilon u^\varepsilon) - \varepsilon p^\varepsilon \partial^2_{xx} u^\varepsilon = 0. \tag{8.13}$$

We sum (8.12) and (8.13), and we get

$$\partial_t(p^\varepsilon q^\varepsilon) + \partial_x(p^\varepsilon q^\varepsilon u^\varepsilon) + \varepsilon \partial_x(u^\varepsilon \partial_x p^\varepsilon - p^\varepsilon \partial_x u^\varepsilon) = 0.$$

With a standard truncation result, noticing that $p^\varepsilon q^\varepsilon, p^\varepsilon q^\varepsilon u^\varepsilon \in L^1_{t,x}$, and $u^\varepsilon \partial_x p^\varepsilon - p^\varepsilon \partial_x u^\varepsilon \in L^2_{t,x}$, we find (8.11).

Thus we have proved that a subsequence of (q^ε) converges in $C_t(\text{w*-}\mathcal{M}_{\text{loc}_x})$ to q satisfying

$$\frac{d}{dt}\int_{\mathbb{R}} p(t,x) q(t,dx) = 0 \qquad \text{in } [\tau, T] \times \mathbb{R}.$$

Thus (1.19) is satisfied in the duality sense in any interval $]t_1, t_2[$ with $0 < t_1 < t_2$. The density ρ also satisfies (1.18) in the duality sense, and it can be directly obtained by the stability of duality problems [2], which also gives the relation $q = \rho u$.

Acknowledgment. The author wishes to thank F. Bouchut for his advice and the numerous talks we had on this topic.

EXISTENCE OF UNDERCOMPRESSIVE TRAVELING WAVES IN THIN FILM EQUATIONS*

A. L. BERTOZZI† AND M. SHEARER‡

Abstract. We consider undercompressive traveling wave solutions of the partial differential equation

$$\partial_t h + \partial_x f(h) = -\partial_x(h^3\partial_x^3 h) + D\partial_x(h^3\partial_x h),$$

when the flux function f has the nonconvex form $f(h) = h^2 - h^3$. In numerical simulations, these waves appear to play a central role in the dynamics of the PDE; they also explain unusual phenomena in experiments of driven contact lines modeled by the PDE. We prove existence of an undercompressive traveling wave solution for sufficiently small nonnegative D and nonexistence when D is sufficiently large.

Key words. undercompressive shocks, traveling waves, heteroclinic orbit, existence

1. Introduction.

The partial differential equation (PDE)

$$\partial_t h + \partial_x f(h) = -\partial_x(h^3\partial_x^3 h) + D\partial_x(h^3\partial_x h) \tag{1.1}$$

describes the flow of a thin liquid film on an inclined flat surface, under the action of gravity, viscous, and surface tension forces. Parameters governing these forces, and the slope of the surface, are incorporated into the dimensionless parameter $D \geq 0$. In particular, $D = 0$ for a vertical surface. The unknown function $h = h(x,t)$ is the (dimensionless) thickness of the thin film layer.

Equation (1.1) arises from the standard lubrication approximation of the Navier–Stokes equations [BB97, BMS99, Gre78]. We consider the specific physical problem in which the film is driven by two counteracting forces, namely, gravity pulling the film down the plane, and a thermal gradient, which induces a surface tension gradient, pushing the film up the plane. The interested reader should see [BMFC98, BMS99] for a discussion of (1.1) and the dimensionless scaling. For this particular problem, the dimensionless flux function in (1.1) is

$$f(h) = h^2 - h^3. \tag{1.2}$$

Equation (1.1) results when we assume the film height is independent of an additional transverse space variable (cf. (6.3) at the end of this paper). Experimental and numerical studies of driven contact lines [THSJ89, BB97, BMFC98, JSMB98] show that traveling wave solutions of the PDE (1.1) play an important role in the motion of the film. The significance of the nonconvexity of the flux function in (1.2) is that (1.1) then admits the possibility of undercompressive traveling waves, which we discuss in detail below.

Driven contact line experiments that can be modeled by (1.1) show some unusual dynamics. First, there are experiments in which there is only one dominant driving force, corresponding to a convex flux function f. For example, $f(h) = h^2$ in the case of dominant Marangoni stress [CHTC90, KT97] or $f(h) = h^3$ in the case of gravitational stress [Hup82, THSJ89, dB92]. For such examples, the film forms a pronounced "capillary ridge" which corresponds mathematically to a nonmonotone traveling wave solution of (1.1). The ridge results from the interaction of surface tension, in the form of the fourth order diffusion on the right-hand side of (1.1), with the driving force, in the form of the convective term $(f(h))_x$. Such ridges have always been associated with instabilities of the film that lead to the formation of finger-like structures [BB97, THSJ89, dB92, JdB92, VIC98] in which h develops a growing oscillatory dependence on the transverse variable.

Secondly, it is interesting to contrast the driven contact line experiments where one force dominates with those experiments involving competing Marangoni and gravitational stresses. Early experiments [LL71] of relatively thick Marangoni-gravity driven films show a stable front with *monotone* decrease of the film profile from the bulk to the contact line. Recent experiments [Fan98, BMFC98] show that for intermediate thickness films, a capillary ridge forms but continues to broaden while the *contact line remains stable* and no fingering occurs. The model (1.1) with the nonconvex flux (1.2) has recently been used to establish that undercompressive traveling waves are responsible for the unusual ensuing dynamics of the front [MB99, BMFC98]. In these papers, the prewetted surface is modeled as a thin precursor layer, avoiding unresolved issues of how to model a propagating liquid/solid/air contact line.

The consideration of traveling waves reduces the fourth order partial differential equation to a third order ordinary differential equation (after integrating once) depending on two parameters, namely the wave speed and the downstream film thickness. In the three-dimensional phase space of the ODE, compressive waves correspond to a codimension zero intersection of the two-dimensional unstable manifold of one equilibrium with the two-dimensional stable manifold of another equilibrium. Generically, this intersection is transverse and hence structurally stable, persisting under perturbations of the equation. For convex flux functions, e.g., $f(h) = h^2$ (Burgers flux), existence of compressive waves follows either from the analysis of Kopell and Howard [KH75] or from an argument involving a Lyapunov function and the Conley index [Mic88, Ren96, BMS99].

In contrast, undercompressive waves, which only arise when the flux is nonconvex, correspond to a codimension one intersection of the one-dimensional unstable manifold of one equilibrium with the two-dimensional stable manifold of another equilibrium. This situation typically only occurs for special values of the parameters in the ODE. The analysis of such special connections is straightforward for corresponding problems in second order ODEs; the phase space is two-dimensional and the Melnikov integral gives a measure of the separation of the manifolds in question. In our situation, the phase space is three-dimensional and the argument is more difficult. Our proof of existence of the undercompressive wave uses, in a central way, a Lyapunov function for the ODE to analyze the behavior of the one-dimensional unstable manifold from the largest equilibrium of the system. We combine this analysis with a shooting argument involving both topological properties of the orbit and quantitative estimates of higher derivatives of the solution and of its turning points. The techniques presented here apply to more general nonconvex flux functions than (1.2) and may be useful in understanding other higher dimensional bifurcation problems.

Undercompressive shock waves have been found in other physically motivated models involving systems of equations with application to dynamic phase transitions in elastic solids [AK91, Jam80, She86], liquid/vapor phase transitions [Sle83, Tru87], plane magnetohydrodynamic waves [Fre97], and multiphase flow related to secondary oil recovery [IMP90, SSMPL87, IMPT92]. Moreover, undercompressive waves have been analyzed in nonconvex conservation laws, with second order dissipation and (third order) dispersion [HL97, HS98, JMS95]. The model (1.1) represents the first realization of undercompressive shocks arising in a scalar conservation law with direct connection to experiments. The fourth order nonlinear diffusion, which has its own curious properties (see [Ber98] and references therein), combined with the nonconvex flux f yields undercompressive waves.

In an earlier paper [BMS99], we identified numerically new traveling wave solutions of (1.1) for $D = 0$ that correspond to undercompressive shock wave solutions of the conservation law. In this paper, we prove the existence of undercompressive traveling waves for small $D \geq 0$. Specifically, we show that for each downstream film thickness h_+ there is an undercompressive traveling wave, provided $D \geq 0$ is not too large. On the other hand, we also show that if D is large enough, then there is no undercompressive traveling waves with right state h_+. The latter property agrees with the limit $D \longrightarrow \infty$, for which second order diffusion dominates, and the theory is classical [Smo94]. In section 2 we discuss preliminaries concerning the phase space, and in section 3 we introduce the Lyapunov function that plays a major part in making the shooting argument work. section 4 contains the proof of existence of the undercompressive waves, while section 5 is a proof of nonexistence for large enough D.

2. Preliminaries. We are interested in traveling wave solutions of the equation

$$\partial_t h + \partial_x f(h) = -\partial_x(h^3\partial_x^3 h) + D\partial_x(h^3\partial_x h), \tag{2.1}$$

with $f(h) = h^2 - h^3$, and $D \geq 0$. On long scales, solutions of (2.1) behave like solutions of the corresponding scalar conservation law

$$\partial_t h + \partial_x f(h) = 0. \tag{2.2}$$

For this equation, recall that characteristics are straight lines

$$\frac{dx}{dt} = f'(h),$$

on which h is constant. A piecewise constant function

$$h(x,t) = \begin{cases} h_- & \text{if} \quad x < st, \\ h_+ & \text{if} \quad x > st \end{cases} \tag{2.3}$$

is a *shock wave solution* (with shock speed s) if the triple h_-, h_+, s satisfies the Rankine–Hugoniot condition

$$-s(h_+ - h_-) + f(h_+) - f(h_-) = 0. \tag{2.4}$$

A shock wave is *compressive* if the characteristics on each side of the shock impinge on the shock. This property is the *Lax entropy condition:*

$$f'(h_+) < s < f'(h_-). \tag{2.5}$$

As we shall see, undercompressive waves violate the Lax entropy condition.

A traveling wave solution $h = h(\xi)$, $\xi = x - st$, of (2.1) with speed s that has far field limits

$$\lim_{\xi\to-\infty} h(\xi) = h_- \text{ and } \lim_{\xi\to\infty} h(\xi) = h_+ \tag{2.6}$$

can be thought of, on large scales, as a "viscous" form of the shock (2.3). The existence of stable traveling wave profiles of (2.1) connecting the state h_- to the state h_+ is a criterion for the admissibility of the shock (2.3) in the large scale dynamics of (2.1). We are interested in the possibility of admissible undercompressive shocks, violating (2.5).

In general, traveling waves satisfy the third order ODE

$$-s(h - h_+) + f(h) - f(h_+) = -h^3h''' + Dh^3h'. \tag{2.7}$$

(In integrating the equation once, we have assumed $h'(\xi) \to 0$ and $h'''(\xi) \to 0$ as $\xi \to \infty$.) Equation (2.7) has two parameters $h_+ \in (0, 1/3)$ and $s > 0$. Possible left states $h = h_-$ (where $h' = 0 = h'''$) are determined by (2.4), the Rankine–Hugoniot condition for shocks.

To discuss (2.7), we begin by rewriting it:

$$h''' = g(h; h_+, s) + Dh', \tag{2.8}$$

where

$$g(h; h_+, s) = -h^{-3}\left(-s(h - h_+) + f(h) - f(h_+)\right). \tag{2.9}$$

At an equilibrium of (2.9), $h = h_e$, $g(h_e, h_+, s) = 0$, and the linearized ODE $u''' = \frac{\partial g}{\partial h}(h_e; h_+, s)u + Du'$ has characteristic equation

$$\lambda^3 - D\lambda - \frac{\partial g}{\partial h}(h_e; h_+, s) = 0. \tag{2.10}$$

For $D = 0$, the three eigenvalues are simply the three cube roots of $\frac{\partial g}{\partial h}(h_e; h_+, s)$. Since $\frac{\partial g}{\partial h}(h_e; h_+, s) = -\frac{1}{h_e^3}(f'(h_e) - s)$, the sign of $\frac{\partial g}{\partial h}(h_e; h_+, s)$ at any equilibrium h_e is related to whether characteristics at h_e, traveling with speed $f'(h_e)$, are faster or slower than the speed s of the traveling wave. For $0 \le D < 3(\frac{1}{2}\frac{\partial g}{\partial h}(h_e; h_+, s))^{2/3}$, there is one real eigenvalue $\lambda(D)$ (satisfying $\lambda(0) = (\frac{\partial g}{\partial h}(h_e; h_+, s))^{1/3}$), and two complex conjugate eigenvalues $\lambda_\pm(D)$. For larger D, all three eigenvalues are real. Moreover,

$$\lambda(D) \neq 0 \quad \text{and} \quad \mathrm{sgn}\Re(\lambda_\pm(\mathrm{D})) = -\mathrm{sgn}\lambda(\mathrm{D}) \quad \text{for all} \quad \mathrm{D}.$$

To describe the structure of equilibria, we write (2.8) as a first order system:

$$\begin{aligned} h' &= v, \\ v' &= w, \\ w' &= g(h; h_+, s) + Dv. \end{aligned} \tag{2.11}$$

We have the following classification of nondegenerate equilibria $(h, v, w) = (h_e, 0, 0)$ for (2.11).

(i) If $f'(h_e) < s$, then $\frac{\partial g}{\partial h}(h_e; h_+, s) > 0$, so that $(h_e, 0, 0)$ has a one-dimensional unstable manifold and a two-dimensional stable manifold on which, for small D,

solutions spiral into the equilibrium due to the complex conjugate pair of eigenvalues with negative real part.

(ii) If $f'(h_e) > s$, then $\frac{\partial g}{\partial h}(h_e; h_+, s) < 0$, so that $(h_e, 0, 0)$ has a one-dimensional stable manifold and a two-dimensional unstable manifold on which, for small D, solutions spiral away from the equilibrium due to the complex conjugate pair of eigenvalues with positive real part.

It is convenient to label the equilibria in order of their corresponding values of h. Physically h_+ plays the role of a precursor layer in an experiment. Thus the relevant range is for h_+ small. Define $b = h_+ \in (0, 1/3)$ and let this be fixed. Treating s as a parameter, let[1] $h = h_m(s) \le h_t(s)$ be the two roots (different from h_+) of (2.4):

$$h + b - (h^2 + bh + b^2) = s$$

for s in the range

$$s_1 = f'(b) \le s \le \frac{2(f((1-b)/2) - f(b))}{(1-3b)} = s_2. \tag{2.12}$$

For brevity, we sometimes write $m = h_m(s), t = h_t(s)$. In particular (see Figure 2.1),

$$b < m < \frac{1-b}{2} < t < 1 - 2b \quad \text{if} \quad s_1 < s < s_2,$$

and

$$b = m; \quad t = 1 - 2b \quad \text{if} \quad s = s_1, \qquad m = t = (1-b)/2 \quad \text{if} \quad s = s_2.$$

Moreover, (with $h_+ = b$) the vector field (2.11) has three equilibria when $s_1 < s < s_2 : B = (b, 0, 0), M = (m, 0, 0), T = (t, 0, 0)$. From the discussion of equilibria above, we see that B and T each have a one-dimensional unstable manifold and a two-dimensional stable manifold, whereas M has a two-dimensional unstable manifold and a one-dimensional stable manifold.

The arguments of Kopell and Howard [KH75, BMS99] show that if B and M (or M and T) are sufficiently close, then there is a trajectory from M to B (or M to T, respectively). The corresponding traveling wave is necessarily compressive since $f'(b) < s < f'(m)$ (and $f'(t) < s < f'(m)$). Such trajectories lie along the intersection of the two-dimensional unstable manifold from M and the two-dimensional stable manifold from B (or T, respectively). This construction is structurally stable in that it persists under small perturbations of the vector field (for example, by changing s while keeping b fixed).

Undercompressive waves correspond to trajectories from T to B, or from B to T. These occur when the one-dimensional unstable manifold from T (from B, respectively) lies in the two-dimensional stable manifold from B (from T, respectively), a codimension one construction. The main result of section 4 is that for b fixed and for all small $D \ge 0$, there is a value of s for which there is such a trajectory from T to B. (The corresponding result from B to T follows by a symmetric argument, but is less significant physically.)

In section 5 we show that for each $b < 1/3$, and for D sufficiently large, there is no value of s for which there is an undercompressive traveling wave from T to B. This result expresses the notion that for large D, second order diffusion dominates fourth order diffusion. In the absence of fourth order diffusion, the only traveling waves are compressive.

[1]Note that the subscript t here does not denote partial derivative. It is an index to denote the specific equilibrium.

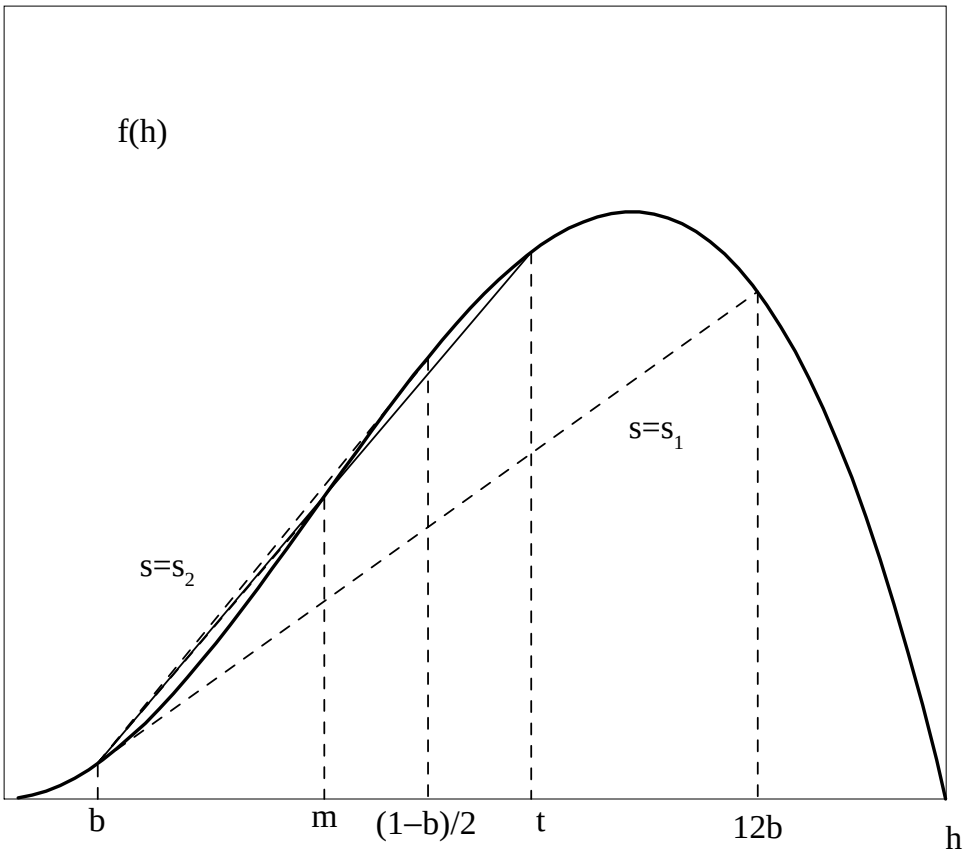

FIG. 2.1. *Flux function $f(h) = h^2 - h^3$, and chords indicating equilibria and wave speeds.*

3. The Lyapunov function. Equation (2.8) has a Lyapunov function

$$L(h) = h''h' + R(h),$$

where

$$\frac{dR}{dh}(h) = -g(h; b, s),$$

which we use extensively in the analysis of traveling waves. The equilibria B, M, T correspond to extrema b, m, t of $R(h)$, as shown in Figure 3.1.

Differentiating along a solution $h(\xi)$ and using the ODE (2.8), we find that

$$L(h)' = (h'')^2 + D(h')^2.$$

Therefore, $L(h)$ increases along trajectories. In particular, $R(h)$ increases at successive critical points of a solution $h(\xi)$ of (2.8). It follows that for any traveling wave solution connecting extrema of $R(h)$ there exist a priori upper and lower bounds for the critical

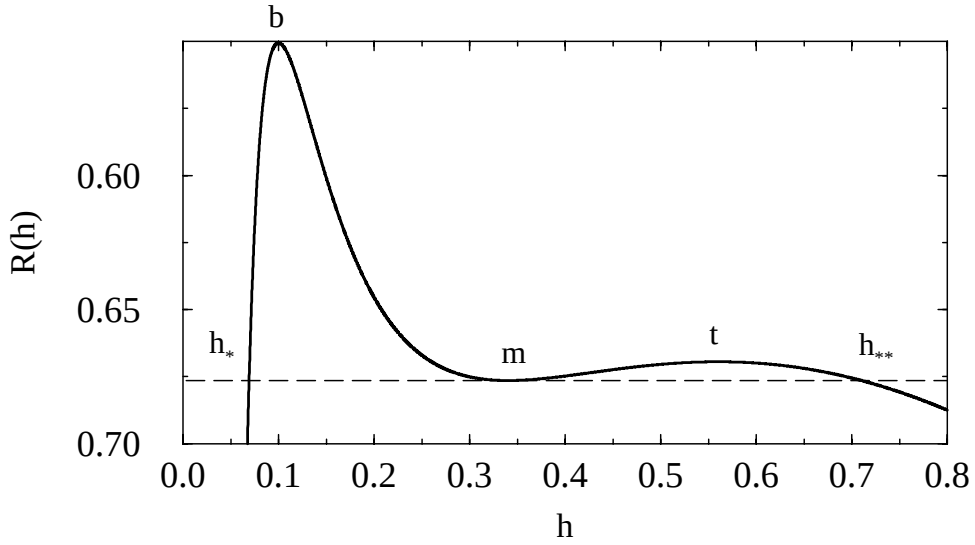

FIG. 3.1. *The function $R = -dg/dh$ in the Lyapunov function. Pictured are the three equilibria, b, m, and t, of* (2.11) *and the a priori upper and lower bounds h_{**} and h_*, defined in* (3.2)*, for a traveling wave solution.*

points h_{crit} of the traveling wave

$$h_* < h_{crit} < h_{**}, \tag{3.1}$$

where h_* and h_{**} are defined by (see Figure 3.1)

$$h_* = \min\{h : R(h) \geq R(m)\}, \quad h_{**} = \max\{h : R(h) \geq R(m)\}. \tag{3.2}$$

Note that R and hence h_*, h_{**} depend on b and s.

4. Existence of an undercompressive wave. In this section, we fix $h_+ = b < 1/3$, and consider the vector field (2.11) with s and D varying. An undercompressive wave occurs when there exists a trajectory (a *heteroclinic orbit*) from the equilibrium $T = (h_t(s), 0, 0)$ to the equilibrium $B = (b, 0, 0)$. We show that for sufficiently small D (depending on the value of b), there exists a special value of s, call it s_*, for which there is such a trajectory.

For each value of s, we consider a special solution of (2.11), corresponding to the branch of the unstable manifold from the equilibrium $(h_t(s), 0, 0)$ that initially decreases in h. Let $h_t(\xi; s)$, $-\infty < \xi$, denote the solution of (2.8) corresponding to this branch. By the stable manifold theorem and the Picard continuation theorem for ODEs, $h_t(\xi; s)$ is smooth and tangent to the unstable manifold of the linearized ODE about h_t and is determined uniquely up to translation in ξ. The goal of this section is to prove that there is an s_* for which

$$\lim_{\xi \longrightarrow \infty} h_t(\xi; s_*) = b.$$

The proof of this result was inspired in part by results from numerical simulations [BMS99, M99]. The argument is a one parameter, one direction shooting argument. In Proposition 4.1 below, we show that for s near s_1, for which b and $h_m(s)$ are

close, $h_t(\xi; s)$ decreases monotonically, reaching zero at a finite value of ξ. On the other hand, in Proposition 4.2, we show that for s near s_2, so that $h_m(s)$ and $h_t(s)$ are close, $h_t(\xi; s)$ has a minimum value above $h = b$; the trajectory then increases without bound. The trajectory we seek lies between these two extremes; its existence is established in Theorem 4.8. While this paper establishes existence of such a special shock speed, uniqueness remains an open problem. However, numerical computations [BMS99, M99] reveal the shock speed and undercompressive wave to be unique.

The first part of this argument is based on the Lyapunov function. First note that there is a value of s, call it s_l, such that the two maxima of $R(h; s)$, b and $h_t(s)$ satisfy $R(b; s) = R(h_t(s); s)$ and

$$R(b; s) < R(h_t(s)) \quad \text{for all} \quad s \quad \text{satisfying } f'(b) < s < s_l.$$

The function R has a global maximum at $h_t(s)$ for s in this range. Figure 3.1 shows a case where $s > s_l$; in this case R has a global maximum at b.

PROPOSITION 4.1. *For all s, $f'(b) < s < s_l$, $h_t(\xi; s)$ decreases monotonically to hit zero at a finite value of ξ.*

Proof. Suppose that $h_t(\xi; s)$ has a local minimum at a finite $\xi = \xi_0$. Then, necessarily $v_t(\xi; s) \equiv (h_t(\xi; s))_\xi$ is zero at ξ_0. Since the Lyapunov function increases along trajectories, we have $R(h_t(\xi_0; s) \geq R(h_t(s))$. However, this contradicts the fact that $h_t(s)$ is a global maximum of R for this range of s. Thus there can be no local minimum at finite ξ_0.

Now we show the solution decreases to hit zero at finite ξ. To see this, we note that since h is monotonically decreasing, it either hits zero at finite ξ_0 or it stays positive for all $\xi < \infty$, which means that because it is decreasing, it has a limit $h \to h_0 \geq 0$. We now show that the latter case leads to a contradiction.

First suppose that $h_0 > 0$. Then the only choices are $h_0 = b$ or $h_0 = h_m(s)$. Otherwise, (2.8) implies that $h''' - Dh'$ will remain bounded away from zero on an interval of the kind $[l_0, \infty)$ which implies that $h'' - Dh$, and hence h'' and h' become unbounded, which is a contradiction. The two equilibria, b and $h_m(s)$ are also ruled out by the properties that $L(h)$ is an increasing function of ξ, $L = R$ at equilibria, and R has a global maximum at $h = h_t(s)$. Thus we can not have that $h_0 > 0$.

Now suppose h decreases monotonically to zero in infinite time. Again, from the ODE, this implies that eventually the $h''' - Dh'$ becomes monotonically unbounded, inconsistent with h decreasing monotonically to zero.

The only choice then is for $h \to 0$ at some finite ξ. ∎

PROPOSITION 4.2. *Let $b \in (0, 1/3)$. There are numbers $D_0, \underline{s}, \overline{s}$ with $s_\ell < \underline{s} < \overline{s} < s_2$ such that for all $D \in [0, D_0]$ and all $s \in [\underline{s}, \overline{s}]$, $h_t(\xi, s)$ has a global minimum between $h_m(s)$ and b. The solution then increases without bound after reaching that minimum.*

Proof. It suffices to prove that $h_t(\xi; s)$ has a global minimum between $h_m(s)$ and b. The result then follows from the Lyapunov function and a similar argument to the first part of the proof of Proposition 4.1.

First we prove that for $D = 0$, there is a range of s, $s_u < s < s_2$ for which $h_t(\xi, s)$ has the property claimed in the proposition. Then we use a perturbation argument to prove the result for small positive D.

To show that $h_t(\xi; s)$ has such a minimum, we first estimate the trajectory at $h_m(s)$ in terms of the parameter $\rho = h_t(s) - h_m(s)$, which decreases to zero as s approaches s_2. In what follows, we consider $\rho > 0$ to be small.

LEMMA 4.3. *Let $D = 0$. Then $h_t(\xi_m; s) = h_m(s)$ for some $\xi_m < \infty$.*

Proof. To simplify notation, consider s fixed, and write $h = h(\xi)$ in place of $h = h_t(\xi, s)$. Then h has the properties

$$(h, h', h'') \longrightarrow (h_t(s), 0, 0) \quad \text{as} \quad \xi \longrightarrow -\infty,$$

and moreover

$$(h, h', h'') \sim (h_t(s), 0, 0) - Ce^{\lambda\xi}(1, \lambda, \lambda^2) \quad \text{as} \quad \xi \longrightarrow -\infty,$$

where

$$\lambda = \left(\frac{\partial g}{\partial h}(h_t(s); b, s)\right)^{1/3}$$

is the positive eigenvalue for the equilibrium $(h_t(s), 0, 0)$ for (2.11). In particular, for ξ sufficiently negative,

$$h(\xi) < h_t(s), v(\xi) = h'(\xi) < 0, w(\xi) = h''(\xi) < 0. \tag{4.1}$$

Now define the open set $O \subset R^3$ by

$$O = \{(h, v, w) : h_m(s) < h < h_t(s), v < 0\}.$$

Then $(h, v, w)(\xi) \in O$ for all $\xi < M$, for some M.

Next note that the vector field (2.11) is uniformly Lipschitz in O, since the only nonlinearity is in $g(h; b, s)$, a function of h alone (for fixed b, s) whose derivative is bounded for $h_m(s) \le h \le h_t(s)$. Therefore, the solution $(h, v, w)(\xi)$ can be continued in ξ as long as it remains in O. That is, either (a) the solution stays in O for all $\xi \in R$, or (b) the solution exits S at some finite $\xi = \xi_T$.

In case (a), the solution must approach an equilibrium as $\xi \longrightarrow \infty$. Thus, $(h, v, w) \longrightarrow (h_m(s), 0, 0)$, or $(h, v, w) \longrightarrow (h_t(s), 0, 0)$. Both possibilities are ruled out by the property that the Lyapunov function must increase along the trajectory, since $R(h_m(s))$ and $R(h_t(s))$ are both less than or equal to the value of the Lyapunov function at $\xi = -\infty$.

In case (b), $(h, v, w)(\xi_T) \in \partial O$. Thus, (i) $h'(\xi_T) = 0$, or (ii) $h(\xi_T) = h_t(s)$, or (iii) $h(\xi_T) = h_m(s)$. But in O, $h''' = g(h; b, s) < 0$, so that h'' is decreasing, hence negative, by (4.1). But this implies that h' is decreasing, and must also be strictly negative, contradicting (i) and ruling out (ii). Hence, (iii) holds, completing the proof of the lemma. □

To proceed further with the proof of Proposition 4.2, we parameterize the unstable manifold

$$\{(h, v, w)(\xi) : -\infty < \xi < \infty\}$$

by h, up to the first minimum of $h(\xi)$. That is, we consider $v = v(h) = h'(\xi)$, and we write (2.8) with $D = 0$ as a nonautonomous equation for $v(h)$:

$$v^2 v'' + v(v')^2 = g(h; b, s). \tag{4.2}$$

The solution of (4.2) we consider satisfies $v(t) = 0$, and $v'(t) > 0$. In fact, higher derivatives of v at $h = t$ can easily be determined using the Taylor series of $v(h)$ about

$h = t$. To simplify notation, we write $h_t(s) = t$, and $h_m(s) = m$. Then $\rho = t - m > 0$. Next, define a new function $G(h;\rho)$ for $\rho \geq 0, t - \rho \leq h \leq t$ by

$$G(h,\rho) = \begin{cases} g(h;b,s)/[(h-t)(h-t+\rho)] & \text{for} \quad t-\rho < h < t, \\ -\dfrac{1}{\rho}\dfrac{\partial g}{\partial h}(t-\rho;b,s) & \text{if} \quad h = t-\rho, \\ \dfrac{1}{\rho}\dfrac{\partial g}{\partial h}(t;b,s) & \text{if} \quad h = t. \end{cases}$$

Then G is as smooth as g, except at $h = t, h = t - \rho$, where, in general, G loses a derivative. For the specific g in this paper, both g and G are rational functions of h, so there is no loss of derivative. Note that $G(h,\rho) > 0 \quad \text{for} \quad t - \rho \leq h \leq t$, and $g(h;b,s) = (h-t)(h-t+\rho)G(h,\rho)$.

We scale (4.2) as follows: Write

$$h = t + \rho\theta, \quad v = \rho^{4/3} y(\theta). \tag{4.3}$$

Then (4.2) becomes

$$y^2 y'' + y y'^2 = \theta(\theta+1)G(t+\rho\theta,\rho). \tag{4.4}$$

From the Taylor series expansion of $y(\theta)$ about $\theta = 0$, where we impose the condition $y(0) = 0$, we find

$$y'(0) = G(t,\rho) = G(t,0) + O(\rho). \tag{4.5}$$

Now Lemma 4.3 implies the following.

LEMMA 4.4. *There are constants $\rho_0 > 0, 0 < \alpha < \beta$, such that for each $\rho \in (0,\rho_0)$, the solution $y(\theta), -1 \leq \theta \leq 0$, of (4.4) satisfying $y(0) = 0$, (4.5) also satisfies*

$$-\beta < y(-1) < -\alpha, \quad \alpha < y'(-1) < \beta.$$

Proof. First note that $\theta = -1$ corresponds to ξ_m in Lemma 4.3. The scaled Lyapunov function is $L(y) = y^2 y' + R(\theta)$, where

$$R(\theta) = \int_\theta^0 \eta(\eta+1)G(t+\rho\eta,\rho)d\eta < 0$$

for $-1 \leq \theta < 0$. Specifically, $\frac{d}{d\theta}L(y) = y y'^2 < 0$, so that $L(y)$ increases as θ, hence y decreases. If $y' = 0$, then $L(y) = R(\theta) < R(0) = 0 = L(0)$. Thus, $L(y)$ has not increased, which is a contradiction. Therefore, $y' > 0$ along the entire trajectory from $\theta = 0$ to $\theta = -1$. The result now follows by bounding the $O(\rho)$ term in G. ∎

From the rescaling (4.3) and the chain rule, we conclude the following.

COROLLARY 4.5. *Let $v(h)$ be the solution of (4.2) corresponding to $y(\theta)$ of Lemma 4.4. Then*

$$-\rho^{4/3}\beta < v(m) = \rho^{4/3} y(-1) < -\rho^{4/3}\alpha; \quad \rho^{1/3}\alpha < \frac{dv}{dh}(m) = \rho^{1/3}\frac{dy}{d\theta}(-1) < \rho^{1/3}\beta. \tag{4.6}$$

Now, for $b \le h \le m$, $g(h) > 0$, so that as long as $v(h) < 0$, (4.2) implies that $v''(h) > 0$. Thus v is a convex function of h whenever v is negative. We use this fact below.

To complete the proof of Proposition 4.2, we suppose that $v(h) < 0$ for $b < h < m$ and look for a contradiction. The idea is to show that for small enough ρ, by estimating v and $v'(h)$ over half this interval, when we integrate (4.2) the integral of g remains bounded away from zero, while the integral of the left-hand side approaches zero.

Note that for all $b < h < m$,

$$0 > v(h) = v(m) - \int_h^m v'(\eta)d\eta \ge v(m) - (m-h)v'(m)$$

(since $v'(\eta) \le v'(m)$ for $\eta \le m$). Therefore,

$$|v(h)| \le |v(m)| + (m-h)K_1\rho^{1/3} \le K\rho^{1/3}, \quad h_M \le h \le m,$$

for some $K > 0$ independent of ρ.

Also, the convexity of v and inequality (4.6) imply that

$$K\rho^{1/3} > v'(m) > v'(h) \ge \frac{v(h) - v(b)}{h - b} \tag{4.7}$$

for all $b < h < m$. Now consider $h_M = (m + b)/2$. The above inequalities imply that

$$|v(h_M)| \le K\rho^{1/3}, \qquad |v'(h_M)| \le K_1\rho^{1/3},$$

where in the second inequality we use (4.7), the bounds on v, and the fact that h_m is not close to b.

Now we integrate (4.2) from h_M to m, integrating the left-hand side by parts:

$$v(m)^2v'(m) - v(h_M)^2v'(h_M) - \int_{h_M}^m v(h)v'(h)^2dh = \int_{h_M}^m g(h)dh.$$

But the left-hand side is order ρ, while the right-hand side is order one, as $\rho \longrightarrow 0$. This contradiction implies that $v(h) = 0$ for some $h \in (b, m)$, for each $\rho > 0$ sufficiently small.

To summarize, we have so far shown that for $D = 0$, there is a range $s_u < s < s_2$ for which the unstable manifold from t decreases to a global minimum between m and b and then increases without bound. To continue the proof of Proposition 4.2, we need to establish the same behavior for small $D > 0$. Since the unstable manifold from t depends continuously on D, away from $s = s_2$ (at $s = s_2$, two equilibria coincide, so the unstable manifold degenerates), there is $D_0 > 0$ and two values of s, say $s_u < \underline{s} < \overline{s} < s_2$ such that for $0 \le D \le D_0$, $\underline{s} \le s \le \overline{s}$, the unstable manifold from t has $h_\xi = v$ changing sign for h between m and b. It then follows from the Lyapunov function argument used previously that the solution $h(\xi; s)$ has a global minimum between m and b.

Finally we note that the solution increases without bound after the local minimum between m and b. This is because, like the preceding arguments based on the Lyapunov function, the solution cannot have a local maximum after hitting this minimum and cannot asymptote to either the fixed point m or b. This completes the proof of Proposition 4.2. □

We now define two distinguished values of h. Let

$$\overline{h} = \max_{s_1 \le s \le s_2} h_{**}(s), \quad \underline{h} = \min_{s_1 \le s \le s_2} h_*(s), \tag{4.8}$$

where $h_* = h_*(s), h_{**} = h_{**}(s)$ are given by (3.2).

LEMMA 4.6. *For all $s \in (s_1, s_2)$, the trajectory $h_t(\xi, s)$ crosses the boundary of the set $\overline{h} < h < \underline{h}$ at most once, either by increasing h above $\underline{h}$ or by decreasing h below $\overline{h}$. In the former case, the solution increases without bound after it leaves this set and in the latter case, the solution hits zero at finite ξ.*

Proof. Suppose the trajectory $h_t(\xi, s)$ crosses the lower boundary $\underline{h}$. Then it is impossible for the solution to turn around. If it did, there would be a local minimum at a value $h_{\min} < \underline{h}$, which by the definition of $\underline{h}$ in (4.8) violates the Lyapunov condition (3.1). Likewise if $h_t(\xi, s)$ crosses the upper boundary $\overline{h}$ it cannot turn around because this would again violate (3.1). ∎

Now define

$$S = \{s \in (s_1, s_2) | h_t(\xi, s) \text{ increases above } \overline{h} \text{ for some finite } \xi\}.$$

For all D satisfying the conditions of Proposition 4.2 we know that S is not empty; it contains at least one interval near s_2. Also, from Proposition 4.1, we know that S does not contain any $s < s_l$. Thus for all D satisfying the conditions of Proposition 4.2, the following special value of s is well defined:

$$s_* = \inf\{S\}. \tag{4.9}$$

Clearly $s_* \ge s_l$.

LEMMA 4.7. *Let D satisfy the conditions of Proposition* 4.2 *and s_* be defined as in* (4.9). *Then the trajectory $h_t(\xi; s_*)$ remains bounded between $\overline{h}$ and $\underline{h}$ and can be continued in this range for all $\xi < \infty$.*

Proof. First we note that $h_t(\xi; s_*)$ stays below $\overline{h}$. Suppose it crosses $\overline{h}$ at finite $\xi = \xi_0$ (i.e., $s_* \in S$). Since solutions of (2.11) have continuous dependence on the parameter s, there then exists an $\epsilon > 0$ so that $s_* - \epsilon' \in S$ for all $0 < \epsilon' < \epsilon$. This contradicts the fact that $s_* = \inf S$. Now we show that $h_t(\xi; s_*)$ stays above $\underline{h}$ for all ξ. Suppose it does not. Then there exists a value ξ_0 at which $h_t(\xi; s_*)$ crosses $\underline{h}$. Again, since solutions of (2.11) have continuous dependence on the parameter s, there exists an $\epsilon > 0$ so that for all $\epsilon > \epsilon' > 0$, $h_t(\xi; s_* + \epsilon')$ crosses the lower bound $\underline{h}$. Hence $s_* + \epsilon' \notin S$. However, this contradicts the fact that s_* is the infimum.

Thus the trajectory $h_t(\xi; s_*)$ is guaranteed to stay between $\underline{h}$ and $\overline{h}$. We need to show that the trajectory can be continued for all time. As in the proof of Lemma 4.3, we can do this by using the continuation part of the Picard theorem for ODEs, provided we can show uniform Lipschitz continuity of $(v, w, g(h))$ as a function of (h, v, w). Since the solution is guaranteed to have h bounded between $\underline{h}$ and $\overline{h}$, by the form of g, Lipschitz continuity is guaranteed for the third component. Moreover, the other two terms are linear in v and w, so that uniform Lipschitz continuity is guaranteed for (h, u, v) in the set $[\underline{h}, \overline{h}] \times R \times R$. The solution can thus be continued for all $\xi < \infty$. ∎

THEOREM 4.8. *Given D satisfying the conditions of the statement of Proposition* 4.2, *and s_* defined in* (4.9), *the unstable manifold $h_t(\xi, s_*)$ (with s_* defined as above) connects the equilibrium $h_t(s_*)$ to the equilibrium b and hence describes an undercompressive wave.*

Proof. We have that $h_t(\xi, s_*)$ is bounded. For ease of notation below, we denote this trajectory simply by $h(\xi)$.

Case 1: There exists a finite $\xi_{\max}$ above which $h(\xi)$ has no extrema, i.e., it is monotone increasing or decreasing. Since h is bounded, it is convergent to a limit as $\xi \to \infty$. That limit must be an equilibrium. If not, then h''' is uniformly bounded away from zero on a semi-infinite line $[\xi_0, \infty)$ and we can show this causes h, h', and h'' to become unbounded. That equilibrium has to be either m, b, or t. However, by comparing the values of the Lyapunov function, we see that the only choice is b, since $R(m) < R(h_t)$, the Lyapunov function can be shown to initially increase by comparing the solution with the predicted linear theory. Note that although this case does imply that $h(\xi) \to b$ as $\xi \to \infty$, this case is not the expected scenario. Note that when D is small, the stable manifold of b has two complex conjugate eigenvalues so that we would expect a trajectory on it to spiral in to b, i.e., we expect such a solution to have an infinite number of local extrema as $\xi \to \infty$.

Case 2: There exists a set of points $X \in R$ where h has an extremum and hence $h_\xi = 0$, and $\sup\{X\} = \infty$.

First note that such points are isolated. This is because the a priori upper and lower bounds on the solution and the fact that it satisfies (2.8) imply that $h(\xi)$ is a global real analytic function, and hence if there is a cluster point for $h_\xi = 0$, then h_ξ must be identically zero, which is clearly not the case. Thus the set X must be a countable set ξ_i and $\xi_i \to \infty$ as $i \to \infty$.

Denote by h_i the value $h(\xi_i)$. Let us suppose without loss of generality that ξ_i are local minima for i odd and maxima for i even. From the Lyapunov function, we see that all extrema satisfy $R(h(\xi_i)) > R(h_t)$. Moreover $R(h_i)$ is an increasing sequence that is also bounded, so it converges to a value R_1. Furthermore, all minima must lie below b. This is because if, say, h_k lies above b, then since $R(h)$ is monotone decreasing on the set $R(h) > R(h_t)$, $h > b$, then $R(h_{k+1}) < R(h_k)$ because h_{k+1} is a local maximum. However, this contradicts the fact that $R(h_i)$ is increasing. Likewise, a similar argument shows that the local maxima all lie above b.

By (3.1) and (4.8), the solution lies between $\underline{h}$ and $\overline{h}$. The proof follows provided we can show that h' and h'' approach zero as $\xi \to \infty$.

To do this, we make some explicit estimates, using (2.8) and the Lyapunov function. First note that since $R(h_i)$ is increasing, the h_i oscillate around $h = b$: $h_i < b$ at a min and $h_{i+1} > b$ at a max. Therefore, there are two convergent subsequences, $h_{2n+1} \to h_1$, $h_{2n} \to h_2$, with $h_2 - h_1 \geq 0$.

Now note that for each ξ_i,

$$R(h_i) - R(h_t) = \int_{-\infty}^{\xi_i} h_{\xi\xi}^2 + D \int_{-\infty}^{\xi_i} h_\xi^2.$$

Taking the limit as $i \to \infty$ and recalling that $D \geq 0$ gives

$$\int_{-\infty}^{\infty} h_{\xi\xi}^2 d\xi \leq D \int_{-\infty}^{\infty} h_\xi^2 d\xi + \int_{-\infty}^{\infty} h_{\xi\xi}^2 d\xi = R_1 - R(h_t) \leq R(b) - R(h_t) < \infty.$$

We now invoke the following interpolation inequality [Tay96, p. 9];

$$\|h_\xi\|_{L^4(R)} \leq C \|h\|_{L^\infty}^{1/2} \|h_{\xi\xi}\|_{L^2(R)}^{1/2}.$$

This means that since h is uniformly bounded and $h_{\xi\xi}$ is bounded in $L^2(R)$ that h_ξ is bounded in $L^4(R)$.

On $[\xi_i, \xi_{i+1}]$, h_ξ has the fixed sign $(-1)^{i+1}$. Now choose $\beta_i \in [\xi_i, \xi_{i+1}]$ so that $|h_\xi|$ attains a maximum on this interval at β_i. Compute

$$\begin{aligned}
|h_\xi^3(\beta_{i+1}) - h_\xi^3(\beta_i)| &= |h_\xi(\beta_{i+1})|^3 + |h_\xi(\beta_i)|^3 \\
&= 3\left|\int_{\beta_i}^{\beta_{i+1}} h_\xi^2 h_{\xi\xi} d\xi\right| \\
&\le 3\int_{\beta_i}^{\beta_{i+1}} |h_\xi|^2 |h_{\xi\xi}| d\xi \\
&\le 3\left[\int_{\beta_i}^{\beta_{i+1}} |h_\xi|^4\right]^{1/2}\left[\int_{\beta_i}^{\beta_{i+1}} |h_{\xi\xi}|^2 d\xi\right]^{1/2} \\
&\le 3\epsilon_i\delta_i,
\end{aligned}$$

where

$$\delta_i = \left[\int_{\beta_i}^{\beta_{i+1}} |h_\xi|^4\right]^{1/2}, \quad \epsilon_i = \left[\int_{\beta_i}^{\beta_{i+1}} |h_{\xi\xi}|^2 d\xi\right]^{1/2},$$

and where $\sum_i \epsilon_i^2$ and $\sum_i \delta_i^2$ are both finite. Thus $\epsilon_i\delta_i \to 0$ as $i \to \infty$. By the choice of β, this also implies that $|h_\xi|^3$ and hence $|h_\xi|$ goes to zero as $\xi \to \infty$. Note that this also implies that h_ξ is uniformly bounded on R.

We now show that $h_{\xi\xi}$ is uniformly bounded independent of ξ. Since h solves the ODE (2.11), and since h is uniformly bounded between $\underline{h}$ and $\overline{h}$, we have that $h_{\xi\xi\xi} - Dh_\xi$, and hence $h_{\xi\xi\xi}$ is uniformly bounded. Thus for any ξ,

$$|h_{\xi\xi}^3(\xi)| = 3|\int_{-\infty}^{\xi} h_{\xi\xi}^2 h_{\xi\xi\xi} d\xi| \le C\|h_{\xi\xi}\|_{L^2}^2 < \infty.$$

Finally note that the Lyapunov function is $h_\xi h_{\xi\xi} + R(h)$. Since it is increasing, and the product $h_\xi h_{\xi\xi}$ goes to zero as $\xi \to \infty$, then $R(h(\xi))$ approaches a constant. The infinite sequence of alternating max and mins implies that that constant has to be $R(b)$.

Finally, since the trajectory $\{(h, h', h'')(\xi) : -\infty < \xi < \infty\}$ is bounded, and there are no periodic orbits, the trajectory must approach an equilibrium as $\xi \longrightarrow \infty$. The equilibrium is necessarily b, since this is the only equilibrium with $R(h) > R(t)$. This completes the proof of Theorem 4.8 ∎

5. Nonexistence of undercompressive waves for large D. In this section, we show that for each $b < 1/3$, and for D sufficiently large, there are no undercompressive traveling wave solutions having $h = b$ as the downstream height. This is formulated precisely in the following theorem, in which, as in the previous section, we fix $h_+ = b$, and consider the vector fields (2.11) to be parameterized by s and D.

THEOREM 5.1. *Let $b \in (0, 1/3)$. Then there is $D_1 > 0$ such that for $D > D_1$ and $s_1 < s < s_2$, there is no orbit from the equilibrium $(h_t(s), 0, 0)$ to the equilibrium $(b, 0, 0)$.*

Proof. We need to show that the unstable manifold from $h_t(s)$ never connects to the fixed point at b.

Recall the ODE is

$$\begin{aligned} h' &= v, \\ v' &= w, \\ w' &= g(h) + Dv, \end{aligned} \tag{5.1}$$

where

$$g(h) = -\frac{f(h) - sh - f(b) + sb}{h^3}.$$

Some of the results in the preceding section apply to this case, in particular Proposition 4.1 and Lemma 4.6. Using these two results, we now show that for sufficiently large D (depending on b) for all s in the region that we are interested in, h_t decreases monotonically to zero, in which case it can never connect to the fixed point at b.

To see that this is true, first note that the linearization of (5.1) near the fixed point $h_t(s)$ yields eigenvalues that satisfy the equation

$$\lambda^3 - \lambda D - g'(h_t) = 0.$$

Since $g'(h_t) \geq 0$, for small D there is one positive real root and two complex roots with negative real part. For sufficiently large D there is one positive real root $\lambda_p \sim \sqrt{D}$ and two real negative roots $\lambda_1 \sim -g'(h_t)/D$ and $\lambda_2 \sim -\sqrt{D}$.

First we note that the Lyapunov function guarantees that the branch of the unstable manifold from h_t that initially increases can not turn around to connect to b. This is because if the solution turns around, it must have a local maximum above h_t; however, the function $R(h)$ decreases monotonically above h_t.

Consider now the branch of the unstable manifold from h_t that initially decreases. We show that for D sufficiently large, this branch decreases to zero at finite ξ.

To linear order the solution looks like

$$h_t(\xi; s) = h_t - e^{\lambda_p \xi} \tag{5.2}$$

for ξ very negative. Also, to linear order,

$$v \sim \lambda_p (h - h_t),$$

and as long as $h > \underline{h}$ (defined in (4.8)) we have an a priori bound for $g(h)$. In particular, we can choose D large enough so that the ODE (5.1) is dominated by the linear behavior (i.e., $g = 0$) of the ODE while $h > \underline{h}$. However, the linear behavior simply has that h decreases monotonically like (5.2). So for D large enough, the solution should decreases monotonically until it hits $\underline{h}$. However, we know that once it hits $\underline{h}$ it continues to decrease by Proposition 4.1.

We now make the above argument rigorous. Introducing the new variables

$$Q = \frac{v}{h - h_t}, \quad P = \frac{w}{h - h_t},$$

the ODE (5.1) is transformed to the system

$$\begin{aligned} Q' &= P - Q^2, \\ P' &= B(h(\xi)) + DQ - QP, \end{aligned} \tag{5.3}$$

$$\text{where } B(h) = \frac{g(h)}{h - h_t}.$$

Note that since g vanishes at h_t, B is bounded and approaches g' at h_t. Also, for $\underline{h} < h < h_t$, $|B|$ is bounded independent of D. Call this bound $M(b)$. This system has a fixed point for $h = h_t$ that corresponds to the positive eigenvalue λ_p above, $Q = \lambda_p$, $P = \lambda_p^2$. Now consider the rectangle

$$R_D = \{(Q,P) | \sqrt{D}/2 < Q < 2\sqrt{D} \text{ and } D/2 < P < 2D\}. \tag{5.4}$$

Choose D to satisfy $D > (4M)^{2/3}$. Then as long as $\underline{h} < h < h_t$, on the boundary of R_D, the vector field in (5.3) points into R_D, which means that the solution remains in R_D. This gives a lower bound on $Q = \frac{h_\xi}{h-h_t}$,

$$\frac{h_\xi}{h - h_t} \geq K > 0,$$

which implies $h_\xi < K(h - h_t)$ so that $h(\xi)$ decreases exponentially: for all $\xi > \xi_0$, $h(\xi) - h_t \leq (h(\xi_0) - h_t)e^{K(\xi - \xi_0)}$ provided $\underline{h} < h(\xi') < h_t$ for all $\xi' < \xi_0$. By the stable manifold theorem, we know there exists such an ξ_0 where $\underline{h} < h(\xi_0) < h_t$. This is sufficient to guarantee that $h(\xi)$ hits $\underline{h}$ at a finite value of ξ. □

6. Summary and conclusions. We have considered traveling wave solutions $h(x - st)$ of the PDE

$$\partial_t h + \partial_x(h^2 - h^3) = -\partial_x(h^3 \partial_x^3 h) + D\partial_x(h^3 \partial_x h). \tag{6.1}$$

Recent numerical experiments [BMS99, M99] show that certain jump initial data give rise to undercompressive structures, in which the leading part of the structure is an undercompressive traveling wave, connecting states h_- to h_+, for which the speed s of the wave violates the Lax entropy condition

$$f'(h_+) < s < f'(h_-).$$

For a fixed value of h_+, the numerics show a special value of h_- for which an undercompressive waves exists when the parameter D in (6.1) is small. Likewise, for large D, the numerics show that undercompressive waves do not exist. In this paper we presented rigorous proofs of both of these numerical observations.

Traveling waves satisfy a third order autonomous ODE in which the downstream thickness h_+ and the wave speed s appear as parameters. For each $h_+ = b < 1/3$, there is a range of s for which the ODE has three (hyperbolic) equilibria, B, M, and T. M has a two-dimensional unstable manifold while B and T have two-dimensional stable manifolds. Compressive waves are heteroclinic orbits from M to either B or T, codimension zero intersections of a two-dimensional stable manifold from one fixed point with a two-dimensional unstable manifold from another fixed point. Such intersections are structurally stable to perturbations and exist for a range of the parameter s. In contrast, undercompressive waves are heteroclinic connections from either T (or B) to B (or T, respectively). The situation that corresponds to the physical problem of interest is the existence of a wave from T to B.

Our analysis relies heavily on the existence of a Lyapunov function for the ODE. It follows directly from the Lyapunov function that there is a range of s (where M is close to B) for which a branch of the unstable manifold from T decreases monotonically to zero. We then consider a range of s for which M is very close to T and rescale the ODE using the distance from M to T as a scaling parameter. By analyzing the

rescaled equation for $D = 0$, we are able to show that whenever M is sufficiently close to T, the initially decreasing branch of the unstable manifold from T has a global minimum (in h) between m and b. Moreover, a perturbation argument shows this property for $D \geq 0$ and small, provided M is not too close to T. We then proceed with an argument that shows that there is an intermediate value of the parameter s, so that M is neither very close to B or to T for which the unstable manifold from T must connect to B. This part of the proof is largely topological, but it includes some explicit estimates on higher derivates of the solution along the unstable manifold from T in order to guarantee that it stays bounded and hence connects to B.

In the last section of the paper, we show that for large values of D, regardless of the speed s of the wave, the unstable manifold from T never connects to B. The result is that there can never exist an undercompressive wave. The proof follows from making a change of variables in the ODE to show that the linear system dominates the dynamics along the unstable manifold, until the solution gets so small in h that it must hit zero at finite ξ.

We mention some related papers discussing third order (ODE) travelling waves that exist only for special parameter values or wave speeds. The paper of Grinfeld [Gri89] deals with travelling waves for Korteweg capillary regularization of a van der Waals fluid and uses Conley index theory to prove existence. The paper [BHP96] deals with traveling waves in the compressive case $f(h) = h^3$ but with a different form of degenerate diffusion. They prove existence of waves with a sharp contact line (h goes to zero) using a two directional shooting method. It would be interesting to see if the methods of these papers also apply to the problem presented here.

It is interesting to note that our arguments extend, with slight modifications, to the case of linear diffusion:

$$\partial_t h + \partial_x(f(h)) = D\partial_x^2 h - \partial_x^4 h. \tag{6.2}$$

In fact, it is the fourth order diffusion that produces the undercompressive shocks. Numerical simulation of (6.2) shows that similar structures occur in this case. The main difference between (2.1) and (6.2) is that the degeneracy in the diffusion in (2.1), in particular in the fourth order term, causes some singular behavior to occur for very small values of h. Numerical computations of the traveling waves for $D = 0$ show that as $b \to 0$, the value of s for which the undercompressive wave occurs approaches $s = 0$ while the value of t approaches $t = 1$. For very small values of b, jump initial data corresponding to very weak Lax shocks evolve to a solution of (6.1) with two shocks, with the special undercompressive wave as the leading shock. Since this undercompressive wave connects $t \sim 1$ to $b \sim 0$, we obtain a solution that reaches a height of order one from initial data of small order. This is a beautiful example of a violation of the maximum principle for convection-diffusion problems of higher order. An open theoretical problem is to prove that with the nonlinear diffusion in (1.1), the undercompressive waves have such singular limits as $b \to 0$.

Numerical simulations of Münch [BMS99, M99] show that the undercompressive wave is the limit of a cascade of bifurcations that occur as the shock speed varies in (2.11). In particular, for small values of D, the phase portrait of the ODE at the critical speed s_* at which the undercompressive wave occurs has unusual structure. The unstable manifold from T is part of the topological boundary of the (two-dimensional) unstable manifold from M, which wraps around the unstable manifold from T in a spiral with an infinite number of turns. The result is that at the critical speed s_*, not only does the unstable manifold from T connect to B but the unstable manifold

from M intersects the stable manifold of B an infinite number of times; there are an infinite number of compressive waves connecting M to B with the undercompressive wave from T to B as their limit. Part of this structure is reminiscent of Silnikov's example [GH86] and we expect that machinery to be useful in studying this problem.

Finally we note that stability of traveling waves yields another interesting set of problems. Numerical simulations show that the undercompressive traveling waves, as solutions of (1.1), are stable with respect to perturbations. However, when there are multiple compressive waves at the same speed and with identical far field states, then some are stable and some are unstable.

A physically relevant problem is to gain more theoretical insight into the stability of traveling waves as plane wave solutions of the two-dimensional PDE

$$\partial_t h + \partial_x(h^2 - h^3) = D\nabla \cdot (h^3 \nabla h) - \nabla \cdot (h^3 \nabla \Delta h). \tag{6.3}$$

This is an important problem for understanding fingering patterns in driven film flow. Numerical simulations (with small D) show that compressive waves are typically unstable to transverse perturbations [THSJ89, BB97, KT97] while undercompressive waves are stable to transverse perturbations [BMFC98, KT98]. These stability differences are reflected in recent and ongoing experiments.

Recent progress has been made in understanding stability of undercompressive waves in systems of conservation laws [GZ98, LZ95]. These techniques will be used to explore stability to one- and two-dimensional perturbations from a more theoretical point of view in the near future [BMSZ99].

ON SOLVABILITY OF THE NONLINEAR WAVE RESISTANCE PROBLEM FOR A SURFACE-PIERCING SYMMETRIC CYLINDER*

CARLO D. PAGANI† AND DARIO PIEROTTI†

Abstract. We solve the wave-resistance problem for a "slender" cylinder semisubmerged in a heavy fluid and moving at uniform, supercritical speed in the direction orthogonal to its generators. We prove that the free boundary and the cylinder profile form a single smooth streamline; moreover, the free boundary is monotone increasing downstream and lies under the level of calm water.

Key words. free boundary, nonlinear boundary condition, hodograph transformation

1. Introduction. Consider a rigid body moving at a uniform speed c on the free surface of a heavy fluid. The unperturbed fluid, which is at rest, is assumed to have a finite constant depth H; compressibility and viscosity are neglected, as is surface tension; moreover, the fluid motion is assumed to be irrotational (all these assumptions are common in the theory of surface gravity waves). The *wave resistance problem* consists of the determination of the steady flow generated by this motion. Notice that we neglect the effect that the perturbed fluid produces on the motion of the body (sea-keeping problem). Besides the general hypotheses stated above, we make three main assumptions:

(a) *Two-dimensional geometry.* The body is an infinitely long, horizontal cylinder moving in the direction orthogonal to its generators and producing two-dimensional disturbances on the fluid which can be completely described in a vertical plane containing the direction of the motion (see Figure 1).

(b) *Supercritical velocity.* We assume

$$c > \sqrt{gH}, \tag{1.1}$$

where g is the acceleration of gravity. As we will see, this condition allows us to consider a flow which is unperturbed at infinity in *both* directions; actually, in the case of subcritical velocity, nontrivial oscillations at backward infinity cannot be excluded (also at the level of the linearized problem; see [1]).

(c) *Slenderness of the body.* We assume that the piercing part of the cylinder is small compared to its length. To be precise, let us choose a reference frame connected with the cylinder and such that the xy-plane is orthogonal to the horizontal generators of the cylinder; the x-axis is directed as the unperturbed flow, the undisturbed free surface is at $y = 0$, and the bottom of the region occupied by the fluid is at $y = -H$. We formulate our assumption by saying that the boundary of the cross section of the "hull" is described by the equation

$$y = \epsilon f(x),$$

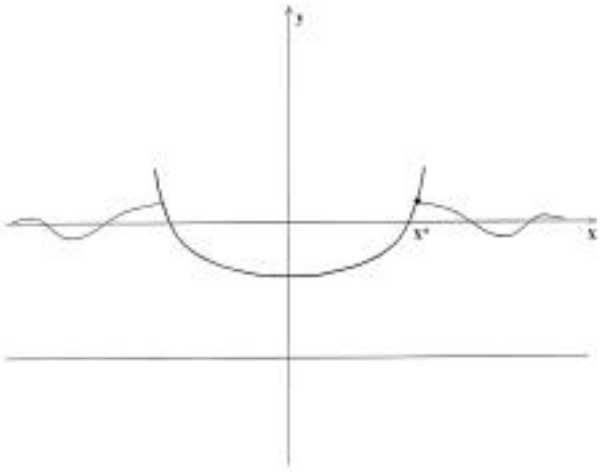

FIG. 1. *Vertical section of the system fluid-cylinder.*

where $\epsilon > 0$ is a small parameter and f is a $\mathcal{C}^1$ symmetric function defined in some interval $J \in \mathbf{R}$ and such that, for some $x_0 > 0$, with $\pm x_0 \in J$,

$$f(x) < 0 \qquad \text{for} \quad x \in (-x_0, x_0),$$

$$f(\pm x_0) = 0,$$

$$f(x) > 0 \qquad \text{for} \quad x \in J \backslash [-x_0, x_0].$$

The choice of a symmetric profile for the cylinder section allows us to simplify the problem by looking for solutions with a definite symmetry (with respect to x) and by reducing the number of unknown parameters (see below). The general, nonsymmetric case will be treated in a forthcoming paper. Finally, it remains to specify the properties of the free surface of the fluid: we assume that it is described by the cartesian curve $y = h(x)$, where h is an unknown symmetric smooth function defined in $\mathbf{R}\backslash[-x^*, x^*]$, for some positive $x^* \in J$. The numbers $\pm x^*$ are the abscissae of the points where the free surface meets the hull, so that $h(\pm x^*) = \epsilon f(\pm x^*)$; clearly, we will also require $h(x) < \epsilon f(x)$ for every $x \in J$ with $|x| > x^*$. Note that the value x^* is unknown and its determination is part of the problem. We set

$$h^*(x) = \begin{cases} h(x) & \text{for } |x| > x^*, \\ \epsilon f(x) & \text{for } |x| \le x^*. \end{cases}$$

Then

$$S^* = \{(x, y) \in \mathbf{R}^2 \, : -H < y < h^*(x)\} \tag{1.2}$$

will denote the region filled with the fluid. We assume (as usual) that the curve $y = h^*(x)$ is a streamline; also, the bottom $y = -H$ is assumed to be a streamline.

To formulate the various equations of the problem, it is convenient to introduce the complex variable $z = x + iy$ and the complex velocity function $\omega(z) = u(x, y) - iv(x, y)$, holomorphic in S^*, with u and v components of the velocity vector. We can now state our problem in the following form: find a real number $x^* > 0$, a real symmetric

function $h \in \mathcal{C}^1(\mathbf{R})$, and a complex function $\omega = u - iv$ holomorphic in S^*, with $\omega(-x+iy) = \bar{\omega}(x+iy)$, such that the following boundary conditions hold:

$$\frac{1}{2}|\omega(x,h(x))|^2 + gh(x) = \text{constant}, \qquad |x| > x^*, \tag{1.3}$$

$$v(x,h(x)) = h'(x)u(x,h(x)), \qquad |x| > x^*, \tag{1.4}$$

$$v(x,\epsilon f(x)) = \epsilon f'(x)u(x,\epsilon f(x)), \qquad |x| < x^*, \tag{1.5}$$

$$v(x,-H) = 0, \qquad x \in \mathbf{R}, \tag{1.6}$$

$$\lim_{|x|\to\infty} \omega(z) = c; \tag{1.7}$$

$$\lim_{|x|\to\infty} h(x) = 0. \tag{1.8}$$

Equations (1.4), (1.5) indicate that the free surface and the wetted hull are arcs of a streamline; (1.6) expresses the same property for the bottom, while (1.3) is the Bernoulli condition on the free surface. Finally, we have the *continuity condition*

$$h(x^*) = \epsilon f(x^*), \tag{1.9}$$

together with the inequality

$$h(x) < \epsilon f(x) \qquad \text{for} \quad x \in J\backslash[-x^*, x^*]. \tag{1.10}$$

Notice that, by using (1.7) and (1.8) in the Bernoulli condition (1.3), one obtains for the constant at the right-hand side the value $\frac{1}{2}c^2$.

The problem outlined above appears in the literature in its *linearized version* (called Neumann–Kelvin problem). This is an artificial problem, obtained by assuming that the profile of the free boundary is a small perturbation of the flat surface, regardless of the size or the shape of the moving body. In this way, one is faced with a linear problem (for the velocity potential or the stream function [1]) in a *fixed* domain; however, this problem is inconsistent, in the sense that it admits an infinite set of solutions depending upon two real parameters (one parameter in the symmetric case). Several different supplementary conditions were proposed [1], [2], [3]; as was noted in [2], all of them give mathematically well-posed statements, but it is not clear which of them better meets the hydrodynamics of the phenomenon.

The aim of this paper is to show the existence of an exact solution of the nonlinear problem for small values of the parameter ϵ, which in the limit case of a beam, i.e., for $\epsilon \to 0$, reduces to the free parallel flow $\omega(z) = c$, $h(x) = 0$.

2. The hodograph transformation. It is convenient to reformulate the problem (as we did in [4]) by using as new independent variables the velocity potential $\varphi = \varphi(x,y)$ and the stream function $\psi = \psi(x,y)$. Let w be the complex potential

$$w = \varphi + i\psi, \qquad w'(z) = \omega(z). \tag{2.1}$$

Then,

$$u = \varphi_x = \psi_y, \qquad v = \varphi_y = -\psi_x. \tag{2.2}$$

The lines $\varphi =$ constant are the equipotential lines, while $\psi =$ constant are the streamlines. The region S^* being simply connected, the potential w is determined by the complex velocity up to an additive constant. Let us now fix the complex constant: the real part is fixed by requiring that $\varphi(0, y) = 0$ (so that φ is antisymmetric with respect to x); the imaginary part is fixed by requiring that the streamline $y = h^*(x)$ is represented by the equation $\psi = 0$. As a consequence, the bottom $y = -H$ will be described by the equation $\psi = -cH$, for we have

$$\psi(x, -H) = -\int_{-H}^{h^*(x)} \psi_y(x, t)dt = -\int_{-H}^{h^*(x)} u(x, t)dt.$$

The last integral represents the total flux crossing any vertical section of S^* and is independent of x; at infinity, where the flow is unperturbed, it becomes $-\int_{-H}^{0} c dt = -cH$.

We recall now that we are looking for a solution which is a small perturbation of the free parallel flow; hence, it is reasonable to assume that $u(x, y) > 0$ uniformly in S^*, and therefore $\omega(z) \neq 0$ in S^*. Moreover, by the first equation of (2.2), the maps $x \mapsto \varphi(x, y)$ and $y \mapsto \psi(x, y)$ are strictly increasing. It follows that there is a conformal map, called the hodograph

$$z \mapsto w(z) \tag{2.3}$$

which maps the domain S^* of the physical plane onto a strip A_H in the hodograph plane (φ, ψ) given by

$$A_H \equiv \{(\varphi, \psi) \in \mathbf{R}^2 : \quad -cH < \psi < 0\}. \tag{2.4}$$

We may also assume that w is one-to-one, so that the inverse map

$$w \mapsto z(w)$$

is well defined on A_H and satisfies

$$\frac{dz}{dw} = \frac{1}{\omega(z)} \equiv \Omega(w). \tag{2.5}$$

As already discussed in [4], in the hodograph plane the flow is better described by the function Ω. By writing $\Omega = U - iV$, the above relation takes the form

$$U = \frac{\partial x}{\partial \varphi} = \frac{\partial y}{\partial \psi}, \qquad V = \frac{\partial x}{\partial \psi} = -\frac{\partial y}{\partial \varphi}. \tag{2.6}$$

By noticing that

$$U = \frac{u}{u^2 + v^2}, \qquad V = -\frac{v}{u^2 + v^2} \tag{2.7}$$

and by the above symmetry assumptions, we easily verify the relations

$$\Omega(-\varphi, \psi) = \bar{\Omega}(\varphi, \psi),$$

and

$$\Omega \to 1/c$$

for $|\varphi| \to \infty$. Then, we can write explicitly

$$x(\varphi,\psi) = \int_0^{\varphi} U(s,\psi)ds, \qquad y(\varphi,\psi) = \frac{1}{c}\psi + \int_{\varphi}^{+\infty} V(s,\psi)ds, \tag{2.8}$$

assuming that the last integral is convergent.

We now specify the boundary conditions that the holomorphic function Ω has to satisfy on ∂A_H. We note first that two points are relevant on the upper boundary of the strip A_H: the images by the hodograph map of the points $P_\pm = (\pm x^*, \epsilon f(x^*))$ where the free boundary meets the hull; let us write $\varphi = \pm\varphi^*$ for the equipotential lines passing through these points. The value of φ^* is unknown and its determination is part of our problem. The arc of the curve between P_+ and P_-, i.e., the wetted part of the hull, is mapped onto the beam

$$I = \{(\varphi,\psi) : \quad \psi = 0, \quad |\varphi| < \varphi^*\}, \tag{2.9}$$

and the free surface onto the half-lines

$$F = \{(\varphi,\psi) : \quad \psi = 0, \quad |\varphi| > \varphi^*\}. \tag{2.10}$$

Furthermore, the image of the bottom of the fluid is the line

$$B = \{(\varphi,\psi) : \quad \psi = -cH, \quad \varphi \in \mathbf{R}\}. \tag{2.11}$$

Now, we observe that the kinematic free surface condition (1.4) is already taken into account by requiring that the free surface is part of the streamline $\psi = 0$, while the Bernoulli condition (1.3), by standard computations, takes the form

$$\frac{1}{2}|\Omega|^{-4}\frac{\partial|\Omega|^2}{\partial\varphi} + gV = 0 \qquad \text{on } F. \tag{2.12}$$

The condition (1.4) becomes

$$V(\varphi,0) + \epsilon f'(x(\varphi,0))U(\varphi,0) = 0 \qquad \text{for } |\varphi| < \varphi^*, \tag{2.13}$$

while the condition on the bottom gives

$$V = 0 \qquad \text{on } B. \tag{2.14}$$

Moreover, we require the asymptotic condition

$$\lim_{|\varphi|\to\infty} \Omega = \frac{1}{c}. \tag{2.15}$$

Finally, by taking into account (2.8), the continuity condition (1.9) has the form

$$\int_{\varphi^*}^{+\infty} V(s,0)ds = \epsilon f\left(\int_0^{\varphi^*} U(s,0)ds\right). \tag{2.16}$$

Equations (2.12)–(2.16) formulate the problem in the hodograph plane.

We point out that the free surface profile, $h(x)$, disappeared among the unknowns; it will be recovered at the end, once the hodograph map is known, as the image of the level line $\psi = 0$. We also notice that (2.12)–(2.15) is a boundary value problem for a

function Ω holomorphic in a *fixed* domain, namely the strip A_H; however, the position of the points $(\pm\varphi^*, 0)$ separating the two different boundary conditions (2.12), (2.13) is unknown.

To solve the problem, we choose the following strategy: first we regard φ^* as a known parameter and find the holomorphic function Ω satisfying (2.12)–(2.15) by means of the implicit function theorem in Banach spaces; then, we put the above solution (which will depend on φ^*) in the continuity condition (2.16) and obtain an equation for the unknown φ^*. The necessity of this two-step procedure is due to the fact that we do not know the limit positions for $\epsilon \to 0$ of the abscissae of the points $P_\pm$, so that we cannot linearize the whole problem for Ω, φ^* around the solution at $\epsilon = 0$.

Assume then that φ^* is known; a rescaling of the independent variables and a further change of the unknowns will prove convenient in the following. By setting

$$\rho = \frac{\varphi}{\varphi^*}, \qquad \sigma = \frac{\psi}{\varphi^*}, \qquad \zeta = \rho + i\sigma, \tag{2.17}$$

the strip A_H becomes

$$A^* \equiv \left\{ (\rho, \sigma) \in \mathbf{R}^2 \, : \quad -\frac{cH}{\varphi^*} < \sigma < 0 \right\}. \tag{2.18}$$

In particular, the beam (2.9) maps onto the interval $(-1, 1)$ of the ρ-axis.

We now observe that, for $\epsilon = 0$, (2.12)–(2.15) admit the constant solution $\Omega = 1/c$. Then, we define the new unknown $\chi = \xi - i\eta$ (as functions of the rescaled variables (2.17)) by subtracting this solution from Ω and dividing by ϵ; namely, we set

$$U(\varphi, \psi) = \frac{1}{c}\Big(1 + \epsilon\xi(\rho, \sigma)\Big), \qquad V(\varphi, \psi) = \frac{\epsilon}{c}\eta(\rho, \sigma). \tag{2.19}$$

We want to write the nonlinear boundary conditions (2.12), (2.13) as formal operator equations in the new variables. We first note that the relations (2.8) take the form

$$x(\varphi, \psi) = \frac{\varphi^*}{c}\int_0^\rho (1 + \epsilon\xi(s, \sigma))ds, \qquad y(\varphi, \psi) = \frac{\varphi^*}{c}\left\{\sigma + \epsilon\int_\rho^{+\infty} \eta(s, \sigma)ds\right\}, \tag{2.20}$$

and that we can define on $(-1, 1)$ the function

$$G(\rho) = f'(x(\varphi, 0)) = f'\left(\frac{\varphi^*}{c}\int_0^\rho (1 + \epsilon\xi(s, 0))ds\right). \tag{2.21}$$

We now set

$$B^I(\chi, \epsilon) = \{\eta + G(\cdot)(1 + \epsilon\xi)\}|_{|\rho|<1,\, \sigma=0}, \tag{2.22}$$

$$B^F(\chi, \epsilon) = \left\{\frac{|1 + \epsilon\chi|^{-4}}{2\epsilon}\frac{\partial}{\partial\rho}|1 + \epsilon\chi|^2 + \frac{g\varphi^*}{c^3}\eta\right\}\Big|_{|\rho|>1,\, \sigma=0}, \tag{2.23}$$

and

$$\mathbf{B}(\chi, \epsilon) = (B^I(\chi, \epsilon), B^F(\chi, \epsilon)). \tag{2.24}$$

Then, it is easily verified that the equation

$$\mathbf{B}(\chi, \epsilon) = 0 \tag{2.25}$$

is equivalent to the conditions (2.12)–(2.13). Moreover, the function χ must be holomorphic in A^*, vanishing for $|\rho| \to \infty$ and satisfying the *linear* condition

$$\eta(\rho, -cH/\varphi^*) = 0.$$

In the next section, we will formulate (2.25) as an operator equation between suitable Banach spaces which takes into account all of the above conditions.

3. The functional setting of the problem. We shall discuss first (section 3.1) a linear problem obtained from (2.25) by letting $\epsilon \to 0$ (formally). The results obtained will suggest the correct functional setting of the nonlinear problem (section 3.2). We recall that we are assuming here that φ^* is a known parameter.

3.1. The linearized problem. As we have already remarked, when $\epsilon = 0$, (2.12)–(2.15) admit the trivial solution $\Omega = 1/c$. Now we assume that Ω can be expanded in powers of ϵ and, according to (2.19), we set

$$\chi(\rho, \sigma) = \tilde{\chi}(\rho, \sigma) + \mathcal{O}(\epsilon); \tag{3.1}$$

by inserting (3.1) into (2.22), (2.23) and by taking the limit $\epsilon \to 0$, we get a problem satisfied by the holomorphic function $\tilde{\chi} = \tilde{\xi} - i\tilde{\eta}$ in the fixed domain A^* (see [5] for the details):

$$\tilde{\xi}_\rho + \frac{\varphi^* g}{c^3}\tilde{\eta} = 0 \qquad \text{for} \quad \sigma = 0, \ \ |\rho| > 1, \tag{3.2}$$

$$\tilde{\eta}(\rho, 0) = -f'\left(\frac{\varphi^*}{c}\rho\right) \qquad \text{for} \quad |\rho| < 1, \tag{3.3}$$

$$\tilde{\eta} = 0 \qquad \text{for} \quad \sigma = -\frac{cH}{\varphi^*}, \ \ \rho \in \mathbf{R}, \tag{3.4}$$

$$\lim_{|\rho| \to \infty} \tilde{\chi} = 0. \tag{3.5}$$

By substituting, in (3.2), $\tilde{\xi}_\rho$ with $-\tilde{\eta}_\sigma$, we obtain a boundary value problem for the harmonic function $\tilde{\eta}$ (the harmonic conjugate $\tilde{\xi}$ is then determined by the requirement of vanishing at infinity).

Problem L. Find $\tilde{\eta}$ harmonic in A^* such that

$$\tilde{\eta}_\sigma - \nu^* \tilde{\eta} = 0 \qquad \text{for} \quad \sigma = 0, \ \ |\rho| > 1,$$

$$\tilde{\eta}(\rho, 0) = -f'\left(\frac{\varphi^*}{c}\rho\right) \qquad \text{for} \quad |\rho| < 1,$$

$$\tilde{\eta} = 0 \qquad \text{for} \quad \sigma = -\frac{cH}{\varphi^*}, \ \ \rho \in \mathbf{R},$$

$$\lim_{|\rho| \to \infty} \tilde{\eta} = 0,$$

where we set

$$\nu^* = \frac{\varphi^* g}{c^3}.$$

Problem L coincides with the problem (1.1)–(1.4) in [5], which was obtained by linearizing (formally) the original nonlinear problem in the physical plane.

By the results of [5, section 3], it turns out that, for every symmetric and smooth enough function f, there exists a unique solution $\tilde{\eta} \in H^1(A^*)$ of the problem L and furthermore, a unique harmonic conjugate $\tilde{\xi}$ also belonging to $H^1(A^*)$; in addition, these functions are continuous in $\bar{A}^*$ and rapidly decreasing at infinity.

Our strategy is to find an appropriate functional setting for the equation $\mathbf{B}(\chi, \epsilon) = 0$ in order to apply the implicit function theorem. To do so, we need further properties of the solutions of the above linear problem. In fact, we must specify a Banach space norm on the space of these solutions in such a way that the boundary operators B^F and B^I are continuously differentiable; as we will show below, this requirement can be satisfied in the Sobolev space $W_p^2(A^*)$ for some $p > 1$. Moreover, we also have to solve the problem L with nonzero boundary data on $|\rho| > 1, \sigma = 0$, in order to prove the invertibility of the Fréchet derivative of the operator $\mathbf{B}$ (see below).

Then, we consider the following boundary value problem:

$$\Delta\tilde{\eta} = 0 \qquad \text{in} \quad A^*, \tag{3.6}$$

$$\tilde{\eta} = k \qquad \text{for} \quad \sigma = 0, \ \ |\rho| < 1, \tag{3.7}$$

$$\tilde{\eta}_\sigma - \nu^* \tilde{\eta} = l \qquad \text{for} \quad \sigma = 0, \ \ |\rho| > 1, \tag{3.8}$$

$$\tilde{\eta} = 0 \qquad \text{for} \quad \sigma = -\frac{cH}{\varphi^*}, \ \ \rho \in \mathbf{R}. \tag{3.9}$$

The key result of this section is the following theorem.

THEOREM 3.1. *Assume that $k \in W_p^{2-\frac{1}{p}}(-1,1)$ and $l \in W_p^{1-\frac{1}{p}}(\mathbf{R}\backslash[-1,1])$ with $p \in (1, 4/3)$. Then, there exists a unique solution $\tilde{\eta} \in W_p^2(A^*)$ of the problem* (3.6)–(3.9).

Proof. We first note that, by Sobolev imbeddings, we have

$$W_p^{2-\frac{1}{p}}(-1,1) \subset H^{1/2}(-1,1)$$

and

$$W_p^{1-\frac{1}{p}}(\mathbf{R}\backslash[-1,1]) \subset H^{-1/2}(\mathbf{R}\backslash[-1,1]).$$

Then, by the same arguments as in Theorem 3.1 of [5], there exists a solution $\tilde{\eta} \in H^1$ of (3.6)–(3.9); if we further assume that l has compact support, we also have that $\tilde{\eta}(\rho, \sigma)$ is smooth for $\rho \in \mathbf{R}\backslash\operatorname{supp} l$ up to the boundary $\sigma = 0$ and it is rapidly decreasing for $|\rho| \to \infty$ (see the proof of Proposition 3.2 of [5]). Let us now take M such that $\operatorname{supp} l \subset (-M, M)$ and consider the regularity of $\tilde{\eta}$ in the rectangle $(-M, M)\times(-cH/\varphi^*, 0)$. In order to apply the regularity theory in polygonal domains, we observe that at the upper side of the rectangle the solution $\tilde{\eta}$ has a Dirichlet datum in $W_p^{2-\frac{1}{p}}$ for $|\rho| < 1$ and a Neumann datum $\eta_\sigma = \nu^*\eta + l \in W_p^{1-\frac{1}{p}}$ for $1 < |\rho| < M$; the second property follows by the Sobolev embedding $H^{1/2}(\mathcal{I}) \subset W_p^{1-\frac{1}{p}}(\mathcal{I})$, which

holds for every $p < 2$ and for every bounded interval $\mathcal{I}$. Then, we can apply Theorem 4.4.3.7 of [6] and conclude that $\tilde{\eta} \in W^2_p((-M, M)\times(-cH/\varphi, 0))$ for every $p \in (1, 4/3)$. By the above discussion, we also have $\tilde{\eta} \in W^2_p(A^*)$. Finally, for generic $l \in W_p^{1-\frac{1}{p}}$, we consider a sequence l_m of functions with compact supports, such that $l_m \to l$ in $W_p^{1-\frac{1}{p}}$ for $m \to \infty$. Then, by known a priori estimates in an infinite strip [6, section 4.2], the corresponding solutions η_m converge in $W^2_p(A^*)$ to the solution $\tilde{\eta}$ of (3.6)–(3.9). □

REMARK 3.2. (i) *We recall that for every $p > 1$ the inclusion $W^2_p(A^*) \subset \mathcal{C}^{0,\alpha}(\bar{A^*})$ holds with $\alpha = 2-2/p$; moreover, for $p > 1$ the space $W^2_p(A^*)$ is an algebra, a crucial property for the functional setting of the nonlinear problem (see below).*

(ii) *Roughly speaking, the reason for the limitation $p < 4/3$ is the following: in the neighborhood of the points $(1, 0)$ and $(-1, 0)$, the solution of the above problem could have a "singular" part proportional to $S(r, \theta) = r^{1/2}\sin(\theta/2)$, where r, θ equal the polar coordinates around the points (see* [5, section 3]*). Then, it is not difficult to check that the function S does not belong to W^2_p in a neighborhood of the origin for $p \geq 4/3$.*

(iii) *Clearly, more regularity of the datum l implies moreregularity for the trace of the solution on $\sigma = 0$, $|\rho| > 1$.*

By assuming further properties on the data, namely that k and l are odd functions, and l is rapidly decreasing at infinity, we can achieve a useful result for the discussion of the nonlinear problem. More precisely, let $\lambda_1 > 0$ be the first positive solution of

$$\tan(\lambda H) = \frac{\lambda c^2}{g}$$

(see [5, Proposition 3.2]). Then, we get the following corollary.

COROLLARY 3.3. *Assume that the functions k and l of Theorem* 3.1 *are odd, that $l \in \mathcal{C}^{0,\alpha}(\mathbf{R}\backslash(-\rho_0, \rho_0))$ for some $\rho_0 > 1$ (with $\alpha = 2 - 2/p$), and that*

$$\sup_{|\rho|\geq\rho_0} e^{\lambda^*|\rho|}|l(\rho)| < \infty,$$

with $\lambda^* = \varphi^*\lambda_1/c$. Then, there is a unique holomorphic function $\tilde{\chi} = \tilde{\xi} - i\tilde{\eta}$ belonging to $W^2_p(A^*)$, satisfying $\tilde{\chi}(-\rho, \sigma) = \overline{\tilde{\chi}(\rho, \sigma)}$ and the boundary conditions (3.7)–(3.9). *Furthermore, $\tilde{\chi}|_{\sigma=0} \in \mathcal{C}^{1,\alpha}(\mathbf{R}\backslash(-\rho_0, \rho_0))$ and the following bounds hold:*

$$\sup_{A^*} e^{\lambda^*|\rho|}|\tilde{\chi}(\rho, \sigma)| < \infty,$$

$$\sup_{|\rho|\geq\rho_0} e^{\lambda^*|\rho|}|\partial_\rho\tilde{\xi}(\rho, 0)| < \infty.$$

The proof is given in the appendix.

REMARK 3.4. *By recalling the relation $\tilde{\xi}_\rho = -\tilde{\eta}_\sigma$, which holds in A^*, we can rephrase the boundary condition* (3.8) *in the form*

$$\tilde{\xi}_\rho + \nu^*\tilde{\eta} = -l \tag{3.10}$$

for $\sigma = 0$, $|\rho| > 1$, where the above relation holds between elements of

$$W_p^{1-\frac{1}{p}}(\mathbf{R}\backslash[-1, 1]) \cap \mathcal{C}^{0,\alpha}(\mathbf{R}\backslash(-\rho_0, \rho_0)).$$

3.2. The solution of the nonlinear problem. Take $\rho_0 > 1$ and denote by $Q_0 \subset \bar{A}^*$ the closed region $[-H^*, 0] \times \mathbf{R}\backslash(-\rho_0, \rho_0)$. Let us define the following set:

$$X = \Big\{ \chi = \xi - i\eta \text{ holomorphic in } A^*, \quad \chi(-\rho, \sigma) = \overline{\chi(\rho, \sigma)},$$

$$\chi \in W_p^2(A^*) \cap \mathcal{C}^{1,\alpha}(Q_0), \quad \eta(\cdot, -\frac{cH}{\varphi^*}) = 0, \quad ||\chi||_* < \infty \Big\}, \tag{3.11}$$

where $1 < p < 4/3$ and

$$||\chi||_* = ||\chi||_{\mathcal{C}^{1,\alpha}(Q_{\rho_0})} + ||\chi||_{W_p^2(A^*)} + \sup_{A^*} e^{\lambda^*|\rho|}|\chi(\rho,\sigma)| + \sup_{Q_{\rho_0}} e^{\lambda^*|\rho|}|\partial_\rho \xi(\rho,\sigma)|.$$

It is not difficult to check that X is a Banach space of continuous functions vanishing at infinity. Let us denote by Y_0 the set of the (real) functions

$$l \in W_p^{1-\frac{1}{p}}(\mathbf{R}\backslash[-1,1]) \cap \mathcal{C}^{0,\alpha}(\mathbf{R}\backslash(-\rho_0, \rho_0)),$$

such that the norm

$$||l|| = ||l||_{W_p^{1-\frac{1}{p}}(\mathbf{R}\backslash[-1,1])} + ||l||_{\mathcal{C}^{0,\alpha}(\mathbf{R}\backslash(-\rho_0,\rho_0))} + \sup_{|\rho|\geq\rho_0} e^{\lambda^*|\rho|}|l(\rho)|,$$

is finite. We now define

$$Y = \{(k,l) \in W_p^{2-\frac{1}{p}}(-1,1) \times Y_0, \quad k(-\rho) = -k(\rho),\, l(-\rho) = -l(\rho)\}, \tag{3.12}$$

with the usual norm for tensor products of Banach spaces. Then, we can state the following.

THEOREM 3.5. *Let f be a symmetric $\mathcal{C}^2$ function defined in an interval $J \supset [-\frac{\varphi^*}{c}, \frac{\varphi^*}{c}]$ and suppose that the Nemitski operator associated to f'' is continuous from $W_p^{3-\frac{1}{p}}(-1,1)$ to $W_p^{2-\frac{1}{p}}(-1,1)$. Then, there exist $\epsilon_0 > 0$ and a bounded open set $\mathcal{U} \subset X$ containing the solution $\tilde{\chi}$ of problem (3.2)–(3.5), such that the operator*

$$\mathbf{B} : \mathcal{U} \times [0, \epsilon_0) \to Y$$

defined by (2.24) is continuously differentiable.

Proof. By recalling the expression (2.22) of B^I, we may choose ϵ_0 and $\mathcal{U}$ such that, if $(\chi, \epsilon) \in \mathcal{U} \times [0, \epsilon_0)$, the relation $\frac{\varphi^*}{c}\int_0^\rho [1 + \epsilon\xi(t,0)]dt \in J$ holds for every $\rho \in [-1,1]$. Then, by our assumptions on f'' and the continuity of the product between functions in $W_p^{2-\frac{1}{p}}(-1,1)$ (see [6, Theorem 1.4.4.2]), the derivative (G-differential) of B^I at $\chi^* = \xi^* - i\eta^*$ in the direction $\chi = \xi - i\eta$ exists and is equal to

$$d_G B^I(\chi^*, \epsilon)\chi = \eta(\rho, 0) - \epsilon f'\left(\frac{\varphi^*}{c}\int_0^\rho [1 + \epsilon\xi^*(t,0)]dt\right)\xi(\rho,0)$$

$$-\epsilon\frac{\varphi^*}{c} f''\left(\frac{\varphi^*}{c}\int_0^\rho [1 + \epsilon\xi^*(t,0)]dt\right)[1 + \epsilon\xi^*(\rho,0)]\int_0^\rho \xi \tag{3.13}$$

with $\rho \in (-1,1)$. Furthermore, the right-hand side of (3.13) defines a bounded linear operator $d_G B^I(\chi^*, \epsilon) : X \to W_p^{2-\frac{1}{p}}(-1,1)$ and one can easily check that the map

$(\chi^*, \epsilon) \mapsto d_G B^I(\chi^*, \epsilon)$ is continuous. Then B^I is Frechet differentiable with continuous derivative in $\mathcal{U} \times [0, \epsilon_0)$. The differentiability of B^I with respect to ϵ is readily verified.

Let us now consider the operator B^F given by (2.23) and take ϵ_0 small enough so that $\inf_{|\rho|\geq 1} |1 + \epsilon\chi| > 0$ for every $\chi \in \mathcal{U}$. Then, by a straighforward calculation we can write

$$B^F(\chi, \epsilon) = \Big\{ |1 + \epsilon\chi|^{-4} [\xi_\rho + \epsilon(\xi_\rho \xi + \eta_\rho \eta)] + \nu^* \eta \Big\}\Big|_{|\rho|>1, \sigma=0}. \tag{3.14}$$

By the above expression, by the continuity of the application $f, g \mapsto f \cdot g$ from $W_p^{2-\frac{1}{p}}(\mathbf{R}\backslash[-1,1]) \times W_p^{1-\frac{1}{p}}(\mathbf{R}\backslash[-1,1])$ into $W_p^{1-\frac{1}{p}}(\mathbf{R}\backslash[-1,1])$ (see [6, Theorem 1.4.4.2]), and by Corollary 3.3, we find that B^F is a well defined, continuous operator from X into Y. Moreover, the G-derivative at χ^* is given by

$$d_G B^F(\chi^*, \epsilon)\chi = \xi_\rho + \nu^* \eta + \mathcal{O}(\epsilon), \tag{3.15}$$

where $\mathcal{O}(\epsilon)$ represents a function depending on χ, χ^*, and their derivatives, whose norm, for $\epsilon \to 0$ (and χ, χ^* in a bounded set of X) is $\mathcal{O}(\epsilon)$. Hence, we obtain as before that

$$d_G B^F(\chi^*, \epsilon) \,:\, X \to Y_0$$

is a bounded linear operator and that the map $(\chi^*, \epsilon) \mapsto d_G B^F(\chi^*, \epsilon)$ is continuous in $\mathcal{U} \times [0, \epsilon_0)$. Finally, again from (3.14) we easily get the differentiability of B^F with respect to ϵ. □

REMARK 3.6. *A sufficient condition for the continuity of the Nemitski operator associated to f'' is that $f \in \mathcal{C}^{3,1}(J)$; for in this case we have $f'' \in W_\infty^2$, so that f, f', and f'' are all continuous from $L^p(J)$ to itself.*

By denoting with $\mathbf{B}' = \mathbf{B}'(\chi, \epsilon)$ the Frechet differential of $\mathbf{B}$ with respect to χ, we get from (3.13) *and* (3.15)

$$\mathbf{B}'(\chi^*, 0)\chi = \Big(\eta\Big|_{|\rho|<1, \sigma=0}, \{\xi_\rho + \nu^* \eta\}\Big|_{|\rho|>1, \sigma=0} \Big),$$

so that, by Theorem 3.1*, Corollary* 3.3 *and Remark* 3.4 *we get the following.*

COROLLARY 3.7. *For every $\chi \in \mathcal{U}$ the operator $\mathbf{B}'(\chi, 0)$ is invertible.*

Now, by applying the implicit function theorem, we obtain the following.

THEOREM 3.8. *Let f satisfy the assumptions of Theorem* 3.5*; then, there exists $\epsilon_0 > 0$ such that, for every $\epsilon \in [0, \epsilon_0)$, the equation $\mathbf{B}(\chi, \epsilon) = 0$ has a unique solution $\chi^\epsilon \in \mathcal{U}$. Moreover, the map $\epsilon \mapsto \chi^\epsilon$ is continuously differentiable.*

4. Proof of the main result. In order to prove the existence of a solution to our problem, we still have to solve the continuity condition (2.16). To do so, some properties of the solution obtained in the previous section are needed; in particular, we investigate its dependence on the parameter φ^*. First, we prove a result which is interesting in itself, since it implies that the free boundary $h(x)$ associated to the solution of our problem must be strictly increasing for x positive.

THEOREM 4.1. *For any fixed $\varphi^* > 0$ and for every small enough $\epsilon \geq 0$, the solution $\chi^\epsilon = \xi^\epsilon - i\eta^\epsilon$ given by Theorem* 3.8 *satisfies*

$$\eta^\epsilon(\rho, 0) < 0 \tag{4.1}$$

for every $\rho \in (0, +\infty)$.

Proof. Let us consider the function η^ϵ in the half strip $[0,+\infty)\times[-\frac{cH}{\varphi^*},0]$. We recall that η^ϵ is continuous, vanishes for $\rho=0$ by symmetry and for $\sigma=-\frac{cH}{\varphi^*}$; furthermore, by the condition $B^I(\chi^\epsilon,\epsilon)=0$, we have $\eta^\epsilon(\rho,0)<0$ for $0<\rho\le 1$ and ϵ small. Assume, for contradiction, that $\sup_{\rho\ge1}\eta^\epsilon(\rho,0)=M>0$; since η^ϵ goes to zero at infinity, it must be $M=\eta^\epsilon(\bar\rho,0)$ for some $\bar\rho>1$. Note that $\bar\rho=\bar\rho(\epsilon)>1$ uniformly for ϵ in a neighborhood of zero. Let us now consider the harmonic function

$$W_M=M\left(\frac{\varphi^*}{cH}\sigma+1\right)$$

and compare W_M with η^ϵ in the domain $A_R=[0,R]\times[-\frac{cH}{\varphi^*},0]$, $R>0$ (a similar procedure, based on comparison methods, has been used in [7]). By the above discussion and assumption, we easily get $W_M(\rho,0)\ge\eta^\epsilon(\rho,0)$ in $[0,R]$, $W_M(0,\sigma)\ge\eta^\epsilon(0,\sigma)=0$ in $[-\frac{cH}{\varphi^*},0]$, $W_M(\rho,-\frac{cH}{\varphi^*})=\eta^\epsilon(\rho,-\frac{cH}{\varphi^*})=0$ in $[0,R]$. Finally, since both $\eta^\epsilon(\rho,\sigma)$ and $\eta^\epsilon_\sigma(\rho,\sigma)$ are vanishing for $\rho\to+\infty$, we conclude that $W_M(R,\sigma)\ge\eta^\epsilon(R,\sigma)$ in $[-\frac{cH}{\varphi^*},0]$ for large enough R. By the maximum principle, $W_M\ge\eta^\epsilon$ in A_R and the equal sign holds at $(\bar\rho,0)$. Then, by the Hopf maximum principle,

$$\frac{\partial\eta^\epsilon}{\partial\sigma}(\bar\rho,0)>\frac{\partial W_M}{\partial\sigma}(\bar\rho,0)=\frac{\varphi^*}{cH}M. \tag{4.2}$$

By recalling (3.14), the boundary condition $B^F(\chi^\epsilon,\epsilon)=0$ at $(\bar\rho,0)$ takes the form

$$\xi^\epsilon_\rho(\bar\rho,0)[1+\epsilon\xi^\epsilon(\bar\rho,0)]+\epsilon\eta^\epsilon_\rho(\bar\rho,0)\eta^\epsilon(\bar\rho,0)+\nu^*\big|1+\epsilon\chi^\epsilon(\bar\rho,0)\big|^4\eta^\epsilon(\bar\rho,0)=0.$$

Now, since $\eta^\epsilon(\rho,0)$ is smooth (see Remark A.2) with a maximum M at $\bar\rho$, and by the relation $\xi_\rho=-\eta_\sigma$, we have

$$\frac{\partial\eta^\epsilon}{\partial\sigma}(\bar\rho,0)=\frac{g\varphi^*}{c^3}\frac{|1+\epsilon\chi^\epsilon(\bar\rho,0)|^4}{1+\epsilon\xi^\epsilon(\bar\rho,0)}M. \tag{4.3}$$

By inserting (4.3) in (4.2) we obtain the relation

$$\frac{c^2}{gH}\frac{1+\epsilon\xi^\epsilon(\bar\rho,0)}{|1+\epsilon\chi^\epsilon(\bar\rho,0)|^4}<1. \tag{4.4}$$

Then, since $c^2/gH>1$, we reach a contradiction for small enough ϵ. Finally, the case $M=0$ is excluded by (4.3) and again by the Hopf principle. □

REMARK 4.2. *From the above result and by recalling the relations* (2.20)*, it follows that the curve in the physical plane parametrized by $x(\varphi^*\rho,0)$ and $y(\varphi^*\rho,0)$ is negative and strictly increasing in $(0,+\infty)$. We remark that such a curve will represent the physical free boundary (for $|\rho|>1$) only if the continuity condition is satisfied.*

In the following, we will emphasize the dependence on φ^* of the operator $\mathbf{B}$ by writing $\mathbf{B}(\chi,\epsilon)=\mathbf{B}(\chi,\epsilon;\varphi^*)$; similarly, we set $\chi^\epsilon(\zeta)=\chi^\epsilon(\zeta;\varphi^*)$ for the solutions of $\mathbf{B}(\chi,\epsilon;\varphi^*)=0$. Notice that also the space X defined by (3.11) depends on φ^*; then, in order to compare solutions for different values of φ^*, it is convenient to discuss a suitable extension of $\mathbf{B}$.

Let us choose $\varphi^*_1>0$, φ^* in a neighborhood of φ^*_1 and define the strip A^*_1 and the space X_1 by setting $\varphi^*=\varphi^*_1$ in (2.18) and (3.11), respectively, but *dropping* the condition $\eta(\cdot,-cH/\varphi^*)=0$; we denote by the same symbol $\mathbf{B}(\cdot,\epsilon;\varphi^*)$ the operator defined in an open bounded set of X_1 by

$$\mathbf{B}(\chi,\epsilon;\varphi^*)=(B^I(\chi,\epsilon;\varphi^*),B^F(\chi,\epsilon;\varphi^*),\eta|_{\sigma=-cH/\varphi^*_1}), \tag{4.5}$$

with B^I, B^F, defined in (2.22)–(2.23). One verifies that the last component of $\mathbf{B}$ takes values in a space of smooth, rapidly decreasing functions on $\mathbf{R}$. We set

$$Y_* = \Big\{ l \in \mathcal{C}^{1,\alpha}(\mathbf{R}), \qquad \sup_{|\rho|\in\mathbf{R}} e^{\lambda^*|\rho|}(|l(\rho)| + |l'(\rho)|) < \infty \Big\}.$$

Note that the inclusion $Y_* \subset W_p^{2-\frac{1}{p}}(\mathbf{R})$ holds.

The following lemma extends some results of the previous section.

LEMMA 4.3. *Take $\varphi_1^* > 0$ such that $\varphi_1^*/c \in J$. Then, the map*

$$(\chi, \epsilon, \varphi^*) \mapsto \mathbf{B}(\chi, \epsilon; \varphi^*)$$

is continuously differentiable from $\mathcal{V} \times [0, \epsilon_0) \times \mathcal{J}$ into $Y \times Y_*$, where $\mathcal{V}$ is an open ball in X_1, $\epsilon_0 > 0$ and $\mathcal{J}$ is an open neighborhood of φ_1^*. Moreover, the operator

$$\mathbf{B}'(\chi, \epsilon; \varphi^*) \,:\, X_1 \to Y \times Y_*,$$

is invertible for every small enough $\epsilon > 0$ and for every $\varphi^* < \frac{c^2}{gH}\varphi_1^*$.

Proof. The first part of the lemma follows by a trivial generalization to the operator (4.5) of the arguments of the previous section. Let us now consider the operator $\mathbf{B}'(\chi, 0; \varphi^*)$; by Remark 3.6, the invertibility of this operator is equivalent to the extension of Theorem 3.1 and Corollary 3.3 to the problem obtained by adding to (3.6)–(3.8) the condition

$$\tilde{\eta} = \kappa \qquad \text{for} \quad \sigma = -cH/\varphi_1^*, \ \rho \in \mathbf{R},$$

with $\kappa \in Y_*$. One verifies that the proofs of Theorem 3.1 and Corollary 3.3 can be suitably generalized to the above problem, provided the condition $\nu^* cH/\varphi_1^* < 1$ holds; but this is equivalent to $\varphi^* < \frac{c^2}{gH}\varphi_1^*$. Now, since by (3.13) and (3.15), $\mathbf{B}'(\chi, \epsilon; \varphi^*) = \mathbf{B}'(\chi, 0; \varphi^*) + \mathcal{O}(\epsilon)$, the lemma follows. ∎

We can now prove the following.

PROPOSITION 4.4. *Let $\varphi^* > 0$ belong to the interval defined in the previous lemma. Then, for any $\rho \in \mathbf{R}$ and for every small $\epsilon \geq 0$, the map*

$$\varphi^* \mapsto \chi^\epsilon(\rho; \varphi^*) \tag{4.6}$$

is continuous.

Proof. Take $0 < \varphi_1^* \leq \varphi_2^*$ and, for the sake of brevity, define $\chi_1^\epsilon = \chi^\epsilon(\cdot; \varphi_1^*)$ $\chi_2^\epsilon = \chi^\epsilon(\cdot; \varphi_2^*)$. Note that the above solutions are defined in two different strips, A_1^*, A_2^*, with $A_2^* \subseteq A_1^*$; nevertheless, we can extend χ_2^ϵ to a strip A^* with $\varphi^* = \varphi_2^*/2$ by the Schwarz reflection principle (see, e.g., [5, Theorem 3.4]). Hence, by taking $\varphi_2^* \leq 2\varphi_1^*$, we can compare the two functions in the larger strip A_1^*. We may assume that χ_1^ϵ and χ_2^ϵ belong to $\mathcal{V}$; define now $\chi_\lambda^\epsilon = \lambda\chi_1^\epsilon + (1-\lambda)\chi_2^\epsilon$ and consider the identity

$$\int_0^1 \mathbf{B}'(\chi_\lambda, \epsilon; \varphi_2^*)(\chi_1^\epsilon - \chi_2^\epsilon) d\lambda = \mathbf{B}(\chi_1^\epsilon, \epsilon; \varphi_2^*) - \mathbf{B}(\chi_2^\epsilon, \epsilon; \varphi_2^*), \tag{4.7}$$

where $\mathbf{B}$ is the operator defined in $W_p^2(A_1^*)$ by (4.5). By Lemma 4.3, it follows that the operator at the left-hand side is invertible for (ϵ, φ_2^*) in a sufficiently small neighborhood of $(0, \varphi_1^*)$. Then, we have

$$\chi_2^\epsilon = \chi_1^\epsilon - \left[\int_0^1 \mathbf{B}'(\chi_\lambda, \epsilon; \varphi_2^*) d\lambda \right]^{-1} [\mathbf{B}(\chi_1^\epsilon, \epsilon; \varphi_2^*) - \mathbf{B}(\chi_2^\epsilon, \epsilon; \varphi_2^*)]. \tag{4.8}$$

Letting now $\varphi_2^* \to \varphi_1^*$, we get

$$\mathbf{B}(\chi_1^\epsilon, \epsilon; \varphi_2^*) \to \mathbf{B}(\chi_1^\epsilon, \epsilon; \varphi_1^*) = 0,$$

in $Y \times Y_*$. Furthermore, we note that

$$\mathbf{B}(\chi_2^\epsilon, \epsilon; \varphi_2^*) = \left(0, 0, \eta_2^\epsilon|_{\sigma=-cH/\varphi_1^*}\right).$$

By recalling that η_2^ϵ is holomorphic and vanishing for $\sigma = -cH/\varphi_2^*$, we can write

$$\eta_2^\epsilon(\cdot, -cH/\varphi_1^*) = cH\left(\frac{1}{\varphi_2^*} - \frac{1}{\varphi_1^*}\right)\partial_\sigma \eta_2^\epsilon(\cdot, -cH/\bar\varphi^*),$$

where $\varphi_1^* < \bar\varphi^* < \varphi_2^*$. Now, since η_2 has been extended by reflection, by the discussion in the appendix we obtain that the function $\partial_\sigma \eta_2(\cdot, -cH/\bar\varphi^*)$ is uniformly bounded in Y_* with respect to $\bar\varphi^*$. Then, we also obtain

$$\lim_{\varphi_2^* \to \varphi_1^*} \mathbf{B}(\chi_2^\epsilon, \epsilon; \varphi_2^*) = 0,$$

in $Y \times Y_*$. By (4.8), we conclude $\chi_2^\epsilon \to \chi_1^\epsilon$ in $\mathcal{V}$. In particular, we have the continuity of the map (4.6). □

Before discussing the continuity equation, we still have to specify an additional assumption on the function f. To do so, we observe that the norm in $W_p^2(A^*)$ of the solution $\tilde\eta(\cdot; \varphi^*)$ of the problem L, is bounded by a constant (depending on φ^*) times the $W_p^{2-\frac{1}{p}}$ norm of the datum $f'(\frac{\varphi^*}{c}\rho)$ on $(-1, 1)$; on the other hand, scaling back to the interval $(-\varphi^*/c, \varphi^*/c)$, the L_p norms of the kth derivative of the above function rescale by a factor $(\varphi^*/c)^{k-1/p}$. Then, for every $\varphi^* > 0$, there exists $C = C(\varphi^*)$ such that

$$||\tilde\chi(\cdot; \varphi^*)||_{W_p^2(A^*)} \le C||f'||_{W_p^{2-\frac{1}{p}}(-\varphi^*/c, \varphi^*/c)}. \tag{4.9}$$

In particular, the quantity $|\tilde\xi(1, 0; \varphi^*)|$ is bounded as above. Then, by recalling the definition of the point x_0 given in Assumption (c) of the introduction, we further assume the following.

Assumption F. *There exists φ_0^*, with $0 < \varphi_0^* < cx_0$, such that*

$$|\tilde\xi(1, 0; \varphi_0^*)| < \frac{g}{c^2}|f(\varphi_0^*/c)|. \tag{4.10}$$

As it follows from the bound (4.9), a sufficient condition for (4.10) is that $f'(x)$ is small enough in a neighborhood of the origin, where $f(x)$ is bounded away from zero.

Let us now consider the continuity equation (2.16); by using (2.20) and the notations of this section, we can write it in the form

$$\frac{\varphi^*}{c}\int_1^{+\infty} \eta^\epsilon(s, 0; \varphi^*)ds = f\left(\frac{\varphi^*}{c}\int_0^1 [1 + \epsilon\xi^\epsilon(s, 0; \varphi^*)]ds\right). \tag{4.11}$$

We can now state the following.

THEOREM 4.5. *Take f satisfying the assumptions of Theorem* 3.5 *and such that Assumption* F *holds. Then,* (4.11) *has a solution in the interval* $(0, cx_0)$.

Proof. By Proposition 4.4, the function

$$\mathcal{F}(\varphi^*) = \frac{\varphi^*}{c}\int_1^{+\infty} \eta^\epsilon(s,0;\varphi^*)ds - f\left(\frac{\varphi^*}{c}\int_0^1 [1+\epsilon\xi^\epsilon(s,0;\varphi^*)]ds\right)$$

is continuous in $(0, cx_0]$ for every ϵ in a neighborhood of zero. Moreover, by Theorem 4.1 and by noting that the right-hand side of (4.11) converges to $f(\varphi^*/c)$ for $\epsilon \to 0$, we find that $\mathcal{F}(cx_0) < 0$ for small enough ϵ. Now, by using the Bernoulli condition $B^F = 0$, we can also write

$$\mathcal{F}(\varphi^*) = \frac{c^2}{2g}\frac{2\xi^\epsilon(1,0;\varphi^*) + \epsilon[\xi^\epsilon(1,0;\varphi^*)^2 + \eta^\epsilon(1,0;\varphi^*)^2]}{|1+\epsilon\chi^\epsilon(1,0;\varphi^*)|^2}$$

$$-f\left(\frac{\varphi^*}{c}\int_0^1 [1+\epsilon\xi^\epsilon(s,0;\varphi^*)]ds\right). \tag{4.12}$$

By Assumption F and recalling that $f(x)$ is negative for $x < x_0$, we have that the right-hand side of (4.12) is strictly positive at φ_0^* for $\epsilon = 0$. Now, since $\chi^\epsilon(1,0;\varphi^*) = \tilde{\chi}(1,0;\varphi^*) + \mathcal{O}(\epsilon)$ we get $\mathcal{F}(\varphi_0^*) > 0$ for every small enough ϵ. Then, the theorem follows. ∎

REMARK 4.6. *By the above theorem, by Theorem* 3.8*, and by relations* (2.17)*,* (2.19)*,* (2.20)*, it follows that there exists a function* $\Omega = U - iV$ *holomorphic in the strip* A_H *defined by* (2.4) *and a positive number* $\varphi^* < cx_0$ *such that* (2.12)–(2.16) *hold for every small enough* $\epsilon > 0$*. Moreover, the map* (2.8) *is one-to-one between* A_H *and the domain* S^* *in the physical plane defined by* (1.2)*, with the free boundary* $h(x)$ *given in parametric form by* $x = x(\varphi, 0)$*,* $y = y(\varphi, 0)$*,* $|\varphi| > \varphi^*$*. Finally, the point* $x^* = x(\varphi^*, 0)$*, the function* $h(x)$*, and the function* $\omega(z)$ *given by* (2.1) *satisfy the conditions* (1.3)–(1.9)*. Notice that these results hold under rather mild geometrical requirements on the curve* $y = f(x)$*; nevertheless, we still have to satisfy the last condition* (1.10) *in the physical plane. To do so, we assume in addition that the function* f *is* convex.

PROPOSITION 4.7. *Let* f *be a convex function satisfying the assumptions of Theorem* 3.5 *and Assumption* F *above; let* $h(x)$ *be defined as in Remark* 4.6*. Then, for every small enough positive* ϵ*, we have* $h(x) < f(x)$ *for* $x \in I\backslash[-x^*, x^*]$*.*

Proof. By symmetry and by the convexity of f, it is enough to prove that $h'(x) \le f'(x^*)$ for $x \ge x^*$. This is equivalent to the condition

$$-\frac{\eta^\epsilon(\rho,0)}{1+\epsilon\xi^\epsilon(\rho,0)} \le f'(x^*) \qquad \text{for} \quad \rho \ge 1,$$

where, as before, $\chi^\epsilon = \xi^\epsilon - i\eta^\epsilon$ is the solution in the (rescaled) hodograph plane. By defining

$$\psi^\epsilon(\rho,\sigma) = \eta^\epsilon(\rho,\sigma) + \epsilon f'(x^*)\xi^\epsilon(\rho,\sigma), \tag{4.13}$$

we get the equivalent condition

$$\psi^\epsilon(\rho,0) \ge -f'(x^*) \qquad \text{for} \quad \rho \ge 1. \tag{4.14}$$

Assume that (4.14) does not hold and set

$$\inf_{\rho\ge 1} \psi^\epsilon(\rho,0) \equiv -m^* < -f'(x^*).$$

Since ψ^ϵ is continuous, vanishing at infinity, and $\psi^\epsilon(1,0) = -f'(x^*)$, it must be $m^* = \psi^\epsilon(\rho^*, 0)$, with $\rho^* = \rho^*(\epsilon) > 1$ uniformly with respect to ϵ. Let us define the comparison function

$$W^* = -(m^* + \epsilon K^*)\frac{\varphi^*}{cH}\,\sigma - m^*,$$

where $K^* < f'(x^*)\inf_{A^*}\xi^\epsilon$. Then, recalling the conditions satisfied by η^ϵ, we get $\psi^\epsilon > W^*$ for $\sigma = -cH/\varphi^*$ and on the segment $\{0\}\times[-cH/\varphi^*, 0]$ for every suitably small ϵ. Furthermore, for $\sigma = 0$ and $0 < \rho < 1$ we get, by using the condition $B^I(\chi^\epsilon, \epsilon) = 0$ and the convexity of f,

$$\psi^\epsilon(\rho,0) = -f'(x(\rho,0))[1+\epsilon\xi^\epsilon(\rho,0)] + \epsilon f'(x^*)\xi^\epsilon(\rho,0)$$

$$= -f'(x^*) + [f'(x^*) - f'(x(\rho,0))][1+\epsilon\xi^\epsilon(\rho,0)] \geq -f'(x^*).$$

Hence, we also have $\psi^\epsilon(\rho,0) \geq W^*(\rho,0) = -m^*$, for $\rho \geq 0$, with the equal sign holding at ρ^*. It follows that $\psi^\epsilon \geq W^*$ in the half strip $[0,+\infty]\times[-cH/\varphi^*, 0]$ and that

$$\frac{\partial\psi^\epsilon}{\partial\sigma}(\rho^*,0) < -(m^* + \epsilon K^*)\frac{\varphi^*}{cH}. \tag{4.15}$$

Now, since ρ^* is a minimum for $\psi^\epsilon(\rho,0)$, we also get $\eta^\epsilon_\rho + \epsilon f'(x^*)\xi^\epsilon_\rho = 0$ at $(\rho^*,0)$, and therefore

$$\xi^\epsilon_\sigma(\rho^*,0) = \epsilon f'(x^*)\eta^\epsilon_\sigma(\rho^*,0).$$

By inserting into (4.15), we obtain

$$\eta^\epsilon_\sigma(\rho^*,0) < -\frac{m^* + \epsilon K^*}{1+\epsilon^2 f'(x^*)^2}\,\frac{\varphi^*}{cH}. \tag{4.16}$$

Notice that $\xi^\epsilon_\rho = -\eta^\epsilon_\sigma > 0$ and $\eta^\epsilon_\rho < 0$ at $(\rho^*,0)$. Moreover, by the Bernoulli condition, we have at the same point

$$\eta^\epsilon_\sigma = \frac{g\varphi^*}{c^3}\,\frac{|1+\epsilon\chi^\epsilon|^4 + \epsilon\eta^\epsilon_\rho}{1+\epsilon\xi^\epsilon}\,\eta^\epsilon$$

$$= -\frac{g\varphi^*}{c^3}\,\frac{|1+\epsilon\chi^\epsilon|^4 + \epsilon\eta^\epsilon_\rho}{1+\epsilon\xi^\epsilon}\,[m^* + \epsilon f'(x^*)\xi^\epsilon]. \tag{4.17}$$

From (4.16), (4.17), and the above remark on η^ϵ_ρ, we get the condition

$$\frac{|1+\epsilon\chi^\epsilon|^4}{1+\epsilon\xi^\epsilon}\,[m^* + \epsilon f'(x^*)\xi^\epsilon] > \frac{c^2}{gH}\,\frac{m^* + \epsilon K^*}{1+\epsilon^2 f'(x^*)^2} \tag{4.18}$$

at the point $(\rho^*, 0)$. Clearly, (4.18) contradicts the condition of supercritical velocity for ϵ small enough, so that the proposition is proven. □

Summing up the discussion of the present section, we can finally state the following.

THEOREM 4.8. *Let f be a convex function satisfying the assumptions of Theorem* 3.5 *and Assumption* F. *Then, for every small enough $\epsilon > 0$, there exists a real number*

$x^* \in (0, x_0)$, a real symmetric function $h(x)$ on $\mathbf{R}\backslash[-x^*, x^*]$, and a complex function ω holomorphic in the domain S^* defined by (1.2) *and satisfying $\omega(-x+iy) = \bar{\omega}(x+iy)$, such that the conditions* (1.3)–(1.10) *hold. Moreover, the function h is negative and monotone increasing for $x > x^*$.*

REMARK 4.9. *We remark that the qualitative shape of the free boundary given by the above theorem agrees with the numerical results obtained in* [8].

REMARK 4.10. *We point out that in the solution above the free boundary and the cylinder profile form a single smooth ($\mathcal{C}^1$) streamline. Nevertheless, it seems reasonable to conjecture that there exist other solutions which are less regular at the points $(\pm x^*, f(\pm x^*))$, where the free boundary meets the hull. This conjecture is supported by the existence of nonvariational solutions of the linearized problem, as shown in* [5, section 4].

Appendix. Proof of Corollary 3.3. Let us recall that we are seeking a function $\tilde{\chi} = \tilde{\xi} - i\tilde{\eta} \in W_p^2(A^*)$, holomorphic in A^*, satisfying the boundary conditions (3.7), (3.9), (3.10), and the properties

$$\tilde{\chi}(-\rho, \sigma) = \overline{\tilde{\chi}(\rho, \sigma)}, \tag{A.1}$$

$$\tilde{\chi}|_{\sigma=0} \in \mathcal{C}^{1,\alpha}(\mathbf{R}\backslash(-\rho_0, \rho_0)),$$

$$\sup_{A^*} e^{\lambda^*|\rho|}|\tilde{\chi}(\rho, \sigma)| < \infty, \tag{A.2}$$

$$\sup_{|\rho|\geq\rho_0} e^{\lambda^*|\rho|}|\partial_\rho \tilde{\xi}(\rho, 0)| < \infty. \tag{A.3}$$

Proof. We first note that for data l and k antisymmetric, the solution $\tilde{\eta}$ given by Theorem 3.5 necessarily satisfies $\eta(-\rho, \sigma) = -\eta(\rho, \sigma)$; therefore, the harmonic conjugate (defined up to an arbitrary constant) is symmetric with respect to ρ, so that (A.1) holds.

By standard continuation results, we may assume that the datum l belongs to $W_p^{1-\frac{1}{p}}(\mathbf{R})$. Then, the solution of the problem (3.6)–(3.9) can be written in the form $\tilde{\eta} = \eta_0 + \eta_1$, where η_0, η_1 are harmonic in A^*, vanish at $\sigma = -\frac{cH}{\varphi^*}$, and satisfy the boundary conditions

$$\partial_\sigma \eta_0 - \nu^* \eta_0 = 0 \qquad \text{for} \quad \sigma = 0, \ \ |\rho| > 1, \tag{A.4}$$

$$\eta_0 = k - \eta_1 \qquad \text{for} \quad \sigma = 0, \ \ |\rho| < 1, \tag{A.5}$$

$$\partial_\sigma \eta_1 - \nu^* \eta_1 = l \qquad \text{for} \quad \sigma = 0, \ \ \rho \in \mathbf{R}. \tag{A.6}$$

We observe that, if η_1 is known, the problem for η_0 is similar to problem L; hence, by the results of [5], the bounds (A.2)–(A.3) hold for the holomorphic function $\chi_0 = \xi_0 - i\eta_0$ (where ξ_0 is the harmonic conjugate of η_0 vanishing at infinity). Thus, we are reduced to proving the bounds for the function η_1 satisfying (A.6) (and for the harmonic conjugate ξ_1). Let us define $H^* = \frac{cH}{\varphi^*}$; by elementary calculations, η_1 has the representation

$$\eta_1(\rho, \sigma) = \frac{1}{2\pi} \int_{\mathbf{R}} e^{ip\rho} \hat{K}_\sigma(p) \hat{l}(p) dp, \tag{A.7}$$

where

$$\hat{K}_\sigma(p) = \frac{\sinh[p(\sigma + H^*)]}{p\cosh(pH^*) - \nu^* \sinh(pH^*)}$$

and $\hat{l}(p)$ is the Fourier transform of l. We point out that the function $\hat{K}_\sigma$ is not singular since the equation $\nu^* \tanh(pH^*) = p$ has only the real solution $p = 0$ for $\nu^* H^* < 1$. We further note that the integral (A.7) is convergent also for $\sigma = 0$. In fact, by Sobolev embedding, $l \in L^q(\mathbf{R})$ for $1 < q < 2$ and therefore, by the Hausdorff–Young theorem, $\hat{l} \in L^p(\mathbf{R})$ for every $p > 2$; thus, the product $\hat{K}_\sigma(p)\hat{l}(p)$ is integrable by Hölder inequality. In particular, we recover the continuity of η_1 up to the boundary $\sigma = 0$ (see Remark 3.2). By the convolution theorem we have

$$\eta_1(\rho, \sigma) = \int_{\mathbf{R}} K_\sigma(\rho - \rho') l(\rho') d\rho', \tag{A.8}$$

where

$$K_\sigma(\rho) = \frac{1}{2\pi} \int_{\mathbf{R}} e^{ip\rho} \frac{\sinh[p(\sigma + H^*)]}{p\cosh(pH^*) - \nu^* \sinh(pH^*)} dp. \tag{A.9}$$

Note that the function $\rho \mapsto K_\sigma(\rho)$ is smooth and rapidly decreasing for $\sigma < 0$ and belongs to $L^2(\mathbf{R})$ for $\sigma = 0$ (actually, to $L^p(\mathbf{R})$ for $1 \le p \le 2$). Moreover, $K_\sigma(-\rho) = K_\sigma(\rho)$.

For $|\rho| > 0$, we can evaluate (A.9) by complex plane integration and find

$$K_\sigma(\rho) = \sum_{n=1}^{\infty} c_n(\sigma) e^{-\lambda_n^* |\rho|}, \tag{A.10}$$

where

$$c_n(\sigma) = \frac{\sin[\lambda_n^*(\sigma + H^*)]}{(1 - \nu^* H^*)\cos(\lambda_n^* H^*) - \lambda_n^* H^* \sin(\lambda_n^* H^*)}$$

and λ_n^* are the positive solutions of the equation

$$\tan(\lambda H^*) = \frac{\lambda}{\nu^*}.$$

Note that $\lambda_n^* H^* \approx (n - 1/2)\pi$ for large n, so that $c_n(0) \sim -1/n\pi$. From (A.10) we get the estimate

$$|K_\sigma(\rho)| \le C e^{-\lambda_1^* |\rho|} \tag{A.11}$$

for $|\rho| \ge \delta > 0$, with C independent of σ.

We can now prove the bounds (A.2)–(A.3) for the holomorphic function $\chi_1 = \xi_1 - i\eta_1$. We set $I_0 = (-\rho_0, \rho_0)$, $I_{\rho,\delta} = (\rho - \delta, \rho + \delta)$; then, by the representation (A.8), the estimate (A.11), and the decaying property of l, we obtain for $|\rho| > \rho_0 + \delta$

$$|\eta_1(\rho, \sigma)| \le \int_{I_{\rho,\delta}} |K_\sigma(\rho - \rho')|\, |l(\rho')|\, d\rho' + \int_{I_0} |K_\sigma(\rho - \rho')|\, |l(\rho')|\, d\rho'$$

$$+ \int_{\mathbf{R}/\{I_{\rho,\delta} \cup I_0\}} |K_\sigma(\rho - \rho')|\, |l(\rho')|\, d\rho'$$

$$\leq C\left\{(||K_\sigma||_{L^2}+||l||_{L^p})e^{-\lambda_1^*|\rho|}+\int_{\mathbf{R}/\{I_{\rho,\delta}\cup I_0\}} e^{-\lambda_1^*(|\rho-\rho'|-|\rho'|)}d\rho'\right\}$$

$$\leq Ce^{-\lambda_1^*|\rho|}, \tag{A.12}$$

with C independent of σ.

By (A.8)–(A.9), we see that the same bound holds for every derivative of η_1 if $\sigma \leq \sigma_0 < 0$. On the other hand, by the condition (A.6) and the assumption on l, the estimate for $\partial_\sigma \eta_1$ extends to $\sigma = 0$ for $|\rho| \geq \rho_0$; the same holds for the function $\partial_\rho \xi_1$ by the Cauchy–Riemann relations, so that (A.3) holds. Furthermore, we have that $\partial_\rho \xi_1(\rho, 0)$ is in $L^1(\mathbf{R})$ (for $|\rho| < \rho_0$ it is in L^p with $p > 1$) and we can write

$$\xi_1(\rho,0)=\int_{-\infty}^{\rho}\partial_\rho\xi_1(\rho,0)=-\int_{\rho}^{-\infty}\partial_\rho\xi_1(\rho,0),$$

where the last equality follows by the symmetry of ξ_1. From the above discussion, it follows also that ξ_1 satisfies the bound (A.12). Then, (A.2) is proved.

It remains to prove the regularity of the traces $\eta_1(\rho, 0)$ and $\xi_1(\rho, 0)$ for $|\rho| \geq \rho_0$. By our assumption on h, by Remark 3.2, and recalling (A.6), we get that the harmonic function η_1 has a Neumann datum in $\mathcal{C}^{0,\alpha}(\mathbf{R}\backslash(-\rho_0, \rho_0))$ on the boundary $\sigma = 0$. Then, by the previous bounds on ξ_1, η_1 and by standard Hölder estimates, $\chi_1|_{\sigma=0} \in \mathcal{C}^{1,\alpha}(\mathbf{R}\backslash(-\rho_0, \rho_0))$ □

REMARK A.1. *The boundedness of the trace function $\partial_\rho \eta_1|_{\sigma=0}$ for $|\rho| \geq \rho_0$ can also be proved from the representation* (A.8). *Actually, for $\sigma < 0$ we get*

$$\partial_\rho\eta_1(\rho,\sigma)=\int_{\mathbf{R}}K'_\sigma(\rho-\rho')l(\rho')d\rho',$$

where $K'_\sigma(\rho)$ is the inverse Fourier transform of the function $ip\hat{K}_\sigma(p)$. We point out that $K'_\sigma(\rho)$ is an odd function in the Schwartz space for $\sigma < 0$; moreover, by the same arguments as before, we get the estimate

$$|K'_\sigma(\rho)| \leq C\frac{e^{-\lambda_1^*|\rho|}}{1-e^{-|\rho|/H^*}}$$

for every $\rho \neq 0$, with C independent of σ. Thus, for $|\rho| > \rho_0 + \delta$ we have

$$|\partial_\rho\eta_1(\rho,\sigma)| \leq \int_{I_{\rho,\delta}}|K'_\sigma(\rho-\rho')|\,|l(\rho)-l(\rho')|\,d\rho'+\int_{\mathbf{R}/\{I_{\rho,\delta}\}}|K_\sigma(\rho-\rho')|\,|l(\rho')|\,d\rho'$$

$$\leq C\left\{\int_{-\delta}^{\delta}\frac{e^{-\lambda_1^*|r|}}{1-e^{-|r|/H^*}}|r|^\alpha dr+\frac{e^{-\lambda_1^*|\delta|}}{1-e^{-|\delta|/H^*}}||l||_{L^1(\mathbf{R})}\right\},$$

where C is independent of σ. The result now follows by the above estimate and by the continuity of the trace $\partial_\rho \eta_1(\rho, 0)$ on $\mathbf{R}\backslash(-\rho_0, \rho_0)$.

REMARK A.2. *It is worthwhile to remark that the above proof can be easily generalized to the case of a datum $l \in \mathcal{C}^{k,\alpha}(\mathbf{R}\backslash(-\rho_0, \rho_0))$, with arbitrary k. As a consequence, the solution of the nonlinear problem is $\mathcal{C}^{k+1,\alpha}$ up to the boundary for $|\rho| > \rho_0$. Hence, by the arbitrariness of k and ρ_0, we conclude that the solution χ^ϵ is actually smooth up to the boundary $\sigma = 0$ for $|\rho| > 1$.*

INTERFACE DEVELOPMENT AND LOCAL SOLUTIONS TO REACTION-DIFFUSION EQUATIONS*

UGUR G. ABDULLA† AND JOHN R. KING‡

Abstract. The evolution of interfaces and the local behavior of solutions near the interface in problems for one-dimensional reaction-diffusion equations are studied. In all cases explicit formulae for the interface, with accuracy up to constant coefficients, are found together with the local solution. The methods used are matched asymptotic expansions for preliminary formal results, and rescaling and a barrier technique for rigorous proof, using special comparison theorems in irregular domains.

Key words. reaction-diffusion equations, evolution of interfaces, nonlinear degenerate parabolic equations, local solutions

1. Introduction. We consider the Cauchy problem (CP) for the reaction-diffusion equation

$$\mathrm{L}u \equiv u_t - (u^m)_{xx} + bu^\beta = 0, \quad x \in \mathbb{R}, \quad 0 < t < T, \tag{1.1}$$

with

$$u(x,0) = u_0(x), \qquad x \in \mathbb{R}, \tag{1.2}$$

where $m > 1,\ b \in \mathbb{R},\ \beta > 0,\ 0 < T \le +\infty$, and u_0 is nonnegative and continuous. Furthermore, we will suppose that $b > 0$ if $\beta < 1$, and b is arbitrary if $\beta \ge 1$ (see Remark 1.1). Such reaction-diffusion equations are widely used models for various physical, chemical, and biological problems involving diffusion with a source or with absorption, such as occurs, for instance, in filtration in porous media, flow of a chemically reacting fluid from a flat surface, evolution of biological populations, etc.

The solution to (1.1), (1.2) may have one or several interfaces separating the regions where $u = 0$ and where $u > 0$. In this paper we are interested in the small-time evolution of interfaces and in the local structure of solutions near the interface. Since (1.1) is invariant under the transformations $x \to -x,\ x \to x + c,\ c \in \mathbb{R}$, without loss of generality we will investigate the case when $\eta(0) = 0$, where

$$\eta(t) = \sup\{x :\ u(x,t) > 0\}.$$

More precisely, we are interested in the short-time behavior of the interface function $\eta(t)$ and local solution near the interface. Furthermore, unless otherwise stated, we shall assume that

$$u_0 \sim C(-x)_+^\alpha \text{ as } x \to 0- \quad \text{for some } C > 0,\ \alpha > 0. \tag{1.3}$$

We present a full description of the small-time behavior of $\eta(t)$ and local solution near $\eta(t)$ for all relevant values of parameters m, b, β, C, and α (see Remark 1.1). The behavior of u_0 as $x \to -\infty$ has no influence on our results. Accordingly, we may suppose that u_0 either is bounded or satisfies some restriction on its growth rate as $x \to -\infty$ which is suitable for existence, uniqueness, and comparison results (see section 3). In addition, in some cases we shall consider the special case

$$u_0(x) = C(-x)_+^{\alpha}, \quad x \in \mathbb{R}, \tag{1.4}$$

namely, when the solution to the problem (1.1), (1.4) is of self-similar form. In these cases our estimations on $\eta(t)$ and the local solution near $\eta(t)$ will be global in time.

Initial development of interfaces in problems for (1.1) have been studied by many authors [2, 4, 6, 7, 8, 10, 13, 17, 18, 19, 22, 25, 27, 28, 29, 30, 31, 33, 34, 35, 36]. All values of m, b, β, C, and α for which the interface initially either shrinks, remains stationary, or expands are known due to these papers. As to local estimations of both interface and solution there is a complete picture only in the case of the semilinear equation ($m = 1$), given in [17, 18]. Accordingly, we are not directly interested in the case of $m = 1$, although when our results contain the semilinear equation as a particular case, it will be mentioned. It should be noted that sometimes this may not be the case. For instance, if $b > 0,\ 0 < \beta < 1,\ \alpha < 2/(m - \beta)$, then the interface initially expands and

$$\eta(t) \sim C_1 t^{1/(2-\alpha(m-1))} \quad \text{as } t \to 0+.$$

Formally, as $m \to 1$ this estimate yields

$$\eta(t) = O(t^{\frac{1}{2}}) \quad \text{as } t \to 0+,$$

while as a matter of fact from [18] it follows that if $m = 1$, then

$$\eta(t) \sim C_2(t \log 1/t)^{\frac{1}{2}} \quad \text{as } \ t \to 0+$$

($C_1,\ C_2$ are positive constants), so that the case $m = 1$ is in some respects a singular limit.

Many of the results of this paper have first been formally established using matched asymptotic expansions (JRK). For rigorous proof rescaling and barrier techniques that use special comparison theorems in irregular domains have been used (UGA). The latter is the main difference of the methods of our paper from those of previous papers (including [17, 18]). Similar barrier techniques using standard comparison theorems in cylindrical domains have been applied earlier [2] to the same problem. As a result, in [2] explicit formulae for the interface and for the local solution have been derived, but only in some particular cases when the small-time behavior of the solution has a uniform character near the interface (see also [4]). In a many cases, however, the behavior is nonuniform in the sense of singular perturbation theory, the dominant balance as $t \to 0+$ between the terms in (1.1) on curves which approach the boundary of the support on the initial line depending on how they do so. In order to apply a barrier technique to these cases as well, it is necessary to investigate mathematical problems of the general theory (existence, uniqueness, and comparison results) of initial-boundary value problems for reaction-diffusion equations in noncylindrical domains with boundary curves which may be nonsmooth and characteristic at the initial moment. These issues have been investigated in a recent

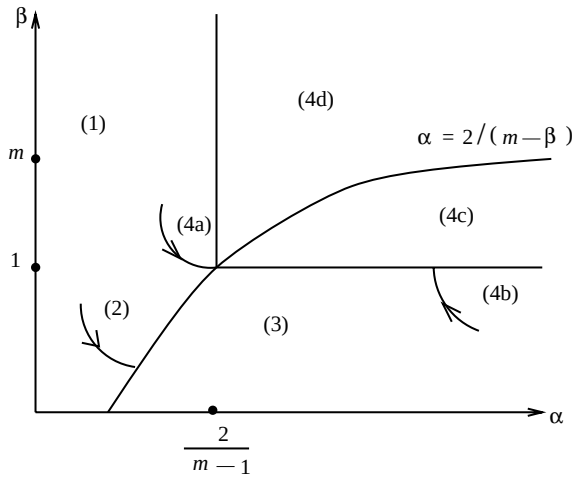

FIG. 1. *Classification of different cases in the* (α, β) *plane for interface development in problem* (1.1)–(1.4).

paper [3]. The comparison theorems from [3] are widely used in the proof of the main results of this paper.

The organization of the paper is as follows: In section 2 we outline the main results. In section 3 we then apply scale of variables methods for some preliminary estimations which are necessary for using our barrier technique. Finally in section 4 we prove the results of section 2.

To avoid difficulties for the reader we give explicit values of some of the constants which appear in sections 2 and 4 (the case I(2)) in the appendix.

REMARK 1.1. *We shall not consider in this paper the case* $b < 0,\ 0 < \beta < 1$ *when, for some range of* m *and* β*, nonuniqueness of the solution to* (1.1), (1.2) *is possible. The Cauchy problem* (1.1), (1.2) *in this range of parameters has been extensively investigated in* [33, 34]. *Existence and boundary regularity results for Cauchy–Dirichlet and Dirichlet problems for equation* (1.1) *in noncylindrical domains with nonsmooth boundaries which are applicable to this case have been established in* [3]*, but in order to prove similar results for the problem of the evolution of interfaces in this case it would be important first to establish special comparison results in such domains as well. It should also be pointed out that by using the results of* [3]*, a similar classification of the evolution of (possible) interfaces and local solutions may be given in the fast diffusion case* $(0 < m < 1)$. *We shall address these issues in a subsequent paper.*

2. Description of main results. We divide the results into the two different subcases:

(I) $b \neq 0$ (either $b > 0,\ \beta > 0$ or $b < 0,\ \beta \geq 1$) and $m > 1$;

(II) $b = 0$.

(I) In this case there are four different subcases, as shown in Figure 1. (In view of our assumptions, the case $b < 0$ relates to the part of the (α, β) plane with $\beta \geq 1$.)

(1) Suppose that $\alpha < 2/(m - \min\{1, \beta\})$. In this case the interface initially expands and

$$\eta(t) \sim \xi_* t^{1/(2-\alpha(m-1))} \quad \text{as} \quad t \to 0+, \tag{2.1}$$

where

$$\xi_* = C^{\frac{m-1}{2-\alpha(m-1)}}\xi'_*, \tag{2.2}$$

and ξ'_* is a positive number depending on m and α only (see Lemma 3.1). For arbitrary $\rho < \xi_*$, there exists a positive number $f(\rho)$ depending on C, m, and α such that

$$u(x,t) \sim f(\rho)t^{\alpha/(2-\alpha(m-1))} \quad \text{as} \quad t \to 0+ \tag{2.3}$$

along the curve $x = \xi_\rho(t) = \rho t^{1/(2-\alpha(m-1))}$. Actually, f is a self-similar solution to the problem (1.1), (1.4) with $b = 0$ (see Lemma 3.1) and

$$f(\rho) \ = C^{2/(2-\alpha(m-1))} f_0\Big(C^{(m-1)/(\alpha(m-1)-2)}\rho\Big), \tag{2.4a}$$

$$f_0(\rho) = \omega(\rho, 1), \qquad \xi'_* = \sup\Big\{x : \ f_0(\rho) > 0\Big\} > 0, \tag{2.4b}$$

where ω is a solution of the CP (1.1), (1.4) with $b = 0, C = 1$. Lower and upper estimations for f are given in (2.27). We also have that

$$\xi'_* = A_0^{\frac{m-1}{2}} \left[\frac{m(2-\alpha(m-1))}{m-1}\right]^{\frac{1}{2}} \xi''_*, \tag{2.5}$$

where $A_0 = \omega(0,1)$ and ξ''_* is some number belonging to the segment $[\xi_1, \xi_2]$, where

$$\begin{aligned} &\xi_1 = \Big(\alpha(m-1)\Big)^{-\frac{1}{2}}, \qquad \xi_2 = 1 && \text{if} \ \ (m-1)^{-1} \le \alpha < 2(m-1)^{-1}, \\ &\xi_1 = 1, && \xi_2 = \Big(\alpha(m-1)\Big)^{-\frac{1}{2}} \qquad \text{if} \ \ 0 < \alpha \le (m-1)^{-1}. \end{aligned} \tag{2.6}$$

In particular, if $\alpha = (m-1)^{-1}$ and $m > 2 - \min\{1, \beta\}$, then the explicit solution of the problem (1.1), (1.4) with $b = 0$ is given by (2.24) and we have

$$\xi_1 = \xi_2 = 1, \quad \xi'_* = m(m-1)^{-1}, \quad f_0(x) = \Big(\xi'_* - x\Big)_+^{1/(m-1)}, \tag{2.7}$$

where $(r)_+ = \max(r, 0)$.
The explicit formulae (2.1) and (2.3) mean that the local behavior of the interface and solution along $x = \xi_\rho(t)$ coincide with those of the problem (1.1), (1.4) with $b = 0$.

(2) Suppose that $b > 0, \ 0 < \beta < 1, \ \alpha = 2/(m-\beta)$ (here we describe the results for the case $m = 1$ as well). In this case the behavior of the interface depends on the constant C. The critical value is

$$C_* = \Big[|b|(m-\beta)^2 \Big/ \Big(2m(m+\beta)\Big)\Big]^{1/(m-\beta)}.$$

First, assume that u_0 is defined by (1.4). If $m + \beta = 2$, then the explicit solution to (1.1), (1.4) is

$$u(x,t) = C(\zeta_* t - x)_+^{1/(1-\beta)}, \qquad \zeta_* = b(1-\beta)C^{\beta-1}\left((C/C_*)^{m-\beta} - 1\right). \tag{2.8}$$

It has an expanding interface if $C > C_*$ and a shrinking interface if $0 < C < C_*$ and is a stationary solution if $C = C_*$.

Let $m + \beta \neq 2$. If $C = C_*$ then u_0 is a stationary solution to (1.1), (1.4). If $C \neq C_*$, then the solution to (1.1), (1.4) is of the self-similar form

$$u(x,t) = t^{1/(1-\beta)} f_1(\zeta), \qquad \zeta = x t^{-\frac{m-\beta}{2(1-\beta)}}, \tag{2.9}$$

$$\eta(t) \quad = \zeta_* t^{\frac{m-\beta}{2(1-\beta)}}, \qquad 0 \le t < +\infty. \tag{2.10}$$

If $C > C_*$ then the interface expands, $f_1(0) = A_1 > 0$ (see Lemma 3.3), and

$$C_1 t^{\frac{1}{1-\beta}} \Big(\zeta_1 - \zeta\Big)_+^{\mu} \le u \le C_2 t^{\frac{1}{1-\beta}} \Big(\zeta_2 - \zeta\Big)_+^{\frac{2}{m-\beta}}, \quad 0 \le x < +\infty, \quad 0 < t < +\infty, \tag{2.11}$$

where

$$\mu = (m-1)^{-1} \quad \text{if} \quad m + \beta > 2; \quad \mu = 2(m-\beta)^{-1} \quad \text{if} \quad 1 \le m < 2 - \beta,$$

which implies

$$\zeta_1 \le \zeta_* \le \zeta_2. \tag{2.12}$$

The right-hand side of (2.11) (respectively, (2.12)) may be replaced by $\bar{C}_2 t^{\frac{1}{1-\beta}} (\bar{\zeta}_2 - \zeta)_+^{\frac{1}{m-1}}$ (respectively, $\bar{\zeta}_2$); see the appendix for the description of all the relevant constants.

Let $m + \beta \neq 2$ and $0 < C < C_*$. Then the interface shrinks and if $m + \beta > 2$, then

$$\begin{aligned} &\left[C^{1-\beta}\Big(-x\Big)_+^{\frac{2(1-\beta)}{m-\beta}} - b(1-\beta)t\right]_+^{\frac{1}{1-\beta}} \le u \\ &\le \left[C^{1-\beta}\Big(-x\Big)_+^{\frac{2(1-\beta)}{m-\beta}} - b(1-\beta)\Big(1-(C/C_*)^{m-\beta}\Big)t\right]_+^{\frac{1}{1-\beta}}, \\ &\qquad\qquad x \in \mathbb{R}, \quad 0 \le t < +\infty, \end{aligned} \tag{2.13}$$

which also implies (2.12), where we replace ζ_1 (respectively, ζ_2) with

$$-C^{-\frac{m-\beta}{2}} \left(b(1-\beta)\right)^{\frac{m-\beta}{2(1-\beta)}}$$

$$\left(\text{respectively, } -C^{-\frac{m-\beta}{2}} \left(b(1-\beta)\left(1-(C/C_*)^{m-\beta}\right)\right)^{\frac{m-\beta}{2(1-\beta)}}\right).$$

However, if $1 \le m < 2 - \beta$, then

$$C_* \left(-\zeta_3 t^{\frac{m-\beta}{2(1-\beta)}} - x\right)_+^{\frac{2}{m-\beta}} \le u \le C_3 \left(-\zeta_4 t^{\frac{m-\beta}{2(1-\beta)}} - x\right)_+^{\frac{2}{m-\beta}}, \quad 0 \le t < +\infty, \tag{2.14}$$

where the left-hand side is valid for $x \ge -\ell_0 t^{\frac{m-\beta}{2(1-\beta)}}$, while the right-hand side is valid for $x \ge -\ell_1 t^{\frac{m-\beta}{2(1-\beta)}}$. From (2.14), (2.12) follows if we replace ζ_1 and ζ_2 with $-\zeta_3$ and $-\zeta_4$, respectively.

When $m+\beta \neq 2$, in general the precise value ζ_* can be found only by solving the similarity ODE $\mathcal{L}^0 f_1 = 0$ (see (4.4b) below) and calculating $\zeta_* = \sup\{\zeta : f_1(\zeta) > 0\}$. It may easily be shown that the described estimations (2.11)–(2.14), together with existence, uniqueness, and comparison results for the original Cauchy problem (1.1),(1.4) (see section 3), imply the unique solvability of the relevant boundary value problems for the similarity ODE, as well as the existence and uniqueness of ζ_*. Respective lower and upper bounds for ζ_* are given in (2.12).
Now assume that u_0 satisfies (1.3) with $\alpha = 2/(m-\beta)$. Then if $C \neq C_*$ we have

$$\eta(t) \sim \zeta_* t^{\frac{m-\beta}{2(1-\beta)}} \quad \text{as} \quad t \to 0+ \tag{2.15}$$

and for arbitrary $\rho < \zeta_*$

$$u(x,t) \sim f_1(\rho) t^{1/(1-\beta)} \quad \text{for} \quad x = \rho t^{\frac{m-\beta}{2(1-\beta)}}, \quad t \to 0+, \tag{2.16}$$

where the right-hand side of (2.16) (respectively, (2.15)) relates to the self-similar solution (2.9) (respectively, to its interface, as in (2.10)). If $m+\beta = 2$ we then have explicit values of ζ_* and $f_1(\rho)$ via (2.8), while in general we have lower and upper bounds via (2.11)–(2.14). If u_0 satisfies (1.3) with $\alpha = 2/(m-\beta)$, $C = C_*$, then the small-time behavior of the interface and the local solution depend on the terms smaller than $C_*(-x)^{2/(m-\beta)}$ in the expansion of u_0 as $x \to 0-$.

(3) Suppose that $b > 0$, $0 < \beta < 1$, $\alpha > 2/(m-\beta)$ (here again we describe the results for the case $m = 1$ as well). In this case the interface initially shrinks and

$$\eta(t) \sim -\ell_* t^{1/\alpha(1-\beta)} \quad \text{as} \quad t \to 0+, \tag{2.17}$$

where $\ell_* = C^{-1/\alpha}(b(1-\beta))^{1/\alpha(1-\beta)}$. For arbitrary $\ell > \ell_*$ we have

$$u(x,t) \sim \Big[C^{1-\beta}(-x)_+^{\alpha(1-\beta)} - b(1-\beta)t\Big]^{1/(1-\beta)} \quad \text{as} \quad t \to 0+ \tag{2.18}$$

along the curve $x = \eta_\ell(t) = -\ell t^{1/\alpha(1-\beta)}$. These results mean that the interface initially coincides with that of the solution

$$\bar{u}(x,t) = \Big[C^{1-\beta}(-x)_+^{\alpha(1-\beta)} - b(1-\beta)t\Big]_+^{1/(1-\beta)}$$

to the problem

$$\bar{u}_t + b\bar{u}^\beta = 0, \qquad \bar{u}(x,0) = C(-x)_+^\alpha.$$

Respective lower and upper estimations are given in section 4 (see (4.16) and (4.19) below).

(4) In this case the interface initially remains stationary. We divide the results into four different subcases (see Figure 1).

(4a) Let $\beta = 1$, $\alpha = 2/(m-1)$. This case reduces to the case $b = 0$ by a simple transformation (see section 3). If u_0 is defined by (1.4), then the unique solution [8, 20] to (1.1), (1.4) is

$$\begin{aligned} &u_C(x,t) = C(-x)_+^{2/(m-1)} \\ &\times \exp(-bt)\Big[1 - (C/\bar{C})^{m-1} b^{-1}\Big(1 - \exp(-b(m-1)t)\Big)\Big]^{1/1-m} \end{aligned} \tag{2.19}$$

for $x \in \mathbb{R},\ t \in [0,T)$, where

$$T = +\infty \quad \text{if} \quad b \geq (C/\bar{C})^{m-1},$$
$$T = \Big(b(1-m)\Big)^{-1} \ln\big[1 - b(\bar{C}/C)^{m-1}\big] \quad \text{if} \quad -\infty < b < (C/\bar{C})^{m-1},$$
$$\bar{C} = \Big[(m-1)^2 \Big/ \Big(2m(m+1)\Big)\Big]^{1/(m-1)}.$$

If u_0 satisfies (1.3), then lower and upper estimations are given by $u_{C\mp\varepsilon}$.

(4b) Let $\beta = 1,\ \alpha > 2/(m-1)$. Then for arbitrary sufficiently small $\varepsilon > 0$, there exist $x_\varepsilon < 0$ and $\delta_\varepsilon > 0$ such that

$$(C-\varepsilon)(-x)_+^\alpha \exp(-bt) \leq u(x,t) \leq (C+\varepsilon)(-x)_+^\alpha \exp(-bt)$$
$$\times \left[1 - \varepsilon\Big(b(m-1)\Big)^{-1}\Big(1 - \exp(-b(m-1)t)\Big)\right]^{1/(1-m)}, \quad x \geq x_\varepsilon,\ \ 0 \leq t \leq \delta_\varepsilon. \tag{2.20}$$

(4c) Let $1 < \beta < m,\ \alpha \geq 2/(m-\beta)$. Then for arbitrary sufficiently small $\varepsilon > 0$ there exist $x_\varepsilon < 0$ and $\delta_\varepsilon > 0$ such that

$$g_{-\varepsilon}(x,t) \leq u(x,t) \leq g_\varepsilon(x,t), \quad x \geq x_\varepsilon,\ \ 0 \leq t \leq \delta_\varepsilon, \tag{2.21}$$

where

$$g_\varepsilon(x,t) = \begin{cases} \big[(C+\varepsilon)^{1-\beta}|x|^{\alpha(1-\beta)} + b(\beta-1)(1-d_\varepsilon)t\big]^{1/(1-\beta)}, & x_\varepsilon \leq x < 0, \\ 0, & x \geq 0, \end{cases}$$

$$d_\varepsilon = \begin{cases} \varepsilon \operatorname{sign} b & \text{if } \alpha > 2/(m-\beta), \\ \left(\Big((C+\varepsilon)/C_*\Big)^{m-\beta} + \varepsilon\right) \operatorname{sign} b & \text{if } \alpha = 2/(m-\beta), \end{cases}$$

and the constant C_* is defined in (I(2)).

(4d) Let either $1 < \beta < m,\ 2/(m-1) \leq \alpha < 2/(m-\beta)$, or $\beta \geq m,\ \alpha \geq 2/(m-1)$. If $\alpha = 2/(m-1)$ then for arbitrary $\varepsilon > 0$ there exist $x_\varepsilon < 0$ and $\delta_\varepsilon > 0$ such that

$$\begin{aligned} &(C-\varepsilon)(-x)_+^{2/(m-1)}(1-\gamma_{-\varepsilon}t)^{1/(1-m)} \leq u \\ &\qquad \leq (C+\varepsilon)(-x)_+^{2/(m-1)}(1-\gamma_\varepsilon t)^{1/(1-m)}, \quad x \geq x_\varepsilon,\ 0 \leq t \leq \delta_\varepsilon, \end{aligned} \tag{2.22}$$

where

$$\gamma_\varepsilon = \Big[2m(m+1)(C+\varepsilon)^{m-1} \Big/ (m-1)\Big] + \varepsilon.$$

However, if $\alpha > 2/(m-1)$ then for arbitrary $\varepsilon > 0$ there exist $x_\varepsilon < 0$ and $\delta_\varepsilon > 0$ such that

$$(C-\varepsilon)(-x)_+^\alpha \leq u \leq (C+\varepsilon)(-x)_+^\alpha (1-\varepsilon t)^{1/(1-m)}, \quad x \geq x_\varepsilon,\ \ 0 \leq t \leq \delta_\varepsilon. \tag{2.23}$$

(II) $b = 0$

REMARK 2.1. *It should be noted that this case has been widely investigated earlier* [7, 8, 14, 15, 28, 30, 31, 36] *(see also the review article* [23]*). Nevertheless, using the*

same techniques as in the case $b \neq 0$, we derive some global estimations (see (2.27)*). The new element here is that we have constructed lower and upper solutions to the corresponding nonlinear ODE for the function $f(\xi)$ in* (2.25).

(1) Let $m > 1,\ 0 < \alpha < 2/(m-1)$. In this case the interface expands. First, assume that $u_0(x)$ is defined by (1.4). Then if $\alpha = 1/(m-1)$ we have an explicit solution to the problem (1.1), (1.4):

$$u(x,t) = C(\xi_* t - x)_+^{1/(m-1)}, \quad \xi_* = C^{m-1} m (m-1)^{-1}. \tag{2.24}$$

If $0 < \alpha < 2/(m-1)$, then the solution to (1.1), (1.4) has the self-similar form

$$u(x,t) = t^{\frac{\alpha}{2+\alpha(1-m)}} f(\xi), \qquad \xi = x t^{-\frac{1}{2+\alpha(1-m)}}, \tag{2.25}$$

$$\eta(t) \quad = \xi_* t^{\frac{1}{2+\alpha(1-m)}}, \qquad 0 \le t < +\infty, \tag{2.26}$$

where ξ_* and f satisfy (2.2), (2.4)–(2.6). Moreover, we have

$$C_4 t^{\frac{\alpha}{2+\alpha(1-m)}} \Big(\xi_3 - \xi\Big)_+^{\frac{1}{m-1}} \le u \le C_5 t^{\frac{\alpha}{2+\alpha(1-m)}} \Big(\xi_4 - \xi\Big)_+^{\frac{1}{m-1}}, \tag{2.27}$$
$$0 \le x < +\infty, \quad 0 < t < +\infty,$$

where ξ_3 (respectively, ξ_4) is defined by the right-hand side of (2.5), where we replace ξ_*'' with $C^{\frac{m-1}{2-\alpha(m-1)}} \xi_1$ (respectively, with $C^{\frac{m-1}{2-\alpha(m-1)}} \xi_2$) and

$$C_4 = C^{2/(2-\alpha(m-1))} A_0 \xi_3^{1/(1-m)}, \qquad C_5 = C^{2/(2-\alpha(m-1))} A_0 \xi_4^{1/(1-m)}.$$

In the particular case $\alpha = (m-1)^{-1}$, when an explicit solution is given by (2.24), we have $\xi_3 = \xi_4 = \xi_*$ and both lower and upper estimations in (2.27) lead to the explicit solution (2.24). In general, when $\alpha \neq (m-1)^{-1}$ the precise value ξ_* relates to the similarity ODE for $f(\xi)$ from (2.25), namely, $\xi_* = \sup\{\xi : f(\xi) > 0\}$. If u_0 satisfies (1.3) with $0 < \alpha < 2/(m-1)$, then (2.1) and (2.3) are valid. Lower and upper bounds for $f(\rho)$ follow from (2.27).

(2) Let $m > 1,\ \alpha = 2/(m-1)$. In this case the interface initially remains stationary. If u_0 is defined by (1.4), then the explicit solution [8, 20] to (1.1), (1.4) is

$$u_C(x,t) = C(-x)_+^{2/(m-1)} \left[1 - (C/\bar{C})^{m-1}(m-1)t\right]^{1/(1-m)}, \quad x \in \mathbb{R}, \quad 0 \le t < T, \tag{2.28}$$

where

$$T = (\bar{C}/C)^{m-1}(m-1)^{-1}$$

and the constant $\bar{C}$ is defined in (I(4)).
If u_0 satisfies (1.3) with $\alpha = 2/(m-1)$, then lower and upper estimations are given by $u_{C \mp \varepsilon}$.

(3) Let $m > 1, \alpha > 2/(m-1)$. In this case also the interface initially remains stationary and for arbitrary sufficiently small $\varepsilon > 0$ there exist $x_\varepsilon < 0$ and $\delta_\varepsilon > 0$ such that

$$(C-\varepsilon)(-x)_+^{\alpha} \le u \le (C+\varepsilon)(-x)_+^{\alpha}(1-\varepsilon t)^{1/(1-m)}, \quad x_\varepsilon \le x, \quad 0 \le t \le \delta_\varepsilon. \tag{2.29}$$

3. Preliminary results. The mathematical theory of nonlinear degenerate parabolic equations began with the paper [32]. The methods and the results of [32] have been developed in [16, 21, 26] for more general equations (including (1.1) as a particular case). Significant progress in high-dimensional problems has been made due to the papers [5, 11, 12]. For a general study we refer to the survey article [23]. Boundary value problems for (1.1) in noncylindrical domains with nonsmooth boundaries have recently been investigated in [3].

Throughout this paper we shall follow the definitions of generalized solutions and of supersolutions (or subsolutions) of initial or initial boundary value problems to (1.1) given in [3]. Comparison theorems from [3] for the solutions of Cauchy–Dirichlet and Dirichlet problems in irregular domains will be extensively used in the proof of the results of section 2.

REMARK 3.1. *It should be noted that in the paper* [3] *it was supposed that solutions (respectively, supersolutions and subsolutions) of the Cauchy–Dirichlet problem are bounded on every bounded time interval. This assumption had no importance in the proof of existence theorems, since the constructed limit solutions possess this property, but it has been used in the proof of uniqueness theorems in* [3]. *However, by using a slight technical modification of the proofs from* [3] *in the case of* $b \geq 0$, *the uniqueness and comparison assertions of Theorems* 2.2 *and* 2.4, *and also Lemma* 2.1 *from* [3], *may be proved without this assumption.*

Suppose that $b \geq 0$ and that u_0 may have unbounded growth as $|x| \to +\infty$. It is well known that in this case some necessary and sufficient conditions must be imposed on the growth rate for existence, uniqueness, and comparison results in the CP (1.1), (1.2). For the slow diffusion equation ((1.1) with $b = 0,\ m > 1$) the optimal growth condition is known due to [9, 20]. In particular, if initial data may be majorized by power law function (1.4), then there exists a unique solution (with $T = +\infty$) and a comparison principle is valid if $0 < \alpha < 2/(m-1)$. If $\alpha = 2/(m-1)$, then existence, uniqueness, and comparison results are valid only locally in time. For instance, from [8, 20] it follows that the unique explicit solution to (1.1), (1.4) with $b = 0,\ \alpha = 2/(m-1), T = (\bar{C}/C)^{m-1}(m-1)^{-1}$ is $u_C(x,t)$ from (2.28).

If the function $u(x,t)$ is a solution to (1.1) with $b = 0$, then the function

$$\bar{u}(x,t) = \exp(-bt)\ u(x, (b(1-m))^{-1}(\exp(b(1-m)t) - 1))$$

is a solution to (1.1) with $b \neq 0,\ \beta = 1$. Hence, from the above mentioned result it follows that the unique solution to CP (1.1), (1.4) with $m > 1,\ b \neq 0,\ \beta = 1,\ \alpha = 2/(m-1)$ is the function $\bar{u}_C(x,t)$ from (2.19).

Necessary and sufficient conditions on the growth rate at infinity for existence, uniqueness, and comparison results for the CP (1.1), (1.2) with $b > 0,\ m > 1,\ \beta > 0$ have been investigated in [22, 24, 6, 1]. We are not interested in describing an optimal result; for our purposes it is enough to mention that if u_0 may be majorized by the function (1.4) with α satisfying $0 < \alpha < 2/(m-1)$, then the CP (1.1), (1.2) with $b > 0,\ m > 1,\ \beta > 0,\ T = +\infty$ has a unique solution and for this class of initial data a comparison principle is valid [24, 6].

In the next four lemmas we establish some preliminary estimations of the solution to CP. The proof of these estimations is based on scale of variables.

LEMMA 3.1. *If* $b = 0$ *and* $m > 1,\ 0 < \alpha < 2/(m-1)$, *then the solution* u *of the CP* (1.1), (1.4) *has a self-similar form* (2.25), *where the self-similarity function* f *satisfies* (2.4). *If* u_0 *satisfies* (1.3), *then the solution to CP* (1.1), (1.2) *satisfies* (2.1)–(2.3).

LEMMA 3.2. *Let u be a solution to the CP* (1.1), (1.2) *and u_0 satisfy* (1.3). *Let one of the following conditions be valid:*

(a) $b > 0, \quad 0 < \beta < 1 < m, \quad 0 < \alpha < 2/(m-\beta)$,

(b) $b \neq 0, \quad \beta \geq 1, \quad m > 1, \quad 0 < \alpha < 2/(m-1)$.

Then u satisfies (2.3).

LEMMA 3.3. *Let u be a solution to CP* (1.1), (1.4) *with* $b > 0,\ 0 < \beta < 1,\ m \geq 1, \alpha = 2/(m-\beta)$. *Then the solution u has the self-similar form* (2.9). *If* $C > C_*$ *then $f_1(0) = A_1$, where A_1 is a positive number depending on m, β, C, and b. If u_0 satisfies* (1.3) *with* $\alpha = 2/(m-\beta),\ C > C_*,$ *then u satisfies*

$$u(0,t) \sim A_1\, t^{1/(1-\beta)} \quad \text{as} \quad t \to 0+. \tag{3.1}$$

LEMMA 3.4. *Let u be a solution to the CP* (1.1)–(1.3) *with* $b > 0,\ 0 < \beta < 1,\ \alpha > 2/(m-\beta)$. *Then for arbitrary $\ell > \ell_*$ (see* (2.17)*) the asymptotic formula* (2.18) *is valid with $x = \eta_\ell(t) = -\ell t^{1/\alpha(1-\beta)}$.*

Proof of Lemma 3.1. The self-similar form (2.25) of the solution to (1.1), (1.4) is a well-known result (see Remark 2.1 in section 2). If we consider a function

$$u_\kappa(x,t) = \kappa u\left(\kappa^{-1/\alpha}x,\ \kappa^{(\alpha(m-1)-2)/\alpha}t\right), \quad \kappa > 0, \tag{3.2}$$

it may easily be checked that this satisfies (1.1), (1.4). Since under the condition of the lemma there exists a unique global solution to (1.1), (1.4), we have

$$u(x,t) = \kappa u\left(\kappa^{-1/\alpha}x,\ \kappa^{(\alpha(m-1)-2)/\alpha}t\right), \quad \kappa > 0. \tag{3.3}$$

If we choose $\kappa = t^{\alpha/(2-\alpha(m-1))}$, then (3.3) implies (2.25) with $f(\xi) = u(\xi,1)$. It is a well-known fact (see Remark 2.1) that f is a unique nonnegative and continuous solution of the relevant boundary value problem for the similarity ODE and there exists an $\xi_* > 0$ such that f is positive and smooth for $\xi < \xi_*$ and $f = 0$ for $\xi \geq \xi_*$. Thus, (2.26) is valid. Now, to find the dependence of f on C we can again use scaling as in [36]. Namely, let ω be a solution of the CP (1.1), (1.4) with $C = 1$. Then it may be easily checked that for arbitrary $\kappa > 0$

$$u(x,t) = \kappa\omega\left(C^{1/\alpha}\kappa^{-1/\alpha}x, \quad C^{2/\alpha}\kappa^{(\alpha(m-1)-2)/\alpha}t\right).$$

By choosing $\kappa = \left(C^{2/\alpha}t\right)^{\alpha/(2-\alpha(m-1))}$ we then have

$$u(x,t) = C^{\frac{2}{2-\alpha(m-1)}}\omega\left(C^{\frac{m-1}{\alpha(m-1)-2}}\xi, 1\right)t^{\alpha/(2-\alpha(m-1))}. \tag{3.4}$$

From (3.4) and (2.25), (2.4) and (2.2) follow.

Now suppose that u_0 satisfies (1.3). Then for arbitrary sufficiently small $\varepsilon > 0$ there exists an $x_\varepsilon < 0$ such that

$$(C-\varepsilon/2)(-x)_+^\alpha \leq u_0(x) \leq (C+\varepsilon/2)(-x)_+^\alpha, \qquad x \geq x_\varepsilon. \tag{3.5}$$

Let $u_\varepsilon(x,t)$ (respectively, $u_{-\varepsilon}(x,t)$) be a solution to the CP (1.1), (1.2) with initial data $(C+\varepsilon)(-x)_+^\alpha$ (respectively, $(C-\varepsilon)(-x)_+^\alpha$). Since the solution to the CP (1.1), (1.2) is continuous there exists a number $\delta = \delta(\varepsilon) > 0$ such that

$$u_\varepsilon(x_\varepsilon,t) \geq u(x_\varepsilon,t), \quad u_{-\varepsilon}(x_\varepsilon,t) \leq u(x_\varepsilon,t) \quad \text{for} \quad 0 \leq t \leq \delta. \tag{3.6}$$

From (3.5), (3.6), and a comparison principle (e.g., Theorem 2.4 of [3]), it follows that

$$u_{-\varepsilon} \le u \le u_{\varepsilon} \quad \text{for} \quad x \ge x_{\varepsilon}, \quad 0 \le t \le \delta. \tag{3.7}$$

Obviously

$$u_{\pm\varepsilon}(\xi_\rho(t), t) = f(\rho; C \pm \varepsilon) t^{\alpha/(2-\alpha(m-1))}, \quad t \ge 0. \tag{3.8}$$

(Furthermore, we denote the right-hand side of (2.4a) by $f(\rho, C)$.) Now taking $x = \xi_\rho(t)$ in (3.7), after multiplying to $t^{-\alpha/(2-\alpha(m-1))}$ and passing to the limit, first as $t \to 0$ and then as $\varepsilon \to 0$, we can easily derive (2.3). Similarly, from (3.7), (2.26), and (2.2), (2.1) easily follows. The lemma is proved.

Proof of Lemma 3.2. As in the proof of Lemma 3.1, (3.5) and (3.6) follow from (1.3). Let the conditions of one of the cases (a) or (b) with $b > 0$ be valid. Then from results mentioned earlier it follows that the existence, uniqueness, and comparison results of the CP (1.1), (1.2) with $u_0 = (C \pm \varepsilon)(-x)_+^\alpha$, $T = +\infty$ hold. As before, from (3.5) and (3.6), (3.7) follows. Now if we take

$$u_\kappa^{\pm\varepsilon}(x,t) = \kappa\, u_{\pm\varepsilon}\left(\kappa^{-1/\alpha} x,\ \kappa^{(\alpha(m-1)-2)/\alpha} t\right), \quad \kappa > 0, \tag{3.9}$$

then $u_\kappa^{\pm\varepsilon}(x,t)$ satisfies the following problem:

$$u_t - (u^m)_{xx} + b\kappa^{(\alpha(m-\beta)-2)/\alpha} u^\beta = 0, \quad x \in \mathbb{R}, \quad t > 0, \tag{3.10a}$$

$$u(x,0) = (C \pm \varepsilon)(-x)_+^\alpha, \quad x \in \mathbb{R}. \tag{3.10b}$$

There exists a unique solution to CP (3.10), which obeys a comparison principle also. Since $\alpha(m-\beta) - 2 < 0$, by using a comparison principle it may easily be proved that

$$\lim_{\kappa \to +\infty} u_\kappa^{\pm\varepsilon}(x,t) = v_{\pm\varepsilon}(x,t), \quad x \in \mathbb{R}, \quad t \ge 0, \tag{3.11}$$

where $v_{\pm\varepsilon}$ is a solution to the CP (1.1), (1.2) with $b = 0$, $u_0 = (C \pm \varepsilon)(-x)_+^\alpha$, $T = +\infty$. Hence, $v_{\pm\varepsilon}$ satisfies (3.8). If we now take $x = \xi_\rho(t)$, where ρ is an arbitrary fixed number satisfying $\rho < \xi_*$, then from (3.11) it follows that

$$\lim_{\kappa \to +\infty} \kappa u_{\pm\varepsilon}\left(\kappa^{-1/\alpha}\xi_\rho(t),\ \kappa^{(\alpha(m-1)-2)/\alpha} t\right) = f(\rho; C \pm \varepsilon) t^{\alpha/(2-\alpha(m-1))}, \quad t > 0. \tag{3.12}$$

If we take $\tau = \kappa^{(\alpha(m-1)-2)/\alpha} t$, then (3.12) implies

$$u_{\pm\varepsilon}(\xi_\rho(\tau), \tau) \sim f(\rho; C \pm \varepsilon)\tau^{\alpha/(2-\alpha(m-1))} \ \text{ as } \ \tau \to 0+. \tag{3.13}$$

As before, (2.3) easily follows from (3.7), (3.13).

Now consider the case (b) with $b < 0$. Suppose that $u_{\pm\varepsilon}$ is a solution of the Dirichlet problem

$$u_t - (u^m)_{xx} + bu^\beta = 0, \qquad |x| < |x_\varepsilon|, \quad 0 < t \le \delta, \tag{3.14a}$$

$$u(x,0) = (C \pm \varepsilon)(-x)_+^\alpha, \qquad |x| \le |x_\varepsilon|, \tag{3.14b}$$

$$u(x_\varepsilon, t) = (C \pm \varepsilon)(-x_\varepsilon)^\alpha, \qquad u(-x_\varepsilon, t) = 0, \quad 0 \le t \le \delta. \tag{3.14c}$$

The function $u_\kappa^{\pm\varepsilon}$, defined as in (3.9), satisfies the Dirichlet problem

$$u_t - (u^m)_{xx} + b\kappa^{(\alpha(m-\beta)-2)/\alpha}u^\beta = 0 \quad \text{in} \quad D_\varepsilon^\kappa,$$

(3.15a)

$$u\left(\kappa^{1/\alpha}x_\varepsilon, t\right) = \kappa(C \pm \varepsilon)(-x_\varepsilon)^\alpha, \quad u\left(-\kappa^{1/\alpha}x_\varepsilon, t\right) = 0, \quad 0 \le t \le \kappa^{(2-\alpha(m-1))/\alpha}\delta,$$

(3.15b)

$$u(x,0) = (C \pm \varepsilon)(-x)_+^\alpha, \qquad |x| \le \kappa^{1/\alpha}|x_\varepsilon|,$$

(3.15c)

where

$$D_\varepsilon^\kappa = \left\{(x,t):\ |x| < \kappa^{1/\alpha}|x_\varepsilon|, \qquad 0 < t \le \kappa^{(2-\alpha(m-1))/\alpha}\delta\right\}.$$

From Theorem 3.1 of [3] it follows that there exists a number $\delta > 0$ (which does not depend on κ) such that both (3.14) and (3.15) have a unique solution.

In view of finite speed of propagation a $\delta = \delta(\varepsilon) > 0$ may be chosen such that

$$u(-x_\varepsilon, t) = 0, \qquad 0 \le t \le \delta. \tag{3.16}$$

Applying the Comparison Theorem 3.4 of [3], from (3.5), (3.6), and (3.16), (3.7) follows for $|x| \le |x_\varepsilon|$, $0 \le t \le \delta$.

The next step consists in the proof of the convergence of the sequences $\{u_\kappa^{\pm\varepsilon}\}$ as $\kappa \to +\infty$. Consider a function

$$g(x,t) = (C+1)(1+x^2)^{\alpha/2}(1-\nu t)^{1/(1-m)}, \quad x \in \mathbb{R}, \quad 0 \le t \le t_0 = \nu^{-1}/2,$$

where

$$\nu = h_* + 1, \quad h_* = h_*(\alpha; m) = \max_{x\in\mathbb{R}} h(x),$$
$$h(x) = (m-1)(C+1)^{m-1}\alpha m(1+x^2)^{\alpha(m-1)/2-2}\left(1 + (\alpha m - 1)x^2\right).$$

Then we have

$$\begin{aligned} \mathrm{L}_\kappa g \equiv g_t - (g^m)_{xx} + b\kappa^{(\alpha(m-\beta)-2)/\alpha}g^\beta \\ = (C+1)(m-1)^{-1}(1+x^2)^{\alpha/2}(1-\nu t)^{m/(1-m)}\mathrm{S} \quad \text{in} \quad D_\varepsilon^\kappa, \\ \mathrm{S} = \nu - h(x) + b(m-1)(C+1)^{\beta-1}\kappa^{(\alpha(m-\beta)-2)/\alpha} \\ \times (1+x^2)^{\alpha(\beta-1)/2}(1-\nu t)^{(\beta-m)/(1-m)}, \end{aligned}$$

and hence

$$\mathrm{S} \ge 1 + R \ \text{ in } \ D_{0\varepsilon}^\kappa = D_\varepsilon^\kappa \cap \left\{(x,t):\ 0 < t \le t_0\right\}, \tag{3.17}$$

where

$$R = O(\kappa^{m-1-2/\alpha}) \ \text{ uniformly for } \ (x,t) \in D_{0\varepsilon}^\kappa \quad \text{as} \quad \kappa \to +\infty.$$

Moreover, we have for $0 < \varepsilon \ll 1$

$$g(x,0) \ge u_\kappa^{\pm\varepsilon}(x,0) \qquad \text{for} \ \ |x| \le \kappa^{1/\alpha}|x_\varepsilon|, \tag{3.18a}$$

$$g(\pm\kappa^{1/\alpha}x_\varepsilon, t) \ge u_\kappa^{\pm\varepsilon}\left(\pm\kappa^{1/\alpha}x_\varepsilon, t\right) \quad \text{for} \ \ 0 \le t \le t_0. \tag{3.18b}$$

Hence, there exists a number $\kappa_0 = \kappa_0(\alpha; m)$ such that for $\kappa \geq \kappa_0$ the Comparison Theorem 3.4 of [3] implies

$$0 \leq u_\kappa^{\pm\varepsilon}(x,t) \leq g(x,t) \quad \text{in} \quad \bar{D}_{0\varepsilon}^\kappa. \tag{3.19}$$

Let G be an arbitrary fixed compact subset of

$$P = \Big\{(x,t):\ x \in \mathbb{R}, \quad 0 < t \leq t_0\Big\}.$$

We take κ_0 so large that $G \subset D_{0\varepsilon}^\kappa$ for $\kappa \geq \kappa_0$. From (3.19) it follows that the sequences $\{u_\kappa^{\pm\varepsilon}\}$, $\kappa \geq \kappa_0$, are uniformly bounded in G. As in [3], it may be proved that they are uniformly Hölder continuous in G and that there exist functions $v_{\pm\varepsilon}$ such that for some subsequence κ'

$$\lim_{\kappa' \to +\infty} u_{\kappa'}^{\pm\varepsilon}(x,t) = v_{\pm\varepsilon}(x,t), \quad (x,t) \in P. \tag{3.20}$$

It may easily be checked that $v_{\pm\varepsilon}$ is a solution to the CP (1.1), (1.2) with $b = 0$, $T = t_0, u_0 = (C \pm \varepsilon)(-x)_+^\alpha$. As before, from (3.8), (3.12), (3.13), and (3.7), the required estimation (2.3) follows. The lemma is proved.

The first assertion of Lemma 3.3 has been proved in [6] for the case $m > 1$. If u_0 satisfies (1.3), the estimation (3.1) may be proved exactly as estimation (2.3) was proved in Lemma 3.1. Finally, the case $m = 1$ may be considered similarly.

Proof of Lemma 3.4. As before, (3.5) and (3.6) follow from (1.3). Suppose that $u_{\pm\varepsilon}$ is a solution of the problem

$$\begin{aligned}
&v_t - (v^m)_{xx} + bv^\beta = 0, && |x| < |x_\varepsilon|, \quad 0 < t \leq \delta,\\
&v(x,0) = (C \pm \varepsilon)(-x)_+^\alpha, && |x| \leq |x_\varepsilon|,\\
&v(x_\varepsilon, t) = (C \pm \varepsilon)(-x_\varepsilon)^\alpha, \quad v(-x_\varepsilon, t) = u(-x_\varepsilon, t), && 0 \leq t \leq \delta.
\end{aligned}$$

Applying a comparison principle (e.g., Theorem 3.4 of [3]), from (3.5) and (3.6), (3.7) follows for $|x| \leq |x_\varepsilon|$, $0 \leq t \leq \delta$. Now if we take

$$u_\kappa^{\pm\varepsilon}(x,t) = \kappa u_{\pm\varepsilon}\left(\kappa^{-1/\alpha}x,\ \kappa^{\beta-1}t\right), \quad \kappa > 0,$$

then $u_\kappa^{\pm\varepsilon}$ satisfies the Dirichlet problem

$$\begin{aligned}
&v_t - \kappa^{\frac{2-\alpha(m-\beta)}{\alpha}}(v^m)_{xx} + bv^\beta = 0 && \text{in} \quad E_\varepsilon^\kappa,\\
&v(x,0) = (C \pm \varepsilon)(-x)_+^\alpha, && |x| \leq \kappa^{1/\alpha}|x_\varepsilon|,\\
&v\left(\kappa^{1/\alpha}x_\varepsilon, t\right) = \kappa(C \pm \varepsilon)(-x_\varepsilon)^\alpha, && v\left(-\kappa^{1/\alpha}x_\varepsilon, t\right) = \kappa u\left(-x_\varepsilon, \kappa^{\beta-1}t\right),\\
&\quad 0 \leq t \leq \kappa^{1-\beta}\delta,
\end{aligned}$$

where

$$E_\varepsilon^\kappa = \Big\{(x,t):\ |x| < \kappa^{1/\alpha}|x_\varepsilon|, \quad 0 < t \leq \kappa^{1-\beta}\delta\Big\}.$$

The next step consists in proving the convergence of the sequences $\{u_\kappa^{\pm\varepsilon}\}$ as $\kappa \to +\infty$. Considering the function $g(x,t) = (C+1)(1+x^2)^{\alpha/2}\exp t$, we have

$$\begin{aligned}
\tilde{\mathrm{L}}_\kappa g \equiv g_t - \kappa^{\frac{2-\alpha(m-\beta)}{\alpha}}(g^m)_{xx} + bg^\beta \geq g\Big[1 - (C+1)^{m-1}\alpha m(1+x^2)^{\frac{\alpha(m-1)}{2}-2}\\
\times\Big(1 + (\alpha m - 1)x^2\Big)\exp\Big((m+1)t\Big)\kappa^{\frac{2-\alpha(m-\beta)}{\alpha}}\Big] \text{ in } E_\varepsilon^\kappa.
\end{aligned} \tag{3.21}$$

Let $t_0 > 0$ be fixed and let $E^\kappa_{0_\varepsilon} = E^\kappa_\varepsilon \cap \{(x,t) : \ 0 < t \le t_0\}$. Then from (3.21) it follows that

$$\tilde{\mathrm{L}}_\kappa g \ge g(1+R) \quad \text{in} \ \ E^\kappa_{0_\varepsilon},$$

where

$$R = O(\kappa^\theta) \text{ uniformly for } (x,t) \in E^\kappa_{0_\varepsilon} \ \text{ as } \ \kappa \to +\infty,$$

$$\theta \ = \Big(2 - \alpha(m-\beta)\Big)\Big/\alpha \quad \text{if} \ \ \alpha < 2/(m-1),$$

$$\theta \ = \beta - 1 \qquad \text{if} \ \ \alpha \ge 2/(m-1).$$

Moreover, we have for $0 < \varepsilon \ll 1$ that

$$g(x,0) \ge u^{\pm\varepsilon}_\kappa(x,0) \quad \text{for} \ \ |x| \le \kappa^{1/\alpha}|x_\varepsilon|.$$

Since

$$u^{\pm\varepsilon}_\kappa\left(-\kappa^{1/\alpha}x_\varepsilon, t\right) = o(\kappa) \quad \text{for} \ \ 0 \le t \le t_0 \quad \text{as } \kappa \to +\infty,$$

we also have

$$g\left(\pm\kappa^{1/\alpha}x_\varepsilon, t\right) \ge u^{\pm\varepsilon}_\kappa\left(\pm\kappa^{1/\alpha}x_\varepsilon, t\right) \quad \text{for} \ \ 0 \le t \le t_0$$

if κ is chosen large enough. Hence, as in the proof of Lemma 3.2, if κ is large enough, a comparison principle (e.g., Theorem 3.4 of [3]) implies (3.19) in $\bar{E}^\kappa_{0_\varepsilon}$, where the respective functions $u^{\pm\varepsilon}_\kappa$ and g apply in the context of this proof. As in [3], it may then be proved that the sequences $\{u^{\pm\varepsilon}_\kappa\}$ are uniformly Hölder continuous on compact subsets of P. Thus there exist functions $v_{\pm\varepsilon}$ such that for some subsequence κ', (3.20) is valid. It may easily be shown that the limit functions $v_{\pm\varepsilon}$ are solutions to the problem

$$v_t + bv^\beta = 0, \quad x \in \mathbb{R}, \quad 0 < t \le t_0; \quad v(x,0) = (C \pm \varepsilon)(-x)^\alpha_+, \quad x \in \mathbb{R},$$

i.e.,

$$v_{\pm\varepsilon}(x,t) = \Big[(C \pm \varepsilon)^{1-\beta}(-x)^{\alpha(1-\beta)}_+ - b(1-\beta)t\Big]^{\frac{1}{1-\beta}}_+ .$$

Let $\ell > \ell_*$ be an arbitrary number and $\varepsilon > 0$ be chosen such that

$$(C-\varepsilon)^{1-\beta}\ell^{\alpha(1-\beta)} > b(1-\beta).$$

If we now take $x = \eta_\ell(t)$ and $\tau = \kappa^{\beta-1}t$, it follows from (3.20) that

$$u_{\pm\varepsilon}(\eta_\ell(\tau),\tau) \sim \Big[(C \pm \varepsilon)^{1-\beta}\ell^{\alpha(1-\beta)} - b(1-\beta)\Big]^{\frac{1}{1-\beta}} \tau^{\frac{1}{1-\beta}} \ \text{ as } \ \tau \to 0+ . \tag{3.22}$$

From (3.7) and (3.22), in view of the arbitrariness of $\varepsilon > 0$, the desired formula (2.18) follows easily. The lemma is proved.

REMARK 3.2. *Lemma* 3.4 *is true also if* $\beta < m \le 1$, *the proof completely coinciding with the one given. We just need to mention that* $\theta = (2 - \alpha(m-\beta))/\alpha$ *if* $\beta < m \le 1$.

4. Proofs of the main results. In this section we prove the main results described in section 2.

(I) $b \neq 0$ and $m > 1$.

(1) Suppose that $\alpha < 2/(m - \min\{1, \beta\})$ The formula (2.3) follows from Lemma 3.2. In view of the arbitrariness of ρ, it implies

$$\liminf_{t\to 0+} \eta(t) t^{1/(\alpha(m-1)-2)} \geq \xi_*. \tag{4.1}$$

Take an arbitrary sufficiently small number $\varepsilon > 0$. Let u_ε be a solution of the CP (1.1), (1.4) with $b = 0$ and with C replaced by $C + \varepsilon$. As before, the second inequality of (3.5) and the first inequality of (3.6) follow from (1.3). Suppose that $b > 0$. In this case, u_ε is a supersolution of (1.1). From (3.5), (3.6), and a comparison principle, the second inequality of (3.7) follows. By Lemma 3.1 we then have

$$\eta(t) \leq (C + \varepsilon)^{\frac{m-1}{2-\alpha(m-1)}} \xi'_* \, t^{1/(2-\alpha(m-1))}, \quad 0 \leq t \leq \delta,$$

and hence

$$\limsup_{t\to 0+} \eta(t) t^{1/(\alpha(m-1)-2)} \leq \xi_*. \tag{4.2}$$

Now suppose that $b < 0$ and $\beta \geq 1$. The function

$$\bar{u}_\varepsilon(x,t) = \exp(-bt) u_\varepsilon \left(x, \Big(b(1-m)\Big)^{-1} \Big[\exp\Big(b(1-m)t\Big) - 1\Big] \right)$$

is a solution to the CP (1.1),(1.4) with $\beta = 1$ and with C replaced by $C + \varepsilon$. As before, from (1.3) the first inequality of (3.6) follows, where we replace u_ε with $\bar{u}_\varepsilon$. Then we make $|x_\varepsilon|$ and δ so small that

$$\bar{u}_\varepsilon < 1 \ \text{ in } \ B = \Big\{(x,t) : \ x \geq x_\varepsilon, \ \ 0 < t \leq \delta\Big\}.$$

Obviously, $\bar{u}_\varepsilon$ is a supersolution of (1.1) in B. From (3.5), (3.6), and a comparison principle, the second inequality of (3.7), with u_ε replaced by $\bar{u}_\varepsilon$, follows. Thus we have

$$\eta(t) \leq (C + \varepsilon)^{\frac{m-1}{2-\alpha(m-1)}} \xi'_* \left\{ \Big(b(1-m)\Big)^{-1} \Big[\exp\Big(b(1-m)t\Big) - 1\Big] \right\}^{1/(2-\alpha(m-1))}, \quad 0 \leq t \leq \delta,$$

which again implies (4.2). From (4.1) and (4.2), (2.1) follows. Finally, (2.5), (2.6), (2.7) follow from (2.27), which we prove later in this section.

(2) $b > 0, \ 0 < \beta < 1, \ m \geq 1, \ \alpha = 2/(m - \beta)$.

First, assume that u_0 is defined by (1.4). As mentioned earlier in section 3, the problem (1.1), (1.4) has a unique global solution and for this class of initial data a comparison principle is valid.

If $m + \beta = 2$ it may be easily checked that the explicit solution to (1.1), (1.4) is given by (2.8).

Let $m + \beta \neq 2$. The self-similar form (2.9) follows from Lemma 3.3. Let $C > C_*$. Consider a function

$$g(x,t) = t^{1/(1-\beta)} f_1(\zeta), \qquad \zeta = x \, t^{-\frac{m-\beta}{2(1-\beta)}}. \tag{4.3}$$

We then have

$$\mathrm{L}g = t^{\beta/(1-\beta)}\mathcal{L}^0 f_1, \tag{4.4a}$$

$$\mathcal{L}^0 f_1 = \frac{1}{1-\beta} f_1 - (f_1^m)'' - \frac{m-\beta}{2(1-\beta)}\zeta f_1' + b f_1^\beta. \tag{4.4b}$$

As a function f_1 we take

$$f_1(\zeta) = C_0(\zeta_0 - \zeta)_+^{\gamma_0}, \qquad 0 < \zeta < +\infty,$$

where $C_0,\ \zeta_0,\ \gamma_0$ are some positive constants. Taking $\gamma_0 = 2/(m-\beta)$, from (4.4b) we have

$$\mathcal{L}^0 f_1 = bC_0^\beta(\zeta_0-\zeta)^{\frac{2\beta}{m-\beta}}\left\{1 - \left(\frac{C_0}{C_*}\right)^{m-\beta} + \frac{C_0^{1-\beta}}{b(1-\beta)}\zeta_0(\zeta_0-\zeta)^{\frac{2-m-\beta}{m-\beta}}\right\}. \tag{4.5}$$

To prove an upper estimation we take $C_0 = C_2,\ \zeta_0 = \zeta_2$ (see Appendix). If $m+\beta > 2$, then we have

$$\mathcal{L}^0 f_1 \geq bC_2^\beta(\zeta_2-\zeta)^{\frac{2\beta}{m-\beta}}\left\{1 - \left(\frac{C_2}{C_*}\right)^{m-\beta} + \frac{C_2^{1-\beta}}{b(1-\beta)}\zeta_2^{\frac{2(1-\beta)}{m-\beta}}\right\} = 0 \quad \text{for } 0 \leq \zeta \leq \zeta_2,$$

while if $1 \leq m < 2-\beta$, we have

$$\mathcal{L}^0 f_1 \geq bC_2^\beta(\zeta_2-\zeta)^{\frac{2\beta}{m-\beta}}\left\{1 - \left(\frac{C_2}{C_*}\right)^{m-\beta}\right\} = 0 \quad \text{for } 0 \leq \zeta \leq \zeta_2.$$

From (4.4a) it follows that

$$\mathrm{L}g \geq 0 \quad \text{for } 0 < x < \zeta_2\, t^{\frac{m-\beta}{2(1-\beta)}}, \quad 0 < t < +\infty, \tag{4.6a}$$

$$\mathrm{L}g = 0 \quad \text{for } x > \zeta_2\, t^{\frac{m-\beta}{2(1-\beta)}}, \qquad 0 < t < +\infty. \tag{4.6b}$$

Lemma 2.1 of [3] implies that g is a supersolution of (1.1) in $\{(x,t):\ x>0,\ t>0\}$. Since

$$g(x,0) = u(x,0) = 0 \qquad \text{for } 0 \leq x < +\infty, \tag{4.7a}$$

$$g(0,t) = u(0,t) \qquad \text{for } 0 \leq t < +\infty, \tag{4.7b}$$

from Comparison Theorem 2.4 of [3], the right-hand side of (2.11) follows.
If $1 \leq m < 2-\beta$ then to prove the lower estimation we take $C_0 = C_1, \zeta_0 = \zeta_1,\ \gamma_0 = 2/(m-\beta)$. Then from (4.5) we derive

$$\mathcal{L}^0 f_1 \leq bC_1^\beta(\zeta_1-\zeta)^{\frac{2\beta}{m-\beta}}\left\{1 - \left(\frac{C_1}{C_*}\right)^{m-\beta} + \frac{C_1^{1-\beta}}{b(1-\beta)}\zeta_1^{\frac{2(1-\beta)}{m-\beta}}\right\} = 0 \quad \text{for } 0 \leq \zeta \leq \zeta_1,$$

and from (4.4a) it follows that

$$\mathrm{L}g \leq 0 \quad \text{for } 0 < x < \zeta_1\, t^{\frac{m-\beta}{2(1-\beta)}}, \quad 0 < t < +\infty, \tag{4.8a}$$

$$\mathrm{L}g = 0 \quad \text{for } x > \zeta_1\, t^{\frac{m-\beta}{2(1-\beta)}}, \qquad 0 < t < +\infty. \tag{4.8b}$$

As before, from Lemma 2.1 of [3], (4.7), and Comparison Theorem 2.4 of [3], the left-hand side of (2.11) follows.
If $m+\beta>2$, then to prove the lower estimation we take $C_0=C_1,\ \zeta_0=\zeta_1, \gamma_0=1/(m-1)$. Then from (4.4b) we have

$$\begin{aligned}
&\mathcal{L}^0 f_1 = C_1(1-\beta)^{-1}(\zeta_1-\zeta)^{\frac{2-m}{m-1}}\\
&\times\left\{\zeta_1-\frac{m+\beta-2}{2(m-1)}\zeta-C_1^{m-1}\frac{m(1-\beta)}{(m-1)^2}+b(1-\beta)C_1^{\beta-1}(\zeta_1-\zeta)^{\frac{m+\beta-2}{m-1}}\right\}\\
&\le C_1(1-\beta)^{-1}(\zeta_1-\zeta)^{\frac{2-m}{m-1}}\\
&\times\left\{\zeta_1-C_1^{m-1}m(1-\beta)(m-1)^{-2}+b(1-\beta)C_1^{\beta-1}\zeta_1^{\frac{m+\beta-2}{m-1}}\right\}=0 \qquad \text{for } 0<\zeta<\zeta_1,
\end{aligned}$$

which again implies (4.8). As before, from Lemma 2.1 of [3], (4.7), and Comparison Theorem 2.4 of [3], the left-hand side of (2.11) follows.

By applying the same analysis it may easily be checked that the alternative upper estimation is valid if $C_0=\bar{C}_2,\ \zeta_0=\bar{\zeta}_2,\ \gamma_0=1/(m-1)$.
Let $m+\beta>2$ and $0<C<C_*$. Consider a function

$$g(x,t)=\left[C^{1-\beta}(-x)_+^{\frac{2(1-\beta)}{m-\beta}}-b(1-\beta)(1-\gamma)t\right]_+^{\frac{1}{1-\beta}}, \qquad x\in\mathbb{R},\quad t>0,$$

where γ is a constant such that $\gamma\in[0,1)$. Let us estimate $\mathrm{L}g$ in

$$\begin{aligned}
M &= \Big\{(x,t):\ -\infty<x<\mu_\gamma(t),\quad t>0\Big\},\\
\mu_\gamma(t) &= -\Big[b(1-\beta)(1-\gamma)C^{\beta-1}t\Big]^{\frac{m-\beta}{2(1-\beta)}}.
\end{aligned}$$

We have

$$\mathrm{L}g=bg^\beta \mathrm{S},$$

$$\begin{aligned}
\mathrm{S}=\gamma&-2mb^{-1}(m-\beta)^{-2}(2-m-\beta)C^{m-\beta}\left[1-\frac{b(1-\beta)(1-\gamma)t}{C^{1-\beta}(-x)^{\frac{2(1-\beta)}{m-\beta}}}\right]^{\frac{m-1}{1-\beta}}\\
&-4mb^{-1}(m-\beta)^{-2}(m+\beta-1)C^{m-\beta}\left[1-\frac{b(1-\beta)(1-\gamma)t}{C^{1-\beta}(-x)^{\frac{2(1-\beta)}{m-\beta}}}\right]^{\frac{m+\beta-2}{1-\beta}}. \qquad \text{(4.9a)}
\end{aligned}$$

Hence

$$\mathrm{S}\Big|_{t=0}=\gamma-\left(\frac{C}{C_*}\right)^{m-\beta}, \qquad \mathrm{S}\Big|_{x=\mu_\gamma(t)}=\gamma. \qquad \text{(4.9b)}$$

Moreover

$$\begin{aligned}
&\mathrm{S}_t=\frac{2mC^{m-1}(1-\gamma)}{(m-\beta)^2}(-x)^{\frac{2(\beta-1)}{m-\beta}}\left[1-C^{\beta-1}(-x)^{\frac{2(\beta-1)}{m-\beta}}b(1-\beta)(1-\gamma)t\right]^{\frac{m+2\beta-3}{1-\beta}}\\
&\times\left[(m+\beta-2)(m-1)C^{\beta-1}b(1-\beta)(-x)^{\frac{2(\beta-1)}{m-\beta}}(1-\gamma)t+(m+\beta-2)(m+2\beta-1)\right]\\
&\ge\ 0 \quad \text{in } M.
\end{aligned}$$

Thus

$$\gamma - (C/C_*)^{m-\beta} \le \mathrm{S} \le \gamma \quad \text{in} \quad M.$$

If we take $\gamma = (C/C_*)^{m-\beta}$ (respectively, $\gamma = 0$), then we have

$$\mathrm{L}g \ge 0 \quad (\text{respectively, } \mathrm{L}g \le 0) \quad \text{in} \quad M, \tag{4.10a}$$

$$\mathrm{L}g = 0 \quad \text{for} \quad x > \mu_\gamma(t), \quad t > 0. \tag{4.10b}$$

As before, from Lemma 2.1 of [3] and a comparison principle, the estimation (2.13) follows.
Let $1 \le m < 2 - \beta$ and $0 < C < C_*$. First, we can establish the following rough estimation:

$$\left[C^{1-\beta}(-x)_+^{\frac{2(1-\beta)}{m-\beta}} - b(1-\beta)\Big(1 - (C/C_*)^{m-\beta}\Big)t\right]_+^{\frac{1}{1-\beta}} \le u(x,t)$$

$$\le C(-x)_+^{\frac{2}{m-\beta}} \quad \text{for} \quad x \in \mathbb{R}, \quad 0 \le t < +\infty. \tag{4.11}$$

To prove the left-hand side we consider the function g as in the case when $m + \beta > 2$ with $\gamma = (C/C_*)^{m-\beta}$. As before, we then derive (4.9a) and, since

$$\mathrm{S}_t \le 0 \quad \text{in} \quad M,$$

we have $S \le 0$ in M. Hence, (4.10) is valid with $\le$ in (4.10a). As before, from Lemma 2.1 of [3] and a comparison principle, the left-hand side of (4.11) follows. To prove the right-hand side of (4.11) it is enough to observe that

$$\mathrm{L}u_0 = bu_0^\beta\Big(1 - (C/C_*)^{m-\beta}\Big) \ge 0 \quad \text{for} \quad x \in \mathbb{R}, \quad t \ge 0,$$

and to apply the comparison principle.
Using (4.11), we can now establish a more accurate estimation (2.14). For that, consider a function

$$g(x,t) = C_0\Big(-\zeta_0\, t^{\frac{m-\beta}{2(1-\beta)}} - x\Big)_+^{\frac{2}{m-\beta}} \quad \text{in} \quad G_\ell,$$

$$G_\ell = \Big\{(x,t) : \zeta(t) = -\ell\, t^{\frac{m-\beta}{2(1-\beta)}} < x < +\infty, \quad 0 < t < +\infty\Big\},$$

where $C_0 > 0$, $\zeta_0 > 0$, $\ell > \zeta_0$ are some constants. Calculating $\mathrm{L}g$ in

$$G_\ell^+ = \Big\{(x,t) : \zeta(t) < x < -\zeta_0\, t^{\frac{m-\beta}{2(1-\beta)}}, \quad 0 < t < +\infty\Big\},$$

we have

$$\mathrm{L}g = bg^\beta \mathrm{S}, \qquad \mathrm{S} = 1 - (C_0/C_*)^{m-\beta} - \Big(b(1-\beta)\Big)^{-1} C_0^{1-\beta}\zeta_0\, t^{\frac{m+\beta-2}{2(1-\beta)}}$$

$$\times \Big(-\zeta_0\, t^{\frac{m-\beta}{2(1-\beta)}} - x\Big)^{\frac{2-m-\beta}{m-\beta}}. \tag{4.12}$$

Hence, if we take $C_0 = C_*$, then

$$\mathrm{L}g \le 0 \quad \text{in} \quad G_\ell^+; \ \mathrm{L}g = 0 \quad \text{in} \quad G_\ell \backslash \bar{G}_\ell^+. \tag{4.13}$$

To obtain a lower estimation we now choose $\zeta_0 = \zeta_3,\ \ell = \ell_0$ (see Appendix). Using (4.11), we then have

$$g(\zeta(t),t) = C_*(\ell_0 - \zeta_3)^{\frac{2}{m-\beta}} t^{\frac{1}{1-\beta}} = \Big(b(1-\beta)\theta_* t\Big)^{\frac{1}{1-\beta}}$$

$$= \left[C^{1-\beta}\ell_0^{\frac{2(1-\beta)}{m-\beta}} - b(1-\beta)\Big(1-(C/C_*)^{m-\beta}\Big)\right]^{\frac{1}{1-\beta}}\ t^{\frac{1}{1-\beta}}$$

$$\le u(\zeta(t),t), \quad t \ge 0, \tag{4.14a}$$

$$g(x,0) = u(x,0) = 0, \qquad 0 \le x \le x_0, \tag{4.14b}$$

$$g(x_0,t) = u(x_0,t) = 0, \qquad t \ge 0, \tag{4.14c}$$

where $x_0 > 0$ is an arbitrary fixed number. By using (4.13), (4.14), and Lemma 2.1 of [3], we can apply Comparison Theorem 3.4 of [3] in

$$G'_{\ell_0} = G_{\ell_0} \cap \Big\{x < x_0\Big\}.$$

Since $x_0 > 0$ is an arbitrary number the desired lower estimation from (2.14) follows.

Let us now prove the right-hand side of (2.14). Since

$$\mathrm{S}_x \ge 0 \quad \text{for} \quad \zeta(t) < x < -\zeta_0\, t^{\frac{m-\beta}{2(1-\beta)}}, \quad t > 0,$$

from (4.12) it follows that

$$\mathrm{S} \ge \mathrm{S}\Big|_{x=\zeta(t)} = 1 - (C_0/C_*)^{m-\beta} - \Big(b(1-\beta)\Big)^{-1} C_0^{1-\beta}\zeta_0(\ell-\zeta_0)^{\frac{2-m-\beta}{m-\beta}}.$$

Taking now $C_0 = C_3,\ \zeta_0 = \zeta_4,\ \ell = \ell_1$ (see Appendix), we have

$$\mathrm{S}\Big|_{x=\zeta(t)} = 0;$$

hence (by using (4.11))

$$\mathrm{L}g \ge 0 \quad \text{in} \quad G^+_{\ell_1},\ \mathrm{L}g = 0 \quad \text{in} \quad G_{\ell_1}\backslash\bar{G}^+_{\ell_1},$$

$$u(\zeta(t),t) \le C\ell_1^{\frac{2}{m-\beta}} t^{\frac{1}{1-\beta}} = C_3(\ell_1-\zeta_4)^{\frac{2}{m-\beta}} t^{\frac{1}{1-\beta}} = g(\zeta(t),t), \quad t \ge 0,$$

and, for arbitrary $x_0 > 0$, (4.14b) and (4.14c) are valid. As before, applying the Comparison Theorem 3.4 of [3] in G'_{ℓ_1}, we then derive the right-hand side of (2.14), since $x_0 > 0$ is arbitrary.

From (2.11), (2.13), and (2.14) it follows that

$$\zeta_1 t^{\frac{m-\beta}{2(1-\beta)}} \le \eta(t) \le \zeta_2 t^{\frac{m-\beta}{2(1-\beta)}}, \quad 0 \le t < +\infty,$$

where the constants ζ_1 and ζ_2 are chosen according to relevant estimations for u. However, it may easily be shown that the proved estimations (2.11), (2.13), and (2.14), together with existence, uniqueness, and comparison results for the original CP (1.1), (1.4) (see section 3), imply the unique solvability of the relevant boundary value problem for the function f_1 from (2.9), as well as the existence of a finite number ζ_* such that $\zeta_* = \sup\{\zeta : f_1(\zeta) > 0\}$. Thus (2.10) is valid. From (2.10) and the respective estimations (2.11), (2.13), or (2.14), the estimation (2.12) follows, where ζ_1 and ζ_2 are chosen according to the relevant estimation for u.

If u_0 satisfies (1.3) with $\alpha = 2/(m-\beta)$ and with $C \neq C_*$, then the asymptotic formulae (2.15) and (2.16) may be proved as the similar estimations (2.1) and (2.3) were in Lemma 3.1.

(3) Suppose that $b > 0,\ 0 < \beta < 1,\ \alpha > 2/(m-\beta),\ m \geq 1$.

Take an arbitrary sufficiently small number $\varepsilon > 0$. From (1.3), (3.5) follows. Then consider a function

$$g_\varepsilon(x,t) = \Big[(C+\varepsilon)^{1-\beta}(-x)_+^{\alpha(1-\beta)} - (1-\beta)(1-\varepsilon)t\Big]_+^{1/(1-\beta)}. \tag{4.15}$$

Let us estimate $\mathrm{L}g$ in

$$M_1 = \Big\{(x,t):\ x_\varepsilon < x < \eta_{\ell(\varepsilon)}(t), \qquad 0 < t \leq \delta_1\Big\},$$

$$\eta_\ell(t) = -\ell t^{1/\alpha(1-\beta)}, \quad \ell(\varepsilon) = (C+\varepsilon)^{-1/\alpha}\Big[b(1-\beta)(1-\varepsilon)\Big]^{1/\alpha(1-\beta)},$$

where $\delta_1 > 0$ is chosen such that $\eta_{\ell(\varepsilon)}(\delta_1) = x_\varepsilon$. We have

$$\begin{aligned}
\mathrm{L}g &= bg_\varepsilon^\beta\{\varepsilon + S\},\\
S &= -b^{-1}m\alpha(\alpha(1-\beta)-1)(C+\varepsilon)^{m-\beta}(-x)^{\alpha(m-\beta-2)}\Big\{g|x|^{-\alpha}\Big/(C+\varepsilon)\Big\}^{m-1}\\
&\quad -b^{-1}m\alpha^2(m+\beta-1)(C+\varepsilon)^{m-\beta}(-x)^{\alpha(m-\beta)-2}\Big\{g|x|^{-\alpha}\Big/(C+\varepsilon)\Big\}^{m+\beta-2}\\
&= -b^{-1}m\alpha(C+\varepsilon)^{m-\beta}(-x)^{\alpha(m-\beta)-2}\Big\{g|x|^{-\alpha}\Big/(C+\varepsilon)\Big\}^{m+\beta-2}S_1,\\
S_1 &= \Big\{(\alpha(1-\beta)-1)\Big[g|x|^{-\alpha}\Big/(C+\varepsilon)\Big]^{1-\beta} + \alpha(m+\beta-1)\Big\}.
\end{aligned}$$

If $m+\beta \geq 2$, then we can choose $x_\varepsilon < 0$ such that (with sufficiently small $|x_\varepsilon|$)

$$|S| < \varepsilon/2 \quad \text{in} \quad M_1.$$

Thus we have

$$\begin{aligned}
\mathrm{L}g_\varepsilon &> b(\varepsilon/2)g_\varepsilon^\beta \quad \Big(\text{respectively, } \mathrm{L}g_{-\varepsilon} < -b(\varepsilon/2)g_{-\varepsilon}^\beta\Big) \text{ in } M_1,\\
\mathrm{L}g_{\pm\varepsilon} &= 0 \quad \text{for } x > \eta_{\ell(\pm\varepsilon)}(t), \quad 0 < t \leq \delta_1,\\
g_\varepsilon(x,0) &\geq u_0(x) \quad \Big(\text{respectively, } g_{-\varepsilon}(x,0) \leq u_0(x)\Big), \quad x \geq x_\varepsilon.
\end{aligned}$$

Since u and g are continuous functions, $\delta = \delta(\varepsilon) \in (0, \delta_1]$ may be chosen such that

$$g_\varepsilon(x_\varepsilon,t) \geq u(x_\varepsilon,t) \quad \Big(\text{respectively, } g_{-\varepsilon}(x_\varepsilon,t) \leq u(x_\varepsilon,t)\Big), \quad 0 \leq t \leq \delta.$$

From Lemma 2.1 of [3] and Comparison Theorem 2.4 of [3] it follows that

$$g_{-\varepsilon} \leq u \leq g_\varepsilon, \qquad x \geq x_\varepsilon, \qquad 0 \leq t \leq \delta, \tag{4.16a}$$

$$\eta_{\ell(-\varepsilon)}(t) \leq \eta(t) \leq \eta_{\ell(\varepsilon)}(t), \qquad 0 \leq t \leq \delta, \tag{4.16b}$$

which imply (2.17) and (2.18).

Let $1 \le m < 2-\beta$. In this case the left-hand side of (4.16) may be proved similarly. Moreover, we can replace $1+\varepsilon$ with 1 in $g_{-\varepsilon}$ and $\eta_{\ell(-\varepsilon)}$.
To prove a relevant upper estimation, consider a function

$$g(x,t) = C_6\left(-\zeta_5 t^{\frac{1}{\alpha(1-\beta)}} - x\right)_+^{\alpha} \quad \text{in } \ G_{\ell,\delta},$$
$$G_{\ell,\delta} = \Big\{(x,t):\ \eta_\ell(t) < x < +\infty, \quad 0 < t < \delta\Big\},$$

where $\ell \in (\ell_*, +\infty)$ and

$$\zeta_5 = (\ell_*/\ell)^{\alpha(1-\beta)}(1-\varepsilon)\ell,$$
$$C_6 = \left[1-(\ell_*/\ell)^{\alpha(1-\beta)}(1-\varepsilon)\right]^{-\alpha}\left[C^{1-\beta} - \ell^{-\alpha(1-\beta)}b(1-\beta)(1-\varepsilon)\right]^{1/(1-\beta)}.$$

From (2.18) it follows that for all $\ell > \ell_*$ and for all sufficiently small $\varepsilon > 0$ there exists a $\delta = \delta(\varepsilon,\ell) > 0$ such that

$$u\Big(\eta_\ell(t), t\Big) \le \left[C^{1-\beta}\ell^{\alpha(1-\beta)} - b(1-\beta)(1-\varepsilon)\right]^{\frac{1}{1-\beta}} t^{\frac{1}{1-\beta}}, \quad 0 \le t \le \delta. \tag{4.17}$$

Calculating Lg in

$$G^+_{\ell,\delta} = \Big\{(x,t):\ \eta_\ell(t) < x < -\zeta_5 t^{\frac{1}{\alpha(1-\beta)}}, \quad 0 < t < \delta\Big\},$$

we have

$$\mathrm{L}g = bg^\beta S, \quad S = 1 - \Big(b(1-\beta)\Big)^{-1} C_6^{1/\alpha}\zeta_5\left\{gt^{1/(\beta-1)}\right\}^{1-\beta-1/\alpha}$$
$$-b^{-1}\alpha m(\alpha m-1)C_6^{2/\alpha}g^{m-\beta-2/\alpha}.$$

Since

$$S_x \ge 0 \quad \text{in } \ G^+_{\ell,\delta},$$

we have

$$S \ge S\big|_{x=\eta_\ell(t)} = 1 - \Big(b(1-\beta)\Big)^{-1} C_6^{1-\beta}\zeta_5(\ell-\zeta_5)^{\alpha(1-\beta)-1}$$
$$-b^{-1}C_6^{m-\beta}\alpha m(\alpha m-1)\left\{(\ell-\zeta_5)t^{1/\alpha(1-\beta)}\right\}^{\alpha(m-\beta)-2}.$$

Then we have

$$S \ge \varepsilon - b^{-1}C_6^{m-\beta}\alpha m(\alpha m-1)\left\{(\ell-\zeta_5)t^{1/\alpha(1-\beta)}\right\}^{\alpha(m-\beta)-2} \quad \text{in } \ G^+_{\ell,\delta}.$$

Hence, we can choose $\delta = \delta(\varepsilon) > 0$ so small that

$$\mathrm{L}g \ge b(\varepsilon/2)g^\beta \quad \text{in } \ G^+_{\ell,\delta}. \tag{4.18a}$$

Using (4.17), we can apply the Comparison Theorem 3.4 of [3] in $G'_{\ell,\delta} = G_{\ell,\delta} \cap \{x < x_0\}$, where $x_0 > 0$ is an arbitrary fixed number. We have

$$\mathrm{L}g = 0 \quad \text{in } \ G'_{\ell,\delta}\backslash\bar{G}^+_{\ell,\delta}, \tag{4.18b}$$

$$u(\eta_\ell(t),t) \le \left[C^{1-\beta}\ell^{\alpha(1-\beta)} - b(1-\beta)(1-\varepsilon)\right]^{\frac{1}{1-\beta}} t^{\frac{1}{1-\beta}}$$

$$= C_6(\ell-\zeta_5)^\alpha t^{\frac{1}{\alpha(1-\beta)}} = g(\eta_\ell(t),t), \quad 0 \le t \le \delta. \tag{4.18c}$$

$$u(x_0,t) = g(x_0,t) = 0, \qquad 0 \le t \le \delta, \tag{4.18d}$$

$$u(x,0) \ = g(x,0) \ = 0, \qquad 0 \le x \le x_0. \tag{4.18e}$$

Since $x_0 > 0$ is arbitrary, from (4.18) and the Comparison Theorem 3.4 of [3], it follows that for all $\ell > \ell_*$ and $\varepsilon > 0$ there exists $\delta = \delta(\varepsilon,\ell) > 0$ such that

$$u(x,t) \le C_6\left(-\zeta_5 t^{\frac{1}{\alpha(1-\beta)}} - x\right)_+^\alpha \quad \text{in} \quad \bar{G}_{\ell,\delta}. \tag{4.19}$$

Obviously, in view of (2.18) (which is valid along $x = \eta_\ell(t)$), δ may be chosen so small that

$$-\ell t^{1/\alpha(1-\beta)} \le \eta(t) \le -\zeta_5 t^{1/\alpha(1-\beta)}, \quad 0 \le t \le \delta. \tag{4.20}$$

Since $\ell > \ell_*$ and $\varepsilon > 0$ are arbitrary numbers, (2.17) follows from (4.20).

(4a) This case is immediate.

(4b) Let $\beta = 1$, $\alpha > 2/(m-1)$. As before, from (1.3), (3.5) follows. Then consider a function

$$g(x,t) = (C-\varepsilon)(-x)_+^\alpha \exp(-bt),$$

which satisfies

$$\mathrm{L}g \le 0 \quad \text{for} \quad x_\varepsilon < x < 0, \quad t > 0; \qquad \mathrm{L}g = 0 \quad \text{for} \quad x > 0, \quad t > 0.$$

Obviously, we can choose $\delta = \delta(\varepsilon) > 0$ such that

$$g(x_\varepsilon,t) \le u(x_\varepsilon,t), \qquad 0 \le t \le \delta_\varepsilon,$$

and from a comparison principle, the left-hand side of (2.20) immediately follows. To prove the right-hand side, consider a function

$$g(x,t) = (C+\varepsilon)(-x)_+^\alpha \exp(-bt)[1-\varepsilon(b(m-1))^{-1}(1-\exp(-b(m-1)t))]^{1/(1-m)}.$$

We have

$$\mathrm{L}g = (m-1)^{-1}(C+\varepsilon)^{1-m}(-x)^{\alpha(1-m)}\exp(-bmt)g^m$$
$$\times\left\{\varepsilon - (m-1)(C+\varepsilon)^{m-1}\alpha m(\alpha m-1)(-x)^{\alpha(m-1)-2}\right\}, \qquad x < 0, \quad t > 0,$$

and hence, if $|x_\varepsilon|$ is small enough,

$$\mathrm{L}g \ge 0 \quad \text{for} \quad x_\varepsilon < x < 0, \quad t > 0; \qquad \mathrm{L}g = 0 \quad \text{for} \quad x > 0, t > 0.$$

As before, a comparison principle implies the right-hand side of (2.20). The estimations (2.21)–(2.23) in the cases (4c) and (4d) may be proved similarly.

(II) $b = 0$.

(1) Let $m > 1$, $0 < \alpha < 2/(m-1)$.

First assume that u_0 is defined by (1.4). The self-similar form (2.25) and the formula (2.26) are well-known results (see Remark 2.1 and Lemma 3.1).

To prove (2.27), consider a function

$$g(x,t) = t^{\alpha/(2-\alpha(m-1))} f(\xi).$$

We have

$$\begin{aligned} \mathrm{L}g &= t^{(m\alpha-2)/(2-\alpha(m-1))}\, \mathcal{L}_t f, \\ \mathcal{L}_t f &= \frac{\alpha}{2-\alpha(m-1)} f - \frac{1}{2-\alpha(m-1)} \xi f' - (f^m)''. \end{aligned}$$

As a function f we take

$$f(\xi) = C_0(\xi_0 - \xi)_+^{1/(m-1)}, \qquad 0 < \xi < +\infty,$$

where C_0 and ξ_0 are some positive constants. Then we have

$$\begin{aligned} &\mathcal{L}_t f = \Big(2-\alpha(m-1)\Big)^{-1} (m-1)^{-1} C_0 (\xi_0 - \xi)^{\frac{2-m}{m-1}} R(\xi) \quad \text{for} \quad 0 \le \xi < \xi_0, \quad t > 0, \\ &R(\xi) = \alpha(m-1)\xi_0 + \Big(1-\alpha(m-1)\Big)\xi - (m-1)^{-1} m \Big(2-\alpha(m-1)\Big) C_0^{m-1}. \end{aligned}$$

To prove an upper estimation we take $C_0 = C_5,\ \xi_0 = \xi_4$. Then we have

$$R(\xi) \ge \nu_\alpha \xi_4 - (m-1)^{-1} m \Big(2-\alpha(m-1)\Big) C_5^{m-1} = 0 \text{ for } 0 \le \xi \le \xi_4,$$

where

$$\nu_\alpha = \left\{1 \ \text{ if } \ \alpha \ge (m-1)^{-1};\ \alpha(m-1) \ \text{ if } \ \alpha < (m-1)^{-1}\right\}.$$

Hence

$$\begin{aligned} \mathrm{L}g &\ge 0 \quad \text{for} \quad 0 < x < \xi_4 t^{1/(2-\alpha(m-1))}, \quad t > 0, \\ \mathrm{L}g &= 0 \quad \text{for} \quad x > \xi_4 t^{1/(2-\alpha(m-1))}, \qquad t > 0, \\ u(0,t) &= g(0,t),\ t \ge 0;\ u(x,0) = g(x,0), \qquad x \ge 0. \end{aligned}$$

Lemma 2.1 of [3] and a comparison principle imply the right-hand side of (2.27). The left-hand side of (2.27) may be established similarly if we take $C_0 = C_4,\ \xi_0 = \xi_3$. (2.2) and (2.4) are well-known results (see Remark 2.1 and Lemma 3.1). Finally, (2.5)–(2.7) easily follow from (2.26) and (2.27). If u_0 satisfies (1.3) with $0 < \alpha < 2/(m-1)$, then (2.1)–(2.3) follow from Lemma 3.1.

The cases (2) and (3) are immediate.

Appendix. We give here explicit values of the constants used in section 2 in the outline of the results for Case (I(2)) and later in section 4 during the proof of these results.

$$\zeta_1 = A_1^{\frac{m-1}{2}} \Big(m(1-\beta)\Big)^{\frac{1}{2}} \Big(1 + b(1-\beta)A_1^{\beta-1}\Big)^{-\frac{1}{2}} (m-1)^{-1}, \quad C_1 = A_1\, \zeta_1^{-\mu}$$

$$\text{if} \ \ m + \beta > 2,$$

$$\zeta_1 = A_1^{\frac{m-1}{2}}\Big(m(1-\beta)\Big)^{\frac12}\Big(1+b(1-\beta)A_1^{\beta-1}\Big)^{-\frac12}\Big(2(m+\beta)\Big)^{\frac12}(m-\beta)^{-1},$$

$$C_1 = A_1\,\zeta_1^{-\frac{2}{m-\beta}} \qquad \text{if} \quad 1 \le m < 2-\beta,$$

$$\zeta_2 = A_1^{\frac{m-1}{2}}\Big(m(1-\beta)\Big)^{\frac12}\Big(1+b(1-\beta)A_1^{\beta-1}\Big)^{-\frac12}\Big(2(m+\beta)\Big)^{\frac12}(m-\beta)^{-1},$$

$$C_2 = A_1\,\zeta_2^{-\frac{2}{m-\beta}} \qquad \text{if} \quad m+\beta > 2,$$

$$\zeta_2 = \Big(A_1/C_*\Big)^{\frac{m-\beta}{2}}, \quad C_2 = C_* \qquad \text{if} \quad 1 \le m < 2-\beta,$$

$$\bar\zeta_2 = A_1^{\frac{m-1}{2}}\left(\frac{2m(1-\beta)}{(m-\beta)(m-1)}\right)^{\frac12}, \qquad \bar C_2 = A_1\,\bar\zeta_2^{-\frac{1}{m-1}} \quad \text{if} \quad m+\beta > 2,$$

$$\bar\zeta_2 = A_1^{\frac{m-1}{2}}\Big(1+b(1-\beta)A_1^{\beta-1}\Big)^{-\frac12}\Big[m(1-\beta)\Big]^{\frac12}(m-1)^{-1}, \quad \bar C_2 = A_1\,\bar\zeta_2^{-\frac{1}{m-1}}$$
$$\text{if} \quad 1 < m < 2-\beta.$$

$$\ell_0 = C_*^{\frac{\beta-m}{2}}\Big(C_*/C\Big)^{\frac{(1-\beta)(m-\beta)}{2-m-\beta}}\Big(b(1-\beta)\theta_*\Big)^{\frac{m-\beta}{2(1-\beta)}},$$

$$\zeta_3 = C_*^{\frac{\beta-m}{2}}\left[\Big(C_*/C\Big)^{\frac{(1-\beta)(m-\beta)}{2-m-\beta}} - 1\right]\Big(b(1-\beta)\theta_*\Big)^{\frac{m-\beta}{2(1-\beta)}},$$

$$\theta_* = \left[1-\Big(C/C_*\Big)^{m-\beta}\right]\left[\Big(C_*/C\Big)^{\frac{(m-\beta)(1-\beta)}{2-m-\beta}} - 1\right]^{-1},$$

$$\ell_1 = C^{\frac{\beta-m}{2}}\left[b(1-\beta)(\delta_*\Gamma)^{-1}\Big(1-\delta_*\Gamma-(1-\delta_*\Gamma)^{-1}\Big(C/C_*\Big)^{m-\beta}\Big)\right]^{\frac{m-\beta}{2(1-\beta)}},$$

$$\zeta_4 = \delta_*\Gamma\ell_1, \qquad \Gamma = 1-\Big(C/C_*\Big)^{\frac{m-\beta}{2}}, \qquad C_3 = C\Big(1-\delta_*\Gamma\Big)^{\frac{2}{\beta-m}},$$

where $\delta_* \in (0,1)$ satisfies

$$g(\delta_*) = \max_{[0;1]} g(\delta), \qquad g(\delta) = \delta^{\frac{2-m-\beta}{m-\beta}}\left[1-\delta\Gamma-(1-\delta\Gamma)^{-1}\Big(C/C_*\Big)^{m-\beta}\right].$$

A NOTE ON THE FORMATION OF SINGULARITIES FOR QUASI-LINEAR HYPERBOLIC SYSTEMS*

MANFRIN RENATO†

Abstract. For quasi-linear strictly hyperbolic systems, we give sufficient conditions which guarantee that singularities of the solution must occur in finite time. Moreover, we improve some of the results of [*Comm. Pure Appl. Math.*, 33 (1980), pp. 241–263] and [*Osaka J. Math.*, 34 (1997), pp. 99–113] for the wave equation $u_{tt} - a(u_x)u_{xx} = 0$. Our assumptions are rather general, in particular, we require only a weak nonlinearity condition and we do not impose restrictions on the size of the initial data.

Key words. formation of singularities, quasi-linear hyperbolic systems, weak nonlinearity

AMS subject classifications. 35L65, 35L67, 35L70

PII. S0036141098341526

Introduction. We shall be concerned with the formation of singularities of solutions for quasi-linear strictly hyperbolic 2×2 systems when the assumption of *genuine nonlinearity* (in the sense of Lax) is replaced by weaker conditions. More precisely, let us recall that the system in $\big[0,\infty\big)\times\mathbb{R}_x$

$$\begin{cases} \dfrac{\partial r}{\partial t} + \lambda(r,s)\dfrac{\partial r}{\partial x} = 0, \\[2ex] \dfrac{\partial s}{\partial t} + \mu(r,s)\dfrac{\partial s}{\partial x} = 0\,, \end{cases} \tag{1}$$

with smooth coefficients $\lambda(r,s) > \mu(r,s)$ (as is well known, general strictly hyperbolic 2×2 systems can be made diagonal, introducing the so-called *Riemann invariants*), is genuinely nonlinear if

$$\frac{\partial\lambda}{\partial r} \neq 0\,, \quad \frac{\partial\mu}{\partial s} \neq 0 \quad \text{for all } r,\, s\,. \tag{2}$$

Then, we will apply our results to the classical vibrating string equation

$$w_{tt} - a(w_x)w_{xx} = 0, \qquad w(0,x) = w_0(x),\ w_t(0,x) = w_1(x) \tag{3}$$

with $a(\eta) > 0$ smooth, which is equivalent to the system

$$\begin{aligned} &u_t - v_x = 0, \\ &v_t - a(u)u_x = 0\,, \end{aligned} \tag{4}$$

where $u = w_x$ and $v = w_t$. In fact, since $a(\eta)$ is typically an even function, we have $a'(0) = 0$ and the 2×2 system (4) is *not* genuinely nonlinear. In [10] Klainerman and Majda considered the nonlinear wave equation (3) assuming that

$$a^{(1)}(0) = \cdots = a^{(p-1)}(0) = 0, \quad a^{(p)}(0) \neq 0, \tag{5}$$

for some integer $p > 1$. They proved that for sufficiently small, nontrivial (essentially) periodic initial data $w_0(x)$, $w_1(x)$, the classical C^2 solution $w(t,x)$ develops singularities in finite time.

