SELF-SIMILAR LATTICE TILINGS AND SUBDIVISION SCHEMES[*]

DING-XUAN ZHOU[†]

Dedicated to Professor Gil Strang on the occasion of his 65th birthday

Abstract. Let $M \in \mathbb{Z}^{s\times s}$ be a dilation matrix and let $\mathcal{D} \subset \mathbb{Z}^s$ be a complete set of representatives of distinct cosets of $\mathbb{Z}^s/M\mathbb{Z}^s$. The self-similar tiling associated with M and $\mathcal{D}$ is the subset of $\mathbb{R}^s$ given by $T(M,\mathcal{D}) = \{\sum_{j=1}^{\infty} M^{-j}\alpha_j : \alpha_j \in \mathcal{D}\}$. The purpose of this paper is to characterize self-similar lattice tilings, i.e., tilings $T(M,\mathcal{D})$ which have Lebesgue measure one. In particular, it is shown that $T(M,\mathcal{D})$ is a lattice tiling if and only if there is no nonempty finite set $\Lambda \subset \mathbb{Z}^s \setminus (\mathcal{D}-\mathcal{D})$ such that $M^{-1}((\mathcal{D}-\mathcal{D})+\Lambda)\cap\mathbb{Z}^s \subset \Lambda$. This set Λ can be restricted to be contained in a finite set K depending only on M and $\mathcal{D}$. We also give a new proof for the fact that $T(M,\mathcal{D})$ is a lattice tiling if and only if $\cup_{n=1}^{\infty}(\sum_{j=0}^{n-1} M^j(\mathcal{D}-\mathcal{D})) = \mathbb{Z}^s$. Two approaches are provided, one based on scrambling matrices and the other based on primitive matrices. These will follow from the characterization of subdivision schemes associated with nonnegative masks in terms of finite powers of finite matrices, without computing eigenvalues or spectral radii. Our characterization shows that the convergence of the subdivision scheme with a nonnegative mask depends only on the location of its positive coefficients.

Key words. self-similar lattice tilings, subdivision schemes, column-stochastic matrices, scrambling matrices, primitive matrices

1. Introduction.

Self-similar tilings are defined in terms of dilation matrices and digit sets. A dilation matrix M in $\mathbb{R}^s (s \in \mathbb{N})$ is an $s \times s$ integer matrix with all the eigenvalues greater than 1 in modulus, i.e., $\lim_{n\to\infty} M^{-n} = 0$. A digit set $\mathcal{D}$ associated with the dilation matrix M is a complete set of representatives of distinct cosets of the quotient group $\mathbb{Z}^s/M\mathbb{Z}^s$. If $m = |\det M|$, then $\mathcal{D}$ consists of m elements $\{\varepsilon_0, \varepsilon_1, \ldots, \varepsilon_{m-1}\}$ and $\varepsilon_i - \varepsilon_j \notin M\mathbb{Z}^s$ for $i \neq j$.

The *self-similar tiling* associated with a dilation matrix M and a digit set $\mathcal{D}$ is defined to be the subset $T(M,\mathcal{D})$ of $\mathbb{R}^s$ as

$$T(M,\mathcal{D}) := \left\{ \sum_{j=1}^{\infty} M^{-j}\alpha_j : \quad \alpha_j \in \mathcal{D} \right\}. \tag{1.1}$$

Self-similar tilings have been studied in a variety of contexts in the literature; see, e.g., [6, 5, 10, 11, 20] and the references therein.

The measure of a self-similar tiling is always a positive integer. Here we are interested in the case when this measure $\text{meas}(T(M,\mathcal{D}))$ is exactly one. If this happens, we call $T(M,\mathcal{D})$ a *self-similar lattice tiling* because the integer translates of $T(M,\mathcal{D})$ tile the space $\mathbb{R}^s$ without overlapping. These lattice tilings provide useful examples not only for fractal geometry but also for wavelet analysis. How to characterize self-similar lattice tilings in terms of the digit sets is our main concern here.

In the univariate case, $M = m > 1$ is a positive integer and $\mathcal{D}$ consists of m integers $\{\varepsilon_0, \varepsilon_1, \ldots, \varepsilon_{m-1}\}$ satisfying $\varepsilon_j \equiv j (\mathrm{mod} m)$ for $j = 0, 1, \ldots, m-1$. Then $T(M, \mathcal{D})$ has measure one if and only if the numbers $\varepsilon_1 - \varepsilon_0, \ldots, \varepsilon_{m-1} - \varepsilon_0$ are relatively prime, i.e., $\gcd(\varepsilon_1 - \varepsilon_0, \ldots, \varepsilon_{m-1} - \varepsilon_0) = 1$. This result was proved independently by Gröchenig and Haas [5] and by Zhou [21].

In the multivariate case, things are more difficult. Gröchenig and Madych [6] used the Cohen condition for orthogonality of refinable functions and obtained many interesting examples of self-similar lattice tilings. A useful necessary condition for self-similar lattice tilings was provided by Lagarias and Wang [10]: if $T(M, \mathcal{D})$ has measure one, then the smallest M-invariant sublattice $\mathbb{Z}[M, \mathcal{D}]$ of $\mathbb{Z}^s$ containing the difference set $\mathcal{D} - \mathcal{D} := \{\alpha - \beta : \alpha, \beta \in \mathcal{D}\}$ is $\mathbb{Z}^s$. A necessary and sufficient condition was given by Gröchenig and Haas [5] in terms of the spectrum of a finite matrix. To apply this condition, one needs to check whether some eigenvalues of the matrix have modulus 1 exactly, which is somehow numerically instable. By the tiling theorem in [11], $T(M, \mathcal{D})$ is a self-similar lattice tiling if and only if $\cup_{n=1}^{\infty} \sum_{j=0}^{n-1} M^j (\mathcal{D} - \mathcal{D}) = \mathbb{Z}^s$. A new proof for this fact will be given in this paper by means of subdivision schemes.

In this paper we show that $T(M, \mathcal{D})$ is a lattice tiling if and only if there is no nonempty finite set $\Lambda \subset \mathbb{Z}^s \setminus (\mathcal{D} - \mathcal{D})$ such that $M^{-1}\big((\mathcal{D} - \mathcal{D}) + \Lambda\big) \cap \mathbb{Z}^s \subset \Lambda$. This set Λ can be restricted to be contained in a finite set K depending only on M and $\mathcal{D}$. The lattice tiling property is also equivalent to $K \subset \sum_{j=0}^{n-1} M^j (\mathcal{D} - \mathcal{D})$ for some $1 \leq n \leq 1 + \#\big(K \setminus (\mathcal{D} - \mathcal{D})\big)$; see Theorem 5. We also provide some criteria for checking self-similar lattice tilings in terms of finite powers of finite matrices. Two approaches will be presented, one based on scrambling matrices (section 3) and the other based on primitive matrices (section 4). Our criteria will be consequences of general characterizations of L_2-convergence of subdivision schemes associated with nonnegative masks. Observe that the characteristic function of the self-similar tiling (1.1) satisfies the refinement equation

$$\phi(x) = \sum_{\alpha \in \mathcal{D}} \phi(Mx - \alpha), \qquad x \in \mathbb{R}^s.$$

The symbol of the corresponding mask is a conjugate quadrature filter. Hence the self-similar lattice tiling can be studied by the convergence of subdivision scheme associated with this equation.

2. Subdivision schemes and transfer operators.

2. Subdivision schemes and transfer operators. Subdivision schemes are often used to solve *refinement equations* of the form

$$\phi(x) = \sum_{\alpha \in \mathbb{Z}^s} a(\alpha) \phi(Mx - \alpha), \qquad x \in \mathbb{R}^s, \tag{2.1}$$

where $a := \{a(\alpha)\}_{\alpha \in \mathbb{Z}^s}$ is a finitely supported sequence called the *refinement mask*. We restrict a to be real-valued in this paper. When $\sum a(\alpha) = m$, the refinement equation (2.1) has a unique compactly supported distributional solution under the normalized condition $\hat{\phi}(0) = 1$ (e.g., [1, 2]). Here $\hat{\phi}$ denotes the Fourier transform of ϕ and ϕ is called the *normalized solution* of (2.1).

In order to find a solution in L_p, we start with the initial function $\phi_0(x) = \Pi_{j=1}^s \varphi(x_j)$, where $x = (x_1, \ldots, x_s)$ and φ is the univariate hat function supported and given on $[0, 2]$ by $\varphi(t) = \min\{t, 2 - t\}$. Then the subdivision scheme associated with (2.1) is defined to be a sequence of functions $\{\phi_n\}$ as

$$\phi_n(x) = \sum_{\alpha \in \mathbb{Z}^s} a(\alpha) \phi_{n-1}(Mx - \alpha), \qquad x \in \mathbb{R}^s, \quad n \in \mathbb{N}.$$

We say that the *subdivision scheme* associated with (2.1) converges in $L_p (1 \leq p \leq \infty)$ if and only if $\{\phi_n\}$ converges in L_p:

$$\lim_{n\to\infty} \|\phi_n - \phi\|_p = \lim_{n\to\infty} \left\{ \int_{\mathbb{R}^s} |\phi_n(x) - \phi(x)|^p dx \right\}^{1/p} = 0.$$

To characterize the L_p-convergence of the subdivision scheme in terms of the mask, one needs the concept of the p-norm joint spectral radius; see, e.g., [8, 2]. It is hard to compute the p-norm joint spectral radius. However, when p is an even integer, Zhou showed in [22] (see also [19]) that the p-norm joint spectral radius of a finite set of matrices can be computed exactly and explicitly by the spectral radius of a single finite matrix.

It is well known (see, e.g., [4, 8]) that the L_2-convergence of subdivision schemes can be characterized in terms of the spectral radius of a finite matrix derived from the transfer operator which was introduced to wavelet analysis by Lawton [12]. In the multivariate case, such a characterization was given independently by Han and Jia [7], Lawton, Lee, and Shen [13], and Strang [18]. To state this fact, let b be the sequence defined by

$$b(\alpha) = \frac{1}{m} \sum_{\beta\in\mathbb{Z}^s} a(\beta)a(\alpha+\beta), \qquad \alpha \in \mathbb{Z}^s.$$

Obviously, the sequence b is finitely supported on $\operatorname{supp} a - \operatorname{supp} a$. The transfer operator is associated with the bi-infinite matrix $(b(M\alpha-\beta))_{\alpha,\beta\in\mathbb{Z}^s}$. To get the finite matrix, we restrict both α, β to be in a finite index set $K \subset \mathbb{Z}^s$ such that the space of all sequences supported in K, $\ell(K)$ is invariant under the operator $(b(M\alpha - \beta))$. Also, we require that K contains Ω, *the support of the sequence* b. Such a set K exists. For example, by [7] we may take

$$K = \mathbb{Z}^s \cap \left(\sum_{n=1}^{\infty} M^{-n}(\Omega \cup M\Omega) \right).$$

Now we have a finite set K, and the sequence b satisfies

$$b(M\alpha - \beta) \neq 0, \quad \beta \in K \qquad \Longrightarrow \qquad \alpha \in K.$$

The finite matrix we need for the L_2-convergence is

$$F := \big(b(M\alpha-\beta)\big)_{\alpha,\beta\in K}. \tag{2.2}$$

A necessary condition for the convergence of the subdivision scheme is the sum rule of order one: $\sum_{\alpha\in\mathbb{Z}^s} a(M\alpha+\beta) = 1$ for every $\beta \in \mathbb{Z}^s$. Under this condition,

$$\sum_{\alpha\in\mathbb{Z}^s} b(M\alpha+\beta) = \frac{1}{m} \sum_{\gamma\in\mathbb{Z}^s} a(\gamma) \sum_{\alpha\in\mathbb{Z}^s} a(M\alpha+\beta+\gamma) = 1 \qquad \forall \beta \in \mathbb{Z}^s.$$

If a sequence v supported on K ($v \in \ell(K)$) satisfies $\sum v(\alpha) = 0$, then the vanishing of $b(M\alpha - \beta)$ for $\beta \in K, \alpha \notin K$ yields

$$\sum_{\alpha\in K} (Fv)_\alpha = \sum_{\alpha\in K}\sum_{\beta\in K} b(M\alpha-\beta)v(\beta) = \sum_{\beta\in K} \left\{ \sum_{\alpha\in\mathbb{Z}^s} b(M\alpha-\beta) \right\} v(\beta) = 0.$$

That means the space

$$V := \left\{ v \in \ell(K) : \sum_{\alpha \in K} v(\alpha) = 0 \right\} \tag{2.3}$$

is invariant under the action of F.

With the above notation, we can now state the following known result [7, 13, 18] on the L_2-convergence of subdivision schemes.

THEOREM A. *Let M be a dilation matrix and let $a := \{a(\alpha)\}_{\alpha \in \mathbb{Z}^s}$ be a finitely supported sequence with $\sum a(\alpha) = m$. Then the subdivision scheme associated with* (2.1) *converges in L_2 if and only if*

(a) $\sum_{\alpha \in \mathbb{Z}^s} a(M\alpha + \beta) = 1 \; \forall \beta \in \mathbb{Z}^s$*;*

(b) $\rho(F|_V) < 1$*, i.e., the spectral radius of the finite matrix F restricted to the invariant subspace V is less than* 1.

This is a very nice characterization. However, one still has to compute the eigenvalues of the matrix, which is not so stable numerically. In particular, for our purpose of self-similar tilings, the mask will be nonnegative. In this case, F is a column-stochastic matrix, i.e., F is nonnegative and for every $\beta \in K$

$$\sum_{\alpha \in K} F_{\alpha,\beta} = \sum_{\alpha \in \mathbb{Z}^s} b(M\alpha - \beta) = 1.$$

Thus, F would have eigenvalues other than 1 on the unit circle, if condition (b) of Theorem A is not true. This difficulty can be overcome by using the special property caused by the nonnegative mask.

3. The L_2-convergence of subdivision schemes with nonnegative masks.

In this section we characterize the L_2-convergence of the subdivision scheme associated with a nonnegative mask in terms of finite powers of the column-stochastic matrix F. This approach depends mainly on a result of *scrambling* column-stochastic matrices used by Jia and Zhou in [9].

A matrix $A = (A_{\alpha,\beta})_{\alpha,\beta \in K}$ is called *column-stochastic* if all its entries are nonnegative and

$$\sum_{\alpha \in K} A_{\alpha,\beta} = 1 \qquad \forall \beta \in K.$$

We say that the column-stochastic matrix A is *scrambling* if each pair of columns has positive entries in some common row. It is well known that AB is column-stochastic if both A and B are, and AB is scrambling if B is scrambling and A is column-stochastic. Denote $\|v\|_1$ as the ℓ_1-norm of sequences. The result from [9] that we need here is the following.

LEMMA. *Let $A = (A_{\alpha,\beta})_{\alpha,\beta \in K}$ be column-stochastic and let V be defined by* (2.3)*. Then*

$$\|A|_V\|_1 := \sup_{0 \neq v \in V} \frac{\|Av\|_1}{\|v\|_1} < 1$$

if and only if A is scrambling.

We are now in a position to state the main result of this section.

THEOREM 1. *Let M be a dilation matrix and let $a := \{a(\alpha)\}_{\alpha \in \mathbb{Z}^s}$ be a finitely supported* nonnegative *sequence with $\sum a(\alpha) = m$. Set K and F as in Theorem A.*

Let $N := \#K$. Then the subdivision scheme associated with (2.1) *converges in L_2 if and only if*

(i) $\sum_{\alpha\in\mathbb{Z}^s} a(M\alpha+\beta) = 1\ \forall\beta\in\mathbb{Z}^s$*;*

(ii) *there exists some integer n with $1 \leq n \leq (3^N - 2^{N+1}+1)/2$ such that the matrix F^n is scrambling.*

Proof. The sufficiency follows from Theorem A, our lemma, and the well-known fact that

$$\rho(F|_V) = \lim_{k\to\infty} \|F^k|_V\|_1^{1/k} = \inf_{k\in\mathbb{N}} \|F^k|_V\|_1^{1/k}.$$

To see the necessity, we suppose that the subdivision scheme converges in L_2. Then condition (i) holds by Theorem A. Theorem A also tells us that

$$\rho(F|_V) = \inf_{k\in\mathbb{N}} \|F^k|_V\|_1^{1/k} < 1.$$

Hence, $\|F^k|_V\|_1 < 1$ for some $k \in \mathbb{N}$. Since F^k is column-stochastic, by our lemma, F^k is scrambling. Observe that condition (ii) is equivalent to the fact that $F^{(3^N-2^{N+1}+1)/2}$ is scrambling. It is sufficient for us to show that $F^{(3^N-2^{N+1}+1)/2}$ is scrambling.

Suppose to the contrary that the column-stochastic matrix $F^{(3^N-2^{N+1}+1)/2}$ is not scrambling. Then there are two distinct elements γ_1 and γ_2 in K such that for every $\alpha\in K$ either $(F^{(3^N-2^{N+1}+1)/2})_{\alpha,\gamma_1}$ or $(F^{(3^N-2^{N+1}+1)/2})_{\alpha,\gamma_2}$ is zero. Let $0 \leq j \leq (3^N - 2^{N+1}+1)/2, \gamma\in\{\gamma_1,\gamma_2\}$. We have

$$(F^{(3^N-2^{N+1}+1)/2})_{\alpha,\gamma} = \sum_{\beta\in K} (F^{(3^N-2^{N+1}+1)/2-j})_{\alpha,\beta}(F^j)_{\beta,\gamma}.$$

Therefore, for every $\beta\in K$, either $(F^j)_{\beta,\gamma_1}$ or $(F^j)_{\beta,\gamma_2}$ is zero, since for some $\alpha\in K$ depending on β, $(F^{(3^N-2^{N+1}+1)/2-j})_{\alpha,\beta} \neq 0$. Here $F^0 = I$. Define

$$I_{j,\gamma} := \{\beta\in K : (F^j)_{\beta,\gamma} > 0\}.$$

Then we know that $I_{j,\gamma} \neq \emptyset$ and for $0 \leq j \leq (3^N-2^{N+1}+1)/2, I_{j,\gamma_1}\cap I_{j,\gamma_2} = \emptyset$. The number of different unordered pairs of disjoint nonempty subsets of K is $(3^N - 2^{N+1} + 1)/2$ (see [16]). Hence, there must exist some $1 \leq p < l \leq (3^N - 2^{N+1}+1)/2$ such that $I_{p,\gamma_1} = I_{l,\gamma_1}$ and $I_{p,\gamma_2} = I_{l,\gamma_2}$. That means, for every $\beta\in K, \gamma\in\{\gamma_1,\gamma_2\}, (F^p)_{\beta,\gamma}$ and $(F^l)_{\beta,\gamma}$ are either both positive or both zero.

Let $q\in\mathbb{N}, \alpha\in K, \gamma\in\{\gamma_1,\gamma_2\}$. Then

$$(F^{p+q(l-p)})_{\alpha,\gamma} = \sum_{\beta\in K} (F^{(q-1)(l-p)})_{\alpha,\beta}(F^l)_{\beta,\gamma}$$

vanishes if and only if

$$(F^{p+(q-1)(l-p)})_{\alpha,\gamma} = \sum_{\beta\in K} (F^{(q-1)(l-p)})_{\alpha,\beta}(F^p)_{\beta,\gamma}$$

equals zero. Hence, for $\gamma\in\{\gamma_1,\gamma_2\}, q\in\mathbb{N}, I_{p+q(l-p),\gamma} = I_{p,\gamma}$. It follows that for any $q\in\mathbb{N}$,

$$I_{p+q(l-p),\gamma_1} \cap I_{p+q(l-p),\gamma_2} = I_{p,\gamma_1}\cap I_{p,\gamma_2} = \emptyset.$$

Thus the column-stochastic matrix $F^{p+q(l-p)}$ is not scrambling. Choose q such that $p+q(l-p) > k$. Then we conclude that F^k is not scrambling, which is a contradiction. This tells us that condition (ii) holds. □

In [15, 3, 9] the uniform convergence of subdivision schemes associated with nonnegative masks was characterized in terms of finite products of m matrices. This in connection with the autocorrelation of the mask yields another way to characterize the L_2-convergence. However, we need a set of m matrices and many more matrix products need to be checked.

The argument for the bound $(3^N - 2^{N+1} + 1)/2$ was provided by Paz [16], who proved that $(3^N - 2^{N+1} + 1)/2$ is a sharp bound for the power in checking scrambling products of several matrices. Here we give a complete proof for the reader's convenience. For a single matrix, this bound can most likely be largely reduced. With the approach given in the next section (Theorem 2) we will need to check only the powers up to $(N-1)^2 + 1$ for our purpose of checking the L_2-convergence. However, Theorem 1 plays an important role in deriving a nice characterization of self-similar lattice tilings (Theorem 5) which is hard to see from Theorem 2.

As a consequence of Theorem 1, we show that the convergence of the subdivision scheme with a nonnegative mask depends only on the location of its positive coefficients.

Corollary 1. *Let a and c be two nonnegative masks satisfying the sum rule of order one:*

$$\sum_{\alpha\in\mathbb{Z}^s} a(M\alpha+\beta) = \sum_{\alpha\in\mathbb{Z}^s} c(M\alpha+\beta) = 1 \qquad \forall \beta\in\mathbb{Z}^s.$$

Suppose $c(\alpha) > 0$ whenever $a(\alpha) > 0$. If the subdivision scheme associated with mask a converges, then the subdivision scheme associated with mask c also converges.

Proof. Let K be given for the mask c as in Theorem A. Denote F_a and F_c as the transfer matrices defined by (2.2) associated with the masks a and c, respectively. Then for $\alpha, \beta \in K$, $(F_a)_{\alpha,\beta} > 0$ implies that $(F_c)_{\alpha,\beta} > 0$.

Since the subdivision scheme associated with mask a converges, by Theorem 1, for some $1 \le n \le (3^{\#K} - 2^{\#K+1} + 1)/2$, the matrix F_a^n is scrambling. Then the matrix F_c^n is also scrambling. By using Theorem 1 again, we conclude that the subdivision scheme associated with mask c also converges. □

4. Primitive matrices and condition E. In this section we present another approach to the L_2-convergence of subdivision schemes associated with nonnegative masks. This approach is based on primitive matrices and the power involved is at most $(N-1)^2 + 1$, much less than $(3^N - 2^{N+1} + 1)/2$ when N is large.

To state the main result here, we need the *Frobenius normal form* of the column-stochastic matrix F:

$$F = \begin{bmatrix} F_1 & 0 & \cdots & 0 & F_{1,k+1} & \cdots & F_{1,d} \\ 0 & F_2 & 0\cdots & 0 & F_{2,k+1} & \cdots & F_{2,d} \\ \vdots & 0 & \ddots & 0 & \vdots & & \vdots \\ 0 & \cdots & 0 & F_k & F_{k,k+1} & & F_{k,d} \\ 0 & \cdots & 0 & 0 & F_{k+1} & & \vdots \\ 0 & \cdots & 0 & 0 & 0 & \ddots & \\ 0 & \cdots & 0 & 0 & 0 & 0 & F_d \end{bmatrix}. \tag{4.1}$$

Here $k \geq 1$ and each F_j is either a 1×1 zero matrix or is irreducible. The blocks $F_1, \ldots, F_k$ are called *isolated*. For each l with $k+1 \leq l \leq d$ (nonisolated block), there exists some i such that $F_{i,l} \neq 0$. The Frobenius normal form for the matrix F can be realized by choosing a suitable order for the set K.

Condition (b) of Theorem A for F is equivalent to condition E. A square matrix A is said to satisfy *condition E* if 1 is a simple eigenvalue of A and all the other eigenvalues are less than 1 in modulus. An irreducible nonnegative matrix A is called *primitive* if A satisfies condition E. Recall that for an irreducible column-stochastic matrix, the primitivity is equivalent to that for some $n \in \mathbb{N}$, A^n is positive (all the entries are positive). The smallest n with this property is called the index of A and can be bounded sharply by $(N-1)^2 + 1$. For these facts on nonnegative matrices, see, e.g., [17].

Using the Frobenius normal form (4.1) we can characterize the L_2-convergence of subdivision schemes with nonnegative masks in terms of primitive matrices.

THEOREM 2. *Let M be a dilation matrix and let $a := \{a(\alpha)\}_{\alpha \in \mathbb{Z}^s}$ be a finitely supported* nonnegative *sequence with $\sum a(\alpha) = m$. Set K and F as in Theorem A. Let $N := \#K$. Assume that the matrix F takes the form* (4.1). *Then the subdivision scheme associated with* (2.1) *converges in L_2 if and only if*

(i) $\sum_{\alpha \in \mathbb{Z}^s} a(M\alpha + \beta) = 1 \; \forall \beta \in \mathbb{Z}^s$;

(ii) *in the form* (4.1), $k = 1$, *and F_1 is primitive.*

Proof. Let us prove the equivalence between condition (b) of Theorem A and condition (ii) of Theorem 2.

Suppose $\rho(F|_V) < 1$. Since F is column-stochastic, it has an eigenvalue 1 with a left eigenvector $[1, \ldots, 1]$. Then F satisfies condition E. Since F is column-stochastic, each of the isolated blocks $F_1, \ldots, F_k$ is also column-stochastic and provides one multiplicity of the eigenvalue 1. Hence, $k = 1$. All the eigenvalues of F_1, including 1, are eigenvalues of F, but F satisfies condition E. Therefore, F_1 satisfies condition E. This in connection with the irreducibility of F_1 implies that F_1 is primitive. Thus condition (ii) of Theorem 2 holds.

Conversely, assume that $k = 1$ and F_1 is primitive. We need to show that $\rho(F_j) < 1$ for $2 \leq j \leq d$.

Suppose to the contrary that for some j with $2 \leq j \leq d$, $\rho(F_j) \geq 1$. Then F_j is not the zero matrix and is irreducible. Since all the eigenvalues of F_j are eigenvalues of F, $\rho(F_j) = 1$. However, F_j is nonnegative. The Perron–Frobenius theorem tells us that F_j has a left positive eigenvector v with eigenvalue 1: $vF_j = v$ and $v = [v_1, \ldots, v_l]$ with $v_1, \ldots, v_l > 0$.

Let $v_{\max} := \max\{v_i : 1 \leq i \leq l\} > 0$ and let $I := \{i : v_i = v_{\max}\} \neq \emptyset$. Then for $i \in I$,

$$v_i = v_{\max} = \sum_{p=1}^{l} v_p (F_j)_{p,i} = v_{\max} \sum_{p \in I} (F_j)_{p,i} + \sum_{p \notin I} v_p (F_j)_{p,i} \leq v_{\max}.$$

Since the equality holds, we know that for $i \in I, p \notin I, (F_j)_{p,i} = 0$. However, F_j is irreducible. Therefore, $I^c = \emptyset$, i.e., $v_1 = v_2 = \cdots = v_l = v_{\max}$. It follows that F_j is column-stochastic. Hence, $F_{i,j} = 0$ for $i \neq j$ and F_j is an isolated block, which is a contradiction.

Thus, we have shown that $\rho(F_j) < 1$ for $2 \leq j \leq d$. But F_1 satisfies condition E. Hence F satisfies condition E, i.e., $\rho(F|_V) < 1$. The proof of Theorem 2 is complete. □

The proof of Theorem 2 yields the following result on general column-stochastic matrices, which is of independent interest.

THEOREM 3. *Let F be column-stochastic and take the Frobenius normal form* (4.1). *Then the following statements are equivalent:*

(i) *F satisfies condition E;*

(ii) *$k = 1$ and F_1 is primitive;*

(iii) *F^n is scrambling for some $n \in \mathbb{N}$;*

(iv) $\rho(F|_V) < 1$.

To apply Theorems 2 and 3, we have to check whether F_1 is primitive. Since F_1 is irreducible, this is equivalent to the fact that F_1^n is scrambling for some $n \in \mathbb{N}$. From the sharp bound $(N-1)^2+1$ for the index of primitive matrices, we know that n can be bounded by $(N-1)^2+1$. The following example shows that, in general, n should be at least $[(N-1)^2/2]+1$.

Example 1. Let A be the following $N \times N$ irreducible column-stochastic matrix:

$$A = \begin{bmatrix} 0 & \cdots & 0 & 1/2 \\ & & & 1/2 \\ & & & 0 \\ & I_{N-1} & & \vdots \\ & & & 0 \end{bmatrix}.$$

Then by computation we see that $A^{[(N-1)^2/2]}$ is not scrambling, while $A^{[(N-1)^2/2]+1}$ is scrambling.

5. Characterizations for self-similar lattice tilings.

In this section we characterize self-similar lattice tilings in terms of finite powers of finite matrices and digit sets.

Observe that the characteristic function $\chi_{T(M,\mathcal{D})}$ of the self-similar tiling (1.1) satisfies the refinement equation

$$\phi(x) = \sum_{\alpha \in \mathcal{D}} \phi(Mx - \alpha) \tag{5.1}$$

with the mask being a $0-1$ sequence (hence, nonnegative). The normalized solution is $\phi = \frac{1}{\text{meas}(T(M,\mathcal{D}))}\chi_{T(M,\mathcal{D})}$. The mask satisfies condition (i) of Theorem 1. Recall from [6] that the symbol of this mask is a conjugate quadrature filter (CQF). Therefore, a well-known fact on CQFs tells us that the integer translates of ϕ are orthonormal (i.e., $T(M,\mathcal{D})$ has measure one) if and only if the subdivision scheme associated with (5.1) converges in L_2. Recall from [7] that for any finitely supported sequence b on $\mathbb{Z}^s$ and any finite set $H \subset \mathbb{Z}^s$, there exists a finite set $K \subset \mathbb{Z}^s$ such that $H \subset K$ and $\ell(K)$ is invariant under $(b(M\alpha - \beta))$. Also, $\ell(K)$ is invariant under $(b(M\alpha - \beta))$ if and only if $M^{-1}(\text{supp} b + K) \cap \mathbb{Z}^s \subset K$. Then we have the following characterization for self-similar lattice tilings.

THEOREM 4. *Let M be a dilation matrix and let $\mathcal{D}$ be a complete set of representatives of distinct cosets of $\mathbb{Z}^s/M\mathbb{Z}^s$. Let $a := \{a(\alpha)\}_{\alpha\in\mathbb{Z}^s}$ be supported on $\mathcal{D}$ and $a(\alpha) = 1$ for $\alpha \in \mathcal{D}$. Let b be the sequence given by*

$$b(\alpha) = \frac{1}{m}\sum_{\beta\in\mathbb{Z}^s} a(\beta)a(\alpha+\beta), \qquad \alpha \in \mathbb{Z}^s.$$

Choose a finite set K such that K contains $\Omega := \mathcal{D}-\mathcal{D}$ and $\ell(K)$ is invariant under the bi-infinite matrix $(b(M\alpha-\beta))$. Let

$$F := \big(b(M\alpha-\beta)\big)_{\alpha,\beta\in K}.$$

Set $N := \#K$. Then the following statements are equivalent:

(1) *$T(M,\mathcal{D})$ is a lattice tiling;*

(2) *there exists some integer n with $1 \le n \le (3^N - 2^{N+1} + 1)/2$ such that the matrix F^n is scrambling;*

(3) *there is no nonempty set $\Lambda \subset K \setminus \Omega$ such that $M^{-1}(\Omega+\Lambda)\cap\mathbb{Z}^s \subset \Lambda$;*

(4) *there is no nonempty finite set $\Lambda \subset \mathbb{Z}^s \setminus \Omega$ such that $M^{-1}(\Omega+\Lambda)\cap\mathbb{Z}^s \subset \Lambda$.*

Proof. The equivalence between statements (1) and (2) follows from Theorem 1.

To see the equivalence between statements (1) and (3), we observe that

$$b(0) = 1.$$

Since F is column-stochastic, it follows that $F_{0,\beta} = 0$ for $\beta \in K\setminus\{0\}$. Then $F_1 = [1]$ is an isolated block in the Frobenius normal form (4.1). By Theorem 2, $T(M,\mathcal{D})$ is a lattice tiling if and only if $[1]$ is the only isolated block in (4.1); that is, there is no nonempty set $\Lambda \subset K\setminus\{0\}$ such that $\ell(\Lambda)$ is invariant under F:

$$F_{\alpha,\beta} > 0, \quad \beta\in\Lambda \qquad \Longrightarrow \qquad \alpha\in\Lambda.$$

Notice that $F_{0,\beta} = b(-\beta) > 0$ for any $\beta\in\Omega$. Therefore, the above statement is equivalent to the fact that there is no nonempty set $\Lambda \subset K\setminus\Omega$ such that

$$F_{\alpha,\beta} = b(M\alpha-\beta) > 0, \quad \beta\in\Lambda \qquad \Longrightarrow \qquad \alpha\in\Lambda,$$

i.e.,

$$M\alpha-\beta\in\Omega, \quad \beta\in\Lambda \qquad \Longrightarrow \qquad \alpha\in\Lambda.$$

This tells us the equivalence between statements (1) and (3). By choosing K to be large enough ($\Lambda \subset K$), we see easily the equivalence between statements (3) and (4). □

Theorem 4 yields a new proof for the first part of the following nice characterization of self-similar tilings. (The second part is new.)

Theorem 5. *Let M be a dilation matrix and let $\mathcal{D}$ be a complete set of representatives of distinct cosets of $\mathbb{Z}^s/M\mathbb{Z}^s$. Define $T(M,\mathcal{D})$ by (1.1). Then $T(M,\mathcal{D})$ is a lattice tiling if and only if*

$$\cup_{n=1}^{\infty}\Big(\sum_{j=0}^{n-1} M^j(\mathcal{D}-\mathcal{D})\Big) = \mathbb{Z}^s. \tag{5.2}$$

Moreover, choose K as in Theorem 4 and let $N = \#K$; then $T(M,\mathcal{D})$ is a lattice tiling if and only if $K \subset \sum_{j=0}^{n-1} M^j(\mathcal{D}-\mathcal{D})$ for some n with $1\le n\le N-m+1$ if and only if $K \subset \sum_{j=0}^{n-1} M^j(\mathcal{D}-\mathcal{D})$ for some $n\in\mathbb{N}$.

Proof. By a translation, we may assume that $0\in\mathcal{D}$. Let a and b be as in Theorem 4. Then the support of b is exactly $\Omega := \mathcal{D}-\mathcal{D}$. Let us prove the first equivalence.

Necessity. Suppose that $T(M,\mathcal{D})$ is a lattice tiling. If (5.2) does not hold, we choose a finite set K such that K contains Ω, $K\cap\big[\mathbb{Z}^s\setminus\cup_{n=1}^{\infty}(\sum_{j=0}^{n-1}M^j\Omega)\big]\ne\emptyset$, and $\ell(K)$ is invariant under $(b(M\alpha-\gamma))$.

Set

$$\Lambda := K \cap \left[\mathbb{Z}^s \setminus \cup_{n=1}^{\infty} \left(\sum_{j=0}^{n-1} M^j \Omega \right) \right].$$

Obviously, $\Lambda \subset K \setminus \Omega$. We state that

$$M^{-1}(\Omega + \Lambda) \cap \mathbb{Z}^s \subset \Lambda.$$

Since $\ell(K)$ is invariant under $(b(M\alpha - \gamma))$, we know that

$$M^{-1}(\Omega + \Lambda) \cap \mathbb{Z}^s \subset M^{-1}(\Omega + K) \cap \mathbb{Z}^s \subset K.$$

Let $\alpha = M^{-1}(\omega + \lambda) \in M^{-1}(\Omega + \Lambda) \cap \mathbb{Z}^s$ with $\omega \in \Omega$ and $\lambda \in \Lambda$. Then $\alpha \in \cup_{j=0}^{n-1} M^j \Omega$ would imply $\lambda = -\omega + M\alpha \in \cup_{j=0}^{n} M^j \Omega$, a contradiction. Therefore, $\alpha \notin \cup_{j=0}^{n-1} M^j \Omega$ for any $n \in \mathbb{N}$. Hence, $\big(M^{-1}(\Omega + \Lambda) \cap \mathbb{Z}^s\big) \cap \big[\cup_{n=1}^{\infty} (\sum_{j=0}^{n-1} M^j \Omega)\big] = \emptyset$. Thus, $M^{-1}(\Omega + \Lambda) \cap \mathbb{Z}^s \subset \Lambda$, and our statement has been proved. This contradicts the condition (4) of Theorem 4. Therefore, (5.2) must be true.

Sufficiency. Suppose (5.2) holds. Choose K as in Theorem 4. Then there exists some $n \in \mathbb{N}$ such that

$$K \subset \sum_{j=0}^{n-1} M^j \Omega. \tag{5.3}$$

Let

$$F := \big(b(M\alpha - \gamma)\big)_{\alpha, \gamma \in K}.$$

We state that

$$\big(F^n\big)_{0,\alpha} > 0 \qquad \forall \alpha \in K.$$

To see this, let $\alpha \in K$. Then (5.3) tells us that there exist $\beta_0, \beta_1, \ldots, \beta_{n-1} \in \Omega$ such that

$$\alpha = \sum_{j=0}^{n-1} M^j \beta_j = \beta_0 + M\beta_1 + \cdots + M^{n-1}\beta_{n-1}.$$

Define

$$\alpha_j := \sum_{i=n-j}^{n-1} M^{i+j-n} \beta_i = \beta_{n-j} + M\beta_{n-j+1} + \cdots + M^{j-1}\beta_{n-1}, \qquad 1 \le j \le n-1.$$

Then

$$M\alpha_{n-1} - \alpha = -\beta_0 \in \Omega \qquad \text{and} \qquad \alpha_1 = \beta_{n-1} \in \Omega.$$

Moreover, for $2 \le j \le n-1$,

$$M\alpha_{j-1} - \alpha_j = \sum_{i=n-j+1}^{n-1} M^{i+j-n} \beta_i - \sum_{i=n-j}^{n-1} M^{i+j-n} \beta_i = -\beta_{n-j} \in \Omega.$$

It follows that $F_{\alpha_{j-1},\alpha_j} = b(M\alpha_{j-1} - \alpha_j) > 0$. Hence,

$$\big(F^n\big)_{0,\alpha} \geq F_{0,\alpha_1}\big(\Pi_{j=2}^{n-1} F_{\alpha_{j-1},\alpha_j}\big) F_{\alpha_{n-1},\alpha} > 0.$$

Thus our statement holds. Hence, F^n is scrambling. By Theorem 4, $T(M, \mathcal{D})$ is a lattice tiling. This proves the sufficiency.

Using the above proof, we can see that $T(M, \mathcal{D})$ is a lattice tiling if $K \subset \sum_{j=0}^{n-1} M^j\Omega$ for some $n \in \mathbb{N}$.

To see the necessity of the second equivalence, choose $1 \leq n \leq 1 + \#(K \setminus \Omega)$ such that

$$K \setminus \sum_{j=0}^{n-1} M^j\Omega = K \setminus \sum_{j=0}^{n} M^j\Omega.$$

Set $\Lambda := K \setminus \sum_{j=0}^{n-1} M^j\Omega \subset K \setminus \Omega \subset K$. Then

$$M^{-1}(\Omega + \Lambda) \cap \mathbb{Z}^s \subset M^{-1}(\Omega + K) \cap \mathbb{Z}^s \subset K.$$

If $\alpha = M^{-1}(\omega + \lambda) \in M^{-1}(\Omega + \Lambda) \cap \mathbb{Z}^s$ with $\omega \in \Omega$ and $\lambda \in \Lambda$, then $\alpha \in \sum_{j=0}^{n-1} M^j\Omega$ would imply $\lambda = -\omega + M\alpha \in \cup_{j=0}^{n} M^j\Omega$, a contradiction. Therefore,

$$\big(M^{-1}(\Omega + \Lambda) \cap \mathbb{Z}^s\big) \cap \left[\sum_{j=0}^{n-1} M^j\Omega\right] = \emptyset.$$

Hence, $M^{-1}(\Omega + \Lambda) \cap \mathbb{Z}^s \subset \Lambda$. Since $T(M, \mathcal{D})$ is a lattice tiling, by Theorem 4, $\Lambda = \emptyset$, i.e., $K \subset \sum_{j=0}^{n-1} M^j\Omega$. Since $\#(K \setminus \Omega) \leq N - m$, the necessity of the second statement is proved. □

As a corollary we obtain another proof of the necessary condition due to Lagarias and Wang [10].

Corollary 2. *Let M be a dilation matrix and let $\mathcal{D}$ be a complete set of representatives of distinct cosets of $\mathbb{Z}^s/M\mathbb{Z}^s$. Define $T(M, \mathcal{D})$ by (1.1). If $T(M, \mathcal{D})$ is a lattice tiling, then the smallest M-invariant sublattice $\mathbb{Z}[M, \mathcal{D}]$ of $\mathbb{Z}^s$ containing the difference set $\mathcal{D} - \mathcal{D}$ is $\mathbb{Z}^s$.*

Let us give an example to show the difference between the necessary condition in [10] and the necessary and sufficient conditions in Theorem 5.

Example 2. Let M and $\mathcal{D}$ be given as

$$M := \begin{bmatrix} 2 & 1 \\ 0 & 2 \end{bmatrix}, \qquad \mathcal{D} := \left\{ \begin{bmatrix} 0 \\ 0 \end{bmatrix}, \begin{bmatrix} 3 \\ 0 \end{bmatrix}, \begin{bmatrix} 0 \\ 1 \end{bmatrix}, \begin{bmatrix} 3 \\ 1 \end{bmatrix} \right\}.$$

Then $\mathbb{Z}[M, \mathcal{D}] = \mathbb{Z}^s$ by [10]. However,

$$\begin{bmatrix} 1 \\ 0 \end{bmatrix} \notin \cup_{n=1}^{\infty} \left(\sum_{j=0}^{n-1} M^j\Omega \right).$$

Hence, $T(M, \mathcal{D})$ is not a lattice tiling.

Proof. Notice that

$$\Omega = \left\{ \begin{bmatrix} 0 \\ 0 \end{bmatrix}, \begin{bmatrix} 3 \\ 0 \end{bmatrix}, \begin{bmatrix} 0 \\ 1 \end{bmatrix}, \begin{bmatrix} 3 \\ 1 \end{bmatrix}, \begin{bmatrix} -3 \\ 1 \end{bmatrix}, \begin{bmatrix} -3 \\ 0 \end{bmatrix}, \begin{bmatrix} 0 \\ -1 \end{bmatrix}, \begin{bmatrix} -3 \\ -1 \end{bmatrix}, \begin{bmatrix} 3 \\ -1 \end{bmatrix} \right\}.$$

Then the second component of each vector in $M^j\Omega$ is in the set $\{0, 2^j, -2^j\}$.

Suppose that for some $n \in \mathbb{N}$ and $\alpha_0, \ldots, \alpha_{n-1} \in \Omega$,

$$\begin{bmatrix} 1 \\ 0 \end{bmatrix} = \sum_{j=0}^{n-1} M^j \alpha_j.$$

Comparing the second components, we see that the second components of $\alpha_0, \ldots, \alpha_{n-1}$ are all zero. But the only vectors with this property in $M^j\Omega$ are in $2^j\Omega_0$, where

$$\Omega_0 = \left\{ \begin{bmatrix} 0 \\ 0 \end{bmatrix}, \begin{bmatrix} 3 \\ 0 \end{bmatrix}, \begin{bmatrix} -3 \\ 0 \end{bmatrix} \right\}.$$

Therefore, the first component of $\sum_{j=0}^{n-1} M^j \alpha_j$ lies in $3\mathbb{Z}$, which is a contradiction. Thus, the condition of Theorem 5 does not hold, and $T(M, \mathcal{D})$ is not a lattice tiling. □

The condition $K \subset \sum_{j=0}^{n-1} M^j(\mathcal{D} - \mathcal{D})$ can be reduced into the *knapsack problem*, which can be solved by a polynomial-time algorithm for the fixed n (see, e.g., [14]). The necessity condition $\mathbb{Z}[M, \mathcal{D}] = \mathbb{Z}^s$ can be easily checked by the solvability of linear diophantine equations.

6. Examples. In this section we provide some examples to show the applicability of the characterizations stated in Theorems 4 and 5.

Example 3. Let M be the dilation matrix

$$M = \begin{bmatrix} a & b \\ 0 & c \end{bmatrix}$$

with $a > 1, c > 1$. Choose $\{k_0 = 0, k_1, \ldots, k_{a-1}\} \subset \mathbb{Z}$ and $\{p_0 = 0, p_1, \ldots, p_{c-1}\} \subset \mathbb{Z}$ such that $k_j \equiv j(\mathrm{mod} a)$ and $p_i \equiv i(\mathrm{mod} c)$. Let $l_0, l_1, \ldots, l_{c-1}$ be arbitrary integers and set

$$\mathcal{D} = \left\{ \begin{bmatrix} l_i + k_j \\ p_i \end{bmatrix} : \quad i = 0, 1, \ldots, c-1; \, j = 0, 1, \ldots, a-1 \right\}.$$

Then $\mathcal{D}$ is a complete set of representatives of distinct cosets of $\mathbb{Z}^2/M\mathbb{Z}^2$. The self-similar tiling $T(M, \mathcal{D})$ is a lattice tiling if and only if $\gcd(k_1, \ldots, k_{a-1}) = 1$ and $\gcd(p_1, \ldots, p_{c-1}) = 1$.

Proof. Let $\varepsilon_1 = (l_{i_1} + k_{j_1}, p_{i_1})^T, \varepsilon_2 = (l_{i_2} + k_{j_2}, p_{i_2})^T \in \mathcal{D}$. Suppose $\varepsilon_1 - \varepsilon_2 \in M\mathbb{Z}^2$. Then for some $\beta = (\beta_1, \beta_2)^T \in \mathbb{Z}^2$,

$$\varepsilon_1 - \varepsilon_2 = \begin{bmatrix} l_{i_1} + k_{j_1} - l_{i_2} - k_{j_2} \\ p_{i_1} - p_{i_2} \end{bmatrix} = M\beta = \begin{bmatrix} a\beta_1 + b\beta_2 \\ c\beta_2 \end{bmatrix}.$$

Both i_1 and i_2 are in $\{0, 1, \ldots, c-1\}$ and $p_i \equiv i(\mathrm{mod} c)$. Hence, $\beta_2 = 0$ and $i_1 = i_2$. It follows that $k_{j_1} - k_{j_2} = a\beta_1 \in a\mathbb{Z}$. But $k_j \equiv j(\mathrm{mod} a)$. We know that $j_1 = j_2$, i.e., $\varepsilon_1 = \varepsilon_2$. This proves that $\mathcal{D}$ is a complete set of representatives of distinct cosets of $\mathbb{Z}^2/M\mathbb{Z}^2$.

To see the second statement, first prove the sufficiency. Suppose $\gcd(k_1, \ldots, k_{a-1}) = 1$ and $\gcd(p_1, \ldots, p_{c-1}) = 1$. We show that $\mathbb{Z}^2 \subset \cup_{n=1}^{\infty} \sum_{j=0}^{n-1} M^j(\mathcal{D} - \mathcal{D})$. Then by Theorem 5, $T(M, \mathcal{D})$ is a lattice tiling.

Let $\alpha = (\alpha_1, \alpha_2)^T \in \mathbb{Z}^2$. Theorem 5 in connection with the characterization of univariate self-similar lattice tilings in [5, 21] (see also the introduction) tells us that there are $n \in \mathbb{N}$ and $i_0, i_1, \ldots, i_{n-1}, \tilde{i}_0, \tilde{i}_1, \ldots, \tilde{i}_{n-1} \in \{0, 1, \ldots, c-1\}$ such that

$$\alpha_2 = \sum_{j=0}^{n-1} c^j (p_{i_j} - p_{\tilde{i}_j}).$$

Then in the same way, there are $N \in \mathbb{N}$ and $\{n_j, \tilde{n}_j\}_{j=0}^{N-1} \subset \{0, 1, \ldots, a-1\}$ such that

$$\sum_{j=0}^{N-1} a^j (k_{n_j} - k_{\tilde{n}_j}) = \alpha_1 - \sum_{j=0}^{n-1} a^j (l_{i_j} - l_{\tilde{i}_j}) - \sum_{j=0}^{n-1} b(p_{i_j} - p_{\tilde{i}_j}) \sum_{q=0}^{j-1} a^q c^{j-1-q}.$$

We may assume that $N \geq n$, since otherwise we need only to choose $n_j = \tilde{n}_j$ for $j = N, \ldots, n-1$.

Observe that

$$M^j = \begin{bmatrix} a^j & b\sum_{q=0}^{j-1} a^q c^{j-1-q} \\ 0 & c^j \end{bmatrix}.$$

Take $i_j = \tilde{i}_j$ for $j = n, \ldots, N-1$. Then

$$\sum_{j=0}^{N-1} M^j \left(\begin{bmatrix} l_{i_j} + k_{n_j} \\ p_{i_j} \end{bmatrix} - \begin{bmatrix} l_{\tilde{i}_j} + k_{\tilde{n}_j} \\ p_{\tilde{i}_j} \end{bmatrix} \right)$$
$$= \begin{bmatrix} \sum_{j=0}^{N-1} a^j (k_{n_j} - k_{\tilde{n}_j}) + \sum_{j=0}^{n-1} a^j (l_{i_j} - l_{\tilde{i}_j}) + \sum_{j=0}^{n-1} b(p_{i_j} - p_{\tilde{i}_j}) \sum_{q=0}^{j-1} a^q c^{j-1-q} \\ \sum_{j=0}^{n-1} c^j (p_{i_j} - p_{\tilde{i}_j}) \end{bmatrix}.$$

The first component of this vector is exactly α_1, while the second is α_2. Therefore, $\alpha \in \sum_{j=0}^{N-1} M^j(\mathcal{D} - \mathcal{D})$. Hence, $\mathbb{Z}^2 \subset \cup_{n=1}^{\infty} \sum_{j=0}^{n-1} M^j(\mathcal{D} - \mathcal{D})$.

To see the necessity, suppose $T(M, \mathcal{D})$ is a lattice tiling. Then by Theorem 5, $\mathbb{Z}^2 \subset \cup_{n=1}^{\infty} \sum_{j=0}^{n-1} M^j(\mathcal{D} - \mathcal{D})$.

Let $N \in \mathbb{N}$ and $\{i_j, \tilde{i}_j\}_{j=0}^{N-1} \subset \{0, 1, \ldots, c-1\}, \{n_j, \tilde{n}_j\}_{j=0}^{N-1} \subset \{0, 1, \ldots, a-1\}$. Then

$$\begin{aligned} &\sum_{j=0}^{N-1} M^j \left(\begin{bmatrix} l_{i_j} + k_{n_j} \\ p_{i_j} \end{bmatrix} - \begin{bmatrix} l_{\tilde{i}_j} + k_{\tilde{n}_j} \\ p_{\tilde{i}_j} \end{bmatrix} \right) \\ &= \begin{bmatrix} \sum_{j=0}^{N-1} a^j (l_{i_j} - l_{\tilde{i}_j} + k_{n_j} - k_{\tilde{n}_j}) + \sum_{j=0}^{N-1} b(p_{i_j} - p_{\tilde{i}_j}) \sum_{q=0}^{j-1} a^q c^{j-1-q} \\ \sum_{j=0}^{n-1} c^j (p_{i_j} - p_{\tilde{i}_j}) \end{bmatrix}. \end{aligned} \tag{6.1}$$

The second component of (6.1) is divisible by $\gcd(p_1, \ldots, p_{c-1})$. Therefore, there must hold $\gcd(p_1, \ldots, p_{c-1}) = 1$.

We also know that $(1, 0)^T \in \sum_{j=0}^{N-1} M^j(\mathcal{D} - \mathcal{D})$ for some N. Suppose the vector (6.1) equals $(1, 0)^T$. Then

$$\sum_{j=0}^{N-1} c^j (p_{i_j} - p_{\tilde{i}_j}) = 0.$$

Hence, $p_{i_0} - p_{\tilde{i}_0} \in c\mathbb{Z}$. But $p_i \equiv i (\mathrm{mod} c)$. Therefore, $i_0 = \tilde{i}_0$. In the same way, $i_1 = \tilde{i}_1, \ldots, i_{N-1} = \tilde{i}_{N-1}$.

Consider the first component of (6.1). It states that

$$1=\sum_{j=0}^{N-1} a^j (k_{n_j}-k_{\tilde{n}_j}).$$

This is divisible by $\gcd(k_1,\dots,k_{a-1})$. Hence, $\gcd(k_1,\dots,k_{a-1})=1$. □

If we take $a=c=2, b=0, p_1=1, k_1=3$, and $l_0=l_1=0$, we obtain Example 2. The case $p_i=i, k_j=j$ was proved in [5].

Let us turn to the necessary condition $\mathbb{Z}[M,\mathcal{D}]=\mathbb{Z}^s$ in our special example. Assume $l_0, = l_1=\cdots=l_{c-1}=0$.

Example 4. Let $M,\mathcal{D}$ as in Example 3 and $l_0=l_1=\cdots=l_{c-1}=0$. Then $\mathbb{Z}[M,\mathcal{D}]=\mathbb{Z}^2$ if and only if $\gcd(p_1,\dots,p_{c-1})=1$ and $\gcd(b,k_1,\dots,k_{a-1})=1$.

Proof. Since $0\in\mathcal{D}, \mathbb{Z}[M,\mathcal{D}]=\mathbb{Z}[\mathcal{D},M\mathcal{D}]$ as shown in [10]. Let Δ be a $2\times(ac)$ matrix whose columns are vectors in $\mathcal{D}$. Then the solvability of linear diophantine equations tells us that $\mathbb{Z}[\mathcal{D},M\mathcal{D}]=\mathbb{Z}^2$ if and only if the greatest common divisor of 2×2 minors of the matrix $[\Delta, M\Delta]$ is one. Note that the columns of $M\Delta$ have the form

$$M\begin{bmatrix} k_j \\ p_i \end{bmatrix} = \begin{bmatrix} ak_j+bp_i \\ cp_i \end{bmatrix}.$$

Each entry of the first row of the matrix $[\Delta, M\Delta]$ is divisible by $\gcd(b,k_1,\dots,k_{a-1}) = 1$, while each entry of the second row is divisible by $\gcd(p_1,\dots,p_{c-1})=1$. The necessity follows easily.

Conversely, if $\gcd(p_1,\dots,p_{c-1})=\gcd(b,k_1,\dots,k_{a-1})=1$, we choose the following 2×2 minors of the matrix $[\Delta, M\Delta]$:

$$\begin{vmatrix} k_j & 0 \\ 0 & p_i \end{vmatrix} = k_j p_i, \qquad \begin{vmatrix} bp_i & 0 \\ cp_i & p_{\tilde{i}} \end{vmatrix} = bp_i p_{\tilde{i}}.$$

The greatest common divisor of these minors is

$$\gcd\bigl(\gcd(k_1,\dots,k_{a-1})\cdot\gcd(p_1,\dots,p_{c-1}), \quad b\cdot[\gcd(p_1,\dots,p_{c-1})]^2\bigr),$$

which equals one. Therefore, the greatest common divisor of 2×2 minors of the matrix $[\Delta, M\Delta]$ is one, and $\mathbb{Z}[M,\mathcal{D}]=\mathbb{Z}^2$. □

Example 5. Let $2\le m\in\mathbb{N}$ and let $M=mI_s$. If $\mathcal{D}$ is a complete set of representatives of distinct cosets of $\mathbb{Z}^s/M\mathbb{Z}^s$ and

$$\Bigl\{0,1,\dots,\Bigl[\frac{m}{2}\Bigr]\Bigr\}^s\subset\mathcal{D},$$

then $T(M,\mathcal{D})$ is a lattice tiling.

Proof. By our assumption,

$$\Bigl\{-\Bigl[\frac{m}{2}\Bigr],\dots,-1,0,1,\dots,\Bigl[\frac{m}{2}\Bigr]\Bigr\}^s\subset\mathcal{D}-\mathcal{D}.$$

Then for $n\in\mathbb{N}$,

$$\Bigl[-\Bigl[\frac{m}{2}\Bigr]\frac{m^n-1}{m-1}, \quad \Bigl[\frac{m}{2}\Bigr]\frac{m^n-1}{m-1}\Bigr]^s\cap\mathbb{Z}^s\subset\sum_{j=0}^{n-1}M^j(\mathcal{D}-\mathcal{D}).$$

Therefore, for sufficiently large n,

$$K \subset \sum_{j=0}^{n-1} M^j(\mathcal{D} - \mathcal{D}).$$

By Theorem 5, $T(M, \mathcal{D})$ is a lattice tiling. $\square$

In particular, for $M = \left[\begin{smallmatrix}3 & 0\\ 0 & 3\end{smallmatrix}\right]$, if $\mathcal{D}$ contains $(0,0)^T, (1,0)^T, (0,1)^T, (1,1)^T$, then $T(M, \mathcal{D})$ is a lattice tiling.

PARAMETRICALLY EXCITED HAMILTONIAN PARTIAL DIFFERENTIAL EQUATIONS[*]

E. KIRR[†] AND M. I. WEINSTEIN[‡]

Abstract. Consider a linear autonomous Hamiltonian system with a time-periodic bound state solution. In this paper we study the structural instability of this bound state relative to time almost periodic perturbations which are small, localized, and Hamiltonian. This class of perturbations includes those whose time dependence is periodic but encompasses a large class of those with finite (quasi-periodic) or infinitely many noncommensurate frequencies. Problems of the type considered arise in many areas of applications including ionization physics and the propagation of light in optical fibers in the presence of defects. The mechanism of instability is radiation damping due to resonant coupling of the bound state to the continuum modes by the time-dependent perturbation. This results in a transfer of energy from the discrete modes to the continuum. The rate of decay of solutions is slow and hence the decaying bound states can be viewed as metastable. These results generalize those of A. Soffer and M. I. Weinstein, who treated localized time-periodic perturbations of a particular form. In the present work, new analytical issues need to be addressed in view of (i) the presence of infinitely many frequencies which may resonate with the continuum as well as (ii) the possible accumulation of such resonances in the continuous spectrum. The theory is applied to a general class of Schrödinger operators.

Key words. Hamiltonian partial differential equations, parametric resonance, time-dependent perturbation theory, Fermi golden rule, energy transfer, metastable states

1. Introduction.

1.1. Overview.

Consider a dynamical system of the form

$$i\partial_t\phi \;=\; H_0\;\phi, \tag{1.1}$$

where H_0 denotes a self-adjoint operator on a Hilbert space $\mathcal{H}$. We further assume that H_0 has only one eigenstate $\psi_0 \in \mathcal{H}$ with corresponding simple eigenvalue λ_0. Thus,

$$b_*(t) \;=\; e^{-i\lambda_0 t}\psi_0 \tag{1.2}$$

is a time-periodic *bound state* solution of the dynamical system (1.1). We next introduce the perturbed dynamical system

$$i\partial_t\phi \;=\; (H_0 \;+\; \varepsilon W(t))\,\phi. \tag{1.3}$$

In this paper we prove that if the perturbation, $\varepsilon W(t)$, is small, "generic," and almost periodic in time,[1] then solutions of the perturbed dynamical system (1.3) tend to zero

[1] See the appendix in section 9 as well as [2, 9] for definitions and results on almost periodic functions.

as $t \to \pm\infty$. It follows that the state, $b_*(t)$, does not continue or deform to a time-periodic or even time-almost-periodic state. Thus, $b_*(t)$ is structurally unstable with respect to this class of perturbations. Our methods yield a detailed description of the transient (t large but finite) and long time ($t \to \pm\infty$) behavior solutions to the initial value problem. Theorems 2.1–2.3 contain precise statements of our main results. The following picture emerges concerning time evolution (1.3) for initial data given by the bound state, ψ_0, of the unperturbed problem. Let

$$P(t) = |(\ \psi_0, \phi(t)\ )|^2 \tag{1.4}$$

be the modulus square of the projection of the solution at time t onto the state ψ_0.[2] Then,

(i) $P(t)\ \sim\ 1 - C_W\ |t|^2$ for $|t|$ small,[3]

(ii) $P(t)\ \sim\ \exp(-2\varepsilon^2\Gamma t)$ for $t \le \mathcal{O}((\varepsilon^2\Gamma)^{-1}),\ \Gamma\ = \mathcal{O}(W^2)$, and

(iii) $P(t)\ \sim\ \langle t\rangle^{-\alpha}$ for $|t| >> (\varepsilon^2\Gamma)^{-1}$ for some $\alpha > 0$.

The time $\tau\ =\ (\varepsilon^2\Gamma)^{-1}$ is called the *lifetime* of the state $b_*(t)$, which can be thought of as being *metastable* due to its slow decay. The mechanism for large time decay is resonant coupling of the bound state with continuous spectrum due to the time-dependent perturbation. Our analysis makes explicit the slow transfer of energy from the discrete to continuum modes and the accompanying radiation of energy out of any compact set.

Phenomena of the type considered here are of importance in many areas of theoretical physics and applications. Examples include ionization physics [3, 4, 10] and the propagation of light in optical fibers in the presence of defects [13]; see the discussion below.

The results of this article generalize those of Soffer and Weinstein [22], where the case

$$W(t)\ =\ \cos(\mu t)\ \beta,\quad \beta = \beta^* \tag{1.5}$$

was considered. The method used is a time-dependent/dynamical systems approach introduced in [21], [23] in a perturbation theory of operators with embedded eigenvalues in their continuous spectrum. These ideas were also used in a study of resonant radiation damping of nonlinear systems [24], as well as in a class of parametric resonance problems [22]; see also [12]. New analytical questions must be addressed in view of (i) the presence of infinitely many frequencies which may resonate with the continuum as well as (ii) the possible accumulation of such resonances in the continuous spectrum. This leads to a careful use of almost periodic properties of the perturbation (Theorems 2.1 and 2.2) and hypothesis **(H6)** (Theorem 2.3), which is easily seen to hold when the perturbation, $W(t)$, consists of a sum over a finite number of frequencies, μ_j.

A special case for which the hypotheses of our theorems are verified is the case of the Schrödinger operator $H_0\ =\ -\Delta\ +\ V(x)$. Here, $V(x)$ is a real-valued function of $x \in \mathbb{R}^3$ which decays sufficiently rapidly as $|x| \to \infty$. In this setting Soffer and Weinstein [22] studied in detail the structural instability of $b_*(t)$ by considering the perturbed dynamical system (1.3) with $W(x,t)\ =\ \beta(x)\ \cos(\mu t)$. Here, we consider

[2] (f, g) denotes the inner product of f and g. If ψ_0 is normalized, then $P(t)$ has the quantum mechanical interpretation of the probability that the system at time t is in the state ψ_0.

[3] We do not discuss the short time behavior in this article; see [12]. This small time behavior is related to the “watched pot” effect in quantum measurement theory [15].

a class of perturbations of the form $W(x,t) \;=\; \sum_j \; \beta_j(x) \;\; \cos \mu_j t$, where the sum may be finite or infinite and where the frequencies μ_j need not be commensurate, e.g., $W(x,t) \;=\; \beta_1(x) \;\; \cos t \;+\; \beta_2(x) \;\; \cos \sqrt{2}t$, where $\beta_i(x),\;\; i = 1,2$, is rapidly decaying as $x \to \infty$.

In addition to the problem of ionization by general time-varying fields, we mention other motivations for considering the class of time-dependent perturbations sketched above and defined in detail in section 2.

(a) An area of application to which our analysis applies is the propagation of light through an optical fiber [13]. In the regime where backscattering can be neglected, the propagation of waves down the length of the fiber is governed by a Schrödinger equation:

$$i\partial_z \phi \;=\; (\; -\Delta_\perp \;+\; V(x_\perp))\,\phi \;+\; W(x_\perp, z)\phi. \tag{1.6}$$

Here, ϕ denotes the slowly varying envelope of the highly oscillatory electric field, a function of z, the direction of propagation along the fiber, and $x_\perp \in \mathbb{R}^2$, the transverse variables. $V(x_\perp)$ denotes an unperturbed index of refraction profile and $W(x_\perp, z)$ the small fluctuations in refractive index along the fiber. These can arise due to defects introduced either accidentally or by design. The models considered allow for distributions of defects which are far more general than periodic. Our analysis addresses the simple situation of energy in a single transverse mode propagating and being radiated away due to coupling by defects to continuum modes. The bound state channel sees an effective damping. In particular the results of this paper have been applied to a study of structural instability of so-called breather modes of planar "soliton wave guides" [12]. The case of multiple transverse modes is of great interest [13]. Here, one has the phenomena of coupling among discrete modes as well as the coupling of discrete to continuum/radiation modes [7]. There is extensive interesting work on this problem in the case where $W(x_\perp, z)$ is a stochastic process in z and radiation is neglected [8].

(b) Nonlinear problems can be viewed as linear time-dependent potential problems where the time-dependent potential is given by the solution. *A priori* one knows little about the time dependence of the solution of a nonlinear problem. Nonlinearity is expected, in general, to excite infinitely many frequencies. Therefore results of a general nature for potentials with very general time dependence are of interest. This point of view is adopted by Sigal [19, 20], who considers the case where the nonlinear term defines a time-periodic perturbation and then proceeds to study the resonance problem via time-independent Floquet analysis applied to the so-called Floquet Hamiltonian. The dilation analytic techniques used were first applied in the context of time-periodic Hamiltonians by Yajima [26, 27, 28]. Floquet-type methods were also used in the time-periodic context by Vainberg [25]. The general class of perturbations we consider are not treatable by Floquet analysis and time-dependent analysis appears necessary.

1.2. Outline of the method. We now give a brief outline of our approach. For simplicity consider the initial value problem

$$i\partial_t \phi(t,x) \;=\; H_0 \;\phi(t,x) \;+\; \varepsilon W(t,x)\;\phi(t,x), \tag{1.7}$$

$$\phi|_{t=0} \;=\; \phi(0), \tag{1.8}$$

where

$$H_0 = -\Delta \; + V(x),\;\; W(t,x) = g(t)\;\beta(x),\;\; g(t) = \sum_j \; g_j \; e^{-i\mu_j t} \tag{1.9}$$

is a real-valued almost periodic function of t, and $\beta(x)$ is a real-valued and rapidly decaying function of x as $|x| \to \infty$. The unperturbed problem ($\varepsilon = 0$) can be trivally written as two decoupled equations governing the bound state amplitude, $a(t)$, and dispersive components, $\phi_d(t)$, of the solution. Specifically, let

$$\phi(t) \ = \ a(t)\ \psi_0(x) \ + \ \phi_d(t,x), \ (\psi_0, \phi_d(t)) \ = \ 0. \tag{1.10}$$

Then,

$$\begin{aligned} i\partial_t a(t) &= \lambda_0 a(t), \\ i\partial_t \ \phi_d(t,x) &= H_0 \ \phi_d(t,x) \end{aligned} \tag{1.11}$$

with initial conditions

$$\begin{aligned} a(0) &= (\psi_0, \phi(0))\,, \\ \phi_d(0) &= \mathbf{P_c}\phi(0), \end{aligned} \tag{1.12}$$

where

$$\mathbf{P_c} f \equiv \ f - (\psi_0, f)\, \psi_0$$

defines the projection onto the continuous spectral part of H_0.

For initial data $a(0) = 1$, $\phi_d(0) = 0$, we have $a(t) = e^{-i\lambda_0 t}$, $\phi_d(t) \equiv 0$, corresponding to the bound state, $b_*(t)$.

We now ask the following:

(a) *Under the small perturbation $\varepsilon W(t,x)$, does the bound state deform or continue to a nearby periodic or even almost periodic solution?*

(b) *How do solutions to the perturbed initial value problem behave as $|t| \to \infty$?*

For small perturbations $\varepsilon W(t,x)$ it is natural to use the decomposition (1.10). Substitution of (1.10) into (1.3) yields a weakly coupled system for $a(t)$ and $\phi_d(t)$. This system is derived and analyzed in detail in sections 4–6.

In order to illustrate the main idea, we introduce a simplified system having the same general character:

$$\begin{aligned} i\partial_t a(t) \ &= \ \lambda_0 \ a(t) \ + \ \varepsilon g(t) \ (\beta\psi_0, \phi_d(t)) \\ i\partial_t \phi_d(t,x) \ &= \ -\Delta\phi_d(t,x) \ + \ \varepsilon a(t) g(t) \beta(x) \psi_0(x). \end{aligned} \tag{1.13}$$

Here, we have replaced H_0 on its continuous spectral part by $-\Delta$.

If $\varepsilon\beta$ is small, then $A(t) \equiv e^{i\lambda_0 t} a(t)$ is slowly varying ($\partial_t A(t) = \mathcal{O}(\varepsilon\beta)$). In particular, we have

$$\begin{aligned} i\partial_t A(t) \ &= \ \varepsilon e^{i\lambda_0 t} \ g(t) \ (\beta\psi_0, \phi_d(t)) \\ i\partial_t \phi_d(t,x) \ &= \ -\Delta\phi_d(t,x) \ + A(t) e^{-i\lambda_0 t} \ \varepsilon g(t) \beta(x) \psi_0(x). \end{aligned} \tag{1.14}$$

Viewing $A(t)$ as nearly constant, we see that the inhomogeneous source term in (1.14) has frequencies $\lambda_0 + \mu_j$; see (1.9). Therefore, if $\lambda_0 + \mu_j > 0$ for some j, then $\lambda_0 + \mu_j$ lies in the continuous spectrum of $-\Delta$ (H_0) and therefore ϕ_d satisfies a resonantly forced wave equation. A careful expansion and analysis to second order in the perturbation $\varepsilon W(t)$ (see the proof of Proposition 4.1) reveals the system for $A(t)$ and $\phi_d(t)$ can be rewritten in the following form, in which the effect of this resonance is made explicit:

$$\partial_t A(t) \ = \ (-\varepsilon^2 \Gamma \ + \ \rho(t))\ A(t) \ + \ E(t; A(t), \phi_d(t)), \tag{1.15}$$

$$i\partial_t \phi_d(t,x) \ = \ H_0 \ \phi_d(t,x) \ + \ \mathbf{P_c} \ F(t,x; A(t), \phi_d(t)). \tag{1.16}$$

The terms $E(t)$ and $F(t,x)$ formally tend to zero if $A(t)$ tends to zero and if the "local energy" of $\phi_d(t)$ tends to zero as $t \to \infty$. The strategy of sections 5 and 6 is to derive coupled estimates for $A(t)$ and a measure of the local energy of ϕ_d from which one can conclude, for $\varepsilon W(t)$ small, that solutions to (1.15)–(1.16) decay in an appropriate sense. The key to the decay of solutions is the constant Γ, given by

$$\Gamma \;\equiv\; \frac{\pi}{4} \sum_{\{j\ :\ \lambda_0+\mu_j>0\}} |g_j|^2\ \left(\mathbf{P_c}\beta\psi_0,\ \delta(H_0-\lambda_0-\mu_j)\mathbf{P_c}\beta\psi_0\right); \tag{1.17}$$

see also hypothesis **(H5)** of section 2. The quantity Γ is a generalization of the well-known Fermi golden rule arising in the theory of radiative transitions in quantum mechanics [3, 4, 10]. For the example at hand, (1.9), the sum in (1.17) is over all j for which $\mu_j+\lambda_0$ is strictly positive, i.e., lies in the continuous spectrum of H_0. Thinking of H_0 as having a spectral decomposition in terms of eigenfunctions and generalized eigenfunctions, let $e(\lambda)$ denote a generalized eigenfunction associated with the energy λ. Then each term in the sum (1.17) is of the form

$$|(\ e(\lambda_0+\mu_j), \beta\psi_0\ )|^2\,. \tag{1.18}$$

Thus, clearly $\Gamma > 0$, generically.

Neglecting for the moment the oscillatory function $\rho(t)$ in (1.15), we see that coupling of the bound state by the time dependent perturbation to the continuum-radiation modes, at the frequencies $\mu_j+\lambda_0>0$, leads to decay of the bound state. The leading order of (1.15)–(1.16) is a normal form in which this internal damping effect is made explicit; energy is transferred from the discrete to the continuous spectral components of the solution while the total energy remains independent of time:

$$\begin{aligned} \|\ \phi(t)\ \|_2^2 \;&=\; |a(t)|^2 \;+\; \|\ \phi_d(t)\ \|_2^2 \\ &=\; |a(0)|^2 \;+\; \|\ \phi_d(0)\ \|_2^2. \end{aligned} \tag{1.19}$$

1.3. Energy flow; contrast with the analysis of [22]. The goal is to show that energy flows out of the bound state channel into dispersive spectral components. The normal form above is the system in which this energy flow is made explicit. Once the normal form (1.15)–(1.16) has been derived, it is natural to seek coupled estimates for $A(t)$ and $\phi_d(t)$ from which their decay can be deduced. This is implemented in section 6. A natural first step is to introduce the auxiliary function

$$\tilde{A}(t) \;\equiv\; e^{\int_0^t\ \rho(s)\ ds}\ A(t) \tag{1.20}$$

for then $\tilde{A}(t)$ satisfies simplified equation of the form

$$\partial_t\tilde{A}(t) \;=\; -\varepsilon^2\Gamma\ \tilde{A}(t) \;+\; \tilde{E}(t;\tilde{A}(t),\phi_d(t)). \tag{1.21}$$

If $\Re\int_0^t\ \rho(s)\ ds$ is uniformly bounded, then modulo time-decay estimates on $\tilde{E}(t;\tilde{A},\phi_d)$ and $F(t;\tilde{A},\phi_d)$, the decay of $\tilde{A}(t)$ and therefore of $A(t)$ follows. For the class of perturbations considered in [22], $\rho(t)$ is a periodic function, having only a finite number of commensurate frequencies, none of them zero. Therefore, in this case $\Re\int_0^t\ \rho(s)\ ds$ is uniformly bounded. However, in the present case $\rho(t)$ is almost periodic with mean $M(\Re\rho)=0$ (see section 9); $\rho(t)$ is displayed in (4.12). $\Re\rho(t)$ has, in general, infinitely many frequencies, $\mu_k-\mu_j,\ k\neq j$ which may accumulate at zero. Most delicate is the case where, along some subsequence, $\mu_k-\mu_j\to 0$. It is well known that the integral of an almost periodic function of mean zero is not necessarily bounded [2], so we are in need of a strategy for estimating the effects of $\Re \int_0^t \rho(s)\, ds$. We address the estimation of $\Re \int_0^t \rho(s)\, ds$ in two different ways corresponding to Theorem 2.3 (see also section 5.1) and Theorems 2.1–2.2 (see also section 5.2). In section 5.1 $\Re \int_0^t \rho(s)\, ds$ is estimated under the hypothesis **(H6)** which requires that the rate of accumulation of a subset of frequencies $\{\mu_j\}_{j\in I}$ is balanced by the decay of the Fourier coefficients g_j as $j \to \infty,\ j \in I$. This leads to a bound on $\Re \int_0^t \rho(s)\, ds$ (Proposition 5.2). In section 5.2 the estimates are based on a more refined analysis; the almost periodic function $\rho(t)$ is decomposed into a part with bounded integral and a part which has mean zero. The latter is controlled using results on the rate at which an almost periodic function approaches its mean.

1.4. Fermi golden rule and obstructions to Poincaré continuation. In the theory of ordinary differential equations it is a standard procedure, given a periodic solution of an unperturbed problem, to seek a periodic or almost periodic solution of a slightly perturbed dynamical system. We now investigate this procedure in the context of (1.7) and its solution $b_*(t)$ for $\varepsilon = 0$. Seek a solution of the form

$$\phi(t) \;=\; b_*(t) \;+\; \phi_1(t) \;+\; \mathcal{O}(\varepsilon^2\beta^2). \tag{1.22}$$

Here, $\phi_1 \;=\; \mathcal{O}(\varepsilon\beta)$.[4] Substitution of (1.22) into (1.7) yields the equation

$$i\partial_t\phi_1 \;=\; H_0\phi_1 \;+\; \varepsilon\beta\, g(t)\, b_*(t). \tag{1.23}$$

This equation has a solution in the class of almost periodic solutions of t with values in the Hilbert space $\mathcal{H}$ only if $\beta\, g(t)\, b_*(t)$ is “orthogonal” to the null space of $i\partial_t - H_0$.

We now derive this condition. Let $e(\zeta)$ be a solution of $H_0 e(\zeta) = \zeta e(\zeta)$. Then, taking the scalar product of (1.23) with $e^{-i\zeta t}\, e(\zeta)$ and applying the operator $\lim_{T\uparrow\infty} T^{-1}\int_0^T \cdot\, dt$ to the resulting equation gives

$$0 \;=\; \lim_{T\uparrow\infty}\, T^{-1}\int_0^T\; e^{i\zeta t}\; e^{-i\lambda_0 t}\; g(t)\; dt\;\; (e(\zeta), \beta\psi_0)\,. \tag{1.24}$$

Substitution of the expansion for $g(t)$ yields

$$\sum_{j\in\mathbb{Z}} g_j\; \delta(\zeta, \lambda_0 + \mu_j)\;\; (e(\zeta), \beta\psi_0) \;=\; 0, \tag{1.25}$$

where $\delta(a,b) \;=\; 0$ if $a \;\neq\; b$ and $\delta(a,a) \;=\; 1$. If ζ, which lies in the spectrum of H_0, satisfies $\zeta \;=\; \lambda_0 + \mu_k$ for some $k \in \mathbb{Z}$ (which will be the case in our example if $\lambda_0 + \mu_k > 0$), then we have that

$$(e(\lambda_0 + \mu_k), \beta\psi_0) \;=\; 0 \tag{1.26}$$

is a necessary condition for the existence of a family of solutions of (1.7) which converges to $b_*(t)$ as the perturbation $W(t)$ tends to zero. We immediately recognize the inner product in (1.26) as the projection of $\beta\psi_0$ onto the generalized eigenmode at the resonant frequency $\lambda_0 + \mu_k$ which arises in (1.17); see also (1.18). Therefore the obstruction to continuation of $b_*(t)$ to a nearby almost periodic state of the system can be identified with the damping mechanism.

[4] This argument is heuristic so we do not specify the norm with which the size of β is measured.

1.5. Outline. The paper is structured as follows. In section 2 we give a general formulation of the problem. The hypotheses on H_0, the unperturbed Hamiltonian, and $W(t)$, the perturbation, are introduced and discussed. There are two types of theorems: Theorems 2.1 and 2.2 and Theorem 2.3. Although the conclusions of these are quite similar, as discussed above, they differ in a key hypothesis on the perturbation $W(t)$, which is relevant in the case where $W(t)$ has infinitely many frequencies which may resonate with the continuous spectrum. In section 3 we apply the results of section 2 to the case of Schrödinger operators $H_0 = -\Delta + V(x)$ defined on $L^2(\mathbb{R}^3)$. To check the key local energy decay hypotheses we use results of Jensen and Kato [5] on expansions of the resolvent of H_0 near zero energy, the edge of the continuous spectrum. In section 4 the dynamical system (1.3) is reformulated as a system governing the interaction of the bound state and dispersive part of the solution. This section contains an important computation in which the key resonance is made explicit and a perturbed "normal form" for the bound state evolution is derived (Proposition 4.1). Sections 5 and 6 contain estimates for the bound state and dispersive parts of the solution for intermediate and large time scales. In section 7 we discuss extensions of our Theorems 2.1–2.3 to a more general class of perturbations. We shall frequently make use of some singular operators which are rigorously defined in section 8, an appendix, and of elements of the theory of almost periodic functions [2, 9], which are assembled in section 9, the second appendix.

Notations and terminology. Throughout this paper we will use the following notations:

$\mathbb{N} = \{1,\ 2,\ 3,\ldots\}$;

$\mathbb{N}_0 = \{0,\ 1,\ 2,\ 3,\ldots\}$;

$\mathbb{Z} = \{\ldots,-3,\ -2,\ -1,\ 0,\ 1,\ 2,\ 3,\ldots\}$;

for z a complex number, $\Re z$ and $\Im z$ denote, respectively, its real and imaginary parts; a generic constant will be denoted by C, D, etc;

$\langle x\rangle = \left(1+|x|^2\right)^{\frac{1}{2}}$;

$\mathcal{L}(\mathcal{A},\mathcal{B}) =$ the space of bounded linear operators from $\mathcal{A}$ to $\mathcal{B}$; $\mathcal{L}(\mathcal{A},\mathcal{A}) \equiv \mathcal{L}(\mathcal{A})$.

Functions of self-adjoint operators are defined via the spectral theorem; see, for example, [17]. The operators containing boundary value of resolvents or singular distributions applied to self-adjoint operators are defined in section 8.

2. General formulation and main results.

Consider the general system

$$\begin{aligned} i\partial_t\phi(t) &= \left(H_0 + W(t)\right)\phi(t),\\ \phi|_{t=0} &= \phi(0). \end{aligned} \tag{2.1}$$

Here, $\phi(t)$ denotes a function of time, t, with values in a complex Hilbert space $\mathcal{H}$.

Hypotheses on H_0.

(H1) H_0 is self-adjoint on $\mathcal{H}$ and both H_0 and $W(t),\ t\in\mathbb{R}^1$, are densely defined on a subspace $\mathcal{D}$ of $\mathcal{H}$.

The norm on $\mathcal{H}$ is denoted by $\|\cdot\|$ and the inner product of $f,g\in\mathcal{H}$, by (f,g).

(H2) The spectrum of H_0 is assumed to consist of an absolutely continuous part, $\sigma_{\rm cont}(H_0)$, with associated spectral projection $\mathbf{P_c}$ and a single isolated eigenvalue λ_0 with corresponding normalized eigenstate, ψ_0, i.e.,

$$H_0\psi_0 = \lambda_0\psi_0,\ \|\psi_0\| = 1. \tag{2.2}$$

The manner in which we shall measure the decay of solutions is typically in a local decay sense, e.g., for the scalar Schrödinger equation governing a function defined on

$\mathbb{R}^n$ we measure local decay using the norms $f \mapsto \|\langle x\rangle^{-s} f\|_{L^2}$, where $s > 0$. So that our theory applies to a class of general systems (involving, for example, vector equations with matrix operators), we assume the existence of self-adjoint "weights" w_- and w_+ such that

(i) w_+ is defined on a dense subspace of $\mathcal{H}$ and on which $w_+ \geq cI, \ \ c > 0$.

(ii) $w_- \in \mathcal{L}(\mathcal{H})$ such that $\mathrm{Range}(w_-) \subseteq \mathit{Domain}(w_+)$.

(iii) $w_+ \ w_- \ \mathbf{P_c} \ = \ \mathbf{P_c}$ on $\mathcal{H}$ and $\mathbf{P_c} \ = \ \mathbf{P_c} \ w_- \ w_+$ on the domain of w_+.

In the scalar case, w_+ and w_- correspond to multiplication by $\langle x\rangle^s$ and $\langle x\rangle^{-s}$, respectively; see section 3.

The following hypothesis ensures that the unperturbed dynamics satisfies sufficiently strong dispersive time-decay estimates. Let $\{\mu_j\}_{j\in\mathbb{Z}}$ denote the set of Fourier exponents associated with the perturbation W (see hypothesis **(H4)** below).

(H3) *Local decay estimates on* e^{-iH_0t}.

Let $r_1 > 1$. There exist w_+ and w_-, as above, and a constant $\mathcal{C}$ such that for all $f \in \mathcal{H}$ satisfying $w_+ f \in \mathcal{H}$ we have

$$\text{(2.3)} \quad (\mathbf{a}) \quad \|w_- e^{-iH_0t}\mathbf{P_c} f\| \leq \mathcal{C}\ \langle t\rangle^{-r_1}\|w_+ f\| \text{ for } t \in \mathbb{R};$$

$$\text{(2.4)} \quad (\mathbf{b}) \quad \|w_- e^{-iH_0t}(H_0 - \lambda_0 - \mu_j - i0)^{-1}\ \mathbf{P_c} f\| \leq\ \mathcal{C}\ \langle t\rangle^{-r_1}\ \|w_+ f\| \text{ for } t \geq 0$$

and for all $j \in \mathbb{Z}$. For $t < 0$ estimate (2.4) is assumed to hold with $-i0$ replaced by $+i0$. See section 8 for the definition of the singular operator in (2.4).

Remark 2.1. There is a good deal of literature on local energy decay estimates of the form (2.3) for $e^{-iH_0t}\mathbf{P_c}$ in the case $H_0 = \ -\Delta + V(x)$ on $L^2(\mathbb{R}^n)$. These results require sufficient regularity and decay of the potential $V(x)$. We refer the reader to [5, 6] and [14]; see also [16, 18].

Remark 2.2. Estimates of the type **(H3b)** are obtained in [22], [23, Appendix A]. A key point here is that we require that one can choose the constant, $\mathcal{C}$, in (2.4) to hold for all μ_j. It appears difficult to deduce this uniformity of the constant by the general arguments used in [22] and [23]. However, in section 3, where we apply our results to a class of Schrödinger operators, we can verify (**H3b**) using known results on the spectral measure.

(H4) Hypotheses on the perturbation $W(t)$.

We consider time-dependent symmetric perturbations of the form

$$\text{(2.5)} \qquad W(t) = \frac{1}{2}\beta_0 + \sum_{j\in\mathbb{N}} \cos(\mu_j t)\ \beta_j \text{ with } \beta_j^* = \beta_j \text{ and } \sum_{j\in\mathbb{N}_0} \|\beta_j\|_{\mathcal{L}(\mathcal{H})} < \infty.$$

In many applications, β_j are spatially localized scalar or matrix functions. Note that formula (2.5) can be rewritten in the form

$$\text{(2.6)} \qquad W(t) = \frac{1}{2}\ \sum_{j\in\mathbb{Z}} \exp(-i\mu_j t)\beta_j,$$

where $\mu_0 = 0$ and for $j < 0$, $\mu_j = -\mu_{-j}, \ \beta_j = \beta_{-j}$. Thus, $W(t)$ is an almost periodic function with values in the Banach space $\mathcal{L}(\mathcal{H})$ with the Fourier exponents $\{\mu_j\}_{j\in\mathbb{Z}}$ and corresponding Fourier coefficients $\{\beta_j\}_{j\in\mathbb{Z}}$; see, for example, [9].

To measure the size of the perturbation W, we introduce the norm

$$\text{(2.7)} \qquad |||W|||\ \equiv\ \frac{1}{2}\sum_{j\in\mathbb{Z}} \|w_+\ \beta_j\|_{\mathcal{L}(\mathcal{H})}\ +\ \frac{1}{2}\sum_{j\in\mathbb{Z}} \|\ \beta_j\ \|_{\mathcal{L}(\mathcal{H}_-,\mathcal{H}_+)},$$

which is assumed to be finite. Here $\mathcal{H}_+$, respectively, $\mathcal{H}_-$, denote the closure of the domain of w_+, respectively, the range of $\mathbf{P_c}$, with norm $f \to \|w_+ f\|$, respectively, $f \to \|w_- f\|$.

Remark 2.3. A special case which arises in various models is

$$W(t) \;=\; g(t)\beta, \tag{2.8}$$

where

$$g(t) \;=\; \sum_j \, g_j \cos \mu_j t, \tag{2.9}$$

$\|w_+\beta\|_{\mathcal{L}(\mathcal{H})} + \;\|\beta\|_{\mathcal{L}(\mathcal{H}_-,\mathcal{H}_+)} \;<\; \infty$ and the sequence $\{g_j\}$ is absolutely summable.

Remark 2.4. Our results are valid in the more general case

$$W(t) = \frac{1}{2}\beta_0 + \sum_{j\in\mathbb{N}} \cos(\mu_j t + \delta_j)\;\beta_j,$$

where β_j are self-adjoint such that expression (2.7) is finite. This follows because the proofs use only the self-adjointness of W and the expansion

$$W(t) = \frac{1}{2}\,\sum_{j\in\mathbb{Z}} \exp(-i\mu_j t)\tilde{\beta}_j,$$

where $\tilde{\beta}_j = e^{-i\mathrm{sgn}(j)\delta_j}\beta_j$ and $\mu_{-j} = -\mu_j,\; \mu_0 = 0$.

We will impose a resonance condition which says that $\{\lambda_0 + \mu_j\}_{j\in\mathbb{Z}} \cap \sigma_{\text{cont}}(H_0)$ is nonempty and that there is nontrivial coupling; see section 1.4. Let us first denote by I_{res} the following set:

$$I_{res} \;=\; \{j \in \mathbb{Z} \;:\; \lambda_0 + \mu_j \in \sigma_{\text{cont}}(H_0)\}. \tag{2.10}$$

(H5) *Resonance condition.* Fermi golden rule.

I_{res} is nonempty and furthermore, there exists $\theta_0 > 0$, independent of W, such that

$$\Gamma \;\equiv\; \frac{\pi}{4} \sum_{j\in I_{res}} (\mathbf{P_c}\beta_j\psi_0,\; \delta(H_0 - \lambda_0 - \mu_j)\mathbf{P_c}\beta_j\psi_0.) \geq \theta_0 |||W|||^2 > 0. \tag{2.11}$$

Remark 2.5. For the exact definition of the Dirac-type operator in (2.11), see section 8. That Γ is finite is a consequence of the estimate (8.8) and

$$\Gamma \leq \frac{C_0}{\pi}\sum_j \|w_+\beta_j\|^2 \leq \frac{C_0}{\pi}|||W|||^2; \tag{2.12}$$

see also [1].

We now state our main results.

THEOREM 2.1. *Let us fix H_0 and $W(t)$ satisfying hypotheses* **(H1)–(H5)**. *Consider the initial value problem*

$$\begin{aligned} &i\partial_t\phi(t) = (H_0 + \varepsilon W(t))\,\phi(t),\\ &\phi|_{t=0} = \phi(0) \end{aligned} \tag{2.13}$$

with $w_+\phi(0) \in \mathcal{H}$. Then, there exists an $\varepsilon_0 > 0$ (depending on $\mathcal{C}$, r_1, and θ_0) such that whenever $|\varepsilon| < \varepsilon_0$, the solution, $\phi(t)$, of (2.13) *satisfies the local decay estimate*

$$\|w_- \ \phi(t)\| \le C\langle t\rangle^{-r_1}\|w_+ \ \phi(0)\|, \quad t \in \mathbb{R}. \tag{2.14}$$

Under the same hypotheses as Theorem 2.1, we obtain more detailed information on the behavior of $\phi(t)$.

THEOREM 2.2. *Assume the hypotheses of Theorem* 2.1. *For any $0 < \gamma < \Gamma$ there exist the constants C and D (depending on $\mathcal{C}$, r_1, θ_0, and γ) such that any solution of* (2.13)*, for $|\varepsilon| < \varepsilon_0$ and $w_+\phi(0) \in \mathcal{H}$, satisfies*

$$\begin{aligned} \phi(x,t) &= a(t)\psi_0 + \phi_d(t), \quad (\psi_0\ ,\ \phi_d(t),\,) \ = \ 0, \\ a(t) &= \ a(0)\ e^{-\varepsilon^2(\Gamma-\gamma)|t|}e^{i\omega(t)} \ + \ R_a(t), \\ P(t) &= \ P(0)\ e^{-2\varepsilon^2(\Gamma-\gamma)|t|} \ + \ R'_a(t), \\ \phi_d(t) &= e^{-iH_0t}\ \mathbf{P_c}\phi(0) \ + \ \tilde{\phi}(t), \end{aligned} \tag{2.15}$$

where Γ is given by (2.11) *and $\omega(t)$ is a real-valued phase given by*

$$\begin{aligned} \omega(t) \ &= \ -\lambda_0 t - \varepsilon\left(\psi_0,\ \int_0^t W(s)ds\ \psi_0\right) \\ &+\frac{1}{4}\varepsilon^2 t\sum_{j\in\mathbb{Z}}\left(\beta_j\psi_0, \text{P.V.}(H_0-\lambda_0-\mu_j)^{-1}\mathbf{P_c}\beta_j\psi_0\right) \\ &+\ \frac{1}{4}\varepsilon^2\ \Re\int_0^t \sum_{j,k\in\mathbb{Z},j\neq k} e^{i(\mu_k-\mu_j)t}\left(\beta_k\psi_0,(H_0-\lambda_0-\mu_j-i0)^{-1}\mathbf{P_c}\beta_j\psi_0\right). \end{aligned} \tag{2.16}$$

$P(t)$ is defined in (1.4) *and for any fixed $T_0 > 0$ we have*

$$|R_a(t)| \ \le \ C\ |\varepsilon|\ |||W|||,\ |t| \le \frac{T_0}{\varepsilon^2\Gamma}, \tag{2.17}$$

$$|R'_a(t)| \ \le \ D\ |\varepsilon|\ |||W|||,\ |t| \le \frac{T_0}{\varepsilon^2\Gamma}. \tag{2.18}$$

Moreover,

$$|R_a(t)| = \mathcal{O}(\langle t\rangle^{-r_1}),\ |R'_a(t)| = \mathcal{O}(\langle t\rangle^{-r_1}),\ |t| \to \infty.$$

Finally, $\tilde{\phi} = \phi_1 + \phi_2$ is given in (4.9) *with $\|w_-\tilde{\phi}(t)\| = \mathcal{O}(\langle t\rangle^{-r_1})$ as $|t| \to \infty$. Therefore, by* **(H3)** *$\|w_-\phi_d(t)\| = \mathcal{O}(\langle t\rangle^{-r_1})$ as $|t| \to \infty$.*

Remark 2.6. Suppose the initial data is given by the bound state of the unperturbed problem, i.e., $\phi(x,0) = \psi_0(x)$, $a(0) = 1$, $\phi_d(0) = 0$. Then, from the expansion of the solution we have that for $0 \le t \le \varepsilon^{-2}\Gamma^{-1}$ that $P(t)$ (see (1.4)) is of order $e^{-2\varepsilon^2(\Gamma-\gamma)t}$ with an error of order ε. Hence it is natural to view the state $\psi_0 e^{-i\lambda_0 t}$ as a metastable state with lifetime $\tau = \varepsilon^{-2}(\Gamma-\gamma)^{-1} \sim \varepsilon^{-2}|||W|||^{-2}$. Although $\gamma > 0$ is arbitrary we have not inferred that the actual lifetime is $\tau = \varepsilon^{-2}\Gamma^{-1}$ under hypotheses **(H1)**–**(H5)**. The reason is that the constants C and D in the estimates (2.17) and (2.18) blow up as $\gamma \searrow 0$. In order to remedy this we need an additional hypothesis.

(H6) *Control of small denominators.*

There exists $\xi > 0$, independent of W, such that

$$\sum_{j\in I_{res},\ k\in\mathbb{Z},\ j\neq k}\left|\frac{1}{\mu_j-\mu_k}(\mathbf{P_c}\beta_k\psi_0, \delta(H_0-\lambda_0-\mu_j)\mathbf{P_c}\beta_j\psi_0)\right| \le \xi\ |||W|||^2. \tag{2.19}$$

Remark 2.7. By (8.8) we have that

$$\sum_{j\in I_{res},\ k\in\mathbb{Z},\ j\neq k} |(\beta_k\psi_0, \delta(H_0-\lambda_0-\mu_j)\beta_j\psi_0)| \leq C\ \pi^{-1}\ |||W|||^2 \tag{2.20}$$

is finite (see also Remark 2.5). Thus, **(H6)** is important only if

$$\inf\{|\mu_j-\mu_k| :\ j,k\in\mathbb{Z},\ j\neq k \text{ and } \lambda_0+\mu_j\in\sigma_{\text{cont}}(H_0)\} = 0, \tag{2.21}$$

i.e., the Fourier exponents $\{\mu_j\}$ are such that $\lambda_0+\mu_j$ accumulate in σ_c. In particular, if the perturbation $W(t)$ consists of a trigonometric polynomial

$$W(t)\ =\ \sum_{j=1}^{N} \cos\mu_j t\ \beta_j, \tag{2.22}$$

then **(H6)** is trivially satisfied.

Remark 2.8. Hypothesis **(H6)** can be imposed by balancing the clustering of the frequencies $\lambda_0+\mu_j$ in the continuous spectrum of H_0 with rapid decay of $(\beta_k\psi_0\ ,\ \delta(H_0-\lambda_0-\mu_j)\ \beta_j\psi_0)$ as $j,k\to\infty$. Let $\beta_j(x) = g_j\ \beta(x)$. Then, $W(t,x) = \sum_j\ g_j\cos(\mu_j t)\ \beta(x)$. Using Remark 2.5 we find that the left-hand side of (2.19) is bounded by $\sum_{j,k\in\mathbb{Z};j\neq k}|g_jg_k|\ |\mu_j-\mu_k|^{-1}\ |||W|||^2$. The constant ξ in (2.19) is finite if, for example, $\mu_j = 2|\lambda_0|+|j|^{-1},\ g_j = |j|^{-2-\tau},\ \tau>0$.

In case **(H6)** is satisfied we have the following improvement of Theorem 2.2.

Theorem 2.3. *Assume the hypotheses* **(H1)**–**(H6)** *hold. Then there exist* ε_0 *and the constants* C, D *(depending on* $\mathcal{C}$, r_1, θ_0 *and* ξ*) such that any solution of* (2.13)*, for* $|\varepsilon|<\varepsilon_0$ *and* $w_+\phi(0)\in\mathcal{H}$*, satisfies*

$$\begin{aligned}
\phi(x,t) &= a(t)\psi_0+\phi_d(t),\quad (\psi_0\ ,\ \phi_d(t))\ =\ 0,\\
a(t) &= a(0)\ e^{-\varepsilon^2\Gamma|t|}\ e^{i\omega(t)}\ +\ R_a(t),\\
P(t) &= P(0)\ e^{-2\varepsilon^2\Gamma|t|}\ +\ R'_a(t),\\
\phi_d(t) &= e^{-iH_0t}\ \mathbf{P_c}\phi(0)\ +\ \tilde{\phi}(t).
\end{aligned} \tag{2.23}$$

Here, $\omega(t)$ *is given by* (2.16) *and* $R_a(t)$, $R'_a(t)$, $w_-\phi_d(t)$ *satisfy the estimates of Theorem* 2.2.

3. An application: The Schrödinger equation. In this section we verify hypotheses **(H1)**–**(H4)** in the particular case of the Schrödinger equation on the three-dimensional space with a time almost periodic and spatially localized perturbing potential:

$$i\partial_t\phi\ =\ (-\Delta+V(x))\,\phi\ +\ \varepsilon W(x,t)\phi \tag{3.1}$$

with $\phi:\mathbb{R}^3\times\mathbb{R}\to\mathbb{C},\ (x,t)\to\phi(x,t)$, and

$$W(x,t) = \frac{1}{2}\beta_0(x)+\sum_{j\in\mathbb{N}}\cos(\mu_jt)\beta_j(x),$$

where $\mu_j\in\mathbb{R},\ j\in\mathbb{N}_0$, and $\beta_j:\mathbb{R}^3\to\mathbb{R},\ j\in\mathbb{N}$, are localized functions. Models of the sort considered in this example occur in the study of ionization of an atom by a time-varying electric field; see [10, 4].

We take $\mathcal{H} = L^2(\mathbb{R}^3)$ and $H_0 \equiv -\Delta + V(x)$, where $V(x)$ is real-valued with moderately short range. More precisely, we suppose that there exists $\sigma > 4$ and a constant D such that

$$|V(x)| \le D(1+|x|)^{-\sigma}. \tag{3.2}$$

Thus, H_0 is self-adjoint and densely defined in L^2. In what follows we assume that H_0 has exactly one eigenvalue which is strictly negative and that the remainder of the spectrum is absolutely continuous and equal to the positive half-line. Our results can be extended to operators with strictly negative, multiple eigenvalues [7].

We first discuss the local decay hypothesis **(H3)**. As weights used to measure local energy decay we take $w_\pm \equiv \langle x\rangle^{\pm s}$, where $s > 7/2$ and fix $r_1 = 3/2$. Our aim is to obtain the estimates

$$\textbf{(H3a)}\quad \|w_- e^{-iH_0t}\mathbf{P_c} f\| \le \mathcal{C}\ \langle t\rangle^{-3/2}\|w_+ f\|, \tag{3.3}$$

$$\textbf{(H3b)}\quad \|w_- e^{-iH_0t}(H_0-\lambda_0-\mu_j-i0)^{-1}\ \mathbf{P_c} f\| \le\ \mathcal{C}\ \langle t\rangle^{-3/2}\ \|w_+ f\| \tag{3.4}$$

for all $\mu_j \in \mathbb{Z}$ with $\mathcal{C}$ independent of j.

We shall assume that the frequencies $\{\lambda_0 + \mu_j\}$ do not accumulate at zero, the edge of the continuous spectrum of H_0:

$$m_* \ \equiv\ \min\{\ |\lambda_0+\mu_j|\ :\ j\in\mathbb{Z}\ \} >\ 0. \tag{3.5}$$

To prove (3.3) and (3.4) we use the spectral representation for the operators $e^{-iH_0t}\ \mathbf{P_c}$ and $e^{-iH_0t}\ (H_0-\lambda_0-\mu_j-i0)^{-1}\mathbf{P_c}$, namely,

$$e^{-iH_0t}\mathbf{P_c} = \int_0^\infty e^{-i\lambda t}E'(\lambda)d\lambda, \tag{3.6}$$

$$e^{-iH_0t}(H_0-\lambda_0-\mu_j-i0)^{-1}\mathbf{P_c} = \int_0^\infty e^{-i\lambda t}(\lambda-\lambda_0-\mu_j-i0)^{-1}E'(\lambda)d\lambda, \tag{3.7}$$

where $E'(\lambda) = \pi^{-1}\ \Im(H_0-\lambda-i0)^{-1}$ is the spectral density induced by H_0, [5].

The technique of getting **(H3a)** from (3.6) is presented in [5, section 10] and it can be summarized in the following way. We decompose the integral in (3.6) in two parts, corresponding to low energies (λ near zero) and high energies (λ away from zero) by writing

$$\begin{aligned} E' &= \chi E' + (1-\chi)E', \\ w_- e^{-iH_0t}\mathbf{P_c} w_- &= \int_0^\infty e^{-i\lambda t}\chi(\lambda) w_- E'(\lambda) w_- d\lambda + \int_0^\infty e^{-i\lambda t}(1-\chi(\lambda)) w_- E'(\lambda) w_- d\lambda \\ &=\ S_1\ +\ S_2. \end{aligned} \tag{3.8}$$

Here, $\chi(\lambda)$ is a smoothed characteristic function of a neighborhood of origin, chosen so that

$$\chi(\lambda)\ \equiv\ 1,\ |\lambda|\ \le\ \frac{1}{2}m_*,$$
$$\chi(\lambda)\ \equiv\ 0,\ |\lambda|\ \ge\ \frac{3}{4}m_*.$$

To estimate the two integrals in (3.8) we make use of the detailed results of [5] on the family of operators $\{E'(\lambda)\}$. First, by Theorem 8.1 and Corollary 8.2 of [5], $w_-\partial_\lambda^k E'(\lambda)w_-$ is bounded on L^2 and satisfies

$$\|\ w_-\partial_\lambda^k E'(\lambda)w_-\ \|_{\mathcal{B}(L^2)} = O(\lambda^{-(k+1)/2}) \text{ as } \lambda\to\infty \tag{3.9}$$

for $k \in \{0,1,2,3\}$. Integration by parts twice in the second integral in (3.8) and use of the estimate (3.9) with $k=2$ yields the estimate

$$\| S_2 \|_{\mathcal{B}(L^2)} \;=\; o(t^{-2}) \text{ as } t \to \infty. \tag{3.10}$$

Next, by Theorem 6.3 of [5] we have the low energy asymptotic expansion

$$w_- E'(\lambda) w_- = -\lambda^{-1/2} B_{-1} + \lambda^{1/2} B_1 + o(\lambda^{1/2}) \text{ as } \lambda \to 0, \tag{3.11}$$

where $B_{-1},\ B_1$ are bounded linear operators on L^2. Use of this expansion in the first integral of (3.8) yields the expansion in $\mathcal{B}(L^2)$:

$$S_1 \;=\; (\pi i)^{-1/2} t^{-1/2} B_{-1} - (4\pi i)^{-1/2} t^{-3/2} B_1 + o(t^{-3/2}) \text{ as } t \to \infty. \tag{3.12}$$

Thus, **(H3a)** is satisfied provided that B_{-1} is the null operator or equivalently $H_0\psi = 0$ has no solution with the property $w_-\psi \in L^2(\mathbb{R}^3)$. The last condition holds for generic potentials $V(x)$ and when it is violated one says that H_0 has *zero energy resonance*; see [5] for details.

In the same way one can prove **(H3b)** from the spectral representation (3.7) provided that the integral is nonsingular, i.e., $\lambda_0+\mu_j < 0$. In the case $\lambda_0+\mu_j \geq m_* > 0$ we first decompose the singular integral in two parts, one away from singularity point, $\lambda_0+\mu_j$, and the other in a neighborhood of it by using the smoothed characteristic function

$$\chi_j(\lambda) \;=\; \chi(\lambda - \lambda_0 - \mu_j), \tag{3.13}$$

which is supported in a neighborhood of $\lambda_0+\mu_j$, which does not include $\lambda = 0$:

$$\begin{aligned} e^{-iH_0 t}(H_0 - \lambda_0 - \mu_j - i0)^{-1}\mathbf{P_c} = \int_0^\infty & e^{-i\lambda t}(\lambda - \lambda_0 - \mu_j)^{-1}(1-\chi_j(\lambda))E'(\lambda)d\lambda \\ + \int_0^\infty & e^{-i\lambda t}(\lambda - \lambda_0 - \mu_j - i0)^{-1}\chi_j(\lambda)E'(\lambda)d\lambda. \end{aligned} \tag{3.14}$$

The nonsingular integral may be treated as above while the singular one defines the singular operator

$$T_j = e^{-iH_0 t}(H_0 - \lambda_0 - \mu_j - i0)^{-1}\chi_j(H_0)\mathbf{P_c}$$

via the spectral theorem. Here, $T_j = \lim_{\eta\searrow 0} T_j^\eta$, where

$$T_j^\eta \equiv e^{-iH_0 t}(H_0 - \lambda_0 - \mu_j - i\eta)^{-1}\chi_j(H_0)\mathbf{P_c}.$$

To estimate its L^2 operator norm we use the integral representation

$$w_- T_j^\eta w_- = \frac{1}{i}\int_t^\infty e^{i(\lambda_0+\mu_j+i\eta)(s-t)} w_- e^{-iH_0 s}\chi_j(H_0)\mathbf{P_c} w_- ds. \tag{3.15}$$

But this reduces to the evaluation of

$$w_- e^{-iH_0 s}\chi_j(H_0)\mathbf{P_c} w_- = \int_0^\infty e^{-i\lambda s}\chi_j(\lambda) w_- E'(\lambda) w_- d\lambda,\ s \geq t, \tag{3.16}$$

where we used again the spectral representation theorem. Integration by parts three times in (3.16) and use of the estimate (3.9) with $k=3$ implies

$$\|w_- e^{-iH_0 s}\chi_j(H_0)\mathbf{P_c} w_-\|_{\mathcal{B}(L^2)} = o(s^{-3}) \text{ as } t \to \infty.$$

Replacing this in (3.15), integrating and passing to the limit as $\eta \searrow 0$ we obtain an $o(t^{-2})$ estimate for T_j which is even better than we need to satisfy **(H3b)**.

Moving now towards hypothesis **(H4)**, we may choose the time-dependent perturbation to be of the form

$$W(x,t) \;=\frac{1}{2}\beta_0 \;+\; \sum_{j\in\mathbb{N}}\cos\mu_j t\;\beta_j(x) \tag{3.17}$$

with β_j rapidly decaying in x, e.g., $\langle x\rangle^{2s}\|\beta_j(x)\| \le C_j$ for all $x\in\mathbb{R}^3$, $j\in\mathbb{N}_0$, where $\sum_{j\in\mathbb{N}_0} C_j < \infty$. Thus, **(H4)** is satisfied as well.

Therefore, our main results Theorems 2.1–2.2 on the structural instability of the unperturbed bound state and large time behavior for systems of the form (3.1) apply provided **(H5)**, the Fermi golden rule resonance condition, holds. For results concerning more general perturbations than the ones in (3.1) see section 7.

4. Decomposition and derivation of the dispersive normal form. The results of this section rely on hypothesis **(H1)** through **(H4)** only, so they may and will be used in proving Theorems 2.1–2.3.

As in [21, 22] and [23], we begin by deriving a decomposition of the solution, $\phi(t)$, which will facilitate the study of its large time behavior. Let

$$\phi(t) = a(t)\psi_0 + \phi_d(t) \tag{4.1}$$

with the orthogonality condition

$$(\psi_0, \phi_d(t)) = 0 \;\text{ for all }\; t. \tag{4.2}$$

Note therefore that $\phi_d \;=\; \mathbf{P_c}\phi_d$.

We proceed by first inserting (4.1) into (2.13), which yields the equation

$$\begin{aligned} i\partial_t a(t)\psi_0 \;+\; i\partial_t\phi_d(t) \;&=\; \lambda_0 a(t)\psi_0 \;+ H_0\phi_d(t)\\ &\quad+\varepsilon a(t)W(t)\psi_0 \;+\; \varepsilon W(t)\phi_d(t). \end{aligned} \tag{4.3}$$

Taking the inner product of (4.3) with ψ_0 we get the following equation for $a(t)$:

$$\begin{aligned} i\partial_t a \;&=\; \lambda_0 a(t) \;+\; \varepsilon\,(\psi_0, W(t)\psi_0)\,a(t) \;+\; \varepsilon\,(\psi_0, W(t)\phi_d)\,,\\ a(0) \;&=\; (\psi_0, \phi(0))\,. \end{aligned} \tag{4.4}$$

In deriving (4.4) we have used that ψ_0 is normalized and the relation

$$(\psi_0, \partial_t\phi_d) = 0, \tag{4.5}$$

a consequence of (4.2).

Applying $\mathbf{P_c}$ to (4.3), we obtain an equation for ϕ_d:

$$\begin{aligned} i\partial_t\phi_d(t) \;&=\; H_0\phi_d(t) \;+\; \varepsilon\mathbf{P_c}W(t)\phi_d(t) \;+\; \varepsilon a(t)\mathbf{P_c}W(t)\psi_0,\\ \phi_d(0) \;&=\; \mathbf{P_c}\phi(0). \end{aligned} \tag{4.6}$$

Since we are after a slow resonant decay phenomenon, it will prove advantageous to extract the fast oscillatory behavior of $a(t)$. We therefore define

$$A(t) \equiv e^{i\lambda_0 t}a(t). \tag{4.7}$$

Then, (4.4) reads

$$\partial_t A \; = \; -i\varepsilon A\left(\psi_0, W(t)\psi_0\right) \; - \; i\varepsilon e^{i\lambda_0 t} \; \left(\psi_0, W(t)\phi_d(t)\right). \tag{4.8}$$

Solving (4.6) by Duhamel's formula we have

$$\begin{aligned}\phi_d(t) = e^{-iH_0t}\phi_d(0) \; - \; i\varepsilon \int_0^t e^{-iH_0(t-s)}\mathbf{P_c}W(s)a(s)\psi_0 ds \\ -i\varepsilon \int_0^t e^{-iH_0(t-s)}\mathbf{P_c}W(s)\phi_d(s) \; ds \\ \equiv \phi_0(t) \; + \; \phi_1(t) \; + \; \phi_2(t).\end{aligned} \tag{4.9}$$

By standard methods, the system (4.8)–(4.9) for $A(t)$ and $\phi_d(t) = \phi(t) - e^{-i\lambda_0 t} \, A(t) \, \psi_0$ has a global solution in t with

$$A \in C^1(\mathbb{R}), \; \|\phi_d(t)\| \in C^0(\mathbb{R}), \; \|w_-\phi_d(t)\| \in C^0(\mathbb{R}).$$

Our analysis of the $|t| \to \infty$ behavior is based on a study of this system.

By inserting (4.9) into (4.8) we get

$$\partial_t A(t) \; = \; -i\varepsilon A(t)\left(\psi_0, W(t)\psi_0\right) \; - \; i\varepsilon e^{i\lambda_0 t}\sum_{j=0}^{2}\left(\psi_0, W(t)\phi_j\right). \tag{4.10}$$

We next give a detailed expansion of the sum in (4.10). It is in the $j = 1$ term that the key resonance is found. This makes it possible to find a normal form for (4.10) in which *internal damping* in the system is made explicit. This damping reflects the transfer of energy from the discrete to continuum modes of the system and the associated radiative decay of solutions.

PROPOSITION 4.1. *For $t > 0$,*

$$\partial_t A(t) \; = \; \left(-\varepsilon^2\Gamma \; + \; \rho(t)\right) \; A(t) \; + \; E(t), \tag{4.11}$$

where Γ is defined in (2.11),

$$\begin{aligned}\rho(t) \; &= \; -i\varepsilon\left(\psi_0, \; W(t)\psi_0\right) \\ &+ \; \frac{i}{4}\varepsilon^2\sum_{j\in\mathbb{Z}}\left(\beta_j\psi_0, \text{P.V.}(H_0 - \lambda_0 - \mu_j)^{-1}\mathbf{P_c}\beta_j\psi_0\right) \\ &+ \; \frac{i}{4}\varepsilon^2\sum_{j,k\in\mathbb{Z}, j\neq k} e^{i(\mu_k - \mu_j)t}\left(\beta_k\psi_0, (H_0 - \lambda_0 - \mu_j - i0)^{-1}\mathbf{P_c}\beta_j\psi_0\right)\end{aligned} \tag{4.12}$$

and

$$\begin{aligned}E(t) \; = \; &-\frac{i}{4}\varepsilon^2 A(0)e^{i\lambda_0 t}\sum_{j,k\in\mathbb{Z}} e^{i\mu_k t} \; \left(\beta_k\psi_0, \; e^{-iH_0 t} \; (H_0 - \lambda_0 - \mu_j - i0)^{-1}\mathbf{P_c}\beta_j\psi_0\right) \\ &-\frac{i}{4}\varepsilon^2 e^{i\lambda_0 t}\sum_{j,k\in\mathbb{Z}} e^{i\mu_k t} \\ &\left(\beta_k\psi_0, \int_0^t e^{-iH_0(t-s)}(H_0 - \lambda_0 - \mu_j - i0)^{-1}\mathbf{P_c}e^{-i(\lambda_0+\mu_j)s}\partial_s A(s)\beta_j\psi_0\right) ds \\ &-i\varepsilon e^{i\lambda_0 t} \; \left(\psi_0, \; W(t)\phi_0(t)\right) \\ &-i\varepsilon e^{i\lambda_0 t} \; \left(\psi_0, \; W(t)\phi_2(t)\right).\end{aligned} \tag{4.13}$$

Here, ϕ_0 and ϕ_2 are given in (4.9).

Although the proposition is stated for $t > 0$, an analogous proposition with $-\varepsilon^2\Gamma$ replaced by $\varepsilon^2\Gamma$ holds for $t < 0$. The modification required to treat $t < 0$ is indicated in the proof.

Remark 4.1. (1) The point of (4.11) is that the source of damping, $\Gamma > 0$, which arises due to the coupling of the discrete bound state to the continuum modes by the almost periodic perturbation is made explicit. Note that $\Re\rho(t)$ is of order $\varepsilon^2|||W|||^2$ as the first two terms of $\rho(t)$ are purely imaginary inducing only a phase shift in the solution, $A(t)$. The last term is of the same order as the damping and may compete with it. A key point of our analysis is to assess the contribution of this last term in (4.12).

(2) The leading order part of (4.11) is the analogue of the dispersive normal form derived in [24] for a class of nonlinear dispersive wave equations.

Proof of Proposition 4.1. Using the expression for $W(t)$ in (2.6), which is a uniform convergent series with respect to $t \in \mathbb{R}$, and the definition $A(t) = e^{i\lambda_0 t}a(t)$, we get from (4.9)

$$\begin{aligned} \phi_1(t) &= -\frac{i\varepsilon}{2}\int_0^t e^{-iH_0(t-s)}e^{-i\lambda_0 s}A(s)\mathbf{P_c}\sum_{j\in\mathbb{Z}} e^{-i\mu_j s}\ \beta_j\psi_0\ ds \\ &= -\frac{i\varepsilon}{2}\sum_{j\in\mathbb{Z}}\int_0^t e^{-iH_0(t-s)}e^{-i(\lambda_0+\mu_j)s}A(s)\mathbf{P_c}\beta_j\psi_0\ ds. \end{aligned} \tag{4.14}$$

We would like to integrate by parts each of the integrals in the above sum. We cannot proceed directly since the resolvents of H_0 in $\lambda_0 + \mu_j,\ j \in \mathbb{Z}$, would appear and hypothesis **(H5)** implies that some of the $\lambda_0 + \mu_j,\ j \in \mathbb{Z}$, are in the spectrum of H_0. Instead we regularize ϕ_1 by defining

$$\phi_1^\eta(t) = -\frac{i}{2}\varepsilon\sum_{j\in\mathbb{Z}}\int_0^t e^{-iH_0(t-s)}e^{-i(\lambda_0+\mu_j+i\eta)s}A(s)\mathbf{P_c}\beta_j\psi_0\ ds \tag{4.15}$$

for η positive and arbitrary and $t > 0$. Note that $\phi_1(t) = \lim_{\eta\searrow 0}\phi_1^\eta(t)$ uniformly with respect to t on compact intervals.

Now, integration by parts for each integral in expression (4.15) and letting η tend to zero from above gives the following expansion of $(\psi_0, W(t)\phi_1(t))$:

$$\begin{aligned} (\psi_0, W(t)\phi_1(t)) &= \left(W(t)\psi_0,\ -\frac{\varepsilon}{2}\ e^{-i\lambda_0 t}\sum_{j\in\mathbb{Z}} e^{-i\mu_j t}A(t)(H_0-\lambda_0-\mu_j-i0)^{-1}\mathbf{P_c}\beta_j\psi_0\right) \\ &+\left(W(t)\psi_0,\ \frac{\varepsilon}{2}A(0)\sum_{j\in\mathbb{Z}} e^{-iH_0 t}(H_0-\lambda_0-\mu_j-i0)^{-1}\mathbf{P_c}\beta_j\psi_0\right) \\ &+\left(W(t)\psi_0,\ \frac{\varepsilon}{2}\sum_{j\in\mathbb{Z}}\int_0^t e^{-iH_0(t-s)}(H_0-\lambda_0-\mu_j-i0)^{-1}\mathbf{P_c}e^{-i(\lambda_0+\mu_j)s}\partial_s A(s)\beta_j\psi_0 ds\right). \end{aligned} \tag{4.16}$$

The definition of the singular operators in the above computation is given in section 8. The choice of regularization, $+i\eta$, in (4.15) ensures that the latter two terms in the expansion of ϕ_1, (4.16), decay dispersively as $t \to +\infty$; see hypothesis **(H3)** and section 6. For $t < 0$, we replace $+i\eta$ with $-i\eta$ in (4.15).

To further expand the first series in (4.16) we use the identities (8.5). The proof of Proposition 4.1 is now completed by substitution of (8.5) in the expansion (4.16) for ϕ_1 and of the result into the second term of the sum in (4.10). □

In the next sections we estimate the remainder terms in (4.9) and (4.11).

5. Estimates on the bound state amplitude. Our strategy is as follows. Equations (4.9) and (4.11) comprise a dynamical system governing $\phi_d(t)$ and $a(t) = A(t)e^{-i\lambda_0 t}$, the solution of which is equivalent to the original equation (1.1). In this and in the following section we derive a coupled system of estimates for $A(t)$ and $\phi_d(t)$. This section is focused on obtaining estimates for the bound state amplitude $A(t)$ in terms of $\phi_d(t)$, while the following section is focused on obtaining dispersive estimates for $\phi_d(t)$ in terms of $A(t)$. We treat only the case $t > 0$ since the modifications for the case $t < 0$ are obvious. The coupled system of estimates shows that $A(t)$ decays in time, provided $\phi_d(t)$ is dispersively decaying and vice-versa. We exploit the assumed smallness of the perturbation εW to "close" the resulting inequalities and prove the decay of both $A(t)$ and $\phi_d(t)$.

The main difference from the strategy employed in [22] for the estimation of the bound state amplitude is related to the presence of *infinitely many* frequencies in the perturbation $W(t)$. In particular, one can have an *accumulation of resonances* in the continuous spectrum of H_0. We have two strategies for obtaining estimates for $A(t)$ which correspond to the use of hypotheses **(H1)**–**(H5)** (Theorems 2.1 and 2.2) or hypotheses **(H1)**–**(H6)** (Theorem 2.3). These strategies revolve around estimation of $\Re \int_0^t \rho(s)\, ds$, where ρ is given by (4.12). Hypothesis **(H6)**, which controls certain "small divisors" which arise from the clustering of frequencies, ensures that

$$\Re \int_0^t \rho(s)\ ds \ \leq\ C\ \varepsilon^2 |||W|||^2. \tag{5.1}$$

This, in turn, implies that the contribution of $\rho(t)$ in the size of $A(t)$ is of order $\varepsilon^2|||W|||^2$. Without hypothesis **(H6)** we carefully decompose $\rho(t)$ as

$$\rho(t) \ =\ \varepsilon^2\sigma(t) \ +\ \eta(t),$$

where $\sigma(t)$ is a real almost periodic function with mean, $M(\sigma)$, zero and $\Re \int_0^t \eta(s)\, ds \leq C\varepsilon^2||W|||^2$. As in the previous case, the contribution of the $\eta(t)$ in the size of $A(t)$ is of order $\varepsilon^2|||W|||^2$. On the other hand, $\sigma(t)$ competes with the damping term $\varepsilon^2\Gamma$ in (4.11), but being oscillatory (i.e., of mean zero) and of the same size as the damping it allows the latter to eventually dominate.

As the above discussion suggests it is simplest to start by assuming **(H6)** to get sharper estimates on $A(t)$ (Theorem 2.3) and then to relax this assumption (Theorem 2.2). We begin with a simple lemma which we shall use in a number of places in this and in the next section.

Lemma 5.1. *Let* $\alpha > 1$.

$$\int_0^t \langle t-s\rangle^{-\alpha}\ \langle s\rangle^{-\beta}\ ds \ \leq C_{\alpha,\beta}\ \langle t\rangle^{-\min(\alpha,\beta)}. \tag{5.2}$$

Proof. The bound is obtained by viewing the integral as decomposed into a part over $[0, t/2]$ and the part over $[t/2, t]$. We estimate the integral over $[0, t/2]$ by bounding $\langle t-s\rangle^{-\alpha}$ by its value at $t/2$ and explicitly computing the remaining integral. The integral over $[t/2, t]$ is computed by bounding $\langle s\rangle^{-\beta}$ by its value at $t/2$ and again computing explicitly the remaining integral. Putting the two estimates together yields the lemma.

We now turn to the estimate for $A(t)$ in terms of the dispersive norm of $\phi_d(t)$ and local decay estimates for $e^{-iH_0t}\mathbf{P_c}(H_0)$.

5.1. Estimates for $A(t)$ under the hypotheses of Theorem 2.3.

PROPOSITION 5.1. *Suppose* **(H1)**–**(H6)** *hold. Then $A(t)$, the solution of* (4.11), *can be expanded as*

$$A(t) \;=\; e^{\int_0^t \rho(s)ds}\left(e^{-\varepsilon^2\Gamma t}A(0) + R_A(t)\right), \tag{5.3}$$

$$R_A(t) \;=\; \int_0^t e^{-\varepsilon^2\Gamma(t-\tau)}\ \tilde{E}(\tau)\ d\tau, \tag{5.4}$$

where $\tilde{E}(t)$ is given in (4.13) *and* (5.9). *For any $\alpha > 1$, there exists a $\delta > 0$ such that $R_A(t)$ satisfies the estimates for $T > 2(\varepsilon^2\Gamma)^{-\alpha}$,*

$$\begin{aligned}\sup_{2(\varepsilon^2\Gamma)^{-\alpha}\le t\le T} \langle t\rangle^{r_1}\ |R_A(t)| \le C_1 e^{-(\varepsilon^2\Gamma)^{-\delta}} &\sup_{0\le\tau\le(\varepsilon^2\Gamma)^{-\alpha}} |E(\tau)| \\ &+ C\varepsilon^2\Gamma^{-1} \sup_{(\varepsilon^2\Gamma)^{-\alpha}\le\tau\le T} \left(\langle\tau\rangle^{r_1}|E(\tau)|\right),\end{aligned} \tag{5.5}$$

$$\sup_{0\le t\le 2(\varepsilon^2\Gamma)^{-\alpha}} \langle t\rangle^{r_1}\ |R_A(t)| \le\ D\ (\varepsilon^2\Gamma)^{-\alpha(r_1+1)} \sup_{0\le\tau\le 2(\varepsilon^2\Gamma)^{-\alpha}} |E(\tau)|. \tag{5.6}$$

Proof. To prove (5.5) we begin with (4.11). Let

$$\tilde{A}(t) \equiv e^{-\int_0^t \rho(s)ds}A(t). \tag{5.7}$$

Then, $\tilde{A}$ satisfies the equation

$$\partial_t\tilde{A} = -\varepsilon^2\Gamma\tilde{A} + \tilde{E}(t), \tag{5.8}$$

$$\tilde{E}(t) \equiv e^{-\int_0^t \rho(s)ds}E(t). \tag{5.9}$$

Solving (5.8) we get

$$\tilde{A}(t) \;=\; e^{-\varepsilon^2\Gamma t}\tilde{A}(0) \;+\; \int_0^t e^{-\varepsilon^2\Gamma(t-s)}\tilde{E}(s)\ ds \tag{5.10}$$

$$\equiv\; e^{-\varepsilon^2\Gamma t}\tilde{A}(0) \;+\; R_A(t). \tag{5.11}$$

Below, in Proposition 5.2 we show that the real part of the integral of $\rho(t)$ is uniformly bounded and of order $\mathcal{O}(\varepsilon^2|||W|||^2)$ for $t \ge 0$. Therefore, for some $C > 0$, we have by (5.7) and (5.9)

$$C^{-1}|\tilde{A}(t)| \le |A(t)| \le C|\tilde{A}(t)|, \tag{5.12}$$

$$C^{-1}|\tilde{E}(t)| \le |E(t)| \le C|\tilde{E}(t)|. \tag{5.13}$$

Consequently, it is sufficient to estimate $\tilde{A}(t)$, in terms of $\tilde{E}(t)$.

Remark 5.1. Estimates of $R_a(t)$, which appear in the statement of Theorem 2.3, are related to those for $R_A(t)$ via

$$R_a(t) \;=\; e^{-i\lambda_0 t+\int_0^t \rho(s)\ ds}\ R_A(t) - \left(1 - e^{\Re\int_0^t \rho(s)ds}\right)e^{-\varepsilon^2\Gamma t}e^{iw(t)}a(0). \tag{5.14}$$

Hence, by Proposition 5.2,

$$|R_a(t)| \ \leq \ C \ |R_A(t)| + \mathcal{O}(\varepsilon^2 |||W|||^2). \tag{5.15}$$

From (5.10) we have for any $M > 0$

$$\begin{aligned} |\tilde{A}(t)| \ &\leq |A(0)| e^{-\varepsilon^2 \Gamma t} + \int_0^M e^{-\varepsilon^2 \Gamma (t-s)} |\tilde{E}(s)| ds + \int_M^t e^{-\varepsilon^2 \Gamma (t-s)} |\tilde{E}(s)| \ ds \\ &= \ |A(0)| e^{-\varepsilon^2 \Gamma t} \ + \ I_1(t) \ + \ I_2(t). \end{aligned} \tag{5.16}$$

Set

$$M = (\varepsilon^2 \Gamma)^{-\alpha}, \quad \alpha > 1.$$

We now estimate the terms $I_1(t)$ and $I_2(t)$ in (5.16) for $2(\varepsilon^2\Gamma)^{-\alpha} \leq t \leq T$.

$$\begin{aligned} \langle t \rangle^{r_1} \ I_1(t) \ &= \ \langle t \rangle^{r_1} \ \int_0^M e^{-\varepsilon^2 \Gamma (t-s)} |\tilde{E}(s)| ds \\ &\leq \ \langle t \rangle^{r_1} e^{-\frac{1}{2}\varepsilon^2 \Gamma t} \cdot \int_0^M e^{-\varepsilon^2 \Gamma (\frac{1}{2} t - s)} \ ds \ \cdot \sup_{0 \leq \tau \leq (\varepsilon^2 \Gamma)^{-\alpha}} |\tilde{E}(\tau)| \\ &\leq \ \sup_{2(\varepsilon^2\Gamma)^{-\alpha} \leq t \leq T} \left(\langle t \rangle^{r_1} e^{-\frac{1}{2}\varepsilon^2 \Gamma t} \right) \cdot C (\varepsilon^2 \Gamma)^{-1} \cdot \sup_{0 \leq \tau \leq (\varepsilon^2 \Gamma)^{-\alpha}} |\tilde{E}(\tau)| \\ &\leq \ C e^{-(\varepsilon^2 \Gamma)^{-\delta}} \sup_{0 \leq \tau \leq (\varepsilon^2 \Gamma)^{-\alpha}} |\tilde{E}(\tau)| \end{aligned} \tag{5.17}$$

for some $\delta > 0$. Therefore,

$$\sup_{2(\varepsilon^2\Gamma)^{-\alpha} \leq t \leq T} \left(\langle t \rangle^{r_1} \ I_1(t) \right) \ \leq \ C e^{-(\varepsilon^2 \Gamma)^{-\delta}} \sup_{0 \leq \tau \leq (\varepsilon^2 \Gamma)^{-\alpha}} |\tilde{E}(\tau)|. \tag{5.18}$$

We estimate $I_2(t)$ on the interval $2(\varepsilon^2\Gamma)^{-\alpha} \leq t \leq T$ as follows:

$$\langle t \rangle^{r_1} \ I_2(t) \ \leq \ \langle t \rangle^{r_1} \ \int_{(\varepsilon^2\Gamma)^{-\alpha}}^t e^{-\varepsilon^2 \Gamma (t-s)} \langle s \rangle^{-r_1} \ ds \ \sup_{(\varepsilon^2\Gamma)^{-\alpha} \leq \tau \leq T} \left(\langle \tau \rangle^{r_1} \tilde{E}(\tau) \right). \tag{5.19}$$

The integral is now bounded above using the estimate

$$\langle t \rangle^{r_1} \ \int_{(\varepsilon^2\Gamma)^{-\alpha}}^t \ e^{-\varepsilon^2 \Gamma (t-s)} \ \langle s \rangle^{-r_1} \ ds \ \leq \ C (\varepsilon^2 \Gamma)^{-1}, \ t \geq 2(\varepsilon^2\Gamma)^{-\alpha}. \tag{5.20}$$

This gives

$$\sup_{2(\varepsilon^2\Gamma)^{-\alpha} \leq t \leq T} \langle t \rangle^{r_1} \ I_2(t) \ \leq \ C (\varepsilon^2 \Gamma)^{-1} \ \sup_{(\varepsilon^2\Gamma)^{-\alpha} \leq \tau \leq T} \left(\langle \tau \rangle^{r_1} \tilde{E}(\tau) \right). \tag{5.21}$$

Assembling the estimates (5.18) and (5.21) yields estimate (5.5) of Proposition 5.1 provided that (5.12) and (5.13) hold. Estimate (5.6) is a simple consequence of the definition of $R_A(t)$.

Thus it remains to prove (5.12) and (5.13). By (5.7) and (5.9) it is necessary and sufficient to verify the following proposition.

Proposition 5.2. *Assume hypotheses* **(H1)**–**(H6)**. *If ρ is given by* (4.12), *then*

$$\Re \int_0^t \rho(s)\ ds \le C\varepsilon^2 |||W|||^2,\ t \ge 0, \tag{5.22}$$

for some constant C depending on $\mathcal{C}$, r_1, and ξ; see **(H6)**.

Proof of Proposition 5.2. Using the estimates (8.7) and (8.9) we can infer that $\rho(t)$, given by (4.12) is a series which converges uniformly on any compact subset of $\mathbb{R}$. For each fixed t, it can therefore be integrated term-by-term to give

$$\begin{aligned}\Re \int_0^t \rho(s) ds &= \frac{\varepsilon^2}{4} \Re\ i \sum_{j,k\in\mathbb{Z}, j\neq k} \int_0^t e^{i(\mu_k-\mu_j)s} \left(\beta_k\psi_0, (H_0-\lambda_0-\mu_j-i0)^{-1}\mathbf{P_c}\beta_j\psi_0\right) ds \\ &= \frac{\varepsilon^2}{4} \sum_{j,k\in\mathbb{Z}, j\neq k} \Re \frac{e^{i(\mu_k-\mu_j)t}-1}{\mu_k-\mu_j} \left(\beta_k\psi_0, (H_0-\lambda_0-\mu_j-i0)^{-1}\mathbf{P_c}\beta_j\psi_0\right). \end{aligned} \tag{5.23}$$

Define

$$\tilde{\rho}_{j,k} \equiv \frac{e^{i(\mu_k-\mu_j)t}-1}{\mu_k-\mu_j} \left(\beta_k\psi_0, (H_0-\lambda_0-\mu_j-i0)^{-1}\mathbf{P_c}\beta_j\psi_0\right).$$

Then (5.23) can be expressed as

$$\Re \int_0^t \rho(s) ds = \frac{\varepsilon^2}{4} \sum_{j,k\in\mathbb{Z}, j\neq k} \Re\tilde{\rho}_{j,k} = \frac{\varepsilon^2}{8} \sum_{j,k\in\mathbb{Z}, j\neq k} \Re(\tilde{\rho}_{j,k}+\tilde{\rho}_{k,j}). \tag{5.24}$$

Now, since

$$\begin{aligned}\tilde{\rho}_{k,j} &= -\frac{e^{-i(\mu_k-\mu_j)t}-1}{\mu_k-\mu_j} \left(\beta_j\psi_0, (H_0-\lambda_0-\mu_k-i0)^{-1}\mathbf{P_c}\beta_k\psi_0\right) \\ &= -\left[\frac{e^{i(\mu_k-\mu_j)t}-1(\ldots)}{\mu_k-\mu_j}\right]^* \left(\beta_k\psi_0, (H_0-\lambda_0-\mu_k+i0)^{-1}\mathbf{P_c}\beta_j\psi_0,\right)\end{aligned}$$

we have

$$\begin{aligned}&\Re(\tilde{\rho}_{j,k}+\tilde{\rho}_{k,j}) \\ &= \Re \frac{e^{i(\mu_k-\mu_j)t}-1}{\mu_k-\mu_j} \left(\beta_k\psi_0, (H_0-\lambda_0-\mu_j-i0)^{-1} - (H_0-\lambda_0-\mu_k+i0)^{-1}\mathbf{P_c}\beta_j\psi_0\right).\end{aligned} \tag{5.25}$$

Moreover, by (8.5) we can infer

$$\Re(\tilde{\rho}_{j,k}+\tilde{\rho}_{k,j}) = \Re\left(e^{i(\mu_k-\mu_j)t}-1\right)\rho_{j,k} + 2\Im\left(e^{-i(\mu_k-\mu_j)t}-1\right)\delta_{j,k},$$

where, for $j \neq k \in \mathbb{Z}$,

$$\rho_{j,k} \equiv \frac{1}{\mu_k-\mu_j} \left(\beta_k\psi_0, (H_0-\lambda_0-\mu_j-i0)^{-1} - (H_0-\lambda_0-\mu_k-i0)^{-1}\mathbf{P_c}\beta_j\psi_0\right), \tag{5.26}$$

and for $j \neq k,\ j \in \mathbb{Z},\ k \in I_{res}$,

$$\delta_{j,k} \equiv \frac{\pi}{\mu_k-\mu_j} \left(\beta_j\psi_0, \delta(H_0-\lambda_0-\mu_k)\beta_k\psi_0\right). \tag{5.27}$$

Thus, by (5.24) and (5.25)

$$\Re\int_0^t \rho(s)ds = \frac{\varepsilon^2}{8}\sum_{j,k\in\mathbb{Z},j\neq k}\Re\big(e^{i(\mu_k-\mu_j)t}-1\big)\rho_{j,k}+\frac{\varepsilon^2}{4}\sum_{k\in I_{res},k\neq j\in\mathbb{Z}}\Im\big(e^{-i(\mu_k-\mu_j)t}-1\big)\delta_{j,k}. \tag{5.28}$$

We now derive a uniform bound for $\Re\ \int_0^t \rho(s)\ ds$.

Estimating the modulus of the above sum, we have for any t

$$\left|\ \Re\ \int_0^t \rho(s)\ ds\ \right|\ \leq\ \frac{\varepsilon^2}{4}\sum_{j,k\in\mathbb{Z},j\neq k}|\rho_{j,k}|+\frac{\varepsilon^2}{2}\sum_{k\in I_{res},k\neq j\in\mathbb{Z}}|\delta_{j,k}|\,. \tag{5.29}$$

By **(H6)**,

$$\sum_{k\in I_{res},k\neq j\in\mathbb{Z}}|\delta_{j,k}|\ \leq\ \pi\xi\ |||W|||^2. \tag{5.30}$$

We now bound the first term in (5.29). This requires an estimate of

$$|\rho_{j,k}| = \left|\frac{1}{\mu_k-\mu_j}\left(\beta_k\psi_0,(H_0-\lambda_0-\mu_j-i0)^{-1}-(H_0-\lambda_0-\mu_k-i0)^{-1}\mathbf{P_c}\beta_j\psi_0\right)\right|$$

for $j\neq k\in\mathbb{Z}$. We rely on the hypothesis **(H3b)** (singular local decay estimate (2.4)), which implies smoothness of the resolvent of H_0 near accumulation points in $\sigma_{\rm cont}(H_0)$ of the set $\{\lambda_0+\mu_j\}_{j\in\mathbb{Z}}$.

In order to treat both $\lambda_0+\mu_j\in\sigma_{\rm cont}(H_0)$ and $\lambda_0+\mu_j\notin\sigma_{\rm cont}(H_0)$ case simultaneously we regularize $\rho_{j,k}$:

$$\rho^\eta_{j,k}\equiv\frac{1}{\mu_k-\mu_j}\left(\beta_k\psi_0,(H_0-\lambda_0-\mu_j-i\eta)^{-1}-(H_0-\lambda_0-\mu_k-i\eta)^{-1}\mathbf{P_c}\beta_j\psi_0\right). \tag{5.31}$$

Clearly $\rho_{j,k}=\lim_{\eta\searrow 0}\rho^\eta_{j,k}$.

Now by the standard resolvent formula we have

$$\rho^\eta_{j,k}=\left(\beta_k\psi_0,(H_0-\lambda_0-\mu_k-i\eta)^{-1}(H_0-\lambda_0-\mu_j-i\eta)^{-1}\mathbf{P_c}\beta_j\psi_0\right).$$

Thus, using the singular local decay estimate **(H3b)**, we get

$$\begin{aligned}
|\rho_{j,k}| &= \left|\lim_{\eta\searrow 0}\int_0^\infty\left(\beta_k\psi_0,e^{-i(H_0-\lambda_0-\mu_k-i\eta)s}(H_0-\lambda_0-\mu_j-i\eta)^{-1}\mathbf{P_c}\beta_j\psi_0\right)ds\right|\\
&\leq\lim_{\eta\searrow 0}\int_0^\infty e^{-\eta s}\left|\left(w_+\beta_k\psi_0,w_-e^{-iH_0s}(H_0-\lambda_0-\mu_j-i\eta)^{-1}\mathbf{P_c}w_-w_+\beta_j\psi_0\right)\right|ds\\
&\leq\|w_+\beta_k\|\|w_+\beta_j\|\int_0^\infty\|w_-e^{-iH_0s}(H_0-\lambda_0-\mu_j-i0)^{-1}\mathbf{P_c}w_-\|ds\\
&\leq\mathcal{C}\|w_+\beta_k\|\|w_+\beta_j\|\int_0^\infty\langle s\rangle^{-r_1}ds\\
&\leq C\|w_+\beta_k\|\|w_+\beta_j\|
\end{aligned} \tag{5.32}$$

for some constant C depending on $\mathcal{C}$ and r_1. Summing on $j,k\in\mathbb{Z},\ j\neq k$, yields

$$\sum_{j,k\in\mathbb{Z},\ j\neq k}|\rho_{j,k}|\ \leq\ C\ |||W|||^2 \tag{5.33}$$

for some $C > 0$; see (2.7). Use of the bounds (5.30) and (5.33) in (5.29) gives

$$\left| \Re \int_0^t \rho(s)\ ds \right| \ \leq\ C\ \varepsilon^2 |||W|||^2$$

for some constant C depending on $\mathcal{C},\ r_1$, and ξ.

This completes the proof of Proposition 5.2 and therewith Proposition 5.1. □

5.2. Estimates for $\boldsymbol{A(t)}$ under the hypotheses of Theorem 2.1. In this subsection we work under the hypotheses of Theorem 2.1. In particular, we drop hypothesis **(H6)**. *We shall reuse the notation $\tilde{A}$ and $\tilde{E}$ for functions which are different from but related to those defined in section* 5.1.

PROPOSITION 5.3. *Suppose* **(H1)–(H5)** *hold. Then $A(t)$, the solution of* (4.11), *can be expanded as*

$$A(t) \ =\ e^{\int_0^t \eta(s)ds}\Big(e^{-\varepsilon^2(\Gamma t - \int_0^t \sigma(s)ds)} A(0) + R_A(t)\Big), \tag{5.34}$$

$$R_A(t) \ =\ \int_0^t \ e^{-\varepsilon^2\Gamma(t-\tau)+\varepsilon^2\int_\tau^t \sigma(s)ds}\ \tilde{E}(\tau)\ d\tau, \tag{5.35}$$

where

$$\sigma(t) \equiv -\frac{\pi}{4}\Re \sum_{j\in I_{res}, j\neq k\in\mathbb{Z}} e^{i(\mu_k-\mu_j)t}\,(\ \beta_k\psi_0, \delta(H_0-\lambda_0-\mu_j)\beta_j\psi_0) \tag{5.36}$$

is a real almost periodic function with mean $M(\sigma) = 0$, η in (5.46) *is a function whose real part has a bounded time integral of order $\mathcal{O}(\varepsilon^2|||W|||^2)$ and $\tilde{E}(t)$ is given in* (5.42)*; see also* (4.13). *For any $\alpha > 1$, there exists $\delta > 0$ such that $R_A(t)$ satisfies the estimates*

$$\begin{aligned} \sup_{2(\varepsilon^2\Gamma/2)^{-\alpha}\leq t\leq T} \langle t\rangle^{r_1}|R_A(t)| \leq C_1 e^{-(\varepsilon^2\Gamma/2)^{-\delta}} & \sup_{0\leq\tau\leq(\varepsilon^2\Gamma/2)^{-\alpha}} |E(\tau)| \\ +C(\varepsilon^2\Gamma)^{-1} & \sup_{(\varepsilon^2\Gamma/2)^{-\alpha}\leq\tau\leq T} \left(\langle\tau\rangle^{r_1}|E(\tau)|\right), \end{aligned} \tag{5.37}$$

$$\sup_{0\leq t\leq 2(\varepsilon^2\Gamma/2)^{-\alpha}} \langle t\rangle^{r_1}\ |R_A(t)| \leq\ D\ (\varepsilon^2\Gamma/2)^{-\alpha(r_1+1)} \sup_{0\leq\tau\leq 2(\varepsilon^2\Gamma/2)^{-\alpha}} |E(\tau)|. \tag{5.38}$$

Proof. As in the previous subsection we begin with the equation for $A(t)$:

$$\partial_t A(t) \ =\ \big(\rho(t)\ -\ \varepsilon^2\Gamma\ \big)\, A(t) + E(t), \tag{5.39}$$

where $\rho(t)$ and $E(t)$ are given by (4.12)–(4.13). In the previous section we transformed away the term $\rho(t)A(t)$ using the "integration factor" $\exp(\int_0^t \rho(s)\ ds)$. Under the current hypotheses, this can't be done because without **(H6)** $\Re\int_0^t \rho(s)\ ds$ may be unbounded as $t \to \infty$, which could cause the estimates (5.12)–(5.13) to break down. Instead, we proceed by a more refined analysis of $\rho(t)$, which we now outline.

We express $\rho(t)$ as $\rho(t) = \varepsilon^2\sigma(t) + \eta(t)$, where $\eta(t)$ has a time integral whose real part can be bounded by the estimates of section 5.1 and a part, $\varepsilon^2\sigma(t)$, which is almost periodic and of mean zero. Using this decomposition of $\rho(t)$ we write (5.39) as

$$\partial_t A(t) \ =\ \big[-\varepsilon^2\Gamma\ +\ \varepsilon^2\sigma(t)\ + \eta(t)\big]\, A(t)\ +\ E(t).$$

Next introduce the change of variables

$$\tilde{A}(t) \ \equiv \ e^{-\int_0^t \eta(s) \ ds} \ A(t) \tag{5.40}$$

and obtain a reduction to

$$\partial_t \tilde{A} = \left[\ -\varepsilon^2 \Gamma \ + \ \varepsilon^2 \sigma(t) \ \right] \tilde{A} \ + \ \tilde{E}(t), \tag{5.41}$$

$$\tilde{E}(t) \equiv e^{-\int_0^t \eta(s) ds} E(t). \tag{5.42}$$

With this strategy in mind we now proceed to derive the decomposition of $\rho(t)$. We are mostly interested in its real part, so we start with it.

$$\begin{aligned}
\Re\rho(t) &= \Re \frac{i\varepsilon^2}{4} \sum_{j,k\in\mathbb{Z},j\neq k} e^{i(\mu_k-\mu_j)t} \left(\beta_k\psi_0, (H_0-\lambda_0-\mu_j-i0)^{-1}\mathbf{P_c}\beta_j\psi_0\right) \\
&= -\frac{\varepsilon^2}{4} \Im \sum_{j,k\in\mathbb{Z},j\neq k} e^{i(\mu_k-\mu_j)t} \left(\beta_k\psi_0, (H_0-\lambda_0-\mu_j-i0)^{-1}\mathbf{P_c}\beta_j\psi_0\right) \\
&\equiv -\frac{\varepsilon^2}{4} \sum_{j,k\in\mathbb{Z},j\neq k} \Im\eta_{j,k} \\
&= \frac{\varepsilon^2}{8} \sum_{j,k\in\mathbb{Z},j\neq k} \Im\left(\eta_{j,k}+\eta_{k,j}\right).
\end{aligned} \tag{5.43}$$

In a manner similar to the derivation of (5.25) from (5.24) we find

$$\Im\eta_{k,j} = \Im e^{i(\mu_k-\mu_j)t} \left(\beta_k\psi_0, (H_0-\lambda_0-\mu_k+i0)^{-1}\mathbf{P_c}\beta_j\psi_0\right). \tag{5.44}$$

Using (8.5) in (5.44) and then replacing it in (5.43) we get

$$\begin{aligned}
\Re\rho(t) \ &= \ \frac{\pi}{4}\varepsilon^2 \Re \sum_{k\in I_{res},k\neq j\in\mathbb{Z}} e^{i(\mu_j-\mu_k)t} \left(\beta_j\psi_0, \delta(H_0-\lambda_0-\mu_k)\beta_k\psi_0\right) \\
&- \frac{1}{8}\varepsilon^2 \Im \sum_{j,k\in\mathbb{Z},j\neq k} e^{i(\mu_k-\mu_j)t} \big(\beta_k\psi_0, \big[(H_0-\lambda_0-\mu_j-i0)^{-1} \\
&\qquad\qquad -(H_0-\lambda_0-\mu_k-i0)^{-1}\big]\mathbf{P_c}\beta_j\psi_0\big) \\
&= \ \Re \ \eta(t) + \varepsilon^2\sigma(t).
\end{aligned}$$

Therefore,

$$\begin{aligned}
\rho(t) \ &= \ \Re\rho(t) \ + \ i\Im\rho(t) \\
&= \ \eta(t) \ + \ \varepsilon^2\sigma(t),
\end{aligned} \tag{5.45}$$

where

$$\begin{aligned}
\eta(t) &= i \ \Im \ \rho(t) - \frac{1}{8}\varepsilon^2 \Im \sum_{j,k\in\mathbb{Z},j\neq k} e^{i(\mu_k-\mu_j)t} \\
&\quad \left(\beta_k\psi_0, \left[(H_0-\lambda_0-\mu_j-i0)^{-1} - (H_0-\lambda_0-\mu_k-i0)^{-1}\mathbf{P_c}\right]\beta_j\psi_0\right), \qquad (5.46) \\
\sigma(t) &= -\frac{\pi}{4}\Re \sum_{j\in I_{res},j\neq k\in\mathbb{Z}} e^{i(\mu_k-\mu_j)t} \left(\ \beta_k\psi_0, \delta(H_0-\lambda_0-\mu_j)\beta_j\psi_0\right);
\end{aligned}$$

see also (5.36).

Note that $\Re \int_0^t \eta(s)ds$ is uniformly bounded in t. To see this, recall the definition of $\rho_{j,k}$ in Lemma 5.2 (see (5.26)):

$$\rho_{j,k} \equiv \frac{1}{\mu_k - \mu_j} \left(\beta_k\psi_0, \left[(H_0 - \lambda_0 - \mu_j - i0)^{-1} - (H_0 - \lambda_0 - \mu_k - i0)^{-1}\right] \mathbf{P_c}\beta_j\psi_0\right).$$

By (8.7), $\Re\ \eta(t)$ given by (5.46) converges uniformly on $t \in \mathbb{R}$. Therefore, for each $t \in \mathbb{R}$ we may integrate the series term-by-term to obtain

$$\Re \int_0^t \eta(s)ds = \frac{1}{8}\varepsilon^2 \sum_{j,k\ j\neq k} \Re(e^{i(\mu_k-\mu_j)t} - 1)\rho_{j,k}. \tag{5.47}$$

Moreover, the modulus of the right-hand side in (5.47) is less or equal than $\frac{1}{4}\varepsilon^2 \sum_{j,k\ j\neq k} |\rho_{j,k}|$, which by (5.32) is bounded by $C\varepsilon^2|||W|||^2$ for some constant C depending only on $\mathcal{C}$ and r_1. Note that we derived (5.32) by using only hypothesis **(H3b)** and not relying on **(H6)**.

Thus we have

$$\Re \int_0^t \eta(s)ds \leq C\varepsilon^2|||W|||^2. \tag{5.48}$$

To summarize, we have split $\rho(t)$ into

$$\rho(t) = \eta(t)\ +\ \varepsilon^2\sigma(t)$$

such that (5.48) is valid. If we now define $\tilde{A}$ as in (5.40), then by (4.11) $\tilde{A}$ satisfies (5.41). Solving (5.41) we get

$$\begin{aligned} \tilde{A}(t) &= e^{-\varepsilon^2\Gamma t+\varepsilon^2\int_0^t \sigma(s)ds}\tilde{A}(0)\ +\ \int_0^t e^{-\varepsilon^2\Gamma(t-\tau)+\varepsilon^2\int_\tau^t \sigma(s)ds}\tilde{E}(s)\ d\tau \\ &\equiv e^{-\varepsilon^2\Gamma t+\varepsilon^2\int_0^t \sigma(s)ds}\tilde{A}(0)\ +\ R_A(t). \end{aligned} \tag{5.49}$$

From (5.42) and (5.48) it is sufficient to estimate $R_A(t)$ in terms of $\tilde{E}(t)$.

Remark 5.2. The estimates of $R_a(t)$ which appear in the statement of Theorem 2.2 are related to those for $R_A(t)$ via

$$R_a(t)\ =\ e^{-i\lambda_0 t+\int_0^t \eta(s)ds}R_A(t) + \left(1 - e^{\varepsilon^2(\int_0^t \sigma(s)ds-\gamma t)+\Re\int_0^t \eta(s)ds}\right)e^{-\varepsilon^2(\Gamma-\gamma)t}e^{iw(t)}a(0). \tag{5.50}$$

Before we estimate $R_A(t)$, we review some properties of the function $\sigma(t)$.

The function $\sigma(t)$ is almost periodic since the sum of the moduli of its Fourier coefficients is finite. Namely, by (2.20), the terms in the series (5.36) defining $\sigma(t)$ are majorized by those of a convergent series (whose sum is $C\pi^{-1}|||W|||^2$). Therefore, the series in (5.36) is uniformly convergent. As the uniform limit of almost periodic functions, $\sigma(t)$ is then itself almost periodic, bounded by

$$\sup_{t\in\mathbb{R}} |\sigma(t)|\ \leq\ C|||W|||^2 \tag{5.51}$$

for some constant C; see also section 9. Moreover, $\sigma(t)$ has mean value zero since all the Fourier exponents are nonzero; see (5.36) and section 9. Therefore

$$\int_\tau^t \sigma(s)ds \leq \frac{\Gamma}{2}(t-\tau),\ \text{for}\ \ t-\tau \geq \mathcal{M} \tag{5.52}$$

provided $\mathcal{M}$ is taken sufficiently large. It can be shown (see section 9 or [2, p. 42]) that (5.52) holds provided

$$\mathcal{M} \geq \frac{4\ \sup_{t\in\mathbb{R}}\{|\sigma(t)|\}\ L(\Gamma/4)}{\Gamma/2}, \tag{5.53}$$

where $L(\Gamma/4)$ (see Definition 9.1) is such that in each interval of length $L(\Gamma/4)$ there is at least one $\Gamma/4$ almost period for σ.

Using (5.51) and then **(H5)**, we can choose

$$\mathcal{M} = 8CL(\Gamma/4)/\theta_0 \tag{5.54}$$

independently of ε and still satisfy (5.53).

We now return to the estimation of R_A. We split the integral in (5.35) into two integrals, one from 0 to $t-\mathcal{M}$ and the other from $t-\mathcal{M}$ to t. For the former we use (5.52) while for the latter we use (5.51). The result is

$$\begin{aligned} |R_A(t)| \ &\leq \int_0^{t-\mathcal{M}} e^{-\frac{1}{2}\varepsilon^2\Gamma(t-\tau)}|\tilde{E}(\tau)|d\tau \\ &\quad + \int_{t-\mathcal{M}}^{t} e^{\varepsilon^2(C|||W|||^2-\Gamma)(t-\tau)}|\tilde{E}(\tau)|d\tau. \end{aligned} \tag{5.55}$$

The first integral in (5.55) can be bounded exactly as the term $\int_0^t e^{-\varepsilon^2\Gamma(t-\tau)}|\tilde{E}(\tau)|d\tau$ in the proof of Proposition 5.1. The second integral in (5.55) is bounded in the following manner:

$$\begin{aligned} &\langle t\rangle^{r_1}\int_{t-\mathcal{M}}^{t} e^{\varepsilon^2(C|||W|||^2-\Gamma)(t-\tau)}|\tilde{E}(\tau)|d\tau \\ &\leq \frac{\langle t\rangle^{r_1}}{\langle t-\mathcal{M}\rangle^{r_1}}\int_{t-\mathcal{M}}^{t} e^{\varepsilon^2(C|||W|||^2-\Gamma)(t-\tau)}d\tau \sup_{t-\mathcal{M}\leq\tau\leq t}\left(\langle\tau\rangle^{r_1}|E(\tau)|\right) \\ &\leq D \sup_{(\varepsilon^2\Gamma/2)^{-\alpha}\leq\tau\leq t}\left(\langle\tau\rangle^{r_1}|E(\tau)|\right). \end{aligned} \tag{5.56}$$

Note that ε and consequently $\varepsilon^2\Gamma \sim \varepsilon^2|||W|||^2$ are small, so we can consider $\mathcal{M} \ll (\varepsilon^2\Gamma/2)^{-\alpha}$ and $D \sim \mathcal{M} \ll (\varepsilon^2\Gamma)^{-1}$. The result is (5.37). A simple bound, using the definition of $R_A(t)$, yields (5.38).

This completes the proof of Proposition 5.3.

6. Dispersive estimates and local decay. In this section we prove the local decay of ϕ_d and the decay in time of the remainder terms, $E(t)$, in bound state amplitude equation (4.11) of section 4. The arguments rely on hypotheses **(H1)**–**(H5)** and results of the previous section, so we will handle Theorem 2.1 first. However, due to the differences between Theorems 2.2 and 2.3 we separately finish their proofs in the final two subsections of this section. We will repeatedly use the following lemma.

LEMMA 6.1. *For any $\eta \in [0, r_1]$ and $j \in \mathbb{Z}$ we have*

$$\left\|\int_0^t w_- e^{-iH_0(t-s)}\mathbf{P_c} f(s)ds\right\| \ \leq\ C\langle t\rangle^{-\eta}\sup_{0\leq\tau\leq t}\left(\langle\tau\rangle^{\eta}\|w_+ f(\tau)\|\right) \tag{6.1}$$

and

$$\left\|\int_0^t w_- e^{-iH_0(t-s)}\mathbf{P_c}(H_0-\lambda_0-\mu_j-i0)^{-1}f(s)\ ds\right\| \ \leq\ C\langle t\rangle^{-\eta}\sup_{0\leq\tau\leq t}\left(\langle\tau\rangle^{\eta}\ \|w_+ f(\tau)\|\right). \tag{6.2}$$

Proof. The proof follows from the assumed local decay estimates on e^{-iH_0t}; see **(H3a)**. Namely, using that $r_1 > 1$,

$$\begin{aligned}\left\|\int_0^t w_- e^{-iH_0(t-s)}\mathbf{P_c} f(s)\ ds\right\| &\le \int_0^t \|w_- e^{-iH_0(t-s)}\ \mathbf{P_c} w_-\|_{\mathcal{L}(\mathcal{H})}\langle s\rangle^{-\eta}\ ds \\ &\quad \cdot \sup_{0\le\tau\le t}\left(\langle\tau\rangle^{\eta}\|w_+ f(\tau)\|\right) \\ &\le C\int_0^t \langle t-s\rangle^{-r_1}\langle s\rangle^{-\eta}\ ds\ \sup_{0\le\tau\le t}\left(\langle\tau\rangle^{\eta}\|w_+ f(\tau)\|\right) \\ &\le C\langle t\rangle^{-\eta}\sup_{0\le\tau\le t}\left(\langle\tau\rangle^{\eta}\,\|w_+ f(\tau)\|\right),\end{aligned}$$

which proves (6.1). The proof of (6.2) is identical and uses the singular local decay estimate of **(H3b)**. □

We now define the norms

$$[A]_\alpha(T) \ = \ \sup_{0\le\tau\le T}\langle\tau\rangle^{\alpha}|A(\tau)| \tag{6.3}$$

and

$$[\phi_d]_{LD,\alpha}(T) \ = \ \sup_{0\le\tau\le T}\langle\tau\rangle^{\alpha}\|w_-\phi_d(\tau)\|. \tag{6.4}$$

Then we have the following.

Proposition 6.1. *For any $T > 0$ and $\eta \in [0,\ r_1]$,*

$$[\phi_d]_{LD,\eta}(T) \le C\left(\ \|w_+\phi_d(0)\|\ +\ |\varepsilon|\ |||W|||\ [A]_\eta(T)\ \right). \tag{6.5}$$

Proof. From (4.9) we get, using the assumed local decay estimate for e^{-iH_0t} and (6.1),

$$\begin{aligned}\|w_-\phi_d(t)\| &\le \sum_{j=0}^{2}\ \|w_-\phi_j(t)\| \\ &\le C\langle t\rangle^{-\eta}\,\|w_+\phi_d(0)\| + \ C|\varepsilon|\langle t\rangle^{-\eta}\ [A]_\eta(t)\ \sup_{0\le s\le t}\|w_+W(s)\psi_0\| \\ &\quad + C\ |\varepsilon|\ |||W|||\ \langle t\rangle^{-\eta}\,[\phi_d]_{LD,\eta}(t).\end{aligned} \tag{6.6}$$

Since $\|w_+W(s)\psi_0\| \le |||W|||\ \|\psi_0\| \ = \ |||W|||$ and $|\varepsilon|\ |||W|||$ is assumed to be small, multiplying both sides of this last equation by $\langle t\rangle^{\eta}$ and taking supremum over $t \le T$ yields (6.5). □

We now estimate $E(t)$.

Proposition 6.2. *Let $T > 0$. For any $\eta \in [0, r_1]$*

$$[E]_\eta(T)\ \le\ C\left(\varepsilon^2|||W|||^2\ |A(0)|\ +\ |\varepsilon|\ |||W|||\ \|w_+\phi_d(0)\|\ +\ |\varepsilon|^3|||W|||^3\ [A]_\eta(T)\right). \tag{6.7}$$

Proof. $E(t)$ is defined in (4.13). From these equations it is seen that we need to bound the following terms:

$$R_1 \equiv \frac{1}{4}\varepsilon^2|A(0)|\sum_{j,k\in\mathbb{Z}}\left|\left(\beta_k\psi_0,\ e^{-iH_0t}\ (H_0-\lambda_0-\mu_j-i0)^{-1}\mathbf{P_c}\beta_j\psi_0\right)\right|,$$

$$R_2 \equiv \frac{1}{4}\varepsilon^2\sum_{j,k\in\mathbb{Z}}\left|\left(\beta_k\psi_0,\int_0^t\ e^{-iH_0(t-s)}(H_0-\lambda_0-\mu_j-i0)^{-1}\mathbf{P_c}e^{-i(\lambda_0+\mu_j)s}\partial_s A(s)\beta_j\psi_0 ds\right)\right|$$

and

$$\begin{aligned}|\varepsilon\left(\psi_0,\ W(t)\phi_0(t)\right)| &= \left|\varepsilon\left(W(t)\psi_0, e^{-iH_0 t}\phi_d(0)\right)\right|,\\ |\varepsilon\left(\psi_0,\ W(t)\phi_2\right)| &= \left|\varepsilon^2\left(W(t)\psi_0, \int_0^t e^{-iH_0(t-s)}\mathbf{P_c}W(s)\phi_d(s)ds\right)\right|.\end{aligned}$$

The estimates of the above terms repeatedly use Lemma 6.1. Let $\eta \in [0, r_1]$.

Estimation of R_1.

$$\begin{aligned}R_1 &= \frac{1}{4}\varepsilon^2|A(0)|\sum_{j,k\in\mathbb{Z}}\left|\left(w_+\beta_k\psi_0,\ w_-e^{-iH_0 t}(H_0-\lambda_0-\mu_j-i0)^{-1}\mathbf{P_c}w_-\ w_+\beta_j\psi_0\right)\right|\\ &\le C|A(0)|\ \varepsilon^2|||W|||^2\ \langle t\rangle^{-\eta} \qquad (6.8)\end{aligned}$$

by the local decay estimates (2.4).