More recently, the technique of [10] was applied by Colombini and Del Santo [2] to study the formation of singularities for system (1). When (2) is replaced by the weaker condition

$$\frac{\partial \lambda}{\partial r} \geq 0 \ (\leq 0) \quad \text{for all } (r,s) \text{ in a neighborhood } W \text{ of the origin in } \mathbb{R}^2 \tag{6}$$

and $\lambda_r(r,s)$ is not identically zero on any open subset of W, they proved the formation of singularities for small, nonconstant periodic initial data.

Then, assuming $a'(\eta) \geq 0 \ (\leq 0)$ for all $\eta \in \mathbb{R}$ and that $a(\eta)$ is not constant on any open interval, they showed that the classical C^2 solutions of (3) with small, nontrivial periodic initial data develop singularities in the second derivatives in finite time.

In this paper, without restrictions on the size of the data and under weak nonlinearity conditions, we prove that nontrivial solutions of (1) and (3) develop singularity in finite time. Our nonlinearity assumptions are of the same type considered in [2], but the class of initial data is more general.

All the proofs are based on the study of the integrals giving the *wave infinitesimal compression ratios* $\frac{\partial x_1}{\partial \alpha}(t,\alpha)$, $\frac{\partial x_2}{\partial \beta}(t,\beta)$; more precisely, let us recall that (see section 2 below)

$$\frac{\partial x_1}{\partial \alpha}(t,\alpha) = e^{h_1(t)-h_1(0)} \left\{ 1 + r_0'(\alpha) \int_0^t \lambda_r\big(r_0(\alpha), s(\tau, x_1(\tau,\alpha))\big)\, e^{h_1(0)-h_1(\tau)}\, d\tau \right\},$$

$$\frac{\partial x_2}{\partial \beta}(t,\beta) = e^{h_2(t)-h_2(0)} \left\{ 1 + s_0'(\beta) \int_0^t \mu_s\big(r(\tau, x_2(\tau,\beta)), s_0(\beta)\big)\, e^{h_2(0)-h_2(\tau)}\, d\tau \right\}, \tag{7}$$

with $\frac{\partial x_1}{\partial \alpha}(t,\alpha) > 0$, $\frac{\partial x_2}{\partial \beta}(t,\beta) > 0$ for all $t \geq 0$, $\alpha, \beta \in \mathbb{R}$, if $\big(r(t,x), s(t,x)\big)$ is a C^1 solution of (1).

In Theorem 1, we prove the formation of singularities for the C^1 solutions of (1) assuming that $\lambda_r(r,s), \mu_s(r,s) \geq 0$, with $\lambda_r(r,s) > 0$ in a dense subset of $\mathbb{R}^2$. This condition is rather restrictive, but it can be applied to the wave equation (3) generalizing the results of [10], [2] in the case $a'(\eta)$ has a zero of even order, i.e., $p = 2k+1$, $k \in \mathbb{N}$, in (5). Moreover, we give a necessary and sufficient condition for the existence of global C^2 solutions. See Theorem 2 and Corollary 5 below.

In Theorems 3 and 4 (ii) the main idea is to consider the characteristic curve $x_1(t,\alpha)$,

$$\frac{dx_1}{dt} = \lambda(r,s)(t,x_1), \quad x_1(0,\alpha) = \alpha, \tag{8}$$

for two nearby values of α; say, α_1, α_2. Then, we compare the corresponding values of the first integral in (7). More precisely, assuming that $\frac{\partial x_1}{\partial \alpha}(t,\alpha_1) > 0$ for all $t \geq 0$, we show that $\frac{\partial x_1}{\partial \alpha}(t,\alpha_2)$ goes to zero in finite time. Thus, the solution must develop a singularity along the characteristic $t \mapsto x_1(t,\alpha_2)$.

Assuming merely that $a'(\eta)\eta > 0 \ (< 0)$ for $\eta \neq 0$, in Theorem 4 (ii) we prove the formation of singularities for the *periodic* solutions of (3). This improves the results of

[10] for $p = 2k,\ k \in \mathbb{N}$, in (5). Let us remark that, in this last result, the periodicity condition plays a central role.

Finally, let us recall that the formation of singularities for 2×2 quasi-linear systems was already investigated in [1], [4], [9], [11], [15]. For $N \times N$ systems the formation of singularities (for small data) was proved by John [7] and Liu [17]. See also [6], [12], and [13],

1. Main results and remarks. Consider the following initial value problem in $\big[0,\infty\big) \times \mathbb{R}_x$:

$$\begin{cases} \dfrac{\partial r}{\partial t} + \lambda(r,s)\dfrac{\partial r}{\partial x} = 0\,, \\ \dfrac{\partial s}{\partial t} + \mu(r,s)\dfrac{\partial s}{\partial x} = 0\,, \end{cases} \tag{1.1}$$

$$r(0,x) = r_0(x), \quad s(0,x) = s_0(x), \tag{1.2}$$

where $\lambda(r,s)\,,\ \mu(r,s)$ are C^1 functions such that

$$\lambda(r,s) > \mu(r,s) \qquad \text{for all } r\,, s, \tag{1.3}$$

i.e., system (1.1) is *strictly hyperbolic*. To begin with, we will prove the following.

THEOREM 1. *Suppose that*

$$\lambda_r(r,s) \geq 0\,, \quad \mu_s(r,s) \geq 0, \tag{1.4}$$

and

$$\lambda_r(r,s) > 0 \quad \textit{in a dense subset of} \quad \mathbb{R}^2\,. \tag{1.5}$$

Moreover, assume that the initial data $r_0(x)$, $s_0(x)$ are C^1 functions satisfying the following conditions:

$$\begin{cases} \big\|r_0(x)\big\|_{C^0} < \infty\,, \qquad \big\|s_0(x)\big\|_{C^1} < \infty\,, \\ \exists\,\alpha \in \mathbb{R} \quad \textit{such that} \quad r_0'(\alpha) < 0\,, \\ \textit{there does not exist the limit} \quad \lim\limits_{x\to+\infty} s_0(x)\,. \end{cases} \tag{1.6}$$

Then, the solution of the Cauchy problem (1.1), (1.2) *must develop singularities in the first derivatives in a finite time.*

As a particular case of the above result, we have the following.

THEOREM 2. *Consider the Cauchy problem in $\big[0,\infty\big) \times \mathbb{R}_x$,*

$$\begin{aligned} &u_{tt} - a(u_x)u_{xx} = 0, \\ &u(0,x) = u_0(x), \quad u_t(0,x) = u_1(x), \end{aligned} \tag{1.7}$$

with bounded initial data $u_0(x) \in C^2\,, u_1(x) \in C^1$. Assume that $a(\eta)$ is a C^1 function such that

$$a(\eta) > 0\,, \quad a'(\eta) \geq 0 \quad \big(\textit{or } a'(\eta) \leq 0\big) \quad \text{for all } \eta \tag{1.8}$$

and $a'(\eta)$ *is not identically zero on any open interval. Then, provided* $\|u_0'(x)\|_{C^1} < \infty$, $\|u_1(x)\|_{C^1} < \infty$, *and the functions*

$$\begin{aligned} l_0(x) &= \frac{1}{2}\left\{ u_1(x) + \int_0^{u_0'(x)} a(\eta)^{1/2} d\eta \right\}, \\ r_0(x) &= \frac{1}{2}\left\{ u_1(x) - \int_0^{u_0'(x)} a(\eta)^{1/2} d\eta \right\} \end{aligned} \tag{1.9}$$

are not both monotone decreasing (*increasing*) *on* $\mathbb{R}$, *the classical* C^2 *solution* $u(t,x)$ *of* (1.7) *will develop a singularity in a finite time.*

The conditions (1.4), (1.6) can be relaxed if we assume that the maps $r \mapsto \lambda_r(r,s)$ and $s \mapsto \lambda_r(r,s)$ have discrete zeroes. More precisely, we have the following.

THEOREM 3. *Assume that* (1.3) *holds and that*

$$\begin{aligned} &\lambda_r(r,s) \geq 0, \\ &\text{the maps} \quad r \mapsto \lambda_r(r,s), \quad s \mapsto \lambda_r(r,s) \end{aligned} \tag{1.10}$$

have discrete zeroes for all s, r, *respectively. Then, provided* $r_0(x)$, $s_0(x) \in C^1$ *and*

$$\begin{cases} \|r_0(x)\|_{C^0} < \infty, \quad \|s_0(x)\|_{C^1} < \infty, \\ \exists\, \alpha_0 \in \mathbb{R} \quad \text{such that} \quad r_0'(\alpha_0) < 0, \end{cases} \tag{1.11}$$

the solution of the Cauchy problem (1.1), (1.2) *must develop singularities in finite time.*

Finally, in the last part of the paper we will prove the following.

THEOREM 4. *Consider the Cauchy problem* (1.7) *with* $u_0(x) \in C^2, u_1(x) \in C^1$ *such that*

$$\big(u_0'(x),\, u_1(x)\big) \quad \text{is a nonconstant vector.}$$

Assume that $a(\eta) > 0$ for all η *and that one of the following conditions holds*:

(i) $a(\eta)$ *is not identically constant on any open interval and*

$$u_0'(x),\, u_1(x) \to 0 \quad \text{as} \quad |x| \to \infty;$$

(ii) $u_0'(x)$, $u_1(x)$ *are periodic functions* (*with common period* $\pi > 0$) *and* $a'(\eta)$ *satisfies*

$$a'(\eta) < 0 \quad \text{for} \quad \eta < 0, \qquad a'(\eta) > 0 \quad \text{for} \quad \eta > 0. \tag{1.12}$$

Then, the solution $u(t,x)$ *of* (1.7) *will develop singularities in finite time.*

Some remarks. (1) Let us remark that, having $\lambda(r,s)$, $\mu(r,s) \in C^1$ and (1.3), the Cauchy problem (1.1), (1.2) has a *unique* local solution $\big(r(t,x),\, s(t,x)\big)$ on the stripe $\big[0,\, T\big) \times \mathbb{R}_x$ for some $T > 0$, provided

$$\|r_0(x)\|_{C^1} < \infty, \quad \|s_0(x)\|_{C^1} < \infty.$$

More generally, by the results of [5, Theorem VI], (see also [3]) we have the following.

THEOREM A (local solvability). *Consider the N-dimensional quasi-linear system in* $\big[0,\infty\big)\times\mathbb{R}_x$

$$\frac{\partial U}{\partial t} \;=\; A\big(t,x,U\big)\,\frac{\partial U}{\partial x} + B\big(t,x,U\big), \tag{1.13}$$

where $A\big(t,x,U\big)$ *is an* $N\times N$ *matrix;* U, $B\big(t,x,U\big)$ *are* N*-dimensional vectors. Besides, assume that for* $|U|$ *bounded* $A\big(t,x,U\big)$ *is a bounded* C^1 *matrix with bounded partial derivatives, while* $B\big(t,x,U\big)$ *is a bounded* C^0 *vector with continuous and bounded partial derivatives with respect to* x, U.

Finally, let us suppose that the system of (1.13) *is regularly hyperbolic. Namely, the matrix* $A\big(t,x,U\big)$ *has* N *real and distinct eigenvalues* $\lambda_1(t,x,U),\dots,\lambda_N(t,x,U)$ *such that, for* $|U|$ *bounded,*

$$\inf\ \big|\lambda_i(t,x,U)-\lambda_j(t,x,U)\big| \;>\; 0 \quad \text{for} \quad i\neq j \tag{1.14}$$

on $\big[0,\infty\big)\times\mathbb{R}_x$. *Then, the Cauchy problem*

$$\begin{aligned} &\frac{\partial U}{\partial t} \;=\; A\big(t,x,U\big)\,\frac{\partial U}{\partial x} + B\big(t,x,U\big)\,,\\ &U(0,x)=U_0(x) \qquad \text{with} \qquad \big\|U_0(x)\big\|_{C^1}<\infty \end{aligned} \tag{1.15}$$

has a unique C^1 *local solution* $U(t,x)\in C^1\big([0,T)\times\mathbb{R}_x\big)^N$, *with* $T>0$ *depending only on the* C^1 *norm of the data, i.e.,* $T=T\big(\|U_0(x)\|_{C^1}\big)$.

(2) Note that in Theorem A the life-span T depends only on the C^1 norm $\|U_0(x)\|_{C^1}$ of the initial data. Thus, if we know that $\|U(t,\cdot)\|_{C^1}$ is uniformly bounded for t bounded, then the Cauchy problem (1.15) has a unique *global* C^1 solution $U(t,x)$. See [8], [14], [18].

Now, let us consider the Cauchy problem (1.7) assuming that (1.8) holds, with $a'(\eta)$ not identically zero on any open interval, and that $\|u_0'(x)\|_{C^1}$, $\|u_1(x)\|_{C^1}<\infty$. Applying the previous arguments, we have the following conclusion.

COROLLARY 5. *The Cauchy problem* (1.7) *has a unique global classical* C^2 *solution if and only if the functions* $l_0(x)$, $r_0(x)$ *are both monotone decreasing* (*increasing*).

Proof. Thanks to Theorem 2, it is sufficient to consider the following case: $a'(\eta)\geq 0$ and $l_0(x)$, $r_0(x)$ are both monotone decreasing functions.

Introducing the Riemann invariants $l(t,x)$, $r(t,x)$ (see section 4 below), it follows that the Cauchy problem (1.7) is equivalent to the following:

$$\begin{cases} \dfrac{\partial l}{\partial t} - k(l-r)\dfrac{\partial l}{\partial x}=0, & l(0,x)=l_0(x),\\[2ex] \dfrac{\partial r}{\partial t} + k(l-r)\dfrac{\partial r}{\partial x}=0, & r(0,x)=r_0(x)\,, \end{cases} \tag{1.16}$$

where $l_0(x)$, $r_0(x)$ are the functions defined in (1.9); $k(\eta)$ is a C^1 function such that $k(\eta)>0$, $k'(\eta)\geq 0$ for all η and $k'(\eta)$ is not identically zero on any open interval.

Let $U(t,x)=\big(l(t,x),r(t,x)\big)$ be the unique (local) solution given by Theorem A. As it is well known, $l(t,x)$, $r(t,x)$ are constant along the characteristic curves (see section 2). Hence, we have

$$|l(t,x)|\leq\|l_0(x)\|_{C^0}\,,\quad |r(t,x)|\leq\|r_0(x)\|_{C^0}\,. \tag{1.17}$$

Moreover, if the initial data $l_0(x)$, $r_0(x)$ are both monotone decreasing, it is easy to prove that

$$\big|\partial_x U(t,x)\big| \le C\,\big\|\partial_x U_0(x)\big\|_{C^0} \quad \text{for all } t \ge 0 \tag{1.18}$$

for a suitable constant $C \ge 0$ independent of t. In fact, let us consider the component $l(t,x)$. By the relations (4.6), (4.7) below, we have

$$l\big(t, x_1(t,\alpha)\big) = l_0(\alpha) \quad \text{with} \quad \frac{\partial x_1}{\partial \alpha}(t,\alpha) \ge \delta > 0 \quad \text{for all } t \ge 0\,, \tag{1.19}$$

because $l_0'(x) \le 0\,, k'(\eta) \ge 0$. Hence, from (1.19) we find

$$|l_x(t,x)| \le \delta^{-1}\,\|l_0'(x)\|_{C^0}\,. \tag{1.20}$$

Clearly, in the same way it follows that $|r_x(t,x)| \le \delta^{-1}\,\|r_0'(x)\|_{C^0}$. Thus, we obtain the estimate (1.18). Finally, from (1.17), (1.18) we deduce that $\big\|U(t,\cdot)\big\|_{C^1}$ is *uniformly* bounded. Thus, applying Theorem A and the above arguments, the classical C^1 (local) solution of (1.16) exists on $\big[0,\infty\big) \times \mathbb{R}_x$. □

(3) The statements of Theorems 1, 3, 4 are still true if we "change" the inequalities. For example, case (ii) of Theorem 4 holds true if we assume that $a'(\eta) > 0$ for $\eta < 0$ and $a'(\eta) < 0$ for $\eta > 0$.

(4) In case (i) of Theorem 4 we may even suppose that $a(\eta)$ is not identically constant in any open subset of $\big(-\varepsilon, \varepsilon\big)$ for some $\varepsilon > 0$.

Notation. In the following $\|\cdot\|_{C^k}$ will denote the C^k norm, i.e.,

$$\big\|f(x)\big\|_{C^k} \stackrel{\text{def}}{=} \sum_{i=0}^{k} \sup_{x\in\mathbb{R}} \big|f^{(i)}(x)\big|\,. \tag{1.21}$$

Furthermore, the letter C will denote a generic constant, occasionally numbered for clarity.

2. The basic identities for the waves infinitesimal compression ratio. In this section, following essentially Majda [16], we compute the *waves infinitesimal compression ratio* for a smooth solution of a 2×2 strictly hyperbolic system in *one* space dimension. We give the proof in detail for convenience of the reader.

Consider the quasi-linear system in $\big[0,\infty\big) \times \mathbb{R}_x$:

$$\begin{aligned} &\frac{\partial r}{\partial t} + \lambda(r,s)\frac{\partial r}{\partial x} = 0\,,\\ &\frac{\partial s}{\partial t} + \mu(r,s)\frac{\partial s}{\partial x} = 0\,, \end{aligned} \tag{2.1}$$

where $\lambda(r,s)$, $\mu(r,s)$ are C^1 functions such that

$$\lambda(r,s) > \mu(r,s) \quad \text{for all } r,\, s\,. \tag{2.2}$$

Let $r = r(t,x)$, $s = s(t,x)$ be a smooth (C^1) bounded solution of (2.1) in $\big[0,T\big)\times\mathbb{R}_x$, with initial data

$$r(0,x) = r_0(x), \quad s(0,x) = s_0(x)\,. \tag{2.3}$$

Then, on the existence domain we define the two families of characteristic curves

$$\text{(I)} \qquad \frac{dx_1}{dt} = \lambda(r,s)(t,x_1), \quad x_1(0,\alpha) = \alpha, \tag{2.4a}$$

$$\text{(II)} \qquad \frac{dx_2}{dt} = \mu(r,s)(t,x_2), \quad x_2(0,\beta) = \beta. \tag{2.4b}$$

From (2.1), (2.3) for all $t \in \big[0,T\big)$ we have

$$r\big(t,x_1(t,\alpha)\big) = r_0(\alpha), \quad s\big(t,x_2(t,\beta)\big) = s_0(\beta), \tag{2.5}$$

i.e., $r(t,x)$ and $s(r,x)$ are constants along the graphs of $x_1(t,\alpha)$, $x_2(t,\beta)$, respectively. Differentiating both sides of (2.4a) with respect to α, we find

$$\frac{d}{dt}\Big(\frac{\partial x_1}{\partial \alpha}\Big) = \lambda_r\, r_\alpha + \lambda_s\, s_x\, \frac{\partial x_1}{\partial \alpha}\,. \tag{2.6}$$

The right-hand side of (2.6) is evaluated on the characteristic $\big(t,x_1(t,\alpha)\big)$, so we have the following identities:

$$\begin{aligned} r_\alpha &= r_0'(\alpha)\,, \\ s_x &= \frac{1}{\lambda-\mu}\,\frac{d}{dt} s\big(t,x_1(t,\alpha)\big)\,. \end{aligned} \tag{2.7}$$

Thus, defining

$$H_1(r,s) = \int_0^s \frac{\lambda_s(r,z)}{\big(\lambda-\mu\big)(r,z)} dz \tag{2.8}$$

it follows that

$$\frac{d}{dt}\Big(\frac{\partial x_1}{\partial \alpha}\Big) = \lambda_r\, r_0'(\alpha) + \frac{dH_1}{dt}\,\frac{\partial x_1}{\partial \alpha}\,. \tag{2.9}$$

Finally, integrating the linear equation (2.9) and noting that

$$\frac{\partial x_1}{\partial \alpha}(0,\alpha) = 1\,,$$

we obtain the 1-*wave infinitesimal compression ratio*:

$$\frac{\partial x_1}{\partial \alpha}(t,\alpha) = e^{h_1(t)-h_1(0)}\left\{1 + r_0'(\alpha)\int_0^t \lambda_r\big(r_0(\alpha), s(\tau,x_1(\tau,\alpha))\big)\, e^{h_1(0)-h_1(\tau)}\, d\tau\right\}, \tag{2.10}$$

where $h_1(t) = H_1\big(r(t,x_1(t,\alpha)), s(t,x_1(t,\alpha))\big) = H_1\big(r_0(\alpha), s(t,x_1(t,\alpha))\big)$.

By the same arguments, and setting

$$H_2(r,s) = \int_0^r \frac{\mu_r(z,s)}{\big(\mu-\lambda\big)(z,s)} dz\,, \tag{2.11}$$

we have the 2-*wave infinitesimal compression ratio*:

$$\frac{\partial x_2}{\partial \beta}(t,\beta) = e^{h_2(t)-h_2(0)}\left\{1 + s_0'(\beta)\int_0^t \mu_s\big(r(\tau,x_2(\tau,\beta)), s_0(\beta)\big)\, e^{h_2(0)-h_2(\tau)}\, d\tau\right\}, \tag{2.12}$$

where $h_2(t) = H_2\big(r(t,x_2(t,\beta)), s(t,x_2(t,\beta))\big) = H_2\big(r(t,x_2(t,\beta)), s_0(\beta)\big)$.

Some other remarks. In the following we will suppose $r(t,x)$, $s(t,x)$ to be a C^1 solution of (2.1) in $\big[0,T\big)\times\mathbb{R}_x$, with C^1 initial data $r_0(x)$, $s_0(x)$ such that

$$\big\|r_0(x)\big\|_{C^0}<\infty,\quad \big\|s_0(x)\big\|_{C^0}<\infty. \tag{2.13}$$

Then, we have the following.

(1) The functions $r(t,x)$, $s(t,x)$ are uniformly bounded; more precisely from (2.5) we see that

$$|r(t,x)|\le\big\|r_0(x)\big\|_{C^0},\quad |s(t,x)|\le\big\|s_0(x)\big\|_{C^0} \tag{2.14}$$

in $\big[0,T\big)\times\mathbb{R}_x$. Hence, by the assumption (2.2) and the definitions (2.8), (2.11) there exist constants $C>1$, $\delta>1$ such that

$$\begin{aligned}&\frac{1}{\delta}\le\lambda\big(r(t,x),s(t,x)\big)-\mu\big(r(t,x),s(t,x)\big)\le\delta\quad\text{on}\quad\big[0,T\big)\times\mathbb{R}_x\quad\text{and}\\ &\frac{1}{C}\le\exp\big\{h_1(t)-h_1(0)\big\}\le C\,,\\ &\frac{1}{C}\le\exp\big\{h_2(t)-h_2(0)\big\}\le C\end{aligned} \tag{2.15}$$

for all $t\in\big[0,T\big)$ and α, $\beta\in\mathbb{R}$. Here C, δ depend only on $\big\|r_0(x)\big\|_{C^0}$, $\big\|s_0(x)\big\|_{C^0}$.

(2) The *infinitesimal compression ratios* for the two waves must satisfy

$$\frac{\partial x_1}{\partial\alpha}(t,\alpha)>0,\quad \frac{\partial x_2}{\partial\beta}(t,\beta)>0 \tag{2.16}$$

for $0\le t<T$ and for all α, $\beta\in\mathbb{R}$.

In fact, assuming, for example, that

$$\frac{\partial x_1}{\partial\alpha}(t_0,\alpha_0)=0\,, \tag{2.17}$$

for some $t_0\in(0,T)$ and $\alpha_0\in\mathbb{R}$, then we can easily find a contradiction.

From (2.10), (2.17) it follows that

$$r_0'(\alpha_0)\neq 0\,. \tag{2.18}$$

On the other hand, by the relation (2.5) we know that $r\big(t,x_1(t,\alpha_0)\big)=r_0(\alpha_0)$; hence having

$$r_0'(\alpha_0)=\frac{\partial r}{\partial x}\big(t,x_1(t,\alpha_0)\big)\ \frac{\partial x_1}{\partial\alpha}(t,\alpha_0)\,, \tag{2.19}$$

it follows that $r_0'(\alpha_0)=0$, because the right-hand side of (2.19) vanishes for $t=t_0$.

(3) For any fixed $\bar\alpha\in\mathbb{R}$ ($\bar\beta\in\mathbb{R}$) the equation

$$x_1(t,\bar\alpha)=x_2(t,\beta),\quad \big(x_1(t,\alpha)=x_2(t,\bar\beta)\big) \tag{2.20}$$

has a unique solution $\beta=\beta(t)$ ($\alpha=\alpha(t)$). The function $t\mapsto\beta(t)$ is C^1, strictly increasing, and verifies the relation

$$\frac{d\beta(t)}{dt}=\frac{\big[\lambda(r,s)-\mu(r,s)\big](t,x_1(t,\bar\alpha))}{\dfrac{\partial x_2}{\partial\beta}(t,\beta(t))}\,. \tag{2.21}$$

Moreover, if $\|s_0'(x)\|_{C^0} < \infty$, then for some constant $C > 1$ we have

$$\bar\alpha + \frac{1}{C}\ln(1+t) \le \beta(t) \le \bar\alpha + C\,t \quad \text{in} \quad [0,T). \tag{2.22}$$

Proof. The existence of a unique solution $\beta = \beta(t)$ of (2.20) is a consequence of the fact that for any $t \in [0,T)$ the Cauchy problem

$$\frac{dx}{d\tau} = \mu(r,s)(\tau,x), \quad x(\tau)\Big|_{\tau=t} = x_1(t,\bar\alpha) \tag{2.23}$$

has a unique solution in $x(\tau,t)$ defined for $\tau \in [0,T)$. Obviously, we set

$$\beta(t) = x(0,t) \tag{2.24}$$

and, since $\lambda(r,s) > \mu(r,s)$, we find that $\beta(t) \ge \bar\alpha$. Then, the relation (2.21) follows from (2) applying the implicit function theorem to (2.20).

To prove the second estimate in (2.22), it is sufficient to observe that

$$x_1(t,\bar\alpha) \le \bar\alpha + t\,\max\big|\lambda(r,s)\big|, \quad \beta(t) = x(0,t) \le x_1(t,\bar\alpha) + t\,\max\big|\mu(r,s)\big| \tag{2.25}$$

for $r = r(t,x)$, $s = s(t,x)$. Finally, from (2.21) and the inequalities of (2.15), we have

$$\frac{d\beta}{dt} \ge \frac{\delta^{-1}}{\dfrac{\partial x_2}{\partial\beta}(t,\beta(t))} \ge \frac{1}{C(1+t)} \tag{2.26}$$

because, by (2.12) and the last inequality of (2.15),

$$\frac{\partial x_2}{\partial\beta}(t,\beta) \le C\Big(1 + C\,|s_0'(\beta)|\,\max|\mu_s(r,s)|\,t\Big). \tag{2.27}$$

Thus, integrating (2.26) we obtain the first estimate in (2.22). ∎

(4) For all t_a, $t_b \ge 0$ and for all $\alpha \in \mathbb{R}$, we have

$$\begin{aligned} \frac{1}{C}\,\frac{\partial x_1}{\partial\alpha}(t_b,\alpha) - C\,|r_0'(\alpha)|\,\big|t_b - t_a\big| \;&\le\; \frac{\partial x_1}{\partial\alpha}(t_a,\alpha) \\ &\le\; C\,\frac{\partial x_1}{\partial\alpha}(t_b,\alpha) + C\,|r_0'(\alpha)|\,\big|t_b - t_a\big|, \end{aligned} \tag{2.28}$$

where $C > 1$ is suitable constant, independent of t_a, t_b, α.

Clearly, a similar estimate holds true for the 2-*wave infinitesimal compression ratio.*

Proof. It is sufficient to consider the expression (2.10) of $\frac{\partial x_1}{\partial\alpha}(t,\alpha)$. In fact, we have

$$\begin{aligned} \frac{\partial x_1}{\partial\alpha}(t_a,\alpha) \;&=\; e^{h_1(t_a)-h_1(t_b)}\,\frac{\partial x_1}{\partial\alpha}(t_b,\alpha) \\ &\quad + r_0'(\alpha)\int_{t_b}^{t_a} \lambda_r\big(r_0(\alpha), s(\tau,x_1(\tau,\alpha))\big)\,e^{h_1(t_a)-h_1(\tau)}\,d\tau\,. \end{aligned} \tag{2.29}$$

Then, using the estimates of (2.15), we obtain (2.28). ∎

3. Proof of Theorem 1. We argue by contradiction. Let $r = r(t,x)$, $s = s(t,x)$ be a C^1 solution to problem (1.1), (1.2) on $\big[0,\infty\big)\times\mathbb{R}_x$. From the assumptions (1.4), (1.5), (1.6) on $\lambda(r,s)$, $\mu(r,s)$, and $s_0(x)$ we can find $\bar\alpha$, $\bar s \in \mathbb{R}$ such that

$$\begin{aligned} &r_0'(\bar\alpha) < 0\,, \\ &\lambda_r\big(r_0(\bar\alpha), s\big) \geq \epsilon > 0 \qquad \text{for} \quad \big|s-\bar s\big| < \eta\,, \end{aligned} \tag{3.1}$$

and

$$\liminf_{x\to+\infty} s_0(x) + 2\eta < \bar s < \limsup_{x\to+\infty} s_0(x) - 2\eta\,, \tag{3.2}$$

for suitable ϵ, $\eta > 0$. Hence, in formula (2.10) for $\frac{\partial x_1}{\partial\alpha}$ with $\alpha = \bar\alpha$, we will have

$$\lambda(\tau) = \lambda_r\big(r_0(\bar\alpha), s(\tau, x_1(\tau,\bar\alpha))\big) \geq \epsilon \tag{3.3}$$

when $\big|s(\tau, x_1(\tau,\bar\alpha)) - \bar s\big| \leq \eta$ and

$$\frac{\partial x_1}{\partial\alpha}(t,\bar\alpha) \leq e^{h_1(t)-h_1(0)}\left(1 + r_0'(\bar\alpha)\,\frac{\epsilon}{C}\int_0^t \chi_{\bar\alpha,\epsilon}(\tau)\,d\tau\right), \tag{3.4}$$

where $\chi_{\bar\alpha,\epsilon}(t)$ is the characteristic function of the set

$$\Omega_{\bar\alpha,\epsilon} = \Big\{t \geq 0 \,\Big|\, \lambda_r\big(r_0(\bar\alpha), s(t, x_1(t,\bar\alpha))\big) \geq \epsilon\Big\}. \tag{3.5}$$

Now, let us consider the equation

$$x_1(t,\bar\alpha) = x_2(t,\beta) \quad \text{for} \quad t \in \big[0,\infty\big)\,. \tag{3.6}$$

From the remarks of the previous section, we know that the unique solution $\beta = \beta(t)$ of (3.6) is a C^1 strictly increasing function and (since $\big\|s_0(x)\big\|_{C^1} < \infty$)

$$\beta(0) = \bar\alpha\,, \quad \beta(t) \geq \bar\alpha + \frac{1}{C}\,\ln(1+t) \tag{3.7}$$

for all $t \geq 0$. Besides, by (2.12) and having $\mu_s(r,s) \geq 0$,

$$s_0'(\beta) \geq 0 \;\Rightarrow\; \frac{\partial x_2}{\partial\beta}(t,\beta) \geq \frac{1}{C}\;; \tag{3.8}$$

hence applying (2.21) and the first inequality of (2.15), we obtain that

$$0 < \frac{d\beta(t)}{dt} = \frac{\big(\lambda(r,s) - \mu(r,s)\big)(t, x_1(t,\bar\alpha))}{\dfrac{\partial x_2}{\partial\beta}(t,\beta(t))} \leq \delta\,C\,, \tag{3.9}$$

when $s_0'(\beta(t)) \geq 0$. To conclude, it is sufficient to observe that the conditions on $s_0(x)$, that is $\big\|s_0(x)\big\|_{C^1} < \infty$ and (3.2), imply that

$$B_{\bar s,\eta} = \Big\{x \geq \bar\alpha \,\Big|\, s_0'(x) \geq 0\,, \quad \big|\bar s - s_0(x)\big| \leq \eta\Big\} \tag{3.10}$$

has *infinite* Lebesgue measure, i.e.,

$$\text{meas}\Big\{B_{\bar{s},\eta}\Big\} = +\infty\,. \tag{3.11}$$

But, for all $t \geq 0$

$$\text{meas}\Big\{B_{\bar{s},\eta} \cap \big[0,\beta(t)\big]\Big\} \leq \int_0^t \frac{d\beta(\tau)}{dt}\chi_{\bar{\alpha},\epsilon}(\tau)\,\chi_0(\tau)\,d\tau \leq \delta\,C\,\int_0^t \chi_{\bar{\alpha},\epsilon}(\tau)\,d\tau\,, \tag{3.12}$$

where $\chi_0(t)$ is the characteristic function of the set $\big\{t\,:\,s_0'\big(\beta(t)\big) \geq 0\,\big\}$.

Thus returning to (3.4), we obtain that there exists $\tilde{T}$, $0 < \tilde{T} < \infty$, such that

$$\frac{\partial x_1}{\partial \alpha}(\tilde{T},\bar{\alpha}) = 0, \tag{3.13}$$

and having

$$\frac{\partial r}{\partial x}(t,x_1(t,\bar{\alpha})) = r_0'(\bar{\alpha})\left(\frac{\partial x_1}{\partial \alpha}(t,\bar{\alpha})\right)^{-1} \tag{3.14}$$

we deduce that the function $r(t,x)$ must develop a singularity along the characteristic $\big(t,x_1(t,\bar{\alpha})\big)$ for some $t\,, 0 < t \leq \tilde{T}$. This completes the proof of Theorem 1. □

4. Proof of Theorem 2. As it is known the quasi-linear wave equation (1.7) can be reduced, introducing the Riemann invariants, to the first order diagonal system

$$\begin{aligned} &\frac{\partial l}{\partial t} - k(l-r)\frac{\partial l}{\partial x} = 0,\\ &\frac{\partial r}{\partial t} + k(l-r)\frac{\partial r}{\partial x} = 0\,, \end{aligned} \tag{4.1}$$

where

$$\begin{aligned} l &= \frac{1}{2}\left\{u_t + \int_0^{u_x} a(\eta)^{1/2}d\eta\right\},\\ r &= \frac{1}{2}\left\{u_t - \int_0^{u_x} a(\eta)^{1/2}d\eta\right\}, \end{aligned} \tag{4.2}$$

and $k(\eta) = a\big(M^{-1}(\eta)\big)^{1/2}$ with $M(\omega) = \int_0^\omega a(\eta)^{1/2}d\eta$. See [10].

Then, thanks to the assumptions (1.8), we have

$$k'(\eta) = \frac{1}{2}\,\frac{a'\big(M^{-1}(\eta)\big)}{a\big(M^{-1}(\eta)\big)} \geq 0 \qquad \big(\text{or } k'(\eta) \leq 0 \text{ if } a'(\eta) \leq 0\big) \tag{4.3}$$

and $k'(\eta)$ is not identically zero on any open interval. Moreover, by the hypotheses on the initial data, we have that $\big\|l_0(x)\big\|_{C^1}\,,\ \big\|r_0(x)\big\|_{C^1} < \infty$ and the function $l_0(x), r_0(x)$ are not both monotone decreasing.

Assume, for instance, that there exists $\alpha \in \mathbb{R}$ such that

$$l_0'(\alpha) > 0\,.$$

Then we have two possibilities:

$$\begin{aligned} &\text{(a)} \quad \text{there does not exist the limit} \quad \lim_{x\to-\infty} r_0(x)\,,\\ &\text{(b)} \quad \lim_{x\to-\infty} r_0(x) = r \in \mathbb{R}\,. \end{aligned} \tag{4.4}$$

In case (a) it is sufficient to apply Theorem 1.

In case (b), we can find $\bar\alpha$ close to α, such that

$$l_0'(\bar\alpha) > 0\,, \quad k'\big(l_0(\bar\alpha) - r\big) > 0\,. \tag{4.5}$$

Then we consider the characteristic

$$\frac{dx_1}{dt} = -k(l-r)(t,x_1), \quad x_1(0,\bar\alpha) = \bar\alpha\,. \tag{4.6}$$

Applying the 1-*wave infinitesimal compression ratio* (2.10), we have

$$\frac{\partial x_1}{\partial\alpha}(t,\bar\alpha) = e^{h_1(t)-h_1(0)}\left\{1 - l_0'(\bar\alpha)\int_0^t k'\big(l_0(\bar\alpha) - r(\tau,x_1(\tau,\bar\alpha))\big)\,e^{h_1(0)-h_1(\tau)}d\tau\right\}\,, \tag{4.7}$$

with $h_1(t) = H_1\big(l_0(\bar\alpha), r(t,x_1(t,\bar\alpha))\big)$ and

$$\lim_{t\to+\infty} r\big(t,x_1(t,\bar\alpha)\big) = r\,. \tag{4.8}$$

In fact $r\big(t,x_1(t,\bar\alpha)\big) = r_0(\beta)$, where β verifies the relation

$$x_1(t,\bar\alpha) = x_2(t,\beta)\,, \tag{4.9}$$

with $x_2(t,\beta)$ the characteristic curve defined by

$$\frac{dx_2}{dt} = k(l-r)(t,x_2), \quad x_2(0,\beta) = \beta\,. \tag{4.10}$$

But, since the data $l_0(x)$, $r_0(x)$ are bounded, there exists $\delta > 0$ such that

$$k(r-l)(t,x) \geq \delta \quad \text{for all } t,\, x\,. \tag{4.11}$$

It follows that the *unique* solution $\beta = \beta(t)$ of (4.9) satisfies

$$\beta(t) \leq \bar\alpha - 2\,\delta\,t \tag{4.12}$$

and thus (4.8) holds. Hence, from (4.7) we deduce that $\frac{\partial x_1}{\partial\alpha}(t,\bar\alpha)$ goes to zero in a finite time. This concludes the proof of Theorem 2. □

5. Proof of Theorem 3. Assume that (1.10), (1.11) hold and, by contradiction, let $r(t,x)$, $s(t,x)$ be a C^1 global solution in $\big[0,\infty\big)\times\mathbb{R}_x$ of the Cauchy problem (1.1), (1.2). Then, recalling the considerations of section 2, we must have

$$\frac{\partial x_1}{\partial\alpha}(t,\alpha) > 0\,, \quad \frac{\partial x_2}{\partial\beta}(t,\beta) > 0 \tag{2.16}$$

for all $t \geq 0$ and for all $\alpha,\,\beta \in \mathbb{R}$. We will prove that the first inequality of (2.16) does not hold.

To begin with, from (1.11) there exists $\alpha_0 \in \mathbb{R}$ such that $r_0'(\alpha_0) < 0$. Then $\frac{\partial x_1}{\partial\alpha}(t,\alpha_0) > 0$ for all $t \geq 0$ and the 1-*wave infinitesimal compression ratio* (2.10) gives the inequality

$$\int_0^t \lambda_r\big(r_0(\alpha_0), s(\tau,x_1(\tau,\alpha_0))\big)e^{h_1(0)-h_1(\tau)}\,d\tau \;<\; \frac{-1}{r_0'(\alpha_0)} \quad \text{for all } t \geq 0\,, \tag{5.1}$$

where $h_1(t) = H_1\big(r_0(\alpha_0), s(t, x_1(t, \alpha_0))\big)$.

Moreover, for the fixed α_0 and for $\beta \geq \alpha_0$, we can solve the equation

$$x_1(t, \alpha_0) = x_2(t, \beta) \tag{5.2}$$

with respect to t; using (2.21), (2.22) we have $t = t(\beta)$ with $t(\beta) : \big[\alpha_0, \infty\big) \to \infty$ a C^1 strictly increasing function such that

$$\frac{dt}{d\beta} = \frac{\dfrac{\partial x_2}{\partial \beta}(t(\beta), \beta)}{\big[\lambda(r,s) - \mu(r,s)\big](t(\beta), x_1(t(\beta), \alpha_0))}\,. \tag{5.3}$$

Hence, we can rewrite (5.1) in the following form:

(5.4)

$$\int_{\alpha_0}^{\bar\beta} \frac{\lambda_r\big(r_0(\alpha_0), s_0(\beta)\big)\,\dfrac{\partial x_2}{\partial \beta}(t(\beta), \beta)\, e^{h_1(0) - h_1(t(\beta))}}{\big[\lambda(r,s) - \mu(r,s)\big](t(\beta), x_1(t(\beta), \alpha_0))}\, d\beta \,<\, \frac{-1}{r_0'(\alpha_0)} \quad \text{for all } \bar\beta \geq \alpha_0\,.$$

Then, having $\lambda_r(r,s) \geq 0$ and $\frac{\partial x_2}{\partial \beta} > 0$, the inequalities of (2.15) give

$$\int_{\alpha_0}^{\bar\beta} \lambda_r\big(r_0(\alpha_0), s_0(\beta)\big)\,\frac{\partial x_2}{\partial \beta}(t(\beta), \beta)\, d\beta \,< C \quad \text{for all } \bar\beta \geq \alpha_0 \tag{5.5}$$

for a suitable constant $C > 0$ depending only on $\big\|r_0(x)\big\|_{C^0}$, $\big\|s_0(x)\big\|_{C^0}$ and $r_0'(\alpha_0)$.

On the other hand, by (2.22)

$$t(\beta) \geq \frac{1}{C}\big(\beta - \alpha_0\big) \quad \text{for} \quad \beta \geq \alpha_0 \tag{5.6}$$

and, using (2.15), (5.3), we deduce that

$$\int_{\alpha_0}^{\bar\beta} \frac{\partial x_2}{\partial \beta}(t(\beta), \beta)\, d\beta \,\geq\, \frac{1}{C_1}\big(\bar\beta - \alpha_0\big) \quad \text{for all } \bar\beta \geq \alpha_0\,. \tag{5.7}$$

Then, defining for $\varepsilon > 0$

$$D_\epsilon = \Big\{\beta \geq \alpha_0 \,\Big|\, \lambda_r\big(r(\alpha_0), s_0(\beta)\big) \leq \varepsilon\Big\}\,, \tag{5.8}$$

the inequalities (5.5), (5.7) give

$$\int_{\alpha_0}^{\bar\beta} \frac{\partial x_2}{\partial \beta}(t(\beta), \beta)\, \chi_{D_\varepsilon}(\beta)\, d\beta \,\geq\, \frac{1}{C_1}\big(\bar\beta - \alpha_0\big) - \frac{C}{\varepsilon} \quad \text{for all } \bar\beta \geq \alpha_0\,, \tag{5.9}$$

where $\chi_{D_\varepsilon}(\beta)$ is the characteristic function of the set D_ϵ.

Now, let us consider α_1 close to α_0 such that

$$r_0'(\alpha) < 0 \quad \text{in} \quad \big[\alpha_0, \alpha_1\big]. \tag{5.10}$$

Solving for $\beta \geq \beta_0 = \max\big\{\alpha_0,\, \alpha_1\big\}$ the equation

$$x_1(t, \alpha_1) = x_2(t, \beta) \tag{5.11}$$

with respect to t, we obtain $t = t_1(\beta)$ with

$$\big|t_1(\beta) - t(\beta)\big| \le C\,\big|\alpha_1 - \alpha_0\big|\,. \tag{5.12}$$

To prove the estimate (5.12), it is sufficient to observe that for any fixed $\beta \in \mathbb{R}$ the equation

$$x_1(t,\alpha) = x_2(t,\beta)$$

implies that

$$\frac{\partial t}{\partial \alpha} = \frac{\dfrac{\partial x_1}{\partial \alpha}(t,\alpha)}{\big[\mu(r,s) - \lambda(r,s)\big](t, x_2(t,\beta))}\,;$$

hence, having

$$0 < \frac{\partial x_1}{\partial \alpha}(t,\alpha) \le e^{h_1(t) - h_1(0)} \quad \text{for} \quad \alpha \in \big[\alpha_0,\, \alpha_1\big] \tag{5.13}$$

since $r_0'(\alpha) \le 0$ in $\big[\alpha_0,\, \alpha_1\big]$, from (2.15) we conclude that

$$\Big|\frac{\partial t}{\partial \alpha}\Big| \le C \quad \text{in} \quad \big[\alpha_0, \alpha_1\big] \tag{5.14}$$

for some $C > 0$, uniformly with respect to $\beta \ge \beta_0$.

To continue, let us prove the following.

LEMMA 1. *For $\big|\alpha_1 - \alpha_0\big|$ small enough, for all $\bar\beta \ge \beta_0 = \max\big\{\alpha_0,\, \alpha_1\big\}$ we have*

$$\int_{\beta_0}^{\bar\beta} \frac{\partial x_2}{\partial \beta}\big(t_1(\beta),\beta\big)\,\chi_{D_\varepsilon}(\beta)\,d\beta \ge \frac{\bar\beta}{C} - C\big(|\beta_0| + |\alpha_0|\big) - \frac{C}{\varepsilon} \tag{5.15}$$

with $C > 1$ independent of $\bar\beta$, ε. Moreover, let us remark that (5.15) *holds true provided $\big|\alpha_1 - \alpha_0\big|$ is sufficiently small, independently of $\varepsilon > 0$.*

Proof. To begin with, let us denote with Ω the subset of $\beta \ge \beta_0 = \max\big\{\alpha_0,\, \alpha_1\big\}$ such that

$$s_0'(\beta) \int_0^{t(\beta)} \mu_s\big(r(\tau, x_2(\tau,\beta)), s_0(\beta)\big)\, e^{h_2(0) - h_2(\tau)}\,d\tau \;\le\; 1\,. \tag{5.16}$$

Then, we can easily see that

$$\frac{\partial x_2}{\partial \beta}\big(t_1(\beta),\beta\big) \;\to\; \frac{\partial x_2}{\partial \beta}\big(t(\beta),\beta\big) \tag{5.17}$$

uniformly in Ω as $\alpha_1 \to \alpha_0$. In fact

$$\frac{\partial x_2}{\partial \beta}\big(t,\beta\big) = e^{h_2(t) - h_2(0)}\left\{1 + s_0'(\beta)\int_0^t \mu_s\big(r(\tau, x_2(\tau,\beta)), s_0(\beta)\big) e^{h_2(0) - h_2(\tau)}\,d\tau\right\}, \tag{5.18}$$

where, by the assumptions on $r_0(x)$ and $s_0(x)$, we know that the terms

$$s_0'(\beta), \quad \mu_s\big(r(\tau, x_2(\tau,\beta)), s_0(\beta)\big), \quad h_2(t)$$

are uniformly bounded. Moreover, having $h_2(t) = H_2\big(r(t, x_2(t,\beta)), s_0(\beta)\big)$, it follows that

$$h_2\big(t_1(\beta)\big) = H_2\big(r_0(\alpha_1), s_0(\beta)\big)\,. \tag{5.19}$$

Thus $h_2\big(t_1(\beta)\big) \to h_2\big(t(\beta)\big) = H_2\big(r_0(\alpha_0), s_0(\beta)\big)$ uniformly as $\alpha_1 \to \alpha_0$. Then, using (5.12) and the condition (5.16), we immediately get (5.17) in Ω.

On the other hand, for $\beta \geq \beta_0 = \max\big\{\alpha_0,\, \alpha_1\big\}$, $\beta \notin \Omega$, we must have

$$s_0'(\beta) \int_0^{t(\beta)} \mu_s\big(r(\tau, x_2(\tau,\beta)), s_0(\beta)\big)\, e^{h_2(0)-h_2(\tau)}\, d\tau > 1; \tag{5.20}$$

thus from (5.18) and the previous considerations, we deduce that

$$\frac{\partial x_2}{\partial \beta}\big(t_1(\beta),\beta\big) \geq \frac{1}{2}\,\frac{\partial x_2}{\partial \beta}\big(t(\beta),\beta\big) \quad \text{for} \quad \beta \geq \beta_0,\ \beta \notin \Omega \tag{5.21}$$

provided $\big|\alpha_1 - \alpha_0\big|$ is sufficiently small.

Taking account of these facts, we will have

$$\begin{aligned}\int_{\beta_0}^{\bar\beta} \frac{\partial x_2}{\partial \beta}\big(t_1(\beta),\beta\big)\,\chi_{D_\varepsilon}(\beta)\,d\beta &\geq \frac{1}{2}\int_{\beta_0}^{\bar\beta} \frac{\partial x_2}{\partial \beta}\big(t(\beta),\beta\big)\,\chi_{D_\varepsilon}(\beta)\,\big(1-\chi_\Omega(\beta)\big)\,d\beta \\ &+ \int_{\beta_0}^{\bar\beta} \frac{\partial x_2}{\partial \beta}\big(t_1(\beta),\beta\big)\,\chi_{D_\varepsilon}(\beta)\,\chi_\Omega(\beta)\,d\beta \\ &\geq \frac{1}{2}\int_{\alpha_0}^{\bar\beta} \frac{\partial x_2}{\partial \beta}\big(t(\beta),\beta\big)\,\chi_{D_\varepsilon}(\beta)\,d\beta - \frac{1}{4C_1}\big(\bar\beta-\beta_0\big) - C\big(\beta_0-\alpha_0\big)\end{aligned} \tag{5.22}$$

for $\big|\alpha_1-\alpha_0\big|$ sufficiently small, with C_1 the same constant appearing in (5.9). Now, from (5.9) and (5.22) we easily obtain the estimate (5.15) with a suitable constant $C > 1$. This completes the proof of Lemma 1. □

Finally, to conclude the proof of Theorem 3, we use the second assumption in (1.10). For α_1 sufficiently close to α_0 the sets

$$\begin{aligned}Z_0 &= \Big\{ s \,\Big|\, \lambda_r\big(r_0(\alpha_0), s\big) = 0,\ |s| \leq \big\|s_0(x)\big\|_{C^0} + 1 \Big\}\,, \\ Z_1 &= \Big\{ s \,\Big|\, \lambda_r\big(r_0(\alpha_1), s\big) = 0,\ |s| \leq \big\|s_0(x)\big\|_{C^0} + 1 \Big\}\end{aligned} \tag{5.23}$$

are finite and disjoint, i.e.,

$$Z_0 \cap Z_1 \,=\, \emptyset\,. \tag{5.24}$$

Hence, taking $\varepsilon > 0$ sufficiently small in the definition (5.8) of D_ε, we have

$$\lambda_r\big(r_0(\alpha_1), s_0(\beta)\big) \geq \eta \quad \text{for all } \beta \in D_\varepsilon \tag{5.25}$$

for some $\eta > 0$. Then, putting together (5.15) and (5.25), we have

$$\begin{aligned}\int_{\beta_0}^{\bar\beta} \lambda_r\big(r_0(\alpha_1), s_0(\beta)\big)\,\frac{\partial x_2}{\partial \beta}\big(t_1(\beta),\beta\big)\,d\beta &\geq \eta \int_{\beta_0}^{\bar\beta} \frac{\partial x_2}{\partial \beta}\big(t_1(\beta),\beta\big)\,\chi_{D_\varepsilon}(\beta)\,d\beta \\ &\geq \frac{\eta\bar\beta}{C} - \eta C\big(|\beta_0| + |\alpha_0|\big) - \frac{\eta\, C}{2\varepsilon}\,.\end{aligned} \tag{5.26}$$

Clearly, the last inequality and $r_0'(\alpha_1) < 0$ imply that

$$\frac{\partial x_1}{\partial \alpha}(t, \alpha_1) \to -\infty \tag{5.27}$$

as $t \to \infty$. This proves Theorem 3. □

6. Proof of Theorem 4.

Case (i). By assumption $u_0'(x)$, $u_1(x)$ are not both constant functions and

$$\lim_{x \to \pm\infty} u_0'(x) = \lim_{x \to \pm\infty} u_1(x) = 0\,. \tag{6.1}$$

We will use the Riemann invariants $l(t,x)$, $r(t,x)$ introduced in section 4. See (4.1), (4.2). From (4.3), we find that

$$k'(\eta) = \frac{1}{2}\,\frac{a'\big(M^{-1}(\eta)\big)}{a\big(M^{-1}(\eta)\big)} \tag{6.2}$$

is not identically 0 on any open interval.

Let us suppose that $l_0(x)$ is not identically 0. Then, we can find $\bar\alpha \in \mathbb{R}$ such that

$$l_0'(\bar\alpha)\, k'\big(l_0(\bar\alpha)\big) > 0\,. \tag{6.3}$$

But, rewriting (4.7), we have

$$\frac{\partial x_1}{\partial \alpha}(t, \bar\alpha) = e^{h_1(t) - h_1(0)} \left\{ 1 - l_0'(\bar\alpha) \int_0^t k'\big(l_0(\bar\alpha) - r(\tau, x_1(\tau, \bar\alpha))\big)\, e^{h_1(0) - h_1(\tau)} d\tau \right\}, \tag{6.4}$$

where

$$k'\big(l_0(\bar\alpha) - r(t, x_1(t, \bar\alpha))\big) \to k'\big(l_0(\bar\alpha)\big) \quad \text{as} \quad t \to +\infty\,. \tag{6.5}$$

In fact, the initial data $l_0(x)$, $r_0(x)$ are uniformly bounded.

Hence, by the arguments of (4.9)–(4.12), we may prove that $r\big(t, x_1(t, \bar\alpha)\big) = r_0(\beta)$, where $\beta = \beta(t)$ satisfies

$$\beta(t) \le \bar\alpha - 2\,\delta\, t \qquad (\delta > 0). \tag{6.6}$$

Thus $r\big(t, x_1(t, \bar\alpha)\big) \to 0$ as $t \to \infty$ and $\frac{\partial x_1}{\partial \alpha}(t, \bar\alpha)$ goes to 0 in finite time. We can proceed in the same way if

$$r_0(x) \not\equiv 0\,.$$

This completes the proof of Case (i) of Theorem 4. □

Case (ii). By contradiction, let $l(t,x)$, $r(t,x)$ be a global C^1 solution of the system (4.1) of the Riemann invariants.

Now, from (1.12) and (6.2), we have

$$k'(\eta) < 0 \quad \text{if} \quad \eta < 0\,, \quad k'(\eta) > 0 \quad \text{if} \quad \eta > 0\,.$$

Clearly, if

$$\max l_0(x) \ne \max r_0(x) \quad \text{or} \quad \min l_0(x) \ne \min r_0(x)\,,$$

then we can proceed as in Case (i): assuming (for example) that $\max l_0(x) > \max r_0(x)$, thanks to the condition (1.12), we can find $\bar\alpha \in \mathbb{R}$ such that

$$l_0'(\bar\alpha) > 0\,, \quad k'\big(l_0(\bar\alpha) - r(t, x_1(t, \bar\alpha))\big) \geq \epsilon > 0 \tag{6.7}$$

for all $t \geq 0$.

Hence, in the following we may assume that $l_0(x)$, $r_0(x)$ are nonconstant periodic functions and that

$$M = \max l_0(x) = \max r_0(x) > \min l_0(x) = \min r_0(x) = m\,. \tag{6.8}$$

We will denote with $\pi > 0$ the common period of the initial data $l_0(x)$, $r_0(x)$.

To begin with, rewriting the system (4.1),

$$\begin{aligned} &\frac{\partial l}{\partial t} - k(l-r)\frac{\partial l}{\partial x} = 0,\\ &\frac{\partial r}{\partial t} + k(l-r)\frac{\partial r}{\partial x} = 0\,, \end{aligned} \tag{4.1}$$

we know that the functions $l(t,x)$, $r(t,x)$ are constant along the characteristics

$$\begin{aligned} &\frac{dx_1}{dt} = -k(l-r)(t, x_1)\,, \quad x_1(0,\alpha) = \alpha,\\ &\frac{dx_2}{dt} = k(l-r)(t, x_2)\,, \quad x_2(0,\beta) = \beta, \end{aligned} \tag{6.9}$$

respectively, and that $l(t,x)$, $r(t,x)$ are periodic of period π with respect to $x \in \mathbb{R}$, i.e.,

$$l(t, x+\pi) = l(t,x)\,, \quad r(t, x+\pi) = r(t,x)\,. \tag{6.10}$$

Besides, we may assume that

$$l_0(0) = M\,. \tag{6.11}$$

Then, for $\varepsilon > 0$ sufficiently small, namely

$$0 < \varepsilon \leq \frac{M-m}{4}\,, \tag{6.12}$$

let us define with $D_\varepsilon = \big(\alpha_\varepsilon,\, \bar\alpha_\varepsilon\big)$ an open interval, containing 0, and such that

$$\begin{aligned} &l_0(x) \geq M - \varepsilon \quad \text{in} \quad D_\varepsilon,\\ &l_0(\alpha_\varepsilon)\,,\ l_0(\bar\alpha_\varepsilon) < M \quad \text{and} \quad l_0'(\bar\alpha_\varepsilon) < 0\,. \end{aligned} \tag{6.13}$$

Clearly, we have

$$\alpha_\varepsilon < 0 < \bar\alpha_\varepsilon \quad \text{and} \quad 0 < \bar\alpha_\varepsilon - \alpha_\varepsilon < \pi\,. \tag{6.14}$$

Besides, let us take an interval $I \subset \big(0,\, \pi\big)$ such that

$$\begin{aligned} &r_0(x) \leq \frac{m+M}{2}\,, \quad r_0'(x) \geq \rho \quad \text{for all } x \in I,\\ &\text{meas}\big(I\big) > 0 \end{aligned} \tag{6.15}$$

with $\rho > 0$. Finally, for $|\eta| \le M - m + 1$, let us define

$$\phi(\eta) \stackrel{\text{def}}{=} -\inf_{s \ge \eta} k'(s) \quad (|s| \le M - m + 1), \tag{6.16}$$

$\phi(\eta)$ is a decreasing function such that $\phi(\eta) > 0$ for $\eta < 0$ and $\phi(\eta) < 0$ for $\eta > 0$.

Then, we have the following.

LEMMA 2. *Let $\bar\alpha \in D_\varepsilon$ such that $l_0'(\bar\alpha) > 0$. Let $t(\beta) : \big(-\infty, \bar\alpha\big] \to \mathbb{R}$ be the C^1 function defined by the equation*

$$x_1\big(t, \bar\alpha\big) = x_2\big(t, \beta\big), \quad \text{with} \quad \beta \le \bar\alpha\,. \tag{6.17}$$

Then, for all $\beta < \bar\alpha$, we have

$$\frac{1}{\bar\alpha - \beta} \int_\beta^{\bar\alpha} \frac{\partial x_2}{\partial \beta}\big(t(y), y\big)\, \chi_{I+\pi\mathbb{Z}}(y)\, dy \le C \left(\frac{1}{l_0'(\bar\alpha)\,\big(\bar\alpha - \beta\big)} + \phi\big(l_0(\bar\alpha) - M\big) \right), \tag{6.18}$$

where $\chi_{I+\pi\mathbb{Z}}(\beta)$ is the characteristic function of the set $I + \pi\mathbb{Z}$ and the constant C is independent of $\bar\alpha \in D_\varepsilon$, $\beta \in \big(-\infty, \bar\alpha\big]$.

Proof. The condition $\frac{\partial x_1}{\partial \alpha}\big(t, \bar\alpha\big) > 0$ implies that (recalling (4.7))

$$\int_0^t k'\big(l_0(\bar\alpha) - r(\tau, x_1(\tau, \bar\alpha))\big)\, e^{h_1(0) - h_1(\tau)}\, d\tau < \frac{1}{l_0'(\bar\alpha)} \tag{6.19}$$

for all $t \ge 0$. Hence, using the change of variable $t = t(\beta)$,

$$\frac{dt}{d\beta} = \frac{-\dfrac{\partial x_2}{\partial \beta}\big(t(\beta), \beta\big)}{2\,k\big(l - r\big)\big(t(\beta), x_1(t(\beta), \bar\alpha)\big)}\,, \tag{6.20}$$

we obtain that

$$\int_\beta^{\bar\alpha} k'\big(l_0(\bar\alpha) - r_0(y)\big) \frac{\dfrac{\partial x_2}{\partial \beta}\big(t(y), y\big)\, e^{h_1(0) - h_1(t(y))}}{k\big(l - r\big)\big(t(y), x_1(t(y), \bar\alpha)\big)}\, dy < \frac{2}{l_0'(\bar\alpha)}\,. \tag{6.21}$$

Now, let us recall that by (2.15)

$$\frac{1}{C} \le \frac{e^{h_1(0) - h_1(t(\beta))}}{k\big(l - r\big)\big(t(\beta), x_1(t(\beta), \bar\alpha)\big)} \le C \tag{6.22}$$

for a suitable constant $C > 1$. Moreover, observe that

$$\beta \in I + \pi\mathbb{Z}\,, \quad \alpha \in D_\varepsilon \;\Rightarrow\; k'\big(l_0(\alpha) - r_0(\beta)\big) \ge \delta_1 \tag{6.23}$$

for a suitable $\delta_1 > 0$, and

$$\beta \notin I + \pi\mathbb{Z} \;\Rightarrow\; k'\big(l_0(\alpha) - r_0(\beta)\big) \ge -\,\phi\big(l_0(\alpha) - M\big), \tag{6.24}$$

where $\phi(\eta)$ is the function defined in (6.16).

Thus, taking into account of (6.22)–(6.24) we find

$$\frac{\delta_1}{C}\int_\beta^{\bar\alpha}\frac{\partial x_2}{\partial\beta}\big(t(y),y\big)\,\chi_{I+\pi\mathbb{Z}}(y)\,dy - C\phi\big(l_0(\bar\alpha)-M\big)\int_\beta^{\bar\alpha}\frac{\partial x_2}{\partial\beta}\big(t(y),y\big)\,dy < \frac{2}{l_0'(\bar\alpha)}\,. \tag{6.25}$$

Clearly, the estimate (6.18) follows immediately from (6.25) if we observe that

$$\frac{\bar\alpha-\beta}{C}\le\int_\beta^{\bar\alpha}\frac{\partial x_2}{\partial\beta}\big(t(y),y\big)\,dy\le C\,\big(\bar\alpha-\beta\big), \tag{6.26}$$

which is a consequence of the fact that, having

$$\frac{1}{\delta}\le k\big(l-r\big)(t,x)\le\delta \tag{6.27}$$

for some $\delta>1$, the function $t(\beta)$ satisfies

$$\frac{\bar\alpha-\beta}{C}\le t(\beta)\le C\big(\bar\alpha-\beta\big)\quad\text{for all }\beta\le\bar\alpha \tag{6.28}$$

for a suitable $C>1$. □

Remark 1. Observe that, introducing for $\omega>0$ the set

$$B_\omega=\Big\{\beta\le\bar\alpha\,\Big|\,\frac{\partial x_2}{\partial\beta}\big(t(\beta),\beta\big)\ge\omega,\quad\beta\in I+\pi\mathbb{Z}\Big\}, \tag{6.29}$$

then the estimate (6.18) gives for $\beta<\bar\alpha$

$$\frac{\operatorname{meas}\Big(B_\omega\cap[\beta,\,\bar\alpha]\Big)}{\bar\alpha-\beta}\le\frac{C}{\omega}\left(\frac{1}{l_0'(\bar\alpha)\big(\bar\alpha-\beta\big)}+\phi\big(l_0(\bar\alpha)-M\big)\right). \tag{6.30}$$

□

Now, let us consider the characteristics $x_2(t,\bar\beta)$ with $\bar\beta\le\bar\alpha$. From the results of section 2, we have easily

$$\begin{aligned}\frac{\partial x_2}{\partial\beta}\big(t,\bar\beta\big) = {}& e^{h_2(t)-h_2(t(\bar\beta))}\,\frac{\partial x_2}{\partial\beta}\big(t(\bar\beta),\bar\beta\big)\left(1-\frac{\partial r}{\partial x}\big(t(\bar\beta),x_2(t(\bar\beta),\bar\beta)\big)\right.\\ &\left.\cdot\int_{t(\bar\beta)}^{t}k'\big(l(\tau,x_2(\tau,\bar\beta))-r_0(\bar\beta)\big)\,e^{h_2(t(\bar\beta))-h_2(\tau)}\,d\tau\right),\end{aligned} \tag{6.31}$$

where

$$\frac{\partial r}{\partial x}\big(t(\bar\beta),x_2(t(\bar\beta),\bar\beta)\big)=\frac{r_0'(\bar\beta)}{\dfrac{\partial x_2}{\partial\beta}\big(t(\bar\beta),\bar\beta\big)}\,. \tag{6.32}$$

Hence, the condition $\frac{\partial x_2}{\partial\beta}\big(t(\bar\beta),\bar\beta\big)\le\omega$ for $\bar\beta\in I+\pi\mathbb{Z}$, $\bar\beta\notin B_\omega$ implies that

$$\frac{\partial r}{\partial x}\big(t(\bar\beta),x_2(t(\bar\beta),\bar\beta)\big)\ge\frac{\rho}{\omega}\,. \tag{6.33}$$

Moreover, observe that $l\big(t, x_2(t,\beta)\big) \geq M - \varepsilon$ gives

$$k'\big(l\big(t, x_2(t,\beta)\big) - r_0(\beta)\big) \geq \delta_1 > 0\,, \quad \text{if} \quad \beta \leq \bar\alpha,\ \beta \in I + \pi\mathbb{Z}\,, \tag{6.34}$$

with $\delta_1 > 0$ the constant of (6.23).

Thus, denoting with $t_\varepsilon(\beta)$ the unique solution of the equation

$$x_1\big(t,\, \bar\alpha_\varepsilon\big) = x_2(t,\, \beta) \quad \text{for} \quad \beta \leq \bar\alpha_\varepsilon\,, \tag{6.35}$$

from (6.31) and the condition $\frac{\partial x_2}{\partial \beta} > 0$, we easily have

$$\frac{\rho}{\omega}\ \delta_1\ \Big(t_\varepsilon(\bar\beta) - t(\bar\beta)\Big) \leq C \tag{6.36}$$

for all $\bar\beta \leq \bar\alpha$, $\bar\beta \in I + \pi\mathbb{Z}$, $\bar\beta \notin B_\omega$. Thus, we have proved the following.

LEMMA 3. *For all $\beta \leq \bar\alpha$, $\beta \in I + \pi\mathbb{Z}$, $\beta \notin B_\omega$ we have*

$$t_\varepsilon(\beta) - t(\beta)\ \leq\ C\,\omega, \tag{6.37}$$

where C does not depend on $\omega > 0$, ε, $\bar\alpha$, $\bar\alpha_\varepsilon$. □

To continue, let us fix $\bar\beta \leq \bar\alpha$, $\bar\beta \in I + \pi\mathbb{Z}$, $\bar\beta \notin B_\omega$ and let us evaluate the quantity

$$t_\varepsilon(\beta) - t(\beta) \tag{6.38}$$

for $\beta \leq \bar\alpha$ near $\bar\beta$. We have the following.

LEMMA 4. *Let $\bar\beta \leq \bar\alpha$, $\bar\beta \in I + \pi\mathbb{Z}$, $\bar\beta \notin B_\omega$, then for all $\beta \leq \bar\alpha$ we have*

$$t_\varepsilon(\beta) - t(\beta)\ \leq\ C\left(\omega + \big(\big|\beta - \bar\beta\big| + 1\big)\ \int_{\bar\alpha}^{\bar\alpha_\varepsilon} \big|l_0'(x)\big|\,dx\right), \tag{6.39}$$

where C is a constant independent of ω, β, $\bar\beta$, and $\bar\alpha \in D_\varepsilon$.

Proof. Let us observe that by (6.27) we have

$$\frac{1}{C}\big(t_\varepsilon(\beta) - t(\beta)\big) \leq x_1\big(t(\beta), \bar\alpha_\varepsilon\big) - x_1\big(t(\beta), \bar\alpha\big) \leq C\big(t_\varepsilon(\beta) - t(\beta)\big) \tag{6.40}$$

for a suitable constant $C > 1$. On the other hand, integrating $\frac{\partial x_1}{\partial \alpha}$ we find

(6.41)

$$\begin{aligned}
x_1\big(t(\beta), \bar\alpha_\varepsilon\big) - x_1\big(t(\beta), \bar\alpha\big) &= \int_{\bar\alpha}^{\bar\alpha_\varepsilon} e^{h_1(t(\beta),x) - h_1(0,x)} \\
&\cdot \left(1 - l_0'(x) \int_0^{t(\beta)} k'\big(l - r\big)(\tau, x_1(\tau,x))\, e^{h_1(0,x) - h_1(\tau,x)}\,d\tau\right) dx \\
&\leq C \int_{\bar\alpha}^{\bar\alpha_\varepsilon} e^{h_1(t(\bar\beta),x) - h_1(0,x)} \\
&\cdot \left(1 - l_0'(x) \int_0^{t(\beta)} k'\big(l - r\big)(\tau, x_1(\tau,x))\, e^{h_1(0,x) - h_1(\tau,x)}\,d\tau\right) dx \\
&\leq C\left(x_1\big(t(\bar\beta), \bar\alpha_\varepsilon\big) - x_1\big(t(\bar\beta), \bar\alpha\big)\right) \\
&+ C \int_{\bar\alpha}^{\bar\alpha_\varepsilon} \left(e^{h_1(t(\bar\beta),x) - h_1(0,x)}\, l_0'(x) \int_{t(\beta)}^{t(\bar\beta)} k'\big(l - r\big)(\tau, x_1(\tau,x))\, e^{h_1(0,x) - h_1(\tau,x)}\,d\tau\right) dx \\
&\leq C\,\omega + C\,\big|t(\beta) - t(\bar\beta)\big| \int_{\bar\alpha}^{\bar\alpha_\varepsilon} \big|l_0'(x)\big|\,dx\,.
\end{aligned}$$

Thus, to conclude the proof it is sufficient to observe that (thanks to the periodicity)

$$\big|t(\beta) - t(\bar\beta)\big| \,\le\, C\,\Big(\big|\beta-\bar\beta\big| + 1\Big) \tag{6.42}$$

for a suitable constant C. □

Remark 2. Let us observe that, since the functions $l(t,x)$, $r(t,x)$ are periodic of period $\pi > 0$ with respect to the variable x, it follows immediately that

$$t_\varepsilon(\beta) - t(\beta) \,\le\, C\,\pi \qquad \text{for all } \beta \le \bar\alpha\,, \tag{6.43}$$

because $\bar\alpha_\varepsilon - \bar\alpha \le \pi$. So the inequality (6.39) is a refinement of trivial estimate (6.43).

From (6.30) and the estimate of Lemma 4, we have the following.

LEMMA 5. *There exists a constant C_1 such that the inequality*

$$0 \le t_\varepsilon(\beta) - t(\beta) \le C_1\,\left(\omega + \int_{\bar\alpha}^{\bar\alpha_\varepsilon} \big|l_0'(x)\big|\,dx\right) \tag{6.44}$$

holds true for all $\beta \le \bar\alpha$ such that

$$\operatorname{dist}\big\{\beta,\, I + \pi\mathbb{Z} \setminus B_\omega\big\} \le 2\pi\,. \tag{6.45}$$

Denoting with $\tilde B_\omega$ the subset of $\beta \le \bar\alpha$ where (6.44) *does not hold, we have*

$$\frac{\operatorname{meas}\Big(\tilde B_\omega \,\cap\, \big[\beta,\,\bar\alpha\big]\Big)}{\bar\alpha - \beta} \,\le\, \frac{C}{\omega}\,\left(\frac{1}{l_0'(\bar\alpha)\big(\bar\alpha-\beta\big)} + \phi\big(l_0(\bar\alpha) - M\big)\right) \tag{6.46}$$

for all $\beta \le \bar\alpha - \pi$. The constants C_1, C are independent of β, $\bar\alpha \in D_\varepsilon$, and ω. □

Observation 1. If $x_0 \in \tilde B_\omega$ $(x_0 \le \bar\alpha - \pi)$, then there exists $k_0 \in \mathbb{Z}$ such that

$$k_0\pi \,\le\, x_0 \,\le\, (k_0+1)\pi \quad \text{ and } \quad I + (k_0-1)\pi\,,\; I + k_0\pi \subset B_\omega\,.$$

Let $L = \big\{k \in \mathbb{Z} \,:\, I + k\pi,\, I + (k+1)\pi \subset B_\omega\big\}$; then for all β, $\beta \le \bar\alpha - \pi$ we have

$$\operatorname{card}\big\{L \cap \big[\beta,\bar\alpha\big]\big\} \,\le\, C\,\operatorname{meas}\Big(B_\omega \cap \big[\beta,\bar\alpha\big]\Big)$$

and $\tilde B_\omega \subset \pi L + \big[0,\,2\pi\big]$. Note that (thanks to the periodicity) for all $t \ge 0$

$$\int_\beta^{\beta+\pi} \frac{\partial x_2}{\partial\beta}(t,y)\,dy = \pi \qquad \text{for all } \beta \in \mathbb{R}\,;$$

moreover, by (2.28), for a suitable constant $C \ge 1$ we have

$$\frac{\partial x_2}{\partial\beta}(\tau,\beta) \le C\,\frac{\partial x_2}{\partial\beta}(t,\beta) + C\,\big|\tau - t\big| \quad \text{for all} \quad t,\,\tau \ge 0\,.$$

This implies that, for $\beta \le \bar\alpha - \pi$,

$$\begin{aligned}\int_\beta^{\bar\alpha} \frac{\partial x_2}{\partial\beta}(t(y),y)\,\chi_{\tilde B_\omega}(y)\,dy \,&\le\, \int_\beta^{\bar\alpha} \frac{\partial x_2}{\partial\beta}(t(y),y)\,\chi_{\pi L + [0,2\pi]}(y)\,dy \\ &\le\, C\,\operatorname{meas}\Big(B_\omega \cap \big[\beta,\bar\alpha\big]\Big)\end{aligned} \tag{6.46a}$$

since $|y_1 - y_2| \le \pi \;\Rightarrow\; |t(y_1) - t(y_2)| \le C\pi$. □

To continue, let us introduce for $\gamma > 0$ the set

$$E_\gamma = \Big\{ \beta \in (0,\, \pi) \,\Big|\, r_0(\beta) \ge M - \gamma \Big\}. \tag{6.47}$$

Then, the following holds.

LEMMA 6. *Let us take $\bar\alpha \in D_\varepsilon$ such that $l_0'(\bar\alpha) > 0$, $M - \gamma < l_0(\bar\alpha)$. Then, for all $\beta < \bar\alpha$*

$$\begin{aligned} &\frac{1}{\bar\alpha - \beta} \int_\beta^{\bar\alpha} \frac{\partial x_2}{\partial \beta}\big(t(y), y\big)\, \chi_{E_\gamma + \pi\mathbb{Z}}(y)\, dy \\ &\qquad \ge \frac{1}{C_2} - \frac{C_2}{-\phi\big(l_0(\bar\alpha) - M + \gamma\big)} \left(\frac{1}{l_0'(\bar\alpha)\big(\bar\alpha - \beta\big)} + \phi\big(l_0(\bar\alpha) - M\big) \right), \end{aligned} \tag{6.48}$$

where $\chi_{E_\gamma + \pi\mathbb{Z}}(\beta)$ is the characteristic function of the set $E_\gamma + \pi\mathbb{Z}$; here $C_2 > 1$ is a suitable constant independent of $\bar\alpha$, β, γ.

Proof. To begin with let us recall that, by the inequalities (6.26),

$$\int_\beta^{\bar\alpha} \frac{\partial x_2}{\partial \beta}\big(t(y), y\big)\, dy = O\big(\bar\alpha - \beta\big).$$

Moreover, we have easily for $\beta \le \bar\alpha$

$$\beta \notin E_\gamma + \pi\mathbb{Z} \;\Rightarrow\; k'\big(l_0(\bar\alpha) - r_0(\beta)\big) \;\ge\; -\phi\big(l_0(\bar\alpha) - M + \gamma\big) > 0\,, \tag{6.49}$$

where $\phi(\eta)$ is defined in (6.16). Thus, from the condition $\frac{\partial x_1}{\partial \alpha}(t, \bar\alpha) > 0$ we find

$$\begin{aligned} &\frac{-\phi\big(l_0(\bar\alpha) - M + \gamma\big)}{C} \int_\beta^{\bar\alpha} \frac{\partial x_2}{\partial \beta}\big(t(y), y\big)\, \big(1 - \chi_{E_\gamma + \pi\mathbb{Z}}(y)\big)\, dy \\ &\qquad - C\phi\big(l_0(\bar\alpha) - M\big) \int_\beta^{\bar\alpha} \frac{\partial x_2}{\partial \beta}\big(t(y)\,, y\big)\, \chi_{E_\gamma + \pi\mathbb{Z}}(y)\, dy \;<\; \frac{2}{l_0'(\bar\alpha)}\,. \end{aligned} \tag{6.50}$$

Thus, we obtain that

$$\begin{aligned} &\int_\beta^{\bar\alpha} \frac{\partial x_2}{\partial \beta}\big(t(y), y\big)\, \big(1 - \chi_{E_\gamma + \pi\mathbb{Z}}(y)\big)\, dy \\ &\le \frac{C}{-\phi\big(l_0(\bar\alpha) - M + \gamma\big)} \left(\frac{1}{l_0'(\bar\alpha)} + \phi\big(l_0(\bar\alpha) - M\big) \int_\beta^{\bar\alpha} \frac{\partial x_2}{\partial \beta}\big(t(y), y\big)\, dy \right), \end{aligned} \tag{6.51}$$

which immediately gives (6.48). □

Remark 3. Let us remark that, since $l_0(x)$, $r_0(x)$ are nonconstant C^1 periodic functions of period $\pi > 0$ such that $\max l_0(x) = \max r_0(x) = M$, then we have

$$\begin{aligned} &0 < \operatorname{meas}\big(E_\gamma\big) \le \pi \quad \text{for all } \gamma > 0\,, \\ &\lim_{\varepsilon \to 0^+} \int_{\alpha_\varepsilon}^{\bar\alpha_\varepsilon} \big|l_0'(x)\big|\, dx = 0\,. \end{aligned} \tag{6.52}$$

The first equation of (6.52) is clear, while the other, recalling the definition of D_ε, is a simple exercise. □

We are now in position to conclude the proof of Case (ii) of Theorem 4. Let us evaluate

$$\frac{\partial x_1}{\partial \alpha}\big(t,\bar\alpha_\varepsilon\big) \quad \text{as} \quad t\to+\infty\,. \tag{6.53}$$

Taking into account that $l_0'(\bar\alpha_\varepsilon)<0$ we must have

$$\int_\beta^{\bar\alpha_\varepsilon} k'\big(l_0(\bar\alpha_\varepsilon)-r_0(y)\big)\frac{\dfrac{\partial x_2}{\partial\beta}\big(t_\varepsilon(y),y\big)\,e^{h_1(0)-h_1(t_\varepsilon(y))}}{k\big(l-r\big)\big(t_\varepsilon(y),x_1(t_\varepsilon(y),\bar\alpha_\varepsilon)\big)}\,dy \;>\; \frac{2}{l_0'(\bar\alpha_\varepsilon)} \tag{6.54}$$

for all $\beta\le\bar\alpha_\varepsilon$.

We will estimate the left-hand side of (6.54) by considering four cases:

(1) $y\le\bar\alpha$, $y\in E_\gamma+\pi\mathbb{Z}$, and $y\notin\tilde B_\omega$;
(2) $y\le\bar\alpha$ and $y\in E_\gamma+\pi\mathbb{Z}\cap\tilde B_\omega$;
(3) $y\le\bar\alpha$, $y\notin E_\gamma+\pi\mathbb{Z}$, and $y\notin\tilde B_\omega$;
(4) $y\le\bar\alpha$ and $y\notin E_\gamma+\pi\mathbb{Z}$, $y\in\tilde B_\omega$.

Here $\tilde B_\omega$ is the set introduced in Lemma 5. Denoting the four sets defined above by J_1, J_2, J_3, and J_4, respectively, and assuming that

$$\begin{aligned}&0<\gamma\le\frac{M-l_0(\bar\alpha_\varepsilon)}{4}\,,\\ &\bar\alpha\in D_\varepsilon\,,\quad l_0'\big(\bar\alpha\big)>0\,,\quad M-\gamma<l_0\big(\bar\alpha\big)\,,\end{aligned}$$

according to the statement of Lemma 6, we have the following.

(1) $y\in J_1\;\Rightarrow\; l_0(\bar\alpha_\varepsilon)-M\le l_0(\bar\alpha_\varepsilon)-r_0(y)\le l_0(\bar\alpha_\varepsilon)-M+\gamma$, thus

$$k'\big(l_0(\bar\alpha_\varepsilon)-r_0(y)\big)\le-\psi\big(l_0(\bar\alpha_\varepsilon),\gamma\big), \tag{6.55}$$

where $\psi\big(l_0(\bar\alpha_\varepsilon),\gamma\big)$ is defined by

$$\psi\big(l_0(\bar\alpha_\varepsilon),\gamma\big)\;\stackrel{\text{def}}{=}\;-\sup\,k'(s)\quad\text{for}\quad l_0(\bar\alpha_\varepsilon)-M\le s\le l_0(\bar\alpha_\varepsilon)-M+\gamma\,. \tag{6.56}$$

Hence, we have

$$\int_\beta^{\bar\alpha}\big\{\,*\,\big\}\,\chi_{J_1}(y)\,dy\le-C\,\psi\big(l_0(\bar\alpha_\varepsilon),\gamma\big)\int_\beta^{\bar\alpha}\frac{\partial x_2}{\partial\beta}\big(t_\varepsilon(y),y\big)\,\chi_{J_1}(y)\,dy\,, \tag{6.57}$$

where $\big\{\,*\,\big\}$ represents the function in the integral of (6.54).

Now, recalling (2.28) of section 2, let us observe that

$$\frac{\partial x_2}{\partial\beta}\big(t_\varepsilon(y),y\big)\ge\frac{1}{C}\frac{\partial x_2}{\partial\beta}\big(t(y),y\big)-C\big|t_\varepsilon(y)-t(y)\big| \tag{6.58}$$

for a suitable constant $C>1$. Thus, we may conclude that

$$\begin{aligned}\int_\beta^{\bar\alpha}\big\{\,*\,\big\}\,\chi_{J_1}(y)\,dy\le&-\frac{1}{C}\,\psi\big(l_0(\bar\alpha_\varepsilon),\gamma\big)\int_\beta^{\bar\alpha}\frac{\partial x_2}{\partial\beta}\big(t(y),y\big)\,\chi_{J_1}(y)\,dy\\ &+C\,\psi\big(l_0(\bar\alpha_\varepsilon),\gamma\big)\max_{y\notin\tilde B_\omega}\big|t_\varepsilon(y)-t(y)\big|\int_\beta^{\bar\alpha}\chi_{J_1}(y)\,dy,\end{aligned} \tag{6.59}$$

where $\max_{y\notin\tilde B_\omega}\big|t_\varepsilon(y)-t(y)\big|$ may be small, according to (6.44) of Lemma 5. □

(2) By the same argument of case (1), we know that $k'\big(l_0(\bar\alpha_\varepsilon)-r_0(y)\big)\le -\psi\big(l_0(\bar\alpha_\varepsilon),\gamma\big)$. But now, since $y\in\tilde B_\omega$, we have only (recall Remark 2)

$$\big|t_\varepsilon(y)-t(y)\big|\le C\pi\,. \tag{6.60}$$

Thus, we find

$$\begin{aligned}\int_\beta^{\bar\alpha}\big\{\,*\,\big\}\,\chi_{J_2}(y)\,dy \le -\frac{1}{C}\,\psi\big(l_0(\bar\alpha_\varepsilon),\gamma\big)\int_\beta^{\bar\alpha}\frac{\partial x_2}{\partial\beta}\big(t(y),y\big)\,\chi_{J_2}(y)\,dy\\ +C\,\pi\,\psi\big(l_0(\bar\alpha_\varepsilon),\gamma\big)\int_\beta^{\bar\alpha}\chi_{J_2}(y)\,dy\,.\qquad\square\end{aligned} \tag{6.61}$$

(3) For $y\notin E_\gamma+\pi\mathbb{Z}$ we have only

$$\big|k'\big(l_0(\bar\alpha_\varepsilon)-r_0(y)\big)\big|\le C\,. \tag{6.62}$$

In this case, to estimate $\int_\beta^{\bar\alpha}\big\{\,*\,\big\}\,\chi_{J_3}(y)\,dy$, let us begin by observing that

$$t_\varepsilon(\beta)=-\int_\beta^{\bar\alpha_\varepsilon}\frac{dt_\varepsilon}{d\beta}\,dy\,,\quad t(\beta)=-\int_\beta^{\bar\alpha}\frac{dt}{d\beta}\,dy \tag{6.63}$$

and that from (6.43), having $0\le\bar\alpha_\varepsilon-\bar\alpha\le\pi$,

$$0\le t_\varepsilon(\beta)-t(\beta)\le C\,\pi,\quad \left|\int_{\bar\alpha}^{\bar\alpha_\varepsilon}\frac{dt_\varepsilon}{d\beta}\,dy\right|\le C\,\pi\,. \tag{6.64}$$

Then, thanks to (6.20), the inequalities of (6.64) imply the following:

$$\left|\int_\beta^{\bar\alpha}\frac{\dfrac{\partial x_2}{\partial\beta}\big(t_\varepsilon(y),y\big)\,dy}{k(l-r)\big(t_\varepsilon(y),x_1(t_\varepsilon(y),\bar\alpha_\varepsilon)\big)}-\int_\beta^{\bar\alpha}\frac{\dfrac{\partial x_2}{\partial\beta}\big(t(y),y\big)\,dy}{k(l-r)\big(t(y),x_1(t(y),\bar\alpha)\big)}\right|\le C\,\pi\,. \tag{6.65}$$

Moreover, from (2.11) and (2.12) of section 2 we have the relations

$$\frac{\partial x_2}{\partial\beta}(t,y)=e^{h_2(t)-h_2(0)}\left\{1-r_0'(y)\int_0^t k'\big(l-r\big)\big(\tau,x_2(\tau,y)\big)\,e^{h_2(0)-h_2(\tau)}\,d\tau\right\} \tag{6.66}$$

with

$$h_2(t)-h_2(0)=\frac{1}{2}\ln\Big(k\big(l-r\big)\big(t,x_2(t,y)\big)\Big)-\frac{1}{2}\ln\Big(k\big(l_0(y)-r_0(y)\big)\Big)\,. \tag{6.67}$$

Thus, we easily find that

$$\begin{aligned}\frac{\dfrac{\partial x_2}{\partial\beta}\big(t_\varepsilon(y),y\big)}{k(l-r)\big(t_\varepsilon(y),x_1(t_\varepsilon(y),\bar\alpha_\varepsilon)\big)}&=\frac{k(l-r)\big(t(y),x_1(t(y),\bar\alpha)\big)^{1/2}}{k(l-r)\big(t_\varepsilon(y),x_1(t_\varepsilon(y),\bar\alpha_\varepsilon)\big)^{1/2}}\\ &\quad\cdot\frac{\dfrac{\partial x_2}{\partial\beta}\big(t(y),y\big)}{k(l-r)\big(t(y),x_1(t(y),\bar\alpha)\big)}\\ &\quad-\frac{r_0'(y)\displaystyle\int_{t(y)}^{t_\varepsilon(y)}k'(l-r)\big(\tau,x_2(\tau,y)\big)\,e^{h_2(0)-h_2(\tau)}\,d\tau}{k(l-r)\big(t_\varepsilon(y),x_1(t_\varepsilon(y),\bar\alpha_\varepsilon)\big)^{1/2}k\big(l_0(y)-r_0(y)\big)^{1/2}}\,,\end{aligned} \tag{6.68}$$

where

$$\frac{k\big(l-r\big)\big(t(y),x_1(t(y),\bar\alpha)\big)^{1/2}}{k\big(l-r\big)\big(t_\varepsilon(y),x_1(t_\varepsilon(y),\bar\alpha_\varepsilon)\big)^{1/2}}=\frac{k\big(l_0(\bar\alpha)-r_0(y)\big)^{1/2}}{k\big(l_0(\bar\alpha_\varepsilon)-r_0(y)\big)^{1/2}}\,. \tag{6.69}$$

Moreover, we can rewrite the above quotient as

$$\begin{aligned}&\frac{k\big(l_0(\bar\alpha)-r_0(y)\big)^{1/2}}{k\big(l_0(\bar\alpha_\varepsilon)-r_0(y)\big)^{1/2}}\\ &=1-\frac{k\big(l_0(\bar\alpha_\varepsilon)-r_0(y)\big)-k\big(l_0(\bar\alpha)-r_0(y)\big)}{k\big(l_0(\bar\alpha_\varepsilon)-r_0(y)\big)^{1/2}\big[k\big(l_0(\bar\alpha)-r_0(y)\big)^{1/2}+k\big(l_0(\bar\alpha_\varepsilon)-r_0(y)\big)^{1/2}\big]}\\ &\stackrel{\text{def}}{=}1-Q\big(y,\bar\alpha,\bar\alpha_\varepsilon\big)\,.\end{aligned} \tag{6.70}$$

Thus, integrating over the set J_1, we find

$$\begin{aligned}\int_\beta^{\bar\alpha}\frac{\dfrac{\partial x_2}{\partial\beta}\big(t_\varepsilon(y),y\big)\,\chi_{J_1}(y)\,dy}{k(l-r)\big(t_\varepsilon(y),x_1(t_\varepsilon(y),\bar\alpha_\varepsilon)\big)}&=\int_\beta^{\bar\alpha}\frac{\dfrac{\partial x_2}{\partial\beta}\big(t(y),y\big)\,\chi_{J_1}(y)\,dy}{k(l-r)\big(t(y),x_1(t(y),\bar\alpha)\big)}\\ &-\int_\beta^{\bar\alpha}\frac{\dfrac{\partial x_2}{\partial\beta}\big(t(y),y\big)}{k(l-r)\big(t(y),x_1(t(y),\bar\alpha)\big)}\,Q\big(y,\bar\alpha,\bar\alpha_\varepsilon\big)\,\chi_{J_1}(y)\,dy\\ &-\int_\beta^{\bar\alpha}\frac{r_0'(y)\displaystyle\int_{t(y)}^{t_\varepsilon(y)}k'(l-r)\big(\tau,x_2(\tau,y)\big)\,e^{h_2(0)-h_2(\tau)}\,d\tau}{k(l-r)\big(t_\varepsilon(y),x_1(t_\varepsilon(y),\bar\alpha_\varepsilon)\big)^{1/2}k\big(l_0(y)-r_0(y)\big)^{1/2}}\,\chi_{J_1}(y)\,dy\,.\end{aligned} \tag{6.71}$$

Now, by the definition of J_1 and from the estimates (6.30), (6.46a), and (6.51) (recall the definition of $\tilde B_\omega$ and observation (1), for $\beta\le\bar\alpha-\pi$ we have

$$\int_\beta^{\bar\alpha}\frac{\dfrac{\partial x_2}{\partial\beta}\big(t(y),y\big)}{2\,k(l-r)\big(t(y),x_1(t(y),\bar\alpha)\big)}\,\chi_{J_1}(y)\,dy\ge t(\beta)-C\,\big(\bar\alpha-\beta\big)\,Y\big(\gamma,\omega,\bar\alpha,\beta\big), \tag{6.72}$$

where the quantity $Y=Y\big(\gamma,\omega,\bar\alpha,\beta\big)$ is given by

$$Y\stackrel{\text{def}}{=}\left(\frac{1}{\omega}+\frac{1}{-\phi\big(l_0(\bar\alpha)-M+\gamma\big)}\right)\left(\frac{1}{l_0'(\bar\alpha)\big(\bar\alpha-\beta\big)}+\phi\big(l_0(\bar\alpha)-M\big)\right). \tag{6.73}$$

Hence, from (6.71), (6.72), and (6.26) we easily have

$$\begin{aligned}\int_\beta^{\bar\alpha}\frac{\dfrac{\partial x_2}{\partial\beta}\big(t_\varepsilon(y),y\big)\,\chi_{J_1}(y)dy}{2\,k(l-r)\big(t_\varepsilon(y),x_1(t_\varepsilon(y),\bar\alpha_\varepsilon)\big)}\ &\ge\ t(\beta)-C\big(\bar\alpha-\beta\big)\,Y\big(\gamma,\omega,\bar\alpha,\beta\big)\\ &-C\,\big(\bar\alpha-\beta\big)\sup_{y\in J_1}Q\big(y,\bar\alpha,\bar\alpha_\varepsilon\big)\\ &-C\big(\bar\alpha-\beta\big)\sup_{y\in J_1}\big|r_0'(y)\big|\,\cdot\,\sup_{y\in J_1}\big|t_\varepsilon(y)-t(y)\big|\,.\end{aligned} \tag{6.74}$$

Now, taking into account that $\frac{\partial x_2}{\partial \beta}(t,y) > 0$ and that by (6.65)

$$\int_\beta^{\bar\alpha} \frac{\dfrac{\partial x_2}{\partial \beta}\big(t_\varepsilon(y),y\big)\,dy}{2\,k(l-r)\big(t_\varepsilon(y),x_1(t_\varepsilon(y),\bar\alpha_\varepsilon)\big)} \;\le\; t(\beta) + C\,\pi\,,$$

from (6.74) we find for the integral over J_3:

$$\begin{aligned} 0 \le \int_\beta^{\bar\alpha} \frac{\dfrac{\partial x_2}{\partial \beta}\big(t_\varepsilon(y),y\big)\,\chi_{J_3}(y)dy}{k(l-r)\big(t_\varepsilon(y),x_1(t_\varepsilon(y),\bar\alpha_\varepsilon)\big)} &\le C\,\pi + C\big(\bar\alpha-\beta\big)\,Y\big(\gamma,\omega,\bar\alpha,\beta\big) \\ &+ C\,\big(\bar\alpha-\beta\big)\,\sup_{y\in J_1} Q\big(y,\bar\alpha,\bar\alpha_\varepsilon\big) \\ &+ C\big(\bar\alpha-\beta\big)\,\sup_{y\in J_1}\big|r_0'(y)\big|\,\cdot\,\sup_{y\in J_1}\big|t_\varepsilon(y)-t(y)\big|\,. \end{aligned} \tag{6.75}$$

Then, recalling (6.62) and that in inequality (6.54) the term $e^{h_1(0)-h_1(t_\varepsilon(y))}$ is uniformly bounded, we immediately obtain the estimate

$$\begin{aligned} \int_\beta^{\bar\alpha} \big\{\,*\,\big\}\chi_{J_3}(y)\,dy \le C\,\pi + C\big(\bar\alpha-\beta\big)\,Y\big(\gamma,\omega,\bar\alpha,\beta\big) \\ +\; C\,\big(\bar\alpha-\beta\big)\,\sup_{y\in J_1} Q\big(y,\bar\alpha,\bar\alpha_\varepsilon\big) \\ +\; C\,\big(\bar\alpha-\beta\big)\,\sup_{y\in J_1}\big|r_0'(y)\big|\,\cdot\,\sup_{y\in J_1}\big|t_\varepsilon(y)-t(y)\big|\,. \end{aligned} \tag{6.76}$$

Remark 4. In the following we will always assume that $0<\gamma\le\frac{M-l_0(\bar\alpha_\varepsilon)}{4}$ and that $l_0(\bar\alpha) > M-\gamma$. Thus, for $y\in J_1\subset E_\gamma+\pi\mathbb{Z}$, we have

$$l_0(\bar\alpha_\varepsilon) \;<\; M-\gamma \;\le\; r_0(y)\,,\; l_0(\bar\alpha) \;\le M\,. \tag{6.77}$$

Moreover, let us observe that $k(\eta)$ is strictly decreasing for $\eta<0$ and strictly increasing for $\eta>0$; in fact, by (1.12),

$$k'(\eta)<0 \quad \text{for} \quad \eta<0\,, \quad k'(\eta)>0 \quad \text{for} \quad \eta>0\,.$$

Thus, for $\gamma>0$ sufficiently small from (6.27), (6.70) it follows that $Q\big(y,\bar\alpha,\bar\alpha_\varepsilon\big)\ge 0$ and

$$\begin{aligned} \sup_{y\in J_1} Q\big(y,\bar\alpha,\bar\alpha_\varepsilon\big) \;&\le \frac{\delta}{2}\,\sup_{y\in J_1}\Big(k\big(l_0(\bar\alpha_\varepsilon)-r_0(y)\big)-k(0)\Big) \\ &\le \frac{\delta}{2}\,\sup_{l_0(\bar\alpha_\varepsilon)-M\le\eta\le 0}\Big(k(\eta)-k(0)\Big) \\ &= \frac{\delta}{2}\,\Big(k\big(l_0(\bar\alpha_\varepsilon)-M\big)-k(0)\Big)\,. \end{aligned} \tag{6.78}$$

The last estimate will be important in the following. □

(4) Finally, if $y\notin E_\gamma+\pi\mathbb{Z}$, $y\in\tilde B_\omega$, we easily obtain

$$\begin{aligned} \int_\beta^{\bar\alpha}\big\{\,*\,\big\}\,\chi_{J_4}(y)\,dy \le C\int_\beta^{\bar\alpha}\frac{\partial x_2}{\partial\beta}\big(t(y),y\big)\,\chi_{J_4}(y)\,dy \\ +\,C\,\pi\int_\beta^{\bar\alpha}\chi_{J_4}(y)\,dy\,. \end{aligned} \tag{6.79}$$

□

Remark 5. Let us remark that the constants appearing in the estimates (6.59), (6.61), (6.76), (6.79) are independent of ε, γ, $\omega > 0$, $\bar\alpha \in D_\varepsilon$, and $\beta < \bar\alpha$. Thus, taking $C_0 > 1$ sufficiently large, in the following we will replace all the above constants by C_0. □

Putting together the above estimates, we have the following.

LEMMA 7. *Let us choose* ε, $D_\varepsilon = \big(\alpha_\varepsilon, \bar\alpha_\varepsilon\big)$ *according to* (6.12)–(6.14) *and* $\omega > 0$ *such that*

$$\left(\omega + \int_{\alpha_\varepsilon}^{\bar\alpha_\varepsilon} \big|l_0'(x)\big|\,dx\right) \le \frac{1}{32}\,\frac{1}{C_0^2\,C_1\,C_2}, \tag{6.80}$$

where C_1, C_2 *are the constants appearing, respectively, in* (6.44) *and* (6.48).

Moreover, assume that

$$\delta\left(k\big(l_0(\bar\alpha_\varepsilon) - M\big) - k(0)\right) \le -\frac{1}{32}\,\frac{1}{C_0^2\,C_2}\,k'\big(l_0(\bar\alpha_\varepsilon) - M\big)\,, \tag{6.81}$$

where $\delta > 1$ *is the constant in* (6.27). *Then, taking* $\gamma \le \big(M - l_0(\bar\alpha_\varepsilon)\big)/4$ *and* $\bar\alpha \in D_\varepsilon$ *such that*

$$l_0'(\bar\alpha) > 0 \quad \textit{and} \quad l_0(\bar\alpha) > M - \gamma\,, \tag{6.82}$$

with $\gamma > 0$ *sufficiently small and* $l_0(\bar\alpha)$ *sufficiently close to* M, *the above estimates imply that in* (6.54)

$$\int_\beta^{\bar\alpha} \big\{\,*\,\big\}\,dy \,\to\, -\infty, \quad \textit{as} \quad \beta \,\to\, -\infty\,. \tag{6.83}$$

Noting that $\big|\int_{\bar\alpha}^{\bar\alpha_\varepsilon}\{*\}\,dy\big| \le C$, (6.83) *proves the formation of singularities in finite time. Hence, if* (6.80), (6.81) *hold, we have proved Case* (ii) *of Theorem* 4.

Proof. From the estimates (6.59), (6.61), (6.76), (6.79) (recall Remark 5) we have

$$\begin{aligned}
\int_\beta^{\bar\alpha} \big\{\,*\,\big\}\,dy \le{}& -\frac{1}{C_0}\,\psi\big(l_0(\bar\alpha_\varepsilon),\gamma\big)\int_\beta^{\bar\alpha}\frac{\partial x_2}{\partial\beta}\big(t(y),y\big)\,\chi_{J_1\cup J_2}(y)\,dy \\
&+ C_0\,\psi\big(l_0(\bar\alpha_\varepsilon),\gamma\big)\,\max_{y\notin\tilde B_\omega}\big|t_\varepsilon(y) - t(y)\big|\int_\beta^{\bar\alpha}\chi_{J_1}(y)\,dy \\
&+ C_0\,\pi\,\psi\big(l_0(\bar\alpha_\varepsilon),\gamma\big)\int_\beta^{\bar\alpha}\chi_{J_2}(y)\,dy \\
&+ C_0\int_\beta^{\bar\alpha}\frac{\partial x_2}{\partial\beta}\big(t(y),y\big)\,\chi_{J_4}(y)\,dy \\
&+ C_0\,\pi\int_\beta^{\bar\alpha}\chi_{J_4}(y)\,dy \\
&+ \int_\beta^{\bar\alpha}\big\{\,*\,\big\}\,\chi_{J_3}(y)\,dy,
\end{aligned} \tag{6.84}$$

where from the definition (6.56) we know that $\psi\big(l_0(\bar\alpha_\varepsilon),\gamma\big)$ is strictly positive because $\gamma \le \big(M - l_0(\bar\alpha_\varepsilon)\big)/4$.

Let us analyze the terms of (6.84). First, from (6.48) we have

$$\frac{1}{C_0}\,\psi\big(l_0(\bar\alpha_\varepsilon),\gamma\big)\int_\beta^{\bar\alpha}\frac{\partial x_2}{\partial\beta}\big(t(y),y\big)\,\chi_{J_1\cup J_2}(y)\,dy \geq \frac{1}{C_0}\,\psi\big(l_0(\bar\alpha_\varepsilon),\gamma\big)\,\frac{\bar\alpha-\beta}{2\,C_2} \tag{6.85}$$
$$\stackrel{\text{def}}{=} K_\gamma\,\big(\bar\alpha-\beta\big),$$

provided $l_0'\big(\bar\alpha\big)>0$ and

$$l_0(\bar\alpha)>M-\gamma\,,\quad l_0(\bar\alpha)\quad\text{is sufficiently close to}\quad M,\quad\text{and}\quad \beta\ll\bar\alpha\ . \tag{6.86}$$

Remark 6. Let us remark again that, by (6.56), $\psi\big(l_0(\bar\alpha_\varepsilon),\gamma\big)>0$ for $0<\gamma\leq\big(M-l_0(\bar\alpha_\varepsilon)\big)/4$; moreover, since $k(\eta)\in C^1$, we have

$$\lim_{\gamma\to0^+}\psi\big(l_0(\bar\alpha_\varepsilon),\gamma\big)=-k'\big(l_0(\bar\alpha_\varepsilon)-M\big)>0\,. \tag{6.87}$$

Thus, we may assume that

$$K\ \leq\ K_\gamma\ \leq\ 2\,K \tag{6.88}$$

for a suitable $K>0$. This fact permits us to estimate the terms of (6.84) *uniformly* with respect to γ, for $\gamma>0$ sufficiently small. □

Next, thanks to (6.46), it follows that

$$C_0\,\pi\,\Big(1+\psi\big(l_0(\bar\alpha_\varepsilon),\gamma\big)\Big)\int_\beta^{\bar\alpha}\chi_{J_2\cup J_4}(y)\,dy\leq\frac{K}{8}\,\big(\bar\alpha-\beta\big), \tag{6.89}$$

provided again that $l_0(\bar\alpha)$ is sufficiently close to M and $\beta\ll\bar\alpha$.

From the estimate (6.51) of the proof of Lemma 6, we find also that

$$C_0\int_\beta^{\bar\alpha}\frac{\partial x_2}{\partial\beta}\big(t(y),y\big)\,\chi_{J_4}(y)\,dy\leq\frac{K}{8}\,\big(\bar\alpha-\beta\big), \tag{6.90}$$

provided the conditions (6.86) are satisfied.

Now, let us consider the second term in (6.84). Using (6.44) and the condition (6.80), we may estimate

$$t_\varepsilon(y)-t(y)\quad\text{for}\quad y\notin\tilde B_\omega\,;$$

then, from (6.88) and the definition of K_γ, we obtain that

$$C_0\,\psi\big(l_0(\bar\alpha_\varepsilon),\gamma\big)\,\max_{y\notin\tilde B_\omega}\big|t_\varepsilon(y)-t(y)\big|\int_\beta^{\bar\alpha}\chi_{J_1}(y)\,dy\leq\frac{K}{8}\,\big(\bar\alpha-\beta\big)\,. \tag{6.91}$$

Finally, let us estimate the term $\int_\beta^{\bar\alpha}\big\{*\big\}\,\chi_{J_3}(y)\,dy$. From (6.43), (6.76), and the result of Remark 4, for $\gamma>0$ sufficiently small, we may write

$$\begin{aligned}\int_\beta^{\bar\alpha}\big\{\,*\,\big\}\chi_{J_3}(y)\,dy\leq{}& C_0\,\pi+C_0\,\big(\bar\alpha-\beta\big)\,Y\big(\gamma,\omega,\bar\alpha,\beta\big)\\ &+C_0\,\frac{\delta}{2}\,\big(\bar\alpha-\beta\big)\,\Big(k\big(l_0(\bar\alpha_\varepsilon)-M\big)-k(0)\Big)\\ &+C_0\big(\bar\alpha-\beta\big)\sup_{y\in J_1}\big|r_0'(y)\big|\ C\,\pi\,,\end{aligned} \tag{6.92}$$

where we have easily

$$C_0\, Y\big(\gamma,\omega,\bar\alpha,\beta\big) \le \frac{K}{8}\,, \quad C_0 \sup_{y\in J_1} \big|r_0'(y)\big|\, C\,\pi \le \frac{K}{8}\,,$$

provided $\gamma > 0$ is sufficiently small and (6.86) holds (note that $\sup_{E_\gamma} |r_0'(y)| \to 0$ as $\gamma \to 0^+$).

Moreover, by assumption (6.81) on $l_0(\bar\alpha_\varepsilon)$ and definition (6.56) of $\psi\big(l_0(\bar\alpha_\varepsilon),\gamma\big)$ we have also the inequality

$$\frac{\delta}{2}\, C_0 \Big(k\big(l_0(\bar\alpha_\varepsilon) - M\big) - k(0)\Big) \le \frac{1}{32}\frac{1}{C_0\, C_2}\,\psi\big(l_0(\bar\alpha_\varepsilon),\gamma\big) \;\le\; \frac{K}{8} \tag{6.93}$$

for $\gamma > 0$ sufficiently small.

Thus, summing up the above estimates, we have proved that

$$\int_\beta^{\bar\alpha} \big\{\, *\,\big\}\, dy \le C_0\pi - \frac{K}{8}\,\big(\bar\alpha - \beta\big), \tag{6.94}$$

provided $\gamma > 0$ is sufficiently small and (6.86) holds. This completes the proof of Lemma 7. □

Conclusion of the proof of case (ii) of Theorem 4. To complete the proof of case (ii) it is now sufficient to find $D_\varepsilon = \big(\alpha_\varepsilon,\, \bar\alpha_\varepsilon\big)$, $\omega > 0$ such that the conditions (6.12)–(6.14) and (6.80), (6.81) are satisfied.

First, let us observe that, since $k(\eta) \in C^1$ and

$$k'(\eta) < 0 \quad \text{for} \quad \eta < 0\,,$$

for every $R > 0$ we can find a sequence $\big\{\eta_n\big\}$ such that $\eta_n < 0\,,\ \eta_n \to 0$, and

$$k'\big(\eta_n\big) \le -\,R\,\Big(k\big(\eta_n\big) - k(0)\Big)\,. \tag{6.95}$$

Thus, for fixed

$$R = 32\, C_0^2\, C_2\, \delta\,,$$

and taking into account that $\max l_0(x) = l_0(0) = M$, we can find easily a sequence $\big\{\alpha_n\big\}\,,\ 0 < \alpha_n < \pi$, such that, as $n \to \infty$,

$$l_0\big(\alpha_n\big) \to M\,, \quad l_0'(\alpha_n) < 0 \tag{6.96}$$

(thanks to Sard's theorem) and

$$k'\big(l_0\big(\alpha_n\big) - M\big) \;\le\; -32\, C_0^2\, C_2\, \delta\,\Big(k\big(l_0(\alpha_n) - M\big) - k(0)\Big)\,. \tag{6.97}$$

Hence, we have verified the condition (6.81).

Moreover, let us observe that for any fixed $n \in \mathbb{N}$, for $\gamma > 0$ sufficiently small, we have also

$$\sup\, k'(s) \;\le\; -16\, C_0^2\, C_2\, \delta\,\Big(k\big(l_0(\alpha_n) - M\big) - k(0)\Big) \tag{6.98}$$

for $l_0\big(\alpha_n\big) - M \le s \le l_0\big(\alpha_n\big) - M + \gamma\,.$

Thus, it is clear that for any fixed $n \in \mathbb{N}$ we have

$$\frac{\delta}{2}\Big(k\big(l_0(\alpha_n) - M\big) - k(0)\Big) \le \frac{1}{32}\frac{1}{C_0^2\, C_2}\,\psi\big(l_0(\alpha_n), \gamma\big) \le \frac{K}{8} \tag{6.99}$$

(that is, (6.93)), provided $\gamma > 0$ is sufficiently small.

To verify also (6.12)–(6.14) and (6.80) (for $\omega > 0$ small), we may easily choose the sequence $\{\alpha_n\}$ which satisfies (6.96), such that

$$\inf_{[0,\alpha_n]} l_0(x) \;\to\; M \tag{6.100}$$

as $n \to \infty$. Clearly, this implies that

$$\lim_{n\to\infty} \int_0^{\alpha_n} \big|l_0'(x)\big|\, dx = 0\,. \tag{6.101}$$

Then, taking for $n_0 \in \mathbb{N}$ sufficiently large

$$\bar{\alpha}_\varepsilon = \alpha_{n_0} \tag{6.102}$$

and $\alpha_\varepsilon < 0$ sufficiently close to 0 all the conditions of Lemma 7 are satisfied. □

ON THE SPATIAL DECAY OF SOLUTIONS TO A QUASI-LINEAR PARABOLIC INITIAL-BOUNDARY VALUE PROBLEM AND THEIR DERIVATIVES*

L. E. PAYNE† AND G. A. PHILIPPIN‡

Abstract. In this paper, we study the spatial decay of the solution of a quasi-linear heat equation in a long cylindrical region if the far end and the lateral surface are held at a zero temperature and a nonzero temperature is applied at the near end. Our result follows from the maximum principle applied to an auxiliary function Φ defined on the solution u and its derivatives.

Key words. parabolic equations, decay bounds, maximum principle

1. Introduction. In this paper, we are interested in the spatial decay of the solution of a quasi-linear heat equation in a long cylindrical region if the far end and the lateral surface are held at zero temperature and a nonzero temperature is applied at the near end. The specific equation we consider is of the form

$$\Delta u - \epsilon(x_3, t)\,\frac{\partial u}{\partial t} + f(u) = 0$$

in $\Omega \times \mathbb{R}^+$, where the generators of the cylinder Ω are parallel to the x_3-axis, Δ denotes the Laplace operator, and the function $f(u)$ may be such that under certain conditions, the solution can blow up at some point in space time. Our goal is to determine data hypotheses which will ensure that the solution remains bounded and to demonstrate that under these hypotheses, the solution decays at least exponentially in x_3, and when ϵ is constant the solution decays for fixed t at least as fast as $e^{-cx_3^2}$, where c depends on t. In fact, we derive an explicit decay bound for the solution and its cross sectional derivatives.

Decay in time for a related problem has previously been studied by the authors [8]. Some of the arguments here are patterned after arguments in that paper.

In section 2, we establish a maximum principle for a combination of u and its derivatives, and in section 3, we use this principle to derive the explicit decay bounds for u and its cross sectional derivatives. Finally, in section 4, we use the results of section 3 to establish further norm bounds.

2. A maximum principle. Let D be a bounded convex domain in the (x_1, x_2)-plane and let $u(\mathbf{x}, t)$ be defined in the finite cylinder $\Omega := D \times [0, L]$ for $0 < t < T$ as the classical solution of the following initial-boundary value problem:

$$\Delta u - \epsilon(x_3, t)\,\frac{\partial u}{\partial t} + f(u) = 0, \quad \mathbf{x} := (x_1, x_2, x_3) \in \Omega, \quad 0 < t < T, \tag{2.1}$$

$$u(\mathbf{x}, t) = 0, \quad \mathbf{x} \in \partial\Omega_L \cup \partial\Omega_{\text{lat}}, \quad 0 < t < T, \tag{2.2}$$

$$u(\mathbf{x},t) = h(x_1,x_2,t), \quad \mathbf{x} \in \partial\Omega_0, \quad 0 < t < T, \tag{2.3}$$

$$u(\mathbf{x},0) = 0, \quad \mathbf{x} \in \Omega, \tag{2.4}$$

with $\partial\Omega_0 := D \times \{0\}, \partial\Omega_L := D \times \{L\}, \partial\Omega_{\text{lat}} := \partial D \times (0,L)$, $\epsilon(x_3,t) > 0, f'(u) \geq 0, uf(u) \geq 0, f(0) = 0$, and $h(x_1,x_2,t)$ is a prescribed bounded function of its arguments such that $h(x_1,x_2,0) = 0$.

In this section, we derive a maximum principle for the quantity

$$\Phi(\mathbf{x},t) := \left\{ \left(\frac{\partial u}{\partial x_1}\right)^2 + \left(\frac{\partial u}{\partial x_2}\right)^2 + au^2 + 2F(u) \right\} g(x_3,t), \tag{2.5}$$

defined on the solution of (2.1), (2.2), (2.3), (2.4), where $F(u)$ and $g(x_3,t)$ are to be appropriately chosen functions and a is a nonnegative constant.

It is well known that the solution of (2.1), (2.2), (2.3), (2.4) will exist up to time of blow-up [1], [5], [6] if in fact the solution does blow up. We shall first assume that T is some time prior to the blow-up time. In section 3, we will demonstrate that if the data are appropriately restricted, the solution will remain bounded for all time and that in this case T may be taken to be infinity. We first establish the following lemma.

LEMMA 2.1. *Let u be a classical solution of* (2.1) *with $f' \geq 0$. Let $g(x_3,t)$ be a particular positive solution of the parabolic inequality*

$$\epsilon(x_3,t)\left(\frac{1}{g}\right)_{,t} - \left(\frac{1}{g}\right)_{,x_3x_3} + \frac{2a}{g} \geq 0. \tag{2.6}$$

Let $F(u)$ be defined as

$$F(u) := \int_0^u f(\eta)\, d\eta. \tag{2.7}$$

Assume moreover that

$$uF' - 2F \geq 0. \tag{2.8}$$

We then conclude that $\Phi(\mathbf{x},t)$ defined in (2.5) *satisfies the following parabolic inequality:*

$$L\Phi := \Delta\Phi - \epsilon(x_3,t)\,\Phi_{,t} + (u_{,\alpha}u_{,\alpha})^{-1} w_\beta \Phi_{,\beta} \geq 0, \tag{2.9}$$

$\mathbf{x} \in \Omega$, $0 < t < T$, where w_β are functions regular throughout $\Omega \times (0,T)$.

In Lemma 2.1 and in the remainder of the paper, we adopt the following notation: $u_{,\alpha} := \frac{\partial u}{\partial x_\alpha}$, $\alpha = 1,2$; $u_{,k} := \frac{\partial u}{\partial x_k}$, $k = 1,2,3$; $u_{,t} := \frac{\partial u}{\partial t}$. Moreover, summation over repeated indices is assumed from 1 to 2 for Greek indices and from 1 to 3 for Latin indices.

For the proof of Lemma 2.1, we compute

$$\Phi_{,\beta} = (2u_{,\alpha\beta}u_{,\alpha} + 2auu_{,\beta} + 2F'u_{,\beta})g, \tag{2.10}$$

$$\begin{aligned}\Phi_{,\beta\beta} = {} & (2u_{,\alpha\beta\beta}u_{,\alpha} + 2u_{,\alpha\beta}u_{,\alpha\beta} + 2au_{,\beta}u_{,\beta} + 2auu_{,\beta\beta} \\ & + 2F''u_{,\beta}u_{,\beta} + 2F'u_{,\beta\beta})\, g,\end{aligned} \tag{2.11}$$

$$\Phi_{,x_3} = (2u_{,\alpha}u_{,\alpha x_3} + 2auu_{,x_3} + 2F'u_{,x_3})\, g + \Phi\frac{g_{,x_3}}{g}, \tag{2.12}$$

$$\begin{aligned}\Phi_{,x_3x_3} = {} & (2u_{,\alpha x_3}u_{,\alpha x_3} + 2u_{,\alpha}u_{,\alpha x_3x_3} + 2au_{,x_3}^2 + 2auu_{,x_3x_3} \\ & +2F''u_{,x_3}^2 + 2F'u_{,x_3x_3})\, g \\ & + \left(\Phi_{,x_3} - \Phi\,\frac{g_{,x_3}}{g}\right)\frac{g_{,x_3}}{g} + \Phi_{,x_3}\,\frac{g_{,x_3}}{g} + \Phi\left(\frac{g_{,x_3}}{g}\right)_{,x_3},\end{aligned} \tag{2.13}$$

$$\begin{aligned}\Delta\Phi = {} & \{2u_{,\alpha kk}u_{,\alpha} + 2u_{,\alpha k}u_{,\alpha k} + 2a|\nabla u|^2 + 2au\Delta u \\ & +2F''|\nabla u|^2 + 2F'\Delta u\}\, g \\ & +2\Phi_{,x_3}\,\frac{g_{,x_3}}{g} + \Phi\left\{\left(\frac{g_{,x_3}}{g}\right)_{,x_3} - \left(\frac{g_{,x_3}}{g}\right)^2\right\},\end{aligned} \tag{2.14}$$

$$\Phi_{,t} = (2u_{,\alpha t}u_{,\alpha} + 2auu_{,t} + 2F'u_{,t})\, g + \Phi\,\frac{g_{,t}}{g}. \tag{2.15}$$

Combining (2.14) and (2.15) leads to

$$\begin{aligned}& \Delta\Phi - \epsilon(x_3,t)\,\Phi_{,t} \\ & = \{2u_{,\alpha k}u_{,\alpha k} + 2a|\nabla u|^2 + 2u_{,\alpha}[\Delta u - \epsilon u_{,t}]_{,\alpha} \\ & \quad +2(F' + au)[\Delta u - \epsilon u_{,t}] + 2F''|\nabla u|^2\}\, g \\ & \quad +2\Phi_{,x_3}\,\frac{g_{,x_3}}{g} + \Phi\left\{\left(\frac{g_{,x_3}}{g}\right)_{,x_3} - \left(\frac{g_{,x_3}}{g}\right)^2 - \epsilon\,\frac{g_{,t}}{g}\right\}.\end{aligned} \tag{2.16}$$

The first two terms on the right-hand side of (2.16) may be estimated as follows:

$$\begin{aligned}2u_{,\alpha k}u_{,\alpha k} + 2a|\nabla u|^2 & \geq 2u_{,\alpha\beta}u_{,\alpha\beta} + 2au_{,\alpha}u_{,\alpha} \\ & \geq \frac{2u_{,\alpha\beta}u_{,\beta}u_{,\alpha\gamma}u_{,\gamma}}{u_{,\delta}u_{,\delta}} + 2au_{,\alpha}u_{,\alpha},\end{aligned} \tag{2.17}$$

where we have used the Schwarz inequality at the last step of (2.17). Making iterated use of (2.10), we may represent $u_{,\alpha\beta}u_{,\beta}u_{,\alpha\gamma}u_{,\gamma}$ as follows:

$$u_{,\alpha\beta}u_{,\beta}u_{,\alpha\gamma}u_{,\gamma} = 2[au + F']^2u_{,\beta}u_{,\beta} + \widetilde{w}_\beta\Phi_{,\beta}, \tag{2.18}$$

where $\widetilde{w}_\beta$ are two functions regular throughout $\Omega\times(0,\infty)$. Combining (2.16), (2.17), and (2.18) leads to

$$\begin{aligned}& \Delta\Phi - \epsilon(x_3,t)\,\Phi_{,t} + \frac{1}{u_{,\alpha}u_{,\alpha}}\,\Phi_{,\beta}w_\beta \\ & \geq \big\{2[au + F']^2 + 2au_{,\alpha}u_{,\alpha} + 2u_{,\alpha}[\Delta u - \epsilon u_{,t}]_{,\alpha} + 2F''|\nabla u|^2 \\ & \quad +2[F' + au][\Delta u - \epsilon u_{,t}]\big\}\, g + \Phi\left\{\left(\frac{g_{,x_3}}{g}\right)_{,x_3} - \left(\frac{g_{,x_3}}{g}\right)^2 - \epsilon\,\frac{g_{,t}}{g}\right\} \\ & = \{2(F' + au)[\Delta u - \epsilon u_{,t} + F'] + 2u_{,\alpha}[\Delta u - \epsilon u_{,t} + F']_{,\alpha} \\ & \quad +2F''u_{,x_3}^2 + 2a[uF' - 2F]\}\, g + \Phi g\left\{\epsilon\left(\frac{1}{g}\right)_{,t} - \left(\frac{1}{g}\right)_{,x_3x_3} + \frac{2a}{g}\right\},\end{aligned} \tag{2.19}$$

from which the conclusion of Lemma 2.1 follows.

From Lemma 2.1 and Nirenberg's maximum principle [7], [10] it follows then that $\Phi(\mathbf{x},t)$ ($\not\equiv$ const.) takes its maximum value either at $(\mathbf{x},t)\in\partial\Omega\times(0,T]$ or initially at $\mathbf{x}\in\Omega$, or at $(\mathbf{x}^*,t^*)\in\Omega\times\{0<t\le T\}$, at which $u_{,\alpha}u_{,\alpha}=0$. Moreover it follows from Friedman's boundary lemma [2], [10] that Φ ($\not\equiv$ const.) cannot take its maximum value on $\partial\Omega_L\cup\partial\Omega_{\rm lat}$ since the normal derivative of Φ is nonpositive on $\partial\Omega_L\cup\partial\Omega_{\rm lat}$. Indeed, we have

$$\frac{\partial\Phi}{\partial n}=\frac{\partial\Phi}{\partial x_3}=0\quad\text{ on }\partial\Omega_L \tag{2.20}$$

and

$$\frac{\partial\Phi}{\partial n}=2u_nu_{nn}g=-2u_n^2gk\le 0\quad\text{ on }\partial\Omega_{\rm lat}, \tag{2.21}$$

where k is the curvature of ∂D. Finally, it is clear that Φ cannot take its maximum value initially since $\Phi=0$ at time $t=0$.

3. Decay bounds for $\mathbf{u^2}$ and $\mathbf{u_{,\alpha}u_{,\alpha}}$. In this section, we want to eliminate the possibility that Φ defined in (2.5) takes its maximum value at $(\mathbf{x}^*,t^*)\in\Omega\times(0,T]$, where $u_{,\alpha}u_{,\alpha}=0$. This will be achieved by making the parameter a small enough. Under such circumstances, Φ will achieve its maximum value on $\partial\Omega_0\times(0,T]$. Decay bounds for u^2 and $u_{,\alpha}u_{,\alpha}$ are then obtained from the above information.

We first consider the linear case corresponding to $f(u)=0$ in (2.1). In this case, of course, we may take $T=\infty$. Let us assume that Φ takes its maximum value at $(\mathbf{x},t^*)\in\Omega\times\mathbb{R}^+$ at which $u_{,\alpha}u_{,\alpha}=0$, i.e., assume

$$\Phi=\{u_{,\alpha}u_{,\alpha}+au^2\}\,g(x_3,t)\le au_M^2g(x_3^*,t^*), \tag{3.1}$$

where $u_M^2:=\max_{\Omega\times\mathbb{R}^+}(u^2)<\infty$ since the boundary data h are bounded. Evaluated at $x_3=x_3^*$, $t=t^*$, we obtain the inequality

$$u_{,\alpha}u_{,\alpha}(x_1,x_2,x_3^*,t^*)\le a[u_M^2-u^2(x_1,x_2,x_3^*,t^*)]. \tag{3.2}$$

Let $d\ell$ denote the element of length along the straight line in D from (x_1^*,x_2^*) to the nearest point $(\bar x_1,\bar x_2)$ of ∂D. We may then write

$$\left|\frac{du}{d\ell}\right|\le[u_{,\alpha}u_{,\alpha}]^{1/2}\le a^{1/2}[u_M^2-u^2(x_1,x_2,x_3^*,t^*)]^{1/2}. \tag{3.3}$$

Integrating along this line, we obtain

$$\frac{\pi}{2}\le\sqrt{a}|\mathbf{x}^*-\overline{\mathbf{x}}|\le\sqrt{a}d, \tag{3.4}$$

where d is the inradius of D. It then follows from (3.4) that the inequality

$$a\ge\frac{\pi^2}{4d^2}=:a_0 \tag{3.5}$$

is a necessary condition for the maximum of Φ to occur at $(\mathbf{x}^*,t^*)$. If (3.5) is violated, then Φ cannot have its maximum at $(\mathbf{x}^*,t^*)$, and it must therefore occur on $\partial\Omega_0=D\times\{0\}$. We are then led to the inequality

$$\Phi\le\max_{\partial\Omega_0\times\mathbb{R}^+}\Phi, \tag{3.6}$$

valid for all $a \in [0, a_0)$. Increasing a to a_0, we are led to the following result.

THEOREM 3.1. *Let u be the classical solution of* (2.1), (2.2), (2.3), (2.4) *with $T = \infty$ and $f \equiv 0$. Let $g(x_3, t) > 0$ be any particular solution of* (2.6). *Then the following inequality holds:*

$$u_{,\alpha}u_{,\alpha} + a_0 u^2 \leq \frac{H^2}{g(x_3, t)} \tag{3.7}$$

with

$$H^2 := \max_{D\times\mathbb{R}^+} \{h_{,\alpha}h_{,\alpha} + a_0 h^2]\, g(0, t)\}, \tag{3.8}$$

where a_0 is given by (3.5).

One possible choice of $g(x_3, t)$ is

$$g^{(1)}(x_3) = e^{\sqrt{2a}x_3}. \tag{3.9}$$

However, in the special case $\epsilon(x_3, t) = 1$, there are other simple choices for g. Note that the case $\epsilon = \text{const.}$ reduces to the case $\epsilon = 1$ by rescaling in t. Thus, in the remainder of the paper, we consider the particular case $\epsilon(x_3, t) = 1$ and observe that we may make the following choices for g:

$$g^{(2)}(t) = e^{2at}, \tag{3.10}$$

$$g^{(3)}(x_3, t) = e^{2at}(t + t_0)^{1/2} \exp\{x_3^2/4(t + t_0)\}, \tag{3.11}$$

where t_0 is an arbitrary positive constant in (3.11). With the choice (3.11) for g inequality (3.7) clearly implies exponential decay in t with fixed x_3 for both u^2 and $u_{,\alpha}u_{,\alpha}$. It also implies that for fixed t, u^2 and $u_{,\alpha}u_{,\alpha}$ both decay $0(e^{-cx_3^2})$ for some $c(t)$ as x_3 increases.

Furthermore, the pointwise decay bound is explicit. It was already shown (see [9]) that this rate of spatial decay holds for u itself, but the methods used in [9] do not carry over to the nonlinear problem (2.1), (2.2), (2.3), (2.4). The decay estimates require of course that the data be such that the quantity H^2 in (3.8) is bounded. In the linear case with $T = \infty$, this implies appropriate decay of h^2 and $h_{,\alpha}h_{,\alpha}$ as $t \longrightarrow \infty$.

It should be remarked that in the case $f(u) \equiv 0$ but $\epsilon(x_3, t)$ is an arbitrary nonnegative function of x_3 and t, the choice (3.9) would imply exponential decay in x_3 for both u^2 and $u_{,\alpha}u_{,\alpha}$, in which case we would have

$$H^2 := \max_{D\times\mathbb{R}^+} \{h_{,\alpha}h_{,\alpha} + a_0 h^2\}.$$

We turn now to the nonlinear case, i.e., the case of (2.1) with $f \not\equiv 0$. For simplicity, we assume that the boundary data $h(x_1, x_2, t)$ are nonnegative so that u will also be nonnegative. Moreover, we assume that $f(s)$ is differentiable on $(0, \infty)$ and satisfies the conditions

$$sf'(s) \geq f(s) > 0, \quad s > 0, \quad f(0) = 0. \tag{3.12}$$

Clearly (3.12) implies (2.8) with $f = F'$ and implies that the positive quantity $\frac{f(s)}{s}$ is nondecreasing in s.

As indicated earlier, the solution of (2.1), (2.2), (2.3), (2.4) with $f \geq 0$ may blow up at some time $\hat{t}$ which may be finite or infinite [1], [5], [6]. However, if blow-up does occur at $\hat{t}$, then the solution of (2.1), (2.2), (2.3), (2.4) will exist in $(0, \hat{t})$ and Lemma 2.1 holds true in $(0, T)$ for $T < \hat{t}$, so that Φ defined in (2.5) with $f = F'$ will assume its maximum value either on $\partial\Omega_0 := D \times \{0\}$ or at an interior point $\mathbf{x}^*$ of Ω at $t^* < T$ where $u_{,\alpha}u_{,\alpha} = 0$. Let us assume this latter situation, i.e., assume the inequality

$$\Phi(\mathbf{x}, t) \leq \Phi(\mathbf{x}^*, t^*). \tag{3.13}$$

Evaluating (3.13) at $x_3 = x_3^*$, $t = t^*$, we obtain the inequality

$$u_{,\alpha}u_{,\alpha} \leq a[u^2(\mathbf{x}^*, t^*) - u^2] + 2[F(u(\mathbf{x}^*, t^*)) - F(u)]. \tag{3.14}$$

Using the generalized mean value theorem and (3.12), we may write

$$\begin{aligned} 2[F(u(\mathbf{x}^*, t^*)) - F(u)] &= \frac{f(s)}{s}[u^2(\mathbf{x}^*, t^*) - u^2] \\ &\leq \frac{f(u(\mathbf{x}^*, t^*))}{u(\mathbf{x}^*, t^*)}[u^2(\mathbf{x}^*, t^*) - u^2], \end{aligned} \tag{3.15}$$

where s is some intermediate value in $(u, u(\mathbf{x}^*, t^*))$. Combining (3.14) and (3.15), we obtain

$$u_{,\alpha}u_{,\alpha} \leq \left\{ a + \frac{f(u(\mathbf{x}^*, t^*))}{u(\mathbf{x}^*, t^*)} \right\} [u^2(\mathbf{x}^*, t^*) - u^2], \tag{3.16}$$

from which we obtain the inequality

$$a \geq \frac{\pi^2}{4d^2} - \frac{f(u(\mathbf{x}^*, t^*))}{u(\mathbf{x}^*, t^*)}, \tag{3.17}$$

in analogy to (3.5). As before, we then conclude that any nonzero Φ cannot reach its maximum at $(\mathbf{x}^*, t^*)$ if we select

$$0 \leq a < a_1 := \frac{\pi^2}{4d^2} - \frac{f(u(\mathbf{x}^*, t^*))}{u(\mathbf{x}^*, t^*)}. \tag{3.18}$$

The value a_1 defined by (3.18) is, however, of no practical use. We obviously need some conditions on the boundary data h which lead to an explicitly computable upper bound for $\frac{f(u)}{u}$ which is strictly dominated by $\frac{\pi^2}{4d^2}$. Such conditions are given in the next lemma.

LEMMA 3.2. *Let $\phi(x_1, x_2)$ be the first Dirichlet eigenfunction of D, i.e.,*

$$\phi_{,\alpha\alpha} + \lambda\phi = 0, \quad \phi > 0 \text{ in } D, \quad \phi = 0 \text{ on } \partial D, \tag{3.19}$$

normalized by

$$\max_D \phi = 1. \tag{3.20}$$

Let x_0, a, M be positive constants such that

$$0 \leq h(x_1, x_2, t) \leq M\phi \frac{1}{\sqrt{t}} \exp\left(-\frac{x_0^2}{4t} - at \right). \tag{3.21}$$

Let $\hat{h}$ *be defined as*

$$\hat{h} := M \max_{t>0} \left\{ \frac{1}{\sqrt{t}} \exp\left(-\frac{x_0^2}{4t} - at \right) \right\} \tag{3.22}$$
$$= \frac{M}{x_0} \left\{ 1 + [4ax_0^2 + 1]^{1/2} \right\}^{1/2} \exp\left(-\frac{1}{2}(4ax_0^2 + 1)^{1/2} \right).$$

Assume (3.12) *and that* $\hat{h}$ *is such that*

$$\frac{f(\hat{h})}{\hat{h}} < \frac{\pi^2}{4d^2} - a. \tag{3.23}$$

Then we conclude that $\frac{f(u)}{u}$ *remains bounded away from* $\frac{\pi^2}{4d^2} - a$ *for all time, i.e., we have*

$$\frac{f(u(\mathbf{x},t))}{u(\mathbf{x},t)} < \frac{\pi^2}{4d^2} - a, \quad \mathbf{x} \in \Omega, \quad t > 0. \tag{3.24}$$

Moreover, we have the following estimate:

$$u(\mathbf{x},t) \le U(\mathbf{x},t) := \frac{M\phi}{\sqrt{t}} \exp\left(-\frac{(x_0 + x_3)^2}{4t} - at \right), \mathbf{x} \in \Omega, t > 0. \tag{3.25}$$

For the proof of Lemma 3.2, we let U satisfy

$$\Delta U - \frac{\partial U}{\partial t} + (\lambda - a)\, U = 0 \quad \text{in } \Omega \times \mathbb{R}^+, \tag{3.26}$$

$$U \ge h \quad \text{on } \partial\Omega_0 \times \mathbb{R}^+, \tag{3.27}$$

$$U \ge 0 \quad \text{on } \partial\Omega_L \times \mathbb{R}^+, \tag{3.28}$$

$$U = 0 \quad \text{on } \partial\Omega_{\text{lat}} \times \mathbb{R}^+, \tag{3.29}$$

$$U(\mathbf{x},t) = 0 \quad \text{in } \Omega, \quad t \longrightarrow 0. \tag{3.30}$$

Suppose now that (3.24) is violated and let $\tilde{t}$ be the first time for which $\frac{f(u)}{u}$ reaches the value $\frac{\pi^2}{4d^2} - a$ at some point $\tilde{\mathbf{x}} \in \Omega$. Then we would have

$$\max_{\mathbf{x}\in\Omega} \frac{f(u(\mathbf{x},t))}{u(\mathbf{x},t)} < \frac{\pi^2}{4d^2} - a \quad \text{for all } t \in [0,\tilde{t}). \tag{3.31}$$

From (3.26), (3.31), and the inequality

$$\lambda > \frac{\pi^2}{4d^2} \tag{3.32}$$

established by Hersch in [3], we then obtain

$$\Delta U - \frac{\partial U}{\partial t} < -U \max_{\mathbf{x}\in\Omega} \frac{f(u(\mathbf{x},t))}{u(\mathbf{x},t)}, \quad t \in [0,\tilde{t}). \tag{3.33}$$

Setting

$$w := U - u, \tag{3.34}$$

we obtain from (2.1) and (3.33)

$$\Delta w - \frac{\partial w}{\partial t} < -w \max_{\Omega} \frac{f(u(\mathbf{x},t))}{u(\mathbf{x},t)}, \quad t \in [0,\tilde{t}). \tag{3.35}$$

It then follows from the maximum principle that $w(\mathbf{x},t)$ is positive in $\Omega \times (0,\tilde{t})$, i.e., we have (3.25) in $(0,\tilde{t})$, and we obtain using (3.20), (3.23)

$$u(\mathbf{x},t) \le \hat{h}, \quad t \in (0,\tilde{t}). \tag{3.36}$$

Finally, (3.36), (3.12), and (3.23) imply the inequality

$$\frac{f(u)}{u} \le \frac{f(\hat{h})}{\hat{h}} < \frac{\pi^2}{4d^2} - a, \quad 0 \le t \le \hat{t}. \tag{3.37}$$

In particular, we have

$$\frac{f(u(\mathbf{x},\tilde{t}))}{u(\tilde{\mathbf{x}},\tilde{t})} < \frac{\pi^2}{4d^2} - a, \tag{3.38}$$

in contradiction to the definition of $(\tilde{\mathbf{x}},\tilde{t})$. We then conclude that $\tilde{t} = \infty$, and the proof of Lemma 3.2 is complete.

As a consequence of Lemma 3.2 together with the assertion that includes (3.18), we obtain exponential decay bounds for u^2 and for $u_{,\alpha}u_{,\alpha}$ given in the next theorem.

THEOREM 3.3. *Under the assumptions of Lemma* 3.2*, let us define*

$$a_1 := \frac{\pi^2}{4d^2} - \frac{f(\hat{h})}{\hat{h}}. \tag{3.39}$$

We then conclude that Φ *given by* (2.5), (3.11) *takes its maximum value on* $\partial\Omega_0 \times (0,t)$ *for all* $a \in [0,a_1)$*. With* $a \longrightarrow a_1$*, we obtain*

$$u_{,\alpha}u_{,\alpha} + a_1 u^2 + 2F(u) \le Q^2(x_3,t) \tag{3.40}$$

with

$$Q^2(x_3,t) := \frac{\mathcal{H}^2}{\sqrt{t+t_0}} \exp\left(-2a_1 t - \frac{x_3^2}{4(t+t_0)}\right) \tag{3.41}$$

and

$$\mathcal{H}^2 := \max_{D\times\mathbb{R}^+} \left\{ [h_{,\alpha}h_{,\alpha} + a_1 h^2 + 2F(h)]\, e^{2a_1 t}\sqrt{t+t_0} \right\}. \tag{3.42}$$

We note that for $t \in \mathbb{R}^+$, (3.21) implies that h must decay at least exponentially in t. However, if we are interested only in a finite time interval $(0,\bar{t})$, then we may take

$$M := \max_{D\times(0,\bar{t})} \left\{ h(x_1,x_2,t)\, t^{1/2} \exp\left(at + \frac{x_0^2}{4t}\right) \right\}. \tag{3.43}$$

Thus with the quantity $\hat{h}$ of (3.22) defined using this value of M and (3.23) satisfied for this modified $\hat{h}$, (3.40) holds for $\mathcal{H}^2$ defined by (3.42) except that now the maximum is taken over $D \times (0,\bar{t}\,)$. It follows from (3.40) that

$$u(\mathbf{x},t) \le \frac{Q(x_3,t)}{\sqrt{a_1}}. \tag{3.44}$$

However, a sharper estimate for $u(\mathbf{x},t)$ may be derived as follows: From (3.40), we have

$$\left|\frac{\partial u}{\partial \ell}\right| \le (u_\alpha u_\alpha)^{1/2} \le \{Q^2(x_3,t) - a_1 u^2\}^{1/2}, \tag{3.45}$$

where $d\ell$ is the element of length along the line joining $\mathbf{P} := (x_1,x_2,x_3,t)$ in $\Omega \times \mathbb{R}^+$ to the nearest point $\tilde{\mathbf{P}} := (\tilde{x}_1,\tilde{x}_2,x_3,t)$ on $\partial\Omega_{\text{lat}} \times \mathbb{R}^+$. Integrating along this line, we obtain

$$\int_0^u \frac{d\eta}{\sqrt{Q^2 - a_1\eta^2}} \le \delta, \tag{3.46}$$

where δ is the distance of $\mathbf{P}$ from the lateral surface of the cylinder. It follows from (3.46) that

$$u \le \frac{Q(x_3,t)}{\sqrt{a_1}} \sin(\sqrt{a_1}\delta) \le \delta Q(x_3,t). \tag{3.47}$$

This estimate reflects the fact that u is small near $\partial\Omega_{\text{lat}}$.

4. Further norm bounds. Clearly a bound for the quantity

$$\Psi(x_3,t) := \sqrt{\int_D u^2 dx_1 dx_2} \tag{4.1}$$

may be obtained by integration of (3.47). However, a bound which imposes somewhat less restrictive hypotheses on the data may be derived from the maximum principle together with the following lemma.

LEMMA 4.1. *Under the assumptions of Lemma* 3.2*, we have the following parabolic inequality for the quantity* $\Psi(x_3,t)$*:*

$$\Psi_{,x_3x_3} - \Psi_{,t} \ge a\Psi, \quad x_3 \in [0,L], \quad t > 0, \tag{4.2}$$

with

$$a := \lambda - \max_{\Omega\times\mathbb{R}^+} \frac{f(u)}{u}, \tag{4.3}$$

where λ *is the first eigenvalue of* D*.*

It follows from (3.32) and (3.37) that a in (4.3) is positive. For the proof of (4.2), we compute

$$\Psi_{,x_3} = \frac{1}{\Psi}\int_D u u_{,x_3} dx_1 dx_2, \tag{4.4}$$

$$\begin{aligned}\Psi_{,x_3x_3} &= \frac{1}{\Psi}\int_D \left(u_{,x_3}^2 + u u_{,x_3x_3}\right) dx_1 dx_2 - \frac{1}{\Psi^3}\left\{\int_D u u_{,x_3} dx_1 dx_2\right\}^2 \\ &\ge \frac{1}{\Psi}\int_D u u_{,x_3x_3} dx_1 dx_2,\end{aligned} \tag{4.5}$$

$$\Psi_{,t} = \frac{1}{\Psi}\int_D u u_{,t} dx_1 dx_2. \tag{4.6}$$

Combining (4.5) and (4.6), we obtain

$$\Psi_{,x_3x_3} - \Psi_{,t} \geq \frac{1}{\Psi}\int_D u\left[u_{,x_3x_3} - u_{,t}\right]\, dx_1dx_2 \tag{4.7}$$
$$= -\frac{1}{\Psi}\int_D u\left[u_{,\alpha\alpha} + f(u)\right]\, dx_1dx_2$$
$$\geq \frac{1}{\Psi}\int_D u^2\left[\lambda - \frac{f(u)}{u}\right]\, dx_1dx_2 \geq a\Psi,$$

which is the desired inequality.

From (4.2) and the maximum principle, we obtain

$$\Psi(x_3,t) \leq \hat{M}(t+t_0)^{-1/2}\exp\left\{-at - x_3^2/4(t+t_0)\right\} \tag{4.8}$$

with an arbitrary constant $t_0 > 0$ and with

$$\hat{M} := \sup_{\mathbb{R}^+}\left\{e^{at}(t+t_0)^{1/2}\left(\int_D h^2 dx_1dx_2\right)^{1/2}\right\}. \tag{4.9}$$

As before, we note that on any finite time interval $[0,\bar{t}\,]$, we may replace (4.3) by

$$a := \lambda - \max_{\Omega\times[0,\bar{t}\,]}\frac{f(u)}{u} \tag{4.10}$$

in Lemma 4.1, and take the supremum over $[0,\bar{t}\,]$ in (4.9).

We note that a bound for Ψ would also follow from Lemma 4.1 and the arguments of Horgan, Payne, and Wheeler [4].

Our explicit decay bounds have not included bounds for the x_3-derivative of u. However, it is possible to derive an explicit decay bound for the Dirichlet integral $D_z(u)$ defined as

$$D_z(u) := \int_0^t\int_z^L\int_D |\nabla u|^2 d\mathbf{x}d\tau. \tag{4.11}$$

We first establish the following result.

LEMMA 4.2. *Under the assumptions of Lemma* 3.2*, the quantity* $D_z(u)$ *defined in* (4.11) *satisfies the differential inequality*

$$D_z(u) \leq \frac{1}{2a\sqrt{\lambda}}\frac{d}{dz}D_z(u), \tag{4.12}$$

where a *and* λ *have the same meaning as in Lemmas* 3.2 *and* 4.1.

Integrating (4.12)*, we obtain*

$$D_z(u) \leq D_0(u)e^{-2a\sqrt{\lambda}z}. \tag{4.13}$$

For the proof of Lemma 4.2, we write

$$\left(uu_{,\alpha}\right)_{,\alpha} + \left(uu_{,x_3}\right)_{,x_3} = |\nabla u|^2 + u[u_{,t} - f(u)]. \tag{4.14}$$

Integrating (4.14) and using the divergence theorem, we obtain

$$D_z(u) = \int_0^t\int_z^L\int_D uf(u)d\mathbf{x}d\tau - \int_0^t\int_D uu_{,x_3}dx_1dx_2d\tau\Big|_{x_3=z} \tag{4.15}$$
$$-\frac{1}{2}\int_z^L\int_D u^2 dx_1dx_2\Big|_{\tau=t}.$$

In (4.15), the first two terms may be bounded as follows:

$$\int_0^t \int_z^L \int_D uf(u) d\mathbf{x} d\tau \le \left(\max_{\Omega \times \mathbb{R}^+} \frac{f(u)}{u} \right) \int_0^t \int_z^L \int_D u^2 d\mathbf{x} d\tau \le \frac{1}{\lambda} \left(\max_{\Omega \times \mathbb{R}^+} \frac{f(u)}{u} \right) D_z(u), \tag{4.16}$$

$$\begin{aligned} -\int_0^t \int_D u u_{,x_3} dx_1 dx_2 d\tau &\le \left\{ \int_0^t \int_D u^2 dx_1 dx_2 d\tau \int_0^t \int_D u_{,x_3}^2 dx_1 dx_2 d\tau \right\}^{1/2} \\ &\le \frac{1}{2\sqrt{\lambda}} \left\{ \int_0^t \int_D u_{,\alpha} u_{,\alpha} dx_1 dx_2 d\tau + \int_0^t \int_D u_{,x_3}^2 dx_1 dx_2 d\tau \right\} \\ &= \frac{1}{2\sqrt{\lambda}} \int_0^t \int_D |\nabla u|^2 dx_1 dx_2 d\tau = -\frac{1}{2\sqrt{\lambda}} \frac{d}{dz} D_z(u) \end{aligned} \tag{4.17}$$

at $x_3 = z$. We are then led to the differential inequality

$$D_z(u) \left[1 - \frac{1}{\lambda} \left(\max_{\Omega \times \mathbb{R}^+} \frac{f(u)}{u} \right) \right] \le \frac{1}{2\sqrt{\lambda}} \frac{d}{dz} D_z(u), \tag{4.18}$$

which leads to the desired inequality (4.12) since we have (3.24) and (3.32).

As it stands, (4.13) is not explicit since $D(u) := D_0(u)$ is not defined in terms of data alone. However, we may derive a bound for $D(u)$ as follows: Let $v(\mathbf{x}, t)$ be an arbitrary Dirichlet integrable function. Then by the triangle inequality, we have

$$\sqrt{D(u)} \le \sqrt{D(u-v)} + \sqrt{D(v)}. \tag{4.19}$$

Let us choose v to be the harmonic function that for each t satisfies

$$\Delta v = 0 \quad \text{in } \Omega \times \mathbb{R}^+, \tag{4.20}$$

$$v = 0 \quad \text{on } (\partial\Omega_L \cup \partial\Omega_{\text{lat}}) \times \mathbb{R}^+, \tag{4.21}$$

$$v = h \quad \text{on } \partial\Omega_0 \times \mathbb{R}^+. \tag{4.22}$$

Making use of the divergence theorem, the Schwarz inequality, and the Rayleigh principle, we compute

$$\begin{aligned} D(u-v) &= -\int_0^t \int_\Omega (u-v)[u_{,\tau} - f(u)] \, d\mathbf{x} d\tau \\ &= -\frac{1}{2} \int_\Omega (u-v)^2 \, d\mathbf{x} \Big|_{\tau=t} - \int_0^t \int_\Omega (u-v) \, v_{,\tau} d\mathbf{x} d\tau \\ &\quad + \int_0^t \int_\Omega (u-v) \, f(u) \, d\mathbf{x} d\tau \\ &\le \left\{ \int_0^t \int_\Omega (u-v)^2 \, d\mathbf{x} d\tau \right\}^{1/2} \end{aligned}$$

$$\times \left\{ \left[\int_0^t \int_\Omega v_{,\tau}^2 d\mathbf{x} d\tau \right]^{1/2} + \left[\int_0^t \int_D f^2(u)\, d\mathbf{x} d\tau \right]^{1/2} \right\}$$

$$\leq \frac{1}{\sqrt{\lambda}} \sqrt{D(u-v)}$$

$$\times \left\{ \left[\int_0^t \int_\Omega v_{,\tau}^2\, d\mathbf{x} d\tau \right]^{1/2} + \left(\max_{\Omega \times \mathbb{R}^+} \left(\frac{f(u)}{u} \right) \right) \left[\int_0^t \int_\Omega u^2\, d\mathbf{x} d\tau \right]^{1/2} \right\}. \tag{4.23}$$

Moreover, using the triangle inequality and the Rayleigh principle, we may write

$$\sqrt{\int_0^t \int_\Omega u^2\, d\mathbf{x} d\tau} \leq \sqrt{\int_0^t \int_\Omega (u-v)^2\, d\mathbf{x} d\tau} + \sqrt{\int_0^t \int_\Omega v^2\, d\mathbf{x} d\tau}$$

$$\leq \frac{1}{\sqrt{\lambda}} \sqrt{D(u-v)} + \sqrt{\int_0^t \int_\Omega v^2\, d\mathbf{x} d\tau}. \tag{4.24}$$

Combining (4.23) and (4.24), and taking (3.23), (3.32) into account, we obtain

$$\frac{a}{\sqrt{\lambda}} \sqrt{D(u-v)} \leq \sqrt{\int_0^t \int_\Omega v_{,\tau}^2\, d\mathbf{x} d\tau} + \frac{f(\hat{h})}{\hat{h}} \sqrt{\int_0^t \int_\Omega v^2\, d\mathbf{x} d\tau}, \tag{4.25}$$

where $\hat{h}$ is defined in (3.22). It is well known that the L_2 integral of a harmonic function is boundable in terms of the L_2 integral of its Dirichlet data (see, e.g., Sigillito [11]). Thus for computable constants A_1 and A_2, we have

$$\sqrt{D(u-v)} \leq A_1 \sqrt{\int_0^t \int_D h_{,\tau}^2\, dx_1 dx_2 d\tau} + A_2 \sqrt{\int_0^t \int_D h^2\, dx_1 dx_2 d\tau}. \tag{4.26}$$

Finally, for computable A_3 and A_4 (see Sigillito [11]), we may write

$$D(v) \leq A_3 \int_0^t \int_D h^2\, dx_1 dx_2 d\tau + A_4 \int_0^t \int_D h_{,\alpha} h_{,\alpha}\, dx_1 dx_2 d\tau. \tag{4.27}$$

Combining (4.19), (4.26), and (4.27), we obtain

$$D(u) \leq \widetilde{D} := B_1 \int_0^t \int_D h^2\, dx_1 dx_2 d\tau + B_2 \int_0^t \int_D h_{,t}^2\, dx_1 dx_2 d\tau$$

$$+ B_3 \int_0^t \int_D h_{,\alpha} h_{,\alpha}\, dx_1 dx_2 d\tau, \tag{4.28}$$

where B_k are computable constants, $k = 1, 2, 3$. Inequalities (4.13) and (4.28) provide the following explicit decay bound for $D_z(u)$:

$$D_z(u) \leq \widetilde{D} e^{-2a\sqrt{\lambda} z}. \tag{4.29}$$

ON A STOCHASTIC HYPERBOLIC SYSTEM IN LINEAR ELASTICITY*

JONG UHN KIM†

Abstract. In this paper we discuss the Cauchy problem for linear elasticity with a space-time white noise forcing term. We show that the solution can be represented by a formula analogous to the Riesz formula for solutions of a wave equation. The solution is a generalized stochastic process and is obtained as the limit of a sequence of ordinary stochastic processes. Our basic tool is the Hilbert space method combined with geometric properties of solutions inherent with a hyperbolic system.

Key words. generalized stochastic process, Gaussian process, white noise, hyperbolic system

0. Introduction. In this paper we present new results on the Cauchy problem for a hyperbolic system with a white noise forcing term associated with linear elasticity:

$$u_{tt}(t,x) = A(t,x,D_x)u(t,x) + F(t,x)\xi(t,x) \quad \text{in } (0,\infty)\times R^n; \tag{0.1}$$

$$u(0,x) = 0, \qquad u_t(0,x) = 0, \qquad \text{in } R^n, \tag{0.2}$$

where $x = (x_1, \dots, x_n) \in R^n$, $u = (u_1, \dots, u_n)$ denotes the displacement from equilibrium. $A(t,x,D_x)$ is a second order matrix differential operator, $F(t,x)$ is a matrix function, and $\xi(t,x)$ stands for a vector-valued space-time white noise. Here we only focus on the nonhomogeneous forcing term, and assume the zero initial conditions. Since the system is linear, nonzero initial conditions can be handled separately. The motion of a one-dimensional elastic medium driven by a random noise is typically described by a one-dimensional wave equation with a space-time white noise. This was discussed by Walsh [15] in the framework of Brownian sheets. A numerical result is shown on the front cover of the monograph [7]. Other versions were investigated by Cabaña [1] and Orsingher [13]. It was also discussed by Da Prato and Zabczyk [3] as an example of abstract evolution equations. A semilinear hyperbolic equation with one-dimensional space variable was discussed by Nualart [12] as a two-parameter stochastic differential equation. Marcus and Mizel [10] studied initial-boundary value problems for a stochastic hyperbolic system in one space dimension. A two-dimensional semilinear wave equation was discussed by Dalang and Frangos [4], and Mueller [11] when the random noise is a white noise in time with smooth spatial covariance.

The purpose of this work is to establish the existence of a solution of (0.1) and (0.2) by a representation formula analogous to the Riesz formula for solutions of a wave equation. The representation formula gives good information on the structure of the solution which is a generalized stochastic process. This motivates our quest for the representation formula. Riesz [14] used analytical theory of integrals of fractional

order to establish the formula

$$u(t,x) = \frac{1}{2^n \pi^{(n-1)/2}((n-1)/2)!} \Lambda^{(n-1)/2} \int_{\Xi(t,x)} f(s,y)\, dy\, ds, \tag{0.3}$$

where $n \geq 3$ is an odd integer, $x \in R^n$, $t \geq 0$, $\Xi(t,x)$ is the backward light cone defined by $(t-s)^2 \geq |x-y|^2$, $0 \leq s \leq t$. Here, u is the solution of

$$\Lambda u = f \qquad \text{for } x \in R^n,\ t \geq 0; \tag{0.4}$$

$$u(0,x) = 0,\ u_t(0,x) = 0 \qquad \text{for } x \in R^n, \tag{0.5}$$

where $\Lambda = \partial_{tt} - \Delta$, and Δ is the Laplacian.

Gaveau [6] applied this formula to the Cauchy problem for a three-dimensional wave equation with a space-time white noise. For a one-dimensional wave equation, the solution can be represented by a stochastic integral because the integral kernel is locally L^2, which is not true in the higher-dimensional case. Gaveau overcame this difficulty by means of the above Riesz formula, for the above integral in (0.3) can be well-defined as a stochastic integral when $f\, dy\, ds$ is replaced by $f\, \xi(dy\, ds)$ where f is locally bounded and ξ is the white noise. Thanks to the explicit structure of the formula, he could first construct a continuous martingale (according to a partial ordering defined in terms of the backward light cone) through the Riesz integral, and then, a solution was obtained by applying the wave operator to this continuous stochastic process. Hence the resulting solution is a generalized stochastic process. However, the particular formula used in [6], which easily generates a martingale, is valid only for odd space dimensions. He also showed that the Cauchy value of this generalized stochastic process is well-defined by the formula of integration by parts.

This work is an outgrowth of our effort to obtain a similar representation formula for the system of equations in linear elasticity. We will show that the unique solution u of the above Cauchy problem (0.1)–(0.2) in any space dimension can be obtained as a generalized stochastic process in the following form:

$$u(t,x;\omega) = L^d V(t,x;\omega), \tag{0.6}$$

where $L = \partial_{tt} I - A(t,x,D_x)$, I is the $n \times n$ identity matrix, d is the smallest integer larger than $(n/2) - 1$, and V is a continuous Gaussian process which satisfies the property of a domain of dependence. In particular, when $n \geq 3$ is an odd integer, $d = (n-1)/2$. Since the Riesz formula is not available in our case, we have to employ an entirely different argument. The core task is to obtain an integral kernel. For this, we use the Hilbert space method combined with the property of a domain of dependence. We then approximate the space-time white noise by truncating the chaos expansion. The corresponding approximate solution is an ordinary stochastic process, and the true solution is obtained as the limit. Our results are completely new and our approach is different from those of all the previous works.

1. Preliminaries and statement of the main result. Throughout this paper, we make the following assumptions.

The matrix operator $A(t,x,D_x)$ is given by

$$A_{ij}(t,x,D_x) = \sum_{k,l=1}^{n} C_{ij}^{kl}(t,x) \frac{\partial^2}{\partial x_k \partial x_l} + \sum_{k=1}^{n} D_{ij}^{k}(t,x) \frac{\partial}{\partial x_k}$$

for $i, j = 1, \dots, n$. All coefficients are real valued and

(I) $C_{ij}^{kl}(t,x) \in C^\infty(R^{n+1})$ and all the derivatives of each C_{ij}^{kl} are bounded on R^{n+1};

(II) $C_{ij}^{kl}(t,x) = C_{kj}^{il}(t,x) = C_{ji}^{lk}(t,x)$ for all $(t,x) \in R^{n+1}$ and every i, j, k, and l;

(III) there is a positive constant c_0 such that

$$\sum_{k,l,i,j} C_{ij}^{kl}(t,x)\epsilon_{ki}\epsilon_{lj} \geq c_0 \sum_{k,i} \epsilon_{ki}\epsilon_{ki} \tag{1.1}$$

for all $(t,x) \in R^{n+1}$ and every symmetric tensor ϵ_{ki};

(IV) $D_{ij}^{k}(t,x) \in C^\infty(R^{n+1})$ and all the derivatives of each D_{ij}^{k} are bounded on R^{n+1};

(V) $F(t,x)$ is an $n \times n$ matrix function whose components are all measurable and bounded on each bounded subset of R^{n+1}.

We now list some known facts about the following deterministic Cauchy problem:

$$u_{tt}(t,x) = A(t,x,D_x)u(t,x) + f(t,x) \quad \text{in } (0,\infty) \times R^n; \tag{1.2}$$

$$u(0,x) = u_0(x), \qquad u_t(0,x) = u_1(x) \quad \text{in } R^n. \tag{1.3}$$

Let a real number s and a positive number T be given.

THEOREM 1.1. *For given $f(t,x) \in L^2(0,T;(H^s(R^n))^n)$, $u_0(x) \in (H^{s+1}(R^n))^n$, and $u_1(x) \in (H^s(R^n))^n$, there is a unique solution $u(t,x)$ of (1.2) and (1.3) in $C([0,T];(H^{s+1}(R^n))^n) \cap C^1([0,T];(H^s(R^n))^n)$.*

Here $H^s(R^n)$ denotes the usual Sobolev space. For the technical details of the proof, see [9].

Next we fix any $t_0 \geq 0$ and $x_0 \in R^n$ and define for $0 \leq t \leq t_0$, $\epsilon > 0$ and $\eta > 0$,

$$\Gamma_{(t_0,x_0)}(t;\epsilon,\eta) = \{x \in R^n \mid |x - x_0| < \epsilon + \eta(t_0 - t)\}. \tag{1.4}$$

$\Gamma_{(t_0,x_0)}(t;\epsilon,\eta)$ is an n-dimensional ball for each $0 \leq t \leq t_0$, and $\cup_{0\leq t\leq t_0}\{(t, \overline{\Gamma_{(t_0,x_0)}(t;\epsilon,\eta)})\}$ is a truncated cone in R^{n+1}.

THEOREM 1.2. *Let $s = m$ be a nonnegative integer, and $T > 0$ be given. Choose any $(t_0,x_0) \in [0,T] \times R^n$. Then there is $\eta > 0$ depending on the coefficients of $A(t,x,D_x)$, but independent of u, f, (t_0,x_0), and ϵ such that the above solution satisfies*

$$\begin{aligned} &\|u(t_0,\cdot)\|^2_{(H^{m+1}(\Gamma(t_0;\epsilon,\eta)))^n} + \|u_t(t_0,\cdot)\|^2_{(H^m(\Gamma(t_0;\epsilon,\eta)))^n} \\ &\leq M\left(\|u_0\|^2_{(H^{m+1}(\Gamma(0;\epsilon,\eta)))^n} + \|u_1\|^2_{(H^m(\Gamma(0;\epsilon,\eta)))^n} + \int_0^{t_0} \|f(h,\cdot)\|^2_{(H^m(\Gamma(h;\epsilon,\eta)))^n}\, dh\right), \end{aligned} \tag{1.5}$$

where M is a positive constant independent of u, f, (t_0,x_0), and ϵ. Here the subscript (t_0,x_0) of Γ has been suppressed.

This has been established for a general first order hyperbolic system in [2]. The same argument can be applied to a second order hyperbolic system. See [5] and [9].

COROLLARY 1.3. *Suppose that the support of u_0 and u_1 is disjoint from $\overline{\Gamma_{(t_0,x_0)}(0;\epsilon,\eta)}$, and the support of f is disjoint from $\cup_{0\leq t\leq t_0}\{(t, \overline{\Gamma_{(t_0,x_0)}(t;\epsilon,\eta)})\}$ for some $(t_0,x_0) \in [0,\infty) \times R^n$ in Theorem 1.1. Then the support of u is disjoint from $\cup_{0\leq t\leq t_0}\{(t, \overline{\Gamma_{(t_0,x_0)}(t;\epsilon,\eta)})\}$.*

If $s < 0$, this can be proved by approximating the solution by a sequence of solutions with smooth initial data and f, for which (1.5) can be applied.

Next we set up a base probability space for generalized stochastic processes. Let $\mathcal{S} = (\mathcal{S}(R^{n+1}))^n$ be the space of R^n-valued rapidly decreasing C^∞ functions on R^{n+1}, and $\mathcal{S}' = (\mathcal{S}'(R^{n+1}))^n$ be its dual equipped with the weak-star topology. $\mathcal{B}(\mathcal{S}')$ stands for the set of all Borel subsets of $\mathcal{S}'$. By the Bochner–Minlos theorem, there is a probability measure μ on $\mathcal{B}(\mathcal{S}')$ such that

$$\int_{\mathcal{S}'} \exp(\sqrt{-1}\langle \omega\,,\, \phi\rangle_n)\, d\mu(\omega) = \exp(-\|\phi\|^2_{(L^2(R^{n+1}))^n}/2) \tag{1.6}$$

for all $\phi \in \mathcal{S}$. Here, $\langle \cdot\,,\, \cdot\rangle_n$ denotes the duality pairing between $\mathcal{S}'$ and $\mathcal{S}$, i.e.,

$$\langle \omega\ ,\ \phi\rangle_n = \sum_{i=1}^n \langle \omega_i\ ,\ \phi_i\rangle,$$

for $\omega = (\omega_1, \dots, \omega_n)$, $\phi = (\phi_1, \dots, \phi_n)$, where $\langle \cdot\,,\, \cdot\rangle$ denotes the duality pairing between $\mathcal{S}'(R^{n+1})$ and $\mathcal{S}(R^{n+1})$. By (1.6), it follows that for each $f \in (L^2(R^{n+1}))^n$, $\langle \omega, f\rangle_n$ can be defined to be a random variable on the probability space $(\mathcal{S}', \mathcal{B}(\mathcal{S}'), \mu)$, and, for each positive integer k,

$$E(|\langle \omega, f\rangle_n|^{2k}) = \int_{\mathcal{S}'} |\langle \omega, f\rangle_n|^{2k}\, d\mu = \frac{(2k)!}{k!\, 2^k} \|f\|^{2k}_{(L^2(R^{n+1}))^n}. \tag{1.7}$$

For more details, see [7]. The above white noise $\xi(t, x)$ is a vector-valued generalized stochastic process in the sense that

$$\xi_\phi(\omega) = (\langle \omega_1, \phi_1\rangle, \dots, \langle \omega_n, \phi_n\rangle) \tag{1.8}$$

is a vector-valued random variable on $(\mathcal{S}', \mathcal{B}(\mathcal{S}'), \mu)$ for each $\phi \in (C_0^\infty(R^{n+1}))^n$. In the meantime, $F\xi$ is a vector-valued generalized stochastic process defined by

$$(F\xi)_\phi(\omega) = \left(\sum_{j=1}^n \langle \omega_j, F_{1j}\phi_1\rangle, \dots, \sum_{j=1}^n \langle \omega_j, F_{nj}\phi_n\rangle \right), \tag{1.9}$$

for each $\phi \in (C_0^\infty(R^{n+1}))^n$. Next we define for each $i, j = 1, \dots, n$,

$$B_{ij}(x_0, x_1, \dots, x_n; \omega) = \langle \omega_j(y),\ F_{ij}(y)\chi_{(x_0,\dots,x_n)}(y)\rangle. \tag{1.10}$$

Here, $y \in R^{n+1}$ denotes the variable for the duality action $\langle \cdot\,,\, \cdot\rangle$, and

$$\chi_{(x_0,\dots,x_n)}(y_0, \dots, y_n) = \begin{cases} (-1)^k & \text{if } 0 \le y_i < x_i \text{ or } x_i < y_i < 0 \\ & \quad \text{for each } i = 0, 1, \dots, n, \\ 0 & \text{otherwise,} \end{cases} \tag{1.11}$$

where k is the number of negative x_i's. For each bounded subset K of R^{n+1}, it holds that

$$\int_{R^{n+1}} \left|\chi_{(x_0,\dots,x_n)}(y) - \chi_{(\tilde{x}_0,\dots,\tilde{x}_n)}(y)\right|^2 dy \le C_K \left|(x_0, \dots, x_n) - (\tilde{x}_0, \dots, \tilde{x}_n)\right| \tag{1.12}$$

for all $(x_0,\dots,x_n),\ (\tilde{x}_0,\dots,\tilde{x}_n) \in K,$ for some positive constant C_K. Thus it follows from (1.7) that for each bounded subset K of R^{n+1} and each positive integer m,

$$E\Big(\big|B_{ij}(x_0,\dots,x_n;\omega) - B_{ij}(\tilde{x}_0,\dots,\tilde{x}_n;\omega)\big|^{2m}\Big) \le C_{m,K}\big|(x_0,\dots,x_n) - (\tilde{x}_0,\dots,\tilde{x}_n)\big|^m \tag{1.13}$$

for all $(x_0,\dots,x_n),\ (\tilde{x}_0,\dots,\tilde{x}_n) \in K,$ for some positive constant $C_{m,K}$. By a partition of unity and the Kolmogorov continuity theorem, there is a continuous version of $B_{ij}(x_0,\dots,x_n;\omega)$. See [8] and [12] for the multiparameter version of Kolmogorov's theorem. From now on, we always mean this continuous version.

LEMMA 1.4. *For each $\phi = (\phi_1,\dots,\phi_n)$ with $\phi_i \in C_0^\infty(R^{n+1}),\ i = 1,\dots,n,$ it holds that*

$$\text{the } i\text{th component of } (F\xi)_\phi(\omega) = \sum_{j=1}^n \int_{R^{n+1}} (-1)^{n+1} \frac{\partial^{n+1}\phi_i}{\partial x_0 \cdots \partial x_n} B_{ij}(x_0,\dots,x_n;\omega)\, dx_0 \dots dx_n \tag{1.14}$$

for almost all ω.

Proof. Since $B_{ij}(x_0,\dots,x_n;\omega)$ is a continuous version of the process defined by (1.10), $B_{ij}(x_0,\dots,x_n;\omega)$ is continuous in $(x_0,\dots,x_n),$ for each $\omega,$ and there is a subset $\Omega \in \mathcal{B}(\mathcal{S}')$ with $\mu(\Omega) = 1,$ such that for each $\omega \in \Omega,$

$$B_{ij}(r_0,\dots,r_n;\omega) = \langle \omega_j(y),\ F_{ij}(y)\chi_{(r_0,\dots,r_n)}(y)\rangle \tag{1.15}$$

for all $(r_0,\dots,r_n)$ with $r_i =$ a rational number, $i = 0,\dots,n.$

Choose any $\phi \in (C_0^\infty(R^{n+1}))^n$ and set

$$\psi = \frac{\partial^{n+1}\phi}{\partial x_0 \dots \partial x_n}(x_0,\dots,x_n). \tag{1.16}$$

Let Π be a cube in R^{n+1} with side length q such that supp $\phi \subset \Pi$. For each $N,$ we divide this cube into N^{n+1} cubes of equal size. For $\nu = 1,\dots,N^{n+1},$ let z^ν denote an interior point of the νth cube whose coordinates are rational numbers. Then we have, for every $\omega \in \Omega,$

$$\int_{R^{n+1}} \psi_i(x_0,\dots,x_n) B_{ij}(x_0,\dots,x_n;\omega)\, dx_0 \cdots dx_n = \lim_{N\to\infty} \frac{q^{n+1}}{N^{n+1}} \sum_{\nu=1}^{N^{n+1}} \langle \omega_j(y),\ F_{ij}(y)\psi_i(z^\nu)\chi_{z^\nu}(y)\rangle. \tag{1.17}$$

But it is easy to see that as a function of $y = (y_0,\dots,y_n),$

$$\frac{q^{n+1}}{N^{n+1}} \sum_{\nu=1}^{N^{n+1}} \psi_i(z^\nu)\chi_{z^\nu}(y)$$

is bounded and compactly supported uniformly in $N,$ and converges to

$$(-1)^k \int_{y_0} \cdots \int_{y_n} \psi_i(x_0,\dots,x_n)\, dx_0 \dots dx_n,$$

as $N \to \infty$, for each y, where k is the number of negative y_i's and

$$\int_{y_i} = \int_{y_i}^{\infty} \qquad \text{for } y_i \geq 0$$

and

$$\int_{y_i} = \int_{-\infty}^{y_i} \qquad \text{for } y_i < 0.$$

Hence, as $N \to \infty$,

$$\frac{q^{n+1}}{N^{n+1}} \sum_{\nu=1}^{N^{n+1}} F_{ij}(y)\psi_i(z^\nu)\chi_{z^\nu}(y) \to (-1)^{n+1} F_{ij}(y)\phi_i(y) \text{ in } L^2(R_y^{n+1}). \tag{1.18}$$

By virtue of (1.7), (1.17), and (1.18), we have (1.14) for almost all ω. □

Next we consider a chaos expansion of the white noise. We follow the construction of an orthonormal basis for $L^2(R^{n+1})$ in [7]. Let $\xi_m(t)$ be the Hermite function of $t \in R$ for $m = 1, 2, \ldots$. Let $\delta^j = (\delta_0^j, \delta_1^j, \ldots, \delta_n^j)$ be the jth multi-index number in some fixed ordering of all $(n+1)$-dimensional multi-indices $\delta = (\delta_0, \ldots, \delta_n)$, each δ_i = a positive integer. This ordering satisfies the property

$$i < j \qquad \text{implies } \delta_0^i + \cdots + \delta_n^i \leq \delta_0^j + \cdots + \delta_n^j.$$

We write

$$\eta_j(x_0, \ldots, x_n) = \xi_{\delta_0^j}(x_0)\xi_{\delta_1^j}(x_1)\cdots\xi_{\delta_n^j}(x_n). \tag{1.19}$$

Then $\{\eta_j\}_{j=1}^{\infty}$ forms an orthonormal basis for $L^2(R^{n+1})$. It follows that for each $\phi \in (C_0^\infty(R^{n+1}))^n$,

$$\begin{aligned} \text{the } i\text{th component of } (F\xi)_\phi(\omega) &= \sum_{j=1}^{n} \langle \omega_j(y),\ F_{ij}(y)\phi_i(y)\rangle \\ &= \lim_{N\to\infty} \sum_{k=1}^{N}\sum_{j=1}^{n} \langle \eta_k(y),\ F_{ij}(y)\phi_i(y)\rangle_{L^2(R_y^{n+1})} \langle \omega_j(y),\ \eta_k(y)\rangle \end{aligned} \tag{1.20}$$

in $L^2(\mathcal{S}', d\mu)$. This will be used to construct a solution in the next section.

We adopt the following definition of a solution to (0.1).

DEFINITION 1.5. *A vector-valued generalized stochastic process $u(t, x_1, \ldots, x_n; \omega)$ is a solution of* (0.1) *in R_+^{n+1} if there is a subset $\Omega \in \mathcal{B}(\mathcal{S}')$ with $\mu(\Omega) = 1$ such that*

$$\ll u,\ L^*\phi \gg = \sum_{i,j=1}^{n} \int_{R_+^{n+1}} (-1)^{n+1} \frac{\partial^{n+1}\phi_i}{\partial t \cdots \partial x_n} B_{ij}(t, x_1, \ldots, x_n; \omega)\, dt \cdots dx_n \tag{1.21}$$

holds for all $\phi \in (C_0^\infty(R_+^{n+1}))^n$, for each $\omega \in \Omega$.

Here, $R_+^{n+1} = \{(t, x) \mid t > 0,\ x \in R^n\}$, $\ll \cdot, \cdot \gg$ is the duality pairing of $(\mathcal{D}'(R_+^{n+1}))^n$ and $(C_0^\infty(R_+^{n+1}))^n$, and L^* is the adjoint of

$$L = \partial_{tt} I - A(t, x, D_x). \tag{1.22}$$

LEMMA 1.6. *Suppose $u(t, x_1, \dots, x_n; \omega)$ is a solution of (0.1) in R_+^{n+1} according to the above definition, i.e., there is a subset $\Omega \in \mathcal{B}(\mathcal{S}')$ with $\mu(\Omega) = 1$ such that for each $\omega \in \Omega$, (1.21) holds for all $\phi \in (C_0^\infty(R_+^{n+1}))^n$. Then, for each $\omega \in \Omega$, $T > 0$ and bounded open subset $\Delta \subset R^n$, we have*

$$\psi(x)u(t, x\,;\,\omega) \in (C([0,T]; H^{-m+1}(R^n)))^n, \tag{1.23}$$

$$\psi(x)u_t(t, x\,;\,\omega) \in (C([0,T]; H^{-m}(R^n)))^n \tag{1.24}$$

for all $\psi \in C_0^\infty(\Delta)$, for some positive integer m.

Proof. Let us set, for $i = 1, \dots, n$,

$$\begin{aligned} &v_i(t, x_1, \dots, x_n; \omega) \\ &\quad = u_i(t, x_1, \dots, x_n; \omega) - \sum_{j=1}^{n} \frac{\partial^n}{\partial x_1 \dots \partial x_n} \int_0^t B_{ij}(s, x_1, \dots, x_n; \omega)\, ds. \end{aligned} \tag{1.25}$$

We fix $\omega \in \Omega$, $T > 0$, and $\Delta \subset R^n$. Let $\eta > 0$ be the number in Theorem 1.2. We note that Theorem 1.2 and Corollary 1.3 are also valid with respect to the reversed time variable. Choose $q > 0$ such that

$$\Delta \subset \{x \in R^n \mid \ |x| < q - T\eta\}. \tag{1.26}$$

Fix any $0 < \epsilon < T/4$, and let $\Psi(t, x) \in C_0^\infty(R_+^{n+1})$ such that

$$\Psi(t, x) = 1 \qquad \text{for } \epsilon \le t \le T + \epsilon,\ |x| \le 2q. \tag{1.27}$$

Since $\Psi v \in (\mathcal{D}'(R_+^{n+1}))^n$ has compact support, there is a positive integer ν such that

$$\Psi v \in (H^{-\nu}(R_+^{n+1}))^n, \tag{1.28}$$

and hence,

$$\Psi v \in (H^{-\nu}(0, \infty\,;\, H^{-\nu}(R^n)))^n. \tag{1.29}$$

In fact, we take $\nu \ge n$ to handle $B_{ij}(t, x_1, \dots, x_n; \omega)$. Next we choose a sequence of functions $\psi_i(t, x) \in C_0^\infty(R_+^{n+1})$, $i = 1, \dots, \nu + 2$, such that $\Psi = 1$ on the support of ψ_1, $\psi_i = 1$ on the support of ψ_{i+1}, for $i = 1, \dots, \nu + 1$, and $\psi_{\nu+2} = 1$, for $2\epsilon \le t \le T$, $|x| \le q$. It is easy to see that

$$\begin{aligned} &\frac{\partial^2}{\partial t^2}(\psi_1 v) \,-\, A(t, x, D_x)(\psi_1 v) \\ &= \psi_1\, A(t, x, D_x) \int_0^t \frac{\partial^n}{\partial x_1 \dots \partial x_n} B(s, x_1, \dots, x_n; \omega)\, ds \\ &\quad + \big(\text{a linear combination of } v \text{ and first order derivatives of } v \\ &\qquad \text{which vanishes outside the support of } \psi_1\big), \end{aligned} \tag{1.30}$$

in the sense of distribution over R_+^{n+1}, where B is R^n-valued, and its ith component is $\sum_{j=1}^n B_{ij}(t, x_1, \dots, x_n; \omega)$.

Since $\psi_1 v = \psi_1 \Psi v \in (H^{-\nu}(0, \infty\,;\, H^{-\nu}(R^n)))^n$, it follows from (1.30)

$$\psi_1 v \in (H^{-\nu+1}(0, \infty\,;\, H^{-\nu-2}(R^n)))^n. \tag{1.31}$$

By repetition of this procedure, we arrive at

$$\psi_{\nu+2}v \in (H^2(0,\infty\,;\,H^{-3\nu-4}(R^n)))^n, \tag{1.32}$$

and hence,

$$\psi_{\nu+2}v \in (C((0,\infty)\,;\,H^{-3\nu-2}(R^n)))^n \cap (C^1((0,\infty)\,;\,H^{-3\nu-4}(R^n)))^n. \tag{1.33}$$

By taking $t = T/2$ as the initial time, we consider the forward and backward Cauchy problem

$$L\theta = \Phi(x)\,A(t,x,D_x)\int_0^t \frac{\partial^n}{\partial x_1\dots\partial x_n}B(s,x_1,\dots,x_n;\omega)\,ds, \tag{1.34}$$

$$\theta(T/2,x) = (\psi_{\nu+2}v)(T/2,x), \qquad \theta_t(T/2,x) = (\psi_{\nu+2}v)_t(T/2,x), \tag{1.35}$$

where $\Phi(x) \in C_0^\infty(R^n)$ with $\Phi(x) = 1$, for $|x| \le q$.

By Theorem 1.1, there is a unique solution

$$\theta \in (C([0,T];H^{-3\nu-3}(R^n)))^n \cap (C^1([0,T];H^{-3\nu-4}(R^n)))^n. \tag{1.36}$$

But, by Corollary 1.3, (1.26), (1.30), (1.34), and (1.35), it holds that

$$\psi(x)v(t,x) = \psi(x)\theta(t,x) \qquad \text{in } [2\epsilon,T]\times\Delta \tag{1.37}$$

for every $\psi(x) \in C_0^\infty(\Delta)$. Now suppose we started out with a smaller number $\tilde\epsilon < \epsilon$. Let $\tilde\nu$ and $\tilde\theta$ correspond to $\tilde\epsilon$ in (1.28) through (1.37). Since $\theta(T/2,x) = \tilde\theta(T/2,x)$ and $\theta_t(T/2,x) = \tilde\theta_t(T/2,x)$ in the open ball $|x| < q$, it again follows from Corollary 1.3 and (1.26) that

$$\psi(x)\theta(t,x) = \psi(x)\tilde\theta(t,x) \qquad \text{in } [0,T]\times\Delta \tag{1.38}$$

for all $\psi \in C_0^\infty(\Delta)$. Meanwhile, we have

$$\psi(x)v(t,x) = \psi(x)\tilde\theta(t,x) \qquad \text{in } [2\tilde\epsilon,T]\times\Delta \tag{1.39}$$

for all $\psi \in C_0^\infty(\Delta)$. By virtue of (1.37), (1.38), and (1.39), we can maintain the same ν for any smaller ϵ and conclude

$$\psi(x)v(t,x) = \psi(x)\theta(t,x) \qquad \text{in } (0,T]\times\Delta \tag{1.40}$$

for every $\psi \in C_0^\infty(\Delta)$. Consequently, (1.23) and (1.24) follow with $m = 3\nu+4$. □

LEMMA 1.7. *In the same setting as above, there is some $\Omega \in \mathcal{B}(\mathcal{S}')$ with $\mu(\Omega) = 1$ such that for each $\omega \in \Omega$, $B_{ij}(0,x;\omega) = 0$ for all $x \in R^n$ and*

$$\begin{aligned} &-\langle u_t(0,x;\omega),\ \phi(0,x)\rangle_\sharp + \langle u(0,x;\omega),\ \phi_t(0,x)\rangle_\sharp \\ &+\int_0^\infty \langle u(t,x;\omega),\ L^*\phi(t,x)\rangle_\sharp\,dt \\ &= \sum_{i,j=1}^n \int_{R_+^{n+1}} (-1)^{n+1}\frac{\partial^{n+1}\phi_i(t,x)}{\partial t\cdots\partial x_n}B_{ij}(t,x_1,\dots,x_n;\omega)\,dt\,dx_1\cdots dx_n \end{aligned} \tag{1.41}$$

for every $\phi(t,x) \in (C_0^\infty(R^{n+1}))^n$, *where* $\langle\cdot\ ,\ \cdot\rangle_\sharp$ *is the duality pairing between* $(\mathcal{D}'(R^n))^n$ *and* $(C_0^\infty(R^n))^n$.

Proof. By the same argument as in the first paragraph of the proof of Lemma 1.4, there is some $\Omega \in \mathcal{B}(\mathcal{S}')$ with $\mu(\Omega) = 1$ such that for each $\omega \in \Omega$, $B_{ij}(0,x;\omega) = 0$, for all $x \in R^n$. By modifying Ω, if necessary, we may assume that for each $\omega \in \Omega$, (1.21) holds for all $\phi \in \big(C_0^\infty(R^{n+1})\big)^n$. Now let us fix $\omega \in \Omega$. Since the tensor product $C_0^\infty(R) \otimes C_0^\infty(R^n)$ is sequentially dense in $C_0^\infty(R^{n+1})$, it is enough to consider ϕ in the form of $\alpha(t)\beta(x)$. Choose any $\alpha(t) \in C_0^\infty(R)$ and $\beta(x) \in (C_0^\infty(R^n))^n$, and choose $T > 0$ such that $\alpha(t) = 0$ for $t \geq T$. We may take Δ and q in (1.26) such that the support of $\beta \subset \Delta$. Since $B_{ij}(t,x;\omega)$ is continuous in $(t,x) \in R^{n+1}$, we can extend the solution of (1.34) and (1.35) to a larger time interval so that

$$\langle u(t,x;\omega),\ \beta(x)\rangle_\sharp\ \in C^1\big([-\epsilon,\, T+\epsilon]\big), \tag{1.42}$$

$$\langle u(t,x;\omega),\ A^*(t,x,D_x)\beta(x)\rangle_\sharp\ \in C^1\big([-\epsilon,\, T+\epsilon]\big) \tag{1.43}$$

for some positive constant ϵ, and

$$\begin{aligned}&\frac{d^2}{dt^2}\langle u*\rho_h,\ \beta\rangle_\sharp(t) - \big(\langle u,\ A^*\beta\rangle_\sharp * \rho_h\big)(t)\\ &= \frac{d}{dt}\sum_{i,j=1}^n \left\langle B_{ij}*\rho_h,\ (-1)^n \frac{\partial^n \beta_i}{\partial x_1 \cdots \partial x_n}\right\rangle_\sharp (t)\end{aligned} \tag{1.44}$$

for each $t \in (-\epsilon/2,\, T+\epsilon/2)$, $0 < h < \epsilon/2$, where $A^*(t,x,D_x)$ is the adjoint of $A(t,x,D_x)$, $\rho_h(t) = \rho(t/h)/h$, with $\rho(t) \in C_0^\infty(R)$ satisfying

$$\rho(t) = \rho(-t) \geq 0; \qquad \rho(t) = 0 \text{ for } |t| \geq 1; \qquad \int_{-\infty}^{\infty} \rho(t)\,dt = 1. \tag{1.45}$$

The convolution is taken with respect to the time variable.

Now we obtain (1.41) by going through the standard procedure: (i) multiply (1.44) by $\alpha(t)$ for $-\epsilon/2 < t < T + \epsilon/2$; (ii) integrate over $[0,T]$; (iii) pass $h \to 0$ with the help of (1.42), (1.43), and the fact $B_{ij}(0,x;\omega) = 0$ for all $x \in R^n$. □

Next we show that the traces of u and u_t with respect to the time variable can be defined as generalized stochastic processes.

LEMMA 1.8. *Let* $u(t,x_1,\dots,x_n;\omega)$ *be a solution of* (0.1) *in* R_+^{n+1}. *Then, for each fixed* $t_0 > 0$, $u(t_0,x_1,\dots,x_n;\omega)$ *and* $u_t(t_0,x_1,\dots,x_n;\omega)$ *are generalized stochastic processes with respect to* $\mathcal{F}(\mathcal{S}')$ *which is the completion of* $\mathcal{B}(\mathcal{S}')$.

Proof. Choose any $\beta(x_1,\dots,x_n) \in (C_0^\infty(R^n))^n$. We have to show that

$$\langle u(t_0,x_1,\dots,x_n;\omega),\ \beta(x_1,\dots,x_n)\rangle_\sharp$$

and

$$\langle u(t_0,x_1,\dots,x_n;\omega),\ \beta(x_1,\dots,x_n)\rangle_\sharp$$

are measurable with respect to $\mathcal{F}(\mathcal{S}')$. Here $\langle\cdot\ ,\ \cdot\rangle_\sharp$ is the duality pairing between $(\mathcal{D}'(R^n))^n$ and $(C_0^\infty(R^n))^n$. Choose a positive number T and an open bounded subset $\Delta \subset R^n$ so that $t_0 < T$ and the support of $\beta \subset \Delta$. Then, by Lemma 1.6, for each fixed $\omega \in \Omega$, where $\Omega \in \mathcal{B}(\mathcal{S}')$ with $\mu(\Omega) = 1$,

$$\langle u(t,x_1,\dots,x_n;\omega),\ \beta(x_1,\dots,x_n)\rangle_\sharp$$

is continuous in $t \in [0,T]$. Consequently,

$$\begin{aligned}(1.46)\qquad &\langle u(t_0,x_1,\dots,x_n;\omega),\ \beta(x_1,\dots,x_n)\rangle_\sharp \\ &= \lim_{h\to 0} \ll u(t,x_1,\dots,x_n;\omega),\ \rho_h(t-t_0)\beta(x_1,\dots,x_n) \gg,\end{aligned}$$

where $\ll \cdot\,,\ \cdot \gg$ is the duality pairing between $(\mathcal{D}'(R^{n+1}_+))^n$ and $(C^\infty_0(R^{n+1}_+))^n$, $\rho_h(t) = \rho(t/h)/h$ and $\rho(t)$ is the same as in (1.45). But, for each sufficiently small h,

$$\ll u(t,x_1,\dots,x_n;\omega),\ \rho_h(t-t_0)\beta(x_1,\dots,x_n) \gg$$

is measurable with respect to $\mathcal{B}(\mathcal{S}')$, because u is a generalized stochastic process with respect to $\mathcal{B}(\mathcal{S}')$. Since (1.46) holds for each $\omega \in \Omega$,

$$\langle u(t_0,x_1,\dots,x_n;\omega),\ \beta(x_1,\dots,x_n)\rangle_\sharp$$

is measurable with respect to $\mathcal{F}(\mathcal{S}')$. By the same argument,

$$\langle u_t(t_0,x_1,\dots,x_n;\omega),\ \beta(x_1,\dots,x_n)\rangle_\sharp$$

is also measurable with respect to $\mathcal{F}(\mathcal{S}')$. □

By virtue of Theorem 1.1, Corollary 1.3, and Lemma 1.6, we have the uniqueness of the solution to (0.1) and (0.2) in the following form.

LEMMA 1.9. *If u_1 and u_2 are solutions of* (0.1) *and* (0.2), *then*

$$(1.47)\qquad u_1 = u_2 \qquad \text{in } R^{n+1}_+$$

for almost all ω.

Let us write with the same η as in Theorem 1.2,

$$(1.48)\qquad \Xi(t_0,x_0;\eta) = \{(t,x) \in R^{n+1} \mid 0 \le t \le t_0,\ |x-x_0| \le \eta(t_0-t)\},$$

and let d be the smallest integer larger than $(n/2)-1$. Our main result is the following.

THEOREM 1.10. *There is a continuous Gaussian process $V(t,x_1,\dots,x_n;\omega)$ with parameter $(t,x_1,\dots,x_n) \in [0,\infty)\times R^n$ such that*

(i) *$L^d V$ is a unique solution of* (0.1) *and* (0.2);

(ii) *$V(t,x_1,\dots,x_n;\omega)$ and $V(\tilde t,\tilde x_1,\dots,\tilde x_n;\omega)$ are independent random variables if $\Xi(t,x_1,\dots,x_n;\eta)$ and $\Xi(\tilde t,\tilde x_1,\dots,\tilde x_n;\eta)$ are disjoint.*

The operator L was defined by (1.22).

2. Proof of the main result. The proof of Theorem 1.10 consists of two basic steps. First, we construct an integral kernel which represents a solution of the deterministic equation:

$$(2.1)\qquad L^d v = f \qquad \text{in } R^{n+1}_+,$$

with zero initial conditions and $f \in L^2_{loc}([0,\infty);(L^2(R^n))^n)$. For this, we use Theorems 1.1, 1.2, and Corollary 1.3. We then obtain approximate solutions by truncating the chaos expansion of the space-time white noise, and prove the convergence to the true solution. Approximation of the white noise is necessary to establish rigorously the existence of a solution according to Definition 1.5.

2.1. Construction of an integral kernel. Consider the initial value problem

$$\begin{cases} Lu^{(1)} = f \qquad \text{in } R_+^{n+1}, \\ u^{(1)}(0,x) = 0, \;\; u_t^{(1)}(0,x) = 0 \quad \text{for } x \in R^n, \end{cases} \tag{2.2}$$

where $f \in L^2_{loc}\big([0,\infty); (L^2(R^n))^n\big)$. Then there is a unique solution

$$u^{(1)} \in C\big([0,\infty); (H^1(R^n))^n\big) \cap C^1\big([0,\infty); (L^2(R^n))^n\big),$$

which satisfies

$$\|u^{(1)}(t,\cdot)\|_{(H^1(R^n))^n} + \|u_t^{(1)}(t,\cdot)\|_{(L^2(R^n))^n} \le C_T \|f\|_{L^2(0,T;(L^2(R^n))^n)} \tag{2.3}$$

for all $0 \le t \le T$. Here and below, C_T stands for generic positive constants depending only on $T > 0$. Next we consider

$$\begin{cases} Lu^{(2)} = u^{(1)} \qquad \text{in } R_+^{n+1}, \\ u^{(2)}(0,x) = 0, \;\; u_t^{(2)}(0,x) = 0 \quad \text{for } x \in R^n. \end{cases} \tag{2.4}$$

We have

$$u^{(2)} \in C\big([0,\infty); (H^2(R^n))^n\big) \cap C^1\big([0,\infty); (H^1(R^n))^n\big),$$

which satisfies

$$\|u^{(2)}(t,\cdot)\|_{(H^2(R^n))^n} + \|u_t^{(2)}(t,\cdot)\|_{(H^1(R^n))^n} \le C_T \|f\|_{L^2(0,T;(L^2(R^n))^n)} \tag{2.5}$$

for all $0 \le t \le T$.

Inductively, we have for $i = 1, \dots, d$,

$$\begin{cases} Lu^{(i+1)} = u^{(i)} \qquad \text{in } R_+^{n+1}, \\ u^{(i+1)}(0,x) = 0, \;\; u_t^{(i+1)}(0,x) = 0 \quad \text{for } x \in R^n. \end{cases} \tag{2.6}$$

It follows that

$$L^{d+1} u^{(d+1)} = f \qquad \text{in } R_+^{n+1} \tag{2.7}$$

and

$$u^{(d+1)} \in C\big([0,\infty); (H^{d+1}(R^n))^n\big) \cap C^1\big([0,\infty); (H^d(R^n))^n\big); \tag{2.8}$$

$$\|u^{(d+1)}(t,\cdot)\|_{(H^{d+1}(R^n))^n} + \|u_t^{(d+1)}(t,\cdot)\|_{(H^d(R^n))^n} \le C_T \|f\|_{L^2(0,T;(L^2(R^n))^n)} \tag{2.9}$$

for all $0 \le t \le T$. Recall that d is the smallest integer larger than $(n/2) - 1$. Let $C_B(R^n)$ be the space of all uniformly bounded continuous functions on R^n. Since $H^{d+1}(R^n) \subset C_B(R^n)$, we find that for each fixed $0 \le t_0 \le T$, $x_0 \in R^n$, the mapping

$$f \mapsto u^{(d+1)}(t_0, x_0) \tag{2.10}$$

is a bounded linear mapping from $(L^2(0,T; L^2(R^n)))^n$ to R^n. Thus there is a matrix function $G = [G_{ij}(t,x;t_0,x_0)]$ with each $G_{ij} \in L^2(0,T; L^2(R^n))$ so that

$$u_i^{(d+1)}(t_0,x_0) = \int_0^T \int_{R^n} \sum_{j=1}^n G_{ij}(t,x;t_0,x_0) f_j(t,x)\, dx\, dt. \tag{2.11}$$

By Corollary 1.3, we find that modification of f outside of $\cup_{0\le t\le t_0}\{(t,\overline{\Gamma_{(t_0,x_0)}(t;\epsilon,\eta)})\}$ does not change the values of $u^{(k)},\ k=1,\dots,d+1,$ in $\cup_{0\le t\le t_0}\{(t,\overline{\Gamma_{(t_0,x_0)}(t;\epsilon,\eta)})\}$. Consequently, it holds that

$$u_i^{(d+1)}(t_0,x_0)=\int_0^{t_0}\int_{\Gamma_{(t_0,x_0)}(t;\epsilon,\eta)}\sum_{j=1}^n G_{ij}(t,x;t_0,x_0)f_j(t,x)\,dx\,dt \tag{2.12}$$

for every $\epsilon>0$. By passing $\epsilon\to 0,$ we arrive at

$$u_i^{(d+1)}(t_0,x_0)=\iint_{\Xi(t_0,x_0;\eta)}\sum_{j=1}^n G_{ij}(t,x;t_0,x_0)f_j(t,x)\,dx\,dt \tag{2.13}$$

which, together with (2.11), implies

$$\text{the support of } G_{ij}(t,x;t_0,x_0)\subset\Xi(t_0,x_0;\eta). \tag{2.14}$$

LEMMA 2.1. *For each $T>0$, the mapping $(t_0,x_0)\mapsto G_{ij}(\,\cdot\,;t_0,x_0)$ is Hölder continuous from $[0,T]\times R^n$ to $L^2([0,T]\times R^n)$, $i,j=1,\dots,n$.*

Proof. Let us write $d+1=(n/2)+\epsilon,$ where $\epsilon=1/2$ if n is odd, and $\epsilon=1$ if n is even. It follows from (2.8) and (2.9)

(2.15)

$$\begin{aligned}
&|u^{(d+1)}(t_0,x_0)-u^{(d+1)}(\tilde t_0,x_0)|\\
&\le C\|u^{(d+1)}(t_0,\cdot)-u^{(d+1)}(\tilde t_0,\cdot)\|_{(H^{(n/2)+(\epsilon/2)}(R^n))^n}\\
&\le C\|u^{(d+1)}(t_0,\cdot)-u^{(d+1)}(\tilde t_0,\cdot)\|^{1-(\epsilon/2)}_{(H^{(n/2)+\epsilon}(R^n))^n}\,\|\int_{\tilde t_0}^{t_0}u_t^{(d+1)}(t,\cdot)\,dt\|^{\epsilon/2}_{(H^{(n/2)+\epsilon-1}(R^n))^n}\\
&\le C_T|t_0-\tilde t_0|^{\epsilon/2}\,\|f\|_{L^2(0,T;(L^2(R^n))^n)}
\end{aligned}$$

for all $t_0,\tilde t_0\in[0,T]$ and all $x_0\in R^n$. In the meantime, by (2.9) and the Sobolev imbedding theorem,

$$|u^{(d+1)}(t_0,x_0)-u^{(d+1)}(t_0,\tilde x_0)|\le C_T|x_0-\tilde x_0|^{\epsilon}\,\|f\|_{L^2(0,T;(L^2(R^n))^n)} \tag{2.16}$$

for all $t_0\in[0,T]$ and all $x_0,\tilde x_0\in R^n$.

This, together with (2.11) and (2.15), yields

$$\begin{aligned}
&\left|\int_0^T\int_{R^n}\sum_{j=1}^n\big(G_{ij}(t,x;t_0,x_0)\ -\ G_{ij}(t,x;\tilde t_0,\tilde x_0)\big)f_j(t,x)\,dx\,dt\right|\\
&\qquad\le C_T(|t_0-\tilde t_0|^{\epsilon/2}+|x_0-\tilde x_0|^{\epsilon})\ \|f\|_{(L^2([0,T]\times R^n))^n},
\end{aligned} \tag{2.17}$$

and thus, for each $i,j=1,\dots,n$,

$$\|G_{ij}(\,\cdot\,;t_0,x_0)-G_{ij}(\,\cdot\,;\tilde t_0,\tilde x_0)\|_{L^2([0,T]\times R^n)}\le C_T(|t_0-\tilde t_0|^{\epsilon/2}+|x_0-\tilde x_0|^{\epsilon}) \tag{2.18}$$

for all $(t_0,x_0),\ (\tilde t_0,\tilde x_0)\in[0,T]\times R^n$. This proves the Hölder continuity of G_{ij}. ∎

2.2. Approximation and convergence. We approximate $F(t,x)$ in (0.1) by

$$F^N(t,x)=\begin{cases}F(t,x) & \text{for } |t|+|x|\le N,\\ 0 & \text{otherwise.}\end{cases} \tag{2.19}$$

Recalling (1.20), we define

$$Q_i^N(t,x;\omega)=\sum_{k=1}^{N}\sum_{j=1}^{n}F_{ij}^N(t,x)\eta_k(t,x)\langle\omega_j,\ \eta_k\rangle. \tag{2.20}$$

Then, for each ω,

$$Q_i^N(t,x;\omega)\in L^2(R_+^{n+1}),\ \ i=1,\dots,n. \tag{2.21}$$

Next we define

$$W_i^N(t,x;\omega)=\int_0^\infty\int_{R^n}\sum_{j=1}^{n}G_{ij}(s,y;t,x)Q_j^N(s,y;\omega)\,dy\,ds. \tag{2.22}$$

Let $W^N=(W_1^N,\dots,W_n^N)$, and $Q^N=(Q_1^N,\dots,Q_n^N)$. Then it holds that for each ω,

$$L^{d+1}W^N=Q^N(t,x;\omega)\qquad\text{in } R_+^{n+1}, \tag{2.23}$$

and, for $j=0,1,\dots,d$,

$$L^jW^N\in C\big([0,\infty);(H^{d+1-j}(R^n))^n\big)\cap C^1\big([0,\infty);(H^{d-j}(R^n))^n\big), \tag{2.24}$$

$$(L^jW^N)(0,x;\omega)=0,\qquad (L^jW^N)_t(0,x;\omega)=0\quad\text{in } R^n. \tag{2.25}$$

Choose any $\mathcal{M}\in\mathcal{B}(\mathcal{S}')$. By virtue of the special structure of W_i^N defined by (2.20) and (2.22), it is apparent that

$$\iint\limits_{R_+^{n+1}}\int_{\mathcal{M}}W^N\cdot\big((L^*)^{d+1}\phi\big)\,d\mu\,dx\,dt=\int_{\mathcal{M}}\iint\limits_{R_+^{n+1}}W^N\cdot\big((L^*)^{d+1}\phi\big)\,dx\,dt\,d\mu \tag{2.26}$$

for all $\phi\in(C_0^\infty(R^{n+1}))^n$. At the same time, we use (2.21), (2.23), (2.24), (2.25), and the same argument as in the proof of Lemma 1.7 to find that

$$\int_{\mathcal{M}}\iint\limits_{R_+^{n+1}}W^N\cdot\big((L^*)^{d+1}\phi\big)\,dx\,dt\,d\mu=\int_{\mathcal{M}}\iint\limits_{R_+^{n+1}}Q^N\cdot\phi\,dx\,dt\,d\mu \tag{2.27}$$

for all $\phi\in(C_0^\infty(R^{n+1}))^n$.

Recalling (1.20), (2.20), and (2.22), we define, for $i=1,\dots,n$,

$$W_i(t,x;\omega)=\sum_{\nu,j=1}^{n}\langle\omega_j(s,y),\ G_{i\nu}(s,y;t,x)F_{\nu j}(s,y)\rangle, \tag{2.28}$$

and write $W = (W_1, \dots, W_n)$. We can use (1.7) in the same way as for (1.20) to find that for each $g \in (L^2(R^{n+1}))^n$,

$$\sum_{k=1}^{N} \sum_{j=1}^{n} \langle \omega_j(z),\, \eta_k(z) \rangle \int_{R^{n+1}} \eta_k(z) g_j(z)\, dz \,\to \sum_{j=1}^{n} \langle \omega_j(z),\, g_j(z) \rangle, \tag{2.29}$$

in $L^2(\mathcal{S}', d\mu)$. The assumption (V), (2.14), (2.18), and (2.29) imply that as $N \to \infty$

$$W_i^N(t,x;\omega) \to W_i(t,x;\omega) \qquad \text{in } L^2(\mathcal{S}', d\mu), \tag{2.30}$$

uniformly in (t,x) of each bounded subset of $[0,\infty) \times R^n$. Hence, we find that for every $\phi \in (C_0^\infty(R^{n+1}))^n$,

$$\iint\limits_{R_+^{n+1}} \int_{\mathcal{M}} W^N \cdot \big((L^*)^{d+1}\phi\big)\, d\mu\, dx\, dt \to \iint\limits_{R_+^{n+1}} \int_{\mathcal{M}} W \cdot \big((L^*)^{d+1}\phi\big)\, d\mu\, dx\, dt, \tag{2.31}$$

as $N \to \infty$.

Meanwhile, for every $\phi \in (C_0^\infty(R^{n+1}))^n$, as $N \to \infty$,

$$\int_{\mathcal{M}} \iint\limits_{R_+^{n+1}} Q^N \cdot \phi\, dx\, dt\, d\mu \to \int_{\mathcal{M}} \sum_{i,j=1}^{n} \langle \omega_j(t,x),\ F_{ij}(t,x)\phi_i(t,x)\pi_+(t) \rangle\, d\mu, \tag{2.32}$$

where

$$\pi_+(t) = \begin{cases} 1 & \text{for } t \ge 0, \\ 0 & \text{otherwise.} \end{cases} \tag{2.33}$$

Thus, for every $\phi \in (C_0^\infty(R^{n+1}))^n$,

$$\iint\limits_{R_+^{n+1}} \int_{\mathcal{M}} W \cdot \big((L^*)^{d+1}\phi\big)\, d\mu\, dx\, dt = \int_{\mathcal{M}} \sum_{i,j=1}^{n} \langle \omega_j,\ F_{ij}\phi_i\pi_+ \rangle\, d\mu. \tag{2.34}$$

Next we will obtain a continuous version of W. Let K be a bounded subset of $[0,\infty) \times R^n$. It follows from (1.7) and (2.18) that for each positive integer m,

$$E\big(\big|W_i(t,x;\omega) - W_i(\tilde{t},\tilde{x};\omega)\big|^{2m}\big) \le C_{m,K} |(t,x) - (\tilde{t},\tilde{x})|^{\epsilon m} \tag{2.35}$$

for all (t,x), $(\tilde{t},\tilde{x}) \in K$, for some positive constant $C_{m,K}$. By a partition of unity and Kolmogorov's theorem, there is a continuous version $V_i(t,x;\omega)$ of $W_i(t,x;\omega)$. We write $V = (V_1, \dots, V_n)$. It is evident that V is a continuous Gaussian process with parameter $(t,x) \in [0,\infty) \times R^n$.

LEMMA 2.2. *For every $\phi \in (C_0^\infty(R^{n+1}))^n$, and every $\mathcal{M} \in \mathcal{B}(\mathcal{S}')$, it holds that*

$$\begin{aligned} &\int_{\mathcal{M}} \iint\limits_{R_+^{n+1}} V \cdot \big((L^*)^{d+1}\phi\big)\, dx\, dt\, d\mu \\ &= \int_{\mathcal{M}} \sum_{i,j=1}^{n} \iint\limits_{R_+^{n+1}} (-1)^{n+1} \frac{\partial^{n+1}\phi_i}{\partial t \partial x_1 \cdots \partial x_n} B_{ij}(t,x;\omega)\, dx\, dt\, d\mu. \end{aligned} \tag{2.36}$$

Proof. Since $E(|W_i(t,x;\cdot)|^2)$ is bounded uniformly in (t,x) of each bounded subset of $[0,\infty)\times R^n$, it is apparent that

$$\iiint_{R_+^{n+1}} \int_{\mathcal{M}} \left|W\cdot\left((L^*)^{d+1}\phi\right)\right| d\mu\,dx\,dt < \infty \tag{2.37}$$

for each $\phi\in(C_0^\infty(R^{n+1}))^n$. In the meantime, $V_i(t,x;\omega)=W_i(t,x;\omega)$ for almost all ω, for each fixed (t,x) so that

$$\iiint_{R_+^{n+1}} \int_{\mathcal{M}} W\cdot\left((L^*)^{d+1}\phi\right) d\mu\,dx\,dt = \iiint_{R_+^{n+1}} \int_{\mathcal{M}} V\cdot\left((L^*)^{d+1}\phi\right) d\mu\,dx\,dt \tag{2.38}$$

and also,

$$\iiint_{R_+^{n+1}} \int_{\mathcal{M}} \left|W\cdot\left((L^*)^{d+1}\phi\right)\right| d\mu\,dx\,dt = \iiint_{R_+^{n+1}} \int_{\mathcal{M}} \left|V\cdot\left((L^*)^{d+1}\phi\right)\right| d\mu\,dx\,dt \tag{2.39}$$

for every $\phi\in(C_0^\infty(R^{n+1}))^n$. Furthermore, $V_i(t,x;\omega)$ is continuous in (t,x) for each ω, and measurable with respect to $\mathcal{B}(\mathcal{S}')$ for each (t,x). Hence, V_i is measurable with respect to the product σ-algebra. By Fubini's theorem, we have

$$\iiint_{R_+^{n+1}} \int_{\mathcal{M}} V\cdot\left((L^*)^{d+1}\phi\right) d\mu\,dx\,dt = \int_{\mathcal{M}} \iiint_{R_+^{n+1}} V\cdot\left((L^*)^{d+1}\phi\right) dx\,dt\,d\mu. \tag{2.40}$$

Meanwhile, it follows from Lemma 1.4 that for every $\phi\in(C_0^\infty(R^{n+1}))^n$,

$$\begin{aligned}&\int_{\mathcal{M}} \sum_{i,j=1}^n <\omega_j,\ F_{ij}\phi_i>\ d\mu\\ &= \int_{\mathcal{M}} \sum_{i,j=1}^n \iiint_{R^{n+1}} (-1)^{n+1}\frac{\partial^{n+1}\phi_i}{\partial t\partial x_1\dots\partial x_n} B_{ij}(t,x_1,\dots,x_n;\omega)\,dx\,dt\,d\mu.\end{aligned} \tag{2.41}$$

Let us choose $\pi(t)\in C^\infty(R)$ with $\pi(t)=1$ for $t\ge 0$, and $\pi(t)=0$ for $t\le -1$, and write

$$\pi^h(t)=\pi(t/h) \qquad \text{for } h>0. \tag{2.42}$$

Then (2.41) is valid with ϕ_i replaced by $\phi_i\pi^h$, and it is easy to see that as $h\to 0$,

$$\sum_{i,j=1}^n \langle\omega_j,\ F_{ij}\phi_i\pi^h\rangle \ \to \sum_{i,j=1}^n \langle\omega_j,\ F_{ij}\phi_i\pi_+\rangle \qquad \text{in } L^2(\mathcal{S}',d\mu). \tag{2.43}$$

Since $B_{ij}(t,x;\omega)$ is continuous in (t,x) for each ω, it follows from (1.15) and Fatou's lemma that for each bounded subset $K\subset[0,\infty)\times R^n$,

$$E\left(\left|B_{ij}(t,x;\cdot)\right|^2\right)\le C_K \tag{2.44}$$

for all $(t,x) \in K$, for some positive constant C_K. We use this for the following procedure:

$$
\begin{aligned}
(2.45)\qquad & \lim_{h\to 0} \int_{\mathcal{M}} \iint_{R^{n+1}} \frac{\partial^n \phi_i(t,x)}{\partial x_1 \cdots \partial x_n} \frac{1}{h} \pi'(t/h)\, B_{ij}(t,x;\omega)\, dx\, dt\, d\mu \\
&= \lim_{h\to 0} \int_{-1}^{0} \int_{|x|\le q} \int_{\mathcal{M}} \frac{\partial^n \phi_i}{\partial x_1 \cdots \partial x_n}(hs,x)\, \pi'(s)\, B_{ij}(hs,x;\omega)\, d\mu\, dx\, ds \\
&= \int_{-1}^{0} \int_{|x|\le q} \left(\lim_{h\to 0} \int_{\mathcal{M}} \frac{\partial^n \phi_i}{\partial x_1 \cdots \partial x_n}(hs,x)\, \pi'(s)\, B_{ij}(hs,x;\omega)\, d\mu \right) dx\, ds \\
&= 0.
\end{aligned}
$$

Here the second equality is justified by the fact that

$$
\int_{\mathcal{M}} \frac{\partial^n \phi_i}{\partial x_1 \cdots \partial x_n}(hs,x)\, \pi'(s)\, B_{ij}(hs,x;\omega)\, d\mu
$$

is bounded uniformly in $0 \le h \le 1$, $-1 \le s \le 0$, and $|x| \le q$, where q is a positive number such that $\phi_i(t,x) = 0$ for $|x| \ge q$. For the last equality, we argue as follows. First, for each fixed s and x, as $h \to 0$,

$$
(2.46)\qquad < \omega_j(y),\ F_{ij}(y) \chi_{(hs,x_1,\dots,x_n)}(y) > \to 0 \quad \text{in } L^2(\mathcal{S}', d\mu).
$$

Next, since $B_{ij}(t,x;\omega)$ is a continuous version of the process defined by (1.10), we have for each fixed s and x,

$$
\begin{aligned}
(2.47)\qquad \lim_{h\to 0} \int_{\mathcal{M}} B_{ij}(hs,x;\omega)\, d\mu &= \lim_{h\to 0} \int_{\mathcal{M}} < \omega_j(y),\ F_{ij}(y) \chi_{(hs,x_1,\dots,x_n)}(y) >\, d\mu \\
&= 0.
\end{aligned}
$$

Hence, the last equality follows.

Similarly, we also have

$$
\begin{aligned}
(2.48)\qquad & \lim_{h\to 0} \int_{\mathcal{M}} \iint_{R^{n+1}} \frac{\partial^{n+1} \phi_i(t,x)}{\partial t \cdots \partial x_n}\, \pi^h(t,x) B_{ij}(t,x;\omega)\, dx\, dt\, d\mu \\
&= \int_{\mathcal{M}} \iint_{R_+^{n+1}} \frac{\partial^{n+1} \phi_i(t,x)}{\partial t \cdots \partial x_n}\, B_{ij}(t,x;\omega)\, dx\, dt\, d\mu.
\end{aligned}
$$

Combining (2.43), (2.45), and (2.48), we finally arrive at

$$
\begin{aligned}
(2.49)\qquad & \int_{\mathcal{M}} \sum_{i,j=1}^{n} \langle \omega_j,\ F_{ij} \phi_i \pi_+ \rangle\, d\mu \\
&= \int_{\mathcal{M}} \sum_{i,j=1}^{n} \iint_{R_+^{n+1}} (-1)^{n+1} \frac{\partial^{n+1} \phi_i}{\partial t \partial x_1 \cdots \partial x_n} B_{ij}(t,x;\omega)\, dx\, dt\, d\mu
\end{aligned}
$$

for all $\phi \in (C_0^\infty(R^{n+1}))^n$. By means of (2.34), (2.38), (2.40), and (2.49), we derive (2.36) and conclude the proof of Lemma 2.2. □

We now show that $L^d V(t,x;\omega)$ is a solution of (0.1) according to Definition 1.5. (2.36) implies that for each $\phi \in (C_0^\infty(R_+^{n+1}))^n$,

$$\ll V,\ (L^*)^{d+1}\phi \gg = \sum_{i,j=1}^{n} \iint_{R_+^{n+1}} (-1)^{n+1} \frac{\partial^{n+1}\phi_i}{\partial t \cdots \partial x_n} B_{ij}(t,x;\omega)\, dx\, dt \tag{2.50}$$

holds for almost all ω. Let K be a compact subset of R_+^{n+1}. Then $C_0^\infty(K)$ is a separable Fréchet space. Hence, there is a countable dense subset $\{\phi^{(\nu)}\}_{\nu=1}^\infty \subset \big(C_0^\infty(K)\big)^n$. For each $\phi^{(\nu)}$, there is $\Omega_\nu \in \mathcal{B}(\mathcal{S}')$ such that $\mu(\Omega_\nu) = 1$, and, for all $\omega \in \Omega_\nu$,

$$\ll V,\ (L^*)^{d+1}\phi^{(\nu)} \gg = \sum_{i,j=1}^{n} \iint_{R_+^{n+1}} (-1)^{n+1} \frac{\partial^{n+1}\phi_i^{(\nu)}}{\partial t \cdots \partial x_n} B_{ij}(t,x;\omega)\, dx\, dt \tag{2.51}$$

holds. Let $\Omega_K = \cap_{\nu=1}^\infty \Omega_\nu$. Then, $\mu(\Omega_K) = 1$, and for all $\omega \in \Omega_K$, (2.51) holds for every $\phi \in \big(C_0^\infty(K)\big)^n$. Since R_+^{n+1} is a countable union of compact subsets, there is $\Omega \in \mathcal{B}(\mathcal{S}')$ such that $\mu(\Omega) = 1$, and for every $\omega \in \Omega$, (2.50) holds for all $\phi \in (C_0^\infty(R_+^{n+1}))^n$. Hence, $L^d V$ is a solution of (0.1) in R_+^{n+1}.

Next we will show that $L^d V$ satisfies the initial conditions (0.2). Choose any $\gamma_1(x),\ \gamma_2(x) \in (C_0^\infty(R^n))^n$, and consider the Cauchy problem:

$$L^*\psi = 0 \qquad \text{in } (-\infty,\infty) \times R^n, \tag{2.52}$$

$$\psi(0,x) = \gamma_1(x), \qquad \psi_t(0,x) = \gamma_2(x) \quad \text{in } R^n. \tag{2.53}$$

Choose a function $\zeta(t) \in C_0^\infty(R)$ such that $\zeta(t) = 1$ for $|t| \le 1$, and $\zeta(t) = 0$ for $|t| \ge 2$. Let us set $\sigma(t,x) = \zeta(t)\psi(t,x)$. The solution of the above Cauchy problem satisfies the property of a domain of dependence, and consequently, $\sigma(t,x) \in (C_0^\infty(R^{n+1}))^n$. Furthermore, it is easy to see

$$L^*\sigma = 2\zeta_t\, \psi_t + \zeta_{tt}\psi \in (C_0^\infty(R^{n+1}))^n, \tag{2.54}$$

where the right-hand side vanishes for $|t| \le 1$. In the meantime, by the same argument as above, we can infer from (2.36) that there is some $\Omega \in \mathcal{B}(\mathcal{S}')$ with $\mu(\Omega) = 1$ such that for each $\omega \in \Omega$,

$$\iint_{R_+^{n+1}} V \cdot \big((L^*)^{d+1}\phi\big)\, dx\, dt = \sum_{i,j=1}^{n} \iint_{R_+^{n+1}} (-1)^{n+1} \frac{\partial^{n+1}\phi_i}{\partial t \cdots \partial x_n} B_{ij}(t,x;\omega)\, dx\, dt \tag{2.55}$$

holds for all $\phi \in (C_0^\infty(R^{n+1}))^n$. With $\phi = \sigma$, the left-hand side can be written as

$$\iint_{R_+^{n+1}} V \cdot \big((L^*)^d L^*\sigma\big)\, dx\, dt = \int_0^\infty \langle L^d V,\ L^*\sigma\rangle_\sharp\, dt, \tag{2.56}$$

because $L^*\sigma \in \big(C_0^\infty(R_+^{n+1})\big)^n$ for $t \ge 0$. Thus (2.55) yields

$$\begin{aligned} &\int_0^\infty \langle L^d V(t,x;\omega),\ L^*\sigma(t,x)\rangle_\sharp\, dt \\ &\quad = \sum_{i,j=1}^{n} \iint_{R_+^{n+1}} (-1)^{n+1} \frac{\partial^{n+1}\sigma_i(t,x)}{\partial t \cdots \partial x_n} B_{ij}(t,x;\omega)\, dx\, dt \end{aligned} \tag{2.57}$$

for all $\omega \in \Omega$. On the other hand, Lemma 1.7 implies that

$$
\begin{aligned}
(2.58) \qquad & -\langle (L^d V)_t(0,x;\omega),\ \gamma_1(x)\rangle_\sharp + \langle L^d V(0,x;\omega),\ \gamma_2(x)\rangle_\sharp \\
& + \int_0^\infty \langle L^d V(t,x;\omega),\ L^*\sigma(t,x)\rangle_\sharp \, dt \\
& = \sum_{i,j=1}^{n} \iint_{R_+^{n+1}} (-1)^{n+1} \frac{\partial^{n+1}\sigma_i(t,x)}{\partial t \cdots \partial x_n} B_{ij}(t,x;\omega)\, dx\, dt
\end{aligned}
$$

for all $\omega \in \Omega$, after modification of Ω if necessary. But we note that this Ω is independent of γ_1 and γ_2. By comparing (2.57) and (2.58), we conclude that

$$
L^d V(0,x;\omega) = 0, \qquad (L^d V)_t(0,x;\omega) = 0 \quad \text{in } R^n
$$

for each $\omega \in \Omega$, because γ_1 and γ_2 were chosen arbitrarily. The uniqueness is given by Lemma 1.9

Now the statement (i) of Theorem 1.10 has been established. The statement (ii) follows easily from (1.6), (2.14), and (2.28).

Final remark. Our goal is to obtain a solution in the form (0.6). If one is interested only in the existence of weak solutions for almost all ω, there is a somewhat direct approach. It follows from Lemma 1.4 that $F\xi \in (H^{-1}_{loc}(R; H^{-n}_{loc}(R^n)))^n$ for almost all ω. Since Theorem 1.1 cannot be applied directly for this function class, it requires some work to obtain a weak solution. This involves localization in the space variables and handling low regularity in the time variable as in the proof of Lemma 1.6. It also needs some extra work to show that the resulting weak solution is a generalized stochastic process. Meanwhile, the structure of such a solution is intractable. The reward for our special procedure for the existence of solution is twofold. First, the representation formula shows globally uniform structure of the solution as a generalized stochastic process. Second, our procedure shows that the solution can be approximated by a sequence of ordinary stochastic processes.

TRAVELING TWO AND THREE DIMENSIONAL CAPILLARY GRAVITY WATER WAVES*

WALTER CRAIG† AND DAVID P. NICHOLLS‡

Abstract. The main results of this paper are existence theorems for traveling gravity and capillary gravity water waves in two dimensions, and capillary gravity water waves in three dimensions, for any periodic fundamental domain. This is a problem in bifurcation theory, yielding curves in the two dimensional case and bifurcation surfaces in the three dimensional case. In order to address the presence of resonances, the proof is based on a variational formulation and a topological argument, which is related to the resonant Lyapunov center theorem.

Key words. water waves, bifurcation theory, traveling waves

1. Introduction.

Nonlinear periodic traveling waves on the free surface of an ideal fluid tend to form hexagonal patterns. This phenomenon is the focus of a number of recent papers on the subject of water waves, and it is the topic of the present article. In previous work, various approximations to the evolution equations for free surface waves are used, in particular the KP system by J. Hammack, N. Scheffner, and H. Segur [11], and J. Hammack, D. McCallister, N. Scheffner, and H. Segur [12], and alternatively with certain formal shallow water expansions of the Euler equations by P. Milewski and J.B. Keller [16]. A natural question is whether similar patterns can be shown to occur in solutions of the full Euler equations themselves. This is the focus of a series of papers by the present authors. In [18] and in [20] we report on hexagonal wave patterns and other phenomena in numerical computations of solutions, which are shown to satisfy spectral criteria for numerical convergence to solutions of Euler's equations. In the present article we describe rigorous existence results for periodic traveling wave solutions in free surfaces. The goal is to prove the existence of nontrivial traveling wave solutions to the water wave problem for gravity and capillary gravity waves in two and three dimensions. In two dimensions this is proven for both gravity and capillary gravity water waves, constituting a new and relatively straightforward approach to the theorems of T. Levi-Civita and D. Struik. In three dimensions we prove the existence of traveling capillary gravity water waves. However, the problem of gravity waves in three dimensions exhibits the phenomena of small divisors, and it remains open. The theorem that we prove is given below.

THEOREM 1.1. *For any spatial period there exist nontrivial periodic traveling wave solutions of the water wave problem in two dimensions for gravity and capillary gravity waves, both in deep water and in water of finite depth. In three dimensions, for any periodic fundamental domain of* $\mathbb{R}^2$ *there exist nontrivial periodic traveling wave solutions of the water wave problem for capillary gravity waves in infinite depth*

water and for water of finite depth.

We show that in fact there are many small amplitude traveling waves bifurcating from uniform flow. A solution of the two dimensional problem is of course also a three dimensional one which is constant in one independent variable. In contrast, for the three dimensional problem, the solutions asserted by this theorem explicitly give fully three dimensional wave patterns, as we will see below.

The early rigorous theorems on traveling water waves concern the two dimensional gravity wave problem, by T. Levi-Civita (1925, [15]) in an infinitely deep fluid, and with similar complex variable techniques by D. Struik (1926, [27]) for a fluid of finite depth. When surface tension effects are included, the analogous two dimensional traveling wave problem was addressed by E. Zeidler [31] and H. Beckert and E. Zeidler [2] for large coefficient of surface tension, and J.T. Beale [1], who also allowed for small surface tension under conditions of nonresonance. Later J. Reeder and M. Shinbrot reproduced these results [24], and M. Jones and J. Toland [13], [14] dealt specifically with the occurrence of resonance.

The only papers of which we are aware[1] that give a rigorous analysis of the three dimensional water wave problem are by J. Reeder and M. Shinbrot [23] and T.Y. Sun [28], in which they prove an existence theorem for periodic traveling capillary gravity waves, whose fundamental domain is a "symmetric diamond." In both papers the authors remark that the three dimensional gravity wave problem is an example of a small denominator problem. The proof in [23] applies to most choices of the parameters of the problem (the spatial periods, the acceleration of gravity g, the fluid depth h, and the Bond number σ/gh^2). However, they must explicitly avoid cases in which a certain linearized operator has a zero eigenvalue of higher multiplicity. These are situations where more than the generic one or two solutions of the linearized equation have the same phase velocity. It is easily shown that these exceptional cases are common, and that they accumulate in parameter space at zero Bond number. The paper [28] also is restricted in the same way, but is in some ways more general as it also contains results for the case of a pressure disturbance applied to the free surface traveling at the phase velocity. The paper [23] also reproves the two dimensional theorems for gravity and for capillary gravity free surface waves, again with the proviso that the parameters are chosen so that a higher multiplicity null eigenvalue is avoided. The two dimensional case without such proviso appears in [13], [14]. With regard to the three dimensional water wave problem without surface tension, see P. Plotnikov [21].