Estimation of R_2. From (4.11) we have that

$$|\partial_s A(s)| \le C|\varepsilon|\ |||W|||\ |A(s)| + |E(s)| \qquad (6.9)$$

since $\Im\rho$ is linear in $|\varepsilon|\ |||W|||$ and $\Re\rho$, Γ are quadratic.

Applying Lemma 6.1 to R_2 we then get

$$\begin{aligned}R_2 &= \tfrac{1}{4}\varepsilon^2\textstyle\sum_{j,k\in\mathbb{Z}}\left|\left(w_+\beta_k\psi_0, \int_0^t w_-e^{-iH_0(t-s)}(H_0-\lambda_0-\mu_j-i0)^{-1}\mathbf{P_c}w_-\partial_s A(s)w_+\beta_j\psi_0 ds\right)\right|\\ &\le\ C\varepsilon^2|||W|||^2\ \langle t\rangle^{-\eta}\big(|\varepsilon|\ |||W|||\ [A]_\eta(t)\ +\ [E]_\eta(t)\big). \qquad (6.10)\end{aligned}$$

Estimation of $|\varepsilon\left(\psi_0,\ W(t)\phi_0(t)\right)|$. Since, by definition, $\phi_d(0) = \mathbf{P_c}\phi_d(0)$ we can apply local decay estimates for $e^{-iH_0 t}$ to get

$$|\varepsilon\left(W(t)\psi_0,\ \phi_0(t)\right)| \le\ C|\varepsilon|\ |||W|||\ \langle t\rangle^{-\eta}\ \|w_+\phi_d(0)\|. \qquad (6.11)$$

Estimation of $|\varepsilon\left(\psi_0,\ W(t)\phi_2\right)|$. Applying Lemma 6.1 as before we get, for $0 \le t \le T$,

$$|\varepsilon\left(\psi_0,\ W(t)\phi_2\right)| \le C\varepsilon^2|||W|||^2\ \langle t\rangle^{-\eta}\ [\phi_d]_{LD,\eta}(T). \qquad (6.12)$$

Using Proposition 6.1 to estimate $[\phi_d]_{LD,\eta}(t)$ in (6.12), we get

$$|\varepsilon\left(\psi_0,\ W(t)\phi_2\right)| \le C\varepsilon^2|||W|||^2\ \langle t\rangle^{-\eta}\left\{\|w_+\phi_d(0)\|\ +\ |\varepsilon|\ |||W|||\ [A]_\eta(t)\right\}. \qquad (6.13)$$

Finally, combining the above estimates, we can bound $[E]_\eta(T)$ for any $\eta \in [0, r_1]$ as follows:

$$\begin{aligned}[E]_\eta(T) \le C\big\{&\varepsilon^2\ |||W|||^2\ |A(0)| + |\varepsilon|\ |||W|||\ \|w_+\phi_d(0)\|\\ &+\ \varepsilon^2|||W|||^2\ [E]_\eta(T) + |\varepsilon|^3|||W|||^3\ [A]_\eta(T)\big\}. \qquad (6.14)\end{aligned}$$

Since $|\varepsilon|\ |||W|||$ is assumed to be small, Proposition 6.2 follows. □

We can now complete the proof of Theorem 2.1. To prove the assertions concerning the infinite time behavior, the key is to establish local decay of ϕ_d, in particular, the uniform boundedness of $[\phi_d]_{LD,r_1}(T)$. This will follow directly from Proposition 6.1 if we prove the uniform boundedness $[A]_{r_1}(T)$, or equivalently, $[\tilde{A}]_{r_1}(T)$.

PROPOSITION 6.3. *Under the hypothesis of Theorem* 2.1, *there exists an* $\varepsilon_0 > 0$ *such that for each real number* ε, $|\varepsilon| < \varepsilon_0$ *there is a constant* C_* *with the property that for any* $T > 0$

$$[A]_{r_1}(T) \le C_*.$$

Proof. We begin with the expansion of $A(t)$ given in Proposition 5.3. Multiplying (5.34) by $\langle t\rangle^{r_1}$, and taking the supremum over $0 \le t \le T$ we have

$$\begin{aligned}[A]_{r_1}(T) \ \le\ C\Bigg(& |A(0)|\ (\varepsilon^2\Gamma/2)^{-r_1} \ + \sup_{0\le\tau\le 2(\varepsilon^2\Gamma/2)^{-\alpha}} \langle\tau\rangle^{r_1}|R_A(\tau)| \\ & + \sup_{2(\varepsilon^2\Gamma/2)^{-\alpha}\le\tau\le T} \langle\tau\rangle^{r_1}|R_A(\tau)|\ \Bigg).\end{aligned} \tag{6.15}$$

The right-hand side of (6.15) is estimated using Proposition 5.3.

$$\begin{aligned}[A]_{r_1}(T) \le C|A(0)|\ (\varepsilon^2\Gamma/2)^{-r_1} \ + D\ (\varepsilon^2\Gamma/2)^{-\alpha(r_1-1)}\ [E]_0(2(\varepsilon^2\Gamma/2)^{-\alpha}) \\ +\ C_1\ e^{-(\varepsilon^2\Gamma/2)^{-\delta}}\ [E]_0(2(\varepsilon^2\Gamma/2)^{-\alpha})\ + C_2\ (\varepsilon^2\Gamma/2)^{-1}[E]_{r_1}(T).\end{aligned}$$

Next, we apply Proposition 6.2 which yields

$$\begin{aligned}[A]_{r_1}(T) \le C|A(0)|\ (\varepsilon^2\Gamma/2)^{-r_1}\ +\ D\ (\varepsilon^2\Gamma/2)^{-\alpha(r_1+1)}\ [E]_0(2(\varepsilon^2\Gamma/2)^{-\alpha}) \\ +\ C_1 e^{-(\varepsilon^2\Gamma/2)^{-\delta}}\ [E]_0(2(\varepsilon^2\Gamma/2)^{-\alpha}) \\ +\ C_2(\varepsilon^2\Gamma/2)^{-1}\big(\varepsilon^2|A(0)||||W|||^2\ +\ |\varepsilon|\ |||W|||\ \|w_+\phi_d(0)\| \\ +\ |\varepsilon|^3|||W|||^3\ [A]_{r_1}(T)\big).\end{aligned} \tag{6.16}$$

Note that by Proposition 6.2 and the simple bound

$$[A]_0(T)\ \le\ \|\phi_0\|,$$

$[E]_0(2(\varepsilon^2\Gamma/2)^{-\alpha})$ is bounded in terms of the initial data and $|\varepsilon|\ |||W|||$.

Choose ε_0 such that

$$1 - \frac{2C_2|||W|||^3}{\Gamma}\varepsilon_0 = 0,$$

where C_2 is the same as in (6).

Then, for $|\varepsilon| < \varepsilon_0$

$$[A]_{r_1}(T) \le C_*. \tag{6.17}$$

Here, C_* depends on $\|\phi_0\|$, $\|w_+\phi_0\|$, r_1, and ε.

This completes the proof of Proposition 6.3 and therewith the $t \to \infty$ asymptotics asserted in Theorems 2.1–2.3. □

It remains to finish the proofs of the Theorems 2.3 and 2.2. Due to some differences we consider them separately in the following two subsections.

6.1. Proof of Theorem 2.3. In order to obtain (2.23) we note that (4.7), (5.3), and (5.14) together with the definition of $\omega(t)$ in (2.16) already gives us

$$\begin{aligned} a(t) &= e^{-i\lambda_0 t+\int_0^t \rho(s)ds}\big(A(0)e^{-\varepsilon^2\Gamma t} + R_A(t)\big) \\ &= a(0)e^{-\varepsilon^2\Gamma t}e^{i\omega(t)} + R_a(t), \end{aligned}$$

which is in fact the second relation in (2.23). The third is a direct consequence of the second since $P(t) = |a(t)|^2$ while the fourth relation is exactly (4.9).

It remains to prove the intermediate time estimate (2.17). The ingredients are contained in (6.7) and its proof. First, by (5.15)

$$|R_a(t)| \ \le C\ |R_A(t)| \ +\ \mathcal{O}(\varepsilon^2|||W|||^2).$$

So, it suffices to prove an $\mathcal{O}(|\varepsilon|\ |||W|||)$ upper bound for R_A.

Using (5.4) and (5.13) we know that

$$|R_A(t)| \le C\int_0^t\ e^{-\varepsilon^2\Gamma(t-\tau)}\ \ |E(\tau)|\ \ d\tau. \tag{6.18}$$

Let T_0 denote an arbitrary fixed positive number. We estimate the equation (6.18) for $t \in [0, T_0(\varepsilon^2\Gamma)^{-1}]$. We bound the exponential in the integrand by one (explicit integration would give something of order $(\varepsilon^2\Gamma)^{-1}$) and bound $|E(\tau)|$ by estimating the expressions in the proof of Proposition 6.2. First, the estimates of Proposition 6.2 for R_1 and $|\varepsilon\,(\psi_0,\ W(t)\phi_0(t))|$ are useful as is. Integration of the bounds (6.8) and (6.11) gives

$$\int_0^t\ e^{-\varepsilon^2\Gamma(t-\tau)}R_1\ d\tau \le C\ \varepsilon^2|||W|||^2\ \|w_+\phi(0)\|,$$

$$\int_0^t\ e^{-\varepsilon^2\Gamma(t-\tau)}\ |\varepsilon\,(\psi_0,\ W(t)\phi_0(t))|\ \ d\tau \le C\ |\varepsilon|\ \ |||W|||\ \|w_+\phi(0)\|. \tag{6.19}$$

To estimate the contributions of R_2, first observe that by (6.9) and Proposition 6.2 with $\eta = 0$

$$|\partial_s A(s)|\ \ \le\ \ C\ |\varepsilon|\ \ |||W|||\ \|w_+\phi(0)\|. \tag{6.20}$$

Therefore, using local decay estimates we have

$$\begin{aligned} \int_0^t\ e^{-\varepsilon^2\Gamma(t-\tau)}R_2\ d\tau \le&\ \ C\ T_0(\varepsilon^2\Gamma)^{-1}\ |\varepsilon|^3|||W|||^3\ \|w_+\phi(0)\| \\ \le&\ \ D|\varepsilon|\ \ |||W|||\ \|w_+\phi(0)\|. \end{aligned}$$

Finally, we come to the contribution of $|\varepsilon\,(\psi_0,\ W(t)\phi_2)|$. We rewrite it as follows:

$$\begin{aligned} |\varepsilon\,(\psi_0,\ W(t)\phi_2)| =&\ \ \varepsilon^2\left|\int_0^t\ \big(W(s)e^{iH_0(t-s)}\mathbf{P_c}W(t)\psi_0, \phi_d(s)\big)ds\right| \\ =&\ \ \left|\int_0^t\ \varepsilon^2(w_+W(s)w_+\cdot w_-e^{iH_0(t-s)}\mathbf{P_c}w_-\cdot w_+W(t)\psi_0,\ w_-\phi_d(s))\ ds\right|. \end{aligned} \tag{6.21}$$

Recall that by (4.9) $\phi_d\ =\ \phi_0\ +\ \phi_1\ +\ \phi_2$, where $\phi_0(t) = e^{-iH_0 t}\phi_d(0)$. Using local decay estimates **(H3a)**, the contribution of the term $\phi_0(t)$ can be bounded by $C\ \varepsilon^2|||W|||^2\ \|w_+\phi_d(0)\|\ \langle\tau\rangle^{-r_1}$. Multiplication of this bound by $e^{-\varepsilon^2\Gamma(t-\tau)}$ and integration with respect to t gives the bound $C\ \varepsilon^2|||W|||^2\|w_+\phi_d(0)\|$. To assess the contributions from $\phi_1+\phi_2$, note that local decay estimates **(H3a)** imply

$$\|w_-(\phi_1+\phi_2)\|\ \le\ C\ |\varepsilon|\ |||W|||\ \|w_+\phi(0)\|. \tag{6.22}$$

Putting together the contributions from ϕ_0 and from $\phi_1+\phi_2$, we have

$$\int_0^t e^{-\varepsilon^2\Gamma(t-\tau)}\left|\varepsilon\left(\psi_0,\ W(t)\phi_2\right)\right|\,d\tau\ \le\ C\left(\ \varepsilon^2|||W|||^2\ \|w_+\phi_d(0)\|\ +\ (\varepsilon^2\Gamma)^{-1}\ |\varepsilon|^3|||W|||^3\right). \tag{6.23}$$

The above estimates and (5.15) imply (2.17). Now, (2.18) is a direct consequence of (2.17) and the relation $P(t)=|a(t)|^2$.

This concludes the proof of Theorem 2.3.

6.2. Proof of Theorem 2.2. As in the proof of Theorem 2.3 relations (4.7), (5.34), (5.50), and the definition of $\omega(t)$ in (2.16) gives

$$\begin{aligned} a(t) &= e^{-i\lambda_0 t+\int_0^t\eta(s)ds}\left(A(0)e^{-\varepsilon^2\left(\Gamma t-\int_0^t\sigma(s)ds\right)}+R_A(t)\right)\\ &= a(0)e^{-\varepsilon^2(\Gamma-\gamma)t}e^{i\omega(t)}+R_a(t), \end{aligned}$$

which is the second relation in (2.15). In what follows, the only difference from the previous argument is in estimating $R_a(t)$.

We start with the relation (5.50):

$$R_a(t)\ =\ e^{-i\lambda_0 t+\int_0^t\eta(s)ds}R_A(t)+\left(1-e^{\varepsilon^2(\int_0^t\sigma(s)ds-\gamma t)+\Re\int_0^t\eta(s)ds}\right)e^{-\varepsilon^2(\Gamma-\gamma)t}e^{iw(t)}a(0). \tag{6.24}$$

Since $\sigma(t)$ is an almost periodic function with zero mean, for any $\gamma>0$ there is an $\mathcal{M}_\gamma>0$ such that whenever $|t|\ge\mathcal{M}_\gamma$

$$\int_0^t\sigma(s)ds\le\gamma t.$$

On the other hand for $|t|<\mathcal{M}_\gamma$, using (5.51) we have

$$\int_0^t\sigma(s)ds\le C\mathcal{M}_\gamma|||W|||^2.$$

So, in both cases,

$$\int_0^t\sigma(s)ds-\gamma t\le C\mathcal{M}_\gamma|||W|||^2.$$

Substituting now in (6.24) and tacking into account that by (5.48),

$$\Re\int_0^t\eta(s)ds\ \le\ C\varepsilon^2|||W|||^2$$

uniformly in t, we get

$$|R_a(t)|\ \le\ C\,|R_A(t)|+\mathcal{O}(\varepsilon^2|||W|||^2). \tag{6.25}$$

It remains to prove an $\mathcal{O}(|\varepsilon|\ |||W|||)$ for $R_A(t)$. Looking now at (5.55) we see that we can bound the exponential by $\max\{1,e^{\varepsilon^2(C|||W|||^2-\Gamma)\mathcal{M}}\}$. Now, the same argument as in the end of the previous subsection will give us the required result.

This completes the proof of Theorem 2.2.

7. Generalizations. In the previous sections we considered perturbations of the form $\varepsilon W(t)$, with $W(t)$ independent of ε. In this section, we shall extend our theory to a more general class of potentials, W_ε, which are small for small ε but which may deform nontrivially as ε varies.

Consider a family of perturbations $\mathcal{W}$ and the general system

$$\begin{aligned} i\partial_t \phi(t) &= \left(H_0 + W(t)\right)\phi(t), \\ \phi|_{t=0} &= \phi(0), \end{aligned} \tag{7.1}$$

where $W \in \mathcal{W}$ (compare to (2.1). The results are as follows.

THEOREM 7.1. *Suppose that H_0 and any $W \in \mathcal{W}$ satisfy hypotheses* **(H1)–(H5)**. *In addition assume the following:*

(H7) *Equi-almost periodicity. There exists a positive constant L_{θ_0}, independent of $W \in \mathcal{W}$, such that in any interval of real numbers of length L_{θ_0}, the function $|||W|||^{-2}\ \sigma(t)$ ($|||W||| \neq 0$), where*

$$\sigma(t) \equiv -\frac{\pi}{4}\Re \sum_{j \in I_{res}, j\neq k \in \mathbb{Z}} e^{i(\mu_k-\mu_j)t}\left(\beta_k\psi_0, \delta(H_0-\lambda_0-\mu_j)\beta_j\psi_0\right) \tag{7.2}$$

has a $\theta_0/4$ almost period, θ_0 is given by **(H5)**. *More precisely, there exists $L_{\theta_0} > 0$ which does not depend on W such that in any interval of length L_{θ_0} there is a number $\tau = \tau(\theta_0/4)$ such that for all $t \in \mathbb{R}$*

$$\left|\ |||W|||^{-2}\sigma(t+\tau)\ -\ |||W|||^{-2}\sigma(t)\ \right|\ \leq\ \theta_0/4. \tag{7.3}$$

If $w_+\phi(0) \in \mathcal{H}$, then there exists an $\varepsilon_0 > 0$ (depending on $\mathcal{C},\ r_1,\ \theta_0,$ and L_{θ_0}) such that whenever $|||W||| < \varepsilon_0$, the solution of (7.1) *satisfies the local decay estimate (identical with the one in Theorem* 2.1)

$$\|w_-\ \phi(t)\| \leq C\langle t\rangle^{-r_1}\|w_+\ \phi_0\|, \quad t \in \mathbb{R}. \tag{7.4}$$

Sketch of the proof. Once we drop ε from all expressions (since it is not present in the actual setting), the arguments in the previous sections hold in this case except the analysis of $\sigma(t)$ in Proposition 5.3. Formulas (5.36) and (7.2) are the same, but now $\mu_j,\ \beta_j,\ j \in \mathbb{Z}$, are not fixed as they define W by **(H4)** and W sweeps a general class $\mathcal{W}$. This may prevent us from finding a fixed time interval, $\mathcal{M}$, independent of $W \in \mathcal{W}$, after which $\sigma(t)$ is within $\Gamma/2$ distance from its mean; see relations (5.52)–(5.54).

Nevertheless, **(H7)** is exactly what we need to overcome the difficulty. A straightforward calculation shows that any $\theta_0/4$ almost period of $|||W|||^{-2}\sigma(t)$ is a $\Gamma/4$ almost period for $\sigma(t)$. Consequently, $L(\Gamma/4)$ in (5.54) is bounded above by $L(\theta_0)$ given in **(H7)**. But the latter is fixed, so we can choose

$$\mathcal{M} = 8CL(\theta_0)/\theta_0 \tag{7.5}$$

independent of $W \in \mathcal{W}$ and still satisfy (5.53) hence (5.52).

Finally, we can close the arguments exactly as we did for Theorem 2.1.

Remark 7.1. Theorems analogous to Theorem 2.2 (respectively, Theorem 2.3) can be proved under hypotheses **(H1)-(H5), (H7)** (respectively, **(H1)–(H6)**).

Examples. **(H7)** holds trivially for

(1) $\mathcal{W} = \{\varepsilon W(t,x) :\ \varepsilon \in \mathbb{R},\ W \text{ fixed}\}$ or

(2) $\mathcal{W} = \{\varepsilon W(\varepsilon^{-1}t, x) : \ \varepsilon \in \mathbb{R} - \{0\}, \ |\varepsilon| \leq 1, \ \ W \text{ fixed}\}$.

In Example (1), ε cancels in the formula $|||W|||^{-2}\sigma(t)$ while in Example (2) we have a time dilation which shrinks the gaps between the almost periods, so the $L(\theta_0)$ valid for $W(t,x)$ is good for the entire family.

(3) There are more general families of perturbations $\mathcal{W}$ for which **(H7)** holds. For example, if $\mathcal{W}$ is equi-almost periodic, see section 9.

8. Appendix: Singular operators. In this section we present the definition and the properties we needed previously for the singular operators

$$e^{-iH_0t}\left(H_0 - \Lambda - i0\right)^{-1}\mathbf{P_c}, \ \delta\left(H_0 - \Lambda\right)\mathbf{P_c}, \ \text{P.V.}\left(H_0 - \Lambda\right)^{-1}\mathbf{P_c}$$

and establish the identities

$$\left(H_0 - \Lambda \mp i0\right)^{-1}\mathbf{P_c} \ = \ \text{P.V.}\left(H_0 - \Lambda\right)^{-1}\mathbf{P_c} \pm i\pi\delta\left(H_0 - \Lambda\right)\mathbf{P_c}$$

suggested by the well-known distributional identities

$$(x \mp i0)^{-1} \ = \ \text{P.V.}\ \frac{1}{x} \ \pm i\pi \ \delta(x).$$

Recall that we are in the complex Hilbert space $\mathcal{H}$ with self-adjoint "weights" $w_\pm$ and projection operator $\mathbf{P_c}$ satisfying (i), (ii), and (iii). We can then construct the complex Hilbert space $\mathcal{H}_+$ as the closure of the domain of w_+ under the scalar product $(f,g)_+ = (w_+f, w_+g)$ and the complex Hilbert space $\mathcal{H}_-$ as the closure of $\mathbf{P_c}\mathcal{H}$ under the scalar product $(f,g)_- = (w_-f, w_-g)$.

By the hypotheses of section 2, H_0 is a self-adjoint operator on $\mathcal{H}$ and satisfies the local decay estimate (2.3). Based on this property, in [11, 22, 23] it is proved that for Λ in the continuous spectrum of H_0 and $t \in \mathbb{R}$

$$T_t \equiv i \lim_{\eta \searrow 0} \int_t^\infty e^{-i(H_0 - \Lambda - i\eta)s} ds \mathbf{P_c},$$
$$T_t^* \equiv -i \lim_{\eta \searrow 0} \int_{-\infty}^{-t} e^{-i(H_0 - \Lambda + i\eta)s} ds \mathbf{P_c}$$

are well defined linear bounded operators from $\mathcal{H}_+$ to $\mathcal{H}_-$. We then define

$$e^{-iH_0t}\left(H_0 - \Lambda - i0\right)^{-1}\mathbf{P_c} \equiv e^{-i\Lambda t}T_t, \tag{8.1}$$
$$e^{+iH_0t}\left(H_0 - \Lambda + i0\right)^{-1}\mathbf{P_c} \equiv e^{+i\Lambda t}T_t^*, \tag{8.2}$$

and

$$\text{P.V.}\left(H_0 - \Lambda\right)^{-1}\mathbf{P_c} \equiv \frac{1}{2}(T_0 + T_0^*), \tag{8.3}$$
$$\delta\left(H_0 - \Lambda\right)\mathbf{P_c} \equiv \frac{1}{2\pi i}(T_0 - T_0^*). \tag{8.4}$$

Note that the definitions imply the identities

$$\left(H_0 - \Lambda \mp i0\right)^{-1}\mathbf{P_c} = \text{P.V.}\left(H_0 - \Lambda\right)^{-1}\mathbf{P_c} \pm i\pi\delta\left(H_0 - \Lambda\right)\mathbf{P_c}. \tag{8.5}$$

Particularly important properties of these operators are their symmetries when viewed as quadratic forms on $\mathcal{H}_+ \times \mathcal{H}_+$. For example, on any $f, \ g \in \mathcal{H}_+$ the quadratic form induced by T_t is given by

$$(f,g) \mapsto (w_+f, w_-T_tg).$$

Note that

$$\lim_{\eta\searrow 0}(f,T_t^\eta g)\equiv\lim_{\eta\searrow 0}\left(f,i\int_t^\infty e^{-i(H_0-\Lambda-i\eta)s}ds\mathbf{P_c}g\right) = (w_+f,w_-T_tg) \tag{8.6}$$

by the following calculation:

$$\begin{aligned}\lim_{\eta\searrow 0}\left(f,i\int_t^\infty e^{-i(H_0-\Lambda-i\eta)s}ds\mathbf{P_c}g\right)&=\lim_{\eta\searrow 0}\left(f,\mathbf{P_c}i\int_t^\infty e^{-i(H_0-\Lambda-i\eta)s}ds\mathbf{P_c}g\right)\\&=\lim_{\eta\searrow 0}\left(f,w_+w_-\mathbf{P_c}i\int_t^\infty e^{-i(H_0-\Lambda-i\eta)s}ds\mathbf{P_c}g\right)\\&=\lim_{\eta\searrow 0}\left(w_+f,w_-i\int_t^\infty e^{-i(H_0-\Lambda-i\eta)s}ds\mathbf{P_c}g\right)\\&=(w_+f,w_-T_tg),\end{aligned}$$

where we used that $\mathbf{P_c}$ is a projection operator commuting with the integral operator, the identity $w_+w_-\mathbf{P_c}=\mathbf{P_c}$ on $\mathcal{H}$, the self-adjointness of $w_\pm$ and $\mathbf{P_c}$, and $\lim_{\eta\searrow 0}w_-T_t^\eta=w_-T_t$ in $\mathcal{L}(\mathcal{H}_+,\mathcal{H})$.

Identity (8.6) suggests the notation

$$(f,g)\mapsto(f,T_tg)$$

for the quadratic form induced by T_t, where $(\cdot,\cdot)$ can formally be treated as the scalar product in $\mathcal{H}$. Moreover, (8.6) implies

$$(f,T_tg)=(T_t^*f,g).$$

Therefore, the quadratic form induced by P.V.$(H_0-\Lambda)^{-1}\mathbf{P_c}$ is the symmetric part of the one induced by T_0 while $\delta(H_0-\lambda)\mathbf{P_c}$ induces the skew-symmetric part of it divided by the factor $i\pi$. As a consequence both the forms corresponding to the last two operators are symmetric.

In conclusion, for any $f,g\in Domain(w_+),\ t\in\mathbb{R}$, and $\Lambda\in\sigma_{\text{cont}}(H_0)$ we have

$$\begin{aligned}(f,e^{\mp iH_0t}(H_0-\Lambda\mp i0)^{-1}\mathbf{P_c}g)&\equiv\big(w_+f,w_-e^{\mp iH_0t}(H_0-\Lambda\mp i0)^{-1}\mathbf{P_c}g\big)\\&\le C_t\ \|w_+f\|\ \|w_+g\|,\end{aligned}\tag{8.7}$$

$$(f,\delta(H_0-\Lambda)\mathbf{P_c}g)\equiv(w_+f,w_-\delta(H_0-\Lambda)\mathbf{P_c}g)\le\ \frac{C_0}{\pi}\ \|w_+f\|\ \|w_+g\|,\tag{8.8}$$

$$(f,\text{P.V.}(H_0-\Lambda)^{-1}\mathbf{P_c}g)\equiv\big(f,w_-\text{P.V.}(H_0-\Lambda)^{-1}\mathbf{P_c}g\big)\le\ C_0\ \|w_+f\|\ \|w_+g\|.\tag{8.9}$$

The inequalities are due to the boundedness of T_t, where C_t denotes the norm of T_t in $\mathcal{L}(\mathcal{H}_+,\mathcal{H}_-)$. Moreover, the following symmetry properties hold:

$$\begin{aligned}(f,e^{\mp iH_0t}(H_0-\Lambda\mp i0)^{-1}\mathbf{P_c}g)&=(e^{\pm iH_0t}(H_0-\Lambda\pm i0)^{-1}\mathbf{P_c}f,g),\\(f,\delta(H_0-\Lambda)\mathbf{P_c}g)&=(\delta(H_0-\Lambda)\mathbf{P_c}f,g),\\(f,\text{P.V.}(H_0-\Lambda)^{-1}\mathbf{P_c}g)&=(\text{P.V.}(H_0-\Lambda)^{-1}\mathbf{P_c}f,g).\end{aligned}$$

9. Appendix: Almost periodic functions. In this section we present the definition and the properties of almost periodic functions we used throughout this paper. We will confine to functions of the form $f:\mathbb{R}\to X$, where X is a complex Banach space with norm denoted by $\|\cdot\|$.

Definition 9.1. *We say that*

$$f : \mathbb{R} \to X$$

is almost periodic if and only if it is continuous and for each $\varepsilon > 0$ there exists a length $L(\varepsilon, f) > 0$ such that in any closed interval of length greater or equal than $L(\varepsilon, f)$ there is at least one τ with the property that for all $t \in \mathbb{R}$ we have

$$\|f(t+\tau) - f(t)\| \leq \varepsilon. \tag{9.1}$$

The number τ with the property above is called an ε almost period for f.

We say that the family, $\mathcal{F}$ of almost periodic functions is equi-almost periodic if $L(\varepsilon, f)$ can be choosen independently of $f \in \mathcal{F}$.

Example. Any continuous periodic function is almost periodic since for any $\varepsilon > 0$ we can choose the length $L(\varepsilon)$ to be the period of the function.

Theorem 9.1. *Any almost periodic function has a relative compact image.*

The proof of the theorem can be found in [9, Property 1, p. 2]. In particular, any almost periodic function $f : \mathbb{R} \to X$ is in the Banach space of all bounded and continuous functions on $\mathbb{R}$ with values in X, $C(X)$, endowed with the uniform norm. The next result is Bochner's characterization of almost periodic functions; see, for example, [9, Bochner's theorem, p. 4].

Theorem 9.2 (Bochner). *Let $f : \mathbb{R} \to X$ be a continuous function. For f to be almost periodic it is necessary and sufficient that the family of functions $\{f(t+h)\}$, $-\infty < h < \infty$, is relatively compact in $C(X)$.*

As a consequence of Bochner's criterion and Property 4 from [9, p. 3] we have the following.

Theorem 9.3. *Suppose $X_1,\ X_2, \ldots, X_{k+1}$ are Banach spaces, $f_i : \mathbb{R} \to X_i,\ 1 \leq i \leq k$ are almost periodic functions, and $g : \prod_{i=1}^{k} \to X_{k+1}$ is continuous. Then $g(f_1(t),\ f_2(t), \ldots, f_k(t))$ is an almost periodic function.*

The last theorem has very important consequences in the theory of almost periodic functions. We will list only those which are useful in our presentation.

Corollary 9.1. *A finite sum of almost periodic functions with values in the same Banach space is an almost periodic function.*

Corollary 9.2. *A product between a complex valued almost periodic function and an arbitrary almost periodic function is an almost periodic function.*

Corollary 9.3. *If $\mathcal{H}$ is a complex Hilbert space, $\mathcal{L}(\mathcal{H})$ is the Banach space of the bounded linear operators on $\mathcal{H}$, and $W : \mathbb{R} \to \mathcal{L}(\mathcal{H})$ is an almost periodic function, then for any $\varphi,\ \psi \in \mathcal{H}$ the following functions are almost periodic:*

$$\begin{aligned}
&t \to W(t)\varphi, \\
&t \to (\psi,\ W(t)\varphi)\,, \\
&t \to (W(t)\psi,\ W(t)\varphi)\,,
\end{aligned}$$

where $(\cdot, \cdot)$ denotes the scalar product on $\mathcal{H}$.

Another essential result in the theory of almost periodic functions is (see, for example, [9, Property 3, p. 3]) the following.

Theorem 9.4. *Any uniform convergent sequence of almost periodic functions converges towards an almost periodic function.*

Corollary 9.4. *If $\{\mu_j\}_{j\in\mathbb{Z}} \subset \mathbb{R}$ and $\{\beta_j\}_{j\in\mathbb{Z}} \subseteq X$ satisfies $\sum_{j\in\mathbb{Z}} \|\beta_j\| < \infty$, then*

$$\sum_{j\in\mathbb{Z}} e^{i\mu_j t}\beta_j$$

is an X-valued almost periodic function of t.

Proof. According to Weierstrass's criterion the series $\sum_{j\in\mathbb{Z}} e^{i\mu_j t}\beta_j$ is uniformly convergent on $\mathbb{R}$.

By Corollary 9.1 and the example above the partial sums of the above series are almost periodic. The result follows now from Theorem 9.4. □

We continue with the harmonic analysis results for almost periodic functions.

THEOREM 9.5 (mean value). *If $f : \mathbb{R} \to X$ is almost periodic, then the following limit exists and it is approached uniformly with respect to $a \in \mathbb{R}$:*

$$\lim_{t\to\infty} \frac{1}{t}\int_a^{a+t} f(s)ds = M(f) \in X.$$

Moreover, whenever

$$t \geq \frac{4\sup_{s\in\mathbb{R}} \|f(s)\| L(\varepsilon/2, f)}{\varepsilon}$$

we have

$$\left\| M(f) - \frac{1}{t}\int_a^{a+t} f(s)ds \right\| \leq \varepsilon$$

for all $a \in \mathbb{R}$.

The proof of the mean value theorem in this form can be found in [2, pp. 39–44]. Note that although Bohr's book considers only complex valued almost periodic functions the proof can be carried on to Banach space valued functions by simply replacing the modulus by the norm and the Lebesque's integral for complex valued functions by the Bochner's integral.

The results of the next theorem are presented in [9, Chapter 2].

THEOREM 9.6 (fundamental theorem). *If $f,\ g : \mathbb{R} \to X$ are almost periodic, then*

(a) *for any $\mu \in \mathbb{R}$,*

$$\lim_{t\to\infty} \frac{1}{t}\int_0^{t} f(s)e^{-i\mu s}ds = a(\mu, f)$$

exists and is nonzero for at most a denumerable set of μ's; if $a(\mu, f) \neq 0$, then $a(\mu, f)$ is called a Fourier coefficient for f while μ is called a Fourier exponent;

(b) *$a(\mu, f) = a(\mu, g)$ for all $\mu \in \mathbb{R}$ if and only if $f \equiv g$;*

(c) *let $\Lambda(f) = \{\mu : \ a(\mu, f) \neq 0\}$ denote the set of Fourier exponents for f; then there is an ordering on $\Lambda(f)$, $\Lambda(f) = \{\mu_1,\ \mu_2, \ldots\}$ independent of the Fourier coefficients, such that for any $\varepsilon > 0$ there exist the numbers $N(\varepsilon) \in \mathbb{N}$, $0 \leq k_{n,\varepsilon} \leq 1$, $n \in \mathbb{N}$, with the property that the trigonometric polynomial*

$$P_\varepsilon(t) = \sum_{n=1}^{N(\varepsilon)} k_{n,\varepsilon} a(\mu_n, f)e^{i\mu_n t}$$

satisfies

$$\|f(t) - P_\varepsilon(t)\| \leq \varepsilon \quad \text{for all } t \in \mathbb{R}.$$

Moreover, $k_{n,\varepsilon}$ can be choosen such that for any fixed n, $\lim_{\varepsilon\searrow 0} k_{n,\varepsilon} = 1$.

In this paper we use a less general result than the above fundamental theorem, namely, the following.

Corollary 9.5. *If $f(t) = \sum_{j\in\mathbb{Z}} e^{i\mu_j t}\beta_j$, where $\{\mu_j\}_{j\in\mathbb{Z}} \subset \mathbb{R}$ and $\sum_{j\in\mathbb{Z}} \|\beta_j\| < \infty$, then $\Lambda(f) = \{\mu_j\}_{j\in\mathbb{Z}}$, $a(\mu_j, f) = \beta_j$, $j \in \mathbb{Z}$, in particular if $\mu_j \neq 0$, $j \in \mathbb{Z}$, then $M(f) = 0$. Moreover, we can arbitrarily order $\Lambda(f)$ and still have that for any $\varepsilon > 0$ there exists a natural number $N(\varepsilon)$ such that*

$$\|f(t) - \sum_{j=-N(\varepsilon)}^{j=N(\varepsilon)} e^{i\mu_j t}\beta_j\| \leq \varepsilon$$

or, in other words, in this particular case the conclusion in part (c) of the fundamental theorem is valid even if we have an arbitrary order on $\Lambda(f)$ and we choose $k_{j,\varepsilon} \equiv 1$.

Proof. By the Weierstrass criterion the series

$$f(t)e^{-i\mu t} = \sum_{j\in\mathbb{Z}} e^{i(\mu_j-\mu)t}\beta_j$$

is uniformly convergent on $\mathbb{R}$. So, when we compute $a(\mu, f)$ we can integrate term by term and therefore use the identities

$$\lim_{t\to\infty} \frac{1}{t}\int_0^t e^{-i\lambda s} ds = \begin{cases} 0 & \text{if} \quad \lambda \neq 0, \\ 1 & \text{if} \quad \lambda = 0 \end{cases}$$

to get the first part of the corollary. The last part is a direct consequence of the fact that f is an absolute and uniform convergent series. □

1. Introduction.

We develop some aspects of general H-convergence and homogenization theory for second order elliptic difference operators and consider several homogenization problems for random discrete elliptic operators with rapidly oscillating coefficients. More precisely, we study the asymptotic behavior of effective coefficients for a family of random difference schemes whose coefficients can be obtained by the discretization of random high-contrast checker-board structures. Then we compare, for various discretization methods, the effective coefficients obtained with the homogenized coefficients for corresponding differential operators.

Many results can also be formulated in terms of the central limit theorem for random walks in random statistically homogeneous media.

Originally, G- and H-convergence of differential operators and Γ-convergence of the corresponding functionals were introduced by Spagnolo [27], De Giorgi [7], [8], and Murat and Tartar [22]. Then these notions were developed and generalized essentially in the works of Bensoussan, Lions, and Papanicolaou [4], Tartar [26], Murat [21], Jikov et al. [28], G. Dal Maso [18], and many others. This resulted in the appearance of advanced homogenization theory.

In recent years, significant progress has been achieved in the homogenization theory of random differential operators. We refer to the original works of Kozlov [13] and Papanicolaou and Varadhan [24], and to the book by Jikov, Kozlov, and Oleinik [11] wherein an additional bibliography can be found. In particular, in case of random high-contrast checker-board structures, the asymptotics of effective diffusion have been constructed in Jikov, Kozlov, and Oleinik [11]. Berlyand and Golden in [5] have improved this result in a special case.

In contrast with differential operators, the homogenization theory of difference operators is not so well developed. There are only a few mathematical works on this subject, among them Künnemann [17], Kozlov [14], [15], and Krasniansky [16]. In

[17] it is proved that the central limit theorem holds for symmetric random walks in random ergodic statistically homogeneous media. Then, many interesting results for various kinds of random walks in random media were obtained in Kozlov [14]. The first homogenization results for difference schemes were formulated and proved in Kozlov [15]. We also mention the work Bricmont and Kupiainen [6] where the central limit theorem was obtained for a class of nonsymmetric random walks.

Perhaps the difference operators with rapidly oscillating coefficients did not attract the attention of mathematicians because these operators did not appear in the classical difference schemes approximation approach (see, for example, Quarteroni and Valli [25]): the fast oscillation of coefficients of difference schemes would contradict the regularity and even the measurability of coefficients of the initial differential equations.

On the other hand, many modern practical and numerical applications involve various homogenization problems for discrete operators with rapidly oscillating coefficients. For instance, when discretizing microinhomogeneous media, due to the natural restrictions, it is not possible to keep the size of the numerical grid much smaller than the typical size of inhomogeneity (the microscopic length scale) of the medium. This leads to the appearance of difference operators with rapidly oscillating coefficients (see, for instance, McCarthy [19], Nœtinger [23]). The most important question here is, How far could the effective coefficients of a difference scheme diverge from ones of corresponding differential operators? The first successful attempt to answer this question was done by Avellaneda, Hou, and Papanicolaou [2] where it was shown that, in the multidimensional case, the finite difference approach does not provide the right homogenized coefficients unless the ratio of the size of a discretization mesh to the microscopic length scale goes to 0.

In the present work we show that the effective coefficients of the difference schemes approximating a family of elliptic PDEs with rapidly oscillating coefficients depend essentially on the discretization method.

The paper is divided into two parts. The first one is devoted to H-convergence and homogenization of difference operators.

Earlier homogenization problems for difference operators were investigated by Kozlov in [15] where a number of homogenization results for difference schemes were obtained. In the present work we extend further the homogenization theory of discrete operators and prove a number of basic statements such as convergence of solutions of the Neumann problem, convergence of energies and of arbitrary solutions, Γ-convergence, and some others. To this end we mainly use the discrete analogue of the compensated compactness technique originally introduced in Murat [21] and Tartar [26] for functions of continuous arguments. Namely, we prove a version of compensated compactness lemma, adapted to difference operators, and then apply it systematically in our considerations in combination with the method of correctors and variational techniques.

For the sake of completeness we also formulate some technical results from Kozlov [15] and give another proof of the homogenization theorem for random difference operators. An additional reason for this is the fact that we use a more general definition of ellipticity than that in [15].

It should be noted that although some basic ideas here have been borrowed from homogenization theory of differential equations, still the peculiarities of difference operators such as the big dimension of difference gradient, the irreducibility and ellipticity conditions in the case of boundary-value problems, and the asymptotic nature of difference schemes, create additional difficulties in studying these operators and make the generalization of homogenization theory to difference operators nontrivial.

In the second part of the paper, we discretize high-contrast two-dimensional checker-board structures, find the asymptotics of effective diffusion, and show that different discretization methods lead to different asymptotics.

1.1. Difference elliptic operators. Let $Q \subset \mathbb{R}^d$ be a smooth bounded domain and let $Q_\varepsilon = Q \cap \varepsilon\mathbb{Z}^d$, where $\mathbb{Z}^d$ is the standard integer lattice in $\mathbb{R}^d$ and $\varepsilon > 0$. We consider the discrete Dirichlet problem in Q_ε:

$$A_\varepsilon u^\varepsilon(x) = \sum_{z,z' \in \Lambda} \partial^\varepsilon_{-z}\left(a^\varepsilon_{zz'}(x)\partial^\varepsilon_{z'} u^\varepsilon(x)\right) = f^\varepsilon(x) \quad \text{in } Q_\varepsilon\,, \qquad u^\varepsilon(x) = 0 \quad \text{on } \partial Q^\Lambda_\varepsilon\,. \tag{1.1}$$

Here Λ is a fixed finite subset of $\mathbb{Z}^d$ symmetric with respect to 0, the matrix $\mathcal{A}^\varepsilon = \{a^\varepsilon_{zz'}\}$ is symmetric, $\partial Q^\Lambda_\varepsilon$ is the boundary of Q_ε defined by

$$\partial Q^\Lambda_\varepsilon \overset{\triangle}{=} (Q_\varepsilon + \varepsilon\Lambda) \setminus Q_\varepsilon = \{x + \varepsilon z \,|\, x \in Q_\varepsilon,\, z \in \Lambda\} \setminus Q_\varepsilon\,,$$

and ∂^ε_z is the standard difference derivative: $(\partial^\varepsilon_z v)(x) \overset{\triangle}{=} \frac{1}{\varepsilon}\left(v(x + \varepsilon\, z) - v(x)\right)$. For any $v^\varepsilon : Q_\varepsilon \mapsto \mathbb{R}$, we introduce the following norm (the $L^2(Q_\varepsilon)$-norm): $\|v^\varepsilon\|^2_{L^2(Q_\varepsilon)} \overset{\triangle}{=} \varepsilon^d \sum_{x \in Q_\varepsilon} |v^\varepsilon(x)|^2$. We say that a function v^ε defined on $\varepsilon\mathbb{Z}^d$ belongs to the space $W^{1,2}_0(Q_\varepsilon)$ if $v(x) = 0$ for $x \notin Q_\varepsilon$. We define the norm on the space $W^{1,2}_0(Q_\varepsilon)$ as follows: $\|v^\varepsilon\|^2_{W^{1,2}_0(Q_\varepsilon)} = \varepsilon^d \sum_{x \in \overline{Q_\varepsilon}} \sum_{i=1}^d |\partial^\varepsilon_{\pm e_i} v^\varepsilon(x)|^2$, where $\{e_i\}_{i=1,\ldots,d}$ is the standard basis in $\mathbb{R}^d$ and $\overline{Q_\varepsilon} \overset{\triangle}{=} Q_\varepsilon + \varepsilon\Lambda = Q_\varepsilon \cup \partial Q^\Lambda_\varepsilon$; $W^{-1,2}(Q_\varepsilon)$ is the dual space to $W^{1,2}_0(Q_\varepsilon)$.

In the summation in (1.1), we can consider only the elements from the set $\Lambda \setminus \{0\}$, as the contribution of the element $\{0\}$ is null.

Definition 1.1. *We say that the family of problems* (1.1) *(or, simply, problem* (1.1)*) is* uniformly elliptic *if there are* $c_1, c_2 > 0$ *and* $\varepsilon_0 > 0$ *such that, for any* $v^\varepsilon \in W^{1,2}_0(Q_\varepsilon)$ *and any* $\varepsilon < \varepsilon_0$,

$$|a^\varepsilon_{zz'}(x)| \le c_1, \tag{1.2}$$

$$c_2\|v^\varepsilon\|^2_{W^{1,2}_0(Q_\varepsilon)} \le \varepsilon^d \sum_{x \in \overline{Q_\varepsilon}} \sum_{z,z' \in \Lambda} a^\varepsilon_{zz'}(x)\partial_{z'} v^\varepsilon(x)\partial_z v^\varepsilon(x)\,. \tag{1.3}$$

Remark 1.2. *The uniform boundedness of the matrix* $\mathcal{A}^\varepsilon$ *implies the following upper bound:*

$$\varepsilon^d \sum_{x \in \overline{Q_\varepsilon}} \sum_{z,z' \in \Lambda} a^\varepsilon_{zz'}(x)\partial_{z'} v^\varepsilon(x)\partial_z v^\varepsilon(x) \le c(\Lambda)\|v^\varepsilon\|^2_{W^{1,2}_0(Q_\varepsilon)}\,.$$

Indeed, it suffices to represent z *as a sum* $z = z^1 + z^2 + \cdots + z^N$ *with* $|z^i| = 1$ *for all* $i = 1 \ldots N$. *Then,*

$$\partial^\varepsilon_z v^\varepsilon(x) = \sum_{k=1}^N \partial^\varepsilon_{z^k} v^\varepsilon(x + z^1 + \cdots + z^{k-1})$$

and the required bound is the consequence of the finiteness of Λ.

In what follows we always assume the uniform ellipticity conditions (1.2)–(1.3) to hold.

It should be noted that, in general, the uniform ellipticity condition (1.3) is rather implicit. For instance, it neither requires the positiveness of the matrix $\{a^{\varepsilon}_{zz'}(x)\}$ nor follows from the estimate

$$c_3|\xi|^2 \le \sum_{z,z'\in\Lambda} a^{\varepsilon}_{zz'}(x)(\xi,z)(\xi,z') \le c_4|\xi|^2, \quad \xi\in\mathbb{R}^d,\ c_3>0\,, \tag{1.4}$$

where $(\cdot,\cdot)$ is the scalar product in $\mathbb{R}^d$. One can easily see this by considering the one-dimensional problem with

$$a^{\varepsilon}_{zz'}(x) = \begin{cases} 1/2 & \text{if } z=z',\ |z|=2,\\ 0 & \text{otherwise.}\end{cases}$$

Clearly, (1.3) is not satisfied although (1.4) holds.

In order to ensure the uniform ellipticity of problem (1.1) one should combine estimates such as (1.4) with a proper irreducibility condition. Below we show that for two important particular classes of difference operators commonly used in applications, the ellipticity conditions can be easily verified.

Suppose we are given a family of functions $p^{\varepsilon}_z(x)$, $x\in Q_\varepsilon$, $z\in\Lambda$, possessing the following properties:

1. positiveness: $p^{\varepsilon}_z(x)\ge 0,\ \sum_{z\in\Lambda}p^{\varepsilon}_z(x)=1$ for each $x\in Q_\varepsilon$,
2. $p^{\varepsilon}_{\pm e_i}(x)\ge\delta>0$, $i=1,\dots,d$,
3. symmetry: $p^{\varepsilon}_z(x)=p^{\varepsilon}_{-z}(x+\varepsilon z)$.

Then, the family of problems

$$u^\varepsilon(x)=\sum_{z\in\Lambda}p^{\varepsilon}_z(x)\,u^\varepsilon(x+\varepsilon z)+\varepsilon^2 f^\varepsilon(x)\quad\text{in } Q_\varepsilon\,,\qquad u^\varepsilon(x)=0\quad\text{on } \partial Q^{\Lambda}_{\varepsilon}\,, \tag{1.5}$$

can be easily rewritten in the form (1.1) with

$$a^{\varepsilon}_{zz'}(x) = \begin{cases} p^{\varepsilon}_z(x) & \text{if } z=z',\ z\neq 0,\\ 0 & \text{otherwise.}\end{cases} \tag{1.6}$$

Proposition 1.3. *Let* $\{p^{\varepsilon}_z(x)\}$ *possess the abovementioned properties* (1), (2), *and* (3). *Then problem* (1.5) *is uniformly elliptic.*

Proof. Summing by parts, one can show after simple calculations that

$$\begin{aligned}\delta\varepsilon^{-d}\|v^\varepsilon\|^2_{W^{1,2}_0(Q_\varepsilon)} &= \delta\sum_{x\in\overline{Q_\varepsilon}}\sum_{i=1}^{d}|\partial^{\varepsilon}_{\pm e_i}v^\varepsilon|^2\\ &\le \sum_{x\in\overline{Q_\varepsilon}}\sum_{z,z'\in\Lambda}a^{\varepsilon}_{zz'}(x)\partial_{z'}v^\varepsilon(x)\partial_z v^\varepsilon(x)\\ &\le C\sum_{x\in\overline{Q_\varepsilon}}\sum_{z\in\Lambda}|\partial^{\varepsilon}_z v^\varepsilon|^2 \le c(\Lambda)\varepsilon^{-d}\|v^\varepsilon\|^2_{W^{1,2}_0(Q_\varepsilon)}\end{aligned}$$

uniformly in ε. This yields the desired result. □

Assumption (2) can be relaxed as follows:

(2′) For some $N > 0$ and $\delta > 0$ and for any $x', x'' \in Q_\varepsilon$, $|x' - x''| = \varepsilon$, there is a finite sequence of vectors $y^1, y^2, \dots, y^k \in \Lambda$, $k \le N$, such that $x'' = x' + \varepsilon \sum_{j=1}^{k} y^j$ and $p^\varepsilon_{y^j}(x' + \varepsilon \sum_{i=1}^{j-1} y^i) \ge \delta$.

Another important class of uniformly elliptic operators is formed by matrices $\{a^\varepsilon_{zz'}(x)\}$ that satisfy the estimate

$$\sum_{z,z' \in \Lambda} a^\varepsilon_{zz'}(x)\, \eta_z\, \eta_{z'} \ge c \sum_{i=1}^{d} |\eta_{\pm e_i}|^2, \qquad \eta \in \mathbb{R}^{|\Lambda|},$$

uniformly in ε and $x \in Q_\varepsilon$; here we assume that all the vectors $\pm e_i$, $i = 1, 2, \dots, d$, are elements of Λ; if it is not the case, the right-hand side (RHS) of the latter formula does not make sense.

Clearly, the uniform ellipticity implies the coerciveness of problem (1.1) and we have the following statement.

Proposition 1.4. *Let problem* (1.1) *be uniformly elliptic and* $f^\varepsilon \in L^2(Q_\varepsilon)$. *Then there exists a unique solution* $u^\varepsilon \in W_0^{1,2}(Q_\varepsilon)$ *and the estimate*

$$\|u^\varepsilon\|_{W_0^{1,2}(Q_\varepsilon)} \le c\|f^\varepsilon\|_{L^2(Q_\varepsilon)}$$

holds uniformly in ε. Henceforth we usually suppose that $f^\varepsilon(\cdot)$ is a discretization of a given function $f \in L^2(Q)$.

We also define the norm on the space $W^{1,2}(Q_\varepsilon)$ by

$$\|v^\varepsilon\|^2_{W^{1,2}(Q_\varepsilon)} = \varepsilon^d \sum_{x \in \overline{Q_\varepsilon}} \sum_{i=1}^{d} |\bar\partial^\varepsilon_{\pm e_i} v^\varepsilon(x)|^2 + \|v^\varepsilon\|^2_{L^2(Q^\varepsilon)},$$

where we use the notation

$$\bar\partial^\varepsilon_z \varphi(x) = \begin{cases} \partial^\varepsilon_z \varphi(x) & \text{if } x + \varepsilon z \in \overline{Q_\varepsilon}, \\ 0 & \text{otherwise.} \end{cases}$$

2. Tools for discrete operators analysis.

2.1. Compensated compactness lemma. One of the main tools in the homogenization of differential operators is the so-called compensated compactness lemma (see Murat [21] and Tartar [26]), which gives a sufficient condition for passing to the limit in the inner product of two weakly converging sequences of vector functions. In this section, we prove the discrete version of this result that serves the case of functions defined on a grid.

First of all, we introduce the discrete divergence as follows: for any vector function $q \in \big(L^2(Q_\varepsilon)\big)^{|\Lambda|}$,

$$\operatorname{div}^\varepsilon_\Lambda q(x) \overset{\triangle}{=} \sum_{z \in \Lambda} \partial^\varepsilon_{-z} q_z(x).$$

It should be emphasized that the above divergence operator depends on the choice of the set Λ.

Lemma 2.1. *Let* q^ε *and* v^ε *be sequences of vector functions from* $\big(L^2(Q_\varepsilon)\big)^{|\Lambda|}$ *such that*

$$q^\varepsilon \xrightarrow[\varepsilon \to 0]{} q^0 \text{ weakly in } L^2(Q_\varepsilon), \operatorname{div}^\varepsilon_\Lambda q^\varepsilon \xrightarrow[\varepsilon \to 0]{} f^0 \text{ in } W^{-1,2}(Q_\varepsilon),$$

$$v^\varepsilon \xrightarrow[\varepsilon \to 0]{} v^0 \text{ weakly in } L^2(Q_\varepsilon), v^\varepsilon_z(x) = \partial^\varepsilon_z u^\varepsilon(x) \text{ for some } u^\varepsilon \in W^{1,2}(Q_\varepsilon).$$

Then, the sequence $(q^\varepsilon\, v^\varepsilon)$ *converges* $\star$*-weakly to* $q^0\, v^0$*:* $\quad q^\varepsilon\, v^\varepsilon \xrightarrow[\varepsilon\to 0]{\star} q^0\, v^0\,.$

Proof. According to Kozlov [15, Proposition 3], the weak convergence of q^ε in $L^2(Q_\varepsilon)$ implies the following weak convergence in $W^{-1,2}(Q_\varepsilon)$:

$$\mathrm{div}_\Lambda^\varepsilon q^\varepsilon \xrightarrow[\varepsilon\to 0]{} \sum_{z\in\Lambda} \frac{\partial}{\partial z} q_z^0 = \sum_{z\in\Lambda} z\,\cdot\,\nabla q_z^0;$$

here the standard notation $\frac{\partial}{\partial z} f(x) = z\,\cdot\,\nabla_x f(x)$ for the derivative along arbitrary vector z has been used. Thus, $\sum_{z\in\Lambda} z\,\cdot\,\nabla q_z^0 = f^0$, and we have

$$\lim_{\varepsilon\to 0} \|\mathrm{div}_\Lambda^\varepsilon (q^\varepsilon - q^0)\|_{W^{-1,2}(Q_\varepsilon)} = 0\,.$$

From now on, the notation like q^0 or v^0 is used both for the functions of continuous argument and for their discretization (see Appendix A). Using the representation $q^\varepsilon\, v^\varepsilon = (q^\varepsilon - q^0)\, v^\varepsilon + q^0\, v^\varepsilon$ and taking into account the $\star$-weak convergence of $q^\varepsilon\, v^0$ to $q^0\, v^0$, one can assume, without loss of generality, that $q^0 = 0$. Also, under the proper choice of additive constant, $\sum_{x\in Q_\varepsilon} u^\varepsilon(x) = 0$. Then, by the Poincaré inequality, the sequence u^ε is uniformly bounded in the $W^{1,2}$-norm. For any $\varphi \in \mathcal{C}_0^\infty(Q)$ we get

$$\begin{aligned}\varepsilon^d \sum_{x\in Q_\varepsilon} q^\varepsilon(x)\, v^\varepsilon(x)\, \varphi(x) \;&= \varepsilon^d \sum_{x\in Q_\varepsilon} \sum_{z\in\Lambda} q_z^\varepsilon(x)\, \partial_z^\varepsilon u^\varepsilon(x)\, \varphi(x) \\ &= \varepsilon^d \sum_{x\in Q_\varepsilon} \sum_{z\in\Lambda} \{q_z^\varepsilon(x)\, \partial_z^\varepsilon(u^\varepsilon(x)\, \varphi(x)) - q_z^\varepsilon(x)\, u^\varepsilon(x)\, \partial_z^\varepsilon \varphi(x)\} + \tau(\varepsilon)\end{aligned}$$

with $\lim_{\varepsilon\to 0} \tau(\varepsilon) = 0$ (see Appendix B). Summing by parts in the latter expression leads to

$$\begin{aligned}&\varepsilon^d \sum_{x\in Q_\varepsilon} q^\varepsilon(x)\, v^\varepsilon(x)\, \varphi(x) \\ &\quad= \varepsilon^d \sum_{x\in Q_\varepsilon} \sum_{z\in\Lambda} \left\{\partial_{-z}^\varepsilon q_z^\varepsilon(x)\, u^\varepsilon(x)\, \varphi(x) - q_z^\varepsilon(x)\, u^\varepsilon(x)\, \partial_z^\varepsilon \varphi(x)\right\} + \tau(\varepsilon) \\ &\quad= \varepsilon^d \sum_{x\in Q_\varepsilon} (\mathrm{div}_\Lambda^\varepsilon\, q^\varepsilon(x)\ , u^\varepsilon\, \varphi) - \varepsilon^d \sum_{x\in Q_\varepsilon} \sum_{z\in\Lambda} q_z^\varepsilon(x)\, u^\varepsilon(x)\, \partial_z^\varepsilon \varphi(x) + \tau(\varepsilon)\,.\end{aligned}$$

Since u^ε is uniformly bounded in $W^{1,2}(Q_\varepsilon)$ and $\mathrm{div}_\Lambda^\varepsilon\, q^\varepsilon$ converges to 0 in the $W^{-1,2}$-norm, the first term in the RHS goes to 0 as $\varepsilon \to 0$. The second term goes to 0 because $q_z^\varepsilon\, \partial_z^\varepsilon \varphi$ converges to 0 in $L^2(Q_\varepsilon)$ weakly. Finally, for any $\varphi \in \mathcal{C}_0^\infty(Q)$, $\lim_{\varepsilon\to 0} \sum_{x\in Q_\varepsilon} \sum_{z\in\Lambda} q_z^\varepsilon(x)\, v_z^\varepsilon(x)\, \varphi(x) = 0\,.$ □

2.2. *H*-convergence and homogenization. In this section, we give the definitions of the H-convergence and the homogenization of discrete operators and then study the main properties of this convergence (see Spagnolo [27], Murat and Tartar [22] for the relevant definitions in case of differential operators).

Consider a family of uniformly elliptic discrete Dirichlet problems,

$$A_\varepsilon u^\varepsilon = \mathrm{div}_\Lambda^\varepsilon \left(\sum_{z'\in\Lambda} a_{zz'}^\varepsilon\, \partial_{z'}^\varepsilon u^\varepsilon\right) = f^\varepsilon\,, \quad u^\varepsilon \in W_0^{1,2}(Q_\varepsilon)\,, \tag{2.1}$$

and denote by $\mathcal{A}^\varepsilon(x)$ the matrices of the coefficients $\{a_{zz'}^\varepsilon(x)\}$. Let $\mathcal{A}(x) = \{a_{zz'}(x)\}$, $x \in Q$, be a $|\Lambda| \times |\Lambda|$ matrix.

Definition 2.2 (H-convergence). *We say that the matrix* $\mathcal{A}^\varepsilon$ H-converges *to* $\mathcal{A}$ *(*$\mathcal{A}^\varepsilon \xrightarrow[\varepsilon\to 0]{H} \mathcal{A}$*) if, for any sequence* $f^\varepsilon \in W^{-1,2}(Q_\varepsilon)$ *such that* $f^\varepsilon \xrightarrow[\varepsilon\to 0]{} f$ *in* $W^{-1,2}(Q_\varepsilon)$*, we have*

$$\begin{aligned} u^\varepsilon \quad &\xrightarrow[\varepsilon\to 0]{} \quad u^0 && \textit{weakly in } W_0^{1,2}(Q_\varepsilon)\,,\\ s^\varepsilon = \sum_{z\in\Lambda} a^\varepsilon_{zz'}\,\partial^\varepsilon_z u^\varepsilon \quad &\xrightarrow[\varepsilon\to 0]{} \quad s^0 = \sum_{z\in\Lambda} a_{zz'}\,\frac{\partial}{\partial z}u^0 && \textit{weakly in } L^2(Q_\varepsilon)\,, \end{aligned}$$

where u^0 *is the solution of the limit Dirichlet problem,*

$$\sum_{z,z'\in\Lambda} -\frac{\partial}{\partial z}\left(a_{zz'}(x)\,\frac{\partial}{\partial z'}u^0\right) = f, \quad u^0 \in W_0^{1,2}(Q).$$

The homogenization is a particular case of H-convergence. Given a matrix-valued function $\mathcal{A}^1(x) = \{a^1_{zz'}(x)\}$, z, $z' \in \Lambda$, $x \in \mathbb{Z}^d$, we define the sequence $\mathcal{A}^\varepsilon$ as follows: $\mathcal{A}^\varepsilon(x) = \mathcal{A}^1(x/\varepsilon)$, $x \in Q_\varepsilon$. Suppose that the corresponding family of problems (defined in (2.1)) is uniformly elliptic.

Definition 2.3. *The constant matrix* $\mathcal{A}$ *is the* homogenized matrix *for* $\mathcal{A}^\varepsilon(x) = \{a^\varepsilon_{zz'}(x)\}$ *if, for any sequence* $f^\varepsilon \in W^{-1,2}(Q_\varepsilon)$ *such that* $f^\varepsilon \xrightarrow[\varepsilon\to 0]{} f$ *in* $W^{-1,2}(Q)$*, the solutions* u^ε *of the Dirichlet problems*

$$\operatorname{div}^\varepsilon_\Lambda\left(\sum_{z'\in\Lambda} a^\varepsilon_{zz'}\,\partial^\varepsilon_{z'}u^\varepsilon\right) = f^\varepsilon,\ \ u^\varepsilon \in W_0^{1,2}(Q_\varepsilon)\,,$$

converge to the solution u^0 *of the limit Dirichlet problem*

$$-\sum_{z,z'\in\Lambda}\frac{\partial}{\partial z}a_{zz'}\frac{\partial}{\partial z'}u^0 = f\,,\ \ u^0 \in W_0^{1,2}(Q), \tag{2.2}$$

in the following sense:

$$\begin{aligned} u^\varepsilon \quad &\xrightarrow[\varepsilon\to 0]{} \quad u^0 && \textit{weakly in } W_0^{1,2}(Q)\,,\\ \sum_{z'\in\Lambda} a^\varepsilon_{zz'}\,\partial^\varepsilon_{z'}u^\varepsilon \quad &\xrightarrow[\varepsilon\to 0]{} \quad \sum_{z\in\Lambda} a_{zz'}\,\frac{\partial}{\partial z}u^0 && \textit{weakly in } L^2(Q)\,. \end{aligned}$$

Remark 2.4. *The dimension of the difference gradient of functions defined on* Q_ε *is equal to* $|\Lambda|$ *and does not coincide with the dimension of the standard gradient of functions defined on* Q*. This is the reason we write the limit equation in the definitions above in a nonstandard form. This allows us to define the convergence of streams. Of course, one can easily transform the limiting equation to the standard form*

$$\sum_{z,z'\in\Lambda}\frac{\partial}{\partial z}a_{zz'}(x)\frac{\partial}{\partial z'} = \sum_{i,j=1}^{d}\frac{\partial}{\partial x_i}\check{a}_{ij}(x)\frac{\partial}{\partial x_j}\,, \quad \check{a}_{ij}(x) = \sum_{z,z'\in\Lambda}(z,e_i)a_{zz'}(x)(z',e_j)\,.$$

One of the remarkable properties of H- and G-convergences of differential operators is the compactness of a family of uniformly elliptic operators; see, for example, Murat and Tartar [22], Zhikov et al. [28]. We proceed by quoting the compactness result for a family of uniformly elliptic difference operators.

Proposition 2.5 (see Kozlov [15, section 2]). *Any uniformly elliptic sequence of problems defined in* (2.1) *contains an H-convergent subsequence. The limit problem involves a second order uniformly elliptic operator in divergence form:*

$$A\,u = -\sum_{z,z'\in\Lambda}\frac{\partial}{\partial z}\left(a_{zz'}(x)\,\frac{\partial}{\partial z'}\,u\right) = -\sum_{i,j=1}^{d}\frac{\partial}{\partial x_i}\left(a_{ij}(x)\,\frac{\partial}{\partial x_j}u\right).$$

In the subsections below we prove a number of general results on H-convergence and homogenization of difference operators that are not exhibited in the existing literature.

2.2.1. Convergence of arbitrary solutions. One of the significant properties of H-convergence is the fact that the H-limit operator depends only on the original sequence of operators and does not depend on the type of boundary conditions and on the domain. In a general form, this can be formulated as follows.

Theorem 2.6 (convergence of arbitrary solutions). *Let a sequence of uniformly elliptic operators A_ε H-converge in a domain Q to the limit operator A, and suppose that a sequence of functions $w^\varepsilon\in W^{1,2}(Q_\varepsilon)$ satisfies the conditions*

$$\begin{aligned} &w^\varepsilon \xrightarrow[\varepsilon\to 0]{} w^0 \quad \textit{weakly in } W^{1,2}(Q_\varepsilon)\,,\\ &\operatorname{div}^\varepsilon_\Lambda\left(\sum_{z'\in\Lambda} a^\varepsilon_{zz'}\,\left(g_{z'}+\partial^\varepsilon_{z'}w^\varepsilon\right)\right) = f\,, \end{aligned} \tag{2.3}$$

where $g\in\left(L^2(Q)\right)^{|\Lambda|}$ and $f\in W^{-1,2}(Q)$ do not depend on ε. Then, w^0 satisfies the homogenized equation

$$-\sum_{z,z'\in\Lambda}\frac{\partial}{\partial z}\left[a_{zz'}\left(g_{z'}+\frac{\partial}{\partial z'}w^0\right)\right] = f\,,$$

and the streams do converge in $L^2(Q_\varepsilon)$ weakly:

$$\sum_{z'\in\Lambda} a^\varepsilon_{zz'}\,\left(g_{z'}+\partial^\varepsilon_{z'}w^\varepsilon\right) \xrightarrow[\varepsilon\to 0]{} \sum_{z'\in\Lambda} a_{zz'}\left(g_{z'}+\frac{\partial}{\partial z'}w^0\right).$$

Proof. Under the conditions of the theorem, the streams are uniformly bounded in $L^2(Q_\varepsilon)$. Thus, taking a proper subsequence, we have $\sum_{z'\in\Lambda} a^\varepsilon_{zz'}\,\left(g_{z'}+\partial^\varepsilon_{z'}w^\varepsilon\right) \xrightarrow[\varepsilon\to 0]{}$ $\xi_z$weakly in $L^2(Q_\varepsilon)$. Passing to the limit in (2.3), one can easily check that $-\sum_{z\in\Lambda}\frac{\partial}{\partial z}\xi_z$ $= f$. We have to prove the relation $\xi_z = \sum_{z'\in\Lambda} a_{zz'}\left(g_{z'}+\frac{\partial}{\partial z'}w^0\right)$. Let u^0 be an arbitrary function from $W^{1,2}_0(Q)$. Denote by u^ε the solution of the Dirichlet problem,

$$\operatorname{div}^\varepsilon_\Lambda\left(\sum_{z'\in\Lambda} a^\varepsilon_{zz'}\,\partial^\varepsilon_{z'}u^\varepsilon\right) = \sum_{z,z'\in\Lambda}\frac{\partial}{\partial z}\left(a_{zz'}\,\frac{\partial}{\partial z'}\,u^0\right),$$

and consider the following identity:

$$\sum_{z\in\Lambda}(g_z+\partial^\varepsilon_z w^\varepsilon)\sum_{z'\in\Lambda} a^\varepsilon_{zz'}\,\partial^\varepsilon_{z'}u^\varepsilon = \sum_{z\in\Lambda}\partial^\varepsilon_z u^\varepsilon\sum_{z'\in\Lambda} a^\varepsilon_{zz'}\,(g_{z'}+\partial^\varepsilon_{z'}w^\varepsilon)\,. \tag{2.4}$$

By the definition of H-convergence, we have

$$\sum_{z'\in\Lambda} a^\varepsilon_{zz'}\,\partial^\varepsilon_{z'} u^\varepsilon \xrightarrow[\varepsilon\to 0]{} \sum_{z'\in\Lambda} a_{zz'}\frac{\partial}{\partial z'}u^0 \quad \text{weakly in } L^2(Q_\varepsilon)\,,$$

while the limiting relation

$$\sum_{z\in\Lambda}(g_z+\partial^\varepsilon_z w^\varepsilon) \xrightarrow[\varepsilon\to 0]{} \sum_{z\in\Lambda}\left(g_z+\frac{\partial}{\partial z}w^0\right) \quad \text{weakly in } L^2(Q_\varepsilon)$$

is an evident consequence of the weak convergence of w^ε . Now, passing to the limit on the left-hand side (LHS) of (2.4), with the help of Lemma 2.1 we obtain

$$\sum_{z\in\Lambda}(g_z+\partial^\varepsilon_z w^\varepsilon)\sum_{z'\in\Lambda} a^\varepsilon_{zz'}\,\partial^\varepsilon_{z'} u^\varepsilon \xrightarrow[\varepsilon\to 0]{\star} \sum_{z\in\Lambda}\left(g_z+\frac{\partial}{\partial z}w^0\right)\sum_{z'\in\Lambda} a_{zz'}\frac{\partial}{\partial z'}u^0\,.$$

The fact that g_z does not depend on ε has also been used here.

Similarly, passing to the limit on the RHS of (2.4) gives

$$\sum_{z\in\Lambda}\partial^\varepsilon_z u^\varepsilon\sum_{z'\in\Lambda} a^\varepsilon_{zz'}\,(g_{z'}+\partial^\varepsilon_{z'} w^\varepsilon) \xrightarrow[\varepsilon\to 0]{\star} \sum_{z\in\Lambda}\frac{\partial}{\partial z}u^0\,\xi_z\,.$$

Finally, considering the fact that u^0 is arbitrary function from $W^{1,2}_0(Q)$, we deduce

$$\xi_z=\sum_{z'\in\Lambda} a^\varepsilon_{zz'}\,\left(g_{z'}+\frac{\partial}{\partial z'}w^0\right)\,. \qquad \square$$

Corollary 2.7 (local property of H-convergence). *If $A_\varepsilon \xrightarrow[\varepsilon\to 0]{H} A$ in a domain Q, then $A_\varepsilon \xrightarrow[\varepsilon\to 0]{H} A$ in any subdomain $Q_1\subset Q$.*

2.2.2. Convergence of energies. In this section, we address a family of Dirichlet problems with nonhomogeneous boundary conditions:

$$\operatorname{div}^\varepsilon_\Lambda\left(\sum_{z'\in\Lambda} a^\varepsilon_{zz'}\,\partial^\varepsilon_{z'}u^\varepsilon\right)=f\,,\ u^\varepsilon-u^0\in W^{1,2}_0(Q_\varepsilon)\,, \tag{2.5}$$

where $u^0\in W^{1,2}(\mathbb{R}^d)$ and $f\in W^{-1,2}(Q)$ are fixed given functions.

We suppose that the family $\{A_\varepsilon\}$ is uniformly elliptic and H-converges to the limit operator A. Then, one can assume without loss of generality that the function u^0 satisfies the equation $A\,u^0=f$ in the domain Q.

In order to show the uniform boundedness of $\{u^\varepsilon\}$ in $W^{1,2}(\overline{Q_\varepsilon})$, we replace u^ε by $u^\varepsilon-u_0$ in (2.5), multiply the resulting equation by $u^\varepsilon-u_0$, and then sum over $\overline{Q}_\varepsilon$. After summation by parts we get

$$\sum_{x\in\overline{Q_\varepsilon}}\sum_{z,z'\in\Lambda} a^\varepsilon_{zz'}(x)\,\partial^\varepsilon_z\big(u^\varepsilon(x)-u_0(x)\big)\,\partial^\varepsilon_{z'}(u^\varepsilon(x)-u_0(x))=\sum_{x\in\overline{Q_\varepsilon}} f(x)\big(u^\varepsilon(x)-u_0(x)\big)$$

$$-\sum_{x\in\overline{Q_\varepsilon}}\sum_{z,z'\in\Lambda} a^\varepsilon_{zz'}(x)\,\partial^\varepsilon_z\big(u^\varepsilon(x)-u_0(x)\big)\,\partial^\varepsilon_{z'}u_0(x).$$

This implies the required boundedness.

By Theorem 2.6 (convergence of arbitrary solution), any weak limiting point of the sequence $\{u^\varepsilon\}$ coincides with u^0 in Q. Hence, the whole family $\{u^\varepsilon\}$ converges to u^0 in $W^{1,2}(\overline{Q_\varepsilon})$ weakly.

Proposition 2.8 (convergence of energies). *Let $A_\varepsilon \xrightarrow[\varepsilon\to 0]{H} A$ and let u^ε be the solution of problem* (2.5). *Then the following limit relation holds true:*

$$\varepsilon^d \sum_{x\in\overline{Q_\varepsilon}} \sum_{z,z'\in\Lambda} a^\varepsilon_{zz'}(x)\,\partial^\varepsilon_z u^\varepsilon(x)\,\partial^\varepsilon_{z'} u^\varepsilon(x) \xrightarrow[\varepsilon\to 0]{} \int_Q \sum_{z,z'\in\Lambda} a_{zz'}(x)\,\frac{\partial}{\partial z}u^0(x)\,\frac{\partial}{\partial z'}u^0(x)\,dx\,.$$

Proof. By (2.5) we have

$$\begin{aligned}
\varepsilon^d &\sum_{x\in\overline{Q_\varepsilon}} \sum_{z,z'\in\Lambda} a^\varepsilon_{zz'}(x)\,\partial^\varepsilon_z (u^\varepsilon-u^0)(x)\,\partial^\varepsilon_{z'}(u^\varepsilon-u^0)(x)\\
&= \varepsilon^d \sum_{x\in\overline{Q_\varepsilon}} \sum_{z,z'\in\Lambda} a^\varepsilon_{zz'}(x)\,\partial^\varepsilon_z u^\varepsilon(x)\,\partial^\varepsilon_{z'}(u^\varepsilon-u^0)(x)\\
&\quad - \varepsilon^d \sum_{x\in\overline{Q_\varepsilon}} \sum_{z,z'\in\Lambda} a^\varepsilon_{zz'}(x)\,\frac{\partial}{\partial z}u^0(x)\,\partial^\varepsilon_{z'}(u^\varepsilon-u^0)(x) + \tau(\varepsilon)\\
&= \varepsilon^d \sum_{x\in Q_\varepsilon} f(x)\,(u^\varepsilon-u^0)(x) - \varepsilon^d \sum_{x\in\overline{Q_\varepsilon}} \sum_{z,z'\in\Lambda} a^\varepsilon_{zz'}(x)\,\frac{\partial}{\partial z}u^0(x)\,\partial^\varepsilon_{z'}u^\varepsilon(x)\\
&\quad + \varepsilon^d \sum_{x\in\overline{Q_\varepsilon}} \sum_{z,z'\in\Lambda} a^\varepsilon_{zz'}(x)\,\frac{\partial}{\partial z}u^0(x)\,\frac{\partial}{\partial z'}u^0(x) \;+\; \tau(\varepsilon)\,;
\end{aligned}$$

here and afterwards $\tau(\varepsilon)$ stands for a generic function that vanishes as $\varepsilon\to 0$. On the other hand,

$$\begin{aligned}
\varepsilon^d &\sum_{x\in\overline{Q_\varepsilon}} \sum_{z,z'\in\Lambda} a^\varepsilon_{zz'}(x)\,\partial^\varepsilon_z (u^\varepsilon-u^0)(x)\,\partial^\varepsilon_{z'}(u^\varepsilon-u^0)(x)\\
&= \varepsilon^d \sum_{x\in\overline{Q_\varepsilon}} \sum_{z,z'\in\Lambda} a^\varepsilon_{zz'}(x)\,\partial^\varepsilon_z u^\varepsilon(x)\,\partial^\varepsilon_{z'}u^\varepsilon(x)\\
&\quad - 2\varepsilon^d \sum_{x\in\overline{Q_\varepsilon}} \sum_{z,z'\in\Lambda} a^\varepsilon_{zz'}(x)\,\frac{\partial}{\partial z}u^0(x)\,\partial^\varepsilon_{z'}u^\varepsilon(x)\\
&\quad + \varepsilon^d \sum_{x\in\overline{Q_\varepsilon}} \sum_{z,z'\in\Lambda} a^\varepsilon_{zz'}(x)\,\frac{\partial}{\partial z}u^0(x)\,\frac{\partial}{\partial z'}u^0(x) + \tau(\varepsilon)\,.
\end{aligned}$$

After subtraction we find

$$\begin{aligned}
\varepsilon^d \sum_{x\in\overline{Q_\varepsilon}} \sum_{z,z'\in\Lambda} a^\varepsilon_{zz'}(x)\,\partial^\varepsilon_z u^\varepsilon(x)\,\partial^\varepsilon_{z'}u^\varepsilon(x) - \varepsilon^d \sum_{x\in\overline{Q_\varepsilon}} \sum_{z,z'\in\Lambda} a^\varepsilon_{zz'}(x)\,\frac{\partial}{\partial z}u^0(x)\,\partial^\varepsilon_{z'}u^\varepsilon(x)\\
- \varepsilon^d \sum_{x\in Q_\varepsilon} f(x)\,(u^\varepsilon-u^0)(x) + \tau(\varepsilon) = 0\,.
\end{aligned} \tag{2.6}$$

Passing to the limit in the last relation, and taking into account the weak convergence of $u^\varepsilon - u^0$ to 0 in $W^{1,2}_0(Q_\varepsilon)$ and the weak convergence of the streams $a^\varepsilon_{zz'}\,\partial^\varepsilon_{z'}u^\varepsilon$ in

$L^2(Q_\varepsilon)$, we obtain

$$\varepsilon^d \sum_{x\in\overline{Q_\varepsilon}} \sum_{z,z'\in\Lambda} a^\varepsilon_{zz'}(x)\,\partial^\varepsilon_z u^\varepsilon(x)\,\partial^\varepsilon_{z'} u^\varepsilon(x) \xrightarrow[\varepsilon\to 0]{} \int_Q \sum_{z,z'\in\Lambda} a_{zz'}(x)\,\frac{\partial}{\partial z} u^0(x)\,\frac{\partial}{\partial z'} u^0(x)\,dx\,. \qquad \square$$

In fact, the result on convergence of energies can be formulated in more "local" form, as follows.

Proposition 2.9. *Under the assumptions of Theorem* 2.6 *one has*

$$\sum_{z,z'\in\Lambda} a^\varepsilon_{zz'}(x)\partial_z w^\varepsilon(x)(\partial_{z'} w^\varepsilon(x) + g_{z'}(x)) \xrightarrow[\varepsilon\to 0]{\star} \sum_{z,z'\in\Lambda} a_{zz'}(x)\frac{\partial}{\partial z} w^0(x)\Big(\frac{\partial}{\partial z'} w^0(x) + g_{z'}(x)\Big). \tag{2.7}$$

Proof. In the expression

$$\sum_{z,z'\in\Lambda} \partial_z w^\varepsilon(x) a^\varepsilon_{zz'}(x)(\partial_{z'} w^\varepsilon(x) + g_{z'}(x))\,,$$

the streams $a^\varepsilon_{zz'}(x)(\partial_{z'} w^\varepsilon(x) + g_{z'}(x))$ converge weakly in $L^2(Q_\varepsilon)$ (by Theorem 2.6) to the limit stream $a_{zz'}(x)\Big(\frac{\partial}{\partial z'} w^0(x) + g_{z'}(x)\Big)$, and the family $\partial_z w^\varepsilon(x)$ converges to $\frac{\partial}{\partial z} w^0(x)$ weakly by the assumption of Theorem 2.6. Now, the desired statement follows from Lemma 2.1. $\square$

Remark 2.10. *In the case of elliptic differential equations, H-convergence of operators implies weak L^1-convergence of the corresponding energy functions. This result relies on the Meyers estimates of the gradient of solutions; see Meyers* [20].

For the difference operators the Meyers-type estimates have not been obtained, so the weak L^1-convergence of energies is an open question.

2.2.3. Neumann problem. The notion of the H-limit operator has been expressed in terms of the operators of the corresponding Dirichlet problems. But, as was already mentioned in the previous section, we can also consider other boundary value problems. In this section, the Neumann problem is investigated.

Definition 2.11. *Let $f \in \big(L^2(Q)\big)^{|\Lambda|}$. We say that $u^\varepsilon \in W^{1,2}(Q_\varepsilon)$ is a solution of the Neumann problem for the equation*

$$\mathrm{div}^\varepsilon_\Lambda \left(\sum_{z'\in\Lambda} a^\varepsilon_{zz'}\,\partial^\varepsilon_{z'} u^\varepsilon \right) = \sum_{z\in\Lambda} \partial^\varepsilon_{-z} f^\varepsilon_z$$

if the relation

$$\sum_{x\in\overline{Q_\varepsilon}} \sum_{z,z'\in\Lambda} a^\varepsilon_{zz'}(x)\,\bar\partial^\varepsilon_z \varphi^\varepsilon(x)\,\bar\partial^\varepsilon_{z'} u^\varepsilon(x) = \sum_{x\in\overline{Q_\varepsilon}} \sum_{z\in\Lambda} f^\varepsilon_z(x)\,\bar\partial^\varepsilon_z \varphi^\varepsilon(x) \tag{2.8}$$

holds true for any $\varphi \in W^{1,2}(Q)$; here we use the notation

$$\bar\partial^\varepsilon_z \varphi = \begin{cases} \partial^\varepsilon_z \varphi & \text{if } x + \varepsilon z \in \overline{Q_\varepsilon}, \\ 0 & \text{otherwise.} \end{cases}$$

Clearly, the functions u^ε are defined up to an additive constant. To fix the choice of the constant, we assume that $\sum_{x\in\overline{Q_\varepsilon}} u^\varepsilon(x) = 0\,.$

In order to study the Neumann problem, we should modify the definition of uniform ellipticity and impose a slightly stronger condition because Definition 1.1 above does not ensure the coerciveness of problem (2.8).

Definition 2.12. *We say that the family of operators* $\{A_\varepsilon\}$ *is* N-elliptic *in a domain* Q_ε *if the inequality*

$$\sum_{x\in\overline{Q_\varepsilon}}\sum_{z,z'\in\Lambda} a^\varepsilon_{zz'}(x)\,\bar\partial^\varepsilon_z\varphi(x)\bar\partial^\varepsilon_{z'}\varphi(x) \ge c\sum_{x\in\overline{Q_\varepsilon}}\sum_{i=1}^{d}\left(\bar\partial^\varepsilon_{\pm e_i}\varphi(x)\right)^2, \quad c>0, \tag{2.9}$$

holds for any φ.

It should be noted that N-ellipticity implies the uniform ellipticity in the same domain Q and that, under the condition of Proposition 1.3, the family of operators is always N-elliptic.

Example. To clarify the difference between the uniform ellipticity and N-ellipticity we provide below a simple one-dimensional example which shows that due to "boundary effects," a uniformly elliptic operator is not necessary N-elliptic.

Let Q be an open interval $(0,1)$, and suppose $\Lambda=\{0,\pm1,\pm2,\pm3\}$. If we set

$$p_{\pm1}(0)=\frac12,\quad p_z(0)=0 \text{ if } z\ne\pm1;$$

$$p_{-1}(1)=\frac12,\quad p_0(1)=\frac12,\quad p_z(1)=0 \text{ if } z\ne-1,\,0;$$

$$p_{\pm3}(2)=\frac12,\quad p_z(2)=0 \text{ if } z\ne\pm3,$$

and extend this function periodically with period 3, then for $\varepsilon=1/n$ with integer $n>3$ we have

$$Q_\varepsilon=\left\{\frac1n,\frac2n,\dots,\frac{n-1}{n}\right\},\quad \overline{Q}_\varepsilon=\left\{\frac{-2}{n},\frac{-1}{n},0,\frac1n,\frac2n,\dots,\frac{n-1}{n},1,\frac{n+1}{n},\frac{n+2}{n}\right\}.$$

Consider the following test function:

$$\varphi^\varepsilon(x)=\begin{cases}1 & \text{if } x=-\frac2n,-\frac3n,\\ 0 & \text{otherwise.}\end{cases}$$

For this function the LHS of (2.9) is equal to zero while the RHS is strictly positive. Thus (2.9) cannot hold. On the other hand, one can easily verify that this problem is uniformly elliptic.

Proposition 2.13. *Suppose that a family of N-elliptic operators $\{A_\varepsilon\}$ H-converges to the operator A in the domain Q. Then the solutions u^ε of problem (2.8) converge, as $\varepsilon\to0$, in $W^{1,2}(Q_\varepsilon)$ to the solution of the limit Neumann problem: for any $\varphi\in W^{1,2}(Q)$,*

$$\int_Q\left(\sum_{z,z'\in\Lambda}a_{zz'}(x)\frac{\partial}{\partial z}\varphi(x)\,\frac{\partial}{\partial z'}u^0(x)\right)dx=\int_Q\left(\sum_{z\in\Lambda}f_z(x)\frac{\partial}{\partial z}\varphi(x)\right)dx\,.$$

Moreover, the streams also converge.

Proof. Using the Poincaré inequality, we derive from the N-ellipticity the uniform coerciveness of problem (2.8). Thus, the family u^ε is uniformly bounded in $W^{1,2}(Q_\varepsilon)$. By Theorem 2.6, any limit point w^0 of the family u^ε satisfies the H-limit equation and

$$\sum_{z'\in\Lambda} a^\varepsilon_{zz'}\,\partial^\varepsilon_{z'}u^\varepsilon \xrightarrow[\varepsilon\to 0]{} \sum_{z'\in\Lambda} a_{zz'}\,\frac{\partial}{\partial z'}w^0 \quad \text{weakly in } L^2(Q_\varepsilon)\,.$$

So, for any $\varphi \in W^{1,2}(Q)$, passing to the limit in (2.8), we get

$$\int_Q \left(\sum_{z,z'\in\Lambda} a_{zz'}(x)\frac{\partial}{\partial z}\varphi(x)\,\frac{\partial}{\partial z'}w^0(x) \right) dx = \int_Q \left(\sum_{z\in\Lambda} f_z(x)\frac{\partial}{\partial z}\varphi(x) \right) dx\,.$$

Moreover, $\int_Q w^0(x)\,dx = 0$. □

2.2.4. Γ-convergence. The results proved in this section exhibit the relation between the H-convergence of operators and a special kind of convergence of corresponding quadratic forms, so-called Γ-convergence, that was introduced originally in De Giorgi [8].

PROPOSITION 2.14. *Let A_ε be a N-elliptic family of operators in a domain Q. Then, $A_\varepsilon \xrightarrow[\varepsilon\to 0]{H} A$ in Q if and only if the following conditions are satisfied:*

1. *For any $u^0 \in W^{1,2}(Q)$ and for any sequence $w^\varepsilon \in W^{1,2}(Q_\varepsilon)$ such that $w^\varepsilon \xrightarrow[\varepsilon\to 0]{} u^0$ weakly in $W^{1,2}(Q_\varepsilon)$, the following inequality holds:*

$$\begin{aligned}\liminf_{\varepsilon\to 0} \varepsilon^d \sum_{x\in\overline{Q_\varepsilon}} \sum_{z,z'\in\Lambda} & a^\varepsilon_{zz'}(x)\,\bar\partial^\varepsilon_z w^\varepsilon(x)\,\bar\partial^\varepsilon_{z'}w^\varepsilon(x)\\ &\geq \int_Q \sum_{z,z'\in\Lambda} a_{zz'}(x)\,\frac{\partial}{\partial z}u^0(x)\,\frac{\partial}{\partial z'}u^0(x)\,dx\,.\end{aligned}$$

2. *For any $u^0 \in W^{1,2}(Q)$, there exists a sequence $u^\varepsilon \in W^{1,2}(Q_\varepsilon)$ such that $u^\varepsilon \xrightarrow[\varepsilon\to 0]{} u^0$ weakly in $W^{1,2}(Q)$, $u^\varepsilon - u^0 \in W^{1,2}_0(Q)$, and*

$$\begin{aligned}\lim_{\varepsilon\to 0} \varepsilon^d \sum_{x\in\overline{Q_\varepsilon}} \sum_{z,z'\in\Lambda} & a^\varepsilon_{zz'}(x)\,\bar\partial^\varepsilon_z u^\varepsilon(x)\,\bar\partial^\varepsilon_{z'}u^\varepsilon(x)\\ &= \int_Q \sum_{z,z'\in\Lambda} a_{zz'}(x)\,\frac{\partial}{\partial z}u^0(x)\,\frac{\partial}{\partial z'}u^0(x)\,dx\,.\end{aligned}$$

Proof. Suppose that $A_\varepsilon \xrightarrow[\varepsilon\to 0]{H} A\,.$

1. Consider the Neumann problem (2.8), with $f_z = \left(\sum_{z'\in\Lambda} a_{zz'}\,\frac{\partial u^0}{\partial z'}\right)_{z\in\Lambda}$, where u^0 is the solution of the H-limit Neumann problem. The solution u^ε of (2.8) provides the minimum in the following variational problem: $E = \inf_{v\in W^{1,2}(Q_\varepsilon)} J^\varepsilon(v)$, where

$$J^\varepsilon(v) = \varepsilon^d \sum_{x\in\overline{Q_\varepsilon}} \sum_{z,z'\in\Lambda} \left[a^\varepsilon_{zz'}(x)\,\bar\partial^\varepsilon_z v(x)\,\bar\partial^\varepsilon_{z'}v(x) - 2a_{zz'}(x)\,\bar\partial^\varepsilon_z v(x)\,\frac{\partial}{\partial z'}u^0(x)\right]\,.$$

For any sequence $\{w^\varepsilon\}$ such that $w^\varepsilon \to u^0$ weakly in $W^{1,2}(Q_\varepsilon)$, we have

$$J^\varepsilon(w^\varepsilon) \geq J^\varepsilon(u^\varepsilon)\,. \tag{2.10}$$

Then, by Proposition (2.13), $\partial^\varepsilon_z u^\varepsilon \xrightarrow[\varepsilon\to 0]{} \dfrac{\partial}{\partial z}u^0$ weakly in $L^2(Q_\varepsilon)$ and, therefore,

$$\begin{aligned}
\varepsilon^d \sum_{x\in\overline{Q_\varepsilon}}\sum_{z,z'\in\Lambda} & a^\varepsilon_{zz'}(x)\,\bar\partial^\varepsilon_z w^\varepsilon(x)\,\bar\partial^\varepsilon_{z'} w^\varepsilon(x) \\
&= J^\varepsilon(w^\varepsilon) + 2\sum_{x\in\overline{Q_\varepsilon}}\sum_{z,z'\in\Lambda} a_{zz'}(x)\,\bar\partial^\varepsilon_z w^\varepsilon(x)\,\frac{\partial}{\partial z'}u^0(x) \\
&\geq J^\varepsilon(u^\varepsilon) + 2\sum_{x\in\overline{Q_\varepsilon}}\sum_{z,z'\in\Lambda} a_{zz'}(x)\,\bar\partial^\varepsilon_z w^\varepsilon(x)\,\frac{\partial}{\partial z'}u^0(x) \\
&= -\sum_{x\in\overline{Q_\varepsilon}}\sum_{z,z'\in\Lambda} a_{zz'}(x)\,\bar\partial^\varepsilon_z u^\varepsilon(x)\,\frac{\partial}{\partial z'}u^0(x) \\
&\quad +2\sum_{x\in\overline{Q_\varepsilon}}\sum_{z,z'\in\Lambda} a_{zz'}(x)\,\bar\partial^\varepsilon_z w^\varepsilon(x)\,\frac{\partial}{\partial z'}u^0(x) \\
&\xrightarrow[\varepsilon\to 0]{} \int_Q \sum_{z,z'\in\Lambda} a_{zz'}(x)\,\frac{\partial}{\partial z}u^0(x)\,\frac{\partial}{\partial z'}u^0(x)\,dx\,.
\end{aligned}$$

Equation (2.8) has also been used here. Now, taking the infimum limit in both sides of (2.10), we obtain the required inequality.

2. It is the statement of Proposition 2.8.

The remaining part of the proposition is an easy consequence of the uniqueness of the H-limit. □

REMARK 2.15. *The statements of Propositions* 2.8 *and* 2.14 *remain valid if we replace the sums over* $x \in \overline{Q_\varepsilon}$ *by the sums over* $x \in Q_\varepsilon$.

2.3. Description of the random environment.

In this section we introduce random difference elliptic operators with statistically homogeneous rapidly oscillating coefficients.

Let $(\Omega, \mathcal{F}, \mu)$ be a standard probability space, where $\mathcal{F}$ is a σ-algebra of subsets of Ω and μ is a probability measure. Let $\{T_x : \Omega \mapsto \Omega;\, x \in \mathbb{Z}^d\}$ be a group of $\mathcal{F}$-measurable transformations which preserve the measure μ:

1. $T_x : \Omega \mapsto \Omega$ is $\mathcal{F}$–measurable for all $x \in \mathbb{Z}^d$,
2. $\mu(T_x\mathcal{B}) = \mu(\mathcal{B})$, for any $\mathcal{B} \in \mathcal{F}$ and $x \in \mathbb{Z}^d$,
3. $T_0 = I\,,\ T_x \circ T_y = T_{x+y}$.

In what follows we assume that the group T_x is ergodic. That is, any $f \in L^1(\Omega)$ such that $f(T_x\,\omega) = f(\omega)$ μ-a.s for each $x \in \mathbb{Z}^d$ is equal to a constant μ-a.s.

Let Λ be a finite subset of $\mathbb{Z}^d$. Given a matrix-valued $\mathcal{F}$-measurable function $\{a_{zz'}(\omega)\}$, $z, z' \in \Lambda$, with values in the space of symmetric $|\Lambda| \times |\Lambda|$ matrices, we define a family of difference operators A^ε with the coefficients

$$a^\varepsilon_{zz'}(x) = a_{zz'}(T_{x/\varepsilon}\omega), \quad x \in \varepsilon\mathbb{Z}^d,\ z, z' \in \Lambda\,. \tag{2.11}$$

We suppose here that $\pm e_i \in \Lambda,\ i = 1, \ldots, d$, and that

$$\sum_{z,z' \in \Lambda} a_{zz'}(\omega)\eta_z\eta_{z'} \geq c\sum_{i=1}^{d} |\eta_{\pm e_i}|^2\,, \quad \eta \in \mathbb{R}^{|\Lambda|}\,. \tag{2.12}$$

$$|a_{zz'}(\omega)| \leq c_1, \quad z, z' \in \Lambda. \tag{2.13}$$

It is easy to see that these inequalities imply the N-ellipticity and the uniform ellipticity of the corresponding family A_ε in any regular domain Q.

In applications, especially in those related to random walks, we usually deal with the following particular case of the above construction.

Let $\{q(\omega, z),\ z \in \mathbb{Z}^d\}$ be a family of random variables such that μ-a.s,

1. $\sum\limits_{z \in \mathbb{Z}^d} q(\omega, z) = 1\,,$
2. $q(T_x\omega, z) = q(T_{x+z}\omega, -z)\,,$
3. $q(\omega, z) \geq 0, \quad q(\omega, \pm e_i) \geq \delta > 0,\ i = 1, \ldots, d$ (ellipticity condition).

We introduce a family of transition probabilities as follows:

$$p_z(x) = q(T_x\omega, z),$$

where the argument ω, treated as a realization of the medium, is omitted. The important characteristic of a family of transition probabilities is the structure of its support:

$$\Lambda = \left\{ z \in \mathbb{Z}^d \mid \operatorname*{ess\,sup}_{\Omega} p_z(x) \neq 0 \right\}.$$

In all the models considered below, the set Λ is finite.

Now, if we denote $p_z^\varepsilon(x) = p_z(\varepsilon^{-1}x),\ x \in Q_\varepsilon,\ z \in \Lambda$, then due to the assumptions on $q(\omega, x)$, problem (1.5) is uniformly and N-elliptic.

It is convenient to define the "ω-divergence" operator:

for any random variable $v \in L^2(\Omega)\,, \quad \operatorname{div}_\omega v(\omega) \overset{\triangle}{=} \sum\limits_{z \in \Lambda} v(T_{-z}\omega) - v(\omega)\,.$

We will use it in the following analysis.

2.4. Homogenization of random operators. This section is devoted to homogenization of the random difference operators introduced in the preceding section. The first proof of the homogenization theorem for such operators was obtained in [15], where the "corrector technique" was used. Here we give another proof of the theorem, which relies on the compensated compactness lemma.

2.4.1. Auxiliary problem. Let us define the following subspaces of $\left(L^2(\Omega)\right)^{|\Lambda|}$ (see Kozlov [15]):

$L^2_{pot}(\Omega, \Lambda)$ is the closure of the set
$\left\{v \in (L^2(\Omega))^{|\Lambda|}\,;\, v_z(\omega) = u(T_z\omega) - u(\omega) \text{ for some } u \in L^\infty(\Omega)\right\}$,
$L^2_{sol}(\Omega, \Lambda)$ is the closure of the set: $\left\{v \in (L^2(\Omega))^{|\Lambda|}\,;\, \operatorname{div}_\omega\, v = 0\right\}$.

For $\lambda \in \mathbb{R}^{|\Lambda|}$ we denote by $\mathcal{V}^2_{pot,\lambda}(\Omega, \Lambda)$ the closed set $\left\{v + \lambda\,;\, v \in L^2_{pot}(\Omega, \Lambda)\right\}$.

Consider the following auxiliary problem: given $\lambda \in \mathbb{R}^{|\Lambda|}$, find $v \in \mathcal{V}^2_{pot,\lambda}(\Omega, \Lambda)$ such that

$$\mathrm{div}_\omega \left(\sum_{z' \in \Lambda} a_{zz'}(\omega)\, v_{z'}(\omega) \right) = 0\,. \tag{2.14}$$

In order to prove the existence and uniqueness of the solution of this problem we introduce the operator

$$\begin{array}{rcl} A_{pot}\ :\ \ L^2_{pot}(\Omega,\Lambda) & \mapsto & L^2_{pot}(\Omega,\Lambda) \\ (v_z)_{z\in\Lambda} & \mapsto & \Pi_{pot}\left(\displaystyle\sum_{z'\in\Lambda} a_{zz'}(\omega)\, v_{z'}(\omega) \right), \end{array}$$

where Π_{pot} is the orthogonal projection onto the subspace $L^2_{pot}(\Omega, \Lambda)$.

In view of the Weyl decomposition (see Kozlov [15]) $\left(L^2(\Omega)\right)^{|\Lambda|} = L^2_{pot}(\Omega, \Lambda) \oplus L^2_{sol}(\Omega, \Lambda)$, we can rewrite the problem (2.14) in the following form: given $\lambda \in \mathbb{R}^{|\Lambda|}$, find $v \in L^2_{pot}(\Omega)$ such that

$$A_{\rm pot} v = \Pi_{pot} \left(\sum_{z' \in \Lambda} a_{zz'}(\omega)\, \lambda_{z'} \right).$$

The operator A_{pot} is coercive. Indeed, for any $v \in L^2_{pot}(\Omega, \Lambda)$, we have

$$\begin{aligned} (A_{pot} v, v) &= \sum_{z\in\Lambda} \left(\Pi_{pot} \left(\sum_{z'\in\Lambda} a_{zz'}(\omega)\, v_{z'}(\omega) \right),\ v_z(\omega) \right)_{L^2(\Omega)} \\ &= \sum_{z\in\Lambda} \left(\sum_{z'\in\Lambda} a_{zz'}(\omega)\, v_{z'}(\omega),\ \Pi_{pot}\left(v_z(\omega)\right) \right)_{L^2(\Omega)} \\ &= \sum_{z\in\Lambda} \left(\sum_{z'\in\Lambda} a_{zz'}(\omega)\, v_{z'}(\omega),\ v_z(\omega) \right)_{L^2(\Omega)}. \end{aligned}$$

According to hypothesis (2.12), this implies $(A_{\rm pot} v, v) \ge c\, E \left[\sum_{i=1}^n |v_{\pm e_i}|^2\right]$, where E stands for the expectation with respect to the measure μ. On the other hand, for any v of the form $v_z(\omega) = u(T_z\omega) - u(\omega)$, $u \in L^2(\Omega)$, we have

$$\begin{aligned} \|v\|^2_{(L^2(\Omega))^{|\Lambda|}} &= E\left[\sum_{z\in\Lambda} |v_z(\omega)|^2 \right] \ =\ E\left[\sum_{z\in\Lambda} |u(T_z\omega) - u(\omega)|^2 \right] \\ &= E\left[\sum_{z\in\Lambda} \left| \sum_{i=0}^{N(z)-1} u(T_{\zeta_{i+1}}\omega) - u(T_{\zeta_i}\omega) \right|^2 \right], \end{aligned}$$

where $\zeta_0 = 0$, $\zeta_{N(z)} = z$, $|\zeta_{i+1} - \zeta_i| = 1$, and $N(z) \le d\,\mathrm{diam}(\Lambda)$. Therefore,

$$\|v\|^2_{(L^2(\Omega))^{|\Lambda|}} \le E\left[d(\mathrm{diam}(\Lambda))^2 |\Lambda| \sum_{i=1}^d (v_{\pm e_i}(\omega))^2 \right] \le c_1(d,\Lambda)\, E\left[\sum_{i=1}^d (v_{\pm e_i}(\omega))^2 \right].$$

By definition, the said set of $v(\omega)$ is dense in $L^2_{pot}(\Omega, \Lambda)$, and by the continuity arguments, the latter estimate holds for any $v \in L^2_{pot}(\Omega, \Lambda)$.

Thus, $(A_{\rm pot} v, v) \ge c_2(d, \Lambda)\, \|v\|^2_{(L^2(\Omega))^{|\Lambda|}}$, and the desired existence and uniqueness follow from the Lax–Milgram lemma.

2.4.2. Homogenization. In this section, we study the family of random operators $\{A_\varepsilon\}$ with statistically homogeneous coefficients given by (2.11). The homogenization theorem for such operators was originally proved in [15]. We give another proof based on the compensated compactness lemma, which seems to be easier and shorter. The main result here is the following theorem.

THEOREM 2.16. *Let the coefficients of A_ε be given by* (2.11), *and suppose the condition* (2.12) *is fulfilled. Then, a.s., the family $\{A_\varepsilon\}$ admits homogenization and the limit matrix $\mathcal{A}^0$ does not depend on ω.*

Proof. For a fixed $f \in W^{-1,2}(Q)$, consider the following Dirichlet problems:

$$\operatorname{div}_\Lambda^\varepsilon \left(\sum_{z' \in \Lambda} a^\varepsilon_{zz'} \partial^\varepsilon_{z'} u^\varepsilon \right) = f\,, \quad u^\varepsilon \in W_0^{1,2}(Q_\varepsilon)\,. \tag{2.15}$$

Since u^ε and $\sum_{z'\in\Lambda} a^\varepsilon_{zz'}\, \partial^\varepsilon_{z'} u^\varepsilon$ are uniformly bounded, respectively, in $W^{1,2}(Q_\varepsilon)$ and $(L^2(Q_\varepsilon))^{|\Lambda|}$, we have

$$u^\varepsilon \xrightarrow[\varepsilon\to 0]{} u^0 \quad \text{weakly in } W_0^{1,2}(Q_\varepsilon)\,,$$
$$s^\varepsilon \xrightarrow[\varepsilon\to 0]{} s^0 \quad \text{weakly in } \left(L^2(Q_\varepsilon)\right)^{|\Lambda|}\,,$$

where s^ε_z stands for $\sum_{z'\in\Lambda} a^\varepsilon_{zz'}\, \partial^\varepsilon_{z'} u^\varepsilon$.

Let $v_z(\omega)$ solve the auxiliary problem (2.14). If we denote $v^\varepsilon(x) \triangleq v\left(T_{x/\varepsilon}\,\omega\right)$, $q^\varepsilon \triangleq v^\varepsilon \mathcal{A}^\varepsilon$, i.e., $\forall z \in \Lambda$, $q^\varepsilon_z = \sum_{z'\in\Lambda} v^\varepsilon_{z'}\, a^\varepsilon_{zz'}$, then, the identity

$$\sum_{x\in Q_\varepsilon} \sum_{z\in\Lambda} s^\varepsilon_z(x)\, v^\varepsilon_z(x) = \sum_{x\in Q_\varepsilon} \sum_{z\in\Lambda} q^\varepsilon_z(x)\, \partial^\varepsilon_z u^\varepsilon(x) \tag{2.16}$$

obviously holds. We introduce a constant matrix $\mathcal{A}$ to satisfy the relation $E(q^\varepsilon) = \lambda\, \mathcal{A}^0$. This matrix is well defined because q^ε is a linear functional of λ. By the Birkhoff ergodic theorem, we have

$$v^\varepsilon \xrightarrow[\varepsilon\to 0]{} E(v^\varepsilon) = \lambda \quad \text{weakly in } L^2(Q_\varepsilon) \text{ a.s.},$$
$$q^\varepsilon \xrightarrow[\varepsilon\to 0]{} E(q^\varepsilon) = \lambda\, \mathcal{A} \quad \text{weakly in } L^2(Q_\varepsilon) \text{ a.s.}$$

It follows from (2.14) and the definition of $\operatorname{div}_\omega$ and $\operatorname{div}^\varepsilon_\Lambda$ that for almost all realizations we have $\operatorname{div}^\varepsilon_\Lambda q^\varepsilon = 0$, while the fact that $v - \lambda \in L^2_{pot}(\Omega, \Lambda)$ implies a.s. the relation $v^\varepsilon_z = \partial^\varepsilon_z \theta^\varepsilon$ for some (in general not statistically homogeneous) functions θ^ε. Also, from (2.15) we have $\operatorname{div}^\varepsilon_\Lambda s^\varepsilon = f$. By Lemma 2.1,

$$\sum_{z\in\Lambda} s^\varepsilon_z\, v^\varepsilon_z \xrightarrow[\varepsilon\to 0]{\star} \sum_{z\in\Lambda} s^0_z\, \lambda_z$$

and

$$\sum_{z\in\Lambda} q^\varepsilon_z\, \partial^\varepsilon_z u^\varepsilon \xrightarrow[\varepsilon\to 0]{\star} \sum_{z,z'\in\Lambda} \lambda_z\, a^0_{zz'}\, \frac{\partial}{\partial z'} u^0\,,$$

or, equivalently,

$$\sum_{z,z'\in\Lambda} v^\varepsilon_{z'}\, a^\varepsilon_{zz'}\, \partial^\varepsilon_z u^\varepsilon \xrightarrow[\varepsilon\to 0]{\star} \sum_{z,z'\in\Lambda} \lambda_z\, a^0_{zz'}\, \frac{\partial}{\partial z'} u^0;$$

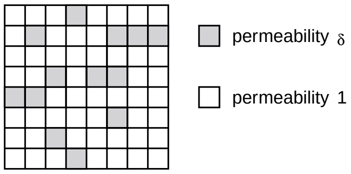

FIG. 3.1. *Example of a realization of the random medium.*

we have also used here Proposition 3 from [15]. Hence, passing to the limit in (2.16) and bearing in mind the fact that λ is an arbitrary vector, we find

$$s_z^0 = \sum_{z' \in \Lambda} a^0_{zz'} \, \frac{\partial}{\partial z'} u^0 \, .$$

Since $\sum_{z\in\Lambda} \frac{\partial}{\partial z} s_z^0 = f$, the function u^0 is the solution of the homogenized problem and $\mathcal{A}^0$ is the limit matrix. □

3. Asymptotic behavior of the effective coefficient. In this second part of the work, we consider the difference operators obtained by discretizing a random two-dimensional high-contrast checker-board structure, as various discretization procedures are applied. For each discretization method, we find the asymptotics of the effective coefficient. The results obtained in this section rely essentially on the fine results from the percolation theory, such as channel property and related statements. For the reader's convenience, we formulate these results and provide necessary definitions in section 3.1.

To define the random media, we split the plane $\mathbb{R}^2$ into regular squares $\{[-\frac{1}{2}, \frac{1}{2}]^2 + j\}$, $j \in \mathbb{Z}^2$, and assign a value of permeability, independently at each square, as follows:

$$\kappa(y) \triangleq \left\{ \begin{array}{lll} \delta & \text{with probability} & p \\ 1 & \text{with probability} & 1-p \end{array} \right. , \quad y \in \left[-\frac{1}{2}, \frac{1}{2} \right]^2 + j, \; j \in \mathbb{Z}^2,$$

where δ is a small strictly positive parameter (see Figure 3.1). Then, we consider the grid $\mathbb{Z}^2$, fix a finite set $\Lambda \subset \mathbb{Z}^2$, and define the transition probabilities $\{p_z(x);\, x \in \mathbb{Z}^2,\, z \in \Lambda\}$ to be a function of $\{\kappa(x+z)\}$, $z \in \Lambda$. Finally, we define the coefficients of operator A_ε in terms of $\{p_z(x)\}$ by (1.6).

Henceforth, we suppose that the properties (1), (2), and (3) in section 1.1 are satisfied. It then follows from the independence of $\kappa(j)$ for different $j \in \mathbb{Z}^2$ that the family $\{p_z(x)\}$ is ergodic. Now, the following assertion is a direct consequence of Theorem 2.16 (see also Kozlov [15, section 2]).

PROPOSITION 3.1.

1. *The operators A_ε G-converge as $\varepsilon \to 0$ to an elliptic operator with constant nonrandom coefficients $\mathcal{A} = \{a_{zz'}\}_{z,z' \in \Lambda \setminus (0,0)}$.*
2. *The limit matrix is isotropic: $\mathcal{A} = a^\delta(p)\, I$ (I is the identity matrix).*

We call $a^\delta(p)$ the effective coefficient and study its asymptotics as $\delta \to 0$ for various $p \in [0, 1]$.

3.1. Some results from percolation theory. In this section, we quote and discuss briefly several results from percolation theory. We consider the so-called site percolation model (see Grimmett [10]) and, following the tradition, say black and

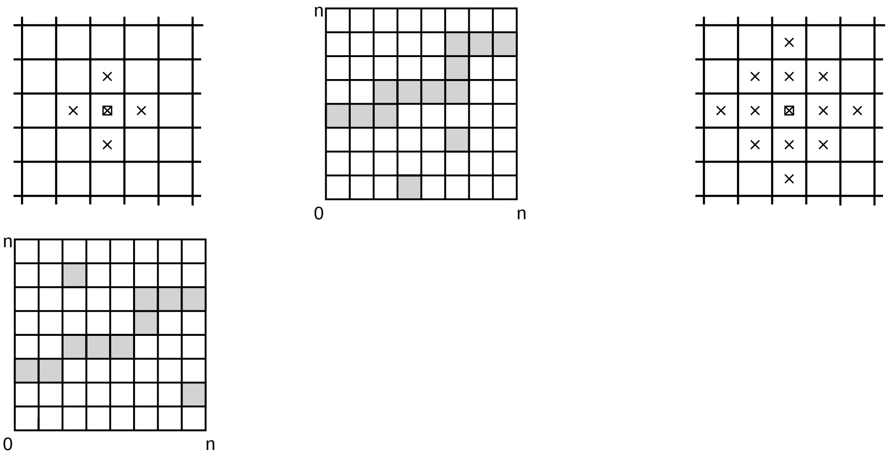

Fig. 3.2. *The neighbor squares and black channels in the cases $\gamma = 1$ (left) and $\gamma = \sqrt{2}$ (right).*

white squares instead of "δ" and "1" squares, respectively. All the squares are enumerated by the coordinates of their centers and the distance $\operatorname{dist}(i, j)$ between squares i and j, $(i, j \in \mathbb{Z}^2)$, is defined as the Euclidean distance $|i - j|$.

Definition 3.2.

- *Two black squares i and j are* γ-connected *if* $\operatorname{dist}(i, j) \leq \gamma$. *As soon as the value of γ is fixed, we just refer to* connected *squares or* neighbor *squares.*
- *Consider the random subgraph containing only the black squares. The connected components of this graph are called* black clusters.
- *A finite set of black squares forms a* black channel *if the squares can be enumerated in such a way that any two successive squares in this enumeration are γ-connected (see Figure* 3.2 *for examples).*

Similarly, we define γ-connected white squares, white clusters and white channels. When the probability p varies, the geometric properties of the black clusters are modified. The more p increases, the bigger are the sizes of the clusters, and they eventually form the unique infinite cluster (see, for example, Grimmett [10]). Below, some basic constructions of percolation theory are presented.

The probability space is introduced as follows. As sample space, we take $K = \Pi_{s \in \mathbb{Z}^2}\{\delta, 1\}$. Each point of K: $\kappa = (\kappa(s); s \in \mathbb{Z}^2)$ is called a configuration. We take $\mathcal{G}$ to be the σ-field of subsets of K generated by the finite dimensional cylinders. And, for each $p \in [0, 1]$, we define the probability measure P_p as the product measure on $(K, \mathcal{G})$ such that the random variables $\kappa(s), s \in \mathbb{Z}^2$ are independent and satisfy $P_p(\kappa(x) = \delta) = p$.

In what follows we identify the probability space $(K, \mathcal{G}, P_p)$ with the general probability space $(\Omega, \mathcal{F}, P)$ defined above.

Let $|C|$ be the cardinal of the cluster which contains the origin. The cluster-size distribution is given by $\theta_n(p) = P_p(|C| = n), \ n \in \mathbb{N}^*$. The probability $\theta(p) = P_p(|C| = +\infty)$ that the origin belongs to the infinite cluster is called the *percolation probability.* There exists a *critical probability* $p_c(\gamma)$, also called the *percolation threshold*, such that

$$\begin{cases} \theta(p) = 0 & \text{if} \quad p \leq p_c(\gamma)\,, \\ \theta(p) > 0 & \text{if} \quad p > p_c(\gamma)\,. \end{cases}$$

Table 3.1
Evolution of the number of infinite cluster with respect to p.

<table>
<tr><th>p</th><th>0</th><th>$p_c(2)$</th><th>$p_c(\sqrt{2})$</th><th>$p_c(1)$</th><th>$1-p_c(2)$</th><th>1</th></tr>
<tr><td>$\gamma = 1$</td><td colspan="2">White</td><td>No infinite cluster</td><td colspan="3">Black</td></tr>
<tr><td>$\gamma = \sqrt{2}$</td><td colspan="2">White</td><td>Black and White</td><td colspan="3">Black</td></tr>
<tr><td>$\gamma = 2$</td><td>White</td><td colspan="3">Black and White</td><td colspan="2">Black</td></tr>
</table>

Thus, for each fixed γ, the *critical probability* is $p_c(\gamma) \overset{\triangle}{=} \sup\{p : \theta(p) = 0\}$.

Figure 3.2 shows the sets of neighbor squares, with respect to the marked square, in the cases $\gamma = 1$ and $\gamma = \sqrt{2}$, and it emphasizes the difference between the structures of channels.

In Table 3.1, we can see, for three different values of γ, the presence of white and black clusters with respect to the values of p. The following relation holds: $p_c(1) + p_c(\sqrt{2}) = 1$, while $p_c(1) \sim 0.59$ and $p_c(\sqrt{2}) \sim 0.41$ (see Kesten [12]).

Moreover, according to Aizenman and Grimmett [1], $p_c(2) < p_c(\sqrt{2})$.

3.1.1. The channel property. Denote by $N(n)$ the number of mutually non-intersecting black channels joining the left and the right sides of the box $[0, n]^2$.

Proposition 3.3 (see Kesten [12, section 11]). *Let $\gamma = 1$ or $\gamma = \sqrt{2}$. If $p > p_c(\gamma)$, then for almost all $\kappa \in K$ the inequality*

$$N(n) \geq c(p)\, n\,, \quad c(p) > 0,$$

holds for any $n \geq n_0(\kappa)$

Remark 3.4. *In fact, this result holds true for any value of γ (see Golden and Kozlov* [9]*).*

Remark 3.5. *For all $\gamma \geq \sqrt{2}$, the percolation models admit the coexistence of the channels of both colors (see Figure* 3.2*).* The geometry of the white and black subgraphs is rather different in subcritical and supercritical zones. In this connection, it is interesting to study carefully what happens near $p_c(\gamma)$.

Proposition 3.6 (see Kesten [12, section 11]). *There exist some strictly positive constants c_1, c_2, c_3, δ_1, δ_2 such that, for $p > p_c(\gamma)$,*

$$P_p\left(N(n) \geq c_1\,(p - p_c(\gamma))^{\delta_1} n\right) \geq 1 - c_2\,(n+1)\,e^{-c_3\, n\,(p-p_c(\gamma))^{\alpha_2}}\,.$$

By the Borel–Cantelli lemma, we have

$$c(p) \geq c_1\,(p - p_c(\gamma))^{\delta_1}\,. \tag{3.1}$$

Remark 3.7. *One can easily check that all the channels can be chosen to be no longer than $\theta(p)\, n$.*

3.2. Behavior of the effective coefficient. In this section, for the checkerboard model introduced above, we consider several discrete models characterized by

- the set of admissible jumps, i.e., the set Λ;
- the corresponding transition probabilities $\{p_z\}_{z\in\Lambda}$.

In all these models, the distribution of $\{p_z\}_{z\in\Lambda}$ will be invariant with respect to rotations at the angle $\pi/2$. This symmetry implies the isotropy of the effective tensor, and thus there is only one scalar effective coefficient $a^\delta(p)$ to be determined.

For each model, we study the limit behavior of the effective coefficient as $\delta \to 0$.

3.2.1. Harmonic mean. We begin by considering the "harmonic mean" model. Namely, we assume that

$$\Lambda = \{\pm(1,0),\, \pm(0,1),\, (0,0)\}$$

and define the transition probabilities as the harmonic mean of the values of $\kappa(\cdot)$ at the corresponding points:

$$p_z(x) = \begin{cases} \dfrac{1}{4}\,\dfrac{2\,\kappa(x)\,\kappa(x+z)}{(\kappa(x)+\kappa(x+z))} & \text{if } z \in \Lambda \setminus \{(0,0)\}\,, \\ 1 - \sum_{z\in\Lambda\setminus\{(0,0)\}} p_z(x) & \text{if } z = (0,0)\,, \\ 0 & \text{if } z \notin \Lambda\,. \end{cases}$$

Clearly, the family $\{p_z(x)\}$ satisfies the conditions (1), (2), and (3) in section 1.1, and moreover, its distribution is isotropic.

Remark 3.8. *The choice of the harmonic mean is natural in the framework of the finite volume approach. Indeed, with this choice for the coefficients, we* conserve the fluxes. *This conservation is violated under another choices (see explanations in McCarthy* [19]*).*

The asymptotic behavior of the effective coefficient $a^\delta(p)$ as $\delta \to 0$ is described by the following statement.

Theorem 3.9. *The effective coefficient $a^\delta(p)$ satisfies, for small δ, the following inequalities:*

$$\begin{array}{ll} 0 < c_1(p) \le a^\delta(p) \le 1 & \text{if } \ 0 \le p < p_c(\sqrt{2}), \\ \delta \le a^\delta(p) \le c_2(p)\,\delta,\ c_2(p) > 0 & \text{if } \ p_c(\sqrt{2}) < p \le 1. \end{array}$$

This means, in particular, that $a^\delta(p)$ does not vanish as $\delta \to 0$ if $p < p_c(\sqrt{2})$.

Proof.

1. *Case* $0 \le p < p_c(\sqrt{2})$.

Consider the percolation model with $\gamma = 1$. By Proposition 3.3, for $0 \le p < 1 - p_c(1)$ there are at least $N(n) = c(p)\,n$ mutually nonintersecting white channels joining the left and the right sides of the square $[0,n]^2$. We denote by C_k the kth channel, $1 \le k \le N(n)$.

Define on the space $\big(L^2(\Omega)\big)^{|\Lambda|}$ the following seminorm:

$$\|\phi\|^2 \overset{\triangle}{=} E\left\{\sum_{z\in\Lambda} p_z(\omega)\,(\phi_z(\omega))^2\right\}, \tag{3.2}$$

where E is the expectation related to the measure μ. In fact, under the assumptions of the theorem, it is a norm, but we will not use this fact.

Let $P_1(z) = z_1$ be the projection onto the first coordinate of vector z. According to Kozlov ([14, Chapter II, section 2], the effective coefficient $a^\delta(p)$ can be calculated as follows:

$$a^\delta(p) = \inf_{\varphi\in L^2_{pot}(\Omega,\Lambda)} \|P_1(z) - \varphi\|^2\,, \tag{3.3}$$

where the subspace $L^2_{pot}(\Omega,\Lambda)$ has been defined in section 2.4.1 of this paper. Denote by $\mathcal{H}$ the linear set $\mathcal{H} = \{\varphi_z(\omega) = \tilde\varphi(T_z\omega) - \tilde\varphi(\omega)\,;\ \tilde\varphi \in L^\infty(\Omega)\}$. This set $\mathcal{H}$ is dense in $L^2_{pot}(\Omega,\Lambda)$ (see section 2.4.1) and the functional $\varphi \to \|z_1 - \varphi\|$ is continuous in $L^2_{pot}(\Omega,\Lambda)$. Therefore, the infimum over $L^2_{pot}(\Omega,\Lambda)$ in (3.3) can be replaced by the infimum over $\mathcal{H}$.

Let φ belong to $\mathcal{H}$: there exists $\tilde{\varphi} \in L^\infty(\Omega)$ such that $\varphi_z(\omega) = \tilde{\varphi}(T_z\,\omega) - \tilde{\varphi}(\omega)$. Then,

$$\|P_1(z) - \varphi\|^2 = E\left\{\sum_{z\in\Lambda} p_z(\omega)(z_1 - (\tilde{\phi}(T_z\,\omega) - \tilde{\phi}(\omega)))^2\right\}.$$

Since T_x is ergodic, by the Birkhoff theorem we have for almost all realizations

$$\begin{aligned}\|P_1(z) - \phi\|^2 &= \lim_{n\to+\infty} \frac{1}{n^2} \sum_{x\in\mathbb{Z}^2\cap[0,n]^2} \sum_{z\in\Lambda} p_z(T_x\,\omega)\,\left(z_1 - \tilde{\phi}(T_{x+z}\,\omega) + \tilde{\phi}(T_x\,\omega)\right)^2 \\ &= \lim_{n\to+\infty} \frac{1}{n^2} \sum_{x\in\mathbb{Z}^2\cap[0,n]^2} \sum_{z\in\Lambda} p_z(x)\,\left(z_1 - \tilde{\phi}(T_{x+z}\,\omega) + \tilde{\phi}(T_x\,\omega)\right)^2 . \qquad (3.4)\end{aligned}$$

Our goal now is to construct a uniformly positive lower bound for $a^\delta(p)$. To this end, on the RHS of the last formula, we first take into account only the points x located inside the channels:

$$\|P_1(z) - \phi\|^2 \geq \liminf_{n\to+\infty} \frac{1}{n^2} \sum_{x\in C}\sum_{z\in\Lambda} p_z(x)\,\left(z_1 - \tilde{\phi}(T_{x+z}\,\omega) + \tilde{\phi}(T_x\,\omega)\right)^2 ,$$

where C stands for the union of white channels. Then, we enumerate the points x along each channel in such a way that any consecutive numbers correspond to neighbor points, and we replace the inner sum over $z \in \Lambda(x)$ by the sum over z such that $x+z$ belong to the same channel as x and have greater index than x. Denote this latter set of z by $\lambda(x)$, and notice that for each x from the union of white channels $\lambda(x)$ is not empty and consists of only one element. For $z \in \lambda(x)$, we clearly have $p_z(x) = 1/4$. Hence,

$$\|P_1 - \varphi\|^2 \geq \liminf_{n\to+\infty} \frac{1}{4\,n^2} \sum_{x\in C}\ \sum_{z\in\lambda(x)} \left(z_1 - \tilde{\phi}(T_{x+z}\,\omega) + \tilde{\phi}(T_x\,\omega)\right)^2 ,$$

If we denote $S(x) = \sum_{z\in\lambda(x)} (z_1 - \tilde{e}(T_{x+z}\,\omega) + \tilde{e}(T_x\,\omega))$, and enumerate the channels $C = \cup_{k=1}^{N(n)} C_k$, then, for the kth channel, we have

$$\begin{aligned}\sum_{x\in C_k} S(x) &= \sum_{x\in C_k}\sum_{z\in\lambda(x)} (z_1 - \tilde{\phi}(T_{x+z}\omega) + \tilde{\phi}(T_x\omega)) \\ &= n + \sum_{x\in C_k}\sum_{z\in\lambda(x)} (-\tilde{\phi}(T_{x+z}\omega) + \tilde{\phi}(T_x\omega)) \\ &= n + \tilde{\phi}(T_{x_s(C_k)}\omega) - \tilde{\phi}(T_{x_f(C_k)}\,\omega) \geq n - c\,,\end{aligned}$$

where $c = 2\,\|\tilde{\phi}\|_{L^\infty(\Omega)}$, and $x_s(C_k)$ and $x_f(C_k)$ are, respectively, the starting and final points of kth channel. Summing up over the channels, we obtain

$$\sum_{x\in C} S(x) \geq (n-c)\,N(n)\,. \qquad (3.5)$$

By the Cauchy inequality, taking into account Remark 3.7, we get

$$\sum_{x\in C} S(x)^2 \geq \frac{\left(\sum_{x\in C} S(x)\right)^2}{\theta(p)\,n\,N(n)}\,.$$

In view of (3.5) this implies

$$\sum_{x\in C} S(x)^2 \ge \frac{(n-c)^2\, N(n)^2}{\theta(p)\, n\, N(n)}\,, \tag{3.6}$$

and

$$\|P_1(z)-\phi\|^2 \ge \lim_{n\to+\infty} \frac{1}{4\,n^2}\frac{c(p)}{\theta(p)}\,(n-c)^2 \ge c_1 > 0\,. \tag{3.7}$$

Hence: $a^\delta(p) \ge c_1 > 0$. The upper bound $a^\delta(p) \le 1$ is obvious and, finally,

$$0 < c_1 \le a^\delta(p) \le 1\,.$$

2. *Case* $p_c(\sqrt{2}) < p \le 1$.

Consider the percolation model with $\gamma = \sqrt{2}$. There are at least $c(p)\,n$ non-intersecting black channels $C_k,\ k = 1, 2, \dots, N(n)$, joining the left and the right sides of the square $[0, n]^2$ (see Proposition 3.3).

Let us denote $\varepsilon = 1/n$ and define functions w^ε on $\varepsilon\mathbb{Z}^2 \cap [0, 1]^2$ as follows:

- $w^\varepsilon(\cdot, 0) = 0\,,\ w^\varepsilon(\cdot, 1) = 1$ (boundary conditions),
- $w^\varepsilon(x) = \frac{(k-1/2)}{N(n)}$ for $x \in \varepsilon C_k$,
- $w^\varepsilon(x) = \frac{k}{N(n)}$ for x from the set bounded by εC_k and εC_{k+1} .

Here, we suppose without loss of generality that the channels do not intersect the bottom and top faces of the square. The above function w^ε has been designed to possess the following properties :

- In the area situated between any two consecutive channels C_k and C_{k+1}, this function is equal to a constant, the constants are different in distinct areas.
- At each channel C_k the function w^ε makes a jump. The values of jumps are uniformly distributed on the channels so that the total increment of w^ε, as x_2 varies from 0 to 1, is equal to one.

By the definition and according to Proposition 3.3, the sequence w^ε is uniformly bounded in $W^{1,2}(Q_\varepsilon)$ and uniformly Lipschitz continuous; moreover, the Lipschitz constant is less than or equal to $c^{-1}(p)$. Thus, for a proper subsequence, we have

$$\begin{aligned} &w^\varepsilon \xrightarrow[\varepsilon\to 0]{} u_0 \quad \text{weakly in } W^{1,2}(Q_\varepsilon)\,,\\ &\sup_{x\in Q} |w^\varepsilon - u_0| \xrightarrow[\varepsilon\to 0]{} 0\,, \end{aligned}$$

where $u_0 \in W^{1,2}(Q)$, $u_0(\cdot, 0) = 0$, $u_0(\cdot, 1) = 1$, and

$$|u_0(x^1) - u_0(x^2)| \le c^{-1}(p)|x^1 - x^2|\,, \quad x^1,\, x^2 \in [0,1]^2\,.$$

Consider the expression

$$J^\varepsilon(w^\varepsilon) = \varepsilon^2 \sum_{x\in Q_\varepsilon}\sum_{z,z'\in\Lambda} a^\varepsilon_{zz'}(x)\,\partial^\varepsilon_z w^\varepsilon(x)\,\partial^\varepsilon_{z'} w^\varepsilon(x) = \varepsilon^2 \sum_{x\in Q_\varepsilon}\sum_{z\in\Lambda} p^\varepsilon_z(x)\,(\partial^\varepsilon_z w^\varepsilon(x))^2\ . \tag{3.8}$$

It follows from the definitions of w^ε and $p^\varepsilon_z(x)$ that

$$J^\varepsilon(w^\varepsilon) \le c^{-2}(p)\,\delta\,. \tag{3.9}$$

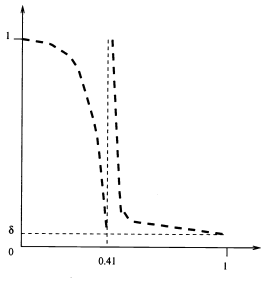

FIG. 3.3. *Illustration of Theorem* 3.10. *The behavior of* $a^\delta(p)$.

Moreover, by Proposition 2.14, $\liminf_{\varepsilon\to 0} J^\varepsilon(w^\varepsilon) \geq a^\delta(p) \int_{[0,1]^2} |\nabla u_0(x)|^2 dx \geq a^\delta(p)$. Combining the last two estimates, we get the desired inequality $a^\delta(p) \leq c^{-2}(p)\,\delta$. The lower bound $a^\delta(p) \geq \delta$ is evident. □

The next result describes the behavior of the effective coefficient $a^\delta(p)$ for p from a neighborhood of the critical point $p_c(\sqrt{2})$.

THEOREM 3.10. *In the vicinity of* $p_c(\sqrt{2})$, *the following inequalities hold:*

$$c_1\,(p_c(\sqrt{2}) - p)^{\alpha_1} \leq a^\delta(p) \quad \textit{if} \ \ p < p_c(\sqrt{2}),$$
$$a^\delta(p) \leq \frac{c_2}{(p - p_c(\sqrt{2}))^{\alpha_2}}\,\delta \quad \textit{if} \ \ p_c(\sqrt{2}) < p,$$

where c_1, c_2, α_1, *and* α_2 *are strictly positive constants.*

Figure 3.3 illustrates this result.

Proof. It is sufficient to substitute the estimate (3.1) in (3.7) and (3.9). The required estimates are now straightforward. □

3.2.2. Comparison with the behavior in continuous media. The asymptotic behavior of the effective coefficient described in the previous section (section 3.2.1) differs essentially from that obtained for the case of differential equations (see Jikov, Kozlov, and Oleinik [11, Chapter 9]). One of the reasons for this disagreement is the fact that we ignore the streams through the neighborhoods of vertices of the checker-board structure.

Here we modify the model of the previous section by involving the streams along the "diagonal directions," so that the asymptotic behavior of the effective coefficient as $\delta \to 0$ in this new model is similar to that obtained for the corresponding differential operator.

Let us begin by describing the scheme of discretization. We set

$$\Lambda = \{(0,0), \pm e_1, \pm e_2, \pm(e_1+e_2), \pm(e_1-e_2)\}, \qquad e_1 \overset{\triangle}{=} (1,0),\ e_2 \overset{\triangle}{=} (0,1),$$

(so, at each step, a trajectory of the corresponding random walk can choose one of the eight nearest points of $\mathbb{Z}^2$ or keep the same position).

In order to assign the values for $p_z(x)$, $|z| = \sqrt{2}$, we consider auxiliary periodic checker-board structure with a cell of periodicity shown in Figure 3.4. The effective coefficient of this medium is equal to $\sqrt{\delta}$ (see Jikov, Kozlov, and Oleinik [11, section 7.2]). This gives us an idea that, for the combination of squares shown in Figure 3.4, the coefficient $p_z(x)$ with $z = (e_1 + e_2)$, should be of order $\sqrt{\delta}$.

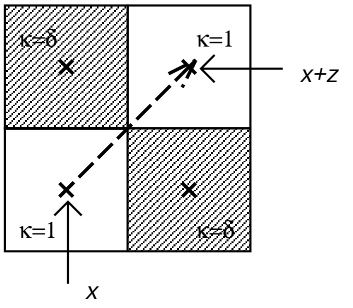

Fig. 3.4.

Inspired by these heuristic arguments, we define the transition probabilities by

$$p_z(x) = \begin{cases} \frac{1}{8}\min\left(\frac{2\,\kappa(x)\,\kappa(x+z)}{\kappa(x)+\kappa(x+z)},\ \sqrt{\frac{\kappa(x+z_1e_1)+\kappa(x+z_2e_2)}{2}\,\frac{\kappa(x)+\kappa(x+z)}{2}}\right) & \text{if } |z| = \sqrt{2}\,, \\ \dfrac{1}{8}\,\dfrac{2\,\kappa(x)\,\kappa(x+z)}{\kappa(x)+\kappa(x+z)} & \text{if } |z| = 1\,, \\ 1 - \sum_{z\in\Lambda, z\neq(0,0)} p_z(x) & \text{if } z = (0,0)\,, \\ p_z(x) = 0 & \text{if } z \notin \Lambda\,. \end{cases}$$

The following theorem describes the asymptotic behavior of the effective coefficient $a^\delta(p)$.

Theorem 3.11. *The effective coefficient $a^\delta(p)$ satisfies, for small δ, the estimates*

$$\begin{array}{ll} 0 < c_1(p) \le a^\delta(p) \le 1 & \textit{if}\ \ 0 \le p < p_c(\sqrt{2}), \\ c_2(p)\,\sqrt{\delta} \le a^\delta(p) \le c_3(p)\,\sqrt{\delta} & \textit{if}\ \ p_c(\sqrt{2}) < p < 1 - p_c(\sqrt{2}), \\ \delta \le a^\delta(p) \le c_4(p)\,\delta & \textit{if}\ \ 1 - p_c(\sqrt{2}) < p \le 1, \end{array}$$

where $c_1(p)$, $c_2(p)$, $c_3(p)$, and $c_4(p)$ are strictly positive.

Thus, the effective coefficient is uniformly positive when $p < p_c(\sqrt{2})$, is of order $\sqrt{\delta}$ when p is between $p_c(\sqrt{2})$ and $1 - p_c(\sqrt{2})$, and is of order δ when $p > 1 - p_c(\sqrt{2})$.

Proof. The cases $0 \le p < p_c(\sqrt{2})$ and $1 - p_c(\sqrt{2}) < p \le 1$ can be studied exactly in the same way as in Theorem 3.9. □

Now, we proceed with the case $p_c(\sqrt{2}) < p < 1 - p_c(\sqrt{2})$.

Consider the percolation model with $\gamma = \sqrt{2}$. Again, for sufficiently large n, there are at least $c(p)\,n$ mutually nonintersecting black $\sqrt{2}$-channels and white $\sqrt{2}$-channels joining the left and the right sides of the square $[0,n]^2$ (see Figure 3.5).

Lower bound. We consider the infinite white cluster. In order to obtain the lower bound for $a^\delta(p)$, we follow part (1) of the proof of Theorem 3.9. We point out that, along each white channel, if both x and $x+z$ belong to the channel and $|z| \le \sqrt{2}$, then $p_z(x) \ge \sqrt{\delta}/8$. Indeed, in this case $\kappa(x) = \kappa(x+z) = 1$ and, by the definition, $p_z(x)$ takes on one of the following values: $\frac{1}{8}$, $\frac{1}{8}\sqrt{\frac{1+\delta}{2}}$, $\frac{1}{8}\sqrt{\delta}$.

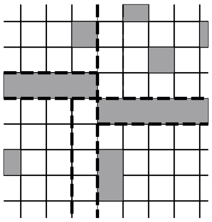

FIG. 3.5. *Intersection between a black and a white channel;* $p \in]\, p_c(\sqrt{2}),\, 1 - p_c(\sqrt{2})[$.

From (3.4), (3.6) and the above estimate of $p_z(x)$, we get

$$\begin{aligned} \|P_1(z) - \varphi\|^2 &= \lim_{n\to+\infty} \frac{1}{n^2} \sum_{x\in\mathbb{Z}^2\cap[0,n]^2} \sum_{z\in\Lambda(x)} p_z(T_x\,\omega)\, \Big(z_1 - \tilde{\phi}(T_{x+z}\,\omega) + \tilde{\phi}(T_x\,\omega)\Big)^2 \\ &\geq \liminf_{n\to+\infty} \frac{\sqrt{\delta}}{8\,n^2} \sum_{x\in C^w} \sum_{z\in\Lambda(x)} \Big(z_1 - \tilde{\phi}(T_{x+z}\,\omega) + \tilde{\phi}(T_x\,\omega)\Big)^2 \\ &\geq \lim_{n\to+\infty} \frac{\sqrt{\delta}}{8\,n^2} \frac{c(p)}{\theta(p)} (n-c)^2 \geq c\sqrt{\delta}\,, \end{aligned}$$

where symbol C^w stands for the union of white channels. By virtue of (3.3), the last inequality implies the required lower bound.

Upper bound. We consider the infinite black cluster and the $N(n) = c(p)\,n$ black channels C_k^b, $k = 1, 2, \dots, N(n)$ in the square $[0,\, n]^2$.

The upper bound $a^\delta(p) \leq c_3(p)\sqrt{\delta}$ can be established with the help of the following auxiliary functions:

- $w^\varepsilon(\cdot, 0) = 0\,,\ w^\varepsilon(\cdot, 1) = 1$;
- $w^\varepsilon(x) = \frac{(k-1/2)}{N(n)}$ for $x \in \varepsilon C_k^b$;
- $w^\varepsilon(x) = \frac{k}{N(n)}$ for x from the set bounded by εC_k^b and εC_{k+1}^b ,

where $\varepsilon = 1/n$. Direct calculations show that $J^\varepsilon(w^\varepsilon) \leq c^{-2}(p)\sqrt{\delta}$; indeed, by the definition of $\{p_z(x)\}$, we have $p_z(x) \leq \delta/8$ if x belongs to a black channel, and $p_z(x) \leq \frac{\sqrt{\delta}}{8}$ if x and $x+z$ are situated at the opposite banks of a black channel. If we denote by u_0 an accumulating point of w^ε, then we have by Proposition 2.14

$$c(p)^{-2}\,\sqrt{\delta} \geq \lim_{\varepsilon\to 0} J^\varepsilon(w^\varepsilon) \geq a^\delta(p) \int_{[0,\,1]^2} |\nabla u_0(x)|^2\, dx \geq a^\delta(p)\,.$$

Comparing these results with Jikov, Kozlov, and Oleinik [11, Chapter 9, Theorem 9.5] shows that the discrete operators considered in this section adopt the asymptotic properties of the corresponding differential operators.

3.2.3. Geometric mean.

We modify here the scheme of discretization of section 3.2.1 by taking the geometric mean in the definition of transition probabilities instead of the harmonic mean:

$$p_z(x) = \begin{cases} \dfrac{1}{4}\sqrt{\kappa(x)\,\kappa(x+z)} & \text{if } z \in \Lambda \setminus \{(0,0)\}\,, \\ 1 - \sum_{z\in\Lambda\setminus\{(0,0)\}} p_z(x) & \text{if } z = (0,0)\,, \\ 0 & \text{if } z \notin \Lambda\,, \end{cases}$$

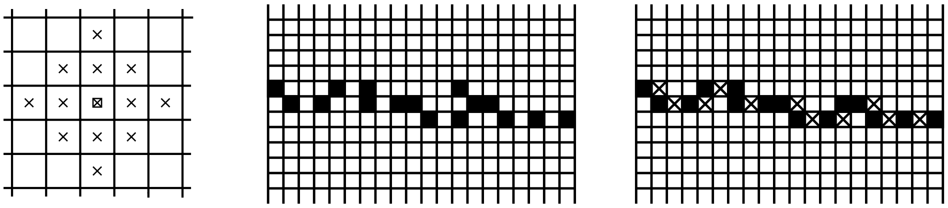

FIG. 3.6. $\gamma = 2$. *The neighbor squares (left), a black channel C_k (center), and one of its possible modifications $\tilde{C}_k$ (right).*

the set Λ being the same as in section 3.2.1 (i.e., with displacements toward the four nearest neighbors). Then, the asymptotic behavior of the effective coefficient $a^\delta(p)$ is described by the following statement.

THEOREM 3.12. *The effective coefficient $a^\delta(p)$ satisfies, for small δ, the estimates:*

$$\begin{array}{ll} 0 < c_1(p) \le a^\delta(p) \le 1 & \text{if } \ 0 \le p < p_c(\sqrt{2}), \\ c_2(p)\sqrt{\delta} \le a^\delta(p) \le c_3(p)\sqrt{\delta} & \text{if } \ p_c(\sqrt{2}) < p < 1 - p_c(2), \\ \delta \le a^\delta(p) \le c_4(p)\,\delta & \text{if } \ 1 - p_c(2) < p \le 1, \end{array}$$

where $c_1(p)$, $c_2(p)$, $c_3(p)$, and $c_4(p)$ are strictly positive.

Proof.

1. In the case $0 \le p < p_c(\sqrt{2})$, we need to justify only the lower bound. It can be done exactly in the same way as in Theorem 3.9. Another way to obtain the lower bound is to notice that for $|z| \ne 0$ the coefficients $p_z(x)$ under consideration majorate the respective coefficients defined as the harmonic mean. By virtue of the convergence of energy result and Theorem 3.9 this implies the desired lower bound.
2. In order to obtain the upper bound for $p_c(\sqrt{2}) < p < 1 - p_c(2)$ one can apply the technique developed in the part (2) of the proof of Theorem 3.9.

   To justify the lower bound in the case $p_c(\sqrt{2}) < p < 1 - p_c(2)$, we consider the percolation model with $\gamma = 2$ (see Remark 3.4). Here we encounter an additional difficulty: for $p \in]1 - p_c(\sqrt{2})\,, 1 - p_c(2)[$ the white 2-channels are not connected in a usual sense.

   We proceed as follows. For each channel C_k we introduce its 1-neighborhood:

   $$C_k^+ = \{x \in \mathbb{Z}^2 \,:\, |x - j| \le 1 \text{ for some } j \in C_k\}\,.$$

   It is easily seen that C_k^+ contains a sequence of squares $\{x_i\}$ denoted by $\tilde{C}_k$, which joins the left and the right sides of the square $[0, n]^2$ and has the following properties:

   - $|x_{i+1} - x_i| = 1$ for any consecutive x_i and x_{i+1};
   - $p_z(x) \ge \sqrt{\delta}/4$ for any x and z such that $x,\, z + z \in \tilde{C}_k$ and $|z| = 1$

   (see Figure 3.6) These sets $\tilde{C}_k$ are connected in a usual sense and consist in general of both white and black squares. Clearly, the number $\tilde{N}(n)$ of mutually nonintersecting sets $\tilde{C}_k$ still satisfies the estimate $\tilde{N}(n) \ge \tilde{c}(p)\,n$, $\tilde{c}(p) > 0$, for sufficiently large n. Then, one can use $\tilde{C}_k$ instead of C_k and argue like in part (1) of the proof of Theorem 3.9.
3. The upper bound in the case $1 - p_c(2) < p \le 1$ requires slightly different arguments than above. Consider the percolation model with $\gamma = 2$, and for each white cluster $\mathbb{C}$ denote by $\mathbb{C}^+$ the 1-neighborhood of $\mathbb{C}$:

   $$\mathbb{C}^+ = \{x \in \mathbb{Z}^2 \,:\, |x - j| \le 1 \text{ for some } j \in \mathbb{C}\}\,.$$

Let $\mathbb{C}^+(0)$ be the set $\mathbb{C}^+$ containing 0, and denote by $W(0)$ the size of $\mathbb{C}^+(0)$. If 0 does not belong to the 1-neighborhood of the union of white clusters, then $\mathbb{C}^+(0)$ is empty and $W(0) = 0$.

We introduce the following sequence of random variables $\tilde{\varphi}^N(\omega) \in L^\infty(\Omega)$:

$$\tilde{\varphi}^N = \begin{cases} -\min\limits_{j \in \mathbb{C}^+(0)} j_1 & \text{if } 1 \le W(0) \le N \\ 0 & \text{otherwise,} \end{cases}$$

and put $\varphi_z^N(\omega) = \tilde{\varphi}^N(T_z\omega) - \tilde{\varphi}^N(\omega)$, $z \in \Lambda$. It is clear that $|\varphi_z^N(\omega)| \le 2N$. According to Kesten [12, Theorem 5.1], the estimate

$$P_p\{W(0) > n\} \le c\,\exp(-c(p)\,n)\,, \quad c(p) > 0\,, \tag{3.10}$$

holds for all $p > 1 - p_c(2)$. Therefore, by the definition of φ_z^N, we have

$$P_p\{\varphi_z^N \ge n\} \le c\,\exp(-c_1(p)\,n)\,, \quad c_1(p) > 0\,, \quad n = 1, 2, \ldots, 2N\,. \tag{3.11}$$

The random variables φ_z^N and p_z possess the following properties:

- if both 0 and z belong to $\mathbb{C}^+(0)$ and $W(0) \le N$, then $P_1(z) - \varphi_z^N = 0$;
- if at least one of them does not belong to $\mathbb{C}^+(0)$, then $p_z = \delta/4$.

In combination with (3.10) and (3.11), this implies

$$\begin{aligned} a^\delta(p) \le \|P_1(z) - \varphi_z^N\| &= E\sum_{z\in\Lambda} p_z(z_1 - \varphi_z^N)^2 \\ &\le c\,\delta\sum_{k=1}^{2N} k\,\exp(-c_1(p)k) + c\,\exp(-c(p)N) \\ &\le \bar{c}\,\delta + c\,\exp(-c(p)N)\,, \end{aligned}$$

where $\bar{c}$ does not depend on N. Passing to the limit as $N \to \infty$ gives $a^\delta(p) \le \bar{c}\,\delta$. □

3.2.4. Arithmetic mean. This section deals with another modification of the scheme of section 3.2.1. Namely, the transition probabilities are defined as the corresponding arithmetic means

$$p_z(x) = \begin{cases} \dfrac{1}{4}\dfrac{\kappa(x) + \kappa(x+z)}{2} & \text{if } z \in \Lambda \setminus \{(0,0)\}\,, \\ 1 - \sum_{z\in\Lambda\setminus\{(0,0)\}} p_z(x) & \text{if } z = (0,0)\,, \\ 0 & \text{if } z \notin \Lambda\,, \end{cases}$$

while the set Λ remains the same as in section 3.2.1.

THEOREM 3.13. *The effective coefficient $a^\delta(p)$ satisfies, for small δ, the estimates*

$$\begin{aligned} &0 < c_1(p) \le a^\delta(p) \le 1 \quad && \textit{if } \ 0 \le p < 1 - p_c(2), \\ &\delta \le a^\delta(p) \le c_2(p)\,\delta && \textit{if } \ 1 - p_c(2) < p \le 1, \end{aligned}$$

where $c_1(p)$ and $c_2(p)$ are strictly positive.

Proof. The first estimate relies on the channel property of the percolation model corresponding to $\gamma = 2$. As in the preceding theorem, we enlarge the white 2-channels to make them connected, and note that along each modified channel the transition probabilities are uniformly positive: $p_z(x) \ge (1+\delta)/8$ if $z \in \Lambda$ and x and $x+z$ belong to a modified channel. As above, this implies the lower bound $a^\delta(p) \ge c_1(p) > 0$.

The proof of the second estimate is exactly the same as that of the last estimate in the preceding theorem. □

Remark 3.14. *The statements of Theorems* 3.9–3.11 *remain unchanged if we assume that the size of mesh $h(\varepsilon)$ of a grid is less than ε while $h(\varepsilon)/\varepsilon$ is a constant.*

Appendices.

Appendix A. Convergence of discrete functions. Let f^ε be an arbitrary function defined in the discrete domain $Q_\varepsilon = \varepsilon\mathbb{Z}^d \cap Q$, and let $\tilde{f}^\varepsilon$ be the piecewise-constant interpolation of f^ε:

$$\tilde{f}^\varepsilon(x) = f^\varepsilon(y) \quad \text{if } y \in Q_\varepsilon \text{ and } x \in y + \left[\frac{-\varepsilon}{2}, \frac{\varepsilon}{2}\right]^d .$$

Definition A.1. *We say that a family of functions $f^\varepsilon \in L^2(Q_\varepsilon)$ converges strongly (resp., weakly) to the function $f \in L^2(Q)$ as $\varepsilon \to 0$ if $\tilde{f}^\varepsilon$ converges strongly (resp., weakly) to f in $L^2(Q)$. For this convergence we use the notation*

$$f^\varepsilon \xrightarrow[\varepsilon\to 0]{} f \quad \text{in } L^2(Q_\varepsilon) \quad (\text{resp., weakly in } L^2(Q_\varepsilon)) .$$

Similarly, one can define the $W^{1,2}(Q)$-convergence of discrete functions with $\tilde{f}^\varepsilon$ being the piecewise linear interpolation of f^ε (instead of the piecewise constant one).

The convergence in $W^{-1,2}(Q)$ can be defined in terms of duality. Namely, we say that $f^\varepsilon \in W^{-1,2}(Q_\varepsilon)$ converges to $f \in W^{-1,2}(Q)$ strongly (resp., weakly) if for any sequence $g^\varepsilon \in W_0^{1,2}(Q_\varepsilon)$ and $g \in W_0^{1,2}(Q)$ such that $g^\varepsilon \to g$ weakly (resp., strongly) in $W^{1,2}(Q)$, we have

$$\langle f^\varepsilon, g^\varepsilon\rangle \xrightarrow[\varepsilon\to 0]{} \langle f, g\rangle .$$

Definition A.2. *Let $w^\varepsilon \in L^2(Q_\varepsilon)$ and $w^0 \in L^2(Q)$. The sequence w^ε* converges $\star$-weakly *to w^0 if for any $\varphi \in \mathcal{C}_0^\infty(Q)$,*

$$\lim_{\varepsilon\to 0} \varepsilon^d \sum_{x\in Q_\varepsilon} w^\varepsilon(x)\,\varphi(x) = \int_Q w^0(x)\,\varphi(x)\,dx .$$

Appendix B. The derivative of a product of discrete functions.

Proposition B.1. *Let f and g belong to $W^{1,2}(Q_\varepsilon)$. Then,*

$$\sum_{z\in Q_\varepsilon} |\partial_z^\varepsilon(fg) - f\partial_z^\varepsilon g - g\partial_z^\varepsilon f| \le \varepsilon \sum_{z\in Q_\varepsilon} |\partial_z^\varepsilon f||\partial_z^\varepsilon g| .$$

Proof. We have

$$\begin{aligned}\varepsilon\,\partial_z^\varepsilon(f(x)\,g(x)) &= f(x+\varepsilon\,z)\,g(x+\varepsilon\,z) - f(x)\,g(x)\\ &= g(x)\,(f(x+\varepsilon\,z) - f(x)) + f(x+\varepsilon\,z)\,(g(x+\varepsilon\,z) - g(x))\\ &= \varepsilon\,[g(x)\,\partial_z^\varepsilon f(x) + f(x+\varepsilon\,z)\,\partial_z^\varepsilon g(x)] .\end{aligned}$$

We have $f(x+\varepsilon\,z) = f(x) + \varepsilon\partial_z^\varepsilon f(x)$. Therefore,

$$\partial_z^\varepsilon(f(x)\,g(x)) = g(x)\,\partial_z^\varepsilon f(x) + f(x)\,\partial_z^\varepsilon g(x) + \varepsilon\partial_z^\varepsilon f(x)\partial_z^\varepsilon g(x),$$

and the desired estimate immediately follows. □

Appendix C. The Friedrichs and Poincaré inequalities.

This appendix is devoted to the Friedrichs and Poincaré inequalities for grid functions. In fact, in order to prove the propositions below, one can follow the same ideas as in the case of the continuous argument. For this reason, we omit the proof.

PROPOSITION C.1. *Let Q be a bounded domain with piecewise smooth boundary and denote the discretization of Q by Q_ε. Then, for any $v^\varepsilon \in W_0^{1,2}(Q_\varepsilon)$ the following inequality holds:*

$$\|v^\varepsilon\|^2_{L^2(Q_\varepsilon)} \leq c(Q)\,\varepsilon^d \sum_{x\in Q_\varepsilon}\sum_{i=1}^{d}(\partial^\varepsilon_{\pm e_i} v^\varepsilon(x))^2 \,. \tag{C.1}$$

PROPOSITION C.2. *Let Q be a smooth bounded domain. Then, for all sufficiently small ε and for any $v^\varepsilon \in W^{1,2}(Q_\varepsilon)$ such that $\sum_{x\in Q_\varepsilon} v^\varepsilon(x) = 0$, the following inequality is satisfied:*

$$\sum_{x\in Q_\varepsilon} |v^\varepsilon(x)|^2 \leq C(q)\,\varepsilon^d \sum_{x\in Q_\varepsilon}\sum_{i=1}^{d} |\bar\partial^\varepsilon_{\pm e_i} v^\varepsilon(x)|^2 \,. \tag{C.2}$$

REMARK C.3. *The statement of Proposition C.2 remains valid for the domain $\overline{Q}_\varepsilon$.*

ABOUT LIFESPAN OF REGULAR SOLUTIONS OF EQUATIONS RELATED TO VISCOELASTIC FLUIDS[*]

JEAN-YVES CHEMIN[†] AND NADER MASMOUDI[‡]

Abstract. We prove existence and uniqueness of local and global solutions for a system of equations concerning an incompressible viscoelastic fluid of the Oldroyd type. We also show a new a priori estimate for the two-dimensional Navier–Stokes system and a losing estimate for the transport equations that allow us to give a sufficient condition of non-breakdown.

Key words. local and global well-posedness, Besov spaces, Oldroyd model

1. Introduction and statement of the results.

An incompressible fluid is subject to the following system of equations:

$$\left\{ \begin{array}{rcl} \dfrac{\partial v}{\partial t} + v \cdot \nabla v & = & \nabla \cdot \sigma, \\ \operatorname{div} v & = & 0, \end{array} \right.$$

where v is the velocity ($v(x,t) \in \mathbb{R}^d$) and σ is the stress tensor (σ is a (d,d) symmetric matrix). Moreover, σ can be decomposed as $\sigma = \tau - p\, Id$, where τ is the tangential part of the stress tensor and $-p\, Id$ is the normal part (p being the pressure which is the Lagrange multiplier for the divergence-free condition). For a Newtonian fluid, τ depends linearly on ∇v and more precisely

$$\tau = 2\nu D(v), \tag{1.1}$$

where $D(v) = \frac{1}{2}(\nabla v +^t \nabla v)$ is the deformation tensor and ν is the viscosity of the fluid ($\nu > 0$). Hence, we recover the classical incompressible Navier–Stokes system.

It turns out that many fluids do not satisfy the Newtonian law $\tau = 2\nu D(v)$ and a general constitutive law satisfied by all fluids does not exist. Some fluids with shear dependent viscosity are such that (1.1) is replaced by

$$\tau = 2\mu(|D(v)|^2) D(v), \tag{1.2}$$

where the viscosity $\mu(|D(v)|^2)$ depends on $|D(v)|$. In the case of the power law, we have

$$\mu(|D(v)|^2) = \nu + \beta |D(v)|^{p-2},$$

where $\nu \geq 0$, $\beta > 0$, and $p \geq 1$. If

$1 \leq p < 2$, we have a shear thinning fluid or a viscoplastic fluid,

$p = 2$, we have the classical Newtonian case,

$p > 2$, we have a shear thickening fluid or dilatant fluid.

In this paper, we are going to study another type of non-Newtonian fluid, namely, fluids with memory. Indeed, for many fluids, it is not possible to determine at some time t the value of τ knowing only $D(u)$ at the same time, and one also has to know the whole history of $D(v)$. In these cases, we say that the fluid has a "memory" and one has to write a differential equation for τ. One of the classical models is the Oldroyd model, which writes

$$\partial_t \tau + v \cdot \nabla \tau + a\tau + F(\tau, \nabla v) = 0,$$

where $a > 0$ and F is a quadratic form in $(\tau, \nabla v)$. It turns out that since the model should be invariant under change of coordinates, F cannot be the most general quadratic form and we get the so-called Oldroyd model with eight constants, which can be rewritten in the following way:

$$\tau + \lambda_1 \frac{\mathcal{D}\tau}{\mathcal{D}t} + \frac{1}{2}\mu_0 tr(\tau) D(v) - \frac{1}{2}\mu_1 \{\tau D(v) + D(v)\tau\} + \frac{1}{2}\nu_1 (\tau : D(v)) Id$$

$$= 2\eta_0 \left[D(v) + \lambda_2 \frac{\mathcal{D}D(v)}{\mathcal{D}t} - \mu_2 D(v)D(v) + \frac{1}{2}(D(v) : D(v)) Id \right],$$

where we have used "objective derivatives" (the so-called Oldroyd derivatives)

$$\frac{\mathcal{D}\tau}{\mathcal{D}t} = \frac{\partial \tau}{\partial t} + v \cdot \nabla \tau + \tau W(v) - W(v)\tau,$$

and $W(v) = \frac{1}{2}(\nabla v -^t \nabla v)$ is the vorticity tensor.

In this paper, we are going to study a simpler model, namely the Oldroyd B model (with only four constants). It is given by

$$\tau + \lambda_1 \frac{\mathcal{D}_b \tau}{\mathcal{D}t} = 2\eta \left(D(v) + \lambda_2 \frac{\mathcal{D}_b D(v)}{\mathcal{D}t} \right), \tag{1.3}$$

where

$$\frac{\mathcal{D}_b \tau}{\mathcal{D}t} = \frac{\partial \tau}{\partial t} + v \cdot \nabla \tau + \tau W(v) - W(v)\tau - b(D(v)\tau + \tau D(v)).$$

In (1.3), λ_1 is the relaxation time, λ_2 is the retardation time ($0 \leq \lambda_2 \leq \lambda_1$), η is the dynamical viscosity of the fluid, and $b \in [-1, 1]$. Fluids of this type have both elastic properties and viscous properties. Indeed, the case $\lambda_2 = \lambda_1 = 0$ corresponds to purely viscous case (incompressible Navier–Stokes equation), while the case $\lambda_1 > \lambda_2 = 0$ is the purely elastic case (the Maxwell model). Decomposing τ into

$$\tau = \tau_{Newtonian} + \tau_{elastic} \quad \text{with} \quad \tau_{Newtonian} = 2\eta \frac{\lambda_2}{\lambda_1} D(v)$$

we find that $\tau_{elastic}$ satisfies

$$\tau_{elastic} + \lambda_1 \frac{\mathcal{D}_b \tau_{elastic}}{\mathcal{D}t} = 2\eta \left(1 - \frac{\lambda_2}{\lambda_1}\right) D(v).$$

Taking

$$a = \frac{1}{\lambda_1}, \quad \mu_2 = \frac{2\eta}{\lambda_1}\left(1 - \frac{\lambda_2}{\lambda_1}\right), \quad \text{and} \quad \mu_1 = 1$$

and writing τ instead of $\tau_{elastic}$, we get the following system of equations:

$$(1.4) \quad (VE) \begin{cases} \dfrac{\partial v}{\partial t} + v\cdot\nabla v - \nu\Delta v + \nabla p &= \mu_1 \nabla\cdot\tau \quad \text{in} \quad \Omega\times(0,T), \\ \dfrac{\partial \tau}{\partial t} + v\cdot\nabla\tau + a\tau + Q(\tau,\nabla v) &= \mu_2 D(v) \quad \text{in} \quad \Omega\times(0,T), \\ \text{div } v &= 0 \quad \text{in} \quad \Omega\times(0,T), \end{cases}$$

where $\Omega = \mathbf{R^d}$ or $\Omega = \mathbf{T^d}$, u is the velocity vector field ($v(x,t) \in \mathbf{R^d}$), τ is the non-Newtonian part of the stress tensor, ($\tau(x,t)$ is a (d,d) symmetric matrix), $(\nabla\cdot\tau)_i = \sum_j \partial_j \tau_{i,j}$, and p is the pressure which is a scalar. The constants ν, a, μ_1, μ_2 are assumed to be nonnegative and the bilinear term Q has the following form:

$$Q(\tau,\nabla v) = \tau W(v) - W(v)\tau - b(D(v)\tau + \tau D(v)),$$

$b \in [-1,1]$, $D(v) = \frac{1}{2}(\nabla v +^t \nabla v)$ is the deformation tensor, and $W(v) = \frac{1}{2}(\nabla v -^t \nabla v)$ is the vorticity tensor. The system must be complemented with the following initial conditions:

$$(1.5) \qquad \begin{cases} v(0,\cdot) = v_0 & \text{in} \quad \Omega, \\ \tau(0,\cdot) = \tau_0 & \text{in} \quad \Omega. \end{cases}$$

Throughout this paper, solution means solution in the sense of distributions. As usual, problems of regularity are motivated by the uniqueness problem.