In this paper our proof is based on a reformulation of the capillary gravity wave problem involving surface integrals, and a variational argument which is similar to that used by A. Weinstein [29] and J. Moser [17] in their work on the resonant Lyapunov center theorem. A higher dimensional null space in the free surface problem compares formally with a case of resonance near an elliptic stationary point of a Hamiltonian system. Furthermore, the water wave problem is Hamiltonian in our chosen coordinates, a fact due initially to V.E. Zakharov [30], and this plays a role in a counting argument via an equivariant cohomological index for a lower bound on the number of distinct solutions. Our approach is bifurcation theoretic, with the novelty that for the three dimensional problem the basic parameter is the two dimensional phase velocity, and solutions occur correspondingly in bifurcation surfaces rather than curves.

The organization of the paper is as follows. In section 2 we introduce the

[1]We have, however, recently received a preprint of the work of M.D. Groves and A. Mielke [10] on three dimensional capillary gravity waves in channels.

Dirichlet–Neumann operator, reformulate the water wave problem in a set of coordinates involving surface integrals which we have found useful [8], [19], and outline the method of Lyapunov–Schmidt. In section 3 we solve the first Lyapunov–Schmidt equation via the implicit function theorem, and in section 4 we pose the problem as a variational problem for the extrema of an action integral. We then reduce the variational problem to a finite dimensional one using the results of section 3, and analyze its set of solutions. Finally, in section 5 we prove the analyticity of the Dirichlet–Neumann operator in appropriate function spaces. In many ways this analysis is the heart of the proof. The method is very similar to the one of W. Craig, U. Schanz, and C. Sulem [7] and D. Nicholls [19]; however, we modify it in a nontrivial way to yield the particular estimates which we require.

2. Formulation of the water wave problem. The water wave problem describes the evolution of an ideal fluid with free surface under the effects of gravity (gravity waves) or gravity and surface tension (capillary gravity waves). An ideal fluid is one which is inviscid, incompressible, and irrotational. To begin we will consider an n dimensional fluid, meaning $n-1$ horizontal dimensions and one vertical dimension, and specialize to two and three dimensions later.

2.1. Classical equations and a surface integral formulation. Consider a fluid region given by

$$S_\eta = \{(x,y) \in \mathbb{R}^{n-1} \times \mathbb{R} \mid -h \leq y \leq \eta(x,t)\}, \tag{2.1}$$

where $\eta(x,t)$ is the free surface, and $0 < h \leq +\infty$. It is well known for an ideal fluid that inside the fluid domain S_η the fluid velocity $\mathbf{u}$ can be expressed as

$$\mathbf{u} = \nabla\varphi, \tag{2.2}$$

since the fluid is irrotational, and further

$$\operatorname{div}[\mathbf{u}] = \operatorname{div}[\nabla\varphi] = \Delta\varphi = 0, \tag{2.3}$$

since the fluid is incompressible. For the problem of water of finite depth the boundary conditions are given by

$$\partial_y\varphi = 0 \qquad \text{at } y = -h, \tag{2.4a}$$

$$\partial_t\eta + \nabla_x\varphi \cdot \nabla_x\eta - \partial_y\varphi = 0 \qquad \text{at } y = \eta(x,t), \tag{2.4b}$$

$$\partial_t\varphi + \tfrac{1}{2}|\nabla\varphi|^2 + g\eta - \sigma\operatorname{div}\left[\frac{\nabla_x\eta}{\sqrt{1+|\nabla_x\eta|^2}}\right] = 0 \qquad \text{at } y = \eta(x,t)\ , \tag{2.4c}$$

where in appropriate units the density of the fluid is taken to be one, g is the acceleration of gravity, and σ/gh^2 is the Bond number of the interface. To consider water of infinite depth we can replace (2.4a) with the following condition:

$$\partial_y\varphi \to 0 \qquad \text{as } y \to -\infty. \tag{2.4d}$$

The horizontal boundary conditions will be periodic, which is to say that in two dimensions our surface is parameterized by a circle, and in three dimensions by a torus; both of these are determined by a lattice $\Gamma \subseteq \mathbb{R}^{n-1}$, generated by a nonsingular matrix $A \in \mathbb{R}^{(n-1)\times(n-1)}$ acting on vectors $j \in \mathbb{Z}^{n-1}$, which in turn has a conjugate

lattice $\Gamma' \subseteq \mathbb{R}^{n-1}$ generated by the matrix $2\pi(A^T)^{-1}$. We recall that a well-behaved function f on the torus $T(\Gamma) = \mathbb{R}^{n-1}/\Gamma$ can be written in terms of its Fourier series

$$f(x) = \sum_{k \in \Gamma'} \hat{f}(k) e^{ik \cdot x}. \tag{2.5}$$

The classical formulation of the water wave problem is given in (2.3), (2.4a) (or (2.4d)), (2.4b), (2.4c) with periodic boundary conditions. We will follow [8], [25], [19], [18] and recast these equations in a surface integral formulation of the water wave problem. We begin with the observation that when the free surface $\eta(x,t)$ and Dirichlet data at the free surface $\xi(x,t) = \varphi(x, \eta(x,t), t)$ are specified, we can in principle solve the full problem, since φ satisfies Laplace's equation with appropriate boundary conditions. In this way the water wave problem is reduced from one posed inside the entire fluid to one posed at the free surface alone. V.E. Zakharov [30] noted this and also made the elegant statement that the surface variables η and ξ are canonically conjugate variables with which one may formulate the water wave problem as a Hamiltonian system, with Hamiltonian

$$H = \int_{T(\Gamma)} \int_{-h}^{\eta} \tfrac{1}{2} |\nabla \varphi|^2 \, dy + \tfrac{1}{2} g \eta^2 + \sigma \left(\sqrt{1 + |\nabla_x \eta|^2} - 1 \right) dx. \tag{2.6}$$

Of course, the full dependence on η and ξ is complicated and not explicit. However, W. Craig and C. Sulem [8] found a more convenient representation of the Hamiltonian by noting that the term $\int_{T(\Gamma)} \int_{-h}^{\eta} |\nabla \varphi|^2 \, dy \, dx$ is a quadratic form in the quantity ξ involving the Dirichlet–Neumann operator.

DEFINITION 2.1. *The Dirichlet–Neumann operator of the free surface is defined by*

$$G(\eta)\, \xi = \nabla \varphi|_{y=\eta} \cdot N_\eta, \tag{2.7}$$

where the potential function φ satisfies (2.3), (2.4a), *$\varphi(x, \eta(x)) = \xi(x)$, and $N_\eta = (-\nabla_x \eta, 1)^T$ is a (nonnormalized) exterior normal.*

This operator is the central tool in our analysis and a deep understanding of its properties is key to the boundary integral formulation. For our purposes its analyticity in appropriate function spaces is the relevant property which we will state and prove in section 5. Using the Dirichlet–Neumann operator and the divergence theorem, the Hamiltonian for the water wave problem can be written as

$$H = \int_{T(\Gamma)} \tfrac{1}{2} \xi (G(\eta)\, \xi) + \tfrac{1}{2} g \eta^2 + \sigma \left(\sqrt{1 + |\nabla_x \eta|^2} - 1 \right) dx. \tag{2.8}$$

By taking the appropriate variations and interpreting them in the correct fashion, or simply taking (2.4b), (2.4c) and substituting in the Dirichlet–Neumann operator in the appropriate way, one arrives at the following formulation of the water wave problem [5], [7]:

$$\partial_t \eta = G(\eta)\, \xi, \tag{2.9a}$$

$$\begin{aligned} \partial_t \xi = -g\eta - \frac{1}{2\left(1 + |\nabla_x \eta|^2\right)} \Big[& |\nabla_x \xi|^2 - (G(\eta)\, \xi)^2 \\ & - 2(G(\eta)\, \xi) \nabla_x \xi \cdot \nabla_x \eta + |\nabla_x \xi|^2 |\nabla_x \eta|^2 - (\nabla_x \xi \cdot \nabla_x \eta)^2 \Big] \end{aligned} \tag{2.9b}$$

$$+\sigma \mathrm{div}\left[\frac{\nabla_x \eta}{\sqrt{1+|\nabla_x \eta|^2}}\right].$$

2.2. A variational principle and the method of Lyapunov–Schmidt. There is a variational formulation, related to the principle of stationary action, whose Euler–Lagrange equations give traveling wave solutions of (2.9). Given the lattice $\Gamma \subseteq \mathbb{R}^{n-1}$, consider a class of mappings from the torus $T(\Gamma) = \mathbb{R}^{n-1}_x/\Gamma$ to a phase space $X = \{u = (\eta(x), \xi(x))^T\}$ (the topology will be specified later). For these mappings we define $n-1$ many *action* functionals

$$I_j(\eta(x), \xi(x)) = \int_{T(\Gamma)} \eta(x) \partial_{x_j} \xi(x)\, dx \tag{2.10}$$

and as well the (averaged) Hamiltonian $H(\eta(x), \xi(x))$ given in (2.8). The formal variational principle is to fix the values of these $n-1$ actions $I_j = a_j$, and consider extremal points of the Hamiltonian H. If such points existed and were sufficiently regular, they would satisfy the Euler–Lagrange equations

$$\delta H = \sum_{j=1}^{n-1} c_j \delta I_j\ , \tag{2.11}$$

which are traveling wave solutions of system (2.9) with Lagrange multiplier the phase velocity $c = (c_1, \ldots, c_{n-1})$. There is a torus action on the phase space X given by $T_\alpha(\eta(x), \xi(x)) = (\eta(x+\alpha), \xi(x+\alpha))$, under which I_j and H are invariant, and in this way every critical point is in fact a member of a torus of critical points in X. These considerations are, however, purely formal, the level sets of I_j are by no means compact, and without further analytic information about the functionals I_j and H this procedure does not give rise to actual solutions of the problem, even in finite dimensional settings such as the Lyapunov center theorem. Nonetheless, a reduction that is related to the method of Lyapunov–Schmidt gives rise to a related finite dimensional variational problem, also invariant with respect to the torus action, whose critical points give traveling wave solutions to (2.9). This procedure is analogous to the resonant Lyapunov center theorem and the reduction by J. Moser [17] of the variational problem to a finite dimensional one which is invariant under a circle action.

In order to set up the problem of traveling surface waves, introduce a frame of reference moving with velocity c, and change variables in (2.9). This leads to the definition of the functions

$$\begin{aligned} F_1(\eta, \xi, c) = {} & g\eta - c \cdot \nabla_x \xi + \frac{1}{2\left(1+|\nabla_x \eta|^2\right)} \Big[|\nabla_x \xi|^2 - (G(\eta)\ \xi)^2 \\ & - 2(G(\eta)\ \xi) \nabla_x \xi \cdot \nabla_x \eta + |\nabla_x \xi|^2 |\nabla_x \eta|^2 - (\nabla_x \xi \cdot \nabla_x \eta)^2 \Big] \\ & - \sigma \mathrm{div}\left[\frac{\nabla_x \eta}{\sqrt{1+|\nabla_x \eta|^2}}\right], \end{aligned} \tag{2.12a}$$

$$F_2(\eta, \xi, c) = c \cdot \nabla_x \eta + G(\eta)\ \xi\ , \tag{2.12b}$$

with which we will abbreviate the problem of traveling waves for the system (2.9) as $F(\eta, \xi, c) = 0$. Let $u = (\eta, \xi)^T$ and $F : X \times C \to Y$, where the Banach spaces X, C,

and Y are to be specified later. A trivial branch of solutions to this problem is given by $(0, c)$ for all c, and from this trivial branch we produce a nontrivial bifurcation branch of solutions. We will use the implicit function theorem and hence must understand the linearization of F about the trivial solution $\partial_u F(0, c) \equiv A(c)$. If $A(c)$ from X to Y is boundedly invertible for some parameter c, then we may refer to the implicit function theorem to obtain a unique solution in a neighborhood of c, namely, the trivial one. The possible bifurcation points are those values of c for which $A(c)$ has a zero eigenvalue. Using the decomposition of Lyapunov–Schmidt, let c_0 be a parameter value for which $A(c_0)$ has a nontrivial null space, and let

$$X_1 = \text{null}(A(c_0)), \tag{2.13a}$$

$$Y_1 = \text{range}(A(c_0)), \tag{2.13b}$$

and X_2 and Y_2 to be such that $X = X_1 \oplus X_2$, $Y = Y_1 \oplus Y_2$. Let P be the orthogonal projection of Y onto Y_1 and $Q = I - P$. The method of Lyapunov–Schmidt replaces the problem $F(u, c) = 0$ by the equivalent pair of equations

$$PF(v + w, c) = 0, \tag{2.14a}$$

$$QF(v + w, c) = 0, \tag{2.14b}$$

where $v \in X_1$ and $w \in X_2$. In cases in which the linearized operator admits certain estimates, the first equation can be solved via the implicit function theorem. In the two dimensional problems, and in the three dimensional gravity capillary wave problem, this can be done. In these cases the second equation turns out to be finite dimensional in character and it will be resolved through a reduced variational problem.

In keeping with the program outlined above we begin by identifying the relevant Banach spaces, X, C, and Y. We recall the following $L^2(T(\Gamma))$ based Sobolev spaces:

$$H^s = \{f \in L^2(T(\Gamma)) \mid \|f\|_{H^s} < \infty\}\ , \tag{2.15a}$$

where

$$\|f\|_{H^s}^2 = \sum_{k \in \Gamma'} \langle k \rangle^{2s} \left| \hat{f}(k) \right|^2\ , \tag{2.15b}$$

and

$$\langle k \rangle^2 = 1 + |k|^2\,. \tag{2.15c}$$

We also introduce the spaces $H_0^s = \{f \in H^s \mid \hat{f}(0) = 0\}$. With these in mind we prove the following lemma.

LEMMA 2.2. *Suppose that $s > \frac{n-1}{2}$. If $\sigma = 0$, then $F : H^{s+1} \times H^{s+1} \to H^s \times H_0^s$ is an analytic transformation. If $\sigma > 0$, then $F : H^{s+2} \times H^{s+1} \to H^s \times H_0^s$ is an analytic transformation.*

Proof. The proof is straightforward and relies heavily upon two facts: first, the Sobolev inequality for $s > \frac{n-1}{2}$,

$$\|uv\|_{H^s} \leq C \|u\|_{H^s} \|v\|_{H^s}\,; \tag{2.16}$$

second is the fact that the Dirichlet–Neumann operator is a bounded linear function as a function of ξ from $H^{s+1} \to H^s$, and an analytic function of η for $\eta, \xi \in H^{s+1}$. This assertion will be proven in section 5. We note that in the case $\sigma > 0$ there is a

second order derivative acting on η, while in the case $\sigma = 0$ there are only first order derivatives acting on η; this accounts for the two different spaces in the statement of the theorem. The fact that the target space of the second component of F is H^s_0 rather than H^s is a result of the following calculation:

$$\begin{aligned}\hat{F}_2(0) &= \int_{T(\Gamma)} c \cdot \partial_x \eta + G(\eta)\ \xi\ dx \\ &= \int_{T(\Gamma)} (\nabla \varphi|_\eta) \cdot N_\eta\ dx \\ &= \int_{T(\Gamma)} \int_{-h}^{\eta} \Delta \varphi\ dy\ dx \\ &= 0,\end{aligned}$$

which is true by the divergence theorem for $w = w(v, c)$ and the fact that φ is harmonic. Finally, analyticity is proven by the fact that the Dirichlet–Neumann operator is analytic, and that all other appearances of η and ξ are in an analytic fashion. □

We note that a corollary of this result is the following.

COROLLARY 2.3. *Suppose that $s > \frac{n-1}{2}$. If $\sigma = 0$, then $A(c) : H^{s+1} \times H^{s+1}_0 \to H^s \times H^s_0$ is bounded. If $\sigma > 0$, then $A(c) : H^{s+2} \times H^{s+1}_0 \to H^s \times H^s_0$ is bounded.*

We now set $X = H^{s+2} \times H^{s+1}_0$ for the case $\sigma > 0$, $X = H^{s+1} \times H^{s+1}_0$ for the case $\sigma = 0$, and $Y = H^s \times H^s_0$ in either case. In the case of the two dimensional problem we let $C = \mathbb{R}$, and in the case of the three dimensional problem we let $C = \mathbb{R}^2$.

2.3. The linearized operator. At this point we will analyze the problem (2.12) linearized around the trivial solution $(u, c) = (0, c)$. In particular we will restrict ourselves to the cases $n = 2$ and $n = 3$, and we identify the set of parameters $c \in \mathbb{R}$ (respectively, $c \in \mathbb{R}^2$) for which $A(c)$ has a nontrivial null space. Linearizing the system (2.12a) about $(u, c) = (0, c)$ involves the Dirichlet–Neumann operator $G(0) = G_0 = |D| \tanh(h|D|)$.

THEOREM 2.4. *The linearization of F about the trivial solution $(0, c)$ is given by*

$$A(c) = \partial_u F(0, c) = \begin{pmatrix} g - \sigma \Delta_x & -c \cdot \nabla_x \\ c \cdot \nabla_x & G_0 \end{pmatrix}. \tag{2.17}$$

Furthermore, given $k \in \Gamma'$, the null eigenvalues of $A(c)$ on X occur when $c \in \mathbb{R}^{n-1}$ is such that

$$\Delta_\sigma(c, k) = (g + \sigma |k|^2)\, |k| \tanh(h\, |k|) - (c \cdot k)^2 = 0\ . \tag{2.18}$$

Given c_0 satisfying (2.18) for some $k_0 \in \Gamma'$, the null space of $A(c_0)$ is even dimensional, and it is generically two dimensional. It is spanned by the eigenfunctions

$$v^1_k(x) = ((c_0 \cdot k) \cos(k \cdot x), (g + \sigma |k|^2) \sin(k \cdot x))^T, \tag{2.19a}$$

$$v^2_k(x) = (-(c_0 \cdot k) \sin(k \cdot x), (g + \sigma |k|^2) \cos(k \cdot x))^T \tag{2.19b}$$

for $k \in \Gamma'$ in the set of solutions of (2.18).

Proof. The proof is a straightforward calculation, but the role of the function $\Delta_\sigma(c, k)$ perhaps needs some explanation. We will always work in function spaces

smooth enough to admit Fourier expansions of our functions $\eta(x)$ and $\xi(x)$; therefore

$$A(c)\begin{pmatrix}\eta(x)\\ \xi(x)\end{pmatrix} = \sum_{k\in\Gamma'}\begin{pmatrix} g+\sigma|k|^2 & -ic\cdot k \\ ic\cdot k & |k|\tanh(h|k|)\end{pmatrix}\begin{pmatrix}\hat\eta(k)\\ \hat\xi(k)\end{pmatrix}e^{ik\cdot x}$$
$$= \sum_{k\in\Gamma'}\hat A_k(c)\begin{pmatrix}\hat\eta(k)\\ \hat\xi(k)\end{pmatrix}e^{ik\cdot x}\ .$$

The operator $A(c)$ is singular if one of the 2×2 blocks of $\hat A(c)$ is singular, which occurs precisely when the determinant $\Delta_\sigma(c,k)$ of the kth 2×2 block is zero, with null vectors determined by the null vector of the singular 2×2 blocks. The 2×2 block $\hat A_0(c)$ has different character, and for all $c\in\mathbb{R}^{n-1}$ it has the null eigenvector $(0,\hat\xi(0))$. It is precisely for this reason that we work in the space $X = H^{s+\rho}\times H_0^{s+1}$, so that the one dimensional subspace $\{(\eta,\xi) = \gamma(0,\hat\xi(0))\}$ does not contribute to the null space of $A(c)$ on X. Regarding the dimension of the null space, if $\hat A_k(c)$ has a null eigenvector, then so does $\hat A_{-k}(c)$; hence the null space of $A(c)$ is even dimensional. □

The relation (2.18) describes the dispersion relation between a wave number k and its phase velocity c_k. The set of solutions of (2.18) can now be described, starting with the two dimensional problem. For $k\in\Gamma'\backslash\{0\}\subseteq\mathbb{R}$ fixed, a phase velocity $c = c_k$ can always be defined through the relation

$$c^2k^2 = (g+\sigma k^2)k\tanh(hk); \tag{2.20}$$

in both cases $\sigma > 0$ and $\sigma = 0$. Therefore, for any specified spatial period Λ there is a phase velocity c such that $\Delta_\sigma(c,k) = 0$ for $k = 2\pi/\Lambda$, giving a solution to the linearized system with period Λ. Of course both $\pm k$ correspond to the same phase velocity c. It is also possible that for a given $c = c_{k_0}$ there is another $k_1\in\Gamma'$ which satisfies (2.20). Physically this corresponds to the situation where a linear gravity wave of lower wave number has the same phase velocity c as one of higher wave number. This situation can occur only if the Bond number satisfies $\sigma/gh^2 < 1/3$, where the relation (2.20) has two roots for choices of c such that $\min_k\{(g+\sigma k^2)k\tanh(hk)\} < c^2 < gh$. These two roots both satisfy $0\le k < \sqrt{g/\sigma}$. The phase velocity c_{k_0} is chosen so that one of these roots k_0 lies in the lattice Γ'. When both roots are in Γ', there is another linear solution with the specified spatial period, and the null space of $A(c_{k_0})$ is four dimensional.

The three dimensional case is only a little more complex. Given a dual lattice $\Gamma'\in\mathbb{R}^2$ and any two generators k_1, k_2 of Γ', there is always a phase velocity $c_0\in\mathbb{R}^2$ which will satisfy relation (2.18) for both. Indeed, given k_1, by the discussion of the previous paragraph we may always choose some $c_1\in\mathbb{R}^2$ which is parallel to k_1 such that (2.18) holds. Of course any other c such that $c_1\cdot k_1 = c\cdot k_1$ will also do, giving a line of solutions of (2.18) through c_1 perpendicular to k_1. The same holds for k_2, and these two lines cannot be parallel; their meeting point is the common solution that we seek. Given this common phase velocity c_0, it may be that relation (2.18) is satisfied by other wave numbers $k\in\Gamma'$ as well as for k_1 and k_2, although this situation is not generic. Indeed the relation (2.18) defines a curve in $\mathbb{R}^2$ which intersects k_1 and k_2 and possibly other points $k_3, k_4, \ldots\in\Gamma'$. This curve is symmetric about the origin, so the solutions of (2.18) appear in pairs $\pm k_\ell$. We will normalize by the choice that $k_\ell\cdot c_0 > 0$. Note that by the above discussion the situation k_ℓ perpendicular to c_0 does not occur. We have shown the following.

PROPOSITION 2.5. *Given any two generators k_1, k_2 of the lattice Γ', there is a phase velocity c_0 satisfying $\Delta_\sigma(k_\ell, c_0) = 0$, $k_\ell \cdot c_0 > 0$ for $\ell = 1, 2$, and therefore* dim ker $A(c_0) \geq 4$.

A second preliminary result is as follows.

PROPOSITION 2.6. *When $\sigma > 0$ and $c_0 \in \mathbb{R}^2$ is fixed, the number of lattice points $k \in \Gamma'$ satisfying $\Delta_\sigma(k, c_0) = 0$ is finite.*

Proof. The asymptotic behavior of the dispersion relation is that $\omega(k)^2 = (g + \sigma|k|^2)|k| \tanh(h|k|) \sim \sigma|k|^3$, while $|c \cdot k|^2 \leq C|k|^2$, and therefore the set of root of (2.18) is bounded. Notice that this finiteness result no longer holds when $\sigma = 0$. □

This paper does not address the three dimensional case with $\sigma = 0$, for the reason that it is a situation in which the phenomenon of small divisors is present. Our analysis depends upon the boundedness properties of the operator $A(c)^{-1}$ between appropriate Banach spaces. When $n \geq 3$ and $\sigma = 0$ there is a dense set of values of $c \in \mathbb{R}^{n-1}$ for which $A(c)$ has a nontrivial null space, which can even be infinite dimensional. In general, the invertibility properties of the inverse operator, even projected orthogonally to its null space, change sensitively and discontinuously with respect to c. It may be that this problem can be solved with methods related to the Nash–Moser implicit function theorem; however, there is at present no published complete proof. Among other things, these are elements of the program outlined in [21]. To describe the phenomenon of small divisors quantitatively, we give the following result.

THEOREM 2.7. *The point spectrum of the operator $A(c)$ consists of the set*

$$\left\{\mu_\pm(k) = \tfrac{1}{2}(g + |k| \tanh(h|k|)) \pm \tfrac{1}{2}\sqrt{(g - |k| \tanh(h|k|))^2 + 4(c \cdot k)^2}\right\}_{k \in \Gamma'}. \tag{2.21}$$

For every choice of the parameters g, h, and $c \in \mathbb{R}^2 \backslash \{0\}$ this set accumulates at $\mu = 0$.

Proof. Under the Fourier transform the operator $A(c)$ is 2×2 block diagonal, with eigenvalues those of the individual blocks. With $\sigma = 0$,

$$\det(\hat{A}(c)_k - \mu I) = \mu^2 - (g + |k| \tanh(h|k|))\mu + (g|k| \tanh(h|k|) - (c \cdot k)^2) \tag{2.22}$$

and the roots of this relation are the eigenvalues given above. Small divisors will occur when $\Delta_0(c, k) = \det \hat{A}(c)_k, k \in \Gamma'$ satisfies $|\Delta_0(c, k)| < |k|^{1/2}$. In this case we call $k \in \Gamma'$ a singular site in the dual lattice. The associated small eigenvalue is

$$\begin{aligned}
\mu_-(k) &= \tfrac{1}{2}(g + |k| \tanh(h|k|)) - \tfrac{1}{2}\sqrt{(g - |k| \tanh(h|k|))^2 + 4(c \cdot k)^2} \\
&= \tfrac{1}{2}(g + |k| \tanh(h|k|)) - \tfrac{1}{2}\sqrt{(g + |k| \tanh(h|k|))^2 - 4\Delta_0(c, k)} \\
&\sim \frac{\Delta_0(c, k)}{(g + |k| \tanh(h|k|))},
\end{aligned}$$

and the latter quantity is $O(|k|^{-1/2})$ for large and singular $k \in \Gamma'$.

It remains to be shown that there exist singular sites in Γ' with arbitrarily large norm. For this it suffices to consider the problem for deep water ($h = +\infty$), since $g|k| \tanh(h|k|) - g|k| \sim O(|k|e^{-2h|k|})$, and thus large singular sites for h infinite are effectively ones for finite h. For any $c \in \mathbb{R}^2 \backslash \{0\}$ choose a sequence $n_j \in \Gamma'$ which obeys an estimate $|c \cdot n_j| < d_0$; this is possible in any lattice. Additionally choose $m = m(n_j) \in \Gamma'$ such that $|c \cdot m| \sim O(|c||m|)$, $|m| < d_0|n_j|^{1/2}$, and $|m \cdot n_j| < O(|n_j|)$.

With this

$$g|n_j+m| = g(|n_j|^2+2n_j\cdot m+|m|^2)^{1/2} = g|n_j|\left(1+O\left(\frac{1}{|n_j|}\right)\right)$$

and

$$(c\cdot(n_j+m))^2 = (c\cdot m)^2+O(|m|)\ . \tag{2.23}$$

For these choices $|n_j+m| = O(|n_j|)$,

$$g|n_j+m|-(c\cdot(n_j+m))^2 = g|n_j|-((c\cdot m)^2+O(|m|))\ , \tag{2.24}$$

and by further adjustment of $m\in\Gamma'$ by choosing it such that $g|n_j+m'|-(c\cdot(n_j+m'))^2$ changes sign for some m' adjacent to m (this lies within the above constraints) we can ensure that $|g|n_j|-(c\cdot m)^2|<O(|m|)$ itself. This choice gives rise to a sequence of lattice sites $k_j = n_j+m(n_j)$ such that $|k_j|\to\infty$ and $\mu_-(k_j)\sim O(|k_j|^{-1/2})$, which is more than enough to prove the statements of the theorem. ∎

We have now identified our function spaces, the types of solutions which we seek, and the possible values of c where such bifurcation branches can be found. We must now solve the two bifurcation equations and we begin with the P equation.

3. Existence of solutions to the *P* equation. In this section we use the implicit function theorem on Banach spaces to solve the P equation of the method of Lyapunov–Schmidt. We have already established that our map $F: X\times C\to Y$ is analytic and that the linearized operator $A(c)$ is bounded from X into Y. It is clear that the projection P, being a bounded operator with finite dimensional null space, will not change either of these properties and so the only condition yet to be satisfied in order to use the implicit function theorem is the boundedness of the inverse operator. In the same way that we consider the range of $A(c)$ by operating by P, we also consider X_2 as our domain by viewing X_1 as part of the parameter space with C. This results in a solution

$$w = w(v,c), \tag{3.1}$$

such that $PF(v+w(v,c),c)=0$. With this in mind it remains to prove the following theorem.

THEOREM 3.1. *$(P\partial_w F(0,c))^{-1}$ is a bounded linear operator from Y_1 to X_2.*

Proof. We begin by identifying a likely candidate to be the inverse operator. If we considered a value of c such that $\Delta_\sigma(c,k)\neq 0$ for all $k\in\Gamma'$, then an inverse can be found by inverting the 2×2 blocks on the Fourier side resulting in

$$\hat{A}(c)_k^{-1} = \frac{1}{\Delta_\sigma(c,k)}\begin{pmatrix} |k|\tanh(h|k|) & ic\cdot k \\ -ic\cdot k & g+\sigma|k|^2\end{pmatrix}. \tag{3.2}$$

This is well defined for all $k\in\Gamma'\backslash\{0\}$. At $k=0$, $\hat{A}(c)_k$ is singular, but since the second component of F has $k=0$ mode equal to zero we can define an inverse in the following way:

$$\hat{A}(c)_0^{-1}\begin{pmatrix}\hat{v}(0)\\ 0\end{pmatrix} \equiv \begin{pmatrix}\frac{\hat{v}(0)}{g}\\ 0\end{pmatrix}. \tag{3.3}$$

We break up the rest of the proof into three parts, corresponding to each of the three cases which we are considering, since each requires a slightly different analysis.

We begin by studying the case of two dimensions, $\sigma = 0$, and a two dimensional null space. In this case $X = H^{s+1} \times H^{s+1}$. Assume that $\hat{A}(c_0)_{\pm k_0}$ is singular. By the discussion of the previous section, all other $\hat{A}(c)_k, k \neq \pm k_0$ are nonsingular. Let $\tilde{\Gamma}' = \Gamma' \backslash \{\pm k_0\}$, $\tilde{\Gamma}'_0 = \Gamma' \backslash \{0, \pm k_0\}$, and consider the estimate

$$\begin{aligned}
&\left\| (P\partial_w F(0,c))^{-1} \begin{pmatrix} u^1 \\ u^2 \end{pmatrix} \right\|_{X_2}^2 \\
&= \left| \frac{\hat{u}^1(0)}{g} \right|^2 + \sum_{k \in \tilde{\Gamma}'_0} \langle k \rangle^{2(s+1)} \left| \frac{|k| \tanh(h|k|) \hat{u}^1(k) + i c_0 k \hat{u}^2(k)}{\Delta_0(c_0, k)} \right|^2 \\
&\quad + \sum_{k \in \tilde{\Gamma}'_0} \langle k \rangle^{2(s+1)} \left| \frac{-i c_0 k \hat{u}^1(k) + g \hat{u}^2(k)}{\Delta_0(c_0, k)} \right|^2 \\
&\leq \left| \frac{\hat{u}^1(0)}{g} \right|^2 + 2 \sum_{k \in \tilde{\Gamma}'_0} \langle k \rangle^{2(s+1)} \frac{(|k| \tanh(h|k|))^2 \left| \hat{u}^1(k) \right|^2 + (c_0 k)^2 \left| \hat{u}^2(k) \right|^2}{\Delta_0(c_0, k)^2} \\
&\quad + 2 \sum_{k \in \tilde{\Gamma}'_0} \langle k \rangle^{2(s+1)} \frac{(c_0 k)^2 \left| \hat{u}^1(k) \right|^2 + g^2 \left| \hat{u}^2(k) \right|^2}{\Delta_0(c_0, k)^2} \\
&= \left| \frac{\hat{u}^1(0)}{g} \right|^2 + 2 \sum_{k \in \tilde{\Gamma}'_0} \langle k \rangle^{2s} \frac{\langle k \rangle^2 \left[(|k| \tanh(h|k|))^2 \left| \hat{u}^1(k) \right|^2 + (c_0 k)^2 \left| \hat{u}^2(k) \right|^2 \right]}{\Delta_0(c_0, k)^2} \\
&\quad + 2 \sum_{k \in \tilde{\Gamma}'_0} \langle k \rangle^{2s} \frac{\langle k \rangle^2 \left[(c_0 k)^2 \left| \hat{u}^1(k) \right|^2 + g^2 \left| \hat{u}^2(k) \right|^2 \right]}{\Delta_0(c_0, k)^2}.
\end{aligned}$$

Now, by using the fact that we can bound $\Delta_0(c_0, k)$ from below by $K_1 + K_2 \langle k \rangle^2$ we continue the estimate,

$$\begin{aligned}
&\left\| (P\partial_w F(0,c))^{-1} \begin{pmatrix} u^1 \\ u^2 \end{pmatrix} \right\|_{X_2}^2 \\
&\leq \left| \frac{\hat{u}^1(0)}{g} \right|^2 + C_1 \sum_{k \in \tilde{\Gamma}'_0} \langle k \rangle^{2s} \left| \hat{u}^1(k) \right|^2 + C_2 \sum_{k \in \tilde{\Gamma}'_0} \langle k \rangle^{2s} \left| \hat{u}^2(k) \right|^2 \\
&\leq C \left[\sum_{k \in \tilde{\Gamma}'} \langle k \rangle^{2s} \left| \hat{u}^1(k) \right|^2 + \sum_{k \in \tilde{\Gamma}'_0} \langle k \rangle^{2s} \left| \hat{u}^2(k) \right|^2 \right] \\
&= C \left\| \begin{pmatrix} u^1 \\ u^2 \end{pmatrix} \right\|_{Y_1}^2.
\end{aligned}$$

The case of $\sigma > 0$ in two dimensions is very similar, and proceeding in the same way as before we can produce an estimate of the form

$$\left\| (P\partial_{u_2} F(0,c))^{-1} \begin{pmatrix} u^1 \\ u^2 \end{pmatrix} \right\|_{X_2}^2$$

$$\leq \left| \frac{\hat{u}^1(0)}{g} \right|^2 + 2 \sum_{k \in \tilde{\Gamma}'_0} \langle k \rangle^{2s} \frac{\langle k \rangle^4 \left[(|k| \tanh(h|k|))^2 \left| \hat{u}^1(k) \right|^2 + (c_0 k)^2 \left| \hat{u}^2(k) \right|^2 \right]}{\Delta_\sigma(c_0, k)^2}$$

$$+ 2 \sum_{k \in \tilde{\Gamma}'_0} \langle k \rangle^{2s} \frac{\langle k \rangle^2 \left[(c_0 k)^2 \left| \hat{u}^1(k) \right|^2 + (g + \sigma |k|^2)^2 \left| \hat{u}^2(k) \right|^2 \right]}{\Delta_\sigma(c_0, k)^2}.$$

Now using the fact that we can produce constants K_3 and K_4 such that $|\Delta_\sigma| \geq K_3 + K_4 \langle k \rangle^3$ we again obtain the estimate desired. The proofs in the cases of higher dimensional null spaces and three dimensions ($\sigma > 0$) are almost the same as the previous except that one has to account for a possibly larger null space for the linearized operator $A(c)$. The sums are over $\tilde{\Gamma}'_0 = \Gamma' \backslash \{0, \pm k_j\}_{j=1}^N$, which serves to omit from them any of the wave numbers k_j such that $\Delta_\sigma(c, k_j) = 0$. Again, the constants K_3 and K_4 can be produced due to the fact that for $|k|$ large enough, $\Delta_\sigma(c, k) > 0$. □

With these estimates in hand it is easy to prove the following theorem.

THEOREM 3.2. *The equation $PF(v + w, c) = 0$ has a solution*

$$w = w(v, c) \tag{3.4}$$

for all (v, c) in a ball $B_\varepsilon(0, c_0)$ which is locally unique, such that

$$PF(v + w(v, c), c) = 0, \tag{3.5a}$$

$$w(0, c) = 0. \tag{3.5b}$$

Furthermore, w is analytic as a function of (v, c), $\|w(v, c)\|_X \leq C \|v\|_X^2$, and it is equivariant under the torus action $T_\alpha w(v, c) = w(T_\alpha v, c)$.

Proof. We use the implicit function theorem in conjunction with Theorem 3.1. □

4. The reduced variational problem. With the choice of $u = v + w(v, c)$ (2.14a) is solved, and we focus on solutions (v, c) which will also result in a solution of (2.14b). The approach that we use is close to that of J. Moser [17], with the novelty that the problem is equivariant with respect to the action of a torus $\mathbb{T}^2$. The variational problem that we solve is equivalent to finding critical points of the Hamiltonian function $H(u)$ of (2.8), when restricted to the subset of phase space $\{u \in X \ : \ I_1(u) = a_1, I_2(u) = a_2\}$. This is not feasible by direct variational methods. Instead, following [17], we pose a reduced variational problem in the finite dimensional space X_1, whose solutions will solve (2.14b). In preparation for this we make an astute choice of $c = c(v)$. The function $u = v + w(v, c)$ solves (2.14a); therefore

$$(\delta H - c \cdot \delta I)(v + w(v, c)) = q(v, c) \in Y_2 \ . \tag{4.1}$$

Let $\{\pm k_1, \ldots \pm k_N\} = K \subseteq \Gamma'$ be the collection of wave numbers for which $\Delta(c_0, k_p) = 0$, which are normalized so that $c_0 \cdot k_p > 0$. We also choose the norm $|v|$ so that it is invariant under the torus action $v \to T_\alpha v$.

LEMMA 4.1. *Suppose that the vector $a = (a_1, a_2)$ is not collinear with any $k_p \in K$, and that $|(a_1, a_2)| < \delta$ for sufficiently small δ. On the set $\{(v, c) \ : \ I_1(v + w(v, c)) = a_1, I_2(v + w(v, c)) = a_2\} \subseteq X_1 \times \mathbb{R}^2$ we can make a choice of $c = c(v)$ to satisfy*

$$\int_{T(\Gamma)} (q(v, c) \ , \ \delta_u I_j(v + w(v, c))) \ dx = 0 \ , \qquad j = 1, 2 \ . \tag{4.2}$$

Furthermore, $c(v)$ is invariant under the action T_α of the torus, $c(T_\alpha v) = c(v)$; $|c(v) - c_0| = O(|v|^2)$; and for $v \neq 0$ $c(v)$ is real analytic in v.

We will defer the proof of this for several pages, for the sake of continuity of the argument. Using both $c(v)$ and $w(v, c(v))$, define the functionals

$$I_j^Q(v) = I_j(v + w(v, c(v))) \ , \qquad j = 1, 2 \ , \tag{4.3}$$

and

$$H^Q(v) = H(v + w(v, c(v))) \ . \tag{4.4}$$

These functionals are invariant under the torus action $T_\alpha : X_1 \to X_1$. For $a = (a_1, a_2)$ not collinear with any of the set K, and for $|a| < \delta$ sufficiently small, consider the subset of the space X_1

$$S(a) = \{v \in X_1 \ : \ I_1^Q(v) = a_1 \ , \ I_2^Q(v) = a_2\} \ . \tag{4.5}$$

Clearly $S(a)$ is also invariant under T_α, and it is a smooth submanifold of X_1, to which Lemma 4.1 applies. Finally define the reduced action functional

$$A(v) = H^Q(v) - c(v) \cdot (I^Q(v) - a) \ . \tag{4.6}$$

THEOREM 4.2. *When $\delta_v I_1^Q$ and $\delta_v I_2^Q$ are linearily independent at all $v \in S(a)$, then $S(a)$ is a submanifold of X_1 of codimension 2. In this case, critical points of $A(v)$ on $S(a)$ correspond to solutions $u = v + w(v, c(v))$, $c(v)$ of the bifurcation equation $QF = 0$ of* (2.14b).

Proof. Choices of (v, c) such that $q(v, c) = 0$ correspond precisely to solutions of the desired equation (2.14b). The choice of $c(v)$ prescribed in Lemma 4.1 is so that q is orthogonal in X_1 to the subspace of normal vectors $N_v(S(a))$. Indeed with $q \in X_1$, and a basis of $N_v(S(a))$ given by $\{\delta_v I_1^Q, \delta_v I_2^Q\}$,

$$\begin{aligned} \int_{T(\Gamma)} (q, \delta_v I_j^Q) dx &= \int_{T(\Gamma)} (q, Q \delta_u I_j(v + w(v, c))) dx \\ &= \int_{T(\Gamma)} (q, \delta_u I_j) dx \\ &= 0 \ . \end{aligned}$$

Now suppose that v is a critical point on $S(a)$ of the functional $A(v)$. For any $\delta v \in T_v(S(a))$ the tangent space, we have the calculation

$$\begin{aligned} \partial_v A(v) \cdot \delta v = &\int_{T(\Gamma)} Q(\delta_u H(v + w) - c(v) \cdot \delta_u I(v + w)) \delta v \ dx \\ &+ \int_{T(\Gamma)} P(\delta_u H(v + w) - c(v) \cdot \delta_u I(v + w))(\partial_v w \cdot \delta v) \ dx \\ = &\ 0, \end{aligned}$$

where the term containing $\partial_v c(v)$ has dropped out as the expression is evaluated on $S(a)$. Furthermore $(\partial_v w \cdot \delta v) \in X_2$, and we have resolved the first bifurcation equation (2.14a), so that the second term is zero as well. Thus for $v \in S(a)$ and $\delta v \in T_v(S(a))$, $\partial_v A(v) \cdot \delta v = \int_{T(\Gamma)} (q, \delta v) dx$, and at critical points it vanishes. Since $c = c(v)$ is chosen so that $\int_{T(\Gamma)} (q, \delta v) dx = 0$ for all $\delta v \perp T_v(S(a))$ as well, indeed critical points

correspond to zeros of $q = q(v, c(v))$. Because $A(v)$ is invariant under the action T_α, so is the set of critical points on $S(a)$. □

At this point in the argument, any choices of a such that $S(a)$ is compact will yield at least one solution of the Euler equations (2.9) ($S(a)$ is a point when $m = 2$). We will, however, be able to use the topology of the quotient space $S(a)/\mathbb{T}^2$ to obtain a more precise and generally larger lower bound on the number of critical orbits of $A(v)$ on $S(a)$.

4.1. Application of a T^2 equivariant cohomological index. Parameterize $v \in X_1$ by $\mathbb{C}^N$ by setting $z = (r_1 e^{i\varphi_1}, \ldots, r_N e^{i\varphi_N})$, and

$$v = \sum_{p=1}^{N} r_p(\cos(\varphi_p) v^1_{k_p} + \sin(\varphi_p) v^2_{k_p}) \ . \tag{4.7}$$

The torus action T_α on X_1 is defined by

$$T_\alpha v = \sum_{p=1}^{N} r_p(\cos(\varphi_p + k_p \cdot \alpha) v^1_{k_p} + \sin(\varphi_p + k_p \cdot \alpha) v^2_{k_p}), \tag{4.8}$$

which in $\mathbb{C}^N$ is efficiently described as $T_\alpha z = (r_p e^{(i\varphi_p + k_p \cdot \alpha)})_{p=1}^N$. A calculation yields that

$$I^Q_j(v) = \frac{1}{2} \int_{T(\Gamma)} (v, J\partial_{x_j} v)\, dx = \sum_{p=1}^{N} k^j_p r^2_p (c_0 \cdot k_p (g + \sigma |k_p|^2)) |T(\Gamma)| \tag{4.9}$$

for $j = 1, 2$ where $J = \left(\begin{smallmatrix} 0 & 1 \\ -1 & 0 \end{smallmatrix}\right)$. Note that we have previously normalized wave numbers so that $c_0 \cdot k_p > 0$, $1 \le p \le N$. We will use the notation $c(p) = c_0 \cdot k_p (g + \sigma |k_p|^2) |T(\Gamma)|$.

Let us start the discussion with the nonresonant case $N = 2$, with $k_1, k_2 \in \Gamma'$ not collinear. Choose a 2×2 change of basis M so that $Mk_1 = (1, 0)^T$ and $Mk_2 = (0, 1)^T$. This gives an equivalent definition of $S(a) = \{v \in X_1 \ : \ MI = Ma = b\}$ and modifies the torus action to a product action $T_\beta z = (z_1 e^{i\beta_1}, z_2 e^{i\beta_2})$, where $M^T \beta = \alpha$. Clearly $S(a)$ is the two dimensional torus

$$S(a) = \{v \ : \ r^2_1 c'(1) = b_1 \ , \ r^2_2 c'(1) = b_2\} \tag{4.10}$$

for positive constants $c'(p) = \sum_q M_{pq} c(q)$, and the orbit under T_β of any point of $S(a)$ consists of the whole set. Therefore the Hamiltonian H is constant on the set, and we have proved the following result.

THEOREM 4.3. *In case $N = 2$ and k_1, k_2 not collinear, whenever a is not collinear with either k_1 or k_2, and $|a| < \delta$, each submanifold $S(a) \in X_1$ corresponds to a solution of* (2.9) *and its translates by T_α. Furthermore the family of solutions $u = v + w(v, c(v)) \in X$, $v \neq 0$, is locally real analytic, forming a four dimensional bifurcation manifold which is invariant under the action of T_α.*

The theorem is the analogue of the original Lyapunov center theorem, in which there are no allowances for resonances. The statement of analyticity is an immediate consequence of the regularity results of Theorem 3.2 and Lemma 4.1, stemming ultimately from the implicit function theorem. In the particular case that $k_1 = (k^1_1, k^2_1)$, and $k_2 = (k^1_1, -k^2_1)$, with $k^1_1 \neq k^2_1$, the curve $\{a_1 = a_2\} \in S(a)$ consists of the symmetric diamond solutions of the three dimensional water wave problem in J. Reeder and M. Shinbrot [23].

Now turn to the resonant case $N \geq 2$. We will consider two possibilities separately, either (i) $N > 2$, for which necessarily there are two noncollinear wave vectors among $\{k_p\}_{p=1}^N$, or else (ii) $N = 2$ and k_1 and k_2 are linearly dependent. The latter case corresponds to the two dimensional resonant problem, with resonant interaction between periodic gravity waves and capillary waves with the same phase velocity; this was previously discussed in M. Jones and J. Toland's work [13], [14]. In case (ii) we will give an independent proof of the existence of at least two distinct periodic solutions; the proof will be put off until the end of the present section.

In case (i) of the preceding paragraph, in which $N > 2$, the wave vectors $\{k_p\}_{p=1}^N$ involved in the kernel X_1 lie within the cone $\{c_0 \cdot k > 0\}$. Choose k_1 to be the leftmost of this collection, k_N to be the rightmost. In case either or both of these are collinear with another from the collection (from our discussion of the dispersion relation in section 2.3, at most two wave vectors can be collinear), take k_1 and/or k_N to be the smaller, and k_2 and/or k_{N-1} to be the bigger. As in the nonresonant case we may make a change of basis M so that $k_1 = (1,0)^T$ and $k_N = (0,1)^T$; without changing notation assume that this is so. Then all other wave vectors are expressed as $k_p = k_p^1 k_1 + k_p^2 k_N$ for rationals $k_p^\ell > 0$, except that in case of collinearity it may be that $k_2 = (k_2^1, 0)^T$ and/or $k_{N-1} = (0, k_{N-1}^2)^T$. All of the other coefficients are positive from this exercise, as k_p lie in the positive cone of the new basis $\{k_1, k_N\}$. We also order the remaining wave vectors $k_p = (k_p^1, k_p^2)^T$ in terms of increasing slope; $k_p^2/k_p^1 \leq k_{p+1}^2/k_{p+1}^1$. It again follows from section 2.3 that at most two wave vectors can have a common slope.

THEOREM 4.4. *Suppose that for all $1 \leq p \leq N$, $k_p^2/k_p^1 \neq a_2/a_1$, and that $|a| < \varepsilon^2$ for sufficiently small ε. Then the set $S(a) = \{v \in X_1 \ : \ I_1 = a_1, \ I_2 = a_2\}$ is a compact submanifold of X_1.*

Proof. From the form (4.9) of the action integrals I_j^Q, it is clear that the gradients $\delta_v I_1^Q$ and $\delta_v I_2^Q$ are independent except when (a_1, a_2) is taken so that two semiaxes of the cylindrical ellipsoids $\{I_1^Q = a_1\}$ and $\{I_2^Q = a_2\}$ coincide, and we can invoke Theorem 4.2. There is in fact more structure than this. When $a_2/a_1 = k_p^2/k_p^1$, and k_p is the sole wave vector with this slope, the intersection must be at $\{z_j = 0, \ j \neq p\} \cap S(a)$, which is a circle (invariant under the action of T_α). In case of multiplicity two, this is at $\{z_j = 0, \ j \neq p, p+1\} \cap S(a)$, which is a T_α invariant ellipsoid homeomorphic to S^3. □

With no further work one can see that for $N > 2$ and for choices of a avoiding the singular cases $\{k_p^2/k_p^1 \ : \ p = 1, \ldots, N\}$ there are at least two distinct solutions of (2.9), corresponding to the maximum and minimum of the reduced Hamiltonian H^Q on $S(a)$. In all cases in which both $a_1, a_2 > 0$ these are truly three dimensional solutions, as they have a nonzero component of $v_p \in X_1$ for at least two linearly independent wave vectors k_p. Indeed, if k_p is the only wave number having slope k_p^2/k_p^1, and if $a_2/a_1 \neq k_p^2/k_p^1$, then $\{z_j = 0 \ : j \neq p\} \cap S(a)$ is empty. In case k_p is collinear with k_{p+1}, but still $a_2/a_1 \neq k_p^2/k_p^1$, then as well $\{z_j = 0 \ : j \neq p, p+1\} \cap S(a) = \emptyset$, since if $z = (0, \ldots z_p, z_{p+1}, \ldots, 0) \in S(a)$, then

$$|z_p|^2 + \frac{k_{p+1}^1}{k_p^1}|z_{p+1}|^2 = \frac{a_1}{k_p^1} = |z_p|^2 + \frac{k_{p+1}^2}{k_p^2}|z_{p+1}|^2 = \frac{a_2}{k_p^2} \ , \tag{4.11}$$

giving the contradiction $a_2/a_1 = k_p^2/k_p^1$. This argument shows that solutions of (2.9) associated with $v \in S(a)$ are genuinely three dimensional in character.

THEOREM 4.5. *Given $v \in S(a)$ with $a_2/a_1 \notin \{k_p^2/k_p^1 \ : \ p = 1, \ldots, N\}$, then v contains nonzero Fourier modes for at least two wave vectors which are not collinear.*

There is further topology of the orbit space $S(a)/T^2$ which will, in cases of resonance $N > 2$, guarantee, in general, that there are more solutions. This will be shown by an argument involving a cohomological index equivariant with respect to the group action of a torus, similar to the topological category argument of J. Moser [17] with the action of a circle. In what follows, $\mathrm{ind}_{T_\alpha}(S)$ will be a T_α equivariant cohomological index of the set S. The following theorem gives a lower bound for distinct critical orbits of a T_α invariant function H^Q on $S(a)$ in this situation, in terms of the index. It furthermore provides an estimate of the index, which is sharp.

THEOREM 4.6. *Let $N > 2$ and choose a as in* Theorem 4.4 *so that $S(a)$ is a compact manifold. Then there exist at least* $\mathrm{ind}_{T_\alpha}(S(a)) + 1$ *distinct critical orbits of H^Q on $S(a)$, corresponding to distinct solutions of* (2.9). *We can furthermore make a choice of the index so that* $\mathrm{ind}_{T_\alpha}(S(a)) = N - 2$.

A standard argument implies that the number of critical points of invariant functionals H on the set $S(a)$ is bounded below by $\mathrm{ind}_{T_\alpha}(S(a)) + 1$. The crux of the proof is to show that, while the topology of $S(a)$ and $S(a)/T^2$ varies depending upon a, in all nonsingular cases one can define an index so that $\mathrm{ind}_{T_\alpha}(S(a)) = N - 2$.

We claim that for all a such that $a_2/a_1 \notin \{k_p^2/k_p^1 \ : \ p = 1, \ldots, N\}$, then $S(a) \simeq S^{2d-1} \times S^{2(N-d)-1}$. Indeed, define

$$J_1 = \frac{1}{a_1} I_1 + \frac{1}{a_2} I_2 = \sum_{p=1}^{N} c(p) \left(\frac{k_p^1}{a_1} + \frac{k_p^2}{a_2} \right) r_p^2$$

and

$$J_2 = \frac{1}{a_1} I_1 - \frac{1}{a_2} I_2 = \sum_{p=1}^{N} c(p) \left(\frac{k_p^1}{a_1} - \frac{k_p^2}{a_2} \right) r_p^2;$$

an equivalent description of $S(a)$ is that

$$S(a) = \{ v \in X_1 \ : \ J_1 = 2, \ J_2 = 0 \} \ . \tag{4.12}$$

Suppose that $k_d^2/k_d^1 < a_2/a_1 < k_{d+1}^2/k_{d+1}^1$, then for $1 \leq p \leq d$ the coefficients $(k_p^1/a_1 - k_p^2/a_2)$ of J_2 are positive, and they are negative for $d+1 \leq p \leq N$. We may write $P = \sum_{p=1}^{d} c(p)(\frac{k_p^1}{a_1} - \frac{k_p^2}{a_2}) r_p^2$, $N = -\sum_{p=d+1}^{N} c(p)(\frac{k_p^1}{a_1} - \frac{k_p^2}{a_2}) r_p^2$; then $J_2(v) = P - N$ and the set $S(a)$ is homeomorphic through radial projections to the manifold

$$\begin{aligned} \tilde{S}(a) &= \{ z \in \mathbb{C}^N \ : \ (P+N)(z) = 2 \ , \ \ (P-N)(z) = 0 \} \\ &= \{ z \in \mathbb{C}^N \ : \ P(z) = 1 \ \text{ and } \ N(z) = 1 \} \ . \end{aligned}$$

This expression makes it is clear that $\tilde{S}(a) \simeq S^{2d-1} \times S^{2(N-d)-1}$, a product of odd dimensional spheres.

We are interested in functions on $S(a)$ which are invariant under the action of T_α; therefore, it is essentially the index of the orbit space $S(a)/T^2 \simeq S^{2d-1} \times S^{2(N-d)-1}/T^2$ which is relevant. As a first example, we will suppose that T_α is a product T^2 action on the manifold $S^{2d-1} \times S^{2(N-d)-1}$, and that it is free (although in the capillary gravity wave problem this is almost never the case);

$$T_\alpha(z_1, \ldots, z_N) = (z_p e^{i\alpha_1 k^1})_{p=1}^{d} (z_p e^{i\alpha_2 k^2})_{p=d+1}^{N} \ . \tag{4.13}$$

Therefore $S(a)$ is a manifold which factors into two odd dimensional spheres, each with a circle action which is equivalent to the Hopf fibration. That is, the orbit space

is $S(a)/T^2 \simeq \mathbb{C}P(d-1) \times \mathbb{C}P(N-d-1)$. In this case we will take the equivariant cohomological index $\operatorname{ind}_{T_\alpha}(S(a))$ to coincide with the Čech cohomology cuplength of the quotient manifold; $\operatorname{cuplength}(S(a)/T^2)$. The following proposition consists of standard facts about the notion of index, Liusternik–Schnirlman category, and cuplength.

PROPOSITION 4.7. *The number of critical points of a C^2 function H on M is bounded below by* $\operatorname{Cat}(M)$. *Furthermore,*

(i) $\operatorname{Cat}(M) \geq \operatorname{cuplength}(M) + 1 \geq \operatorname{ind}_{T_\alpha}(M) + 1$;

(ii) $\operatorname{cuplength}(M_1 \times M_2) = \operatorname{cuplength}(M_1) + \operatorname{cuplength}(M_2)$;

(iii) *when* $M \simeq \mathbb{C}P(q)$, *then* $\operatorname{Cat}(M) = \operatorname{cuplength}(M) + 1 = q + 1$.

We deduce from (ii) *and* (iii) *that*

(iv) $\operatorname{Cat}(\mathbb{C}P(d-1) \times \mathbb{C}P(N-d-1)) \geq N - 1$.

The remaining task is to produce the same lower bound in the general case, in which the torus action T_α on $S(a)$ is not free, and when the action of T_α is as a twisted product. We note that, while T_α is not a free action, at least the stabilizers $s(z) = \{\alpha \in T^2 \ : \ T_\alpha z = z\}$ are always finite. The following argument is an adaptation of the classical one of A. Borel, which we learned from T. Goodwillie and D. Sinha.

The first step in the construction of a T_α equivariant cohomology for $S(a)$ is to identify a universal total space $E = S^\infty \times S^\infty$ and the classifying space $E/T^2 = B_{T^2} \sim \mathbb{C}P^\infty \times \mathbb{C}P^\infty$; see, for example, E. Fadell and P. Rabinowitz [9] or Rabinowitz [22]. The action of T_α on $E \times S(a)$ is free, and because E is contractible and the only isotropy subgroups which appear are finite, the space $S(a)/T^2$ and the homotopy orbit space $(E \times S(a))/T^2$ have the same rational cohomology.

The cohomology of the classifying space B_{T^2} is generated by two elements $y_1 = y \otimes 1$ and $y_2 = 1 \otimes y$, where y is the generator of the cohomology of $\mathbb{C}P^\infty$. Because of the presence of more than one generator, the construction of [9] will not work directly. We note, however, that in the same vein a well-defined index based on cuplength can be defined for any graded subalgebra of $H^*(B;\mathbb{Q})$. Let Y be a finitely generated graded subalgebra of $H^*(B;\mathbb{Q})$ with a basis $\{y_1, \ldots, y_q\}$, and let $F \ : \ (E \times S(a))/T^2 \to B_{T^2}$ be a classifying map. We define an equivariant cohomological index to be

$$\operatorname{ind}_Y((E \times S(a))/T^2) = \max\{|k| \ : \ k \in \mathbb{N}^q, F^*(y^k) \neq 0\} \ .$$

This index coincides with that of E. Fadell and P. Rabinowitz [9] when Y is generated by one element, and with the usual cuplength when $Y = H^*(B;\mathbb{Q})$. In our situation we will take Y to be generated by $\{y_1, y_2\}$, which is the latter case.

The rational cohomology of the homotopy orbit space $(E \times S(a))/T^2$ is obtained using the Leray–Serre spectral sequences. This calculation can be paraphrased in terms of Poincaré series. The E_2 page of the spectral sequence is $E_2^{p,q} = H^p(B_{T^2}) \otimes H^q(S(a))$, whose associated Poincaré series is

$$P_B(t) = (1 - t^2)^{-2} \ .$$

One nontrivial differential occurs at the E_{2p} page, and another at the $E_{2(N-p)}$ page (or in the inverse order, if $N/2 < p$), resulting in the Poincaré polynomial for the quotient

$$\begin{aligned} P_{(E\times S(a))/T^2}(t) &= \frac{(1-t^{2p})(1-t^{2(N-p)})}{(1-t^2)^2} \\ &= (1 + t^2 + \cdots + t^{2(p-1)})(1 + t^2 + \cdots + t^{2(N-p-1)}) \ . \end{aligned}$$

The coefficients of $P_{(E\times S(a))/T^2}(t)$ give the Betti numbers β_j of $S(a)/T^2$, as its rational cohomology coincides with that of the homotopy orbit space. From this expression, $\beta_{2(N-2)} = 1$; hence $H^{2(N-2)}((E \times S(a))/T^2; \mathbb{Q})$ is one dimensional, and there is some nonzero element in the coset of $\{y_1^\gamma y_2^{N-2-\gamma}\}_{\gamma=0}^{N-2}$. All higher cohomology classes vanish. We deduce that there are classes $x_1, x_2 \in H^2$ for which the cup product $x_1^\gamma x_2^{N-2-\gamma}$ is nonzero, so that $\operatorname{ind}_{T_\alpha}((E \times S(a))/T^2) = N - 2$. Applying Proposition 4.7, we conclude the result of Theorem 4.6.

We note for further interest that for Morse functions H on $S(a)/T^2$, the Morse inequalities state that the number of critical points is at least $P_{(E\times S(a))/T^2}(1) = \sum_{j=1}^{2(N-2)} \beta_j = p(N-p)$. This estimate exceeds $N-1$, strictly so if $p \neq 1, N-1$. The equivariant cohomology of products of spheres under torus actions is relevant in other problems, in particular in the problem of resonant tori in dynamical systems; it is discussed further in W. Craig and D. Haskell [6].

4.2. Two dimensional capillary gravity waves. The point of this short subsection is to provide an alternate proof of the existence of gravity waves in two dimensions [15], [27], and capillary gravity waves in two dimensions, both in the regular case [31], [2], [1] and in the presence of resonance [13], [14]. This can be done in the present framework, considering the circle $T(\Gamma) = \mathbb{R}/\Gamma$ and setting our basic function space to be $X = H^s(T(\Gamma))$. The null space of the linearized operator A is denoted by X_1; in the nonresonant case it is two dimensional, and in the case of resonance it is four dimensional. By Theorem 3.2 we obtain a solution to (2.14a) in a ball $B_\mathcal{E}(0, c_0)$ which is analytic in both variables (v, c). The relevant functionals for the variational problem are

$$I_1 = \int_{S^1} \eta \partial_{x_1} \xi \, dx \ , \tag{4.14}$$

and H gives as in (2.8) by a one dimensional integral. In the two dimensional problem the group action is a circle action on $S(a)$ which leaves the functions H, I invariant. Furthermore, the one dimensional version of Lemma 4.1 holds [16, Lemma 2, p. 739], giving an analytic function $c = c(v)$ such that $q = F(v + w(v, c(v)), c(v))$ is in the tangent space of $S(a) = \{v \in X_1 \ : \ I^Q(v) = a\}$. The object is to solve (2.14b) using the reduced variational problem.

In the nonresonant case, $N = 1$ and each subset $S(a) \in X_1, a > 0$, is a one dimensional submanifold consisting entirely of solutions of (2.9), related to each other by translation by T_α; this is the analog of Theorem 4.3. The solutions are in fact analytic in v, as in the classical Lyapunov center theorem.

We now consider the resonant case. Let us suppose that the null space of $A(c_0)$ is generated by Fourier modes $k_1, k_2 = Rk_1 \in \Gamma' \simeq \mathbb{Z}$. For small Bond number, we have in fact $k_1 \ll k_2$. The subset of X_1 with fixed momentum is

$$S(a) = \{v \in X_1 \ : \ I_1 = c(1)|z_1|^2 + c(2)|z_2|^2 = a\} \ . \tag{4.15}$$

The circle action on $S(a)$ is given by $T_\alpha z = (z_1 e^{i\alpha}, z_2 e^{iR\alpha})$, and incidentally the quotient $S(a)/T_\alpha$ is never a manifold. Nonetheless, the submanifold $S(a) \simeq S^3$ is compact, and therefore the function H is either constant, or else has at least two distinct critical values, namely, its maximum and its minimum. This gives rise to at least two distinct critical circles of H on $S(a)$, invariant under T_α.

THEOREM 4.8. *The two dimensional gravity wave problem and the two dimensional capillary gravity wave problem have analytic families of periodic solutions bifurcating from each c_k, $k \in \Gamma'$, for which the null space X_1 is two dimensional. In*

case of resonance in the capillary gravity wave problem, X_1 is four dimensional and there are at least two distinct solutions on every level surface $S(a)$ of the momentum I_1, for sufficiently small $a > 0$.

We remark that we would not obtain a better lower estimate for the number of critical orbits of H on $S(a)$ from an index theory argument, or even from a more refined argument by Morse theory, if indeed we were to show that H was a Morse function on $S(a)/T^2$.

4.3. Proof of Lemma 4.1. To finish this section we give a proof of Lemma 4.1, which is based on the implicit function theorem. From Theorem 3.2 we have the estimate $\|w(v,c)\|_X \leq C\,\|v\|_X^2$, and we also find

$$\begin{aligned}\|q\|_Y &= \|\delta_u H(v+w) - c\cdot\delta_u I(v+w)\|_Y \\ &\leq \big\|Q(\delta_u^2 H(0)(v+w) - c_0\cdot\delta_u I(v+w))\big\|_Y \\ &\quad + \|Q(\delta_u H_3(v+w) - (c-c_0)\cdot\delta_u I(v+w))\|_Y \\ &= \|Q(\delta_u H_3(v+w) - (c-c_0)\cdot\delta_u I(v))\|_Y \ .\end{aligned}$$

The notation is that $I = (I_1, I_2)$, that $\delta_u H(u) = \delta_u^2 H(0)u + \delta_u H_3(u)$ describes the Taylor series expansion with remainder, and we have used that Q projects orthogonally in X onto an invariant subspace of J (a symplectic subspace) so that $Q\delta_u I(u) = \delta_u I(Qu)$. Letting $v = \sum_{p=1}^N r_p[\cos(\varphi_p)v_{k_p}^1 + \sin(\varphi_p)v_{k_p}^2]$ as in (4.7), we compute the quantities

$$\begin{aligned}\delta_u I_\ell(v) &= \sum_{p=1}^N r_p(\cos(\varphi_p)J\partial_{x_\ell}v_{k_p}^1 + \sin(\varphi_p)J\partial_{x_\ell}v_{k_p}^2) \\ &= \sum_{p=1}^N r_p\cos(\varphi_p)J\partial_{x_\ell}\begin{pmatrix} c_0\cdot k_p\cos(k_p\cdot x) \\ (g+\sigma|k_p|^2)\sin(k_p\cdot x)\end{pmatrix} \\ &\quad + r_p\sin(\varphi_p)J\partial_{x_\ell}\begin{pmatrix} -c_0\cdot k_p\sin(k_p\cdot x) \\ (g+\sigma|k_p|^2)\cos(k_p\cdot x)\end{pmatrix}\end{aligned}$$

and

$$(4.16)\quad \int_{T(\Gamma)}(\delta_u I_\ell(v), \delta_u I_j(v))\ dx = \sum_{p=1}^N r_p^2(k_p^j k_p^\ell)|T(\Gamma)|((c_0\cdot k_p)^2 + (g+\sigma|k_p|^2)^2)\ .$$

Let us suppose that $a = (a_1, a_2)$ is not collinear with any wave vector in the set K, and that (v,c) satisfies $I(v + w(v,c)) = a$. Define the quantity

$$\begin{aligned}m(v,c) &= \frac{1}{|v|^2}\int_{T(\Gamma)}(q(v,c)\ ,\ \delta_u I_j(v+w(v,c)))\ dx \\ &= \frac{1}{|v|^2}\left(\int_{T(\Gamma)} -\sum_{\ell=1}^2 (c-c_0)_\ell(\delta_u I_\ell(v), \delta_u I_j(v))dx + O(|v|^3)\right)\ ,\end{aligned}$$

which maps $X_1\times\mathbb{R}^2$ to $\mathbb{R}^2$, and whose vanishing implies (4.2). To analyze the set $m(v,c) = 0$, evaluate m on a line $\{v = \rho e : \rho\in\mathbb{R}, |e|_{X_1} = 1\}$ through the origin, setting $m_e(\rho, c) = m(\rho e, c)$. Clearly $m_e(0, c_0) = 0$, and taking the derivative with

respect to c,

$$\partial_{c_\ell} m_{e,j}(\rho, c) = -\frac{1}{|v|^2} \int_{T(\Gamma)} (\delta_u I_\ell(v), \delta_u I_j(v)) dx|_{v=\rho e} + O(|\rho|)$$
$$= -\int_{T(\Gamma)} (\delta_u I_\ell(e), \delta_u I_j(e)) dx + O(|\rho|) \ .$$

If this Jacobian is invertible, the implicit function theorem implies the existence of a solution $c(\rho)$ of $m_e(\rho, c) = 0$ in a sufficiently small neighborhood of the origin. From (4.16) we see that $\partial_{c_\ell} m_{ej}(0, c)$ is a sum with nonnegative coefficients of symmetric rank one matrices $k_p k_p^T$. As long as two linearly independent k_p of the sum have their respective coefficients nonzero, it is invertible, and the statement of the lemma holds for sufficiently small ε. Let us suppose then that $\partial_c m_e(0, c)$ is not invertible, for purposes of contradiction. Then both

$$\partial_{c_j} m_{e,\ell}(0, c_0) = -\sum_s C_{p_s}^{(1)} k_{p_s}^j k_{p_s}^\ell \ ,$$
$$I_j(e) = \sum_s C_{p_s}^{(2)} k_{p_s}^j,$$

where all k_{p_s} are collinear, and where the coefficients are $C_{p_s}^{(1)} = ((c_0 \cdot k_p)^2 + (g + \sigma|k_p|^2)^2)|T(\Gamma)|$, $C_{p_s}^{(2)} = ((c_0 \cdot k_p)(g + \sigma|k_p|^2))|T(\Gamma)|$. However, for $v = \rho e$, we have $(a_1, a_2) = (I_1(v + w(v, c)), I_2(v + w(v, c))) = \rho^2 (I_1(e), I_2(e)) + O(|\rho|^4)$ and this in turn is $\rho^2 \sum_s C_{p_s}^{(2)} (k_{p_s}^1, k_{p_s}^2) + O(|\rho|^4)$. For sufficiently small ρ this is incompatible with the hypothesis of noncollinearity of the lemma, and hence $\partial_c m_e(0, c_0)$ must be invertible.

Once a solution $c(v)$ of $m(v, c) = 0$ is established for $v \neq 0$, another argument using the statement of the implicit function theorem implies that $c(v)$ is locally real analytic away from the origin. Indeed, for $\rho \neq 0$ and for $e \in S_1 = \{v \in X_i : |v| = 1\}$ such that $(I_1(e), I_2(e)) \not\sim k_p$, the implicit function theorem implies that the solution $c(v) = C(\rho e)$ is real analytic in the parameter e. This concludes the proof of the lemma.

5. Analyticity of the Dirichlet–Neumann operator. The one remaining detail in our proof is the analyticity of the Dirichlet–Neumann operator. This was first established in the two dimensional setting by R. Coifman and Y. Meyer [4], and in the three dimensional setting by W. Craig, U. Schanz, and C. Sulem [7]. The result in general n dimensions was proven by D. Nicholls [19], as a generalization of the method of W. Craig, U. Schanz, and C. Sulem. All of these authors proved the following result in differing numbers of dimensions.

THEOREM 5.1. *Consider functions η such that $|\eta|_{L^\infty} < hR_0$, $|\eta|_{C^1} < R_0$, and $|\eta|_{C^{s+1}} < \infty$. There exists $R_0 > 0$ such that the Dirichlet–Neumann operator $G(\eta)$ is analytic in η in the neighborhood,*

$$\{\eta \mid \ |\eta|_{C^1} < R_0, |\eta|_{C^{s+1}} < \infty\}, \tag{5.1}$$

as a linear map in ξ from $W^{s+1,q} \to W^{s,q}$.

In this theorem C^s is the space of s times continuously differentiable functions, and $W^{s,q}$ is the L^q based Sobolev space of s times differentiable functions. In his thesis D. Nicholls [19] modified this theorem in two dimensions by only requiring $\eta \in W^{s+1,q}$, which is used to prove the result of this paper in two dimensions with

$\sigma = 0$. The approach of W. Craig, U. Schanz, and C. Sulem [7] was to perform estimates on the Dirichlet–Neumann operator by always placing C^s norms on η terms and $W^{s,q}$ norms on ξ terms. This produces a very clean result, which is not, however, useful for the applications in the present paper. In this section we replace the C^{s+1} derivative with a $W^{s+1,q}$ at the cost of a C^2 derivative on ξ. In this section we generalize this procedure to higher dimensions for use in the three dimensional result.

5.1. An exact implicit formula. The method of W. Craig, U. Schanz, and C. Sulem [7] begins with an exact implicit formula for the Dirichlet–Neumann operator. The formula is in terms of smoothing and singular integral operators which one can analyze using the theorem of M. Christ and J. Journé [3]. In this section we consider n dimensional real space $\mathbb{R}^n$ and will use the notation $x = (x', x_n) \in \mathbb{R}^{n-1} \times \mathbb{R}$ for a point in $\mathbb{R}^n$ rather than the (x, y) notation of previous sections.

THEOREM 5.2. *An exact implicit formula for the Dirichlet–Neumann operator in $n \geq 2$ dimensions is*

$$(I - B(\eta))\ G(\eta)\ \xi = |D_{x'}| \tanh(h\,|D_{x'}|)\ \xi + A(\eta)\ \xi, \tag{5.2}$$

where

$$A(\eta)\ \zeta = -\left(1 + e^{-2h|D_{x'}|}\right)^{-1} |D_{x'}|\, M(\eta)\ \zeta\ ,$$
$$B(\eta)\ \zeta = -\left(1 + e^{-2h|D_{x'}|}\right)^{-1} |D_{x'}|\, L(\eta)\ \zeta\ ,$$

and

$$M(\eta)\ \zeta = \int m_n(x', y')\zeta(y')\ dy'\ ,$$
$$L(\eta)\ \zeta = \int l_n(x', y')\zeta(y')\ dy'\ .$$

In two dimensions

$$\begin{aligned} m_2(x', y') = \frac{1}{\pi} \Bigg[& \frac{1}{(x' - y')^2} \left\{ \frac{(x' - y')\partial_{y'}\eta(y') - (\eta(x') - \eta(y'))}{1 + q_1^2} \right\} \\ & + \frac{1}{(x' - y')^2 + 4h^2} \left\{ \frac{(x' - y')\partial_{y'}\eta(y') + (\eta(x') + \eta(y'))}{1 + \frac{4h}{\sqrt{(x'-y')^2+4h^2}} q_2 + q_2^2} \right\} \\ & + \frac{2h}{(x' - y')^2 + 4h^2} \left\{ \frac{1}{1 + \frac{4h}{\sqrt{(x'-y')^2+4h^2}} q_2 + q_2^2} - 1 \right\} \Bigg] \end{aligned}$$

and

$$l_2(x', y') = -\frac{1}{2\pi} \left[\log(1 + q_1^2) + \log\left(1 + \frac{4h}{\sqrt{(x' - y')^2 + 4h^2}} q_2 + q_2^2 \right) \right].$$

In these formulae we set

$$q_1(x', y') = \frac{\eta(x') - \eta(y')}{|x' - y'|},$$
$$q_2(x', y') = \frac{\eta(x') + \eta(y')}{\sqrt{|x' - y'|^2 + 4h^2}}\ .$$

In $n \geq 3$ dimensions,

$$m_n(x',y') = \frac{2}{\omega_n}\left[\frac{1}{|x'-y'|^n}\left\{\frac{(x'-y')\cdot\nabla_{y'}\eta(y') - (\eta(x')-\eta(y'))}{(1+q_1^2)^{n/2}}\right\}\right.$$
$$+\frac{1}{\left(|x'-y'|^2+4h^2\right)^{\frac{n}{2}}}\left\{\frac{(x'-y')\cdot\nabla_{y'}\eta(y') + (\eta(x')+\eta(y'))}{\left(1+\frac{4h}{\sqrt{|x'-y'|^2+4h^2}}q_2+q_2^2\right)^{n/2}}\right\}$$
$$\left.+\frac{2h}{\left(|x'-y'|^2+4h^2\right)^{\frac{n}{2}}}\left\{\frac{1}{\left(1+\frac{4h}{\sqrt{|x'-y'|^2+4h^2}}q_2+q_2^2\right)^{n/2}}-1\right\}\right],$$

and

$$l_n(x',y') = \frac{2}{(n-2)\omega_n}\left[\frac{1}{|x'-y'|^{n-2}}\left\{\frac{1}{(1+q_1^2)^{(n-2)/2}}-1\right\}\right.$$
$$\left.+\frac{1}{\left(|x'-y'|^2+4h^2\right)^{(n-2)/2}}\left\{\frac{1}{\left(1+\frac{4h}{\sqrt{|x'-y'|^2+4h^2}}q_2+q_2^2\right)^{(n-2)/2}}-1\right\}\right],$$

where $\omega_n = 2\sqrt{\pi}^n/\Gamma(\frac{n}{2})$.

Proof. The proof of this result can be found in the paper of W. Craig, U. Schanz, and C. Sulem [7] for the case of three dimensions, or in the thesis of D. Nicholls [19] for the general case. The essence of the proof is that one can express solutions of Laplace's equation at a point in terms of the function itself and the fundamental solution. From here one takes appropriate derivatives, evaluates at the free surface, identifies the Dirichlet–Neumann operator, and then recognizes the linear terms as convolutions and writes them as $|D_{x'}|\tanh(h\,|D_{x'}|)$. In case that the depth h is infinite, the above Fourier multiplier is replaced by $|D_{x'}|$, the expression q_2 vanishes, and the subsequent analysis is similar but simpler. We will carry out the analysis for the case h finite in the remainder of this section. ∎

5.2. Proof of analyticity. The principal ingredients are the formulae of section 5.1 for the Dirichlet–Neumann operator and the theorems on singular and smoothing integral operators of section 5.3. The method we use is similar to the one employed by W. Craig, U. Schanz, and C. Sulem [7] and D. Nicholls [19]. We modify the approach by considering function spaces which are relevant to our current purpose. In particular, we will require only that $\eta \in W^{s+1,q}$ rather than C^{s+1} in the two dimensional setting, and $\eta \in W^{s+2,q}$ rather than C^{s+1} in the three dimensional setting, representing an improvement in the smoothness required of η—however, at the cost of the information and elegance of the proof of W. Craig, U. Schanz, and C. Sulem [7], in particular information involving $|\eta|_{C^1}$.

By investigating the analyticity properties of the operators $A(\eta)$ and $B(\eta)$, along with the analyticity of the operator $(I - B(\eta))$, we will show that the Dirichlet–Neumann operator itself is analytic. We begin by considering the operator $B(\eta)$.

THEOREM 5.3. *In the setting of the two dimensional water wave problem ($n = 2$), if $1 < q < \infty$ and $s > \max(\frac{1}{q}, 2)$, then $B(\eta)$ satisfies the estimate*

$$\|B(\eta)\ \xi\|_{W^{s,q}} < C\,\|\eta\|^2_{W^{s+1,q}}\,\|\xi\|_{W^{s,q}}\,. \tag{5.3}$$

Furthermore, the operator $B(\eta)$ is analytic as a function of η on the space $W^{s,q}$. In the setting of the three dimensional water wave problem ($n = 3$), if $1 < q < \infty$ and $s > \max(\frac{2}{q}, 3)$, then $B(\eta)$ satisfies the estimate

$$\|B(\eta)\ \xi\|_{W^{s,q}} < C\,\|\eta\|^2_{W^{s+2,q}}\,\|\xi\|_{W^{s,q}}\,. \tag{5.4}$$

Furthermore, the operator $B(\eta)$ is analytic as a function of η on the space $W^{s,q}$.

The proof of this theorem depends upon the following two lemmas which are proven in W. Craig, U. Schanz, and C. Sulem [7] and D. Nicholls [19].

LEMMA 5.4. *The operator $\left(1 + e^{-2h|D_{x'}|}\right)^{-1}$ and the Riesz potential $R_j(D_{x'}) = i\frac{D_{x'_j}}{|D_{x'}|}$ are bounded on $W^{s,q}$ for $1 < q < \infty$ and $s \geq 0$.*

LEMMA 5.5. *Given functions $f \in C^s$ and $g \in W^{s,q}$ the following interpolation identity holds for some constant $K(s)$:*

$$\|fg\|_{W^{s,q}} \leq K(s)\left[|f|_{L^\infty}\,\|g\|_{W^{s,q}} + |f|_{C^s}\,\|g\|_{L^q}\right]. \tag{5.5}$$

We may now proceed with the proof of Theorem 5.3. Since

$$|D_{x'}| = -\sum_{j=1}^{n-1} R_j(D_{x'})\partial_{x'_j},$$

and we have Lemma 5.4, we need only consider two types of integral operators, $\partial_{x'_j}$ applied to

$$P_2 = \int -\frac{1}{2\pi}\log(1 + q_1^2)\ \xi(y')\ dy',$$
$$Q_2 = \int -\frac{1}{2\pi}\log(1 + \kappa_h q_2 + q_2^2)\ \xi(y')\ dy'$$

in two dimensions and

$$P_n = \int \frac{2}{(n-2)\omega_n}\frac{1}{|x' - y'|^{n-2}}\left\{\frac{1}{(1+q_1^2)^{(n-2)/2}} - 1\right\}\xi(y')\ dy'$$
$$Q_n = \int \frac{2}{(n-2)\omega_n}\frac{1}{\left(|x' - y'|^2 + 4h^2\right)^{(n-2)/2}}$$
$$\times\left\{\frac{1}{(1+\kappa_h q_2 + q_2^2)^{(n-2)/2}} - 1\right\}\xi(y')\ dy'$$

in $n \geq 3$ dimensions, where $\kappa_h = 4h/\sqrt{|x' - y'|^2 + 4h^2}$. Applying the derivative operator to the above quantities results in the following formulae:

$$\partial_{x'}P_2 = -\frac{1}{\pi}\int \frac{q_1}{1+q_1^2}\left[\frac{\partial_{x'}\eta(x')}{|x' - y'|} - \frac{(\eta(x') - \eta(y'))(x' - y')}{|x' - y'|^3}\right]\xi(y')\ dy',$$

$$\partial_{x'}Q_2 = -\frac{1}{2\pi}\int \frac{1}{1+\kappa_h q_2+q_2^2}\left[-q_2\frac{4h(x'-y')}{\left(|x'-y'|^2+4h^2\right)^{3/2}}\right.$$
$$\left.+(\kappa_h+2q_2)\left\{\frac{\partial_{x'}\eta(x')}{\left(|x'-y'|^2+4h^2\right)^{1/2}} -\frac{(\eta(x')+\eta(y'))(x'-y')}{\left(|x'-y'|^2+4h^2\right)^{3/2}}\right\}\right]\xi(y')\,dy'$$

in two dimensions and

$$\partial_{x'_j}P_n = -\frac{2}{\omega_n}\int\frac{x'_j-y'_j}{|x'-y'|^n}\left\{\frac{1}{(1+q_1^2)^{(n-2)/2}}-1\right\}\xi(y')\,dy'$$
$$-\frac{2}{\omega_n}\int\frac{1}{|x'-y'|^{n-2}}\frac{q_1}{(1+q_1^2)^{n/2}}\left[\frac{\partial_{x'_j}\eta(x')}{|x'-y'|}\right.$$
$$\left.-\frac{(\eta(x')-\eta(y'))(x'_j-y'_j)}{|x'-y'|^3}\right]\xi(y')\,dy'\ ,$$
$$\partial_{x'_j}Q_n = \frac{2}{\omega_n}\int\frac{x'_j-y'_j}{\left(|x'-y'|^2+4h^2\right)^{n/2}}\left\{\frac{1}{(1+\kappa_h q_2+q_2^2)^{(n-2)/2}}-1\right\}\xi(y')\,dy'$$
$$+\frac{2}{(n-2)\omega_n}\int\frac{1}{\left(|x'-y'|^2+4h^2\right)^{(n-2)/2}}\frac{1}{(1+\kappa_h q_2+q_2^2)^{n/2}}$$
$$\times\left\{-q_2\frac{4h(x'_j-y'_j)}{\left(|x'-y'|^2+4h^2\right)^{3/2}}\right.$$
$$\left.+(\kappa_h+2q_2)\cdot\left[\frac{\partial_{x'_j}\eta(x')}{\left(|x'-y'|^2+4h^2\right)^{1/2}}-\frac{(\eta(x')+\eta(y'))(x'_k-y'_k)}{\left(|x'-y'|^2+4h^2\right)^{3/2}}\right]\right\}\xi(y')\,dy'$$

in $n\geq 3$ dimensions. It is not difficult to see that the singular and smoothing integral operator theorems of section 5.3 apply to the above operators if we keep in mind that $d=n-1$. Indeed, in the seven principal terms appearing in the expression for the operator $\partial_{x'_j}Q_n$ and in the notation of Theorem 5.21, we have $(p,\rho,\lambda)=(1,n-2,1)$, $(2,n-2,0)$, $(1,n,0)$, $(0,n-1,1)$, $(1,n-1,0)$, $(1,n,0)$, and $(0,n,1)$. It is also useful to use Lemma 5.5 to pull out functions which depend on x' from the y' integrals, and interpolate.

The goal is not to show that $B(\eta)$ is analytic but rather to show that $(I-B(\eta))^{-1}$ is analytic. With this in mind we make the following estimate concerning powers of the operator $B(\eta)$ and then conclude analyticity of $(I-B(\eta))^{-1}$.

COROLLARY 5.6. *In the setting of the two dimensional water wave problem ($n=2$), if $1<q<\infty$ and $s>\max(\frac{1}{q},2)$, then the powers of $B(\eta)$ satisfy the following estimate:*

$$\left\|B(\eta)^j\ \xi\right\|_{W^{s,q}} < C^j\left\|\eta\right\|^{2j}_{W^{s+1,q}}\left\|\xi\right\|_{W^{s,q}}. \tag{5.6}$$

Thus, for $\|\eta\|_{W^{s+1,q}}$ small enough, the operator $(I-B(\eta))^{-1}$ exists, satisfies the

estimate

$$\left\|(I - B(\eta))^{-1}\ \xi\right\|_{W^{s,q}} < 1 + \tilde{C}\,\|\xi\|_{W^{s,q}}\,, \tag{5.7}$$

and is analytic as a function of η *on* $W^{s,q}$*. In the setting of the three dimensional water wave problem* ($n = 3$)*, if* $1 < q < \infty$ *and* $s > \max(\frac{2}{q}, 3)$*, then the powers of* $B(\eta)$ *satisfy the following estimate:*

$$\left\|B(\eta)^j\ \xi\right\|_{W^{s,q}} < C^j\,\|\eta\|^{2j}_{W^{s+2,q}}\,\|\xi\|_{W^{s,q}}\,. \tag{5.8}$$

Thus, for $\|\eta\|_{W^{s+2,q}}$ *small enough, the operator* $(I - B(\eta))^{-1}$ *exists, satisfies the estimate*

$$\left\|(I - B(\eta))^{-1}\ \xi\right\|_{W^{s,q}} < 1 + \tilde{C}\,\|\xi\|_{W^{s,q}}\,, \tag{5.9}$$

and is analytic as a function of η *on* $W^{s,q}$*.*

Proof. We restrict to the case of $n = 2$ as the $n = 3$ case is virtually identical. We already have the estimate

$$\|B(\eta)\ \xi\|_{W^{s,q}} < C\,\|\eta\|^2_{W^{s+1,q}}\,\|\xi\|_{W^{s,q}}\,,$$

and we now proceed via induction. The case $j = 1$ is clearly true, so we assume that the corollary is true for j and analyze $(j + 1)$,

$$\begin{aligned}\left\|B(\eta)^{j+1}\ \xi\right\|_{W^{s,q}} &= \left\|B(\eta)^j B(\eta)\ \xi\right\|_{W^{s,q}} \\ &< C^j\,\|\eta\|^{2j}_{W^{s+1,q}}\,\|B(\eta)\ \xi\|_{W^{s,q}} \\ &< C^{j+1}\,\|\eta\|^{2(j+1)}_{W^{s+1,q}}\,\|\xi\|_{W^{s,q}}\,.\end{aligned}$$

Therefore, the estimate on the jth power holds true. To compute $(I - B(\eta))^{-1}$ we use the Neumann series

$$(I - B(\eta))^{-1} = I + \sum_{j=1}^{\infty} B^j(\eta)$$

and note that it converges in the radius of convergence of the series

$$\sum_{j=1}^{\infty} C^j\,\|\eta\|^{2j}_{W^{s+1,q}}\,.$$

In other words, the Neumann series converges when $\|\eta\|_{W^{s+1,q}} < 1/\sqrt{C}$, and we are done. ∎

We now turn our attention to the operators $A(\eta)$. While the operators $B(\eta)$ map $W^{s,q}$ into $W^{s,q}$ and thereby preserve derivatives, we should expect the operators $A(\eta)$ to map $W^{s+1,q}$ into $W^{s,q}$. This is incorporated into our proof by using a variation of integration by parts, given below, to remove all $\partial_{y'}$ derivatives from $\eta(y')$ terms and place them elsewhere. We give the version of integration by parts in the following lemma proven in W. Craig, U. Schanz, and C. Sulem [7] and D. Nicholls [19].

LEMMA 5.7. *Consider* $x, y \in \mathbb{R}^n$*,* $R(q_1)$ *an odd continuous function of* q_1*, and* $\eta \in C^1(\mathbb{R}^n)$*; then we have that*

$$\int \frac{x - y}{|x - y|^n} \cdot \nabla_y (R(q_1))\xi(y)\ dy = -\int R(q_1)\frac{x - y}{|x - y|^n} \cdot \nabla_y \xi(y)\ dy. \tag{5.10}$$

We are can now prove an estimate on the operator $A(\eta)$ which is given in the following theorem.

THEOREM 5.8. *In the setting of the two dimensional water wave problem ($n = 2$), if $1 < q < \infty$ and $s > \max(\frac{1}{q}, 2)$, then $A(\eta)$ satisfies the estimate*

$$\|A(\eta)\ \xi\|_{W^{s,q}} < C\,\|\eta\|^2_{W^{s+1,q}}\,\|\xi\|_{W^{s+1,q}}\,. \tag{5.11}$$

Furthermore, the operator $A(\eta)$ is analytic as a function of η from the space $W^{s+1,q}$ to the space $W^{s,q}$. In the setting of the three dimensional water wave problem ($n = 3$), if $1 < q < \infty$ and $s > \max(\frac{2}{q}, 3)$, then $A(\eta)$ satisfies the estimate

$$\|A(\eta)\ \xi\|_{W^{s,q}} < C\,\|\eta\|^2_{W^{s+2,q}}\,\|\xi\|_{W^{s+1,q}}\,. \tag{5.12}$$

Furthermore, the operator $A(\eta)$ is analytic as a function of η from the space $W^{s+1,q}$ to the space $W^{s,q}$.

Proof. As before, since

$$|D_{x'}| = -\sum_{j=1}^{n-1} R_j(D_{x'})\partial_{x'_j}$$

is the Riesz potential given in Lemma 5.4, we need consider only two types of integral operators, $\partial_{x'_j}$ applied to

$$\begin{aligned}
P_2 &= \int \frac{1}{\pi}\frac{1}{(x'-y')^2}\left\{\frac{(x'-y')\partial_{y'}\eta(y') - (\eta(x')-\eta(y'))}{1+q_1^2}\right\}\xi(y')\,dy',\\
Q_2 &= \int \frac{1}{\pi}\frac{1}{(x'-y')^2+4h^2}\left\{\frac{(x'-y')\partial_{y'}\eta(y')}{1+\kappa_h q_2+q_2^2}\right.\\
&\quad\left.+\frac{(\eta(x')+\eta(y'))}{1+\kappa_h q_2+q_2^2}\right\}\xi(y')\,dy',\\
R_2 &= \int \frac{1}{\pi}\frac{2h}{(x'-y')^2+4h^2}\left\{\frac{1}{1+\kappa_h q_2+q_2^2}-1\right\}\xi(y')\,dy'
\end{aligned}$$

in two dimensions and

$$\begin{aligned}
P_n &= \int \frac{2}{\omega_n}\frac{1}{|x'-y'|^n}\left\{\frac{(x'-y')\cdot\nabla_{y'}\eta(y') - (\eta(x')-\eta(y'))}{(1+q_1^2)^{n/2}}\right\}\xi(y')\,dy',\\
Q_n &= \int \frac{2}{\omega_n}\frac{1}{\left(|x'-y'|^2+4h^2\right)^{n/2}}\left\{\frac{(x'-y')\cdot\nabla_{y'}\eta(y')}{(1+\kappa_h q_2+q_2^2)^{n/2}}\right.\\
&\quad\left.+\frac{(\eta(x')+\eta(y'))}{(1+\kappa_h q_2+q_2^2)^{n/2}}\right\}\xi(y')\,dy',\\
R_n &= \int \frac{2}{\omega_n}\frac{2h}{\left(|x'-y'|^2+4h^2\right)^{n/2}}\left\{\frac{1}{(1+\kappa_h q_2+q_2^2)^{n/2}}-1\right\}\xi(y')\,dy'
\end{aligned}$$

in $n \geq 3$ dimensions. All we need to do is apply the differential operator $\partial_{x'_j}$ to each of these integrals, use Lemma 5.7 wherever appropriate, and then note that the singular

and smoothing integral operator theorems of section 5.3 can be used. Keeping in mind the facts that

$$\partial_{x_j'} q_1(x',y') = \frac{\partial_{x_j'}\eta(x')}{|x'-y'|} - \frac{(\eta(x')-\eta(y'))(x_j'-y_j')}{|x'-y'|^3},$$
$$\partial_{x_j'} q_2(x',y') = \frac{\partial_{x_j'}\eta(x')}{\left(|x'-y'|^2+4h^2\right)^{1/2}} - \frac{(\eta(x')+\eta(y'))(x_j'-y_j')}{\left(|x'-y'|^2+4h^2\right)^{3/2}},$$
$$\partial_{x_j'}\kappa_h(x',y') = -\frac{4h(x_j'-y_j')}{\left(|x'-y'|^2+4h^2\right)^{3/2}},$$

we compute the derivatives in two dimensions as

$$\begin{aligned}
\partial_{x'}P_2 = &-\frac{2}{\pi}\int \frac{1}{(x'-y')^3}\left\{\frac{(x'-y')\cdot\nabla_{y'}\eta(y')-(\eta(x')-\eta(y'))}{(1+q_1^2)^{n/2}}\right\}\xi(y')\,dy' \\
&+\frac{1}{\pi}\int \frac{1}{(x'-y')^2}\left\{\frac{\partial_{y'}\eta(y')-\partial_{x'}\eta(x')}{1+q_1^2}\right. \\
&\left.- \frac{\left[(x'-y')\partial_{y'}\eta(y')-(\eta(x')-\eta(y'))\right]2q_1\partial_{x'}q_1}{\left(1+q_1^2\right)^2}\right\}\xi(y')\,dy', \\
\partial_{x'}Q_2 = &-\frac{2}{\pi}\int \frac{x'-y'}{\left((x'-y')^2+4h^2\right)^2}\left\{\frac{(x'-y')\partial_{y'}\eta(y')+(\eta(x')+\eta(y'))}{1+\kappa_h q_2+q_2^2}\right\}\xi(y')\,dy' \\
&+\frac{1}{\pi}\int \frac{1}{(x'-y')^2+4h^2}\left\{\frac{\partial_{y'}\eta(y')+\partial_{x'}\eta(x')}{1+\kappa_h q_2+q_2^2}\right. \\
&\left.- \frac{\left[(x'-y')\partial_{y'}\eta(y')+(\eta(x')+\eta(y'))\right](q_2\partial_{x'}\kappa_h+(\kappa_h+2q_2)\partial_{x'}q_2)}{(1+\kappa_h q_2+q_2^2)^2}\right\}\xi(y')\,dy', \\
\partial_{x'}R_2 = &-\frac{2}{\pi}\int \frac{2h(x'-y')}{\left((x'-y')^2+4h^2\right)^2}\left\{\frac{1}{1+\kappa_h q_2+q_2^2}-1\right\}\xi(y')\,dy' \\
&-\frac{1}{\pi}\int \frac{2h}{(x'-y')^2+4h^2}\frac{(q_2\partial_{x'}\kappa_h+(\kappa_h+2q_2)\partial_{x'}q_2)}{\left(1+\kappa_h q_2+q_2^2\right)^2}
\end{aligned}$$

and in $n=3$ dimensions as

$$\begin{aligned}
\partial_{x_j'}P_n = &\frac{2}{\omega_n}\int \frac{x_j'-y_j'}{|x'-y'|^{n+2}}\left\{\frac{(x'-y')\cdot\nabla_{y'}\eta(y')-(\eta(x')-\eta(y'))}{(1+q_1^2)^{n/2}}\right\}\xi(y')\,dy' \\
&+\frac{2}{\omega_n}\int \frac{1}{|x'-y'|^n}\left\{\frac{\partial_{y_j'}\eta(y')-\partial_{x_j'}\eta(x')}{\left(1+q_1^2\right)^{n/2}}\right. \\
&\left.-\frac{\left[(x'-y')\cdot\nabla_{y'}\eta(y')-(\eta(x')-\eta(y'))\right](nq_1\partial_{x_j'}q_1)}{\left(1+q_1^2\right)^n}\right\}\xi(y')\,dy', \\
\partial_{x_j'}Q_n = &-\frac{2n}{\omega_n}\int \frac{x_j'-y_j'}{\left(|x'-y'|^2+4h^2\right)^{(n+2)/2}} \\
&\times\left\{\frac{(x'-y')\cdot\nabla_{y'}\eta(y')+(\eta(x')+\eta(y'))}{\left(1+\kappa_h q_2+q_2^2\right)^{n/2}}\right\}\xi(y')\,dy'
\end{aligned}$$

$$+\frac{2}{\omega_n}\int \frac{1}{\left(|x'-y'|^2+4h^2\right)^{n/2}}\left\{\frac{\partial_{y_j'}\eta(y')+\partial_{x_j'}\eta(x')}{(1+\kappa_h q_2+q_2^2)^{n/2}}\right.$$
$$\left.-\frac{[(x'-y')\cdot\nabla_{y'}\eta(y')+(\eta(x')+\eta(y'))]\,(q_2\partial_{x_j'}\kappa_h+(\kappa_h+2q_2)\partial_{x_j'}q_2)}{(1+\kappa_h q_2+q_2^2)^{n}}\right\}\xi(y')\,dy',$$

$$\partial_{x_j'}R_n=-\frac{2n}{\omega_n}\int\frac{2h(x_j'-y_j')}{\left(|x'-y'|^2+4h^2\right)^{(n+2)/2}}\left\{\frac{1}{(1+\kappa_h q_2+q_2^2)^{n/2}}-1\right\}\xi(y')\,dy'$$
$$-\frac{n}{\omega_n}\int\frac{2h}{\left(|x'-y'|^2+4h^2\right)^{n/2}}\frac{q_2\partial_{x_j'}\kappa_h+(\kappa_h+2q_2)\partial_{x_j'}q_2}{(1+\kappa_h q_2+q_2^2)^{(n+2)/2}}\xi(y')\,dy'.$$

As noted before, we can now use the theorems of section 5.3 in combination with Lemma 5.7 to arrive at the conclusion of the theorem. □

Now that we have Corollary 5.6 and Theorem 5.8, we can finally state and prove the theorem regarding analyticity of the Dirichlet–Neumann operator.

THEOREM 5.9. *In the setting of the two dimensional water wave problem ($n=2$), if $1<q<\infty$ and $s>\max(\frac{1}{q},2)$, then the Dirichlet–Neumann operator $G(\eta)\,\xi$ is analytic as a function of $\eta\in W^{s+1,q}$, as a bounded linear operator from $W^{s+1,q}$ to $W^{s,q}$. In the setting of the three dimensional water wave problem ($n=3$), if $1<q<\infty$ and $s>\max(\frac{2}{q},3)$, then the Dirichlet–Neumann operator $G(\eta)\,\xi$ is analytic as a function of $\eta\in W^{s+2,q}$, as a bounded linear operator from $W^{s+1,q}$ to $W^{s,q}$.*

Proof. Theorem 5.2 gives the exact implicit formula

$$(I-B(\eta))G(\eta)\xi=|D_{x'}|\tanh(h\,|D_{x'}|)\xi+A(\eta)\xi,$$

and thus, since $(I-B(\eta))$ is boundedly invertible, we can write

$$G(\eta)\xi=(I-B(\eta))^{-1}\,|D_{x'}|\tanh(h\,|D_{x'}|)\xi+(I-B(\eta))^{-1}A(\eta)\xi.$$

Since Corollary 5.6 and Theorem 5.8 give us analyticity and appropriate boundedness of relevant operators we have the statement of the theorem. □

5.3. Singular and smoothing integral operators. In this section we briefly outline the statement and proofs of theorems concerning the boundedness properties of certain singular and smoothing integral operators relevant to the proof the the analyticity of the Dirichlet–Neumann operator outlined above. The bulk of these theorems were first presented in W. Craig, U. Schanz, and C. Sulem [7] and U. Schanz [25] in general n dimensions for use in the analyticity proof of the Dirichlet–Neumann operator in three dimensions where $\eta\in C^{s+1}$ and $\xi\in W^{s,q}$. The others were first presented by D. Nicholls [19] in one dimension for use in the proof of the analyticity of the Dirichlet–Neumann operator in two dimensions which only required that $\eta,\xi\in W^{s,q}$ for $s>\frac{d}{q}$. Here we extend the program of D. Nicholls [19] by proving his result in d dimensions, and further reducing the smoothness required of η and ξ.

Let $x,y\in\mathbb{R}^d$, and consider functions $\eta:\mathbb{R}^d\to\mathbb{R}$ and $\xi:\mathbb{R}^d\to\mathbb{R}$. Our goal is to study two classes of integral operators. The first is singular and has the general form

$$C_p(\eta)\;\xi(x)=\int k(x-y)c_p(q_1)\xi(y)\,dy,$$

where $k(x-y)$ is a convolution kernel of Calderón–Zygmund type satisfying standard estimates outlined below. Recall that $q_1(\eta; x, y) = (\eta(x) - \eta(y))/|x-y|$, and consider $c_p : \mathbb{R} \to \mathbb{R}$ which is analytic in the interval $|z| < R_0$ such that $c_p(z) = \mathcal{O}(|z|^p)$ for $|z|$ small. The second class of operators is smoothing and has the general form

$$C_{p,h}(\eta)\ \xi(x) = \int K_h(x-y) c_{p,h}(q_2, \kappa_h) \xi(y)\ dy,$$

where

$$K_h(x) = \frac{1}{\left(|x|^2 + 4h^2\right)^{\rho/2}} \prod_{l=1}^{d} \left(\frac{x_l}{\left(|x|^2 + 4h^2\right)^{1/2}} \right)^{\beta_l},$$

with $\beta = \sum_{l=1}^{d} \beta_l$,

$$q_2(\eta; x, y) = \frac{\eta(x) + \eta(y)}{\left(|x-y|^2 + 4h^2\right)^{1/2}}, \quad \kappa_h(x,y) = \frac{4h}{\left(|x-y|^2 + 4h^2\right)^{1/2}}.$$

We consider $c_{p,h}(z, w) : \mathbb{R}^2 \to \mathbb{R}$ which is analytic for $\{|z| < R_0, |w| < 2\}$ such that $c_{p,h}(z,w) = \mathcal{O}(|z|^p |w|^\lambda)$ for $|z|$ and $|w|$ small. We will require that $p + \rho + \lambda > d$. We will establish Sobolev estimates for the operators C_p and $C_{p,h}$ in the following theorems. The first, concerning bounds on C_p, requires the use of a deep theorem of M. Christ and J. Journé [3] on L^q bounds for Calderón–Zygmund commutators. The theorem concerning bounds on the operators $C_{p,h}$ requires nothing more than careful estimates as the operator is smoothing rather than singular.

To place ourselves in the setting for the theorem of M. Christ and J. Journé [3], we define the standard estimates.

DEFINITION 5.10. *A kernel K on $\mathbb{R}^d$ is said to satisfy standard estimates if there exist $\delta > 0$ and $c_K < \infty$ such that for all distinct $x, y \in \mathbb{R}^d$ and all $z \in \mathbb{R}^d$ such that $|x - z| \le \frac{|x-y|}{2}$,*

(i) $|K(x,y)| \le c_K |x-y|^{-d}$;
(ii) $|K(x,y) - K(z,y)| \le c_K (\frac{|x-z|}{|x-y|})^\delta |x-y|^{-d}$;
(iii) $|K(y,x) - K(y,z)| \le c_K (\frac{|x-z|}{|x-y|})^\delta |x-y|^{-d}$.

With this definition in hand we state the following theorem.

THEOREM 5.11 (M. Christ and J. Journé [3, Theorem 4]). *Consider the singular integral operator with kernel*

$$L(x-y) \prod_{j=1}^{m} \left(\int_0^1 b_j(tx + (1-t)y)\ dt \right), \tag{5.13}$$

where each $b_j \in L^\infty$ and L satisfies the standard estimates. Then for $0 < q < \infty$,

$$\left\| \int L(x-y) \prod_{j=1}^{m} \left(\int_0^1 b_j(tx + (1-t)y)\ dt \right) \xi(y)\ dy \right\|_{L^q} \le c_q c_L m^N \left(\prod_{j=1}^{m} |b_j|_{L^\infty} \right) \|\xi\|_{L^q}. \tag{5.14}$$

One may take $N = 2 + \delta_L$, for δ_L and c_L which appear in the standard estimates.

The first step in analyzing the boundedness of the operators $C_p(\eta)$ is to first consider the simplified operator

$$S_p(\eta_1, \ldots, \eta_p)\ \xi(x) = \int K(x-y) \left(\prod_{j=1}^{p} q_1(\eta_j) \right) \xi(y)\ dy,$$

where K is a Calderón–Zygmund kernel which satisfies standard estimates. There are two related theorems which one can prove concerning this operator. The first is due to W. Craig, U. Schanz, and C. Sulem [7].

THEOREM 5.12 (W. Craig, U. Schanz, and C. Sulem [7]). *Let $\eta_1, \ldots, \eta_p \in C^1$, then the singular integral operator $S_p(\eta_1, \ldots, \eta_p)$ is bounded on L^q and satisfies*

$$\|S_p(\eta_1, \ldots, \eta_p)\ \xi\|_{L^q} \leq C_0 p^M \left(\prod_{j=1}^{p} |\eta_j|_{C^1} \right) \|\xi\|_{L^q}\,, \tag{5.15}$$

with exponent $M = 3 + \min(\delta_K, 1)$.

The second is an extension to general d dimensions of a result proven by D. Nicholls [19].

THEOREM 5.13. *Let $1 \leq r \leq p$, $\eta_j \in C^2$ for $j \neq r$, $\xi \in C^1 \bigcap W^{1,q}$, and $\eta_r \in L^\infty \bigcap L^q$. Consider K of the form*

$$K(x,y) = \begin{cases} \frac{1}{|x-y|^d}, \\ \frac{x-y}{|x-y|^{d+1}}. \end{cases} \tag{5.16}$$

Then the singular integral operator $S_p(\eta_1, \ldots, \eta_p)$ is bounded on L^q and satisfies

$$\begin{aligned} \|S_p(\eta_1, \ldots, \eta_p)\ \xi\|_{L^q} \leq C \Bigg\{ & |\eta_r|_{L^\infty} \left(\prod_{j=1, j\neq r}^{p} |\eta_j|_{C^1} \right) \|\partial_y \xi\|_{L^q} \\ & + |\eta_r|_{L^\infty} \sum_{s=1, s\neq r}^{p} \left(\prod_{j=1, j\neq r, s}^{p} |\eta_j|_{C^1} \right) |\eta_s|_{C^2} \|\xi\|_{L^q} \\ & + \left(\prod_{j=1, j\neq r}^{p} |\eta_j|_{C^1} \right) |\xi|_{C^1} \|\eta_r\|_{L^q} \\ & + |\xi|_{L^\infty} \left(\prod_{j=1, j\neq r}^{p} |\eta_j|_{C^1} \right) \|\partial_y \eta_r\|_{L^q} \\ & + |\xi|_{L^\infty} \sum_{s=1, s\neq r}^{p} \left(\prod_{j=1, j\neq r, s}^{p} |\eta_j|_{C^1} \right) |\eta_s|_{C^2} \|\eta_r\|_{L^q} \Bigg\}. \end{aligned} \tag{5.17}$$

The proofs of both of these results rely on the following lemmas. We state without proof the first two (see [19]) which are used in the proof of Theorem 5.12.

LEMMA 5.14. *Suppose that $x \neq y$. If $f_1, \ldots, f_p \in C^1$, then*

$$\prod_{j=1}^{p} q_1(f_j) = \sum_{l \in \mathcal{L}} \left(\prod_{k=1}^{p} \frac{(x-y)_{l_k}}{|x-y|} \right) \left(\int_0^1 \partial_{x_{l_k}} f_j(tx + (1-t)y)\ dt \right), \tag{5.18}$$

where $\mathcal{L}$ is the set of all integer p-tuples $(l_1, \ldots, l_p)$ such that $1 \le l_1, \ldots, l_p \le d$.

LEMMA 5.15. *If $k(x,y)$ is a Calderón–Zygmund kernel satisfying standard estimates, then the kernel of the form*

$$\zeta(x,y) = k(x,y) \prod_{k=1}^{p} \frac{(x-y)_{l_k}}{|x-y|}, \tag{5.19}$$

where $1 \le l_k \le d$, also satisfies standard estimates.

The following two lemmas are the analogues of the above two in the case that a y derivative is applied to $q_1(f)$. The proof of Lemma 5.16 is significantly different from the proof of Lemma 5.14 so we present it here. However, the proof of Lemma 5.17 is sufficiently close to that of Lemma 5.15 that we omit it.

LEMMA 5.16. *Suppose that $x \neq y$. If $f \in C^2$, then*

$$\begin{aligned} \frac{x-y}{|x-y|} \cdot \nabla_y q_1(f) &= -\frac{x-y}{|x-y|^2} \cdot \nabla_y f(y) + \frac{f(x)-f(y)}{|x-y|^2} \\ &= \frac{1}{|x-y|^2} \sum_{k=1}^{d} (x-y)_k \sum_{j=1}^{d} (x-y)_j \int_0^1 b_{j,k}(x,y,t)\, dt, \end{aligned} \tag{5.20}$$

where

$$b_{j,k} = \int_0^1 \tau \partial_{y_j} \partial_{y_k} f(t[\tau x + (1-\tau)y] + (1-t)y)\, d\tau \tag{5.21}$$

and $b_{j,k} \in L^\infty$.

Proof. The first line of (5.20) is realized by a simple calculation of the derivative of $q_1(f)$ with respect to y. For the second line we begin with the fundamental theorem of calculus which states that for $f \in C^1$,

$$f(b) - f(a) = \sum_{j=1}^{d} \int_0^1 (b-a)_j \partial_{u_j} f(tb + (1-t)a)\, dt.$$

Provided that $f \in C^2$ this can also be done for ∇f resulting in the following:

$$\nabla_u f(b) - \nabla_u f(a) = \sum_{k=1}^{d} \hat{e}_k \sum_{j=1}^{d} \int_0^1 (b-a)_j \partial_{u_j} \partial_{u_k} f(tb + (1-t)a)\, dt,$$

where $\hat{e}_k$ is the kth unit vector. We now set $b = \tau x + (1-\tau)y$ and $a = y$, dot with $(x-y)$, and integrate in τ from 0 to 1. Using the fundamental theorem of calculus on the $\nabla_u f(b)$ term we arrive at

$$\begin{aligned} &(f(x) - f(y)) - (x-y) \cdot \nabla_u f(y) \\ &\qquad = \sum_{k=1}^{d} (x-y)_k \sum_{j=1}^{d} (x-y)_j \int_0^1 \tau \int_0^1 \partial_{u_j} \partial_{u_k} f(t[\tau x + (1-\tau)y] + (1-t)y)\, dt\, d\tau. \end{aligned}$$

We now multiply both sides by $\frac{1}{|x-y|^2}$ and the theorem is proven. That $b_{j,k}(x,y,t) \in L^\infty$ is due to the facts that $f \in C^2$ and $\tau \in [0,1]$. ∎

LEMMA 5.17. *A Calderón–Zygmund kernel of the type*

$$\zeta(x,y) = k(x,y)\frac{1}{|x-y|^2}\sum_{r,s}(x-y)_r(x-y)_s\prod_{k=1}^{p}\frac{(x-y)_{l_k}}{|x-y|}, \tag{5.22}$$

where $1 \le r,s,l_k \le d$ *and* $k(x,y)$ *is a Calderón–Zygmund kernel satisfying standard estimates, also satisfies standard estimates.*

At this point we can prove both Theorem 5.12 and Theorem 5.13. We begin with Theorem 5.12.

Proof of Theorem 5.12. The main idea is to use the theorem of M. Christ and J. Journé [3] on the operator $S_p(\eta_1,\ldots,\eta_p)$. Define

$$L(x,y) = K(x,y)\prod_{j=1}^{p}\frac{(x-y)_{l_k}}{|x-y|},$$

with K as defined in the statement of the theorem and $1 \le l_k \le d$ as in Lemma 5.14. By Lemma 5.14 we can write the kernel of S_p

$$K(x,y)\prod_{j=1}^{p} q_1(\eta_j)$$

as a finite sum of terms of the form

$$L(x,y)\prod_{j=1}^{p}\int_0^1 \partial_{x_{l_k}}\eta_j(tx+(1-t)y)\,dt.$$

By Lemma 5.15 we know that $L(x,y)$ satisfies standard estimates with $c_L = 3pc_K$ and $\delta_L = \min(\delta_K,1)$. Therefore we can apply the theorem of M. Christ and J. Journé above to each term

$$\left\|\int L(x,y)\prod_{j=1}^{p}\left(\int_0^1 \partial_{x_{l_k}}\eta_j(tx+(1-t)y)\,dt\right)\xi(y)\,dy\right\|_{L^q} \le c_L p^N\left(\prod_{j=1}^{p}\left|\partial_{x_{l_k}}\eta_j\right|_{L^\infty}\right)\|\xi\|_{L^q}.$$

By the definition of the C^1 norm the theorem is proven. □

The proof of Theorem 5.13 is in many ways a corollary of Theorem 5.12 and is presented below.

Proof of Theorem 5.13. The main idea is to use the theorem of M. Christ and J. Journé [3] on the operator S_p. We begin with the calculation

$$\begin{aligned} S_p\xi(x) &= \int K(x,y)\left(\prod_{j=1}^{p} q_1(\eta_j)\right)\xi(y)\,dy \\ &= \int K(x,y)\left(\prod_{j=1,j\neq r}^{p} q_1(\eta_j)\right)\frac{\eta_r(x)\xi(y)-\eta_r(y)\xi(y)}{|x-y|}\,dy \end{aligned}$$

$$
\begin{aligned}
&= \int K(x,y) \left(\prod_{j=1, j\neq r}^{p} q_1(\eta_j) \right) q_1(\xi)\eta_r(y)\, dy \\
&\quad + \int K(x,y) \left(\prod_{j=1, j\neq r}^{p} q_1(\eta_j) \right) \frac{\eta_r(x)\xi(y)}{|x-y|}\, dy \\
&\quad - \int K(x,y) \left(\prod_{j=1, j\neq r}^{p} q_1(\eta_j) \right) \frac{\eta_r(y)\xi(x)}{|x-y|}\, dy \\
&= I_1 + I_2 + I_3.
\end{aligned}
$$

Using Theorem 5.12 with the roles of η_r and ξ interchanged we can estimate the integral I_1 in appropriate fashion. We note that this estimate requires that $\eta_j, \xi \in C^1$ for $j \neq r$, and $\eta_r \in L^q$. The two integrals I_2 and I_3 can be handled in the same way as one another, again with the roles of η_r and ξ switched. We choose I_2 and begin by pulling $\eta_r(x)$ out in front of the integral. The $\eta_r(x)$ factor will be estimated using the L^∞ norm. Now we are left with a singular integral operator much like that of Theorem 5.12 except that the singular term is too singular. At this point we require the special form of K. In the case $K(x,y) = \frac{x-y}{|x-y|^{d+1}}$ we bring the factor $\frac{x-y}{|x-y|}$ out of the integral by using its L^∞ bound and thereby reduce to the case of $K(x,y) = \frac{1}{|x-y|^d}$. In this case we write

$$
\frac{K(x,y)}{|x-y|} = \frac{1}{|x-y|^{d+1}} = \operatorname{div}_y \left[\frac{x-y}{|x-y|^{d+1}} \right].
$$

We now integrate by parts which results in a kernel of the right singularity at the cost of derivatives appearing on the other terms in the integrand. Without loss of generality consider $K(x,y) = \frac{1}{|x-y|^d}$; then the integral I_2 becomes

$$
\begin{aligned}
I_2 &= \eta_r(x) \int \frac{K(x,y)}{|x-y|} \left(\prod_{j=1, j\neq r}^{p} q_1(\eta_j) \right) \xi(y)\, dy \\
&= -\eta_r(x) \left\{ \int \frac{(x-y)}{|x-y|^{d+1}} \cdot \nabla_y \left[\prod_{j=1, j\neq r}^{p} q_1(\eta_j) \right] \xi(y)\, dy \right. \\
&\qquad \left. + \int \left(\prod_{j=1, j\neq r}^{p} q_1(\eta_j) \right) \frac{(x-y)}{|x-y|^{d+1}} \cdot \nabla_y \left[\xi(y) \right]\, dy \right\} \\
&= -\eta_r(x) \left\{ \sum_{s=1, s\neq r}^{p} \int \frac{1}{|x-y|^d} \left(\prod_{j=1, j\neq r, s}^{p} q_1(\eta_j) \right) \frac{(x-y)}{|x-y|} \cdot \nabla_y \left[q_1(\eta_s) \right] \xi(y)\, dy \right. \\
&\qquad \left. + \int \frac{1}{|x-y|^d} \left(\prod_{j=1, j\neq r}^{p} q_1(\eta_j) \right) \frac{(x-y)}{|x-y|} \cdot \nabla_y \left[\xi(y) \right]\, dy \right\}.
\end{aligned}
$$

Now, from Lemmas 5.16 and 5.17 we can estimate these two terms as long as $\xi \in W^{1,q}$, $\eta_r \in L^\infty$, and $\eta_j \in C^2$ for $j \neq r$. As mentioned earlier, the term I_3 can be handled

analogously with the requirements that $\xi \in L^\infty$, $\eta_r \in W^{1,q}$, and $\eta_j \in C^2$ for $j \neq r$. The estimate in the statement of the theorem is now realized. ∎

As a precursor to estimating the operators $C_p(\eta)$ in $W^{s,q}$ norm, we estimate the following simplified operators:

$$S_p(\eta, \ldots, \eta)\ \xi(x) = \int k(x,y) q_1(\eta)^p \xi(y)\ dy.$$

These will lead to the operator $C_p(\eta)$ since the only difference is the presence in $C_p(\eta)$ of the analytic function $c_p(q_1(\eta))$ which we will expand in a Taylor series, giving rise to a sum of operators of the form $S_p(\eta, \ldots, \eta)$. With this in mind we prove the following theorem.

THEOREM 5.18. *If $d = 1$, the following estimate holds for $\eta \in W^{s+1,q}$ and $\xi \in W^{s,q}$, $s > \max(\frac{1}{q}, 2)$:*

$$\left\| \partial_x^s S_p(\eta, \ldots, \eta)\ \xi \right\|_{L^q} \leq C \left\| \eta \right\|_{W^{s+1,q}}^p \left\| \xi \right\|_{W^{s,q}}. \tag{5.23}$$

If $d = 2$, the following estimate holds for $\eta \in W^{s+2,q}$ and $\xi \in W^{s,q}$, $s > \max(\frac{2}{q}, 3)$:

$$\left\| \partial_x^s S_p(\eta, \ldots, \eta)\ \xi \right\|_{L^q} \leq C \left\| \eta \right\|_{W^{s+2,q}}^p \left\| \xi \right\|_{W^{s,q}}. \tag{5.24}$$

In order to prove this theorem we need the following lemma which is proven in W. Craig, U. Schanz, and C. Sulem [7] and D. Nicholls [19].

LEMMA 5.19. *Let S_p be defined as*

$$S_p(\eta, \ldots, \eta)\ \xi(x) = \int K(x,y) q_1(\eta)^p \xi(y)\ dy. \tag{5.25}$$

Then the lth derivative of this operator is

$$\partial_x^l S_p(\eta, \ldots, \eta)\xi(x) = \sum_{m=0}^{l} \sum_{\sum \alpha_k = m} S_p(\partial_x^{\alpha_1}\eta, \ldots, \partial_x^{\alpha_p}\eta)\ \partial_x^{l-m}\xi(x). \tag{5.26}$$

We are now ready to prove Theorem 5.18.

Proof of Theorem 5.18. By Lemma 5.19 we have

$$\left\| \partial_x^s S_p(\eta, \ldots, \eta)\xi(x) \right\|_{L^q} \leq \sum_{m=0}^{s} \sum_{\sum \alpha_k = m} \left\| S_p(\partial_x^{\alpha_1}\eta, \ldots, \partial_x^{\alpha_p}\eta)\ \partial_x^{s-m}\xi(x) \right\|_{L^q}.$$

Since we wish to avoid using a C^{s+1} derivative we diverge a little from the approach of W. Craig, U. Schanz, and C. Sulem [7] and split the previous sum into three parts. The first will contain all terms where at least one derivative hits the function ξ. The second will contain terms with no derivatives on ξ but not all s derivatives on one η. The final part will contain all terms where all s derivatives are on one of the η.

Each part will consist of terms of the form

$$\left\| S_p(\partial_x^{\alpha_1}\eta, \ldots, \partial_x^{\alpha_p}\eta)\ \partial_x^{s-m}\xi(x) \right\|_{L^q}.$$

If $m < s$, then at least one derivative hits ξ and we can use Theorem 5.12 to make the estimate

$$\begin{aligned} \left\| S_p(\partial_x^{\alpha_1}\eta, \ldots, \partial_x^{\alpha_p}\eta)\ \partial_x^{s-m}\xi(x) \right\|_{L^q} &\leq C \left(\prod_{j=1}^{p} |\partial_x^{\alpha_j}\eta|_{C^1} \right) \left\| \partial_x^{s-m}\xi \right\|_{L^q} \\ &\leq C\, |\eta|_{C^1}^{p-1}\, |\partial_x^m \eta|_{C^1} \left\| \partial_x^{s-m}\xi \right\|_{L^q}. \end{aligned}$$

The second line comes from the interpolation

$$|\partial_x^\alpha \eta|_{C^1} \leq C\,|\eta|_{C^1}^{1-\frac{\alpha}{m}}\,|\partial_x^m \eta|_{C^1}^{\frac{\alpha}{m}}\,.$$

By being wasteful with derivatives we can estimate this by $C\,|\eta|_{C^1}^{p-1}\,|\eta|_{C^s}\,\|\eta\|_{W^{s,q}}$. By our choice of s for $d=1$ we can estimate this by $C\,\|\eta\|_{W^{s+1,q}}^p\,\|\xi\|_{W^{s,q}}$. Similarly, by the choice of s for $d=2$ we can estimate this by $C\,\|\eta\|_{W^{s+2,q}}^p\,\|\xi\|_{W^{s,q}}$. If we consider $m=s$ but $\alpha_r \neq s$, then we make the estimate, based on Theorem 5.12

$$\begin{aligned}\|S_p(\partial_x^{\alpha_1}\eta,\ldots,\partial_x^{\alpha_p}\eta)\;\xi(x)\|_{L^q} &\leq C\left(\prod_{j=1}^p |\partial_x^{\alpha_j}\eta|_{C^1}\right)\|\xi\|_{L^q}\\ &\leq C\,|\eta|_{C^s}^p\,\|\xi\|_{L^q}\,.\end{aligned}$$

Again, by our choice of s we can make the appropriate estimate. Finally, in the case where $\alpha_r = s$ we use Theorem 5.13 to make the estimate

$$\begin{aligned}&\|S_p(\eta,\ldots,\partial_x^s\eta,\ldots,\eta)\;\xi(x)\|_{L^q}\\ &\quad\leq C\left(\prod_{j=1}^p |\partial_x^{\alpha_j}\eta|_{C^1}\right)\|\xi\|_{L^q}\\ &\quad\leq C\,|\eta|_{C^1}^{p-1}\,\{|\eta|_{C^1}\,|\xi|_{C^1}\,\|\partial_x^s\eta\|_{L^q}\\ &\qquad+|\eta|_{C^1}\left(|\partial_x^s\eta|_{L^\infty}\,\|\partial_x\xi\|_{L^q}+|\xi|_{L^\infty}\left\|\partial_x^{s-1}\eta\right\|_{L^q}\right)\\ &\qquad+(p-1)\,|\eta|_{C^2}\,(|\partial_x^s\eta|_{L^\infty}\,\|\partial_x\xi\|_{L^q}+|\xi|_{L^\infty}\,\|\partial_x^s\eta\|_{L^q})\}\,.\end{aligned}$$

Once again, without being careful about derivatives one can make the appropriate estimate given the choice of s. □

Finally, we are in a position to establish the analyticity of the singular integral operators C_p in one and two dimensions in the appropriate function spaces.

THEOREM 5.20. *If $d=1$, $\eta \in W^{s+1,q}$, and $s > \max(\frac{1}{q},2)$, then the singular integral operator $C_p(\eta)$ is bounded on $W^{s,q}$ and*

$$\|C_p(\eta)\;\xi\|_{W^{s,q}} \leq C\,\|\eta\|_{W^{s+1,q}}^p\,\|\xi\|_{W^{s,q}}\,. \tag{5.27}$$

Furthermore, the operator $C_p(\eta)$ is analytic as a mapping on $W^{s,q}$ and thus its Taylor series converges in operator norm. If $d=2$, $\eta \in W^{s+2,q}$, and $s > \max(\frac{2}{q},3)$, then the singular integral operator $C_p(\eta)$ is bounded on $W^{s,q}$ and

$$\|C_p(\eta)\;\xi\|_{W^{s,q}} \leq C\,\|\eta\|_{W^{s+2,q}}^p\,\|\xi\|_{W^{s,q}}\,. \tag{5.28}$$

Furthermore, the operator $C_p(\eta)$ is analytic as a mapping on $W^{s,q}$ and thus its Taylor series converges in operator norm.

Proof. The idea behind the proof is to expand the analytic function $c_p(z)$ in its Taylor series expansion to reduce C_p to an infinite sum of operators S_p which have the appropriate decay. In brief we write

$$\begin{aligned}C_p(\eta)\;\xi(x) &= \int k(x,y)c_p(q_1)\xi(y)\,dy\\ &= \sum_{l=p}^\infty \frac{c_p^{(l)}(0)}{l!}S_p(\eta,\ldots,\eta)\;\xi(x).\end{aligned}$$

The proof now proceeds in exactly the same manner as in W. Craig, U. Schanz, and C. Sulem [7] or D. Nicholls [19], where we use Theorem 5.18 rather than the $C^{s+1} - W^{s,q}$ estimates of these papers. ∎

For the smoothing integral operators $C_{p,h}$ there is a development which can be followed which is very similar to, though not as delicate as, the one presented above for the singular integral operators C_p. Due to the choices of s which we will make, the estimates which we need have already been established by W. Craig, U. Schanz, and C. Sulem in two dimensions [7], and in d dimensions by D. Nicholls [19]. We state the result for completeness, and present the corollary which we use.

THEOREM 5.21. *Let $p+\rho+\lambda > d$, and suppose that $|\eta|_{L^\infty} < hR_0$ and $|\eta|_{C^s} < \infty$. Then $C_{p,h}$ is bounded from L^q to $W^{s,q}$ and*

$$\|C_{p,h}(\eta)\ \xi\|_{W^{s,q}} < C\,|\eta|_{L^\infty}^{p-1}\,|\eta|_{C^s}\,\|\xi\|_{L^q}\,. \tag{5.29}$$

Furthermore, the operator $C_{p,h}$ is analytic as a mapping from L^q to $W^{s,q}$ in the set

$$\{\eta \mid |\eta|_{L^\infty} < hR_0 \text{ and } |\eta|_{C^s} < \infty\}. \tag{5.30}$$

Consequently, $C_{p,h}$ is represented by its Taylor series expansion.

The corollary that we use is the following.

COROLLARY 5.22. *If $d = 1$, $\eta \in W^{s+1,q}$, and $s > \max(\frac{1}{q}, 2)$, then the smoothing integral operator $C_{p,h}$ is bounded from L^q to $W^{s,q}$ and*

$$\|C_{p,h}(\eta)\ \xi\|_{W^{s,q}} < C\,\|\eta\|_{W^{s+1,q}}^{p}\,\|\xi\|_{L^q}\,. \tag{5.31}$$

Furthermore, the operator $C_{p,h}$ is analytic as a mapping from L^q to $W^{s,q}$ and thus is represented by its Taylor series expansion. If $d = 2$, $\eta \in W^{s+2,q}$, and $s > \max(\frac{2}{q}, 3)$, then the smoothing integral operator $C_{p,h}$ is bounded from L^q to $W^{s,q}$ and

$$\|C_{p,h}(\eta)\ \xi\|_{W^{s,q}} < C\,\|\eta\|_{W^{s+2,q}}^{p}\,\|\xi\|_{L^q}\,. \tag{5.32}$$

Furthermore, the operator $C_{p,h}$ is analytic as a mapping from L^q to $W^{s,q}$ and thus is represented by its Taylor series expansion.

STABILITY AND HOPF BIFURCATION FOR FULLY NONLINEAR PARABOLIC-HYPERBOLIC EQUATIONS*

HERBERT KOCH† AND STUART S. ANTMAN‡

Abstract. We develop the principle of linearized stability and a Hopf bifurcation theorem as elements of a geometric theory for fully nonlinear parabolic-hyperbolic problems. Crucial steps in our work are showing the differentiability of the time-t map, showing that the admissible initial data form a manifold (whose failure to be linear is due to the general boundary conditions we study), and analyzing the spectrum of the generator of the linearized semigroup. This paper provides the abstract framework for the study of a class of concrete problems of self-sustained oscillations of nonlinearly viscoelastic bodies like that treated by Antman and Koch [*SIAM J. Appl. Math.*, 60 (2000), pp. 1357–1387]. Our equations are intrinsically interesting: They provide an example of a new kind of semiflow that combines properties of ordinary differential equations and parabolic equations in a novel way.

Key words. Hopf bifurcation, linearized stability, fully nonlinear parabolic-hyperbolic equations, oblique boundary conditions, nonlinear viscoelasticity

1. Introduction.

In this paper we extend the so-called geometrical theory of parabolic equations of Henry [13] to fully nonlinear parabolic-hyperbolic equations with fully nonlinear boundary conditions, which include oblique boundary conditions. We establish well-posedness and determine the structure of the local semiflow near an equilibrium. A main motivation for the theory we develop is to treat self-sustained oscillations of nonlinearly viscoelastic solids (cf. [7]). A feature of such problems, which is illustrated in our examples, is that the boundary conditions have a very rich structure.

Notation. Lower-case boldface symbols represent n-tuples of real numbers, e.g., $\mathbf{x} = (x_1, \dots, x_n)$, or functions with values in $\mathbb{R}^n$. Upper-case boldface symbols represent $n \times n$ matrices, e.g., $\mathbf{Q} = (q_{ij})$, or functions with such values. We denote the $\frac{1}{2}n(n+1)$-dimensional space of symmetric $n \times n$ matrices by Sym^n. The zero and identity matrices are denoted $\mathbf{O}$ and $\mathbf{I}$. We denote the inner product of two n-tuples $\mathbf{a}$ and $\mathbf{b}$ by $\mathbf{a} \cdot \mathbf{b} \equiv \sum_{j=1}^n a_j b_j$ and denote the inner product of two $n \times n$ matrices $\mathbf{A}$ and $\mathbf{B}$ by $\mathbf{A} : \mathbf{B} \equiv \sum_{j,k=1}^n A_{jk} B_{jk}$. We also set $\mathbf{A} : \mathbf{ab} \equiv \mathbf{a} \cdot \mathbf{A} \cdot \mathbf{b} \equiv \sum_{j,k=1}^n A_{jk} a_j b_k$. Any matrix $\mathbf{A}$, symmetric or not, is said to be *positive-definite* if its quadratic form $\mathbf{a} \cdot \mathbf{A} \cdot \mathbf{a}$ (which only involves the symmetric part of $\mathbf{A}$) is positive-definite. We denote the (infrequently used) zero third-order tensor by $\mathbf{O}$.

The gradient $(\partial u/\partial x_1, \dots, \partial u/\partial x_n)$ of a scalar-valued function u of $\mathbf{x}$ is denoted by $u_{\mathbf{x}}$. Likewise, the matrix $\left(\partial^2 u/\partial x_i \partial x_j\right)$ of second partial derivatives of u with respect to $\mathbf{x}$ is denoted by $u_{\mathbf{xx}}$. The gradient of a scalar-valued function F with

respect to a symmetric matrix argument $\mathbf{Q}$ is the symmetric matrix denoted by $F_{\mathbf{Q}}$. It is defined to be the unique symmetric matrix $\mathbf{A}$ such that $\partial_\varepsilon F(\mathbf{Q}+\varepsilon\mathbf{B})|_{\varepsilon=0} = \mathbf{A}:\mathbf{B}$ for all symmetric $\mathbf{B}$. We employ obvious generalizations of these conventions.

Let $\mathcal{A}$ and $\mathcal{B}$ be open subsets of Banach spaces, let $k \geq 0$ be an integer, and let $\sigma \in (0,1]$. Then $C^k(\mathcal{A},\mathcal{B})$ denotes the space of all k-times continuously differentiable functions from $\mathcal{A}$ to $\mathcal{B}$. If $\mathcal{A}$ and $\mathcal{B}$ are subsets of $\mathbb{R}^n$, then $C^{k,\sigma}(\mathcal{A},\mathcal{B})$ denotes the space of all k-times continuously differentiable functions from $\mathcal{A}$ to $\mathcal{B}$ whose kth order derivatives are Hölder continuous with exponent σ. When $\mathcal{B}$ is obvious, we suppress it. We extend this notation in the obvious way if $\mathcal{A}$ is contained in the closure of its interior.

We now formulate our initial-boundary-value problem. Let $\Omega \subset \mathbb{R}^n$ be a bounded domain with smooth boundary Γ and let T be a positive number. We set $\Omega_T = \Omega \times [0,T)$ and $\Gamma_T = \Gamma \times [0,T)$. We shall study an initial-boundary-value problem for a scalar-valued function $\Omega \times [0,T] \ni (\mathbf{x},t) \mapsto u(\mathbf{x},t)$. Let $\mathcal{I}$ be an interval containing 0 and let ζ be a parameter in $\mathcal{I}$. The domains of the functions defining the differential equation and the boundary condition for our problem are

$$\mathcal{F} = \bar{\Omega} \times (\mathbb{R} \times \mathbb{R}^n \times \mathrm{Sym}^n)^2 \times \mathcal{I}, \quad \mathcal{B} = \Gamma \times (\mathbb{R} \times \mathbb{R}^n)^2 \times \mathcal{I}. \tag{1.1}$$

We are given the functions

$$\mathcal{F} \ni (\mathbf{x},u,\mathbf{p},\mathbf{Q},\dot{u},\dot{\mathbf{p}},\dot{\mathbf{Q}},\zeta) \mapsto F(\mathbf{x},u,\mathbf{p},\mathbf{Q},\dot{u},\dot{\mathbf{p}},\dot{\mathbf{Q}},\zeta) \in C^{k+1}(\mathcal{F},\mathbb{R}), \tag{1.2a}$$

$$\mathcal{B} \ni (\mathbf{x},u,\mathbf{p},\dot{u},\dot{\mathbf{p}},\zeta) \mapsto B(\mathbf{x},u,\mathbf{p},\dot{u},\dot{\mathbf{p}},\zeta) \in C^{k+2}(\mathcal{B},\mathbb{R}). \tag{1.2b}$$

In (1.2) the dots appearing over u, $\mathbf{p}$, $\mathbf{Q}$ have no operational significance; the symbols $\dot{u}$, $\dot{\mathbf{p}}$, $\dot{\mathbf{Q}}$ merely identify the arguments to be filled by functions that are the derivatives of the functions filling the slots occupied by u, $\mathbf{p}$, $\mathbf{Q}$.

We study the initial-boundary-value problem

$$u_{tt} - F(\mathbf{x},u,u_{\mathbf{x}},u_{\mathbf{xx}},u_t,u_{\mathbf{x}t},u_{\mathbf{xx}t},\zeta) = 0 \quad \text{in } \Omega_T, \tag{1.3a}$$

$$B(\mathbf{x},u,u_{\mathbf{x}},u_t,u_{\mathbf{x}t},\zeta) = 0 \quad \text{on } \Gamma_T, \tag{1.3b}$$

$$u(\cdot,0) = u_0(\cdot) \quad \text{in } \Omega, \tag{1.3c}$$

$$u_t(\cdot,0) = u_1(\cdot) \quad \text{in } \Omega. \tag{1.3d}$$

Note that (1.3b) can be specialized to a Dirichlet condition in which u is prescribed, or to a Neumann condition in which the normal derivative of u is prescribed, or to a mixed condition in which the normal derivative of u is a prescribed function of u. For the applications we want to treat, we need much of the generality of (1.3b), which we may term an *oblique* boundary condition because it involves derivatives other than normal derivatives to Γ_T in space-time. Of course, the nature of the boundary condition can vary from point to point on the boundary, but our smoothness assumptions in (1.2b) prevent, e.g., a Dirichlet condition being specified on a region of Γ_T that touches another such region on which a Neumann condition is specified. In our applications in section 2, Γ is a union of disjoint hypersurfaces in $\mathbb{R}^n$. For such Γ's we can prescribe different kinds of boundary conditions on each component.

For interpreting semiflows and semigroups, it is convenient to replace (1.3) with an equivalent system for the pair $(u,\dot{u})$ containing only first derivatives with respect to t:

$$
\begin{aligned}
u_t - \dot{u} &= 0 && \text{in } \Omega_T,\\
\dot{u}_t - F(\mathbf{x}, u, u_{\mathbf{x}}, u_{\mathbf{xx}}, \dot{u}, \dot{u}_{\mathbf{x}}, \dot{u}_{\mathbf{xx}}, \zeta) &= 0 && \text{in } \Omega_T,\\
B(\mathbf{x}, u, u_{\mathbf{x}}, \dot{u}, \dot{u}_{\mathbf{x}}, \zeta) &= 0 && \text{on } \Gamma_T,\\
u(\cdot, 0) &= u_0(\cdot) && \text{in } \Omega,\\
\dot{u}(\cdot, 0) &= u_1(\cdot) && \text{in } \Omega.
\end{aligned} \tag{1.4}
$$

Our basic assumption for ensuring that (1.3) or (1.4) be dissipative is the following.

HYPOTHESIS 1.1. *The symmetric matrix $F_{\dot{\mathbf{Q}}}$ is positive-definite. The vector $B_{\dot{\mathbf{p}}}$ is transversal to Γ.*

The basic result that enables us to talk about solutions to this problem and to formulate conditions for their periodicity is the following.

THEOREM 1.2. *Let Hypothesis* 1.1 *hold and let $u_0, u_1 \in C^{2,\sigma}(\bar{\Omega})$ satisfy the compatibility condition*

$$
B(\mathbf{x}, u_0, u_{0\mathbf{x}}, u_1, u_{1\mathbf{x}}) = 0 \quad \textit{for} \quad \mathbf{x} \in \Gamma. \tag{1.5}
$$

Then for T sufficiently small, there exists a unique solution to (1.3) *for which u_{tt} and $u_{\mathbf{x}\mathbf{x}t}$ are Hölder continuous.*

The corresponding solution $(u, \dot{u})$ of (1.4) is denoted

$$
(u(\cdot, t), \dot{u}(\cdot, t)) = \boldsymbol{\phi}(t, u_0, u_1, \zeta). \tag{1.6}
$$

In section 2, we give some examples of quasi-linear equations of the form (1.3) from solid mechanics. We prove a linearized stability principle (Theorem 3.6) and a Hopf bifurcation theorem (Theorem 3.8) under further assumptions on the dependence on the parameter ζ of solutions of the linearization of (1.3) about a steady solution, but we postpone to section 3 a detailed statement of the results because they depend on the introduction of further technical concepts. Section 3, the last of the three introductory sections, gives precise statements of these and other theorems, and organizes the logical structure of the paper.

During the last two decades, there has been an extensive development of the geometrical theory for partial differential equations. We mention the theory for weak solutions for quasilinear parabolic equations of Amann and the work on parabolic equations of Lunardi. See Amann [2], [3], [4] and Lunardi [19], which contain extensive references.

The theory of parabolic-hyperbolic equations can be subsumed under the theory of analytic semigroups for nonlinear equations. Nevertheless, the semiflows for parabolic-hyperbolic equations are strikingly different from those for parabolic equations. In particular, local semiflows for parabolic-hyperbolic equations do not regularize, although the autonomous linearized problem still defines an analytic semigroup.

We treat initial data that merely form a Banach manifold, rather than a Banach space, in order to accommodate general boundary conditions of the sort that arise in the concrete applications described in section 2. It consequently seems that neither our problem nor corresponding problems for purely parabolic equations can be treated by the available abstract methods for the latter, because these methods cannot handle general boundary conditions (1.3b) under natural structure conditions. We derive geometric properties of the local semiflow by first establishing differentiability of the semiflow.

The semiflow is not compact because the spectrum of the generator of the semigroup for linear equations contains points other than eigenvalues of finite multiplicity.

The control of this additional spectrum is very delicate. Even for scalar equations, we need the deep results of Agmon, Douglis, and Nirenberg [1] to clarify the behavior of the essential spectrum.

We also need a new proof of the Hopf bifurcation theorem that is closer to the original proof of Hopf [14] (see Howard and Kopell [15]) than to those used by Crandall and Rabinowitz [9] or Guckenheimer and Holmes [12]: We characterize solutions of period T by

$$\boldsymbol{\phi}(T, u, \dot{u}, \zeta) = (u, \dot{u}). \tag{1.7}$$

We use bifurcation methods to solve this equation. Obviously this approach only requires regularity of the semiflow $\boldsymbol{\phi}$ together with the usual conditions on the spectrum (but now formulated for the linearized semigroup).

Our major concerns are showing that the admissible initial data form a Banach manifold, which is generally not a Banach space, demonstrating the regularity of the flow, and controlling the spectrum of the semigroup generated by linear equations. In confronting these issues, we strive to make the exposition as flexible as possible.

We restrict our attention to scalar equations. It is, however, clear that the same arguments apply as well for general systems with mixed Dirichlet–Neumann boundary conditions. The requisite modifications will be discussed where they are necessary. The optimal smoothness of the constitutive functions F and B is of minor importance. Only in Theorem 3.3 do we bother to impose smoothness assumptions that require a treatment different from that for C^∞ constitutive functions.

For simplicity, we consider only strong solutions in the Hölder spaces $C^{2,\sigma}$, neglecting the available divergence structure in the physical models. The arguments can easily be adapted to weak solutions. The crucial results of Agmon, Douglis, and Nirenberg [1] and Solonnikov [24], however, are not available in that generality for weak solutions, though similar estimates for weak solutions no doubt hold under appropriate conditions.

2. Examples. We now give some examples of quasilinear problems for nonlinearly viscoelastic bodies, to which our theory can readily be applied.

2.1. Shearing of a viscoelastic layer due to friction on its face. Let $u(x,t)$ denote the displacement transverse to the x-axis of a layer of an incompressible viscoelastic material of strain-rate type. Then u satisfies

$$\begin{aligned} &\rho(x)u_{tt} = \sigma(u_x, u_{xt}, x)_x, \\ u(0,t) = 0, \qquad &\sigma(u_x(1,t), u_{xt}(1,t), 1) = f(\zeta - u_t(1,t)), \end{aligned} \tag{2.1}$$

where ρ is the density, where σ is the given constitutive function delivering the shear stress with $\sigma_b(a,b,x) \geq \text{const} > 0$ for all a, b, x, and where $-f(v)$ is the given friction force produced by a belt moving on the boundary $x = 1$ with velocity v relative to that of the viscoelastic layer. Here ζ is the actual speed of the belt. This problem for f of stick-slip type is treated in [7].

2.2. Antiplane shearing of a viscoelastic tube due to friction on one bounding surface. A version of (2.1) with two independent spatial variables $(x_1, x_2) = \mathbf{x}$ corresponds to the antiplane motion of an infinite viscoelastic tube with a (doubly-

connected) cross section Ω lying between bounding curves $\mathcal{S}_1$ and $\mathcal{S}_2$:

$$\begin{aligned} \rho(\mathbf{x})u_{tt} &= \frac{\partial}{\partial x_1}\sigma_1(u_{\mathbf{x}}, u_{\mathbf{x}t}, \mathbf{x}) + \frac{\partial}{\partial x_2}\sigma_2(u_{\mathbf{x}}, u_{\mathbf{x}t}, \mathbf{x}), \\ u(\mathbf{x}, t) &= 0 \quad \text{for} \quad \mathbf{x} \in \mathcal{S}_1, \\ \nu_1\sigma_1(u_{\mathbf{x}}, u_{\mathbf{x}t}, \mathbf{x}) + \nu_2\sigma_2(u_{\mathbf{x}}, u_{\mathbf{x}t}, \mathbf{x}) &= f(\zeta - u_t(\mathbf{x}, t), \mathbf{x}) \quad \text{for} \quad \mathbf{x} \in \mathcal{S}_2, \end{aligned} \tag{2.2}$$

where σ_1 and σ_2 are given constitutive functions satisfying Hypothesis 1.1, and where (ν_1, ν_2) is the unit outer normal to $\mathcal{S}_2$.

Problems in nonlinear solid mechanics, like these, in which there is but one dependent variable are rare. Typically, there are several dependent variables, as in the version of problem (2.1) for compressible materials and as in the following example.

2.3. Beck's problem for an extensible, shearable, nonlinearly viscoelastic rod. We study the deformation in a plane of a naturally straight rod of scaled unit length 1. Let $\boldsymbol{i}, \boldsymbol{j}$ be an orthonormal pair of vectors. In our model, a configuration of the rod at time t is specified by a curve $[0,1] \ni x \mapsto \boldsymbol{r}(x,t) \in \operatorname{span}\{\boldsymbol{i}, \boldsymbol{j}\}$ and a unit-vector field $[0,1] \ni x \mapsto \boldsymbol{a}(\theta(x,t)) \equiv \cos\theta(x,t)\,\boldsymbol{i} + \sin\theta(x,t)\,\boldsymbol{j}$. The vector $\boldsymbol{r}(x,t)$ may be interpreted as the position at time t of a material point lying along the line of centroids of the rod in its straight, natural configuration at a distance x from one end. The vector $\boldsymbol{a}(\theta(x,t))$ may be interpreted as the unit normal at time t to the deformed image of the section at x. We set $\boldsymbol{b}(\theta(x,t)) = -\sin\theta(x,t)\boldsymbol{i} + \cos\theta(x,t)\,\boldsymbol{j}$. If the rod is viscoelastic of strain-rate type and if the only loads on it are applied at its ends, then its geometrically exact equations of motion have the form

$$\begin{aligned} A(x)\boldsymbol{r}_{tt} &= [N(\nu, \eta, \theta_x, \nu_t, \eta_t, \theta_{xt}, x)\boldsymbol{a}(\theta) + H(\nu, \eta, \theta_x, \nu_t, \eta_t, \theta_{xt}, x)\boldsymbol{b}(\theta)]_x, \\ I(x)\theta_{tt} &= [M(\nu, \eta, \theta_x, \nu_t, \eta_t, \theta_{xt}, x)]_x \\ &\quad + \nu H(\nu, \eta, \theta_x, \nu_t, \eta_t, \theta_{xt}, x) - \eta N(\nu, \eta, \theta_x, \nu_t, \eta_t, \theta_{xt}, x), \end{aligned} \tag{2.3}$$

where

$$\nu \equiv \boldsymbol{r}_x \cdot \boldsymbol{a}, \qquad \eta \equiv \boldsymbol{r}_x \cdot \boldsymbol{b},$$

where A and I are given positive-valued functions and where

$$(\nu, \eta, \mu, \dot\nu, \dot\eta, \dot\mu, x) \mapsto N(\nu, \eta, \mu, \dot\nu, \dot\eta, \dot\mu, x), H(\nu, \eta, \mu, \dot\nu, \dot\eta, \dot\mu, x), M(\nu, \eta, \mu, \dot\nu, \dot\eta, \dot\mu, x)$$

are given constitutive functions with (the symmetric part of)

$$\begin{pmatrix} N_{\dot\nu} & N_{\dot\eta} & N_{\dot\mu} \\ H_{\dot\nu} & H_{\dot\eta} & H_{\dot\mu} \\ M_{\dot\nu} & M_{\dot\eta} & M_{\dot\mu} \end{pmatrix}$$

uniformly positive-definite. When their arguments are evaluated at (x,t), $H\boldsymbol{a} + H\boldsymbol{b}$ is the contact force and M is the contact couple exerted at time t by the material to the right of x on the material to the left of x. We assume that the end $x = 0$ of the rod is welded to the normal to $\boldsymbol{i}$ at $\mathbf{0}$, so that

$$\boldsymbol{r}(0,t) = \mathbf{0}, \qquad \theta(0,t) = 0. \tag{2.4}$$

We assume that the end $x = 1$ is hinged and is subject to a compressive follower load of magnitude ζ which always acts normal to the section at $x = 1$, so that

$$\begin{aligned} N(\nu(1,t), \eta(1,t), \theta_x(1,t), \nu_t(1,t), \eta_t(1,t), \theta_{xt}(1,t), 1) &= -\zeta, \\ H(\nu(1,t), \eta(1,t), \theta_x(1,t), \nu_t(1,t), \eta_t(1,t), \theta_{xt}(1,t), 1) &= 0, \\ M(\nu(1,t), \eta(1,t), \theta_x(1,t), \nu_t(1,t), \eta_t(1,t), \theta_{xt}(1,t), 1) &= 0. \end{aligned} \tag{2.5}$$

It is this interesting boundary condition and variants thereof that characterize Beck's problem. (For a discussion of the formulation of this problem, its generalizations to deformations in space, and some of the elementary properties of its solutions, see Antman [5] and Antman and Kenney [6].)

3. Outline and main results. We now give a detailed account of our results and methods.

Let $\mathcal{Z}$ be a topological space of parameters ζ. Let $\mathcal{X}$ be a Hausdorff space. For each $\zeta \in \mathcal{Z}$, let $\mathcal{U}(\zeta)$ be a subset of $\mathcal{X}$, whose elements $\mathbf{z}$ we shall identify with the pair (u_0, u_1). A *parametrized local semiflow* on $\mathcal{U} = \{(\mathbf{z}, \zeta) : \mathbf{z} \in \mathcal{U}(\zeta), \zeta \in \mathcal{Z}\}$ is a function pair $(\boldsymbol{\phi}, \hat{T})$, where $\hat{T}(\cdot, \zeta)$ is a lower-semicontinuous positive-valued function from $\mathcal{U}(\zeta)$ to the extended real line, with

$$\begin{gathered}\boldsymbol{\phi} \in C(\{(t, \mathbf{z}) : \mathbf{z} \in \mathcal{U},\ 0 \le t < \hat{T}(\mathbf{z}, \zeta)\},\ \mathcal{U}(\zeta)),\\ \hat{T}(\boldsymbol{\phi}(t, \mathbf{z}, \zeta)) + t = \hat{T}(\mathbf{z}, \zeta) \quad \text{if} \quad 0 \le t < \hat{T}(\mathbf{z}, \zeta),\\ \boldsymbol{\phi}(0, \mathbf{z}, \zeta) = \mathbf{z},\\ \boldsymbol{\phi}(t + s, \mathbf{z}, \zeta) = \boldsymbol{\phi}(s, \boldsymbol{\phi}(t, \mathbf{z}, \zeta), \zeta) \quad \text{if} \quad s + t < \hat{T}(\mathbf{z}, \zeta).\end{gathered}$$

$\hat{T}(\mathbf{z}, \zeta)$ is the *life span* of the trajectory $\boldsymbol{\phi}(\cdot, \mathbf{z}, \zeta)$ starting at $\mathbf{z}$ at time $t = 0$.

For $\sigma \in (0, 1]$, let $h^{k,\sigma}$ be the closure of C^∞ in $C^{k,\sigma}$ and let

$$\mathcal{H}^{2,\sigma}(\zeta) = \{(u_0, u_1) \in (h^{2,\sigma})^2 : B(\mathbf{x}, u_0, u_{0\mathbf{x}}, u_1, u_{1\mathbf{x}}, \zeta) = 0 \text{ if } \mathbf{x} \in \Gamma\}. \tag{3.1}$$

Let us identify $\mathbf{z} = (u_0, u_1)$, $\mathcal{U}(\zeta) = \mathcal{H}^{2,\sigma}(\zeta)$, and $\mathcal{Z} = \mathcal{I}$ where $\mathcal{I}$ is an interval of $\mathbb{R}$ containing 0. We shall prove the following more precise variant of Theorem 1.2 below.

THEOREM 3.1. *Problem* (1.4) *defines a parametrized local semiflow* $\boldsymbol{\phi}$ *on* $\mathcal{U}$.

A crucial ingredient for a geometric theory is a differentiable structure on $\mathcal{H}^{2,\sigma}(\zeta)$ and on $\mathcal{U}$. We say that a subset $\mathcal{E}$ of a Banach space $\mathcal{X}$ is a *C^k-Banach submanifold* of $\mathcal{X}$ if there is a Banach space $\mathcal{Y}$, a C^k map $\mathcal{X} \ni \mathbf{w} \mapsto \psi(\mathbf{w}) \in \mathcal{Y}$ with its derivative $\psi_{\mathbf{w}}$ surjective, and a linear injective map $L : \mathcal{Y} \to \mathcal{X}$ such that

$$\mathcal{E} = \psi^{-1}(\{0\}), \quad \mathcal{X} = [\psi_{\mathbf{w}}(\mathbf{w})]^{-1}(\{0\}) \oplus L(\mathcal{Y}) \quad \text{for all } \mathbf{w} \in \mathcal{E}. \tag{3.2}$$

In general, one should localize this notion, and for global considerations, one should require paracompactness, weak continuity, or both. This global naive definition however suffices for our purposes because we want to carry out a local analysis by using the chain rule, the implicit-function theorem, and the contraction-mapping principle. It is a simple exercise to show that classical constructions for finite-dimensional manifolds provide local structure maps in our setting. The map L always exists if $\mathcal{X}$ is finite-dimensional. At the level considered in this paper, the main difference between finite-dimensional and infinite-dimensional subspaces consists in the necessity of requiring the existence of L ab initio for the latter: Submanifolds certainly do not have better properties than linear subspaces, which do not necessarily have complementing subspaces.

THEOREM 3.2. *The set* $\mathcal{U} = \{(\mathbf{z}, \zeta) : \mathbf{z} \in \mathcal{H}^{2,\sigma}(\zeta),\ \zeta \in \mathcal{Z}\}$ *is a* C^k *Banach submanifold of* $(h^{2,\sigma})^2 \times \mathcal{I}$ *(in consequence of the choices* $\mathcal{Y} = h^{1,\sigma}(\Gamma)$, $\psi(u, v; \zeta) := B(\mathbf{x}, u, u_{\mathbf{x}}, v, v_{\mathbf{x}}; \zeta)$, *and* $Lg = (0, w, 0)$, *where* $w|_\Gamma = 0$ *and* $\boldsymbol{\nu} \cdot w_{\mathbf{x}} = g$ *on* Γ*). Moreover,* $\mathcal{H}^{2,\sigma}(\zeta)$ *is a* C^k*-Banach submanifold of* $h^{2,\sigma}$ *for all* ζ *with the same space* $\mathcal{Y}$ *and the same operator* L *for all* ζ *and structure maps depending continuously on* ζ, *i.e., the map* $\mathcal{I} \ni \zeta \mapsto \psi(\cdot, \zeta) \in C^1$ *is continuous.*

We now describe the regularity of the semiflow. On Ω_T we define Hölder spaces $C_{\mathrm{P}}^{j,\sigma}(\Omega_T)$, $j = 0, 1, 2$, for parabolic equations by the norms

(3.3a)
$$\|u\|_{C_{\mathrm{P}}^{0,\sigma}(\Omega_T)} = \max\left\{\|u\|_\infty, \sup_{0<|\mathbf{x}-\mathbf{y}|^2+|t-s|\le 1}\left\{\frac{|u(\mathbf{x},t)-u(\mathbf{y},s)|}{(|\mathbf{x}-\mathbf{y}|^2+|t-s|)^{\sigma/2}}\right\}\right\},$$

(3.3b)
$$\|u\|_{C_{\mathrm{P}}^{1,\sigma}(\Omega_T)} = \max\left\{\|u\|_\infty, \|u_{\mathbf{x}}\|_{C_{\mathrm{P}}^{0,\sigma}(\Omega_T)}, \sup_{\mathbf{x},\,0<|t-s|\le 1}\left\{\frac{|u(\mathbf{x},t)-u(\mathbf{x},s)|}{|t-s|^{(1+\sigma)/2}}\right\}\right\},$$

(3.3c)
$$\|u\|_{C_{\mathrm{P}}^{2,\sigma}(\Omega_T)} = \max\left\{\|u\|_\infty, \|u_t\|_{C_{\mathrm{P}}^{0,\sigma}(\Omega_T)}, \|u_{\mathbf{x}}\|_{C_{\mathrm{P}}^{1,\sigma}(\Omega_T)}\right\}.$$

Denote the closures of C^∞ in $C_{\mathrm{P}}^{j,\sigma}$ by $h_{\mathrm{P}}^{j,\sigma}$. We set

$$Y^{2,\sigma}(\Omega_T) = \{u : u, u_t \in h_{\mathrm{P}}^{2,\sigma}(\Omega_T)\} \tag{3.4a}$$

with the norm

$$\|u\|_{Y^{2,\sigma}} = \max\{\|u\|_{C_{\mathrm{P}}^{2,\sigma}}, \|u_t\|_{C_{\mathrm{P}}^{2,\sigma}}\}. \tag{3.4b}$$

THEOREM 3.3. *The local semiflow $\boldsymbol{\phi}$ for* (1.3) *is of class C^k, i.e., for $(u_0, u_1) \in \mathcal{H}^{2,\sigma}(\zeta)$, there is a neighborhood $\mathcal{V}$ of (u_0, u_1, ζ) in $\mathcal{U}$ and a $t_0 > 0$ such that*

$$[(v_0, v_1, \zeta) \mapsto \boldsymbol{\phi}(\cdot, v_0, v_1, \zeta)] \in C^k(\mathcal{V}, Y^{2,\sigma}(\Omega_{t_0})), \tag{3.5a}$$
$$\boldsymbol{\phi}(\cdot,\cdot,\cdot,\zeta)|_{(0,t_0)\times\mathcal{V}} \in C^k(\mathcal{U}\times(0,t_0), (C^{2,\sigma}(\Omega))^2). \tag{3.5b}$$

We continue with the study of the semiflow near a fixed point. Suppose that $u^0(\cdot,\zeta) \in C^3(\bar\Omega)$ is a stationary solution of (1.3). The linearization of (1.3) about u^0 is

$$v_{tt} - \mathbf{G} : v_{\mathbf{xx}} - \mathbf{g}\cdot v_{\mathbf{x}} - \gamma v - \mathbf{H} : v_{\mathbf{x}\mathbf{x}t} - \mathbf{h}\cdot v_{\mathbf{x}t} - \eta v_t = 0 \quad \text{in } \Omega_T, \tag{3.6a}$$
$$\mathbf{a}\cdot v_{\mathbf{x}} + \alpha v + \mathbf{b}\cdot v_{\mathbf{x}t} + \beta v_t = 0 \quad \text{on } \Gamma_T, \tag{3.6b}$$
$$v(\cdot,0) = v_0(\cdot) \quad \text{in } \Omega, \tag{3.6c}$$
$$v_t(\cdot,0) = v_1(\cdot) \quad \text{in } \Omega, \tag{3.6d}$$

where

$$\begin{array}{lll} \mathbf{G} \equiv F_{\mathbf{P}}, & \mathbf{g} \equiv F_{\mathbf{p}}, & \gamma \equiv F_u, \\ \mathbf{H} \equiv F_{\dot{\mathbf{P}}}, & \mathbf{h} \equiv F_{\dot{\mathbf{p}}}, & \eta \equiv F_{\dot u}, \\ & \mathbf{a} \equiv B_{\mathbf{p}}, & \alpha \equiv B_u, \\ & \mathbf{b} \equiv B_{\dot{\mathbf{p}}}, & \beta \equiv B_{\dot u}, \end{array} \tag{3.6e}$$

where the arguments of F and its derivatives are

$$(\mathbf{x}, u^0(\mathbf{x},\zeta), u^0_{\mathbf{x}}(\mathbf{x},\zeta), u^0_{\mathbf{xx}}(\mathbf{x},\zeta), 0, \mathbf{0}, \mathbf{O}, \zeta)$$

and those of B and its derivatives are

$$(\mathbf{x}, u^0(\mathbf{x},\zeta), u^0_{\mathbf{x}}(\mathbf{x},\zeta), 0, \mathbf{0}, \zeta).$$

Just as in (1.3), we can replace this problem with one containing just first derivatives with respect to t. We make this replacement without comment.

We define

$$\mathcal{H}_0^{2,\sigma}(\zeta) = \left\{(v_0, v_1) \in (h^{2,\sigma})^2 : \ \mathbf{a} \cdot v_{0\mathbf{x}} + \alpha v_0 + \mathbf{b} \cdot \ v_{1\mathbf{x}} + \beta v_1 = 0 \quad \text{on} \quad \Gamma\right\}, \tag{3.7}$$

where the arguments of $\mathbf{a}, \alpha, \mathbf{b}, \beta$ are those just shown. Then we have the following.

THEOREM 3.4. *Problem* (3.6) *defines an analytic semigroup* $t \mapsto S(t;\zeta)$ *on* $\mathcal{H}_0^{2,\sigma}(\zeta)$.

Let $\Sigma(L)$ denote the spectrum of a linear operator L.

COROLLARY 3.5. *Denote the generator of* $S(\cdot,\zeta)$ *by* $A(\zeta)$. *Then*

$$\Sigma(S(t,\zeta)) = e^{\Sigma(tA(\zeta))} \cup \{0\}.$$

Remark. There is a small imprecision in our notation: In contrast to the situation for semigroups for parabolic equations, the spectrum of $A(\zeta)$ may depend on the space (as may happen for hyperbolic equations; see [8]). We shall see that this is not the case under the reasonable assumptions we shall impose, thereby justifying a posteriori the notation of the corollary. The corollary is an immediate consequence of analyticity, up to the statement that 0 is in the spectrum of the semigroup. This will be a consequence of Proposition 4.5 below.

THEOREM 3.6 (Principle of linearized stability). *The following statements are equivalent:*

(i) $\Sigma(A(\zeta)) \subset \{z \in \mathbb{C} : \Re\, z < 0\}$.

(ii) *The trivial solution of* (3.6) *is exponentially stable.*

(iii) *The stationary solution* u^0 *of* (1.3) *is exponentially stable, i.e., solutions of* (1.3) *starting sufficiently close to* u^0 *approach* u^0 *exponentially.*

These assertions are independent of the $\sigma \in (0,1]$ *appearing in* (3.7).

The equivalence of (i) and (ii) is contained in Corollary 3.5. The equivalence of (ii) and (iii) follows from the next lemma.

LEMMA 3.7. *Let* $w \mapsto \phi(w)$ *be a differentiable map of a neighborhood* $\mathcal{W}$ *of* 0 *in a Banach space* $\mathcal{X}$ *with* $\phi(0) = 0$. *Then* $S = \phi_w(0)$ *has its spectrum strictly inside the unit disk if and only if there exist a neighborhood* $\tilde{\mathcal{W}}$ *of* 0, *a positive number* c, *and a number* $\delta \in [0,1)$ *such that the iterated maps* ϕ^k *satisfy*

$$|\phi^k(v)| \le c\delta^k \tag{3.8}$$

for $\mathbf{x} \in \tilde{\mathcal{W}}$.

Proof. The assertion about the spectrum is equivalent to the existence of j and $\delta < 1$ such that $\|S^j w\| \le \delta \|w\|$. Similarly, (3.8) is equivalent to the existence of an invariant neighborhood $\tilde{W}$ of zero, of j, and of δ such that

$$\|\phi^j(w)\| \le \delta \|w\|$$

for $w \in \tilde{W}$. The assertion follows now by simple calculus considerations. There are no changes in the context of Banach manifolds. □

In the application to the proof of Theorem 3.6, ϕ is the evaluation of the semiflow $\boldsymbol{\phi}(\cdot,\cdot,\zeta)$ at the same time t.

The semigroup $S(\cdot;\zeta)$ has a generator $A(\zeta)$. We shall show that isolated eigenvalues of the generator depend differentiably on ζ. Then the conditions of the following theorem make sense.

THEOREM 3.8 (Hopf bifurcation theorem). *Let* (1.2a), (1.2b) *and Hypothesis* 1.1 *hold. Let* λ_0 *be a simple nonzero eigenvalue of* $A(0)$ *lying on the imaginary axis. Then there is an interval* (ζ_-, ζ_+) *containing* 0 *and a unique continuous function* $(\zeta_-, \zeta_+) \ni \zeta \mapsto \hat{\lambda}(\zeta)$ *such that* $\hat{\lambda}(0) = \lambda_0$ *and* $\hat{\lambda}(\zeta)$ *is an isolated simple eigenvalue of* $A(\zeta)$ *for each* $\zeta \in (\zeta_-, \zeta_+)$. *Moreover,* $\hat{\lambda} \in C^k(\zeta_-, \zeta_+)$. *Let* $v^{\pm}$ *be a basis for the eigenspace corresponding to the eigenvalues* $\pm\lambda_0$ *such that, with* $\lambda = i\mu$, $S(t)v^+ = \cos(t\mu)v^+ + \sin(t\mu)v^-$. *Suppose that:*

(i) *If there is an integer* n *such that* $n\lambda_0$ *is an eigenvalue of* $A(0)$, *then* $n = \pm 1$ (*this is the* weak nonresonance condition).

(ii) $\Re\, \lambda_\zeta(0) \neq 0$. (*This is the* transversality condition).

(iii) *There are only isolated eigenvalues of finite multiplicity of the generator on the closed right half space.* (*This is satisfied under mild assumptions on the constitutive functions.*)

Then there exist an interval $[0, \varepsilon_0)$ *and unique* C^k *maps*

$$[0, \varepsilon_0) \ni \varepsilon \mapsto \hat{u}(\cdot, \cdot; \varepsilon) \in C^{2,\alpha}_{\mathrm{P}}(\Omega \times \mathbb{R}),$$
$$\hat{T} : [0, \varepsilon_0) \to (0, \infty), \quad \hat{\zeta} : [0, \varepsilon_0) \to \mathbb{R}$$

such that $\hat{u}(\cdot, \cdot; \varepsilon)$ *and* $\hat{\zeta}(\varepsilon)$ *satisfy* (1.3), $\hat{u}(x, \cdot; \varepsilon)$ *has period* $\hat{T}(\varepsilon)$, *and*

$$\begin{gathered} \hat{T}(0) = 2\pi/|\lambda_0|, \quad \hat{T}'_\varepsilon(0) = 0, \qquad \hat{\zeta}(0) = 0, \quad \hat{\zeta}_\varepsilon(0) = 0, \\ \int_\Omega \hat{u}(\mathbf{x}, t; \varepsilon)v^+ = \varepsilon, \qquad \int_\Omega \hat{u}(\mathbf{x}, t; \varepsilon)v^- = 0. \end{gathered} \tag{3.9}$$

Moreover, every small solution of (1.3) *having period close to* $\hat{T}(0)$ *is given by a time shift of* $\hat{u}(\cdot, \cdot; \varepsilon)$.

Suppose that (i) *is replaced with the* strong nonresonance condition:

(iv) *If there is a real number* r *such that* $r\lambda_0$ *is an eigenvalue of* $A(0)$, *then* $r = \pm 1$.

Then every small periodic solution of (1.3) *is given by a time shift of* $\hat{u}(\cdot, \cdot; \varepsilon)$.

Let (ii), (iii), *and* (iv) *hold. If the trivial solution is stable for* $\zeta > 0$ *and if* $\hat{\zeta}_{\varepsilon\varepsilon}(0) > 0$ (*i.e., if the bifurcation is supercritical*), *then* $\hat{u}(\cdot, \cdot; \varepsilon)$ *is unstable. If the trivial solution is stable for* $\zeta > 0$ *and if* $\hat{\zeta}_{\varepsilon\varepsilon}(0) < 0$ (*i.e., if the bifurcation is subcritical*), *then* $\hat{u}(\cdot, \cdot; \varepsilon)$ *is stable. The remaining two cases are analogous.*

There are many normalizations for $u(\cdot, \cdot, \varepsilon)$ equivalent to (3.19), with the equivalence justified by the implicit-function theorem. The normalization (3.19) says that the orthogonal projection of $\tilde{u}(\cdot, \cdot, \varepsilon)$ onto the space spanned by v^+ and v^- lies on a given line parametrized by ε.

In order to carry out our analysis and to use Theorems 3.6 and 3.8, we need some general information about the nature of the spectrum. The spectrum in the right half space can be controlled under natural weak assumptions on the coefficients by using the regularity results of [1] together with the next proposition. To treat specific problems one requires detailed information about the point spectrum. This information is obtained for (2.1) in [7].

Consider the problem

$$(\mathbf{G} + \theta\mathbf{H}) : v_{\mathbf{xx}} = 0 \quad \text{in } \Omega, \tag{3.10a}$$
$$(\mathbf{b} + \theta\mathbf{a}) \cdot v_{\mathbf{x}} = 0 \quad \text{on } \Gamma. \tag{3.10b}$$

Let $\mathcal{R}$ be the unbounded component of the subset of $\mathbb{C}$ consisting of all θ such that problem (3.10) is elliptic in the sense of Agmon, Douglis, and Nirenberg.

PROPOSITION 3.9. *If $\theta \in \mathcal{R}$, then θ is also in $\mathcal{R}$ for small perturbations of the coefficients. There are only isolated eigenvalues of finite multiplicity of the generator of the semigroup defined by* (3.5) *in* $\mathcal{R}$.

For completeness we present an unusual feature of the semiflow, which we need only for the linear equation. It takes, however, only a slight additional effort to prove the following compactness result also for the nonlinear problem. Consider the problem

$$F(\mathbf{x}, u, u_{\mathbf{x}}, u_{\mathbf{xx}}, u_t, u_{t\mathbf{x}}, u_{t\mathbf{xx}}, \zeta) = \mu u_t \qquad \text{in } \Omega_T, \tag{3.11a}$$

$$B(\mathbf{x}, u, u_{\mathbf{x}}, u_t, u_{t\mathbf{x}}, \zeta) = 0 \qquad \text{on } \Gamma_T, \tag{3.11b}$$

$$u(\cdot, 0) = u_0(\cdot) \qquad \text{in } \Omega, \tag{3.11c}$$

where the term μu_t on the right-hand side is of minor importance. It is needed to prevent 0 from being in the spectrum of an operator with compact resolvent.

For $u_0 \in C^{2,\sigma}$ and fixed $\zeta \in \mathcal{I}$ there exists μ such that (3.11) defines a local flow $\boldsymbol{\psi}$ on $C^{2,\sigma}$ and $h^{2,\sigma}$ in a neighborhood of u_0.

THEOREM 3.10. *The map*

$$\mathcal{H}^{2,\sigma}(\zeta) \ni (u_0, u_1) \mapsto (\boldsymbol{\phi}(t, u_0, u_1, \zeta) - (\boldsymbol{\psi}(t, u_0, \zeta), \boldsymbol{\psi}_t(t, u_0, \zeta))) \in (C^{2,\sigma})^2 \tag{3.12}$$

is compact for $t > 0$ whenever it is defined. More precisely, this map is the composition of a continuous and differentiable nonlinear map and a compact linear inclusion, which maps bounded sets to precompact sets.

Remark. Observe that $\dot{\boldsymbol{\phi}}$ is defined for negative time. Theorem 3.10 implies that $\boldsymbol{\phi}$ is a compact perturbation of a noncompact map. This implies that the semiflow is not smoothing.

Now suppose for simplicity and essentially without loss of generality that $u = 0$ satisfies (3.11) with zero initial data. The linearization of (3.11) about $u = 0$ is

$$\mathbf{G} : v_{\mathbf{xx}} + \mathbf{g} \cdot v_{\mathbf{x}} + \gamma v + \mathbf{H} : v_{\mathbf{xx}t} + \mathbf{h} \cdot v_{\mathbf{x}t} + \eta v_t = \mu v_t \quad \text{in } \Omega_T, \tag{3.13a}$$

$$\mathbf{a} \cdot v_{\mathbf{x}} + \alpha v + \mathbf{b} \cdot v_{\mathbf{x}t} + \beta v_t = 0 \qquad \text{on } \Gamma_T, \tag{3.13b}$$

$$v(\cdot, 0) = 0 \qquad \text{in } \Omega. \tag{3.13c}$$

The coefficients depend on $\mathbf{x}$ but not on t. We shall see that (3.13) defines an analytic group on $h^{2,\sigma}$ (and on $C^{2,\sigma}$). Hence the spectrum of the group is determined by the spectrum of the generator. On the other hand, this group describes the parabolic-hyperbolic semigroup up to a compact perturbation. Hence we can control the essential spectrum of the parabolic-hyperbolic semigroup provided we can control the spectrum of the generator of the group defined by (3.13), i.e., if we can control $\mathcal{R}$. This can be done under conditions that can often be readily verified.

THEOREM 3.11. *Let Hypothesis* 1.1 *hold. Suppose that* (i) *F has divergence form, i.e., that there is a vector-valued function $\mathbf{f}$ and a function M such that*

$$F = \partial_{\mathbf{x}} \cdot \mathbf{f}(u, u_{\mathbf{x}}, u_t, u_{t\mathbf{x}}) + M(u, u_{\mathbf{x}}, u_t, u_{t\mathbf{x}}, \zeta),$$

(ii) *$\mathbf{G}$ is uniformly positive-definite for all $\mathbf{x}$, and* (iii) *the boundary function B has the form*

$$B(\mathbf{x}, u, u_{\mathbf{x}}, u_t, u_{t\mathbf{x}}, \zeta) = \boldsymbol{\nu} \cdot \mathbf{f}(\mathbf{x}, u, u_{\mathbf{x}}, u_t, u_{t\mathbf{x}}, \zeta) + H(\mathbf{x}, u, u_t, u_{\mathbf{x}}, \zeta), \tag{3.14}$$

where H depends only on tangential components of $u_{\mathbf{x}}$. Then $\mathcal{R}$ contains the right closed half plane $\{\mu \in \mathbb{C} : \Re\, \mu \geq 0\}$. In particular, hypothesis (iii) *in Theorem* 3.8 *is satisfied.*

As mentioned above, there are important differences between our work and that of Da Prato and Lunardi [10]: We do not prove a center-manifold theorem, the space of admissible initial data is not a linear space, and the equations are different. The obstacle to using the techniques of [10], Potier-Ferry [21], [22], Renardy [23], and Xu and Marsden [25] is that the space of admissible initial data is not a linear space. We shall return to this point in the discussion of section 8.

We complete this introduction by giving an outline of the paper. We start with a study of linear equations in section 4 and continue with the manifold structure of $\mathcal{H}^{2,\sigma}$ in section 5. Section 6 is devoted to well-posedness questions. In section 7 we state, prove, and apply an abstract Hopf bifurcation theorem. In section 8, we check that our physical examples have the requisite properties.

4. The linear equation. In this section we obtain bounds and regularity results for the linearized parabolic-hyperbolic equation by exploiting estimates for associated linear parabolic equations. Then we study the spectrum of the generator of the semigroup for our linearized problem, which leads to the treatment of associated linear elliptic problems and of a local flow closely related to the local semiflow we intend to study.

The linear parabolic problem. We consider the linear parabolic problem

$$u_t - \mathbf{H} : u_{\mathbf{xx}} - \mathbf{h} \cdot u_{\mathbf{x}} - \eta u = f \qquad \text{in } \Omega_T, \tag{4.1a}$$

$$\mathbf{b} \cdot u_{\mathbf{x}} + \beta u = g \qquad \text{in } \Gamma_T, \tag{4.1b}$$

$$u(\cdot, 0) = u_0(\cdot) \quad \text{on } \Omega \tag{4.1c}$$

with $\mathbf{H}, \mathbf{h}, \eta \in C^{\sigma}_{\mathrm{P}}$, $\mathbf{b}, \beta \in C^{1,\sigma}$, $\mathbf{H}$ uniformly positive-definite, and $\mathbf{b}$ transversal at the boundary. We first state a standard existence result.

THEOREM 4.1. *Let $u_0 \in C^{2,\sigma}(\Omega)$, $g \in C^{1,\sigma}_{\mathrm{P}}(\Gamma_T)$, and $\mathbf{b} \cdot u_{0\mathbf{x}} + \beta u_0 = g(\cdot, 0)$ for $\mathbf{x} \in \Gamma$. Then there exist a constant $c > 0$ and a unique classical solution $u \in C^{2,\sigma}_{\mathrm{P}}(\Omega_T)$ of* (4.1) *that satisfies*

$$\|u\|_{C^{2,\sigma}_{\mathrm{P}}(\Omega_T)} \le c \left(\|u_0\|_{C^{2,\sigma}(\Omega)} + \|f\|_{C^{\sigma}_{\mathrm{P}}(\Omega_T)} + \|g\|_{C^{1,\sigma}_{\mathrm{P}}(\Gamma_T)} \right). \tag{4.2}$$

The constant remains bounded if T tends to zero.

This type of estimate is well known and can essentially be found in Friedman [11], Ladyženskaja, Ural'ceva, and Solonnikov [18], and Solonnikov [24]. The approach of the first two books could be applied to our problem, although the results stated there do not directly cover Theorem 4.1.

To justify (4.2) without technical difficulty, we make use of the fact that (4.1) is a scalar equation. (Nevertheless, similar results hold for Petrovskii parabolic systems [24], and all our results are readily extended to these systems. The algebraic conditions for these systems, especially the complementing condition, are natural but quite complicated in general.)

Sketch of the proof. First we consider the whole-space problem with frozen coefficients. After a linear transformation and a neglect of the lower-order terms, (4.1a) reduces to the pure heat equation, which is obviously parabolic. For the complementing condition we flatten the boundary in the neighborhood of an arbitrary point, freeze the coefficients, and apply affine transformations. We thus obtain the problem

$$u_t - \Delta u = 0 \quad \text{in } \{\mathbf{x} : x_n < 0\}, \tag{4.3a}$$

$$u_n - d u_1 = 0 \quad \text{in } \{\mathbf{x} : x_n = 0\}, \tag{4.3b}$$

where $d \in \mathbb{R}$.

Let $u = q(x_n)\exp(i\sum_{j=1}^{n-1} x^j\xi_j + \tau t)$ be a nonconstant solution to (4.3). Then $u = \text{const}\,\exp(i\sum_{j=1}^{n-1} x^j\xi_j + \rho x_n + \tau t)$ with $\tau = -|\xi|^2 + \rho^2$ and $\rho = id\xi_1$. Hence $\tau = -|\xi|^2 - d^2\xi_1^2 < 0$ and the complementing condition of [24] is satisfied for problem (4.1). Theorem 4.1 is now a very special case of Theorem 4.9 of [24]. □

Having estimates and existence results for C^σ or for h^σ is more or less equivalent. More precisely, suppose that L is a linear operator from C^σ to itself for $0 < \sigma < 1$. Then L maps h^σ to itself because h^σ is the closure of $C^{\sigma+\varepsilon}$ in C^σ, since L maps $C^{\sigma+\varepsilon}$ to itself (and hence to h^σ), and finally because a C^σ estimate implies immediately an a priori estimate in h^σ.

Let us now assume that L maps h^σ to itself for $0 < \sigma < 1$. Clearly $C^\sigma \subset h^{\sigma-\varepsilon}$. Let $f \in C^\sigma$. We approximate f in $h^{\sigma-\varepsilon}$ by f_j such that $\|f_j\|_{C^\sigma} \le c\|f\|_{C^\sigma}$. Then $\|Lf_j\|_{C^\sigma} = \|Lf_j\|_{h^\sigma} \le c\|f_j\|_{h^\sigma} = c\|f_j\|_{C^\sigma}$, which is uniformly bounded. Moreover, Lf_j converges to Lf in $C^{\sigma-\varepsilon}$. Hence $\|Lf\|_{C^\sigma} \le c\|f\|_{C^\sigma}$. Below we use this simple observation without mention.

The semigroup defined by the parabolic-hyperbolic equation. We turn to the linear parabolic-hyperbolic problem

$$u_{tt} - \mathbf{G} : u_{\mathbf{xx}} - \mathbf{g}\cdot u_{\mathbf{x}} - \gamma u - \mathbf{H} : u_{\mathbf{xx}t} - \mathbf{h}\cdot u_{\mathbf{x}t} - \eta u_t = w \qquad \text{in } \Omega_T, \tag{4.4a}$$

$$\mathbf{a}\cdot u_{\mathbf{x}} + \alpha u + \mathbf{b}\cdot u_{\mathbf{x}t} + \beta u_t = g \qquad \text{in } \Gamma_T, \tag{4.4b}$$

$$u(\cdot,0) = u_0(\cdot) \quad \text{in } \Omega, \tag{4.4c}$$

$$u_t(\cdot,0) = u_1(\cdot) \quad \text{in } \Omega \tag{4.4d}$$

with coefficients depending on $\mathbf{x}$ but not on t. Considering (4.4a) as a parabolic equation for u_t, we infer from Theorem 4.1 the following a priori estimate for $u \in Y^{2,\sigma}$:

$$\|u_t\|_{C_{\mathrm{P}}^{2,\sigma}(\Omega_T)} \le c\left(\|u_1\|_{C^{2,\sigma}(\Omega)} + \|w\|_{C_{\mathrm{P}}^{\sigma}} + \|g\|_{C_{\mathrm{P}}^{1,\sigma}} + \|u\|_{C_{\mathrm{P}}^{2,\sigma}}\right). \tag{4.5}$$

Since

$$\begin{aligned}\|u(t)\|_{C^{2,\sigma}(\Omega)} &\le \|u_0\|_{C^{2,\sigma}} + \left\|\int_0^t u_t(\cdot,\tau)d\tau\right\|_{C_{\mathrm{P}}^{2,\sigma}(\Omega_t)}\\ &\le \|u_0\|_{C^{2,\sigma}} + c\int_0^t \|u_t(\tau)\|_{C^{2,\sigma}(\Omega)}d\tau\end{aligned} \tag{4.6}$$

and since $u(\cdot,t+s) - u(\cdot,t) = \int_t^{t+s} u_t(\cdot,\tau)\,d\tau$, we obtain

$$\begin{aligned}\|u_t\|_{C_{\mathrm{P}}^{2,\sigma}} \le c\Big(&\|u_0\|_{C_{\mathrm{P}}^{2,\sigma}} + \|u_1\|_{C_{\mathrm{P}}^{2,\sigma}} + \|w\|_{C_{\mathrm{P}}^{\sigma}} + \|g\|_{C_{\mathrm{P}}^{1,\sigma}}\\ &+ \int_0^T \|u_t\|_{C^{2,\sigma}(\Omega_\tau)}d\tau + T^{1-\sigma/2}\|u_t\|_{C_{\mathrm{P}}^{2,\sigma}(\Omega_T)}\Big).\end{aligned} \tag{4.7}$$

For T sufficiently small, Gronwall's inequality now implies that

$$\|u_t\|_{C_{\mathrm{P}}^{2,\sigma}(\Omega_T)} \le c(\|u_0\|_{C^{2,\sigma}(\Omega)} + \|u_1\|_{C^{2,\sigma}(\Omega)} + \|w\|_{C_{\mathrm{P}}^{\sigma}(\Omega_T)} + \|g\|_{C_{\mathrm{P}}^{1,\sigma}(\Gamma_T)})\,. \tag{4.8}$$

This motivates the definition of the space $Y^{2,\sigma}$. The a priori estimate (4.8) can be used to get the following well-posedness result for the linear equation, at first for small t and then, by iteration, for arbitrary t. We omit the proof because the arguments

are standard and because we shall obtain this result as a special case of a result for a nonlinear problem.

PROPOSITION 4.2. *Suppose that* $u_0, u_1 \in C^{2,\sigma}$, $w \in C^\sigma$, *and* $g \in C^{1,\sigma}$, *and that*

$$\mathbf{a} \cdot u_{0\mathbf{x}} + \alpha u_0 + \mathbf{b} \cdot u_{1\mathbf{x}} + \beta u_1 = g(\cdot, 0) \quad \text{on } \Gamma. \tag{4.9}$$

Then there exists a unique solution $u \in Y^{2,\sigma}$ *of* (4.5), *which satisfies*

$$\|u\|_{Y^{2,\sigma}} \le ce^{ct}(\|u_0\|_{C^{2,\sigma}} + \|u_1\|_{C^{2,\sigma}} + \|w\|_{C^\sigma_{\mathrm{P}}} + \|g\|_{C^{1,\sigma}_{\mathrm{P}}}). \tag{4.10}$$

Proposition 4.2 can be applied in the special case that $w \equiv 0$ and $g \equiv 0$. The map $(u_0, u_1, t) \mapsto (u(t), u_t(t))$ is a semigroup $S(\cdot)$ on the subspace $\mathcal{H}_1^{2,\sigma}(\zeta)$ of $C^{2,\sigma}(\Omega) \times C^{2,\sigma}(\Omega)$ consisting of those functions satisfying (4.9) with $g = 0$. We shall see that this semigroup is analytic, i.e., there is a bounded holomorphic extension of the time variable to a sector in the complex plane.

Since regularity is not an issue at the moment, we suppose that u is sufficiently smooth and satisfies (4.4) with $w = 0$, $g = 0$, and coefficients independent of t. Then $u_{tt} \in C^\sigma_{\mathrm{P}}$. The function $v = tu_{tt}$ satisfies

$$v_t - \mathbf{H} : v_{\mathbf{xx}} - \mathbf{h} \cdot v_{\mathbf{x}} - \eta v = u_{tt} + t(\mathbf{G} : u_{\mathbf{xx}t} + \mathbf{g} \cdot u_{\mathbf{x}t} + \gamma u_t) \tag{4.11}$$

with similar boundary conditions. It follows that there is a function c depending continuously on t such that

$$\|v\|_{C^{2,\sigma}_{\mathrm{P}}} \le c\|u\|_{Y^{2,\sigma}} \le c\left(\|u_0\|_{C^{2,\sigma}} + \|u_1\|_{C^{2,\sigma}}\right), \tag{4.12}$$

$$\|u_{tt}(t)\|_{C^{2,\sigma}} \le ct^{-1}\left(\|u_0\|_{C^{2,\sigma}} + \|u_1\|_{C^{2,\sigma}}\right). \tag{4.13}$$

These a priori estimates can easily be turned into an estimate for all solutions. Proposition 4.2 implies that problem (4.4) with coefficients independent of t defines a semigroup on $\mathcal{H}_1^{2,\sigma}$, which is analytic by (4.13) and the obvious estimate $\|u_t(t)\|_{C^{2,\sigma}} \le c$.

As mentioned above, Proposition 4.2 depends on Petrovskii parabolicity with respect to $\dot{u}$, which is not hard to check also for Example 2.3.

The spectrum. We turn to the spectrum of the semigroup defined by problem (4.4). In the first step, for given u, we consider the following elliptic problem for v:

$$\mathbf{H} : v_{\mathbf{xx}} + \mathbf{h} \cdot v_{\mathbf{x}} + \eta v - \mu v = -\mathbf{G} : u_{\mathbf{xx}} - \mathbf{g} \cdot u_{\mathbf{x}} - \gamma u - w \quad \text{in } \Omega_T, \tag{4.14a}$$

$$\mathbf{a} \cdot v_{\mathbf{x}} + \alpha v = -\mathbf{b} \cdot u_{\mathbf{x}} - \beta u + g \quad \text{in } \Gamma_T. \tag{4.14b}$$

PROPOSITION 4.3. *Suppose that the real part of* μ *is sufficiently large. Then*

$$\|v\|_{C^{2,\sigma}} \le c\left(\|u\|_{C^{2,\sigma}} + \|w\|_{C^\sigma} + \|g\|_{C^{1,\sigma}}\right), \tag{4.15}$$

and $v \in C^{2,\sigma}$ *if* $u \in C^{2,\sigma}$ *and* $w \in C^\sigma$.

Proof. It is clear that $v \in C^{2,\sigma}$ if $u \in C^{2,\sigma}$. The parabolic equation (4.1) generates a semigroup. Hence μ is in the resolvent set of the operator

$$u \mapsto \mathbf{H} : u_{\mathbf{xx}} + \mathbf{h} \cdot u_{\mathbf{x}} + \eta u \tag{4.16}$$

on $\{u : \mathbf{a} \cdot u_{\mathbf{x}} + \alpha u = 0\}$ if its real part is sufficiently large. Hence we obtain (4.15) by Schauder estimates. It is again not hard to see that this result holds for systems and in particularly it applies to systems with coefficients obtained from linearizing Example 2.3. □

We use Proposition 4.3 to reduce the problem (3.13) for a partial differential equation into one for an ordinary differential equation on $h^{2,\sigma}$. By the implicit-function theorem we can solve the next two equations.

$$F(\mathbf{x}, u, u_{\mathbf{x}}, u_{\mathbf{xx}}, v, v_{\mathbf{x}}, v_{\mathbf{xx}}, \zeta) - \mu v = 0 \quad \text{in } \Omega, \tag{4.17a}$$

$$B(\mathbf{x}, u, u_{\mathbf{x}}, v, v_{\mathbf{x}}, \zeta) = 0 \quad \text{on } \Gamma, \tag{4.17b}$$

$$u_t = v \tag{4.17c}$$

for v in terms of u and ζ if u is in the neighborhood of a given function $\tilde{u}$ since the derivative at $\tilde{u}$ is an invertible map if μ is sufficiently large. Hence we may rewrite problem (4.17) in the form

$$u_t = \Psi(u) \tag{4.18}$$

with Ψ a k-times differentiable vector field in the neighborhood of the given function u_0. The following proposition is now obvious.

PROPOSITION 4.4. *Problem* (4.17) *defines a k-times differentiable local flow in a neighborhood $\mathcal{U} \subset C^{2,\sigma}$ of u_0.*

Similar but simpler arguments apply to the linear problem

$$\mathbf{G} : u_{\mathbf{xx}} + \mathbf{g} \cdot u_{\mathbf{x}} + \gamma u + \mathbf{H} : u_{t\mathbf{xx}} + \mathbf{h} \cdot u_{t\mathbf{x}} + \eta u_t = \mu u_t - w \quad \text{in } \Omega_T, \tag{4.19a}$$

$$\mathbf{a} \cdot u_{\mathbf{x}} + \alpha u + \mathbf{b} \cdot u_{t\mathbf{x}} + \beta u_t = f \quad \text{in } \Gamma_T, \tag{4.19b}$$

$$u(\cdot, 0) = u_0(\cdot) \quad \text{on } \Omega. \tag{4.19c}$$

This problem defines a group $\hat{S}$ on $C^{2,\sigma}$ and on $h^{2,\sigma}$ if $w = 0$ and $f = 0$, implicitly parametrized by ζ. The solution of (4.19) satisfies

$$\|u(t)\|_{C^{2,\sigma}} \leq c \left(\|u_0\|_{C^{2,\sigma}} + \int_0^t (\|w(\tau)\|_{C^\sigma(\Omega))} + \|f(\tau)\|_{C^{1,\sigma}(\Gamma)}) \, d\tau \right). \tag{4.20}$$

Let u be the solution to problem (4.4). Then $v(\cdot, t) = u(\cdot, t) - \hat{S}(t)u_0$ satisfies

$$\mathbf{G} : v_{\mathbf{xx}} + \mathbf{g} \cdot v_{\mathbf{x}} + \gamma v + \mathbf{H} : v_{t\mathbf{xx}} + \mathbf{h} \cdot v_{t\mathbf{x}} + \eta v_t = \mu u_t + u_{tt} \quad \text{in } \Omega_T, \tag{4.21a}$$

$$\mathbf{a} \cdot v_{\mathbf{x}} + \alpha v + \mathbf{b} \cdot v_{t\mathbf{x}} + \beta v_t = 0 \quad \text{in } \Gamma_T, \tag{4.21b}$$

$$v(\cdot, 0) = 0 \quad \text{on } \Omega. \tag{4.21c}$$

From (4.20) we obtain

$$\|v(t)\|_{C^{2,\sigma}} + \|v_t(t)\|_{C^{2,\sigma}} \leq c \int_0^t (\|u_{tt}\|_{C^\sigma} + \|u_t\|_{C^\sigma}) \, d\tau. \tag{4.22}$$

We have seen that the semigroup S defined by Proposition 4.2 is analytic; hence

$$u_{tt}(t) \in C^{2,\sigma}, \tag{4.23}$$

$$\|u_{tt}(t)\|_{C^{2,\sigma}} \leq ct^{-1} \left(\|u_0\|_{C^{2,\sigma}} + \|u_1\|_{C^{2,\sigma}} \right). \tag{4.24}$$

Thus, the map

$$\mathcal{H}_1^{2,\sigma} \ni (u_0, u_1) \mapsto u_{tt} \in L^1([0, T], C^\sigma(\Omega)) \tag{4.25}$$

is compact. Similarly, the map to u_t is compact.

For later use we formulate our conclusion, which we obtain now from (4.20):

PROPOSITION 4.5. *The map*

$$\mathcal{H}^{2,\sigma} \ni (u_0, u_1) \mapsto ((\hat{S}(t)u_0, \hat{S}_t(t)u_0) - S(t)[u_0, u_1]) \in (C^{2,\sigma})^2 \tag{4.26}$$

is compact.

The same arguments provide a proof of Theorem 3.10. Proposition 4.5 yields the first half of the control of the spectrum: If we can control the spectrum of the generator of $\hat{S}$ defined by (4.19), then we can also control the spectrum of the generator of $S(t)$. That control is provided by the Theorem 3.11.

Proof of Theorem 3.11. The notion of ellipticity of [1] does not depend on lower-order terms. The assertion of Theorem 3.11 is equivalent to the following: Suppose that $\Re\,\lambda \geq 0$ and that $\mu \in \mathbb{R}$ is sufficiently large. Then

$$(\mathbf{G} + \lambda\mathbf{H}) : u_{\mathbf{xx}} - \mu u = 0 \quad \text{in } \Omega, \tag{4.27a}$$

$$(\mathbf{G} + \lambda\mathbf{H}) : \boldsymbol{\nu} u_{\mathbf{x}} + \mathbf{d} \cdot u_{\mathbf{x}} = 0 \quad \text{on } \Gamma \tag{4.27b}$$

is elliptic, where $\mathbf{d} = \partial h/\partial u_{\mathbf{x}}$ is a tangential vector field.

We obtain the obvious energy estimate

$$\mu \int_\Omega u\bar{u} + \int_\Omega (\mathbf{G} + \lambda\mathbf{H}) : u_{\mathbf{x}}\bar{u}_{\mathbf{x}} + \int_\Gamma \mathbf{d} \cdot u_{\mathbf{x}}\bar{u} = 0. \tag{4.28}$$

Taking the real part of (4.28), integrating it by parts on the boundary, and using trace estimates, we get

$$\mu \int_\Omega u\bar{u} + \int_\Omega \mathbf{G} : u_{\mathbf{x}}\bar{u}_{\mathbf{x}} \leq c\|u\|_2\|u_{\mathbf{x}}\|_2. \tag{4.29}$$

This implies the L^2-estimates provided that μ is sufficiently large.

In particular, we can exclude the possibility of growing exponential solutions for the half space problem with constant coefficients, and hence the ellipticity and complementing conditions of [1] are satisfied. Thus problem (4.27) is elliptic for λ in the closed right half plane. □

The assumptions are satisfied in Example 2.1 provided that $\sigma_a(a, b, x) > 0$ everywhere, and are satisfied in Example 2.2 provided that (the symmetric part of) $\begin{pmatrix} \partial\sigma_1/\partial p_1 & \partial\sigma_1/\partial p_2 \\ \partial\sigma_2/\partial p_1 & \partial\sigma_2/\partial p_2 \end{pmatrix}$ is positive-definite. The arguments apply also to Example 2.3 provided that (the symmetric part of)

$$\begin{pmatrix} N_\nu & N_\eta & N_\mu \\ H_\nu & H_\eta & H_\mu \\ M_\nu & M_\eta & M_\mu \end{pmatrix}$$

is positive-definite. Incidentally, it is interesting to note that global existence theorems do not require this definiteness.

5. The manifold of admissible initial data.

Proof of Theorem 3.2. We suppress the dependence on ζ. By standard trace theory there is a linear map

$$J : C^{2,\sigma}(\Gamma) \times C^{1,\sigma}(\Gamma) \to C^{2,\sigma}(\Omega) \tag{5.1}$$

which has the properties

$$J(u_0,u_1)|_\Gamma = u_0, \tag{5.2}$$

$$\boldsymbol{\nu}\cdot J(u_0,u_1)_{\mathbf{x}|_\Gamma} = u_1. \tag{5.3}$$

Assumption 1.1 allows us to take

$$B(\mathbf{x},u_0,u_{0\mathbf{x}},u_1,u_{1\mathbf{x}}) = \boldsymbol{\nu}\cdot u_{0\mathbf{x}t} - \tilde{B}(\mathbf{x},u_0,u_{0\mathbf{x}},u_1,u_{1\mathbf{x}}), \tag{5.4}$$

where only tangential components of $u_{1\mathbf{x}}$ enter into $\tilde{B}$.

Let $\mathcal{X} = (C^{2,\sigma}(\Omega))^2$, $\mathcal{Y} = C^{1,\sigma}(\Gamma)$, $\psi(u_0,u_1) := B(\mathbf{x},u_0,u_{0,\mathbf{x}},u_1,u_{1,\mathbf{x}})$, and $L(z) := (0,J(0,z))$. We easily verify that $\psi \in C^k(\mathcal{X},\mathcal{Y})$, L has closed range, and $z = \psi'(u_0,u_1)[L(z)]$. This implies that the set $E = \psi^{-1}(\{0\})$ is a C^k-submanifold of $C^{2,\sigma}$. It is not hard to see that this construction has the requisite dependence on ζ. Moreover, the argument carries over without the special choice of (5.4), because any oblique boundary condition can be written in this form. Finally, we obtain the same assertions in the spaces $h^{2,\sigma}$. □

The key property of the problem used in this proof is the representation (5.4). The obvious generalization to systems is clearly satisfied in Example 2.3.

6. Well-posedness.

Proofs of Theorems 3.1 *and* 3.3. We want to find solutions to (1.3) for $(u_0,u_1) \in \mathcal{H}^{2,\sigma}$. Define the operators $\mathfrak{A}$ and $\mathfrak{B}$ by

$$\mathfrak{A}v = F_{\dot{\mathbf{P}}} : v_{\mathbf{xx}}, \quad \mathfrak{B}v = B_{\dot{\mathbf{p}}}\cdot v_{\mathbf{x}}, \tag{6.1a,b}$$

where the derivatives of F and B are evaluated at (u_0,u_1). We rewrite (1.3) as

$$w_t - \mathfrak{A}w = G(u,w) \quad \text{in } \Omega_T, \tag{6.2a}$$

$$\mathfrak{B}w = H(u,w) \quad \text{on } \Gamma_T, \tag{6.2b}$$

$$w(\cdot,0) = 0 \quad \text{in } \Omega, \tag{6.2c}$$

where $u(x,t) = u_0(x) + \int_0^t [w(x,\tau)+u_1(x)]d\tau$, and

$$G(u,w) = F(\mathbf{x},u,u_{\mathbf{x}},u_{\mathbf{xx}},u_1+w,(u_1+w)_{\mathbf{x}},(u_1+w)_{\mathbf{xx}}) - \mathfrak{A}w, \tag{6.3a}$$

$$H(u,w) = B(\mathbf{x},u,u_{\mathbf{x}},u_1+w,(u_1+w)_{\mathbf{x}}) - \mathfrak{B}w. \tag{6.3b}$$

The main property of G and B is that they are quadratic in the highest-order derivatives.

Obviously, solving (1.3) is equivalent to solving (6.2). The following estimates require no more than an inspection of the difference quotients involved.

LEMMA 6.1. *Let* $u = u_0 + tu_1 + \int_0^t w\,d\tau$ *and* $\bar{u} = u_0 + tu_1 + \int_0^t \bar{w}\,d\tau$. *Then the following estimates hold with* c *depending on* $\|u_0\|_{C^{2,\sigma}}$, $\|u_1\|_{C^{1,\alpha}}$, $\|w_{\mathbf{xx}}\|_{L^\infty}$ *and* $\|\bar{w}_{\mathbf{xx}}\|_{L^\infty}$:

$$\begin{aligned}\|G(u,w)-G(u,\bar{w})\|_{C^\sigma_{\mathrm{P}}} &+ \|H(u,w)-H(u,\bar{w})\|_{C^{1,\sigma}_{\mathrm{P}}}\\ &\le c\|(w-\bar{w})_{\mathbf{xx}}\|_\infty\left(\|w\|_{C^{2,\sigma}_{\mathrm{P}}}+\|\bar{w}\|_{C^{2,\sigma}_{\mathrm{P}}}\right)\\ &\quad + c\left(\|w_{\mathbf{xx}}\|_\infty+\|\bar{w}_{\mathbf{xx}}\|_\infty\right)\|w-\bar{w}\|_{C^{2,\sigma}_{\mathrm{P}}},\end{aligned} \tag{6.4a}$$

$$\begin{aligned}\|G(u,w)-G(\bar{u},w)\|_{C^\sigma_{\mathrm{P}}} &+ \|\ H(u,w)-H(\bar{u},w)\|\|_{C^{1,\sigma}_{\mathrm{P}}}\\ &\le c\Big(\|(u-\bar{u})_{\mathbf{xx}}\|_\infty\|w\|_{C^{2,\sigma}_{\mathrm{P}}(\Omega_T)}+\|u-\bar{u}\|_{C^{2,\sigma}_{\mathrm{P}}(\Omega_T)}\Big).\end{aligned} \tag{6.4b}$$

We construct the solution (more precisely, its time derivative) as a fixed point of the map J from $\tilde{w}$ to the solution w of

$$w_t - \mathfrak{A}w = G(\tilde{u}, \tilde{w}) \quad \text{in } \Omega_T, \tag{6.5a}$$

$$\mathfrak{B}w = H(\tilde{u}, \tilde{w}) \quad \text{on } \Gamma_T, \tag{6.5b}$$

$$w(\cdot, 0) = 0 \quad \text{in } \Omega, \tag{6.5c}$$

where $\tilde{u} = u_0 + \int_0^t (\tilde{w} + u_1)\, d\tau$. By Theorem 4.1 and Lemma 6.1 (with $\bar{w} = 0$) we have

$$\|w\|_{C^{2,\sigma}_{\mathrm{P}}} \le c(t^{\sigma/2}\|\tilde{w}\|_{C^{2,\sigma}_{\mathrm{P}}} + 1) \tag{6.6}$$

where c is uniformly bounded for $t \le 1$ if $\|\tilde{w}_{\mathbf{xx}}\|_\infty \le c\|u_1\|_{C^2}$. We choose $R = 2c$, $t = c^{-2/\sigma}$, and $Y_0 = \{w \in C^{2,\sigma}(\Omega_t) : w(\cdot, 0) = 0, \|w\|_{Y^\sigma} \le R\}$. Then J maps Y_0 to itself. Moreover, by Lemma 6.1 and Theorem 4.1,

$$\|J(w) - J(\bar{w})\|_{C^{2,\sigma}_{\mathrm{P}}} \le ct^{\sigma/2}\|w - \bar{w}\|_{C^{2,\sigma}_{\mathrm{P}}}. \tag{6.7}$$

Hence J is a contraction if t is sufficiently small. The contraction-mapping principle implies the existence of a solution.

Clearly J is k-times continuously differentiable with respect to all the data. It is differentiable at the fixed point, and the derivative with respect to w is invertible because J is a strict contraction. The implicit-function theorem implies that the fixed point w is k-times continuously differentiable with respect to initial data, constitutive functions, and parameters.

Since these statements remain true for the space $h^{2,\sigma}$, the regularity assertions about the semiflow in Theorems 3.1 and 3.3 hold. The semicontinuity of the life span $\hat{T}$ follows from the fact that if u is a solution of (1.3) in the time interval $[0, T)$ and if $0 < t < T$, then we can find a neighborhood $\mathcal{N}$ of the initial data $u(\cdot, 0), v(\cdot, 0)$ such that we can solve (1.3) up to time t for initial data in $\mathcal{N}$. This in turn is a consequence of our construction and of continuous dependence on the data. □

This proof clearly applies also to Example 2.3.

7. Hopf bifurcation. In this section we prove the Hopf bifurcation theorem by following the scheme in the original paper by Hopf [14]. Solutions of period T are solutions to

$$\mathbf{z} - \boldsymbol{\phi}(T, \mathbf{z}, \zeta) = \mathbf{0}. \tag{7.1}$$

Let $\boldsymbol{\psi}$ be a local coordinate map at $\mathbf{0}$ parametrized by ζ. Then (7.1) is equivalent to

$$\hat{\mathbf{z}} - \boldsymbol{\psi}^{-1}(\boldsymbol{\phi}(T, \boldsymbol{\psi}(\hat{\mathbf{z}}, \zeta), \zeta), \zeta) = \mathbf{0}, \tag{7.2}$$

where $\mathbf{z} = \boldsymbol{\psi}(\hat{\mathbf{z}}, \zeta)$ and $\boldsymbol{\psi}^{-1}$ refers to the inverse with respect to the first variable. We define $\hat{\boldsymbol{\phi}}(T, \hat{\mathbf{z}}, \zeta) = \boldsymbol{\psi}^{-1}(\boldsymbol{\phi}(T, \boldsymbol{\psi}(\mathbf{z}, \zeta), \zeta), \zeta)$ and drop the circumflexes and abbreviate (7.2) as (7.1). The assumptions are clearly invariant with respect to this introduction of local coordinates.

7A. Abstract Hopf bifurcation. We reformulate the Hopf bifurcation theorem in a more abstract setting. Let $\mathcal{U}$ be an open subset of the Banach space $\mathcal{X}$ and let $\mathcal{I} = \mathbb{R}$ be the parameter space. We suppose that $\boldsymbol{\phi}$ is a local parameter-dependent semiflow on the open set $\mathcal{U} \subset \mathcal{X} \times \mathcal{I}$ of class C^{k+2} with $k \ge 3$. We assume that $\mathbf{0} \in \mathcal{U}$

and that $\boldsymbol{\phi}(t, \mathbf{0}, \zeta) = \mathbf{0}$ for ζ small and $t < \hat{T}(0, \zeta)$. Then $\hat{T}(0, \zeta) = \infty$. We suppose that

$$\mathbf{S}(t, \zeta) := \boldsymbol{\phi}_{\mathbf{z}}(t, \mathbf{0}, \zeta) \tag{7.3}$$

is a (strongly) continuous semigroup.

HYPOTHESIS 7.1. *The number* 1 *is an isolated double eigenvalue of* $\mathbf{S}(T, 0)$ *with two-dimensional eigenspace* $\mathcal{X}_{\mathrm{c}}$. *There exists a basis* $(\mathbf{e}_1, \mathbf{e}_2)$ *for* $\mathcal{X}_{\mathrm{c}}$ *such that the restriction of* $\mathbf{S}(t, 0)$ *to* $\mathcal{X}_{\mathrm{c}}$ *has the matrix representation*

$$\begin{pmatrix} \cos \omega t & \sin \omega t \\ -\sin \omega t & \cos \omega t \end{pmatrix}, \tag{7.4}$$

where $T\omega = 2\pi$.

For ordinary differential equations and some partial differential equations there are center-manifold theorems which reduce the dimension of the problem. In favorable cases (for which there are no other eigenvalues on the unit circle) $\mathcal{X}_{\mathrm{c}}$ is the center subspace, hence the subscript c. The $\mathbf{S}(\cdot, \zeta)$-invariant complement is denoted $\mathcal{X}_{\mathrm{h}}$. In favorable cases $\mathcal{X}_{\mathrm{h}}$ is the hyperbolic subspace (the sum of the stable and the unstable subspaces), hence the subscript h.

Hypothesis 7.1 is a weak nonresonance condition. It implies that $\mathbf{S}(t, 0)$ has isolated simple eigenvalues $e^{\alpha(0)t}$ with $\alpha(0) = i\omega$ for $t \neq T$ in a neighborhood of T. Since isolated simple eigenvalues depend differentiably on parameters, we obtain eigenvalues $e^{\alpha(\zeta)t}$ for fixed t and a C^{k-1} function $\alpha(\zeta)$. It is clear that $e^{\alpha(\zeta)t}$ is an eigenvalue of $\mathbf{S}(t, \zeta)$ for small ζ and all $t \geq 0$.

We use the inner product $\langle a_1\mathbf{e}_1 + a_2\mathbf{e}_2, b_1\mathbf{e}_1 + b_2\mathbf{e}_2 \rangle = a_1b_1 + a_2b_2$ on $\mathcal{X}_{\mathrm{c}}$. The subspace $\mathcal{X}_{\mathrm{h}}$ is the range of $\mathbf{z} \mapsto \mathbf{z} - \mathbf{S}(T, 0)\mathbf{z}$. Let $\mathbf{P}_{\mathrm{c}}$ be the projection of $\mathcal{X}$ onto $\mathcal{X}_{\mathrm{c}}$ along $\mathcal{X}_{\mathrm{h}}$ and let $\mathbf{P}_{\mathrm{h}} = \mathbf{I} - \mathbf{P}_{\mathrm{c}}$.

HYPOTHESIS 7.2.

$$\Re \alpha_{\zeta}(0) \neq 0. \tag{7.5}$$

This hypothesis ensures that the eigenvalue of the generator crosses the imaginary axis transversally.

HYPOTHESIS 7.3. *The number* 1 *is the only point on the unit circle that lies in the spectrum of* $\mathbf{S}(T, 0)$.

HYPOTHESIS 7.4. *The spectrum of* $\mathbf{P}_{\mathrm{h}}\mathbf{S}(1, 0)\mathbf{P}_{\mathrm{h}}$ *is contained in the open unit ball.*

THEOREM 7.5 (Hopf bifurcation theorem). *Let Hypotheses* 7.1 *and* 7.2 *hold. Then there exist an interval* $[0, \varepsilon_0)$ *and unique* C^k *maps*

$$\begin{aligned} \big[0, \varepsilon_0) \ni \varepsilon \quad &\mapsto \tilde{\mathbf{z}}(\varepsilon) \in \mathcal{X}, \\ \big[0, \varepsilon_0) \ni \varepsilon \quad &\mapsto \tilde{T}(\varepsilon) \in (0, \infty), \\ \big[0, \varepsilon_0) \ni \varepsilon \quad &\mapsto \tilde{\zeta}(\varepsilon) \in \mathbb{R} \end{aligned}$$

such that $\tilde{\mathbf{z}}(\varepsilon)$, $\tilde{T}(\varepsilon)$, *and* $\tilde{\zeta}(\varepsilon)$ *satisfy* (7.1), *with*

$$\tilde{T}(0) = 2\pi/|\lambda_0|, \qquad \tilde{T}'(0) = 0, \qquad \tilde{\zeta}(0) = 0, \qquad \tilde{\zeta}'(0) = 0, \tag{7.6}$$

$$\mathbf{P}_{\mathrm{c}}\tilde{\mathbf{z}}(\varepsilon) = \varepsilon\mathbf{e}_1. \tag{7.7}$$

Moreover, if $(T, \mathbf{z}, \zeta)$ *is another solution of* (7.1) *with* T *close to* T_0, $\mathbf{z}$ *small, and* ζ *small, then there exist* ε *and* t *such that*

$$\mathbf{z} = \boldsymbol{\phi}(t, \tilde{\mathbf{z}}(\varepsilon), \tilde{\zeta}(\varepsilon)). \tag{7.8}$$

If, furthermore, Hypothesis 7.3 *holds, then every small periodic solution has a period close to* T_0 *and hence all small solutions of* (7.1) *are of the form* (7.8).

Finally suppose that Hypothesis 7.4 *holds. If the bifurcation is subcritical, then the periodic solution is stable for small* ε. *If the bifurcation is supercritical, then it is unstable for small* ε.

Theorem 3.8 is an immediate consequence of this theorem. To see this we recall first that the semiflow is defined on $\tilde{\mathcal{U}} = \{(\mathbf{z}, \zeta) : \mathbf{z} \in \mathcal{H}^{2,\sigma}(\zeta),\ \zeta \in \mathcal{I}\}$. By Theorem 3.2 there is a C^k diffeomorphism from a neighborhood $\mathcal{U}$ of $\mathbf{0}$ in $\mathcal{H}^{2,\sigma}(0) \times \mathbb{R}$ to $\tilde{\mathcal{U}}$. Using these coordinates we obtain a parameter-dependent semiflow on $\mathcal{U}$. The assumptions are invariant with respect to the introduction of local coordinates. This implies Theorem 3.8 provided that we can justify the different normalization in Theorem 3.8. This, however, is an immediate consequence of the regularity of the bifurcating branch and the regularity of the diffeomorphism.

7B. Proof of the abstract theorem.

Proof of Theorem 7.5. We make a linear change of variables so that $\mathcal{X}_\mathrm{c}$ and $\mathcal{X}_\mathrm{h}$ are invariant subspaces for $\mathbf{S}(t, \zeta)$ for small ζ. Here we lose one derivative. (This loss could be avoided by a bit more work.) We denote by $\mathbf{S}_\mathrm{h}(t, \zeta)$ the induced semigroup on $\mathcal{X}_\mathrm{h}$ and by $\mathbf{S}_\mathrm{c}(t, \zeta)$ the induced semigroup on $\mathcal{X}_\mathrm{c}$. The nonresonance condition is equivalent to the statement that 1 is in the resolvent set of $\mathbf{S}_\mathrm{h}(2\pi/\omega, 0)$. Hence 1 is in the resolvent set of $\mathbf{S}_\mathrm{h}(\pi/\omega, 0)$. It is also in the resolvent set of $\mathbf{S}_\mathrm{c}(\pi/\omega, 0)$ and in the resolvent set of $\mathbf{S}(\pi/\omega, 0)$.

The groups $\mathbf{S}(t, \zeta)$ define a linear group on the bilinear mappings $(\mathbf{z}_\mathrm{c}, \mathbf{v}_\mathrm{c}) \mapsto \mathbf{M} : \mathbf{z}_\mathrm{c}\mathbf{v}_\mathrm{c}$ from $\mathcal{X}_\mathrm{C}$ to $\mathcal{X}$ by

$$\mathbf{S}(t, \zeta)(\mathbf{M})(\mathbf{z}_\mathrm{c}, \mathbf{v}_\mathrm{c}) := \mathbf{S}(t, \zeta)\mathbf{M} : [\mathbf{S}_\mathrm{c}(-t, \zeta)\mathbf{z}_\mathrm{c}][\mathbf{S}_\mathrm{c}(-t, \zeta)\mathbf{v}_\mathrm{c}]. \tag{7.9}$$

Now

$$\mathbf{S}(\pi/\omega, 0)(\mathbf{M})(\mathbf{z}_\mathrm{c}, \mathbf{v}_\mathrm{c}) = \mathbf{S}(\pi/\omega, 0)\mathbf{M} : \mathbf{z}_\mathrm{c}\mathbf{v}_\mathrm{c}, \tag{7.10}$$

and by the considerations above, 1 is not in the spectrum of the operator induced by $\mathbf{S}(\pi/\omega, 0)$. Hence there exists a unique quadratic map $\mathbf{M}$ that satisfies

$$\begin{aligned} &\mathbf{M} : \mathbf{z}_\mathrm{c}\mathbf{z}_\mathrm{c} - \mathbf{S}(\pi/\omega, \zeta)\mathbf{M} : [\mathbf{S}_\mathrm{c}(-\pi/\omega, \zeta)\mathbf{z}_\mathrm{c}][\mathbf{S}_\mathrm{c}(-\pi/\omega, \zeta)\mathbf{z}_\mathrm{c}] \\ &= -\tfrac{1}{2}\boldsymbol{\phi}_{\mathbf{z}_\mathrm{c}\mathbf{z}_\mathrm{c}}(\pi/\omega, 0, \zeta) : [\mathbf{S}_\mathrm{c}(-\pi/\omega, \zeta)\mathbf{z}_\mathrm{c}][\mathbf{S}_\mathrm{c}(-\pi/\omega, \zeta)\mathbf{z}_\mathrm{c}]. \end{aligned} \tag{7.11}$$

We could define $\mathbf{M}$ for t in a neighborhood of the time π/ω as well as at time $\pi/k\omega$ for positive integers k by the same argument. We shall see later that $\mathbf{M}$ does not depend on t. Let

$$\tilde{\mathbf{z}} := \mathbf{z} - \mathbf{M} : \mathbf{z}_\mathrm{c}\mathbf{z}_\mathrm{c}. \tag{7.12}$$

The map $\mathbf{z} \mapsto \tilde{\mathbf{z}}$ is smooth and invertible near the origin. Let $\tilde{\boldsymbol{\phi}}$ be the local semiflow in the coordinates $\tilde{\mathbf{z}}$. Then

$$\tilde{\boldsymbol{\phi}}_{\tilde{\mathbf{z}}_\mathrm{c}\tilde{\mathbf{z}}_\mathrm{c}}(0, \pi/\omega, \zeta) = \mathbf{O} \tag{7.13}$$

because

(7.14)
$$\begin{aligned}\tilde{\boldsymbol{\phi}}(\pi/\omega,\tilde{\mathbf{z}},\zeta) &= \boldsymbol{\phi}(\pi/\omega,\tilde{\mathbf{z}}-\mathbf{M}:\tilde{\mathbf{z}}\tilde{\mathbf{z}},\zeta)+\mathbf{M}:[\mathbf{S}_{\mathrm{c}}(\pi/\omega,\zeta)\mathbf{z}_{\mathrm{c}}][\mathbf{S}_{\mathrm{c}}(\pi/\omega,\zeta)\mathbf{z}_{\mathrm{c}}]+O(|\mathbf{z}|^3)\\ &= \mathbf{S}(\pi/\omega,\zeta)(\tilde{\mathbf{z}}-\mathbf{M}:\tilde{\mathbf{z}}\tilde{\mathbf{z}})+\tfrac{1}{2}\boldsymbol{\phi}_{\mathbf{zz}}(\pi/\omega,\mathbf{0},\zeta):\tilde{\mathbf{z}}\tilde{\mathbf{z}}\\ &\quad +\mathbf{M}:[\mathbf{S}_{\mathrm{c}}(\pi/\omega,\zeta)\tilde{\mathbf{z}}_{\mathrm{c}}][\mathbf{S}_{\mathrm{c}}(\pi/\omega,\zeta)\tilde{\mathbf{z}}_{\mathrm{c}}]+O(|\tilde{\mathbf{z}}|^3).\end{aligned}$$

This implies the same property at $k\pi/\omega$, and the same arguments can be applied at times $\pi/k\omega$. On the other hand, the vanishing of the second derivatives is equivalent to (7.11). Thus we do get the same η for all rational multiples of π/ω, and by continuity, (7.13) holds for all t. We keep our new coordinates and drop the tilde in what follows.

We rewrite (7.1) as a system

$$\mathbf{z}_{\mathrm{h}}-\boldsymbol{\phi}_{\mathrm{h}}(t,\mathbf{z}_{\mathrm{c}}+\mathbf{z}_{\mathrm{h}},\zeta)=\mathbf{0}, \tag{7.15}$$

$$\mathbf{z}_{\mathrm{c}}-\boldsymbol{\phi}_{\mathrm{c}}(t,\mathbf{z}_{\mathrm{c}}+\mathbf{z}_{\mathrm{h}},\zeta)=\mathbf{0}. \tag{7.16}$$

Using the implicit-function theorem, we solve (7.15) for $\mathbf{z}_{\mathrm{h}}$ in terms of t, $\mathbf{z}_{\mathrm{c}}$, and ζ near $(T,\mathbf{0},0)$. We denote the function which we obtain in this way by $\tilde{\mathbf{z}}_h$. Then

$$\tilde{\mathbf{z}}_{\mathrm{h}}(t,\mathbf{0},\zeta)=\mathbf{0},\quad \frac{\partial\tilde{\mathbf{z}}_{\mathrm{h}}}{\partial\mathbf{z}_{\mathrm{c}}}(t,\mathbf{0},\zeta)=\mathbf{O},\quad \frac{\partial^2\tilde{\mathbf{z}}_{\mathrm{h}}}{\partial\mathbf{z}_{\mathrm{c}}^2}(t,\mathbf{0},\zeta)=\mathbf{O},$$

where the last statement depends on our choice of coordinates. We substitute the function just obtained into the second equation and rewrite it as

$$\mathbf{z}_{\mathrm{c}}-\mathbf{g}(t,\mathbf{z}_{\mathrm{c}},\zeta)=\mathbf{0}, \tag{7.17}$$

where $\mathbf{g}=\boldsymbol{\phi}_{\mathrm{c}}(t,\mathbf{z}_{\mathrm{c}}+\tilde{\mathbf{z}}_{\mathrm{h}}(t,\mathbf{z}_{\mathrm{c}},\zeta),\zeta)$. Then

$$\mathbf{g}_{t\mathbf{z}_{\mathrm{c}}}(T,\mathbf{0},0)=\partial_t\mathbf{S}_{\mathrm{c}}(T,\mathbf{0},0)=\begin{pmatrix}0&\omega\\-\omega&0\end{pmatrix}, \tag{7.18}$$

$$\mathbf{g}_{\mathbf{z}_{\mathrm{c}}\mathbf{z}_{\mathrm{c}}}(t,\mathbf{0},\zeta)=\mathbf{O}, \tag{7.19}$$

$$\mathbf{g}_{\zeta\mathbf{z}_{\mathrm{c}}}(T,\mathbf{0},0)=\partial_\zeta\mathbf{S}_{\mathrm{c}}(T,\mathbf{0},0)=\begin{pmatrix}\Re\,z&\Im\,z\\-\Im\,z&\Re\,z\end{pmatrix}, \tag{7.20}$$

where, with α as in Hypothesis 7.2,

$$z=T\alpha_\zeta(0). \tag{7.21}$$

Equality (7.20) can be obtained as follows: The differential of the map $A\mapsto e^{AT}$ has a two-dimensional null space at $\left(\begin{smallmatrix}0&\omega\\-\omega(0)&0\end{smallmatrix}\right)$ spanned by matrices of the form $\left(\begin{smallmatrix}a&0\\0&-a\end{smallmatrix}\right)$ and $\left(\begin{smallmatrix}0&b\\b&0\end{smallmatrix}\right)$ because

$$\det\begin{pmatrix}a-\lambda&b+\omega\\b-\omega&-a-\lambda\end{pmatrix}=\lambda^2+\omega^2-a^2-b^2. \tag{7.22}$$

Now

$$\frac{d}{da}\exp\begin{pmatrix}a&\omega T\\-\omega T&a\end{pmatrix}=\begin{pmatrix}T&0\\0&T\end{pmatrix}, \tag{7.23}$$

$$\frac{d}{db}\exp\begin{pmatrix} 0 & (b+\omega)T \\ -(b+\omega)T & a \end{pmatrix} = \begin{pmatrix} 0 & \omega \\ -\omega & 0 \end{pmatrix}. \tag{7.24}$$

Checking the eigenvalues gives (7.20).

We seek solutions of (7.17) of the form $\mathbf{z_C} = \varepsilon \mathbf{e}_1$. Then

$$\mathbf{e}_1 - \mathbf{h}(T, \varepsilon\mathbf{e}_1, \zeta) = \mathbf{0}, \quad \text{where} \quad \mathbf{h} = \mathbf{g}/\varepsilon. \tag{7.25}$$

Now $\mathbf{h} \in C^{k-1}$ because $\mathbf{g}(t, \mathbf{0}, \zeta) = \mathbf{0}$ and

$$\mathbf{h}(T, \mathbf{0}, 0) = \mathbf{e}_1, \tag{7.26}$$

$$\mathbf{h}_t(T, \mathbf{0}, 0) = \partial_t \mathbf{S}_{\mathrm{c}}(T, 0)\mathbf{e}_1 = \begin{pmatrix} 0 \\ -\omega \end{pmatrix}, \tag{7.27}$$

$$\mathbf{h}_\zeta(T, \mathbf{0}, 0) = \partial_\zeta \mathbf{S}_{\mathrm{c}}(T, 0)\mathbf{e}_1 = \begin{pmatrix} \Re\, z \\ \Im\, z \end{pmatrix}, \tag{7.28}$$

where $\Re\, z \neq 0$. Hence we can solve (7.26) for ζ and t in terms of ε. We obtain a parametrization of the points on the orbits of the periodic solutions by

$$\bar{\mathbf{z}}(s, \varepsilon) = \boldsymbol{\phi}(s\tilde{T}(\varepsilon), \varepsilon\mathbf{e}_1 + \tilde{\mathbf{z}}_{\mathrm{h}}(\tilde{T}(\varepsilon), \varepsilon\mathbf{e}_1, \tilde{\zeta}(\varepsilon))). \tag{7.29}$$

We observe that $\bar{\mathbf{z}}_{\varepsilon\varepsilon}(s, 0) = \mathbf{0}$ because $\partial^2 \tilde{\mathbf{z}}_{\mathrm{h}}(t, \mathbf{0}, \zeta(0))/\partial {\mathbf{z}_{\mathrm{c}}}^2 = \mathbf{O}$.

Our approach is based on the implicit-function theorem. Thus all small solutions with period close to T are of that form. Suppose that there is a sequence of periodic solutions with initial points $\mathbf{z}_i$, parameters ζ_i, and frequencies ω_i with $\mathbf{z}_i \to 0$ and $\zeta_i \to 0$. (The frequency of a solution is 2π divided by its least period.) Suppose that there were a subsequence such that $\omega_i \to \infty$. Then a multiple of $2\pi/\omega_i$ would be close to T and hence $\mathbf{z}_i$ would be of the form described by (7.8). This is a contradiction since the minimal period of these $\mathbf{z}_i$ is close to T. Thus the minimal periods are bounded from below. Let $\bar{\omega}$ be an accumulation point of the sequence ω_i. It is not hard to see that $e^{i\omega t}$ is necessarily an eigenvalue of $\mathbf{S}(t, 0)$. This implies the uniqueness statements.

7C. Stability.

Continuation of the proof of Theorem 7.5. We have constructed a smooth family of periodic solutions that satisfy

$$\boldsymbol{\phi}(\tilde{T}(\varepsilon), \tilde{\mathbf{z}}(\varepsilon), \tilde{\zeta}(\varepsilon)) = \tilde{\mathbf{z}}(\varepsilon). \tag{7.30}$$

The stability of these periodic solutions is determined by Floquet multipliers. In the following we shall relate the Floquet multiplier that is connected to the bifurcation to second derivatives of $\tilde{\zeta}$ with respect to ε and to the direction in which the eigenvalue crosses.

We differentiate identity (7.30) with respect to ε to get

$$\mathbf{0} = \mathbf{U}\tilde{\mathbf{z}}_\varepsilon - \tilde{\mathbf{z}}_\varepsilon + \boldsymbol{\phi}_t \tilde{T}_\varepsilon + \boldsymbol{\phi}_\zeta \tilde{\zeta}_\varepsilon, \tag{7.31}$$

where $\mathbf{U}(\varepsilon) := \boldsymbol{\phi}_{\mathbf{z}}(\tilde{T}(\varepsilon), \tilde{\mathbf{z}}(\varepsilon), \tilde{\zeta}(\varepsilon))$. We differentiate (7.31):

$$\begin{aligned} \mathbf{0} = {} & \boldsymbol{\phi}_{\mathbf{zz}} : \tilde{\mathbf{z}}_\varepsilon \tilde{\mathbf{z}}_\varepsilon + \mathbf{U}(\varepsilon)\tilde{\mathbf{z}}_{\varepsilon\varepsilon} - \tilde{\mathbf{z}}_{\varepsilon\varepsilon} + 2\tilde{T}_\varepsilon \boldsymbol{\phi}_{t\mathbf{z}} \tilde{\mathbf{z}}_\varepsilon + \boldsymbol{\phi}_{tt}(\tilde{T}_\varepsilon)^2 \\ & + \boldsymbol{\phi}_t \tilde{T}_{\varepsilon\varepsilon} + 2\boldsymbol{\phi}_{t\zeta}\tilde{\zeta}_\varepsilon \tilde{T}_\varepsilon + 2\tilde{\zeta}_\varepsilon \boldsymbol{\phi}_{\zeta\mathbf{z}} \tilde{\mathbf{z}}_\varepsilon + \boldsymbol{\phi}_{\zeta\zeta}(\tilde{\zeta}_\varepsilon)^2 + \boldsymbol{\phi}_\zeta \tilde{\zeta}_{\varepsilon\varepsilon}. \end{aligned} \tag{7.32}$$

This identity can be evaluated at $\varepsilon = 0$, where

$$\boldsymbol{\phi}_t = \boldsymbol{\phi}_{tt} = \boldsymbol{\phi}_\zeta = \boldsymbol{\phi}_{\zeta\zeta} = \boldsymbol{\phi}_{t\zeta} = \mathbf{0}$$

because

$$\boldsymbol{\phi}(t, \mathbf{0}, \zeta) = \mathbf{0}, \quad \tilde{\mathbf{z}}_\varepsilon = \mathbf{e}_1, \quad \tilde{\mathbf{z}}_{\varepsilon\varepsilon} = \mathbf{0}$$

by construction, and where

$$\boldsymbol{\phi}_{\mathbf{zz}} : \tilde{\mathbf{z}}_\varepsilon \tilde{\mathbf{z}}_\varepsilon = \boldsymbol{\phi}_{\mathbf{zz}} : \mathbf{e}_1\mathbf{e}_1 = \mathbf{0}, \qquad \tilde{T}_\varepsilon \boldsymbol{\phi}_{t\mathbf{z}} \tilde{\mathbf{z}}_\varepsilon = \omega \tilde{T}_\varepsilon \mathbf{e}_2,$$
$$\tilde{\zeta}_\varepsilon \boldsymbol{\phi}_{\zeta\mathbf{z}} \mathbf{e}_1 = \zeta_\varepsilon(\Re\, z\mathbf{e}_1 + \Im\, z\mathbf{e}_2).$$

Thus

$$\tilde{\zeta}_\varepsilon \Re z \mathbf{e}_1 + (\tilde{\zeta}_\varepsilon \Im\, z + \tilde{T}_\varepsilon \omega)\mathbf{e}_2 = \mathbf{0} \tag{7.33}$$

at $\varepsilon = 0$, whence $\tilde{\zeta}_\varepsilon(0) = 0 = \tilde{T}_\varepsilon(0)$.

We differentiate (7.32) and evaluate the derivative at $\varepsilon = 0$:

$$\mathbf{0} = \mathbf{U}_{\varepsilon\varepsilon}(0)\mathbf{e}_1 + (\mathbf{U}(0) - \mathbf{I})\tilde{\mathbf{z}}_{\varepsilon\varepsilon\varepsilon}(0) + 2\tilde{T}_{\varepsilon\varepsilon}(0)\boldsymbol{\phi}_{t\mathbf{z}}\mathbf{e}_1 + 2\tilde{\zeta}_{\varepsilon\varepsilon}(0)\boldsymbol{\phi}_{\zeta\mathbf{z}}\mathbf{e}_1. \tag{7.34}$$

We apply $\mathbf{P}_\mathrm{c}$ and take the inner product with $\mathbf{e}_1$. Since $\mathbf{P}_\mathrm{c}\tilde{\mathbf{z}}_{\varepsilon\varepsilon\varepsilon}(\varepsilon) = \mathbf{0}$ by construction, it follows that $\mathbf{P}_\mathrm{c}\mathbf{U}(0)\tilde{\mathbf{z}}_{\varepsilon\varepsilon\varepsilon}(0) = \mathbf{0}$, and thus we arrive at the crucial identity

$$\langle \mathbf{e}_1, \mathbf{P}_\mathrm{c}\mathbf{U}_{\varepsilon\varepsilon}(0)\mathbf{e}_1\rangle + 2\Re\, z\tilde{\zeta}_{\varepsilon\varepsilon}(0) = 0. \tag{7.35}$$

We need our special coordinates for this identity. In general coordinates it looks much more complicated.

The Floquet multipliers of the periodic solutions parametrized by ε are defined in terms of Poincaré sections. A useful Poincaré section for us is the half space $\mathfrak{P} = \mathcal{X}_\mathrm{h} \times \{\mathbf{z}_\mathrm{c} : \mathbf{z}_\mathrm{c} = \lambda\mathbf{e}_1 \text{ for } \lambda > 0\}$. Let $\mathbf{Q}(\varepsilon)$ be the projection onto $\mathcal{X}_\mathrm{h} \times \langle \mathbf{e}_1\rangle$ along $\varepsilon^{-1}\boldsymbol{\phi}_t(\tilde{T}(\varepsilon), \tilde{\mathbf{z}}(\varepsilon), \tilde{\zeta}(\varepsilon))$ where $\langle \mathbf{e}_1\rangle$ denotes the span of $\mathbf{e}_1$. The Floquet multipliers are the elements of the spectrum of $\mathbf{V}(\varepsilon) := \mathbf{Q}(\varepsilon)\boldsymbol{\phi}_\mathbf{z}(\tilde{T}(\varepsilon), \tilde{\mathbf{z}}(\varepsilon), \tilde{\zeta}(\varepsilon))$ where $\mathbf{V}(\varepsilon)$ is understood as an operator on $\mathcal{X}_\mathrm{h} \times \langle \mathbf{e}_1\rangle$. The periodic solution is stable if the spectrum of $\mathbf{V}(\varepsilon)$ is contained in the open unit ball in the complex plane. It is unstable if a part of the spectrum is outside the closed unit ball. Clearly $\mathbf{Q}$ is the projection along $\mathbf{e}_2$ in the limit $\varepsilon \to 0$ and $\mathbf{Q}(0) = \mathbf{P}_\mathrm{h} + \mathbf{P}_{\mathbf{e}_1}\mathbf{P}_\mathrm{c}$ where $\mathbf{P}_{\mathbf{e}_1}$ denotes the projection along $\mathbf{e}_2$ to $\langle \mathbf{e}_1\rangle$ in $\mathcal{X}_1 = \mathbf{e}_1$, and 1 is a a simple isolated eigenvalue of $\mathbf{V}(0)$. $\mathbf{V}$ depends differentiably on ε. Thus there exists a smooth family of eigenvalues $\mu(\varepsilon)$ of $\mathbf{V}(\varepsilon)$ with $\mu(0) = 0$. The other part of the spectrum is contained in the open unit ball for small ε if this is true at $\varepsilon = 0$. The assertion about stability now follows from the formulas

$$\mu_\varepsilon(0) = 0, \qquad \mu_{\varepsilon\varepsilon}(0) = -\Re\, z\tilde{\zeta}_{\varepsilon\varepsilon}(0), \tag{7.36}$$

which we shall prove below.

There exists a parametrized family of eigenvectors $\mathbf{e}(\varepsilon)$, which we assume to be smooth and normalized by $\mathbf{P}_{\mathbf{e}_1}\mathbf{P}_\mathrm{c}\mathbf{e}(\varepsilon) = \mathbf{e}_1$. We evualuate the derivative of the identity

$$\mathbf{V}(\varepsilon)\mathbf{e}(\varepsilon) = \mu(\varepsilon)\mathbf{e}(\varepsilon) \tag{7.37}$$

at $\varepsilon = 0$ to get

$$\mathbf{V}_\varepsilon(0)\mathbf{e}_1 + \mathbf{V}(0)\mathbf{e}_\varepsilon(0) = \mu_\varepsilon(0)\mathbf{e}_1 + \mathbf{e}_\varepsilon(0). \tag{7.38}$$

Clearly

$$\varepsilon^{-1}\boldsymbol{\phi}_t(\tilde{T}(\varepsilon),\tilde{\mathbf{z}}(\varepsilon),\tilde{\zeta}(\varepsilon)) \to \alpha(0)/\pi e_2 \quad \text{as} \quad \varepsilon \to 0. \tag{7.39}$$

We shall later show that $\frac{d}{d\varepsilon}[\varepsilon^{-1}\boldsymbol{\phi}_t(\tilde{\mathbf{z}}(\varepsilon),\tilde{T}(\varepsilon),\tilde{\zeta}(\varepsilon))] \to \mathbf{0}$ as $\varepsilon \to 0$. Thus

$$\mathbf{Q}_\varepsilon(0) = \mathbf{O}, \tag{7.40}$$

and, since $\mathbf{U}_\varepsilon \mathbf{e}_1 = \mathbf{0}$,

$$\mu_\varepsilon(0)\mathbf{e}_1 = \mathbf{V}(0)\mathbf{e}_\varepsilon(0) - \mathbf{e}_\varepsilon(0). \tag{7.41}$$

Hence, because of the normalization, we get

$$\mathbf{V}(0)\mathbf{e}_\varepsilon(0) - \mathbf{e}_\varepsilon(0) = \mathbf{0}, \tag{7.42}$$

which implies that

$$\mathbf{e}_\varepsilon(0) = \mathbf{0} \tag{7.43}$$

and that $\mu_\varepsilon(0) = 0$. Let

$$\mathbf{j}(\varepsilon) := \frac{d^2}{d\varepsilon^2}\boldsymbol{\phi}_t(\tilde{T}(\varepsilon),\tilde{\mathbf{z}}(\varepsilon),\tilde{\zeta}(\varepsilon)) = \frac{d}{d\varepsilon}(\boldsymbol{\phi}_{t\mathbf{z}}\tilde{\mathbf{z}}_\varepsilon + \boldsymbol{\phi}_{tt}\tilde{T}_\varepsilon + \boldsymbol{\phi}_{t\zeta}\tilde{\zeta}_\varepsilon), \tag{7.44}$$

which we evaluate at $\varepsilon = 0$:

$$\mathbf{j}(0) = \frac{d}{d\varepsilon}(\boldsymbol{\phi}_{t\mathbf{z}}\mathbf{e}_1) = \boldsymbol{\phi}_{t\mathbf{zz}} : \mathbf{e}_1\mathbf{e}_1 = \mathbf{0} \tag{7.45}$$

because $\tilde{T}_\varepsilon(0) = 0$, $\tilde{\zeta}_\varepsilon(0) = 0$, $\boldsymbol{\phi}_{tt}(t,0,\zeta) = \mathbf{0}$, and $\boldsymbol{\phi}_{t\zeta}(t,0,\zeta)) = \mathbf{0}$. The last identity in (7.45) holds because

$$\boldsymbol{\phi}_{\mathbf{zz}}(t,\mathbf{0},\zeta) : \mathbf{e}_1\mathbf{e}_1 = \mathbf{0} \tag{7.46}$$

by the choice of local coordinates. This implies the statement of (7.39) by l'Hôpital's rule.

We differentiate (7.37) a second time and evaluate the derivative at $\varepsilon = 0$ to obtain

$$\mathbf{V}_{\varepsilon\varepsilon}\mathbf{e}_1 + \mathbf{V}\mathbf{e}_{\varepsilon\varepsilon} - \mathbf{e}_{\varepsilon\varepsilon} = \mu_{\varepsilon\varepsilon}\mathbf{e}_1 + \mathbf{e}_{\varepsilon\varepsilon} \qquad \text{at } \varepsilon = 0. \tag{7.47}$$

We apply $\mathbf{P}_{\mathrm{c}}$, take the scalar product with $\mathbf{e}_1$, and obtain

$$\begin{aligned} \mu_{\varepsilon\varepsilon} \quad &= \mathbf{P}_{\mathrm{c}}\mathbf{V}_{\varepsilon\varepsilon}\mathbf{e}_1 = \mathbf{P}_{\mathrm{c}}\mathbf{Q}_{\varepsilon\varepsilon}\mathbf{e}_1 + \mathbf{P}_{\mathbf{e}_1}\mathbf{P}_{\mathrm{c}}\mathbf{U}_{\varepsilon\varepsilon}\mathbf{e}_1 \\ &= \mathbf{P}_{\mathbf{e}_1}\mathbf{P}_{\mathrm{c}}\mathbf{U}_{\varepsilon\varepsilon}\mathbf{e}_1 = -\Re z\tilde{\zeta}_{\varepsilon\varepsilon}\mathbf{e}_1 \quad \text{at } \varepsilon = 0, \end{aligned} \tag{7.48}$$

where the second equality holds because of (7.39), the third equality holds because $\mathbf{Q}(\varepsilon)\mathbf{e}_1 = \mathbf{0}$ for all ε, and the fourth equality is a consequence of (7.35). ∎

8. Discussion. We have shown that under reasonable and weak assumptions, the initial-boundary-value problem (1.3) defines a smooth semiflow on a nonlinear manifold. Moreover, we reduced the question of determining whether a Hopf bifurcation occurs to determining how the disposition of eigenvalues depends on the parameter ζ; this has to be carried out on a case-by-case basis. This is done in [7] for Example 2.1. In general, the assumptions on the eigenvalues could be checked numerically.

We had to use a nonstandard approach because all the abstract approaches we are aware of require the space of admissible initial values to be a vector space. Even though we can transform the local semiflow to a semiflow on a linear space, we do not know how to apply the usual techniques. The difficulty is the following: In the abstract approach one tries to understand the problem as an ordinary differential equation

$$\dot{x} = G(x)$$

in a Banach space with an unbounded nonlinear operator G. Linear problems of this type are well understood, and using the theory for them one may tackle the nonlinear problem.

In our case, G is defined on a Banach manifold. Let $\boldsymbol{\psi}$ be a local coordinate map. Then the flow can be expressed in local coordinates by

$$(\mathbf{z}, t) \to \boldsymbol{\psi}^{-1}(\boldsymbol{\phi}(t, \boldsymbol{\psi}(\mathbf{z}))).$$

Formally, this can be differentiated to obtain the differential equation

$$\dot{\mathbf{z}} = (\boldsymbol{\psi}^{-1})' \circ F(\boldsymbol{\psi}(\mathbf{z}), t).$$

In our case $F : C^{2,\alpha} \to C^{\alpha}$. At this point we cannot use our local coordinates, which are not continuous in the topology of C^{α}. Thus we could not apply the approach of [10], [17], [21], [22], [23], or [25], and we reverted to the approach of Hopf [14] as in [16]. On the other hand, these papers treat problems in all of $\mathbb{R}^n$, or problems with Dirichlet boundary conditions or periodic boundary conditions, so that they could work in a linear space.

Our study reveals that the solutions of the equations of viscoelasticity have some properties that are very similar to those for parabolic equations (e.g., the linearizations define analytic semigroups) and have other properties that are very different (e.g., noncompactness of the flow).

We have restricted our attention to scalar problems primarily for simplicity of exposition. This is not at all essential. In connection with Example 2.3 we have discussed the extension to systems. Similarly, it is likely that our approach works as well for other problems. This is certainly true for parabolic problems, but it should be true, for example, for some integro-differential equations of other kinds of viscoelasticity. Our methods can handle a variety of generalizations, e.g., problems in which Ω_T is not cylindrical.

Acknowledgment. We are grateful to the Mathematical Institute at Oberwolfach for providing facilities that enabled us to collaborate face-to-face at a critical stage of our work.

STRONG ASYMPTOTICS OF ORTHONORMAL POLYNOMIALS WITH THE AID OF GREEN'S FUNCTION*

FRANZ PEHERSTORFER† AND ROBERT STEINBAUER†

Abstract. We give explicit asymptotic representations as well as ratio asymptotics of the orthogonal polynomials with asymptotically periodic reflection coefficients in terms of Green's function. All the limit relations will hold uniformly compact outside the support of the measure of orthogonality. Furthermore, with the help of harmonic measures we will characterize all those sets, i.e., supports of orthogonality measures, where orthogonal polynomials with asymptotically periodic reflection coefficients exist.

Key words. orthogonal polynomials, unit circle, arcs, asymptotics, asymptotically periodic reflection coefficients, Green's function, harmonic measures

1. Introduction.

Let $\{\Phi_n(z,\sigma) = \kappa_n z^n + \cdots\}_{n\in\mathbb{N}_0}$, $\kappa_n := \kappa_n(\sigma) > 0$, be a sequence of orthonormal polynomials on the unit circle with respect to the positive measure σ, i.e.,

$$\frac{1}{2\pi}\int_0^{2\pi} \Phi_n(e^{i\varphi},\sigma)\overline{\Phi_m(e^{i\varphi},\sigma)}\,d\sigma(\varphi) = \delta_{nm}.$$

All the measures appearing in this paper are understood to be probability measures, i.e., they are normalized by

$$\frac{1}{2\pi}\int_0^{2\pi} d\sigma(\varphi) = 1.$$

If the support of σ is an infinite set, then it is well known that the orthonormal polynomials are uniquely determined and can be completely described by the reflection coefficients

$$a_n := a_n(\sigma) =: \frac{\Phi_{n+1}(0,\sigma)}{\kappa_{n+1}}.$$

All these reflection coefficients are located in the open unit disk and generate the orthonormal polynomials iteratively by the recurrence relation

$$\sqrt{1-|a_n|^2}\,\Phi_{n+1}(z,\sigma) = z\Phi_n(z,\sigma) + a_n\Phi_n^*(z,\sigma), \quad n\in\mathbb{N}_0, \quad \Phi_0(z,\sigma) = 1, \tag{1.1}$$

†Institut für Analysis und Numerik, Johannes Kepler Universität Linz, 4040 Linz-Auhof, Austria (franz.peherstorfer@jk.uni-linz.ac.at, robert.steinbauer@jk.uni-linz.ac.at).

where $\Phi_n^*(z,\sigma) := z^n\overline{\Phi_n(1/\bar{z},\sigma)}$ denotes the reversed polynomial. It is easy to see that the leading coefficients κ_n are given by

$$\kappa_n = \left(\prod_{j=0}^{n-1}(1-|a_j|^2)\right)^{-1/2}.$$

In this paper we study orthonormal polynomials whose reflection coefficients are asymptotically periodic. That is, there exists a periodic sequence $\{a_n^0\}_{n\in\mathbb{N}_0}$ with

$$a_{n+N}^0 = a_n^0, \quad n\in\mathbb{N}_0, \quad N\in\mathbb{N} \text{ fixed}, \quad |a_n^0|<1,$$

and

$$\lim_{\nu\to\infty} a_{\nu N+j} = a_j^0, \quad j=0,\dots,N-1. \tag{1.2}$$

We shall investigate the asymptotic behavior as well as ratio asymptotics of such orthonormal polynomials $\Phi_n(z,\sigma)$ as $n\to\infty$ outside the support of the orthogonality measure σ. So far, only comparative asymptotics for the perturbed and unperturbed orthonormal polynomials outside the support of the orthogonality measures were known (see [2, 23]). We shall derive explicit and strong limit representations in terms of Green's function, corresponding to the essential part of the support of the orthogonality measure, which consists of a finite union of arcs on the unit circle. For asymptotics on the support, see a forthcoming paper of the authors [24]. Furthermore, with the aid of harmonic measures we will characterize those unions of subarcs of the unit circle on which orthonormal polynomials with asymptotically periodic reflection coefficients live. By the way, let us recall the well-known fact (see, e.g., [25, section 11.5]) that polynomials orthogonal on a bounded set of the real line can be considered as special cases of polynomials orthogonal on the unit circle. Hence all the above results in particular give corresponding results for polynomials orthogonal on several intervals of the real line. For asymptotic representations of such polynomials and for related references, see [7] and [19]. Finally let us mention that the investigated polynomials play, apart from their use in numerical analysis, also an important role in problems of physics when the spectrum consists of several bands, for instance, in certain models of solid state physics [13], [28] and of nonlinear waves and solitons [16, 26, 4] but also in the field of complex iteration [3].

The proofs of all of our results are given at the end in section 5.

2. Some important preliminary notations and facts. Let us consider the periodic sequence of reflection coefficients $\{a_n^0\}_{n\in\mathbb{N}_0}$, $|a_n^0|<1$, and $a_{n+N}^0 = a_n^0$ for all $n\in\mathbb{N}_0$; $N\in\mathbb{N}$ fixed. The corresponding orthonormal polynomials are denoted by $\{\Phi_n(z,\sigma_0)\}_{n\in\mathbb{N}_0}$. It is well known that the polynomials of the second kind, defined by

$$\Psi_n(z,\sigma_0) := \frac{1}{2\pi}\int_0^{2\pi}\frac{e^{i\varphi}+z}{e^{i\varphi}-z}\left(\Phi_n(e^{i\varphi},\sigma_0)-\Phi_n(z,\sigma_0)\right)d\sigma_0(\varphi), \quad n\in\mathbb{N}, \tag{2.1}$$

and $\Psi_0(z,\sigma_0) := 1$ can be generated recursively in the same way as the orthonormal polynomials $\Phi_n(z,\sigma_0)$ (see (1.1)) by using the sequence of reflection coefficients $\{-a_n^0\}_{n\in\mathbb{N}_0}$ instead of $\{a_n^0\}_{n\in\mathbb{N}_0}$.

If we consider the m-shifted, $m\in\mathbb{N}$ fixed, sequence of reflection coefficients $\{a_{n+m}^0\}_{n\in\mathbb{N}_0}$ and if we proceed as in (1.1) and (2.1), respectively, we get the mth

associated orthonormal polynomials $\{\Phi_n^{[m]}(z,\sigma_0)\}_{n\in\mathbb{N}_0}$ and $\{\Psi_n^{[m]}(z,\sigma_0)\}_{n\in\mathbb{N}_0}$, respectively, which will be used in Corollary 3.5.

Now let us define the value

$$L := 2\left(\prod_{j=0}^{N-1}\left(1-|a_j^0|^2\right)\right)^{1/2} \tag{2.2}$$

and the monic polynomials

$$\begin{aligned}\mathcal{T}(z) &:= \frac{1}{2}\big(P_N(z,\sigma_0)+\Omega_N(z,\sigma_0)+P_N^*(z,\sigma_0)+\Omega_N^*(z,\sigma_0)\big) = z^N+\cdots,\\ R(z) &:= \mathcal{T}^2(z)-L^2z^N = z^{2N}+\cdots,\end{aligned} \tag{2.3}$$

where $\{P_n(z,\sigma_0)\}_{n\in\mathbb{N}_0}$ and $\{\Omega_n(z,\sigma_0)\}_{n\in\mathbb{N}_0}$ denote the monic orthogonal polynomials and the polynomials of the second kind, respectively, i.e.,

$$\begin{aligned}P_n(z,\sigma_0) &= \frac{\Phi_n(z,\sigma_0)}{\kappa_n(\sigma_0)} = \left(\prod_{j=0}^{n-1}(1-|a_j^0|^2)\right)^{1/2}\Phi_n(z,\sigma_0),\\ \Omega_n(z,\sigma_0) &= \left(\prod_{j=0}^{n-1}(1-|a_j^0|^2)\right)^{1/2}\Psi_n(z,\sigma_0).\end{aligned}$$

It can be shown that $\mathcal{T}$ and R have all their zeros on the unit circle; all the zeros of $\mathcal{T}$ are simple and those of R are at most double.

Remark. Let us note that for convenience of the reader we use a slightly different notation than in [22, 23]. Here, in contrast to [22, 23], R may have double zeros. So we can write

$$R(z) =: R^0(z)\mathcal{U}^2(z);$$

compare (4.1) below, where R^0 and $\mathcal{U}$ are self-reversed polynomials and where $\mathcal{U}$ vanishes exactly at the double zeros of R. Now R^0 corresponds to R from [22, 23].

We continue with the definition of the real set

$$E_l := \big\{\varphi\in[0,2\pi] : |\mathcal{T}(e^{i\varphi})|\le L\big\}.$$

From Geronimus's paper [10] one can derive that E_l consists of l, $l\le N$, disjoint intervals, while all the sets $\big\{\varphi\in[0,2\pi] : |\mathcal{T}(e^{i\varphi})|\le K\big\}$, with $0<K<L$, consist of exactly N intervals. That is, $l<N$ occurs if and only if there exist points ψ's such that $|\mathcal{T}(e^{i\varphi})|$ has a local extremum at ψ and $|\mathcal{T}(e^{i\psi})|=L$. In such a case, R has a double root at $e^{i\psi}$. It has also been shown by Geronimus [8, 9, 10] for the real case (see also [15]) that

$$\big(\operatorname{supp}(\sigma_0)\big)' = E_l$$

and $\operatorname{supp}(\sigma_0)\setminus E_l$ is a finite set. Let

$$\Gamma_{E_l} := \{e^{i\varphi} : \varphi\in E_l\}$$

be the corresponding arcs on the unit circle. Let us point out that all the zeros of the polynomial R are located on Γ_{E_l}, where each boundary point of Γ_{E_l} is a simple zero of R.

By (1.2) the $\Phi_n(z,\sigma)$'s can be considered as a compact perturbation of the "periodic" orthogonal polynomials $\Phi_n(z,\sigma_0)$. Hence, it is known that

$$\big(\mathrm{supp}(\sigma)\big)' = \big(\mathrm{supp}(\sigma_0)\big)' = \Gamma_{E_l}; \tag{2.4}$$

see [9] and [12, Theorem 3] for the case $N = 1$. (In fact, the proof given in [12] can easily be extended to the general case $N \in \mathbb{N}$.)

For the study of the asymptotic behavior of the orthonormal polynomials $\Phi_n(z,\sigma)$ outside the support of their orthogonality measure we exclude the case that all the a_j^0's are zero, which would imply that $\lim a_n = 0$; hence,

$$\sum_{j=0}^{N-1} |a_j^0| > 0. \tag{2.5}$$

If (2.5) is not fulfilled, one can apply the known theory dealing with orthogonal polynomials from Geronimus' class (i.e., $\sum |a_n| < \infty$) or from Szegö's class (i.e., $\sum |a_n|^2 < \infty$) or from Nevai's class (i.e., $a_n \to 0$).

Throughout this paper we will use the sequence of polynomials $\{\Phi_n(z,\sigma_0)\}_{n\in\mathbb{N}_0}$ with periodic reflection coefficients as a comparison system.

Let us start our considerations with the following settings:

$$\begin{aligned} y^{\pm}(z) &:= \frac{\mathcal{T}(z) \pm \sqrt{R(z)}}{L}, \qquad z \in \mathbb{C} \setminus \Gamma_{E_l}, \\ \Phi_n^{\pm}(z,\sigma_0) &:= \Phi_{n+N}(z,\sigma_0) - y^{\pm}(z)\Phi_n(z,\sigma_0), \\ \Phi_n^{*,\pm}(z,\sigma_0) &:= \Phi_{n+N}^*(z,\sigma_0) - y^{\pm}(z)\Phi_n^*(z,\sigma_0), \end{aligned}$$

where we take that branch of the square root $\sqrt{R}$ for which $\sqrt{R(0)} = 1$. By the above statements on the zeros of R, both functions $y^{\pm}$ are analytic on $\mathbb{C} \setminus \Gamma_{E_l}$ and the following estimates hold (cf. [23, Lemma 2.1]):

$$|y^+(z)| > 1 \quad \text{and} \quad |y^-(z)| < 1 \quad \text{on } \mathbb{C} \setminus \Gamma_{E_l}. \tag{2.6}$$

The functions $\{\Phi_n^{\pm}\}_{n\in\mathbb{N}_0}$ and $\{\Phi_n^{*,\pm}\}_{n\in\mathbb{N}_0}$ satisfy the same recurrence relation (1.1) as the orthonormal polynomials $\{\Phi_n(z,\sigma_0)\}_{n\in\mathbb{N}_0}$ and they will be important in the following.

Next, let us define two finite sets $\mathcal{N}$ and $\mathcal{N}^*$ by

$$\begin{aligned} \mathcal{N} &:= \big\{z \in \mathbb{C} \setminus \Gamma_{E_l} : \Phi_m^-(z,\sigma_0) = 0, m \in \{0,\dots,N-1\}\big\}, \\ \mathcal{N}^* &:= \big\{z \in \mathbb{C} \setminus \Gamma_{E_l} : \Phi_m^{*,-}(z,\sigma_0) = 0, m \in \{0,\dots,N-1\}\big\}. \end{aligned}$$

It will turn out that the points from $\mathcal{N}$ and $\mathcal{N}^*$, respectively, are exceptional in $\mathbb{C} \setminus \Gamma_{E_l}$ in the sense that the orthogonal polynomials $\Phi_n(z,\sigma_0)$ behave asymptotically differently at these points.

Since $\mathcal{N}$ and $\mathcal{N}^*$ will play a crucial role in what follows, let us describe basic facts of these sets. As a first remarkable property we note that by

$$\big(\mathcal{N} \cap \{|\,z\,| = 1\}\big) = \big(\mathcal{N}^* \cap \{|\,z\,| = 1\}\big) =: \{e^{i\xi_1},\dots,e^{i\xi_p}\} \tag{2.7}$$

one can describe exactly the mass-points of σ_0, i.e., $\sigma_0(\{\xi_1\}),\dots,\sigma_0(\{\xi_p\}) > 0$; see [23, Remark 2.2]. Furthermore,

$$\mathcal{N} \subset \{|z| \le 1\}, \qquad \mathcal{N}^* \subset \{|z| \ge 1\},$$

and

$$\mathcal{N}^* = \{1/\bar{z} : z \in \mathcal{N} \setminus \{0\}\}.$$

It will be interesting for the following to remark that the set $\mathcal{N}$ may indeed contain points from the interior of the unit circle. The simplest way to see this is to consider the sequence of reflection coefficients $\{a_n(\sigma_0)\} = \{0, a, 0, a, \dots\}$, $a \neq 0$; i.e., $N = 2$. Then

$$\Phi_{2k+1}(0, \sigma_0) = P_{2k+1}(0, \sigma_0) = 0 \quad \text{for all } k \in \mathbb{N}_0.$$

Hence,

$$\Phi_1^-(0, \sigma_0) = \Phi_3(0, \sigma_0) - y^-(0)\Phi_1(0, \sigma_0) = 0$$

and $0 \in \mathcal{N}$. But also $\mathcal{N} \cap \{0 < |z| < 1\} \neq \emptyset$ is possible as examples show.

On the other hand, $\mathcal{N} \cap \{|z| < 1\} \neq \emptyset$ is only possible for periods $N \geq 2$. For the period-1-case the set $\mathcal{N}$ is either empty, if σ_0 has no mass-point, or consists exactly of the point $e^{i\xi_1}$, where ξ_1 is the only mass-point of σ_0. This can easily be seen from the relation [23, (2.41)]

$$\mathcal{N} \subseteq \{z \in \mathbb{C} : P_1(z, \sigma_0) = \Omega_1(z, \sigma_0)\} \cup \{e^{i\xi_1}\},$$

where the set on the right-hand side is either equal to $\{e^{i\xi_1}\}$ if there is a ξ_1 or empty otherwise, since $P_1(z, \sigma_0) = z + a_0(\sigma_0)$, $\Omega_1(z, \sigma_0) = z - a_0(\sigma_0)$, and $a_0(\sigma_0) \neq 0$.

Finally, let us introduce the function

$$Y(z) := \left(\frac{\mathcal{T}(z) + \sqrt{R(z)}}{L}\right)^{1/N} = \sqrt[N]{y^+(z)}, \quad z \in \mathbb{C} \setminus \Gamma_{E_l}. \tag{2.8}$$

Note that by this definition the function Y is multiple-valued if $N > 1$, but both Y^N and $|Y|$ are single-valued on $\mathbb{C} \setminus \Gamma_{E_l}$. By (2.6) Y maps $\mathbb{C} \setminus \Gamma_{E_l}$ onto $\{|\,z\,| > 1\}$, the exterior of the unit disk.[1] Furthermore,

$$Y(z) = \mathcal{O}(z) \quad \text{as } z \text{ tends to infinity.}$$

On the arcs we have

$$|Y(z)| = \lim_{r \to 1} |Y(rz)| = 1, \quad z \in \Gamma_{E_l}.$$

Hence $\ln|Y(z)|$ is the real Green's function of $\mathbb{C} \setminus \Gamma_{E_l}$ with pole at infinity (for the definition of Green's function, see, e.g., [18, section 5.2] or [27, section 9.7]; compare also the beginning of section 4). Further, by

$$\big(\mathcal{T}(z) - \sqrt{R(z)}\big)\big(\mathcal{T}(z) + \sqrt{R(z)}\big) = L^2 z^N$$

and by the self-reversed property $\mathcal{T} = \mathcal{T}^*$ and $R = R^*$, one obtains

$$\lim_{z \to \infty} \frac{\mathcal{T}(z) - \sqrt{R(z)}}{L} = \lim_{\substack{y \to 0 \\ y = 1/\bar{z}}} \overline{\left[\frac{\mathcal{T}(y) - \sqrt{R(y)}}{L y^N}\right]} = \frac{L}{2}.$$

[1] Recall that we always assume (2.5) to hold true. Otherwise Γ_{E_l} would be the entire unit circle, $\mathbb{C} \setminus \Gamma_{E_l}$ would be disconnected, and the following statements would hold true only for $\{|z| > 1\}$ and not for $\mathbb{C} \setminus \Gamma_{E_l}$.

From this relation we derive

$$\lim_{z\to\infty}\frac{Y(z)}{z} = \sqrt[N]{2/L} =: \frac{1}{C(\Gamma_{E_l})},$$

i.e.,

$$C(\Gamma_{E_l}) = \sqrt[N]{L/2} = \left(\prod_{j=0}^{N-1}\left(1-|a_j^0|^2\right)\right)^{1/2N}$$

is the capacity of the set Γ_{E_l}.

3. Asymptotics of the orthonormal polynomials. In this section we study asymptotics of orthonormal polynomials with asymptotically periodic reflection coefficients. This section is organized as follows: First we will describe the asymptotic behavior of the "periodic" orthonormal polynomials $\{\Phi_n(z,\sigma_0)\}$ on the entire complex plane (see Proposition 3.1 and the remark thereafter). Next we shall state our asymptotic results concerning the polynomials $\{\Phi_n(z,\sigma)\}$ and give some additional remarks. All the proofs will be given in section 5.

Throughout this section we assume that the reflection coefficients $\{a_n\}$ converge sufficiently fast towards the periodic sequence $\{a_n^0\}$. To be precise, we suppose that

$$\sum_{n=0}^{\infty}|a_n - a_n^0| < \infty. \tag{3.1}$$

Let us recall the estimates

$$|Y(z)| > 1 \quad \text{on } \mathbb{C}\setminus\Gamma_{E_l} \tag{3.2}$$

and

$$\left|\frac{z}{Y(z)}\right| < 1 \quad \text{on } \mathbb{C}\setminus\Gamma_{E_l}, \tag{3.3}$$

which follow from (2.6), (2.8), and the relation $\mathcal{T}^2(z) - R(z) = L^2 z^N$.

With the inequalities (3.2) and (3.3) in mind the asymptotic behavior of the "periodic" orthonormal polynomials $\Phi_n(z,\sigma_0)$ outside the arcs Γ_{E_l} can be completely described with the aid of the function $Y(z)$ as follows.

PROPOSITION 3.1. *Let* (2.5) *be fulfilled. Then the following asymptotics hold for every* $m \in \{0,\dots,N-1\}$:

$$\begin{aligned}\lim_{\nu\to\infty}\left[\Phi_{m+\nu N}(z,\sigma_0) - Y^{\nu N}(z)\frac{L}{2}\frac{\Phi_m^-(z,\sigma_0)}{\sqrt{R(z)}}\right] = 0,\\ \lim_{\nu\to\infty}\left[\Phi^*_{m+\nu N}(z,\sigma_0) - Y^{\nu N}(z)\frac{L}{2}\frac{\Phi_m^{*,-}(z,\sigma_0)}{\sqrt{R(z)}}\right] = 0\end{aligned} \tag{3.4}$$

uniformly on compact subsets of $\mathbb{C}\setminus\Gamma_{E_l}$. *Furthermore,*

$$\Phi_{m+\nu N}(z,\sigma_0) = \left(\frac{z}{Y(z)}\right)^{\nu N}\frac{(-L)}{2}\frac{\Phi_m^+(z,\sigma_0)}{\sqrt{R(z)}} \underset{\nu\to\infty}{\longrightarrow} 0 \qquad \textit{for } z\in\mathcal{N},$$

$$\Phi^*_{m+\nu N}(z,\sigma_0) = \left(\frac{z}{Y(z)}\right)^{\nu N}\frac{(-L)}{2}\frac{\Phi_m^{*,+}(z,\sigma_0)}{\sqrt{R(z)}} \underset{\nu\to\infty}{\longrightarrow} 0 \qquad \textit{for } z\in\mathcal{N}^*.$$

We will also need the following lemma.

LEMMA 3.2. *Let us define the functions,* $n = \nu N + m$,

$$\mathcal{G}_n(z,\sigma_0) := -\frac{L\big(y^-(z)\big)^\nu}{z^n A(z)}\,\Phi_m^+(z,\sigma_0),$$
$$\mathcal{H}_n(z,\sigma_0) := -\frac{L\big(y^-(z)\big)^\nu}{z^{n+1} A(z)}\,\Phi_m^{*,+}(z,\sigma_0),$$

where the polynomial A *is given by* $A(z) = P_N^*(z,\sigma_0) - P_N(z,\sigma_0)$. *Then, under the assumptions* (2.5) *and* (3.1),

$$\lim_{n\to\infty}\big(\Phi_n^*(z,\sigma)\mathcal{G}_n(z,\sigma_0) - z\Phi_n(z,\sigma)\mathcal{H}_n(z,\sigma_0)\big) =: \Delta(z) \tag{3.5}$$

exists uniformly compact on $\mathbb{C}\setminus\big(\Gamma_{E_l}\cup\{e^{i\xi_1},\dots,e^{i\xi_p}\}\big)$; *notation as in* (2.7). *Furthermore, the function* Δ *is analytic and has no zeros outside the unit circle.*

From Proposition 3.1 we can derive strong asymptotics for the asymptotically periodic orthonormal polynomials $\Phi_n(z,\sigma)$ as follows.

THEOREM 3.3. *Suppose that* (2.5) *and* (3.1) *are fulfilled. Further, let the functions* Y *and* $\Delta(z)$ *be given in* (2.8) *and* (3.5), *respectively. Then for all* $k\in\mathbb{N}_0$ *the relation*

$$\lim_{\nu\to\infty}\frac{\Phi_{m+\nu N}^{(k)}(z,\sigma)}{(\nu N)_k Y^{\nu N-k}(z)} = \Delta(z)\big(Y'(z)\big)^k\frac{L}{4}\,\frac{\Phi_m^-(z,\sigma_0)}{\sqrt{R(z)}} \tag{3.6}$$

holds uniformly on compact subsets of $\mathbb{C}\setminus\big(\Gamma_{E_l}\cup\mathcal{N}\cup\mathcal{M}_k\big)$, *and the relation*

$$\lim_{\nu\to\infty}\frac{\big(\Phi_{m+\nu N}^*(z,\sigma)\big)^{(k)}}{(\nu N)_k Y^{\nu N-k}(z)} = \Delta(z)\big(Y'(z)\big)^k\frac{L}{4}\,\frac{\Phi_m^{*,-}(z,\sigma_0)}{\sqrt{R(z)}} \tag{3.7}$$

holds uniformly on compact subsets of $\mathbb{C}\setminus\big(\Gamma_{E_l}\cup\mathcal{N}^*\cup\mathcal{M}_k\big)$, *where*

$$\mathcal{M}_k = \begin{cases}\emptyset & \text{if } k=0,\\ \{Y'=0\} & \text{if } k\ge 1.\end{cases}$$

Here, $f^{(k)}(z)$ *denotes the* k*th derivative of the function* f *with respect to* z *and* $(n)_k := n(n-1)\times\cdots\times(n-k+1)$ *(and* $(n)_0 := 1$*).*

The next theorem gives important comparative asymptotics and will also be needed for the proof of Theorem 3.3.

THEOREM 3.4. *Suppose that* (2.5) *and* (3.1) *are fulfilled and let* $k\ge 0$ *be an arbitrary integer. Then, with the same notation as in Theorem* 3.3, *we have*

$$\lim_{n\to\infty}\frac{\Phi_n^{(k)}(z,\sigma)}{\Phi_n^{(k)}(z,\sigma_0)} = \frac{1}{2}\Delta(z) \tag{3.8}$$

uniformly on compact subsets of $\mathbb{C}\setminus\big(\Gamma_{E_l}\cup\mathcal{N}\cup\mathcal{M}_k\big)$ *and*

$$\lim_{n\to\infty}\frac{\big(\Phi_n^*(z,\sigma)\big)^{(k)}}{\big(\Phi_n^*(z,\sigma_0)\big)^{(k)}} = \frac{1}{2}\Delta(z) \tag{3.9}$$

uniformly on compact subsets of $\mathbb{C} \setminus \big(\Gamma_{E_l} \cup \mathcal{N}^* \cup \mathcal{M}_k\big)$.

For the following corollaries let us consider the zeros of Δ, i.e., the set $\{\Delta = 0\}$, where the function Δ is given in (3.5). Then

$$\{\Delta = 0\} \subset \{|\,z\,| = 1\} \quad \text{and} \quad \{e^{i\varphi} : \varphi \in \operatorname{supp}(\sigma) \setminus E_l\} \subseteq \{\Delta = 0\}$$

(see [23, Remark 3.2]).

COROLLARY 3.5. *Let* k, j *be any nonnegative integers and suppose that* (2.5) *and* (3.1) *are satisfied. Then*

$$\lim_{\nu\to\infty} \frac{\Phi_{(\nu N+k)+j}(z,\sigma)}{\Phi_{\nu N+k}(z,\sigma)} = \frac{1}{2}\left(\frac{\Phi_k^{*,-}(z,\sigma_0)}{\Phi_k^{-}(z,\sigma_0)}\, D_j^k(z) + C_j^k(z)\right) \tag{3.10}$$

holds uniformly on compact subsets of $\mathbb{C} \setminus \big(\Gamma_{E_l} \cup \mathcal{N} \cup \{\Delta = 0\}\big)$. *Here the polynomials* C_j^k *and* D_j^k *are given by*

$$\begin{aligned} C_j^k(z) &:= \Phi_j^{[k]}(z,\sigma_0) + \Psi_j^{[k]}(z,\sigma_0),\\ D_j^k(z) &:= \Phi_j^{[k]}(z,\sigma_0) - \Psi_j^{[k]}(z,\sigma_0); \end{aligned}$$

recall the definition of the k*th associated polynomials from section* 2.

Corollary 3.5 shows that the sequence $\{\Phi_{n+j}(z,\sigma)/\Phi_n(z,\sigma)\}_{n\in\mathbb{N}_0}$ contains N convergent subsequences with N different limit-functions. If we take $j = N$, then $\Phi_{n+N}(z,\sigma)/\Phi_n(z,\sigma)$ is convergent as n tends to infinity as follows.

COROLLARY 3.6. *Let* (2.5) *and* (3.1) *be fulfilled. Then there holds*

$$\lim_{n\to\infty} \frac{\Phi_{n+N}(z,\sigma)}{\Phi_n(z,\sigma)} = \frac{\mathcal{T}(z) + \sqrt{R(z)}}{L} = Y^N(z) \tag{3.11}$$

uniformly on compact subsets of $\mathbb{C} \setminus \big(\Gamma_{E_l} \cup \mathcal{N} \cup \{\Delta = 0\}\big)$.

At the end of this section let us state some additional remarks.

Remark. As we learned quite recently, Barrios and López [2] have shown that the limit relation (3.11) holds true even under weaker assumptions. For the case $N = 1$ compare also a recent result of Bello and López [1, Theorem 1].

Remark. It is obvious that from Theorem 3.3 one immediately can derive strong asymptotics for the reproducing kernel-function

$$K_n(z,\xi;\sigma) := \sum_{k=0}^{n} \Phi_k(z,\sigma)\overline{\Phi_k(\xi,\sigma)}$$

outside the set $\Gamma_{E_l} \cup \mathcal{N} \cup \mathcal{N}^*$ by making use of the Christoffel–Darboux formula (cf. [25, Theorem 11.4.2])

$$K_n(z,\xi;\sigma) = \frac{\Phi_{n+1}^*(z,\sigma)\overline{\Phi_{n+1}^*(\xi,\sigma)} - \Phi_{n+1}(z,\sigma)\overline{\Phi_{n+1}(\xi,\sigma)}}{1 - z\bar{\xi}}.$$

Remark. Let us point out that Theorem 3.4, and consequently also Theorem 3.3, does not hold true in general at the points from $\mathcal{N}$ and $\mathcal{N}^*$, respectively. An easy way to see this is to consider the reflection coefficients

$$\begin{aligned} \{a_n(\sigma_0)\} &:= \{0, a, 0, a, 0, \dots\},\\ \{a_n(\sigma)\} &:= \{b_0, a, b_1, a, b_2, \dots\}, \end{aligned}$$

where $b_n \to 0$ sufficiently fast such that (3.1) is fulfilled. Suppose further that all the b_n's are different from zero. Then $0 \in \mathcal{N}$ and

$$\Phi_{2m+1}(0,\sigma) = b_m \neq 0 \qquad \text{while} \qquad \Phi_{2m+1}(0,\sigma_0) = 0 \qquad \text{for all } m \in \mathbb{N}_0.$$

Hence, the quotient $\Phi_n(z,\sigma)/\Phi_n(z,\sigma_0)$ does not exist at $z = 0$ for all odd n, and consequently,

$$\frac{\Phi_n(0,\sigma)}{\Phi_n(0,\sigma_0)} \not\to \frac{1}{2}\Delta(0).$$

Since $\{Y' = 0\} \neq \emptyset$ is possible, one also has to stay away from this set if $k > 0$.

Remark. Even though (3.6) does not hold true on the set $\mathcal{N}$ in general, we can say at least that

$$\frac{\Phi_n^{(k)}(z,\sigma)}{n^k Y^n(z)} = \mathcal{O}(1) \quad \text{on } \mathcal{U}(z) \tag{3.12}$$

for every neighborhood $\mathcal{U}(z)$ of $z \in \mathcal{N}$ with $\mathcal{U}(z) \cap \Gamma_{E_l} = \emptyset$; $k \in \mathbb{N}_0$ fixed. This can easily be derived from the maximum principle since the functions at the left-hand side of (3.12) are analytic on $\mathcal{U}(z)$ and uniformly bounded on $\partial\mathcal{U}(z)$. An analogous estimate as in (3.12) also holds true for the reversed polynomials $\big(\Phi_n^*(z,\sigma)\big)^{(k)}$ on $\mathcal{N}^*$.

4. Characterization of the arcs. In this section we will characterize those subsets of the unit circle, where orthogonal polynomials with asymptotically periodic reflection coefficients exist. Such subsets will be unions of finitely many arcs which we again will denote by Γ_{E_l}. To be precise, we shall describe those arcs Γ_{E_l}, respectively, intervals E_l, which coincide with the accumulation points of the support of a measure σ, i.e., $(\mathrm{supp}(\sigma))' = E_l$, whose corresponding reflection coefficients behave asymptotically periodic.

Additional to the notations in the previous sections, let

$$E_l =: \bigcup_{j=1}^{l} [\varphi_{2j-1}, \varphi_{2j}], \quad \varphi_i \neq \varphi_k \text{ for } i \neq k.$$

Of course, there is a one-to-one relation between the arcs $\Gamma_{E_l} := \bigcup_{j=1}^{l} \{e^{i\varphi} : \varphi \in [\varphi_{2j-1}, \varphi_{2j}]\}$ and the self-reversed polynomials, which vanish exactly at the boundary points of the arcs,

$$R^0(z) := \rho \prod_{j=1}^{2l} (z - e^{i\varphi_j}), \qquad \rho = (-1)^l \exp\left\{ -\frac{i}{2} \sum_{j=1}^{2l} \varphi_j \right\}.$$

Let us point out that the polynomial R^0 is of degree $2l$ while the polynomial R, defined in (2.3), was of degree $2N \geq 2l$, where N denoted the length of the period of the asymptotically periodic reflection coefficients under consideration. Furthermore, R had $N - l$ additional double zeros in the interior of the arcs. Hence, we can write

$$R(z) =: R^0(z)\mathcal{U}^2(z), \tag{4.1}$$

where $\mathcal{U}$ is again a self-reversed polynomial of degree $N - l$ whose zeros are all simple and are located in the interior of the arcs.

To state the next theorem we need to recall the following definitions.

By $g(z) := g(z,\infty)$ we denote the (real) Green's function for the set $\mathbb{C} \setminus \Gamma_{E_l}$ with pole at ∞. This function is uniquely determined by the following properties:

(1) $g(z)$ is harmonic on $\mathbb{C} \setminus \Gamma_{E_l}$,
(2) $g(z) - \ln|z|$ is harmonic near ∞,
(3) $\lim_{z \to e^{i\varphi}} g(z) = 0$ for all $\varphi \in E_l$
(compare, e.g., [18, section 5.2] or [27, section 9.7]).

The harmonic measure $\omega(\Gamma_j) := \omega(\Gamma_j, \infty)$ at ∞ of the arcs

$$\Gamma_j := \Gamma_{[\varphi_{2j-1}, \varphi_{2j}]} = \{e^{i\varphi} : \varphi \in [\varphi_{2j-1}, \varphi_{2j}]\}, \quad j = 1, \ldots, l,$$

is given by

$$\omega(\Gamma_j) = \lim_{\gamma_j} \frac{1}{2\pi} \int_{\gamma_j} \frac{\partial}{\partial n_\zeta} g(\zeta)\, |d\zeta| =: \frac{1}{2\pi} \int_{\partial \Gamma_j} \frac{\partial}{\partial n_\zeta} g(\zeta)\, |d\zeta|, \quad j = 1, \ldots, l. \tag{4.2}$$

Here, γ_j means a closed Jordan curve which encycles Γ_j counterclockwise and where the limit over γ_j is understood to approximate the arc Γ_j, i.e., the integration of the second integral in (4.2) is performed twice, once from $e^{i\varphi_{2j-1}}$ to $e^{i\varphi_{2j}}$, where $(\partial/\partial n_\zeta) g(\zeta)$ is approached from outside the unit disk, and once from $e^{i\varphi_{2j}}$ to $e^{i\varphi_{2j-1}}$, where $(\partial/\partial n_\zeta) g(\zeta)$ is approached from inside the unit disk. Furthermore, n_ζ denotes the unit normal derivative at $\zeta \in \Gamma_j$ and $|d\zeta|$ is the differential of arc length on Γ_j (see, e.g., [17, Chapter I.10, p. 38], [29, section 4, p. 140]).

Let us give a more convenient representation of the harmonic measures:

LEMMA 4.1. *Let $\Gamma_{E_l} = \bigcup_{j=1}^{l} \Gamma_j$, where $\Gamma_j := \{e^{i\varphi} : \varphi \in [\varphi_{2j-1}, \varphi_{2j}]\}$, be a union of arcs on the unit circle. Then there exists a uniquely determined polynomial $S_l = S_l^*$ of degree l, normalized by $i\, S_l(0) = \sqrt{R^0(0)}$, which satisfies*

$$\int_{\varphi_{2j}}^{\varphi_{2j+1}} \frac{S_l(e^{i\varphi})}{\sqrt{R^0(e^{i\varphi})}}\, d\varphi = 0 \quad \text{for } j = 1, \ldots, l-1. \tag{4.3}$$

Furthermore, the harmonic measures $\omega(\Gamma_j)$, $j = 1, \ldots, l$, are of the form

$$\omega(\Gamma_j) = \frac{1}{2\pi} \int_{\varphi_{2j-1}}^{\varphi_{2j}} \left| \frac{S_l(e^{i\varphi})}{\sqrt{R^0(e^{i\varphi})}} \right| d\varphi. \tag{4.4}$$

Now, the following characterization holds.

THEOREM 4.2. *The following statements are equivalent:*

(i) *There exists a measure σ with corresponding asymptotically N-periodic reflection coefficients*[2] *and $(\mathrm{supp}(\sigma))' = E_l$, $l \le N$.*

(ii) *There exist self-reversed polynomials $\mathcal{T}(z) = \mathcal{T}^*(z) = z^N + \cdots$ of degree l, $l \le N$, and $\mathcal{U}(z) = \mathcal{U}^*(z) = \beta z^{N-l} + \cdots$ of degree $N - l$ such that the quadratic polynomial equation*

$$\mathcal{T}^2(z) - R^0(z)\mathcal{U}^2(z) = L^2 z^N \qquad \text{with} \quad L > 0 \tag{4.5}$$

holds.

(iii) *There exists a self-reversed polynomial $S_l = S_l^*$ of degree l with $i\, S_l(0) = \sqrt{R^0(0)} = \beta$, and positive integers k_j, $j = 1, \ldots, l$, satisfying $\sum_{j=1}^{l} k_j = N$, such that*

$$\int_{\varphi_{2j}}^{\varphi_{2j+1}} \frac{S_l(e^{i\varphi})}{\sqrt{R^0(e^{i\varphi})}}\, d\varphi = 0 \quad \text{for } j = 1, \ldots, l-1 \tag{4.3}$$

[2] Note that we assume only that $\lim_{\nu \to \infty} a_{\nu N + j} = a_j^0$, $j = 0, \ldots, N-1$, and do not suppose the strong condition (3.1).

and

$$\int_{\varphi_{2j-1}}^{\varphi_{2j}} \left| \frac{S_l(e^{i\varphi})}{\sqrt{R^0(e^{i\varphi})}} \right| d\varphi = \frac{2k_j\pi}{N} \quad \textit{for } j = 1, \dots, l. \tag{4.6}$$

(iv) *There exist positive integers* k_j, $j = 1, \dots, l$ *satisfying* $\sum_{j=1}^{l} k_j = N$, *such that*

$$\omega(\Gamma_j) = \frac{k_j}{N} \quad \textit{for } j = 1, \dots, l.$$

Remark. (a) For alternative characterizations for the existence of self-reversed polynomials $\mathcal{T}$ and $\mathcal{U}$ which satisfy a quadratic equation of the form (4.5), i.e., for the existence of a "periodic" measure σ_0, see also [22, section 3].

(b) For the case of several real intervals the counterpart of Theorem 4.2 can be found in [19, pp. 191–194].

5. Proofs. *Proof of Proposition* 3.1 *and Lemma* 3.2. The limit-relations in Proposition 3.1 are rewritings of the authors' results [23, Theorem 2.1 and Remark 2.1] and Lemma 3.2 is [23, Theorem 3.1]. □

Since we will use Theorem 3.4 for the proof of Theorem 3.3, we start with the following.

Proof of Theorem 3.4. For $k = 0$ this is Theorem 3.2 in [23]. It suffices to prove our theorem only for $k = 1$ since the general statements then follow immediately by an induction argument. Let us write

$$\frac{\Phi_n'(z,\sigma)}{\Phi_n'(z,\sigma_0)} = \frac{\Phi_n(z,\sigma_0)}{\Phi_n'(z,\sigma_0)} \left(\frac{\Phi_n(z,\sigma)}{\Phi_n(z,\sigma_0)} \right)' + \frac{\Phi_n(z,\sigma)}{\Phi_n(z,\sigma_0)}. \tag{5.1}$$

Since the theorem is true for $k = 0$, we know that

$$\lim_{n\to\infty} \frac{\Phi_n(z,\sigma)}{\Phi_n(z,\sigma_0)} = \frac{1}{2}\Delta(z) \tag{5.2}$$

and

$$\lim_{n\to\infty} \left(\frac{\Phi_n(z,\sigma)}{\Phi_n(z,\sigma_0)} \right)' = \frac{1}{2}\Delta'(z) \tag{5.3}$$

uniformly on compact subsets of $\mathbb{C} \setminus \big(\Gamma_{E_l} \cup \mathcal{N}\big)$. Note that Δ' exists everywhere on $\mathbb{C} \setminus \big(\Gamma_{E_l} \cup \mathcal{N}\big)$ and is analytic there, since Δ is analytic. Next we show that

$$\lim_{n\to\infty} \frac{\Phi_n(z,\sigma_0)}{\Phi_n'(z,\sigma_0)} = 0 \qquad \text{uniformly compact on } \mathbb{C} \setminus \big(\Gamma_{E_l} \cup \mathcal{N} \cup \{Y' = 0\}\big). \tag{5.4}$$

Together with (5.1) to (5.3) this will prove (3.8) for $k = 1$.

To see (5.4) let $m \in \{0, \dots, N-1\}$ be arbitrary but fixed. From (3.4) we obtain

$$\lim_{\nu\to\infty} \left(\Phi_{m+\nu N}'(z,\sigma_0) - \frac{L}{2} \left(Y^{\nu N}(z) \frac{\Phi_m^-(z,\sigma_0)}{\sqrt{R(z)}} \right)' \right) = 0 \tag{5.5}$$

uniformly compact on $\mathbb{C} \setminus \big(\Gamma_{E_l} \cup \mathcal{N}\big)$. But

$$\left(Y^{\nu N}(z) \frac{\Phi_m^-(z,\sigma_0)}{\sqrt{R(z)}} \right)' = (\nu N) Y^{\nu N-1}(z) Y'(z) \frac{\Phi_m^-(z,\sigma_0)}{\sqrt{R(z)}} + Y^{\nu N}(z) \left(\frac{\Phi_m^-(z,\sigma_0)}{\sqrt{R(z)}} \right)'.$$

The derivative $\big(\Phi_m^-(z,\sigma_0)/\sqrt{R(z)}\big)'$ exists everywhere on $\mathbb{C}\setminus\Gamma_{E_l}$. Now, (5.5) and (3.4) give

$$\lim_{\nu\to\infty}\frac{\Phi'_{m+\nu N}(z,\sigma_0)}{\nu N\Phi_{m+\nu N}(z,\sigma_0)}=\frac{Y'(z)}{Y(z)}$$

uniformly on compact subsets of $\mathbb{C}\setminus\big(\Gamma_{E_l}\cup\mathcal{N}\big)$. Since Y'/Y exists on $\mathbb{C}\setminus\Gamma_{E_l}$, is different from zero on $\mathbb{C}\setminus(\Gamma_{E_l}\cup\{Y'=0\})$, and is independent of m, (5.4) follows. This finishes the proof of (3.8).

In exactly the same way one also shows (3.9). □

Proof of Theorem 3.3. For the proof of Theorem 3.3 we have to put together the results of Proposition 3.1 and Theorem 3.4. Therefore, let us write

$$\frac{\Phi^{(k)}_{m+\nu N}(z,\sigma)}{(\nu N)_k Y^{\nu N-k}(z)}=\frac{\Phi^{(k)}_{m+\nu N}(z,\sigma)}{\Phi^{(k)}_{m+\nu N}(z,\sigma_0)}\cdot\frac{\Phi^{(k)}_{m+\nu N}(z,\sigma_0)}{(\nu N)_k Y^{\nu N-k}(z)}. \tag{5.6}$$

Since we know that the first factor at the right-hand side tends to $\Delta/2$ by Theorem 3.4, we have to study only the second factor. By (3.4) and the fact that $(\nu N)_k Y^{\nu N-k}\to\infty$ we have

$$\begin{aligned}\lim_{\nu\to\infty}\frac{\Phi^{(k)}_{m+\nu N}(z,\sigma_0)}{(\nu N)_k Y^{\nu N-k}(z)}&=\frac{L}{2}\lim_{\nu\to\infty}\frac{\big(Y^{\nu N}(z)\Phi_m^-(z,\sigma_0)/\sqrt{R(z)}\big)^{(k)}}{(\nu N)_k Y^{\nu N-k}(z)}\\&=\frac{L}{2}\big(Y'(z)\big)^k\ \frac{\Phi_m^-(z,\sigma_0)}{\sqrt{R(z)}}.\end{aligned} \tag{5.7}$$

The first part of the theorem follows now from (5.6) and (5.7). The asymptotics of $(\Phi_n^*(z,\sigma))^{(k)}$ are shown in the same way. □

Proof of Corollary 3.5. From the identity

$$2\Phi_{n+j}(z,\sigma)=\big(\Phi_n(z,\sigma)+\Phi_n^*(z,\sigma)\big)\Phi_j^{[n]}(z,\sigma)+\big(\Phi_n(z,\sigma)-\Phi_n^*(z,\sigma)\big)\Psi_j^{[n]}(z,\sigma)$$

(see [20, Corollary 3.1]) we obtain

$$\begin{aligned}&\frac{2\Phi_{(\nu N+k)+j}(z,\sigma)}{\Phi_{\nu N+k}(z,\sigma)}\\&\quad=\left(1+\frac{\Phi^*_{\nu N+k}(z,\sigma)}{\Phi_{\nu N+k}(z,\sigma)}\right)\Phi_j^{[\nu N+k]}(z,\sigma)+\left(1-\frac{\Phi^*_{\nu N+k}(z,\sigma)}{\Phi_{\nu N+k}(z,\sigma)}\right)\Psi_j^{[\nu N+k]}(z,\sigma).\end{aligned} \tag{5.8}$$

It is easy to see that

$$\begin{aligned}\lim_{\nu\to\infty}\Phi_j^{[\nu N+k]}(z,\sigma)&=\Phi_j^{[k]}(z,\sigma_0),\\\lim_{\nu\to\infty}\Psi_j^{[\nu N+k]}(z,\sigma)&=\Psi_j^{[k]}(z,\sigma_0)\end{aligned} \tag{5.9}$$

uniformly on each compact set, since all the involved polynomials are of fixed degree j. From Theorem 3.3 we obtain that

$$\lim_{\nu\to\infty}\frac{\Phi^*_{\nu N+k}(z,\sigma)}{\Phi_{\nu N+k}(z,\sigma)}=\frac{\Phi_k^{*,-}(z,\sigma_0)}{\Phi_k^-(z,\sigma_0)} \tag{5.10}$$

holds uniformly compact on $\mathbb{C} \setminus (\Gamma_{E_l} \cup \mathcal{N} \cup \mathcal{N}^* \cup \{\Delta = 0\})$. But all the functions in (5.10) are uniformly bounded around points from $\mathcal{N}^* \cap \{|z| > 1\}$; compare the last remark before section 4. Hence, Vitali's theorem shows that (5.10) holds uniformly on compact subsets of $\mathbb{C} \setminus (\Gamma_{E_l} \cup \mathcal{N} \cup \{\Delta = 0\})$. Together with (5.8) and (5.9) this finishes the proof. □

Proof of Corollary 3.6. Since the "periodic" orthonormal polynomials $\Phi_n(z, \sigma_0)$ satisfy the limit relation (3.10) as well, we obtain from Corollary 3.5 that

$$\lim_{n\to\infty} \left(\frac{\Phi_{n+N}(z,\sigma)}{\Phi_n(z,\sigma)} - \frac{\Phi_{n+N}(z,\sigma_0)}{\Phi_n(z,\sigma_0)} \right) = 0$$

uniformly on compact subsets of $\mathbb{C} \setminus \big(\Gamma_{E_l} \cup \mathcal{N} \cup \{\Delta = 0\}\big)$. Hence, it suffices to consider only the ratio $\Phi_{n+N}(z, \sigma_0)/\Phi_n(z, \sigma_0)$.

From Corollary 2.1(a) in [23] we have

$$\lim_{n\to\infty} \Phi_n^+(z, \sigma_0) = 0$$

uniformly on compact subsets of $\mathbb{C} \setminus \Gamma_{E_l}$. But

$$\Phi_n^+(z, \sigma_0) = \Phi_n(z, \sigma_0) \left(\frac{\Phi_{n+N}(z, \sigma_0)}{\Phi_n(z, \sigma_0)} - y^+(z) \right)$$

and $\Phi_n(z, \sigma_0) \to \infty$ uniformly on compact subsets of $\mathbb{C} \setminus (\Gamma_{E_l} \cup \mathcal{N})$ by Proposition 3.1. This gives the assertion. □

Proof of Lemma 4.1. The proof of the existence of the polynomial S_l is very similar to the one given in [29, pp. 225–226]. Recall that S_l has complex coefficients, and, hence, (4.3) can be considered as a linear system of $l - 1$ equations for $l - 1$ unknowns. If $l = 1$, the only condition is $i\, S_l(0) = \sqrt{R^0(0)}$.

Let g denote the real Green's function for the set $\mathbb{C} \setminus \Gamma_{E_l}$ with pole at ∞ and let $\tilde{g}$ be its (up to an additive constant) harmonic conjugate. By the complex Green's function G we understand the function

$$G(z) := g(z) + i\tilde{g}(z).$$

Now let us consider $g(\zeta) = g(x, y)$ with $\zeta = x + iy$. For $\zeta = e^{i\varphi} \in \Gamma_{E_l}$ we have

$$\begin{aligned}
\zeta G'(\zeta+) &= \zeta\big(g_x(\zeta+) + i\tilde{g}_x(\zeta+)\big) = \zeta\big(g_x(\zeta+) - ig_y(\zeta+)\big) \\
&= \big(g_x(\zeta+)\cos\varphi + g_y(\zeta+)\sin\varphi\big) - i\big(g_y(\zeta+)\cos\varphi - g_x(\zeta+)\sin\varphi\big) \\
&= \frac{d}{d_{n_\zeta}} g(\zeta+) - i\frac{d}{d_{t_\zeta}} g(\zeta+) \\
&= \frac{d}{d_{n_\zeta}} g(\zeta+),
\end{aligned}$$

where $g(\zeta+)$ means the limit of $g(y)$ as $y \to \zeta$ from outside the unit disk and where $(d/d_{t_\zeta})g(\zeta+)$ denotes the tangential derivative of g, which is zero since g vanishes identically on the arcs Γ_{E_l}. If we approach the arcs from the interior of the unit disk (now the unit normal is $-\zeta$) we get in the same way as above

$$\zeta G'(\zeta-) = -\frac{d}{d_{n_\zeta}} g(\zeta-).$$

Hence, the harmonic measures $\omega(\Gamma_j)$ from (4.2) are of the form

$$\omega(\Gamma_j) = \frac{1}{2\pi} \int_{\Gamma_j} \zeta\big(G'(\zeta+) - G'(\zeta-)\big)\, |d\zeta|.$$

In order to prove (4.4) we have to show that the derivative of the complex Green's function (which is single-valued) satisfies

$$\zeta\big(G'(\zeta+) - G'(\zeta-)\big) = \left| \frac{S_l(e^{i\varphi})}{\sqrt{R^0(e^{i\varphi})}} \right|, \quad \zeta = e^{i\varphi}, \tag{5.11}$$

since $|d\zeta| = d\varphi$.[3] Let us give an explicit representation of G. We claim that

$$G(z) = \frac{1}{2} \int_{z_1}^{z} \frac{1}{\zeta} \left(1 - \frac{iS_l(\zeta)}{\sqrt{R^0(\zeta)}} \right) d\zeta, \qquad z_1 := e^{i\varphi_1}, \tag{5.12}$$

where the integration is performed along a path in the complex plane cut along Γ_{E_l}. Indeed, G is analytic on $\mathbb{C} \setminus \Gamma_{E_l}$ with

$$G(z) = \log z + \mathcal{O}(1) \quad \text{as } z \to \infty,$$

since the integrand in (5.12) behaves as $2/\zeta$ for large ζ; compare (5.26). Finally, we have to show that

$$\lim_{\zeta \to z} G(\zeta) \text{ is purely imaginary for } z \in \Gamma_{E_l}. \tag{5.13}$$

Let us start to point out two facts: First, with $z_k := e^{i\varphi_k}$,

$$\operatorname{Re} \left\{ \int_{z_{2j}}^{z_{2j+1}} \frac{1}{\zeta} \left(1 - \frac{iS_l(\zeta)}{\sqrt{R^0(\zeta)}} \right) d\zeta \right\} = 0, \quad j = 1, \ldots, l-1,$$

where the path of integration is on the unit circle. This follows from (4.3) and $d\zeta/\zeta = i\, d\varphi$ for $\zeta = e^{i\varphi}$. Second, $iS_l(\zeta)/\sqrt{R^0(\zeta)}$ is real for $\zeta \in \Gamma_{E_l}$ and, hence, the integrand $\big[\big(1 - iS_l(\zeta)/\sqrt{R^0(\zeta)}\big)/\zeta\big]\, d\zeta$ in (5.12) is purely imaginary on Γ_{E_l}.

Now recall that the integral in (5.12) is independent of the path of integration as long as it does not cross the arcs Γ_{E_l}, because the integrand is analytic on $\mathbb{C} \setminus \Gamma_{E_l}$. From the two facts above, property (5.13) follows, and so G is indeed the complex Green's function on $\mathbb{C} \setminus \Gamma_{E_l}$ with pole at infinity. Now it is easy to see that

$$G'(z) = \frac{1}{2z} \left(1 - \frac{iS_l(z)}{\sqrt{R^0(z)}} \right),$$

and (5.11) follows, since $\sqrt{R(\zeta+)} = -\sqrt{R(\zeta-)}$ and $iS_l(\zeta)/\sqrt{R^0(\zeta)}$ is real and positive on Γ_{E_l}. This completes the proof. □

Proof of Theorem 4.2. First of all, let us point out that every measure σ with asymptotically periodic reflection coefficients can be considered as a compact perturbation of the measure σ_0 with periodic reflection coefficients and, therefore, the accumulation points of $\operatorname{supp}(\sigma)$ and $\operatorname{supp}(\sigma_0)$ coincide; compare (2.4). Hence, it suffices

[3] In case an equation of the form (4.5) holds, we have $G(z) = \log Y(z)$, where Y is defined as in (2.8), and $G'(z) = Y'(z)/Y(z)$. Then, by straightforward calculation, using (5.21), (5.22), and (4.5), property (5.11) follows.

to show that the parts (ii), (iii), and (iv) of the theorem are equivalent with the fact that there exists a "periodic" measure σ_0 on the arcs Γ_{E_l}, respectively, intervals E_l.

The equivalence of (i) and (ii) has been shown by the authors in [22, Theorem 4.4]. Let us now prove the equivalence of (ii) and (iii) by showing both implications.

(ii) *implies* (iii). Let us define the real trigonometric polynomials

$$\begin{aligned}\mathcal{R}^0(\varphi) &:= e^{-il\varphi}R^0(e^{i\varphi}),\\ \tau(\varphi) &:= e^{-i(N/2)\varphi}\mathcal{T}(e^{i\varphi}),\\ u(\varphi) &:= e^{-i((N-l)/2)\varphi}\mathcal{U}(e^{i\varphi}),\end{aligned}$$

which satisfy, as a consequence of (4.5),

$$\tau^2(\varphi) - \mathcal{R}^0(\varphi)u^2(\varphi) = L^2. \tag{5.14}$$

By the geometry of (5.14) we can write the derivative of τ in the form

$$\tau'(\varphi) = \frac{N}{2}u(\varphi)s_l(\varphi), \tag{5.15}$$

where s_l is a real trigonometric polynomial of degree $l/2$, and consequently

$$\mathcal{R}^0(\varphi)\big[\tau'(\varphi)\big]^2 = \frac{N^2}{4}\big(\tau^2(\varphi) - L^2\big)s_l^2(\varphi). \tag{5.16}$$

For $\varphi \in (\varphi_{2j}, \varphi_{2j+1})$, $j = 1, \dots, l-1$, we have

$$\mathcal{R}^0(\varphi) > 0, \qquad \text{hence,} \qquad \left|\frac{\tau(\varphi)}{L}\right| > 1,$$

where the second inequality follows from (5.14). It is not difficult to see that the above differential equation (5.16) has for $\varphi \in (\varphi_{2j}, \varphi_{2j+1})$ the solution

$$\frac{\tau(\varphi)}{L} = \pm\cosh\left(\frac{N}{2}\int_{\varphi_{2j}}^{\varphi}\frac{s_l(\psi)}{\sqrt{\mathcal{R}^0(\psi)}}\,d\psi\right). \tag{5.17}$$

Now recall that $\tau(\varphi_{2j}) = \tau(\varphi_{2j+1}) = \pm L$. Hence, if we set

$$S_l(z) := z^{l/2}s_l(\varphi), \quad z = e^{i\varphi}, \tag{5.18}$$

property (4.3) follows.

Next let $[\psi_1, \psi_2] \subseteq [\varphi_{2j-1}, \varphi_{2j}]$, $j = 1, \dots, l$, be the maximal subinterval, where τ is monotone. Then, again by (5.14)

$$\tau(\psi_1) = -\tau(\psi_2) = \pm L \quad \text{and} \quad \left|\frac{\tau(\varphi)}{L}\right| \le 1 \quad \text{on } [\psi_1, \psi_2].$$

Further,

$$\frac{\tau(\varphi)}{L} = \pm\cos\left(\frac{N}{2}\int_{\psi_1}^{\varphi}\frac{|s_l(\psi)|}{\sqrt{|\mathcal{R}^0(\psi)|}}\,d\psi\right) \tag{5.19}$$

solves the differential equation (5.16); and from $\tau(\psi_1)/L = -\tau(\psi_2)/L = \pm 1$ we obtain that

$$\frac{N}{2}\int_{\psi_1}^{\psi_2}\frac{|s_l(\psi)|}{\sqrt{|\mathcal{R}^0(\psi)|}}\,d\psi = \pi.$$

This gives (4.6).

It remains to show that the polynomial S_l, defined in (5.18), satisfies

$$S_l = S_l^* \quad \text{and} \quad i\,S_l(0) = \sqrt{R^0(0)}.$$

The first property is an immediate consequence of (5.18). For the second one we need the following considerations: We have

$$\tau'(\varphi) = \frac{d}{d\varphi}\big(e^{-i(N/2)\varphi}\mathcal{T}(e^{i\varphi})\big) = ie^{-i(N/2)\varphi}\left(e^{i\varphi}\mathcal{T}'(e^{i\varphi}) - \frac{N}{2}\mathcal{T}(e^{i\varphi})\right),$$

and multiplying this equation by $e^{i(N/2)\varphi}$ gives

$$e^{i(N/2)\varphi}\tau'(\varphi) = \widetilde{\mathcal{T}}(e^{i\varphi}), \tag{5.20}$$

where the polynomial $\widetilde{\mathcal{T}}$ is defined by

$$\widetilde{\mathcal{T}}(z) := iz\,\mathcal{T}'(z) - \frac{iN}{2}\,\mathcal{T}(z) = \frac{iN}{2}z^N + \cdots. \tag{5.21}$$

By (5.20) the polynomial $\widetilde{\mathcal{T}}$ is self-reversed, i.e., $\widetilde{\mathcal{T}} = \widetilde{\mathcal{T}}^*$, and from (5.15), (5.18), and (5.20) we obtain that

$$\widetilde{\mathcal{T}}(z) = \frac{N}{2}\,\mathcal{U}(z)S_l(z). \tag{5.22}$$

Comparing the leading coefficients gives

$$S_l(z) = \frac{i}{\beta}z^l + \cdots - \frac{i}{\overline{\beta}}. \tag{5.23}$$

From (4.1) we see that $|\beta| = 1$ and thus $S_l(0) = -i/\overline{\beta} = -i\beta = -i\sqrt{R^0(0)}$.

(iii) *implies* (ii). Motivated by (5.17), we define

$$\tau(z) := L\cosh\left(\frac{N}{2}\int_{\varphi_1}^{z}\frac{s_l(\xi)}{\sqrt{\mathcal{R}^0(\xi)}}\,d\xi\right), \tag{5.24}$$

where the path of integration is outside E_l and where the functions $s_l(z)$ and $\mathcal{R}^0(z)$, $z \in \mathbb{C}$, are the extensions of the real trigonometric polynomials

$$\begin{aligned} s_l(\varphi) &:= e^{-i(l/2)\varphi}S_l(e^{i\varphi}),\\ \mathcal{R}^0(\varphi) &:= e^{-il\varphi}R^0(e^{i\varphi}), \end{aligned} \qquad \varphi \in \mathbb{R}.$$

Obviously, τ is analytic on the cut complex plane $\mathbb{C} \setminus E_l$. A little bit of further investigation, using the well-known relation $\cosh(iz) = \cos(z)$, shows that τ is continuous on $\mathbb{R}$. Hence, τ is analytic on the entire complex plane. Next we will show that $\tau(\varphi)$, $\varphi \in \mathbb{R}$, is a real trigonometric polynomial of degree $N/2$. One way to do this is to prove that for every $y \in \mathbb{C}$

$$\mathcal{T}(y) := y^{N/2}\tau(-i\ln y) \tag{5.25}$$

defines a self-reversed algebraic polynomial of degree N, since then

$$\tau(\varphi) = e^{-i(N/2)\varphi}\mathcal{T}(e^{i\varphi}).$$

First we show that $\mathcal{T}$ is an entire function, i.e., analytic on the entire complex plane: From (4.3) and (4.6) one obtains that

$$\tau(z+2\pi) = (-1)^N \tau(z) \text{ for all } z \in \mathbb{C}.$$

Hence, it doesn't matter which branch of the logarithm we take in (5.25) and we end up with an analytic function on $\mathbb{C} \setminus \{0\}$. But $\mathcal{T}$ is also continuous, and thus analytic, at $y = 0$, which can be seen as follows: By our assumption on S_l we have

$$\frac{S_l(0)}{\sqrt{R^0(0)}} = -i \qquad \text{and} \qquad \lim_{\zeta\to\infty} \frac{S_l(\zeta)}{\sqrt{R^0(\zeta)}} = i \tag{5.26}$$

and hence

$$\int_{\varphi_1}^{-i\ln y} \frac{S_l(e^{i\xi})}{\sqrt{R^0(e^{i\xi})}}\, d\xi = \mathcal{O}(\ln y) \quad \text{as } y \to 0 \text{ or } \infty.$$

Now it is not difficult to see that

$$\mathcal{T}(y) = y^{N/2} L \cosh\left(\frac{N}{2} \int_{\varphi_1}^{-i\ln y} \frac{S_l(e^{i\xi})}{\sqrt{R^0(e^{i\xi})}}\, d\xi \right) = \mathcal{O}(1) \quad \text{as } y \to 0, \tag{5.27}$$

and $\mathcal{T}$ is indeed an entire function. In a way very similar as in (5.27) one obtains

$$\frac{\mathcal{T}(y)}{y^N} = \mathcal{O}(1) \qquad \text{as} \quad y \to \infty, \tag{5.28}$$

and by Liouville's theorem $\mathcal{T}$ has to be a polynomial of degree N. Using definition (5.25) we see that $\mathcal{T}$ is also self-reversed.

Summing up, we have shown that τ from (5.24) is for $z = \varphi \in \mathbb{R}$ a real trigonometric polynomial. Again by the relation $\cosh(iz) = \cos(z)$ we obtain the estimates

$$\begin{aligned} |\tau(\varphi)| &\geq L \quad \text{on } \mathbb{R} \setminus E_l, \\ |\tau(\varphi)| &\leq L \quad \text{on } E_l. \end{aligned}$$

As an immediate consequence, τ has $N + l$ extremal points on E_l. By [22, Corollary 3.2(c)] this is sufficient for the existence of self-reversed polynomials $\mathcal{T}$ and $\mathcal{U}$ satisfying (4.5); in fact, the polynomial $\mathcal{T}$ is given by (5.25), respectively, (5.27). This completes the proof of the equivalence of (ii) and (iii).

The remaining equivalence of (iii) and (iv) is just a consequence of Lemma 4.1. □

Acknowledgment. The authors thank Professor Paul Nevai of the Ohio State University for numerous conversations regarding the results of this paper. In particular, he suggested a generalization of [23, Theorem 3.2], which is included here as Theorem 3.4.

A MONOTONICITY PROPERTY INVOLVING ${}_3F_2$ AND COMPARISONS OF THE CLASSICAL APPROXIMATIONS OF ELLIPTICAL ARC LENGTH*

ROGER W. BARNARD†, KENT PEARCE†, AND KENDALL C. RICHARDS‡

Abstract. Conditions are determined under which ${}_3F_2\left(-n,a,b;a+b+2,\varepsilon-n+1;1\right)$ is a monotone function of n satisfying $ab\cdot{}_3F_2\left(-n,a,b;a+b+2,\varepsilon-n+1;1\right)\geq ab\cdot{}_2F_1\left(a,b;a+b+2;1\right)$. Motivated by a conjecture of Vuorinen [*Proceedings of Special Functions and Differential Equations*, K. S. Rao, R. Jagannathan, G. Vanden Berghe, J. Van der Jeugt, eds., Allied Publishers, New Delhi, 1998], the corollary that ${}_3F_2(-n,-\frac{1}{2},-\frac{1}{2};1,\varepsilon-n+1;1)\geq\frac{4}{\pi}$, for $1>\epsilon\geq\frac{1}{4}$ and $n\geq 2$, is used to determine surprising hierarchical relationships among the 13 known historical approximations of the arc length of an ellipse. This complete list of inequalities compares the Maclaurin series coefficients of ${}_2F_1$ with the coefficients of each of the known approximations, for which maximum errors can then be established. These approximations range over four centuries from Kepler's in 1609 to Almkvist's in 1985 and include two from Ramanujan.

Key words. hypergeometric, approximations, elliptical arc length

1. Introduction.

Let $L(x,y)$ be the arc length of an ellipse with semiaxes of length x and y (with $x\geq y>0$) and let $\lambda\equiv\dfrac{x-y}{x+y}$. In 1742, Maclaurin [12] determined that

$$L(x,y)=\pi(x+y)\cdot{}_2F_1\left(-\frac{1}{2},-\frac{1}{2};1;\lambda^2\right), \tag{1}$$

where ${}_2F_1$ is the hypergeometric function defined by

$${}_2F_1\left(a,b;c;z\right)\equiv 1+\sum_{n=1}^{\infty}\frac{(a)_n(b)_n z^n}{(c)_n n!}$$

with the Appell (or Pochhammer) symbol $(a)_n\equiv a(a+1)\cdots(a+n-1)$ for $n\geq 1$ and $(a)_0\equiv 1$, $a\neq 0$. (For more background information, see [2], [14], [9], and the recent survey article [8] by the first author.) In [2], Almkvist and Berndt compiled and presented the list of the approximations in Table 1.1 for

$$G(\lambda)\equiv{}_2F_1\left(-\frac{1}{2},-\frac{1}{2};1;\lambda^2\right)=\frac{L(x,y)}{\pi(x+y)}.$$

These approximations and their historical and recent connections to the approximations of π can be found in the Borweins' book [10]. Another excellent source for historical and current studies of these topics is the book [5] by Anderson, Vamanamurthy, and Vuorinen.

TABLE 1.1
Approximations of $G(\lambda) \equiv {}_2F_1(-\frac{1}{2}, -\frac{1}{2}; 1; \lambda^2)$ (see [2]).

Discoverer(s) and year of discovery	Approximation $A_p(\lambda)$	δ_p = first nonzero term in the Maclaurin series for $\Delta_p(\lambda) \equiv A_p(\lambda) - G(\lambda)$
Kepler, 1609	$A_1(\lambda) \equiv (1-\lambda^2)^{1/2}$	$\delta_1 = -\frac{3}{4}\lambda^2$
Euler, 1773	$A_2(\lambda) \equiv (1+\lambda^2)^{1/2}$	$\delta_2 = \frac{1}{4}\lambda^2$
Sipos, 1792 Ekwall, 1973	$A_3(\lambda) \equiv \dfrac{2}{1+\sqrt{1-\lambda^2}}$	$\delta_3 = \frac{7}{64}\lambda^4$
Peano, 1889	$A_4(\lambda) \equiv \frac{3}{2} - \frac{1}{2}(1-\lambda^2)^{1/2}$	$\delta_4 = \frac{3}{64}\lambda^4$
Muir, 1883	$A_5(\lambda) \equiv \left(\dfrac{(1+\lambda)^{3/2} + (1-\lambda)^{3/2}}{2}\right)^{2/3}$	$\delta_5 = -\frac{1}{64}\lambda^4$
Lindner, 1904-1920 Nyvoll, 1978	$A_6(\lambda) \equiv \left(1 + \dfrac{\lambda^2}{8}\right)^2$	$\delta_6 = -\frac{1}{2^8}\lambda^6$
Selmer, 1975	$A_7(\lambda) \equiv 1 + \dfrac{\lambda^2/4}{1-\lambda^2/16}$	$\delta_7 = -\frac{3}{2^{10}}\lambda^6$
Ramanujan, 1914 Fergestad, 1951	$A_8(\lambda) \equiv 3 - \sqrt{4-\lambda^2}$	$\delta_8 = -\frac{1}{2^9}\lambda^6$
Almkvist, 1978	$A_9(\lambda) \equiv 2\dfrac{\left(1+\sqrt{1-\lambda^2}\right)^2 + \lambda^2\sqrt{1-\lambda^2}}{\left(1+\sqrt{1-\lambda^2}\right)\left(1+\sqrt[4]{1-\lambda^2}\right)^2}$	$\delta_9 = \frac{15}{2^{14}}\lambda^8$
Bronshtein and Semendyayev, 1964 Selmer, 1975	$A_{10}(\lambda) \equiv \dfrac{64-3\lambda^4}{64-16\lambda^2}$	$\delta_{10} = -\frac{9}{2^{14}}\lambda^8$
Selmer, 1975	$A_{11}(\lambda) \equiv \frac{3}{2} + \dfrac{\lambda^2}{8} - \dfrac{1}{2}\left(1 - \dfrac{\lambda^2}{2}\right)^{1/2}$	$\delta_{11} = -\frac{5}{2^{14}}\lambda^8$
Jacobsen and Waadeland, 1985	$A_{12}(\lambda) \equiv \dfrac{256 - 48\lambda^2 - 21\lambda^4}{256 - 112\lambda^2 + 3\lambda^4}$	$\delta_{12} = -\frac{33}{2^{18}}\lambda^{10}$
Ramanujan, 1914	$A_{13}(\lambda) \equiv 1 + \dfrac{3\lambda^2}{10 + \sqrt{4-3\lambda^2}}$	$\delta_{13} = -\frac{3}{2^{17}}\lambda^{10}$

Recently, several inequalities between various mean values and the hypergeometric function were proved in [10], [15], and the dependence of the hypergeometric function ${}_2F_1(a, b; c; z)$ on its parameters was studied in [4], [6]. These results led to a conjecture of Vuorinen (see [16]) concerning Muir's approximation A_5. Vuorinen conjectured (see [16]) that

$$A_5(\lambda) \leq G(\lambda) \quad \text{for all } \lambda \in [0,1]. \tag{2}$$

That is, Vuorinen conjectured that A_5 is a *lower bound* for G. This conjecture was recently proved by the authors in [9] which has become the genesis of the present article. Moreover, the results here attest to the adage that a single conjecture may have many ramifications. Also, note that A_5 is one of the mean values studied in [15]. More approximations for hypergeometric functions in terms of such mean values are actively being sought. For example, let $\nu \in \mathbf{R}\backslash\{0\}$ and define

$$M_\nu(\lambda) \equiv \left[\frac{(1+\lambda)^\nu + (1-\lambda)^\nu}{2}\right]^{1/\nu}.$$

H. Alzer [3] originally made the following conjecture.

CONJECTURE. *The inequalities*

$$M_\alpha(\lambda) \le G(\lambda) \le M_\beta(\lambda) \quad \textit{hold for all } \lambda \in (0,1) \tag{3}$$

if and only if

$$\alpha \le 3/2 \quad \textit{and} \quad \beta \ge (\ln 2)/\left(\ln \frac{\pi}{2}\right) \approx 1.53.$$

As noted by Alzer [3], it follows from our results (see the set of inequalities in expression (4)) that (3) holds with $\alpha = 3/2$ and $\beta = 2$. Moreover, for a fixed λ, $M_\nu(\lambda)$ is an increasing function of ν. Thus it follows that (3) holds for all $\alpha \le 3/2$ and $\beta \ge 2$. It can be shown that $\alpha = 3/2$ is sharp.

2. Main results. In an earlier paper (see [9]), the authors were able to verify inequality (2) by working with the original version of Vuorinen's conjecture in terms of the eccentricity (see (5) and (6)). In this direction, a generating function argument (motivated by [7]) was used to obtain the following general result (which will also be applied in this paper to obtain Theorem 2.5).

THEOREM 2.1 (see [9]). *Suppose $a, b > 0$. Then for any ε satisfying $1 > \varepsilon \ge \frac{ab}{a+b+1}$, it follows that*

$${}_3F_2\left(-n, a, b; a+b+1, \varepsilon - n + 1; 1\right) \ge 0,$$

for all integers $n \ge 1$, where ${}_3F_2$ is the generalized hypergeometric function.

In light of the conjecture in (2), the following question naturally arises:

> *Which of the remaining approximations given in Table* 1.1 *are upper bounds or lower bounds for G?*

An attempt to compare an approximation A_p with G motivates an analysis of the term δ_p (the first nonzero term in the Maclaurin series representation for the error function $\Delta_p(\lambda) \equiv A_p(\lambda) - G(\lambda)$). What information does δ_p provide? Certainly the leading term can be viewed as a measure of accuracy of the given approximation, and the error function $\Delta_p(\lambda)$ will have the same sign as δ_p for *sufficiently small* λ. For example, $\delta_1 < 0$ and it follows directly that A_1 is a lower bound for G, as Kepler intended (see [2, p. 599]). In this case, the sign of δ_1 is indicative of the sign of $\Delta_1(\lambda)$ *for all* $\lambda \in [0,1]$. Almkvist and Berndt proved (see [2, p. 603]) that Ramanujan's first estimate A_8 is a lower bound for G by proving the significantly stronger result that the nonzero Maclaurin series coefficients of Δ_8 all have the same (negative) sign. A numerical investigation suggests that a similar trait might be shared by other approximations given in Table 1.1. In this article, it will be shown that all of the approximations given in Table 1.1 satisfy the following property:

> *The sign of the error function $\Delta_p(\lambda)$ coincides with the sign of the leading term δ_p for all $\lambda \in [0,1]$.*

Moreover, for all but two of the approximations, it will be established that the nonzero Maclaurin series coefficients of Δ_p all have the same sign as δ_p. (Only Euler's approximation and Muir's approximation fail to satisfy this condition.) As a consequence of the forthcoming results, each function $|\Delta_p|$ is a strictly increasing function of λ, for $p = 1, \ldots, 13$. Therefore, $0 = |\Delta_p(0)| < |\Delta_p(\lambda)| < |\Delta_p(1)|$ for all $\lambda \in (0,1)$. For example, the maximum error for Ramanujan's second estimate is $|\Delta_{13}(1)| = |\frac{14}{11} - \frac{4}{\pi}| \approx 0.000512$ and satisfies $|\Delta_{13}(1)| < |\Delta_p(1)|$ for $p = 1, \ldots, 12$. In this direction, we will prove the following three propositions.

PROPOSITION 2.2. *Let* $G(\lambda) \equiv \sum_{n=0}^{\infty} \alpha_n \lambda^{2n}$ *and* $A_p(\lambda) \equiv \sum_{n=0}^{\infty} \beta_n^{(p)} \lambda^{2n}$ *where* $\alpha_n \equiv (\frac{(-1/2)_n}{n!})^2$ *and each* A_p *is defined as in Table* 1.1. *Then*

$$\beta_n^{(12)} \leq \alpha_n \leq \beta_n^{(9)} \quad \text{for all integers } n \geq 0.$$

Therefore, the error functions $|\Delta_9|$ *and* $|\Delta_{12}|$ *are strictly increasing and*

$$A_{12}(\lambda) \leq G(\lambda) \leq A_9(\lambda) \quad \text{for all } \lambda \in [0,1].$$

PROPOSITION 2.3. *Let* $G(\lambda) \equiv \sum_{n=0}^{\infty} \alpha_n \lambda^{2n}$ *and* $A_p(\lambda) \equiv \sum_{n=0}^{\infty} \beta_n^{(p)} \lambda^{2n}$ *where* $\alpha_n \equiv (\frac{(-1/2)_n}{n!})^2$ *and each* A_p *is defined as in Table* 1.1. *Then*

$$\beta_n^{(1)} \leq \beta_n^{(6)} \leq \beta_n^{(7)} \leq \beta_n^{(8)} \leq \beta_n^{(10)} \leq \beta_n^{(11)} \leq \beta_n^{(13)} \leq \alpha_n \leq \beta_n^{(4)} \leq \beta_n^{(3)}$$

for all integers $n \geq 0$. *Therefore, the corresponding error functions* $|\Delta_p|$ *are strictly increasing and*

$$A_1(\lambda) \leq A_6(\lambda) \leq A_7(\lambda) \leq A_8(\lambda) \leq A_{10}(\lambda) \leq A_{11}(\lambda) \leq A_{13}(\lambda) \leq G(\lambda) \leq A_4(\lambda) \leq A_3(\lambda)$$

for all $\lambda \in [0,1]$.

The next proposition addresses the two remaining estimates: Euler's approximation A_2 and Muir's approximation A_5. The claim will be made that

$$A_5(\lambda) \equiv \left(\frac{(1+\lambda)^{3/2} + (1-\lambda)^{3/2}}{2} \right)^{2/3} \leq G(\lambda) \leq (1+\lambda^2)^{1/2} \equiv A_2(\lambda) \tag{4}$$

for all $\lambda \in [0,1]$. As we have noted, the nonzero Maclaurin series coefficients of Δ_2 and Δ_5 (as functions of λ) do not have constant sign. In order to verify the inequalities in (4), we make use of the known fact due to Landen and Ivory (e.g., see [2, p. 598]) that

$$G(\lambda) \equiv {}_2F_1\left(-\frac{1}{2}, -\frac{1}{2}; 1; \lambda^2\right) = \frac{2x}{x+y} \cdot {}_2F_1\left(\frac{1}{2}, -\frac{1}{2}; 1; \xi^2\right), \tag{5}$$

where $\lambda \equiv (x-y)/(x+y)$ and $\xi \equiv (1/x)\sqrt{x^2-y^2}$ is the eccentricity of the original ellipse (see (1)). Without loss of generality, assume that $1 = x \geq y \geq 0$. A change of variable from λ to ξ can be accomplished in (4) by using (5) and the substitutions $\lambda = (1-y)/(1+y)$ and $y = \sqrt{1-\xi^2}$. Multiplying through by $(1+y)/2$ and simplifying, we see that the inequalities in (4) are equivalent to

$$\left(\frac{1 + (1-\xi^2)^{3/4}}{2} \right)^{2/3} \leq {}_2F_1\left(\frac{1}{2}, -\frac{1}{2}; 1; \xi^2\right) \leq (1 - \xi^2/2)^{1/2} \tag{6}$$

for all $\xi \in [0,1]$. (The first inequality in (6) is the original version of Vuorinen's conjecture [16].)

It is interesting to note that one can show that the functions in (6) can be shown to satisfy the stated inequalities by establishing that the coefficients of their respective Maclaurin series, *expanded in powers of* ξ, satisfy the corresponding inequality relationships. In view of the preceding discussion, we now state the following proposition.

PROPOSITION 2.4 (see [9]). *Let G and A_p be as defined in Table* 1.1 *and let*

$$1+\sum_{n=1}^{\infty} b_n\xi^{2n} \equiv \left(\frac{1+(1-\xi^2)^{3/4}}{2}\right)^{2/3} \quad \textit{and} \tag{7}$$

$$1+\sum_{n=1}^{\infty} c_n\xi^{2n} \equiv (1-\xi^2/2)^{1/2}. \tag{8}$$

It follows that

$$b_n \le \frac{(1/2)_n(-1/2)_n}{n!\cdot n!} \le c_n \quad \textit{for all integers } n \ge 1.$$

Therefore, (6) *holds and is equivalent to $A_5(\lambda) \le G(\lambda) \le A_2(\lambda)$ for all $\lambda \in [0,1]$.*

Remark. If we apply the identity in (5) with $\lambda = (1-\sqrt{1-\xi^2})/(1+\sqrt{1-\xi^2})$, the definition of A_2, and simplify, we obtain $\Delta_2(\lambda) = 2[(1-\xi^2/2)^{1/2} - {}_2F_1(\frac{1}{2},-\frac{1}{2};1;\xi^2)]/(1+\sqrt{1-\xi^2})$. Proposition 2.4 implies that $(1-\xi^2/2)^{1/2} - {}_2F_1(\frac{1}{2},-\frac{1}{2};1;\xi^2)$ is a strictly increasing function of ξ. Therefore $\Delta_2(\lambda)$ is a strictly increasing function of ξ. Since $\xi = \frac{2\sqrt{\lambda}}{1+\lambda}$ is a strictly increasing function of λ on [0,1], it follows that $|\Delta_2|$ is a strictly increasing function of λ. A similar argument can be applied to $|\Delta_5|$.

Although some of the inequalities in the above propositions are straightforward, several proved to be surprisingly challenging to verify. In particular, the effort involving Almkvist's approximation A_9 precipitated the discovery of some deeper results involving the generalized hypergeometric function ${}_3F_2$, which are also of independent interest. In this direction, our main general results are as follows.

THEOREM 2.5. *Let $1 > a \ge b > -1$ and $1 > \varepsilon \ge \frac{(a+1)(b+2)}{a+b+4}$. Then $T_n \equiv {}_3F_2\left(-n,a,b;a+b+2,\varepsilon-n+1;1\right)$ satisfies*

$$ab(T_n - T_{n+1}) \ge 0 \quad \text{for all integers } n \ge 2.$$

COROLLARY 2.6. *Let $1 > a \ge b > -1$ and $1 > \varepsilon \ge \frac{(a+1)(b+2)}{a+b+4}$. Then $T_n \equiv {}_3F_2\left(-n,a,b;a+b+2,\varepsilon-n+1;1\right)$ satisfies*

$$abT_n \ge abT_{n+1} \ge ab\cdot {}_2F_1\left(a,b;a+b+2;1\right) \quad \text{for all integers } n \ge 2.$$

COROLLARY 2.7. *Let $1 > \varepsilon \ge \frac{1}{4}$. Then $T_n \equiv {}_3F_2\left(-n,-\frac{1}{2},-\frac{1}{2};1,\varepsilon-n+1;1\right)$ satisfies*

$$T_n \ge T_{n+1} \ge \frac{4}{\pi} \quad \text{for all integers } n \ge 2.$$

3. Verification of coefficient inequalities.

Proof of Proposition 2.2. *Part* I: *Almkvist's Approximation A_9.* Let $s \equiv (1-\lambda^2)^{1/2}$ and $\beta_n \equiv \beta_n^{(9)}$. It follows that

$$A_9(\lambda) = 2\left[\frac{(1+s)+(1-s)s}{(1+\sqrt{s})^2}\right] = \sum_{n=0}^{\infty}\beta_n\lambda^{2n},$$

which implies that

$$2(1+2s-s^2) = (1+2\sqrt{s}+s)\sum_{n=0}^{\infty}\beta_n\lambda^{2n}. \tag{9}$$

By replacing s by $(1-\lambda^2)^{1/2}$ and applying $(1-\lambda^2)^q = \sum_{n=0}^{\infty} \frac{(-q)_n}{n!}\lambda^{2n}$, we may change (9) to the form

$$2\lambda^2 + 4\sum_{n=0}^{\infty} \frac{(-1/2)_n}{n!}\lambda^{2n} = \sum_{n=0}^{\infty} \beta_n \lambda^{2n} + 2\sum_{n=0}^{\infty}\sum_{k=0}^{n} \frac{(-1/4)_{n-k}}{(n-k)!}\beta_k \lambda^{2n} + \sum_{n=0}^{\infty}\sum_{k=0}^{n} \frac{(-1/2)_{n-k}}{(n-k)!}\beta_k \lambda^{2n}.$$

Equating the coefficients of λ^{2n}, we obtain $\beta_0 = 1$, $\beta_1 = 1/4$, and

$$4\frac{(-1/2)_n}{n!} = \beta_n + 2\sum_{k=0}^{n} \frac{(-1/4)_{n-k}}{(n-k)!}\beta_k + \sum_{k=0}^{n} \frac{(-1/2)_{n-k}}{(n-k)!}\beta_k \quad \text{for } n \geq 2.$$

Solving for β_n, we have the recursive relationship

$$\beta_n = \frac{(-1/2)_n}{n!} - \frac{1}{2}\sum_{k=0}^{n-1} \frac{(-1/4)_{n-k}}{(n-k)!}\beta_k - \frac{1}{4}\sum_{k=0}^{n-1} \frac{(-1/2)_{n-k}}{(n-k)!}\beta_k \quad \text{for } n \geq 2. \tag{10}$$

We will use (10) and induction to show that

$$\beta_n \geq \alpha_n \quad \text{for all } n \geq 0. \tag{11}$$

First note that $\beta_n = \alpha_n$ for $n = 0, 1, 2$. Now let $n \geq 2$ and suppose that $\beta_k \geq \alpha_k$ for all $k = 0, \ldots, n-1$. Since the coefficients of β_k in (10) are all positive, it follows that

$$\beta_n \geq \frac{(-1/2)_n}{n!} - \frac{1}{2}\sum_{k=0}^{n-1} \frac{(-1/4)_{n-k}}{(n-k)!}\alpha_k - \frac{1}{4}\sum_{k=0}^{n-1} \frac{(-1/2)_{n-k}}{(n-k)!}\alpha_k.$$

Thus (11) will be established if we can verify that

$$\frac{(-1/2)_n}{n!} - \frac{1}{2}\sum_{k=0}^{n-1} \frac{(-1/4)_{n-k}}{(n-k)!}\alpha_k - \frac{1}{4}\sum_{k=0}^{n-1} \frac{(-1/2)_{n-k}}{(n-k)!}\alpha_k \geq \alpha_n \quad \text{for } n \geq 2. \tag{12}$$

Next we use the identities $(c)_{n-k} = \frac{(-1)^k (c)_n}{(1-c-n)_k}$ and $(1)_n = n!$ and add the corresponding nth term of each summation to both sides. Then (12) becomes

$$\frac{(-1/2)_n}{n!} - \frac{(-1/4)_n}{2 \cdot n!}\sum_{k=0}^{n} \frac{(-n)_k}{(5/4-n)_k}\alpha_k - \frac{(-1/2)_n}{4 \cdot n!}\sum_{k=0}^{n} \frac{(-n)_k}{(3/2-n)_k}\alpha_k \geq \frac{\alpha_n}{4}. \tag{13}$$

Now we apply $\alpha_k \equiv \left(\frac{(-1/2)_k}{k!}\right)^2$ and the definition of ${}_3F_2$, then divide both sides of (13) by $\frac{-(-1/2)_n}{4 \cdot n!}$, and simplify. Then inequality (13) becomes

$$P(n) \cdot {}_3F_2\left(-n, -\frac{1}{2}, -\frac{1}{2}; 1, \frac{5}{4} - n; 1\right) + {}_3F_2\left(-n, -\frac{1}{2}, -\frac{1}{2}; 1, \frac{3}{2} - n; 1\right) \geq Q(n), \tag{14}$$

where $P(n) \equiv 2\frac{(-1/4)_n}{(-1/2)_n}$ and $Q(n) \equiv 4 - \frac{(-1/2)_n}{n!}$. For $n \geq 2$, these can be shown to satisfy

$$P(n) \leq P(n+1) \quad \text{and} \tag{15}$$

$$Q(n) \geq Q(n+1). \tag{16}$$

We first note that inequality (14) can be confirmed directly for $n = 2, \ldots, 6$. An application of Corollary 2.7 (to be proved in the following section), with the respective values of $\varepsilon = 1/4$ and $\varepsilon = 1/2$, yields

$${}_3F_2\left(-n, -\frac{1}{2}, -\frac{1}{2}; 1, \frac{5}{4} - n; 1\right) \geq \frac{4}{\pi} \quad \text{and} \tag{17}$$

$${}_3F_2\left(-n, -\frac{1}{2}, -\frac{1}{2}; 1, \frac{3}{2} - n; 1\right) \geq \frac{4}{\pi} \tag{18}$$

for all $n \geq 2$. From inequalities (15)–(18) with $n \geq 6$, it follows that

$$P(n) \cdot {}_3F_2\left(-n, -\frac{1}{2}, -\frac{1}{2}; 1, \frac{5}{4} - n; 1\right) + {}_3F_2\left(-n, -\frac{1}{2}, -\frac{1}{2}; 1, \frac{3}{2} - n; 1\right)$$
$$\geq P(6)\frac{4}{\pi} + \frac{4}{\pi} \geq Q(6) \geq Q(n).$$

Therefore, inequality (14) holds for all $n \geq 2$ and hence $\beta_n^{(9)} \equiv \beta_n \geq \alpha_n$ for all $n \geq 0$. That is, Almkvist's approximation satisfies the property that all of the nonzero Maclaurin series coefficients of Δ_9 are positive. This concludes the proof of Part I of Proposition 2.2.

Proof of Proposition 2.2. *Part* II: *Jacobsen and Waadeland's Approximation* A_{12}. Now we seek to show that the approximation A_{12} satisfies the property that all of the nonzero Maclaurin series coefficients of Δ_{12} are negative. Let $a = 3$, $b = -112$, $c = 256$, and $D = \sqrt{b^2 - 4ac}$. It follows that

$$\frac{1}{au^2 + bu + c} = \frac{2a}{D}\left[\frac{1}{2au + b - D} - \frac{1}{2au + b + D}\right] = \sum_{n=0}^{\infty} d_n u^n \quad \text{for} \quad |u| < \left|\frac{D+b}{2a}\right|,$$

where

$$d_n \equiv \frac{2a}{D}\left[\frac{(-1)^n(2a)^n}{(b-D)^{n+1}} - \frac{(-1)^n(2a)^n}{(b+D)^{n+1}}\right] = \frac{1}{D}\left(\frac{2a}{D-b}\right)^{n+1}\left[\left(\frac{b-D}{b+D}\right)^{n+1} - 1\right].$$

It follows that $d_n > 0$ for all $n \geq 0$ and

$$\begin{aligned} A_{12}(\lambda) &\equiv \frac{256 - 48\lambda^2 - 21\lambda^4}{256 - 112\lambda^2 + 3\lambda^4} \\ &= -7 + \frac{2048 - 832\lambda^2}{256 - 112\lambda^2 + 3\lambda^4} \\ &= -7 + (2048 - 832\lambda^2)\sum_{n=0}^{\infty} d_n \lambda^{2n}. \end{aligned}$$

Now let $\beta_n \equiv \beta_n^{(12)}$. Then the nonzero Maclaurin series coefficients for A_{12} are given by $\beta_0 = 1$ and

$$\beta_n = 2048 d_n - 832 d_{n-1} \quad \text{for all } n \geq 1.$$

Since $(x^{n+1}-1)/(x-1) > x$ for $x \equiv (b-D)/(b+D) > 1$, it follows easily that $(2048d_n)/(832d_{n-1}) > 1$ for all $n \geq 1$. Thus

$$\beta_n > 0 \quad \text{for all } n \geq 0. \tag{19}$$

Direct calculation reveals that $\beta_n = \alpha_n$ for $n = 0, \ldots, 4$. Also note that

$$(256 - 112\lambda^2 + 3\lambda^4) \sum_{n=0}^{\infty} \beta_n \lambda^{2n} = 256 - 48\lambda^2 - 21\lambda^4.$$

Hence

$$\sum_{n=3}^{\infty} (256\beta_n - 112\beta_{n-1} + 3\beta_{n-2})\lambda^{2n} = 0. \tag{20}$$

Thus the coefficients of λ^{2n} in (20) are zero for all $n \geq 3$. Solving for β_n and using (19), we have

$$\beta_n = (112\beta_{n-1} - 3\beta_{n-2})/256 < \frac{112}{256}\beta_{n-1} \quad \text{for all } n \geq 3.$$

Now suppose that $\beta_n \leq \alpha_n$ for some integer $n \geq 4$, where $\alpha_n \equiv (\frac{(-1/2)_n}{n!})^2$. Then

$$\beta_{n+1} < \frac{112}{256}\beta_n \leq \frac{112}{256}\alpha_n = \frac{112}{256}\frac{\alpha_n}{\alpha_{n+1}}\alpha_{n+1} = \frac{112}{256}\left(\frac{n+1}{n-\frac{1}{2}}\right)^2 \alpha_{n+1} \leq \alpha_{n+1}.$$

Thus $\beta_n^{(12)} \equiv \beta_n \leq \alpha_n$ for all integers $n \geq 0$. This concludes the proof of Part II of Proposition 2.2. □

Before proving Proposition 2.3, we first observe that the nine approximations involved have the following respective Maclaurin series representations (recursive relationships satisfied by $\beta_n^{(13)}$ and $\beta_n^{(3)}$ are developed in the appendix):

$$A_1(\lambda) \equiv (1-\lambda^2)^{1/2} = 1 + \sum_{n=1}^{\infty} \frac{(-1/2)_n}{n!}\lambda^{2n}, \tag{21}$$

$$A_6(\lambda) \equiv \left(1 + \frac{\lambda^2}{8}\right)^2 = 1 + \frac{\lambda^2}{4} + \frac{\lambda^4}{64}, \tag{22}$$

$$A_7(\lambda) \equiv 1 + \frac{\lambda^2/4}{1-\lambda^2/16} = 1 + \frac{\lambda^2}{4} + \sum_{n=2}^{\infty} \frac{1}{2^{4n-2}}\lambda^{2n}, \tag{23}$$

$$A_8(\lambda) \equiv 3 - \sqrt{4-\lambda^2} = 1 + \frac{\lambda^2}{4} - \sum_{n=2}^{\infty} \frac{(-1/2)_n}{n!2^{2n-1}}\lambda^{2n}, \tag{24}$$

$$A_{10}(\lambda) \equiv \frac{64 - 3\lambda^4}{64 - 16\lambda^2} = 1 + \frac{\lambda^2}{4} + \sum_{n=2}^{\infty} \frac{1}{2^{2n+2}}\lambda^{2n}, \tag{25}$$

$$A_{11}(\lambda) \equiv \frac{3}{2} + \frac{\lambda^2}{8} - \frac{1}{2}\left(1 - \frac{\lambda^2}{2}\right)^{1/2} = 1 + \frac{\lambda^2}{4} - \sum_{n=2}^{\infty} \frac{(-1/2)_n}{n!2^{n+1}}\lambda^{2n}, \tag{26}$$

$$A_{13}(\lambda) \equiv 1 + \frac{3\lambda^2}{10 + \sqrt{4 - 3\lambda^2}} = 1 + \frac{\lambda^2}{4} + \sum_{n=2}^{\infty} \beta_n^{(13)} \lambda^{2n}, \tag{27}$$

$$A_4(\lambda) \equiv \frac{3}{2} - \frac{1}{2}(1 - \lambda^2)^{1/2} = 1 + \frac{\lambda^2}{4} - \frac{1}{2} \sum_{n=2}^{\infty} \frac{(-1/2)_n}{n!} \lambda^{2n}, \tag{28}$$

$$A_3(\lambda) \equiv \frac{2}{1 + \sqrt{1 - \lambda^2}} = 1 + \frac{\lambda^2}{4} + \sum_{n=2}^{\infty} \beta_n^{(3)} \lambda^{2n}. \tag{29}$$

Proof of Proposition 2.3. We seek to establish the following inequalities regarding the specified Maclaurin series coefficients:

$$\beta_n^{(1)} \le \beta_n^{(6)} \le \beta_n^{(7)} \le \beta_n^{(8)} \le \beta_n^{(10)} \le \beta_n^{(11)} \le \beta_n^{(13)} \le \alpha_n \le \beta_n^{(4)} \le \beta_n^{(3)} \tag{30}$$

for all $n \ge 0$. Referring to (21)–(29), we note that the inequalities in (30) are trivial for $n = 0$ and $n = 1$. Thus we must verify (30) for all $n \ge 2$. The first two inequalities are immediate while the next three inequalities follow directly by induction. We now proceed to prove the remaining inequalities in (30).

• Claim I. $\beta_n^{(11)} \le \beta_n^{(13)} \le \alpha_n$ *for all* $n \ge 2$.

Let $\beta_n \equiv \beta_n^{(13)}$ and $\gamma_n \equiv \beta_n^{(11)}$, where $\beta_n^{(11)} \equiv \frac{-(-1/2)_n}{n! 2^{n+1}}$ for $n \ge 2$ (see (26)) and recall that $\alpha_n \equiv (\frac{(-1/2)_n}{n!})^2$. The nonzero Maclaurin series coefficients of Ramanujan's second estimate A_{13} can be shown to satisfy (see the appendix) $\beta_0 = 1$, $\beta_1 = 1/4$, $\beta_2 = 1/64$, and

$$\beta_n = \phi_{n-1} - 2^{-5}\beta_{n-1} \quad \text{for all } n \ge 3, \quad \text{where} \quad \phi_n \equiv -\frac{(-1/2)_n (3/4)^n}{16 \cdot n!}. \tag{31}$$

Applying (31) twice, we have

$$\beta_n = \phi_{n-1} - 2^{-5}\phi_{n-2} + 2^{-10}\beta_{n-2} \quad \text{for all } n \ge 4. \tag{32}$$

Direct calculation reveals that Claim I holds for $n = 2, 3, 4$. That is, $\gamma_n \le \beta_n \le \alpha_n$ for $n = 2, 3, 4$. Now let $n \ge 5$ and suppose that

$$\gamma_k \le \beta_k \le \alpha_k \quad \text{for all } k = 2, \ldots, n-1. \tag{33}$$

Then (32) and (33) together imply that

$$\begin{aligned} &\phi_{n-1} - 2^{-5}\phi_{n-2} + 2^{-10}\gamma_{n-2} \\ &\le \overbrace{\phi_{n-1} - 2^{-5}\phi_{n-2} + 2^{-10}\beta_{n-2}}^{\beta_n} \le \phi_{n-1} - 2^{-5}\phi_{n-2} + 2^{-10}\alpha_{n-2}. \end{aligned} \tag{34}$$

It can be shown (see the appendix) that

$$\gamma_n \le \phi_{n-1} - 2^{-5}\phi_{n-2} + 2^{-10}\gamma_{n-2} \quad \text{and} \tag{35}$$

$$\alpha_n \ge \phi_{n-1} - 2^{-5}\phi_{n-2} + 2^{-10}\alpha_{n-2} \tag{36}$$

for all $n \ge 5$. Therefore, using inequalities (34)–(36) and induction, we have $\gamma_n \le \beta_n \le \alpha_n$ for all $n \ge 2$. This completes the proof of Claim I.

• Claim II. $\alpha_n \le \beta_n^{(4)} \le \beta_n^{(3)}$ *for all* $n \ge 2$.

If we now apply (28), the first inequality in Claim II becomes

$$\alpha_n \equiv \left(\frac{(-1/2)_n}{n!}\right)^2 \leq \frac{-(-1/2)_n}{2 \cdot n!} \equiv \beta_n^{(4)} \quad \text{for all } n \geq 2.$$

This is equivalent to

$$\frac{-2(-1/2)_n}{n!} \leq 1 \quad \text{for all } n \geq 2$$

which follows by induction. The second inequality in Claim II involves the Maclaurin series coefficients of Sipos and Ekwall's approximation A_3 which can be shown to satisfy the following recursive relationship (see the appendix): $\beta_0^{(3)} = 1$, $\beta_1^{(3)} = 1/4$, $\beta_2^{(3)} = 1/8$, and

$$\beta_n^{(3)} = -\frac{1}{2}\sum_{k=0}^{n-1} \frac{(-1/2)_{n-k}}{(n-k)!}\beta_k^{(3)} \quad \text{for all } n \geq 2. \tag{37}$$

Note that

$$-\frac{1}{2}\sum_{k=0}^{n-1} \frac{(-1/2)_{n-k}}{(n-k)!}\beta_k^{(3)} = \frac{-(-1/2)_n}{2 \cdot n!} - \frac{1}{2}\sum_{k=1}^{n-1} \frac{(-1/2)_{n-k}}{(n-k)!}\beta_k^{(3)} \tag{38}$$

for all $n \geq 2$, and

$$\frac{-(-1/2)_{n-k}}{2 \cdot (n-k)!}\beta_k^{(3)} > 0 \quad \text{for } k = 1, \ldots, n-1. \tag{39}$$

Therefore, (37)–(39) together yield

$$\beta_n^{(4)} \equiv \frac{-(-1/2)_n}{2 \cdot n!} \leq \beta_n^{(3)} \quad \text{for all } n \geq 2.$$

This concludes the proof of Claim II and Proposition 2.3. □

Remarks on the Proof of Proposition 2.4. From (8), we have that $c_n \equiv \dfrac{(1/2)^n(-1/2)_n}{n!}$ for all $n \geq 1$. By induction, it can be shown that

$$\frac{(1/2)_n(-1/2)_n}{n! \cdot n!} \leq c_n \quad \text{for all } n \geq 1.$$

In an earlier paper (see [9]), the authors use the logarithmic derivative and Cauchy products to obtain the recursive relationship for b_n (with b_n as defined in (7)) given by

$$b_{n+1} = \frac{1}{2(n+1)}\left[\left(\frac{5}{4}n - \frac{1}{2}\right)b_n - \sum_{k=0}^{n-2}(k+1)b_{k+1}\frac{\left(-\frac{1}{4}\right)_{n-k}}{(n-k)!}\right]. \tag{40}$$

Theorem 2.1, together with (40), was then used (see [9]) to establish that

$$b_n \leq \frac{(1/2)_n(-1/2)_n}{n! \cdot n!} \quad \text{for all } n \geq 1. \qquad \square$$

4. Proofs of general results involving ${}_3F_2$. We will make use of the following classical identities which we include for the reader's convenience ($F \equiv {}_3F_2$).

IDENTITY 1 {see [13, p. 440, eq. (33)]}.

$$F(\rho,a,b;c,\sigma;1) - F(\rho+1,a,b;c,\sigma+1;1) = \frac{-ab(\sigma-\rho)}{c\sigma(\sigma+1)} \cdot F(\rho+1,a+1,b+1;c+1,\sigma+2;1).$$

IDENTITY 2 {see [11, p. 59, eq. (3.1.1)]}.

$$F(-n,a,b;c,d;1) = \frac{(d-b)_n}{(d)_n} \cdot F(-n,c-a,b;c,1+b-d-n;1).$$

IDENTITY 3 {see [13, p. 440, eq. (26)]}.

$$\sigma \cdot F(\rho,a,b;c,\sigma;1) = \rho \cdot F(\rho+1,a,b;c,\sigma+1;1) + (\sigma-\rho) \cdot F(\rho,a,b;c,\sigma+1;1).$$

IDENTITY 4 {see [14, p. 82, eq. (14)]}.

$$(a_1-a_2)\cdot F(a_1,a_2,a_3;b_1,b_2;z) = a_1 \cdot F(a_1+1,a_2,a_3;b_1,b_2;z) - a_2 \cdot F(a_1,a_2+1,a_3;b_1,b_2;z).$$

IDENTITY 5 {see [13, p. 440, eq. (30)]}.

$$F(\sigma,a,b;c,d;1) - F(\sigma+1,a,b;c,d;1) = \frac{-ab}{cd} \cdot F(\sigma+1,a+1,b+1;c+1,d+1;1).$$

Proof of Theorem 2.5. Define $T_n \equiv F(-n,a,b;a+b+2,\varepsilon-n+1;1)$, where $F \equiv {}_3F_2$. Let $1 > a \geq b > -1$ and $1 > \varepsilon \geq \frac{(a+1)(b+2)}{a+b+4}$. For $n \geq 2$, it follows that

$$\begin{aligned}
T_{n+1} - T_n &= F(-n-1,a,b;a+b+2,\varepsilon-n;1) - F(-n,a,b;a+b+2,\varepsilon-n+1;1) \\
&= \frac{-ab(\varepsilon+1)}{(\varepsilon-n)(\varepsilon-n+1)(a+b+2)} F(-n,a+1,b+1;a+b+3,\varepsilon-n+2;1) \\
&\quad \{\text{using Identity 1 with } \rho = -n-1,\ \sigma = \varepsilon-n\} \\
&= \frac{-ab(\varepsilon+1)}{(n-\varepsilon)(n-\varepsilon-1)(a+b+2)} \frac{(\varepsilon-n-b+1)_n}{(\varepsilon-n+2)_n} \\
&\quad \times F(-n,b+2,b+1;a+b+3,b-\varepsilon;1) \\
&\quad \{\text{using Identity 2}\} \\
&= \frac{-ab(\varepsilon+1)(b-\varepsilon)_n}{(n-\varepsilon)(n-\varepsilon-1)(a+b+2)(-1-\varepsilon)_n(b-\varepsilon)} \\
&\quad \times [(b+1)F(-n,b+2,b+2;a+b+3,b+1-\varepsilon;1) \\
&\quad + (-\varepsilon-1)F(-n,b+2,b+1;a+b+3,b+1-\varepsilon;1)], \qquad (41)
\end{aligned}$$

where (41) follows from Identity 3 (with $\rho = b+1$, $\sigma = b-\varepsilon$) and the identity $(1-\alpha-n)_n = (-1)^n(\alpha)_n$.
Identity 4 (with $a_1 = -n$ and $a_2 = b+1$) implies that

$$\begin{aligned}
&F(-n,b+2,b+2;a+b+3,b+1-\varepsilon;1) \\
&\quad = \frac{1}{b+1}[(n+b+1)F(-n,b+2,b+1;a+b+3,b+1-\varepsilon;1) \\
&\quad + (-n)F(-n+1,b+2,b+1;a+b+3,b+1-\varepsilon;1)]. \qquad (42)
\end{aligned}$$

Now let $G_n = F(-n, b+2, b+1; a+b+3, b+1-\varepsilon; 1)$ and use (41) and (42). Then we have that

$$\begin{aligned} T_{n+1} - T_n &= \frac{-ab(\varepsilon+1)(b-\varepsilon)_n}{(n-\varepsilon)(n-\varepsilon-1)(a+b+2)(-1-\varepsilon)_n(b-\varepsilon)} \\ &\quad \times[(n+b+1)G_n - nG_{n-1} + (-\varepsilon-1)G_n] \\ &= \frac{-ab(\varepsilon+1)(b-\varepsilon)_n}{(n-\varepsilon)(n-\varepsilon-1)(a+b+2)(-1-\varepsilon)_n(b-\varepsilon)} \\ &\quad \times[n(G_n - G_{n-1}) + (b-\varepsilon)G_n]. \end{aligned} \tag{43}$$

Applications of Identity 5 (with $\sigma = -n$) followed by Identity 2 yield

$$\begin{aligned} G_n - G_{n-1} &= F(-n, b+2, b+1; a+b+3, b+1-\varepsilon; 1) \\ &\quad - F(-n+1, b+2, b+1; a+b+3, b+1-\varepsilon; 1) \\ &= \frac{-(b+2)(b+1)}{(a+b+3)(b+1-\varepsilon)} F(-n+1, b+3, b+2; a+b+4, b+2-\varepsilon; 1) \\ &= \frac{-(b+2)(b+1)}{(a+b+3)(b+1-\varepsilon)} \cdot \frac{(-\varepsilon)_{n-1}}{(b+2-\varepsilon)_{n-1}} \\ &\quad \times F(-n+1, a+1, b+2; a+b+4, \varepsilon-n+2; 1). \end{aligned} \tag{44}$$

Identity 2 also implies that

$$G_n = \frac{(-\varepsilon)_n}{(b+1-\varepsilon)_n} F(-n, a+1, b+1; a+b+3, \varepsilon-n+1; 1). \tag{45}$$

Combining (43)–(45), we have

$$\begin{aligned} T_{n+1} - T_n &= \frac{-ab(\varepsilon+1)(b-\varepsilon)_n}{(n-\varepsilon)(n-\varepsilon-1)(a+b+2)(-1-\varepsilon)_n(b-\varepsilon)} \\ &\times \left[\frac{-n(b+2)(b+1)(-\varepsilon)_{n-1}}{(a+b+3)(b+1-\varepsilon)(b+2-\varepsilon)_{n-1}} F(-n+1, a+1, b+2; a+b+4, \varepsilon-n+2; 1) \right. \\ &\quad \left. + (b-\varepsilon) \frac{(-\varepsilon)_n}{(b+1-\varepsilon)_n} F(-n, a+1, b+1; a+b+3, \varepsilon-n+1; 1) \right]. \end{aligned} \tag{46}$$

Now make use of $\frac{(b-\varepsilon)_n}{(b+1-\varepsilon)_n} = \frac{(b-\varepsilon)}{(n+b-\varepsilon)}$, $\frac{(-\varepsilon)_n}{(-1-\varepsilon)_n} = \frac{(-1-\varepsilon+n)}{(-1-\varepsilon)}$, $\frac{(-\varepsilon)_{n-1}}{(-1-\varepsilon)_n} = \frac{1}{(-1-\varepsilon)}$, and multiply both sides by $-ab$. Then (46) becomes

$$\begin{aligned} ab(T_n - T_{n+1}) &= \frac{(ab)^2(\varepsilon+1)}{(n-\varepsilon)(n-\varepsilon-1)(a+b+2)(b-\varepsilon)} \\ &\times \left[\frac{-n(b+2)(b+1)(b-\varepsilon)}{(a+b+3)(-1-\varepsilon)(n+b-\varepsilon)} F(-n+1, a+1, b+2; a+b+4, \varepsilon-n+2; 1) \right. \\ &\quad \left. + (b-\varepsilon) \frac{(n-1-\varepsilon)(b-\varepsilon)}{(-1-\varepsilon)(n+b-\varepsilon)} F(-n, a+1, b+1; a+b+3, \varepsilon-n+1; 1) \right] \\ &= \frac{(ab)^2}{(n-\varepsilon)(n-\varepsilon-1)(a+b+2)(n+b-\varepsilon)} \\ &\quad \times \left[\frac{n(b+2)(b+1)}{(a+b+3)} F(-(n-1), a+1, b+2; a+b+4, \varepsilon-(n-1)+1; 1) \right. \\ &\quad \left. + (\varepsilon-b)(n-\varepsilon-1) F(-n, a+1, b+1; a+b+3, \varepsilon-n+1; 1) \right], \end{aligned} \tag{47}$$

where $n+b-\varepsilon > n-\varepsilon-1 > n-2 \geq 0$, $n-\varepsilon > 0$, and $\varepsilon - b > \varepsilon - \frac{(a+1)(b+2)}{a+b+4} \geq 0$. Since $1 > \varepsilon \geq \frac{(a+1)(b+2)}{a+b+4} > \frac{(a+1)(b+1)}{a+b+3}$, Theorem 2.1 implies that

$$F\left(-(n-1), a+1, b+2; a+b+4, \varepsilon-(n-1)+1; 1\right) \geq 0 \quad \text{and}$$
$$F\left(-n, a+1, b+1; a+b+3, \varepsilon-n+1; 1\right) \geq 0.$$

Therefore, (47) is the product and sum of nonnegative quantities and thus

$$ab(T_n - T_{n+1}) \geq 0 \quad \text{for all integers } n \geq 2. \qquad \square$$

In order to prove Corollary 2.6, we will make use of the following two lemmas.

LEMMA 4.1. *Let n be a positive integer and $0 < \varepsilon < 1$. Then*

$$\frac{(-n)_k}{(\varepsilon-n+1)_k} \geq 1 \quad \textit{for all } k = 0, \ldots, n-1.$$

Proof of Lemma 4.1. Note that the desired inequality holds at $k = 0$. Now let $n \geq 2$ and suppose that

$$\frac{(-n)_k}{(\varepsilon-n+1)_k} \geq 1 \quad \text{for some } k \text{ with } 0 \leq k \leq n-2.$$

Then

$$\frac{(-n)_{k+1}}{(\varepsilon-n+1)_{k+1}} = \frac{(-n)_k(-n+k)}{(\varepsilon-n+1)_k(\varepsilon-n+1+k)} \geq \frac{(-n)_k}{(\varepsilon-n+1)_k} \geq 1. \qquad \square$$

LEMMA 4.2. *Define $\psi_n(a,b,c,\varepsilon) \equiv \frac{(a)_n(b)_n(-n)_n}{n!(c)_n(\varepsilon-n+1)_n}$. Let (a,b,c,ε) be in the domain of ψ_n for all $n \geq 2$ with $\varepsilon < c-a-b$. Then*

$$\lim_{n\to\infty} \psi_n(a,b,c,\varepsilon) = 0.$$

Proof of Lemma 4.2. Since $(1-c-n)_n = (-1)^n(c)_n$, it follows that

$$\psi_n = \frac{(a)_n(b)_n(1)_n}{n!(c)_n(-\varepsilon)_n} = \frac{\Gamma(a+n)\Gamma(b+n)\Gamma(c)\Gamma(-\varepsilon)}{\Gamma(a)\Gamma(b)\Gamma(c+n)\Gamma(-\varepsilon+n)} n^{c-a-b-\varepsilon} n^{a+b+\varepsilon-c}.$$

It is known that (see [1, p. 257, eq. (6.1.46)])

$$\lim_{n\to\infty} \frac{\Gamma(r+n)}{\Gamma(s+n)} n^{s-r} = 1.$$

If $a+b+\varepsilon-c < 0$, then

$$\lim_{n\to\infty} \psi_n = \lim_{n\to\infty} \frac{\Gamma(a+n)\Gamma(b+n)\Gamma(c)\Gamma(-\varepsilon)}{\Gamma(a)\Gamma(b)\Gamma(c+n)\Gamma(-\varepsilon+n)} n^{c-a-b-\varepsilon} \cdot \lim_{n\to\infty} n^{a+b+\varepsilon-c} = 0. \qquad \square$$

Proof of Corollary 2.6. Let $1 > a \geq b > -1$ and $1 > \varepsilon \geq \frac{(a+1)(b+2)}{a+b+4}$ and define

$$T_n \equiv {}_3F_2\left(-n, a, b; a+b+2, \varepsilon-n+1; 1\right).$$

Theorem 2.5 implies that the sequence $\{abT_n\}_{n=2}^{\infty}$ is a monotone (nonincreasing) sequence. Now define

$$S_n \equiv 1 + \frac{(a)_n(b)_n(-n)_n}{n!(a+b+2)_n(\varepsilon-n+1)_n} + \sum_{k=1}^{n-1} \frac{(a)_k(b)_k}{k!(a+b+2)_k}.$$

Using the definition of ${}_3F_2$, Lemma 4.1, and the fact that $\dfrac{ab(a)_k(b)_k}{k!(a+b+2)_k} \geq 0$ for $k = 1, \ldots, n-1$, we obtain

$$abT_n = ab + \frac{ab(a)_n(b)_n(-n)_n}{n!(a+b+2)_n(\varepsilon-n+1)_n} + \sum_{k=1}^{n-1} \frac{ab(a)_k(b)_k(-n)_k}{k!(a+b+2)_k(\varepsilon-n+1)_k} \geq abS_n$$

for all $n \geq 2$.
Applying Lemma 4.2 with $c = a+b+2$, we have

$$\lim_{n\to\infty} S_n = {}_2F_1\left(a, b; a+b+2; 1\right).$$

Since $abT_n \geq abS_n$ for all $n \geq 2$, it follows that $\{abT_n\}_{n=2}^{\infty}$ is a bounded monotone sequence. Thus

$$abT_n \geq \lim_{n\to\infty} abT_n \geq \lim_{n\to\infty} abS_n = ab \cdot {}_2F_1\left(a, b; a+b+2; 1\right) \quad \text{for all } n \geq 2. \qquad \square$$

Proof of Corollary 2.7. Choose $a = b = -1/2$ and $1 > \varepsilon \geq 1/4$ and define

$$T_n \equiv {}_3F_2\left(-n, -\frac{1}{2}, -\frac{1}{2}; 1, \varepsilon-n+1; 1\right).$$

It is known that (see [14, p. 49])

$${}_2F_1\left(-\frac{1}{2}, -\frac{1}{2}; 1; 1\right) = \frac{4}{\pi}.$$

Corollary 2.6 implies that

$$T_n \geq T_{n+1} \geq \frac{4}{\pi} \quad \text{for all } n \geq 2. \qquad \square$$

5. Appendix.

5.1. Recursive relationship for Maclaurin series coefficients of Ramanujan's second estimate A_{13}. Writing $\beta_n \equiv \beta_n^{(13)}$, we have

$$3\lambda^2(10 - \sqrt{4-3\lambda^2}) = (A_{13}(\lambda) - 1)(10^2 - (\sqrt{4-3\lambda^2})^2) = (96 + 3\lambda^2)\sum_{n=1}^{\infty} \beta_n \lambda^{2n}$$

which implies that

$$10 - 2\left(1 - \frac{3}{4}\lambda^2\right)^{1/2} = (32 + \lambda^2)\sum_{n=1}^{\infty} \beta_n \lambda^{2n-2}.$$

Applying $(1-x)^q = \sum_{n=0}^{\infty} \frac{(-q)_n}{n!} x^n$ and simplifying yields

$$8 - 2\sum_{n=1}^{\infty} \frac{(-1/2)_n (3/4)^n}{n!} \lambda^{2n} = 32\beta_1 + \sum_{n=1}^{\infty} (32\beta_{n+1} + \beta n)\lambda^{2n}.$$

Thus $\beta_0 = 1$, $\beta_1 = 1/4$, $\beta_2 = 1/64$, and

$$\beta_{n+1} = \frac{-(-1/2)_n (3/4)^n}{16 \cdot n!} - \frac{\beta_n}{32} \quad \text{for all } n \geq 1.$$

Letting $\phi_n \equiv -\dfrac{(-1/2)_n (3/4)^n}{16 \cdot n!}$, we obtain

$$\beta_{n+1} = \phi_n - 2^{-5}\beta_n \quad \text{for all } n \geq 2. \qquad \square$$

5.2. Recursive relationship for Maclaurin series coefficients of Sipos and Ekwall's estimate A_3. Writing $\beta_n \equiv \beta_n^{(3)}$ and using the Cauchy product, we have

$$2 = A_3(\lambda)(1 + \sqrt{1-\lambda^2}) = \sum_{n=0}^{\infty} \beta_n \lambda^{2n} + \sum_{n=0}^{\infty} \sum_{k=0}^{n} \frac{(-1/2)_{n-k}}{(n-k)!} \beta_k \lambda^{2n}.$$

Thus $\beta_0^{(3)} = 1,\ \beta_1^{(3)} = 1/4,\ \beta_2^{(3)} = 1/8,$ and

$$\beta_n^{(3)} = \frac{-1}{2} \sum_{k=0}^{n-1} \frac{(-1/2)_{n-k}}{(n-k)!} \beta_k^{(3)} \quad \text{for all } n \geq 2. \qquad \square$$

5.3. Establishing inequality (35). Let $\phi_n \equiv \frac{-(-1/2)_n (3/4)^n}{16 \cdot n!}$, $\gamma_n \equiv \beta_n^{(11)} = \frac{-(-1/2)_n}{n! 2^{n+1}}$, and $n \geq 4$. Inequality (35) claims that $\gamma_n \leq \phi_{n-1} - 2^{-5}\phi_{n-2} + 2^{-10}\gamma_{n-2}$.

Direct calculation reveals that the desired inequality holds for $n = 4, \ldots, 7$. Now suppose that $n \geq 7$. Since $\gamma_{n-2} > 0$, we have

$$\begin{aligned}
&\gamma_n - \phi_{n-1} + 2^{-5}\phi_{n-2} - 2^{-10}\gamma_{n-2} < \gamma_n - \phi_{n-1} + 2^{-5}\phi_{n-2} \\
&\quad = \frac{-(-1/2)_n}{n! 2^{n+1}} + \frac{(-1/2)_{n-1}(3/4)^{n-1}}{16 \cdot (n-1)!} - 2^{-9} \frac{(-1/2)_{n-2}(3/4)^{n-2}}{(n-2)!} \\
&\quad = -2^{-9} \frac{(-1/2)_{n-2}(3/4)^{n-2}}{(n-2)!} \cdot \left[\frac{2^9 (4/3)^{n-2}(n-3/2)(n-5/2)}{n(n-1)2^{n+1}} - \frac{2^5 (3/4)(n-5/2)}{(n-1)} + 1 \right] \\
&\quad = -2^{-9} \frac{(-1/2)_{n-2}(3/4)^{n-2}}{(n-2)!} \cdot \left[\frac{2^{n+4}(n-3/2)(n-5/2)}{3^{n-2} n(n-1)} - \frac{24(n-5/2)}{(n-1)} + 1 \right].
\end{aligned}$$

Since $\frac{(n-5/2)}{(n-1)} \geq \frac{1}{2}$, it follows that

$$\frac{2^{n+4}(n-3/2)(n-5/2)}{3^{n-2} n(n-1)} - \frac{24(n-5/2)}{(n-1)} + 1 \leq \frac{2^{n+4}(n-3/2)(n-5/2)}{3^{n-2} n(n-1)} - 11.$$

Thus

$$\begin{aligned}
&\gamma_n - \phi_{n-1} + 2^{-5}\phi_{n-2} - 2^{-10}\gamma_{n-2} \\
&\quad < -2^{-5} \cdot 9 \frac{(-1/2)_{n-2}(3/4)^{n-2}}{(n-2)!} \cdot \left[\frac{2^n (n-3/2)(n-5/2)}{3^n n(n-1)} - \frac{11 \cdot 2^{-4}}{3^2} \right]
\end{aligned}$$

$$\leq \frac{-9(-1/2)_{n-2}(3/4)^{n-2}}{32(n-2)!}\cdot\left[\left(\frac{2}{3}\right)^n-\frac{11}{144}\right]$$
$$\leq \frac{-9(-1/2)_{n-2}(3/4)^{n-2}}{32(n-2)!}\cdot\left[\left(\frac{2}{3}\right)^7-\frac{11}{144}\right]<0.$$

Hence the claim in (35) is established. □

5.4. Establishing inequality (36). Let $\phi_n \equiv -\frac{(-1/2)_n(3/4)^n}{16\cdot n!}$, $\alpha_n \equiv (\frac{(-1/2)_n}{n!})^2$, and $n \geq 4$.

Inequality (36) claims that $\phi_n - 2^{-5}\phi_{n-1} + 2^{-10}\alpha_{n-1} \leq \alpha_{n+1}$. Note that

$$\begin{aligned}
&\phi_{\ n} - 2^{-5}\phi_{n-1} + 2^{-10}\alpha_{n-1} - \alpha_{n+1}\\
&= -\frac{(-1/2)_n(3/4)^n}{16\cdot n!} + 2^{-5}\frac{(-1/2)_{n-1}(3/4)^{n-1}}{16\cdot(n-1)!} + 2^{-10}\left(\frac{(-1/2)_{n-1}}{(n-1)!}\right)^2 - \left(\frac{(-1/2)_{n+1}}{(n+1)!}\right)^2\\
&= \frac{(-1/2)_{n-1}}{(n-1)!}\left\{\frac{-(n-3/2)3^n}{n2^{2n+4}} + \frac{3^{n-1}}{2^{2n+7}} + \frac{(-1/2)_{n-1}}{2^{10}(n-1)!} - \frac{(n-3/2)(n-1/2)(-1/2)_{n+1}}{n(n+1)\cdot(n+1)!}\right\}\\
&= \frac{(-1/2)_{n-1}}{(n-1)!}\left\{\frac{3^{n-1}}{2^{2n+4}}\left[\frac{3(3/2-n)}{n}+\frac{1}{2^3}\right] + \frac{(-1/2)_{n-1}}{(n-1)!}\left[\frac{1}{2^{10}} - \frac{(n-3/2)^2(n-1/2)^2}{n^2(n+1)^2}\right]\right\}\\
&= \frac{(-1/2)_{n-1}}{(n-1)!}\left\{\frac{U(n)}{V(n)}+1\right\}V(n),
\end{aligned}$$

where

$$U(n) \equiv \frac{3^{n-1}}{2^{2n+4}}\left[\frac{3(3/2-n)}{n}+\frac{1}{2^3}\right]$$

and

$$V(n) \equiv \frac{(-1/2)_{n-1}}{(n-1)!}\left[\frac{1}{2^{10}} - \frac{(n-3/2)^2(n-1/2)^2}{n^2(n+1)^2}\right].$$

It follows that $V(n) > 0$. Now let $W(n) \equiv U(n)/V(n)$. Since $(-1/2)_{n-1} < 0$, we will be finished if we can show that $W(n)+1 > 0$ for all $n \geq 4$. Direct calculation again yields $W(4)+1 > 0$. For $n \geq 4$, it is easy to check that

$$\begin{aligned}
W(n+1) - W(n) &= \frac{\frac{3^n}{2^{2n+6}}\left[\frac{3(1/2-n)}{n+1}+\frac{1}{2^3}\right]}{\frac{(-1/2)_n}{n!}\left[\frac{1}{2^{10}} - \frac{(n-1/2)^2(n+1/2)^2}{(n+1)^2(n+2)^2}\right]}\\
&\quad - \frac{\frac{3^{n-1}}{2^{2n+4}}\left[\frac{3(3/2-n)}{n}+\frac{1}{2^3}\right]}{\frac{(-1/2)_{n-1}}{(n-1)!}\left[\frac{1}{2^{10}} - \frac{(n-3/2)^2(n-1/2)^2}{n^2(n+1)^2}\right]}\\
&= \left\{\frac{\frac{3^{n-1}}{2^{2n+4}}}{\frac{(-1/2)_{n-1}}{(n-1)!}}\right\}\left\{\frac{3n}{4(n-3/2)}Z(n+1) - Z(n)\right\}, \qquad (48)
\end{aligned}$$

where $Z(n) \equiv [\frac{3(3/2-n)}{n}+\frac{1}{2^3}]/[\frac{1}{2^{10}} - \frac{(n-3/2)^2(n-1/2)^2}{n^2(n+1)^2}]$. Direct calculation reveals that the expression in (48) is nonnegative for $n = 4$ and $n = 5$. For $n \geq 6$, it can be shown by a straightforward calculation that $0 < Z(n+1) \leq Z(n)$. Hence $\frac{3n}{4(n-3/2)}Z(n+1) - Z(n) \leq Z(n+1) - Z(n) \leq 0$ for all $n \geq 6$. Thus $W(n+1) - W(n) \geq 0$ for all $n \geq 4$ since $(-1/2)_{n-1} < 0$. Therefore, $W(n)+1 \geq W(4)+1 > 0$ for all $n \geq 4$. This establishes the claim in (36). □

DISTRIBUTIONAL SOLUTIONS OF NONHOMOGENEOUS DISCRETE AND CONTINUOUS REFINEMENT EQUATIONS*

RONG-QING JIA†, QINGTANG JIANG‡, AND ZUOWEI SHEN§

Abstract. Discrete and continuous refinement equations have been widely studied in the literature for the last few years, due to their applications to the areas of wavelet analysis and geometric modeling. However, there is no "universal" theorem that deals with the problem about the existence of compactly supported distributional solutions for both discrete and continuous refinement equations simultaneously. In this paper, we provide a uniform treatment for both equations. In particular, a complete characterization of the existence of distributional solutions of nonhomogeneous discrete and continuous refinement equations is given, which covers all cases of interest.

Key words. nonhomogeneous, discrete and continuous refinement equations, existence, uniqueness

1. Introduction and notations.

Let M be a dilation matrix, that is, an $s \times s$ real matrix whose eigenvalues lie outside the closed unit disk. We are interested in the following nonhomogeneous refinement equation:

$$\phi(x) = g(x) + \int_{\mathbb{R}^s} d\mu(y)\phi(Mx - y), \quad x \in \mathbb{R}^s, \tag{1.1}$$

where $\phi = (\phi_1, \ldots, \phi_r)^T$ is the unknown, $g = (g_1, \ldots, g_r)^T$ is a given $r \times 1$ vector of compactly supported distributions on $\mathbb{R}^s$, and μ is an $r \times r$ matrix of finite complex Borel measures on $\mathbb{R}^s$ with compact supports. Let $\mu = (\mu_{lj})_{1 \le l,j \le r}$. Then (1.1) can be written in the component form

$$\phi_l(x) = g_l(x) + \sum_{j=1}^{r} \int_{\mathbb{R}^s} \phi_j(Mx - y) d\mu_{lj}(y), \quad l = 1, \ldots, r. \tag{1.2}$$

When each μ_{lj} is a discrete Borel measure, (1.1) becomes a discrete refinement equation; when each μ_{lj} is absolutely continuous with respect to the Lebesgue measure, (1.1) is a continuous refinement equation. If $g = 0$, then (1.1) becomes a homogeneous refinement equation:

$$\phi(x) = \int_{\mathbb{R}^s} d\mu(y)\phi(Mx - y). \tag{1.3}$$

Refinement equations are fundamental to wavelet theory and subdivision. In the context of wavelet theory, the key step to the construction of wavelets is to construct suitable refinable functions. In the context of subdivision, the limiting surface of a subdivision process is a linear combination of integer translates of the refinable function corresponding to the subdivision scheme.

For the scalar case ($r = 1$), a homogeneous discrete refinement equation can be written as

$$\phi(x) = \sum_{\alpha \in \mathbb{Z}^s} a(\alpha)\phi(Mx - \alpha), \quad x \in \mathbb{R}^s, \tag{1.4}$$

where the refinement mask a is finitely supported. Existence and uniqueness of the solutions of (1.4) were studied in [3] and [7] for the case when the dilation matrix M is two times the $s \times s$ identity matrix I_s. In particular, for the univariate case $s = 1$, it was proved in [7] that (1.4) has a nontrivial L_1-solution with compact support only if $\sum_{\alpha \in \mathbb{Z}^s} a(\alpha) = 2^n$ for some positive integer n.

For the vector case ($r > 1$), the coefficients $a(\alpha)$, $\alpha \in \mathbb{Z}^s$ in (1.4) become $r \times r$ complex matrices. Existence of compactly supported distributional solutions is characterized by spectral properties of the matrix $\Delta := \sum_\alpha a(\alpha)/|\det(M)|$. The spectral radius of Δ is denoted by $\rho(\Delta)$.

Existence (and uniqueness) of compactly supported distributional solutions of the vector refinement equation was investigated in [14] for the case when $s = 1$ and $M = (2)$. One of the main results of [14] states as follows: Suppose that there is a single eigenvalue λ of Δ with $|\lambda| = \rho(\Delta) < 2$; then the vector refinement equation (1.4) has k independent compactly supported distributional solutions, where k is the multiplicity of the eigenvalue 1 of Δ. This result was improved in [5]. It is still valid under a weak assumption that $\rho(\Delta) < 2$. A complete characterization of the existence of the compactly supported distributional solutions was given in [17] (for the case $M = 2I_s$) and in [24] (for the case $r = 2$, $s = 1$, and $M = (2)$). It states that the vector refinement equation (1.4) has a nontrivial compactly supported distributional solution if and only if there exists a nonnegative integer n such that 2^n is an eigenvalue for Δ.

Nonhomogeneous discrete refinement equations were investigated in [9] and [22]. For the case $s = 1, M = (2)$, and $r = 1$, necessary and sufficient conditions for existence and uniqueness of nontrivial compactly supported distributional solutions were given independently in [9] and [22].

Homogeneous continuous refinement equations were studied by many authors (see [4], [6], [8], [12], [15], [16], [18], [19], and [21]). The interested readers should consult the aforementioned references for details.

Although a lot of work has been done on this subject, there is no "universal" theorem that covers all cases. In this paper, we give a uniform treatment of the existence and uniqueness of distributional solutions of both discrete and continuous nonhomogeneous refinement equations in the most general setting, for the case of an arbitrary dilation matrix, any number of functions and any number of variables. The main idea is to use an iteration scheme in the Fourier domain with *real* variables. This approach enables us to unify the treatment for both discrete and continuous refinement equations.

While revising this paper, we became aware of recent papers of [10] and [23] related to our work. In contrast to our general results which are applicable to arbitrary dilation matrices, both papers deal with the case $M = 2I_s$ only.

Here is a brief outline of the present paper. Section 2 is devoted to a complete characterization of the existence of compactly supported distributional solutions of (1.1) in terms of g and μ. In section 3, several examples are given to illustrate our theory.

We now turn to the basics needed in this paper.

Let $\mathbb{C}^r$ denote the linear space of all $r \times 1$ complex vectors. The norm (or length) of a vector $\xi = (\xi_1, \ldots, \xi_r) \in \mathbb{C}^r$ is defined as

$$|\xi| := |\xi_1| + \cdots + |\xi_r|, \quad \xi = (\xi_1, \ldots, \xi_r) \in \mathbb{C}^r. \tag{1.5}$$

By $\mathbb{C}^{r\times r}$ we denote the linear space of all $r \times r$ complex matrices. For an $r \times r$ complex matrix $A = (a_{ij})_{1\le i,j\le r} \in \mathbb{C}^{r\times r}$, its norm is defined to be the maximum of the norm of its column vectors, i.e.,

$$\|A\| := \max\left\{ \sum_{i=1}^{r} |a_{ij}| : j = 1, 2, \ldots, r \right\}.$$

For a linear space F, F^r is denoted as the linear space

$$\left\{ (f_1, \ldots, f_r)^T : f_1, \ldots, f_r \in F \right\}.$$

When F is a Banach space equipped with the norm $\|\cdot\|$, the space F^r is also a Banach space with the norm given by

$$\|f\| := \sum_{j=1}^{r} \|f_j\|, \qquad f = (f_1, \ldots, f_r)^T \in F^r.$$

The space $\mathbb{R}^s$ is the s-dimensional Euclidean space equipped with the norm in (1.5). The set of all positive integers is denoted by $\mathbb{N}$; and $\mathbb{N}_0 := \mathbb{N} \cup \{0\}$ is the set of all nonnegative integers.

A nonnegative integer $\alpha = (\alpha_1, \ldots, \alpha_s) \in \mathbb{N}_0^s$ is also used as a multi-index. Its length is the norm of α given in (1.5). For two multi-indices $\alpha = (\alpha_1, \ldots, \alpha_s)$ and $\beta = (\beta_1, \ldots, \beta_s)$, $\beta \le \alpha$ whenever $\beta_j \le \alpha_j$ for $j = 1, \ldots, s$.

For $\alpha = (\alpha_1, \ldots, \alpha_s) \in \mathbb{N}_0^s$ and $x = (x_1, \ldots, x_s) \in \mathbb{R}^s$, set $x^\alpha := x_1^{\alpha_1} \cdots x_s^{\alpha_s}$. We also use x^α to denote the function whose value at any x is x^α. The space P_n is the set of all polynomials of (total) degree at most n. For $j = 1, \ldots, s$, D_j denotes the partial derivative with respect to the jth coordinate and D^α is the differential operator $D_1^{\alpha_1} \cdots D_s^{\alpha_s}$. More generally, for a given polynomial $p(x) = \sum_\alpha c_\alpha x^\alpha$, $x \in \mathbb{R}^s$, the corresponding differential operator is

$$p(D) := \sum_\alpha c_\alpha D^\alpha.$$

Finally, for a given nonnegative integer α, the factorial of α is defined as $\alpha! := \alpha_1! \cdots \alpha_s!$.

Next, we list some basic notations of tempered distributions used in this paper. Let φ be a C^∞ function on $\mathbb{R}^s$. The seminorm $\|\cdot\|_{(m,\alpha)}$ of φ for a nonnegative integer m and a multi-index α is defined as

$$\|\varphi\|_{(m,\alpha)} := \sup_{x\in\mathbb{R}^s} \{(1 + |x|)^m |D^\alpha \varphi(x)|\}.$$

A function $\varphi \in C^\infty(\mathbb{R}^s)$ is said to be rapidly decreasing if $\|\varphi\|_{(m,\alpha)} < \infty \ \forall\ m \in \mathbb{N}_0$ and all $\alpha \in \mathbb{N}_0^s$. On the other hand, a continuous function f on $\mathbb{R}^s$ is said to be slowly increasing if there exists a polynomial p in s variables such that

$$|f(x)| \le |p(x)| \qquad \forall\, x \in \mathbb{R}^s.$$

Let $\mathcal{S}(\mathbb{R}^s)$ be the Schwartz space which is the space of all rapidly decreasing functions on $\mathbb{R}^s$ equipped with the metric

$$d(f,g) := \sum_{m=0}^{\infty} \sum_{|\alpha|=m} \frac{1}{2^m} \frac{\|f-g\|_{(m,\alpha)}}{1+\|f-g\|_{(m,\alpha)}}, \qquad f, g \in \mathcal{S}(\mathbb{R}^s).$$

A linear continuous functional on $\mathcal{S}(\mathbb{R}^s)$ is called a tempered distribution. The space $\mathcal{S}'(\mathbb{R}^s)$ is the linear space of all tempered distributions on $\mathbb{R}^s$. For example, the Dirac function δ given by

$$\langle \delta, \varphi \rangle := \varphi(0) \qquad \forall\, \varphi \in \mathcal{S}(\mathbb{R}^s)$$

is a tempered distribution. A slowly increasing continuous function $f \in \mathbb{R}^s$ induces a tempered distribution by

$$\langle f, \varphi \rangle := \int_{\mathbb{R}^s} f(x)\varphi(x)dx \qquad \forall\, \varphi \in \mathcal{S}(\mathbb{R}^s).$$

Let f be a tempered distribution on $\mathbb{R}^s$. We say that f vanishes on an open set $G \in \mathbb{R}^s$ if $\langle f, \varphi \rangle = 0$ for every $\varphi \in \mathcal{S}(\mathbb{R}^s)$ supported in G. Let W be the union of all open subsets G of $\mathbb{R}^s$ in which f vanishes. The complement of W is the support of f and denoted by $\mathrm{supp} f$. If $\mathrm{supp} f$ is a compact subset of $\mathbb{R}^s$, then we say that f is compactly supported.

The Fourier transform of a function φ in $\mathcal{S}(\mathbb{R}^s)$ is defined by

$$\widehat{\varphi}(\omega) := \int_{\mathbb{R}^s} \varphi(x) e^{-ix\cdot\omega} dx, \qquad \omega \in \mathbb{R}^s,$$

where i stands for the imaginary unit, and $x \cdot \omega := x_1\omega_1 + \cdots + x_s\omega_s$ for $x = (x_1, \ldots, x_s)$ and $\omega = (\omega_1, \ldots, \omega_s)$.

The Fourier transform of $f \in \mathcal{S}'(\mathbb{R}^s)$ is the tempered distribution $\widehat{f}$ defined by

$$\langle \widehat{f}, \varphi \rangle = \langle f, \widehat{\varphi} \rangle \qquad \forall\, \varphi \in \mathcal{S}(\mathbb{R}^s).$$

For example, the Fourier transform of the Dirac function δ is the constant 1. Let p be a polynomial and $f \in \mathcal{S}'(\mathbb{R}^s)$; the Fourier transform of $p(-iD)f$ is $p\widehat{f}$. In particular, the Fourier transform of $p(-iD)\delta$ is p.

The Fourier transform of a compactly supported distribution is an analytic function. Recall that a function f on $\mathbb{R}^s$ is said to be analytic if f can be expanded into a power series

$$f(x) = \sum_{\alpha \in \mathbb{N}_0^s} c_\alpha x^\alpha,$$

which converges for every $x \in \mathbb{R}^s$. The coefficients c_α are given by $c_\alpha = D^\alpha f(0)/\alpha!$. We use $\mathcal{A}(\mathbb{R}^s)$ to denote the linear space of all analytic functions on $\mathbb{R}^s$.

We will also use the following identity:

$$\langle f, \varphi\rangle = (2\pi)^{-s/2}\langle \widehat{f}, \widehat{\varphi}\rangle \qquad \forall\, f \in \mathcal{S}'(\mathbb{R}^s), \varphi \in \mathcal{S}(\mathbb{R}^s).$$

A vector of distributions $\phi = (\phi_1, \ldots, \phi_r)^T \in (\mathcal{S}'(\mathbb{R}^s))^r$ is called a solution of (1.1) if

$$\langle \phi, \varphi\rangle = \langle g, \varphi\rangle + \left\langle \phi, \int_{\mathbb{R}^s} \overline{(d\mu(y))^T}\varphi(M^{-1}(\cdot + y))/|\det(M)| \right\rangle$$

holds $\forall \varphi = (\varphi_1, \ldots, \varphi_r)^T \in (\mathcal{S}(\mathbb{R}^s))^r$.

2. Existence of solutions. The problem of the existence of distributional solutions of discrete and continuous refinement equations can be handled simultaneously in the Fourier domain. For this, recall that the Fourier transform of μ_{lj} is given by

$$\widehat{\mu}_{lj}(\omega) = \int_{\mathbb{R}^s} e^{-i\omega\cdot y}\, d\mu_{lj}(y), \quad \omega \in \mathbb{R}^s.$$

Thus, refinement equation (1.1) can be written as

$$\widehat{\phi}(\omega) = \widehat{g}(\omega) + H(N\omega)\widehat{\phi}(N\omega), \quad \omega \in \mathbb{R}^s, \tag{2.1}$$

where $N := (M^{-1})^T$ and

$$H(\omega) := (1/|\det(M)|)\widehat{\mu}(\omega) = (1/|\det(M)|)(\widehat{\mu}_{lj}(\omega))_{1\le l,j\le r}, \quad \omega \in \mathbb{R}^s. \tag{2.2}$$

For a nonnegative integer n, we denote by P_n^r the linear space of all $r \times 1$ vectors of polynomials of degree at most n. For $f \in (\mathcal{A}(\mathbb{R}^s))^r$, define

$$f^{[n]}(\omega) := \sum_{|\alpha|\le n} D^\alpha f(0)\omega^\alpha/\alpha!, \qquad \omega \in \mathbb{R}^s.$$

Clearly, $f^{[n]}$ belongs to P_n^r. Let L_n be the linear operator defined on P_n^r by

$$L_n p := \big(H(N\cdot)p(N\cdot)\big)^{[n]}, \quad p \in P_n^r.$$

The linear operator L_n can be viewed as follows. Let $\sum_{\alpha\in\mathbb{N}_0^s} v_\alpha\omega^\alpha$, $\omega \in \mathbb{R}^s$, be the Taylor expansion of $H(N\omega)p(N\omega)$. Then, $L_n p(\omega) = \sum_{|\alpha|\le n} v_\alpha\omega^\alpha$.

Suppose $\widehat{\phi}$ satisfies (2.1). Then for any $n \in \mathbb{N}_0$,

$$\widehat{\phi}^{[n]} = \widehat{g}^{[n]} + \big(H(N\cdot)\widehat{\phi}(N\cdot)\big)^{[n]} = \widehat{g}^{[n]} + L_n\widehat{\phi}^{[n]}.$$

Hence, $p := \widehat{\phi}^{[n]} \in P_n^r$ is a solution of the following linear equation:

$$p - L_n p = \widehat{g}^{[n]}. \tag{2.3}$$

Next we show that if (2.3) has a solution $p \in P_n^r$ for a sufficiently large integer n, then (2.1) has a compactly supported distributional solution ϕ such that $\widehat{\phi}^{[n]} = p$. For this, we first note that if f is a compactly supported *continuous function*, then using Taylor's formula (see, e.g., [20, Theorem 7.7]) we have

$$\widehat{f}(\omega) = \sum_{|\alpha|\le n} \frac{D^\alpha\widehat{f}(0)}{\alpha!}\omega^\alpha + \sum_{|\alpha|=n+1} \frac{D^\alpha\widehat{f}(\xi)}{\alpha!}\omega^\alpha,$$

where ξ is a point on the straight line segment from 0 to ω. Note that

$$D^\alpha \widehat{f}(\xi) = \int_{\mathbb{R}^s} (-ix)^\alpha f(x) e^{-ix\cdot\xi}\, dx.$$

Since f is a compactly supported continuous function, the set $K := \operatorname{supp} f$ is a compact set of $\mathbb{R}^s$. Hence,

$$\left|D^\alpha \widehat{f}(\xi)\right| \le \int_K |x|^{|\alpha|} |f(x)|\, dx < \infty.$$

Therefore, there exists a constant C_n such that

$$\left| \widehat{f}(\omega) - \sum_{|\alpha|\le n} D^\alpha \widehat{f}(0)\omega^\alpha/\alpha! \right| \le C_n |\omega|^{n+1} \qquad \forall\, \omega \in \mathbb{R}^s. \tag{2.4}$$

The following lemma extends the above estimate to compactly supported *distributions*. The key to our extension is the well-known fact that a *compactly supported* distribution is of finite order (see [2, Theorem 2.22]).

LEMMA 2.1. *Suppose f is a compactly supported distribution on $\mathbb{R}^s$. Then for a given nonnegative integer n, there exists a polynomial q_n in s variables such that*

$$\left| \widehat{f}(\omega) - \sum_{|\alpha|\le n} D^\alpha \widehat{f}(0)\omega^\alpha/\alpha! \right| \le |\omega|^{n+1} q_n(\omega) \qquad \forall\, \omega \in \mathbb{R}^s. \tag{2.5}$$

Proof. Since f is compactly supported, there exists a positive integer m and compactly supported continuous functions f_β ($|\beta| \le m$) such that $f = \sum_{|\beta|\le m} D^\beta f_\beta$. Hence,

$$\widehat{f}(\omega) = \sum_{|\beta|\le m} (i\omega)^\beta \widehat{f}_\beta(\omega), \qquad \omega \in \mathbb{R}^s.$$

Set $c_{\alpha,\beta} := D^\alpha \widehat{f}_\beta(0)/\alpha!$ for $\alpha \in \mathbb{N}_0^s$ and $|\beta| \le m$. Write $\widehat{f}$ as the sum of h_1 and h_2, where

$$h_1(\omega) := \sum_{|\beta|\le m} (i\omega)^\beta \sum_{|\alpha|\le n} c_{\alpha,\beta}\omega^\alpha, \qquad \omega \in \mathbb{R}^s,$$

and

$$h_2(\omega) := \sum_{|\beta|\le m} (i\omega)^\beta \left(\widehat{f}_\beta(\omega) - \sum_{|\alpha|\le n} c_{\alpha,\beta}\omega^\alpha \right), \qquad \omega \in \mathbb{R}^s.$$

It follows from (2.4) that there exists a polynomial u such that

$$|h_2(\omega)| \le |\omega|^{n+1} u(\omega) \qquad \forall\, \omega \in \mathbb{R}^s.$$

But h_1 is a polynomial, so there exists a polynomial v such that

$$\left| h_1(\omega) - \sum_{|\alpha|\le n} D^\alpha h_1(0)\omega^\alpha/\alpha! \right| \le |\omega|^{n+1} v(\omega) \qquad \forall\, \omega \in \mathbb{R}^s.$$

Since $D^\alpha \widehat{f}(0) = D^\alpha h_1(0)\ \forall\ |\alpha| \le n$, we conclude that (2.5) holds with $q_n = u + v$. ∎

To state the next theorem, we define

$$c_0 := \sup_{\omega\in\mathbb{R}^s} \|H(\omega)\|. \tag{2.6}$$

Since each measure μ_{lj} $(l, j = 1, \dots, r)$ is finite, by (2.2), $\|H(\omega)\|$ is bounded on $\mathbb{R}^s$. Hence, $c_0 < \infty$. We also recall that $\rho(N)$ is the spectral radius of the matrix N.

THEOREM 2.2. *Suppose* (2.3) *has a solution* $p \in P_n^r$ *for some nonnegative integer* n *satisfying* $\rho(N)^{n+1} < 1/c_0$. *Then* (2.1) *has a compactly supported distributional solution* ϕ *such that* $\widehat{\phi}^{[n]} = p$.

Proof. In this proof, the number n is fixed. The proof is based on the following iteration scheme. It starts with the $r \times 1$ vector $\phi_0 := p(-iD)\delta$, with the jth entry of ϕ_0 $p_j(-iD)\delta$, where p_j is the jth entry of the vector p and δ is the Dirac function. Each entry of ϕ_0 is supported at the origin and $\widehat{\phi}_0 = p$. For $k = 1, 2, \dots$, the $r \times 1$ vectors ϕ_k are defined recursively by

$$\widehat{\phi}_k(\omega) := \widehat{g}(\omega) + H(N\omega)\widehat{\phi}_{k-1}(N\omega). \tag{2.7}$$

In particular, $\widehat{\phi}_1^{[n]} = \widehat{g}^{[n]} + L_n p = p$. By (2.7) we have

$$\begin{aligned}\widehat{\phi}_{k+1}(\omega) - \widehat{\phi}_k(\omega) &= H(N\omega)\big(\widehat{\phi}_k(N\omega) - \widehat{\phi}_{k-1}(N\omega)\big)\\ &= \left(\prod_{j=1}^{k} H(N^j\omega)\right)\big(\widehat{\phi}_1(N^k\omega) - \widehat{\phi}_0(N^k\omega)\big).\end{aligned}$$

Since $\|H(\omega)\| \le c_0\ \forall\ \omega \in \mathbb{R}^s$, we have

$$|\widehat{\phi}_{k+1}(\omega) - \widehat{\phi}_k(\omega)| \le c_0^k |\widehat{\phi}_1(N^k\omega) - \widehat{\phi}_0(N^k\omega)| \qquad \forall\, \omega \in \mathbb{R}^s \text{ and } k \in \mathbb{N}_0. \tag{2.8}$$

Note that $\widehat{\phi}_1^{[n]} - \widehat{\phi}_0^{[n]} = 0$. By Lemma 2.1, there exists a polynomial q (depending on n) such that

$$|\widehat{\phi}_1(N^k\omega) - \widehat{\phi}_0(N^k\omega)| \le |N^k\omega|^{n+1} q(N^k\omega) \qquad \forall\, \omega \in \mathbb{R}^s \text{ and } k \in \mathbb{N}_0. \tag{2.9}$$

Since $\rho(N)^{n+1} < 1/c_0$ and $\rho(N) < 1$, there is $\varepsilon > 0$ such that $t := (\rho(N)+\varepsilon)^{n+1} c_0 < 1$ and $\rho(N) + \varepsilon < 1$. Hence,

$$|N^k\omega| \le C(\rho(N) + \varepsilon)^k |\omega| \qquad \forall\, \omega \in \mathbb{R}^s \text{ and } k \in \mathbb{N}_0, \tag{2.10}$$

for some constant C (depending on ε). This implies that there exists a polynomial Q with $q(N^k\omega) \le Q(\omega)\ \forall\ k \in \mathbb{N}_0$ and all $\omega \in \mathbb{R}^s$. Combining (2.8), (2.9), and (2.10), we obtain

$$|\widehat{\phi}_{k+1}(\omega) - \widehat{\phi}_k(\omega)| \le t^k |C\omega|^{n+1} Q(\omega) \qquad \forall\, \omega \in \mathbb{R}^s \text{ and } k \in \mathbb{N}_0, \tag{2.11}$$

which means that for each $\omega \in \mathbb{R}^s$, $(\widehat{\phi}_k(\omega))_{k\in\mathbb{N}}$ is a Cauchy sequence. Hence,

$$f(\omega) := \lim_{k\to\infty} \widehat{\phi}_k(\omega), \quad \omega \in \mathbb{R}^s,$$

is well defined. Moreover, $(\widehat{\phi}_k)_{k\in\mathbb{N}}$ converges to f uniformly on an arbitrary compact subset of $\mathbb{R}^s$. So f is an $r\times 1$ vector of continuous functions on $\mathbb{R}^s$. Furthermore, we deduce from (2.11) that

$$\begin{aligned}|\widehat{\phi}_k(\omega)-p(\omega)| &\le \sum_{j=0}^{k-1}|\widehat{\phi}_{j+1}(\omega)-\widehat{\phi}_j(\omega)|\\ &\le (1-t)^{-1}|C\omega|^{n+1}Q(\omega),\quad \omega\in\mathbb{R}^s.\end{aligned}\tag{2.12}$$

Consequently,

$$|f(\omega)-p(\omega)|\le (1-t)^{-1}|C\omega|^{n+1}Q(\omega),\quad \omega\in\mathbb{R}^s.$$

Hence, f is an $r\times 1$ vector of slowly increasing continuous functions with $f^{[n]}=p$. Therefore, there is a unique $\phi\in(\mathcal{S}'(\mathbb{R}^s))^r$ such that $f=\widehat{\phi}$, and ϕ satisfies (2.1).

It remains to prove that ϕ is compactly supported. Let K be a compact subset of $\mathbb{R}^s$ such that

$$\{0\}\cup \operatorname{supp}\,\mu\cup\big(M(\operatorname{supp}\,g)\big)\subseteq K.$$

Let

$$\Omega:=\sum_{n=1}^{\infty}M^{-n}K.$$

Recall that $\phi_0=p(-iD)\delta$. By our choice of K,

$$\operatorname{supp}\,\phi_0=\{0\}\subseteq K.$$

It can be easily proved inductively that $\operatorname{supp}\phi_k\subseteq\Omega\ \forall\ k\in\mathbb{N}_0$ (see [13]). Suppose φ belongs to $(\mathcal{S}(\mathbb{R}^s))^r$ and $\operatorname{supp}\varphi\subset\mathbb{R}^s\setminus\Omega$. Since $\widehat{\varphi}$ is rapidly decreasing and since (2.12) is valid, there exists a constant C such that

$$\big|\widehat{\phi}_k(\omega)^T\widehat{\varphi}(\omega)\big|\le C(1+|\omega|)^{-s-1}\qquad\forall\,\omega\in\mathbb{R}^s\text{ and }k\in\mathbb{N}_0.$$

Thus, the Lebesgue dominated convergence theorem leads to

$$\lim_{k\to\infty}\int_{\mathbb{R}^s}\widehat{\phi}_k(\omega)^T\widehat{\varphi}(\omega)\,d\omega=\int_{\mathbb{R}^s}f(\omega)^T\widehat{\varphi}(\omega)\,d\omega.$$

In other words, $\lim_{k\to\infty}\langle\widehat{\phi}_k,\widehat{\varphi}\rangle=\langle\widehat{\phi},\widehat{\varphi}\rangle$. Therefore, we obtain

$$\langle\phi,\varphi\rangle=(2\pi)^{-s/2}\langle\widehat{\phi},\widehat{\varphi}\rangle=(2\pi)^{-s/2}\lim_{k\to\infty}\langle\widehat{\phi}_k,\widehat{\varphi}\rangle=\lim_{k\to\infty}\langle\phi_k,\varphi\rangle=0.$$

Hence, $\langle\phi,\varphi\rangle=0\ \forall\ \varphi\in(\mathcal{S}(\mathbb{R}^s))^r$ supported in $\mathbb{R}^s\setminus\Omega$, which implies that ϕ is supported in Ω. □

Theorem 2.2 reduces the problem of the existence of solutions of (1.1) to that of (2.3).

In order to study (2.3), we shall use the notation introduced in [1]. For $|\beta|=k$, write

$$(M^T\omega)^\beta=\sum_{|\alpha|=k}m_{\alpha,\beta}\omega^\alpha,\quad\omega\in\mathbb{R}^s.$$

The coefficients $m_{\alpha,\beta}$ ($|\alpha| = k, |\beta| = k$) are uniquely determined by the matrix M and the number k. The matrix $(m_{\alpha,\beta})_{|\alpha|=k,|\beta|=k}$ will be denoted by M_k. For $k \in \mathbb{N}_0$, let J_k be the set $\{\alpha \in \mathbb{N}_0^s : |\alpha| = k\}$. The cardinality of J_k is $d_k := \binom{k+s-1}{s-1}$. The ordering $\prec$ on J_k is defined as follows. For $\alpha = (\alpha_1, \ldots, \alpha_s) \in J_k$ and $\beta = (\beta_1, \ldots, \beta_s) \in J_k$, $\alpha \prec \beta$ whenever there exists some j, $1 \le j \le s$, such that $\alpha_j < \beta_j$ and $\alpha_i = \beta_i$ for $i = j+1, \ldots, s$.

Replacing ω by $M^T\omega$ in (2.1), we have

$$\hat{\phi}(M^T\omega) = \hat{g}(M^T\omega) + H(\omega)\hat{\phi}(\omega), \quad \omega \in \mathbb{R}^s. \tag{2.13}$$

Write $\hat{\phi}(\omega) = \sum_{\beta\in\mathbb{N}_0^s} v_\beta \omega^\beta$, $H(\omega) = \sum_{\beta\in\mathbb{N}_0^s} H_\beta \omega^\beta$, and $\hat{g}(\omega) = \sum_{\beta\in\mathbb{N}_0^s} g_\beta \omega^\beta$, $\omega \in \mathbb{R}^s$. Substituting the above expressions into (2.13) and comparing the coefficients of both sides, we obtain

$$\sum_{|\beta|=k} m_{\alpha,\beta} v_\beta - \sum_{0\le\gamma\le\alpha} H_{\alpha-\gamma} v_\gamma = h_\alpha, \qquad |\alpha| = k, \tag{2.14}$$

where

$$h_\alpha := \sum_{|\beta|=k} m_{\alpha,\beta} g_\beta, \qquad |\alpha| = k. \tag{2.15}$$

Denote by $v_{[k]}$ the $(rd_k) \times 1$ column vector defined by $v_{[k]} := (v_\beta)_{|\beta|=k}$. The column vector $v_{[k]}$ is ordered from the top to the bottom as follows. For α, β with $|\alpha| = |\beta| = k$, if $\alpha \prec \beta$, then the segment v_α is put at the top of the segment v_β. The $(rd_k) \times 1$ column vector $h_{[k]} := (h_\beta)_{|\beta|=k}$ is defined similarly.

The notation $B \otimes C$ stands for $(b_{ij}C)$, the (right) Kronecker product of two matrices $B = (b_{ij})$ and C. With this, (2.14) can be rewritten as

$$(M_k \otimes I_r)\, v_{[k]} - \sum_{j=0}^{k} (H_{\alpha-\gamma})_{|\alpha|=k,|\gamma|=j} v_{[j]} = h_{[k]}, \tag{2.16}$$

where $H_{\alpha-\gamma}$ is understood to be 0 if $\gamma \le \alpha$ does not hold. When $|\alpha| = k$ and $|\gamma| = k$, we have $(H_{\alpha-\gamma})_{|\alpha|=k,|\gamma|=k} = I_{d_k} \otimes H(0)$. It follows from (2.16) that

$$T_k \begin{bmatrix} v_{[0]} \\ v_{[1]} \\ \vdots \\ v_{[k]} \end{bmatrix} = \begin{bmatrix} h_{[0]} \\ h_{[1]} \\ \vdots \\ h_{[k]} \end{bmatrix}, \tag{2.17}$$

where the matrix T_k is given by

$$T_k := \begin{bmatrix} I_r & 0 & 0 & \cdots & 0 \\ 0 & M_1 \otimes I_r & 0 & \cdots & 0 \\ 0 & 0 & M_2 \otimes I_r & \cdots & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & 0 & \cdots & M_k \otimes I_r \end{bmatrix} \tag{2.18}$$

$$- \begin{bmatrix} H(0) & 0 & 0 & \cdots & 0 \\ (H_\alpha)_{|\alpha|=1} & I_{d_1} \otimes H(0) & 0 & \cdots & 0 \\ (H_\alpha)_{|\alpha|=2} & (H_{\alpha-\gamma})_{|\alpha|=2,|\gamma|=1} & I_{d_2} \otimes H(0) & \cdots & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ (H_\alpha)_{|\alpha|=k} & (H_{\alpha-\gamma})_{|\alpha|=k,|\gamma|=1} & (H_{\alpha-\gamma})_{|\alpha|=k,|\gamma|=2} & \cdots & I_{d_k} \otimes H(0) \end{bmatrix}.$$

Therefore, ϕ satisfies (2.1) if and only if, for each $k \in \mathbb{N}_0$, $v_{[0]}, v_{[1]}, \ldots, v_{[k]}$ satisfy (2.17).

Let $\lambda_1, \ldots, \lambda_s$ be the eigenvalues of M. As usual, for $\beta = (\beta_1, \ldots, \beta_s) \in \mathbb{N}_0^s$, $\lambda^\beta := \lambda_1^{\beta_1} \cdots \lambda_s^{\beta_s}$.

LEMMA 2.3. *Let k be a nonnegative integer. Suppose λ^β is not an eigenvalue of $H(0)$ for any $\beta \in \mathbb{N}_0^s$ with $|\beta| = k$. Then the matrix*

$$M_k \otimes I_r - I_{d_k} \otimes H(0)$$

is nonsingular.

Proof. Suppose B is an $s \times s$ matrix. For $\alpha \in J_k$ we write

$$(B\omega)^\alpha = \sum_{|\beta|=k} b_{\alpha,\beta}^{[k]} \omega^\beta, \quad \omega \in \mathbb{R}^s,$$

where $b_{\alpha,\beta}^{[k]}$ are complex numbers. Let $B^{[k]}$ denote the matrix $(b_{\alpha,\beta}^{[k]})_{|\alpha|=k,|\beta|=k}$. Suppose C is also an $s \times s$ matrix. It is easily seen that

$$(BC)^{[k]} = B^{[k]} C^{[k]}.$$

Since the eigenvalues of M are $\lambda_1, \ldots, \lambda_s$, there exists an invertible $s \times s$ matrix U such that the matrix $\Lambda := U^{-1} M^T U$ is a lower triangular matrix with $\lambda_1, \ldots, \lambda_s$ being the entries in its main diagonal. We also note that $M_k = ((M^T)^{[k]})^T$ by the definition of M_k.

In order to establish the lemma, it suffices to show that the matrix $(M^T)^{[k]} \otimes I_r - I_{d_k} \otimes H(0)^T$ is nonsingular. For that, we observe that

$$\left[(U^{-1})^{[k]} \otimes I_r\right] \left[(M^T)^{[k]} \otimes I_r - I_{d_k} \otimes H(0)^T\right] \left[U^{[k]} \otimes I_r\right] = \Lambda^{[k]} \otimes I_r - I_{d_k} \otimes H(0)^T.$$

Clearly, $\Lambda^{[k]}$ is a lower triangular matrix with λ^β ($|\beta| = k$) being the entries in its main diagonal. Thus, $\Lambda^{[k]} \otimes I_r - I_{d_k} \otimes H(0)^T$ is a lower triangular block matrix with diagonal blocks $\lambda^\beta I_r - H(0)^T$. Since λ^β is not an eigenvalue of $H(0)$ for any β with $|\beta| = k$, we conclude that the matrix $\Lambda^{[k]} \otimes I_r - I_{d_k} \otimes H(0)^T$ is nonsingular. □

We are in a position to establish the main result of this paper. In what follows, for $k \in \mathbb{N}_0$, T_k is the matrix given in (2.18), and $h_{[k]}$ is the vector $(h_\alpha)_{|\alpha|=k}$ with h_α given in (2.15). Finally, $\lambda_1, \ldots, \lambda_s$ are the eigenvalues of M.

THEOREM 2.4. *Suppose $H(0)$ has no eigenvalues of the form λ^β, $\beta \in \mathbb{N}_0^s$, then (1.1) has a unique compactly supported distributional solution. Suppose $H(0)$ has eigenvalues of the form λ^β for some $\beta \in \mathbb{N}_0^s$. Let $n_0 := \max\{|\beta| : \lambda^\beta$ is an eigenvalue of $H(0)\}$. Then (1.1) has a compactly supported distributional solution ϕ if and only if the linear equation*

$$T_{n_0} \begin{bmatrix} v_{[0]} \\ v_{[1]} \\ \vdots \\ v_{[n_0]} \end{bmatrix} = \begin{bmatrix} h_{[0]} \\ h_{[1]} \\ \vdots \\ h_{[n_0]} \end{bmatrix} \tag{2.19}$$

has a solution. Furthermore, let $v_{[0]}, v_{[1]}, \ldots, v_{[n_0]}$ be a solution of the above linear equation and $v_{[j]} = (v_\alpha)_{|\alpha|=j}$ ($j = 0, \ldots, n_0$). Then there is a unique compactly supported distributional solution ϕ of (1.1) satisfying $\widehat{\phi}^{[n_0]}(\omega) = \sum_{|\alpha| \le n_0} v_\alpha \omega^\alpha$, $\omega \in \mathbb{R}^s$.

Proof. Let n be a nonnegative integer satisfying $\rho(N)^{n+1} < 1/c_0$, where c_0 is given by (2.6). Suppose that $H(0)$ has no eigenvalues of the form λ^β, $\beta \in \mathbb{N}_0^s$. Then $M_j \otimes I_r - I_{d_j} \otimes H(0)$ is nonsingular for every $j \in \mathbb{N}_0$ by Lemma 2.3. Therefore, there is a unique solution $v_{[0]}, v_{[1]}, \ldots, v_{[n]}$ that satisfies the linear equation (2.17) for $k = n$. Hence, (1.1) has a unique compactly supported distributional solution by Theorem 2.2.

Next, suppose $H(0)$ has eigenvalues of the form λ^β for some $\beta \in \mathbb{N}_0^s$. Let $v_{[0]}, v_{[1]}, \ldots, v_{[n_0]}$ be a solution of the linear equation (2.19). By Lemma 2.3, $M_k \otimes I_r - I_{d_k} \otimes H(0)$ is nonsingular for $k > n_0$. Hence, we can find $v_{[n_0+1]}, \ldots, v_{[n]}$ from $v_{[0]}, \ldots, v_{[n_0]}$ by using (2.17) for $k = n_0 + 1, \ldots, n$. This implies that (2.3) has a solution $p = \sum_{|\beta| \le n} p_\beta \omega^\beta \in P_n^r$ with $(p_\beta)_{|\beta|=k} = v_{[k]}$, $0 \le k \le n$. By Theorem 2.2, (1.1) has a compactly supported distributional solution ϕ such that $\widehat{\phi}^{[n]} = p$. Consequently, $\widehat{\phi}^{[n_0]}(\omega) = \sum_{|\alpha| \le n_0} v_\alpha \omega^\alpha$, $\omega \in \mathbb{R}^s$, where v_α ($|\alpha| \le n_0$) are determined by $(v_\alpha)_{|\alpha|=j} = v_{[j]}$ for $j = 0, \ldots, n_0$.

Finally, we establish the uniqueness of the solution. Let ϕ and ψ be two compactly supported distributional solutions of (1.1) with $\hat{\phi}^{[n_0]} = \hat{\psi}^{[n_0]}$. Write $\hat{\phi}(\omega) = \sum_{\alpha \in \mathbb{N}_0^s} v_\alpha \omega^\alpha$ and $\hat{\psi}(\omega) = \sum_{\alpha \in \mathbb{N}_0^s} u_\alpha \omega^\alpha$, $\omega \in \mathbb{R}^s$. For $k \in \mathbb{N}_0$, let $v_{[k]} := (v_\alpha)_{|\alpha|=k}$ and $u_{[k]} := (u_\alpha)_{|\alpha|=k}$. We claim that $u_{[k]} = v_{[k]}$ $\forall\, k \in \mathbb{N}_0$. This is shown by induction on k. It is clear that $u_{[k]} = v_{[k]}$ for $k = 0, \ldots, n_0$. Consider $k > n_0$. Assume that $u_{[j]} = v_{[j]}$ for $j = 0, \ldots, k-1$. It follows from (2.17) that

$$\begin{aligned}
&(M_k \otimes I_r)\, u_{[k]} - \sum_{j=0}^{k} (H_{\alpha-\gamma})_{|\alpha|=k,|\gamma|=j} u_{[j]} \\
&= (M_k \otimes I_r)\, v_{[k]} - \sum_{j=0}^{k} (H_{\alpha-\gamma})_{|\alpha|=k,|\gamma|=j} v_{[j]}.
\end{aligned}$$

Since $u_{[j]} = v_{[j]}$ for $j = 0, \ldots, k-1$, we have that

$$(M_k \otimes I_r - I_{d_k} \otimes H(0))\, u_{[k]} = (M_k \otimes I_r - I_{d_k} \otimes H(0))\, v_{[k]}.$$

But the matrix $M_k \otimes I_r - I_{d_k} \otimes H(0)$ is nonsingular for $k > n_0$. Therefore, $u_{[k]} = v_{[k]}$. This shows $\phi = \psi$, as desired. ∎

When $H(0)$ has no eigenvalues of the form λ^β, $\beta \in \mathbb{N}_0^s$, the homogeneous equation (1.3) has only the trivial solution. The following corollary generalizes the result of [14], [17], and [24] to an arbitrary dilation matrix.

COROLLARY 2.5. *Homogeneous refinement equation* (1.3) *has a nontrivial compactly supported distributional solution if and only if* $H(0)$ *has an eigenvalue of the form* λ^β, $\beta \in \mathbb{N}_0^s$. *Furthermore, the number of linearly independent compactly supported solutions of* (1.3) *is the same as the dimension of the space* $\ker(T_{n_0})$, *where* $n_0 := \max\{|\beta| : \lambda^\beta$ *is an eigenvalue of* $H(0)\}$.

Suppose that ϕ and ψ are two compactly supported distributional solutions of (1.1). Then $\phi - \psi$ is a solution of the corresponding homogeneous equation (1.3). Thus we have the following corollary.

COROLLARY 2.6. *Suppose* $H(0)$ *has eigenvalues of the form* λ^β *for some* $\beta \in \mathbb{N}_0^s$. *Let* S *be the set of all compactly supported distributional solutions of* (1.1). *If* (1.1) *has at least one solution, then* S *is a linear manifold whose dimension is the same as that of* $\ker(T_{n_0})$, *where* $n_0 := \max\{|\beta| : \lambda^\beta$ *is an eigenvalue of* $H(0)\}$.

3. Examples. In this section we give several examples to illustrate our theory.

Example 1. The following interesting example was first studied in [11]. Let $r = 2$ and $s = 1$. Consider the discrete refinement equation

$$\phi = \sum_{j=0}^{3} a(j)\phi(2\cdot - j), \tag{3.1}$$

where

$$a(0) = \begin{bmatrix} h_1 & 1 \\ h_2 & h_3 \end{bmatrix}, \qquad a(1) = \begin{bmatrix} h_1 & 0 \\ h_4 & 1 \end{bmatrix},$$

$$a(2) = \begin{bmatrix} 0 & 0 \\ h_4 & h_3 \end{bmatrix}, \qquad a(3) = \begin{bmatrix} 0 & 0 \\ h_2 & 0 \end{bmatrix},$$

and h_1, h_2, h_3, h_4 are given by

$$h_1 = -\frac{t^2 - 4t - 3}{2(t+2)}, \qquad h_2 = -\frac{3(t^2-1)(t^2-3t-1)}{4(t+2)^2},$$

$$h_3 = \frac{3t^2 + t - 1}{2(t+2)}, \qquad h_4 = -\frac{3(t^2-1)(t^2-t+3)}{4(t+2)^2}.$$

It was proved in [11] that the refinement equation has a unique continuous nontrivial solution $\phi = (\phi_1, \phi_2)^T$ for $|t| < 1$. In particular, when $t = -0.2$, the shifts of ϕ_1 and ϕ_2 are orthogonal, and corresponding orthogonal double wavelets were constructed there.

Consider the case $|t| > 1$. We note that $H(\omega) = \sum_{j=0}^{3} a(j)e^{-ij\omega}/2$, $\omega \in \mathbb{R}$. The matrix $H(0)$ has two eigenvalues 1 and t. Therefore, (3.1) has compactly supported distributional solutions only if $t = 2^n$ for some positive integer (see [14]). The case $t = 2$ was discussed in [24], and it was shown there that (3.1) has *two* linearly independent solutions.

Here we consider the case $t = 4$. Write $H(\omega) = H_0 + H_1\omega + H_2\omega^2 + \cdots$, $\omega \in \mathbb{R}$, where $H_0, H_1, H_2, \ldots$ are 2×2 matrices. For the case $t = 4$, $n_0 = 2$, the corresponding matrix T_2 is given by

$$T_2 = -\begin{bmatrix} H(0) - I_2 & 0 & 0 \\ H_1 & H(0) - 2I_2 & 0 \\ H_2 & H_1 & H(0) - 4I_2 \end{bmatrix}.$$

A simple computation yields $\dim(\ker(T_2)) = 1$ for $t = 4$. By Corollary 2.5 we conclude that (3.1) has *one* linearly independent compactly supported distributional solution. Moreover, if ϕ is a nontrivial solution of (3.1), then we must have $\hat{\phi}(0) = 0$. This is in sharp contrast to the case $t = 2$.

Example 2. Let $r = 2$, $M = 2I_s$, and $g = 0$. Suppose

$$H(\omega) = \begin{bmatrix} h_{11}(\omega) & h_{12}(\omega) \\ h_{21}(\omega) & h_{22}(\omega) \end{bmatrix}, \quad \omega \in \mathbb{R}^s, \qquad \text{and} \qquad H(0) = \begin{bmatrix} 1 & 0 \\ 0 & 2 \end{bmatrix}. \tag{3.2}$$

In this case, $n_0 = 1$, and

$$T_1 = -\begin{bmatrix} H(0) - I_2 & & & & \\ D_1 H(0) & H(0) - 2I_2 & & & \\ D_2 H(0) & 0 & H(0) - 2I_2 & & \\ \vdots & \vdots & \vdots & \ddots & \\ D_s H(0) & 0 & 0 & \cdots & H(0) - 2I_2 \end{bmatrix}.$$

If $D_j h_{21}(0) = 0 \ \forall \ j = 1, \ldots, s$, then $\dim(\ker(T_1)) = s + 1$. So (1.3) has exactly $s + 1$ linearly independent solutions by Corollary 2.5. Otherwise, (1.3) has exactly s linearly independent solutions. Moreover, the homogeneous refinement equation (1.3) has a compactly supported distributional solution ϕ such that $\hat{\phi}(0) \neq 0$ if and only if $D_j h_{21}(0) = 0 \ \forall \ j = 1, \ldots, s$. For discrete refinement equations, this recovers the result of Theorem 4 in [24].

The next two examples are devoted to nonhomogeneous refinement equations.

Example 3. Let $r = 2$, $s = 1$, $M = (2)$, and $g = (g_1, g_2)^T$. Suppose the conditions in (3.2) are satisfied. In this case, $n_0 = 1$, and T_1 is the 4×4 matrix given by

$$T_1 = -\begin{bmatrix} H(0) - I_2 & 0 \\ H'(0) & H(0) - 2I_2 \end{bmatrix} = -\begin{bmatrix} 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ h'_{11}(0) & h'_{12}(0) & -1 & 0 \\ h'_{21}(0) & h'_{22}(0) & 0 & 0 \end{bmatrix}.$$

By Theorem 2.4, (1.1) has a compactly supported distributional solution if and only if the linear equation

$$T_1 v = [\hat{g}_1(0), \hat{g}_2(0), 2\hat{g}'_1(0), 2\hat{g}'_2(0)]^T$$

has a solution v in $\mathbb{C}^4$. Let S be the set of all compactly supported distributional solutions of (1.1). There are two possible cases: $h'_{21}(0) \neq 0$ and $h'_{21}(0) = 0$. In the former case, (1.1) has a solution if and only if $\hat{g}_1(0) = 0$, and $\dim(S) = 1$ by Corollary 2.6. In the latter case, i.e., $h'_{21}(0) = 0$, (1.1) has a compactly supported distributional solution if and only if $\hat{g}_1(0) = 0$ and $\hat{g}_2(0) h'_{22}(0) = 2\hat{g}'_2(0)$. If this is the case, then $\dim(S) = 2$.

Example 4. Let $r = 2$, $s = 2$, $M = 2I_2$, and $g = (g_1, g_2)^T$. Suppose the conditions in (3.2) are satisfied. In this case, $n_0 = 1$, and T_1 is the 6×6 matrix given by

$$T_1 = -\begin{bmatrix} 0 & 0 & & & & \\ 0 & 1 & & & & \\ D_1 h_{11}(0) & D_1 h_{12}(0) & -1 & 0 & & \\ D_1 h_{21}(0) & D_1 h_{22}(0) & 0 & 0 & & \\ D_2 h_{11}(0) & D_2 h_{12}(0) & 0 & 0 & -1 & 0 \\ D_2 h_{21}(0) & D_2 h_{22}(0) & 0 & 0 & 0 & 0 \end{bmatrix}.$$

By Theorem 2.4, (1.1) has a compactly supported distributional solution if and only if the linear equation

$$T_1 v = [\hat{g}_1(0), \hat{g}_2(0), 2D_1\hat{g}_1(0), 2D_1\hat{g}_2(0), 2D_2\hat{g}_1(0), 2D_2\hat{g}_2(0)]^T$$

has a solution v in $\mathbb{C}^6$. Let S be the set of all compactly supported distributional solutions of (1.1). There are two possible cases.

Case 1. Suppose $D_1h_{21}(0) = 0$ and $D_2h_{21}(0) = 0$. By Theorem 2.4, (1.1) has a compactly supported distributional solution if and only if

$$\hat{g}_1(0) = 0, \quad 2D_1\hat{g}_2(0) = \hat{g}_2(0)D_1h_{22}(0), \quad \text{and} \quad 2D_2\hat{g}_2(0) = \hat{g}_2(0)D_2h_{22}(0).$$

In this case, Corollary 2.6 confirms that $\dim(S) = 3$, since the dimension of $\ker(T_1)$ is 3.

Case 2. Suppose $D_1h_{21}(0) \neq 0$ or $D_2h_{21}(0) \neq 0$. In this case (1.1) has a compactly supported distributional solution if and only if $\hat{g}_1(0) = 0$ and

$$D_1h_{21}(0)\big(2D_2\hat{g}_2(0) - \hat{g}_2(0)D_2h_{22}(0)\big) = D_2h_{21}(0)\big(2D_1\hat{g}_2(0) - \hat{g}_2(0)D_1h_{22}(0)\big).$$

In this case, $\dim(S) = 2$ by the fact that the dimension of $\ker(T_1)$ is 2.

STUDY OF A CLASS OF REGULARIZATIONS OF $1/|X|$ USING GAUSSIAN INTEGRALS*

MARY BETH RUSKAI† AND ELISABETH WERNER‡

Abstract. This paper presents a comprehensive study of the functions

$$V_m^p(x) = \frac{pe^{x^p}}{\Gamma(m+1)} \int_x^\infty (t^p - x^p)^m e^{-t^p} dt$$

for $x > 0$, $m > -1$, and $p > 0$. For large x these functions approximate x^{1-p}. The case $p = 2$ is of particular importance because the functions $V_m^2(x) \approx 1/x$ can be regarded as one-dimensional regularizations of the Coulomb potential $1/|x|$ which are finite at the origin for $m > -\frac{1}{2}$.

The limiting behavior and monotonicity properties of these functions are discussed in terms of their dependence on m and p as well as x. Several classes of inequalities, some of which provide tight bounds, are established. Some differential equations and recursion relations satisfied by these functions are given. The recursion relations give rise to two classes of polynomials, one of which is related to confluent hypergeometric functions. Finally, it is shown that, for integer m, the function $1/V_m^2(x)$ is convex in x and this implies an analogue of the triangle inequality. Some comments are made about the range of p and m to which this convexity result can be extended and several related questions are raised.

Key words. Gaussian integrals, Coulomb potential, inequalities, Appell polynomials, confluent hypergeometric functions

1. Introduction.

1.1. Definitions and background.

In this paper we study the functions

$$V_m(x) = \frac{2e^{x^2}}{\Gamma(m+1)} \int_x^\infty (t^2 - x^2)^m e^{-t^2} dt, \quad m > -1, \tag{1}$$
$$V_{-1}(x) = \frac{1}{|x|}$$

and their generalizations

$$V_m^p(x) = \frac{pe^{x^p}}{\Gamma(m+1)} \int_x^\infty (t^p - x^p)^m e^{-t^p} dt, \tag{2}$$
$$V_{-1}^p(x) = x^{1-p}$$

for $0 < p < \infty$. These functions are well defined for $x > 0$ and can be extended to complex m with $\Re(m) > -1$. For $\Re(m) > -\frac{1}{2}$ they are also well defined for $x = 0$. Using symmetry or the equivalent forms (4) and (7) below, they can be extended to

even functions on $\mathbf{R}$ or $\mathbf{R} \setminus \{0\}$. However, it suffices to consider only nonnegative x and in this paper we restrict ourselves to that. We also restrict ourselves to real m.

Letting $p = 2$ in (2) yields (1). However, because this case is more important in applications we often drop the superscript and simply write $V_m(x)$ for $V_m^2(x)$.

Our interest was motivated by studies of atoms in magnetic fields where these functions arise naturally for integer m. V_m can be regarded as a (two-dimensional) expectation of the (three-dimensional) Coulomb potential $1/|\mathbf{r}|$ with the state $\gamma_m(r,\theta) = \frac{1}{\sqrt{\pi m!}} e^{-im\theta} r^m e^{-r^2/2}$ (where we have used cylindrical coordinates $\mathbf{r} = (x, r, \theta)$ with the nonstandard convention $r = \sqrt{y^2+z^2}$ if $\mathbf{r} = (x, y, z)$ in rectangular coordinates). The state γ_m describes an electron in the lowest of the so-called "Landau levels" with angular momentum m in the direction of the field. In this context, it is natural to rewrite (1) in the form

$$V_m(x) = \frac{2}{\Gamma(m+1)} \int_0^\infty \frac{r^{2m} e^{-r^2}}{\sqrt{x^2+r^2}} r dr, \tag{3}$$

$$= \frac{1}{\Gamma(m+1)} \int_0^\infty \frac{u^m e^{-u}}{\sqrt{x^2+u}} du \tag{4}$$

for $m > -1$. In this form, it is easy to see that $V_m(x) \approx 1/|x|$ for large x. The importance of V_m goes back at least to Schiff and Snyder [20] and played an essential role in the Avron, Herbst, and Simon [2] study of the energy asymptotics of hydrogen in a strong magnetic field. More recently, work in astrophysics and the work of Lieb, Solovej, and Yngvason [13, 14] on asymptotics of many-electron atoms in strong magnetic fields has renewed interest in this subject. Motivated by the work in [13, 14], Brummelhuis and Ruskai [7, 8] have developed one-dimensional models of many-electron atoms in strong magnetic fields using the functions $V_m(x)$ as one-dimensional analogues of the Coulomb potential.

In the case of many-electron atoms, the antisymmetry required by the Pauli exclusion principle suggests replacing the simple "one-electron" expectation above by an N-electron analogue in which the state γ_m is replaced by a Slater determinant of such states. This is discussed in detail in [8] where it is shown that, in the simple case corresponding to $m = 0 \ldots N-1$, the analogous one-dimensional potentials have the form

$$V_{\mathrm{av}}^N(x) = \frac{1}{N} \sum_{m=0}^{N-1} V_m(x). \tag{5}$$

In section 3 we obtain recursion relations for V_m which, in addition to being of considerable interest in their own right, are extremely useful for studying potentials of the form (5).

For $m = 0$ the function

$$\frac{1}{\sqrt{2}} V_0\left(\frac{x}{\sqrt{2}}\right) = e^{x^2/2} \int_x^\infty e^{-t^2/2} dt \tag{6}$$

occurs in many other contexts and is sometimes called the "Mills ratio" [15]. Although it has been extensively studied, the class of inequalities we consider in section 4.1 appears to be new (although some of our bounds coincide with known inequalities in other classes) and the realization that $1/V_0(x)$ is convex seems to be relatively recent [18, 19, 7].

The replacement of x^2 by x^p in (6) has been considered by Gautschi [10] and Mascioni [12], who (after seeing the preprint [16]) extended the results of section 4.1 to this situation.

For the analysis of this generalization, it is useful to observe that (2) can be rewritten as

$$V_m^p(x) = \frac{1}{\Gamma(m+1)} \int_0^\infty \frac{u^m e^{-u}}{(x^p+u)^{\frac{p-1}{p}}} du. \tag{7}$$

In this form, it is easy to verify that $V_m^p(x) \approx x^{p-1}$ for large x and that for $p = 1$, $V_m^1(x) = 1$ for all m.

Our first result shows that $V_m^p(x)$ is continuous in m and that our definition for $m = -1$ is natural.

PROPOSITION 1. *For all $x > 0$, $\lim_{m\to -1^+} x^{p-1} V_m^p(x) = 1$.*

Proof. Note that

$$\frac{x^{p-1}}{(x^p+u)^{\frac{p-1}{p}}} = \frac{1}{\left(1+\frac{u}{x^p}\right)^{\frac{p-1}{p}}}$$

so that (7) implies

$$1 - x^{p-1} V_m^p(x) = \frac{1}{\Gamma(m+1)} \int_0^\infty u^m e^{-u} \left[1 - \left(1+\frac{u}{x^p}\right)^{\frac{1-p}{p}}\right] du. \tag{8}$$

Since $\Gamma(m+1)$ becomes infinite as $m \to -1$, the desired result follows if the integral on the right-hand side above remains finite. To see that this is true, it is convenient to let $g(z) = \frac{1}{z}(1-(1+z)^{\frac{1-p}{p}})$ and note that (8) implies

$$\left|1 - x^{p-1} V_m^p(x)\right| \le \frac{1}{\Gamma(m+1)} \int_0^\infty \frac{u^{m+1} e^{-u}}{x^p} \left|g\left(\frac{u}{x^p}\right)\right| du. \tag{9}$$

It is easy to see that the large u portion of this integral causes no problems since $|g(z)|$ is bounded by a polynomial in z when $z > 1$. (For $p \ge 1$, it is bounded uniformly by 1; for $0 < p < 1$, it is bounded by a polynomial, namely, $|g(z)| \le 1 + (1+z)^k$, where $k \in \mathbf{N}$, $k \ge \frac{1}{p}$.) To see that it is also well behaved for small u, we first note that for $p > 0$, $(1+z)^{\frac{1-p}{p}}$ is analytic for $\Re(z) > -1$. Then $g(z)$ has a removable singularity at $z = 0$ and can be extended to an analytic function on $\Re(z) > -1$. Thus, for small u, the integrand behaves like $x^{-p} u^{m+1} e^{-u}$, which ensures that the integral in (9) is finite for $m = -1$. □

The rest of this paper is organized as follows. In the next part of this section we summarize the properties of V_m in the important case $p = 2$. We then conclude the introduction with a summary of convexity results, including some open questions. In section 2 we state and prove the basic properties of V_m^p for general p. In section 3 we derive recursion relations for V_m^p and study their consequences. Among these is a connection with confluent hypergeometric functions. In section 4.1 we prove some optimal bounds for V_0. The optimal upper bound had been established earlier independently by Wirth [19] and by Szarek and Werner [18], who also showed that the upper bound is equivalent to the convexity of $1/V_0$. In section 4.2 we discuss several classes of inequalities, beginning with optimal bounds on $V_0(x)$. We then consider optimal bounds on the ratio $R_m(x) = V_m(x)/V_{m-1}(x)$ and show that these have

important consequences. In particular, we show that the upper bound is equivalent to the convexity (in x) of $1/V_m(x)$ and that the ratios increase with x. Proofs of the ratio bounds are then given in section 5 where we also consider extensions to other p. Because the proof of the ratio bounds is via induction on m, the results of sections 4 and 5 are established only for integer m. However, we believe that they hold for all $m > -1$.

1.2. Properties of $V_m(x)$. We now summarize some properties of $V_m(x)$ along with comments about the history and brief remarks about the proofs. Unless otherwise stated, these properties hold for $m > -1$ and $x > 0$.

(a) $$\frac{1}{\sqrt{x^2+m}} > V_m(x) > \frac{1}{\sqrt{x^2+m+1}},$$

where the first inequality holds for $m > 0$ and the second for $m > -1$.
To prove the upper bound, which appears to be new, observe that $\mu = [u^{m-1}e^{-u}/\Gamma(m)]du$ is a probability measure on $(0,\infty)$. For fixed x, one can then apply Jensen's inequality to the concave function $f_x(u) = u(u+x^2)^{-1/2}$ to obtain

$$V_m(x) = \frac{1}{m}\int_0^\infty f_x(u)d\mu(u) \le \frac{1}{m} f_x\left(\int_0^\infty \frac{u^m e^{-u}du}{\Gamma(m)}\right)$$

$$= \frac{1}{m} f_x(m) = \frac{1}{\sqrt{x^2+m}}.$$

The lower bound was proved earlier (at least for integer m) by Avron, Herbst, and Simon [2], who applied a similar argument to the probability measure $[u^m e^{-u}/\Gamma(m+1)]du$ and the convex function $f_x(u) = (u+x^2)^{-1/2}$.

(b) $V_m(x)$ is decreasing in m. In particular, $V_{m+1}(x) < V_m(x) < \frac{1}{x}$.
The first inequality follows easily from property (a), which implies $V_m(x) < \frac{1}{\sqrt{x^2+m}} < V_{m-1}(x)$. Alternatively, one could use integration by parts on (4). The second inequality is easily verified from the integral representation (4). That $V_m(x)$ also decreases with m for noninteger jumps is more difficult, and the proof is postponed to section 2, where it follows from the more general Theorem 6.

(c) The expression $mV_m(x)$ is increasing in $m > -1$, $m \in \mathbf{R}$.
For integer jumps this holds for $m \ge -1$. Indeed, it is obvious that $-V_{-1} < 0 \cdot V_0 < V_1$. For integer jumps with $m \ge 1$, one can use property (a) to see that

$$mV_m(x) > \frac{m}{\sqrt{x^2+m+1}} > \frac{m-1}{\sqrt{x^2+m-1}} > (m-1)V_{m-1}(x). \tag{10}$$

The proof for general m is postponed to Theorem 6 in section 2. The fact that $V_m(x)$ is decreasing in m, while $mV_m(x)$ is increasing gives an indication of the delicate behavior of V_m.

(d) For $m > -1/2$, the definition of $V_m(x)$ can be extended to $x = 0$ and

$$V_m(0) = \frac{\Gamma(m+\frac{1}{2})}{\Gamma(m+1)}. \tag{11}$$

For integer m, this becomes

$$V_m(0) = \frac{(2m)!}{2^{2m}(m!)^2}\sqrt{\pi} = \frac{1\cdot 3\cdot 5\ldots(2m-1)}{2\cdot 4\cdot 6\ldots(2m)}\sqrt{\pi}, \tag{12}$$

while for large m Stirling's formula implies

$$V_m(0) \approx \left(\frac{m-\frac{1}{2}}{m}\right)^m \left(\frac{e}{m}\right)^{1/2} \approx \frac{1}{\sqrt{m}}, \tag{13}$$

which is consistent with property (a). Boyd [6, 15] has proved the more precise estimates

$$\frac{\sqrt{m+\frac{3}{4}+\frac{1}{32m+48}}}{m+\frac{1}{2}} < V_m(0) < \frac{1}{\sqrt{m+\frac{1}{4}+\frac{1}{32m+32}}}. \tag{14}$$

(e) For all $m \geq 0$, V_m satisfies the differential equation

$$V_m'(x) = 2x\left(V_m - V_{m-1}\right). \tag{15}$$

This can easily be verified using integration by parts in (4).

(f) For each fixed $m \geq 0$, $V_m(x)$ is decreasing in x.
This follows directly from (b) and (e).

(g) For $a > 0$, the expression $aV_m(ax)$ increases with a. Hence $aV_m(ax) > V(x)$ when $a > 1$ and $aV_m(ax) < V(x)$ when $a < 1$.
This property follows easily from the definition (3) or (4) and the observation that $\frac{a}{\sqrt{a^2x^2+u}} = \frac{1}{\sqrt{x^2+\frac{u}{a^2}}}$ is increasing in a. It is used in the proof of Theorem 6 and is important in the study of one-dimensional models for atoms in magnetic fields in which the electron-electron interaction takes the form of convex combinations of $\frac{1}{\sqrt{2}}V_m(\frac{|x_j-x_k|}{\sqrt{2}})$.

(h) $V_0(x)$ is convex in $x > 0$; however, $V_m(x)$ is *not* convex when $m > \frac{1}{2}$.
For $m = 0$, the differential equation (15) becomes $V_0'(x) = 2[xV_0 - 1]$. Since $xV_0 = \int_0^\infty \frac{e^{-u}}{\sqrt{1+u/x^2}}du$ is increasing for $x > 0$, it follows that $V_0(x)$ is convex.
When $m > \frac{1}{2}$, it follows from (15) and (b) that $\lim_{x\to 0} V_m'(x) = 0$. Since V_m' is negative, V_m' must decrease on some small interval $(0, x_0)$. One can also show $\lim_{x\to\infty} V_m'(x) = 0$, so that one expects that there is an x_1 such that V_m is concave on $(0, x_1)$ and convex on (x_1, ∞). In section 3 we will see that the convexity is recovered for the averaged potential V_m^{av}.

(i) For integer m, $1/V_m(x)$ is convex in $x > 0$.
This will be proved in section 4.3 as Theorem 23. For large x, $1/V_m(x) \approx x$ so that the deviation from linearity is very small and the second derivative close to zero. This makes the proof quite delicate and lengthy.
The convexity of $1/V_m(x)$ can be rewritten as

$$\frac{1}{\frac{1}{2}V_m\left(\frac{x+y}{2}\right)} \leq \frac{1}{V_m(x)} + \frac{1}{V_m(y)}.$$

Using property (g) with $a = \frac{1}{2}$, one easily finds that the convexity of $1/V_m(x)$ implies

$$\frac{1}{V_m(x+y)} \leq \frac{1}{V_m(x)} + \frac{1}{V_m(y)}.$$

This subadditivity inequality plays the role of the triangle inequality in applications. (See, e.g., [7].)

(j) Asymptotic estimates.
For large x, it follows from property (a) that

$$\frac{m}{2(x^2+m)^{3/2}} \le \frac{1}{x} - V_m(x) < \frac{m+1}{2x^3}. \tag{16}$$

The asymptotic expansion

$$V_m(x) = \frac{1}{x} - \frac{m+1}{2x^3} + \frac{3(m+2)(m+1)}{8x^5} + O\left(\frac{1}{x^7}\right) \tag{17}$$

can easily be obtained from (4). For details, let $p = 2$ in the proof of Proposition 7, which gives a similar expansion for $p > 1$.
It follows from properties (a) and (c) that $V_m(x)$ decreases monotonically to zero for each fixed x as $m \to \infty$. In fact, since $V_m(x)$ is decreasing in x for all m, it suffices to show this for $x = 0$, which is easy since $V_m(0) < m^{-1/2}$.

(k) The Fourier transform is given by

$$\widehat{V}_m(\xi) \equiv \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} V_m(x)\, e^{-ix\xi} dx = \frac{4^{m+1}}{\sqrt{2\pi}} \int_0^{\infty} \frac{s^m\, e^{-s}}{(|\xi|^2 + 4s)^{m+1}}\, ds. \tag{18}$$

This follows from (3) and the standard formula (e.g., see (v) on page 131 of [17]) $\mathcal{F}(\frac{1}{\sqrt{|x|^2+|w|^2}})(\xi) = \frac{1}{\sqrt{2\pi}} \int_0^{\infty} \frac{1}{s} e^{-\frac{1}{2}(s+|w|^2|\xi|^2/s)}\, ds$ after a change in the order of integration.

1.3. Convexity summary. For large x, $V_m^p(x) \approx x^{1-p}$, which is convex in x for $p > 1$ and concave for $p < 1$. For $m > -\frac{1}{2}$ these convexity properties cannot be extended to $V_m^p(x)$ on all of $(0, \infty)$; they would be inconsistent with the differential equation and monotonicity properties in Proposition 5. However, as discussed after Proposition 11, the averaged potentials $V_{\mathrm{av}}^{p,N}$ have the same convexity as x^{1-p} on the half-line.

The convexity of $1/V_m^p(x)$ is the motivation for sections 4 and 5. This question is already delicate for $p = 2$ and its verification becomes increasingly difficult for larger p. Although, as discussed in section 5.4, we have evidence that convexity holds for all $p \ge 2$, our methods give this result only for a limited range of p. Moreover, because our proof is inductive, we have established convexity and ratio bounds of section 4.2 only for integer m. It would be interesting to find another approach which would extend these results to noninteger m and all $p \ge 2$. Since $1/V_m^p(x) \approx x^{p-1}$, which is concave for $1 < p < 2$, we cannot expect convexity of $1/V_m^p$ in this range.

As discussed above, one important consequence of the convexity of $1/V_m(x)$ is an analogue of the triangle inequality. For all values of p we have $[V_m^p(x)]^{\frac{1}{1-p}} \approx x$ for large x, which suggests a triangle inequality of the form

$$[V_m^p(x+y)]^{\frac{1}{1-p}} \le [V_m^p(x)]^{\frac{1}{1-p}} + [V_m^p(y)]^{\frac{1}{1-p}}.$$

It would be interesting to know the range of p (and m) for which this holds. For $p > 2$ the convexity of $1/V_m^p(x)$ implies only the weaker inequality

$$[V_m^p(x+y)]^{\frac{1}{1-p}} \le 2^{\frac{p-2}{p-1}} \left([V_m^p(x)]^{\frac{1}{1-p}} + [V_m^p(y)]^{\frac{1}{1-p}} \right).$$

Finally, one could also ask if $V_m(x)$ is convex in m. In particular, is $2V_m(x) \le V_{m+1}(x) + V_{m-1}(x)$ or, equivalently by (15), is $V_m'(x)$ increasing in m?

2. General p. We now study the basic properties of V_m^p in detail. As one would expect from $V_m^p(x) \approx x^{1-p}$, the behavior of V_m^p is often quite different for $p > 1$ and $p < 1$. At the boundary, $p = 1$, $V_m^1(x) = 1$ for all x. Proposition 2 describes the monotonicity and limiting behavior of $V_m^p(x)$ as p varies with m and x fixed. Proposition 3 gives a simple expression for V_m^p in the special case that $1/p$ is an integer.

The next four results generalize properties of section 1.2 to general p. Proposition 4 generalizes the inequalities from property (a); Proposition 5 generalizes properties (d), (e), (f), and (g); and Theorem 6 extends the monotonicity properties (b) and (c). Moreover, the proof of monotonicity for noninteger jumps is provided here. Finally, Proposition 7 gives the asymptotic behavior of $V_m^p(x)$ for large x when $p > 1$.

PROPOSITION 2. *Let $m > -1$ and $x > 0$ be fixed. Then we have*

(i) $\lim_{p\to 0} V_m^p(x) = \infty$;

(ii) *for all $x \geq 1$, V_m^p is decreasing in p; moreover,*

$$\text{if } x > 1, \quad \lim_{p\to\infty} V_m^p(x) = 0, \quad \text{and}$$

$$\text{if } x = 1, \quad \lim_{p\to\infty} V_m^p(1) = \frac{1}{\Gamma(m+1)} \int_0^\infty \frac{u^m e^{-u} du}{1+u};$$

(iii) *for all $0 < x < 1$ and $m > 0$, $\lim_{p\to\infty} V_m^p(x) = \frac{1}{m}$.*

Proof. We use the expression (7) for V_m^p.

(i) Since $\lim_{p\to 0}(x^p + u)^{1/p} = \infty$ for $x > 1$,

$$\lim_{p\to 0} V_m^p(x) \geq \lim_{p\to 0} \frac{1}{\Gamma(m+1)} \int_1^3 \frac{u^m e^{-u}(x^p+u)^{\frac{1}{p}} du}{x^p + u} = \infty.$$

(ii) Differentiating (7) yields

$$\frac{d}{dp} V_m^p(x) = \frac{1}{\Gamma(m+1)} \int_0^\infty \frac{u^m e^{-u}}{p^2 (x^p+u)^{\frac{2p-1}{p}}} \times \Big[(1-p) x^p \ln(x^p) - (x^p+u)\ln(x^p+u) \Big] du. \tag{19}$$

For $x = 1$ or $p = 1$, the first term in square brackets above is zero, leaving a quantity which is clearly negative. When both $x > 1$ and $p > 1$, both terms in (19) are clearly negative. When $x > 1$ and $0 < p < 1$, the quantity in square brackets in (19) is negative since

$$\begin{aligned}(1-p)x^p \ln(x^p) - (x^p+u)\ln(x^p+u) \\ \leq x^p \ln(x^p) - (x^p+u)\ln(x^p+u) < 0.\end{aligned}$$

The last inequality follows from the fact that the function $f(w) = w \ln w$ is increasing for $w > 1$. Thus, $\frac{d}{dp} V_m^p(x) \leq 0$ for all $x \geq 1$ and for all $p \in (0, \infty)$.

(iii) Since $\lim_{p\to\infty}(x^p + u)^{1/p} = 1$ for $x < 1$,

$$\lim_{p\to\infty} V_m^p(x) = \frac{1}{\Gamma(m+1)} \int_0^\infty u^{m-1} e^{-u} du = \frac{1}{m}. \qquad \square$$

Remark. The behavior for $x < 1$ depends upon m. For "small" m, there is a p_0 such that V_m^p decreases (below 1) on $(0, p_0)$ and increases on (p_0, ∞) to $\frac{1}{m}$. For "big" m, V_m^p simply decreases to $\frac{1}{m}$ as p increases.

The next result shows that in the special case that $1/p$ is an integer, V_m^p reduces to a polynomial in $x^p = x^{1/n}$ of degree $n-1$.

PROPOSITION 3. *For $n \in \mathbf{N}$, $n \geq 2$,*

$$V_m^{1/n}(x) = \frac{1}{\Gamma(m+1)} \sum_{k=0}^{n-1} \binom{n-1}{k} \Gamma(m+n-k)\ x^{k/n}$$

for all $x \geq 0$ and $m > -1$.

Proof. It follows from (7) that for $p = \frac{1}{n}$

$$V_m^{1/n}(x) = \frac{1}{\Gamma(m+1)} \int_0^\infty \left(x^{1/n} + u\right)^{n-1} u^m e^{-u} du.$$

When n is an integer ≥ 2, the result then follows easily from the binomial expansion applied to $(x^{\frac{1}{n}} + u)^{n-1}$ and the definition of the Γ-function.

PROPOSITION 4. *For all $x > 0$*

$$\frac{1}{(x^p + m + 1)^{\frac{p-1}{p}}} \leq V_m^p(x) \leq \frac{1}{(x^p + m)^{\frac{p-1}{p}}} \quad \text{for } p > 1,$$

where the first inequality holds for $m > -1$ and the second for $m \geq 0$.

$$(x^p + m + 1)^{\frac{1-p}{p}} \geq V_m^p(x) \geq (x^p + m)^{\frac{1-p}{p}} \quad \text{for } \frac{1}{2} \leq p < 1,$$

where the first inequality holds for $m > -1$ and the second for $m \geq 0$.

$$V_m^p(x) \geq (x^p + m + 1)^{\frac{1-p}{p}} \quad \text{for } 0 < p \leq \frac{1}{2},$$

and the inequality holds for $m > -1$.

Proof. The proofs are done using Jensen's inequality as in property (a) of section 1.2.