The formal energy estimate is the following:

$$\frac{1}{2}\frac{d}{dt}(\mu_2\|v(t)\|_{L^2}^2 + \mu_1\|\tau(t)\|_{L^2}^2) + \nu\mu_2\|\nabla v(t)\|_{L^2}^2 + a\mu_1\|\tau(t)\|_{L^2}^2 \leq |b|\,\|Dv(t)\|_{L^\infty}\|\tau(t)\|_{L^2}^2.$$

The system (1.4) describes the motion of an incompressible fluid satisfying the Oldroyd [19] constitutive law. The existence and uniqueness of local strong solutions in Hilbert spaces H^s have been established by Guillopé and Saut in [14]. These solutions are global if the coupling between the two equations is small as well as the initial data [15]. The case of L^s–L^r solutions has been treated by Fernandez Cara, Guillén, and Ortega in [16]. Results for the stationary problem are due to M. Renardy (see [20]). Recently, for $b = 0$, the existence of global weak solutions has been proved by Lions and Masmoudi [17].

In this paper, we show existence and uniqueness results for local and global solutions in some limit spaces, i.e., spaces invariant by the Navier–Stokes scaling. We also show that in two dimensions, the $L^1_T(L^\infty_x)$ norm of τ controls the equation. For this we show two results about the two-dimensional (2-D) Navier–Stokes system and about a losing a priori estimate for the transport equation satisfied by τ.

Our first result is related to Sobolev spaces and uses the special structure of the system (VE).

Theorem 1.1. *Let (v_0, τ_0) be an initial data in H^s with s strictly greater than $d/2$. Then a unique strictly positive maximal time $T^\star$ exists so that a unique solution (v, τ) exists in the space $L^\infty_{loc}([0, T^\star[; H^s)$. Moreover, this solution is such that v belongs to*

$$L^2_{loc}([0, T^\star[; H^{s+1}) \cap L^\infty_{loc}(]0, T^\star[; H^{s+1-\varepsilon}) \quad \textit{for any strictly positive } \varepsilon.$$

We have the following necessary condition for blow up:

$$T^\star < \infty \Longrightarrow \int_0^{T^\star} \left(\frac{\mu_1}{\mu_2 \nu} \|\tau(t)\|^2_{L^\infty} + \|\nabla v(t)\|_{L^\infty} \right) dt = +\infty.$$

As we shall see in section 2, the proof of this result in very classical. It is in the spirit of the well-known Beale–Kato–Majda criterion (see [2]). We want to improve the above necessary condition for blow up. The theorem is the following.

Theorem 1.2. *In two space dimensions, the necessary condition for blow up of Theorem 1.1 above becomes*

$$T^\star < \infty \Longrightarrow \int_0^{T^\star} (\|\tau(t)\|_{L^\infty} + |b| \, \|\tau(t)\|^2_{L^2}) dt = +\infty.$$

The first thing to notice here is that the required regularity is far from the regularity prescribed by the scaling. Let us say a word about this. One of the key concepts of the fundamental work of Fujita and Kato (see [12]) about local well-posedness for the incompressible Navier–Stokes system is the scaling invariance. It means that if a vector field v is a solution of incompressible Navier–Stokes system with initial data v_0, then $v_\lambda(t, x) \stackrel{\text{def}}{=} \lambda v(\lambda^2 t, \lambda x)$ is a solution of incompressible Navier–Stokes system with initial data $v_{0,\lambda}(x) \stackrel{\text{def}}{=} \lambda v_0(\lambda x)$. An easy computation will convince the reader that

$$|v_{0,\lambda}|_{H^{\frac{d}{2}-1}} = |v_0|_{H^{\frac{d}{2}-1}}.$$

We want to solve the system (VE) for initial data whose regularity fits with this scaling, as, for instance, for the usual incompressible Navier–Stokes system. This requires the use of Besov spaces. Let us recall the definitions of these spaces. For this, we need the Littlewood–Paley decomposition.

Proposition 1.3. *Let us denote by $\mathcal{D}(\Omega)$ the space of C^∞ functions whose support is compact and included in Ω. Let us define $\mathcal{C}$ to be the ring of center 0 of small radius $1/2$ and great radius 2. There exist two nonnegative radial functions χ and φ belonging, respectively, to $\mathcal{D}(B(0,1))$ and to $\mathcal{D}(\mathcal{C})$ so that*

$$\chi(\xi) + \sum_{q \geq 0} \varphi(2^{-q}\xi) = 1, \tag{1.6}$$

$$|p - q| \geq 2 \Rightarrow \mathrm{Supp}\ \varphi(2^{-\mathrm{q}}\cdot) \cap \mathrm{Supp}\ \varphi(2^{-\mathrm{p}}\cdot) = \emptyset. \tag{1.7}$$

For instance, one can take $\chi \in \mathcal{D}(B(0,1))$ such that $\chi \equiv 1$ on $B(0, 1/2)$ and take

$$\varphi(\xi) = \chi(2\xi) - \chi(\xi).$$

Then we are able to define the Littlewood–Paley decomposition. Let us denote by $\mathcal{F}$ the Fourier transform on $\mathbf{R^d}$. Let $h,\ \widetilde{h},\ \Delta_q,\ S_q\ (q \in \mathbb{Z})$ be defined as follows:

$$
\begin{aligned}
h = \mathcal{F}^{-1}\varphi \quad \text{and} \quad \widetilde{h} &= \mathcal{F}^{-1}\chi, \\
\Delta_q u = \mathcal{F}^{-1}(\varphi(2^{-q}\xi)\mathcal{F}u) &= 2^{qd}\int h(2^q y)u(x-y)dy, \\
S_q u = \mathcal{F}^{-1}(\chi(2^{-q}\xi)\mathcal{F}u) &= 2^{qd}\int \widetilde{h}(2^q y)u(x-y)dy.
\end{aligned}
$$

In this paper, we shall use Bony's decomposition which consists of writing

$$
uv = T_u v \ + \ T_v u \ + \ R(u,v),
$$

where

$$
T_u v \overset{\text{def}}{=} \sum_{q \in \mathbf{Z}} S_{q-1}u\Delta_q v \quad \text{and} \quad R(u,v) \overset{\text{def}}{=} \sum_{|q-q'|\leq 1} \Delta_{q'}u\Delta_q v.
$$

The Besov spaces we are going to use are homogeneous ones.

Definition 1.4. *Let s be a real number and let p and r be two real numbers greater than 1. Then we define the norm*

$$
\|u\|_{\widetilde{B}^s_{p,r}} \overset{def}{=} \|S_0 u\|_{L^p} + \left\| (2^{qs}\|\Delta_q u\|_{L^p})_{q\in\mathbf{N}} \right\|_{\ell^r(\mathbf{N})}
$$

and the seminorm

$$
\|u\|_{B^s_{p,r}} \overset{def}{=} \left\| (2^{qs}\|\Delta_q u\|_{L^p})_{q\in\mathbf{Z}} \right\|_{\ell^r(\mathbf{Z})}.
$$

Definition 1.5.

- *Let s be a real number and let p and r be two real numbers greater than 1. We denote by $\widetilde{B}^s_{p,r}$ the space of tempered distributions u such that $\|u\|_{\widetilde{B}^s_{p,r}}$ is finite.*
- *If $s < d/p$ or $s = d/p$ and $r = 1$, we define the homogeneous Besov space $B^s_{p,r}$ as the closure of compactly supported smooth functions for the norm $\|\cdot\|_{B^s_{p,r}}$.*

Remarks. It is obvious that all of those spaces are Banach spaces. Moreover, if $p = 2$, the Besov spaces can be described in the following way. The norm $\|u\|_{B^s_{2,r}}$ is equivalent to

$$
\left\| 2^{qs}\left(\int_{2^q \leq |\xi| \leq 2^{q+1}} |\widehat{u}(\xi)|^2 d\xi \right)^{\frac{1}{2}} \right\|_{\ell^r(\mathbf{Z})}.
$$

Let us point out that $B^s_{2,2}$ is a usual Sobolev space H^s and that $B^s_{\infty,\infty}$ is the usual Hölder space C^s.

Now we state the following theorems.

Theorem 1.6 (existence). *Let p be in $[1,+\infty[$ and let us define $s_c \overset{def}{=} \frac{d}{p}$.*

If (v_0,τ_0) belongs to $B^{s_c-1}_{p,1} \times B^{s_c}_{p,1}$, then a strictly positive real number T exists such that a solution (v,τ) of (VE) exists on $[0,T]\times\mathbf{R^d}$; this solution belongs to

$$
C([0,T];B^{s_c-1}_{p,1}) \cap L^\infty_{loc}(]0,T];B^{s_c}_{p,\infty}) \cap L^1([0,T];B^{s_c+1}_{p,1}) \times L^\infty([0,T];B^{s_c}_{p,1}).
$$

Moreover, a strictly positive constant c exists such that if

$$\mu_1\mu_2 \leq c\ a\nu \quad \textit{and} \quad \|v_0\|_{B^{s_c-1}_{p,1}} + \frac{\mu_1}{a}\|\tau_0\|_{B^{s_c}_{p,1}} \leq c\nu,$$

then the above time T may be $+\infty$.

Moreover, if we define T_{VE} by

$$T_{VE} \overset{def}{=} +\infty \;\; \textit{if}\; \mu_1\mu_2 \leq c\nu a \quad \textit{and} \quad T_{VE} \overset{def}{=} -\frac{1}{a}\log\left(1 - \frac{c\nu a}{2\mu_1\mu_2}\right) \;\; \textit{if}\; \mu_1\mu_2 \geq c\nu a, \tag{1.8}$$

then the above time T may be bounded from below by $\min\{T_{VE}, T_{(v_0,\tau_0)}\}$, where $T_{(v_0,\tau_0)}$ is the greatest strictly positive number such that

$$\mu_1\frac{1-e^{-aT}}{a}\|\tau_0\|_{B^{s_c}_{p,1}} + \sum_q 2^{q(s_c-1)}\|\Delta_q v_0\|_{L^p}(1 - e^{-c\nu 2^{2q}T}) \leq c\nu.$$

Now let us state a uniqueness theorem. The uniqueness, as, for instance, in the work of Danchin and Desjardins about the KdV-type model (see [10]), requires a restriction on p.

Theorem 1.7 (uniqueness). *Let p be in $[1, 2d[$ and let us define $s_c \overset{def}{=} \frac{d}{p}\cdot$*

If (v_0, τ_0) belongs to $B^{s_c-1}_{p,1} \times B^{s_c}_{p,1}$, then a unique strictly positive real number $T^\star$ exists such that a unique solution (v, τ) of (VE) exists on $[0, T^\star[\times \mathbf{R^d}$ in the space

$$C([0, T^\star[; B^{s_c-1}_{p,1}) \cap L^1_{loc}([0, T^\star[; B^{s_c+1}_{p,1}) \times L^\infty_{loc}([0, T^\star[; B^{s_c}_{p,1}).$$

Moreover, a strictly positive constant c exists such that, if

$$\mu_1\mu_2 \leq c\ a\nu \quad \textit{and} \quad \|v_0\|_{B^{s_c-1}_{p,1}} + \frac{\mu_1}{a}\|\tau_0\|_{B^{s_c}_{p,1}} \leq c\nu,$$

then the above time T may be $+\infty$. And if $T^\star$ is finite, then

$$\int_0^{T^\star} (\|\nabla v(t,\cdot)\|_{L^\infty} + \|\tau(t,\cdot)\|_{L^\infty})dt = +\infty.$$

Now we want to state an equivalent of Theorem 1.2 in the framework of Besov spaces. Unfortunately, it will be impossible to get it for critical regularity. Thus, we need the following theorem.

Theorem 1.8. *Let p be in $[1, 2d[$ and let us assume that, for some σ strictly greater than s_c, the initial data (v_0, τ_0) belongs to $B^{s_c-1}_{p,1} \cap B^{\sigma-1}_{p,1} \times B^{s_c}_{p,1} \cap B^{\sigma}_{p,1}$, then the (unique) solution belongs to*

$$C([0, T^\star[; B^{\sigma-1}_{p,1}) \cap L^\infty_{loc}(]0, T^\star[; B^{\sigma}_{p,\infty}) \cap L^1_{loc}([0, T^\star[; B^{\sigma+1}_{p,1}) \times L^\infty_{loc}([0, T^\star[; B^{\sigma}_{p,1}).$$

Moreover, if the initial data (v_0, τ_0) belongs to L^2, and if $b = 0$, then the solution satisfies the energy estimate

$$\mu_2\|v(t)\|^2_{L^2} + \mu_1\|\tau(t)\|^2_{L^2} + 2\int_0^t \Big(\nu\mu_2\|\nabla v(t')\|_{L^2} + a\mu_1\|\tau(t')\|^2_{L^2}\Big)dt' = \mu_2\|v_0\|^2_{L^2} + \mu_1\|\tau_0\|^2_{L^2}.$$

Finally, for this last theorem, we take $p = 2$, $s \geq d/2$ and impose the same regularity for v_0 and τ_0. In fact, we are going to use the particular form of the equation and will not have to impose any restriction on the coupling to get the global existence. For this theorem, we take nonhomogenous Besov spaces. We can also work in Sobolev spaces if we impose in addition that $s > d/2$.

Theorem 1.9. *Let $s \geq \frac{d}{2}$. A constant c exists such that for all nonnegative constants ν, a, μ_1, μ_2 and for any $(v_0, \tau_0) \in \widetilde{B}^s_{2,1} \times \widetilde{B}^s_{2,1}$ satisfying*

$$\|v_0\|_{B^s_{2,1}} \leq c \ \min(\nu, \sqrt{a\nu}) \quad \textit{and} \quad \|\tau_0\|_{B^s_{2,1}} \leq c \ \min(\nu, \sqrt{a\nu}) \frac{\sqrt{\mu}_2}{\sqrt{\mu}_1},$$

a unique global solution (v, τ) of (1.4) exists in

$$C([0, +\infty[; \widetilde{B}^s_{2,1}) \cap L^1([0, +\infty[; \widetilde{B}^{s+1}_{2,1}) \times L^\infty(0, \infty; \widetilde{B}^s_{2,1}) \cap L^1([0, +\infty[; \widetilde{B}^s_{2,1}).$$

The structure of this text will be the following.

- The second section is devoted to the proof of the local well-posedness. We use the very classical Friedrichs method.
- The third section consists of the proof of an a priori estimate for solutions of 2-D incompressible Navier–Stokes equations.
- The fourth section is the proof of a losing a priori estimate for solutions of transport equations. This means that we estimate the norm of the solutions of a transport equation in norms of Besov spaces whose index decreases in time; estimates of this type have been proved in [1] and in [8].
- In the fifth section, we study global well-posedness in the case of small data.

2. Local well-posedness and energy methods. We shall use the very classical Friedrichs method (also called the Galerkin method in the periodic case) which consists of an approximation of the system (VE) by a cut-off in the frequency space.

Let us define the operator J_n by

$$J_n a \overset{\text{def}}{=} \mathcal{F}^{-1}(\mathbf{1}_{B(0,n)}(\xi)\widehat{u}(\xi)),$$

where $\mathcal{F}$ denotes the Fourier transform in the space variables. Let us consider the approximate (VE_n) system

$$(VE_n) \begin{cases} \partial_t v_n - \nu J_n \Delta v_n &= J_n \mu_1 P \nabla \cdot \tau_n + J_n \mathcal{Q}(J_n v_n, J_n v_n), \\ \partial_t \tau_n + J_n(J_n v_n \cdot \nabla J_n \tau_n) + a J_n \tau_n &= \mu_2 D(v_n) + J_n Q(J_n \tau_n, J_n \nabla v_n), \\ \operatorname{div} v_n &= 0, \\ (v_n, \tau_n)_{|t=0} &= (J_n v_0, J_n \tau_0). \end{cases}$$

It is obvious that all the bilinear operators on the right are continuous on $L^2 \times L^2$. Then, the above system appears as a system of ordinary differential equations on L^2. Thus, the usual Cauchy–Lipschitz theorem implies the existence of a strictly positive maximal time T_n such that a unique solution exists which is continuous in time with value in L^2. However, as $J_n^2 = J_n$, we claim that $J_n(v_n, \tau_n)$ is also a solution, so uniqueness implies that $J_n(v_n, \tau_n) = (v_n, \tau_n)$. So (v_n, τ_n) is also a solution of the following system, still denoted by (VE_n):

$$(VE_n) \begin{cases} \partial_t v_n - \nu \Delta v_n &= \mu_1 P \nabla \cdot \tau_n + J_n \mathcal{Q}(v_n, v_n), \\ \partial_t \tau_n + J_n(v_n \cdot \nabla \tau_n) + a \tau_n &= \mu_2 D(v_n) + J_n Q(\tau_n, \nabla v_n), \\ \operatorname{div} v_n &= 0, \\ (v_n, \tau_n)_{|t=0} &= (J_n v_0, J_n \tau_0). \end{cases}$$

The system (VE_n) turns out to be an ordinary differential equation in L^2. So thanks to the Cauchy–Lipschitz theorem, a unique maximal solution exists on an interval $[0,T_n^\star[$ which is continuous in time with value in L^2. The main step consists of the proof of the following property:

For any real s strictly greater than $d/2$, a strictly positive constant c and a strictly positive time T exist so that, for any n, we have $T_n^\star \geq T$, and

$$\sup_{\substack{t\in[0,T]\\ n\in\mathbf{N}}} E_s((v_n,\tau_n),t)+c\nu\mu_2\int_0^T\|\nabla v_n(t)\|_{H^s}^2dt+c\mu_1 a\int_0^T\|\tau_n(t)\|_{H^s}^2dt\leq 2E_s((v,\tau),0), \tag{2.1}$$

where we defined

$$E_\sigma((v,\tau),t)\overset{\text{def}}{=}\mu_2\|v(t)\|_{H^\sigma}^2+\mu_1\|\tau(t)\|_{H^\sigma}^2.$$

Let us prove this estimate. As J_n are Fourier multipliers, they commute with constant coefficient differentiations; thus, applying the operator Δ_q to the system (VE_n), we obtain, by an energy estimate,

$$\begin{aligned}I_n(t)&\overset{\text{def}}{=}\frac{d}{dt}(\mu_2\|\Delta_q v_n(t)\|_{L^2}^2+\mu_1\|\Delta_q\tau_n\|_{L^2}^2)+2\mu_2\nu\|\nabla\Delta_q v_n(t)\|_{L^2}^2+2\mu_1 a\|\Delta_q\tau_n\|_{L^2}^2\\&=2\mu_2(\Delta_q J_n(v_n\cdot\nabla v_n)|\Delta_q v_n)_{L^2}-2\mu_1(\Delta_q J_n(v_n\cdot\nabla\tau_n)|\Delta_q\tau_n)_{L^2}\\&\qquad\qquad-2\mu_1(\Delta_q J_n Q(\tau u_n,\nabla v_n)|\Delta_q\tau_n)_{L^2}.\end{aligned}$$

Using that J_n is a real Fourier multiplier and that $J_n v_n=v_n$, we get

$$\begin{aligned}&\frac{d}{dt}(\mu_2\|\Delta_q v_n(t)\|_{L^2}^2+\mu_1\|\Delta_q\tau_n\|_{L^2}^2)+2\mu_2\nu\|\nabla\Delta_q v_n(t)\|_{L^2}^2+2\mu_1 a\|\Delta_q\tau_n\|_{L^2}^2\\&=2\mu_2(\Delta_q(v_n\cdot\nabla v_n)|\Delta_q v_n)_{L^2}-2\mu_1(\Delta_q(v_n\cdot\nabla\tau_n)|\Delta_q\tau_n)_{L^2}-2\mu_1(\Delta_q Q(\tau_n,\nabla v_n)|\Delta_q\tau_n)_{L^2}.\end{aligned}$$

Up to the end of the proof of the inequality (2.1), we shall drop the index n.

The classical tame estimates for the product in Sobolev spaces (see, for instance, Corollary 2.4.1 of [5]) imply that

$$\|Q(\tau,\nabla v)\|_{H^s}\leq C\Big(\|\tau(t)\|_{L^\infty}\|\nabla v(t)\|_{H^s}+\|\tau(t)\|_{H^s}\|\nabla v(t)\|_{L^\infty}\Big).$$

Thus, we infer that

$$\begin{aligned}&\Big|2\mu_1(\Delta_q Q(\tau,\nabla v)|\Delta_q\tau)_{L^2}\Big|\\&\leq C(1+|b|)\mu_1 2^{-qs}c_q(t)\Big(\|\tau(t)\|_{L^\infty}\|\nabla v(t)\|_{H^s}+\|\tau(t)\|_{H^s}\|\nabla v(t)\|_{L^\infty}\Big)\|\Delta_q\tau(t)\|_{L^2},\end{aligned} \tag{2.2}$$

where, as throughout this section, $c_q(t)$ denotes a positive series such that

$$\forall t\,,\ \sum_q c_q^2(t)=1.$$

Now we have to estimate terms of the type $(\Delta_q(v\cdot\nabla a)|\Delta_q a)_{L^2}$. To do so, we use Bony's decomposition and write that

$$v\cdot\nabla a=\sum_{j=1}^d\Big\{T_{v^j}\partial_j a+T_{\partial_j a}v^j+R(\partial_j a,v^j)\Big\}.$$

The classical results about paraproduct and remainder operator (see, for instance, Theorem 2.4.1. of [5]) imply that

$$\|T_{\partial_j a} v^j\|_{H^s} + \|R(\partial_j a, v^j)\|_{H^s} \leq C\|a\|_{L^\infty}\|\nabla v\|_{H^s}.$$

Thus we get

$$\left|2\mu_1\left(\Delta_q \sum_{j=1}^{d}(T_{\partial_j a}v^j + R(\partial_j a, v^j))|\Delta_q a\right)_{L^2}\right| \leq C\mu_1 2^{-qs}c_q(t)\|a(t)\|_{L^\infty}\|\nabla v(t)\|_{H^s}\|\Delta_q a(t)\|_{L^2}. \tag{2.3}$$

To estimate the last term, we start from a formula proved in [7]. Let us recall it:

$$\begin{aligned}\sum_{j=1}^{d}(\Delta_q T_{v^j}\partial_j a|\Delta_q a)_{L^2} = &\sum_{j,q'}([\Delta_q, S_{q'-1}v^j]\partial_j \Delta_{q'} a|\Delta_q a)_{L^2}\\ &+\frac{1}{2}\sum_{j,q',q''}\Big((S_{q''-1}v^j - S_{q'-1}v^j)\Delta_q\Delta_{q'}a|\partial_j\Delta_q\Delta_{q''}a\Big)_{L^2}.\end{aligned}$$

As we have, by definition of the operators Δ_q, that

$$[S_{q'-1}v^j, \Delta_q]b(x) = 2^{qd}\int (S_{q'-1}v^j(x) - S_{q'-1}v^j(y))h(2^q(x-y))b(y)dy,$$

we infer that

$$|[S_{q'-1}v^j, \Delta_q]b(x)| \leq C\|\nabla v\|_{L^\infty}2^{qd}\int |x-y||h(2^q(x-y)||b(y)|dy.$$

Thus we get that

$$\|[S_{q'-1}v^j, \Delta_q]b\|_{L^2} \leq C2^{-q}\|\nabla v\|_{L^\infty}\|b\|_{L^2}.$$

Moreover, thanks to Lemma 3.1, and using the fact that $|q'-q''| + |q'-q| \leq N_0$, we obtain that

$$\|(S_{q''-1}v^j - S_{q'-1}v^j)\Delta_q\Delta_{q'}a\|_{L^2} \leq C2^{-q}\|\nabla v\|_{L^\infty}\|\Delta_{q'}a\|_{L^2}.$$

Thus we get that

$$\left|2\mu_1\left(\Delta_q \sum_{j=1}^{d}T_{v^j}\partial_j a|\Delta_q a\right)_{L^2}\right| \leq C(1+|b|)\mu_1 2^{-qs}c_q(t)\|a(t)\|_{H^s}\|\nabla v(t)\|_{L^\infty}\|\Delta_q a(t)\|_{L^2} \tag{2.4}$$

Finally, applying estimates (2.2)–(2.4), we get

$$\begin{aligned}J_q(t) \overset{\text{def}}{=} &\frac{d}{dt}(\mu_2\|\Delta_q v(t)\|_{L^2}^2 + \mu_1\|\Delta_q\tau\|_{L^2}^2) + 2\mu_2\nu\|\nabla\Delta_q v_n(t)\|_{L^2}^2 + 2\mu_1 a\|\Delta_q\tau_n\|_{L^2}^2\\ \leq\ &Cc_q(t)2^{-qs}\Big(\|\nabla v(t)\|_{L^\infty}\mu_2\|v(t)\|_{H^s}\|\Delta_q v(t)\|_{L^2}\\ &\qquad + (1+|b|)\|\nabla v(t)\|_{L^\infty}\mu_1\|\tau(t)\|_{H^s}\|\Delta_q\tau(t)\|_{L^2}\\ &\qquad + \|\tau(t)\|_{L^\infty}\mu_1\|\nabla v(t)\|_{H^s}\|\Delta_q\tau(t)\|_{L^2}\Big).\end{aligned} \tag{2.5}$$

Then, summing in q gives

$$\frac{d}{dt}E_s(v,\tau)(t)+2\mu_2\nu\|\nabla v(t)\|_{H^s}^2+2\mu_1 a\|\tau_n\|_{H^s}^2\leq C(1+|b|)\|\nabla v(t)\|_{L^\infty}E_s(v,\tau)(t)$$
$$+\left(\frac{C\mu_1}{\mu_2\nu}\right)^{\frac{1}{2}}\|\tau(t)\|_{L^\infty}(\mu_2\nu)^{\frac{1}{2}}\|\nabla v(t)\|_{H^s}\mu_1^{\frac{1}{2}}\|\tau(t)\|_{H^s}.$$

So this implies that

$$\frac{d}{dt}E_s((v,\tau),t)+\mu_2\nu\|\nabla v(t)\|_{H^s}^2\leq C\left(\frac{\mu_1}{\mu_2\nu}\|\tau(t)\|_{L^\infty}^2+(1+|b|)\|\nabla v(t)\|_{L^\infty}\right)E_s((v,\tau),t).$$

The Gronwall lemma implies that, for any time t,

$$E_s((v,\tau),t)+\mu_2\nu\int_0^t\|\nabla v(t')\|_{H^s}^2dt'$$
$$\leq E_s((v,\tau),0)\exp C\int_0^t\left(\frac{\mu_1}{\mu_2\nu}\|\tau(t')\|_{L^\infty}^2+(1+|b|)\|\nabla v(t')\|_{L^\infty}\right)dt'.$$

Let us define T_n as

$$T_n\overset{\text{def}}{=}\sup\left\{t\,/\,\forall t'\leq t\,,\;E_s((v_n,\tau_n),t')+\mu_2\nu\int_0^{t'}\|\nabla v_n(t'')\|_{H^s}^2dt''\leq 2E_s((v,\tau),0)\right\}.$$

As $s>d/2$, the Sobolev embedding implies that, for any $t\leq T_n$,

$$\int_0^t\left(\frac{\mu_1}{\mu_2\nu}\|\tau_n(t')\|_{L^\infty}^2+\|\nabla v_n(t')\|_{L^\infty}\right)dt'$$
$$\leq C(1+|b|)\left(\frac{(tE_s((v,\tau),0)}{\mu_2\nu}\right)^{\frac{1}{2}}\left(1+\left(\frac{tE_s((v,\tau),0)}{\mu_2\nu}\right)^{\frac{1}{2}}\right)\cdot$$

Thus, it is easily inferred that if

$$T\leq\min\left\{T_n,\frac{\mu_2\nu}{C(1+|b|)E_s((v,\tau),0)}\right\},$$

then, for any $n\in N$ and any $t\in[0,T]$, we have

$$E_s((v_n,\tau_n),t)+\mu_2\nu\int_0^t\|\nabla v_n(t')\|_{H^s}^2dt'\leq 2E_s((v,\tau),0).$$

So this implies that, for any $n\in\mathbf{N}$,

$$t_n\geq\frac{\mu_2\nu}{CE_s((v,\tau),0)}\cdot$$

Standard compactness arguments imply the existence of a solution (v,τ) in $L_T^\infty(H^s)$ so that the vector field v belongs to $L^2([0,T];H^{s+1})$.

Now let us use the smoothing effect of the heat equation; let us consider a solution of (VE) which belongs to $L^\infty([0,T];H^s)$. Then it is obvious that

$$f\overset{\text{def}}{=}-v\cdot\nabla v+\nabla p+\nabla\cdot\tau\in L_T^\infty(H^{s-1}).$$

So the smoothing effect of the heat equation, as described for instance in [6], implies that if

$$\partial_t v - \nu \Delta v = f,$$

then, for any $p \in [1, \infty]$, we get

$$\|\Delta_q v\|_{L^p_T(L^2)} \leq \frac{C}{\nu} 2^{-q(s+1)} T^{\frac{1}{p}} \|f\|_{L^\infty_T(H^{s-1})} + \left(\frac{C}{2^{2q}\nu}\right)^{\frac{1}{p}} \|\Delta_q v(0)\|_{L^2}.$$

So taking $p = 1$ in the above estimate implies that, for any ε, the series $(\Delta_q v)_{q\in\mathbf{N}}$ is convergent in $L^1_T(H^{s+1-\varepsilon})$. Thus, for any strictly positive t_0, a strictly positive time t_1 exists so that $v(t_1, \cdot)$ belongs to $H^{s+1-\varepsilon}$. Let us apply the above estimate with $p = \infty$; we get that v belongs to $L^\infty([t_1, T]; H^{s+1-\varepsilon})$. Thanks to Sobolev embeddings, the fact that v is in $L^1_T(H^{s+1-\varepsilon})$ implies that v belongs to $L^1_T(Lip)$.

Let us prove the uniqueness. Let us consider two solutions (v_1, τ_1) and (v_2, τ_2) of (VE) in $L^\infty_{loc}([0, T^\star[; H^s)$. These solutions are such that v_j belongs to

$$L^2_{loc}([0, T^\star[; H^{s+1}) \cap L^\infty_{loc}(]0, T^\star[; H^{s+1-\varepsilon}).$$

Denoting by (w, θ) the difference between those two solutions, we have the following system:

$$\begin{cases} \dfrac{\partial w}{\partial t} - \nu\Delta w + v_2 \cdot \nabla w &= \mu_1 \nabla \cdot \theta - w \cdot \nabla v_1 - \nabla p, \\ \dfrac{\partial \theta}{\partial t} + v_1 \cdot \nabla \theta + a\theta &= \mu_2 D w - Q(\theta, \nabla v_1) - Q(\tau_2, \nabla w) - w \cdot \nabla \tau_2, \\ \operatorname{div} w &= 0. \end{cases}$$

By the L^2 energy estimate, we get

$$\frac{d}{dt}\big(\mu_2 \|w(t)\|^2_{L^2} + \mu_1 \|\theta(t)\|^2_{L^2}\big) + 2\mu_2 \nu \|\nabla w(t)\|^2_{L^2} + 2\mu_1 a \|\theta(t)\|^2_{L^2}$$
$$\leq 2\mu_1 \Big|(Q(\tau_2, \nabla w)|\theta)_{L^2} + (Q(\theta, \nabla v_1)|\theta)_{L^2}\Big| + 2\mu_1 \Big|(w \cdot \nabla \tau_2|\theta)_{L^2}\Big| + 2\mu_2 \Big|(w \cdot \nabla v_1|w)_{L^2}\Big|.$$

The following L^2 estimates are obvious:

$$\begin{aligned} |\mu_2(w \cdot \nabla v_1|w)_{L^2}| &\leq \mu_2 \|\nabla v_1||_{L^\infty} ||w||^2_{L^2}, \\ |\mu_1(Q(\theta, \nabla v_1)|\theta)_{L^2}| &\leq \mu_1(1 + |b|)\|\nabla v_1||_{L^\infty} \|\theta\|^2_{L^2}, \quad \text{and} \\ |\mu_1(Q(\tau_2, \nabla w)|\theta)_{L^2}| &\leq \mu_1(1 + |b|)\|\tau_2||_{L^\infty} \|\nabla w\|_{L^2} \|\theta\|_{L^2} \\ &\leq \frac{\nu\mu_2}{4} \|\nabla w\|^2_{L^2} + \frac{4\mu_1(1 + |b|)^2}{\mu_2 \nu} \|\tau_2\|^2_{L^\infty} \|\theta\|^2_{L^2}. \end{aligned}$$

To estimate the term $\mu_1(w \cdot \nabla \tau_2|\theta)_{L^2}$, we have to be a little more careful. Using the law of product in Sobolev spaces, we get, as s is strictly greater than $d/2$,

$$\|w \cdot \nabla \tau_2\|_{L^2} \leq \|\nabla w\|_{L^2} \|\tau_2\|_{H^s},$$

which yields

$$\begin{aligned} |\mu_1(w \cdot \nabla \tau_2|\theta)_{L^2}| &\leq \mu_1 \|\nabla w\|_{L^2} ||\tau_2||_{H^s} ||\theta||_{L^2} \\ &\leq \frac{\nu\mu_2}{4} ||\nabla w||^2_{L^2} + \frac{4\mu_1^2}{\mu_2 \nu}(1 + |b|)^2 ||\tau_2||^2_{H^s} ||\theta||^2_{L^2}. \end{aligned}$$

Plugging these estimates together, we infer

$$\begin{aligned}&\frac{d}{dt}\left(\mu_2\|w(t)\|_{L^2}^2+\mu_1\|\theta(t)\|_{L^2}^2\right)+\mu_2\nu\|\nabla w(t)\|_{L^2}^2+\mu_1 a\|\theta(t)\|_{L^2}^2\\ &\quad\leq C\left(\|\nabla v_1(t)\|_{L^\infty}+\frac{\mu_1}{\mu_2\nu}(1+|b|)^2\|\tau_2(t)\|_{H^s}^2\right)\left(\mu_2\|w(t)\|_{L^2}^2+\mu_1\|\theta(t)\|_{L^2}^2\right).\end{aligned}$$

So we get uniqueness by the Gronwall lemma.

3. Some a priori estimates for the 2-D Navier–Stokes system. Before stating Theorem 3.3 and Lemma 3.5, we recall some basic facts about Littlewood–Paley theory. We refer to [6] and [18] for the proof of the following results and for the multiplication law in Besov spaces.

Lemma 3.1.

$$\|\Delta_q u\|_{L^b}\leq 2^{d(\frac{1}{a}-\frac{1}{b})q}\|\Delta_q u\|_{L^a}\quad\text{for } b\geq a\geq 1,$$

$$\|e^{t\Delta}\Delta_q u\|_{L^b}\leq C2^{-ct2^{2q}}\|\Delta_q u\|_{L^b}.$$

Then the following corollary is obvious.

Corollary 3.1. *If $b\geq a\geq 1$, then we have the following continuous embeddings:*

$$B_{b,r}^{s-d\left(\frac{1}{a}-\frac{1}{b}\right)}\subset B_{a,r}^s.$$

Finally, we define the following space which will be used to control the system in dimension 2.

Definition 3.2. *Let p be in $[1,\infty]$ and r in $\mathbf{R}$; the space $\widetilde{L}_T^p(C^r)$ is the space of the distributions u such that*

$$\|u\|_{\widetilde{L}^p(0,T;C^r)}\overset{def}{=}\sup_q 2^{qr}\|\Delta_q u\|_{L_T^p(L^\infty)}<\infty.$$

Now let us state one of the two theorems about the 2-D Navier–Stokes system that we shall prove in this section.

Theorem 3.3. *Let v be the solution of the 2-D Navier–Stokes system with initial data in L^2 that belongs to $L_T^2(H^1)$ and an external force f in $L_T^1(C^{-1})\cap L_T^2(H^{-1})$; then, for any strictly positive ε, a T_0 in the interval $]0,T[$ exists such that*

$$\|\nabla v\|_{\widetilde{L}^1_{[T_0,T]}(C^0)}\leq\varepsilon.$$

The proof of this theorem will require two lemmas. The first one follows.

Lemma 3.4. *A constant C exists such that if v is the solution of the 2-D Navier–Stokes system with an initial data in L^2 that belongs to $L_T^2(H^1)$ and an external force f in $L_T^2(H^{-1})$, then*

$$\sum_q\|\Delta_q v\|_{L_T^\infty(L^2)}^2\leq\Big(1+\frac{C}{\nu}\|v_0\|_{L^2}^2\Big)\Big(\|v_0\|_{L^2}^2+\frac{C}{\nu}\|f\|_{L_T^2(H^{-1})}^2\Big).$$

To prove this lemma, we apply the operator Δ_q to the equation and, by energy estimate, we deduce that

$$\begin{aligned}\frac{1}{2}\frac{d}{dt}\|\Delta_q(t)\|_{L^2}^2+c\nu 2^{2q}\|\Delta_q(t)\|_{L^2}^2&\leq c\nu 2^{2q}\|\Delta_q v(t)\|_{L^2}^2\\ &\quad+\frac{C}{\nu}\Big(2^{-2q}\|\Delta_q f(t)\|_{L^2}^2+\|\Delta_q(v\otimes v)(t)\|_{L^2}^2\Big).\end{aligned}$$

So by integration and summation in q, we get

$$\sum_q \|\Delta_q v\|^2_{L^\infty_T(L^2)} \leq \|v_0\|^2_{L^2} + \frac{C}{\nu}(\|f\|^2_{L^2_T(H^{-1})} + \|v\|^4_{L^4_T(L^4)}).$$

Applying the classical inequality $\|a\|^4_{L^4} \leq C\|a\|^2_{L^2}\|a\|^2_{H^1}$, we get the result by the use of the standard energy estimate.

The second lemma is the following.

Lemma 3.5. *Let v be a solution of the Navier–Stokes system with initial data in L^2 and an external force f in $\widetilde{L}^1_T(C^{-1}) \cap L^2_T(H^{-1})$,*

$$(NS_\nu)\begin{cases} \dfrac{\partial v}{\partial t} + v\cdot\nabla v - \nu\Delta v &= -\nabla p + f,\\ \operatorname{div} v &= 0,\\ v|_{t=0} &= v_0. \end{cases}$$

Then we have the following a priori estimate:

$$\|v\|_{\widetilde{L}^1_T(C^1)} \leq CE_\nu(v_0,T) + \frac{C}{\nu}\|f\|_{\widetilde{L}^1_T(C^{-1})} + \frac{C}{\nu^2}\|\nabla v\|_{L^2_T(L^2)}\Big(\|v_0\|^2_{L^2} + \frac{2}{\nu}\|f\|^2_{L^2_T(H^{-1})}\Big),$$

where $E_\nu(v_0,T)$ is defined by

$$E_\nu(v_0,T) \overset{def}{=} \sup_q \|\Delta_q v_0\|_{L^2}\frac{1-e^{-c\nu T 2^{2q}}}{\nu}.$$

To prove this lemma, we first apply the operator Δ_q to the (NS_ν) system; this gives

$$\begin{aligned}\|\Delta_q v(t)\|_{L^\infty} \leq \|\Delta_q v_0\|_{L^\infty} e^{-\nu c 2^{2q} t} &+ \int_0^t e^{-\nu c 2^{2q}(t-t')}\|\Delta_q f(t')\|_{L^\infty} dt'\\ &+ \int_0^t e^{-\nu c 2^{2q}(t-t')}\|\Delta_q \mathcal{Q}(v(t'),v(t'))\|_{L^\infty} dt',\end{aligned}$$

with

$$\mathcal{Q}(v,v) = \sum_{i,j} A^{i,j}(D)(v^i v^j),$$

where $A^{i,j}(D)$ are homogeneous Fourier multipliers of degree 1. Using that

$$2^{-q}\|\Delta_q v_0\|_{L^\infty} \leq \|\Delta_q v_0\|_{L^2} \leq C\|v_0\|_{L^2}$$

thus yields, after integration in time, that

$$\|v\|_{\widetilde{L}^1_T(C^1)} \leq CE_\nu(v_0,T) + \frac{C}{\nu}\Big(\|\mathcal{Q}(v,v)\|_{\widetilde{L}^1_T(C^{-1})} + \|f\|_{\widetilde{L}^1_T(C^{-1})}\Big). \tag{3.1}$$

Denoting by $\widetilde{\varphi}^{i,j}(\xi) = \varphi(\xi)A^{i,j}(\xi) \in \mathcal{D}(\mathbf{R^2}\setminus\{\mathbf{0}\})$ we get

$$\|\Delta_q A^{i,j}(D)(v^i v^j)\|_{L^\infty} \leq C2^q\|\varphi^{i,j}(2^{-q}D)(v^i v^j)\|_{L^\infty}.$$

Then using the Bony's decomposition, we get

$$\begin{aligned}\varphi^{i,j}(2^{-q}D)(v^iv^j) &= \sum_{\substack{p'\geq q-2\\ |p-p'|\leq 2}} \varphi^{i,j}(2^{-q}D)(\Delta_p v^i \Delta_{p'} v^j)\\ &\quad+ \sum_{\substack{p'\geq q-2\\ p<p'-2}} \varphi^{i,j}(2^{-q}D)(\Delta_p v^i \Delta_{p'} v^j) + \sum_{\substack{p\geq q-2\\ p'<p-2}} \varphi^{i,j}(2^{-q}D)(\Delta_p v^i \Delta_{p'} v^j).\end{aligned}$$

For the first term, using the localization Lemma 3.1 and the fact that $|p-p'|\leq 2$, we have

$$\begin{aligned}\|\varphi^{i,j}(2^{-q}D)(\Delta_p v^i \Delta_{p'} v^j)\|_{L^\infty} &\leq 2^q\|\Delta_p v^i \Delta_{p'} v^j\|_{L^2} \leq C2^{q-p}2^{\frac{p}{2}}\|\Delta_p v^i\|_{L^2}2^{\frac{p'}{2}}\|\Delta_{p'}v^j\|_{L^\infty}\\ &\leq C2^{q-p'}\|v\|_{H^{\frac12}}2^{\frac{p'}{2}}\|\Delta_{p'}v^j\|_{L^\infty}.\end{aligned}$$

Hence summing up over p (a finite set for any fixed p'), integrating over $[0,T]$, and using the Hölder inequality, we get

$$\begin{aligned}\left\|\sum_{\substack{p'\geq q-2\\ |p-p'|\leq 2}} \varphi^{i,j}(2^{-q}D)(\Delta_p v^i \Delta_{p'} v^j)\right\|_{L^1_T(L^\infty)} &\leq \sum_{p'\geq q-2} C2^{q-p'}\|v\|_{L^4_T(H^{\frac12})}2^{\frac{p'}{2}}\|\Delta_{p'}v^j\|_{L^{\frac43}(L^\infty)}\\ &\leq C\|v\|_{L^4_T(H^{\frac12})}\|v\|_{\widetilde{L}^{\frac43}(C^{\frac12})},\end{aligned}\tag{3.2}$$

where we have used that $2^{\frac{p'}{2}}\|\Delta_{p'}v^j\|_{L^{\frac43}(L^\infty)} \leq \|v\|_{\widetilde{L}^{\frac43}(C^{\frac12})}$.

The second and the third terms are treated in the same way, we treat, for instance, the second one. We have

$$\begin{aligned}\|\varphi^{i,j}(2^{-q}D)(\Delta_p v^i \Delta_{p'} v^j)\|_{L^\infty} &\leq \|\Delta_p v^i\|_{L^\infty}\|\Delta_{p'}v^j\|_{L^\infty}\\ &\leq C2^p\|\Delta_p v^i\|_{L^2}\|\Delta_{p'}v^j\|_{L^\infty}\\ &\leq C2^{\frac{p-q}{2}}\|v\|_{H^{\frac12}}2^{\frac{p'}{2}}\|\Delta_{p'}v^j\|_{L^\infty}.\end{aligned}\tag{3.3}$$

Hence integrating over $[0,T]$, using the Hölder inequality, and noticing that the sum over p' can be restricted to the set $q+2\geq p'\geq q-2$ which is finite, we get

$$\left\|\sum_{\substack{p'\geq q-2\\ p\leq p'-2}} \varphi^{i,j}(2^{-q}D)(\Delta_p v^i \Delta_{p'} v^j)\right\|_{L^1_T(L^\infty)} \leq \sum_{p\leq q} C2^{\frac{p-q}{2}}\|v\|_{L^4_T(H^{\frac12})}\|v\|_{\widetilde{L}^{\frac43}_T(C^{\frac12})}.\tag{3.4}$$

Therefore, taking the supremum over q, we deduce that

$$\|\mathcal{Q}(v,v)\|_{\widetilde{L}^1_T(C^{-1})} \leq C\|v\|_{L^4_T(H^{\frac12})}\|v\|_{\widetilde{L}^{\frac43}_T(C^{\frac12})}.$$

Then by interpolation, we merely get that

$$\|v\|_{L^4_T(H^{\frac12})} \leq \|v\|^{1/2}_{L^2_T(H^1)}\|v\|^{1/2}_{L^\infty_T(L^2)}.$$

On the other hand, we have for all q

$$\begin{aligned}2^{\frac{q}{2}}\|\Delta_q v\|_{L^{\frac43}_T(L^\infty)} &\leq 2^{\frac{q}{2}}\|\Delta_q v\|^{1/2}_{L^1_T(L^\infty)}\|\Delta_q v\|^{1/2}_{L^2_T(L^\infty)}\\ &\leq 2^{\frac{q}{2}}\|\Delta_q v\|^{1/2}_{L^1_T(L^\infty)}\ 2^{\frac{q}{2}}\|\Delta_q v\|^{1/2}_{L^2_T(L^2)}\\ &\leq \|v\|^{1/2}_{\widetilde{L}^1_T(C^1)}\|v\|^{1/2}_{L^2_T(H^1)}.\end{aligned}$$

Thus, we infer that

$$\|\mathcal{Q}(v,v)\|_{\widetilde{L}^1_T(C^{-1})} \leq C\|v\|_{L^2_T(H^1)}\|v\|^{\frac{1}{2}}_{L^\infty_T(L^2)}\|v\|^{\frac{1}{2}}_{\widetilde{L}^1_T(C^1)}.$$

So plugging this estimate into (3.1), we obtain that

$$\|v\|_{\widetilde{L}^1_T(C^1)} \leq CE_\nu(v_0,T) + \frac{C}{\nu}\|f\|_{\widetilde{L}^1_T(C^{-1})} + C\|v\|_{L^2_T(H^1)}\|v\|^{\frac{1}{2}}_{L^\infty_T(L^2)}\|v\|^{\frac{1}{2}}_{\widetilde{L}^1_T(C^1)}.$$

But the energy estimate implies that

$$\|v\|_{L^\infty_T(L^2)} \leq \left(\|v_0\|^2_{L^2} + \frac{2}{\nu}\|f\|^2_{L^2_T(H^{-1})}\right)^{\frac{1}{2}}.$$

Thus, we infer that

$$\begin{aligned}\|v\|_{\widetilde{L}^1_T(C^1)} &\leq CE_\nu(v_0,T) + \frac{C}{\nu}\|f\|_{\widetilde{L}^1_T(C^{-1})} \\ &\qquad + \frac{C}{\nu}\|\nabla v\|_{L^2_T(L^2)}\left(\|v_0\|^2_{L^2} + \frac{2}{\nu}\|f\|^2_{L^2_T(H^{-1})}\right)^{\frac{1}{4}}\|v\|^{\frac{1}{2}}_{\widetilde{L}^1_T(C^1)} \\ &\leq CE_\nu(v_0,T) + \frac{C}{\nu}\|f\|_{\widetilde{L}^1_T(C^{-1})} \\ &\qquad + \frac{C}{\nu^2}\|\nabla v\|^2_{L^2_T(L^2)}\left(\|v_0\|^2_{L^2} + \frac{2}{\nu}\|f\|^2_{L^2_T(H^{-1})}\right)^{\frac{1}{2}} + \frac{1}{2}\|v\|_{\widetilde{L}^1_T(C^1)}.\end{aligned}$$

This concludes the proof of the lemma.

Now let us go the the proof of Theorem 3.3. First let us apply Lemma 3.5 between some T_0 in the interval $]0,T[$ and T. This gives

$$\begin{aligned}\|v\|_{\widetilde{L}^1_{[T_0,T]}(C^1)} \leq CE_\nu(v_{T_0},T-T_0) + \frac{C}{\nu}\|f\|_{L^1_{[T_0,T]}(C^{-1})} \\ + \frac{C}{\nu^2}\|\nabla v\|_{L^2_{[T_0,T]}(L^2)}\left(\|v_0\|^2_{L^2} + \frac{2}{\nu}\|f\|^2_{L^2_T(H^{-1})}\right).\end{aligned}$$

Lemma 3.4 implies in particular that, for any positive ε, an integer q_0 exists such that

$$\sup_{q\geq q_0}\|\Delta_q v\|_{L^\infty_T(L^2)} \leq \frac{\varepsilon\nu}{4C}\cdot$$

Then it turns out that

$$E_\nu(v_{T_0},T-T_0) \leq \frac{\varepsilon}{4C} + C\|v_0\|_{L^2}\nu 2^{2q_0}(T-T_0). \tag{3.5}$$

Now it is easy to choose T_0 such that, for any T' between T_0 and T, we get

$$\|f\|_{L^1_{[T',T]}(C^{-1})} \leq \frac{\varepsilon\nu}{4C} \quad \text{and} \quad \|\nabla v\|_{L^2_{[T',T]}(L^2)} \leq \frac{\varepsilon\nu^2}{4C}\left(\|v_0\|^2_{L^2} + \frac{2}{\nu}\|f\|^2_{L^2_T(H^{-1})}\right)^{-1}.$$

4. A losing a priori estimate. The core of this section is the proof of a losing estimate for transport equation in the spirit of [1]. After this proof, we shall apply this estimate in order to prove Theorem 1.2.

THEOREM 4.1. *Let σ and β be two elements of* $]0,1[$. *A constant C exists that satisfies the following properties.*

Let T and λ be two positive numbers and v a smooth divergence-free vector field so that

$$\sigma - \lambda \|\nabla v\|_{\widetilde{L}^1_T(C^0)} \geq \beta. \tag{4.1}$$

Consider two smooth functions f and g so that f is the solution of

$$(T)\left\{\begin{array}{rcl} \partial_t f + v\cdot\nabla f + Q(\nabla v, f) &=& g,\\ f_{|t=0} &=& f_0.\end{array}\right.$$

Then we have, if $\lambda \geq 2C$,

$$M^\sigma_\lambda(f) \leq 2\|f_0\|_{B^\sigma_{p,\infty}} + \frac{2C}{\lambda} M^{\sigma+1}_\lambda(v) + TM^\sigma_\lambda(g), \tag{4.2}$$

where

$$(4.3) \quad M^\sigma_\lambda(c) \overset{def}{=} \sup_{\substack{t\in[0,T]\\ q}} 2^{q\sigma-\Phi_{q,\lambda}(t)} \|\Delta_q c(t)\|_{L^p} \quad \textit{with}$$

$$(4.4)\, \Phi_{q,\lambda}(t,t') \overset{def}{=} \lambda \int_{t'}^t \|S_q\nabla v(t'')\|_{L^\infty} dt'' + \lambda \int_{t'}^t \|f(t'')\|_{L^\infty} dt''\,,\ \Phi_{q,\lambda}(t) = \Phi_{q,\lambda}(t,0).$$

To prove this theorem, we transform the transport equation (T) along the flow of v, in the following equation (T_q) on $f_q \overset{\text{def}}{=} \Delta_q f$, which is a transport equation along the flow of $S_q v$.

$$(T_q)\left\{\begin{array}{rcl} \partial_t f_q + S_q v\cdot\nabla f_q &=& \Delta_q g - R_q(v,f),\\ f_{q|t=0} &=& \Delta_q f_0.\end{array}\right.$$

Let us admit for a while the following estimate:

$$2^{q\sigma-\Phi_{q,\lambda}(t)} \|R_q(v(t),f(t))\|_{L^p} \leq Ce^{C\lambda\|\nabla v\|_{\widetilde{L}^1_T(C^0)}}$$

$$(4.5)\times\left(\|f(t)\|_{L^\infty} M^{\sigma+1}_\lambda(v) + \left(\|S_q\nabla v(t)\|_{L^\infty} + \sum_{|q'-q|\leq N} \|\Delta_{q'}\nabla v(t)\|_{L^\infty}\right) M^\sigma_\lambda(f)\right).$$

Let us denote by ψ_q the flow of the vector field $S_q v$. The equation (T_q) may be rewritten as

$$(\widetilde{T}_q) \qquad \frac{d}{dt} f_q(t,\psi_q(t,x)) = \Delta_q g(t,\psi_q(t,x)) - R_q(v(t),f(t))(\psi_q(t,x)).$$

As the vector field v, and of course also the vector field $S_q v$ is divergence-free, we get, after time integration in $(\widetilde{T}_q)$, that

$$\|f_q(t)\|_{L^p} \leq \|f_q(0)\|_{L^p} + \int_0^t \|\Delta_q g(t')\|_{L^p} dt' + \int_0^t \|R_q(v(t'),f(t'))\|_{L^p} dt'.$$

After a multiplication by $2^{q\sigma-\Phi_{q,\lambda}(t)}$, we get

$$\begin{aligned}2^{q\sigma-\Phi_{q,\lambda}(t)}\|f_q(t)\|_{L^p} \leq 2^{q\sigma}\|\Delta_q f_0\|_{L^p} + \int_0^t 2^{-\Phi_{q,\lambda}(t,t')}2^{q\sigma-\Phi_{q,\lambda}(t')}\|\Delta_q g(t')\|_{L^p}dt' \\ + \int_0^t 2^{-\Phi_{q,\lambda}(t,t')}2^{q\sigma-\Phi_{q,\lambda}(t')}\|R_q(v(t'),f(t'))\|_{L^p}dt'.\end{aligned}$$

Then, using the inequality (4.5), we get

$$\begin{aligned}M^\sigma_\lambda(f) \leq \|f_0\|_{B^\sigma_{p,\infty}} + TM^\sigma_\lambda(g) + e^{C\lambda\|\nabla v\|_{\widetilde{L}^1_T(C^0)}}M^\sigma_\lambda(f)\sup_{\substack{t\in[0,T]\\ q}}\int_0^t 2^{-\Phi_{q,\lambda}(t,t')} \\ \times\left(\|f(t')\|_{L^\infty}M^{\sigma+1}_\lambda(v) + M^\sigma_\lambda(f)\left(\|S_q\nabla v(t')\|_{L^\infty} + \sum_{|q'-q|\leq N}\|\Delta_{q'}\nabla v(t')\|_{L^\infty}\right)\right)dt'.\end{aligned}$$

As $\lambda\|\nabla v\|_{\widetilde{L}^1_T(C^0)}$ is smaller than $(\sigma-\beta)$, we have

$$e^{C\lambda\|\nabla v\|_{\widetilde{L}^1_T(C^0)}} \leq e^{C(\sigma-\beta)}.$$

Moreover, by definition of $\Phi_{q,\lambda}(t,t')$, it is obvious that

$$\int_0^t 2^{-\Phi_{q,\lambda}(t,t')}\|f(t')\|_{L^\infty}dt' \leq \frac{1}{\lambda\log 2} \quad\text{and}\quad \int_0^t 2^{-\Phi_{q,\lambda}(t,t')}\|S_q\nabla v(t')\|_{L^\infty}dt' \leq \frac{1}{\lambda\log 2}\cdot$$

Then we obtain that

$$\begin{aligned}M^\sigma_\lambda(f) &\leq \|f_0\|_{B^\sigma_{p,\infty}} + \frac{C}{\lambda}M^{\sigma+1}_\lambda(v) + C\|\nabla v\|_{\widetilde{L}^1_T(C^0)}M^\sigma_\lambda(f) + TM^\sigma_\lambda(g) + \frac{C}{\lambda}M^\sigma_\lambda(f) \\ &\leq \|f_0\|_{B^\sigma_{p,\infty}} + \frac{C}{\lambda}M^{\sigma+1}_\lambda(v) + TM^\sigma_\lambda(g) + \frac{C}{\lambda}M^\sigma_\lambda(f).\end{aligned}$$

This proves the theorem of course if we prove the estimate (4.5). First of all, let us decompose the operator R_q. We have

$$\begin{aligned}R_q(v,f) &= \sum_{\ell=1}^{8}R^\ell_q(v,f) \quad\text{with} \\ R^1_q(v,f) &= \sum_{j=1}^{d}\Delta_q(T_{\partial_j f}v^j), \\ R^2_q(v,f) &= \sum_{j=1}^{d}[\Delta_q, T_{v^j}\partial_j]f, \\ R^3_q(v,f) &= \sum_{j=1}^{d}T_{(v^j-S_qv^j)}\partial_j\Delta_q f, \\ R^4_q(v,f) &= \sum_{j=1}^{d}-T_{\partial_j\Delta_q f}S_qv^j, \\ R^5_q(v,f) &= \sum_{j=1}^{d}\Delta_q\partial_j R(v^j,f) - R(S_qv^j,\Delta_q\partial_j f),\end{aligned}$$

$$R_q^6(v,f)=\sum_{j=1}^d \Delta_q Q(T_{\nabla v},f),$$

$$R_q^7(v,f)=\sum_{j=1}^d \Delta_q Q(T_f,\nabla v),\quad \text{and}$$

$$R_q^8(v,f)=\sum_{j=1}^d \Delta_q Q(R(\nabla v,f)).$$

If f is a solution of (T), then

$$\partial_t f_q+\Delta_q(v\cdot\nabla f)+\Delta_q Q(\nabla v,f)=\Delta_q g.$$

Now, let us use Bony's decomposition of the products $v^j\partial_j f$. We thus get

$$(4.6)\ v^j\partial_j f=T_{v^j}\partial_j f+T_{\partial_j f}v^j+R(v^j,\partial_j f)\quad\text{and}\quad \Delta_q Q(\nabla v,f)=\sum_{\ell=6}^{8}R_q^\ell(v,f).$$

Then we have the following equalities:

$$\begin{aligned}\Delta_q(v\cdot\nabla f)&=R_q^1(v,f)+\sum_{j=1}^d \Delta_q T_{v^j}\partial_j f+\Delta_q R(v^j,\partial_j f)\\&=\sum_{\ell=1}^2 R_q^\ell(v,f)+\sum_{j=1}^d T_{v^j}\partial_j\Delta_q f+\Delta_q R(v^j,\partial_j f),\\&=\sum_{\ell=1}^3 R_q^\ell(v,f)+\sum_{j=1}^d T_{S_q v^j}\partial_j\Delta_q f+\Delta_q R(v^j,\partial_j f).\end{aligned}$$

Then, using the definition of the paraproduct and the fact that the vector field v is divergence-free, we infer that

$$\Delta_q(v\cdot\nabla f)=\sum_{\ell=1}^5 R_q^\ell(v,f)+S_q v\cdot\nabla\Delta_q f.$$

Now let us prove that each term $R_q^\ell(v,f)$ can be estimated with the right term of inequality (4.5).

Let us begin with $R_q^1(v,f)$. By definition of the paraproduct, we have

$$R_q^1(v,f)=\sum_{j=1}^d\sum_{q'}\Delta_q(S_{q'-1}\partial_j f\Delta_{q'}v^j).$$

As $|q-q'|>N$, the above term is then equal to 0, and we deduce that

$$\|R_q^1(v(t),f(t))\|_{L^p}\le C\sum_{|q-q'|\le N}\|S_{q'-1}\nabla f\|_{L^\infty}\|\Delta_{q'}v(t)\|_{L^p}.$$

Using the fact that, if $|q-q'|\le N$, then $\|S_{q'-1}\nabla f\|_{L^\infty}\le C2^q\|f(t)\|_{L^\infty}$, and we infer that

$$\|R_q^1(v(t),f(t))\|_{L^p}\le C2^q\|f(t)\|_{L^\infty}\sum_{|q-q'|\le N}\|\Delta_{q'}v(t)\|_{L^p}.$$

So we claim that

$$\begin{aligned}&2^{q\sigma-\Phi_{q,\lambda}(t)}\|R_q^1(v(t),f(t))\|_{L^p}\\&\quad\leq C\|f(t)\|_{L^\infty}M_\lambda^{\sigma+1}(v)\sum_{|q-q'|\leq N}2^{-\lambda\int_0^t\|S_q\nabla v(t')\|_{L^\infty}dt'+\lambda\int_0^t\|S_{q'}\nabla v(t')\|_{L^\infty}dt'}.\end{aligned}$$

However, it is obvious that

$$\int_0^t\|S_{q'}\nabla v(t')\|_{L^\infty}dt'-\int_0^t\|S_q\nabla v(t')\|_{L^\infty}dt'\leq\int_0^t\|(S_{q'}-S_q)\nabla v(t')\|_{L^\infty}dt'.$$

Using the fact that $|q-q'|\leq N_0$ and that

$$\|\Delta_q u\|_{L^p}\leq C2^{-q}\|\nabla\Delta_q u\|_{L^p},$$

we get

$$\int_0^t\|S_{q'}\nabla v(t')\|_{L^\infty}dt'-\int_0^t\|S_q\nabla v(t')\|_{L^\infty}dt'\leq C\|\nabla v\|_{\widetilde{L}^1_T(C^0)}. \tag{4.7}$$

Thus it turns out that

$$2^{q\sigma-\Phi_{q,\lambda}(t)}\|R_q^1(v(t),f(t))\|_{L^p}\leq C\|f(t)\|_{L^\infty}2^{C\lambda\|\nabla v\|_{\widetilde{L}^1_T(C^0)}}M_\lambda^{\sigma+1}(v). \tag{4.8}$$

Now let us look at $R_q^2(v,f)$. By definition of the paraproduct, we have

$$\begin{aligned}R_q^2(v,f)&=-\sum_{j=1}^d\sum_{q'}[S_{q'-1}v^j\partial_j\Delta_{q'},\Delta_q]f\\&=-\sum_{j=1}^d\sum_{q'}[S_{q'-1}v^j,\Delta_q]\partial_j\Delta_{q'}f.\end{aligned}$$

The terms of the above sum are equal to 0 except if $|q-q'|\leq N$. Moreover, by definition of the operators Δ_q, we have

$$[S_{q'-1}v^j,\Delta_q]\partial_j\Delta_{q'}f(x)=2^{qd}\int_{\mathbf{R^d}}h(2^q(x-y))(S_{q'-1}v^j(x)-S_{q'-1}v^j(y))\partial_j\Delta_{q'}f(y)dy.$$

So we infer that

$$|[S_{q'-1}v^j,\Delta_q]\partial_j\Delta_{q'}f(x)|\leq2^{-q}\|\nabla S_{q'-1}v\|_{L^\infty}2^{qd}\Big(\Big(2^q|\cdot|\times|h(2^q\cdot)|\Big)\star|\partial_j\Delta_{q'}f|\Big)(x).$$

Then we have, using inequality (4.7),

$$\begin{aligned}&2^{q\sigma-\Phi_{q,\lambda}(t)}\|[S_{q'-1}v^j,\Delta_q]\partial_j\Delta_{q'}f\|_{L^p}\\&\quad\leq CM_\lambda^\sigma(f)\sum_{|q-q'|\leq N}2^{C\lambda\|v\|_{\widetilde{L}^1_T(C^1)}}(\|\nabla(S_{q'-1}-S_q)v(t)\|_{L^\infty}+\|S_qv(t)\|_{L^\infty}).\end{aligned}$$

We thus get

$$\begin{aligned}&2^{q\sigma-\Phi_{q,\lambda}(t)}\|R_q^2(v(t),f(t))\|_{L^p}\leq CM_\lambda^\sigma(f)2^{C\lambda\|v\|_{\widetilde{L}^1(C^1)}}\\&\qquad\times\left(\|S_q\nabla v(t)\|_{L^\infty}+\sum_{|q-q'|\leq N}\|\nabla(S_{q'-1}-S_q)v(t)\|_{L^\infty}\right).\end{aligned} \tag{4.9}$$

The estimate about $R^3_q(v,f)$ is very easy to prove. By definition of the paraproduct, we have

$$R^3_q(v,f) = \sum_{q'} (S_{q'-1}v^j - S_q v^j)\Delta_{q'}\Delta_q f,$$

so we get

$$\|R^3_q(v,f)\|_{L^p} \leq C \sum_{q' \geq q} 2^{q-q'} \|\Delta_{q'}\nabla v(t)\|_{L^\infty} \|D_q f(t)\|_{L^p}.$$

So by definition of $M^\sigma_\lambda(f)$ it is obvious that

$$2^{q\sigma-\Phi_{q,\lambda}(t)}\|R^3_q(v(t),f(t))\|_{L^p} \leq CM^\sigma_\lambda(f) \sum_{q'\geq q} 2^{q-q'}\|\Delta_{q'}v(t)\|_{L^\infty}. \tag{4.10}$$

Now let us estimate $R^4_q(v,f)$. By definition of the paraproduct, we have

$$R^4_q(v,f) = \sum_{j=1}^{d}\sum_{q'} S_{q'-1}\Delta_q\partial_j f \Delta_{q'} S_q v^j.$$

It is obvious by definition of the operators S_q and Δ_q that if $q' \leq q$, then $S_{q'-1}\Delta_q = 0$ and if $q' \geq q+1$, then $\Delta_{q'}S_q = 0$. So

$$R^4_q(v,f) = \sum_{j=1}^{d} S_{q-1}\Delta_q\partial_j f\Delta_q S_q v^j.$$

It turns out that

$$2^{q\sigma-\Phi_{q,\lambda}(t)}\|R^4_q(v(t),f(t))\|_{L^p} \leq CM^\sigma_\lambda(f)\|S_q\nabla v(t)\|_{L^\infty}. \tag{4.11}$$

The estimate of $R^5_q(v,f)$ is a little bit more delicate. We have, using the fact that v is divergence-free,

$$\begin{aligned}
R^5_q(v,f) &= \sum_{\ell=1}^{2} R^{5,\ell}_q(v,f) \quad \text{with}\\
R^{5,1}_q(v,f) &= \sum_{j=1}^{d} \partial_j\Delta_q R((\mathrm{Id}-S_q)v^j, f) \quad \text{and}\\
R^{5,2}_q(v,f) &= \sum_{j=1}^{d} \Delta_q R(S_q v^j, \partial_j f) - R(S_q v^j, \partial_j\Delta_q f).
\end{aligned}$$

The estimate of $R^{5,1}_q(v,f)$ is analogous to the one of $R^5_q(v,f)$. We get

$$2^{qs-\Phi_{q,\lambda}(t)}\|R^{5,1}_q(v(t),f(t))\|_{L^p} \leq Ce^{C\lambda\|\nabla v\|_{\widetilde{L}^1_T(C^0)}} M^s_\lambda(f)\sum_{q'\geq q} 2^{q-q'}2^{q'}\|\Delta_{q'}v(t)\|_{L^\infty}. \tag{4.12}$$

By definition of the remainder operators, it turns out that

$$R^{5,2}_q(v,f) = \sum_{\substack{|q'-q''|\leq 1\\ q'\geq q-N}} [\Delta_q, \Delta_{q'}S_q(v^j)]\Delta_{q''}\partial_j f.$$

Always along the same lines, we get

$$2^{qs-\Phi_{q,\lambda}(t)}\|R_q^{5,2}(v(t),f(t))\|_{L^p} \leq Ce^{C\lambda\|\nabla v\|_{\widetilde{L}^1_T(C^0)}} M^s_\lambda(f)\sum_{q'\geq q} 2^{q-q'}2^{q'}\|\Delta_{q'}v(t)\|_{L^\infty}. \tag{4.13}$$

The term $R_q^6(v,f)$ is estimated exactly as the term $R_q^1(v,f)$, the term $R_q^7(v,f)$ exactly as the term $R_q^3(v,f)$, and the term $R_q^8(v,f)$ exactly as the term $R_q^5(v,f)$. So putting together estimates (4.8)–(4.13), we get the estimate (4.5) and thus Theorem 4.1.

Now we return to the proof of Theorem 1.2. We assume that we have a solution given by Theorem 1.1 on an interval $[0,T[$. Let us assume that

$$T<\infty \quad \text{and} \quad \int_0^T (\|\tau(t,\cdot)\|_{L^\infty}+b\|\tau(t)\|^2_{L^2})dt<\infty.$$

We want to prove that we can prolong the solution.

Theorem 1.1 says that, for any T_0 in $]0,T[$, the solution (v,τ) of (VE) belongs to the space $L^\infty_{loc}([T_0,T[;H^{s+1}\times H^s)$. Sobolev-type embeddings of Corollary 3.1 imply that

$$(v,\tau)\in L^\infty_{loc}\Big([T_0,T[;\widetilde{B}^{s+1-2\left(\frac12-\frac1p\right)}_{p,\infty}\times \widetilde{B}^{s-2\left(\frac12-\frac1p\right)}_{p,\infty}\Big).$$

Choosing $p=\infty$ in the above assertion implies that $(v,\tau)\in L^\infty_{loc}(\widetilde{C}^s\times\widetilde{C}^{s-1})$. As s is greater than 1, the tensor τ belongs to $L^2([T_0,T];L^2)\cap L^1([T_0,T];C^0)$. So we can apply Theorem 3.3. We thus choose T_0 such that, with the notations of Theorem 4.1, we have

$$\|\nabla v\|_{\widetilde{L}^1_{[T_0,T]}(C^0)}\leq \frac{s-1-\beta}{2\lambda}.$$

The losing estimate of Theorem 4.1 applied with $\sigma=s-1$ and between T_0 and T says exactly that the tensor τ satisfies

$$M^{s-1}_\lambda(\tau)\leq 2\|\tau_0\|_{C^{s-1}}+\left(\frac{C}{\lambda}+T-T_0\right)M^s_\lambda(v). \tag{4.14}$$

Now we have to estimate ∇v. The 2-D Navier–Stokes equation can be written as

$$\partial_t v-\nu\Delta v=P(v\cdot\nabla v)+PD\tau,$$

wherein P denotes the Leray projector on the divergence-free vector field. Along the exact same lines as in the proof of Theorem 4.1, we have

$$\begin{aligned}&2^{qs-\Phi_{q,\lambda}(t)}\|P(v\cdot\nabla v)-P(S_qv\cdot\nabla\Delta_qv)\|_{L^\infty}\\ &\qquad\leq CM^s_\lambda(v)\left(\|S_q\nabla v(t)\|_{L^\infty}+\sum_{q'\geq q}2^{q-q'}\|\nabla\Delta_{q'}v(t)\|_{L^\infty}\right).\end{aligned}\tag{4.15}$$

Moreover, it is obvious that

$$2^{q(s-\frac32)-\Phi_{q,\lambda}(t)}\|P(S_qv\cdot\nabla\Delta_qv)\|_{L^\infty}\leq C\|v(t)\|_{H^{\frac12}}M^s_\lambda(v).$$

So it turns out that

$$
\begin{aligned}
&2^{qs-\Phi_{q,\lambda}(t)}\|\Delta_q P(v\cdot\nabla v)\|_{L^\infty}\\
&\le CM^s_\lambda(v)\left(\|S_q\nabla v(t)\|_{L^\infty}+\sum_{q'\ge q}2^{(q-q'}\|\nabla v(t)\|_{L^\infty}+2^{\frac{q}{2}}\|v(t)\|_{H^{\frac12}}\right).
\end{aligned}
\tag{4.16}
$$

Using well-known estimates on the heat equation (see, for instance, [6]) and inequalities (4.14) and (4.16), we get that

$$M^s_\lambda(v)\le\|v_0\|_{C^s}+2\|\tau_0\|_{C^{s-1}}+\left(\frac{C}{\lambda}+T-T_0+2^{\frac{q}{2}}F_q(T_0,T)\right)M^s_\lambda(v)$$

with

$$F_q(T_0,T)\stackrel{\text{def}}{=}\sup_{t\in[T_0,T]}\int_{T_0}^t e^{c\nu 2^{2q}(t-t')}\|v(t')\|_{H^{\frac12}}\,dt'.$$

Hölder inequality implies immediately that

$$F_q(T_0,T)\le\frac{C}{\nu^{\frac34}}2^{-\frac{q}{2}}\|v\|_{L^4_{T_0,T]}(H^{\frac12})}.$$

We thus infer that

$$M^s_\lambda(v)\le\|v_0\|_{C^s}+2\|\tau_0\|_{C^{s-1}}+\left(\frac{C}{\lambda}+T-T_0+\frac{C}{\nu^{\frac34}}\|v\|_{L^4_{T_0,T]}(H^{\frac12})}\right)M^s_\lambda(v).$$

Now it is enough to choose T_0 such that the quantity

$$\frac{C}{\lambda}+T-T_0+\frac{C}{\nu^{\frac34}}\|v\|_{L^4_{[T_0,T]}(H^{\frac12})}$$

is small enough. Then as s is greater than 1, the solution (v,τ) of the system (VE) is such that $(\nabla v,\tau)$ belongs to $L^\infty([T_0,T^\star]\times\mathbf{R^2})$; this concludes the proof of Theorem 1.2.

5. Local and global existence for initial data in Besov spaces. The proof of Theorems 1.6 and 1.7 is based on the following lemma.

LEMMA 5.1. *Let s be in the interval $]-s_c,s_c+1]$. A constant C exists which satisfies the following properties.*

Let us consider any divergence-free vector field v in $L^1_T(B^{s_c+1}_{p,1})$ and any solution (w,τ) of the following linear system:

$$
(VEL)\left\{
\begin{array}{rcl}
\partial_t w-\nu\Delta w &=& P\mu_1\nabla\tau+f,\\
\partial_t\tau+v\cdot\nabla\tau+Q(\tau,\nabla v)+a\tau &=& \mu_2 Dw+g,\\
(w,\tau)_{|t=0} &=& (w_0,\tau_0)
\end{array}
\right.
$$

with $(w_0,\tau_0)\in B^{s-1}_{p,1}\times B^s_{p,1}$ and $(f,g)\in L^1_T(B^{s-1}_{p,1})\times L^1_T(B^s_{p,1})$.

Let us define

$$T_{VE}\stackrel{def}{=}+\infty\ \ \textit{if}\ \ \mu_1\mu_2\le c\nu a\qquad\textit{and}\qquad T_{VE}\stackrel{def}{=}-\frac1a\log\left(1-\frac{c\nu a}{2\mu_1\mu_2}\right)\ \ \textit{if}\ \ \mu_1\mu_2\ge c\nu a.\tag{5.1}$$

Then, if $T \leq T_{VE}$, we get for some λ big enough

$$\begin{aligned} \|w_\lambda\|_{L^1_T(B^{s+1}_{p,1})} \leq \frac{C}{\nu} \Bigg(& \sum_q 2^{q(s-1)} \|\Delta_q w_0\|_{L^p} (1 - e^{C^{-1}\nu 2^{2q}T}) + \|f_\lambda\|_{L^1_T(B^{s-1}_{p,1})} \\ & + \mu_1 \frac{1 - e^{-aT}}{a} \Big(\|\tau_0\|_{B^s_{p,1}} + \|g_\lambda\|_{L^1_T(B^s_{p,1})} \Big) \Bigg), \end{aligned} \tag{5.2}$$

$$\begin{aligned} \|w_\lambda\|_{L^\infty_T(B^{s-1}_{p,1})} \leq C \Bigg(& \|w_0\|_{B^{s-1}_{p,1}} + \|f_\lambda\|_{L^1_T(B^{s-1}_{p,1})} \\ & + \mu_1 \frac{1 - e^{-aT}}{a} \Big(\|\tau_0\|_{B^s_{p,1}} + \|g_\lambda\|_{L^1_T(B^s_{p,1})} \Big) \Bigg), \end{aligned} \tag{5.3}$$

$$\begin{aligned} \|\tau_\lambda\|_{L^\infty_T(B^s_{p,1})} \leq & \, C \left(1 + \frac{\mu_1 \mu_2}{\nu a} (1 - e^{-aT}) \right) \left(\|\tau_0\|_{B^s_{p,1}} + \|g_\lambda\|_{L^1_T(B^s_{p,1})} \right) \\ & + \frac{C \mu_2}{\nu} \left(\sum_q 2^{q(s-1)} \|\Delta_q w_0\|_{L^p} (1 - e^{C^{-1}\nu 2^{2q}T}) + \|f_\lambda\|_{L^1_T(B^{s-1}_{p,1})} \right) \end{aligned} \tag{5.4}$$

with

$$a_\lambda(t) \overset{def}{=} a(t) \exp \left(-\lambda \int_0^t \|\nabla v(t')\|_{B^{s_c}_{p,1}} dt' \right).$$

Remark. The condition (1.8) $\mu_1 \mu_2 \leq c \nu a$ means that the coupling effect between the two equations is less important than the viscosity effect on the time interval $[0, T]$. Let us also note that, in any case, spatially if $a = 0$, we may take

$$T_{VE} = \frac{\nu}{2C\mu_1\mu_2} \cdot$$

To prove the above lemma, we start with an estimate on τ (inequality (5.6) below) and then plug it into a standard estimate on w.

We apply the operator Δ_q on the transport equation on τ; we thus get

$$\begin{aligned} \partial_t \Delta_q \tau + v \cdot \nabla \Delta_q \tau + a \Delta_q \tau \ &= \ \mu_2 D \Delta_q w + \Delta_q g + R_q(v, \tau) \quad \text{with} \\ R_q(v, \tau) &\overset{\text{déf}}{=} [v \cdot \nabla, \Delta_q] \tau - \Delta_q Q(\tau, \nabla v). \end{aligned}$$

Let us admit for a while the following estimate:

$$\|R_q(v(t), \tau(t))\|_{L^p} \leq C 2^{-qs} c_q(t) \|\nabla v(t)\|_{B^{s_c+1}_{p,1}} \|\tau(t)\|_{B^s_{p,1}}, \tag{5.5}$$

where, as all along this section, $c_q(t)$ denote a positive series whose sum over q is 1. As the vector field v is divergence-free, we get, using integration along the characteristics that

$$\begin{aligned} e^{at} \|\Delta_q \tau(t)\|_{L^p} \leq \|\Delta_q \tau_0\|_{L^p} + C 2^{-qs} & \int_0^t c_q(t') \|\nabla v(t')\|_{B^{s_c+1}_{p,1}} e^{at'} \|\tau(t')\|_{B^s_{p,1}} dt' \\ & + C \mu_2 2^q \int_0^t e^{at'} \|\Delta_q w(t')\|_{L^p} dt' + C \int_0^t e^{at'} \|\Delta_q g(t')\|_{L^p} dt'. \end{aligned}$$

Then, using the multiplication by $2^{qs}\exp\Big(-\lambda\int_0^t\|\nabla v(t')\|_{B^{s_c}_{p,1}}dt'\Big)$, we get

$$\begin{aligned}e^{at}\|\Delta_q\tau_\lambda(t)\|_{L^p}\leq{}&\|\Delta_q\tau_0\|_{L^p}\\&+C\int_0^t c_q(t')e^{-\lambda\int_{t'}^t\|\nabla v(t'')\|_{B^{s_c}_{p,1}}dt''}\|\nabla v(t')\|_{B^{s_c}_{p,1}}e^{at'}\|\tau_\lambda(t')\|_{B^s_{p,1}}dt'\\&+C\mu_2 2^q\int_0^t e^{at'}2^{q(s+1)}\|\Delta_q w_\lambda(t')\|_{L^p}dt'+C\int_0^t e^{at'}2^{qs}\|\Delta_q g_\lambda(t')\|_{L^p}dt'.\end{aligned}$$

Taking the sum over q, we get

$$\begin{aligned}e^{at}\|\tau_\lambda(t)\|_{B^s_{p,1}}\leq\|\tau_0\|_{B^s_{p,1}}&+C\int_0^t e^{-\lambda\int_{t'}^t\|\nabla v(t'')\|_{B^{s_c}_{p,1}}dt''}\|\nabla v(t')\|_{B^{s_c}_{p,1}}e^{at'}\|\tau_\lambda(t')\|_{B^s_{p,1}}dt'\\&+C\mu_2\int_0^t e^{at'}\|w_\lambda(t')\|_{B^{s+1}_{p,1}}dt'+C\int_0^t e^{at'}\|g_\lambda(t')\|_{B^s_{p,1}}dt'.\end{aligned}$$

From this estimate, we get that

$$\begin{aligned}\|e^{at}\tau_\lambda(t)\|_{L^\infty_T(B^s_{p,1})}\leq{}&\|\tau_0\|_{B^s_{p,1}}+\frac{C}{\lambda}\|\tau_\lambda\|_{L^\infty_T(B^s_{p,1})}\\&+C\mu_2\int_0^T e^{at}\|w_\lambda(t)\|_{B^{s+1}_{p,1}}dt+C\int_0^T e^{at}\|g_\lambda(t)\|_{B^s_{p,1}}dt.\end{aligned}$$

So, if λ is large enough, we obtain

$$\|e^{at}\tau_\lambda(t)\|_{L^\infty_T(B^s_{p,1})}\leq 2\|\tau_0\|_{B^s_{p,1}}+C\mu_2\int_0^T e^{at}\|w_\lambda(t)\|_{B^{s+1}_{p,1}}dt+C\int_0^T e^{at}\|g_\lambda(t)\|_{B^s_{p,1}}dt.\tag{5.6}$$

In particular, this implies that

$$\|\tau_\lambda(t)\|_{L^1_T(B^s_{p,1})}\leq C\frac{1-e^{aT}}{a}\Big(\|\tau_0\|_{B^s_{p,1}}+\mu_2\|w_\lambda\|_{L^1_T(B^{s+1}_{p,1})}+\|g_\lambda\|_{L^1_T(B^s_{p,1})}\Big).\tag{5.7}$$

Classical estimates about the heat equation (see, for instance, [6]) give

$$\|\Delta_q w(t)\|_{L^p}\leq C\|\Delta_q w_0\|_{L^p}e^{-C^{-1}\nu 2^{2q}t}+C\int_0^t e^{-C^{-1}\nu 2^{2q}(t-t')}\|\Delta_q\widetilde{f}(t')\|_{L^p}dt'\tag{5.8}$$

with $\widetilde{f}\overset{\text{def}}{=}f+\mu_1\nabla\cdot\tau$. Then multiplying by $2^{qs}\exp\Big(-\lambda\int_0^t\|\nabla v(t')\|_{B^{s_c}_{p,1}}dt'\Big)$, taking the sum over q and integrating in time, we get

$$\|w_\lambda\|_{L^1_T(B^{s+1}_{p,1})}\leq\frac{C}{\nu}\left(\sum_q\|\Delta_q w_0\|_{L^p}(1-e^{-C^{-1}\nu 2^{2q}T})+\|\widetilde{f}_\lambda\|_{L^1_T(B^{s-1}_{p,1})}\right).$$

By the definition of $\widetilde{f}$, we obtain, applying the estimate (5.7),

$$\begin{aligned}\|w_\lambda\|_{L^1_T(B^{s+1}_{p,1})}\leq\frac{C}{\nu}\Bigg(&\sum_q\|\Delta_q w_0\|_{L^p}(1-e^{-C^{-1}\nu 2^{2q}T})+\|\widetilde{f}_\lambda\|_{L^1_T(B^{s-1}_{p,1})}\\&+\mu_1\frac{1-e^{aT}}{a}\Big(\|\tau_0\|_{B^s_{p,1}}+\mu_2\|w_\lambda\|_{L^1_T(B^{s+1}_{p,1})}+\|g_\lambda\|_{L^1_T(B^s_{p,1})}\Big)\Bigg).\end{aligned}$$

Then the condition (1.8) gives the estimate (5.2). To prove the inequality (5.3), let us go back to the estimate (5.8). Multiplying by $2^{q(s-1)}$ and taking the supremum in time gives

$$(5.9)\quad 2^{q(s-1)}\|\Delta_q w_\lambda\|_{L^\infty_T(L^p)} \leq C2^{q(s-1)}\|\Delta_q w_0\|_{L^p} + \int_0^T 2^{q(s-1)}\|\Delta_q \widetilde{f}_\lambda(t)\|_{L^p}dt.$$

Summing over q and using that

$$\|w_\lambda\|_{L^\infty_T(B^{s-1}_{p,1})} \leq \sum_q 2^{q(s-1)}\|\Delta_q w_\lambda\|_{L^\infty_T(L^p)},$$

we claim that

$$\|w_\lambda\|_{L^\infty_T(B^{s-1}_{p,1})} \leq C(\|w_0\|_{B^{s-1}_{p,1}} + \|\widetilde{f}_\lambda\|_{L^1_T(B^s_{p,1})}).$$

Then using the estimates (5.2) and (5.7) gives the inequality (5.3). To obtain the inequality (5.4), it is enough to plug the estimate (5.2) into (5.6).

Remark. In fact, we proved a better estimate which is

$$\sum_q 2^{q(s-1)}\|\Delta_q w_\lambda\|_{L^\infty_T(L^p)} \leq C(\|w_0\|_{B^{s-1}_{p,1}} + \|\widetilde{f}_\lambda\|_{L^1_T(B^s_{p,1})}).$$

However, we have to prove the inequality (5.5). The law of product in Besov spaces implies that

$$\|Q(\tau(t),\nabla v(t))\|_{B^s_{p,1}} \leq C\|\tau(t)\|_{B^s_{p,1}}\|\nabla v(t)\|_{B^{s_c}_{p,1}}$$

because s is in the interval $]-s_c, s_c+1]$. Thus, we have

$$\|\Delta_q Q(\tau(t),\nabla v(t))\|_{L^p} \leq Cc_q(t)2^{-qs}\|\tau(t)\|_{B^s_{p,1}}\|\nabla v(t)\|_{B^{s_c}_{p,1}}.$$

Then let us observe that, in [9], it is proved that

$$\|[v(t)\cdot\nabla, \Delta_q]\tau(t)\|_{L^p} \leq Cc_q(t)2^{-qs}\|\nabla v(t)\|_{B^{s_c}_{p,1}}\|\tau(t)\|_{B^s_{p,1}}.$$

The estimate (5.5) is proved and so is the lemma.

Now let us prove Theorem 1.6. As $\mathcal{D}$ (the space of smooth compactly supported functions) is dense in $B^{s_c-1}_{p,1}\times B^{s_c}_{p,1}$, let us consider a sequence $(v_{n,0},\tau_{n,0})$ of $\mathcal{D}$ which converges to (v_0,τ_0) in the Banach space $B^{s_c-1}_{p,1}\times B^{s_c}_{p,1}$ and such that for all n, we have $||v_{n,0}||_{B^{s_c}_{p,1}} \leq ||v_0||_{B^{s_c}_{p,1}}$ and $||\tau_{n,0}||_{B^{s_c-1}_{p,1}} \leq \|\tau_0\|_{B^{s_c-1}_{p,1}}$.

Theorem 1.1 claims that a smooth solution (v_n,τ_n) exists on a time interval $[0,T_n[$. Let us define

$$v_{n,L} = e^{\nu t\Delta}v_{n,0} \quad\text{and}\quad w_n = v_n - v_{n,L}.$$

Now let us apply the above Lemma 5.1 with $s = s_c$ and

$$f_n = \mathcal{Q}(w_n,w_n) + 2\mathcal{Q}(v_{n,L},w_n) + \mathcal{Q}(v_{n,L},v_{n,L}),\quad v = v_n,\quad g = 0.$$

Let us define

$$W_{n,\lambda}(T) = \nu||w_{n,\lambda}||_{L^1_T(B^{s_c+1}_{p,1})} + ||w_{n,\lambda}||_{L^\infty_T(B^{s_c-1}_{p,1})},$$

where we recall that

$$w_\lambda(t) = w(t)\exp\left(-\lambda\int_0^t \|\nabla v(t')\|_{B^{s_c}_{p,1}}dt'\right).$$

Then we get, for any $T \leq \min(T_{VE}, T_n)$,

$$W_{n,\lambda}(T) \leq C\left(||f_{n,\lambda}||_{L^1_T(B^{s_c-1}_{p,1})} + \frac{\mu_1}{a}(1-e^{-a\ T})||\tau_{n,0}||_{B^{s_c}_{p,1}}\right).$$

Let us estimate $||f_{n,\lambda}||_{L^1_T(B^{s_c-1}_{p,1})}$. As $B^{s_c}_{p,1}$ is an algebra,

$$||Q(a,b)||_{L^1_T(B^{s_c-1}_{p,1})} \leq C||a||_{L^2_T(B^{s_c}_{p,1})}\ ||b||_{L^2_T(B^{s_c}_{p,1})}.$$

Then using classical interpolation results, we get

$$||a||_{L^2_T(B^{s_c}_{p,1})} \leq ||a||^{1/2}_{L^1_T(B^{s_c+1}_{p,1})}||a||^{1/2}_{L^\infty_T(B^{s_c-1}_{p,1})}.$$

We thus infer that

$$||f_{n,\lambda}||_{L^1_T(B^{s_c-1}_{p,1})} \leq C\left(W^2_{n,\lambda} + W_{n,\lambda}||v_{n,L}||_{L^2_T(B^{s_c}_{p,1})} + ||v_{n,L}||^2_{L^2_T(B^{s_c}_{p,1})}\right).$$

Using Lemma 5.1, we get that

$$W_{n,\lambda}(T) \leq C\left(||v_{n,L}||^2_{L^2_T(B^{s_c}_{p,1})} + W^2_{n,\lambda}(T) + \frac{\mu_1}{a}(1-e^{-a\ T})||\tau_{n,0}||_{B^{s_c}_{p,1}}\right).$$

Let $T \leq \min\{T_{(v_{n,0},\tau_{n,0})}, T_{VE}, T_n\}$, where $T = T_{(v_{n,0},\tau_{n,0})}$ is such that

$$\frac{C\mu_1}{a\nu}(1-e^{-a\ T})||\tau_{n,0}||_{B^{s_c}_{p,1}} + \frac{C}{\nu}\left(\sum_q 2^{q(s-1)}\|\Delta_q v_{n,0}\|_{L^p}(1-e^{C^{-1}\nu 2^{2q}T})\right) \leq \frac{1}{8C}.$$

We can see easily that $T_{(v_{n,0},\tau_{n,0})}$ goes to $T_{(v_0,\tau_0)}$, when n goes to ∞. Next we recall that (see, for instance, [6])

$$||v||_{L^p_T(B^{s_c-1+\frac{2}{p}}_{p,1})} \leq \sum_q 2^{q(s-1)}\|\Delta_q v\|_{L^p}\left(\frac{1-e^{C^{-1}\nu 2^{2q}T}}{\nu}\right)^{1/p}.$$

So we get

$$W_{n,\lambda}(T) \leq CW^2_{n,\lambda}(T) + \frac{1}{5C}$$

and, since $W_{n,\lambda}(0) = 0$ and that $W_{n,\lambda}(t)$ is continuous in t, we deduce that for all T

$$W_{n,\lambda}(T) \leq \frac{1}{2C}.$$

This can be rewritten as follows:

$$\nu||w_n||_{L^1_T(B^{s_c+1}_{p,1})} + ||w_n||_{L^\infty_T(B^{s_c-1}_{p,1})} \leq \frac{1}{2C}\exp\left(\lambda||v_{n,L}||_{L^1_T(B^{s_c+1}_{p,1})} + \lambda||w_n||_{L^1_T(B^{s_c+1}_{p,1})}\right).$$

If C is chosen big enough, we get

$$||w_n||_{L^1_T(B^{s_c+1}_{p,1})} \leq \frac{1}{3}\exp(||w_n||_{L^1_T(B^{s_c+1}_{p,1})}).$$

Then using the following lemma, we conclude easily that $||w_n||_{L^1_T(B^{s_c+1}_{p,1})} \leq 1$.

Lemma 5.2. *If $f(t)$ is a continuous function satisfying for any t in $[0,T]$*

$$f(t) \leq \eta e^{f(t)}$$

with $\eta < \frac{1}{e}$ and $f(0)=0$, then we have for all $t \in [0,T]$,

$$f(t) \leq e\eta.$$

Then we deduce that w_n is bounded in $L^\infty_T(B^{s_c-1}_{p,1}) \cap L^1_T(B^{s_c+1}_{p,1})$. Using Lemma 5.1 for τ, we get that τ_n is bounded in $L^\infty_T(B^{s_c}_{p,1})$. The explosion condition in Sobolev spaces and the fact that $||\nabla v||_{L^\infty} \leq ||v||_{B^{s_c+1}_{p,1}}$ and $||\tau||_{L^\infty} \leq ||\tau||_{B^{s_c}_{p,1}}$ show that $T_n \geq \min\{T_{(v_{n,0},\tau_{n,0})}, T_{VE}\}$ and hence, one can take $T = \min\{T_{(v_0,\tau_0)}, T_{VE}\}$.

Now let us prove the uniqueness part. We recall that we assume here that p is in the interval $[1,2d]$. This means that $s_c \geq \frac{1}{2}$. Let us consider (v,τ) a solution of (VE) in $L^\infty_T(B^{s_c-1}_{p,1}) \cap L^1_T(B^{s_c+1}_{p,1}) \times L^\infty_T(B^{s_c}_{p,1})$. It is obvious that

$$\partial_t v \in L^1_T(B^{s_c-1}_{p,1}) \quad \text{and that} \quad \partial_t \tau \in L^1_T(B^{s_c-1}_{p,1}).$$

So we get $(v-v_0, \tau-\tau_0) \in C([0,T]; B^{s_c-1}_{p,1} \times B^{s_c-1}_{p,1})$. Let us consider two solutions (v_j,τ_j) of (VE) associated to the same initial data. The difference $(w,\theta) \overset{\text{def}}{=} (v_1-v_2, \tau_1-\tau_2)$ is in $C([0,T]; B^{s_c-1}_{p,1} \times B^{s_c-1}_{p,1})$ and satisfies

$$\left\{\begin{array}{rcl} \partial_t w - \nu\Delta w & = & P\mu_1\nabla\tau + 2\mathcal{Q}(v_1+v_2,w), \\ \partial_t\theta + v_1\cdot\nabla\theta + a\theta & = & \mu_2 Dw - Q(\theta,\nabla v_1) - Q(\tau_2,\nabla w) - w\cdot\nabla\tau_2, \\ (w,\theta)_{|t=0} & = & (0,0). \end{array}\right.$$

Applying Lemma 5.1 with $s = s_c - 1$, we get

$$\nu||w_\lambda||_{L^1_T(B^{s_c}_{p,1})} + ||w_\lambda||_{L^\infty_T(B^{s_c-2}_{p,1})} + ||\theta_\lambda||_{L^\infty_T(B^{s_c-1}_{p,1})} \leq C\left(||f_\lambda||_{L^1_T(B^{s_c-2}_{p,1})} + ||g_\lambda||_{L^1_T(B^{s_c-1}_{p,1})}\right),$$

where

$$f_\lambda = 2\mathcal{Q}(v_1+v_2,w) \quad \text{and} \quad g_\lambda = 2\mathcal{Q}(v_1+v_2,w) = -Q(\theta,\nabla v_1) - Q(\tau_2,\nabla w) - w\cdot\nabla\tau_2.$$

Since we are looking for uniqueness, we can forget the λ. In what follows the constant C will denote $C\exp(-\lambda\int_0^T \|\nabla v_1(t')\|_{B^{s_c}_{p,1}} dt')$. Using classical results for products in Besov spaces and the fact that $s_c + (s_c-1) \geq 0$, we get

$$\begin{array}{rcl} ||f||_{L^1_T(B^{s_c-2}_{p,1})} & \leq & C\left(||v_1||_{L^2_T(B^{s_c}_{p,1})} + ||v_2||_{L^2_T(B^{s_c}_{p,1})}\right)||w||_{L^2_T(B^{s_c-1}_{p,1})} \\ & \leq & C\left(||v_1||_{L^2_T(B^{s_c}_{p,1})} + ||v_2||_{L^2_T(B^{s_c}_{p,1})}\right)||w||^{\frac{1}{2}}_{L^1_T(B^{s_c}_{p,1})}||w||^{\frac{1}{2}}_{L^\infty_T(B^{s_c-2}_{p,1})} \end{array}$$

and

$$||g||_{L^1_T(B^{s_c-1}_{p,1})} \leq C\left(\|v_1\|_{L^1_T(B^{s_c+1}_{p,1})}||\theta||_{L^\infty_T(B^{s_c-1}_{p,1})} + ||\tau_2||_{L^\infty_T(B^{s_c}_{p,1})}||w||_{L^1_T(B^{s_c}_{p,1})}\right).$$

So, uniqueness is proved by application of the Gronwall lemma.

Finally, we prove Theorem 1.9. Rewriting (2.5) in the framework of Besov spaces, we get for $q \geq 0$

$$\begin{aligned}V_q(t) &\overset{\text{def}}{=} \frac{d}{dt}(\mu_2\|\Delta_q v(t)\|^2_{L^2} + \mu_1\|\Delta_q\tau\|^2_{L^2}) + 2\mu_2\nu\|\nabla\Delta_q v_n(t)\|^2_{L^2} + 2\mu_1 a\|\Delta_q\tau_n\|^2_{L^2}\\ &\leq Cc_q(t)2^{-qs}\biggl(\|\nabla v(t)\|_{B^s_{p,1}}\mu_2\|v(t)\|_{B^s_{p,1}}\|\Delta_q v(t)\|_{L^2}\\ &\qquad\qquad + \|\nabla v(t)\|_{B^s_{p,1}}\mu_1\|\tau(t)\|_{B^s_{p,1}}\|\Delta_q\tau(t)\|_{L^2}\\ &\qquad\qquad + \|\tau(t)\|_{B^s_{p,1}}\mu_1\|\nabla v(t)\|_{B^s_{p,1}}\|\Delta_q\tau(t)\|_{L^2}\biggr),\end{aligned}$$

where the series $c_q(t)$ is now such that $\sum_q c_q(t) = 1$. Then using that

$$(\mu_2\|\Delta_q v(t)\|^2_{L^2} + \mu_1\|\Delta_q\tau\|^2_{L^2}) \geq \frac{1}{2}(\sqrt{\mu}_2\|\Delta_q v(t)\|_{L^2} + \sqrt{\mu}_1\|\Delta_q\tau\|_{L^2})^2$$

and that

$$\begin{aligned}2\mu_2 2^{2q}\nu\|\Delta_q v(t)\|^2_{L^2} + 2\mu_1 a\|\Delta_q\tau\|^2_{L^2} &\geq (2^q\sqrt{\nu\mu_2}\|\Delta_q v(t)\|_{L^2} + \sqrt{a\mu_1}\|\Delta_q\tau\|_{L^2})\\ &\quad\times\min(\sqrt{\nu},\sqrt{a})(\sqrt{\mu}_2\|\Delta_q v(t)\|_{L^2} + \sqrt{\mu}_1\|\Delta_q\tau\|_{L^2}),\end{aligned}$$

we get

$$\begin{aligned}&\frac{d}{dt}(\sqrt{\mu}_2\|\Delta_q v(t)\|_{L^2} + \sqrt{\mu}_1\|\Delta_q\tau\|_{L^2}) + \min(\sqrt{\nu},\sqrt{a})(2^q\sqrt{\nu\mu_2}\|\Delta_q v(t)\|_{L^2} + \sqrt{a\mu_1}\|\Delta_q\tau\|_{L^2})\\ &\leq Cc_q(t)2^{-qs}\biggl(\|\nabla v(t)\|_{B^s_{p,1}}\sqrt{\mu_2}\|v(t)\|_{B^s_{p,1}}\\ &\qquad + \|\nabla v(t)\|_{B^s}\sqrt{\mu}_1\|\tau(t)\|_{B^s_{p,1}} + \|\tau(t)\|_{B^s_{p,1}}\sqrt{\mu}_1\|\nabla v(t)\|_{B^s_{p,1}}\biggr).\end{aligned}$$

Then multiplying by 2^{qs} and summing in q, we get

$$\begin{aligned}\frac{d}{dt}\biggl(\sqrt{\mu}_2\|v\|_{B^s_{p,1}} + \sqrt{\mu}_1\|\tau\|_{B^s_{p,1}}\biggr) &+ \min(\sqrt{\nu},\sqrt{a})(\sqrt{\nu\mu_2}\|v\|_{B^{s+1}_{p,1}} + \sqrt{a\mu_1}\|\tau\|_{B^s_{p,1}})\\ &\leq C\|v(t)\|_{B^{s+1}_{p,1}}\biggl(\sqrt{\mu_2}\|v(t)\|_{B^s_{p,1}} + \sqrt{\mu}_1\|\tau\|_{B^s_{p,1}}\biggr).\end{aligned}$$

Thus, if

$$(\sqrt{\mu}_2\|v_0\|_{B^s_{p,1}} + \sqrt{\mu}_1\|\tau_0\|_{B^s_{p,1}}) \leq c\min(\sqrt{\nu},\sqrt{a})\sqrt{\nu\mu_2},$$

we get the global existence.

ESTIMATES FOR PERIODIC AND DIRICHLET EIGENVALUES OF THE SCHRÖDINGER OPERATOR[*]

T. KAPPELER[†] AND B. MITYAGIN[‡]

Abstract. Consider the Schrödinger equation $-y'' + Vy = \lambda y$ for a complex-valued potential V of period 1 in the weighted Sobolev space H^w of 2-periodic functions $f : \mathbb{R} \to \mathbb{C}$,

$$H^w \equiv H^w_{\mathbb{C}} := \left\{ f(x) = \sum_{k=-\infty}^{\infty} \hat{f}(k) e^{i\pi kx} | \; \|f\|_w < \infty \right\},$$

where

$$\|f\|_w := \left(2 \sum_k w(k)^2 \; |\hat{f}(k)|^2 \right)^{1/2}$$

and $w = (w(k))_{k \in \mathbb{Z}}$ denotes a symmetric, submultiplicative weight sequence. Denote by $\lambda_n = \lambda_n(V)$ $(n \geq 0)$ the periodic eigenvalues of $-\frac{d^2}{dx^2} + V$ when considered on the interval $[0, 2]$, listed in such a way that $\lambda_{2n}, \lambda_{2n-1} = n^2\pi^2 + 0(1)$, and denote by $\mu_n = \mu_n(V)$ $(n \geq 1)$ the Dirichlet eigenvalues of $-\frac{d^2}{dx^2} + V$ considered on $[0, 1]$, listed in such a way that $\mu_n = n^2\pi^2 + 0(1)$.

THEOREM. *There exist (absolute) constants $K_1, K_2 > 0$, so that for any 1-periodic potential V in H^w,*

$$\sum_{n \geq N} w(2n)^2 |\lambda_{2n} - \lambda_{2n-1}|^2 \leq K_1(1 + \|V\|_w)^{K_2}$$

and

$$\sum_{n \geq N} w(2n)^2 |\mu_n - \lambda_{2n}|^2 \leq K_1(1 + \|V\|_w)^{K_2},$$

where $N := K_1(1 + \|V\|_w)^2$.

1. Introduction.

1.1. Summary of the results.

Consider the Schrödinger equation on the interval $[0, 2]$,

$$-y'' + Vy = \lambda y, \tag{1.1}$$

where V is a complex-valued periodic potential of *period* 1 in the weighted Sobolev space of 2-periodic functions,

$$H^w \equiv H^w_{\mathbb{C}} := \left\{ f(x) = \sum_k \hat{f}(k) e^{i\pi kx} \; | \; \|f\|_w < \infty \right\}$$

with

$$\|f\|_w := \left(2 \sum_k w(k)^2 \; |\hat{f}(k)|^2 \right)^{1/2}$$

and $w = (w(k))_{k\in\mathbb{Z}}$ with $w(k) \geq 1 \; \forall k \in \mathbb{Z}$ is a symmetric weight $(w(k) = w(-k) \; \forall k \in \mathbb{Z})$ which is submultiplicative,

$$w(k+j) \leq w(k)w(j) \; \forall k, j \in \mathbb{Z}.$$

As an example of a submultiplicative weight we mention the Abel–Sobolev weight $w_{a,b}(k) := (1+|k|)^a e^{b|k|}$ with $a \geq 0$ and $b \geq 0$. An element $f \in H^{w_{a,b}}$ can be viewed as a complex-valued function $F(z) = \sum_{k\in\mathbb{Z}} \hat{f}(k)e^{i\pi kz}$, $z = x+iy$, analytic in the strip $|y| < \frac{b}{\pi}$ and such that $F(x + i\frac{b}{\pi})$ as well as $F(x - i\frac{b}{\pi})$ are in the Sobolev space H^a, defined by the weight $w(k) := (1+|k|)^a$. More generally, $w(k) := (1+|k|)^a e^{b|k|^\alpha}$ is a submultiplicative weight for $0 \leq \alpha \leq 1, a \geq 0$ and $b \geq 0$; a function $f \in H^w$ is a function of Gevrey class.

The spectrum $spec_{Per}(L)$ of the operator $L := -\frac{d^2}{dx^2} + V$, when considered on the interval $[0, 2]$ and with periodic boundary conditions, is discrete and is a sequence $\lambda_n = \lambda_n(V)$ $(n \geq 0)$ with the property that $\text{Re}\lambda_n \to +\infty$ for $n \to \infty$. Here, the eigenvalues λ_n are enumerated with their algebraic multiplicities and ordered so that

$$\text{Re}\lambda_n < \text{Re}\lambda_{n+1} \qquad \text{or} \qquad \text{Re}\lambda_n = \text{Re}\lambda_{n+1} \text{ and } \text{Im}\lambda_n \leq \text{Im}\lambda_{n+1}.$$

Notice that adding a constant to the potential V results in a shift of the eigenvalues by the same constant. Hence we restrict ourselves—without loss of generality—to potentials V of mean zero and introduce the subspace $H_0^w \subseteq H^w$,

$$H_0^w := \left\{ f \in H_{\mathbb{C}}^w \;\middle|\; \int_0^2 f(x)dx = 0 \right\}.$$

For the weight $w \equiv 1$, the spaces H_0^w and H^w are also denoted by L_0^2 and L^2, respectively. For n sufficiently large (cf. Lemma 1.4 in section 1.2 for a reminder), the eigenvalues come in pairs $\{\lambda_{2n}, \lambda_{2n-1}\}$, i.e., λ_{2n} and λ_{2n-1} are close to each other and separated from the rest of $spec_{per}(L)$ by a distance of size n.

In section 2 of this paper, we prove the following theorem.

Theorem 1.1. *There exist (absolute) constants $K_1, K_2 > 0$ so that for any 1-periodic potential V in H_0^w*

$$\sum_{n\geq N} w(2n)^2 \; |\lambda_{2n} - \lambda_{2n-1}|^2 \leq K_1(1 + \|V\|_w)^{K_2}, \tag{1.2}$$

where $N := K_1(1 + \|V\|_w)^2$.

(See Proposition 2.16 and section 2.8 for details.)

In the next theorem we state the main two terms in the asymptotics of the sequence of gap lengths, $\gamma_n := \lambda_{2n} - \lambda_{2n-1}$ as $n \to \infty$. For this purpose introduce

$$\rho(n) := \hat{V}(2n) + \frac{1}{\pi^2} \sum_j \frac{\hat{V}(n-j)}{n-j} \frac{\hat{V}(n+j)}{n+j}. \tag{1.3}$$

Notice that the last term in (1.3) is a convolution and well defined as $\hat{V}(0) = 0$.

Theorem 1.2. *There exist (absolute) constants $K_3, K_4 > 0$ so that for any 1-periodic potential V in H_0^w*

$$\sum_{n\geq N}(1+|n|)^2 w(2n)^2 \min_{\pm} \mid (\lambda_{2n}-\lambda_{2n-1}) \pm 2\sqrt{\rho(n)\rho(-n)} \mid^2 \leq K_3(1+\|V\|_w)^{K_4}, \tag{1.4}$$

where $N := K_3(1+\|V\|_w)^2$.

(See Theorem 2.20 and section 2.9 for further details.)

In our previous paper [8], we obtained estimate (1.2) and a weaker form of estimate (1.4) for the Abel–Sobolev weights

$$w_{a,b} := (1+|k|)^a e^{b|k|}, \quad (a \geq 0, b \geq 0),$$

using a Fourier approach. By a refined analysis we obtain in section 2 of the present paper estimates (1.2) for general submultiplicative weights and a two-terms asymptotic (1.3)–(1.4) for the gap lengths. It turns out that submultiplicative weights provide the right setup for applications to a KAM theorem for the Korteweg–deVries equation (cf. [2]), as will be shown in a subsequent paper. Further, we present in the present paper an analysis of the Riesz spaces together with estimates for the Dirichlet eigenvalues. Let us explain this in more detail.

In section 3, we analyze the Riesz spaces E_n (n sufficiently large), i.e., the images of the Riesz projectors defined by a circle of appropriate size around $n^2\pi^2$ as contour and the operator $L := \frac{d^2}{dx^2}+V$, considered on $[0,1]$ with periodic (for n even) or antiperiodic (for n odd) boundary conditions (cf. (1.16)). We study the structure of L by computing the matrix representation of the restriction of $L-\lambda_{2n}$ to E_n with respect to an orthonormal basis f_n, φ_n, where f_n is a periodic or antiperiodic eigenfunction in E_n. Moreover, we estimate the entries of this matrix which will be important for estimates of the Dirichlet eigenvalues (cf. Theorem 3.5 and Proposition 3.6).

In section 4 we obtain estimates for the Dirichlet eigenvalues $\mu_n(V)$ ($n \geq 1$) of the operator $-\frac{d^2}{dx^2}+V$, considered on the interval $[0,1]$. The eigenvalues $\mu_n \equiv \mu_n(V)$ are ordered in such a way that

$$\mathrm{Re}\mu_n < \mathrm{Re}\mu_{n+1} \qquad \text{or} \qquad \mathrm{Re}\mu_n = \mathrm{Re}\mu_{n+1} \text{ and } \mathrm{Im}\mu_n \leq \mathrm{Im}\mu_{n+1}. \tag{1.5}$$

Theorem 1.3. *There exist (absolute) constants $K_5, K_6 > 0$ so that for any 1-periodic potential V in H_0^w*

$$\sum_{n\geq N} w(2n)^2|\mu_n - \lambda_{2n}|^2 \leq K_5(1+\|V\|_w)^{K_6}, \tag{1.6}$$

where $N := K_5(1+\|V\|_w)^{K_6}$.

It turns out that by the methods used to prove Theorem 1.3, one can obtain similar results for the eigenvalues of L_{bc}, where L_{bc} is the operator L with boundary conditions bc from a special class $\mathcal{B}$. In section 5, this class is defined and the spectrum of the operators L_{bc} is analyzed.

It is well known that the decay of the gap lengths $\gamma_n := \lambda_{2n} - \lambda_{2n-1}$, associated to $spec_{Per}(L)$, depends on the smoothness properties of V (cf., e.g., [7], [13], [20]). In particular Marčenko [13] obtains polynomial decay of the gap lengths in terms of the Sobolev class of the potential and Trubowitz [20] proves exponential decay for real analytic potentials. Conversely, the question of smoothness of an L_2-potential in terms of the decay of the gap lengths has been addressed as well, mainly for real-valued potentials (cf. [13], [15], [20]) but more recently also for complex-valued potentials. It turns out that for complex-valued potentials, the decay of the gap lengths does not suffice to determine the smoothness: Sansuc and Tkachenko [19] proved that a periodic complex-valued potential $V \in L_0^2$ belongs to the Sobolev space H_0^N iff the following two conditions are satisfied:

$$\sum_{n\geq 1}(1+|n|)^{2N}\,|\lambda_{2n}-\lambda_{2n-1}|^2 < \infty \ ; \quad \sum_{n\geq 1}(1+|n|)^{2N}\,|\mu_n-\lambda_{2n}|^2 < \infty,$$

where, as above, $(\mu_n)_{n\geq 1}$ denote Dirichlet eigenvalues.

The condition of the weight sequence $(w(n))_{n\in\mathbb{Z}}$ to be submultiplicative could be seen as purely technical and convenient in the proofs of the inequalities stated in the theorems above, but it may be too restrictive for results like Theorem 1.1. Moreover, the submultiplicativity implies that

$$\lim_{n\to\infty}\frac{\log w(n)}{n} = \omega_* < \infty.$$

Thus, for $\omega > \omega_*$,

$$w(n) \leq C_\omega e^{\omega|n|} \quad \forall n \in \mathbb{Z} \tag{1.7}$$

for some constant $C_\omega > 0$ and $w(n)$ cannot grow faster than an exponential function. Notice, however, that the slightest violation of the growth restriction (1.7) gives a weight sequence which does not have the property stated by Theorem 1.1. This follows from Harrell's and Grigis's analysis of the gap lengths for (real) polynomial potentials. If V is a Mathieu potential

$$V(x) = t\cos(2\cdot 2\pi x) \quad 0 \leq x \leq 1, \tag{1.8}$$

then Harrell [6] (cf. [1]) proved that the gap lengths γ_n satisfy the asymptotic estimates (cf. [4, formula (1.8)])

$$\gamma_n = \frac{t^n}{8^{n-1}((n-1)!)^2}\left(1+0\left(\frac{1}{n^2}\right)\right),$$

and therefore, for some a, depending on t,

$$\gamma_n > e^{-2n\log n + an}. \tag{1.9}$$

Hence, if $w(n) := e^{b|n|\log|n|}$ with $b > 2$, the analogue of Theorem 1.1 does not hold. Indeed, we have

$$\|V\|_w^2 = \frac{\pi|t|^2}{2}w(4)^2 < \infty,$$

but (compare with (1.2))

$$\sum_{n\geq N} w(2n)^2|\gamma_n|^2 \geq \sum_{n\geq N} e^{4bn\log n}e^{-4n\log n+2an} = \infty.$$

A more refined analysis due to Grigis (see [4, Theorem 0.2]) shows that the above weight is bad with any $b > 0$, i.e., does not have the property stated by Theorem 1.1.

1.2. Preliminaries. General references on Schrödinger operators on the interval and Hill's operator can be found, e.g., in [11], [12], [18].

In this section we put together some well-known spectral properties of the operator $L := -\frac{d^2}{dx^2} + V$ in a form convenient for our further analysis. The following three lemmas are particular results in the general theory of nonselfadjoint boundary value problems developed by Keldysh [9], [10]. Many details can be found in [14], section 6 of chapter 1, in particular in subsection 6.3 (Lemmas 6.6 and 6.7) and 6.4 (p. 34); cf. also the appendix (pp. 215–219) where the paper [9] is translated into English.

Let us consider Dirichlet boundary conditions, $bc = Dir$, as well as periodic Per^+ and antiperiodic Per^- boundary conditions, $bc = Per^{\pm}$, i.e., for functions y in $H^2_{\mathbb{C}}[0,1]$,

(Dir) $\quad y(0) = 0\ ; \quad y(1) = 0;$

(Per^+) $\quad y(1) = y(0)\ ; \quad y'(1) = y'(0);$

(Per^-) $\quad y(1) = -y(0)\ ; \quad y'(1) = -y'(1).$

For $V \in L^2_{\mathbb{C}}[0,1]$ with $\int_0^1 V(x)dx = 0$ introduce the operator $L := D^2 + V$, where $D = \frac{1}{i}\frac{d}{dx}$. Given one of the above boundary conditions bc, denote by L_{bc} the closed operator in $L^2_{\mathbb{C}}[0,1]$ with domain $dom(L_{bc}) := \{f \in H^2_{\mathbb{C}}([0,1]) | f \text{ satisfies } bc\}$. Let $spec_{bc}(L) \equiv spec(L_{bc})$ be the spectrum of L_{bc}. For the potential $V \equiv 0$, i.e., $L = D^2$, $spec_{bc}(D^2)$ can be given explicitly,

$$spec_{Dir}(D^2) = \{k^2\pi^2 | k \geq 1\}, \tag{1.10}$$

$$spec_{Per^+}(D^2) = \{0\} \cup \{(2k)^2\pi^2, (2k)^2\pi^2 | k \geq 1\}, \tag{1.11}$$

$$spec_{Per^-}(D^2) = \{(2k-1)^2\pi^2, (2k-1)^2\pi^2 | k \geq 1\}. \tag{1.12}$$

For $r > 0$ and $k \in \mathbb{Z}_{\geq 0}$, let $\mathcal{D}(k) \equiv \mathcal{D}_r(k)$ be the open disc in $\mathbb{C}$ with center $k^2\pi^2$ and radius r

$$\mathcal{D}(k) := \{z \in \mathbb{C} \mid \quad |z - k^2\pi^2| < r\}$$

and, for $r_1, r_2 > 0, \mathcal{R} \equiv \mathcal{R}_{r_1,r_2}$ the open rectangle in $\mathbb{C}$

$$\mathcal{R} := \{x + iy \mid \quad -r_1 < x < r_2;\ |y| < r_2\}.$$

Denote by $\|V\|$ the L^2-norm of $V \in L^2_{\mathbb{C}}[0,2], \|V\| = (2\sum_k |\hat{V}(k)|^2)^{1/2}$.

Lemma 1.4. *There exist absolute constants $K_7 \geq 1$ and $K_8 \geq 1$ so that, for any given $M \geq 1$, boundary condition $bc \in \{Dir, Per^{\pm}\}$, $N \geq 2K_8(M+1)$, and 1-periodic potential $V \in L^2_{\mathbb{C}}[0,2]$ with $\|V\| \leq M$, the following holds:*

$$spec(L_{bc}) \subset \mathcal{R} \cup \bigcup_{k=N+1}^{\infty} \mathcal{D}(k), \tag{1.13}$$

where $\mathcal{D}(k) \equiv \mathcal{D}_r(k)$ with $r := K_8(M+1)$ and $\mathcal{R} = \mathcal{R}_{r_1,r_2}$ with $r_1 = K_7(1+M)^{4/3}$ and $r_2 = (N^2+N)\pi^2$.

We point out that $spec_{Per^+}(D^2) \cup spec_{Per^-}(D^2)$ (cf. (1.11) and (1.12)) is the spectrum $spec_{Per}(D^2)$ of the operator D^2 on $[0,2]$ with periodic boundary conditions. Obviously, for any 1-periodic potential V,

$$spec_{Per^+}(L) \cup spec_{Per^-}(L) \subseteq spec_{Per}(L).$$

For a real-valued potential the converse inclusion

$$spec_{Per}(L) \subseteq spec_{Per^+}(L) \cup spec_{Per^-}(L) \tag{1.14}$$

also holds, as one can see from an elementary application of Floquet theory. More generally, by a simple counting argument, Lemma 1.4 implies that (1.14) holds for complex-valued potentials.

The periodic eigenvalues of L on $[0,2]$ have been denoted by $(\lambda_n)_{n\geq 0}$ (cf. (1.7)). According to Lemma 1.4, the eigenvalues λ_{2n-1} and λ_{2n} are close to $n^2\pi^2$ for n sufficiently large. At certain occasions (cf., e.g., section 2.8), one of the two eigenvalues, either λ_{2n} or λ_{2n-1}, will satisfy a certain property, but it will not be possible to decide which of the two. For such a situation, it is convenient to introduce λ_n^+, λ_n^- as a different notation for the eigenvalues $\lambda_{2n}, \lambda_{2n-1}$,

$$\{\lambda_n^+, \lambda_n^-\} = \{\lambda_{2n}, \lambda_{2n-1}\}.$$

By Lemma 1.4, it follows that the Riesz projectors $P_* \equiv P_{*;bc}$ and $P_k \equiv P_{k;bc}$ are well defined for $\|V\| \leq M$,

$$P_* := \frac{1}{2\pi i}\int_{\partial\mathcal{R}} (z - L_{bc})^{-1} dz, \tag{1.15}$$

$$P_k := \frac{1}{2\pi i}\int_{\partial\mathcal{D}(k)} (z - L_{bc})^{-1} dz, \quad (k \geq N+1), \tag{1.16}$$

where the contours $\partial\mathcal{R}$ and $\partial\mathcal{D}(k)$ are counterclockwise oriented. Denote by $\|T\|_{\mathcal{L}(L^2)}$ the operator norm of a bounded linear operator $T : L^2_{\mathbb{C}}[0,1] \to L^2_{\mathbb{C}}[0,1]$.

Lemma 1.5. *There exist absolute constants K_9 and K_{10} so that under the same assumptions as in Lemma* 1.4*,*

$$\|P_*\|_{\mathcal{L}(L^2)} \leq K_9 \log(2+M), \tag{1.17}$$

$$\|P_k\|_{\mathcal{L}(L^2)} \leq K_{10}, \quad (k \geq N+1). \tag{1.18}$$

Further, for any $f \in L^2_{\mathbb{C}}[0,1]$,

$$f = P_* f + \sum_{k=N+1}^{\infty} P_k f, \tag{1.19}$$

where the series (1.19) *converges in L^2.*

Lemma 1.6. *There exists an absolute constant $K_{11} \geq 1$ so that under the same assumptions as in Lemma* 1.4*,*

$$\|(\lambda - L_{bc})^{-1}(Id - P_k)\|_{\mathcal{L}(L^2)} \leq K_{11}\frac{1}{k} \quad \forall \lambda \in \mathcal{D}_r(k), \quad \forall k \geq N+1. \tag{1.20}$$

2. Periodic eigenvalues.

2.1. Fourier block decomposition. Denote by L the Schrödinger operator $L := D^2 + V$, $D = \frac{1}{i}\frac{d}{dx}$ with a complex-valued potential $V \in H_0^w$ of period 1, considered as an unbounded operator on $L^2_{\mathbb{C}}[0,2]$, with periodic boundary conditions. For $V = 0$, the spectrum is discrete: $0, \pi^2, \pi^2, (2\pi)^2, (2\pi)^2, \dots$; i.e., the eigenvalues $k^2\pi^2$ are double for $k \geq 1$ and the eigenvalues $(n+1)^2\pi^2$ and $n^2\pi^2$ are $(2n+1)\pi^2$ apart. Further, for $n \geq 1$, $e^{in\pi x}, e^{-in\pi x}$ is a basis of the eigenspace corresponding to the eigenvalue $n^2\pi^2$. Viewing the potential V as a perturbation of D^2, it follows that for n sufficiently large, L has a pair of eigenvalues near $n^2\pi^2$, isolated from the remaining spectrum of L. Our aim is to obtain an estimate for the distance between the two eigenvalues and to compare eigenfunctions and eigenvalues with the corresponding ones for $V = 0$. Notice, however, that L might have double eigenvalues of geometric multiplicity 1 as V is complex-valued.

The Fourier series decomposition leads to an isometric isomorphism $\mathcal{F}$ between $L^2_{\mathbb{C}}[0,2]$ and $\ell^2(\mathbb{Z})$ with $\mathcal{F}(e^{i\pi kx}) = e_k$, $(e_k)_{k\in\mathbb{Z}}$ being the standard basis in $\ell^2(\mathbb{Z})$. Decompose $\hat{L} = \mathcal{F}L\mathcal{F}^{-1}$ with respect to the orthogonal sum $\ell^2(\mathbb{Z}) = \mathbb{C}e_{-n} \oplus \mathbb{C}e_n \oplus \ell^2(\mathbb{Z}\backslash\{\pm n\})$. To express $\hat{L}$, introduce the involution operator $J : \ell^2(\mathbb{Z}) \to \ell^2(\mathbb{Z})$,

$$(Ja)(k) := a(-k)\ (k \in \mathbb{Z})$$

and the shift operator $\mathcal{S} : \ell^2(\mathbb{Z}) \to \ell^2(\mathbb{Z})$,

$$(\mathcal{S}a)(k) := a(k+1)\ (k \in \mathbb{Z}).$$

$\mathcal{S}^n = \mathcal{S} \circ \cdots \circ \mathcal{S}$ denotes the n*th iterate of $\mathcal{S}$. For any subset $K \subset \mathbb{Z}$, the restriction of $\mathcal{S}$ on $\ell^2(K)$ with values in $\ell^2(\mathcal{S}(K))$ is denoted by $\mathcal{S}$ as well. This leads to the block decomposition of $\hat{L} - \lambda, \lambda = n^2\pi^2 + z$,

$$\hat{L} - (n^2\pi^2 + z) = \begin{pmatrix} -z & \hat{V}(-2n) & (\mathcal{S}^n J\hat{V})^t_{\mathbb{Z}(n)} \\ \hat{V}(2n) & -z & (\mathcal{S}^{-n} J\hat{V})^t_{\mathbb{Z}(n)} \\ (\mathcal{S}^n \hat{V})_{\mathbb{Z}(n)} & (\mathcal{S}^{-n}\hat{V})_{\mathbb{Z}(n)} & A_n - z \end{pmatrix}, \tag{2.1}$$

where $\mathbb{Z}(n) := \mathbb{Z}\backslash\{\pm n\}$, the superscript t denotes the transpose, and $A_n : \ell^2(\mathbb{Z}\backslash\{\pm n\}) \to \ell^2(\mathbb{Z}\backslash\{\pm n\})$ is the linear operator with matrix representation

$$A_n(j,k) = \pi^2(k^2 - n^2)\delta_{jk} + \hat{V}(j-k), \quad (j,k \in \mathbb{Z}(n)).$$

The (possibly) complex number $\lambda = n^2\pi^2 + z$ is a periodic eigenvalue of L if there exists a 2-periodic function $f \in H^2_{\mathbb{C}}([0,2])$ such that $(L - \lambda)f = 0$. With

$$x^f := \hat{f}(-n), \quad y^f := \hat{f}(n), \quad F := (\hat{f}(k))_{\mathbb{Z}(n)},$$

the equation $(L - \lambda)f = 0$, or its equivalent $(\hat{L} - \lambda)\hat{f} = 0$, leads to the following homogeneous system of equations:

$$-zx^f + \hat{V}(-2n)y^f + [\mathcal{S}^n J\hat{V}, F]_{\mathbb{Z}(n)} = 0, \tag{2.2}$$

$$\hat{V}(2n)x^f - zy^f + [\mathcal{S}^{-n} J\hat{V}, F]_{\mathbb{Z}(n)} = 0, \tag{2.3}$$

$$(\mathcal{S}^n\hat{V})_{\mathbb{Z}(n)}x^f + (\mathcal{S}^{-n}\hat{V})_{\mathbb{Z}(n)}y^f + (A_n - z)F = 0, \tag{2.4}$$

where $[a,b]_K = \sum_{k\in K} a(k)b(k)$ (no complex conjugation). Equation (2.4) will be referred to as *the external equation.* The system of equations (2.2)–(2.4) is analyzed as follows. First we solve the external equation (2.4) for F, regarding x^f, y^f, and z as parameters. The solution F of (2.4) is then substituted into the equations (2.2)–(2.3). This leads to a linear homogeneous system of two equations for the unknowns x^f, y^f with parameter z. The determinant of this system vanishes iff $\lambda = n^2\pi^2 + z$ is an eigenvalue of L. In section 3.3 we will also consider the inhomogneous version of the system (2.2)–(2.4) in order to obtain, among other results, an orthonormal basis of the root space of a double eigenvalue of L of geometric multiplicity 1.

2.2. Analysis of the external equation. To analyze the operator $(A_n - z) : \ell^2(\mathbb{Z}(n)) \to \ell^2(\mathbb{Z}(n))$, we write $A_n = D_n + B_n$, where D_n is the diagonal part of A_n (recall that $\hat{V}(0) = 0$),

$$D_n(k,j) := \pi^2(k^2 - n^2)\delta_{kj}, \quad (k,j \in \mathbb{Z}(n) = \mathbb{Z}\backslash\{\pm n\}). \tag{2.5}$$

Notice that D_n is invertible and that B_n has matrix elements

$$B_n(k,j) = \hat{V}(k-j), \quad (k,j \in \mathbb{Z}(n)).$$

Write

$$A_n - z = D_n - (z - B_n) = (Id - T_n)D_n; \quad T_n := (z - B_n)D_n^{-1}, \tag{2.6}$$

where T_n is an operator on $\ell^2(\mathbb{Z}(n))$ with matrix elements

$$(z\delta_{kj} - \hat{V}(k-j))\frac{1}{\pi^2(j - n^2)}.$$

Further, denote by $\|V\|$ the norm of V in $L^2_{\mathbb{C}}([0,2]), \|V\| = (2\sum_k |\hat{V}(k)|^2)^{1/2}$.

Lemma 2.1. (i) *For $n \geq 1$,*

$$\|D_n^{-1}\| \;\leq\; \frac{1}{\pi^2}\frac{1}{n}, \tag{2.7}$$

$$\|T_n\| \;\leq\; \frac{1}{3n}(|z| + \|V\|); \tag{2.8}$$

(ii) *for $n \geq 1$ and $z \in \mathbb{C}$ with $|z| + \|V\| \;\leq\; n$,*

$$\|(A_n - z)^{-1}\| \;\leq\; \frac{2}{\pi^2}\frac{1}{n}. \tag{2.9}$$

Proof. (i) (2.7) follows from (2.5). Concerning (2.8) we prove $\|T_n\|_{HS} \leq \frac{1}{3n}(|z| + \|V\|)$ with $\|T_n\|_{HS}$ denoting the Hilbert–Schmidt norm of T (which leads to a stronger version of (2.8) as $\|T_n\| \leq \|T_n\|_{HS}$):

$$\begin{aligned} \|T_n\|^2_{HS} &= \sum_{j,k\in\mathbb{Z}(n)} \frac{|z\delta_{kj} - \hat{V}(k-j)|^2}{|\pi^2(k^2-n^2)|^2} \\ &\leq \sum_{k\in\mathbb{Z}(n)} \frac{1}{\pi^4}\frac{2|z|^2 + 2\|\hat{V}\|^2}{(k-n)^2(k+n)^2}. \end{aligned}$$

As

$$\sum_{k\neq\pm n}\frac{1}{(k-n)^2(k+n)^2}=\frac{1}{6}\left(\frac{\pi}{n}\right)^2-\frac{3}{8}\frac{1}{n^4}, \tag{2.10}$$

we conclude that $\|T_n\|_{HS}\leq\frac{1}{3n}(|z|+\|V\|)$.

(ii) If $\|T_n\|\leq\frac{1}{2}, (A_n-z)$ is invertible (cf. (2.6)) and

$$\|(A_n-z)^{-1}\| \;\leq\; 2\|D_n^{-1}\| \;\leq\; \frac{2}{\pi^2}\frac{1}{n}.$$

In view of (2.8), $\|T_n\|\leq 1/2$ for $|z|+\parallel V\parallel\leq n$. □

As an immediate consequence of Lemma 2.1, one obtains the following proposition.

PROPOSITION 2.2. *Let $n\geq 1$ and $z\in\mathbb{C}$ satisfy $|z|+\parallel V\parallel\leq n$. Then, for any choice of x^f, y^f in $\mathbb{C}$, (2.4) has a unique solution F*

$$F=(z-A_n)^{-1}(\mathcal{S}^n\hat{V})_{\mathbb{Z}(n)}x^f+(z-A_n)^{-1}(\mathcal{S}^{-n}\hat{V})_{\mathbb{Z}(n)}y^f. \tag{2.11}$$

Substituting the solution F, given by (2.11), into (2.2)–(2.3), one gets

$$\begin{pmatrix} -z+\alpha(-n,z) & \hat{V}(-2n)+\beta(-n,z)\\ \hat{V}(2n)+\beta(n,z) & -z+\alpha(n,z)\end{pmatrix}\begin{pmatrix} x^f\\ y^f\end{pmatrix}=\begin{pmatrix}0\\0\end{pmatrix}, \tag{2.12}$$

where, for $n\in\mathbb{Z}\backslash\{0\}$, satisfying $|z|+\|V\|\leq n$, we define, with $A_n:=A_{|n|}$,

$$\alpha(n,z):=[\mathcal{S}^{-n}J\hat{V},(z-A_n)^{-1}(\mathcal{S}^{-n}\hat{V})_{\mathbb{Z}(n)}]_{\mathbb{Z}(n)}, \tag{2.13}$$

$$\beta(n,z):=[\mathcal{S}^{-n}J\hat{V},(z-A_n)^{-1}(\mathcal{S}^{n}\hat{V})_{\mathbb{Z}(n)}]_{\mathbb{Z}(n)}. \tag{2.14}$$

In the following sections, the coefficients $\alpha(n,z)$ and $\beta(n,z)$ will be analyzed. Often, we will write $[\cdot,\cdot]$, for $[\cdot,\cdot]_{\mathbb{Z}(n)}$.

2.3. Identity for $\boldsymbol{\alpha(n,z)}$. Throughout this and the following section, we assume that $n\geq 1$ and $z\in\mathbb{C}$ are such that $|z|+\|V\|\leq n$. To simplify notation we drop the subindex n in A_n, B_n, D_n, and T_n with the understanding that n is fixed in this subsection. Denote by $(z-A)^t$ the transpose of $z-A, (z-A)^t(j,k):=(z-A)(k,j)(\forall k,j\in\mathbb{Z}(n))$.

LEMMA 2.3. (i) $J\mathcal{S}^n=\mathcal{S}^{-n}J$;

(ii) $(z-A)=J(z-A)^tJ$.

Proof. Part (i) is verified in a straightforward way. Regarding (ii), it is to prove that for $k,j\in\mathbb{Z}(n)$,

$$(z-A)(k,j)=(z-A)(-j,-k). \tag{2.15}$$

The identity (2.15) follows from the definition

$$(z-A)(k,j)=z\delta_{kj}-\pi^2(k^2-n^2)\delta_{kj}-\hat{V}(k-j)$$

and the identities

$$\delta_{kj}=\delta_{(-j)(-k)};\quad \hat{V}(k-j)=\hat{V}(-j-(-k)). \qquad □$$

We obtain the following identity for $\alpha(n,z)$.

LEMMA 2.4. $\alpha(n,z) = \alpha(-n,z)$.

Proof. With $(\mathcal{S}^{-n}\hat{V})_{\mathbb{Z}(n)} = \mathcal{S}^{-n}\hat{V}_{\mathbb{Z}\setminus\{0,2n\}}$ and $(z-A)^{-1} = (J(z-A)^tJ)^{-1} = J((z-A)^{-1})^tJ$ (Lemma 2.3) it follows that

$$\begin{aligned}\alpha(n,z) &= [\mathcal{S}^{-n}J\hat{V}, (J(z-A)^tJ)^{-1}\mathcal{S}^{-n}\hat{V}_{\mathbb{Z}\setminus\{0,2n\}}]_{\mathbb{Z}(n)} \\ &= [J\mathcal{S}^{n}\hat{V}, J((z-A)^{-1})^tJ\mathcal{S}^{-n}\hat{V}_{\mathbb{Z}\setminus\{0,2n\}}]_{\mathbb{Z}(n)} \\ &= [(z-A)^{-1}\mathcal{S}^{n}\hat{V}, J\mathcal{S}^{-n}\hat{V}_{\mathbb{Z}\setminus\{0,2n\}}]_{\mathbb{Z}(n)} \\ &= [\mathcal{S}^{n}J\hat{V}, (z-A)^{-1}\mathcal{S}^{n}\hat{V}]_{\mathbb{Z}(n)} \\ &= \alpha(-n,z). \qquad \square\end{aligned}$$

As a consequence of Lemma 2.4, the vanishing of the determinant of the 2 × 2 matrix in (2.12) leads to the following equation for z:

$$(z-\alpha(n,z))^2 - \Big(\hat{V}(2n)+\beta(n,z)\Big)\Big(\hat{V}(-2n)+\beta(-n,z)\Big) = 0. \tag{2.16}$$

Equation (2.16) is solved in two steps: for ζ given, we first solve the following equation, referred to as the z-equation, for z:

$$z = \alpha(n,z)+\zeta. \tag{2.17}$$

Substituting the solution $z = z(\zeta)$ of (2.17) into (2.16), we obtain the following equation for ζ, referred to as the ζ-equation:

$$\zeta^2 - \Big(\hat{V}(2n)+\beta(n,z(\zeta))\Big)\Big(\hat{V}(-2n)+\beta(-n,z(\zeta))\Big) = 0. \tag{2.18}$$

In the next four sections, (2.17) and (2.18) will be analyzed.

2.4. Estimates of $\alpha(n,z)$ and the z-equation (2.17).

In this section we solve (2.17), using the contractive mapping principle. For this purpose we need the following lemma.

LEMMA 2.5. *For $n \geq 1$ and $z \in \mathbb{C}$ satisfying $|z| + \|V\| \leq n$,*

(i) $|\alpha(n,z)| \leq \|V\|^2/3n$;

(ii) $|\frac{d}{dz}\alpha(n,z)| \leq \|V\|^2/9n^2$.

Proof. (i) By the definition (2.13) and Lemma 2.1,

$$|\alpha(n,z)| \leq \|V\|\|(z-A)^{-1}\|\,\|V\| \leq \frac{2}{\pi^2}\frac{1}{n}\|V\|^2.$$

(ii) Notice that

$$\frac{d}{dz}\alpha(n,z) = [\mathcal{S}^{-n}J\hat{V}, -(z-A)^{-2}\mathcal{S}^{-n}\hat{V}]_{\mathbb{Z}(n)},$$

and therefore,

$$\left|\frac{d}{dz}\alpha(n,z)\right| \leq \|V\|\|(z-A)^{-1}\|^2\|V\| \leq \frac{4}{\pi^4}\frac{1}{n^2}\|V\|^2. \qquad \square$$

Denote by $\mathcal{D}_M \equiv \mathcal{D}_M(0)$ the disc $\{z \in \mathbb{C} | |z| < M\}$ and denote by $\overline{\mathcal{D}_M}$ its closure.

Proposition 2.6. *Let $V \in L^2_0$. Then for any $M > 0$ and $n \geq 1$ satisfying $n \geq \|V\| + M$, and for any $\zeta \in \mathcal{D}_{M/2}$, the equation*

$$z = \zeta + \alpha(n, z) \tag{2.19}$$

has a unique solution $z_n = z_n(\zeta)$ in $\mathcal{D}_M$. The solution $z_n(\zeta)$ depends analytically on $\zeta \in \mathcal{D}_{M/2}$.

Proof. For $z \in \overline{\mathcal{D}_M}$,

$$|z| + \|V\| \leq M + \|V\| \leq n,$$

and thus, by Lemma 2.5, $|\alpha(n, z)| \leq M/3$. It follows that for $\zeta \in \mathcal{D}_{M/2}, z \in \overline{\mathcal{D}_M}$

$$|\zeta| + |\alpha(n, z)| \leq M/2 + M/3 < M.$$

Thus, for $\zeta \in \mathcal{D}_{M/2}$, $g(z) := \zeta + \alpha(n, z)$ defines a map on $\overline{\mathcal{D}_M}$ into $\overline{\mathcal{D}_M}$. Furthermore, g is a contraction, as for any $z_1, z_2 \in \mathcal{D}_M$

$$|g(z_1) - g(z_2)| < \frac{1}{9}|z_1 - z_2|,$$

where we used that by Lemma 2.5

$$\sup_{|z| \leq M} \left| \frac{d}{dz}\alpha(n, z) \right| \leq \frac{1}{9}\frac{1}{n^2}\|V\|^2 \leq \frac{1}{9}.$$

Hence there exists a fixed point $z = z(\zeta)$ of g with $|z| \leq M$, z with

$$\frac{dz}{d\zeta} = \left(1 - \frac{d\alpha}{dz}(n, z(\zeta))\right)^{-1} \quad \forall |\zeta| < M/2. \qquad \square$$

In a next step, we analyze (2.18). To obtain estimates for the coefficient $\beta(n, z)$ we need to establish bounds for the norm of the operator $T = (z - B)D^{-1}$ introduced in section 2.2, viewed as an operator on a weighted ℓ^2-space.

2.5. Estimates of norms of T_n. Recall that, with n arbitrary and fixed, $T \equiv T_n = (z - B)D^{-1} : \ell^2(\mathbb{Z}(n)) \to \ell^2(\mathbb{Z}(n))$ is a bounded operator (cf. (2.6)). If $V \in H^w_0, T$ can also be viewed as an element in $\mathcal{L}(\ell^2_{\mathcal{S}^{\pm n}w}(\mathbb{Z}(n)))$, where $\mathcal{S}^{\pm n}w$ is the shifted weight

$$(\mathcal{S}^{\pm n}w)(j) := w(\pm n + j). \tag{2.20}$$

Denote by $W_\pm : \ell^2_{\mathcal{S}^{\pm n}w}(\mathbb{Z}(n)) \to \ell^2(\mathbb{Z}(n))$ the diagonal operator given by

$$W_\pm(k, j) = w(k \pm n)\delta_{kj}.$$

Notice that $W_\pm : \ell^2_{\mathcal{S}^{\pm n}w}(\mathbb{Z}(n)) \to \ell^2(\mathbb{Z}(n))$ is an isometry. Therefore,

$$\|T_\pm\|_{\mathcal{L}(\ell^2)} = \|T_n\|_{\mathcal{L}(\ell^2_{\mathcal{S}^{\pm n}w})}, \tag{2.21}$$

where $T_\pm := W_\pm T_n W_\pm^{-1} : \ell^2(\mathbb{Z}(n)) \to \ell^2(\mathbb{Z}(n))$.

Lemma 2.7. *For $n \geq 1$*

$$\|T_n\|_{\mathcal{L}(\ell^2_{\mathcal{S}^{\pm n}w})} \leq \frac{|z| + \|V\|_w}{3n}.$$

Proof. In view of (2.21) it suffices to estimate the Hilbert–Schmidt norm of $T_\pm$ in $\mathcal{L}(\ell^2)$. As w is submultiplicative,

$$\frac{(\mathcal{S}^{\pm n}w)(j)}{(\mathcal{S}^{\pm n}w)(k)} \le w(j-k).$$

In view of (2.21), (2.6), and $\hat{V}(0) = 0$,

$$\begin{aligned}\|T_\pm\|_{HS}^2 &= \sum_{j,k\neq\pm n} \left|\frac{\mathcal{S}^{\pm n}w(j)}{\mathcal{S}^{\pm n}w(k)}\right|^2 |\hat{V}(j-k)|^2 \frac{1}{\pi^4|k^2-n^2|^2} \\ &\quad + \sum_{k\neq\pm n} |z|^2 \frac{1}{\pi^4|k^2-n^2|^2} \\ &\le (\|V\|_w^2 + |z|^2) \sum_{k\neq\pm n} \frac{1}{\pi^4} \frac{1}{(k-n)^2(k+n)^2} \\ &\le \frac{|z|^2+\|V\|_w^2}{9}\frac{1}{n^2},\end{aligned}$$

where in the last inequality, we again use (2.10). This estimate leads to $\|T_\pm\|_{HS} \le \frac{|z|+\|V\|_n}{3n}$. □

As an immediate consequence of Lemma 2.7 one obtains the following corollary.

COROLLARY 2.8. *For $n \ge 1$, and $z \in \mathbb{C}$ with $|z|+\|V\|_w \le n$, $Id-T_n$ is invertible and*

$$\|(Id-T_n)^{-1}\|_{\mathcal{L}(\ell^2_{\mathcal{S}^{\pm n}w})} \le 2.$$

Corollary 2.8 can be used to obtain an estimate of the solution F of the external equation established in Proposition 2.2. According to (2.11),

$$F = x^f F_+ + y^f F_-,$$

where

$$F_\pm = (z-A_n)^{-1}(\mathcal{S}^{\pm n}\hat{V})_{\mathbb{Z}(n)}. \tag{2.22}$$

COROLLARY 2.9. *For $n \ge 1$ and $z \in \mathbb{C}$ with $|z| + \|V\|_w \le n$,*

$$\|F_\pm\|_{\ell^2_{\mathcal{S}^{\pm n}w}} \le \frac{2}{\pi^2 n}\|V\|_w.$$

Proof. By (2.6), $(z-A_n)^{-1} = -D_n^{-1}(Id-T_n)^{-1}$, and by Corollary 2.8

$$\|(Id-T_n)^{-1}\|_{\mathcal{L}(\ell^2_{\mathcal{S}^{\pm n}w})} \le 2.$$

As D_n is the diagonal operator on $\ell^2(\mathbb{Z}(n))$ with coefficients $D_n(k,j) = \pi^2(k^2-n^2)\delta_{kj}$, we have

$$\|D_n^{-1}\|_{\mathcal{L}(\ell^2_{\mathcal{S}^{\pm n}w})} \le \frac{1}{\pi^2 n}.$$

Combining these estimates yields the claimed estimate. □

2.6. Estimate for $\boldsymbol{\beta(n,z)}$. Substitute, for $z \in \mathbb{C}$ satisfying $|z| + \|V\| \leq n$,

$$(z - A)^{-1} = -D^{-1} - D^{-1}T(Id - T)^{-1}$$

into the expression for $\beta(n,z)$ to obtain

$$\begin{aligned} \beta(n,z) &= \beta_1(n) + \beta_2(n,z) \\ &= \beta_1(n) + \beta_2(n,0) + z\int_0^1 \left(\frac{d}{dz}\beta\right)(n,tz)dt, \end{aligned} \tag{2.23}$$

where

$$\beta_1(n) := -[\mathcal{S}^{-n}J\hat{V}, D^{-1}(\mathcal{S}^n\hat{V})_{\mathbb{Z}(n)}]_{\mathbb{Z}(n)}, \tag{2.24}$$

$$\beta_2(n,z) := -[\mathcal{S}^{-n}J\hat{V}, D^{-1}T(Id - T)^{-1}(\mathcal{S}^n\hat{V})_{\mathbb{Z}(n)}]_{\mathbb{Z}(n)}. \tag{2.25}$$

The term $\beta_1(n)$ is independent of z and

$$\beta_1(n) = \frac{1}{\pi^2}\left(\frac{\hat{V}}{k} * \frac{\hat{V}}{k}\right)(2n), \tag{2.26}$$

or

$$\beta_1(n) = \frac{1}{\pi^2}\sum_{k \neq \pm n} \frac{\hat{V}(n-k)}{n-k}\frac{\hat{V}(n+k)}{n+k}, \tag{2.27}$$

where we use that $-D(k,j) = -\pi^2(k^2 - n^2)\delta_{kj} = \pi^2(n-k)(n+k)\delta_{kj}$. In the subsequent lemmas, $\beta_1(n), \beta_2(n,0)$, and $\frac{d}{dz}\beta(n,z)$ are estimated separately. Given the weight w and $\alpha > 1/2$, introduce a new weight $(w_\alpha(k))_{k\in\mathbb{Z}}$,

$$w_\alpha(k) := \left(1 + |\frac{k}{2}|\right)^\alpha w(k).$$

Notice that w_α is again symmetric and submultiplicative.

LEMMA 2.10. $(\sum_{n\in\mathbb{Z}} w_1(2n)^2\beta_1(n)^2)^{1/2} \leq \|V\|_w^2$.

Proof. By Lemmas A.1 and A.2 (in particular, Lemma A.2 for $\alpha = 1$) and (2.26),

$$\left(\sum_{n\in\mathbb{Z}} w_1(2n)^2\beta_1(n)^2\right)^{1/2} \leq \frac{1}{\pi^2}\left\|\frac{\hat{V}}{k} * \frac{\hat{V}}{k}\right\|_{w_1} \leq \frac{6}{\pi^2}\left\|\frac{\hat{V}}{k}\right\|_{w_1}^2 \leq \|\hat{V}\|_w^2. \qquad \square$$

LEMMA 2.11. *For* $|n| \geq n_w := M + \|V\|_w$,

$$(1 + |n|)w(2n)\sup_{|z|\leq M}|\beta_2(n,z)| \leq \frac{1}{3}\|V\|_w^2.$$

Proof. By (2.25), for any $|z| \leq M$ and $|n| \geq n_w$,

$$\begin{aligned} |\beta_2(n,z)| &= \frac{1}{\pi^2}\left|\left(\frac{\hat{V}}{k} * \frac{\mathcal{S}^{-n}T(Id-T)^{-1}(\mathcal{S}^n\hat{V})_{\mathbb{Z}(n)}}{k}\right)(2n)\right| \\ &\leq \frac{1}{\pi^2}\sum_{k\neq\pm n}\frac{|\hat{V}(n-k)|}{|n-k|}\frac{|a_{(n)}(n+k)|}{|n+k|}, \end{aligned} \tag{2.28}$$

where

$$a_{(n)}(k) := \mathcal{S}^{-n}T(Id-T)^{-1}(\mathcal{S}^n\hat{V})_{\mathbb{Z}(n)}(k), \quad (k \in \mathbb{Z}\backslash\{-2n, 0\}).$$

Using that $\|T\|_{\mathcal{L}(\ell^2_{\mathcal{S}^n w})} \leq \frac{M+\|V\|_w}{3|n|} = \frac{n_w}{3|n|}$ (Lemma 2.7) and $\|(Id-T)^{-1}\|_{\mathcal{L}(\ell^2_{\mathcal{S}^n_w})} \leq 2$ (Corollary 2.8), we conclude that

$$\|a_{(n)}\|_w \leq \frac{n_w}{3|n|}2\|V\|_w \leq \frac{2}{3}\|V\|_w. \tag{2.29}$$

As w_1 is submultiplicative, we then obtain from (2.28)

$$\begin{aligned}&(1+|n|)w(2n)|\beta_2(n,z)|\\ &\leq \frac{1}{\pi^2}\sum_{k\neq\pm n} 2w(n-k)|\hat{V}(n-k)|2w(n+k)|a_{(n)}(n+k)|\\ &\leq \frac{4}{\pi^2}\|V\|_w\|a_{(n)}\|_w \leq \frac{1}{3}\|V\|^2_w. \qquad \square\end{aligned}$$

Lemma 2.12.

$$\left(\sum_{|n|\geq n_w}(1+|n|)^4 w(2n)^2|\beta_2(n,0)|^2\right)^{1/2} \leq (1+n_w)\|V\|^3_w.$$

Proof. By (2.25),

$$\beta_2(n,0) = [\mathcal{S}^{-n}J\hat{V}, D^{-1}BD^{-1}(Id-T_{z=0})^{-1}(\mathcal{S}^n\hat{V})_{\mathbb{Z}(n)}]_{\mathbb{Z}(n)}.$$

Write $(Id-T_{z=0})^{-1} = Id + T_{z=0}(Id-T_{z=0})^{-1}$ to obtain $\beta_2(n,0) = \beta_3(n) + \beta_4(n)$ with

$$\begin{aligned}\beta_3(n) :=&[\mathcal{S}^{-n}J\hat{V}, D^{-1}BD^{-1}\mathcal{S}^n\hat{V})_{\mathbb{Z}(n)}]_{\mathbb{Z}(n)},\\ \beta_4(n) :=&[\mathcal{S}^{-n}J\hat{V}, D^{-1}BD^{-1}\mathcal{S}^n a_{(n)}]_{\mathbb{Z}(n)},\end{aligned}$$

and

$$a \equiv a_{(n)} := \mathcal{S}^{-n}T_{z=0}(Id-T_{z=0})^{-1}(\mathcal{S}^n\hat{V})_{\mathbb{Z}(n)}.$$

Let us first treat β_3. As w is submultiplicative,

$$w(2n) \leq w(n-k)w(n+k) \leq w(n-k)w(n+j)w(k-j),$$

one obtains, for $|n| \geq n_w$,

$$\begin{aligned}&(1+|n|)^2 w(2n)\beta_3(n)\\ &\leq \frac{1}{\pi^4}\sum_{\substack{k\neq\pm n\\ j\neq\pm n}}(1+|n|)^2\frac{w(n-k)|\hat{V}(n-k)|}{|n-k||n+k|}w(k-j)|\hat{V}(k-j)|\frac{w(n+j)|\hat{V}(n+j)|}{|n-j||n+j|}\\ &= \frac{1}{\pi^4}(R_1+R_2+R_3+R_4),\end{aligned} \tag{2.30}$$

where R_1, R_2, R_3, R_4 denote the partial sums corresponding to the index sets I_1, I_2, I_3, $I_4 \subseteq \{(k,j) \in \mathbb{Z}^2 | k \neq \pm n, j \neq \pm n\}$ defined as follows:

$$\begin{aligned} I_1 &:= \{|k-n| > |n|; \quad |j-n| > |n| \quad | \quad k, j \neq \pm n\},\\ I_2 &:= \{|k-n| > |n|; \quad |j-n| < |n| \quad | \quad k, j \neq \pm n\},\\ I_3 &:= \{|k-n| < |n|; \quad |j-n| > |n| \quad | \quad k, j \neq \pm n\},\\ I_4 &:= \{|k-n| < |n|; \quad |j-n| < |n| \quad | \quad k, j \neq \pm n\}. \end{aligned}$$

Let us first estimate $R_2(n)$. For k, j with $|k-n| > |n|, |j-n| < |n|$, one has $1 + |n| \leq |k-n|$ and $1 + |n| \leq |j+n|$, and thus,

$$\frac{(1+|n|)^2}{|k-n||j+n|} \leq \frac{|k-n|}{|k-n|}\frac{|j+n|}{|j+n|} \leq 1.$$

Therefore, $R_2(n)$ is bounded by

$$\sum_{(k,j)\in I_2} \frac{w(n-k)|\hat{V}(n-k)|}{|n+k|} w(k-j)|\hat{V}(k-j)| \frac{w(n+j)|\hat{V}(n+j)|}{|n-j|}. \tag{2.31}$$

Let $\xi(j) := w(j)|\hat{V}(j)|$. Then

$$\sum_{\substack{|j-n|<|n|\\ j\neq n}} \xi(k-j)\frac{\xi(n+j)}{|n-j|} = \sum_{\substack{|\ell-2n|<|n|\\ 2n-\ell\neq 0}} \xi(k+n-\ell)\frac{\xi(\ell)}{|2n-\ell|} \leq \rho. \tag{2.32}$$

Hence, for $h \in \ell_2(\mathbb{Z})$,

$$\begin{aligned} &\sum_{|n|\geq n_w} |h(n)| R_2(n) \leq \sum_{n,k,\ell} |h(n)| \frac{\xi(n+k)}{|k+n|} \frac{\xi(k+n-\ell)\xi(\ell)}{|2n-\ell|}\\ &= \sum_{n,k,\ell} \frac{h(n)\xi(k+n-\ell)}{2n-\ell} \frac{\xi(n-k)\xi(\ell)}{|k+n|}\\ &\leq \left(\sum_{n,k,\ell} \frac{|h(n)|^2 \xi(k+n-\ell)^2}{|2n-\ell|^2}\right)^{1/2} \left(\sum_{n,k,\ell} \frac{\xi(n-k)^2\xi(\ell)^2}{|k+n|^2}\right)^{1/2}\\ &\leq \left(\sum_{n,j,\ell} \frac{|h(n)|^2 \xi(j)^2}{|2n-\ell|^2}\right)^{1/2} \left(\sum_{j,\ell,n} \frac{\xi(j)^2\xi(\ell)^2}{|2n-j|^2}\right)^{1/2}\\ &\leq \cdot 2\|h\| \ \|\xi\| \cdot 2\|\xi\|^2 = 4\|h\| \ \|\xi\|^3. \end{aligned}$$

Thus we have proved that

$$\left(\sum_{|n|\geq n_w} R_2(n)^2\right)^{1/2} \leq 4\|\xi\|^3 \leq 4\|V\|_w^3.$$

Using the convolution estimate $\|U * V\|_{\ell^2} \leq \|U\|_{\ell^2}\|V\|_{\ell^1}$ one obtains, for $j = 1$, 3, and 4,

$$\left(\sum_{|n|\geq n_w} R_j(n)^2\right)^{1/2} \leq 4\|V\|_w^3.$$

Hence,

$$\begin{aligned}&\left(\sum_{|n|\geq n_w}(1+|n|)^4 w(2n)^2|\beta_3(n)|^2\right)^{1/2}\\ &\leq \frac{1}{\pi^4}4\cdot 4\cdot \|V\|_w^3 \leq \|V\|_w^3.\end{aligned}$$

To estimate $\beta_4(n)$ we proceed similarly. By definition,

$$\beta_4(n)=\sum_{k\neq\pm n}\hat{V}(n\leq k)\sum_{j\neq\pm n}\frac{1}{\pi^2(k^2-n^2)}\hat{V}(k-j)\frac{1}{\pi^2(j^2(j^2-n^2)}a(n+j),$$

whence

$$\begin{aligned}&(1+|n|)^2 w(2n)|\beta_4(n)|\\ &\leq \frac{1}{\pi^4}\sum_{\substack{k\neq\pm n\\ j\neq\pm n}}(1+|n|)^2\frac{w(n-k)\hat{V}(n-k)}{|n-k|\;|n+k|}w(k-j)\hat{V}(k-j)\frac{w(n+j)|a(n+j)|}{|n-j|\;|n+j|}\\ &=\frac{1}{\pi^4}(Q_1+Q_2+Q_3+Q_4),\end{aligned}$$

where Q_1, Q_2, Q_3, Q_4 denote the partial sums corresponding to the index sets I_1, I_2, I_3, I_4 defined above. Each of the four terms $Q_i = Q_i(n)(1 \leq i \leq 4)$ is estimated in the same way, so we concentrate only on one of them, say, Q_2. Similarly as in (2.31) we obtain

$$\sum_{(k,j)\in I_2}\frac{w(n-k)|\hat{V}(n-k)|}{|n+k|}w(k-j)|\hat{V}(k-j)|w(n+j)\frac{|a(n+j)|}{|n-j|}.$$

Let $\eta(j)\equiv\eta_{(n)}(j) := w(j)|a(j)|$ and $\xi(j) := w(j)|\hat{V}(j)|$. Then

$$\sum_{\substack{|j-n|<|n|\\ j\neq n}}\xi(k-j)\frac{\eta(n+j)}{|n-j|}=\sum_{\substack{|\ell-2n|<|n|\\ 2n-\ell\neq 0}}\xi(k+n-\ell)\frac{\eta(\ell)}{|2n-\ell|}\leq\delta_{(n)}(n+k),$$

where

$$\delta_{(n)}(k+n) := \sum_{\ell\neq 2n,0}\xi(k+n-\ell)\frac{\eta_{(n)}(\ell)}{|2n-\ell|}.$$

Using the convolution estimate $\|U * V\|_{\ell^2} \leq \|U\|_{\ell^2}\|V\|_{\ell^1}$ one concludes that (with $2\cdot\sum_{j\geq 1}\frac{1}{j^2} = 2\cdot\frac{\pi^2}{6} < 4$)

$$\|\delta_{(n)}\|_{\ell^2}\leq\|\eta_{(n)}\|_{\ell^2}\|\xi\|_{\ell^2}\left(\sum_{j\neq 0}\frac{1}{j^2}\right)^{1/2}\leq 2\|\eta_{(n)}\|_{\ell^2}\|\xi\|_{\ell^2}.$$

As $\|T_{Z=0}\|_{\mathcal{L}(\ell^2_{\mathcal{S}^n w})} \leq \frac{n_w}{3|n|}$ (Lemma 2.7) and $\|(Id{-}I_{Z=0})^{-1}\|_{\mathcal{L}(\ell^2_{\mathcal{S}^n w})} \leq 2$ (Corollary 2.8), one has

$$\|\eta_{(n)}\|_{\ell^2}\leq\frac{nw}{3|n|}1\|V\|_w,\quad(\forall|n|\geq n_w).$$

Hence,

$$\|\delta_{(n)}\|_{\ell^2} \le \frac{4n_w}{3|n|}\|V\|_w^2, \quad (\forall |n| \ge n_w).$$

This leads to

$$Q_2(n) \le \sum_{\substack{|k-n|>|n| \\ k\neq -n}} \xi(n-k)\frac{\delta_{(n)}(k+n)}{|k+n|} \le \|\xi\|_{\ell^2}\frac{4n_w}{3|n|}\|V\|_w^2 \cdot 2,$$

and hence,

$$\begin{aligned}\left(\sum_{|n|\ge w_w} Q_2(n)^2\right)^{1/2} &\le \frac{8n_w}{3}\|V\|_w^3\left(\sum_{|n|\ge n_w}\frac{1}{n^2}\right)^{1/2} \\ &\le \frac{16n_w}{3}\|V\|_w^3.\end{aligned}$$

Similar estimates hold for Q_1, Q_3, and Q_4, and thus,

$$\begin{aligned}&\left(\sum_{|n|\ge n_w}(1+|n|)^4 w(2n)^2|\beta_4(n)|^2\right)^{1/2} \\ &\le 4\cdot\frac{1}{\pi^4}\cdot\frac{16n_w}{3}\|V\|_w^3.\end{aligned}$$

Combined with the estimate for $\beta_3(n)$, this leads to the claimed statement. ∎

LEMMA 2.13.

$$\left(\sum_{|n|\ge n_w}(1+|n|)^4 w(2n)^2 \sup_{|z|\le M}\left|\frac{d}{dz}\beta(n,z)\right|^2\right)^{1/2} \le 2(1+n_w)^{1/2}\|V\|_w^2.$$

Proof. Let $\eta(n,z) := \frac{d}{dz}\beta(n,z)$ and notice that

$$\eta(n,z) = -[\mathcal{S}^{-n}J\hat{V}, (z-A)^{-2}(\mathcal{S}^n\hat{V})_{\mathbb{Z}(n)}]_{\mathbb{Z}(n)}.$$

Recall that $(z-A)^{-1} = -D^{-1}(Id-T)^{-1} = -D^{-1} - D^{-1}T(Id-T)^{-1}$ and thus

$$\begin{aligned}(z-A)^{-2} &= \left(-D^{-1} - D^{-1}T(Id-T)^{-1}\right)(z-A)^{-1} \\ &= D^{-2} + D^{-2}T(Id-T)^{-1} - D^{-1}T(Id-T)^{-1})(z-A)^{-1} \\ &= D^{-2} + D^{-2}T(Id-T)^{-1} + D^{-1}T(Id-T)^{-1}D^{-1}(Id-T)^{-1}.\end{aligned}$$

This is used to write $\eta(n,z)$ as a sum,

$$\eta(n,z) = \eta_1(n) + \eta_2(n,z) + \eta_3(n,z),$$

where

$$\begin{aligned}\eta_1(n) &:= -\,[\mathcal{S}^{-n}J\hat{V}, D^{-2}(\mathcal{S}^n\hat{V})_{\mathbb{Z}(n)}]_{\mathbb{Z}(n)}, \\ \eta_2(n,z) &:= -\,[\mathcal{S}^{-n}J\hat{V}, D^{-2}T(Id-T)^{-1}(\mathcal{S}^n\hat{V})_{\mathbb{Z}(n)}]_{\mathbb{Z}(n)}, \\ \eta_3(n,z) &:= -\,[\mathcal{S}^{-n}J\hat{V}, D^{-1}T(Id-T)^{-1}D^{-1}(Id-T)^{-1}(\mathcal{S}^n\hat{V})_{\mathbb{Z}(n)}]_{\mathbb{Z}(n)}.\end{aligned}$$

The three terms η_1, η_2, and η_3 are estimated separately. The coefficient η_1 is independent of z and

$$\eta_1(n) = \frac{1}{\pi^4}\left(\frac{\hat{V}}{k^2} * \frac{\hat{V}}{k^2}\right)(2n) = \frac{1}{\pi^4}\sum_{k\neq\pm n}\frac{\hat{V}(n-k)}{(n-k)^2}\frac{\hat{V}(n+k)}{(n+k)^2}.$$

Hence, by Lemmas A.1 and A.2 (cf. formula (A.2) for $\alpha = 2$),

$$\left(\sum_{n\in\mathbb{Z}} w_2(2n)^2\eta_1(n)^2\right)^{1/2} \le \frac{1}{\pi^4}\left\|\frac{\hat{V}}{k^2} * \frac{\hat{V}}{k^2}\right\|_{w_2} \le \frac{6}{\pi^4}\left\|\frac{\hat{V}}{k^2}\right\|_{w_2}^2 \le \frac{6}{\pi^4}\|\hat{V}\|_w^2. \tag{2.33}$$

To estimate $\eta_2(n,z)$, introduce, for $|z| \le M, |n| \ge n_w$, and $k \in \mathbb{Z}\backslash\{-2n, 0\}$,

$$a(k,z) \equiv a_{(n)}(k,z) := -\mathcal{S}^{-n}T(Id-T)^{-1}(\mathcal{S}^n\hat{V})_{\mathbb{Z}(n)}(k).$$

Then $\|T\|_{\mathcal{L}(\ell^2_{\mathcal{S}^n_w})} \le \frac{n_w}{3|n|}$ (Lemma 2.7) and $\|(Id-T)^{-1}\|_{\mathcal{L}(\ell^2_{\mathcal{S}^n_w})} \le 2$ (Corollary 2.8); hence

$$\|a_{(n)}\|_w \le \frac{n_w}{3|n|}2\|V\|_w,$$

and, as $w_2(n) = (1+|n|)^2w(2n)$ is submultiplicative,

$$\begin{aligned}(1+|n|)^2w(2n)|\eta_2(n,z)| &\le \frac{1}{\pi^4}\left|\frac{\hat{V}}{k^2} * \frac{a_{(n)}}{k^2}\right|(2n)\\ &\le \frac{1}{\pi^4}\sum_{k\neq\pm n}\frac{(1+|n-k|)^2}{|n-k|^2}w(n-k)|\hat{V}(n-k)|\frac{(1+|n+k|)^2}{|n+k|^2}|a_{(n)}(n+k)|\\ &\le \frac{4^2}{\pi^4}\|V\|_w\|a_{(n)}\|_w \le \frac{4^2}{\pi^4}\frac{2}{3}\frac{n_w}{|n|}\|V\|_w^2\end{aligned}$$

and

$$\begin{aligned}&\left(\sum_{|n|\ge n_w}(1+|n|)^4w(2n)^2\sup_{|z|\le M}|\eta_2(n,z)|^2\right)^{1/2}\\ &\le \frac{4^2}{\pi^4}\frac{2}{3}\|V\|_w^2\left(n_w^2\sum_{|n|\ge n_w}\frac{1}{n^2}\right)^{1/2} \le \frac{4^2}{\pi^4}\frac{2}{3}(2(1+n_w))^{1/2}\|V\|_w^2 \le \frac{4^2}{\pi^4}(1+n_w)^{1/2}\|V\|_w^2.\end{aligned} \tag{2.34}$$

Hence, we used that $N^2\sum_{|n|\ge N}\frac{1}{n^2} \le 2N^2(\frac{1}{N^2} + \int_N^\infty\frac{dx}{x^2}) = 2(1+N)$. To estimate $\eta_3(n,z)$, we proceed in the same way as for $\eta_2(n,z)$. Introduce, for $|z| \le M, |n| \ge n_w$, and $k \in \mathbb{Z}\backslash\{-2n, 0\}$,

$$a(k,z) \equiv a_{(n)}(k,z) = \mathcal{S}^{-n}T(Id-T)^{-1}D^{-1}(Id-T)^{-1}(\mathcal{S}^n\hat{V})_{\mathbb{Z}(n)}(k).$$

Then, by Lemma 2.7 and Corollary 2.8,

$$\|a_{(n)}\|_w \le \frac{n_w}{3|n|} 2 \frac{1}{\pi^2|n|} 2\|V\|_w,$$

where we use that $|D_{kk}^{-1}| = \frac{1}{\pi^2|n^2-k^2|} \le \frac{1}{\pi^2|n|}$ $\forall k \in \mathbb{Z}(n)$. As w_2 is submultiplicative,

$$\begin{aligned}
&(1+|n|)^2 w(2n)|\eta_3(n,z)| \le \frac{1+|n|}{\pi^2} \left| \frac{\hat{V}}{k} * \frac{a(n)}{k} \right| (2n) \\
&\le \frac{1+|n|}{\pi^2} \sum_{k \neq \pm n} \frac{1+|n-k|}{|n-k|} w(n-k)|\hat{V}(n-k)| \frac{1+|n-k|}{|n+k|} w(n+k)|a_{(n)}(n+k)| \\
&\le \frac{4}{\pi^2}(1+|n|)\|V\|_w \|a_{(n)}\|_w \\
&\le \frac{4^2}{\pi^4} \frac{1}{3} \frac{|n|+1}{|n|} \frac{n_w}{|n|} \|V\|_w^2
\end{aligned}$$

and, with

$$\begin{aligned}
&\left(\sum_{|n| \ge n_w} \left(\frac{1+|n|}{n^2} \right)^2 \right)^{1/2} \le \sqrt{2} \left(\left(\frac{1+n_w}{n_w^2} \right)^2 + \int_{n_w}^{\infty} \left(\frac{1}{x^4} + \frac{2}{x^3} + \frac{1}{x^2} \right) dx \right)^{1/2} \\
&\quad \le 4 n_w^{-1/2},
\end{aligned}$$

one obtains

$$\begin{aligned}
&\left(\sum_{|n| \ge n_w} (1+|n|)^4 w(2n)^2 \sup_{|z| \le M} |\eta_3(n,z)|^2 \right)^{1/2} \\
&\quad \le \frac{4^3}{\pi^4} \frac{1}{3} \frac{4}{\sqrt{n_w}} n_w \|V\|_w^2 \le \frac{4^4 n_w^{1/2}}{3\pi^4} \|V\|_w^2.
\end{aligned} \tag{2.35}$$

Combining (2.34)–(2.35), we get

$$\begin{aligned}
&\left(\sum_{|n| \ge n_w} (1+|n|)^4 w(2n)^2 \sup_{|z| \le M} \left| \frac{d}{dz} \beta(n,z) \right|^2 \right)^{1/2} \\
&\le \frac{6 + 4^2 + 4^{4/3}}{\pi^4} (n_w+1)^{1/2} \|V\|_w^2 \le 2(n_w+1)^{1/2} \|V\|_w^2. \qquad \square
\end{aligned}$$

The previous lemmas lead us to the following main result of this section.