PROPOSITION 5. *For all $x > 0$*

(i) *for $m > -\frac{1}{p}$, $V_m^p(0)$ is defined and $V_m^p(0) = \frac{\Gamma(m+\frac{1}{p})}{\Gamma(m+1)}$;*

(ii) *for all $m \geq 0$, $x > 0$, V_m^p satisfies the differential equation*

$$\frac{d}{dx} V_m^p(x) = p x^{p-1} \left(V_m^p(x) - V_{m-1}^p(x)\right); \tag{20}$$

(iii) *for all $m > -1$, V_m^p is decreasing in x if $p > 1$, identically equal to 1 for all x if $p = 1$, and increasing in x if $p < 1$;*

(iv) *let $m > -1$ and $x > 0$; for $a > 0$, the expression $a^{p-1} V_m^p(ax)$ increases in a if $p > 1$ and decreases in a if $p < 1$.*

Proof. The proofs are straightforward extensions of those given in section 1.2. In (iii), one can verify that V_m^p is also increasing for $0 < p < \frac{1}{2}$ by computing the derivative directly.

THEOREM 6. *For each fixed $x > 0$, and for m in the region $m > -1$,*

(i) *$V_m^p(x)$ is strictly decreasing in m for $p > 1$ and strictly increasing in m for $p < 1$;*

(ii) *$mV_m^p(x)$ is strictly increasing in m for $p > 1$ and strictly decreasing in m for $p < 1$.*

Proof. To prove (i) we differentiate (7) to get

$$\frac{d}{dm}V_m^p(x) = \frac{1}{\Gamma(m+1)}\int_0^\infty \frac{u^m \ln u\ e^{-u}}{(x^p+u)^{1-\frac{1}{p}}}du - V_m^p(x)\frac{\Gamma'(m+1)}{\Gamma(m+1)}. \tag{21}$$

Using the same procedure as that used (see, e.g., [1, 11]) to obtain the standard integral representation

$$\psi(z) \equiv \frac{\Gamma'(z)}{\Gamma(z)} = \int_0^\infty \left[\frac{e^{-s}}{s} - \frac{1}{s(1+s)^z}\right] ds, \tag{22}$$

one finds

$$\begin{aligned}
&\frac{1}{\Gamma(m+1)}\int_0^\infty \frac{u^m \ln u\ e^{-u}}{(x^p+u)^{1-\frac{1}{p}}}du \\
&= \frac{1}{\Gamma(m+1)}\int_{s=0}^\infty \frac{ds}{s}\int_0^\infty [e^{-s}-e^{-su}]\frac{e^{-u}u^m}{(x^p+u)^{1-\frac{1}{p}}}du \\
&= V_m^p(x)\int_0^\infty \frac{e^{-s}}{s}ds - \frac{1}{\Gamma(m+1)}\int_0^\infty \frac{ds}{s(s+1)^{m+\frac{1}{p}}}\int_0^\infty \frac{e^{-w}w^m dw}{[x^p(s+1)+w]^{1-\frac{1}{p}}} \\
&= V_m^p(x)\int_0^\infty \frac{e^{-s}}{s}ds - \int_0^\infty V_m^p(x(s+1)^{\frac{1}{p}})\frac{ds}{s(s+1)^{m+\frac{1}{p}}},
\end{aligned}$$

where we made the change of variable $w = (s+1)u$ to obtain $V_m^p(x(s+1)^{\frac{1}{p}})$. Now we use Proposition 5 with $a = (s+1)^{\frac{1}{p}} > 1$ to obtain

$$\begin{aligned}
\frac{1}{\Gamma(m+1)}\int_0^\infty \frac{u^m \ln u\ e^{-u}}{(x^p+u)^{1-\frac{1}{p}}}du &\le \int_0^\infty V_m^p(x)\left(\frac{e^{-s}}{s} - \frac{1}{s(s+1)^{m+1}}\right)ds \\
&= V_m^p(x)\ \psi(m+1)
\end{aligned}$$

when $p > 1$. For $p < 1$, Proposition 5 gives the inequality in the opposite direction. Hence inserting the result in (21) yields

$$\frac{d}{dm}V_m(x)\begin{cases} <0 & \text{if } p>1, \\ >0 & \text{if } p>1. \end{cases}$$

To prove (ii) it is slightly more convenient to consider the logarithmic derivative $\frac{d}{dm}\ln[mV_m^p(x)]$ and show that it is positive for $p > 1$ and negative for $p < 1$. Proceeding as above, we find for $p > 1$

$$\begin{aligned}
\frac{d}{dm}\ln[mV_m^p(x)] &= \frac{1}{m} + \frac{\frac{d}{dm}[V_m^p(x)]}{V_m^p(x)} \\
&= \frac{1}{m} + \int_0^\infty \frac{e^{-s}}{s}ds - \frac{1}{V_m^p(x)}\int_0^\infty \frac{V_m^p\left[x(s+1)^{1/p}\right]}{s\ (s+1)^{m+\frac{1}{p}}}ds - \psi(m+1) \\
&< \frac{1}{m} + \int_0^\infty \frac{e^{-s}}{s}ds - \int_0^\infty \frac{1}{s(s+1)^m}ds - \psi(m+1) \\
&= \frac{1}{m} + \psi(m) - \psi(m+1) \\
&= \frac{1}{m} - \int_0^\infty \frac{1}{(s+1)^{m+1}} = 0,
\end{aligned}$$

where we have used (22) and the following inequality with $a = (s+1)^{1/p}$.

$$V_m^p(ax) \left\{ \begin{array}{c} < \\ > \end{array} \right\} a V_m^p(x) \quad \text{for} \quad \left\{ \begin{array}{c} p > 1 \\ p < 1 \end{array} \right\} \tag{23}$$

for all $a \geq 1$. This is easily verified and implies that the inequality proved above for $\frac{d}{dm} \ln [m V_m^p(x)]$ is reversed when $p < 1$. □

The following result gives the asymptotic behavior of $V_m^p(x)$ for large x.

PROPOSITION 7. *For $p > 1$, $V_m^p(x)$ has the asymptotic expansion*

$$\frac{1}{x^{p-1}} - \frac{(p-1)(m+1)}{p\ x^{2p-1}} + \frac{(2p^2-3p+1)(m^2+3m+2)}{2p^2\ x^{3p-1}} + O\left(\frac{1}{x^{4p-1}}\right).$$

Proof. This follows from (7) since

$$\begin{aligned} V_m^p(x) &= \frac{1}{\Gamma(m+1)\ x^{p-1}} \int_0^\infty \frac{u^m e^{-u}}{\left(1+\frac{u}{x^p}\right)^{\frac{p-1}{p}}} du \\ &= \frac{1}{\Gamma(m+1)\ x^{p-1}} \int_0^\infty u^m e^{-u} \left[1 - \frac{(p-1)\ u}{p\ x^p} + \frac{(p-1)(2p-1)\ u^2}{2p^2\ x^{2p}} + \cdots\right] du \\ &= \frac{1}{x^{p-1}} \left[1 - \frac{(p-1)\ \Gamma(m+2)}{p\ \Gamma(m+1)\ x^p} + \frac{(2p^2-3p+1)\ \Gamma(m+3)}{(2p^2)\ \Gamma(m+1)\ x^{2p}} + O\left(\frac{1}{x^{3p}}\right)\right]. \end{aligned}$$

3. Recursion relations and their consequences.

3.1. Recursion relations for V_m^p. Although the case $p = 2$ is of primary interest in applications, we continue to study general p is this section, as the proofs for general p are identical to those for $p = 2$. In these recursions, our convention that $V_{-1}^p(x) = x^{1-p}$ plays an important role.

PROPOSITION 8. *For all $m \in \mathbf{R}$, $m \geq 1$, for all $x > 0$,*

$$V_m^p(x) = \frac{1}{m} \left[\left(m - 1 + \frac{1}{p} - x^p\right) V_{m-1}^p(x) + x^p V_{m-2}^p(x)\right]. \tag{24}$$

Proof. For $m = 1$, one gets that

$$V_1^p(x) = p e^{x^p} \left[\left(\frac{1}{p} - x^p\right) \int_x^\infty e^{-t^p} dt + x\right] = \left(\frac{1}{p} - x^p\right) V_0^p(x) + x^{p-1} V_{-1}^p(x).$$

For $m > 1$, using (2) and integration by parts, we find

$$\begin{aligned} V_m^p(x) &= \frac{p e^{x^p}}{\Gamma(m+1)} \int_x^\infty (t^p - x^p)^{m-1} (t^p - x^p) e^{-t^p} dt \\ &= \frac{p e^{x^p}}{m\Gamma(m)} \left[-x^p \int_x^\infty e^{-t^p} (t^p - x^p)^{m-1} dt \right. \\ &\qquad \left. + \frac{1}{p} \int_x^\infty e^{-t^p} ((t^p - x^p)^{m-1} + (m-1) p t^p (t^p - x^p)^{m-2}) dt\right] \\ &= \frac{p e^{x^p}}{m\Gamma(m)} \left[\left(m - 1 + \frac{1}{p} - x^p\right) \int_x^\infty e^{-t^p} (t^p - x^p)^{m-1} dt \right. \\ &\qquad \left. + \ (m-1) x^p \int_x^\infty (t^p - x^p)^{m-2} e^{-t^p} dt\right] \\ &= \frac{1}{m} \left[\left(m - 1 + \frac{1}{p} - x^p\right) V_{m-1}^p(x) + + x^p V_{m-2}^p(x)\right]. \end{aligned}$$

Repeated application of (24) gives a useful corollary. For $m \in \mathbf{R}$, let $\lfloor m \rfloor$ denote the "floor" of m, i.e., the largest natural number less than or equal to m.

COROLLARY 9. *Let $m \in \mathbf{R}$, $m \geq 1$, and let $n \in \mathbf{N}$ such that $n \leq \lfloor m \rfloor$. Then*

$$V_m^p(x) = \frac{1}{pm}\Big[(1-px^p)V_{m-1}^p(x) + V_{m-2}^p(x) + \cdots [p(m-n)+1]V_{m-n}^p(x) + px^pV_{m-n-1}^p(x)\Big]. \tag{25}$$

In particular, if m is a positive integer, then

$$V_m^p(x) = \frac{1}{pm}\left[(1-px^p)V_{m-1}^p(x) + \sum_{k=0}^{m-2} V_k^p(x) + px^pV_{-1}^p(x)\right]. \tag{26}$$

The expression (26) is well defined for $x = 0$. Putting $x = 0$ and using Proposition 5(i), we obtain the (presumably well-known) identity

$$\frac{\Gamma(m+\frac{1}{p})}{\Gamma(m+1)} = \frac{1}{pm}\sum_{k=0}^{m-1}\frac{\Gamma(k+\frac{1}{p})}{\Gamma(k+1)}. \tag{27}$$

3.2. Averaged potentials. These recursion relations are quite useful for studying the average of the first N of the V_m. For N a positive integer, we extend (5) to

$$V_{\text{av}}^{p,N}(x) = \frac{1}{N}\sum_{m=0}^{N-1} V_m^p(x). \tag{28}$$

Note that for $p = 1$, $V_{\text{av}}^{1,N}(x) = 1$ for all $x \geq 0$.

The next result follows immediately from (26).

COROLLARY 10. $V_{\text{av}}^{p,N}(x) = pV_N^p(x) - \frac{px^p}{N}\left[V_{-1}^p(x) - V_{N-1}^p(x)\right]$.

For the important case $p = 2$, this reduces to

$$V_{\text{av}}^N(x) = 2V_N(x) - \frac{2x^2}{N}\left[V_{-1}(x) - V_{N-1}(x)\right]. \tag{29}$$

The function $V_0(|x|)$ is convex on $(0,\infty)$ but has a cusp at $x = 0$. However, as discussed in property (f), for higher m both the convexity and cusp are lost. Thus, for higher m, the V_m are somewhat smoother than one might want for one-dimensional approximations to the Coulomb potential. The next result, although straightforward, is important because it implies that the averaged potentials $V_{\text{av}}^N(x)$ retain the cusp and convexity properties of V_0 near the origin.

PROPOSITION 11. *The function $V_{\text{av}}^N(x)$ is convex for all $x > 0$ and*

$$\lim_{x\to 0+}\frac{d}{dx}V_{\text{av}}^N(x) = -\frac{2}{N}.$$

Proof. Using (5) and (15) one finds

$$\frac{d}{dx}NV_{\text{av}}^N(x) = \sum_{m=0}^{N-1} 2x[V_m(x) - V_{m-1}] = 2x[V_{N-1} - V_{-1}] = 2xV_{N-1} - 2.$$

Therefore, to show that $V_{\rm av}^N$ is convex, we need to show that

$$xV_{N-1} = \frac{1}{\Gamma(N)} \int_0^\infty \frac{u^{N-1}e^{-u}du}{(1+\frac{u}{x^2})^{\frac{1}{2}}}$$

is increasing. This holds as, for $x > 0$, the function $h_u(x) = [1 + u/x^2]^{-1/2}$ is increasing.

Similarly, one can show that for $p > 1$, $V_{\rm av}^{p,N}$ is convex on $(0, \infty)$ and

$$\lim_{x\to 0+} \frac{d}{dx} V_{\rm av}^{p,N}(x) = -\frac{p}{N}.$$

For $p < 1$, the derivative becomes infinite at the origin; however, concavity of $V_{\rm av}^{p,N}$ on $(0, \infty)$ still holds.

3.3. Polynomials defined by recursion. We now observe that by repeatedly using (24) to eliminate the V_m^p with the largest value of m from (25) allows us to write V_m^p in terms of the two "lowest" functions (e.g., V_0^p and V_{-1}^p in the case of integer m) and that the coefficients in such expressions define two classes of polynomials related to confluent hypergeometric functions. We discuss the properties of these polynomials in some detail. First, we make the statement above explicit.

COROLLARY 12. *For $m \geq 1$ there are polynomials $P_m^p(y)$ and $Q_m^p(y)$ of degree $\lfloor m \rfloor$ such that*

$$V_m^p(x) = P_m^p(x^p)V_{m-\lfloor m\rfloor}^p(x) + x^p Q_{m-1}^p(x^p)V_{m-\lfloor m\rfloor-1}^p(x). \tag{30}$$

In the case of integer m (30) becomes

$$\begin{aligned} V_m^p(x) &= P_m^p(x^p)V_0^p(x) + x^p Q_{m-1}^p(x^p)V_{-1}^p(x) \\ &= P_m^p(x^p)V_0^p(x) + xQ_{m-1}^p(x^p), \end{aligned} \tag{31}$$

where the second expression follows from our convention $V_{-1}^p(x) = x^{1-p}$. We define $P_m^p(y) = 1$ for $m \in [0, 1)$ and $Q_m^p(y) = 0$ for $m \in [-1, 0)$. Then (30) holds trivially for $m \in [0, 1)$.

Proof. The desired polynomials are defined recursively. First let

$$P_m^p(y) = \frac{1}{m}\left(m - 1 + \frac{1}{p} - y\right) \quad \text{for} \quad m \in [1, 2) \quad \text{and} \tag{32}$$

$$Q_m^p(y) = \frac{1}{m+1} \quad \text{for} \quad m \in [0, 1). \tag{33}$$

Then (30) holds because it is equivalent to (24) for $m \in [1, 2)$. For $m \geq 2$ define $P_m^p(y)$ by

$$P_m^p(y) = \frac{1}{m}\left[\left(m - 1 + \frac{1}{p} - y\right) P_{m-1}^p(y) + y\ P_{m-2}^p(y)\right] \tag{34}$$

and for $m \geq 1$ define $Q_m^p(y)$ by

$$Q_m^p(y) = \frac{1}{m+1}\left[\left(m + \frac{1}{p} - y\right) Q_{m-1}^p(y) + y\ Q_{m-2}^p(y)\right]. \tag{35}$$

It is straightforward to use induction to check that (24) yields (30). ∎

We now restrict ourselves to $m \in \mathbf{N}$ and study these polynomials in more detail. The first few polynomials are given in the following table.

m	P_m^p	Q_m^p
0	1	1
1	$\frac{1}{p} - y$	$\frac{1}{2}(1 + \frac{1}{p} - y)$
2	$\frac{1}{2}\left[\left(y - \frac{1}{p}\right)^2 + \frac{1}{p}\right]$	$\frac{1}{3}\left[y + \frac{1}{2}(1 + \frac{1}{p} - y)(2 + \frac{1}{p} - y)\right]$

The following useful results, which hold for $m \geq 1$, are easily checked by induction. $B(x, y) = \frac{\Gamma(x)\Gamma(y)}{\Gamma(x+y)}$ is the beta function.

$$P_m^p(0) = \frac{\Gamma(m + \frac{1}{p})}{\Gamma(m+1)\Gamma(\frac{1}{p})} = \frac{1}{m\ B(m, \frac{1}{p})},$$
$$Q_m^p(0) = \frac{\Gamma(m + 1 + \frac{1}{p})}{\Gamma(m+2)\Gamma(\frac{1}{p})} = \frac{1}{(m+1)\ B(m+1, \frac{1}{p})},$$

$$P_m^p(y) = \frac{1}{m}\left[\frac{1}{p}\sum_{j=0}^{m-1} P_j^p(y) - y\ P_{m-1}^p(y)\right], \quad \text{and} \tag{36}$$

$$Q_m^p(y) = \frac{1}{m+1}\left[\frac{1}{p}\sum_{j=0}^{m-1} Q_j^p(y) - y\ Q_{m-1}^p(y) + 1\right]. \tag{37}$$

We now obtain two expressions for $\frac{d}{dx}V_m^p(x)$. First, observe that using (31) in (20) yields

$$\frac{d}{dx}V_m^p(x) = px^{p-1}\left(\left[P_m^p(x^p) - P_{m-1}^p(x^p)\right]V_0^p(x) + x\left[Q_{m-1}^p(x^p) - Q_{m-2}^p(x^p)\right]\right).$$

Differentiating (31) yields, after some simplifications,

$$\begin{aligned}\frac{d}{dx}V_m^p(x) = px^{p-1}\big[&(P_m^p)'(x^p)V_0^p(x) + P_m^p(x^p)\left[V_0^p(x) - V_{-1}^p(x)\right] \\ &+\ x^p(Q_{m-1}^p)'(x^p)V_{-1}^p(x) + \tfrac{1}{p}Q_{m-1}^p(x^p)V_{-1}^p(x)\big],\end{aligned}$$

where $(P_m^p)'(y)$ denotes $\frac{d}{dy}P_m^p(y)$. Equating these expressions yields

$$\begin{aligned}&-\left[(P_m^p)'(x^p) + P_{m-1}^p(x^p)\right]V_0^p(x) \\ &\quad = \left[x^p\left(Q_{m-1}^p\right)'(x^p) - P_m^p(x^p) + (\tfrac{1}{p} - x^p)Q_{m-1}^p(x^p) + x^pQ_{m-2}^p(x^p)\right]V_{-1}^p(x).\end{aligned} \tag{38}$$

This provides motivation for the following lemma.

LEMMA 13. *For $m \in \mathbf{N}$, $m \geq 1$,*

$$\frac{d}{dy}P_m^p(y) = -P_{m-1}^p(y) \quad \textit{and} \tag{39}$$

$$y\ \frac{d}{dy}Q_{m-1}^p(y) = P_m^p(y) - (m+1)Q_m^p(y) + mQ_{m-1}^p(y). \tag{40}$$

Proof. We first prove (39) by induction. It can be verified for $m = 1, 2$ using the table above. Then using (34), we find

$$\begin{aligned} & m\frac{d}{dy}P_m^p(y) \\ &= \left(m - 1 + \tfrac{1}{p} - y\right)\frac{d}{dy}P_{m-1}^p(y) - P_{m-1}^p(y) + y\frac{d}{dy}P_{m-2}^p(y) + P_{m-2}^p(y) \\ &= -P_{m-1}^p(y) - \left(m - 2 + \tfrac{1}{p} - y\right)P_{m-2}^p(y) - y\ P_{m-3}^p(y) \\ &= -mP_{m-1}^p(y). \end{aligned}$$

This implies that the coefficient of V_0^p in (38) is identically zero. Therefore the coefficient of V_{-1}^p must also be identically zero. Substituting $y = x^p$ gives

$$\begin{aligned} y\ \frac{d}{dy}Q_{m-1}^p(y) &= P_m^p(y) + \left(y - \frac{1}{p}\right)Q_{m-1}^p(y) - yQ_{m-2}^p(y) \\ &= P_m^p(y) - (m+1)Q_m^p(y) + mQ_{m-1}^p(y), \end{aligned}$$

where we used (35). □

Note that since the left-hand side of (40) is a polynomial of degree $m - 1$, this implies the coefficients of the y^m terms in P_m^p and $(m+1)Q_m^p(y)$ are identical. In fact, one can use (34) and (35) to see that the leading terms of P_m^p is $(-1)^m y^m/m!$ and that of Q_m^p is $(-1)^m y^m/(m+1)!$.

A set of polynomials $\{p_n(x)\}$belongs to the class known as Appell polynomials [4] if they satisfy $\frac{d}{dx}p_n(x) = p_{n-1}(x)$. Therefore, (39) implies that for each fixed p, the set $(-)^m P_m^p(y)$ forms a family of Appell polynomials.

One can use (39) in (34) to replace P_{m-1}^p and P_{m-2}^p by derivatives of P_m^p and obtain a second order differential equation satisfied by P_m^p. This allows us to obtain a relationship between the polynomials P_m^p and confluent hypergeometric functions, which we denote by ${}_1F_1(\alpha, \gamma, y)$.

THEOREM 14. *For $m \in \mathbf{N}$, $m \geq 1$, $P_m^p(y)$ satisfies the differential equation*

$$y\phi''(y) - \left(m - 1 + \frac{1}{p} - y\right)\phi'(y) - m\phi(y) = 0. \tag{41}$$

Standard techniques show that (41) has a polynomial solution of the form $\phi(y) = \sum_{k=0}^m b_k y^k$ with $b_k = -\frac{m+1-k}{k(m+\frac{1}{p}-k)}b_{k-1}$, $k \geq 1$, $b_0 \neq 0$ arbitrary, and a second solution of the form $\phi(y) = \sum_{k=0}^\infty c_k y^{k+m+1/p}$ with $c_k = -\frac{k-1+\frac{1}{p}}{k(m+\frac{1}{p}+k)}c_{k-1}$, $k \geq 1$, $c_0 \neq 0$ arbitrary. Since $P_m^p(0) = \frac{1}{m\ B(m,\frac{1}{p})}$, we conclude that $b_k = \frac{(-1)^k}{k!\ (m-k)B(m-k,\frac{1}{p})}$ and

$$P_m^p(y) = \sum_{k=0}^m \frac{(-1)^k\Gamma(m + \frac{1}{p} - k)}{\Gamma(k+1)\Gamma(m+1-k)\Gamma(\frac{1}{p})}\ y^k.$$

The restriction that $1/p$ be noninteger in the next result is neither serious nor unexpected in view of Proposition 3.

COROLLARY 15. *Let $p \neq \frac{1}{n}$ for $n \in \mathbf{N}$. Then*

$$P_m^p(y) = \frac{1}{m\ B(m, \frac{1}{p})}\ e^{-y}\ {}_1F_1\left(1 - \tfrac{1}{p}, 1 - \tfrac{1}{p} - m, y\right). \tag{42}$$

Proof. Write $\phi(y) = e^{-y}\widehat{\phi}(y)$. Then it follows from (41) that $\widehat{\phi}$ satisfies

$$y\widehat{\phi}''(y) - \left(m - 1 + \frac{1}{p} + y\right)\widehat{\phi}'(y) - \left(1 - \frac{1}{p}\right)\widehat{\phi}(y) = 0, \tag{43}$$

which has the form of the differential equation satisfied by the confluent hypergeometric function. Comparing the behavior of $P_m^p(y)$ near $y = 0$ with that of the well-known solutions to (43) suffices to complete the proof. ∎

It is well known [3] that for real α and γ, ${}_1F_1(\alpha, \gamma, y)$ has at most finitely many zeros on the real line. Hence, the same holds for P_m^p. In fact, we can show that P_m^p has no zeros when m is even and exactly one when m is odd.

To show this, it is convenient to introduce the new variable $z = \frac{1}{p} - y$ and write $P_m^p(y) = \tilde{P}_m^p(\frac{1}{p} - y)$. The first few of these polynomials are $\tilde{P}_0^p(z) = 1$, $\tilde{P}_1^p(z) = z$, and $\tilde{P}_2^p(z) = \frac{1}{2}(z^2 + \frac{1}{p})$.

LEMMA 16. *For $m \in \mathbf{N}$, $m \geq 2$, the polynomials $\tilde{P}_m^p(z)$ satisfy*

(i) $\tilde{P}_m^p(z) = \frac{1}{m}[(m - 1 + z)\tilde{P}_{m-1}^p(z) + (\frac{1}{p} - z)\tilde{P}_{m-2}^p(z)]$,

(ii) $\tilde{P}_m^p(z) = \frac{1}{m}[\frac{1}{p}\sum_{j=0}^{m-2}\tilde{P}_j^p(z) + z\tilde{P}_{m-1}^p(z)]$, *and*

(iii) $\frac{d}{dz}\tilde{P}_m^p(z) = \tilde{P}_{m-1}^p(z)$.

Proof. The proof follows immediately from substitution in (34), (36), and (39).

COROLLARY 17. *For $m \in \mathbf{N}$, $m \geq 0$, all coefficients in the polynomials $\tilde{P}_m^p(z)$ are positive.*

Proof. This follows immediately from the explicit expressions above for $\tilde{P}_m^p$ when $m = 0, 1$ and part (ii) of Lemma 16.

PROPOSITION 18. *Let $m \in \mathbf{N}$, $m \geq 1$.*

(i) *If m is even, $\tilde{P}_m^p(z) \geq 0$.*

(ii) *If m is odd, $\tilde{P}_m^p(z)$ has exactly one root z_m.*

Moreover, the roots form a strictly decreasing sequence with $-m + 1 \leq z_m \leq 0$.

Proof. First note that Corollary 17 implies that $\tilde{P}_m^p(z) \geq 0$ for all $z \geq 0$ and $\lim_{z\to\infty}\tilde{P}_m^p(z) = \infty$. Now we claim that

$$\lim_{z\to-\infty}\tilde{P}_m^p(z) = \begin{cases} -\infty & \text{if } m \text{ is odd,} \\ \infty & \text{if } m \text{ is even.} \end{cases}$$

This can easily be verified by induction using part (i) of Lemma 16 above.

For m odd, $\tilde{P}_m^p(z)$ has at least one root z_m. We now prove by induction that z_m is the only root if m is odd and that $\tilde{P}_m^p(z) \geq 0$ for all z if m is even. The induction hypothesis is easily seen to hold for $m = 0, 1$. Suppose it is true up to $m - 1$ and consider $\tilde{P}_m^p$, with m odd. Then, by Lemma 16(iii), $\frac{d}{dz}\tilde{P}_m^p(z) = \tilde{P}_{m-1}^p(z)$. Since $m - 1$ is even, by the induction hypothesis $\tilde{P}_{m-1}^p(z) \geq 0$. Thus $\tilde{P}_m^p(z)$ is increasing for all $z \in \mathbf{R}$, which implies that for m odd $\tilde{P}_m^p(z)$ has only one root. Since $\tilde{P}_m^p(z) > 0$ when $z > 0$, that one root must satisfy $z_m \leq 0$.

If m is even, then $\frac{d}{dz}\tilde{P}_m^p(z) = \tilde{P}_{m-1}^p(z)$ which, by the induction hypothesis, has exactly one root $z_{m-1} \leq 0$. Therefore $\tilde{P}_m^p(z)$ has a local extremum at z_{m-1}. Since $\frac{d^2}{(dz)^2}\tilde{P}_m^p(z) = \tilde{P}_{m-2}^p(z)$ and $m - 2$ is even, $\tilde{P}_{m-2}^p(z) \geq 0$ by the induction hypothesis and z_{m-1} is a local minimum for $\tilde{P}_m^p(z)$. By Lemma 16(i) we have

$$m\tilde{P}_m^p(z_{m-1}) = \left(\frac{1}{p} - z_{m-1}\right)\tilde{P}_{m-2}^p(z_{m-1})$$

since $\tilde{P}^p_{m-1}(z_{m-1}) = 0$. But by the induction hypothesis $z_{m-1} \le 0$ and $\tilde{P}^p_{m-2}(z_{m-1}) > 0$, so that $\tilde{P}^p_m(z_{m-1}) > 0$ as required.

It remains to be shown that the roots are decreasing and bounded below by $-(m-1)$. Both can be easily checked for $m = 1, 3$ and then proved by induction using Lemma 16(i). We now let m be odd. Since $\tilde{P}^p_m(z)$ is increasing, to show that $z_m > -m+1$, it suffices to show that $\tilde{P}^p_m(-m+1) < 0$. For $z = -m+1$ the recursion relation reduces to

$$m\tilde{P}^p_m(-m+1) = \left(\tfrac{1}{p} + m - 1\right) \tilde{P}^p_{m-2}(-m+1),$$

which is negative by the induction assumption hypothesis that $z_{m-2} \ge -m+3$. To show that $z_m < z_{m-2}$ it suffices to show that $\tilde{P}^p_m(z_{m-2}) > 0$. But

$$m\tilde{P}^p_m(z_{m-2}) = (m - 1 + z_{m-2})P^p_{m-1}(z_{m-2}) \ge 0$$

since $P^p_{m-2}(z_{m-2}) = 0$, $z_{m-2} > -m+3 > -m+1$, and $P^p_{m-1}(z)$ is positive. □

We now restate the results above in terms of the behavior of the original polynomials $P^p_m(y)$.

COROLLARY 19. *Let $m \in \mathbf{N}$, $m \ge 1$. Then*

(i) *if m is even, then $P^p_m(y) \ge 0$ for all $y \in \mathbf{R}$;*
(ii) *if m is odd, then $P^p_m(y)$ has exactly one root $y_m \ge 0$;*
(iii) *for all $m \ge 1$,*

$$\lim_{y\to-\infty} P^p_m(y) = \infty,$$

$$\lim_{y\to\infty} P^p_m(y) = \begin{cases} -\infty & \text{if } m \text{ is odd,} \\ \infty & \text{if } m \text{ is even.} \end{cases}$$

Although we were able to obtain an explicit expression for the polynomials $P^p_m(x)$ relating them to confluent hypergeometric functions and analyze their behavior in some detail, we do not have much information about $Q^p_m(x)$. This is, at least in part, because (40) mixes $Q^p_m(x)$ and $P^p_m(x)$ and does not lead directly to a differential equation for $Q^p_m(x)$. It would be interesting to know more about the polynomials $Q^p_m(x)$.

4. Inequalities and convexity.

4.1. Inequalities for $V_0(x)$. We first illustrate our strategy by proving a special class of inequalities for V_0. The convexity of $1/V_0(x)$ follows directly from the optimal upper bound in this class as given in Theorem 20 below. Although, as discussed at the end of this section, these inequalities generalize to V_m, the resulting upper bound is not sufficient to establish the convexity of $1/V_m$. For this we need a bound on the ratio $V_m(x)/V_{m-1}(x)$. Nevertheless, these simple inequalities for V_0, which can also be interpreted as ratio bounds, are of some interest in their own right in a variety of applications. Because the geometric strategy is also used in our more complex proofs of ratio bounds, we think there is some merit in presenting it first here.

We now define

$$g_k(x) = \frac{k}{(k-1)x + \sqrt{x^2 + k}}. \tag{44}$$

THEOREM 20. *For $x \ge 0$*

$$g_\pi(x) \le V_0(x) < g_4(x) \tag{45}$$

and these inequalities are optimal for functions of the form (44) *with equality only at* $g_\pi(0) = V_0(0) = \sqrt{\pi}$.

Proof. It is easy to see that the family of functions $g_k(x)$ is increasing in k and that $0 < g_k(x) < 1/x$. In order to prove that the upper bound is optimal, we first observe that $g_k'(x) = -k[g_k(x)]^2[x + (k-1)\sqrt{x^2+k}\,]/\sqrt{x^2+k}$ and $xg_k(x) - 1 = -kg_k(x)/[x + \sqrt{x^2+k}\,]$. Then one can verify that

$$\begin{aligned} g_k'(x) &> 2[xg_k(x) - 1] \\ &\iff \frac{k}{\sqrt{x^2+k}}\,\frac{(k-1)\sqrt{x^2+k}+x}{(k-1)x+\sqrt{x^2+k}} < \frac{2k}{x+\sqrt{x^2+k}} \\ &\iff (k-2)x^2 + k(k-3) < (k-2)x\sqrt{x^2+k} \\ &\iff x^2(k-2)(k-4) + k(k-3)^2 < 0 \end{aligned} \tag{46}$$

when $k > 3$. We now restrict attention to $3 \le k \le 4$ and let $h_k(x) = g_k(x) - V_0(x)$. For $k = 4$, the expression (46) implies $g_4'(x) < 2[xg_k(x) - 1]$ so that $h_4'(x) < 2xh_4(x)$ for all $x \ge 0$; whereas for $k < 4$ this holds only for $x < a_k = \sqrt{\frac{k(k-3)^2}{(k-2)(4-k)}}$. Since both $V_0(x)$ and $g_k(x)$ are positive and bounded above by $1/x$, their difference also satisfies $|h_k(x)| < 1/x \to 0$.

For $k = 4$, if $h_4(x) \le 0$ for some $x > 0$, then $h_4'(x) < 2xh_4(x)$ is negative and thus h_4 is negative and strictly decreasing from a certain x on, which contradicts $\lim_{x\to\infty} h_4(x) = 0$. Thus $h_4(x) > 0$ so that $g_4(x) > V_0(x)$ for all x. Now suppose that for some $k < 4$, g_k is an upper bound, i.e., $h_k(x) \ge 0$ for all $x \ge 0$. In particular, $h_k(x) \ge 0$ for all $x > a_k$. For $k < 4$, we find, however, that $h_k'(x) > 2xh_k(x)$ holds for $x > a_k$. Thus we get $h_k(x) \ge 0$ and strictly increasing for all $x > a_k$ which contradicts $\lim_{x\to\infty} h_k(x) = 0$. Thus the upper bound *cannot* hold when $x > a_k$ and $k < 4$. The lower bound also fails for $k > \pi$ since then $h_k(0) = g_k(0) - V_0(0) = \sqrt{k} - \sqrt{\pi} > 0$.

To establish the improved lower bound $g_\pi \le V_0(x)$, we note that the argument above implies that $h_k(x)$ is negative for $x > a_k$ and $3 < k \le \pi$. However, for $k < \pi$ we have $h_k(0) < 0$ so that $h_k(x)$ is also negative for very small x. If $h_k(x)$ is ever nonnegative, we can let b denote the first place $h_k(x)$ touches or crosses the x-axis, i.e., $h_k(b) = 0$ and $h_k(x) < 0$ for $x < b$. Then h_k must be increasing on some interval of the form (x_0, b). However, by the remarks above, $h_k(b) = 0$ implies $b \le a_k$ so that $h_k'(x) < 2xh_k(x) < 0$ on (x_0, b). Since this contradicts h_k increasing on (x_0, b), we must have $h_k(x) < 0$ for all $x \ge 0$ if $k < \pi$.

Thus we have proved the lower bound $g_k(x) < V_0(x)$ on $[0, \infty)$ for $k < \pi$. Since g_k is continuous and increasing in k, it follows that $g_\pi(x) \le V_0(x)$. To show that this inequality is strict except at $x = 0$, note that the right derivative of h_k at 0 satisfies $h_k'(0) = 2 - k$ so that $h_\pi'(0) < 0$ and $h_\pi(x)$ is negative at least on some small interval $(0, x_1)$. Then we can repeat the argument above to show that $h_\pi(x) < 0$ if $x > 0$. □

As discussed in [7, 18, 19] the upper bound implies the convexity of $1/V_0(x)$ on $(0, \infty)$; in fact, it is not hard to use the fact that (15) reduces to $\frac{d}{dx}V_0(x) = 2(xV_0 - 1)$ to see that the upper bound is equivalent to convexity. It was established independently by Wirth [19] and by Szarek and Werner [18]. (The latter actually proved slightly more by using (1) to define an asymmetric extension of $V_0(x)$ to negative x. They showed in [18] that this extension is convex for $x > -\frac{1}{\sqrt{2}}$.)

Both bounds in (45) are sharper than the inequalities of Komatsu [9, 15]. The weaker lower bound $g_3(x) < V_0(x)$ was used in [7] to show that the function

$[1/V_0(x) - x]^2 / V_0(x)$ is decreasing for $x \geq 0$. The lower bound $g_\pi(x) \leq V_0(x)$ was established earlier by Boyd [5] as the optimal bound in a different class of inequalities. There is an extensive literature (see, e.g., [15]) on bounds for $V_0(x)$; however, the class of inequalities obtained using functions of the form $g_k(x)$ does not seem to have been considered before so that the optimality of bounds of this type for $k = \pi$ and $k = 4$ seems new.

Mascioni [12] generalized the upper bound to $p \geq 2$ for which he showed

$$V_0^p(x) < \frac{4p}{3px^{p-1} + \sqrt{p^2x^{2p-2} + 8p(p-1)x^{p-2}}}$$

and also showed that this implies convexity of $1/V_0^p(x)$ for $p \geq 2$.

In view of property (a) of section 1.2, it would seem natural to try to generalize (20) using functions of the form

$$g_k^m(x) = \frac{k}{(k-1)x + \sqrt{x^2 + m + k}}. \tag{47}$$

Note that the functions g_k^m are increasing in k and that $\lim_{k\to\infty} g_k^m(x) = \frac{1}{x}$. Therefore property (a) implies that

$$g_1^m(x) \leq V_m(x) < \lim_{k\to\infty} g_k^m(x).$$

As g_k^m is continuous in k, there must exist i_m and j_m such that

$$g_{i_m}^m(x) \leq V_m(x) < g_{j_m}^m(x). \tag{48}$$

However, we have not obtained explicit expressions for i_m and j_m. One might expect that the optimal lower bound occurs when i_m is chosen to satisfy $g_{i_m}^m(0) = V_m(0)$. However, numerical evidence shows that this is false; in fact, this choice for i_m does not even yield an inequality.

4.2. Ratio bounds. One of our main goals is to show that the function $\frac{1}{V_m(x)}$ is convex for integer $m \geq 1$. The key to this is the realization that (45) can also be rewritten to give bounds on the ratio $V_0(x)/V_{-1}(x) = xV_0(x)$. We now let

$$G_k^m(y) = \frac{ky}{(k-1)y - m + \sqrt{(y+m)^2 + ky}} \tag{49}$$

and note that $xg_k(x) = G_k^0(x^2)$ so that (45) is equivalent to

$$G_\pi^0(x^2) \leq xV_0(x) = \frac{V_0(x)}{V_{-1}(x)} < G_4^0(x^2).$$

For integer $m > 0$, convexity of $\frac{1}{V_m(x)}$ can be shown to be equivalent to

$$R_m(x) \equiv \frac{V_m(x)}{V_{m-1}(x)} < G_4^m(x^2).$$

In addition to this upper bound, we can show the following theorem.

THEOREM 21. *Let $m \in \mathbf{N}$, $m \geq 0$. Then the inequalities*

$$G_8^{m-1}(x^2) < R_m(x) < G_4^m(x^2) \tag{50}$$

hold and are optimal in k for the class of functions of the form $G_k^m(x^2)$.

The upper bound is optimal in k for all m. The lower bound is optimal in the sense that 8 is the largest integer for which the lower bound in (50) holds for all m. However, as we discuss at the end of section 5.3, for fixed m one can find $k(m)$ such that $G^{m-1}_{k(m)}(x^2) < R_m(x)$ holds with $k(m) > 8$.

Since $G^m_k(y)$ is increasing in both m and k, its behavior at zero and infinity allows us to also draw some conclusions about the optimality in m of (50). $R_m(0) = 1 - \frac{1}{2m}$ and $G^m_k(0) = 1 - \frac{1}{1+2m}$ for all k. Therefore, $G^\nu_k(0) < R_m(0) < G^\mu_{k'}(0)$ implies $\nu \le m - \frac{1}{2}$ and $\mu \ge m - \frac{1}{2}$ for all k, k'. Thus, if we insist that m be integer, there is no choice of k which allows $m-1$ to be replaced by m in the lower bound when $m > 0$ or m by $m-1$ in the upper bound. This argument does not, however, rule out the possibility of bounds of the form $G^{m-1/2}_k(x^2) < R_m(x) < G^{m-1/2}_{k'}(x^2)$.

To examine the behavior at infinity, note that

$$G^m_k(y) = 1 - \frac{1}{2y} + \frac{4m+k+2}{8y^2} + O\left(\frac{1}{y^3}\right) \quad \text{and}$$
$$R_m(\sqrt{y}) = 1 - \frac{1}{2y} + \frac{4m+6}{8y^2} + O\left(\frac{1}{y^3}\right),$$

where the asymptotic expansion for R_m follows from Proposition 7. It then follows that $R_m(\sqrt{y}) < G^\mu_{k'}(y)$ implies $\mu > m+1-\frac{k}{4}$. Thus m is optimal for the upper bound if $k \le 4$ and any attempt to decrease m would require an increase in k. Furthermore, $\mu = m$ implies $k \ge 4$ so that the upper bound in (50) is optimal in k.

We postpone the proof of Theorem 21, which requires a lengthy computation even for the case $p = 2$, to the next section. Our proof uses induction on m. Therefore, we are able to establish (50) and the theorems in the next section only for m a positive integer. We believe that they are also true for noninteger m. However, a proof would require either a different method or independent verification of the upper bound for an initial range, such as $-1 < m < 0$.

The ratio $R_m(x)$ is of interest in its own right, and our results are sufficient to establish that it is increasing in x on $(0, \infty)$. This is proved in the next section after Theorem 23, which uses a similar argument.

THEOREM 22. *For $m \in \mathbf{N}$, the ratio $R_{m+1}(x) = \frac{V_{m+1}(x)}{V_m(x)}$ is increasing in x.*

4.3. Convexity of $1/V_m$. We now prove some important consequences of Theorem 21. The first is the following.

THEOREM 23. *For all $m \in \mathbf{N}$, the function $1/V_m(x)$ is convex on $[0, \infty)$.*

Proof. We need to show that

$$\left(\frac{1}{V_m(x)}\right)'' = \frac{2[V_m(x)']^2 - V_m(x)(V_m(x))''}{V_m(x)^3} > 0. \tag{51}$$

It follows from the differential equation (15) and the recursion relation (24) that

$$V_m(x)'' = 2\left[V_m(x)(1 + 2m + 2x^2) - 2V_{m-1}(x)(x^2 + m)\right]$$

so that (51) holds if and only if

$$[V_m(x)]^2(1 + 2m - 2x^2) + 2V_{m-1}(x)V_m(x)(3x^2 - m) - 4x^2[V_{m-1}(x)]^2 \le 0.$$

After division by $[V_{m-1}(x)]^2$ this can be rewritten as $P[R_m(x)] \le 0$, where

$$P(z) = z^2(1 + 2m - 2x^2) + 2z(3x^2 - m) - 4x^2.$$

Writing the roots of $P(z) = Az + 2Bz + C$ in the nonstandard form $\frac{-C}{B \pm \sqrt{B^2 - AC}}$, we find that $G_4^m(x^2)$ is either the smaller of two positive roots (when $x^2 > m + \frac{1}{2}$) or the only positive root (when $x^2 < m + \frac{1}{2}$). Since $P(0) < 0$ in both cases, we can conclude that

$$z < G_4^m(x^2) \quad \text{implies} \quad P(z) < 0.$$

Therefore, it follows from the upper bound in Theorem 21 that $P[R_m(x)] < 0$; hence (51) holds. □

Proof of Theorem 22. Using (15) one finds that

$$\frac{d}{dx} R_{m+1}(x) = 2x \left[\frac{R_{m+1}(x)}{R_m(x)} - 1 \right].$$

After rewriting this in terms of V_m and then using the recursion relation (24) with $p = 2$ to eliminate V_{m+1}, one finds that $R'_{m+1}(x) \geq 0$ if and only if

$$2(m+1)[R_m(x)]^2 - (2m + 1 - 2x^2)R_m(x) - 2x^2 \leq 0.$$

The polynomial $P(z) = 2(m+1)z^2 - (2m+1-2x^2)z - 2x^2$ has one positive and one negative root, and $R'_{m+1}(x) \geq 0$ if and only if $R_m(x)$ lies between these two roots. Since $1 \geq R_m(x) > 0$, it follows that $R_{m+1}(x)$ is increasing if and only if $R_m(x)$ is less than the larger root, i.e.,

$$R_m(x) \leq \frac{4x^2}{\sqrt{4(x^2+m)^2 + 1 + 4m + 12x^2} + 2x^2 - 2m - 1},$$

where we have again written the root in the nonstandard form $\frac{C}{-B + \sqrt{B^2 - AC}}$. Then using the upper bound of Theorem 21, we see that it suffices to show that

$$\begin{aligned} R_m(x) &\leq \frac{4x^2}{\sqrt{(x^2+m)^2 + 4x^2} + 3x^2 - m} \\ &\leq \frac{4x^2}{\sqrt{4(x^2+m)^2 + 1 + 4m + 12x^2} + 2x^2 - 2m - 1} \end{aligned}$$

or equivalently that

$$\begin{aligned} &\sqrt{(x^2+m)^2 + 4x^2} + 3x^2 - m \\ &\qquad \geq \sqrt{4(x^2+m)^2 + 1 + 4m + 12x^2} + 2x^2 - 2m - 1, \end{aligned}$$

which is easily checked.

5. Proof of ratio bounds. The proofs in this section, although elementary, are quite long and tedious. The details were checked using Mathematica.

5.1. Differential inequality. In order to prove Theorem 21, it suffices to establish the following.

LEMMA 24. *Let* G_k^m *be given by* (49). *Then*

(i) *for* $m \geq 1$, $\frac{d}{dx} G_4^m(x^2) \leq 2x\left(\frac{G_4^m(x^2)}{G_4^{m-1}(x^2)} - 1\right)$;

(ii) *for* $m \geq 4$, $\frac{d}{dx} G_8^m(x^2) \geq 2x\left(\frac{G_8^m(x^2)}{G_8^{m-1}(x^2)} - 1\right)$,

but the inequality (ii) *does not hold for* $m < 4$.

Proof. The proof is based on the elementary principle that if a function on the half-line is zero at the origin and increasing, then it is nonnegative. Unfortunately, the actual verification is rather tedious and requires the repeated use of this principle. For simplicity, we put $x^2 = y$ and assume $y \geq 0$. Then (i) is equivalent to

$$E_m(y) \equiv \left(\frac{G_4^m(y)}{G_4^{m-1}(y)} - 1 \right) - \frac{d}{dy} G_4^m(y) \geq 0. \tag{52}$$

Let $B_m = (m^2 + y^2 + 4y + 2my)^{\frac{1}{2}}$. Then

$$G_4^m(y) = \frac{4y}{B_m + 3y - m}$$

and

$$E_m(y) = \frac{B_m \left[4m + (B_m + 3y - m)(B_{m-1} - B_m + 1)\right] - (4m^2 + 8y + 4my)}{B_m \ (B_m + 3y - m)^2}.$$

Thus $E_m(y) \geq 0$ if and only if

$$\begin{aligned} &B_m(3m + B_{m-1}[B_m + 3y - m]) + m^3 + 2my \\ &\geq 3m^2 + 4y + 11y^2 + m^2 y + 5my^2 + 3y^3 + B_m((y+m)^2 + y). \end{aligned}$$

We put

$$\begin{aligned} s &= s(y,m) = 3m^2 + 4y + 11y^2 + m^2 y + 5my^2 + 3y^3, \\ t &= t(y,m) = 2my + m^3, \quad \text{and} \\ h &= h(y,m) = (y+m)^2 + y - 3m. \end{aligned}$$

Then $E_m(y) \geq 0$ if and only if

$$B_m B_{m-1}(B_m + 3y - m) \geq B_m h + s - t. \tag{53}$$

Notice that both sides of (53) are positive. For the left-hand side this follows immediately from $B_m > m$. For the right-hand side, note that $B_m h(0) + s(0) - t(0) = 0$ and

$$\begin{aligned} &\frac{d}{dy}\left[B_m h(y) + s(y)t(y)\right] \\ &= \frac{1}{B_m}\left[6y + 12my + 9m^2 y + 12y^2 + 9my^2 + 3y^3 \right. \\ &\qquad \left. + \ B_m(22y + 10my + 9y^2) + 4B_m - 2mB_m + 3m^3 - 6m + m^2 B_m\right]. \end{aligned}$$

Now observe that

$$\begin{aligned} &4B_m - 2mB_m + 3m^3 - 6m + m^2 B_m \\ &\qquad = 3m(m^2 - 2) + B_m(m^2 - 2m + 4) \geq 3m(m^2 - 1) \geq 0 \end{aligned}$$

since $m \geq 1$ and $B_m \geq m$. Hence $B_m h + s - t$ is increasing in y and the right-hand side of (53) is also positive. Therefore we can square both sides of (53) to conclude that it is equivalent to

$$F(y) = B_m f_1(y) - f_2(y) \geq 0, \tag{54}$$

where

$$f_1(y) = (m+y)(y^3 + my^2 + 3y^2 - m^2y - 3my + 2y - m^3 + 2m^2)$$

and

$$\begin{aligned} f_2(y) = {} & y^5 + 3my^4 + 5y^4 + 2m^2y^3 + 5my^3 + 2y^3 \\ & - 2m^3y^2 - 3m^2y^2 - 3m^4y - m^3y + 6m^2y - m^5 + 2m^4. \end{aligned}$$

Note that $F(0) = 0$. Therefore, to prove (54) it is enough to show that $\frac{d}{dy}F(y) = B_m f_1'(y) + \frac{f_1(y)(2+y+m)}{B_m} - f_2'(y) \geq 0$, or equivalently

$$D(y) \equiv d_1(y) - B_m d_2(y) \geq 0, \tag{55}$$

where

$$\begin{aligned} d_1(y) &= B_m^2 f_1'(y) + f_1(y)(2+y+m) \\ &= 6m^3 - m^4 - 3m^5 + 12my + 4m^2y - 13m^3y - 7m^4y + 20y^2 \\ &\quad + 14my^2 + 7m^2y^2 + 2m^3y^2 + 48y^3 + 49my^3 + 18m^2y^3 + 30y^4 \\ &\quad + 17my^4 + 5y^5 \quad \text{and} \\ d_2(y) &= f_2'(y) = 6m^2 - m^3 - 3m^4 - 6m^2y - 4m^3y \\ &\qquad + 6y^2 + 15my^2 + 6m^2y^2 + 20y^3 + 12my^3 + 5y^4. \end{aligned}$$

Note that $D(0) = 0$. Therefore, to prove (55) it is enough to show that $\frac{d}{dy}D(y) = d_1'(y) - B_m d_2'(y) - \frac{d_2(y)(2+y+m)}{B_m} \geq 0$, or equivalently

$$G(y) \equiv B_m g_1(y) - g_2(y) \geq 0, \tag{56}$$

where

$$\begin{aligned} g_1(y) &= d_1'(y) \\ &= 12m + 4m^2 - 13m^3 - 7m^4 + 40y + 28my + 14m^2y + 4m^3y \\ &\qquad + 144y^2 + 147my^2 + 54m^2y^2 + 120y^3 + 68my^3 + 25y^4 \quad \text{and} \\ g_2(y) &= B_m^2 d_2'(y) + d_2(y)(2+y+m) \\ &= 12m^2 + 4m^3 - 13m^4 - 7m^5 - 18m^2y - 13m^3y - 3m^4y \\ &\quad + 60y^2 + 180my^2 + 183m^2y^2 + 58m^3y^2 + 298y^3 \\ &\quad + 353my^3 + 122m^2y^3 + 170y^4 + 93my^4 + 25y^5. \end{aligned}$$

Note that $G(0) = 0$. Therefore, to prove (56) it is enough to show that $\frac{d}{dy}G(y) = B_m g_1'(y) + \frac{g_1(y)(2+y+m)}{B_m} - g_2'(y) \geq 0$, or equivalently

$$H(y) = h_1(y) - B_m h_2(y) \geq 0, \tag{57}$$

where

$$\begin{aligned} h_1(y) &= B_m^2 g_1'(y) + g_1(y)(2+y+m) \\ &= 24m + 60m^2 + 6m^3 - 13m^4 - 3m^5 + 240y + 300my + 460m^2y \\ &\qquad + 347m^3y + 113m^4y + 1520y^2 + 2246my^2 + 1663m^2y^2 + 482m^3y^2 \\ &\qquad + 2112y^3 + 2233my^3 + 738m^2y^3 + 930y^4 + 497my^4 + 125y^5 \quad \text{and} \\ h_2(y) &= g_2'(y) \\ &= -18m^2 - 13m^3 - 3m^4 + 120y + 360my + 366m^2y + 116m^3y \\ &\qquad + 894y^2 + 1059my^2 + 366m^2y^2 + 680y^3 + 372my^3 + 125y^4. \end{aligned}$$

Note that $H(0) = 12m(2 + 5m + 2m^2) > 0$. Therefore, to prove (57) it is enough to show that $\frac{d}{dy}H(y) = h_1'(y) - B_m h_2'(y) - \frac{h_2(y)(2+y+m)}{B_m} \geq 0$, or equivalently

$$l_1(y)B_m - l_2(y) \geq 0, \tag{58}$$

where

$$\begin{aligned}
l_1(y) &= h_1'(y) \\
&= 240 + 300m + 460m^2 + 347m^3 + 113m^4 + 3040y + 4492my \\
&\quad + 3326m^2y + 964m^3y + 6336y^2 + 6699my^2 + 2214m^2y^2 \\
&\quad + 3720y^3 + 1988my^3 + 625y^4 \quad \text{and} \\
l_2(y) &= B_m^2 h_2'(y) + h_2(y)(2 + y + m) \\
&= 84m^2 + 316m^3 + 347m^4 + 113m^5 + 720y + 2520my + 5046m^2y \\
&\quad + 3899m^3y + 1077m^4y + 9180y^2 + 15780my^2 + 11727m^2y^2 \\
&\quad + 3178m^3y^2 + 12202y^3 + 13145my^3 + 4202m^2y^3 + 4970y^4 \\
&\quad + 2613my^4 + 625y^5.
\end{aligned}$$

Note that $l_1(y) \geq 0$ and $l_2(y) \geq 0$ for all $y \geq 0$. Therefore (58) holds, if and only if $L(y) = B_m^2(l_1(y))^2 - (l_2(y))^2 \geq 0$, which follows immediately from the fact that all the coefficients are positive in

$$\begin{aligned}
L(y) = 4(&14400m^2 + 36000m^3 + 75936m^4 + 97368m^5 + 78972m^6 + 37188m^7 \\
&+ 8136m^8 + 57600y + 172800my + 717360m^2y + 1373400m^3y \\
&+ 1732428m^4y + 1360314m^5y + 599454m^6y + 111444m^7y + 1344000y^2 \\
&+ 3838560my^2 + 8437260m^2y^2 + 11062920m^3y^2 + 8495031m^4y^2 \\
&+ 3499083m^5y^2 + 595986m^6y^2 + 9342880y^3 + 24217360my^3 \\
&+ 32546720m^2y^3 + 24561680m^3y^3 + 9950080m^4y^3 + 1694280m^5y^3 \\
&+ 17918380y^4 + 37038224my^4 + 34271234m^2y^4 + 15627870m^3y^4 \\
&+ 2862630m^4y^4 + 15343236y^5 + 23700982my^5 + 13930330m^2y^5 \\
&+ 2982516m^3y^5 + 6445963y^6 + 6618363my^6 + 1887294m^2y^6 \\
&+ 1302640y^7 + 667056my^7 + 101250y^8).
\end{aligned}$$

To prove (ii) we proceed similarly, but now let $B_m(y) = \sqrt{(y+m)^2 + 8y}$ and $E_m(y) = \frac{d}{dy}G_8^m(y) - (\frac{G_8^m(y)}{G_8^{m-1}(y)} - 1)$, noting that

$$G_8^m(y) = \frac{8y}{B_m + 7y - m}.$$

We now need to show that $E_m(y) \geq 0$ for all $m \geq 4$. As the argument is similar to that above, we omit the details except to indicate the steps leading to the condition $m \geq 4$. Observe that $E_m(y) \geq 0$ if and only if

$$\begin{aligned}
&B_m((y+m)^2 + y - 7m) \\
&+ 7m^2 - m^3 + 24y - 2my + 5m^2y + 55y^2 + 13my^2 + 7y^3 \\
&\qquad \geq B_m B_{m-1}(7y - m + B_m).
\end{aligned} \tag{59}$$

Again, both sides of the inequality are positive. Hence we can square both sides of the inequality and, as above, get that (59) is equivalent to

$$F(y) = f_1(y) - B_m f_2(y) \geq 0, \tag{60}$$

with the appropriate f_1 and f_2. Again $F(0) = 0$. Therefore, in order to prove (60), it is enough to show that $\frac{d}{dy}F(y) \geq 0$, or equivalently, after rewriting,

$$D(y) = B_m d_1(y) - d_2(y) \geq 0, \tag{61}$$

with the appropriate d_1 and d_2. And again, $D(0) = 0$. We repeat the procedure: to prove (61), it is enough to show that $\frac{d}{dy}D(y) \geq 0$, or equivalently

$$e_1(y) - B_m e_2(y) \geq 0,$$

with the appropriate e_1 and e_2. Both e_1 and e_2 turn out to be positive for $y \geq 0$. Therefore (61) holds if

$$\begin{aligned} &L(y) = (e_1(y))^2 - (B_m e_2(y))^2 \geq 0, \\ &L(0) = 0, \text{ and} \\ &L'(0) = 192m^2(m-4)(1+2m)(480+64m+90m^2+33m^3). \end{aligned}$$

Thus $L'(0) \geq 0$ if and only if $m \geq 4$. For all $m \geq 4$, $L''(y) \geq 0$ for all $y \geq 0$. This finishes (ii). □

5.2. Proof of Theorem 21. We will prove by induction that $R_m(x) < G_4^m(x^2)$ for $m = 0, 1, 2, 3, \ldots$. As observed earlier, this inequality holds for $m = 0$, since it is then equivalent to the upper bound in (45). Let

$$H_m(x) = G_4^m(x^2) - R_m(x).$$

Then the upper bound in Theorem 21 is equivalent to $H_m(x) \geq 0$. This can be verified using the strategy of section 4.1 if the following conditions hold:

(i) $H_m(0) > 0$.
(ii) $\lim_{x\to\infty} H_m(x) = 0$.
(iii) $H_m'(x) \leq F_{\text{pos}}(x)H_m(x)$ for some strictly positive function $F_{\text{pos}}(x) > 0$.

Conditions (i) and (ii) hold. Indeed,

$$H_m(0) = \frac{2m}{1+2m} - \frac{\Gamma(m)\Gamma(m+\frac{1}{2})}{\Gamma(m+1)\Gamma(m-\frac{1}{2})} = \frac{1}{2m(1+2m)}$$

and

$$\lim_{x\to\infty} H_m(x) = 0,$$

since $\lim_{x\to\infty} R_m(x) = 1$, and for all $k \geq 1$, $\lim_{x\to\infty} G_k^m(x) = 1$.

We now check condition (iii). It follows from Lemma 24(i) and (52) that

$$\begin{aligned} H_m'(x) &\leq 2x\left[\frac{G_4^m(x^2)}{G_4^{m-1}(x^2)} - \frac{R_m(x)}{R_{m-1}(x)}\right] \\ &= \frac{2x}{G_4^{m-1}(x^2)R_{m-1}(x)}\left[G_4^m(x^2)R_{m-1}(x) - G_4^{m-1}(x^2)R_m(x)\right] \\ &\leq \frac{2x}{R^{m-1}(x)}\left[G_4^m(x^2) - R_m(x)\right] \\ &= \frac{2x}{R^{m-1}(x)}H_m(x), \end{aligned}$$

where the inequality follows from the induction hypothesis $R_{m-1}(x) < G_4^{m-1}(x^2)$. Thus (iii) holds with $F_{\rm pos}(x) = 2x/R_{m-1}(x)$.

For $m \geq 4$, the lower bound is proved similarly. One considers $H_m(x) = R_m(x) - G_8^m(x^2)$ instead and uses Lemma 24(ii). The cases R_1, R_2, and R_3 have to be verified directly as Lemma 24(ii) covers only the cases R_m for $m \geq 4$.

Using (24), $R_1 \geq G_8^0$ is equivalent to showing that

$$\frac{x}{V_0(x)} \geq \frac{9x + 14x^3 + (2x^2-1)\sqrt{8+x^2}}{2(7x + \sqrt{8+x^2})}.$$

As V_0 is always positive, this inequality holds trivially for those x for which the right-hand side is negative or zero. Therefore we need only to prove the inequality on the interval $[x_0, \infty)$, $x_0 \simeq 0.2511$, where

$$9x + 14x^3 + (2x^2-1)\sqrt{8+x^2} \geq 0.$$

Hence we need to show that for all $x \in [x_0, \infty)$,

$$\begin{aligned} V_0(x) &\leq 2x \frac{7x + \sqrt{8+x^2}}{9x + 14x^3 + (2x^2-1)\sqrt{8+x^2}} \\ &= 2x \frac{6x^2 - 1}{1 + 6x^2 + 12x^4 - 2x\sqrt{8+x^2}}. \end{aligned} \tag{62}$$

Put $h_1(x) = 2x \frac{6x^2-1}{1+6x^2+12x^4-2x\sqrt{8+x^2}}$. By Theorem 20 of section 4.1, inequality (62) is true for all $x \in [x_0, \infty)$, for which

$$g_4(x) \leq h_1(x).$$

This last inequality holds only on an interval $[x_0, x_1]$, $x_1 \simeq 1.399$. For all $x \geq x_1$, we show that

$$h_1(x) < \frac{1}{x}$$

and

$$h_1' \leq 2(xh_1 - 1).$$

Then (62) follows as in section 4.1.

Next, we find that $R_2 \geq G_8^1$ is equivalent to $V_0(x) \geq h_2(x)$, where

$$h_2(x) = 2x \frac{3 + 9x^2 + 14x^4 + (2x^2-3)(8x^2 + (1+x^2)^2)^{\frac{1}{2}}}{-3 - 7x^2 + 32x^4 + 28x^6 + (3 - 4x^2 + 4x^4)(8x^2 + (1+x^2)^2)^{\frac{1}{2}}}$$

and $R_3 \geq G_8^2$ is equivalent to $V_0(x) \leq h_3(x)$, where

$$h_3(x) = \frac{2x}{N(x)} \left[-30 - 23x^2 + 32x^4 + 28x^6 + \sqrt{8x^2 + (2+x^2)^2}\ (15 - 8x^2 + 4x^4) \right],$$

with

$$\begin{aligned} N(x) &= 30 + 3x^2 - 42x^4 + 92x^6 + 56x^8 \\ &+ (8x^2 + (2+x^2)^2)^{\frac{1}{2}}(-15 + 18x^2 - 12x^4 + 8x^6). \end{aligned}$$

Again, we have to check these inequalities for V_0 only for those x for which the right-hand sides are positive. We then proceed as for R_1 and show that $g_\pi \geq h_2$ up to a certain x_2 and that $h_2 < \frac{1}{x}$, $h_2' \geq 2(xh_1 - 1)$ on $[x_2, \infty)$. Similarly, we show that $g_4 \leq h_3$ up to a certain x_3 and that $h_3 < \frac{1}{x}$, $h_3' \leq 2(xh_1 - 1)$ on $[x_3, \infty)$. □

Note that these arguments also show that on the interval $[x_1, \infty)$ the function h_1 is a better upper bound for V_0 than g_4; on $[x_2, \infty)$ the function h_2 is a better lower bound for V_0 than g_π; and on $[x_3, \infty)$ the function h_3 is a better upper bound for V_0 than g_4. In fact, $h_3 \leq h_1 \leq g_4$ for $x > x_3$.

5.3. Optimality of bounds. We still need to consider optimality of the lower bound in upper bound in (50) in the parameter k. We continue the strategy above using similar notation so that now $B_m = \sqrt{(y+m)^2 + ky}$ and $E_m(y) = [\frac{G_k^m(y)}{G_k^{m-1}(y)} - 1] - \frac{d}{dy} G_k^m(y)$ with

$$G_k^m(y) = \frac{ky}{B_m + (k-1)y - m}.$$

Then $E_m(y) \leq 0$ if and only if

$$2B_m B_{m-1}(B_m + (k-1)y - m) \leq 2B_m(y + (y+m)^2 - (k-1)m) + P, \tag{63}$$

where

$$\begin{aligned} P = {} & -2m^2 + 2km^2 - 2m^3 - 2ky + k^2y - 4my - 6m^2y + 2km^2y \\ & - 2y^2 - 2ky^2 + 2k^2y^2 - 6my^2 + 4kmy^2 - 2y^3 + 2ky^3. \end{aligned}$$

For $m \geq 1$ and $k \geq 2$ both sides of the inequality are positive. Therefore we can square both sides and get that $E_m(y) \leq 0$ if and only if

$$F(y) = f_1(y) - B_m f_2(y) \geq 0,$$

where

$$\begin{aligned} f_1(y) = {} & -16km^4 + 8k^2m^4 + 32m^5 - 16km^5 - 20k^2m^2y + 8k^3m^2y + 8km^3y \\ & - 4k^2m^3y + 160m^4y - 96km^4y + 8k^2m^4y - 4k^3y^2 + k^4y^2 \\ & + 120km^2y^2 - 84k^2m^2y^2 + 12k^3m^2y^2 + 320m^3y^2 - 224km^3y^2 \\ & + 32k^2m^3y^2 + 20k^2y^3 - 20k^3y^3 + 4k^4y^3 + 152kmy^3 - 124k^2my^3 \\ & + 24k^3my^3 + 320m^2y^3 - 256km^2y^3 + 48k^2m^2y^3 + 56ky^4 - 52k^2y^4 \\ & + 12k^3y^4 + 160my^4 - 144kmy^4 + 32k^2my^4 + 32y^5 - 32ky^5 + 8k^2y^5, \\ f_2(y) = {} & 4\big(-4km^3 + 2k^2m^3 + 8m^4 - 4km^4 - 3k^2my + k^3my + 2km^2y \\ & - k^2m^2y + 32m^3y - 20km^3y + 2k^2m^3y + k^2y^2 + 16kmy^2 - 12k^2my^2 \\ & + 2k^3my^2 + 48m^2y^2 - 36km^2y^2 + 6k^2m^2y^2 + 10ky^3 - 9k^2y^3 + 2k^3y^3 \\ & + 32my^3 - 28kmy^3 + 6k^2my^3 + 8y^4 - 8ky^4 + 2k^2y^4\big). \end{aligned}$$

Then $F(0) = 0$ and in order that $F \geq 0$, we must have $\frac{d}{dy}F(0) \geq 0$. Computing $\frac{d}{dy}F(y)$, we find that $\frac{d}{dy}F(0) = 0$. We apply the same procedure as in the proof of Lemma 24, compute the successive derivatives, and evaluate them at 0. Evaluating the derivative at 0, in the fourth step of the procedure gives the value

$$24k^3m(1+2m)(km - 6m - k).$$

Therefore, in order that (63) (which is the condition for the lower bound) holds for all $m \geq 2$, we have to have at least that $k \geq \lim_{m\to\infty} \frac{6m}{m-1} = 6$. Thus for $m = 2$, $k \geq 12$ will do, for $m = 3$, $k \geq 9$, for $m = 4$, $k \geq 8$, and so forth. Therefore, as G_k^m is increasing in k, it seems a natural choice to pick $k = 12$ or bigger for the lower bound. And indeed, one can check that G_k^m satisfies the lower bound condition of Lemma 24 for $k \geq 12$ and $m \geq 2$. However, it is not true that for $k > 8$, G_k^{m-1} is a lower bound for R_m for *all* $m \geq 1$. It is a lower bound for all $m \geq m(k)$, from a certain $m(k)$ on. Thus the induction in the proof of Theorem 21 cannot start at $m = 0$ or $m = 1$. For $m < m(k)$, there exists x_m such that $R_m - G_k^{m-1} \geq 0$ on $[0, x_m]$ and $R_m - G_k^{m-1} < 0$ on (x_m, ∞).

5.4. Extensions to general *p*. For $p = 1$, all the functions involved are identically equal to 1 and hence trivially convex. For large x, $1/V_m^p(x) \approx x^{p-1}$ and x^{p-1} is concave for $1 < p < 2$. Hence we cannot expect convexity of $1/V_m^p$ on $(0, \infty)$ for p in $(1, 2)$. It was shown in [12] that $\frac{1}{V_0^p}$ is not convex on $\mathbf{R}^+$ for $0 < p < 1$. Therefore, we study only generalizations to $p > 2$. Our method of proof yields verification of the convexity of $\frac{1}{V_m^p}$ for all $m \geq 1$ up to at least $p = 4$. However, this method breaks down for larger p.

We generalize our previous notation to $R_m^p(x) = \frac{V_m^p(x)}{V_{m-1}^p(x)}$ and observe that

$$\frac{d}{dx} R_m^p(x) = px^{p-1} \left[\frac{R_m^p(x)}{R_{m-1}^p(x)} - 1 \right]. \tag{64}$$

For $k \geq 1$, $m \geq 0$, $p \geq 1$ we generalize G_k^m to

$$G_k^{m,p}(x^p) = \frac{kpx^p}{p[(k-1)x^p - m] + \sqrt{p^2(x^p + m)^2 + 2kp(p-1)x^p}}.$$

The proofs of Theorems 21, 22, and 23 can be extended provided that the analogue of Lemma 24 holds. This is not the case for large p. However, although the generalization of the upper bound in Theorem 21 is a necessary and sufficient condition for convexity of $1/V_m^p(x)$, Lemma 24 is only a sufficient condition for Theorem 21. Indeed, we were able to establish the lower bound in Theorem 21 for $m = 1, 2, 3$ even though part (ii) of Lemma 24 does not hold for $m < 4$. Hence, the fact that Lemma 24 breaks down for large p does not preclude convexity of $1/V_m^p(x)$. On the contrary, numerical evidence suggests that $\frac{1}{V_m^p}$ is convex for all $p \geq 2$.

LEMMA 25. *For all* $4 \geq p \geq 2$, $m \geq 1$,

$$\frac{d}{dx} G_4^{m,p}(x^p) \leq px^{p-1} \left[\frac{G_4^{m,p}(x^p)}{G_4^{m-1,p}(x^p)} - 1 \right].$$

This is equivalent to

$$E_m^p = px^{p-1} \left[\frac{G_4^{m,p}(x^p)}{G_4^{m-1,p}(x^p)} - 1 \right] - \frac{d}{dx} G_4^{m,p}(x^p) \geq 0,$$

which allows us to make some remarks about the range of validity. Although Lemma 25 can probably be extended to some higher p, it does *not* hold for all p, m. On the contrary, for all $m \geq 1$ there exists $p(m)$ and an interval $(x_1^{p(m)}, x_2^{p(m)})$ such that $E_m^p < 0$ on that interval for all $p \geq p(m)$. For example, numerical results show that

for $m = 1$, an interval on which $E_m < 0$ exists when $p \geq 10$; for $m = 2$ when $p \geq 14$; and for $m = 3$ when $p \geq 18$.

For simplicity, we sketch only the proof of Lemma 25 and give the final expressions for $p = 3$. Similar expressions can be given for $p = 4$. We have checked the details using Mathematica but omit the long formulas. As the expressions involved are monotone in p, this suffices for the entire interval $2 \leq p \leq 4$.

Proof. Let $B_m = \sqrt{p^2(y+m)^2 + 8p(p-1)y}$. Then $E_m^p \geq 0$ is equivalent to

$$\begin{aligned} &B_m B_{m-1}(B_m + 3py - pm) \\ &\quad \geq pB_m \left[p(y+m)^2 + y(5p-8) - 3pm\right] + p^2 \left\{3m^2p - m^3p \right. \\ &\qquad + \left. y(-8 + 8m + 8p - 6mp + m^2p) + y^2(-24 + 23p + 5mp) + 3py^3\right\}. \end{aligned}$$

Following the procedure used to prove Lemma 24(i), we eventually find that it would suffice to show that

$$l_1(y)B_m - l_2(y) \geq 0, \tag{65}$$

where, for $p = 3$,

$$\begin{aligned} l_1(y) = 3(&5120 + 2880m + 13800m^2 + 11034m^3 + 3051m^4 + 169600y \\ &+ 199632my + 116820m^2y + 26028m^3y + 298296y^2 + 239706my^2 \\ &+ 59778m^2y^2 + 133920y^3 + 53676my^3 + 16875y^4) \qquad \text{and} \\ l_2(y) = 27(&-2048m + 192m^2 + 3448m^3 + 3678m^4 + 1017m^5 25600y \\ &+ 49920my + 76152m^2y + 45330m^3y + 9693m^4y + 200000y^2 \\ &+ 250152my^2 + 139266m^2y^2 + 28602m^3y^2 + 195880y^3 \\ &+ 157254my^3 + 37818m^2y^3 + 59640y^4 + 23517my^4 + 5625y^5). \end{aligned}$$

Both $l_1(y)$ and $l_2(y)$ in (65) are positive, and hence (65) is equivalent to

$$L = l_1(y)^2 B_m^2 - l_2(y)^2 \geq 0,$$

which can be verified for $m \geq 1$. □

Acknowledgments. It is a pleasure to thank Professor S. Kwapien for the argument leading to the upper bound in property (a), and Professors R. Askey and M. Ismail for helpful discussions about the properties of hypergeometric functions. We would also like to thank Professor V. Mascioni for providing a copy of [12] before publication, and Professor Fink for drawing our attention to reference [15].

UNIQUENESS OF EQUILIBRIUM CONFIGURATIONS IN SOLID CRYSTALS*

WILFRID GANGBO† AND ROBERTO VAN DER PUTTEN‡

Abstract. In this article, under suitable assumptions, it is proved that $\inf_{\mathbf{u}\in\mathcal{U}_\Lambda} E[\mathbf{u}]$ is dual to $\sup_{(a,b)}\{\int_\Omega a(\mathbf{F}(\mathbf{x}))d\mathbf{x} + \int_\Lambda b(\mathbf{y})d\mathbf{y}\}$, where, $E[\mathbf{u}] := \int_\Omega (h(\det D\mathbf{u}) - \mathbf{F}\cdot\mathbf{u})d\mathbf{x}$. Here, the infimum is performed over $\mathcal{U}_\Lambda$, the set of all orientation-preserving deformations $\mathbf{u} \in C^1(\Omega)^d$ that are homeomorphisms from $\bar{\Omega}$ onto $\bar{\Lambda}$, and the supremum is performed over the set of all upper semicontinuous functions a, b such that $a(\mathbf{z}) + \alpha b(\mathbf{y}) \le h(\alpha) - \mathbf{y}\cdot\mathbf{z}$. This duality result turns out to be important in the study of existence and uniqueness of smooth minimizers of E. Note that $M \to h(\det M)$ is not coercive and thus direct methods of the calculus of variations don't apply here.

Introduction. The theory of duality, one of the main tools in the calculus of variations, is well developed within the context of convex variational problems of the form $\inf_{\mathcal{U}} \int_\Omega L(\mathbf{x}, \mathbf{u}(\mathbf{x}), D\mathbf{u}(\mathbf{x}))d\mathbf{x}$, where the real-valued function $M \to L(\mathbf{x}, \mathbf{u}, M)$ defined on the set $\mathbf{R}^{d\times d}$ of the $d \times d$ matrices is convex for each $\mathbf{x} \in \Omega$ and $\mathbf{u} \in \mathbf{R}^d$. We recall that in the particular case $L(\mathbf{x}, \mathbf{u}, M) = g(M) - \mathbf{F}(\mathbf{x})\cdot\mathbf{u}$, where g is convex and coercive, then the duality statement is as follows: the infimum

$$\inf\left\{\int_\Omega L(\mathbf{x}, \mathbf{u}(\mathbf{x}), D\mathbf{u}(\mathbf{x}))d\mathbf{x} : \mathbf{u} \in W_0^{1,p}(\Omega, \mathbf{R}^d)\right\}$$

and the supremum

$$\sup\left\{-\int_\Omega g^*(-\mathbf{p}(\mathbf{x}))d\mathbf{x} : \mathbf{p} \in L^q(\Omega, \mathbf{R}^{d\times d}),\ \operatorname{div}\mathbf{p} = \mathbf{F}\right\}$$

coincide, where g^* is the Legendre transform of g. Furthermore, the extremum is attained in both problems (see [10]). An important class of nonconvex functions that occur in nonlinear elasticity theory is the class of *polyconvex* functions. There is no available theory of duality for that class. Recall that a real-valued function W of $\mathbf{R}^{d\times d}$ into $\mathbf{R}\cup\{+\infty\}$ is said to be *polyconvex* if it can be written as a convex function of the minors of M (see [8]). In this paper we consider a special class of polyconvex functions of the form $L(\mathbf{x}, \mathbf{u}, M) := W(M) - \mathbf{F}(\mathbf{x})\cdot\mathbf{u}$ and introduce a maximization problem, dual to $\inf_{\mathcal{U}} \int_\Omega L(\mathbf{x}, \mathbf{u}, D\mathbf{u})d\mathbf{x}$. As an application we study stable configurations of solid crystals occupying a reference configuration Ω and subject to a body force $\mathbf{F}$. If the crystal undergoes a deformation represented by a map $\mathbf{u} : \Omega \to \mathbf{R}^d$, $d \ge 2$ (in general $d = 3$), then its total energy functional is

$$E[\mathbf{u}] := \int_\Omega (W(D\mathbf{u}) - \mathbf{F}\cdot\mathbf{u})d\mathbf{x},$$

where W represents the *Helmholtz free energy density.* In the framework of the continuum theory proposed by Ericksen [11] and [12], which has stimulated a growing body of work (see [23], [22], [21], [20], [25], [29], [28], [27], [26]), W belongs to a class of energy density functions that are invariant under change of lattice basis and frame:

$$W(M) = W(QMH) \tag{1}$$

for all $M \in \mathbf{R}^{d\times d}$, all $Q \in \mathbf{R}^{d\times d}$ such that $Q^TQ = I$, $\det Q > 0$, and all $H \in \mathbf{Z}^{d\times d}$, $|\det H| = 1$. The class of the energy densities suggested by Ericksen contains those of the form

$$W(M) = h(\det M) \qquad (M \in \mathbf{R}^{d\times d}), \tag{2}$$

where h is a convex function. In fact, it was shown by Chipot and Kinderlehrer [7] and Fonseca [15] that if W is of the form (1), then its quasi-convex envelope QW is of the form (2). Let us point out that the class of functions in (1) does not fall in the updated class of energy density functions of solid crystals. However, for purely mathematical interest, in what follows we choose to study the case where W satisfies (1), $QW = W$, and we still interpret the functional E as a solid crystal energy functional.

Following previous works (see, for instance, [17]) we assume that

$$h \in C^2(0, +\infty) \text{ is strictly convex,} \tag{3}$$

$$h(t) \to +\infty \text{ as } t \to 0^+ \text{ and } h(t)/t \to +\infty \text{ as } t \to +\infty. \tag{4}$$

We extend h to $\mathbf{R}$ by setting

$$h(t) := +\infty \text{ if } t \le 0. \tag{5}$$

Requirements (4) and (5) are imposed to make it energically impossible to compress part of the body of the crystal to zero volume, to extend part of the body excessively, or to change orientation. A typical example of body force is the gravity $\mathbf{F} = -g\,\mathbf{e}_d$, which can be written as the L^1-limit of a sequence of diffeomorphisms. Here we have set $\mathbf{e}_d := (0, \dots, 0, 1)$.

If the crystal undergoes a deformation $\bar{\mathbf{u}}$ under the action of the body force $\mathbf{F}$, then

$$-\operatorname{div}(\sigma_{\bar{\mathbf{u}}}) = \mathbf{F} \quad \text{in} \quad \Omega, \tag{6}$$

where $\sigma_{\bar{\mathbf{u}}}$ is the stress tensor $\frac{\partial W}{\partial M}(D\bar{\mathbf{u}})$. Solutions of (6) could be interpreted as critical points of the functional E.

A problem of great interest in nonlinear elasticity is the so-called *pure displacement boundary value problem:* given a diffeomorphism $\mathbf{u}_o$ from $\bar{\Omega}$ onto $\bar{\Lambda}$, where $\Lambda \subset \mathbf{R}^d$ is an open, bounded set, find $\bar{\mathbf{u}}$ *stable solution* of (6) such that the restrictions of $\bar{\mathbf{u}}$ and $\mathbf{u}_o$ on $\partial\Omega$ coincide. Stability means that not only is $\bar{\mathbf{u}}$ a critical point of E, but $\bar{\mathbf{u}}$ minimizes E over $\mathcal{U}_o$, the set of all maps $\mathbf{u}$ from $\bar{\Omega}$ onto $\bar{\Lambda}$ that are in $C^1(\Omega)^d$, $\det D\mathbf{u} > 0$, and such that the restrictions of $\mathbf{u}$ and $\mathbf{u}_o$ on $\partial\Omega$ coincide. Since $M \to h(\det M)$ is not coercive, and $\mathcal{U}_o$ is not closed under the weak topology on L^p spaces, the problem of minimizing E over $\mathcal{U}_o$ escapes the classical methods of the calculus of variations, and there is currently a wide literature on the subject. When $\mathbf{u}_o$ is the identity map and $\mathbf{F} = -g\,\mathbf{e}_d$ is the gravity force, Fonseca and Tartar [17]

showed that E has infinitely many minimizers in the set of displacements that are in $W^{1,\infty}(\Omega)^d$. Also, Chipot and Kinderlehrer [7] proved for E existence of parametrized measure minimizers by enlarging the set $\mathcal{U}_o$ to a set of Radon measures. We show that if $\mathbf{F} \in C^1(\bar{\Omega})^d$ is a homeomorphism, such that $\det D\mathbf{F} \in C^1(\bar{\Omega})^d$, $\det D\mathbf{F} > 0$, if Λ and $\mathbf{F}(\Omega)$ are convex, then the infimum

$$\inf_{\mathcal{U}_o} E \tag{7}$$

coincides with the infimum

$$\inf_{\mathcal{U}_\Lambda} E \tag{8}$$

and (8) admits a unique minimizer. Here, $\mathcal{U}_\Lambda$ is the set of all orientation-preserving maps $\mathbf{u} \in C^1(\Omega)^d$ that are homeomorphisms from $\bar{\Omega}$ onto $\bar{\Lambda}$.

One can interpret (8) as finding $\bar{\mathbf{u}}$ stable solution of the equations

$$\begin{cases} -\operatorname{div}\left[\frac{\partial W}{\partial M}(D\bar{\mathbf{u}})\right] &= \mathbf{F} \quad \text{in} \quad \Omega, \\ \bar{\mathbf{u}}(\Omega) &= \Lambda. \end{cases} \tag{9}$$

Uniqueness of a minimizer in (8) clearly implies that, in general, (7) does not admit a minimizer. In fact, sharper conclusions hold for a relaxation of (8): we substitute $\mathcal{U}_\Lambda$ by a bigger set $\mathcal{U}'_\Lambda$ containing maps which may not be smooth. We define $\mathcal{U}'_\Lambda$ to be the set of all maps $\mathbf{u}$ from Ω onto Λ that are one-to-one almost everywhere and such that $|\det D\mathbf{u}| \neq 0$ almost everywhere in the weak sense. Since it is delicate to define determinants of maps $\mathbf{u} \in \mathcal{U}'_\Lambda$ we define absolute values of determinants of these maps in the weak sense (see Definition 1.3). We denote by I the extension of $-E$ to $\mathcal{U}'_\Lambda$. In this new setting, under the assumptions that Ω, Λ, are bounded sets and $\mathbf{F} \in L^1(\Omega)^d$ is one-to-one, $(d-1)$-nondegenerate (see Definition 1.2), we prove that the following problem admits a unique maximizer

$$\sup_{\mathcal{U}'_\Lambda} I[\mathbf{u}], \tag{10}$$

where

$$I[\mathbf{u}] := \int_\Omega (\mathbf{F} \cdot \mathbf{u} - h(|\det D\mathbf{u}|))d\mathbf{x}.$$

If $\bar{\mathbf{u}}$ is the unique maximizer in (10), even if we drop the assumption that $\mathbf{F}$ is $(d-1)$-nondegenerate, then there exists a convex function $\psi_o : \mathbf{R}^d \to \mathbf{R}$ such that $\mathbf{F} = D\psi_o^* \circ \bar{\mathbf{u}}$, and

$$H(|\det D\bar{\mathbf{u}}|) = \psi_o^* \circ \bar{\mathbf{u}}. \tag{11}$$

Here

$$H(t) = h(t) - th'(t) \qquad (t \in \mathbf{R}),$$

and ψ_o^* is for the Legendre transform of ψ_o. One can readily check that

$$H \text{ is decreasing and } H(0, +\infty) = \mathbf{R}, \tag{12}$$

and so, if H^{-1} is of class C^1, smoothness of $|\det D\bar{\mathbf{u}}|$ is a straightforward consequence of (11). To understand the relation $\mathbf{F} = D\psi_o^* \circ \bar{\mathbf{u}}$, one can divide the computation of

the supremum in (10) into two steps. First, for each function $\alpha > 0$, we maximize $\mathbf{u} \to \int_\Omega \mathbf{F} \cdot \mathbf{u} d\mathbf{x}$ over the set of all $\mathbf{u}$ such that $\mathbf{u}(\Omega) = \Lambda$ and $|\det D\mathbf{u}| = \alpha$. Note that this intermediary variational problem is a Monge problem (see [3] and [18] in the case where $\alpha \equiv \chi_\Omega d\mathbf{x}$), and so the supremum is obtained for a map $\mathbf{u}^\alpha$ of the form $D\psi^\alpha \circ \mathbf{F}$, where ψ^α is a convex function. A sufficient condition for ψ^α to be differentiable at $\mathbf{F}(\mathbf{x})$ and thus for $D\psi^\alpha \circ \mathbf{F}$ to be well defined at $\mathbf{x}$ is that $\mathbf{F}$ be $(d-1)$-nondegenerate. Formally, if α_∞ maximizes the functional $\alpha \to \int_\Omega (\mathbf{F} \cdot D\psi^\alpha \circ \mathbf{F} - h(\alpha)) d\mathbf{x}$ over the set of all $\alpha > 0$, then $\bar{\mathbf{u}} = D\psi^{\alpha_\infty} \circ \mathbf{F}$ is a maximizer in (10).

Uniqueness of minimizers of E over $\mathcal{U}_\Lambda$ and $\mathcal{U}_o$ may clearly fail if we don't assume that $\mathbf{F}$ is $(d-1)$-nondegenerate. For instance, let $\mathbf{u}_o$ be the identity map, $\mathbf{F} \equiv 0$, and $h(t) = t^2/2 + 1/(2t^2)$. Since h attains it minimum for $t = 1$, any map $\mathbf{u} \in \mathcal{U}_o$ such that $\det D\mathbf{u} = 1$ is a minimizer of E over $\mathcal{U}_o$ and $\mathcal{U}_\Lambda$ where $\Lambda = \Omega$. Hence, E admits infinitely many minimizers over both sets $\mathcal{U}_o$ and $\mathcal{U}_\Lambda$. As shown in [17] it is necessary to have that $\det D\mathbf{F}(\mathbf{x}) \geq 0$ for E to admit a minimizer over $\mathcal{U}_o$.

Our primary and new contribution is to show that (10) is dual to the minimization problem (13):

$$\inf_{\mathcal{A}} J[\psi, \phi], \tag{13}$$

where

$$J[\psi, \phi] := \int_\Omega \psi(\mathbf{F}(\mathbf{x})) d\mathbf{x} + \int_\Lambda \phi(\mathbf{y}) d\mathbf{y}, \tag{14}$$

and $\mathcal{A}$ is the set of all pairs (ψ, ϕ) such that $\psi : \mathbf{R}^d \to \mathbf{R} \cup \{+\infty\}$ and $\phi : conv(\Lambda) \to \mathbf{R} \cup \{+\infty\}$ are lower semicontinuous, not identically $+\infty$, and

$$\psi(\mathbf{z}) + \alpha\phi(\mathbf{y}) + h(\alpha) \geq \mathbf{y} \cdot \mathbf{z}$$

for all $\mathbf{y} \in conv(\Lambda)$, all $\mathbf{z} \in \mathbf{R}^d$, and all $\alpha > 0$. To obtain the above duality result we first show that if μ is a finite positive measure on $\mathbf{R}^d$ of finite moments $M_o(\mu)$ and $M_1(\mu)$ (see (20)), then

$$\sup_{\gamma \in \Gamma(\mu)} \bar{I}[\gamma] = \inf_{(\psi,\phi) \in \mathcal{A}} J_\mu[\psi, \phi], \tag{15}$$

where

$$J_\mu[\psi, \phi] := \int_{\mathbf{R}^d} \psi(\mathbf{z}) d\mu(\mathbf{z}) + \int_\Lambda \phi(\mathbf{y}) d\mathbf{y},$$

and

$$\bar{I}[\gamma] := \int_C (\mathbf{y} \cdot \mathbf{z} - h(\alpha)) d\gamma(\alpha, \mathbf{y}, \mathbf{z}).$$

Here, $\Gamma[\mu]$ is the set of all Borel measures on $C := (0, +\infty) \times \mathbf{R}^d \times \mathbf{R}^d$ such that

$$\int_C f(\mathbf{z}) d\gamma(\alpha, \mathbf{y}, \mathbf{z}) = \int_{\mathbf{R}^d} f(\mathbf{z}) d\mu(\mathbf{z})$$

and

$$\int_C \alpha f(\mathbf{y}) d\gamma(\alpha, \mathbf{y}, \mathbf{z}) = \int_\Lambda f(\mathbf{y}) d\mathbf{y}$$

for all $f \in C_o(\mathbf{R}^d)$.

In fact, one can view $\Gamma(\mu)$ as a set containing $\mathcal{W}$, the set that consists of all Borel maps $\mathbf{w} : \mathbf{R}^d \to \Lambda$ such that the push forward of μ by $\mathbf{w}$ is absolutely continuous with respect to Lebesgue measure, say, $\mathbf{w}\sharp\mu = d\mathbf{y}/\beta(\mathbf{y})$ for some Borel function $\beta : \Lambda \to (0, +\infty)$. The inclusion $\mathcal{W} \subset \Gamma(\mu)$ means that we identify $\mathbf{w} \in \mathcal{W}$ to $\gamma^{\mathbf{w}} \in \Gamma(\mu)$, defined by

$$\int_C f(\alpha, \mathbf{y}, \mathbf{z}) d\gamma^{\mathbf{w}}(\alpha, \mathbf{y}, \mathbf{z}) := \int_{\mathbf{R}^d} f(\beta(\mathbf{w}(\mathbf{z})), \mathbf{w}(\mathbf{z}), \mathbf{z}) d\mu(\mathbf{z}) \tag{16}$$

for all $f \in C_o(\mathbf{R} \times \mathbf{R}^d \times \mathbf{R}^d)$. This definition makes sense provided that $\mathbf{w}$ is defined almost everywhere with respect to μ. Observe that if $\mu = \mu_{\mathbf{F}}$ where $\mu_{\mathbf{F}}[A] := |\mathbf{F}^{-1}[A]|$ is the d-dimensional Lebesgue measure of $\mathbf{F}^{-1}[A]$, then

$$\bar{I}[\gamma^{\mathbf{w}}] = I[\mathbf{w} \circ F]. \tag{17}$$

The plan is to first establish (15) and prove that the variational problems involved admit extremums under the general assumptions that h satisfies (3), (4), and (5) and that μ is a finite positive measure on $\mathbf{R}^d$ whose moments of order one are finite. Next we show that $\bar{I}$ admits a unique maximizer γ_o over $\Gamma(\mu)$. That maximizer can be parametrized over Λ: there is a map $\mathbf{m} : \Lambda \to \mathbf{R}^d$ and a function $\beta : \Lambda \to \mathbf{R}$, defined $\chi_\Lambda d\mathbf{y}$-almost everywhere such that

$$\int_C f(\alpha, \mathbf{y}, \mathbf{z}) d\gamma_o(\alpha, \mathbf{y}, \mathbf{z}) := \int_\Lambda f(\beta(\mathbf{y}), \mathbf{y}, \mathbf{m}(\mathbf{y})) d\mathbf{y}$$

for all $f \in C_o(\mathbf{R} \times \mathbf{R}^d \times \mathbf{R}^d)$. Then, we show that if $\mu_{\mathbf{F}}[A] := |\mathbf{F}^{-1}[A]|$ where $\mathbf{F}$ is one-to-one and $(d-1)$-nondegenerate, then every γ_o maximizing $\bar{I}$ over $\Gamma(\mu)$ is of the form $\gamma^{\mathbf{w}}$ (see (16)). Roughly speaking, $\mu[\mathbf{R}^d \setminus \mathbf{m}(\Lambda)] = 0$, $\mathbf{m}$ has an inverse $\mathbf{w}$ defined μ-almost everywhere. We combine (15) and (17) to deduce that $\mathbf{w} \circ F$ maximizes I, and that (10) is dual to (13). Simple examples such as $\mathbf{F}(\mathbf{x}) \equiv \mathbf{c}$ and $h(t) = t^2 + 1/t^2$ show that uniqueness of maximizer of $\bar{I}$ over $\Gamma(\mu)$ does not imply uniqueness of maximizer of I over $\mathcal{U}'_\Lambda$ unless the body force $\mathbf{F}$ is one-to-one and $(d-1)$-nondegenerate.

The remainder of the paper is organized as follows. In section 2 we prove existence of a minimizer (ψ_o, ϕ_o) of J_μ over $\mathcal{A}$ under the assumptions that h satisfies (3), (4), and (5) and that μ is a finite positive measure on $\mathbf{R}^d$ of finite moments $M_o(\mu)$ and $M_1(\mu)$. We write the Euler–Lagrange equations corresponding to the variational problem $\inf_{\mathcal{A}} J_\mu$ and deduce that if in addition μ vanishes on $(d-1)$-rectifiable subsets of $\mathbf{R}^d$, then there exist a convex function ψ and a positive Borel function β such that $D\psi\sharp\mu = d\mathbf{y}/\beta(\mathbf{y})$ and $\gamma_o = \gamma^{D\psi}$ maximizes $\bar{I}$ over $\Gamma(\mu)$. It is well known that a convex function is differentiable everywhere except on a $(d-1)$-rectifiable set (see [1]), and so the assumption that μ vanishes on $(d-1)$-rectifiable subsets of $\mathbf{R}^d$ is necessary to guarantee that $D\psi$ exists almost everywhere with respect to μ, so that the measure $\gamma_o = \gamma^{D\psi}$ be well-defined. Here, the analytical arguments used to write the Euler–Lagrange equations corresponding to $\inf_{\mathcal{A}} J_\mu$ are similar to the one independently introduced by Caffarelli–Varadhan [5] and the first author [18]. Having γ_o of the form $\gamma^{D\psi}$ readily yields that the duality (15) holds. By an approximation argument we extend (15) to the case where μ fails to vanish on $(d-1)$-rectifiable subsets of $\mathbf{R}^d$ and still obtain that supports of every maximizers of $\bar{I}$ over $\Gamma(\mu)$ are contained in the graph of a map from Λ into $(0, +\infty) \times \mathbf{R}^d$. We also show that the maximizer γ_o of $\bar{I}$ over $\Gamma(\mu)$ is unique.

In section 3, we assume that the given body force $\mathbf{F}$ belongs to $L^1(\Omega)$ and apply results of section 2 with $\mu[A] := |\mathbf{F}^{-1}[A]|$ to obtain that (10) is dual to (13). If in addition $\mathbf{F}$ is $(d-1)$-nondegenerate and one-to-one, then I admits a unique maximizer $\bar{\mathbf{u}}$ over $\mathcal{U}'_\Lambda$. Furthermore, $\bar{\mathbf{u}}$ satisfies $D\psi_o^* \circ \bar{\mathbf{u}} = \mathbf{F}$ and satisfies the Hamilton–Jacobi equation $H(|\det D\bar{\mathbf{u}}|) = \psi_o^* \circ \bar{\mathbf{u}}$ for some lower semicontinuous, convex function $\psi_o : \mathbf{R}^d \to \mathbf{R}$. Note that if $D\psi_o$ is differentiable almost everywhere with respect to μ, then we can conclude that $\bar{\mathbf{u}} = D\psi_o \circ \mathbf{F}$. Conversely, we show that if $\bar{\mathbf{u}} \in \mathcal{U}'_\Lambda$, $\psi_o : \mathbf{R}^d \to \mathbf{R}$ is a lower semicontinuous, convex function such that $H(|\det D\bar{\mathbf{u}}|) = \psi_o^* \circ \bar{\mathbf{u}}$ and $\mathbf{F} = D\psi_o^* \circ \bar{\mathbf{u}}$, then $\bar{\mathbf{u}}$ is the unique maximizer of I over $\mathcal{U}'_\Lambda$.

In section 4, using Caffarelli's regularity results on smoothness of convex potentials [4], [5], [6], we prove that if $\mathbf{F}$ and $\det D\mathbf{F}$ are of class C^1, if Λ and $\mathbf{F}(\Omega)$ are convex sets, then $\bar{\mathbf{u}}$ is of class C^1 and is the unique minimizer of E over $\mathcal{U}_\Lambda$. A corollary of this result is that given a diffeomorphism $\mathbf{u}_o$ of $\bar{\Omega}$ onto $\bar{\Lambda}$, the infima $\inf_{\mathcal{U}_\Lambda} E$ and $\inf_{\mathcal{U}_o} E$ coincide.

Four appendices are also provided. In Appendix A, we review basic facts about convex functions and study needed properties of the transformations introduced in Definition 1.6, $\phi \to \phi^\sharp$, $\psi \to \psi_\sharp$ from the set of real-valued functions to the set of convex functions. In Appendix C, we state that every one-to-one map $\mathbf{u} \in \mathcal{U}_\Lambda$ of class $C^1(\Omega) \cap C(\bar{\Omega})$ such that $\det D\mathbf{u} + \frac{1}{\det D\mathbf{u}}$ is bounded is a pointwise limit of a sequence of one-to-one maps $(\mathbf{u}_n) \subset \mathcal{U}_o$ of class $C^1(\Omega) \cap C(\bar{\Omega})$ with $\det D\mathbf{u}_n = \det D\mathbf{u}$. This approximation result is used in section 4 to prove that the infima $\inf_{\mathcal{U}_\Lambda} E$ and $\inf_{\mathcal{U}_o} E$ coincide. In Appendix D we recall facts on existence and smoothness of optimal maps in the Monge problem.

We next summarize the main results of the paper.

THEOREM 0.1 (main results). *Suppose that Ω, $\Lambda \subset \mathbf{R}^d$ are bounded open sets, that* (3), (4), *and* (5) *hold, and that $\mathbf{F} \in L^1(\Omega)^d$ is a Borel map. Then we have the following.*

(i) *Duality. J admits a minimizer (ψ_o, ϕ_o) over $\mathcal{A}$ and we have that $\inf_{\mathcal{A}} J[\psi, \phi] = \sup_{\mathcal{U}'_\Lambda} I[\mathbf{u}]$.*

(ii) *Uniqueness of a minimizer. If in addition $\mathbf{F}$ is one-to-one almost everywhere with respect to the d-dimensional Lebesgue measure and $|\mathbf{F}^{-1}(N)| = 0$ whenever N is $(d-1)$-rectifiable, then I admits a unique maximizer $\bar{\mathbf{u}}$ over $\mathcal{U}'_\Lambda$; we also have that $\bar{\mathbf{u}} = D\psi_o \circ \mathbf{F}$, and $H(|\det D\bar{\mathbf{u}}|) = \psi_o^* \circ \bar{\mathbf{u}}$, where (ψ_o, ϕ_o) minimizes J over $\mathcal{A}$.*

(iii) *Smoothness of the minimizer. Assume in addition that Ω is connected, its boundary $\partial\Omega$ is Lipschitz, and $\Lambda, \mathbf{F}(\Omega)$ are convex. If $\mathbf{F}$ and $\det D\mathbf{F}$ belong to $C^1(\bar{\Omega})^d$ and $\det D\mathbf{F} > 0$ on $\bar{\Omega}$, then $\bar{\mathbf{u}} \in \mathcal{U}_\Lambda \cap C^{0,s}(\bar{\Omega})^d$, $0 < \det D\bar{\mathbf{u}} \in C^{0,s}(\bar{\Omega}) \cap C^1(\Omega)$ for all $0 < s < 1$, $\bar{\mathbf{u}}$ is the unique minimizer of E over $\mathcal{U}_\Lambda$. Furthermore, we have that $-\operatorname{div}[\frac{\partial W}{\partial M}(D\bar{\mathbf{u}})] = \mathbf{F}$ in Ω in the weak sense.*

Proof. Parts (i) and (ii) follow from Theorem 3.1, and (iii) is a consequence of Theorem 4.1. □

Simple calculations show that the duality result obtained in Theorem 0.1 is

$$\inf_{\mathcal{U}'_\Lambda} \left\{ \int_\Omega (h(\det D\mathbf{u}) - \mathbf{F} \cdot \mathbf{u}) d\mathbf{x} \right\} = \sup_b \left\{ \int_\Omega L_b(\mathbf{F}(\mathbf{x})) d\mathbf{x} + \int_\Lambda b(\mathbf{y}) d\mathbf{y} \right\}, \tag{18}$$

where the supremum is performed over the set of all upper semicontinuous functions $b : \mathbf{R}^d \to \mathbf{R}$ and

$$L_b(\mathbf{z}) := \inf_{\mathbf{y} \in conv(\Lambda)} \{-\mathbf{y} \cdot \mathbf{z} - h^*(b(\mathbf{y}))\}.$$

1. Notations and definitions. For the convenience of the reader we collect together some of the notation introduced throughout the text.

• If $\Omega \subset \mathbf{R}^d$, then $\overline{\Omega}$ denotes the closure of Ω.

• B_R is the closed ball of center 0 and radius $R > 0$.

• $|A|$ stands for the d-dimensional Lebesgue measure of the set $A \subset \mathbf{R}^d$, and $\int_{\mathbf{R}^d} G d\mathbf{x}$ is the Lebesgue integral of G.

• If μ is a Borel measure on $\mathbf{R}^d$, then we denote by $\operatorname{spt}\mu$ the support of μ, which refers to the smallest closed set K such that $\mu[\mathbf{R}^d \setminus K] = 0$. If μ is absolutely continuous with respect to the d-dimensional Lebesgue measure and $\mu[A] = \int_A f d\mathbf{x}$ for $A \subset \mathbf{R}^d$ Borel, then we write $\mu = f d\mathbf{x}$.

• If μ is a Borel measure on $\mathbf{R}^d$ and $\mathbf{v} : \mathbf{R}^d \to \mathbf{R}^m$ is a Borel map, then we define $\mathbf{v}_{\#}\mu$ to be the Borel measure on $\mathbf{R}^m$ given by $\mathbf{v}_{\#}\mu[B] := \mu[\mathbf{v}^{-1}(B)]$ for $B \subset \mathbf{R}^m$.

• The characteristic function of $A \subset \mathbf{R}^d$ is denoted by χ_A.

• If $\psi : \mathbf{R}^d \to \mathbf{R} \cup \{+\infty\}$ is not identically $+\infty$, then the Legendre–Fenchel transform of ψ is the convex, lower semicontinuous function $\psi^* : \mathbf{R}^d \to \mathbf{R} \cup \{+\infty\}$ defined by

$$\psi^*(\mathbf{y}) := \sup_{\mathbf{x} \in \mathbf{R}^d} \{\mathbf{x} \cdot \mathbf{y} - \psi(\mathbf{x})\}. \tag{19}$$

• The subdifferential of a convex function $\psi : \mathbf{R}^d \to \mathbf{R} \cup \{+\infty\}$ is the set $\partial\psi \subset \mathbf{R}^d \times \mathbf{R}^d$ consisting of all $(\mathbf{x}, \mathbf{y})$ satisfying

$$\psi(\mathbf{z}) - \psi(\mathbf{x}) \geq \mathbf{y} \cdot (\mathbf{z} - \mathbf{x}) \qquad \text{for all } \mathbf{z} \in \mathbf{R}^d.$$

If $(\mathbf{x}, \mathbf{y}) \in \partial\psi$, we may also write $\mathbf{y} \in \partial\psi(\mathbf{x})$. Recall $\mathbf{x} \in \partial\psi^*(\mathbf{y})$ whenever $\mathbf{y} \in \partial\psi(\mathbf{x})$, while the converse also holds true if ψ is convex lower semicontinuous. In that case $\partial\psi$ is a closed set. In general, the set $\partial\psi(\mathbf{x}) \subset \mathbf{R}^d$ is closed and convex.

• **id** stands for the identity map $\mathbf{id}(\mathbf{x}) = \mathbf{x}$.

• We denote the set of all $d \times d$ matrices whose entries are real numbers by $\mathbf{R}^{d\times d}$.

• We denote the set of all homeomorphism from $A \subset \mathbf{R}^d$ onto $B \subset \mathbf{R}^d$ by $Diff^0(A, B)$. If $k \geq 1$ is an integer, $\Omega, \Lambda \subset \mathbf{R}^d$ are open, then $Diff^k(\Omega, \Lambda)$ is the set of all maps $\mathbf{v} \in Diff^0(\Omega, \Lambda)$ such that $\mathbf{v} \in C^k(\Omega)^d$ and $\mathbf{v}^{-1} \in C^k(\Lambda)^d$. We denote the set of all maps $\mathbf{v} \in Diff^0(\bar{\Omega}, \bar{\Lambda})$ such that $\mathbf{v}$ is of class C^k in a neighborhood of $\bar{\Omega}$ and $\mathbf{v}^{-1}$ is of class C^k in a neighborhood of $\bar{\Lambda}$ by $Diff^k(\bar{\Omega}, \bar{\Lambda})$.

• We define $\mathcal{U}_o$ to be the set of all continuous maps $\mathbf{u}$ from $\bar{\Omega}$ onto $\bar{\Lambda}$ that are in $C^1(\Omega)^d$, such that $\det D\mathbf{u} > 0$, $\mathbf{u}$, and $\mathbf{u}_o$ coincide on $\partial\Omega$. $\mathcal{U}_\Lambda$ is the set of all orientation-preserving maps $\mathbf{u} \in C^1(\Omega)^d$ that are homeomorphisms from $\bar{\Omega}$ onto $\bar{\Lambda}$. $\mathcal{U}'_\Lambda$ is the set of all maps $\mathbf{u}$ from Ω onto Λ that are one-to-one almost everywhere and such that $|\det D\mathbf{u}| \neq 0$ almost everywhere in the weak sense.

• We define $\mathcal{A}$ to be the set of all pairs of functions (ψ, ϕ) such that $\psi : \mathbf{R}^d \to \mathbf{R} \cup \{+\infty\}$, $\phi : conv(\Lambda) \to \mathbf{R} \cup \{+\infty\}$ are lower semicontinuous, not identically $+\infty$, and $\psi(\mathbf{z}) + \alpha\phi(\mathbf{y}) + h(\alpha) \geq \mathbf{y} \cdot \mathbf{z}$ for all $\mathbf{y} \in conv(\Lambda)$, $\mathbf{z} \in \mathbf{R}^d$, and all $\alpha > 0$.

We recall definitions needed in that which follows.

DEFINITION 1.1. *Let $A, B \subset \mathbf{R}^d$. We say that $\mathbf{v} : A \to B$ is* one-to-one almost everywhere *from A onto B (with respect to the d-dimensional Lebesgue measure) if $|B \setminus \mathbf{v}(A)| = 0$, if there exists a set $N \subset A$ such that $|N| = 0$, and if the restriction of $\mathbf{v}$ to $A \setminus N$ is one-to-one. By abuse of language we omit the expression "with respect to the d-dimensional Lebesgue measure."*

DEFINITION 1.2. *Let $A, B \subset \mathbf{R}^d$. We say that a Borel map $\mathbf{v} : A \to B$ is* nondegenerate *if $|\mathbf{v}^{-1}(N)| = 0$ whenever $|N| = 0$. We say that $\mathbf{v}$ is $(d-1)$-*nondegenerate *if $|\mathbf{v}^{-1}(N)| = 0$ whenever N is $(d-1)$-rectifiable.*

Recall that $N \subset \mathbf{R}^d$ is $(d-1)$-rectifiable if N is a countable union of $(d-1)$-hypersurfaces of class C^1, union a set of zero $(d-1)$-dimensional Hausdorff measure.

DEFINITION 1.3. *Let $A, B \subset \mathbf{R}^d$, and let $\beta_o \in L^1(A)$, $\beta_1 \in L^1(B)$ be nonnegative functions. Let $\mathbf{v} : A \to B$ be a* one-to-one almost everywhere *Borel map from A onto B. We say that $\beta_1(\mathbf{v}(\mathbf{x}))|\det D\mathbf{v}(\mathbf{x})| = \beta_o(\mathbf{x})$ in A* in the weak sense *if*

$$\int_A \varphi(\mathbf{v}(\mathbf{x}))\beta_o(\mathbf{x})d\mathbf{x} = \int_B \varphi(\mathbf{y})\beta_1(\mathbf{y})d\mathbf{y}$$

for all $\varphi \in C_o(\mathbf{R}^d)$.

Remark 1.4. Note that if $\mathbf{v}$ is *one-to-one almost everywhere*, and if $|\mathbf{v}^{-1}[C]| = |C|$ for every Borel set C, then $|\det D\mathbf{v}| = 1$ *in the weak sense* although $D\mathbf{v}$ may not exist.

DEFINITION 1.5. *Let μ and ν be two Borel measures on $\mathbf{R}^d$. We say that the Borel map $\mathbf{v} : \mathbf{R}^d \to \mathbf{R}^d$ pushes μ forward to ν and we write $\mathbf{v}\sharp\mu = \nu$ if $\mu[\mathbf{v}^{-1}(B)] = \nu[B]$ for all Borel sets $B \subset \mathbf{R}^d$.*

DEFINITION 1.6. *If ϕ and ψ are two real valued functions of subsets of $\mathbf{R}^d$ into $\mathbf{R} \cup \{+\infty\}$, then we define $\phi^\sharp$ and $\psi_\sharp$ to be the following convex functions of $\mathbf{R}^d$ into $\mathbf{R} \cup \{+\infty\}$:*

$$\phi^\sharp(\mathbf{z}) := \sup_{\mathbf{y} \in conv(\Lambda)} \{\mathbf{y} \cdot \mathbf{z} + h^*(-\phi(\mathbf{y}))\} \quad \text{and} \quad \psi_\sharp(\mathbf{y}) := \sup_{\alpha > 0} \left\{ \frac{\psi^*(\mathbf{y}) - h(\alpha)}{\alpha} \right\}.$$

2. An auxiliary variational problem: Duality. Throughout this section we assume that $\Lambda \subset \mathbf{R}^d$ is an open bounded set whose closure is contained in the closed ball B_{R_o} of center 0 and radius R_o. We assume that h satisfies (3), (4), (5) and μ is a finite positive measure on $\mathbf{R}^d$ of finite moments $M_o(\mu)$ and $M_1(\mu)$, where

$$M_o(\mu) := \mu[\mathbf{R}^d] < +\infty, \quad M_1(\mu) := \int_{\mathbf{R}^d} |\mathbf{z}| d\mu(\mathbf{z}) < +\infty. \tag{20}$$

We define

$$J_\mu[\psi, \phi] := \int_{\mathbf{R}^d} \psi(\mathbf{z})d\mu(\mathbf{z}) + \int_\Lambda \phi(\mathbf{y})d\mathbf{y}$$

and

$$\bar{I}[\gamma] := \int_C (\mathbf{y} \cdot \mathbf{z} - h(\alpha))d\gamma(\alpha, \mathbf{y}, \mathbf{z}),$$

where C is the set $(0, \infty) \times \mathbf{R}^d \times \mathbf{R}^d$. Let $\Gamma[\mu]$ be the set of all Borel measures on C such that

$$\int_C f(\mathbf{z})d\gamma(\alpha, \mathbf{y}, \mathbf{z}) = \int_{\mathbf{R}^d} f(\mathbf{z})d\mu(\mathbf{z})$$

and

$$\int_C \alpha f(\mathbf{y})d\gamma(\alpha, \mathbf{y}, \mathbf{z}) = \int_\Lambda f(\mathbf{y})d\mathbf{y}$$

for all $f \in C_o(\mathbf{R}^d)$. Observe that for every $(\psi, \phi) \in \mathcal{A}$ and every $\gamma \in \Gamma(\mu)$ we have that

$$J_\mu[\psi, \phi] = \int_C (\psi(\mathbf{z}) + \alpha\phi(\mathbf{y}))d\gamma \geq \int_C (\mathbf{y} \cdot \mathbf{z} - h(\alpha))d\gamma = \bar{I}[\gamma],$$

and so

$$\sup_{\Gamma(\mu)} \bar{I}[\gamma] \leq \inf_{\mathcal{A}} J_\mu[\psi, \phi]. \tag{21}$$

We establish the reverse inequality in this section.

Remark 2.1. Note that if $(\psi, \phi) \in \mathcal{A}$, then we have that

$$\psi^-(\mathbf{z}) \leq R_o|\mathbf{z}| + |h(1)| + \inf_{conv(\Lambda)} \phi^+ \tag{22}$$

for all $\mathbf{z} \in \mathbf{R}^d$ and

$$\phi^-(\mathbf{y}) \leq |\mathbf{y}||\mathbf{z}| + |h(1)| + \psi^+(\mathbf{z}) \tag{23}$$

for all $\mathbf{y} \in \text{conv}\,(\Lambda)$, $\mathbf{z} \in \mathbf{R}^d$. Combining (20), (22), and (23) we deduce that both $\int_{\mathbf{R}^d} \psi(\mathbf{z}) d\mu(\mathbf{z})$, $\int_\Lambda \phi(\mathbf{y}) d\mathbf{y}$ exist although they may be $+\infty$ and $J_\mu[\psi, \phi]$ is well-defined.

LEMMA 2.2. *The set $\mathcal{A}$ contains at least an element (ψ, ϕ). Also, there exists a constant c_a depending only on h, Λ, $M_o[\mu]$ such that*

(i) $|\inf_{\mathcal{A}} J_\mu| \leq c_a(1 + M_1[\mu])$;

(ii) *if ψ, ϕ are convex and $|J_\mu[\psi, \phi] - \inf_{\mathcal{A}} J_\mu| \leq 1$, then*

$$\int_\Lambda |\phi(\mathbf{y})| d\mathbf{y} \text{ and } \int_{\mathbf{R}^d} |\psi(\mathbf{z})| d\mu(\mathbf{z}) \leq c_a(1 + M_1[\mu]);$$

(iii) *if in addition $Lip(\psi) \leq R_o$, then we have that*

$$\psi(\mathbf{z}) \leq R_o|\mathbf{z}| + RR_o + \frac{c_a}{\mu[B_R]}(1 + M_1[\mu]) \qquad (\mathbf{z} \in \mathbf{R}^d).$$

Proof. Step 1. The set $\mathcal{A}$ is nonempty since it contains (ψ_o, ϕ_o), where $\phi_o(\mathbf{y}) := 1$ on $\text{conv}\,(\Lambda)$, $\psi_o(\mathbf{z}) := R_o|\mathbf{z}| - c$ on $\mathbf{R}^d$, and $c := \inf_{\alpha>0}\{h(\alpha) + \alpha\}$. We deduce that

$$\inf_{\mathcal{A}} J_\mu \leq J_\mu[\psi_o, \phi_o] \leq |\Lambda| + R_o M_1[\mu] - cM_o[\mu]. \tag{24}$$

If $(\psi, \phi) \in \mathcal{A}$, then

$$J_\mu[\psi, \phi] \geq -(\alpha\phi(\mathbf{y}_o) + h(\alpha))M_o[\mu] - R_o M_1[\mu] + \int_\Lambda \phi(\mathbf{y}) d\mathbf{y} \tag{25}$$

for all $\alpha > 0$ and all $\mathbf{y}_o \in \Lambda$. Setting $\alpha := |\Lambda|/M_o[\mu]$ in (25) and using (24) we have that

$$|\inf_{\mathcal{A}} J_\mu| \leq c_1, \tag{26}$$

where $c_1 := |\Lambda| + R_o M_1[\mu] + h(|\Lambda|/M_o[\mu])M_o[\mu]$.

Step 2. Let $(\psi, \phi) \in \mathcal{A}$ be such that $|J_\mu[\psi, \phi] - \inf_{\mathcal{A}} J_\mu| \leq 1$. In light of (25) we have that

$$\int_\Lambda \phi(\mathbf{y}) d\mathbf{y} \leq 1 + \inf_{\mathcal{A}} J_\mu + (\alpha\phi(\mathbf{y}_o) + h(\alpha))M_o[\mu] + R_o M_1[\mu] \tag{27}$$

for all $\alpha > 0$ and all $\mathbf{y}_o \in \Lambda$. Choosing α and $\mathbf{y}_o$ appropriately in (27) we have that

$$\left| \int_\Lambda \phi(\mathbf{y}) d\mathbf{y} \right| \leq c_2(1 + M_1[\mu]), \tag{28}$$

where c_2 is a constant depending only on h, Λ, $M_o[\mu]$. Combining (26) and (28) we deduce that there exists a constant c_3 depending only on h, Λ, and $M_o[\mu]$ such that

$$\left|\int_\Lambda \phi(\mathbf{y})d\mathbf{y}\right|, \quad \left|\int_{\mathbf{R}^d} \psi(\mathbf{z})d\mu(\mathbf{z})\right| \le c_3(1+M_1[\mu]). \tag{29}$$

Step 3. Assume that $(\psi,\phi)\in\mathcal{A}$, ϕ is convex on $conv(\Lambda)$, ψ is convex on $\mathbf{R}^d$, and $|J_\mu[\psi,\phi]-\inf_{\mathcal{A}} J_\mu|\le 1$. In light of (29) there exists $\mathbf{z}_o\in\mathbf{R}^d$ such that

$$|\psi(\mathbf{z}_o)|\le c_3(1+M_1[\mu])/\mu[\mathbf{R}^d]. \tag{30}$$

Integrating (23) over $\mathbf{R}^d$ we have that

$$M_o[\mu]\phi^-(\mathbf{y})\le|\mathbf{y}|M_1[\mu]+|h(1)|M_o[\mu]+\int_{\mathbf{R}^d}\psi^+(\mathbf{z})d\mu(\mathbf{z}) \tag{31}$$

for all $\mathbf{y}\in conv(\Lambda)$. Either $\inf_{conv(\Lambda)}\phi^+>0$, in which case

$$\phi^-\equiv 0 \qquad \text{on } conv(\Lambda), \tag{32}$$

or $\inf_{conv(\Lambda)}\phi^+=0$, in which case (22) and (29) imply that there exists a constant c_4 depending only on h, Λ, and $M_o[\mu]$ such that

$$\int_{\mathbf{R}^d}|\psi(\mathbf{z})|d\mu(\mathbf{z})\le c_4(1+M_1[\mu]),$$

which, combined with (31), yields

$$M_o[\mu]\phi^-(\mathbf{y})\le|\mathbf{y}|M_1[\mu]+|h(1)|M_o[\mu]+c_4(1+M_1[\mu]) \tag{33}$$

for all $\mathbf{y}\in conv(\Lambda)$. Using (32) and (33) we deduce that in any case, there exists a constant c_5 depending only on h, Λ, and $M_o[\mu]$ such that

$$\phi^-(\mathbf{y})\le c_5(1+M_1[\mu]) \tag{34}$$

for all $\mathbf{y}\in conv(\Lambda)$. In light of (29) and (34) we have that there exists a constant c_6 depending only on h, Λ, and $M_o[\mu]$ such that

$$\int_\Lambda|\phi(\mathbf{y})|d\mathbf{y}\le c_6(1+M_1[\mu]). \tag{35}$$

Since ϕ is convex, (35) implies that for each $K\subset\Lambda$ compact set, there exists a constant c_K depending only on h, Λ, $M_o[\mu]$, and K such that (see [13, p. 236])

$$|\phi|_{L^\infty(K)}+|D\phi|_{L^\infty(K)}\le c_K(1+M_1[\mu]). \tag{36}$$

Now, (22) and (36) imply that there exists a constant c_7 depending only on h, Λ, and $M_o[\mu]$ such that

$$\psi^-(\mathbf{z})\le R_o|\mathbf{z}|+c_7(1+M_1[\mu]) \tag{37}$$

for all $\mathbf{z}\in\mathbf{R}^d$. By (29) and (37) we have that there exists a constant c_8 depending only on h, Λ, and $M_o[\mu]$ such that

$$\int_{\mathbf{R}^d}|\psi(\mathbf{z})|d\mu(\mathbf{z})\le c_8(1+M_1[\mu]). \tag{38}$$

This concludes the proof of (ii).

Step 4. By (38),

$$\mu[B_R] \inf_{B_R} |\psi| \le c_8(1 + M_1[\mu]),$$

and so, if in addition $Lip(\psi) \le R_o$, we readily obtain (iii). This concludes the proof of the lemma. □

PROPOSITION 2.3. *Suppose that μ satisfies* (20) *such that (μ_n) is a sequence of Borel measures, that $M_o[\mu_n] = M_o[\mu]$ $(n = 1, 2, \ldots)$, that (μ_n) converges weak $*$ to μ, and that $(M_1[\mu_n])$ converges to $M_1[\mu]$. Then the following hold:*

(i) *There exists $(\psi_\mu, \phi_\mu) \in \mathcal{A}$ minimizing J_μ over $\mathcal{A}$, and*

$$\inf_{\mathcal{A}} J_\mu \le \liminf_{n \to +\infty} (\inf_{\mathcal{A}} J_{\mu_n}).$$

(ii) *We have that* $\limsup_{n \to +\infty} (\sup_{\Gamma(\mu_n)} \bar{I}) \le \sup_{\Gamma(\mu)} \bar{I}$.

(iii) *If $\sup_{\Gamma(\mu)} \bar{I} \ne -\infty$, then there exists $\gamma_\mu \in \Gamma(\mu)$ maximizing $\bar{I}$ over $\Gamma(\mu)$.*

Proof. Step 1. We shall show in Step 5 that (i) is a direct consequence of the following statement: If $(f_n, g_n) \in \mathcal{A}$ is such that $|\inf_{\mathcal{A}} J_{\mu_n} - J_{\mu_n}(f_n, g_n)| \le 1/n$, then there exists $(\psi_\mu, \phi_\mu) \in \mathcal{A}$ such that

$$J_\mu(\psi_\mu, \phi_\mu) \le \liminf_{n \to +\infty} J_{\mu_n}(f_n, g_n) \qquad (n = 1, 2, \ldots). \tag{39}$$

To proceed, let $R_1 > 0$ be such that

$$\mu[\mathrm{int}(B_{R_1})] > 1/2\mu[\mathbf{R}^d]. \tag{40}$$

Note that since (μ_n) converges weak $*$ to μ, in light of (40) we may assume without loss of generality that (see [13, p. 59])

$$\mu_n[\mathrm{int}(B_{R_1})] > 1/2M_o[\mu] = 1/2M_o[\mu_n] \tag{41}$$

for all $n = 1, 2, \ldots$. Define

$$\phi_n := (f_n)_\sharp, \qquad \psi_n := (\phi_n)^\sharp.$$

By Lemma A.1 (ii)–(iii) ψ_n and ϕ_n are convex functions, $\psi_n \le f_n$, $\phi_n \le g_n$, and

$$Lip(\psi_n) \le R_o; \tag{42}$$

hence

$$J_{\mu_n}(\psi_n, \phi_n) \le J_{\mu_n}(f_n, g_n) \tag{43}$$

for all $n = 1, 2, \ldots$. Since in addition $|\inf_{\mathcal{A}} J_{\mu_n} - J_{\mu_n}(\psi_n, \phi_n)| \le 1/n$, by Lemma 2.2 and (41) there exists a constant $\bar{c} > 0$ independent of n such that

$$\int_\Lambda |\phi_n(\mathbf{y})| d\mathbf{y} \le \bar{c} \tag{44}$$

and

$$|\psi_n(\mathbf{z})| \le R_o|\mathbf{z}| + \bar{c} \qquad (\mathbf{z} \in \mathbf{R}^d). \tag{45}$$

Using (45) we deduce that the sequence (ψ_n) is bounded in $W^{1,\infty}(B_{R'})$ for every $R' > 0$. Since ψ_n is convex, we may find a subsequence of (ψ_n) that we still label (ψ_n), converging in $L^\infty_{loc}(\mathbf{R}^d)$ to a convex function $\psi_\mu : \mathbf{R}^d \to \mathbf{R}$. One can readily check the following claims.

Step 2. Claim. We have that

$$\limsup_{n\to+\infty} \int_{B_R^c} (R_o|\mathbf{z}| + \bar{c}) d\mu_n(\mathbf{z}) \leq \int_{B_{R-2}^c} (R_o|\mathbf{z}| + \bar{c}) d\mu(\mathbf{z})$$

for all $R > 2$.

Step 3. Claim. We have that $\lim_{n\to+\infty} \int_{\mathbf{R}^d} |\psi_n - \psi_\mu| d\mu_n = 0$.

We next prove the following.

Step 4. Claim. We have that $\liminf_{n\to+\infty} \int_{\mathbf{R}^d} \psi_\mu d\mu_n \geq \int_{\mathbf{R}^d} \psi_\mu d\mu$.

Proof: For $R > 1$ let $l_R : \mathbf{R} \to [0,1]$ be of class C^∞ such that

$$l_R(t) = \begin{cases} 1 & \text{if} \quad |t| \leq R-1, \\ 0 & \text{if} \quad |t| \geq R. \end{cases} \tag{46}$$

We have that

$$\chi_{B_R^c} \leq 1 - l_R(|\mathbf{z}|) \leq \chi_{B_{R-2}^c}. \tag{47}$$

Because (μ_n) converges weak $*$ to μ and $(M_1[\mu_n])$ converges to $M_1[\mu]$, using (45) and (47) we have that

$$\begin{aligned} \liminf_{n\to+\infty} \int_{\mathbf{R}^d} \psi_\mu d\mu_n &\geq \int_{\mathbf{R}^d} \psi_\mu l_R d\mu - \int_{\mathbf{R}^d} (R_o|\mathbf{z}| + \bar{c})(1 - l_R(|\mathbf{z}|)) d\mu \\ &\geq \int_{\mathbf{R}^d} \psi_\mu l_R d\mu - \int_{B_{R-2}^c} (R_o|\mathbf{z}| + \bar{c}) d\mu. \end{aligned} \tag{48}$$

Letting R go to $+\infty$ in (48) we conclude the proof of Claim 4.

Now, combining Claims 3 and 4 we have that

$$\int_{\mathbf{R}^d} \psi_\mu d\mu \leq \liminf_{n\to+\infty} \int_{\mathbf{R}^d} \psi_n d\mu_n. \tag{49}$$

Similarly, since ϕ_n is convex (44) implies that there exists a convex function $\phi_\mu : conv(\Lambda) \to \mathbf{R} \cup \{+\infty\}$ such that up to a subsequence, (ϕ_n) converges pointwise to ϕ_μ in Λ and

$$\int_\Lambda \phi_\mu d\mathbf{y} \leq \liminf_{n\to+\infty} \int_\Lambda \phi_n d\mathbf{y}. \tag{50}$$

Because $(\psi_n, \phi_n) \in \mathcal{A}$, we obtain that $(\psi_\mu, \phi_\mu) \in \mathcal{A}$. Thanks to (43), (49), and (50) we have that

$$\inf_{\mathcal{A}} J_\mu \leq J_\mu(\psi_\mu, \phi_\mu) \leq \liminf_{n\to+\infty} J_{\mu_n}(f_n, g_n), \tag{51}$$

which proves (39).

Step 5. Taking $\mu_n \equiv \mu$ for all n in (51) we have that there exists $(\psi_\mu, \phi_\mu) \in \mathcal{A}$ minimizing J_μ over $\mathcal{A}$. Next, assuming (f_n, g_n) minimizes J_{μ_n} over $\mathcal{A}$, (51) implies that $\inf_{\mathcal{A}} J_\mu \leq \liminf_{n\to+\infty} (\inf_{\mathcal{A}} J_{\mu_n})$ which completes the proof of (i).

If $\limsup_{n\to+\infty}(\sup_{\Gamma(\mu_n)})\bar{I} = -\infty$, then (ii) is straightforward to obtain.

Step 6. Now we prove (ii). If $\limsup_{n\to+\infty}(\sup_{\Gamma(\mu_n)})\bar{I} = -\infty$, then (ii) is straightforward to obtain. Therefore we may assume without loss of generality that

$$\limsup_{n\to+\infty}(\sup_{\Gamma(\mu_n)}\bar{I}) > -\infty.$$

Note first that since by (21) $\sup_{\Gamma(\mu_n)}\bar{I} \leq \inf_{\mathcal{A}} J_{\mu_n}$, using the fact that $(M_1[\mu_n])$ converges to $M_1[\mu]$, and Lemma 2.2 (i) we have that $\limsup_{n\to+\infty}(\sup_{\Gamma(\mu_n)}\bar{I}) < +\infty$. Let (n_j) be such that

$$\limsup_{n\to+\infty}(\sup_{\Gamma(\mu_n)}\bar{I}) = \lim_{j\to+\infty}(\sup_{\Gamma(\mu_{n_j})}\bar{I}).$$

Choose e_1 a real number independent of j, smaller than $\sup_{\Gamma(\mu_{n_j})}\bar{I}$ for all $j \in \mathbf{N}$ and let $\gamma_{n_j} \in \Gamma(\mu_{n_j})$ be such that

$$\sup_{\Gamma(\mu_{n_j})}\bar{I} \leq \bar{I}[\gamma_{n_j}] + 1/n_j.$$

One can readily check that $\int_C h(\alpha)d\gamma_{n_j}$ is less than or equal to $R_o M_1[\mu_{n_j}] + 1 - e_1$, and so there exists a constant e_2 independent of j such that

$$\int_C |h(\alpha)|d\gamma_{n_j} \leq e_2 \tag{52}$$

for all $j \in \mathbf{N}$. By Proposition B.1, (52) implies that there exists a subsequence of (n_j) that we still label (n_j) and a Borel measure $\gamma \in \Gamma(\mu)$ such that (γ_{n_j}) converges weak $*$ to γ. Because h satisfies (4), $\bar{\Lambda}$ is contained in B_{R_o} and $\gamma_{n_j}[(0,+\infty)\times\Lambda^c\times\mathbf{R}^d] = 0$ we deduce that there exists a constant e_3 such that $m_R : (\alpha,\mathbf{y},\mathbf{z}) \to h(\alpha) - \mathbf{y}\cdot\mathbf{z} - e_3 + R_o|\mathbf{z}|$ is nonnegative for γ_{n_j}-almost every $(\alpha,\mathbf{y},\mathbf{z}) \in C$. Hence, if we define $k_R : (\alpha,\mathbf{y},\mathbf{z}) \to l_R(\alpha + |\mathbf{y}| + |\mathbf{z}|)$, then

$$\begin{aligned}\lim_{j\to+\infty}\int_C m_R d\gamma_{n_j} &\geq \lim_{j\to+\infty}\int_C m_R k_R d\gamma_{n_j}\\ &= \int_C m_R k_R d\gamma.\end{aligned} \tag{53}$$

Consequently,

$$\lim_{j\to+\infty}\int_C (h(\alpha) - \mathbf{y}\cdot\mathbf{z})d\gamma_{n_j} + R_o M_1[\mu_{n_j}] \geq \int_C (h(\alpha) - \mathbf{y}\cdot\mathbf{z})k_R d\gamma + R_o M_1[\mu]. \tag{54}$$

Letting R go to $+\infty$ in (54), using that $(M_1[\mu_{n_j}])$ converges to $M_1[\mu]$ we obtain that

$$\limsup_{n\to+\infty}(\sup_{\Gamma(\mu_n)}\bar{I}) \leq \bar{I}[\gamma] \leq \sup_{\Gamma(\mu)}\bar{I} \tag{55}$$

and conclude the proof of (ii).

Step 7. Setting $\mu_n = \mu$ for all $n \in \mathbf{N}$ in (55) we obtain (iii). □

THEOREM 2.1 (duality). *Suppose that h satisfies* (3), (4), (5) *and that μ satisfies* (20). *Then the following hold:*

(i) *There exists a pair (ψ_μ, ϕ_μ) of convex functions minimizing J_μ over $\mathcal{A}$ such that $(\psi_\mu)_\sharp = \phi_\mu$ and $(\phi_\mu)^\sharp = \psi_\mu$ and $Lip(\psi_\mu) \le R_o$.*

(ii) *The duality relation $\sup_{\Gamma(\mu)} \bar{I} = \inf_{\mathcal{A}} J_\mu$ holds. Defining on C the measure γ by*

$$\int_C g d\gamma = \int_\Lambda \frac{1}{\beta_\mu(\mathbf{y})} g(\beta_\mu(\mathbf{y}), \mathbf{y}, D\psi_\mu^*(\mathbf{y})) d\mathbf{y}$$

for all $g \in C_o(\mathbf{R} \times \mathbf{R}^d \times \mathbf{R}^d)$, we have that γ is the unique maximizer of $\bar{I}$ over $\Gamma(\mu)$. Here $\beta_\mu : \Lambda \to (0, +\infty)$ is a Borel map such that $\beta_\mu(\mathbf{y})(\psi_\mu)_\sharp(\mathbf{y}) + \psi_\mu(D\psi_\mu^*(\mathbf{y})) = \mathbf{y} \cdot D\psi_\mu^*(\mathbf{y}) - h(\beta_\mu(\mathbf{y}))$ for almost every $\mathbf{y} \in \Lambda$.

(iii) *If we assume in addition that $\mu[N] = 0$ for every $(d-1)$-rectifiable subset N of $\mathbf{R}^d$, then γ is of the form $\gamma = \gamma^{D\psi}$, i.e., γ can be parametrized on $(\mathbf{R}^d, \mu)$:*

$$\int_C g d\gamma = \int_{\mathbf{R}^d} g(\beta_\mu(D\psi_\mu(\mathbf{z})), D\psi_\mu(\mathbf{z}), \mathbf{z}) d\mu(\mathbf{z})$$

for all $g \in C_o(\mathbf{R} \times \mathbf{R}^d \times \mathbf{R}^d)$.

Proof. By Proposition 2.3 there exists a pair (ψ_μ, ϕ_μ) minimizing J over $\mathcal{A}$. By Lemma A.1 (iii)–(iv) the pairs $(\psi_\mu, (\psi_\mu)_\sharp)$ and $(((\psi_\mu)_\sharp)^\sharp, (\psi_\mu)_\sharp)$ minimize J over $\mathcal{A}$ and $(((\psi_\mu)_\sharp)^\sharp)_\sharp = (\psi_\mu)_\sharp$. Hence, we may assume without loss of generality that ψ_μ, ϕ_μ are convex, $(\psi_\mu)_\sharp = \phi_\mu$, and $(\phi_\mu)^\sharp = \psi_\mu$, and so

$$Lip(\psi_\mu) \le R_o \tag{56}$$

(see Lemma A.1). This concludes the proof of (i).

Step 1. We first give the proof of (ii) in the special case when there exists $R > 0$ such that the support of μ is contained in B_R and $\mu[N] = 0$ for every $(d-1)$-rectifiable subset N of $\mathbf{R}^d$.

Step 2. For $G \in C_o(\mathbf{R}^d)$ and $r > 0$ define

$$\psi_r(\mathbf{z}) := \begin{cases} \psi_\mu(\mathbf{z}) + rG(\mathbf{z}) & \text{if} \quad \mathbf{z} \in B_R, \\ +\infty & \text{if} \quad \mathbf{z} \notin B_R \end{cases}$$

and

$$\phi_r := (\psi_r)_\sharp.$$

We have that ψ_r^* is finite at every point of $\mathbf{R}^d$ and so $D\psi_r^*$ exists except on a $(d-1)$-rectifiable set (see [1]). Hence, $S_r := D\psi_r^* : \Lambda \to B_R$ is well-defined μ-almost everywhere. In light of Lemma A.1 let $\beta_r : \Lambda \to (0, +\infty)$ be the unique Borel function such that

$$\beta_r(\mathbf{y})\phi_r(\mathbf{y}) + \psi_r(S_r(\mathbf{y})) = \mathbf{y} \cdot S_r(\mathbf{y}) - h(\beta_r(\mathbf{y})). \tag{57}$$

Note that β_r is well-defined μ-almost everywhere. By (56) $|\psi_r|_{L^\infty(B_R)}$ is bounded independently of $|r| \le 1$ and so Lemma A.1 implies

$$c \le \beta_r(\mathbf{y}) \le 1/c \tag{58}$$

for all $\mathbf{y} \in \Lambda$ and for some constant $c > 0$ independent of r. Observe that (57) implies

$$-\frac{r}{\beta_o(\mathbf{y})} G(S_o(\mathbf{y})) \leq \phi_r(\mathbf{y}) - \phi_o(\mathbf{y}) \leq -\frac{r}{\beta_r(\mathbf{y})} G(S_r(\mathbf{y})) \tag{59}$$

for all $\mathbf{y} \in \Lambda$. This, together with (58), yields

$$|\phi_r(\mathbf{y}) - \phi_o(\mathbf{y})| \leq \frac{r}{c} |G|_{L^\infty(\mathbf{R}^d)} \tag{60}$$

for all $\mathbf{y} \in \Lambda$.

Step 3. Claim. Whenever $S_o(\mathbf{y})$ exists we have that $(\phi_r(\mathbf{y}) - \phi_o(\mathbf{y}))/r$ tends to $-G(S_o(\mathbf{y}))/\beta_o(\mathbf{y})$ as r tends to 0.

Proof. Fix $\mathbf{y}$ such that $S_o(\mathbf{y})$ exists and assume that $(r_j) \subset (0, +\infty)$ is a sequence converging to 0,

$$S_{r_j}(\mathbf{y}) \to \mathbf{z}_o, \qquad \beta_{r_j}(\mathbf{y}) \to \alpha_o, \tag{61}$$

as j tends to $+\infty$. Since (ψ_r) converges uniformly to ψ_o on B_R and by (60) (ϕ_r) converges uniformly to ϕ_o on Λ, (57) implies that

$$\alpha_o \phi_o(\mathbf{y}) + \psi_o(\mathbf{z}_o) = \mathbf{y} \cdot \mathbf{z}_o - h(\alpha_o). \tag{62}$$

Since $S_o(\mathbf{y}) = D\psi_o^*(\mathbf{y})$ exists, (62) and Lemma A.1 imply

$$\alpha_o = \beta_o(\mathbf{y}) \quad \text{and} \quad \mathbf{z}_o = S_o(\mathbf{y}).$$

Because $(r_j) \subset (0, +\infty)$ is arbitrary we deduce that $(S_r(\mathbf{y}))$ converges to $S_o(\mathbf{y})$ and $(\beta_r(\mathbf{y}))$ converges to $\beta_o(\mathbf{y})$ as r tends to 0. This together with (59) yields Claim 3.

Step 4. Claim. S_o pushes $d\mathbf{y}/\beta_o(\mathbf{y})$ forward to μ.

Proof. Note that $J_\mu[\psi_o, \phi_o] = J_\mu[\psi_\mu, \phi_\mu]$ and so (ψ_o, ϕ_o) also minimizes J_μ over $\mathcal{A}$. This combined with Claim 3 implies

$$0 = \lim_{r \to 0} \frac{J_\mu[\psi_r, \phi_r] - J_\mu[\psi_o, \phi_o]}{r} = \int_{\mathbf{R}^d} G d\mu - \int_\Lambda \frac{G \circ S_o}{\beta_o} d\mathbf{y}. \tag{63}$$

Since G is arbitrary in (63), we conclude Claim 4.

Step 5. Using (57) and Claim 4 we have that

$$\begin{aligned} J_\mu[\psi_o, \phi_o] = \int_\Lambda \frac{\psi_o \circ S_o + \beta_o \phi_o}{\beta_o} d\mathbf{y} &= \int_\Lambda \frac{\mathbf{y} \cdot S_o(\mathbf{y}) - h(\beta_o(\mathbf{y}))}{\beta_o(\mathbf{y})} d\mathbf{y} \\ &= \int_C (\mathbf{y} \cdot \mathbf{z} - h(\alpha)) d\gamma_\mu = \bar{I}[\gamma_\mu], \end{aligned} \tag{64}$$

where we have defined the measure γ_μ by

$$\int_C g d\gamma_\mu = \int_\Lambda \frac{1}{\beta_o(\mathbf{y})} g(\beta_o(\mathbf{y}), \mathbf{y}, S_o(\mathbf{y})) d\mathbf{y}$$

for all $g \in C_o(\mathbf{R} \times \mathbf{R}^d \times \mathbf{R}^d)$. Clearly $\gamma_\mu \in \Gamma(\mu)$. Combining (21) and (64) we deduce that

$$\sup_{\Gamma(\mu)} \bar{I} = \inf_{\mathcal{A}} J_\mu. \tag{65}$$

Step 6. We complete the proof of (ii). Assume now that μ satisfies only (20). Let (μ_n) be a sequence of Borel measures on $\mathbf{R}^d$ such that $\mu_n[N] = 0$ whenever N is a $(d-1)$-rectifiable subset of $\mathbf{R}^d$, $M_o[\mu_n] = M_o[\mu]$, $spt(\mu_n)$ is bounded for all $n = 1, 2, \ldots$, and $(M_1[\mu_n])$ converges to $M_1[\mu]$ as n tends to $+\infty$. Combining Proposition 2.3 and (65) we have that

$$\inf_{\mathcal{A}} J_\mu \le \liminf_{n\to+\infty}(\inf_{\mathcal{A}} J_{\mu_n}) \le \limsup_{n\to+\infty}(\sup_{\Gamma(\mu_n)} \bar{I}) \le \sup_{\Gamma(\mu)} \bar{I}. \tag{66}$$

Combining (21) and (66) we deduce that

$$\sup_{\Gamma(\mu)} \bar{I} = \inf_{\mathcal{A}} J_\mu.$$

This proves that duality persists under the sole assumption that μ satisfies only (20). In light of Proposition 2.3 and the above duality result, if γ maximizes $\bar{I}$ over $\Gamma(\mu)$, we have that

$$\int_C (\psi_\mu(\mathbf{z}) + \alpha\phi_\mu(\mathbf{y}) + h(\alpha) - \mathbf{y}\cdot\mathbf{z}) d\gamma = 0,$$

and so

$$\psi_\mu(\mathbf{z}) + \alpha\phi_\mu(\mathbf{y}) + h(\alpha) - \mathbf{y}\cdot\mathbf{z} = 0$$

for every $(\alpha, \mathbf{y}, \mathbf{z}) \in D'$ where $D' \subset C$ is such that $\gamma[C \setminus D'] = 0$. Let A be the subset of Λ where $D\psi_\mu^*$ exists. Since $H^d[\Lambda \setminus A] = 0$ we deduce that $\gamma[C \setminus D'' = 0$ where

$$D'' := (0, +\infty) \times A \times \mathbf{R}^d.$$

In light of Lemma A.1, there exists a Borel function $\beta_\mu : \Lambda \to (0, +\infty)$ such that

$$D := D' \cap D'' \subset \{(\beta_\mu(\mathbf{y}), \mathbf{y}, D\psi_\mu^*(\mathbf{y})) \mid \mathbf{y} \in A\}. \tag{67}$$

Since $\gamma[C \setminus D] = 0$, (67) implies the representation formula

$$\int_C g d\gamma = \int_\Lambda \frac{1}{\beta_\mu(\mathbf{y})} g(\beta_\mu(\mathbf{y}), \mathbf{y}, D\psi_\mu^*(\mathbf{y})) d\mathbf{y} \tag{68}$$

for all $g \in C_o(\mathbf{R} \times \mathbf{R}^d \times \mathbf{R}^d)$, and so γ is uniquely determined. This concludes the proof of (ii).

Step 7. We complete the proof of (iii). Assume that μ satisfies (20) and $\mu[N] = 0$ whenever N is a $(d-1)$-rectifiable subset of $\mathbf{R}^d$. Since $\gamma[C]$ is finite, (68) implies that $1/\beta_\mu \in L^1(\Lambda)$. Choosing $g \equiv g(\mathbf{z})$ in (68) we obtain that $D\psi_\mu^*$ is the optimal map in the Monge problem that pushes $d\mathbf{y}/\beta_\mu(\mathbf{y})$ forward to μ, and so $D\psi_\mu^*$ is one-to-one with respect to Lebesgue measure, its inverse is $D\psi_\mu$ and is one-to-one with respect to μ (see Proposition D.1). This together with the representation formula of γ given in (ii) proves (iii). □

Remark 2.4. Note that if h satisfies (3), (4), (5) and μ is a measure whose support is contained in B_R for some $R > 0$, then by Step 1 of the proof of Theorem 2.1 we obtain that ψ_μ^* can be extended to a convex, lower semicontinuous function which is finite on $\mathbf{R}^d$. If $\beta_\mu : \Lambda \to (0, +\infty)$ is the Borel function such that $\beta_\mu(\mathbf{y})(\psi_\mu)_\sharp(\mathbf{y}) + \psi_\mu(D\psi_\mu^*(\mathbf{y})) = \mathbf{y}\cdot D\psi_\mu^*(\mathbf{y}) - h(\beta_\mu(\mathbf{y}))$ for almost every $\mathbf{y} \in \Lambda$, and ψ_μ is convex, lower semicontinuous, since $H \circ \beta_\mu = \psi_\mu^*$, we then deduce that there exists a constant $c > 0$ such that $c \le \beta_\mu \le 1/c$.

3. Existence of equilibrium configuration. Throughout this section we assume that $\Omega, \Lambda \subset \mathbf{R}^d$ are two open bounded sets whose closures are contained in the closed ball B_{R_o} of center 0 and radius R_o. We assume that h satisfies (3), (4), (5) and $\mathbf{F} \in L^1(\Omega)^d$ is a Borel map. The aim of this section is to prove that a direct consequence of section 2 is that problem

$$\inf_{(\psi,\phi)\in\mathcal{A}} J[\psi,\phi] \tag{69}$$

and problem

$$\sup_{\mathbf{u}\in\mathcal{U}'_\Lambda} I[\mathbf{u}] \tag{70}$$

are dual of each other. Here

$$I[\mathbf{u}] := \int_\Omega (\mathbf{F}\cdot\mathbf{u} - h(|\det D\mathbf{u}|))d\mathbf{x} \qquad (\mathbf{u}\in\mathcal{U}'_\Lambda),$$

and J is defined as in (14) by

$$J[\psi,\phi] := \int_\Omega \psi(\mathbf{F}(\mathbf{x}))d\mathbf{x} + \int_\Lambda \phi(\mathbf{y})d\mathbf{y}.$$

We also show that if in addition $\mathbf{F}$ is one-to-one almost everywhere and $|\mathbf{F}^{-1}(N)| = 0$ whenever N is $(d-1)$-rectifiable, then (70) admits a unique minimizer. The inequality

$$\sup_{\mathbf{u}\in\mathcal{U}'_\Lambda} I[\mathbf{u}] \le \inf_{(\psi,\phi)\in\mathcal{A}} J[\psi,\phi]$$

is straightforward. Indeed, if $\mathbf{u}\in\mathcal{U}'_\Lambda$ and $(\psi,\phi)\in\mathcal{A}$, then

$$\mathbf{F}\cdot\mathbf{u} - h(|\det D\mathbf{u}|) \le \psi\circ\mathbf{F} + |\det D\mathbf{u}|\cdot\phi\circ\mathbf{u}$$

almost everywhere in Ω, which by integration yields $I[\mathbf{u}] \le J[\psi,\phi]$. Because $\mathbf{u}\in\mathcal{U}'_\Lambda$ and $(\psi,\phi)\in\mathcal{A}$ are arbitrary we have that

$$\sup_{\mathbf{u}\in\mathcal{U}'_\Lambda} I[\mathbf{u}] \le \inf_{(\psi,\phi)\in\mathcal{A}} J[\psi,\phi]. \tag{71}$$

The task in this section is to establish the reverse inequality.

LEMMA 3.1. *Suppose that* (3), (4), *and* (5) *hold and that* $\psi_o : \mathbf{R}^d \to \mathbf{R}$ *is convex, lower semicontinuous. If* $\bar{\mathbf{u}}\in\mathcal{U}'_\Lambda$, $\mathbf{F} = D\psi_o^*\circ\bar{\mathbf{u}}$, *and* $H(|\det D\bar{\mathbf{u}}|) = (\psi_o)^*\circ\bar{\mathbf{u}}$, *then* $I[\bar{\mathbf{u}}] = J[\psi_o,(\psi_o)_\sharp]$, $\bar{\mathbf{u}}$ *is a maximizer of* I *over* $\mathcal{U}'_\Lambda$, *and the pair* $(\psi_o,(\psi_o)_\sharp)$ *minimizes* J *over* $\mathcal{A}$.

Proof. Define $\phi_o := (\psi_o)_\sharp$. Because $|\det D\bar{\mathbf{u}}| \neq 0$ almost everwhere in the weak sense, we have that $|\bar{\mathbf{u}}^{-1}[N]| = 0$ whenever $|N| = 0$. Also, since the convex functions ϕ_o and $(\psi_o)^*$ are differentiable everywhere except on a $(d-1)$-rectifiable set, we have that both ϕ_o and $(\psi_o)^*$ are differentiable at $\bar{\mathbf{u}}(\mathbf{x})$ for almost every $\mathbf{x}\in\Omega$. By Lemma A.1, for these $\mathbf{x}\in\Omega$ we may define $\alpha(\mathbf{x}) > 0$ and $\mathbf{z}(\mathbf{x}) \in \partial\psi_o^*(\bar{\mathbf{u}}(\mathbf{x}))$ such that

$$H(\alpha(\mathbf{x})) = \psi_o^*(\bar{\mathbf{u}}(\mathbf{x})) \tag{72}$$

and

$$\alpha(\mathbf{x})\phi_o(\bar{\mathbf{u}}(\mathbf{x})) + \psi_o(\mathbf{z}(\mathbf{x})) = \mathbf{z}(\mathbf{x})\cdot\bar{\mathbf{u}}(\mathbf{x}) - h(\alpha(\mathbf{x})). \tag{73}$$

We use the fact that H is decreasing, $H(|\det D\bar{\mathbf{u}}|) = \psi_o^* \circ \bar{\mathbf{u}}$, and (72) to obtain that

$$\alpha(\mathbf{x}) = |\det D\bar{\mathbf{u}}(\mathbf{x})|. \tag{74}$$

Since ψ_o^* is differentiable at $\bar{\mathbf{u}}(\mathbf{x})$ and $\mathbf{z}(\mathbf{x}) \in \partial\psi_o^*(\bar{\mathbf{u}}(\mathbf{x}))$ we deduce that

$$\mathbf{z}(\mathbf{x}) = \mathbf{F}(\mathbf{x}). \tag{75}$$

By (73), (74), and (75) we obtain that

$$|\det D\bar{\mathbf{u}}(\mathbf{x})|\phi_o(\bar{\mathbf{u}}(\mathbf{x})) + \psi_o(\mathbf{F}(\mathbf{x})) = \mathbf{F}(\mathbf{x}) \cdot \bar{\mathbf{u}}(\mathbf{x}) - h(|\det D\bar{\mathbf{u}}(\mathbf{x})|),$$

which by integration yields $I[\bar{\mathbf{u}}] = J[\psi_o, \phi_o]$. Since $(\psi_o, \phi_o) \in \mathcal{A}$ (71) implies $\bar{\mathbf{u}}$ maximizes I over $\mathcal{U}'_\Lambda$ and $(\psi_o, (\psi_o)_\sharp)$ minimizes J over $\mathcal{A}$. □

THEOREM 3.1 (main results). *Suppose that* (3), (4), *and* (5) *hold. Then we have the following.*

(i) $\inf_{\mathcal{A}} J[\psi, \phi] = \sup_{\mathcal{U}'_\Lambda} I[\mathbf{u}]$.

(ii) *If* $\mathbf{F}$ *is one-to-one almost everywhere and* $(d-1)$*-nondegenerate, then* I *admits a unique maximizer* $\bar{\mathbf{u}}$ *over* $\mathcal{U}'_\Lambda$, $\bar{\mathbf{u}} = D\psi_\mu \circ \mathbf{F}$, *and* $I[\bar{\mathbf{u}}] = J[\psi_\mu, (\psi_\mu)_\sharp]$, *and the map* $\bar{\mathbf{u}}$ *satisfies the Hamilton–Jacobi equation* $H(|\det D\bar{\mathbf{u}}|) = \psi_\mu^* \circ \bar{\mathbf{u}}$ *for some lower semicontinuous convex function* $\psi_\mu : \mathbf{R}^d \to \mathbf{R}$ *such that* $Lip(\psi_\mu) \le R_o$ *and* $\psi_\mu = ((\psi_\mu)_\sharp)^\sharp$.

(iii) *If* $\mathbf{F}$ *satisfies the assumptions in* (ii) *and in addition* $\mathbf{F} \in L^\infty(\Omega)^d$, *then there exists a constant* $c > 0$ *such that* $c \le |\det D\bar{\mathbf{u}}| \le 1/c$, *and we may extend* ψ_μ^* *into a Lipschitz, convex function in a neighborhood of* $conv(\bar{\Lambda})$.

Proof. We define on $\mathbf{R}^d$ the measure μ given by

$$\mu[A] := |\mathbf{F}^{-1}[A]|$$

for $A \subset \mathbf{R}^d$. Note that

$$J[\psi, \phi] = \int_{\mathbf{R}^d} \psi d\mu + \int_\Lambda \phi d\mathbf{y},$$

which, using the notation of section 2, is $J_\mu[\psi, \phi]$, and the following condition on the moments is satisfied:

$$M_o[\mu] = |\Omega| < +\infty, \qquad M_1[\mu] = |\mathbf{F}|_{L^1(\Omega)} < +\infty. \tag{76}$$

By Theorem 2.1 (i) there exists a pair (ψ_μ, ϕ_μ) of convex functions minimizing J_μ over $\mathcal{A}$ such that $(\psi_\mu)_\sharp = \phi_\mu$ and $(\phi_\mu)^\sharp = \psi_\mu$ and $Lip(\psi_\mu) \le R_o$.

Step 1. Assume first that $\mathbf{F}$ is one-to-one almost everywhere, $(d-1)$-nondegenerate. Note that $\mu[N] = 0$ whenever N is a $(d-1)$-rectifiable subset of $\mathbf{R}^d$. Since ψ_μ is convex, the set where ψ_μ is not differentiable is $(d-1)$-rectifiable (see [1]) and so

$$\bar{\mathbf{u}}(\mathbf{x}) := D\psi_\mu(\mathbf{F}(\mathbf{x})) \tag{77}$$

is defined for almost every $\mathbf{x} \in \Omega$. In light of Theorem 2.1 (iii) $D\psi_\mu$ is the optimal map in the Monge problem that pushes μ forward to $d\mathbf{y}/\beta_\mu(\mathbf{y})$ where $\beta_\mu : \Lambda \to (0, +\infty)$ is a Borel function such that

$$\beta_\mu(\mathbf{y})(\psi_\mu)_\sharp(\mathbf{y}) + \psi_\mu(D\psi_\mu^*(\mathbf{y})) = \mathbf{y} \cdot D\psi_\mu^*(\mathbf{y}) - h(\beta_\mu(\mathbf{y}))$$

for almost every $\mathbf{y} \in \Lambda$. Note that in light of Remark 2.4, if in addition $\mathbf{F} \in L^\infty(\Omega)^d$, then we may assume without loss of generality that ψ_μ^* is Lipschitz on $conv(\bar{\Lambda})$. We have that $D\psi_\mu$ is one-to-one on $\mathbf{R}^d$ up to a set of zero measure with respect to μ and $D\psi_\mu$ maps $\mathbf{R}^d$ onto Λ. We deduce that

(78) $\quad \bar{\mathbf{u}}$ is one-to-one up to a set of zero measure with respect to $\chi_\Omega d\mathbf{x}$.

Recall that in light of Theorem 2.1 (iii) the measure γ_μ defined on C by

$$\int_C g d\gamma_\mu = \int_{\mathbf{R}^d} g(\beta_\mu(D\psi_\mu(\mathbf{z})), D\psi_\mu(\mathbf{z}), \mathbf{z}) d\mu(\mathbf{z})$$

for all $g \in C_o(\mathbf{R} \times \mathbf{R}^d \times \mathbf{R}^d)$ maximizes $\bar{I}$ over $\Gamma(\mu)$. Therefore we have that

$$\int_\Omega f(\bar{\mathbf{u}}(\mathbf{x}))\beta_\mu(\bar{\mathbf{u}}(\mathbf{x}))d\mathbf{x} = \int_\Lambda f(\mathbf{y})d\mathbf{y}$$

for all $f \in C_o(\mathbf{R}^d)$. Consequently,

$$|\det D\bar{\mathbf{u}}| = \beta_\mu \circ \bar{\mathbf{u}}. \tag{79}$$

Using (78), (79), and the fact that $\beta_\mu > 0$ we obtain that

$$\bar{\mathbf{u}} \in \mathcal{U}'_\Lambda. \tag{80}$$

Since $\beta_\mu(\psi_\mu)_\sharp + \psi_\mu \circ D\psi_\mu^* = \mathbf{id} \cdot D\psi_\mu^* - h \circ \beta_\mu$ Lemma A.1 implies $H \circ \beta_\mu = \psi_\mu^*$, and so using (79) we obtain that

$$H(|\det D\bar{\mathbf{u}}|) = \psi_\mu^* \circ \bar{\mathbf{u}}. \tag{81}$$

By Lemma 3.1, (77), (80), and (81) we obtain that $\bar{\mathbf{u}}$ maximizes I over $\mathcal{U}'_\Lambda$ and $I[\bar{\mathbf{u}}] = J[\psi_\mu, (\psi_\mu)_\sharp]$. Therefore, we have proved (i) under the assumption that $\mathbf{F}$ is one-to-one almost everywhere, $(d-1)$-nondegenerate.

Step 2. We prove that $\bar{\mathbf{u}}$ is the unique maximizer of I over $\mathcal{U}'_\Lambda$. Indeed, if $\mathbf{u}$ is another maximizer of I over $\mathcal{U}'_\Lambda$, the duality relation between (10) and (13) implies

$$\mathbf{F}(\mathbf{x}) \cdot \mathbf{u}(\mathbf{x}) - h(|\det D\mathbf{u}(\mathbf{x})|) = \psi_\mu(\mathbf{F}(\mathbf{x})) + |\det D\mathbf{u}(\mathbf{x})|\phi_\mu(\mathbf{u}(\mathbf{x}))$$

for all almost every $\mathbf{x} \in \Omega$, and so, by Lemma A.1 (i),

$$\mathbf{u}(\mathbf{x}) \in \partial\psi_\mu(\mathbf{F}(\mathbf{x})) \tag{82}$$

for these $\mathbf{x}$. Since ψ_μ is differentiable everywhere in B_R except on a $(d-1)$-rectifiable set and $\mathbf{F}$ is $(d-1)$-nondegenerate, (82) implies $\mathbf{u}(\mathbf{x}) = D\psi_\mu(\mathbf{F}(\mathbf{x})) = \bar{\mathbf{u}}(\mathbf{x})$ for all almost every $\mathbf{x} \in \Omega$. This concludes the proof of (ii).

Step 3. If $\mathbf{F}$ satisfies the assumptions in (ii) and in addition $\mathbf{F} \in L^\infty(\Omega)^d$, then there exists $R > 0$ such that the support of μ is contained in B_R. Using Remark 2.4 and (79) we obtain (iii).

Step 4. We now prove (i) under the sole assumption that $\mathbf{F} \in L^1(\Omega)^d$. For each $n \in \mathbf{N}$ we may find $\mathbf{F}_n \in L^\infty(\Omega)^d$ that is one-to-one almost everywhere, $(d-1)$-nondegenerate, and such that

$$|\mathbf{F}_n - \mathbf{F}|_{L^1(\Omega)} \to 0$$

as n tends to $+\infty$. Define

$$J_n[\psi,\phi] := \int_{\mathbf{R}^d} \psi(\mathbf{F}_n(\mathbf{x}))d\mathbf{x} + \int_\Lambda \phi(\mathbf{y})d\mathbf{y}$$

and

$$I_n[\mathbf{u}] := \int_\Omega (\mathbf{F}_n \cdot \mathbf{u} - h(|\det D\mathbf{u}|))d\mathbf{x}.$$

By (ii) there exists $\psi_n : \mathbf{R}^d \to \mathbf{R}$ convex function such that $Lip(\psi_n) \le R_o$ and

$$J_n[\psi_n, (\psi_n)_\sharp] = \inf_{\mathcal{A}} J_n = \sup_{\mathcal{U}'_\Lambda} I_n. \tag{83}$$

Using that $Lip(\psi_n) \le R_o$ we have that

$$J_n[\psi_n, (\psi_n)_\sharp] \ge \inf_{\mathcal{A}} J - R_o|\mathbf{F}_n - \mathbf{F}|_{L^1(\Omega)} \tag{84}$$

and using that $\mathbf{u}(\Omega) \subset \Lambda \subset B_{R_o}$ for all $\mathbf{u} \in \mathcal{U}'_\Lambda$ we deduce that

$$\sup_{\mathcal{U}'_\Lambda} I_n \le \sup_{\mathcal{U}'_\Lambda} I + R_o|\mathbf{F}_n - \mathbf{F}|_{L^1(\Omega)}. \tag{85}$$

Combining (83), (84), and (85) we obtain (i). □

COROLLARY 3.2 (characterization of maximizers of I). *Suppose that* (3), (4), (5) *hold and that* $\mathbf{F} \in L^1(\Omega)^d$. *Assume that* $\bar{\mathbf{u}} \in \mathcal{U}'_\Lambda$. *Then* $\bar{\mathbf{u}}$ *maximizes* I *over* $\mathcal{U}'_\Lambda$ *if and only if there exists a lower semicontinuous convex function* $\psi_o : \mathbf{R}^d \to \mathbf{R}$ *such that* $D\psi_o^*$ *exists almost everywhere in* Λ, $\mathbf{F} = D\psi_o^* \circ \bar{\mathbf{u}}$, *and* $H(|\det D\bar{\mathbf{u}}|) = \psi_o^* \circ \bar{\mathbf{u}}$ *on* Ω.

Proof. Step 1. Assume that $\bar{\mathbf{u}}$ maximizes I over $\mathcal{U}'_\Lambda$. By Theorem 3.1 there exists a lower semicontinuous convex function $\psi_o : \mathbf{R}^d \to \mathbf{R}$ such that $I[\bar{\mathbf{u}}] = J[\psi_o, \phi_o]$ and $\psi_o = (\phi_o)^\sharp$, where $\phi_o := (\psi_o)_\sharp$. We deduce that

$$|\det D\bar{\mathbf{u}}(\mathbf{x})|\phi_o(\bar{\mathbf{u}}(\mathbf{x})) + \psi_o(\mathbf{F}(\mathbf{x})) = \mathbf{F}(\mathbf{x}) \cdot \bar{\mathbf{u}}(\mathbf{x}) - h(|\det D\bar{\mathbf{u}}(\mathbf{x})|)) \tag{86}$$

for almost every $\mathbf{x} \in \Omega$. Since ψ_o^* is differentiable at almost every $\bar{\mathbf{u}}(\mathbf{x})$, using (86) and Lemma A.1 we deduce that

$$\mathbf{F} = D\psi_o^* \circ \bar{\mathbf{u}} \tag{87}$$

and

$$H(|\det D\bar{\mathbf{u}}|) = \psi_o^* \circ \bar{\mathbf{u}}. \tag{88}$$

Step 2. The converse implication is given by Lemma 3.1, and we conclude the proof of the lemma. □

4. Smoothness of equilibrium configurations. Throughout this section, unless the contrary is explicitly stated, we assume that $\Omega, \Lambda \subset \mathbf{R}^d$ are two open bounded sets. Recall that $d \ge 2$ is an integer. We now state the main result of this section.

THEOREM 4.1 (smoothness of maximizers of I). *Assume that* Ω *is connected, its boundary* $\partial\Omega$ *is Lipschitz,* Λ *and* $\mathbf{F}(\bar{\Omega})$ *are convex. Assume that* $\mathbf{F}, \det D\mathbf{F} \in C^1(\bar{\Omega})^d$, $0 < \det D\mathbf{F}$ *on* $\bar{\Omega}$, $\mathbf{F}$ *is a homeomorphism of* $\bar{\Omega}$ *onto* $\mathbf{F}(\bar{\Omega})$. *If* h *satisfies* (3), (4), *and* (5), *then the following hold:*

(i) *Problem* $\sup_{\mathcal{A}} -J$ *and* $\inf_{\mathcal{U}_\Lambda} E$ *are dual to each other, and there exists a unique* $\bar{\mathbf{u}}$ *minimizing* E *over* $\mathcal{U}_\Lambda$.

(ii) *We have that* $\bar{\mathbf{u}} \in C^1(\Omega)^d \cap C^{0,s}(\bar{\Omega})^d$, $\det D\bar{\mathbf{u}} \in C^{0,s}(\bar{\Omega}) \cap C^1(\Omega)$ *for all* $0 < s < 1$, *and* $\det D\bar{\mathbf{u}} + 1/\det D\bar{\mathbf{u}} \in L^\infty(\Omega)$.

(iii) *Furthermore,* $\bar{\mathbf{u}}$ *satisfies the partial differential equations* (9) *in the weak sense and* (11) *pointwise.*

Proof. Step 1. To show (i), it suffices to check that the map $\bar{\mathbf{u}}$ maximizing I over $\mathcal{U}'_\Lambda$ belongs to $\mathcal{U}_\Lambda$. By Theorem 3.1 there exists a lower semicontinuous, convex function $\psi_o : \mathbf{R}^d \to \mathbf{R}$ such that $\bar{\mathbf{u}} := D\psi_o \circ \mathbf{F} \in \mathcal{U}'_\Lambda$, $H \circ |\det D\bar{\mathbf{u}}| = \psi_o^* \circ \bar{\mathbf{u}}$,

$$I[\bar{\mathbf{u}}] = J[\psi_o, (\psi_o)_\sharp], \tag{89}$$

and $D\psi_o$ pushes $f_o d\mathbf{z}$ forward to $d\mathbf{y}/\beta_o(\mathbf{y})$, where

$$f_o(\mathbf{z}) := \frac{1}{\det D\mathbf{F}(\mathbf{F}^{-1}(\mathbf{z}))} \qquad (\mathbf{z} \in \mathbf{F}(\bar{\Omega})),$$

and $\beta_o : \Lambda \to (0, +\infty)$ is defined by $\beta_o(\mathbf{y})(\psi_o)_\sharp(\mathbf{y}) + \psi_o(D\psi_o^*(\mathbf{y})) = \mathbf{y} \cdot D\psi_o^*(\mathbf{y}) - h(\beta_o(\mathbf{y}))$. By Lemma A.1 we have that

$$H \circ \beta_o = \psi_o^*. \tag{90}$$

Since $\mathbf{F}$ is bounded we may assume without loss of generality that ψ_o^* is Lipschitz on $\bar{\Lambda}$ and because the inverse H^{-1} of H is of class C^1, (90) and Proposition D.2 imply that $\beta_o \in C^1(\bar{\Lambda})$. Clearly, f_o is of class C^1, bounded below and above on $\mathbf{F}(\bar{\Omega})$. Using Proposition D.2 again, using that $D\psi_o$ pushes $f_o d\mathbf{z}$ forward to $d\mathbf{y}/\beta_o(\mathbf{y})$ and that the density functions f_o and $1/\beta_o(\mathbf{y})$ are smooth we deduce that $D\psi_o \in C^{0,s}(\mathbf{F}(\bar{\Omega}))^d \cap C^{1,s}(\mathbf{F}(\Omega))^d$ for all $0 < s < 1$. This proves (i) and (ii). Note that there exists a constant $c > 0$ such that

$$c \le \det D\bar{\mathbf{u}} \le 1/c. \tag{91}$$

Step 2. Let $\mathbf{v} \in C_o^\infty(\Omega)^d$, let K be the support of $\mathbf{v}$, and for each $|r| < 1$ define

$$\mathbf{u}_r := \bar{\mathbf{u}} + r\mathbf{v}.$$

Since $\bar{\mathbf{u}} \in C^1(K)$, $\mathbf{u}_r = \bar{\mathbf{u}}$ on $\Omega \setminus K$, and (91) holds we deduce that $(D\mathbf{u}_r)$ converges uniformly to $D\bar{\mathbf{u}}$ on Ω and there exists $r_o > 0$ such that

$$c/2 \le \det D\mathbf{u}_r(\mathbf{x}) \le 2/c \tag{92}$$

for almost every $\mathbf{x} \in \Omega$ and for every $|r| < r_o$. Thanks to Remark 4.1, since $\mathbf{u}_r \in C^1(\Omega)^d \cap C(\bar{\Omega})^d$, $\mathbf{u}_r$ and $\bar{\mathbf{u}}$ agree on $\partial\Omega$, (92) implies that $\mathbf{u}_r$ is one-to-one from $\bar{\Omega}$ onto $\bar{\mathbf{u}}(\bar{\Omega})$ and $\mathbf{u}_r \in \mathcal{U}_\Lambda$. Using that $\bar{\mathbf{u}}$ maximizes I over $\mathcal{U}_\Lambda$ we have that

$$0 = -\lim_{r\to 0}(I[\mathbf{u}_r] - I[\bar{\mathbf{u}}])/r = \lim_{r\to 0}\int_K (W(D\mathbf{u}_r) - W(D\bar{\mathbf{u}}))/r d\mathbf{x} - \int_K \mathbf{F}\cdot\mathbf{v} d\mathbf{x}. \tag{93}$$

Since $(D\mathbf{u}_r)$ converges uniformly to $D\bar{\mathbf{u}}$ on Ω, $\{AdjD\mathbf{u}_r\}_r$ and $AdjD\bar{\mathbf{u}}$ are uniformly bounded by a constant $c_1 > 0$. Now note that DW is bounded on $\{M \in \mathbf{R}^{d\times d} : c/2 \le \det M \le 2/c, |AdjM| < c_1\}$, and so (92) and (93) yield

$$0 = \int_K DW(D\bar{\mathbf{u}}) \cdot D\mathbf{v} d\mathbf{x} = \int_K \mathbf{F}\cdot\mathbf{v} d\mathbf{x}. \tag{94}$$

Since $\mathbf{v}$ is arbitrary in (94) we read off

$$-\operatorname{div}(DW(D\bar{\mathbf{u}})) = \mathbf{F} \qquad \text{in } \Omega$$

in the weak sense.

This concludes the proof of Theorem 4.1. □

Remark 4.1. If $\mathbf{u}_o \in C^1(\Omega)^d \cap C(\bar{\Omega})^d$ is one-to-one on Ω, $\det D\mathbf{u}_o$ is positive, and $\mathbf{u}_o(\Omega) := \Lambda$, then by the invariance of domain theorem the set Λ is open (see [16]). If $\mathbf{u} \in C^1(\Omega)^d \cap C(\bar{\Omega})^d$ agrees with $\mathbf{u}_o$ on $\partial\Omega$, then

$$deg(\mathbf{u}, \Omega, \mathbf{y}) = deg(\mathbf{u}_o, \Omega, \mathbf{y}) = \begin{cases} 1 & \text{if} \quad \mathbf{y} \in \Lambda, \\ 0 & \text{if} \quad \mathbf{y} \notin \bar{\Lambda}, \end{cases} \tag{95}$$

where $deg(\mathbf{u}, \Omega, \mathbf{y})$ stands for the topological degree of $\mathbf{u}$ at $\mathbf{y}$ on Ω. If in addition $\det D\mathbf{u} > 0$ in Ω, then (95) implies $\mathbf{u}$ is one-to-one and $\mathbf{u}(\Omega) = \Lambda$. Hence $\mathbf{u} \in \mathcal{U}_\Lambda$. In particular, $\mathcal{U}_o$ is a subset of $\mathcal{U}_\Lambda$ (see, for instance, [16] for properties of the topological degree theory).

COROLLARY 4.2. *Assume that* $\mathbf{u}_o \in C^1(\Omega)^d \cap C(\bar{\Omega})^d$ *is one-to-one on* $\bar{\Omega}$, $\det D\mathbf{u}_o$ *is positive and belongs to* $C^1(\Omega)$, $\det D\mathbf{u}_o + 1/\det D\mathbf{u}_o \in L^\infty(\Omega)$, *and* $\mathbf{u}_o(\Omega) = \Lambda$. *Under the assumptions of Theorem* 4.1 *the infima in* (7) *and* (8) *coincide.*

Proof. Thanks to Remark 4.1 we have that $\inf_{\mathcal{U}_\Lambda} E \le \inf_{\mathcal{U}_o} E$. To conclude the proof of the corollary it suffices to show the reverse inequality. Let $\bar{\mathbf{u}}$ be the minimizer of E over $\mathcal{U}_\Lambda$. By Proposition C.1 there exists a sequence $(\mathbf{u}_n) \subset \mathcal{U}_o$ such that $||\mathbf{u}_n - \bar{\mathbf{u}}||_1 ||\mathbf{F}||_\infty \le 1/n$ and

$$\det D\mathbf{u}_n = \det D\bar{\mathbf{u}} \qquad \text{almost everywhere in } \Omega$$

for each $n = 1, 2, \ldots$. We have that

$$E[\mathbf{u}_n] = E[\bar{\mathbf{u}}] + \int_\Omega \mathbf{F} \cdot (\bar{\mathbf{u}} - \mathbf{u}_n) d\mathbf{x} \le \inf_{\mathcal{U}_\Lambda} E + 1/n.$$

This concludes the proof of Corollary 4.2. □

Appendix A. Properties of the map $\phi \to \phi^\sharp$. Throughout this section Λ is an open subset of $\mathbf{R}^d$ contained in the closed ball B_R of center 0 and radius $R > 0$, $h \in C^2(0, +\infty)$ is strictly convex and satisfies the growth conditions (4). Recall that

$$H(t) := h(t) - th'(t) \qquad (t \in (0, +\infty)).$$

Suppose that $\tilde{\phi} : conv(\Lambda) \to \mathbf{R}$, $\tilde{\psi} : \mathbf{R}^d \to \mathbf{R} \cup \{+\infty\}$ are lower semicontinuous, and define the convex functions

$$\psi(\mathbf{z}) = \tilde{\phi}^\sharp(\mathbf{z}) := \sup_{\mathbf{y} \in conv(\Lambda)} \{\mathbf{y} \cdot \mathbf{z} + h^*(-\tilde{\phi}(\mathbf{y}))\} \qquad (\mathbf{z} \in \mathbf{R}^d), \tag{96}$$

and

$$\phi(\mathbf{y}) = \tilde{\psi}_\sharp(\mathbf{y}) := \sup_{\alpha > 0} \left\{ \frac{(\tilde{\psi})^*(\mathbf{y}) - h(\alpha)}{\alpha} \right\} \qquad (\mathbf{y} \in \mathbf{R}^d). \tag{97}$$

LEMMA A.1. *Let* $\mathbf{y}_o, \mathbf{z}_o \in \mathbf{R}^d$. *The following statements hold:*

(i) *The supremum in* $\phi(\mathbf{y}_o)$ *is attained for* $\beta(\mathbf{y}_o) \in (0, +\infty)$ *provided that* $(\tilde{\psi})^*(\mathbf{y}_o)$ *is finite. If* $S(\mathbf{y}_o) \in \partial(\tilde{\psi})^*(\mathbf{y}_o)$, *then we have that* $S(\mathbf{y}_o) \in \beta(\mathbf{y}_o)\partial\phi(\mathbf{y}_o)$, *and* $H(\beta(\mathbf{y}_o))$

$= (\tilde{\psi})^*(\mathbf{y}_o)$. *Consequently, the pair* $(\beta(\mathbf{y}_o), S(\mathbf{y}_o))$ *or in other words the pair* $(\beta(\mathbf{y}_o), D\tilde{\psi}^*(\mathbf{y}_o))$ *is uniquely determined if* $(\tilde{\psi})^*$ *is differentiable at* $\mathbf{y}_o$; β, S *are Borel functions.*

(ii) *If* $\psi \not\equiv +\infty$, *then* $Lip(\psi) \leq R$.

(iii) *If* $(\tilde{\psi}, \tilde{\phi}) \in \mathcal{A}$, *then* $\phi \leq \tilde{\phi}$ *on* $conv(\Lambda)$ *and* $\psi \leq \tilde{\psi}$ *on* $\mathbf{R}^d$.

(iv) *We have that* $((\tilde{\phi}^\sharp)_\sharp)^\sharp = \tilde{\phi}^\sharp$ *on* $\mathbf{R}^d$ *and* $((\tilde{\psi}_\sharp)^\sharp)_\sharp = \tilde{\psi}_\sharp$ *on* $conv(\Lambda)$.

Proof. Step 1. We first prove (i). Note that in light of (4), $\phi(\mathbf{y}_o)$ is finite if and only if $(\tilde{\psi})^*(\mathbf{y})$ is finite, in which case existence of a maximizer $\beta(\mathbf{y}_o)$ in $\phi(\mathbf{y}_o)$ is a straightforward to obtain. Next, observe that if $S(\mathbf{y}_o) \in \partial(\tilde{\psi})^*(\mathbf{y}_o)$, then the auxiliary function $K : (\alpha, \mathbf{y}, \mathbf{z}) \to \alpha\phi(\mathbf{y}) + \tilde{\psi}(\mathbf{z}) + h(\alpha) - \mathbf{y} \cdot \mathbf{z}$ attains its minimum at $(\beta(\mathbf{y}_o), \mathbf{y}_o, S(\mathbf{y}_o))$. Exploiting the fact that both functions K and $\frac{\partial K}{\partial \alpha}$ vanish at $(\beta(\mathbf{y}_o), \mathbf{y}_o, S(\mathbf{y}_o))$ we deduce that

$$-\phi(\mathbf{y}_o) = h'(\beta(\mathbf{y}_o)) \text{ and } H(\beta(\mathbf{y}_o)) = \mathbf{y}_o \cdot S(\mathbf{y}_o) - \tilde{\psi}(S(\mathbf{y}_o)).$$

Step 2. Since $K(\beta(\mathbf{y}_o), \mathbf{y}_o, \mathbf{z})$ and $K(\beta(\mathbf{y}_o), \mathbf{y}, S(\mathbf{y}_o))$ are greater than or equal to $K(\beta(\mathbf{y}_o), \mathbf{y}_o, S(\mathbf{y}_o))$, we readily deduce that $S(\mathbf{y}_o) \in \beta(\mathbf{y}_o)\partial\phi(\mathbf{y}_o)$. Using the fact that $\tilde{\psi}(S(\mathbf{y}_o)) + (\tilde{\psi})^*(\mathbf{y}_o) = \mathbf{y}_o \cdot S(\mathbf{y}_o)$, the equation $H(\beta(\mathbf{y}_o)) = \mathbf{y}_o \cdot S(\mathbf{y}_o) - \tilde{\psi}(S(\mathbf{y}_o))$ reads off $H(\beta(\mathbf{y}_o)) = (\tilde{\psi})^*(\mathbf{y}_o)$. This concludes the proof of (i). Since $\Lambda \subset B_R$ we conclude (ii).

Step 3. The proof of (iii) is straightforward.

Step 4. We now prove (iv). We have that $(\tilde{\phi}^\sharp, (\tilde{\phi}^\sharp)_\sharp) \in \mathcal{A}$ and because $(\tilde{\phi}^\sharp, \tilde{\phi}) \in \mathcal{A}$, (iii) implies that $(\tilde{\phi}^\sharp)_\sharp \leq \tilde{\phi}$ on $conv(\Lambda)$. Using the fact that the operator $\varphi \to \varphi^\sharp$ is nonincreasing we deduce that $((\tilde{\phi}^\sharp)_\sharp)^\sharp \geq \tilde{\phi}^\sharp$ on $\mathbf{R}^d$. But (iii) and $(\tilde{\phi}^\sharp, (\tilde{\phi}^\sharp)_\sharp) \in \mathcal{A}$ also imply that $((\tilde{\phi}^\sharp)_\sharp)^\sharp \leq \tilde{\phi}^\sharp$ on $\mathbf{R}^d$. Consequently, $((\tilde{\phi}^\sharp)_\sharp)^\sharp = \tilde{\phi}^\sharp$ on $\mathbf{R}^d$. Likewise, $((\tilde{\psi}_\sharp)^\sharp)_\sharp = \tilde{\psi}_\sharp$ on $conv(\Lambda)$.

This concludes the proof of Lemma A.1. □

LEMMA A.2. *Suppose that* $\tilde{\psi} \equiv +\infty$ *on the complement of* B_R *and that* $|\tilde{\psi}|_{L^\infty(B_R)} < +\infty$. *Let* β *be defined as in Lemma* A.1. *Then there exists a constant* c *depending only on* h, R, *and* $|\tilde{\psi}|_{L^\infty(B_R)}$ *such that* $c \leq \beta(\mathbf{y}) \leq 1/c$ *for all* $\mathbf{y}$.

Proof. Set $t_o := R^2 + |\tilde{\psi}|_{L^\infty(B_R)}$. Since $\tilde{\psi} \equiv +\infty$ on the complement of B_R we obtain that $|(\tilde{\psi})^*|_{L^\infty(B_R)} \leq t_o$. Using (12) and Lemma A.1 (i) we conclude the lemma with $c := \max\{H^{-1}(t_o), 1/H^{-1}(-t_o)\}$. □

Appendix B. Compacity of a special class of measures. Throughout this section we assume that $\Lambda \subset \mathbf{R}^d$ is an open bounded set whose closure is contained in the closed ball B_{R_o} of center 0 and radius R_o. If μ is a finite positive measure on $\mathbf{R}^d$, we recall that the moments $M_o(\mu)$ and $M_o(\mu)$ are defined in (20), $C := (0, \infty) \times \mathbf{R}^d \times \mathbf{R}^d$, and $\Gamma[\mu]$ is the set of all Borel measures on C such that

$$\int_C f(\mathbf{z}) d\gamma(\alpha, \mathbf{y}, \mathbf{z}) = \int_{\mathbf{R}^d} f(\mathbf{z}) d\mu(\mathbf{z})$$

and

$$\int_C \alpha f(\mathbf{y}) d\gamma(\alpha, \mathbf{y}, \mathbf{z}) = \int_\Lambda f(\mathbf{y}) d\mathbf{y}$$

for all $f \in C_o(\mathbf{R}^d)$.

PROPOSITION B.1. *Suppose that* μ *satisfies* (20), *that* (μ_n) *is a sequence of Borel measures converging weak* $*$ *to* μ, $M_o[\mu_n] = M_o[\mu]$ $(n = 1, 2, \ldots)$, *and that*

h satisfies (4). *If $\gamma_n \in \Gamma(\mu_n)$ and the sequence of real numbers $(\int_C |h(\alpha)|d\gamma_n)$ is bounded independently of n, then there exists a sequence $(n_j) \subset \mathbf{N}$ and a Borel measure $\gamma \in \Gamma(\mu)$ such that (γ_{n_j}) converges weak $*$ to γ.*

Proof. Because $\gamma_n \in \Gamma(\mu_n)$ we have that $\gamma_n[C] = M_o[\mu]$, and so there exists a sequence $(n_j) \subset \mathbf{N}$ and a Borel measure γ on C such that (γ_{n_j}) converges weak $*$ to γ. We next introduce the functions

$$k(\alpha, \mathbf{y}) := l_R(\alpha + |\mathbf{y}|) \qquad (\alpha > 0, \mathbf{y} \in \mathbf{R}^d),$$

where, for $R > 1$, $l_R : \mathbf{R} \to [0, 1]$ is of class C^∞ and satisfies

$$l_R(t) = \begin{cases} 1 & \text{if} \quad |t| \le R - 1, \\ 0 & \text{if} \quad |t| \ge R. \end{cases} \tag{98}$$

If $f \in C_o(\mathbf{R}^d)$, then

$$\begin{aligned} \left| \int_C f(\mathbf{z})(1 - k(\alpha, \mathbf{y}))d\gamma_{n_j} \right| &= \left| \int_{\alpha > (R-1)/2} f(\mathbf{z})(1 - k(\alpha, \mathbf{y}))d\gamma_{n_j} \right| \\ &\le 2(|f|_\infty |\Lambda|)/(R - 1). \end{aligned} \tag{99}$$

Using (99) and the fact that $\gamma_{n_j} \in \Gamma(\mu_{n_j})$ we have that

$$\left| \int_{\mathbf{R}^d} f(\mathbf{z})d\mu_{n_j}(\mathbf{z}) - \int_C f(\mathbf{z})k(\alpha, \mathbf{y})d\gamma_{n_j} \right| \le 2(|f|_\infty |\Lambda|)/(R - 1). \tag{100}$$

Letting first j go to $+\infty$ and then R go to $+\infty$ in (100) we deduce that

$$\int_{\mathbf{R}^d} f(\mathbf{z})d\mu(\mathbf{z}) = \int_C f(\mathbf{z})d\gamma. \tag{101}$$

Define the function

$$\beta(R) := M \sup_t \{t/|h(t)| \mid t \ge (R - 1)/2\} \qquad (R > 1),$$

where $M > 0$ is a constant independent of n such that $\int_C |h(\alpha)|d\gamma_n \le M$ for all $n \in \mathbf{N}$. Since $\gamma_{n_j} \in \Gamma(\mu_{n_j})$, if A_R is the subset of all $(\alpha, \mathbf{y}, \mathbf{z}) \in C$ such that $|\mathbf{z}| > (R - 1)/2$ and $|\alpha| \le (R - 1)/2$, then we have that

$$\left| \int_\Lambda f(\mathbf{y})d\mathbf{y} - \int_C \alpha f(\mathbf{y})k(\alpha, \mathbf{z})d\gamma_{n_j} \right| \le \left| \int_C \alpha f(\mathbf{y})(1 - k(\alpha, \mathbf{z}))d\gamma_{n_j} \right| \tag{102}$$

and

$$\begin{aligned} \left| \int_C \alpha f(\mathbf{y})(1 - k(\alpha, \mathbf{z}))d\gamma_{n_j} \right| &\le 2 \int_{\alpha > (R-1)/2} \alpha |f(\mathbf{y})|(1 - k(\alpha, \mathbf{z}))d\gamma_{n_j} \\ &\quad + \int_{A_R} \alpha |f(\mathbf{y})|(1 - k(\alpha, \mathbf{z}))d\gamma_{n_j} \\ &\le 2|f|_\infty \Big(\beta(R) + R(\mu[B^c_{\frac{R-1}{2}}] + 1/n_j) \Big). \end{aligned}$$

Hence

$$\left| \int_C \alpha f(\mathbf{y})(1 - k(\alpha, \mathbf{z}))d\gamma_{n_j} \right| \le 2|f|_\infty \Big(\beta(R) + \int_{B^c_{\frac{R-1}{2}}} (2|\mathbf{z}| + 1)d\mu + R/n_j \Big). \tag{103}$$

In light of (4) $\beta(R)$ tends to 0 as R tends to $+\infty$. Using (102) and letting first j go to $+\infty$ and then R tend to $+\infty$ in (103), since $M_o[\mu], M_1[\mu] < +\infty$, we deduce that

$$\int_\Lambda f(\mathbf{y})d\mathbf{y} = \int_C \alpha f(\mathbf{y})d\gamma. \tag{104}$$

Since $f \in C_o(\mathbf{R}^d)$ is arbitrary (101) and (104) yield $\gamma \in \Gamma(\mu)$, which concludes the proof of Proposition B.1. □

Appendix C. Density of the set of maps with prescribed boundary values.

PROPOSITION C.1. *Suppose that $d \geq 2$, $\Omega, \Lambda \subset \mathbf{R}^d$ are two open, bounded sets, that $\partial\Omega$ is Lipschitz, and that Λ is convex. Let $\mathbf{u}, \mathbf{u}_o \in C^1(\Omega)^d \cap C(\bar{\Omega})^d$ be such that $\det D\mathbf{u}, \det D\mathbf{u}_o$ are positive, of class $C^1(\Omega)$, with $\det D\mathbf{u} + \frac{1}{\det D\mathbf{u}}$ and $\det D\mathbf{u}_o + \frac{1}{\det D\mathbf{u}_o}$ in $L^\infty(\Omega)$. Suppose furthermore that $\mathbf{u}_o$ is one-to-one on $\bar{\Omega}$, that $\mathbf{u}$ is one-to-one on Ω, and that $\mathbf{u}(\Omega) = \mathbf{u}_o(\Omega) = \Lambda$. Then there exists a sequence $(\mathbf{u}_n) \subset C^1(\Omega)^d \cap C(\bar{\Omega})^d$ of one-to-one maps from $\bar{\Omega}$ onto $\bar{\Lambda}$ converging almost everywhere in Ω to $\mathbf{u}$ and such that for each integer n*

$$\begin{cases} \det D\mathbf{u}_n = \det D\mathbf{u} & \text{almost everywhere in } \Omega, \\ \mathbf{u}_n = \mathbf{u}_o & \text{on } \partial\Omega. \end{cases} \tag{105}$$

Proof. Step 1. Using Theorem 7 in [9] we find $\mathbf{b} \in Diff^1(\Omega) \cap Diff^0(\bar{\Omega})$ such that

$$\begin{cases} \det D\mathbf{u}_0(\mathbf{b}(\mathbf{x}))\det D\mathbf{b}(\mathbf{x}) = \det D\mathbf{u}(\mathbf{x}) & \text{in } \Omega, \\ \mathbf{b}(\mathbf{x}) = \mathbf{x} & \text{on } \partial\Omega. \end{cases} \tag{106}$$

Define the maps

$$\mathbf{v} := \mathbf{u}_o \circ \mathbf{b}, \qquad \mathbf{s} := \mathbf{u} \circ \mathbf{v}^{-1}.$$

Clearly

$$\begin{cases} \det D\mathbf{v} = \det D\mathbf{u} & \text{in } \Omega, \\ \mathbf{v}(\mathbf{x}) = \mathbf{u}_o(\mathbf{x}) & \text{on } \partial\Omega. \end{cases} \tag{107}$$

We have that

$$\mathbf{s}(\Lambda) = \mathbf{u}(\mathbf{b}^{-1}[\mathbf{u}_o^{-1}(\Lambda)]) = \mathbf{u}(\Omega) = \Lambda$$

and $\mathbf{s}$ is measure-preserving in the sense that

$$\int_\Lambda G(\mathbf{s}(\mathbf{y}))d\mathbf{y} = \int_\Lambda G(\mathbf{x})d\mathbf{x}$$

for all $G \in C_o(\mathbf{R}^d)$.

Step 2. Since Λ is convex and bounded, there exists a map $T \in Diff^1(\Lambda, (0,1)^d) \cap Diff^0(\bar{\Lambda}, [0,1]^d)$. One can choose T, for instance, to be the optimal map that rearranges $\frac{\chi_\Lambda}{|\Lambda|}d\mathbf{x}$ onto $\chi_{[0,1]^d}d\mathbf{x}$ in the Monge problem, where optimality is measured against the cost function $c(\mathbf{x}-\mathbf{y}) = |\mathbf{x}-\mathbf{y}|^2$. Using T we deduce that the following known result for $[0,1]^d$ (see, for instance, [2] and [30]) holds for any convex, bounded

set Λ: there exists a sequence $(\mathbf{s}_n) \subset C^1(\Lambda)^d \cap C(\bar{\Lambda})^d$ of maps from $\bar{\Lambda}$ onto $\bar{\Lambda}$ that are one-to-one on Λ, that converge pointwise almost everywhere in Λ to $\mathbf{s}$ such that

$$\begin{cases} \det D\mathbf{s}_n &= 1 \quad \text{in} \quad \Lambda, \\ \mathbf{s}_n(\mathbf{y}) &= \mathbf{y} \quad \text{on} \quad \partial\Lambda \end{cases} \tag{108}$$

for $n = 1, 2, \ldots$. Define

$$\mathbf{u}_n(\mathbf{x}) := \mathbf{s}_n(\mathbf{v}(\mathbf{x})) \qquad (\mathbf{x} \in \bar{\Omega}).$$

By (107) and (108) we deduce that $(\mathbf{u}_n)$ satisfies the conclusions of Proposition C.1. □

Appendix D. Background on the Monge problem. In this section we present a brief description of the Monge problem, a theory which has attracted a lot of attention. Throughout this section we keep our focus only on the case that is relevant to the study of solid crystals, the case studied by [3], [19], etc. Let $\mu = f d\mathbf{x}$, $\nu = g d\mathbf{x}$ be finite measures on $\mathbf{R}^d$ with equal total mass. Let $O_1, O_2 \subset \mathbf{R}^d$ be two open sets such that $\bar{O}_1$ is the support of μ and $\bar{O}_2$ is the support of ν. The Monge mass transport problem consists of finding an optimal way of rearranging μ onto ν against a cost function which we choose here to be $c(\mathbf{x} - \mathbf{y}) = |\mathbf{x} - \mathbf{y}|^2$. The corresponding variational problem is to minimize the total work

$$K[T] := \int_{\mathbf{R}^d} |\mathbf{x} - T\mathbf{x}|^2 d\mu(\mathbf{x})$$

over the set $\mathcal{T}$ of all Borel maps $T : \mathbf{R}^d \to \mathbf{R}^d$ that push μ forward to ν. Define

$$K'[S] := \int_{\mathbf{R}^d} |\mathbf{y} - S\mathbf{y}|^2 d\nu(\mathbf{y})$$

and let $\mathcal{S}$ be the set of all Borel maps $S : \mathbf{R}^d \to \mathbf{R}^d$ that push ν forward to μ. The following results are known in a setting more general than the one herein.

PROPOSITION D.1 (general theorem).

(i) *Existence and uniqueness of optimal maps: there exists a unique T_o minimizing K over $\mathcal{T}$. Likewise, there exists a unique S_o minimizing K' over $\mathcal{S}$. We have that $S_o(T_o(\mathbf{x})) = \mathbf{x}$ for μ-almost every $\mathbf{x} \in \mathbf{R}^d$, $T_o(S_o(\mathbf{y})) = \mathbf{y}$ for ν-almost every $\mathbf{y} \in \mathbf{R}^d$.*

(ii) *Characterization of optimal maps: a map T_o is a minimizer of K over $\mathcal{T}$ if and only if $T_o \in \mathcal{T}$ and T_o is the gradient of a convex function $\psi_o : \mathbf{R}^d \to \mathbf{R} \cup \{+\infty\}$. Similarly, a map S_o is a minimizer of K' over $\mathcal{S}$ if and only if $S_o \in \mathcal{S}$ and S_o is the gradient of a convex function $\phi_o : \mathbf{R}^d \to \mathbf{R} \cup \{+\infty\}$.*

(iii) *The sets $T_o(O_1)$ and O_2 coincide up to a set of zero measure.*

Proof. We refer the reader to [19]. □

PROPOSITION D.2 (smoothness of optimal maps). *Assume that O_1, O_2 are bounded, $|\partial O_1| = |\partial O_2| = 0$, $f + 1/f \in L^\infty(O_1)$, $g + 1/g \in L^\infty(O_2)$, O_2 is convex, and ψ_o, ϕ_o are the convex functions obtained in Proposition* D.1. *Then we have the following:*

(i) *$\psi_o \in C^{1,s}(O_1)$ for some $0 < s < 1$, and ψ_o is strictly convex in O_1.*

(ii) *If in addition O_1 is convex, then $\psi_o \in C^{1,s}(\bar{O}_1)^d$ for some $0 < s < 1$.*

(iii) *If O_1 is convex and in addition $f \in C^{0,\bar{s}}(O_1)$, $g \in C^{0,\bar{s}}(O_2)$, then $D\psi_o \in C^{1,s}(O_1)^d \cap C^{0,\bar{s}}(\bar{O}_1)^d$, $D\phi_o \in C^{1,s}(O_2)^d \cap C^{0,\bar{s}}(\bar{O}_2)^d$ for all $0 < s < \bar{s}$. We have that $D\psi_o \in Diff^0(\bar{O}_1, \bar{O}_2)$.*

Proof. Smoothness properties of ψ_o and ϕ_o as stated in (i), (ii), and (iii) are established in [4], [5], and [6]. If $D\psi_o \in C^{0,\bar{s}}(\bar{O}_1)^d$ and $D\phi_o \in C^{0,\bar{s}}(\bar{O}_2)^d$, then by Proposition D.1 we have that $D\psi_o \in Diff^0(\bar{O}_1, \bar{O}_2)$. □

VORTEX STATE OF d-WAVE SUPERCONDUCTORS IN THE GINZBURG–LANDAU ENERGY *

FANGHUA LIN† AND TAI-CHIA LIN‡

Abstract. We find a minimizer of a reduced form of the Ginzburg–Landau free energy for d-wave superconductors having distinct degree-one vortices. For a single vortex in the vortex core, we analytically recover the vortex structure with fourfold symmetry.

Key words. Ginzburg–Landau energy, d-wave, superconductor, vortex

1. Introduction.

In the 1910s, low-temperature superconductivity was observed on metals and alloys (cf. [9]). Recently, high-temperature superconductivity has been found on some copper-oxide superconductors (cf. [12]). The vortex state of high-temperature superconductors is different from the vortex state of low-temperature superconductors. When the applied magnetic field is close to the lower critical field H_{c_1}, the single vortex is expected to be symmetric in low-temperature superconductors but it may be asymmetric (fourfold symmetric) in high-temperature superconductors (cf. [8], [31]). Moreover, as the applied magnetic field is close to the upper critical field H_{c_2}, Abrikosov type vortex lattices are expected to be triangular in low-temperature superconductors but they may be rectangular in high-temperature superconductors (cf. [1], [8], [27], [30], [31], etc).

To distinguish low-temperature and high-temperature superconductivity, an s-wave and a d-wave order parameter were introduced (cf. [13], [21]). Soininen et al. [3] and Soininen, Kallin, and Berlinsky [28] introduced the Ginzburg–Landau free energy with an s-wave and a d-wave order parameter. Ren, Xu, and Ting (cf. [24], [25]) present a microscopic derivation of the Ginzburg–Landau equations from the Gor'kov equations by using the finite temperature Green's-function approximation method. From [31], we learned the two fields Ginzburg–Landau free energy is given by

$$\begin{aligned} G(\Psi_s,\Psi_d,A) = \int_{\mathbb{R}^2} & \kappa^2|\ \mathrm{curl}\ A-H|^2+\alpha_s(T)|\Psi_s|^2 \\ & +\tfrac{1}{2}(1-|\Psi_d|^2)^2+\tfrac{4}{3}|\Psi_s|^4+\tfrac{8}{3}|\Psi_s|^2|\Psi_d|^2+\tfrac{2}{3}(\Psi_s^2\Psi_d^{*^2}+\Psi_d^2\Psi_s^{*^2}) \\ & +2|\textstyle\prod\Psi_s|^2+|\prod\Psi_d|^2+\{\prod_x\Psi_s\prod_x^*\Psi_d^*-\prod_y\Psi_s\prod_y^*\Psi_d^*+\mathrm{H.C.}\}\,, \end{aligned} \tag{1.1}$$

where Ψ_s is the s-wave order parameter, Ψ_d is the d-wave order parameter and A is the vector-valued magnetic potential, $\prod = i\nabla - A$, H is a constant applied magnetic field, κ is the Ginzburg–Landau parameter, and

$$\alpha_s(T) = C_s/(1-T/T_c)\,. \tag{1.2}$$

Here C_s is a positive constant, T is the current temperature, and T_c is the d-wave transition temperature.

As the current temperature T is close to T_c, Franz et al. [8] observed that in a predominantly d-wave superconductor, the s-wave component is generically very small. They also provided approximation formulas for the order parameters Ψ_d and Ψ_s as follows:

$$|\Psi_s| \ll |\Psi_d|, \quad |\nabla\Psi_s| \ll |\nabla\Psi_d| \quad \text{as } T \to T_c\,. \tag{1.3}$$

Affleck, Franz, and Amin [1] obtained the leading order in $(1 - T/T_c)$ as

$$\Psi_s = \xi \left(\prod{}_x^2 - \prod{}_y^2\right) \Psi_d\,, \tag{1.4}$$

where ξ is a parameter satisfying that $\xi \to 0$ as $T \to T_c$. In [7], Du derived (1.4) by the formal asymptotic analysis.

We learned from [5] and [6] that it is reasonable to ignore the magnetic field in strongly type II superconductors when the applied magnetic field is close to H_{c1} and $T \to T_c$. Hence it is valuable to study the two fields Ginzburg–Landau model (1.1) without the magnetic field (i.e., $A, H \equiv 0$). Moreover, Rosenstein et al. [6] took (1.3) and (1.4) into (1.1) and modified the free energy (1.1) as follows:

$$G(\Psi_d) = \int_{\mathbb{R}^2} |\nabla\Psi_d|^2 + \frac{1}{2}(1 - |\Psi_d|^2)^2 + \beta\,|\mathbb{B}\Psi_d|^2\,dx\,dy\,, \tag{1.5}$$

where $\mathbb{B} = \partial_x^2 - \partial_y^2$ and β is a parameter satisfying that $\beta \to 0$ as $T \to T_c$. Here we have ignored the magnetic field (i.e., $A, H \equiv 0$) for strongly type II superconductors.

It is hard to find the minimizer of (1.5) by the standard direct method. Suppose that $\Psi_d \in H^2(\mathbb{R}^2\,;\mathbb{C})$ is a minimizer of (1.5) over $H^2(\mathbb{R}^2\,;\mathbb{C})$. Then it is easy to check that

$$\begin{aligned} G(\Psi_d + v) = \;& G(\Psi_d) + \int_{\mathbb{R}^2} |\nabla v|^2 - (1 - |\Psi_d|^2)|v|^2 + 2(\Psi_d \cdot v)^2 \\ & + \int_{\mathbb{R}^2} 2|v|^2(\Psi_d \cdot v) + \frac{1}{2}|v|^4 + \beta|\mathbb{B}v|^2\,, \end{aligned} \tag{1.6}$$

for any test function $v \in C_0^\infty(\mathbb{R}^2)$. Hereafter, $z_1 \cdot z_2 = \frac{1}{2}(\bar{z_1}z_2 + z_1\bar{z_2})\ \forall\ z_1, z_2 \in \mathbb{C}$. Let $v_n(z) = \delta_n v_0(z)\sin[\delta_n^{-2/3}(x+y)]$ for $z = x + iy \in \mathbb{C} \cong \mathbb{R}^2$, where v_0 is a test function with a nonempty compact support and $\{\delta_n\}$ is a sequence of positive numbers such that $\delta_n \to 0$ as $n \to \infty$. Here we use the fact that the complex plane $\mathbb{C}$ is isomorphic to $\mathbb{R}^2$. Now we replace v in (1.6) by v_n and we obtain that $G(\Psi_d + v_n) \to G(\Psi_d)$ but $\|\Psi_d + v_n\|_{H^2} \to \infty$ as $n \to \infty$. Hence $\Psi_d + v_n$'s form a minimizing sequence but $\Psi_d + v_n$'s have no converging subsequence even weakly converging subsequences in $H^2_{loc}(\mathbb{R}^2\,;\mathbb{C})$. Thus the free energy (1.5) has a defect on minimization.

From [30], we learned a Ginzburg–Landau energy functional (without the magnetic field) as follows:

$$E(\Psi_d) = \int_{\mathbb{R}^2} |\nabla\Psi_d|^2 + \frac{1}{2}(1 - |\Psi_d|^2)^2 + \eta\,(|\partial_x^2\,\Psi_d|^2 + |\partial_y^2\,\Psi_d|^2)\,dx\,dy\,, \tag{1.7}$$

where η is a constant depending on the current temperature T. The term $|\partial_x^2\Psi_d|^2 + |\partial_y^2\Psi_d|^2$ breaks the circular symmetry and accounts for the square symmetry. Furthermore, Park and Huse [22] introduced a more generalized Ginzburg–Landau free

energy (without the magnetic field) for d-wave superconductors as follows:

$$F(\Psi_d) = \int_{\mathbb{R}^2} |\nabla\Psi_d|^2 + \frac{1}{2}(1-|\Psi_d|^2)^2 + \gamma_1 |\Delta\Psi_d|^2 \, dx\, dy + \int_{\mathbb{R}^2} \beta_1 \left(|\mathbb{B}\Psi_d|^2 - 4|\partial_x\partial_y \Psi_d|^2\right) dx\, dy\,, \tag{1.8}$$

where $\Delta = \partial_x^2 + \partial_y^2$ and β_1, γ_1 are parameters tending to zero as $T \to T_c$.

Hereafter, we assume that $|\Psi_d| \to 1$ and all the derivatives of Ψ_d decay fast as $|(x,y)| \to \infty$. Such an assumption is consistent with the results in [8] and [31]. Using integration by parts, we may transform (1.8) into

$$\tilde{G}(\Psi_d) = \int_{\mathbb{R}^2} |\nabla\Psi_d|^2 + \frac{1}{2}(1-|\Psi_d|^2)^2 + \beta\,|\mathbb{B}\Psi_d|^2 + \gamma\,|\Delta\Psi_d|^2 \, dx\, dy\,, \tag{1.9}$$

where β, γ are parameters tending to zero as $T \to T_c$. In this paper, we assume that $\beta, \gamma > 0$ and $\beta, \gamma \to 0$ as $T \to T_c$. In particular, such an assumption includes the case that $0 < \gamma \ll \beta$, i.e., (1.9) is a small perturbation of (1.5).

In section 2, we approximate (1.9) by

$$G_\epsilon(\Psi_d) = \int_{\frac{1}{\epsilon}\Omega} |\nabla\Psi_d|^2 + \frac{1}{2}(1-|\Psi_d|^2)^2 + \beta|\mathbb{B}\Psi_d|^2 + \gamma\,|\Delta\Psi_d|^2 \, dx\, dy\,, \tag{1.10}$$

where $0 < \epsilon \ll 1$ is a small parameter, Ω is a bounded smooth domain in $\mathbb{R}^2$ having an interior point at the origin, and $\frac{1}{\epsilon}\Omega = \{(\frac{x}{\epsilon}, \frac{y}{\epsilon}) : (x,y) \in \Omega\}$. In the rest of this paper, we prove that the minimizer of (1.10) has distinct degree-one vortices in section 3. In section 4, we replace $\frac{1}{\epsilon}\Omega$ in (1.10) by B_{R_0}, where B_{R_0} is a disk with radius R_0 and center at the origin. Here $R_0 > 0$ is a large constant satisfying $1 \ll R_0 \le 1/\epsilon$. Then (1.10) becomes

$$\hat{G}(\Psi_d) = \int_{B_{R_0}} |\nabla\Psi_d|^2 + \frac{1}{2}(1-|\Psi_d|^2)^2 + \beta|\mathbb{B}\Psi_d|^2 + \gamma\,|\Delta\Psi_d|^2 \, dx\, dy\,, \tag{1.11}$$

where $\beta > 0$ is a small parameter as $T \to T_c$, $\gamma = C\,\beta$, and C is a positive constant independent of β. We then study the critical point of (1.11) and find out its single vortex structure with fourfold symmetry. The single vortex structure of d-wave superconductors having fourfold symmetry is well known in physics (cf. [5], [6], [8], [27], and [31]). Here we give a mathematical proof of such a vortex structure.

2. Preliminaries. To investigate vortices in d-wave superconductors, we assume that the order parameter Ψ_d satisfies $|\Psi_d| \to 1$ and all the derivatives of Ψ_d decay fast as $|(x,y)| \to \infty$. Such an assumption is consistent with the results in [8] and [31]. Hence we may approximate (1.9) by

$$G_\epsilon(\Psi_d) = \int_{\frac{1}{\epsilon}\Omega} |\nabla\Psi_d|^2 + \frac{1}{2}(1-|\Psi_d|^2)^2 + \beta|\mathbb{B}\Psi_d|^2 + \gamma\,|\Delta\Psi_d|^2 \, dx\, dy\,, \tag{2.1}$$

where $0 < \epsilon \ll 1$ is a small parameter, Ω is a bounded smooth domain in $\mathbb{R}^2$ having an interior point at the origin, and $\frac{1}{\epsilon}\Omega = \{(\frac{x}{\epsilon}, \frac{y}{\epsilon}) : (x,y) \in \Omega\}$. Rescaling the spatial variables x, y by ϵ, (2.1) becomes

$$\hat{G}_\epsilon(\Psi_d) = \int_{\Omega} |\nabla\Psi_d|^2 + \frac{1}{2\epsilon^2}(1-|\Psi_d|^2)^2 + \delta_\epsilon|\mathbb{B}\Psi_d|^2 + \gamma_\epsilon\,|\Delta\Psi_d|^2 \, dx\, dy\,, \tag{2.2}$$

where

$$\delta_\epsilon = \beta\,\epsilon^2 \quad \text{and} \quad \gamma_\epsilon = \gamma\,\epsilon^2\,. \tag{2.3}$$

Of course, (2.3) implies that $0 < \delta_\epsilon, \gamma_\epsilon = O(\epsilon^2)$ as $\epsilon \to 0+$. In sections 2 and 3, we study (2.2) with an assumption that $0 < \delta_\epsilon, \gamma_\epsilon = O(\epsilon^2)$ as $\epsilon \to 0+$.

This kind of approximation can also be found in s-wave superconductors. The conventional s-wave Ginzburg–Landau free energy (cf. [9]) without the magnetic field is

$$\int_{\mathbb{R}^2} \frac{1}{2}|\nabla u|^2 + \frac{1}{4}(1-|u|^2)^2\,,$$

where $u \in \mathbb{C}$ is the s-wave order parameter. Under the hypothesis that $|u| \to 1$ and all the derivatives of u decay fast at $|(x,y)| \to \infty$, we may approximate the s-wave Ginzburg–Landau free energy by

$$\int_{\frac{1}{\epsilon}\Omega} \frac{1}{2}|\nabla u|^2 + \frac{1}{4}(1-|u|^2)^2\,,$$

where $0 < \epsilon \ll 1$ is a small parameter and Ω is a bounded smooth domain in $\mathbb{R}^2$ having an interior point at the origin. Then we rescale the spatial variables by ϵ and obtain the energy functional as follows:

$$E_\epsilon(u) = \int_\Omega \frac{1}{2}|\nabla u|^2 + \frac{1}{4\epsilon^2}(1-|u|^2)^2\,, \tag{2.4}$$

where $u : \Omega \to \mathbb{C}$ is the s-wave order parameter. There are many investigations on the free energy (2.4). For the readers who are interested in these works, please refer to [2], [15], [17], [23], [29], etc.

In [2] and [29], we learn the minimizer of E_ϵ over $H^1_g(\Omega)$ having n degree-one vortices in Ω, where

$$H^1_g(\Omega) = \{u \in H^1(\Omega\,;\,\mathbb{C}) \,:\, u = g \quad \text{on } \partial\Omega\}\,,$$

and $g : \partial\Omega \to S^1$ is smooth with degree $n \geq 1$. Furthermore, the minimizer u_ϵ of (2.4) satisfies

(1) $E_\epsilon(u_\epsilon) = n\pi \log \frac{1}{\epsilon} + W_g(a_1,\dots,a_n) + o_\epsilon(1)$ as $\epsilon \to 0+$,
(2) u_ϵ converges to u_* (up to a subsequence) in $C^2_{loc}(\bar\Omega\backslash\{a_1,\dots,a_n\})$ as $\epsilon \to 0+$,
(3) $(a_1,\dots,a_n) \in \Omega^n$ is a global minimizer of the renormalized energy W_g defined in [2],

where $o_\epsilon(1)$ is a small quantity which tends to zero as $\epsilon \to 0+$,

$$u_*(z) = \prod_{j=1}^n \frac{z-a_j}{|z-a_j|}\, e^{i\,h(z)} \quad \forall z \in \Omega\,, \tag{2.5}$$

and h is a real-valued harmonic function. Since $\mathbb{R}^2$ is isomorphic to $\mathbb{C}$, we may consider $\Omega \subset \mathbb{R}^2 \cong \mathbb{C}$. Note that the domain Ω is assumed star-shaped in [2]. However, Struwe [29] generalized results of [2] for all bounded smooth domains.

For the minimizer of (2.2), we prove the following theorem.

THEOREM 2.1. *Suppose* $0 < \delta_\epsilon, \gamma_\epsilon = O(\epsilon^2)$ *as* $\epsilon \to 0+$. *Then there exists a minimizer* u_ϵ *of* (2.2) *over* $H^1_g(\Omega)$ *such that*

(i) $u_\epsilon \in H^2(\Omega)$ *has* n *degree-one vortices in* Ω,
(ii) $\hat{G}_\epsilon(u_\epsilon) = 2n\pi \log \frac{1}{\epsilon} + O(1)$ *as* $\epsilon \to 0+$,
(iii) u_ϵ *converges to* u_* *(up to a subsequence) strongly in* $L^2(\Omega)$ *and weakly in* $H^1_{loc}(\Omega \backslash \{a_1, \dots, a_n\})$,
(iv) $(a_1, \dots, a_n) \in \Omega^n$ *is a global minimizer of the renormalized energy* W_g *in* [2].

Remark 1. We may consider the energy functional (2.2) with $0 < \delta_\epsilon, \gamma_\epsilon = O(\epsilon^2)$ as a small perturbation of (2.4). However, the perturbation terms are of higher order derivatives. Hence the Euler–Lagrange equation of (2.2) is a singular perturbation problem and the perturbation terms are of the 4th order derivatives. Until now, there is no general theorem on such a singular perturbation problem.

3. Proof of Theorem 2.1. To prove the existence of a minimizer, we define a comparison map as follows:

$$U_\epsilon(z) = \prod_{j=1}^{n} U_0\left(\frac{z - b_j}{\epsilon}\right) e^{i\, H_\epsilon(z)}, \tag{3.1}$$

for $z \in \Omega \subset \mathbb{C}$, where b_j's are n distinct points in Ω and H_ϵ is a real-valued smooth function in Ω such that

$$U_\epsilon = g \quad \text{on } \partial\Omega, \quad \|H_\epsilon\|_{C^2(\Omega)} = O(1).$$

Hereafter, U_0 is the symmetric vortex solution (cf. [4], [10], [11]) defined by

$$U_0(z) = f(R)\, e^{i\,\theta} \quad \text{for } z \in \mathbb{C}, \tag{3.2}$$

where $R = |z|$ and (R, θ) is the polar coordinate in $\mathbb{C}$. Moreover, $f(R)$ satisfies

$$\begin{cases} f'' + \frac{1}{R} f' - \frac{1}{R^2} f + (1 - f^2) f = 0 & \text{for } R > 0, \\ f(0) = 0, f(\infty) = 1. \end{cases} \tag{3.3}$$

From [4] and [11], the symmetric vortex solution U_0 satisfies the following lemma.

Lemma 3.1.
(i) $f(R) = \alpha_0 R + \alpha_1 R^3 + O(R^5)$ *as* $R \to 0+$, *where* $\alpha_0 > 0, \alpha_1 \in \mathbb{R}$ *are constants,*
(ii) $f(R) = 1 - \frac{1}{2R^2} + O(R^{-4})$ *as* $R \to +\infty$,
(iii) $U_0 = f(R)\, e^{i\theta}$ *is analytic in* $\mathbb{C}$.

Hence it is easy to check that

$$\hat{G}_\epsilon(U_\epsilon) = 2\pi n \log \frac{1}{\epsilon} + O(1) \quad \text{as } \epsilon \to 0+. \tag{3.4}$$

Now fix $0 < \epsilon \ll 1$. We claim that $\inf_{u \in H^1_g(\Omega)} \hat{G}_\epsilon(u)$ attains a minimizer $u_\epsilon \in H^2(\Omega)$. Let $\{u_k\}$ be a minimizing sequence such that

$$\hat{G}_\epsilon(u_k) \to \inf_{u \in H^1_g(\Omega)} \hat{G}_\epsilon(u). \tag{3.5}$$

Then by (2.2), (3.4), and (3.5), we have

$$\liminf_{k \to \infty} \int_\Omega |\nabla u_k|^2 + |\mathbb{B} u_k|^2 + |\Delta u_k|^2 \, dx\, dy < +\infty.$$

Hence there exists a subsequence $\{u_{k_j}\}$ such that

$$\|u_{k_j}\|_{H^2} \le K_\epsilon \quad \forall j \ge 1\,, \tag{3.6}$$

where $K_\epsilon > 0$ is a constant independent of j. Thus (3.6) implies

$$u_{k_j} \to u_\epsilon \quad \text{weakly in} \quad H^2(\Omega) \quad \text{as} \ \ j \to \infty\,. \tag{3.7}$$

Therefore by Fatou's lemma, u_ϵ is a minimizer of $\hat{G}_\epsilon$ over $H^1_g(\Omega)$.

From (2.2), (2.4), (3.4), and u_ϵ is a minimizer of $\inf_{u\in H^1_g(\Omega)} \hat{G}_\epsilon(u)$, we obtain

$$E_\epsilon(u_\epsilon) \le \pi\, n\, \log\, \frac{1}{\epsilon} \,+\, O(1)\,. \tag{3.8}$$

Moreover, by (3.8) and [29], we have

$$E_\epsilon(u_\epsilon) = \pi\, n\, \log\, \frac{1}{\epsilon} \,+\, O(1)\,. \tag{3.9}$$

Hence (3.4) and (3.9) imply that

$$\delta_\epsilon \int_\Omega |\mathbb{B} u_\epsilon|^2\, dx\, dy = O(1) \tag{3.10}$$

and

$$\gamma_\epsilon \int_\Omega |\Delta u_\epsilon|^2\, dx\, dy = O(1)\,. \tag{3.11}$$

Thus we complete the proof of (ii).

By (3.9) and Propositions 1.1 and 1.2 in [16], we complete the proof of (i). Furthermore, we obtain that u_ϵ converges to u_* (up to a subsequence) strongly in $L^2(\Omega)$ and weakly in $H^1_{loc}(\Omega\backslash\{a_1,\dots,a_n\})$, where $a_1,\dots,a_n \in \Omega$, $u_*(z) = \prod_{j=1}^n \frac{z-a_j}{|z-a_j|}\, e^{i\,h(z)} \forall z \in \Omega \subset \mathbb{C}$ and h is a real-valued function. Now we show that h is a harmonic function as follows: Consider the Euler–Lagrange equation of $\hat{G}_\epsilon$ with respect to the minimizer u_ϵ. Then u_ϵ satisfies

$$\Delta u_\epsilon + \frac{1}{\epsilon^2}(1-|u_\epsilon|^2)u_\epsilon - \delta_\epsilon\, \mathbb{B}^2 u_\epsilon - \gamma_\epsilon\, \Delta^2 u_\epsilon = 0 \quad \text{in } \Omega\,. \tag{3.12}$$

Perform the wedge product with u_ϵ and (3.12). This is a standard trick to erase the cubic nonlinear term in (3.12) (cf. [26] and [29]). Then we have

$$u_\epsilon \wedge \Delta u_\epsilon - \delta_\epsilon\, u_\epsilon \wedge \mathbb{B}^2 u_\epsilon - \gamma_\epsilon\, u_\epsilon \wedge \Delta^2 u_\epsilon = 0 \quad \text{in } \Omega\,. \tag{3.13}$$

Let $p \in C^\infty_0(\Omega)$ be a test function. Multiply (3.13) by p and integrate it on Ω. Then using integration by parts, we obtain

$$\begin{aligned} &-\int_\Omega (u_\epsilon \wedge \partial_x u_\epsilon) p_x + (u_\epsilon \wedge \partial_y u_\epsilon) p_y \\ &= \delta_\epsilon \int_\Omega (u_\epsilon \wedge \mathbb{B} u_\epsilon)\mathbb{B} p + 2(\partial_x u_\epsilon \wedge \mathbb{B} u_\epsilon) p_x - 2(\partial_y u_\epsilon \wedge \mathbb{B} u_\epsilon) p_y \\ &\quad + \gamma_\epsilon \int_\Omega (u_\epsilon \wedge \Delta u_\epsilon)\Delta p + 2(\partial_x u_\epsilon \wedge \Delta u_\epsilon) p_x + 2(\partial_y u_\epsilon \wedge \Delta u_\epsilon) p_y. \end{aligned} \tag{3.14}$$

Here we have used the following formulas:

$$u \wedge \Delta u = \partial_x (u \wedge \partial_x u) + \partial_y (u \wedge \partial_y u),$$
$$u \wedge \mathbb{B}^2 u = \mathbb{B}(u \wedge \mathbb{B}u) - 2(u_x \wedge \mathbb{B}u_x - u_y \wedge \mathbb{B}u_y),$$
$$u \wedge \Delta^2 u = \Delta(u \wedge \Delta u) - 2(u_x \wedge \Delta u_x + u_y \wedge \Delta u_y).$$

Hence by $0 < \gamma_\epsilon, \delta_\epsilon = O(\epsilon^2)$, (3.9)–(3.11), (3.14), and the Holder inequality, the limit map u_* satisfies

$$u_* \wedge \Delta u_* = 0 \quad \text{in distribution sense}. \tag{3.15}$$

Thus u_* is a canonical harmonic map, i.e., h is a harmonic function. Therefore we complete the proof of (iii).

Now we prove (iv) as follows: Let $(\tilde{a}_1, \ldots, \tilde{a}_n) \in \Omega^n$ be a global minimizer of the renormalized energy W_g. The definition of W_g can be found in [2]. Then we define another comparison map as follows:

$$V_\epsilon(z) = \begin{cases} u_\epsilon(z - \tilde{a}_j + a_j) & \text{if } z \in B_{\epsilon^\alpha}(\tilde{a}_j), j = 1, \ldots, n, \\ \tilde{U}_\epsilon(z) & \text{if } z \in \Omega_{\epsilon^\alpha} \equiv \Omega \backslash \cup_{j=1}^n B_{\epsilon^\alpha}(\tilde{a}_j), \end{cases} \tag{3.16}$$

where $0 < \alpha < 1$ is a constant and $\tilde{U}_\epsilon$ is a minimizer of E_ϵ over $H^1_{\tilde{g}}(\Omega_{\epsilon^\alpha})$. Here the boundary condition $\tilde{g}$ is defined by

$$\tilde{g} = \begin{cases} g & \text{on } \partial\Omega, \\ u_\epsilon(\cdot - \tilde{a}_j + a_j) & \text{on } \partial B_{\epsilon^\alpha}(\tilde{a}_j), j = 1, \ldots, n. \end{cases} \tag{3.17}$$

Hence by (iii), [2], and [29], $\tilde{U}_\epsilon$ satisfies

$$\tilde{U}_\epsilon \to \prod_{j=1}^n \frac{z - \tilde{a}_j}{|z - \tilde{a}_j|} e^{i\tilde{h}(z)} \quad \text{in } C^2(\Omega_{\epsilon^\alpha}) \quad \text{as } \epsilon \to 0+, \tag{3.18}$$

where $\tilde{h}$ is a harmonic function. The convergence of (3.18) may be up to a subsequence. However, this does not affect the following argument. Thus by (3.18) and [2], it is easy to check that

$$\hat{G}_\epsilon(V_\epsilon) = \sum_{j=1}^n \int_{B_{\epsilon^\alpha}(a_j)} \hat{g}_\epsilon(u_\epsilon) + 2\pi n\alpha \log \frac{1}{\epsilon} + 2W_g(\tilde{a}_1, \ldots, \tilde{a}_n) + o_\epsilon(1), \tag{3.19}$$

where $\hat{g}_\epsilon(u) = |\nabla u|^2 + \frac{1}{2\epsilon^2}(1 - |u|^2)^2 + \delta_\epsilon |\mathbb{B}u|^2 + \gamma_\epsilon |\Delta u|^2$ is the energy density of $\hat{G}_\epsilon$ and $o_\epsilon(1)$ is a small quantity which tends to zero as $\epsilon \to 0+$. On the other hand, by (iii) and [2], we have

$$\int_{\hat{\Omega}_{\epsilon^\alpha}} \frac{1}{2}|\nabla u_\epsilon|^2 + \frac{1}{4\,\epsilon^2}(1 - |u_\epsilon|^2)^2 \geq \pi n\alpha \log \frac{1}{\epsilon} + W_g(a_1, \ldots, a_n) + o_\epsilon(1), \tag{3.20}$$

where $\hat{\Omega}_{\epsilon^\alpha} = \Omega \backslash \cup_{j=1}^n B_{\epsilon^\alpha}(a_j)$. Hence (3.20) implies that

$$\hat{G}_\epsilon(u_\epsilon) \geq \sum_{j=1}^n \int_{B_{\epsilon^\alpha}(a_j)} \hat{g}_\epsilon(u_\epsilon) + 2\pi n\alpha \log \frac{1}{\epsilon} + 2W_g(a_1, \ldots, a_n) + o_\epsilon(1). \tag{3.21}$$

Thus by (3.19) and (3.21), we obtain

$$W_g(a_1, \ldots, a_n) \leq W_g(\tilde{a}_1, \ldots, \tilde{a}_n) + o_\epsilon(1). \tag{3.22}$$

Since $(\tilde{a}_1, \ldots, \tilde{a}_n)$ is a global minimizer of W_g, then we complete the proof of (iv) by (3.22).

4. Single vortex structure in the vortex core. In this section, we assume that the single vortex structure is in the vortex core B_{R_0}, where $R_0 > 0$ is a large constant satisfying $1 \ll R_0 \leq \frac{1}{\epsilon}$. Hereafter, we denote B_{R_0} as a disk in $\mathbb{R}^2$ with radius R_0 and center at the origin. To study the vortex structure in the vortex core, we restrict (1.9) in the vortex core B_{R_0} as follows:

$$\hat{G}(\Psi_d) = \int_{B_{R_0}} |\nabla \Psi_d|^2 + \frac{1}{2}(1 - |\Psi_d|^2)^2 + \beta\, |\mathbb{B}\Psi_d|^2 + \gamma\, |\Delta \Psi_d|^2 \, dx\, dy\,, \tag{4.1}$$

where $\gamma = C\beta, C > 0$ is a constant independent of β, and $\beta > 0$ is a small parameter tending to zero as $T \to T_c$. We investigate (4.1) with $\beta > 0$ a small parameter to see the phase transition of d-wave superconductors.

The Euler–Lagrange equation of (4.1) is

$$\Delta \Psi_d + (1 - |\Psi_d|^2)\Psi_d - \beta\, (\mathbb{B}^2 + C\, \Delta^2)\Psi_d = 0 \quad \text{in } B_{R_0}\,. \tag{4.2}$$

Note that $E \equiv \mathbb{B}^2 + C\, \Delta^2$ is an elliptic operator as $C > 0$. Moreover, by the Lax–Milgram theorem, $E : H_0^2(B_{R_0}\,; \mathbb{C}) \to H^{-2}(B_{R_0}\,; \mathbb{C})$ is invertible and we denote E^{-1} as its inverse. Hence the standard elliptic regularity theorem (cf. [20]) can be applied in (4.2).

We state the main result on (4.2) as follows.

THEOREM 4.1. *There exists a solution Ψ_d of* (4.2) *satisfying*

$$\Psi_d(z, \beta) = f(R)\, e^{i\,\theta} + \beta(a(R)\, e^{-4i\,\theta} + b(R)\, e^{4i\,\theta} + c(R))\, e^{i\,\theta} + O(\beta^2) \quad \text{as } \beta \to 0\,, \tag{4.3}$$

where a, b, and c are smooth real-valued functions.

Equation (4.3) implies that the d-wave order parameter Ψ_d is fourfold symmetric in the vortex core. In [27], we learn a well-approximated solution of (4.2) with fourfold symmetry. Here we find an exact solution of (4.2) with the fourfold symmetry.

Proof. Proof of Theorem 4.1.

To solve (4.2), we set

$$\Psi_d(z, \beta) = U_0(z) + \beta w_1(z) + \beta^2 w_2(z) + \beta^3 w(z, \beta)\,, \tag{4.4}$$

where U_0 is the symmetric vortex solution defined in (3.2) and (3.3). Here w_1 satisfies

$$L\, w_1 - E\, U_0 = 0 \text{ in } B_{R_0}\,, \quad w_1 = 0 \text{ on } \partial B_{R_0}\,, \tag{4.5}$$

where $Lv = \Delta v + (1 - |U_0|^2)v - 2(U_0 \cdot v)U_0$ is the linearized operator of (4.2) with respect to a trivial solution $(\Psi_d, \beta) = (U_0, 0)$. In addition, w_2 satisfies that

$$\begin{aligned} L\, w_2 &= 2(U_0 \cdot w_1)w_1 + |w_1|^2 U_0 + E\, w_1 \quad \text{in } B_{R_0}\,, \\ w_2 &= 0 \quad \text{on } \partial B_{R_0}\,. \end{aligned} \tag{4.6}$$

It is easy to check that

$$EU_0 = h_{-3}(R)\, e^{-3i\,\theta} + h_1(R)\, e^{i\,\theta} + h_5(R)\, e^{5i\,\theta}\,, \tag{4.7}$$

where h_{-3}, h_1, and h_5 are real-valued smooth functions. By [14], [18], [19], and [23], L is a bijection from $H_0^1(B_{R_0}\,; \mathbb{C})$ onto $H^{-1}(B_{R_0}\,; \mathbb{C})$. Hence by (4.5)–(4.7), we have

$$w_1 = a(R)\, e^{-3i\,\theta} + b(R)\, e^{5i\,\theta} + c(R)\, e^{i\,\theta}\,, \tag{4.8}$$

$$w_2 = \sum_{k=0}^{2} a_{1-4k}(R)\, e^{i\,(1-4k)\,\theta} \;+\; a_{1+4k}(R)\, e^{i\,(1+4k)\,\theta}\,, \tag{4.9}$$

where a, b, c, and $a_{1\pm 4k}$'s are smooth real-valued functions.

Taking (4.4) into (4.2), we obtain that

$$\begin{aligned} L\,w = \;& 2[(U_0\cdot(w_2+\beta w))w_1 + (U_0\cdot w_1)(w_2+\beta w)] + \beta|w_2+\beta w|^2 U_0 \\ & +\beta(U_0\cdot(w_2+\beta w))(w_2+\beta w) + 2(w_1\cdot(w_2+\beta w))U_0 \\ & +|w_1+\beta(w_2+\beta w)|^2(w_1+\beta(w_2+\beta w)) + Ew_2 + \beta E w \quad \text{in } B_{R_0}\,. \end{aligned} \tag{4.10}$$

Hence (4.10) is equivalent to

$$\begin{aligned} E^{-1}\,L\,w = \;& E^{-1}\{2[(U_0\cdot(w_2+\beta w))w_1 + (U_0\cdot w_1)(w_2+\beta w)] + \beta|w_2+\beta w|^2 U_0 \\ & +\beta(U_0\cdot(w_2+\beta w))(w_2+\beta w) + 2(w_1\cdot(w_2+\beta w))U_0 \\ & +|w_1+\beta(w_2+\beta w)|^2(w_1+\beta(w_2+\beta w))\} + w_2 + \beta w \quad \text{in } B_{R_0}\,. \end{aligned} \tag{4.11}$$

Note that (4.11) has a trivial solution $(w,\beta) = (w_3, 0)$, where w_3 satisfies that

$$\begin{aligned} L\,w_3 \;& = 2[(U_0\cdot w_2)w_1 + (U_0\cdot w_1)w_2] + 2(w_1\cdot w_2)U_0 \\ & \quad + |w_1|^2 w_1 + E\,w_2 \;\text{ in }\; B_{R_0}\,, \\ w_3 \;& = 0 \;\text{ on }\; \partial B_{R_0}\,. \end{aligned} \tag{4.12}$$

Since U_0, w_1, w_2 are smooth functions and L is bijective from $H_0^1(B_{R_0}\,;\mathbb{C})$ onto $H^{-1}(B_{R_0}\,;\mathbb{C})$, then the standard elliptic regularity theorem implies that w_3 is also a smooth function. Furthermore, since E is bijective from $H_0^2(B_{R_0}\,;\mathbb{C})$ onto $H^{-2}(B_{R_0}\,;\mathbb{C})$ and $H^{-1}(B_{R_0}\,;\mathbb{C})$ is embedded in $H^{-2}(B_{R_0}\,;\mathbb{C})$, then E is a bijection from $H_0^2(B_{R_0}\,;\mathbb{C})$ $\cap\, H^3(B_{R_0}\,;\mathbb{C})$ onto $H^{-1}(B_{R_0}\,;\mathbb{C})$. We denote E^{-1} as the inverse of E. Hence $E^{-1}\,L$ is a bijection from $H_0^1(B_{R_0}\,;\mathbb{C})$ onto $H_0^2(B_{R_0}\,;\mathbb{C}) \cap H^3(B_{R_0}\,;\mathbb{C})$. Thus by the implicit function theorem, (4.11) has a unique solution $w \in H_0^1(B_{R_0}\,;\mathbb{C})$ as $|\beta|$ is sufficiently small. Moreover, the standard elliptic regularity theorem may imply the smoothness of w. Therefore (4.2) has a solution Ψ_d satisfying (4.4) as $|\beta|$ is sufficiently small. By (4.4), (4.8), and (4.9), we obtain (4.3) and complete the proof of Theorem 4.1. ∎

Final remark. By (1.4) with $A \equiv 0$ and (4.3), we have

$$\Psi_s(z) = \xi\mathbb{B}[U_0 + \beta(a(R)\, e^{-4i\,\theta} + b(R)\, e^{4i\,\theta} + c(R))\, e^{i\,\theta} + O(\beta^2)] \tag{4.13}$$

as $\beta \to 0$. Since $U_0(z) = f(R)\, e^{i\,\theta}$, then

$$\mathbb{B}U_0(z) = \frac{1}{2}\left(f' + \frac{1}{R}\,f\right)'\, e^{-i\,\theta} + \frac{1}{2}\left[\left(f' - \frac{1}{R}f\right)' - \frac{2}{R}\left(f' - \frac{1}{R}\,f\right)\right] e^{3i\,\theta}\,. \tag{4.14}$$

Hence by (i), (ii) of Lemma 3.1 and (4.14), $\mathbb{B}U_0$ satisfies

$$\mathbb{B}U_0(z) = 4\alpha_1\, R\, e^{-i\,\theta} + O(R^3) \quad \text{as } R \to 0+ \tag{4.15}$$

and

$$\mathbb{B}U_0(z) = -\,\frac{1}{2\,R^2}\, e^{-i\,\theta} \;+\; \frac{3}{2\,R^2}\, e^{3i\,\theta} + O(R^{-4}) \quad \text{as } R \to +\infty\,. \tag{4.16}$$

By (4.15) and (4.16), the degree of $\mathbb{B}U_0$ is minus one in B_{r_1} and three in B_{R_1} as $0 < r_1 \ll 1$ and $R_1 \gg 1$. Moreover, by [4] and [11], it is easy to check that

$$\frac{d}{d\,z}\,\mathbb{B}\,U_0(z) \;\neq 0 \quad \text{if } \mathbb{B}U_0(z) = 0\,. \tag{4.17}$$

Hence (iii) of Lemma 3.1 and (4.17) imply that $\mathbb{B}U_0$ has only simple zeros in $\mathbb{C}$. Thus $\mathbb{B}U_0$ has a single zero with degree minus one at the origin and another four zeros with degree one away from the origin. Therefore as $|\beta|$ is sufficiently small, Ψ_s has a single zero with degree minus one near the origin and another four zeros with degree one away from the origin. This indicates the four-lobe structure of Ψ_s in the vortex core. The numerical simulation can be found in [7], [8], and [31].

Acknowledgments. The second author wishes to express his sincere thanks to B. Rosenstein for helpful discussions. He also sincerely thanks the referees for their suggestions.

COEXISTENCE WITH CHEMOTAXIS*

LE DUNG†

Dedicated to Professor Jack Hale on his 70th birthday

Abstract. We study the existence of positive solutions to a coupled system of elliptic equations modeling competition in a bio-reactor with chemotactic response. A fixed point index technique is used to derive sufficient conditions for coexistence solutions.

Key words. chemotaxis, cross diffusion, fixed point index

1. Introduction.

The purpose of this paper is to consider the existence of positive solutions to the system

$$\begin{cases} -A_0 u_0 & = & -f_0(x,\vec{u}), & x \in \Omega, \\ -A_i u_i + \operatorname{div}(u_i \Phi_i(u_0)\nabla u_0) & = & f_i(x,\vec{u}), & x \in \Omega, \end{cases} \tag{1.1}$$

with the boundary conditions

$$\frac{\partial u_i}{\partial n} + r_i\left(x, \frac{\partial u_0}{\partial n}\right)u = u_0^i, \quad \frac{\partial u_0}{\partial n} + r_0(x)u_0 = S_0, \quad x \in \partial\Omega. \tag{1.2}$$

Here, $\vec{u} = (u_0, u_1, \ldots, u_m)$ and A_i are linear elliptic operators defined on an open bounded set Ω of $\mathbb{R}^n$. In this form (1.1) and (1.2) model the steady state solutions of a reaction-diffusion system describing the competition in a nonmixed bio-reactor where u_0 represents the concentration of a nutrient and u_i the densities of the species of cells (or bacteria). In addition to the derivative terms in the operator A_i reflecting the random diffusive flux and the convection effect in the model, the term $(u_i\Phi_i(u_0)(u_0)_x)_x$ reflects the chemotactic flux response of each species to the presence of the nutrient u_0. The function Φ_i, the so-called sensitivity rate, is included to indicate that the sensitivity of cells to the nutrient may vary at different levels of nutrient concentration.

Ever since the appearance of the work of Keller and Segel [17] on an aggregation model for the slime mold *Dictyostelium discoideum*, there has been great interest in modeling chemotaxis and in the mathematical analysis of systems like the Keller–Segel model. Here, we note the work of Schaff [22] and Lin, Ni, and Takagi [21] on steady states and the work of Jäger and Luckhaus [16] and Herrero and Velázquez [15] on finite time blowup of solutions.

More recently, analytic work was done by Allegretto, Xie, and Yang [1] on a similar system of two equations modeling the chemotactic response of endothelial cells to the tumor angiogenesis factor. In [23], a bifurcation analysis was carried out to study the coexistence in unmixed chemostats with chemotactic effects following the pioneering work in this area by Lauffenburger and coworkers [18, 19, 20]. These authors assumed that the space dimension is one and used numerical methods to study the following system:

$$\begin{array}{lll} -S_{xx} & = & -f_1(S)u_1 - f_2(S)u_2, \\ -d_i(u_i)_{xx} + d_i[\Phi_i(S)u_i S_x]_x & = & [f_i(S) - k_i]u_i \end{array} \tag{1.3}$$

with boundary conditions

$$\begin{aligned} &\frac{\partial S}{\partial x}(0,t) = 0, \quad S(1,t) = 1, \\ &\frac{\partial u_i}{\partial x}(0,t) = 0 = \frac{\partial u_i}{\partial x}(1,t) - u_i(1,t)\Phi_i(S(1,t))\frac{\partial S}{\partial x}(1,t). \end{aligned}$$

The authors assume that the chemotactic sensitivity Φ follows the receptor law

$$\Phi_i(S) = \frac{\alpha_i}{(a_i + S)^2},$$

where α_i, a_i are positive constants. Many different forms have been used in the literature including constant $\Phi = \alpha$ and the log law, $\Phi = \alpha/(a + S)$. The functions $f_i(S)$ represent the functional response of the ith organism to nutrient concentration S and typically are bounded functions satisfying $f_i(0) = 0$, $f_i' > 0$. The constants k_i are cell death rates. One can see that the system (1.1), (1.2) (with $u_0 = S$) includes the above as its special case.

Recently, Wang [23] made use of bifurcation techniques to study the existence of positive steady states of a single species and one-dimensional system (1.3) and also obtained a result on global existence of time-dependent solutions. The argument seems to work only if the "washout state" (see section 3) is spatial homogeneous.

There has been great interest in finding conditions for the existence of at least one steady state of reaction-diffusion systems. Many authors have investigated this problem within the different contexts of biology, ecology, etc., using various techniques. Since the problem is nonvariational, one successful method is the use of topological index theory of fixed points applying to the fixed point form of the system in certain appropriate Banach spaces. We mention here the early works [2, 14]. The main difficulty is to establish certain a priori estimates for the solutions. The couplings in the diffusion terms make this task even more nontrivial. One should recall that there are examples, even with simple reaction terms, where the corresponding time-dependent system can exhibit blowup phenomena (see [15, 16]). Under reasonable conditions, we will obtain in section 2 a priori estimates for the L^∞ norm of solutions to (1.1). Once this is done, the existence of at least one solution follows from the Brouwer–Leray–Schauder degree theory in a standard fashion.

However, it can happen that certain solutions to the system can be found directly by simple inspections. For instance, the system (1.3) has homogeneous boundary conditions for u_i and therefore has trivially a solution with $u_i \equiv 0$ for $i \geq 1$ and appropriate S. Biologically speaking, this solution represents the situation where all the species are washed out from the culture; we then refer to this solution as the "washout" or trivial solution. In this case; the above existence conclusion does not

seem to give interesting results. The main purpose of this paper is to find sufficient conditions for other nontrivial solutions to exist.

Recently, efforts have been made to determine sufficient conditions for nontrivial or positive solutions of (1.4) as certain special (or trivial) solutions were already known. In particular, in [3, 4, 6, 9, 11] homotopy arguments have been employed to give sufficient conditions in terms of eigenvalue problems. The problem was usually considered without chemotactic effect and was equivalent to solving a system of elliptic equations

$$A_i u_i = f_i(x, u_0, \dots, u_m), \quad x \in \Omega,\ i = 0, \dots, m, \tag{1.4}$$

equipped with boundary conditions on $\partial\Omega$. The fixed point form then reads

$$U = K \circ F(U). \tag{1.5}$$

Here, K is the inverse of $\operatorname{diag}\{A_i\}$ and F is defined by the f_i's. The techniques in these works seem to be applicable only for problems of the form (1.4) which has the couplings that occur *only* in the reaction terms f_i. That is, the left-hand side of (1.4) depends only on u_i. Therefore, the methods in the aforementioned works are not well suited for strongly coupled elliptic systems whose fixed point form is not (1.5). On the other hand, one may try to write the fixed point form as $U = \Sigma(U)$ and make use of the degree theory in positive cones (see [2]). However, in doing so, one would quickly find that certain differentiability of the operator Σ needs to be verified. In our case, for this purpose alone, more estimates and extra smoothness assumptions would need to be made on the system (note also the couplings and nonlinearities in the boundary conditions (1.2)).

Nevertheless, in a joint work with Hal Smith [10], we were able to employ arguments similar to [6, 11] to give sufficient conditions for positive coexistence. However, certain unnecessary and biologically unrealistic restrictions on the sensitivity rate Φ_i and the space dimension n (≤ 3) had to be made.

In section 3 of this paper, we will generalize the techniques and revisit the results in [10]. Here, we are able to consider (1.1) in arbitrary dimension space and greatly relax the restriction on the functions Φ_i. Furthermore, we will present an abstract fixed point result for (1.1), (1.2). The existence results in section 2 are just simple consequences of the abstract ones. In fact, section 3.1 unifies the treatments in [3, 6, 11] and [10]. Moreover, they can also be used to study the existence of periodic solutions for strongly coupled parabolic systems (see [5]).

2. The model and existence results. Let Ω be a bounded domain in $\mathbb{R}^n$ with smooth boundary $\partial\Omega$. Consider the following elliptic operators

$$A_i u = \Delta u - b_i(x)\nabla u - c_i u, \quad i = 0, \dots, m,$$

and the elliptic system

$$\begin{cases} -A_0 u_0 = -f_0(x, \vec{u}), & x \in \Omega, \\ -A_i u_i + \operatorname{div}(u_i \Phi_i(u_0)\nabla u_0) = f_i(x, \vec{u}), & x \in \Omega, \\ \dfrac{\partial u_i}{\partial n} + r_i\left(x, \dfrac{\partial u_0}{\partial n}\right)u = u_0^i, \quad \dfrac{\partial u_0}{\partial n} + r_0(x)u_0 = S_0, & x \in \partial\Omega, \end{cases} \tag{2.1}$$

where $\vec{u} = (u_0, u_1, \dots, u_m)$. Hereafter, b_i are continuous vector-valued functions and c_i are continuous functions on Ω. The boundary data $u_0^i(x), S_0(x)$ are bounded functions on $\partial\Omega$.

In this section, we will consider nonhomogeneous boundary conditions in (2.1) and give sufficient conditions which guarantee certain a priori estimates for the solutions. The existence of at least one solution then follows from the standard Leray–Schauder theory.

We make the following assumptions on the characteristics of the system (2.1).

(H.1) For $i = 0, \dots, m$, $b_i \in C(\bar{\Omega}, \mathbb{R}^n)$, $c_i \in C(\bar{\Omega}, \mathbb{R})$. Also, we assume that $\Phi_i : \mathbb{R}_+ \to \mathbb{R}_+$ is continuous differentiable. Moreover, there exist C^2 functions $B_i(x)$, $i = 0, \dots, m$, such that $b_i(x) = \nabla B_i(x)$.

(H.2) $r_0 \in C(\partial\Omega, \mathbb{R}_+)$ and $r_0(x), c_0(x) \geq 0$. Moreover, $c_0(x) > 0$ or r_0 is not identically zero on $\partial\Omega$. $u_0^i(x), S_0(x)$ are nonnegative bounded continuous functions on $\partial\Omega$. For $i \geq 1$, we assume that $|r_i(x, \bullet)|$ is locally bounded.

(H.3) $f_0(x, \vec{u}) \geq 0$ for positive $\vec{u} = (u_0, \dots, u_m) \in \mathbb{R}_+^{m+1}$. Furthermore, for $i > 0$, $f_i(x, \vec{u})$ satisfies the following asymptotically linear growth condition:

$$|f_i(x, \vec{u})| \leq C(u_0)|\vec{u}| + C(u_0), \quad \text{for } |\vec{u}| \text{ large}, \tag{2.2}$$

where $C(u_0)$ is bounded if $|u_0|$ is bounded.

For later use we denote by S_* the unique (by (H.2)) solution of the equation

$$\begin{cases} -\Delta S_* + b_0(x)\nabla S_* + c_0 S_* = 0, & x \in \Omega, \\ \dfrac{\partial S_*}{\partial n} + r_0(x) S_* = S_0(x), & x \in \partial\Omega. \end{cases} \tag{2.3}$$

Remark 2.1. In (H.1) we have assumed that the convection vectors b_i are potential vector fields. In fact, this assumption is not essential for the proof of the following theorems. However, without this assumption one would have to restrict to domains Ω in $\mathbb{R}^3$ (see Remark 2.4 after the proof of Theorem 2.1). We remark that the condition $\Phi' > 0$ had to be assumed in [10]. On the other hand, as a trivial generalization using Sobolev inequalities, the growth condition in (H.3) can be relaxed to certain subcritical growth conditions.

We first show that the L^∞ norm of positive solutions can be controlled by their L^1 norm.

THEOREM 2.1. *Assume* (H.1)–(H.3). *Let $\vec{u}$ be any nonnegative bounded solutions to* (2.1). *Then there exists a continuous function $K_1(\cdot)$ such that*

$$\|\vec{u}\|_\infty \leq K_1(\|\vec{u}\|_1). \tag{2.4}$$

Therefore, to obtain a priori L^∞ estimates we need only to control the L^1 norms of the solutions. There are ways to achieve this. Being inspired by the system (1.3) (see also [10]), we can consider the following assumptions on the convection and reaction terms f_i.

(F.1) There is a continuously differentiable extension of Φ_i to all of $\mathbb{R}$ and

$$r_i\left(x, \frac{\partial u_0}{\partial n}\right) + \Phi_i(u_0)\frac{\partial u_0}{\partial n} + \frac{\partial B_i}{\partial n} \geq 0$$

on $\partial\Omega$ for all (not necessarily nonnegative) function u_0 satisfying $u_0 \leq S_*$ in Ω, and $\frac{\partial u_0}{\partial n} = S_0 - r_0 u_0$.

(F.2) There exist positive constants h_i, β, C such that

$$-h_0 f_0(x, \vec{u}) + \sum_{i=1}^m h_i f_i(x, \vec{u}) \leq \beta \sum_{i=0}^m h_i u_i + C \tag{2.5}$$

for all $\vec{u} = (u_0, \dots, u_m) \in \mathbb{R}_+^{m+1}$. Moreover, there is a positive constant θ such that

$$c_i - \Delta B_i(x) - \beta \geq \theta \quad \text{for all } x \in \Omega, \quad i = 1, \dots, m.$$

We then have the following theorem.

THEOREM 2.2. *Under the conditions* (F1), (F.2), *there is a positive constant* K_3 *independent of* $\vec{u}$ *such that*

$$\|u_i\|_1 \leq K_2, \quad i = 1, \dots, m. \tag{2.6}$$

The proof is simple by integrating the equations over Ω and adding the results (see [10, Theorem 2]). Combining the above estimates we have the following.

COROLLARY 2.3. *Under the conditions* (H.1)–(H.3) *and* (F1), (F.2), *for any* $\nu \in (0,1)$, *if* $u_0^i \in C^\nu(\partial\Omega)$, *then there is a positive constant* K_3 *independent of* $\vec{u}$ *such that*

$$\|u_i\|_{C^\nu(\Omega)} \leq K_3, \quad i = 0, \dots, m. \tag{2.7}$$

Having established these a priori estimates, we study the solvability of (2.1) using Leray–Schauder degree theory. Since we will be interested only in nonnegative solutions and make use of maximum principles we will assume hereafter the following.

(F.3) f_i is continuous in its arguments and $f_i(x, \vec{u}) \geq 0$ for all $i > 0$, $x \in \Omega$, and $\vec{u} \in \mathbb{R}_+^m$. Moreover, $f_0(x, \vec{u})$ vanishes if $u_0 = 0$. Assume also that $u_0^i, S_0 \in C^\nu(\Omega)$ for some $\nu \in (0,1)$.

We should remark that the assumption $f_i(x, \vec{u}) \geq 0$ is not really needed here. In fact, because the solutions of (2.1) are shown to be uniformly bounded by Corollary 2.3, this condition can be fulfilled by adding ku_i, with k sufficiently large, to both sides of the ith equation and redefining f_i.

We set up a fixed point equation in the positive cone X_+ of $X := \prod_0^{m+1} C^\nu(\Omega)$ for (2.1) as follows (compare to [10, pp. 305–306]). Given $\psi = (\psi_0, \dots, \psi_m)$ in X_+, we denote by $S, u_1, \dots, u_m$ the solutions to the system

$$\begin{cases} -A_0 S = -f_0(x, \psi), & x \in \Omega, \\ -A_i u_i + \operatorname{div}(u_i \Phi_i(S) \nabla(S)) = f_i(x, \psi), & x \in \Omega, \\ \dfrac{\partial u_i}{\partial n} + r_i\left(x, \dfrac{\partial S}{\partial n}\right) u_i = u_0^i, \quad \dfrac{\partial S}{\partial n} + r_0(x) S = S_0, & x \in \partial\Omega. \end{cases} \tag{2.8}$$

We then define $F(\psi) = \vec{u} = (u_0, \dots, u_m)$ with $u_0 = [S]_+$ and u_i, for $i > 0$, as above. We have the following lemma.

LEMMA 2.2. *Assume that* (H.1)–(H.3) *and* (F.1)–(F.3) *hold. Then* $F : X_+ \to X_+$ *is a well-defined completely continuous operator. Moreover, fixed points of* F *in* X_+ *are solutions of* (2.1).

Next, we have the following consequence of the a priori estimates derived in Theorem 2.1.

LEMMA 2.3. *Let the assumptions of Lemma* 2.2 *hold. Then there is an* $R > 0$ *such that*

$$F(\lambda U) = U, \quad \lambda \in [0,1], \tag{2.9}$$

has no solution $U \in X_+$ *satisfying* $\|U\| = R$.

The above result allows us to compute the index of the map F and then obtain the existence of at least one solution to the system as follows.

THEOREM 2.4. *For $r > 0$, let $C_r = \{u \in X_+ : \|u\| < r\}$. With R given by* Lemma 2.3*, we have*

$$\operatorname{ind}(F, C_R) = +1.$$

In particular, there is a fixed point of F in C_R.

Proof. The fact that $\operatorname{ind}(F, P_R) = +1$ follows by using a standard homotopy using the parameter λ in (2.9) and (2.16). In particular, we consider the family of maps $H(\lambda, U) = F(\lambda U)$, which is a well-defined homotopy in C_R thanks to Lemma 2.3, and find

$$\operatorname{ind}(F, C_R) = \operatorname{ind}(H(0, \bullet), C_R) = +1.$$

The last equality follows from the fact that $H(0, U) = F(0)$ is a constant map (cf. Lemma 2.2). □

We conclude this section by giving the proofs of the stated lemmas and theorems.

2.1. A priori estimates. The fact that $f_0(x, \vec{u}) \geq 0$ and comparison principles give immediately the estimate $u_0 \leq S_*$. This and (H.1), (H.2), and the boundary condition for u_0 imply that there exists a positive constant $C(S_*)$ such that

$$|\Phi_i(u_0)|, \quad \left|\frac{\partial u_0}{\partial n}\right|, \quad \left|r_i\left(x, \frac{\partial u_0}{\partial n}\right)\right| \leq C(S_*) \quad \text{on } \partial\Omega. \tag{2.10}$$

We should remark that (2.10) does not give us any information on the derivative ∇u_0 inside the domain Ω.

Proof of Theorem 2.1. Dropping the subscripts, we write the equation for $u = u_i$ in the form

$$\begin{cases} -\operatorname{div}(\nabla u - (\nabla B + \Phi(u_0)\nabla u_0)u) + (c - \Delta B)u = f(x, \vec{u}) & \text{on } \Omega, \\ \dfrac{\partial u}{\partial n} + ru = u_0^i & \text{on } \partial\Omega. \end{cases} \tag{2.11}$$

Here we use the fact that $\nabla B \nabla u = \operatorname{div}(u\nabla B) - u\Delta B$. Set $\Phi_*(S) = \int_0^S \Phi(s)ds$. We introduce new variables

$$U = e^{-(B+\Phi_*(u_0))}u, \ \vec{U} = E(u_0)\vec{u}, \ \text{with } E(u_0) = \operatorname{diag}\{e^{-(B_i+\Phi_{*,i}(u_0))}\},$$

and observe the following:

$$\begin{aligned} \nabla u - (\nabla B + \Phi(u_0)\nabla u_0)u &= e^{B+\Phi_*(u_0)}\nabla U, \\ \frac{\partial u}{\partial n} &= e^{B+\Phi_*(u_0)}\left(\frac{\partial U}{\partial n} + \frac{\partial(B + \Phi_*(u_0))}{\partial n}U\right). \end{aligned}$$

We can see that (2.11) implies

$$\begin{cases} -\operatorname{div}(e^{B+\Phi_*(u_0)}\nabla U) + (c - \Delta B)e^{B+\Phi_*(u_0)}U = f(x, E^{-1}(u_0)\vec{U}) \text{ on } \Omega, \\ \dfrac{\partial U}{\partial n} + \left(r + \dfrac{\partial(B + \Phi_*(u_0))}{\partial n}\right)U = u_0^i e^{B+\Phi_*(u_0)} \text{ on } \partial\Omega. \end{cases} \tag{2.12}$$

Our system becomes a quasi-linear system of elliptic equations with the couplings occurring in the diffusion rates $e^{B+\Phi_*(u_0)}$. However, the new system is nondegenerate. That is, since $u_0 \geq 0$ and u_0 is bounded, we can find positive constants λ, Λ (depending on S_*) such that

$$0 < \lambda \leq e^{B+\Phi_*(u_0)} \leq \Lambda. \tag{2.13}$$

This also shows that the L^1 norms of U and u are comparable. Moreover, the growth condition (2.2) now reads

$$|f(x, E^{-1}(u_0)\vec{U})| \leq C(S_*)|\vec{U}| + C(S_*) \quad \text{for } |\vec{U}| \text{ large.} \tag{2.14}$$

Since solutions of the uniformly elliptic system (2.12) are also solutions of the corresponding parabolic system, whose nonlinearities satisfy (2.14), a more general result [8, 7] can be applied here to give the estimate (2.4) for $\vec{U}$. The same is true for $\vec{u}$ since the L^∞ norms of $\vec{U}, \vec{u}$ are comparable. The proof is complete. □

Remark 2.4. Without the assumption that b_i are potential vector fields, one can still make use of the change of variables $U = e^{-\Phi_*(u_0)}u$, but the equation for U in (2.12) will have the term $U\nabla u_0$. This will cause some difficulties in using the Moser-type iteration technique to obtain (2.4). One needs to control the term ∇u_0 but this quantity depends on some integral of u from the equation of u_0. Therefore, certain restrictions such as $n \leq 3$ should be made. We refer to [10, page 299] for the details. However, we want to remark that the assumption $\Phi' \geq 0$ in [10] is unnecessary due to the argument in this remark and by repeating the lines in [10, page 300]. On the other hand, we should remark that the above result does not hold for the parabolic-elliptic systems of Keller–Segel [15, 16, 17] where blowup may occur even though the L^1 norms of solutions are conserved. However, in the one-dimensional case, we are able to show in [5] that (2.4) continues to hold for parabolic versions of (2.1).

Proof of Corollary 2.3. From Theorems 2.1 and 2.2 we see that the L^∞ norms of the right-hand sides of the equations of (2.1) are bounded by some finite constant independent of u_i. From the L^p theory of elliptic equation (see [12, Theorem 19.1, p. 74]) we have

$$\|u_0\|_{W^{2,p}(\Omega)} \leq C_p(\|u_0\|_p + \|f_0(x, \vec{u})\|_p) \leq K(p)$$

for all $p \in (1, \infty)$. $C_p, K(p)$ are constants independent of S. Taking p sufficiently large and using the Sobolev imbedding theorem, we can see that $\|u_0\|_{C^{1+\nu}(\Omega)}$ is bounded. Thus, if we write the equation of u_i in its divergence form

$$-\mathrm{div}(\nabla u_i - \Phi_i(u_0)\nabla u_0 u_i) + b_i(x)\nabla u_i + c_i u = f_i(x, \vec{u}),$$

which has bounded Hölder continuous coeffients, then u_i, as a bounded weak solution to the above equation, is C^β Hölder continuous with bounded Hölder norm (see [13, Chapter 8]) for some $\beta \in (0, 1)$. Now, with $u_i \in C^\beta(\Omega)$ with uniformly bounded norms, we see that the right-hand sides of the equations are also bounded in $C^\beta(\Omega)$. The Schauder estimates (see [13, Chapter 6]) imply that $u_0 \in C^{2+\beta}(\Omega)$. This improves the regularity of the coefficients of the equation for u_i, $i > 0$, considering u_0 as a parameter. Applying Schauder's estimates again we can conclude that u_i belongs to $C^{2+\beta}(\Omega)$ as well. In addition, the $C^{2+\beta}$ norms of u_i are uniformly bounded. Our proof is complete. □

2.2. Existence.

Proof of Lemma 2.2. The proof is standard and we will only sketch the main points here (cf. [10, Lemma 3.1]). By (H.2), it is well known that the first equation has a unique solution u_0 in $C^{2+\nu}(\Omega)$ (see [13, Theorem 6.31]). Clearly, $u_0 = [S]_+ \geq 0$. By the maximum principle argument we can show that $S_* \geq S$. On the other hand, in the equation for $u = u_i$ we set $\Phi_*(S) = \int_0^S \Phi(s)ds$ and introduce the new variable $U = e^{-(B+\Phi_*(S))}u$ as in the proof of Theorem 2.1 to find that

$$\begin{cases} -\mathrm{div}(a(x)\nabla U) + d(x)U = g(x) & \text{on } \Omega, \\ \dfrac{\partial U}{\partial n} + R(x)U = 0 & \text{on } \partial\Omega \end{cases} \tag{2.15}$$

with

$$a(x) = e^{B+\Phi_*(S)}, \quad d(x) = (c - \Delta B)e^{B+\Phi_*(S)}, \quad g(x) = f(x, \vec{\psi}(x)),$$

$$R(x) = r\left(x, \frac{\partial S}{\partial n}(x)\right) + \frac{\partial B}{\partial n}(x) + \Phi(S(x))\frac{\partial S}{\partial n}(x).$$

The boundary condition of u_0 implies $\frac{\partial u_0}{\partial n} = S_0 - r_0 u_0$, so that, by (F.1), $R(x) \geq 0$ on $\partial\Omega$. Also, by (F.2), $d(x) > 0$. (In fact, this assumption in (F.2) is used only for the L^1 estimate of Theorem 2.2. Here, one can always achieve this by adding Ku_i to both sides of the equation, for K large enough.) The maximum principle for linear elliptic equations [13, Corollary 3.2] applies to the above equation for U ($g(x) \geq 0$) and shows that $U(x) > 0$. Therefore, $u(x) > 0$ in Ω.

Therefore, one can solve for S from its equation in (2.8) and substitute the result into the equation for U. The above facts about the coefficients of the equation of U also imply that we can solve for U_i, and thus u_i, uniquely in $C^{2+\nu}(\Omega)$ from their equations in (2.8). Hence, F is well defined and maps X_+ into itself. The complete continuity of F follows in a standard way using Schauder's estimates for uniformly elliptic equations (see Corollary 2.3). Finally, if $(u_0, \ldots, u_m) \in X_+$ is a fixed point of F then, because $f_0(x, u_0, \ldots, u_m) = 0$ as $u_0 = 0$ and (H.2), a maximum principle argument shows that $S \geq 0$ so that $u_0 \equiv S$. In this case, (2.8) and (2.1) coincide and our last claim follows. □

Proof of Lemma 2.3. The above equation (2.9) is equivalent to

$$\begin{cases} -A_0 u_0 & = & -f_0(x, \lambda\vec{u}), & x \in \Omega, \\ -A_i u_i + \mathrm{div}(u_i \Phi_i(u_0)\nabla u_0) & = & f_i(x, \lambda\vec{u}), & x \in \Omega, \\ \dfrac{\partial u_i}{\partial n} + r_i\left(x, \dfrac{\partial u_0}{\partial n}\right)u_i = 0, & & \dfrac{\partial u_0}{\partial n} + r_0(x)u_0 = S_0, & x \in \partial\Omega. \end{cases} \tag{2.16}$$

Define f_λ for $\lambda \in [0,1]$ by $f_\lambda = (\hat{f}_0, \ldots, \hat{f}_m)$, where $\hat{f}_0(x, \vec{u}) = f_0(x, \lambda\vec{u})$, $\hat{f}_i(x, \vec{u}) = f_i(x, \lambda\vec{u})$, $1 \leq i \leq m$. Then it is easy to check that if f satisfies (F.1) and (F.2) of section 2, which we are assuming, then f and f_λ, with $\lambda \in [0,1]$, also satisfy these assumptions with a common set of constants h_i, β, C, θ , which are independent of $\lambda \in [0,1]$. Therefore the L^1 estimates of Theorem 2.2 and the L^∞ estimates of Theorem 2.1 hold for the solutions of (2.16) using the same constants K_1, K_2. Consequently, we may take $R = K_3$, the constant given in Corollary 2.3, to complete our proof. □

3. Existence of positive steady states. As we mentioned in the introduction, in applying Theorem 2.4 to the system (1.3) we do not obtain interesting results, unless u_0^i is not identically zero, since we already observe that $u_0 = S_*$ and $u_i = 0$ for $i > 0$ is a solution of (1.3). This solution describes the situation when all species except the nutrient have been washed out from the reactor. In fact, this is a common scenario in biological models when certain "trivial" solutions have been known to exist by simple inspections. Hence, it is important to find conditions which guarantee the existence of other solutions which have positive components. Such solutions are called the *coexistence* states of the system.

In this section we will look at this question for the system (2.1) and restrict ourselves to the case $m \leq 2$. In biological terms, we will consider the coexistence problem for models of one nutrient and no more than two species. We then consider the following conditions.

(F.4) We assume that $u_0^i \equiv 0$ on $\partial\Omega$. For $i > 0$, $f_i(x, \vec{u})$ vanishes when $u_i = 0$ and $f_0(x, \vec{u}) = 0$ if $u_i = 0$ for all $i \neq 0$. Moreover, f_i has continuous partial derivatives $\frac{\partial f_i}{\partial u_i}$ satisfying $\frac{\partial f_i}{\partial u_i} > 0$.

Again, the assumption that $\frac{\partial f_i}{\partial u_i} > 0$ is not essential here since we can add ku_i, k sufficiently large, to both sides of the ith equation and redefine f_i.

It is clear that (2.1) has a solution $(S_*, 0, \ldots, 0)$ to which we refer as the "washout" solution of (2.1) and recall that $S_*(x) > 0$ for all x. From (F.4), we see that there can be two types of solutions to (2.1) in addition to this washout solution:

$$\text{Semitrivial solutions:} \quad (u_0, u_1, 0) \quad (u_0, 0, u_2); \quad \text{Positive solutions:} \quad (u_0, u_1, u_0),$$

where the components $u_i > 0$. In what follows we will study the existence of solutions of these types. To this end, we will make use of the abstract results presented below (section 3.1) to compute the fixed point index of the map F. To start, let us rewrite the fixed point form of (2.1) in the following way.

From the proof of Lemma 2.2, for any $\psi \in X_+$ given, we can write $u_0 = F_0(\psi)$ given by

$$u_0 = [S]_+, \text{with } -A_0 S = -f_0(x, \psi(x)) \quad \text{and} \quad \frac{\partial S}{\partial n} + r_0(x)S = S_0 \quad \text{on } \partial\Omega. \tag{3.1}$$

Substitute u_0, which depends on ψ, into the other equations. From the proof of Lemma 2.2, (2.15) is regularly elliptic for any such u_0. Thus we can define

$$K_i(\psi) = \left\{ -A_i \bullet + \alpha \operatorname{div}(\bullet \Phi_i(u_0) \nabla u_0), \frac{\partial \bullet}{\partial n} + r_i\left(x, \frac{\partial u_0}{\partial n}\right) \bullet \right\}^{-1}, \tag{3.2}$$

$$\bar{F}_i(\psi)(x) = f_i(x, \psi(x)).$$

Hence, $K_i(\psi)$ is a linear strongly positive and compact map for each $\psi \in X_+$. We can write $u = F(\psi)$ in the form

$$u_0 = F_0(\psi), \quad u_i = F_i(\psi) := K_i(\psi) \circ \bar{F}_i(\psi). \tag{3.3}$$

It is the purpose of the next section to study the fixed point problem for a system in which the operator is of the form (3.3). We want to remark that the result applies trivially to the nonchemotactic problems as well so that the following can be considered as an abstract version of the cases treated in [3, 6, 10, 11].

3.1. An index result. In order to state our main result of this section we will need some notation. Let X_i, $i = 0, \dots, m$, be ordered Banach spaces with positive cones C_i. Set $X = \oplus_{i=0}^m X_i$ and $C = \oplus_{i=0}^m C_i$.

Let Ω be an open set in C containing 0 and let $F_i : \bar{\Omega} \to C_i$ be completely continuous operators. Denote by $u = (u_0, \dots, u_m)$ a generic element in C. We define $F : \bar{\Omega} \to C$ by

$$F(u) = (F_0(u), \dots, F_m(u)).$$

Let $\mathcal{B}$ be the collection of subsets of $M = \{0, \dots, m\}$. For each nonempty $\beta \in \mathcal{B}$, we write $X_\beta = \oplus_{i\in\beta} X_i$, $C_\beta = \oplus_{i\in\beta} C_i$. If $\beta = \emptyset$ we set $X_\beta = C_\beta = \{0\}$. In what follows, we will regard X_β, C_β as subspaces and subsets of X. We also define

$$F_\beta(u) : \bar{\Omega} \to C_\beta, \quad F_\beta(u) = (F_i(u))_{i\in\beta}.$$

For each $\beta \in \mathcal{B}$, we set

$$Z_\beta = \{u = (u_0, \dots, u_m) \in \Omega \ : \ F(u) = u, \quad u_i > 0 \quad \text{if } i \in \beta, \quad u_i = 0 \quad \text{if otherwise}\}.$$

Thus, Z_β is the set of fixed points of F on the "face" (or edge) C_β of C. In particular, if $\beta = M$, then Z_β consists of all positive fixed points, that is, all of their components are positive. Otherwise, we refer to Z_β ($\beta \neq M$) as the set of semitrivial fixed points. Also, $Z_\emptyset = \{0\}$ if $F(0) = 0$. If $\beta \neq \emptyset$ we can also think of Z_β as the set of positive fixed points of $F_\beta|_{C_\beta}$.

If $Z_\beta \neq \emptyset$ we set $\alpha = M \setminus \beta$ and assume that there exist open sets $W_\beta \subset \Omega \cap C_\beta$ and $W_\alpha \subset \Omega \cap C_\alpha$ with $0 \in W_\alpha$ such that $Z_\beta \subset W_\beta$. For $u \in \Omega$, we write $u = (u_\beta, u_\alpha)$ and consider the neighborhood $W_\beta \oplus W_\alpha$ of Z_β in Ω. For each fixed $u_\beta \in W_\beta$, $u_\alpha \in W_\alpha$ we assume that $F_\alpha(u_\beta, u_\alpha)$ can be expressed in the form

$$F_\alpha(u_\beta, u_\alpha) = K_\alpha(u_\beta, u_\alpha) \circ \bar{F}_\alpha(u_\beta, u_\alpha), \tag{3.4}$$

where $K_\alpha : W_\beta \oplus W_\alpha \to L(X_\alpha)$, the Banach space of bounded linear maps from X_α into itself, and $\bar{F}_\alpha : W_\beta \oplus W_\alpha \to X_\alpha$. Assume also that K_α is continuous in (u_β, u_α) and $\bar{F}_\alpha(u_\beta, \cdot) : W_\alpha \to X_\alpha$ is continuously differentiable (with respect to u_α) with its partial derivative denoted by $\partial_\alpha \bar{F}_\alpha$. We assume that $\partial_\alpha \bar{F}_\alpha(u_\beta, u_\alpha)$ is continuous in $W_\beta \oplus W_\alpha$.

For $\beta \in \mathcal{B}$ such that $Z_\beta \neq \emptyset$, we assume that

$$\bar{F}_\alpha(u_\beta, 0) = 0 \quad \text{for all } u_\beta \in W_\beta. \tag{3.5}$$

Set $B_\alpha(u_\beta, u_\alpha) = K_\alpha(u_\beta, u_\alpha) \circ \partial_\alpha \bar{F}_\alpha(u_\beta, u_\alpha)$. We consider the following condition.

(E_1) For each $u = (u_\beta, 0) \in Z_\beta$, 1 is not an eigenvalue of $B_\alpha(u_\beta, 0)$ corresponding to a positive eigenvector of $B_\alpha(u_\beta, 0)$.

Remark 3.1. If F_α is differentiable, one can easily see that (3.5) implies that $B_\alpha(u_\beta, 0)$ coincides with $\partial_\alpha F_\alpha(u_\beta, 0)$. However, since we do not assume any differentiability on K_α, $\partial_\alpha F_\alpha(u_\beta, u_\alpha)$ is not differentiable in general. We keep such notation to emphasize this fact.

Consider the following situations for the spectral radius r of $B_\alpha(u_\beta, 0)$:

(E_+) $r(B_\alpha(u_\beta, 0)) < 1$ for all $u_\beta \in Z_\beta$;

(E_-) $r(B_\alpha(u_\beta, 0)) > 1$ for all $u_\beta \in Z_\beta$.

We then set

$$\sigma(\beta) = \begin{cases} 1 & \text{if } (E_+) \text{ holds,} \\ 0 & \text{if } (E_-) \text{ holds.} \end{cases} \tag{3.6}$$

For each $\beta \in \mathcal{B}$ such that $\beta \neq \emptyset$ and $Z_\beta \neq \emptyset$, there exists an open neighborhood U_β of Z_β, as a subset of C_β, such that the set of fixed points of F_β in $\Omega \cap C_\beta$ is exactly Z_β. So, $\mathrm{ind}(F_\beta|_{C_\beta}, U_\beta)$ is well defined. If 0 is a fixed point of F, then $Z_\emptyset = \{0\}$ and, by Lemma 3.4 below, (E_1) implies that such a neighborhood $U_\emptyset$ of 0 in C exists. We then define the "face" indices

$$i(\beta) = \begin{cases} \mathrm{ind}(F_\beta|_{C_\beta}, U_\beta), & \beta \neq \emptyset, \\ \mathrm{ind}(F, U_\emptyset), & \beta = \emptyset. \end{cases} \tag{3.7}$$

If U is an open set and Z is the set of fixed points of F in U, then we also define the local index of the fixed point set Z by $i(F, Z) = \mathrm{ind}(F, U)$.

The index result then reads as follows.

THEOREM 3.1. *Suppose that* (3.5), (E_1), *and either* (E_+) *or* (E_-) *hold for each* β. *Moreover,* $B_\alpha(u_\beta, 0)$ *is strongly positive for all* $u_\beta \in Z_\beta$. *We assert that*

(i) $i(F, Z_\beta) = \sigma(\beta) i(\beta)$. *Here,* $i(F, Z_\beta)$ *is the local index of the fixed point set* Z_β;

(ii) *if*

$$\mathrm{ind}(F, \Omega) \neq \sum_{\beta \in \mathcal{B}, \beta \neq M, Z_\beta \neq \emptyset} \sigma(\beta) i(\beta), \tag{3.8}$$

then there exists at least a positive solution to $F(u) = u$.

Remark 3.2. The assumption that $B_\alpha(u_\beta, 0)$ is strongly positive can be dropped. The proof of Proposition 3.4 reveals that instead of (E_+), (E_-), we need only to assume that

(E'_+) For $u_\beta \in Z_\beta$, $B_\alpha(u_\beta, 0)$ has no positive eigenvector corresponding to an eigenvalue greater than 1.

(E'_-) For each $\beta \in \mathcal{B}$ with $Z_\beta \neq \emptyset$, there exists a positive $p_\alpha \in C_\alpha$ such that $v = B_\alpha(u_\beta, 0)v + tp_\alpha$ has no positive solution v for all $t > 0$.

Regarding (E'_-), we remark that it is easy to verify, especially when Z_β is a singleton (see Remark 3.5). In this case, we need only to assume that $B_\alpha(u_\beta, 0)$ has a positive eigenvector p_α corresponding to an eigenvalue $\lambda_\alpha > 1$.

Remark 3.3. In terms of stability of fixed points, condition (E_+) (resp., (E_-)) simply says that every element of Z_β is "stable" (resp., "unstable") to invasion by the α-variable ($\alpha = M \setminus \beta$). We also say that Z_β is "attracting" (resp., "repelling") in the complementary direction C_α of the cone C_β. We then observe that the right-hand side of (3.8) is just the sum of the face indices of attracting semitrivial fixed point set Z_β.

As a simple consequence of Theorem 3.1, we assert the following.

COROLLARY 3.2. *If* $\mathrm{ind}(F, \Omega) \neq 0$ *and* Z_β *is "repelling" for all* β *such that* $Z_\beta \neq \emptyset$, *then there is at least one positive fixed point of* F *in* Ω.

To prove Theorem 3.1 we need to compute the index of the map in a neighborhood of the "face" fixed point set Z_β. To this end, we need the following lemmas.

Suppose X_1 and X_2 are ordered Banach spaces with positive cones C_1 and C_2, respectively. We define $X = X_1 \oplus X_2$ and $C = C_1 \oplus C_2$.

Let Ω be an open set in C containing 0 and let $F_i : \bar{\Omega} \to C_i$ be completely continuous operators, $i = 1, 2$. Denote generic elements in C by (u, v) with $u \in C_1$ and $v \in C_2$. Let $F : \bar{\Omega} \to C$, a nonlinear map given by

$$F(u, v) = (F_1(u, v), F_2(u, v)). \tag{3.9}$$

We consider the following fixed point problem.

$$F(u, v) = (u, v). \tag{3.10}$$

Suppose $U \subset C_1$, $V \subset C_2$ are bounded open sets and

$$\bar{F}_2(u, 0) = 0 \quad \text{for all } u \in \bar{U}, \tag{3.11}$$

$$F_1(u, 0) \neq u \quad \text{for all } u \in \partial U. \tag{3.12}$$

Suppose that $Z_1 = \{u \in U \ : \ u = F_1(u, 0)\}$, the set of fixed points of $F_1(u, 0)$ in C_1, is not empty. By (3.11), if $u \in Z_1$ then $(u, 0)$ is a solution of (3.10) on the face C_1. As in (3.4), for each $u \in U$, we assume that the operator F_2 can be expressed in the form

$$F_2(u, v) = K(u, v) \circ \bar{F}_2(u, v), \tag{3.13}$$

where $K : U \oplus V \to L(X_2)$, the Banach space of bounded linear maps from X_2 into itself, and $\bar{F}_2 : U \oplus V \to X_2$. Assume also that K is continuous in u, v (not necessarily differentiable) and $\bar{F}_2(u, \cdot) : V \to X_2$ is continuously differentiable in v with its partial derivative denoted by $\partial_v \bar{F}_2(u, v)$. We suppose that $\partial_v \bar{F}_2(u, v)$ is continuous in $U \oplus V$ and denote

$$B(u, v) = K(u, v) \circ \partial_v \bar{F}_2(u, v), \quad (u, v) \in U \oplus V. \tag{3.14}$$

Then $B(u, v)$ is a map from $U \oplus V$ into C_2. Consider the following condition.

(B) For each $u \in Z_1$, $B(u, 0)$ is compact and 1 is not an eigenvalue of $B(u, 0)$ corresponding to a positive eigenvector.

The following decoupling technique is useful in computing the index of $F(u, v)$.

PROPOSITION 3.3. *Assume* (B) *and that* $tv \in V$ *for any* $v \in V$ *and* $t \in [0, 1]$. *Suppose that*

$$F(u, v) = (u, v) \quad \textit{has no solution in closure } (U \oplus V) \textit{ with } v > 0. \tag{3.15}$$

Then $\operatorname{ind}(F, U \oplus V) = \operatorname{ind}(H, U \oplus V)$, *where* $H(u, v) = (F_1(u, 0), B(u, 0)v)$.

Note that the equation $(u, v) = H(u, v)$ has been decoupled. That is, one can solve u from the first equation and then substitute the result into the second one.

Proof. By (3.11), $\bar{F}_2(u, 0) = 0$ so that we can write for $t \in [0, 1]$

$$\bar{F}_2(u, tv) = t \int_0^1 \partial_v \bar{F}_2(u, tsv) v ds. \tag{3.16}$$

We consider the following homotopy in $E = U \oplus V$.

$$H(t, u, v) = \left(F_1(u, tv), K(u, tv) \int_0^1 \partial_v \bar{F}_2(u, tsv) v ds \right), \ t \in [0, 1], (u, v) \in E. \tag{3.17}$$

Recall that $K(u,v)$ is a linear map. By (3.16), $H(1,u,v) = F(u,v)$. If there exists $t \in (0,1]$ such that $H(t,u,v)$ has a fixed point $(u,v) \in \partial E$, the boundary of E relative to C, then $v > 0$ since otherwise $u \in Z_1$; but then $(u,0) \notin \partial E$ because of (3.12). Thus, $v > 0$ and (u,tv) is a fixed point of $F(u,v)$ (cf. (3.16)), a contradiction to (3.15). If $H(0,u,v) = (u,v)$ has a solution $(u,v) \in \partial E$ then $u \in Z_1$ and $v > 0$. By (3.17), we have that $v = K(u,0) \circ \partial_v \bar{F}_2(u,0)v = B(u,0)v$ and v is thus a positive eigenvector to $B(u,0)$ with respect to the eigenvalue 1, a contradiction to (B). Hence, the homotopy (3.17) is well defined on E.

Consequently, by the homotopy invariance,

$$\operatorname{ind}(F,E) = \operatorname{ind}(H(1,\bullet),E) = \operatorname{ind}(H(0,\bullet),E). \tag{3.18}$$

This proves the claim since $H(0,\bullet)$ is exactly H. □

In fact, the assumption (3.15) comes from (B) if V is a small neighborhood of 0. Let us denote $C_2(r) = \{v \in C_2 \ : \ \|v\| < r\}$. We then have the next lemma.

LEMMA 3.4. *Assume* (B). *If $V = C_2(r)$ with r sufficiently small, then* (3.15) *is satisfied.*

Proof. Suppose (3.15) is not true for every small $r > 0$. Then there exist sequences of elements $\{u_n\}$,$\{v_n\}$ such that $u_n \in U$, $v_n > 0$, and $\|v_n\| \to 0$ and

$$u_n = F_1(u_n,v_n), \quad v_n = F_2(u_n,v_n) = K(u_n,v_n)\int_0^1 \partial_v \bar{F}_2(u_n,sv_n)v_n ds \quad \text{for all } n.$$

We set $w_n = v_n/\|v_n\|$ and find that

$$w_n = K(u_n,v_n)\int_0^1 \partial_v \bar{F}_2(u_n,sv_n)w_n ds \quad \text{for all } n.$$

By the compactness and continuity of K and $\partial_v \bar{F}_2(\bullet)$, we easily see that $\{w_n\}$ is precompact. Also, the compactness of F_1 implies $\{u_n\}$ is precompact. Without loss of generality, we suppose that $u_n \to u$ and $w_n \to w > 0$. It follows that $u = F_1(u,0)$ and $w = B(u,0)w$. Hence, $u \in Z_1$ and $w > 0$ is an eigenvector of $B(u,0)$ to the eigenvalue 1, a contradiction to (B). The proof is complete. □

We now compute the index of $H(u,v) = (F_1(u,0), B(u,0)v)$. We state the result in a slightly more general form as follows.

PROPOSITION 3.4. *Let $B : U \to L(X_2)$ such that $B(u)$ is a linear operator for every $u \in U$. Assume that $H(u,v) = (F_1(u,0), B(u)v)$ is completely continuous. We then have*

(i) $\operatorname{ind}(H, U \oplus V) = \operatorname{ind}(F_1|_U, U)$ *if for any $u \in Z_1$, $B(u)$ has no positive eigenvector to an eigenvalue greater than one;*

(ii) $\operatorname{ind}(H, U \oplus V) = 0$ *if there exists an element $p \in C_2$ such that, for any $u \in Z_1$, we have*

$$v \neq B(u)v + tp \quad \text{for all } v \in \partial V \quad \text{for all } t > 0. \tag{3.19}$$

Proof. (i). Consider the following homotopy:

$$G(t,u,v) = (F_1(u,0), tB(u)v), \quad t \in [0,1]. \tag{3.20}$$

If $G(t,u,v) = (u,v)$ for some $(u,v) \in \partial E$ and $t \in [0,1]$, then obviously $u \in Z_1$ and $t > 0$ and $v > 0$. But this means that v is a positive eigenvector to the eigenvalue

$t^{-1} > 1$ of $B(u)$ and contradicts our assumption. Thus, by the homotopy invariance of the degree

$$\operatorname{ind}(F, E) = \operatorname{ind}(H(0, \bullet), E) = \operatorname{ind}(G(1, \bullet), E) = \operatorname{ind}(G(0, \bullet), E).$$

However, $G(0, \bullet)$ can be viewed as the product of two maps, $G_1 \equiv F_1|_U$ on U and $G_2 \equiv 0$ on V. Since $\operatorname{ind}(0, V) = +1$, by the product theorem of Leray ([24, Theorem 13.F]) we have

$$\operatorname{ind}(F, E) = \operatorname{ind}(G_1, U) \times \operatorname{ind}(G_2, V) = \operatorname{ind}(F_1|_U, U).$$

Case (ii). We consider the following homotopy:

$$G(t, u, v) = (F_1(u, 0), B(u)v + tp), \quad t \geq 0. \tag{3.21}$$

If $(u, v) \in \partial E$ is a solution of $G(t, u, v) = (u, v)$, then $u \in Z_1$ and $u > 0$. Moreover, $u \in \partial V$ satisfies $v = B(u)v + tp$. This contradicts (B) if $t = 0$ and (3.19) if $t > 0$. Hence, the above homotopy (3.21) is well defined on E.

However, for t large, since $(u, v) \to B(u)v$ is compact, obviously $G(t, u, v)$ has no solution in the bounded set E and therefore $\operatorname{ind}(G(t, \bullet), E)$ must be zero for t large. By homotopy invariance we have that

$$\operatorname{ind}(F, E) = \operatorname{ind}(G(0, \bullet), E) = 0.$$

This completes the proof. □

Since $F_2(u, \bullet)$ maps V into the positive cone C_2 and $F_2(u, 0) = 0$ we easily see that $B(u, 0)$ is a positive linear map. Under a slightly stronger assumption, but often verified in applications, we have the following consequence of Proposition 3.3 and Proposition 3.4

PROPOSITION 3.5. *In addition to* (B), (3.11), (3.12), *and* (3.15), *if we assume further that* $B(u, 0)$ *is strongly positive for all* $u \in Z_1$, *then*

(i) $\operatorname{ind}(F, U \oplus V) = \operatorname{ind}(F_1, U)$ *if for any* $u \in Z_1$, *the spectral radius* $r(B(u, 0)) < 1$.

(ii) $\operatorname{ind}(F, U \oplus V) = 0$ *if for any* $u \in Z_1$, *the spectral radius* $r(B(u, 0)) > 1$.

Proof. We need only to show that the assumptions in (i) and (ii) imply accordingly those of Proposition 3.4 but these facts are just consequences of (ii) and (iv), respectively, of [2, Theorem 3.2]. In particular, by (iv) of [2, Theorem 3.2], we can take any $p > 0$ in C_2 and see that (3.19) is satisfied if $r(B(u, 0)) > 1$. □

Remark 3.5. In fact, the existence of an element p required by (ii) can be guaranteed without the assumption that $B(u, 0)$ is strongly positive. For example, if there exists a demi-interior element p in C_2 (see [4, 3]), then by using the fact that $r(B(u, 0))$ is also an eigenvalue with positive eigenvector for $(B(u, 0))^*$ one can show that (3.19) holds. Another example is the special case when $Z_1 = \{u\}$, i.e., a singleton, then one can take p to be the positive eigenvector to an eigenvalue $\lambda > 1$ of $B(u, 0)$. Indeed, suppose that there is a solution $x > 0$ for some $t > 0$ for $x = B(u, 0)x + tp$. Then there exists a real $\sigma_0 \geq 0$ such that $x \geq \sigma_0 p$ but $x \not\geq \sigma p$ for $\sigma > \sigma_0$. Hence,

$$x = B(u, 0)x + tp \geq B(u, 0)(\sigma_0 p) + tp \geq (\sigma_0 + t)p,$$

which contradicts the maximality of σ_0.

Remark 3.6. If $X_1 = \{0\}$, then we can identify X_2 with $X = \{0\} \oplus X_2$ and the element 0 of X_2 with Z_1. If $K = I$ the identity map, the partial derivative $\partial_v F_2(0, 0)$

can be identified with the right derivative $(F_2)'_+(0)$ in the direction of the cone C_2 (see [2]). In this way, the results of Proposition 3.4 and Proposition 3.5 are generalizations of those in [2, section 13].

We are now ready to give the next proof.

Proof of Theorem 3.1. Let $\beta \in \mathcal{B}$, $\beta \neq \emptyset$. We set $\alpha = M \setminus \beta$. By Lemma 3.4 and (E_1), we can find $r > 0$ sufficiently small such that with $V_\alpha = C_\alpha(r)$ such that $F(u) = u$ has no solution of the form $u = (u_\beta, u_\alpha)$ with $u_\alpha \in V_\alpha$ and $\|u_\alpha\| = r$. We may assume that $U_\beta \subset W_\beta$ and $V_\alpha \subset W_\alpha$.

By Proposition 3.5, $\text{ind}(F, U_\beta \oplus V_\alpha) = \sigma(\beta) i(\beta)$. This gives (i).

Moreover, it is obvious that we can choose U_β, V_α such that the open sets $U_\beta \oplus V_\alpha$ ($\beta \neq M$, $\alpha = M \setminus \beta$) and $U_\emptyset$ are disjoint sets which contain all but positive fixed points of F in Ω. Now, by the additvity property of indices, if (3.8) holds, then the set of positive fixed points of F in Ω must be nonempty. □

3.2. Existence of semitrivial solutions. We see that (3.3) is of the form studied in section 3.1 (see (3.4)). Following the notations in that section, we set $M = \{0, \dots, m\}$ and

$$Z_\beta = \{\vec{u} = (u_0, \dots, u_m) \ : \ F(\vec{u}) = \vec{u}, \quad u_i > 0 \quad \text{if } i \in \beta, \quad u_i = 0 \quad \text{if otherwise}\}.$$

Due to the nonhomogeneity of the boundary condition for u_0 we see that any solution to (2.1) must have $u_0 \neq 0$ so that $Z_\emptyset = \emptyset$. We study first $Z_{\{0\}}$, the set of solutions with $u_0 > 0$ and $u_i = 0$ for all $i \neq 0$. By (F.4), the system reduces to (2.3) so that $Z_{\{0\}}$ consists of exactly the washout solution $\vec{u}_* = (S_*, 0, \dots, 0)$.

In order to apply the results in section 3.1 to compute the face index of $Z_{\{0\}}$ we define

$$K_{\{0\}}(\vec{u}_*) = \text{diag}\{K_1(\vec{u}_*), \dots, K_m(\vec{u}_*)\}, \quad \bar{F}_{\{0\}} = (\bar{F}_1, \dots, \bar{F}_m).$$

We then consider the eigenvalue problem for the operator

$$B_{\{0\}}(\vec{u}_*) = K_{\{0\}}(\vec{u}_*) \circ \partial_{\{0\}} \bar{F}_{\{0\}}. \tag{3.22}$$

By (F.4), $\frac{\partial f_i}{\partial u_j}(x, \vec{u}_*) = 0$ if $j \neq i$. It is easy to see that the eigenvalue problem $B_{\{0\}}(\vec{u}_*)\phi = \lambda\phi$ with $\phi = (U_1, \dots, U_m)$ is equivalent to the system of m equations

$$\begin{cases} -A_i U_i + \text{div}(U_i \Phi_i(S_*) \nabla S_*) = \lambda^{-1} U_i \frac{\partial}{\partial u_i} f_i(x, S_*, 0, \dots, 0), \quad x \in \Omega, \\ \dfrac{\partial U_i}{\partial n} + r_i\left(x, \dfrac{\partial S_*}{\partial n}\right) U_i = 0, \quad x \in \partial\Omega. \end{cases} \tag{3.23}$$

Our principal assumption concerns these eigenvalue problems. In order to guarantee the existence of solutions other than the washout state solution we shall assume that the latter is unstable in its complementary directions. In the light of Theorem 3.1 we shall require that $Z_{\{0\}}$ is "repelling" so that Z_β is nonempty for some $\beta \neq \{0\}$. In terms of the eigenvalue problem (3.23), the condition (E_-) now reads

(E_i) The largest eigenvalue of (3.23) is greater than 1. We say that (E) holds if (E_i) holds for $1 \leq i \leq m$.

Remark 3.7. By using a change of variable as in the proof of Lemma 2.2, we can write (3.23) as

$$\begin{cases} -\text{div}(a_i(x)\nabla U_i) + d_i(x) U_i = \lambda^{-1} g_i(x) U_i \quad \text{on } \Omega, \\ \dfrac{\partial U_i}{\partial n} + R_i(x) U_i = 0 \quad \text{on } \partial\Omega. \end{cases}$$

It is well known that there is only one positive eigenfunction to (3.23) which is the one that corresponds to the largest eigenvalue.

In the same way, Condition (B) of section 3.1 can be restated as follows.

(B′) The largest eigenvalue of (3.23) does not equal 1 for $1 \le i \le m$.

Concerning the eigenvalue problem for $B_{\{0\}}(\vec{u}_*)$ we assert the following (see [11, Lemma 3.2]).

LEMMA 3.8. *If* (B′) *holds, then* 1 *is not an eigenvalue of* $B_{\{0\}}(\vec{u}_*)$ *corresponding to an eigenvector in* X_+. *Moreover, if* (E_i) *holds for some* i *then* $B_{\{0\}}(\vec{u}_*)$ *has an eigenvalue larger than* 1 *with a corresponding eigenvector in* X_+.

Proof. The claims are trivially true if we notice that if ϕ_i, $i > 0$, is the principal eigenfunction of (3.23) to the principal eigenvalue λ_i, then the vector $(u_0, \dots, u_m)$ with $u_j = 0$ if $j \neq i$ and $u_i = \phi_i$ is an eigenvector of $B_{\{0\}}(\vec{u}_*)$ in X_+ corresponding to the eigenvalue λ_i. □

We then have this corollary (see (3.6) for the definition of σ).

COROLLARY 3.6. *Assume* (B′). *If for some* i, $1 \le i \le m$, (E_i) *holds, then*

(i) $\sigma(\{0\}) = 0$;

(ii) *for* $Z_+ = \{u = (u_0, \dots, u_m) \ : \ u = F(u),\ u_i > 0,$ *for some* $i > 0\}$, $\operatorname{ind}(F, Z_+) = 1$;

(iii) *there exists a semitrivial (single-population) equilibrium of* (2.1).

Proof. It is important to point out that, unless $m = 1$, the map $B_{\{0\}}(\vec{u}_*)$ is positive but not strongly positive (otherwise, the positive eigenvector must be unique by the Krein–Rutman theorem). However, since $Z_{\{0\}}$ is a singleton, Lemma 3.8 and Remark 3.2 can be used here to compute $\sigma(\{0\})$. Hence, if (E_i) holds for some i, then (E'_-) is verified so that $\sigma(\{0\}) = 0$.

For item (ii), it is clear that the set of fixed points of F in C_R (see Theorem 2.4) is the union of Z_+ and $Z_{\{0\}}$. By item (i) of Theorem 3.1, Theorem 2.4, and the additivity property of index we have

$$1 = \operatorname{ind}(F, C_R) = i(F, Z_{\{0\}}) + i(F, Z_+) = \sigma(\{0\})i(\{0\}) + i(F, Z_+) = i(F, Z_+).$$

The last equality comes from the fact that $\sigma(\{0\}) = 0$ as we just proved above. Finally, letting $i > 0$, we can easily see that (iii) is a direct consequence of (ii) setting $u_j = 0$ for all $j > 0$ and $j \neq i$. □

3.3. The case of two species. We now turn attention to the two-species case, that is, $m = 2$. It is assumed that for $i = 1, 2$, the principal eigenvalue of the eigenvalue problem (3.23) is greater than 1. Corollary 3.6 then implies the existence of at least one single-population equilibrium for each of the two populations. Thus, $Z_{\{0,1\}}$ and $Z_{\{0,2\}}$, the sets of single-population equilibria for which $u_1 > 0$ or $u_2 > 0$, are nonempty.

Let $\beta = \{0, 1\}$ and $\alpha = \{0, 1, 2\} \backslash \beta = \{2\}$. We define (see (3.1), (3.2))

$$F_\beta(\psi) = (F_0(\psi), K_1(\psi) \circ \bar{F}_1(\psi)),\ F_\alpha(\psi) = K_2(\psi) \circ \bar{F}_2(\psi).$$

Then $F(\psi) = (F_\beta(\psi), F_\alpha(\psi))$. In order to apply the results in section 3.1 to compute the local index of Z_β we need to consider eigenvalue problem for the operator

$$B_\alpha(u) = K_\alpha(u) \circ \partial_\alpha \bar{F}_\alpha(u) = K_2(u) \circ \partial_2 \bar{F}_2(u) \tag{3.24}$$

for $u = (u_0, u_1, 0) \in Z_\beta$. Note that $K_2(u)$ is strongly positive. By (F.3) $B_\alpha(u)$ is also a strongly positive operator. It is easy to see that the eigenvalue problem $B_\beta(u)\phi = \lambda\phi$

is equivalent to the following problem:

$$\begin{cases} -A_2\phi + \operatorname{div}(\phi\Phi_2(u_0)\nabla u_0) = \lambda^{-1}\phi\frac{\partial}{\partial u_2}f_2(x,u_0,u_1,0), & x\in\Omega,\\ \dfrac{\partial\phi}{\partial n} + r_i\left(x,\dfrac{\partial u_0}{\partial n}\right)\phi = 0, & x\in\partial\Omega. \end{cases}$$

Using a similar analysis for the case $\beta=\{0,2\}$, we are led to the following.

Let us denote $Z_i = Z_{\{0,i\}}$, and the elements of Z_i by $\hat{U}_i$, that is, $\hat{U}_1=(\hat{u}_{01},\hat{u}_1,0)$ and $\hat{U}_2=(\hat{u}_{02},0,\hat{u}_2)$. Conditions (E_+) and (E_-) of section 3.1 suggest that we consider the following conditions.

(D_+) For each $i=1,2$, and for any $\hat{U}_i\in Z_i$, and $i,j\in\{1,2\}$ with $j\neq i$, the largest eigenvalue of

$$\begin{cases} -A_i\phi + \operatorname{div}(\phi\Phi_i(\hat{u}_{0j})\nabla(\hat{u}_{0j})) = \lambda^{-1}\phi\frac{\partial}{\partial u_i}f_i(x,\hat{U}_j),\\ \dfrac{\partial\phi}{\partial n} + r_i\left(x,\dfrac{\partial(\hat{u}_{0j})}{\partial n}\right)\phi = 0 \end{cases} \tag{3.25}$$

is greater than 1.

(D_-) For each i, the eigenvalues of (3.25) are all less than 1.

In biological terms, (D_+) says that every u_1-single population steady state is stable to invasion by u_2 and conversely. (D_-) says that every u_1-single population steady state is unstable to invasion by u_2 and conversely. In either case, we might expect the existence of a positive steady state (u_0,u_1,u_2), that is, a steady state with $u_i>0$ for $i=1,2$. The main result of this section asserts that this is the case.

THEOREM 3.7. *Let $m=2$ and assume (E_i) holds for $i=1,2$ and either (D_+) or (D_-) holds. Then the system (2.1) has at least one positive solution.*

Proof. By Corollary 3.6, $\sigma(\{0\})=0$. Let $\beta=\{0,1\}$ or $\{0,2\}$. If (D_+) (resp., (D_-)) holds, then (E_+) (resp., (E_-)) of section 3.1 holds so that $\sigma(\beta)=1$ (resp., 0). Note also that, in this case, $B_\alpha(\hat{U})$ is strongly positive for any $\hat{U}\in Z_i$.

Since (E_i) holds for $i=1,2$, by (ii) of Corollary 3.6 we see that the face index $i(\beta)=1$. In fact, $i(\beta)$ is just the local index of Z_β as the set of positive fixed points of F restricted to the face X_β so that we can apply (ii) of Corollary 3.6.

Therefore, the right-hand side of (3.8) can be computed as follows.

$$\sum_{\beta=\{0\},\{0,1\},\{0,2\}}\sigma(\beta)i(\beta) = \begin{cases} 2 & \text{if } (D_+) \text{ holds},\\ 0 & \text{if } (D_-) \text{ holds}. \end{cases}$$

In both cases this quantity is not equal to $\operatorname{ind}(F,C_R)=1$. By (ii) of Theorem 3.1 our theorem now follows. ∎

Acknowledgments. The author would like to thank the anonymous referees for valuable constructive comments which led to many improvements of this work.

HARMONIC MOMENTS AND AN INVERSE PROBLEM FOR THE HEAT EQUATION*

MISHIO KAWASHITA†, YAROSLAV V. KURYLEV‡, AND HIDEO SOGA†

Abstract. In the paper, we study an inverse problem for the heat equation. We introduce a class of bilinear forms on the space of harmonic polynomials (called harmonic moments), which are represented by the Dirichlet-to-Neumann map. We investigate the uniqueness, stability, and reconstruction of the inverse problem.

The inverse data are given in the terms of the bilinear forms and can be exchanged into the data of the Dirichlet-to-Neumann map. The reconstruction (of the density) is accomplished in two different ways: one is due to the idea of the mollifier and the other to the representation by the Carleman kernel in the complex analysis. The error terms are estimated depending on the degree of the harmonic polynomials. We estimates norms of the data on an arbitrary time interval by the norms on some fixed interval (e.g., $0 < t < 2$).

Key words. inverse problem, heat equation, harmonic moments, reconstruction of a coefficient

1. Introduction.

This paper is devoted to the solution of the inverse boundary problem for the heat equation. Let Ω be a connected bounded domain in $\mathbb{R}^n$ $(n \geq 2)$ with C^l ($l = 2, 3, \dots$) boundary Γ. Consider the mixed problem for the heat equation

$$\begin{cases} (\rho(x)\partial_t - \triangle)u(t,x) = 0 & \text{in} \quad (0,+\infty)\times\Omega, \\ u(t,x') = f(t,x') & \text{on} \quad (0,+\infty)\times\Gamma, \\ u(0,x) = 0 & \text{on} \quad \Omega. \end{cases} \tag{1.1}$$

The density $\rho(x)$ is a $C^{l+\sigma}$ $(0 < \sigma < 1)$ function on $\overline{\Omega}$ satisfying

$$0 < \rho_1 \leq \rho(x) \leq \rho_2 (< +\infty). \tag{1.2}$$

The inverse data used in the paper is a set of normal derivatives $\frac{\partial u^p}{\partial \nu}|_{(0,2)\times\Gamma}$, where u^p is the solution of (1.1) with

$$f(t,x') = \chi(t)\, p(x'). \tag{1.3}$$

Here $\chi(t)$ is a (arbitrary) fixed C^∞ function satisfying $0 \leq \chi(t) \leq 1$ in $\mathbb{R}$, $\chi(t) = 1$ for $t \geq 1$ and $\chi(t) = 0$ for $t \leq 1/2$. The function $p(x')$ in (1.3) is the boundary value of a harmonic polynomial $p(x)$ (i.e., $\triangle p = 0$).

We assume that $\frac{\partial u^p}{\partial \nu}|_{(0,2)\times\Gamma}$ or, more precisely,

$$\int_\Gamma \int_0^t \frac{\partial u^p}{\partial \nu}(s,x')\, q(x')\, dx' ds, \quad 0 < t < 2, \tag{1.4}$$

are given for all sources f of form (1.3) with $p \in HP^m$, where

$$HP^m = \{\text{harmonic polynomials of degree} \le m\} \qquad (m = 0, 1, 2, \dots),$$

and all $q \in HP^m$.

In this paper we describe algorithms for an approximate reconstruction of ρ given approximate integrals (1.4) with $p, q \in HP^m$, $m = 0, 1, 2, \dots$. The algorithms lead to explicit formulae for an approximate solution of the inverse problem under consideration together with an error estimate in the corresponding reconstruction procedure. These error estimates depend upon the parameter m and a "measurement" error, i.e., an error in the inverse data (1.4) and of the logarithmic character. The algorithms are described in section 3, where we do not use a quasi-analytic continuation of the inverse data, and in section 4, where we utilize results on quasi-analytic continuation (see, e.g., [Car], [L]). The corresponding formulae together with the error estimates are given in Theorems 3.4 and 4.4.

The method used in the paper is the parabolic analog of the moments method introduced in [K-S] for the solution of the inverse boundary spectral problem for the elliptic operator $A_\rho = -\rho^{-1}\triangle$. Its main idea is to utilize the generating properties of the products of harmonic polynomials. These polynomials belong to the null-space of the operator A_ρ. The considered generating properties are, in fact, an algebraic version of the well-known fact (see, e.g., [Cal]) that the linear combinations of the products of harmonic functions are dense in $L^2(\Omega)$.

This fact was extensively used for solving inverse boundary problems (see [S-U] for the pioneering work in this direction). In the parabolic case the study of the inverse problems for the system (1.1) and even for some more general parabolic equations was carried out by a number of authors. The main results dealt with the question of uniqueness and stability in the identification of the unknown coefficient(s) via various sets of the inverse data on the boundary. A very good introduction to this area together with a number of advanced results is given in [Is, Chapter 9]. However, we would like to stress that our main goal is not only to obtain stability estimates but also to develop some reconstruction procedures and to obtain stability estimates for these procedures. In its turn such procedures may show useful for the numerical solution of inverse boundary problems. Indeed, the acoustic variant of the moments method was successfully used in [K-P] for the numerical solution of some model inverse problems.

In the note [K-K-S] we have partially announced the results (only in sections 2 and 3) with an explanation of the key idea of the proofs.

In the present paper we confine ourselves to the problems of stability in Hölder classes. However, the method may also be used (see, e.g., [K-P], [K-S]) to analyze stability in Sobolev classes. The case of the other types of boundary conditions may be considered as well. This will be done elsewhere.

2. Direct problem and uniqueness of inverse problem. Consider the mixed problem (1.1) and denote by $u^p(t, x)$ its solution with the source f of form (1.3). When p, $q \in HP^\infty (= \cup_{m=0}^\infty HP^m)$, we define $\Phi_\rho(t; p, q)$ by

$$\Phi_\rho(t; p, q) = \int_\Omega \rho(x) u^p(t, x) \overline{q(x)}\, dx. \tag{2.1}$$

We define also the harmonic moments $M_\rho(p, q)$ corresponding to ρ:

$$M_\rho(p, q) = \int_\Omega \rho(x) p(x) \overline{q(x)}\, dx. \tag{2.2}$$

In this section we discuss some properties of $\Phi_\rho(t;p,q)$ and relations between $\Phi_\rho(t;p,q)$, $M_\rho(p,q)$, and the response operator

$$R_\rho : p(x') \mapsto \frac{\partial u^p}{\partial \nu}|_{(0,+\infty)\times\Gamma}.$$

THEOREM 2.1. *$\Phi_\rho(t;p,q)$ is a bilinear mapping from $HP^\infty \times HP^\infty \to C^0(\overline{\mathbb{R}_+})$ with the following properties:*

(i) $$\left\|\Phi_\rho(\cdot;p,q)\right\|_{C^0(\overline{\mathbb{R}_+})} \le C \left\|p\right\|_{L^2(\Omega)} \left\|q\right\|_{L^2(\Omega)},$$

(ii) $$\left\|\Phi_\rho(\cdot;p,q) - \Phi_{\tilde\rho}(\cdot;p,q)\right\|_{C^0(\overline{\mathbb{R}_+})} \le C \left\|\rho-\tilde\rho\right\|_{C^0(\overline{\Omega})} \left\|p\right\|_{L^2(\Omega)} \left\|q\right\|_{L^2(\Omega)},$$

(iii) $$\left|\Phi_\rho(t;p,q) - M_\rho(p,q)\right| \le Ce^{-C'\lambda_0 t} \left\|p\right\|_{L^2(\Omega)} \left\|q\right\|_{L^2(\Omega)},$$

where λ_0 is the first eigenvalue of the Dirichlet problem for the Euclidean Laplacian $-\triangle$ on Ω, and where C, C' are positive constants determined from ρ_1, ρ_2; C' does not depend on λ_0.

Note (1). We denote by C, C' different constants which depend upon Ω, ρ_1, and ρ_2. In the case of their dependence upon some other parameters we note this dependence explicitly.

Note (2). Hereafter we denote the norm $\left\|\cdot\right\|_{L^2(\Omega)}$ only by $\left\|\cdot\right\|$.

Proof. Consider the mixed problem

$$\begin{cases} \partial_t w(t,x) - \rho^{-1}\triangle w(t,x) = 0 & \text{in} \quad (0,+\infty)\times\Omega, \\ w(t,x') = 0 & \text{on} \quad (0,+\infty)\times\Gamma, \\ w(0,x) = f(x) & \text{on} \quad \Omega, \end{cases}$$

and denote by $\{\lambda_j\}_{j=1,2,\dots}$, $\lambda_1 < \lambda_2 \le \cdots$ the eigenvalues of the self-adjoint differential operator $-\rho^{-1}\triangle$ with the domain $H^2(\Omega)\cap H_0^1(\Omega)$ in the Hilbert space $L^2_\rho(\Omega)$ with the inner product $(f,g)_\rho \equiv \int_\Omega \rho(x) f(x)\overline{g(x)}\,dx$. We can express the solution $w(t,\cdot) = E(t)f$ in the form

$$E(t)f = \sum_{j=1}^{\infty} e^{-\lambda_j t}(f,\varphi_j)_\rho\,\varphi_j, \tag{2.3}$$

where the functions $\{\varphi_j\}_{j=1,2,\dots}$ are the L^2_ρ-orthonormal eigenfunctions corresponding to the eigenvalues λ_j. Note that the first eigenvalue λ_1 is estimated by λ_0, i.e., $\lambda_0\rho_2^{-1} \le \lambda_1 \le \lambda_0\rho_1^{-1}$.

Then we have

$$u^p(t,x) - \chi(t)p(x) = \int_0^t E(t-s)(-\chi'(s)p(x))\,ds. \tag{2.4}$$

Since $L^2_\rho(\Omega) = L^2(\Omega)$ as a set and $\rho_1\left\|f\right\|^2 \le \left\|f\right\|_\rho^2 (= (f,f)_\rho) \le \rho_2\left\|f\right\|^2$, (2.3) yields that

$$\left\|\int_0^t E(t-s)(-\chi'(s)p(x))\,ds\right\| \le (\rho_2/\rho_1)^{1/2} e^{\lambda_1(1-t)} \sup_{s\in\mathbb{R}}\left|\chi'(s)\right| \left\|p\right\|.$$

Thus, we obtain

$$\begin{aligned}
&\left|\Phi_\rho(t;p,q) - \int_\Omega \rho(x)p(x)\overline{q(x)}\,dx\right| \\
&\quad\le \left|(1-\chi(t))\int_\Omega \rho p\overline{q}\,dx\right| + \left|\int_\Omega \rho(u-\chi p)\overline{q}\,dx\right| \\
&\quad\le \left(e^{\lambda_1}\rho_2 + (\rho_2/\rho_1)^{1/2}e^{\lambda_1}\left\|\chi'\right\|_{C^0(\overline{\mathbb{R}_+})}\right)e^{-\lambda_1 t}\left\|p\right\|\left\|q\right\|,
\end{aligned}$$

which proves (i) and (iii).

Denote by $\tilde{u}^p(t,x)$ the solution of (1.1) with $\tilde{\rho}(x)$ instead of $\rho(x)$, and by $\widetilde{E}(t)$ the operator of form (2.3) corresponding to $\tilde{\rho}$. We see that

$$u^p(t,x) - \tilde{u}^p(t,x) = \int_0^t E(t-s)\{(\tilde{\rho}-\rho)\rho^{-1}\partial_s\tilde{u}^p(s,\cdot)\}\,ds.$$

Therefore (1.2) implies that

$$\left\|u^p(t,x) - \tilde{u}^p(t,x)\right\| \le \rho_1^{-1}\,(\rho_2/\rho_1)^{1/2}\,\left\|\rho-\tilde{\rho}\right\|_{C^0(\overline{\Omega})}\int_0^t \left\|\partial_s\tilde{u}(s,\cdot)\right\|\,ds. \tag{2.5}$$

From (2.4) it follows that $\partial_s\tilde{u}^p(s,\cdot) = -\int_0^s \partial_t\widetilde{E}(s-t)[\chi'(t)p]\,dt = \chi'(s)p - \int_0^s \widetilde{E}(s-t)\chi''(t)p\,dt$, which yields that

$$\begin{aligned}
\left\|\partial_s\tilde{u}^p(s,\cdot)\right\| &\le \left|\chi'(s)\right|\left\|p\right\| \\
&\quad + (\rho_2/\rho_1)^{1/2}\int_0^1 e^{-\tilde{\lambda}_1(s-t)}\,dt\left\|\chi''\right\|_{C^0(\overline{\mathbb{R}_+})}\left\|p\right\|.
\end{aligned}$$

In the above, $\tilde{\lambda}_1$ is the first eigenvalue of the self-adjoint realization of $-\tilde{\rho}^{-1}\triangle$ on $L^2_{\tilde{\rho}}(\Omega)$. Combining this with (2.5), we obtain

$$\begin{aligned}
\left|\Phi_\rho(t;p,q) - \Phi_{\tilde{\rho}}(t;p,q)\right| &\le \left|\int_\Omega(\tilde{\rho}-\rho)u(t,\cdot)\overline{q}\,dx\right| \\
&\quad + \left|\int_\Omega \tilde{\rho}\{u(t,\cdot)-\tilde{u}(t,\cdot)\}\overline{q}\,dx\right| \\
&\le C\left\|\rho-\tilde{\rho}\right\|_{C^0(\overline{\Omega})}\left\|p\right\|\left\|q\right\|.
\end{aligned}$$

This completes the proof of Theorem 2.1. □

The following lemma shows the relationship between the form $\Phi_\rho(t;p,q)$ and the response operator R_ρ:

LEMMA 2.2. *For any p, $q \in HP^\infty$, we have*

$$\begin{aligned}
\Phi_\rho(t;p,q) &= \int_\Gamma\int_0^t R_\rho[p|_\Gamma](s,x')\,ds\,\overline{q(x')}\,dx' \\
&\quad - \int_0^t \chi(s)\,ds\int_\Gamma p(x')\frac{\partial\overline{q(x')}}{\partial\nu}\,dx'.
\end{aligned}$$

Proof. By integration by parts we have

$$\begin{aligned}\int_\Omega \int_0^t \{(\partial_s - \rho^{-1}\triangle)u^p(s,x)\}\overline{q(x)}\rho(x)\,ds\,dx \\ = \int_\Omega u^p(t,x)\overline{q(x)}\rho(x)\,dx - \int_\Omega u^p(0,x)\overline{q(x)}\rho(x)\,dx \\ - \int_\Omega \int_0^t u^p(s,x)\overline{\triangle q(x)}\,ds\,dx \\ - \int_\Gamma \int_0^t \frac{\partial u^p}{\partial \nu}(s,x')\overline{q(x')}\,ds\,dx' + \int_\Gamma \int_0^t u^p(s,x')\overline{\frac{\partial q}{\partial \nu}(x')}\,ds\,dx'.\end{aligned}$$

As u^p is a solution of (1.1) and $q \in HP^\infty$, the above inequality implies that

$$\begin{aligned}0 = \Phi_\rho(t;p,q) - \int_\Gamma \int_0^t R_\rho[p|_\Gamma](s,x')\overline{q(x')}\,ds\,dx' \\ + \int_\Gamma \int_0^t \chi(s)\,ds\,p(x')\overline{\frac{\partial q}{\partial \nu}(x')}\,dx'.\end{aligned}$$

This proves Lemma 2.2. □

In the inverse problems, generally, we expect to recover ρ by the measurements expressed in terms of the response operator. Lemma 2.2 implies that our original setting of the inverse problem may be reduced to the inversion of the mapping : $\rho \mapsto \Phi_\rho$.

We start with verifying the uniqueness of the inverse problem.

THEOREM 2.3. *If for any p, $q \in HP^\infty$, $\Phi_\rho(t;p,q)$ is equal to $\Phi_{\tilde\rho}(t;p,q)$ on an interval $(1 <) a < t < b$, then ρ coincides with $\tilde\rho$.*

Remark. Lemma 2.2 means that $\Phi_\rho = \Phi_{\tilde\rho}$ if $R_\rho = R_{\tilde\rho}$, and therefore the unique determination of ρ by R_ρ is derived from Theorem 2.3.

The proof of Theorem 2.3 is based on the following lemma.

LEMMA 2.4. *Any polynomial can be expressed as a linear combination of products of the harmonic polynomials.*

For the proof of Lemma 2.4, see [K-S, Proposition 3].

Proof of Theorem 2.3. The solution $u^p(t,x)$ in (1.1) becomes analytic in t for $t > 1$ (cf. (2.3)). Therefore, if $\Phi_\rho(t;p,q) = \Phi_{\tilde\rho}(t;p,q)$ on (a,b), $\Phi_\rho(t;p,q)$ is equal to $\Phi_{\tilde\rho}(t;p,q)$ on $(1,+\infty)$. Hence, by (iii) of Theorem 2.1, we have

$$M_\rho(p,q) = \lim_{t\to\infty} \Phi_\rho(t;p,q) = \lim_{t\to\infty} \Phi_{\tilde\rho}(t;p,q) = M_{\tilde\rho}(p,q), \quad p,q \in HP^\infty.$$

By Lemma 2.4 this implies that

$$\int_\Omega \rho(x)x^\alpha\,dx = \int_\Omega \tilde\rho(x)x^\alpha\,dx$$

for any multi-index α. As the domain Ω is bounded, this implies that $\rho = \tilde\rho$. The proof is complete. □

3. Reconstruction of $\rho(x)$. In this section, we reconstruct $\rho(x)$ approximately, by employing the harmonic moments $M_\rho(p,q)$ with $p,q \in HP^m$, where m is a sufficiently large positive integer.

The reconstruction is based on the fact that the Gaussian distribution

$$(\sqrt{\pi})^{-n}\mu^n \exp(-\mu^2 \left|x\right|^2) = (\sqrt{\pi})^{-n}\mu^n \sum_{k=0}^{\infty} \frac{1}{k!}(-\mu^2 \left|x\right|^2)^k$$

tends to the Dirac δ-function as $\mu \to +\infty$. (Note that $\int_{\mathbb{R}^n} \mu^n \exp(-\mu^2|y|^2)\, dy = (\sqrt{\pi})^n$ for any $\mu > 0$.) Namely, we use the following.

LEMMA 3.1. *Let*

$$\delta_\mu^m(x) = (\sqrt{\pi})^{-n}\mu^n \sum_{k=0}^{m/2} \frac{(-\mu^2 \left|x\right|^2)^k}{k!},$$

where $\mu \geq 1$ and m is a positive even integer. Then for any $\rho(x) \in C^{l+\sigma}(\overline{\Omega})$ $(0 \leq l \leq m/2,$ integer, $0 < \sigma < 1)$ we have

$$\left\| \rho(\cdot) - \int_\Omega \delta_\mu^m(\cdot - y)\rho(y)\, dy \right\|_{C^l(\mu^{-1/2})} \leq C \left\|\rho\right\|_{C^{l+\sigma}} \{\mu^{-\sigma} + (C'\mu)^{m+n+2} m^{-m/2+l}\},$$

where C, C' are independent of ρ, μ, and m. Here we denote by $\left\|\rho\right\|_{C^{l+\sigma}}$ the $C^{l+\sigma}$-norm of ρ in $\overline{\Omega}$ and by $\left\|\rho\right\|_{C^l(\epsilon)}$ the C^l-norm of ρ in $\overline{\Omega_\epsilon}$. In its turn, $\Omega_\epsilon = \{x \in \Omega | \text{dist } (x, \Gamma) > \epsilon\}$.

Proof. For $f \in C^l(\overline{\Omega})$ we denote by Df the C^l-continuation of f onto $\mathbb{R}^n$ with supp $[Df] \subset \{x | \text{dist } (x, \Omega) < 1\}$ and $\left\|Df\right\|_{C^l(\mathbb{R}^n)} \leq 2\left\|f\right\|_{C^l}$. As $\int_{\mathbb{R}^n} \delta_\mu^\infty\ (x)\, dx = 1$, then for any $\left|\alpha\right| \leq l$

$$\partial_x^\alpha \rho(x) - \partial_x^\alpha \int_\Omega \delta_\mu^m(x-y)\rho(y)\, dy = \int_{\mathbb{R}^n} \delta_\mu^\infty(y)(\partial_x^\alpha \rho(x) - \partial_x^\alpha D\rho(x-y))\, dy$$
$$+ \int_{\mathbb{R}^n \setminus \Omega} \partial_x^\alpha \delta_\mu^\infty(x-y) D\rho(y)\, dy + \int_\Omega (\partial_x^\alpha \delta_\mu^\infty(x-y) - \partial_x^\alpha \delta_\mu^m(x-y))\rho(y)\, dy$$
$$= I_1 + I_2 + I_3.$$

Note that $\delta_\mu^\infty(x) - \delta_\mu^m(x) = (\sqrt{\pi})^{-n}\mu^n(-1)^{m/2+1} F_m(\mu^2|x|^2)$, where $F_m(X) = X^{m/2+1} R_m(X)$ and

$$R_m(X) = \frac{1}{(m/2)!} \int_0^1 (1-\theta)^{m/2} e^{-\theta X}\, d\theta.$$

Then, $\sup_{0 \leq \theta \leq 1} \theta^{q_2} e^{-\theta X} \leq q_2! X^{-q_2}$ for any nonnegative integer q_2, and we have

$$|\partial_X^{q_1+q_2} R_m(X)| \leq \frac{q_2! X^{-q_2}}{(m/2)!} \int_0^1 (1-\theta)^{m/2} \theta^{q_1}\, d\theta = \frac{q_1! q_2!}{(m/2+q_1+1)!} X^{-q_2},$$

which yields

$$|\partial_X^q F_m(X)| \leq \frac{2^q}{(m/2+1-q)!} X^{m/2+1-q} \quad \text{for any } X \geq 0, q = 0, 1, \ldots, m/2+1.$$

Using this estimate, we can get

$$|\partial_x^\alpha((\partial_X^q F_m)(\mu^2|x|^2))| \le \frac{2^q 4^{|\alpha|}|\alpha|!\mu^{|\alpha|}}{(m/2+1-q-|\alpha|)!}(\mu|x|)^{2(m/2+1-q)-|\alpha|}$$
$$\text{for any } x \in \mathbb{R}^n, q+|\alpha| \le m/2+1, \mu > 0$$

by induction in $|\alpha|$. Hence, for $|\alpha| \le m/2+1$ we obtain

$$\left|\partial_x^\alpha(\delta_\mu^\infty(x) - \delta_\mu^m(x))\right| \le \frac{4^{|\alpha|}|\alpha|!}{(m/2+1-|\alpha|)!}(\sqrt{\pi})^{-n}\mu^{n+|\alpha|}(\mu\left|x\right|)^{m+2-|\alpha|}.$$

This implies that

$$\begin{aligned}\left|I_3\right| &\le (\sqrt{\pi})^{-n}\mu^{n+|\alpha|}\frac{4^{|\alpha|}\,|\alpha|!}{(m/2+1-|\alpha|)!}(\mu r_0)^{m+2-|\alpha|}\int_\Omega \rho(y)\,dy \\ &\le (\sqrt{\pi})^{-n}4^{|\alpha|}\,|\alpha|!\mu^n\frac{(m/2)^{|\alpha|}}{r_0^{|\alpha|}}\frac{(\mu r_0)^{(m+2)}}{(m/2)!}\int_\Omega \rho(y)\,dy \\ &\le Cr_0^2\,|\alpha|!\mu^{n+m+2}\left(\frac{2m}{r_0}\right)^{|\alpha|}\frac{(2er_0^2)^{m/2}}{m^{(m+1)/2}}\int_\Omega \rho(y)\,dy,\end{aligned}$$

where $r_0 = \operatorname{diam}(\Omega)$ and we use Stirling formula to estimate $(\frac{m}{2})!$ for sufficiently large m.

Since $|x-y| \ge \mu^{-1/2}$ holds if $x \in \Omega_{\mu^{-1/2}}$ and $y \in \mathbb{R}^n \setminus \Omega$, we obtain

$$\begin{aligned}\left|I_2\right| &\le C\left\|\rho\right\|_{C^0}\int_{\mathbb{R}^n\setminus\Omega}\mu^{n+|\alpha|}(1+\mu\left|x-y\right|)^{|\alpha|}e^{-\mu^2|x-y|^2}\,dy \\ &\le C\left\|\rho\right\|_{C^0}\mu^{|\alpha|}e^{-\mu/2}\int_{\mathbb{R}^n}(1+|y|)^{|\alpha|}e^{-|y|^2}\,dy.\end{aligned}$$

At last

$$\begin{aligned}\left|I_1\right| &\le \int_{|y|\le\mu^{-1/2}}\delta_\mu^\infty(y)\left\|\rho\right\|_{C^{l+\sigma}}|y|^\sigma\,dy \\ &\qquad + \int_{|y|>\mu^{-1/2}}\delta_\mu^\infty(y)\{\left\|D\rho\right\|_{C^l(\mathbb{R}^n)} + \left\|\rho\right\|_{C^l(\mathbb{R}^n)}\}\,dy \\ &\le \mu^{-\sigma}\int_{\mathbb{R}^n}|y|^\sigma e^{-|y|^2}\,dy\left\|\rho\right\|_{C^{l+\sigma}} + Ce^{-\mu/2}\int_{\mathbb{R}^n}e^{-|y|^2/2}\,dy\left\|\rho\right\|_{C^l}.\end{aligned}$$

Combining the above estimates, we obtain Lemma 3.1.

The proof is complete. □

We fix a basis $\{p_i^m\}_{i=1,\dots,N(m)}$ in HP^m so that $\{p_i^m\} \subset \{p_i^{m+1}\}$. Lemma 2.4 means that any x^α $(\left|\alpha\right| \le m)$ is expressed in the form

$$x^\alpha = \sum_{i,j=1}^{N(m)} C_{i,j}^\alpha p_i^m(x)\overline{p_j^m(x)}.$$

The function $\delta_\mu^m(x-y)$ in Lemma 3.1 is then decomposed into a sum of polynomials $x^\alpha y^\beta$:

$$\delta_\mu^m(x-y) = \sum_{|\alpha+\beta|\le m} C_{m,\alpha,\beta}\,\mu^{n+|\alpha+\beta|}x^\alpha y^\beta.$$

Therefore the integral $\int_\Omega \delta_\mu^m(x-y)\rho(y)\,dy$ is then represented in terms of the harmonic moments $M_\rho(p,q)$:

$$\int_\Omega \delta_\mu^m(x-y)\rho(y)\,dy = \sum_{|\alpha+\beta|\le m} C_{m,\alpha,\beta}\,\mu^{n+|\alpha+\beta|}x^\alpha \sum_{i,j=1}^{N(m)} C_{ij}^\beta M_\rho(p_i^m,p_j^m).$$

This representation together with Lemma 3.1 implies the possibility of an approximate reconstruction of ρ in terms of the harmonic moments. For this end we introduce the polynomials $Q_\mu^m(x;M)$, where M is a bilinear form on $HP^\infty \times HP^\infty$:

$$Q_\mu^m(x;M) = \sum_{|\alpha+\beta|\le m} C_{m,\alpha,\beta}\mu^{n+|\alpha+\beta|}x^\alpha \sum_{i,j=1}^{N(m)} C_{ij}^\beta M(p_i^m,p_j^m). \tag{3.1}$$

THEOREM 3.2. (i) *The mapping : $M \mapsto Q_\mu^m(x;M)$ is continuous in the following sense:*

$$\begin{aligned}&\left\|Q_\mu^m(\cdot;M) - Q_\mu^m(\cdot;\widetilde{M})\right\|_{C^l}\\ &\le C\mu^n e^{C'\mu^2}\left\|M-\widetilde{M}\right\|_m \max_{|\beta|\le m}\sum_{i,j=1}^{N(m)}\left|C_{ij}^\beta\right|\left\|p_i^m\right\|\left\|p_j^m\right\|,\end{aligned} \tag{3.2}$$

where

$$\left\|M-\widetilde{M}\right\|_m = \sup\left\{\frac{\left|M(p,q)-\widetilde{M}(p,q)\right|}{\|p\|\,\|q\|};\quad p,q\in HP^m\right\}.$$

(ii) *Let $\rho(x)\in C^{l+\sigma}(\overline{\Omega})$ $(0\le l\le m/2,$ integer $0<\sigma<1)$. Then we have*

$$\begin{aligned}&\left\|\rho(\cdot)-Q_\mu^m(\cdot,M_\rho)\right\|_{C^l(\mu^{-1/2})}\\ &\qquad\le C\left\|\rho\right\|_{C^{l+\sigma}}\{\mu^{-\sigma}+(C'\mu)^{(m+n+2)}m^{-m/2+l}\}.\end{aligned} \tag{3.3}$$

Here, the constants C, C' are independent of ρ, μ, and m.

Proof. The estimate (3.3) of Theorem 3.2 follows from Lemma 3.1 immediately. The estimate (3.2) is also easily checked:

$$\begin{aligned}\left\|Q_\mu^m(\cdot;M)-Q_\mu^m(\cdot;\widetilde{M})\right\|_{C^l} \le &\sum_{|\alpha+\beta|\le m}\left|C_{m,\alpha,\beta}\right|\mu^{n+|\alpha+\beta|}r_1^{|\alpha|}\\ &\left\|M-\widetilde{M}\right\|_m\sum_{i,j=1}^{N(m)}\left|C_{ij}^\beta\right|\left\|p_i^m\right\|\left\|p_j^m\right\|,\end{aligned}$$

where $r_1=\max\{|x|\,;\,x\in\Omega\}$. Since each $C_{m,\alpha,\beta}$ is the coefficient of the expansion of $\delta_\mu^m(x-y)$, we obtain

$$\sum_{|\alpha+\beta|\le m}\left|C_{m,\alpha,\beta}\right|\mu^{n+|\alpha+\beta|}r_1^{|\alpha|} \le (\sqrt{\pi})^{-n}\,\mu^n e^{n\mu^2(r_1+1)^2},$$

which implies the estimate (3.2). ∎

From Theorem 3.2 and Theorem 2.1, we have the following.

COROLLARY 3.3. *Let $\Phi_\rho(t;p,q)$ be the function of form* (2.1). *Then*

$$\begin{aligned}&\left\|\rho(\cdot)-Q_\mu^m(\cdot;\Phi_\rho(t;\cdot,\cdot))\right\|_{C^l(\mu^{-1/2})}\\&\quad\le C\left\|\rho\right\|_{C^{l+\sigma}}\{\mu^{-\sigma}+(C\mu)^{m+n+2}m^{-m/2+l}\}\\&\qquad+e^{C'\mu^2}e^{-C\lambda_0 t}\max_{|\beta|\le m}\sum_{i,j=1}^{N(m)}\left|C_{ij}^\beta\right|\left\|p_i^m\right\|\left\|p_j^m\right\|\end{aligned}$$

for constants C, C' independent of ρ, μ, and m.

Corollary 3.3 implies that we can reconstruct ρ approximately via given $\Phi_\rho(t;\cdot,\cdot)$. Indeed, for any $\epsilon>0$ and compact set D in Ω, there exist μ, m, and t such that $\left\|\rho(\cdot)-Q_\mu^m(\cdot;\Phi_\rho(t;\cdot,\cdot))\right\|_{C^l(D)}<\epsilon$.

Analysis of the estimate in Corollary 3.3 involves an estimate of $\sum_{i,j=1}^{N(m)}|C_{ij}^\beta|\left\|p_i^m\right\|\left\|p_j^m\right\|$. Together with an optimal choice of the parameter μ this gives the final estimate which involves only m and t.

THEOREM 3.4. *Let $\Phi_\rho(t;p,q)$ be the functional defined by* (2.1) *and $Q^m(x;\Phi_\rho)$—the polynomials defined by formula* (3.1) *with $M=\Phi_\rho$ and $\mu=e^{-a}m^{1/2}$. If we choose $a>0$ sufficiently large, then there exist constants $C>0$, $c_1>0$, and $c_2>0$ such that*

$$\begin{aligned}&\left\|\rho(\cdot)-Q^m(\cdot;\Phi_\rho(t;\cdot,\cdot))\right\|_{C^l(e^{a/2}m^{-1/4})}\\&\qquad\le C\{(\left\|\rho\right\|_{C^{l+\sigma}}+1)m^{-\sigma/2}+e^{c_1m-c_2\lambda_0 t}\}.\end{aligned}$$

Proof. We employ the directional moments of order q:

$$X_e^q(x)=\langle x,e\rangle^q,\qquad e\in\mathbf{S}^{n-1},$$

where $\mathbf{S}^{n-1}$ is the unit sphere in $\mathbb{R}^n$ and $\langle\cdot,\cdot\rangle$ stands for the scalar product in $\mathbb{R}^n$. The main idea of the proof is to find a representation

$$x^\alpha=\sum_{\gamma=1}^{P(q)}c_\gamma^\alpha X_{e_\gamma}^q(x)$$

and to estimate $\sum_{\gamma=1}^{P(q)}|c_\gamma^\alpha|$, $|\alpha|=q\le m$.

Consider polynomials of the form $X_{e_1}^{q_1}(x)\ X_{e_2}^{q_2}(x)$, where $\langle e_1,e_2\rangle=0$. Then (for details see [K-S])

$$X_{e_\phi}^q(x)=\sum_{q_1+q_2=q}C_{q_1}^q\cos^q(\phi)\ \tan^{q_1}(\phi)\ X_{e_1}^{q_1}(x)X_{e_2}^{q_2}(x),\tag{3.4}$$

where $e_\phi=e_1\cos(\phi)+e_2\sin(\phi)$ and $C_{q_1}^q$ are the binomial coefficients.

Equation (3.4) with $\phi=\phi_1,\dots,\phi_{q+1}$, where $\tan(\phi_i)\ne\tan(\phi_j)$, $i\ne j$, form a system of linear equations for the unknown $X_{e_1}^{q_1}(x)X_{e_2}^{q_2}(x)$. The corresponding matrix is essentially the Vandermonde matrix for $\tan(\phi_i)$, $i=1,\dots,q+1$. In the following we take $\tan(\phi_i)=1+(i-1)/q$. Then

$$X_{e_1}^{q_1}(x)X_{e_2}^{q_2}(x)=\sum_{i=1}^{q+1}\frac{1}{C_{q_1}^q\cos^q(\phi_i)}\ \frac{\Delta_{q_1,i}}{\Delta}X_{e_{\phi_i}}^q(x),\tag{3.5}$$

where Δ, $\Delta_{q_1,i}$ denote the determinant and (q_1,i) minor of the Vandermonde matrix, correspondingly.

Denote by $\Delta_{q_1}(z)$ the determinant of the Vandermonde matrix with z instead of $\tan(\phi_{q_1})$:

$$\Delta_{q_1}(z) = \sum_{j=1}^{q+1} \Delta_{q_1,j} z^{j-1}.$$

As, on the other hand,

$$\Delta_{q_1}(z) = \Pi_{i<j;i,j\neq q_1}(\tan(\phi_i)-\tan(\phi_j))\Pi_{i<q_1}(z-\tan(\phi_i))\Pi_{i>q_1}(\tan(\phi_i)-z),$$

we obtain that

$$\frac{\Delta_{q_1,j}}{\Delta} = \frac{1}{2\pi i}\int_\Gamma \frac{\Delta_{q_1}(z)}{\Delta}\frac{dz}{z^j}, \tag{3.6}$$

where Γ is, e.g., a circle of the radius 1. However,

$$\frac{\Delta_{q_1}(z)}{\Delta} = \Pi_{i<q_1}\frac{(z-\tan(\phi_i))}{(\tan(\phi_{q_1})-\tan(\phi_i))}\ \Pi_{i>q_1}\frac{(\tan(\phi_i)-z)}{(\tan(\phi_i)-\tan(\phi_{q_1}))}.$$

However, as $\tan(\phi_i) = 1+(i-1)/q$,

$$\Pi_{i\neq q_1}|(\tan(\phi_i)-\tan(\phi_{q_1}))| \geq \left(\frac{q!}{q^q C_{q_1}^q}\right) \geq \frac{C^{-q}}{C_{q_1}^q}.$$

Substitution of this estimate into (3.6) leads to the estimate

$$\left|\frac{\Delta_{q_1,j}}{\Delta}\right| \leq C^q C_{q_1}^q. \tag{3.7}$$

Returning to the estimate for $X_{e_1}^{q_1}(x)\ X_{e_2}^{q_2}(x)$, $q_1+q_2=q$, we use the estimate $\cos(\phi_i)\geq 5^{-1/2}$. Hence (3.5), (3.7) yield that

$$X_{e_1}^{q_1}(x)\ X_{e_2}^{q_2}(x) = \sum_{i=1,\dots,q+1} c_{q_1,i} X_{e_{\phi_i}}^q(x), \quad |c_{q_1,i}|\leq C^q. \tag{3.8}$$

Let us consider $x^\alpha = x_1^{\alpha_1}\cdots x_n^{\alpha_n}$. In the same way as in the proof of Proposition 3 in [K-S], by induction in the number of the variables $x_1,\dots,x_n$, we can show that the formula (3.8) yields the representation

$$x^\alpha = \sum_{\gamma=1}^{P(q)} c_\gamma^\alpha X_{e_\gamma}^q(x), \quad |\alpha| = q,$$

for some $e_\gamma \in S^{n-1}$. From the steps of the induction, it follows that

$$P(q)\leq (1+q)^n, \quad |c_\gamma^\alpha|\leq C^q.$$

Furthermore

$$X_e^q = 2^{-q}(Z_e+\overline{Z}_e)^q = 2^{-q}\sum_{q_1=0}^{q} C_{q_1}^q Z_e^{q_1}\,\overline{Z}_e^{q-q_1},$$

where $Z_e = \langle x, e\rangle + i\langle x, e'\rangle$ for an arbitrary e' such that $\langle e, e'\rangle = 0$. Then

$$x^\alpha = \sum_{\gamma=1}^{P(q)} c_\gamma^\alpha X_{e_\gamma}^q = \sum_{\gamma=1}^{P(q)} c_\gamma^\alpha 2^{-q} \sum_{q_1=0}^{q} C_{q_1}^q Z_{e_\gamma}^{q_1} \overline{Z}_{e_\gamma}^{q-q_1}$$
$$= \sum_{j,k=1}^{N(q)} c_{j,k}^\alpha \, p_j(x)\overline{p}_k(x).$$

Here p_j are harmonic polynomials of the form $p_j(x) = Z_{e_\gamma}^{q_1}(x)$ with $q_1 \le q$ and $p_k(x) = Z_{e_\gamma}^{q-q_1}(x)$. Moreover, as $\sum_{q_1=0}^{q} C_{q_1}^q = 2^q$, we have

$$\sum_{j,k}^{N(q)} \left|c_{j,k}^\alpha\right| = \sum_{\gamma=1}^{P(q)} \left|c_\gamma^\alpha\right| 2^{-q} \sum_{q_1=0}^{q} \left|C_{q_1}^q\right| \le q^n C^q \le (C_n)^q.$$

As $\|p_j\| \, \|p_k\| \le V(\Omega)(1+r_1)^q$, where $V(\Omega)$ is the volume of Ω, the above estimate together with Theorem 3.2 and Corollary 3.3 give rise to the following estimate:

$$\left\|\rho(\cdot) - Q_\mu^m(\cdot; \Phi_\rho(t;\cdot,\cdot))\right\|_{C^l(\mu^{-1/2})} \le C\{\|\rho\|_{C^{l+\sigma}} (\mu^{-\sigma}$$
$$+(C\mu)^{m+n+2} m^{-m/2+l}) + e^{C'\mu^2 - C\lambda_0 t} C^m\}.$$

Thus, inserting $\mu = e^{-a} m^{1/2}$ into the above inequality and taking $a > 0$ large enough, we obtain the estimate in Theorem 3.4. □

Analyzing the proof of Theorem 3.4, we obtain also the following stability estimate which will be used in section 4.

LEMMA 3.5. *Let $M, \widetilde{M}$ be bilinear forms on HP^m. Let $Q_\mu^m(x; M)$ and $Q_\mu^m(x; \widetilde{M})$ be given by formula* (3.1). *Then we have*

$$\left\|Q_\mu^m(\cdot; M) - Q_\mu^m(\cdot; \widetilde{M})\right\|_{C^l(\Omega)} \le C^m e^{c'\mu^2} \left\|M - \widetilde{M}\right\|_m.$$

4. Analytic estimates and stability. In the analysis of section 3 we have not used the fact that $\Phi_\rho(t;\cdot,\cdot)$ is an analytic function when Re $(t) > 1$, which makes it possible to improve the estimates of Corollary 3.3 and Theorem 3.4 and to obtain some further stability results for the considered inverse problem. Namely, by means of the analyticity, we can obtain the required estimates on an interval given in advance (e.g., on $0 < t < 2$).

We start with stability estimates.

LEMMA 4.1. *Let $\rho, \widetilde{\rho}$ satisfy the condition* (1.2) *and*

$$\left\|\Phi_\rho(\cdot; p, q) - \Phi_{\widetilde{\rho}}(\cdot; p, q)\right\|_{C^0(0,2)} \le \epsilon \, \|p\| \, \|q\|, \quad p, q \in HP^m.$$

Then we have

$$|M_\rho(p,q) - M_{\widetilde{\rho}}(p,q)| \le C e^{-C\lambda_0^{1/2} |\lg \epsilon|^{1/2}} ||p|| \, ||q||. \tag{4.1}$$

Proof. Set $z = \frac{t-2}{t}$. Then the map $t \to z$ becomes conformal from the half plane Re $(t) > 1$ onto the unit disk $|z| < 1$. Consider the function

$$f(z) = \Phi_\rho(t; p, q) - \Phi_{\widetilde{\rho}}(t; p, q), \quad z = z(t),$$

which is analytic in the unit disk. Moreover, by Theorem 2.1, we have

$$\begin{aligned} |f(z)| &\le C||p||\ ||q|| \qquad \text{in} \quad |z| \le 1, \\ |f(z)| &\le \epsilon||p||\ ||q|| \qquad \text{on} \quad -1 \le z \le 0. \end{aligned}$$

By the Milloux theorem (see, e.g., [G; Chapter VIII, section 4, Theorem 6]) these estimates imply that when $z = 1 - \zeta$, Im $(z) = 0$,

$$|f(z)| \le C||p||\ ||q||\epsilon^{\zeta/\pi}.$$

Taking $\zeta = 2/t$, we see that

$$|\Phi_\rho(t; p, q) - \Phi_{\tilde\rho}(t; p, q)| \le C||p||\ ||q||\epsilon^{2/\pi t}.$$

This estimate together with Theorem 2.1 (iii), where $t = (\frac{2|\lg\epsilon|}{C\pi\lambda_0})^{1/2}$, proves the lemma.

The proof is complete. □

Lemma 4.1 together with Theorem 3.2(ii) and Lemma 3.5 leads to the following stability result.

THEOREM 4.2. *Let $\rho, \widetilde\rho$ satisfy the condition* (1.2) *and*

$$||\Phi_\rho(\cdot; p, q) - \Phi_{\tilde\rho}(\cdot; p, q)||_{C^0(0,2)} \le \epsilon||p||||q||, \quad p, q \in HP^m.$$

Then we have

$$\begin{aligned} \left\|\rho - \widetilde\rho\right\|_{C^l(\mu^{-1/2})} \le C[(\left\|\rho\right\|_{C^{l+\sigma}} + \left\|\tilde\rho\right\|_{C^{l+\sigma}})\{\mu^{-\sigma} + (C\mu)^{m+n+2}m^{-m/2+l}\} \\ + C^m e^{C\mu^2} e^{-C\lambda_0^{1/2}|\lg\epsilon|^{1/2}}]. \end{aligned}$$

Proof. Obviously

$$\begin{aligned} \left\|\rho - \tilde\rho\right\|_{C^l(\mu^{-1/2})} \le \left\|\rho - Q_\mu^m(x, M_\rho)\right\|_{C^l(\mu^{-1/2})} \\ + \left\|\tilde\rho - Q_\mu^m(x, M_{\tilde\rho})\right\|_{C^l(\mu^{-1/2})} \\ + \left\|Q_\mu^m(x, M_\rho) - Q_\mu^m(x, M_{\tilde\rho})\right\|_{C^l(\mu^{-1/2})}. \end{aligned} \tag{4.2}$$

The first two terms in the right-hand side of (4.2) may be estimated by means of (3.3). To estimate the third term we use the relation (4.1) together with Lemma 3.5 with $M_\rho, M_{\tilde\rho}$ instead of $M, \widetilde M$. Therefore the theorem is obtained. The proof is now complete. □

Remark 1. If we take $\mu = e^{-a}m^{1/2}$, where a is a sufficiently large positive number which depends upon Ω, ρ_1, ρ_2, and l, the above estimate may be simplified in the following way:

$$\begin{aligned} \left\|\rho - \widetilde\rho\right\|_{C^l(e^{a/2}m^{-1/4})} \le C\{(\left\|\rho\right\|_{C^{l+\sigma}} + \left\|\tilde\rho\right\|_{C^{l+\sigma}})m^{-\sigma/2} \\ + \exp(C_1 m - C_2\lambda_0^{1/2}|\lg\epsilon|^{1/2})\}. \end{aligned}$$

Remark 2. From the proof of Theorem 4.2, we can also obtain the following conditional stability result: There exist constants a, C, and C_1 such that the inequality

$$\left\|\rho - \widetilde\rho\right\|_{C^l(e^{a/2}m^{-1/4})} \le CEm^{-\sigma/2} + e^{C_1 m}\epsilon$$

holds for any ρ, $\widetilde{\rho} \in C^{l+\sigma}(\overline{\Omega})$, satisfying $\|\rho\|_{C^{l+\sigma}(\overline{\Omega})} \leq E$ and $\|\widetilde{\rho}\|_{C^{l+\sigma}(\overline{\Omega})} \leq E$ if we have

$$|M_\rho(p,q) - M_{\tilde{\rho}}(p,q)| \leq \epsilon \|p\| \|q\| \qquad \text{for any } p, q \in HP^\infty.$$

Our next goal is to improve the reconstruction procedure described in section 3 for the case when $\Phi_\rho(t;\cdot,\cdot)$ is known with some error.

Let $\Psi_\epsilon(t;p,q)$ $(p,q \in HP^m)$ satisfy the following estimates on $0 \leq t \leq 2$:

$$\|\Phi_\rho(\cdot;p,q) - \Psi_\epsilon(\cdot;p,q)\|_{C^0(0,2)} \leq \epsilon \|p\| \|q\|. \tag{4.3}$$

Set

$$w(t) = \frac{\{1-(t-1)^2\}^{1/2} - i}{\{1-(t-1)^2\}^{1/2} + i}.$$

Then $w(t)$ becomes a conformal map of the half plane Re $(t) > 1$ with a slit along the interval $(1,2)$ onto the unit disk $|w| < 1$. The slit is transformed onto the left semicircle $|w| = 1, \text{Re}\,(w) < 0$, and the line Re $(t) = 1$ onto the right semicircle $|w| = 1, \text{Re}\,(w) > 0$. The function $f_\epsilon(w;p,q) = \Psi_\epsilon(t;p,q)$ $(t \in (1,2),\ w = w(t))$ is defined on the left semicircle and satisfies

$$|f(w) - f_\epsilon(w)| \leq \epsilon \|p\| \|q\| \qquad \text{on } |w| = 1,\ \text{Re}\,(w) < 0, \tag{4.4}$$

where $f(w;p,q) = \Phi_\rho(t;p,q)$ $(t \in (1,2),\ w = w(t))$.

For the quasi-analytic continuation of $f_\epsilon(w)$ we use the construction suggested in [L] which is based upon the Carleman lemma [Car]. Let

$$\sigma_\epsilon = \frac{1}{t^2} \log \frac{Ct}{\epsilon},$$

with some $t \geq 2$. We define $\tilde{f}_\epsilon^t(z)$ by the following formula:

$$\tilde{f}_\epsilon^t(z) = \frac{e^{-\sigma_\epsilon}}{2\pi i} \int_{\frac{\pi}{2}}^{\frac{3\pi}{2}} f_\epsilon(w) \exp\left\{\sigma_\epsilon \left(\frac{w-1}{z-1}\right)^2\right\} \frac{iwd\phi}{z-w}, \quad w = e^{i\phi}. \tag{4.5}$$

THEOREM 4.3. *Let $\tilde{f}_\epsilon^t(z)$ be given by* (4.5)*, where f_ϵ satisfies* (4.4)*. Then for $t > 2$ large enough, we have*

$$|M_\rho(p,q) - \tilde{f}_\epsilon^t(1-2/t)| \leq C \|p\| \|q\| (t\epsilon^{1/t^2} + e^{-C\lambda_0 t}). \tag{4.6}$$

Proof. By $\mathcal{O}$ (see Figure 1), we denote the domain obtained as the intersection of the unit disk and the sector of the angle $\pi/2$ with its vertex in the point $(1,0)$, which is symmetric with respect to the real axis.

Since the function $f(w;p,q)$ is continued analytically in the unit disk, by the Cauchy formula for the holomorphic function $z \to f(z)\exp\left(\frac{\sigma_\epsilon(z-1)^2t^2}{4}\right)$, we have

$$f(1-2/t) = \frac{e^{-\sigma_\epsilon}}{2\pi i} \int_{\partial\mathcal{O}} f(z) \exp\left(\frac{\sigma_\epsilon(z-1)^2t^2}{4}\right) \frac{dz}{1-2/t-z},$$

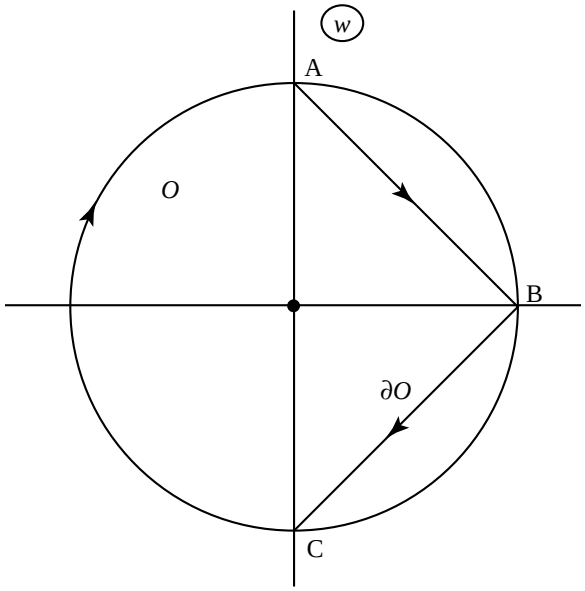

FIG. 1.

where the contour $\partial\mathcal{O}$ consists of the left semicircle (in Re $(z) < 0$) and the broken line ABC (see Figure 1). Hence

$$
\begin{aligned}
&|\tilde{f}_\epsilon^t(1-2/t) - f(1-2/t)| \\
&\leq \frac{e^{-\sigma_\epsilon}}{2\pi} \int_{\frac{\pi}{2}}^{\frac{3\pi}{2}} |\tilde{f}_\epsilon(z) - f(z)| \exp\left(\frac{\sigma_\epsilon t^2}{4} \mathrm{Re}\ (z-1)^2\right) \left|\frac{dz}{1-2/t-z}\right| \\
&+ \frac{e^{-\sigma_\epsilon}}{2\pi} \int_{ABC} |f(z)| \exp\left(\frac{\sigma_\epsilon t^2}{4} \mathrm{Re}\ (z-1)^2\right) \left|\frac{dz}{1-2/t-z}\right| \\
&= I_1 + I_2,
\end{aligned} \tag{4.7}
$$

where $z = e^{i\phi}, \phi \in (\frac{\pi}{2}, \frac{3\pi}{2})$, in the first integral I_1.

For $z = e^{i\phi}$, $\phi \in (\frac{\pi}{2}, \frac{3\pi}{2})$, we have Re $(z-1)^2 \leq 2$ and $|1-2/t-z| \geq 1$. Hence the inequality (4.4) yields the following estimate for I_1:

$$
I_1 \leq C\epsilon \left\|p\right\| \left\|q\right\| e^{\sigma_\epsilon(t^2-1)} \leq Ct\epsilon^{1/t^2} \left\|p\right\| \left\|q\right\|, \tag{4.8}
$$

where the last estimate follows from the definition of σ_ϵ.

To estimate I_2, we use the fact that Re $\{(z-1)^2\} = 0$ and $|1-2/t-z| \geq \frac{\sqrt{2}}{t}$ on ABC. Taking into account the estimate (i) of Theorem 2.1 and $|\Phi_\rho(t,p,q)| \leq C \left\|p\right\| \left\|q\right\|$ for Re $t \geq 1$, we see that

$$
I_2 \leq Ct \left\|p\right\| \left\|q\right\| e^{-\sigma_\epsilon} \leq Ct\epsilon^{1/t^2} \left\|p\right\| \left\|q\right\|. \tag{4.9}
$$

Since we clearly have $|w(t) - (1-2/t)| \leq C/t^2$, there is a constant $C > 0$ such that $\left|t - \tilde{t}\right| \leq C$ holds for $t \geq 1$ and $\tilde{t}$ satisfying $1 - 2/t = w(\tilde{t})$. Hence, taking into

account Theorem 2.1 (iii), we see that

$$\left|f(1-2/t)-M_\rho\right| = \left|\Phi_\rho(\tilde{t};p,q)-M_\rho(p,q)\right| \le Ce^{-C'\lambda_0 t}\left\|p\right\|\left\|q\right\|. \tag{4.10}$$

The inequality (4.6) follows from (4.7)–(4.10).

The proof is complete. □

Remark. The consideration leading to (4.9) is a special case of the results obtained by Lavrent'ev (see [L, Chapter I, Proof III]).

For any bilinear form $\Psi_\epsilon(t;p,q)$ from $HP^m \times HP^m$ to $C^0[0,2]$, we set

$$M_\rho^\epsilon(p,q) = \tilde{f}_\epsilon^t(1-2/t), \qquad t = |\log\epsilon|^{1/3}\lambda_0^{-1/3}, \tag{4.11}$$

where $\tilde{f}_\epsilon^t$ is the function in (4.5) with $f_\epsilon(w) = \Psi_\epsilon(t;p,q)$, $w = w(t)$. Then Theorem 4.3 implies that

$$\left|M_\rho(p,q) - M_\rho^\epsilon(p,q)\right| \le C|\log\epsilon|^{1/3}e^{-C'\lambda_0^{2/3}|\log\epsilon|^{1/3}}\left\|p\right\|\left\|q\right\|.$$

By the above estimate and the estimates (3.3), (3.2), and proof of Theorem 3.4, we come to the following.

THEOREM 4.4. *Let $\Psi_\epsilon : HP^m \times HP^m \to C^0(0,2)$ be a bilinear form which is ϵ-close to Φ_ρ in the sense of* (4.3). *For this Ψ_ϵ, we define M_ρ^ϵ by* (4.11). *Then we have*

$$\begin{aligned}\left\|\rho(\cdot) - Q_\mu^m(\cdot;M_\rho^\epsilon)\right\|_{C^l(\mu^{-1/2})} \le C[&\left\|\rho\right\|_{C^{l+\sigma}}(\mu^{-\sigma}+(C\mu)^{m+n+2}m^{-m/2+l})\\ &+|\log\epsilon|^{1/3}\mu^n e^{C''\mu^2}C^m e^{-C'\lambda_0^{2/3}|\log\epsilon|^{1/3}}].\end{aligned}$$

In particular, for $\mu = e^{-a}m^{1/2}$ with $a > 0$ large enough, we have

$$\begin{aligned}&\left\|\rho(\cdot) - Q^m_{e^{-a}m^{1/2}}(\cdot;M_\rho^\epsilon)\right\|_{C^l(e^{a/2}m^{-1/4})}\\ &\le C(1+\left\|\rho\right\|_{C^{l+\sigma}})(m^{-\sigma/2}+\exp(Cm - C'\lambda_0^{2/3}|\log\epsilon|^{1/3})).\end{aligned}$$

Acknowledgments. The authors would like to thank Professor G. Nakamura, Professor E. Somersalo, and Professor K. Peat for their interest in this paper.

EXPLICIT COMPUTATION OF ORTHONORMAL SYMMETRIZED HARMONICS WITH APPLICATION TO THE IDENTITY REPRESENTATION OF THE ICOSAHEDRAL GROUP*

YIBIN ZHENG† AND PETER C. DOERSCHUK‡

Abstract. A novel method to explicitly compute orthonormal symmetrized harmonics is presented and the method is applied to the identity representation of the icosahedral group. Spherical viruses have icosahedral symmetry and the motivating application is the parametric representation of spherical viruses for use in inverse problems based on x-ray scattering data and cryoelectron microscopy images. The symmetrized harmonics are computed in the form of linear combinations of spherical harmonics of one order and therefore have simple rotational properties which is valuable in the electron microscopy application. The method is based on equating the expansions of a symmetrized delta function in spherical and in symmetrized harmonics from which bilinear equations for the weights in the linear combinations can be derived. The explicit character of the calculation is reflected in the fact that both explicit expressions and an efficient recursive algorithm are derived for computing the weights in the linear combinations.

1. Introduction.

An important problem in biophysics is the determination of the three-dimensional distribution of electron density in so-called "spherical" viruses [1] from x-ray scattering and electron microscopy data [2]. This is a large class of viruses, including both viruses of plants and animals, where all viral particles of a particular viral type are identical, each viral type has a particle diameter of 10^2–10^3Å, and each viral particle has all the symmetries of the icosahedron. Two approaches to analyzing such data are to represent the electron density either as a truncated orthonormal expansion [3, 4] or as a piecewise-constant function with icosahedrally symmetric boundaries that are described using truncated orthonormal expansions [5] and then solve a nonlinear least squares problem for the coefficients in the expansion. Because the viral particles are roughly spherical in shape and the icosahedral symmetry is a rotational symmetry, it is natural to use spherical coordinates and express the basis functions in the orthonormal expansion of the electron density as products of functions on the sphere and radial functions. Similarly, for the approach based on the piecewise-constant function, it is natural to describe the boundary by its radius from the origin as a function of the angles, in which case the basis functions in the expansion are functions on the sphere.

In this paper we describe a new method for explicitly[1] computing sets of functions that are representations of rotational groups in three dimensions and demonstrate the method on the identity representation of the icosahedral group, i.e., we explicitly compute a complete orthonormal basis for icosahedrally symmetric functions on the sphere. We call the functions in this basis "icosahedrally symmetric basis functions" (abbreviated ISBFs) and are not yet specific about which basis we will explicitly compute (see section 2). Using the ISBFs in the orthonormal expansions involved in the biophysics problems of the previous paragraph is much superior to the natural alternative of using spherical harmonics (denoted by $Y_{l,m}(\theta,\phi)$, where, here and elsewhere, (θ,ϕ) are spherical coordinates). For example: (1) The constraint that the particle has icosahedral symmetry is built into the functions rather than having to be added as a constraint in the nonlinear least squares problem. (2) There are many fewer ISBFs than $Y_{l,m}$ functions so many fewer coefficients have to be determined by nonlinear least squares in order to determine the electron density at a given level of resolution. (3) By incorporating the icosahedral symmetry directly in the mathematical description of the electron density by use of the ISBFs, we remove certain nonuniqueness problems in the nonlinear least squares problems.

There has been extensive work on ISBFs [7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19], which are basis functions for the identity representation of the icosahedral group (the only representation needed in our application), and also on the more general problem of basis functions for all five irreducible representations of the icosahedral group [9, 17]. Sometimes ISBFs are called "icosahedral harmonics" [12, 20, 14] but, in analogy with spherical harmonics terminology, we reserve "icosahedral harmonics" for a collection of basis functions for all five irreducible representations. In the majority of previous work, ISBFs are described as linear combinations of spherical harmonics of fixed order which leads to simple rotational properties which are important for our electron microscopy applications. In this framework, the only task is to determine the coefficients of the linear combination. In a minority of previous work (e.g., [14]), ISBFs are described as polynomials in the rectangular coordinates.

Although extensive work has been done, existing results are limited in two aspects that are important for our application: (1) Explicit expressions in terms of standard operations ($+$, $-$, $\times$, $\div$, and complex exponentiation) for ISBFs of arbitrary order are not provided. (2) The algorithms provided to derive an ISBF for some particular order are laborious, especially for orders greater than 29 when there can be two or more ISBFs of a single order. Reflecting these limitations, the most extensive tables of which we are aware [12, 18] tabulate ISBFs only up to order 30 (and in fact only one of two functions of order 30 is tabulated) or 44, respectively, while in a medium resolution x-ray diffraction interpolation problem we have required functions of order roughly 85. In the previous work [18] most closely related to the present paper, the derivation is unnecessarily complicated and not rigorous due to the "Q" operator in [18], implementation of the resulting algorithm requires symbolic derivatives in

[1] By "explicit" we mean relationships from which formulas such as those given in section 7 can be computed. This is a weaker notion of "explicit" than is standard in, for example, spherical harmonics, where [6, Eqs. (3.53) and (3.50)]

$$Y_{l,m}(\theta,\phi) = \sqrt{\frac{2l+1}{4\pi}\frac{(l-m)!}{(l+m)!}}P_{l,m}(\cos\theta)\exp(im\phi),$$

$$P_{l,m}(x) = \frac{(-1)^m}{2^l l!}(1-x^2)^{m/2}\frac{\mathrm{d}^{l+m}}{\mathrm{d}x^{l+m}}(x^2-1)^l.$$

order to compute the "$c_{p,q}$" numbers in [18] (numerical approximations of the derivatives are essentially impossible because determination of an lth order ISBF requires derivatives through lth order), the resulting algorithm in [18] is very slow compared to the algorithm of this paper, and the matrix-factorization implications of (15) in [18] are not appreciated or exploited. In another related work [19], the authors base their approach on projection operators applied to spherical harmonics (as in equation (1) of the present paper) followed by Gram–Schmidt orthogonalization and do all of the necessary integrals numerically to machine precision by noting that the integrands of interest are polynomials and that, therefore, suitably high-order Gaussian quadrature formulas can compute the integrals to machine precision. These machine precision results are then represented using square roots and rational numbers, and tables to order 15 are provided. In contrast with the approach of [19], we apply projection operators to delta functions rather than spherical harmonics, expand the result in spherical harmonics and in ISBFs, and by equating the two expansions derive a bilinear system of equations from which the weights in the expansion of an ISBF in terms of spherical harmonics can be derived symbolically rather than numerically to machine precision. In summary, in this paper we remove the limitations indicated above and the resulting algorithm is highly suitable for computer implementation in either numerical or symbolic programming languages; software is available from the authors.

2. Approach. Our goal is to determine ISBFs such that (1) each function is real valued, (2) the set of functions are a complete orthonormal basis for smooth icosahedrally symmetric functions on the sphere, and (3) each function is a linear combination of $Y_{l,m}$ for some fixed l. Let $\int \mathrm{d}\Omega$ mean $\int_{\theta=0}^{\pi}\int_{\phi=0}^{2\pi}\sin(\theta)\mathrm{d}\theta\mathrm{d}\phi$. Then the orthonormality referred to in the second property is $\int I_\alpha^*(\theta,\phi)I_{\alpha'}(\theta,\phi)\mathrm{d}\Omega = \delta_{\alpha,\alpha'}$, where I_α denotes an ISBF from a not-yet-specified basis. Since rotation of $Y_{l,m}$ gives a function that is a linear combination of $\{Y_{l,m'} : m' = -l,\ldots,+l\}$ [21], the third property assures that the ISBFs will have simple properties under rotations, which is important in electron microscopy [2].

Goals (1)–(3) of the previous paragraph do not uniquely define the ISBFs when there are two or more ISBFs (denoted by $I_{\alpha_1},\ldots,I_{\alpha_p}$) in the subspace $\mathcal{S}_l$ spanned by $\{Y_{l,m} : m = -l,\ldots,+l\}$. In particular, if $O \in \mathcal{R}^{p\times p}$ is an orthonormal matrix, then the p functions $(I_{\alpha_1},\ldots,I_{\alpha_p})^T$ could be replaced by the p functions $O(I_{\alpha_1},\ldots,I_{\alpha_p})^T$ and still satisfy goals (1)–(3). A method to chose the basis in the subspace $\mathcal{S}_l$ so that the basis has meaningful representation-theoretic or spectral-theoretic properties is an open question. In this paper (see section 6) the basis is chosen so that the matrix of expansion coefficients, expanding ISBFs in terms of spherical harmonics, is triangular. This choice of basis minimizes the number of terms when computing ISBFs from spherical harmonics. Except for sections 6–8, all results in the paper are true for any basis satisfying goals (1)–(3).

A standard group-theoretic approach to determine the ISBFs is to apply projection operators [22, pp. 92–94] to the spherical harmonics. For the identity representation of a group, the projection operator has a simple form and a candidate ISBF, that is, the projection operator applied to the (l,m)th spherical harmonic, is

$$J_{l,m}(\theta,\phi) = \frac{1}{g}\sum_{k=0}^{g-1} P(T_k)Y_{l,m}(\theta,\phi), \tag{1}$$

where $g = 60$ is the order of the icosahedral group, T_k is the kth rotation of the

icosahedral group, and the scalar transformation operator $P(T)$ applied to a function $\psi(\mathbf{r})$ is defined by $P(T)\psi(\mathbf{r}) = \psi(T^{-1}\mathbf{r})$. (We are using the notation of [22].) While this method appears to be direct, it has some serious difficulties: First,

$$P(T_k)Y_{l,m}(\theta,\phi) = \sum_{m'=-l}^{+l} D_{l,m,m'}(T_k)Y_{l,m'}(\theta,\phi),$$

where the $D_{l,m,m'}(T_k)$ are the complicated Wigner's D coefficients [21], so it is difficult to perform the sum of (1) analytically for general l and m. Second, for a fixed l, Laporte's results (see Theorem 3.1) state that there are only $N_l \leq 2l+1$ linearly independent ISBFs that can be constructed from $\{Y_{l,m} : m = -l, \ldots, +l\}$) while (1) will generate $2l+1$ candidates. Therefore, N_l functions must be chosen from among the $2l+1$ candidates. Furthermore, no set of N_l functions from among the candidates is guaranteed to be orthonormal, so a set of N_l linearly independent functions must then be orthogonalized by the Gram–Schmidt procedure. This orthogonalization is also difficult to perform analytically for general l and m. In summary, it is difficult to derive, by way of (1), expressions for an orthonormal set of ISBFs that are explicit functions of the indices.

Our approach is also based on projections. However, rather than projecting a spherical harmonic, as in (1), we project a delta function located at spherical coordinates (θ_0, ϕ_0), i.e., $\delta(\cos\theta - \cos\theta_0)\delta(\phi - \phi_0)$. The result of the projection is a symmetrized delta function denoted by $\Delta(\theta_0, \phi_0; \theta, \phi)$:

$$\Delta(\theta_0,\phi_0;\theta,\phi) = \frac{1}{g}\sum_{k=0}^{g-1} P(T_k)[\delta(\cos\theta - \cos\theta_0)\delta(\phi - \phi_0)].$$

This projection is easy to compute because the result of applying a rotation to a delta function is just another delta function at different coordinates: $P(T_k)[\delta(\cos\theta - \cos\theta_0)\delta(\phi - \phi_0)] = \delta(\cos\theta - \cos\theta_k)\delta(\phi - \phi_k)$. Furthermore, it is straightforward to expand the symmetrized delta function $\Delta(\theta_0, \phi_0; \theta, \phi)$ as a weighted sum of spherical harmonics:

$$\Delta(\theta_0,\phi_0;\theta,\phi) = \sum_{l=0}^{\infty}\sum_{m=-l}^{+l} w_{l,m}(\theta_0,\phi_0)Y_{l,m}(\theta,\phi),$$

specifically,

$$\Delta(\theta_0,\phi_0;\theta,\phi) = \frac{1}{g}\sum_{k=0}^{g-1}\sum_{l=0}^{\infty}\sum_{m=-l}^{+l} Y^*_{l,m}(\theta_k,\phi_k)Y_{l,m}(\theta,\phi). \tag{2}$$

In addition, because the ISBFs are a complete orthonormal fixed basis for the subspace of totally symmetric functions, we know the expansion of $\Delta(\theta_0, \phi_0; \theta, \phi)$ as a weighted sum of ISBFs:

$$\Delta(\theta_0,\phi_0;\theta,\phi) = \sum_{\alpha} I^*_{\alpha}(\theta_0,\phi_0)I_{\alpha}(\theta,\phi). \tag{3}$$

In order to assure that each ISBF is a linear combination of $Y_{l,m}$ for fixed l we constrain the ISBF, denoted by $I_{l,n}$, to have the form

$$I_{l,n}(\theta,\phi) = \sum_{m=-l}^{+l} b_{l,n,m}Y_{l,m}(\theta,\phi), \tag{4}$$

where $l \in \{0, 1, \dots\}$, $n \in \{0, 1, \dots, N_l - 1\}$ (see Theorem 3.1 for the value of N_l), and the weights $b_{l,n,m}$ are unknown and are in fact the goal of these calculations. It is the matrix constructed from $b_{l,n,m}$ (l fixed) that will be made triangular in section 6, thereby selecting a particular orthonormal basis as described above. Finally, by equating (2) and (3) and using (4), we can derive nonlinear equations for the weights $b_{l,n,m}$ and these nonlinear equations can be solved recursively to give explicit formulas for the $b_{l,n,m}$.

3. Preliminaries. For the spherical harmonics $Y_{l,m}$ we use the conventions of [6] and exploit the standard result [6, Eq. (3.53)] that $Y_{l,m}(\theta, \phi) = N_{l,m} P_{l,m}(\cos\theta) e^{im\phi}$, where $P_{l,m}(x)$ are the associated Legendre functions [6, Eq. (3.49)] and

$$N_{l,m} = \sqrt{\frac{2l+1}{4\pi} \frac{(l-m)!}{(l+m)!}}.$$

Laporte [14] proves the following result regarding N_l.

THEOREM 3.1 (Laporte [14]). *For l even, the number N_l (denoted by $N_l^{(\mathrm{e})}$) satisfies the relationship*

$$\frac{1}{(1-x^6)(1-x^{10})} = \sum_{l=0}^{\infty} N_l^{(\mathrm{e})} x^l$$

while for l odd, the number N_l (denoted by $N_l^{(\mathrm{o})}$) is

$$N_l^{(\mathrm{o})} = \begin{cases} N_{l-15}^{(\mathrm{e})}, & l \geq 15, \\ 0, & 0 \leq l < 15. \end{cases}$$

For our concrete calculations, we choose the coordinate system used by Altmann [7] and Laporte [14] in which the z axis passes through two opposite vertices and the xz plane includes one edge of the icosahedron.

4. The bilinear equations for $b_{l,n,m}$. The first proposition about the $b_{l,n,m}$ coefficients can be determined simply from the choice that $I_{l,n}$ are real and $Y_{l,-m}(\theta, \phi) = (-1)^m Y_{l,m}^*(\theta, \phi)$ [6, Eq. (3.54)].

PROPOSITION 4.1. *For each $l = 0, 1, \dots$, $n = 0, \dots, N_l - 1$, and $m = -l, \dots, +l$,*

$$b_{l,n,m} = (-1)^m b_{l,n,-m}^*.$$

The second proposition, based on the orthonormality of the $Y_{l,m}$, relates the orthonormality of the $b_{l,n,m}$ coefficients to the orthonormality of the $I_{l,n}$.

PROPOSITION 4.2. *$I_{l,n}$ and $I_{l',n'}$ ($l \neq l'$; $l, l' = 0, 1, \dots$; $n = 0, \dots, N_l - 1$; $n' = 0, \dots, N_{l'} - 1$) are orthonormal for any choice of $b_{l,n,m}$. For fixed $l = 0, 1, \dots$ the $I_{l,n}$ ($n = 0, \dots, N_l - 1$) are orthonormal if and only if*

$$\sum_{m=-l}^{+l} b_{l,n,m} b_{l,n',m}^* = \delta_{n,n'}.$$

Let (θ_0, ϕ_0) be the (arbitrary) spherical coordinates of a delta function within the first asymmetric unit. Let $\{(\theta_k, \phi_k) : k = 1, 2, \dots, 59\}$ be spherical coordinates of delta functions in the remaining 59 asymmetric units generated by applying rotations

in the icosahedral group. The locations of these additional 59 delta functions are given by Proposition 4.3 below.

PROPOSITION 4.3. *As a function of the parameters θ_0 and ϕ_0, the 60 symmetry-related positions on the unit sphere are*

$$\begin{aligned}
&\{(\theta_k,\phi_k) : k = 0,1,\ldots,59\}\\
&\quad = \{(\theta_0,\phi_k) : k = 0,1,\ldots,4\} \bigcup \left(\bigcup_{n=0}^{4} \left\{ \left(\gamma_n, \alpha_n + k\frac{2\pi}{5} \right) : k = 0,1,\ldots,4 \right\} \right)\\
&\qquad \bigcup \left(\bigcup_{n=0}^{4} \left\{ \left(\pi - \gamma_n, \pi - \alpha_n + k\frac{2\pi}{5} \right) : k = 0,1,\ldots,4 \right\} \right)\\
&\qquad \bigcup \{(\pi - \theta_0, \pi - \phi_k) : k = 0,1,\ldots,4\},
\end{aligned}$$

where ϕ_k, γ_k, and α_k $(k = 0,1,\ldots,4)$ are related to θ_0 and ϕ_0 by

$$\begin{aligned}
\phi_k &= \phi_0 + k\frac{2\pi}{5},\\
\cos\gamma_k &= \frac{1}{\sqrt{5}}(\cos\theta_0 + 2\sin\theta_0\cos\phi_k),\\
\cos\alpha_k &= \frac{2 - \sin\theta_0\cos\phi_k}{\sqrt{5 - (\cos\theta_0 + 2\sin\theta_0\cos\phi_k)^2}}.
\end{aligned}$$

The following proposition is used in the simplification of the the bilinear equation determining the $b_{l,n,m}$ coefficients.

PROPOSITION 4.4. *For any θ_0 and ϕ_0,*

$$\sum_{k=0}^{59} Y_{l,m}(\theta_k,\phi_k) = \begin{cases} 5N_{l,m}\Big[P_{l,m}(\cos\theta_0)\left(e^{im\phi_0} + (-1)^l e^{-im\phi_0}\right) \\ \quad + \sum_{k=0}^{4} P_{l,m}(\cos\gamma_k)\left(e^{im\alpha_k} + (-1)^l e^{-im\alpha_k}\right)\Big], & m = 5\mu \text{ with } \mu \in \mathcal{Z},\\ 0 & \text{otherwise,} \end{cases}$$

where $\mathcal{Z}$ are the integers.

Equate the expressions for $\Delta(\theta_0,\phi_0;\theta,\phi)$ in terms of spherical harmonics (2) and ISBFs (3) to find that

$$\sum_{l=0}^{\infty}\sum_{n=0}^{N_l-1} I_{l,n}(\theta_0,\phi_0) I_{l,n}(\theta,\phi) = \frac{1}{60}\sum_{k=0}^{59}\sum_{l=0}^{\infty}\sum_{m=-l}^{+l} Y^*_{l,m}(\theta_k,\phi_k) Y_{l,m}(\theta,\phi). \tag{5}$$

Replace $I_{l,n}(\theta,\phi)$ by its expansion in terms of $Y_{l,m}(\theta,\phi)$ (4), multiply by $Y^*_{l',m'}(\theta,\phi)$, integrate over solid angles in θ and ϕ, and use the orthonormality of the spherical harmonics to obtain (after renaming the indices $l' \to l$, $m' \to m$) one form (Proposition 4.5, equation (6)) of the fundamental equation for determining the $b_{l,n,m}$ coefficients. Use Proposition 4.4 in (6) or (4) in (6) to obtain two alternative forms ((7) and (8), respectively). The results are summarized in the following proposition.

PROPOSITION 4.5. *The $b_{l,n,m}$ ($l = 0, 1, \ldots$; $n = 0, \ldots, N_l - 1$; $m = -l, \ldots, +l$) coefficients satisfy each of the following equivalent relationships for arbitrary θ_0 and ϕ_0:*

$$\sum_{n=0}^{N_l-1} b_{l,n,m} I_{l,n}(\theta_0, \phi_0) = \frac{1}{60} \sum_{k=0}^{59} Y_{l,m}^*(\theta_k, \phi_k), \tag{6}$$

$$\sum_{n=0}^{N_l-1} b_{l,n,m} I_{l,n}(\theta_0, \phi_0) = \begin{cases} \frac{1}{12} N_{l,m} \Big[P_{l,m}(\cos\theta_0) \left(e^{im\phi_0} + (-1)^l e^{-im\phi_0} \right) \\ \quad + \sum_{k=0}^{4} P_{l,m}(\cos\gamma_k) \left(e^{im\alpha_k} + (-1)^l e^{-im\alpha_k} \right) \Big]^*, & m = 5\mu \text{ with } \mu \in \mathcal{Z}, \\ 0 & \text{otherwise}, \end{cases} \tag{7}$$

$$\sum_{n=0}^{N_l-1} \sum_{m'=-l}^{+l} b_{l,n,m'} b_{l,n,m} Y_{l,m'}(\theta_0, \phi_0) = \frac{1}{60} \sum_{k=0}^{59} Y_{l,m}(\theta_k, \phi_k) \tag{8}$$

for any $l = 0, 1, \ldots$ and $m = -l, \ldots, +l$.

Notice that there is no coupling between different values of l in (6), (7), and (8). From (7) we immediately obtain the following properties of the $b_{l,n,m}$ coefficients.

PROPOSITION 4.6.

1. *If $m \neq 5\mu$ with $\mu \in \mathcal{Z}$, then $b_{l,n,m} = 0$.*
2. *For l even, $b_{l,n,m}$ is real. For l odd, $b_{l,n,m}$ is imaginary.*
3. *$b_{l,n,m} = b_{l,n,-m}(-1)^{l+m}$.*
4. *For l odd, $b_{l,n,0} = 0$.*

Using these properties, we can simplify the expression for the $I_{l,n}$ as follows.

PROPOSITION 4.7.

$$I_{l,n}(\theta, \phi) = \begin{cases} \sum_{m=0}^{+l} \frac{2}{1+\delta_{m,0}} N_{l,m} b_{l,n,m} P_{l,m}(\cos\theta) \cos m\phi, & l \text{ even}, \\ \sum_{m=1}^{+l} 2 N_{l,m} i b_{l,n,m} P_{l,m}(\cos\theta) \sin m\phi, & l \text{ odd}. \end{cases} \tag{9}$$

Proposition 4.7 implies that the ISBFs are completely determined by the $b_{l,n,m}$ coefficients for which $m \geq 0$. Therefore in the remainder of the paper, we assume $m \geq 0$ and $m' \geq 0$. Also, we absorb the "i" that occurs for l odd into $b_{l,n,m}$ so that the new definition of $b_{l,n,m}$ is always real (Proposition 4.6(2)). The calculation of the $b_{l,n,m}$ coefficients is the same in plan but different in details for l even versus l odd. We will show the l even case and then state the results for l odd.

Notice in equation (8) that the $b_{l,n,m}$ coefficients enter only through the quantity $\sum_{n=0}^{N_l-1} b_{l,n,m} b_{l,n,m'}$. Therefore, define

$$C_{l,m,m'} = \sum_{n=0}^{N_l-1} b_{l,n,m} b_{l,n,m'}. \tag{10}$$

The remainder of the calculation is in two parts: (1) explicit computation of the $C_{l,m,m'}$ constants and (2) factorization of (10) to determine the $b_{l,n,m}$ coefficients.

5. Calculation of $C_{l,m,m'}$. Denote the integer part function by $\lfloor\cdot\rfloor$. Use Proposition 4.7 in Proposition 4.5 and specialize to the case of l even, $m = 5\mu$ with $\mu = 0, \ldots, \lfloor l/5 \rfloor$ and $m' = 5\mu'$ with $\mu' = 0, \ldots, \lfloor l/5 \rfloor$ to get the result that

$$\begin{aligned}&\sum_{m'=0}^{l} C_{l,m,m'} \frac{2N_{l,m'}}{1+\delta_{m',0}} P_{l,m'}(\cos\theta_0)\cos m'\phi_0 \\ &= \frac{1}{6} N_{l,m}\left[P_{l,m}(\cos\theta_0)\cos m\phi_0 + \sum_{k=0}^{4} P_{l,m}(\cos\gamma_k)\cos m\alpha_k\right]. \end{aligned} \tag{11}$$

Multiply both sides of (11) by $\cos m''\phi_0$, integrate from 0 to 2π with respect to ϕ_0, and then divide by 2π. After using the orthonormality of $\cos m\phi_0$ and renaming m'' to m' we obtain Proposition 5.1, which is the basis for computing the $C_{l,m,m'}$.

PROPOSITION 5.1. *For l even, $m = 5\mu$ with $\mu = 0, \ldots, \lfloor l/5 \rfloor$ and $m' = 5\mu'$ with $\mu' = 0, \ldots, \lfloor l/5 \rfloor$,*

$$\begin{aligned}N_{l,m'} C_{l,m,m'} P_{l,m'}(\cos\theta_0) &= \frac{1}{6} N_{l,m}\left[P_{l,m'}(\cos\theta_0)\delta_{m,m'}\frac{1+\delta_{m',0}}{2}\right. \\ &\left. + \frac{1}{2\pi}\int_0^{2\pi}\sum_{k=0}^{4} P_{l,m}(\cos\gamma_k)\cos(m\alpha_k)\cos(m'\phi_0)\mathrm{d}\phi_0\right]. \end{aligned} \tag{12}$$

Equation (12) is of the form $C_{l,m,m'} f_{l,m'}(\theta_0) = h_{l,m,m'}(\theta_0)$. Therefore, for fixed l, m, and m', the functions $f_{l,m'}(\cdot)$ and $h_{l,m,m'}(\cdot)$ are proportional and $C_{l,m,m'}$ is the constant of proportionality. We are unable to compute the value of the integral contained in $h_{l,m,m'}(\cdot)$. However, we can compute $\lim_{\theta_0\to 0}(1/m'!)\mathrm{d}^{m'}/\mathrm{d}\theta_0^{m'}$ of both $f_{l,m'}(\cdot)$ and $h_{l,m,m'}(\cdot)$ and the resulting functions continue to have the same constant of proportionality. Define constants $g_{l,m'}$ and $D_{l,m,m'}$ by

$$g_{l,m'} = \left[\frac{1}{m'!}\frac{\mathrm{d}^{m'}}{\mathrm{d}\theta_0^{m'}} P_{l,m'}(\cos\theta_0)\right]_{\theta_0=0}, \tag{13}$$

$$D_{l,m,m'} = \sum_{k=0}^{4}\left[\frac{1}{m'!}\frac{\mathrm{d}^{m'}}{\mathrm{d}\theta_0^{m'}}\frac{1}{2\pi}\int_0^{2\pi} P_{l,m}(\cos\gamma_k)\cos(m\alpha_k)\cos(m'\phi_0)\mathrm{d}\phi_0\right]_{\theta_0=0}. \tag{14}$$

Substitute these definitions into the limit of the m'th derivative of (12) to obtain the final equation for determining $C_{l,m,m'}$ in terms of $g_{l,m'}$, $D_{l,m,m'}$, and the standard formula for $N_{l,m}$.

PROPOSITION 5.2. *For l even, $m = 5\mu$ with $\mu = 0, \ldots, \lfloor l/5 \rfloor$ and $m' = 5\mu'$ with $\mu' = 0, \ldots, \lfloor l/5 \rfloor$,*

$$N_{l,m'} C_{l,m,m'} g_{l,m'} = \frac{1}{6} N_{l,m}\left[g_{l,m'}\delta_{m,m'}\frac{1+\delta_{m',0}}{2} + D_{l,m,m'}\right]. \tag{15}$$

We are unable to directly evaluate the derivatives in (13) and (14) and then set $\theta_0 = 0$ so instead we use the following proposition.

PROPOSITION 5.3. *Let $f(\cdot)$ be a function with continuous arbitrary order derivatives. If $\lim_{\theta\to 0} f(\theta)/\theta^m = C$ and $|C| < \infty$, then*

$$\left[\frac{1}{m!}\frac{\mathrm{d}^m}{\mathrm{d}\theta^m} f(\theta)\right]_{\theta=0} = \lim_{\theta\to 0}\frac{f(\theta)}{\theta^m} = C. \tag{16}$$

```
Initialization: c_{l,m,-1} = 0, c_{m-1,m,m'} = 0.

        Compute z_{m'} using equation (40);
        for( m = m' ; m ≤ L ; m ++ ){
              Compute c_{m,m,m'} using equation (44);
              for( l = m + 1 ; l ≤ L ; l ++ ){
                    Compute c_{l,m,m'} using equation (42);
              }
        }
}
```

FIG. 1. *Recursive algorithm to compute* $c_{l,m,m'}$.

Using Proposition 5.3 we can evaluate $g_{l,m'}$ and $D_{l,m,m'}$ (see Appendices A and B) with the results that

$$g_{l,m'} = \frac{(-1)^{m'}(l+m')!}{2^{m'}m'!(l-m')!},$$
$$D_{l,m,m'} = \frac{5}{2^{m'}}c_{l,m,m'},$$

where $c_{l,m,m'}$ can be computed either explicitly by

$$c_{l,m,m'} = 2^{-l}\sum_{i=\lfloor\frac{l+m}{2}\rfloor}^{l}(-1)^{l-i}\frac{(2i)!}{(l-i)!i!}\left(\frac{1}{\sqrt{5}}\right)^{2i-l-m}\sum_{j=0}^{2i-l-m}\frac{2^j}{(2i-l-m-j)!j!}$$
$$\times\sum_{p=0,2,\ldots}^{m}\frac{m!}{p!}\left(\frac{2}{\sqrt{5}}\right)^{m-p}\sum_{q=0}^{m-p}\left(-\frac{1}{2}\right)^{q}\frac{\delta_{m',j+p+q}}{(m-p-q)!q!}$$

or recursively as shown in Figure 1.

6. Factorization of $C_{l,m,m'}$ to compute $b_{l,n,m}$. Once we have $C_{l,m,m'}$, we use (10) to calculate $b_{l,n,m}$ using well-known matrix factorization algorithms. Note that there is no interaction between different values of l in (10) and so in this section l takes some fixed value and that value is suppressed in the matrix notation. Let $\mathbf{C}$ and $\mathbf{b}$ be matrices of dimensions $\lfloor l/5\rfloor \times \lfloor l/5\rfloor$ and $N_l \times \lfloor l/5\rfloor$, respectively, in which the (n,μ)th elements are $C_{l,5n,5\mu}$ and $b_{l,n,5\mu}$, respectively. Equation (10) is then equivalent to

$$\mathbf{C} = \mathbf{b}^{\mathrm{T}}\mathbf{b}. \tag{17}$$

Therefore, $\mathbf{C}$ is symmetric and positive semidefinite. By orthonormality of ISBFs within the same l it follows that $\mathbf{b}\mathbf{b}^{\mathrm{T}} = \mathbf{I}_{N_l}$ (Proposition 4.2), where $\mathbf{I}_q$ is the $q \times q$ identity matrix and therefore $\mathbf{C}$ is also idempotent. Because $\mathbf{C}$ is idempotent, any factorization of $\mathbf{C}$ will be row orthonormal as described in Proposition 6.1.

PROPOSITION 6.1. *Let* $\mathbf{U} \in \mathcal{R}^{n\times n}$. *If* $\mathbf{V} \in \mathcal{R}^{m\times n}$ *is (row) full rank and* $\mathbf{U} = \mathbf{V}^{\mathrm{T}}\mathbf{V}$, *then* $\mathbf{V}$ *is row orthonormal if and only if* $\mathbf{U}$ *is idempotent.*

Note that if $\mathbf{b}$ is a solution to (17), then for any $N_l \times N_l$ orthogonal matrix $\mathbf{O}$, $\mathbf{b}' = \mathbf{O}\mathbf{b}$ is also a solution. For this reason we may add an additional constraint on $\mathbf{b}$ requiring it to be upper triangular, which implies $b_{l,n,5\mu} \equiv 0$ for $\mu < n$.

One algorithm to factor $\mathbf{C}$ is eigenvalue decomposition. Because $\mathbf{C}$ is idempotent $\mathbf{C}$ has only two eigenvalues, 0 and 1. Rows of $\mathbf{b}$ span the same space as eigenvectors of $\mathbf{C}$ with eigenvalues 1. Gram–Schmidt orthogonalization may be used on these eigenvectors to obtain orthogonal row vectors of $\mathbf{b}$. This algorithm requires all elements of $\mathbf{C}$ and it usually does not generate an upper triangular solution.

An alternative factorization algorithm is the Cholesky factorization, which is the algorithm we have used in computer codes. In this algorithm $b_{l,n,m}$ are computed by

$$b_{l,n,5n} = \sqrt{C_{l,5n,5n} - \sum_{n'=0}^{n-1} b_{l,n',5n}^2}, \tag{18}$$

$$b_{l,n,5n'} = \frac{1}{b_{l,n,5n}}\left(C_{l,5n',5n} - \sum_{k=0}^{n-1} b_{l,k,5n} b_{l,k,5n'}\right), \quad n' = n+1, \ldots, N_l - 1. \tag{19}$$

Equations (18) and (19) should be applied in the order $n = 0, 1, \ldots, N_l - 1$ to ensure that the $b_{l,m,m'}$ that occur on the right-hand side are already determined by the time they are needed. This algorithm requires only elements of $C_{l,m,m'}$ for the index values $0 \le m' \le 5N_l$ and $m' \le m \le l$. This is a computational advantage because computation of $C_{l,m,m'}$ can be expensive especially for large l, m, m'. The algorithm generates an upper triangular $\mathbf{b}$.

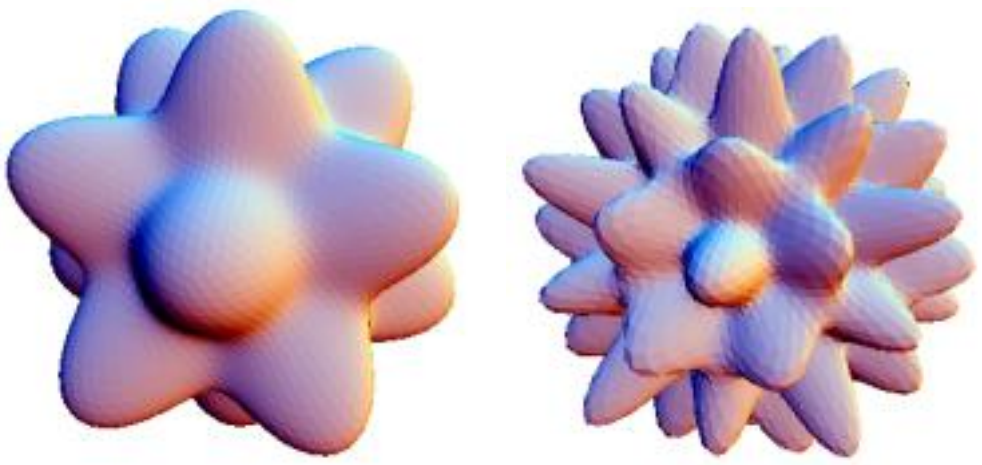
7. Numerical example. For $l \in \{0, 1, \ldots, 29\}$ there are either zero or one harmonic for each l and the cases with one harmonic are $l \in \{0, 6, 10, 12, 15, 16, 18, 20\text{–}22, 24\text{–}28\}$. By evaluating the recursions of this paper we have computed the harmonics through $l = 85$. Here we state only the first four harmonics in unnormalized form as computed symbolically by *Mathematica*:

$$\begin{aligned}
I_{0,0}(\theta,\phi) &= 1,\\
I_{6,0}(\theta,\phi) &= 2^3\cdot 3^2\cdot 5\cdot 11 P_{6,0}(\cos\theta) - P_{6,5}(\cos\theta)\cos 5\phi,\\
I_{10,0}(\theta,\phi) &= 2^8\cdot 3^4\cdot 5^2\cdot 7\cdot 13\cdot 19 P_{10,0}(\cos\theta) + 2^5\cdot 3^2\cdot 5\cdot 19 P_{10,5}(\cos\theta)\cos 5\phi\\
&\quad + P_{10,10}(\cos\theta)\cos 10\phi,\\
I_{12,0}(\theta,\phi) &= 2^8\cdot 3^5\cdot 5^2\cdot 7^2\cdot 11\cdot 17 P_{12,0}(\cos\theta) - 2^4\cdot 3^2\cdot 5\cdot 7\cdot 11 P_{12,5}(\cos\theta)\cos 5\phi\\
&\quad + P_{12,10}(\cos\theta)\cos 10\phi.
\end{aligned}$$

(Division of the stated formula by $\sqrt{2^2\pi}$, $2^4\cdot 3^2\cdot 5^2\sqrt{11\pi/13}$, $2^9\cdot 3^4\cdot 5^4\sqrt{7\cdot 13\cdot 19\pi}$, or $2^9\cdot 3^4\cdot 5^3\cdot 7\cdot 11\sqrt{5\cdot 7\cdot 17\pi}$ will normalize $I_{0,0}$, $I_{6,0}$, $I_{10,0}$, or $I_{12,0}$, respectively.) In Figure 2 we show a spherical plots of $I_{6,0}$ and $I_{12,0}$ which clearly exhibit the icosahedral symmetry of $I_{6,0}$ and $I_{12,0}$.

8. The l odd case. The calculations are similar to the case of l even. Here we list only the major results. The explicit expression for $c_{l,m,m'}$ (37) is modified to

$$\begin{aligned}
c_{l,m,m'} = (-1)2^{-l} &\sum_{i=\lfloor \frac{l+m}{2}\rfloor}^{l} (-1)^{l-i}\frac{(2i)!}{(l-i)!i!}\left(\frac{1}{\sqrt{5}}\right)^{2i-l-m}\sum_{j=0}^{2i-l-m}\frac{2^j}{(2i-l-m-j)!j!}\\
&\times \sum_{p=1,3,\ldots}^{m}\frac{m!}{p!}\left(\frac{2}{\sqrt{5}}\right)^{m-p}\sum_{q=0}^{m-p}\left(-\frac{1}{2}\right)^q\frac{\delta_{m',j+p+q}}{(m-p-q)!q!}.
\end{aligned}$$



$I_{6,0}(\theta,\phi)$ $I_{12,0}(\theta,\phi)$

FIG. 2. *The ISBFs for* $(l,n)=(6,0)$ *and* $(l,n)=(12,0)$. *For each value of* θ *and* ϕ *the distance of the surface from the origin is* $c_{l,n}+I_{l,n}(\theta,\phi)$, *where* $c_{l,n}=2\max_{\theta,\phi}(|I_{l,n}(\theta,\phi)|)$.

For the recursive calculations, the initial conditions of z_m are modified to $z_1=1, z_2=-1$ and (44) is modified to

$$c_{m,m,m'}=\left(-\frac{1}{\sqrt{5}}\right)^{m-1}\frac{(2m)!}{m!}\left(\frac{1}{2}\right)\binom{m}{m'}z_{m'}.$$

9. Generalization to other representations and other rotational groups. The idea of applying the projection operator to the delta function can be applied to other finite groups of coordinate rotations and to higher dimensional representations.

Let g be the order of the finite group $\mathcal{G}$ of coordinate rotations; N be the number of irreducible representations; and d_p, for $p=0,\ldots,N-1$, be the dimension of the pth irreducible representation. For the icosahedral group, these values are $g=60$, $N=5$, and $d_p=1,3,3,4,5$ [23, p. 324]. Let $\Gamma^p(T_k)_{j,j'}$ for $p=0,\ldots,N-1$, $k=0,\ldots,g-1$, and $j,j'=1,\ldots,d_p$ be the matrix elements of the kth member of the group in the pth unitary irreducible representation which, for the icosahedral group, are tabulated in [15].

We continue to use the notation and results of [22] specialized to square integrable functions on the sphere which are indicated by $L^2(\theta,\phi)$. Let $f(\theta,\phi)\in L^2(\theta,\phi)$. By [22, Theorem I, p. 92] it follows that

$$f(\theta,\phi)=\sum_{p=0}^{N-1}\sum_{j=0}^{d_p-1}a_j^p f_j^p(\theta,\phi), \tag{20}$$

where $f_j^p(\theta,\phi)$ is a normalized basis function transforming as the jth row of the d_p-dimensional unitary irreducible representation Γ^p of $\mathcal{G}$, a_j^p are a set of complex numbers, and the sum on p is over all the inequivalent unitary irreducible representations of $\mathcal{G}$. Following [22, p. 93] we define the projection operator $\mathcal{P}_{j,j'}^p$ by

$$\mathcal{P}_{j,j'}^p=\frac{d_p}{g}\sum_{T\in\mathcal{G}}\Gamma^p(T)_{j,j'}^* P(T).$$

By [22, Theorem II, p. 93] it follows that

$$\mathcal{P}^p_{j,j} f(\theta,\phi) = a^p_j f^p_j(\theta,\phi),$$

where a^p_j and $f^p_j(\theta,\phi)$ are the coefficients and basis functions of the expansion of $f(\theta,\phi)$ (20) that relate to the jth row of Γ^p.

We apply these results to $\delta(\cos\theta - \cos\theta_0)\delta(\phi-\phi_0)$ to find that

$$\begin{aligned}
\delta(\cos\theta-\cos\theta_0)\delta(\phi-\phi_0) &= \sum_{p=0}^{N-1}\sum_{j=0}^{d_p-1} a^p_j \Delta^p_j(\theta_0,\phi_0;\theta,\phi),\\
a^p_j\Delta^p_j(\theta_0,\phi_0;\theta,\phi) &= \mathcal{P}^p_{j,j}\delta(\cos\theta-\cos\theta_0)\delta(\phi-\phi_0)\\
&= \frac{d_p}{g}\sum_{k=1}^{g}\Gamma^p(T_k)^*_{j,j}\delta(\cos\theta-\cos\theta_k)\delta(\phi-\phi_k), \qquad (21)
\end{aligned}$$

where (θ_k,ϕ_k) are the symmetry-related positions, e.g., for the icosahedral group, (θ_k,ϕ_k) are given by Proposition 4.3. The normalization a^p_j is set by the condition $\int \Delta^p_j(\theta_0,\phi_0;\theta,\phi)\mathrm{d}\Omega = 1$.

The symmetrized delta functions $\Delta^p_j(\theta_0,\phi_0;\theta,\phi)$ define subspaces, denoted by $(L^p_j)^2(\theta,\phi)$, of the Hilbert space $L^2(\theta,\phi)$ by

$$(L^p_j)^2(\theta,\phi) = \left\{ f(\theta,\phi)\in L^2(\theta,\phi) : f(\theta,\phi) = \int \Delta^p_j(\theta_0,\phi_0;\theta,\phi) f(\theta_0,\phi_0)\mathrm{d}\Omega_0 \right\}.$$

Each subspace contains only a certain type of basis function, the union of the subspaces is all of $L^2(\theta,\phi)$, and the only function in the intersection of any pair of the subspaces is the zero function.

The goal is to determine a complete orthonormal fixed basis in each subspace. Denote the fixed basis functions by $I^p_j(\theta,\phi;\alpha)$ where α is an index. We proceed exactly as in the previous sections of the paper devoted to the identity representation of the icosahedral group. First, one can show that α can be written as l,n and

$$I^p_j(\theta,\phi;l,n) = \sum_{m=-l}^{+l} b^p_j(l,n,m) Y_{l,m}(\theta,\phi).$$

Second, one can expand $\Delta^p_j(\theta_0,\phi_0;\theta,\phi)$ as a weighted sum of $Y_{l,m}(\theta,\phi)$:

$$\Delta^p_j(\theta_0,\phi_0;\theta,\phi) = \sum_{l=0}^{\infty}\sum_{m=-l}^{+l} w^p_j(\theta_0,\phi_0;l,m) Y_{l,m}(\theta,\phi),$$

specifically (by using (21)),

$$\Delta^p_j(\theta_0,\phi_0;\theta,\phi) = \frac{d_p}{g a^p_j}\sum_{k=1}^{g}\Gamma^p(T_k)^*_{j,j}\sum_{l=0}^{\infty}\sum_{m=-l}^{+l} Y^*_{l,m}(\theta_k,\phi_k) Y_{l,m}(\theta,\phi). \qquad (22)$$

Third, since $I^p_j(\theta,\phi;l,n)$ are a complete orthonormal fixed basis for $(L^p_j)^2(\theta,\phi)$, it follows that

$$\Delta^p_j(\theta_0,\phi_0;\theta,\phi) = \sum_{l=0}^{\infty}\sum_{n=0}^{N^p_j(l)} \left(I^p_j(\theta_0,\phi_0;l,n)\right)^* I^p_j(\theta,\phi;l,n). \qquad (23)$$

Fourth, by equating the expansions for $\Delta_j^p(\theta_0, \phi_0; \theta, \phi)$ provided by (22) and (23), one arrives at an equation that is exactly a generalization of (5). From this point forward, the $I_j^p(\theta, \phi; l, n)$ can be obtained by using the same methods already used for the identity representation of the icosahedral group.

10. Conclusion. We have described a novel method for explicitly computing orthonormal symmetrized harmonics and have applied the method to the identity representation of the icosahedral group. The work was motivated by the analysis of data from spherical viruses. Other applications of icosahedral symmetry include fullerenes [24] and quasi crystals [10]. A *Mathematica* program to obtain exact closed-form expressions for ISBFs of arbitrary order and a C program to calculate their numerical values are available from the authors upon request.

The same approach can be used to determine general explicit expressions for other groups and the particular examples of tetrahedrally and octahedrally symmetric basis functions have been done by the authors. Moreover, since the icosahedrally symmetric delta function can be viewed as the result of applying the projection operator of the identity representation of the icosahedral group to the regular delta function, we believe the same technique can be employed to calculate basis functions for the other four irreducible representations of the icosahedral group. These functions are of great interest in quantum mechanical problems with an icosahedrally symmetric potential, of which one example is the C_{60} molecule. Work in this direction is already in progress and will be reported in a future publication.

Appendix A. Computation of $g_{l,m'}$. Since

$$P_{l,m}(x) = \frac{(-1)^m(1-x^2)^{m/2}}{2^l l!}\frac{\mathrm{d}^{l+m}}{\mathrm{d}x^{l+m}}(x^2-1)^l = (-1)^m(1-x^2)^{m/2}G_{l,m}(x), \tag{24}$$

where

$$G_{l,m}(x) = \frac{1}{2^l l!}\frac{\mathrm{d}^{l+m}}{\mathrm{d}x^{l+m}}(x^2-1)^l \tag{25}$$

is a polynomial of order $l-m$, we find that

$$P_{l,m'}(\cos\theta_0) = (-1)^{m'}(\sin\theta_0)^{m'}G_{l,m'}(\cos\theta_0).$$

Using Proposition 5.3 we obtain

$$g_{l,m'} = \lim_{\theta_0\to 0}\frac{P_{l,m'}(\cos\theta_0)}{\theta_0^{m'}} = (-1)^{m'}G_{l,m'}(1) = \frac{(-1)^{m'}(l+m')!}{2^{m'}m'!(l-m')!}.$$

Appendix B. Computation of $D_{l,m,m'}$. We begin the calculation of $D_{l,m,m'}$ by recalling the trigonometric and polynomial definitions of the Chebyshev polynomials of the first kind:

$$T_m(x) = \cos(m\arccos x) = \sum_{p=0,2,\ldots}^{m}\binom{m}{p}x^{m-p}(x^2-1)^{p/2}. \tag{26}$$

Define $R_{l,m}(x,y)$ by

$$\begin{aligned} R_{l,m}(x,y) &= P_{l,m}\big((y+2x)/\sqrt{5}\,\big)\cos\Big(m\arccos\Big((2-x)/\sqrt{5-(y+2x)^2}\Big)\Big) \\ &= \Big(-\frac{1}{\sqrt{5}}\Big)^m G_{l,m}\Big(\frac{1}{\sqrt{5}}(y+2x)\Big) \\ &\quad\times \sum_{p=0,2,\ldots}^{m}\binom{m}{p}(2-x)^{m-p}[5x^2+y^2-1+4x(y-1)]^{p/2}, \end{aligned} \tag{27}$$

where we have used (25) and (26). $R_{l,m}(x,y)$ derives its importance from the fact that $R_{l,m}(\sin\theta_0\cos\phi_k,\cos\theta_0) = P_{l,m}(\cos\gamma_k)\cos(m\alpha_k)$ which is central in the definition of $D_{l,m,m'}$ (14). Since $R_{l,m}(x,y)$ is a polynomial of order l in x and y it can be written in the form

$$R_{l,m}(x,y) = \sum_{m''=0}^{l} c_{l,m,m''}(y)x^{m''}, \tag{28}$$

where $c_{l,m,m''}(y)$ is a polynomial in y of order at most l.

PROPOSITION B.1. *Define* $A_{m'',m'}$ *by*

$$A_{m'',m'} = \frac{1}{2\pi}\int_0^{2\pi}(\cos\phi_k)^{m''}\cos(m'\phi_0)\mathrm{d}\phi_0. \tag{29}$$

Then

1. *if* $m'' < m'$, *then* $A_{m'',m'} = 0$,
2. $A_{m',m'} = (1/2^{m'})\cos\frac{2\pi}{5}km'$.

Define $Q_{l,m,m'}(\theta_0)$ by

$$Q_{l,m,m'}(\theta_0) = \frac{1}{2\pi}\int_0^{2\pi} R_{l,m}(\sin\theta_0\cos\phi_k,\cos\theta_0)\cos(m'\phi_0)\mathrm{d}\phi_0,$$

which is the first step on the path from $R_{l,m}(\sin\theta_0\cos\phi_k,\cos\theta_0)$ to $D_{l,m,m'}$. Note that all dependence of $R_{l,m}(\sin\theta_0\cos\phi_k,\cos\theta_0)$ on ϕ_k (and thus on ϕ_0) comes from the first argument x. Using Proposition B.1 and (28) we obtain

$$Q_{l,m,m'}(\theta_0) = \sum_{m''=m'}^{l} c_{l,m,m''}(\cos\theta_0)(\sin\theta_0)^{m''}A_{m'',m'}. \tag{30}$$

Furthermore, by Proposition 5.3 and (30),

$$\Big[\frac{1}{m'!}\frac{\mathrm{d}^{m'}}{\mathrm{d}\theta_0^{m'}}Q_{l,m,m'}(\theta_0)\Big]_{\theta_0=0} = \lim_{\theta_0\to 0}\frac{Q_{l,m,m'}(\theta_0)}{\theta_0^{m'}} = c_{l,m,m'}(1)\frac{1}{2^{m'}}\cos\frac{2\pi}{5}km'. \tag{31}$$

In addition, if m' is an integer multiple of 5, then $\sum_{k=0}^{4}\cos\frac{2\pi}{5}km' = 5$. Using this fact and (31) in the definition of $D_{l,m,m'}$ (14) we obtain

$$D_{l,m,m'} = \frac{5}{2^{m'}}c_{l,m,m'}(1). \tag{32}$$

It remains only to calculate $c_{l,m,m'}(1)$. In the following two subsections we provide two methods, a finite summation and a recurrence, both based on the observation that

$$R_{l,m}(x,1) = \sum_{m'=0}^{l} c_{l,m,m'}(1)x^{m'}. \tag{33}$$

That is, $c_{l,m,m'}(1)$ is the coefficient of the term $x^{m'}$ in the lth order polynomial $R_{l,m}(x,1)$. For notational convenience, from now on we shall rewrite $c_{l,m,m'}(1)$ as $c_{l,m,m'}$ and $R_{l,m}(x,1)$ as $R_{l,m}(x)$.

B.1. Explicit expression for $c_{l,m,m'}$. Substituting $y = 1$ into (27) we obtain

$$R_{l,m}(x) = \left(-\frac{2}{\sqrt{5}}\right)^m G_{l,m}\left(\frac{1}{\sqrt{5}}(1+2x)\right)H_m(x), \tag{34}$$

where

(35)

$$H_m(x) = (1-x-x^2)^{m/2}T_m\left(\frac{2-x}{2\sqrt{1-x-x^2}}\right) = \sum_{p=0,2,\ldots}^{m}\binom{m}{p}\left(1-\frac{x}{2}\right)^{m-p}\left(\frac{\sqrt{5}}{2}x\right)^p.$$

The function $G_{l,m}(\cdot)$ can be evaluated for an arbitrary argument from its definition in (25): take the derivative term by term of the binomial expansion of $(x^2-1)^l$ to obtain

$$G_{l,m}(x) = \frac{1}{2^l l!}\sum_{i=\lfloor\frac{l+m}{2}\rfloor}^{l}\binom{l}{i}(-1)^{l-i}\frac{(2i)!}{(2i-l-m)!}x^{2i-l-m}.$$

By further use of the binomial expansion, we can obtain the following expression for $R_{l,m}(x)$:

$$\begin{aligned} R_{l,m}(x) = 2^{-l}&\sum_{i=\lfloor\frac{l+m}{2}\rfloor}^{l}(-1)^{l-i}\frac{(2i)!}{(l-i)!i!}\left(\frac{1}{\sqrt{5}}\right)^{2i-l-m}\sum_{j=0}^{2i-l-m}\frac{2^j x^j}{(2i-l-m-j)!j!} \\ &\times\sum_{p=0,2,\ldots}^{m}\frac{m!}{p!}\left(\frac{2}{\sqrt{5}}\right)^{m-p}x^p\sum_{q=0}^{m-p}\left(-\frac{1}{2}\right)^q\frac{x^q}{(m-p-q)!q!}. \end{aligned} \tag{36}$$

From (36) and (33) it is clear that an explicit expression for $c_{l,m,m'}$ is

$$\begin{aligned} c_{l,m,m'} = 2^{-l}&\sum_{i=\lfloor\frac{l+m}{2}\rfloor}^{l}(-1)^{l-i}\frac{(2i)!}{(l-i)!i!}\left(\frac{1}{\sqrt{5}}\right)^{2i-l-m}\sum_{j=0}^{2i-l-m}\frac{2^j}{(2i-l-m-j)!j!} \\ &\times\sum_{p=0,2,\ldots}^{m}\frac{m!}{p!}\left(\frac{2}{\sqrt{5}}\right)^{m-p}\sum_{q=0}^{m-p}\left(-\frac{1}{2}\right)^q\frac{\delta_{m',j+p+q}}{(m-p-q)!q!}. \end{aligned} \tag{37}$$

B.2. Recursive calculation of $c_{l,m,m'}$. Using the recursive relation for Chebyshev polynomials

$$T_{m+1}(x) - 2xT_m(x) + T_{m-1}(x) = 0$$

and (35) we can derive the following recursive relation for $H_m(x)$:

$$H_{m+1}(x) + (x-2)H_m(x) + (1-x-x^2)H_{m-1}(x) = 0 \tag{38}$$

with the initial condition $H_0(x) = 1, H_1(x) = 1 - x/2$. The solution of (38) is

$$\begin{aligned} H_m(x) &= \frac{1}{2}\left[\left(1 + \frac{-1+\sqrt{5}}{2}x\right)^m + \left(1 - \frac{\sqrt{5}+1}{2}x\right)^m\right] \\ &= \frac{1}{2}\sum_{m'=0}^{m}\binom{m}{m'} z_{m'}x^{m'}, \end{aligned} \tag{39}$$

where

$$z_{m'} = \left(\frac{-1+\sqrt{5}}{2}\right)^{m'} + (-1)^{m'}\left(\frac{\sqrt{5}+1}{2}\right)^{m'}.$$

Note that $z_{m'}$ satisfies the recursion

$$z_{m'+1} + z_{m'} - z_{m'-1} = 0 \tag{40}$$

with the initial condition $z_0 = 2$ and $z_1 = -1$.

Using (34), (24), and the recursion for $P_{l,m}(x)$ in l

$$(l+1-m)P_{l+1,m}(x) - (2l+1)xP_{l,m}(x) + (l+m)P_{l-1,m}(x) = 0,$$

we can derive a recursion for $R_{l,m}(x)$ in l:

$$(l+1-m)R_{l+1,m}(x) - (2l+1)\frac{1}{\sqrt{5}}(1+2x)R_{l,m}(x) + (l+m)R_{l-1,m}(x) = 0. \tag{41}$$

Substitute (33) into (41). The coefficient of each power of x must vanish separately, which leads to the recursion

$$(l+1-m)c_{l+1,m,m'} - (2l+1)\frac{1}{\sqrt{5}}(c_{l,m,m'} + 2c_{l,m,m'-1}) + (l+m)c_{l-1,m,m'} = 0. \tag{42}$$

To initialize (42) to compute $c_{l,m,m'}$, note that $c_{l,m,-1} = 0$ and $c_{m-1,m,m'} = 0$. We still need $c_{m,m,m'}$ to start the recursion, but

$$\sum_{m'=0}^{m} c_{m,m,m'}x^{m'} = R_{m,m}(x) = \left(-\frac{1}{\sqrt{5}}\right)^m \frac{(2m)!}{m!}H_m(x) \tag{43}$$

so by (39)

$$c_{m,m,m'} = \left(-\frac{1}{\sqrt{5}}\right)^m \frac{(2m)!}{m!}\left(\frac{1}{2}\right)\binom{m}{m'}z_{m'}. \tag{44}$$

Given an integer L, Figure 1 shows an algorithm, with control structures written in the C programming language, to calculate all $c_{l,m,m'}$ for $l \le L, m' \le M' = 5N_L, m' \le m \le l$. Because the factorization algorithm described in section 6 uses only $C_{l,m,m'}$ for which $0 \le m' \le 5N_l, m' \le m \le l$, it follows that for any single l we need only to compute $c_{l,m,m'}$ for $0 \le m' \le 5N_l, m' \le m \le l$.

Acknowledgments. The authors are grateful to an anonymous reviewer for pointing out [19]. The authors were motivated by discussions with Professor John E. Johnson (Department of Molecular Biology, The Scripps Research Institute) regarding the modeling of spherical viruses.

PERIODIC SOLUTIONS OF HAMILTONIAN SYSTEMS*

YANHENG DING† AND CHENG LEE‡

Abstract. Two sequences of periodic solutions with large and small norms, respectively, are obtained for Hamiltonian systems of the type

$$-\mathcal{J}\dot{z} = \xi F_z(t,z) + \eta G_z(t,z),$$

where F is superquadratic at $z=\infty$ and G is subquadratic at $z=0$.

Key words. Hamiltonian system, periodic solution, variational method

AMS subject classifications. 34B30, 34C25

PII. S0036141099358178

1. Introduction and statement of results. In recent years, several papers Ambrosetti, Brézis, and Cerami [2], Ambrosetti, Azorero, and Peral [1], and Bartsch and Willem [4] investigated the structure of solutions of semilinear elliptic equations of the type

$$Au = \xi\nabla\Phi(u) + \eta\nabla\Psi(u),$$

where A is the Laplacian on a smoothly bounded domain $\Omega \subset \mathbb{R}^N$, $\xi, \eta \in \mathbb{R}$ are given constants, $\Phi \in \mathcal{C}^1(H_0^1(\Omega), \mathbb{R})$ is superquadratic at $u=\infty$, and $\Psi \in \mathcal{C}^1(H_0^1(\Omega), \mathbb{R})$ is subquadratic at $u=0$. The results have also been extended to problems of periodic solutions of some special Hamiltonian systems in [4] and of wave equations, etc., in [6, 7].

Hamiltonian systems have been extensively studied via critical point theory since the publication of the pioneer work by Rabinowitz [15] (see [5] and references therein). In the present paper we consider the existence of infinitely many periodic solutions for the following Hamiltonian system:

$$\dot{z} = \mathcal{J}\nabla_z H_{\xi\eta}(t,z), \tag{HS$_{\xi\eta}$}$$

where $\mathcal{J} := \left(\begin{smallmatrix} 0 & -I \\ I & 0 \end{smallmatrix}\right)$ denotes the standard symplectic matrix on $\mathbb{R}^{2N}$, and $H_{\xi\eta}$ is of the form

$$H_{\xi\eta}(t,z) = \xi F(t,z) + \eta G(t,z), \tag{1.1}$$

where ξ, η are real constants and with F, $G \in \mathcal{C}^1(\mathbb{R}\times\mathbb{R}^{2N})$ being T-periodic in t.

To establish the existence of solutions with large norms, we mainly need the following assumptions on F:

(F1) there are $\mu > 2$, $\bar{r} > 0$ such that

$$0 < \mu F(t,z) \le F_z(t,z)z \quad \text{for all } |z| \ge \bar{r};$$

(F2) there are $\nu > 2$ and a_1, $a_2 > 0$ such that, letting $\nu' := \nu/(\nu-1)$,

$$|F_z(t,z)|^{\nu'} \le a_1 + a_2 F_z(t,z)z \quad \text{for all } (t,z);$$

and on G

(G1) there are $\tau \in [0, 1)$ and a_3, $a_4 > 0$ such that

$$|G(t,z)| + |G_z(t,z)z| \le a_3 + a_4|F(t,z)|^\tau \quad \text{for all } (t,z).$$

For obtaining solutions with small energies we assume

(F3) $F(t,0) = 0$ and $F_z(t,z) = o(|z|)$ uniformly in t as $z \to 0$;

(G2) $G(t,0) = 0$, $G_z(t,z)z/|z|^2 \to \infty$ as $z \to 0$ uniformly in t, and there are $1 < \alpha < 2 < \beta$ and $\underline{r}$, $a_5 > 0$ such that

$$G_z(t,z)z \le \alpha G(t,z) \quad \text{for all } t \in \mathbb{R} \text{ and } 0 < |z| \le \underline{r},$$
$$a_5|G_z(t,z)|^\beta \le G(t,z) \quad \text{for all } (t,z) \in \mathbb{R} \times B_{\underline{r}},$$

where $B_{\underline{r}} := \{z \in \mathbb{R}^{2N} : \ |z| \le \underline{r}\}$.

Letting $|u|_p$ denote the usual $L^p([0,T],\mathbb{R}^{2N})$-norm for $p \in [1, \infty]$ and $I_{\xi\eta}(u)$ the energy for a T-periodic solution u of $(\mathrm{HS}_{\xi\eta})$,

$$I_{\xi\eta}(u) = \int_0^T \left(\frac{1}{2}\dot{u}\mathcal{J}u - H_{\xi\eta}(t,u)\right) dt,$$

and the first result reads as follows.

THEOREM 1.1. *Let $H_{\xi\eta}(t,z)$ be of the form* (1.1).

(a) *Assume* (F1), (F2),

(F4) $F(t,-z) = F(t,z)$ *for all* (t,z),

and (G1) *with* $\tau < 2/\nu$. *Then for every* $\xi \ne 0$, $\eta \in \mathbb{R}$, $(\mathrm{HS}_{\xi\eta})$ *has a sequence of* T*-periodic solutions* (u_n) *satisfying* $\xi I_{\xi\eta}(u_n) \to \infty$ *and* $|u_n|_\infty \to \infty$ *as* $n \to \infty$.

(b) *Assume* (F3), (F4), (G2) *and*

(G3) $G(t,-z) = G(t,z)$ *for all* $(t,z) \in \mathbb{R} \times B_{\underline{r}}$.

Then for every $\xi \in \mathbb{R}$, $\eta \ne 0$, $(\mathrm{HS}_{\xi\eta})$ *has a sequence of* T*-periodic solutions* (v_n) *satisfying* $\eta I_{\xi\eta}(v_n) < 0, \eta I_{\xi\eta}(v_n) \to 0$, *and* $|v_n|_\infty \to 0$ *as* $n \to \infty$.

(c) *If, moreover,* $H_{\xi\eta}$ *can be represented as* $H_{\xi\eta} = a(t)\hat{H}_{\xi\eta}(z)$ *with* $\hat{H}_{\xi\eta}(z) \ne 0$ *almost everywhere (a.e.) in* z *and* $a(t)$ *having minimal period* T, *then each solution of the sequences* (u_n) *and* (v_n) *has also minimal period* T.

The next result is related to the situation where F is independent of t.

THEOREM 1.2. *Let $H_{\xi\eta}(t,z)$ be of the form* (1.1).

(a) *Assume* (F1), (F2),

(F5) $F(t,z) = F(z)$, *i.e., F is independent of t,*

and (G1) *with* $\tau < 2/\nu$. *Then the conclusion of Theorem* 1.1(a) *holds. If, in addition,* $\eta \ne 0$, $G(t,z) = a(t)\hat{G}(z)$ *with* $\hat{G}(z) \ne 0$ *a.e. in* z *and* $a(t)$ *having minimal period* T, *then each* u_n *has also minimal period* T.

(b) *Assume* (F3), (F5), (G2), *and*

(G4) $G(t,z) = G(z)$ *for all* $z \in B_{\underline{r}}$.

Then, for all $T > 0$, $(HS_{\xi\eta})$ has a sequence of T-periodic solutions (v_n) satisfying $0 < -\eta I_{\xi\eta}(v_n) \to 0$ and $0 < \inf_{t\in[0,T]} |v_n(t)| \le |v_n|_\infty \to 0$ as $n \to \infty$.

Remarks. Some remarks are in order.

(1) First, part (a) of Theorems 1.1 and 1.2 are results of symmetries with perturbation. In this direction, it seems that there are no papers discussing the case where F does depend on t and is even in z. If F is independent of t, many results are known; see, e.g., [3, 15, 12, 13], etc., where G is bounded jointly sometimes with certain restrictions on $\partial G/\partial t$. In particular, a result of [13] applies to the case where $F(z)$ satisfies (F1), and there are $2 < p_1 \le p_2 \le 2p_1$, $1 \le p < 2p_1/p_2$, $q > 0$ such that $a_1|z|^{p_1} - a_2 \le F(z) \le a_3|z|^{p_2} + a_4$, $|G(t,z)| \le a_5(|z|^p + 1)$, $|G_z(t,z)| \le a_5(|z|^{q-1} + 1)$, and $|G_t(t,z)| \le a_5(|z|^q + 1)$. Clearly this does not cover, e.g., the case $F(z) = |z|^\mu + |z|^{3\mu}$ and $G(t,z) \sim |z|^{1/3}$ near $z = \infty$, which is indeed contained in our results.

(2) In part (b) of Theorems 1.1 and 1.2 the Hamiltonian $H_{\xi\eta}$ may not be defined on whole $\mathbb{R}^{2N}$, i.e., it is sufficient for obtaining the results if $H_{\xi\eta}$ is defined locally in a neighborhood of $0 \in \mathbb{R}^{2N}$ in which the symmetry and subquadratic conditions are satisfied. When it is given on $\mathbb{R}^{2N}$, we may ignore its states (symmetric or not, growing slowly or fast as $|z| \to \infty$) outside an arbitrarily small neighborhood of $0 \in \mathbb{R}^{2N}$. More precisely, our proof in section 5 together with [10] shows that the system

$$\dot z = \mathcal{J} G_z(t,z)$$

has a sequence of T-periodic solutions (v_n) satisfying $0 > \int_0^T \left(\frac{1}{2}\dot v_n \mathcal{J} v_n - G(t,v_n)\right) dt \to 0$ provided that

(i) there exist $\alpha \in (1,2)$, $\beta \ge \alpha$, and $\underline{r}$, $c > 0$ such that $G \in \mathcal{C}^1(\mathbb{R}\times B_{\underline{r}}, \mathbb{R})$, T-periodic in t, $G(t,0) = 0$, and, whenever $z \ne 0$,

$$0 < G_z(t,z)z \le \alpha G(t,z) \quad \text{and} \quad c\,|G_z(t,z)|^\beta \le G(t,z);$$

(ii) either $G(t,z)$ is even in $z \in B_{\underline{r}}$ or $G(t,z) = G(z)$ is independent of t.

(3) In part (b) of Theorem 1.2 the solution sequence (v_n) can be chosen so that the corresponding minimal period sequence (T_n) (where $T_n > 0$ denotes the minimal period of v_n) satisfying $T_n \to 0$. Indeed, given $T > 0$, let v_1 be a T-periodic solution with minimal period $T_1 = T/k_1$ for some $k_1 \in \mathbb{N}$ and $0 < -\eta I_{\xi\eta}(v_1), |v_1|_\infty \le 1$. Then let v_2 be a $T_1/2$-periodic solution with minimal period $T_2 = T_1/2k_2 = T/2k_1k_2$ for some $k_2 \in \mathbb{N}$ and $0 < -\eta I_{\xi\eta}(v_2), |v_2|_\infty \le 1/2$. Inductively, we can choose a $T_{n-1}/2$-periodic solution v_n with minimal period $T_n = T_{n-1}/2k_n = T/2^{n-1}k_1\cdots k_n$ for some $k_n \in \mathbb{N}$ and $0 < -\eta I_{\xi\eta}(v_n), |v_n|_\infty \le 1/n$. Clearly, v_n is T-periodic and $T_n \to 0, 0 < -\eta I_{\xi\eta}(v_n) \to 0, |v_n|_\infty \to 0$ as $n \to \infty$.

(4) It seems interesting to make a comparison with a result of Rabinowitz [16] where he proved that if $H(z) := H_{\xi\eta}(z)$ is superquadratic at $z = \infty$ (i.e., $0 < \mu H(z) \le \nabla H(z)z$ for all $|z|$ large), then for all $T > 0, R > 0$, $(\mathrm{HS}_{\xi\eta})$ possesses a T-periodic solution Z_T with $|z_T|_\infty \ge R$. Theorem 1.2(b), on the other hand, says that if $H(z)$ is subqudratic at $z = 0$, then for all $T > 0, \varepsilon > 0$, $(\mathrm{HS}_{\xi\eta})$ has a T-periodic solution z_T with $|z_T|_\infty \le \varepsilon$.

(5) Clearly, it may happen that the Hamiltonian $H_{\xi\eta}$ satisfies both the superquadratic (at $z = \infty$) and the subquadratic (at $z = 0$) conditions so that the system $(\mathrm{HS}_{\xi\eta})$ has the two sequences of periodic solutions. For this case, compared to the result of [4], in part (a) of Theorems 1.1 and 1.2 the subquadratic term G is no longer symmetric.

(6) Part (c) of Theorem 1.1 is a consequence of the following proposition. (The second conclusion of Theorem 1.2(a) can be verified similarly.)

PROPOSITION 1.3. *Suppose* $H \in \mathcal{C}^1(\mathbb{R}^{2N}, \mathbb{R})$, $H_z(z) \neq 0$ *for* $z \neq 0$, *and* $a \in \mathcal{C}(\mathbb{R}, \mathbb{R})$ *has the minimal period* T. *If* u *is a nonconstant* T*-periodic solution of*

$$-\mathcal{J}\dot{z} = a(t)H_z(z), \tag{1.2}$$

then u *has the minimal period* T.

Proof. See [10]. By the existence and uniqueness theorem of ordinary differential equations, $u(t) \neq$ any equilibrium everywhere. Let T_0 denote the minimal period of u. Using (1.2) one obtains $a(t+T_0)H_z(u(t)) = a(t)H_z(u(t))$ and so $a(t+T_0) = a(t)$ for all t, which clearly implies that $T_0 = T$. □

(7) Theorem 1.1(b) was established essentially in [10]. Thus it remains to prove part (a) of Theorems 1.1, 1.2 and part (b) of Theorem 1.2.

Apart from the preliminaries in section 2, we prove part (a) of Theorems 1.1, 1.2 in sections 3 and 4 by using Rabinowitz variational setting. Finally in section 5, of special interest is that a new index theory is developed, which is similar to Benci's pseudoindex. We use this new index theory, together with some approximation arguments, to prove part (b) of the theorems.

2. Preliminaries. Without loss of generality, assume $T = 2\pi$ for notational convenience. Let $S^1 := \mathbb{R}/[0, 2\pi]$, $L^2 := L^2(S^1, \mathbb{R}^{2N})$ with the usual inner product $(\cdot,\cdot)_{L^2}$ and norm $|\cdot|_2$, $W^{1,2} := W^{1,2}(S^1, \mathbb{R}^{2N})$, and consider the self-adjoint operator $A := -\mathcal{J}d/dt$ acting on L^2 with domain $\mathcal{D}(A) = W^{1,2}$. The spectrum $\sigma(A) = \mathbb{Z}$ and each $k \in \mathbb{Z}$ is an eigenvalue of multiplicity $2N$ corresponding to the eigenfunction $e^{kt\mathcal{J}}e_j$ for $j = 1, \dots, 2N$, where $e^{kt\mathcal{J}} := \cos kt\, I + \sin kt\, \mathcal{J}$ and $e_1, \dots, e_{2N}$ denote the usual orthogonal basis of $\mathbb{R}^{2N}$. Let $E(k)$ denote the eigenspace associated to eigenvalue k. Then

$$\begin{aligned} E(k) &= e^{kt\mathcal{J}}\mathbb{R}^{2N} = \left\{e^{kt\mathcal{J}}c :\ c \in \mathbb{R}^{2N}\right\} \\ &= \left\{\sum_{j=1}^{2N} c_j e^{kt\mathcal{J}}e_j :\ c_j \in \mathbb{R} \text{ for all } j = 1, \dots, 2N\right\}. \end{aligned}$$

Each $u \in L^2$ has the expression

$$u = \sum_{k\in\mathbb{Z}} e^{kt\mathcal{J}}c_k(u) = \sum_{j\in\mathbb{Z}}\sum_{j=1}^{2N} c_{kj}(u)e^{kt\mathcal{J}}e_j, \qquad c_k(u) \in \mathbb{R}^{2N},\ c_{kj}(u) \in \mathbb{R}.$$

We have the orthogonal decomposition

$$L^2 = L^- \oplus L^0 \oplus L^+, \qquad u = u^- + u^0 + u^+,$$

where $L^0 = E(0) = \mathbb{R}^{2N}$, and $L^\pm$ is the closure of $\oplus_{k\in\mathbb{N}}E(\pm k)$ in L^2. Let $E := \mathcal{D}(|A|^{1/2}) = W^{1/2,2}(S^1, \mathbb{R}^{2N})$ equipped with the inner product

$$\begin{aligned} (u, v) &:= 2\pi c_0(u)c_0(v) + 2\pi\sum_{k\in\mathbb{Z}} |k|c_k(u)c_k(v) \\ &= 2\pi\sum_{j=1}^{2N} c_{0j}(u)c_{0j}(v) + 2\pi\sum_{k\in\mathbb{Z}}\sum_{j=1}^{2N} |k|c_{kj}(u)c_{kj}(v) \end{aligned}$$

and norm $\|u\|^2 = (u,u)$. There holds the decomposition

$$E = E^- \oplus E^0 \oplus E^+ \quad \text{with} \quad E^0 = E(0) \text{ and } E^\pm = E \cap L^\pm,$$

orthogonal with respect to both $(\cdot,\cdot)_{L^2}$ and $(\cdot,\cdot)$. It is known that E is compactly embedded in L^p for all $p \in [1,\infty)$.

LEMMA 2.1. *For each $p \in [2,\infty)$ there is $C_p > 0$ such that*

$$|u|_p \le C_p m^{-1/p}\|u\|$$

for all $u \in (\oplus_{k=-m+1}^{m-1} E(k))^\perp$, the orthogonal complement in E, where (and below) $|\cdot|_p$ denotes the usual L^p-norm.

Proof. If $p = 2$, the conclusion is clear. Suppose $p > 2$. For $u = \sum_{|j|\ge m} e^{jt\mathcal{J}} c_j(u) \in E$, by the Hausdorff–Young and Hölder inequalities,

$$\begin{aligned} |u|_p &\le c_p \left(\sum_{|j|\ge m} |c_j|^q \right)^{1/q} \\ &\le c_p' \left(\sum_{|j|\ge m} |j|^{-q/(2-q)} \right)^{(2-q)/2q} \|u\|, \end{aligned}$$

where $1/p + 1/q = 1$. Since

$$\sum_{|j|\ge m} |j|^{-q/(2-q)} \le 2\int_m^\infty x^{-q/(2-q)}dx = \frac{2-q}{q-1} m^{-2(q-1)/(2-q)},$$

the lemma follows. □

Next, for later use in estimating a certain index we consider the following operator on L^2,

$$A_{V,\vartheta} u := V(t) \sum_{k\in\mathbb{Z}} \vartheta_k e^{kt\mathcal{J}} c_k(u) = V(t) \sum_{k\in\mathbb{Z}} \sum_{j=1}^{2N} \vartheta_k c_{kj}(u) e^{kt\mathcal{J}} e_j,$$

where $V : S^1 \to \mathbb{R}$, a given real function, and $\vartheta = (\vartheta_k) \in \ell^p(\mathbb{Z})$, the Banach space of real number sequences with $|\vartheta|_p = \left(\sum_{k\in\mathbb{Z}} |\vartheta_j|^p\right)^{1/p} < \infty$ $(p \ge 1)$. Note that both the multiplication operator V with $\mathcal{D}(V) = \{u \in L^2 : Vu \in L^2\}$ and the operator ϑ defined by $\vartheta e^{kt\mathcal{J}} e_j = \vartheta_k e^{kt\mathcal{J}} e_j$ are self-adjoint. Moreover, $\vartheta : L^2 \to L^2$ is compact and it is not difficult to check that if $V \in L^p, \vartheta \in \ell^p$ $(p \ge 2)$, then $\vartheta(L^2) \subset \mathcal{D}(V), A_{V,\vartheta} = V \circ \vartheta, A_{V,\vartheta}^* = \vartheta \circ V$, and $A_{V,\vartheta} : L^2 \to L^2$ is compact with $\|A_{V,\vartheta}\| \le C_p |V|_p |\vartheta|_p$. Let $l_1(V,\vartheta) \ge l_2(V,\vartheta) \ge \cdots$ denote the repeated eigenvalues of $|A_{V,\vartheta}| := (A_{V,\vartheta}^* A_{V,\vartheta})^{1/2}$. Assuming $V \in L^p$ and $\vartheta \in \ell^p$, recall that the "p-norm" is defined by

$$\|A_{V,\vartheta}\|_p := \left(\sum_n l_n(V,\vartheta)^p \right)^{1/p} \quad \text{for } p \in [1,\infty) \quad \text{and} \quad \|A_{V,\vartheta}\|_\infty := \|A_{V,\vartheta}\|.$$

It is known that

$$\|A_{V,\vartheta}\|_p^2 = \|A_{V,\vartheta}^* A_{V,\vartheta}\|_{p/2} \quad \text{for } p \ge 2 \tag{2.1}$$

and for any complete orthogonal sequence (ψ_n)

$$\|A_{V,\vartheta}\|_2 = \left(\sum_n |A_{V,\vartheta}\psi_n|_2^2\right)^{1/2} \tag{2.2}$$

as well as, letting $\mathcal{B}$ denote the family of orthogonal sequences in L^2,

$$\|A_{V,\vartheta}\|_p = \sup_{(\phi_n),(\psi_n)\in\mathcal{B}} \Big(|(\phi_n, A_{V,\vartheta}\psi_n)_{L^2}|^p\Big)^{1/p}. \tag{2.3}$$

Let $\{\lambda_n(V,\vartheta)\}$ be the set of all eigenvalues of $A^*_{V,\vartheta}A_{V,\vartheta}$, and $\mathcal{N}(V,\vartheta)$ the number of eigenvalues of $A^*_{V,\vartheta}A_{V,\vartheta}$ which are ≥ 1. We will apply the following.

LEMMA 2.2 (cf. [18]). *For $p \in [2,\infty], V \in L^p$, and $\vartheta \in \ell^p$, there is $C_p > 0$ such that*

$$\mathcal{N}(V,\vartheta) \leq C_p |V|_p^p |\vartheta|_p^p.$$

Proof. Using (2.2) with the basis $(e^{kt\mathcal{J}}e_j)$ one gets easily that

$$\|A_{V,\vartheta}\|_2 = \sqrt{2N}\,|V|_2|\vartheta|_2,$$

and plainly there holds

$$\|A_{V,\vartheta}\|_\infty \leq |V|_\infty |\vartheta|_\infty.$$

Now fixing arbitrarily $(\psi_n),(\phi_n) \in \mathcal{B}$, the operator $(V,\vartheta) \to ((\phi_n, A_{V,\vartheta}\psi_n))$ from $L^p \times \ell^p$ into ℓ^p satisfies

$$|(\phi_n, A_{V,\vartheta}\psi)|_2 \leq \|A_{V,\vartheta}\|_2 \leq \sqrt{2N}\,|V|_2|\vartheta|_2,$$
$$|(\phi_n, A_{V,\vartheta}\psi_n)|_\infty \leq \|A_{V,\vartheta}\|_\infty \leq |V|_\infty|\vartheta|_\infty.$$

Thus by a complex interpolation one sees for $p \in (2,\infty)$

$$|(\phi_n, A_{V,\vartheta}\psi_n)|_p \leq C_p|V|_p|\vartheta|_p$$

with C_p independent of $(\phi_n),(\psi_n) \in \mathcal{B}$, which, together with (2.3), implies

$$\|A_{V,\vartheta}\|_p \leq C_p|V|_p|\vartheta|_p \quad \text{for all } p \in [2,\infty]. \tag{2.4}$$

(2.1) and (2.4) then yield

$$(\mathcal{N}(V,\vartheta))^{2/p} \leq \left(\sum_n \lambda_n(V,\vartheta)^{p/2}\right)^{2/p} = \|A^*_{V,\vartheta}A_{V,\vartheta}\|_{p/2} = \|A_{V,\vartheta}\|_p^2 \leq C_p^2|V|_p^2|\vartheta|_p^2,$$

and so the desired result follows. □

Finally, recall that the group $\mathcal{G} = \mathbb{Z}/2 =: \{\mathrm{id}, -\mathrm{id}\}$ acts on L^2 by

$$T_{id}\,u = u \qquad \text{and} \qquad T_{-id}\,u = -u \tag{2.5}$$

and the group $\mathcal{G} = S^1 := \{e^{i\theta} :\ \theta \in [0, 2\pi)\}$, where $i = \sqrt{-1}$, acts on L^2 by

$$(T_\theta\,u)(t) = u(t+\theta), \tag{2.6}$$

so that L^2 becomes a $\mathcal{G}$-space. Since these actions commute with A, the eigenspace $E(k)$ is invariant under each of the actions for all k.

When L^2 is regarded as a $\mathbb{Z}/2$-space, we arrange the positive eigenvalues of A by (repeated in multiplicity) $1 \le \lambda_1 \le \lambda_2 \le \cdots$ corresponding to the eigenfunctions ω_n (i.e., $A\omega_n = \lambda_n \omega_n$) and set

$$E_k = E(k) \text{ for } k \le 0 \text{ and } E_k = \mathbb{R}\,\omega_k \text{ for } k \in \mathbb{N}. \tag{2.7}$$

Then each $u \in L^2$ has the expression $u = u^- + u^0 + \sum_{k\in\mathbb{N}} c_k(u)\omega_k$ with $c_k(u) \in \mathbb{R}$.

When L^2 is regarded as a S^1-space, it is convenient to consider the complexification $\mathbb{R}^{2N} \cong \mathbb{C}^N$ and $L^2 \cong L^2(S^1, \mathbb{C}^N)$, and to set

$$E_k = e^{ikt}\mathbb{C}^N \text{ for } k \le 0 \text{ and } E_k = e^{i\bar{k}t}\mathbb{C} \text{ for } k \in \mathbb{N}, \text{ where } \bar{k} := \left[\frac{k+N-1}{N}\right]. \tag{2.8}$$

Note that, in this case, each $u \in L^2$ has the expression

$$u(t) = \sum_{k\le 0} e^{ikt}c_k(u) + \sum_{k\ge 1} e^{i\bar{k}t}c_k(u),\ c_k(u) \in \mathbb{C}^N$$

(regarding $\mathbb{C}$ as a subspace of $\mathbb{C}^N$), and the S^1-action reads as

$$(T_\theta\, u)(t) = \sum_{k\le 0} e^{ik\theta}e^{ikt}c_k(u) + \sum_{k\ge 1} e^{i\bar{k}\theta}e^{i\bar{k}t}c_k(u).$$

We will also consider another action on L^2 defined by

$$(\hat{T}_\theta\, u)(t) := c_0(u) + \sum_{k<0} e^{i\theta}e^{ikt}c_k(u) + \sum_{k>0} e^{i\theta}e^{i\bar{k}t}c_k(u). \tag{2.9}$$

Throughout the paper we denote

$$E_l^m := \oplus_{k=l}^m E_k, \quad E_{-l} := E_{-l}^0 \oplus E^+, \quad \text{and} \quad E^m := E^- \oplus E^0 \oplus E_1^m,$$

where it is understood that E_k takes different forms in different situations corresponding to (2.7) and (2.8), respectively.

3. Rabinowitz variational setting. In this section we always assume (F1)–(F2) and (G1) are satisfied. Observe that (F1)–(F2) imply that

$$c_1|z|^\mu \le F(t,z) \le c_2|z|^\nu \quad \text{whenever } |z| \ge \bar{r}, \tag{3.1}$$

where (and below) c_j's denote positive constants. Set

$$\Phi(u) := \int_0^{2\pi} F(t,u) \text{ and } \Psi(u) := \int_0^{2\pi} G(t,u).$$

Then $\Phi,\ \Psi \in \mathcal{C}^1(E,\mathbb{R})$ and

$$\Phi'(u)u \ge \mu\Phi(u) - c_3 \quad \text{for all } u \in E, \tag{3.2}$$

$$|\Psi(u)| + |\Psi'(u)u| \le c_3 + c_4|\Phi(u)|^\tau \quad \text{for all } u \in E. \tag{3.3}$$

Consider the functional

$$I_{\xi\eta}(u) := \frac{1}{2}(\|u^+\|^2 - \|u^-\|^2) - \xi\Phi(u) - \eta\Psi(u).$$

Then $I_{\xi\eta} \in \mathcal{C}^1(E, \mathbb{R})$ and its critical points give rise to periodic solutions of $(\mathrm{HS}_{\xi\eta})$.

We will consider only the case where $\xi > 0$ and $\eta \in \mathbb{R}$. The other case can be dealt with by considering the functional $-I_{\xi\eta}$ similarly. Furthermore, noting that (F1)–(F2) and (G1) remain true if F, G are replaced by ξF, $|\eta| G(t, z)$, respectively, with the constants a_j $(j = 1, 2, 3, 4)$ depending possibly on ξ, η, we can assume, for notational simplification and without loss of generality, that $\xi = 1$, $\eta = 1$, and denote simply $I(u) = I_{\xi\eta}(u)$.

It is easy to check using (3.1)–(3.3) that there exist $\alpha_1 > 0$, $\Lambda > 0$ such that if $u \in E$ satisfies

$$I_0(u) := \frac{1}{2}(\|u^+\|^2 - \|u^-\|^2) - \Phi(u) \geq \frac{\mu + 2}{4\mu}\Phi'(u)u - \Phi(u) - |\Psi'(u)u|,$$

then

$$1 \leq \Phi(u) + \alpha_1 \leq \Lambda(I_0(u)^2 + 1)^{1/2}. \tag{3.4}$$

Note in particular that if $u \in \mathcal{K}(I) := \{u \in E : I'(u) = 0\}$, then (3.4) holds. Indeed, since

$$I(u) = I(u) - \frac{1}{2}I'(u)u = \frac{1}{2}\Phi'(u)u - \Phi(u) + \frac{1}{2}\Psi'(u)u - \Psi(u),$$

we have

$$I_0(u) = \frac{1}{2}\Phi'(u)u - \Phi(u) + \frac{1}{2}\Psi(u) - \Psi(u).$$

Set for $u \in E$

$$Q(u) := 2\Lambda(I_0(u)^2 + 1)^{1/2}, \quad \theta(u) := Q(u)^{-1}(\Phi(u) + \alpha_1), \quad \text{and} \quad \rho(u) := \chi(\theta(u)),$$

where $\chi \in \mathcal{C}^\infty(\mathbb{R}, \mathbb{R})$ such that $\chi(s) = 1$ for $s \leq 1, \chi(s) = 0$ for $s \geq 2$, and $\chi'(s) \in (-2, 0)$ for $s \in (1, 2)$. Consider the functional $J \in \mathcal{C}^1(E, \mathbb{R})$ defined by

$$J(u) := \frac{1}{2}(\|u^+\|^2 - \|u^-\|^2) - \Phi(u) - \rho(u)\Psi(u) = I_0(u) - \rho(u)\Psi(u).$$

By assumption, $|J(u) - J(T_g u)| = \rho(u)|\Psi(u) - \Psi(T_g u)|$ for all $g \in \mathcal{G}$, where $\mathcal{G}$ stands for the $\mathbb{Z}/2$ or S^1 according to (F4) or (F5), respectively, and, using (3.2)–(3.4), it is not difficult to check that

$$|J(u) - J(T_g u)| \leq \alpha_2(|J(u)|^\tau + 1) \ \text{ for all } u \in E \text{ and } g \in \mathcal{G}. \tag{3.5}$$

Moreover, one can verify the following (cf. [17, Proposition 10.16]).

LEMMA 3.1. *There exists $M > 0$ such that $J(u) = I(u)$ for u in a neighborhood of $\mathcal{K}(J) \cap J^{-1}[M, \infty)$.*

Therefore, it is sufficient for obtaining large norm solutions to show that J possesses an unbounded sequence of positive critical values.

In the following let $J_l := J|_{E_{-l}}$, the restriction of J on E_{-l}. Recall that a sequence $(u_j) \subset E$ (resp., E_{-l}) is called a $(PS)_c$-sequence for J (resp., J_l) if it satisfies $J(u_j) \to c$ and $J'(u_j) \to 0$ (resp., $J_l'(u_j) \to 0$), and a sequence (u_l) with $u_l \in E_{-l}$ is called a $(PS)_c^*$-sequence for J if it satisfies $J(u_l) \to c$ and $J_l'(u_l) \to 0$. J (resp., J_l) is said to satisfy $(PS)_c$ condition if any $(PS)_c$-sequence for J (resp., J_l)

has a convergent subsequence, and J is said to satisfy $(PS)^*_c$ condition if any $(PS)^*_c$-sequence for J has a convergent subsequence. We can verify easily by (3.1)–(3.3) the following lemma.

LEMMA 3.2. *There is a positive constant denoted again by M such that for all $c \geq M$, J and J_l satisfy $(PS)_c$ condition, and J also satisfies $(PS)^*_c$ condition.*

By (3.1)–(3.3) there are again positive constants γ_j such that for all $u \in E$

$$\frac{1}{2}\big(\|u^+\|^2 - \|u^-\|^2\big) - \gamma_1|u|_\nu^\nu - \gamma_2 \leq J(u) \leq \frac{1}{2}\big(\|u^+\|^2 - \|u^-\|^2\big) - \gamma_3|u|_\mu^\mu + \gamma_4. \tag{3.6}$$

Using this fact and Lemma 2.1, we have the following.