PROPOSITION 2.14. *The following statements hold:*

(i) $\left(\sum_{|n| \ge n_w} (1+|n|)^4 w(2n)^2 \sup_{|z| \le M} |\beta_2(n,z)|^2 \right)^{1/2} \le 2(1+n_w)^{3/2} \|V\|_w^2,$

(ii) $\left(\sum_{|n| \ge n_w} (1+|n|)^2 w(2n)^2 |\beta_1(n)|^2 \right)^{1/2} \le \|V\|_w^2,$

(iii) $\left(\sum_{|n| \ge n_w} (1+|n|)^2 w(2n)^2 \sup_{|z| \le M} |\beta(n,z)|^2 \right)^{1/2} \le 2(1+n_w)^{3/2} \|V\|_w^2.$

Proof. (i) By (2.23), for $|z| \le M$,

$$|\beta_2(n,z)| \le |\beta_2(n,0)| + M \sup_{|z| \le M} \left| \frac{d}{dz} \beta(n,z) \right|$$

with $M + \|V\|_w = n_w$

$$\begin{aligned}&\left(\sum_{|n|\ge n_w}(1+|n|)^4 w(2n)^2 \sup_{|z|\le M}|\beta_2(n,z)|^2\right)^{1/2}\\ &\le \|V\|_w^3 + 2M(1+n_w)^{1/2}\|V\|_w^2\\ &\le \|V\|_w^2(\|V\|_w + 2M)(1+n_w)^{1/2};\end{aligned}$$

(ii) Lemma 2.10;

(iii) It follows from conditions (i) and (ii). □

2.7. The ζ-equation. In this section, we analyze the ζ-equation, stated in (2.18),

$$\zeta^2 - \left(\hat{V}(2n) + \beta(n, z(\zeta))\right)\left(\hat{V}(-2n) + \beta(-n, z(\zeta))\right) = 0. \tag{2.36}$$

Given $M > 0$ and $V \in L_0^2$, define

$$r_n := \max_{\varepsilon=\pm1}|\hat{V}(\varepsilon 2n)| + \max_{\varepsilon=\pm1}|\beta_1(\varepsilon n)| + \max_{\substack{|z|\le M\\ \varepsilon=\pm1}}|\beta_2(\varepsilon n, z)|, \tag{2.37}$$

and let $n_* := M + \|V\|$. By Lemmas 2.10 and 2.11, applied for the weight $w = 1$,

$$r_n \le \|V\| + 2\|V\|^2 \quad \forall n \text{ with } |n| \ge n_*.$$

Proposition 2.15. *Assume that $M > 0$ satisfies*

$$3(1+\|V\|)^2 \le \frac{M}{4}. \tag{2.38}$$

Then, for $n \ge n_*, \zeta$-equation (2.36) *has exactly two (counted with multiplicity) solutions in the disc $\overline{\mathcal{D}_{r_n}}$.*

Notation. We label these two solutions by ζ_n^+, ζ_n^- in an arbitrary way, but then we keep them fixed.

Proof. Clearly, $\zeta^2 = 0$ has precisely two roots in any disc $\mathcal{D}_r$. For $|\zeta| = Kr_n$ with $1 < K < 2$ close to 1 and any $n \ge n_*$, by (2.37) and (2.23),

$$\sup_{|z|\le M}|\left(\hat{V}(2n) + \beta(n,z)\right)\left(\hat{V}(-2n) + \beta(-n,z)\right)| \le r_n^2 < |\zeta|^2 \tag{2.39}$$

and $|\zeta| < 2r_n \le \frac{M}{2}$. Taking into account (2.38), it follows from Proposition 2.6 that $z_n(\zeta) \in \mathcal{D}_M$ depends analytically on ζ for $|\zeta| < M/2$ and $n \ge n_*$. Therefore, the left side of (2.36), denoted by $g(\zeta)$, is an analytic function of ζ in $\mathcal{D}_{M/2}$ and, by (2.39),

$$g(\zeta) = \zeta^2 + g_1(\zeta)\ ; \quad |g_1(\zeta)| < |\zeta|^2 \quad \text{for } |\zeta| \le \frac{M}{2}.$$

Therefore, by Rouché's theorem, (2.36) has precisely two roots in $\mathcal{D}_{Kr_n}$. As the two roots are independent of K, and $1 < K < 2$ is arbitrarily close to 1, we conclude that $\zeta_n^\pm \in \overline{\mathcal{D}_{r_n}}$. □

Let, for $n \ge n_*$,

$$z_n^\pm := z(\zeta_n^\pm) = \zeta_n^\pm + \alpha(n, z(\zeta_n^\pm)), \tag{2.40}$$

where $\zeta_n^\pm$ are the two solutions of (2.36), given by Proposition 2.15, and define

$$\lambda_n^\pm := n^2\pi^2 + z_n^\pm. \tag{2.41}$$

Then $\lambda_n^\pm$ is a pair of periodic eigenvalues, $\lambda_n^\pm \in spec_{per}(-\frac{d^2}{dx^2}+V)$. In the next section we want to deduce estimates for the gap length sequence $(\lambda_n^+ - \lambda_n^-)_{n\geq 1}$.

2.8. Gap length estimates.

PROPOSITION 2.16. *Assume that $M > 0$ satisfies*

$$3(1+\|V\|_w)^2 \leq \frac{M}{4}.$$

Then, with $n_w := M + \|V\|_w$,

$$\left(\sum_{n\geq n_w} w(2n)^2|\lambda_n^+ - \lambda_n^-|^2\right)^{1/2} \leq 8(1+n_w)^{3/2}(1+\|V\|_w)^2.$$

Remark. With $N := 13(1+\|V\|_w)^2, K_1 = 500$ and $K_2 = 5$. Proposition 2.16 gives Theorem 1.1.

Proof. Notice that, for $n \geq n_w$, by (2.19),

$$|\lambda_n^+ - \lambda_n^-| = |z_n^+ - z_n^-| \leq |\zeta_n^+ - \zeta_n^-| + \sup_{|z|\leq M}\left|\frac{d}{dz}\alpha(n,z)\right| |z_n^+ - z_n^-|. \tag{2.42}$$

By Lemma 2.5, (as $|z| + \|V\| \leq M + \|V\|_w = n_w \leq n$),

$$\left|\frac{d}{dz}\alpha(n,z)\right| \leq \frac{\|V\|^2}{9n^2} \leq \frac{\|V\|^2}{9n_w^2} \leq \frac{1}{9}. \tag{2.43}$$

Substituting the estimate (2.43) into (2.42) yields

$$\frac{1}{2}|z_n^+ - z_n^-| \leq |\zeta_n^+ - \zeta_n^-|.$$

As $|\zeta_n^+ - \zeta_n^-| \leq |\zeta_n^+| + |\zeta_n^-| \leq 2r_n$, with r_n defined by (2.37), we then conclude that, for $n \geq n_w$,

$$|z_n^+ - z_n^-| \leq 4r_n.$$

In view of Proposition 2.14,

$$\left(\sum_{n\geq n_w} w(2n)^2 r_n^2\right)^{1/2} \leq 4\cdot 2(1+n_w)^{3/2}(1+\|V\|_w)^2. \qquad \square$$

2.9. Gap length asymptotics. In this section, we obtain the first two terms in the asymptotics of $\lambda_n^+ - \lambda_n^-$ for $n \to \infty$. Let

$$\begin{aligned} &\rho(\pm n) := \hat{V}(\pm 2n) + \beta_1(\pm n), \\ &\eta(z) \equiv \eta(n,z) := \beta_2(-n,z)\rho(n) + \beta_2(n,z)\rho(-n) + \beta_2(-n,z)\beta_2(n,z), \end{aligned} \tag{2.44}$$

where the decomposition $\beta(\pm n, z) = \beta_1(\pm n) + \beta_2(\pm n, z)$ has been defined in (2.24)–(2.25). Then (2.36) can be written as

$$\zeta^2 - \rho(n)\rho(-n) - \eta(z(\zeta)) = 0. \tag{2.45}$$

Lemma 2.17. *Assume that $M > 0$ satisfies $3(1 + \|V\|_w)^2 \leq \frac{M}{4}$. Then the following estimates hold:*

(i) $|\rho(n)| \leq \frac{M}{4} \quad \forall n$; $\|\varrho\|_w \leq \|V\|_w + \|V\|_w^2$;

(ii) $\left(\sum_{n \geq n_w} (1 + |n|)^2 w(2n)^2 \sup_{|z| \leq M} |\eta(n, z)|\right)^{1/2} \leq 4(1 + n_w)^{3/2}(1 + \|V\|_w)^2$.

Proof. (i) By Lemma 2.10, $|\beta_1(n)| \leq \|V\|^2$, and therefore,

$$|\rho(n)| \leq 2(1 + \|V\|)^2 \leq \frac{M}{4}.$$

Moreover, we have $\|\varrho\|_w < \|V\|_w + \|V\|_w^2$. (ii) By the definition of $\eta(n, z)$, and Proposition 2.14(i)

$$\begin{aligned}
&\sum_{n \geq n_w} (1 + |n|)^2 w(2n)^2 \sup_{|z| \leq M} |\eta(n, z)| \\
&\leq 2 \left(\sum_{|n| \geq n_w} (1 + |n|)^4 w(2n)^2 \sup_{|z| \leq M} |\beta_2(n, z)|^2 \right)^{1/2} 2(1 + \|V\|_w)^2 \\
&+ \sum_{n \geq n_w} (1 + |n|)^2 w(2n)^2 \sup_{|z| \leq M} |\beta_2(n, z)|^2 \\
&\leq 4(1 + \|V\|_w)^2 \cdot 2(1 + n_w)^{3/2}(1 + \|V\|_w)^2 + 4(1 + n_w)^3(1 + \|V\|_w)^4 \\
&\leq 12(1 + n_w)^3(1 + \|V\|_w)^4. \qquad \square
\end{aligned}$$

Lemma 2.18. *Assume that $M > 0$ satisfies $3(1 + \|V\|_w)^2 \leq \frac{M}{4}$. Then, for $n \geq n_w$, either of the two roots $\hat{\zeta} \in \{\zeta_n^\pm\}$ satisfies*

$$\min_{\pm} |\hat{\zeta} \pm (\rho(n)\rho(-n))^{1/2}| \leq 5 \sup_{|z| \leq M} |\eta(z)|^{1/2}.$$

Proof. Choose an arbitrary root R of $R^2 = \rho(n)\rho(-n)$ and let $s := \sup_{|z| \leq M} |\eta(z)|$. We distinguish the following two cases.

Case 1: $|R^2| \leq 4s$: we have, with $\hat{z} = z_n^\pm$ for $\hat{\zeta} = \zeta_n^\pm$,

$$\begin{aligned}
|(\hat{\zeta} \pm R)^2| &\leq 2|\hat{\zeta}^2| + 2|R^2| \\
&\leq 2|R^2| + 2|\eta(\hat{z})| + 2|R^2| \\
&\leq 4|R^2| + 2|\eta(\hat{z})| \leq 18s \leq (5s^{1/2})^2.
\end{aligned}$$

Case 2: $|R^2| > 4s$: in this case, $|R^2| > 0$ and (2.45) can be rewritten as

$$\zeta^2 = R^2 \left(1 + \frac{\eta(z(\zeta))}{R^2}\right), \tag{2.46}$$

where $z(\zeta)$ is a solution of the z-equation (2.17). Let $\xi := \frac{\zeta}{R}$. Then, (2.46) can be written as

$$\xi^2 = 1 + \frac{\eta(z(\zeta))}{R^2}. \tag{2.47}$$

By assumption, $|R^2| > 4s$ and, as $|z(\zeta)| \leq M$, $|\eta(z(\zeta))/R^2| \leq \frac{1}{4}$. Denoting by $(1+w)^{1/2}$ the branch of the square root determined by $1^{1/2} = 1$, we obtain the equations

$$\xi = F_{\pm}(\xi), \tag{2.48}$$

where $F_{\pm}(\xi) := \pm(1 + \frac{\eta(z)}{R^2})^{1/2}$, with $z \equiv z(R\xi)$. Let us first consider the equation $\xi = F_+(\xi)$. Let $\mathcal{D}_{\frac{1}{4}}(1) := \{\xi \in \mathbb{C} \quad | \quad |\xi - 1| < \frac{1}{4}\}$ and notice that, for $\xi \in \overline{\mathcal{D}_{\frac{1}{4}}(1)}, \zeta = R\xi$ satisfies $|\zeta| \leq \frac{M}{4}\frac{5}{4} < \frac{M}{2}$, where we used the estimate $|R| \leq \frac{M}{4}$ of Lemma 2.17(i). According to Proposition 2.6, $z = \zeta + \alpha(n, z)$ has a unique solution $z(\zeta) \in \mathcal{D}_M$. This shows that $F_+(\xi) = (1 + \frac{\eta(z(R\xi))}{R^2})^{1/2}$ is well defined for $\xi \in \overline{\mathcal{D}_{1/4}(1)}$.

As $|(1+x)^{1/2} - 1| \leq \frac{2}{3}|x|$ for $x \in \overline{\mathcal{D}_{1/4}(0)}$ and $|R^2| > 4s$, we conclude that F_+ maps $\overline{\mathcal{D}_{1/4}(1)}$ into itself. Furthermore, F_+ is continuous, and therefore, by Brower's fixed point theorem, $\xi = F_+(\xi)$ admits at least one fixed point $\xi^I \in \overline{\mathcal{D}_{1/4}(1)}$,

$$\xi^I = F_+(\xi^I) = \left(1 + \frac{\eta(z^I)}{R^2}\right)^{1/2},$$

where $z^I = z(R\xi^I)$ and ξ^I satisfies the estimate

$$|\xi^I - 1| \leq \left|\left(1 + \frac{\eta(z^I)}{R^2}\right)^{1/2} - 1\right| \leq \frac{2}{3}\left|\frac{\eta(z^I)}{R^2}\right| \leq \frac{2}{3} \cdot \frac{1}{2}\frac{s^{1/2}}{|R|},$$

where, for the last inequality, we used that $|R^2| > 4s$. Hence, $\zeta^I := R\xi^I$ satisfies

$$|\zeta^I - R| \leq \frac{1}{2}\sup_{|z| \leq M}|\eta(z)|^{1/2} = \frac{1}{2}s^{1/2}.$$

The same arguments can be used to show that there exists a solution $\xi^{II} \in \overline{\mathcal{D}_{1/4}(-1)}$ of the equation $\xi = F_-(\xi)$ so that $\zeta^{II} := R\xi^{II}$ satisfies

$$|\zeta^{II} + R| \leq \frac{1}{2}\sup_{|z| \leq M}|\eta(z)|^{1/2} = \frac{1}{2}s^{1/2}.$$

Therefore, with $2|R| \geq 4s^{1/2}$

$$\begin{aligned} |\zeta^I - \zeta^{II}| &= |2R - (R - \zeta^I) - (\zeta^{II} + R)| \\ &\geq 2|R| - \frac{1}{2}S^{1/2} - \frac{1}{2}S^{1}2 \geq 3S^{1/2} > 0; \end{aligned} \tag{2.49}$$

hence, $\zeta^I \neq \zeta^{II}$. Moreover, ζ^I and ζ^{II} are solutions of (2.45) and thus satisfy, in view of (2.36),

$$|\zeta^I|, |\zeta^{II}| \leq r_n := \max_{\pm}|\hat{V}(\pm 2n)| + \max_{\pm}|\beta_1(\pm n)| + \max_{|z| \leq M}|\beta_2(\pm n, z)|.$$

Therefore, by Proposition 2.15, $\{\zeta^I, \zeta^{II}\} = \{\zeta_n^+, \zeta_n^-\}$. □

For later use, we state the following application of Lemma 2.18.

COROLLARY 2.19. *Let $V \in H_0^w$ be a 1-periodic potential. Then for M with $3(1+\|V\|_w)^2 \leq \frac{M}{4}$,*

$$\left(\sum_{h\geq n_w} w(2n)^2|\zeta_n^\pm|^2\right)^{1/2} \leq 9(1+n_w)^{3/2}(1+\|V\|_w)^4.$$

Proof. By (2.45)

$$\begin{aligned}&\left(\sum_{n\geq n_w} w(2n)^2|\zeta_n^\pm|^2\right)^{1/2}\\ &\leq \left(\sum_{n\geq n_w} w(2n)^2|\rho(n)\rho(-n)|\right)^{1/2} + \left(\sum_{n\geq n_w} w(2n)^2 \sup_{|z|\leq M}|\eta(n,z)|\right)^{1/2}.\end{aligned}$$

By Lemma 2.17,

$$\left(\sum_{n\geq n_w} w(2n)^2 \sup_{|z|\leq M}|\eta(n,z)|\right)^{1/2} \leq 4(1+n_w)^{3/2}(1+\|V\|_w)^2$$

and, with $\rho(n) = \hat{V}(2n) + \beta_1(n)$,

$$\begin{aligned}&\left(\sum_{n\geq n_w} w(2n)^2|\rho(n)\rho(-n)|\right)^{1/2}\\ &\leq \left(\sum_{n\geq n_w} w(2n)^2|\rho(n)|^2\right)^{1/2}\left(\sum_{n\geq n_w} w(2n)^2|\rho(-n)|^2\right)^{1/2}\\ &\leq (\|V\|_w + \|V\|_w^2)^2 \leq (1+\|V\|_w)^4,\end{aligned}$$

where we have used Lemma 2.17. □

Recall that $\lambda_n^\pm = n^2\pi^2 + z_n^\pm$ denote periodic eigenvalues of the operator $-\frac{d^2}{dx^2}+V$ and $\rho(\pm n)$ have been defined in (2.44).

THEOREM 2.20. *Let $V \in H_0^w$ be 1-periodic. Then, for any $M > 0$ with $3(1+\|V\|_w)^2 \leq \frac{M}{4}$ and $n_w = M + \|V\|_w$,*

$$\begin{aligned}&\left(\sum_{n\geq n_w}(1+|n|)^2 w(2n)^2\left(\min_{\pm}\left((\lambda_n^+-\lambda_n^-)\pm 2(\rho(n)\rho(-n))^{1/2}\right)\right)^2\right)^{1/2}\\ &\leq 50(1+n_w)^{3/2}(1+\|V\|_w)^4. \qquad (2.50)\end{aligned}$$

Remark. With $N := 13(1+\|V\|_w)^2, K_3 := 10^6$, and $K_4 := 14$, Theorem 2.20 gives Theorem 1.2.

Proof. For $n \geq n_w, \lambda_n^+ - \lambda_n^- = z_n^+ - z_n^-$. Furthermore, $z_n^\pm = \zeta_n^\pm + \alpha(n, z_n^\pm)$ and, by

Lemma 2.18 $\min_\pm|(\zeta_n^+-\zeta_n^-)\pm 2(\rho(n)\rho(-n))^{1/2}| \le 10\sup_{|z|\le M}|\eta(n,z)|^{1/2}$. Therefore,

$$\begin{aligned}&\min_\pm|(\lambda_n^+-\lambda_n^-)\pm 2(\rho(n)\rho(-n))^{1/2}|\\&\le \min_\pm|(\zeta_n^+-\zeta_n^-)\pm 2(\rho(n)\rho(-n))^{1/2}| + \left(\sup_{|z|\le M}\left|\frac{d}{dz}\alpha(n,z)\right|\right)|z_n^+-z_n^-|\\&\le 10\sup_{|z|\le M}|\eta(n,z)|^{1/2}+\frac{\|V\|^2}{n^2}|z_n^+-z_n^-|,\end{aligned}$$

where for the last inequality we used Lemma 2.5(ii). By Lemma 2.17(ii) (estimate for $\sup_{|z|\le M}|\eta(n,z)|^{1/2}$) and by Proposition 2.16 (estimate for $|z_n^+-z_n^-|=|\lambda_n^+-\lambda_n^-|$),

$$\begin{aligned}&\left(\sum_{n\ge n_w}(1+|n|)^2w(2n)^2\min_\pm|(\lambda_n^+-\lambda_n^-)\pm 2(\rho(n)\rho(-n))^{1/2}|^2\right)^{1/2}\\&\le 10\left(4(1+n_w)^{3/2}(1+\|V\|_w)^2\right)\\&+\|V\|^2\left(\sum_{n\ge n_w}\frac{(1+n)^2}{n^4}w(2n)^2|z_n^+-z_n^-|^2\right)^{1/2}\\&\le 40(1+n_w)^{3/2}(1+\|V\|_w)^2+\|V\|_w^2 8(1+n_w)^{3/2}(1+\|V\|_w)^2\\&\le 50(1+n_w)^{3/2}(1+\|V\|_w)^4. \qquad \square\end{aligned}$$

3. Eigenfunctions and Riesz's spaces.

3.1. Eigenfunctions. In this section we review the estimates of the Fourier coefficients of an L_2-normalized eigenfunction f corresponding to a periodic eigenvalue $\lambda = n^2\pi^2+z$ of $L=-\frac{d^2}{dx^2}+V$. f is a 2-periodic function in $H^2_{loc}(\mathbb{R};\mathbb{C})$ satisfying

$$(L-\lambda)f=0;\ \|f\|=1.$$

Recall that $x^f := \hat{f}(-n), y^f := \hat{f}(n)$, and $F := (\hat{f}(k))_{k\in\mathbb{Z}(n)}$. By Proposition 2.2, $F = x^fF_+ + y^fF_-$ and, by (2.22), $F_\pm := (z-A_n)^{-1}(\mathcal{S}^{\pm n}\hat{V})_{\mathbb{Z}(n)}$. For $n\ge n_w$, F_+ and F_- satisfy the estimates (cf. Corollary 2.9)

$$\|F_+\|_{\ell^2_{\mathcal{S}^n w}} \le \frac{2}{\pi^2 n}\|V\|_w, \tag{3.1}$$

$$\|F_-\|_{\ell^2_{\mathcal{S}^{-n} w}} \le \frac{2}{\pi^2 n}\|V\|_w. \tag{3.2}$$

By the normalization of f

$$1=\int_0^2 f(x)\overline{f(x)}dx = 2\left(|x^f|^2+|y^f|^2+\sum_{k\ne\pm n}|\hat{f}(k)|^2\right). \tag{3.3}$$

In particular, one has

$$|x^f|^2+|y^f|^2\le\frac{1}{2}. \tag{3.4}$$

Hence, by Cauchy's inequality $|F(k)| \leq (|x^f|^2 + |y^f|^2)^{1/2}(|F_+(k)|^2 + |F_-(k)|^2)^{1/2}$, we obtain in view of (3.1)–(3.2)

$$\|F\|_{\ell^2(\mathbb{Z}(n))} \leq \left(\frac{1}{2} \cdot 2 \cdot \frac{2}{\pi^2 n}\|V\|\right)^{1/2} \leq \frac{1}{4n}\|V\|_w.$$

Thus, for n with $n \geq n_w$,

$$\|F\|_{\ell^2(\mathbb{Z}(n))} \leq \frac{1}{4}.$$

Together with (3.3)–(3.4), this yields

$$\frac{1}{4} \leq |x^f|^2 + |y^f|^2 \leq \frac{1}{2}. \tag{3.5}$$

We summarize our estimates as follows.

Lemma 3.1. *Let $V \in H_0^w$ be 1-periodic. Then for any $M > 0$ and $n \geq n_w$ with*

$$3(1 + \|V\|_w)^2 \leq \frac{M}{4}; \; n \geq n_w := M + \|V\|_w,$$

an eigenfunction f with $\|f\| = 1$, corresponding to an eigenvalue λ with $|\lambda - n^2\pi^2| \leq M$, has the following properties:

(i) $f(x) = x^f e^{-in\pi x} + y^f e^{in\pi x} + x^f F_+ + y^f F_-$;
(ii) $\frac{1}{4} \leq |x^f|^2 + |y^f|^2 \leq \frac{1}{2}$;
(iii) $\|F_+\|_{\ell^2_{\mathcal{S}^{n_w}}} \leq \frac{\|V\|_w}{4n}$; $\|F_-\|_{\ell^2_{\mathcal{S}^{-n_w}}} \leq \frac{\|V\|_w}{4n}$.

3.2. Riesz's spaces. Given a 1-periodic potential $V \in H_0^w$, let $M > 0$ satisfy $3(1 + \|V\|_w)^2 \leq \frac{M}{4}$. For $n \geq n_w := M + \|V\|_w$, there are precisely two (counted with multiplicity) eigenvalues, λ_n^+ and λ_n^-, near $n^2\pi^2$ of $L = -\frac{d^2}{dx^2} + V$. Recall that $specL = specL_{Per^+} \cup specL_{Per^-}$. Denote by $P_n^{\pm}$ the Riesz projectors corresponding to the boundary conditions $Per^{\pm}$ (cf. (1.16)) and let

$$E_{2n} := P_n^+(L^2[0,1]); \quad E_{2n-1} := P_n^-(L^2[0,1]), \quad (\forall n \geq 1).$$

If $\lambda_n^+ \neq \lambda_n^-$ or $\lambda_n^+ = \lambda_n^-$ is of geometric multiplicity 2, there exist two linearly independent eigenfunctions, corresponding to the eigenvalues λ_n^+ and λ_n^-, and E_n is given by the linear span of these two eigenfunctions. In the case where $\lambda_n^+ = \lambda_n^-$ is of geometric multiplicity 1, E_n denotes the root space of λ_n^+. Notice that this case might happen if the potential V is complex-valued. As an example we mention $V = \varepsilon e^{2\pi ix}$ ($\varepsilon \neq 0$ arbitrary). The periodic eigenvalues of $-\frac{d^2}{dx^2} + \varepsilon e^{2\pi ix}$ (considered on the interval $[0,2]$) are given by $n^2\pi^2$ ($n \geq 0$), where for every $n \geq 1, n^2\pi^2$ is a double eigenvalue of geometric multiplicity 1 (cf. [3], [5] for details).

Let us describe E_n in the case where $\lambda_n^+ = \lambda_n^-$ is of geometric multiplicity 1 in more detail. Denote by f an L_2-normalized eigenfunction corresponding to $\lambda_n^+ = \lambda_n^-$, $Lf = \lambda_n^+ f$. Choose an L_2-normalized element φ in E_n, orthogonal to f. Then $E_n = span(f, \varphi)$ and φ satisfies

$$(L - \lambda_n^+)\varphi = \xi_n f$$

with $\xi_n \neq 0$. Denote by $c(x,\lambda)$ and $s(x,\lambda)$ the fundamental solution of $-y'' + Vy = \lambda y$ with

$$c(0,\lambda) = 1, \quad c'(0,\lambda) = 0; \quad s(0,\lambda) = 0, \quad s'(0,\lambda) = 1. \tag{3.6}$$

Lemma 3.2. *Assume $\lambda_{2n} = \lambda_{2n-1}$ and $\int_0^1 s(x, \lambda_{2n})^2 dx \neq 0$. Then λ_{2n} is of geometric multiplicity 2 iff λ_{2n} is a Dirichlet eigenvalue of the operator L on $[0, 1]$.*

Proof. Assume that $\lambda \equiv \lambda_{2n}$ is of geometric multiplicity 2. Then the fundamental solutions $c(x, \lambda)$ and $s(x, \lambda)$ are eigenfunctions, both either periodic or antiperiodic, and $s(0, \lambda) = 0$. It follows that $s(1, \lambda) = 0$, and therefore, λ is a Dirichlet eigenvalue. Conversely, assume that $\lambda \in spec_{Dir}(L)$ is a double periodic eigenvalue. Then $\Delta(\lambda) := c(1, \lambda) + s'(1, \lambda) = \pm 2$ and $\dot{\Delta}(\lambda) := \frac{d}{d\lambda}\Delta(\lambda) = 0$, as well as

$$s(1, \lambda) = 0. \tag{3.7}$$

By the Wronskian identity,

$$1 = c(1, \lambda)s'(1, \lambda) - c'(1, \lambda)s(1, \lambda) = c(1, \lambda)s'(1, \lambda)$$

and, combined with $\Delta(\lambda) = \pm 2$, one obtains

$$c(1, \lambda) = s'(1, \lambda) = \pm 1. \tag{3.8}$$

Take the derivative of the Wronskian identity with respect to λ and use $\dot{\Delta}(\lambda) = 0$ to conclude that

$$\begin{aligned} 0 = {} & \dot{c}(1, \lambda)c'(1, \lambda) + c(1, \lambda)\dot{s}'(1, \lambda) \\ & -\dot{c}'(1, \lambda)s(1, \lambda) - c'(1, \lambda)\dot{s}(1, \lambda) \\ = {} & \pm\left(\dot{c}(1, \lambda) + \dot{s}'(1, \lambda)\right) - c'(1, \lambda)\dot{s}(1, \lambda) \\ = {} & 0 - c'(1, \lambda)\dot{s}(1, \lambda). \end{aligned}$$

As $\lambda \in spec_{Dir}(L)$, and $\int_0^1 s(x, \lambda)^2 dx \neq 0, \dot{s}(1, \lambda) \neq 0$, and therefore,

$$c'(1, \lambda) = 0, \tag{3.9}$$

i.e., λ is a Neumann eigenvalue of the operator L on $[0, 1]$. By (3.6)–(3.9), $c(x, \lambda)$ and $s(x, \lambda)$ are both periodic eigenfunctions of L on $[0, 2]$; hence, λ has geometric multiplicity 2. □

3.3. Orthonormal basis of E_n. In this section we obtain properties for an orthonormal basis f, φ of the two-dimensional subspace E_n introduced above ($n \geq n_w$, where $n_w := M + \|V\|_w$). Here f is an eigenfunction of $L = -\frac{d^2}{dx^2} + V$, with $\|f\|_{L^2} = 1$, corresponding to the eigenvalue $\lambda^+ \equiv \lambda_n^+$

$$Lf = \lambda^+ f \tag{3.10}$$

and φ is an element in E_n with

$$\langle \phi, f \rangle = 0; \quad \|\varphi\|_{L^2} = 1. \tag{3.11}$$

Notice that φ is determined up to a scalar $\kappa \in \{z \in \mathbb{C} \mid |z| = 1\}$. Here $\langle p, q \rangle$ denotes the L_2-inner product

$$\langle p, q \rangle = \int_0^2 p(x)\overline{q(x)} dx.$$

In the case when $\lambda^+ \equiv \lambda_n^+$ is a double eigenvalue, φ satisfies an equation of the form

$$L\varphi = \lambda^+ \varphi + \xi f \quad (\lambda^+ = \text{ double eigenvalue}), \tag{3.12}$$

where $\xi \equiv \xi_n = 0$ if λ_n^+ has geometric multiplicity 2 and $\xi \neq 0$ if λ^+ has geometric multiplicity 1. In the case where $\lambda^- \equiv \lambda_n^- \neq \lambda_n^+$, choose a normalized eigenfunction $f^- \equiv f_n^-$ of λ^- such that the following holds:

$$0 \leq a := \langle f^-, f \rangle \leq 1; \quad \|f^-\|_{L^2} = 1. \tag{3.13}$$

Write f^- as a linear combination of f and φ,

$$f^- = af + b\varphi, \tag{3.14}$$

where now the scalar κ for φ (cf. (3.11)) is chosen in such a way that $0 \leq b$. Then $a^2 + b^2 = 1$, and $b \neq 0$, or

$$a = \cos\theta; \quad b = \sin\theta; \quad 0 < \theta \leq \pi/2. \tag{3.15}$$

The function $\varphi = \frac{1}{b} f^- - \frac{a}{b} f$ satisfies

$$\begin{aligned} L\varphi &= \lambda^- \frac{1}{b} f^- - \lambda^+ \frac{a}{b} f \\ &= \lambda^+ \left(\frac{1}{b} f^- - \frac{a}{b} f \right) + (\lambda^- - \lambda^+) \frac{1}{b} f^- \\ &= \lambda^+ \varphi + (\lambda^+ - \lambda^-) \frac{1}{b} (f - f^-) - (\lambda^+ - \lambda^-) \frac{1}{b} f. \end{aligned}$$

Thus, in the case $\lambda^+ \neq \lambda^-$, with $\lambda \equiv \lambda^+$,

$$L\varphi = \lambda\varphi + \xi f + \gamma h, \tag{3.16}$$

where $\gamma \equiv \gamma_n = \lambda_n^+ - \lambda_n^-, h = \frac{1}{b}(f - f^-)$, and $\xi \equiv \xi_n$ is defined by

$$\xi_n := -(\lambda_n^+ - \lambda_n^-) \frac{1}{b} \qquad (\text{case } \lambda_n^+ \neq \lambda_n^-). \tag{3.17}$$

Notice that (3.12) has the same form as (3.16) if we set h equal to 0. It turns out that we will no longer have to treat the following three cases separately.

Case 1. $\lambda^+ = \lambda^-$ *and* $\xi = 0$;

Case 2. $\lambda^+ = \lambda^-$ *and* $\xi \neq 0$;

Case 3. $\lambda^+ \neq \lambda^-$.

The next result shows that the term $\gamma h = (\lambda^+ - \lambda^-) \frac{1}{b}(f - f^-)$ in (3.16) is well under control.

LEMMA 3.3. *If $\lambda^+ \neq \lambda^-$, then $b \neq 0$ and $\|h\| \leq \sqrt{2}$.*

Proof. By (3.15), $b = sin\theta \neq 0$ for $\lambda^+ \neq \lambda^-$. By (3.14) and (3.15), $h = \frac{1}{b}(f - f^-) = \frac{1-\cos\theta}{\sin\theta} f - \varphi$, and therefore, as f and φ are orthogonal,

$$\|h\|^2 = \left| \frac{1 - \cos\theta}{\sin\theta} \right|^2 + 1 \leq 2$$

as $\frac{1-\cos\theta}{\sin\theta} = \frac{2\sin^2\frac{\theta}{2}}{2\cos\frac{\theta}{2}\sin\frac{\theta}{2}} = \tan\frac{\theta}{2} \leq 1$ for $0 < \theta \leq \frac{\pi}{2}$. □

In the remaining part of this section our aim is to obtain estimates for ξ_n (cf. (3.12) and (3.17)). To this end, we write (3.16) in Fourier space. Introduce

$$\varphi = x^\varphi e^{-in\pi x} + y^\varphi e^{in\pi x} + \sum_{k \neq \pm n} \Phi(k) e^{ik\pi x}; \quad \Phi = (\Phi(k))_{k \in \mathbb{Z}(n)},$$

and, similarly

$$h = x^h e^{-in\pi x} + y^h e^{in\pi x} + \sum_{k \neq \pm n} H(k) e^{ik\pi x}, \quad H := (H(k))_{k \in \mathbb{Z}(n)}. \tag{3.18}$$

In view of (2.2)–(2.4), (3.16) leads to the following inhomogeneous system:

$$-zx^\varphi + \hat{V}(-2n)y^\varphi + [\mathcal{S}^n J\hat{V}, \Phi]_{\mathbb{Z}(n)} = \xi_n x^f + \gamma_n x^h, \tag{3.19}$$

$$\hat{V}(2n)x^\varphi - zy^\varphi + [\mathcal{S}^{-n} J\hat{V}, \Phi]_{\mathbb{Z}(n)} = \xi_n y^f + \gamma_n y^h, \tag{3.20}$$

$$(\mathcal{S}^n \hat{V})_{\mathbb{Z}(n)} x^\varphi + (\mathcal{S}^{-n}\hat{V})_{\mathbb{Z}(n)} y^\varphi + (A_n - z)\Phi = \xi_n F + \gamma_n H, \tag{3.21}$$

where, as usual, $z \equiv z_n^+ = \lambda_n^+ - n^2\pi^2$.

We use this system to obtain an estimate for ξ_n. The sequence Φ is obtained from (3.21),

$$\begin{aligned} \Phi = {} & (z - A_n)^{-1}(\mathcal{S}^n\hat{V})_{\mathbb{Z}(n)} x^\varphi + (z - A_n)^{-1}(\mathcal{S}^n\hat{V})_{\mathbb{Z}(n)} y^\varphi \\ & - (z - A_n)^{-1}\xi_n F - (z - A_n)^{-1}\gamma_n H \end{aligned} \tag{3.22}$$

and, by (2.11), F is given by

$$F = (z - A_n)^{-1}(\mathcal{S}^n\hat{V})_{\mathbb{Z}(n)} x^f + (z - A_n)^{-1}(\mathcal{S}^{-n}\hat{V})_{\mathbb{Z}(n)} y^f. \tag{3.23}$$

Hence,

$$\begin{aligned} \Phi = {} & (z - A_n)^{-1}(\mathcal{S}^n\hat{V})_{\mathbb{Z}(n)} x^\varphi + (z - A_n)^{-1}(\mathcal{S}^n\hat{V})_{\mathbb{Z}(n)} y^\varphi \\ & - (z - A_n)^{-2}(\mathcal{S}^n\hat{V})_{\mathbb{Z}(n)} \xi_n x^f - (z - A_n)^{-2}(\mathcal{S}^{-n}\hat{V})_{\mathbb{Z}(n)} \xi_n y^f \\ & - (z - A_n)^{-1}\gamma_n H. \end{aligned}$$

In this form, substitute Φ into (3.19)–(3.20) to obtain, with $\alpha(n,z)$ and $\beta(n,z)$ defined by (2.13) and (2.14),

$$\begin{aligned} & \begin{pmatrix} -z + \alpha(n,z) & \hat{V}(-2n) + \beta(-n,z) \\ \hat{V}(2n) + \beta(n,z) & -z + \alpha(n,z) \end{pmatrix} \begin{pmatrix} x^\varphi \\ y^\varphi \end{pmatrix} \\ & = \xi_n \begin{pmatrix} x^f - \frac{d}{dz}\alpha(n,z)x^f - \frac{d}{dz}\beta(-n,z)y^f \\ y^f - \frac{d}{dz}\beta(n,z)x^f - \frac{d}{dz}\alpha(n,z)y^f \end{pmatrix} \\ & \quad + \gamma_n \begin{pmatrix} x^h + [\mathcal{S}^n J\hat{V}, (z - A_n)^{-1}H] \\ y^h + [\mathcal{S}^{-n} J\hat{V}, (z - A_n)^{-1}H] \end{pmatrix}, \end{aligned}$$

where we used $\alpha(n,z) = \alpha(-n,z)$, Lemma 2.4, and (cf. Lemma 2.5)

$$\frac{d}{dz}\alpha(n,z) = -[\mathcal{S}^{-n} J\hat{V}, (z - A_n)^{-2}(\mathcal{S}^{-n}\hat{V})_{\mathbb{Z}(n)}]_{\mathbb{Z}(n)}$$

and

$$\frac{d}{dz}\beta(n,z) = -[\mathcal{S}^{-n} J\hat{V}, (z - A_n)^{-2}(\mathcal{S}^{n}\hat{V})_{\mathbb{Z}(n)}]_{\mathbb{Z}(n)}.$$

Therefore,

$$\xi_n \left(Id_2 - \tfrac{d}{dz} \begin{pmatrix} \alpha(n,z) & \beta(-n,z) \\ \beta(n,z) & \alpha(n,z) \end{pmatrix} \right) \begin{pmatrix} x^f \\ y^f \end{pmatrix} \tag{3.24}$$

$$= \begin{pmatrix} -\zeta_n^+ & \hat{V}(-2n) + \beta(-n,z) \\ \hat{V}(2n) + \beta(n,z) & -\zeta_n^+ \end{pmatrix} \begin{pmatrix} x^\varphi \\ y^\varphi \end{pmatrix}$$

$$-\gamma_n \begin{pmatrix} x^h + [\mathcal{S}^n J\hat{V}, (z - A_n)^{-1} H] \\ y^h + [\mathcal{S}^{-n} J\hat{V}, (z - A_n)^{-1} H] \end{pmatrix},$$

where $\zeta_n^+ = z_n^+ - \alpha(n, z_n^+), Id_2$ denotes the 2×2 identity matrix, and to simplify notation, $[\cdot,\cdot] = [\cdot,\cdot]_{\mathbb{Z}(n)}$. Let $V \in H_0^w$ be 1-periodic and choose $M > 0$ with $3(1 + \|V\|)^2 \leq \frac{M}{4}$. By Lemma 2.5, for any $n \geq n_w := M + \|V\|_w$ and $z = z_n^+$

$$\left| \frac{d}{dz} \alpha(n,z) \right| \leq \frac{1}{9} \frac{\|V\|^2}{n^2} \leq \frac{1}{9}, \tag{3.25}$$

where we use that, by Lemma 2.5 and Propositions 2.6 and 2.15, $|z_n^+| \leq M$. Further, by Lemma 2.13, applied to $w = 1$,

$$(1 + |n|)^2 \left| \frac{d}{dz} \beta(n,z) \right| \leq 2(1 + n_w)^{1/2} \|V\|^2, \quad (|n| \geq n_w, \quad |z| \leq M).$$

Use that for $|n| \geq n_w$, $\frac{\|V\|^2}{1+|n|} \leq \frac{M/12}{n_w} \leq \frac{1}{12}$. Thus, for $|n| \geq n_w$ and $z \equiv z_n^+$,

$$\left| \frac{d}{dz} \beta(n,z) \right| \leq \frac{1}{6}. \tag{3.26}$$

Combining (3.25) and (3.26), the left-hand side of (3.24) can be estimated from below, for $n \geq n_w$,

$$\begin{aligned} &\left\| \xi_n \left(Id_2 - \frac{d}{dz} \begin{pmatrix} \alpha(n,z) & \beta(-n,z) \\ \beta(n,z) & \alpha(n,z) \end{pmatrix} \right) \begin{pmatrix} x^f \\ y^f \end{pmatrix} \right\|^2 \\ &\qquad \geq |\xi_n|^2 \left(|x^f|^2 \left(1 - \frac{1}{10} \right) + |y^f|^2 \left(1 - \frac{1}{10} \right) \right) \geq \left(\frac{1}{3} |\xi_n| \right)^2, \end{aligned} \tag{3.27}$$

where we used that $\frac{1}{4} \leq |x^f|^2 + |y^f|^2$ (cf. Lemma 3.1). Further, we need an estimate for $[\mathcal{S}^{\pm} J\hat{V}, (z - A_n)^{-1} H]$ with H as in (3.18).

LEMMA 3.4. *For* $n \geq n_w$,

(i) $|x^h| \leq \sqrt{2}$; $|y^h| \leq \sqrt{2}$;

(ii) $|[\mathcal{S}^{\pm n} J\hat{V}, (z - A_n)^{-1} H]| \leq \frac{\|V\|}{\pi n}$.

Proof. The proof of (i) follows from Lemma 3.3. To prove (ii), notice that for $n \geq n_w$ and $z = z_n^+$,

$$\begin{aligned} &|[\mathcal{S}^{\pm n} J\hat{V}, (z - A_n)^{-1} H]| \\ &\qquad \leq \|V\| \|(z - A_n)^{-1}\| \|H\| \leq \frac{2}{\pi^2} \frac{1}{n} \|V\| \sqrt{2} \\ &\qquad \leq \frac{2}{\pi^2} \frac{1}{n} \|V\| \sqrt{2}, \end{aligned}$$

where we used that $\sqrt{2}\|H\| \leq \|h\| \leq \sqrt{2}$ (cf. (3.18), Lemma 3.3), and $\|(z-A_n)^{-1}\| \leq \frac{2}{\pi^2}\frac{1}{n}$ by Lemma 2.1. □

Lemma 3.4 enables us to obtain an estimate *from above* of the right-hand side of (3.24). Lemma 3.4 and estimate (3.27), together with $|x^\varphi|^2 + |y^\varphi|^2 \leq 1$, are used to deduce from (3.24) that, for $n \geq n_w = M + \|V\|_w$,

$$\begin{aligned}\frac{1}{3}|\xi_n| &\leq \Big(|\zeta_n^+| + |\hat{V}(2n)| + |\beta(n,z)|\Big) \\ &\quad + \Big(|\zeta_n^+| + |\hat{V}(-2n)| + |\beta(-n,z)|\Big) + |\gamma_n|\left(\sqrt{2} + \frac{2\|V\|}{\pi n}\right) \\ &\leq 2|\zeta_n^+| + |\hat{V}(2n)| + |\hat{V}(-2n)| + |\beta(n,z)| + |\beta(-n,z)| + 3|\gamma_n|.\end{aligned} \tag{3.28}$$

Estimate (3.28), combined with earlier estimates for $\beta(\pm n, z)$ and γ_n, leads to the following inequality:

$$|\xi_n| \leq \frac{C}{w(2n)} \qquad \forall n \geq n_w, \tag{3.29}$$

where $C > 0$ depends only on $\|V\|_w$. In fact, the following stronger statement holds.

THEOREM 3.5. *Let $V \in H_0^w$ be a 1-periodic potential and let $M > 0$ satisfy $3(1+\|V\|_w)^2 \leq \frac{M}{4}$. Then the sequence $(\xi_n)_{n\geq n_w}$ (cf. (3.12), (3.17)) satisfies*

$$\left(\sum_{n\geq n_w} w(2n)^2|\xi_n|^2\right)^{1/2} \leq 120(1+n_w)^2(1+\|V\|_w)^2$$

with $n_w := M + \|V\|_w$.

Proof. The terms on the right side of (3.28) are estimated separately. Recall that, by Corollary 2.19,

$$\left(\sum_{n\geq n_w} w(2n)^2|\zeta_n^+|^2\right)^{1/2} \leq 5(1+n_w)^2(1+\|V\|_w)^2, \tag{3.30}$$

by Proposition 2.14,

$$\left(\sum_{|n|\geq n_w} w(2n)^2 \sup_{|z|\leq M}|\beta(n,z)|^2\right)^{1/2} \leq 2(1+n_w)^2(1+\|V\|_w)^2, \tag{3.31}$$

and by Proposition 2.16, with $|\gamma_n| = |\lambda_n^+ - \lambda_n^-|$,

$$\left(\sum_{n\geq n_w} w(2n)^2|\gamma_n|^2\right)^{1/2} \leq 8(1+n_w)^2(1+\|V\|_w)^2. \tag{3.32}$$

Combining (3.30)–(3.32) with (3.28) leads to the following estimate:

$$\frac{1}{3}\left(\sum_{n\geq n_w} w(2n)^2|\xi_n|^2\right)^{1/2} \leq 40(1+n_w)^2(1+\|V\|_w)^2. \qquad \square$$

3.4. Restriction of L on E_n. Here we summarize the results of sections 3.1–3.3 as a statement on the structure of the restriction of L on the Riesz spaces E_n.

PROPOSITION 3.6. *Let $V \in H_0^w$ be a 1-periodic potential. Then, for n sufficiently large, the Riesz space E_n has an orthonormal basis $f \equiv f_n$, $\varphi \equiv \varphi_n$ such that*

$$L_{Per^\varepsilon} f = \lambda_{2n} f; \quad L_{Per^\varepsilon} \varphi = \lambda_{2n} \varphi + \xi_n f + \gamma_n h,$$

where $\varepsilon \in \{+,-\}$ is $+$ for n even and $-$ for n odd and $h \equiv h_n \in E_n$. Moreover, the following inequalities hold:

$$\|h\| \leq 2; \quad |\xi_n| \leq \frac{C}{w(2n)}; \quad |\gamma_n| \leq \frac{C}{w(2n)}$$

with $C > 0$ independent of n. (For stronger estimates, cf. (3.30) *and* (3.32).*)*

4. Dirichlet spectrum.

4.1. Candidates for Dirichlet eigenfunctions. In section 3.2 we have introduced, for n sufficiently large, the two-dimensional subspaces E_n,

$$E_{2n} = \text{Range}(P_n^+); \quad E_{2n-1} = \text{Range}(P_n^-). \tag{4.1}$$

We have chosen an orthonormal basis (f, φ) of E_n with f being a normalized eigenfunction for the eigenvalue $\lambda \equiv \lambda_n^+$,

$$Lf = \lambda f,$$

and we showed that φ satisfies an equation of the form

$$L\varphi = \lambda\varphi + \xi f + \gamma h, \tag{4.2}$$

where $\gamma \equiv \gamma_n = \lambda_{2n} - \lambda_{2n-1}, h$ satisfies $\|h\| \leq 2$ (cf. Lemma 3.3), and estimates for ξ have been established in Theorem 3.5. The following lemma gives an element G in E_n, satisfying Dirichlet boundary conditions.

LEMMA 4.1. *Assume that $3(1 + \|V\|_w)^2 \leq \frac{M}{4}$ and $n \geq n_w = M + \|V\|_w$. Then there exists an element G in E_n of the form*

$$G = \alpha f + \beta \varphi; \quad 0 \leq \alpha \leq 1; \quad |\alpha|^2 + |\beta|^2 = 1 \tag{4.3}$$

so that

$$G(0) = 0; \quad G(1) = 0.$$

Proof. First consider the case where $f(0) = 0$. Then, as f is either periodic or antiperiodic,

$$f(1) = \pm f(0) = 0. \tag{4.4}$$

Thus $G := f$ has the required properties. If $f(0) \neq 0$, notice that $\tilde{G}(x) := -f(0)\varphi(x) + \varphi(0)f(x)$ is a nonzero element in E_n, satisfying Dirichlet boundary conditions. Then $G := \kappa \frac{\tilde{G}}{\|\tilde{G}\|} = \alpha f + \beta \varphi$, with $\kappa \in \mathbb{C}, |\kappa| = 1$, chosen to guarantee $0 \leq \alpha \leq 1$, has the stated properties. □

Using (4.2) and (4.3) one obtains

$$\begin{aligned} LG &= \alpha Lf + \beta L\varphi \\ &= \alpha\lambda f + \beta(\lambda\varphi + \xi f + \gamma h) \\ &= \lambda G + \xi\beta f + \gamma\beta h. \end{aligned} \tag{4.5}$$

For $n \geq n_w$, both $\xi \equiv \xi_n$ and $\gamma \equiv \gamma_n$ are small and G almost looks like a Dirichlet eigenfunction.

In the next sections we prove that λ, respectively, G, are good approximations of the Dirichlet eigenvalue μ_n, respectively, Dirichlet eigenfunction g.

4.2. Fourier block decomposition. Let L_{Dir} be the closed operator $L_{Dir} = -\frac{d^2}{dx^2} + V$ with domain $domL_{Dir} := \{f \in H^2[0,1] \quad | \quad f(0) = 0; \quad f(1) = 0\}$. In this section, let us fix n with $n \geq \max(n_w, 2K_8(M+1))$ (cf. Lemma 1.4 for K_8). $P_{Dir} \equiv P_{n,Dir}$ denotes the Riesz projector

$$P_{Dir} := \frac{1}{2\pi i}\int_{|z-n^2\pi^2|=M} (z - L_{Dir})^{-1} dz$$

acting on $L^2([0,1];\mathbb{C})$. Let $Q_{Dir} := Id - P_{Dir}$. Notice that

$$Q_{Dir} f \in domL_{Dir} \qquad \forall f \in domL_{Dir}, \tag{4.6}$$

$$Q_{Dir} L_{Dir} f = L_{Dir} Q_{Dir} f \qquad \forall f \in domL_{Dir}, \tag{4.7}$$

and

$$Q_{Dir} \cdot P_{Dir} = 0; \quad P_{Dir} \cdot Q_{Dir} = 0; \quad P_{Dir}^2 = P_{Dir}; \quad Q_{Dir}^2 = Q_{Dir}. \tag{4.8}$$

According to Lemma 1.5,

$$\|P_{Dir}\| \leq K_{10},$$

K_{10} being an absolute constant, and, therefore

$$\|Q_{Dir}\| \leq K_{10} + 1.$$

Notice that (cf. (1.13) and (1.16))

$$\text{Range} P_{Dir} = \{ag \mid a \in \mathbb{C}\},$$

where g is an L^2-normalized eigenfunction for the Dirichlet eigenvalue $\mu \equiv \mu_n$,

$$L_{Dir} g = \mu g; \qquad \|g\| = 1.$$

As G (cf. Lemma 4.1) is in $dom(L_{Dir})$, it admits a decomposition

$$G = P_{Dir} G + Q_{Dir} G = \kappa g + u, \tag{4.9}$$

where $u \in \text{Range}(Q_{Dir}) \subset dom(L_{Dir})$. Therefore,

$$L_{Dir} G = \kappa\mu g + L_{Dir} u \tag{4.10}$$

and

$$P_{Dir}u = 0; \quad Q_{Dir}u = u. \tag{4.11}$$

Hence, (4.7) implies that $Q_{Dir}L_{Dir}u = L_{Dir}u$, and thus,

$$L_{Dir}u \in \mathrm{Range}(Q_{Dir}). \tag{4.12}$$

On the other hand, by (4.5), $LG = \lambda G + R$, where

$$R := \xi\beta f + \gamma\beta h. \tag{4.13}$$

Thus by (4.9),

$$L_{Dir}G = \lambda\kappa g + \lambda u + P_{Dir}R + Q_{Dir}R. \tag{4.14}$$

The left sides of (4.10) and (4.14) being the same, we conclude that

$$\kappa\mu g + L_{Dir}u = \kappa\lambda g + \lambda u + P_{Dir}R + Q_{Dir}R. \tag{4.15}$$

This equation leads to the following lemma.

LEMMA 4.2. *Assume that* $3(1 + \|V\|_w)^2 \leq \frac{M}{4}$ *and* $n \geq \max(n_w, 2K_8(M + 1))$. *Then*

$$\kappa(\mu - \lambda)g = P_{Dir}R, \tag{4.16}$$

$$(L_{Dir} - \lambda)u = Q_{Dir}R. \tag{4.17}$$

Proof. Apply P_{Dir} to (4.15). In view of (4.7), (4.8), and (4.11)

$$P_{Dir}L_{Dir}u = P_{Dir}L_{Dir}Q_{Dir}u = P_{Dir}Q_{Dir}L_{Dir}u = 0.$$

Further, use that $P_{Dir}g = g$ and $P_{Dir}Q_{Dir}R = 0$ to conclude the identity (4.16). Similarly, by applying Q_{Dir} to (4.15), the second identity (4.17) is obtained. □

4.3. External equation. In this section we obtain estimates for the difference $\mu - \lambda$ between the nth Dirichlet eigenvalue $\mu \equiv \mu_n$ and the eigenvalue $\lambda \equiv \lambda_{2n}$. Recall that $G = \alpha f + \beta\varphi$ with $|\alpha|^2 + |\beta|^2 = 1$ (cf. (4.3)), $U \equiv U_n = Q_{Dir}G = G - \kappa g$ (cf. (4.9)), $L\varphi = \lambda\varphi + \xi f + \gamma h$ (cf. (4.2)), and $R = \beta(\xi f + \gamma h)$ (cf. (4.13)).

LEMMA 4.3. *Assume that* $3(1 + \|V\|_w)^2 \leq \frac{M}{4}$ *and* $n \geq \max(n_w, 2K_8(M + 1))$. *Then*

$$\|u_n\| \leq K_{11}\frac{1}{n}(|\xi_n| + 2|\gamma_n|),$$

where $K_8 > 0$ *is the absolute constant from Lemma* 1.4 *and* $K_{11} > 0$ *is the absolute constant from Lemma* 1.6.

Proof. Apply Lemma 1.6 to (4.17) to get

$$\|u\| \leq \|(\lambda - L_{Dir})^{-1}Q_{Dir}R\| \leq K_{11}\frac{1}{n}\|R\|.$$

By the definition (4.13) and $|\beta| \leq 1$,

$$\|R\| \leq |\xi| + 2|\gamma|,$$

where we used that $\|f\| = 1$ and $\|h\| \leq \sqrt{2}$ (cf. Lemma 3.3). □

From the estimate of $\|u\|$ we obtain an estimate of $\kappa \equiv \kappa_n$ in $G = \kappa g + u$ from below.

LEMMA 4.4. *Assume that* $3(1 + \|V\|_w)^2 \leq \frac{M}{4}$. *Then there exists* N_w *with* $N_w \geq \max(1 + n_w, 2K_8(M+1))$ *so that*

$$|\kappa_n| \geq \frac{1}{2} \qquad \forall n \geq N_w.$$

Proof. By (4.9), $|\kappa| = \|\kappa g\| = \|G - u\| \geq \|G\| - \|u\| = 1 - \|u\|$. By Lemma 4.3, $\|u\| \leq K_{11}\frac{1}{n}(|\xi| + 2|\gamma|)$, and by Theorem 3.5

$$|\xi_n| \leq 120(1 + n_w)^2(1 + \|V\|_w)^2 \quad \forall n \geq n_w$$

and (cf. Proposition 2.16)

$$|\gamma_n| \leq 8(1 + n_w)^{3/2}(1 + \|V\|_w)^2.$$

Thus, for $n \geq N_w$, with N_w defined by

$$N_w := 300(K_8 + K_{11})(1 + n_w)^2(1 + \|V\|_w)^2; \quad N_w \geq e, \tag{4.18}$$

it follows that $\|u\| \leq 1/2$, and thus $|\kappa| \geq 1/2$. □

4.4. Estimates for the Dirichlet eigenvalues. From the identity (4.16) we deduce an estimate for $\mu - \lambda$, using the bound for κ established in Lemma 4.4.

THEOREM 4.5. *Assume* $3(1 + \|V\|_w)^2 \leq \frac{M}{4}$. *Then, for any* $n \geq N_w$, *with* N_w *given by* (4.18),

$$|\mu_n - \lambda_n^+| \leq 2 \cdot K_{10}(|\xi_n| + 2|\gamma_n|),$$

where K_{10} *is an absolute constant given by Lemma* 1.5.

Proof. By (4.16)

$$|\kappa||\mu - \lambda| \leq \|P_{Dir}\|\|R\| \leq K_{10}\|R\| \tag{4.19}$$

and, by (4.13)

$$\|R\| \leq |\xi| + 2|\gamma|, \tag{4.20}$$

where we used that $\|f\| = 1, \|h\| \leq \sqrt{2}$, and $|\beta| \leq 1$. Combine the estimates (4.19) and (4.20) with the estimate $|\kappa| \geq \frac{1}{2}$ of Lemma 4.4 to obtain the claimed statement. □

Combined with the estimates for γ_n (Proposition 2.16) and for ξ_n (Theorem 3.5) we obtain the following theorem.

THEOREM 4.6. *Assume* $3(1 + \|V\|_w)^2 \leq \frac{M}{4}$. *Then, with* N_w *given by* (4.18),

$$\left(\sum_{n \geq N_w} w(2n)^2|\mu_n - \lambda_n^+|^2\right)^{1/2} \leq 300K_{10}13^2(1 + \|V\|_w)^6.$$

Proof. By Theorem 3.5,

$$\left(\sum_{n \geq n_w} w(2n)^2|\xi_n|^2\right)^{1/2} \leq 120(1 + n_w)^2(1 + \|V\|_w)^2.$$

By Proposition 2.16

$$\left(\sum_{n\geq n_w} w(2n)^2|\lambda_n^+-\lambda_n^-|^2\right)^{1/2} \leq 80(1+n_w)^{3/2}(1+\|V\|_w)^2.$$

Apply this to Theorem 4.5 to obtain the claimed statements. □

5. Spectrum for a special class of boundary conditions.

5.1. Special class of boundary conditions. An elementary observation (Lemma 4.1) provided us with a nonzero function G_n in the periodic or antiperiodic 2-dimensional Riesz subspace E_n (cf. (4.1)) which satisfied Dirichlet boundary conditions. If the boundary condition has such a feature, the results of section 4 can be extended. This is explained in section 5.2.

We ask the question which boundary conditions *bc*, given by two linearly independent, homogeneous equations, have the property that, for any n, the 2-dimensional subspace E_n contains a nonzero function satisfying these *bc*. Any boundary conditions *bc* for the operator $L = -\frac{d^2}{dx^2} + V$ on $[0,1]$, given by two linearly independent homogeneous equations, is a 2-dimensional subspace $\mathcal{E}$ in

$$\mathbb{C}^4 = \mathbb{C}^2 \times \mathbb{C}^2 = \{(y_0, y_0';\, y_1, y_1')\},$$

where we think of $y_0 = y(0), y_0' = y'(0), y_1 = y(1)$, and $y_1' = y'(1)$ as given by a solution $y(x) \equiv y(x,\lambda)$ of $Ly = \lambda y$. We want $\mathcal{E}$ to have a nontrivial intersection with both 2-dimensional subspaces

$$\mathcal{E}^+ := \{(y_0, y_0';\, y_1, y_1') \in \mathbb{C}^4 \mid y_0 = y_1;\, y_0' = y_1'\}$$

and

$$\mathcal{E}^- := \{(y_0, y_0';\, y_1, y_1') \in \mathbb{C}^4 \mid y_0 = -y_1;\, y_0' = -y_1'\},$$

i.e., with 2-dimensional planes of periodic and antiperiodic boundary conditions. It implies that

$$\dim(\mathcal{E} \cap \mathcal{E}^+) \geq 1; \quad \dim(\mathcal{E} \cap \mathcal{E}^-) \geq 1.$$

But

$$\mathcal{E}^+ \cap \mathcal{E}^- = \{0\},$$

which is obvious from the definition of $\mathcal{E}^+$ and $\mathcal{E}^-$. Therefore,

$$\dim(\mathcal{E} \cap \mathcal{E}^\pm) = 1 \tag{5.1}$$

and

$$\mathcal{E} \cap \mathcal{E}^+ = \{ze^+ | z \in \mathbb{C}\}; \quad e^+ := (a,b;a,b) \neq 0, \tag{5.2}$$

$$\mathcal{E} \cap \mathcal{E}^- = \{ze^- | z \in \mathbb{C}\}; \quad e^- := (c,d;-c,-d) \neq 0. \tag{5.3}$$

We conclude that

$$\mathcal{E} = \{\xi e^+ + \eta e^- | \xi, \eta \in \mathbb{C}\}.$$

It is easy to see that the orthogonal complement of $\mathcal{E}$ in $\mathbb{C}^4$ is given by

$$\mathcal{E}^\perp = \{\xi \ell_1 + \eta \ell_2 | \xi, \eta \in \mathbb{C}\},$$

where $\ell_1 = (b, -a; b, -a)$ and $\ell_2 = (d, -c; -d, c)$. Hence,

$$\mathcal{E} = \{(y_0, y_0'; y_1, y_1') \in \mathbb{C}^2 \times \mathbb{C}^2 | b(y_0 + y_1) - a(y_0' + y_1') = 0; d(y_0 - y_1) - c(y_0' - y_1') = 0\}.$$

In this way, we come, by necessity, to the following two homogeneous linear equations:

$$\begin{aligned} b(y_0 + y_1) - a(y_0' + y_1') &= 0, \\ d(y_0 - y_1) - c(y_0' - y_1') &= 0. \end{aligned} \tag{5.4}$$

They are linearly independent for any pairs $(a, b) \neq 0,\ (c, d) \neq 0$ given by (5.2) and (5.3).

We can assume without loss of generality that

$$|a|^2 + |b|^2 = 1; \quad |c|^2 + |d|^2 = 1. \tag{5.5}$$

5.2. Spectrum for L_{bc} with bc of class $\mathcal{B}$. In this section we consider only *regular boundary conditions* (see [16, section 4.8(b)] of the type (5.4). A simple verification along the definition [16, section 4.8(b), (39)] shows that the *boundary conditions* (5.4) *are regular iff*

$$ac \neq 0 \qquad \text{or} \qquad a = c = 0. \tag{5.6}$$

We denote by $\mathcal{B}$ the class of boundary conditions (5.4) which satisfy (5.5) and (5.6).

Examples. (i) Dirichlet $bc : (a, b) = (c, d) = (0, 1)$.

(ii) Neumann $bc : (a, b) = (c, d) = (1, 0)$.

(iii) More generally, if $(a, b) = e^{i\theta}(c, d)$, i.e., $\det\left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right) = 0$, and $ac \neq 0$, let $\beta := \frac{b}{a}$. Then the boundary conditions bc (5.4) can be rewritten as

$$y'(0) = \beta y(0); \quad y'(1) = \beta y(1),$$

so bc splits and the conditions at the left and right end points of the interval $[0, 1]$ are the same.

Let us analyze $spec(L_{bc})$ for the potential $V = 0$ and boundary conditions bc from the class $\mathcal{B}$. The domain of L_{bc} is defined as

$$domL_{bc} := \{f \in H^2[0, 1] | (f_0, f_0';\ f_1, f_1') \in (5.4)\}.$$

We write, routinely,

$$\begin{gathered} -f'' = \lambda f; \qquad \lambda = \omega^2; \\ f = p \cos \omega x + q \frac{\sin \omega x}{\omega} \end{gathered}$$

and try to find all ω's such that, with this f, the linear system (5.4) has a nonzero solution $(p, q) \in \mathbb{C}^2$. This leads to the characteristic equation

$$(bd + ac\omega^2) \frac{\sin \omega}{\omega} = 0$$

or

$$(bd + ac\lambda)\frac{\sin\sqrt{\lambda}}{\sqrt{\lambda}} = 0.$$

If $a = c = 0$ (Dirichlet *bc*, cf. example (i) above), then

$$spec(L_{bc}) = \{\pi^2 k^2 | k \in \mathbb{Z}_{\geq 1}\}$$

and all eigenvalues are simple. If $ac \neq 0$,

$$spec(L_{bc}) = \{\lambda_0\} \cup \{\pi^2 k^2 | k \in \mathbb{Z}_{\geq 1}\},$$

where $\lambda_0 = -\frac{bd}{ac}$. In this case all eigenvalues are simple, except if $\lambda_0 = \pi^2 k^2$ for some $k \in \mathbb{Z}_{\geq 1}$.

Now we can claim that for any $V \in L^2[0,1]$ and $L = -\frac{d^2}{dx^2} + V$, the operator L_{bc} with *bc* from the class $\mathcal{B}$ has a discrete spectrum *spec*(L_{bc}) which consists, up to a possible additional eigenvalue ν_0, of a sequence $(\nu_n)_{n\geq 1}$ which we enumerate as in (1.5). Further, the operator L_{bc}, its resolvent and Riesz projectors have all the properties stated in Lemmas 1.4–1.6 with obvious semantic adjustments.

Property (5.1) gives a substitute for Lemma 4.1. Now we have all the tools to repeat the constructions and the proofs of section 4 for *bc* in the class $\mathcal{B}$ to get the following theorem.

Theorem 5.1. *There exist absolute constants K_{12}, K_{13} such that for any 1-periodic potential V in H_0^w and any bc in the class $\mathcal{B}$,*

$$\sum_{n\geq N} w(2n)^2 |\nu_n - \lambda_{2n}|^2 \leq K_{12}(1 + \|V\|_w)^{K_{13}},$$

where $N = K_{12}(1 + \|V\|_w)^{K_{13}}$.

Appendix. We present two lemmas used in section 1.7 concerning the convolution operation in sequence spaces. For a weight $v = (v(k))_{k\in\mathbb{Z}}$ let

$$C_v^2 := \sup_{m\in\mathbb{Z}} \sum_{k\in\mathbb{Z}} \left(\frac{v(m)}{v(k)v(m-k)}\right)^2$$

and denote by $\ell_v^2 \equiv \ell_v^2(\mathbb{Z};\mathbb{C})$ the space of sequences $(a(k))_{k\in\mathbb{Z}}$ with

$$\|a\|_v := \left(\sum_k v(k)^2 |a(k)|^2\right)^{1/2} < \infty.$$

Lemma A.1. *If $C_v < \infty$, then $\ell_v^2(\mathbb{Z};\mathbb{C})$ is a convolution algebra and*

$$\|a * b\|_v \leq C_v \|a\|_v \|b\|_v.$$

Remark. Lemma A.1 is a special case of a much more general result due to Nikolski [17].

Proof of Lemma A.1. Let $a, b \in \ell_v^2$ be with norm 1 and define $c = (c(k))_{k\in\mathbb{Z}}$ by

$$c(k) := \sum_j a(k-j)b(j).$$

We have to show that $(v(k)c(k))_{k\in\mathbb{Z}}$ is a sequence in ℓ^2. Let $\alpha(k) := v(k)|a(k)|$ and $\beta(k) := v(k)|b(k)|$ $(k \in \mathbb{Z})$.

For any sequence $\gamma(k))_{k\in\mathbb{Z}}$ in ℓ^2,

$$\begin{aligned}\sum_k v(k)|c(k)||\gamma(k)| &\leq \sum_k \sum_j |\gamma(k)| \frac{v(k)}{v(k-j)v(j)} \alpha(k-j)\beta(j) \\ &\leq \left(\sum_{i,j} |\frac{v(i+j)}{v(i)v(j)}|^2 |\gamma(i+j)|^2 \right)^{1/2} \left(\sum_{i,j} (\alpha(i)\beta(j))^2 \right)^{1/2},\end{aligned}$$

where for the last inequality we used Cauchy's inequality in $\ell^2(\mathbb{Z}\times\mathbb{Z})$. As $\sum_{i,j} \alpha(i)^2\beta(j)^2 = 1$ by assumption and

$$\sum_{i,j} \left| \frac{v(i+j)}{v(i)v(j)} \gamma(i+j) \right|^2 \leq \sum_m \sum_j \left| \frac{v(m)}{v(m-j)v(j)} \right|^2 |\gamma(m)|^2 \leq C_v^2 \sum_m |\gamma(m)|^2$$

with $(\gamma(m))_{m\in\mathbb{Z}} \in \ell^2$ arbitrary, it follows that $\|c\|_v \leq C_v$. □

For any submultiplicative weight $(w(k))_{k\in\mathbb{Z}}$ and $\alpha \geq 0$, define

$$w_\alpha(k) := \left(1 + \frac{|k|}{2}\right)^\alpha w(k).$$

Notice that w_α is again submultiplicative.

LEMMA A.2. *If* $\alpha > 1/2$, *then* $C_{w_\alpha} < \infty$.

Proof of Lemma A.2. As w is submultiplicative,

$$\frac{w_\alpha(k)}{w_\alpha(j)w_\alpha(k-j)} \leq \frac{(1+\frac{1}{2}|k|)^\alpha}{(1+\frac{1}{2}|j|)^\alpha(1+\frac{1}{2}|k-j|)^\alpha},$$

and therefore,

$$C_{w_\alpha} \leq C(\alpha),$$

where $C(\alpha) < \infty$ is a constant satisfying

$$\sum_j \left(\left(1 + \frac{|j|}{2}\right) \left(1 + |\frac{k-j}{2}|\right) \right)^{-2\alpha} \leq C(\alpha)^2 \left(1 + \frac{|k|}{2}\right)^{-2\alpha}. \tag{A.1}$$

By an elementary computation one could show that

$$C(\alpha)^2 \leq 2(1+2^{2\alpha})\frac{2\alpha+1}{2\alpha-1}. \qquad \square \tag{A.2}$$

DETERMINING CONDUCTIVITY WITH SPECIAL ANISOTROPY BY BOUNDARY MEASUREMENTS*

GIOVANNI ALESSANDRINI[†] AND ROMINA GABURRO[†]

Abstract. We prove results of uniqueness and stability at the boundary for the inverse problem of electrical impedance tomography in the presence of possibly anisotropic conductivities. We assume that the unknown conductivity has the form $A = A(x, a(x))$, where $a(x)$ is an unknown scalar function and $A(x, t)$ is a given matrix-valued function. We also deduce results of uniqueness in the interior among conductivities A obtained by piecewise analytic perturbations of the scalar term a.

Key words. inverse boundary value problems, anisotropic conductivity, singular solutions

1. Introduction.

In this paper we shall consider the inverse conductivity problem in an anisotropic medium. Given, in a domain $\Omega \subset \mathbb{R}^n$ (representing an electrostatic conductor), a symmetric, positive definite matrix $A = A(x)$, $x \in \Omega$ (the conductivity tensor), the Dirichlet-to-Neumann map associated to A is the operator Λ_A which, for each solution u (the electrostatic potential) of the elliptic equation

$$\operatorname{div}(A\nabla u) = 0 \quad \text{in} \quad \Omega, \tag{1.1}$$

associates to its Dirichlet data $u|_{\partial\Omega}$ (the boundary voltage) the corresponding Neumann data (the boundary current density)

$$\Lambda_A \, u|_{\partial\Omega} = A \, \nabla u \cdot \nu|_{\partial\Omega}. \tag{1.2}$$

The inverse conductivity problem then consists of determining A from the knowledge of Λ_A. While for the case when A is a priori known to be isotropic (that is, $A(x) = a(x)\, I$, where a is a scalar function) the uniqueness issue can be considered solved (see [SU], [N]), the situation is more complicated in the anisotropic case.

Since Tartar's observation [KV1] that any diffeomorphism of Ω which keeps the boundary points fixed has the property of leaving the Dirichlet-to-Neumann map unchanged, whereas A is modified, different lines of research have been pursued.

One direction has been the one of proving that the conductivity A is uniquely determined up to a change of variables in the space coordinates (see [LeU], [S], [N], [LaU]).

Another direction has been the one of assuming that the conductivity A is a priori known to depend on a restricted number of unknown spatially dependent parameters. Kohn and Vogelius [KV1] suggested the study of matrices A which are completely known with the exception of one of their eigenvalues. In [A] it is considered the case when $A(x)$ is a priori known to have the structure $A(x) = A(a(x))$, where $t \to A(t)$ is a given matrix-valued function and $a = a(x)$ is an unknown scalar function. In other words, it is assumed that at each point x the conductivity may take one value among

a one-parameter family of admissible matrices $A(t)$ which is a priori known. In [A] results of uniqueness and stability at the boundary are proven under the additional assumption of monotonicity

$$D_t A(t) \geq \text{Const.}\, I \ > 0.$$

Lionheart [L] has proven results of uniqueness at the boundary when $A(x)$ has the structure

$$A(x) \ = \ a(x)\, A_0(x),$$

where $A_0(x)$ is given and $a \ = \ a(x)$ is an unknown scalar parameter. This structure condition may be interpreted as if at every point the anisotropic character of the conductivity were known with the exception of a scaling factor $a(x)$ which may vary from point to point.

The aim of this paper is to show that the method of singular solutions introduced in [A] enables us also to treat the case when $A(x)$ has the more general structure

$$A(x) \ = \ A(x,\, a(x)),$$

where $a(x)$ is an unknown scalar function and $A(x,\, t)$ is given and satisfies the monotonicity assumption

$$D_t A(x,\, t) \geq \text{Const.}\, I \ > 0\,.$$

We shall prove results of uniqueness and stability at the boundary which improve in various respects the results in [A] and can also be applied to the problem introduced in [L].

In Theorem 2.1 we shall prove a result of Lipschitz continuity of the boundary values of $A(x,\, a(x))$ in terms of its corresponding Dirichlet-to-Neumann map.

Theorem 2.2 gives Hölder estimates on the dependence from the Dirichlet-to-Neumann map of higher order derivatives of $A(x,\, a(x))$. This theorem is expressed in a local form. Theorem 2.3 contains the uniqueness result in the determination of $A(x,\, a(x))$ and its derivatives on the boundary. Also in this case, the result is expressed in local terms.

Theorem 2.4 gives a global uniqueness result of $A(x,\, a(x))$ among perturbations $A(x,\, b(x))$, where $a(x) - b(x)$ is piecewise analytic. The procedure under which Theorem 2.3 implies global uniqueness results in the piecewise analytic category is by now well known (see [KV2], [A], [L]); we wish to stress, however, that the present result does not require any condition of higher order differentiability on the given matrix $A(x,\, t)$; this also gives a substantial improvement to Theorem 3.4 in [L].

We conclude the paper with a discussion of the so-called one-eigenvalue-problem treated by Kohn and Vogelius [KV1]. In fact, we observe that this problem does not precisely fit the scheme of our Theorems 2.1–2.4 since, in this case, the monotonicity assumption is not satisfied. We present, however, some arguments showing how the monotonicity assumption can be relaxed in such a way that Theorems 2.1–2.4 continue to hold and, at the same time, it enables us to encompass the one-eigenvalue-problem.

The plan of the paper is as follows. In section 2 we give some basic definitions and the statements of the main Theorems 2.1–2.4. Section 3 contains the proofs of the stability results, Theorems 2.1 and 2.2. Section 4 contains the proofs of the uniqueness results, Theorems 2.3 and 2.4. Finally, section 5 contains the discussion of a generalization of the above theorems which enables us also to treat the one-eigenvalue-problem by Kohn and Vogelius.

2. Main results. In what follows we shall need the following quantitative formulation of the Lipschitz regularity of the boundary of Ω.

Definition 2.1. *Given positive numbers L, r, and h satisfying $h \geq Lr$, we say that a bounded domain $\Omega \in \mathbb{R}^n$ has a Lipschitz boundary if, for every $x^0 \in \partial\Omega$, there exists a rigid transformation of coordinates which maps x^0 into the origin such that, setting $x = (x', x_n)$, $x' \in \mathbb{R}^{n-1}$, $x_n \in \mathbb{R}$, we have*

$$\begin{aligned}&\Omega \cap \{ x = (x', x_n) \mid \ |x'| < r, |x_n| < h\} \\ &= \{ x = (x', x_n) \mid \ |x'| < r, |x_n| < h, x_n \geq f(x') \},\end{aligned}$$

where $f = f(x')$ is a Lipschitz function defined for $|x'| < r$, which satisfies

$$\begin{gathered} f(0) = 0, \\ |f(x') - f(y')| \leq L\,|x' - y'| \end{gathered}$$

for every x', $y' \in \mathbb{R}^{n-1}$, with $|x'|$, $|y'| < r$.

Let us introduce here the class of functions $A(x, t)$ which will be considered as admissible conductivities in our results.

Definition 2.2. *Given $p > n$, $E > 0$, and denoting by Sym_n the class of $n \times n$ real-valued symmetric matrices, we say that $A(\cdot, \cdot) \in \mathcal{H}$ if the following conditions hold:*

$$A \in W^{1,p}(\Omega \times [\lambda^{-1}, \lambda], Sym_n), \tag{2.1}$$

$$D_t A \in W^{1,p}(\Omega \times [\lambda^{-1}, \lambda], Sym_n), \tag{2.2}$$

$$\begin{aligned} supess_{t \in [\lambda^{-1}, \lambda]} \Big(&\| A(\cdot, t) \|_{L^p(\Omega)} + \| D_x A(\cdot, t) \|_{L^p(\Omega)} \\ &+ \| D_t A(\cdot, t) \|_{L^p(\Omega)} + \| D_t D_x A(\cdot, t) \|_{L^p(\Omega)} \Big) \leq E, \end{aligned} \tag{2.3}$$

$$\begin{aligned} \lambda^{-1}|\xi|^2 \leq A(x,t)\xi \cdot \xi \leq \lambda|\xi|^2 \quad &for\ almost\ every\ x \in \Omega, \\ &for\ every\ t \in [\lambda^{-1}, \lambda],\ \xi \in \mathbb{R}^n, \end{aligned} \tag{2.4}$$

$$\begin{aligned} D_t A(x,t)\, \xi \cdot \xi \geq E^{-1}|\xi|^2 \quad &for\ almost\ every\ x \in \Omega, \\ &for\ every\ t \in [\lambda^{-1}, \lambda],\ \xi \in \mathbb{R}^n. \end{aligned} \tag{2.5}$$

We observe that (2.4) is a condition of uniform ellipticity, whereas (2.5) is a condition of monotonicity with respect to the last variable t. Denoting by $\langle \cdot, \cdot \rangle$ the $L^2(\partial\Omega)$-pairing between $H^{\frac{1}{2}}(\partial\Omega)$ and its dual $H^{-\frac{1}{2}}(\partial\Omega)$, the Dirichlet-to-Neumann map

$$\Lambda_{A(x,a)} : H^{\frac{1}{2}}(\partial\Omega) \longrightarrow H^{-\frac{1}{2}}(\partial\Omega)$$

is defined by

$$\langle \Lambda_{A(x,a)}\, u, \phi \rangle = \int_\Omega A(x, a(x)) \nabla u(x) \cdot \nabla \phi(x)\, dx$$

for any $\phi \in H^1(\Omega)$ and for any $u \in H^1(\Omega)$ which is a weak solution to

$$\operatorname{div}(A(x,\, a(x))\, \nabla u(x)) \;=\; 0.$$

We shall denote by $\|\cdot\|_*$ the norm on the Banach space of bounded linear operators between $H^{\frac{1}{2}}(\partial\Omega)$ and $H^{-\frac{1}{2}}(\partial\Omega)$.

THEOREM 2.1 (Lipschitz stability of boundary values). *Given $p > n$, let Ω be a bounded domain with Lipschitz boundary with constants L, r, h. Let a, b satisfy*

$$\lambda^{-1} \le a(x), b(x) \le \lambda \qquad \textit{for every } x \in \Omega, \tag{2.6}$$

$$\| a \|_{W^{1,p}(\Omega)}\,,\ \| b \|_{W^{1,p}(\Omega)} \le E. \tag{2.7}$$

Let $A \in \mathcal{H}$; then we have

$$\| A(x,\, a(x)) - A(x,\, b(x)) \|_{L^\infty(\partial\Omega)} \le C \, \| \Lambda_{A(x,\, a)} - \Lambda_{A(x,\, b)} \|_* \,. \tag{2.8}$$

Here $C > 0$ is a constant which depends only on n, p, L, r, h, $diam(\Omega)$, λ, and E.

THEOREM 2.2 (Hölder stability of derivatives at the boundary). *Let a, b satisfy* (2.6), (2.7) *and let $A \in \mathcal{H}$. Given $y \in \partial\Omega$ and a neighborhood U of y in $\bar\Omega$, assume that, for some positive integer k and some α, $0 < \alpha < 1$, we have*

$$A \in C^{k,\,\alpha}(\,\bar U \times [\lambda^{-1}, \lambda]\,), \tag{2.9}$$

$$\| A \|_{C^{k,\,\alpha}(\,\bar U \times [\lambda^{-1},\,\lambda])} \le E_k, \tag{2.10}$$

$$\| a - b \|_{C^{k,\,\alpha}(\,\bar U)} \le E_k. \tag{2.11}$$

Then, for every neighborhood W of y in $\bar\Omega$ such that $\bar W \subset U$,

$$\begin{aligned} &\| D^k(A(x,a(x)) - A(x,b(x))) \|_{L^\infty(\partial\,\Omega\,\cap\,\bar W)} \\ &\le C \, \| \Lambda_{A(x,\, a)} - \Lambda_{A(x,\, b)} \|_*^{\delta_k\, \alpha}, \end{aligned} \tag{2.12}$$

where

$$\delta_k \;=\; \prod_{j\,=\,0}^{k} \frac{\alpha}{\alpha + j}. \tag{2.13}$$

Here $C > 0$ is a constant which depends only on n, p, L, r, h, $diam(\Omega)$, $dist(W \cap \partial\Omega,\, \Omega \setminus U)$, λ, E, α, k, and E_k.

THEOREM 2.3 (uniqueness at the boundary). *Let a, b satisfy* (2.6), (2.7) *and let $A \in \mathcal{H}$. Given $y \in \partial\Omega$ and a neighborhood U of y in $\bar\Omega$, assume that, for some positive integer k, we have*

$$a - b \in C^k(\bar U)\,. \tag{2.14}$$

If

$$\Lambda_{A\,(x,\, a(x))} \;=\; \Lambda_{A\,(x,\, b(x))},$$

then

$$D^j(a-b) \;=\; 0 \qquad \text{on } \partial\Omega \cap \bar{U} \qquad \text{for all } j \le k. \tag{2.15}$$

If, in addition, we have

$$A \in C^{\,k}\Big(\bar{U} \times [\lambda^{-1}, \lambda]\Big), \tag{2.16}$$

then

$$D^j(A(x\,,\,a(x))) \;=\; D^j(A(x\,,\,a(x))) \qquad \text{on } \partial\Omega \cap \bar{U} \qquad \text{for all } j \le k. \tag{2.17}$$

Theorem 2.4 (uniqueness in the interior). *Let a, b satisfy* (2.6), (2.7) *with $p = \infty$. Let $A \in \mathcal{H}$ and, in addition, $A \in W^{1,\,\infty}\big(\Omega \times [\lambda^{-1}, \lambda],\ Sym_n\big)$. Suppose that Ω can be partitioned into a finite number of Lipschitz domains, $\{A_j\}_{j\,=\,1,\ldots\,,N}$ such that $a - b$ is analytic on each $\bar{A}_j$.*

If

$$\Lambda_{A(x,\,a)} \;=\; \Lambda_{A(x,\,b)},$$

then we have

$$A(x,\, a(x)) \;=\; A(x,\, b(x)) \qquad \text{in } \Omega. \tag{2.18}$$

3. Proofs of the stability theorems. We need to introduce a unitary vector field $\tilde{\nu}$ locally defined near $\partial\Omega$ such that (i) $\tilde{\nu}$ is $C^{\,\infty}$ smooth, and (ii) $\tilde{\nu}$ is nontangential to $\partial\Omega$. To this purpose we shall make use of the following lemmas.

Lemma 3.1. *For every $x^0 \in \partial\Omega$, let $(x^{\prime},\, x_n)$ be the coordinates suited for the local representation of $\partial\Omega$ given by Definition* 2.1. *Let $x \;=\; (x^{\prime},\; f(x^{\prime}))$ be such that $|x^{\prime}| \le \rho$, where $\rho \;=\; \frac{h}{2L}$, then, picking $l \;=\; \frac{h}{2}$, we have that the truncated cone*

$$T_l(x) = \{\, z = (z^{\prime},\, z_n) \mid f(x^{\prime}) - l < z_n < f(x^{\prime}), \\ |z^{\prime} - x^{\prime}| < -L\,(f(x^{\prime}) - z_n)\}$$

has an empty intersection with Ω.

Proof. It suffices to verify that the base of $T_l(x)$ is contained in the cylinder

$$C_{r,\,h} \;=\; \{x \;=\; (x^{\prime},\, x_n)|\; |x^{\prime}| < r,\; |x_n| < h\}.$$

Hence, the verification consists of elementary calculations. □

Lemma 3.2. *There exists a finite number of points $x^1, \ldots\,, x^k \in \partial\Omega$ and rotations $R_l : \mathbb{R}^n \longrightarrow \mathbb{R}^n$, $l = 1, \ldots\,, k$, such that* (i) *the open cylinders $V_l = x^{\,l} + R_{\,l} C_{\rho,\,h}$ cover $\partial\Omega$,* (ii) *the axis of each cylinder V_l coincides with the nth coordinate axis for the local representation of $\partial\Omega$ near $x^{\,l}$ given by Definition* 2.1, *and* (iii) *for every $x \in \partial\Omega \cap V_l$, $l \;=\; 1, \ldots\,, k$, the truncated cone $x + R_{\,l} T_{\,l}(0)$ does not intersect Ω.*

Proof. The proof follows easily from the previous lemma and the compactness of $\partial\Omega$. □

Lemma 3.3. *For any $x^0 \in \partial\Omega$, let V_l be the cylinder introduced in the previous lemma such that $x^0 \in V_l$. Setting $\tilde{\nu}$ as the nth coordinate unit vector along the axis of V_l which points to the exterior of Ω, we have that the point*

$$z_\sigma \;=\; x^0 + \sigma\tilde{\nu} \tag{3.1}$$

satisfies

$$C\sigma \le d(z_\sigma, \partial\Omega) \le \sigma \qquad \textit{for every } \sigma,\ 0 \le \sigma \le \sigma^0\,, \tag{3.2}$$

where σ^0 *and* C *depend only on* L, r, h.

Proof. The proof is an elementary consequence of Definition 2.1 and the previous lemmas. □

Let us recall some results about singular solutions of elliptic equations. We consider elliptic operators

$$L\ =\ \frac{\partial}{\partial x_i}\left(a_{ij}\frac{\partial}{\partial x_j}\right) \qquad \text{in } B_R\ =\ \left\{x \in \mathbb{R}^n |\, |x| < R\right\}, \tag{3.3}$$

where the coefficient matrix $(a_{ij}(x))$ is symmetric and satisfies

$$\lambda^{-1}|\,\xi|^2 \le a_{ij}(x)\xi_i\,\xi_j \le \lambda|\,\xi|^2 \qquad \text{for every } x,\ \xi,\ x \in B_R,\ \xi \in \mathbb{R}^n, \tag{3.4}$$

and also

$$\|\, a_{ij}\,\|_{\,W^{1,\,p}(B_R)} \le E, \qquad i,\ j\ =\ 1, \dots, n, \tag{3.5}$$

where $p > n$ and λ, E are positive constants.

Theorem 3.4 (singular solutions). *Let* L *satisfy* (3.3)–(3.5). *For every spherical harmonic* S_m *of degree* $m\ =\ 0,\ 1,\ 2, \dots$, *there exists* $u \in W^{2,\,p}_{loc}(B_R \setminus \{0\})$ *such that*

$$Lu\ =\ 0 \qquad \textit{in } B_R \setminus \{\,0\}, \tag{3.6}$$

and furthermore

$$u(x) = log\,|\, Jx\,|\, S_0\left(\frac{Jx}{|\,Jx\,|}\right) + w(x), \qquad when\, n\ =\ 2\, and\, m = 0, \tag{3.7}$$

$$u(x) = |\,Jx\,|^{\,2-n-m}\, S_m\left(\frac{Jx}{|\,Jx\,|}\right) + w(x) \qquad otherwise, \tag{3.8}$$

where J *is the positive definite symmetric matrix such that* $J\ =\ \sqrt{(a_{ij}(0))^{-1}}$ *and* w *satisfies*

$$|\,w(x)| + |\,x\,|\,|Dw(x)| \le C\,|\,x\,|^{\,2-n-m+\alpha} \quad in \quad B_R \setminus \{\,0\,\}, \tag{3.9}$$

$$\left(\int_{r<|x|<2r} |D^2w|^p\right)^{\frac{1}{p}} \le C\, r^{-n-m+\alpha+\frac{n}{p}} \quad \textit{for every } r,\ 0 < r < R/2. \tag{3.10}$$

Here α *is any number such that* $0 < \alpha < 1 - \frac{n}{p}$, *and* C *is a constant depending only on* α, n, p, R, λ, *and* E.

Proof. See Theorem 1.1 in [A]. □

We shall also need the following lemma.

Lemma 3.5. *Let the hypotheses of Theorem* 3.4 *be satisfied. For every* $m\ =\ 0,\ 1,\ 2, \dots$, *there exists a spherical harmonic* S_m *of degree* m *such that the solution* u *on* (3.6) *given by Theorem* 3.4 *also satisfies*

$$|Du(x)| > |x|^{\,1-(n+m)} \tag{3.11}$$

for every x, $0 < |x| < r_0$, where $r_0 > 0$ depends only on λ, E, p, m, and R.

Proof. The proof of this lemma can be obtained along the same lines as the proof of [A, Lemma 3.1]. □

LEMMA 3.6. *Let Ω be a domain in $\mathbb{R}^n$ $(n \geq 2)$ with Lipschitz boundary $\partial\Omega$. Let $A \in \mathcal{H}$ and let a be a function satisfying conditions* (2.6), (2.7). *Then we have*

$$A(\cdot,\, a(\cdot)) \in W^{1,\,p}(\Omega,\, Sym_n), \tag{3.12}$$

and furthermore,

$$\| A(\cdot,\, a(\cdot)) \|_{W^{1,\,p}(\Omega)} \leq CE(1+ \| a \|_{W^{1,\,p}(\Omega)}), \tag{3.13}$$

where C is a positive constant depending only on λ, Ω, n, and p.

Proof. We observe that the two functions

$$\begin{aligned} t &\longrightarrow A(x,\, t), \\ t &\longrightarrow D_x A(x,\, t) \end{aligned}$$

are absolutely continuous functions for almost every $x \in \Omega$ (see [M, Lemma 3.1.1]). Then the following identities hold:

$$A(x,\, a(x)) = A(x,\, \lambda) - \int_{a(x)}^{\lambda} D_t A(x,\, t)\, dt\,, \tag{3.14}$$

$$D_x A(x,\, t)|_{t\,=\,a(x)} = D_x A(x,\, \lambda) - \int_{a(x)}^{\lambda} D_t D_x A(x,\, t)\, dt \tag{3.15}$$

for almost every $x \in \Omega$.

We obtain

$$\| A(\cdot,\, a(\cdot)) \|_{L^p(\Omega)} \leq \lambda\, E. \tag{3.16}$$

Similarly, by (3.15) and by the Sobolev inequality

$$\| D_t A(\cdot,\, t) \|_{L^\infty(\Omega)} \leq C\Big(\| D_t A(\cdot,\, t) \|_{L^p(\Omega)} + \| D_x D_t A(\cdot,\, t) \|_{L^p(\Omega)} \Big),$$

we deduce

$$\| D_x A(\cdot,\, a(\cdot)) \|_{L^p(\Omega)} \leq \lambda\, E + CE \| D_x a \|_{L^p(\Omega)}\,. \tag{3.17}$$

By (3.16), (3.17), the proof is completed. □

Proof of Theorem 2.1. We start from the identity (see, for instance, [A])

$$\int_\Omega (A(x,\, a) - A(x,\, b)) Du \cdot Dv \;=\; \langle (\Lambda_{A(x,\,a)} - \Lambda_{A(x,\,b)})\, u,\, v \rangle, \tag{3.18}$$

where u, v are two arbitrary solutions to

$$\operatorname{div}(A(x,\, a)\operatorname{grad} u) \;= 0\,, \qquad \operatorname{div}(A(x,\, b)\operatorname{grad} v) \;=\; 0\,,$$

respectively. Let $x^0 \in \partial\Omega$ be such that

$$|(a-b)(x^0)| \;= \| a-b \|_{L^\infty(\,\partial\Omega)},$$

and set, for convenience, $(a-b)(x^0) > 0$. Let V_l be one of the neighborhoods, selected in Lemmas 3.2 and 3.3, such that $x^0 \in V_l$. We let $\tilde{\nu}$ be defined according to Lemma 3.3. Let us consider $z_\sigma = x^0 + \sigma\tilde{\nu}$, where σ satisfies $0 < \sigma \leq \min\{\sigma_0, \frac{r_0}{2}\}$, where σ_0 is the number fixed in Lemma 3.3, and r_0 is the number appearing in Lemma 3.5 when the integer m is chosen to be equal to zero. We observe that we can continue $a(x)$, $b(x)$ to $B_R(z_\sigma)$ in such a way that $A(x,\, a(x))$ and $A(x,\, b(x))$ continue to satisfy uniform bounds of ellipticity and on the $W^{1,\,p}$-norm. We now consider the ball $B_\rho(z_\sigma)$, with $\rho = r_0$ and fix the two solutions $u,\, v \in W^{2,\,p}(\Omega)$ found in Theorem 3.4 having a Green function type of singularity at z_σ, that is, $m = 0$ and

$$u(x) = |J_a(x-z_\sigma)|^{\,2-n} + O(|x-z_\sigma|^{\,2-n+\alpha}), \tag{3.19}$$

$$v(x) = |J_b(x-z_\sigma)|^{\,2-n} + O(|x-z_\sigma|^{\,2-n+\alpha}), \tag{3.20}$$

where $J_a = \sqrt{A(z_\sigma,\, a(z_\sigma))^{-1}}$, $J_b = \sqrt{A(z_\sigma,\, b(z_\sigma))^{-1}}$.

Applying (3.18) to the two solutions u, v above, we obtain

$$\begin{aligned} &\| \Lambda_{A(x,\,a)} - \Lambda_{A(x,\,b)} \|_* \| u \|_{H^{\frac12}(\partial\Omega)} \| v \|_{H^{\frac12}(\partial\Omega)} \\ &\geq \left| \int_{B_\rho(z_\sigma)\,\cap\,\Omega} (A(x,\, a(x)) - A(x,\, b(x)))\, Du \cdot Dv \right| \\ &- \left| \int_{\Omega\,\setminus\,B_\rho(z_\sigma)} (A(x,\, a(x)) - A(x,\, b(x)))\, Du \cdot Dv \right|. \end{aligned} \tag{3.21}$$

Then using (3.9) we end up with

$$\begin{aligned} &\left| \int_{B_\rho(z_\sigma)\,\cap\,\Omega} \frac{(A(x,\,a) - A(x,\,b))J_a^2(x-z_\sigma)\cdot J_b^2(x-z_\sigma)}{|J_a(x-z_\sigma)|^{\,n}|J_b(x-z_\sigma)|^{\,n}} \right| \\ &\leq C \int_{B_\rho(z_\sigma)\,\cap\,\Omega} |x-z_\sigma|^{\,2-2n+\alpha} \\ &+ \int_{\Omega\,\setminus\,B_\rho(z_\sigma)} |A(x,\,a) - A(x,\,b)|\, |x-z_\sigma|^{\,2-2n} \\ &+ \| \Lambda_{A(x,\,a)} - \Lambda_{A(x,\,b)} \|_* \| u \|_{H^{\frac12}(\partial\,\Omega)} \| v \|_{H^{\frac12}(\partial\,\Omega)}\ . \end{aligned} \tag{3.22}$$

We recall that, by Lemma 3.6 and by our assumptions, $A(x,\, a(x)) \in W^{1,\,p}(\Omega)$ with $p > n$; hence $A(x, a(x))$ is Hölder continuous with exponent $\beta = 1 - \frac{n}{p}$ in $\bar{\Omega}$. Therefore,

$$A(x,\, a(x)) - A(x,\, b(x)) \;=\; A(x^0,\, a(x^0)) - A(x^0,\, b(x^0)) + O(|x-x^0|^{\beta}).$$

We obtain

$$\begin{aligned} &\int_{B_\rho(z_\sigma)\,\cap\,\Omega} \frac{J_b^{\,2}(A(x^0,\, a(x^0)) - A(x^0,\, b(x^0)))J_a^{\,2}(x-z_\sigma)\cdot(x-z_\sigma)}{|J_a(x-z_\sigma)|^{\,n}|J_b(x-z_\sigma)|^{\,n}} \\ &\leq C \int_{B_\rho(z_\sigma)\,\cap\,\Omega} |x-z_\sigma|^{\,2-2n}|x-x^0|^{\,\beta} \\ &+ C \int_{B_\rho(z_\sigma)\,\cap\,\Omega} |x-z_\sigma|^{\,2-2n+\alpha} \\ &+ \int_{\Omega\,\setminus\,B_\rho(z_\sigma)} |A(x,\,a) - A(x,\,b)|\, |x-z_\sigma|^{\,2-2n} \\ &+ \| \Lambda_{A(x,\,a)} - \Lambda_{A(x,\,b)} \|_* \| u \|_{H^{\frac12}(\partial\,\Omega)} \| v \|_{H^{\frac12}(\partial\,\Omega)}\ . \end{aligned} \tag{3.23}$$

We now consider the quantity $J_b^2(A(x^0,\, a)-A(x^0,\, b))J_a^2(x-z_\sigma)\cdot(x-z_\sigma)$, which appears on the left-hand side of (3.23). Recalling that $J_a^2 = A(z_\sigma,\, a(z_\sigma))^{-1}$, we have

$$|J_a^2 - A(x^0,\, a(x^0))^{-1}| \le C|z_\sigma - x^0|^{\,\beta} \le C\sigma^{\,\beta}$$

and likewise, $|J_b^2 - A(x^0,\, b(x^0))^{-1}| \le C\sigma^{\,\beta}$. Therefore,

$$\begin{aligned}
&J_b^2(A(x^0,\, a)-A(x^0,\, b))\, J_a^2(x-z_\sigma)\cdot(x-z_\sigma)\\
&\ge (A(x^0,\, b)^{-1} - A(x^0,\, a)^{-1})(x-z_\sigma)\cdot(x-z_\sigma)\\
&-C\sigma^{\beta}(a(x^0)-b(x^0))|x-z_\sigma|^2.
\end{aligned}$$

Using the ellipticity assumption (2.4) and the monotonicity assumption (2.5), we compute

$$\begin{aligned}
&(A(x^0,\, b)^{-1} - A(x^0,\, a)^{-1})(x-z_\sigma)\cdot(x-z_\sigma)\\
&= \left(\int_{a(x^0)}^{b(x^0)} D_t(A(x^0,\, t))^{-1}\, dt\right)(x-z_\sigma)\cdot(x-z_\sigma)\\
&= \left(\int_{a(x^0)}^{b(x^0)} -A^{-1}(x^0,\, t)\, D_tA(x^0,\, t)\, A^{-1}(x^0,\, t)\, dt\right)(x-z_\sigma)\cdot(x-z_\sigma)\\
&\ge \int_{b(x^0)}^{a(x^0)} E^{-2}\lambda^{-2}\, |x-z_\sigma|^2\, dt.
\end{aligned}$$

Hence, we have

$$\begin{aligned}
&J_b^2(A(x^0,\, a)-A(x^0, b))\, J_a^2(x-z_\sigma)\cdot(x-z_\sigma)\\
&\ge (E^{-2}\lambda^{-2} - C\sigma^{\,\beta})(a(x^0)-b(x^0))\, C\, |x-z_\sigma|^2
\end{aligned}$$

and, choosing

$$\sigma \le \Big(\frac{1}{2C}E^{-2}\,\lambda^{-2}\Big)^{\frac{1}{\beta}},$$

we obtain

$$\begin{aligned}
&J_b^2(A(x^0,\, a)-A(x^0,\, b))\, J_a^2(x-z_\sigma)\cdot(x-z_\sigma)\\
&\ge C\,(a(x^0)-b(x^0))\,|x-z_\sigma|^2.
\end{aligned}\tag{3.24}$$

By applying (3.24) to (3.23),

$$\begin{aligned}
&\|\, a-b\,\|_{L^{\,\infty}(\partial\Omega)} \int_{B_\rho(z_\sigma)\,\cap\,\Omega} |x-z_\sigma|^{\,2-2n}\\
&\le C\Big\{ \int_{B_\rho(z_\sigma)\,\cap\,\Omega} |x-z_\sigma|^{\,2-2n}|x-x^0|^{\,\beta}\\
&\quad+ \int_{B_\rho(z_\sigma)\,\cap\,\Omega} |x-z_\sigma|^{\,2-2n+\alpha}\\
&\quad+ \int_{\Omega\,\setminus\, B_\rho(z_\sigma)} |A(x,\, a)-A(x,\, b)|\,|x-z_\sigma|^{\,2-2n}\\
&\quad+ \|\,\Lambda_{A(x,\,a)} - \Lambda_{A(x,\,b)}\,\|_*\|\, u\,\|_{H^{\frac{1}{2}}(\partial\,\Omega)}\|\, v\,\|_{H^{\frac{1}{2}}(\partial\,\Omega)}\Big\}.
\end{aligned}$$

By estimating the integrals appearing above and the $H^{\frac{1}{2}}(\partial\Omega)$ norms of u and v, we obtain

$$\| a-b \|_{L^\infty(\partial\,\Omega)}\, \sigma^{2-n} \le C\Big\{\sigma^{2-n+\beta}+\sigma^{2-n+\alpha}+C + \| \Lambda_{A(x,\,a)}-\Lambda_{A(x,\,b)} \|_*\, \sigma^{2-n}\Big\};$$

see [A, Proof of Theorem 1.2] for details. Therefore,

$$\| a-b \|_{L^\infty(\partial\,\Omega)} \le C\Big\{\omega(\sigma)+ \| \Lambda_{A(x,\,a)}-\Lambda_{A(x,\,b)} \|_* \Big\}, \tag{3.25}$$

where $\omega(\sigma)\to 0$ as $\sigma \to 0$. From (3.25) we obtain the following estimate:

$$\| a-b \|_{L^\infty(\partial\,\Omega)} \le C \,\| \Lambda_{A(x,\,a)}-\Lambda_{A(x,\,b)} \|_* \,. \tag{3.26}$$

Recalling that, for almost every $x\in\Omega$, the function

$$t \longrightarrow A(x,\,t)$$

is absolutely continuous on $[\lambda^{-1},\,\lambda]$, we may write

$$\begin{aligned} |A(x,\,a(x))-A(x,\,b(x))| &= \left| \int_{b(x)}^{a(x)} D_tA(x,\,t)\,dt \right| \\ &\le \int_{b(x)}^{a(x)} \mathrm{Sup}_{\,t,\,x}|\,D_tA(x,\,t)\,|\,dt \\ &\le C\,|\,(a(x)-b(x))\,| \end{aligned}$$

for every $x\in\bar\Omega$. Taking the L^∞-norm on both sides, we obtain

$$\| A(x,\,a)-A(x,\,b) \|_{L^\infty(\partial\,\Omega)} \le C\ \| a-b \|_{L^\infty(\partial\,\Omega)} \,. \tag{3.27}$$

By combining (3.26) and (3.27) we obtain (2.8). □

Proof of Theorem 2.2. Possibly reducing the values of h, r in Definition 2.1, it suffices to consider the case when $U = V_l\cap\bar\Omega$, where V_l is one of the cylinders found in Lemma 3.2 and $W = \frac{1}{2}\,V_l\cap\bar\Omega$, where $\frac{1}{2}\,V_l$ is the cylinder having the same center as V_l and half sizes compared to V_l. First, we shall prove

$$\left\| \frac{\partial^j}{\partial\tilde\nu^j}(a-b) \right\|_{L^\infty(\partial\Omega\,\cap\,\bar W)} \le C\,\| \Lambda_{A(x,\,a)}-\Lambda_{A(x,\,b)} \|_*^{\delta_j} \quad \text{for every } j\le k, \tag{3.28}$$

where δ_j is given by (2.13) and $\tilde\nu$ is the unit vector introduced in Lemma 3.3. We proceed by induction on k. Using (3.26) in the proof of Theorem 2.1, we have that (3.28) is satisfied when $k = 0$. Let us assume that (3.28) holds when $j = k-1$, and let us prove it for $j = k$.

Let m be a positive integer. Let $x^0\in\partial\Omega\cap W$ be such that (up to exchanging the roles of a and b)

$$(-1)^k\frac{\partial^k}{\partial\tilde\nu^k}(a-b)(x^0) \;=\; \left\| \frac{\partial^k}{\partial\tilde\nu^k}(a-b) \right\|_{L^\infty\,(\partial\,\Omega\,\cap\,\bar W)} . \tag{3.29}$$

Let $z_\sigma = x^0 + \sigma\tilde{\nu}$, with $\sigma \le \min\{\sigma_0, \frac{\rho}{2}\}$, where σ_0 is the number appearing in Lemma 3.3 and $\rho = \min\{r_0, \frac{h}{4L}\}$, where r_0 is the number chosen in Lemma 3.5 in dependence of m. We consider the ball $B_\rho(z_\sigma)$; we have that $B_\rho(z_\sigma) \cap \Omega$ will be nonempty and also

$$B_\rho(z_\sigma) \cap \bar{\Omega} \subset U. \tag{3.30}$$

As we did in Theorem 2.1, we can continue $A(x, a(x))$, $A(x, b(x))$ outside of Ω. Consequently, let u, v be the solutions obtained in Theorem 3.4 having a singularity at z_σ and corresponding to the spherical harmonic S_m indicated in Lemma 3.5. We apply (3.18) to two such solutions. We now use the property

$$A(x, t) \in C^1(\bar{U} \times [\lambda^{-1}, \lambda])$$

and from the Lagrange theorem, for every $x \in \bar{U}$ there exists $t(x)$, $0 < t(x) < 1$, such that

$$\begin{aligned}\Big(A(x, a(x)) - A(x, b(x))\Big) Du \cdot Dv = {} & (a(x) - b(x)) \\ & \cdot D_t A(x, t)|_{t = c(x)} Du \cdot Dv,\end{aligned}$$

where $c(x) = a(x) + t(x)(b(x) - a(x))$, hence

$$\begin{aligned}&\| \Lambda_{A(x, a)} - \Lambda_{A(x, b)} \|_* \| u \|_{H^{\frac{1}{2}}(\partial\Omega)} \| v \|_{H^{\frac{1}{2}}(\partial\Omega)} \\ &\ge \int_\Omega (A(x, a) - A(x, b)) Du \cdot Dv \\ &\ge \int_{B_\rho(z_\sigma) \cap \Omega} (a - b)\Big(D_t A(x, t)|_{t = c}\Big) Du \cdot Dv \\ &- \int_{\Omega \setminus B_\rho(z_\sigma)} |A(x, a) - A(x, b)|\, |Du|\, |Dv|.\end{aligned}$$

From the formulas (3.8)–(3.9) we have

$$\begin{aligned}|Du - Dv| \le {} & C(|x - z_\sigma|^{1-n-m} \,|a(z_\sigma) - b(z_\sigma)| \\ & + |x - z_\sigma|^{1-n-m+\alpha}) \\ \le {} & C\Big(|x - z_\sigma|^{1-n-m} |a(x^0) - b(x^0)| \\ & + |x - z_\sigma|^{1-n-m} \sigma^\beta + |x - z_\sigma|^{1-n-m+\alpha}\Big),\end{aligned}$$

and since $|x - z_\sigma| \ge C\sigma$, for every $x \in B_\rho(z_\sigma)$ and $\alpha < \beta$,

$$\begin{aligned}|Du - Dv| \le {} & C(|x - z_\sigma|^{1-n-m} |\, a(x^0) - b(x^0)| \\ & + |x - z_\sigma|^{1-n-m+\alpha}).\end{aligned} \tag{3.31}$$

Let us compute

$$\begin{aligned}& D_t A(x, t)|_{t = c(x)} Du \cdot Dv \\ &= D_t A(x, t)|_{t = c(x)} Du \cdot Du + D_t A(x, t)|_{t = c(x)} Du \cdot (Dv - Du) \\ &\ge C\, |Du|^2 \\ &- C\, |Du| \Big\{ |x - z_\sigma|^{1-n-m} |\, a(x^0) - b(x^0)| + |x - z_\sigma|^{1-n-m+\alpha} \Big\}.\end{aligned}$$

Therefore,

$$\begin{aligned} &D_tA(x,\,t)|_{\,t\,=\,c\,(x)}Du\cdot Dv\\ &\geq\ C\,|x-z_\sigma|^{\,2-2(n+m)}-\ C|x-z_\sigma|^{\,2-2(n+m)}|\,a(x^0)-b\,(x^0)|\\ &-C\,|x-z_\sigma|^{\,2-2(n+m)}\Big(1-|\,a(x^0)-b\,(x^0)|-|x-z_\sigma|^{\,\alpha}\Big) \end{aligned}\tag{3.32}$$

for almost every $x\in B_\rho(z_\sigma)\cap\Omega$.

Recalling that (3.28) holds for $j\,=\,0$, we obtain

$$\begin{aligned} &D_tA(x,\,t)|_{\,t\,=\,c\,(x)}Du\cdot Dv\\ &\geq C|x-z_\sigma|^{\,2-2(n+m)}\Big(1-C\ \parallel\Lambda_{A(x,\,a)}-\Lambda_{A(x,\,b)}\parallel_*-|x-z_\sigma|^{\,\alpha}\Big) \end{aligned}$$

for almost every $x\in B_\rho(z_\sigma)\cap\Omega$. Let us observe that, without loss of generality, we can assume

$$\parallel\Lambda_{A(x,\,a)}-\Lambda_{A(x,\,b)}\parallel_*\leq\frac{1}{2C};\tag{3.33}$$

in fact, if we had the opposite inequality we would trivially obtain

$$\begin{aligned} \parallel D^k(a-b)\parallel_{L^{\,\infty}(\partial\,\Omega)}\ &\leq\ E_k\\ &\leq E_k(2C)^{\,\delta_k}\parallel\Lambda_{A(x,\,a)}-\Lambda_{A(x,\,b)}\parallel_*^{\delta_k}, \end{aligned}$$

which would prove the induction step. Hence, using (3.33), we have

$$D_{\,t}A(x,\,t)|_{\,t\,=\,c\,(x)}\geq C|x-z_\sigma|^{\,2-2(n+m)}\Big(\frac{1}{2}-|x-z_\sigma|^{\,\alpha}\Big)\tag{3.34}$$

for almost every $x\in B_\rho(z_\sigma)\cap\Omega$.

Possibly choosing a smaller value of ρ, we may assume that

$$|x-z_\sigma|^{\,\alpha}<\frac{1}{4}\quad\text{for every } x\in B_\rho(z_\sigma),$$

and therefore,

$$D_{\,t}A(x,\,t)|_{\,t\,=\,c\,(x)}Du\cdot Dv\geq C\,|x-z_\sigma|^{\,2-2(n+m)}\tag{3.35}$$

for almost every $x\in B_\rho(z_\sigma)\cap\Omega$.

Note that every $x\in U$ can be uniquely represented as

$$x\ =\ y-s\tilde{\nu},\tag{3.36}$$

where $y\in\partial\Omega$ and $0\leq s\leq\sigma_0$, where $0<\sigma_0<h-L\,r$.

Hence, by Taylor's formula we have

$$\begin{aligned} \left\|\frac{\partial^{\,k}}{\partial\tilde{\nu}^k}(a-b)\right\|_{L^{\,\infty}(\partial\,\Omega\,\cap\,\bar{W})}s^k\ &\leq\ k\,!\,(a-b)(x)\\ &+C\Bigg\{\sum_{j\,=\,0}^{k-1}\left\|\frac{\partial^j}{\partial\tilde{\nu}^j}(a-b)\right\|_{L^{\,\infty}(\partial\,\Omega\,\cap\,\bar{W})}s^j\\ &+\,s^k|x-x^0|^{\,\alpha}\Bigg\}. \end{aligned}\tag{3.37}$$

We obtain

$$\begin{aligned}
&\| \Lambda_{A(x,\,a)} - \Lambda_{A(x,\,b)} \|_* \| u \|_{H^{\frac{1}{2}}(\partial\,\Omega)} \| v \|_{H^{\frac{1}{2}}(\partial\,\Omega)} \\
&\geq \int_{B_\rho(z_\sigma)\,\cap\,\Omega} (a-b) D_t A(x,\,t)|_{\,t\,=\,c} Du \cdot Dv \\
&\quad - \int_{\Omega\,\setminus\,B_\rho(z_\sigma)} |A(x,\,a) - A(x,\,b)|\,|x - z_\sigma|^{\,2-2(n+m)} \\
&\geq \left\| \frac{\partial^{\,k}}{\partial\tilde{\nu}^{\,k}}(a-b) \right\|_{L^{\,\infty}(\partial\,\Omega)} \int_{B_\rho(z_\sigma)\,\cap\,\Omega} (d(x,\,\partial\Omega))^{\,k} D_t A(x,\,t)|_{\,t\,=\,c} Du \cdot Dv \\
&\quad - \sum_{j\,=\,0}^{k-1} \left\| \frac{\partial^{\,j}}{\partial\tilde{\nu}^{\,j}}(a-b) \right\|_{L^{\,\infty}(\partial\,\Omega)} \int_{B_\rho(z_\sigma)\,\cap\,\Omega} (d(x,\,\partial\Omega))^{\,j} D_t A(x,\,t)|_{\,t\,=\,c} Du \cdot Dv \\
&\quad - \int_{B_\rho(z_\sigma)\,\cap\,\Omega} (d(x,\,\partial\Omega))^{\,k} |x - x^0|^{\,\alpha} D_t A(x,\,t)|_{\,t\,=\,c} Du \cdot Dv \\
&\quad - \int_{\Omega\,\setminus\,B_\rho(z_\sigma)} |A(x,\,a) - A(x,\,b)|\,|x - z_\sigma|^{\,2-2(n+m)}.
\end{aligned}$$

Therefore,

$$\begin{aligned}
&\left\| \frac{\partial^{\,k}}{\partial\tilde{\nu}^{k}}(a-b) \right\|_{L^{\,\infty}(\partial\,\Omega)} \int_{B_\rho(z_\sigma)\,\cap\,\Omega} |x - z_\sigma|^{\,2-2(n+m)} (d(x,\,\partial\Omega))^{\,k} \\
&\leq C \Bigg\{ \int_{\Omega\,\setminus\,B_\rho(z_\sigma)} |\,a(x) - b(x)|\,|x - z_\sigma|^{\,2-2(n+m)} \\
&\qquad + \int_{B_\rho(z_\sigma)\,\cap\,\Omega} |x - z_\sigma|^{\,2-2(n+m)} |x - z_\sigma|^{\,2-2(n+m)} |x - x^0|^{\,\alpha} (d(x,\,\partial\Omega))^{\,k} \\
&\qquad + \sum_{j\,=\,0}^{k-1} \int_{B_\rho(z_\sigma)\,\cap\,\Omega} |x - z_\sigma|^{\,2-2(n+m)} (d(x,\,\partial\Omega))^{\,j} \left\| \frac{\partial^{\,j}}{\partial\tilde{\nu}^{\,j}}(a-b) \right\|_{L^{\,\infty}(\partial\,\Omega)} \\
&\qquad + \| \Lambda_{A(x,\,a)} - \Lambda_{A(x,\,b)} \|_* \| u \|_{H^{\frac{1}{2}}(\partial\,\Omega)} \| v \|_{H^{\frac{1}{2}}(\partial\,\Omega)} \Bigg\}.
\end{aligned}$$

Choosing m sufficiently large, depending only on k, estimating the integrals in the above formula (see [A, Proof of Theorem 1.2]), and recalling the induction hypothesis, we obtain

$$\left\| \frac{\partial^{\,k}}{\partial\tilde{\nu}^{\,k}}(a-b) \right\|_{L^{\,\infty}(\partial\,\Omega\,\cap\,\bar{W})} \leq C \left\{ \| \Lambda_{A(x,\,a)} - \Lambda_{A(x,\,b)} \|_*^{\,\delta^{\,k-1}} \sigma^{-k} + \sigma^{\,\alpha} \right\}$$

for every $0 < \sigma \leq \sigma_0$.

By optimizing the choice of σ, we obtain (3.28) for $j = k$. Let us now recall the interpolation inequality

$$\begin{aligned}
\| Df \|_{L^{\,\infty}(\partial\,\Omega\,\cap\,\bar{U})} \leq C \Bigg\{ &\left\| \frac{\partial}{\partial\tilde{\nu}} f \right\|_{L^{\,\infty}(\partial\,\Omega)} \\
&+ \| f \|_{L^{\,\infty}(\partial\,\Omega\,\cap\,\bar{U})}^{\frac{\alpha}{1-\alpha}} \| f \|_{C^{\,1+\alpha}(\bar{U})}^{\frac{1}{1+\alpha}} \Bigg\}
\end{aligned} \tag{3.38}$$

for every $f \in C^{1,\alpha}(\bar{\Omega})$ (see, for instance, (3.17) in [A, Lemma 3.2]). From (3.28) and an iterated use of (3.38), we obtain

$$\| D^k(a-b) \|_{L^\infty(\partial\Omega \cap \bar{W})} \leq C \| \Lambda_{A(x,a)} - \Lambda_{A(x,b)} \|_*^{\delta_k} . \tag{3.39}$$

Finally, we observe that, by an elementary induction argument, for every multi-index β, $|\beta| \leq k$ the following identity holds:

$$\begin{aligned} D^\beta A(x, a(x)) \; = \sum_{\gamma+\delta \leq \beta} & P_{\gamma\delta}(a(x), \dots, D^{|\delta|}a(x)) \\ & \cdot D_x^\gamma D_t^{|\delta|} A(x, a(x)), \end{aligned} \tag{3.40}$$

where $P_{\gamma\delta}$ is a polynomial. Hence, recalling hypothesis (2.9), which has not been used yet, we obtain

$$\| D^k(A(x, a(x)) - A(x, b(x))) \|_{L^\infty(\partial\Omega \cap \bar{W})} \leq C \| a - b \|^\alpha_{C^k(\partial\Omega \cap \bar{W})} , \tag{3.41}$$

which in combination with (3.39) readily implies (2.12). □

4. Proofs of the uniqueness theorems.

Proof of Theorem 2.3. Let us observe that it suffices to prove (2.15) and (2.17) on $\partial\Omega \cap \bar{W}$, where W is an arbitrary open subset of $\bar{\Omega}$ such that $\bar{W} \subset U$. Therefore, similarly to what we did in the proof of Theorem 2.2, we can reduce ourselves to the case when $U = V_l \cap \bar{\Omega}$, $W = \frac{1}{2}V_l \cap \bar{\Omega}$, where V_l is one of the cylinders found in Lemma 3.2. Let $\tilde{\nu}$ be the unit vector introduced in Lemma 3.3, suited for the neighborhood U. As a first step, let us prove

$$\frac{\partial^j}{\partial \tilde{\nu}^j}(a-b) \; = \; 0 \qquad \text{on } \partial\Omega \cap \bar{W} \quad \text{for every } j \leq k, \tag{4.1}$$

by induction on k. When $k = 0$, (4.1) is a consequence of Theorem 2.1 (see also (3.26)). Let us assume that (4.1) holds for every $j \leq k-1$, and suppose by contradiction that there exists a point $x^0 \in \partial\Omega \cap \bar{W}$ such that, without loss of generality,

$$(-1)^k \frac{\partial^k}{\partial \tilde{\nu}^k}(a-b)(x^0) > 0.$$

Let m be a positive integer to be chosen later on, and let r_0 be accordingly defined as in Lemma 3.5. Let $z_\sigma = x^0 + \sigma\tilde{\nu}$, $\sigma > 0$, and $\rho > 0$ be chosen as we did in Theorem 2.2. Possibly choosing a smaller value of ρ, by (3.30) and the representation (3.36), Taylor's formula gives us

$$(a-b)(x) \geq \frac{1}{2}\frac{(-s)^k}{k\,!}\frac{\partial^k}{\partial \tilde{\nu}^k}(a-b)(x^0) \quad \text{for every } x \in U.$$

We intend to consider again the formula (3.18) with u, v being the singular solutions chosen in the proof of Theorem 2.2. For almost every $x \in \Omega$ we have

$$A(x, a(x)) - A(x, b\,(x)) \; = \int_{b(x)}^{a(x)} D_t A(x, t)\, dt, \tag{4.2}$$

and by the monotonicity assumption (2.5)

$$\begin{aligned}\Big(\int_{b\,(x)}^{a(x)} D_t A(x,\, t)\, dt\Big)\xi\cdot\xi \;&=\; \int_{b\,(x)}^{a(x)} D_t A(x,\, t)\xi\cdot\xi\, dt\\ &\geq \int_{b(x)}^{a(x)} E^{-1}|\,\xi\,|^2\, dt\\ &= (a-b)(x)E^{-1}|\,\xi\,|^2.\end{aligned}$$

In other words,

$$\int_{b(x)}^{a(x)} D_t A(x,\, t)\, dt \;=\; (a-b)(x)M(x) \qquad \text{for every } x\in U,$$

where the matrix M satisfies

$$M(x)\xi\cdot\xi \geq E^{-1}|\,\xi\,|^2 \qquad \text{for almost every } x\in U, \quad \text{for every } \xi\in\mathbb{R}^n.$$

By rephrasing the arguments leading to (3.35) and by using the induction hypothesis, which enables us to assume that the continuations of $a(x)$, $b(x)$ to $B_R(z_\sigma)\setminus\bar{\Omega}$ coincide, we obtain

$$M(x)\, Du\cdot Dv \geq C\,|x-z_\sigma|^{\,2-2(n+m)} \qquad \text{for almost every } x\in U. \tag{4.3}$$

From (3.18) we obtain

$$\begin{aligned}0 \;&=\; \int_\Omega (A(x,\, a)-A(x,\, b))\, Du\cdot Dv\\ &= \int_{\Omega\,\cap\, B_\rho(z_\sigma)} (A(x,\, a)-A(x,\, b))\, Du\cdot Dv\\ &\quad + \int_{\Omega\,\setminus\, B_\rho(z_\sigma)} (A(x,\, a)-A(x,\, b))\, Du\cdot Dv\\ &\geq \int_{\Omega\,\cap\, B_\rho(z_\sigma)} (a-b)(x)\, M(x)\, Du\cdot Dv\\ &\quad - C\int_{\Omega\,\setminus\, B_\rho(z_\sigma)} |\,a-b\,|\,|x-z_\sigma|^{\,2-2(n+m)}.\end{aligned}$$

Using (4.3), and provided we choose $m>\frac{k-1}{2}$,

$$\begin{aligned}0 \geq \frac{1}{2}\frac{(-1)^{\,k}}{k\,!}\frac{\partial^{\,k}}{\partial\tilde{\nu}^{\,k}}(a-b)(x^0)\int_{\Omega\,\cap\, B_\rho(z_\sigma)} (d(x,\,\partial\Omega))^{\,k}\,|x-z_\sigma|^{\,2-2(n+m)}\\ - C\int_{\Omega\,\setminus\, B_\rho(z_\sigma)} |\,a-b\,|\,|x-z_\sigma|^{\,2-2(n+m)}\,,\end{aligned}$$

and therefore,

$$\frac{(-1)^k}{k\,!}\frac{\partial^{\,k}}{\partial\tilde{\nu}^{\,k}}(a-b)(x^0) \leq C\,\sigma^{\,n+2m-2-k}\,.$$

Picking m such that $n+2m-2-k>0$ and letting $\sigma \to 0$, we are led to a contradiction. Then we can conclude that (4.1) holds, and consequently,

$$D^{\,j}(a-b) \;=\; 0 \qquad \text{on } \partial\Omega\cap W \quad \text{for every } j \le k. \tag{4.4}$$

Finally, (2.17) follows from (2.15) and (3.40). □

Proof of Theorem 2.4. It suffices to prove iteratively that $a\;=\;b$ on each A_j. This is obtained by the argument developed in [A, Proof of Corollary 1.1], which is based on the result of uniqueness at the boundary on the analytic continuation of $a-b$ within each A_j and on the Runge approximation theorem (see [KV2] and also [G, Theorem 2.4]). We remark that this last theorem requires only the Lipschitz continuity of the conductivity $A(x,\,a(x))$. Therefore, without need of higher order differentiability on $A(x,\,t)$, the method in [A, Proof of Corollary 1.1] also applies to the present situation. □

5. The one-eigenvalue-problem. Kohn and Vogelius have considered the case in which the $n-1$ eigenvalues and eigenvectors of a conductivity matrix A are known (see [KV1]). Their result is the following theorem.

THEOREM 5.1. *Let A, B be two symmetric, positive definite matrices with entries in $L^{\infty}(\Omega)$, and let $\{\lambda_{\,j}\}_{j\,=\,1,\dots\,,n}$, $\{\bar\lambda_{\,j}\}_{j\,=\,1,\dots\,,n}$ and $\{e_j\}_{j=1,\dots\,,n}$, $\{\bar e_j\}_{j=1,\dots\,,n}$ be the corresponding eigenvalues and eigenvectors. For $x^0\in\partial\Omega$, let B be a neighborhood of x^0 relative to $\bar\Omega$, and suppose that*

$$A,\,B\in C^{\infty}(B) \quad \textit{and } \partial\Omega\cap B \textit{ is } C^{\infty}, \tag{5.1}$$

$$e_j \;=\; \bar e_j, \quad \lambda_j \;=\; \bar\lambda_j \quad \textit{in } B, \quad 1\le j\le n-1\,, \tag{5.2}$$

$$e_n(x^0)\cdot\nu(x^0) \;\neq\; 0\,, \tag{5.3}$$

$$\Lambda_A(\phi) \;=\; \Lambda_B(\phi) \quad \textit{for every } \phi\in H^{\frac12}(\partial\Omega) \textit{ with } \operatorname{supp}(\phi)\subset B\cap\partial\Omega. \tag{5.4}$$

Then

$$D^k\lambda_n(x^0) \;=\; D^k\bar\lambda_n(x^0) \quad \textit{for any } k\;\ge 0. \tag{5.5}$$

Let us rephrase the problem of Kohn and Vogelius in terms of our setting. Letting $a(x)$ be the nth eigenvalue, the conductivity matrix A has the structure

$$A \;=\; A(x,\,a(x)), \quad \text{where}$$

$$A(x,\,t) \;=\; R(x)\begin{pmatrix} \lambda_1(x) & 0 & \dots & 0 \\ 0 & \lambda_2(x) & \dots & 0 \\ \vdots & \vdots & & \vdots \\ 0 & 0 & \dots & \lambda_{n-1}(x) \\ 0 & 0 & \dots & t \end{pmatrix} R^{\top}(x),$$

where $\lambda_1(x), \dots, \lambda_{n-1}(x)$ are given positive functions and, for each x, $R(x)$ is a known orthogonal matrix. In this case, we have

$$D_{\,t}A(x,\,t) \;=\; R(x)\begin{pmatrix} 0 & 0 & \dots & 0 \\ 0 & 0 & \dots & 0 \\ 0 & 0 & \dots & 0 \\ \vdots & \vdots & & \vdots \\ 0 & 0 & \dots & 1 \end{pmatrix} R^{\top}(x).$$

We observe that the property (2.5) of monotonicity is not satisfied in this case; in fact, the following equality holds:

$$D_tA(x,\,t)\,\xi\cdot\xi \;=\; |(R^{\top}(x)\,\xi)_n|^{\,2} \tag{5.6}$$

for every $x\in\Omega$, $t\in[\lambda^{-1},\,\lambda]$, $\xi\in\mathbb{R}^n$, where the subscript n denotes the nth component.

However, it is possible to modify our previous arguments in order to prove theorems analogous to Theorems 2.1–2.4 as follows. Notice that condition (5.3) is not needed here.

CLAIM. *Theorems* 2.1, 2.2, 2.3, 2.4 *continue to hold if the monotonicity assumption* (2.5) *is replaced by*

$$E^{-1}|(R^{\top}(x)\,\xi)_n|^{\,2}\le D_{\,t}\,A(x,\,t)\,\xi\cdot\xi\le E\,|(R^{\top}(x)\,\xi)_n|^{\,2} \tag{5.7}$$

for almost every $x\in\Omega$, for every $t\in[\lambda^{-1},\,\lambda]$, for every $\xi\in\mathbb{R}^n$, where $R\,=\,R(x)$ is a given orthogonal matrix depending on the space variable x.

Proof of the Claim. For the sake of brevity, we shall point out only the crucial modification in the proof of Theorem 2.1, since the corresponding changes in the subsequent theorems follow by straightforward adaptations.

Let us recall that we have obtained

$$\begin{aligned}
&\int_{B_{\,\rho}(z_\sigma)\,\cap\,\Omega}\frac{J_b^{\,2}(A(x^0,\,a(x^0))-A(x^0,\,b(x^0)))\,J_a^{\,2}(x-z_\sigma)\cdot(x-z_\sigma)}{|J_{\,a}(x-z_\sigma)|^{\,n}\,|J_{\,b}(x-z_\sigma)|^{\,n}}\\
&\le C\int_{B_{\,\rho}(z_\sigma)\,\cap\,\Omega}|x-z_\sigma|^{\,2-2n}\,|x-x^0|^{\,\beta}\\
&\quad+\,C\int_{B_{\,\rho}(z_\sigma)\,\cap\,\Omega}|x-z_\sigma|^{\,2-2n+\,\alpha}\\
&\quad+\int_{\Omega\,\setminus\,B_\rho(z_\sigma)}|A(x,\,a)-A(x,\,b)|\,|x-z_\sigma|^{\,2-2n}\\
&\quad+\|\,\Lambda_{A(x,\,a)}-\Lambda_{A(x,\,b)}\,\|_*\|\,u\,\|_{H^{\frac12}(\partial\,\Omega)}\|\,v\,\|_{L^{\frac12}(\partial\,\Omega)}\,.
\end{aligned}$$

Notice that the monotonicity assumption was used for obtaining a lower bound on the left-hand side. Assuming (5.7), we proceed as follows:

$$\begin{aligned}
&J_b^{\,2}(A(x^0,\,a)-A(x^0,\,b))\,J_a^{\,2}(x-z_\sigma)\cdot(x-z_\sigma)\\
&\ge\Big((A(x^0,\,b))^{-1}-(A(x^0,\,a))^{-1}\Big)(x-z_\sigma)\cdot(x-z_\sigma)\\
&\quad-C\,\sigma^{\,\beta}(a(x^0)-b(x^0))\,|x-z_\sigma|^2\\
&=\left(\int_{a(x^0)}^{b(x^0)}D_{\,t}(A(x^0,\,t))^{-1}\,dt\right)(x-z_\sigma)\cdot(x-z_\sigma)\,dt\\
&\quad-C\,\sigma^{\,\beta}\,(a(x^0)-b(x^0))\,|x-z_\sigma|^2.
\end{aligned} \tag{5.8}$$

And now (assuming without loss of generality $R(x^0) = I$)

$$\begin{aligned}
&\int_{a(x^0)}^{b(x^0)} D_t A^{-1}\,\xi\cdot\xi\,dt\\
&= \int_{b(x^0)}^{a(x^0)} A^{-1}\,(D_t A)\,A^{-1}\,\xi\cdot\xi\,dt\\
&= \int_{b(x^0)}^{a(x^0)} (D_t A)\,A^{-1}\xi\cdot A^{-1}\,\xi\,dt\\
&\geq C\int_{b(x^0)}^{a(x^0)} \Big(\xi\cdot e_n\Big)^{2}\,dt\\
&= \ C\,(a(x^0)-b(x^0))\,(\xi\cdot e_n)^2,
\end{aligned}$$

where e_n denotes the nth coordinate unit vector. Then we obtain

$$\begin{aligned}
&J_b^{\,2}(A(x^0,\,a)-A(x^0,\,b))\,J_a^{\,2}\,(x-z_\sigma)\cdot(x-z_\sigma)\\
&\geq C\,(a(x^0)-b(x^0))\,|\,(x-z_\sigma)_n\,|^{\,2}\\
&-C\,\sigma^{\,\beta}\,(a(x^0)-b(x^0))\,|x-z_\sigma|^2,
\end{aligned}$$

and hence

$$\begin{aligned}
&\|\,a-b\,\|_{\,L^{\,\infty}(\partial\,\Omega)}\ \int_{B_{\,\rho}(z_\sigma)\,\cap\,\Omega}\frac{(x-z_\sigma)_n^2}{|x-z_\sigma|^{\,2n}}\\
&\leq C\Big\{\int_{B_\rho(z_\sigma)\,\cap\,\Omega}|x-z_\sigma|^{\,2-2n}\,|x-x^0|^{\,\beta}\\
&\qquad+\int_{B_\rho(z_\sigma)\,\cap\,\Omega}|x-z_\sigma|^{\,2-2n+\,\alpha}\\
&\qquad+\int_{B_\rho(z_\sigma)\,\cap\,\Omega}\sigma^{\,\beta}\,|x-z_\sigma|^{\,2-2n}\\
&\qquad+\int_{\Omega\,\setminus\,B_\rho(z_\sigma)}|A(x,\,a)-A(x,\,b)\,|\,|x-z_\sigma|^{\,2-2n}\\
&\qquad+\|\,\Lambda_{A(x,\,a)}-\Lambda_{A(x,\,b)}\,\|_*\|\,u\,\|_{H^{\frac{1}{2}}(\partial\,\Omega)}\|\,v\,\|_{H^{\frac{1}{2}}(\partial\,\Omega)}\Big\}.
\end{aligned}\tag{5.9}$$

We need to estimate the quantity $\int_{B_{\,\rho}(z_\sigma)\,\cap\,\Omega}\frac{(x-z_\sigma)_n}{|x-z_\sigma|^{\,2n}}$ from below.

Let $B_r(P)$ be a ball with center P on the axis passing through z_σ and x^0 and radius $r\leq\min\Big\{\frac{r^0}{2}-\frac{3}{4}\sigma,\,\sigma\Big\}$. In this case, we have that $B_r(P)\subset\subset(B_\rho(z_\sigma)\cap\Omega)$, and we consider a cube Q inscribed in $B_r(P)$ with an axis parallel to e_n. Then we can compute

$$\int_Q\frac{|(x-z_\sigma)_n|^{\,2}}{|x-z_\sigma|^{\,2n}}\geq C\sigma^{\,2-n},\tag{5.10}$$

and next the proof can proceed as before. □

DYNAMICS OF AN INTERIOR SPIKE IN THE GIERER–MEINHARDT SYSTEM*

XINFU CHEN† AND MICHAŁ KOWALCZYK‡

Abstract. We study the dynamics of an interior spike of the Gierer–Meinhardt system. Under certain assumptions on the domain size, the diffusion coefficients, and the decay rates, we prove that the velocity of the center of the spike is proportional to the negative gradient of $R(\xi,\xi)$, where $R(x,\xi)$ is the regular part of the Green's function of the Laplacian with the Neumann boundary condition. Hence, an interior spike moves towards local minima of $R(\xi,\xi)$ and therefore stays as an interior spike forever. This dynamics is fundamentally different from that of the shadow Gierer–Meinhardt system where an interior spike moves towards the closest point on the boundary.

Key words. Gierer–Meinhardt system, activator-inhibitor reaction, spikes, spike dynamics

1. Introduction.

1.1. The Gierer–Meinhardt system.

We consider the Gierer–Meinhardt system, for $A = A(x,t)$ and $H = H(x,t)$,

$$\begin{cases} A_t = D_A \Delta A - k_A A + l_A A^2/H, & x \in \delta\Omega = \{\delta z \mid z \in \Omega\}, t > 0, \\ H_t = D_H \Delta H - k_H H + l_H A^2, & x \in \delta\Omega, t > 0, \\ \partial_n A = 0 = \partial_n H, & x \in \partial(\delta\Omega), t > 0, \\ A(x,0) = A_0(x) > 0, \quad H(x,0) = H_0(x) > 0, & x \in \delta\Omega. \end{cases} \tag{1.1}$$

Here $\Omega \subset \mathbb{R}^N$, $N = 2, 3$, is a bounded domain with C^3 boundary and *unit volume*, Δ is the Laplace operator, ∂_n is the exterior normal derivative, and δ is the size of the physical domain. System (1.1) was proposed in [6] (see also [12]) as a model for biochemical reactions of activator-inhibitor type in which a short-range substance, the activator A, promotes its own production as well as that of a rapidly diffusing antagonist, the inhibitor H.

In this paper, we assume that D_A, D_H, k_A, and k_B, representing the diffusion coefficients and the decaying rates of species A and H, are positive constants and satisfy

$$\frac{k_A}{k_H} \ll 1, \qquad \frac{D_A}{k_A} \ll \delta^2 \ll \frac{D_H}{k_H}. \tag{1.2}$$

These conditions reflect the following scenario: (i) the half-life ($\ln 2/k_A$) of the activator A is much longer than that of the inhibitor H; (ii) with respect to the size δ

of the domain and the half-life of the species, the diffusion rate $D_A/(k_A\delta^2)$ of A is small whereas that of H is large; namely, regional population differences of A are not easily evened out in the life time of the component A, whereas regional population differences of H are almost instantaneously evened out by the diffusion. In such a scenario, a local increase in the concentration of the activator will be further amplified (due to the $l_A A^2/H$ term), forming regions with high concentration of the activator surrounded by the "sea" of, essentially uniformly distributed, inhibitors. We speak of *spikes* if the activator concentrates near a single point or a set of isolated points. Since stability results available at this point ([8, 17] in one dimension and [19, 20] in two dimensions) seem to suggest that in the range of parameters considered in the present paper, spikes concentrated at more than one point are unstable; therefore, here we study only the dynamics of single spike solutions.

We introduce dimensionless constants

$$\tau = \frac{k_A}{k_H}, \quad \varepsilon^2 = \frac{D_A}{k_A\delta^2}, \quad D = \frac{D_H}{k_H\delta^2}, \tag{1.3}$$

and we rescale the independent and dependent variables via

$$t \mapsto \frac{t}{k_A}, \quad x \mapsto \delta x, \quad A \mapsto \frac{k_H}{l_H\varepsilon^N}A, \quad H \mapsto \frac{k_A l_B}{k_H l_A}\varepsilon^N H. \tag{1.4}$$

Then the Gierer–Meinhardt system (1.1) takes the nondimensional form

$$\begin{cases} A_t = \varepsilon^2\Delta A - A + f(A,H), & x \in \Omega, t > 0, \\ \tau H_t = D\Delta H - H + \varepsilon^{-N}g(A), & x \in \Omega, t > 0, \\ \partial_n A = 0 = \partial_n H, & x \in \partial\Omega, t > 0, \\ A(x,0) = A_0(x) > 0, \quad H(x,0) = H_0(x) > 0, & x \in \Omega, \end{cases} \tag{1.5}$$

where

$$f(A,H) = A^2H^{-1}, \qquad g(A) = A^2. \tag{1.6}$$

Formally, as $D \to \infty$ one obtains the following *shadow* Gierer–Meinhardt system, for $A = A(x,t)$ and $H = H(t)$:

$$\begin{cases} A_t = \varepsilon^2\Delta A - A + f(A,H), & x \in \Omega, t > 0, \\ \tau H_t = -H + \varepsilon^{-N} \fint_\Omega g(A), & x \in \Omega, t > 0, \\ \partial_n A = 0 = \partial_n H, & x \in \partial\Omega, t > 0, \\ A(x,0) = A_0(x) > 0, \quad H(0) = \fint_\Omega H_0(x)dx > 0, & x \in \Omega. \end{cases} \tag{1.7}$$

Note that steady states to (1.7), after the change of variables $y = x/\varepsilon$, are solutions to

$$\Delta_y A - A + f(A, \fint_{\Omega_\varepsilon} A\,dy) = 0, \quad y \in \Omega_\varepsilon := \varepsilon^{-1}\Omega. \tag{1.8}$$

In recent years there has been much interest in studying (1.5), (1.7), and especially the associated steady state problem (1.8). In a series of papers [14, 15, 16], Ni and Takagi (also with Lin [11]) established the existence of stationary spikes (solutions to (1.8) with homogeneous Neumann boundary condition) concentrating at points of maximal mean curvature of $\partial\Omega$. We refer the readers to the recent review article by Ni [13] and the references therein for more details on this subject.

In [3] we studied the evolution of single-spike solutions to (1.7) and showed that a single, interior spike located at $\xi = \xi(t) \in \Omega$ moves toward the boundary $\partial\Omega$ with velocity

$$\dot{\xi} := \frac{d}{dt}\xi(t) \propto \nabla_\xi e^{-2\mathrm{d}(\xi)/\varepsilon}, \tag{1.9}$$

where $\mathrm{d}(\xi)$ is the distance from ξ to $\partial\Omega$. From this formula, one sees that single interior spikes for the shadow Gierer–Meinhardt system move towards their closest points on $\partial\Omega$, possibly with the exception of those which have more than one closest point on the boundary. We would like to point out that the dynamics (1.9) for the shadow Gierer–Meinhardt system (1.7) was first derived by Iron and Ward in [7], whereas in [3] we provided a rigorous proof (see also related work [19]).

In the present paper we assume that D is large, but $D \ll \varepsilon^2 e^{\max_{\xi\in\Omega}\mathrm{d}(\xi)/4\varepsilon}$. In such a case one does not expect the spike to move exponentially slowly. In fact we show that if $\varepsilon^{3-2N-\kappa} \ll D \ll \varepsilon^2 e^{\max_{\xi\in\Omega}\mathrm{d}(\xi)/4\varepsilon}$ for some $\kappa > 0$, then an interior spike moves with a velocity

$$\dot{\xi} \propto -\varepsilon^2 D^{-1}\, D_\xi R(\xi,\xi), \tag{1.10}$$

where D_ξ is the total derivative with respect to ξ, and $R(x,\xi)$ is the regular part of the Green's function for Δ with the Neumann boundary condition. Since $R(\xi,\xi) \to \infty$ as $x, \xi \to \partial\Omega$, one sees from the formula (1.10) that an interior spike moves towards local minima of $R(\xi,\xi)$ and hence stays in Ω forever.

Clearly, the dynamics (1.10) for the Gierer–Meinhardt system (1.5) is totally different from the dynamics (1.9) for the shadow Gierer–Meinhardt system (1.7).

The main purpose of this paper is to prove rigorously the asymptotic formula (1.10), following the so called *invariant manifold approach* developed by Alikakos and Fusco in [1, 2] to study motions of circular fronts (bubbles) in solutions to the Cahn–Hilliard equation.

1.2. Statement of the main result. In this paper we shall use the following notation:

$$\langle\phi\rangle := \int_\Omega \phi(x)\,dx, \qquad \langle\phi,\psi\rangle := \langle\phi\psi\rangle = \int_\Omega \phi\psi, \quad \|u\|_p := \|u\|_{L^p(\Omega)}, \quad \Omega_\varepsilon := \varepsilon^{-1}\Omega.$$

We assume that $\tau \ll 1$ and $D \gg 1$. Then we can argue from (1.5) that $H(\cdot,t)$ is almost a constant equal to $\varepsilon^{-N}\langle g(A)\rangle = \varepsilon^{-N}\langle g(A(\cdot,t))\rangle$. (Recall that the volume of Ω is 1.) Hence, it is convenient to decompose H as

$$\begin{aligned} H(x,t) &= \varepsilon^{-N}\langle g(A)\rangle + h(x,t),\\ h(x,t) &= h_0(t) + h_1(x,t),\\ h_0(t) &:= \langle H\rangle - \varepsilon^{-N}\langle g(A)\rangle,\\ h_1(x,t) &:= H(x,t) - \varepsilon^{-N}\langle g(A)\rangle - h_0(t) = H - \langle H\rangle. \end{aligned}$$

Then (1.5) can be written in terms of unknowns A, h_0, and h_1:

$$\begin{cases} A_t - \varepsilon^2\Delta A + A = f(A, \varepsilon^{-N}\langle g(A)\rangle + h_0 + h_1), & x\in\Omega, t>0,\\ \tau h_{0,t} + h_0 = -\tau\varepsilon^{-N}\langle g'(A)A_t\rangle, & t>0,\\ \tau h_{1,t} - D\Delta h_1 + h_1 = \varepsilon^{-N}[g(A) - \langle g(A)\rangle], & x\in\Omega, t>0,\\ \partial_n A = 0 = \partial_n h_1, & x\in\partial\Omega, t>0. \end{cases} \tag{1.11}$$

If we ignore h_0 and h_1 and use the stretched variable $y = x/\varepsilon$, the first equation of (1.11) becomes

$$A_t - \Delta_y A + A = f(A, \textstyle\int_{\Omega_\varepsilon} g(A)dy), \qquad y \in \Omega_\varepsilon, t > 0, \tag{1.12}$$

which is the limit, as $\tau \to 0$, of the shadow Gierer–Meinhardt system (1.7). Since $\varepsilon \ll 1$, a solution to the equation

$$-\Delta_y A + A = f(A, \textstyle\int_{\mathbb{R}^N} g(A)dy) \qquad \text{in } \mathbb{R}^N \tag{1.13}$$

will be almost a stationary solution.

With f and g given by (1.6), it is known that (1.13) has a unique, positive, radially symmetric solution, which we denote by $W(r), r = |y|$. As $W(r) \to 0$ exponentially fast as $r \to \infty$, for every $\xi \in \Omega$, $\{A = W(|x - \xi|/\varepsilon), h_0 = 0, h_1 = 0\}$ is almost an equilibrium of (1.11). In what follows, a solution with $A(x,t) \approx W(|x - \xi(t)|/\varepsilon)$, $h_0 \approx 0$ and $h_1 \approx 0$ will be called a *spike solution* located at $\xi(t)$ at time t.

We consider only spikes that initially stay away from the boundary. To this end we define $\mathrm{d}(\xi) =$ distance from ξ to $\partial\Omega$ and let μ be a parameter in the range $\max_{\xi\in\Omega} \mathrm{d}(\xi) > \mu > 4\varepsilon \log(D\varepsilon^{-2})$. We set

$$\Omega^\mu = \{\xi \in \Omega \mid \mathrm{d}(\xi) > \mu\}. \tag{1.14}$$

Observe that if D satisfies $\varepsilon^{3-2N-\kappa} \ll D \ll e^{\max_{\xi\in\Omega} \mathrm{d}(\xi)/8\varepsilon}$ for some $\kappa > 0$, then $\Omega^\mu \neq \emptyset$ for all sufficiently small ε.

It is convenient to work with approximate solutions to (1.11) which have compact support. Hence, we modify $W(|y|)$ and $W(|x - \xi|/\varepsilon)$ into compactly supported functions $W^\varepsilon(y)$ and $w^\varepsilon(x, \xi)$ as follows. Let $\zeta(s)$ be a cutoff function such that $\zeta = 1$ if $|s| < 1/2$, $\zeta = 0$ if $|s| > 1$, and $|D^n\zeta| \le 2^{n+1}$, $n = 1, 2, 3$. We define

$$\begin{aligned} &W^\varepsilon(y) = W(|y|)\zeta(|y|\varepsilon/\mu), && y \in \mathbb{R}^N, \\ &w^\varepsilon(x,\xi) = W^\varepsilon(|x-\xi|/\varepsilon) = W(|x-\xi|/\varepsilon)\zeta(|x-\xi|/\mu), && x, \xi \in \Omega. \end{aligned} \tag{1.15}$$

We define *the approximate invariant manifold* $\mathcal{M}$ by

$$\mathcal{M} = \{w^\varepsilon(\cdot, \xi) \mid \xi \in \bar{\Omega}\}. \tag{1.16}$$

It is known (see Lemma 3.1 to follow) that there exists a positive constant $c_0 > 0$ (depending only on Ω) such that if $\mathrm{dist}(A(\cdot,t), \mathcal{M}) \le c_0\varepsilon^{N/2}$, then we can uniquely decompose $A(\cdot, t)$ as

$$A(x,t) = w^\varepsilon(x, \xi(t)) + \phi(x,t), \quad \xi(t) \in \bar{\Omega}, \quad \|\phi(\cdot,t)\|_2 = \mathrm{dist}(A(\cdot,t),\mathcal{M}) := \inf_{w\in\mathcal{M}} \|A - w\|_2. \tag{1.17}$$

We define

$$T^* := \sup\{T > 0 \mid \mathrm{dist}(A(\cdot,t), \mathcal{M}) \le c_0\varepsilon^{N/2},\ \xi(t) \in \Omega^\mu \ \ \forall\, t \in [0, T]\ \}. \tag{1.18}$$

THEOREM 1.1 (quasi-invariance of the manifold $\mathcal{M}$). *Let $\kappa \in (0, 1/8)$ be any fixed constant. Let ε, τ, D, and μ be positive parameters such that there hold the relations*

$$0 < \varepsilon < 1, \quad 0 < \tau < 1, \quad \varepsilon^{2-N-2\kappa} < D, \quad 4\varepsilon \log(D\varepsilon^{-2}) < \mu < \max_{\xi\in\Omega} \mathrm{d}(\xi). \tag{1.19}$$

Let (A, h_0, h_1) *be solutions to* (1.11) *with initial values* $h_0(0), h_1(\cdot, 0)$, *and* $A(\cdot, 0) = w^\varepsilon(\cdot, \xi_0) + \phi(\cdot, 0)$, *where* $\langle h_1(\cdot, 0)\rangle = 0$, $\xi_0 \in \Omega^\mu$, *and* $\|\phi(\cdot, 0)\|_2 = \operatorname{dist}(A(\cdot, 0), \mathcal{M})$. *Assume that*

$$|h_0(0)| + \|h_1(\cdot, 0)\|_\infty + \varepsilon^{-N/2}\|\phi(\cdot, 0)\|_2 \le D^{-1}\varepsilon^{2-N-\kappa}. \tag{1.20}$$

Decompose A *as in* (1.17) *in the interval* $[0, T^*]$ *with* T^* *defined as in* (1.18).

There exist small positive constants ε_0 *and* τ_0 *and a positive constant* C_0, *all of which depend only on* Ω *and* κ, *such that if* $\varepsilon \in (0, \varepsilon_0]$ *and* $\tau \in (0, \tau_0]$, *then*

$$|h_0(t)| + \|h_1(\cdot, t)\|_\infty + \varepsilon^{-N/2}\|\phi(\cdot, t)\|_2 \le C_0 D^{-1}\varepsilon^{2-N-\kappa} < c_0 \qquad \forall t \in (0, T^*). \tag{1.21}$$

In addition, either $T^* = \infty$ *or* $\mathrm{d}(\xi(T^*)) = \mu$ *(i.e.,* $\xi(T^*) \in \partial\Omega^\mu$*).*

To describe the dynamics of the spike (and therefore show that $T^* = \infty$), we introduce the Green's function $G(x, \xi)$ of Δ with the Neumann boundary condition; i.e, for each $\xi \in \Omega$, $G(\cdot, \xi)$ solves

$$\begin{cases} -\Delta_x G(x, \xi) = \delta(x - \xi) - 1 & \text{in } \Omega, \\ \partial_n G = 0 & \text{on } \partial\Omega, \\ \int_\Omega G(x, \xi)\, dx = 0. & \end{cases} \tag{1.22}$$

Let $\Gamma(x) = -(2\pi)^{-1}\log|x|$ for $N = 2$ and $= (4\pi|x|)^{-1}$ for $N = 3$ be the fundamental solution of Δ and let $R(x, \xi) := G(x, \xi) - \Gamma(x - \xi)$ be the regular part of the Green's function.

Theorem 1.2 (dynamics of an interior spike). *In addition to the assumptions of the previous theorem we assume that*

$$\|h_1(\cdot, 0) - (D\Delta)^{-1}\{[w^\varepsilon(\cdot, \xi_0)]^2 - \langle (w^\varepsilon(\cdot, \xi_0)^2)\rangle\}\|_\infty \le D^{-2}\varepsilon^{4-2N-2\kappa}.$$

The following formula holds true:

$$\dot{\xi} = \alpha_0 D^{-1}\varepsilon^2 \left(-D_\xi R(\xi, \xi) + O(\varepsilon)\mathrm{d}(\xi)^{-N} + O(\varepsilon^{3-2N-2\kappa}D^{-1})\right) \quad \forall\, t \in (0, T^*), \tag{1.23}$$

where α_0, *given in* (2.13) *below, is a positive constant depending only on* N.

Consequently, if we further assume that $D \ge \varepsilon^{2-N-3\kappa}$ *and* μ *is sufficiently small, then* $T^* = \infty$ *and* $\xi(t) \in \Omega^\mu$ *for all* $t > 0$.

Remark 1.1. Condition (1.19) implicitly imposes an upper bound on D:

$$D < \varepsilon^2 e^{\mu/(4\varepsilon)} < \varepsilon^2 e^{\max_{\xi\in\Omega} \mathrm{d}(\xi)/(4\varepsilon)}.$$

If D is too large, say, $\log(D) > 1/\varepsilon$, then (1.5) should be considered as a small perturbation of the shadow Gierer–Meinhardt system, and therefore the dynamics (1.9) should prevail.

Intuitively, for any given $\xi \in \Omega$, making the magnitudes of the right-hand sides of (1.9) and (1.10) equal should give us the critical size of D to determine which dynamics dominates. We believe that when D is exponentially large, i.e., $\log(D) = O(1/\varepsilon)$, our analysis in [3] and the analysis presented in this paper can be combined to obtain the leading order expansion of the velocity of motion of single interior spikes, which somehow should be the sum of the right-hand sides of (1.10) and (1.9).

Remark 1.2. Our lower bound $\varepsilon^{2-N-2\kappa}$ for the magnitude of D for the quasi-invariance of the manifold $\mathcal{M}$ in Theorem 1.1 is possibly sharp. Indeed, it is proved in [20] that when $N = 2$ and $D = 1$, the stationary spike attains a maximum of the order $O(|\ln\varepsilon|)$ as $\varepsilon \to 0$, whereas in our case the spikes remain bounded by a constant independent on ε.

Remark 1.3. One of the main points of our paper is to study the dynamics of a single spike in the case when $D = D(\varepsilon)$ and τ is a small parameter *independent* on ε or D. In this context we refer the reader to [3] where the key spectral estimate (Lemma 3.2 to follow) is established. Although we believe that this estimate is true for more general systems than the one considered here, for instance, with A^2/H replaced by A^p/H^q and A^2 replaced by A^r/H^s, where $qr/[(p-1)(s+1)] > 1$; however, at the moment such results are only available in the one-dimensional case [17]. Given higher dimensional generalization of the spectral estimate in [17], one could easily adopt our method to study the dynamics of interior spikes for the more general Gierer–Meinhardt system.