LEMMA 3.3. *For each $n \in \mathbb{N}$ there are $R_n > r_n > 0$ such that*

$$\sup J(E^n \backslash B_{R_n}) \leq 0 \quad \textit{and} \quad \alpha_n := \sup J(E^n) < \infty; \tag{3.7}$$

$$\inf J(\partial B_{r_n} \cap (E^{n-1})^\perp) \geq \gamma_5 n^{2/(\nu-2)}. \tag{3.8}$$

Without loss of generality we assume $R_n < R_{n+1}$ for all n. Let

$$D_l^n := B_{R_n} \cap E_{-l}^n,$$
$$\Gamma_l^n := \{\gamma \in \mathcal{C}(D_l^n, E_{-l}) : \ \gamma \text{ satisfies } (\gamma_1) \text{ and } (\gamma_2)\},$$

where

(γ_1) $\gamma = \mathrm{id}$ on $(\partial B_{R_n} \cap E_{-l}^n) \cup (D_l^n \cap \mathrm{Fix}\mathcal{G})$;

(γ_2) γ is $\mathcal{G}$-invariant in the following sense (cf. (2.5) and (2.6), (2.9)):

$$\begin{aligned} &\gamma(-u) = -\gamma(u) \ \text{ if } \mathcal{G} = \mathbb{Z}/2, \\ &\gamma(\hat{T}_\theta u) = T_\theta \gamma(u) \ \text{ for all } \theta \in [0,\, 2\pi) \ \text{ if } \mathcal{G} = S^1. \end{aligned} \tag{3.9}$$

Set also, taking $\phi_k \in E_k$ with $\|\phi_k\| = 1$ for all $k \in \mathbb{N}$,

$$U_l^n := \{u \in D_l^{n+1} : \ u = x + c\phi_{n+1} \text{ with } x \in E_{-l}^n \text{ and } c \geq 0\},$$
$$\Lambda_l^n := \{\lambda \in \mathcal{C}(U_l^n, E_{-l}) : \ \lambda|_{D_l^n} \in \Gamma_l^n, \lambda = id \text{ on } Q_l^n\},$$

where $Q_l^n := (U_l^n \cap \partial B_{R_{n+1}}) \cup ((U_l^n \cap E_{-l}^n) \backslash D_l^n) \cup (U_l^n \cap \mathrm{Fix}\mathcal{G})$. Define the minimax values for J_l:

$$b_l^n := \inf_{\gamma \in \Gamma_l^n} \sup_{u \in D_l^n} J(\gamma(u)),$$

$$c_l^n := \inf_{\lambda \in \Lambda_l^n} \sup_{u \in U_l^n} J(\lambda(u)).$$

LEMMA 3.4. *There holds*

$$\gamma_5 n^{2/(\nu-2)} \leq b_l^n \leq c_l^n \leq \alpha_{n+1} \quad \textit{for all } n, l \in \mathbb{N}.$$

Proof. Plainly, by definition and (3.7), $b_l^n \leq c_l^n \leq \alpha_n$. Set for $\gamma \in \Gamma_l^n$

$$\mathcal{O} := \{u \in D_l^n : \ \|\gamma(u)\| < r_n\}.$$

Since $0 \in \mathrm{Fix}\mathcal{G}$ and $\gamma = \mathrm{id}$ on $\partial D_l^n \cup (D_l^n \cap \mathrm{Fix}\mathcal{G})$, $\mathcal{O} \cap \partial D_l^n = \emptyset$, $\mathcal{O}$ is an open bounded invariant neighborhood of 0 in E_{-l}^n. Let $P : E_{-l}^n \to E_{-l}^{n-1}$ be the orthogonal

projection, and consider the composion $P\circ\gamma : \mathcal{O} \to E^{n-1}_{-l}$ which clearly keeps $\mathcal{O}\cap \mathrm{Fix}\mathcal{G}$ fixed. By the Borsuk–Ulam theorem (for its S^1-version, see [11]), $P\circ\gamma$ has a zero $u \in \partial\mathcal{O}$. Thus $\|\gamma(u)\| = r_n$ and $\gamma(u) \in (E^{n-1})^\perp$. Now (3.8) applies. □

By virtue of this lemma there exists a subsequence denoted again by $(l) \subset \mathbb{N}$ such that for all $n \in \mathbb{N}$, as $l \to \infty$,

$$b^n_l \to b_n, \quad c^n_l \to c_n, \quad \text{and} \quad \gamma_5 n^{2/(\nu-2)} \le b_n \le c_n \le \alpha_{n+1}. \tag{3.10}$$

LEMMA 3.5. *If $c_n > b_n \ge M$, then J has a critical value $\hat{c}_n \in [b_n, c_n]$.*

Proof. See [17] for the $\mathbb{Z}/2$-action case. The result for the S^1-action case can be proved similarly. Since $b_n < c_n$, we have $b^n_l < c^n_l$ for all l large. Let $\delta \in (0, c^n_l - b^n_l)$ and

$$\Lambda^n_l(\delta) := \{\lambda \in \Lambda^n_l : \ J(\lambda(u)) \le b^n_l + \delta \text{ for all } u \in D^n_l\},$$
$$c^n_l(\delta) := \inf_{\lambda\in\Lambda^n_l(\delta)} \sup_{u\in U^n_l} J(\lambda(u)).$$

Since J_l satisfies $(PS)_c$ for $c \ge M$, a standard deformation argument shows that $c^n_l(\delta)$ is a critical value of J_l. Then by $(PS)^*_c$ for $c \ge M$ one sees that J has a critical value in $[b_n, c_n]$. □

LEMMA 3.6. *If $b_n = c_n$ for all $n \ge \hat{n}$, then*

$$b_n \le \gamma_6 n^{1/(1-\tau)} \quad \textit{for all } n \in \mathbb{N}.$$

Proof. By the choice of E_k (cf. (2.7)–(2.8)) $D^{n+1}_l = \cup_{g\in\mathcal{G}} T_g(U^n_l)$ and for any $u \in D^{n+1}_l \backslash E^n_{-l}$ there is a unique $(x, g) \in (U^n_l \backslash D^n_l) \times \mathcal{G}$ such that $T_g x = u$. Each $\lambda \in \Lambda^n_l$ extends to $\gamma \in \Gamma^{n+1}_l$ via $\gamma(u) = T_g(\lambda(T^{-1}_g u))$, and thus by (3.5)

$$\begin{aligned} b^{n+1}_l &\le \sup_{u\in D^{n+1}_l} J(\gamma(u)) = \sup_{u\in U^n_l, g\in\mathcal{G}} J(T_g\lambda(u)), \\ &\le \sup_{u\in U^n_l} \big(J(\lambda(u)) + \alpha_2(|J(\lambda(u))|^{1/(1-\tau)} + 1)\big). \end{aligned}$$

Therefore for all n, l

$$b^{n+1}_l \le c^n_l + \alpha_2(|c^n_l|^{1/(1-\tau)} + 1)$$

which induces as $l \to \infty$

$$b_{n+1} \le b_n + \alpha_2(b_n^{1/(1-\tau)} + 1) \quad \text{for } n \ge \hat{n}.$$

Now the conclusion follows as done in [17]. □

4. Large norm solutions. We now turn to prove part (a) of the theorems.

Proof of Theorems 1.1(a) and 1.2(a). Observe that (3.6) implies on E^+

$$J(u) \ge f(u) - \gamma_2, \qquad \text{where} \qquad f(u) := \frac{1}{2}\|u\|^2 - \gamma_1|u|^\nu_\nu \in \mathcal{C}^2(E^+, \mathbb{R}).$$

Let $f_m := f|_{E^m_1}$, the restriction of f on E^m_1. Plainly, f and f_m satisfy the $(PS)_c$ and f satisfies the $(PS)^*_c$ for all c. Let BL denote the unit sphere of the vector space L and $SL := \partial(BL)$. We set for $n, m \in \mathbb{N}$ with $n < m$

$$A^m_n := \{\sigma \in \mathcal{C}(S\mathbb{R}^{m-n+1}, E^m_1) : \ \sigma(-x) = -\sigma(x) \text{ for all } x\} \tag{4.1}$$

if $\mathcal{G} = \mathbb{Z}/2$ is concerned (for proving Theorem 1.1(a)) and

$$A_n^m := \{\sigma \in \mathcal{C}(S\mathbb{C}^{m-n+1}, E_1^m) : \ \sigma(\hat{T}_\theta z) = T_\theta \sigma(z) \text{ for all } (z,\theta)\} \tag{4.2}$$

if $\mathcal{G} = S^1$ is concerned (for proving Theorem 1.2(a)). Define

$$\beta_n^m := \sup_{\sigma \in A_n^m} \min_{x \in SL} J(\sigma(x)),$$

where $L = \mathbb{R}^{m-n+1}$ and $L = \mathbb{C}^{m-n+1}$ corresponding to (4.1) and (4.2), respectively. Then it is easy to see that

$$\gamma_5 n^{2/(\nu-2)} \le \beta_n^m \le \alpha_n, \tag{4.3}$$

$$\beta_n^m \le \beta_{n+1}^m, \tag{4.4}$$

and β_n^m is a critical value of f_m. We can choose a sequence $m_j \to \infty$ such that the following limit exists:

$$\beta_n = \lim_{j\to\infty} \beta_n^{m_j} \qquad \text{for each } n \in \mathbb{N}.$$

Since f satisfies $(PS)_c^*$, each β_n is a critical value of f. Moreover, $\beta_n \le \beta_{n+1}$ by (4.4), and $\beta_n \to \infty$ by (4.3). We have the following claims:

1. $b_n \ge \beta_n - \gamma_2$ for all $n \in \mathbb{N}$;
2. along a subsequence $n_j \to \infty$ there is $u_{n_j} \in \mathcal{K}(f)$ satisfying

$$\beta_{n_j} \ge f(u_{n_j}) \ge C_p n_{n_j}^{p\nu/2(\nu-2)} \quad \text{for all } j,$$

where $C_p > 0$ independent of (u_{n_j}).

Postponing to show claims 1, 2, we first complete the proofs of Theorems 1.1(a) and 1.2(a). By the assumption $\tau < 2/\nu$, we have $1/(1-\tau) < p\nu/2(\nu-2)$ for $p > 2$ but closing sufficiently to 2. Then for j large enough, $b_{n_j} \ge \gamma_6 n_j^{p\nu/2(\nu-2)}$ in virtue of claims 1 and 2, which, jointly with Lemmas 3.4, 3.6, and 3.5 implies that J has an unbounded sequence of positive critical values, and thus we have part (a).

We now turn to the claims. Only the case of S^1-action is considered here because the other case can be dealt with similarly.

For proving claim 1 it is sufficient to show that for any $\gamma \in \Gamma_l^n$ and $\sigma \in A_n^m$, the intersection

$$\gamma(D_l^n) \cap \sigma(S\mathbb{C}^{m-n+1}) \ne \emptyset. \tag{4.5}$$

To verify this, let $P_l^m : E_{-l} \to E_{-l}^m$ be the orthogonal projection, and consider the composition $g := P_l^m \circ \gamma : D_l^n \to E_{-l}^m$. By a S^1-version of Borsuk–Ulam theorem (cf. [11] and [19]), $g(D_l^n) \cap \sigma(S\mathbb{C}^{m-n+1}) \ne \emptyset$. Thus there is $u_m \in D_l^n$ and $z_m \in S\mathbb{C}^{m-n+1}$ such that $P_l^m(\gamma(u_m)) = \sigma(z_m)$. Since D_l^n and $S\mathbb{C}^{m-n+1}$ are compact, along a subsequence as $m \to \infty, \gamma(u_m) \to \gamma(u), \sigma(z_m) \to \sigma(z)$ with $u \in D_l^n, z \in S\mathbb{C}^{m-n+1}$ and $\gamma(u) = \sigma(z)$. (4.5) is proved.

Next we prove claim 2. Recall that the index of a functional $g \in \mathcal{C}^2(X, \mathbb{R})$, X a Hilbert space, at $x \in X$ is defined by

$$\begin{aligned} \operatorname{Ind}(g,x) :&= \#\{\lambda : \lambda \le 0 \text{ is an eigenvalue of } g''(x)\} \\ &= \max\{\dim H : \ H \subset X, \text{ a subspace on which } g''(x) \text{ is nonpositive}\}. \end{aligned}$$

First we show that if $\beta_n < \beta_{n+1}$, then there is $u_n \in E^+$ satisfying

$$f(u_n) \le \beta_n, \quad f'(u_n) = 0, \quad \text{and} \quad \mathrm{Ind}(f, u_n) \ge 2n - 1. \tag{4.6}$$

Since $\beta_n < \beta_{n+1}$, we have $\beta_n^{m_j} < \beta_{n+1}^{m_j}$ for m_j large. By a result of Marino–Prodi (cf. [9, 18]), for any $0 < \varepsilon < (\beta_{n+1}^{m_j} - \beta_n^{m_j})/8$, we can take $\varphi_\varepsilon \in \mathcal{C}(E_1^{m_j}, \mathbb{R})$ which satisfies $(PS)_c$, has only finitely many nondegenerate critical points, and

$$\varphi_\varepsilon(u) = f(u) \text{ if } \|u - \mathcal{K}(f_{m_j})\| \ge \varepsilon, \qquad \|\varphi_\varepsilon - f_{m_j}\|_{\mathcal{C}^2} \le \varepsilon.$$

Define

$$\beta_n^{m_j}(\varepsilon) := \sup_{\sigma \in A_n^{m_j}} \min_{u \in S\mathbb{C}^{m-n+1}} \varphi_\varepsilon(\sigma(u)).$$

Take a regular value of φ_ε, $a_\varepsilon \in (\beta_n^{m_j} + 5\varepsilon,\, \beta_n^{m_j} + 6\varepsilon)$. Then

$$\beta_n^{m_j}(\varepsilon) < a_\varepsilon - 2\varepsilon < a_\varepsilon < \beta_{n+1}^{m_j}(\varepsilon),$$

and the homotopy group

$$\pi_{2(m_j-n)-1}([\varphi_\varepsilon \ge a_\varepsilon], p) \ne 0 \quad \text{for some } p \in [\varphi_\varepsilon \ge a_\varepsilon], \tag{4.7}$$

where $[\varphi_\varepsilon \ge a_\varepsilon] := \{u \in E_1^{m_j} :\ \varphi_\varepsilon(u) \ge a_\varepsilon\}$ (cf. [3]). On the other hand,

$$\pi_l([\varphi_\varepsilon \ge a_\varepsilon], p) = 0 \ \text{ for all } p \in [\varphi_\varepsilon \ge a_\varepsilon] \text{ and } l \le 2m_j - L(\varphi_\varepsilon, a_\varepsilon) - 1, \tag{4.8}$$

where $L(\varphi_\varepsilon, a_\varepsilon) := \max\{\mathrm{Ind}(\varphi_\varepsilon, u) :\ u \in \mathcal{K}(\varphi_\varepsilon), \varphi_\varepsilon(u) \le a_\varepsilon\}$. (4.7) and (4.8) imply that there is $u_\varepsilon \in \mathcal{K}(\varphi_\varepsilon)$ such that $\varphi_\varepsilon(u_\varepsilon) \le a_\varepsilon$ and $\mathrm{Ind}(\varphi_\varepsilon, u_\varepsilon) > 2n - 1$. Therefore, by $(PS)_c$, along a subsequence as $\varepsilon \to 0$, $u_\varepsilon \to u_n^{m_j} \in \mathcal{K}(f_{m_j})$ satisfying $f(u_n^{m_j}) \le \beta_n^{m_j}$ and $\mathrm{Ind}(f_{m_j}, u_n^{m_j}) \ge 2n - 1$. Now, by $(PS)_c^*$, letting $j \to \infty$ along a subsequence yields (4.6).

Let $u \in \mathcal{K}(f)$. Note that $(f''(u)v, v) = \|u\|^2 - \gamma_1\nu(\nu-1)(|u|^{\nu-2}v, v)_{L^2}$. Having this in mind we consider the operator $A_{\hat{V},\hat{\vartheta}}$ defined before (cf. section 2), where $\hat{\vartheta} = (\vartheta_k)$ with $\vartheta_k = 0$ for all $k \le 0$ and $\vartheta_k = k^{-1/2}$ for all $k \in \mathbb{N}$, and $\hat{V} = (\gamma_1\nu(\nu-1)|u|^{\nu-2})^{1/2}$. Clearly $\hat{V} \in L^p$ and $\hat{\vartheta} \in \ell^p$ for all $p > 2$, and the restriction of the operator $\hat{\vartheta}$ on L^+ is an isometry from L^+ to E^+. Letting $v := \hat{\vartheta}h$ for $h \in L^+, (f''(u)v, v) \le 0$ if and only if $(A_{\hat{V},\hat{\vartheta}}h, h)_{L^2} \ge |h|_2^2$. Therefore, $\mathrm{Ind}(f, u) = \mathcal{N}(\hat{V}, \hat{\vartheta})$, and so by Lemma 2.2,

$$\mathrm{Ind}(f, u) \le C_p|\hat{V}|_p^p|\hat{\vartheta}|_p^p \le C_p'||u|^{(\nu-2)/2}|_p^p \le C_p''|u|_\nu^{p(\nu-2)/2} \ \text{ for all } p > 2. \tag{4.9}$$

Since $f'(u) = 0$, one has $f(u) = f(u) - 1/2f'(u)u = (\nu/2 - 1)\gamma_1|u|_\nu^\nu$. In particular, we have by (4.6) and (4.9) (for $n \ge 2$)

$$\beta_n \ge f(u_n) = \frac{\nu - 2}{2}\gamma_1|u_n|_\nu^\nu \ge C_p n^{2\nu/p(\nu-2)},$$

that is, claim 2.

The proofs are completed. □

5. Solutions with small energies. We consider only the case where $\eta > 0$. (F3) and (G2) imply that there exist $\gamma \in [\alpha, 2)$, $r_0 \in (0, \underline{r}]$, and $a_6 > 0$ such that

$$0 < \nabla_z H_{\xi\eta}(t,z)z \le \gamma H_{\xi\eta}(t,z) \qquad \text{for all } t \in \mathbb{R} \text{ and } z \in B_{r_0}\backslash\{0\}, \tag{5.1}$$

$$a_6|\nabla_z H_{\xi\eta}(t,z)|^\beta \le H_{\xi\eta}(t,z) \qquad \text{for all } t \in \mathbb{R} \text{ and } z \in B_{r_0}. \tag{5.2}$$

Let $\chi = \chi(s) \in \mathcal{C}^\infty(\mathbb{R}, [0,1])$ be such that $\chi(s) = 0$ for $s \le r_0/2, \chi(s) = 1$ for $s \ge r_0$, and

$$\chi'(s) > 0 \qquad \text{for all } s \in (r_0/2, r_0). \tag{5.3}$$

Set $M = \inf\{H_{\xi\eta}(t,z)/r_0^\gamma : \ t \in \mathbb{R} \text{ and } |z| = r_0\}$. Consider $\tilde{H}_{\xi\eta} : \mathbb{R} \times \mathbb{R}^{2N} \to \mathbb{R}$ defined by

$$\tilde{H}_{\xi\eta}(t,z) = (1 - \chi(|z|))H_{\xi\eta}(t,z) + \chi(|z|)M|z|^\gamma.$$

Then by definition and (5.1)–(5.3),

$$\tilde{H}_{\xi\eta}(t,z) \ge M|z|^\gamma \qquad \text{for all } (t,z); \tag{5.4}$$

$$0 < \nabla_z \tilde{H}_{\xi\eta}(t,z)z \le \gamma \tilde{H}_{\xi\eta}(t,z) \qquad \text{for all } z \ne 0. \tag{5.5}$$

Without loss of generality, we assume $T = 2\pi$. Define $I \in \mathcal{C}^1(E, \mathbb{R})$ by

$$I(u) = \int_0^{2\pi} \tilde{H}_{\xi\eta}(t,u)dt - \frac{1}{2}\big(\|u^+\|^2 - \|u^-\|^2\big).$$

Then each critical point u of I with $|u|_\infty < r_0/2$ is a 2π-periodic solution of $(\mathrm{HS}_{\xi\eta})$.

We will give only the proof of Theorem 1.2(b). For the details of proof corresponding to the $\mathbb{Z}/2$-action case (i.e., Theorem 1.1(b)) we refer to [10]. Recall that in [10], a sequence $0 < c_n \to 0$ of minimax values for I was obtained as limits $c_n = \lim_{l\to\infty} c_l^n$, where $c_l^n := \sup\{\inf I(A \cap E_{-l}) : A \text{ is closed, symmetric, and } \mathbb{Z}/2\text{-genus}(A \cap E_{-l}) \ge 2N(l+n+1)\}$ (here $E_{-l} = \oplus_{j\ge -l}E(j)$). However, this does not work in the S^1-action situation. Indeed, for any $R > 0$, the S^1-genus$(S_R E(0)) = \infty$, and so the similar minimax values $= \infty$. Thus we have to try another way.

LEMMA 5.1. *For each $n \in \mathbb{N}$, there are $r_m > 0, \alpha_m > 0$ and $0 < \beta_m \to 0$ such that*

(i) $\inf I\big(S_{r_m\delta}E^m\big) \ge \alpha_m\delta^2 r_m^2$ *for all* $\delta \in [0,1]$;

(ii) $\sup I\big((E^{m-1})^\perp\big) \le \beta_m$.

Proof. Using the direct sum decomposition and the fact that $\dim(E^0 \oplus E_1^m) < \infty$, one has $|u|_\gamma^\gamma \ge c_1|u^-|_\gamma^\gamma + c_2\|u^0\|^2 + c_m\|u^+\|^2$ for all $u \in B_1E^m$. Therefore

$$\begin{aligned} I(u) &\ge \frac{1}{2}\|u^-\|^2 + c_3\|u^0\|^2 + c(m)\|u^+\|^\gamma - \frac{1}{2}\|u^+\|^2 \\ &= \frac{1}{2}\|u^-\|^2 + c_3\|u^0\|^2 + \left(c(m) - \frac{1}{2}\|u^+\|^{2-\gamma}\right)\|u^+\|^\gamma \\ &\ge \alpha_m\|u\|^2 \end{aligned}$$

if $u \in E^m$ with $\|u\| \le r_m := \min\{1, c(m)^{1/(2-\gamma)}\}$, where α_m is a positive constant depending on m. (i) is proved.

Let $u \in (E^{m-1})^{\perp}$. By Lemma 2.1, $|u|_\gamma \le c_\gamma m^{-1/2}\|u\|$ and so

$$I(u) \le c_1|u|_\gamma^\gamma - \frac{1}{2}\|u\|^2 \le c_2 m^{-\gamma/2}\|u\|^\gamma - \frac{1}{2}\|u\|^2$$
$$\le b_m := c_2\big(1-\frac{\gamma}{2}\big)\big(\frac{c_2\gamma}{m}\big)^{\gamma/(2-\gamma)}.$$

Clearly, $b_m \to 0$ as $m \to \infty$, and (ii) follows. □

In the following, fix arbitrarily $n \in \mathbb{N}$. Consider $I_l := I|_{E_{-ln}}$, the restriction of I onto E_{-ln} for all $l \in \mathbb{N}$. A standard verification shows that I and I_l satisfy the $(PS)_c$ condition, and I also satisfies the $(PS)_c^*$ condition for all $c \in \mathbb{R}$. Let H^l denote the set of all homeomorphisms $\lambda : E_{-ln} \to E_{-ln}$ satisfying

($\lambda 1$) λ is equivariant, i.e., $\lambda(T_\theta u) = T_\theta \lambda(u)$ for all $(\theta, u) \in [0, 2\pi) \times E_{-ln}$;

($\lambda 2$) $\lambda(0) = 0$;

($\lambda 3$) for any compact set K in a finite dimensional invariant space $Y \subset E_{-ln}$ and an $\varepsilon > 0$ there is a finite dimensional invariant space $Z \subset E_{-ln}$ with $Y \subset Z$ and an equivariant homeomorphism $\tilde\lambda : Z \to Z$ such that $\|\tilde\lambda(u) - \lambda(u)\| \le \varepsilon$ for all $u \in K$.

Let $(I_l)_a := \{u \in E_{-ln} :\ I(u) \ge a\}$ and $K_l^a := \{u \in E_{-ln} :\ I(u) = a \text{ and } I_l'(u) = 0\}$ for $a \in \mathbb{R}$. We recall the following standard result of deformation (cf. [8]).

LEMMA 5.2. *For any $0 \ne c \in \mathbb{R}$, if $\mathcal{N}$ is a neighborhood of K_l^c, then there exist $\bar\varepsilon > \varepsilon > 0$ and $\eta \in \mathcal{C}([0,1] \times E_{-ln}, E_{-ln})$ such that*

(a) $\eta_t \in H^l$ *for all* $t \in [0,1]$;

(b) $\eta_0(u) = u$ *for all* $u \in E_{-ln}$;

(c) $\eta_t(u) = u$ *if* $u \notin I^{-1}([c-\bar\varepsilon, c+\bar\varepsilon])$;

(d) $I(\eta_t(u)) \ge I(u)$ *for all* $(t,u) \in [0,1] \times E_{-ln}$;

(e) $\eta_1((I_l)_{c-\varepsilon} \backslash \mathcal{N}) \subset (I_l)_{c+\varepsilon}$;

(f) *if* $K_c^l = \emptyset, \eta_1((I_l)_{c-\varepsilon}) \subset (I_l)_{c+\varepsilon}$.

Set

$$\tilde E_{-ln} := \big(\oplus_{j=1}^{ln} E(-j)\big) \oplus E^+,$$
$$W_n^l := \big(\oplus_{j=1}^{l} E(-jn)\big) \oplus \overline{\oplus_{j=1}^{\infty} E(jn)},$$
$$\Sigma_n^l := \big\{A \subset E_{-ln} :\ A \text{ is closed, invariant and } A \subset W_n^l \oplus E(0)\big\}.$$

Let Σ be the set of all closed invariant subsets of E and let gen: $\Sigma \to \mathbb{N} \cup \{0, \infty\}$ be the S^1-index, that is, for $A \in \Sigma$

$$\operatorname{gen}(A) = \min\Big\{k \in \{0\} \cup \mathbb{N} :\ \begin{matrix}\text{there are } \phi \in \mathcal{C}(A, \mathbb{C}^k \backslash \{0\}) \text{ and } n \in \{0\} \cup \mathbb{N} \text{ such} \\ \text{that } \phi(T_\theta u) = e^{in\theta}\phi(u) \text{ for all } (u, e^{i\theta}) \in A \times S^1\end{matrix}\Big\}.$$

Define for $A \in \Sigma \cap E_{-ln}$

$$\operatorname{gen}_l(A) = \inf_{\lambda \in H^l} \operatorname{gen}\big(\lambda(A) \cap \tilde E_{-ln}\big)$$

and set

$$\Gamma_n^l := \{A \in \Sigma_n^l :\ \operatorname{gen}_l(A) \ge (l+1)N\}.$$

It is not difficult to check the following (cf. [8, Propositions 2.2(vii) and 2.11(i)]):

$$\eta(A) \in \Gamma_n^l \quad \text{for all } A \in \Gamma_n^l \text{ and } \eta \in H^l. \tag{5.6}$$

Since for $A \in \Gamma_n^l$, $(l+1)N \le \mathrm{gen}_l(A) \le \mathrm{gen}(A \cap \tilde{E}_{-ln})$ and

$$A \cap \tilde{E}_{-ln} \subset \big(\oplus_{j=1}^{l} E(-jn)\big) \oplus \big(\overline{\oplus_{j\in\mathbb{N}} E(jn)}\big),$$

one has $A \cap \big(\overline{\oplus_{j\in\mathbb{N}} E(jn)}\big) \neq \emptyset$. Thus

$$A \cap \big(E^{n-1}\big)^{\perp} \neq \emptyset \quad \text{for all } A \in \Gamma_n^l. \tag{5.7}$$

Moreover, by definition, the set

$$C_n^l := S_{r_n}\Big(\big(\oplus_{j=1}^{l} E(-jn)\big) \oplus E(n) \oplus E(0)\Big) \in \Gamma_n^l. \tag{5.8}$$

Now we are in a position to give the proof of Theorem 1.2(b).

Proof of Theorem 1.2(b). Fix $n \in \mathbb{N}$. For any $l \in \mathbb{N}$ we define the following minimax values for I_l:

$$b_n^l := \sup_{A\in\Gamma_n^l} \min_{u\in A} I(u).$$

Lemma 5.1(i) and (5.8) imply that $\alpha_n \le b_n^l$ for all $l \in \mathbb{N}$, and Lemma 5.1(ii) and (5.7) imply that $b_n^l \le \beta_n$ for all $l \in \mathbb{N}$, that is

$$\alpha_n \le b_n^l \le \beta_n \quad \text{for all } l \in \mathbb{N}. \tag{5.9}$$

By Lemma 5.2 and (5.6), (5.9), b_n^l is a critical value of I_l (cf. [9, 14, 17, 20]). Let $u_n^l \in E_{-ln}$ be such that

$$I(u_n^l) = b_n^l \quad \text{and} \quad I_l'(u_n^l) = 0.$$

Then by the $(PS)_c^*$ condition, along a subsequence as $l \to \infty$, $u_n^l \to u_n$ such that

$$\alpha_n \le I(u_n) \le \beta_n \quad \text{and} \quad I'(u_n) = 0. \tag{5.10}$$

Now by (5.5) and (5.10),

$$\begin{aligned}\beta_n \ge I(u_n) &= I(u_n) - \frac{1}{2} I'(u_n)u_n \\ &\ge \big(1 - \frac{\gamma}{2}\big) \int_0^{2\pi} \tilde{H}_{\xi\eta}(u_n),\end{aligned}$$

which, together with (5.4), implies

$$M|u_n|_\gamma^\gamma \le \gamma \int_0^{2\pi} \tilde{H}_{\xi\eta}(u_n) \le \frac{2\gamma\beta_n}{2-\gamma}. \tag{5.11}$$

By (G2) and the Hölder inequality $(1/\beta + 1/\beta' = 1, 1/\gamma + 1/\gamma' = 1)$

$$\begin{aligned}\|u_n^+\|^2 &= \int_0^{2\pi} \nabla \tilde{H}_{\xi\eta}(u_n)u_n^+ \\ &\le c_1|u_n^+|_{\beta'} \left(\int_{|u_n(t)|\le 1} |\nabla \tilde{H}_{\xi\eta}(u_n)|^\beta\right)^{1/\beta} + c_1|u_n^+|_\gamma \left(\int_{|u_n(t)|>1} |\nabla \tilde{H}_{\xi\eta}(u_n)|^{\gamma'}\right)^{1/\gamma'} \\ &\le c_2\|u_n^+\| \left[\left(\int_0^{2\pi} \tilde{H}_{\xi\eta}(u_n)\right)^{1/\beta} + \left(\int_0^{2\pi} \tilde{H}_{\xi\eta}(u_n)\right)^{1/\gamma'}\right]\end{aligned}$$

and so

$$\|u_n^+\| \le c_2\Big[\Big(\frac{2\beta_n}{2-\gamma}\Big)^{1/\beta} + \Big(\frac{2\beta_n}{2-\gamma}\Big)^{1/\gamma'}\Big]. \tag{5.12}$$

Similarly

$$\|u_n^-\| \le c_2\Big[\Big(\frac{2\beta_n}{2-\gamma}\Big)^{1/\beta} + \Big(\frac{2\beta_n}{2-\gamma}\Big)^{1/\gamma'}\Big]. \tag{5.13}$$

Equations (5.11)–(5.13) then yield

$$\|u_n\| \le c_3\Big[\Big(\frac{2\beta_n}{2-\gamma}\Big)^{1/\beta} + \Big(\frac{2\beta_n}{2-\gamma}\Big)^{1/\gamma'} + \Big(\frac{2\beta_n}{2-\gamma}\Big)^{1/\gamma}\Big]. \tag{5.14}$$

Since $\beta_n \to 0$ as $n \to \infty$, it follows from (5.14) that

$$\|u_n\| \to 0 \quad \text{as } n \to \infty. \tag{5.15}$$

Furthermore, since $I'(u_n) = 0, u_n$ solves

$$\dot z = \mathcal{J}\nabla \tilde H_{\xi\eta}(z),$$

and we obtain

$$\begin{aligned}\int_0^{2\pi} |\dot u_n|^2 &= \int_0^{2\pi} |\nabla \tilde H_{\xi\eta}(u_n)|^2 \\ &\le c_1 \int_0^{2\pi} \Big(\tilde H_{\xi\eta}(u_n)^{2/\gamma'} + \tilde H_{\xi\eta}(u_n)^{2/\beta}\Big) \\ &\le c_2 \left[\Big(\int_0^{2\pi} \tilde H_{\xi\eta}(u_n)\Big)^{2/\beta} + \Big(\int_0^{2\pi} \tilde H_{\xi\eta}(u_n)\Big)^{2/\gamma'}\right],\end{aligned}$$

which, jointly with (5.11), implies

$$|\dot u_n|_2 \to 0 \quad \text{as } n \to \infty. \tag{5.16}$$

Now (5.15) and (5.16) give the conclusion that

$$\|u_n\|_{W^{1,2}} \to 0 \quad \text{as } n \to \infty$$

and therefore, for n large, u_n solves ($\mathrm{HS}_{\xi\eta}$).

Finally we show that $u_n(t) \ne 0$ for all t. Indeed, if $u_n(t_0) = 0$ for some $t_0 \in \mathbb{R}$, then since $H_{\xi\eta}$ is independent t, one has

$$M|u_n(t)|^\gamma \le H_{\xi\eta}(u_n(t)) \equiv H_{\xi\eta}(u_n(t_0)) = 0,$$

i.e., $u_n(t) \equiv 0$, a contradiction.

The proof is complete. □

GLOBAL EXISTENCE AND RELAXATION LIMIT FOR SMOOTH SOLUTIONS TO THE EULER–POISSON MODEL FOR SEMICONDUCTORS*

G. ALÌ†, D. BINI†, AND S. RIONERO‡

Abstract. We establish the global existence of smooth solutions of the Cauchy problem for the one-dimensional Euler–Poisson model for semiconductors, under the assumption that the initial data are perturbations of a stationary solution of the drift-diffusion equations. The resulting evolutionary solutions converge asymptotically in time to the unperturbed state.

Key words. Euler–Poisson, semiconductors, asymptotic behavior, smooth solutions

1. Introduction. In this paper, we study the global existence and the asymptotic behavior of smooth solutions of the initial value problem for the Euler–Poisson (or hydrodynamic) model for semiconductors in one space dimension. In scaled variables, let n, u, T, and E denote the electron number density, the electron velocity, the electron temperature, and the electric field, respectively. The (nondimensional) Euler–Poisson model consists of a hydrodynamic part,

$$n_t + (nu)_x = 0, \tag{1.1}$$

$$(nu)_t + \left(nu^2 + nT\right)_x = nE - \frac{nu}{\tau}, \tag{1.2}$$

$$\left(\frac{nu^2}{2} + \frac{nT}{\gamma - 1}\right)_t + \left[\left(\frac{nu^2}{2} + \frac{\gamma nT}{\gamma - 1}\right) u - \kappa T_x\right]_x = nuE - \frac{1}{\sigma}\left(\frac{nu^2}{2} + \frac{n(T - T_L)}{\gamma - 1}\right), \tag{1.3}$$

supplemented by the Poisson equation

$$E_x = n - b. \tag{1.4}$$

Here, the positive constants γ ($\gamma > 1$), τ, and σ are the adiabatic exponent, the (scaled) momentum relaxation time, and the (scaled) energy relaxation time, respectively. The coefficient $\kappa = \tau\kappa'$ is the heat conductivity. In this paper, we will consider the case $\kappa = 0$, so that the hydrodynamic part of the model is hyperbolic. The functions $T_L(x)$ and $b(x)$ are the lattice temperature and the doping profile, respectively. For simplicity, we assume that the lattice temperature is constant. Then, we can set $T_L = 1$. We assume that the doping profile satisfies the conditions

$$b(x) \in C^2(\mathbb{R}), \tag{1.5}$$

$$b(x) > 0, \quad x \in \mathbb{R}, \qquad \lim_{x \to \pm\infty} b(x) = b^{\pm} > 0. \tag{1.6}$$

The condition (1.5) could be weakened, for instance, assuming that there exists a function $B(x) \in C^2(\mathbb{R})$ such that

$$B(x) > 0, \quad B'(x) \in L^1(\mathbb{R}) \cap H^1(\mathbb{R}), \quad b(x) - B(x) \in H^1(\mathbb{R}).$$

The hydrodynamic model (1.1)–(1.4) has been introduced in [4] and [5], to describe electron flow when the transport of energy in the semiconductor plays a crucial role, as in submicron devices or in the occurrence of high field phenomena [16]. A careful discussion of the physical validity of this model can be found in [3].

Now we consider the transformation

$$t = \frac{t'}{\tau}, \qquad u = \tau u'. \tag{1.7}$$

Skipping the prime, the transformed variables satisfy

$$n_t + (nu)_x = 0, \tag{1.8}$$

$$(\alpha n u)_t + \left(\alpha n u^2 + nT\right)_x = nE - nu, \tag{1.9}$$

$$\left(\frac{\alpha}{2} n u^2 + \frac{nT}{\gamma - 1}\right)_t + \left(\frac{\alpha}{2} n u^3 + \frac{\gamma n T}{\gamma - 1} u - \kappa' T_x\right)_x = nuE - \frac{1}{\beta}\left(\frac{\alpha}{2} n u^2 + \frac{n(T-1)}{\gamma - 1}\right), \tag{1.10}$$

$$E_x = n - b, \tag{1.11}$$

where

$$\alpha = \tau^2, \quad \beta = \tau\sigma.$$

In terms of the original physical variables, we have

$$\alpha = \frac{k_B T_L}{m_e \bar{x}^2} \tau_p^2, \quad \beta = \frac{k_B T_L}{m_e \bar{x}^2} \tau_p \tau_w,$$

where k_B is the Boltzmann constant, m_e is the electron mass, τ_p is the momentum relaxation time, τ_w is the energy relaxation time, and $\bar{x}$ is a characteristic length scale. Typically, for an n^+-n-n^+ channel in a MOSFET [8], α is of order 10^{-2} and β of order 1.

We treat the positive numbers α and β as parameters. If α, $\beta \neq 0$, the system (1.8)–(1.11) is perfectly equivalent to the original system (1.1)–(1.4). A preliminary numerical and theoretical study of this model with nonzero heat conductivity $\kappa = \tau\kappa_0 nT$, where κ_0 is a positive constant, can be found in [8]. More recently, for the same model (with constant $\kappa > 0$), the global existence of smooth solutions, in a bounded domain and for small initial data, has been proved in [6] under the assumption that the doping profile is close enough to a constant function. If $\kappa' = 0$, (1.8)–(1.11) constitute a hyperbolic-elliptic system. Some analytic results are known for the related isentropic hydrodynamic model. In particular, the existence of weak solutions has been proved in [13] and [14], and the global existence of smooth solutions for small initial data has been proved in [11].

If $\alpha = 0$ and $\beta \neq 0$, we obtain a parabolic-elliptic system, known as the energy-transport model. The hydrodynamic part of this system is strongly parabolic if $\kappa' > 0$

and weakly parabolic if $\kappa' = 0$. For the time-dependent energy-transport model, no rigorous analytic results are known. The existence and uniqueness of stationary solutions for a general class of energy-transport models has been established in [7].

If $\alpha = \beta = 0$, we obtain the well-known time-dependent drift-diffusion model (see [16]).

The formal limits of (1.8)–(1.11) as α or β tend to zero have been obtained first in [2] and [1]. In some cases, this formal procedure can be rigorously justified. For $\kappa' = 0$, singular relaxation limit results have been obtained in [14] for the isentropic model and in [9] for the full system. In particular, in the last paper the authors postulate the existence of a time-dependent solution $(\bar{n}, \bar{u}, \bar{T}, \bar{E})(x,t)$ of the original system (1.1)–(1.4), satisfying the uniform bound

$$||(\bar{n}, \bar{u}, \bar{T})||_{L^\infty(\mathbb{R}\times\mathbb{R}_+)} \le \bar{C}, \tag{1.12}$$

where the positive constant $\bar{C}$ is independent on τ. Then, as τ tends to zero with β constant, the function $(n,u,T,E)(x,t) = (\bar{n}, \frac{1}{\tau}\bar{u}, \bar{T}, \bar{E})(x, \frac{1}{\tau}t)$ tends to a weak solution of (1.8)–(1.11) with $\alpha = 0$.

Also, we mention the singular relaxation limit result in [6], connecting the Euler–Poisson system (1.1)–(1.4), with $\kappa > 0$, to the drift-diffusion system as τ and σ tend to zero, with $0 \le 2\sigma - \tau \le M\sqrt{\tau\sigma}$.

In this paper, we are mainly interested in studying the global existence (in time) of solutions of the initial value problem for (1.8)–(1.11), with $\beta > \alpha \ge 0$ and $\kappa' = 0$.

Generally speaking, as time increases, we expect the solutions of (1.8)–(1.11) to approach the solutions of the corresponding stationary system. In particular, from (1.8), any stationary solution must satisfy

$$nu = j = \text{constant}. \tag{1.13}$$

If $j = 0$, the stationary solution reduces to $(n,u,T,E) = (\mathcal{N}, 0, 1, \mathcal{E})$, where $\mathcal{N}$ and $\mathcal{E}$ satisfy the stationary drift-diffusion equations

$$\begin{aligned} &\mathcal{N}_x = \mathcal{N}\mathcal{E}, \\ &\mathcal{E}_x = \mathcal{N} - b. \end{aligned} \tag{1.14}$$

In [11], the authors prove the existence and uniqueness of solutions to a slightly more general system than (1.14), satisfying the conditions

$$\mathcal{N}(x) - b(x) \in H^1(\mathbb{R}), \qquad \lim_{x\to-\infty} \mathcal{E}(x) = 0. \tag{1.15}$$

The function $\mathcal{N}(x)$ belongs to $C^2(\mathbb{R})$, and satisfies the estimate [11]

$$\inf_{x\in\mathbb{R}} b(x) \le \mathcal{N}(x) \le \sup_{x\in\mathbb{R}} b(x), \tag{1.16}$$

which ensures the strict positivity of $\mathcal{N}(x)$.

With these motivations, we assume that the initial data for (1.8)–(1.11),

$$\begin{aligned} &n(x,0) = n_0(x), \quad u(x,0) = u_0(x), \quad T(x,0) = T_0(x), \\ &E(x,0) = E_0(x) \equiv \int_{-\infty}^{x} (n_0(x') - b(x'))dx', \end{aligned} \tag{1.17}$$

are given as perturbations of the stationary solution $(\mathcal{N}(x), 0, 1, \mathcal{E}(x))$, satisfying (1.14). More precisely, we assume that the differences

$$n_0(x) - \mathcal{N}(x), \quad u_0(x) - 0, \quad T_0(x) - 1, \quad E_0(x) - \mathcal{E}(x)$$

belong to $H^2(\mathbb{R})$, and their H^2-norms are small enough. Also, we assume the conditions

$$\begin{aligned} &n(x,t) - b(x) \in H^1(\mathbb{R}), \\ &\lim_{x\to-\infty} E(x,t) = \lim_{x\to-\infty} u(x,t) = 0 \quad \forall t \in (0,+\infty). \end{aligned} \tag{1.18}$$

The only requirement for the unperturbed state is that

$$||\mathcal{E}||_{C^2} < +\infty. \tag{1.19}$$

Under these assumptions, we will show that the solution of the initial value problem (1.8)–(1.11) exists uniquely and globally in time and that it is a classical solution for $t > 0$. Moreover, it decays exponentially in the H^2-norm to the stationary solution, according to the estimate

$$\begin{aligned} &||(n - \mathcal{N}, \tau u, T - 1, E - \mathcal{E})(\cdot, t)||^2_{H^2} \\ &\leq K' e^{-Ct} ||(n - \mathcal{N}, \tau u, T - 1, E - \mathcal{E})(\cdot, 0)||^2_{H^2}, \end{aligned} \tag{1.20}$$

with K' and C positive constants independent on τ.

The a priori estimate (1.20) yields a remarkable consequence. Since (1.20) is valid also for $\alpha \equiv \tau^2 = 0$, it is possible to extend our global existence result to the energy-transport model. More precisely, let $(n^\alpha, u^\alpha, T^\alpha, E^\alpha)(x,t)$ be a solution of the system (1.8)–(1.11). Then, using (1.20) and the independence on α of the constants K' and C, there exist some limit functions $(\bar{n}, \bar{T}, \bar{E})(x,t)$ to which $(n^\alpha, T^\alpha, E^\alpha)(x,t)$ converge as α tends to zero. The limit solution satisfies the energy-transport model (1.8)–(1.11), with $\alpha = 0$. This result is closely related to the relaxation results proved in [9].

The proof of the estimate (1.20) is based on an energy method which is a modification of a method previously introduced in [15] for the compressible Navier–Stokes equations.

In [11], an a priori estimate of the kind (1.20) is derived for the isentropic model, under special assumptions on the doping profile. These assumptions amount to saying that the doping profile has to be close to a constant function, in a suitable norm. Using this condition it is possible to ensure the smallness of the C^2-norm of $\mathcal{E}$, which is required in the proof of the a priori estimate. The same kind of restriction on the doping profile is assumed in [6], with similar motivations. Unfortunately, this restriction is not compatible with the physical case of a doping profile with large gradient variations. This problem is not present in our approach, since the smallness of the C^2-norm of $\mathcal{E}$ is not required. The main idea is that, if (1.19) holds, we can control the effect of the first two derivatives of $\mathcal{E}$ on the solution of (1.8)–(1.11) by using a suitable weighted energy which combines the L^2-norm of the solution and the L^2-norm of its derivatives, as expounded in section 4.

The same method, with minor modifications, can be applied to the two- and three-dimensional version of (1.8)–(1.11). This extension will be the subject of a subsequent paper.

In section 2 we derive the perturbation equations around a given stationary solution, along with the appropriate initial data and boundary conditions. Then, in section 3, we discuss the positive definiteness of some functionals related to the definition of the energy. In the subsequent section, we apply the energy method in order to prove the a priori estimate (1.20). Finally, in section 5, we state and prove the consequent global existence result and asymptotic decay of the perturbation.

2. Perturbation equations. In this section, we derive the perturbation equations of system (1.8)–(1.11) around a steady solution $(n, u, T, E) = (\mathcal{N}, 0, 1, \mathcal{E})$, where $(\mathcal{N}, \mathcal{E})$ is the unique solution of (1.14), (1.15).

We consider the variable transformations

$$n = \mathcal{N} + v, \tag{2.1}$$

$$T = 1 + \theta, \tag{2.2}$$

$$E = \mathcal{E} + e, \tag{2.3}$$

with

$$|v| < \inf \mathcal{N}, \qquad |\theta| < 1. \tag{2.4}$$

The resulting equations for v, u, θ, and e are

$$v_t + [(\mathcal{N} + v)u]_x = 0, \tag{2.5}$$

$$\alpha u_t + \alpha u u_x + \frac{1}{\mathcal{N} + v}\left[(\mathcal{N} + v)(1 + \theta)\right]_x = e - u + \mathcal{E}, \tag{2.6}$$

$$\theta_t + u\theta_x + (\gamma - 1)(1 + \theta)u_x = au^2 - \frac{\theta}{\beta}, \tag{2.7}$$

$$e_x = v, \tag{2.8}$$

with

$$a = (\gamma - 1)\left(1 - \frac{\alpha}{2\beta}\right).$$

The initial data for v, u, θ, and e are given by

$$v(x, 0) = n_0(x) - \mathcal{N}(x), \qquad \theta(x, 0) = T_0(x) - 1, \tag{2.9}$$

$$u(x, 0) = u_0(x), \qquad e(x, 0) = \int_{-\infty}^{x} [n_0(y) - \mathcal{N}(y)]dy. \tag{2.10}$$

It is convenient to express the perturbations v and θ as

$$v = \mathcal{N}\nu,$$
$$\theta = (1 + \nu)^{\gamma - 1}(1 + s) - 1.$$

Inequalities (2.4) hold if

$$|\nu|, |s| < \frac{\log 2}{\gamma} \equiv \epsilon. \tag{2.11}$$

The functions ν, u, s, and e satisfy

$$\nu_t + [(1 + \nu)u]_x = -\mathcal{E}(1 + \nu)u, \tag{2.12}$$

$$\alpha u_t + \alpha u u_x + \frac{1}{1+\nu}\left[(1+\nu)^\gamma (1+s)\right]_x$$

$$= e - u - \mathcal{E}\left[(1+\nu)^{\gamma-1}(1+s) - 1\right], \tag{2.13}$$

$$s_t + u s_x = -\frac{(1+\nu)^{\gamma-1}(1+s) - 1}{\beta(1+\nu)^{\gamma-1}}$$

$$+\frac{a u^2}{(1+\nu)^{\gamma-1}} + (\gamma-1)\mathcal{E}(1+s)u, \tag{2.14}$$

$$e_x = \mathcal{N}\nu. \tag{2.15}$$

The initial data for ν and s are given by

$$\nu(x,0) = \frac{n_0(x)}{\mathcal{N}(x)} - 1, \quad s(x,0) = T_0(x)\left(\frac{\mathcal{N}(x)}{n_0(x)}\right)^{\gamma-1} - 1. \tag{2.16}$$

For regular solutions, the initial value problems (2.12)–(2.15), (2.16), (2.10), and (1.8)–(1.11), (1.17) are equivalent. Conditions (1.18) become

$$\begin{aligned} &\mathcal{N}(x)\nu(x,t) \in H^1(\mathbb{R}), \\ &\lim_{x\to-\infty} e(x,t) = \lim_{x\to-\infty} u(x,t) = 0 \quad \forall t \in (0,+\infty). \end{aligned} \tag{2.17}$$

Using (2.12), (2.17), and the choice of e_0 in (2.10), the constraint (2.15) can be replaced by the evolution equation

$$e_t + u e_x = -\mathcal{N}u. \tag{2.18}$$

Equations (2.12)–(2.14), (2.18) constitute a quasi-linear system of partial differential equations. It can be written in the form

$$I_\alpha \partial_t U + A_\alpha(U)\partial_x U = S_\alpha(U,x), \tag{2.19}$$

with $U = (\nu, u, s, e)$ and

$$I_\alpha = \operatorname{diag}(1, \alpha, 1, 1), \tag{2.20}$$

$$A_\alpha(U) = \begin{pmatrix} u & 1+\nu & 0 & 0 \\ \gamma(1+\nu)^{\gamma-2}(1+s) & \alpha u & (1+\nu)^{\gamma-1} & 0 \\ 0 & 0 & u & 0 \\ 0 & 0 & 0 & u \end{pmatrix}, \tag{2.21}$$

$$S_\alpha(U,x) = \begin{pmatrix} -\mathcal{E}(1+\nu)u \\ e - u - \mathcal{E}\left[(1+\nu)^{\gamma-1}(1+s) - 1\right] \\ -\frac{(1+\nu)^{\gamma-1}(1+s) - 1 - a\beta u^2}{\beta(1+\nu)^{\gamma-1}} + (\gamma-1)\mathcal{E}(1+s)u \\ -\mathcal{N}u \end{pmatrix}. \tag{2.22}$$

3. Positive definiteness of some functionals of Liapunov type. This section deals with the positive definiteness of some functionals of Liapunov type. The main results are summarized in the final lemma. They will be used in the subsequent section.

We introduce the energy densities

$$\begin{aligned}\mathcal{H}_0 &= \frac{\alpha}{2}\mathcal{N}(1+\nu)u^2 - \frac{\lambda_0}{\beta}\alpha(1+\nu)ue + \frac{1}{2}\left(1+\frac{\lambda_0}{\beta\mathcal{N}}\right)e^2 \\ &+\frac{\mathcal{N}}{\gamma-1}\left[(1+\nu)^\gamma - 1 - \gamma\nu\right](1+s) + \mathcal{N}\nu s + \frac{\mathcal{N}(1+\nu)s^2}{2(\gamma-1)}, \qquad (3.1)\\ \mathcal{H}_i &= \frac{\alpha}{2}\mathcal{N}(1+\nu)(\partial_x^i u)^2 - \frac{\lambda_i}{\beta}\alpha(1+\nu)\partial_x^i u\partial_x^i e \\ &+\frac{1}{2}\left(1+\frac{\lambda_i}{\beta\mathcal{N}}\right)(\partial_x^i e)^2 + \frac{\gamma}{2}\mathcal{N}(1+s)(1+\nu)^{\gamma-2}(\partial_x^i\nu)^2 \\ &+\mathcal{N}(1+\nu)^{\gamma-1}\partial_x^i\nu\partial_x^i s + \frac{\mathcal{N}(1+\nu)^\gamma(\partial_x^i s)^2}{2(\gamma-1)(1+s)}, \quad i=1,2. \qquad (3.2)\end{aligned}$$

Here, λ_0 and λ_i are positive constants. With an appropriate choice of λ_0 and λ_i, and if $|\nu|$ and $|s|$ are small enough, $\mathcal{H}_0$ and $\mathcal{H}_i$ are positive semidefinite, as asserted by the following lemma.

LEMMA 3.1. *If $0 \le \alpha < \beta$, $\lambda_i < 1/2$, and $|\nu|, |s| \le \epsilon'$ for some constant $\epsilon' < 1$, then there exist positive constants $k_{\mathcal{H}}$, $K_{\mathcal{H}}$ (depending on γ, $||\mathcal{N}||_{C^0}$, and ϵ', not depending on α) such that $\mathcal{H}_i$ ($i = 0, 1, 2$) satisfies*

$$k_{\mathcal{H}}|\partial_x^i(\nu, \tau u, s, e)| \le \mathcal{H}_i \le K_{\mathcal{H}}|\partial_x^i(\nu, \tau u, s, e)|,$$

where $\tau = \sqrt{\alpha}$.

Proof. We can decompose the energy densities as

$$\begin{aligned}\mathcal{H}_0 &= g_0(\nu, s) + h(\tau u, e), \\ \mathcal{H}_i &= g(\partial_x^i\nu, \partial_x^i s) + h(\tau\partial_x^i u, \partial_x^i e), \quad i=1,2,\end{aligned} \qquad (3.3)$$

where g_0, g, and h are the quadratic forms

$$\begin{aligned}g_0(X,Y) &= \mathcal{N}\left\{a(\nu)\frac{\gamma}{2}X^2 + b(\nu)XY + \frac{(1+\nu)}{2(\gamma-1)}Y^2\right\}, \\ g(X,Y) &= \mathcal{N}(1+\nu)^{\gamma-1}\left\{\left(\frac{1+s}{1+\nu}\right)\frac{\gamma}{2}X^2 + XY + \left(\frac{1+\nu}{1+s}\right)\frac{Y^2}{2(\gamma-1)}\right\}, \\ h(X,Y) &= \frac{\mathcal{N}}{2}(1+\nu)X^2 - \frac{\lambda_i}{\beta}\tau(1+\nu)XY + \frac{1}{2}\left(1+\frac{\lambda_i}{\beta\mathcal{N}}\right)Y^2.\end{aligned}$$

Here, the functions $a(\nu)$ and $b(\nu)$ are defined by

$$\begin{aligned}a(\nu) &= \frac{(1+\nu)^\gamma - 1 - \gamma\nu}{(\gamma/2)(\gamma-1)\nu^2} \quad \text{if } \nu \ne 0, \qquad a(0) = 1, \\ b(\nu) &= \frac{(1+\nu)^{\gamma-1} - 1}{(\gamma-1)\nu}(1+\nu) \quad \text{if } \nu \ne 0, \qquad b(0) = 1.\end{aligned}$$

First, we show that g_0 is positive definite for $|\nu| \le \epsilon' < 1$. It is simple to check that $a(\nu)$ and $b(\nu)$ are strictly positive and continuous functions for $|\nu| \le \epsilon'$. In particular, a is a decreasing function if $\gamma < 2$, a constant function if $\gamma = 2$, and an increasing function if $\gamma > 2$, and b is an increasing function. Then we have

$$\begin{aligned}&\frac{m_0}{2}\left(\gamma X^2 - 2|XY| + \frac{1}{\gamma-1}Y^2\right) \\ &\le g_0(X,Y) \le \frac{M_0}{2}\left(\gamma X^2 + 2|XY| + \frac{1}{\gamma-1}Y^2\right),\end{aligned}$$

where

$$m_0 = \inf \mathcal{N} \min\{a(-\epsilon'), a(\epsilon'), b(-\epsilon'), 1-\epsilon'\},$$
$$M_0 = \sup \mathcal{N} \max\{a(-\epsilon'), a(\epsilon'), b(\epsilon'), 1+\epsilon'\}.$$

The positive definiteness of g_0 follows immediately from the inequality

$$\frac{m_0}{2}\mu_0^-(X^2+Y^2) \le g_0(X,Y) \le \frac{M_0}{2}\mu_0^+(X^2+Y^2), \tag{3.4}$$

with

$$\mu_0^{\pm} = \frac{\gamma}{2} + \frac{1}{2(\gamma-1)} \pm \sqrt{\left(\frac{\gamma}{2} - \frac{1}{2(\gamma-1)}\right)^2 + 1}.$$

Next, we consider the quadratic form g. If $|\nu|, |s| \le \epsilon' < 1$, we have

$$\frac{m}{2}\left(\frac{\gamma}{r}X^2 + 2XY + \frac{r}{\gamma-1}Y^2\right)$$
$$\le g(X,Y) \le \frac{M}{2}\left(\frac{\gamma}{r}X^2 + 2XY + \frac{r}{\gamma-1}Y^2\right),$$

where

$$m = \inf \mathcal{N}(1-\epsilon')^{\gamma-1}, \quad M = \sup \mathcal{N}(1+\epsilon')^{\gamma-1}, \quad r = \frac{1+\nu}{1+s}.$$

The function r is bounded in the interval $(\frac{1-\epsilon'}{1+\epsilon'}, \frac{1+\epsilon'}{1-\epsilon'})$. The positive definiteness of g follows from the inequality

$$\frac{m}{2}\min \mu^-(r)(X^2+Y^2) \le g(X,Y) \le \frac{M}{2}\max \mu^+(r)(X^2+Y^2), \tag{3.5}$$

with

$$\mu^{\pm}(r) = \frac{\gamma}{2r} + \frac{r}{2(\gamma-1)} \pm \sqrt{\left(\frac{\gamma}{2r} - \frac{r}{2(\gamma-1)}\right)^2 + 1}.$$

Finally, the quadratic form h is positive definite if and only if

$$\alpha(1+\nu)\left(\frac{\lambda_i}{\beta}\right)^2 - \frac{\lambda_i}{\beta} - \mathcal{N} < 0,$$

which implies

$$\alpha\frac{\lambda_i}{\beta} < \frac{1+\sqrt{1+4\alpha\mathcal{N}(1+\nu)}}{2(1+\nu)}.$$

This inequality is always satisfied if $\lambda_i \le 1/2$ and $|\nu| < 1$. We have

$$\frac{1}{4}\inf \mu_h^-(X^2+Y^2) \le h(X,Y) \le \frac{1}{4}\sup \mu_h^+(X^2+Y^2), \tag{3.6}$$

where

$$\mu_h^{\pm} = 1 + \frac{\lambda_i}{\beta\mathcal{N}} + \mathcal{N}(1+\nu) \pm \sqrt{\left(1 + \frac{\lambda_i}{\beta\mathcal{N}} - \mathcal{N}(1+\nu)\right)^2 + \frac{\lambda_i^2}{\beta}(1+\nu)^2}.$$

The thesis of the lemma follows from (3.3), (3.4), (3.5), and (3.6). ∎

Now we define the functionals

$$\begin{aligned}\mathcal{D}_0 = \frac{\mathcal{N}}{\beta}\Big\{&(\beta - \alpha\lambda_0)u^2 + \frac{\lambda_0}{\mathcal{N}}e^2 - \frac{\lambda_0}{\mathcal{N}}\mathcal{E}(\gamma-1)e\nu - \frac{\lambda_0}{\mathcal{N}}\mathcal{E}es \\ &+(\gamma - 1 + \gamma\lambda_0)\nu^2 + (2+\lambda_0)\nu s + \frac{s^2}{\gamma-1}\Big\}, \end{aligned} \tag{3.7}$$

$$\begin{aligned}\mathcal{D}_i = \frac{\mathcal{N}}{\beta}\Big\{&(\beta - \alpha\lambda_i)(\partial_x^i u)^2 + \frac{\lambda_i}{\mathcal{N}}(\partial_x^i e)^2 \\ &+(\gamma - 1 + \gamma\lambda_i)(\partial_x^1\nu)^2 + (2+\lambda_i)\partial_x^1\nu\partial_x^1 s + \frac{(\partial_x^1 s)^2}{\gamma-1}\Big\}, \quad i = 1,2. \end{aligned} \tag{3.8}$$

We prove that the quadratic forms $\mathcal{D}_0$ and $\mathcal{D}_i$, are positive definite, with an appropriate choice of λ_0 and λ_i.

LEMMA 3.2. *If $0 \le \alpha < \beta$, $\lambda_i < 1$ $(i = 0,1,2)$, and*

$$\lambda_0 < \frac{4}{\gamma-1}\inf\left\{\frac{\mathcal{N}}{\mathcal{N}+\mathcal{E}^2}\right\}, \qquad \lambda_1, \lambda_2 < \frac{4}{\gamma-1},$$

then there exist positive constants $k_{\mathcal{D}}$, $K_{\mathcal{D}}$ (depending on γ and $||(\mathcal{N},\mathcal{E})||_{C^0}$, not depending on α) such that $\mathcal{D}_i$ $(i = 0,1,2)$ satisfy

$$k_{\mathcal{D}}|\partial_x^i U|^2 \le \mathcal{D}_i \le K_{\mathcal{D}}|\partial_x^i U|^2.$$

Proof. We can decompose the quadratic form $\beta\mathcal{D}_0/\mathcal{N}$ as

$$\beta\mathcal{D}_0/\mathcal{N}(u,e,\nu,s) = (\beta - \alpha\lambda_0)u^2 + \mathcal{D}'(e,\nu,s).$$

The coefficient of u^2 is positive, since $\lambda_0 < 1$ and

$$0 < \beta(1-\lambda_0) < \beta - \alpha\lambda_0 \le \beta. \tag{3.9}$$

The matrix associate to the quadratic form $\mathcal{D}'$ with respect to (e,ν,s) is

$$A = \begin{pmatrix} \lambda_0/\mathcal{N} & -\frac{1}{2}\lambda_0(\gamma-1)\mathcal{E}/\mathcal{N} & -\frac{1}{2}\lambda_0\mathcal{E}/\mathcal{N} \\ -\frac{1}{2}\lambda_0(\gamma-1)\mathcal{E}/\mathcal{N} & \gamma - 1 + \lambda_0\gamma & 1 + \lambda_0/2 \\ -\frac{1}{2}\lambda_0\mathcal{E}/\mathcal{N} & 1 + \lambda_0/2 & 1/(\gamma-1) \end{pmatrix}.$$

This matrix is definite positive if its determinant is positive together with the determinants of the following minors:

$$A_1 = \begin{pmatrix} \gamma - 1 + \lambda_0\gamma & 1 + \lambda_0/2 \\ 1 + \lambda_0/2 & 1/(\gamma-1) \end{pmatrix}, \qquad A_2 = \begin{pmatrix} 1/(\gamma-1) \end{pmatrix}.$$

Explicitly, these conditions amount to

$$\begin{aligned} &\frac{\lambda_0^2}{4\mathcal{N}}\left[\frac{4}{\gamma-1} - \lambda_0\left(\frac{\mathcal{N}+\mathcal{E}^2}{\mathcal{N}}\right)\right] > 0, \\ &\frac{\lambda_0}{4}\left(\frac{4}{\gamma-1} - \lambda_0\right) > 0, \\ &\frac{1}{\gamma-1} > 0. \end{aligned}$$

The previous inequalities are satisfied altogether if

$$0 < \lambda_0 < \frac{4}{\gamma - 1} \inf \left\{ \frac{\mathcal{N}}{\mathcal{N} + \mathcal{E}^2} \right\},$$

which holds by hypothesis. We can conclude that $\mathcal{D}_0$ is positive definite. Moreover, using (3.9), we can determine appropriate constants $k_{\mathcal{D}}$, $K_{\mathcal{D}}$, independent on α, such that the thesis holds. The positive definiteness of $\mathcal{D}_1$ and $\mathcal{D}_2$ follows immediately from the previous discussion, after setting $\mathcal{E} = 0$ and replacing λ_0 with λ_1 and λ_2, respectively. ∎

The following lemma follows immediately from Lemmas 3.1 and 3.2.

LEMMA 3.3. *If* $0 \le \alpha < \beta$, $|\nu|, |s| \le \epsilon' < 1$, *and*

$$\lambda_i < 1/2, \qquad \lambda_i < \frac{4}{\gamma - 1} \inf \left\{ \frac{\mathcal{N}}{\mathcal{N} + \mathcal{E}^2} \right\}, \qquad i = 0, 1, 2, \tag{3.10}$$

then there exist some positive constants $k_{\mathcal{H}}$, $K_{\mathcal{H}}$, $k_{\mathcal{D}}$, $K_{\mathcal{D}}$ *(dependent on* γ *and* ϵ'*) such that the functions* $\mathcal{H}_i$ *and* $\mathcal{D}_i$ *(*$i = 0, 1, 2$*) satisfy*

$$k_{\mathcal{H}} ||\partial_x^i(\nu, \tau u, s, e)||_{L^2}^2 \le \int \mathcal{H}_i dx \le K_{\mathcal{H}} ||\partial_x^i(\nu, \tau u, s, e)||_{L^2}^2, \tag{3.11}$$

$$k_{\mathcal{D}} ||\partial_x^i U||_{L^2}^2 \le \int \mathcal{D}_i dx \le K_{\mathcal{D}} ||\partial_x^i U||_{L^2}^2. \tag{3.12}$$

In particular, (3.11) *implies*

$$\int \mathcal{H}_i dx \le K'_{\mathcal{H}} ||\partial_x^i U||_{L^2}^2, \tag{3.13}$$

with

$$K'_{\mathcal{H}} = \max\{1, \beta\} K_{\mathcal{H}}.$$

4. A priori estimates. In this section, we establish a basic energy estimate for any given local solution of (2.12)–(2.15), with $|U| < \epsilon$. The constant ϵ is defined in (2.11).

For some fixed positive number T, we assume that a solution of (2.12)–(2.14), (2.18) exists for $t \in (0, T)$, and define

$$\mathcal{U}(T) = \sup_{0 \le t \le T} ||U(\cdot, t)||_{H^2}^2. \tag{4.1}$$

Using the standard Sobolev inequalities, there exists a positive constant $C_{\mathcal{U}}$ such that

$$\sup_{0 \le t \le T} ||U(\cdot, t)||_{C^1} \le C_{\mathcal{U}} \mathcal{U}(T). \tag{4.2}$$

We introduce the energy

$$\mathcal{W} = \int (\mathcal{H}_0 + \eta_1 \mathcal{H}_1 + \eta_2 \mathcal{H}_2)\, dx,$$

where the energy densities $\mathcal{H}_i$ are defined by (3.1), (3.2) and η_1, η_2 are positive constants to be determined.

LEMMA 4.1. *If $0 \le \alpha < \beta$, there exist positive constants ϵ', η_1, and η_2 such that if the solution is so small that $\mathcal{U}(T) \le \epsilon'$, the following a priori estimate holds for $t \in [0,T]$:*

$$\mathcal{W}(t) \le e^{-Ct}\mathcal{W}(0), \tag{4.3}$$

where the constant $C = k_{\mathcal{D}}/(4K'_{\mathcal{H}})$ is independent on α.

Proof. To begin with, we consider the function $\mathcal{H}_0$ defined by (3.1). A long but straightforward calculation shows that

$$\begin{aligned}
&\partial_t \mathcal{H}_0 = \{\cdots\}_x \\
&-\frac{\mathcal{N}}{\beta}(1+\nu)\left\{\left[\beta - \alpha\lambda_0 - (2\beta-\alpha)\frac{(1+\nu)^{\gamma-1}-1+s}{2(1+\nu)^{\gamma-1}}\right]u^2\right. \\
&+\frac{\lambda_0}{\mathcal{N}}e^2 + \left[\frac{((1+\nu)^{\gamma-1}-1)^2}{(\gamma-1)(1+\nu)^{\gamma-1}} + \frac{\lambda_0\nu}{1+\nu}((1+\nu)^{\gamma}-1)\right] \\
&\left.+\left[\frac{(1+\nu)^{2(\gamma-1)}-1}{(\gamma-1)(1+\nu)^{\gamma-1}} + \lambda_0(1+\nu)^{\gamma-1}\nu\right]s + \frac{s^2}{\gamma-1}\right\} \\
&+\mathcal{E}(1+\nu)\left[\frac{\lambda_0}{\beta}((1+\nu)^{\gamma-1}(1+s)-1)e + \alpha\frac{\lambda_0}{\beta}eu^2 + \mathcal{N}us^2\right] \\
&= \{\cdots\}_x - \mathcal{D}_0 + \mathcal{I}_0.
\end{aligned} \tag{4.4}$$

Here and in the following, the symbol $\{\cdots\}_x$ denotes the gradient of some unspecified function. This kind of term is not relevant, since it is going to vanish after integration with respect to x on the real line. In (4.4), $\mathcal{D}_0$ is the quadratic form defined by (3.7), and $\mathcal{I}_0$ collects all the remaining terms. For $|U| < \epsilon$, $\mathcal{I}_0$ is essentially cubic in the dependent variables, meaning that

$$|\mathcal{I}_0| \le c'_0|U|^3 \tag{4.5}$$

for some positive constant c'_0, independent on α. We note that c'_0 depends on the function $\mathcal{E}$, which appears in $\mathcal{I}_0$. Now, we integrate (4.4) with respect to x on the real line, and estimate the resulting right-hand side. From (4.5), we have

$$\int \mathcal{I}_0 dx \le c'_0||U||_{C^0}||U||^2_{L^2} \le c_0\mathcal{U}||U||^2_{L^2}, \tag{4.6}$$

with $c_0 \equiv c'_0 C_{\mathcal{U}}$. In conclusion, using (3.12), at zero order we find the estimate

$$\partial_t\left(\int \mathcal{H}_0 dx\right) = -\int \mathcal{D}_0 dx + \int \mathcal{I}_0 dx \le -(k_{\mathcal{D}} - c_0\mathcal{U})||U||^2_{L^2}. \tag{4.7}$$

Next, we consider the function $\mathcal{H}_1$, defined by (3.2). We find

$$\begin{aligned}
&\partial_t \mathcal{H}_1 = \{\cdots\}_x - \mathcal{D}_1 + \mathcal{I}_1 \\
&+\frac{\lambda_1}{\beta}\mathcal{E}\mathcal{N}\left[\alpha(1+\nu)^2 u u_x - (1+\nu)^{\gamma-1}(1+s)\nu\nu_x\right. \\
&\left.-\left(\frac{\beta}{\lambda_1} + \frac{1+\nu}{\mathcal{N}}\right)ue_x\right] + \frac{\lambda_1}{\beta}\mathcal{E}_x(1+\nu)\left[(1+\nu)^{\gamma-1}(1+s)-1\right]e_x \\
&-\mathcal{E}_x\mathcal{N}\left\{\left[(1+\nu)^{\gamma}(1+s)-1-\nu\right]u_x + (1+\nu)^{\gamma-1}(1+s)u\nu_x\right\}.
\end{aligned} \tag{4.8}$$

In (4.8), $\mathcal{D}_1$ is the quadratic form defined by (3.8) and $\mathcal{I}_1$ collects all the remaining terms not involving $\mathcal{E}$.

We integrate (4.8) with respect to x on the real line, and estimate the right-hand side for $|U| < \epsilon$. The function $\mathcal{I}_1$ is bounded by

$$|\mathcal{I}_1| \leq c_1'(|U| + |U_x|)|U_x|^2. \tag{4.9}$$

Then we have

$$\int \mathcal{I}_1 dx \leq c_1' ||U||_{C^1} ||U_x||_{L^2}^2 \leq c_1 \mathcal{U} ||U_x||_{L^2}^2, \tag{4.10}$$

with $c_1 \equiv c_1' C_{\mathcal{U}}$. For the remaining terms in (4.8) involving $\mathcal{E}$, we find

$$\begin{aligned} &\int \left\{ \frac{\lambda_1}{\beta} \mathcal{E}\mathcal{N} \left[\alpha(1+\nu)^2 u u_x - (1+\nu)^{\gamma-1}(1+s)\nu\nu_x \right.\right. \\ &\left. - \left(\frac{\beta}{\lambda_1} + \frac{1+\nu}{\mathcal{N}} \right) u e_x \right] + \frac{\lambda_1}{\beta} \mathcal{E}_x (1+\nu) \left[(1+\nu)^{\gamma-1}(1+s) - 1 \right] e_x \\ &\left. - \mathcal{E}_x \mathcal{N} \left[\left((1+\nu)^{\gamma}(1+s) - 1 - \nu \right) u_x + (1+\nu)^{\gamma-1}(1+s) u \nu_x \right] \right\} dx \\ &\leq 2 d_1 ||\mathcal{E}||_{C^1} ||U||_{L^2} ||U_x||_{L^2} \leq d_1 ||\mathcal{E}||_{C^1} \left(\frac{||U||_{L^2}^2}{\alpha_1} + \alpha_1 ||U_x||_{L^2}^2 \right). \end{aligned} \tag{4.11}$$

Here, d_1 is a positive constant, α_1 is a positive parameter that will be appropriately chosen later. In conclusion, using (3.12), at first order we find the estimate

$$\begin{aligned} \partial_t \left(\int \mathcal{H}_1 dx \right) &\leq \frac{d_1}{\alpha_1} ||\mathcal{E}||_{C^1} ||U||_{L^2}^2 \\ &- \left(k_{\mathcal{D}} - c_1 \mathcal{U} - \alpha_1 d_1 ||\mathcal{E}||_{C^1} \right) ||U_x||_{L^2}^2. \end{aligned} \tag{4.12}$$

Next, we consider the function $\mathcal{H}_2$, defined by (3.2). Derivating with respect to time, and using the identity

$$e_{xx} = \mathcal{N}\nu_x + \mathcal{E} e_x,$$

we can write

$$\partial_t \mathcal{H}_2 = \{\cdots\}_x - \mathcal{D}_2 + \mathcal{I}_2 + \text{terms containing } \mathcal{E},\ \mathcal{E}_x,\ \mathcal{E}_{xx}. \tag{4.13}$$

In (4.13), $\mathcal{D}_2$ is the quadratic form defined by (3.8), and $\mathcal{I}_2$ collects all the remaining terms not involving the function $\mathcal{E}$.

We integrate (4.13) with respect to x on the real line, and estimate the right-hand side for $|U| < \epsilon$ and $|\nu_x| < \epsilon$. We find that $\mathcal{I}_2$ is bounded by

$$|\mathcal{I}_2| \leq c_2' \left\{ (|U| + |U_x|)|U_{xx}|^2 + |U_x|^3 \right\}. \tag{4.14}$$

Then we have

$$\begin{aligned} \int \mathcal{I}_2 dx &\leq c_2' \left\{ ||U||_{C^1} ||U_{xx}||_{L^2}^2 + ||U||_{C^0} ||U_x||_{L^2}^2 \right\} \\ &\leq c_2 \mathcal{U} \left\{ ||U_{xx}||_{L^2}^2 + ||U_x||_{L^2}^2 \right\}, \end{aligned} \tag{4.15}$$

with $c_2 \equiv c_2' C_{\mathcal{U}}$.

The remaining terms involving $\mathcal{E}$ and its first two derivatives can be estimated as

$$\begin{aligned} &\int \{\text{terms containing } \mathcal{E},\, \mathcal{E}_x,\, \mathcal{E}_{xx}\}\, dx \\ &\leq d_2 ||\mathcal{E}||_{C^2} \left(\frac{||U||_{L^2}^2 + ||U_x||_{L^2}^2}{2\alpha_2} + \alpha_2 ||U_{xx}||_{L^2}^2 \right). \end{aligned} \tag{4.16}$$

Here, d_2 is a positive constant, α_2 is a positive parameter that will be appropriately chosen later. In conclusion, using (3.12), at second order we find the estimate

$$\begin{aligned} &\partial_t \left(\int \mathcal{H}_2 dx \right) \leq \frac{d_2}{2\alpha_2} ||\mathcal{E}||_{C^2} (||U||_{L^2}^2 + ||U_x||_{L^2}^2) \\ &+c_2 \mathcal{U} ||U_x||_{L^2}^2 - (k_{\mathcal{D}} - c_2 \mathcal{U} - \alpha_2 d_2 ||\mathcal{E}||_{C^2})\, ||U_{xx}||_{L^2}^2. \end{aligned} \tag{4.17}$$

Now we can estimate the energy $\mathcal{W}$ by using (4.7), (4.12), and (4.17). We find

$$\begin{aligned} &\partial_t \mathcal{W} \equiv \partial_t \left(\int \mathcal{H}_0 dx + \eta_1 \int \mathcal{H}_1 dx + \eta_2 \int \mathcal{H}_2 dx \right) \\ &\leq - \left(k_{\mathcal{D}} - c_0 \mathcal{U} - \frac{\eta_1 d_1}{\alpha_1} ||\mathcal{E}||_{C^1} - \frac{\eta_2 d_2}{2\alpha_2} ||\mathcal{E}||_{C^2} \right) ||U||_{L^2}^2 \\ &-\eta_1 \left(k_{\mathcal{D}} - \bar{c}_1 \mathcal{U} - \alpha_1 d_1 ||\mathcal{E}||_{C^1} - \frac{\eta_2 d_2}{2\eta_1 \alpha_2} ||\mathcal{E}||_{C^2} \right) ||U_x||_{L^2}^2 \\ &-\eta_2 \left(k_{\mathcal{D}} - c_2 \mathcal{U} - \alpha_2 d_2 ||\mathcal{E}||_{C^2} \right) ||U_{xx}||_{L^2}^2, \end{aligned} \tag{4.18}$$

with $\bar{c_1} = c_1 + (\eta_2/\eta_1) c_2$. We recall that $k_{\mathcal{D}}$, c_0, c_1, c_2, d_1, and d_2 are positive constants (independent on α), α_1, α_2, η_1, and η_2 are positive parameters to be chosen. We choose

$$\alpha_1 = \frac{k_{\mathcal{D}}}{4 d_1 ||\mathcal{E}||_{C^1}}, \qquad \alpha_2 = \frac{k_{\mathcal{D}}}{2 d_2 ||\mathcal{E}||_{C^2}}, \tag{4.19}$$

$$\eta_1 = \frac{2 k_{\mathcal{D}}^2}{k_{\mathcal{D}}^2 + 16 d_1^2 ||\mathcal{E}||_{C^1}^2}, \qquad \eta_2 = \frac{\eta_1 k_{\mathcal{D}}^2}{4 d_2^2 ||\mathcal{E}||_{C^2}^2}. \tag{4.20}$$

Substituting in (4.18), we obtain

$$\begin{aligned} &\partial_t \mathcal{W} \leq - (k_{\mathcal{D}}/2 - c_0 \mathcal{U})\, ||U||_{L^2}^2 \\ &-\eta_1 (k_{\mathcal{D}}/2 - \bar{c}_1 \mathcal{U})\, ||U_x||_{L^2}^2 - \eta_2 (k_{\mathcal{D}}/2 - c_2 \mathcal{U})\, ||U_{xx}||_{L^2}^2. \end{aligned} \tag{4.21}$$

If the solution satisfies

$$\mathcal{U}(T) \leq \epsilon' \equiv \min \left\{ \epsilon, \frac{k_{\mathcal{D}}}{4 \max\{c_0, \bar{c}_1, c_2\}} \right\}, \tag{4.22}$$

we have

$$\partial_t \mathcal{W} \leq -(k_{\mathcal{D}}/4) \left(||U||_{L^2}^2 + \eta_1 ||U_x||_{L^2}^2 + \eta_2 ||U_{xx}||_{L^2}^2 \right). \tag{4.23}$$

Then, using (3.13), we get the estimate

$$\partial_t \mathcal{W} \leq - \frac{k_{\mathcal{D}}}{4 K_{\mathcal{H}}'} \mathcal{W}. \tag{4.24}$$

The a priori estimate sought follows immediately from (4.24). □

LEMMA 4.2. *With the same assumptions of Lemma* 4.1, *the following a priori estimate holds for* $t \in [0, T]$*:*

$$||(\nu, \tau u, s, e)(\cdot, t)||^2_{H^2} \leq Ke^{-Ct}||(\nu, \tau u, s, e)(\cdot, 0)||^2_{H^2}, \tag{4.25}$$

where $\tau = \sqrt{\alpha}$*, and the positive constant* C *and* K *are given by*

$$C = \frac{k_{\mathcal{D}}}{4K_{\mathcal{H}} \max\{1, \beta\}}, \qquad K = \frac{K_{\mathcal{H}} \max\{1, \eta_1, \eta_2\}}{k_{\mathcal{H}} \min\{1, \eta_1, \eta_2\}}.$$

5. Global existence in time and asymptotic decay of the perturbation. In this section we state and prove the main theorem of the paper, Theorem 5.1, asserting the global existence in time of classical solutions of the perturbation equations (2.12)–(2.15) and their decay to the unperturbed state. We assume that the reader is familiar with the classical results on the local existence and continuation of regular solutions of quasi-linear hyperbolic systems (see [12]).

Let us consider the Euler–Poisson system (2.12)–(2.15). Using (2.12), (2.17), and the choice of e_0 in (2.10), we have shown in section 2 that the constraint (2.15) can be replaced by the evolution equation (2.18), obtaining the quasi-linear system (2.19). In particular, if $\alpha \neq 0$, (2.19) can be written in the form

$$\partial_t U + A(U)\partial_x U = S(U, x, t), \tag{5.1}$$

with $U = (\nu, u, s, e)$ in the state space $G = \{U : |\nu| < 1, |s| < 1\} \subseteq \mathbb{R}^4$, and

$$A = I_\alpha^{-1} A_\alpha, \qquad S = I_\alpha^{-1} S_\alpha.$$

The system (5.1) is hyperbolic and the matrix $A(U)$ satisfies the following property: for any U there is a positive definite symmetric matrix $\tilde{A}(U)$ smoothly varying with U, and a positive constant c, so that, $\forall U \in G_1$, $\bar{G}_1 \subset G$,

1. $cV \cdot V \leq (\tilde{A}(U)V) \cdot V \leq c^{-1} V \cdot V \ \forall V \in G$;
2. $\tilde{A}(U)A(U)$ is symmetric.

Specifically, the symmetry condition is satisfied with $G_1 = \{U : |\nu| < \epsilon, |s| < \epsilon\}$ and

$$\tilde{A}(U) = \begin{pmatrix} \gamma(1+\nu)^{\gamma-2}(1+s) & 0 & (1+\nu)^{\gamma-1} & 0 \\ 0 & \alpha(1+\nu) & 0 & 0 \\ (1+\nu)^{\gamma-1} & 0 & (1+\nu)^{\gamma}/(1+s) & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}.$$

We denote $U_0 = (\nu_0, u_0, s_0, e_0)$. Now, we are ready to state the global existence theorem announced at the beginning of this section.

THEOREM 5.1 (global existence and asymptotic decay). *If* $0 < \alpha < \beta$ *and* $U_0 \in H^2$*, then there is a positive constant* ϵ' *such that, if*

$$||U_0||_{H^2} < \epsilon',$$

the equations (2.12)–(2.15)*, with condition* (2.17)*, have a unique classical solution* $U(x, t) \in C^1(\mathbb{R} \times [0, \infty))$*. Furthermore,*

$$U \in C^0([0, \infty), H^2) \cap C^1([0, \infty), H^1)$$

and

$$||(\nu, \tau u, s, e)(\cdot, t)||^2_{H^2} \leq Ke^{-Ct}||(\nu, \tau u, s, e)(\cdot, 0)||^2_{H^2},$$

where K and C are positive constants, given by Lemma 4.2*, and $\tau = \sqrt{\alpha}$.*

Proof. Standard methods yield immediately the local H^2 existence of a unique classical solution to the initial value problem for (2.12)–(2.15), written in the form (5.1). Then, using Lemma 4.2, the local solution can be prolonged for all times and the estimate (4.25) holds globally. □

We remark that the constants in the estimate (4.25) are independent on α. Then, the estimate is also valid as α tends to zero, and the limit function is a solution of (2.12)–(2.15) with $\alpha = 0$. This result is better expressed in terms of the original variables $(n, u, T, E)(x, t)$ in (1.1)–(1.4). Using (1.7), we define the rescaled variables

$$(n', u', T', E')(x, t') = \left(n, \frac{1}{\tau}u, T, E\right)\left(x, \frac{1}{\tau}t'\right)$$

and, recalling (1.17), we consider the initial data

$$(n', u', T', E')(x, 0) = (n_0, u_0, T_0, E_0)(x).$$

Using Theorem 5.1, if the initial data for the primed variables are close enough to the steady solution $(\mathcal{N}, 0, 1, \mathcal{E})(x)$ in H^2, then

$$\begin{aligned} &||(n' - \mathcal{N}, \tau u', T' - 1, E' - \mathcal{E})(\cdot, t')||^2_{H^2} \\ &\leq K'e^{-Ct'}||(n_0 - \mathcal{N}, \tau u_0, T_0 - 1, E_0 - \mathcal{E})||^2_{H^2}, \end{aligned} \tag{5.2}$$

with K' and C positive constants independent on τ. This implies

$$\begin{aligned} &||(n - \mathcal{N}, u, T - 1, E - \mathcal{E})(\cdot, t)||^2_{H^2} \\ &\leq K'e^{-C\tau t}||(n_0 - \mathcal{N}, \tau u_0, T_0 - 1, E_0 - \mathcal{E})||^2_{H^2}. \end{aligned} \tag{5.3}$$

THEOREM 5.2 (relaxation). *Let $\beta > 0$. For any fixed $\alpha \equiv \tau^2 > 0$, let $(n, u, T, E) = (n^\alpha, u^\alpha, T^\alpha, E^\alpha)(x, t)$ be a global solution of* (1.1)–(1.4)*, satisfying* (5.3)*. Then, there exist some functions $(\hat{n}, \hat{T}, \hat{E})$ which are a smooth solution of* (1.8)–(1.11)*, with $\alpha = 0$, and such that, as α tends to zero,*

$$(n^\alpha, T^\alpha, E^\alpha)\left(x, \frac{1}{\tau}t\right) \to (\hat{n}, \hat{T}, \hat{E})(x, t) \quad \text{in } C([0, \infty); H^2).$$

Furthermore,

$$\begin{aligned} &||(\hat{n} - \mathcal{N}, \hat{T} - 1, \hat{E} - \mathcal{E})(\cdot, t)||^2_{H^2} \\ &\leq K'e^{-Ct}||(n - \mathcal{N}, T - 1, E - \mathcal{E})(\cdot, 0)||^2_{H^2}, \end{aligned} \tag{5.4}$$

where K' and C are positive constants.

OPTIMAL SCHAUDER ESTIMATES FOR PARABOLIC PROBLEMS WITH DATA MEASURABLE WITH RESPECT TO TIME*

LUCA LORENZI†

Abstract. We prove some optimal Schauder estimates for the solution to second-order parabolic equations with coefficients which are measurable with respect to time and Hölder continuous with respect to space variables in the strip $[0,T]\times\mathbb{R}^n$. We allow also polynomially or exponentially weighted Hölder norms.

Key words. linear parabolic equations in $\mathbb{R}^n$ with measurable coefficients, Cauchy problems, weighted spaces, Schauder estimates

1. Introduction.

In this paper, we prove some sharp Schauder estimates and regularity properties for the parabolic second-order Cauchy problem

$$\begin{cases} D_t u(t,x) = \displaystyle\sum_{i,j=1}^{n} q_{i,j}(t,x) D_{i,j} u(t,x) + \sum_{i=1}^{n} b_i(t,x) D_i u(t,x) \\ \qquad + c(t,x)u(t,x) + f(t,x), \qquad (t,x)\in[0,T]\times\mathbb{R}^n, \\ u(0,x) = u_0(x), \qquad x\in\mathbb{R}^n. \end{cases} \tag{1.1}$$

Problem (1.1) has been studied in [7], [8], [9], where the coefficients $Q=[q_{i,j}]$, $B=[b_j]$, and c are bounded and continuous functions in $[0,T]\times\mathbb{R}^n$, Hölder continuous with respect to the space variables, with Hölder norms not depending on t. Moreover, $Q(t,x)$ is assumed to be a definite positive matrix, uniformly with respect to (t,x), and problem (1.1) is studied in the space of bounded and continuous functions in $[0,T]\times\mathbb{R}^n$.

In this paper, we extend the results of [7], [8], [9] to the case of less regular coefficients and of weighted Hölder norms. To be more precise, we analyze the case where the coefficients are bounded and measurable in $[0,T]\times\mathbb{R}^n$ and Hölder continuous in x, uniformly with respect to the variable t. Moreover, we study problem (1.1) in the context of the weighted space $UC_p(\mathbb{R}^n)$ choosing as p either the polynomial function, defined by $p(x)=1+|x|^{2m}$ $\forall x\in\mathbb{R}^n$ ($m\in\mathbb{N}\cup\{0\}$), or the exponential function, defined by $p(x)=\exp((1+|S^{1/2}x|^2)^{1/2})$, $\forall x\in\mathbb{R}^n$, S being any strictly positive and symmetric matrix. We assume also that $Q(t,x)$ is a strictly definite positive and symmetric matrix in $\mathcal{P}\times\mathbb{R}^n$, where $\mathcal{P}$ is a measurable set in $[0,T]$ such that $\mathcal{P}^c\cap[0,T]$ is negligible.

The problem of determining Schauder estimates for parabolic problems, when the coefficients are not continuous in time, has been treated by several authors. Brandt [2] deals with interior Hölder regularity with respect to the space variables, for a wide class of parabolic second-order operators with discontinuous coefficients, by means of a maximum principle and a perturbation argument. Then in [6], the results of [2] are

†Department of Mathematics, University of Parma, via M. D'Azeglio 85/A, I-43100 Parma, Italy (lorenzi@prmat.math.unipr.it).

extended by showing Hölder regularity results, also with respect to the time variable, for the solution to the second-order parabolic problem considered in [2]. Even if in [2] and [6] the authors consider also differential operators with coefficients and datum f that may be discontinuous in time, they are concerned with classical solutions since the proofs of their results are based, essentially, on the maximum principle in [5].

Other related papers concerning Schauder estimates for second-order initial-boundary problems are [10], [14], [3], [1], and [4]. Lieberman [10] is concerned with parabolic problems in bounded domains where the coefficients and the inhomogeneous term are Hölder continuous with respect to the space variables, measurable in time, and, possibly, unbounded near the boundary.

In [3], the authors are concerned with interior $W^{2,p}_{\mathrm{loc}}(\mathbb{R}^n)$ estimates for a solution to a second-order elliptic equation in nondivergence form assuming that the coefficients B and c vanish in $\mathbb{R}^n$ while Q does not depend on t and belongs to $VMO(\mathbb{R}^n)$. In [1], the authors provide interior and boundary estimates in $W^{1,2}_p$ for parabolic problems in the cylinder $\Omega\times(0,T)$, with a smooth enough lateral surface, assuming the second-order operator L to coincide with its principal part and having coefficients in VMO.

Finally, the paper [14] deals with an existence and uniqueness result for the classical solution to (1.1) in weighted spaces, where the weight p is a smooth function depending also on the time variable and increasing no more than polynomially and the coefficients Q, B, and $c<0$ are continuous $\mathbb{R}\times\mathbb{R}^n$. Before stating our main result, we give the following definition of solution to problem (1.1).

DEFINITION 1.1. *A function $u:[0,T]\times\mathbb{R}^n\to\mathbb{R}$ is called a solution to* (1.1) *if the following conditions are fulfilled:*

(i) *$u/p\in \mathrm{Lip}\,([0,T]\times\mathbb{R}^n)$, its first- and second-order space derivatives are continuous and bounded functions in $[0,T]\times\mathbb{R}^n$;*

(ii) *$u(0,x)=u_0(x)$ for any $x\in\mathbb{R}^n$;*

(iii) *there exists a negligible set $F\subset[0,T]\times\mathbb{R}^n$ such that $D_tu(t,x)=\mathcal{A}u(t,x)+f(t,x)$ for any $(t,x)\in([0,T]\times\mathbb{R}^n)\setminus F$. Moreover, for any $x\in\mathbb{R}^n$, the set $F(x)=\{t\in[0,T]:(t,x)\in F\}$ is measurable with measure T.*

THEOREM 1.2. *For any $u_0\in C^{2+\theta}_p(\mathbb{R}^n)$ and any measurable function $f:[0,T]\times\mathbb{R}^n\to\mathbb{R}$ such that $f(t,\cdot)\in C^\theta_p(\mathbb{R}^n)$, for any $t\in[0,T]$ and $\sup_{t\in[0,T]}\|f(t,\cdot)\|_{C^\theta_p(\mathbb{R}^n)}<+\infty$, there exists a unique function $u:[0,T]\times\mathbb{R}^n\to\mathbb{R}$ solution to problem* (1.1) *in the sense of Definition* 1.1 *belonging to $B([0,T];C^{2+\theta}_p(\mathbb{R}^n))$. Moreover, there exists a positive constant C, independent of (u,u_0,f), such that*

$$\sup_{t\in[0,T]}\|u(t,\cdot)\|_{C^{2+\theta}_p(\mathbb{R}^n)}\le C\left(\|u_0\|_{C^{2+\theta}_p(\mathbb{R}^n)}+\sup_{t\in[0,T]}\|f(t,\cdot)\|_{C^\theta_p(\mathbb{R}^n)}\right). \tag{1.2}$$

Note that for $p\equiv1$, Theorem 1.2 gives an optimal regularity result in the usual Hölder spaces. Owing to the lack of regularity of the coefficients with respect to the variable t, we do not expect the solution to problem (1.1) to be continuously t-differentiable in the whole of $[0,T]\times\mathbb{R}^n$ even if the coefficients are smooth with respect to x. Nevertheless, the discontinuity of the coefficients does not influence the regularity of the solution with respect to the space variables. This is not surprising since in [6] a similar result has been proved in bounded domains.

To solve problem (1.1), we first consider, in section 3, the particular case where Q, B, and c are independent of x. In such a case, we are able to find out an explicit representation of the solution u in terms of the data.

Then in section 4, we solve the Cauchy problem (1.1) using the classical method of continuity. First, in section 4.1, we find an a priori estimate for the solution to

problem (1.1). More precisely, we prove that if u solves the Cauchy problem (1.1) in the sense of Definition 1.1, then there exists a positive constant C such that

$$\sup_{t\in[0,T]}\|u(t,\cdot)\|_{C_p^{2+\theta}(\mathbb{R}^n)}\le C\bigg(\|u_0\|_{C_p^{2+\theta}(\mathbb{R}^n)}+\sup_{t\in[0,T]}\|f(t,\cdot)\|_{C_p^{\theta}(\mathbb{R}^n)}\bigg). \tag{1.3}$$

There are several methods to get (1.3). One consists of observing that the Krylov maximum principle holds in our situation and then applying a generalized version of the maximum principle in [5]. Here we prefer to apply the classical method of freezing of coefficients. For this purpose, we heavily use the boundedness of the coefficients in the whole of $[0,T]\times\mathbb{R}^n$

Then in section 4.2, thanks to the a priori estimate, we show, using a classical perturbation argument, that the Cauchy problem (1.1) admits a solution in the sense of Definition 1.1.

Finally, in the appendix, we prove four technical lemmas that have been used throughout the paper.

2. Notations and preliminaries.

DEFINITION 2.1. *For any $k\in\mathbb{N}$, $BUC^k(\mathbb{R}^n)$ denotes the Banach space of all the bounded and continuously differentiable up to the kth-order functions f for which $D^\alpha f$ is uniformly continuous in $\mathbb{R}^n$ for any α with length k. It is normed by*

$$\|f\|_{BUC^k(\mathbb{R}^n)}=\sum_{|\alpha|=0}^{k}\|D^\alpha f\|_\infty. \tag{2.1}$$

DEFINITION 2.2. *For any $T>0$, $\mathrm{Lip}\,([0,T]\times\mathbb{R}^n)$ denotes the vector space of all the functions $f:[0,T]\times\mathbb{R}^n\to\mathbb{R}$ such that*

$$\|f(t_2,x_2)-f(t_1,x_1)\|\le C\big(|t_2-t_1|^2+|x_2-x_1|^2\big)^{1/2}\quad\forall(t_j,x_j)\in[0,T]\times\mathbb{R}^n,\quad j=1,2, \tag{2.2}$$

for some positive constant C. Moreover, we define

$$[f]_{\mathrm{Lip}\,([0,T]\times\mathbb{R}^n)}=\inf\{C:\ (2.2)\ \textit{holds}\}$$

and we norm $\mathrm{Lip}\,([0,T]\times\mathbb{R}^n)$ by

$$\|f\|_{\mathrm{Lip}\,([0,T]\times\mathbb{R}^n)}=\|f\|_{L^\infty([0,T]\times\mathbb{R}^n)}+[f]_{\mathrm{Lip}\,([0,T]\times\mathbb{R}^n)}. \tag{2.3}$$

DEFINITION 2.3. *For any $\theta\in\mathbb{R}\backslash\mathbb{N}$, $C^\theta(\mathbb{R}^n)$ denotes the Banach space of all the functions f that are bounded and continuously differentiable up to the $[\theta]$-order such that for any $\alpha\in\mathbb{N}^n$ with length $[\theta]$,*

$$[D^\alpha f]_{\theta-[\theta]}:=\sup_{x,y\in\mathbb{R}^n,\ x\ne y}\frac{|D^\alpha f(y)-D^\alpha f(x)|}{|y-x|^{\theta-[\theta]}}<+\infty.$$

$C^\theta(\mathbb{R}^n)$ is normed by

$$\|f\|_{C^\theta(\mathbb{R}^n)}=\sum_{|\alpha|=0}^{[\theta]}\|D^\alpha f\|_\infty+\sum_{|\alpha|=[\theta]}[D^\alpha f]_{\theta-[\theta]}. \tag{2.4}$$

Throughout this paper, we will consider two families of weight functions: the polynomial weights, defined by $p(x)=1+|x|^{2m}$ for any $m\in\mathbb{N}\cup\{0\}$ and any $x\in\mathbb{R}^n$

and the exponential weights, defined by $p(x) = \exp\left((1 + \langle Sx, x\rangle)^{1/2}\right)$ for any $x \in \mathbb{R}^n$, S being any strictly positive and symmetric matrix. Moreover, we will deal with the following weighted spaces.

DEFINITION 2.4. *For any $k \in \mathbb{N}$ and any $\theta \in \mathbb{R} \cap \mathbb{N}^c$, $UC_p^k(\mathbb{R}^n)$ and $C_p^\theta(\mathbb{R}^n)$ denote the Banach spaces of all the functions f such that f/p belongs to $BUC^k(\mathbb{R}^n)$ and $C^\theta(\mathbb{R}^n)$, respectively. They are normed by*

$$\|f\|_{UC_p^k(\mathbb{R}^n)} = \|f/p\|_{BUC^k(\mathbb{R}^n)} \quad \text{and} \quad \|f\|_{C_p^\theta(\mathbb{R}^n)} = \|f/p\|_{C^\theta(\mathbb{R}^n)}. \tag{2.5}$$

In what follows, we will often use the following characterization of the previous weighted spaces.

LEMMA 2.5. *For any $k \in \mathbb{N}$ and any $\theta \in \mathbb{R}_+ \cap \mathbb{N}^c$, the following characterizations hold:*

(i) *$UC_p^k(\mathbb{R}^n)$ consists of all the continuously differentiable up to the kth-order functions f such that $(D^\alpha f)/p$ belongs to $BUC(\mathbb{R}^n)$ for any α with $|\alpha| \le k$. Moreover, the norm*

$$|\!|\!| f |\!|\!|_{UC_p^k(\mathbb{R}^n)} = \sum_{|\alpha|=0}^{k} \left\| \frac{D^\alpha f}{p} \right\|_\infty \qquad \forall f \in UC_p^k(\mathbb{R}^n)$$

is equivalent to the norm defined in (2.5).

(ii) *$C_p^\theta(\mathbb{R}^n)$ consists of all the continuously differentiable up to the $[\theta]$-order functions f such that for any $\alpha \in \mathbb{N}^n$ with $|\alpha| \le k$, $(D^\alpha f)/p$ belongs to $C^{\theta-[\theta]}(\mathbb{R}^n)$. Moreover, the norm*

$$|\!|\!| f |\!|\!|_{C_p^\theta(\mathbb{R}^n)} = \sum_{|\alpha|=0}^{[\theta]} \left\| \frac{D^\alpha f}{p} \right\|_\infty + \sum_{|\alpha|=[\theta]} \left[\frac{D^\alpha f}{p} \right]_{\theta-[\theta]} \qquad \forall f \in C_p^\theta(\mathbb{R}^n)$$

is equivalent to the norm defined in (2.5).

3. The case of coefficients not depending on x.

3.1. The case $f \equiv 0$. In this subsection, we are concerned with the following problem: *determine a function $u : [r, T] \times \mathbb{R}^n \to \mathbb{R}$ $(0 \le r < T)$ solution to the Cauchy problem*

$$\begin{cases} D_t u(t,x) = \displaystyle\sum_{i,j=1}^{n} q_{i,j}(t) D_{i,j} u(t,x) + \sum_{i=1}^{n} b_i(t) D_i u(t,x) + c(t) u(t,x), \\ \qquad\qquad (t,x) \in [r,T] \times \mathbb{R}^n, \\ u(r,x) = u_0(x), \qquad x \in \mathbb{R}^n, \end{cases} \tag{3.1}$$

under the following assumptions:

H1. $q_{i,j}(\cdot), b_j(\cdot)$ $(i,j = 1, \dots, n)$ and $c(\cdot)$ are measurable functions in $[0,T]$ bounded by a positive constant M;

H2. there exists a positive constant C_0 such that $\sum_{i,j=1}^n q_{i,j}(t)\xi_i\xi_j \ge C_0$ for any $|\xi| = 1$ almost everywhere (a.e.) in $[0,T]$.

We shall denote by $\mathcal{A}(t)$ the differential operator in the right-hand side of (3.1), by $Q_0(t)$ the matrix with elements $(Q_0)_{i,j}(t) = q_{i,j}(t)$, and by $B_0(t)$ the vector with components $(B_0)_j(t) = b_j(t)$.

By formally applying the Fourier transform to our Cauchy problem, we get the following representation for the solution to (3.1):

$$u(t,x)=\frac{\exp(C(t,r))}{(4\pi)^{n/2}(\det Q(t,r))^{1/2}}\int_{\mathbb{R}^n}\exp\left(-\frac{1}{4}\langle Q(t,r)^{-1}y,y\rangle\right)u_0(x-y+B(t,r))dy, \tag{3.2}$$

where

$$(Q(t,r))_{i,j}=\int_r^t q_{i,j}(s)ds,\quad (B(t,r))_j=\int_r^t b_j(s)ds,\quad C(t,r)=\int_r^t c(s)ds. \tag{3.3}$$

We now consider the family of linear operators $\{G(t,r)\}_{\{0\le r<t\}}$ defined by

$$\begin{aligned}G(t,r)\varphi(x)=&\frac{\exp(C(t,r))}{(4\pi)^{n/2}(\det Q(t,r))^{1/2}}\\&\times\int_{\mathbb{R}^n}\exp\left(-\frac{1}{4}\langle Q(t,r)^{-1}(y+B(t,r)),y+B(t,r)\rangle\right)\varphi(x-y)dy\end{aligned}$$

for any $\varphi\in UC_p(\mathbb{R}^n)$, p being either the polynomial or the exponential weight function.

LEMMA 3.1. *For any $\varphi\in UC_p(\mathbb{R}^n)$ and any $0\le r<s<t\le T$, $G(t,r)\varphi=G(t,s)G(s,r)\varphi$.*

Proof. We observe that for any $0\le r<s<t\le T$, $Q(t,r)=Q(t,s)+Q(s,r)$, $B(t,r)=B(t,s)+B(s,r)$, $C(t,r)=C(t,s)+C(s,r)$. Then, taking advantage of the Fubini–Tonelli theorem and integrating by parts, it is easy to prove the assertion. □

THEOREM 3.2. *Let $p:\mathbb{R}^n\to\mathbb{R}$ be defined by $p(x)=1+|x|^{2m}$ ($m\in\mathbb{N}\cup\{0\}$). Then for any $0\le r<t\le T$, $G(t,r)$ is a bounded linear operator mapping $UC_p(\mathbb{R}^n)$ into $UC_p^3(\mathbb{R}^n)$. Moreover, there exist positive constants $C(k,l,T)$ ($k,l=0,\dots,3$, $k\le l$) depending only on k, l, T, the sup norm of the coefficients, and on the constant C_0 in* H2 *such that*

$$\|G(t,r)\|_{\mathcal{L}(UC_p^k(\mathbb{R}^n);UC_p^l(\mathbb{R}^n))}\le C(k,l,T)(t-r)^{-(l-k)/2},\qquad 0\le l\le k\le 3. \tag{3.4}$$

Proof. We begin by showing that estimate (3.4) holds true when $k=l$. We observe that

$$\begin{aligned}\frac{p(x-y+B(t,r))}{p(x)}&=\frac{1+|x-y+B(t,r)|^{2m}}{1+|x|^{2m}}\\&\le 2^{2m-1}+2^{4m-2}\big(|y|^{2m}+n^mM^{2m}|t-r|^{2m}\big)\end{aligned} \tag{3.5}$$

for any $0\le r<t\le T$ and x, $y\in\mathbb{R}^n$. Moreover,

$$\begin{aligned}\left\|D_x\left(\frac{p(\cdot-y+B(t,r))}{p(\cdot)}\right)\right\|_\infty&\le 2^{2m-1}m\Big[3+2^{2m}\big(|y|^{2m}+n^mM^{2m}|t-r|^{2m}\big)\\&\quad+2^{2m-2}\big(|y|^{2m-1}+n^{m-1/2}M^{2m-1}|t-r|^{2m-1}\big)\Big]\end{aligned} \tag{3.6}$$

for any $y\in\mathbb{R}^n$ and any $0\le r<t$. Taking advantage of (3.5) and (3.6), it is easy to check that for any $\varphi\in UC_p(\mathbb{R}^n)$, the function $G(t,r)\varphi$ belongs to $UC_p(\mathbb{R}^n)$ and there exists a positive constant $C(0,T)$ such that

$$\|G(t,r)\varphi\|_{UC_p(\mathbb{R}^n)}\le C(0,T)\|\varphi\|_{UC_p(\mathbb{R}^n)},\qquad 0\le r<t\le T. \tag{3.7}$$

Then we observe that for any $\varphi \in UC_p^k(\mathbb{R}^n)$ $(k \le 3)$,

$$D^\alpha G(t,r)\varphi = G(t,r)D^\alpha \varphi \qquad \forall |\alpha| \le k. \tag{3.8}$$

Therefore, estimate (3.4) follows, in this particular case, from (3.7), (3.8), and Lemma 2.5.

We now consider the case $0 = k < l \le 3$ and observe that for any $\varphi \in UC_p(\mathbb{R}^n)$ and any $j = 1, \dots, n$, the function $G(t,r)\varphi$ is differentiable in $\mathbb{R}^n$ and its derivatives up to the third order are given by the following formulas:

$$\begin{aligned} D_j G(t,r)\varphi(x) = &-\frac{\exp(C(t,r))}{2(4\pi)^n}\int_{\mathbb{R}^n} (Q(t,r)^{-1/2}y)_j \exp\left(-\frac{1}{4}|y|^2\right) \\ &\times \varphi(x - Q(t,r)^{1/2}y + B(t,r))dy; \end{aligned} \tag{3.9}$$

$$\begin{aligned} D_i D_j G(t,r)\varphi(x) = &-\frac{\exp(C(t,r))}{2(4\pi)^n}\int_{\mathbb{R}^n} (Q(t,r)^{-1})_{j,i} \exp\left(-\frac{1}{4}|y|^2\right) \\ &\times \varphi(x - Q(t,r)^{1/2}y + B(t,r))dy \\ &+ \frac{\exp(C(t,r))}{4(4\pi)^n}\int_{\mathbb{R}^n} (Q(t,r)^{-1/2}y)_i (Q(t,r)^{-1/2}y)_j \\ &\times \exp\left(-\frac{1}{4}|y|^2\right)\varphi(x - Q(t,r)^{1/2}y + B(t,r))dy; \end{aligned} \tag{3.10}$$

$$\begin{aligned} D^3_{i,j,k} G(t,r)\varphi(x) = &\frac{\exp(C(t,r))}{4(4\pi)^n}\left[\int_{\mathbb{R}^n} (Q(t,r)^{-1})_{j,k}(Q(t,r)^{-1/2}y)_i \right. \\ &\times \exp\left(-\frac{1}{4}|y|^2\right)\varphi(x - Q(t,r)^{1/2}y + B(t,r))dy \\ &+ \int_{\mathbb{R}^n} (Q(t,r)^{-1})_{k,i}(Q(t,r)^{-1/2}y)_j \exp\left(-\frac{1}{4}|y|^2\right) \\ &\times \varphi(x - Q(t,r)^{1/2}y + B(t,r))dy \\ &+ \int_{\mathbb{R}^n} (Q(t,r)^{-1})_{j,i}(Q(t,r)^{-1/2}y)_k \exp\left(-\frac{1}{4}|y|^2\right) \\ &\times \varphi(x - Q(t,r)^{1/2}y + B(t,r))dy \\ &+ \frac{1}{2}\int_{\mathbb{R}^n} (Q(t,r)^{-1/2}y)_i (Q(t,r)^{-1/2}y)_j (Q(t,r)^{-1/2}y)_k \\ &\left. \times \exp\left(-\frac{1}{4}|y|^2\right)\varphi(x - Q(t,r)^{1/2}y + B(t,r))dy\right]. \end{aligned} \tag{3.11}$$

We recall here that $Q(t,r)^{1/2}$ is defined for any $0 \le r < t \le T$ by the following formula:

$$Q(t,r)^{1/2} = \frac{1}{2\pi \mathrm{i}}\int_\gamma \sqrt{\lambda}(\lambda I - Q(t,r))^{-1}d\lambda, \tag{3.12}$$

where γ is any oriented envelope of the spectrum of $Q(t,r)$ contained in the angle $\Sigma = \{\lambda \in \mathbb{C} : \arg\lambda \in [0, \pi/2]\}$ and $\sqrt{\lambda}$ is the principal value of the square root in $\mathbb{C}$.

Then, using estimates (3.5) and (3.6), we easily deduce that for any multiindex α with $|\alpha| \le 3$, the functions $D^\alpha G(t,r)\varphi \in UC_p(\mathbb{R}^n)$. Moreover, there exist positive

constants $\widetilde{C}_k(T)$ $(k=1,2,3)$ such that

$$\|D_jG(t,r)\varphi\|_{UC_p(\mathbb{R}^n)}\le\widetilde{C}_1(T)(t-r)^{-1/2}\|\varphi\|_{UC_p(\mathbb{R}^n)},\qquad 0\le r<t\le T; \tag{3.13}$$

$$\|D^2_{i,j}G(t,r)\varphi\|_{UC_p(\mathbb{R}^n)}\le\widetilde{C}_2(T)(t-r)^{-1}\|\varphi\|_{UC_p(\mathbb{R}^n)},\qquad 0\le r<t\le T; \tag{3.14}$$

$$\|D^3_{i,j,k}G(t,r)\varphi\|_{UC_p(\mathbb{R}^n)}\le\widetilde{C}_3(T)(t-r)^{-3/2}\|\varphi\|_{UC_p(\mathbb{R}^n)},\qquad 0\le r<t\le T. \tag{3.15}$$

From (3.13)–(3.15) we deduce that there exist three positive constants $C(k,T)$ $(k=1,2,3)$ depending only on the sup norm of the coefficients and on the constant C_0 in H2 such that (3.4) holds.

To conclude, we consider the case $0<k<l\le 3$ and observe that for any $\alpha\in\mathbb{N}^n$ such that $|\alpha|>k$, there exists $\beta\in\mathbb{N}^n$ such that $|\beta|=k$ and

$$D^\alpha G(t,r)\varphi=D^{\alpha-\beta}D^\beta G(t,r)\varphi=D^{\alpha-\beta}G(t,r)D^\beta\varphi.$$

Then (3.4) follows from the previous two cases. □

We now consider the case of exponential weight function.

THEOREM 3.3. *Let $p:\mathbb{R}^n\to\mathbb{R}$ be defined by $p(x)=\exp((1+\langle Sx,x\rangle)^{1/2})$. Then for any $0\le r<t\le T$, $G(t,r)$ is a bounded linear operator mapping $UC_p(\mathbb{R}^n)$ into $UC_p^3(\mathbb{R}^n)$. Moreover, for any k, $l=0,\dots,3$, $k\le l$, there exists a positive constant $D(k,l,T)$ depending on the sup norm of the coefficients, on T, and on the constant C_0 in* H2 *such that*

$$\|G(t,r)\|_{\mathcal{L}(UC_p^k(\mathbb{R}^n);UC_p^l(\mathbb{R}^n))}\le D(k,l,T)(t-r)^{-(l-k)/2},\qquad 0\le k\le l\le 3. \tag{3.16}$$

Proof. The proof is similar to the one given in the case of the polynomial weight function. In fact, we observe that

$$\begin{aligned}\frac{p(x-y+B(t,r))}{p(x)}&=\exp\Big((1+|S^{1/2}(x-y+B(t,r))|^2)^{1/2}-(1+|S^{1/2}x|^2)^{1/2}\Big)\\&\le\exp\Big(|S^{1/2}(y-B(t,r))|\Big)\\&\le\exp\Big(\|S^{1/2}\|Mn^{1/2}(t-r)\Big)\exp\big(\|S^{1/2}\||y|\big)\end{aligned} \tag{3.17}$$

and

$$\left\|D_x\left(\frac{p(\cdot-y+B(t,r))}{p(\cdot)}\right)\right\|_\infty\le 2\|S^{1/2}\|\exp\Big(\|S^{1/2}\|Mn^{1/2}(t-r)\Big)\exp\big(\|S^{1/2}\||y|\big) \tag{3.18}$$

for any x, $y\in\mathbb{R}^n$, $0\le r<t\le T$. To derive estimate (3.18), it suffices to observe that

$$\begin{aligned}\left|D_x\left(\frac{p(x-y+B(t,r))}{p(x)}\right)\right|&=\left|\frac{S(x-y+B(t,r))}{\big(1+\|S^{1/2}(x-y+B(t,r))\|^2\big)^{1/2}}-\frac{Sx}{(1+\|S^{1/2}x\|^2)^{1/2}}\right|\\&\quad\times\frac{p(x-y+B(t,r))}{p(x)}\le 2\|S^{1/2}\|\frac{p(x-y+B(t,r))}{p(x)}.\end{aligned}$$

Therefore, reasoning as in the case of the polynomial weight function, it can be easily proved that for any $\varphi\in UC_p^k(\mathbb{R}^n)$, $G(t,r)\varphi\in UC_p^k(\mathbb{R}^n)$ $(k=0,\dots,3)$ and fulfills the following estimate (cf. Lemma 2.5):

$$|\!|\!|G(t,r)\varphi|\!|\!|_{UC_p^k(\mathbb{R}^n)}\le\widetilde{d}_0\exp\Big((M+Mn^{1/2}\|S^{1/2}\|)T\Big)|\!|\!|\varphi|\!|\!|_{UC_p^k(\mathbb{R}^n)} \tag{3.19}$$

for any $0 \le r < t \le T$ and any $k = 0, \dots, 3$, where

$$\widetilde{d}_j = (4\pi)^{-n/2} \int_{\mathbb{R}^n} |y|^j \exp(n^{1/2} M^{1/2} \|S^{1/2}\| |y|) \exp\Big(-\frac{1}{4}|y|^2 \Big) dy, \qquad j = 0, \dots, 3.$$

Therefore, thanks to Lemma 2.5, we get (3.16) in the case $k = l$.

Next we observe that for any $\varphi \in UC_p(\mathbb{R}^n)$, $G(t,r)\varphi \in UC_p^3(\mathbb{R}^n)$, and (cf. (3.9)–(3.11))

$$\|D_i G(t,r)\varphi\|_{UC_p(\mathbb{R}^n)} \le \frac{C_0^{-1/2} \widetilde{d}_1}{2(t-r)^{1/2}} \exp\Big(M(1 + n^{1/2}\|S^{1/2}\|)T \Big) \|\varphi\|_{UC_p(\mathbb{R}^n)}; \tag{3.20}$$

$$\|D_{i,j}^2 G(t,r)\varphi\|_{UC_p(\mathbb{R}^n)} \le \frac{C_0^{-1}(2\widetilde{d}_0 + \widetilde{d}_2)}{4(t-r)} \exp\Big(M(1 + n^{1/2}\|S^{1/2}\|)T \Big) \|\varphi\|_{UC_p(\mathbb{R}^n)}; \tag{3.21}$$

$$\|D_{i,j,k}^3 G(t,r)\varphi\|_{UC_p(\mathbb{R}^n)} \le \frac{C_0^{-3/2}(6\widetilde{d}_1 + \widetilde{d}_3)}{8(t-r)^{3/2}} \exp\Big(M(1 + n^{1/2}\|S^{1/2}\|)T \Big) \|\varphi\|_{UC_p(\mathbb{R}^n)} \tag{3.22}$$

for any $i, j, k = 1, \dots, n$ and any $0 \le r < t \le T$. Then, taking Lemma 2.5 into account, from (3.20)–(3.22) we easily deduce (3.16). The case $0 < k < l \le 3$ can be proved as in Theorem 3.2. □

The estimates of Theorems 3.2 and 3.3 may be extended by interpolation to weighted Hölder norms, thanks to the following lemma.

LEMMA 3.4. *Let p be either the polynomial or the exponential weight function. Then for any $\sigma \in (0,1)$, any $0 \le \alpha < \beta$, and any $m \in \mathbb{N}$ such that $\alpha + \sigma(\beta - \alpha) \notin \mathbb{N}$ and $\sigma m \notin \mathbb{N}$, it holds that*

$$(UC_p(\mathbb{R}^n); UC_p^m(\mathbb{R}^n))_{\sigma,\infty} = C_p^{\sigma m}(\mathbb{R}^n);$$
$$(UC_p^\alpha(\mathbb{R}^n); UC_p^\beta(\mathbb{R}^n))_{\sigma,\infty} = C_p^{\alpha + \sigma(\beta-\alpha)}(\mathbb{R}^n),$$

with equivalence of the norms.

Proof. See [11, Theorems 1.2, 1.3, 1.7, and 1.8]. □

THEOREM 3.5. *Let p be the polynomial or the exponential weight function. Then for any $0 \le \alpha \le \beta \le 3$ and any $0 \le r < t$, $G(t,r)$ is a bounded linear operator mapping $UC_p^\alpha(\mathbb{R}^n)$ into $UC_p^\beta(\mathbb{R}^n)$. Moreover, there exists a positive constant $C(\alpha,\beta)$ such that for any $0 \le r < t \le T$,*

$$\|G(t,r)\|_{\mathcal{L}(UC_p^\alpha(\mathbb{R}^n); UC_p^\beta(\mathbb{R}^n))} \le C(\alpha,\beta)(t-r)^{-(\beta-\alpha)/2}. \tag{3.23}$$

Proof. It is sufficient to use the interpolation arguments of [11, Theorems 1.4 and 1.9]. □

The regularity properties of $G(t,r)\varphi$ are proved by the next lemmas. First, we deal with strong continuity.

LEMMA 3.6. *Suppose that p is either the polynomial or the exponential weight function. Then for any $\varphi \in UC_p(\mathbb{R}^n)$, $G(t,r)\varphi$ tends to φ in $UC_p(\mathbb{R}^n)$ as t tends to r.*

Proof. We start considering the case of polynomial weight function and observe that

$$\begin{aligned}
&\left|\frac{p(x-y+B(t,r))}{p(x)}-1\right| \\
&\quad=\left|\frac{|x-y+B(t,r)|^{2m}-|x|^{2m}}{1+|x|^{2m}}\right| \\
&\quad\le(1+|x|)^{-2m}\sum_{j=1}^{m}\binom{m}{k}|x|^{2(m-k)}\left||y-B(t,r)|^2-2\langle x,y-B(t,r)\rangle\right|^k \\
&\quad\le\sum_{k=1}^{m}\sum_{j=0}^{k}\binom{m}{k}\binom{k}{j}2^{2k-1}\Big(|y|^{2k-j}+\|B(t,r)\|^{2k-j}\Big). \qquad (3.24)
\end{aligned}$$

Then, taking advantage of (3.5) and (3.24) and setting

$$d_l=(4\pi)^{-n/2}\int_{\mathbb{R}^n}|y|^l\exp\left(-\frac{1}{4}|y|^2\right)dy,\qquad l\in\mathbb{N}\cup\{0\},$$

we deduce that for any $\varphi\in UC_p^1(\mathbb{R}^n)$,

$$\begin{aligned}
&\left|\frac{G(t,r)\varphi(x)}{1+|x|^{2m}}-\frac{\varphi(x)}{1+|x|^{2m}}\right| \\
&=\frac{\exp(C(t,r))}{(4\pi)^{n/2}}\int_{\mathbb{R}^n}\exp\left(-\frac{1}{4}|y|^2\right)\left|\frac{\varphi(x-Q(t,r)^{1/2}y+B(t,r))}{p(x-Q(t,r)^{1/2}y+B(t,r))}-\frac{\varphi(x)}{p(x)}\right| \\
&\quad\times\frac{p(x-Q(t,r)^{1/2}y+B(t,r))}{p(x)}dy \\
&\quad+\frac{\exp(C(t,r))}{(4\pi)^{n/2}}\int_{\mathbb{R}^n}\exp\left(-\frac{1}{4}|y|^2\right)\left|\frac{\varphi(x)}{p(x)}\right|\left|\frac{p(x-Q(t,r)^{1/2}y+B(t,r))}{p(x)}-1\right|dy \\
&\quad+|\exp(C(t,r))-1|\|\varphi\|_{UC_p(\mathbb{R}^n)} \\
&\le\exp(C(t,r))\|D\varphi\|_{UC_p(\mathbb{R}^n)}\Big[2^{2m-1}d_1(nM)^{1/2}|t-r|^{1/2}\Big(1+2^{2m-1}n^mM^{2m}|t-r|^{2m}\Big) \\
&\quad+2^{4m-2}d_{2m}n^{m+1/2}M^{m+1}|t-r|^{m+1}+2^{4m-2}d_{2m+1}n^{m+1/2}M^{m+1/2}|t-r|^{m+1/2} \\
&\quad+2^{2m-1}n^{1/2}M|t-r|+2^{4m-2}M^{2m+1}n^{m+1/2}|t-r|^{2m+1}\Big] \\
&\quad+|\exp(C(t,r))-1|\|\varphi\|_{UC_p(\mathbb{R}^n)} \\
&\quad\times\sum_{k=1}^{m}\sum_{j=0}^{k}\binom{m}{k}\binom{k}{j}2^{2k-1}\Big(d_{2k+j}(nM)^{k-j/2}|t-r|^{k-j/2}+n^{k-j/2}M^{2k-j}|t-r|^{2k-j}\Big),
\end{aligned}$$

and the right side of the previous inequality tends to 0 as t tends to r. Then by density, taking (3.4) into account, we can prove that for any $\varphi\in UC_p(\mathbb{R}^n)$, $G(t,r)\varphi$ tends uniformly to φ as t tends to r.

We now move on to consider the case of exponential weight function. We observe that for any $y\in\mathbb{R}^n$ and $0\le r<t$ we have

$$\begin{aligned}
\left\|\frac{p(\cdot-Q(t,r)^{1/2}y+B(t,r))}{p(\cdot)}-1\right\|_\infty&\le\exp\big(\|S^{1/2}\||B(t,r)|+\|S^{1/2}\||y|\big) \\
&\quad-\exp\big(-\|S^{1/2}\||B(t,r)|-\|S^{1/2}\||y|\big)
\end{aligned}$$

$$\le 2\|S^{1/2}\|(nM)^{1/2}\Big(|t-r|^{1/2}|y| + M^{1/2}|t-r|\Big)$$
$$\times \exp\Big(\|S^{1/2}\|(nMT)^{1/2}\big(|y| + (nMT)^{1/2}\big)\Big). \tag{3.25}$$

Using estimates (3.17) and (3.25) and reasoning as in the case of polynomial weight function, the assertion can be proved. □

In the next lemma we describe the smoothing properties of $G(t,r)$.

LEMMA 3.7. *Suppose that p is either the polynomial or the exponential weight function. Then for any $\varphi \in UC_p(\mathbb{R}^n)$ and any $r \in [0,T)$, the function $u : [r,T]\times\mathbb{R}^n \to \mathbb{R}$ defined by $u(t,x) = G(t,r)\varphi(x)$ is twice differentiable with respect to the variable x in $[0,T]\times\mathbb{R}^n$ and it is differentiable with respect to the variable t for any $t \in E_r \times \mathbb{R}^n$, where E_r is defined by*

$$E_r = \{t \in (r,T] :\ Q,\ B,\ C \text{ are differentiable at } t\},$$

and Q, B, and C are defined in (3.3). *Moreover, $D_t u(t,x) = \mathcal{A}(t)u(t,x)$ for any $(t,x) \in E_r \times \mathbb{R}^n$.*

Proof. We begin the proof by considering $\varphi \in UC_p^2(\mathbb{R}^n)$ and observing that E_r is a measurable set and the measure of $[r,T]\backslash E_r$ is equal to zero. Moreover, from (3.12) we deduce that $Q(t,r)^{1/2}$ is differentiable with respect to the variable t at any $t \in E_r$. Hence we can easily show that u is differentiable with respect to the variable t at each point $(t,x) \in E_r \times \mathbb{R}^n$ and

$$D_t u(t,x) = c(t)u(t,x) + (4\pi)^{-n/2}\exp(C(t,r))$$
$$\times \int_{\mathbb{R}^n} \left\langle (D\varphi)(x + Q(t,r)^{1/2}y + B(t,r)), \frac{d}{dt}(Q(t,r)^{1/2})y \right\rangle \exp\left(-\frac{1}{4}|y|^2\right) dy$$
$$+ (4\pi)^{-n/2}\exp(C(t,r)) \int_{\mathbb{R}^n} \langle (D\varphi)(x + Q(t,r)^{1/2}y + B(t,r)), B_0(t)\rangle \exp\left(-\frac{1}{4}|y|^2\right) dy.$$

Then, integrating by parts the first integral that occurs in the definition of $D_t u$, we get

$$\int_{\mathbb{R}^n} \left\langle (D\varphi)(x + Q(t,r)^{1/2}y + B(t,r)), \frac{d}{dt}(Q(t,r)^{1/2})y \right\rangle \exp\left(-\frac{1}{4}|y|^2\right) dy$$
$$= \sum_{i,j=1}^n \left(\frac{d}{dt}(Q(t,r)^{1/2})\right)_{i,j} \int_{\mathbb{R}^n} y_j \exp\left(-\frac{1}{4}|y|^2\right)(D_i\varphi)(x + Q(t,r)^{1/2}y + B(t,r))dy$$
$$= 2\sum_{i,j,k=1}^n \left(\frac{d}{dt}(Q(t,r)^{1/2})\right)_{i,j} (Q(t,r)^{1/2})_{k,j}$$
$$\times \int_{\mathbb{R}^n} (D_{i,k}\varphi)(x + Q(t,r)^{1/2}y + B(t,r)) \exp\left(-\frac{1}{4}|y|^2\right) dy$$
$$= \sum_{i,k=1}^n \left(\frac{d}{dt}(Q(t,r)^{1/2})Q(t,r)^{1/2}\right)_{i,k}$$
$$\times \int_{\mathbb{R}^n} (D_{i,k}\varphi)(x + Q(t,r)^{1/2}y + B(t,r)) \exp\left(-\frac{1}{4}|y|^2\right) dy$$
$$+ \sum_{i,k=1}^n \left(\frac{d}{dt}(Q(t,r)^{1/2})Q(t,r)^{1/2}\right)_{k,i}$$

$$\times \int_{\mathbb{R}^n} (D_{i,k}\varphi)(x+Q(t,r)^{1/2}y+B(t,r))\exp\left(-\frac{1}{4}|y|^2\right)dy$$
$$= \int_{\mathbb{R}^n} \mathrm{Tr}\left[\left(\frac{d}{dt}Q(t,r)^{1/2}Q(t,r)^{1/2}+Q(t,r)^{1/2}\frac{d}{dt}Q(t,r)^{1/2}\right)\right.$$
$$\left.\times\,(D^2\varphi)(x+Q(t,r)^{1/2}y+B(t,r))\right]\exp\left(-\frac{1}{4}|y|^2\right)dy$$
$$= \int_{\mathbb{R}^n} \mathrm{Tr}\big[Q_0(t)(D^2\varphi)(x+Q(t,r)^{1/2}y+B(t,r))\big]\exp\left(-\frac{1}{4}|y|^2\right)dy,$$

so that

$$D_t u(t,x) = \frac{\exp(C(t,r))}{(4\pi)^{n/2}}\int_{\mathbb{R}^n}\mathcal{A}(t)\varphi(x+Q(t,r)^{1/2}y+B(t,r))\exp\left(-\frac{1}{4}|y|^2\right)dy.$$

Then an elementary computation shows that $G(t,r)\mathcal{A}(t)\varphi = \mathcal{A}(t)(G(t,r)\varphi)$. Next we suppose that $\varphi \in UC_p(\mathbb{R}^n)$ and observe that there exists a sequence $\{\varphi_k\}_{k\in\mathbb{N}}$ belonging to $UC_p^2(\mathbb{R}^n)$ such that $\varphi_k \to \varphi$ in $UC_p(\mathbb{R}^n)$ as $k\to+\infty$. Taking advantage of (3.5) and (3.17), we deduce that for any $t\in(r,T]$, $G(t,r)\varphi_k$ tends to $G(t,r)\varphi$ as $k\to+\infty$ in $UC_p^2(\mathbb{R}^n)$, so that $\mathcal{A}(t)G(t,r)\varphi_k \to \mathcal{A}(t)G(t,r)\varphi$ for any $(t,x)\in(0,T]\times\mathbb{R}^n$. We now observe that $G(t,r)\varphi$ is differentiable with respect to the variable t at any point $(t,x)\in E_r\times\mathbb{R}^n$ and

$$(D_tG(t,r)\varphi)(x) = (4\pi)^{-n/2}D_t\Big(\exp(C(t,r))\big[\det Q(t,r)\big]^{-1/2}\Big)$$
$$\times\int_{\mathbb{R}^n}\exp\left(-\frac{1}{4}\langle Q(t,r)^{-1}(y+B(t,r)),y+B(t,r)\rangle\right)\varphi(x-y)dy$$
$$-\frac{\exp(C(t,r))}{4(4\pi)^{n/2}\det Q(t,r)^{1/2}}\int_{\mathbb{R}^n}\exp\left(-\frac{1}{4}\langle Q(t,r)^{-1}\big(y+B(t,r)\big),y+B(t,r)\rangle\right)$$
$$\times\,\varphi(x-y)D_t\big(\langle Q(t,r)^{-1}\big(y+B(t,r)\big),y+B(t,r)\rangle\big)dy.$$

Therefore, $G(t,r)\varphi$ is differentiable with respect to the variable t in $(r,T]\times\mathbb{R}^n$. Moreover, $D_t\varphi_k(t,x)$ tends to $D_t\varphi(t,x)$ as $k\to+\infty$ for any $(t,x)\in E_r\times\mathbb{R}^n$ and the proof is now complete. □

3.2. The nonhomogeneous case. In this subsection, we will consider the Cauchy problem

$$\text{(3.26)}\qquad \begin{cases} u_t(t,x) = \mathcal{A}(t)u(t,x)+f(t,x), & (t,x)\in[0,T]\times\mathbb{R}^n,\\ u(0,x) = u_0(x), & x\in\mathbb{R}^n. \end{cases}$$

under assumptions H1 and H2 (cf. section 3.1). We will denote by p either the polynomial or the exponential weight function.

We give the following definition of the "mild solution" to problem (3.26).

DEFINITION 3.8. *Suppose that*

(i) $f : [0,T] \times \mathbb{R}^n \to \mathbb{R}$ *is such that* $f/p \in L^\infty([0,T] \times \mathbb{R}^n)$ *and* $x \to f(r,x)$ *is a measurable function for any* $r \in [0,T]$;

(ii) $u_0 : \mathbb{R}^n \to \mathbb{R}$ *is such that* $u_0/p \in L^\infty(\mathbb{R}^n)$.

Then the function $u : [0,T] \times \mathbb{R}^n \to \mathbb{R}$ *defined by*

$$u(t,x) = G(t,0)u_0(x) + \int_0^t G(t,r)f(r,\cdot)(x)dr \tag{3.27}$$

is called the "mild" solution to problem (3.26).

In what follows, we deal with the space $B([0,T]; C_p^\theta(\mathbb{R}^n))$, $\theta \in (0,1)$.

DEFINITION 3.9. *For any* $T > 0$ *and any* $\theta \in \mathbb{R}_+$, $B([0,T]; C_p^\theta(\mathbb{R}^n))$ *denotes the vector space of all the functions* f *such that for any* $t \in [0,T]$, $f(t,\cdot) \in C_p^\theta(\mathbb{R}^n)$ *and* $\sup_{t\in[0,T]} \|f(t,\cdot)\|_{C_p^\theta(\mathbb{R}^n)} < +\infty$.

We are going to study the main properties of the "mild" solution to problem (3.26). The following lemma will be useful.

LEMMA 3.10. *Suppose that* $R \in L^\infty([0,T]; \mathbb{R}^{n^2})$, $S \in L^\infty([0,T]; \mathbb{R}^n)$, *and* $d \in L^\infty([0,T])$. *Then there exist three sequences* $\{R^{(k)}\}_{k\in\mathbb{N}} \in C([0,T]; \mathbb{R}^{n^2})$, $\{S^{(k)}\}_{k\in\mathbb{N}} \in C([0,T]; \mathbb{R}^n)$, *and* $\{d^{(k)}\}_{k\in\mathbb{N}} \in C([0,T])$ *such that*

(i) $R^{(k)}(t) \to R(t)$, $S^{(k)}(t) \to S(t)$, $d^{(k)}(t) \to d(t)$ *a.e. in* $[0,T]$ *as* $k \to +\infty$;

(ii) $\|R^{(k)}\|_{C([0,T];\mathbb{R}^{n^2})} \le \|R\|_{B([0,T];\mathbb{R}^{n^2})}$;

(iii) $\|S^{(k)}\|_{C([0,T];\mathbb{R}^n)} \le \|S\|_{B([0,T];\mathbb{R}^n)}$;

(iv) $\|d^{(k)}\|_{C([0,T])} \le \|d\|_{B([0,T])}$.

Moreover, if R *is uniformly strictly definite positive a.e. in* $[0,T]$, *then* $R^{(k)}$ *is also, independently of* k.

Proof. Let us consider the case of R, the others being similar. We define the matrix $R^{(k)}$ as follows:

$$(R^{(k)})_{i,j}(t) = \left(\frac{k}{4\pi}\right)^{1/2} \int_0^T r_{i,j}(s) \exp\left(-\frac{k}{4}|t-s|^2\right) ds, \qquad i,j = 1,\dots,n.$$

Then it is easy to check that $R^{(k)}$ admits a subsequence converging a.e. to the matrix R. Moreover, it can be easily proved that

$$\langle R^{(k)}x, x\rangle \ge (4\pi)^{-1/2} C \exp\left(-\frac{1}{4}T^2\right), \qquad x \in \mathbb{R}^n \qquad \forall k \in \mathbb{N}$$

and C is the constant of coercivity of R. □

LEMMA 3.11. *Let* θ, α *be two positive real numbers such that* $0 < \theta < \alpha < 1$. *Then for any interval* $I \subset \mathbb{R}$ *and any* $\varphi : I \to C_p^\theta(\mathbb{R}^n)$ *such that for any* $x \in \mathbb{R}^n$, *the real function* $t \to \varphi(t)(x)$ *is measurable in* I *and* $\|\varphi(t)\|_{C_p^\alpha(\mathbb{R}^n)} \le c(t)$ *(resp.,* $\|\varphi\|_{C_p^{2+\alpha}(\mathbb{R}^n)} \le c(t)$*) with* $c \in L^1([0,T])$, *the function*

$$f(x) = \int_I \varphi(t)(x)dt, \qquad x \in \mathbb{R}^n,$$

belongs to $C_p^\alpha(\mathbb{R}^n)$ *(resp.,* $C_p^{2+\alpha}(\mathbb{R}^n)$*) and there exists a positive constant* K, *independent of* φ, *such that*

$$\|f\|_{C_p^\alpha(\mathbb{R}^n)} \le K\|c\|_{L^1([0,T])} \qquad (\textit{resp.,}\ \|f\|_{C_p^{2+\alpha}(\mathbb{R}^n)} \le K\|c\|_{L^1([0,T])}).$$

Proof. See [12, section 3] and [11, Lemmas 3.1 and 3.2]. □

Thanks to Lemma 3.11 and Theorem 3.5, we can prove the following theorem. For a similar statement, see also [13, Theorem 2.2].

THEOREM 3.12. *Suppose that f is a measurable function belonging to $B([0,T];C_p^\theta(\mathbb{R}^n))$, $\theta\in(0,1)$. Then the function $v:[0,T]\times\mathbb{R}^n\to\mathbb{R}$ defined by*

$$v(t,x)=\int_0^t G(t,r)f(r,\cdot)(x)dr\qquad\forall(t,x)\in[0,T]\times\mathbb{R}^n$$

belongs to $B([0,T];C_p^{2+\theta}(\mathbb{R}^n))$ and there exists a positive constant C, independent of f, such that

$$\sup_{t\in[0,T]}\|v(t,\cdot)\|_{C_p^{2+\theta}(\mathbb{R}^n)}\le C\sup_{t\in[0,T]}\|f(t,\cdot)\|_{C_p^\theta(\mathbb{R}^n)}. \tag{3.28}$$

Proof. We begin the proof by remarking that $r\to G(t,r)f(r,\cdot)(x)$ is measurable in $[0,t]$ for any $(t,x)\in(0,T]\times\mathbb{R}^n$ (cf. the appendix, Lemma A.1). Next we recall that for any pair of Banach spaces X and Y with $Y\subset X$ and any $\beta\in(0,1)$, $(X,Y)_{\beta,\infty}$ denotes the vector space of all $x\in X$ such that $\sup_{t>0}t^{-\beta}K(t,x)<+\infty$, where $K(t,x)=\inf_{a+b=x,\ a\in X,\ b\in Y}\left(\|a\|_X+t\|b\|_Y\right)$ (see [15, Chapter 1]).

Then, following [13], we split $v(t)$ as $v(t)=a(\xi,t)+b(\xi,t)$, where

$$a(\xi,t)=\begin{cases}\displaystyle\int_0^\xi G(t,t-r)f(t-r,\cdot)(x)dr & \text{if } \xi\le t,\\ \displaystyle\int_0^t G(t,t-r)f(t-r,\cdot)(x)dr & \text{if } \xi>t;\end{cases}$$

$$b(\xi,t)=\begin{cases}\displaystyle\int_\xi^t G(t,t-r)f(t-r,\cdot)(x)dr & \text{if } \xi\le t,\\ 0 & \text{if } \xi>t.\end{cases}$$

Taking advantage of Lemma 3.11 and estimate (3.23), we deduce that $a(\xi,t)\in C_p^\alpha(\mathbb{R}^n)$ and $b(\xi,t)\in C_p^{2+\alpha}(\mathbb{R}^n)$ for every t and there exist two positive constants $C(\alpha,\theta)$, $C(2+\alpha,\theta)$ such that

$$\|a(\xi)\|_{C_p^\alpha(\mathbb{R}^n)}\le C(\alpha,\theta)\xi^{1-(\alpha-\theta)/2}\sup_{r\in[0,T]}\|f(r,\cdot)\|_{C_p^\theta(\mathbb{R}^n)};$$
$$\|b(\xi)\|_{C_p^{2+\alpha}(\mathbb{R}^n)}\le C(2+\alpha,\theta)\xi^{-(\alpha-\theta)/2}\sup_{r\in[0,T]}\|f(r,\cdot)\|_{C_p^\theta(\mathbb{R}^n)}.$$

Therefore, there exists a positive constant $\widetilde{C}(\alpha,\theta)$ such that

$$\xi^{-1+(\alpha-\theta)/2}K(\xi,v(t))\le\widetilde{C}(\alpha,\theta)\sup_{0\le r\le T}\|f(r,\cdot)\|_{C_p^\theta(\mathbb{R}^n)},\qquad\xi>0.$$

Hence we deduce that $v(t)\in(C_p^\alpha(\mathbb{R}^n),C_p^{2+\alpha}(\mathbb{R}^n))_{1-(\alpha-\theta)/2,\infty}$ and the statement follows from Lemma 3.4. □

LEMMA 3.13. *For any measurable function f belonging to $B([0,T];C_p^\theta(\mathbb{R}^n))$ and any $u_0\in C_p^{2+\theta}(\mathbb{R}^n)$, the function u defined by* (3.27) *is such that u/p is a Lipschitz continuous function in $[0,T]\times\mathbb{R}^n$.*

Proof. We begin by proving that for any $x\in\mathbb{R}^n$, $t\to u(t,x)$ is a Lipschitz continuous function in $[0,T]$. Let us show that the function $t\to G(t,0)u_0(x)$ is

Lipschitz continuous in $[0,T]$ for any $x \in \mathbb{R}^n$. For this purpose we consider the function $G_k(t,0)u_0$ defined by

$$G_k(t,0)u_0(x) = \frac{\exp\left(C^{(k)}(t,0)\right)}{(4\pi)^{n/2}} \times \int_{\mathbb{R}^n} \exp\left(-\frac{1}{4}|y|^2\right) u_0(x - Q^{(k)}(t,0)^{1/2}y + B^{(k)}(t,0))dy,$$

where $Q^{(k)}$, $B^{(k)}$, and $C^{(k)}$ are defined as in (3.3) with $q_{i,j}$, b_j, and c replaced by $q_{i,j}^{(k)}$, $b_j^{(k)}$, and $c^{(k)}$ defined in Lemma 3.10. From Lemma 3.7, we deduce that the function $(t,x) \to G_k(t,0)u_0(x)$ is differentiable in $[0,T]\times\mathbb{R}^n$ with respect to the variable t and solves in that strip the Cauchy problem (3.26) with $f \equiv 0$ and $q_{i,j}$, b_j, and c replaced by $q_{i,j}^{(k)}$, $b_j^{(k)}$, and $c^{(k)}$, respectively $(i,j = 1,\dots,n)$. Taking Lemma 3.10 and estimates (3.5), (3.17) into account, it is easy to show that $G_k(t,0)u_0(x)$ tends to $G(t,0)u_0(x)$ as $k \to +\infty$ for any $(t,x) \in [0,T]\times\mathbb{R}^n$. Moreover, from the same estimates quoted above, we deduce that there exists a positive constant $C_1(T)$, independent of x and $k \in \mathbb{N}$, such that

$$|D_x^j G_k(t,0)u_0(x)| \le C_1(T)p(x)\|u_0\|_{C_p^{2+\theta}(\mathbb{R}^n)} \tag{3.29}$$

for any $(t,x) \in [0,T]\times\mathbb{R}^n$, any $k \in \mathbb{N}$, and any $j = 0,1,2$ (cf. Theorems 3.2 and 3.3). Hence

$$|D_t G_k(t,0)u_0(x)| \le (n^2+n+1)MC_1(T)p(x)\|u_0\|_{C_p^{2+\theta}(\mathbb{R}^n)}$$

for any $(t,x) \in [0,T]\times\mathbb{R}^n$ and any $k \in \mathbb{N}$. Consequently, for any t_1, $t_2 \in [0,T]$,

$$|G_k(t_2,0)u_0(x) - G_k(t_1,0)u_0(x)| \le (n^2+n+1)MC_1(T)p(x)\|u_0\|_{C_p^{2+\theta}(\mathbb{R}^n)}|t_2 - t_1|.$$

As $k \to +\infty$, we deduce that $t \to G(t,0)u_0(x)$ is a Lipschitz continuous function and

$$[G(\cdot,0)u_0(x)]_{\mathrm{Lip}([0,T])} \le (n^2+n+1)MC_1(T)p(x) \qquad \forall x \in \mathbb{R}^n. \tag{3.30}$$

Let us consider the function

$$v(t,x) = \int_0^t G(t,r)f(r,\cdot)(x)dr.$$

Define the approximate semigroup $G_k(t,r)$ as in the case $r = 0$ and the function v_k by the formula

$$v_k(t,x) = \int_0^t G_k(t,r)f(r,\cdot)(x)dr.$$

As is easily seen, $v_k(t,x)$ tends to $v(t,x)$ as $k \to +\infty$ for any $(t,x) \in [0,T]\times\mathbb{R}^n$. From Lemma 3.7, we deduce that $t \to G_k(t,r)f(r,\cdot)(x)$ is differentiable with respect to the variable t in $[r,T]\times\mathbb{R}^n$. Moreover, there exists a positive constant $C_2(T)$, independent of k, such that

$$|D_x^j G_k(t,r)f(s,\cdot)(x)| \le C_2(T)p(x)(t-r)^{-(j-\theta)/2}\|f\|_{B([0,T];C_p^\theta(\mathbb{R}^n))}, \qquad j = 0,1,2. \tag{3.31}$$

To prove the previous estimate, it suffices to use the formula (3.23) and Lemma 3.10, recalling that $Q_0^{(k)}$ are strictly definite positive matrices, uniformly with respect to $t \in [0,T]$ and $k \in \mathbb{N}$. Then from (3.31), we deduce that

$$|D_t G_k(t,r)f(r,\cdot)(x)| \le (n^2 + nT^{1/2} + T)MC_2(T)p(x)\|f\|_{B([0,T];C_p^\theta(\mathbb{R}^n))}(t-r)^{-1+\theta/2}. \tag{3.32}$$

Therefore,

$$\begin{aligned} &|G_k(t_2,r)f(r,\cdot)(x) - G_k(t_1,r)f(r,\cdot)(x)| \\ &\le (n^2 + nT^{1/2} + T)MC_2(T)p(x)\|f\|_{B([0,T];C_p^\theta(\mathbb{R}^n))}(t_1-r)^{-1+\theta/2}|t_2-t_1| \end{aligned} \tag{3.33}$$

for any $0 \le r < t_1 \le t_2 \le T$. From (3.33), we easily deduce that $v(\cdot,x)$ is a Lipschitz continuous function in $[0,T]$. In fact, for any $0 \le t_1 \le t_2 \le T$, we have

$$\begin{aligned} |v_k(t_2,x) - v_k(t_1,x)| &\le \left| \int_{t_1}^{t_2} G_k(t_2,r)f(r,\cdot)(x)dr \right| \\ &\quad + \int_0^{t_1} \big|G_k(t_2,r)f(r,\cdot)(x) - G(t_1,r)f(r,\cdot)(x)\big|dr \\ &\le C_3(T)p(x)\|f\|_{B([0,T];C_p^\theta(\mathbb{R}^n))}|t_2-t_1|, \end{aligned} \tag{3.34}$$

$C_3(T)$ being a positive constant independent of (x,k). As k tends to infinity, we deduce that $v(\cdot,x)/p(x)$ is a Lipschitz function uniformly with respect to the variable x.

We are now in a position to prove that u/p is a Lipschitz continuous function in $[0,T] \times \mathbb{R}^n$. Suppose that t_1, $t_2 \in [0,T]$ and x_1, $x_2 \in \mathbb{R}^n$. Then

$$\begin{aligned} \left| \frac{u(t_2,x_2)}{p(x_2)} - \frac{u(t_1,x_1)}{p(x_1)} \right| &\le \left| \frac{u(t_2,x_2)}{p(x_2)} - \frac{u(t_1,x_2)}{p(x_2)} \right| + \left| \frac{u(t_1,x_2)}{p(x_2)} - \frac{u(t_1,x_1)}{p(x_1)} \right| \\ &\le \left[\frac{u(\cdot,x)}{p(x)} \right]_{\mathrm{Lip}\,([0,T])} |t_2-t_1| + \left\| D_x\left(\frac{u(t_1,\cdot)}{p} \right) \right\|_{L^\infty(\mathbb{R}^n)} |x_2-x_1|, \end{aligned} \tag{3.35}$$

and the assertion follows from (3.30), (3.34), and Theorems 3.2, 3.3, and 3.12. □

We are now in a position to prove the following existence theorem.

THEOREM 3.14. *Let $u_0 \in C_p^{2+\theta}(\mathbb{R}^n)$ with $0 < \theta < 1$ and let f be a measurable function belonging to $B([0,T];C_p^\theta(\mathbb{R}^n))$. The mild solution to* (3.26) *is twice continuously differentiable with respect to the space variables and it is differentiable with respect to t a.e. in $[0,T] \times \mathbb{R}^n$. Moreover, u is a solution to problem* (3.26) *in the sense of Definition* 1.1 *and*

$$\sup_{t\in[0,T]} \|u(t,\cdot)\|_{C_p^{2+\theta}(\mathbb{R}^n)} \le C\left(\|u_0\|_{C_p^{2+\theta}(\mathbb{R}^n)} + \sup_{t\in[0,T]} \|f(t,\cdot)\|_{C_p^\theta(\mathbb{R}^n)} \right) \tag{3.36}$$

for some positive constant C, independent of (u,u_0,f).

Proof. We start the proof considering the function v in Theorem 3.12. By Theorem 3.12 and Lemma 3.13, we already know that v is a continuous function in $[0,T] \times \mathbb{R}^n$ belonging to $B([0,T];C_p^{2+\theta}(\mathbb{R}^n))$. Therefore, $t \to v(t)$ belongs to $B([0,T];C^{2+\theta}(K)) \cap C([0,T];C(K))$ for any compact set $K \subset \mathbb{R}^n$ so that $v \in C([0,T];C^2(K))$, and hence v and its first- and second-order derivatives are continuous in $[0,T] \times \mathbb{R}^n$.

Thanks to Lemma 3.13, we deduce that $v(t,x)$ is differentiable a.e. in $[0,T]\times\mathbb{R}^n$ with respect to the variable t. Moreover,

$$D_t v(t,x) = \int_0^t D_t G(t,r) f(r,\cdot)(x)dr + f(t,x). \tag{3.37}$$

Let us prove that for any $x\in\mathbb{R}^n$, (3.37) holds in the sense of distributions. For this purpose, we observe that for any $\varphi\in C_0^\infty([0,T])$, we have (see also Lemmas A.1 and A.3 in the appendix)

$$\begin{aligned}
&\int_0^T \varphi'(t)dt\int_0^t G(t,r)f(r,\cdot)(x)dr\\
&\quad=\int_0^T dr\int_r^T \varphi'(t)G(t,r)f(r,\cdot)(x)dt\\
&\quad=-\int_0^T \varphi(r)f(r,x)dr-\int_0^T \varphi(t)dt\int_0^t D_tG(t,r)f(r,\cdot)(x)dr.
\end{aligned}$$

Here we have used the absolutely continuity of the function $t\to G(t,r)f(r,\cdot)(x)$ in $[r,T]$ and the measurability of the function $r\to f(r,x)$. To prove that $t\to G(t,r)f(r,\cdot)(x)$ is an absolutely continuous function in $[r,T]$ for any $(r,x)\in[0,T]\times\mathbb{R}^n$, it suffices to take (3.32) into account, observing that $t\to G_k(t,r)f(r,\cdot)(x)$ is an absolutely continuous function and $D_tG_k(t,r)f(r,\cdot)(x)$ tends to $D_tG(t,r)f(r,\cdot)(x)$ as $k\to+\infty$ a.e. in $[r,T]$.

Therefore, for any $x\in\mathbb{R}^n$, there exists a measurable set $F(x)$ with measure T such that

$$\begin{aligned}
D_t\int_0^t G(t,r)f(r,\cdot)(x)dr &= \int_0^t D_tG(t,r)f(r,\cdot)(x)dr + f(t,x)\\
&= \mathcal{A}(t)v(t,x)+f(t,x)
\end{aligned}\tag{3.38}$$

for any $t\in F(x)$.

Next we observe that the function

$$(t,x)\to\int_0^t G(t,r)f(r,\cdot)(x)dr$$

is measurable in $[0,T]\times\mathbb{R}^n$. Therefore, we can conclude that (3.37) holds a.e. in $[0,T]\times\mathbb{R}^n$. Then we consider the function $(t,x)\to G(t,0)u_0(x)$ and we observe that

$$D_xG(t,0)u_0(x)=G(t,0)D_xu_0(x),\qquad D_x^2G(t,0)u_0(x)=G(t,0)D_x^2u_0(x) \tag{3.39}$$

for any $(t,x)\in[0,T]\times\mathbb{R}^n$. Then it is easy to check that $G(\cdot,0)D_x^ju_0\in C_p([0,T]\times\mathbb{R}^n)$ $(j=0,1,2)$. From (3.23) and (3.28), we deduce that $u\in B([0,T];C_p^{2+\theta}(\mathbb{R}^n))$ and fulfills the estimate (3.36). □

To conclude this section, we show that the "mild" solution is the unique solution to problem (3.26).

THEOREM 3.15. *For any $u_0\in C_p^{2+\theta}(\mathbb{R}^n)$, $f\in B([0,T];C_p^\theta(\mathbb{R}^n))$, problem* (3.26) *admits a unique solution in the sense of Definition* 1.1.

Proof. Let us prove that problem (3.26) with $u_0\equiv 0$ and $f\equiv 0$ admits the trivial function as a unique solution. For this purpose, suppose that u is a solution in $[0,T]\times\mathbb{R}^n$ and fix a function $\varphi\in C^3(\mathbb{R}^n)$ with support in $B(0,1)$ and equal to

1 in $B(0,1/2)$. Then with any $x_0 \in \mathbb{R}^n$ we associate the function φ_{x_0} defined by $\varphi_{x_0}(x) = \varphi(x - x_0)$ and we define the function $v_{x_0} : [0,T] \times \mathbb{R}^n \to \mathbb{R}$ by $v_{x_0} = u\varphi_{x_0}$. As is easily seen, v_{x_0} is a Lipschitz continuous function in $[0,T] \times \mathbb{R}^n$. Moreover, it fulfills the Cauchy problem (3.26) in $[0,T] \times \mathbb{R}^n$ with $u_0 \equiv 0$ and f replaced by the function f_{x_0} given by

$$f_{x_0}(t,x) = -2\sum_{i,j=1}^n q_{i,j}(t)D_i u(t,x)D_j\varphi_{x_0}(x) - \sum_{i,j=1}^n q_{i,j}(t)u(t,x)D_{i,j}\varphi_{x_0}(x) - \sum_{j=1}^n b_j(t)u(t,x)D_j\varphi_{x_0}(x) \qquad \forall (t,x) \in [0,T] \times \mathbb{R}^n.$$

Next we observe that v_{x_0}, $f_{x_0} \in L^p([0,T] \times \mathbb{R}^n)$ for any $p \geq 1$. Consequently, we can apply the Fourier transform to the function $v_{x_0}(t,\cdot)$. As is easily checked, $\widehat{v}_{x_0}$ solves the following problem:

$$\begin{cases} D_t\widehat{v}_{x_0}(t,\xi) = \left(-\sum_{i,j=1}^n q_{i,j}(t)\xi_i\xi_j + \mathrm{i}\sum_{j=1}^n b_j(t)\xi_j + c(t)\right)\widehat{v}(t,\xi) + \widehat{f}_{x_0}, \\ \qquad\qquad (t,\xi) \in A \times \mathbb{R}^n, \\ \widehat{v}_{x_0}(0,\xi) = 0, \qquad \xi \in \mathbb{R}^n, \end{cases} \tag{3.40}$$

where A is a measurable set with measure T. Indeed, $\widehat{v}_{x_0}(\cdot,\xi)$ belongs to Lip $([0,T])$ for any $\xi \in \mathbb{R}^n$ with Lipschitz constant independent of ξ. In fact, $v_{x_0} \in$ Lip $([0,T] \times \mathbb{R}^n)$. Therefore, for any t_1, $t_2 \in [0,T]$,

$$|\widehat{v}_{x_0}(t_2,\xi) - \widehat{v}_{x_0}(t_1,\xi)| \leq \int_{B(x_0,1)} |v(t_2,x) - v(t_1,x)|dx \leq \omega_n[v]_{\mathrm{Lip}\,([0,T]\times\mathbb{R}^n)}|t_2 - t_1|,$$

where ω_n denotes, as usual, the Lebesgue measure of the unit ball in $\mathbb{R}^n$. Hence from the uniqueness of the solution to problem (3.40) in Lip $([0,T])$, we deduce that $\widehat{v}_{x_0}$ is given by the formula

$$\widehat{v}_{x_0}(t,\xi) = \int_0^t \exp\left(-\sum_{i,j=1}^n \int_s^t q_{i,j}(r)\xi_i\xi_j dr + \mathrm{i}\sum_{j=1}^n \xi_j\int_s^t b_j(r)dr + \int_s^t c(r)dr\right)\widehat{f}_{x_0}(s,\xi)ds$$

for any $(t,\xi) \in [0,T] \times \mathbb{R}^n$. Then taking the anti-Fourier transform of $\widehat{v}_{x_0}$, we get the following representation formula for v_{x_0}:

$$v_{x_0}(t,x) = \int_0^t G(t,r)f_{x_0}(r,\cdot)(x)dr \qquad \forall (t,x) \in [0,T] \times \mathbb{R}^n. \tag{3.41}$$

We now observe that f_{x_0} is a measurable function belonging to $B([0,l];C_p^\theta(\mathbb{R}^n))$ for any $0 < l \leq T$ and there exists a positive constant $C_1(p,T)$, independent of x_0, such that

$$\|f_{x_0}\|_{B([0,l];C_p^\theta(\mathbb{R}^n))} \leq C_1(p,T)\Big(\|u\|_{B([0,l];C_p^\theta(\mathbb{R}^n))} + \|u\|_{B([0,l];C_p^{1+\theta}(\mathbb{R}^n))}\Big). \tag{3.42}$$

Therefore, thanks to Theorem 3.12 we deduce that $v_{x_0} \in B([0,l];C_p^{2+\theta}(\mathbb{R}^n))$ for any $0 < l \leq T$ and

$$\|v_{x_0}\|_{B([0,l];C_p^{2+\theta}(\mathbb{R}^n))} \leq C_2(p,T)\Big(\|u\|_{B([0,l];C_p^\theta(\mathbb{R}^n))} + \|u\|_{B([0,l];C_p^{1+\theta}(\mathbb{R}^n))}\Big) \tag{3.43}$$

for some positive constant $C_2(p,T)$, independent of x_0. Recalling that $\varphi_{x_0} \equiv 1$ in $B(x_0,1/2)$, we deduce that $u \in B([0,T];C_p^\theta(B(x_0,1/2)))$ for any $x_0 \in \mathbb{R}^n$, and

$$\|u\|_{B([0,l];C_p^{2+\theta}(B(x_0,1/2)))} \le C_2(p,T)\Big(\|u\|_{B([0,l];C_p^\theta(\mathbb{R}^n))} + \|u\|_{B([0,l],C_p^{1+\theta}(\mathbb{R}^n))}\Big). \tag{3.44}$$

Since $C_2(p,T)$ is independent of $x_0 \in \mathbb{R}^n$, it is immediate to show that $u \in B([0,T];C_p^\theta(\mathbb{R}^n))$. Moreover, (3.44) can be extended to the whole of $\mathbb{R}^n$ by replacing the constant $C_2(p,T)$ with a new constant $C_3(p,T)$.

Then, taking advantage of [12, Proposition 1.1.3], we deduce that for any $\varepsilon > 0$, there exist two positive constants $K_1(\theta,\varepsilon)$ and $K_2(\theta,\varepsilon)$, independent of $l \in (0,T]$, such that

$$\|u\|_{B([0,l];C_p^\theta(\mathbb{R}^n))} \le \varepsilon\|u\|_{B([0,l];C_p^{2+\theta}(\mathbb{R}^n))} + K_1(\theta,\varepsilon)\|u\|_{B([0,l];C_p(\mathbb{R}^n))} \tag{3.45}$$

and

$$\|u\|_{B([0,l];C_p^{1+\theta}(\mathbb{R}^n))} \le \varepsilon\|u\|_{B([0,l];C_p^{2+\theta}(\mathbb{R}^n))} + K_2(\theta,\varepsilon)\|u\|_{B([0,l];C_p(\mathbb{R}^n))}. \tag{3.46}$$

Therefore, from (3.45) and (3.46), we deduce that there exists a positive constant $C_4(p,T)$, independent of x_0, such that

$$\|u\|_{B([0,l];C_p^{2+\theta}(\mathbb{R}^n))} \le C_4(p,T)\|u\|_{B([0,l];C_p(\mathbb{R}^n))}. \tag{3.47}$$

Then from Theorems 3.2 and 3.3, formula (3.41), estimates (3.42) and (3.47), and Lemma A.5 in the appendix, we deduce that

$$\left|\frac{u(s,x)}{p(x)}\right| \le C_5(p,T)\int_0^s \|u\|_{B([0,r];C_p(\mathbb{R}^n))}dr \qquad \forall (s,x) \in [0,T]\times B(x_0,1/2), \tag{3.48}$$

$C_5(p,T)$ being independent of x_0. Therefore, (3.48) can be extended to the whole of $[0,T]\times\mathbb{R}^n$ and

$$\|u\|_{B([0,t];C_p(\mathbb{R}^n))} \le C_5(p,T)\int_0^t \|u\|_{B([0,s];C_p(\mathbb{R}^n))}ds \qquad \forall t \in [0,T].$$

By means of Gronwall's inequality, we deduce that $u \equiv 0$ in $[0,T]\times\mathbb{R}^n$. □

4. The case of coefficients depending on (t,x). In this section, we are concerned with the following problem: *determine a function $u : [0,T]\times\mathbb{R}^n \to \mathbb{R}$ solution to the Cauchy problem*

$$\begin{cases} D_t u(t,x) = \displaystyle\sum_{i,j=1}^n q_{i,j}(t,x)D_{i,j}u(t,x) + \sum_{i=1}^n b_i(t,x)D_i u(t,x) \\ \qquad\qquad + c(t,x)u(t,x) + f(t,x), & (t,x) \in [0,T]\times\mathbb{R}^n, \\ u(0,x) = u_0(x), & x \in \mathbb{R}^n, \end{cases} \tag{4.1}$$

under the following assumptions on data:

(H1) $q_{i,j}$, b_j $(i,j = 1,\dots,n)$, and c belong to $L^\infty([0,T]\times\mathbb{R}^n) \cap B([0,T];C^\theta(\mathbb{R}^n))$ $(\theta \in (0,1))$;

(H2) there exists a positive constant C_0 such that $\sum_{i,j=1}^n q_{i,j}(t,x)\xi_i\xi_j \ge C_0$ for any $|\xi| = 1$ and any $(t,x) \in \mathcal{D}\times\mathbb{R}^n$, where $\mathcal{D}^c$ is a measurable set such that $\mathcal{D}^c \cap [0,T]$ is negligible;

(H3) $u_0 \in C_p^{2+\theta}(\mathbb{R}^n)$ and f is a measurable function belonging to $B([0,T];C_p^\theta(\mathbb{R}^n))$. For the sake of simplicity, we shall denote by $\mathcal{A}(t,x)$ the differential operator defined in (4.1), by $Q_0(t,x)$ the matrix having as elements the functions $q_{i,j}(t,x)$, by $B_0(t,x)$ the vector with components $(B_0)_j(t,x) = b_j(t,x)$, and by p either the polynomial or the exponential weight function.

4.1. A priori estimates and uniqueness of the solution. In this first part of section 4, we are interested in finding an a priori estimate for the solution to problem (4.1).

THEOREM 4.1. *Suppose that u is a solution to problem* (4.1) *in* $[0,T]\times\mathbb{R}^n$, *in the sense of Definition* 1.1, *belonging to* $B([0,T];C_p^{2+\theta}(\mathbb{R}^n))$. *Then u satisfies*

$$\sup_{t\in[0,T]} \|u(t,\cdot)\|_{C_p^{2+\theta}(\mathbb{R}^n)} \le C\left(\|u_0\|_{C_p^{2+\theta}(\mathbb{R}^n)} + \sup_{t\in[0,T]} \|f(t,\cdot)\|_{C_p^\theta(\mathbb{R}^n)}\right) \tag{4.2}$$

for some positive constant C, independent of (u,u_0,f).

Proof. Estimate (4.2) will be proved in two steps.

Step 1. Let us show that there exists a positive constant $\widetilde{C}$, independent of $T^*\in(0,T]$, such that

$$\|u\|_{B([0,T^*];C_p^{2+\theta}(\mathbb{R}^n))} \le \widetilde{C}\Big(\|u\|_{B([0,T^*];C_p(\mathbb{R}^n))} + \|u_0\|_{C_p^{2+\theta}(\mathbb{R}^n)} + \|f\|_{B([0,T^*];C_p^\theta(\mathbb{R}^n))}\Big) \tag{4.3}$$

for any $T^* \le T$. For this purpose, let $\psi \in C^3(\mathbb{R}^n)$ be such that $\psi \equiv 1$ in $B(0,1/2)$ with support in $B(0,1)$. With any $\delta > 0$ we associate the function $\psi_\delta \in C^3(\mathbb{R}^n)$ defined by $\psi_\delta(x) = \psi((x-x_0)/\delta)$ for any $x \in \mathbb{R}^n$. Then we consider the function $v_\delta = u\psi_\delta$ and observe that v_δ is a solution, in the sense of Definition 1.1, of the following Cauchy problem:

$$\begin{cases} D_t v_\delta(t,x) = \mathcal{A}(t,x)v_\delta(t,x) + f(t,x) - g_\delta(t,x), & (t,x)\in[0,T]\times\mathbb{R}^n, \\ v_\delta(0,x) = u_0(x)\psi_\delta(x), & x\in\mathbb{R}^n, \end{cases} \tag{4.4}$$

where

$$\begin{aligned} g_\delta(t,x) = 2\sum_{i,j=1}^n q_{i,j}(t,x)D_i u(t,x)D_j\psi_\delta(x) + \sum_{i,j=1}^n q_{i,j}(t,x)u(t,x)D_{i,j}^2\psi_\delta(x) \\ +\sum_{i=1}^n b_i(t,x)u(t,x)D_i\psi_\delta(x) \qquad \forall (t,x)\in[0,T^*]\times\mathbb{R}^n. \end{aligned} \tag{4.5}$$

Then we fix $x_0 \in \mathbb{R}^n$ and rewrite problem (4.4) in the following form:

$$\begin{cases} D_t v_\delta(t,x) = \mathcal{A}(t,x_0)v_\delta(t,x) + \big(\mathcal{A}(t,x) - \mathcal{A}(t,x_0)\big)v_\delta(t,x) \\ \qquad\qquad + f(t,x) - g_\delta(t,x), & (t,x)\in[0,T]\times\mathbb{R}^n, \\ v_\delta(0,x) = u_0(x)\psi_\delta(x), & x\in\mathbb{R}^n. \end{cases} \tag{4.6}$$

An easy computation shows that $u_0\psi_\delta \in C_p^{2+\theta}(\mathbb{R}^n)$ and

$$\|u_0\psi_\delta\|_{C_p^{2+\theta}(\mathbb{R}^n)} \le C(\delta)\|u_0\|_{C_p^{2+\theta}(\mathbb{R}^n)}, \tag{4.7}$$

$C(\delta)$ being a positive constant, independent of x_0, tending to $+\infty$ as $\delta \to 0$. We now prove that the function $k = \mathcal{A}(\cdot,\cdot)v_\delta - \mathcal{A}(\cdot,x_0)v_\delta$ belongs to $B([0,T];C_p^\theta(\mathbb{R}^n))$. For this purpose, we observe that for any x_1, $x_2 \in B(x_0,\delta)$, $y \in \partial B(x_0,\delta)$, any i, $j \in \mathbb{N}$, $1 \le i,j \le n$, and any $t \in [0,T]$,

$$\begin{aligned}
&\left|\big[q_{i,j}(t,x_2)-q_{i,j}(t,x_0)\big]\frac{D_{i,j}v_\delta(t,x_2)}{p(x_2)} - \big[q_{i,j}(t,x_1)-q_{i,j}(t,x_0)\big]\frac{D_{i,j}v_\delta(t,x_1)}{p(x_1)}\right| \\
&\quad \le |q_{i,j}(t,x_2)-q_{i,j}(t,x_1)|\left|\frac{D_{i,j}v_\delta(t,x_2)}{p(x_2)} - \frac{D_{i,j}v_\delta(t,y)}{p(y)}\right| \\
&\qquad + |q_{i,j}(t,x_1)-q_{i,j}(t,x_0)|\left|\frac{D_{i,j}v_\delta(t,x_2)}{p(x_2)} - \frac{D_{i,j}v_\delta(t,x_1)}{p(x_1)}\right| \\
&\quad \le 3\delta^\theta [q_{i,j}(t,\cdot)]_{C^\theta(\mathbb{R}^n)}\left[\frac{D_{i,j}v_\delta(t,\cdot)}{p}\right]_{C^\theta(\mathbb{R}^n)}|x_2-x_1|^\theta. \qquad (4.8)
\end{aligned}$$

Suppose now that $x_2 \in B(x_0,\delta)$, $x_1 \in \mathbb{R}^n\backslash B(x_0,\delta)$. Then

$$\begin{aligned}
&\left|\big[q_{i,j}(t,x_2)-q_{i,j}(t,x_0)\big]\frac{D_{i,j}v_\delta(t,x_2)}{p(x_2)} - \big[q_{i,j}(t,x_1)-q_{i,j}(t,x_0)\big]\frac{D_{i,j}v_\delta(t,x_1)}{p(x_1)}\right| \\
&\quad = \left|\big[q_{i,j}(t,x_2)-q_{i,j}(t,x_0)\big]\left[\frac{D_{i,j}v_\delta(t,x_2)}{p(x_2)} - \frac{D_{i,j}v_\delta(t,x_1)}{p(x_1)}\right]\right| \\
&\quad \le \delta^\theta [q_{i,j}(t,\cdot)]_{C^\theta(\mathbb{R}^n)}\left[\frac{D_{i,j}v_\delta(t,\cdot)}{p}\right]_{C^\theta(\mathbb{R}^n)}|x_2-x_1|^\theta. \qquad (4.9)
\end{aligned}$$

Moreover,

$$\big\|\big[q_{i,j}(t,\cdot)-q_{i,j}(t,x_0)\big]D_{i,j}v_\delta(t,\cdot)\big\|_{C_p(\mathbb{R}^n)} \le \delta^\theta [q_{i,j}(t,\cdot)]_{C^\theta(\mathbb{R}^n)}\|D_{i,j}v_\delta(t,\cdot)\|_{C_p(\mathbb{R}^n)}. \qquad (4.10)$$

From (4.8)–(4.10), we deduce that

$$\big\|\big[q_{i,j}(t,\cdot)-q_{i,j}(t,x_0)\big]v_\delta(t,\cdot)\big\|_{C_p^\theta(\mathbb{R}^n)} \le 3\delta^\theta [q_{i,j}(t,\cdot)]_{C^\theta(\mathbb{R}^n)}\|D_{i,j}v_\delta(t,\cdot)\|_{C_p^\theta(\mathbb{R}^n)}. \qquad (4.11)$$

In the same way, it can be proved that

$$\big\|\big[b_j(t,\cdot)-b_j(t,x_0)\big]D_jv_\delta(t,\cdot)\big\|_{C_p^\theta(\mathbb{R}^n)} \le 3\delta^\theta [b_j(t,\cdot)]_{C^\theta(\mathbb{R}^n)}\|D_jv_\delta(t,\cdot)\|_{C_p^\theta(\mathbb{R}^n)} \qquad (4.12)$$

for any $j = 1,\dots,n$ and

$$\big\|\big[c(t,\cdot)-c(t,x_0)\big]v_\delta(t,\cdot)\big\|_{C_p^\theta(\mathbb{R}^n)} \le 3\delta^\theta [c(t,\cdot)]_{C^\theta(\mathbb{R}^n)}\|v_\delta(t,\cdot)\|_{C_p^\theta(\mathbb{R}^n)}. \qquad (4.13)$$

Then, recalling that for any $\varphi \in C^1(\mathbb{R}^n)$, $\|\varphi\|_{C^\theta(\mathbb{R}^n)} \le 3\|\varphi\|_{C^1(\mathbb{R}^n)}$, and taking Lemma 2.5 into account, we deduce that $k \in B([0,T];C_p^\theta(\mathbb{R}^n))$ and there exists a positive constant $C(T)$, independent of x_0, δ and $T^* \in (0,T]$, such that

$$\|k\|_{B([0,T^*];C_p^\theta(\mathbb{R}^n))} \le C(T)\delta^\theta \|v_\delta\|_{B([0,T^*];C_p^{2+\theta}(\mathbb{R}^n))}. \qquad (4.14)$$

As far as g_δ is concerned, we observe that it belongs to $B([0,T];C_p^\theta(\mathbb{R}^n))$ for any $\delta > 0$, and if $\delta \le 1$, $t \in [0,T]$,

$$\|g_\delta(t,\cdot)\|_{C_p^\theta(\mathbb{R}^n)} \le \delta^{-2-\theta}\Bigg[2\sum_{i,j=1}^n \|q_{i,j}(t,\cdot)\|_{C^\theta(\mathbb{R}^n)}\|D\psi\|_{C^\theta(\mathbb{R}^n)}\|u(t,\cdot)\|_{C_p^{1+\theta}(\mathbb{R}^n)} + \sum_{i,j=1}^n \|q_{i,j}(t,\cdot)\|_{C^\theta(\mathbb{R}^n)}\|u(t,\cdot)\|_{C_p^\theta(\mathbb{R}^n)}\|D^2\psi\|_{C^\theta(\mathbb{R}^n)} + \sum_{j=1}^n \|b_j(t,\cdot)\|_{C^\theta(\mathbb{R}^n)}\|u(t,\cdot)\|_{C_p^\theta(\mathbb{R}^n)}\|D\psi\|_{C^\theta(\mathbb{R}^n)}\Bigg]. \tag{4.15}$$

Thanks to Theorems 3.14 and 3.15 and estimates (4.14) and (4.15), we can find a positive constant $D_0(T)$, independent of x_0 and δ, such that

$$\|v_\delta\|_{B([0,T^*];C_p^{2+\theta}(\mathbb{R}^n))} \le D_0(T)\Big(C(\delta)\|u_0\|_{C_p^{2+\theta}(\mathbb{R}^n)} + C(T)\delta^\theta\|v_\delta\|_{B([0,T^*];C_p^{2+\theta}(\mathbb{R}^n))} + \|g_\delta\|_{B([0,T^*];C_p^\theta(\mathbb{R}^n))} + \|f\|_{B([0,T^*];C_p^\theta(\mathbb{R}^n))}\Big). \tag{4.16}$$

Therefore, for any $\delta \le \delta_0 = \min\,(1,(D_0(T)C(T))^{-1})$, recalling that $v_\delta \equiv u$ in $B(x_0,\delta/2)$, we deduce that

$$\|u\|_{B([0,T^*];C_p^{2+\theta}(B(x_0,\delta/2)))} \le D_1(T,\delta)\Big(\|u_0\|_{C_p^{2+\theta}(\mathbb{R}^n)} + \|f\|_{B([0,T^*];C_p^\theta(\mathbb{R}^n))} + \|g_\delta\|_{B([0,T^*];C_p^\theta(\mathbb{R}^n))}\Big), \tag{4.17}$$

where $D_1(T,\delta) = \frac{D_0(T)\max\,(C(\delta),1)}{1-D_0(T)C(T)\delta^\theta}$. A direct inspection of (4.15) shows that (4.17) is independent of the point x_0. Therefore,

$$\|u\|_{B([0,T^*];C_p^2(\mathbb{R}^n))} \le D_1(T,\delta)\Big(\|u_0\|_{C_p^{2+\theta}(\mathbb{R}^n)} + \|f\|_{B([0,T^*];C_p^\theta(\mathbb{R}^n))} + \|g_\delta\|_{B([0,T^*];C_p^\theta(\mathbb{R}^n))}\Big). \tag{4.18}$$

Moreover, it can be easily proved that for any $t \in [0,T]$ and any $\delta \le \delta_0$

$$\left[D_{i,j}\frac{u(t,\cdot)}{p}\right]_{C^\theta(\mathbb{R}^n)} \le 2^{\theta+1}\delta^{-\theta}D_1(T,\delta) \times \Big(\|u_0\|_{C_p^{2+\theta}(\mathbb{R}^n)} + \|f\|_{B([0,T^*];C_p^\theta(\mathbb{R}^n))} + \|g_\delta\|_{B([0,T^*];C_p^\theta(\mathbb{R}^n))}\Big). \tag{4.19}$$

Consequently, for any $T^* \in (0,T]$,

$$\|u\|_{B([0,T^*];C_p^{2+\theta}(\mathbb{R}^n))} \le D_2(T,\delta)\Big(\|u_0\|_{C_p^{2+\theta}(\mathbb{R}^n)} + \|f\|_{B([0,T^*];C_p^\theta(\mathbb{R}^n))} + \|g_\delta\|_{B([0,T^*];C_p^\theta(\mathbb{R}^n))}\Big), \tag{4.20}$$

where $D_2(T,\delta) = \big(2^{\theta+1}\delta^{-\theta}n^2+1\big)D_1(T,\delta)$. Then, taking (3.45), (3.46), and Lemma 2.5 into account, from (4.15) and (4.20), we deduce that there exist two positive constants $D_3(T)$ and $K(\theta,\varepsilon)$ such that for any $\delta \le 1$,

$$\|g_\delta\|_{B([0,T^*];C_p^\theta(\mathbb{R}^n))} \le \delta^{-2-\theta}D_3(T)\Big(\varepsilon\|u\|_{B([0,T^*];C_p^{2+\theta}(\mathbb{R}^n))} + K(\theta,\varepsilon)\|u\|_{B([0,T^*];C_p(\mathbb{R}^n))}\Big). \tag{4.21}$$

From (4.20) and (4.21), we easily deduce that for ε sufficiently small and $\delta \le \delta_0$,

$$\begin{aligned}&\|u\|_{B([0,T^*];C_p^{2+\theta}(\mathbb{R}^n))}\\ &\le D_4(T,\delta,\varepsilon)\Big(\|u_0\|_{C_p^{2+\theta}(\mathbb{R}^n)}+\|u\|_{B([0,T^*];C_p(\mathbb{R}^n))}+\|f\|_{B([0,T^*];C_p^{\theta}(\mathbb{R}^n))}\Big),\end{aligned}\tag{4.22}$$

$D_4(T,\delta,\varepsilon)$ being a positive constant, and (4.3) follows.

Step 2. Let us fix $x_0 \in \mathbb{R}^n$ and rewrite problem (4.1) in the following form:

$$\begin{cases} D_t u(t,x) = \mathcal{A}(t,x_0)u(t,x) + \big(\mathcal{A}(t,x)-\mathcal{A}(t,x_0)\big)u(t,x) + f(t,x),\\ \qquad\qquad (t,x)\in[0,T]\times\mathbb{R}^n,\\ u(0,x)=u_0(x), \qquad x\in\mathbb{R}^n. \end{cases}\tag{4.23}$$

Then an easy computation shows that $g(t,x)=(\mathcal{A}(t,x)-\mathcal{A}(t,x_0))u(t,x)$ belongs to $B([0,T];C_p^{\theta}(\mathbb{R}^n))$ with norm independent of x_0. Therefore, thanks to Theorems 3.14 and 3.15, we deduce that u admits the following representation:

$$u(t,x)=G(t,0)u_0(x)+\int_0^t G(t,s)\big[\big(\mathcal{A}(s,\cdot)-\mathcal{A}(s,x_0)\big)u(s,\cdot)+f(s,\cdot)\big](x)ds.\tag{4.24}$$

Then for any $s\in[0,t]$,

$$\begin{aligned}&\left|\frac{\mathcal{A}(s,x)u(s,x)}{p(x)}-\frac{\mathcal{A}(s,x_0)u(t,x)}{p(x)}\right|\\ &\quad\le\Bigg[\sum_{i,j=1}^n \|q_{i,j}\|_{B([0,s];C^{\theta}(\mathbb{R}^n))}\|D_x^2u\|_{B([0,s];C_p^{\theta}(\mathbb{R}^n))}\\ &\qquad+\sum_{j=1}^n\|b_j\|_{B([0,s];C^{\theta}(\mathbb{R}^n))}\|D_xu\|_{B([0,s];C_p^{\theta}(\mathbb{R}^n))}\\ &\qquad+\|c\|_{B([0,s];C^{\theta}(\mathbb{R}^n))}\|u\|_{B([0,s];C_p(\mathbb{R}^n))}\Bigg]|x-x_0|^{\theta}\\ &\quad\le C_1(T)\Big(\|u\|_{B([0,s];C_p(\mathbb{R}^n))}+\|u_0\|_{C_p^{2+\theta}(\mathbb{R}^n)}+\|f\|_{B([0,s];C_p^{2+\theta}(\mathbb{R}^n))}\Big)|x-x_0|^{\theta},\end{aligned}\tag{4.25}$$

where $C_1(T)$ is a positive constant independent of x_0. Therefore, from (3.5), (3.17), and (4.25), we deduce that there exists a positive constant $C_2(T)$, independent of x_0, such that for any $x\in B(x_0,1)$,

$$\begin{aligned}&\left|\frac{G(t,s)\big(\mathcal{A}(s,x)-\mathcal{A}(s,x_0)\big)u(s,\cdot)(x)}{p(x)}\right|\\ &\qquad\le C_2(T)\Big(\|u\|_{B([0,s];C_p(\mathbb{R}^n))}+\|u_0\|_{C_p^{2+\theta}(\mathbb{R}^n)}+\|f\|_{B([0,s];C_p^{2+\theta}(\mathbb{R}^n))}\Big).\end{aligned}\tag{4.26}$$

Then taking advantage of (4.24), (4.26), and Lemma A.5 in the appendix, we deduce that

$$\left|\frac{u(t,x)}{p(x)}\right|\le C_3(T)\left[\|u_0\|_{C_p^{2+\theta}(\mathbb{R}^n)}+\int_0^t\|u\|_{B([0,s];C_p(\mathbb{R}^n))}ds+\|f\|_{B([0,t];C_p^{\theta}(\mathbb{R}^n))}\right]\tag{4.27}$$

for some positive constant $C_3(T)$, independent of x_0, and for any $(t,x) \in [0,T] \times B(x_0,1)$. Then we extend the previous estimate to the whole of $\mathbb{R}^n$ by observing that (4.27) is independent of x_0. By means of Gronwall's inequality, we deduce that there exists a positive constant $C_4(T)$ such that

$$\|u\|_{B([0,t];C_p(\mathbb{R}^n))} \le C_4(T)\Big(\|u_0\|_{C_p^{2+\theta}(\mathbb{R}^n)} + \|f\|_{B([0,t];C_p^\theta(\mathbb{R}^n))}\Big) \qquad \forall t \in [0,T]. \tag{4.28}$$

From (4.3) and (4.28), we deduce (4.2). □

4.2. Existence of the solution. Now we are in a position to prove that problem (4.1) admits a solution. For this purpose, we use the classical method of continuity.

THEOREM 4.2. *For any $u_0 \in C_p^{2+\theta}(\mathbb{R}^n)$ and any measurable function f belonging to $B([0,T];C_p^\theta(\mathbb{R}^n))$, problem (4.1) admits a unique solution in the sense of Definition 1.1. Moreover, there exists a positive constant C such that*

$$\|u\|_{B([0,T];C_p^\theta(\mathbb{R}^n))} \le C\Big(\|u_0\|_{C_p^{2+\theta}(\mathbb{R}^n)} + \|f\|_{B([0,T];C_p^\theta(\mathbb{R}^n))}\Big). \tag{4.29}$$

Proof. With any $\lambda \in [0,1]$ we associate the differential operator $\mathcal{A}_\lambda = \lambda\mathcal{A} + (1-\lambda)\Delta$. As is easily seen, the coefficients of $\mathcal{A}_\lambda$ are bounded in $B([0,T];C^\theta(\mathbb{R}^n))$ by positive constants independent of λ. Moreover (cf. assumption H2),

$$\langle \lambda Q(t,x)\xi + (1-\lambda)\xi, \xi\rangle \ge \min(C_0,1)|\xi|^2 \qquad \forall (t,x) \in \mathcal{D} \times \mathbb{R}^n.$$

Next we denote by $\mathcal{F}$ the set of all the $\lambda \in [0,1]$ such that for any $u_0 \in C_p^{2+\theta}(\mathbb{R}^n)$ and any function f belonging to $B([0,T];C_p^\theta(\mathbb{R}^n))$, (P_λ) admits a solution where

$$(\mathrm{P}_\lambda) \quad \begin{cases} D_t u(t,x) = \mathcal{A}_\lambda u(t,x) + f(t,x), & (t,x) \in [0,T] \times \mathbb{R}^n, \\ u(0,x) = u_0(x), & x \in \mathbb{R}^n. \end{cases} \tag{4.30}$$

Taking advantage of Theorem 4.1, we deduce that there exists a positive constant C_1, independent of λ, such that if u_λ is a measurable solution to (P_λ), then

$$\|u_\lambda\|_{B([0,T];C_p^{2+\theta}(\mathbb{R}^n))} \le C_1\Big(\|u_0\|_{C_p^{2+\theta}(\mathbb{R}^n)} + \|f\|_{B([0,T];C_p^\theta(\mathbb{R}^n))}\Big). \tag{4.31}$$

We observe that by section 3, $\lambda = 0$ belongs to $\mathcal{F}$. Now we prove that $\mathcal{F}$ is a closed subset of $[0,1]$. For this purpose suppose that $\{\lambda_n\}_{n\in\mathbb{N}} \subset \mathcal{F}$ tends to λ as $n \to +\infty$. Let u_{λ_n} be the solution to problem (P_{λ_n}). Then $u_{\lambda_n} - u_{\lambda_m}$ turns out to be a solution to the Cauchy problem

$$\begin{cases} D_t\big(u_{\lambda_n} - u_{\lambda_m}\big)(t,x) = \mathcal{A}_{\lambda_n}(t,x)\Big(u_{\lambda_n}(t,x) - u_{\lambda_m}(t,x)\Big) \\ \qquad\qquad + \big(\mathcal{A}_{\lambda_n} - \mathcal{A}_{\lambda_m}\big)(t,x)u_{\lambda_m}(t,x), \qquad (t,x) \in [0,T] \times \mathbb{R}^n, \\ \big(u_{\lambda_n} - u_{\lambda_m}\big)(0,x) = 0, \qquad x \in \mathbb{R}^n. \end{cases} \tag{4.32}$$

Taking advantage of Lemma 2.5 and (4.31), it can be easily proved that $(\mathcal{A}_{\lambda_n} - \mathcal{A}_{\lambda_m})u_{\lambda_m}$ is measurable, belongs to $B([0,T];C_p^\theta(\mathbb{R}^n))$, and

$$\begin{aligned} \|\big(\mathcal{A}_{\lambda_n} - \mathcal{A}_{\lambda_m}\big)u_{\lambda_m}\|_{C_p^\theta(\mathbb{R}^n)} &\le C(p)|\lambda_n - \lambda_m|\Big(\|u_0\|_{C_p^{2+\theta}(\mathbb{R}^n)} + \|f\|_{B([0,T];C_p^\theta(\mathbb{R}^n))}\Big) \\ &\times \left(\sum_{i,j=1}^n \|q_{i,j}\|_{B([0,T];C^\theta(\mathbb{R}^n))} + \sum_{j=1}^n \|b_j\|_{B([0,T];C^\theta(\mathbb{R}^n))} + \|c\|_{B([0,T];C^\theta(\mathbb{R}^n))}\right). \end{aligned} \tag{4.33}$$

From (4.33), we deduce that $\{u_{\lambda_n}\}_{n\in\mathbb{N}}$ is a Cauchy sequence in $B([0,T];C_p^{2+\theta}(\mathbb{R}^n))$. Therefore, there exists $u \in B([0,T];C_p^{2+\theta}(\mathbb{R}^n))$ such that $u_{\lambda_n} \to u$ as $n \to +\infty$. We remark here that u_{λ_n}, $D_x u_{\lambda_n}$, $D_x^2 u_{\lambda_n} \in C([0,T]\times\mathbb{R}^n)$. Hence u and its first- and second-order space derivatives are continuous functions in $[0,T]\times\mathbb{R}^n$. Moreover, $D_t(u_{\lambda_n} - u_{\lambda_m})$ is a Cauchy sequence in $L^\infty(G)$, where G is a measurable subset of $[0,T]\times\mathbb{R}^n$ with negligible complement in $[0,T]\times\mathbb{R}^n$ and such that for any $x\in\mathbb{R}^n$, the set $G(x) = \{t\in[0,T] : (t,x)\in G\}$ is measurable with measure T and $D_t u_{\lambda_n} = \mathcal{A}(\cdot,\cdot)u_{\lambda_n} + f$ in G. Therefore, there exists a measurable function h such that $D_t u_{\lambda_n} \to h$ in $L^\infty(G)$. By assumption, $u_{\lambda_n}(\cdot,x)$, $x\in\mathbb{R}^n$, is Lipschitz continuous in $[0,T]$. Therefore, from (4.31) and (4.33), we deduce that

$$\begin{aligned}\Big|\frac{u_{\lambda_n}(t_2,x)}{p(x)} - \frac{u_{\lambda_n}(t_1,x)}{p(x)}\Big| &\le \int_{t_1}^{t_2}\frac{|D_t u_{\lambda_n}(s,x)|}{p(x)}ds\\ &\le C_2\Big(\|u_0\|_{C_p^{2+\theta}(\mathbb{R}^n)} + \|f\|_{B([0,T];C_p^\theta(\mathbb{R}^n))}\Big)|t_2-t_1| \qquad (4.34)\end{aligned}$$

for any t_1, $t_2\in[0,T]$, any $x\in\mathbb{R}^n$, and some positive constant C_2. As $n\to+\infty$ we deduce that $u(\cdot,x)$ is a Lipschitz continuous function for any $x\in\mathbb{R}^n$. Then, reasoning as in (3.35), we can prove that $u/p \in \mathrm{Lip}\,([0,T]\times\mathbb{R}^n)$. Now it is an easy task to show that for any $x\in\mathbb{R}^n$, there exists a measurable set $H(x)$ with measure T such that $h(t,x) = D_t u(t,x)$ and $D_t u(t,x) = \mathcal{A}(t,x)u(t,x) + f(t,x)$ for any $t\in H(x)$. Next we observe that $D_t u$, h, and $\mathcal{A}(\cdot,\cdot)u + f$ are a.e. defined and measurable in $[0,T]\times\mathbb{R}^n$. Therefore, thanks to the Fubini–Tonelli theorem, it can be proved that $D_t u = h$ and $D_t u = \mathcal{A}(\cdot,\cdot)u + f$ a.e. in $[0,T]\times\mathbb{R}^n$ so that condition (iii) in Definition 1.1 holds. Consequently, $\mathcal{F}$ is closed in $[0,1]$.

Now we prove that $\mathcal{F}$ is open in $[0,1]$. Thanks to (4.31), for any $\lambda\in\mathcal{F}$, we can define the operator $\mathcal{M}(\lambda)$ that with any pair (u_0,f) of initial data associates the solution to problem (P_λ). Suppose that $\lambda_0\in\mathcal{F}$ and consider λ next to λ_0. Then we write (P_λ) in the following form:

$$\begin{cases} D_t u(t,x) = \mathcal{A}_{\lambda_0}(t,x)u(t,x) + \big(\mathcal{A}_\lambda - \mathcal{A}_{\lambda_0}\big)(t,x)u(t,x) + f(t,x),\\ \qquad\qquad (t,x)\in[0,T]\times\mathbb{R}^n,\\ u(0,x) = u_0(x), \qquad x\in\mathbb{R}^n. \end{cases} \qquad (4.35)$$

As is easily seen, for any $u\in B([0,T];C_p^{2+\theta}(\mathbb{R}^n))$, $(\mathcal{A}_\lambda - \mathcal{A}_{\lambda_0})u$ is a measurable function belonging to $B([0,T];C_p^\theta(\mathbb{R}^n))$ and satisfying estimate (4.33) with (λ_n,λ_m) replaced by (λ,λ_0) and u_{λ_n} replaced by u. Therefore, we deduce that if u is a measurable solution to (P_λ), then u solves the following fixed-point problem

$$u = F(u) := \mathcal{M}(\lambda_0)(u_0,0) + \mathcal{M}(\lambda_0)(0,\big(\mathcal{A}_\lambda - \mathcal{A}_{\lambda_0}\big)u) + M(\lambda_0)(0,f). \qquad (4.36)$$

F is a contraction map in $\mathcal{X} = \{f\in B([0,T];C_p^{2+\theta}(\mathbb{R}^n)) : f \text{ is measurable in } [0,T]\times\mathbb{R}^n\}$ that is a Banach space when endowed with the norm of $B([0,T];C_p^{2+\theta}(\mathbb{R}^n))$. In fact, F maps $\mathcal{X}$ into itself. Moreover, for any u_1, $u_2\in\mathcal{X}$,

$$\begin{aligned}\|F(u_2) - F(u_1)\|_{B([0,T];C_p^{2+\theta}(\mathbb{R}^n))} &= \|\mathcal{M}(\lambda_0)(0,\mathcal{A}_\lambda - \mathcal{A}_{\lambda_0})(u_2-u_1)\|_{B([0,T];C_p^{2+\theta}(\mathbb{R}^n))}\\ &\le C_3(p,Q_0,B_0,c)|\lambda-\lambda_0|\|u_1-u_2\|_{B([0,T];C_p^{2+\theta}(\mathbb{R}^n))}\end{aligned}$$

for some positive constant $C_3(p,Q_0,B_0,c)$. Therefore, for $|\lambda-\lambda_0|$ sufficiently small, F is a contraction map in $B([0,T];C_p^{2+\theta}(\mathbb{R}^n))$, and consequently (4.36) admits a unique

solution $u \in B([0,T];C_p^{2+\theta}(\mathbb{R}^n))$. Then it is easy to show that such u is a solution to (P_λ). Therefore, $\lambda \in \mathcal{F}$. Being an open and closed set, $\mathcal{F}$ coincides with $[0,1]$ and the assertion follows. □

Appendix.

LEMMA A.1. *For any $f : [0,T] \times \mathbb{R}^n \to \mathbb{R}$ such that $f/p \in L^\infty([0,T] \times \mathbb{R}^n)$ and $f(r,\cdot)$ is measurable for any $r \in [0,T]$, we define the functions $L(f)$, $M(f) : [0,T]^2 \times \mathbb{R}^n \to \mathbb{R}$ as follows:*

$$L(f)(t,r,x) = \begin{cases} G(t,r)f(r,\cdot)(x), & (t,r,x) \in E(T) \times \mathbb{R}^n, \\ 0 & \text{elsewhere in } [0,T]^2 \times \mathbb{R}^n, \end{cases}$$

and

$$M(f)(t,r,x) = \begin{cases} D_t G(t,r)f(r,\cdot)(x), & (t,r,x) \in \big(\widetilde{E}(T) \cap (E_0 \times [0,T])\big) \times \mathbb{R}^n, \\ 0 & \text{elsewhere in } [0,T]^2 \times \mathbb{R}^n, \end{cases}$$

where $E(T) = \{(t,r) \in [0,T]^2 : r \le t\}$, $\widetilde{E}(T) = \{(t,r) \in [0,T]^2 : r < t,\ t \in E_0\}$, and E_0 is defined in Lemma 3.7. Then the following properties hold true:

(i) *$L(f)$ and $M(f)$ are measurable in $[0,T]^2 \times \mathbb{R}^n$;*
(ii) *for any $x \in \mathbb{R}^n$, the functions $L(f)(\cdot,\cdot,x)$ and $M(f)(\cdot,\cdot,x)$ are measurable in $[0,T]^2$;*
(iii) *for any $(t,x) \in [0,T] \times \mathbb{R}^n$, the functions $L(f)(t,\cdot,x)$ and $M(f)(t,\cdot,x)$ are measurable in $[0,T]$;*
(iv) *for any $(r,x) \in [0,T] \times \mathbb{R}^n$, the functions $L(f)(\cdot,r,x)$ and $M(f)(\cdot,r,x)$ are measurable in $[0,T]$;*
(v) *the function $N(f) : E_0 \times \mathbb{R}^n \to \mathbb{R}$ defined by*

$$N(f)(t,x) = \int_0^t D_t G(t,r)f(r,\cdot)(x)dr$$

for any $(t,x) \in E_0 \times \mathbb{R}^n$, is measurable.

Proof. We sketch the proof. Let us consider $L(f)$ and suppose that f is a continuous function in $[0,T] \times \mathbb{R}^n$ with $f/p \in L^\infty([0,T] \times \mathbb{R}^n)$. Then $L(f)$ is a continuous function in $E(T)$. Hence it is measurable in $[0,T]^2 \times \mathbb{R}^n$. Next we suppose that f is a measurable function with support contained in $[0,T] \times B(0,h)$ for some $h \in [0,T]$. From Lusin's theorem, we deduce that there exists a sequence $\{f_k\}_{k\in\mathbb{N}}$ of continuous functions converging to f a.e. in $[0,T] \times \mathbb{R}^n$ and such that $\|f_k/p\|_\infty \le \|f/p\|_\infty$ for any $k \in \mathbb{N}$. Then an easy application of the dominated convergence theorem shows that the sequence $\{L(f_k)\}_{k\in\mathbb{N}}$ converges to $L(f)$ as $k \to +\infty$ in $E(T) \cap ([0,T] \times \mathcal{C}) \times \mathbb{R}^n$. Here $\mathcal{C}$ denotes the set of all $r \in [0,T]$ such that $f_k(r,\cdot) \to f(r,\cdot)$ a.e. in $\mathbb{R}^n$ as $k \to +\infty$. Obviously, $\mathcal{C}$ is a measurable set in $[0,T]$ with measure T. Hence $L(f)$ is still a measurable function. Next, with any measurable function f such that $f/p \in L^\infty([0,T] \times \mathbb{R}^n)$, we associate the sequence $\{f_k\}_{k\in\mathbb{N}}$ defined by $f_k \equiv f$ in $[0,T] \times B(0,k)$ and $f_k \equiv 0$ elsewhere in $[0,T] \times \mathbb{R}^n$. $L(f_k)$ is measurable and converges to $L(f)$ everywhere in $[0,T]^2 \times \mathbb{R}^n$. Hence $L(f)$ is measurable in $[0,T]^2 \times \mathbb{R}^n$.

The same technique can be used to prove that for any $t \in [0,T]$ and any $x \in \mathbb{R}^n$, the functions $L(f)(t,\cdot,x)$, $L(f)(\cdot,\cdot,x)$ are measurable in $[0,T]$ and $[0,T]^2$, respectively. Moreover, to prove that $t \to Lf(t,r,x)$ is measurable in $[0,T]$ for any $(r,x) \in [0,T] \times \mathbb{R}^n$, it suffices to observe that the function $t \to G(t,r)f(r,\cdot)(x)$ is continuous in $(r,T]$.

We now consider the function $M(f)$. We observe that for any continuous function f such that f/p is bounded in $[0,T]\times\mathbb{R}^n$, then $M(f)$ is measurable in $[0,T]^2\times\mathbb{R}^n$. In fact, let us consider the approximating functions $Q_0^{(k)}$, $B_0^{(k)}$, and $c^{(k)}$ defined in Lemma 3.10 and the semigroup G_k defined as G with Q_0, B_0, and c replaced by $Q_0^{(k)}$, $B_0^{(k)}$, and $c^{(k)}$, respectively. Then it is easy to check that the function $(t,r,x)\to D_tG_k(t,r)f(r,\cdot)(x)$ is continuous in $\widetilde{E}(T)\times\mathbb{R}^n$. Moreover, $D_tG_k(t,r)f(r,\cdot)(x)\to D_tG(t,r)f(r,\cdot)(x)$ as $k\to+\infty$ for any $(t,r,x)\in(\widetilde{E}(T)\cap[(\mathcal{F}\cap E_0)\times[0,T]])\times\mathbb{R}^n$. Here $\mathcal{F}$ denotes the set of all $t\in[0,T]$ such that $Q_0^{(k)}$, $B_0^{(k)}$, and $c^{(k)}$ converge to Q_0, B_0, and c, respectively. Hence $M(f)$ is measurable in $[0,T]^2\times\mathbb{R}^n$. Then, reasoning as in the case of $L(f)$, it can be easily proved that $M(f)$ is measurable for any measurable function f such that f/p is bounded.

By the same technique, it can be proved that the function $(t,r)\to M(f)(t,r,x)$ is measurable for any $x\in\mathbb{R}^n$. Next, by virtue of the dominated convergence theorem, it can be easily proved that for any t and any $x\in\mathbb{R}^n$, the function $M(f)(t,\cdot,x)$ is measurable in $[0,T]$. Then, reasoning as in the proof of the measurability of the function $L(f)$ it can be easily shown that for any $(r,x)\in[0,T]\times\mathbb{R}^n$ the function $M(f)(\cdot,r,x)$ is measurable in $[0,T]$.

To conclude we consider the function $N(f)$. By the previous results, we already know that the function $r\to D_tG(t,r)f(r,\cdot)(x)$ is measurable in $[0,T]$ for any $(t,x)\in E\times\mathbb{R}^n$. Moreover, thanks to Theorem 3.5 and Lemma 3.7, we deduce that there exists a positive constant D such that $\|D_tG(t,r)f(r,\cdot)(x)\|\le Dp(x)|t-r|^{1-\theta/2}$ a.e. in $[0,t]$. Consequently, $N(f)$ is well defined. Then we observe that $M(f)$ is integrable in $[0,T]^2\times K$ for any compact set $K\subset\mathbb{R}^n$. Thanks to the Fubini–Tonelli theorem, we easily deduce that $N(f)$ is a measurable function in $[0,T]\times\mathbb{R}^n$. □

LEMMA A.2. *Suppose that*

(i) $u\in\mathrm{Lip}\,([0,T]\times\mathbb{R}^n)$ *with support contained in a compact set* $[0,T]\times K\subset[0,T]\times\mathbb{R}^n$;

(ii) u *is twice continuously differentiable with respect to the variable* x *in* $[0,T]\times\mathbb{R}^n$;

(iii) u *is differentiable with respect to the variable* t *for any* $(t,x)\in F\subset[0,T]\times\mathbb{R}^n$ *and* $D_tu(t,x)=\mathcal{A}(t,x)u(t,x)$ *for any* $(t,x)\in F$, *where* F *is a measurable set such that its complement in* $[0,T]\times\mathbb{R}^n$ *is negligible and for any* $x\in\mathbb{R}^n$, *the set* $F(x)=\{t\in[0,T]:\ (t,x)\in F\}$ *is measurable in* $[0,T]$ *with measure* T.

Then there exists a measurable set $A\subset[0,T]$ *with measure* T *such that for any* $(t,\xi)\in A\times\mathbb{R}^n$, *we have*

$$D_t\widehat{u}(t,\xi)=\left(-\sum_{i,j=1}^n q_{i,j}(t)\xi_i\xi_j+\mathrm{i}\sum_{j=1}^n b_j(t)\xi_j+c(t)\right)\widehat{u}(t,\xi),$$

where $\widehat{u}(t,\cdot)$ *denotes the Fourier transform of the function* $u(t,\cdot)$.

Proof. By assumption, F^c is negligible. Therefore, there exists a measurable set A with measure T such that $\mathbb{R}^n\backslash F(t)$ is negligible for any $t\in A$. Here $F(t)=\{x\in\mathbb{R}^n:\ (t,x)\in F\}$. Hence for any $t_0\in A$, we have

$$\begin{aligned}&(t-t_0)^{-1}\int_{\mathbb{R}^n}\big[u(t,x)-u(t_0,x)\big]\exp(-\mathrm{i}\,x\cdot\xi)dx\\&\quad=(t-t_0)^{-1}\int_{F(t_0)}\big[u(t,x)-u(t_0,x)\big]\exp(-\mathrm{i}\,x\cdot\xi)dx.\end{aligned}$$

Next we observe that $u(\cdot,x)$ is differentiable with respect to the variable t in t_0 for any $x \in F(t_0)$ and

$$|u(t,x)-u(t_0,x)| \le [u]_{\mathrm{Lip}\,(\mathbb{R}^n)}\chi_K|t-t_0|.$$

Applying the dominated convergence theorem, we deduce that the Fourier transform of u is differentiable with respect to the variable t at each point $(t,x) \in A \times \mathbb{R}^n$ and

$$D_t\widehat{u}(t,\xi) = \int_{F(t)} D_t u(t,x)\exp(-\mathrm{i}\,x\cdot\xi)dx.$$

By assumption,

$$D_t u(t,x) = \sum_{i,j=1}^n q_{i,j}(t)D^2_{i,j}u(t,x) + \sum_{j=1}^n b_j(t)D_j u(t,x) + c(t)u(t,x) \qquad \forall (t,x)\in F.$$

In particular, the previous relationship holds for any $t \in A$ and any $x \in F(t)$. Hence

$$\begin{aligned} D_t\widehat{u}(t,\xi) &= \sum_{i,j=1}^n q_{i,j}(t)\int_{\mathbb{R}^n} D^2_{i,j}u(t,x)\exp(-\mathrm{i}\,x\cdot\xi)dx \\ &\quad + \sum_{j=1}^n b_j(t)\int_{\mathbb{R}^n} D_j u(t,x)\exp(-\mathrm{i}\,x\cdot\xi)dx + c(t)\int_{\mathbb{R}^n} u(t,x)\exp(-\mathrm{i}\,x\cdot\xi)dx \\ &= \left(-\sum_{i,j=1}^n q_{i,j}(t)\xi_i\xi_j + \mathrm{i}\sum_{j=1}^n b_j(t)\xi_j + c(t)\right)\widehat{u}(t,\xi) \quad \forall (t,\xi)\in A\times\mathbb{R}^n. \end{aligned}$$

□

LEMMA A.3. *Suppose that f is a measurable function belonging to $B([0,T];C(\mathbb{R}^n))$. Then for any $r \in [0,T]$ and any $x \in \mathbb{R}^n$, the functions $f(r,\cdot)$ and $f(\cdot,x)$ are measurable in $\mathbb{R}^n$ and $[0,T]$, respectively.*

Proof. We begin by observing that, trivially, for any $r \in [0,T]$, the function $f(r,\cdot)$ is measurable in $\mathbb{R}^n$. Next we consider the function $f(\cdot,x)$. By Fubini's theorem, there exists a measurable set $\mathcal{D} \subset \mathbb{R}^n$ such that its complement is negligible and the function $f(\cdot,x)$ is measurable in $[0,T]$ for any $x \in \mathcal{D}$. Then with any $x \in \mathbb{R}^n$ we associate a sequence $\{x_n\}_{n\in\mathbb{N}} \subset \mathcal{D}$ converging to x as $n \to +\infty$. Since $f(r,\cdot) \in C(\mathbb{R}^n)$ for any $r \in [0,T]$, we immediately deduce that $f(\cdot,x)$ is the pointwise limit of the sequence of measurable functions $f(\cdot,x_n)$. Consequently, $f(\cdot,x)$ is measurable in $[0,T]$. □

COROLLARY A.4. *Let p be either the polynomial or the exponential weight function and f a measurable function belonging to $B([0,T];C^\theta_p(\mathbb{R}^n))$. Then for any $r \in [0,T]$ and any $x \in \mathbb{R}^n$, the functions $f(r,\cdot)$ and $f(\cdot,x)$ are measurable in $\mathbb{R}^n$ and $[0,T]$, respectively.*

Proof. It suffices to apply Lemma A.3 to the function f/p. □

LEMMA A.5. *Suppose that p is either the polynomial or the exponential weight function. Then for any function $f : [0,T]\times\mathbb{R}^n \to \mathbb{R}$ such that f/p is a bounded and Lipschitz continuous, the function $t \to \|f\|_{B([0,t];C_p(\mathbb{R}^n))}$ is Lipschitz continuous in $[0,T]$.*

Proof. It suffices to observe that for any t_1, $t_2 \in [0,T]$, we have

$$\left|\|f\|_{B([0,t_2];C_p(\mathbb{R}^n))} - \|f\|_{B([0,t_1];C_p(\mathbb{R}^n))}\right| \le [f/p]_{\mathrm{Lip}\,([0,T]\times\mathbb{R}^n)}|t_2-t_1|.$$

OPTIMAL APPROXIMATIONS OF TRANSPORT EQUATIONS BY PARTICLE AND PSEUDOPARTICLE METHODS*

ALBERT COHEN† AND BENOIT PERTHAME†

Abstract. The convergence rate of particle methods for solving linear transport equations is revisited. Denoting h the initial discretization parameter, we prove a quasi-optimal rate of convergence like $h^{s-\varepsilon}$ for all $\varepsilon > 0$ for an initial data in the Sobolev space $W^{s,p}$ when choosing appropriate initial integration rules and general convolution. As it is well known, this suboptimality is due to the form and width of the convolution kernel. In particular, it can be fixed by computing an additional quantity, the cell deformation. Then one can restore the optimal rate of convergence, up to the first order ($s = 1$), while keeping the built-in conservative aspect. To avoid these additional computations and move to higher order optimality, another strategy is introduced and analyzed. It is based on a discretization of the solution at initial time by local averages but differs from the usual particle methods: the local averages are viewed as point values of an approximation of the solution, and the regularization of the solution at time $t > 0$ is performed by interpolation rather than convolution. This strategy allows us to recover optimal error estimates in L^p or Sobolev norms (up to any prescribed order).

1. Introduction.

Particle methods are of common use for the numerical simulation of transport equations. These methods typically operate in three steps:

(i) The initial value $u_0(x) := u(x, t = 0)$ is approximated in the distribution sense by a linear combination $v_0(x) := \sum_k \alpha_k \delta_{x_k}$ of Dirac masses, with weights α_k that represent the integral of u_0 in a neighborhood the point x_k.

(ii) One follows the time evolution of the *p*article solution that corresponds to the initial measure v_0. Due to the form of the equation, this exact solution (in the distribution sense) can be written $v(x,t) = \sum_k \alpha_k(t)\delta_{x_k(t)}$. The evolution of the weights $\alpha_k(t)$ and locations $x_k(t)$ of the particles is described by ordinary differential equations that can be simulated by high order numerical techniques.

(iii) In order to recover a proper approximation of the solution $u(x,t)$ at some time $t > 0$, one needs to regularize the particle solution $v(x,t)$. Such a regularization is usually performed by a convolution product with a so-called "cut-off function" φ after a proper scaling $\varphi_\varepsilon(x) := \varepsilon^{-d}\varphi(x/\varepsilon)$ that takes into account the initial tightness of the particle discretization.

These methods have been widely used to solve conservative nonlinear transport equations: see [11] and [7] for recent applications to incompressible fluid dynamics (more precisely, vortex methods), and [10] for applications to kinetic equations (more precisely, Vlasov equations). In a linear context, they have been analyzed in [14] (see also [7] and [13] for a general introduction to these methods and their numerical analysis). We recall here the main features in the specific setting of the model

transport problem

$$\frac{\partial u}{\partial t} + \sum_{i=1}^{d} \frac{\partial}{\partial x_i}(a_i u) + a_0 u = f, \quad x \in \mathbb{R}^d, \ 0 \le t \le T, \tag{1.1}$$

with some initial data $u_0(x) := u(x, 0)$. In order to simplify the analysis, we assume here that the data f and the coefficients a_i are C^∞ functions in space and time, and that a_i and its derivatives are uniformly bounded on $\mathbb{R}^d \times [0, T]$, $1 \le i, j \le d$. These assumptions ensure that the evolution operator

$$E_t : \ u(0) \mapsto u(t) := u(\cdot, t) \tag{1.2}$$

is well defined and bounded in all Sobolev spaces $W^{s,p}$, $s \ge 0$, $1 \le p \le \infty$ (see [14]). It can be built through the method of characteristics. One can define a family of C^∞ diffeomorphisms Φ_t for $0 \le t \le T$, by $\Phi_t(x) = z(t)$ where z is the solution of

$$\frac{\partial z_i}{\partial t} = a_i(z), \quad i = 1, \ldots, d, \quad z(0) = x. \tag{1.3}$$

When the initial data u_0 is smooth enough, say, C^1, the classical solution of (1.1) exists and is built as follows: for all $x \in \mathbb{R}^d$, the value $v_x(t) = u(\Phi_t(x), t)$ is given by an ordinary differential equation

$$\frac{d}{dt} v_x(t) = f(\Phi_t(x), t) - \tilde{a}_0(\Phi_t(x), t) v_x(t), \quad v_x(0) = u_0(x), \tag{1.4}$$

with $\tilde{a}_0 := a_0 + \mathrm{div} a$. In particular the value is preserved on the characteristics curves $\Phi_t(x)$ if $f = \tilde{a}_0 = 0$.

Particle methods allow us to treat solutions that are not necessarily continuous. They are particularly well adapted to the conservative form of (1.1) as shown by the following example: given an initial discretization parameter h, one defines a weak approximation of u_0 by the measure

$$v_h(0) := \sum_{k \in \mathbb{Z}^d} \alpha_k \delta(\cdot - kh), \tag{1.5}$$

where δ_x denotes the Dirac function at some point x and

$$\alpha_k := \int_{kh + Q_h} u_0(x) dx, \quad Q_h := \left[-\frac{h}{2}, \frac{h}{2} \right]^d. \tag{1.6}$$

If $f = 0$, the solution of (1.1) in the distribution sense corresponding to the initial data (1.5) is exactly given at time t by

$$v_h(t) = \sum_{k \in \mathbb{Z}^d} \alpha_k(t) \delta(\cdot - x_k(t)), \tag{1.7}$$

where $x_k(t) = \Phi_t(kh)$ and the weights $\alpha_k(t)$ are solutions of the ordinary differential equations

$$\frac{d}{dt} \alpha_k(t) + a_0(x_k(t), t) \alpha_k(t) = 0, \quad \alpha_k(0) = \alpha_k. \tag{1.8}$$

The value of $\alpha_{k,t}$ is an approximation of the integral of the real solution u_t over the transported domain $\Phi_t(kh+Q_h)$. In particular, this approximation is consistent with the conservation of this quantity when $a_0 = 0$.

When the source term is nonzero, it needs to be approximated in a proper way: a possibility is to take

$$f_h = \sum_{k\in\mathbb{Z}^d} \beta_k(t)\delta(x - x_k(t)), \tag{1.9}$$

where $\beta_{k,t}$ takes account of the source f over $\Phi_t(kh + Q_h)$. Since the shape of this transported domain is not exactly known in practice, one usually uses a quadrature formula of the type

$$\beta_k(t) := w_k(t)f(x_k(t), t), \quad w_k(t) = h^d|\det(D\Phi_t)(kh)|. \tag{1.10}$$

The particle solution is then again given by (1.7) with weights satisfying the ordinary differential equations

$$\frac{d}{dt}\alpha_k(t) + a_0(x_k(t), t)\alpha_k(t) = \beta_k(t), \quad \alpha_k(0) = \alpha_k. \tag{1.11}$$

The regularization by convolution with $\varphi_\varepsilon := \varepsilon^{-d}\varphi(\cdot/\varepsilon)$ yields an approximation $u_{h,\varepsilon}(t)$ of the real solution $u(\cdot, t)$ at time $t \in]0, T]$, with the expression

$$u_{h,\varepsilon}(t) := v_h(t) * \varphi_\varepsilon = \sum_{k\in\mathbb{Z}^d} \alpha_k(t)\varphi_\varepsilon(\cdot - x_k(t)). \tag{1.12}$$

For a given $h > 0$, the value of $\varepsilon > 0$ needs to be chosen in such a way that the error $\|u(t)-u_{h,\varepsilon}(t)\|$ in some prescribed norm—or an estimation of this error—is optimized.

Intuitively, this optimal choice solves a compromise. On the one hand, if ε is small in comparison to the minimal distance between the points $x_k(t)$, the approximate solution defined by (1.12) will vanish away from these points and is thus irrelevant. On the other hand, if ε is too large, the approximate solution will contain only low frequencies and will necessarily lack accuracy.

This compromise is expressed in the classical error estimate for such methods [14]. If φ is a $W^{m,1}$ function such that $\int \varphi = 1$, $\int |x|^r|\varphi(x)|dx < \infty$ and

$$\int x_1^{k_1} \cdots x_d^{k_d}\varphi(x_1, \ldots, x_d) = 0, \quad |k| := k_1 + \cdots + k_d \le r - 1 \tag{1.13}$$

for some prescribed $m > 0$ and integer $r > 0$, then the following error estimate can be proved to hold: there is a constant $C(t)$ depending only on the time t such that for all $0 < h \le \varepsilon \le 1$,

$$\|u(t) - u_{h,\varepsilon}(t)\|_{L^p} \le C(t)\Big(\varepsilon^r|u_0|_{W^{r,p}} + (h/\varepsilon)^m\|u_0\|_{W^{m,p}}\Big). \tag{1.14}$$

The optimization of (1.14) obliges to choose $\varepsilon \sim h^{m/(m+r)}$, yielding a suboptimal estimate in $h^{mr/(m+r)}$, depending strongly on the choice of the function φ (through the smoothness m and the number r of vanishing moments). With the best possible choice of φ and the parameters, for a given initial regularity $W^{s,p}$ (i.e., with φ such that $s = m = r\}$), one thus obtains only the error estimate $h^{s/2}\|u_0\|_{W^{s,p}}$. However, since the particle method is based on a discretization of step size h, an optimal result should yield an estimate in $Ch^s\|u_0\|_{W^{s,p}}$.

The explanation of this lack of accuracy is simple. The necessity to choose ε substantially larger than h is somehow related to the fact that for $t > 0$ the grid of particle $(x_k(t))_{k\in\mathbb{Z}^d}$ is no longer uniform. In contrast, one can easily design a function φ such that the optimal estimate

$$\|u(t) - u_{h,h}(t)\|_{L^p} \leq C(t)h^s\|u_0\|_{W^{s,p}} \tag{1.15}$$

holds at time $t = 0$. To do so, it is sufficient to impose that the operator

$$f \mapsto Pf := \sum_{k\in\mathbb{Z}^d} \langle f, \chi_{Q_1}(\cdot - k)\rangle\varphi(\cdot - k) \tag{1.16}$$

reproduces polynomials up to order $[s]$ and use classical approximation theory arguments as in [2] or [15]. Concrete examples of functions φ satisfying such properties are provided in particular by the biorthogonal wavelet theory developed in [6] (see also Chapter II in [5]). The suboptimality of (1.14) reveals a weakness of the convolution method for regularization: in terms of approximation theory, convolution is better adapted to translation invariant data, and optimal error rates are lost out of this setting. On the other hand, as h goes to zero, the spacing between the particles at time t is still in $\mathcal{O}(h)$ (with constants depending on t), so that it is reasonable to search for an alternate method that yields the optimal error estimate in $h^s\|u_0\|_{W^{s,p}}$.

In the present paper, we propose to go further in the search for accuracy. A first possibility, which yields a quasi-optimal method in $h^{s-\beta}$, $\beta > 0$, is to play with the initial integration rule. We choose a better formula than (1.6), replacing the indicator function by a function $\tilde{\varphi}$. This yields

$$\alpha_k = \int u_0(x)\tilde{\varphi}(x - kh)dx.$$

We first show that, with appropriate functions $\tilde{\varphi}$, one can already obtain this quasi-optimal error estimate. This result is already interesting because it proves that particle methods are potentially better than finite volumes methods (another conservative method) which only converge with the rate $h^{1/2}$ for BV data. A second method consists of using a better reconstruction of $u_{h,\varepsilon}$. We show that it is possible to adapt locally the width of the convolution kernel with the help of new differential equations which describe the deformation of the initial grid. Then an optimal rate can be restored, keeping the natural conservation property of particle methods, but this method is limited to first order estimates.

To go further we propose a third method to restore the optimal error estimate at any order and without solving new differential equations. It is based on a different regularization technique. The main idea underlying this technique is to approximate the initial value by a smooth function $v_{0,h}$ whose point values on the grid $h\mathbb{Z}^d$ are given by local averages of u_0 and to follow the evolution of this function on the transported grid using the ordinary differential equation (1.4). At time $t > 0$, convolution is then replaced by an interpolation process that requires a particular design in order to obtain the optimal result. We refer to this strategy as a "pseudoparticle" method, since formally it also amounts to solving ordinary differential equations for each trajectory related to an initial grid point, but the solutions no longer describe the evolution of a combination of Dirac masses and thus the local conservation of mass is lost (it can nevertheless be restored by a correction that does not change the optimal order of accuracy). It should pointed out that interpolation techniques have already been

considered in [1] for the purpose of improving the accuracy of the vortex methods at large time.

The outline of the paper is the following. We first present in section 2 the quasi-optimal method based on appropriately choosing the initial weights. In section 3, we prove the optimal estimate based on convolution with a locally varying kernel. A very simple one-dimensional example of the pseudoparticle strategy (and a proof of its optimality) is described in section 4. We then describe in section 5 the pseudoparticle method, in particular the discretization of the initial value u_0 and the interpolation process at time $t > 0$. Finally, we derive in section 6 the optimal error estimates for this method. Throughout the paper, $C(t)$ will always denote a constant which is independent of the various parameters (initial value, mesh size h) but may vary with t.

2. A quasi-optimal estimate with improved initial quadrature. We consider the particle methods described in the introduction with $f = 0$ for the sake of simplicity. In this section, we show a quasi-optimal a priori L^p-estimates, in $C_\beta h^{s-\beta}$ for all $\beta > 0$, when the initial data u_0 has $W^{s,p}$ smoothness. It is obtained by improving the initial weights through a particular initial "quadrature" formula based on an appropriate averaging function $\tilde{\varphi}$. Notice that at initial time $t = 0$, the optimal approximation rate h^s can be obtained by choosing the pair averaging-convolution $(\tilde{\varphi}, \varphi)$ with particular relations; see (1.16) and sections 4 and 5. However, this optimality is lost in general for time $t > 0$ due to the particle dynamic and considerations on $\tilde{\varphi}$ are enough for the present quasi-optimal result.

More specifically, for our first construction we consider a compactly supported function $\tilde{\varphi} \in C^0(\mathbb{R}^d)$ which satisfies the conditions

$$\sum_{k\in\mathbb{Z}^d} \tilde{\varphi}(. - k) = 1, \tag{2.1}$$

$$\sum_{k\in\mathbb{Z}^d} k_1^{p_1} \cdots k_d^{p_d} \tilde{\varphi}(y - k) = y_1^{p_1} \cdots y_d^{p_d}, \quad |p| \le m - 1. \tag{2.2}$$

In the particle method described in the introduction, we use the initial weights (again with the notation $\tilde{\varphi}_h(y) = \tilde{\varphi}(h^{-1}y)$)

$$\alpha_k(0) = \int_{\mathbb{R}^d} u_0(y)\tilde{\varphi}_h(y - kh)dy. \tag{2.3}$$

We also introduce a compactly supported continuous cut-off $\varphi \in W^{m,1}$ such that

$$\int_{\mathbb{R}^d} \varphi = 1, \tag{2.4}$$

$$\int_{\mathbb{R}^d} x_1^{k_1} \cdots x_d^{k_d} \varphi(x_1, \ldots, x_d) = 0, \ \ |k| \le r - 1, \tag{2.5}$$

and $\int_{\mathbb{R}^d} |x|^r |\varphi(x)|dx < \infty$. Then, defining the particle solution as in the introduction, we have the following result.