Remark 1.4. One notices that taking smaller κ in our theorems makes the results stronger. Nevertheless, we cannot take $\kappa = 0$. We expect terms involving $\log\varepsilon$ will come up if we set $\kappa = 0$.

In (1.23), the term $O(\varepsilon^{3-2N-2\kappa}D^{-1})$ does not match with the combination $\mathcal{E}_\kappa := \varepsilon^{2-N-\kappa}D^{-1}$. We believe that the actual size of this term should be $O(\mathcal{E}_\kappa)$. To prove this, one needs an approximation better than approximating H by a constant function. This could, for instance, be accomplished by finding an ansatz for H from the equation $D\Delta H - H + \varepsilon^{-N}W^2 = 0$ (c.f. [20]).

Remark 1.5. We observe that since w^ε is bounded by a constant independent on ε, therefore the assumptions on $h_1(\cdot, 0)$ in Theorems 1.1 and 1.2 can be satisfied simultaneously.

Remark 1.6. When $N = 2$ and Ω is a disk of radius $1/\sqrt{\pi}$ (so area of Ω is 1), we have an explicit formula for $R(x,\xi)$. Indeed, identifying points as complex numbers, the Green's function is given by

$$G(z,\xi) = -\frac{1}{2\pi}(\ln|z-\xi| + \ln|\bar{\xi}z - 1/\pi|) + \frac{1}{4}(|z|^2 + |\xi|^2) + K_0, \quad K_0 = -\frac{3}{4\pi}\ln\pi + \frac{5}{16\pi}\ .$$

It then follows that

$$R(\xi,\xi) = -\frac{1}{2\pi}\ln\left||\xi|^2 - 1/\pi\right| + \frac{1}{2}|\xi|^2 + K_0, \qquad D_\xi R(\xi,\xi) = \frac{2-\pi|\xi|^2}{1-\pi|\xi|^2}\,\xi \quad \forall \xi \in \Omega.$$

Hence, a spike will move towards the origin in the radial direction.

For more explicit formulae of the regular part $R(x,\xi)$ of the Green's function of certain other domains, see Fraenkel [5].

Later, in Lemma 3.5, we shall show that for any smooth domain Ω, $|D_\xi R(\xi,\xi)| \propto \mathrm{d}(\xi)^{1-N}$ as $\xi \to \partial\Omega$, so that $D_\xi R(\xi,\xi)$ is the leading order term in (1.23).

In the next section we shall formally derive the dynamics of $\xi(t)$. Then in the subsequent sections, we verify the dynamics rigorously.

In what follows, we shall always assume that ε and τ are small positive constants and that D, μ satisfy (1.19).

2. Formal derivation of the dynamics.

To better explain our idea of the proof, here we first provide a formal derivation of the dynamics (1.23).

Let $W(r)$ be the solution to (1.13) and $W^\varepsilon, w^\varepsilon$ be functions defined in (1.15). We define

$$\begin{aligned} \sigma^\varepsilon &= \textstyle\int_{\mathbb{R}^N} g(W^\varepsilon(|y|))\,dy = \varepsilon^{-N}\int_{|x-\xi|<\mu} g(w^\varepsilon(x,\xi))\,dx\,, \\ r^\varepsilon = r^\varepsilon(x,\xi) &= \varepsilon^2\Delta w^\varepsilon - w^\varepsilon + f(w^\varepsilon,\sigma^\varepsilon) \\ &= \Delta_y W^\varepsilon - W^\varepsilon + f(W^\varepsilon,\sigma^\varepsilon)|_{y=(x-\xi)/\varepsilon}\,. \end{aligned} \tag{2.1}$$

Since $W(y)$ decays to zero exponentially fast as $|y| \to \infty$, we can regard r^ε as zero. (On the contrary, for the shadow Gierer–Meinhardt system, r^ε is the main term forcing a spike to move towards the boundary.)

If we decompose $A(x,t)$ as in (1.17), then the first equation of (1.11) can be written as

$$\sum_{j=1}^N w^\varepsilon_{\xi_j}\dot\xi_j + \phi_t = \mathcal{L}^\xi\phi + f_H(w^\varepsilon,\sigma^\varepsilon)(h_0+h_1) + r^\varepsilon + \mathcal{N}, \tag{2.2}$$

where

$$\begin{aligned} \mathcal{L}^\xi\phi &= \varepsilon^2\Delta\phi - \phi + f_A(w^\varepsilon,\sigma^\varepsilon)\phi + f_H(w^\varepsilon,\sigma^\varepsilon)\varepsilon^{-N}\langle g'(w^\varepsilon)\phi\rangle, \\ \mathcal{N} &= f(w^\varepsilon+\phi, \varepsilon^{-N}\langle g(w^\varepsilon+\phi)\rangle + h_0 + h_1) - f(w^\varepsilon,\sigma^\varepsilon) \\ &\quad - f_A(w^\varepsilon,\sigma^\varepsilon)\phi - f_H(w^\varepsilon,\sigma^\varepsilon)(\varepsilon^{-N}\langle g'(w^\varepsilon)\phi\rangle + h_0 + h_1). \end{aligned} \tag{2.3}$$

Multiplying (2.2) by $w^\varepsilon_{\xi_i}$ and using

$$\int_\Omega w^\varepsilon_{\xi_i}w^\varepsilon_{\xi_j} = \delta_{ij}\langle|w^\varepsilon_{\xi_i}|^2\rangle, \qquad \int_\Omega \phi_t w^\varepsilon_{\xi_i} = -\int_\Omega \phi w^\varepsilon_{\xi_i,t} = -\sum_{j=1}^N\int_\Omega \phi w^\varepsilon_{\xi_i\xi_j}\dot\xi_j$$

(since $\phi \perp T\mathcal{M}$, $\langle\phi, w_{\xi_i}\rangle = 0$ for all i), we obtain

$$\langle|w^\varepsilon_{\xi_i}|^2\rangle\dot\xi_i - \sum_{j=1}^N\langle w^\varepsilon_{\xi_i\xi_j},\phi\rangle\dot\xi_j = \int_\Omega w^\varepsilon_{\xi_i}\mathcal{L}^\xi(\phi) + \int_\Omega f_H(w^\varepsilon,\sigma^\varepsilon)(h_0+h_1)w^\varepsilon_{\xi_i} + \int_\Omega \mathcal{N}w^\varepsilon_{\xi_i}. \tag{2.4}$$

Since w_{ξ_i} is almost in the kernel of $\mathcal{L}^\xi$ and therefore it is in the kernel of its adjoint ${\mathcal{L}^\xi}^*$, we can ignore terms involving ϕ and $\mathcal{N}$ to obtain

$$\dot\xi_i\langle|w^\varepsilon_{\xi_i}|^2\rangle \approx \int_\Omega f_H(w^\varepsilon,\sigma^\varepsilon)(h_0+h_1)w^\varepsilon_{\xi_i} = \int_\Omega (h_0+h_1)[Q(w^\varepsilon,\sigma^\varepsilon)]_{\xi_i}, \tag{2.5}$$

where

$$Q(w,\sigma) = \int_0^w f_H(s,\sigma)\,ds = -\frac{w^3}{3\sigma^2} \qquad \forall\, w,\sigma \in (0,\infty). \tag{2.6}$$

Since $Q(w^\varepsilon,\sigma^\varepsilon)_{\xi_i} = -Q(w^\varepsilon,\sigma^\varepsilon)_{x_i}$ and $Q \equiv 0$ on $\partial\Omega$, we have

$$\dot\xi_i\langle|w^\varepsilon_{\xi_i}|^2\rangle \approx \int_\Omega Q(w^\varepsilon,\sigma^\varepsilon)(h_0+h_1)_{x_i} = \int_\Omega Q(w^\varepsilon,\sigma^\varepsilon)h_{1,x_i}\,. \tag{2.7}$$

Because τ is small and D is large, the third equation of (1.11) for h_1 gives

$$h_1 \approx \varepsilon^{-N}(-D\Delta)^{-1}(g(w^\varepsilon) - \langle g(w^\varepsilon)\rangle). \tag{2.8}$$

Writing the Green's function for Δ as $G(x,x') = \Gamma(x-x') + R(x,x')$ and using the fact that $\langle G(\cdot,x')\rangle = 0$, we then have

$$\begin{aligned} h_1 &\approx \varepsilon^{-N} D^{-1} \int_\Omega G(x,x')[g(w^\varepsilon) - \langle g(w^\varepsilon)\rangle](x')\,dx' = \varepsilon^{-N} D^{-1} \int_\Omega G(x,x') g(w^\varepsilon)\,dx' \\ &= \varepsilon^{-N} D^{-1} \int_\Omega \Gamma(x-x') g(w^\varepsilon)(x')\,dx' + \varepsilon^{-N} D^{-1} \int_\Omega R(x,x') g(w^\varepsilon)(x')\,dx' m \\ &=: h_{11} + h_{12}\ . \end{aligned}$$

Therefore,

$$\dot{\xi}_i \langle |w^\varepsilon_{\xi_i}|^2 \rangle \approx \int_\Omega [Q(w^\varepsilon,\sigma^\varepsilon) h_{11,x_i} + Q(w^\varepsilon,\sigma^\varepsilon) h_{12,x_i}]\ . \tag{2.9}$$

Since w^ε and h_{11} are radially symmetric about ξ and w^ε has compact support,

$$\int_\Omega Q(w^\varepsilon,\sigma^\varepsilon) h_{11,x_i} = \int_{\mathbb{R}^N} Q(w^\varepsilon,\sigma^\varepsilon) h_{11,x_i} = 0. \tag{2.10}$$

Hence

$$\begin{aligned} \dot{\xi}_i \langle |w^\varepsilon_{\xi_i}|^2 \rangle &\approx \varepsilon^{-N} D^{-1} \int_{\Omega\times\Omega} Q(w^\varepsilon,\sigma^\varepsilon)(x) R_{x_i}(x,x') g(w^\varepsilon(x',\xi))\,dx'dx \\ &= \varepsilon^{N} D^{-1} \int_\Omega \left(\int_\Omega \varepsilon^{-N} Q(w^\varepsilon(x,\xi),\sigma^\varepsilon) R_{x_i}(x,x')\,dx \right) \varepsilon^{-N} g(w^\varepsilon(x',\xi))\,dx'\ . \end{aligned}$$

Observe that as $\varepsilon \to 0$,

$$\begin{aligned} &\varepsilon^{-N} g(w^\varepsilon(x',\xi)) \to c_1 \delta(x'-\xi), && c_1 := \textstyle\int_{\mathbb{R}^N} g(W(y))\,dy, \\ &\varepsilon^{-N} Q(w^\varepsilon(x,\xi)) \to -c_2 \delta(x-\xi), && c_2 = \textstyle\int_{\mathbb{R}^N} |Q(W(y))|\,dy, \\ &\varepsilon^{2-N} \textstyle\int_\Omega |w^\varepsilon_{\xi_i}|^2 = \int_{\Omega_\varepsilon} |W^\varepsilon_{y_i}|^2 \to c_3, && c_3 := \tfrac{1}{N} \textstyle\int_{\mathbb{R}^N} |\nabla W|^2. \end{aligned} \tag{2.11}$$

We then have

$$\dot{\xi}_i \approx -\frac{c_1 c_2}{c_3} \frac{\varepsilon^2}{D} R_{x_i}(\xi,\xi) = -\frac{c_1 c_2 \varepsilon^2}{2 c_3 D} D_\xi R(\xi,\xi) =: -\alpha_0 \varepsilon^2 D^{-1} D_\xi R(\xi,\xi), \tag{2.12}$$

by using the fact that $R(\xi,x) = R(x,\xi)$ so $\nabla_x R(\xi,\xi) = \nabla_\xi R(\xi,\xi) = \frac{1}{2} D_\xi R(\xi,\xi)$.

Finally, using the definition of g, σ, and Q we have

$$\alpha_0 := \frac{c_1 c_2}{2 c_3} = \frac{N \int_{\mathbb{R}^N} W^3}{6 \int_{\mathbb{R}^N} |\nabla W|^2 \int_{\mathbb{R}^N} W^2} = \frac{N \int_{\mathbb{R}^N} (|\nabla W|^2 + W^2)}{6 \int_{\mathbb{R}^N} |\nabla W|^2}\ . \tag{2.13}$$

Here in the last equality, we have used the identity $\int_{\mathbb{R}^N} W^3 / \int_{\mathbb{R}^N} W^2 = \int_{\mathbb{R}^N} (|\nabla W|^2 + W^2)$ obtained by integrating $0 = W(-\Delta W + W - W^2 / \int_{\mathbb{R}^N} W^2)$ over $\mathbb{R}^N$.

In what follows we shall make the derivation of (2.12) rigorous.

3. Preliminaries.

3.1. The ground state $\boldsymbol{W}$. With $f(A,H) = A^2/H$, (1.13) for W reads

$$-\Delta W + W - \frac{W^2}{\int_{\mathbb{R}^N} W^2} = 0 \qquad \text{in } \mathbb{R}^N.$$

It is well known that this equation possesses a unique, nonnegative, radially symmetric solution W (refered to as the ground state) with its unique maximum attained at the origin. In addition, there exists a positive constant K such that as $r \to \infty$,

$$|D_y^\alpha W(y)| \le K e^{-|y|}, \qquad \alpha = 0, 1, 2. \tag{3.1}$$

For more details on the ground state solution W, see [4, 10, 9, 18, 21] and the references therein.

From (3.1) one sees that there exists a positive constant C, which is independent of ε and μ, such that $r^\varepsilon(x,\xi)$ defined in (2.1) satisfies

$$|r^\varepsilon(x,\xi)| + |\nabla_\xi r^\varepsilon(x,\xi)| \le C e^{-\mu/(2\varepsilon)} \le C D^{-2} \varepsilon^4 \qquad \forall x, \xi \in \Omega,$$

since $\mu \ge 4\varepsilon \log(D\varepsilon^{-2})$.

3.2. Local coordinates near $\boldsymbol{\mathcal{M}}$. For convenience, in what follows we shall often drop the superscript and write $\sigma^\varepsilon = \sigma$, $w^\varepsilon = w$, etc.

Lemma 3.1. *There exists a positive constant c_0 depending only on Ω such that if $\varepsilon \in (0,1]$ and*

$$\operatorname{dist}(u, \mathcal{M}) = \inf_{w \in \mathcal{M}} \|u - w\|_{L^2(\Omega)} < c_0 \varepsilon^{N/2}, \tag{3.2}$$

then there exists a unique $\xi \in \bar{\Omega}$ such that

$$u = w(\cdot, \xi) + \psi, \qquad \|\psi\|_2 = \operatorname{dist}(u, \mathcal{M}). \tag{3.3}$$

Consequently, if $\xi \in \Omega$, then $\psi \perp T_\xi \mathcal{M}$, the tangent space of $\mathcal{M}$ at $w(\cdot,\xi)$; that is, $\langle \psi, w_{\xi_i}(\cdot,\xi)\rangle = 0$ for all $i = 1, \dots, N$. The standard proof of this result is left to the reader.

3.3. Eigenvalue estimates. Multiplying (2.2) by ϕ and integrating over Ω yields, after using $\phi \perp T_\xi \mathcal{M}$,

$$\frac{1}{2}\frac{d}{dt}\|\phi\|_2^2 = \langle \mathcal{L}^\xi \phi, \phi\rangle + h_0 \langle f_H, \phi\rangle + \langle h_1 f_H, \phi\rangle + \langle r^\varepsilon + \mathcal{N}, \phi\rangle, \tag{3.4}$$

where the operator $\mathcal{L}^\xi$ can be written as

$$\mathcal{L}^\xi \phi = \varepsilon^2 \Delta\phi - \phi + 2\sigma^{-1} w\phi - 2\varepsilon^{-N}\sigma^{-2}\langle w, \phi\rangle w^2, \qquad w = w^\varepsilon(\cdot,\xi), \sigma = \sigma^\varepsilon. \tag{3.5}$$

Lemma 3.2. *There exists a positive constant ν which is independent of ε and μ such that for all sufficiently small positive ε,*

$$\langle \mathcal{L}^\xi \phi, \phi\rangle \le -\nu\{\varepsilon^2 \|\nabla\phi\|_2^2 + \|\phi\|_2^2\} \qquad \forall \phi \in H^1(\Omega), \quad \phi \perp T_\xi \mathcal{M}, \quad \xi \in \Omega^\mu. \tag{3.6}$$

This lemma was first established in [3, Lemma 2.4]; for completeness we include the proof in the section 8. It is worth mentioning here that this eigenvalue estimate is the key to our whole analysis.

3.4. Some L^∞ estimates for parabolic equations.

LEMMA 3.3. *There exists a positive constant $C(\Omega)$ such that for every constant $D \geq 1$, $\tau > 0$, and $T > 0$, and functions $v_0 : \Omega \to (0,\infty)$ and $F(\cdot,\cdot) : \Omega \times (0,T) \to (0,\infty)$, the solution v to*

$$\left\{\begin{array}{ll} \tau v_t - D\Delta v + v = F(x,t) & \text{in } \Omega \times (0,T), \\ \partial_n v = 0 & \text{on } \partial\Omega \times (0,T), \\ v(\cdot,0) = v_0(\cdot) & \text{in } \Omega \times \{0\} \end{array}\right. \tag{3.7}$$

satisfies

$$\min_{\Omega\times[0,T]} v \geq \frac{1}{C(\Omega)} \min\left\{ \min_{\bar\Omega} v_0,\ \min_{[0,T]} \int_\Omega F(x,t)\,dx \right\}. \tag{3.8}$$

LEMMA 3.4. *For each $p > N/2$, there exists a positive constant $C(\Omega, p)$ such that for every positive constant T, τ and η, and every function $F \in L^\infty((0,T); L^p(\Omega))$ and $v_0 \in L^\infty(\Omega)$ with $\langle v_0\rangle = \langle F(\cdot,t)\rangle = 0$ for all t, the solution v to*

$$\left\{\begin{array}{ll} \tau v_t - \Delta v + \eta v = F(x,t) & \text{in } \Omega \times (0,T), \\ \partial_n v = 0 & \text{on } \partial\Omega \times (0,T), \\ v(x,0) = v_0(x) & \text{in } \Omega \times \{0\} \end{array}\right. \tag{3.9}$$

satisfies, for every $t_0 \in [0,T]$,

$$\|v(\cdot,t_0)\|_\infty \leq \|v_0\|_\infty + C(\Omega,p) \sup_{0\leq s\leq t_0} \|F(\cdot,s)\|_p\,. \tag{3.10}$$

We leave the proofs of the above two lemmas until the last section.

3.5. The regular part of the Green's function. We assume that Ω is a bounded domain in $\mathbb{R}^N$ ($N = 2,3$) with C^3 boundary and of unit volume. We denote by $G(x,\xi)$ the Green's function for Δ in Ω with homogeneous Neumann boundary condition, i.e., the solution to (1.22). For each $\xi \in \Omega$ sufficiently close to the boundary $\partial\Omega$, the distance function $\mathrm{d}(x)$ defined as the distance from x to $\partial\Omega$ will be smooth near ξ so that there is a unique reflection point $\xi^* = \xi - 2\mathrm{d}(\xi)\nabla_\xi \mathrm{d}(\xi)$ of ξ about $\partial\Omega$.

LEMMA 3.5. *For all ξ sufficiently close to $\partial\Omega$,*

$$G(x,\xi) = \Gamma(x-\xi) + R(x,\xi), \quad R(x,\xi) = \Gamma(x-\xi^*) + J(x,\xi), \tag{3.11}$$

where $\xi^* = \xi - 2\mathrm{d}(\xi)\nabla_\xi\mathrm{d}(\xi) \in \Omega^c$ is the unique reflection point of ξ with respect to $\partial\Omega$ and the function $J(x,\xi)$ satisfies

$$|\nabla_x J(\xi,\xi)| \leq C(\Omega)\ \mathrm{d}(\xi)^{2-N}. \tag{3.12}$$

Consequently,

$$D_\xi R(\xi,\xi) = 2\nabla_x R(\xi,\xi) = 2^{2-N}(\omega_N)^{-1}\mathrm{d}(\xi)^{1-N}[-\nabla_\xi \mathrm{d}(\xi) + O(\mathrm{d}(\xi))] \quad \text{as} \ \ \xi \to \partial\Omega, \tag{3.13}$$

where ω_N is the area of the unit sphere in $\mathbb{R}^N$.

We leave the proof until the last section of the paper.

4. L^∞ estimates.

4.1. A lower bound on H.

LEMMA 4.1. *Assume that $D > 1$, $\tau > 0$, and that the initial value $H(\cdot, 0)$ of H satisfies*

$$\|H(x,0) - \sigma^\varepsilon\|_\infty \leq \frac{\sigma^\varepsilon}{4}\ . \tag{4.1}$$

There exists a constant $C = C(\Omega) > 0$ such that for all $t \in (0, T^*)$,

$$H(x,t) \geq \frac{1}{C(\Omega)}\ . \tag{4.2}$$

Proof. First of all, the constant $\sigma^\varepsilon := \int_{\mathbb{R}^N} (W^\varepsilon(y))^2 dy = \varepsilon^{-N} \int_{|x-\xi|\leq\mu} (w^\varepsilon)^2 dx$ is bounded and positive, uniformly in $\varepsilon \in (0, 1]$.

When $t \in (0, T^*)$, $A = w + \phi$ with $\|\phi\|_2 \leq c_0 \varepsilon^{N/2}$. It then follows that

$$\bar\sigma(t) := \varepsilon^{-N} \int_\Omega g(A) = \varepsilon^{-N} \int_\Omega A^2 = \varepsilon^{-N} \int_\Omega (w+\phi)^2 \in (\sigma^\varepsilon/2, 3\sigma^\varepsilon/2) \tag{4.3}$$

(taking smaller c_0 if necessary). The assertion of the lemma then follows directly from Lemma 3.3 with $F(x,t) = \varepsilon^{-N} g(A)$. ☐

4.2. An upper bound for A.

LEMMA 4.2. *There exists a positive constant $C(\Omega)$ such that*

$$\|A\|_{\infty,\Omega\times[0,T^*]} \leq C(\Omega), \qquad \|\phi\|_{\infty,\Omega\times[0,T^*]} \leq C(\Omega)\ . \tag{4.4}$$

Proof. Set $y = x/\varepsilon$. Then (1.5) can be written as

$$A_t - \Delta_y A + A = f(A, H) \qquad \text{in } \Omega_\varepsilon \times (0, T^*).$$

Fix $p \in (N/2, 2)$. Then the local and boundary parabolic estimates yield

$$\|A\|_{\infty,\Omega\times[0,T^*]} \leq \|A(\cdot,0)\|_\infty + C \sup_{0<t\leq T^*} \sup_{y\in\Omega_\varepsilon} (\|A(\cdot,t)\|_{L^2(B_1(y)\cap\Omega_\varepsilon)} + \|f(A,H)\|_{L^p(B_1(y)\cap\Omega_\varepsilon)}), \tag{4.5}$$

where C depends only on the $C^{2+\alpha}$ norm of $\partial\Omega_\varepsilon$ and hence is bounded independently on $\varepsilon \in (0, 1]$. As $f(A, H) = A^2/H$,

$$\begin{aligned}\|f(A,H)\|_{L^p(B_1(y)\cap\Omega_\varepsilon)} &\leq \frac{\|A^2\|_{p,\Omega_\varepsilon}}{\min H} \leq C\ \|A\|_\infty^{2-2/p} \|A\|_{2,\Omega_\varepsilon}^{2/p} \\ &\leq \delta\|A\|_\infty + C(\delta)\|A\|_{2,\Omega_\varepsilon}^{2/(2-p)} = \delta\|A\|_\infty + C(\delta)\left(\int_\Omega \varepsilon^{-N} A^2 dx\right)^{1/(2-p)}.\end{aligned}$$

Taking small δ, we then obtain from (4.5) that

$$\begin{aligned}\|A\|_{\infty,\Omega\times[0,T^*]} &\leq \Big\{\|A(\cdot,0)\|_\infty + C \sup_{(0,T^*)} [\bar\sigma(t) + C(\delta)\bar\sigma^{1/(2-p)}(t)]\Big\}(1 - C\delta)^{-1} \\ &\leq C(\Omega),\end{aligned}$$

where $\bar\sigma(t)$ is as in (4.3). The proof of the lemma is complete. ☐

5. The flow in the normal space to $\mathcal{M}$.

5.1. Estimates for ϕ. With f and g given by (1.6),

$$H = \varepsilon^{-N}\langle (w+\phi)^2\rangle + h = \sigma + 2\varepsilon^{-N}\langle \phi w\rangle + \varepsilon^{-N}\|\phi\|_2^2 + h,$$

and (2.2) reads

$$\nabla_\xi w \cdot \dot{\xi} + \phi_t = r^\varepsilon + \mathcal{L}^\xi \phi - \frac{w^2}{\sigma^2} h - \mathcal{N}[w,\phi], \tag{5.1}$$

where $r^\varepsilon = \varepsilon^2 \Delta w - w + w^2/\sigma$ and

$$\mathcal{N}[w,\phi] = \frac{\phi^2}{H} - \frac{\varepsilon^{-N}\|\phi\|_2^2 w^2}{\sigma^2} - \frac{(h + 2\varepsilon^{-N}\langle w\phi\rangle + \varepsilon^{-N}\|\phi\|_2^2)w\phi}{\sigma H} + \frac{w^2(H-\sigma)^2}{\sigma^2 H}\ . \tag{5.2}$$

LEMMA 5.1. *The following estimates hold for all $t \in [0, T^*]$:*

$$|\mathcal{N}[w,\phi]| \le C\ (\ \phi^2 + \varepsilon^{-N}\|\phi\|_2^2 w^2 + h^2 w^2\ ), \tag{5.3}$$

$$\frac{1}{2}\frac{d}{dt}\|\phi\|_2^2 \le (\varepsilon^2\|\nabla\phi\|_2^2 + \|\phi\|_2^2)\left(\varepsilon^{-N/2}\|\phi\|_2 - \frac{\nu}{2}\right) + C(\nu)(\varepsilon^N\|h\|_\infty^2 + |r^\varepsilon|_\infty^2), \tag{5.4}$$

where $\nu > 0$ is the constant in Lemma 3.2.

Proof. The estimate (5.3) follows from Lemma 4.1, the bounds

$$\|\phi\|_2 \le c_0 \varepsilon^{N/2}, \qquad \|w\|_p^p = \varepsilon^N \int_{\mathbb{R}^N} (W^\varepsilon)^p dy = O(\varepsilon^N) \quad \forall\, p > 1, \tag{5.5}$$

and a straightforward calculation.

To prove (5.4), we multiply (5.1) by ϕ, integrate over Ω, and use $\phi \perp \mathcal{M}$, obtaining

$$\frac{1}{2}\frac{d}{dt}\|\phi\|_2^2 \le \langle \mathcal{L}^\xi\phi, \phi\rangle + |\langle r^\varepsilon, \phi\rangle| + |\langle w^2 h\sigma^{-2}, \phi\rangle| + |\langle \mathcal{N}[w,\phi], \phi\rangle|. \tag{5.6}$$

Let ν be the constant in Lemma 3.2. Using the bounds in (5.5), we can estimate

$$\begin{aligned}
|\langle r^\varepsilon, \phi\rangle| &\le \frac{\nu}{8}\|\phi\|_2^2 + C\|r^\varepsilon\|_\infty^2,\\
|\langle w^2 h\sigma^{-2}, \phi\rangle| &\le C\varepsilon^{N/2}\|\phi\|_2\|h\|_\infty \le \frac{\nu}{8}\|\phi\|_2^2 + C\varepsilon^N\|h\|_\infty^2,\\
|\langle \phi^2, \phi\rangle| &\le \|\phi\|_3^3 \le C\varepsilon^{-N/2}\|\phi\|_2(\varepsilon^2\|\nabla\phi\|_2^2 + \|\phi\|_2^2),\\
\varepsilon^{-N}\|\phi\|_2^2|\langle w^2\phi\rangle| &\le C\varepsilon^{-N/2}\|\phi\|_2^3,\\
|\langle h^2 w^2 \phi\rangle| &\le C\varepsilon^{N/2}\|h\|_\infty^2\|\phi\|_2 \le C\varepsilon^N\|h\|_\infty^2.
\end{aligned}$$

Substituting these estimates into (5.6) and (5.3), and using Lemma 3.2, we then obtain (5.4). □

5.2. Estimates for h. We first estimate h_1. It is convenient to further decompose $h_1 = h_{11} + h_{12}$, where

$$\begin{aligned}
&\tau D^{-1} h_{11,t} - \Delta h_{11} + D^{-1} h_{11} = \varepsilon^{-N} D^{-1}(w^2 - \langle w^2\rangle)\ ,\\
&\tau D^{-1} h_{12,t} - \Delta h_{12} + D^{-1} h_{12} = \varepsilon^{-N} D^{-1}[(2\phi w + \phi^2) - \langle 2\phi w + \phi^2\rangle].
\end{aligned}$$

Both h_{11} and h_{12} satisfy the homogeneous Neumann boundary condition, $h_{12}(\cdot, 0) \equiv 0$, and $h_{11}(x,0) = h_1(x,0) = H(x,0) - \langle H(\cdot,0)\rangle$.

LEMMA 5.2. *Assume that $h_{12}(\cdot,0) \equiv 0$ and for some $\kappa \in (0,1/4)$, $\|h_{11}(\cdot,0)\|_\infty \leq D^{-1}\varepsilon^{2-N-\kappa}$. Then there exists $C = C(\kappa,\Omega)$ such that*

$$\|h_{11}\|_{\infty,\Omega\times[0,T^*]} \leq CD^{-1}\varepsilon^{2-N-\kappa} \ , \tag{5.7}$$

$$\|h_{12}\|_{\infty,\Omega\times[0,T^*]} \leq CD^{-1}\varepsilon^{2-N-\kappa}(\varepsilon^{-N/2}\|\phi\|_2). \tag{5.8}$$

Proof. We set $p = N/(2-\kappa) \in (N/2, 2)$. Using Lemma 3.4 we obtain

$$\begin{aligned} \|h_{11}\|_{\infty,\Omega\times[0,T^*]} &\leq \|h_{11}(\cdot,0)\|_\infty + CD^{-1}\sup\nolimits_{0<s<T^*}\|\varepsilon^{-N}w^2\|_p \ , \\ \|h_{12}\|_{\infty,\Omega\times[0,T^*]} &\leq CD^{-1}\sup\nolimits_{0<s<T^*}\|\varepsilon^{-N}(2w\phi+\phi^2)\|_p \ . \end{aligned} \tag{5.9}$$

Since $\varepsilon^{-N}\|w^2\|_p \leq C\varepsilon^{-N+N/p} = C\varepsilon^{2-N-\kappa}$, the estimate (5.7) follows from (5.9).

Also, we have

$$\|\varepsilon^{-N}w\phi\|_p \leq \varepsilon^{-N}\|\phi\|_2\|w\|_{2p/(2-p)} \leq C\varepsilon^{-N+N(2-p)/(2p)}\|\phi\|_2 = C\varepsilon^{-N-\kappa}(\varepsilon^{-N/2}\|\phi\|_2) \ ,$$
$$\|\varepsilon^{-N}\phi^2\|_p \leq \varepsilon^{-N}\|\phi\|_2^{2/p}\|\phi\|_\infty^{2-2/p} \leq C\varepsilon^{2-N-\kappa}(\varepsilon^{-N/2}\|\phi\|_2)$$

since $\|\phi\|_\infty \leq C$ and $\varepsilon^{-N/2}\|\phi\|_2 \leq c_0$. The inequality (5.8) then follows from (5.9) and the preceding estimates. □

In what follows we denote

$$\mathcal{E}_\kappa = \mathcal{E}_\kappa(\varepsilon, D) = D^{-1}\varepsilon^{2-N-\kappa} \quad \text{for } \kappa \in (0,1/4) \ . \tag{5.10}$$

We shall now estimate h_0, which solves

$$h_{0,t} + \tau^{-1}h_0 = -2\varepsilon^{-N}\int_\Omega AA_t \ . \tag{5.11}$$

LEMMA 5.3. *The following estimate holds true for all $t \in [0,T^*]$,*

$$\frac{1}{2}\frac{d}{dt}h_0^2+\tau^{-1}h_0^2 \leq C(\kappa,\Omega)[\|r^\varepsilon\|_\infty^2+\|h\|_\infty^2+\varepsilon^{-N}\|\phi\|_2^2+\varepsilon^{-N}|h_0|(\varepsilon^2\|\nabla\phi\|_2^2+\|\phi\|_2^2)]. \tag{5.12}$$

Proof. Substituting

$$\int_\Omega AA_t = \int_\Omega (w+\phi)\{r^\varepsilon + \mathcal{L}^\xi\phi - \sigma^{-2}w^2h + \mathcal{N}[w,\phi]\}$$

into (5.11) and using a straightforward calculation similar to that in the proofs of Lemmas 5.1 and 5.2, we obtain (5.12). We omit the details. □

5.3. Proof of Theorem 1.1. Adding estimates (5.4) and (5.12) we obtain

$$\begin{aligned} \frac{1}{2}\frac{d}{dt}(h_0^2 + \varepsilon^{-N}\|\phi\|_2^2) \leq (C|h_0| + C\varepsilon^{-N}\|\phi\|_2^2) - \nu/2\varepsilon^{-N}(\varepsilon^2\|\nabla\phi\|_2^2 + \|\phi\|_2^2) \\ +(C-\tau^{-1})h_0^2 + C\|h\|_\infty^2 + C\varepsilon^{-N}\|r^\varepsilon\|_\infty^2 \ . \end{aligned} \tag{5.13}$$

By Lemma 5.2,

$$\begin{aligned} \|h\|_\infty^2 = \|h_0 + h_{11} + h_{12}\|_\infty^2 &\leq 2h_0^2 + 2\|h_{11}\|_\infty^2 + 2\|h_{12}\|_\infty^2 \\ &\leq 2h_0^2 + C(\mathcal{E}_\kappa)^2(1+\varepsilon^{-N}\|\phi\|_2^2) \ . \end{aligned}$$

Since $\|r^\varepsilon\|_\infty \le Ce^{-\mu/(2\varepsilon)} < CD^{-2}\varepsilon^4$, taking τ_0, ε_0, c_0 (in Lemma 3.1) sufficiently small we obtain from (5.13) that if $\varepsilon \in (0, \varepsilon_0], \tau \in (0, \tau_0]$, then

$$\begin{aligned}\frac{1}{2}\frac{d}{dt}(h_0^2 + \varepsilon^{-N}\|\phi\|_2^2) &\le -\frac{1}{2\tau}h_0^2 - (\nu/4 - C|h_0|)\varepsilon^{-N}(\varepsilon^2\|\nabla\phi\|^2 + \|\phi\|_2^2) + C_2(\mathcal{E}_\kappa)^2 \\ &\le -\frac{1}{C_1}(h_0^2 + \varepsilon^{-N}\|\phi\|^2) + C_2(\mathcal{E}_\kappa)^2 \qquad (5.14)\end{aligned}$$

for all $t \in [0, \hat{T}]$, where $[0, \hat{T}]$ is the maximal interval in $[0, T^*]$ in which $|h_0| \le \nu/(8C)$. Here C_1 and C_2 are constants depending only on N, κ, and Ω.

Applying Gronwall's inequality to (5.14), we conclude that there exists a constant $C = C(\Omega, \kappa, N)$ such that when $\varepsilon \in (0, \varepsilon_0]$ and $\tau \in (0, \tau_0]$,

$$h_0^2 + \varepsilon^{-N}\|\phi\|_2^2 \le C(\mathcal{E}_\kappa)^2 = C(D^{-1}\varepsilon^{2-N-\kappa})^2$$

for all $t \in (0, \hat{T}]$. Since we assume that $D > \varepsilon^{2-N-2\kappa}$, we see from the above estimate that, taking ε_0 smaller if necessary, $|h_0| \le \nu/(16C)$ and $\varepsilon^{-N/2}\|\phi\|_2 \le c_0/2$. Thus, we must have $\hat{T} = T^*$ and, by the definition of T^*, either $T^* = \infty$ or $\xi(T^*) \in \partial\Omega^\mu$. This completes the proof of Theorem 1.1. □

6. The flow in the tangent space of $\mathcal{M}$.

In what follows, we assume that $\varepsilon \in (0, \varepsilon_0]$, $\tau \in (0, \tau_0]$, and that D and μ satisfy (1.19). Then the assertion of Theorem 1.1 holds true.

6.1. The velocity.

Lemma 6.1. *For all* $t \in [0, T^*)$,

$$\dot{\xi} = \frac{\varepsilon^2}{3\sigma^2 c_3}\Big(\mathrm{I} + O(\mathcal{E}_\kappa)\Big)\Big(-\varepsilon^{-N}\langle\nabla_x h_{11}, w^3\rangle + O(\varepsilon^{-1}{\mathcal{E}_\kappa}^2)\Big), \qquad (6.1)$$

where I *is the identity matrix and* $c_3 = N^{-1}\int_{\mathbb{R}^N}|\nabla W(y)|^2 dy$.

Proof. Multiplying (5.1) by w_{ξ_j} and integrating the resulting equation over Ω yields

$$\sum_{i=1}^N \dot{\xi}_i\Big(\langle w_{\xi_i}, w_{\xi_j}\rangle - \langle w_{\xi_i\xi_j}, \phi\rangle\Big) = \langle r^\varepsilon, w_{\xi_j}\rangle + \langle\mathcal{L}^\xi\phi, w_{\xi_j}\rangle - \langle\sigma^{-2}w^2 h, w_{\xi_j}\rangle + \langle\mathcal{N}, w_{\xi_j}\rangle. \qquad (6.2)$$

Note that

$$\begin{aligned}&\langle w_{\xi_i}, w_{\xi_j}\rangle = \varepsilon^{N-2}\int_{\mathbb{R}^N} W^\varepsilon_{y_i}W^\varepsilon_{y_j}\,dy = \varepsilon^{N-2}c_3\delta_{ij}(1 + O(e^{-\mu/\varepsilon}))\ , \\ &|\langle w_{\xi_i\xi_j}, \phi\rangle| \le C\varepsilon^{N-2}(\varepsilon^{-N/2}\|\phi\|_2) \le C\varepsilon^{N-2}\mathcal{E}_\kappa\ .\end{aligned} \qquad (6.3)$$

Hence, (6.2) can be written as

$$c_3\varepsilon^{N-2}(\mathrm{I} + O(\mathcal{E}_\kappa))\dot{\xi} = \langle r^\varepsilon, w_\xi\rangle + \langle\mathcal{L}^\xi\phi, w_\xi\rangle - \langle\sigma^{-2}w^2 h, w_\xi\rangle + \langle\mathcal{N}, w_\xi\rangle. \qquad (6.4)$$

We shall now estimate each term on the right-hand side.

First of all,

$$|\langle r^\varepsilon, w_\xi\rangle| \le \|r^\varepsilon\|_\infty|\langle|w_\xi|\rangle \le Ce^{-\mu/(2\varepsilon)}\varepsilon^{N-1} \le C\varepsilon^{N-1}{\mathcal{E}_\kappa}^2. \qquad (6.5)$$

Denote

$$\begin{aligned}(\mathcal{L}^\xi)^*\psi &= \varepsilon^2\Delta\psi - \psi + 2\sigma^{-1}w\psi - 2\varepsilon^{-N}\sigma^{-2}\langle w^2\psi\rangle w\\ &= \mathcal{L}^\xi\psi - 2\sigma^{-2}\varepsilon^{-N}(\langle w^2\psi\rangle w - \langle w\psi\rangle w^2).\end{aligned}$$

Then $(\mathcal{L}^\xi)^* w_\xi = \mathcal{L}^\xi w_\xi = r^\varepsilon_\xi$. It follows that

$$|\langle\mathcal{L}^\xi\phi, w_\xi\rangle| = |\langle\phi, (\mathcal{L}^\xi)^* w_\xi\rangle| = |\langle\phi, r^\varepsilon_\xi\rangle| \le Ce^{-\mu/(2\varepsilon)}\varepsilon^{N/2}\mathcal{E}_\kappa \le \varepsilon^{N-1}{\mathcal{E}_\kappa}^2.$$

Next, from (5.3) we obtain

$$\begin{aligned}|\langle\mathcal{N}, w_\xi\rangle| &\le C\int_\Omega(\phi^2 + \varepsilon^{-N}\|\phi\|_2^2 w^2 + h^2w^2)|w_\xi|\\ &\le C\varepsilon^{N-1}[\varepsilon^{-N}\|\phi\|_2^2 + \|h\|_\infty^2] \le C\varepsilon^{N-1}{\mathcal{E}_\kappa}^2.\end{aligned}$$

As $h = h_0(t) + h_1(x,t) = h_0 + h_{11} + h_{12}$,

$$\langle\sigma^{-2}w^2h, w_\xi\rangle = \langle\sigma^{-2}w^2h_1, w_\xi\rangle = \langle\sigma^{-2}w^2h_{11}, w_\xi\rangle + \langle\sigma^{-2}w^2h_{12}, w_\xi\rangle$$

and

$$|\langle\sigma^{-2}w^2h_{12}, w_\xi\rangle| \le C\varepsilon^{N-1}\|h_{12}\|_\infty \le C\varepsilon^{N-1}{\mathcal{E}_\kappa}^2 \tag{6.6}$$

by Lemma 5.2.

Finally, observe that

$$\langle w^2h_{11}, w_\xi\rangle = -\frac{1}{3}\langle h_{11}, (w^3)_x\rangle = \frac{1}{3}\langle\nabla_x h_{11}, w^3\rangle.$$

Substituting all these estimates into (6.4) we then obtain (6.1) and complete the proof of the lemma. □

Lemma 6.2. *Under the assumptions of Theorem* 1.2, *formula* (1.23) *holds with* α_0 *given by* (2.13).

Proof. From (6.1), it suffices to estimate the term $\langle\nabla_x h_{11}, w^3\rangle$.

We write $h_{11} = h_{110} + h_{111}$, where

$$\begin{aligned}&-\Delta h_{110} = D^{-1}\varepsilon^{-N}[w^2 - \langle w^2\rangle],\\ &\tau D^{-1}h_{111,t} - \Delta h_{111} + D^{-1}h_{111} = -D^{-1}(\tau h_{110,t} + h_{110})\end{aligned} \tag{6.7}$$

with the homogeneous Neumann boundary condition for both h_{110} and h_{111}. Note that

$$h_{111}(\cdot,0) = h_{11}(\cdot,0) - h_{110}(\cdot,0) = h_1(\cdot,0) - (D\Delta)^{-1}(w(\cdot,\xi_0)^2 - \langle w^2(\cdot,\xi_0)\rangle).$$

Using the Green's function for the Δ, we have

$$\begin{aligned}h_{110}(x) &= D^{-1}\varepsilon^{-N}\int_\Omega\Gamma(x-\eta)w^2(\eta,\xi)\,d\eta + D^{-1}\varepsilon^{-N}\int_\Omega R(x,\eta)w^2(\eta,\xi)\,d\eta\\ &\overset{\text{def}}{=} \psi_1(|x-\xi|) + \psi_2(x,\xi).\end{aligned}$$

Note that $\langle w^3, \nabla_x\psi_1\rangle = 0$ so that $\langle\nabla_x h_{110}, w^3\rangle = \langle\nabla_x\psi_2, w^3\rangle$.

As $|\nabla_x \nabla_\xi R(x,\xi)| \le C(\Omega)\mathrm{d}(\xi)^{-N}$ for all $x \in \Omega$,

$$\begin{aligned}
&\left|\int_\Omega R_{x_i}(x,\eta) w^2(\eta,\xi)\,d\eta - R_{x_i}(x,\xi)\int_\Omega w^2(\eta,\xi)\,d\eta\right| \\
&\le \int_{|\eta-\xi|\le\mu} |R_{x_i}(x,\eta) - R_{x_i}(x,\xi)| w^2(\eta,\xi)\,d\eta \\
&\le \int_{|\eta-\xi|<\mu/2} |\nabla_x\nabla_\xi R|\,|\eta-\xi|\;w^2 d\eta \\
&+ \int_{\mu/2<|\eta-\xi|\le\mu} |R_{x_i}(x,\eta) - R_{x_i}(x,\xi)| w^2(\eta,\xi)\,d\eta \le C\varepsilon^{N+1}\mathrm{d}(\xi)^{-N}.
\end{aligned}$$

Similarly, since $|\nabla_x\nabla_x R(x,\xi)| \le C\mathrm{d}(\xi)^{-N}$,

$$\left|\int_\Omega R_{x_i}(x,\xi) w^3(x,\xi)\,dx - R_{x_i}(\xi,\xi)\int_\Omega w^3(x,\xi)\,d\eta\right| \le C\varepsilon^{N+1}\mathrm{d}(\xi)^{-N}.$$

It then follows that

$$\begin{aligned}
\langle \varepsilon^{-N} w^3, h_{110,\xi}\rangle &= D^{-1}\int_\Omega \varepsilon^{-N} w^3(x,\xi)\int_\Omega \varepsilon^{-N} R_{x_i}(x,\eta) w^2(\eta,\xi)\,d\eta dx \\
&= D^{-1} R_{x_i}(\xi,\xi)\int_{\mathbb{R}^N} W^2 \int_{\mathbb{R}^N} W^3 + O(\varepsilon) D^{-1}\mathrm{d}(\xi)^{-N}\,. \qquad (6.8)
\end{aligned}$$

On the other hand, by Lemma 3.4 we have

$$\begin{aligned}
\|h_{111}\|_\infty &\le \|h_{110}(\cdot,0)\|_\infty + \sup_{0<t<T^*} D^{-1}(\tau\|h_{110,t}\|_p + \|h_{110}\|_p) \\
&\le C{\mathcal{E}_\kappa}^2 + D^{-2}\sup_{0<t<T^*}(\tau\|\Delta^{-1}[\varepsilon^{-N} w\nabla_\xi w\cdot\dot{\xi}]\|_p + \|\Delta^{-1}\varepsilon^{-N} w^2\|_p) \\
&\le C{\mathcal{E}_\kappa}^2 + CD^{-2}\sup_{0<t<T^*}[(\tau|\dot{\xi}|+1)\varepsilon^{-N}\|w^2\|_p] \\
&\le C{\mathcal{E}_\kappa}^2
\end{aligned}$$

since from (5.7) and (6.1) $|\dot{\xi}| = o(1)$ as long as $t < T^*$. Thus,

$$\varepsilon^{-N}|\langle w^2 h_{111}, w_{\xi_i}\rangle| \le C\varepsilon^{-1}\|h_{111}\|_\infty \le C\varepsilon^{-1}{\mathcal{E}_\kappa}^2. \qquad (6.9)$$

Hence, from (1.23), the preceding estimates, and the definition of α_0, we obtain

$$\dot{\xi} = \alpha_0\varepsilon^2 D^{-1}\Big(\mathrm{I} + O(\mathcal{E}_\kappa)\Big)\Big(-D_\xi R(\xi,\xi) + O(\varepsilon)\mathrm{d}(\xi)^{-N} + O(\varepsilon^{3-2N-2\kappa}D^{-1})\Big).$$

Finally, notice that $|\mathcal{E}_\kappa D_\xi R(\xi,\xi)| \le C\mathrm{d}(\xi)^{1-N}\varepsilon^{2-N-\kappa}D^{-1} = C\varepsilon^{3-2N-\kappa}D^{-1}[\varepsilon/\mathrm{d}(\xi)]^{N-1}$ $\le C\varepsilon^{3-2N-2\kappa}D^{-1}$. Equation (1.23) thus follows. □

6.2. Proof of Theorem 1.2. It remains to show that $T^* = \infty$ when $D > \varepsilon^{3-2N-3\kappa}$ and μ is small.

When $\xi(t)$ is near the boundary $\partial\Omega$, we have, from (1.23) and (3.13),

$$\dot{\xi} = 2^{2-N}\alpha_0\varepsilon^2(\omega_N D)^{-1}\mathrm{d}(\xi)^{1-N}\Big(\nabla_\xi\mathrm{d}(\xi) + O(\varepsilon/\mathrm{d}(\xi)) + O(\varepsilon^{3-2N-2\kappa}D^{-1}\mathrm{d}(\xi)^{N-1})\Big).$$

It then follows that $\frac{d}{dt}\mathrm{d}(\xi(t)) > 0$ whenever $\xi(t)$ is close enough to the boundary. Consequently, $\mathrm{d}(\xi(t)) > \mu$ for all $t \in [0, T^*]$ if we take μ small enough. Therefore, by Theorem 1.1, $T^* = \infty$. □

7. Proofs of auxiliary lemmas.

Proof of Lemma 3.3. Integrating the differential equation over Ω yields

$$\tau\frac{d}{dt}\int_\Omega v+\int_\Omega v=\int_\Omega F(x,t)\,dx\geq \min_{[0,T]}\int_\Omega F(x,t)\,dx\,. \tag{7.1}$$

Gronwall's inequality then gives

$$\int_\Omega v(x,t)\,dx\geq \min\left\{\int_\Omega v_0(x)\,dx,\ \min_{[0,T]}\int_\Omega f(x,t)\,dx\right\}\,. \tag{7.2}$$

To prove (3.10), we consider two cases: (i) $t_0\in[0,\tau]$; (ii) $t_0\in[\tau,T]$.

Case (i): $t_0\in[0,\tau]$. Comparing v with a subsolution $\underline{v}=e^{-t/\tau}\min_{\bar\Omega}v_0$ gives

$$v(x,t_0)\geq \underline{v}\geq \frac{1}{e}\min_{\bar\Omega}v_0\quad \forall\, x\in\Omega. \tag{7.3}$$

Case (ii): $t_0\in[\tau,T]$. We define

$$s=D(t-t_0)/\tau+1,\qquad \tilde v=e^{(t-t_0)/\tau}v=e^{(s-1)/D}v\,.$$

Then $\tilde v_s-\Delta\tilde v\geq 0$ so that there exists $\tilde C(\Omega)$ such that

$$\min_\Omega \tilde v(\cdot,1)\geq \tilde C(\Omega)\int_\Omega \tilde v(\cdot,0)=\tilde C(\Omega)e^{-1/D}\int_\Omega v(\cdot,t_0-\tau/D); \tag{7.4}$$

namely,

$$\min_\Omega v(\cdot,t_0)\geq \tilde C(\Omega)e^{-1/D}\int_\Omega v(\cdot,t_0-\tau/D)\quad \forall t_0\in[\tau,T]. \tag{7.5}$$

Combining (7.2)–(7.5) then yields the assertion (3.10) of the lemma. □

Proof of Lemma 3.4. Since the equation is linear we can assume that $v_0\equiv 0$. In addition, by the change of variables $t'=t/\tau$ we can also assume that $\tau=1$. Furthermore, we can assume that $\eta=0$ because, by defining $\tilde v=e^{\eta t}v$ and $\tilde F=e^{\eta t}F$, if (3.10) holds for $(\tilde v,\tilde F)$, then it automatically holds for (v,F) by the assumption that $\eta\geq 0$. Thus it suffices to establish (3.10) for the case when $\tau=1$, $\eta=0$, and $v_0\equiv 0$.

Integrating the differential equation over Ω yields $\langle v\rangle=0$ for all $t\in[0,T]$.

Multiplying the differential equation by v and integrating the resulting equation over Ω gives

$$\begin{aligned}\frac{1}{2}\frac{d}{dt}\int_\Omega v^2+\int_\Omega|\nabla v|^2&=\int_\Omega Fv\\ &\leq \|F\|_{(2^*)'}\|v\|_{2^*}\leq C(\delta)\|F\|^2_{(2^*)'}+\delta\|v\|^2_{2^*},\end{aligned}$$

where $2^*=2N/(2-N)$ for $N\geq 3$ and any large number when $N=2$. First applying the Poincare inequality $\|v\|_{2^*}\leq C(\Omega)\|\nabla v\|_2$, then choosing $\delta=1/(2C(\Omega))$, and finally applying the Gronwall's inequality, we then obtain

$$\|v(\cdot,t)\|_2\leq C\sup_{0<s<t}\|F(\cdot,s)\|_p$$

for any $p>(2^*)'=2N/(2+N)$ when $N\geq 3$ and $p>1$ when $N=2$. The assertion of the lemma then follows from the parabolic estimate

$$\|v(\cdot,t)\|_\infty\leq C(\Omega,p)\sup_{0<s<t}(\|v(\cdot,s)\|_2+\|f(\cdot,s)\|_p)\quad \forall p\in(N/2,\infty),$$

since $v(\cdot,0)=0$. The proof of the lemma is complete. $\square$

Proof of Lemma 3.5. Since (3.13) follows directly from (3.12) and the definition of Γ and ξ^*, we need to show only (3.12).

Note that $J(x,\xi) := G(x,\xi) - \Gamma(x-\xi) - \Gamma(x-\xi^*)$ satisfies $\Delta_x J(x,\xi) = 1$ in Ω, $\partial_n J(x,\xi) = b(x,\xi)$ on $\partial\Omega$, and $\int_\Omega J(x,\xi)dx = c(\xi)$, where

$$b(x,\xi) = -\partial_n\Gamma(x-\xi) - \partial_n\Gamma(x-\xi^*), \quad c(\xi) = -\int_\Omega (\Gamma(x-\xi)+\Gamma(x-\xi^*))\,dx\ .$$

A geometric argument shows that for all $x\in\partial\Omega$ and $\xi\in\Omega$,

$$|b(x,\xi)| = \frac{1}{\omega_N}\left|\frac{(x-\xi)\cdot n(x)}{|x-\xi|^N} + \frac{(x-\xi^*)\cdot n(x)}{|x-\xi^*|^N}\right| \le C(\Omega)|\xi-x|^{2-N}. \tag{7.6}$$

Using the Green's formula and noting that $\langle G(\cdot,\xi)\rangle = 0$, we have

$$J(x,\xi) = c(\xi) + \int_{\partial\Omega} b(x',\xi)G(x,x')\,dS_{x'},$$
$$\nabla_x J(x,\xi) = \int_{\partial\Omega} b(x',\xi)\nabla_x G(x,x')\,dS_{x'}. \tag{7.7}$$

Using the known fact that $|\nabla_x G(x,x')| \le C(\Omega)|x-x'|^{1-N}$, we then obtain from (7.6) and (7.7) that

$$|\nabla_x J(\xi,\xi)| \le C(\Omega)\int_{\partial\Omega}|\xi-x'|^{2-N}|x'-\xi|^{1-N}dS_{x'} \le C(\Omega)\mathrm{d}(\xi)^{2-N}.$$

This completes the proof. $\square$

8. Proof of Lemma 3.2. In this section, we prove Lemma 3.2.

We first consider the problem on $\mathbb{R}^N$, $N=2,3$. In what follows, $\langle f\rangle_* = \int_{\mathbb{R}^N} f(x)dx$.

Set $\sigma_0 = \langle W^2\rangle_*$. Then

$$\Delta W - W + \sigma_0^{-1}W^2 = 0 \qquad \text{in } \mathbb{R}^N\ .$$

Lemma 8.1. *Let* L_0 *be an operator defined as*

$$\mathrm{L}_0\phi \overset{\text{def}}{=} \Delta\phi - \phi + 2\sigma_0^{-1}W\phi.$$

Then the following conditions hold:

(1) *The principal eigenvalue* λ_0 *of* L_0 *is positive and its associated eigenfunction* ϕ_0 *is positive.*
(2) *Zero is an eigenvalue of* L_0 *with multiplicity* N*; its associated eigenspace is spanned by* $W_{x_1},\ldots,W_{x_N}$.
(3) *There exists* $\nu_0 > 0$ *such that*

$$\mathrm{L}_0(\phi,\phi) \overset{\text{def}}{=} \langle -|\nabla\phi|^2 - \phi^2 + 2\sigma_0^{-1}W\phi^2\rangle_* \ \le\ \nu_0\langle\phi^2\rangle_*$$

for all $\phi\in H^1(\mathbb{R}^N)$ *satisfying* $\phi\perp\phi_0, W_{x_1},\ldots,W_{x_N}$ *(in* $L^2(\mathbb{R}^N)$ *sense).*

This lemma follows directly from more general results of [16].

Lemma 8.2. *Let* L_1 *be an operator defined by*

$$\mathrm{L}_1\phi \overset{\text{def}}{=} \mathrm{L}_0\phi - \sigma_0^{-2}\langle W\phi\rangle_* W^2 - \sigma_0^{-2}\langle W^2\phi\rangle_* W. \tag{8.1}$$

Then L_1 *has the following properties:*

(1) *The operator* L_1 *is self-adjoint.*
(2) *The function* W *is an eigenfunction of* L_1 *with eigenvalue* $-\sigma_0^{-2}\langle W^3\rangle_*$.
(3) *For each* $i=1,\dots,N$, W_{x_i} *is an eigenfunction of* L_1 *with eigenvalue zero.*
(4) *Assume that* $N\le 3$. *Then there exists a positive constant* $\nu_1\in(0,1]$ *such that*

$$\mathrm{L}_1(\phi,\phi)\overset{\text{def}}{=}\langle-|\nabla\phi|^2-\phi^2\rangle_*+2\sigma_0^{-1}\langle W\phi^2\rangle_*-2\sigma_0^{-2}\langle W\phi\rangle_*\langle W^2\phi\rangle_*\;\le\;-\nu_1\langle\phi^2\rangle_*$$

for all $\phi\in H^1(\mathbb{R}^N)$ *satisfying* $\phi\perp W_{x_1},\dots,W_{x_N}$.

Proof. The first three assertions follow by direct verification. To prove assertion (4), we need to consider only those ϕ which are orthogonal to $W, W_{x_1},\cdots,W_{x_N}$. We will argue by contradiction. Since the essential spectrum of L_1 lies in $(-\infty,-1]$, if assertion (4) is not true, then there exists (λ,ϕ) such that

(i) λ is real and nonnegative,
(ii) $\phi\perp W, W_{x_1},\dots,W_{x_N}$, and
(iii) $\mathrm{L}_1\phi=\lambda\phi$.

We will show that conditions (i)–(iii) cannot hold simultaneously.

From the definition of L_1 and conditions (ii) and (iii), we have

$$(\mathrm{L}_0-\lambda)\phi=\sigma_0^{-2}\langle W^2\phi\rangle_*W. \tag{8.2}$$

First we claim that $\lambda\ne\lambda_0$. In fact, if $\lambda=\lambda_0$, then $(\mathrm{L}_0-\lambda_0)\phi\perp\phi_0$ so that $\langle W^2\phi\rangle_*\langle W\phi_0\rangle_*=0$. Consequently, as $\phi_0>0$ and $W>0$, $\langle W^2\phi\rangle_*=0$, so that $(\mathrm{L}_0-\lambda_0)\phi=0$. Thus ϕ is a multiple of ϕ_0. But this contradicts $\langle W^2\phi\rangle_*=0$. Hence, $\lambda\ne\lambda_0$.

Restricted to the space orthogonal to $W_{x_1},\dots,W_{x_N}$, $\mathrm{L}_0-\lambda$ is invertible, so that (8.2) implies that

$$\phi=\alpha(\mathrm{L}_0-\lambda)^{-1}W,\qquad \alpha=\sigma_0^{-2}\langle W^2\phi\rangle_*.$$

Hence, $\alpha\ne0$. Taking the inner product with $\sigma_0^{-2}W^2/\alpha$, we obtain

$$\begin{aligned}1&=\sigma_0^{-2}(W^2,(\mathrm{L}_0-\lambda)^{-1}W)\\&=\sigma_0^{-1}(\mathrm{L}_0W,(\mathrm{L}_0-\lambda)^{-1}W)\qquad(\text{as }\mathrm{L}_0W=\sigma_0^{-1}W^2)\\&=\sigma_0^{-1}((\mathrm{L}_0-\lambda)W,(\mathrm{L}_0-\lambda)^{-1}W)+\sigma_0^{-1}\lambda(W,(\mathrm{L}_0-\lambda)^{-1}W)\\&=\sigma_0^{-1}\langle W^2\rangle+\sigma_0^{-1}\lambda(W,(\mathrm{L}_0-\lambda)^{-1}W)\\&=1+\sigma_0^{-1}\lambda(W,(\mathrm{L}_0-\lambda)^{-1}W).\end{aligned}$$

Consider the function $F(z)=(W,(\mathrm{L}_0-z)^{-1}W)$ for $z\in(0,\lambda_0)\cup(\lambda_0,\infty)$. We have

$$F'(z)=(W,(\mathrm{L}_0-z)^{-2}W)=((\mathrm{L}_0-z)^{-1}W,(\mathrm{L}_0-z)^{-1}W)>0.$$

Since $\mathrm{L}_0(W+\frac12x\cdot\nabla W)=W$, ${\mathrm{L}_0}^{-1}W=W+\frac12x\cdot\nabla W+\Sigma_{i=1}^Nc_iW_{x_i}$. It then follows that $F(0)=(W,W+\frac12x\cdot\nabla W)=(1-\frac N4)\langle W^2\rangle>0$ as $N\le3$. Thus, $F(z)>0$ for all $z\in(0,\lambda_0)$. As $F(\infty)=0$, we also have $F(z)<0$ for all $z\in(\lambda_0,\infty)$. Hence, we have $\lambda\notin(0,\infty)$.

Finally, we show that $\lambda\ne0$. In fact, if $\lambda=0$, then as $\phi\perp W_{x_i}$ for all i, $\phi=\alpha{\mathrm{L}_0}^{-1}W=\alpha(W+\frac12x\cdot\nabla W)$. But this implies that $(\phi,W)=\alpha(1-\frac12)\langle W^2\rangle_*>0$, contradicting the assumption $\phi\perp W$. This completes the proof of the lemma. □

Remark 8.1. If $N = 4$, one sees that $\phi = W + \frac{1}{2}x \cdot \nabla W$ is an eigenfunction of L_0 with eigenvalue zero.

Next, we extend Lemma 8.2 to large balls $B_R = \{x \mid |x| < R\}$.

LEMMA 8.3. *Assume $N \leq 3$. There exist positive constants R_0 and ν_2 such that for each $R > R_0$ and each $\phi \in H^1(B_R)$ satisfying $\phi \perp W_{x_i}$, $i = 1, \ldots, N$ in $L^2(B_R)$ there holds*

$$\begin{aligned}(8.3)\quad {\mathrm{L}_1}^R(\phi,\phi) &\overset{\text{def}}{=} \int_{B_R}(-|\nabla\phi|^2 - \phi^2 + 2{\sigma_0}^{-1}W\phi^2) - 2\sigma_0^{-2}\int_{B_R} W\phi \int_{B_R} W^2\phi \\ &\leq\ -\nu_2 \int_{B_R}(|\nabla\phi|^2 + \phi^2).\end{aligned}$$

Proof. We will argue by contradiction. Suppose the assertion is not true. Then there exists a sequence $\{R_k, \phi_k\}_{k=1}^{\infty}$ such that $R_k > k, \phi_k \in H^1(B_{R_k})$, $\phi_k \perp W_{x_i}$ in $L^2(B_{R_k})$ for all i, $\int_{B_{R_k}}(|\nabla\phi_k|^2 + \phi_k^2) = 1$, and

$$(8.4)\qquad \limsup_{k\to\infty} {\mathrm{L}_1}^{R_k}(\phi_k,\phi_k) \geq 0.$$

Since H^1 is weakly compact and the embedding $H^1 \to L^2$ is compact, we can assume, by taking a subsequence if necessary, that there exists $\phi \in H^1(\mathbb{R}^N)$ such that $\lim_{k\to\infty}\phi_k = \phi$, weakly in $H^1(B_R)$ and strongly in $L^2(B_R)$ for every $R > 0$. In addition, $\|\phi\|_{H^1(\mathbb{R}^N)} \leq 1$.

Since W decays exponentially fast, we have, $\langle\phi W_{x_i}\rangle_* = \lim_{k\to\infty}\int_{B_{R_k}} \phi_k W_{x_i} = 0$ for all $i = 1, \ldots, N$. In addition, as $k \to \infty$,

$$\begin{aligned}\gamma_k &\overset{\text{def}}{=} \int_{B_k} 2\sigma_0 {-} 1 W\phi_k - 2\sigma_0^{-2}\int_{B_{R_k}} W\phi_k \int_{B_{R_k}} W^2\phi_k \\ &\to \gamma \overset{\text{def}}{=} 2\sigma_0^{-1}\langle W\phi^2\rangle_* - 2\sigma_0^{-2}\langle W\phi\rangle_*\langle W^2\phi\rangle_*.\end{aligned}$$

If $\phi \equiv 0$, then $\gamma = 0$ so that

$${\mathrm{L}_1}^{R_k}(\phi_k,\phi_k) = \gamma_k - 1 < -1/2$$

for all large k. But this contradicts (8.4).

If $\phi \not\equiv 0$, then by Lemma 8.2, as $\phi \perp W_{x_j}$ for all j, $\mathrm{L}_1(\phi,\phi) \leq -\nu_1\langle\phi^2\rangle_*$. As $\phi \in H^1(R)$, there exists a large M such that $\|\phi\|^2_{H^1(\mathbb{R}^N\setminus B_M)} \leq \frac{1}{2}\nu_1\langle\phi^2\rangle_*$. Consequently,

$$\gamma - \int_{B_M}(|\nabla\phi|^2 + \phi^2)dx \leq -\frac{1}{2}\nu_1\langle\phi^2\rangle_*.$$

It then follows that

$$\limsup_{k\to\infty} {\mathrm{L}_1}^{R_k}(\phi_k,\phi_k) \leq \limsup_{k\to\infty}\left\{\gamma_k - \int_{B_M}(|\nabla\phi_k|^2 + \phi_k^2)\right\} \leq \gamma - \int_{B_M}(|\nabla\phi|^2 + \phi^2) < 0\ .$$

Again, we obtain a contradiction. The proof is now complete. □

Proof of Lemma 3.2. We will denote

$$\langle f\rangle_\varepsilon = \int_{\Omega_\varepsilon} f, \qquad \Omega_\varepsilon = \frac{1}{\varepsilon}\Omega.$$

We also set

$$\mathcal{L}^{\xi,\varepsilon}(\phi,\psi) \overset{\text{def}}{=} \langle -\nabla\phi\cdot\nabla\psi - \phi\psi + 2\sigma^{-1}w\phi\psi\rangle_\varepsilon - 2\sigma^{-2}\langle w\phi\rangle_\varepsilon\langle w^2\psi\rangle_\varepsilon.$$

We will show that there exists a positive constant ν which is independent of ε such that for every sufficiently small positive ε,

$$\mathcal{L}^{\xi,\varepsilon}(\phi,\phi) \le -\nu\langle|\nabla\phi|^2+\phi^2\rangle_\varepsilon \quad \forall\,\phi, \langle\phi, w_{\xi_i}(\cdot,\xi)\rangle_\varepsilon = 0, \tag{8.5}$$

which is equivalent to the spectral estimate in Lemma 3.2. By scaling, we can assume that $\langle\phi^2+|\nabla\phi|^2\rangle_\varepsilon = 1$. Set $\mathrm{d}_\varepsilon(\xi) = \frac{\mathrm{dist}(\xi)}{\varepsilon}$ and $R = \mathrm{d}_\varepsilon(\xi)$. (Note that $R \ge 2|\ln(D\varepsilon^{-2})| \ge R_0$ if ε is sufficiently small.) Translating Ω_ε if necessary, we can always achieve $\xi = 0$.

Let ${\mathrm{L}_1}^R(\phi,\phi)$ be defined as in (8.4). As $|w-W|_{L^\infty} + |\sigma-\sigma_0| = O(\varepsilon)$ and $|W| = O(\varepsilon)$ outside B_R, we have

$$\mathcal{L}^{\xi,\varepsilon}(\phi,\phi) = L^R(\phi,\phi) - \int_{\Omega_\varepsilon\setminus B_R}(|\nabla\phi|^2+\phi^2) + O(\varepsilon). \tag{8.6}$$

Now let $\phi^R = \phi - \sum_{i=1}^N c_iW_{x_i}$ be the $L^2(B_R)$ orthogonal projection of ϕ on $\{W_{x_1},\dots,W_{x_N}\}^\perp$. Then, $0 = \langle\phi W_{x_i}\rangle_\varepsilon = \int_{B_R}\phi W_{x_i} + O(\varepsilon)$, so that $c_i = O(\varepsilon)$ for all i. Hence, $\|\phi-\phi^R\|_{H^1(B_R)} = O(\varepsilon)$ and

$${\mathrm{L}_1}^R(\phi,\phi) = {\mathrm{L}_1}^R(\phi^R,\phi^R) + O(\varepsilon). \tag{8.7}$$

From Lemma 8.2 we have

$${\mathrm{L}_1}^R(\phi^R,\phi^R) \le -\nu_1\int_{B_R}\Big(|\nabla\phi^R|^2 + (\phi^R)^2\Big) = -\nu_1\int_{B_R}(|\nabla\phi|^2+\phi^2) + O(\varepsilon)\ .$$

Combining this with (8.6) and (8.7) then gives

$$\begin{aligned}\mathcal{L}^{\xi,\varepsilon}(\phi,\phi) &\le -\int_{\Omega_\varepsilon\setminus B_R}(|\nabla\phi|^2+\phi^2) - \nu_1\int_{B_R}(|\nabla\phi|^2+\phi^2) + O(\varepsilon)\\ &\le -\nu_1\langle\phi^2+|\nabla\phi|^2\rangle_\varepsilon + O(\varepsilon).\end{aligned} \tag{8.8}$$

Taking ε sufficiently small, we then obtain the assertion of the lemma. □

BIORTHOGONAL WAVELET SPACE: PARAMETRIZATION AND FACTORIZATION[*]

HOWARD L. RESNIKOFF[†], JUN TIAN[‡¶], AND RAYMOND O. WELLS, JR.[§¶]

Abstract. In this paper we study the algebraic and geometric structure of the space of compactly supported biorthogonal wavelets. We prove that any biorthogonal wavelet matrix pair (which consists of the scaling filters and wavelet filters) can be factored as the product of primitive paraunitary matrices, a pseudo identity matrix pair, an invertible matrix, and the canonical Haar matrix. Compared with the factorization results of orthogonal wavelets, it now becomes apparent that the difference between orthogonal and biorthogonal wavelets lies in the pseudo identity matrix pair and the invertible matrix, which in the orthogonal setting will be the identity matrix and a unitary matrix. Thus by setting the pseudo identity matrix pair to be the identity matrix and using the Schmidt orthogonalization method on the invertible matrix, it is very straightforward to convert a biorthogonal wavelet pair into an orthogonal wavelet.

Key words. biorthogonal wavelets, parametrization, Pollen product, vanishing moment

1. Introduction.

The theory of wavelet analysis has grown explosively in the last fifteen years. The terminology "wavelet" was first introduced, in the context of a mathematical transform, in 1984 by Grossmann and Morlet [12]. In 1988, Daubechies [9] introduced a class of compactly supported orthogonal wavelets with growing smoothness for increasing support. Mallat [22] and Meyer [23] presented the theory of multiresolution analysis. The spline family was first studied by Battle [1], Chui [5], and Lemarié [21]. The necessary and sufficient conditions for orthonormal wavelet bases were given by Cohen [7] and Lawton [20]. Except for the *Haar wavelet*, compactly supported orthogonal wavelets can not be symmetric, though symmetry is highly desired, for example, in the applications in signal processing, where symmetry corresponds to linear phase. To obtain symmetry and keep the property of perfect reconstruction, the orthogonal condition was replaced by biorthogonality and the theory of biorthogonal wavelets [6, 8, 30] was established. (One of the earliest examples of a nonorthogonal biorthogonal representation is in Paley and Wiener's book on the Fourier transform in the complex domain [24].) At the same time, pioneer work has been done by many scientists from mathematics, physics, and engineering. For more details of wavelet theory, we refer to [3, 4, 10, 14, 23, 26, 27, 31, 32].

In this paper we will study the algebraic and geometric structure of the space of compactly supported biorthogonal wavelets. We will prove that any biorthogonal wavelet matrix pair can be decomposed into four components: an orthogonal component $V(z)$, a pseudo identity matrix pair, an invertible matrix G, and a constant matrix $\mathbf{H}$. There have been several factorization results for biorthogonal wavelets

reported in [2, 11, 14, 19], etc. Our contribution in this paper is that we require a zeroth order vanishing moment condition (2.3) on the wavelet matrix. This vanishing moment condition is necessary, because it is required for the existence of scaling functions and wavelet functions. So we are placing emphasis on the wavelet factorization instead of perfect reconstruction filter banks. This paper is also partly motivated by the problem of finding nontrivial mappings between orthogonal and biorthogonal wavelets. To achieve this goal, we arrange our factorization formula so that it is closely connected with the factorization formula for orthogonal wavelets, which is another difference between our factorization and those in [2, 11, 14, 19].

The paper is organized as follows. In section 2 we give a brief review of some definitions and properties of biorthogonal and orthogonal wavelets. The parametrization of biorthogonal wavelets is presented in section 3. We will define a group structure on biorthogonal wavelets under the Pollen product. Because of its special role in the biorthogonal factorization, the pseudo identity matrix pair will be studied in section 4. We propose a sufficient condition on the pseudo identity matrix pair such that it can be factored as the product of primitive pseudo identity matrices. We discuss conversion between orthogonal and biorthogonal wavelets in section 5, and a simple example is given in section 6. We conclude the paper in section 7.

Note that in this paper we will assume entries in wavelet matrices are real-valued. The generalization to a subfield F of complex numbers $\mathbf{C}$ *closed under complex conjugation* is straightforward. Some examples of F will be the rational numbers $\mathbf{Q}$, the real numbers $\mathbf{R}$, the Gaussian rational numbers $\mathbf{Q}(i) := \mathbf{Q} + i\mathbf{Q}$, and the complex numbers $\mathbf{C}$ itself.

2. Preliminaries. For a matrix $A = (a_{i,j})$ consisting of m rows of vectors with only a finite number of entries $a_{i,j}$ being nonzero, define submatrices A_k of size $m \times m$ of A in the following manner:

$$A_k = (a_{i,km+j}), \quad 0 \le i \le m-1, 0 \le j \le m-1.$$

In other words, A is expressed in terms of block matrices in the form

$$A = (\ldots, A_{-1}, A_0, A_1, \ldots),$$

where, for instance,

$$A_0 = \begin{pmatrix} a_{0,0} & a_{0,1} & \cdots & a_{0,m-1} \\ \vdots & & & \vdots \\ a_{m-1,0} & a_{m-1,1} & \cdots & a_{m-1,m-1} \end{pmatrix}.$$

From the matrix A, we construct the formal power series

$$A(z) := \sum_{k \in \mathbf{Z}} A_k z^{-k} = \sum_{k=k_0}^{k_1} A_k z^{-k}, \tag{2.1}$$

where k_0 and k_1 are the smallest and largest indices that $A_k \ne 0$, respectively. We call $A(z)$ the *Laurent series* of the matrix A and k_0 the *leading index*. We can equally well write $A(z)$ as an $m \times m$ matrix

$$A(z) = \begin{pmatrix} \sum_k a_{0,km} z^{-k} & \cdots & \sum_k a_{0,km+m-1} z^{-k} \\ \vdots & & \vdots \\ \cdots & \sum_k a_{i,km+j} z^{-k} & \cdots \\ \vdots & & \vdots \\ \sum_k a_{m-1,km} z^{-k} & \cdots & \sum_k a_{m-1,km+m-1} z^{-k} \end{pmatrix},$$

which we will refer to as the *polyphase decomposition* of A. For the case of $m = 2$, we find

$$A(z) = \begin{pmatrix} \cdots a_{0,-2} z + a_{0,0} + a_{0,2} z^{-1} \cdots, & \cdots a_{0,-1} z + a_{0,1} + a_{0,3} z^{-1} \cdots \\ \cdots a_{1,-2} z + a_{1,0} + a_{1,2} z^{-1} \cdots, & \cdots a_{1,-1} z + a_{1,1} + a_{1,3} z^{-1} \cdots \end{pmatrix}.$$

Let

$$g := k_1 - k_0 + 1$$

be the number of nonzero terms in the summation (2.1) and call g the *genus* of the Laurent series $A(z)$ and the matrix A. Thus A has a size of $m \times mg$. Finally we define the *adjoint* $\tilde{A}(z)$ of the Laurent series $A(z)$ by

$$\tilde{A}(z) := A^*(z^{-1}) := \sum_{k=k_0}^{k_0+g-1} A_k^* z^k = \sum_{k=-k_0-g+1}^{-k_0} A_{-k}^* z^{-k},$$

where $A_k^* := \overline{A_k^t}$ is the Hermitian adjoint of the $m \times m$ matrix A_k. When A_k is a real matrix, $A_k^* = A_k^t$.

DEFINITION 2.1. *A pair of $m \times mg$ matrices $L = (l_{i,j}), R = (r_{i,j})$ is said to be a* biorthogonal wavelet matrix pair *of rank m and genus g if their polyphase decompositions $L(z)$ and $R(z)$ satisfy*

$$L(z)\tilde{R}(z) = mI_m \tag{2.2}$$

and

$$\sum_j l_{i,j} = \sum_j r_{i,j} = \begin{cases} m & \text{if } i = 0, \\ 0 & \text{if } 1 \le i \le m-1, \end{cases} \tag{2.3}$$

where I_m is the $m \times m$ identity matrix.

We call L the *analysis matrix* and R the *synthesis matrix* of the biorthogonal wavelet matrix pair. We will refer to (2.2) and (2.3) as the *perfect reconstruction* and *linear* conditions defining a biorthogonal wavelet matrix pair, respectively. The perfect reconstruction condition (2.2) is equivalent to saying that $L(z), R(z)$ are invertible polynomials in $\mathrm{SL}(m; \mathbf{R}[z, z^{-1}])$ (a proof can be found in [11]), that is,

$$\det(L(z)) = c_l z^{-b}, \quad \det(R(z)) = c_r z^{-b}, \quad \text{with } c_l c_r = m \tag{2.4}$$

for some integer b. Note that in the theory of wavelet analysis, we will systematically employ the linear constraint (2.3) in addition to the perfect reconstruction condition (2.2). Actually (2.3) (which is exactly the zeroth order vanishing moment condition of scaling functions and wavelet functions) is a necessary condition for the existence of scaling functions and wavelet functions. This is one of the main differences between wavelets and perfect reconstruction filter banks.

For a biorthogonal wavelet matrix pair (L, R), suppose that $\phi(x)$ and $\tilde{\phi}(x)$ are L^2 solutions of the refinement equations

$$\phi(x) = \sum_k l_{0,k}\phi(mx-k), \quad \tilde{\phi}(x) = \sum_k r_{0,k}\tilde{\phi}(mx-k),$$

and define $\psi^1(x), \dots, \psi^{m-1}(x), \tilde{\psi}^1(x), \dots, \tilde{\psi}^{m-1}(x)$ by

$$\psi^i(x) := \sum_k r_{i,k}\phi(mx-k), \quad \tilde{\psi}^i(x) := \sum_k l_{i,k}\tilde{\phi}(mx-k), \quad i = 1, \dots, m-1,$$

then $\psi^1_{j,k}, \dots, \psi^{m-1}_{j,k}, \tilde{\psi}^1_{j,k}, \dots, \tilde{\psi}^{m-1}_{j,k}$ constitute a weak dual frame of $L^2(\mathbf{R})$, that is, for any $f(x), g(x) \in L^2(\mathbf{R})$,

$$\lim_{J\to\infty} \sum_{i=1}^{m-1} \sum_{j=-J}^{J} \sum_{k=-\infty}^{\infty} \langle f, \psi^i_{j,k}\rangle \langle \tilde{\psi}^i_{j,k}, g\rangle = \langle f, g\rangle,$$

where

$$\psi^i_{j,k}(x) := m^{j/2}\psi^i(m^j x - k), \quad \tilde{\psi}^i_{j,k}(x) := m^{j/2}\tilde{\psi}^i(m^j x - k).$$

We call $\phi(x), \psi^1(x), \dots, \psi^{m-1}(x), \tilde{\phi}(x), \tilde{\psi}^1(x), \dots, \tilde{\psi}^{m-1}(x)$ the *analysis scaling function*, *analysis wavelet functions*, *synthesis scaling function*, and *synthesis wavelet functions*, respectively. With some additional conditions [6, 8, 20, 30], one can derive a (strong) dual frame and even dual Riesz bases of $L^2(\mathbf{R})$.

A special and also widely used subset of biorthogonal wavelets are the orthogonal wavelets.

DEFINITION 2.2. *An $m \times mg$ matrix A is said to be an* orthogonal wavelet matrix *of rank m and genus g if (A, A) is a biorthogonal wavelet matrix pair.*

Similarly, starting from an orthogonal wavelet matrix A, one can define the *scaling function* $\phi(x)$ and the *wavelet functions* $\psi^1(x), \dots, \psi^{m-1}(x)$ and their rescaled and translated version $\psi^i_{j,k}$. In this setting, the wavelet functions $\psi^1(x), \dots, \psi^{m-1}(x)$ will generate a tight frame, that is, for any $f(x) \in L^2(\mathbf{R})$,

$$f(x) = \sum_{i=1}^{m-1} \sum_{j=-\infty}^{\infty} \sum_{k=-\infty}^{\infty} (d_i)_{j,k}\psi^i_{j,k}(x),$$

where the coefficients are given by

$$(d_i)_{j,k} = \int_{\mathbf{R}} f(x)\psi^i_{j,k}(x)\,dx.$$

With an additional Cohen condition [7] or equivalent Lawton condition [20], $\psi^i_{j,k}(x)$ constitute an orthonormal basis of $L^2(\mathbf{R})$.

3. Parametrization of biorthogonal wavelets. In this section we formulate the parametrization of the space of compactly supported biorthogonal wavelets. Borrowing the eigenfilter approach from [29], the following lemma will be derived.

LEMMA 3.1. *If (L, R) is a biorthogonal wavelet matrix pair of rank m and genus g, then there exist unit column vectors $v_1, v_2, \ldots, v_d$ such that*

$$L(z) = z^{-k_0} V_1(z) V_2(z) \cdots V_d(z) C(z) L(1), \tag{3.1}$$

$$R(z) = z^{-k_0} V_1(z) V_2(z) \cdots V_d(z) D(z) R(1), \tag{3.2}$$

where k_0 is the leading index of L, $d = b - mk_0$, where b is the integer appearing in (2.4)*, and*

$$V_i(z) = I_m - v_i v_i^* + v_i v_i^* z^{-1}, \quad i = 1, 2, \ldots, d,$$

$$C(z) = \sum_{k=0}^{k_c} C_k z^{-k}, \quad D(z) = \sum_{k=k_d}^{0} D_k z^{-k},$$

with $k_c \leq g - 1$, and

$$C(z)\tilde{D}(z) = I_m, \quad \det(C(z)) = \det(D(z)) = 1, \quad C(1) = D(1) = I_m.$$

Let v be a unit column vector, that is, $v^* v = 1$. Define the Laurent matrix

$$V(z) := I - vv^* + vv^* z^{-1}, \tag{3.3}$$

and let V be the corresponding $m \times 2m$ matrix. We will say that a matrix V of the form (3.3) is a *primitive paraunitary matrix*. It is easy to verify (see [29]) that

$$V(z)\tilde{V}(z) = I_m, \quad \det(V(z)) = z^{-1}.$$

Proof of Lemma 3.1. Without loss of generality, assume $k_0 = 0$ (and so $b = d$), and

$$L(z) = \sum_{k=0}^{g-1} L_k z^{-k}, \quad R(z) = \sum_{k=k_r}^{k_r+g-1} R_k z^{-k}.$$

Now

$$L(z)\tilde{R}(z) = \left(\sum_{k=0}^{g-1} L_k z^{-k}\right)\left(\sum_{k=k_r}^{k_r+g-1} R_k^* z^k\right) = \left(\sum_{k=0}^{g-1} L_k z^{-k}\right)\left(\sum_{k=-k_r-g+1}^{-k_r} R_{-k}^* z^{-k}\right)$$
$$= L_0 R_{k_r+g-1}^* z^{k_r+g-1} + \cdots + L_{g-1} R_{k_r}^* z^{k_r-g+1} = mI_m.$$

From (2.4)

$$\det(L(z)) = c_l z^{-d}, \quad \det(R(z)) = c_r z^{-d}, \quad \text{with } c_l c_r = m$$

for some integer $d \geq 0$.

If $d > 0$, then $k_r + g - 1$ must be positive (otherwise $\det(R(z)) \neq c_r z^{-d}$). It follows that

$$L_0 R_{k_r+g-1}^* = 0.$$

So L_0 must be a singular matrix (if $R^*_{k_r+g-1} = 0$, then $L_0 R^*_{k_r+g-2} = 0$). Then choose a vector v_1 of unit length such that

$$v_1{}^* L_0 = 0,$$

and define

$$V_1(z) = I_m - v_1 v_1{}^* + v_1 v_1{}^* z^{-1},$$

as a primitive paraunitary matrix. Note that

$$\tilde{V}_1(z) = I_m - v_1 v_1{}^* + v_1 v_1{}^* z.$$

Define

$$L^1(z) = \tilde{V}_1(z) L(z), \quad R^1(z) = \tilde{V}_1(z) R(z).$$

It follows that (L^1, R^1) is a biorthogonal wavelet matrix pair of rank m and

$$L(z) = V_1(z) L^1(z), \quad R(z) = V_1(z) R^1(z). \tag{3.4}$$

Notice that

$$\begin{aligned} L^1(z) &= (I_m - v_1 v_1{}^* + v_1 v_1{}^* z) \left(\sum_{k=0}^{g-1} L_k z^{-k} \right) \\ &= \left(v_1 v_1{}^* L_1 + (I_m - v_1 v_1{}^*) L_0\right) + \cdots + (I_m - v_1 v_1{}^*) L_{g-1} z^{-g+1} = \sum_{k=0}^{l^1} L^1_k z^{-k}, \end{aligned}$$

where $l^1 \le g-1$. Take the determinant on both sides of (3.4)

$$c_l z^{-d} = z^{-1} \det(L^1(z)), \quad c_r z^{-d} = z^{-1} \det(R^1(z)),$$

which implies that

$$\det(L^1(z)) = c_l z^{-d+1}, \quad \det(R^1(z)) = c_r z^{-d+1}.$$

Thus the degree of the determinant $\det(L^1(z))$ is increased by 1, compared with $\det(L(z))$. Proceeding in this fashion, we obtain

$$L(z) = V_1(z) V_2(z) \cdots V_d(z) L^d(z), \quad R(z) = V_1(z) V_2(z) \cdots V_d(z) R^d(z), \tag{3.5}$$

where $\det(L^d(z)) = c_l, \det(R^d(z)) = c_r$, and

$$L^d(z) = \sum_{k=0}^{l^d} L^d_k z^{-k}, \quad R^d(z) = \sum_{k=k_1}^{k_2} R^d_k z^{-k},$$

with $l^d \le l^{d-1} \le \cdots \le l^1 \le g-1$. We claim that $k_2 = 0$. If not, then k_2 must be positive (since $\det(R^d(z)) = c_r$). Apply the factorization one more time to obtain $L^d(z) = V_{d+1}(z) L^{d+1}(z)$, where $\det(L^{d+1}(z)) = c_l z$ which is impossible, since $L^{d+1}(z)$ is the summation of nonpositive powers of z.

Because $L(1)\tilde{R}(1) = mI_m$, $L(1), R(1)$ are invertible matrices. Now set

$$L^d(z) = C(z) L(1), \quad R^d(z) = D(z) R(1), \tag{3.6}$$

with

$$C(z) = \sum_{k=0}^{k_c} C_k z^{-k}, \quad D(z) = \sum_{k=k_d}^{0} D_k z^{-k},$$

where $k_c = l^d, C_k = L^d_k(L(1))^{-1}, k_d = k_1, D_k = R^d_k(R(1))^{-1}$. Since $V_i(1) = I_m, i = 1, \ldots, d$, we have $\det(C(z)) = \det(D(z)) = 1$. Combining (3.5) and (3.6), the lemma follows. ◻

Remark 1. It is possible to have $d = 0$ and $C(z) \neq I_m$, that is, a biorthogonal wavelet matrix pair with no primitive paraunitary matrices in the factorization. A simple example is

$$L(z) = \begin{pmatrix} 2 - z^{-1} & z^{-1} \\ -1 & 1 \end{pmatrix}, \quad R(z) = \begin{pmatrix} 1 & 1 \\ -z & -z+2 \end{pmatrix}. \tag{3.7}$$

Next we will study the structure of the matrix pair $(L(1), R(1))$ appearing in the factorization of Lemma 3.1. For this purpose, we define a *biorthogonal Haar wavelet matrix pair* (H_L, H_R) to be a biorthogonal wavelet matrix pair with genus g equal to 1. Thus in the polyphase decomposition there is exactly only one term in the summations, that is,

$$H_L(z) = z^{-k_L} \begin{pmatrix} l_{0,0} & \cdots & l_{0,m-1} \\ \vdots & & \vdots \\ \cdots & l_{i,j} & \cdots \\ \vdots & & \vdots \\ l_{m-1,0} & \cdots & l_{m-1,m-1} \end{pmatrix}$$

and

$$H_R(z) = z^{-k_R} \begin{pmatrix} r_{0,0} & \cdots & r_{0,m-1} \\ \vdots & & \vdots \\ \cdots & r_{i,j} & \cdots \\ \vdots & & \vdots \\ r_{m-1,0} & \cdots & r_{m-1,m-1} \end{pmatrix},$$

where $k_L, k_R \in \mathbf{Z}$. It is easy to verify that $k_L = k_R$. And without loss of generality, we will always assume $k_L = k_R = 0$ for a biorthogonal Haar wavelet matrix pair (H_L, H_R), since a multiplication with z^{-k} is just a shift of index j in $l_{i,j}$ and $r_{i,j}$.

Let us now provide a characterization of biorthogonal Haar wavelet matrix pairs. Recall that the general linear group GL_{m-1} is the group of $(m-1) \times (m-1)$ matrices G such that G is invertible.

Theorem 3.2. *Two $m \times m$ matrices H_L, H_R constitute a biorthogonal Haar wavelet matrix pair if and only if*

$$H_L = \begin{pmatrix} 1 & 0 \\ 0 & G \end{pmatrix} \mathbf{H}, \quad H_R = \begin{pmatrix} 1 & 0 \\ 0 & (G^{-1})^* \end{pmatrix} \mathbf{H},$$

where $G \in \mathrm{GL}_{m-1}$ is an invertible matrix, and $\mathbf{H}$ is the canonical Haar matrix *of* *rank m, which is defined by*

$$\mathbf{H} := \begin{pmatrix} 1 & 1 & \cdots & \cdots & \cdots & \cdots & 1 \\ -\sqrt{m-1} & \sqrt{\frac{1}{m-1}} & \cdots & \cdots & \cdots & \cdots & \sqrt{\frac{1}{m-1}} \\ \vdots & \ddots & \ddots & \cdots & \cdots & \cdots & \vdots \\ 0 & 0 & \cdots & -\sqrt{\frac{im}{i+1}} & \sqrt{\frac{m}{i^2+i}} & \cdots & \sqrt{\frac{m}{i^2+i}} \\ \vdots & \cdots & \cdots & \cdots & \ddots & \ddots & \vdots \\ 0 & \cdots & \cdots & \cdots & 0 & -\sqrt{\frac{m}{2}} & \sqrt{\frac{m}{2}} \end{pmatrix},$$

where $i = m-1, \dots, 2, 1$.

Proof. First, assume H_L and H_R are of the form

$$H_L = \begin{pmatrix} 1 & 0 \\ 0 & G \end{pmatrix} \mathbf{H}, \quad H_R = \begin{pmatrix} 1 & 0 \\ 0 & (G^{-1})^* \end{pmatrix} \mathbf{H}.$$

By the definition of the canonical Haar matrix $\mathbf{H}$, we have

$$\mathbf{H}\tilde{\mathbf{H}} = mI_m, \quad \mathbf{H} \begin{pmatrix} 1 \\ 1 \\ \vdots \\ 1 \end{pmatrix} = \begin{pmatrix} m \\ 0 \\ \vdots \\ 0 \end{pmatrix}.$$

Now it is easy to check that H_L and H_R will satisfy (2.2) and (2.3). Thus H_L and H_R is a biorthogonal Haar wavelet matrix pair.

Conversely, if (H_L, H_R) is a biorthogonal Haar wavelet matrix pair, define

$$L = \frac{1}{m} H_L \tilde{\mathbf{H}}, \quad R = \frac{1}{m} H_R \tilde{\mathbf{H}},$$

then

$$H_L = L\mathbf{H}, \quad H_R = R\mathbf{H}.$$

From the linear constraint (2.3)

$$\begin{pmatrix} m \\ 0 \\ \vdots \\ 0 \end{pmatrix} = H_L \begin{pmatrix} 1 \\ 1 \\ \vdots \\ 1 \end{pmatrix} = L\mathbf{H} \begin{pmatrix} 1 \\ 1 \\ \vdots \\ 1 \end{pmatrix} = L \begin{pmatrix} m \\ 0 \\ \vdots \\ 0 \end{pmatrix},$$

then L should be of the form

$$L = \begin{pmatrix} 1 & \alpha \\ 0 & G_1 \end{pmatrix},$$

where α is an $(m-1)$ dimensional row vector and G_1 is an $(m-1) \times (m-1)$ matrix. Similarly

$$R = \begin{pmatrix} 1 & \beta \\ 0 & G_2 \end{pmatrix}$$

for an $(m-1)$ dimensional row vector β and an $(m-1)\times(m-1)$ matrix G_2. Since

$$mI_m = H_L\tilde{H}_R = L\mathbf{H}\tilde{\mathbf{H}}\tilde{R} = mL\tilde{R},$$

it follows that

$$L\tilde{R} = I_m,$$

that is,

$$\begin{pmatrix} 1 & \alpha \\ 0 & G_1 \end{pmatrix}\begin{pmatrix} 1 & 0 \\ \beta^* & {G_2}^* \end{pmatrix} = I_m.$$

Thus

$$G_2 = ({G_1}^{-1})^*, \quad \alpha = \beta = 0. \qquad \square$$

Let (L, R) be a biorthogonal wavelet matrix pair of rank m and let $L(z), R(z)$ be their Laurent series. Define the *characteristic Haar matrix pair* $(\chi(L), \chi(R))$ of (L, R) by

$$\chi(L) := L(1), \quad \chi(R) := R(1).$$

We now have the following theorem which relates biorthogonal wavelet matrix pairs to biorthogonal Haar wavelet matrix pairs.

THEOREM 3.3. *If (L, R) is a biorthogonal wavelet matrix pair of rank m, then $(\chi(L), \chi(R))$ is a biorthogonal Haar wavelet matrix pair of rank m. Thus χ is a well defined mapping from biorthogonal wavelet matrix pairs of rank m to biorthogonal Haar wavelet matrix pairs of rank m.*

Proof. Evaluate (2.2) and (2.3) at $z = 1$; thus it follows that $(\chi(L), \chi(R))$ is a biorthogonal wavelet matrix pair of rank m and genus 1. $\square$

With Lemma 3.1, Theorem 3.2, and Theorem 3.3, we now have a complete characterization of biorthogonal wavelet matrix pairs.

THEOREM 3.4 (biorthogonal factorization theorem). *A pair of $m \times mg$ matrices (L, R) is a biorthogonal wavelet matrix pair of rank m if and only if there exist primitive paraunitary matrices $V_1, \dots, V_d$, $d \geq 0$, such that*

$$L(z) = z^{-k_0}V_1(z)V_2(z)\cdots V_d(z)C(z)\begin{pmatrix} 1 & 0 \\ 0 & G \end{pmatrix}\mathbf{H},$$

$$R(z) = z^{-k_0}V_1(z)V_2(z)\cdots V_d(z)D(z)\begin{pmatrix} 1 & 0 \\ 0 & (G^{-1})^* \end{pmatrix}\mathbf{H},$$

where $k_0 \in \mathbf{Z}$, $d = b - mk_0$, b is the exponent of $\det(L(z))$, *$G \in \mathrm{GL}_{m-1}$ is an invertible matrix, $\mathbf{H}$ is the canonical Haar matrix of rank m, and*

$$C(z) = \sum_{k=0}^{k_c} C_k z^{-k}, \quad D(z) = \sum_{k=k_d}^{0} D_k z^{-k},$$

with $k_c \leq g-1$, and

$$C(z)\tilde{D}(z) = I_m, \quad C(1) = D(1) = I_m.$$

Proof. It is straightforward to verify that a pair of (L, R) with the above form of factorization is indeed a biorthogonal wavelet matrix pair.

For the converse part, the proof comes from Lemma 3.1, Theorem 3.2, and Theorem 3.3. □

Remark 2. Note that in the above theorem, d can be 0, i.e., there are no $V_i(z)$ factors. Such a biorthogonal wavelet matrix pair is given in (3.7).

For two biorthogonal wavelet matrix pairs of rank m, (L^1, R^1) and (L^2, R^2), that have the same characteristic Haar matrix pair, we define the *Pollen product* by the formula

$$L^1 \diamond_{H_L} L^2 := L, \quad R^1 \diamond_{H_R} R^2 := R$$

if their Laurent series satisfy

$$L(z) = L^1(z) H_L^{-1} L^2(z), \quad R(z) = R^1(z) H_R^{-1} R^2(z),$$

where

$$H_L = \chi(L^1) = \chi(L^2), \quad H_R = \chi(R^1) = \chi(R^2).$$

The characteristic Haar matrix pair of (L, R) is also (H_L, H_R). The set of biorthogonal wavelet matrix pairs of the same characteristic Haar matrix pair is a group under this product.

THEOREM 3.5. *Given a biorthogonal Haar wavelet matrix pair (H_L, H_R), let* $\mathrm{WM}(H_L, H_R)$ *be the collection of biorthogonal wavelet matrix pairs whose characteristic Haar matrix pair is (H_L, H_R). Then* $\mathrm{WM}(H_L, H_R)$ *is a group with the noncommutative product*

$$((L^1, R^1), (L^2, R^2)) \longmapsto \left(L^1 \diamond_{H_L} L^2, R^1 \diamond_{H_R} R^2\right)$$

and the unit element is (H_L, H_R).

The proof of this theorem is elementary and is omitted.

With the Pollen product, we can rephrase Theorem 3.4 into a factorization inside the group $\mathrm{WM}(H_L, H_R)$.

THEOREM 3.6. *For a biorthogonal wavelet matrix pair (L, R) of rank m and genus g, there exist biorthogonal wavelet matrix pairs $(L^1, R^1), \ldots, (L^d, R^d)$, and (C^1, D^1) such that*

$$L = z^{-k_0} L^1 \diamond_{H_L} L^2 \diamond_{H_L} \cdots \diamond_{H_L} L^d \diamond_{H_L} C^1, \quad R = z^{-k_0} R^1 \diamond_{H_R} R^2 \diamond_{H_R} \cdots \diamond_{H_R} R^d \diamond_{H_R} D^1,$$

where $k_0 \in \mathbf{Z}$, $H_L = \chi(L), H_R = \chi(R)$, and

$$L^i(z) = V_i(z) H_L = (I_m - v_i {v_i}^* + v_i {v_i}^* z^{-1}) H_L,$$

$$R^i(z) = V_i(z) H_R = (I_m - v_i {v_i}^* + v_i {v_i}^* z^{-1}) H_R,$$

with unit column vectors $v_1, \ldots, v_d$, $i = 1, \ldots, d$, and

$$C^1(z) = \sum_{k=0}^{k_c} C_k^1 z^{-k}, \quad D^1(z) = \sum_{k=k_d}^{0} D_k^1 z^{-k},$$

with $k_c \leq g - 1$, and

$$C^1(z) \tilde{D^1}(z) = m I_m.$$

4. The pseudo identity matrix pair. In the factorization process in the previous section, a biorthogonal wavelet matrix pair is reduced to a matrix pair $(C(z), D(z))$ with the following four properties:

1. $C(z) = \sum_{k=0}^{k_c} C_k z^{-k}, D(z) = \sum_{k=k_d}^{0} D_k z^{-k}$,
2. $C(z)\tilde{D}(z) = I_m$,
3. $\det(C(z)) = \det(D(z)) = 1$,
4. $C(1) = D(1) = I_m$.

The above four properties are redundant. With a $C(z)$ satisfying properties 1 and 3, there always exists a $D(z)$ satisfying properties 1, 2, and 3. With property 2, all other three properties of $D(z)$ can be derived from those of $C(z)$. With properties 1 and 2, property 3 can be derived from property 4. Actually, properties 3 and 4 are just normalization conditions. In the rest of this section, we will concentrate on properties 1 and 2.

In an orthogonal setting (i.e., $C = D$), one can prove that $C(z)$ and $D(z)$ must be equal to the identity matrix I_m. However, in a biorthogonal setting, there exist nontrivial pairs of $(C(z), D(z))$ satisfying all four properties. Here is an example:

$$C(z) = \begin{pmatrix} -1 & 1 \\ -4 & 3 \end{pmatrix} + \begin{pmatrix} 2 & -1 \\ 4 & -2 \end{pmatrix} z^{-1}, \quad D(z) = \begin{pmatrix} -2 & -4 \\ 1 & 2 \end{pmatrix} z + \begin{pmatrix} 3 & 4 \\ -1 & -1 \end{pmatrix}.$$

For convenience, we will call $(C(z), D(z))$ a pseudo identity matrix pair.

Definition 4.1. *A matrix pair* $(C(z), D(z))$ *is a* pseudo identity matrix pair *if*

$$C(z) = \sum_{k=0}^{k_c} C_k z^{-k}, \quad D(z) = \sum_{k=k_d}^{0} D_k z^{-k}, \quad C(z)\tilde{D}(z) = I_m, \quad C(1) = D(1) = I_m.$$

In this section, we will study the structure of the pseudo identity matrix pair. When the size is of $m \times 2m$ (which is the minimal length for a nontrivial pair), we have the following lemma.

Lemma 4.2. *If two* $m \times 2m$ *matrices* C *and* D *satisfy*

$$C(z) = C_0 + C_1 z^{-1}, \quad D(z) = D_{-1} z + D_0, \quad C(z)\tilde{D}(z) = I_m, \quad C(1) = D(1) = I_m,$$

then there exists an $m \times m$ *nilpotent matrix* N, $N^2 = 0$, *such that*

$$C(z) = I_m - N + N z^{-1}, \quad D(z) = -N^* z + I_m + N^*.$$

Proof. Since $C(1) = D(1) = I_m$, we have

$$C_0 = I_m - C_1, \quad D_0 = I_m - D_{-1}.$$

Now

$$\begin{aligned} C(z)\tilde{D}(z) &= \left(I_m - C_1 + C_1 z^{-1}\right)\left(I_m - D_{-1}^* + D_{-1}^* z^{-1}\right) \\ &= I_m - C_1 - D_{-1}^* + C_1 D_{-1}^* + \left(D_{-1}^* + C_1 - 2C_1 D_{-1}^*\right) z^{-1} + C_1 D_{-1}^* z^{-2}. \end{aligned}$$

It follows that

$$C_1 D_{-1}^* = 0, \tag{4.1}$$

$$D_{-1}^* + C_1 - 2C_1 D_{-1}^* = 0. \tag{4.2}$$

Substituting (4.1) into (4.2), we have

$$D^*_{-1} = -C_1.$$

Combined with (4.1), it follows that

$$(C_1)^2 = 0. \qquad \square$$

For an $m \times m$ nilpotent matrix N, with $N^2 = 0$, define the Laurent matrix pair

$$L_N(z) := I_m - N + Nz^{-k}, \quad R_N(z) := -N^* z^k + I_m + N^*, \tag{4.3}$$

and let (L_N, R_N) be the corresponding matrix pair. We will say that a matrix pair (L_N, R_N) of form (4.3) is a *primitive pseudo identity matrix pair of degree k*. It's easy to verify that (L_N, R_N) is indeed a pseudo identity matrix pair. In addition, for any positive integer n,

$$(L_N(z))^n = I_m - nN + nNz^{-k}, \quad (R_N(z))^n = -nN^* z^k + I_m + nN^*.$$

In the case of $m = 2$, $N^2 = 0$ implies

$$N = \begin{pmatrix} w & u \\ v & -w \end{pmatrix}$$

for some w, u, v satisfying $uv = -w^2$, which means N has parameter freedom of 2. So when $m = 2$, a primitive pseudo identity matrix pair will be of the form

$$L_N(z) = \begin{pmatrix} 1 - w(1 - z^{-k}) & -u(1 - z^{-k}) \\ -v(1 - z^{-k}) & 1 + w(1 - z^{-k}) \end{pmatrix},$$

$$R_N(z) = \begin{pmatrix} 1 + w(-z^k + 1) & v(-z^k + 1) \\ u(-z^k + 1) & 1 - w(-z^k + 1) \end{pmatrix},$$

with $uv = -w^2$.

Lemma 4.3. *For*

$$C(z) = \sum_{k=0}^{k_c} C_k z^{-k}, \quad D(z) = \sum_{k=k_d}^{0} D_k z^{-k},$$

if

$$C(z)\tilde{D}(z) = I_m$$

and both C_{k_c-1} and D_{k_d+1} are invertible matrices, then there exists a nilpotent matrix N, with $N^2 = 0$, such that

$$C(z) = \left(\sum_{k=0}^{k_c-1} C^1_k z^{-k}\right) L_N(z), \quad D(z) = \left(\sum_{k=k_d+1}^{0} D^1_k z^{-k}\right) R_N(z),$$

with

$$L_N(z) = I_m - N + Nz^{-1}, \quad R_N(z) = -N^* z + I_m + N^*.$$

Proof. Since

$$C(z)\tilde{D}(z) = \left(\sum_{k=0}^{k_c} C_k z^{-k}\right)\left(\sum_{k=k_d}^{0} D_k^* z^k\right) = \left(\sum_{k=0}^{k_c} C_k z^{-k}\right)\left(\sum_{k=0}^{-k_d} D_{-k}^* z^{-k}\right) = I_m,$$

we have

$$C_{k_c} D_{k_d}^* = 0, \quad C_{k_c} D_{k_d+1}^* + C_{k_c-1} D_{k_d}^* = 0.$$

Now set

$$N = (C_{k_c-1})^{-1} C_{k_c} = -D_{k_d}^* (D_{k_d+1}^*)^{-1},$$

then

$$N^2 = 0, \quad C_{k_c} N = 0, \quad N D_{k_d}^* = 0,$$

$$-C_{k_c-1} N + C_{k_c} = 0, \quad N D_{k_d+1}^* + D_{k_d}^* = 0.$$

So

$$C(z)(L_N(z))^{-1} = \left(\sum_{k=0}^{k_c} C_k z^{-k}\right)(I_m + N - N z^{-1}) = \sum_{k=0}^{k_c-1} C_k^1 z^{-k},$$

$$D(z)(R_N(z))^{-1} = \left(\sum_{k=k_d}^{0} D_k z^{-k}\right)(N^* z + I_m - N^*) = \sum_{k=k_d+1}^{0} D_k^1 z^{-k}.$$

That is,

$$C(z) = C^1(z) L_N(z) = \left(\sum_{k=0}^{k_c-1} C_k^1 z^{-k}\right) L_N(z),$$

$$D(z) = D^1(z) R_N(z) = \left(\sum_{k=k_d+1}^{0} D_k^1 z^{-k}\right) R_N(z). \qquad \square$$

Notice that the genus of C^1 and D^1 is reduced by one (from $k_c + 1$ to k_c and from $-k_d + 1$ to $-k_d$) simultaneously, compared with C and D. The reduction from (C, D) to (C^1, D^1) totally depends on whether or not C_{k_c-1} and D_{k_d+1} are invertible. We formulate this condition as follows.

Condition 1. *For $m = 2$,*

$$C(z) = \sum_{k=0}^{k_c} C_k z^{-k}, \quad D(z) = \sum_{k=k_d}^{0} D_k z^{-k},$$

if

$$C(z)\tilde{D}(z) = I_2,$$

and p is the smallest positive integer such that $C_{k_c-p} \neq 0$, then both C_{k_c-p} and D_{k_d+p} are invertible matrices.

Because of the symmetry of C and D, if p' is the smallest positive integer such that $D_{k_d+p'} \neq 0$, then the above condition asserts that both $C_{k_c-p'}$ and $D_{k_d+p'}$ are invertible.

THEOREM 4.4. *If Condition 1 is true, then for any pair (C, D) of rank 2 satisfying*

$$C(z) = \sum_{k=0}^{k_c} C_k z^{-k}, \quad D(z) = \sum_{k=k_d}^{0} D_k z^{-k}, \quad C(z)\tilde{D}(z) = I_2, \quad C(1) = D(1) = I_2,$$

there exist nilpotent matrices $N_1, N_2, \ldots, N_q, N_i^2 = 0, i = 1, 2, \ldots, q$, such that

$$C(z) = L_{N_q}(z) \cdots L_{N_2}(z) L_{N_1}(z), \quad D(z) = R_{N_q}(z) \cdots R_{N_2}(z) R_{N_1}(z),$$

with

$$L_{N_i}(z) = I_2 - N_i + N_i z^{-k_i}, \quad R_{N_i}(z) = -N_i^* z^{k_i} + I_2 + N_i^*, \quad \text{for } i = 1, 2, \ldots, q,$$

and

$$k_1 + k_2 + \cdots + k_q = k_c = -k_d.$$

Proof. Assume k_1 is the smallest integer such that either $C_{k_c-k_1}$ or $D_{k_d+k_1}$ is nonzero. By Condition 1, both $C_{k_c-k_1}$ and $D_{k_d+k_1}$ are invertible matrices. Similar to the proof of Lemma 4.3, from

$$\begin{aligned} C(z)\tilde{D}(z) &= \left(\sum_{k=0}^{k_c} C_k z^{-k}\right)\left(\sum_{k=k_d}^{0} D_k^* z^k\right) \\ &= \left(\sum_{k=0}^{k_c-k_1} C_k z^{-k} + C_{k_c} z^{-k_c}\right)\left(\sum_{k=0}^{-k_d-k_1} D_{-k}^* z^{-k} + D_{k_d}^* z^{-k_d}\right) = I_2, \end{aligned}$$

we have

$$C_{k_c} D_{k_d}^* = 0, \quad C_{k_c} D_{k_d+k_1}^* + C_{k_c-k_1} D_{k_d}^* = 0.$$

Define

$$N_1 = (C_{k_c-k_1})^{-1} C_{k_c} = -D_{k_d}^* (D_{k_d+k_1}^*)^{-1},$$

$$L_{N_1}(z) = I_2 - N_1 + N_1 z^{-k_1}, \quad R_{N_1}(z) = -N_1^* z^{k_1} + I_2 + N_1^*.$$

Then it can be easily verified that

$$N_1^2 = 0,$$

$$C(z) = \left(\sum_{k=0}^{k_c-k_1} C_k^1 z^{-k}\right) L_{N_1}(z) = C^1(z) L_{N_1}(z),$$

$$D(z) = \left(\sum_{k=k_d+k_1}^{0} D_k^1 z^{-k} \right) R_{N_1}(z) = D^1(z) R_{N_1}(z).$$

The genus of C^1 and D^1 is reduced by k_1, compared with C and D. Now repeating the genus reduction procedure on the new pair (C^1, D^1), one can eventually obtain

$$C(z) = L_{N_q}(z) \cdots L_{N_2}(z) L_{N_1}(z), \quad D(z) = R_{N_q}(z) \cdots R_{N_2}(z) R_{N_1}(z),$$

with $k_1 + k_2 + \cdots + k_q = k_c = -k_d$. □

Remark 3. Note that Condition 1 is actually a very strong condition to guarantee the existence of a nilpotent matrix for the genus reduction procedure. All we need for such a genus reduction is a weaker condition

$$-C_{k_c-p} N + C_{k_c} = 0, \quad N D^*_{k_d+p} + D^*_{k_d} = 0$$

for some nilpotent matrix N, $N^2 = 0$. The advantage of Condition 1 is that it's much easier to check.

THEOREM 4.5. *If* Condition 1 *is true, and a pair of matrices* (L, R) *is a biorthogonal wavelet matrix pair of rank* 2*, then there exist primitive paraunitary matrices* $V_1, \ldots, V_d$*,* $d \geq 0$*, and primitive pseudo identity matrix pairs* (L_{N_1}, R_{N_1})*,* (L_{N_2}, R_{N_2})*,* $\ldots$*,* (L_{N_q}, R_{N_q})*,* $q \geq 0$*, such that*

$$L(z) = z^{-k_0} V_1(z) \cdots V_d(z) L_{N_q}(z) \cdots L_{N_1}(z) \begin{pmatrix} 1 & 0 \\ 0 & c \end{pmatrix} \begin{pmatrix} 1 & 1 \\ -1 & 1 \end{pmatrix},$$

$$R(z) = z^{-k_0} V_1(z) \cdots V_d(z) R_{N_q}(z) \cdots R_{N_1}(z) \begin{pmatrix} 1 & 0 \\ 0 & c^{-1} \end{pmatrix} \begin{pmatrix} 1 & 1 \\ -1 & 1 \end{pmatrix},$$

where $k_0 \in \mathbf{Z}$*,* $d = b - 2k_0$*,* b *is the exponent of* $\det(L(z))$*,* $c \neq 0$ *is a constant.*

5. Conversion between orthogonal and biorthogonal wavelets. Theorem 3.4 tells us that a biorthogonal wavelet matrix pair (L, R) can be decomposed into four components:

$$L(z) = V(z) C(z) \begin{pmatrix} 1 & 0 \\ 0 & G \end{pmatrix} \mathbf{H}, \quad R(z) = V(z) D(z) \begin{pmatrix} 1 & 0 \\ 0 & (G^{-1})^* \end{pmatrix} \mathbf{H},$$

with

$$V(z) = z^{-k_0} V_1(z) V_2(z) \cdots V_d(z),$$

$(C(z), D(z))$ is the pseudo identity matrix pair discussed in section 4, G is an invertible matrix, and $\mathbf{H}$ is the canonical Haar matrix. Only the first and second components $V(z), (C(z), D(z))$ contain the variable z. The fourth component $\mathbf{H}$ is a constant matrix, depending only on the rank m. The third component G doesn't contain z, and it can be easily determined by the value of $L(1)$ (or equivalently $R(1)$), since

$$L(1) = \begin{pmatrix} 1 & 0 \\ 0 & G \end{pmatrix} \mathbf{H}.$$

When looking at the determinant, if

$$\det(L(z)) = c_l z^{-b}, \quad \det(R(z)) = c_r z^{-b}, \quad c_l c_r = m,$$

then

$$\det(V(z)) = z^{-b}, \quad \det(C(z)) = \det(D(z)) = 1, \quad \det(G) = c_l/\sqrt{m}, \quad \det(\mathbf{H}) = \sqrt{m}.$$

Thus these four components have distinctive determinant values from each other.

Recall that in the theory of orthogonal wavelet matrices [13, 16, 25, 26, 28, 29], we have the following characterization result.

THEOREM 5.1 (orthogonal factorization theorem). *An $m \times mg$ matrix A is an orthogonal wavelet matrix if and only if there exist primitive paraunitary matrices $V_1, \ldots, V_d, d \geq 0$, such that*

$$A(z) = z^{-k} V_1(z) V_2(z) \cdots V_d(z) \begin{pmatrix} 1 & 0 \\ 0 & U \end{pmatrix} \mathbf{H},$$

where $k \in \mathbf{Z}$, $U \in U_{m-1}$ is a unitary matrix, that is, $U^* U = I_{m-1}$, and $\mathbf{H}$ is the canonical Haar matrix of rank m.

Comparing Theorem 5.1 with Theorem 3.4, it is now clear that the difference between a biorthogonal wavelet matrix pair and an orthogonal wavelet matrix lies in the pseudo identity matrix pair $(C(z), D(z))$ and the invertible matrix G. If $C(z)$ and $D(z)$ are both equal to the identity matrix and G is unitary, then a biorthogonal wavelet matrix pair (L, R) is actually an orthogonal wavelet matrix (and $L = R$). Thus to "orthogonalize" a biorthogonal wavelet matrix pair (L, R), one needs to and only needs to throw away the pseudo identity matrix pair $(C(z), D(z))$ and "orthogonalize" the invertible matrix G.

In linear algebra, a standard method to convert an invertible matrix to a unitary matrix is the Schmidt orthogonalization method. Given an invertible matrix $G \in GL_{m-1}$, its $m-1$ row vectors $\alpha_1, \ldots, \alpha_{m-1}$ are linearly independent. Now define

$$e_1 := \frac{\alpha_1}{||\alpha_1||};$$

then e_1 is a unit vector and has the same direction as α_1. From α_2 we construct a unit vector e_2 perpendicular to e_1 by

$$\beta_2 = \alpha_2 - \langle \alpha_2, e_1 \rangle e_1, \quad e_2 := \frac{\beta_2}{||\beta_2||}.$$

Proceeding in this fashion, we can define $e_3, \ldots, e_{m-1}$ by

$$\beta_3 = \alpha_3 - \langle \alpha_3, e_1 \rangle e_1 - \langle \alpha_3, e_2 \rangle e_2, \quad e_3 := \frac{\beta_3}{||\beta_3||},$$

$$\vdots$$

$$\beta_{m-1} = \alpha_{m-1} - \langle \alpha_{m-1}, e_1 \rangle e_1 - \cdots - \langle \alpha_{m-1}, e_{m-2} \rangle e_{m-2}, \quad e_{m-1} := \frac{\beta_{m-1}}{||\beta_{m-1}||}.$$

Then the matrix

$$U := \begin{pmatrix} e_1 \\ e_2 \\ \vdots \\ e_{m-1} \end{pmatrix}$$

is a unitary matrix.

Thus using the Schmidt orthogonalization method, we can convert a biorthogonal wavelet matrix pair to an orthogonal matrix with the same rank. (Note that orthogonalizing the analysis matrix and synthesis matrix will give the same orthogonal wavelet matrix.) Conversely we can retrieve invertible matrices from a unitary matrix by setting up a mapping from unitary matrices to invertible matrices. By adding an additional pseudo identity matrix pair, one can construct biorthogonal wavelet matrix pairs from orthogonal wavelet matrices.

In general, any mapping from the invertible matrix group to the unitary matrix group will define a mapping from biorthogonal wavelet matrix pairs to orthogonal wavelet matrices,

$$\begin{aligned}(L, R) &\longrightarrow A,\\ (C(z), D(z)) &\longmapsto I_m,\\ G &\longmapsto U.\end{aligned}$$

Next, we will discuss one interesting case, namely, how to preserve the vanishing moments. It can be proved that the vanishing moment conditions of scaling functions and/or wavelet functions can be translated into equivalent conditions on the wavelet matrix (or matrix pair). First, let's assume the orthogonal wavelet matrix A has vanishing moments up to order n on the scaling function $\phi(x)$, that is,

$$\sum_j a_{0,j} = m, \tag{5.1}$$

$$\sum_j a_{0,j} j^k = 0, \quad k = 1, \ldots, n. \tag{5.2}$$

The zeroth order vanishing moment condition (5.1) is already in the definition of an orthogonal wavelet matrix. For the first order vanishing moment ($k = 1$), since

$$\begin{aligned}\sum_j a_{0,j} j &= \sum_j \left(\sum_{l=0}^{m-1} a_{0,mj+l}(mj + l) \right)\\ &= m \sum_j j \left(\sum_{l=0}^{m-1} a_{0,mj+l} \right) + \sum_{l=1}^{m-1} l \left(\sum_j a_{0,mj+l} \right)\end{aligned}$$

and

$$A'(z) = \left(\sum_j A_j z^{-j} \right)' = -\sum_j j A_j z^{-j-1},$$

$$A'(1) = -\sum_j j A_j,$$

it follows that the first order vanishing moment of the scaling function $\phi(x)$ is equivalent to a linear equation on the entries of the first row of $A(1)$ and $A'(1)$. Similarly, one can convert all vanishing moment conditions (up to order n) of the scaling function and/or wavelet functions into some linear equations on the entries of

$A(1), A'(1), A^{(2)}(1), \ldots, A^{(n)}(1)$. Equivalently, with a biorthogonal wavelet matrix pair (L, R), one can also convert all vanishing moment conditions into linear equations of $L(1), L'(1), L^{(2)}(1), \ldots,$ $L^{(n)}(1)$, and $R(1), R'(1), R^{(2)}(1), \ldots, R^{(n)}(1)$.

Thus a sufficient condition to preserve the vanishing moment conditions when constructing a biorthogonal wavelet matrix pair (L, R) from an orthogonal wavelet matrix A is that

$$L(1) = R(1) = A(1),$$

$$L'(1) = R'(1) = A'(1),$$

$$\vdots$$

$$L^{(n)}(1) = R^{(n)}(1) = A^{(n)}(1).$$

One could choose a $(C(z), D(z))$ component pair such that

$$C(1) = D(1) = I_m,$$

$$C^{(k)}(1) = D^{(k)}(1) = 0, \quad k = 1, \ldots, n.$$

Then the resulting biorthogonal wavelet matrix pair (L, R)

$$L(z) = A(z)C(z), \quad R(z) = A(z)D(z)$$

will preserve all vanishing moments from A. For example, one can take

$$C(z) = I_m + N(1 - z^{-1})^{n+1}, \quad D(z) = I_m - N^*(1 - z)^{n+1},$$

with an $m \times m$ nilpotent matrix N, satisfying $N^2 = 0$.

6. Examples. In this section we will give a simple example to illustrate the factorization of biorthogonal wavelet matrices. We take the 3-5 biorthogonal wavelet matrix pair from [8]. The analysis matrix L is given by

$$L = \begin{pmatrix} -\frac{1}{4} & \frac{1}{2} & \frac{3}{2} & \frac{1}{2} & -\frac{1}{4} & 0 \\ \frac{1}{2} & -1 & \frac{1}{2} & 0 & 0 & 0 \end{pmatrix}.$$

Its Laurent series is

$$L(z) = \begin{pmatrix} -\frac{1}{4} & \frac{1}{2} \\ \frac{1}{2} & -1 \end{pmatrix} + \begin{pmatrix} \frac{3}{2} & \frac{1}{2} \\ \frac{1}{2} & 0 \end{pmatrix} z^{-1} + \begin{pmatrix} -\frac{1}{4} & 0 \\ 0 & 0 \end{pmatrix} z^{-2}.$$

The four component decomposition will be

$$L(z) = V_1(z)C(z) \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix} \mathbf{H},$$

where

$$V_1(z) = I_2 - v_1 v_1^t + v_1 v_1^t z^{-1} = \begin{pmatrix} \frac{1}{5} & -\frac{2}{5} \\ -\frac{2}{5} & \frac{4}{5} \end{pmatrix} + \begin{pmatrix} \frac{4}{5} & \frac{2}{5} \\ \frac{2}{5} & \frac{1}{5} \end{pmatrix} z^{-1},$$

with

$$v_1 = \begin{pmatrix} \frac{2}{\sqrt{5}} \\ \frac{1}{\sqrt{5}} \end{pmatrix},$$

and

$$C(z) = \begin{pmatrix} \frac{41}{40} & \frac{1}{8} \\ \frac{1}{5} & 1 \end{pmatrix} + \begin{pmatrix} 0 & -\frac{1}{10} \\ -\frac{1}{4} & -\frac{1}{20} \end{pmatrix} z^{-1} + \begin{pmatrix} -\frac{1}{40} & -\frac{1}{40} \\ \frac{1}{20} & \frac{1}{20} \end{pmatrix} z^{-2}, \quad \mathbf{H} = \begin{pmatrix} 1 & 1 \\ -1 & 1 \end{pmatrix}.$$

Consequently, the synthesis matrix R can be factored as

$$R(z) = V_1(z)D(z) \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix} \mathbf{H},$$

where $(C(z), D(z))$ is a pseudo identity matrix pair. Now since C_1 in $C(z)$ is invertible, based on the techniques in Lemma 4.3, $C(z)$ can be further factored as

$$\begin{aligned} C(z) &= L_{N_1}(z) \cdot L_{N_2}(z) \\ &= \left(I_2 - \begin{pmatrix} \frac{1}{5} & \frac{1}{10} \\ -\frac{2}{5} & -\frac{1}{5} \end{pmatrix} + \begin{pmatrix} \frac{1}{5} & \frac{1}{10} \\ -\frac{2}{5} & -\frac{1}{5} \end{pmatrix} z^{-1} \right) \\ &\quad \cdot \left(I_2 - \begin{pmatrix} -\frac{1}{4} & -\frac{1}{4} \\ \frac{1}{4} & \frac{1}{4} \end{pmatrix} + \begin{pmatrix} -\frac{1}{4} & -\frac{1}{4} \\ \frac{1}{4} & \frac{1}{4} \end{pmatrix} z^{-1} \right). \end{aligned}$$

Thus

$$\begin{aligned} D(z) = &\left(- \begin{pmatrix} \frac{1}{5} & -\frac{2}{5} \\ \frac{1}{10} & -\frac{1}{5} \end{pmatrix} z + I_2 + \begin{pmatrix} \frac{1}{5} & -\frac{2}{5} \\ \frac{1}{10} & -\frac{1}{5} \end{pmatrix} \right) \\ &\cdot \left(- \begin{pmatrix} -\frac{1}{4} & \frac{1}{4} \\ -\frac{1}{4} & \frac{1}{4} \end{pmatrix} z + I_2 + \begin{pmatrix} -\frac{1}{4} & \frac{1}{4} \\ -\frac{1}{4} & \frac{1}{4} \end{pmatrix} \right). \end{aligned}$$

To derive an orthogonal wavelet matrix A from L, one can simply throw away $C(z)$ and get

$$A(z) = V_1(z) \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix} \begin{pmatrix} 1 & 1 \\ -1 & 1 \end{pmatrix} = \begin{pmatrix} -\frac{1}{5} & \frac{3}{5} \\ \frac{2}{5} & -\frac{6}{5} \end{pmatrix} + \begin{pmatrix} \frac{6}{5} & \frac{2}{5} \\ \frac{3}{5} & \frac{1}{5} \end{pmatrix} z^{-1}.$$

For illustration, we include the graphs of the analysis scaling function and the synthesis scaling function constructed from the 3-5 biorthogonal wavelet matrix pair (L, R), and the graph of the scaling function constructed from the orthogonal wavelet matrix A in Figures 1 and 2, respectively. The analysis scaling function in Figure 1 is a linear spline function, and it is in $C^{1-\epsilon}$, for any $0 < \epsilon < 1$, while the synthesis scaling function is not even continuous. The scaling function of the "orthogonalized" wavelet matrix A in Figure 2 is in $C^{0.3219}$. Thus in this example, the smoothness of the "orthogonalized" scaling function is between those of the analysis scaling function and the synthesis scaling function of the original biorthogonal wavelet.

7. Conclusions. In this paper we study the algebraic and geometric structure of the space of compactly supported biorthogonal wavelets. The wavelet matrix can be real-valued, complex-valued, or in any subfield of complex numbers closed under the complex conjugation. We present a complete characterization of biorthogonal wavelet matrix pairs. The conversion between orthogonal and biorthogonal wavelets is provided. We also discuss how to preserve the vanishing moment condition in such a conversion. There are still several open problems in the factorization of biorthogonal wavelet matrix pairs, such as how to construct symmetric biorthogonal wavelets from the factorization formula, the smoothness estimate of biorthogonal wavelets from the factorization formula, etc. We are currently investigating these problems and the progress will be reported in a forthcoming paper.

Acknowledgments. We would like to thank Clayton Scott of Rice University for valuable assistance. We also thank the reviewers. Their comments have enhanced the paper considerably. Tian and Wells would like to thank their colleagues in the Computational Mathematics Laboratory of Rice University, from where they are on

leave of absence.

After completion of this work, Fritz Keinert [17] showed to us a counterexample of Condition 1 (and even the weaker condition) as follows:

$$\begin{aligned} C(z) &= \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} + \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix} (z^{-1} - z^{-2}), \\ D(z) &= \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix} (z^2 - z) + \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}. \end{aligned}$$

For the above pseudo identity matrix pair (C, D), they can be factored as

$$\begin{aligned} C(z) &= \left(I_2 - N + Nz^{-1}\right) \cdot \left(I_2 + N - Nz^{-2}\right), \\ D(z) &= \left(N^* z^2 + I_2 - N^*\right) \cdot \left(-N^* z + I_2 + N^*\right), \end{aligned}$$

where

$$N = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}.$$

Thus they could still be factored as the product of primitive pseudo identity matrix pairs even though Condition 1 could not hold. Finding the necessary and sufficient condition such that a pseudo identity matrix pair could be factored as the product of primitive pseudo identity matrix pairs remains an open problem. Keinert develops a numerical algorithm to generate all pseudo identity matrix pairs by an explicit parametrization. Interested readers are referred to [18]. He also drew our attention to [15], which obtained a similar result to Theorem 3.6 in this paper. We would like to thank Keinert for his helpful comments and for sharing his work with us.

ASYMPTOTIC BEHAVIOR OF SOLUTIONS TO THE SYSTEM OF COMPRESSIBLE ADIABATIC FLOW THROUGH POROUS MEDIA[*]

KENJI NISHIHARA[†] AND MASATAKA NISHIKAWA[‡]

Abstract. Hsiao and Serre in [*Chinese Ann. Math. Ser. B,* 16B (1995), pp. 1–14] showed the solution to the system

$$\begin{cases} v_t - u_x = 0, & (t,x) \in R_+ \times R, \\ u_t + p(v,s)_x = -\alpha u, & \alpha > 0, \\ s_t = 0 \end{cases}$$

with initial data

$$(v,u,s)(0,x) = (v_0,u_0,s_0)(x) \to (\underline{v}, u_\pm, \underline{s}) \qquad \text{as} \quad x \to \pm\infty$$

tends to the following nonlinear parabolic equation time-asymptotically:

$$\begin{cases} \tilde{v}_t = -\frac{1}{\alpha} p(\tilde{v}, s_0)_{xx}, & (t,x) \in R_+ \times R, \\ \tilde{u} = -\frac{1}{\alpha} p(\tilde{v}, s_0)_x. \end{cases}$$

In this paper we find its convergence rate, which will be optimal.

1. Introduction.

We consider the Cauchy problem for the equation of the form

$$\begin{cases} v_t - u_x = 0, & (t,x) \in R_+ \times R, \\ u_t + p(v,s)_x = -\alpha u, & \alpha > 0, \\ s_t = 0, \end{cases} \tag{1.1}$$

which can be used to model the adiabatic gas flow through porous media. Here v is the specific volume, u denotes the velocity, s stands for the entropy, and p denotes the pressure with $p > 0$, $p_v < 0$ for $v > 0$. A typical example of p is $p(v,s) = (\gamma - 1)v^{-\gamma}e^s$ $(\gamma > 1)$.

In Hsiao and Serre [2, 3], it has been proved that the solution of the Cauchy problem (1.1) with

$$(v,u,s)(0,x) = (v_0,u_0,s_0)(x) \to (v_\pm, u_\pm, s_\pm), \quad v_+ = v_-, s_+ = s_- \qquad \text{as} \quad x \to \pm\infty \tag{1.2}$$

can be described time-asymptotically by the solution of the following equations:

$$\begin{cases} \tilde{v}_t = -\frac{1}{\alpha} p(\tilde{v}, s_0)_{xx}, \quad (t,x) \in R_+ \times R, \\ \tilde{u} = -\frac{1}{\alpha} p(\tilde{v}, s_0)_x \end{cases} \tag{1.3}$$

or

$$\begin{cases} \tilde{v}_t - \tilde{u}_x = 0, \qquad\qquad (t,x) \in R_+ \times R, \\ p(\tilde{v}, s_0)_x = -\alpha \tilde{u}. \end{cases} \tag{1.3$'$}$$

The system (1.3′) is obtained from (1.1) by approximating the momentum equation $(1.1)_2$ (the second equation of (1.1)) with Darcy's law.

In the case of isentropic flow, namely, $s(t,x) \equiv \mathit{constant}$, Hsiao and Liu [4] have proved that the solution to the Cauchy problem (1.1) converges to that of (1.3) with a rate $t^{-\frac{1}{2}}$ in the sense of the $L^2 \cap L^\infty$-norm. More precisely, for any smooth function $m_0(x)$ with compact support satisfying

$$\int_R m_0(x)dx = 1, \tag{1.4}$$

we put

$$\begin{cases} \hat{v} \equiv -\dfrac{u_+ - u_-}{\alpha} m_0(x) e^{-\alpha t}, \\ \hat{u} \equiv e^{-\alpha t} \left[u_- + (u_+ - u_-) \displaystyle\int_{-\infty}^x m_0(y)dy \right] \end{cases} \tag{1.5}$$

and uniquely determine $(\tilde{v}, \tilde{u})(t,x)$ by

$$\int_R \{v_0(x) - \tilde{v}(0,x)\}dx = \frac{u_+ - u_-}{-\alpha}. \tag{1.6}$$

Then it holds that

$$\|(v - \tilde{v} - \hat{v}, u - \tilde{u} - \hat{u})(t, \cdot)\|_{L^2 \cap L^\infty} = O(t^{-\frac{1}{2}}). \tag{1.7}$$

Moreover, the first author has obtained sharper rates than that [9]. Precisely, if we put $(v - \tilde{v} - \hat{v}, u - \tilde{u} - \hat{u}) = (V_x, z)$ due to (1.7), it holds that

$$\|(V_x, z)(t, \cdot)\|_{L^2(R)} = O(t^{-\frac{1}{2}}, t^{-1}) \tag{1.8}$$

and

$$\|(V_x, z)(t, \cdot)\|_{L^\infty(R)} = O(t^{-\frac{3}{4}}, t^{-\frac{5}{4}}), \tag{1.9}$$

which are based on the L^2-energy estimates for the reformulated problem

$$\begin{cases} V_{tt} + \{p_v(\tilde{v})V_x\}_x + \alpha V_t = \dfrac{1}{\alpha} p(\tilde{v})_{xt} - \{p(V_x + \tilde{v} + \hat{v}) - p(\tilde{v}) - p_v(\tilde{v})V_x\}_x, \\ V(0,x) = \displaystyle\int_{-\infty}^x (v - \tilde{v} - \hat{v})(0,y)dy, \ V_t(0,x) = (u - \tilde{u} - \hat{u})(0,x). \end{cases} \tag{1.10}$$

Moreover, the fact that V_{tt} decays quickly suggests that V has parabolic structure as $t \to \infty$. In fact, it is also shown that, if $v_+ = v_-$ and $(V, z)(0, x) \in L^1(R) \times L^1(R)$, then

$$\|(V_x, z)(t, \cdot)\|_{L^\infty(R)} = O(t^{-1}, t^{-\frac{3}{2}}). \tag{1.11}$$

In the nonisentropic case, the asymptotic stability in the case of $v_+ = v_-$ and $s_+ = s_-$ has been obtained in [2, 3]. Our purpose in this paper is to obtain its convergence rate, especially its second order term of asymptotic, which is on the same line as in [9, 10, 11]. See also Gallay and Raugel [1].

In the case of $v_+ \neq v_-$ and $s_+ = s_-$, Hsiao and Luo [5] have obtained the stability theorem. Furthermore, in Marcati and Pan [8], the stability results with convergence rates have been obtained in the following cases: (1) $v_+ = v_-$ and $s_+ = s_-$; (2) $p(v_-, s_-) = p(v_+, s_+)$. Hence the case $s_+ \neq s_-$ has been partly solved. We note that in these papers all data are so small that the solutions are smooth. Since large data generally yield the singularity after a finite time, we need to consider the weak solution to treat large data. See also Hsiao and Luo [6] and the references therein.

Throughout this paper we denote several generic constants by c or C. By $H^m(R)$ denote the usual Sobolev space with its norm

$$\|f\|_m := \sum_{k=0}^{m} \|\partial_x^k f\|, \quad \|\cdot\| = \|\cdot\|_0 = \|\cdot\|_{L^2(R)}.$$

2. Preliminaries and theorems. For simplicity, we restrict our case to $v_+ = v_- := \underline{v}$, $u_+ = u_- := 0$, $s_+ = s_- := \underline{s}$, so that $(\hat{v}, \hat{u})(t, x) \equiv (0, 0)$. The constant α is normalized to 1 without loss of generality.

First, let us consider the problem (1.3) in order to reformulate our problem (1.1), (1.2). Since $\tilde{u}$ is defined by $(1.3)_2$, we investigate the Cauchy problem of $\tilde{v}$ to the parabolic equation

$$\begin{cases} \tilde{v}_t + p(\tilde{v}, s_0)_{xx} = 0, & (t, x) \in R_+ \times R, \\ \tilde{v}(0, x) = \tilde{v}_0(x) \to \underline{v} & (x \to \pm\infty). \end{cases} \tag{2.1}$$

Equation $(2.1)_1$ has a stationary solution $\bar{v}(x)$ defined by

$$p(\bar{v}(x), s_0(x)) = p(\underline{v}, \underline{s}). \tag{2.2}$$

For a typical form of $p(v, s)$ in gas dynamics, $\bar{v}$ is given by

$$\bar{v}(x) = e^{\frac{1}{\gamma}(s_0(x) - \underline{s})}\underline{v}. \tag{2.3}$$

Our first proposition is on the property of $\tilde{v}$, which is necessary to investigate the behavior of solutions to (1.1), (1.2).

Proposition 2.1 (asymptotic property of $\tilde{v}$). *Suppose that $p(v, s)$ is a smooth function with $p > 0, p_v < 0$ for $v > 0$. If $(\tilde{v}_0 - \bar{v}, s_0 - \underline{s}) \in H^6(R) \times H^6(R)$ is sufficiently small, then there exists a unique global solution $\tilde{v}(t, x)$ to* (2.1)*, which satisfies that*

$$\partial_t^i(\tilde{v} - \bar{v}) \in C([0, \infty); H^{6-2i}(R)), \partial_t^j q_x \in C([0, \infty); H^{5-2j}(R)),$$

$$q_{tttx} \in L^2(0, \infty; L^2(R)),$$

where $q = p(\bar{v}, s) - p(\tilde{v}, s)$ *and* $i = 0, 1, 2, 3,\ j = 0, 1, 2,$ *and that*

$$\begin{aligned}&\sum_{k=0}^{3}(1+t)^{2k}\|\partial_t^k(\tilde{v}-\bar{v})(t)\|^2 + \sum_{k=0}^{2}(1+t)^{2k+1}\|\partial_t^k q_x(t)\|^2 \\ &+ \int_0^t \left(\sum_{k=1}^{3}(1+\tau)^{2k-1}\|\partial_t^k(\tilde{v}-\bar{v})(\tau)\|^2 + \sum_{k=0}^{3}(1+\tau)^{2k}\|\partial_t^k q_x(\tau)\|^2\right) d\tau \\ &\le C\|(\tilde{v}_0(\cdot)-\bar{v}(\cdot), s_0(\cdot)-\underline{s})\|_6^2.\end{aligned} \tag{2.4}$$

Moreover, if $(\tilde{v}_0 - \bar{v}, s_0 - \underline{s}) \in L^1(R) \times L^1(R)$ *is assumed, then* $\tilde{v}$ *satisfies*

$$\begin{cases} \|\tilde{v}(t,\cdot) - (\bar{v}(\cdot) + \bar{\theta}_0(t,\cdot))\|_{L^\infty} \le C(1+t)^{-1}, \\ \|(\tilde{v} - \bar{\theta}_0)_t(t,\cdot)\|_{L^\infty} \le C(1+t)^{-2}, \\ \|(\tilde{v} - \bar{\theta}_0)_{tt}(t,\cdot)\|_{L^\infty} \le C(1+t)^{-\frac{11}{4}}, \\ \|\tilde{v}(t,\cdot) - (\bar{v}(\cdot) + \bar{\theta}_0(t,\cdot))\|_{L^2} \le C(1+t)^{-\frac{3}{4}}, \\ \|(\tilde{v} - \bar{\theta}_0)_t(t,\cdot)\|_{L^2} \le C(1+t)^{-\frac{7}{4}}, \\ \|(\tilde{v} - \bar{\theta}_0)_{tt}(t,\cdot)\|_{L^2} \le C(1+t)^{-\frac{5}{2}}, \end{cases} \tag{2.5}$$

where $\bar{\theta}_0$ *is given by the explicit formula*

$$\bar{\theta}_0(t,x) = \frac{-p_v(\underline{v},\underline{s})}{-p_v(\bar{v},s)} \int_R G(t,x-y)\{\tilde{v}_0(y) - \bar{v}(y)\}dy \tag{2.6}$$

by using the Green function of $v_t + p_v(\underline{v},\underline{s})v_{xx} = 0$.

Remark 1. In Proposition 2.1, we assume that the initial disturbance is in $H^6(R)$ in order to obtain the decay estimates for $\tilde{v}_{ttt},\ q_{tttx}$, etc., which will be used in the proofs of Theorems 1 and 2 below. The function $\bar{\theta}_0(t,x)$ satisfies

$$(\bar{\theta}_0)_t = \frac{\underline{a}}{a(x)}(a(x)\bar{\theta}_0)_{xx}, \tag{2.7}$$

where $a(x) = -p_v(\bar{v}(x), s_0(x))$ and $\underline{a} = -p_v(\underline{v},\underline{s})$. Since $\|(a(\cdot)\bar{\theta}_0, a(\cdot)\bar{\theta}_{0t})(t)\|_{L^\infty} = O(t^{-\frac{1}{2}}, t^{-\frac{3}{2}})$, etc., we can say from (2.5) that $\bar{v}(x) + \bar{\theta}_0(t,x)$ is an asymptotic profile of $\tilde{v}$ as $t \to \infty$. It seems to be curious, because $\bar{\theta}_0$ satisfies (2.7) instead of $(\bar{\theta}_0)_t = (a(x)\bar{\theta}_0)_{xx}$, the linearized equation of (2.1) around $\tilde{v}$. However, we have adopted $\bar{\theta}_0$ in (2.6) which has an explicit formula.

We also obtain the asymptotic property of $\tilde{u}$.

PROPOSITION 2.2. *The function* $\tilde{u}$ *defined by* $(1.3')_2$ *for* $\tilde{v}$ *obtained in Proposition* 2.1 *satisfies*

$$\begin{cases} \|(\tilde{u} - \bar{q}_{0x})(t,\cdot)\|_{L^\infty} \le C(1+t)^{-\frac{3}{2}}\log(2+t), \\ \|(\tilde{u} - \bar{q}_{0x})(t,\cdot)\|_{L^2} \le C(1+t)^{-\frac{5}{4}}, \end{cases} \tag{2.8}$$

where $\bar{q}_0$ *is given by*

$$\bar{q}_0(t,x) = -p_v(\underline{v},\underline{s}) \int_R G(t,x-y)\{\tilde{v}_0(y) - \bar{v}(y)\}dy. \tag{2.9}$$

The proofs of Propositions 2.1 and 2.2 will be given in section 3.

We now turn to the original problem (1.1), (1.2) with $v_\pm = \underline{v}$ and $u_\pm = 0$. If $\tilde{v}_0(x) = \underline{v} + \frac{\delta_0}{\sqrt{4\pi}} \exp(-\frac{(x-x_0)^2}{4})$, $\delta_0 = \int_R (v_0(y) - \underline{v})dy$, then $\int_R (v_0 - \tilde{v}_0)(x)dx = 0$. Hence $\int_R (v - \tilde{v})(t,x)dx \equiv 0$ follows from $(1.1)_1$ and $(1.3')_1$. Thus, putting

$$(V,z)(t,x) = \left(\int_{-\infty}^x (v-\tilde{v})(t,y)dy, (u-\tilde{u})(t,x) \right), \tag{2.10}$$

we have the reformulated problem

$$(RP) \qquad \begin{cases} V_t - z = 0, \\ z_t + \{p(V_x + \tilde{v}, s) - p(\tilde{v}, s)\}_x + z = p(\tilde{v}, s)_{xt}, \\ (V,z)(0,x) = (V_0, z_0)(x) \\ \qquad\qquad := \left(\int_{-\infty}^x \{v_0(y) - \tilde{v}(0,y)\}dy, u_0(x) - \tilde{u}(0,x) \right) \\ \qquad\qquad \to 0 \qquad \text{as} \qquad x \to \pm\infty, \end{cases}$$

where $s(t,x) \equiv s_0(x) =: s(x)$.

Hsiao and Serre [2, 3] have shown that $(\tilde{v}, \tilde{u})(t,x) \to (\bar{v}(x), 0)$ as $t \to \infty$ and that $(V_x, z) = (v - \tilde{v}, u - \tilde{u})(t,x) \to 0$ as $t \to \infty$ under suitable smallness conditions. Namely, the solution (v,u) to (1.1), (1.2) tends to $(\bar{v}(x), 0)$ as t tends to infinity. In this paper, we obtain those convergence rates by applying not only the L^2-energy method but also the Green function of parabolic equation.

Using the property of $\tilde{v}$ in Proposition 2.1, we obtain the following first main theorem based on the L^2-energy method.

Theorem 1. *In addition to the assumptions in Proposition* 2.1*, suppose that* $v_0 - \tilde{v}_0 \in L^1(R)$. *If* $(V_0, z_0) \in H^3(R) \times H^2(R)$ *is sufficiently small, then there exists a unique global solution* $(V,z)(t,x)$ *to* (RP)*, which satisfies*

$$\begin{aligned} &\sum_{k=0}^{1} (1+t)^k \|\partial_x^k V(t)\|^2 + \sum_{k=2}^{3} (1+t)^k \|\partial_x^{k-1} P(t)\|^2 + \sum_{k=0}^{1} (1+t)^{k+2} \|\partial_x^k z(t)\|^2 \\ &+ (1+t)^3 \|z_{xx}(t)\|^2 + (1+t)^4 \|P_{xt}(t)\|^2 + \sum_{k=0}^{1} (1+t)^{2k+3} \|\partial_x^k z_t(t)\|^2 + (1+t)^5 \|z_{tt}(t)\|^2 \\ &+ \int_0^t \left\{ \|V_x(\tau)\|^2 + (1+\tau)\|P_x(\tau)\|^2 + (1+\tau)^2 \|P_{xx}(\tau)\|^2 + (1+\tau)^3 \|P_{xt}(\tau)\|^2 \right\} d\tau \\ &+ \int_0^t \left\{ \sum_{k=0}^{2} (1+\tau)^{k+1} \|\partial_x^k z(\tau)\|^2 + \sum_{k=0}^{1} (1+\tau)^{k+3} \|\partial_t^k z_t(\tau)\|^2 + (1+\tau)^5 \|z_{tt}(\tau)\|^2 \right\} d\tau \\ &\le C \left(\|V_0\|_3^2 + \|z_0\|_2^2 + \|(\tilde{v}_0(\cdot) - \bar{v}(\cdot), s_0(\cdot) - \underline{s})\|_6^2 \right). \end{aligned} \tag{2.11}$$

Here $P = P(V_x) = P(V_x; \tilde{v}, s)(t,x) := p(V_x(t,x) + \tilde{v}(t,x), s(x)) - p(\tilde{v}(t,x), s(x))$.

Proof. The proof is given by the same method as in [9]. □

Remark 2. The decay estimate of (V_x, z), corresponding with (1.9), is derived as follows. By the Sobolev inequality and $C^{-1}|V_x| \le |P(V_x)| \le C|V_x|$,

$$\begin{cases} \|V_x(t,\cdot)\|_{L^\infty} \le C\|P(t;V_x,\tilde{v},s)\| \\ \qquad\qquad\qquad \le C\|P(t;V_x,\tilde{v},s)\|^{\frac{1}{2}}\|P(t;V_x,\tilde{v},s)_x\|^{\frac{1}{2}} \\ \qquad\qquad\qquad \le C\|V_x(t)\|^{\frac{1}{2}}\|P(t;V_x,\tilde{v},s)_x\|^{\frac{1}{2}} \\ \qquad\qquad\qquad \le C(1+t)^{-\frac{1}{4}}(1+t)^{-\frac{1}{2}} = C(1+t)^{-\frac{3}{4}} \end{cases}$$

and

$$\begin{aligned} \|z(t,\cdot)\|_{L^\infty} &\le C\|z(t)\|^{\frac{1}{2}}\|z_x(t)\|^{\frac{1}{2}} \\ &\le C(1+t)^{-\frac{1}{2}}(1+t)^{-\frac{3}{4}} = C(1+t)^{-\frac{5}{4}}. \qquad \square \end{aligned}$$

Next, we obtain the optimal convergence rate, corresponding with (1.11), assuming that $(V_0, z_0) \in L^1(R) \times L^1(R)$. The linearized problem of (RP) is

$$\begin{cases} V_{tt} + \{p_v(\tilde{v},s)V_x\}_x + V_t = p(\tilde{v},s)_{xt} - F_x, \\ V(0,x) = V_0(x), V_t(0,x) = z_0(x), \end{cases} \tag{2.12}$$

where $F = p(V_x + \tilde{v}, s) - p(\tilde{v}, s) - p_v(\tilde{v}, s)V_x$. Regarding (2.12) as the parabolic equation of V with "forcing terms," we have the expression

$$\begin{aligned} V(t,x) = &\int_R G(t,x-y)V_0(y)dy - \int_0^t\int_R G(t-\tau,x-y)(V_{tt}+F_x)dyd\tau \\ &+ \int_0^t\int_R G(t-\tau,x-y)p(\tilde{v},s)_{xt}dyd\tau \\ &- \int_0^t\int_R G(t-\tau,x-y)\{(p_v(\tilde{v},s)-p_v(\underline{v},\underline{s}))V_x\}_x dyd\tau, \end{aligned} \tag{2.13}$$

which are estimated by using the result in Theorem 1. Thus we have the following theorem.

THEOREM 2. *In addition to the assumptions in Theorem* 1, *suppose that* $(V_0, z_0) \in L^1(R) \times L^1(R)$. *Then the global solution* (V, z) *to* (RP) *satisfies*

$$\begin{cases} \|(V_x, z)(t)\|_{L^\infty} = O(t^{-1}, t^{-\frac{3}{2}}), \\ \|(V_x, z)(t)\|_{L^2} = O(t^{-\frac{3}{4}}, t^{-\frac{5}{4}}). \end{cases} \tag{2.14}$$

Combining Propositions 2.1 and 2.2 and Theorem 2, we have the last theorem.

THEOREM 3. *Suppose the same assumptions as those in Theorem* 2. *Then the global solution to* (1.1), (1.2) *satisfies*

$$\begin{cases} \|v(t,\cdot) - (\bar{v}(\cdot) + \bar{\theta}_0(t,\cdot))\|_{L^\infty} \le C(1+t)^{-1}, \\ \|u(t,\cdot) - \bar{q}_{0x}(t,\cdot)\|_{L^\infty} \le C(1+t)^{-\frac{3}{2}}\log(2+t), \\ \|v(t,\cdot) - (\bar{v}(\cdot) + \bar{\theta}_0(t,\cdot))\|_{L^2} \le C(1+t)^{-\frac{3}{4}}, \\ \|u(t,\cdot) - \bar{q}_{0x}(t,\cdot)\|_{L^2} \le C(1+t)^{-\frac{5}{4}}. \end{cases} \tag{2.15}$$

Remark 3. If, eventually, $\int_R (v_0 - \bar{v})(x)dx = 0$, then we can put $(V, z)(t, x) = (\int_{-\infty}^{x}(v(t, y) - \bar{v}(y))dy, (u - \bar{u})(t, x))$, which yields the simpler problem

$$\begin{cases} V_t - z = 0, \\ z_t + \{p(V_x + \bar{v}, s) - p(\bar{v}, s)\}_x + z = 0. \end{cases}$$

In the result, we have $\|v(t, \cdot) - \bar{v}(\cdot)\|_{L^\infty} = O(t^{-1})$ instead of (2.15). Hence, the estimate (2.15) almost implies that the diffusion wave $\bar{\theta}_0(t, x)$ carries on the amount $\int_R (v_0(x) - \bar{v}(x))dx$. In (2.15), we could not remove $\log(2 + t)$.

The proofs of Theorems 1–3 will be done in sections 4–5.

3. Asymptotic behavior of the parabolic equation. In this section, we prove Propositions 2.1 and 2.2. By setting θ as

$$\theta := \tilde{v} - \bar{v}, \tag{3.1}$$

the Cauchy problem (2.1) is rewritten as

$$\begin{cases} \theta_t = q(\theta, x)_{xx}, \\ \theta|_{t=0} = \theta_0(x) \equiv \tilde{v}_0(x) - \bar{v}(x), \end{cases} \tag{3.2}$$

where

$$q(\theta, x) \equiv p(\bar{v}(x), s(x)) - p(\theta + \bar{v}(x), s(x)). \tag{3.3}$$

Applying the L^2-energy method, we first prove the following proposition.

PROPOSITION 3.1. *Suppose that $p(v, s)$ is a smooth function with $p > 0, p_v < 0$ for $v > 0$. If $(\theta_0, s_0 - \underline{s}) \in H^6(R) \times H^6(R)$ is sufficiently small, then there exists a unique global solution $\theta(t, x)$ to* (3.2)*, which satisfies that*

$$\begin{aligned} &\partial_t^i \theta \in C([0, \infty); H^{6-2i}(R)), \partial_t^j q_x \in C([0, \infty); H^{5-2j}(R)), \\ &\quad q_{tttx} \in L^2(0, \infty; L^2(R)), \end{aligned}$$

where $i = 0, 1, 2, 3$ and $j = 0, 1, 2$, and that

$$\begin{aligned} &\sum_{k=0}^{3}(1 + t)^{2k}\|\partial_t^k \theta(t)\|^2 + \sum_{k=0}^{2}(1 + t)^{2k+1}\|\partial_t^k q_x(t)\|^2 \\ &+ \int_0^t \left(\sum_{k=1}^{3}(1 + \tau)^{2k-1}\|\partial_t^k \theta(\tau)\|^2 + \sum_{k=0}^{3}(1 + \tau)^{2k}\|\partial_t^k q_x(\tau)\|^2\right) d\tau \\ &\leq C\|(\theta_0(\cdot), s_0(\cdot) - \underline{s})\|_6^2. \end{aligned} \tag{3.4}$$

Next, using the Green function, we obtain an asymptotic profile under the assumption of $\theta_0 \in L^1(R)$, which gives the optimal decay rates of θ.

PROPOSITION 3.2. *In addition to the assumptions in Proposition* 3.1*, suppose* *that* $(\theta_0, s_0 - \underline{s}) \in L^1(R) \times L^1(R)$. *Then the global solution* $\theta(t,x)$ *to* (3.2) *satisfies*

$$\begin{cases} \|(\theta - \bar{\theta}_0)(t,\cdot)\|_{L^\infty} \leq C(1+t)^{-1}, \\ \|(\theta - \bar{\theta}_0)_t(t,\cdot)\|_{L^\infty} \leq C(1+t)^{-2}, \\ \|(\theta - \bar{\theta}_0)_{tt}(t,\cdot)\|_{L^\infty} \leq C(1+t)^{-\frac{11}{4}}, \\ \|(\theta - \bar{\theta}_0)(t,\cdot)\|_{L^2} \leq C(1+t)^{-\frac{3}{4}}, \\ \|(\theta - \bar{\theta}_0)_t(t,\cdot)\|_{L^2} \leq C(1+t)^{-\frac{7}{4}}, \\ \|(\theta - \bar{\theta}_0)_{tt}(t,\cdot)\|_{L^2} \leq C(1+t)^{-\frac{5}{2}}. \end{cases} \tag{3.5}$$

Since

$$\begin{aligned} \tilde{u} &= -p(\theta + \bar{v}, s_0)_x = -\{p(\theta + \bar{v}, s_0) - p(\underline{v}, \underline{s})\}_x \\ &= -\{p(\theta + \bar{v}, s_0) - p(\bar{v}, s_0)\}_x = q_x, \end{aligned}$$

we also estimate $\tilde{u}$ by using the Green function. Differentiating q in t, we obtain $q_t = -p_v(\theta + \bar{v}, s_0)\theta_t$. Substituting this into (3.2), we have

$$q_t = -p_v(\theta + \bar{v}, s_0) q_{xx}. \tag{3.6}$$

Then the following proposition holds.

PROPOSITION 3.3. *Suppose the same assumptions as those in Proposition* 2.2. *Then the global solution* $q(t,x)$ *of* (3.6) *with* $\tilde{u} = q_x$ *satisfies*

$$\begin{cases} \|(q - \bar{q}_0)(t,\cdot)\|_{L^\infty} \leq C(1+t)^{-1}, \\ \|(q - \tilde{q}_0)_x(t,\cdot)\|_{L^\infty} \leq C(1+t)^{-\frac{3}{2}} \log(2+t), \\ \|(q - \bar{q}_0)(t,\cdot)\|_{L^2} \leq C(1+t)^{-\frac{3}{4}}, \\ \|(q - \tilde{q}_0)_x(t,\cdot)\|_{L^2} \leq C(1+t)^{-\frac{5}{4}}. \end{cases} \tag{3.7}$$

The assertions of Proposition 2.1 follow from Proposition 3.1 and 3.2, and those of Proposition 2.2 follow from Proposition 3.3. The proofs of Propositions 3.1 and 3.2 will be divided into several steps. Proposition 3.3 will be proved at the end of this section.

Proof of Proposition 3.1. The proof is given by the combination of the local existence with a priori estimates. Since the local existence theorem is obtained in a standard way [7], we devote ourselves to the estimates under the a priori assumption

$$N_1(T) := \sup_{0 \leq t \leq T} \left\{ \sum_{k=0}^{3} (1+t)^k \|\partial_t^k \theta(t)\| + \sum_{k=0}^{2} (1+t)^{k+\frac{1}{2}} \|\partial_t^k q_x(t)\| \right\} \leq \varepsilon. \tag{3.8}$$

Estimate 1. Multiplying $(3.2)_1$ by $q(\theta, x)$ and integrating it over $[0,t] \times R$, we get

$$\begin{aligned} &\int_R Q(\theta, x) dx + \int_0^t \int_R \{q(\theta, x)_x\}^2 dx d\tau \\ &\qquad = \int_R Q(\theta, x) dx \bigg|_{t=0} \leq C \|(\theta_0, s_0 - \underline{s})\|^2, \end{aligned} \tag{3.9}$$

where $Q(\theta, x) = \int_0^\theta q(\eta, x)d\eta$, which is equivalent to θ^2.

Estimate 2. Define $\bar{V} = q(\theta, x)_x$. Then

$$\bar{V}_t = q_{xt}. \tag{3.10}$$

Mutiplying (3.10) by $(1+t)\bar{V}$ and integrating it over R, we have

$$\frac{1}{2}\frac{d}{dt}\left\{(1+t)\int_R q_x^2 dx\right\} + (1+t)\int_R (-p_v)\theta_t^2 dx = \frac{1}{2}\int_R q_x^2 dx. \tag{3.11}$$

Integrating (3.11) and applying (3.9), we get

$$\begin{aligned} &(1+t)\int_R q_x^2 dx + \int_0^t (1+\tau)\int_R (-p_v)\theta_t^2 dx d\tau \\ &\le C\|(\theta_0, s_0 - \underline{s})\|_1^2. \end{aligned} \tag{3.12}$$

Estimate 3. Differentiate $(3.2)_1$ in t:

$$(\theta_t)_t = \{q(\theta, x)_t\}_{xx}. \tag{3.13}$$

Multiplying (3.13) by $(1+t)^2 q_t$ and integrating it over R, we have

$$\begin{aligned} &\frac{1}{2}\frac{d}{dt}\left\{(1+t)^2\int_R (-p_v)\theta_t^2 dx\right\} + (1+t)^2\int_R q_{tx}^2 dx \\ &= (1+t)\int_R (-p_v)\theta_t^2 dx - (1+t)^2\int_R (-p_v)_t\theta_t^2 dx \\ &\le (1+t)\int_R (-p_v)\theta_t^2 dx + C(1+t)^2 \sup|\theta_t| \int_R \theta_t^2 dx, \end{aligned} \tag{3.14}$$

and hence, by (3.12) and $N_1(T) \le \varepsilon$,

$$\begin{aligned} &(1+t)^2\int_R (-p_v)\theta_t^2 dx + \int_0^t (1+\tau)^2\int_R q_{tx}^2 dx d\tau \\ &\le C\|(\theta_0, s_0 - \underline{s})\|_2^2. \end{aligned} \tag{3.15}$$

Estimate 4. Multiply (3.13) by $-p_v(\theta + \bar{v}, s)$ to obtain

$$q_{tt} = (-p_v)q_{txx} + (-p_v)_t\theta_t. \tag{3.16}$$

Multiplying (3.16) by $(1+t)^3(-q_{txx})$ yields

$$\begin{aligned} &\frac{1}{2}\frac{d}{dt}\left\{(1+t)^3\int_R q_{tx}^2 dx\right\} + (1+t)^3\int_R (-p_v)q_{txx}^2 dx \\ &= \frac{3}{2}(1+t)^2\int_R q_{tx}^2 dx + (1+t)^3\int_R q_{txx}(p_v)_t\theta_t dx \end{aligned} \tag{3.17}$$

and

$$\begin{aligned} &(1+t)^3\int_R q_{tx}^2 dx + \int_0^t (1+\tau)^3\int_R (-p_v)q_{txx}^2 dx d\tau \\ &\le C\|(\theta_0, s_0 - \underline{s})\|_3^2 \end{aligned} \tag{3.18}$$

in a similar fashion to Estimate 3.