THEOREM 2.1. *We assume* (2.1), (2.2) for some $m > \frac{d}{p'}$ and $1 \le p \le \infty$, (2.4), and (2.5). Then there is a constant $C(m, t)$ which also depends on r, φ, and $\tilde{\varphi}$ such that for all $0 < h \le \varepsilon$,

$$\|u(t) - u_{h,\varepsilon}(t)\|_{L^p} \le C(t, m)\Big(\varepsilon^r \|u_0\|_{W^{r,p}} + (h/\varepsilon)^m \|u_0\|_{L^p}\Big). \tag{2.6}$$

Proof. As in the classical analysis of particle methods (see [14], [13], or [7]), we set $u_\varepsilon = u * \varphi_\varepsilon$ and we have to estimate

$$\|u(t) - u_{h,\varepsilon}(t)\|_{L^p} \le \|u(t) - u_\varepsilon(t)\|_{L^p} + \|u_\varepsilon(t) - u_{h,\varepsilon}(t)\|_{L^p}. \tag{2.7}$$

The first term in the right-hand side of the above inequality is classically upper bounded by $C(s,\varphi)\varepsilon^r \|u_0\|_{W^{r,p}}$ thanks to the assumptions (2.4), (2.5).

The second term is first treated as usual by an inverse estimate which yields

$$\begin{aligned} \|u_\varepsilon(t) - u_{h,\varepsilon}(t)\|_{L^p} &= \|\varphi_\varepsilon * (u(t) - v_h(t))\|_{L^p} \\ &\le C\varepsilon^{-m} \|u(t) - v_h(t)\|_{W^{-m,p}} \\ &\le C(t)\varepsilon^{-m} \|u(0) - v_h(0)\|_{W^{-m,p}}, \end{aligned}$$

where the last inequality comes from the stability of the evolution operator in $W^{-m,p}$. Introducing next the operators

$$u \mapsto P_h u := \sum_{k\in\mathbb{Z}^d} \langle u, \tilde\varphi_h(y - kh)\rangle \delta_{kh} \tag{2.8}$$

and

$$u \mapsto P_h^* u := \sum_{k\in\mathbb{Z}^d} u(kh)\tilde\varphi_h(y - kh), \tag{2.9}$$

we see that

$$\begin{aligned} \|u(0) - v_h(0)\|_{W^{-m,p}} &= \sup_{\|w\|_{W^{m,p'}}=1} |\langle w, u(0) - P_h u(0)\rangle| \\ &= \sup_{\|w\|_{W^{m,p'}}=1} |\langle w - P_h^* w, u(0)\rangle| \\ &\le C\|u(0)\|_{L^p} \sup_{\|w\|_{W^{m,p'}}=1} \|w - P_h^* w\|_{L^{p'}}, \end{aligned}$$

with $1/p' + 1/p = 1$. We finally remark that the assumptions (2.1) and (2.2) ensure that the interpolation operator P^* reproduces polynomials up to the degree $m-1$. Thus classical approximation theory argument yield the direct estimate

$$\|w - P_h^* w\|_{L^{p'}} \le Ch^m \|w\|_{W^{m,p'}}, \tag{2.10}$$

provided that $m > d/p'$ so that P_h^* can be applied to the functions in $W^{m,p'}$ which are then continuous. This allows us to derive the estimate in $(h/\varepsilon)^m \|u_0\|_{L^p}$ for the second term of (2.7). ∎

Remark 2.1. In particular, if $s \le r$, the optimal choice of the cut-off parameter $\varepsilon = h^{m/(m+s)}$ gives the convergence rate $h^{sm/(m+s)}$. As m tends to infinity, this rate tends to the optimal value h^s. But, whatever is the choice of $\tilde\varphi$, we should expect that the constant $C(t,m)$ tends to infinity with m.

Remark 2.2. Our method is in essence close to the method introduced in [3], which performs regularization of the initial condition before particle discretization. However, in [3], this regularization is performed at scale ε, resulting in more costful computations for the initial weights.

Remark 2.3. We can give examples of functions $\tilde\varphi$. The function Q_1 only satisfies (1.1) and thus the result holds with $m = 1$. For the hat function, see (4.1) below, one readily checks that the conditions (2.2) hold with $m = 2$. More generally, one can build examples at any order m in various manners. A possibility is to take the so-called

Deslaurier–Dubuc interpolatory scaling functions ϕ_m which are the autocorrelation $\varphi_m * \varphi_m(-\cdot)$ of the Daubechies orthonormal scaling function with support in $[0, 2m-1]$ (see Chapter II in [5]). In this case, (2.2) holds with order $2m$, the case $m = 1$ corresponding to the hat function $\phi_1 = \chi_{[0,1]} * \chi_{[-1,0]}$. Another possibility is to use cardinal splines of odd degree $2p + 1$, but these are nonlocal functions for $p \geq 1$. A last simple possibility is to replace the functions $\tilde{\varphi}_h(\cdot - kh)$ by the nodal basis functions of quadrilateral Lagrange finite elements of degree $m - 1$: these bases are not obtained from the shifts of a single function (except for $m = 2$), but they still yield an interpolation operator P_h^* with good approximation properties, which is the main tool needed in the above proof.

Remark 2.4. In the case of L^1 estimates, one can use BV smoothness in place of $W^{1,1}$ to derive the same rate, which allows discontinuities even in one dimension for the solution and is useful for applications.

3. A first order estimate with local convolutions. In this section we show that it is possible to restore the right order of convergence for particles methods in using a local convolution operator. Then the idea is to use a convolution with the indicator function of the local cell obtained in deforming the initial cell by the linearized flow—this depends of the point $x_k(t)$ under consideration. The advantage of this method is to keep the built-in local conservation of "mass" useful for many applications. The drawback is that, in order to adapt locally the convolution, we need to follow additional quantities (the deformation by the flow of the tangent space). This idea has already been used in the vortex case, in order to reduce the constant in the error estimate, by T.Y. Hou [12].

In order to simplify the analysis we limit ourselves to first order approximations in L^1 norms and we consider only the simplest case of initial weights given by (1.6). We introduce at time t the parallelepipedic cell $Q_{k,h}(t)$ obtained in deforming the initial cells Q_h with the linearized flow around the trajectory $x_k(t)$. In other words, we consider the linear operators (here the matrix Da is $\frac{\partial a_i}{\partial x_j}$)

$$\frac{d\mathcal{L}_{k,h}(t)}{dt} = Da\Big(x_k(t)\Big) \cdot \mathcal{L}_{k,h}(t), \tag{3.1}$$

$$\mathcal{L}_{k,h}(0) = Id. \tag{3.2}$$

And $Q_{k,h}(t) = \mathcal{L}_{k,h}(t) \cdot Q_h$. Next we consider the reconstruction

$$\tilde{u}_h(t,x) = \sum_{k \in \mathbb{Z}^d} \alpha_k(t) Vol\Big(Q_{k,h}(t)\Big)^{-1} \chi_{Q_{k,h}(t)}(x - x_k(t)), \tag{3.3}$$

where χ_E denotes the indicator function of the set E. Then we have the following theorem.

THEOREM 3.1. *We make the assumptions of the introduction for* (1.1) *and the above construction. Then there is a constant such that*

$$\|u(t) - \tilde{u}_h(t)\|_{L^1} \leq C(t)h \tag{3.4}$$

for all $u_0 \in BV(\mathbb{R}^d)$.

Remark 3.1. In the conservative case, $a_0 = 0$, we have

$$\int_{\mathbb{R}^d} \tilde{u}_h(t,x)dx = \sum_{k\in\mathbb{Z}^d} \alpha_k(t) Vol\Big(Q_{k,h}(t)\Big)^{-1} Vol\Big(Q_{h,k}(t)\Big)$$

$$= \sum_{k\in\mathbb{Z}^d} \alpha_k(0) = \int_{\mathbb{R}^d} u^0(x)dx,$$

and the method is indeed conservative.

Remark 3.2. It is possible to reach a second order of accuracy, for $u_0 \in W^{2,1}$, but this requires us to follow in time the second deformations of the cells. Another issue is to reconstruct the cells from the only points $x_k(t)$ since they give asymptotically a good approximation of the deformed cells. This point of view is treated in sections 4–6.

Proof. We again simplify the notations and consider only the case $a_0 = 0$. To begin with, we interpret our reconstruction of $\tilde{u}_h$ as a local convolution introducing the function $\varphi(t,y,z)$ as

$$\begin{aligned} \tilde{u}_h(t,x) &= \sum_{\mathbb{Z}^d} \alpha_h(t) Vol\Big(Q_{k,h}(t)\Big)^{-1} \chi_{Q_{k,h}(t)}(x - x_k(t)) \\ &= \int_{\mathbb{R}^d} v_h(t,y)\varphi(t,y,x-y)dy, \end{aligned} \tag{3.5}$$

where

$$\varphi(t,y,z) = Vol\Big(Q_{Y(0),h}(t)\Big)^{-1} \chi_{Q_{Y(0),h}(t)}(z),$$

the value of $Y(0)$ as a function of y being given through the characteristics

$$\frac{dY(s)}{ds} = a\Big(Y(s)\Big), \quad Y(t) = y.$$

This function $\varphi(t,y,z)$ satisfies the equation

$$\frac{\partial\varphi}{\partial t} + a(y).\nabla_y\varphi + Da(y).\nabla_z(z\varphi) = 0, \tag{3.6}$$

$$\varphi(0,x,z) = h^{-d}\chi_{Q_h}(z). \tag{3.7}$$

To prove this, we introduce the coupled trajectories

$$\frac{dY(t)}{dt} = a\Big(Y(t)\Big), \quad Y(0) = y,$$

$$\frac{dZ(t)}{dt} = Da\Big(Z(t)\Big).Z(t), \quad Z(0) = z.$$

Then the function $\psi(t,Y(t),Z(t)) = \chi_{Q_{Y(0),h}(t)}\Big(Z(t)\Big)$ satisfies

$$\psi(t,Y(t),Z(t)) = \chi_{Q_h}(z) = \psi(0,y,z).$$

Indeed, with a notation similar to (3.1), $Z(t) = \mathcal{L}_y(t).z$, therefore $Z(t) \in Q_{Y(0),h}(t)$ if and only if $z \in Q_h$. Therefore we have

$$\frac{\partial\psi}{\partial t} + a(y).\nabla_y\psi + Da(y).z\ \nabla_z\psi = 0,$$

and the equation on φ follows after some algebraic manipulations of this equation.

We now come back to estimate the error. We write the equation on $\tilde{u}_h(t,x)$, thanks to (3.5), and using the notation $z = x - y$, $\varphi = \varphi(t, y, x - y)$,

$$\frac{\partial \tilde{u}_h}{\partial t} + \mathrm{div}_x\Big(a(x).\tilde{u}_h\Big)$$

$$= \int_{\mathbb{R}^d} \left[\frac{\partial v_h(t,y)}{\partial t}\varphi(t,y,x-y) + v_h(t,y)\left[\frac{\partial \varphi}{\partial t} + \mathrm{div}_x\Big(a(x)\varphi\Big)\right]\right] dy$$

$$= \int_{\mathbb{R}^d} v_h(t,y)\left[\frac{\partial \varphi}{\partial t} + a(y)(\nabla_y\varphi - \nabla_z\varphi) + \varphi \mathrm{div}\ a(x) + a(x).\nabla_z\varphi\right] dy$$

$$= \int_{\mathbb{R}^d} v_h(t,y)\left[\frac{\partial \varphi}{\partial t} + a(y)\nabla_y\varphi + \varphi \mathrm{div}\ a(x) + [a(x) - a(y)].\nabla_z\varphi\right] dy$$

$$= \int_{\mathbb{R}^d} v_h(t,y)\left[\frac{\partial \varphi}{\partial t} + a(y)\nabla_y\varphi + \varphi[\mathrm{div}\ a(y) + O(z)]\right.$$

$$\left. + [Da(y).z + O(z^2)].\nabla_z\varphi\right] dy$$

$$= \int_{\mathbb{R}^d} v_h(t,y)\left[\frac{\partial \varphi}{\partial t} + a(y)\nabla_y\varphi + Da(y).\nabla_z(z.\varphi) + O(z^2)D_z\varphi + O(z)\varphi\right] dy$$

$$= \int_{\mathbb{R}^d} v_h(t,y)[O(z^2)D_z\varphi + O(z)\varphi] dy.$$

Here we have used (3.6). Next, φ is supported by $\{|z| \le Ch\}$. Also, the regularity of the coefficients, the special structure of (3.6), and its scaling in z/h show that $\|D_z\varphi(t,y,z)\|_{L^1_z}$ is uniformly bounded in c/h and thus we obtain from the above equalities

$$\frac{\partial \tilde{u}_h}{\partial t} + \mathrm{div}_x\Big(a(x).\tilde{u}_h\Big) = hR(t,x),$$

with R uniformly bounded in $L^\infty((0,T); L^1(\mathbb{R}^d))$ for all $T > 0$. Therefore, by a comparison with the same equation for u, we obtain the desired estimate

$$\|(u - \tilde{u}_h)(t)\|_{L^1(\mathbb{R}^d)} \le \|(u - \tilde{u}_h)(0)\|_{L^1(\mathbb{R}^d)} + C(t)h \le C(t)h. \qquad \square$$

4. A simple one-dimensional example. In this section, we assume that $d = 1$, i.e., we work in one space dimension, and we consider (1.1). We shall describe the pseudoparticle method in this simple setting and prove its optimality. The main arguments (in particular the key estimates (2.4), (2.8), and (2.10) below) are only sketched here, since they are detailed in more general settings in the next section.

From the hat function

$$\varphi(x) = \max\{1 - |x|, 0\} \tag{4.1}$$

and its scaled version $\varphi_h = h^{-1}\varphi(\cdot/h)$, we can define an approximation of u_0 defined by

$$v_{0,h} = \sum_{k\in\mathbb{Z}^d} \alpha_k \varphi_h(\cdot - kh), \tag{4.2}$$

with

$$\alpha_k := \int_{(k-1/2)h}^{(k+1/2)h} u_0(x)dx. \tag{4.3}$$

Note that this approximation is exactly the convolution of the measure $v_{0,h}$ defined in (1.5) by φ_h. The operator mapping u_0 to $v_{0,h}$ is local, L^p-stable, and reproduces polynomials up to degree 1. It is well known in approximation theory [2], [15] that these properties yield the error estimate

$$\|u_0 - v_{0,h}\|_{L^p} \leq Ch^s \|u_0\|_{W^{s,p}} \tag{4.4}$$

for $0 < s \leq 2$. Note also that we have $v_{0,h}(kh) = h^{-1}\alpha_k$: the local averages over the intervals $[(k-1/2)h, (k+1/2)h]$ coincide with the point values of the approximation $v_{0,h}$.

Now define $v_h(t)$ to be the solution of (1.1) with initial value $v_{0,h}$. The values $v_h(t)$ at the points $x_k(t)$ can thus be computed since they are the solution of the ordinary differential equations (1.4) with initial value $h^{-1}\alpha_k$. Moreover, from the stability property of the evolution operator, we have

$$\|u(t) - v_h(t)\|_{L^p} \leq C(t)h^s \|u_0\|_{W^{s,p}} \tag{4.5}$$

for $0 < s \leq 2$. In order to recover an optimal approximation of $u(t)$, one can thus try to approximate $v_h(t)$ from its samples at points $x_k(t)$. Note that in one dimension, for fixed t, the sequence $(x_k(t))_{k\in\mathbb{Z}}$ is increasing and that there exists strictly positive constants $C_1(t)$ and $C_2(t)$ such that

$$C_1(t)h \leq |x_{k+1}(t) - x_k(t)| \leq C_2(t)h. \tag{4.6}$$

We can thus define a unique function $u_h(t)$ which is affine on each interval $[x_k(t), x_{k+1}(t)[$, $k \in \mathbb{Z}$ and such that $u_h(t, x_k(t)) = v_h(t, x_k(t))$. We then have the following result.

THEOREM 4.1. *For all $t \in [0, T]$, there exists a constant $C(t)$ such that*

$$\|u(t) - u_h(t)\|_{L^p} \leq C(t)h^s \|u_0\|_{W^{s,p}} \tag{4.7}$$

for all $0 < s < 1 + 1/p$.

Proof. From classical theory, the function $v_{0,h}$ satisfies an inverse estimate

$$\|v_{0,h}\|_{W^{s',p}} \leq Ch^{s-s'} \|v_{0,h}\|_{W^{s,p}} \tag{4.8}$$

for $0 \leq s < s' \leq 1 + 1/p$ (the limitation of s by above corresponds to the Sobolev regularity of the function φ which belongs to $W^{s,p}$ only for $s \leq 1 + 1/p$).

By the $W^{s,p}$-stability of the evolution operator and of the approximation operator $u_0 \mapsto v_{0,h}$, we get

$$\|v_h(t)\|_{W^{s',p}} \leq C(t)h^{s-s'} \|u_0\|_{W^{s,p}}. \tag{4.9}$$

We next use the approximation properties of the interpolation operator that defines $u_{t,h}$: from the upper inequality in (4.6) we obtain the estimate

$$\|u_h(t) - v_h(t)\|_{L^p} \leq C(t)h^{s'} \|v_h\|_{W^{s',p}} \tag{4.10}$$

for $1/p < s' < 2$ (in this case, the limitation of s' by below is necessary since $u_h(t)$ is obtained by an interpolation process which is well defined in Sobolev spaces $W^{s,p}$ only for $s > 1/p$).

Combining (4.10) and (4.9) for some s', $\max(s, 1/p) < s' < 2$, we obtain

$$\|u_h(t) - v_h(t)\|_{L^p} \leq C(t)h^s \|u_0\|_{W^{s,p}}, \tag{4.11}$$

which together with (4.5) yields the optimal estimate (4.7). ∎

Remark 4.1. The limitation $s \leq 1+1/p$ is related to the smoothness of the initial approximation, while $s \leq 2$ is related to its degree of accuracy. Both aspects should thus be considered for raising the order of the present method.

Remark 4.2. If the initial value u_0 is in $W^{s,p}$ with $s > 1/p$—and thus continuous—one can also apply the same linear interpolation process on the values of the real solution at the points $x_k(t)$. This clearly yields the same error estimate without the restriction $s \leq 1 + 1/p$ but still $s \leq 2$ due to the order of the method.

5. The pseudoparticle method. In order to raise the order of the method, we need a better approximation at the start. To do so, we consider the B-spline functions defined recursively by $B_0 = \chi_{[0,1]}$ and

$$B_n = \chi_{[0,1]} * B_{n-1} = (*)^{n+1}\chi_{[0,1]}. \tag{5.1}$$

We recall some basic properties here and refer to [1] for a general introduction: B_n is piecewise polynomial of degree n on the intervals $[k, k+1]$, $k \in \mathbb{Z}$, has support $[0, n+1]$, and is contained in $W^{s,p}$ if and only if $s < n + 1/p$.

Of importance to us is the reproduction of polynomials of degree up to n in the space generated by the translates of B_n: for $m = 0, \ldots, n$, one has

$$x^m := \sum_{k\in\mathbb{Z}} (k^m + Q_{m-1}(k))B_n(x-k), \tag{5.2}$$

where Q_{m-1} are uniquely determined polynomials of degree $m-1$.

Finally, recall that the translates $B_n(\cdot - k)$, $k \in \mathbb{Z}$, constitute a Riesz basis of their span. In particular, there exists a dual spline function $r(x) = \sum r_k B_n(\cdot - k)$ (infinitely supported with exponential decay if $n \geq 1$) such that

$$\langle r(x-k), B_n(\cdot - l)\rangle = \delta_{k,l}. \tag{5.3}$$

Here we want to use the function $\varphi(x) := B_n(x_1)\cdots B_n(x_d)$ (and its shifted and dilated versions $\varphi(h^{-1}\cdot - k)$, $k \in \mathbb{Z}^d$) to generalize the hat function that was used in the example of the previous section. To do so, we also need a proper discretization method that generalizes (4.2) and (4.3). In other word, we want to build an approximation operator

$$P_h f := \sum_{k\in\mathbb{Z}^d} h^{-m}\langle f, \tilde{\varphi}(h^{-1}\cdot - k)\rangle \varphi(h^{-1}\cdot - k) \tag{5.4}$$

onto the spaces

$$V_h := \mathrm{Span}\{\varphi(h^{-1}\cdot - k)\ ;\ k \in \mathbb{Z}^d\}, \tag{5.5}$$

where $\tilde{\varphi}$ is a compactly supported function that was chosen to be $\chi_{[-1/2,1/2]}$ in the example of the previous section. Although it seems natural to choose $\tilde{\varphi} = \chi_{[-1/2,1/2]^d}$,

the construction of $\tilde{\varphi}$ needs to be slightly more refined in order that the operator P_h has some good approximation properties. Such properties are related to the invariance of polynomials of degree up to n under the action of P_h. There are many ways to construct functions $\tilde{\varphi}$ that will yield this property.

In [6] it is shown how to build such a function with the additional prescriptions that P_h is a projector (i.e., $P_h^2 = P_h$) (or equivalently that $\langle \varphi(\cdot - k), \tilde{\varphi}(\cdot - l)\rangle = \delta_{k,l}$), and that the spaces $\widetilde{V}_h$ generated by $\tilde{\varphi}$ satisfy $\widetilde{V}_{2h} \subset \widetilde{V}_h$ (similarly to the spaces V_h).

Here we ignore these additional properties, and we give below a simple criterion for the design of $\tilde{\varphi}$.

LEMMA 5.1. *Let g be any compactly supported univariate function such that $\int g = 1$ and*

$$\int x^m g(x)dx = Q_{m-1}(0) \tag{5.6}$$

for $m = 1, \dots, n$. Then one has the identities

$$\sum_{k\in\mathbb{Z}} \left[\int y^m g(y-k)dy \right] B_n(x-k) = x^m \tag{5.7}$$

for $m = 0, \dots, n$. Defining $\tilde{\varphi}(x) = g(x_1)\cdots g(x_d)$, it follows that the corresponding operator P_h is a projector and satisfies $P_h f = f$ for all f polynomial of degree less than or equal to n in each coordinate.

Proof. We first remark that (5.3) and (5.2) give

$$k^m + Q_{m-1}(k) = \int x^m r(x-k)dx, \quad m = 0, \dots, n. \tag{5.8}$$

Now since

$$\int x^m f(x-k)dx = \sum_{l=0}^{m} \binom{m}{l} (-k)^{m-l} \int x^l f(x)dx, \tag{5.9}$$

the identities $\int x^m g(x)dx = \int x^m r(x)dx$, $m = 0, \dots, n$, imply

$$\int x^m g(x-k)dx = \int x^m g(x-k)dx = k^m + Q_{m-1}(k), \quad m = 0, \dots, n, \tag{5.10}$$

so that (5.7) holds.

Rescaling these identities by a factor h and using the tensor product structure of P_h shows that this operator preserves all polynomials $x_1^{m_1} \cdots x_d^{m_d}$, $d_i \le n$, and thus all polynomials of degree less than or equal to n in each coordinate. ∎

Remark 5.1. According to the previous lemma, the only prescription in the choice of g is its compact support and the value of its $n+1$ first moments. A simple choice consists of choosing g piecewise constant with support $[0, n+1]$, i.e., $g = \sum_{k=0}^{n} g_k B_0(\cdot - k)$: one easily checks that the coefficients g_k are uniquely determined from the moments $\int x^m g(x)$.

We are now ready to describe in full generality the pseudoparticle method. We use the notation $u_t = u(t)$, $u_{t,h} = u_h(t)$... Given the initial value u_0, we thus define the approximation

$$v_{0,h} = P_h u_0 = \sum_{k\in\mathbb{Z}^d} \alpha_k \varphi_h(\cdot - kh), \tag{5.11}$$

where $\varphi_h := h^{-d}\varphi(h^{-1}\cdot)$ and $\alpha_k := \langle u_0, \tilde{\varphi}(h^{-1}\cdot - k)\rangle$. Note that with the choice of g suggested by Remark 5.1, the values of α_k are linear combinations of the integrals of u_0 over cubes of width h in the neighborhood of the grid point kh.

The values of $v_{0,h}$ at the grid points are then given by

$$v_{0,h}(kh) = \sum_{l\in\mathbb{Z}^d} \alpha_l \varphi_h(kh - lh), \tag{5.12}$$

i.e., by a simple convolution of the sequence α_l with a local (and separable) discrete sequence.

As in the example of the previous section, the values $v_{t,h} := v_h(t)$ at the points $x_k(t)$ at time $t > 0$ can be computed, since they are the solutions of the ordinary differential equations (1.4) with initial value $v_{0,h}(kh)$.

We then need a proper interpolation procedure in order to construct the approximation $u_{t,h}$ of the solution at time t from the point values $v_{t,h}(x_k(t))$. This task is more difficult than in the previous example: in the multivariate setting the points of the transported grid are not ordered in a simple way. Yet we can take advantage of the fact that, as h goes to zero, these grid points are locally close to the transport of the initial square grid by the linearized flow.

To do so, we first define

$$S(t) := \sup_{x\in\mathbb{R}^d} \|D\Phi_t(x)\| \ \text{ and } \ \widetilde{S}(t) := \sup_{x\in\mathbb{R}^d} \|(D\Phi_t)^{-1}(x)\|, \tag{5.13}$$

where $\|.\|$ is the standard norm for $d \times d$ matrices. From the assumptions on the coefficients a_i, these quantities stay finite for $t \in [0, T]$.

From now on, we fix $t \in]0, T]$, and we consider the partition of $\mathbb{R}^d$ by the cubes

$$Q^t_{k,h} := (n+1)khS(t) + Q^t_h, \ \ k \in \mathbb{Z}^d, \ \text{ with } \ Q^t_h := [0, (m+1)hS(t)]^d. \tag{5.14}$$

On each of these cubes, we shall define $u_{t,h}$ as a polynomial of degree n in each coordinate.

Note that the choice of the width $(n+1)hS(t)$ ensures that each cube $Q^t_{k,h}$ contains at least $(n+1)^d$ points of the transported grid $\Phi_t(h\mathbb{Z}^d)$ and at most $N(t) := (n+1)^d hS(t)\tilde{S}(t)$ points. The main problem here is that these sets do not generally contain a unisolvent set of $(n+1)^d$ points that allows us to define a unique interpolation polynomial of degree n in each coordinate. However, this problem is solved for h small enough since, as we already mentioned above, the grid points are locally close to a regular mesh.

The polynomial approximation on $Q^t_{k,h}$ will thus be obtained from the values of $v_{t,h}$ at the points $x_k(t)$ that are situated in this cube. Therefore we write

$$u_{t,h} = I^t_{k,h} v_{t,h} \ \text{ on } \ Q^t_{k,h}. \tag{5.15}$$

To define a proper interpolation procedure $I^t_{k,h}$, we first transfer the problem on the unit cube $Q := [0, 1]^d$ through the affine transformation

$$T^t_{k,h} : \ x \mapsto (n+1)hS(t)x + (n+1)khS(t) \tag{5.16}$$

that maps Q onto $Q^t_{k,h}$. The problem is now to find an appropriate construction of a polynomial V of degree n in each variable, given some points $x_1, \ldots, x_q$, $(n+1)^d \leq q \leq N(t)$ in Q and values $y_1, \ldots, y_q$.

We first consider the canonical basis $(g_l)_{l=1,\dots,(n+1)^d}$, $g_l(x) = x_1^{m_1(l)} \cdots x_d^{m_d(l)}$, for the space of multivariate polynomials of degree n in each variable, and we write

$$V(x) = \sum_{l=1,\dots,(n+1)^d} z_l g_l. \tag{5.17}$$

We choose the vector $(z_l)_{l=1,\dots,(n+1)^d}$ to be the image of the vector $(y_1, \dots, y_q)$ by a rectangular matrix $P = (p_{i,j})$ that we construct in the following way:

(i) We solve the problem $\min_P \sum_{i,j} |p_{i,j}|^2$ under the constraints of polynomial exactness: P applied to $(g_l(x_1), \dots, g_l(x_q))$ is equal to the canonical basis vector δ_l corresponding to $V(x) = g_l$. This problem always has a unique solution.

(ii) In the case where there exists a solution P^* such that $\sum_{i,j} |p^*_{i,j}|^2 \le K(t)$, for some $K(t)$ that we specify below, we choose $P = P^*$. Otherwise, we choose $p_{1,1} = 1$ and $p_{i,j} = 0$ otherwise.

Imposing a limitation on $\sum_{i,j} |p^*_{i,j}|^2$ implies a stability property in the L^∞ norm: we have

$$\|V\|_{L^\infty(Q)} \le \widetilde{K}(t) \max_{k=1,\dots,q} |y_k|, \tag{5.18}$$

where $\tilde{K}(t)$ depends only on $K(t)$ and $N(t)$.

The constant $K(t)$ should be chosen large enough to ensure that for h small enough, we are always in the first case of (ii), i.e., $\sum_{i,j} |p^*_{i,j}|^2 \le K(t)$.

This is made possible by the fact that for h small enough, the grid points are locally close to the regular mesh obtained by the transport of the square grid $h\mathbb{Z}^d$ by the linearized flow.

More precisely, if A is a $d \times d$ invertible linear transformation, we consider the unisolvent set of points $(Ax_1, \dots, Ax_{(n+1)^d})$ where

$$\{x_1, \dots, x_{(n+1)^d}\} := \{0, 1/(n+1), 2/(n+1), \dots, n/(n+1)\}^d, \tag{5.19}$$

and we define P_A to be the square matrix that maps the value y_i at these points to the coordinates z_i of the unique Lagrange interpolation polynomial. Then $K(t)$ should be chosen strictly larger than the quantity

$$K_{lim}(t) := \sup_{x \in \mathbb{R}^d} \|P_{D\Phi_t(x)}\|_2^2 \ (< +\infty) \tag{5.20}$$

(for example, take $K(t) := 2K_{lim}(t)$ where $\|P\|_2^2 := \sum_{i,j} |p_{i,j}|^2$). Such a choice ensures that for h small enough, a simple interpolation procedure produces a solution P^* that corresponds to the first case of (ii).

We summarize below the properties that hold for our interpolation procedure.

PROPOSITION 5.2. *The interpolation operator $I^t_{k,h}$ is L^∞-stable, i.e.,*

$$\|u_{t,h}\|_{L^\infty(Q^t_{k,h})} \le C(t) \|v_{t,h}\|_{L^\infty(Q^t_{k,h})}, \tag{5.21}$$

independently of h and k. Moreover, for $h \le h_0(t)$, it is exact for polynomials up to order n in each coordinate.

6. Error estimates. In this section we shall obtain the optimal error estimate for the approximation $u_{t,h}$. For this, we need several preliminary results that concern the approximation by $v_{t,h}$ and should be viewed as the generalization of estimate (4.4)

and (4.8) in section 4. We recall the approximation operator

$$P_h f = \sum_{k\in\mathbb{Z}^d} h^{-d}\langle f, \tilde\varphi(h^{-1}\cdot -k)\rangle \varphi(h^{-1}\cdot -k), \tag{6.1}$$

where φ is the B-spline of order n and $\tilde\varphi$ the corresponding dual function constructed in the previous section. One can easily see that operator is L^p-stable and that its norm in L^p is independent of h: defining p' the conjugate exponent of p (i.e., $1/p+1/p'=1$), we have

$$\begin{aligned}\|P_h f\|_{L^p} &\le Ch^{-d}\|\varphi(h^{-1}\cdot)\|_{L^p}\|(\langle f,\tilde\varphi(h^{-1}\cdot -k)\rangle)_{k\in\mathbb{Z}^d}\|_{\ell^p}\\ &\le Ch^{d(1/p-1)}\|(\langle f,\tilde\varphi(h^{-1}\cdot -k)\rangle)_{k\in\mathbb{Z}^d}\|_{\ell^p}\\ &\le Ch^{d(1/p-1)}\|\tilde\varphi(h^{-1}\cdot)\|_{L^{p'}}\|(\|f\|_{L^p(\mathrm{Supp}(\tilde\varphi(h^{-1}\cdot -k)))})_{k\in\mathbb{Z}^d}\|_{\ell^p}\\ &\le C\|(\|f\|_{L^p(\mathrm{Supp}(\tilde\varphi(h^{-1}\cdot -k)))})_{k\in\mathbb{Z}^d}\|_{\ell^p}\\ &\le C\|f\|_{L^p}.\end{aligned}$$

Here we have used Hölder inequality, and the compact supports of φ and $\tilde\varphi$ which ensure that the support of $\varphi(h^{-1}\cdot -k)$ overlaps a controlled number ($[2n]^d$) of supports of other $\varphi(h^{-1}\cdot -l)$ and similarly for $\tilde\varphi$. We shall reuse this type of argument in the following section.

Here we shall make an important use of fractional Sobolev spaces $W^{s,p}$. Let us recall that when s is not an integer, these spaces can be identified by the Besov spaces $B^s_{p,p}$ for all $p\in[1,+\infty]$ (see, e.g., [16]). In particular, if Q is a cube, the seminorm for $W^{s,p}(Q)$ can be expressed in an equivalent manner by

$$|f|_{W^{s,p}(Q)} = \|(2^{sj}\omega_m(f,2^{-j})_{L^p})_{j\ge 0}\|_{\ell^p}, \tag{6.2}$$

where m is any integer strictly larger than s and $\omega_m(f,t)_{L^p}$ is the mth order L^p modulus of smoothness:

$$\omega_m(f,t)_{L^p} := \sup_{|h|\le t}\|(\Delta_h)^m f\|_{L^p(Q_t)}, \tag{6.3}$$

with $\Delta_h f := f(\cdot)-f(\cdot-h)$ the finite difference operator and $Q_t := \{x\in Q \text{ such that } x, x-h,\dots,x-mh\in Q\}$. Recall also that $\varphi\in W^{s,p}$ if and only if $s<n+1/p$.

LEMMA 6.1. *The approximation operator P_h satisfies the direct estimate*

$$\|u-P_h u\|_{L^p} \le Ch^s|u|_{W^{s,p}} \tag{6.4}$$

for $0<s\le n+1$. Consequently one has, for $t\in[0,T]$,

$$\|u_t - v_{t,h}\|_{L^p} \le C(t)h^s\|u_0\|_{W^{s,p}}. \tag{6.5}$$

Proof. The estimate (6.4) is classical in approximation theory, although it does not always appear in this precise form, so we shall sketch only the proof here.

We define the cubes $J_{k,h} := kh+[0,h]^d$, $k\in\mathbb{Z}^d$. We also define larger cubes $\widetilde{J}_{k,h} := kh+[-nh,(n+1)h]^d$. With the choice of $\tilde\varphi$ supported like φ in $[0,n+1]^d$ as suggested by Remark 5.1, it follows that the value of $P_h f$ on $J_{k,h}$ is only influenced by the value of f on $\widetilde{J}_{k,h}$. In particular, we have a local L^p-stability estimate

$$\|P_h f\|_{L^p(J_{k,h})} \le C\|f\|_{L^p(\widetilde{J}_{k,h})}. \tag{6.6}$$

From the Deny–Lions theorem (see, e.g., [4]) and a classical scaling argument, we have the estimate

$$\inf_{g\in\Pi_n} \|f-g\|_{L^p(\widetilde{J}_{k,h})} \le Ch^s |f|_{W^{s,p}(\widetilde{J}_{k,h})} \tag{6.7}$$

for the local approximation by polynomials of global degree n. For $k \in \mathbb{Z}^d$, we consider $g_k \in \Pi_n$ such that $\|f-g_k\|_{L^p(\widetilde{J}_{k,h})} \le 2\inf_{g\in\Pi_n} \|f-g\|_{L^p(\widetilde{J}_{k,h})}$. Combining the polynomial reproduction property of P_h and the local L^p-stability property (6.6) together with the estimate (6.7), we obtain

$$\begin{aligned} \|f-P_hf\|_{L^p(J_{k,h})} &\le \|f-g_k\|_{L^p(J_{k,h})} + \|P_hf-P_hg_k\|_{L^p(J_{k,h})} \\ &\le C\|f-g_k\|_{L^p(\widetilde{J}_{k,h})} \le Ch^s|f|_{W^{s,p}(\widetilde{J}_{k,h})}. \end{aligned}$$

Elevating to the power p and summing on k (or taking the supremum in the case $p=\infty$) yields (6.4), using the fact that a cube $\widetilde{J}_{k,h}$ overlaps a controlled number ($[4n]^d$) of other cubes $\widetilde{J}_{l,h}$.

It follows that

$$\|u_0 - v_{0,h}\|_{L^p} \le Ch^s \|u_0\|_{W^{s,p}}, \tag{6.8}$$

which yields (6.5) by the stability of the linear evolution operator. ∎

For the following results, we assume that $h \le 1$ and we denote by j_h the positive integer such that $2^{j_h}h \in]1/2, 1]$.

LEMMA 6.2. *The functions in the space* $V_h = \mathrm{Span}\{\varphi_h(\cdot - kh)\ ;\ k\in\mathbb{Z}^d\}$ *satisfy the inverse estimate*

$$\|f_h\|_{W^{s',p}} \le Ch^{s-s'}\|f_h\|_{W^{s,p}}, \quad f_h \in V_h, \tag{6.9}$$

for $0 \le s \le s' < n + 1/p$. *In particular we have*

$$\|v_{0,h}\|_{W^{s',p}} \le Ch^{s-s'}\|v_{0,h}\|_{W^{s,p}}. \tag{6.10}$$

Proof. We first prove this result when $s = 0$, i.e., with the L^p norm on the left side of (6.9). We first consider the case where s' is an integer. Here it suffices to remark that if $m = (m_1, \dots, m_d)$ is such that $m_1 + \cdots + m_d = s'$, and if $f_h = \sum_{k\in\mathbb{Z}^d} c_k\varphi(h^{-1}\cdot - k) \in V_h$, we have

$$\begin{aligned} \|\partial^m f_h\|_{L^p} &\le \|h^{-s'} \sum_{k\in\mathbb{Z}^d} c_k[\partial^m\varphi](h^{-1}\cdot - k)\|_{L^p} \\ &\le Ch^{-s'}h^{d/p}\|(c_k)_{k\in\mathbb{Z}^d}\|_{\ell^p}, \end{aligned}$$

where the last inequality makes use of the fact that the support of $\varphi(h^{-1}\cdot - k)$ overlaps a controlled number ($[2n]^d$) of supports of other $\varphi(h^{-1}\cdot - l)$.

In order to obtain (6.9) we use the reverse L^p-stability property of the B-splines which yields

$$h^{d/p}\|(c_k)_{k\in\mathbb{Z}^d}\|_{\ell^p} \le C\|f_h\|_{L^p}. \tag{6.11}$$

One possible technique to prove (6.11) is to use the the compactly supported dual function $\tilde{\varphi}^c$ (such as those built in [6]) that satisfies $\langle\varphi(\cdot - k), \tilde{\varphi}(\cdot - l)\rangle = \delta_{k,l}$ and to evaluate the coefficients c_k using Hölder's inequality as follows:

$$\begin{aligned} |c_k| &= |h^{-d}\langle f_h, \tilde{\varphi}^c(h^{-1}\cdot - k)\rangle| \\ &\le C\|f_h\|_{L^p(\mathrm{Supp}(\tilde{\varphi}^c(h^{-1}\cdot - k)))}. \end{aligned}$$

This yields (6.11) by elevating to the power p and summing on k (or taking the supremum in the case $p = \infty$).

The case where s is not an integer can be treated by an interpolation argument, except for the values of s between n and $n + 1/p$. For such values, we need a specific argument that we give here.

For this, we need to evaluate $\omega_m(f_h, 2^{-j})_{L^p}$. We first remark that

$$\omega_m(f_h, 2^{-j})_{L^p} \leq C\|(c_k)_{k\in\mathbb{Z}^d}\|_{\ell^p} h^d \omega_m(\varphi_h, 2^{-j})_{L^p}, \tag{6.12}$$

so that

$$|f_h|_{W^{s',p}} \leq C\|(c_k)_{k\in\mathbb{Z}^d}\|_{\ell^p} h^d |\varphi_h|_{W^{s',p}}. \tag{6.13}$$

We thus want to evaluate $|\varphi_h|_{W^{s',p}}$. For $j \leq j_h$, we use the crude estimate

$$\omega_m(\varphi_h, 2^{-j})_{L^p} \leq \|\varphi_h\|_{L^p} \leq Ch^{d(1/p-1)}. \tag{6.14}$$

For $j \geq j_h$, we exploit the fact that $\varphi \in W^{s',p}$ to obtain the estimate

$$\omega_m(\varphi_h, 2^{-j})_{L^p} \leq C2^{s'(j_h-j)} h^{d(1/p-1)} \varepsilon_{j-j_h}, \tag{6.15}$$

where $(\varepsilon_n)_{n\geq 0}$ is an ℓ^p sequence. It follows that

$$\begin{aligned} |\varphi_h|_{W^{s',p}} &\leq \|(2^{js'}\omega_m(f_h, 2^{-j})_{L^p})_{j\geq 0}\|_{\ell^p} \\ &\leq \|(2^{js'}\omega_m(f_h, 2^{-j})_{L^p})_{0\leq j\leq j_h}\|_{\ell^p} + \|(2^{js'}\omega_m(f_h, 2^{-j})_{L^p})_{j\geq j_h}\|_{\ell^p} \\ &\leq C2^{j_h s'} h^{d(1/p-1)} \leq Ch^{-s'+d(1/p-1)}. \end{aligned}$$

Combining with (6.13), we obtain

$$|f_h|_{W^{s',p}} \leq C\|(c_k)_{k\in\mathbb{Z}^d}\|_{\ell^p} h^{-s'+d/p}, \tag{6.16}$$

which together with (6.11) yields the inverse estimate.

Finally, in order to treat the case $0 < s < s'$, we use a multiscale decomposition of f_h to obtain

$$\begin{aligned} \|f_h\|_{W^{s',p}} &\leq \|f_h - P_{2h}f_h\|_{W^{s',p}} + \|P_{2h}f_h - P_{4h}f_h\|_{W^{s',p}} + \cdots \\ &\quad + \|P_{2^{j_h-1}h}f_h - P_{2^{j_h}h}f_h\|_{W^{s',p}} + \|P_{2^{j_h}h}f_h\|_{W^{s',p}} \\ &\leq C[h^{-s'}\|f_h - P_{2h}f_h\|_{L^p} + (2h)^{-s'}\|P_{2h}f_h - P_{4h}f_h\|_{L^p} + \cdots \\ &\quad + \|P_{2^{j_h}h}f_h\|_{L^p}] \\ &\leq C\left[\|f_h\|_{L^p} + \sum_{j=1}^{j_j} (2^j h)^{-s'}\|f_h - P_{2^j h}f_h\|_{L^p}\right] \\ &\leq C\left[\|f_h\|_{L^p} + \left(\sum_{j=1}^{j_j} (2^j h)^{-s'+s}\right)|f_h|_{W^{s,p}}\right] \\ &\leq Ch^{s-s'}\|f_h\|_{W^{s,p}}, \end{aligned}$$

where we have successively used the inverse estimate for $s = 0$, the L^p-stability of the projectors P_h, and the direct estimate of Lemma 6.1. □

LEMMA 6.3. *The approximation operator is stable in $W^{s,p}$, i.e.,*

$$\|P_h f\|_{W^{s,p}} \leq C\|f\|_{W^{s,p}}, \tag{6.17}$$

for $0 < s < n + 1/p$.

Proof. In the case where s is an integer we can use a particular property of the B-spline: if $s \leq n$, one has

$$B_n^{(s)} = (\Delta_1)^s B_{n-s}, \tag{6.18}$$

where $\Delta_1 f = f(\cdot) - f(\cdot - 1)$ (this is easily proved by induction on s, using the definition of B-splines). If we now consider the operator

$$A_0 f := \sum_{k \in \mathbb{Z}} \langle f, r(\cdot - k) \rangle B_n(\cdot - k), \tag{6.19}$$

acting on univariate function, we can derive from (6.18) and integration by part the following commutation formula:

$$(A_0 f)^{(s)} = A_s f^{(s)}, \text{ where } A_s f := \sum_{k \in \mathbb{Z}} \langle f, r_s(\cdot - k) \rangle B_{n-s}(\cdot - k), \tag{6.20}$$

by r_s is obtained from $r = r_0$ by

$$r_{m+1}(x) := -\int_x^{x+1} r_m(t) dt. \tag{6.21}$$

In particular, the functions r_m are compactly supported. After tensor product and rescaling of a factor h, we obtain for $m = (m_1, \ldots, m_d)$ such that $m_1 + \cdots + m_d = s$,

$$\partial^m (P_h f) = \sum_{k \in \mathbb{Z}^d} h^{-d} \langle \partial^m f, \tilde{\varphi}_m(h^{-1} \cdot - k) \rangle \varphi_m(h^{-1} \cdot - k), \tag{6.22}$$

where $\varphi_m(x) = B_{n-m_1}(x_1) \cdots B_{n-m_d}(x_d)$ and $\tilde{\varphi}(x) = r_{m_1}(x_1) \cdots r_{m_d}(x_d)$. Using the same arguments as for the L^p-stability of P_h we thus obtain

$$\|\partial^m (P_h f)\|_{L^p} \leq C \|\partial^m f\|_{L^p}, \tag{6.23}$$

independently of h.

As for the inverse estimate of the previous lemma, the case where s is not an integer can be treated by an interpolation argument, except for the values of s between n and $n + 1/p$. We thus give a specific argument here, although a bit involved.

When s is not an integer, the spaces $W^{s,p} := B^s_{p,p}$ also have a simple characterization through approximation properties by stable L^p-projectors onto the spaces V_h.

Here we shall use the specific projector P_h^c, associated with the dual function φ^c constructed in [6], such that the spaces $\widetilde{V}_h$ generated by $\tilde{\varphi}$ satisfy $\widetilde{V}_{2h} \subset \widetilde{V}_h$. This last property implies that

$$P_2^c h P_h^c f = P_2 h f. \tag{6.24}$$

For such projectors and $a \in [1/2, 1[$, we have the norm equivalence

$$\|f\|_{B^s_{p,p}} \sim \|P_a^c\|_{L^p} + \|(2^{sj} \|P^c_{2^{j+1}a} f - P^c_{2^j a} f\|_{L^p})_{j \geq 0}\|_{\ell^p}, \tag{6.25}$$

with constants that do not depend on a. We refer to [5], [8], and [9] for a description of the general mechanism (involving direct estimates, inverse estimates, and interpolation of function spaces) that yields such norm equivalences.

Combining (6.24) with (6.25), we obtain

$$\begin{aligned}\|P_h^c f\|_{B^s_{p,p}} &\leq C\|P^c_{2^{j_h}h}\|_{L^p} + \|(2^{sj}\|P^c_{2^{j+1}h}f - P^c_{2^j h}f\|_{L^p})_{0\leq j\leq j_h}\|_{\ell^p}\\ &\leq C\|f\|_{B^s_{p,p}}.\end{aligned}$$

We have thus proved the $W^{s,p}$-stability for P_h^c, uniformly in h. In order to see that the same property holds for P_h, we write

$$\begin{aligned}\|P_h f\|_{B^s_{p,p}} &\leq \|P_h^c f\|_{B^s_{p,p}} + \|P_h^c f - P_h f\|_{B^s_{p,p}}\\ &\leq C[\|f\|_{B^s_{p,p}} + h^{-s}\|P_h^c f - P_h f\|_{L^p}]\\ &\leq C[\|f\|_{B^s_{p,p}} + h^{-s}(\|P_h^c f - f\|_{L^p} + \|P_h f - f\|_{L^p})]\\ &\leq C\|f\|_{B^s_{p,p}},\end{aligned}$$

where we have used the inverse estimate of Lemma 6.2 together with the direct estimate for both P_h and P_h^c. □

If we combine Lemma 6.2 and Lemma 6.3 together with the stability of the evolution operator, we obtain an inverse estimate of the type

$$\|v_{t,h}\|_{W^{s',p}} \leq C(t)h^{s-s'}\|u_0\|_{W^{s,p}} \tag{6.26}$$

for $t \in [0,T]$ and $0 \leq s \leq s' < n - 1 + 1/p$. We are now ready to prove the main result. At this point we make a technical assumption on the order of the B-spline: n is large enough so that $d/p \leq n + 1/p$.

THEOREM 6.4. *The approximation of u_t by the pseudoparticle method satisfies*

$$\|u_t - u_{t,h}\|_{L^p} \leq C(t)h^s\|u_0\|_{W^{s,p}} \tag{6.27}$$

for $0 < s < n - 1 + 1/p$.

Proof. On each cube $Q^t_{k,h}$, we consider a polynomial $p^t_{k,h} \in \Pi_n$ such that

$$\|v_{t,h} - p^t_{k,h}\|_{L^p(Q^t_{k,h})} \leq 2\inf_{g\in\Pi_n}\|v_{t,h} - g\|_{L^p(Q^t_{k,h})} \leq Ch^{s'}|v_{t,h}|_{W^{s',p}(Q^t_{k,h})} \tag{6.28}$$

and we set $r^t_{k,h} = v_{t,h} - p^t_{k,h}$. According to Lemma 5.3, we have

$$v_{t,h} - u_{t,h} = r^t_{k,h} - I^t_{k,h}r^t_{k,h} \tag{6.29}$$

for $h \leq h_0(t)$. We thus have

$$\begin{aligned}\|v_{t,h} - u_{t,h}\|_{L^p(Q^t_{k,h})} &\leq C(t)h^{d/p}\|v_{t,h} - u_{t,h}\|_{L^\infty(Q^t_{k,h})}\\ &= C(t)h^{d/p}\|r^t_{k,h} - I^t_{k,h}r^t_{k,h}\|_{L^\infty(Q^t_{k,h})}\\ &\leq C(t)h^{d/p+\sigma}|r^t_{k,h}|_{W^{\sigma,\infty}(Q^t_{k,h})}.\end{aligned}$$

Here the direct estimate for $I^t_{k,h}$ uses the L^∞-stability of this operator (Proposition 5.2) together with the Deny–Lions theorem, by the same argument as in Lemma 6.1.

Now choose s' such that $\max\{d/p, s\} < s' < n+1/p$, and such that $\sigma := s' - d/p > 0$ is not an integer. The Sobolev embedding of $W^{s',p}$ into $W^{\sigma,\infty}$ gives after rescaling

$$|r^t_{k,h}|_{W^{\sigma,\infty}(Q^t_{k,h})} \leq C(t)\Big(|r^t_{k,h}|_{W^{s',p}(Q^t_{k,h})} + h^{-s'}\|r^t_{k,h}\|_{L^p(Q^t_{k,h})}\Big). \tag{6.30}$$

Using that $|p^t_{k,h}|_{W^{s',p}(Q^t_{k,h})} = 0$ and (6.28), we thus obtain

$$|r^t_{k,h}|_{W^{\sigma,\infty}(Q^t_{k,h})} \leq C(t)|v_{t,h}|_{W^{s',p}(Q^t_{k,h})}. \tag{6.31}$$

Combining (6.31) with the estimate for $\|v_{t,h} - u_{t,h}\|_{L^p(Q^t_{k,h})}$, we thus obtain

$$\|v_{t,h} - u_{t,h}\|_{L^p(Q^t_{k,h})} \leq C(t)h^{s'}|v_{t,h}|_{W^{s',p}(Q^t_{k,h})}. \tag{6.32}$$

Together with (6.26), this yields

$$\|v_{t,h} - u_{t,h}\|_{L^p(Q^t_{k,h})} \leq C(t)h^s\|u_0\|_{W^{s,p}(Q^t_{k,h})}, \tag{6.33}$$

and thus

$$\|v_{t,h} - u_{t,h}\|_{L^p} \leq C(t)h^s\|u_0\|_{W^{s,p}}, \tag{6.34}$$

by elevating to the power p and summing on k (or taking the supremum in the case $p = \infty$). Combining (6.34) and (6.5), we finally obtain the optimal estimate (6.27). □

Remark 6.1. The pseudoparticle method is by essence not conservative: if $a_0 = f = 0$, in which case $\int u_t(x)dx = \int u_0(x)dx$, we do not have $\int u_{t,h}(x)dx = \int u_0(x)dx$ in contrast to the classical particle method. However, we can always apply a global correction to the solution $u_{t,h}$ in such a way that this conservation holds. For example, we can add a correction of the form $A\Phi(x)$, where Φ is smooth, globally supported, and such that $\int \Phi(x)dx = 1$ and where $A = \int(u_0(x) - u_{t,h}(x))dx$. We then remark that the estimate (6.27) of Theorem 6.4 yields $|A| \leq C(t)h^s\|u_0\|_{W^{s,p}}$, so that the corrected solution will also satisfy an optimal estimate of the same type.

Remark 6.2. The approximation of u_t by $u_{t,h}$ is optimal in L^p norms. However, $u_{t,h}$ is discontinuous. We end by showing that by applying the operator P_h, one can always regularize this approximation in order to obtain optimal estimates in smoother norms.

THEOREM 6.5. *The regularized approximation of* u_t *by* $\tilde{u}_{t,h} := P_h u_{t,h}$ *satisfies*

$$\|u_t - \tilde{u}_{t,h}\|_{W^{s',p}} \leq C(t)h^{s-s'}\|u_0\|_{W^{s,p}} \tag{6.35}$$

for $0 < s' < s < n + 1/p$.

Proof. We write

$$\|u_t - \tilde{u}_{t,h}\|_{W^{s',p}} \leq \|P_h u_t - P_h u_{t,h}\|_{W^{s',p}} + \|u_t - P_h u_t\|_{W^{s',p}}. \tag{6.36}$$

The first term satisfies

$$\begin{aligned}\|P_h u_t - P_h u_{t,h}\|_{W^{s',p}} &\leq Ch^{-s'}\|P_h u_t - P_h u_{t,h}\|_{L^p} \\ &\leq Ch^{-s'}\|u_t - u_{t,h}\|_{L^p} \\ &\leq C(t)h^{s-s'}\|u_0\|_{W^{s,p}}\end{aligned}$$

by the inverse estimate of Lemma 6.2, the L^p-stability of P_h, and the L^p error estimate of Theorem 6.4. For the second term, we need a direct estimate in $W^{s',p}$ for P_h. This is easily obtained by the following multiscale technique:

$$\begin{aligned}\|f - P_h f\|_{W^{s',p}} &\leq \sum_{j\geq 0}\|P_{2^{-j}h}f - P_{2^{-(j+1)}h}f\|_{W^{s',p}} \\ &\leq C\sum_{j\geq 0}(2^{-j}h)^{-s'}\|P_{2^{-j}h}f - P_{2^{-(j+1)}h}f\|_{L^p} \\ &\leq C\sum_{j\geq 0}(2^{-j}h)^{-s'}\|P_{2^{-j}h}f - f\|_{L^p} \\ &\leq C\sum_{j\geq 0}(2^{-j}h)^{s-s'}|f|_{W^{s,p}} \\ &\leq Ch^{s-s'}|f|_{W^{s,p}},\end{aligned}$$

where we have used both the direct and inverse estimates of Lemma 6.1 and Lemma 6.2. We thus have the optimal estimate for both terms in (6.36), which concludes the proof. □

STABILITY WITH RESPECT TO PSEUDODIFFERENTIAL PERTURBATIONS OF SOME NONLINEAR DIFFUSIVE EQUATIONS*

MICHELLE SCHATZMAN†

Abstract. Let $g^\varepsilon(k)$ be an even function of $k \in \mathbb{Z}$ which satisfies the inequality

$$\forall k \in \mathbb{Z}, \quad g^\varepsilon(k) \le \rho - \nu|k|^2.$$

Assume, moreover, that $\forall k$, $g^\varepsilon(k)$ tend to a limit $g^0(k)$ as ε tends to 0. Define a linear operator L^ε on periodic functions of period 2π by

$$\big(L^\varepsilon u\big)\widehat{\ }(k) = g^\varepsilon(k)\widehat{u}(k).$$

Joulin has asked whether the solution of

$$u_t^\varepsilon = L^\varepsilon u^\varepsilon - \big(u_x^\varepsilon\big)^2/2$$

converges to the solution of the analogous problem for $\varepsilon = 0$. It is proved here that the answer is positive. Such a positive answer is a means of validating a number of theoretical procedures in the analysis of nonlinear phenomena and particularly of combustion phenomena.

1. Presentation of the problem.

Denote by $\mathbb{T} = \mathbb{R}/2\pi\mathbb{Z}$ the torus of length 2π and by $\mathcal{D}'_\sharp$ the set of distributions over $\mathbb{T}$, i.e., the set of periodic distributions of period 2π. The space L^p over $\mathbb{T}$ will be denoted by $L^p_\sharp$, and the Sobolev space of functions with s derivatives in $L^2_\sharp$ will be likewise denoted by $H^s_\sharp$. The Fourier coefficient $\widehat{u}(k)$ is defined for any distribution u on $\mathbb{T}$ and any integer $k \in \mathbb{Z}$ by

$$\widehat{u}(k) = \langle u, \exp(-ik\cdot)\rangle.$$

Let ν be a strictly positive number and let ρ be a real number; let $\mathcal{G}$ be the class of even functions from $\mathbb{Z}$ to $\mathbb{R}$ which satisfy the estimate

$$\forall k \in \mathbb{Z}, \quad g(k) \le \rho - \nu|k|^2. \tag{1.1}$$

To each function $g \in \mathcal{G}$, we associate a pseudodifferential linear operator L by

$$\big(Lu\big)\widehat{\ }(k) = g(k)\widehat{u}(k). \tag{1.2}$$

Let g^ε be a sequence of functions belonging to $\mathcal{G}$, which converge point-wise to a limit g^0 in the following sense:

$$\forall k \in \mathbb{Z}, \quad \lim_{\varepsilon\to 0} g^\varepsilon(k) = g^0(k). \tag{1.3}$$

No further assumption is made on the convergence.

The pseudodifferential operator associated with g^ε is denoted by L^ε.

Joulin has asked the following question: is it true that the solution u^ε of the initial value problem

$$\begin{aligned} &\frac{\partial u^\varepsilon}{\partial t} = L^\varepsilon u^\varepsilon - \frac{1}{2}\left(\frac{\partial u^\varepsilon}{\partial x}\right)^2, \quad (x,t) \in \mathbb{T} \times (0,T), \\ &u^\varepsilon(x,0) = \phi(x), \quad x \in \mathbb{T} \end{aligned} \tag{1.4}$$

converges to the solution of the limiting initial value problem

$$\begin{aligned} &\frac{\partial u^0}{\partial t} = L^0 u^0 - \frac{1}{2}\left(\frac{\partial u^0}{\partial x}\right)^2, \quad (x,t) \in \mathbb{T} \times (0,T), \\ &u^0(x,0) = \phi(x), \quad x \in \mathbb{T}, \end{aligned} \tag{1.5}$$

as ε tends to 0?

The motivation for this question comes from a rather general procedure for analyzing nonlinear phenomena in physics and specifically combustion phenomena [3], [4], [1]. In these analyses, one assumes that the behavior of the linear part of the problem is described in Fourier variable: an asymptotic is assumed on the high modes behavior of this linear operator.

Practically, a specific form of the linear operator is assumed in order to simplify the mathematical procedure. However, it would be important to found this procedure more rigorously; after all, if it were unfounded, it would mean that the results would be strongly dependent on the details of the behavior of the linear operator.

The perturbation procedure consists of expanding the symbol g^ε of the operator under study, usually for small wave numbers, assuming that the symbol satisfies reasonable assumptions for large wave numbers, so that the model will be well posed; in particular, it would be very awkward to make an assumption of the form

$$|k| - \nu|k|^2 - \varepsilon|k|^3 \le g^\varepsilon(k) \le |k| - \nu|k|^2 + \varepsilon|k|^3, \tag{1.6}$$

since the rightmost inequality does not guarantee that the symbol g^ε is bounded for large wave numbers.

On the other hand, we could replace the respective coefficients $-\varepsilon$ and ε of the cubic terms in (1.6), respectively, by $-\mu - \varepsilon$ and $-\mu + \varepsilon$, with μ a positive number, and the theory presented here would apply in a straightforward manner.

The diffusion assumption means that estimate (1.1) holds, i.e., $-g^\varepsilon(k)$ has at least quadratic growth at infinity. It is mathematically possible to consider more general behaviors for the symbol, but it may be not extremely useful from the point of view of the applications.

The purpose of this paper is to show that the answer to Joulin's question is positive: if the initial data ϕ belong to $H^1_\sharp$, then u^ε tends to u^0 in $C^0\big([0,T];H^1_\sharp\big)$, for all finite T, as ε tends to 0.

The outline of the proof is as follows: the first step consists of obtaining an existence proof for (1.4), with bounds in $C^0\big([0,T];H^1(\mathbb{T})\big)$ which are independent of $\varepsilon \in [0,1]$. Once these estimates are obtained, we use an almost straightforward Gronwall lemma argument to conclude: the almost refers to the fact that we have to use an integral equation whose kernel contains a factor $t^{-3/4}$, so that a bit of care is required to attain the desired conclusion.

The difficulty comes from the fact that the only obvious estimates that we can obtain on $\exp(tL^\varepsilon)$ are in $L^2_\sharp$ and $H^s_\sharp$; since the nonlinear term has its values in $L^1_\sharp$, we decompose $\exp\bigl(tL^\varepsilon\bigr)$ as follows:

$$\exp\bigl(tL^\varepsilon\bigr) = \exp\bigl(tM^\varepsilon\bigr)\exp\bigl(t\nu\partial_{xx}/2\bigr);$$

the operator M^ε is defined as

$$M^\varepsilon = L^\varepsilon - \nu\partial_{xx}/2$$

and it has essentially the same properties as L^ε; but the operator ∂_{xx} is very well understood, and, in particular, an elementary calculation gives the norm of $\exp\bigl(t\nu\partial_{xx}/2\bigr)$ and of $\partial_x \exp\bigl(t\nu\partial_{xx}/2\bigr)$ as operators from $L^1_\sharp$ to $L^2_\sharp$. This calculation accounts for the fact that the kernel contains a term in $t^{-3/4}$.

It should be noted that the technique presented here is strongly dependent on the fact that the spatial dimension is equal to 1 and the growth of the nonlinearity is at most quadratic.

2. Existence and estimates. In this section, we prove an existence theorem with uniform bounds for a linear operator L defined by (1.2) and a symbol $g \in \mathcal{G}$.

THEOREM 2.1. *Assume that ϕ belongs to $H^2_\sharp$. Then, $\forall T > 0$, there exists a unique solution u of* (1.4)*, which has the following functional property:*

$$u \in C^0\bigl([0,T], H^2_\sharp\bigr) \cap C^1\bigl([0,T]; L^2_\sharp\bigr);$$

Moreover, the following estimate holds:

$$\sup_{g\in\mathcal{G}} \max_{0\le t\le T} |u(\cdot,t)|_{H^2_\sharp} < +\infty.$$

We first prove some auxiliary results on the semigroup $\exp\bigl(tL\bigr)$ and on an integral equation involving it.

LEMMA 2.2. *The operator L generates a holomorphic semigroup in $H^s_\sharp$. This semigroup is denoted by $\exp\bigl(tL\bigr)\forall s \ge 0$, and it satisfies the estimates*

$$\bigl\|\exp\bigl(tL\bigr)\bigr\|_{\mathcal{L}(H^s_\sharp)} \le e^{\rho t}. \tag{2.1}$$

Moreover, there exists a constant C such that $\forall t \ge 0$

$$\bigl\|\exp\bigl(tL\bigr)\bigr\|_{\mathcal{L}(L^1_\sharp, L^2_\sharp)} \le \frac{Ce^{\rho t}}{t^{1/4}}, \tag{2.2}$$

$$\bigl\|\partial_x \exp\bigl(tL\bigr)\bigr\|_{\mathcal{L}(L^1_\sharp, L^2_\sharp)} \le \frac{Ce^{\rho t}}{t^{3/4}}. \tag{2.3}$$

Proof. As is obvious in its Fourier representation, L is self-adjoint and bounded from above in the spaces $H^s_\sharp$; thus it generates a holomorphic semigroup $\exp\bigl(tL\bigr)$ in each of these spaces. The estimate (2.1) is clear in Fourier representation.

Denote the heat kernel by

$$\mathcal{E}(x,t) = \frac{1}{\sqrt{4\pi t}} \exp\left(-\frac{x^2}{4t}\right).$$

A straightforward calculation gives

$$|\mathcal{E}(\cdot,t)|_{L^2(\mathbb{R})} \le Ct^{-1/4},$$
$$|\partial_x \mathcal{E}(\cdot,t)|_{L^2(\mathbb{R})} \le Ct^{-3/4}.$$

Therefore, if z belongs to $L^1_\sharp$, the following estimates hold:

$$|\mathcal{E}(\cdot,t) * z|_{L^2_\sharp} \le Ct^{-1/4} |z|_{L^1_\sharp}, \tag{2.4}$$

$$|\partial_x \mathcal{E}(\cdot,t) * z|_{L^2_\sharp} \le Ct^{-3/4} |z|_{L^1_\sharp}. \tag{2.5}$$

We decompose L as

$$L = \nu\partial_{xx}/2 + M,$$

where M is given in Fourier space by

$$\big(Mu\big)\widehat{\ } = \big(g(k) + \nu k^2/2\big)\widehat{u}(k). \tag{2.6}$$

Since M and ∂_x commute, it is immediate that

$$\big\|\exp\big(tL\big)\big\|_{\mathcal{L}(L^1_\sharp, L^2_\sharp)} \le \big\|\exp\big(tM\big)\big\|_{\mathcal{L}(L^2_\sharp)} \big\|\exp\big(\nu t\partial_{xx}\big)\big\|_{\mathcal{L}(L^2_\sharp, L^1_\sharp)}.$$

By analogy with (2.1), we have

$$\big\|\exp\big(tM\big)\big\|_{\mathcal{L}(L^2_\sharp)} \le e^{\rho t}.$$

When we combine the above relation with (2.4) we find (2.2); we obtain (2.3) analogously. □

We define now for all functions u and v in $C^0\big([0,T]; L^2_\sharp\big)$ two bilinear forms

$$B_0(u,v)(\cdot,t) = \int_0^t \exp\big((t-s)L\big)\big[u(\cdot,s)v(\cdot,s)\big]\, ds, \tag{2.7}$$

$$B_1(u,v)(\cdot,t) = \int_0^t \partial_x \exp\big((t-s)L\big)\big[u(\cdot,s)v(\cdot,s)\big]\, ds. \tag{2.8}$$

The first properties of these bilinear forms are described in the following lemma.

LEMMA 2.3. *The bilinear forms B_0 and B_1 map $C^0\big([0,T], L^2_\sharp\big)^2$ to $C^0\big([0,T], L^2_\sharp\big)$, and there exists a constant C such that the following estimate holds:*

$$|B_0(u,v)(\cdot,t)|_{L^2_\sharp} \le C \int_0^t e^{\rho(t-s)}(t-s)^{-1/4} |u(\cdot,s)|_{L^2_\sharp} |v(\cdot,s)|_{L^2_\sharp}\, ds, \tag{2.9}$$

$$|B_1(u,v)(\cdot,t)|_{L^2_\sharp} \le C \int_0^t e^{\rho(t-s)}(t-s)^{-3/4} |u(\cdot,s)|_{L^2_\sharp} |v(\cdot,s)|_{L^2_\sharp}\, ds. \tag{2.10}$$

Proof. Estimate (2.9) is an immediate consequence of (2.2), and estimate (2.10) is an immediate consequence of (2.3). There remains to prove that the mappings $t \mapsto B_i(u,v)(\cdot,t)$ are continuous for $i = 0, 1$. Consider, for instance, the case $i = 1$, the case $i = 0$ being analogous. We observe that for $h > 0$,

$$\begin{aligned} &B_1(u,v)(\cdot,t+h) - B_1(u,v)(\cdot,t) \\ &= \int_0^t \partial_x \exp(sL)\big[(uv)(\cdot,t+h-s) - (uv)(\cdot,t-s)\big]\, ds \\ &\quad + \int_t^{t+h} \partial_x \exp(sL)\big[(uv)(\cdot,t+h-s)\big]\, ds. \end{aligned} \tag{2.11}$$

By uniform continuity of u and v from $[0,T]$ to $H^1_\sharp$, we can see that

$$\max_{0\le t\le T-h} |u(\cdot,t+h-s)v(\cdot,t+h-s)-u(\cdot,t-s)v(\cdot,t-s)|_{L^1_\sharp}=\zeta(h),$$

which tends to 0 as h tends to 0. Therefore

$$\left|\int_0^t \partial_x \exp(sL)\Big[(uv)(\cdot,t+h-s)-(uv)(\cdot,t-s)\Big]\,ds\right|_{L^2_\sharp}$$
$$\le C\zeta(h)\int_0^T \frac{e^{\rho t}}{t^{3/4}}\,dt.$$

The second term in the right-hand side of (2.11) is handled in a straightforward fashion:

$$\left|\int_t^{t+h} \partial_x \exp(sL)\big[(uv)(\cdot,t+h-s)\big]\,ds\right|_{L^2_\sharp}$$
$$\le C\int_t^{t+h} \frac{e^{\rho t}}{t^{3/4}}\,dt\|u\|_{C^0([0,T];L^2_\sharp)}\|v\|_{C^0([0,T];L^2_\sharp)}.$$

Thus $t\mapsto B_1(u,v)(\cdot,t)$ is continuous from the right on $[0,T)$; a similar argument would show that it is continuous from the left on $(0,T]$: details are left to the reader. ∎

The last information we need is on the following integral equation:

$$y(t)=f(t)+M_1\int_0^t (t-s)^{-3/4}y(s)\,ds, \tag{2.12}$$

and the related integral inequality

$$y(t)\le f(t)+M_1\int_0^t (t-s)^{-3/4}y(s)\,ds, \tag{2.13}$$

where M_1 is a real number.

LEMMA 2.4. *For all $M_1\in\mathbb{R}$ and all f in $L^1_{\rm loc}(\mathbb{R}^+)$, there exists a unique solution $y\in L^1_{\rm loc}(\mathbb{R}^+)$ of (2.12), given by*

$$y(t)=f(t)+\int_0^t K_1(t-s)f(s)\,ds,$$

where the kernel K_1 is locally integrable on $\mathbb{R}^+$ and nonnegative.

If M_1 is a nonnegative number and if f and y are nonnegative functions in $L^1_{\rm loc}(\mathbb{R}^+)$ satisfying (2.13), then for almost every t,

$$y(t)\le f(t)+\int_0^t K_1(t-s)f(s)\,ds.$$

Proof. The kernel K_1 will be obtained explicitly. Denoting by Γ the Euler function, we define for all σ of positive real part a locally integrable function χ^σ over $\mathbb{R}$ by

$$\chi^\sigma=\begin{cases}\Gamma(\sigma)^{-1}x^{\sigma-1} & \text{if } x>0,\\ 0 & \text{otherwise.}\end{cases}$$

It is classical that χ^σ can be extended as an entire function from $\mathbb{C}$ to $\mathcal{D}'(\mathbb{R})$ and that χ^0 can be identified with the Dirac mass δ at 0; see, for instance, [2, chapter III, page 72], where the indices are shifted by 1 relatively to the notation used here. Moreover, we have the following convolution identity $\forall\sigma$ and τ in $\mathbb{C}$:

$$\chi^\sigma * \chi^\tau = \chi^{\sigma+\tau}. \tag{2.14}$$

Equation (2.12) can be solved easily if y and f are extended by 0 for $t \le 0$: it is rewritten as the convolution equation

$$y = f + M\chi^{1/4} * y, \tag{2.15}$$

where $M = M_1\Gamma(1/4)^{-1}$. However, the fundamental solution of (2.15) is

$$\delta + \sum_{j=1}^{\infty} M^j \big(\chi^{1/4}\big)^j = \delta + \sum_{j=1}^{\infty} M^j \chi^{j/4},$$

thanks to (2.14). There remains to check that the kernel

$$K_1(t) = \sum_{j=1}^{\infty} M^j \chi^{j/4}(t)$$

is locally integrable on $\mathbb{R}$. But this kernel contains only three unbounded terms in a neighborhood of 0: those relative to the indices $j = 1$ to 3; it also converges nicely: a direct application of the asymptotic formula for the Γ function yields

$$\frac{\Gamma((j+5)/4)}{\Gamma((j+4)/4)} \sim \big((j+1)/4\big)^{1/4}.$$

Therefore the series

$$K_1(t) - \sum_{j=1}^{3} \frac{M^j t^{(j-4)/4}}{\Gamma(j/4)} = \sum_{j=4}^{\infty} \frac{M^j t^{(j-4)/4}}{\Gamma(j/4)}$$

converges $\forall t > 0$ and its sum is analytical with respect to the variable $t^{1/4}$. The uniqueness of the solution of (2.12) is a consequence of general theorems on the convolution algebra of distributions on $\mathbb{R}$ with support bounded on the left.

Consider the integral inequality

$$y(t) \le f(t) + M_1 \int_0^t (t-s)^{-3/4} y(s)\, ds;$$

here we assume that y and f are nonnegative. Thus we obtain immediately by substituting the inequality satisfied by y in the right-hand side of (2.13):

$$y \le \sum_{j=0}^{n} M^j \chi^{j/4} * f + M^{n+1}\chi^{(n+1)/4} * y.$$

As n tends to infinity, the last term of the right-hand side of this inequality tends to 0 as n tends to infinity, and (2.13) holds in the limit. □

With these preparations, we can pass now to local existence: we transform (1.4) into an integral equation, which can be written as

$$u(\cdot,t) = \exp\bigl(tL\bigr)\phi - \int_0^t \exp\bigl((t-s)L\bigr)\frac{\bigl(u_x(\cdot,s)\bigr)^2}{2}\,ds. \tag{2.16}$$

LEMMA 2.5. *Assume that ϕ belongs to $H^1_\sharp$. For all $R > |\phi|_{H^1_\sharp}$, there exists $\tau > 0$ such that* (2.16) *possesses a unique solution u belonging to $C^0\bigl([0,\tau];H^1_\sharp\bigr)$ which satisfies*

$$\forall t \in [0,\tau], \quad |u(\cdot,t) - \phi|_{H^1_\sharp} \le R. \tag{2.17}$$

Proof. The proof is basically a straightforward application of the strict contraction theorem. Define a mapping $\mathcal{T}$ on $C^0\bigl([0,\tau];H^1_\sharp\bigr)$ by

$$(\mathcal{T}u)(\cdot,t) = \exp(tL)\phi - B_0\bigl(u_x,u_x\bigr)/2. \tag{2.18}$$

Thanks to Lemmas 2.2 and 2.3, if u belongs to the ball $\mathcal{B}_R$ of radius R about 0 in $C^0\bigl([0,\tau];H^1_\sharp\bigr)$, then $\mathcal{T}u$ belongs to $C^0\bigl([0,\tau];H^1_\sharp\bigr)$ and

$$|\mathcal{T}u(\cdot,t)|_{L^2_\sharp} \le e^{\sigma t}|\phi|_{L^2_\sharp} + \frac{CR^2}{2}\int_0^t \frac{e^{\rho s}}{s^{1/4}}\,ds,$$
$$|\partial_x\mathcal{T}u(\cdot,t)|_{L^2_\sharp} \le e^{\sigma t}|\phi_x|_{L^2_\sharp} + \frac{CR^2}{2}\int_0^t \frac{e^{\rho s}}{s^{3/4}}\,ds.$$

Moreover, if u^1 and u^2 belong to $\mathcal{B}_R$, we have

$$(\mathcal{T}u^1 - \mathcal{T}u^2) = -B_0\bigl(u^1_x - u^2_x, u^1_x + u^2_x\bigr)/2,$$

so that

$$\bigl|\bigl(\mathcal{T}u^1 - \mathcal{T}u^2\bigr)(\cdot,t)\bigr|_{L^2_\sharp} \le CR|u^1-u^2|_{C^0([0,\tau];H^1_\sharp)}\int_0^t \frac{e^{\rho s}}{s^{1/4}}\,ds,$$
$$\bigl|\bigl(\partial_x\mathcal{T}u^1 - \partial_x\mathcal{T}u^2\bigr)(\cdot,t)\bigr|_{L^2_\sharp} \le CR|u^1-u^2|_{C^0([0,\tau];H^1_\sharp)}\int_0^t \frac{e^{\rho s}}{s^{3/4}}\,ds.$$

Given $R > |\phi|_{H^1_\sharp}$, we can choose τ such that

$$\begin{aligned}&\left(e^{\sigma\tau}|\phi|_{L^2_\sharp} + \frac{CR^2}{2}\int_0^\tau \frac{e^{\rho s}}{s^{1/4}}\,ds\right)^2\\ &\quad + \left(e^{\sigma\tau}|\phi_x|_{L^2_\sharp} + \frac{CR^2}{2}\int_0^\tau \frac{e^{\rho s}}{s^{3/4}}\,ds\right)^2 \le R^2\end{aligned} \tag{2.19}$$

and

$$C^2R^2\left(\int_0^\tau \frac{e^{\rho s}}{s^{1/4}}\,ds\right)^2 + \left(\int_0^\tau \frac{e^{\rho s}}{s^{3/4}}\,ds\right)^2 < 1. \tag{2.20}$$

Condition (2.19) ensures that $\mathcal{T}$ maps $\mathcal{B}_R$ to itself, and condition (2.20) implies that $\mathcal{T}$ is a strict contraction over $\mathcal{B}_R$. Thus, by the strict contraction principle, there is a unique $u \in \mathcal{B}_R$ which satisfies (2.16). The lemma is proved. ∎

If ϕ is smoother, we have a stronger result.

LEMMA 2.6. *Assume that ϕ belongs to $H^2_\sharp$; then the solution defined on $[0,\tau]$ at Lemma 2.5 belongs to $C^0([0,\tau];H^2_\sharp)$. Moreover, u_t belongs to $C^0\big([0,\tau];L^2_\sharp\big)$ and u solves (1.4).*

Proof. Formally, the second derivative $w = u_{xx}$ satisfies the integral equation

$$w = \exp\big(tL\big)\phi_{xx} - \int_0^t \partial_x \exp\big((t-s)L\big)\big[u_x(\cdot,s)w(\cdot,s)\big]\,ds. \tag{2.21}$$

If we prove that (2.21) possesses a unique solution, then a classical argument will imply that w is indeed the second derivative of u with respect to x. However, we may rewrite (2.21) as

$$w = \exp\big(tL\big)\phi_{xx} - B_1(w,u_x). \tag{2.22}$$

If we define a linear operator $\mathcal{U}$ by

$$\mathcal{U}w = -B_1(w,u_x),$$

and a function $\omega \in C^0([0,\tau];L^2_\sharp)$ by

$$\omega(\cdot,t) = \exp\big(tL\big)\phi_{xx},$$

we solve formally (2.22) by

$$w = \sum_{j=0}^{\infty} \mathcal{U}^j\omega.$$

Estimate (2.10) and Lemma 2.4 imply that the series on the right-hand side of the above equation converges in $C^0([0,\tau];L^2_\sharp)$; the uniqueness is an immediate consequence of the Gronwall-type estimate obtained at Lemma 2.4 applied to the inequality

$$\big|\big(w^1-w^2\big)(\cdot,t)\big|_{L^2_\sharp} \le \int_0^t \frac{Ce^{\rho s}}{s^{3/4}}\,\big|\big(w^1-w^2\big)(\cdot,s)\big|_{L^2_\sharp}\,ds.$$

The classical argument which ensures that the function w obtained as a solution of (2.22) is the second derivative of u with respect to x can be sketched as follows: we define

$$u_h(x,t) = u(x+h,t), \quad \phi_h(x) = \phi(x+h);$$

then, subtracting (2.16) translated by h from (2.16), and differentiating with respect to x, we obtain

$$u_{h,x} - u_x = e^{tL}\big(\phi_{h,x}-\phi_x\big) - B_1\big(u_{h,x}-u_x,(u_{h,x}+u_x)/2\big). \tag{2.23}$$

The triangle inequality implies then that

$$\begin{aligned}&\big|\big(u_{h,x}-u_x\big)(\cdot,t)\big|_{L^2_\sharp}\\ &\quad\le e^{\sigma t}\,|\phi_{h,x}-\phi_x|_{L^2_\sharp} + CR\int_0^t \big|\big(u_{h,x}-u_x\big)(\cdot,s)\big|_{L^2_\sharp}\,\frac{e^{\rho(t-s)}}{(t-s)^{3/4}}\,ds.\end{aligned}$$

If we let $M_1 = RCe^{\rho\tau}$, then we can apply the Gronwall-type estimate of Lemma 2.4, and we find that

$$\big|\big(u_{h,x} - u_x\big)(\cdot,t)\big|_{L^2_\sharp} \le \left(e^{\sigma t} + \int_0^t K_1(t-s)e^{\sigma s}\,ds\right)|\phi_{h,x} - \phi_x|_{L^2_\sharp}\,.$$

Under our assumptions on ϕ,

$$|\phi_{h,x} - \phi_x|_{L^2_\sharp} \le h\,|\phi_{xx}|_{L^2_\sharp}\,,$$

so that, uniformly on $[0,\tau]$,

$$\big|\big(u_{h,x} - u_x\big)(\cdot,t)\big|_{L^2_\sharp} \le C'h. \tag{2.24}$$

We subtract from (2.23) divided by h (2.21), and we get

$$z_h(\cdot,t) = e^{tL}\psi_h - B_1\big(z_h,u_x\big) - B_1\big(u_{h,x} - u_x, (u_{h,x} - u_x)/(2h)\big),$$

where we have used the notations

$$z_h = \frac{u_{x,h} - u_x}{h} - w, \quad \psi_h = \frac{\phi_{h,x} - \phi_h}{h} - \phi_{xx}.$$

A new application of the Gronwall-type inequality of Lemma 2.4 enables us to conclude that

$$\lim_{h\to 0}\ \max_{0\le t\le\tau} |z_h(\cdot,t)|_{L^2_\sharp} = 0,$$

and this proves the first statement of the lemma.

Once that u belongs to $C^0\big([0,\tau];H^2_\sharp\big)$, we see that Lu belongs to $C^0\big([0,\tau];L^2_\sharp\big)$, and $\big(u_x\big)^2$ belongs to $C^0\big([0,\tau];H^1_\sharp\big)$ since $H^1_\sharp$ is a multiplication algebra. A standard argument shows that (1.4) holds in the sense of distributions; thanks to the above functional information, its three terms belong to $C^0\big([0,\tau];L^2_\sharp\big)$, and this concludes the proof of the lemma. □

Let us prove now some a priori estimates.

LEMMA 2.7. *Under the assumptions of Lemma* 2.6*, we have the estimates* $\forall t \in [0,\tau]$

$$|u(\cdot,t)|_{H^1_\sharp} \le \Big(2e^{2\rho t}\,|\phi_x|^2_{L^2_\sharp} + |\phi|^2_{L^2_\sharp}\Big)^{1/2}. \tag{2.25}$$

Proof. Thanks to Lemma 2.6, we can differentiate (1.4) with respect to x; denoting by $v = u_x$, we observe immediately that v satisfies the equation

$$\frac{\partial v}{\partial t} = Lv - \frac{\partial_x\big((v)^2\big)}{2}. \tag{2.26}$$

We multiply (2.26) by v, and we integrate; we find that on the interval of existence $[0,\tau]$,

$$\frac{1}{2}\frac{d}{dt}\int_{\mathbb{T}} |v|^2\,dx = \int_{\mathbb{T}} \big(Lv\big)v\,dx - 2\int_{\mathbb{T}} \big(v\big)^2 v_x\,dx.$$

Under our assumptions, the expression $(v)^2 v_x$ is integrable, so that the last term of the above equality integrates to 0 by periodicity; we have the inequality $\forall k \in \mathbb{N}$:

$$g(k) \leq \rho; \tag{2.27}$$

this inequality and (2.26) imply the differential inequality

$$\frac{d}{dt} |v|^2_{L^2_\sharp} \leq 2\rho |v|^2_{L^2_\sharp},$$

which implies by a Gronwall lemma the following inequality:

$$|v|_{L^2_\sharp} \leq e^{\rho t} |\phi_x|_{L^2_\sharp},$$

which is valid on the interval of existence of u. On the other hand, if we integrate (1.1) on one period, we find that $\widehat{u}(0,t)$ is independent of t. Therefore, we have also the inequality

$$\sum_{k\in\mathbb{Z}} |\widehat{u}(k,t)|^2 \leq \left|\widehat{\phi}(0)\right|^2 + \sum_{k\in\mathbb{Z}\setminus\{0\}} |\widehat{v}(k,t)|^2.$$

These two relations imply that

$$|u(\cdot,t)|^2_{H^1_\sharp} \leq \left(2e^{2\rho t} |\phi_x|^2_{L^2_\sharp} + |\phi|^2_{L^2_\sharp}\right).$$

This shows the desired estimate. □

Now we can complete the proof of Theorem 2.1.

Proof of Theorem 2.1. Let R be defined by

$$R = \left(2e^{2\rho T} |\phi_x|^2_{L^2_\sharp} + |\phi|^2_{L^2_\sharp}\right)^{1/2} + 1, \tag{2.28}$$

and let τ be the upper bound of the existence time for a solution of the integral equation (2.16). Lemma 2.5 implies $\tau > 0$. If τ is larger than T, the theorem is proved; assume that $\tau \leq T$; then thanks to Lemma 2.7 we must have estimate (2.25) $\forall t < \tau$. With the help of Lemma 2.6, we have also

$$|u_{xx}(\cdot,t)|_{L^2_\sharp} \leq e^{\sigma t} |\phi_{xx}|_{L^2_\sharp} + CR \int_0^t \frac{e^{\rho(t-s)}}{(t-s)^{3/4}} |u_{xx}(\cdot,s)|_{L^2_\sharp}\, ds$$

which implies the a priori estimate

$$|u_{xx}|_{L^2_\sharp} \leq e^{\sigma t} |\phi_{xx}|_{L^2_\sharp} + \int_0^t K_1(t-s) e^{\sigma s}\, ds\, |\phi_{xx}|_{L^2_\sharp}.$$

In particular, we infer from (1.4) that u is Lipschitz continuous from $[0,\tau)$ to $L^2_\sharp$ and that the Lipschitz constant depends only on the $H^2_\sharp$ norm of the initial data and on T. These observations imply that the solution can be extended up to the time $t = \tau$. Then thanks to (2.25) we have

$$|u(\cdot,\tau)|_{H^1_\sharp} \leq \left(2e^{2\rho\tau} |\phi_x|^2_{L^2_\sharp} + |\phi|^2_{L^2_\sharp}\right)^{1/2} \leq R - 1.$$

Thanks to the local existence results Lemmas 2.5 and 2.6, we can find $\tau_1 > \tau$ such that the solution exists on $[0,\tau_1]$, takes its values in $H^2_\sharp$, and satisfies the estimate (2.25) with τ replaced by τ_1. This contradicts the assumption that τ was the upper bound of the existence times for which (2.25) holds and concludes the proof of the theorem. □

We have obtained an existence result which used as a technical step the assumption that the initial data belong to $H^2_\sharp$; this assumption can be removed, and we have the following proposition.

PROPOSITION 2.8. *Assume that ϕ belongs to $H^1_\sharp$. Then, $\forall T > 0$, there exists a unique solution u of* (1.4) *in the sense of distributions, which belongs to $C^0\big([0,T], H^1_\sharp\big)$ and which satisfies estimate* (2.25) *and the identity*

$$\forall t \in \mathbb{R}^+, \quad \int_{\mathbb{T}} u(x,t)\,dx = \int_{\mathbb{T}} \phi(x)\,dx. \tag{2.29}$$

Proof. We approximate the initial data $\phi \in H^1_\sharp$ by a sequence $\phi_n \in H^2_\sharp$ which converges to ϕ in the $H^1_\sharp$ norm; Theorem 2.1 implies that there is a solution u_n to (1.4) with initial data ϕ_n, and that this solution satisfies $\forall t \in [0,T]$ the estimate

$$\begin{aligned} |u_n(\cdot,t)|_{H^1_\sharp} &\le \Big(2e^{2\rho t}\,|\phi_{n,x}|^2_{L^2_\sharp} + |\phi_n|^2_{L^2_\sharp}\Big)^{1/2} \\ &\le \Big(2e^{2\rho T}\,|\phi_{n,x}|^2_{L^2_\sharp} + |\phi_n|^2_{L^2_\sharp}\Big)^{1/2} = R. \end{aligned} \tag{2.30}$$

We subtract the integral equation for u_m from the integral equation for u_n and we obtain

$$\begin{aligned} u_n - u_m = {}& \exp\big(Lt\big)(\phi_n - \phi_m) \\ & - B_0\big(u_{n,x} - u_{m,x}, (u_{n,x} + u_{m,x})/2\big). \end{aligned}$$

This relation implies the integral inequality

$$\begin{aligned} &\big|\big(u_{n,x} - u_{m,x}\big)(\cdot,t)\big|_{L^2_\sharp} \\ &\quad \le e^{\sigma t}\,|\phi_{n,x} - \phi_{m,x}|_{L^2_\sharp} + \int_0^t \frac{CRe^{\rho(t-s)}}{(t-s)^{3/4}}\,\big|\big(u_{n,x} - u_{m,x}\big)(\cdot,s)\big|_{L^2_\sharp}\,ds, \end{aligned}$$

and arguing as in the proof of Lemma 2.6, we infer that $\big(u_{n,x}\big)$ is a Cauchy sequence in $C^0\big([0,T]; L^2_\sharp\big)$. A similar argument shows that the sequence $(u_n)_n$ is a Cauchy sequence in $C^0\big([0,T]; H^1_\sharp\big)$. The limit of this Cauchy sequence solves (2.16) and satisfies (2.25); it is classical that (1.4) is solved by u in the sense of distributions. Conversely, if u belongs to $C^0\big([0,T]; H^1_\sharp\big)$, and solves (1.4), it also solves (2.16). The uniqueness is proved as follows: let v be another solution of (1.4) which belongs to $C^0\big([0,T]; H^1_\sharp\big)$, and let

$$R' = \max\big(|u|_{C^0([0,T];H^1_\sharp)}, |v|_{C^0([0,T];H^1_\sharp)}\big);$$

we subtract the integral equation for v from the integral equation for u, and we find that

$$\big(u_x - v_x\big)(\cdot,t) = -B_1\big(u_x - v_x, (u_x + v_x)/2\big),$$

and we obtain immediately the estimate

$$\big|\big(u_x - v_x\big)(\cdot,t)\big|_{L^2_\sharp} \le \int_0^t \frac{CR' e^{\rho s}}{s^{3/4}} |(u_x - v_x)(\cdot, t-s)|_{L^2_\sharp}\, ds;$$

thanks to Lemma 2.4, v must be equal to u. The last estimate holds by continuity: we have observed in the proof of Lemma 2.6 that it holds when the initial data belong to $H^2_\sharp$; therefore, by continuity, it still holds when the initial data belong to $H^1_\sharp$. □

3. Continuity with respect to ε. In this section, we prove the continuity result which is the object of this article. Assume therefore that the sequence g^ε of elements of $\mathcal{G}$ converges to g^0 as in (1.3). We denote by L^ε and L^0 the pseudodifferential operators defined by (1.2) with g replaced, respectively, by g^ε and g^0, and by M^ε and M^0 the analogous operators defined by (2.6). Then, $\forall \psi \in L^2_\sharp$, $\exp(tL^\varepsilon)\psi$ and $\exp(tL^0)\psi$ converge strongly in $L^2_\sharp$, respectively, to $\exp(tL^0)\psi$ and $\exp(tM^0)\psi$. These convergences are uniform on all compact subsets of $L^2_\sharp$ and on the compact interval $[0,T]$.

This strong convergence, together with one more integral inequality, will suffice to prove the last result presented here.

PROPOSITION 3.1. *Assume that ϕ belongs to $H^1_\sharp$; as ε tends to 0, u^ε tends to u^0 in $C^0\big([0,T]; H^1_\sharp\big) \forall T > 0$.*

Proof. Let R be defined by (2.30). We subtract from the integral equation (2.16) the analogous equation for $\varepsilon = 0$ and we get the identity

$$\begin{aligned} u^\varepsilon_x(\cdot,t) - u^0_x(\cdot,t) &= \big[\exp\big(tL^\varepsilon\big) - \exp\big(tL^0\big)\big]\phi_x \\ &\quad - \int_0^t \partial_x \exp\big((t-s)L^\varepsilon\big)\big[u^\varepsilon_x(\cdot,s) - u^0_x(\cdot,s)\big]\frac{u^\varepsilon_x(\cdot,s) + u^0_x(\cdot,s)}{2}\, ds \\ &\quad - \frac{1}{2}\int_0^t \partial_x\big[\exp\big((t-s)L^\varepsilon\big) - \exp\big((t-s)L^0\big)\big]\big(u^0_x(\cdot,s)\big)^2\, ds. \end{aligned} \tag{3.1}$$

We define $y^\varepsilon(t) = \big|u^\varepsilon_x(\cdot,t) - u^0_x(\cdot,t)\big|_{L^2_\sharp}$, and we observe that

$$\begin{aligned} &\left|\int_0^t \partial_x \exp\big((t-s)L^\varepsilon\big)\big[u^\varepsilon_x(\cdot,s) - u^0_x(\cdot,s)\big]\frac{u^\varepsilon_x(\cdot,s) + u^0_x(\cdot,s)}{2}\, ds\right|_{L^2_\sharp} \\ &\quad \le RCe^{\rho T}\int_0^t \frac{y^\varepsilon(s)\, ds}{(t-s)^{3/4}}; \end{aligned}$$

on the other hand, the second integral in the right-hand side of (3.1) is split into a term integrated from 0 to $t-\alpha$ and a term from $t-a$ to t; the second term is estimated as

$$\begin{aligned} &\left|\int_{t-\alpha}^t \partial_x\big[\exp((t-s)L^\varepsilon) - \exp((t-s)L^0)\big]\big[u^0_x(\cdot,s)^2\big]\, ds\right|_{L^2_\sharp} \\ &\quad \le \int_0^\alpha \frac{2Ce^{\rho s}\, ds}{s^{3/4}} \le C'\alpha^{1/4}. \end{aligned}$$

We use the strong convergence of $\exp(tM^\varepsilon)$ to estimate the first term. Indeed, the set $\big\{u^0_x(\cdot,s) : 0 \le s \le T\big\}$ is compact in $L^2_\sharp$, and therefore, the set $\big\{u^0_x(\cdot,s)^2 : 0 \le s \le T\big\}$ is compact in $L^1_\sharp$; thanks to estimate (2.5), $\forall \alpha > 0$, the set

$$\big\{\partial_x \exp\big(t\nu\partial_{xx}\big)u^0_x(\cdot,s)^2 : 0 \le s \le T, \alpha \le t \le T\big\} = K(\alpha)$$

is compact in $L^2_\sharp$; therefore, writing

$$\begin{aligned}&\big[\exp((t-s)L^\varepsilon)-\exp((t-s)L^0)\big]\big[u^0_x(\cdot,s)^2\big]\\&\quad=\big[\exp((t-s)M^\varepsilon)-\exp((t-s)M^0)\big]\exp\big((t-s)\nu\partial_{xx}\big)\big[u^0_x(\cdot,s)^2\big],\end{aligned}$$

we see that

$$\sup_{\substack{\alpha\le t\le T\\0\le s\le t-\alpha}}\big|\partial_x\big[\exp((t-s)L^\varepsilon)-\exp((t-s)L^0)\big]\big[u^0_x(\cdot,s)^2\big]\big|_{L^2_\sharp}=\zeta(\varepsilon,\alpha)$$

tends to 0 as ε tends to 0. Of course, this convergence is *not* uniform with respect to α. Finally, we let

$$\zeta(\varepsilon)=\big|\big[\exp(tL^\varepsilon)-\exp(tL^0)\big]\phi_x\big|_{L^2_\sharp}$$

which tends to 0 as ε tends to 0, thanks to the strong convergence of $\exp(tL^\varepsilon)$ to $\exp(tL^0)$.

Thus y^ε satisfies the integral inequality

$$y^\varepsilon(t)\le\zeta(\varepsilon)+C'\alpha^{1/4}+T\zeta(\varepsilon,\alpha)+M_1\int_0^t\frac{y^\varepsilon(s)\,ds}{(t-s)^{1/4}},$$

where we have chosen

$$M_1=RCe^{\rho T}.$$

Given $\beta>0$, we may always choose α and then ε_0 such that $\forall\varepsilon\le\varepsilon_0$,

$$\zeta(\varepsilon)+C'\alpha^{1/4}+T\zeta(\varepsilon,\alpha)\le\beta;$$

then, the convergence of y^ε to 0 in $C^0([0,T])$ is an immediate consequence of Lemma 2.4. This proves that u^ε_x converges to u^0_x in $C^0([0,T];L^2_\sharp)$. On the other hand, we have seen in the proof of Lemma 2.7 that the zero Fourier coefficient of $u^\varepsilon(\cdot,t)$ is independent of time; thus the convergence of u^ε_x implies the convergence of u^ε in $C^0([0,T];L^2_\sharp)$, hence its convergence in $C^0([0,T];H^1_\sharp)$. This completes the proof of the result. □

4. Conclusion. The result presented here is rather particular. Let us point out some generalizations one might consider: the nonlinearity u^2_x could be replaced by a more general nonlinearity in one dimension; but if the growth of the nonlinearity is faster than quadratic, the local existence theorem presented here fails; it can probably be cured if one is prepared to work with smoother initial data. If one would like to work in dimension 2 or larger, the estimates obtained at Lemma 2.2 are not strong enough: in particular (2.3) is replaced by an analogous estimate in dimension n with a power $t^{-(n+2)/4}$ instead of $t^{-3/4}$. Once we lose the local integrability of this kernel, we have to change methods to obtain something and probably to work in much smoother spaces.

One may wonder whether it could be possible to show estimates on $\exp(tL^\varepsilon)$ as an operator from L^p to L^p: this is indeed possible; however, the lack of precise information on the behavior of $g(k)-g(k-1)$ as $|k|$ tends to infinity seems to exclude semigroup estimates; however, it is quite possible that there should be an estimate with a kernel including negative fractional powers, which might be sufficient for such purposes. But the proof of continuity with respect to these perturbations seems much more difficult in a general case than in the simple case described here.

Acknowledgments. It is a pleasure to thank Guy Joulin for providing me with this question and for sharing with me enlightening conversations on this subject. One of the anonymous referees was instrumental in enhancing the quality of this article by his or her precise reading and well-founded criticisms; deep thanks are owed to her or him.

RESONANCE POCKETS OF HILL'S EQUATIONS WITH TWO-STEP POTENTIALS*

SHAOBO GAN† AND MEIRONG ZHANG‡

Abstract. In this paper, we use the rotation number approach to study in detail the characteristic values of Hill's equations with two-step periodic potentials. As a result, the global structure of resonance pockets is described completely. The results in this paper show that resonance pockets behave in a sensible and fairly rich way even in this simplest case.

1. Introduction. In this paper we are concerned with the global structure of resonance pockets of parameterized Hill's equations

$$\ddot{x} + (\lambda + \varepsilon p(t))x = 0, \tag{1.1}$$

where $p(t)$ is a 2π-periodic step potential of two steps. For a general 2π-periodic potential, the resonance region R of (1.1) means the set of those parameters (λ, ε) in the (λ, ε)-plane such that (1.1) admits solutions $x(t)$ which are unbounded. The resonance pockets of (1.1), which will be explained more clearly later, are "compact" or "closed" parts of R.

The resonance region R of (1.1) can be described completely in theory. For any fixed parameter ε, R consists of the complement of all spectrum intervals of (1.1). More precisely, let $q(t)$ be a 2π-periodic potential such that $q \in L^1(0, 2\pi)$. Consider the eigenvalue problem

$$\ddot{x} + (\lambda + q(t))x = 0. \tag{1.2}$$

By Theorem 2.1 of Magnus and Winkler [10] or Theorem 8.1, Chapter III of Hale [6], it is well known that problem (1.2) has a sequence of the periodic eigenvalues

$$\lambda_0^P(q) < \lambda_1^P(q) \le \lambda_2^P(q) < \cdots < \lambda_{2n-1}^P(q) \le \lambda_{2n}^P(q) < \cdots$$

with respect to the periodic boundary conditions (P): $x(0) - x(2\pi) = \dot{x}(0) - \dot{x}(2\pi) = 0$. Meanwhile, problem (1.2) also has a sequence of the antiperiodic eigenvalues

$$\lambda_1^A(q) \le \lambda_2^A(q) < \cdots < \lambda_{2n-1}^A(q) \le \lambda_{2n}^A(q) < \cdots$$

with respect to the antiperiodic boundary conditions (A): $x(0) + x(2\pi) = \dot{x}(0) + \dot{x}(2\pi) = 0$. Let us rewrite them as

$$\underline{\lambda}_n(q) = \lambda_n^A(q) \quad \text{and} \quad \overline{\lambda}_n(q) = \lambda_{n+1}^A(q) \qquad \text{when } n \text{ is odd},$$

‡Department of Mathematical Sciences,Tsinghua University, Beijing 100084, People's Republic of China (mzhang@math.tsinghua.edu.cn).

$$\underline{\lambda}_n(q) = \lambda_{n-1}^P(q) \quad \text{and} \quad \overline{\lambda}_n(q) = \lambda_n^P(q) \qquad \text{when } n \text{ is even.}$$

These eigenvalues, called characteristic values of (1.2) as a whole [10, p. 12], have the following order (see Theorem 2.1 of [10]):

$$\overline{\lambda}_0(q) < \underline{\lambda}_1(q) \le \overline{\lambda}_1(q) < \cdots < \underline{\lambda}_n(q) \le \overline{\lambda}_n(q) < \cdots.$$

Now the resonance region R of (1.1) is given by

$$R = \bigcup_{n=0}^{\infty} R_n,$$

where

$$R_0 = \{(\lambda, \varepsilon) : \lambda < \overline{\lambda}_0(\varepsilon p)\}, \qquad R_n = \{(\lambda, \varepsilon) : \underline{\lambda}_n(\varepsilon p) < \lambda < \overline{\lambda}_n(\varepsilon p)\},\ n = 1, 2, \ldots.$$

A typical example is the Mathieu case: $p(t) = \cos t$. In this case, $\underline{\lambda}_n(p_\varepsilon) < \overline{\lambda}_n(p_\varepsilon)$ holds for all $\varepsilon \neq 0$, $n \in \mathbb{N}$. Thus each resonance region R_n is like a "tongue" which approaches to the point $((n/2)^2, 0)$ on the λ-axis. These are the so-called Arnold tongues (resonance tongues, instability tongues); see section 25, Chapter 5 of [1] and section III.8 of Hale [6]. However, for the near Mathieu case $p(t) = \cos t + \beta \cos 2t$ or the square wave case $p(t) = \operatorname{sign} \cos t$, besides the resonance tongues, it is also observed that some resonance regions R_n would have some closed subregion, namely, $\underline{\lambda}_n(\varepsilon p) = \overline{\lambda}_n(\varepsilon p)$ for some nonzero parameter ε. These interesting phenomena are called resonance pockets; see [1, 4, 6]. One may find in [3] the historical development of the study for resonance regions of Hill's equations. For resonance tongues of certain nonlinear systems, one can refer to [2, 5, 7, 9, 13]. A geometric explanation using singularity theory to the appearance of resonance pockets is given in [3] and has been developed in [2, 4]. Such an idea is very fruitful in explaining the pockets near the λ-axis. However, so far as we know, the global structure for all resonance pockets are not available even for the simplest case—the square wave case.

Note that the problem of resonance pockets of the Hill's equations is just to study the coexistence problem [10, p. 90] of characteristic values:

$$\overline{\lambda}_n(\varepsilon p) = \underline{\lambda}_n(\varepsilon p). \tag{1.3}$$

Such a coexistence problem for general potentials $p(t)$ is extraordinarily difficult. A preliminary idea is to approximate general potentials by step ones. In doing so, we can give a complete analysis of the simplest case, i.e., the 2π-periodic two-step potentials:

$$p(t) = p_{c_1,c_2,t_1}(t) := \begin{cases} c_1 & \text{if } 0 \le t < t_1, \\ c_2 & \text{if } t_1 \le t < 2\pi, \end{cases} \tag{1.4}$$

where $c_1 \neq c_2$, $0 < t_1 < 2\pi$. Denote $t_2 = 2\pi - t_1$. Our result is the following theorem.

THEOREM 1.1. *Let $p(t)$ be given by* (1.4). *Then the number of resonance pockets in the nth resonance region R_n of* (1.1) *is exactly*

$$N_n = \begin{cases} n-2 & \text{if } \frac{nt_1}{2\pi} \text{ is an integer,} \\ n-1 & \text{if } \frac{nt_1}{2\pi} \text{ is not an integer.} \end{cases}$$

This result shows that the coexistence problem (1.3) and the global structure of the corresponding Hill's equations (1.1) depend on the ratio of $t_1/2\pi$ in a very sensible way, while the global structure of (1.1) behaves in an elegant way for "generic" two-step potentials.

COROLLARY 1.2. *When t_1 in (1.4) is incommensurable with π, i.e., t_1/π is irrational, the nth resonance region R_n of (1.1) contains exactly $n-1$ resonance pockets for each $n \in \mathbb{N}$. Moreover, all of resonance pockets are transversal.*

When the square wave potential $p(t)$ (i.e., $c_1 = -1$, $c_2 = +1$, and $t_1 = t_2 = \pi$) is considered, the structure of resonance pockets behaves as follows.

COROLLARY 1.3. *The number of resonance pockets in the nth resonance region R_n of (1.1) with the square wave potential $p(t)$ is exactly*

$$N_n = \begin{cases} n-2 & \text{if } n \text{ is even,} \\ n-1 & \text{if } n \text{ is odd.} \end{cases}$$

Note that the problem for two-step potentials is not too difficult because (1.1) can be solved using trigonometric functions. In particular, the discriminate of (1.1) can be computed explicitly; cf. (1.5). Now characteristic values can be determined by

$$\begin{aligned} \operatorname{tr} P_\lambda &= 2\cos(t_1\sqrt{\lambda+\varepsilon c_1})\cos(t_2\sqrt{\lambda+\varepsilon c_2}) \\ &\quad - \left(\sqrt{\frac{\lambda+\varepsilon c_1}{\lambda+\varepsilon c_2}} + \sqrt{\frac{\lambda+\varepsilon c_2}{\lambda+\varepsilon c_1}}\right)\sin(t_1\sqrt{\lambda+\varepsilon c_1})\sin(t_2\sqrt{\lambda+\varepsilon c_2}) = \pm 2; \end{aligned} \tag{1.5}$$

cf. Lemma 2.3 and p. 116 of [10]. However, (1.5) is not easily analyzed. Due to the coexistence of characteristic values, there is some difficulty in solving (1.5) even numerically. Because of this reason, we adopt in this paper the rotation number approach to characteristic values [8, 11, 12].

The paper is organized as follows. In section 2, the rotation number approach to characteristic values with general periodic potentials is reviewed. Some results concerning the coexistence and the characterization of characteristic values using the solutions of (2.3) (see next section) are given. These results may be of some independent interest. In section 3, we obtain the coexistence conditions and the equations for characteristic values. The results on resonance pockets are proved in section 4.

2. Rotation number approach to characteristic values. Let $\mathcal{P}$ denote the collection of all 2π-periodic functions $q(t)$ such that $q \in L^1(0, 2\pi)$.

Assume that $q \in \mathcal{P}$ and consider eigenvalue problem (1.2). We intend to use the rotation number function to characterize all characteristic values $\underline{\lambda}_n(q)$ and $\overline{\lambda}_n(q)$. Let $y = -\dot{x}$ in (1.2). Then (1.2) is equivalent to the following linear planar system:

$$\dot{x} = -y, \qquad \dot{y} = (\lambda + q(t))x. \tag{2.1}$$

In the polar coordinates: $x = r\cos\theta$, $y = r\sin\theta$,

$$\dot{r} = (\lambda + q(t) - 1)r\cos\theta\sin\theta, \tag{2.2}$$

$$\dot{\theta} = (\lambda + q(t))\cos^2\theta + \sin^2\theta =: \Xi(t, \theta; \lambda). \tag{2.3}$$

Let $\Theta(t; \theta_0, \lambda)$ be the unique solution of (2.3) satisfying the initial condition: $\Theta(0; \theta_0, \lambda) = \theta_0$. As the vector field $\Xi(t, \theta; \lambda)$ is 2π-periodic in t and is π-periodic in θ, one has

$$\Theta(t + 2m\pi; \theta_0, \lambda) = \Theta(t; \Theta(2m\pi; \theta_0, \lambda), \lambda) \tag{2.4}$$

$$\Theta(t; \theta_0 + n\pi, \lambda) = \Theta(t; \theta_0, \lambda) + n\pi \tag{2.5}$$

for all $t,\ \theta_0,\ \lambda \in \mathbb{R}$ and $m,\ n \in \mathbb{Z}$. Thus the rotation number of (2.3)

$$\rho(\lambda) = \rho(\lambda; q) = \lim_{t\to\infty} \frac{\Theta(t; \theta_0, \lambda) - \theta_0}{t}$$

exists and is independent of θ_0; see Theorem 2.1, Chapter 2 of Hale [6].

The solutions $\Theta(t;\theta_0,\lambda)$ depend continuously on the parameter λ. As $\Xi(t,\theta;\lambda)$ is nondecreasing with respect to λ, then so does $\Theta(t;\theta_0,\lambda)$ according to the comparison theorem. From Corollary 2.1, Chapter 2 of Hale [6], one knows that the rotation number function $\rho(\lambda)$ is continuous and nondecreasing. Furthermore, it can be proved that $\rho(\lambda)=0$ for $\lambda \ll -1$, and $\lim_{\lambda\to+\infty}\rho(\lambda)=+\infty$. Now all characteristic values can be determined using $\rho(\lambda)$.

PROPOSITION 2.1. *$\underline{\lambda}_n(q)=\min\{\lambda\in\mathbb{R}:\rho(\lambda)=n/2\}$ for all $n\in\mathbb{N}$, and $\overline{\lambda}_n(q)=\max\{\lambda\in\mathbb{R}:\rho(\lambda)=n/2\}$ for all $n\in\mathbb{Z}^+$.*

Proof. The relationship between spectrum and rotation number has been well developed in [8, 11, 12]. This characterization of characteristic values using rotation number function is a classical result; cf. Theorems 4.3 and 4.4 of [11]. As a proof is not given in [11], we sketch here, for completeness, the proof based on Theorem 2.1 of [10].

Let P_λ be the Poincaré matrix associated with the system (2.1), i.e.,

$$P_\lambda(x_0,y_0)=(x(2\pi;x_0,y_0,\lambda),y(2\pi;x_0,y_0,\lambda)),$$

where $(x(t;x_0,y_0,\lambda),y(t;x_0,y_0,\lambda))$ is the solution of (2.1) satisfying

$$(x(0;x_0,y_0,\lambda),y(0;x_0,y_0,\lambda))=(x_0,y_0).$$

If $\underline{\lambda}_n(q)\le\lambda\le\overline{\lambda}_n(q)$ for some $n\in\mathbb{N}$, it follows from Theorem 2.1 of [10] that $|\operatorname{tr}P_\lambda|\ge 2$ and P_λ has real eigenvalues $\mu_{1,2}$: $P_\lambda v_i=\mu_i v_i$, $v_i\in\mathbb{R}^2\backslash\{0\}$, $i=1,\ 2$. Let $\theta_i\in\mathbb{R}$ be such that $v_i=r_i(\cos\theta_i,\sin\theta_i)$, $i=1,\ 2$. Then $\Theta(2\pi;\theta_i,\lambda)=\theta_i+k_i\pi$ and $\rho(\lambda)=k_1/2=k_2/2=k/2$, where $k=k_\lambda\in\mathbb{Z}$ for each $\lambda\in[\underline{\lambda}_n(q),\overline{\lambda}_n(q)]$. As $\rho(\lambda)$ is continuous, k_λ is independent of $\lambda\in[\underline{\lambda}_n(q),\overline{\lambda}_n(q)]$. In fact, it can be proved that

$$\rho(\lambda)=n/2 \qquad \text{for all } \ \lambda\in[\underline{\lambda}_n(q),\overline{\lambda}_n(q)]. \tag{2.6}$$

On the other hand, if $\lambda\in(\overline{\lambda}_n(q),\underline{\lambda}_{n+1}(q))$ for some $n\in\mathbb{Z}^+$, then $|\operatorname{tr}P_\lambda|<2$. Therefore eigenvalues $\mu_{1,2}$ of P_λ are on the unit circle: $\mu_1=\bar{\mu}_2=e^{\alpha\sqrt{-1}}$ for some $\alpha=\alpha_\lambda\in\mathbb{R}\backslash\pi\mathbb{Z}$. In this case, one has

$$\rho(\lambda)=\alpha/2\pi \pmod{\mathbb{Z}}\notin\frac{1}{2}\mathbb{Z}. \tag{2.7}$$

Now (2.6) and (2.7) show that $\underline{\lambda}_n(q)$ and $\overline{\lambda}_n(q)$ are the endpoints of the interval $\rho^{-1}(n/2)\subset\mathbb{R}$. □

Let $h:\mathbb{R}\to\mathbb{R}$ be a homeomorphism such that

$$h(\vartheta+n\pi)\equiv h(\vartheta)+n\pi \tag{2.8}$$

for all $\vartheta\in\mathbb{R}$ and all $n\in\mathbb{Z}$. One can define the rotation number of h as

$$\rho(h)=\lim_{m\to\infty}\frac{h^m(\vartheta_0)-\vartheta_0}{2m\pi}$$

(independent of the choice of ϑ_0).

Let $h_\lambda:\mathbb{R}\to\mathbb{R}$ be the Poincaré map of (2.3), i.e., $h_\lambda(\vartheta)=\Theta(2\pi;\vartheta,\lambda)$ for $\vartheta\in\mathbb{R}$. By (2.5), h_λ satisfies (2.8). Now the rotation number $\rho(\lambda)$ is same as $\rho(h_\lambda)$.

PROPOSITION 2.2. *Let h be a homeomorphism of $\mathbb{R}$ satisfying* (2.8) *and n be an integer. Then*

(i) $\rho(h) \geq n/2$ *iff* $\max_{\vartheta\in\mathbb{R}}(h(\vartheta) - (\vartheta + n\pi)) \geq 0$.
(ii) $\rho(h) \leq n/2$ *iff* $\min_{\vartheta\in\mathbb{R}}(h(\vartheta) - (\vartheta + n\pi)) \leq 0$.

Proof. Let us prove (i). Assume that $h(\vartheta_0) \geq \vartheta_0 + n\pi$ for some $\vartheta_0 \in \mathbb{R}$. Using (2.8), it is easy to see that $h^m(\vartheta_0) \geq \vartheta_0 + mn\pi$ for all $m \in \mathbb{N}$. Thus

$$\rho(h) = \lim_{m\to+\infty} \frac{h^m(\vartheta_0) - \vartheta_0}{2m\pi} \geq \frac{n}{2}.$$

Conversely, let $M_0 = \max_{\vartheta\in\mathbb{R}}(h(\vartheta) - (\vartheta + n\pi))$. If $M_0 < 0$, we need to prove that $\rho(h) < n/2$. Notice that

$$h(\vartheta) \leq \vartheta + (n\pi + M_0) \qquad \text{for all } \vartheta \in \mathbb{R}$$

implies that

$$h^m(\vartheta) \leq \vartheta + m(n\pi + M_0)$$

for all $m \in \mathbb{N}$ and all $\vartheta \in \mathbb{R}$. Thus

$$\rho(h) = \lim_{m\to+\infty} \frac{h^m(\vartheta) - \vartheta}{2m\pi} \leq \frac{n}{2} + \frac{M_0}{2\pi} < \frac{n}{2}.$$

Conclusion (ii) can be proved similarly. □

PROPOSITION 2.3. *Let n be an integer. Then the following hold.*
(i) $\lambda = \underline{\lambda}_n(q)$ *iff* $\max_{\theta_0}(\Theta(2\pi;\theta_0,\lambda) - (\theta_0 + n\pi)) = 0$.
(ii) $\lambda = \overline{\lambda}_n(q)$ *iff* $\min_{\theta_0}(\Theta(2\pi;\theta_0,\lambda) - (\theta_0 + n\pi)) = 0$.

Proof. By the comparison theorem for solutions, it can be proved that $\Theta(2\pi;\theta_0,\lambda)$ is strictly increasing with respect to λ. Now the results follow from Propositions 2.1 and 2.2. □

It follows from Proposition 2.3 that the coexistence $\overline{\lambda}_n(q) = \underline{\lambda}_n(q)$ can be described using the solutions $\Theta(2\pi;\theta_0,\lambda)$ in the following way.

PROPOSITION 2.4. $\overline{\lambda}_n(q) = \underline{\lambda}_n(q)$ $(= \lambda)$ *iff* $\Theta(2\pi;\theta_0,\lambda) \equiv \theta_0 + n\pi$ *for all* θ_0.

It follows also from Proposition 2.3 that if $\lambda = \overline{\lambda}_n(q)$ or $\lambda = \underline{\lambda}_n(q)$, then it is necessary that there exists some $\vartheta_0 \in \mathbb{R}$ such that

$$\Theta(2\pi;\vartheta_0,\lambda) = \vartheta_0 + n\pi \qquad \text{and} \qquad \left.\frac{d\Theta(2\pi;\vartheta,\lambda)}{d\vartheta}\right|_{\vartheta=\vartheta_0} = 1. \tag{2.9}$$

We show using the Hamiltonian structure of (2.1) that condition (2.9) is also sufficient for λ to be a characteristic value.

PROPOSITION 2.5. $\lambda = \overline{\lambda}_n(q)$ *or* $\underline{\lambda}_n(q)$ *iff* λ *satisfies* (2.9) *for some* $\vartheta_0 \in \mathbb{R}$. $\theta_0 \in \mathbb{R}$.

Proof. For any fixed $\vartheta \in \mathbb{R}$, let $r = R(t;\vartheta,\lambda)$ and $\theta = \Theta(t;\vartheta,\lambda)$ be the solutions of (2.2) and (2.3) satisfying $R(0;\vartheta,\lambda) = 1$ and $\Theta(0;\vartheta,\lambda) = \vartheta$.

Let $P_\lambda : \mathbb{R}^2 \to \mathbb{R}^2$ be the Poincaré map of (2.1). Then P_λ is area-preserving because (2.1) is a Hamiltonian system. Using the solutions $R(t;\vartheta,\lambda)$ and $\Theta(t;\vartheta,\lambda)$, P_λ is given by

$$P_\lambda(r\cos\vartheta,\, r\sin\vartheta) = rR(2\pi;\vartheta,\lambda)(\cos\Theta(2\pi;\vartheta,\lambda),\, \sin\Theta(2\pi;\vartheta,\lambda)) \tag{2.10}$$

for all $r \in \mathbb{R}$ and all ϑ.

Let ϑ_0 be any fixed real number. For any ϑ_1 near ϑ_0, consider the following sector:

$$S = \{(r\cos\vartheta,\, r\sin\vartheta) \in \mathbb{R}^2 : 0 \le r \le 1,\ \vartheta_0 \le \vartheta \le \vartheta_1\}.$$

Then S has area $\frac{1}{2}(\vartheta_1 - \vartheta_0)$. The image $S' = P_\lambda(S)$ is

$$S' = \{(r'\cos\vartheta',\, r'\sin\vartheta') \in \mathbb{R}^2 :\ 0 \le r' \le R(2\pi; \Theta^{-1}(\vartheta';\lambda),\lambda),\\ \Theta(2\pi;\vartheta_0,\lambda) \le \vartheta' \le \Theta(2\pi;\vartheta_1,\lambda)\},$$

where $\Theta^{-1}(\cdot;\lambda)$ is the inverse of $\Theta(2\pi;\,\cdot,\,\lambda)$. Thus S' has area

$$\frac{1}{2}\int_{\Theta(2\pi;\vartheta_0,\lambda)}^{\Theta(2\pi;\vartheta_1,\lambda)} R^2(2\pi;\Theta^{-1}(\vartheta';\lambda),\lambda)d\vartheta' = \frac{1}{2}\int_{\vartheta_0}^{\vartheta_1} R^2(2\pi;\vartheta,\lambda)\frac{d\Theta(2\pi;\vartheta,\lambda)}{d\vartheta}d\vartheta.$$

As P_λ is area-preserving,

$$\frac{1}{2}(\vartheta_1 - \vartheta_0) \equiv \frac{1}{2}\int_{\vartheta_0}^{\vartheta_1} R^2(2\pi;\vartheta,\lambda)\frac{d\Theta(2\pi;\vartheta,\lambda)}{d\vartheta}d\vartheta.$$

Thus

$$\frac{d\Theta}{d\vartheta}(2\pi;\vartheta,\lambda) \equiv \frac{1}{R^2(2\pi;\vartheta,\lambda)}. \tag{2.11}$$

Assume now that $\vartheta_0 \in \mathbb{R}$ satisfies (2.9). Then $\Theta(2\pi;\vartheta_0,\lambda) = \vartheta_0 + n\pi$. Moreover, by the second equality in (2.9) and by (2.11), $R(2\pi;\vartheta_0,\lambda) = 1$. Now we get from (2.10) that

$$\begin{aligned} P_\lambda(\cos\vartheta_0,\,\sin\vartheta_0) &= R(2\pi;\vartheta_0,\lambda)(\cos\Theta(2\pi;\vartheta_0,\lambda),\,\sin\Theta(2\pi;\vartheta_0,\lambda))\\ &= (\cos(\vartheta_0 + n\pi),\,\sin(\vartheta_0 + n\pi))\\ &= (-1)^n(\cos\vartheta_0,\,\sin\vartheta_0). \end{aligned}$$

This shows that P_λ has a nonzero fixed point $(\cos\vartheta_0,\,\sin\vartheta_0)$ if n is even, which yields a nonzero 2π-periodic solution of (2.1). Thus λ is a periodic eigenvalue of (1.2). The case that n is odd implies that λ is an antiperiodic eigenvalue of (1.2). □

3. Two classes of conditions. Let $q(t) \in \mathcal{P}$ be the 2π-periodic potential given by

$$q(t) = q_{b_1,b_2,t_1}(t) := \begin{cases} b_1 & \text{for } 0 \le t < t_1\ (< 2\pi),\\ b_2 & \text{for } t_1 \le t < 2\pi. \end{cases} \tag{3.1}$$

Denote $t_2 = 2\pi - t_1$. We consider the following linear equation:

$$\ddot{x} + q(t)x = 0,$$

or, its equivalent system

$$\dot{x} = -y, \qquad \dot{y} = q(t)x.$$

As in section 2, let $x = r\cos\theta,\ y = r\sin\theta$. Then θ satisfies

$$\dot{\theta} = q(t)\cos^2\theta + \sin^2\theta =: \Xi(t,\theta). \tag{3.2}$$

Let $\Theta(t;\theta_0)$ be the solution of (3.2) satisfying the initial condition $\Theta(0;\theta_0) = \theta_0$. Denote $\Theta(\theta_0) := \Theta(2\pi;\theta_0)$. For any fixed $n \in \mathbb{N}$, we want to find the explicit conditions on $b_1,\ b_2,\ t_1,\ t_2$ so that

$$\Theta(\theta_0) \equiv \theta_0 + n\pi \qquad \text{for all } \theta_0 \in \mathbb{R}. \tag{3.3}$$

By Proposition 2.4, condition (3.3) is related with the coexistence of characteristic values.

In order to study (3.3), we need not consider the trivial case $b_1 = b_2$. Hence we assume that $b_1 \neq b_2$ in (3.1).

PROPOSITION 3.1. *Condition* (3.3) *holds iff* $b_1,\ b_2,\ t_1,\ t_2$ *satisfy* $b_1 > 0,\ b_2 > 0$, *and*

$$t_1\sqrt{b_1} = k\pi \quad \text{and} \quad t_2\sqrt{b_2} = (n-k)\pi \tag{3.4}$$

for some integer k *with* $0 < k < n$.

Proof. Let $\Theta_1(\theta_0) := \Theta(t_1;\theta_0)$. We have four cases to be discussed.

Case 1. $b_1 = a_1^2 > 0$ and $b_2 = a_2^2 > 0$. Assume that (3.3) holds. In this case, by integrating (3.2) on $[0, t_1]$ and $[t_1, 2\pi]$, respectively, we have the following two equalities:

$$\int_{\theta_0}^{\Theta_1(\theta_0)} \frac{d\theta}{a_1^2\cos^2\theta + \sin^2\theta} = t_1, \tag{3.5}$$

$$\int_{\Theta_1(\theta_0)}^{n\pi+\theta_0} \frac{d\theta}{a_2^2\cos^2\theta + \sin^2\theta} = t_2 \tag{3.6}$$

for all θ_0. Differentiating (3.5) and (3.6) with respect to θ_0, one has

$$\frac{1}{a_1^2\cos^2\theta_0 + \sin^2\theta_0} = \frac{\Theta_1'(\theta_0)}{a_1^2\cos^2\Theta_1(\theta_0) + \sin^2\Theta_1(\theta_0)}, \tag{3.7}$$

$$\frac{1}{a_2^2\cos^2\theta_0 + \sin^2\theta_0} = \frac{\Theta_1'(\theta_0)}{a_2^2\cos^2\Theta_1(\theta_0) + \sin^2\Theta_1(\theta_0)} \tag{3.8}$$

for all $\theta_0 \in \mathbb{R}$. From these we obtain

$$\sin(\Theta_1(\theta_0) - \theta_0)\sin(\Theta_1(\theta_0) + \theta_0) \equiv 0.$$

As $\Theta_1(\theta_0)$ is continuous in θ_0, we have either

$$\Theta_1(\theta_0) - \theta_0 \equiv k\pi \qquad \text{for some } k \in \mathbb{Z} \tag{3.9}$$

or

$$\Theta_1(\theta_0) + \theta_0 \equiv k\pi \qquad \text{for some } k \in \mathbb{Z}. \tag{3.10}$$

If (3.9) holds, then k satisfies $0 < k < n$ because $\theta_0 < \Theta_1(\theta_0) < \theta_0 + n\pi$ in this case. Note that

$$\int_0^{\pi} \frac{d\theta}{a^2\cos^2\theta + \sin^2\theta} = \frac{\pi}{a} \qquad (a > 0).$$

It now follows from (3.5) and (3.6) that

$$a_1t_1 = k\pi \quad \text{and} \quad a_2t_2 = (n-k)\pi \qquad \text{for some } 0 < k < n. \tag{3.11}$$

Conversely, if (3.11) is satisfied for some $0 < k < n$, it is easy to see that $\Theta_1(\theta_0) \equiv \theta_0 + k\pi$ and $\Theta(\theta_0) \equiv \Theta_1(\theta_0) + (n-k)\pi \equiv \theta_0 + n\pi$, i.e., equality (3.3) holds for all θ_0.

Assume now that (3.10) is satisfied. Let $\theta_0 = \ell\pi + \alpha$, where $\ell \in \mathbb{Z}$ and $\alpha \in [-\pi/2, \pi/2)$. Thus, by (3.10), $\Theta_1(\theta_0) = (k-\ell)\pi - \alpha$. It follows from (3.5) that

$$\begin{aligned} t_1 &= \int_{\ell\pi+\alpha}^{(k-\ell)\pi-\alpha} \frac{d\theta}{a_1^2\cos^2\theta + \sin^2\theta} \\ &= \left\{ \int_{\ell\pi+\alpha}^{\ell\pi} + \int_{\ell\pi}^{(k-\ell)\pi} + \int_{(k-\ell)\pi}^{(k-\ell)\pi-\alpha} \right\} \frac{d\theta}{a_1^2\cos^2\theta + \sin^2\theta} \\ &= \frac{(k-2\ell)\pi}{a_1} - 2\int_0^{\alpha} \frac{d\theta}{a_1^2\cos^2\theta + \sin^2\theta} \\ &= \frac{(k-2\ell)\pi}{a_1} - \frac{2}{a_1}\arctan\left(\frac{1}{a_1}\tan\alpha\right). \end{aligned}$$

Namely,

$$k\pi - a_1 t_1 = 2\ell\pi + 2\arctan\left(\frac{1}{a_1}\tan\theta_0\right). \tag{3.12}$$

Note that equality (3.12) cannot hold for all $\theta_0 \in \mathbb{R}$. Thus (3.10) cannot happen in this case.

We remark here that if (3.6) is used, one can obtain

$$a_2 t_2 - (n-k)\pi = 2\ell\pi + 2\arctan\left(\frac{1}{a_2}\tan\theta_0\right). \tag{3.13}$$

This also implies that (3.10) cannot happen in this case.

Case 2. $b_1 \le 0$ and $b_2 = a_2^2 > 0$. As $\Psi(\theta) = b_1\cos^2\theta + \sin^2\theta$ has zeros $\theta = \theta_\pm = \pm\arctan\sqrt{-b_1} + j\pi$, $j \in \mathbb{Z}$, we have $\Theta_1(\theta_\pm) = \theta_\pm$. Let now $\theta_0 = \theta_\pm$ in (3.6). Then

$$t_2 = \int_{\theta_\pm}^{\theta_\pm + n\pi} \frac{d\theta}{a_2^2\cos^2\theta + \sin^2\theta} = \frac{n\pi}{a_2}.$$

Thus $a_2 t_2 = n\pi$. This condition, together with (3.6), implies that $\Theta_1(\theta_0) \equiv \theta_0$ for all θ_0, which is impossible because $\Theta_1(\theta_0) = \Theta(t_1; \theta_0)$ is determined by differential equation

$$\dot\theta = b_1\cos^2\theta + \sin^2\theta, \qquad t \in [0, t_1].$$

Case 3. $b_1 > 0$ and $b_2 \le 0$. As characteristic values are invariant under translations of potentials $q_s(t)$ $(= q(t+s))$, one can transfer this case to Case 2.

Case 4. $b_1 \le 0$ and $b_2 \le 0$. In this case the vector field $\Xi(t,\theta) = q(t)\cos^2\theta + \sin^2\theta \le \Psi(\theta) := -\beta^2\cos^2\theta + \sin^2\theta$, where $\beta = \min\{\sqrt{-b_1}\,,\ \sqrt{-b_2}\,\}$. Thus

$$\dot\theta = \Xi(t,\theta) \le -\beta^2\cos^2\theta + \sin^2\theta = \Psi(\theta).$$

As $\Psi(\theta)$ has zeros $\theta_\pm = \pm\arctan\beta + j\pi$, $j \in \mathbb{Z}$, the comparison theorem shows that $\Theta(2\pi; \theta_\pm) \le \theta_\pm$. As a result, (3.3) does not hold for all θ_0. □

Another class of conditions on $b_1,\ b_2,\ t_1,\ t_2$ is when the following holds:

$$\exists\ \theta_0 \text{ such that } \Theta(\theta_0) = \theta_0 + n\pi \text{ and } \left.\frac{d\Theta(\vartheta)}{d\vartheta}\right|_{\vartheta=\theta_0} = 1. \tag{3.14}$$

By Proposition 2.5, condition (3.14) is related with the determination of characteristic values.

PROPOSITION 3.2. *Condition* (3.14) *is equivalent to either*

$$a_1 \sin\frac{a_1 t_1}{2}\cos\frac{a_2 t_2 - n\pi}{2} + a_2 \cos\frac{a_1 t_1}{2}\sin\frac{a_2 t_2 - n\pi}{2} = 0 \tag{3.15}$$

or

$$a_1 \cos\frac{a_1 t_1}{2}\sin\frac{a_2 t_2 - n\pi}{2} + a_2 \sin\frac{a_1 t_1}{2}\cos\frac{a_2 t_2 - n\pi}{2} = 0, \tag{3.16}$$

where $a_1 = \sqrt{b_1}$ *and* $a_2 = \sqrt{b_2}$.

Proof. We consider the first case that $b_1 = a_1^2 > 0$ and $b_2 = a_2^2 > 0$ in the proof of Proposition 3.1. Note that the equalities (3.5) and (3.6) now read as

$$\int_{\vartheta}^{\Theta_1(\vartheta)} \frac{d\theta}{a_1^2\cos^2\theta + \sin^2\theta} = t_1$$

and

$$\int_{\Theta_1(\vartheta)}^{\Theta(\vartheta)} \frac{d\theta}{a_2^2\cos^2\theta + \sin^2\theta} = t_2$$

for all ϑ. Differentiating these equations with respect to ϑ at $\vartheta = \theta_0$, we can once again obtain equalities (3.7) and (3.8) for this specific θ_0 by simply noticing the conditions in (3.14). Now we can proceed as in the proof of Proposition 3.1 and conclude that either (3.11) holds or both of (3.12) and (3.13) hold for this specific θ_0.

Note that (3.11) is a special case of (3.12) and (3.13) with $\ell = 0$ and $\theta_0 = 0$. Eliminating θ_0 from (3.12) and (3.13), we arrive at

$$a_1 \tan\frac{k\pi - a_1 t_1}{2} = a_2 \tan\frac{a_2 t_2 - (n-k)\pi}{2}. \tag{3.17}_k$$

Observe that if $k' = k + 2$ then $(3.17)_{k'}$ is the same as $(3.17)_k$. Thus $(3.17)_k$ yield actually only two equations:

$$a_1 \tan\frac{a_1 t_1}{2} + a_2 \tan\frac{a_2 t_2 - n\pi}{2} = 0,$$

and

$$a_1 \cot\frac{s a_1 t_1}{2} + a_2 \cot\frac{a_2 t_2 - n\pi}{2} = 0.$$

These are just the conditions (3.15) and (3.16), respectively, which are described in the proposition. The converse can also be proved. These prove the proposition for Case 1.

One can prove in the other cases similarly if the complex cosine and sine functions are used in (3.15) and (3.16). □

Let $q(t) = q_{b_1,b_2,t_1}(t)$ be given by (3.1). It follows from Proposition 3.1 that the coexistence $\overline{\lambda}_n(q_{b_1,b_2,t_1}) = \underline{\lambda}_n(q_{b_1,b_2,t_1})$ $(= \lambda)$ is determined by

$$t_1\sqrt{\lambda + b_1} = k\pi \qquad \text{and} \qquad t_2\sqrt{\lambda + b_2} = (n-k)\pi$$

for some $0 < k < n$. Namely, $b_1,\ b_2,\ t_1$ satisfy

$$H_{n,k}: \quad b_2 - b_1 = \left((n-k)\pi/t_2\right)^2 - \left(k\pi/t_1\right)^2, \qquad 0 < k < n. \tag{3.18}$$

We will see from the next section that these surfaces $H_{n,k}$ in the $(b_1,\ b_2,\ t_1)$-space play a fundamental role in analyzing resonance pockets.

4. Application to resonance pockets. Now we apply the results in section 3 to the resonance pockets of Hill's equations (1.1) with two-step potentials, where $p(t) = p_{c_1,c_2,t_1}(t)$ is given by (1.4). Correspondingly, the parameters (b_1, b_2, t_1) in (3.1) are $(c_1\varepsilon, c_2\varepsilon, t_1)$ in this case.

Fix an integer $n \geq 2$. Starting from $\varepsilon = 0$ where $\underline{\lambda}_n(\varepsilon p) = \overline{\lambda}_n(\varepsilon p) = (n/2)^2$, if $\varepsilon \neq 0$ is such that $(c_1\varepsilon, c_2\varepsilon, t_1)$ hits $H_{n,k}$ for some $0 < k < n$, then one gets a resonance pocket inside R_n of (1.1). Explicitly, $(c_1\varepsilon, c_2\varepsilon, t_1) \in H_{n,k}$ is given by

$$\varepsilon = \varepsilon_{n,k} := \frac{1}{c_2 - c_1}\left(((n-k)\pi/t_2)^2 - (k\pi/t_1)^2\right), \tag{4.1}$$

where $\lambda = \underline{\lambda}_n(\varepsilon p) = \overline{\lambda}_n(\varepsilon p)$ is

$$\lambda = \lambda_{n,k} := (k\pi/t_1)^2 - c_1\varepsilon_{n,k} = \frac{1}{c_2 - c_1}\left(c_2\left((n-k)\pi/t_2\right)^2 - c_1\left(k\pi/t_1\right)^2\right). \tag{4.2}$$

Now we can complete the proof of Theorem 1.1. We need only to analyze (4.1). Note that $\varepsilon_{n,k}$ is decreasing when k runs from 1 to $n-1$. If t_1 is such that $nt_1/2\pi$ is not an integer, then all $\varepsilon_{n,k} \neq 0$ for $k = 1, \ldots, n-1$. Note that $\underline{\lambda}_n(\varepsilon p) = \overline{\lambda}_n(\varepsilon p) = (n/2)^2$ when $\varepsilon = 0$. Thus $\underline{\lambda}_n(\varepsilon p) = \overline{\lambda}_n(\varepsilon p)$ iff $\varepsilon = \varepsilon_{n,k}$, $k = 1, \ldots, n-1$, or $\varepsilon = 0$. As a result, R_n contains exactly $n-1$ pockets. When $nt_1/2\pi = k_0$ is an integer, then $0 < k_0 < n$ and $\varepsilon_{n,k_0} = 0$. As a result, $\underline{\lambda}_n(\varepsilon p) = \overline{\lambda}_n(\varepsilon p)$ iff $\varepsilon = \varepsilon_{n,k}$, $k = 1, \ldots, n-1$. Thus R_n contains exactly $n-2$ pockets. This completes the proof of Theorem 1.1. □

We remark that by Proposition 3.2, characteristic values $\lambda = \underline{\lambda}_n(\varepsilon p)$ and $\lambda = \overline{\lambda}_n(\varepsilon p)$ of (1.1) are determined by

$$\begin{aligned}&\sqrt{\lambda + c_1\varepsilon}\,\sin\frac{t_1\sqrt{\lambda + c_1\varepsilon}}{2}\cos\frac{t_2\sqrt{\lambda + c_2\varepsilon} - n\pi}{2}\\ &+\sqrt{\lambda + c_2\varepsilon}\,\cos\frac{t_1\sqrt{\lambda + c_1\varepsilon}}{2}\sin\frac{t_2\sqrt{\lambda + c_2\varepsilon} - n\pi}{2} = 0,\end{aligned} \tag{4.3}$$

$$\begin{aligned}&\sqrt{\lambda + c_1\varepsilon}\,\cos\frac{t_1\sqrt{\lambda + c_1\varepsilon}}{2}\sin\frac{t_2\sqrt{\lambda + c_2\varepsilon} - n\pi}{2}\\ &+\sqrt{\lambda + c_2\varepsilon}\,\sin\frac{t_1\sqrt{\lambda + c_1\varepsilon}}{2}\cos\frac{t_2\sqrt{\lambda + c_2\varepsilon} - n\pi}{2} = 0;\end{aligned} \tag{4.4}$$

see (3.15) and (3.16).

Let $\lambda = \Lambda_1(\varepsilon)$ and $\lambda = \Lambda_2(\varepsilon)$ be the solutions of (4.3) and (4.4) starting at $\Lambda_1(0) = \Lambda_2(0) = (n/2)^2$, respectively. At $(\lambda, \varepsilon) = (\lambda_{n,k}, \varepsilon_{n,k})$, we have

$$\frac{d\Lambda_1}{d\varepsilon} = -\frac{c_1t_1^3(n-k)^2 + c_2t_2^3k^2}{t_1^3(n-k)^2 + t_2^3k^2}, \tag{4.5}$$

$$\frac{d\Lambda_2}{d\varepsilon} = -\frac{c_1t_1 + c_2t_2}{2\pi}, \tag{4.6}$$

when k is odd, and

$$\frac{d\Lambda_1}{d\varepsilon} = -\frac{c_1t_1 + c_2t_2}{2\pi}, \tag{4.7}$$

$$\frac{d\Lambda_2}{d\varepsilon} = -\frac{c_1t_1^3(n-k)^2 + c_2t_2^3k^2}{t_1^3(n-k)^2 + t_2^3k^2}, \tag{4.8}$$

when k is even. Similarly, at the point $(\lambda, \varepsilon) = ((n/2)^2, 0)$, we get from (4.3) and (4.4) that

$$\frac{d\Lambda_1}{d\varepsilon} = -\frac{c_1(\frac{nt_1}{2} + \sin\frac{nt_1}{2}) + c_2(\frac{nt_2}{2} - \sin\frac{nt_1}{2})}{n\pi}, \tag{4.9}$$

$$\frac{d\Lambda_2}{d\varepsilon} = -\frac{c_1(\frac{nt_1}{2} - \sin\frac{nt_1}{2}) + c_2(\frac{nt_2}{2} + \sin\frac{nt_1}{2})}{n\pi}. \tag{4.10}$$

From (4.5)–(4.10), it is easy to check that

$$\left.\frac{d\Lambda_1}{d\varepsilon}\right|_{\varepsilon=\varepsilon_{n,k}} = \left.\frac{d\Lambda_2}{d\varepsilon}\right|_{\varepsilon=\varepsilon_{n,k}} \iff \varepsilon_{n,k} = 0 \tag{4.11}$$

and

$$\left.\frac{d\Lambda_1}{d\varepsilon}\right|_{\varepsilon=0} = \left.\frac{d\Lambda_2}{d\varepsilon}\right|_{\varepsilon=0} \iff \sin\frac{nt_1}{2} = 0. \tag{4.12}$$

Proof of Corollary 1.2. Assume that t_1 is such that t_1/π is irrational. Then $\varepsilon_{n,k} \neq 0$ and $\sin\frac{nt_1}{2} \neq 0$. By (4.11) and (4.12), we have

$$\frac{d\Lambda_1}{d\varepsilon} \neq \frac{d\Lambda_2}{d\varepsilon}$$

at all $(\lambda, \varepsilon) = (\lambda_{n,k}, \varepsilon_{n,k})$ and at $((n/2)^2, 0)$. This means that all resonance pockets in this case are transversal in the (λ, ε)-plane. □

A typical combinatorics structure in this case is plotted in Figure 4.1. The characteristic values are found by solving (4.3) and (4.4) numerically. We remark that suitable ratios for sizes of resonance pockets need a careful choice of the irrational number $t_1/2\pi$ such that it is badly approximated by rational numbers. In Figure 4.1, one of the pockets in R_5 near the λ-axis is very small and is almost invisible.

Assume now that $t_1/2\pi$ is rational. There are two cases to be discussed. The first one is when $n \in \mathbb{N}$ is such that $nt_1/2\pi$ is not an integer. By Theorem 1.1, the nth resonance region R_n of (1.1) has $n-1$ resonance pockets, which are all transversal by (4.11) and (4.12). The second case is when $nt_1/2\pi = k_0$ is an integer. Then all resonance pockets inside R_n, except the two pockets

$$\left\{(\lambda, \varepsilon) : \underline{\lambda}_n(\varepsilon p) < \lambda < \overline{\lambda}_n(\varepsilon p),\ \varepsilon \in (0, \varepsilon_{n,k_0-1})\right\}$$

and

$$\left\{(\lambda, \varepsilon) : \underline{\lambda}_n(\varepsilon p) < \lambda < \overline{\lambda}_n(\varepsilon p),\ \varepsilon \in (\varepsilon_{n,k_0+1}, 0)\right\},$$

are also transversal.

In particular, for the square wave case, i.e., $c_1 = -1$, $c_2 = +1$ and $t_1 = t_2 = \pi$, we know that all pockets inside R_n are transversal if n is odd, and all pockets, except the two pockets

$$\left\{(\lambda, \varepsilon) : \underline{\lambda}_n(\varepsilon p) < \lambda < \overline{\lambda}_n(\varepsilon p),\ 0 < \varepsilon < n\right\}$$

and

$$\left\{(\lambda, \varepsilon) : \underline{\lambda}_n(\varepsilon p) < \lambda < \overline{\lambda}_n(\varepsilon p),\ -n < \varepsilon < 0\right\},$$

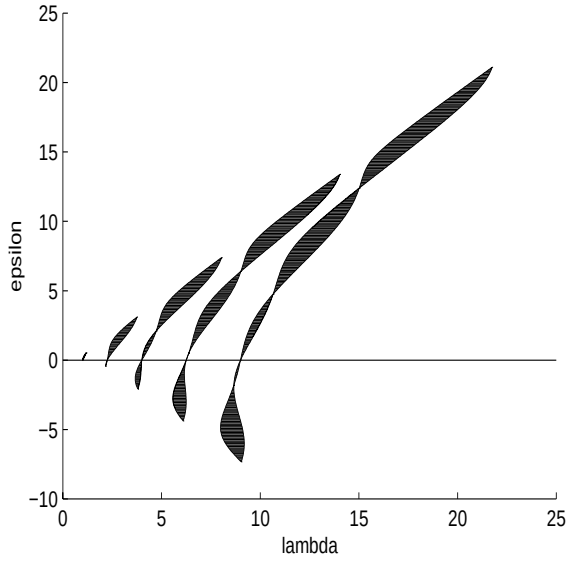

FIG. 4.1. *Resonance pockets for "generic" two-step potentials. Here* $c_1 = -1$, $c_2 = +1$, *and* $t_1 = (\sqrt{5} - 1)\pi$.

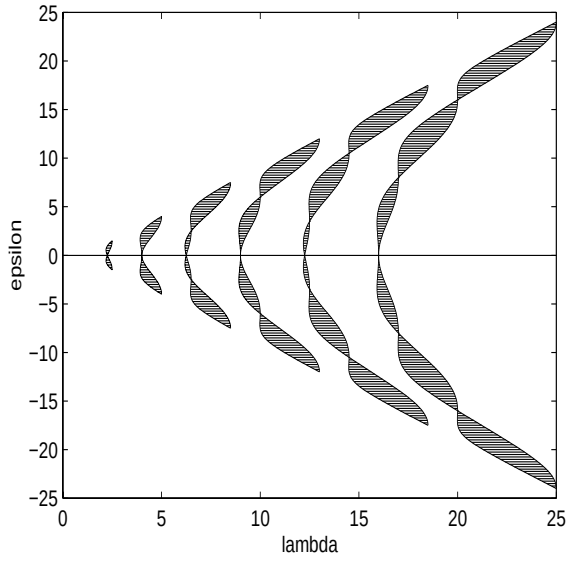

FIG. 4.2. *Resonance pockets for the square wave potential.*

are transversal when n is even. As $-\varepsilon \operatorname{sign} \cos t \equiv \varepsilon \operatorname{sign} \cos(t + \pi)$, the resonance pockets in the square wave case are symmetric with respect to the λ-axis, because characteristic values are invariant when the potentials are translated. This proves Corollary 1.3.

In Figure 4.2, the resonance pockets inside R_n, $n = 3, \ldots, 8$, of the square wave Hill's equations are plotted.

Theorem 1.1 shows that, when $p_\varepsilon(t) = \varepsilon p_{c_1,c_2,t_1}(t)$ is dependent on ε in a linear way, each resonance region of

$$\ddot{x} + (\lambda + p_\varepsilon(t))x = 0 \tag{4.13}$$

contains at most finitely many resonance pockets. However, when general families of two-step potentials

$$p_\varepsilon(t) = p_{b_1(\varepsilon),b_2(\varepsilon),t_1(\varepsilon)}(t)$$

are considered (which depend on ε in a nonlinear way), some resonance regions R_n of (4.13) may contain infinitely many resonance pockets. One example presenting infinitely many resonance pockets inside R_2 is given in [14]. In fact, one can use (3.15), (3.16), and (3.18) to give a global description to all resonance pockets inside all resonance regions R_n of (4.13).

When t_1 is such that t_1/π is irrational, it follows from Corollary 1.2 that all resonance pockets are transversal. This implies that the global structure of resonance pockets of (1.1) is preserved when $p(t)$ has certain kind of smooth perturbations.

Finally, we remark that even for step potentials, the structure of resonance pockets is not easily analyzed. It seems that our approach here is not applicable even to the case $p(t)$ is a three-step potential.

Acknowledgments. The authors thank two anonymous referees for their many suggestions which improve significantly the presentation of the present version. In fact some of their suggestions are actually reflected in the introduction. This revised version was completed when the second author was visiting the Center for Dynamical Systems and Nonlinear Studies, Georgia Institute of Technology. He would like to thank the Center and Professor Shi Jin for their support and their kind hospitality.

PARTIAL REGULARITY FOR ALMOST MINIMIZERS OF QUASI-CONVEX INTEGRALS*

FRANK DUZAAR†, ANDREAS GASTEL‡, AND JOSEPH F. GROTOWSKI†

Abstract. We consider almost minimizers of variational integrals whose integrands are quasi-convex. Under suitable growth conditions on the integrand and on the function determining the almost minimality, we establish almost everywhere regularity for almost minimizers and obtain results on the regularity of the gradient away from the singular set. We give examples of problems from the calculus of variations whose solutions can be viewed as such almost minimizers.

Key words. quasi convexity, partial regularity, almost minimizers

1. Introduction.

One of the most basic questions in the calculus of variations is that of existence and regularity of minimizers of regular functionals subject to some sort of boundary conditions. To fix ideas we consider a functional

$$\mathcal{F}(u) = \int_U f(x, u, Du)\, dx \tag{1.1}$$

for $x \in U$, a domain in $\mathbb{R}^n$, u mapping U into $\mathbb{R}^N$; then $\mathcal{F}$ is *regular* if $f(x, u, p)$ is convex in p. Appropriate growth conditions on f can be imposed to ensure that the Euler equation corresponding to $\mathcal{F}$ is elliptic, or at least degenerate elliptic; however, even under reasonable assumptions on f, in the case of systems of equations (i.e., $N>1$) one cannot, in general, expect that minimizers of $\mathcal{F}$ will be classical, i.e., C^2-solutions. This was first shown by De Giorgi [DeG]; we refer the reader to [G1, Chapter II.3] for further discussion. It is thus of interest to consider questions of partial regularity. The *regular set* of a solution u is defined by

$$\operatorname{Reg} u = \{x \in U \mid u \text{ is continuous on a neighborhood of } x\}$$

and the *singular set* by

$$\operatorname{Sing} u = U \setminus \operatorname{Reg} u.$$

Partial regularity theory involves estimating the size of $\operatorname{Sing} u$ (i.e., showing that $\operatorname{Sing} u$ has zero n-dimensional Lebesgue measure or better, controlling the Hausdorff dimension of $\operatorname{Sing} u$), and showing higher regularity on $\operatorname{Reg} u$. There is a wealth of literature covering the existence and regularity of minimizers (and, more generally, of stationary points) of regular functionals; we refer the reader to the monographs [G1], [G2], and the literature contained therein.

The condition (for $\mathcal{F}$ to be regular) that the integrand be convex in the gradient is quite restrictive. There are a number of interesting and important problems in the

calculus of variations which are not regular; in addition, weak lower semicontinuity, an essential notion for showing the existence of minimizers, is implied by convexity (in appropriate Sobolev spaces), but not vice versa. This led Morrey to introduce the notion of *quasi convexity* in the paper [M1]; we postpone giving a precise definition until section 2 and simply note here that Morrey showed that, in many circumstances, quasi convexity and weak lower semicontinuity are equivalent, and refer the reader additionally to [Da], [Ba], and [AF] for discussion, literature, and further references.

The first results on partial regularity for minimizers of general quasi-convex integrands were obtained by Evans [Ev]. He considered integrals of the form $\mathcal{F}(u) = \int_U f(Du)\,dx$ and showed, under the principle assumption of uniform strict quasi convexity (see (H2) of the current paper), that a minimizer u of such an $\mathcal{F}$ satisfies $\mathcal{L}^n(\operatorname{Sing} u) = 0$ and that Du is Hölder continuous for all exponents between 0 and 1; see [Ev, section 2] for precise statements. These results were extended independently by Fusco–Hutchinson [FH] and Giaquinta–Modica [GM] to more general functionals of the form (1.1) under assumptions comparable to our (H1)–(H4) and to an additional assumption concerning the Hölder continuity of the integrand $f(x, u, p)$ in x and u; see [FH, section 2] and [GM, Theorem 1.1]. Note in particular that in these results Du is shown to be Hölder continuous for some exponent depending on the Hölder continuity of the integrand f.

In the current paper we wish to consider a more general class of functions than minimizers, namely, *almost minimizers*. Writing $\mathcal{F}(u; D)$ for $\int_D f(x, u, Du)\,dx$, an almost minimizer (at x_0) for $\mathcal{F}$ is a function u for which

$$\mathcal{F}(u; B_\rho(x_0)) \le \mathcal{F}(u + \varphi; B_\rho(x_0)) + \omega(\rho) \int_{B_\rho(x_0)} (1 + |Du|^2 + |D\varphi|^2)dx \tag{1.2}$$

for all suitable test functions φ with $\operatorname{supp}\varphi \subset B_\rho(x_0)$; see Definition 2.1 for a precise statement. Here ω is a real-valued function. Obviously ω identically vanishing corresponds to the case of $\mathcal{F}$-minimizers, and minimal conditions on ω (continuous and nondecreasing at 0 with $\omega(0) = 0$) ensure that the term almost minimizer makes sense. In the next section we impose some additional (mild) conditions on ω and give examples that show that solutions of a number of problems in the calculus of variations (precisely, minimizers subject to certain constraints) are almost minimizers of suitable functionals; hence the notion of an almost minimizer is in fact useful.

A comparable but more restrictive definition of an almost minimizer was given by Anzellotti [An]. In that paper the author shows partial regularity for almost minimizers of the (regular) functional with integrand given by $a^{\alpha\beta}(x)D_\alpha u D_\beta u + g(x)$ for suitably regular $a^{\alpha\beta}$ and g; see [An, Theorem 1.5]. Anzellotti's definition was more restrictive in two respects; he required Hölder continuity for the function ω and required a sharper inequality than (1.2). We also mention that there is another related concept for regular integrands, namely, that of a quasi minimizer (or Q-minimizer); here the right-hand side of (1.2) is replaced by $Q\,\mathcal{F}(u + \varphi; B_\rho(x_0))$ for some constant $Q \ge 1$; see [G1, Chapter IX] for details and further references.

We also note here that there are close ties between the current setting and the study of elliptic parametric variational problems in geometric measure theory. In particular, our notion of an almost minimizer is analogous to Almgren's definition of an $(\mathbf{F}, \varepsilon, \delta)$-minimizer; see [Al, Chapter III]. Indeed our regularity result, Theorem 2.2, is the analogue of Almgren's regularity theorem [Al, Theorem III.3.7] in the current setting; of course [Al, Theorem III.3.7] is broader in scope, and the proof is considerably more involved than the proof of our regularity result. We refer the

reader to [Ev, section 1] for more comments on the connections to geometric measure theory and restrict ourselves here to noting the above-mentioned work of Almgren [Al], as well as the paper of Bombieri [Bo]. The closest analogue of the current paper in the setting of geometric measure theory is the paper [DS], where the authors prove optimal regularity results for almost minimizing rectifiable currents of general elliptic integrands.

The main regularity result of this paper is given in Theorem 2.2. We consider integrals of the form $F(u) = \int_U f(Du)\,dx$ and show, under reasonable conditions on f (the main one being uniform strict quasi convexity) and the function ω, that (F, ω)-minimizers are regular away from a set of zero-measure. In addition we obtain an optimal local modulus of continuity for Du on $\operatorname{Reg} u$. The structure of the proof and the nature of our definition of an almost minimizer enable us to extend this result to families of such integrals. This allows us to obtain, as an easy corollary, partial regularity for *minimizers* of integrals of the form $F(u) = \int_U f(x, Du)\,dx$, where f is quasi-convex, but where we only require a Dini condition (cf. [HW, section 1]) on the continuity of the coefficients in x. In particular, we do not need to assume that the coefficients are Hölder continuous with respect to x, in contrast to the results of [FH] and [GM] (of course, the results there admit u-dependency, in contrast to the current paper). Indeed, even for minimizers of regular integrals of the form $F(u) = \int_U f(x, Du)\,dx$, in the case of systems (i.e., $N > 1$) this appears to be the first time that partial regularity results have been obtained for coefficients which are not Hölder continuous (there are a number of results for scalar valued problems; we mention here specifically [HW] and the recent paper [Ko]).

We wish to briefly comment on our technique. The central idea in our proof is that of A-harmonic approximation, as expressed in Lemma 4.2. This idea, too, has its origins in the field of geometric measure theory, specifically in Simon's proof of the regularity theorem of Allard [A]; see [S1, section 23], and cf. [Bo]. The point here is to show that for $A \in \operatorname{Bil}(\operatorname{Hom}(\mathbb{R}^n, \mathbb{R}^N))$, which is rank-one elliptic, a function which is "approximately A-harmonic," i.e., a function g for which $\int_U A(Dg, D\varphi)\,dx$ is sufficiently small for all test functions φ, lies L^2-close to some A-harmonic function. Lemma 4.2 is due to Duzaar–Steffen (see [DS, Lemma 3.3]). The lemma is also vital to the paper [DG], where the authors give an elementary, self-contained approach to partial regularity for nonlinear elliptic systems of divergence type.

Many of the advantages of the approach of [DG] are relevant in the current paper. In particular we note that the arguments in both papers avoid the technical complications associated with using Gehring's lemma [Ge]; as noted above, in the current setting this is essential to obtaining the optimal modulus of continuity. Furthermore the A-harmonic approximation lemma is the only time where we argue indirectly; hence we keep some control on the sensitivity to the structure constants in our proof.

In section 2 we discuss our assumptions on the integrand f and the function ω and give a number of examples (as discussed above, these are concerned with applications of the partial regularity theorem and with showing that the notion is in fact useful; we also show how the result is optimal in a certain sense). The remainder of the paper is concerned with the proof of the regularity theorem.

We close this section by briefly summarizing the notation we use in this paper. As noted above, we consider a domain $U \subset \mathbb{R}^n$ and maps from U to $\mathbb{R}^N$, where we take $n \geq 2$, $N \geq 1$. For a given set X we denote by $\mathcal{L}^n(X)$ its n-dimensional Lebesgue measure. We write $B_\rho(x_0) = \{x \in \mathbb{R}^n : |x - x_0| < \rho\}$, and further $B_\rho = B_\rho(0)$, $B = B_1$. For bounded $X \subset \mathbb{R}^n$ we denote the average of a given $g \in L^1(X)$ by

$⨍_X g\,dx$, i.e., $⨍_X g\,dx = \frac{1}{\mathcal{L}^n(X)}\int_X g\,dx$. In particular, we write $g_{x_0,\rho} = ⨍_{B_\rho(x_0)} g\,dx$. We let α_n denote the volume of the unit ball in $\mathbb{R}^n$, i.e., $\alpha_n = \mathcal{L}^n(B)$. We write $\mathrm{Bil}(\mathrm{Hom}(\mathbb{R}^n,\mathbb{R}^N))$ for the space of bilinear forms on the space $\mathrm{Hom}(\mathbb{R}^n,\mathbb{R}^N)$ of linear maps from $\mathbb{R}^n$ to $\mathbb{R}^N$.

2. Assumptions, examples, and the partial regularity theorem. We consider a function $\omega : [0,\infty) \to [0,\infty)$, and define

$$\Omega(r) := \left(\int_0^r \frac{\sqrt{\omega(\rho)}}{\rho}\,d\rho\right)^2.$$

We impose the following conditions:

(ω0) ω is nondecreasing;

(ω1) $r \mapsto \omega(r)/r^{2\alpha}$ is nonincreasing for some $\alpha \in (0,1)$;

(ω2) $\omega(r) \le 1$ for all r; and

(ω3) $\Omega(r)$ is finite for some $r > 0$.

Note that all the arguments involving ω in this paper are local in nature; therefore (ω2) is always realizable. In addition (ω3) shows that $\Omega(r)$ is in fact finite for all positive r. Before we discuss some of the consequences of (ω0)–(ω3) we define the central concept of the paper, that of an almost minimizer.

DEFINITION 2.1. *Consider a functional $\mathcal{F}$ defined on $H^{1,2}_{loc}(U,\mathbb{R}^N)$ and $\omega : [0,\infty) \to [0,\infty)$. A function $u \in H^{1,2}_{loc}(U,\mathbb{R}^N)$ is called $(\mathcal{F},\omega)$-minimizing at $x_0 \in U$ if, for all $\rho > 0$ with $B_\rho(x_0) \subset\subset U$, there holds*

$$\mathcal{F}(u;B_\rho(x_0)) \le \mathcal{F}(u+\varphi;B_\rho(x_0)) + \omega(\rho)\int_{B_\rho(x_0)} (1+|Du|^2+|D\varphi|^2)\,dx \tag{2.1}$$

for all $\varphi \in H^{1,2}_0(B_\rho(x_0),\mathbb{R}^N)$.

A function u is $(\mathcal{F},\omega)$-minimizing if u is $(\mathcal{F},\omega)$-minimizing at each $x_0 \in U$.

We now note some less immediate consequences of the above conditions, which we will need in section 5. From (ω1) we see

$$\omega(tr) \le t^{2\alpha}\omega(r) \qquad \text{for } t \ge 1, \tag{2.2}$$

and from the definition of Ω we thus have

$$\Omega(tr) \le t^{2\alpha}\Omega(r) \qquad \text{for } t \ge 1. \tag{2.3}$$

We further have, for $0 < \tau < 1$, $r > 0$, $j \in \mathbb{N} \cup \{0\}$

$$\frac{1}{\alpha}(1-\tau^\alpha)\sqrt{\omega(\tau^j r)} = \frac{\sqrt{\omega(\tau^j r)}}{(\tau^j r)^\alpha}\int_{\tau^{j+1}r}^{\tau^j r} \rho^{\alpha-1}\,d\rho \le \int_{\tau^{j+1}r}^{\tau^j r} \frac{\sqrt{\omega(\rho)}}{\rho}\,d\rho. \tag{2.4}$$

This estimate has two useful consequences. We first note

$$\sum_{j=0}^{\infty} \sqrt{\omega(\tau^j r)} \le \frac{\alpha}{1-\tau^\alpha}\sqrt{\Omega(r)}. \tag{2.5}$$

In addition we see

$$\omega(r) \le \Omega(r) \tag{2.6}$$

for all $r > 0$. We note further that ($\omega 0$) and ($\omega 1$) imply continuity of ω at 0, as well as $\omega(0) = 0$.

We now discuss our assumptions on the functional in question. We consider functionals of the form

$$F(u) := \int_U f(Du)\, dx,$$

where U is a domain in $\mathbb{R}^n$, and $f : \mathrm{Hom}(\mathbb{R}^n, \mathbb{R}^N) \to \mathbb{R}$ satisfies the following conditions:

(H1) there exist positive constants c_1 and c_2 such that, for all $p \in \mathrm{Hom}(\mathbb{R}^n, \mathbb{R}^N)$,

$$c_1^{-1}|p|^2 - c_2 \le f(p) \le c_1|p|^2 + c_2;$$

(H2) the function f is *(uniformly) strictly quasi-convex*, i.e., there exists $\lambda > 0$ such that for all $B_\rho(x_0) \subset\subset U$, $p \in \mathrm{Hom}(\mathbb{R}^n, \mathbb{R}^N)$, $\varphi \in C_0^1(B_\rho(x_0), \mathbb{R}^N)$ there holds

$$\int_{B_\rho(x_0)} \Big(f(p + D\varphi) - f(p) \Big)\, dx \ge \lambda \int_{B_\rho(x_0)} |D\varphi|^2\, dx;$$

(H3) the function f is C^2 and there exists a nonnegative constant L such that for all $p \in \mathrm{Hom}(\mathbb{R}^n, \mathbb{R}^N)$ there holds $|D^2 f(p)| \le L$.

Note that the upper bound in (H1) follows from (H3), and the lower bound is only useful for questions of existence; cf. [M2, 4.4.7], [Ev, p. 228]. We include the condition here largely for completeness in the examples which follow.

Condition (H2) implies the *Legendre–Hadamard condition*; see [M2, 4.4.3, 4.4.1] or [Fe, 5.1.10], i.e.,

$$\sum_{i,j=1}^{N} \sum_{\alpha,\beta=1}^{n} \frac{\partial^2 f}{\partial p_\alpha^i \partial p_\beta^j}(p) \xi^i \xi^j \eta_\alpha \eta_\beta \ge \lambda |\xi|^2 |\eta|^2 \tag{2.7}$$

for all $p \in \mathrm{Hom}(\mathbb{R}^n, \mathbb{R}^N)$, $\xi \in \mathbb{R}^N$, and $\eta \in \mathbb{R}^n$.

From condition (H3) we have

$$|Df(p) - Df(\tilde{p})| \le L|p - \tilde{p}|\,; \tag{2.8}$$

this condition also implies the existence of a modulus of continuity of $D^2 f$, more precisely of a family of monotone nondecreasing, concave functions $\nu(M, \cdot) : [0, \infty) \to [0, \infty)$ for $M > 0$ satisfying $\nu(M, 0) = 0$ and

$$|D^2 f(p) - D^2 f(\tilde{p})| \le \nu(M, |p - \tilde{p}|^2) \tag{2.9}$$

for all $p, \tilde{p} \in \mathrm{Hom}(\mathbb{R}^n, \mathbb{R}^N)$ with $|p| \le M$.

For the proof of our main theorem we will initially strengthen (H3) by further imposing

(H4) $D^2 f$ is uniformly continuous.

In conjunction with (H3) this leads to the existence of a monotone nondecreasing, concave function $\nu : [0, \infty) \to [0, \infty)$ satisfying $\nu(0) = 0$ and

$$|D^2 f(p) - D^2 f(\tilde{p})| \le \nu(|p - \tilde{p}|^2) \tag{2.10}$$

for all $p, \tilde{p} \in \mathrm{Hom}(\mathbb{R}^n, \mathbb{R}^N)$. At the end of the paper (Corollary 5.3) we show how the arguments can be modified to remove (H4).

We are now in a position to state our main result.

THEOREM 2.2. *On a domain $U \subseteq \mathbb{R}^n$ consider a function ω satisfying ($\omega 0$)–($\omega 3$), and a function f which satisfies* (H2) *and* (H3). *Let F be the functional on $H^{1,2}(U,\mathbb{R}^N)$ given by $F(u) = \int_U f(Du)\,dx$. Let $u \in H^{1,2}(U,\mathbb{R}^N)$ be (F,ω)-minimizing on U. Then there exists a relatively closed subset of U,* $\operatorname{Sing} u$, *such that*

$$u \in C^1(U \setminus \operatorname{Sing} u)\,.$$

Further $\operatorname{Sing} u \subseteq \Sigma_1 \cup \Sigma_2$, *where here*

$$\Sigma_1 = \left\{ x_0 \in U \ : \ \liminf_{\rho\to 0^+} \fint_{B_\rho(x_0)} |Du - (Du)_{x_0,\rho}|^2\,dx > 0 \right\}, \quad \textit{and}$$

$$\Sigma_2 = \left\{ x_0 \in U \ : \ \sup_{\rho>0} |(Du)_{x_0,\rho}| = \infty \right\}\ ;$$

in particular $\mathcal{L}^n(\operatorname{Sing} u) = 0$.

In addition, in a neighborhood of any $x_0 \in U\setminus \operatorname{Sing} u$ and for any β with $\alpha < \beta < 1$, Du has a modulus of continuity given by

$$\mu(r) = c\left(r^\beta + \sqrt{\Omega(r)}\right)\,,$$

where c is a constant depending only on $\limsup_{\rho\to 0} |(Du)_{x_0,\rho}|$, *on β, on the dimensions n and N, on the structural parameters λ, L, and α, and on the functions $\omega(\cdot)$ and $\nu(\cdot)$.*

With a view to applications (see, in particular, Example 1 below) we are also interested in being able to consider a different functional at each point, i.e., a functional of the form

$$F_{x_0}(u) := \int_U f_{x_0}(Du)\,dx$$

for $x_0 \in U$. Given a family of such functionals, the analogues of (H2) and (H3) are

(h2) the functions f_{x_0} are *uniformly strictly quasi-convex*, i.e., there exists $\lambda > 0$ such that for all $B_\rho(x_0) \subset\subset U$, $p \in \operatorname{Hom}(\mathbb{R}^n,\mathbb{R}^N)$, $\varphi \in C_0^1(B_\rho(x_0),\mathbb{R}^n)$ there holds

$$\int_{B_\rho(x_0)} \Big(f_{x_0}(p + D\varphi) - f_{x_0}(p) \Big)\,dx \geq \lambda \int_{B_\rho(x_0)} |D\varphi|^2\,dx;$$

(h3) the functions f_{x_0} are C^2 and there exists $L \geq 0$ such that for all $p \in \operatorname{Hom}(\mathbb{R}^n,\mathbb{R}^N)$ and $x_0 \in U$ there holds $|D^2 f_{x_0}(p)| \leq L$.

Just as we imposed the additional condition (H4) to obtain a uniform modulus of continuity above, we will have occasion to require that

(h4) the second derivatives $D^2 f_{x_0}$ admit a *uniform* modulus of continuity, i.e., there exists a monotone nondecreasing, concave function $\nu : [0,\infty) \to [0,\infty)$ satisfying $\nu(0) = 0$ and

$$|D^2 f_{x_0}(p) - D^2 f_{x_0}(\tilde{p})| \leq \nu(|p - \tilde{p}|^2) \tag{2.11}$$

for all $p, \tilde{p} \in \operatorname{Hom}(\mathbb{R}^n,\mathbb{R}^N)$ and $x_0 \in U$.

We can now state the regularity result for families of functionals: the proof follows exactly the same lines as the proof of Theorem 2.2.

COROLLARY 2.3. *The conclusion also holds when* $\{F_{x_0}\}_{x_0\in U}$ *is a family of functionals arising from functions* $\{f_{x_0}\}_{x_0\in U}$ *satisfying* (h2), (h3), *and* (h4), ω *is as above, and* $u \in H^{1,2}(U,\mathbb{R}^N)$ *is* (F_{x_0},ω)*-minimizing at each* $x_0 \in U$.

We now give a few examples of almost minima and applications of the partial regularity result.

Example 1. Consider u minimizing a functional of the form

$$G(u) := \int_U g(x, Du)\,dx\,,$$

where here the frozen coefficients

$$g_{x_0}(p) := g(x_0, p)$$

satisfy (h2), (h3), and (h4), and in addition

$$|g(x,p) - g(\tilde{x},p)| \le \omega(|x-\tilde{x}|)(1+|p|^2) \tag{2.12}$$

for all $x, \tilde{x} \in U$ and all $p \in \mathrm{Hom}(\mathbb{R}^n,\mathbb{R}^N)$ for some ω satisfying (ω1)–(ω3). Writing

$$G_{x_0}(u) := \int_U g_{x_0}(Du)\,dx = \int_U g(x_0, Du)\,dx,$$

we have that u is (G_{x_0},ω)-minimizing at each $x_0 \in U$.

Example 2 (solutions of an obstacle problem). We wish to minimize $\int_U |Dv|^2\,dx$ amongst all functions $v \in H_0^{1,2}(U,\mathbb{R}^N)$ satisfying

$$v^i \ge \psi^i, \qquad (i = 1,\dots,N),$$

where the given functions ψ^i are nonpositive on ∂U and in the class $C^{1,\alpha}$. In order to see that a minimizer u is an almost minimizer of the Dirichlet integral with $\omega(\rho) = c\rho^{2\alpha}$ (for a positive constant c), we argue as follows. (Note that this example is essentially the same as [An, Example 3.2], but for completeness we repeat the arguments here.)

Fix $B_\rho(x_0) \subset\subset U$ and let $h : B_\rho(x_0) \to \mathbb{R}^N$ be the (vector-valued) harmonic function coinciding with u on $\partial B_\rho(x_0)$. Since h is harmonic (and hence minimizing), we have

$$\begin{aligned}\int_{B_\rho(x_0)} |Du|^2\,dx &= \int_{B_\rho(x_0)} |Dh|^2\,dx + \int_{B_\rho(x_0)} |D(u-h)|^2\,dx \\ &\le \int_{B_\rho(x_0)} |D(u+\varphi)|^2\,dx + \int_{B_\rho(x_0)} |D(u-h)|^2\,dx\end{aligned} \tag{2.13}$$

for all $\varphi \in H_0^{1,2}(B_\rho(x_0),\mathbb{R}^N)$. On the other hand, the harmonicity of h and the minimality of u also imply

$$\begin{aligned}&\int_{B_\rho(x_0)} D(u-h)\cdot D(u-v)\,dx = \int_{B_\rho(x_0)} Du\cdot D(u-v)\,dx \\ &= \frac{1}{2}\frac{d}{dt}\bigg|_{t=0^+}\left[\int_{B_\rho(x_0)} |Du|^2\,dx - \int_{B_\rho(x_0)} |(1-t)Du + tDv|^2\,dx\right] \le 0\end{aligned}$$

for all $v \in H^{1,2}(B_\rho(x_0), \mathbb{R}^N)$ with $v = u$ on $\partial B_\rho(x_0)$ and $v^i \geq \psi^i$. We set $v^i = h^i \vee \psi^i = \max\{h^i, \psi^i\}$ for $i = 1, \ldots, N$ and infer

$$\int_{B_\rho(x_0)} D(u-h) \cdot D(u - h \vee \psi)\, dx \leq 0;$$

hence

$$\begin{aligned}\int_{B_\rho(x_0)} |D(u-h)|^2\, dx &\leq \int_{B_\rho(x_0)} D(u-h) \cdot D(h \vee \psi - h)\, dx \\ &\leq \frac{1}{2}\int_{B_\rho(x_0)} |D(u-h)|^2\, dx + \frac{1}{2}\int_{B_\rho(x_0)} |D(h \vee \psi - h)|^2\, dx\end{aligned}$$

and therefore

$$\int_{B_\rho(x_0)} |D(u-h)|^2\, dx \leq \int_{B_\rho(x_0)} |D(h \vee \psi - h)|^2\, dx. \tag{2.14}$$

The last integral can be estimated by $c\rho^{n+2\alpha}$, as can be seen by the inequality

$$\begin{aligned}&\int_{B_\rho(x_0)} |D(h^i \vee \psi^i - h^i)|^2\, dx \\ &= \int_{B_\rho(x_0)} (D(h^i \vee \psi^i) - (D\psi^i)_{x_0,\rho}) \cdot D(h^i \vee \psi^i - h^i)\, dx \\ &\leq \int_{B_\rho(x_0)} |D(h^i \vee \psi^i) - (D\psi^i)_{x_0,\rho}|\, |D(h^i \vee \psi^i - h^i)|\, dx \\ &= \int_{\{h^i \leq \psi^i\}} |D\psi^i - (D\psi^i)_{x_0,\rho}|\, |D(\psi^i - h^i)|\, dx \\ &\leq \frac{1}{2}\int_{B_\rho(x_0)} |D\psi^i - (D\psi^i)_{x_0,\rho}|^2\, dx + \frac{1}{2}\int_{B_\rho(x_0)} |D(h^i \vee \psi^i - h^i)|^2\, dx\end{aligned}$$

for $i = 1, \ldots, N$, which implies

$$\int_{B_\rho(x_0)} |D(h \vee \psi - h)|^2\, dx \leq \int_{B_\rho(x_0)} |D\psi - (D\psi)_{x_0,\rho}|^2\, dx \leq c\rho^{n+2\alpha}. \tag{2.15}$$

Combining (2.13), (2.14), and (2.15), we have shown the asserted almost minimality of u. If we only know that the φ^i's are in $C^1(U)$, with a modulus of continuity given by

$$|D\psi(x_0) - D\psi(x)| \leq \mu(|x_0 - x|)\,,$$

the same argument can be applied to show the almost minimality for a function ω given by $\omega(s) = \mu^2(s)$.

Example 3 (almost minimizers of the Dirichlet integral; optimality). As a more general result, we have that every function $u : U \to \mathbb{R}^N$ of class $C^{1,\alpha}$ is an almost minimizer of the Dirichlet integral with $\omega(\rho) = c\rho^{2\alpha}$ for some constant $c > 0$. The proof is a simplified version of the arguments in Example 2, consisting of establishing (2.13) and the inequality

$$\int_{B_\rho(x_0)} |D(u-h)|^2\, dx \leq \int_{B_\rho(x_0)} |Du - (Du)_{x_0,\rho}|^2\, dx \leq c\alpha_n \rho^{n+2\alpha}, \tag{2.16}$$

which is proved exactly like (2.15).

Note in particular that this example shows that our regularity theorem is optimal in the case of Hölder-continuous moduli of continuity. We can in fact show the same for an arbitrary ω satisfying conditions (ω0)-(ω3).

We begin by noting for an arbitrary $u \in C^1(B_\rho(x_0), \mathbb{R}^N)$ that we can combine (2.13) and (2.16) to see

$$\int_{B_\rho(x_0)} |Du|^2\,dx \le \int_{B_\rho(x_0)} |D(u+\varphi)|^2\,dx + \int_{B_\rho(x_0)} |Du - (Du)_{x_0,\rho}|^2\,dx. \tag{2.17}$$

In order to construct our example, we first consider $v : \mathbb{R} \to \mathbb{R}$ given by

$$v(s) = \int_0^s \sqrt{\Omega}(|t|)\,dt\,.$$

We calculate

$$\begin{aligned} \frac{1}{2}\int_{-\rho}^{\rho} |v'(s) - v'_{0,\rho}|^2\,ds &= \int_0^\rho \left|\sqrt{\Omega}(s) - \fint_0^\rho \sqrt{\Omega}(r)\,dr\right|^2 ds \\ &= \int_0^\rho [\sqrt{\Omega}(s)]^2\,ds + \frac{1}{\rho}\left(\int_0^\rho \sqrt{\Omega}(s)\,ds\right)^2 - \frac{2}{\rho}\left(\int_0^\rho \sqrt{\Omega}(s)\,ds\right)^2 \\ &= \int_0^\rho \Omega(s)\,ds - \frac{1}{\rho}\left(\int_0^\rho \sqrt{\Omega}(s)\,ds\right)^2. \end{aligned} \tag{2.18}$$

Since $\sqrt{\omega}(r) = r(\sqrt{\Omega})'(r)$, ($\omega$0) can be expressed as $r(\sqrt{\Omega})'(r) \le s(\sqrt{\Omega})'(s)$ for $r \le s$. Using this in (2.18), we see

$$\begin{aligned} \frac{1}{2}\frac{d}{d\rho}\int_{-\rho}^{\rho} |v'(s) - v'_{0,\rho}|^2\,ds &= \Omega(\rho) + \left(\fint_0^\rho \sqrt{\Omega}(s)\,ds\right)^2 - 2\sqrt{\Omega}(\rho)\fint_0^\rho \sqrt{\Omega}(s)\,ds \\ &= \left(\sqrt{\Omega}(\rho) - \fint_0^\rho \sqrt{\Omega}(s)\,ds\right)^2 \\ &= \left(\fint_0^\rho \left(\int_s^\rho (\sqrt{\Omega})'(t)\,dt\right)\,ds\right)^2 \\ &\le \left(\fint_0^\rho \left(\int_s^\rho \frac{\rho}{t}(\sqrt{\Omega})'(\rho)\,dt\right)\,ds\right)^2 \\ &= \left(\int_0^\rho (\log\rho - \log s)\,ds\right)^2 [(\sqrt{\Omega})'(\rho)]^2 \\ &= \rho^2[(\sqrt{\Omega})'(\rho)]^2 \\ &= \omega(\rho). \end{aligned} \tag{2.19}$$

Integrating this expression, we see

$$\frac{1}{2}\int_{-\rho}^{\rho} |v'(s) - v'_{0,\rho}|^2\,ds \le \int_0^\rho \omega(s)\,ds \le \rho\omega(\rho). \tag{2.20}$$

Consider now a real-valued function u defined on B, the unit ball in $\mathbb{R}^n$, given by

$$u(x) = \int_0^{x_1} \sqrt{\Omega}(|t|)\,dt.$$

In view of ($\omega 3$) we see that $u \in C^1(B)$, and the modulus of continuity of Du is given by $\sqrt{\Omega}$. We consider an arbitrary ball $B_\rho(x_0) \in B$; due to the symmetry of u with respect to x^1, it suffices to consider x_0 with $x_0^1 \geq 0$. We first consider the case that $x_0^1 < 2\rho$. We have, using (2.20) and (2.2),

$$
\begin{aligned}
(2.21) \qquad \int_{B_\rho(x_0)} |Du - (Du)_{x_0,\rho}|^2 \, dx &\leq \alpha_{n-1}\rho^{n-1} \int_{x_0^1-\rho}^{x_0^1+\rho} |v'(s) - v'_{x_0^1,\rho}|^2 \, ds \\
&\leq \alpha_{n-1}\rho^{n-1} \int_{x_0^1-\rho}^{x_0^1+\rho} |v'(s) - v'_{0,x_0^1+\rho}|^2 \, ds \\
&\leq \alpha_{n-1}\rho^{n-1} \int_{-x_0^1-\rho}^{x_0^1+\rho} |v'(s) - v'_{0,x_0^1+\rho}|^2 \, ds \\
&\leq 2\alpha_{n-1}\rho^{n-1}(x_0^1+\rho)\omega(x_0^1+\rho) \\
&\leq 2 \cdot 3^{1+2\alpha}\alpha_{n-1}\rho^n\omega(\rho) \, .
\end{aligned}
$$

For $x_0^1 \geq 2\rho$ we begin by noting that $\sqrt{\Omega}$ is monotone nondecreasing on the interval $(x_0^1 - \rho, x_0^1 + \rho)$. Keeping this in mind, and using ($\omega 1$) twice, we have

$$
\begin{aligned}
\int_{x_0^1-\rho}^{x_0^1+\rho} |v'(s) - v'_{x_0^1,\rho}|^2 \, ds &= \int_{x_0^1-\rho}^{x_0^1+\rho} \left| \sqrt{\Omega}(s) - (\sqrt{\Omega})_{x_0^1,\rho} \right|^2 \, ds \\
&\leq \int_{x_0^1-\rho}^{x_0^1+\rho} \left| \sqrt{\Omega}(s) - \sqrt{\Omega}(x_0^1-\rho) \right|^2 \, ds \\
&\leq \int_{x_0^1-\rho}^{x_0^1+\rho} \left[\int_{x_0^1-\rho}^{s} \frac{\sqrt{\omega}(\sigma)}{\sigma} \, d\sigma \right]^2 \, ds \\
&\leq \frac{\omega(x_0^1-\rho)}{(x_0^1-\rho)^{2\alpha}} \int_{x_0^1-\rho}^{x_0^1+\rho} \left[\int_{x_0^1-\rho}^{s} \frac{d\sigma}{\sigma^{1-\alpha}} \right]^2 \, ds \\
&\leq \frac{\omega(\rho)}{\alpha^2\rho^{2\alpha}} \int_{x_0^1-\rho}^{x_0^1+\rho} [s^\alpha - (x_0^1-\rho)^\alpha]^2 \, ds \\
&\leq \frac{2\rho\omega(\rho)}{\alpha^2\rho^{2\alpha}} [(x_0^1+\rho)^\alpha - (x_0^1-\rho)^\alpha]^2 \\
&\leq 2(3^\alpha - 1)^2\alpha^{-2}\rho\omega(\rho) \, .
\end{aligned}
$$

Hence we have

$$
\begin{aligned}
(2.22) \qquad \int_{B_\rho(x_0)} |Du - (Du)_{x_0,\rho}|^2 \, dx &\leq \alpha_{n-1}\rho^{n-1} \int_{x_0^1-\rho}^{x_0^1+\rho} |v'(s) - v'_{x_0^1,\rho}|^2 \, ds \\
&\leq 2(3^\alpha - 1)^2\alpha^{-2}\alpha_{n-1}\rho^n\omega(\rho) \, .
\end{aligned}
$$

In view of (2.17), the estimates (2.21) and (2.22) show that u is an ω-almost minimizer for the Dirichlet integral on the unit ball B.

Example 4 (volume-constrained minimizers). For a fixed $v_0 \in H^{1,2}(U, \mathbb{R}^N)$ we define $\mathcal{H}_{v_0}$ to be the set of functions v in $H^{1,2}(U, \mathbb{R}^N)$ such that $v = v_0$ on ∂U and $\int_U v \, dx = \int_U v_0 \, dx$. We then consider $u \in \mathcal{H}_{v_0}$ such that

$$
(2.23) \qquad \int_U |Du|^2 \, dx \leq \int_U |Dv|^2 \, dx
$$

for all $v \in \mathcal{H}_{v_0}$; that is, the function u minimizes the Dirichlet integral amongst all functions satisfying a given (vector-valued, signed) *volume constraint*. We will show here that u is an almost minimizer for the Dirichlet integral, for a function $\omega(r) = Cr$ for a suitable constant C. This example was also given by Anzellotti [An, Example 3.2]. In the current situation, due to our more general definition of an almost minimizer (see the comments in the introduction) the calculations are somewhat easier; in particular, in contrast to the result of Anzellotti, the constrained minimizer is an almost minimizer for the same functional. Having said that, we should also state that our calculations are similar to those in [An].

We wish to show for all $x_0 \in U$

$$\int_{B_\rho(x_0)} |Du|^2\,dx \le \int_{B_\rho(x_0)} |D(u+\varphi)|^2 dx + C\rho \int_{B_\rho(x_0)} (1 + |Du|^2 + |D\varphi|^2)\,dx \tag{2.24}$$

for all test functions $\varphi \in H_0^{1,2}(B_\rho(x_0), \mathbb{R}^N)$, for all ρ with $B_\rho(x_0) \subset\subset U$. Define $R_0 = \sup_{x\in U}\{\sup\{r \,|\, B_r(x) \subset\subset U\}\}$, and set $\rho_0 = \rho_0(x_0) = \min\{R_0/4, \operatorname{dist}(x_0, \partial U), 1\}$. Obviously it suffices to establish (2.24) for all ρ with $0 < \rho \le \rho_0$. Let ψ be a fixed function in $H_0^{1,2}(B_{R_0/4}, \mathbb{R}^N)$ with $\int_{B_{R_0/4}} \psi^i \ne 0, i = 1, \dots, N$. We fix $y_0 \in U$ such that $B' = B_{R_0/4}(y_0) \subset U$ and $B' \cap B_\rho(x_0) = \emptyset$. Define $\eta \in H_0^{1,2}(B', \mathbb{R}^N)$ by $\eta(x) = \psi(x - y_0)$.

For a given test function $\varphi \in H_0^{1,2}(B_\rho(x_0), \mathbb{R}^N)$, for $i = 1, \dots, N$ we define $t_i \in \mathbb{R}$ by

$$t_i = \frac{-\int_{B_\rho(x_0)} \varphi^i\,dx}{\int_{B'} \eta^i\,dx} = \frac{-\int_{B_\rho(x_0)} \varphi^i\,dx}{\int_{B_{R_0/4}} \psi^i\,dx}\,. \tag{2.25}$$

Poincaré's inequality yields the estimate

$$|t_i| \le c_3 \rho^{\frac{n}{2}+1} \left(\int_{B_\rho(x_0)} |D\varphi^i|^2\,dx \right)^{1/2} \tag{2.26}$$

for a constant c_3 depending only on n, U, and the fixed function ψ.

We next define a function w via

$$w^i(x) = \begin{cases} u^i(x) + \varphi^i(x), & x \in B_\rho(x_0), \\ u^i(x) + t_i \eta^i(x), & x \in B', \\ u^i(x), & x \in U \setminus (B_\rho(x_0) \cup B') \end{cases}$$

for $i = 1, \dots, N$. We see immediately that $w \in H^{1,2}(U, \mathbb{R}^N)$ and that $w\big|_{\partial U} = u\big|_{\partial U} = v_0\big|_{\partial U}$. From (2.25) we also have that $\int_U w\,dx = \int_U u\,dx$, meaning that $w \in \mathcal{H}_{v_0}$. We thus have from (2.23)

$$\int_{B_\rho(x_0)} |Du|^2\,dx \le \int_{B_\rho(x_0)} |D(u+\varphi)|^2\,dx + \int_{B'} |Du + tD\eta|^2\,dx - \int_{B'} |Du|^2\,dx\,, \tag{2.27}$$

where $tD\eta$ denotes $\{t_i D_\alpha \eta^i\}_{i=1,\dots,N}^{\alpha=1,\dots,n}$. We then estimate

$$\int_{B'} |Du + tD\eta|^2\,dx - \int_{B'} |Du|^2\,dx \le 2\Big|\sum_{i=1}^N \int_{B'} Du^i \cdot D\eta^i\,dx\,\Big| + \sum_{i=1}^N t_i^2 \int_{B'} |D\eta^i|^2\,dx\,.$$

Using (2.26), we see that the second term on the right can be bounded above by $c_4\rho^{n+2}\int_{B_\rho(x_0)} |D\varphi|^2\,dx$ for c_4 depending only on n, U, and ψ. We further have, after applying the Cauchy–Schwarz and then Young inequalities, and taking into account (2.23),

$$\begin{aligned}
2\left|\sum_{i=1}^N t_i \int_{B'} Du^i \cdot D\eta^i\,dx\right| &\le 2\left(\int_U |Du|^2\,dx\right)^{1/2}\left(\sum_{i=1}^N t_i^2 \int_{B'} |D\eta^i|^2\,dx\right)^{1/2}\\
&\le 2\left(\int_U |Dv_0|^2\,dx\right)^{1/2}\left(c_4\rho^{n+2}\int_{B_\rho(x_0)} |D\varphi|^2\,dx\right)^{1/2}\\
&\le c_5\left(\rho^{n+1} + \rho\int_{B_\rho(x_0)} |D\varphi|^2\,dx\right)
\end{aligned}$$

for $c_5 = c_4 + \int_U |Dv_0|^2\,dx$.

Combining these estimates in (2.27), we have (noting that $c_5 \ge c_4$, $\rho \le 1$)

$$\begin{aligned}
\int_{B_\rho(x_0)} |Du|^2\,dx &\le \int_{B_\rho(x_0)} |D(u+\varphi)|^2\,dx + c_5\rho^{n+1} + (c_5\rho + c_4\rho^{n+2})\int_{B_\rho(x_0)} |D\varphi|^2\,dx\\
&\le \int_{B_\rho(x_0)} |D(u+\varphi)|^2\,dx + 2c_5\rho\left(1 + \int_{B_\rho(x_0)} |D\varphi|^2\,dx\right),
\end{aligned}$$

which is the desired estimate.

We also note (again, cf. [An, section 3]) that the same arguments hold for functionals of the form $\int_U A^{\alpha\beta}(x) D_\alpha u D_\beta u\,dx$, under suitable assumptions on the functions $\{A^{\alpha\beta}\}$.

Finally, it should be mentioned here that comparable examples exist in the setting of geometric measure theory; see, e.g., [Al], [Ta], and [DS].

3. The Caccioppoli inequality. We begin by stating an elementary technical lemma from Fusco–Hutchinson, [FH, Lemma 3.2] (cf. [G1, Chapter V, Lemma 3.1]); for completeness we include the result here.

LEMMA 3.1. *Let h be nonnegative and bounded on $[\rho/2, \rho]$, and satisfy*

$$h(t) \le \theta h(s) + A(s-t)^{-2} + B$$

for positive constants A, B, and θ with $0 < \theta < 1$, for all s and t with $\rho/2 \le s < t < \rho$. Then there exists a constant c depending only on θ such that

$$h(\rho/2) \le c(A\rho^{-2} + B)\,.$$

We now prove a suitable version of the Caccioppoli inequality. The proof is close to that of [Ev, Lemma 5.1] and [GM, Proposition 4.1].

LEMMA 3.2. *Let f satisfy* (H2) *and* (H3), *and ω satisfy* (ω0), (ω1), *and* (ω2). *Let F be the functional on $H^{1,2}(U, \mathbb{R}^N)$ given by $F(u) = \int_U f(Du)\,dx$. Then there*

exist positive constants $\rho_1 = \rho_1(\lambda, \omega(\cdot))$ and $c_6 = c_6(\lambda, L)$ (without loss of generality we take $c_6 \geq 1$) such that for every $B_\rho(x_0) \subset\subset U$ with $\rho \leq \rho_1$, $p_0 \in \mathrm{Hom}(\mathbb{R}^n, \mathbb{R}^N)$ and every $u \in H^{1,2}(B_\rho(x_0), \mathbb{R}^N)$ which is (F, ω)-minimizing at x_0 there holds

$$\begin{aligned}(3.1)\qquad &\int_{B_{\rho/2}(x_0)} |Du - p_0|^2\, dx \\ &\leq c_6 \left[\rho^{-2} \int_{B_\rho(x_0)} |u - p_0(x - x_0)|^2\, dx + \alpha_n \omega(\rho) \rho^n (1 + |p_0|^2)\right].\end{aligned}$$

Proof. For $\frac{\rho}{2} \leq t < s \leq \rho$ choose $\eta \in C_0^\infty(B_\rho(x_0), [0,1])$, $\eta \equiv 1$ on $B_t(x_0)$, $\eta \equiv 0$ outside $B_s(x_0)$, and $|\nabla \eta| \leq 2/(s-t)$. We set

$$\begin{aligned}\varphi &:= \eta(u - p_0(x - x_0)), \\ \psi &:= (1 - \eta)(u - p_0(x - x_0)).\end{aligned}$$

Then

$$(3.2)\qquad D\varphi + D\psi = Du - p_0$$

and, with $v(x) := u(x) - p_0(x - x_0)$,

$$(3.3)\qquad |D\varphi|^2 \leq 2|Du - p_0|^2 + \frac{8}{(s-t)^2}|v|^2,$$

$$(3.4)\qquad |D\psi|^2 \leq 2|Du - p_0|^2 + \frac{8}{(s-t)^2}|v|^2.$$

From (H2) and (3.2) we have

$$(3.5)\qquad \lambda \int_{B_s(x_0)} |D\varphi|^2\, dx \leq \int_{B_s(x_0)} [f(p_0 + D\varphi) - f(p_0)]\, dx = I + II + III\,,$$

where

$$\begin{aligned}I &= \int_{B_s(x_0)} [f(Du - D\psi) - f(Du)]\, dx\,, \\ II &= \int_{B_s(x_0)} [f(Du) - f(Du - D\varphi)]\, dx, \qquad \text{and} \\ III &= \int_{B_s(x_0)} [f(p_0 + D\psi) - f(p_0)]\, dx\,.\end{aligned}$$

The (F, ω)-minimality and (3.3), along with $(\omega 2)$, imply

$$\begin{aligned}(3.6)\qquad II &\leq \omega(s) \int_{B_s(x_0)} \left(1 + |Du|^2 + |D\varphi|^2\right) dx \\ &\leq \omega(s) \int_{B_s(x_0)} \left(1 + 2|p_0|^2 + 4|Du - p_0|^2 + \frac{8}{(s-t)^2}|v|^2\right) dx \\ &\leq \frac{\lambda}{2} \int_{B_s(x_0)} |Du - p_0|^2\, dx + \frac{8}{(s-t)^2} \int_{B_s(x_0)} |v|^2\, dx \\ &\quad + 2\alpha_n \omega(\rho) \rho^n (1 + |p_0|^2),\end{aligned}$$

as long as ρ is sufficiently small that $8\omega(\rho) \le \lambda$; by $(\omega 0)$ and $(\omega 1)$ we can choose $\rho_1 > 0$ such that this holds for all $\rho \in (0, \rho_1]$. For the other terms we have (via (2.8) and (3.2), as well as (3.4))

$$
\begin{aligned}
I + III &\le L \int_{B_s(x_0)} \Big(|Du - p_0| + |D\psi|\Big)|D\psi|\, dx \\
&= L \int_{B_s(x_0)\setminus B_t(x_0)} \Big(|Du - p_0| + |D\psi|\Big)|D\psi|\, dx \\
&\le \frac{L}{2} \int_{B_s(x_0)\setminus B_t(x_0)} |Du - p_0|^2\, dx + \frac{3L}{2} \int_{B_s(x_0)\setminus B_t(x_0)} |D\psi|^2\, dx \\
&\le \frac{7L}{2} \int_{B_s(x_0)\setminus B_t(x_0)} |Du - p_0|^2\, dx + \frac{12L}{(s-t)^2} \int_{B_s(x_0)} |v|^2\, dx.
\end{aligned} \tag{3.7}
$$

Combining (3.6) and (3.7) in (3.5) and noting $D\varphi = Du - p_0$ on $B_t(x_0)$ we see

$$
\begin{aligned}
\frac{\lambda}{2} \int_{B_t(x_0)} |Du - p_0|^2\, dx &\le \frac{7L + \lambda}{2} \int_{B_s(x_0)\setminus B_t(x_0)} |Du - p_0|^2\, dx \\
&+ \frac{12L + 8}{(s-t)^2} \int_{B_s(x_0)} |v|^2\, dx + 2\alpha_n \omega(\rho) \rho^n (1 + |p_0|^2).
\end{aligned} \tag{3.8}
$$

Thus we have

$$
\begin{aligned}
\int_{B_t(x_0)} |Du - p_0|^2\, dx &\le \frac{7L + \lambda}{7L + 2\lambda} \int_{B_s(x_0)} |Du - p_0|^2\, dx \\
&+ \frac{24L + 16}{7L(s-t)^2} \int_{B_s(x_0)} |v|^2\, dx + \frac{4}{7L} \alpha_n \omega(\rho) \rho^n (1 + |p_0|^2).
\end{aligned} \tag{3.9}
$$

Since $\frac{7L+\lambda}{7L+2\lambda} < 1$ we can apply Lemma 3.1 to conclude (3.1). ∎

4. Approximate A-harmonicity and A-harmonic approximation. The next lemma is a prerequisite for applying the A-harmonic approximation technique.

LEMMA 4.1. *Let ω satisfy $(\omega 2)$, and f satisfy* (H2), (H3), *and* (H4). *Let F be the functional on $H^{1,2}(U, \mathbb{R}^N)$ given by $F(u) = \int_U f(Du)\, dx$. Then there exists $c_7 = c_7(n, L)$ such that for every $u \in H^{1,2}(U, \mathbb{R}^N)$ that is (F, ω)-minimizing at x_0, every ball $B_\rho(x_0) \subset\subset U$, and every $p_0 \in \mathrm{Hom}(\mathbb{R}^n, \mathbb{R}^N)$ we have*

$$
\begin{aligned}
&\left| \rho^{-n} \int_{B_\rho(x_0)} D^2 f(p_0)(Du - p_0, D\varphi)\, dx \right| \\
&\le c_7 \Big[\omega^{1/2}(\rho)(1 + \Phi + |p_0|^2) + \nu^{1/2}(\Phi)\Phi^{1/2} \Big] \sup_{B_\rho(x_0)} |D\varphi|
\end{aligned} \tag{4.1}
$$

for all $\varphi \in C_0^1(B_\rho(x_0), \mathbb{R}^N)$. Here we write

$$
\Phi = \Phi(x_0, \rho, p_0) := \fint_{B_\rho(x_0)} |Du - p_0|^2\, dx. \tag{4.2}
$$

Proof. Without loss of generality we take $x_0 = 0$. We first note

$$
\begin{aligned}
\int_{B_\rho} Df(Du) \cdot D\varphi\, dx &= \int_{B_\rho} Df(Du) \cdot D\varphi\, dx - \int_{B_\rho} Df(p_0) \cdot D\varphi\, dx \\
&= \int_{B_\rho} \int_0^1 D^2 f(p_0 + \tau(Du - p_0))\, (Du - p_0, D\varphi) d\tau dx.
\end{aligned} \tag{4.3}
$$

Initially we assume $|D\varphi| \le 1$ on B_ρ. For positive s we have from the (F,ω)-minimality of u

$$
\begin{aligned}
(4.4)\quad & \int_{B_\rho} D^2 f(p_0)(Du - p_0, D\varphi)\,dx \\
&\ge \frac{1}{s}\left[\int_{B_\rho} (f(Du) - f(Du + sD\varphi))\,dx - \omega(\rho)\int_{B_\rho}\left(1 + |Du|^2 + s^2|D\varphi|^2\right)dx\right] \\
&\qquad + \int_{B_\rho} D^2 f(p_0)(Du - p_0, D\varphi)\,dx \\
&\ge \frac{1}{s}\left[-\int_{B_\rho}\int_0^s \frac{d}{dt} f(Du + tD\varphi)\,dt\,dx + s\int_{B_\rho} D^2 f(p_0)(Du - p_0, D\varphi)\,dx\right. \\
&\qquad \left. - \omega(\rho)\int_{B_\rho}\left(1 + s^2 + |Du|^2\right)dx\right] \qquad \text{since } |D\varphi| \le 1 \\
&= \frac{1}{s}\left[\int_{B_\rho}\int_0^s \Big(Df(Du) - Df(Du + tD\varphi)\Big)\cdot D\varphi\,dt\,dx\right. \\
&\qquad + s\int_{B_\rho}\int_0^1 \Big(D^2 f(p_0) - D^2 f(p_0 + \tau(Du - p_0))\Big)\,d\tau(Du - p_0, D\varphi)\,dx \\
&\qquad \left. - \omega(\rho)\int_{B_\rho}\left(1 + s^2 + |Du|^2\right)dx\right] \qquad \text{via (4.3)} \\
&\ge -\frac{1}{s}\left[\frac{L}{2}s^2\alpha_n\rho^n + s\sqrt{2L}\int_{B_\rho}\nu^{1/2}(|Du - p_0|^2)|Du - p_0|\,dx\right. \\
&\qquad \left. + \omega(\rho)\int_{B_\rho}\left(1 + s^2 + |Du|^2\right)dx\right] \qquad \text{via (2.8), (2.10), (H3)} \\
&\ge -\frac{L}{2}s\alpha_n\rho^n\,dx - \sqrt{2L}\,\alpha_n\rho^n\nu^{1/2}\left(\fint_{B_\rho}|Du - p_0|^2\,dx\right)\left(\fint_{B_\rho}|Du - p_0|^2\,dx\right)^{1/2} \\
&\qquad - \frac{\omega(\rho)}{s}\int_{B_\rho}\left(1 + s^2 + 2|Du - p_0|^2 + 2|p_0|^2\right)dx \\
&\ge -\alpha_n\rho^n\left[\frac{L}{2}s + \sqrt{2L}\,\nu^{1/2}(\Phi)\Phi^{1/2} + \frac{2\omega(\rho)}{s}(1 + s^2 + \Phi + |p_0|^2)\right];
\end{aligned}
$$

we have used the Jensen and Hölder inequalities to obtain the second to last inequality. Completely analogously we see

$$
\begin{aligned}
(4.5)\quad & \int_{B_\rho} D^2 f(p_0)(Du - p_0, D\varphi)\,dx \\
&\qquad \le \alpha_n\rho^n\left[\frac{L}{2}s + \sqrt{2L}\,\nu^{1/2}(\Phi)\Phi^{1/2} + \frac{2\omega(\rho)}{s}(1 + s^2 + \Phi + |p_0|^2)\right].
\end{aligned}
$$

By choosing $s := \omega^{1/2}(\rho)$ and using $(\omega 2)$ we have the desired conclusion for φ such that $|D\varphi| \le 1$ with $c_7 = \alpha_n(4 + L)$. By a simple scaling argument this yields the result for general φ. □

We close this section by giving a result which is central to our technique, the A-harmonic approximation lemma. The lemma was first proven in [DS, Lemma 3.3];

cf. [S2, section 1.6] for the case $A = id$ (i.e., the harmonic approximation lemma); for completeness, we quote it here.

LEMMA 4.2. *Consider fixed positive λ and L, and n, $N \in \mathbb{N}$ with $n \geq 2$. Then for any given $\varepsilon > 0$ there exists $\delta = \delta(n, N, \lambda, L, \varepsilon) \in (0, 1]$ with the following property: if $A \in \mathrm{Bil}(\mathrm{Hom}(\mathbb{R}^n, \mathbb{R}^N))$ is rank-one elliptic with ellipticity constant $\lambda > 0$ and upper bound L, then for any $u \in H^{1,2}(B_\rho(x_0), \mathbb{R}^N)$ (for some $\rho > 0$, $x_0 \in \mathbb{R}^n$) satisfying*

$$\rho^{-n} \int_{B_\rho(x_0)} |Du|^2 \, dx \leq 1, \qquad \text{and}$$

$$\left| \rho^{-n} \int_{B_\rho(x_0)} A(Du, D\varphi) \, dx \right| \leq \delta(n, N, \lambda, L, \varepsilon) \sup |D\varphi|$$

for all $\varphi \in C_0^1(B_\rho(x_0), \mathbb{R}^N)$, there exists an A-harmonic function $h \in H^{1,2}(B_\rho(x_0), \mathbb{R}^N)$ such that

$$\rho^{-n} \int_{B_\rho} |Dh|^2 \, dx \leq 1 \qquad \text{and} \quad \rho^{-n-2} \int_{B_\rho} |h - u|^2 \, dx \leq \varepsilon.$$

Here h is called *A-harmonic* if

$$\int_{B_\rho} A(Dh, D\varphi) \, dx = 0$$

for all $\varphi \in C_0^\infty(B_\rho(x_0), \mathbb{R}^N)$.

5. Proof of the main theorem. To prove the result we follow the general lines of [DG, section 3]. We first establish appropriate smallness conditions sufficient to deduce growth estimates on Φ.

PROPOSITION 5.1. *Consider u satisfying the conditions of Theorem 2.2, and β fixed, $\alpha < \beta < 1$. We write $\Phi(x_0, r)$ for $\Phi(x_0, r, (Du)_{x_0,r})$. Then we can find positive constants c_8, c_9, and δ, and $\theta \in (0, 1)$ (with c_8 depending only on n, N, λ, and L, and with c_9, θ, and δ depending only on these quantities as well as β) such that the smallness conditions $\rho \leq \rho_1$,*

$$\nu(\Phi(x_0, \rho)) + \Phi(x_0, \rho) \leq \delta^2/2\,, \tag{5.1}$$

and

$$c_8 \omega(\rho)(1 + |(Du)_{x_0,\rho}|^4) \leq \delta^2 \tag{5.2}$$

together imply the growth condition

$$\Phi(x_0, \theta\rho) \leq \theta^{2\beta} \Phi(x_0, \rho) + c_9 \omega(\rho)(1 + |(Du)_{x_0,\rho}|^4). \tag{5.3}$$

Here ρ_1 depending on λ and $\omega(\cdot)$ is given in Lemma 3.2.

Proof. From Lemma 4.1 we have (with $c_{10} := 1 + \sqrt{2} c_7$)

$$\begin{aligned} \left| \rho^{-n} \int_{B_\rho(x_0)} D^2 f(p_0)(Du - p_0, D\varphi) \, dx \right| &\leq c_{10} \Big[\Phi(x_0, \rho, p_0) \\ &+ \nu^{1/2}(\Phi(x_0, \rho, p_0)) \Phi^{1/2}(x_0, \rho, p_0) + (\omega(\rho)/2)^{1/2}(1 + |p_0|^2) \Big] \sup_{B_\rho(x_0)} |D\varphi|. \end{aligned} \tag{5.4}$$

We set

$$w = \frac{u - p_0(x - x_0)}{2c_{10}\sqrt{\Phi(x_0, \rho, p_0) + \delta^{-2}\omega(\rho)(1 + |p_0|^2)^2}} \tag{5.5}$$

and deduce from (5.4) that for all $\varphi \in C_c^\infty(B_\rho(x_0), \mathbb{R}^n)$ there holds

$$\begin{aligned} &\left|\rho^{-n}\int_{B_\rho(x_0)} D^2 f(p_0)(Dw, D\varphi)\,dx\right| \\ &\le \tfrac{1}{2}\Big[\Phi^{1/2}(x_0, \rho, p_0) + \nu^{1/2}(\Phi(x_0, \rho, p_0)) + \delta/\sqrt{2}\Big] \sup_{B_\rho(x_0)} |D\varphi| \\ &\le \Big[\nu(\Phi(x_0, \rho, p_0)) + \Phi(x_0, \rho, p_0) + \delta^2/2\Big]^{1/2} \sup_{B_\rho(x_0)} |D\varphi| \end{aligned} \tag{5.6}$$

and (since $c_{10} \ge \max\{\alpha_n, 1\}$),

$$\rho^{-n}\int_{B_\rho(x_0)} |Dw|^2\,dx \le \frac{\alpha_n}{4c_{10}^2} \le 1. \tag{5.7}$$

We further set

$$A(\xi, \eta) := D^2 f(p_0)(\xi, \eta). \tag{5.8}$$

From (2.7) we see that the bilinear form A satisfies the conditions of Lemma 4.2. For positive ε to be determined later, we denote by $\delta = \delta(n, N, \lambda, L, \varepsilon) \in (0, 1]$ the corresponding constant from Lemma 4.2; via this lemma the *smallness condition*

$$\nu(\Phi(x_0, \rho, p_0)) + \Phi(x_0, \rho, p_0) \le \delta^2/2 \tag{5.9}$$

guarantees the existence of an A-harmonic $h \in H^{1,2}(B_\rho(x_0), \mathbb{R}^N)$ satisfying

$$\rho^{-n}\int_{B_\rho(x_0)} |Dh|^2\,dx \le 1 \qquad \text{and} \tag{5.10}$$

$$\rho^{-n-2}\int_{B_\rho(x_0)} |w - h|^2\,dx \le \varepsilon. \tag{5.11}$$

We also note that h satisfies the estimate

$$\rho^{-2}\sup_{B_{\rho/2}(x_0)} |Dh|^2 + \sup_{B_{\rho/2}(x_0)} |D^2 h|^2 \le c_{11}\rho^{-n-2}\int_{B_\rho(x_0)} |Dh|^2 dx \le \frac{c_{11}}{\rho^2}\,, \tag{5.12}$$

with $c_{11} = c_{11}(n, N, \lambda, L)$ (without loss of generality we take $c_{11} \ge 1$). For elliptic A the first inequality follows from a standard argument due to Campanato (see [Ca, Teorema 9.2]) combined with the Sobolev and Poincaré inequalities; the same arguments are valid in the current setting because the Legendre–Hadamard condition is satisfied; cf. [Ev, p. 236]. The second inequality follows from (5.10). For $\theta \in (0, 1/4]$ we can thus apply Taylor's theorem to h at x_0 to deduce

$$\sup_{x \in B_{2\theta\rho}(x_0)} |h(x) - h(x_0) - Dh(x_0)(x - x_0)|^2 \le \frac{c_{11}}{\rho^2}(2\theta\rho)^4 = 16c_{11}\theta^4\rho^2.$$

Thus we have, using also (5.11),

$$(2\theta\rho)^{-n-2}\int_{B_{2\theta\rho}(x_0)}|w-h(x_0)-Dh(x_0)(x-x_0)|^2dx \tag{5.13}$$
$$\le 2(2\theta\rho)^{-n-2}\left(\int_{B_{2\theta\rho}(x_0)}|w-h|^2dx+\int_{B_{2\theta\rho}(x_0)}|h-h(x_0)-Dh(x_0)(x-x_0)|^2dx\right)$$
$$\le 2(2\theta\rho)^{-n-2}(\rho^{n+2}\varepsilon+16c_{11}\alpha_n(2\theta\rho)^n\theta^4\rho^2)$$
$$= 2^{-n-1}\theta^{-n-2}\varepsilon+8c_{11}\alpha_n\theta^2.$$

We now set $\gamma = 2c_{10}\sqrt{\Phi(x_0,\rho,p_0)+\delta^{-2}\omega(\rho)(1+|p_0|^2)^2}$. Taking advantage of the fact that u and $u-(p_0+\gamma Dh(x_0))(x-x_0)$ have the same mean value on balls centered at x_0 we have

$$(2\theta\rho)^{-n-2}\int_{B_{2\theta\rho}(x_0)}|u-u_{x_0,2\theta\rho}-(p_0+\gamma Dh(x_0))(x-x_0)|^2dx \tag{5.14}$$
$$\le (2\theta\rho)^{-n-2}\int_{B_{2\theta\rho}(x_0)}|u-p_0(x-x_0)-\gamma(h(x_0)+Dh(x_0)(x-x_0))|^2dx$$
$$= \gamma^2(2\theta\rho)^{-n-2}\int_{B_{2\theta\rho}(x_0)}|w-h(x_0)-Dh(x_0)(x-x_0)|^2dx$$
$$\le 4c_{10}^2\left(2^{-n-1}\theta^{-n-2}\varepsilon+8c_{11}\alpha_n\theta^2\right)\left(\Phi(x_0,\rho,p_0)+\delta^{-2}\omega(\rho)(1+|p_0|^2)^2\right)$$
$$\le c_{12}\left(\theta^{-n-2}\varepsilon+\theta^2\right)\left(\Phi(x_0,\rho,p_0)+\delta^{-2}\omega(\rho)(1+|p_0|^2)^2\right),$$

where we have used (5.13) in the second to last line; here we have set $c_{12}=(2^{1-n}+32\alpha_nc_{11})c_{10}^2+1$, which depends only on n, N, λ, and L. We now fix $p_0=(Du)_{x_0,\rho}$. With $P=(Du)_{x_0,\rho}+\gamma Dh(x_0)$ we deduce from (5.14), assuming $\rho\le\rho_1$,

$$\Phi(x_0,\theta\rho)=\alpha_n^{-1}(\theta\rho)^{-n}\int_{B_{\theta\rho}(x_0)}|Du-(Du)_{x_0,\theta\rho}|^2\,dx$$
$$\le \alpha_n^{-1}(\theta\rho)^{-n}\int_{B_{\theta\rho}(x_0)}|Du-P|^2\,dx$$
$$\le 2^nc_6\alpha_n^{-1}(2\theta\rho)^{-n-2}\int_{B_{2\theta\rho}(x_0)}|u-u_{x_0,2\theta\rho}-P(x-x_0)|^2\,dx$$
$$+2^nc_6\omega(2\theta\rho)(1+|P|^2)$$
$$\le 2^nc_6c_{12}\alpha_n^{-1}\left(\theta^{-n-2}\varepsilon+\theta^2\right)\left(\Phi(x_0,\rho)+\delta^{-2}\omega(\rho)(1+|(Du)_{x_0,\rho}|^2)^2\right)$$
$$+2^nc_6\omega(\rho)(1+|P|^2)\,; \tag{5.15}$$

here the second to last inequality follows from Lemma 3.2, the last from (5.14). Under the additional smallness condition

$$2c_{11}\gamma^2\le 1 \tag{5.16}$$

we have, using (5.10) and (5.12),

$$1+|P|^2\le 1+2|(Du)_{x_0,\rho}|^2+2\gamma^2|Dh(x_0)|^2 \tag{5.17}$$
$$\le 1+2|(Du)_{x_0,\rho}|^2+2c_{11}\gamma^2\rho^{-n}\int_{B_\rho(x_0)}|Dh|^2\,dx$$
$$\le 1+2|(Du)_{x_0,\rho}|^2+2c_{11}\gamma^2$$
$$\le 2(1+|(Du)_{x_0,\rho}|^2)\,.$$

We now fix θ sufficiently small that

$$2^{n+1}c_6c_{12}\alpha_n^{-1}\theta^2 \le \theta^{2\beta}, \tag{5.18}$$

and then set $\varepsilon := \theta^{n+4}$, which also fixes δ; without loss of generality we assume that δ is sufficiently small that we have $8c_{10}^2c_{11}\delta^2 < 1$. Note that θ, ε, and δ depend on n, N, λ, L, α, and β.

We now set $c_8 = 32c_{10}^2c_{11}$ and $c_9 = 2^{n+2}c_6(\delta^{-2}+1)$. In view of the smallness conditions (5.9), (5.16), and (5.18), inequalities (5.15) and (5.17) then yield the desired result. □

For a given $M > 0$ we can find $\Phi_0(M) > 0$ (dependent also on n, N, λ, L, β, and $\nu(\,\cdot\,)$) sufficiently small that

$$\nu(2\Phi_0(M)) + 2\Phi_0(M) \le \delta^2/2 \qquad \text{and} \tag{5.19}$$

$$\Phi_0(M) \le \frac{1}{4}M^2\theta^n(1-\theta^\beta)^2. \tag{5.20}$$

Given this, we can also find $\rho_0(M) \in (0, \rho_1]$ (dependent also on n, N, λ, L, β, $\nu(\,\cdot\,)$ and $\omega(\,\cdot\,)$) so small that, writing $c_{13}(M)$ for $\frac{c_8+c_9}{\theta^{2\alpha}-\theta^{2\beta}}(1+16M^4)$ (with c_{13} thus depending also on n, N, λ, L, α and β), we have

$$c_{13}(M)\omega(\rho_0(M)) \le \min\{\delta^2, \Phi_0(M)\} \qquad \text{and} \tag{5.21}$$

$$c_{13}(M)\Omega(\rho_0(M)) \le \tfrac{1}{4}M^2\theta^n(1-\theta^\alpha)^2. \tag{5.22}$$

If the quantities $\Phi(x_0,\rho)$ and ρ are sufficiently small for some $B_\rho(x_0)$, the next lemma shows that we can iterate Proposition 5.1.

LEMMA 5.2. *For $M_0 > 0$ and $B_\rho(x_0) \subset\subset U$, suppose that the conditions*

$$\begin{aligned} &\text{(i)} && |(Du)_{x_0,\rho}| \le M_0, \\ &\text{(ii)} && \rho \le \rho_0(M_0), && \textit{and} \\ &\text{(iii)} && \Phi(x_0,\rho) \le \Phi_0(M_0) \end{aligned}$$

are satisfied. Then the smallness conditions (5.1) *and* (5.2) *are fulfilled on $B_{\theta^j\rho}(x_0)$ for all $j \in \mathbb{N}$. Furthermore there exists*

$$\Upsilon_{x_0} := \lim_{j\to\infty}(Du)_{x_0,\theta^j\rho},$$

and there exists c_{14} depending only on n, N, λ, L, α, β, and M_0 such that for all $r < \rho$ there holds

$$\fint_{B_r(x_0)} |Du - \Upsilon_{x_0}|^2\,dx \le c_{14}\Big(\Big(\frac{r}{\rho}\Big)^{2\beta}\Phi(x_0,\rho) + \Omega(r)\Big). \tag{5.23}$$

Proof. In order to show the first part of the lemma we prove two statements by induction. Precisely, for $j \in \mathbb{N}\cup\{0\}$ we shall show

$$\begin{aligned} &\mathbf{(I)}_j && \Phi(x_0,\theta^j\rho) \le \theta^{2\beta j}\Phi(x_0,\rho) + c_{13}(M_0)\omega(\theta^j\rho) && \text{and} \\ &\mathbf{(II)}_j && |(Du)_{x_0,\theta^j\rho}| \le 2M_0\,. \end{aligned}$$

Note first that $(\mathrm{II})_\mathrm{j}$ combined with (5.21) and (iii) yields

$$(\mathbf{I}')_\mathrm{j} \qquad \Phi(x_0,\theta^j\rho)\le 2\Phi_0(M_0)\,.$$

We now proceed to the proof by induction. The case $j=0$ follows immediately from (5.19), (5.21), and the monotonicity of ν and of ω. We assume $(\mathrm{I})_\ell$ and $(\mathrm{II})_\ell$ for $\ell=0,\dots,j-1$. We first calculate, using (5.3), $(\mathrm{II})_\ell$ for $\ell=0,\dots,j-1$ and $(\omega 1)$,

$$\begin{aligned}
\Phi(x_0,\theta^j\rho)&\le \theta^{2\beta j}\Phi(x_0,\rho)+c_9\sum_{\ell=0}^{j-1}\theta^{2\beta\ell}\omega(\theta^{j-\ell-1}\rho)(1+|(Du)_{x_0,\theta^{j-\ell-1}\rho}|^4)\\
&\le \theta^{2\beta j}\Phi(x_0,\rho)+c_9\theta^{-2\alpha}\left(\sum_{\ell=0}^{j-1}\theta^{2(\beta-\alpha)\ell}\right)\omega(\theta^j\rho)(1+16M_0^4)\\
&\le \theta^{2\beta j}\Phi(x_0,\rho)+\frac{c_9(1+16M_0^4)}{\theta^{2\alpha}-\theta^{2\beta}}\omega(\theta^j\rho)\\
&\le \theta^{2\beta j}\Phi(x_0,\rho)+c_{13}(M_0)\omega(\theta^j\rho)\,,
\end{aligned}$$

showing $(\mathrm{I})_\mathrm{j}$. To show $(\mathrm{II})_\mathrm{j}$ we estimate

$$\begin{aligned}
|(Du)_{x_0,\theta^j\rho}|&\le M_0+\sum_{\ell=1}^{j}|(Du)_{x_0,\theta^\ell\rho}-(Du)_{x_0,\theta^{\ell-1}\rho}| && \text{via (iii)}\\
&\le M_0+\sum_{\ell=1}^{j}\left[\fint_{B_{\theta^\ell\rho}(x_0)}|Du-(Du)_{x_0,\theta^{\ell-1}\rho}|^2\,dx\right]^{1/2}\\
&\le M_0+\theta^{-n/2}\sum_{\ell=1}^{j}\left[\fint_{B_{\theta^{\ell-1}\rho}(x_0)}|Du-(Du)_{x_0,\theta^{\ell-1}\rho}|^2\,dx\right]^{1/2}\\
&\le M_0+\theta^{-n/2}\sum_{\ell=0}^{j-1}\sqrt{\theta^{2\beta\ell}\Phi(x_0,\rho)+c_{13}(M_0)\omega(\theta^\ell\rho)} && \text{via (I)}_\ell,\ \ell=0,\dots,j-1\\
&\le M_0+\theta^{-n/2}\left(\frac{\sqrt{\Phi(x_0,\rho)}}{1-\theta^\beta}+\frac{\sqrt{c_{13}(M_0)}}{1-\theta^\alpha}\sqrt{\Omega(\rho)}\right) && \text{via (2.5)}\\
&\le M_0+\theta^{-n/2}\left(\frac{\sqrt{\Phi_0(M_0)}}{1-\theta^\beta}+\frac{\sqrt{c_{13}(M_0)\Omega(\rho_0(M_0))}}{1-\theta^\alpha}\right) && \text{via (iii), (ii)}\\
&\le 2M_0 && \text{via (5.20), (5.22).}
\end{aligned}$$

The conclusion of the lemma then follows from $(\mathrm{I}')_\mathrm{j}$ and $(\mathrm{II})_\mathrm{j}$ after taking into account (5.19) and (5.21).

Analogously we calculate, for $k>j$,

$$\begin{aligned}
|(Du)_{x_0,\theta^j\rho}-(Du)_{x_0,\theta^k\rho}|&\le\sum_{\ell=j+1}^{k}|(Du)_{x_0,\theta^\ell\rho}-(Du)_{x_0,\theta^{\ell-1}\rho}|\\
&\le\theta^{-n/2}\left(\frac{\sqrt{\Phi(x_0,\rho)}}{1-\theta^\beta}\theta^{\beta j}+\frac{\sqrt{c_{13}(M_0)}}{1-\theta^\alpha}\sqrt{\Omega(\theta^j\rho)}\right);
\end{aligned}$$

this shows that $\{(Du)_{x_0,\theta^j\rho}\}$ is a Cauchy sequence. For

$$\Upsilon_{x_0}:=\lim_{j\to\infty}(Du)_{x_0,\theta^j\rho}$$

we thus have, with $c_{15} = \sqrt{2}\theta^{-n/2}\Big(\frac{1+\sqrt{c_{13}(M_0)}}{1-\theta^\alpha}\Big)$ depending only on n, N, λ, L, α, β, and M_0,

$$|(Du)_{x_0,\theta^j\rho} - \Upsilon_{x_0}| \le c_{15}\Big[\theta^{2\beta j}\Phi(x_0,\rho) + \Omega(\theta^j\rho)\Big]^{1/2}$$

for all j. Combining this with $(\mathrm{I})_\mathrm{j}$ and setting $c_{16} = 2(c_{13}(M_0) + c_{15}^2)$ (note that c_{16} has the same dependencies as c_{15}) we have, using also (2.6),

$$\begin{aligned}