Estimate 5. Similar methods to Estimates 3 and 4 give the estimates

$$\begin{aligned}&(1+t)^4\int_R(-p_v)\theta_{tt}^2dx+\int_0^t(1+\tau)^4\int_R q_{ttx}^2dxd\tau\\&\quad\le C\|(\theta_0,s_0-\underline{s})\|_4^2,\end{aligned}\tag{3.19}$$

$$\begin{aligned}&(1+t)^5\int_R q_{ttx}^2dx+\int_0^t(1+\tau)^5\int_R(-p_v)q_{ttxx}^2dxd\tau\\&\quad\le C\|(\theta_0,s_0-\underline{s})\|_5^2,\end{aligned}\tag{3.20}$$

and

$$\begin{aligned}&(1+t)^6\int_R(-p_v)\theta_{ttt}^2dx+\int_0^t(1+\tau)^6\int_R q_{tttx}^2dxd\tau\\&\quad\le C\|(\theta_0,s_0-\underline{s})\|_6^2.\end{aligned}\tag{3.21}$$

Combining Estimates 1–5 completes the proof of Proposition 3.1. □

Remark 4. Since $q(\theta,x)=p(\bar{v},s)-p(\theta+\bar{v},s)=-p_v(\cdot,s)\theta$, the Sobolev inequality and (3.4) yield

$$\begin{aligned}\sup_R|\theta|&\le C\sup_R|q|\\&\le C\|q(t)\|^{\frac12}\|q_x(t)\|^{\frac12}\\&\le C\|\theta(t)\|^{\frac12}\|q_x(t)\|^{\frac12}\le C(1+t)^{-\frac14}.\end{aligned}\tag{3.22}$$

Due to $q_t=-p_v(\theta+\bar{v},s)\theta_t$, we have

$$\begin{aligned}\sup_R|\theta_t|&\le C\sup_R|q_t|\\&\le C\|q_t(t)\|^{\frac12}\|q_{tx}(t)\|^{\frac12}\\&\le C\|\theta_t(t)\|^{\frac12}\|q_{tx}(t)\|^{\frac12}\le C(1+t)^{-\frac54}.\end{aligned}\tag{3.23}$$

Since $q_{tt}=-p_{vv}\theta_t^2-p_v\theta_{tt}$,

$$\begin{aligned}\sup\nolimits_R|q_{tt}|&\le C\|q_{tt}(t)\|^{\frac12}\|q_{ttx}(t)\|^{\frac12}\\&\le C\left(\|\theta_t^2(t)\|+\|\theta_{tt}(t)\|\right)^{\frac12}\|q_{ttx}(t)\|^{\frac12}\\&\le C\left(\|\theta_t(t)\|_{L^\infty}\|\theta_t(t)\|+\|\theta_{tt}(t)\|\right)^{\frac12}\|q_{ttx}(t)\|^{\frac12}\\&\le C(1+t)^{-\frac94}\end{aligned}\tag{3.24}$$

and

$$\sup_R|\theta_{tt}|\le C\left(\sup_R|q_{tt}|+\sup_R|\theta_t(t)|^2\right).\tag{3.25}$$

Therefore,

$$\sup_R |\theta_{tt}(t)| \le C(1+t)^{-\frac{9}{4}}. \tag{3.26}$$

Proof of Proposition 3.2.

First step. We first investigate the Cauchy problem for the homogeneous linearized equation to $(3.2)_1$:

$$\begin{cases} \bar{\theta}_t = (a(x)\bar{\theta})_{xx}, \\ \bar{\theta}|_{t=0} = \theta_0(x), \end{cases} \tag{3.27}$$

where $a(x) \equiv -p_v(\bar{v}(x), s(x)) \to -p_v(\underline{v}, \underline{s}) \equiv \underline{a}$ as $x \to \pm\infty$. To obtain the precise decay estimates of $\bar{\theta}$, we here again combine the L^2-energy method with the explicit formula using the Green function. First, multiplying $(3.27)_1$ by $a(x)\bar{\theta}$ and integrating it over $[0,t] \times R$, we have

$$\frac{1}{2}\int_R a(x)\bar{\theta}^2 dx + \int_0^t \int_R \{(a(x)\bar{\theta})_x\}^2 dx d\tau = \frac{1}{2}\int_R a(x)\bar{\theta}_0^2 dx. \tag{3.28}$$

Next, multiplying $(3.27)_1$ by $a(x)$ and differentiating it in x, we obtain

$$(a(x)\bar{\theta})_{xt} = \{a(x)(a(x)\bar{\theta})_{xx}\}_x. \tag{3.29}$$

Multiplying (3.29) by $(1+t)(a(x)\bar{\theta})_x$ and integrating it over $[0,t] \times R$, we have

$$\begin{aligned} &\frac{1}{2}(1+t)\int_R \{(a(x)\bar{\theta})_x\}^2 dx + \int_0^t (1+\tau)\int_R a(x)\{(a(x)\bar{\theta})_{xx}\}^2 dx d\tau \\ &\quad = \frac{1}{2}\int_R \{(a(x)\bar{\theta}_0)_x\}^2 dx + \int_0^t \int_R \{(a(x)\bar{\theta})_x\}^2 dx d\tau. \end{aligned} \tag{3.30}$$

By virtue of (3.28) and $(a(x)\bar{\theta})_{xx} = \bar{\theta}_t$, we obtain

$$\begin{aligned} &(1+t)\int_R \{(a(x)\bar{\theta})_x\}^2 dx + \int_0^t (1+\tau)\int_R a(x)\left[\{(a(x)\bar{\theta})_{xx}\}^2 + \bar{\theta}_t^2\right] dx d\tau \\ &\quad \le C\|(\theta_0, s_0 - \underline{s})\|_1^2. \end{aligned} \tag{3.31}$$

Since $(\partial_t^k \bar{\theta})_t = (a(x)\partial_t^k \bar{\theta})_{xx}, k = 1, 2, 3,$ similar estimates to those above give the following.

Lemma 3.1. *If $(\theta_0, s - \underline{s}) \in H^6(R) \times H^6(R)$, then it holds that*

$$\begin{aligned} &\sum_{k=0}^{3}\left\{(1+t)^{2k}\int_R a(x)(\partial_t^k \bar{\theta})^2 dx + (1+t)^{2k+1}\int_R \{(a(x)\partial_t^k \bar{\theta})_x\}^2 dx\right\} \\ &\quad + \sum_{k=0}^{2}\int_0^t (1+\tau)^{2k}\int_R \{a(x)(\partial_t^k \bar{\theta})_x\}^2 dx d\tau \\ &\quad + \sum_{k=0}^{2}\int_0^t (1+\tau)^{2k+1}\int_R a(x)[\{(a(x)\partial_t^k \bar{\theta})_{xx}\}^2 + (\partial_t^k \bar{\theta}_t)^2] dx d\tau \\ &\quad \le C\|(\theta_0, s_0 - \underline{s})\|_6^2. \end{aligned} \tag{3.32}$$

Remark 5. By the Sobolev inequality and (3.32), we obtain

$$\begin{aligned}\sup_R|\bar{\theta}| &= \sup_R |a(x)^{-1}| \sup_R |a(x)\bar{\theta}| \\ &\le C\|\sqrt{a(x)}\bar{\theta}(t)\|^{\frac{1}{2}}\|(a(x)\bar{\theta})_x(t)\|^{\frac{1}{2}} \\ &\le C(1+t)^{-\frac{1}{4}},\end{aligned} \tag{3.33}$$

$$\begin{aligned}\sup_R|\bar{\theta}_t| &\le C\|\sqrt{a(x)}\bar{\theta}_t(t)\|^{\frac{1}{2}}\|(a(x)\bar{\theta}_t)_x(t)\|^{\frac{1}{2}} \\ &\le C(1+t)^{-\frac{5}{4}},\end{aligned} \tag{3.34}$$

and

$$\begin{aligned}\sup_R|\bar{\theta}_{tt}| &\le C\|\sqrt{a(x)}\bar{\theta}_{tt}(t)\|^{\frac{1}{2}}\|(a(x)\bar{\theta}_{tt})_x(t)\|^{\frac{1}{2}} \\ &\le C(1+t)^{-\frac{9}{4}}.\end{aligned} \tag{3.35}$$

Second step. Assuming that $\theta_0 \in L^1(R)$, we now obtain an asymptotic profile $\bar{\theta}_0$ of $\bar{\theta}$ defined in (2.6). Rewrite $(3.27)_1$ as

$$\bar{\theta}_t = \underline{a}\bar{\theta}_{xx} + \{(a(x)-\underline{a})\bar{\theta}\}_{xx}$$

to have the expression

(3.36)

$$\bar{\theta}(t,x) = \int_R G(t,x-y)\theta_0(y)dy + \int_0^t\int_R G(t-\tau,x-y)\{(a(y)-\underline{a})\bar{\theta}(\tau,y)\}_{yy}dyd\tau,$$

where

$$G(t,x) = \frac{1}{\sqrt{4\pi\underline{a}t}}\exp\left(-\frac{x^2}{4\underline{a}t}\right).$$

Integration by parts yields

$$\begin{aligned}&\int_{\frac{t}{2}}^t\int_R G\cdot\{(a(y)-\underline{a})\bar{\theta}(\tau,y)\}_{yy}dyd\tau \\ &\quad= -\frac{1}{\underline{a}}\int_{\frac{t}{2}}^t\int_R G_\tau\cdot(a(y)-\underline{a})\bar{\theta}(\tau,y)dyd\tau \\ &\quad= -\frac{1}{\underline{a}}\left[\int_R G\cdot(a(y)-\underline{a})\bar{\theta}(\tau,y)dy\right]_{\frac{t}{2}}^t + \frac{1}{\underline{a}}\int_{\frac{t}{2}}^t\int_R G\cdot(a(y)-\underline{a})\bar{\theta}_\tau(\tau,y)dyd\tau \\ &\quad= -\frac{1}{\underline{a}}(a(x)-\underline{a})\bar{\theta}(t,x) + \frac{1}{\underline{a}}\int_R G\left(\frac{t}{2},x-y\right)(a(y)-\underline{a})\bar{\theta}(\tau,y)dy \\ &\qquad+\frac{1}{\underline{a}}\int_{\frac{t}{2}}^t\int_R G\cdot(a(y)-\underline{a})\bar{\theta}_\tau(\tau,y)dyd\tau.\end{aligned}$$

Hence by (3.36)

$$
\begin{aligned}
(\bar\theta-\bar\theta_0)(t,x) &= \frac{1}{a(x)}\int_R G\left(\frac{t}{2},x-y\right)(a(y)-\underline{a})\bar\theta\left(\frac{t}{2},y\right)dy \\
&\quad+\frac{\underline{a}}{a(x)}\int_0^{\frac{t}{2}}\int_R G_{yy}(t-\tau,x-y)(a(y)-\underline{a})\bar\theta(\tau,y)dyd\tau \\
&\quad+\frac{1}{a(x)}\int_{\frac{t}{2}}^{t}\int_R G(t-\tau,x-y)(a(y)-\underline{a})\bar\theta_\tau(\tau,y)dyd\tau \\
&\equiv I_1+I_2+I_3.
\end{aligned}
\tag{3.37}
$$

Here we have used $\bar\theta_0=\frac{\underline{a}}{a(x)}\int_R G\cdot\theta_0(y)dy$.

By $\theta_0\in L^1(R)$, it is easy to see

$$
|\bar\theta_0(t,x)|\le Ct^{-\frac{1}{2}}. \tag{3.38}
$$

Since $s_0-\underline{s}\in L^1(R)$, $a(y)-\underline{a}\in L^1(R)$. Hence

$$
\begin{aligned}
|I_1| &\le C\sup_R\left|G\left(\frac{t}{2},x-y\right)\right|\sup_R\left|\bar\theta\left(\frac{t}{2},y\right)\right|\|a(\cdot)-\underline{a}\|_{L^1} \\
&\le Ct^{-\frac{3}{4}},
\end{aligned}
\tag{3.39}
$$

$$
\begin{aligned}
|I_2| &\le C\int_0^{\frac{t}{2}}\sup_R|G_{yy}|\sup_R|\bar\theta(\tau,y)|\|a(\cdot)-\underline{a}\|_{L^1}d\tau \\
&\le C\int_0^{\frac{t}{2}}(t-\tau)^{-\frac{3}{2}}(1+\tau)^{-\frac{1}{4}}d\tau, \\
&\le Ct^{-\frac{3}{4}},
\end{aligned}
\tag{3.40}
$$

and

$$
\begin{aligned}
|I_3| &\le C\int_{\frac{t}{2}}^{t}\sup_R|G|\sup_R|\bar\theta_\tau(\tau,y)|\|a(\cdot)-\underline{a}\|_{L^1}d\tau \\
&\le C\int_0^{\frac{t}{2}}(t-\tau)^{-\frac{1}{2}}(1+\tau)^{-\frac{5}{4}}d\tau \\
&\le Ct^{-\frac{3}{4}}.
\end{aligned}
\tag{3.41}
$$

Here we have used (3.33) and (3.34). Combining (3.37)–(3.41), we obtain

$$
\sup_R|(\bar\theta-\bar\theta_0)(t,x)|\le Ct^{-\frac{3}{4}}. \tag{3.42}
$$

Next, we estimate $\sup_R |(\bar\theta - \bar\theta_0)_t(t,x)|$. Differentiate (3.37) in t to have

$$\begin{aligned}(\bar\theta-\bar\theta_0)_t(t,x) &= \frac{1}{a(x)}\int_R G_t\left(\frac{t}{2},x-y\right)(a(y)-\underline{a})\bar\theta\left(\frac{t}{2},y\right)dy\\ &+\frac{1}{a(x)}\int_R G\left(\frac{t}{2},x-y\right)(a(y)-\underline{a})\bar\theta_\tau\left(\frac{t}{2},y\right)dy\\ &+\frac{\underline{a}}{a(x)}\int_0^{\frac{t}{2}}\int_R G_{yyt}\cdot(a(y)-\underline{a})\bar\theta(\tau,y)dyd\tau\\ &+\frac{1}{a(x)}\int_{\frac{t}{2}}^{t}\int_R G\cdot(a(y)-\underline{a})\bar\theta_{\tau\tau}(\tau,y)dyd\tau.\end{aligned} \tag{3.43}$$

In a similar fashion to the previous estimates, we have

$$\sup_R |(\bar\theta-\bar\theta_0)_t(t,x)| \le Ct^{-\frac{7}{4}}. \tag{3.44}$$

Differentiating (3.43) in t, we also obtain

$$\sup_R |(\bar\theta-\bar\theta_0)_{tt}(t,x)| \le Ct^{-\frac{11}{4}}. \tag{3.45}$$

Here, we go back to (3.37). By virtue of (3.42) and (3.44),

$$\begin{cases}\sup_R|\bar\theta(t,x)| \le \sup_R|\bar\theta_0(t,x)| + Ct^{-\frac{3}{4}} \le Ct^{-\frac{1}{2}},\\ \sup_R|\bar\theta_t(t,x)| \le \sup_R|(\bar\theta_0)_t(t,x)| + Ct^{-\frac{7}{4}} \le Ct^{-\frac{3}{2}}.\end{cases} \tag{3.46}$$

Therefore, applying (3.46), instead of (3.33) and (3.34), to (3.37), we obtain

$$\sup_R |\bar\theta(t,x)-\bar\theta_0(t,x)| \le Ct^{-1}. \tag{3.47}$$

Similarly, we have

$$\sup_R |(\bar\theta-\bar\theta_0)_t(t,x)| \le Ct^{-2}. \tag{3.48}$$

However, this method is not applicable to $(\bar\theta-\bar\theta_0)_{tt}$ because we have $\bar\theta_{ttt}$ in the expression of $(\bar\theta-\bar\theta_0)_{tt}$.

The L^2-estimates to $\bar\theta-\bar\theta_0$ are also obtained by applying the Hausdorff–Young inequality. Thus we have the following lemma.

Lemma 3.2. *In addition to the assumption in Lemma* 3.1*, if* $(\theta_0, s-\underline{s}) \in L^1(R)\times L^1(R)$*, then it holds that as* $t\to\infty$*,*

$$\begin{cases}\|((\bar\theta-\bar\theta_0),(\bar\theta-\bar\theta_0)_t,(\bar\theta-\bar\theta_0)_{tt})(t,\cdot)\|_{L^\infty} = O(t^{-1},t^{-2},t^{-\frac{11}{4}}),\\ \|((\bar\theta-\bar\theta_0),(\bar\theta-\bar\theta_0)_t,(\bar\theta-\bar\theta_0)_{tt})(t,\cdot)\|_{L^2} = O(t^{-\frac{3}{4}},t^{-\frac{7}{4}},t^{-\frac{5}{2}}).\end{cases} \tag{3.49}$$

Third step. We now turn to (3.2). The perturbation $\Theta := \theta-\bar\theta$ satisfies

$$\begin{cases}\Theta_t = (a(x)\Theta)_{xx} + \Phi(\theta,x)_{xx},\\ \Theta|_{t=0} = 0,\end{cases} \tag{3.50}$$

where

$$\Phi(\theta, x) = -\{p(\theta + \bar{v}, s) - p(\bar{v}, s) - p_v(\bar{v}, s)\theta\}. \tag{3.51}$$

Similar to (3.37), we have the expression

$$\begin{aligned}
\Theta(t, x) &= \frac{1}{a(x)} \int_R G\left(\frac{t}{2}, x - y\right)(a(y) - \underline{a})\Theta\left(\frac{t}{2}, y\right) dy \\
&\quad + \frac{1}{a(x)} \int_0^{\frac{t}{2}} \int_R G_t \cdot (a(y) - \underline{a})\Theta(\tau, y) dy d\tau \\
&\quad + \frac{1}{a(x)} \int_{\frac{t}{2}}^{t} \int_R G \cdot (a(y) - \underline{a})\Theta_\tau(\tau, y) dy d\tau \\
&\quad + \frac{\underline{a}}{a(x)} \int_0^{\frac{t}{2}} \int_R G_{yy} \cdot \Phi dy d\tau + \frac{1}{a(x)} \int_{\frac{t}{2}}^{t} \int_R G_t \cdot \Phi(\tau, y) dy d\tau \\
&\equiv II_1 + II_2 + II_3 + II_4 + II_5.
\end{aligned} \tag{3.52}$$

We estimate each term in (3.52). By virtue of (3.22), (3.23), and (3.46),

$$\begin{aligned}
\|\Theta(t)\|_{L^\infty} &\leq \|\theta(t)\|_{L^\infty} + \|\bar{\theta}(t)\|_{L^\infty} \\
&\leq C(1 + t)^{-\frac{1}{4}}
\end{aligned} \tag{3.53}$$

and

$$\begin{aligned}
\|\Theta_t(t)\|_{L^\infty} &\leq \|\theta_t(t)\|_{L^\infty} + \|\bar{\theta}_t(t)\|_{L^\infty} \\
&\leq C(1 + t)^{-\frac{5}{4}}.
\end{aligned} \tag{3.54}$$

Hence II_1–II_3 are easily estimated as

$$|II_1, II_2, II_3| \leq Ct^{-\frac{3}{4}}. \tag{3.55}$$

Estimates of II_4 and II_5 are as follows:

$$\begin{aligned}
|II_4| &\leq C \int_0^{\frac{t}{2}} \sup_R |\Phi| \|G_{yy}(t - \tau)\|_{L^1} d\tau \\
&\leq C \int_0^{\frac{t}{2}} \sup_R |\theta|^2 (t - \tau)^{-1} d\tau \\
&\leq Ct^{-\frac{1}{2}}
\end{aligned} \tag{3.56}$$

and

$$
\begin{aligned}
|II_5| &\leq C \left| -\left[\int_R G\Phi(\tau,y)dy\right]_{\frac{t}{2}}^{t} + \int_{\frac{t}{2}}^{t}\int_R G\Phi_\tau(\tau,y)dyd\tau \right| \\
&\leq C\left\{ |\Phi(\theta,x)| + \left|\int_R G\left(\frac{t}{2},x-y\right)\Phi dy\right| \right. \\
&\qquad\qquad \left. + \int_{\frac{t}{2}}^{t} \sup_R |\Phi_\tau(\tau,y)| \|G(t-\tau)\|_{L^1} d\tau \right\} \\
&\leq C\left\{ \sup_R |\theta|^2 + \int_{\frac{t}{2}}^{t} \sup_R|\theta| \sup_R |\theta_t| d\tau \right\} \\
&\leq Ct^{-\frac{1}{2}}.
\end{aligned} \tag{3.57}
$$

Therefore, we obtain

$$
\|\Theta(t)\|_{L^\infty} \leq C(1+t)^{-\frac{1}{2}}, \tag{3.58}
$$

and hence

$$
\|\theta(t)\|_{L^\infty} \leq \|\Theta(t)\|_{L^\infty} + \|\bar{\theta}(t)\|_{L^\infty} \leq C(1+t)^{-\frac{1}{2}}. \tag{3.59}
$$

Applying (3.54) and (3.58), instead of (3.53), to (3.52) again, we have

$$
\|\Theta(t)\|_{L^\infty} \leq C(1+t)^{-\frac{3}{4}}. \tag{3.60}
$$

If we obtain faster decay of $\|\Theta_t(t)\|_{L^\infty}$ than (3.54), then $\|\Theta(t)\|_{L^\infty}$ will decay faster than (3.60). Hence we next estimate $\|\Theta_t(t)\|_{L^\infty}$ using the explicit formula. Since Θ_t satisfies

$$
\begin{cases}
(\Theta_t)_t = (\underline{a}\Theta_t)_{xx} + \{(a(x)-\underline{a})\Theta_t\}_{xx} + (\Phi(\theta,x)_t)_{xx}, \\
\Theta_t|_{t=0} = \Phi(\theta_0,x)_{xx},
\end{cases} \tag{3.61}
$$

we also have the expression, similar to (3.52),

$$
\begin{aligned}
\Theta_t(t,x) &= \frac{\underline{a}}{a(x)}\int_R G\left(\frac{t}{2},x-y\right)(a(y)-\underline{a})\Theta_t\left(\frac{t}{2},y\right)dy \\
&\quad + \frac{1}{a(x)}\int_0^{\frac{t}{2}}\int_R G_t\cdot(a(y)-\underline{a})\Theta_t(\tau)dyd\tau + \frac{1}{a(x)}\int_{\frac{t}{2}}^{t}\int_R G\cdot(a(y)-\underline{a})\Theta_{tt}(\tau)dyd\tau \\
&\quad + \frac{1}{a(x)}\left\{\int_R G_t\left(\frac{t}{2},x-y\right)\Phi\left(\frac{t}{2}\right)dy + \int_0^{\frac{t}{2}}\int_R G_{tt}\cdot\Phi dyd\tau\right\} \\
&\quad + \frac{1}{a(x)}\left\{\int_{\frac{t}{2}}^{t}\int_R G\cdot\Phi_{tt}(\tau,y)dyd\tau + \int_R G\left(\frac{t}{2},x-y\right)\Phi_t dy - \Phi_t(\theta,x)\right\}. \\
&\equiv III_1 + III_2 + III_3 + III_4 + III_5.
\end{aligned} \tag{3.62}
$$

Applying (3.54) and (3.59), we obtain

$$
\begin{aligned}
|III_1| &\le C\sup_R\left|G\left(\frac{t}{2}\right)\right|\sup_R|\Theta_t|\|a(\cdot)-\underline{a}\|_{L^1}\\
&\le Ct^{-\frac{7}{4}}, \qquad (3.63)
\end{aligned}
$$

$$
\begin{aligned}
|III_2| &\le C\|a(\cdot)-\underline{a}\|_{L^1}\int_0^{\frac{t}{2}}\sup_R|G_t(t-\tau)|\sup_R|\Theta_t(\tau,y)|d\tau\\
&\le C\int_0^{\frac{t}{2}}(t-\tau)^{-\frac{3}{2}}(1+\tau)^{-\frac{5}{4}}d\tau \qquad (3.64)\\
&\le Ct^{-\frac{7}{4}},
\end{aligned}
$$

and

(3.65)

$$
\begin{aligned}
|III_4| &\le C\left\{\sup_R\left|G_t\left(\frac{t}{2}\right)\right|\sup_R\left|\Phi\left(\frac{t}{2},y\right)\right|+\int_0^{\frac{t}{2}}\|G_{tt}(t-\tau)\|_{L^1}\sup_R|\Phi(\tau,y)|d\tau\right\}\\
&\le C\left\{(1+t)^{-1-1}+\int_0^{\frac{t}{2}}(t-\tau)^{-2}(1+\tau)^{-1}d\tau\right\}\\
&\le C(1+t)^{-2}\log(2+t).
\end{aligned}
$$

Since

$$
\|\Theta_{tt}(t)\|_{L^\infty}\le\|\theta_{tt}(t)\|_{L^\infty}+\|\bar{\theta}_{tt}(t)\|_{L^\infty}\le C(1+t)^{-\frac{9}{4}}
$$

by (3.26), (3.49), and $\|(\bar{\theta}_0)_{tt}(t)\|_{L^\infty}\le C(1+t)^{-\frac{5}{2}}$, we have

$$
\begin{aligned}
|III_3| &\le C\|a(\cdot)-\underline{a}\|_{L^1}\int_{\frac{t}{2}}^t\sup_R|G(t-\tau)|\sup_R|\Theta_{tt}(\tau,y)|d\tau\\
&\le C\int_{\frac{t}{2}}^t(t-\tau)^{-\frac{1}{2}}(1+\tau)^{-\frac{9}{4}}d\tau\le Ct^{-\frac{7}{4}} \qquad (3.66)
\end{aligned}
$$

and

$$
\begin{aligned}
|III_5| &\le C\bigg\{\int_{\frac{t}{2}}^t\|G(t-\tau)\|_{L^1}\sup_R|\Phi_{tt}(\tau)|d\tau+\left\|G\left(\frac{t}{2}\right)\right\|_{L^1}\sup_R\left|\Phi_t\left(\frac{t}{2}\right)\right|\\
&\qquad+\sup_R|\Phi_t(t,y)|\bigg\}\\
&\le C\bigg\{\int_{\frac{t}{2}}^t(\sup_R|\theta_t(\tau)|^2+\sup_R|\theta(\tau)|\sup_R|\theta_{tt}(\tau)|)d\tau \qquad (3.67)\\
&\qquad+\sup_R\left|\theta\left(\frac{t}{2}\right)\right|\sup_R\left|\theta_t\left(\frac{t}{2}\right)\right|+\sup_R|\theta(t)|\sup_R|\theta_t(t)|\bigg\}\\
&\le C\left\{\int_{\frac{t}{2}}^t(1+\tau)^{-\frac{5}{2}}d\tau+(1+t)^{-\frac{7}{4}}\right\}\le Ct^{-\frac{3}{2}}.
\end{aligned}
$$

Here we have used $|\partial_t \Phi(\theta, x)| \le C|\theta||\theta_t|, |\partial_{tt}\Phi(\theta, x)| \le C(|\theta_t|^2 + |\theta||\theta_{tt}|)$. Combining (3.62)–(3.67) we have

$$\|\Theta_t(t)\|_{L^\infty} \le Ct^{-\frac{3}{2}}, \tag{3.68}$$

and hence

$$\|\theta_t(t)\|_{L^\infty} \le \|\Theta_t(t)\|_{L^\infty} + \|\bar{\theta}_t(t)\|_{L^\infty} \le Ct^{-\frac{3}{2}}. \tag{3.69}$$

Applying (3.68), instead of (3.54), and (3.69) to (3.62) again, we have

$$\|\Theta_t(t)\|_{L^\infty} \le C(1+t)^{-\frac{7}{4}}. \tag{3.70}$$

We now go back to the estimate of $\|\Theta(t)\|_{L^\infty}$. Applying (3.60) and (3.70) to (3.52), we obtain the sharper estimate

$$\|\Theta(t)\|_{L^\infty} \le C(1+t)^{-1}\log(2+t). \tag{3.71}$$

By differentiating $(3.61)_1$ with respect to t, we have the explicit formula of Θ_{tt}, similar to (3.62). Estimating all terms, we obtain

$$\|\Theta_{tt}(t)\|_{L^\infty} \le C(1+t)^{-\frac{11}{4}}, \tag{3.72}$$

the details of which are omitted. If we apply (3.72) to (3.62), then we get

$$\|\Theta_t(t)\|_{L^\infty} \le C(1+t)^{-2}\log(2+t). \tag{3.73}$$

The L^2-estimates of Θ are also obtained by the Hausdorff–Young inequality:

$$\begin{cases} \|\Theta(t)\|_{L^2} \le C(1+t)^{-\frac{3}{4}}, \\ \|\Theta_t(t)\|_{L^2} \le C(1+t)^{-\frac{7}{4}}, \\ \|\Theta_{tt}(t)\|_{L^2} \le C(1+t)^{-\frac{5}{2}}. \end{cases} \tag{3.74}$$

Once more, applying (3.74) to (3.52) and (3.62), we obtain

$$\begin{cases} \|\Theta(t)\|_{L^\infty} \le C(1+t)^{-1}, \\ \|\Theta_t(t)\|_{L^\infty} \le C(1+t)^{-2}. \end{cases} \tag{3.75}$$

Thus we obtain the following lemma.

LEMMA 3.3. *In addition to the assumptions in Lemma* 3.1, *if* $(\theta_0, s - \underline{s}) \in L^1(R) \times L^1(R)$, *then it holds that as* $t \to \infty$,

$$\begin{cases} \|(\Theta, \Theta_t, \Theta_{tt})(t, \cdot)\|_{L^\infty} = O(t^{-1}, t^{-2}, t^{-\frac{11}{4}}), \\ \\ \|(\Theta, \Theta_t, \Theta_{tt})(t, \cdot)\|_{L^2} = O(t^{-\frac{3}{4}}, t^{-\frac{7}{4}}, t^{-\frac{5}{2}}). \end{cases} \tag{3.76}$$

Combining Lemmas 3.2 and 3.3, we conclude the proof of Proposition 3.2. □

Proof of Proposition 3.3. Rewrite (3.6) as

$$q_t - \underline{a}q_{xx} = -\{p_v(\theta + \bar{v}, s_0) + \underline{a}\}q_{xx} \tag{3.77}$$

to have the expression

(3.78)

$$q(t,x)=\int_R G(t,x-y)q_0(y)dy-\int_0^t\int_R G(t-\tau,x-y)\{p_v(\theta+\bar{v},s_0)+\underline{a}\}q_{yy}dyd\tau.$$

Here we put $q(0,x)=q_0(x)$ and $\underline{a}=-p_v(\underline{v},\underline{s})$. Integration by parts yields

(3.79)

$$\begin{aligned}&-\int_0^{\frac{t}{2}}\int_R G(t-\tau,x-y)\{p_v(\theta+\bar{v},s_0)+\underline{a}\}q_{yy}dyd\tau\\&\quad=\int_0^{\frac{t}{2}}\int_R G(t-\tau,x-y)(q_\tau-\underline{a}\theta_\tau)dyd\tau\\&\quad=\left\{\left[\int_R G(t-\tau,x-y)(q-\underline{a}\theta)dy\right]_0^{\frac{t}{2}}-\int_0^{\frac{t}{2}}\int_R G_\tau(t-\tau,x-y)(q-\underline{a}\theta)dyd\tau\right\}.\end{aligned}$$

Thus we obtain

(3.80)

$$\begin{aligned}(q-\bar{q}_0)(t,x)=&\int_R G\cdot(q-\underline{a}\theta)dy\Big|_{\tau=\frac{t}{2}}-\int_0^{\frac{t}{2}}\int_R G_\tau(t-\tau,x-y)(q-\underline{a}\theta)dyd\tau\\&-\int_{\frac{t}{2}}^t\int_R G(t-\tau,x-y)\{p_v(\theta+\bar{v},s_0)+\underline{a}\}q_{yy}dyd\tau\end{aligned}$$

and

(3.81)

$$\begin{aligned}(q-\bar{q}_0)_x(t,x)=&\int_R G_x\cdot(q-\underline{a}\theta)dy\Big|_{\tau=\frac{t}{2}}-\int_0^{\frac{t}{2}}\int_R G_{x\tau}(t-\tau,x-y)(q-\underline{a}\theta)dyd\tau\\&-\int_{\frac{t}{2}}^t\int_R G_x(t-\tau,x-y)\{p_v(\theta+\bar{v},s_0)+\underline{a}\}q_{yy}dyd\tau.\end{aligned}$$

Here we have used $\bar{q}_0(t,x)=\underline{a}\int_R G(t,x-y)\theta_0(y)dy$. Dividing the final term of (3.81) as

$$-\left(\int_{\frac{t}{2}}^{t-1}+\int_{t-1}^t\right)\int_R G_x\cdot\{p_v(\theta+\bar{v},s_0)+\underline{a}\}q_{yy}dyd\tau=(i)+(ii),$$

we seek the L^∞-estimate of (i) and (ii). Noting that

$$\begin{cases}q-\underline{a}\theta=-\{p(\theta+\bar{v},s_0)-p(\bar{v},s_0)-p_v(\bar{v},s_0)\theta+(p_v(\bar{v},s_0)-p_v(\underline{v},\underline{s}))\theta\}\\ \qquad\quad=O(|\theta|^2+|a(x)-\underline{a}||\theta|),\\ p_v(\theta+\bar{v},s_0)+\underline{a}=p_v(\theta+\bar{v},s_0)-p_v(\bar{v},s_0)+p_v(\bar{v},s_0)-p_v(\underline{v},\underline{s})\\ \qquad\qquad\qquad\quad=O(|\theta|+|a(x)-\underline{a}|),\end{cases}$$

we obtain

$$\begin{aligned}
|(i)| &\leq C\int_{\frac{t}{2}}^{t-1}\int_R |G|(|\theta|+|a(y)-\underline{a}|)|\theta_\tau|dyd\tau\\
&\leq C\int_{\frac{t}{2}}^{t-1}\|G(t-\tau)\|_{L^\infty}\left(\|\theta(\tau)\|_{L^2}\|\theta_\tau(\tau)\|_{L^2}+\|a(y)-\underline{a}\|_{L^1}\|\theta_\tau(\tau)\|_{L^\infty}\right)d\tau\\
&\leq C\int_{\frac{t}{2}}^{t-1}(t-\tau)^{-1}(1+\tau)^{-\frac{3}{2}}d\tau \leq Ct^{-\frac{3}{2}}\log(2+t)
\end{aligned}$$

and

$$\begin{aligned}
|(ii)| &\leq C\int_{t-1}^{t}\|G(t-\tau)\|_{L^2}\|\theta_\tau(\tau)\|_{L^\infty}\left(\|\theta(\tau)\|_{L^2}+\|a(y)-\underline{a}\|_{L^2}\right)d\tau\\
&\leq C\int_{t-1}^{t}(t-\tau)^{-\frac{3}{4}}(1+\tau)^{-\frac{3}{2}}d\tau \leq Ct^{-\frac{3}{2}}.
\end{aligned}$$

The other terms are estimated in a similar fashion to Proposition 3.2. The details are omitted. □

4. Pointwise estimate by the approximate Green function. In this final section, we devote ourselves to the proof of Theorem 2. In an expression obtained by differentiating V of (2.13) in x, $\int_{\frac{t}{2}}^{t}\int_R G_x\cdot\{(p_v(\tilde{v},s)+\underline{a})V_y\}_y dyd\tau$ is rewritten as follows:

$$\begin{aligned}
&-\int_{\frac{t}{2}}^{t}\int_R G_x\cdot\{(p_v(\tilde{v},s)+\underline{a})V_y\}_y dyd\tau\\
&=-\int_{\frac{t}{2}}^{t}\int_R G_{yy}\cdot(p_v(\tilde{v},s)+\underline{a})V_y dyd\tau\\
&=\frac{1}{\underline{a}}\int_{\frac{t}{2}}^{t}\int_R G_\tau\cdot(p_v(\tilde{v},s)+\underline{a})V_y dyd\tau\\
&=\frac{1}{\underline{a}}\left\{\left[\int_R G\cdot(p_v(\tilde{v},s)+\underline{a})V_y dy\right]_{\frac{t}{2}}^{t}-\int_{\frac{t}{2}}^{t}\int_R G\cdot\{(p_v(\tilde{v},s)+\underline{a})V_y\}_\tau dyd\tau\right\}\\
&=\frac{(p_v(\tilde{v},s)+\underline{a})}{\underline{a}}V_x(t,x)-\frac{1}{\underline{a}}\int_R G\cdot(p_v(\tilde{v},s)+\underline{a})V_y dy\Big|_{\tau=\frac{t}{2}}\\
&\quad-\frac{1}{\underline{a}}\int_{\frac{t}{2}}^{t}\int_R G\cdot\{(p_v(\tilde{v},s)+\underline{a})V_y\}_\tau dyd\tau,
\end{aligned}$$

where G is defined in (2.6) and $\underline{a}=-p_v(\underline{v},\underline{s})$. Hence

$$
\begin{aligned}
V_x(t,x) &= \frac{\underline{a}}{-p_v(\tilde{v},s)}\int_R G_x(t,x-y)V_0(y)dy \\
&\quad -\frac{\underline{a}}{-p_v(\tilde{v},s)}\left(\int_0^{\frac{t}{2}}+\int_{\frac{t}{2}}^t\right)\int_R G_x\{F_y+V_{\tau\tau}\}dyd\tau \\
&\quad +\frac{\underline{a}}{-p_v(\tilde{v},s)}\left(\int_0^{\frac{t}{2}}+\int_{\frac{t}{2}}^t\right)\int_R G_x p(\tilde{v},s)_{y\tau}dyd\tau \\
&\quad -\frac{1}{-p_v(\tilde{v},s)}\int_R \left(p_v(\tilde{v},s)+\underline{a}\right)G\left(\frac{t}{2}\right)V_y\left(\frac{t}{2}\right)dy \\
&\quad -\frac{\underline{a}}{-p_v(\tilde{v},s)}\int_0^{\frac{t}{2}}\int_R \left(p_v(\tilde{v},s)+\underline{a}\right)G_{yy}V_y dyd\tau \\
&\quad -\frac{1}{-p_v(\tilde{v},s)}\int_{\frac{t}{2}}^t\int_R \left\{\left(p_v(\tilde{v},s)+\underline{a}\right)V_y\right\}_\tau Gdyd\tau \\
&= J_1+(J_{21}+J_{22})+(J_{31}+J_{32})+J_4+J_5+J_6.
\end{aligned}
\tag{4.1}
$$

By $V_0 \in L^1(R)$, it is easy to see

$$
|J_1| \le Ct^{-1}. \tag{4.2}
$$

To estimate all other terms, we use (2.5) in Proposition 2.1 and (2.11) in Theorem 1. Integration by parts in x yields

$$
\begin{aligned}
|J_{21}| &\le C\left|\int_0^{\frac{t}{2}}\left(\int_R G_{yy}Fdy+\int_R G_y z_\tau dy\right)d\tau\right| \\
&\le C\left[\int_0^{\frac{t}{2}}\int_R |G_{yy}||F|dyd\tau+\left|\left[\int_R G_y zdy\right]_0^{\frac{t}{2}}-\int_0^{\frac{t}{2}}\int_R G_{y\tau}zdyd\tau\right|\right] \\
&\le C\left[\int_0^{\frac{t}{2}}\sup_R|G_{yy}(t-\tau)|\|V_y(\tau)\|^2d\tau+\left\|G_y\left(\frac{t}{2}\right)\right\|\left\|z\left(\frac{t}{2}\right)\right\|\right. \\
&\qquad \left.+\sup_R|G_y(t)|\|z(0)\|_{L^1}+\int_0^{\frac{t}{2}}\|G_\tau(t-\tau)\|\|z_y(\tau)\|d\tau\right] \\

&=C\left|\left[\int_R Gp(\tilde{v},s)_\tau dy\right]_{\frac{t}{2}}^{t}-\int_{\frac{t}{2}}^{t}\int_R Gp(\tilde{v},s)_{\tau\tau}dyd\tau\right|\\
&\le C\Bigg\{\sup_R|\tilde{v}_\tau(t)|+\sup_R\left|\tilde{v}_\tau\left(\frac{t}{2}\right)\right|\left\|G\left(\frac{t}{2}\right)\right\|_{L^1}\\
&\qquad+\int_{\frac{t}{2}}^{t}\left(\sup_R|\tilde{v}_\tau|^2+\sup_R|\tilde{v}_{\tau\tau}|\right)\|G(t-\tau)\|_{L^1}d\tau\Bigg\}\\
&\le C\left(t^{-\frac{3}{2}}+t^{-\frac{5}{2}+1}\right)\le Ct^{-\frac{3}{2}}.
\end{aligned}
\tag{4.6}
$$

For the last three terms, we have

$$
\begin{aligned}
|J_4|&\le C\left(\sup_R|V_y(t)|\|\tilde{v}(t,\cdot)-\bar{v}(\cdot)\|\left\|G\left(\frac{t}{2}\right)\right\|+\|s(\cdot)-\underline{s}\|_{L^1}\sup_R\left|G\left(\frac{t}{2}\right)\right|\sup_R|V_y(t)|\right)\\
&\le C\left(t^{-\frac{3}{4}-\frac{1}{4}-\frac{1}{4}}+t^{-\frac{1}{2}-\frac{3}{4}}\right)\le Ct^{-\frac{5}{4}},
\end{aligned}
\tag{4.7}
$$

$$
\begin{aligned}
|J_5| &\le C\left(\int_0^{\frac{t}{2}}\sup_R|V_y(\tau)|\|\tilde{v}(t,\cdot)-\bar{v}(\cdot)\|\|G_{yy}(t-\tau)\|d\tau\right.\\
&\qquad\qquad \left.+\|s(\cdot)-\underline{s}\|_{L^1}\int_0^{\frac{t}{2}}\sup_R|G_{yy}(t-\tau)|\sup_R|V_y(\tau)|d\tau\right)\\
&\le C\left(\int_0^{\frac{t}{2}}(1+\tau)^{-\frac{3}{4}}(1+\tau)^{-\frac{1}{4}}(t-\tau)^{-\frac{5}{4}}d\tau+\int_0^{\frac{t}{2}}(t-\tau)^{-\frac{3}{2}}(1+\tau)^{-\frac{3}{4}}d\tau\right)\\
&\le C\left\{t^{-\frac{5}{4}}\log(2+t)+t^{-\frac{3}{2}+\frac{1}{4}}\right\}\le Ct^{-\frac{5}{4}}\log(2+t),
\end{aligned}
\tag{4.8}
$$

and

$$
\begin{aligned}
|J_6| \le C&\left(\int_{\frac{t}{2}}^{t}\sup_R|z_y(\tau)|\|G(t-\tau)\|\|\tilde{v}(t,\cdot)-\bar{v}(\cdot)\|d\tau\right.\\
&\qquad+\|s(\cdot)-\underline{s}\|_{L^1}\int_{\frac{t}{2}}^{t}\sup_R|z_y(\tau)|\sup_R|G(t-\tau)|d\tau\\
&\qquad\left.+C\int_{\frac{t}{2}}^{t}\sup_R|\tilde{v}_t(\tau)|\sup_R|V_y(\tau)|\|G(t-\tau)\|_{L^1}d\tau\right)\\
\le C&\left(t^{-\frac{3}{2}-\frac{1}{4}+\frac{3}{4}}+t^{-\frac{3}{2}+\frac{1}{2}}+t^{-\frac{3}{2}-\frac{3}{4}+1}\right)\le Ct^{-1}.
\end{aligned}
\tag{4.9}
$$

Combining (4.2)–(4.9) we have the desired rate

$$
\sup_R|V_x(t,x)|\le Ct^{-1}. \tag{4.10}
$$

Next, we estimate $\sup_x|z(t,x)|$ in a similar way to that above. Differentiating (2.13) in t, we have

$$
\begin{aligned}
z(t,x)=&\int_R G_t(t,x-y)V_0(y)dy+\int_R G\cdot p(\tilde{v},s)_{y\tau}dy\Big|_{\tau=\frac{t}{2}}\\
&-\left\{\int_0^{\frac{t}{2}}\int_R G_\tau\cdot p(\tilde{v},s)_{y\tau}dyd\tau-\int_{\frac{t}{2}}^{t}\int_R G\cdot p(\tilde{v},s)_{y\tau\tau}dyd\tau\right\}\\
&-\int_R G\cdot\{F_y+V_{\tau\tau}\}dy\Big|_{\tau=\frac{t}{2}}\\
&+\left\{\int_0^{\frac{t}{2}}\int_R G_t\{F_y+V_{\tau\tau}\}dyd\tau+\int_{\frac{t}{2}}^{t}\int_R G\cdot\{F_{yt}+V_{\tau\tau\tau}\}dyd\tau\right\}\\
&-\int_R\left\{(p_v(\tilde{v},s)+\underline{a})\,G_y\right\}_y Vdy\Big|_{\tau=\frac{t}{2}}\\
&-\int_0^{\frac{t}{2}}\int_R\left\{(p_v(\tilde{v},s)+\underline{a})\,G_y\right\}_{yt}Vdyd\tau\\
&-\int_{\frac{t}{2}}^{t}\int_R\left\{(p_v(\tilde{v},s)+\underline{a})\,V_y\right\}_\tau G_ydyd\tau.
\end{aligned}
\tag{4.11}
$$

Here we have used the integration by parts to gather the derivatives of G in the part on the domain $\left[0,\frac{t}{2}\right]$ and, on the other hand, to gather those in the other part on the domain $\left[\frac{t}{2}, t\right]$. By almost the same calculations as the estimate of $\sup_R |V_x(t,x)|$, we have the desired rate

$$\sup_R |z(t,x)| \leq Ct^{-\frac{3}{2}}. \tag{4.12}$$

Applying the Hausdorff–Young inequality, we also have the L^2-estimate

$$\|(V_x, z)(t,\cdot)\|_{L^2} = O(t^{-\frac{3}{4}}, t^{-\frac{5}{4}}),$$

which completes the proof of Theorem 2. □

Remark 6. We can also get

$$\|V(t,\cdot)\|_{L^\infty} \leq Ct^{-\frac{1}{2}}, \quad \|V(t,\cdot)\|_{L^2} \leq Ct^{-\frac{1}{4}}.$$

ON THE PLACEMENT OF AN OBSTACLE OR A WELL SO AS TO OPTIMIZE THE FUNDAMENTAL EIGENVALUE[*]

EVANS M. HARRELL II[†], PAWEL KRÖGER[‡], AND KAZUHIRO KURATA[§]

Abstract. We investigate how to place an obstacle B within a domain Ω in Euclidean space so as to maximize or minimize the principal Dirichlet eigenvalue for the Laplacian on $\Omega \setminus B$. The shape of B is fixed a priori (usually as a ball), and only its position varies. We establish that for a certain class of domains the minimizing B is in contact with $\partial\Omega$, while the maximizing B is in the interior, typically at the center (supposing that the domain is sufficiently symmetric for this statement to be meaningful). Under special circumstances we can characterize the optimizing configurations with multiple obstacles. Our method relies on the Hadamard perturbation formula and a moving plane analysis.

Similar facts are proved when the hard obstacle is replaced by a central nonnegative potential function supported in B, and we consider the Schrödinger operator with this potential. Complementary facts are proved when the obstacle is replaced by a central nonpositive potential function.

Key words. Schrödinger equation, optimal eigenvalue, Hadamard, obstacle

1. Introduction.

In this article we study how to minimize or maximize the fundamental eigenvalue of the Laplacian or Schrödinger operator defined within a fixed, bounded, open domain Ω, with zero Dirichlet boundary conditions on the boundary. Inside this domain we shall place an obstacle or a well, the position of which is under our control, and our goal is to locate the optimal position of the piece under our control.

The obstacles we consider may be hard, by which we mean that zero Dirichlet conditions are additionally imposed on the boundary of some open subset B of Ω, or they may be soft, by which we mean that the operator we analyze is of the following form:

$$-\nabla^2 \; + \; \alpha \; \chi_B(\mathbf{x}), \tag{1.1}$$

where $\alpha > 0$ and χ_B is the indicator function of the region B. Loosely, a hard obstacle corresponds to $\alpha = +\infty$. The term "well" refers to the situation where the constant α in operator (1.1) is negative. These operators are defined in standard ways (e.g., [Da95]), and by our sign convention the fundamental eigenvalue with an obstacle is positive and denoted λ; in the case of a well, λ might be negative. We recall that λ is nondegenerate and has an eigenfunction u which does not change sign. As usual, we choose $u(\mathbf{x}) > 0$ and normalize it in L^2 on Ω (respectively, on $\Omega \setminus B$ in the case of a hard obstacle).

Of particular interest for the light they shed on the relationship of geometry to the fundamental eigenvalue are the following questions about the placement of the interior obstacle:

1. Is it true that the optimal placement of an obstacle so as to minimize λ is in contact with the boundary, while the optimal placement to maximize λ is in the interior?

2. Given an affirmative answer to question 1, can the optimal position be located precisely?

For the placement of wells, we pose the same questions, with our expectations regarding the minimizing and maximizing positions reversed. In this article we shall describe some circumstances when the first question can be answered affirmatively, and some more narrow circumstances when the second question can be answered.

These expectations are suggested by perturbative analysis. If either α or the size of B is small, then to leading order in perturbation theory the effect of adding a soft obstacle or well is asymptotic to

$$\alpha \int_B u^2 d^n x\,.$$

Thus (for example, considering the case with $\alpha > 0$) the strategy to minimize λ is to place the obstacle near the boundary, while the strategy to maximize λ is to place the obstacle in the interior, near the maximum of $u(x)$. The situation with a small hard obstacle is similar (using the estimates in [Fl95]), while the situation with a well is reversed.

In many of the situations in this article the inside region B will be a ball. It is clear that for many purposes it is only necessary for B to have certain reflection symmetries, but we have preferred to focus on the case where the statement of the result is simplest. (See section 4, Example 7.)

In 1995, E. B. Davies asked two of us (E.H. and P.K.) questions of this type, for a hard spherical obstacle within a sphere. We answered the questions privately, using methods like those of this article: The minimizing position of the interior sphere is at the boundary of Ω, while the maximizing position is at the center of the exterior Ω. Quite recently we have learned from Ashbaugh and Chatelain [As99] that in response to the same query from A. G. Ramm, they have answered it with similar methods.

Independently, one of us (K.K.) had been considering the problem of placing a positive potential with a specified integral within a region Ω, so as to minimize λ. This work appears in [CGIKO99].

In both these independent lines of investigation, the minimizing obstacles are in contact with the boundary. One aim here is to explore this phenomenon further.

We are not aware of other work on this problem, although there are some asymptotic estimates for small obstacles (especially [Fl95]), and some work on optimization of capacity on annular domains in [Fl93] and [Co94].

Our technique is to treat the motion of the obstacle or well as a perturbation, and estimate the perturbation with a reflection technique reminiscent of the classical method of moving planes [Al60], [Se71], [BeNi91], which, curiously, has heretofore not been used as much in spectral theory as in nonlinear analysis.

The first insight we use is that a translation of the obstacle or well can be regarded as a perturbation of a boundary. For a hard obstacle, the Hadamard boundary perturbation formula [Ha08], [GaSc53] applies. When specialized to the case of a translation, it reads simply as follows.

Proposition 1.1 (the Hadamard perturbation formula, special case). *Let B be an interior hard obstacle which can be moved rigidly a positive distance in the direction of a unit vector* $\mathbf{v}$*. The boundary of B is assumed piecewise smooth. Then*

$$\frac{\partial \lambda}{\partial \mathbf{v}} = \int_{\partial B} |\nabla u|^2 \, \mathbf{n} \cdot \mathbf{v} \, dS. \tag{1.2}$$

Here and throughout, $\mathbf{n}$ is the unit normal at the surface of the obstacle B. Our choice of orientation is outward with respect to B and hence inward with respect to Ω. We recall for later purposes that at a boundary with zero Dirichlet conditions, the gradient of u is parallel to the normal vector, provided the latter is defined.

When $\alpha > 0$ is finite, the derivative of the eigenvalue with respect to a translation of a soft obstacle is obtainable from Green's theorem. As for Hadamard's formula, the derivative is proportional to a certain surface integral. As a first step in deriving the formula for this derivative, we prepare an estimate for the eigenvalue $\lambda(\epsilon)$ and L^2-normalized eigenfunction $u(\epsilon)$ of a soft obstacle $B(\epsilon)$ obtained by shifting B by a distance ϵ.

Lemma 1.2. (a) *There exist constants $\epsilon_0 > 0$ and C, depending only on Ω, such that*

$$|\lambda(\epsilon) - \lambda| \leq C\epsilon$$

for every $0 < \epsilon < \epsilon_0$.

(b) $\|u(\epsilon) - u\|_{L^\infty(\Omega)} \to 0$ *as $\epsilon \to 0$.*

Proof. According to the min-max principle,

$$\lambda(\epsilon) \leq \int_\Omega |\nabla u|^2 \, dx + \alpha \int_\Omega \chi_{B(\epsilon)} u^2 \, dx = \lambda + \alpha \int_\Omega (\chi_{B(\epsilon)} - \chi_B) u^2 \, dx.$$

Recall that u and $u(\epsilon) \in L^\infty(\Omega)$ with $\|u(\epsilon)\|_\infty \leq C_1$, with C_1 depending only on Ω (see, e.g., [GiTr83, Theorem 8.15]). Since also

$$\int_\Omega |(\chi_{B(\epsilon)} - \chi_B)| \, dx \leq C_2 \epsilon,$$

we obtain

$$\lambda(\epsilon) - \lambda \leq C_3 \epsilon.$$

By an analogous argument, $\lambda - \lambda(\epsilon) \leq C_4 \epsilon$, completing the proof of (a).

Next, it is easy to see that $\{u(\epsilon)\}_{0<\epsilon<\epsilon_0}$ is bounded in $H_0^1(\Omega)$, so there exists a subsequence of $\{u(\epsilon)\}_{0<\epsilon<\epsilon_0}$ which converges weakly in $H_0^1(\Omega)$. Actually, $u(\epsilon)$ must converge to u weakly in $H_0^1(\Omega)$ and strongly in $L^2(\Omega)$, since the weak limit of any subsequence of $\{u(\epsilon)\}_{0<\epsilon<\epsilon_0}$ is the first eigenfunction u associated to λ and hence unique. Let $w(\epsilon) := u(\epsilon) - u$. Then $w(\epsilon)$ satisfies

$$-\Delta w(\epsilon) + (\alpha \chi_{B(\epsilon)} - \lambda) w(\epsilon) = (\lambda(\epsilon) - \lambda) u(\epsilon) - \alpha(\chi_{B(\epsilon)} - \chi_B) u.$$

Applying the uniform L^∞ estimate from [GiTr83, Theorem 8.15] to $w(\epsilon)$, we have

$$\|w(\epsilon)\|_{L^\infty(\Omega)} \leq \|w(\epsilon)\|_{L^2(\Omega)} + C_5 |\lambda(\epsilon) - \lambda| + C_6 \|\chi_{B(\epsilon)} - \chi_B\|_{L^1(\Omega)}.$$

This yields the desired estimate. □

We shall need the following elementary formula.

LEMMA 1.3. *Suppose $\zeta \in C^1(\Omega)$. Then*

$$\frac{1}{\epsilon}\left(\int_{B(\epsilon)} \zeta^2\, dx - \int_B \zeta^2\, dx\right) \to \int_{\partial B} \zeta^2 (\mathbf{v}\cdot\mathbf{n})\, dS$$

as $\epsilon \to 0$.

Proof. Since $\int_{B(\epsilon)} \zeta^2\, dx = \int_B \zeta^2(\mathbf{y}+\epsilon\mathbf{v})\, dy$, we get

$$\begin{aligned}\frac{1}{\epsilon}\left(\int_{B(\epsilon)} \zeta^2\, dx - \int_B \zeta^2\, dx\right) &= \int_{B(\epsilon)}\left(\frac{\zeta(\mathbf{y}+\epsilon\mathbf{v})-\zeta(\mathbf{y})}{\epsilon}\right)(\zeta(\mathbf{y}+\epsilon(\mathbf{v}))+\zeta(\mathbf{y}))dy\\ &\to 2\int_B \frac{\partial\zeta}{\partial\mathbf{v}}\zeta dy = \int_B \nabla\cdot\ \left(\zeta^2\mathbf{v}\right) dy.\end{aligned}$$

The divergence theorem implies the desired result. □

PROPOSITION 1.4. *Consider the case of a soft obstacle or a well* (1.1), *where B is assumed to have a piecewise smooth boundary. Suppose that B can be moved rigidly a positive distance in the direction of a unit vector* $\mathbf{v}$. *Then*

$$\frac{\partial\lambda}{\partial\mathbf{v}} \;=\; \alpha\int_{\partial B} |u|^2\mathbf{n}\cdot\ \mathbf{v}\ dS. \tag{1.3}$$

Proof. We denote by $\lambda(\epsilon)$ and λ the fundamental eigenvalues of the operators $-\Delta+\alpha\chi_{B(\epsilon)}$ and $-\Delta+\alpha\chi_B$, respectively. Here $B(\epsilon)=\{\mathbf{y}\in\mathbf{R}^n;\mathbf{y}=\mathbf{x}+\epsilon\mathbf{v}\}$ for small $\epsilon>0$. We choose $0<\epsilon<\epsilon_0$, where $\epsilon_0>0$ is sufficiently small so that $B(\epsilon)\subset\Omega$. We also denote by $u(\epsilon)$ and u the L^2-normalized eigenfunctions associated with $\lambda(\epsilon)$ and λ, respectively. Thus $u(\epsilon)$ and u satisfy

$$\int_\Omega \nabla u(\epsilon)\cdot\nabla\phi + \alpha\chi_{B(\epsilon)}u(\epsilon)\phi\, dx = \lambda(\epsilon)\int_\Omega u(\epsilon)\phi\, dx$$

and

$$\int_\Omega \nabla u\cdot\nabla\psi + \alpha\chi_B u\psi\, dx = \lambda\int_\Omega u\psi\, dx$$

for every $\phi,\psi\in H_0^1(\Omega)$. Substituting $\phi=u$ and $\psi=u(\epsilon)$, we have

$$(\lambda(\epsilon)-\lambda)\int_\Omega u(\epsilon)u\, dx = \alpha\int_\Omega(\chi_{B(\epsilon)}-\chi_B)u(\epsilon)u\, dx.$$

By Lemma 1.2(b), we have

$$\left|\int_\Omega u(\epsilon)u\, dx - \int_\Omega u^2\, dx\right| = o(1)$$

and

$$\left|\int_\Omega(\chi_{B(\epsilon)}-\chi_B)(u(\epsilon)u-u^2)\, dx\right| = o(\epsilon).$$

Hence it follows from Lemma 1.2(a) that

$$\frac{(\lambda(\epsilon)-\lambda)}{\epsilon} = \frac{\alpha}{\epsilon}\int_\Omega(\chi_{B(\epsilon)}-\chi_B)u^2\, dx + o(1).$$

Since $u \in C^{1,\beta}(\Omega)$ for $0 < \beta < 1$ (see, e.g., [GiTr83]), Lemma 1.3 yields

$$\frac{d\lambda}{d\mathbf{v}} = \frac{d\lambda(\epsilon)}{d\epsilon}|_{\epsilon=0} = \alpha \int_{\partial B} u^2(\mathbf{v}\cdot\mathbf{n})\,dS. \qquad \square$$

Since the possible centers of the obstacle or well form a compact subset of Ω, it is immediate from Lemmas 1.2 and 1.3 that under the assumptions of this article, *the maximizing and minimizing positions of B exist.*

2. The technique of domain reflection. If a domain has a certain reflection property with respect to an axis of symmetry of the obstacle, then we shall be able to identify the sign of the directional derivative of the fundamental eigenvalue with respect to the position of an obstacle or well. Roughly speaking, when this property holds, we shall show that the eigenvalue increases as the obstacle moves away from a nearby portion of the boundary of Ω.

To avoid complications, we henceforth assume that the set B is convex as well as piecewise smooth. We also require that it be reflection-symmetric about some hyperplane (or plane, or line) P of dimension $n-1$. When we consider specific examples, B will often be a ball.

Definition. *Let P be a hyperplane of dimension $n-1$ which intersects Ω. For any connected set S which does not intersect P, we let S^P denote its reflection through P. The domain Ω is said to have the* interior reflection property *with respect to P if there is a connected component Ω_s of $\Omega \setminus P$ such that Ω_s^P is a proper subset of the other connected component Ω_b of $\Omega \setminus P$. Any such P will be called a* hyperplane of interior reflection *for Ω. Moreover, Ω_s will be called the* small side *of Ω (and Ω_b will be called the* big side*).*

The following theorem states formally that when this property holds, the eigenvalue is strictly increasing as a symmetric obstacle is moved away from the small side.

Theorem 2.1. *Assume that Ω has the interior reflection property with respect to a hyperplane P about which the set B is reflection-symmetric. Suppose that B is translated in the direction of a unit vector $\mathbf{v}$ perpendicular to P and pointing from the small side to the big side.*

Then, in the case of a hard or soft obstacle,

$$\frac{d\lambda}{d\mathbf{v}} \; > \; 0.$$

In the case of a well,

$$\frac{d\lambda}{d\mathbf{v}} \; < \; 0.$$

Remark. Actually, the soft obstacle or well here could be any reflection-symmetric function supported within the closure of B, not just its indicator function.

Proof. There are three cases to consider, that of a hard obstacle, a soft obstacle, and a well. We consider the hard obstacle last.

For the other two cases, we claim that for any point $\mathbf{x}$ of ∂B which is on the small side of Ω, $u(\mathbf{x}) < u(\mathbf{x}^P)$. The theorem will then follow in these cases from (1.3).

To establish the claim, we consider $w(\mathbf{x}) := u(\mathbf{x}) - u\left(\mathbf{x}^P\right)$ on the small side Ω_s. On the interior of this region,

$$\left(-\nabla^2 \; + \; \alpha\chi_B\right) w \; = \; \lambda\, w,$$

while on its boundary, $w(\mathbf{x}) \leq 0$. Observing that w is strictly negative on part of that boundary and that λ is less than the fundamental Dirichlet eigenvalue of $-\nabla^2 + \alpha\chi_B$, we conclude from the maximum principle [PrWe84] that $w(\mathbf{x}) < 0$ in the interior of this region, and hence that $u(\mathbf{x}) < u(\mathbf{x}^P)$ for $\mathbf{x}$ in ∂B on the small side of Ω.

This establishes the claim except for the case of a hard obstacle, where we use the Hadamard formula (1.2) in place of (1.3). This time we consider the function $w(\mathbf{x}) := u(\mathbf{x}) - u(\mathbf{x}^P)$ on the small side Ω_s but excluding B. Just as before, the maximum principle tells us that $w(\mathbf{x}) < 0$ on the interior of this region. To finish the proof in this case, we appeal to the boundary-point lemma of [Se71, p. 308], according to which, at every smooth point of the part of ∂B on the small side, either the normal derivative of $w(\mathbf{x})$ is strictly positive or else the second derivative of $w(\mathbf{x})$ in this direction is strictly positive. However, the latter possibility is excluded because it contradicts the eigenvalue equation (since the Laplacian of w is negative while all second derivatives in tangential directions at the boundary are 0). Hence $|\nabla u(\mathbf{x})| < |\nabla u(\mathbf{x}^P)|$ for $\mathbf{x}$ in ∂B on the small side of Ω. The theorem then follows from (1.2). □

In the final section of this article we consider many examples where it can be shown that either the domain Ω or a suitable related domain Ω' contains a dense subset of points which lie on a hyperplane of interior reflection. In preparation for that we state here an obvious corollary of Theorem 2.1.

Corollary 2.2. *Let $\mathbf{x} \in \Omega$ denote the center of a spherical obstacle B. At any maximizing $\mathbf{x}$,*

(a) *Ω has no hyperplane P of interior reflection containing $\mathbf{x}$.*

Moreover, at any minimizing $\mathbf{x}$, either statement (a) *above is true, or else*

(b) *∂B intersects the small side of $\partial\Omega$.*

Convexity ensures that Ω enjoys the interior reflection property with respect to some secant plane passing through any point sufficiently close to the boundary. This immediately implies the following.

Corollary 2.3. *Assume that Ω is convex and that B is a ball of radius ρ. There exists $R_0 > 0$ depending on Ω such that if $\rho < R_0$, then there are neighborhoods $N_{1,2}$ of the boundary, such that*

(a) *the maximizing* (*resp., minimizing*) *obstacle* (*resp., well*) *for λ lies outside N_1; and*

(b) *any obstacle* (*resp., well*) *which minimizes* (*resp., maximizes*) *λ subject to being located within N_2 must touch the boundary of Ω.*

In principle, given any convex Ω it is straightforward to identify neighborhoods $N_{1,2}$ explicitly. In the following section we consider some cases where $N_2 = \Omega$ and where the optimal positions can be determined exactly, sometimes even without convexity.

At the level of generality of Corollary 2.3 there is a "hole" in the interior of a convex Ω within which we can say little about the optimal placement of obstacles. With a reflection symmetry, however, the hole can be reduced to a slit, because together with convexity this implies that every point of Ω is either reflection-symmetric or else on a hyperplane of interior reflection.

Corollary 2.4. *Suppose Ω and the obstacle are as in* Corollary 2.3, *and in addition that Ω is symmetric with respect to reflection through a hyperplane H. Then at the minimizing position the obstacle is in contact with the boundary, while at the maximizing position its center is on H.*

Next we note an extension of Theorem 2.1 to the case of Schrödinger operators, which is useful for discussions of soft obstacles and of interest in its own right.

Theorem 2.5. *Consider the Schrödinger operator $\mathcal{H} := -\nabla^2 + V(\mathbf{x})$ on a domain Ω, where the potential $V(\mathbf{x})$ is a real-valued function in $L^\infty(\Omega)$ (or more generally satisfying conditions guaranteeing that the fundamental eigenvalue is discrete; see, e.g.,* [ReSi78]*). Assume that Ω has the interior reflection property with respect to a hyperplane P about which the set B is reflection-symmetric, and that on the small side Ω_s,*

$$V(\mathbf{x}) \geq V\left(\mathbf{x}^P\right) \text{ almost everywhere.}$$

Suppose that B is translated in the direction of a unit vector $\mathbf{v}$ perpendicular to P and pointing from the small side to the big side.

Then, in the case of a hard or soft obstacle (i.e., $-\nabla^2 + V(\mathbf{x}) + \alpha\, \chi_{\mathrm{B}}(\mathbf{x})$),

$$\frac{d\lambda}{d\mathbf{v}} > 0.$$

In the case of a well,

$$\frac{d\lambda}{d\mathbf{v}} < 0.$$

Proof. The proof is like that of Theorem 2.1. This time, however, $w(\mathbf{x}) := u(\mathbf{x}) - u\left(\mathbf{x}^P\right)$ is no longer a solution of the eigenvalue equation on Ω_s but is instead a subsolution, i.e.,

$$(H - \lambda)w(\mathbf{x}) = -\left(V\left(\mathbf{x}\right) - V\left(\mathbf{x}^P\right)\right) u\left(\mathbf{x}^P\right) \leq 0.$$

This, however, suffices for the maximum principle, by the following argument.

First we observe that $w(x) \leq 0$ on Ω_s as before. Indeed, if $U = \{w(x) > 0\}$ were nonempty, then the inequality in the proof of Theorem 2.5 would imply that $\lambda \geq \mu_1$, where μ_1 is the first eigenvalue of H on U. However, $U \subset \Omega_s \subset \Omega$ and λ is the first eigenvalue of H on Ω. As a consequence of the unique continuation theorem (e.g., [JeKe85]), we find that $\mu_1 > \lambda$, which is a contradiction.

Next, to conclude that $w(x) < 0$ in Ω_s, we appeal to the strong maximum principle. □

We close this section by observing that for sufficiently small α, any globally minimizing soft obstacle (resp., maximizing well) touches the boundary.

Theorem 2.6. *Suppose Ω is convex and that it contains a soft spherical obstacle, i.e., a potential $\alpha\, \chi_B(x)$, where B is a sufficiently small ball. Then there exists $\alpha_0 > 0$ such that for every α with $0 < \alpha < \alpha_0$, when B is at the position where it minimizes the first eigenvalue, it touches the boundary $\partial\Omega$.*

Proof. We let $B_\epsilon(\mathbf{w})$ denote the obstacle when centered at $\mathbf{w}$, and we assume that the radius $\epsilon > 0$ of the obstacle is sufficiently small.

First we claim that there exists a compact subset $G \subset \Omega$, independent of ϵ, such that if $\mathbf{w} \in G'$ and $\overline{B(\mathbf{w})} \subset \Omega$, then $B(\mathbf{w})$ cannot be an optimal obstacle. Here $G' := \Omega \setminus G$. This follows from Corollary 2.3. We observe that G may be chosen independently of ϵ for ϵ sufficiently small; the choice of G depends only on Ω.

Let ψ be the L^2-normalized first eigenfunction of the Dirichlet Laplacian on Ω, and let $[\Omega]^\delta = \{x \in \Omega; \psi(x) > \delta\}$ for $\delta > 0$. Then there exists a small $\delta > 0$ such that $G \subset\subset [\Omega]^\delta$. We fix a value of the radius $\epsilon > 0$ sufficiently small so that

$$\epsilon < \min(\mathrm{dist}(\partial G, \partial[\Omega]^\delta), (1/2)\mathrm{dist}(\partial\Omega, \partial[\Omega]^\delta)).$$

Next we assert that, as shown in [CGIKO99], there exists a small $\alpha_0 > 0$ such that if $\mathbf{w} \in G$, then $B_\epsilon(\mathbf{w})$ cannot be a minimizing obstacle for any $0 < \alpha < \alpha_0$, because

$$\|u(\epsilon, \mathbf{w}) - \psi\|_{L^\infty(\Omega)} \leq C\alpha$$

for some constant C which does not depend on $\mathbf{w}$.

Here $u(\epsilon, \mathbf{w})$ denotes the L^2-normalized first eigenfunction of $-\Delta + \alpha\chi_{B_\epsilon(\mathbf{w})}$. Note that if $\mathbf{w} \in G$, then $B_\epsilon(\mathbf{w}) \subset \{\psi(x) > \delta\}$, and we can find a ball $B_\epsilon(\mathbf{w}') \subset \{\psi(x) < \delta\}$. Hence, for sufficiently small α_0,

$$\int_{B_\epsilon(\mathbf{w})} u(\epsilon, \mathbf{w})^2 \, dx > \int_{B_\epsilon(\mathbf{w}')} u(\epsilon, \mathbf{w})^2 \, dx$$

for all $0 < \alpha < \alpha_0$. Together with the variational principle, this implies that $B_\epsilon(\mathbf{w})$ cannot be a minimizing obstacle for $\mathbf{w} \in G$ and for $0 < \alpha < \alpha_0$, completing the proof. □

3. Optimization at a vertex or corner. It is not difficult to show that an ellipse has the interior reflection property with respect to any secant line which is perpendicular to the boundary at one of its crossing points and which does not coincide with one of the axes. It thus follows fairly easily from Theorem 2.1 that if the radius of the ball B is sufficiently small so that it fits inside an elliptical domain Ω, then the minimizing ball touches the boundary. Actually, we can locate the minimizing position at the vertex of the ellipse, and the maximizing position at the center, for a class of domains generalizing the ellipse (see Theorem 3.2, below).

We shall show that this phenomenon, that minimizing obstacles are located at parts of the boundary where the curvature is maximized, also occurs in certain other situations. Unfortunately, we are not able to determine the degree of generality of this phenomenon.

We begin by extending Theorem 2.1 to the case where B moves along the boundary; to keep the statement simple, we restrict it to the case of spherical B.

PROPOSITION 3.1. *Let B be a ball which is tangent to the boundary of Ω, assumed of class C^2 in a neighborhood of the point of contact. Suppose furthermore that Ω has the interior reflection property with respect to a hyperplane P normal to the boundary at the point of contact. Then λ is strictly increasing as B is moved in contact with the boundary towards the big side.*

Sketch of the proof. The argument is by domain perturbation as for Theorem 2.1, with the further complication that as the domain B moves along a smooth boundary, it is not only translated and but also continuously rotated. For nonspherical domains, Propositions 1.1 and 1.4 would need to be modified with additional terms to reflect this. For spherical domains, however, the additional terms do not arise, and the formulae for the directional derivatives are as before. □

We next identify a class of roughly elliptical regions for which we can carry out a complete analysis of the maximizing and minimizing positions of an obstacle or well.

DEFINITION. *A* vertex *of a domain with boundary of class C^2 is a point on the boundary at which the curvature is locally maximal. Outward pointing corners of a piecewise C^2 boundary are also considered vertices.*

THEOREM 3.2. *Let Ω be a two-dimensional convex domain with the following properties:*

(a) *Ω is reflection symmetric with respect to both the x and y Cartesian axes.*

(b) *The boundary of* Ω *is of class* C^2 *for* $x, y \neq 0$.

(c) *In any quadrant of the plane, the curvature of the boundary of* Ω *is monotonic as a function of* x (*or equivalently of* y *or of the arclength* s).

Suppose that the obstacle (*resp., well*) B *is a disk.*

If the radius of B *is less than the radius of curvature at the vertex of* Ω, *then* λ *is minimized* (*resp., maximized*) *when* B *is in contact with a vertex, and maximized* (*resp., minimized*) *when the obstacle* (*resp., well*) *is at the origin.*

This theorem certainly generalizes to three-dimensional ellipsoidal domains Ω which are rotationally symmetric. We also remark that, as a special case, when both Ω and B are balls, λ is a strictly increasing function of the distance of B from the boundary until it reaches the center, where it is maximized. (This answers the query of Davies [Da95a].)

Theorem 3.2. is a direct corollary of the following.

Proposition 3.3. *A region as in Theorem* 3.2 *enjoys the interior reflection property with respect to any line normal to its boundary, except for the lines of symmetry* (*x and y axes*). *The small side of the normal line at a boundary point* P *is the side of increasing curvature of the boundary moving from* P.

Proof. We may and shall assume without loss of generality that the curvature of the boundary of Ω is strictly increasing as a function of y in the first quadrant of the plane (and hence strictly monotonic in any quadrant of the plane). We also orient the arclength s counterclockwise, so that s is an increasing function of y. We observe that Ω is convex and that in the first quadrant the distance from the origin to a point on $\partial\Omega$ increases with y. For simplicity we assume that $\partial\Omega$ is of class C^2 even at the possibly exceptional points ($x = 0$ or $y = 0$); it will be clear that this does not affect the result.

Let φ be the angle of the normal to the boundary as measured counterclockwise from the x-axis. Because of our assumptions, the angle φ can be used to parametrize the points of $\partial\Omega$; we henceforth do this, and use the notation $P(\varphi)$ for those points. Let L designate the normal line to $\partial\Omega$ at some specific $P(\alpha)$ in the first quadrant.

We claim first that if $\beta :=$ the angle $> \alpha$ where L intersects $\partial\Omega$, then $\beta < \pi + \alpha$. The statement that $\beta < \pi + \alpha$ is easily seen to be equivalent to the statement that L passes above the center of Ω, which in turn means that $\varphi < \theta$, where θ is the usual polar coordinate of $P(\alpha)$.

In order to show that the reflection of $\partial\Omega$ for $\alpha < \varphi_+ < \beta$ fits within Ω, we make some definitions. Let ℓ_+ be the distance from $P(\varphi_+)$ to L and let t be as the distance from $P(\alpha)$ to the point on L closest to $P(\varphi_+)$. At a given value of t, there is an analogous point $P(\varphi_-)$ on the other side of L, at some $\varphi_- < \alpha$; we define the distance from $P(\varphi_-)$ to L as ℓ_-.

We thus need to show that $\ell_+ \leq \ell_-$ for the same value of t. Hence we consider the maps $\varphi_\pm \to t$, for which

$$dt = \sin(\varphi - \alpha) ds = \frac{1}{\kappa(\varphi)} \left|\sin(\varphi - \alpha)\right| d\varphi.$$

Here, κ designates the curvature of the boundary at the point corresponding to φ. For $\alpha < \phi < \alpha + \frac{\pi}{2}$,

$$t(\varphi) - t(2\alpha - \varphi) = \int_\alpha^\varphi \left(\frac{1}{k(\phi)} - \frac{1}{k(2\alpha - \phi)}\right) |\sin(\phi - \alpha)| d\phi < 0 \qquad \text{for } \theta < \alpha + \frac{\pi}{2},$$

since the integrand is negative.

Furthermore, this difference is negative for all $\alpha < \varphi < \beta$ because the integral is antisymmetric about $\frac{\pi}{2} + \alpha$ and $\beta < \left(\frac{\pi}{2} + \alpha\right) + \left(\frac{\pi}{2} - \alpha\right) = \pi$. We conclude that $t(\varphi) > t(2\alpha - \varphi)$ ($2\alpha - \varphi$ is the angle reflected through α) for this range of φ, and therefore if we consider the two maps $\varphi \to t$, we see

$$|\varphi - \alpha|(t)_{\text{above } L} > |\varphi - \alpha|(t)_{\text{below } L}.$$

Also, both $t(\varphi)$ and $t(2\alpha - \varphi)$ are monotonic increasing functions of φ for $\varphi > \alpha$.

Since $\frac{d\ell_\pm}{ds} = \cot(\varphi - \alpha)$ and cot is a decreasing function for $0 < |\varphi - \alpha| < |\beta - \alpha| < \pi$, we conclude by integrating that

$$\ell_+ < \ell_- \qquad \text{for } 0 < t < t(\beta). \qquad \square$$

THEOREM 3.4. (a) *Suppose that Ω and B are as in Theorem* 3.2, *and that the radius of B is small enough for it to fit within Ω but larger than the radius of curvature at its vertex. Then λ is minimized* (*resp., maximized*) *when B is in as close as possible to a vertex and maximized* (*resp., minimized*) *when the obstacle* (*resp., well*) *is at the origin.*

(b) *Suppose that Ω is an equilateral polygon centered at the origin. Then λ is minimized* (*resp., maximized*) *when the ball is as close as possible to any vertex of Ω and maximized* (*resp., minimized*) *when the obstacle* (*resp., well*) *is at the origin.*

Proof. We discuss the case of an obstacle. As usual, the case of a well uses the same argument, with a reversal of "maximal" and "minimal."

Part (a) is an obvious variant of Theorem 3.2. It is necessary only to notice that if B is anywhere other than at the origin, the interior reflection holds with respect to the horizontal or vertical plane through the center of B. By Corollary 2.2, the only possibility for the maximizing position is the center, whereas at the minimizing position B is in contact with $\partial\Omega$.

To localize the minimizer more precisely, we observe that if the contact point is not a point of symmetry of $\partial\Omega$, and B is not obstructed from displacements to the small side of Ω, then Proposition 3.1 excludes the configuration as a candidate for a minimizer. It is moreover easy to see that any attainable point of symmetry other than a vertex is excluded from being a contact point of a minimizing obstacle. (It would in fact be a constrained maximizing position, given contact with the boundary.) The only remaining possibility is that described in statement (a).

The argument for part (b) is similar. From Theorem 2.1, using the symmetry of the polygon we see that if the center of B is anywhere other than at the center of Ω, then it lies on a hyperplane of interior reflection, and λ decreases as B moves perpendicularly away from any line of symmetry of Ω. The argument at the boundary is much as for case (a). The perpendicular line from the point of contact is a hyperplane of interior reflection except when the contact is at the midpoint of an edge of the polygon, but λ decreases when the point of contact is moved away from a midpoint on either side. The claim then results from possibility (b) of Corollary 2.2. $\square$

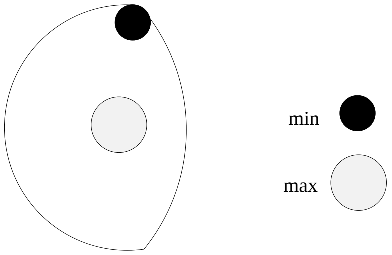
4. Extensions and some instructive examples. Although at first sight our technique seems to be restricted to regular, convex regions, we now proceed to illustrate by example how it can be extended. In this section we describe only problems with obstacles. In most cases, however, the same examples illustrate the situation for wells, with the usual reversal of "min" and "max."

We shall omit details of the proofs when they consist only of recalling Corollary 2.2 and elementary exercises in finding possible hyperplanes of interior reflection.

Example 1. Let Ω be a finite region bounded by two spheres in R^N, and suppose that a spherical obstacle B has radius ρ small enough so that it fits into Ω. For definiteness, suppose that the larger sphere has its center at the origin and radius R, and that the smaller one has its center on the x_1-axis at coordinate $x_1 = a \geq 0$, and radius $r \leq R$.

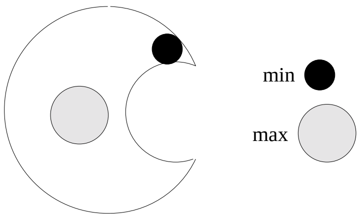
There are five possibilities as follow.

(a) Ω is gibbous (simply connected and convex: Ω is the intersection of two balls, and $R - r < a < R + r$). Then at the minimizing positions of B, it is as near as possible to a vertex. (There are two such positions if $N = 2$, and otherwise they form a sphere of dimension $N - 2$.) At the maximizing position $\mathbf{x}$ the center of B is located on the x_1-axis with x_1 in the interval $[\frac{R-r+a}{2}, \frac{R^2-r^2+a^2}{2a}] \cap [a - r + \rho, R - \rho]$. (Note: $\frac{R^2-r^2+a^2}{2a}$ is the x-coordinate of the intersection of the two circles.)



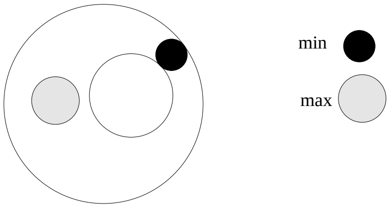
Example 1(a)

(b) Ω is crescent (simply connected and nonconvex: Ω is the intersection of the larger ball and the exterior of the smaller ball, and $R - r < a < R + r$). Then at the minimizing positions of B, it is as near as possible to a vertex. (There are two such positions if $N = 2$, and otherwise they form a sphere of dimension $N - 2$.) At the maximizing position $\mathbf{x}$ the center of B is located on the x_1-axis with x_1 in the interval $[\frac{-R-r+a}{2}, 0] \cap [-R + \rho, a - r - \rho]$.



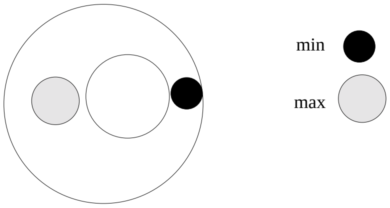
Example 1(b)

(c) Ω is annular but not concentrically so, and $\rho > \frac{R-(r+a)}{2}$. This is essentially like the case of the crescent: At the minimizing positions of B, it is as near as possible to the point $x_1 = R$ on the x_1-axis. (There are two such positions if $N = 2$, and otherwise they form a sphere of dimension $N - 2$.) The maximizing position $\mathbf{x}$ of the center of B is located on x_1-axis with x_1 in the interval $[\frac{-R-r+a}{2}, 0] \cap [-R+\rho, a-r-\rho]$, as in part (b).



Example 1(c)

(d) Ω is annular but not concentrically so, and $\rho < \frac{R-(r+a)}{2}$. The maximizing position $\mathbf{x}$ of B is as in parts (b) and (c). The minimizing positions satisfy $a+r+\rho < x_1 < \frac{a+R+r}{2}$.



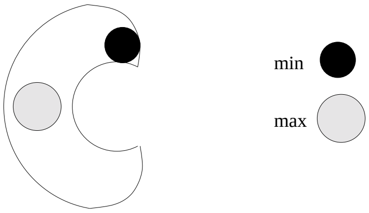
Example 1(d)

(e) Ω is a concentric annulus (spherical shell). Necessarily, $\rho < \frac{R-r}{2}$. At maximum, the position of the center $\mathbf{x}$ of B satisfies $r + \rho \leq |\mathbf{x}| \leq \frac{R+r}{2}$. At minimum, either $\mathbf{x}$ is in the same annulus or else $|\mathbf{x}| = R - \rho$ (contact with the outer boundary).

These possibilities rely on Corollary 2.2; among the hyperplanes of interior reflection to consider are horizontal hyperplanes and the bisecting planes of the spheres. Our technique does not allow us to eliminate one of the two possibilities for the minimum in 1(e). We suspect the true alternative to be that the minimizing obstacle is in contact with the outer boundary, and we will establish this in Example 12 when the inner radius is sufficiently small and the obstacle is soft.

Example 2. Horseshoe-shaped domains: Let Ω_0 be the concentric annular domain of Example 1(e) in 2 dimensions, and let S_α be the sector $|x_2| < \alpha x_1$ for some $\alpha > 0$. For some fixed opening angle $\beta \leq \pi/2$, let $\sigma_\pm$ denote two open circular sectors of radius $R-r$ and centered at the inner edge of Ω_0, i.e., at $(\frac{r}{(1+\alpha^2)^{1/2}}, \pm\frac{\alpha r}{(1+\alpha^2)^{1/2}})$, such that one edge lies on ∂S_α. $\Omega := \{\Omega_0 \cap S_\alpha^c\} \cup \sigma_- \cup \sigma_+$. The hard or soft obstacle is a disk of radius $< R-r$.

The maximizing position is on the x_1-axis and is otherwise as in Example 1(e), while the unique two minimizing positions have the obstacle wedged in the corners of the sectors $\sigma_\pm$.



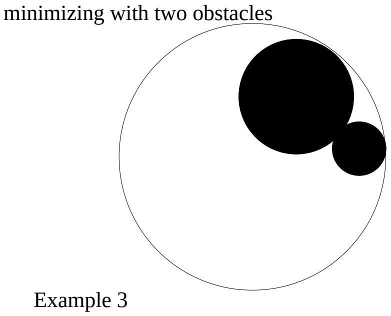
Example 2

The proof is obtained by noting that rays from the origin other than the negative x_1-axis are lines of interior reflection whenever they intersect Ω_0, as are rays beginning at $(\frac{r}{(1+\alpha^2)^{1/2}}, \pm\frac{\alpha r}{(1+\alpha^2)^{1/2}})$ and passing through $\sigma_\pm$.

We note that appending $\sigma_\pm$ allowed us to be precise about the minimizing position; without them, the minimizing position would be in contact with ∂S_α, but our method would not give the exact position.

Example 3. (a) A ball Ω with two interior hard spherical obstacles B_1 and B_2, which can be placed independently, and may have different radii, the sum of which is less than the radius of Ω. In this case the minimizing configuration has both obstacles touching the boundary and each other. In the maximizing configuration the centers of B_1 and B_2 lie on a diameter of Ω.

(b) The same example, except that one of the obstacles is allowed to be soft. The maximizing and minimizing configurations are as for part (a).

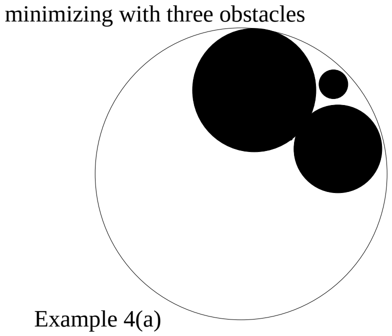


We observe that the minimizing configuration disconnects Ω.

Denote by $\mathbf{x_1}$ and $\mathbf{x_2}$ the centers of the balls B_1 and B_2, respectively. We begin by considering the relative positions of the balls as fixed a priori and treating them as a single obstacle. Unless they lie on a diameter of Ω, the line passing through both their centers is a line of interior reflection. We thus conclude that at maximum they lie on a diameter of Ω, while at minimum at least one of them touches $\partial\Omega$.

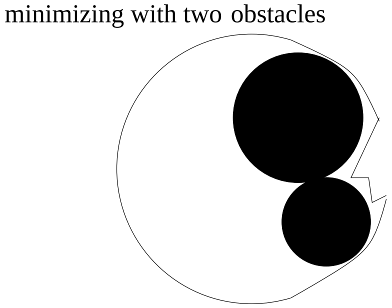
Having established that at least one obstacle touches the boundary when λ_1 is minimized, we can assume for the minimizing problem that one spherical obstacle is fixed to $\partial\Omega$ in some standard orientation, rotating the entire problem as necessary, while letting the position of the second obstacle vary. This, however, is the situation of Example 1(b). Hence we know that at minimum the two obstacles touch each other and $\partial\Omega$.

Example 4. (a) The same as Example 3, except that we also insert a third, hard obstacle of positive capacity and any shape small enough that it can be translated and rotated so as to fit inside $\Omega_s :=$ the smaller of the two domains into which Ω is disconnected at the minimizing configuration of Example 3. (Ω_1 is of course defined only up to rotations of the two larger obstacles about the center of Ω.) Then the minimizing configuration is as in Example 3, with the third obstacle anywhere within Ω_1. This can be a unique minimizer or highly nonunique, depending on the size and shape of the third obstacle.



Example 4(a)

(b) As a variant of (a), we replace the large sphere Ω with $\Omega' := \Omega \setminus \Upsilon$, where $\Upsilon \subset \Omega_1$ for some fixed possible Ω_1 as in (a), and is otherwise an arbitrary closed set of positive capacity. We consider Ω' as the exterior region, and insert two spherical obstacles. Then the minimizing configuration is as in Example 3, oriented so that Υ lies within the Ω_1 created by the disconnection of Ω. Again, this can be unique or nonunique.



Example 4(b)

Here we recall the principle of domain monotonicity, which shows that the minimal fundamental eigenvalue for Example 3 is the same as the that of the larger of the two domains into which Ω is disconnected. In case (a), if the third obstacle were inserted into this domain, the eigenvalue would strictly increase (cf. [Co95], [McG96], [McG98]). On the other hand, the eigenvalue is unaffected in comparison to Example 3 if the third obstacle is inserted into Ω_1. Case (b) follows by virtually the same argument, recalling Theorem 2.5.

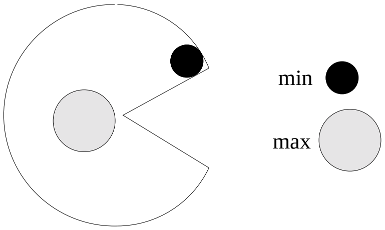
Example 5. Balls with sectors or lines (resp., hyperplane) segments removed.

(a) Consider a domain Ω formed by removing from a ball of radius R centered at the origin, some subset Υ of a closed sector S symmetric about the x_1-axis, within the half-plane $x_1 \geq a \geq 0$; otherwise, Υ is assumed closed and of positive capacity. We call the angle between the edge of the sector and the positive x_1-axis β. The obstacle is a hard or soft ball of radius $\rho < \frac{a+R}{2}$.

The maximizing position is then within the triangle (2 dimensions) or cone (3 or more dimensions) bounded by $x_1 = \frac{a-R}{2}$, $x_1 = 0$, and the cone with vertex at the origin and making an angle of $arccot(\cot\ \beta\ +\ \frac{\mathrm{a}}{\mathrm{R-a}} \csc\ \beta\ )$ with the negative x_1-axis. (Further restrictions on the maximizing position could be precisely formulated if ρ is not sufficiently small.)

The minimizing position(s) are in contact with S (possibly penetrating into its interior).

(b) As a special case of (a), suppose that Υ is a symmetric sector with vertex at $x_1 = a$, including the limiting case of a line segment. Then we can more precisely say that the maximizing position lies on the negative x_1-axis with $\frac{a-R}{2} < x_1 < 0$, and the minimizing positions are in contact with both the spherical part of $\partial\Omega$ and with ∂S. The minimizing position is not unique.

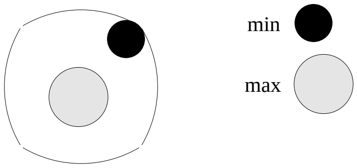


Example 5

Here we identify as hyperplanes of interior reflection all planes perpendicular to the x_1-axis with intersection at $-R < x_1 < \frac{a-R}{2}$, all planes perpendicular to the x_1-axis with intersection at $0 \leq x_1 < R$, and all planes through the origin which do not intersect S. It is a trigonometric exercise with the latter which leads to the angle identified.

As for case (b), there are additional hyperplanes of interior reflection consisting of all hyperplanes through the origin except those containing the x_1-axis.

Example 6. Let Ω be an equilateral n-sided polygon, modified by the replacement of its edges with outward circular arcs of equal angular measure $\leq \frac{2\pi}{n}$, containing a hard or soft circular obstacle B. Then the maximizing position $\mathbf{x}$ of the center of B is at the center of the polygon, and the minimizing positions of B put it as near as possible to a vertex.



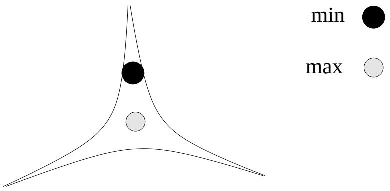
Example 6

(Straightforward exercise.)

Example 7. Let Ω be a rectangle and suppose that the convex obstacle B has two axes of symmetry parallel to the sides of the rectangle. We consider translations of the obstacle B. The maximizing position is at the center and the minimizing position is as near as possible to a vertex.

The proof is similar to the proof of Theorem 3.4.

Example 8. Let Ω be an equilateral triangle, modified by the replacement of its edges with inward circular arcs of equal angular measure $\leq \frac{\pi}{2}$, containing a hard or soft circular obstacle B. Then the maximizing position $\mathbf{x}$ of the center of B is at the center of the triangle, and the minimizing positions of B put it as near as possible to a vertex.



Example 8

(Straightforward exercise.)

Example 9. Let Ω be the concentric annulus (or spherical shell) of Example 1(e), and suppose that it contains two independently placeable hard obstacles as in Example 3(a). In the maximizing configuration, the two obstacles lie on a common hyperplane which bisects both spheres, and on opposite sides of the center. In the minimizing configuration, either the two obstacles lie on a common hyperplane which bisects both spheres, and on the same side of the center, or else they are in contact with each other (or both).

In this case, unless the obstacles are positioned as claimed, then if one of them is treated as fixed, the hyperplane passing through the origin and through the center of the second obstacle is a hyperplane of interior reflection.

Example 10. Let H be the portion of a regular helix in R^n, $n \geq 3$, at distance R from the x_1-axis for $-L \leq x_1 \leq L$. Define $\Omega := \{\mathbf{x} : \text{dist}(\mathbf{x}, H) < r\}$ for some $r < R$. (This looks like a spring with hemispherical caps on both ends.) Let the hard or soft obstacle be a ball B of radius $\rho < r$. Then the minimizing positions of B put it into contact with either of the two tips where H intersects $\partial\Omega$. At the maximizing position the center $\mathbf{x}$ of B lies on the plane perpendicular to H intersecting H at $x_1 = 0$.

Remark. Moreover, there exists $\rho_0 > 0$, depending on the specific geometry of the helix, such that for $\rho < \rho_0$ there is an upper bound on $|\mathbf{x}|$ strictly smaller than the one needed for B to fit within Ω. We do make it precise here.

The proof in this case requires a small twist in the interior reflection property on which Theorem 2.1 relies. Whereas Ω does not have the standard interior reflection property as given in the definition above Theorem 2.1, it has the following alternative property: Any hyperplane perpendicular to H other than the one intersecting it at $x_1 = 0$ divides Ω into two pieces, one of which is congruent to a subset of the other, by a half rotation instead of a reflection (equivalently, by two reflections). Applying this operation, rather than a reflection as in the proof of Theorem 2.1, we still see that the values of u and $|\nabla u|$ on one half of ∂B dominate those on the other half pointwise, allowing us to show that λ is strictly monotonic with respect to displacements tangential to H by (1.2) or, respectively, (1.3).

Our next example involves a soft obstacle and shows that our analysis is stable with respect to some perturbations of Ω which destroy both convexity and symmetry.

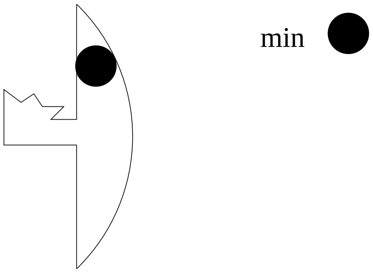
Example 11. A half ellipse with a small handle: Let $\Omega_0 := \{(x, y) \in R^2; x^2 + (y/l)^2 < 1, x > 0\}$, where l is a fixed constant, $l > 1$. Now consider the domain $\Omega_\epsilon := \mathit{interior}\,(\Omega_0 \cup H_\epsilon)$, where H_ϵ is a "handle" with the following properties:

(i) H_ϵ is a closed subset of $\{x \leq 0\}$,

(ii) $H_\epsilon \subset \{|y| \leq \epsilon\}$,

(iii) $0 < vol(H) \leq C\epsilon$ for some fixed positive constant C.

Fix the radius $r < 1$ of a spherical soft obstacle B, and denote $L_{\Omega_\epsilon} := -\Delta + \alpha\chi_B$ on Ω_ϵ. We claim that for all $\epsilon > 0$ and sufficiently small, the minimizing obstacle is situated within Ω_0 at the greatest possible distance from the x-axis. (There are two possibilities, one with $y > 0$ and one with $y < 0$.)



Example 11

Proof. We assume that ϵ is sufficiently small that the obstacle does not fit into the handle. All horizontal lines with $\{|y| > \epsilon\}$ are lines of interior symmetry for Ω_ϵ, so at the minimizing positions for the obstacle, either it is in contact with the boundary or else its center lies within $\{|y| \leq \epsilon\}$. The argument used to prove Theorem 3.2 is easily adapted for Ω_ϵ, and shows that the only possible minimizing positions are either as stated in the theorem, i.e., with the maximal value of $|y|$, or else confined to a strip of the form $\{|y| \leq c_1\epsilon\}$, where c_1 is a constant depending only on l.

We next eliminate the possible positions in the epsilonic strip by a continuity argument, for we know by the modification of Theorem 3.2 that for Ω_0, an obstacle in the strip gives rise to a fundamental eigenvalue strictly larger than when the obstacle is at the maximal value of $|y|$ (i.e., the unique two minimizing positions for Ω_0).

Consider the operator $L_\Omega := -\Delta + \alpha\chi_B$ on some domain Ω with Dirichlet boundary conditions on $\partial\Omega$ for a ball $B \subset \Omega$ of radius r, and denote, respectively, by $\lambda_\Omega(B)$ and $u_{\Omega,B}(B)(\mathbf{x})$ the first eigenvalue and L^2-normalized first eigenfunction.

Case 1. Candidate positions where B does not lie wholly inside Ω_0. In this case, according to Lemma 1.2, the obstacle can be shifted into the interior of Ω_0, raising λ by a small error. By a variant of the argument for Theorem 2.5 and uniform control on $\|u\|_\infty$ (e.g., [GiTr83, Theorem 8.15]), this error tends to 0 as $\epsilon \to 0$ uniformly in these possible candidate positions. Hence it suffices to consider only candidate positions inside Ω_0.

Case 2. Candidate positions inside Ω_0 and inside the epsilonic strip $\{|y| \leq c_1\epsilon\}$. Here estimates as in [HiMa91], [GeZh94], [McG96], [McG98] show that $\lambda_{\Omega_\epsilon}(B) \to \lambda_{\Omega_0}(B)$ as $\epsilon \to 0$.

Example 12. Example 1(e) revisited: Ω is a concentric annulus (spherical shell) of outer radius R and inner radius r. In it we place a soft spherical obstacle centered at $\mathbf{w}$ and of radius ρ; as in 1(e), necessarily, $\rho < \frac{R-r}{2}$. If r is sufficiently small, then at the minimizing position the support $|\mathbf{w}| = R - \rho$, i.e., the obstacle touches the outer boundary of the annulus.

The strategy of the proof is rather general and can be applied to some other cases as indicated below. For this reason we discuss it in some detail. For simplicity, we discuss the case of two dimensions.

Fix the radius ρ of the obstacle and the coupling α. We already know that $\mathbf{w} \in \mathcal{C}_1 \cup \mathcal{C}_2$, where

$$\mathcal{C}_1 := \{r + \rho \leq |\mathbf{x}| \leq (R + r)/2\}, \quad \mathcal{C}_2 = \{|\mathbf{x}| = R - \rho\}.$$

Note that $R/2 < R - \rho$, and

$$\mathcal{C}_1 \subset \mathcal{C}_1^* \equiv \{\rho \leq |\mathbf{x}| \leq R/2\}.$$

We denote by Λ and Λ^r the minima of the fundamental eigenvalues given a soft obstacle of radius ρ in domains $\Omega_0 = \{|x| < R\}$ and Ω_r, respectively.

Now we claim the following.

Claim A. We have $|\Lambda - \Lambda^r| \leq C/|\log r|$, where C is a constant independent of r.

Indeed, denoting by $B_*^r = B_{*,\rho}^r$ the optimal ball for the problem on Ω_r, we have $\Lambda^\epsilon = \lambda_{\Omega_r}(B_*^r) \geq \lambda_{\Omega_0}(B_*^r) \geq \Lambda$ because of domain monotonicity. Here $\lambda_\Omega(B)$ is the first eigenvalue of $-\Delta + \alpha\chi_B$ on Ω. On the other hand, denoting by $B_* = B_{*,\rho}$ the optimal ball for the problem on Ω_0, we know by [Sw63, Theorem 2], for example, that

$$\lambda_{\Omega_r}(B_*) \leq \lambda_{\Omega_r}(B_*) + \frac{C}{|\log r|}.$$

This yields

$$\Lambda^r \leq \Lambda + \frac{C}{|\log r|},$$

which implies Claim A.

We know that for $B_*^r(\mathbf{w}(r))$,

$$\rho + r \leq |\mathbf{w}(r)| \leq (R + r)/2 \quad \text{ or } \quad |\mathbf{w}(r)| = R - \rho.$$

If the conclusion did not hold, then there would exist a subsequence $\{r_j\}, r_j \to 0$ and $B^{r_j}(\mathbf{w}(r_j))$, such that

$$\rho + r_j \leq |\mathbf{w}(r_j)| \leq (R + r_j)/2.$$

By passing if necessary to a further subsequence, we may assume that $\mathbf{w}(r_j)$ converges to $\mathbf{w}_0$ with $|\mathbf{w}_0| \in [\rho, R/2]$. We use the notation

$$B_0 = B_\rho(w_0), \quad B_*^j = B_*^{r_j}(w(r_j)),$$

for simplicity. Next we claim the following.

Claim B. As $j \to \infty$, $\lambda_{\Omega_{r_j}}(B_*^j) - \lambda_{\Omega_{r_j}}(B_0) \to 0$.

Again using [Sw63], we obtain

$$|\lambda_{\Omega_{r_j}}(B_0) - \lambda_{\Omega_0}(B_0)| \to 0.$$

Granting (B), we get

$$|\lambda_{\Omega_{r_j}}(B_*^j) - \lambda_{\Omega_0}(B_0)| \leq |\lambda_{\Omega_{r_j}}(B_*^j) - \lambda_{\Omega_{r_j}}(B_0)| + |\lambda_{\Omega_{r_j}}(B_0) - \lambda_{\Omega_0}(B_0)| \to 0.$$

Combining this with (A), we conclude that

$$\lambda_{\Omega_0}(B_0) = \Lambda,$$

which contradicts the definition of B_0 and the stated fact about Λ. Thus, we conclude the desired statement.

It remains only to prove Claim B.

We shall show that

$$|\lambda_{\Omega_{r_j}}(B_*^j) - \lambda_{\Omega_{r_j}}(B_0)| \leq \alpha M |B_*^j \ominus B_0|^{1/2},$$

where $A \ominus B = (A \setminus B) \cup (B \setminus A)$. As a consequence we obtain $\lambda_{\Omega_{r_j}}(B_*^j) - \lambda_{\Omega_{r_j}}(B_0) \to 0$.

First, by definition, $\lambda_{\Omega_{r_j}}(B_*^j) \leq \lambda_{\Omega_{r_j}}(B_0)$. Denote by ϕ_{r_j} the normalized eigenfunction associated with $\lambda_{\Omega_{r_j}}(B_*^j)$. Then

$$\begin{aligned}
\lambda_{\Omega_{r_j}}(B_0) &\leq \int_{\Omega_{r_j}} |\nabla \phi_{r_j}|^2 + \alpha \chi_{B_0} \phi_{r_j}^2 \\
&= \int |\nabla \phi_{r_j}|^2 + \alpha \chi_{(B_*^j)} \phi_{r_j}^2 \, dx + \alpha \left(\int_{B_0} \phi_{r_j}^2 \, dx - \int_{B_*^j} \phi_{r_j}^2 \, dx \right) \\
&\leq \lambda_{\Omega_{r_j}}(B_*^j) + \alpha \int_{B_0 \ominus (B_*^j)} \phi_{r_j}^2 \, dx \\
&\leq \lambda_{\Omega_{r_j}}(B_*^j) + \alpha \|\phi_{r_j}\|_{L^4(\Omega_{r_j})}^2 |B_0 \ominus (B_*^j)|^{1/2}.
\end{aligned}$$

It is easy to see that $\lambda_{\Omega_{r_j}}(B_*^j)$ is bounded, and hence that $\int_{\Omega_{r_j}} |\nabla \phi_{r_j}|^2 \leq M$. By the Sobolev embedding theorem, we obtain $\|\phi_{r_j}\|_{L^4(\Omega_{r_j})}^2 \leq M$, yielding the desired estimate.

The strategy of the perturbation argument used for Example 12 can be used in many other situations. To summarize, let Ω_ϵ be a (singular) perturbation of Ω and assume, for simplicity, $\Omega_\epsilon \subset \Omega$. For a fixed $D \subset \Omega$, assume that $\lambda^\epsilon(D) \to \lambda(D)$ as $\epsilon \to 0$. Here $\lambda^\epsilon(D)$ and $\lambda(D)$ are the fundamental eigenvalues of $-\Delta + \alpha \chi_D$ on Ω_ϵ and Ω, respectively. We denote by $\Lambda = \lambda(B(x_0))$ and $\Lambda_\epsilon = \lambda(B(x_\epsilon))$ the optimal eigenvalues on Ω_ϵ and Ω, respectively. Then, if $x_0 \in \mathcal{C}_0$ and $x_\epsilon \in \mathcal{C}_0 \cup \mathcal{C}_\epsilon$ with $\mathcal{C}_\epsilon \subset \mathcal{C}$, and if $\inf_{y \in \mathcal{C}} \lambda(B(y)) > \Lambda$, then $x_\epsilon \in \mathcal{C}_0$ for sufficiently small ϵ.

We close by stating another perturbative result related to Examples 5 and 12.

Example 13. In two dimensions, let $\Omega_\epsilon = \{\epsilon < |x| < b\} \setminus \{(r, \theta); \epsilon < r < b, |\theta| \leq \beta\}$ with $\beta < \pi/2$, and suppose that it contains a soft spherical obstacle. Then for sufficiently small ϵ, at the minimizing position the obstacle is as close as the corner points $(r, \theta) = (b, \pm\beta)$.

Acknowledgments. This collaboration was made possible by two visiting invitations, that of Pawel Kröger to the Georgia Institute of Technology in Atlanta in April, 1995, and that of Evans Harrell and Kazuhiro Kurata to the Erwin Schrödinger Institut in Vienna in May, 1998. We are grateful to those institutions, as well as the French C.N.R.S. and the University of Toulouse 1 and 3, for their hospitality. Moreover, we wish to thank Ivor McGillivray for useful references.

AN EXACTLY SOLVABLE MODEL FOR THE INTERACTION OF LINEAR WAVES WITH KORTEWEG–DE VRIES SOLITONS[*]

P. D. MILLER[†] AND S. R. CLARKE[‡]

Abstract. Under certain mode-matching conditions, small-amplitude waves can be trapped by coupling to solitons of nonlinear fields. We present a model for this phenomenon, consisting of a linear equation coupled to the Korteweg–de Vries (KdV) equation. The model has one parameter, a coupling constant κ. For one value of the coupling constant, $\kappa = 1$, the linear equation becomes the linearized KdV equation, for which the linear waves can indeed be trapped by solitons and, moreover, for which the initial value problem for the linear waves has been solved exactly by Sachs [S83] in terms of quadratic forms in the Jost eigenfunctions of the associated Schrödinger operator. We consider in detail a different case of weaker coupling, $\kappa = 1/2$. We show that in this case linear waves may again be trapped by solitons, and like the stronger coupling case $\kappa = 1$, the initial value problem for the linear waves can also be solved exactly, this time in terms of linear forms in the Jost eigenfunctions. We present a family of exact solutions, and we develop the completeness relation for this family of exact solutions, finally giving the solution formula for the initial value problem. For $\kappa = 1/2$, the scattering theory of linear waves trapped by solitons is developed. We show that there exists an explicit increasing sequence of bifurcation values of the coupling constant, $\kappa = 1/2, 1, 5/3, \ldots$, for which some linear waves may become trapped by solitons. By studying a third-order eigenvalue equation, we show that for $\kappa < 1/2$ all linear waves are scattered by solitons, and that for $1/2 < \kappa < 1$, as well as for $\kappa > 1$, some linear waves are *amplified* by solitons.

Key words. solitons, Korteweg–de Vries equation, coupled systems, completeness relations, wave trapping

1. Introduction.

This paper is concerned with solving the coupled system of equations

$$\partial_t A + \partial_x \left[\frac{1}{2}A^2 + \partial_x^2 A\right] = 0, \tag{1}$$

$$\partial_t B + \partial_x \left[\kappa A B + \partial_x^2 B\right] = 0\,, \tag{2}$$

where κ is a real parameter. Of course, the nonlinear equation for $A(x,t)$ is simply the Korteweg–de Vries (KdV) equation, and it can be solved independently by the inverse-scattering transform [GGKM67]. The coupled system (1) and (2) is a partially linearized version of the system proposed by Hirota and Satsuma [HS81] as a model for the dynamics of coupled long waves.

The coupled system (1) and (2) can be solved exactly when $\kappa = 1$ and when $\kappa = 1/2$. The case of $\kappa = 1$ is well known, for then the equation (2) is just the KdV equation itself linearized about the solution $A(x,t)$. An elementary exact solution of the linear equation (2) in this case is given by $B(x,t) = \partial_x A(x,t)$. Further solutions can be expressed in terms of derivatives of the squared eigenfunctions of the related Schrödinger operator with potential A [S83].

The case of $\kappa = 1/2$ is essentially different. In this case, the linear equation (2) is no longer the linearization of KdV about *any* solution. An elementary exact solution of the linear equation in this case is given simply by $B(x, t) = A(x, t)$. The main goal of this paper is to construct the *general* solution of the initial value problem for this linear equation when $A(x, t)$ is a multisoliton solution of KdV.

One way to make clear the difference between the cases $\kappa = 1$ and $\kappa = 1/2$ is to consider $A(x, t)$ to be the simple soliton solution of KdV (1):

$$A(x,t) = 12\eta^2 \mathrm{sech}^2(\eta(x - 4\eta^2 t - \alpha)) = -V(\chi)\,, \tag{3}$$

where $\chi = x - ct - \alpha$ and the velocity is $c = 4\eta^2$. If we look for solutions of the linear equation (2) that are traveling waves with speed c, we find the equation

$$[-\kappa V(\chi)B(\chi) + B''(\chi)]' = cB'(\chi)\,. \tag{4}$$

Integrating once, using vanishing boundary conditions at $\chi = \pm\infty$, yields a Schrödinger eigenvalue problem for B:

$$-B''(\chi) + \kappa V(\chi)B(\chi) = EB(\chi)\,, \tag{5}$$

where $E = -c$. For $\kappa = 1/2$, it follows from the fact that $B(x, t) = A(x, t)$ is a solution of (2) that the function $B(\chi) = V(\chi)$ is an eigenfunction of the Schrödinger operator with eigenvalue $E = -c = -4\eta^2$. Since it has no zeros, it is the ground state eigenfunction. We will see below that there is also one excited state for $\kappa = 1/2$, although it is not relevant here since it corresponds to a different velocity. On the other hand, for $\kappa = 1$, $B(x, t) = \partial_x A(x, t)$ is a solution of (2), which implies that the function $B(\chi) = \partial_x V(\chi)$ is an eigenfunction of the Schrödinger operator with the same eigenvalue $E = -c = -4\eta^2$. In this case, the eigenfunction has a single zero and therefore is the first excited state. It follows that there are at least two eigenvalues for $\kappa = 1$. In fact, there are exactly three states in this case. A final observation is that from the construction of the one-soliton solution of KdV (see (8), (9), and (10) below) it follows that for $\kappa = 1/6$, the function $B(\chi) = V(\chi)$ is an eigenfunction of the Schrödinger operator with eigenvalue $E = -c/4 = -\eta^2$. It is the ground state and the only eigenfunction. These relationships are summarized in Figure 1.1. We will have more to say about this picture when we discuss the trapping of linear waves by solitons for general values of κ in section 6.

The rest of this paper is primarily concerned with developing the general solution of the initial value problem for (2) with $\kappa = 1/2$ when $A(x, t)$ is an N-soliton solution of KdV (1). In section 2 we show how for $\kappa = 1/2$ a large family of exact solutions of (2) can be obtained from the simultaneous solutions of the Lax pair for KdV. When the solution of KdV contains only solitons and no radiation, the construction of Lax eigenfunctions is completely algorithmic and algebraic, and consequently the corresponding family of solutions of (2) for $\kappa = 1/2$ can be obtained with great practicality. In section 3 we then establish that in the N-soliton case there are enough of these exact solutions of (2) for $\kappa = 1/2$ to expand for fixed t any absolutely continuous $L^1(\mathbb{R})$ function of x. This fact then leads to a general solution formula for (2) simply by expanding the initial data. We present and discuss this formula in section 4. There will turn out to be N linearly independent solutions that are asymptotically confined to the union of soliton trajectories and can therefore be considered to be bound states. In section 5 we compute the scattering matrix that relates the asymptotic behavior of bound states for $t \to -\infty$ to the corresponding behavior for $t \to +\infty$. In section 6 we

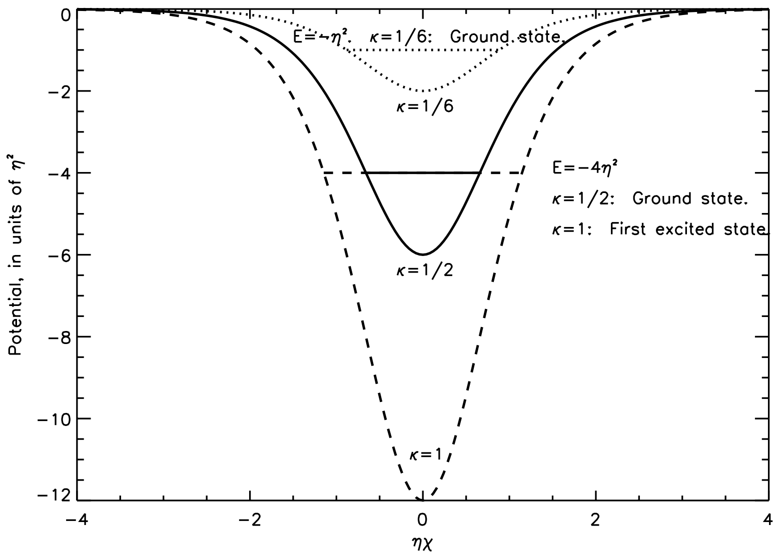

FIG. 1.1. *Energy levels of the* $12\kappa\eta^2\mathrm{sech}^2(\eta\chi)$ *potential for three different values of the coupling constant* κ.

consider general values of the coupling constant κ and describe the behavior of some solutions of (2) when $A(x,t)$ is a one-soliton solution of KdV (1). These calculations indicate the exceptional nature of the two values $\kappa = 1/2$ and $\kappa = 1$. In the appendix, we describe several physical applications of the coupled system (1) and (2) to topics in molecular dynamics, mechanics, soliton theory, and the fluid dynamics of internal waves.

2. Exact solution formulas for $\kappa = 1/2$. As is well known [GGKM67], the KdV equation (1) is the compatibility condition for a pair of linear equations involving a complex parameter λ for an auxiliary function $f(x,t,\lambda)$. This pair of linear equations is

$$(6) \qquad \partial_x^2 f = -\frac{\lambda^2}{4} f - \frac{1}{6} A f \qquad \text{and} \qquad \partial_t f = \frac{1}{6}\partial_x A \cdot f + \left(\lambda^2 - \frac{1}{3}A\right)\partial_x f$$

and is called a Lax pair. A simultaneous solution $f(x,t,\lambda)$ of these linear equations exists if and only if the function $A(x,t)$ satisfies KdV (1). Suppose that this is the case. Then, it is a direct matter to verify that for fixed but arbitrary $\lambda \in \mathbb{C}$, the two functions defined by

$$(7) \qquad B(x,t) := \partial_x \left[f(x,t,\lambda) \exp\left(\pm \frac{i}{2}(\lambda x + \lambda^3 t) \right) \right]$$

are solutions of the linear equation (2) when $\kappa = 1/2$. Note here an important point of departure from the other solvable case, namely, $\kappa = 1$, where (2) is the linearized KdV equation. In the latter case, particular solutions are expressed in terms of the x-derivative of the *square* of the Lax eigenfunction $f(x,t,\lambda)$ [GGKM74, S83]. By contrast, the formula (7) for solutions of (2) for $\kappa = 1/2$ is linear in $f(x,t,\lambda)$. This fact leads to some important simplifications.

The formula (7) is only really practical to use if one can explicitly compute the function $f(x,t,\lambda)$. This will be the case if the solution $A(x,t)$ of KdV (1) is a pure N-soliton solution. For each fixed t, $A(x,t)$ is then a reflectionless potential of the Schrödinger equation in the Lax pair (6). The multisoliton solutions of KdV and the associated solutions of the Lax pair are constructed as follows [KM56]. Let $f_+(x,t,\lambda)$ be given by

$$f_+(x,t,\lambda) := \left(1+\sum_{n=0}^{N-1}\lambda^{n-N}f_n(x,t)\right)\exp\left(-\frac{i}{2}(\lambda x+\lambda^3 t)\right)\,, \tag{8}$$

where the $f_n(x,t)$ are unknown coefficients. Choose N positive numbers $\eta_1 > \eta_2 > \cdots > \eta_N$, and N arbitrary real numbers $\alpha_1,\ldots,\alpha_N$, and insist that $f_+(x,t,\lambda)$ satisfy the relations

$$f_+(x,t,2i\eta_n) = (-1)^{n+1}\exp(2\eta_n\alpha_n)f_+(x,t,-2i\eta_n) \tag{9}$$

for all $n=1,\ldots,N$. It is easy to see that these relations imply a square linear algebraic system for the coefficients $f_n(x,t)$. The determinant of the system is always nonzero, and so the coefficients $f_n(x,t)$ are determined uniquely from the soliton eigenvalues $\{\lambda_n = 2i\eta_n\}$ and the norming constants $\{\alpha_n\}$ in terms of exponential functions. From this construction, it can be shown that if one chooses

$$A(x,t) := 6i\partial_x f_{N-1}(x,t)\,, \tag{10}$$

then $f_+(x,t,\lambda)$ and $f_-(x,t,\lambda) := f_+(x,t,-\lambda)$ are two simultaneous solutions of the Lax pair (6), and the function $A(x,t)$ defined by (10) satisfies KdV (1). The two functions $f_\pm(x,t,\lambda)$ are linearly independent for all nonzero $\lambda \neq \pm 2i\eta_n$. According to the linear relations (9) that determine the coefficients, at the exceptional values of λ the two functions are proportional.

The solution $A(x,t)$ of KdV so constructed represents the interaction of N solitons. In particular, as $t \to \pm\infty$, the solution can be represented in the form

$$A(x,t) \sim \sum_{n=1}^{N} A_n^\pm(x,t)\,, \qquad \text{where} \qquad A_n^\pm(x,t) := 12\eta_n^2\operatorname{sech}^2(\eta_n(x-\alpha_n^\pm)-4\eta_n^3 t)\,, \tag{11}$$

where the asymptotic phase constants $\alpha_n^\pm$ are functions of the η_n and α_n.

Below we will need the asymptotic behavior of the functions $f_\pm(x,t,\lambda)$ as $x \to \pm\infty$ for λ and t fixed. It can be shown that the coefficient functions $f_n(x,t)$ remain bounded as $x \to \pm\infty$. Then, letting x tend to $\pm\infty$ in the linear relations (9), one finds from dominant balance arguments that

$$\lim_{x\to\pm\infty}\left(1+\sum_{n=0}^{N-1}\lambda^{n-N}f_n(x,t)\right)\Bigg|_{\lambda=\pm 2i\eta_n} = 0\,. \tag{12}$$

These relations imply that

$$\lim_{x\to\pm\infty}\left(1+\sum_{n=0}^{N-1}(\pm\lambda)^{n-N}f_n(x,t)\right) = \lambda^{-N}\prod_{n=1}^{N}(\lambda-2i\eta_n)\,. \tag{13}$$

Therefore, for all $\lambda\in\mathbb{C}$,

$$\lim_{x\to\pm\infty} f_+(x,t,\lambda)\exp\left(\frac{i}{2}(\lambda x+\lambda^3 t)\right) = \lambda^{-N}\prod_{n=1}^{N}(\lambda\mp 2i\eta_n)\,. \tag{14}$$

The large $|x|$ asymptotics for the other solution $f_-(x,t,\lambda)$ follow from the definition $f_-(x,t,\lambda) = f_+(x,t,-\lambda)$. From these asymptotics, it is easy to construct the appropriate linear combinations of $f_\pm(x,t,\lambda)$ that correspond to the Jost functions of the Schrödinger equation, normalized at $x = \pm\infty$.

In the formula (7) we have a choice of sign in the exponent. In fact, it is easy to see that if one considers the totality of solutions obtained for all complex λ, the choice of sign is redundant. In what follows, we adopt a particular choice of the sign and maintain generality by using both Lax eigenfunctions $f_+(x,t,\lambda)$ and $f_-(x,t,\lambda)$. Thus, the particular solutions of the linear equation (2) for $\kappa = 1/2$ that we will consider below will be denoted by $h_\pm(x,t,\lambda)$, given by

$$h_\pm(x,t,\lambda) := \partial_x g_\pm(x,t,\lambda)\,, \qquad \text{where} \qquad g_\pm(x,t,\lambda) := f_\pm(x,t,\lambda)\exp\left(\frac{i}{2}(\lambda x + \lambda^3 t)\right)\,. \tag{15}$$

From the Schrödinger equation (6) for $f_\pm(x,t,\lambda)$, it follows that $g_\pm(x,t,\lambda)$ satisfies the ODE

$$-i\partial_x^2 g_\pm - i\frac{A}{6}g_\pm = \lambda\partial_x g_\pm\,. \tag{16}$$

This ODE plays an important role in suggesting the completeness relation for the solutions $h_\pm(x,t,\lambda)$.

3. The completeness relation for $\boldsymbol{\kappa = 1/2}$. Having in hand a large family of exact solutions of the linear equation (2) for $\kappa = 1/2$ is certainly useful, but we may then ask whether there are enough of these solutions to construct the general solution of the initial value problem by superposition. A *completeness relation* is a formula that gives the expansion of arbitrary initial data in terms of such a collection of functions. In this section, we will establish the completeness relation for the exact solutions $h_\pm(x,t,\lambda)$ obtained in section 2.

The form of the completeness relation is suggested by a similar argument to that used by Sachs [S83] in his investigation of the completeness of squared eigenfunction solutions to the linearized KdV equation. The idea is that ideally we would like to have a differential eigenvalue problem in standard form satisfied by the functions $h_\pm(x,t,\lambda)$:

$$L(t)h_\pm(x,t,\lambda) = \lambda h_\pm(x,t,\lambda)\,, \tag{17}$$

where λ is the eigenvalue and $L(t)$ is some second-order linear differential operator in x. Then, using the two explicit solutions $h_\pm(x,t,\lambda)$ of this problem, we could solve the inhomogeneous problem

$$L(t)\psi - \lambda\psi = \phi \tag{18}$$

by variation of parameters, i.e., by writing ψ as a linear combination of $h_\pm(x,t,\lambda)$ with nonconstant coefficients, and substituting into (18). For a fixed function $\phi(x)$, this determines $\psi(x,t,\lambda)$, and we have thus constructed the resolvent of the operator $L(t)$,

$$\psi(x,t,\lambda) = (L(t) - \lambda\mathbb{I})^{-1}\phi(x)\,. \tag{19}$$

If the spectrum of $L(t)$ is contained in a bounded region of the complex plane (and also under some milder conditions), then the Dunford–Taylor integral of the resolvent on a positively oriented contour enclosing the spectrum yields the identity operator

$$-\frac{1}{2\pi i}\oint \psi(x,t,\lambda)\,d\lambda = -\frac{1}{2\pi i}\oint (L(t)-\lambda\mathbb{I})^{-1}\phi(x)\,d\lambda = \phi(x)\,. \tag{20}$$

However, we do not have a second-order eigenvalue problem for $h_\pm(x,t,\lambda)$. Instead we have the second-order equation (16) for $g_\pm(x,t,\lambda)$. However, we make the *guess* that a similar procedure will apply here. Namely, for appropriate side conditions (see below) we solve the inhomogeneous equation

$$-i\partial_x^2\psi - i\frac{A}{6}\psi - \lambda\partial_x\psi = \phi \tag{21}$$

for $\psi(x,t,\lambda)$ using variation of parameters with the two functions $g_\pm(x,t,\lambda)$ solving the homogeneous equation (16), and then we differentiate the resulting formula with respect to x. Formally speaking only, we have thus constructed the resolvent of the "operator"

$$L(t) = -i\partial_x - i\frac{A}{6}\partial_x^{-1}\,. \tag{22}$$

The obstruction to rigor here is that ∂_x^{-1} is not well defined. Nonetheless, we are guided to hypothesize that

$$-\frac{1}{2\pi i}\oint \partial_x\psi(x,t,\lambda)\,d\lambda = \phi(x) \tag{23}$$

for an appropriate contour of integration. This formula turns out to be correct, although a direct proof must be supplied. The proof we use follows Miller and Akhmediev [MA98].

3.1. Solving the inhomogeneous problem. We express the solution of the inhomogeneous problem in the form

$$\psi(x,t,\lambda) = C_+(x,t,\lambda)g_+(x,t,\lambda) + C_-(x,t,\lambda)g_-(x,t,\lambda)\,, \tag{24}$$

subject to the usual "reduction of order" condition

$$\partial_x C_+(x,t,\lambda)\cdot g_+(x,t,\lambda) + \partial_x C_-(x,t,\lambda)\cdot g_-(x,t,\lambda) = 0\,. \tag{25}$$

Substituting (24) into the equation for ψ, and using (25), one finds

$$\partial_x C_+(x,t,\lambda) = -i\frac{\phi(x)g_-(x,t,\lambda)}{W(g_+,g_-)} \qquad \text{and} \qquad \partial_x C_-(x,t,\lambda) = i\frac{\phi(x)g_+(x,t,\lambda)}{W(g_+,g_-)}\,, \tag{26}$$

where $W(g_+,g_-) := g_+\partial_x g_- - g_-\partial_x g_+$ is the Wronskian.

From the differential equation (16) satisfied by $g_\pm(x,t,\lambda)$, it follows that

$$\partial_x W(g_+,g_-) = i\lambda W(g_+,g_-)\,. \tag{27}$$

Using the large $|x|$ asymptotics of $f_\pm(x,t,\lambda)$ obtained in section 2, one then solves (27) uniquely and finds that

$$W(g_+,g_-) = i\lambda^{1-2N}\exp(i(\lambda x+\lambda^3 t))\prod_{n=1}^{N}(\lambda^2+4\eta_n^2)\,. \tag{28}$$

In solving the inhomogeneous equation (21) for ψ, we really should impose appropriate side conditions. Here, the side conditions we use are not related to boundary conditions in x as much as to analyticity conditions in λ. It is easy to check that for each $x_{0,U}$, the function $\psi_U(x,t,\lambda)$ defined by

$$\begin{aligned}(29)\qquad \psi_U(x,t,\lambda) \;&=\; -\int_{x_{0,U}}^{x} \frac{g_-(z,t,\lambda)\exp(-i(\lambda z+\lambda^3 t))\phi(z)}{\lambda^{1-2N}\prod_{n=1}^{N}(\lambda^2+4\eta_n^2)}\,dz\cdot g_+(x,t,\lambda)\\ &\quad+\int_{-\infty}^{x} \frac{g_+(z,t,\lambda)\exp(-i(\lambda z+\lambda^3 t))\phi(z)}{\lambda^{1-2N}\prod_{n=1}^{N}(\lambda^2+4\eta_n^2)}\,dz\cdot g_-(x,t,\lambda)\end{aligned}$$

is a solution analytic in λ for $\Im(\lambda)>0$ and $|\lambda|$ sufficiently large. Similarly, $\psi_L(x,t,\lambda)$ defined for each $x_{0,L}$ by

$$\begin{aligned}(30)\qquad \psi_L(x,t,\lambda) \;&=\; -\int_{x_{0,L}}^{x} \frac{g_-(z,t,\lambda)\exp(-i(\lambda z+\lambda^3 t))\phi(z)}{\lambda^{1-2N}\prod_{n=1}^{N}(\lambda^2+4\eta_n^2)}\,dz\cdot g_+(x,t,\lambda)\\ &\quad-\int_{x}^{\infty} \frac{g_+(z,t,\lambda)\exp(-i(\lambda z+\lambda^3 t))\phi(z)}{\lambda^{1-2N}\prod_{n=1}^{N}(\lambda^2+4\eta_n^2)}\,dz\cdot g_-(x,t,\lambda)\end{aligned}$$

is a solution analytic for $\Im(\lambda)<0$ and $|\lambda|$ sufficiently large. The qualification of $|\lambda|$ being sufficiently large is necessary because the expressions have poles at the soliton eigenvalues in the respective half-planes where the two functions $g_\pm(x,t,\lambda)$ become proportional. However, these are the only finite singularities, and both solutions $\psi_U(x,t,\lambda)$ and $\psi_L(x,t,\lambda)$ are meromorphic in the whole of their respective open half-planes.

The arbitrariness of the parameters $x_{0,U}$ and $x_{0,L}$ would seem to be a problem; however, it will turn out that these terms contribute nothing to the Dunford–Taylor integral that we will prove gives the required completeness relation.

3.2. Integrating the resolvent.

Here we show that the guess we made is indeed correct.

THEOREM 3.1. *Let $\phi(x)$ be an absolutely continuous function in $L^1(\mathbb{R})$. Let $x_{0,U}$ and $x_{0,L}$ be constants, and let $t\in\mathbb{R}$ be fixed. Then,*

$$(31)\qquad \phi(x) = -\frac{1}{2\pi i}\lim_{R\to\infty}\left[\int_{C_U}\partial_x\psi_U(x,t,\lambda)\,d\lambda+\int_{C_L}\partial_x\psi_L(x,t,\lambda)\,d\lambda\right],$$

where C_U is the positively oriented half-circle from R to $-R$ in the upper half-plane and C_L is the positively oriented half-circle from $-R$ to R in the lower half-plane.

Proof. First, we show that the terms depending on the arbitrary parameters $x_{0,U}$ and $x_{0,L}$ converge to zero as $R\to\infty$. This will justify calling the function ψ_U or ψ_L

a "resolvent" even though the inverse is not unique. Consider the integral

$$
\begin{aligned}
J_U &:= \int_{C_U} \partial_x \left[-\int_{x_{0,U}}^{x} \frac{g_-(z,t,\lambda)\exp(-i(\lambda z+\lambda^3 t))\phi(z)}{\lambda^{1-2N}\prod_{n=1}^{N}(\lambda^2+4\eta_n^2)}\,dz\cdot g_+(x,t,\lambda)\right] d\lambda \\
&= -\int_{C_U} \frac{\lambda^{2N}h_+(x,t,\lambda)}{\lambda\prod_{n=1}^{N}(\lambda^2+4\eta_n^2)}\int_{x_{0,U}}^{x} g_-(z,t,\lambda)\exp(-i(\lambda z+\lambda^3 t))\phi(z)\,dz\,d\lambda\,,
\end{aligned}
\tag{32}
$$

where we have used the relation (25). Recall that

$$
\begin{aligned}
h_+(x,t,\lambda) &= \sum_{n=1}^{N}\lambda^{-n}\partial_x f_{N-n}(x,t)\,, \\
g_-(z,t,\lambda)\exp(-i(\lambda z+\lambda^3 t)) &= 1+\sum_{n=1}^{N}(-\lambda)^{-n}f_{N-n}(z,t)\,.
\end{aligned}
\tag{33}
$$

Therefore, for all λ with $|\lambda| = R > 1$,

$$
|h_+(x,t,\lambda)| \leq \frac{1}{R}\sum_{n=1}^{N}|\partial_x f_{N-n}(x,t)| \tag{34}
$$

and

$$
\sup_{z\in\mathbb{R}}|g_-(z,t,\lambda)\exp(-i(\lambda z+\lambda^3 t))| \leq 1+\sup_{z\in\mathbb{R}}\sum_{n=1}^{N}|f_{N-n}(z,t)|\,. \tag{35}
$$

This latter relation assumes the uniform boundedness of the functions $f_k(z,t)$ in z. Finally, it is clear that for $|\lambda| = R > \sup_n 2\eta_n$

$$
\left|\lambda^{1-2N}\prod_{n=1}^{N}(\lambda^2+4\eta_n^2)\right| \geq R\prod_{n=1}^{N}\left(1-\frac{4\eta_n^2}{R^2}\right). \tag{36}
$$

It follows that for all λ with $|\lambda| = R$ sufficiently large,

$$
|J_U| \leq \frac{K(x,t)}{R}\|\phi\|_1 \tag{37}
$$

where

$$
K(x,t) = \pi\prod_{n=1}^{N}\left(1-\frac{4\eta_n^2}{R^2}\right)^{-1}\cdot\left(\sum_{n=1}^{N}|\partial_x f_{N-n}(x,t)|\right)\cdot\left(1+\sup_{z\in\mathbb{R}}\sum_{n=1}^{N}|f_{N-n}(z,t)|\right). \tag{38}
$$

The bound (37) clearly vanishes as $R \to \infty$. A nearly identical argument shows that the integral

$$J_L \quad := \quad \int_{C_L} \partial_x \left[-\int_{x_{0,L}}^{x} \frac{g_-(z,t,\lambda)\exp(-i(\lambda z+\lambda^3 t))\phi(z)}{\lambda^{1-2N}\prod_{n=1}^{N}(\lambda^2+4\eta_n^2)}\,dz\cdot g_+(x,t,\lambda)\right] d\lambda \tag{39}$$

satisfies the same bound (37) as J_U.

Now we consider integrating the second terms of $\partial_x\psi_U(x,t,\lambda)$ and $\partial_x\psi_L(x,t,\lambda)$, respectively. For brevity, define

$$Y(x,z,t,\lambda) := \frac{g_+(z,t,\lambda)\exp(-i(\lambda z+\lambda^3 t))h_-(x,t,\lambda)}{\lambda^{1-2N}\prod_{n=1}^{N}(\lambda^2+4\eta_n^2)}\,. \tag{40}$$

Note that this can be written as

$$\begin{aligned} Y(x,z,t,\lambda) &= \exp\left(i\lambda(x-z)\right)\frac{\left(1+\sum_{n=1}^{N}\frac{f_{N-n}(z,t)}{\lambda^n}\right)}{\lambda\prod_{n=1}^{N}\left(1+\frac{4\eta_n^2}{\lambda^2}\right)} \\ &\quad\times\ \left(i\lambda\left(1+\sum_{n=1}^{N}\frac{f_{N-n}(x,t)}{(-\lambda)^n}\right)+\sum_{n=1}^{N}\frac{\partial_x f_{N-n}(x,t)}{(-\lambda)^n}\right), \end{aligned} \tag{41}$$

and therefore,

$$Y(x,z,t,\lambda) = i\exp(i\lambda(x-z))\left(1+\Delta(x,z,t,\lambda)\right)\,, \tag{42}$$

where $\Delta(x,z,t,\lambda)=O(\lambda^{-1})$ uniformly in x and z for fixed t. It also follows from additional cancellation that for $z=x$, $\Delta(x,x,t,\lambda)=O(\lambda^{-2})$ uniformly in x. Finally, derivatives of Δ are controlled as well: $\partial_z\Delta(x,z,t,\lambda)=O(\lambda^{-1})$ uniformly. The integral we need to compute for the contribution of $\partial_x\psi_U(x,t,\lambda)$ is

$$\begin{aligned} \int_{C_U}\int_{-\infty}^{x} Y(x,z,t,\lambda)\phi(z)\,dz\,d\lambda = {}& i\int_{C_U}\int_{-\infty}^{x}\exp(i\lambda(x-z))\phi(z)\,dz\,d\lambda \\ &+\ i\int_{C_U}\int_{-\infty}^{x}\Delta(x,z,t,\lambda)\exp(i\lambda(x-z))\phi(z)\,dz\,d\lambda\,. \end{aligned} \tag{43}$$

Note that since the integrand is analytic in the upper half-plane, the first term can be written as

$$i\int_{C_U}\int_{-\infty}^{x}\exp(i\lambda(x-z))\phi(z)\,dz\,d\lambda = -i\int_{-R}^{R}\int_{-\infty}^{x}\exp(i\lambda(x-z))\phi(z)\,dz\,d\lambda\,. \tag{44}$$

In order to control the error term, it is necessary to integrate by parts once:

$$\begin{aligned} i\int_{C_U}\int_{-\infty}^{x}\Delta(x,z,t,\lambda)\exp(i\lambda(x-z))\phi(z)\,dz\,d\lambda &= -\phi(x)\int_{C_U}\frac{\Delta(x,x,t,\lambda)}{\lambda}\,d\lambda \\ +\ \int_{C_U}\int_{-\infty}^{x}\frac{\exp(i\lambda(x-z))}{\lambda}&\partial_z(\Delta(x,z,t,\lambda)\phi(z))\,dz\,d\lambda\,. \end{aligned} \tag{45}$$

The boundary term at $z=-\infty$ vanishes because $\Delta(x,z,t,\lambda)$ is bounded there, ϕ is continuous and integrable, and $\exp(i\lambda(x-z))$ is exponentially small for $\Im(\lambda)>0$. Since the exponential is bounded in magnitude by unity for $\Im(\lambda)>0$ and the contour is of length πR, the above estimates of Δ imply that there exist $K_0(x,t)$, $K_1(x,t)$, and $K_2(x,t)$ all positive, such that

$$\begin{aligned}&\left|\int_{C_U}\int_{-\infty}^{x}\Delta(x,z,t,\lambda)\exp(i\lambda(x-z))\phi(z)\,dz\,d\lambda\right|\\ &\qquad=\frac{K_0(x,t)}{R^2}|\phi(x)|+\frac{K_1(x,t)}{R}\|\phi\|_1+\frac{K_2(x,t)}{R}\|\phi'\|_1\,.\end{aligned}\tag{46}$$

This proves that

$$\lim_{R\to\infty}\int_{C_U}\int_{-\infty}^{x}Y(x,z,t,\lambda)\phi(z)\,dz\,d\lambda=-i\lim_{R\to\infty}\int_{-R}^{R}\int_{-\infty}^{x}\exp(i\lambda(x-z))\phi(z)\,dz\,d\lambda\,.\tag{47}$$

Similar arguments applied to the contribution of $\partial_x\psi_L(x,t,\lambda)$ show that

$$-\lim_{R\to\infty}\int_{C_L}\int_{x}^{\infty}Y(x,z,t,\lambda)\phi(z)\,dz\,d\lambda=-i\lim_{R\to\infty}\int_{-R}^{R}\int_{x}^{\infty}\exp(i\lambda(x-z))\phi(z)\,dz\,d\lambda\,,\tag{48}$$

and therefore,

$$\begin{aligned}&-\frac{1}{2\pi i}\lim_{R\to\infty}\left[\int_{C_U}\partial_x\psi_U(x,t,\lambda)\,d\lambda+\int_{C_L}\partial_x\psi_L(x,t,\lambda)\,d\lambda\right]\\ &\qquad=\frac{1}{2\pi}\lim_{R\to\infty}\int_{-R}^{R}\int_{-\infty}^{\infty}\exp(i\lambda(x-z))\phi(z)\,dz\,d\lambda=\phi(x)\end{aligned}\tag{49}$$

with the last equality following from Fourier inversion. This establishes (31) and the theorem. □

As it stands, the completeness relation given in Theorem 3.1 is not really an expansion of $\phi(x)$ in terms of the functions $h_-(x,t,\lambda)$ because the expansion coefficients themselves depend on x. This is easily remedied by casting the right-hand side of the completeness relation into a more useful form. We do this now.

THEOREM 3.2. *Let $\phi(x)$ be an absolutely continuous function in $L^1(\mathbb{R})$. Let $t\in\mathbb{R}$ be fixed, and choose any $w\in\mathbb{R}\cup\{-\infty,+\infty\}$. Define the mode function*

$$H(x,t,\lambda):=\lambda^N h_-(x,t,\lambda)\,,\tag{50}$$

which is an entire function of λ, and the amplitudes

$$\begin{aligned}b^+(t,\lambda)&:=\int_w^{\infty}\frac{\lambda^N g_+(z,t,\lambda)\exp(-i(\lambda z+\lambda^3 t))}{\lambda\prod_{n=1}^{N}(\lambda^2+4\eta_n^2)}\phi(z)\,dz\,,\\ b^-(t,\lambda)&:=\int_{-\infty}^{w}\frac{\lambda^N g_+(z,t,\lambda)\exp(-i(\lambda z+\lambda^3 t))}{\lambda\prod_{n=1}^{N}(\lambda^2+4\eta_n^2)}\phi(z)\,dz\,,\end{aligned}\tag{51}$$

and set $b(t,\lambda) := b^+(t,\lambda) + b^-(t,\lambda)$. The amplitudes have simple poles at $\lambda = 0$ and $\lambda = \pm 2i\eta_n$ for $n = 1,\ldots,N$. Finally, set

$$b_0(t) := \frac{1}{2} \operatorname*{Res}_{\lambda=0} \left(b^+(t,\lambda) - b^-(t,\lambda)\right) \qquad \textit{and} \qquad b_n^{\pm}(t) := \mp \operatorname*{Res}_{\lambda=\pm 2i\eta_n} b^{\mp}(t,\lambda)\,. \tag{52}$$

Then we have the expansion

$$\begin{aligned}\phi(x) = {} & \lim_{R\to\infty} \frac{1}{2\pi i} \mathrm{P.V.} \int_{-R}^{R} b(t,\lambda) H(x,t,\lambda)\, d\lambda \\ & + b_0(t) H(x,t,0) + \sum_{n=1}^{N} \left[b_n^-(t) H(x,t,-2i\eta_n) + b_n^+(t) H(x,t,2i\eta_n)\right]\,.\end{aligned} \tag{53}$$

Remark 1. Since w is now fixed and not a function of x, this expansion (53) is a true completeness relation, expressing an arbitrary given function $\phi(x)$ as a sum of known functions $H(x,t,\lambda)$. From the exact formulas (50), (15), and (8), it is clear that the part of the expansion (53) represented by the singular integral is Fourier-like, with the corresponding components of the solution, $H(x,t,\lambda)$ for $\lambda \in \mathbb{R}$ being bounded oscillatory functions tending to complex exponentials for large x. On the other hand, the discrete contributions to the solution represent bound states. The $2N+1$ bound state terms in (53) are not linearly independent. From the fact that at the eigenvalues $\pm 2i\eta_n$ the functions $g_-(x,t,\lambda)$ are all linear combinations of the same N functions $f_0(x,t),\ldots,f_{N-1}(x,t)$, it is clear that only N of the bound states are linearly independent. These facts are easiest to see when one takes w to ∞ or $-\infty$. Then, half of the contributions from the eigenvalues disappear, and it remains only to express the bound state at zero, $H(x,t,0)$, in terms of $H(x,t,\pm 2i\eta_n)$. This can be done directly. From the exact formulas (50), (15), and (8), we see that

$$H(x,t,0) = (-1)^N \partial_x f_0(x,t)\,, \tag{54}$$

and making use of the relations (9) satisfied by f_+ at the eigenvalues,

$$H(x,t,2i\eta_n) = (-1)^{n+1} \exp(-2\eta_n\alpha_n) \sum_{p=0}^{N-1} (2i\eta_n)^p \partial_x f_p(x,t)\,. \tag{55}$$

Expressing $H(x,t,0)$ in terms of $H(x,t,2i\eta_n)$ is therefore a polynomial interpolation problem. Introduce the polynomial

$$P(\lambda) = \sum_{p=0}^{N-1} \partial_x f_p(x,t)\lambda^p\,. \tag{56}$$

Given isolated values of this polynomial

$$P(2i\eta_n) = (-1)^{n+1} \exp(2\eta_n\alpha_n) H(x,t,2i\eta_n) \qquad \text{for} \qquad n = 1,\ldots,N\,, \tag{57}$$

we are to find $P(0)$ and thus $H(x,t,0) = (-1)^N \partial_x f_0(x,t) = (-1)^N P(0)$. Expressing $P(\lambda)$ explicitly in terms of Lagrange polynomials gives

$$P(\lambda) = \sum_{n=1}^{N} (-1)^{n+1} \exp(2\eta_n\alpha_n) H(x,t,2i\eta_n) \prod_{k\neq n} \frac{\lambda - 2i\eta_k}{2i\eta_n - 2i\eta_k}\,, \tag{58}$$

and therefore

$$H(x,t,0)=\sum_{n=1}^{N}\left[(-1)^{n}\exp(2\eta_n\alpha_n)\prod_{k\neq n}\frac{\eta_k}{\eta_n-\eta_k}\right]H(x,t,2i\eta_n)\,. \tag{59}$$

There is, indeed, a similar expression for $H(x,t,0)$ in terms of $H(x,t,-2i\eta_n)$. □

Remark 2. An important distinction between the completeness relation stated in Theorem 3.2 and that found by Sachs [S83] for derivatives of squared Schrödinger eigenfunctions is in the nature of the singularity at $\lambda=0$. Sachs shows that in the expansion of ϕ in terms of derivatives of squared eigenfunctions, there is an apparent singularity at $\lambda=0$ that is in fact removable. On the other hand, the integral in Theorem 3.2 is essentially singular and the residue contribution of $b_0(t)$ is nonzero. □

Proof of Theorem 3.2. We first establish that in the formulas (29) for $\partial_x\psi_U(x,t,\lambda)$ and (30) for $\partial_x\psi_L(x,t,\lambda)$ we may replace x in the limits of integration by any other value without changing the result of the theorem. That is, we will now show that the integral

$$\int_{C_U}\int_{-\infty}^{w}Y(x,z,t,\lambda)\phi(z)\,dz\,d\lambda-\int_{C_L}\int_{w}^{\infty}Y(x,z,t,\lambda)\phi(z)\,dz\,d\lambda\,, \tag{60}$$

which we have already seen converges as R tends to infinity to $-2\pi i\phi(x)$ in the case that $w=x$, is in fact independent of w. Holding R fixed and differentiating with respect to w, we must show that for sufficiently large R,

$$\phi(w)\oint_{|\lambda|=R}Y(x,w,t,\lambda)\,d\lambda\equiv 0 \tag{61}$$

identically in x, w, and t. Being as the integrand is meromorphic in the finite λ plane, we can evaluate the integral by residues. There are simple poles at $\lambda=0$ and $\lambda=\pm 2i\eta_n$ for $n=1,\ldots,N$. Using the linear relations (9) satisfied by $f_\pm$ at the eigenvalues $\lambda=2i\eta_n$, we find

$$\begin{aligned}\operatorname*{Res}_{\lambda=2i\eta_k}\;Y(x,w,t,\lambda)&=\sum_{p=0}^{N-1}\frac{(2i\eta_k)^{N+p-1}}{D_k}\partial_x f_p(x,t)\\&\quad+\sum_{p,q=0}^{N-1}(-1)^{N-q}\frac{(2i\eta_k)^{p+q-1}}{D_k}f_q(w,t)\partial_x f_p(x,t)\,,\\\operatorname*{Res}_{\lambda=-2i\eta_k}\;Y(x,w,t,\lambda)&=\sum_{p=0}^{N-1}(-1)^{N-p}\frac{(2i\eta_k)^{N+p-1}}{D_k}\partial_x f_p(x,t)\\&\quad+\sum_{p,q=0}^{N-1}(-1)^{N-p}\frac{(2i\eta_k)^{p+q-1}}{D_k}f_q(w,t)\partial_x f_p(x,t)\,,\end{aligned} \tag{62}$$

where

$$D_k:=\prod_{n\neq k}(2i\eta_k-2i\eta_n)\prod_{n=1}^{N}(2i\eta_k+2i\eta_n)\,. \tag{63}$$

Similarly, for the residue at zero,

$$\operatorname*{Res}_{\lambda=0} \; Y(x,w,t,\lambda) = (-1)^N \frac{f_0(w,t)\partial_x f_0(x,t)}{\displaystyle\prod_{n=1}^{N} 4\eta_n^2}\,. \tag{64}$$

Adding all the residues and collecting coefficients of the terms $\partial_x f_p(x,t)$ and $f_q(w,t)$ $\partial_x f_p(x,t)$, we find that the sum of the residues will be zero if

$$I_p := \sum_{k=1}^{N} \frac{(2i\eta_k)^p}{D_k} = 0 \tag{65}$$

for all odd $p = 1, 3, 5, \ldots, 2N-3$, and if

$$\frac{1}{\displaystyle\prod_{n=1}^{N} 4\eta_n^2} + 2\sum_{k=1}^{N} \frac{1}{2i\eta_k D_k} = 0\,. \tag{66}$$

These expressions are themselves sums of residues of *meromorphic* differentials. Thus, by inspection, one finds that for $p = 1, 3, 5, \ldots, 2N-3$,

$$I_p = \frac{1}{2\pi i} \oint_C \frac{\lambda^p \, d\lambda}{\displaystyle\prod_{n=1}^{N} (\lambda^2 + 4\eta_n^2)}\,, \tag{67}$$

where C is any simple counterclockwise oriented contour that encircles the points $\lambda = 2i\eta_n$ for $n = 1, \ldots, N$ (but without enclosing the conjugate eigenvalues or $\lambda = 0$). With p bounded by $2N-3$, the path of integration can be blown out to infinity in the upper half-plane and then brought down to the real axis so that

$$I_p = \frac{1}{2\pi i} \int_{-\infty}^{\infty} \frac{\lambda^p \, d\lambda}{\displaystyle\prod_{n=1}^{N} (\lambda^2 + 4\eta_n^2)} = 0 \tag{68}$$

with the last equality following from the oddness of the integrand for odd p. Finally, consider the integral I_{-1} defined by

$$I_{-1} := \frac{1}{2\pi i} \oint_C \frac{d\lambda}{\lambda \displaystyle\prod_{n=1}^{N} (\lambda^2 + 4\eta_n^2)}\,. \tag{69}$$

Evaluating the residues inside C, we find

$$I_{-1} = \sum_{k=1}^{N} \frac{1}{2i\eta_k \displaystyle\prod_{n\neq k} (2i\eta_k - 2i\eta_n) \prod_{n=1}^{N} (2i\eta_k + 2i\eta_n)}\,. \tag{70}$$

On the other hand, we can again blow the contour C out to infinity in the upper half-plane and bring it down to the real axis. This time, there is a singularity at $\lambda = 0$, so the Plemelj formula must be used. We find

$$I_{-1} = -\frac{1}{2} \cdot \frac{1}{\displaystyle\prod_{n=1}^{N} 4\eta_n^2} + \frac{1}{2\pi i}\text{P. V.} \int_{-\infty}^{\infty} \frac{d\lambda}{\lambda \displaystyle\prod_{n=1}^{N}(\lambda^2 + 4\eta_n^2)} . \tag{71}$$

Once again, by oddness, the principal value integral vanishes identically, and then combining this result with the previous expression, we obtain the required vanishing.

This shows that for any w,

$$\phi(x) = -\frac{1}{2\pi i} \lim_{R\to\infty} \left[\int_{C_U} \int_{-\infty}^{w} Y(x,z,t,\lambda)\phi(z)\,dz\,d\lambda - \int_{C_L} \int_{w}^{\infty} Y(x,z,t,\lambda)\phi(z)\,dz\,d\lambda\right] . \tag{72}$$

Establishing (53) and therefore the theorem now amounts to using the residue theorem once again to deform the integration paths C_U and C_L in (72) to the real axis. One finds discrete contributions at the poles $\lambda = \pm 2i\eta_n$, and then applying the Plemelj formula to contract the contour to the real axis in the neighborhood of $\lambda = 0$ gives a discrete contribution proportional to $H(x,t,0)$ and the principal value regularization of the singular integral over the continuous spectrum. □

4. Solution of the initial value problem for $\boldsymbol{\kappa = 1/2}$. It is easy to see that when $A(x,t)$ is an N-soliton solution of KdV (1), one can use the completeness relation to solve the initial value problem

$$\partial_t B + \partial_x \left[\frac{1}{2}AB + \partial_x^2 B\right] = 0\,, \qquad B(x,0) = \phi(x)\,. \tag{73}$$

Setting $t = 0$, and picking a convenient value of w, say, $w = +\infty$, one computes the amplitudes (51) and discrete coefficients (52). Then, because the function $H(x,t,\lambda)$ satisfies (2) for $\kappa = 1/2$ and for each complex λ, the expression

$$\begin{aligned} B(x,t) := \quad & \lim_{R\to\infty} \frac{1}{2\pi i}\text{P. V.} \int_{-R}^{R} b(0,\lambda)H(x,t,\lambda)\,d\lambda \\ & + b_0(0)H(x,t,0) + \sum_{n=1}^{N} \left[b_n^-(0)H(x,t,-2i\eta_n) + b_n^+(0)H(x,t,2i\eta_n)\right] , \end{aligned} \tag{74}$$

provides the solution of the initial value problem (73), generally in the sense of distributions. That is, $B(x,0) = \phi(x)$ by Theorem 3.2, and for each test function $\varphi(x,t)$ that is differentiable in t and three times differentiable in x and has compact support in $(x,t) \in \mathbb{R} \times \mathbb{R}_+$, one shows by exchanging the order of integration that

$$\int_0^{\infty} \int_{-\infty}^{\infty} \left[\partial_t\varphi(x,t) + \frac{1}{2}A(x,t)\partial_x\varphi(x,t) + \partial_x^3\varphi(x,t)\right] B(x,t)\,dx\,dt = 0\,. \tag{75}$$

The solution will be classical in as much as it is possible to differentiate with respect to x and t under the integral sign in the solution formula (74). This requires additional smoothness and decay assumptions on the initial data $\phi(x)$ that we do not consider here.

5. Scattering of bound states for $\kappa = 1/2$. Of particular interest in applications is the N-dimensional (recall that $A(x,t)$ is an N-soliton solution of KdV) subspace of solutions of (2) for $\kappa = 1/2$ consisting of bound states. This subspace represents linear waves that are trapped by the solitons of the potential $A(x,t)$. For large $|t|$, these bound state solutions are all confined to the trajectories of the solitons. Therefore, it follows that each bound state $B(x,t)$ has two asymptotic representations:

$$B(x,t) \sim \sum_{n=1}^{N} \beta_n^{\pm} A_n^{\pm}(x,t)\,, \qquad t \to \pm\infty\,, \tag{76}$$

for some constants $\beta_n^{\pm}$ depending on $B(x,t)$, where $A_n^{\pm}(x,t)$ are defined by (11). Since there are exactly N linearly independent bound states, it follows that the constants β_n^{+} are completely determined from the constants β_n^{-}. In particular, there exists an invertible $N \times N$ matrix $\mathbf{T}$ with entries depending only on the data specifying the N-soliton solution $A(x,t)$, such that

$$\beta_j^{+} = \sum_{k=1}^{N} T_{jk}\beta_k^{-}\,. \tag{77}$$

The matrix $\mathbf{T}$ is called the *bound state scattering matrix.* In this section, we compute the scattering matrix explicitly and show that its elements only depend on the soliton eigenvalues $\eta_1, \ldots, \eta_N$.

If $A(x,t)$ is an N-soliton solution of KdV (1), then a family of solutions to (2) for $\kappa = 1/2$, parametrized by complex λ, is given by

$$h_+(x,t,\lambda) = \frac{A(x,t)}{6i\lambda} + \sum_{n=0}^{N-2} \lambda^{n-N}\partial_x f_n(x,t)\,. \tag{78}$$

We want to analyze these solutions in the limit of large $|t|$, in a frame of reference traveling with constant velocity c.

The first step is to see how the coefficients $f_n(x,t)$ behave for large $|t|$. Let $\chi = x - ct$ be fixed as $\tau = t$ goes to either $+\infty$ or $-\infty$. Begin by taking $\eta_m^2 < 4c < \eta_{m-1}^2$ to see how the coefficients behave in between the solitons. In the limit $\tau \to +\infty$, the equations (9) imply that

$$\begin{aligned} 1 \quad &+ \quad \sum_{k=0}^{N-1} (-2i\eta_n)^{k-N} f_k \quad \to \quad 0\,, \quad n = 1, \ldots, m-1\,, \\ 1 \quad &+ \quad \sum_{k=0}^{N-1} (2i\eta_n)^{k-N} f_k \quad \to \quad 0\,, \quad n = m, \ldots, N\,. \end{aligned} \tag{79}$$

This is an invertible Vandermonde system for the coefficients f_k, so that as $\tau \to +\infty$, the f_k all become constants, independent of χ and τ. Thus, $\partial_x f_k(x,t)$ vanishes between the solitons for all k. The analogous result holds as $\tau \to -\infty$. This shows that the solutions of (2) for $\kappa = 1/2$ described by the formula (78) are asymptotically confined to the individual frames of reference of the moving solitons in the potential field $A(x,t)$.

Now set $c = 4\eta_m^2$ to go into the moving frame of reference of one of the solitons. Taking the limit $\tau \to +\infty$ yields

$$
\begin{aligned}
1 \quad + \quad & \sum_{k=0}^{N-1} (-2i\eta_n)^{k-N} f_k \quad \to \quad 0 \,, \quad n = 1, \ldots, m-1 \,, \\
1 \quad + \quad & \sum_{k=0}^{N-1} (2i\eta_n)^{k-N} f_k \quad \to \quad 0 \,, \quad n = m+1, \ldots, N \,.
\end{aligned}
\tag{80}
$$

This is a system of $N-1$ equations in N unknowns, so it can be used to asymptotically eliminate $\partial_\chi f_0$ through $\partial_\chi f_{N-2}$ in favor of $\partial_\chi f_{N-1}$, which we know is proportional to the N-soliton solution of KdV, $A(x,t)$. Thus, as $\tau \to +\infty$, with $c = 4\eta_m^2$,

$$
\partial_\chi f_k = Q_{mk} \partial_\chi f_{N-1} = \frac{1}{6i} Q_{mk} A
\tag{81}
$$

for $k = 0, \ldots, N-2$, where the numbers Q_{mk} are the unique solution of the inhomogeneous system of linear algebraic equations

$$
\begin{aligned}
(-2i\eta_n)^{-1} \quad + \quad & \sum_{k=0}^{N-2} (-2i\eta_n)^{k-N} Q_{mk} \quad = \quad 0 \,, \quad n = 1, \ldots, m-1 \,, \\
(2i\eta_n)^{-1} \quad + \quad & \sum_{k=0}^{N-2} (2i\eta_n)^{k-N} Q_{mk} \quad = \quad 0 \,, \quad n = m+1, \ldots, N \,.
\end{aligned}
\tag{82}
$$

One can similarly show that as $\tau \to -\infty$, with $c = 4\eta_m^2$,

$$
\partial_\chi f_k = Q_{mk}^* \partial_\chi f_{N-1} = \frac{1}{6i} Q_{mk}^* A
\tag{83}
$$

for $k = 0, \ldots, N-2$, where the star denotes complex conjugation.

Now consider particular solutions $B_j(x,t)$ of (2) for $\kappa = 1/2$ obtained as linear combinations of N others expressed by the formula (78) evaluated on the N soliton eigenvalues. The formula for $B_j(x,t)$ is

$$
B_j(x,t) = \sum_{k=1}^{N} F_{jk} h_+(x,t,2i\eta_k) = \sum_{k=1}^{N} F_{jk} \left[-\frac{A(x,t)}{12\eta_k} + \sum_{n=0}^{N-2} (2i\eta_k)^{n-N} \partial_x f_n(x,t) \right] \,,
\tag{84}
$$

where $\mathbf{F} = \{F_{jk}\}$ is a matrix of arbitrary constants. From the asymptotics of $f_n(x,t)$, we have as $\tau \to -\infty$ with $c = 4\eta_m^2$

$$
B_j \to A \sum_{k=1}^{N} F_{jk} G_{km}^- \,, \qquad \text{where} \qquad G_{km}^- := -\frac{1}{12\eta_k} + \frac{1}{6i} \sum_{n=0}^{N-2} (2i\eta_k)^{n-N} Q_{mn}^* \,.
\tag{85}
$$

So, with the choice that the matrix $\{F_{jk}\}$ is the inverse of the matrix $\mathbf{G}^- = \{G_{km}^-\}$, the particular solution $B_j(x,t)$ of (2) for $\kappa = 1/2$ will be completely confined as $t \to -\infty$ to the frame of reference moving with speed $c = 4\eta_j^2$, where it will be locally indistinguishable from the solution $A(x,t)$ of KdV. Let us now determine how $B_j(x,t)$

will behave in the various soliton frames as $t \to +\infty$. Passing to the limit of $\tau \to +\infty$ in the frame with velocity $c = 4\eta_m^2$ gives

$$(86)\quad B_j \to A \sum_{k=1}^{N} F_{jk} G_{km}^{+}\,, \qquad \text{where} \qquad G_{km}^{+} := -\frac{1}{12\eta_k} + \frac{1}{6i}\sum_{n=0}^{N-2} (2i\eta_k)^{n-N} Q_{mn}\,.$$

These asymptotics give us a formula for the bound state scattering matrix:

$$(87) \qquad \mathbf{T} := \left[(\mathbf{G}^{-})^{-1}\mathbf{G}^{+}\right]^{T}\,.$$

It is clear that the elements of $\mathbf{T}$ depend only on the N soliton eigenvalues $\eta_1, \dots, \eta_N$. There is no dependence on the soliton phase variables $\alpha_1, \dots, \alpha_N$. Therefore, the asymptotic scattering properties of linear waves in (2) with $\kappa = 1/2$ are insensitive to phase shifts among the solitons in the potential $A(x,t)$. As a concrete example of the scattering matrix, we compute it explicitly for $N = 2$ for arbitrary $\eta_1 > \eta_2 > 0$:

$$(88) \qquad \mathbf{T} = \frac{1}{\eta_1^2 - \eta_2^2}\begin{bmatrix} (\eta_1 - \eta_2)^2 & 2\eta_2(\eta_1 - \eta_2) \\ 2\eta_1(\eta_1 - \eta_2) & -(\eta_1 - \eta_2)^2 \end{bmatrix}\,.$$

The fact that T_{22} is negative means that it is possible for the interactions of the solitons in $A(x,t)$ to convert trapped linear waves of elevation into waves of depression, and vice-versa.

6. General values of $\boldsymbol{\kappa}$. We expect that for most values of κ, the linear waves satisfying (2) will not be permanently trapped by solitons present in the potential $A(x,t)$. This is suggested by considering the simplest case, namely, taking $A(x,t)$ to be the one-soliton solution of KdV (1). The soliton travels with velocity $c = 4\eta^2$ so that $A = -V(\chi)$ with $\chi = x - ct - \alpha$. Corresponding traveling wave solutions $B(\chi)$ of the linear problem that propagate with the same velocity and decay as $\chi \to \pm\infty$ satisfy

$$(89) \qquad -B''(\chi) + \kappa V(\chi)B(\chi) = -cB(\chi)\,.$$

Since c is fixed, we can view this as an eigenvalue equation with κ as the eigenvalue. We therefore expect that only isolated values of κ will admit nontrivial decaying solutions $B(\chi)$. We have already seen that $\kappa = 1/2$ and $\kappa = 1$ are indeed eigenvalues. For $\kappa = 1/2$ the eigenfunction $B(\chi)$ is an even function of χ, while for $\kappa = 1$ the eigenfunction $B(\chi)$ is odd in χ. Since eigenfunctions of (89) must be nondegenerate and therefore have either odd or even parity in χ, there cannot exist a nontrivial bound state eigenfunction of (89) for all $\kappa \in [1/2, 1]$ because the eigenfunction would have to change parity from one endpoint to the other. Therefore, at least one value of $\kappa \in [1/2, 1]$ is not an eigenvalue. For such κ, there is no bound state traveling wave solution of (2) that is trapped in the soliton trajectory.

We can be more precise about this phenomenon. The left-hand side of (89) can also be viewed as a Schrödinger operator $L(\kappa)$ depending on a coupling constant κ, and the condition for wave trapping by solitons is simply that $-c \in \Sigma_{\mathrm{p}}(L(\kappa))$, where Σ_{p} denotes the point spectrum. The number of discrete eigenvalues is a nondecreasing function of $\kappa > 0$, corresponding to the deepening of the potential well. There is an infinite unbounded sequence of *cutoff* values κ_n^{cut} of κ at which the number of eigenvalues changes by one, and the new eigenvalue is born from the continuum. Each eigenvalue, once born, is distinct and is a decreasing function of κ. From these arguments, it follows that there exists an infinite unbounded sequence of *bifurcation* values κ_n^{bif} of κ at which one eigenvalue crosses the level $E = -c$, and a bound state traveling wave solution of (2) exists.

It is easy to find the bifurcation points because the hyperbolic secant squared potential is so well understood. The potential $\kappa V(\chi)$ is exactly reflectionless for $12\kappa = n(n+1)$ for $n = 1, 2, 3, \ldots$. The corresponding energy levels are $E_{n,k} = -k^2\eta^2$ for $k = 1, \ldots, n$. Therefore, for $n > 1$ in this sequence, there is always one eigenvalue that is exactly equal to $-c = -4\eta^2$. The corresponding eigenstate is always the $(n-1)$st state and therefore has $n-2$ zeros. It follows that the bifurcation points are $\kappa = \kappa_n^{\mathrm{bif}} = (n+1)(n+2)/12$ for $n = 1, 2, 3, \ldots$.

The fact that some linear waves may be permanently trapped by isolated solitons at a bifurcation point $\kappa = \kappa_n^{\mathrm{bif}}$ does not necessarily imply that there will be no losses to radiation when solitons in the field $A(x,t)$ interact with one another. Such a lossless interaction might suggest the "integrability" of the linear equation (2). We have indeed seen that this is the case for the first two bifurcation points, $\kappa = \kappa_1^{\mathrm{bif}} = 1/2$ and $\kappa = \kappa_2^{\mathrm{bif}} = 1$, but it is by no means clear that the trend continues for higher-order bifurcation points. For the rest of this section, we therefore restrict attention to the case $N = 1$, that is, we take the nonlinear field $A(x,t)$ to be a one-soliton solution of KdV (1).

Using (3) and the change of variables $x' = \eta(x - 4\eta^2 t - \alpha)$ and $t' = \eta^3 t$, (2) becomes, after dropping primes,

$$\partial_t B + \partial_x[-4B + 12\kappa\,\mathrm{sech}^2(x)B + \partial_x^2 B] = 0\,. \tag{90}$$

This equation is of course solved by separation of variables. We seek separated solutions $B(x,t) = b_\sigma(x)\exp(\sigma t)$ and obtain the third-order eigenvalue problem

$$[4b_\sigma(x) - 12\kappa\,\mathrm{sech}^2(x)b_\sigma(x) - b_\sigma''(x)]' = \sigma b_\sigma(x)\,, \tag{91}$$

where the prime denotes differentiation with respect to x. In this context, what we have been calling "trapped linear waves" correspond to bound-state eigenfunctions of (91) with $\sigma = 0$. Such solutions have finite mass and energy and are stationary in the moving frame of reference of the soliton $A(x,t)$. As we know, such eigenfunctions with $\sigma = 0$ exist only at the bifurcation values of $\kappa = \kappa_n^{\mathrm{bif}}$. However, it is clear that for general values of κ there are other possibilities. There may be eigenvalues σ that are purely imaginary, giving rise to oscillating modes that travel in the soliton frame. More generally, if an eigenvalue has a nonzero real part for some κ, then there will be a mode that is either amplified or exponentially damped as it propagates with the soliton.

The eigenvalue problem (91) has two simple symmetries. Whenever $b_\sigma(x)$ is an eigenfunction with eigenvalue σ, then $b_\sigma(-x)$ is an eigenfunction with eigenvalue $-\sigma$ and $b_\sigma(x)^*$ is an eigenfunction with eigenvalue σ^*. Therefore, the eigenvalues either come in purely real pairs $(|\sigma|, -|\sigma|)$, purely imaginary pairs $(i|\sigma|, -i|\sigma|)$, or in complex quartets $(\sigma, -\sigma, \sigma^*, -\sigma^*)$. These symmetries indicate the distinguished role of $\sigma = 0$ as a point that if it appears in the spectrum for some κ can signal a bifurcation in the number of eigenvalues. This explains our terminology and notation for the values $\kappa = \kappa_n^{\mathrm{bif}}$.

Most points on the imaginary σ axis correspond to continuous spectrum. This can be seen by the following argument. Let κ be fixed. Suppose $\sigma = i\omega$ with $\omega \in \mathbb{R}$. For large $|x|$, the solutions of (91) have the form of linear combinations of $\exp(ik_{\omega,j}x)$ where $k = k_{\omega,j}$ are the three roots of $k^3 + 4k - \omega = 0$. Exactly one of these roots, say, $k = k_{\omega,0}$, is real, while the other two form a complex-conjugate pair. If we seek a generalized eigenfunction normalized to $\exp(ik_{\omega,0}x)$ as $x \to -\infty$ through a "shooting" method, we have three complex constants to exploit: the coefficient of the decaying mode for large negative x, and the coefficients of the decaying mode for large positive x and the finite amplitude contribution for large positive x. Matching the values of $b_{i\omega}(x)$, $b'_{i\omega}(x)$, and $b''_{i\omega}(x)$ at $x = 0$ gives three complex equations in three complex unknowns. If this system of equations is solvable at all, one expects it to be solvable for almost all real ω, yielding a generalized eigenfunction. For exceptional values of ω where there is not a generalized eigenfunction, there will be a genuine bound-state eigenfunction since the spectrum is a closed set.

We have used a numerical Fourier-based collocation (pseudospectral) method to find the discrete eigenvalues of (91) over a range of values of the coupling constant κ. Essentially this involves approximating the continuous function $b_\sigma(x)$ by a periodic discrete series. Then the derivative ∂_x can be approximated to exponential accuracy by a derivative matrix $\mathbf{D}$ for which an explicit formula is given in [CHQZ88]. This is then used to construct a discrete approximation to the operator on the left-hand side of (91). Standard techniques can then be used to obtain the eigenvalues and eigenvectors of this matrix. The corresponding eigenfunctions always decay exponentially, but sometimes they decay *very* slowly for large x of one or the other sign—luckily not both. To obtain accurate results it was necessary in these cases to change the dependent variable by multiplying by an appropriate exponential function of x to enhance the decay on the slowly decaying side without changing decay into growth on the other side. Our results over the range $0 < \kappa < 5$ are shown in Figure 6.1. The bifurcation values κ_n^{bif} appear to be of two different types. If n is odd, then when κ increases through the value $\kappa = \kappa_n^{\mathrm{bif}}$, a new pair of real eigenvalues is born from the origin $\sigma = 0$. As κ is further increased, the pair of eigenvalues moves at first away from the imaginary axis and then changes direction and contracts toward the origin. When κ increases through the even bifurcation value $\kappa = \kappa_{n+1}^{\mathrm{bif}}$, the pair enters the origin and re-emerges as a complex eigenvalue quartet. Further increasing the value of κ causes the quartet of eigenvalues to move through a maximum in the magnitude of the real part and then toward the imaginary axis with the magnitude of the real part decreasing to zero while the magnitude of the imaginary part increases without bound. It does not appear that the quartet of eigenvalues ever disappears into the continuous spectrum, although it comes arbitrarily close as κ increases. This scenario is repeated again and again as κ increases through each odd bifurcation value. Representative eigenfunctions are plotted in Figure 6.2. Here, one can see that when the eigenvalue σ has a nonzero imaginary part, the decay of the eigenfunction can be quite slow on the "downstream" side of the soliton. As remarked above, this effect is compensated for in our numerics by working with a modified eigenfunction.

There are no discrete eigenvalues at all for $\kappa < 1/2$ (and in particular for $\kappa < 0$), and for all κ satisfying $1/2 < \kappa < 1$ and $\kappa > 1$, there is always at least one eigenvalue with a nonzero real part, which corresponds to an exponentially growing eigenfunction and therefore instability. The values $\kappa = 1/2$ and $\kappa = 1$ are distinguished as the only values for which there exist discrete eigenvalues and at the same time all eigenvalues have zero real parts, so the system is neutrally stable. For all other values of κ, either there are no discrete eigenvalues at all in which case all initial conditions for (2) disperse away algebraically in time, or there are discrete eigenvalues with positive real parts in which case the linear waves are amplified by the soliton in the field $A(x, t)$.

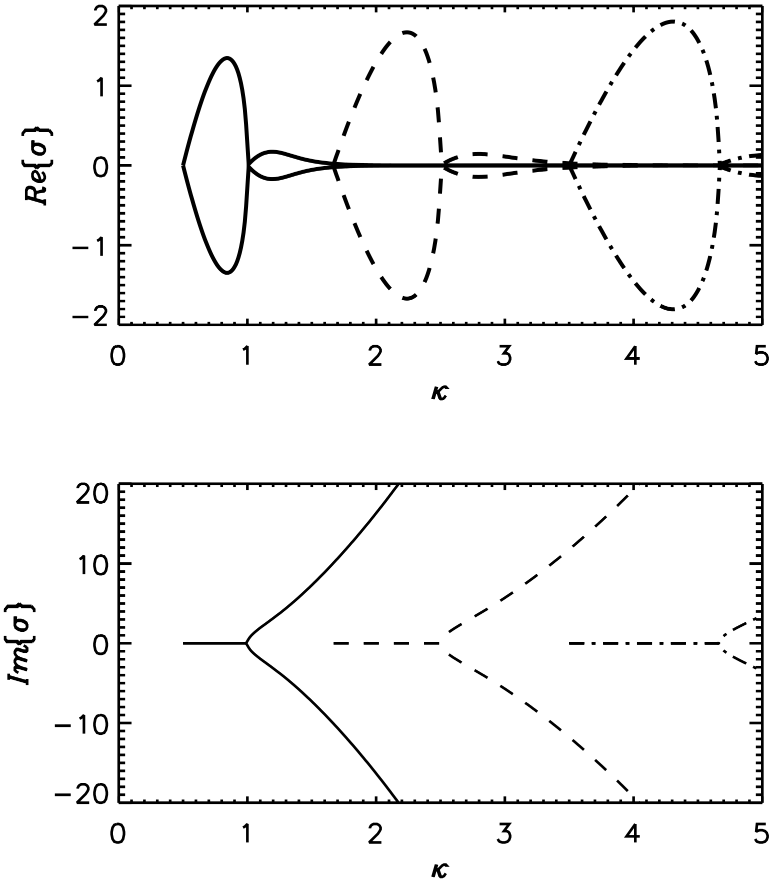

FIG. 6.1. *Real (above) and imaginary (below) parts of the discrete eigenvalues σ for the eigenvalue problem* (91) *as a function of the parameter κ. Different eigenvalue branches are displayed with different styles of lines (solid, dashed, etc.).*

7. Conclusion. The coupled system consisting of the KdV equation (1) and the linear equation (2) is integrable for two distinct values of the coupling parameter κ. The integrable case of $\kappa = 1$ has been studied by other authors [GGKM74, S83]. In this paper, we have given new results for the other integrable case, namely, $\kappa = 1/2$. In particular, we have shown how to construct the general solution of (2) for $\kappa = 1/2$ when the nonlinear field $A(x,t)$ is an N-soliton solution of the KdV equation. This general solution is represented in terms of a number of bound states (equal to the number N of solitons in the field $A(x,t)$) and a continuum superposition of radiative states given by a singular integral. With the help of numerical computations, we have placed the integrable cases in context by examining the behavior of the linear equation (2) for general values of κ, when $A(x,t)$ is a one-soliton solution of KdV. These calculations show that the linear equation (2) behaves as an unstable dynamical system for most positive κ. The integrable value of $\kappa = 1$, for which the equation (2) is the linearized KdV equation, is an isolated stable point, since a small change of either sign in the value of κ will lead to the presence of exponentially growing modes. The other integrable value of $\kappa = 1/2$ represents the boundary between a

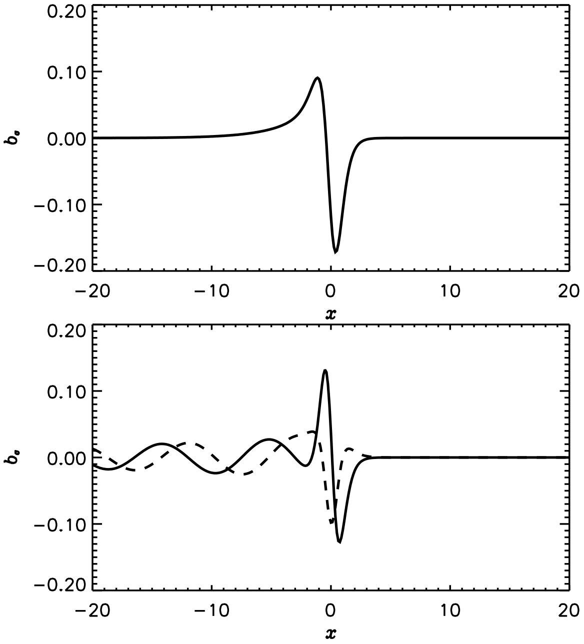

FIG. 6.2. *Above: the real-valued eigenfunction corresponding to the eigenvalue σ with positive real part for $\kappa = 0.85$. Below: the complex-valued eigenfunction corresponding to the eigenvalue σ in the first quadrant for $\kappa = 1.2$. The solid curve is the real part and the dashed curve is the imaginary part.*

stable system without any bound states for $\kappa < 1/2$ and an exponentially unstable system for $\kappa > 1/2$.

In physical applications of the coupled system (1) and (2) as discussed in the appendix, the presence of instabilities indicates that more terms need to be included in the model. However, in the stable cases the model is indeed expected to be physically meaningful. And in this regard, the two integrable cases can provide useful starting points for perturbation theory.

As a final remark, let us indicate the kind of calculations that are possible for the coupled system (1) and (2) for $\kappa = 1/2$ with the aid of the completeness relation. For a family of relevant initial data for the linear equation, one can explicitly compute the projection onto the bound states and consequently determine the long time behavior of the corresponding solution of (2). Also, the long time behavior of the dispersive part of the solution can be computed from the explicit representation of this component of the solution as a singular integral. We leave such applications of the completeness relation for further investigations.

Appendix A. Some applications. It is useful to keep in mind some applications in which the coupled system (1) and (2) might arise. In fact, such equations appear in the modeling of coupling of acoustic phonons in long polymer molecules. Many organic polymers (e.g., DNA and α-helix proteins like acetanelide) may be considered from the mechanical point of view as long chains of nearly identical masses. This "backbone" of the molecule supports a longitudinal vibrational mode in which the masses are all moving in tandem with zero frequency (i.e., simple translation) in

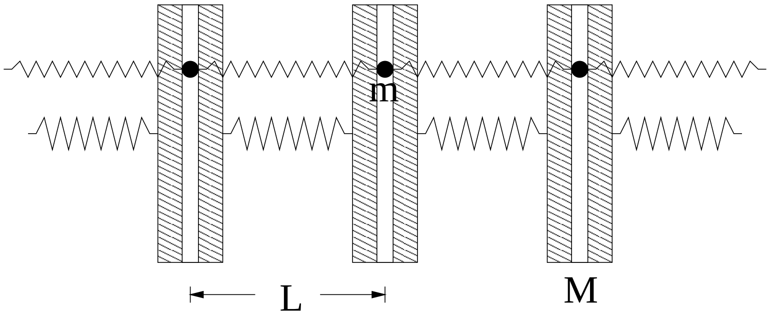

FIG. A.1. *The equilibrium configuration of the mechanical model.*

the long-wave limit; the associated quanta are called acoustic phonons. In the presence of intrinsic weak nonlinearity, the KdV equation describes these vibrations in the long-wave limit. Usually, the masses making up the chain contain internal degrees of freedom (e.g., the "breathing" modes of base-pairs in DNA, and the so-called amide I exciton modes of the C=O bond in each peptide group of an α-helix protein). The coupling of these internal degrees of freedom to the motion of the backbone leads to a variety of interesting dynamical models (e.g., the discrete sine-Gordon equation for DNA and the discrete nonlinear Schrödinger equation for α-helix proteins).

We may consider a situation in which the internal degrees of freedom are themselves acoustic phonons associated with transverse vibrational modes. This can be visualized with the help of a concrete mechanical model, whose equilibrium configuration is shown in Figure A.1. The backbone is made of heavy masses M connected by stiff springs. Mounted on each heavy mass is a transversely-oriented frictionless track in which rides a small mass m. The mass M is assumed to include the mass of the track and small mass m. The small masses are themselves connected by weaker springs. Assigning longitudinal displacements u_n to the large masses M and transverse displacements v_n to the small masses m in the frictionless tracks, the Hamiltonian of the mechanical model is

$$H = \sum_n \left[\frac{1}{2}M\dot{u}_n^2 + \frac{1}{2}m\dot{v}_n^2 + W(L+u_{n+1}-u_n)\right.$$

$$\left. +V\left(\sqrt{(L+u_{n+1}-u_n)^2+(v_{n+1}-v_n)^2}\right)\right] ,$$

(A1)
where W is the potential energy of the stiff springs connecting the large masses and V is the potential energy of the weaker springs.

The associated equations of motion are

$$\begin{aligned} M\ddot{u}_n &= W'(L+u_{n+1}-u_n) - W'(L+u_n-u_{n-1}) \\ &\quad + S(D_{n+1})(L+u_{n+1}-u_n) - S(D_n)(L+u_n-u_{n-1}), \\ m\ddot{v}_n &= S(D_{n+1})(v_{n+1}-v_n) - S(D_n)(v_n-v_{n-1}) , \end{aligned}$$

(A2)
where we have set $S(D) := V'(D)/D$ and $D_n := \sqrt{(L+u_n-u_{n-1})^2+(v_n-v_{n-1})^2}$.

It is clear that one may take the undisturbed state of the internal modes $v_{n+1} = v_n$ for all n to hold exactly, in which case only the backbone motion is relevant. We will be interested in small amplitude, linear motions of the v_n, and how they are affected by the motion of the backbone.

The disparity between the masses M and m, and that of the strengths of the associated springs, is introduced by letting μ be a small parameter and assuming $m = \mu M$ and $V = \mu U$ (and correspondingly, $S = \mu Z$). We make the small-amplitude long-wave ansatz

$$u_n(t) = hu(X = hn, T = ht) \qquad \text{and} \qquad v_n(t) = hv(X = hn, T = ht)\,,$$

(A3)
where h is a small lattice-spacing parameter. Expanding the functions W and Z in Taylor series about the equilibrium position, the equations of motion become

$$\begin{aligned} Mh^3\partial_T^2 u = {}& h^3 W''(L)\partial_X^2 u + \frac{h^5}{12}W''(L)\partial_X^4 u \\ & + h^5 W'''(L)\partial_X u \cdot \partial_X^2 u + O(h^6) + O(h^3\mu)\,, \\ Mh^3\partial_T^2 v = {}& h^3 Z(L)\partial_X^2 v + \frac{h^5}{12}Z(L)\partial_X^4 v \\ & + h^5 Z'(L)\partial_X^2 u \cdot \partial_X v + h^5 Z'(L)\partial_X u \cdot \partial_X^2 v + O(h^6). \end{aligned}$$

(A4)
Trapping of v-waves by u-waves becomes possible if the wave speeds are equal. Therefore, we assume that $W''(L) = Z(L) = Mc^2$. Changing variables to $\chi = X - cT$ and $\tau = h^2 T$ yields

$$\begin{aligned} Mh^2\partial_\tau^2 u - 2Mc\partial_\chi\partial_\tau u &= \frac{Mc^2}{12}\partial_\chi^4 u + W'''(L)\partial_\chi u \cdot \partial_\chi^2 u + O(h) + O(\mu/h^2)\,, \\ Mh^2\partial_\tau^2 v - 2Mc\partial_\chi\partial_\tau v &= \frac{Mc^2}{12}\partial_\chi^4 v + Z'(L)\partial_\chi^2 u \cdot \partial_\chi v + Z'(L)\partial_\chi u \cdot \partial_\chi^2 v + O(h)\,. \end{aligned}$$

(A5)
As $h \downarrow 0$ with $\mu \ll h^2$, we find the coupled system

$$\begin{aligned} \partial_\tau A &+ \partial_\chi \left[\frac{1}{2}A^2 + \frac{c}{24}\partial_\chi^2 A\right] = 0\,, \\ \partial_\tau B &+ \partial_\chi \left[\frac{Z'(L)}{W'''(L)}AB + \frac{c}{24}\partial_\chi^2 B\right] = 0 \end{aligned}$$

(A6)
as a formal limit, where $A = W'''(L)\partial_\chi u/(2Mc)$ and $B = \partial_\chi v$. After a simple rescaling of χ and τ, this becomes (1) and (2) with $\kappa = Z'(L)/W'''(L)$. As described in section 6, the influence of solitons on linear waves can be qualitatively different for different values of the coupling constant κ with important bifurcations occurring at the values $\kappa = \kappa_n^{\mathrm{bif}} = (n+1)(n+2)/12$ for $n = 1, 2, 3, \ldots$. As we have seen, this coupled system can be solved exactly in (at least) two cases: $\kappa = 1$ and $\kappa = 1/2$. The former case is just the linearized KdV; see Sachs [S83]. The latter case is the one that is solved in the main text of this paper.

Consider this example with the potential of the strong and weak springs given respectively by

(A7)
$$W(D) := \frac{1}{2}\kappa_w D^2 + \frac{1}{24}\alpha D^4 \qquad \text{and} \qquad V(D) := \mu(\frac{1}{2}\kappa_v D^2 + \frac{1}{24}\beta D^4)\,.$$

Thus $\beta = 3\alpha\kappa$ and the condition that the wave speeds are equal is

(A8)
$$\frac{1}{2}\alpha L^2(\kappa - 1) = \kappa_w - \kappa_v\,.$$

The effect of each bifurcation point in κ is now clear. At $\kappa = 1/2$ the first harmonic of the v-waves begins to resonate with the u-waves. As κ increases through $\kappa = 1$ we pass through a transition from supercritical resonance to subcritical resonance. Similarly, at the odd bifurcation points, $\kappa = \kappa_{2m-1}^{\rm bif}$ for $m = 1, 2, 3, \ldots$, the mth harmonic v-wave begins to resonate with the u-waves. Then at the even bifurcation points, $\kappa = \kappa_{2m}^{\rm bif}$ for $m = 1, 2, 3, \ldots$, the nature of the resonance for this mode changes from supercritical to subcritical.

Coupled systems of equations like the pair (1) and (2) often arise as formal asymptotic reductions of mechanical models for complicated one-dimensional waves. Often these asymptotic models are integrable. For example, in an elastic rod, the interaction between axial twist waves and helical deformation waves gives rise to an integrable Manakov system of coupled nonlinear Schrödinger equations [LG99].

The coupled system (1) and (2) for $\kappa = 1/2$ is also intimately connected with an integrable multicomponent (an arbitrary number of components, all appearing symmetrically) coupled KdV equation [MC99]. Indeed, from one point of view it is this connection that yields the solvability of (1) and (2) for $\kappa = 1/2$ described in detail in this paper. The solution method presented here also can be used to give the complete solution of the coupled KdV system. That system in turn can be interpreted as a phenomenological model for the transport of the mass integral through an N-soliton solution of KdV [MC99].

Finally, we would like to point out that there are also some applications in which linear equations of the form (2) occur with $\kappa A(x, t)$ being a given function. In this case, $c(x, t) = \kappa A(x, t)$ represents a given spatiotemporal modulation of the speed of linear dispersive waves, say, due to propagation in an inhomogeneous medium. Such problems arise in the modeling of the propagation of weak internal waves in a channel of varying width [CG99]. For such applications, we may view the solvability of the coupled system (1) and (2) for $\kappa = 1$ and $\kappa = 1/2$ as a kind of (big) catalog of special cases of the function $c(x, t)$ for which the linear equation (2) is solvable in its own right. For other values of $\kappa > 1/2$ the linear wave system is unstable, while for all values of $\kappa < 1/2$ it is stable.

EXTENDING GEOMETRIC SINGULAR PERTURBATION THEORY TO NONHYPERBOLIC POINTS—FOLD AND CANARD POINTS IN TWO DIMENSIONS[*]

M. KRUPA[†][‡] AND P. SZMOLYAN[†]

Abstract. The geometric approach to singular perturbation problems is based on powerful methods from dynamical systems theory. These techniques have been very successful in the case of normally hyperbolic critical manifolds. However, at points where normal hyperbolicity fails, the well-developed geometric theory does not apply. We present a method based on blow-up techniques, which leads to a rigorous geometric analysis of these problems. A detailed analysis of the extension of slow manifolds past fold points and canard points in planar systems is given. The efficient use of various charts is emphasized.

1. Introduction.

We consider singularly perturbed ordinary differential equations (ODEs) in the standard form

$$\begin{aligned} \varepsilon\dot{x} &= f(x,y,\varepsilon), \\ \dot{y} &= g(x,y,\varepsilon), \end{aligned} \qquad x \in \mathbb{R}^n, \quad y \in \mathbb{R}^m, \quad 0 < \varepsilon \ll 1, \tag{1.1}$$

where f, g are C^k-functions with $k \geq 3$. Properties of solutions of (1.1) can be studied using geometric methods from dynamical systems theory. This approach, known as *geometric singular perturbation theory*, has been very successful in many contexts, yet has encountered difficulties in certain situations. In this article we show how some of the limitations of geometric singular perturbation theory can be removed.

Before describing our results we present a brief survey of the existing theory. Let τ denote the independent variable in (1.1). The variable τ is referred to as the *slow* time scale. By switching to the *fast* time scale $t := \tau/\varepsilon$ one obtains the equivalent system

$$\begin{aligned} x' &= f(x,y,\varepsilon), \\ y' &= \varepsilon g(x,y,\varepsilon). \end{aligned} \tag{1.2}$$

One tries to analyze the dynamics of (1.1) by suitably combining the dynamics of the *reduced problem*

$$\begin{aligned} 0 &= f(x,y,0), \\ \dot{y} &= g(x,y,0) \end{aligned} \tag{1.3}$$

and the dynamics of the *layer problem*

$$\begin{aligned} x' &= f(x,y,0), \\ y' &= 0, \end{aligned} \tag{1.4}$$

which are the limiting problems for $\varepsilon = 0$ on the slow and the fast time scales, respectively.

The foundation of geometric singular perturbation theory was laid by Fenichel [8]. The basic reasoning is as follows. The reduced problem (1.3) is a dynamical system on the set $S := \{(x,y) \in \mathbb{R}^{n+m} : f(x,y,0) = 0\}$. In the following we refer to S as the *critical manifold*. A normally hyperbolic invariant manifold of equilibria $S_0 \subset S$ of the layer problem (1.4) persists as a locally invariant slow manifold S_ε of (1.1) for ε sufficiently small. The restriction of (1.1) to S_ε is a small smooth perturbation of the reduced problem (1.3). Moreover, there exist a stable and an unstable invariant foliation with base S_ε with the dynamics along each foliation being a small perturbation of the suitable restriction of the dynamics of (1.4). For an excellent introduction to geometric singular perturbation theory and an overview of applications, we refer the reader to the survey by Jones [11].

However, despite many efforts, points on the critical manifold S where normal hyperbolicity breaks down remained a major obstacle to the geometric theory. This was a definite shortcoming in view of the abundance of nonhyperbolic points in applications.

One cause for the breakdown of normal hyperbolicity of a critical manifold S are bifurcation points due to a zero eigenvalue of the Jacobian $\frac{\partial f}{\partial x}$. The most common case are folded critical manifolds. A well-known phenomenon in this context are relaxation oscillations, i.e., solutions slowly moving towards a fold point, jumping from the fold point to another stable branch of S, following the slow dynamics again until another fold point is reached, jumping again, etc., thus, possibly forming periodic solutions [9], [18], and [20].

Another delicate phenomenon occuring at folds are *canard solutions* which were discovered and first analyzed by Benoit, Callot, Diener, and Diener [3]; see also [2]. A canard solution is a solution of a singularly perturbed system which is contained in the intersection of an attracting slow manifold and a repelling slow manifold. The existence of a canard solution can lead to *canard explosion*, i.e., a transition from a small limit cycle to a relaxation oscillation through a sequence of *canard cycles* [3], [6], [7]. For planar vector fields canards are nongeneric and occur persistently in one-parameter families; yet in dimensions larger than two they can occur in generic situations [2], [19], [23].

In this article we show how geometric singular perturbation theory can be extended to *fold points* and *canard points* in planar systems, i.e., we restrict our attention to the case $n = m = 1$. A fold point corresponds to the situation when the critical manifold has a generic fold. Depending on the stability properties of the critical manifold and on the direction of the reduced flow, a number of cases are possible. We analyze the so-called *jump point*, for which the reduced flow is directed towards the fold. This is the situation which is relevant for relaxation oscillations. We show how the slow manifolds (existing by the normally hyperbolic theory) extend in the neighborhood of the singularity. The treatment of the fold point is a refinement of the analysis in our earlier work [13]. A canard point is a fold point with an additional degeneracy leading to a possibility of a canard solution. Again we analyze how slow manifolds extend and show that a canard solution occurs along a codimension one curve in the parameter plane. In a complementary work [15] we carry out a similar analysis for singularities of pitchfork and transcritical type.

Our approach relies on the blow-up method, which is a way of partially desingularizing the vector field in the neighborhood of a singular point. After a blow-up transformation, standard methods from dynamical systems theory can be applied. Our proof of the existence of a canard solution is based on a variant of the Melnikov method. The blow-up method was first applied to a singular perturbation problem in the pioneering work of Dumortier and Roussarie [6], who analyzed the existence of *canard cycles* in the van der Pol equation. One of the purposes of this work is to build a bridge between the methods of [6] and geometric singular perturbation theory; in particular, we use the blow-up method to answer the question of extending slow manifolds near nonhyperbolic singularities.

The sequel of this article [14] is devoted to relaxation oscillations and canard explosion. The methods and results of this paper are of central importance in our analysis of these phenomena. Since the analysis of canard cycles is a more delicate problem, we find it advantageous to treat these issues separately. In particular, we prefer to use blow-up to obtain local results which in a second step can be used to study global phenomena. We feel that this point of view is also useful in the analysis of related problems. In this sense, our work is intended as a complement to the more global approach in the work of Dumortier [5] and Dumortier and Roussarie [6].

In this article and in [14] we restrict our attention to the planar case. However, the analysis carries over to higher-dimensional problems with one-dimensional critical manifolds containing fold points. By means of a center-manifold reduction, all normally hyperbolic directions can be eliminated and one recovers the planar problems considered here. A well-known problem where this is relevant is the traveling wave problem for the FitzHugh–Nagumo equation [11]. For a similar approach to problems with higher-dimensional critical manifolds, we refer the reader to [17] and [23].

The article is organized as follows. Section 2 contains the description and the analysis of a generic fold. Here we give a detailed expository presentation of the blow-up method. In section 3 we analyze a canard point.

2. Generic fold.

2.1. Assumptions and results. Consider the singularly perturbed ODE (1.2), where $(x, y) \in \mathbb{R}^2$ and ε is a small real parameter. Suppose that (x_0, y_0) is such that

$$f(x_0, y_0, 0) = 0, \qquad \frac{\partial f}{\partial x}(x_0, y_0, 0) = 0. \tag{2.1}$$

Our goal is to obtain a characterization of the dynamics in a neighborhood of (x_0, y_0) for sufficiently small values of ε. We make the following nondegeneracy assumptions:

$$\frac{\partial^2 f}{\partial x^2}(x_0, y_0, 0) \neq 0, \quad \frac{\partial f}{\partial y}(x_0, y_0, 0) \neq 0, \quad g(x_0, y_0, 0) \neq 0. \tag{2.2}$$

We assume, without loss of generality, that

$$(x_0, y_0) = (0, 0), \quad \frac{\partial^2 f}{\partial x^2}(0, 0, 0) > 0, \quad \frac{\partial f}{\partial y}(x_0, y_0, 0) < 0$$

hold.

As before let $S = \{(x, y) : f(x, y, 0) = 0\}$ be the critical manifold. The nondegeneracy assumptions imply that there exists a neighborhood U of the origin such that

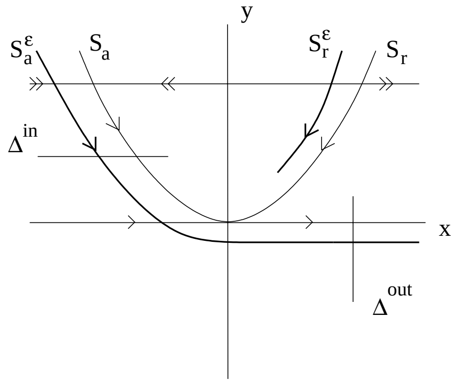

FIG. 2.1. *Critical manifold, slow manifolds, and sections for the fold point.*

$(0,0)$ is the only point in $U \cap S$, where $\frac{\partial f}{\partial x}$ vanishes and that $S \cap U$ is approximately a parabola. Let S_a (resp., S_r) denote its left (resp., right) branch, so that $S = S_a \cup S_r$ (see Figure 2.1). The assumption $\frac{\partial^2 f}{\partial x^2}(0,0,0) > 0$ implies that for $y > 0$ the branch S_a is attracting and the branch S_r is repelling for the layer problem, which also explains the notation. The origin is nonhyperbolic, weakly attracting from the left and weakly repelling to the right (see Figure 2.1).

To determine the reduced dynamics we solve the equation $f(x, y, 0) = 0$ for y as a function of x, i.e., $y = \varphi(x)$. The reduced dynamics is then determined by

$$\varphi'(x)\dot{x} = g(x, \varphi(x), 0), \tag{2.3}$$

which is singular at $x = 0$. Our assumptions on f and g imply that the direction of the reduced flow is determined by the sign of $g(0,0,0)$. We assume $g(0,0,0) < 0$. This implies that the reduced flow on S_a and S_r is directed towards the fold point; see Figure 2.1. Actually, orbits on S_a and S_r reach the fold point in finite time due to the singularity at the fold point. The only possibility to continue from there in the singular limit is along the (weakly) unstable fiber of the layer problem along the positive x-axis. Thus, the curve $S_a \cup \{(x, 0), x > 0\}$ is expected to be a zeroth order approximation. This is the situation relevant to relaxation oscillations; we refer to this case as *jump point*. The case $g(0,0,0) > 0$ can be analyzed similarly.

It follows from the standard theory [8] that outside an arbitrarily small neighborhood V of $(0,0)$, the manifolds S_a and S_r perturb smoothly to locally invariant manifolds $S_{a,\varepsilon}$ and $S_{r,\varepsilon}$ for sufficiently small $\varepsilon \neq 0$. We would like to point out that $S_{a,\varepsilon}$ and $S_{r,\varepsilon}$ are actually very simple. They consist of single solutions. Note that the slow manifolds are obtained as sections $\varepsilon =$ const. of two-dimensional, locally invariant, center-like manifolds M_a (resp., M_r) of the extended system

$$\begin{aligned} x' &= f(x, y, \varepsilon), \\ y' &= \varepsilon g(x, y, \varepsilon), \\ \varepsilon' &= 0 \end{aligned} \tag{2.4}$$

in the extended phase space $\mathbb{R}^3$. For this extended system $S \times \{0\}$ is a manifold of equilibria. Outside of a neighborhood of the fold point $(0,0,0)$ the linearization of system (2.4) at points $S_a \times \{0\}$ has a double zero eigenvalue and one uniformly hyperbolic (stable) eigenvalue. This allows us to conclude the existence of the attracting center-like manifold M_a; the manifold M_r is obtained in a similar way. At the fold point $(0,0,0)$ the linearization has a triple eigenvalue zero and the construction of the slow manifolds breaks down. We focus our attention on S_a and investigate how $S_{a,\varepsilon}$ as well as nearby solutions behave as they pass near the fold point. We expect that close to the fold point a transition from slow motion along $S_{a,\varepsilon}$ to a fast motion almost parallel to the unstable fibers occurs. A similar analysis could be carried out for $S_{r,\varepsilon}$.

Remark 2.1. It is known that the slow manifolds M_a and M_r and hence their sections $S_{a,\varepsilon}$ and $S_{r,\varepsilon}$ are not unique and are determined only up to $O(e^{-c/\varepsilon})$, where c is some positive constant. We make an arbitrary choice of M_a and M_r and indicate at the end that our results are independent of this choice.

We now view the previously introduced neighborhood U as a neighborhood of $(0,0,0)$ in $\mathbb{R}^3$. We pick U sufficiently small, so that $g(x,y,\varepsilon) \neq 0$ for $(x,y,\varepsilon) \in U$. Before stating the main results we rewrite system (1.2) (resp., (2.4)) in a canonical form. By rescaling x, y, ε, and t we obtain

$$\begin{aligned} x' &= -y + x^2 + h(x,y,\varepsilon), \\ y' &= \varepsilon g(x,y,\varepsilon), \\ \varepsilon' &= 0 \end{aligned} \tag{2.5}$$

with $h(x,y,\varepsilon) = O(\varepsilon, xy, y^2, x^3)$, $g(x,y,\varepsilon) = -1 + O(x,y,\varepsilon)$, where the new function g is related to the original one by the rescaling. This form of the equations will be used throughout the forthcoming analysis.

For small $\rho > 0$ and a suitable interval $J \subset \mathbb{R}$ let

$$\Delta^{in} = \{(x, \rho^2), x \in J\}$$

be a section in U transverse to S_a and let

$$\Delta^{out} = \{(\rho, y), y \in \mathbb{R}\}$$

be a section in U transverse to the fast fibers (see Figure 2.1). Note, that the same constant ρ is used throughout this paper.

Let $\pi : \Delta^{in} \to \Delta^{out}$ be the transition map for the flow of (1.2).

THEOREM 2.1. *Under the assumptions made in this section there exists $\varepsilon_0 > 0$ such that the following assertions hold for $\varepsilon \in (0, \varepsilon_0]$:*

1. *The manifold $S_{a,\varepsilon}$ passes through Δ^{out} at a point $(\rho, h(\varepsilon))$, where $h(\varepsilon) = O(\varepsilon^{2/3})$.*
2. *The transition map π is a contraction with contraction rate $O(e^{-c/\varepsilon})$, where c is a positive constant.*

In the context of matched asymptotic expansions assertion (1) of the theorem is well known; see, e.g., [18]. A blow-up based derivation of the asymptotic expansion of $h(\varepsilon)$ is given in [16]. Assertion (2) of the theorem explains why the nonuniqueness of the slow manifold M_a (resp., $S_{a,\varepsilon}$) does not affect our results. Two different choices of these manifolds are exponentially close at Δ^{in} and even more so at Δ^{out} due to the exponential contraction during the passage.

2.2. Blow-up. In this section we define and describe the blow-up transformation. The basic observation is that the fold point $(0,0,0)$ is a more degenerate equilibrium point of system (2.5) than the other points of the critical manifold S. The linearization of system (2.5) at the origin has a triple zero eigenvalue while the linearization at the other points of the critical manifold S has a double zero eigenvalue and one negative (resp., positive) eigenvalue for $x < 0$ (resp., $x > 0$).

The important insight in [6] is that blow-up techniques are the right tool to analyze nilpotent equilibria like the fold point, viewed as a degenerate equilibrium of the extended system (2.4). The blow-up method is essentially a clever coordinate transformation by which the degenerate equilibrium is "blown-up" to a two-sphere. In certain directions transverse to the sphere and even on the sphere, one gains enough hyperbolicity to allow a complete analysis by standard techniques. The technique is a generalization of the well known blow-up methods for degenerate equilibria of planar vector fields [5]. In the simplest situations this corresponds to blowing-up the degenerate equilibrium to the circle $r = 0$ by rewriting the vector field in polar coordinates $(r, \vartheta) \in \mathbb{R} \times S^1$. The analysis is often simplified substantially by using a quasi-homogeneous blow-up, i.e. by using different powers (weights) of r for different variables in the defining transformation.

The blow-up transformation for system (2.5) is

$$x = \bar{r}\bar{x}, \quad y = \bar{r}^2\bar{y}, \quad \varepsilon = \bar{r}^3\bar{\varepsilon} \tag{2.6}$$

with weights 1, 2, and 3. We define $B = S^2 \times [0, \rho]$, where the constant $\rho > 0$ is related to ε_0 by $\varepsilon_0 = \rho^3$. We consider the blow-up transformation as a mapping

$$\Phi : B \to \mathbb{R}^3 \tag{2.7}$$

with $(\bar{x}, \bar{y}, \bar{\varepsilon}) \in S^2$. We choose $\rho > 0$ sufficiently small such that system (2.4) is described by the canonical form (2.5) in the region $\Phi(B)$. We will be interested only in nonnegative values of $\bar{\varepsilon}$ and $\bar{r}$, but everything that follows makes sense for negative values as well, i.e., there are no technical problems at ∂B.

Let X denote the vector field corresponding to (2.5). Since X vanishes at the point $(0, 0, 0)$, there exists a vector field $\bar{X}$ on B such that $\Phi_* \bar{X} = X$, where Φ_* is induced by Φ. It remains to study the vector field $\bar{X}$ on the manifold B. Note that this suffices, since $\Phi(B)$ is a full neighborhood of the origin. In principle one could use spherical coordinates on S^2; however, this would lead to rather lengthy computations. It is natural and almost mandatory to use different charts for the manifold B to simplify the analysis. One reason for this is that—as we will see later—the dynamics in the individual charts is very different.

We will now introduce the charts used later in this paper. Loosely speaking, we will define a chart K_2, which describes a neighborhood of the upper half-sphere defined by $\bar{\varepsilon} > 0$, and charts K_1 and K_3 which describe neighborhoods of parts of the equator of S^2 which are needed in the analysis. In problems where a neighborhood of the whole equator needs to be analyzed, two further charts must be defined analogously. The subscripts in K_1, K_2, and K_3 denote the order in which the charts are used later.

The charts K_1, K_2, and K_3 are obtained by setting $\bar{y} = 1$, $\bar{\varepsilon} = 1$, and $\bar{x} = 1$, respectively, in the blow-up transformation (2.6). The blow-up transformation in the charts K_i, $i = 1, 2, 3$ is given by

$$x = r_1 x_1, \quad y = r_1^2, \quad \varepsilon = r_1^3 \varepsilon_1, \tag{2.8}$$

$$x = r_2 x_2, \quad y = r_2^2 y_2, \quad \varepsilon = r_2^3, \tag{2.9}$$

$$x = r_3, \quad y = r_3^2 y_3, \quad \varepsilon = r_3^3 \varepsilon_3 \tag{2.10}$$

with coordinates $(x_1, r_1, \varepsilon_1) \in \mathbb{R}^3$, $(x_2, y_2, r_2) \in \mathbb{R}^3$, and $(r_3, y_3, \varepsilon_3) \in \mathbb{R}^3$. The point $(0, 0, 0)$ is blown-up to the plane $r_i = 0$, $i = 1, 2, 3$. In our analysis we will need to change coordinates between these charts on their overlap domains. A simple computation gives the following lemma.

LEMMA 2.2. *Let κ_{12} denote the change of coordinates from K_1 to K_2. Then κ_{12} is given by*

$$x_2 = x_1 \varepsilon_1^{-1/3}, \quad y_2 = \varepsilon_1^{-2/3}, \quad r_2 = r_1 \varepsilon_1^{1/3} \quad \textit{for } \varepsilon_1 > 0, \tag{2.11}$$

and κ_{12}^{-1} is given by

$$x_1 = x_2 y_2^{-1/2}, \quad r_1 = r_2 y_2^{1/2}, \quad \varepsilon_1 = y_2^{-3/2} \quad \textit{for } y_2 > 0\ . \tag{2.12}$$

Let κ_{23} denote the change of coordinates from K_2 to K_3. Then κ_{23} is given by

$$r_3 = r_2 x_2, \quad y_3 = y_2 x_2^{-2}, \quad \varepsilon_3 = x_2^{-3} \quad \textit{for } x_2 > 0, \tag{2.13}$$

and κ_{23}^{-1} is given by

$$x_2 = \varepsilon_3^{-1/3}, \quad y_2 = y_3 \varepsilon_3^{-2/3}, \quad r_2 = r_3 \varepsilon_3^{1/3} \quad \textit{for } \varepsilon_3 > 0\ . \tag{2.14}$$

The above constructions make perfect sense if restricted to B. We introduce the following notation: $\bar{P}$ denotes an object in the blow-up which corresponds to an object P in the original problem. If $\bar{P}$ is described in one of the charts, then P_i denotes the object in chart K_i, $i = 1, 2, 3$. This notation is used only when necessary, mostly to denote various invariant manifolds.

Remark 2.2. In the work of Dumortier and Roussarie the chart K_2 corresponding to a directional blow-up in the direction of ε is called *family rescaling*, and charts used near the equator are called *phase directional rescaling.*

2.3. Blow-up of (1.2) with $\varepsilon = 0$. It is instructive to recall how the usual blow-up method applies to the layer problem, i.e., system (2.5) with $\varepsilon = 0$. Setting $\bar{\varepsilon} = 0$ in (2.6) defines a (planar, polar) blow-up of the degenerate equilibrium at the origin. To see this, note that $B \cap \{\bar{\varepsilon} = 0\} = S^1 \times [0, \rho]$, where $S^1 = \{(\bar{x}, \bar{y}, 0) \in S^2\}$. Due to the equation $\varepsilon' = 0$, the set $S^1 \times [0, \rho]$ is invariant for $\bar{X}$, which, restricted to $S^1 \times [0, \rho]$, is the blow-up of (1.2) with $\varepsilon = 0$.

Let $\bar{X}_0 = \bar{X}|_{S^1 \times [0,\rho]}$. Figure 2.2 shows the phase portrait of $\bar{X}_0$. We briefly describe this phase portrait, referring the reader to the sections on charts K_1 and K_3 for technical details. On the invariant circle S^1, there are four equilibria: p_a, p_r, q_{in}, q_{out}. These equilibria are hyperbolic for the flow on S^1, the points p_a and q_{out} are attracting, and p_r and q_{in} are repelling. The points p_a and p_r are end points of the blown-up critical manifolds $\bar{S}_a$ and $\bar{S}_r$, which are lines of equilibria for $\bar{X}_0$. Hence the radial direction is nonhyperbolic at p_a and p_r. The points q_{in} and q_{out} are the intersection points of S^1 with the blow-up of the critical fiber. These points are hyperbolic in the radial direction.

2.4. Dynamics in chart K_2. The dynamics of the blown-up vector field $\bar{X}$ in a neighborhood of the upper half-sphere is studied in chart K_2. The transformation (2.9) is just a rescaling of (x, y), since $r_2 = \varepsilon^{1/3}$. By inserting (2.9) into system (2.5) we obtain the vector field $\bar{X}$ in chart K_2. Since $r_2' = 0$, this blown-up system is still a

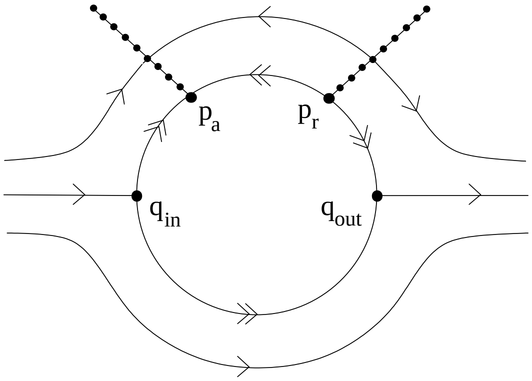

FIG. 2.2. *Phase portrait of the blown-up vector field for $\bar{\varepsilon} = 0$.*

family of planar vector fields with parameter r_2. We now desingularize the equations by rescaling time $t_2 := r_2 t$, so that the factor r_2 disappears. This desingularization is necessary to obtain a nontrivial flow on the blown-up locus $r_2 = 0$. We obtain

$$\begin{aligned} x_2' &= x_2^2 - y_2 + O(r_2), \\ y_2' &= -1 + O(r_2), \\ r_2' &= 0, \end{aligned} \tag{2.15}$$

where $'$ denotes differentiation with respect to t_2.

Remark 2.3. The rescaled form (2.15) of the original problem plays a crucial role in all approaches to the fold point by means of asymptotic expansions; e.g. [12], [18], and [20]. In these investigations solutions of (2.15) are used as inner solutions connecting (*matching*) solutions obtained as perturbations of the reduced problem to solutions obtained as solutions of the layer problem.

We first consider the case $r_2 = 0$, which gives

$$\begin{aligned} x_2' &= x_2^2 - y_2, \\ y_2' &= -1. \end{aligned} \tag{2.16}$$

This is a Riccati equation whose solutions can be expressed in terms of special functions. The relevant results can be found in [18, pp. 68–72]. Here we restate the results needed in our analysis. For the sake of readability we omit the subscript 2 of the variables.

PROPOSITION 2.3 (see [18]). *The Riccati equation* (2.16) *has the following properties:*

1. *Every orbit has a horizontal asymptote $y = y_r$, where y_r depends on the orbit such that $x \to \infty$ as y approaches y_r from above.*
2. *There exists a unique orbit γ_2 which can be parametrized as $(x, s(x))$, $x \in \mathbb{R}$ and is asymptotic to the left branch of the parabola $x^2 - y = 0$ for $x \to -\infty$. The orbit γ_2 has a horizontal asymptote $y = -\Omega_0 < 0$ such that $x \to \infty$ as y approaches $-\Omega_0$ from above.*
3. *The function $s(x)$ has the asymptotic expansions*

$$s(x) = x^2 + \frac{1}{2x} + O\left(\frac{1}{x^4}\right), \quad x \to -\infty,$$

$$s(x) = -\Omega_0 + \frac{1}{x} + O\left(\frac{1}{x^3}\right), \quad x \to \infty.$$

4. *All orbits to the right of γ_2 are backward asymptotic to the right branch of the parabola $x^2 - y = 0$.*
5. *All orbits to the left of γ_2 have a horizontal asymptote $y = y_l > y_r$, where y_l depends on the orbit, such that $x \to -\infty$ as y approaches y_l from below.*

Remark 2.4. The constant Ω_0 is the smallest positive zero of

$$J_{-1/3}(2z^{3/2}/3) + J_{1/3}(2z^{3/2}/3),$$

where $J_{-1/3}$ (resp., $J_{1/3}$) are Bessel functions of the first kind [18].

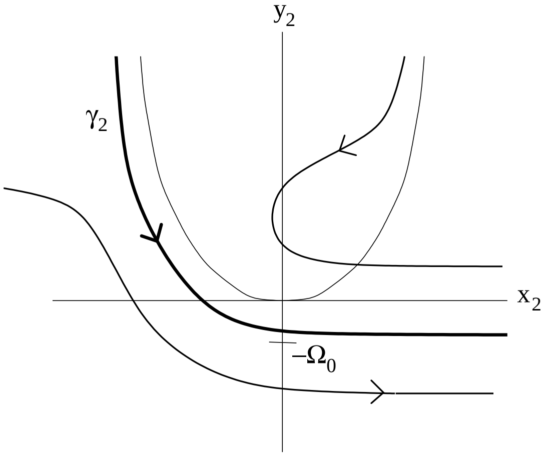

FIG. 2.3. *Solutions of the Riccati equation* (2.16).

The assertions of Proposition 2.3 are illustrated in Figure 2.3. We will see that the orbit $\bar{\gamma}$ corresponding to the special solution γ_2 is backward asymptotic to the equilibrium p_a on the equator of S^2. The importance of the orbit $\bar{\gamma}$ is that it "leads" the incoming attracting slow manifold across the upper half of the sphere S^2 to the point q_{out} from where take-off in the direction of the fast flow occurs.

We need to describe the transition map for (2.15) within a bounded domain D_2. Within such a domain we can deduce properties of the flow of (2.15) from Proposition 2.3 by using regular perturbation theory. A detailed study of the effect of the $O(r_2)$ perturbations outside D_2, i.e., close to infinity, will be carried out in the charts K_1 and K_3. For $\delta > 0$ we define the following sections:

$$\Sigma_2^{in} = \{(x_2, y_2, r_2) \,:\, y_2 = \delta^{-2/3}\}, \quad \Sigma_2^{out} = \{(x_2, y_2, r_2) \,:\, x_2 = \delta^{-1/3}\}.$$

Let Π_2 be the transition map of the flow (2.15) from Σ_2^{in} to Σ_2^{out}. Let $q_0 = \gamma_2 \cap \Sigma_2^{in}$.

PROPOSITION 2.4. *The transition map Π_2 has the following properties:*

1.

$$\Pi_2(q_0) = (\delta^{-1/3}, -\Omega_0 + \delta^{1/3} + O(\delta), 0).$$

2. *A neighborhood of q_0 is mapped diffeomorphically onto a neighborhood of $\Pi_2(q_0)$.*

Proof. The proof follows directly from Proposition 2.3 and regular perturbation theory. □

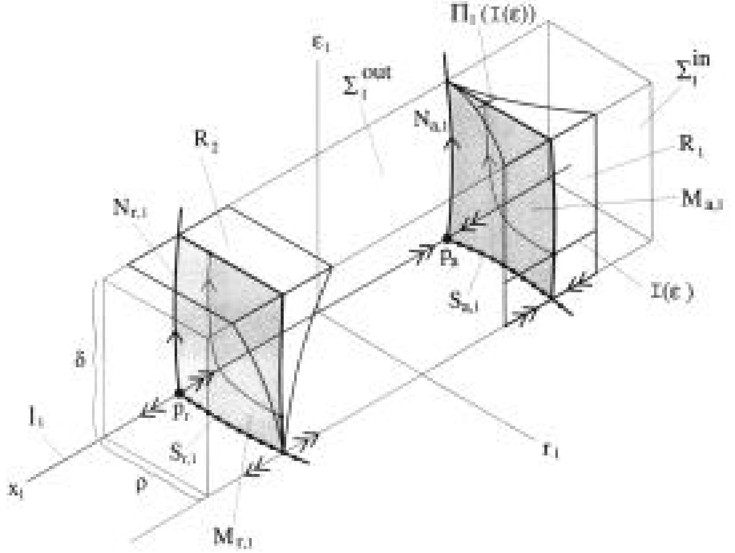

FIG. 2.4. *Geometry and dynamics in chart K_1.*

2.5. Dynamics in chart K_1. Chart K_1 is used to analyze the dynamics of the blown-up vector field $\bar{X}$ in a neighborhood of the equator containing the equilibria p_a and p_r. By inserting (2.8) into system (2.5), we obtain the vector field $\bar{X}$ in chart K_1. We desingularize the blown-up vector field $\bar{X}$ by dividing by r_1. This gives

$$\begin{aligned} x_1' &= -1 + x_1^2 + \frac{1}{2}\varepsilon_1 x_1 + O(r_1), \\ r_1' &= \frac{1}{2} r_1 \varepsilon_1(-1 + O(r_1)), \\ \varepsilon_1' &= \frac{3}{2}\varepsilon_1^2(1 + O(r_1)), \end{aligned} \tag{2.17}$$

where $'$ denotes differentiation with respect to a rescaled time variable t_1.

Remark 2.5. The equation for ε_1' is obtained from the equation $\varepsilon' = 0$, which implies the relation $3r_1^2 r_1' \varepsilon_1 + r_1^3 \varepsilon_1' = 0$. Hence $\varepsilon = r_1^3 \varepsilon_1$ is a constant of motion in chart K_1. Nevertheless, we will see that it is useful to treat the blown-up system as a three-dimensional problem. This seemingly artificial construction is actually crucial for the whole approach.

Remark 2.6. For $r_1 > 0$, system (2.17) has the same orbits as the blown-up vector field $\bar{X}$ with the corresponding solutions having a different time parametrization. Since we deal only with transition maps between sections, time parametrization of solutions has no significance to our analysis.

System (2.17) has two invariant subspaces, namely, the plane $r_1 = 0$ and the plane $\varepsilon_1 = 0$. Their intersection is the invariant line $l_1 := \{(x_1, 0, 0) \ : \ x_1 \in \mathbb{R}\}$; see Figure 2.4. The dynamics on l_1 is governed by $x_1' = -1 + x_1^2$. There are two equilibria $p_a = (-1, 0, 0)$ and $p_r = (1, 0, 0)$. For the flow on the line l_1 both points are hyperbolic, the relevant eigenvalue is -2 for p_a and 2 for p_r, i.e., p_a is attracting and p_r is repelling. The dynamics in the invariant plane $\varepsilon_1 = 0$ is governed by

$$\begin{aligned} x_1' &= -1 + x_1^2 + O(r_1), \\ r_1' &= 0. \end{aligned} \tag{2.18}$$

This system has a normally hyperbolic curve $S_{a,1}$ of equilibria emanating from p_a and a curve $S_{r,1}$ of equilibria emanating from p_r; see Figure 2.4. For r_1 small, this follows from the implicit function theorem. Actually, $S_{a,1}$ and $S_{r,1}$ are precisely the branches of the critical manifold S described in section 2.1; this also explains the notation. Along the curve $S_{a,1}$ the linearization of (2.18) has one zero eigenvalue, the other eigenvalue is negative and close to -2 for r_1 small. Along $S_{r,1}$ the situation is similar; however, the nonzero eigenvalue is positive and close to 2 for r_1 small.

Remark 2.7. Equation (2.18) is the directional (in the positive y-direction) blow-up of the fold point $(0, 0)$ of the layer problem, i.e., system (1.2) with $\varepsilon = 0$. The line $l_1 = 0$ corresponds to the fold point. We have gained normal hyperbolicity of the lines of equilibria $S_{a,1}$ (resp., $S_{r,1}$) at the points p_a (resp., p_r) due to the blow-up (compare Figure 2.2).

The dynamics in the invariant plane $r_1 = 0$ is governed by

$$\begin{aligned} x_1' &= -1 + x_1^2 + \frac{1}{2}\varepsilon_1 x_1, \\ \varepsilon_1' &= \frac{3}{2}\varepsilon_1^2\ . \end{aligned} \tag{2.19}$$

We recover the equilibria points p_a and p_r; however, there exists an additional zero eigenvalue due to the second equation. The corresponding eigenvector is $(-1, 4)$ at both equilibria. Hence, there exist one-dimensional center manifolds $N_{a,1}$ at p_a and $N_{r,1}$ at p_r along which ε_1 increases for $\varepsilon_1 > 0$. Note that the branch of the attracting center manifold $N_{a,1}$ at p_a in the half space $\varepsilon_1 > 0$ is unique, while the repelling center manifold $N_{r,1}$ at p_r in the half space $\varepsilon_1 > 0$ is not unique; see Figure 2.4. We collect the information we have obtained so far in the following lemma.

LEMMA 2.5. *The linearization of system* (2.17) *at* p_j, $j = a, r$ *has the following real eigenvalues:* $\lambda_1 = -2$ *at* p_a *and* $\lambda_1 = 2$ *at* p_r *with eigenvector* $(1, 0, 0)$ *corresponding to the flow on* l_1, $\lambda_2 = 0$ *with an eigenvector tangent to* $S_{j,1}$, *and* $\lambda_3 = 0$ *with an eigenvector* $(-1, 0, 4)$ *corresponding to the center direction in the invariant plane* $r_1 = 0$.

We restrict our attention to the set

$$D_1 := \{(x_1, r_1, \varepsilon_1) : \ x_1 \in \mathbb{R}, 0 \le r_1 \le \rho,\ 0 \le \varepsilon_1 \le \delta\},$$

where $\rho > 0$ is the constant defining the sections Δ^{in} and Δ^{out} in section 2.1 and $\delta > 0$ is the constant defining the sections Σ_2^{in} and Σ_2^{out} in section 2.4. Note that all objects defined later extend smoothly to negative values of r_1 and ε_1; i.e., there are no problems due to the boundaries $r_1 = 0$ and $\varepsilon_1 = 0$. We have the following result.

PROPOSITION 2.6. *For* ρ, δ *sufficiently small the following assertions hold for system* (2.17):

1. *There exists an attracting two-dimensional* C^k*-center manifold* $M_{a,1}$ *at* p_a *which contains the line of equilibria* $S_{a,1}$ *and the center manifold* $N_{a,1}$. *In* D_1 *the manifold* $M_{a,1}$ *is given as a graph* $x_1 = h_a(r_1, \varepsilon_1)$. *The branch of* $N_{a,1}$ *in* $r_1 = 0$, $\varepsilon_1 > 0$ *is unique.*

2. *There exists a repelling two-dimensional C^k-center manifold $M_{r,1}$ at p_r which contains the line of equilibria $S_{r,1}$ and the center manifold $N_{r,1}$. In D_1 the manifold $M_{r,1}$ is given as a graph $x_1 = h_r(r_1, \varepsilon_1)$. The branch of $N_{r,1}$ in $r_1 = 0$, $\varepsilon_1 > 0$ is not unique.*
3. *There exists a stable invariant foliation $\mathcal{F}^s$ with base $M_{a,1}$ and one-dimensional fibers. For any $c > -2$ there exists a choice of positive ρ and δ such that the contraction along $\mathcal{F}^s$ during a time interval $[0, T]$ is stronger than e^{cT}.*
4. *There exists an unstable invariant foliation $\mathcal{F}^u$ with base $M_{r,1}$ and one-dimensional fibers. For any $c < 2$ there exists a choice of positive ρ and δ such that the expansion along $\mathcal{F}^u$ during a time interval $[0, T]$ is stronger than e^{cT}.*
5. *The unique branch of $N_{a,1}$ in $r_1 = 0$, $\varepsilon_1 > 0$ is equal to $\gamma_1 := \kappa_{12}^{-1}(\gamma_2)$, wherever κ_{12}^{-1} is defined, i.e., along the part of γ_2 corresponding to $y_2 > 0$.*

Proof. Assertions (1)–(4) follow from Lemma 2.5 and center manifold theory; see, e.g., [4], [10]. Proposition 2.3 and the coordinate transformation (2.12) imply that $\kappa_{12}^{-1}(\gamma_2)$ has the expansion

$$\left(x_2 \left(x_2^2 + \frac{1}{2x_2} + O\left(\frac{1}{x_2^4}\right)\right)^{-1/2},\ 0,\ \left(x_2^2 + \frac{1}{2x_2} + O\left(\frac{1}{x_2^4}\right)\right)^{-3/2} \right)$$

as $x_2 \to -\infty$. Expanding these terms in powers of x_2 shows that $\kappa_{12}^{-1}(\gamma_2)$ converges to p_a tangent to the center-direction $(-1, 0, 4)$ as $x_2 \to -\infty$. This and the uniqueness of the branch of $N_{a,1}$ in $r_1 = 0$, $\varepsilon_1 > 0$ imply assertion (5). □

Remark 2.8. Clearly, the center manifold $M_{a,1}$ in chart K_1 corresponds to a locally invariant manifold $\bar{M}_a$ of the blown-up vector field $\bar{X}$. The importance of assertion (5) in the above proposition is that it allows us to track the manifold $\bar{M}_a$ as it moves across the sphere S^2 guided by the special orbit $\bar{\gamma}$ corresponding to the solution γ_2 of the Riccati equation.

We now define the following sections:

$$\Sigma_1^{in} := \{(x_1, r_1, \varepsilon_1) \in D_1 \ :\ r_1 = \rho\}, \quad \Sigma_1^{out} := \{(x_1, r_1, \varepsilon_1) \in D_1 \ :\ \varepsilon_1 = \delta\}.$$

Remark 2.9. Note that Σ_1^{in} maps under the blow-up transformation (2.8) to Δ^{in} and Σ_1^{out} maps under the coordinate transformation (2.11) to Σ_2^{in}. An important part of our description of the flow near the fold is the description of the transition map from Σ_1^{in} to Σ_1^{out} near the center manifolds $M_{a,1}$ and $M_{r,1}$. Since the neighborhood of $M_{a,1}$ corresponds to the neighborhood of the attracting branch of the slow manifold of (1.2), we are more interested in understanding the dynamics near $M_{a,1}$. Yet the analysis of the two cases is very similar, so we handle them simultaneously.

Let R_1 be the rectangle in Σ_1^{in} defined by $|1+x_1| \le \beta_1$, and let R_2 be the rectangle in Σ_1^{out} defined by $|1 - x_1| \le \beta_1$ for sufficiently small $\beta_1 > 0$. The constants ρ, δ, and β_1 can be chosen such that $M_{a,1} \cap \Sigma_1^{in} \subset R_1$ and $M_{r,1} \cap \Sigma_1^{out} \subset R_2$. For $0 \le \tilde{\varepsilon} \le \delta$ and $0 \le \tilde{r} \le \rho$, let $I_a(\tilde{\varepsilon})$ be the line $R_1 \cap \{\varepsilon_1 = \tilde{\varepsilon}\}$ and $I_r(\tilde{r})$ be the line $R_2 \cap \{r_1 = \tilde{r}\}$.

In the neighborhood of p_j, $j = a, r$, the flow of (2.17) carries Σ_1^{in} to Σ_1^{out}. Let $\Pi_1 : \Sigma_1^{in} \to \Sigma_1^{out}$ be the transition map defined by the flow of (2.17). The map Π_1 is well defined on R_1, at least for small enough values of ρ, δ, and β_1. The map Π_1 is defined in a wedge-shaped set in Σ_1^{in} around $M_{r,1}$ that shrinks to $S_{r,1}$ for $\varepsilon_1 \to 0$. The reason for this difference is that $M_{a,1}$ is attracting and $M_{r,1}$ is repelling. We have the following estimate of transition times.

LEMMA 2.7. *The transition time T of a solution of system* (2.17) *from a point $p = (x_1, \rho, \varepsilon_1) \in \Sigma_1^{in}$ to the point $\Pi_1(p) \in \Sigma_1^{out}$ satisfies*

$$T = \frac{2}{3}\left(\frac{1}{\varepsilon_1} - \frac{1}{\delta}\right)(1 + O(\rho)) . \tag{2.20}$$

Proof. The evolution of ε_1 determines the transition time of solutions from Σ_1^{in} to Σ_1^{out}. The relevant equation is

$$\varepsilon_1' = \frac{3}{2}\varepsilon_1^2(1 - O(r_1)) . \tag{2.21}$$

The result follows immediately by integrating (2.21). □

PROPOSITION 2.8. *For ρ, δ, and β_1 sufficiently small the transition map $\Pi_1 : \Sigma_1^{in} \to \Sigma_1^{out}$ defined by the flow of system* (2.17) *has the following properties:*

1. *$\Pi_1(R_1)$ is a wedge-like region in Σ_1^{out}. $\Pi_1^{-1}(R_2)$ is a wedge-like region in Σ_1^{in}.*
2. *More precisely, for fixed $c < 2$ there exists a constant K depending on the constants c, ρ, δ, and β_1 such that*
   (i) *for $\varepsilon_1 \in (0, \delta]$ the map $\Pi_1|I_a(\varepsilon_1)$ is a contraction with contraction rate bounded by $Ke^{-\frac{2c}{3}\left(\frac{1}{\varepsilon_1}-\frac{1}{\delta}\right)}$.*
   (ii) *for $r_1 \in (0, \rho]$ the map $\Pi_1^{-1}|I_r(r_1)$ is a contraction with contraction rate bounded by $Ke^{-\frac{2c}{3}\left(\frac{\rho^3}{r_1^3\delta}-\frac{1}{\delta}\right)}$.*

Proof. The assertions follow from Proposition 2.6 and Lemma 2.7. The estimate for the contraction rate of Π_1^{-1} in the second assertion uses the identity $\varepsilon_1\rho^3 = \delta r_1^3$ for $p = (x_{1,in}, \rho, \varepsilon_1)$ and $\Pi_1(p) = (x_{1,out}, r_1, \delta)$ to express the transition time in terms of r_1. □

All our results concerning the dynamics in chart K_1 are illustrated in Figure 2.4.

2.6. Dynamics in chart K_3. We use chart K_3 to analyze the dynamics of the blown-up vector field $\bar{X}$ in a neighborhood of the equator containing the point q_{out}. Applying transformation (2.10) to system (2.5) and desingularizing by dividing out the factor r_3, we obtain

$$\begin{aligned} r_3' &= r_3F(r_3, y_3, \varepsilon_3), \\ y_3' &= \varepsilon_3(-1 + O(r_3)) - 2y_3F(r_3, y_3, \varepsilon_3), \\ \varepsilon_3' &= -3\varepsilon_3F(r_3, y_3, \varepsilon_3), \end{aligned} \tag{2.22}$$

where $F(r_3, y_3, \varepsilon_3) := 1 - y_3 + O(r_3)$. The planes $\varepsilon_3 = 0$ and $r_3 = 0$ and the y_3-axis are invariant under the flow of (2.22).

LEMMA 2.9. *The point $q_{out} = (0, 0, 0)$ is a hyperbolic equilibrium of system* (2.22) *with eigenvalues: $\lambda_1 = 1$ with eigenvector $(1, 0, 0)$ corresponding to the flow in $\varepsilon_3 = 0$, $\lambda_2 = -2$ with eigenvector $(0, 1, 0)$ corresponding to the flow on the y_3-axis, and $\lambda_3 = -3$ with eigenvector $(0, 1, 1)$ corresponding to the flow in $r_3 = 0$.*

Proof. Computation. □

Now we transform the part of the special orbit γ_2 (introduced in Proposition 2.3) corresponding to $x_2 > 0$ to chart K_3; i.e., we define $\gamma_3 := \kappa_{23}(\gamma_2)$.

LEMMA 2.10. *The orbit γ_3 lies in the plane $r_3 = 0$, converges to q_{out} as $\varepsilon_3 \to 0$, and is tangent at q_{out} to the vector $(0, 1, 0)$.*

Proof. The coordinate transformation (2.13) and assertion (3) from Proposition 2.3 imply that the orbit γ_3 has the expansion $(0,\ -\Omega_0\varepsilon_3^{2/3} + \varepsilon_3 + O(\varepsilon_3^{5/3}),\ \varepsilon_3\ )$ as $\varepsilon_3 \to 0$. The lemma follows. □

Lemma 2.10 implies that parts of the manifold $\bar{M}_a$ corresponding to $\bar{r} > 0$ come close to the equilibrium q_{out}. Hence, we need a precise description of the dynamics of system (2.22) close to q_{out}. This is a somewhat delicate problem because of the *resonance* $\lambda_2 = \lambda_1 + \lambda_3$, which implies that there exists no smooth transformation of the nonlinear flow to the flow of the corresponding linearization. It turns out that, due to the simple form of the equations, it is quite easy to work out the lowest order approximation of the flow.

For the description of the flow in a neighborhood of q_{out} we define sections Σ_3^{in} and Σ_3^{out} as follows:

$$\Sigma_3^{in} = \{(r_3, y_3, \varepsilon_3) \;:\; r_3 \in [0, \rho],\, y_3 \in [-\beta_3, \beta_3],\, \varepsilon_3 = \delta\},$$
$$\Sigma_3^{out} = \{(r_3, y_3, \varepsilon_3) \;:\; r_3 = \rho,\, y_3 \in [-\beta_3, \beta_3],\, \varepsilon_3 \in [0, \delta]\},$$

where ρ and δ are the same constants as before, and $\beta_3 > 0$ is sufficiently small; see Figure 2.5.

Let Π_3 be the transition map from Σ_3^{in} to Σ_3^{out}. Our goal is to obtain a formula for the map Π_3. Before stating the relevant result we need to discuss the structure of (2.22) in more detail. We first divide (2.22) by the factor $F(r_3, y_3, \varepsilon_3)$, which is close to one near q_{out}, and obtain

$$\begin{aligned} r_3' &= r_3, \\ y_3' &= -2y_3 - \frac{\varepsilon_3}{1 - y_3} + r_3\varepsilon_3 G(r_3, y_3, \varepsilon_3), \\ \varepsilon_3' &= -3\varepsilon_3, \end{aligned} \tag{2.23}$$

where $G(r_3, y_3, \varepsilon_3)$ is a C^k-function. Consider (2.23) with $r_3 = 0$, namely,

$$\begin{aligned} y_3' &= -2y_3 - \frac{\varepsilon_3}{1 - y_3}, \\ \varepsilon_3' &= -3\varepsilon_3. \end{aligned} \tag{2.24}$$

By construction, system (2.24) is, up to rescaling of time, the Riccati equation (2.16) transformed to K_3. The corresponding linearization has eigenvalues $\lambda_2 = -2$ and $\lambda_3 = -3$; hence, (2.16) can be linearized by a near identity transformation of the form

$$y_3 = \psi(\tilde{y}_3, \varepsilon_3), \tag{2.25}$$

where the function ψ is C^k smooth and $\psi(\tilde{y}_3, \varepsilon_3) = \tilde{y}_3 + O(\tilde{y}_3\varepsilon_3)$; see [22]. The corresponding inverse transformation is denoted by $\tilde{y}_3 = \tilde{\psi}(y_3, \varepsilon_3) = y_3 + O(y_3\varepsilon_3)$. Under the transformation (2.25) system (2.23) becomes

$$r_3' = r_3, \tag{2.26a}$$
$$\tilde{y}_3' = -2\tilde{y}_3 - \varepsilon_3 + r_3\varepsilon_3 H(r_3, \tilde{y}_3, \varepsilon_3), \tag{2.26b}$$
$$\varepsilon_3' = -3\varepsilon_3, \tag{2.26c}$$

with a C^k-function H. We have the following result.

Proposition 2.11. *The transition map* Π_3 *for system* (2.22) *has the form*

$$\Pi_3(r_3, y_3, \delta) = \begin{pmatrix} \rho \\ \Pi_{32}(r_3, y_3, \delta) \\ \left(\frac{r_3}{\rho}\right)^3 \delta \end{pmatrix}$$

with $\Pi_{32}(r_3, y_3, \delta)$ *given by*

$$\Pi_{32}(r_3, y_3, \delta) = (\tilde{\psi}(y_3, \delta) - \delta)\left(\frac{r_3}{\rho}\right)^2 + O(r_3^3 \ln r_3).$$

Proof. In the following we suppress the subscript 3 in system (2.26). Fix $(r_i, \tilde{y}_i, \delta) \in \Sigma^{in}$ and $(\rho, \tilde{y}_o, \varepsilon_o) \in \Sigma^{out}$. Consider a solution $(r, \tilde{y}, \varepsilon)(t)$ of (2.26) and $T > 0$ such that $r(0) = r_i$, $r(T) = \rho$, $\tilde{y}(0) = \tilde{y}_i$, $\tilde{y}(T) = \tilde{y}_o$, $\varepsilon(0) = \delta$, $\varepsilon(T) = \varepsilon_o$. We will now compute $(T, \tilde{y}_o, \varepsilon_o)$ as a function of $(r_i, \tilde{y}_i)$. Equations (2.26a) and (2.26c) have explicit solutions $r = e^t r_i$, $\varepsilon = \delta e^{-3t}$. The requirement $r(T) = \rho$ produces an expression for T, namely,

$$T = \ln\left(\frac{\rho}{r_i}\right). \tag{2.27}$$

Let z be a new coordinate defined by $\tilde{y} = e^{-2t}(\tilde{y}_i - \delta + z) + \delta e^{-3t}$. We get the following equation for z:

$$z' = r_i H^z(z, r_i, \tilde{y}_i, t), \tag{2.28}$$

where $H^z(z, r_i, \tilde{y}_i, t) = \delta H(e^t r_i, e^{-2t}(\tilde{y}_i - \delta + z) + \delta e^{-3t}, \delta e^{-3t})$. The transition time T is still given by (2.27). Note that the function H^z is uniformly bounded on the relevant domain. Using (2.28) we obtain $z(T) = r_i O(T) = O(r_i \ln(\frac{\rho}{r_i}))$. It follows that

$$\tilde{y}(T) = (\tilde{y}_i - \delta)\left(\frac{r_i}{\rho}\right)^2 + O\left(\frac{r_i^3}{\rho^2} \ln\left(\frac{\rho}{r_i}\right)\right). \tag{2.29}$$

Hence

$$\begin{aligned}\Pi_{32}(r_3, y_3, \delta) &= \psi\left((\tilde{\psi}(y_3, \delta) - \delta)\left(\frac{r_3}{\rho}\right)^2 + O(r_3^3 \ln r_3), \left(\frac{r_3}{\rho}\right)^3 \delta\right)\\ &= (\tilde{\psi}(y_3, \delta) - \delta)\left(\frac{r_3}{\rho}\right)^2 + O(r_3^3 \ln r_3)\end{aligned}$$

and the result follows. □

Remark 2.10. The following observation will be used later in this paper to obtain the leading order asymptotics of the extended slow manifold $S_{a,\varepsilon}$. The y_3 coordinate of the point where the special orbit γ_3 intersects the section Σ_3^{in} is $y_3^* = \delta^{2/3} s(\delta^{-1/3})$ (see the proof of Lemma 2.10). By comparing the asymptotics of γ_3 and the exact solution of system (2.26) restricted to $r_3 = 0$, i.e., the Riccati equation written in the linearizing coordinates $(\tilde{y}_3, \varepsilon_3)$, it follows that $\tilde{\psi}(y_3^*, \delta) - \delta = -\Omega_0 \delta^{2/3}$.

2.7. Phase portrait on the upper part of S^2. The sphere S^2 is invariant under the desingularization of the blown-up vector field $\bar{X}$. The equator S^1 is invariant. On S^1 there are four equilibria p_a, p_r, q_{in}, q_{out}. These equilibria are hyperbolic for the flow on S^1, the points p_a and q_{out} are attracting, and p_r and q_{in} are repelling. All orbits in $S^{2,+}$ are forward asymptotic to q_{out}. The special orbit $\bar{\gamma}$ is backward asymptotic to p_a and, as it arrives at q_{out}, it is tangent to S^1. Besides $\bar{\gamma}$ there exist two families of trajectories: backward asymptotic to p_r or backward asymptotic to q_{in}. The corresponding phase portrait of S^2 is shown in Figure 2.6.

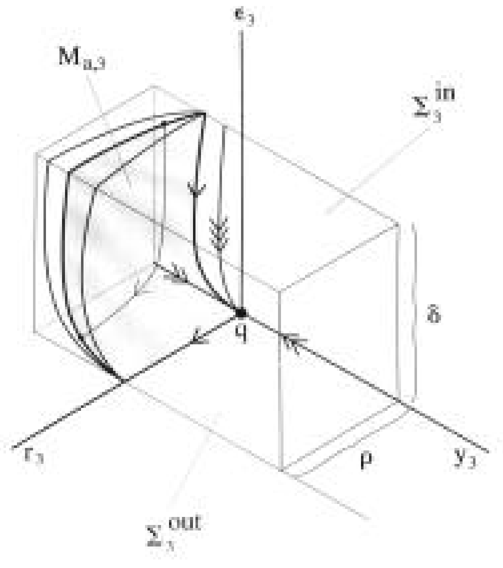

FIG. 2.5. *Geometry and dynamics of system* (2.22) *near the equilibrium* q_{out}.

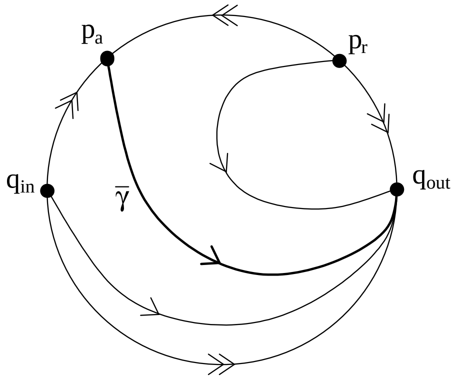

FIG. 2.6. *Blow-up of a fold (jump) point restricted to* S^2.

2.8. Proof of the main result. In this section we prove Theorem 2.1 by combining the results obtained in the individual charts. The idea of the proof is to analyze the evolution of the center manifold $M_{a,1}$ and the rectangle R_1 under the flow of the blown-up vector field $\bar{X}$. We denote the corresponding global invariant manifold by $\bar{M}_a$. The intersection of $\bar{M}_a$ with $S^{2,+}$ is the special orbit $\bar{\gamma}$ connecting the equilibria p_a and q_{out}. It follows that a trajectory starting in or nearby $\bar{M}_a$ will remain close to $\bar{\gamma}$ until it reaches the vicinity of q_{out}. There the trajectory follows the local dynamics near q_{out} and is repelled in the unstable direction of q_{out}.

Proof of Theorem 2.1. We define the map $\Pi : \Sigma_1^{in} \to \Sigma_3^{out}$ by

$$\Pi := \Pi_3 \circ \kappa_{23} \circ \Pi_2 \circ \kappa_{12} \circ \Pi_1.$$

The map Π is the transition map from Σ_1^{in} to Σ_3^{out} for the flow induced by the blown-up vector field $\bar{X}$ on B. We will analyze $\Pi(R_1 \cap M_{a,1})$ and then use the fact that, by construction, the transition map π is given by $\pi = \Phi \circ \Pi \circ \Phi^{-1}$ for $\varepsilon > 0$.

It follows from Proposition 2.8 that $\Pi_1(R_1 \cap M_{a,1}) \subset \Sigma_1^{out}$ is a smooth curve transverse to the set $\{r_1 = 0\}$. It follows that $\kappa_{12}(\Pi_1(R_1 \cap M_{a,1}))$ is a smooth curve transverse to the plane $\{r_2 = 0\}$. Proposition 2.4 implies that the image of this curve under Π_2 has the form $\{(\delta^{-1/3}, h_2^{out}(r_2), r_2) \ : \ r_2 \in [0, \rho\delta^{1/3}]\}$, where $h_2^{out} : [0, \rho\delta^{1/3}] \to \mathbb{R}$ is a smooth function. Under the transformation κ_{23}, this curve transforms to a smooth curve of the form $\{(r_3, h_3^{in}(r_3), \delta) : r_3 \in [0, \rho]\}$ with $(0, h_3^{in}(0), \delta) = \kappa_{23}(\gamma_2 \cap \Sigma_2^{out})$. Proposition 2.11 now implies that $\Pi(R_1 \cap M_{a,1})$ has the form $\{(\rho, h_3^{out}(\varepsilon_3), \varepsilon_3) : \varepsilon_3 \in [0, \delta]\}$, where $h_3^{out}(\varepsilon_3) = O(\varepsilon_3^{2/3})$. This proves assertion (1) of the theorem.

We now prove assertion (2). It follows from Proposition 2.8 that $\Pi_1(R_1)$ is a wedge-like region around $\Pi(R_1 \cap M_{a,1})$ of width $O(e^{-c/\varepsilon_1})$, where $c > 0$ is some constant. Since κ_{12}, Π_2 and κ_{23} are diffeomorphisms restricted to Σ_1^{out}, Σ_2^{in}, and Σ_2^{out}, respectively, it follows that $\kappa_{23} \circ \Pi_2 \circ \kappa_{12} \circ \Pi_1(R_1)$ is also a wedge-like region of width $O(e^{-c/\varepsilon_1})$ around $\kappa_{23} \circ \Pi_2 \circ \kappa_{12} \circ \Pi_1(R_1 \cap M_{a,1})$. Finally, we apply Proposition 2.11 to conclude that $\Pi(R_1)$ is a wedge-like region of width $O(e^{-c/\varepsilon_1})$ around $\Pi(R_1 \cap M_{a,1})$. The evolution of R_1 in the three charts is shown in Figure 2.7. Because $\varepsilon = \rho^3\varepsilon_1 = \rho^3\varepsilon_3$ is a constant of motion for the flow of $\bar{X}$, lines $\varepsilon_1 = \varepsilon/\rho^3$ in Σ_1^{in} are mapped to lines $\varepsilon_3 = \varepsilon/\rho^3$ in Σ_3^{out}. Restricted to such lines the map Π is a contraction with contraction rate $O(e^{-c/\varepsilon_1})$ for some $c > 0$. Assertion (2) follows by applying the appropriate blow-down transformations. □

The dynamics of the blown-up vector field $\bar{X}$, and in particular the center manifold $\bar{M}_a$, are shown in Figure 2.7.

Remark 2.11. Remark 2.10 implies that the function $h_3^{out}(\varepsilon_3)$ has the asymptotic expansion

$$h_3^{out}(\varepsilon_3) = -\Omega_0\varepsilon_3^{2/3} + o(\varepsilon_3^{2/3}).$$

The corresponding expansion for the function $h(\varepsilon)$ in Theorem 2.1 is

$$h(\varepsilon) = -\Omega_0\varepsilon^{2/3} + o(\varepsilon^{2/3}).$$

This result is well known; see, e.g., [18], where it is also shown that the next term in the expansion is $O(\varepsilon \ln \varepsilon)$. Our analysis, in particular the description of the map Π_3 in Proposition 2.11, shows that the occurrence of this term is due to the resonance $\lambda_2 = \lambda_1 + \lambda_3$ at the equilibrium q_{out}; see section 2.6.

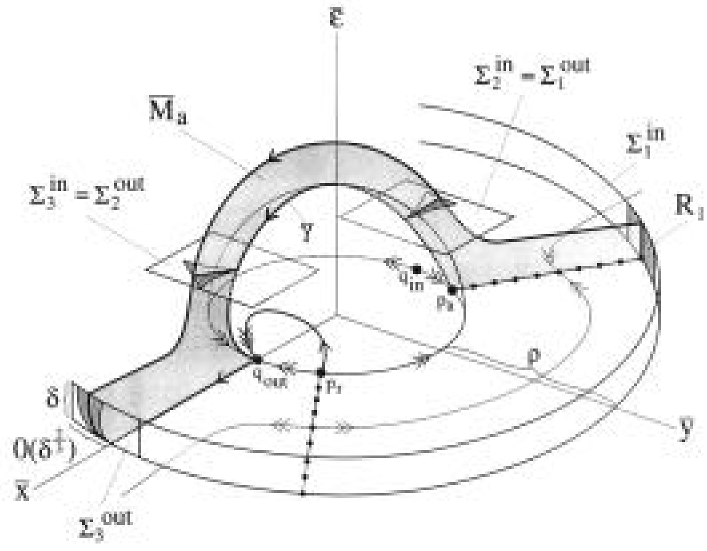

FIG. 2.7. *Geometry and dynamics of the blown-up vector field $\bar{X}$.*

3. Canard point.

3.1. Assumptions and results. In this section we consider a one parameter family of ODEs similar to (1.2), namely,

$$\begin{aligned} x' &= f(x, y, \lambda, \varepsilon), \\ y' &= \varepsilon g(x, y, \lambda, \varepsilon). \end{aligned} \tag{3.1}$$

We assume that $(x_0, y_0) = (0, 0)$ is a nondegenerate fold point of the critical manifold $f(x, y, \lambda, 0) = 0$ for $\lambda_0 = 0$. We assume further that $g(0, 0, 0, 0) = 0$. This gives the following set of defining conditions for the considered singularity:

$$f(0,0,0,0) = 0, \quad \frac{\partial f}{\partial x}(0,0,0,0) = 0, \quad g(0,0,0,0) = 0 \tag{3.2}$$

with the nondegeneracy assumptions

$$\frac{\partial^2 f}{\partial x^2}(0,0,0,0) \neq 0, \quad \frac{\partial f}{\partial y}(0,0,0,0) \neq 0. \tag{3.3}$$

This implies that the critical manifold has a nondegenerate fold point for λ in a suitable interval. Without loss of generality we assume that the fold point is $(0, 0)$ for all values of λ. This can always be achieved by a λ-dependent translation. The remaining nondegeneracy assumptions defining a canard point are

$$\frac{\partial g}{\partial x}(0,0,0,0) \neq 0, \quad \frac{\partial g}{\partial \lambda}(0,0,0,0) \neq 0\ . \tag{3.4}$$

These conditions insure that the nullcline $g(x, y, \lambda, 0) = 0$ is transverse to the critical manifold S and the intersection point of S and $g(x, y, \lambda, 0) = 0$ passes through the fold point $(0, 0)$ with nonzero speed as λ varies.

Let the critical manifold S, its left and right branches S_a and S_r, and the neighborhoods U and V be defined as in section 2. The manifolds $S_{a,\varepsilon}$ and $S_{r,\varepsilon}$ exist outside of V just as they did for a simple fold. Here we ask basically the same question, namely, How can S_a and S_r be extended? The situation is, however, quite different, since, for special choices of λ and ε, $S_{a,\varepsilon}$ extends to $S_{r,\varepsilon}$. This is caused by the special structure of the slow flow for $\lambda = 0$.

As in the case of the fold point, the reduced dynamics is governed by the equation

$$\dot{x} = \frac{g(x, \varphi(x), 0, 0)}{\varphi'(x)}, \tag{3.5}$$

where $\varphi(x)$ is obtained by solving the equation $f(x, y, 0, 0)$ for y as a function of x. It follows from the above assumptions that the right-hand side of (3.5) is a smooth function at the origin. Let $x_0(t)$ denote a maximal solution of (3.5) with the property that $x_0(0) = 0$. It follows that $x_0(t)$ exists and passes through the fold point (see Figure 3.1a). If $x_0(t)$ connects S_a to S_r then, heuristically, one can expect a connection from $S_{a,\varepsilon}$ to $S_{r,\varepsilon}$. In what follows we show that such a connection exists along a curve in the (λ, ε)-plane.

Remark 3.1. The case when $x_0(t)$ connects S_r to S_a can also be treated with the methods of this article, but it is less interesting and will be omitted.

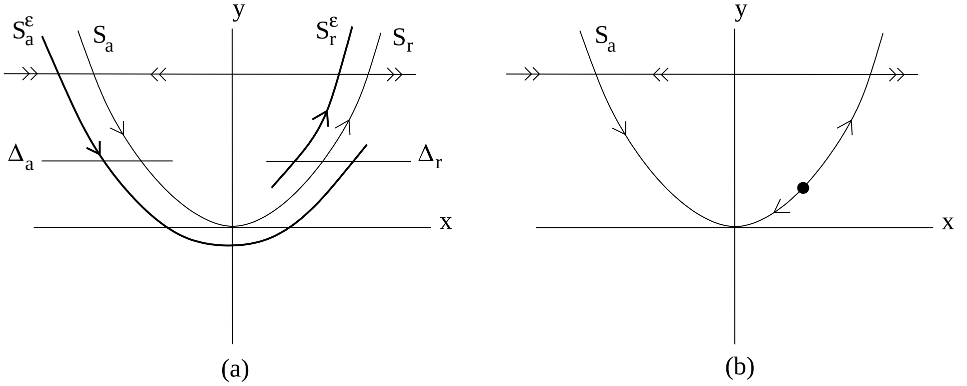

FIG. 3.1. *Reduced flow. (a) $\lambda = 0$, (b) $\lambda > 0$.*

It follows from assumptions (3.2) and (3.3) that using simple coordinate changes (scaling and translations) one can transform (3.1) to the canonical form

$$\begin{aligned} x' &= -yh_1(x, y, \lambda, \varepsilon) + x^2 h_2(x, y, \lambda, \varepsilon) + \varepsilon h_3(x, y, \lambda, \varepsilon), \\ y' &= \varepsilon\left(\pm x h_4(x, y, \lambda, \varepsilon) - \lambda h_5(x, y, \lambda, \varepsilon) + y h_6(x, y, \lambda, \varepsilon)\right), \end{aligned} \tag{3.6}$$

where

$$\begin{aligned} &h_3(x, y, \lambda, \varepsilon) = O(x, y, \lambda, \varepsilon), \\ &h_j(x, y, \lambda, \varepsilon) = 1 + O(x, y, \lambda, \varepsilon), \quad j = 1, 2, 4, 5. \end{aligned}$$

We assume that the sign in front of the term xh_4 is positive. In this case, $x_0(t)$ connects S_a to S_r. Clearly, the signs of the various terms in the above equation correspond to a certain choice of signs in the nondegeneracy conditions made earlier. The parameter λ has been rescaled such that the reduced flow has an equilibrium on S_r for $\lambda > 0$ (see Figure 3.1b).

We introduce the following notation:

$$a_1 = \frac{\partial h_3}{\partial x}(0,0,0,0), \quad a_2 = \frac{\partial h_1}{\partial x}(0,0,0,0), \quad a_3 = \frac{\partial h_2}{\partial x}(0,0,0,0),$$
$$a_4 = \frac{\partial h_4}{\partial x}(0,0,0,0), \quad a_5 = h_6(0,0,0,0),$$

and define

$$A = -a_2 + 3a_3 - 2a_4 - 2a_5. \tag{3.7}$$

The constant A will show up in various computations and results related to the analysis of the dynamics near the canard point. In particular, we will need the genericity condition $A \neq 0$ in the analysis of canard explosion in [14].

For $j = a, r$ let $\Delta_j = \{(x, \rho^2), x \in I_j\}$ be a section of S_j near the fold point with ρ sufficiently small and suitable intervals I_j (see Figure 3.1a). Define $q_{j,\varepsilon} = \Delta_j \cap S_{j,\varepsilon}$. Let π be the transition map for the flow of (3.1) from Δ_a to Δ_r. The following theorem describes the behavior of $S_{a,\varepsilon}$ and $S_{r,\varepsilon}$ near the canard point.

THEOREM 3.1. *Assume that system* (3.1) *satisfies the defining conditions* (3.2)–(3.4) *of a canard point. Assume that the solution $x_0(t)$ of the reduced problem connects S_a to S_r. Then there exists $\varepsilon_0 > 0$ and a smooth function $\lambda_c(\sqrt{\varepsilon})$ defined on* $[0, \varepsilon_0]$ *such that for $\varepsilon \in (0, \varepsilon_0]$ the following assertions hold:*

1. $\pi(q_{a,\varepsilon}) = q_{r,\varepsilon}$ *if and only if* $\lambda = \lambda_c(\sqrt{\varepsilon})$.
2. *The function λ_c has the expansion*

$$\lambda_c(\sqrt{\varepsilon}) = -\left(\frac{a_1 + a_5}{2} + \frac{1}{8}A\right)\varepsilon + O(\varepsilon^{3/2}). \tag{3.8}$$

3. *The transition map π is defined only for λ in an interval around $\lambda_c(\sqrt{\varepsilon})$ of width $O(e^{-c/\varepsilon})$ for some $c > 0$.*
4.

$$\frac{\partial}{\partial \lambda}(\pi(q_{a,\varepsilon}) - q_{r,\varepsilon})\bigg|_{\lambda = \lambda_c(\sqrt{\varepsilon})} > 0.$$

Remark 3.2. For $\lambda = \lambda_c(\sqrt{\varepsilon})$ the slow manifold $S_{a,\varepsilon}$ extends to the slow manifold $S_{r,\varepsilon}$, i.e., the slow manifold consists of a single *canard solution*. We use the term canard solution only for solutions with this property. In other works all solutions of system (1.1) which follow $S_{r,\varepsilon}$ for a time interval of order $O(1)$ are called canard solutions. The solution described in the above theorem is then called a *maximal canard* solution.

For the special case of the van der Pol equation the above results are contained in [6]. Here we treat the general case of a canard point and identify the important parameter A. Also, besides using the same blow-up our proof of the existence of a canard solution based on extending slow manifolds combined with a Melnikov-type argument is new.

3.2. Blow-up. The analysis in this section is, in many aspects, similar to that in section 2. In particular we apply a blow-up transformation, yet the weights (powers of r) must be different than in the case of simple fold. Furthermore, the parameter λ is now included in the blow-up. The blow-up transformation Φ maps $B = S^2 \times [-\mu, \mu] \times [0, \rho]$ to $\mathbb{R}^4$ according to

$$x = \bar{r}\bar{x}, \quad y = \bar{r}^2\bar{y}, \quad \varepsilon = \bar{r}^2\bar{\varepsilon}, \quad \lambda = \bar{r}\bar{\lambda}. \tag{3.9}$$

The constants μ and ρ are chosen small enough such that equations (3.6) are valid in $\Phi(B)$. Let $\bar{X}$ denote the corresponding blown up vector field. In section 2 we used the charts K_1, K_2, and K_3 to obtain the dynamics of $\bar{X}$. Here charts K_1 and K_2 are sufficient to describe the relevant phenomena. In chart K_1, the blow-up transformation (3.9) is

$$x = r_1x_1, \quad y = r_1^2, \quad \varepsilon = r_1^2\varepsilon_1, \quad \lambda = r_1\lambda_1, \tag{3.10}$$

where $(x_1, r_1, \varepsilon_1, \lambda_1)$ are the coordinates in $\mathbb{R}^4$. In chart K_2, the blow-up transformation (3.9) is

$$x = r_2x_2, \quad y = r_2^2y_2, \quad \varepsilon = r_2^2, \quad \lambda = r_2\lambda_2, \tag{3.11}$$

where $(x_2, y_2, r_2, \lambda_2)$ are the coordinates in $\mathbb{R}^4$. A simple computation gives the following lemma.

LEMMA 3.2. *Let κ_{12} denote the change of coordinates from K_1 to K_2. Then κ_{12} is given by*

$$x_2 = x_1\varepsilon_1^{-1/2}, \quad y_2 = \varepsilon_1^{-1}, \quad r_2 = r_1\varepsilon_1^{1/2}, \quad \lambda_2 = \varepsilon_1^{-1/2}\lambda_1 \quad \textit{for } \varepsilon_1 > 0. \tag{3.12}$$

Similarly, $\kappa_{21} = \kappa_{12}^{-1}$ is given by

$$x_1 = x_2y_2^{-1/2}, \quad r_1 = r_2y_2^{1/2}, \quad \varepsilon_1 = y_2^{-1}, \quad \lambda_1 = \lambda_2y_2^{-1/2} \qquad \textit{for } y_2 > 0. \tag{3.13}$$

3.3. Dynamics in chart K_2—preliminary analysis. After dividing out a factor r_2 in a manner analogous to that in section 2, the transformed equations (3.6) have the form

$$\begin{aligned} x_2' &= -y_2 + x_2^2 + r_2G_1(x_2, y_2) + O(r_2(\lambda_2 + r_2)), \\ y_2' &= x_2 - \lambda_2 + r_2G_2(x_2, y_2) + O(r_2(\lambda_2 + r_2)), \end{aligned} \tag{3.14}$$

where

$$G(x_2, y_2) = \begin{pmatrix} G_1(x_2, y_2) \\ G_2(x_2, y_2) \end{pmatrix} = \begin{pmatrix} a_1x_2 - a_2x_2y_2 + a_3x_2^3 \\ a_4x_2^2 + a_5y_2 \end{pmatrix}.$$

Remark 3.3. It turns out that for $r_2 = \lambda_2 = 0$ the system (3.14) is integrable. For this reason the $O(r_2)$ and $O(\lambda_2)$ terms are crucial for the analysis.

Setting $r_2 = \lambda_2 = 0$ in (3.14) we obtain

$$\begin{aligned} x_2' &= -y_2 + x_2^2, \\ y_2' &= x_2. \end{aligned} \tag{3.15}$$

Equation (3.15) is integrable. More precisely, we have the following lemma.

Lemma 3.3. *The function*

$$H(x_2, y_2) = \frac{1}{2}e^{-2y_2}\left(y_2 - x_2^2 + \frac{1}{2}\right) \tag{3.16}$$

is a constant of motion for (3.15).

Proof. A computation gives

$$\begin{aligned} x_2' &= e^{2y_2}\frac{\partial H}{\partial y_2}(x_2, y_2), \\ y_2' &= -e^{2y_2}\frac{\partial H}{\partial x_2}(x_2, y_2). \end{aligned} \tag{3.17}$$

The result follows. □

Lemma 3.3 implies that the solutions of (3.15) are determined by the level curves of $H(x_2, y_2)$. Observe that (3.15) has an equilibrium at $(0,0)$ of center type, surrounded by a family of periodic orbits $H(x_2, y_2) = h$, $h \in (0, 1/4)$. The sets $H(x_2, y_2) = h$, $h \leq 0$, correspond to unbounded solutions. The locus of the solution determined by $h = 0$ is the parabola $x_2^2 - y_2 = 1/2$, and this solution is given by

$$\gamma_{c,2}(t_2) = (x_{c,2}(t_2), y_{c,2}(t_2)) = \left(\frac{1}{2}t_2, \frac{1}{4}t_2^2 - \frac{1}{2}\right), \quad t_2 \in \mathbb{R}.$$

The special solution $\bar{\gamma}_c$ is of central importance to the canard phenomenon. We will see that $\bar{\gamma}_c$ connects the endpoint p_a of the critical manifold S_a across the sphere S^2 to the endpoint p_r of the critical manifold S_r. As in the analysis of the fold point, the points p_a and p_r lie on the equator of S^2 and will be studied in chart K_1. Our goal is to investigate how this connection breaks under perturbation. The tool for this investigation will be a variant of the Melnikov method in which again both charts K_1 and K_2 will be used.

3.4. Dynamics in chart K_1. We proceed in a manner analogous to that in section 2.5 and obtain the following system of equations:

$$\begin{aligned} x_1' &= -1 + x_1^2 + r_1(a_1\varepsilon_1 x_1 - a_2 x_1 + a_3 x_1^3) - \frac{1}{2}\varepsilon_1 x_1 F(x_1, r_1, \varepsilon_1, \lambda_1) \\ &\quad + O(r_1(r_1 + \lambda_1)), \end{aligned} \tag{3.18a}$$

$$r_1' = \frac{1}{2}r_1\varepsilon_1 F(x_1, r_1, \varepsilon_1, \lambda_1), \tag{3.18b}$$

$$\varepsilon_1' = -\varepsilon_1^2 F(x_1, r_1, \varepsilon_1, \lambda_1), \tag{3.18c}$$

$$\lambda_1' = -\frac{1}{2}\lambda_1\varepsilon_1 F(x_1, r_1, \varepsilon_1, \lambda_1), \tag{3.18d}$$

where

$$F(x_1, r_1, \varepsilon_1, \lambda_1) = x_1 - \lambda_1 + r_1(a_4 x_1^2 + a_5) + O(r_1(r_1 + \lambda_1)).$$

It suffices to consider $\lambda_1 \in (-\mu, \mu)$, where $\mu > 0$ can be chosen small. Many features of the dynamics in chart K_1 are analogous to section 2.5; therefore, we provide fewer details. The hyperplanes $r_1 = 0$, $\varepsilon_1 = 0$, and $\lambda_1 = 0$ are invariant, and the invariant line $l_1 := \{(x_1, 0, 0, 0) \; : \; x_1 \in \mathbb{R}\}$ contains two equilibria $p_a = (-1, 0, 0, 0)$ and $p_r = (1, 0, 0, 0)$ which are endpoints of lines of equilibria $S_{a,1}$ and $S_{r,1}$, respectively. For the flow on the line l_1, the equilibrium p_a is attracting and p_r is repelling. Considered as equilibria of system (3.18), both equilibria have a triple eigenvalue zero.

In the invariant plane $r_1 = \lambda_1 = 0$ system (3.18) reduces to

$$\begin{aligned} x_1' &= -1 + x_1^2 - \frac{1}{2}\varepsilon_1 x_1^2, \\ \varepsilon_1' &= -\varepsilon_1^2 x_1. \end{aligned} \tag{3.19}$$

Consequently, the sign of ε_1' is negative for initial conditions near p_r, which implies that the repelling center manifold $N_{r,1}$ at p_r in the half space $\varepsilon_1 > 0$ is unique. The attracting center manifold $N_{a,1}$ at p_a in the half space $\varepsilon_1 > 0$ is also unique, just as in section 2.5. Let

$$D_1 := \{(x_1, r_1, \varepsilon_1, \lambda_1) : \ -2 < x_1 < 2, 0 \le r_1 \le \rho, \ 0 \le \varepsilon_1 \le \delta, -\mu < \lambda_1 < \mu\},$$

where δ, ρ, and μ will be chosen small.

PROPOSITION 3.4. *Choose $c_1 < 2 < c_2$. The constants ρ, δ and μ can be chosen sufficiently small such that the following assertions hold for system* (3.18):

1. *There exists an attracting three-dimensional C^k-center manifold $M_{a,1}$ at p_a that contains the line of equilibria $S_{a,1}$ and the center manifold $N_{a,1}$. In D_1 the manifold $M_{a,1}$ is given as a graph $x_1 = h_a(r_1, \varepsilon_1, \lambda_1)$. The branch of $N_{a,1}$ in $r_1 = \lambda_1 = 0$, $\varepsilon_1 > 0$ is unique and equal to $\gamma_{c,1} := \kappa_{21}(\gamma_{c,2})$, where $\gamma_{c,2}$ is the part of the special trajectory introduced in section* 3.3, *corresponding to x_2 close to $-\infty$.*
2. *There exists a repelling three-dimensional C^k-center manifold $M_{r,1}$ at p_r which contains the line of equilibria $S_{r,1}$ and the center manifold $N_{r,1}$. In D_1 the manifold $M_{r,1}$ is given as a graph $x_1 = h_r(r_1, \varepsilon_1, \lambda_1)$. The branch of $N_{r,1}$ in $r_1 = \lambda_1 = 0$, $\varepsilon_1 > 0$ is unique and equal to $\kappa_{21}(\gamma_{c,2})$ for x_2 close to ∞.*
3. *There exists a stable invariant foliation $\mathcal{F}^s$ with base $M_{a,1}$ and one-dimensional fibers. There exist positive constants $K_{a,1}$ and $K_{a,2}$ such that the contraction along $\mathcal{F}^s$ in a time interval of length T can be estimated by $K_{a,2}e^{-c_2 T}$ from below and by $K_{a,1}e^{-c_1 T}$ from above.*
4. *There exists an unstable invariant foliation $\mathcal{F}^u$ with base $M_{r,1}$ and one-dimensional fibers. There exist positive constants $K_{r,1}$ and $K_{r,2}$ such that the expansion along $\mathcal{F}^u$ in a time interval of length T can be estimated by $K_{r,1}e^{c_1 T}$ from below and by $K_{r,2}e^{c_2 T}$ from above.*

Proof. The proof is analogous to the proof of Proposition 3.4. □

We now define the following sections:

$$\begin{aligned} \Sigma_{a,1}^{in} &:= \{(x_1, r_1, \varepsilon_1, \lambda_1) \in D_1 \ : \ r_1 = \rho, |1 + x_1| < \beta\}, \\ \Sigma_{a,1}^{out} &:= \{(x_1, r_1, \varepsilon_1, \lambda_1) \in D_1 \ : \ \varepsilon_1 = \delta, |1 + x_1| < \beta\}, \\ \Sigma_{r,1}^{in} &:= \{(x_1, r_1, \varepsilon_1, \lambda_1) \in D_1 \ : \ \varepsilon_1 = \delta, |1 - x_1| < \beta\}, \\ \Sigma_{r,1}^{out} &:= \{(x_1, r_1, \varepsilon_1, \lambda_1) \in D_1 \ : \ r_1 = \rho, |1 - x_1| < \beta\}, \end{aligned}$$

where $\beta > 0$ is chosen small. For $j = a, r$, let $\Pi_{j,1}$ be the transition map defined by the flow of (3.18a) from section $\Sigma_{j,1}^{in}$ to $\Sigma_{j,1}^{out}$. With these definitions, results analogous to Lemma 2.7 and Proposition 2.8 hold for the canard point as well.

3.5. Phase portrait on $S_0^{2,+}$. Based on the analysis in charts K_1 and K_2, we can now describe the dynamics of $\bar{X}$ restricted to $S_0^{2,+}$, i.e., for $\bar{r} = \bar{\lambda} = 0$. The equator S^1 is invariant. On S^1 there are four equilibria: p_a, p_r, q_{in}, q_{out}. These equilibria are hyperbolic for the flow on S^1, the points p_a and q_{out} are attracting, and p_r and q_{in} are repelling. The special trajectory $\bar{\gamma}_c$ is a connecting orbit between p_a and p_r. Besides $\bar{\gamma}_c$, there are three types of orbits in $S^{2,+}$: a concentric family of periodic orbits, an equilibrium of center type, and a family of orbits joining q_{in} to q_{out}. The corresponding phase portrait is shown in Figure 3.2.

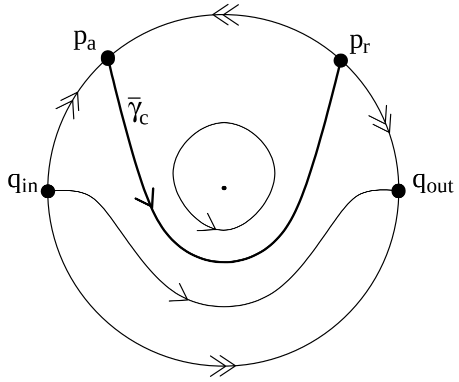

FIG. 3.2. *Blow-up of a canard point restricted to $S_0^{2,+}$ for $\bar{\lambda} = 0$.*

Remark 3.4. It turns out that the connection $\bar{\gamma}_c$ from p_a to p_r breaks for $\bar{\lambda} \neq 0$. Some important aspects of the dynamics near $S_0^{2,+}$ leading to Theorem 3.1 can be understood by investigating whether the intersection of the three-dimensional center manifolds $\bar{M}_a$ and $\bar{M}_r$ at $\bar{\gamma}_c$ is transverse. The relevant computation is carried out in the next section. Bifurcations from the center equilibrium and the family of periodic orbits and their relevance to canard explosion are studied in [14].

3.6. Melnikov computation of the separation between $M_{a,2}$ and $M_{r,2}$. The analysis of the previous sections implies that $M_{a,2}$ and $M_{r,2}$ intersect along $\gamma_{c,2}$ for $r_2 = \lambda_2 = 0$. To prove Theorem 3.1 we compute the first order separation between $M_{a,2}$ and $M_{r,2}$ with respect to r_2 and λ_2. The splitting of the manifolds off the sphere for $\lambda_2 = 0$ is shown in Figure 3.3. All functions defined below are considered as functions of $r_2 \in [0, \rho]$ and $\lambda_2 \in (-\mu, \mu)$, for small $\rho > 0$ and $\mu > 0$, without indicating this dependence explicitly. In the formulas below we drop the subscript of the time variable t_2 from chart K_2, i.e., $t = t_2$.

Let $\gamma_{a,1}$ be the trajectory of system (3.18) contained in $M_{a,1}$ for which $r_1\sqrt{\varepsilon_1} = r_2$. Let $\gamma_{a,2}(t) = (x_{a,2}(t), y_{a,2}(t))$ be the continuation of $\gamma_{a,1}$ to chart K_2, i.e., $\gamma_{a,2}$ is a solution of (3.14), parametrized such that $x_{a,2}(0) = 0$. Analogously, let $\gamma_{r,1}$ be the trajectory of (3.18) contained in $M_{r,1}$ for which $r_1\sqrt{\varepsilon_1} = r_2$ and let $\gamma_{r,2}(t) = (x_{r,2}(t), y_{r,2}(t))$ be the corresponding, backward continued solution of (3.14) parametrized such that $x_{r,2}(0) = 0$.

With these definitions, measuring the separation of $M_{a,2}$ and $M_{r,2}$ corresponds to measuring $y_{a,2}(0) - y_{r,2}(0)$, which is equivalent to estimating the *distance function*

$$\mathcal{D}_c(r_2, \lambda_2) := H(0, y_{a,2}(0)) - H(0, y_{r,2}(0)), \tag{3.20}$$

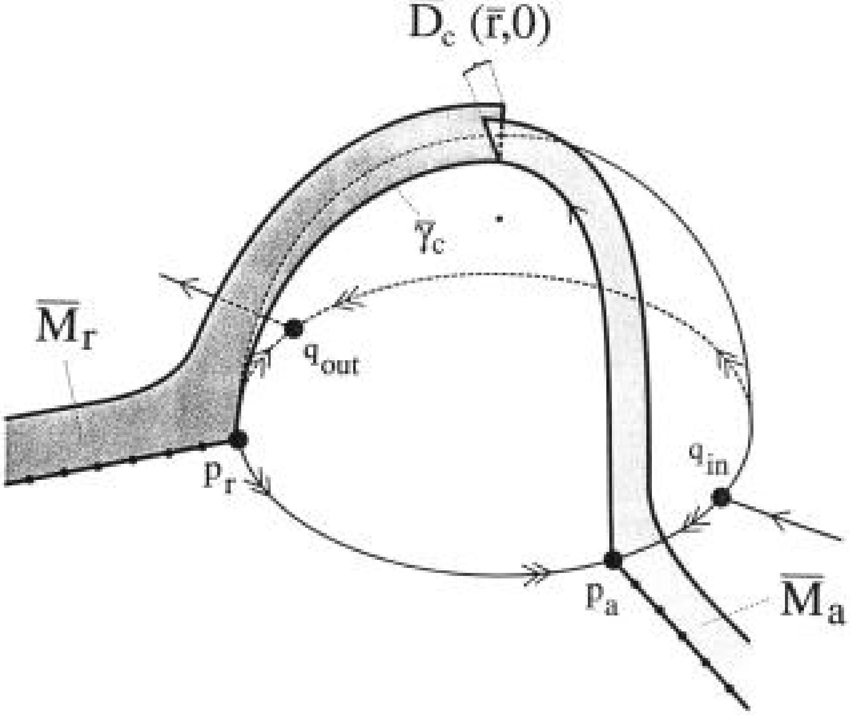

FIG. 3.3. *Splitting of $\bar{M}_a$ and $\bar{M}_r$ for $\bar{\lambda} = 0$.*

since $\frac{\partial H}{\partial y_2}(0, y_2) \neq 0$ for $y_2 < 0$. We define

$$d_{r_2} = \int_{-\infty}^{\infty} \text{grad}H(\gamma_{c,2}(t)) \cdot G(\gamma_{c,2}(t))dt, \tag{3.21}$$

where G is the function defined in section 3.3. Similarly we define

$$d_{\lambda_2} = \int_{-\infty}^{\infty} \text{grad}H(\gamma_{c,2}(t)) \cdot \begin{pmatrix} 0 \\ -1 \end{pmatrix} dt. \tag{3.22}$$

We will prove the following result.

PROPOSITION 3.5. *For ρ and μ small enough, the distance function $\mathcal{D}_c(r_2, \lambda_2)$ is a C^k-function and has the expansion*

$$\mathcal{D}_c(r_2, \lambda_2) = d_{r_2} r_2 + d_{\lambda_2}\lambda_2 + O(2). \tag{3.23}$$

Proof. By construction $\mathcal{D}_c$ is C^k smooth and $\mathcal{D}_c(0,0) = 0$. Thus we have to verify the expansion. We carry out the computation for r_2. The result for λ_2 can be obtained in a similar way. We set $\lambda_2 = 0$ and consider $r_2 \in [0, \rho]$. We will show that

$$H(0, y_{a,2}(0)) = r_2 \int_{-\infty}^{0} \text{grad}H(\gamma_{c,2}(t)) \cdot G(\gamma_{c,2}(t))dt + O(r_2^2). \tag{3.24}$$

An analogous argument yields

$$H(0, y_{r,2}(0)) = -r_2 \int_{0}^{\infty} \text{grad}H(\gamma_{c,2}(t)) \cdot G(\gamma_{c,2}(t))dt + O(r_2^2), \tag{3.25}$$

which implies the proposition.

We define $T(r_2, \delta) < 0$ such that $y_{a,2}(T) = \delta^{-1}$, where δ is the constant from the definition of $\Sigma_{1,a}^{out}$. We write

$$H(0, y_{a,2}(0)) = H(x_{a,2}(T), \delta^{-1}) + \int_T^0 \frac{dH}{dt}(\gamma_{a,2}(t))dt.$$

By standard methods [4]

$$\int_T^0 \frac{dH}{dt}(\gamma_{a,2}(t))dt = r_2 \int_T^0 \operatorname{grad} H(\gamma_{a,2}(t)) \cdot G(\gamma_{a,2}(t))dt + O(r_2^2).$$

It turns out to be very natural to compute $H(x_{a,2}(T), \delta^{-1})$ in chart K_1. We begin by parametrizing $\gamma_{a,1}$ by ε_1, i.e.,

$$\gamma_{a,1}(\varepsilon_1) = \left(x_{a,1}(\varepsilon_1), \frac{r_2}{\sqrt{\varepsilon_1}}, \varepsilon_1, 0\right), \quad \varepsilon_1 \in \left[\left(\frac{r_2}{\rho}\right)^2, \delta\right],$$

where ρ is the constant used in the definition of $\Sigma_{a,1}^{in}$. Let $H_1 = H \circ \kappa_{12}$, i.e.,

$$H_1(x_1, \varepsilon_1) = H\left(\frac{x_1}{\sqrt{\varepsilon_1}}, \frac{1}{\varepsilon_1}\right) = e^{-2/\varepsilon_1}\left(\frac{1}{4} + \frac{1}{2\varepsilon_1} - \frac{x_1^2}{2\varepsilon_1}\right). \tag{3.26}$$

We wish to estimate $H_1(x_{a,1}(\delta), \delta)$. Note that $H_1(x_{a,1}((\frac{r_2}{\rho})^2), (\frac{r_2}{\rho})^2)$ is exponentially small in r_2. Hence,

$$H_1(x_{a,1}(\delta), \delta) = \int_{(\frac{r_2}{\rho})^2}^{\delta} \frac{d}{d\varepsilon_1} H_1(x_{a,1}(\varepsilon_1), \varepsilon_1)d\varepsilon_1 + O(r_2^2).$$

From (3.26) we obtain

$$\begin{aligned} \frac{\partial H_1}{\partial x_1} &= -e^{-2/\varepsilon_1}\frac{x_1}{\varepsilon_1}, \\ \frac{\partial H_1}{\partial \varepsilon_1} &= e^{-2/\varepsilon_1}\frac{1}{\varepsilon_1^2}\left(\frac{1}{2}x_1^2 - \frac{x_1^2}{\varepsilon_1} + \frac{1}{\varepsilon_1}\right). \end{aligned} \tag{3.27}$$

Note that $\frac{dH_1}{d\varepsilon_1}$ evaluated along a trajectory of (3.18) is given by

$$\frac{dH_1}{d\varepsilon_1} = \frac{\partial H_1}{\partial x_1}\frac{x_1'}{\varepsilon_1'} + \frac{\partial H_1}{\partial \varepsilon_1},$$

where x_1' and ε_1' are given by (3.18a) and (3.18c), respectively. By using (3.27), expanding and using the relation $r_1 = r_2/\sqrt{\varepsilon_1}$ to eliminate r_1, we obtain the following formula for $\frac{dH_1}{d\varepsilon_1}$ evaluated along a trajectory of (3.18):

(3.28)
$$\frac{dH_1}{d\varepsilon_1}(x_1, \varepsilon_1) = e^{-2/\varepsilon_1}\varepsilon_1^{-7/2}\left[r_2(a_1x_1\varepsilon_1 - a_2x_1 + a_3x_1^3 + \frac{1 - x_1^2}{x_1}(a_4x_1^2 + a_5)) + \frac{1}{\sqrt{\varepsilon_1}}O(r_2^2)\right].$$

We set

$$\eta(x_1, \varepsilon_1) = e^{-2/\varepsilon_1}\varepsilon_1^{-7/2}\left(a_1x_1\varepsilon_1 - a_2x_1 + a_3x_1^3 + \frac{1 - x_1^2}{x_1}(a_4x_1^2 + a_5)\right). \tag{3.29}$$

It follows that

$$\int_{(\frac{r_2}{\rho})^2}^{\delta} \frac{d}{d\varepsilon_1} H_1(x_{a,1}(\varepsilon_1),\varepsilon_1)d\varepsilon_1 = r_2 \int_{(\frac{r_2}{\rho})^2}^{\delta} \eta(x_{a,1}(\varepsilon_1),\varepsilon_1)d\varepsilon_1 + O(r_2^2),$$

where we have used that the integral of the error term in (3.28) is $O(r_2^2)$ because of the exponentially small prefactor. To complete the computation, recall that $(x_{c,1}(\varepsilon_1),\varepsilon_1)$ parametrizes $N_{a,1}$, and, by center manifold theory,

$$|x_{c,1}(\varepsilon_1) - x_{a,1}(\varepsilon_1)| = O(r_1) = O\left(\frac{r_2}{\sqrt{\varepsilon_1}}\right).$$

By using this estimate it follows that

$$H_1(x_{a,1}(\delta),\delta) = r_2 \int_0^{\delta} \eta(x_{c,1}(\varepsilon_1),\varepsilon_1)d\varepsilon_1 + O(r_2^2),$$

where we have again used the exponentially small prefactor of the integrand to estimate the error caused by first replacing $x_{a,1}$ by $x_{c,1}$ and then changing the interval of integration to $[0,\delta]$. By applying the change of variables formula, we transform this integral to chart K_2 and obtain

$$\int_0^{\delta} \eta(x_{c,1}(\varepsilon_1),\varepsilon_1)d\varepsilon_1 = \int_{-\infty}^{T} \mathrm{grad} H(\gamma_{c,2}(t)) \cdot G(\gamma_{c,2}(t))dt.$$

The result follows. □

Remark 3.5. The formulas for the constants d_{r_2} and d_{λ_2} are the usual Melnikov integrals for the splitting of saddle-saddle connections for perturbations of planar Hamiltonian vector fields. However, the situation considered above is not covered by the usual Melnikov theory.

Proof of Theorem 3.1. It follows from the above results that for $(r_2,\lambda_2) \in [0,\rho) \times (-\mu,\mu)$ a connection from $S_{a,\varepsilon}$ to $S_{r,\varepsilon}$ exists if and only if

$$\mathcal{D}_c(r_2,\lambda_2) = 0. \tag{3.30}$$

We have shown that $\mathcal{D}_c(r_2,\lambda_2) = d_{r_2}r_2 + d_{\lambda_2}\lambda_2 + O(2)$. Hence, (3.30) can be solved for λ_2 by the implicit function theorem provided that $d_{\lambda_2} \neq 0$. The solution has the expansion

$$\lambda_2 = -\frac{d_{r_2}}{d_{\lambda_2}} r_2 + O(r_2^2). \tag{3.31}$$

By using the parametrization of $\gamma_{c,2}$ and repeated integration by parts, we compute

$$\begin{aligned} d_{r_2} &= \int_{-\infty}^{\infty} e^{-2y_2}(-a_1x_2^2 + (a_2 - a_4 + a_5)x_2^2y_2 + (a_4 - a_3)x_2^4 - a_5y_2^2)dt \\ &= -\frac{e}{4}\left(a_1 + a_5 + \frac{1}{4}A\right)\int_{-\infty}^{\infty} e^{-t^2/2}dt \end{aligned} \tag{3.32}$$

and

$$d_{\lambda_2} = -\int_{-\infty}^{\infty} \frac{1}{2}e^{-2y_2}dt = -\frac{e}{2}\int_{-\infty}^{\infty} e^{-t^2/2}dt. \tag{3.33}$$

This proves assertion (1). Property (2) follows by applying transformation (3.11) to the the expansion (3.31). Assertion (3) follows from the above combined with Proposition 3.4 because $M_{a,2}$ must be exponentially close to $M_{r,2}$ to reach the section $\Sigma_{r,1}^{out}$. Finally, the inequality $d_{\lambda_2} < 0$ implies that the intersection of the slow manifolds breaks as described in assertion (4). □

Remark 3.6. It is known that the function λ_c from Theorem 3.1 which describes the canard curve actually has a power series in ε; see [3], [7], [19]. It is interesting to observe that this fact can be explained by a symmetry property of the blow-up transformation. The form of the blow-up transformation (3.9) implies that the transformation

$$(\bar{x}, \bar{y}, \bar{r}, \bar{\lambda}) \mapsto (-\bar{x}, \bar{y}, -\bar{r}, -\bar{\lambda}) \tag{3.34}$$

is a time-reversal symmetry of the blown-up vector field $\bar{X}$; i.e., it maps orbits to orbits. Note that for prescribed slow manifolds outside V, the canard curve is uniquely determined. Since the transformation (3.34) maps a canard curve to a canard curve, it follows that $-\lambda_{c,2}(r_2) = \lambda_{c,2}(-r_2)$ and consequently $\lambda_c(r_2) = \lambda_{c,2}(-r_2)$. From this we conclude that an asymptotic expansion of the canard curve is quadratic in r_2 and hence is a power series in ε. If the original vector field is smooth and the slow manifolds are chosen smooth, then, by a theorem of Schwartz [21], λ_c is a smooth function of ε.

The function λ_c depends on the choice of the slow manifolds. However all slow manifolds are exponentially close and the corresponding functions λ_c differ only by exponentially small terms and have the same asymptotic expansion.

Acknowledgments. The authors would like to thank Freddy Dumortier, Stephan van Gils, Alexandra Milik, and Martin Wechselberger for helpful discussions.

INFINITE DIMENSIONAL GEOMETRIC SINGULAR PERTURBATION THEORY FOR THE MAXWELL–BLOCH EQUATIONS*

GOVIND MENON[†] AND GYÖRGY HALLER[‡]

Abstract. We study the Maxwell–Bloch equations governing a two-level laser in a ring cavity. For Class A lasers, these equations have two widely separated time scales and form a singularly perturbed, semilinear hyperbolic system with two distinct characteristics. We extend Fenichel's geometric singular perturbation theory [N. Fenichel, *J. Differential Equations*, 31 (1979), pp. 53–98] to the Maxwell–Bloch equations by proving the persistence of a $C^k, 0 < k < \infty$, slow manifold under an unbounded perturbation. The proof is obtained by a modified graph transform method. We use uniform decay estimates of Constantin, Foias, and Gibbon [*Nonlinearity*, 2 (1989), pp. 241–269] to obtain a cone condition. These estimates rely on the energy preserving nature of the nonlinearity and the existence of two distinct characteristics. The cone condition and the fact that the unbounded perturbation generates a continuous group are used to define the graph transform. The slow manifold is a globally attracting, positively invariant manifold, with infinite dimension and codimension, that contains the attractor of the system. The slow manifold depends only continuously on ε and converges uniformly on (strongly) compact sets to the critical manifold. This enables us to rigorously decouple the slow and fast time scales and obtain a reduced (but still infinite-dimensional) dynamical system described by a functional differential equation.

1. Introduction.

1.1. The Maxwell–Bloch equations.

We shall study the asymptotic dynamics of the laser equations proposed by Risken and Nummedal [25]. These are amplitude equations describing a two-level laser derived by a semiclassical approximation. The electric field obeys the classical Maxwell equations, and the light-matter interaction is modeled by the quantum mechanical Bloch equations. There are numerous simplifications in this model, several of which are pointed out in [25]. Nevertheless, these equations are quite faithful to the underlying physics and are also mathematically tractable in certain limits. The equations we will study are

$$E_\tau + E_x = \kappa(P - E), \tag{1.1}$$

$$P_\tau = \gamma_\perp[ED - (1 + i\delta)P], \tag{1.2}$$

$$D_\tau = \gamma_\parallel \left[\lambda + 1 - D - \frac{\lambda}{2}(E^* P + E P^*) \right]. \tag{1.3}$$

$E, P \in \mathbb{C}$, and $D \in \mathbb{R}$ are periodic on the domain $[0, 1]$; E is the electric field, P is the polarization of the gain medium, and D is a measure of the population inversion;

$\kappa, \gamma_{\perp}, \gamma_{\|} > 0$ are phenomenological damping constants; $\lambda > 0$ is a pumping term; $\delta \in \mathbb{R}$ is a detuning parameter. All the variables are dimensionless and have been scaled to the continuous wave (cw) solutions. By these we mean spatially homogeneous steady states of (1.1)–(1.3) that correspond to a steady output from the laser. In another scaling these equations are also known as the Lorenz PDE. The Lorenz ODEs are contained in the system (1.1)–(1.3) when $\delta = 0$, and attention is restricted to real valued, spatially independent solutions.

Constantin, Foias, and Gibbon were the first to study these equations rigorously [9]. They proved the existence of global weak solutions and a C^{∞} global attractor in L^2 with finite Hausdorff dimension. Recently Xin and Moloney studied the equations in three dimensions with the addition of a transverse dispersive term [28]. They proved the existence and uniqueness of weak solutions in L^p, $2 \leq p < \infty$, and an attractor with finite regularity. Naturally, one must expect the dynamics to depend strongly on the parameter values, and in some parameter ranges the analysis will be easier than in others. Kovacic and Wettergren studied the Maxwell–Bloch equations (in a different scaling) near an integrable limit in [20, 27], respectively. The motivation there is to use the knowledge of the geometry of the integrable limit to understand the dynamics when the damping and forcing are small.

1.2. Adiabatic elimination for Class A lasers. Different types of lasers have vastly different dynamics because of the wide variation in parameters $\kappa, \gamma_{\perp}$, and $\gamma_{\|}$. Arecchi proposed a characterization of lasers based on the range of damping parameters, and we shall consider what he terms Class A lasers [1, p. 17]. For this class of lasers, we have $\gamma_{\perp} \approx \gamma_{\|} \gg \kappa$. This scaling has also been called the good cavity limit [10], but strictly speaking, the good cavity limit refers to the case where $\gamma_{\perp} + \gamma_{\|} \geq \kappa$ and includes a much broader range of dynamics than we consider. Nevertheless, the range of Class A lasers is sufficiently wide to be physically and mathematically interesting. For Class B lasers, $\gamma_{\perp} \gg \kappa \tilde{>} \gamma_{\|}$, and for Class C lasers, all three damping constants are comparable. For Class A and B lasers one may hope to simplify the dynamics by separating the evolution on fast and slow time scales. Such adiabatic eliminations are common in the physics literature (see the expository article [1] and the references therein). Our aim is to examine such a reduction from a more mathematical viewpoint. The simplest case is of Class A lasers, and we consider only this scaling henceforth.

Let $\gamma_{\perp} \rightarrow \frac{1}{\varepsilon}, \gamma_{\|} \rightarrow \frac{\gamma_{\|}}{\varepsilon}$, with $0 < \varepsilon \ll 1$. The laser equations are rewritten as

$$E_{\tau} + E_x = \kappa(P - E), \tag{1.4}$$

$$\varepsilon P_{\tau} = ED - (1 + i\delta)P, \tag{1.5}$$

$$\varepsilon D_{\tau} = \gamma_{\|} \left[\lambda + 1 - D - \frac{\lambda}{2}(E^* P + E P^*) \right]. \tag{1.6}$$

This suggests we formally eliminate the "fast" variables P and D, i.e., we set the left-hand sides of (1.5) and (1.6) to zero, solve for P, D as functions of E, and substitute in (1.4). This adiabatic approximation is often used in the physics literature [1, 10, 15] although it is typically used with finite-dimensional modal truncations [16, pp. 156, 290]. It is not apparent that this formal reduction is valid or if the solutions to the singular limit are similar to those of the full system. Indeed, we will show that this reduction leads to false predictions about the asymptotic behavior.

The failure of the formal reduction should not be unexpected. The laser equations are a semilinear hyperbolic system with two characteristics: $x - t$ =constant and

x =constant. The formal reduction procedure eliminates one of these characteristics and thus neglects essential information. Nevertheless, there is some merit in studying the reduced system since it provides some insight into the range of possible asymptotic behavior. We may then attempt to verify if similar behavior persists when $\gamma_\perp$ and $\gamma_\|$ are sufficiently large but finite.

1.3. Geometric singular perturbation theory. A rigorous geometric theory for singularly perturbed ODE was developed by Fenichel [12]. To apply his methods to this problem, one would proceed as follows. First, one regularizes the problem by rescaling time, $t = \frac{\tau}{\varepsilon}$. The new time scale, t, is referred to as fast time. In this variable, the laser equations are

$$E_t = \varepsilon[-E_x + \kappa(P - E)], \tag{1.7}$$

$$P_t = ED - (1 + i\delta)P, \tag{1.8}$$

$$D_t = \gamma_\| \left[\lambda + 1 - D - \frac{\lambda}{2}(E^* P + EP^*) \right]. \tag{1.9}$$

Here E changes slowly with time ($O(\varepsilon)$), and P and D have a time rate of change that is $O(1)$. In the limit $\varepsilon = 0$ the slow variable E is constant. The fast variables still change rapidly except at the equilibria of (1.7)–(1.9). Solving for these equilibria we see that they form a manifold, $\mathcal{M}_0$, given as a graph over the slow variable E. Thus the singularities of the slow time system (1.4)–(1.6) are equilibria of the fast time system (1.7)–(1.9). The formal reduction is equivalent to the assumption that $\mathcal{M}_0$ remains invariant and there is a well-defined flow in slow time restricted to it. How good is this assumption? Some intuition is provided by considering ODE.

The underlying geometry is essentially the same for singularly perturbed ODE. We are given a manifold of equilibria and we want to justify a reduction of the flow to this manifold. Under the crucial hypothesis of *normal hyperbolicity*, Fenichel proved that a compact manifold of equilibria, $\mathcal{M}_0$, continues smoothly to a family of *slow manifolds*, $\mathcal{M}_\varepsilon$, for sufficiently small $\varepsilon > 0$. Furthermore, if we consider the augmented system obtained by appending the equation $\varepsilon_t = 0$ to the ODE, then these manifolds are contained in a global center manifold given as a graph over the slow variable and ε. The singular perturbation problem is then reduced to a regular perturbation problem restricted to this center manifold, and asymptotic expansions in ε are reduced to Taylor series calculations. Fenichel's methods are powerful, and several problems that lie outside the reach of conventional (and typically heuristic) asymptotic methods are easily studied within his framework. There has been much progress in this area; see [19] for a readable introduction.

For PDE the situation is not so simple. There are several obstructions, some of which are technical; for instance, the phase space is no longer locally compact. But another obstruction is essential. For $\varepsilon > 0$ the perturbed flow is not close to the unperturbed flow in the C^1 topology because of the unbounded operator $\varepsilon\partial_x$. Hence there are no general persistence theorems that one can invoke to prove the existence of the slow manifolds $\mathcal{M}_\varepsilon$ (the definitive results in this direction are due to Bates, Lu, and Zeng and may be found in a set of articles beginning with [4]). Furthermore, even if these manifolds exist, one should not expect them to fit together smoothly in ε or to be contained in a smooth global center manifold restricted to which we obtain a regular perturbation problem. Thus there are difficulties in justifying the existence of asymptotic expansions. The addition of an unbounded perturbation also leads to some unexpected phenomenon. For example, one finds new instabilities that are hidden in the adiabatic elimination. Risken and Nummedal [25] showed that the cw solutions of (1.1)–(1.3) are linearly unstable for sufficiently large λ. On the other hand, the adiabatic elimination predicts that these solutions are always stable. We comment on this point again in section 6.

1.4. Main results. The goals of this paper are to understand rigorously the relation between the adiabatic elimination and the full Maxwell–Bloch system and to develop in the process geometric singular perturbation theory for PDE in the setting of a concrete example. Our main theorem, Theorem 4.1, establishes the persistence of a globally attracting, positively invariant manifold diffeomorphic to the manifold of equilibria. This manifold contains the attractor of the system. In infinite dimensions, the persistence of a global invariant manifold under unbounded perturbations is itself a significant fact, and Theorem 4.1 lies considerably outside the scope of general theorems in this field (see, e.g., [2, 3, 8, 4]). This being said, we must in fairness note that the proof relies strongly on the structure of the Maxwell–Bloch equations and is special to this system. There are two facts that play a key role in the analysis. The first is that the addition of the unbounded perturbation for $\varepsilon > 0$ corresponds to the splitting of characteristics that are parallel in the limit. The second is that the nonlinearities of the Maxwell–Bloch equations satisfy strong energy estimates that follow from their physical origin. In particular, the nonlinearities in (1.1)–(1.3) appear only as skew terms and ensure the uniform decay of the polarization and inversion (see 2.5). These estimates were derived by Constantin, Foias, and Gibbon [9]. We utilize these estimates to establish a cone condition of the flow similar to that in [4, 13]. The cone condition, and the fact that the unbounded perturbation generates a continuous group, are crucial ingredients of the proof.

The convergence of the slow manifold to the critical manifold is subtly altered by the unbounded perturbation. We are only able to prove that the convergence is uniform on strongly compact sets (Theorem 6.1). However, one should keep in mind that the phase space is not locally compact.

As a sidelight, we note that the persistence theorem provides an example of an inertial manifold (albeit infinite dimensional) in a problem with no diffusion. Infinite-dimensional inertial manifolds for reaction diffusion equations coupled to ODE (e.g., the Hodgkin–Huxley equations) have been studied by Marion [22]. Marion's methods are a natural complement to methods used for reaction diffusion equations [13] and depend on the control over high wave numbers provided by diffusion. Our methods are quite different and depend strongly on the absence of diffusion.

The rest of this paper is organized as follows. Section 2 contains a priori estimates and results on well-posedness. Section 3 studies the peculiarities of the singular limit. Sections 4 and 5 are dedicated to a proof of the main theorem. The existence of the invariant manifold provides a basis for rigorously decoupling the slow and fast time scales in the system. This is considered in section 6. We also remark on the relation between the formal limit and the slow dynamics there.

2. Existence and uniqueness.

In this section we will prove that the laser equations define a smooth (C^∞) dynamical system in the space of continuous functions. Constantin, Foias, and Gibbon [9] proved that the laser equations define a Lipschitz dynamical system in L^2. The reason for choosing a more restrictive phase space is that smoothness of the flow is essential for invariant manifold techniques. The obstruction to smoothness in L^2 is the quadratic nonlinearity in (1.8) and (1.9). The product of two L^2 functions does not lie in L^2 in general. For continuous functions, however, multiplication is a smooth map. The motivation for choosing L^2 as a phase space is that the laser rises out of noise and the initial data cannot be prepared to be smooth. In view of this, choosing C^0 as the phase space is obviously a restriction in our study. Nevertheless, Theorem 4.2 of [9] states that asymptotically all solutions approach an attractor composed of C^∞ functions. Thus, in order to study asymptotic behavior it is sufficient to restrict our attention to continuous functions.

Our work relies strongly on the a priori estimates proved by Constantin, Foias, and Gibbon and the estimates of this section are largely rescaled versions of their work [9]. A derivation of these estimates, motivated by the underlying physics, may be found in their work. We make no claim to originality for these estimates, and they are included for completeness and to prove well-posedness of the laser equations in a form appropriate for this paper.

To better illustrate the structure of the equations, we rescale the dependent variables. Define $\mu = \sqrt{\lambda\gamma_{\|}}$ and set

$$u = E\ , \quad v = \mu P, \ w = D. \tag{2.1}$$

Thus, (1.7)–(1.9) are transformed to

$$u_t = \varepsilon\left[-u_x + \kappa\left(\frac{v}{\mu} - u\right)\right], \tag{2.2}$$

$$v_t = \mu u w - (1 + i\delta)v, \tag{2.3}$$

$$w_t = \gamma_{\|}(\lambda + 1 - w) - \frac{\mu}{2}(u^* v + u v^*). \tag{2.4}$$

2.1. Notation. The space of continuous functions from the circle into a Euclidean space $\mathbb{E}$ is denoted by $C(S^1;\mathbb{E})$. The phase space for our dynamical system is $\mathbb{X} = \mathbb{X}_1 \times \mathbb{X}_2$, where $\mathbb{X}_1 = C(S^1;\mathbb{C})$ and $\mathbb{X}_2 = C(S^1;\mathbb{C}\times\mathbb{R})$. A typical element of $\mathbb{X}$ is denoted by the triplet (u, v, w). The norm in $\mathbb{X}_1$ is $\|u\| = \sup_{x\in S^1}|u(x)|$, and the norm of $(v, w) \in \mathbb{X}_2$ is $\|(v, w)\| = \sup_{x\in S^1}(|v(x)|^2 + |w(x)|^2)^{1/2}$. The norm of $(u, v, w) \in \mathbb{X}$ is $(\|u\|^2 + \|(v, w)\|^2)^{1/2}$. The projections from $\mathbb{X}$ into $\mathbb{X}_i$ are denoted by Π_i. The space of k-linear maps between two Banach spaces $\mathbb{Y}_1$ and $\mathbb{Y}_2$ will be denoted as $L^k(\mathbb{Y}_1, \mathbb{Y}_2)$. For $k = 1$, we drop the superscript.

2.2. A priori estimates. Notice that if $\varepsilon > 0$, it is sufficient to obtain a priori estimates for either the slow or fast system since they are equivalent. In the rest of this section $\varepsilon > 0$ is fixed.

We first derive a pointwise decay estimate. For all $x \in S^1$, we have

$$\begin{aligned}\partial_t(|v(t,x)|^2 + |w(t,x)|^2) &= -2|v|^2 - 2\gamma_{\|}|w|^2 + 2(\lambda+1)\gamma_{\|}w\\ &\le -2\beta(|v|^2 + |w|^2) + \gamma_{\|}(\lambda+1)^2,\end{aligned}$$

where $\beta = \min(1, \gamma_{\|}/2)$. Integrating the resulting inequality and taking the sup over $x \in S^1$ we obtain

$$\begin{aligned}\|(v,w)(t)\|^2 &\le e^{-2\beta t}(\|(v,w)(0)\|^2) + (\lambda+1)^2\frac{\gamma_{\|}}{2\beta}|1 - e^{-2\beta t}|\\ &=: e^{-2\beta t}(\|(v,w)(0)\|^2) + \rho_v^2|1 - e^{-2\beta t}|,\end{aligned} \tag{2.5}$$

where we have defined the constant $\rho_v^2 = \gamma_{\|}(\lambda+1)^2/2\beta$. The miraculous cancellation in the nonlinear terms that leads to this strong energy estimate is actually a consequence of the underlying physics; see [9] for details. Since the nonlinear terms uv^* and uw in (2.3)–(2.4) do not influence the change in energy, we say that the nonlinearity is energy preserving. Equation (2.2) admits an equally strong estimate. A smooth solution satisfies

$$(\partial_t + \varepsilon\partial_x)(|u(t,x)|^2) = -2\kappa\varepsilon|u(t,x)|^2 + 2\frac{\varepsilon\kappa}{\mu}\,\mathrm{Re}\,(u^*v)$$
$$\leq -\varepsilon\kappa|u(t,x)|^2 + \frac{\varepsilon\kappa}{\mu^2}|v(t,x)|^2.$$

Integrating this inequality along the characteristic $x - \varepsilon t$ =constant, we have

$$|u(t,x)|^2 \leq e^{-\varepsilon\kappa t}|u(0,x-\varepsilon t)|^2 + \frac{\varepsilon\kappa}{\mu^2}\int_0^t e^{-\varepsilon\kappa(t-s)}|v(s,x-\varepsilon(t-s))|^2 ds. \tag{2.6}$$

Taking the sup over $x \in S^1$, and using the energy estimate (2.5), we obtain

$$\|u(t)\|^2 \leq e^{-\varepsilon\kappa t}\|u(0)\|^2 + \frac{\varepsilon\kappa}{\mu^2}e_{2\beta}(t)\|(v,w)(0)\|^2 + \frac{\rho_v^2}{\mu^2}(1-e^{-\varepsilon\kappa t}), \tag{2.7}$$

where we have defined the exponentially decaying function

$$e_\alpha(t) = \frac{e^{-\varepsilon\kappa t} - e^{-\alpha t}}{\alpha - \varepsilon\kappa}, \tag{2.8}$$

assuming that $\varepsilon\kappa < \alpha$.

These energy estimates will be used to establish the existence of global mild solutions. They also immediately establish the existence of positively invariant regions in $\mathbb{X}$. Trajectories will satisfy $\|(v,w)(t)\| < \|(v,w)(0)\|$, for all $t > 0$, provided

$$\|(v,w)(0)\| > \rho_v. \tag{2.9}$$

Let $c(\varepsilon) = \sup_{t\geq 0}\varepsilon\kappa e_{2\beta}(t)/(1-e^{-\varepsilon\kappa t})$. Since $e_{2\beta}(t) \leq te^{-\varepsilon\kappa t}$ we find that

$$c(\varepsilon) \leq \sup_{y>0}\frac{y}{e^y - 1} = 1.$$

Suppose that the initial conditions satisfy (2.9). The energy estimate (2.7) shows that a sufficient condition for $\|u(t)\| < \|u(0)\|$ for all $t > 0$ is

$$\|u(0)\|^2 > \frac{\|(v,w)(0)\|^2}{\mu^2} + \frac{\rho_v^2}{\mu^2}. \tag{2.10}$$

Conditions (2.9) and (2.10) show that the region

$$\mathcal{D}_0 = \{\|u\|^2 \leq 4\rho_v^2/\mu^2, \|(v,w)\|^2 \leq 2\rho_v^2\} \tag{2.11}$$

is strictly positively invariant. $\mathcal{D}_0$ is also an absorbing region for the flow. The energy estimates (2.5) and (2.7) show that all trajectories enter $\mathcal{D}_0$ at the slow exponential rate $e^{-\varepsilon\kappa t}$ and that the time taken to enter $\mathcal{D}_0$ is uniform on bounded sets.

Remark 2.1. It is important to note that the size of the absorbing region is uniform for $0 < \varepsilon\kappa < 2\beta$. We will use this in our construction of slow manifolds.

Let $(u_i, v_i, w_i), i = 1, 2$, be two smooth solutions. We will estimate the growth of their difference. Define $(\xi,\eta,\zeta) = (u_1,v_1,w_1) - (u_2,v_2,w_2)$ and $(\bar{u},\bar{v},\bar{w}) = ((u_1,v_1,w_1) + (u_2,v_2,w_2))/2$. The differences satisfy

$$\xi_t = \varepsilon\left[-\xi_x + \kappa\left(\frac{\eta}{\mu} - \xi\right)\right], \tag{2.12}$$

$$\eta_t = -(1+i\delta)\eta + \mu(\bar{u}\zeta + \bar{w}\xi), \tag{2.13}$$

$$\zeta_t = -\gamma_{\|}\zeta - \mu\,\mathrm{Re}\,(\bar{u}^*\eta + \bar{v}^*\xi). \tag{2.14}$$

Equations (2.13) and (2.14) give the pointwise error estimate

$$\begin{aligned}\partial_t(|\eta|^2+|\zeta|^2) &= -2|\eta|^2-2\gamma_{\|}|\zeta|^2+2\mu\,\mathrm{Re}\,(\xi\eta^*\bar{w}-\xi\zeta\bar{v}^*)\\ &\le -\beta(|\eta|^2+|\zeta|^2)+\frac{\mu^2|\xi|^2}{\beta}(|\bar{v}|^2+|\bar{w}|^2).\end{aligned}$$

In the second step we have used the elementary inequality $2pq \le \beta p^2 + q^2/\beta$. Integrating and taking the sup over $x \in S^1$, we obtain

$$\|(\eta,\zeta)(t)\|^2 \le e^{-\beta t}\|(\eta,\zeta)(0)\|^2+\frac{\mu^2}{\beta}\int_0^t e^{-\beta(t-s)}\|\xi(s)\|^2\|(\bar{v},\bar{w})(s)\|^2 ds. \tag{2.15}$$

The definition of $(\bar{v},\bar{w})$, combined with the energy estimate (2.5), gives

$$\|(\bar{v},\bar{w})(t)\|^2 \le C \quad \forall t\ge 0, \tag{2.16}$$

where C is a constant that is uniform for initial conditions in any fixed ball.

An energy estimate for ξ can be obtained from (2.12). For two smooth solutions we have

$$\begin{aligned}(\partial_t+\varepsilon\partial_x)(|\xi|^2) &= 2\varepsilon\kappa\left(-|\xi|^2+\frac{1}{\mu}\,\mathrm{Re}\,(\xi^*\eta)\right)\\ &\le 2\varepsilon\kappa\left(-|\xi|^2+\frac{|\xi|^2}{2}+\frac{|\eta|^2}{2\mu^2}\right) = -\varepsilon\kappa|\xi|^2+\frac{\varepsilon\kappa}{\mu^2}|\eta|^2.\end{aligned}$$

Integrating this inequality along the characteristic $x-\varepsilon t$ =constant, we have

$$|\xi(t,x)|^2 \le e^{-\varepsilon\kappa t}|\xi(0,x-\varepsilon t)|^2+\frac{\varepsilon\kappa}{\mu^2}\int_0^t e^{-\varepsilon\kappa(t-s)}|\eta(s,x-\varepsilon(t-s))|^2 ds,$$

and taking the sup over $x\in S^1$ we obtain

$$\|\xi(t)\|^2 \le e^{-\varepsilon\kappa t}\|\xi(0)\|^2+\frac{\varepsilon\kappa}{\mu^2}\int_0^t e^{-\varepsilon\kappa(t-s)}\|(\eta,\zeta)(s)\|^2 ds. \tag{2.17}$$

Since the expressions $\|\xi(t)\|^2$ and $\|(\eta(t),\zeta(t))\|^2$ occur often below, we now introduce separate notation for them. Let

$$a(t)=\|\xi(t)\|^2, \quad b(t)=\|(\eta,\zeta)(t)\|^2. \tag{2.18}$$

Combining the inequalities (2.15), (2.16), and (2.17) with the notation of (2.18), we obtain

$$\begin{aligned}b(t) &\le b(0)e^{-\beta t}+\frac{C\mu^2}{\beta}\int_0^t e^{-\beta(t-s)}\left(e^{-\varepsilon\kappa s}a(0)+\frac{\varepsilon\kappa}{\mu^2}\int_0^s e^{-\varepsilon\kappa(s-\tau)}b(\tau)d\tau\right)ds\\ &= b(0)e^{-\beta t}+\frac{C\mu^2}{\beta}a(0)e_\beta(t)+\frac{C\varepsilon\kappa}{\beta}\int_0^t\int_0^s e^{-\beta(t-s)-\varepsilon\kappa(s-\tau)}b(\tau)d\tau ds\\ &= b(0)e^{-\beta t}+\frac{C\mu^2}{\beta}a(0)e_\beta(t)+\frac{C\varepsilon\kappa}{\beta}\int_0^t b(\tau)e^{-\beta t+\varepsilon\kappa\tau}\int_\tau^t e^{(\beta-\varepsilon\kappa)s}ds d\tau.\end{aligned}$$

Computing the inner integral we obtain the estimate

$$b(t)\le b(0)e^{-\beta t}+\frac{C\mu^2}{\beta}a(0)e_\beta(t)+\frac{C\varepsilon\kappa}{\beta}\int_0^t e_\beta(t-\tau)b(\tau)d\tau. \tag{2.19}$$

Here $e_\beta(t)$ is defined as in (2.8). Thus, we have $e_\beta(t) \le te^{-\varepsilon\kappa t}$ for positive times (we suppose that $0 < \varepsilon\kappa < \beta$). As in [9], we apply Gronwall's inequality to (2.19), and use the resulting estimate in (2.17) to obtain

$$\sup_{t\in[0,T]} (a(t) + b(t)) \le C(T, \|(u_i, v_i, w_i)(0)\|)(a(0) + b(0)).$$

We have made the assumption that $t \ge 0$ for simplicity. One may work through the estimates again to find that for any fixed $T > 0$,

$$\sup_{t\in[-T,T]} (a(t) + b(t)) \le C(T, \|(u_i, v_i, w_i)(0)\|)(a(0) + b(0)). \tag{2.20}$$

2.3. Existence of a smooth flow. We now define precisely the dynamical system we will be studying and then prove the existence of a smooth global flow.

Definition 2.2. *$(u(t), v(t), w(t)) \in \mathbb{X}$ is a* mild solution *to the laser equations* (2.2)–(2.4) *if it satisfies the integral equations*

$$u(t) = e^{-\varepsilon\kappa t}e^{-\varepsilon t\partial_x}u(0) + \frac{\varepsilon\kappa}{\mu}\int_0^t e^{-\varepsilon\kappa(t-s)}e^{-\varepsilon(t-s)\partial_x}v(s)ds, \tag{2.21}$$

$$v(t) = e^{-(1+i\delta)t}v(0) + \mu\int_0^t e^{-(1+i\delta)(t-s)}u(s)w(s)ds, \tag{2.22}$$

$$w(t) = e^{-\gamma_\| t}w(0) + (\lambda + 1)(1 - e^{-\gamma_\| t}) - \mu\int_0^t e^{-\gamma_\|(t-s)}\,\mathrm{Re}\,(u(s)^*v(s))ds. \tag{2.23}$$

The notation $e^{-\varepsilon t\partial_x}$, with $t \in \mathbb{R}$, refers to the one parameter linear group generated by the wave equation $u_t + \varepsilon u_x = 0$ in $C(S^1;\mathbb{C})$. It is defined by the shift map $(e^{-\varepsilon t\partial_x}u)(x) = u(x - \varepsilon t)$.

Remark 2.3. The integrals in (2.21)–(2.23) are interpreted as elements in $\mathbb{X}$. Since we are considering continuous functions, the integrals are well defined if and only if they are defined at each point $x \in S^1$. Notice that the product $u(s)w(s)$ is a well-defined continuous function. In [9] the laser equations do not admit a variation of constants formula in L^2. In our work a variation of constants formula is essential.

Remark 2.4. The integral equations (2.22) and (2.23) are equivalent to the differential equations (2.3) and (2.4) since the right-hand side of the differential equations contains no unbounded operator. Thus the a priori estimates (2.5) and (2.15) apply to *all* mild solutions, not just smooth solutions. The a priori estimates on u and ξ, (2.7) and (2.17), are extended to all mild solutions by approximating continuous functions with C^1 functions.

Theorem 2.5 (C^∞ flow). *The laser equations define a C^∞ global flow in the sense of mild solutions. That is, there exists a C^∞ map $\Phi : \mathbb{R} \times \mathbb{X} \to \mathbb{X}$ with the following properties:*

(a) *$\Phi(t, u_0, v_0, w_0)$ is the unique solution to* (2.21)–(2.23) *with initial conditions $\Phi(0, u_0, v_0, w_0) = (u_0, v_0, w_0)$.*

(b) *The set of maps $\varphi_t : \mathbb{X} \to \mathbb{X}, t \in \mathbb{R}$ defined by $\varphi_t(u_0, v_0, w_0) = \Phi(t, u_0, v_0, w_0)$ is a one parameter group of C^∞ diffeomorphisms of $\mathbb{X}$.*

Sketch of the proof. A contraction mapping argument shows that for every point in $\mathbb{X}$ within the ball of radius ρ there is a unique mild solution defined for a time interval $[-T(\rho), T(\rho)]$. A well-known theorem of Segal [26] asserts that solutions fail to exist after a finite time, T_{crit}, if and only if they blow up, i.e., $\|(u(t), v(t), w(t))\| \to \infty$ as $t \to T_{crit}$. The a priori estimates (2.5) and (2.7) show that this is impossible.

Thus through every point (u_0, v_0, w_0) there is a unique solution for all $t \in \mathbb{R}$ denoted by $\Phi(t, u_0, v_0, w_0)$ with $\Phi(0, u_0, v_0, w_0) = (u_0, v_0, w_0)$. Let φ_t be defined as in (b). Clearly, $\varphi_0 = \mathrm{Id}$. Then (2.20) shows that each φ_t is continuous (in fact, locally Lipschitz). The group property follows from uniqueness of solutions.

The proof that the flow is C^∞ is by induction on the order of the derivative. Each step of the argument follows. For any positive integer r, formal differentiation of the equations for the $(r-1)$th derivative yields a linear integral equation that the rth derivative must satisfy (for $r = 1$, we differentiate (2.21)–(2.23)). The existence of a unique solution to this integral equation on a time interval $[-T(\rho, r), T(\rho, r)]$ is proven by a contraction mapping argument. Gronwall estimates show that the derivative grows at worst exponentially in time. Thus, the derivatives of the flow are defined for all $t \in \mathbb{R}$. This is a standard calculation (see, e.g., [6, 18]) and we omit the details. The heart of the matter is that the nonlinear terms on the right-hand side of (2.22)–(2.23) are smooth, and thus all derivatives exist. □

Remark 2.6. We did not need the full strength of the estimates for differences (2.15)–(2.17) in this proof. The estimates will be used in section 4 to prove the cone property.

2.4. Asymptotic dynamics.

The laser equations are dissipative. All trajectories must enter the trapping region $\mathcal{D}_0$ in finite time. To capture the asymptotic behavior of the system, we define the global attractor

$$\mathcal{A} = \bigcap_{t \geq 0} \varphi_t(\mathcal{D}_0).$$

Since $\mathcal{D}_0$ is absorbing and closed, this agrees with the definition of the attractor as the ω-limit set of the absorbing ball

$$\omega(\mathcal{D}_0) = \bigcap_{T \geq 0} \overline{\bigcup_{t \geq T} \varphi_t(\mathcal{D}_0)}.$$

Although the flow is dissipative, it is not smoothing, and it is not obvious that this definition of the attractor is meaningful. However, this follows from the asymptotic smoothing property of the laser equations proved by Constantin, Foias, and Gibbon [9]; see also [23]. Let $\mathcal{B}$ denote the attractor in L^2. The main result of Constantin, Foias, and Gibbon is that $\mathcal{B}$ is composed of C^∞ functions and that it has finite Hausdorff dimension. Thus it also has finite topological dimension. In [23] the regularity result was improved: The attractor $\mathcal{B}$ is in every Gevrey class G^s for $s > 1$, i.e., the attractor is "almost analytic." Furthermore, the estimates in [9, 23] show that the attractor is compact by the Arzela–Ascoli theorem. Since the inclusion $\iota : \mathbb{X} \to L^2$ is continuous, these results apply immediately to the flow in $\mathbb{X}$. Applying the regularity result we see that $\iota(\mathcal{A}) = \mathcal{B}$. Furthermore, since $\mathcal{B}$ is compact, the inverse map restricted to $\mathcal{B}$ is continuous. Hence $\mathcal{A}$ and $\mathcal{B}$ are homeomorphic and have the same topological dimension.

These theorems are independent of the scaling assumptions of our paper. We assert that under suitable scaling hypotheses, one can simplify the geometry further by constructing a normally hyperbolic invariant manifold that contains the attractor.

3. Geometry in the limit $\varepsilon = 0$.

If $\varepsilon = 0$, then $u_t = 0$ in (2.2). By inspection one sees the existence of a manifold of equilibria, $\mathcal{M}_0$, given as the graph of a map $h : \mathbb{X}_1 \to \mathbb{X}_2$. We denote its components by $h(u) = (h_v(u), h_w(u))$. These maps are defined pointwise for $x \in S^1$ by

$$h_v(u)(x) = \mu(1-i\delta)\frac{(\lambda+1)u(x)}{1+\delta^2+\lambda|u(x)|^2}, \quad h_w(u)(x) = \frac{(1+\delta^2)(\lambda+1)}{1+\delta^2+\lambda|u(x)|^2}. \tag{3.1}$$

For large $|u(x)|$ the denominator dominates; therefore, $\mathcal{M}_0$ is uniformly bounded. The pointwise maps $h_v(u)(x)$ and $h_w(u)(x)$ are C^∞ as functions of $u(x)$. Since pointwise operations extend naturally in $C(S^1)$, we find that h is C^∞ as a map between $\mathbb{X}_1 \to \mathbb{X}_2$. Thus, $\mathcal{M}_0$ is a C^∞ manifold.

In this limit we can solve the laser equations explicitly. We split (u, v) into their real and imaginary parts, i.e., $(u, v) = (\mathrm{Re}(u), \mathrm{Re}(v)) + i(\mathrm{Im}(u), \mathrm{Im}(v))$, and then rewrite (2.3)–(2.4) as

$$\partial_t \begin{pmatrix} \mathrm{Re}(v) \\ \mathrm{Im}(v) \\ w \end{pmatrix} = A(u) \begin{pmatrix} \mathrm{Re}(v) \\ \mathrm{Im}(v) \\ w \end{pmatrix} + \begin{pmatrix} 0 \\ 0 \\ \gamma_\| (\lambda+1) \end{pmatrix}, \tag{3.2}$$

where $A(u)$ is the bounded multiplication operator defined by

$$A(u) = \begin{pmatrix} -1 & \delta & \mu\mathrm{Re}(u) \\ -\delta & -1 & \mu\mathrm{Im}(u) \\ -\mu\mathrm{Re}(u) & -\mu\mathrm{Im}(u) & -\gamma_\| \end{pmatrix}. \tag{3.3}$$

Thus, the solution to the laser equations (2.3)–(2.4) in this limit is $u = u(x)$, and

$$\begin{pmatrix} \mathrm{Re}(v)(t) \\ \mathrm{Im}(v)(t) \\ w(t) \end{pmatrix} = e^{tA(u)} \begin{pmatrix} \mathrm{Re}(v)(0) \\ \mathrm{Im}(v)(0) \\ w(0) \end{pmatrix} + \int_0^t e^{(t-s)A(u)} \begin{pmatrix} 0 \\ 0 \\ \gamma_\| (\lambda+1) \end{pmatrix} ds. \tag{3.4}$$

Here u is treated as a parameter and the fibers of constant u are invariant under the flow. Within each fiber, trajectories decay to the equilibrium $(u, h(u))$. The next lemma states that the decay rate is uniform over $\mathcal{M}_0$.

LEMMA 3.1. $\|e^{tA(u)}\| \le e^{-\beta t}$ *for all* $u \in \mathbb{X}_1$.

Proof. This follows from an estimate similar to (2.5). The operator $A(u)$ is broken into two parts: a diagonal matrix that is independent of u and a skew matrix that depends on u. The skew matrix does not influence the growth or decay of energy, and hence u cannot influence the decay in $\|(v, w)(t)\|$. □

Clearly, Lemma 3.1 reflects a strong stability of $\mathcal{M}_0$ that depends on the skew nonlinearity. As we have emphasized earlier, this is actually a consequence of the underlying physics. Figure 3.1 describes the geometry of the flow with two key geometric objects. The first is the critical manifold $\mathcal{M}_0$, the second is the smooth invariant family $\mathcal{F}_{u_0} := \{(u, v, w) | u = u_0\}$ parametrized by $u_0 \in \mathbb{X}_1$. There is a purely metric characterization of $\mathcal{F}_{u_0}$: For any $0 < \gamma < \beta$ these manifolds are γ-stable manifolds in the sense of Chow, Lin, and Lu [7]; i.e., for $t \in \mathbf{R}_+$ and fixed $(u_0, h(u_0))$ the set of points $\{(u, v, w) : \|\varphi_t(u, v, w) - \varphi_t(u_0, h(u_0))\| = O(e^{-\gamma t})\}$ is identical to $\mathcal{F}_{u_0}$. For $\varepsilon > 0$ the system is dissipative in the $\mathbb{X}_1$ direction as well, and all trajectories are sucked into the absorbing region $\mathcal{D}_0$. Thus, it is sufficient to show that $\mathcal{M}_0$ and $\mathcal{F}_{u_0}$ persist within $\mathcal{D}_0$. Roughly speaking, we shall show that there is an $\varepsilon_* > 0$ so that for all $0 \le \varepsilon \le \varepsilon_*$, there is a smooth (but not C^∞) invariant manifold $\mathcal{M}_\varepsilon$ given as a graph $(u, h_\varepsilon(u))$ over $\Pi_1(\mathcal{D}_0)$ that contains the asymptotic dynamics (in particular the attractor $\mathcal{A}$) and is exponentially attracting.

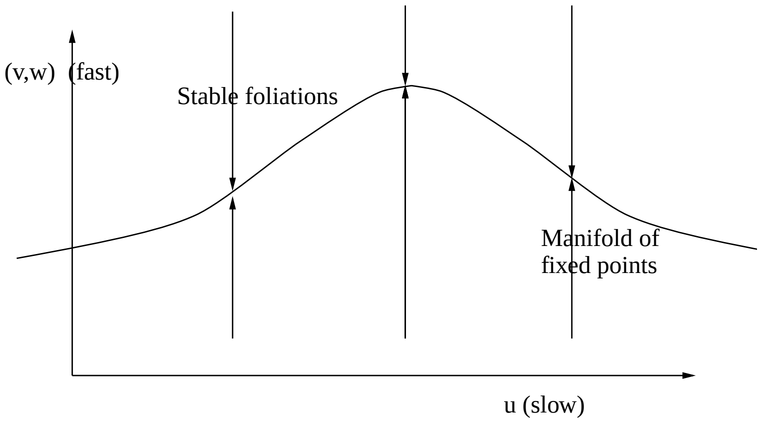

FIG. 3.1. *Geometry in the singular limit $\varepsilon = 0$.*

4. Existence of the invariant manifold.

4.1. The main theorem.

THEOREM 4.1. *For any integer r, there is an $\varepsilon_*(r) > 0$ so that for each $\varepsilon \in [0, \varepsilon_*(r)]$ there is a positively invariant C^r manifold, $\mathcal{M}_\varepsilon$, given as a graph over $\Pi_1(\mathcal{D}_0)$. This manifold attracts all initial conditions exponentially fast and contains the attractor $\mathcal{A}$ of the Maxwell–Bloch equations.*

Sections 4 and 5 are devoted to a proof of the main theorem. The consequences of this theorem are explored in section 6.

4.2. The modified equations. We will use Hadamard's graph transform method to prove the existence of a persisting manifold [14]. We will restrict our attention to the flow within an absorbing ball and modify the nonlinearity outside this ball. This approach has been used to prove the existence of finite-dimensional attracting manifolds for dissipative dynamical systems (e.g., reaction diffusion equations) [13].

Let $R_1 = 2\rho_v/\mu$ and $R_2 = \sqrt{2}\rho_v$. Then R_1 and R_2 are sufficiently large that the region

$$\mathcal{D} = \{\|u\|_{\mathbb{X}_1} \leq 2R_1, \|(v, w)\|_{\mathbb{X}_2} \leq 2R_2\} \tag{4.1}$$

is absorbing and positively invariant (see (2.11) and the discussion preceding it). We denote this region by $\mathcal{D}$ and note that $\mathcal{D} = 2\mathcal{D}_0$.

Let $\chi_1 : \mathbb{C} \to [0, 1]$ be a C^∞ function with compact support that takes the values $\chi_1(s) = 1,\ 0 \leq |s| \leq 1,\ \chi_1(s) = 0$ for $2 \leq |s| < \infty$ and has uniformly bounded derivative $|D\chi_1(s)| \leq 2$. Let $\chi_2 : \mathbb{C} \times \mathbb{R} \to [0, 1]$ be a cut-off function with analogous properties. Define the cut-off functions $\chi_{R_i} : \mathbb{X}_i \to [0, 1]$ by $\chi_{R_1}(u)(x) = \chi_1(u(x)/R_1)$ and $\chi_{R_2}(v, w)(x) = \chi_2((v(x), w(x))/R_2)$. One may prove that χ_{R_i}, $i = 1, 2$, are C^∞. As is common in invariant manifold theory, we will modify the laser equations so as to obtain global estimates. Let

$$\kappa\left(\frac{v}{\mu} - u\right)\chi_{R_1}(u)\chi_{R_2}(v, w) = g(u, v, w) \quad \text{and} \quad u\chi_{R_1}(u) = f(u). \tag{4.2}$$

Consider the modified laser equations

$$u_t = -\varepsilon u_x + \varepsilon g(u, v, w), \tag{4.3}$$

$$v_t = -(1 + i\delta)v + \mu f(u)w, \tag{4.4}$$

$$w_t = \gamma_\| (\lambda + 1 - w) - \mu \mathrm{Re}(f(u)v^*). \tag{4.5}$$

We modify only the u term in the nonlinearity in (2.3)–(2.4). This allows us to retain an estimate similar to the energy estimate (2.15).

LEMMA 4.1. *For* $(u_i, v_i, w_i) \in \mathbb{X}$, $i = 1, 2$, *we have*

(a) $\|f(u_1, v_1, w_1) - f(u_2, v_2, w_2)\| \le 5\|u_1 - u_2\|$,

(b) $\|g(u_1, v_1, w_1) - g(u_2, v_2, w_2)\| \le \kappa(5+4\sqrt{2})(\|u_1 - u_2\| + \mu^{-1}\|(v_1, w_1) - (v_2, w_2)\|)$.

Proof. Without loss of generality suppose $\max(|u_i(x)|) = |u_2(x)|$. If $|u_2(x)| \le 2R_1$,

$$\begin{aligned} &|u_1\chi_{R_1}(u_1)(x) - u_2\chi_{R_1}(u_2)(x)| \\ &\le |u_1(x) - u_2(x)||\chi_{R_1}(u_1)(x)| + |u_2(x)||\chi_{R_1}(u_1)(x) - \chi_{R_1}(u_2)(x)| \\ &\le |u_1(x) - u_2(x)| + 2R_1 \frac{2}{R_1}|u_1(x) - u_2(x)| \le 5\|u_1 - u_2\|. \end{aligned}$$

If $\min(|u_1(x)|, |u_2(x)|) > 2R_1$, the above inequality is trivial since the left-hand side is zero. Finally, if $|u_2(x)| > 2R_1$ and $|u_1(x)| \le 2R_1$, we have

$$|u_1\chi_{R_1}(u_1)(x) - u_2\chi_{R_1}(u_2)(x)| = |u_1\chi_{R_1}(u_1)(x) - u_1\chi_{R_1}(u_2)(x)| \le 4\|u_1 - u_2\|. \tag{4.6}$$

Taking the sup over x we obtain (a). Similar calculations show that the difference in g is bounded by

$$\kappa\left(\left(5 + \frac{4R_2}{\mu R_1}\right)\|u_1 - u_2\| + \left(\frac{5}{\mu} + \frac{4R_1}{R_2}\right)\|(v_1, w_1) - (v_2, w_2)\|\right).$$

But $R_2/R_1 = \mu/\sqrt{2}$. Simplifying the above estimate, we obtain (b). □

Remark 4.2. We make the following important observation regarding the modified flow. Suppose $\|u(0)\| > 2R_1$. Then there exists an open interval I in S^1 so that $|u(0)(x)| > 2R_1$ for all $x \in I$, and hence $g((u, v, w)(0)) = 0$, on this interval. Integrating (4.3) along the characteristic $x - \varepsilon t =$ constant, we find that $u(t, x)$ is constant on the characteristics through $I \times \{t = 0\}$. Thus, $\|u(t)\| > 2R_1$ for all $t \in \mathbb{R}$, and the region $\{\|u\| > 2R_1\}$ in phase space is invariant for the modified flow. This implies its complement is also invariant. Hence the phase space splits into two *invariant* regions, the closed cylinder $\{\|u\| \le 2R_1\}$ and its exterior.

Remark 4.3. Within the region $\{\|u\| \le R_1, \|(v, w)\| \le R_2\}$ the modified and unmodified equations agree on a dense set, and hence their flows agree locally in time. But by the choice of R_i, this region is positively invariant, and thus the flows agree for all positive time. As a result they have identical asymptotic dynamics within this region. We will prove the following invariant manifold theorem for the mild formulation of the modified equations (4.3)–(4.5). The mild formulation is

$$u(t) = e^{-\varepsilon t\partial_x}u(0) + \varepsilon\int_0^t e^{-\varepsilon(t-s)\partial_x} g(u(s), v(s), w(s))ds, \tag{4.7}$$

$$v(t) = e^{-(1+i\delta)t}v(0) + \mu\int_0^t e^{-(1+i\delta)(t-s)} f(u(s))w(s)ds, \tag{4.8}$$

$$\begin{aligned} w(t) = {} & e^{-\gamma_\| t}w(0) + (\lambda + 1)(1 - e^{-\gamma_\| t}) \\ & -\mu\int_0^t e^{-(t-s)\gamma_\|} \mathrm{Re}\,(f(u(s))^* v(s))ds. \end{aligned} \tag{4.9}$$

Theorem 4.4. *For any integer r, there exists an $\varepsilon_*(r) > 0$ so that for each $\varepsilon \in [0, \varepsilon_*(r)]$ there is a C^r manifold, $\mathcal{M}_\varepsilon$, invariant under the flow of the modified Maxwell–Bloch equations* (4.7)–(4.9). *$\mathcal{M}_\varepsilon$ is given as a graph over $\Pi_1(\mathcal{D})$. This manifold attracts all points in the absorbing region exponentially fast and contains the attractor $\mathcal{A}$ of the Maxwell–Bloch equations* (2.21)–(2.23).

Theorem 4.4 implies Theorem 4.1 because, by Remark 4.3, the asymptotic dynamics of modified and unmodified systems agree within $\mathcal{D}_0$. Since $\mathcal{D}_0$ is only positively invariant, the invariance of the manifold in Theorem 4.4 is weakened to positive invariance in Theorem 4.1.

4.3. A priori estimates. We reconsider the a priori estimates of section 2 in light of the above modifications. Henceforth, in sections 4 and 5, φ_t denotes the flow of the modified equations (4.7)–(4.9). In all that follows, we will only consider trajectories that start within the positively invariant region $\mathcal{D}$. Thus the constants, C_j, that occur in inequalities will generally depend on R_i and the parameters $\kappa, \lambda, \gamma_\|$, and μ. We also assume that the time t is positive.

Remark 4.2 implies the uniform bound

$$\|u(t)\| \leq 2R_1, \quad t \in \mathbb{R}, \tag{4.10}$$

for all trajectories starting within $\mathcal{D}$. The modification has also been chosen so that the energy estimate (2.15) is unchanged (i.e., we retain the cancellation of nonlinear terms). Thus, by the choice of R_2 trajectories starting within $\mathcal{D}$ satisfy the uniform bound

$$\|(v, w)(t)\| \leq 2R_2, \quad t \geq 0. \tag{4.11}$$

Estimates for differences between trajectories are derived as in section 2. As in (2.17) we have

$$a(t) \leq e^{C_1 \varepsilon t} a_0 + C_2 \varepsilon \int_0^t e^{C_1 \varepsilon (t-s)} b(s) ds \tag{4.12}$$

for $C_i = C_i(\kappa, \mu, R_i), i = 1, 2$. The analogue of (2.15) is derived from (4.3) and (4.4). The differences (η, ζ) now satisfy

$$\begin{aligned} \partial_t(|\eta|^2 + |\zeta|^2) &= -2|\eta|^2 - 2\gamma_\| |\zeta|^2 + 2\mathrm{Re}\,(\eta^*(f(u_1)w_1 - f(u_2)w_2)) \\ &\quad -2\mathrm{Re}\,(\zeta(f(u_1)v_1^* - f(u_2)v_2^*)) \\ &= -2|\eta|^2 - 2\gamma_\| |\zeta|^2 + \mathrm{Re}\,((f(u_1) - f(u_2))(\bar{w}\eta^* - \bar{v}^*\zeta)). \end{aligned} \tag{4.13}$$

Notice that the choice of the modification is such that the term involving $f(u_1)+f(u_2)$ cancels. This is important as it ensures that we retain the uniform decay normal to the manifold $\mathcal{M}_0$, independent of the basepoint u. One can now use Lemma 4.1 and the energy estimate (4.11) in (4.13) and integrate to find

$$b(t) \leq e^{-\beta t} b(0) + C_3 \int_0^t e^{-\beta(t-s)} a(s) ds. \tag{4.14}$$

The constant C_3 depends only on the parameters $\kappa, \mu, \lambda, \beta$ and the radii R_i. We also need lower estimates on $a(t)$ and $b(t)$ that are derived similarly. For example, (4.3) yields

$$(\partial_t + \varepsilon \partial_x)|\xi(t, x)|^2 \geq -C\varepsilon|\xi|(|\xi| + |\eta|) \geq -C_1 \varepsilon |\xi|^2 - C_2 \varepsilon |\eta|^2,$$

so that integrating between $t_1 \leq t_2$ and taking the sup over x we have

$$a(t_2) \geq e^{-C_1\varepsilon(t_2-t_1)}a(t_1) - C_2\varepsilon \int_{t_1}^{t_2} e^{-C_1\varepsilon(t_2-s)}b(s)ds. \tag{4.15}$$

Finally, from (4.13) and the energy estimate (4.11) we have the pointwise inequality

$$\partial_t(|\eta(t,x)|^2 + |\zeta(t,x)|^2) \geq -3\tilde{\beta}(|\eta|^2 + |\zeta|^2) - C|\xi|^2, \tag{4.16}$$

where we have defined $\tilde{\beta} = \max(1, \gamma_{\|})$. Integrating this inequality and taking the sup over $x \in S^1$ we obtain

$$b(t_2) \geq e^{-3\tilde{\beta}(t_2-t_1)}b(t_1) - C_4 \int_{t_1}^{t_2} e^{-3\tilde{\beta}(t_2-s)}a(s)ds. \tag{4.17}$$

These a priori estimates can be used to prove the existence of a C^∞ flow for the dynamical system defined by (4.7)–(4.9) as in Theorem 2.5. We will not state a separate theorem.

4.4. The cone property. The graph transform will be defined by applying the map φ_T to Lipschitz sections of the normal bundle of the critical manifold $\mathcal{M}_0$. Over sufficiently large time we expect the flow to contract strongly in the normal direction. This is made precise in the cone condition formulated by Conley, and used since then by several authors. It is an essential geometric feature in the persistence theorem of Bates, Lu, and Zeng and a comprehensive list of references may be found in their article [4].

Choose $T > 0$ so that

$$e^{-\beta T/2} = \frac{1}{32}. \tag{4.18}$$

T will be held fixed in all that follows. In the following propositions ε_* denotes an upper limit that may only decrease from one assertion to the next. This follows the convention in [4]. For $(u, v, w) \in \mathcal{D}$, we will use the cone

$$K_L(u,v,w) = \{(u_1,v_1,w_1) \in \mathcal{D} : \|(v_1,w_1) - (v,w)\|_{\mathbb{X}_2} \leq L\|u_1 - u\|_{\mathbb{X}_1}\}. \tag{4.19}$$

Lemma 4.2 (the moving cone lemma). *There exists $\varepsilon_* > 0$ and $L > 0$ such that for $\varepsilon \in [0, \varepsilon_*]$, $t \in [0,T]$, and each point $(u,v,w) \in \mathcal{D}$, the cone $K_L(u,v,w)$ is carried by the diffeomorphism φ_t into the cone $K_L(\varphi_t(u,v,w))$.*

Remark 4.5. The statement of Lemma 4.2 is uniform over all points in the absorbing region. Geometrically, this implies a squeezing property of the flow.

Proof. $\mathcal{D}$ is positively invariant: thus for any $(u,v,w) \in \mathcal{D}$, $L > 0$, and $t \geq 0$, φ_t carries the cone $K_L(u,v,w)$ into $\mathcal{D}$. It remains to prove that for suitable $L > 0$, if two trajectories start in $\mathcal{D}$ and satisfy $b_0 \leq L^2 a_0$, then $b(t) \leq L^2 a(t)$ for all $t \in [0,T]$. Since the initial conditions lie in $\mathcal{D}$, $a(t)$ and $b(t)$ must satisfy the a priori estimates (4.12) and (4.14). Our proof will demonstrate a technique of dealing with these coupled inequalities by exploiting the gap in the exponential rates.

For any $\gamma \in (C_1\varepsilon, \beta)$ we define $|a|_{\gamma,t} = \sup_{s\in[0,t]} a(s)e^{\gamma s}$. Similarly, we define $|b|_{\gamma,t}$. It follows that $|a|_{\gamma,t}$ is an increasing function of t. We will use $\gamma = \beta/2$, though the argument will work for any γ that satisfies the gap condition $C_1\varepsilon < \gamma < \beta$. We further assume that ε_* is so small that $C_1\varepsilon_* < \beta/2$.

We multiply (4.12) by $e^{\beta s/2}$ to obtain

$$\begin{aligned} a(s)e^{\beta s/2} &\leq e^{(\beta/2+C_1\varepsilon)s}a_0 + C_2\varepsilon\int_0^s e^{(\beta/2+C_1\varepsilon)(s-\tau)}e^{\beta\tau/2}b(\tau)d\tau \\ &\leq e^{(\beta/2+C_1\varepsilon)s}a_0 + \frac{C_2\varepsilon}{\beta/2+C_1\varepsilon}\left(e^{(\beta/2+C_1\varepsilon)s}-1\right)|b|_{\beta/2,s} \\ &\leq e^{(\beta/2+C_1\varepsilon)s}\left(a_0+\varepsilon C_2 s|b|_{\beta/2,s}\right). \end{aligned}$$

In the last step we have used the elementary inequality $1-e^{-t}\leq t$ for positive t. Taking the sup over $s\in[0,t]$, and using the fact that $|a|_{\gamma,s}$ is an increasing function of s, we obtain

$$|a|_{\beta/2,t}\leq e^{(\beta/2+C_1\varepsilon)t}\left(a_0+C_2\varepsilon t|b|_{\beta/2,t}\right). \tag{4.20}$$

We apply a similar calculation to (4.14) to obtain

$$\begin{aligned} b(s)e^{\beta s/2} &\leq b_0e^{-\beta s/2}+C_3\int_0^s e^{-\beta(s-\tau)/2}e^{\beta\tau/2}a(\tau)d\tau \\ &\leq b_0+C_3\frac{(1-e^{-\beta s/2})}{\beta/2}|a|_{\beta/2,s}\leq b_0+C_3s|a|_{\beta/2,s}. \end{aligned}$$

Taking the sup over $s\in[0,t]$ we find

$$|b|_{\beta/2,t}\leq b_0+C_3t|a|_{\beta/2,t}. \tag{4.21}$$

Combining the inequalities (4.20) and (4.21) we find

$$|b|_{\beta/2,t}\leq b_0+C_3te^{(\beta/2+C_1\varepsilon)t}\left(a_0+C_2\varepsilon t|b|_{\beta/2,t}\right). \tag{4.22}$$

We suppose that ε_* is chosen so small that for all $\varepsilon\in[0,\varepsilon_*]$, we have

$$\varepsilon e^{(\beta/2+C_1\varepsilon)t}C_2C_3t^2\leq\frac{1}{2}. \tag{4.23}$$

Then using the hypothesis $b_0\leq l^2a_0$, and (4.23) in (4.22) we find

$$|b|_{\beta/2,t}\leq a_0\left[\frac{l^2+C_3te^{(\beta/2+C_1\varepsilon)t}}{1-\varepsilon C_2C_3t^2e^{(\beta/2+C_1\varepsilon)t}}\right]=:a_0\theta(t,\varepsilon), \tag{4.24}$$

where we have defined a new function $\theta(t,\varepsilon)$ to simplify notation. Furthermore, we set $t_1=0$, and $t_2=t$ in the backward time estimate (4.15) to deduce that

$$\begin{aligned} a_0 &\leq e^{C_1\varepsilon t}a(t)+C_2\varepsilon\int_0^t e^{C_1\varepsilon s}b(s)ds \\ &\leq e^{C_1\varepsilon t}\left(a(t)+C_2\varepsilon t|b|_{\beta/2,t}\right). \end{aligned} \tag{4.25}$$

Thus, combining (4.24) and (4.25), we have

$$|b|_{\beta/2,t}\leq\theta(t,\varepsilon)a_0\leq\theta(t,\varepsilon)e^{C_1\varepsilon t}\left(a(t)+C_2\varepsilon t|b|_{\beta/2,t}\right). \tag{4.26}$$

We reduce ε_* if necessary so that $\sup_{t\in[0,T]}\varepsilon C_2t\theta(t,\varepsilon)e^{C_1\varepsilon t}\leq 1/2$. Then we have

$$b(t)\leq e^{-\beta/2t}|b|_{\beta/2,t}\leq\frac{\theta(t,\varepsilon)e^{-(\beta/2-C_1\varepsilon)t}}{1-C_2\varepsilon t\theta(t,\varepsilon)e^{C_1\varepsilon t}}a(t). \tag{4.27}$$

Thus, the cone condition (i.e., $b(t) \leq L^2 a(t)$) will be satisfied if we ensure that for all $t \in [0,T]$ we have

$$\tilde{\theta}(t,\varepsilon) := \frac{\theta(t,\varepsilon)e^{-(\beta/2 - C_1\varepsilon)t}}{1 - C_2\varepsilon t\theta(t,\varepsilon)e^{C_1\varepsilon t}} - L^2 \leq 0. \tag{4.28}$$

The function $\tilde{\theta}(t,\varepsilon)$ is smooth in t and ε for $0 \leq t \leq T, 0 \leq \varepsilon \leq \varepsilon_*$, since by the choice of ε_* the denominator is bounded away from zero. Notice that if we let $t = 0$ in (4.24) we have $\theta(0,\varepsilon) = L^2$; hence $\tilde{\theta}(0,\varepsilon) = 0$. If $\varepsilon = 0$, then the inequality (4.28) reduces to

$$\tilde{\theta}(t,0) = -L^2(1 - e^{-\beta t/2}) + C_3 t \leq 0. \tag{4.29}$$

Thus we choose

$$L^2 \geq 2C_3 \max\left(2/\beta, T(1 - e^{-\beta T/2})^{-1}\right) = 2C_3 T\frac{32}{31} \tag{4.30}$$

(see 4.18). This choice ensures that $\tilde{\theta}(t,0)$ is a decreasing function of t in the range $[0,T]$ and the inequality (4.29) is an equality only at $t = 0$. But then to show that (4.28) is true for small positive ε, it suffices to ascertain its validity near $t = 0$. The choice of L in (4.30) ensures that the slope

$$\frac{d\tilde{\theta}(t,0)}{dt}|_{t=0} \leq -C_3 < 0,$$

which implies that for sufficiently small ε_* the inequality $\max_{t\in[0,T]} \tilde{\theta}(t) \leq 0$ is satisfied. In other words, $b(t) \leq L^2 a(t)$ for all $t \in [0,T]$. □

Remark 4.6. To simplify some estimates later, we further suppose that

$$L^2 = 8\max(C_3 T, C_9), \tag{4.31}$$

where C_9 is a constant that occurs in the proof of Lemma 5.1. This simplifies some estimates in the proof of existence and smoothness of the slow manifold $\mathcal{M}_\varepsilon$.

A point about the proof that an expert may find strange is the use of direct estimates on the flow as opposed to estimates from the linearization near the manifold. The laser equations admit strong estimates which is why this approach works. Typically, the best one can do is obtain a cone condition in a neighborhood of the manifold. Another unusual feature is the use of a Lipschitz constant L that is not small. In Fenichel's work [11] the slope of the Lipschitz sections (i.e., L) is small. The distinction is that we use a single coordinate chart for $\mathcal{M}_0$, so L is finite to account for the nonzero slope of $\mathcal{M}_0$. This is to avoid a global coordinate transformation that would lead to vexing technical difficulties.

The next three lemmas pick out special cases of estimates in the moving cone lemma that will be used in the proof that the graph transform is a contraction mapping (see Proposition 4.11).

Lemma 4.3. *Suppose that $a_0 = 0$. Then there is $\varepsilon_* > 0$ so that for all $\varepsilon \in [0,\varepsilon_*]$,*

$$b(T) \leq b_0/16.$$

Proof. The inequality (4.20) with $t = T$, and $a_0 = 0$, reduces to

$$|a|_{\beta/2,T} \leq C_2\varepsilon T e^{(\beta/2 + C_1\varepsilon)T}|b|_{\beta/2,T},$$

and inserting this in (4.21) we have

$$\begin{aligned}|b|_{\beta/2,T} &\leq b_0 + \varepsilon C_2 C_3 T^2 e^{(\beta/2+C_1\varepsilon)T}|b|_{\beta/2,T}\\ &\leq b_0 + \frac{1}{2}|b|_{\beta/2,T}\end{aligned}$$

by the choice of ε_* in Lemma 4.2 (see (4.23)). Thus $|b|_{\beta/2,T} \leq 2b_0$. But then

$$b(T) \leq e^{-\beta T/2}|b|_{\beta/2,T} \leq \frac{2}{32}b_0 = \frac{1}{16}b_0. \qquad \square$$

LEMMA 4.4. *Suppose $b_0 = 0$. There is $\varepsilon_* > 0$ such that for all $\varepsilon \in [0, \varepsilon_*]$,*

$$b(T) \leq \left(\frac{3L}{4}\right)^2 a_0.$$

Proof. A calculation similar to that above reveals that $b(T) \leq 2C_3 T e^{C_1\varepsilon T} a_0$. When $\varepsilon = 0$ this reduces to

$$b(T) \leq 2C_3 T a_0 \leq \frac{L^2}{4} a_0$$

by the choice of L^2 in Remark 4.6. Thus, for sufficiently small ε_* we obtain the required estimate. $\square$

We conclude with a backward time estimate.

LEMMA 4.5. *Suppose $a(T) = 0$. There is $\varepsilon_* > 0$ such that for all $\varepsilon \in [0, \varepsilon_*]$*

$$a_0 \leq \frac{1}{4L^2} b(T).$$

Proof. We use (4.15) with $t_1 = t$ and $t_2 = T$ to find

$$\begin{aligned}a(t) &\leq e^{C_1\varepsilon(T-t)}a(T) + C_2\varepsilon \int_t^T e^{C_1\varepsilon(s-t)}b(s)ds\\ &= C_2\varepsilon \int_t^T e^{C_1\varepsilon(s-t)}b(s)ds\end{aligned}$$

by our hypothesis. We multiply by $e^{\beta t/2}$ and take the sup over $t \in [0, T]$ to obtain

$$|a|_{\beta/2,T} \leq \frac{C_2\varepsilon}{\beta/2 - C_1\varepsilon}|b|_{\beta/2,T}.$$

Similarly by (4.17), the backward time estimate for $b(t)$ is

$$b(t) \leq e^{3\tilde{\beta}(T-t)}b(T) + C_4 \int_t^T e^{3\tilde{\beta}(s-t)}a(s)ds.$$

We multiply by $e^{\beta t/2}$ and take the sup in t to obtain

$$\begin{aligned}|b|_{\beta/2,T} &\leq e^{3\tilde{\beta}T}\left(b(T) + \frac{C_4 e^{-\beta T/2}}{3\tilde{\beta} - \beta/2}|a|_{\beta/2,T}\right)\\ &\leq e^{3\tilde{\beta}T}\left(b(T) + \frac{C_4 e^{-\beta T/2}}{3\tilde{\beta} - \beta/2}\frac{C_2\varepsilon}{\beta/2 - C_1\varepsilon}|b|_{\beta/2,T}\right).\end{aligned}$$

Let ε_* be so small that for all $\varepsilon \in [0, \varepsilon_*]$,

$$\varepsilon \frac{C_4}{3\tilde{\beta} - \beta/2} \frac{C_2}{2\beta - C_1\varepsilon} e^{(3\tilde{\beta}-\beta/2)T} \leq \frac{1}{2}.$$

Then $|b|_{\beta/2,T} \leq 2e^{3\tilde{\beta}T} b(T)$, and hence

$$a_0 \leq |a|_{\beta/2,T} \leq \varepsilon \frac{2C_2 e^{3\tilde{\beta}T}}{\beta/2 - C_1\varepsilon} b(T).$$

We further reduce ε_* if necessary to obtain $a_0 \leq b(T)/4L^2$ for all $\varepsilon \in [0, \varepsilon_*]$. □

4.5. The graph transform. Define the metric space

$$\mathcal{S}_L = \left\{ h : \Pi_1(\mathcal{D}) \to \mathbb{X}_2 | \ \operatorname{Lip}(h) \leq L, \sup_{u \in \Pi_1(\mathcal{D})} \|h(u)\|_{\mathbb{X}_2} \leq 2R_2 \right\}$$

with the distance function

$$d(h_1, h_2) = \sup_{u \in \Pi_1(\mathcal{D})} \|h_1(u) - h_2(u)\|_{\mathbb{X}_2}.$$

$\mathcal{S}_L$ is complete in this metric. We show below that for any $h \in \mathcal{S}_L$, the image of graph (h) under $\varphi_t, t \in [0, T]$, is the graph of a function in $\mathcal{S}_L$. Taking $t = T$, we define the *graph transform* $\mathcal{G} : \mathcal{S}_L \to \mathcal{S}_L$ by graph $(\mathcal{G}(h)) = \varphi_T$(graph (h)). Most of this subsection is devoted to showing that this definition is unambiguous.

Proposition 4.7 (uniqueness). *Fix $h \in S_L$ and a point $u \in \Pi_1(\mathcal{D})$. There is at most one preimage $u_0 \in \Pi_1(\mathcal{D})$ so that $\Pi_1(\varphi_t(u_0, h(u_0))) = u$.*

Proof. Suppose that $u_1 \neq u_2$ but $\Pi_1(\varphi_t(u_1, h(u_1)) - \varphi_t(u_2, h(u_2))) = 0$. Since $\operatorname{Lip}(h) \leq L$, the point $(u_2, h(u_2))$ lies in the cone $K_L(u_1, h(u_1))$. By the moving cone lemma $\varphi_t(u_2, h(u_2)) \in K_L(\varphi_t(u_1, h(u_1)))$. But then $\Pi_1(\varphi_t(u_1, h(u_1)) - \varphi_t(u_2, h(u_2))) \neq 0$. □

To prove the existence of at least one preimage requires more effort. If $\Pi_1(\mathcal{D})$ were finite-dimensional one could use topological arguments based on degree and the Wazewski principle to prove existence (see, e.g., [3]). This approach would fail here since the manifold to be constructed has both infinite dimension and infinite codimension. Moreover, though we know that there is a solution for $\varepsilon = 0$, we cannot use an implicit function theorem (e.g., as in Fenichel's work [11]) to establish existence for $\varepsilon > 0$ since the perturbation is not Lipschitz in ε. We resort to an explicit solution of the modified equations (4.3)–(4.5) in backward time.

Let $u_T \in \Pi_1(\mathcal{D})$ be fixed. We will show that there exists $(u_0, h(u_0)) \in \mathcal{D}$ such that $\Pi_1(\varphi_T(u_0, h(u_0))) = u_T$. We will rewrite the modified differential equations (4.3)–(4.5) as integral equations in a form different from the mild formulation (4.7)–(4.9). The motivation for this will be clear in the consequent estimates.

Let $S(t, s; u_T)$, $t, s \in \mathbb{R}$, be the two-parameter family in $L(\mathbb{X}_2, \mathbb{X}_2)$ defined as the solution operator to the following linear nonautonomous differential equation:

$$(4.32) \quad \begin{pmatrix} \operatorname{Re}(v)_t \\ \operatorname{Im}(v)_t \\ w_t \end{pmatrix} = \begin{pmatrix} -1 & \delta & \mu \operatorname{Re} f_1(t) \\ -\delta & -1 & \mu \operatorname{Im} f_1(t) \\ -\mu \operatorname{Re} f_1(t) & -\mu \operatorname{Im} f_1(t) & -\gamma_\| \end{pmatrix} \begin{pmatrix} \operatorname{Re}(v) \\ \operatorname{Im}(v) \\ w \end{pmatrix},$$

where

$$f_1(t) = f(e^{\varepsilon(T-t)\partial_x} u_T),$$

and f is defined in (4.2). $S(t,s;u_T)$ is well defined since the right-hand side is a bounded linear operator, and we have the a priori estimate

$$|v(t,x)|^2 + |w(t,x)|^2 \leq e^{-2\beta(t-s)}(|v(s,x)|^2 + |w(s,x)|^2),$$

which ensures the existence of global solutions. In fact, this a priori estimate proves the following.

LEMMA 4.6. $\|S(t_1,t_2;u_T)\| \leq e^{-\beta(t_1-t_2)}$ *for each* $u_T \in \mathbb{X}_1$.

Any mild solution to (4.7)–(4.9) that passes through u_T at time T must satisfy the integral equations

$$u(t) = e^{\varepsilon(T-t)\partial_x} u_T - \varepsilon \int_t^T e^{\varepsilon(s-t)\partial_x} g(u(s),v(s),w(s))ds, \tag{4.33}$$

$$\begin{aligned} \begin{pmatrix} v(t) \\ w(t) \end{pmatrix} = S(t,0;u_T) \begin{pmatrix} v(0) \\ w(0) \end{pmatrix} \\ + \int_0^t S(t,s;u_T) \begin{pmatrix} 0 \\ \gamma_{\|}(\lambda+1) \end{pmatrix} ds \\ +\mu \int_0^t S(t,s;u_T) F(u(s)) \begin{pmatrix} v(s) \\ w(s) \end{pmatrix} ds, \end{aligned} \tag{4.34}$$

where $F(u(s))$ is a skew-symmetric multiplication operator in $L(\mathbb{X}_2, \mathbb{X}_2)$ whose only nonzero terms are

$$\begin{aligned} F_{13} = -F_{31} = \mathrm{Re}(f(u(s))) - f(e^{\varepsilon(T-s)\partial_x} u_T), \\ F_{23} = -F_{32} = \mathrm{Im}(f(u(s))) - f(e^{\varepsilon(T-s)\partial_x} u_T) \end{aligned} \tag{4.35}$$

(we split v into its real and imaginary parts). The virtue of rewriting the equations in this form is that the nonlinear terms are now small. More precisely, by Lemma 4.1 and (4.33)–(4.34), the norm of F is bounded by

$$\begin{aligned} \sup_{s\in[0,T]} \|F(u(s))\| = \sup_{s\in[0,T]} \|f(u(s)) - f(e^{\varepsilon(T-s)\partial_x} u_T)\| \\ \leq 5 \sup_{s\in[0,T]} \|u(s) - e^{\varepsilon(T-s)\partial_x} u_T\| \leq \varepsilon C_5 T \end{aligned} \tag{4.36}$$

for a constant $C_5 = \sup \|g(u,v,w)\| = C_5(\mu,\kappa,R_i)$.

PROPOSITION 4.8 (existence). *There is* $\varepsilon_* > 0$ *such that for each* $\varepsilon \in [0,\varepsilon_*]$ *there exists* $u_0 \in \Pi_1(\mathcal{D})$ *with* $\Pi_1(\varphi_T(u_0,h(u_0))) = u_T$.

Proof. If a preimage exists it must lie in $\Pi_1(\mathcal{D})$ by Remark 4.2. To prove the existence of such a preimage we use iteration on the integral equations (4.33) with the additional condition $(v,w)(0) = h(u(0))$.

Let $u^0(t) = 0$ and $(v,w)^0(t) = 0$ for $0 \leq t \leq T$. For $n \geq 0$ we define the sequence of iterates

$$u^{n+1}(t) = e^{\varepsilon(T-t)\partial_x} u_T - \varepsilon \int_t^T e^{\varepsilon(s-t)\partial_x} g(u^n(s),v^n(s),w^n(s))ds, \tag{4.37}$$

$$\begin{aligned} \begin{pmatrix} v^{n+1}(t) \\ w^{n+1}(t) \end{pmatrix} = S(t,T;u_T) h(u^{n+1}(0)) \\ + \int_0^t S(t,s;u_T) \begin{pmatrix} 0 \\ \gamma_{\|}(\lambda+1) \end{pmatrix} ds \\ + \int_0^t S(t,s;u_T) F(u^{n+1}(s)) \begin{pmatrix} v^n(s) \\ w^n(s) \end{pmatrix} ds. \end{aligned} \tag{4.38}$$

Notice that we solve (4.37) before (4.38).

The sequence defined above satisfies some uniform bounds. First, it is clear that

$$\|u^{n+1}(t) - e^{\varepsilon(T-t)\partial_x} u_T\|_{0,T} \leq \varepsilon T \sup \|g(u,v,w)\| = \varepsilon C_5 T. \tag{4.39}$$

Thus, by Lemmas 4.1, 4.6, and (4.36), we have

$$\|(v,w)^{n+1}(t)\| \leq e^{\beta(T-t)}\|h\| + \frac{(1-e^{-\beta t})}{\beta}(\lambda+1) + 5\varepsilon C_5 T \int_0^t e^{-\beta(t-s)}\|(v,w)^n(s)\| ds.$$

Now $\|h\| \leq 2R_2$ since $h \in \mathcal{S}_L$, so reducing ε_* further if necessary we have

$$\|(v,w)^{n+1}\|_{0,T} \leq \frac{1}{2}\|(v,w)^n\|_{0,T} + \frac{(\lambda+1)}{\beta} + 2R_2 e^{\beta T},$$

where $\|\cdot\|_{0,T} = \sup_{t\in[0,T]}\|\cdot\|$. This implies the uniform bound

$$\sup_{n\geq 0}\|(v,w)^n\|_{0,T} \leq C_6(\beta,\mu,\kappa,\lambda,R_i,T). \tag{4.40}$$

Next, we note that by (4.37) and Lemma 4.1, the difference between consequent iterates of u must satisfy

$$\|u^{n+1} - u^n\|_{0,T} \leq \varepsilon C_7 T(\|u^n - u^{n-1}\|_{0,T} + \|(v,w)^n - (v,w)^{n-1}\|_{0,T}). \tag{4.41}$$

We will estimate each term in the difference between $(v,w)^{n+1}$ and $(v,w)^n$ separately (see (4.38)). The first term is controlled by the uniform Lipschitz constant L.

$$\begin{aligned} &\sup_{t\in[0,T]} \|S(t,T;u_T)(h(u^{n+1}(0)) - h(u^n(0)))\| \\ &\leq \sup_{t\in[0,T]} \|S(t,T;u_T)\|\|h(u^{n+1}(0)) - h(u^n(0))\| \\ &\leq \sup_{t\in[0,T]} e^{-\beta(t-T)} L\|u^{n+1}(0) - u^n(0)\| \leq e^{\beta T} L\|u^{n+1} - u^n\|_{0,T} \\ &\leq \varepsilon C_7 T e^{\beta T} L(\|u^n - u^{n-1}\|_{0,T} + \|(v,w)^n - (v,w)^{n-1}\|_{0,T}) \end{aligned} \tag{4.42}$$

by Lemma 4.6 and inequality (4.41). The differences between the terms on the second line of (4.38) cancel, and the differences between the integrands in the third line are estimated as follows:

$$\begin{aligned} &\left\| F(u^{n+1}(s)) \begin{pmatrix} v^n(s) \\ w^n(s) \end{pmatrix} - F(u^n(s)) \begin{pmatrix} v^{n-1}(s) \\ w^{n-1}(s) \end{pmatrix} \right\| \\ &\leq \|F(u^n)\|\|(v,w)^n - (v,w)^{n-1}\| + \|(v,w)^n\|\|F(u^{n+1}) - F(u^n)\| \\ &\leq \varepsilon C_5 T\|(v,w)^n(s) - (v,w)^{n-1}(s)\| + 5C_6\|u^{n+1}(s) - u^n(s)\|. \end{aligned}$$

In the last step we have used Lemma 4.1 and the uniform estimates (4.36) and (4.40). These terms estimate the integrands. Take the sup over $t \in [0,T]$ and combine the resulting inequality with (4.41) and (4.42) to conclude that the difference between two iterates in (v,w) must satisfy

$$\|(v,w)^{n+1} - (v,w)^n\|_{0,T} \leq \varepsilon C_8 T(\|u^n - u^{n-1}\|_{0,T} + \|(v,w)^n - (v,w)^{n-1}\|_{0,T}). \tag{4.43}$$

We choose ε_* so small that $\max(C_7, C_8)\varepsilon_* T < 1/2$. Then the sequence of iterates is a contraction in the Banach space $C([0,T];\mathbb{X})$. The limit is a trajectory $(u,v,w)(t)$ with $u(T) = u_T$ and $(v,w)(0) = h(u(0))$. □

Remark 4.9. A closer look reveals that we have not used the condition that T is large anywhere in the proof. Thus we have in fact established the stronger statement that for fixed u_T and any $t \in [0,T]$, there is a preimage u_0 so that $\Pi_1(\varphi_t(u_0, h(u_0))) = u_T$. Since u_0 is obtained from a contraction mapping, a slight variant of this argument may be used to prove the existence and uniqueness simultaneously, providing another proof of Proposition 4.7 without invoking Lemma 4.2 (the moving cone lemma). However, the moving cone lemma is of independent interest, and as the proof of Proposition 4.7 shows, it directly implies uniqueness of the preimage.

In essence, the proof reduces to compensating for the unbounded perturbation by viewing the equation in a rotating frame. However, despite the direct proof, the proposition is not trivial. The perturbation is not small but the argument works since the unbounded part of the perturbation generates a unitary group.

We are now in a position to conclude that the graph transform is well defined as a map from $\mathcal{S}_L$ into itself.

Corollary 4.10. $\mathcal{G} : \mathcal{S}_L \to \mathcal{S}_L$.

Proof. Proposition 4.7 and Proposition 4.8 prove that the image of a Lipschitz graph in $\mathcal{S}_L$ is a graph. That the image is also Lipschitz, with Lipschitz constant L, follows from the moving cone lemma. Finally, since $\mathcal{D}$ is positively invariant, the image must satisfy $\|\mathcal{G}(h)\| \le 2R_2$. Thus the graph transform is well defined. □

Now we establish that the graph transform is a contraction mapping on $\mathcal{S}_L$.

Proposition 4.11. *For $\varepsilon \in [0, \varepsilon_*]$ the graph transform $\mathcal{G} : \mathcal{S}_L \to \mathcal{S}_L$ is a contraction.*

Proof. Let $h_i \in \mathcal{S}_L$, $i = 1, 2$. We will show that $d(\mathcal{G}(h_1), \mathcal{G}(h_2)) \le d(h_1, h_2)/2$. Fix u_T in $\Pi_1(\mathcal{D})$. Let $(u_i, h_i(u_i))$ be the unique preimages of $(u_T, \mathcal{G}(h_i)(u_T))$. The distance

$$
\begin{aligned}
& \|\mathcal{G}(h_1)(u_T) - \mathcal{G}(h_2)(u_T)\| \\
& = \|\Pi_2(\varphi_T(u_1, h_1(u_1)) - \varphi_T(u_2, h_2(u_2)))\| \\
& \le \|\Pi_2(\varphi_T(u_1, h_1(u_1)) - \varphi_T(u_1, h_2(u_1)))\| && (4.44)\\
& \qquad + \|\Pi_2(\varphi_T(u_1, h_2(u_1)) - \varphi_T(u_2, h_2(u_1)))\| && (4.45)\\
& \qquad + \|\Pi_2(\varphi_T(u_2, h_2(u_1)) - \varphi_T(u_2, h_2(u_2)))\|. && (4.46)
\end{aligned}
$$

By Lemma 4.3, (4.44) $\le \|h_1(u_1) - h_2(u_1)\|/4$. By Lemma 4.4, (4.45) $\le 3L\|u_1 - u_2\|/4$. And by Lemma 4.3, (4.46) $\le \|h_2(u_1) - h_2(u_2)\|/4 \le L/4\|u_1 - u_2\|$. Thus,

$$
\begin{aligned}
\|\mathcal{G}(h_1)(u_T) - \mathcal{G}(h_2)(u_T)\| &\le \frac{1}{4}\|h_1(u_1) - h_2(u_1)\| + L\|u_1 - u_2\| \\
&\le \frac{1}{4} d(h_1, h_2) + L\|u_1 - u_2\|.
\end{aligned}
$$

Furthermore, by the backward time estimate in Lemma 4.5

$$\|u_1 - u_2\| \le \frac{1}{2L}\|\mathcal{G}(h_1)(u_T) - \mathcal{G}(h_2)(u_T)\|$$

so that

$$\|\mathcal{G}(h_1)(u_T) - \mathcal{G}(h_2)(u_T)\| \le \frac{1}{2} d(h_1, h_2).$$

Since u_T was arbitrary, the lemma is proved. □

COROLLARY 4.12. *There is a unique solution to $\mathcal{G}(h_\varepsilon) = h_\varepsilon$ in $\mathcal{S}_L$. The graph of h_ε, denoted by $\mathcal{M}_\varepsilon$, is invariant under φ_t.*

Proof. We have established that $\varphi_T(\mathcal{M}_\varepsilon) = \mathcal{M}_\varepsilon$. If $0 < t < T$, then $\varphi_t(\mathcal{M}_\varepsilon)$ is the graph of a Lipschitz map in $\mathcal{S}_L$. This follows from Remark 4.9 and the moving cone lemma (notice that Lemma 4.2 is true for all $t \in [0, T]$). But then $\varphi_{T+t}(\mathcal{M}_\varepsilon) = \varphi_t(\mathcal{M}_\varepsilon)$ so that $\varphi_t(\mathcal{M}_\varepsilon)$ is also a fixed point of $\mathcal{G}$. By uniqueness, it follows that $\varphi_t(\mathcal{M}_\varepsilon) = \mathcal{M}_\varepsilon$. Since φ_t is a diffeomorphism, we must have $\varphi_t(\mathcal{M}_\varepsilon) = \mathcal{M}_\varepsilon$ for all $t \in \mathbb{R}$. □

$\mathcal{M}_\varepsilon$ is a *slow manifold*, as it is given as a graph over the slow variable, u. It is clear that all solutions within $\mathcal{D}_0$ are attracted exponentially fast onto the slow manifold. Indeed, given any point in $\mathcal{D}_0$ that does not lie in $\mathcal{M}_\varepsilon$, we may construct a graph in $\mathcal{S}_L$ that passes through this point. Then Proposition 4.11 shows that this graph is attracted exponentially fast onto $\mathcal{M}_\varepsilon$. In particular, this means that the attractor $\mathcal{A}$ is contained within $\mathcal{M}_\varepsilon$. Hence this construction partially answers the open question in [9] on the existence of an inertial manifold in the Maxwell–Bloch equations in the sense that we significantly simplify the geometry of the flow and prove the existence of a smooth, normally hyperbolic invariant manifold attracting all initial conditions. The answer is only partial since this manifold is infinite dimensional.

5. Smoothness of the invariant manifold.

The smoothness of the slow manifold, $\mathcal{M}_\varepsilon$, is established by differentiating the following functional equation that h must satisfy:

$$h(\Pi_1(\varphi_T(u, h(u)))) = \Pi_2(\varphi_T(u, h(u))), \quad u \in \Pi_1(\mathcal{D}). \tag{5.1}$$

For brevity we let $u_T = \Pi_1(\varphi_T(u, h(u)))$ so that (5.1) may be rewritten as

$$h(u_T) = \Pi_2(\varphi_T(u, h(u))), \quad u \in \Pi_1(\mathcal{D}). \tag{5.2}$$

We differentiate (5.2) to obtain a nonlinear functional equation that the derivative of h must satisfy. We prove the existence of a solution to this equation by a contraction mapping argument.

5.1. Notation.

We use the notation in [12] for differentiation. Let $\mathbb{X}_i, \mathbb{Y}$ be Banach spaces. If $F : \mathbb{X} \to \mathbb{Y}$, then $DF : \mathbb{X} \to L(\mathbb{X}, \mathbb{Y})$. If F is a function of several variables, say, $F : \mathbb{X}_1 \times \cdots \times \mathbb{X}_n \to \mathbb{Y}$, then $DF = (D_1F, \ldots, D_nF)$, where $D_iF : \mathbb{X}_1 \times \cdots \times \mathbb{X}_n \to L(\mathbb{X}_i, \mathbb{Y})$. In the interest of brevity we denote

$$P_i = D_i(\Pi_1 \circ \varphi_T), \quad Q_i = D_i(\Pi_2 \circ \varphi_T), \quad i = 1, 2. \tag{5.3}$$

5.2. C^1 smoothness.

Differentiating (5.2) with respect to u we obtain

$$Dh(u_T)Du_T(u) = Q_1(u, h(u)) + Q_2(u, h(u))Dh(u).$$

Since $u_T = \Pi_1 \circ \varphi_T(u, h(u))$, its derivative is

$$Du_T(u) = P_1(u, h(u)) + P_2(u, h(u))Dh(u).$$

Thus, we obtain the formal expression

$$Dh(u_T) = [Q_1 + Q_2Dh(u)]\,[P_1 + P_2Dh(u)]^{-1} \tag{5.4}$$

for the derivative of h. (Here and henceforth we suppress the arguments of P_i, Q_i to simplify notation.) When $\varepsilon = 0$, the derivatives satisfy $P_1 = \mathrm{Id}$, $P_2 = 0$, and

$\|Q_2\| \le e^{-\beta T}$. Furthermore, $u_T = u$. Thus, in this limit, (5.4) reduces to $Dh(u) = Q_1 + Q_2 Dh(u)$, which has a unique solution since $\|Q_2\|$ is small. This suggests that we use iteration to solve (5.4) for $\varepsilon > 0$.

We now define the function space in which we wish to construct the derivative Dh. Let

$$\mathcal{T}_L = \left\{ A : \Pi_1(\mathcal{D}) \to L(\mathbb{X}_1, \mathbb{X}_2) | \sup_{u \in \Pi_1(\mathcal{D})} \|A(u)\|_{L(\mathbb{X}_1,\mathbb{X}_2)} \le L \right\}$$

be the metric space of continuous maps with the distance function

$$d(A_1, A_2) = \sup_{u \in \Pi_1(\mathcal{D})} \|A_1(u) - A_2(u)\|_{L(\mathbb{X}_1,\mathbb{X}_2)}.$$

$\mathcal{T}_L$ is complete in this metric.

We also define a map $\mathcal{F} : \mathcal{T}_L \to \mathcal{T}_L$ as

$$\mathcal{F}(A)(u_T) = [Q_1 + Q_2 A(u)] [P_1 + P_2 A(u)]^{-1}. \tag{5.5}$$

We shall prove that $\mathcal{F}$ is a contraction and the unique fixed point $\mathcal{F}(A) = A$ is the derivative of h. This will imply that $\mathcal{M}_\varepsilon$ is at least of class C^1.

We will use the following lemmas to estimate the terms in (5.5).

Lemma 5.1. *There is $\varepsilon_* > 0$ so that for $\varepsilon \in [0, \varepsilon_*]$*

(a) $\sup_{u\in\Pi_1(\mathcal{D})} \|P_1 - e^{-\varepsilon T \partial_x}\|_{L(\mathbb{X}_1,\mathbb{X}_1)} = O(\varepsilon)$,

(b) $\sup_{u\in\Pi_1(\mathcal{D})} \|P_2\|_{L(\mathbb{X}_1,\mathbb{X}_2)} = O(\varepsilon)$,

(c) $\sup_{u\in\Pi_1(\mathcal{D})} \|Q_1\|_{L(\mathbb{X}_2,\mathbb{X}_1)} \le L/4$,

(d) $\sup_{u\in\Pi_1(\mathcal{D})} \|Q_2\|_{L(\mathbb{X}_2,\mathbb{X}_2)} \le 1/8$.

Proof. The proof entails estimating the growth of derivatives using the equation of variations. The arguments are direct but tedious so we will omit a few details. The main point is that despite the singular perturbation, we can control the derivatives with knowledge of the limit $\varepsilon = 0$ provided we account for the unbounded terms properly (e.g., as in statement (a) of the lemma).

We start by redefining $S(t, s; u_0)$, $t, s \in \mathbf{R}$, as the solution operator to the linear nonautonomous differential equation (4.32) with

$$f_1(t) = f(e^{-\varepsilon t \partial_x} u_0). \tag{5.6}$$

Notice that Lemma 4.6 remains valid with this definition of f_1. The mild formulation is the obvious analogue of (4.33)–(4.34) provided we redefine $F(u)$ as the skew-symmetric multiplication operator whose only nonzero terms are

$$\begin{aligned} F_{13} &= -F_{31} = \mathrm{Re}(f(u(s)) - f(e^{-\varepsilon s \partial_x} u_0)), \\ F_{23} &= -F_{32} = \mathrm{Im}(f(u(s)) - f(e^{-\varepsilon s \partial_x} u_0)). \end{aligned} \tag{5.7}$$

The estimate (4.36) shows that $F(u(s))$ is uniformly small on $[0, T]$. Differentiating (4.33) with respect to the initial point u_0, we obtain linear integral equations that the derivatives must satisfy.

$$\begin{aligned} D_{u_0} u(t) = e^{-\varepsilon t \partial_x} &+ \varepsilon \int_0^t e^{-\varepsilon(t-s)\partial_x} \left(D_1 g D_{u_0} u(s) + D_2 g D_{u_0} v(s) \right) ds \\ &+ \varepsilon \int_0^t e^{-\varepsilon(t-s)\partial_x} D_3 g D_{u_0} w(s) ds \end{aligned} \tag{5.8}$$

and

$$\begin{aligned}\begin{pmatrix} D_{u_0}v(t) \\ D_{u_0}w(t) \end{pmatrix} &= D_{u_0}S(t,0;u_0)\begin{pmatrix} v_0 \\ w_0 \end{pmatrix} \\ &\quad + \int_0^t D_{u_0}(S(t,s;u_0))\left(\begin{pmatrix} 0 \\ \lambda+1 \end{pmatrix} + F(u(s))\begin{pmatrix} v(s) \\ w(s) \end{pmatrix}\right) ds \\ &\quad + \int_0^t S(t,s;u_0)DF(u(s))D_{u_0}u(s)\begin{pmatrix} v(s) \\ w(s) \end{pmatrix} ds \\ &\quad + \int_0^t S(t,s;u_0)F(u(s))\begin{pmatrix} D_{u_0}v(s) \\ D_{u_0}w(s) \end{pmatrix} ds. \end{aligned} \tag{5.9}$$

The derivative of $S(t,0;u_0)$ is computed from its definition in (4.32). Since $S(t,0;u_0)$ is defined by the solution to a system of linear nonautonomous equations, its derivative $D_{u_0}S(t,0;u_0)$ is a linear map from $\mathbb{X}_1 \to L(\mathbb{X}_2,\mathbb{X}_2)$ defined for any $u_1 \in \mathbb{X}_1$ by

$$D_{u_0}S(t,0;u_0)u_1 = \int_0^t S(t,s;u_0)(D_{u_0}G(s,0;u_0)u_1)S(s,0;u_0)ds,$$

where $G(t,0;u_0)$ is the matrix defined on the right-hand side of (4.32) with $f_1(t)$ redefined as in (5.6). It follows from Lemma 4.1 and Lemma 4.6 that $\|D_{u_0}S(t,0;u_0)\| \leq 5te^{-\beta t}$. Thus the "linear" part of $D_{u_0}(v(t),w(t))$ is bounded for all u_0 and for all $t \in [0,T]$ by some constant C_9. By the choice of L (see Remark 4.6) $C_9 \leq L/8$. The nonlinear part in (5.9) (i.e., the terms with F and DF) are $O(\varepsilon)$ by Lemma 4.6 and the estimate (4.36). The nonlinear terms in (5.8) are also $O(\varepsilon)$ since $D_i g$ is uniformly bounded (see Lemma 4.1). Thus, one may prove that a solution to the equation of variations (5.8) and (5.9) exists for sufficiently small ε_* by a contraction mapping argument as in the proof of Proposition 4.8. Then Gronwall estimates show that $\sup_{t\in[0,T]} \max(\|D_{u_0}u(t)\|, \|D_{u_0}(v(t),w(t))\|) \leq C(T,Q_i)$ for all $(u_0,v_0,w_0) \in \mathcal{D}$ so that for all $\varepsilon \in [0,\varepsilon_*]$,

$$\|D_{u_0}u(T) - e^{-\varepsilon T\partial_x}\|_{L(\mathbb{X}_1,\mathbb{X}_1)} \leq \varepsilon C(T,R_i).$$

This proves (a). Similarly, the deviation of Q_1 from its linear part is $O(\varepsilon)$ and for small ε we have (c). Estimates (b) and (d) are obtained from the equation of variations for the derivative in (v_0,w_0). These are

$$\begin{aligned} D_{(v_0,w_0)}u(t) &= \varepsilon\int_0^t e^{-\varepsilon(t-s)\partial_x}\left[D_1gD_{(v_0,w_0)}u(s) + D_2gD_{(v_0,w_0)}v(s)\right] ds \\ &\quad + \varepsilon\int_0^t e^{-\varepsilon(t-s)\partial_x}D_3gD_{(v_0,w_0)}w(s)ds, \\ \begin{pmatrix} D_{(v_0,w_0)}v(t) \\ D_{(v_0,w_0)}w(t) \end{pmatrix} &= S(t,0;u_0) + \int_0^t S(t,s;u_0)DF(u(s))D_{(v_0,w_0)}u(s)ds \\ &\quad + \int_0^t S(t,s;u_0)F(u(s))\begin{pmatrix} D_{(v_0,w_0)}v(s) \\ D_{(v_0,w_0)}w(s) \end{pmatrix} ds. \end{aligned}$$

Again, the nonlinear terms are $O(\varepsilon)$ so these equations can be solved by a contraction mapping argument. Gronwall estimates show that $\|D_{(v_0,w_0)}u(t)\|$ and $\|D_{(v_0,w_0)}(v(t), w(t)) - S(t,0;u_0)\|$ are $O(\varepsilon)$ with constants that depend only on R_i and T. But $\|S(t,0;u_0)\|$ is exponentially decaying by Lemma 4.6, and since T has been chosen so large that $e^{-\beta T/2} = 1/32$, we may further reduce ε_* to obtain (b) and (d). □

LEMMA 5.2. *There is $\varepsilon_* > 0$ so that for each $\varepsilon \in [0, \varepsilon_*]$ and $A \in \mathcal{T}_L$ we have*

$$\sup_{u \in \Pi_1(\mathcal{D})} \|[P_1 + P_2 A(u)]^{-1}\|_{L(\mathbb{X}_1, \mathbb{X}_1)} \leq 1 + O(\varepsilon) \leq 2.$$

Proof. We fix $u \in \Pi_1(\mathcal{D})$ and write

$$\begin{aligned}[P_1 + P_2 A]^{-1} &= [e^{-\varepsilon T \partial_x} - (e^{-\varepsilon T \partial_x} - P_1 - P_2 A)]^{-1} \\ &= e^{\varepsilon T \partial_x} [\mathrm{Id} - e^{\varepsilon T \partial_x} (e^{-\varepsilon T \partial_x} - P_1 - P_2 A)]^{-1}.\end{aligned}$$

This suggests that we write the inverse as a Neumann series. If $A \in \mathcal{T}_L$, then its norm is bounded by L. Thus by Lemma 5.1,

$$\|e^{-\varepsilon T \partial_x} - P_1 + P_2 A(u)\| \leq \|e^{-\varepsilon T \partial_x} - P_1\| + L\|P_2\| \leq C\varepsilon. \tag{5.10}$$

Also note that $e^{\varepsilon T \partial_x}$ is an isometry on $\mathbb{X}_1$. Thus, the Neumann series converges for $[P_1 + P_2 A]^{-1}$ for ε_* sufficiently small, and the norm of the sum does not exceed $1 + O(\varepsilon)$, which for sufficiently small ε is less than 2. □

Let $A \in \mathcal{T}_L$. Then we obtain

$$\|\mathcal{F}(A)\| \leq (\|Q_1\| + L\|Q_2\|)(1 + O(\varepsilon))$$

by the previous lemma. Furthermore, by Lemma 5.1, $\|Q_1\| + \|Q_2\| L \leq L/2$. Thus, for ε_* sufficiently small $\|\mathcal{F}(A)\| \leq L$, and hence $\mathcal{F}$ is well defined. The next proposition shows that for sufficiently small ε_*, it is in fact a contraction.

PROPOSITION 5.1. *There is $\varepsilon_* > 0$ such that for $\varepsilon \in [0, \varepsilon_*]$ the mapping $\mathcal{F} : \mathcal{T}_L \to \mathcal{T}_L$ is a contraction.*

Proof. We let $A, B \in \mathcal{T}_L$, fix $u \in \Pi_1(\mathcal{D})$, and let $u_T = \Pi_1 \circ \varphi_T(u, h(u))$. Then

$$\begin{aligned}&\mathcal{F}(A)(u_T) - \mathcal{F}(B)(u_T) = Q_2(A(u) - B(u))[P_1 + P_2 A(u)]^{-1} \\ &+(Q_1 + Q_2 B(u)) \left([P_1 + P_2 A(u)]^{-1} - [P_1 + P_2 B(u)]^{-1}\right).\end{aligned} \tag{5.11}$$

Applying Lemmas 5.1 and 5.2 to the first term we have

$$\|Q_2(A(u) - B(u))[P_1 + P_2 A(u)]^{-1}\| \leq \frac{2}{8}\|A(u) - B(u)\|. \tag{5.12}$$

We use the identity $(M - A)^{-1} - (M - B)^{-1} = (M - A)^{-1}(A - B)(M - B)^{-1}$ and Lemma 5.2 to estimate the second term in (5.11)

$$\begin{aligned}&(Q_1 + Q_2 B(u)) \left([P_1 + P_2 A(u)]^{-1} - [P_1 + P_2 B(u)]^{-1}\right) \\ &\leq 4(\|Q_1\| + L\|Q_2\|)\|P_2\|\|A(u) - B(u)\| \leq 2L\|P_2\|\|A(u) - B(u)\| \\ &\leq C\varepsilon\|A(u) - B(u)\| \leq \frac{1}{2}\|A(u) - B(u)\|\end{aligned} \tag{5.13}$$

for sufficiently small ε_*. Thus, $\|\mathcal{F}(A)(u_T) - \mathcal{F}(B)(u_T)\| \leq 3/4\|A(u) - B(u)\|$. Since u was arbitrary, this proves the lemma. □

To complete the proof that $\mathcal{M}_\varepsilon$ is C^1, we must show that the unique fixed point of $\mathcal{F}$ is indeed the derivative Dh. This step is essentially the same as Proposition 7 in Fenichel's paper [11], so the proof is omitted.

5.3. C^k smoothness. Higher order smoothness will be proven using the following bootstrapping argument of Fenichel [11]. The unique fixed point $A = \mathcal{F}(A)$ can be realized as the limit of a sequence of iterates $A^n = \mathcal{F}^n A^0$ with $A^0 = 0$. For any $u \in \Pi_1(\mathcal{D})$,

$$A^{n+1}(u_T) = [Q_1 + Q_2 A^n(u)][P_1 + P_2 A^n(u)]^{-1}. \tag{5.14}$$

Since h is C^1, the maps $P_i = P_1(u, h(u))$ and Q_i are differentiable, so A^{n+1} is differentiable if A^n is. Thus, to show that the limit A is differentiable it suffices to show that the sequence $\{DA^n\}$ converges in the space $C(\Pi_1(\mathcal{D}), L^2(\mathbb{X}_1, \mathbb{X}_2))$.

We will show this with estimates similar to those of Proposition 5.1. From the proof of Proposition 5.1 (in particular, (5.12) and (5.13) with $A^{n-1} = A$ and $A^n = B$) we see that the principal term in the contraction estimate at the nth step is

$$\begin{aligned} &\|(P_1 + P_2 A^{n-1})^{-1}\| \left(\|Q_2\| + \|P_2\| \|Q_1 + Q_2 A^n\| \|(P_1 + P_2 A^n)^{-1}\|\right) \\ &\quad \le (1 + C\varepsilon)\left(\frac{1}{8} + C\varepsilon\right) := \alpha_1 \end{aligned} \tag{5.15}$$

by Lemma 5.1 and Lemma 5.2. Higher order derivatives can be obtained in the same way. Differentiating (5.14) we obtain

$$\begin{aligned} DA^{n+1}(u_T) Du_T(u) &= Q_2 DA^n(u)[P_1 + P_2 A^n(u)]^{-1} \\ &-[Q_1 + Q_2 A^n][P_1 + P_2 A^n]^{-1} P_2 DA^n [P_1 + P_2 A^n]^{-1} + \text{lower order terms}, \end{aligned} \tag{5.16}$$

where the lower order terms do not involve derivatives in A. Thus, the principal term in the contraction estimate is now

$$\begin{aligned} &\left(\|Q_2\| + \|P_2\| \|Q_1 + Q_2 A^n\| \|(P_1 + P_2 A^n)^{-1}\|\right) \|(P_1 + P_2 A^{n-1})^{-1}\|^2 \\ &\quad \le (1 + C\varepsilon)^2 \left(\frac{1}{8} + C\varepsilon\right) := \alpha_2. \end{aligned} \tag{5.17}$$

For ε_* sufficiently small, $\alpha_2 < 1$ holds for $0 \le \varepsilon \le \varepsilon_*$. Let $a_n = \sup_u \|DA^{n+1}(u_T) - DA^n(u_T)\|$. It follows from (5.16) and (5.17) that

$$a_{n+1} \le \alpha_2 a_n + r_n,$$

where r_n is a remainder term obtained from the differences in lower order terms. r_n diminishes to zero as n increases since A^n converges. Thus, for any $\eta > 0$ there exists an N such that $r_n \le \eta$ for all $n \ge N$. Hence,

$$a_{N+m} \le \alpha_2^m a_N + \frac{\eta}{1 - \alpha_2},$$

and thus $\limsup_{n\to\infty} a_n \le \eta/(1 - \alpha_2)$. Since η was arbitrary, $a_n \to 0$, and it follows that the sequence $\{DA^n\}$ converges. Thus, $\mathcal{M}_\varepsilon$ is of class C^2.

We now proceed inductively. To show that $\mathcal{M}_\varepsilon$ is C^k assuming that it is C^{k-1}, it is sufficient to show that the sequence $\{D^k A^n\}$ converges. Each term in the sequence is of the form

$$\begin{aligned} D^k A^{n+1}(u_T) Du_T(u) &= Q_2 D^k A^n(u)[P_1 + P_2 A^n(u)]^{-k} \\ &-[Q_1 + Q_2 A^n][P_1 + P_2 A^n]^{-1} P_2 D^k A^n [P_1 + P_2 A^n]^{-k} + \text{terms of order } k-1, \end{aligned}$$

and the principal term in the contraction estimate is bounded by

$$(1+C\varepsilon)^k\left(\frac{1}{8}+C\varepsilon\right):=\alpha_k.$$

For $\varepsilon_*(k)$ sufficiently small, $\alpha_k<1$ for all $\varepsilon\in[0,\varepsilon_*]$ and the sequence $\{D^kA^n\}$ is convergent. Thus, $\mathcal{M}_\varepsilon$ is of class C^k. The manifold is not C^∞ since it is clear that $\varepsilon_*(k)$ must decrease to zero as k increases arbitrarily. This completes the proof of the C^k smoothness and the proof of Theorem 4.4.

6. Geometric singular perturbation theory.

6.1. Notation. In this section we need to distinguish carefully between the flow for different values of ε. To emphasize this, we will use the superscript ε. For example, φ_t^ε denotes the flow with a particular choice of ε, $(u^\varepsilon(t),v^\varepsilon(t),w^\varepsilon(t))$ denotes a trajectory, and $\mathcal{A}_\varepsilon$ denotes the attractor for φ_t^ε. We use the same notation for the modified and unmodified flow, but the flow under consideration will be clear from the context.

6.2. Reduced dynamics and the slaving principle. Theorem 4.4 provides a rigorous decomposition of the flow and a justification of the "slaving principle." First consider the modified flow. Since $\mathcal{M}_\varepsilon$ is invariant, any trajectory on it must satisfy

$$u(t)=e^{-\varepsilon t\partial_x}u(0)+\varepsilon\int_0^t e^{-\varepsilon(t-s)\partial_x}g(u(s),h^\varepsilon(u(s)))ds, \tag{6.1}$$

$$h_v^\varepsilon(u(t))=e^{-(1+i\delta)t}h_v^\varepsilon(u(0))+\mu\int_0^t e^{-(1+i\delta)(t-s)}f(u(s))h_w^\varepsilon(u(s))ds, \tag{6.2}$$

$$\begin{aligned} h_w^\varepsilon(u(t)) &= e^{-\gamma_\| t}h_w^\varepsilon(u(0))+(\lambda+1)(1-e^{-\gamma_\| t})\\ &\quad -\mu\int_0^t e^{-(t-s)\gamma_\|}\,\mathrm{Re}\,(f(u(s))^*h_v^\varepsilon(u(s)))ds. \end{aligned} \tag{6.3}$$

Thus, the slow dynamics decouples from the fast dynamics. This is only half the story: we have established the existence of a reduced equation that is a *functional* differential equation, but we have not prescribed a formula to compute the reduced equation. Theorem 4.4 proves the existence of a family of invariant manifolds $\{\mathcal{M}_\varepsilon\}_{\varepsilon\in[0,\varepsilon_*]}$. In Fenichel's theory [12] these manifolds $\mathcal{M}_\varepsilon$ fit together smoothly in ε and there is a global center manifold given as a function $h(\varepsilon,u)=h^\varepsilon(u)$. Thus we may expand $h^\varepsilon(u)=h(0,u)+D_1h(0,u)\varepsilon+R(u,\varepsilon)$, where $R=o(\varepsilon)$. In infinite dimensions the situation is considerably more delicate. The issue is, of course, the unbounded term $\varepsilon\partial_x$. For flows that are close in the C^1 topology, it usually follows from an implicit function theorem, or the proof of the existence of the invariant manifold, that the unperturbed and perturbed manifolds are close. In the presence of unbounded perturbations the convergence of h^ε to h^0 is expressed in the following theorem.

THEOREM 6.1. $\|h^\varepsilon(u)-h^0(u)\|\to 0$ *uniformly on compact sets.*

Proof. The only information we have is that $\mathcal{M}_\varepsilon$ is invariant under the flow φ_t^ε. Thus the proof will rely on the closeness of φ_t^ε to φ_t^0. We fix $u\in\Pi_1(\mathcal{D}_0)$ and let $u(0)=u$. We will estimate the difference $h^\varepsilon(u)-h^0(u)$ by using the integral equations (6.1)–(6.3). When $\varepsilon=0$, (6.1)–(6.3) reduce to the algebraic equations $u(t)\equiv u$ and

$$\begin{pmatrix} 1 & \delta & -\mu\mathrm{Re}f(u)\\ -\delta & 1 & -\mu\mathrm{Im}f(u)\\ \mu\mathrm{Re}f(u) & \mu\mathrm{Im}f(u) & \gamma_\| \end{pmatrix}\begin{pmatrix}\mathrm{Re}\,h_v^0(u)\\ \mathrm{Im}\,h_v^0(u)\\ h_w^0(u)\end{pmatrix}=\begin{pmatrix}0\\0\\ \gamma_\|(\lambda+1)\end{pmatrix}, \tag{6.4}$$

or, more briefly,

$$B(u)h^0(u) = (0, 0, \gamma_{\|}(\lambda + 1))^T, \tag{6.5}$$

where $B(u)$ is the multiplication operator in (6.4). This is the expression that was computed in (3.1). For every $x \in S^1$, the matrix $B(u(x))$ is invertible since

$$\det(B(u(x))) = \gamma_{\|}(1 + \delta^2) + \mu^2 |f(u)(x)|^2 \geq \gamma_{\|}(1 + \delta^2) \tag{6.6}$$

is uniformly bounded away from zero. Thus, $B(u)$ is invertible and its inverse, $B(u)^{-1}$, is the multiplication operator in $L(\mathbb{X}_2, \mathbb{X}_2)$ defined for every $x \in S^1$ by the matrix $B(u(x))^{-1}$. From the algebraic formula for the inverse of a matrix, and the estimate (6.6), we see that

$$\sup_{u \in \Pi_1(\mathcal{D})} \|B(u)^{-1}\| \leq C_B(R_1). \tag{6.7}$$

Define the function $\Psi : \mathbb{X} \to \mathbb{X}_2$ by

$$\Psi(u, v, w) = B(u) \begin{pmatrix} v \\ w \end{pmatrix} - \begin{pmatrix} 0 \\ \gamma_{\|}(\lambda + 1) \end{pmatrix}. \tag{6.8}$$

Notice that $\Psi(u, v, w) = 0$ if and only if $(v, w) = h^0(u)$. Let K be a compact subset of $\Pi_1(\mathcal{D})$. We will show that $\lim_{\varepsilon \downarrow 0} \sup_{u \in K} \|\Psi(u, h^\varepsilon(u))\| = 0$. This implies the theorem since

$$h^\varepsilon(u) - h^0(u) = B(u)^{-1}B(u)h^\varepsilon(u) - B(u)^{-1}(0, \gamma_{\|}(\lambda+1))^T = B(u)^{-1}\Psi(u, h^\varepsilon(u)), \tag{6.9}$$

and hence from (6.7) we obtain

$$\sup_{u \in K} \|h^\varepsilon(u) - h^0(u)\| \leq C_B \sup_{u \in K} \|\Psi(u, h^\varepsilon(u))\|.$$

We will consider the components of Ψ separately. The first two components of Ψ are $(1 + i\delta)h_v^\varepsilon(u) - \mu f(u) h_w^\varepsilon(u)$ (taking the real and imaginary components together). We estimate this term using (6.2). We start with the initial condition $(u, v, w)(0) = (u, h^\varepsilon(u))$ and then calculate that for any $t > 0$,

$$\begin{aligned}(1 - e^{-(1+i\delta)t}) \left[-(1 + i\delta)h_v^\varepsilon(u) + \mu f(u) h_w^\varepsilon(u)\right] &= (1 + i\delta)\Bigg[h_v^\varepsilon(u^\varepsilon(t)) - h_v^\varepsilon(u) \\ -\mu \int_0^t e^{-(1+i\delta)(t-s)} \left(f(u^\varepsilon(s))h_w^\varepsilon(u^\varepsilon(s)) - f(u)h_w^\varepsilon(u)\right) ds\Bigg]\end{aligned} \tag{6.10}$$

(since u is a constant, we can take $\mu f(u) h_w^\varepsilon(u)$ under the integral sign). Notice that

$$\begin{aligned}\mathrm{Lip}(f h_w^\varepsilon) &\leq \left(\sup_u \|f(u)\|\right) \mathrm{Lip}(h_w^\varepsilon) + \left(\sup_u \|h_w^\varepsilon(u)\|\right) \mathrm{Lip}(f) \\ &\leq 2R_1 L + 2R_2 \cdot 5 := C_{10}\end{aligned}$$

by Lemma 4.1 and the definition of $\mathcal{S}_L$. Thus, we obtain from (6.10) that

$$\begin{aligned}&\|(1 + i\delta)h_v^\varepsilon(u) - \mu f(u)h_w^\varepsilon(u)\| \\ &\leq \frac{|1 + i\delta|}{|1 - e^{-(1+i\delta)t}|}\left[L\|u^\varepsilon(t) - u\| + \mu \int_0^t C_{10} e^{-(t-s)} \|u^\varepsilon(s) - u\| ds\right] \\ &\leq C_{11}\left[\frac{\|u^\varepsilon(t) - u\|}{|1 - e^{-(1+i\delta)t}|} + \frac{1 - e^{-t}}{|1 - e^{-(1+i\delta)t}|} \sup_{s \in [0,t]} \|u^\varepsilon(s) - u\|\right].\end{aligned}$$

Notice that $(1-e^{-t})/|1-e^{-(1+i\delta)t}|$ is uniformly bounded for all $t>0$. And for t in any fixed domain $(0,T]$ we have $1/|1-e^{-(1+i\delta)t}| \leq C(T)/t$. Thus we find that

$$(6.11)\quad \|(1+i\delta)h_v^\varepsilon(u)-\mu f(u)h_w^\varepsilon(u)\| \leq C\left[\frac{\|u^\varepsilon(t)-u\|}{t}+\sup_{s\in[0,t]}\|u^\varepsilon(s)-u\|\right].$$

A similar calculation shows that we obtain the same result for the second component of Ψ. Thus, we find

$$(6.12)\qquad \|\Psi(u,h^\varepsilon(u))\| \leq C\left[\frac{\|u^\varepsilon(t)-u\|}{t}+\sup_{s\in[0,t]}\|u^\varepsilon(s)-u\|\right].$$

Finally, we use (6.1) to estimate the difference $u^\varepsilon(t)-u$. The difference consists of two parts, the deviation from the linear part of the flow $e^{-\varepsilon t\partial_x}u$ and the deviation of the linear flow from the nonlinear flow. Precisely,

$$\|u^\varepsilon(t)-u\| \leq \|u^\varepsilon(t)-e^{-\varepsilon t\partial_x}u\|+\|e^{-\varepsilon t\partial_x}u-u\| \leq C\varepsilon t+\|e^{-\varepsilon t\partial_x}u-u\|.$$

Inserting this estimate in (6.12) we have

$$(6.13)\quad \|\Psi(u,h^\varepsilon(u))\| \leq C\left[\frac{\|e^{-\varepsilon t\partial_x}u-u\|}{t}+\sup_{s\in[0,t]}\|e^{-\varepsilon t\partial_x}u-u\|+\varepsilon(1+t)\right].$$

For fixed t and u, the right-hand side of (6.13) goes to zero as $\varepsilon\downarrow 0$. Next suppose that we fix t but consider u ranging over a compact subset K. Since functions in K are equicontinuous, $\sup_{u\in K}\|e^{-\varepsilon t\partial_x}u-u\| \to 0$ as $\varepsilon\downarrow 0$. □

The estimate (6.13) highlights why the convergence of h^ε to h^0 is not any better than uniform convergence on compact subsets. Since t is a free parameter, the estimate is best when we take the infimum with respect to t. Since the flow is continuous in t we must have $\sup_{s\in[0,t]}\|u^\varepsilon(s)-u\| \to 0$ as $t\to 0$. But the first term in (6.12) may not have a limit. The reason is that $\lim_{t\downarrow 0}\|e^{-\varepsilon t\partial_x}u-u\|/t$ does not exist for most functions (in the sense of category). If u is C^1, then we find that

$$\|\Psi(u,h^\varepsilon(u))\| \leq C\left(\|Du\|_\infty\varepsilon+\sup_{s\in[0,t]}\|Du\|_\infty\varepsilon t+\varepsilon(1+t)\right),$$

and since t is a free parameter, we take the infimum over t to find

$$(6.14)\qquad \|\Psi(u,h^\varepsilon(u)) \leq C(\|Du\|_\infty+1)\varepsilon.$$

Another example of more rapid convergence is provided by taking K to be a bounded subset of $C^{0,\alpha}(S^1;\mathbf{C})$, the space of Hölder continuous functions with modulus $\alpha\in(0,1]$. In this case we find that

$$\sup_{u\in K}\|e^{-\varepsilon t\partial_x}u-u\| \leq H\varepsilon^\alpha t^{\alpha-1},$$

where H is the maximum Hölder seminorm of the functions in K. Then we take the infimum in t on both sides of (6.13) to find that

$$\sup_{u\in K}\|h^\varepsilon(u)-h^0(u)\| \leq C\varepsilon^\alpha.$$

6.3. Formal asymptotic expansions. Equations (6.1)–(6.3) are also the starting point for a formal asymptotic expansion. Theorem 6.1 shows that we can control the remainder only if $u(s)$ has some smoothness in x. However, a *formal* asymptotic expansion may be obtained by using the invariance of $\mathcal{M}_\varepsilon$. Make the ansatz

$$h^\varepsilon(u) = h^0(u) + \varepsilon h_1(u) + \varepsilon^2 h_2(u) + \cdots. \tag{6.15}$$

Substituting this ansatz in (6.1)–(6.3) and matching the powers of ε we obtain after some calculations that

$$h_n(u) = c_n(u)\partial_x^n u + d_n(u, \partial_x u, \ldots, \partial_x^{n-1}u), \quad n \geq 1, \tag{6.16}$$

where $c_n(u)(x)$ depends only on $u(x)$. This expansion suggests that $h^\varepsilon(u)(x)$ actually depends on the germ of u at x. Thus, we expect $h^\varepsilon(u)$ to have a nonlocal dependence on u. The expansion also suggests that the reduced equation (6.17) is not hyperbolic because $h_n(u)$ includes higher order diffusive and dispersive terms. In fact, the reduced equation cannot be hyperbolic for if it were, there would be no asymptotic smoothing on the attractor. Similar questions arise in hyperbolic conservation laws with relaxation. We refer especially to the article by Chen, Levermore, and Liu, section 2 of which contains the same geometric description of formal reductions in the context of conservation laws [5].

6.4. Regular dynamics. We can now revert to a description of the unmodified Maxwell–Bloch equations in the slow (and natural) time scale. Changing the time scale to $\tau = \varepsilon t$ we have for all $u(0) \in \Pi_1(\mathcal{D}_0)$ and $\tau \geq 0$,

$$u(\tau) = e^{-\kappa\tau}e^{-\tau\partial_x}u(0) + \frac{\kappa}{\mu}\int_0^\tau e^{-\kappa(\tau-s)}e^{-(\tau-s)\partial_x}h_v^\varepsilon(u(s))ds. \tag{6.17}$$

We have used the positive invariance of $\Pi_1(\mathcal{D}_0)$ and the fact that $g(u,v,w)$ reduces to v within the domain $\mathcal{D}_0$. To make the comparison with the formal reduction precise, we shall write (6.17) as

$$\begin{aligned} u(\tau) = e^{-\kappa\tau}e^{-\tau\partial_x}u(0) &+ \frac{\kappa}{\mu}\int_0^\tau e^{-\kappa(\tau-s)}e^{-(\tau-s)\partial_x}h_v^0(u(s))ds \\ &+ \frac{\kappa}{\mu}\int_0^\tau e^{-\kappa(\tau-s)}e^{-(\tau-s)\partial_x}(h_v^\varepsilon(u(s)) - h_v^0(u(s)))ds. \end{aligned} \tag{6.18}$$

The attractor $\mathcal{A}_\varepsilon$ is an invariant set contained in $\mathcal{M}_\varepsilon$. On the attractor, the reduction is valid uniformly in time. Applying (6.14) to $u \in \Pi_1(\mathcal{A}_\varepsilon)$ we have

$$\begin{aligned} &\left\| u(\tau) - e^{-\kappa\tau}e^{-\tau\partial_x}u(0) - \frac{\kappa}{\mu}\int_0^\tau e^{-\kappa(\tau-s)}e^{-(\tau-s)\partial_x}h_v^0(u(s))\right\| \\ &\leq \frac{\kappa}{\mu}\int_0^\tau e^{-\kappa(\tau-s)}\|h^\varepsilon(u(s)) - h^0(u(s))\|ds \leq C\varepsilon\left(\sup_{u\in\mathcal{A}_\varepsilon}\|Du\|_\infty + 1\right) \end{aligned}$$

for all τ. Unfortunately, this isn't enough as the estimates of section 4 in [9] show that $\sup_{u\in\mathcal{A}_\varepsilon}\|Du\|_\infty = O(1/\varepsilon)$. Furthermore, based on numerical evidence we expect that this estimate is sharp. In several parameter regimes the Lorenz ODEs have periodic solutions with arbitrarily large period. These solutions in turn imply the existence of traveling wave solutions to the Maxwell–Bloch equations with gradients of $O(1/\varepsilon)$. In fact, estimating $\sup_{u\in\mathcal{A}_\varepsilon}\|\partial_x^n u\|_\infty$ we find that the series (6.16) diverges even on the attractor.

6.5. Change of stability under perturbation. The guiding philosophy of geometric singular perturbation for ODEs is that normally hyperbolic manifolds within the formally reduced flow persist for the perturbed flow, provided the critical manifold is normally hyperbolic. As an example of this, Fenichel proved a theorem of Anosov on the persistence of periodic orbits for a singularly perturbed ODE [12]. A simpler example is to consider hyperbolic fixed points. Let the reduced flow have an exponentially attracting fixed point, and let the critical manifold be exponentially attracting. Then Theorem 12.1 in [12] shows that the fixed point persists for $\varepsilon > 0$ and remains attracting.

Even this simple assertion is false for PDE; i.e., the unbounded perturbation may change the stability type of a fixed point within the persisting slow manifold. For simplicity suppose $\delta = 0$ and consider only real (u, v, w). In this case the reduced equation is a gradient dynamical system with a double well potential, and $u = 1$ is a spatially homogenous equilibrium of the reduced equation. It is attracting since it lies at the minimum of the well. A calculation reveals that the point $(u, v, w) = (1, h^0(1)) = (1, \mu, 1)$ is an equilibrium of the full equations for all $\varepsilon > 0$. Nevertheless, it need not retain the stability type of the $\varepsilon = 0$ limit. Risken and Nummedal [25] showed that the fixed point is unstable for large λ for all positive ε and the number of linearly unstable modes diverges like $1/\varepsilon$. Thus the divergence between the formal limit and the full system is dramatic for small ε.

6.6. Conclusions. We have developed a geometric method of studying the singularly perturbed Maxwell–Bloch equations. The main merit of this method is that it rigorously separates the dynamics of this problem into slow and fast evolution. The geometric principles underlying the method are simple and thus it should be of use in other problems. However, the Maxwell–Bloch equations have several simplifying features and there are often many technical difficulties inherent in a rigorous analysis of PDEs with multiple scales. Thus transporting these ideas to other PDEs will be a difficult (but rewarding) task. Moreover, we have shown that global invariant manifolds with infinite dimension and codimension arise naturally in evolution equations with two scales. One may rigorously find reduced equations for such systems, but these are functional differential equations, and naive approximations to these equations seem to fail. There are several subtle features in geometric singular perturbation theory in infinite dimensions, and the Maxwell–Bloch equations illustrate some of these in a setting with few technicalities.

There have been several recent developments in geometric singular perturbation theory for PDE. We mention the work by Li et al. [21], Haller [17], and Zeng [29] on the damped and driven nonlinear Schrödinger equation. The motivation and methods are different there: in that case the $\varepsilon = 0$ limit is integrable, and a lot of effort is expended in solving problems associated with nonhyperbolicity and weak hyperbolicity. We also mention that Hale, Raugel, Sell, and coworkers have studied PDE in thin domains (see the references in [24]).

Acknowledgments. We thank Professors N. Ercolani, J. Moloney, and G. Kovacic for initiating and encouraging our interest in the Maxwell–Bloch equations. It is also a pleasure to thank Dr. Chongchun Zeng for his assistance. We thank Professor J. Mallet-Paret for pointing out the connection with PDE in thin domains, and Professor E. Titi for bringing to our attention the work by M. Marion. The authors are indebted to the anonymous referees for spotting errors and suggesting several improvements in the manuscript.

RIDGELETS AND THE REPRESENTATION OF MUTILATED SOBOLEV FUNCTIONS*

EMMANUEL J. CANDES†

Abstract. We show that ridgelets, a system introduced in [E. J. Candes, *Appl. Comput. Harmon. Anal.*, 6 (1999), pp. 197–218], are optimal to represent smooth multivariate functions that may exhibit linear singularities. For instance, let $\{u \cdot x - b > 0\}$ be an arbitrary hyperplane and consider the singular function $f(x) = 1_{\{u \cdot x - b > 0\}} g(x)$, where g is compactly supported with finite Sobolev L_2 norm $\|g\|_{H^s}$, $s > 0$. The ridgelet coefficient sequence of such an object is as sparse as if f were without singularity, allowing optimal partial reconstructions. For instance, the n-term approximation obtained by keeping the terms corresponding to the n largest coefficients in the ridgelet series achieves a rate of approximation of order $n^{-s/d}$; the presence of the singularity does not spoil the quality of the ridgelet approximation. This is unlike all systems currently in use, especially Fourier or wavelet representations.

Key words. Sobolev spaces, Fourier transform, singularities, ridgelets, orthonormal ridgelets, nonlinear approximation, sparsity

1. Introduction.

1.1. Ideal representations of Sobolev classes.

It is well known that trigonometric series and wavelets are well adapted to represent functions taken from L_2 Sobolev classes [1]. For a nonnegative integer s, the L_2 Sobolev norm is

$$\|f\|_{H^s}^2 = \|f\|_2^2 + \|f^{(s)}\|_2^2,$$

where $f^{(s)}$ is the sth derivative of f; and, more generally, the norm of f is defined by means of the Fourier transform; let $\mathcal{F}$ be the classical Fourier transform,

$$(\mathcal{F}f)(\xi) = \hat{f}(\xi) = \int f(x) e^{-ix\cdot\xi}\, dx; \tag{1.1}$$

then,

$$\|f\|_{H^s}^2 = \int |\hat{f}(\xi)|^2 (1 + |\xi|^{2s})\, d\xi$$

when $s > 0$ is not necessarily an integer. (Of course, when s is an integer, the two definitions are equivalent thanks to the Plancherel formula; see [13], for example.)

Both wavelet and Fourier bases provide unconditional bases for these Sobolev spaces H^s defined, say, on the torus. Abstractly, a basis $(\phi_i)_{i\in\mathcal{I}}$ is an unconditional

basis for a functional class $\mathcal{F}$ if shrinking the coefficients preserves the norm of the object: i.e., if we let

$$\theta_i(f) = \langle f, \phi_i \rangle$$

and consider

$$\tilde{f} = \sum_i \theta_i' \phi_i, \quad |\theta_i'| \le |\theta_i|,$$

then

$$\|\tilde{f}\|_{\mathcal{F}} \le C\, \|f\|_{\mathcal{F}}.$$

We quote Donoho [8]: "An orthogonal basis of L_2 which is also an unconditional basis of a functional space $\mathcal{F}$ is an optimal basis for compressing, estimating, and recovering functions in $\mathcal{F}$."

For instance, suppose that f is a function defined on the circle $\mathbf{T}$ with bounded Sobolev norm and let f_n be the n-term trigonometric nonlinear approximation of f obtained by keeping the terms corresponding to the n largest coefficients in the expansion. Then,

$$\|f - f_n\|_2 \le C\, n^{-s} \|f\|_{H^s(T)}.$$

The same is true for nice periodic wavelets and essentially no orthogonal basis would give a better rate of approximation: that is, for any orthobasis $(\phi_i)_{i \in \mathcal{I}}$, let $Q_n(f)$ be the best n-term approximation in that basis

$$Q_n(f) = \arg\min \|f - g\|_2, \quad g = \sum_{m=1}^{n} \lambda_m \phi_{i_m};$$

then, letting $\mathcal{F}$ be the Sobolev ball $\mathcal{F} = \{f,\ \|f\|_{H^s(T)} \le 1\}$, there is a lower bound on the error of approximation

$$\sup_{f \in \mathcal{F}} \|f - Q_n(f)\|_2 \ge C\, n^{-s}.$$

Another instance of this property is that in any orthobasis $(\phi_i)_{i \in \mathcal{I}}$ the number of terms greater than $1/n$ is greater than $c \cdot n^{2/(2s+1)}$. In both Fourier and wavelet bases, $n^{2/(2s+1)}$ is the order of the number of coefficients that exceed $1/n$, and in this sense we may say that these bases are the most "economical" for representing elements from $H^s(T)$.

1.2. Singularities: The one-dimensional case. However, these nice properties are very fragile. For instance, it is well known that trigonometric series provide poor reconstructions of discontinuous functions. On the interval $[0, 1]$, let f be the periodic function defined by $f(t) = t - H(t - t_0)$, where $H(t)$ is the step function $1_{\{t>0\}}$. The best L_2 n-term approximation of f by trigonometric series gives only an L_2 error of order $O(n^{-1/2})$. This is a general fact: if g is a nice function taken from the Sobolev class H^s (with support contained in (0,1)), then the rate of approximation of $H(t - b)g(t)$ is no better than $O(n^{-1/2})$. The discontinuity spoils the representation, and we need a lot of different terms to reconstruct the discontinuity with good accuracy. (This phenomenon is well known from engineers and is often referred to as the Gibbs phenomenon or ringing effect.)

One of the reasons why wavelets are so attractive is that they are the best bases for representing objects composed with singularities (see the discussion of Mallat's heuristics in [8]). As an example, our simple discontinuous object $H(\cdot - b)g(\cdot)$ has a rate of approximation in a nice wavelet basis of order $O(n^{-s})$. Whereas the singularity had a dramatic effect on the sparsity of Fourier coefficients, it does not affect the sparsity of wavelet coefficients as the number of wavelet coefficients exceeding $1/n$ is still of order $n^{2/(2s+1)}$. The singularity does not spoil the wavelet representation. This miracle may explain the spread of wavelet methods in data compression, statistical estimation, inverse problems, etc., as in practical applications the signals that are to be recovered exhibit these kinds of discontinuities (see the survey paper [11]).

1.3. Singularities: The higher-dimensional case. Under a certain viewpoint, however, the picture changes dramatically when the dimension is greater than one. On $[0,1]^d$, suppose now that we want to represent the simple object

$$f(x) = H(u \cdot x - t_0)g(x), \quad g \in H^s \text{ and supp } g \subset [0,1]^d. \tag{1.2}$$

The object f is singular on the hyperplane $u \cdot x = t_0$ (u is a unit vector) but may be very smooth elsewhere. Then, the number of wavelet coefficients exceeding $1/n$ is greater than $n^{2(1-1/d)}$, yielding L_2 rates of approximation only of order $O(n^{-\frac{1}{2(d-1)}})$. This lower bound holds even when g is as nice as we want, i.e., $g \in C^\infty$. Translated into the framework of image compression, it says that both wavelet bases and Fourier bases are severely inefficient at representing edges in images. Wavelets can deal with point-like phenomena, but they cannot deal with line-like phenomena in dimension 2, plane-like phenomena in dimension 3, etc.

In harmonic analysis, there has recently been much interest in finding new dictionaries and ways of representing functions by linear combinations of elements of those. Examples include wavelets, wavelet-packets, Gabor functions, brushlets, etc. The purpose of this paper is to show that ridgelets, a system introduced by [4], are as efficient for representing objects with discontinuities like (1.2) as wavelets are for representing discontinuous functions in one dimension.

1.4. Achievements and overview. The ridgelet construction will briefly be reviewed in section 2. In a nutshell, a ridgelet is a ridge function of the form

$$\psi_{a,u,b}(x) = \frac{1}{a^{1/2}}\psi\left(\frac{u \cdot x - b}{a}\right), \quad a > 0, u \in S^{d-1}, b \in \mathbb{R}, \tag{1.3}$$

where ψ is univariate and oscillatory. The fundamental result is that there is a discrete family (ψ_{a_n,u_n,b_n}) which is a frame for L_2 spaces of compactly supported functions. (We will simply refer to this family as ψ_n.) The frame property says that for any element $f \in L_2[0,1]^d$ there exist two constants $A, B > 0$ with the property

$$A\,\|f\|^2 \le \sum_n |\langle f, \psi_n\rangle|^2 \le B\,\|f\|^2.$$

A consequence of the previous display is the existence of a dual set of ridgelets $(\widetilde{\psi_n})$ (the dual frame) and of the decomposition

$$f = \sum_n \langle f, \widetilde{\psi_n}\rangle \psi_n = \sum_n \langle f, \psi_n\rangle, \widetilde{\psi_n} \tag{1.4}$$

with equality holding in an L_2 sense.

To measure the sparsity of an arbitrary sequence (θ_n), we will use the weak-ℓ_p or Marcinkiewicz quasi norm, defined as follows: let $|\theta|_{(n)}$ be the nth largest entry in the sequence $(|\theta_n|)$; we set

$$|\theta|_{w\ell_p} = \sup_{n>0} n^{1/p} |\theta|_{(n)}. \tag{1.5}$$

Equipped with a nice ridgelet frame, the key result of our paper (section 4) is the following: let us consider a template f such as in (1.2) and let α ($\alpha_n = \langle f, \psi_n \rangle$) denote the ridgelet coefficient sequence of f. Then, the sequence α is sparse as if f were not singular in the sense that

$$\|\alpha\|_{w\ell_p} \le C \, \|g\|_{H^s} \quad \text{with } 1/p = s/d + 1/2, \tag{1.6}$$

where the constant C does not depend on f; or equivalently, the number of ridgelet coefficients exceeding $1/n$ is bounded by $C\, n^p \, \|g\|_{H^s}$. (Throughout the paper, the letter C will denote a positive constant whose value may differ at different occurrences, even within a single formula.) There might be some ambiguity about the notation $\|g\|_{H^s}$ since g is not uniquely determined by f. In this paper, we will implicitly take the norm $\|g\|_{H^s}$ as being the minimum norm of all those elements in H^s whose restriction to $\{u \cdot x > t_0\}$ coincide with f; i.e.,

$$\|g\|_{H^s} := \inf\{\|h\|_{H^s}, \, f(x) = H(u \cdot x - t_0) h(x), \, \operatorname{supp} h \subset [0,1]^d\}.$$

There is a direct consequence of this result. Consider the n-term f_n ridgelet approximation obtained by extracting from the exact series (1.4) the terms corresponding to the n largest coefficients. Then,

$$\|f - f_n\| \le C \, n^{-s/d} \, \|g\|_{H^s}, \tag{1.7}$$

where, again, the constant C is independent of f. *The presence of the singularity does not ruin the sparsity of the ridgelet series.* This is unlike wavelet or Fourier analysis. Hence, we have a very concrete, constructive, and stable procedure—namely, the thresholding of ridgelet coefficients—to obtain near-optimal nonlinear approximations. The author is not aware of any other system with similar features.

In dimension 2, Donoho introduced an orthonormal basis, closely related to the ridgelet system, that he calls "orthonormal ridgelets." Section 5 will show that both results (1.6) and (1.7) continue to hold with orthonormal ridgelets in place of "pure" ridgelets.

1.5. Methodology. The method that is used to prove (1.6) and (1.7) involves the study of the Fourier transform along rays going through the origin (section 3). Before we proceed further, (r, θ) will index the standard polar coordinates system and throughout the paper we will abuse notation in writing $f(r, \theta)$ instead of $(f \circ \mathcal{C})(r, \theta)$, where $\mathcal{C}$ is the change of coordinates from polar to cartesian. In two dimensions, let us now consider the singular function f defined by

$$f(x_1, x_2) = 1_{\{x_1 > 0\}} \, g(x_1, x_2)$$

with g in H^s, $s \in \mathbb{N}$, and supp $g \subset [0,1]^d$. The argument relies on a bound that is available on the integral over the "polar" segment $\{(r, \theta), \, 2^j \le r \le 2^{j+1}\}$ of the squared modulus of the Fourier transform. Indeed, there exists a constant C not depending on f such that

$$\int_{2^j \le r \le 2^{j+1}} |\hat{f}(r,\theta)|^2 \, dr \\ \le C\, \epsilon_j^2(\theta) 2^{-j} 2^{-2js} \|g\|_{H^s}^2 + C\, 2^{-j} \min(1, 2^{-2js} |\sin\theta|^{-2s}) \|g\|_{H^s}^2 \tag{1.8}$$

with $\sum_j \int_0^{2\pi} \epsilon_j^2(\theta)\, d\theta \le 1$. A d-dimensional version of (1.8) will be given in section 3.

The singularity $1_{\{x_1 > 0\}}$ causes the Fourier transform to decay very slowly in the critical directions $\theta = 0, \pi$. (This set of directions is sometimes referred to as the wavefront.) Indeed, for $\theta = 0$, say, $|\hat{f}(r,\theta)| \sim r^{-1}$ and, therefore, for this critical value of θ, $\int_{2^j \le r \le 2^{j+1}} |\hat{f}(r,\theta)|^2 \, dr \sim 2^{-j}$, which is the content of (1.8). However, this effect is really local and our estimate (1.8) pictures the decay of the Fourier transform as θ moves away from the singular rays. The result is nonasymptotic since it describes the situation at a finite distance 2^j ($j \ge 0$) from the origin. For instance, in dimension 2 the order of magnitude of the modulus of the Fourier transform at a point with polar coordinates $(2^j, \theta)$ is $2^{-j(s+1)} |\sin\theta|^{-s}$. It is interesting to observe that the smoothness of the object governs the size of the Fourier transform as θ approaches $0, \pi$. Although this phenomenon may not have been extensively studied in the literature, it perhaps corresponds to some new kind of microlocal analysis and we believe that this is of independent interest.

The localization of the Fourier transform near the wavefront is the key property driving our main results (1.6) and (1.7). Extensions and limitations of these results will be discussed in section 6.

2. Ridgelets. In this section, $\hat{g}$ will denote the Fourier transform of g. In d dimensions, the ridgelet construction starts with a univariate function ψ satisfying an oscillatory condition, namely,

$$\int |\hat{\psi}(\xi)|^2 / |\xi|^d \, d\xi < \infty. \tag{2.1}$$

A ridgelet is a function of the form

$$\frac{1}{a^{1/2}} \psi\left(\frac{u \cdot x - b}{a}\right), \tag{2.2}$$

where a and b are scalar parameters and u is a vector of unit length. In what follows, we will suppose that ψ is normalized so that $\int |\hat{\psi}(\xi)|^2 |\xi|^{-d} d\xi = 1$. Of course, a ridgelet is a ridge function whose profile displays an oscillatory behavior (like a wavelet). A ridgelet has a scale a, an orientation u, and a location parameter b. Ridgelets are concentrated around hyperplanes: roughly speaking, the ridgelet (2.2) is supported near the strip $\{x, |u \cdot x - b| \le a\}$.

Remarkably, one can represent any function as a superposition of these ridgelets. Define the ridgelet coefficients

$$\mathcal{R}_f(a,u,b) = \int f(x)\, a^{-1/2} \psi\left(\frac{u \cdot x - b}{a}\right) dx; \tag{2.3}$$

then, for any $f \in L_1 \cap L_2(\mathbb{R}^d)$, we have

$$f(x) = (2\pi)^{-(d-1)} \int \mathcal{R}_f(a,u,b) a^{-1/2} \psi\left(\frac{u \cdot x - b}{a}\right) d\mu(a,u,b), \tag{2.4}$$

where $d\mu(a,u,b) = da/a^{d+1}\,du\,db$ (du being the uniform measure on the sphere). Furthermore, this formula is stable as one has a Parseval relation

$$\|f\|_2^2 = (2\pi)^{-(d-1)} \int |\mathcal{R}_f(a,u,b)|^2 d\mu(a,u,b). \tag{2.5}$$

Similar to the continuous transform, there is a discrete transform. Consider the following discrete collection of ridgelets:

$$\{\psi_{j,\ell,k}(x) = 2^{j/2}\psi(2^j u_{j,\ell}\cdot x - kb_0),\ j \geq j_0, u_{j,\ell} \in \Sigma_j, k \in \mathbb{Z}\}. \tag{2.6}$$

The scale a and location parameter b are discretized dyadically, as in the theory of wavelets. However, unlike wavelets, ridgelets are directional and here the interesting aspect is the discretization of the directional variable u. This variable is sampled at increasing resolution, so that at scale j the discretized set Σ_j is a net of nearly equispaced points at a distance of order 2^{-j}. A detailed exposition on the ridgelet construction is given in [4]. In two dimensions, for instance, a ridgelet is of the form

$$\{\, 2^{j/2}\psi(2^j(x_1\cos\theta_{j,\ell} + x_2\sin\theta_{j,\ell} - 2\pi k 2^{-j}))\,\}_{(j\geq j_0,\ell,k)},$$

where the directional parameter $\theta_{j,\ell}$ is sampled with increasing angular resolution at increasingly fine scales, something like the following:

$$\theta_{j,\ell} = 2\pi\ell 2^{-j}.$$

The key result [4] is that the discrete collection $(\psi_{j,\ell,k})$ is a frame for square integrable functions supported on the unit cube. There exist two constants A and B such that for any $f \in L_2([0,1]^d)$, we have

$$A\,\|f\|_{L_2}^2 \leq \sum_{j,\ell,k} |\langle f, \psi_{j,\ell,k}\rangle|^2 \leq B\,\|f\|_{L_2}^2. \tag{2.7}$$

The previous equation says that the datum of the ridgelet transform at the points $(a,u,b) = (2^j, u_{j,\ell}, k2^{-j})$—with the parameter range as in (2.6)—suffices to reconstruct the function perfectly. In this sense, this is analogous to the Shannon sampling theorem for the reconstruction of bandlimited functions. Indeed, standard arguments show that there exists a dual collection $(\tilde{\psi}_{j,\ell,k})$ with the property

$$f = \sum_{j,\ell,k} \langle f, \tilde{\psi}_{j,\ell,k}\rangle \psi_{j,\ell,k} = \sum_{j,\ell,k} \langle f, \psi_{j,\ell,k}\rangle \tilde{\psi}_{j,\ell,k}, \tag{2.8}$$

where the notation $\langle\cdot,\cdot\rangle$ stands here and throughout the remainder of this paper for the usual inner product of L_2: $\langle f, g\rangle = \int f(x)g(x)dx$.

At times, we will use the compact notation ψ_ν ($\nu \in \mathcal{N}$) for our ridgelet frames and, therefore, we will keep in mind that the index runs ν through an enumeration of the triples (j,ℓ,k).

3. Localization of the Fourier transform. The purpose of this section is to quantify the size of the Fourier transform of an object f, where f is given by

$$f(x) = H(x_1)\,g(x),$$

where g is compactly supported and with finite Sobolev norm (recall $H(t) = 1_{\{t>0\}}$).

To formulate our statement in d dimensions, we introduce the spherical coordinates defined by $x_1 = r\cos\theta_1$, $x_2 = r\sin\theta_1\cos\theta_2$, $\dots$, $x_d = r\sin\theta_1\sin\theta_2\dots\sin\theta_{d-1}$, $0 \le \theta_1,\dots,\theta_{d-2} \le \pi$, $0 \le \theta_{d-1} < 2\pi$. In what follows, we will simply refer to $(\theta_2,\dots,\theta_{d-1})$ as φ, and $d\varphi$ will denote the element of the surface area on S^{d-2}, i.e., $d\varphi = \sin\theta_2^{d-3}\dots\sin\theta_{d-2}d\theta_2\dots d\theta_{d-1}$. With these notations, the uniform measure du on the sphere may thus be rewritten as $du = (\sin\theta_1)^{d-2}\,d\theta_1 d\varphi$. From now on, we will often refer to a unit vector u by means of its polar coordinates (θ,φ), $\theta\in[0,\pi]$, $\varphi\in S^{d-2}$.

We now state our d-dimensional localization result about the modulus of the Fourier transform.

Theorem 3.1. *Let f be given by $f(x) = H(x_1)\,g(x)$ with g in H^s, $s = 0,1,2,\dots$, and* supp $g \subset [-1,1]^d$, *and put $\sigma = s + (d-2)/2$. Then, there exists a universal constant C such that for any $j \ge 0$,*

$$\text{(3.1)}\quad \int_{2^j\le r\le 2^{j+1}}\int |\hat f(r,\theta,\varphi)|^2\,dr d\varphi \\ \le C\,\epsilon_j^2(\theta)2^{-j}2^{-2j\sigma}\|g\|_{H^s}^2 + C\,2^{-j}\min(1,2^{-2j\sigma}|\sin\theta|^{-2\sigma})\|g\|_{H^s}^2,$$

where $\sum_j |S^{d-2}|\int\epsilon_j^2(\theta)(\sin\theta)^{d-2}d\theta \le 1$.

As we emphasized earlier, the Fourier transform decays very slowly in the directions $\theta = 0,\pi$ because of the singularity H. However, (3.1) is not a statement about the decay of $\hat f$ along the singular rays $\theta = 0,\pi$; rather it is about the decay of the Fourier transform as θ moves away from the critical directions $\theta = 0,\pi$. Roughly speaking, the order of magnitude of the modulus of the Fourier transform at a point with polar coordinates $(2^j,\theta)$ is $2^{-j(\sigma+1)}|\sin\theta|^{-\sigma}$ with $\sigma = s + (d-2)/2$.

Remark. The inequality involves a regular term (the first term of the right-hand side of (3.1)) as if one were simply analyzing an object from H^s and a singular term (the second one) essentially due to the discontinuity across the hyperplane $x_1 = 0$.

Proof. We will prove the result by induction. The result is true for $s = 0$ since letting $I_j(\theta)$ be the left-hand side of (3.1)

$$I_j(\theta) \equiv \int_{2^j\le r\le 2^{j+1}}\int |\hat f(r,\theta,\varphi)|^2\,dr d\varphi,$$

we have, by definition,

$$\sum_{j\ge0}2^{j(d-1)}\int I_j(\theta)(\sin\theta)^{d-2}\,d\theta = \sum_{j\ge0}2^{j(d-1)}\int_{2^j}^{2^{j+1}}\int|\hat f(r,\theta,\varphi)|^2\,dr d\theta d\varphi \\ \le \sum_{j\ge0}\int_{2^j\le|\xi|\le 2^{j+1}}|\hat f(\xi)|^2\,d\xi \le \|f\|_{L_2}^2 \le \|g\|_{L_2}^2.$$

Assume now that the result holds until $n-1$ ($n\in\mathbb{N}$), and take $g\in H^n$. For any tempered distribution in $\mathbb{R}^d$ S, we have the well-known relationship

$$\mathcal{F}\{\partial_\ell S\} = i\xi_\ell\hat S,$$

where in the previous display $i^2 = -1$, and ∂_ℓ is the partial derivative with respect to the ℓth coordinate. We will simply apply this formula to the tempered distribution $f = H\,g$. First, for any $1\le\ell\le d$, we have

$$\text{(3.2)}\qquad \partial_\ell f = H\,\partial_\ell g + g\,\partial_\ell H.$$

We observe that the second term, $g\,\partial_\ell H$, is nonzero only if $\ell = 1$ in which case it is a distribution supported on $x_1 = 0$, namely, $g\,\delta_{\{x_1=0\}}$. Let h be the restriction of g on $x_1 = 0$. By the trace theorem [15] we know that h is in $H^{n-1/2}(\mathbb{R}^{d-1})$ and, more precisely,

$$\|h\|_{H^{n-1/2}} \le C\,\|g\|_{H^n}.$$

Let us now choose $u = \xi/|\xi|$ and let $\xi = (\xi_1, \xi')$ so that $\xi' = \pi(\xi)$, where π is the orthogonal projection onto $\xi_1 = 0$. For this particular choice of u, we have

$$i|\xi|\hat{f}(\xi) = u\cdot\mathcal{F}\{\nabla f\}(\xi) = u\cdot\mathcal{F}\{H\,\nabla g\}(\xi) + \xi_1/|\xi|\,\hat{h}(\pi(\xi)) \tag{3.3}$$

since the Fourier transform of $g\,\delta_{\{x_1=0\}}$ is given by $\hat{h}(\pi(\xi)) = (\hat{h}\circ\pi)(\xi)$. The first term of the right-hand side of (3.3) is effortlessly going through the induction step. Indeed, we have

$$|u\cdot\mathcal{F}\{H\,\nabla g\}|^2(\xi) \le \sum_{i=1}^{d} |\mathcal{F}\{H\,\partial_\ell g\}|^2(\xi);$$

it is clear that for any ℓ, $\partial_\ell g \in H^{n-1}$ and therefore the induction hypothesis implies that

$$\begin{aligned}\int_{2^j\le r\le 2^{j+1}} \int |u\cdot\mathcal{F}\{H\,\nabla g\}|^2(r,\theta,\varphi)\,drd\varphi \\ \le C\,2^{-j}\epsilon_j^2(\theta)2^{-2j(\sigma-1)} + C\,2^{-j}\min(1, 2^{-2j(\sigma-1)}|\sin\theta|^{-2(\sigma-1)}).\end{aligned} \tag{3.4}$$

We split the analysis of the second term of the right-hand side of (3.3) into two separate cases: namely, $\sin\theta \ge 2^{-j}$ and $\sin\theta < 2^{-j}$. In the former case, we have

$$\begin{aligned}\int_{2^j}^{2^{j+1}} \int |(\hat{h}\circ\pi)(r,\theta,\varphi)|^2\,drd\varphi &= \int_{2^j}^{2^{j+1}} \int |\hat{h}(r\sin\theta,\varphi)|^2\,drd\varphi \\ &= |\sin\theta|^{-1} \int_{2^j|\sin\theta|}^{2^{j+1}|\sin\theta|} \int |\hat{h}(\rho,\varphi)|^2\,d\rho d\varphi \\ &\le 2^{-j(d-2)}|\sin\theta|^{-(d-1)} \int_{2^j\le|\xi'|/|\sin\theta|\le 2^{j+1}} |\hat{h}(\xi')|^2\,d\xi'.\end{aligned}$$

The degree of smoothness of h ($h \in H^{n-1/2}$) now allows us to bound the right-hand side of the previous display; i.e.,

$$\sum_{j=-\infty}^{\infty} |2^j\sin\theta|^{2(n-1/2)} \int_{2^j|\sin\theta|\le|\xi'|\le 2^{j+1}|\sin\theta|} |\hat{h}(\xi')|^2\,d\xi' \sim \|h\|^2_{\dot{H}^{n-1/2}} \le C\,\|g\|^2_{H^n},$$

which implies

$$\int_{2^j|\sin\theta|\le|\xi'|\le 2^{j+1}|\sin\theta|} |\hat{h}(\xi')|^2\,d\xi' \le C\,\eta_j^2(\theta)\,|2^j\sin\theta|^{-2(n-1/2)}\,\|g\|^2_{H^n}$$

with $\sum_j \eta_j^2(\theta) \le 1$.

To summarize, we have

$$\int_{2^j \le r \le 2^{j+1}} \int |(\hat{h} \circ \pi)(r, \theta, \varphi)|^2 \, dr d\varphi \le C \, 2^{-2j(\sigma - 1/2)} |\sin \theta|^{-2\sigma} \, \|g\|_{H^s}^2 \tag{3.5}$$

in any dimension $d \ge 2$.

To finish the proof, we simply recall (3.3) which gives the inequality

$$|\hat{f}(\xi)|^2 = 2|\xi|^{-2} \left(|u \cdot \mathcal{F}\{H \, \nabla g\}(\xi)|^2 + |\hat{h}(\pi(\xi))|^2 \right).$$

The polar integral of each term of the right-hand side of this inequality is bounded via (3.4) and (3.5), respectively, yielding the desired conclusion. The case $\sin \theta \ge 2^{-j}$ is now fully proved.

We finally treat the case $\sin \theta < 2^{-j}$. On one hand h is bounded in $H^{n-1/2}$ and therefore in L_2, since $n \ge 1$. On the other hand, h is compactly supported and hence

$$\sup_{|\xi'| \le 1} |\hat{h}(\xi')| \le \|h\|_{L_1} \le C \, \|h\|_{L_2} \le C \, \|g\|_{H^n}.$$

In this case, we simply write

$$\begin{aligned} \int_{2^j \le r \le 2^{j+1}} \int |\hat{h}(r \sin \theta, \varphi)|^2 \, dr d\varphi &\le 2^j |S^{d-2}| \sup_{2^j |\sin \theta| \le |\xi'| \le 2^{j+1} |\sin \theta|} |\hat{h}(\xi')|^2 \\ &\le C \, 2^j \|g\|_{H^n}^2, \end{aligned}$$

and the result for $\sin \theta < 2^{-j}$ now follows from (3.3). The proof of the theorem is complete. □

4. Main result. In this section, we will suppose that we are given a ridgelet frame satisfying the following mild assumptions.

1. ψ is R times differentiable and has vanishing moments through order D; $\min(R, D) \ge s + (d-1)/2$.

2. ψ is of rapid decay; namely, for any $\gamma > 0$ and $0 \le r \le R$, one can find a constant C such that

$$|\psi^{(r)}(t)| \le C \cdot (1 + |t|)^{-\gamma}.$$

The sequence of ridgelet coefficients of a given function f will be denoted by α: $\alpha_{j,\ell,k} = \langle f, \psi_{j,\ell,k} \rangle$.

We state our main result.

THEOREM 4.1. *Let $g \in H^s$, $s > 0$, with* supp $g \subset [-1,1]^d$ *and put $f(x) = H(u \cdot x - b) \, g(x)$, where H is the step function $H(t) = 1_{\{t > 0\}}$. Then, the ridgelet coefficient sequence α of f satisfies*

$$\|\alpha\|_{w\ell_{p^*}} \le C \, \|g\|_{H^s} \quad \textit{with} \quad 1/p^* = s/d + 1/2,$$

where d is the dimension of the space.

Preliminary remark. For any (j, ℓ, k), we have the following basic inequality:

$$|\alpha_{j,\ell,k}| \le 2^{j/2} (1 + |k|)^{-\gamma} \|f\|_2, \quad |k| \ge 2^{j+1},$$

because of the rapid decay of ψ. Indeed, we have

$$|\psi_{j,\ell,k}(x)| \le C \, (1 + 2^j |u_{j,\ell} \cdot x - k 2^{-j}|)^{-\gamma},$$

and, therefore, it is not hard to check that for $|k| \geq 2^{j+1}$

$$\sup_{[-1,1]^d} |\psi_{j,\ell,k}(x)| \leq C\, 2^{j/2}(1+|k|)^{-\gamma}.$$

Our claim is then a simple consequence of this last inequality. Thus, if ψ has a sufficient decay, then the subsequence $\{(\alpha_{j,\ell,k}),\ k \geq 2^{j+1}\}$ is in ℓ_p for any $p > 0$; hence it is enough to restrict our attention to the set $|k| \leq 2^{j+1}$.

In order to prove the theorem, we will need a result which is a corollary of Theorem 3.1.

Corollary 4.2. *Under the assumptions of Theorem* 3.1*, the ridgelet coefficient sequence α of f may be decomposed as*

$$\alpha_{j,\ell,k} = a_{j,\ell,k} + b_{j,\ell,k},$$

where the sequences a and b enjoy the following properties.

1. *The sequence a verifies*

$$\sum_{\ell,k} |a_{j,\ell,k}|^2 \leq C\, \epsilon_j^2 2^{-2js}\, \|g\|_{H^s}^2 \tag{4.1}$$

with $\sum_j \epsilon_j^2 \leq 1$, and

2. *the sequence b is localized both in angle and in location.*

(i) *Localization in angle. For $1 \leq m < j$, let $\Lambda_{j,m}$ be the set of indices such that*

$$\Lambda_{j,m} := \{\ell,\ 2^{-m} \leq |\sin\theta_{j,\ell}| \leq 2^{-m+1}\} \tag{4.2}$$

(for $m = j$, we will take $\Lambda_{j,m}$ to be $\{\ell,\ |\sin\theta_{j,\ell}| \leq 2^{-(j-1)}\}$); then,

$$\sum_{\ell\in\Lambda_{j,m}} \sum_k |b_{j,\ell,k}|^2 \leq C\, 2^{-j}\, 2^{-(j-m)(2s-1)}\, \|g\|_{H^s}^2. \tag{4.3}$$

(ii) *Localization in ridge location. For any $n > 0$, there is a constant C (independent of f) such that*

$$|b_{j,\ell,k}| \leq C\, 2^{j/2}\left(1 + \big||k| - |2^j \sin\theta_{j,\ell}|\big|\right)^{-n}\, \|g\|_{H^s}. \tag{4.4}$$

Not surprisingly, this decomposition involves a regular and a singular contribution as well.

Proof of Corollary 4.2. Again, we prove the result by induction. For any compactly supported element of L_2, we have

$$\sum_j \sum_{\ell,k} |\alpha_{j,\ell,k}|^2 \leq C\, \|f\|_{L_2}^2 \leq C\, \|g\|_{L_2}^2,$$

which proves the claim in this case since one can simply take $b \equiv 0$.

Suppose now that the claim is true up to $s - 1 \in \mathbb{N}$ and take g in H^s. Recall that the ridgelet $\psi_{j,\ell,k}$ is given by $2^{j/2}\psi(2^j u_{j,\ell}\cdot x - k)$. The starting point is to express the ridgelet coefficient $\alpha_{j,\ell,k}$ as a line integral in the Fourier domain [4]

$$\alpha_{j,\ell,k} = \int_{\mathbb{R}} \hat{f}(\lambda, u_{j,\ell}) 2^{-j/2}\hat{\psi}(2^{-j}\lambda)e^{-ik2^{-j}\lambda}\, d\lambda, \tag{4.5}$$

where $\hat{f}(\lambda, u) = \hat{f}(\lambda u_1, \dots, \lambda u_d)$. In the previous equation, the range of λ is the real line and not only the positive axis (polar coordinates). However, we can convert (λ, u) to classical polar coordinates (r, θ, φ) via the obvious relationship $(\lambda, u) = (-\lambda, -u)$. The decomposition (3.3) then suggests rewriting $\alpha_{j,\ell,k}$ as

$$\alpha_{j,\ell,k} = a^{(0)}_{j,\ell,k} + b^{(0)}_{j,\ell,k},$$

where

$$a^{(0)}_{j,\ell,k} = 2^{-j}\, u_{j,\ell} \cdot \int_{\mathbb{R}} \mathcal{F}\{H\,\nabla g\}(\lambda, u_{j,\ell}) 2^{-j/2} \frac{\hat{\psi}(2^{-j}\lambda)}{2^{-j}\lambda} e^{-ik2^{-j}\lambda}\, d\lambda$$

and

$$b^{(0)}_{j,\ell,k} = 2^{-j} \cos\theta_{j,\ell} \int_{\mathbb{R}} \hat{h}(\lambda \sin\theta_{j,\ell}, \varphi_{j,\ell}) \frac{\hat{\psi}(2^{-j}\lambda)}{2^{-j}\lambda} e^{-ik2^{-j}\lambda}\, d\lambda.$$

Let Ψ be the primitive of ψ defined by $\Psi(x) = \int_{-\infty}^{x} \psi(t)\, dt$. Then, Ψ satisfies the conditions listed at the beginning of the section (with the obvious modification $\min(R, D) \geq s - 1 + (d-1)/2$) and $\hat{\Psi}(\lambda) = -i\hat{\psi}(\lambda)/\lambda$. Therefore, we may apply the induction hypothesis to the sequence a and obtain

$$a^{(0)}_{j,\ell,k} = 2^{-j} a^{(1)}_{j,\ell,k} + 2^{-j} b^{(1)}_{j,\ell,k},$$

where $a^{(1)}$ and $b^{(1)}$, respectively, satisfy properties (4.1) and (4.3)–(4.4) with $(s-1)$ in place of s. Now, define the sequences a and b by

$$a_{j,\ell,k} = 2^{-j} a^{(1)}_{j,\ell,k}$$

and

$$b_{j,\ell,k} = 2^{-j} b^{(1)}_{j,\ell,k} + b^{(0)}_{j,\ell,k}.$$

It is clear that $a_{j,\ell,k}$ and $2^{-j} b^{(1)}_{j,\ell,k}$ satisfy conditions (4.1) and (4.3)–(4.4), respectively. Thus we need only to check that the sequence $b^{(0)}$ verifies (4.3) and (4.4). In the original domain, $b^{(0)}_{j,\ell,k}$ is given by

$$b^{(0)}_{j,\ell,k} = \langle g\, \delta_{\{x_1=0\}}, \Psi_{j,\ell,k} \rangle$$

and, therefore, with the the same notations as in section 3, i.e., $h(x') = g(0, x')$,

$$|b^{(0)}_{j,\ell,k}| \leq \|h\|_{L_1} \sup_{x \in \text{ supp } g\delta_{\{x_1=0\}}} |\Psi_{j,\ell,k}(x)|.$$

First, it is easy to see that $\Psi_{j,\ell,k}$ is bounded by $C\, 2^{j/2} \left(1 + \big||k| - |2^j \sin\theta_{j,\ell}|\big|\right)^{-n}$ on the support of $g\, \delta_{\{x_1=0\}}$ and second, we have $\|h\|_{L_1} \leq C\|h\|_{L_2} \leq C\|g\|_{H^{1/2}}$ which is bounded since $g \in H^s$, $s \geq 1$. This finishes the verification of (4.4). It remains to check (4.3).

Sampling results. In a separate paper, we have established the following sampling results: let $\alpha_{j,\ell,k}$ be the ridgelet coefficients of a compactly supported distribution S; first,

$$\sum_k |\alpha_{j,\ell,k}|^2 \leq C \int_{\mathbb{R}} |\hat{S}(\lambda, u_{j,\ell})|^2 |\hat{\psi}(2^{-j}\lambda)|^2 (1 + |2^{-j}\lambda|^2)\, d\lambda; \tag{4.6}$$

second, we recall that at scale j, the set of discrete angular variables $\{u_{j,\ell}, \ell \in \Lambda_j\}$ consists of points approximately uniformly distributed on the sphere; for any subset Λ_j' of Λ_j, we have

$$(4.7) \quad \sum_{\ell \in \Lambda_j'} \sum_k |\alpha_{j,\ell,k}|^2 \\ \leq C\, 2^{j(d-1)} \int_{\mathbb{R}} |\hat{\psi}(2^{-j}\lambda)|^2 (1 + |2^{-j}\lambda|^{2d})\, d\lambda \int_{\Sigma_j'} \sum_{|\alpha| \leq d-1} |D^\alpha \hat{S}(\lambda, u)|^2\, du,$$

where Σ_j' is the set of points on the sphere defined by

$$\Sigma_j' \equiv \left\{ u \in S^{d-1}, \inf_{\ell \in \Lambda_j'} \|u - u_{j,\ell}\|_2 \leq 2^{-j} \right\}.$$

Here α is a multi-index $\alpha = (\alpha_1, \ldots, \alpha_d)$ and D^α stands for the classical partial derivative with respect to the cartesian coordinate system $D^\alpha S = \partial_1^{\alpha_1} \ldots \partial_d^{\alpha_d}$. Thus, (4.7) is a kind of uniform sampling inequality. In a nutshell, (4.7) holds because the points $\{u_{j,\ell}, \ell \in \Lambda_j\}$ are quasi-uniformly distributed on the sphere (at a distance of order 2^{-j}); that is, for any point $u \in S^{d-1}$,

$$\#\{\ell, \|u_{j,\ell} - u\|_2 \leq \delta\} \leq C\, 2^{j(d-1)} \delta^{d-1}.$$

We apply this result to the distribution $S = g\, \delta_{\{x_1 = 0\}}$, that is, to the restriction of f to the hyperplane $\{x_1 = 0\}$ (see section 3 for details). The Fourier transform of S is the function $\hat{S} = \hat{h} \circ \pi$ that we introduced in section 3. With $\Lambda_{j,m}$, $0 \leq m < j$, as in (4.2), we have

$$\inf_{\ell \in \Lambda_{j,m}} \|u - u_{j,\ell}\|_2 \leq 2^{-j} \quad \Rightarrow \quad 2^{-m} - 2^{-j} \leq \sin\theta \leq 2^{-m+1} + 2^{-j}$$

and we omit the proof of this simple inclusion. Therefore, in this context (4.7) gives

$$(4.8) \quad \sum_{\ell \in \Lambda_{j,m}} \sum_k |b_{j,\ell,k}^{(0)}|^2 \leq C\, 2^{j(d-1)} \int_{2^{-m} - 2^{-j} \leq \sin\theta \leq 2^{-m+1} + 2^{-j}} I(\theta)\, (\sin\theta)^{d-2}\, d\theta,$$

where $I(\theta)$ is given by

$$\int_{\mathbf{S}^{d-2}} \int_{\mathbb{R}} \sum_{|\alpha| \leq d-1} |D^\alpha \hat{S}(\lambda, \theta, \varphi)|^2 |\hat{\psi}(2^{-j}\lambda)|^2 (1 + |2^{-j}\lambda|^{2d})\, d\lambda d\varphi.$$

Now, if ψ has r vanishing moments and is of regularity r, we have

$$(4.9) \quad \sup_{2^\ell \leq |\lambda| \leq 2^{\ell+1}} |\hat{\psi}(2^{-j}\lambda)| \leq C\, 2^{-|j-\ell| r}.$$

It is then easy to check that

$$(4.10) \quad I(\theta) \leq C\, 2^{-j} 2^{-2j\sigma} |\sin\theta|^{-2\sigma}\, \|g\|_{H^s}^2.$$

To see why this is true, we simply write

$$I(\theta) \leq \sum_\ell \sup_{2^\ell \leq |\lambda| \leq 2^{\ell+1}} |\hat{\psi}(2^{-j}\lambda)|^2 (1 + |2^{-j}\lambda|^{2d}) I_\ell(\theta),$$

where

$$I_\ell(\theta) = \int_{2^\ell \le |\lambda| \le 2^{\ell+1}} \int \sum_{|\alpha| \le d-1} |D^\alpha \hat{S}(\lambda, \theta, \varphi)|^2 \, d\lambda d\varphi.$$

In the proof of Theorem 3.1 (3.5), we obtained

$$\int_{2^\ell \le |\lambda| \le 2^{\ell+1}} \int |\hat{S}(\lambda, \theta, \varphi)|^2 \, d\lambda d\varphi \le C \, 2^\ell 2^{-2\ell\sigma} |\sin\theta|^{-2\sigma} \|g\|_{H^s}^2. \tag{4.11}$$

Now, $D^\alpha \hat{S}$ is the Fourier transform of the distribution $(-i)^{|\alpha|} \, x^\alpha \, S$, which is the restriction of $(-i)^{|\alpha|} \, x^\alpha \, g$ to the hyperplane $\{x_1 = 0\}$. Because g is compactly supported, we have that

$$\|x^\alpha \, g\|_{H^s} \le C \, \|g\|_{H^s}$$

since the multiplication by a C_0^∞ function is a bounded operation from H^s onto itself. Therefore, inequality (4.11) applies to $D^\alpha \hat{S}$, and we have the upper bound

$$I_\ell(\theta) \le C \, 2^\ell 2^{-2\ell\sigma} |\sin\theta|^{-2\sigma} \|g\|_{H^s}^2.$$

Inequality (4.10) comes from the previous inequality together with the size estimate (4.9).

Combining (4.10) and (4.8) finally gives (recall $2\sigma = 2s + d - 2$)

$$\sum_{\ell \in \Lambda_{j,m}} \sum_k |b_{j,\ell,k}^{(0)}|^2 \le C \, 2^{-2js} \, \|g\|_{H^s}^2 \int_{2^{-m} - 2^{-j} \le \sin\theta \le 2^{-m+1} + 2^{-j}} |\sin\theta|^{-2s} \, d\theta,$$

which, in turn, gives the desired conclusion

$$\sum_{\ell \in \Lambda_{j,m}} \sum_k |b_{j,\ell,k}^{(0)}|^2 \le C \, 2^{-m} 2^{-2(j-m)s} \, \|g\|_{H^s}^2.$$

The corollary is established. □

Proof of Theorem 4.1. Let s be a positive integer. Following on Corollary 4.2, to prove that α is in $w_{\ell_{p^*}}$ $(1/p^* = s/d + 1/2)$, it is sufficient to prove that both a and b are in $w_{\ell_{p^*}}$. The membership of a to $w_{\ell_{p^*}}$ follows from well-known arguments and is straightforward.

The $w\ell_{p^*}$ boundedness of the sequence $(b_{j,\ell,k})$ will be deduced from Corollary 4.2. We identify two subsequences corresponding, respectively, to the indices $|k| > 2^{j+1} |\sin\theta_{j,\ell}|$ and $|k| \le 2^{j+1} |\sin\theta_{j,\ell}|$; the interesting contribution concerns the latter subsequence. We prove that

1. the subsequence $\{b_{j,\ell,k}, \, |k| \le 2^{j+1} |\sin\theta_{j,\ell}|\}$ has a finite $w_{\ell_{p^*}}$ norm, and
2. the ℓ_p norm of the subsequence $\{b_{j,\ell,k}, \, |k| > 2^{j+1} |\sin\theta_{j,\ell}|\}$ is bounded for any $p > 0$.

We prove the first assertion. Letting $N(\epsilon)$ be the cardinality of those elements whose absolute value exceeds ϵ, namely,

$$N(\epsilon) = \# \, \epsilon \, \{(j, \ell, k), \, |k| \le 2^{j+1} |\sin\theta_{j,\ell}|, \text{ such that (s.t.) } |b_{j,\ell,k}| \ge \epsilon\},$$

we want to show that

$$\sup_{\epsilon > 0} \epsilon N^{1/p^*}(\epsilon) \le C \, \|g\|_{H^s}$$

since the left-hand side is an equivalent definition of the weak-ℓ_{p^*} norm (1.5).

Put

$$N_{j,m}(\epsilon) = \#\{(\ell,k),\, \ell \in \Lambda_{j,m},\, |k| \le 2^{j+1}|\sin\theta_{j,\ell}|, \text{ s.t.} |b_{j,\ell,k}| \ge \epsilon\}.$$

Corollary 4.2 posits the existence of a constant K such that $|b_{j,\ell,k}|^2 \le K\, 2^{-j}\|g\|^2_{H^s}$ (4.3) and therefore, it is clear that $N_{j,m}(\epsilon) = 0$ if $2^j \ge K\,\epsilon^{-2}\|g\|^2_{H^s}$. In what follows, we will let η be defined by $\eta = \epsilon/\|g\|_{H^s}$. Regardless of the condition $|b_{j,\ell,k}| \ge \epsilon$, the cardinality of the index set $\{(\ell,k),\, \ell \in \Lambda_{j,m},\, |k| \le 2^{j+1}|\sin\theta_{j,\ell}|\}$ is bounded by $C\,2^{d(j-m)}$. Further, the bound on the ℓ_2 norm of the $b_{j,\ell,k}$'s (Corollary 4.2) gives

$$N_{j,m}(\epsilon) \le C\, \min(2^{(j-m)d}, \eta^{-2}2^{-j}2^{(j-m)(1-2s)})$$

whenever $2^j \le K\,\eta^{-2}$.

Let $N_j(\epsilon)$ be the number of coefficients whose absolute values exceed ϵ, i.e.,

$$N_j(\epsilon) = \#\{(\ell,k),\, |k| \le 2^{j+1}|\sin\theta_{j,\ell}|,\, |b_{j,\ell,k}| \ge \epsilon\}.$$

Then, a simple calculation gives

$$\begin{aligned} N_j(\epsilon) = \sum_m N_{j,m}(\epsilon) &\le C \sum_m \min(2^{(j-m)d}, \eta^{-2}2^{-j}2^{(j-m)(1-2s)}) \\ &\le C\, \min(2^{jd}, \eta^{-2d/\alpha}2^{-jd/\alpha}), \end{aligned}$$

where $\alpha = d + 2s - 1$. To summarize, we have

$$N_j(\epsilon) \le C \begin{cases} 0 & 2^j \ge K\,\eta^{-2}, \\ \eta^{-2d/\alpha}2^{-jd/\alpha} & \eta^{-2/(1+\alpha)} \le 2^j \le K\,\eta^{-2}, \\ 2^{jd} & 2^j \le \eta^{-2/(1+\alpha)}. \end{cases}$$

Summing over the scales yields

$$\begin{aligned} N(\epsilon) = \sum_{j=0}^{\infty} N_j(\epsilon) &\le C \sum_{j:2^j \le \eta^{-2/(1+\alpha)}} 2^{jd} + C \sum_{j:\eta^{-2/(1+\alpha)} \le 2^j \le K\,\eta^{-2}} \eta^{-2d/\alpha}2^{-jd/\alpha} \\ &\le C\,\eta^{-2d/(1+\alpha)} = C\,\eta^{-p^*} = C\,\epsilon^{-p^*}\,\|g\|^{p^*}_{H^s} \end{aligned}$$

with $1/p^* = s/d + 1/2$. This finishes the proof of the first assertion.

We now turn to the second assertion. It clearly follows from (4.4) that for any $q > 0$ we have

$$\sum_{k:|k|>2^{j+1}|\sin\theta_{j,\ell}|} |b_{j,\ell,k}|^q \le C\,2^{jq/2}(2^j|\sin\theta_{j,\ell}|)^{1-nq}\|g\|^q_{H^s},$$

since n may be chosen arbitrarily large and, in particular, greater than $1/q$. Summing over the ℓ's, $\ell \in \Lambda_{j,m}$ gives

$$\sum_{\ell\in\Lambda_{j,m}} \sum_{k:|k|>2^{j+1}|\sin\theta_{j,\ell}|} |b_{j,\ell,k}|^q \le C\,2^{jq/2}2^{(1-nq)(j-m)}2^{(j-m)(d-1)}\|g\|^q_{H^s}.$$

Now, we must keep in mind that we have available a bound on the ℓ_2 norm (4.3); i.e.,

$$\sum_{\ell\in\Lambda_{j,m}} \sum_{k:|k|>2^{j+1}|\sin\theta_{j,\ell}|} |b_{j,\ell,k}|^2 \le C\,2^{-j}2^{-(j-m)(2s-1)}\|g\|^2_{H^s}.$$

The interpolation inequality will yield the ℓ_p boundedness. Recall that for any sequence a_n we have

$$\|a\|_{\ell_p} \le \|a\|_{\ell_q}^{\theta} \, \|a\|_{\ell_2}^{1-\theta}, \quad 1/p = \theta/q + (1-\theta)/2. \tag{4.12}$$

This interpolation inequality applied to our subsequence gives

$$\left(\sum_{\ell \in \Lambda_{j,m}} \sum_{k:|k|>2^{j+1}|\sin\theta_{j,\ell}|} |b_{j,\ell,k}|^p \right)^{1/p} \le C \left[2^{j/2} 2^{-(j-m)(n-d/q)} \right]^{\theta} \left[2^{-j/2} 2^{-(j-m)(s-1/2)} \right]^{1-\theta} \|g\|_{H^s}.$$

In the previous inequality, the value of n may be chosen arbitrarily large and, hence, summing up the previous inequalities results in the upper bound

$$\sum_{\ell} \sum_{k:|k|>2^{j+1}|\sin\theta_{j,\ell}|} |b_{j,\ell,k}|^p \le C \, 2^{-jp(1/2-\theta)} \, \|g\|_{H^s}^p. \tag{4.13}$$

This establishes the boundedness in ℓ_p for any $p > 0$. Indeed for $p > 0$, choose q small enough so that $\theta < 1/2$ (4.12), i.e., $1/q > 2/p + 1/2$, and apply (4.13). The theorem is proved for $s = 1, 2, \ldots$.

Interpolation theory allows us to extend the result to the half line $s > 0$. Indeed, let T be the operator

$$T : \, g \mapsto (\alpha_\nu)$$

that maps g into the ridgelet coefficient sequence (α_ν) of f, $f(x) = H(u \cdot x - b)g(x)$, with u and b fixed. We abuse notations—as it is understood that we are concerned with elements supported on the unit cube—and let H^s be the Banach space defined by

$$H^s := \{g, \; g \in H^s \text{ and supp } g \subset [0,1]^d\}$$

equipped with the norm $\| \cdot \|_{H^s}$. We proved that for any $n \ge 1$, $\|T\|$ is a bounded operator from H^n to $w\ell_p$, $1/p = n/d + 1/2$. In addition, T is bounded from L_2 to ℓ_2 (where again we understand $L_2([0,1]^d)$). On one hand, it is well known that (L_2, H^n) is an interpolation couple [2] and that for any $n > 0$ and any $0 < \theta < 1$, we have

$$(L_2, H^n)_{\theta,2} = H^{n\theta};$$

see [14], for example. On the other, letting ℓ_2 be the space of real-valued sequences

$$\ell_2 = \left\{ a, \; \sum_{n \ge 1} |a_n|^2 < \infty \right\},$$

and similarly for $w\ell_p$, $p > 0$, we have

$$(\ell_2, w\ell_p)_{\theta,2} = \ell_{p^*,2}, \quad 1/p^* = (1-\theta)/2 + \theta/p.$$

Here, $\ell_{p,2}$, $p > 0$ is the Lorentz space of real sequences

$$\left(\sum_{n \ge 1} |a|_{(n)}^2 n^{2/p-1} \right)^{1/2} < \infty,$$

where we recall that $|a|_{(n)}$ is the nth largest entry in the sequence $(|a_n|)$. The interpolation theorem [2] gives that

$$T : H^{n\theta} \to \ell_{p^*,2}$$

is bounded and further that

$$\|T\|_{H^{n\theta}\to\ell_{p^*,2}} \leq C\, \|T\|^{1-\theta}_{L_2\to\ell_2} \|T\|^{\theta}_{H^n\to w\ell_p}.$$

Hence, for any $s > 0$, pick $n > s$ and put $\theta = s/n$. We have

$$\frac{1}{p^*} = \frac{1}{2}\left(1 - \frac{s}{n}\right) + \frac{s}{n}\left(\frac{n}{d} + \frac{1}{2}\right) = \frac{s}{d} + \frac{1}{2},$$

and, therefore, our analysis gives that T is bounded from H^s to $\ell_{p^*,2}$. This completes the proof of our theorem since for any sequence a and any $p > 0$, we have

$$\|a\|_{\ell_{p,2}} \leq \|w\ell_p\|. \qquad \square$$

Remark. We proved a slightly stronger result than that announced in our theorem since for any $s \geq 0$ the ridgelet coefficient sequence obeys

$$\|\alpha\|_{\ell_{p,2}} \leq C\, \|g\|_{H^s},\ 1/p = s/d + 1/2.$$

4.1. Finite approximations. We now exploit Theorem 4.1 to derive nonlinear approximation bounds. The compact notation $(\psi_\nu)_{\nu\in\mathcal{N}}$ introduced in section 2 will be used to denote the frame elements.

Suppose that f is of the form

$$f(x) = g_0(x) + H(u \cdot x - b) g_1(x), \tag{4.14}$$

where

$$\|g_i\|_{H^s} \leq C, \quad i = 0, 1.$$

From the exact series

$$f = \sum_{\nu\in\mathcal{N}} \alpha_\nu \widetilde{\psi}_\nu,$$

extract the n-term approximation f_n obtained by keeping the n terms corresponding to the n largest coefficients. Then, we have the following result.

Corollary 4.3. *With the previous assumptions, there exists a constant C (not depending on f) such that*

$$\|f - f_n\|_2 \leq C\, n^{-s/d} \sup_{i=0,1} \|g_i\|_{H^s(\mathbb{R}^d)}. \tag{4.15}$$

As we will see below, the convergence rate of n-term ridgelet approximations is, in some sense, optimal.

Theorem 4.1 gives that the coefficients (α_ν) of f are bounded in $w\ell_{p^*}$. Letting $|\alpha|_{(n)}$ be the nth largest entry in α (in absolute values), we have

$$f - f_n = \sum_\nu \alpha_\nu 1_{\{|\alpha_\nu| \geq |\alpha|_{(n)}\}} \widetilde{\psi}_\nu.$$

The lemma stated below then gives the desired conclusion, namely,

$$\|f - f_n\|_2^2 \le A^{-1} \sum_{m>n} |\alpha|_{(m)}^2 \le A^{-1}\, C\, n^{-2s/d} \|\alpha\|_{w\ell_{p^*}}^2,$$

where A is the constant appearing on the left-hand side of (2.7).

LEMMA 4.4. *Let $(a_\nu)_{\nu\in\mathcal{N}}$ be a sequence in ℓ_2 and let*

$$\tilde{f} = \sum_{\nu\in\mathcal{N}} a_\nu \tilde{\psi}_\nu.$$

Then,

$$\|\tilde{f}\|_2^2 \le A^{-1} \|a\|_{\ell_2}^2.$$

Proof. We let $\tilde{F}$ be the synthesis operator defined by $\tilde{F}a = \sum a_\nu \tilde{\psi_\nu}$ and let F be the analysis operator $Ff = (\langle f, \psi_\nu\rangle)_{\nu\in\mathcal{N}}$. The property (2.7) gives

$$\|\tilde{f}\|^2 = \|\tilde{F}a\|^2 \le A^{-1} \|F\,\tilde{F}a\|_{\ell_2}^2.$$

Now, it is easy to see that $F\,\tilde{F}$ is the orthogonal projector onto the range of F and has, therefore, a norm (as an operator from ℓ_2 onto itself) bounded by 1. Consequently, we have

$$\|\tilde{f}\|^2 \le A^{-1} \|F\,\tilde{F}a\|_{\ell_2}^2 \le A^{-1} \|a\|_{\ell_2}^2,$$

which is what needed to be shown. □

4.2. Optimality. In this section, we detail the sense in which Corollary 4.3 is optimal. Consider a class of templates of the form (4.14): i.e., let $\mathcal{F}(C)$ be the class defined by

$$\mathcal{F}(C) = \{f,\ f \text{ satisfies (4.14)},\ \|g_i\|_{H^s} \le C, \text{ and } \operatorname{supp} g_i \subset [0,1]^d,\ i = 0,1\}. \tag{4.16}$$

In the above definition, the singular hyperplane is not fixed; two elements from $\mathcal{F}(C)$ may be singular along two different hyperplanes.

The class $\mathcal{F}(C)$ contains, of course, the Sobolev ball $H^s(C) = \{f,\ \|f\|_{H^s} \le C, \text{ and } \operatorname{supp} f \subset [0,1]^d\}$. In any orthobasis $(\phi)_{i\in\mathcal{I}}$, there is a lower bound on the convergence of the best n-term approximation $Q_n(f)$ in that basis,

$$\sup_{f\in H^s(C)} \|f - Q_n(f)\|_2 \ge C\, n^{-s/2}.$$

As a consequence, no orthobasis exists that provides better rates than those obtained in Corollary 4.3. There is even a broader notion of optimality based on information theoretic concepts such as the Kolmogorov ϵ-entropy or the minimum description length (MDL) paradigm.

Let $\mathcal{F}$ be a compact set of functions in $L^2([0,1]^d)$. The Kolmogorov ϵ-entropy $N(\epsilon, \mathcal{F})$ of the class $\mathcal{F}$ is the minimum number of bits that is required to specify any element f from $\mathcal{F}$ within an accuracy of ϵ. In other words, let ℓ be a fixed counting number and let $E_\ell :\ \mathcal{F} \to \{0,1\}^\ell$ be a functional which assigns a bit string of length ℓ to each $f \in \mathcal{F}$. Let $D_\ell :\ \{0,1\}^\ell \to L_2[0,1]^d$ be a mapping which assigns to each bit string of length ℓ a function. The coder-decoder pair (E_ℓ, D_ℓ) will be said to achieve a distortion $\leq \epsilon$ over $\mathcal{F}$ if

$$\sup_{f\in\mathcal{F}} \|D_\ell(E_\ell(f)) - f\| \leq \epsilon.$$

The Kolmogorov ϵ-entropy (minimax description length) may then be defined as

$$L^*(\epsilon, \mathcal{F}) = \min\{\ell :\ \exists (E_\ell, D_\ell) \text{ achieving distortion } \leq \epsilon \text{ over } \mathcal{F}\}.$$

The minimum number of bits needed to reconstruct any f taken from our class of templates $\mathcal{F}(C)$ (4.16) satisfies

$$N(\epsilon, \mathcal{F}(C)) \geq N(\epsilon, H^s) \geq C\, \epsilon^{2/s}.$$

A strategy identical to that developed in [9, Theorem 2], however, gives a simple way to exploit the sparsity of the ridgelet sequence to construct a coder-decoder pair of length $O(\log(\epsilon^{-1})\epsilon^{2/s})$ that achieves a distortion of ϵ. The construction is based on simple uniform quantization of the ridgelet coefficients α_i, followed by simple run length coding. Hence, we have available a very concrete way of obtaining near-optimal (possibly within log-like factors) compression rates.

5. Orthonormal ridgelets. In dimension 2, Donoho [10] introduced a new orthonormal basis whose elements he called "orthonormal ridgelets." We will not detail why these elements relate to ridgelets. We quote from [7]: "Such a system can be defined as follows: let $(\psi_{j,k}(t) : j \in \mathbb{Z}, k \in \mathbb{Z})$ be an orthonormal basis of Meyer wavelets for $L^2(\mathbb{R})$ [12], and let $(w^0_{i_0,\ell}(\theta),\ \ell = 0, \dots, 2^{i_0}-1;\ w^1_{i,\ell}(\theta),\ i \geq i_0,\ \ell = 0, \dots, 2^i-1)$ be an orthonormal basis for $L^2[0, 2\pi)$ made of periodized Lemarié scaling functions $w^0_{i_0,\ell}$ at level i_0 and periodized Meyer wavelets $w^1_{i,\ell}$ at levels $i \geq i_0$. (We suppose a particular normalization of these functions.) Let $\hat{\psi}_{j,k}(\omega)$ denote the Fourier transform of $\psi_{j,k}(t)$, and define ridgelets $\rho_\lambda(x)$, $\lambda = (j, k; i, \ell, \varepsilon)$ as functions of $x \in \mathbb{R}^2$ using the frequency-domain definition

$$\hat{\rho}_\lambda(\xi) = |\xi|^{-\frac{1}{2}}(\hat{\psi}_{j,k}(|\xi|)w^\varepsilon_{i,\ell}(\theta) + \hat{\psi}_{j,k}(-|\xi|)w^\varepsilon_{i,\ell}(\theta + \pi))/2\ . \tag{5.1}$$

Here the indices run as follows: $j, k \in \mathbb{Z}$, $\ell = 0, \dots, 2^{i-1} - 1$; $i \geq i_0$, $i \geq j$. Notice the restrictions on the range of ℓ and on i. Let λ denote the set of all such indices λ. It turns out that $(\rho_\lambda)_{\lambda\in\Lambda}$ is a complete orthonormal system for $L^2(\mathbb{R}^2)$."

There is a close connection between "pure" and orthonormal ridgelets. Pure ridgelets are supported on lines in the Fourier domain: that is, the frequency representation of a pure ridgelet is given by (provided that the profile ψ is real-valued)

$$\hat{\psi}_{j,\ell,k}(\xi) = (\hat{\psi}_{j,k}(|\xi|)\delta(\theta - 2\pi 2^{-j}\ell) + \hat{\psi}_{j,k}(-|\xi|)\delta(\theta + \pi - 2\pi 2^{-j}\ell))/2 \tag{5.2}$$

using a formulation emphasizing the resemblance with (5.1). In the ridgelet construction, the angular variable θ is uniformly sampled at each scale, the sampling step being inversely proportional to the scale. In contrast, the sampling idea is replaced by the wavelet transform for orthonormal ridgelets. This is the reason why orthonormal ridgelets can perfectly reconstruct objects from $L^2(\mathbb{R}^2)$ without support constraints. It is interesting to note that the restriction on the range, namely, $i \geq j$ in the definition (5.1), gives angular scaling functions at scales inversely proportional to the sampling steps of pure ridgelets.

THEOREM 5.1. *Let $g \in H^s(\mathbb{R}^2)$, $s > 0$, with compact support and put $f(x) = H(u \cdot x - b)\, g(x)$. Then the orthonormal ridgelet coefficient sequence α of f obeys*

$$\|\alpha\|_{w\ell_p} \le C\, \|g\|_{H^s} \quad \text{with} \quad 1/p = s/2 + 1/2$$

for some constant C not depending on f. It then follows that the truncated n-term partial reconstruction f_n achieves the error bound

$$\|f - f_n\|_2 \le C\, n^{-s/2} \|g\|_{H^s}.$$

Proof. The proof is an application of Theorem 3.1 and consists of minor modifications to the proof of Theorem 4.1. In the following, we outline the essential steps, thus avoiding worthless repetition.

Begin with $\varepsilon = 0$ $(i = j)$ and observe that

$$|\langle f, \rho_\lambda \rangle| = \left| \int \hat{f}(\lambda, \theta)\, |\lambda|^{1/2} (\hat{\psi}_{j,k}(|\lambda|) w_{j,\ell}^{\varepsilon=0}(\theta) + \hat{\psi}_{j,k}(-|\lambda|) w_{j,\ell}^{\varepsilon=0}(\theta + \pi))\, d\lambda d\theta \right| /2$$

$$\le 2^{j/2} \int |w_{j,\ell}^{\varepsilon=0}(\theta)| J^+(\theta) d\theta/2 + 2^{j/2} \int |w_{j,\ell}^{\varepsilon=0}(\theta + \pi)| J^-(\theta) d\theta/2, \tag{5.3}$$

where

$$J^{\pm}(\theta) = \left| \int \hat{f}(\lambda, \theta)\, |2^{-j}\lambda|^{1/2} \hat{\psi}_{j,k}(\pm|\lambda|) d\lambda \right|.$$

The point of this paper has been precisely to bound quantities like $J^{\pm}(\theta)$. For instance, let $I_{j,\ell} = \{\theta, |\theta - 2\pi\, 2^{-j}\ell| \le 2^{-j}\}$ and set

$$\beta_{j,\ell,k} = 2^j \int_{I_{j,\ell}} \left| \int \hat{f}(\lambda, \theta) |2^{-j}\lambda|^{1/2} \hat{\psi}_{j,k}(|\lambda|) d\lambda \right|.$$

Then, we proved that (dimension 2)

$$\|\beta\|_{w\ell_p} \le C\, \|g\|_{H^s}, \quad 1/p = s/2 + 1/2.$$

Compare the previous inequality with (4.5) and Theorem 4.1. Second, the scaling function is localized near the interval $I_{j,\ell}$; for any $\gamma > 0$, there is a constant C such that

$$|w_{j,\ell}^{\varepsilon=0}(\theta)| \le C\, 2^{j/2} (1 + 2^j |\theta - 2\pi\, \ell 2^{-j}|)^{-\gamma}.$$

Hence, a reasoning similar to the one developed for Theorem 4.1 gives

$$\|\alpha^{\varepsilon=0}\|_{w\ell_p} \le C\, \|g\|_{H^s}, \quad 1/p = s/2 + 1/2. \tag{5.4}$$

The point is that the contributions associated with the orthonormal ridgelets corresponding to parameter values $i > j$ become negligible as i goes to infinity. This is due to the compactness of the support of f. Letting D be $\partial/\partial\theta$, standard wavelet calculations give

$$\langle f, \rho_\lambda \rangle = I_n^+ + I_n^-,$$

$$I_n^+ = \int D^n \hat{f}(\lambda, \theta)\, |\lambda|^{1/2} (\hat{\psi}_{j,k}(|\lambda|) D^{-n} w_{i,\ell}^{\varepsilon=1}(\theta)\, d\theta,$$

and similarly for I_n^-. Both terms are treated identically. Since

$$|D^{-n} w_{i,\ell}^{\varepsilon=1}(\theta)| \le C\, 2^{-i(n-1/2)} (1 + 2^i|\theta - 2\pi\,\ell 2^{-i}|)^{-\gamma}$$

we have

$$|I_n^+| \le C\, 2^{-in} 2^{i/2} 2^{j/2} \int (1 + 2^i|\theta - 2\pi\,\ell 2^{-i}|)^{-\gamma} J_n^+(\theta)\, d\theta,$$

where now

$$J_n^{\pm}(\theta) = \left| \int (\partial_\theta^n \hat{f})(\lambda, \theta)\, |2^{-j}\lambda|^{1/2} \hat{\psi}_{j,k}(\pm|\lambda|) d\lambda \right|.$$

Observe now that

$$\partial_\theta \hat{f}(\lambda, \theta) = \lambda(-\sin\theta(\partial_1 \hat{f})(\lambda, \theta) + \cos\theta(\partial_2 \hat{f})(\lambda, \theta)),$$

and this formula may be iterated to obtain derivatives with respect to the angular variable θ of higher orders.

We may then substitute polar derivatives with respect to θ by cartesian derivatives and obtain (letting D be either $\partial/\partial x_1$ or $\partial/\partial x_2$)

$$|I_n^+| \le C\, 2^j 2^{-(i-j)(n-1/2)} \int (1 + 2^i|\theta - 2\pi\,\ell 2^{-i}|)^{-\gamma} \sum_{|\alpha| \le n} J_\alpha^+(\theta)\, d\theta,$$

$$J_\alpha^+(\theta) = \left| \int (D^\alpha \hat{f})(\lambda, \theta)\, |2^{-j}\lambda|^{|\alpha|+1/2} \hat{\psi}_{j,k}(|\lambda|) d\lambda \right|.$$

We already argued in the proof of Corollary 4.2 that, because of the compactness of the support of the distribution f, the estimates we obtained for $\hat{f}$ are valid for the derivatives $D^\alpha \hat{f}$. Hence, we essentially have the same bound as in (5.3) but for an exponentially decaying factor $2^{-(i-j)(n-1/2)}$, where n might be chosen as large as we want. It is then not too difficult to check that the sequence $\alpha^{\varepsilon=1}$ satisfies

$$\|\alpha^{\varepsilon=1}\|_{w\ell_p} \le C\, \|g\|_{H^s}, \quad 1/p = s/2 + 1/2.$$

The $w\ell_p$ boundedness of the sequence α naturally follows from this last display and (5.4). □

6. Discussion. Unlike any known system, ridgelets allow optimal partial reconstructions of L_2 Sobolev functions with linear singularities. These good approximations are, moreover, simply obtained by thresholding the exact ridgelet series (1.4).

6.1. Ridgelets and functional classes. As we pointed out in the introduction, wavelets are optimal to represent smooth functions with point-singularities. From a functional viewpoint, we may say that wavelets provide unconditional bases for the Besov spaces and the Triebel spaces [13] and, therefore, they provide near-optimal approximations to elements taken from functional balls of such spaces. A natural question would be, What are the functional spaces that are naturally associated with ridgelets? The analysis that we presented already suggests an answer. It is certainly possible to build new functional spaces whose typical elements resemble our mutilated

Sobolev objects. In this direction, we might be tempted to consider, for instance, convex combinations of objects like (1.2); let

$$\mathcal{S}_H = \left\{ f = \sum_i a_i f_i, \ \sum_i |a_i| \le 1 \right\},$$

where the f_i's are our templates, i.e., functions of the form

$$f_i(x) = H(u_i \cdot x - b_i) g_i(x), \quad \|g_i\|_{H^s} \le 1, \text{ supp } g \subset [0,1]^d.$$

Our functional class $\mathcal{S}_H$ would then be meant to represent objects composed of singularities across hyperplanes: typical elements of this class are discontinuous across these same hyperplanes and otherwise smooth. There may be an arbitrary number of singularities which may be located in all orientations and positions. In the author's unpublished thesis [3], it is then proved that ridgelets provide near-optimal representations of objects of this kind, as expected.

This is, indeed, part of a larger picture. A new notion of smoothness may be introduced leading to new functional classes that are naturally associated with ridgelets. This new notion of smoothness is nonclassical; it is discussed in [3] and briefly exposed in [7]. Full details will be provided in a separate paper.

6.2. Curved singularities. We would like to emphasize that this paper considered only linear singularities. Ridgelets are not able to efficiently represent smooth functions with curved singularities. For instance, in dimension d, consider the indicator function of the unit ball

$$f(x) = 1_{\{|x| \le 1\}},$$

and let α denote the ridgelet coefficient sequence of f. Then, [3] shows that

$$\#\{n, \text{ s.t.} \, |\alpha_n| \ge 1/n\} \ge C \, n^{2(1-1/d)}, \tag{6.1}$$

yielding partial reconstructions converging only at the rate $n^{-\frac{1}{2(d-1)}}$. We quote from [7]: "Unfortunately, the task that ridgelets must face is somewhat more difficult than the task which wavelets must face, since zero-dimensional singularities are inherently simpler objects than higher-dimensional singularities. In effect, zero-dimensional singularities are all the same—points—while a one-dimensional singularity—lying along a one-dimensional set—can be curved or straight." It is remarkable, however, that both wavelet and ridgelets, two fundamentally different systems, achieve the same degree of sparsity.

The method of localization enables us to obtain sharper approximation bounds on objects with curved singularities. The localization idea is rather straightforward and has been, for instance, previously deployed in the time frequency literature. We outline this idea in dimension 2: first, partition the unit square into small squares, and smoothly localize the function into smooth pieces supported on or near those squares; then take the ridgelet transform on each piece. This is the basis of the so-called *monoscale ridgelet transform* [5]. Again, partial reconstructions simply obtained by keeping the largest coefficients are shown to provide good approximation bounds (of higher order than wavelet or ridgelet approximations).

Further, [6] developed a new approach, namely, the *curvelet transform* that combines ideas from ridgelet analysis and wavelet analysis. In two dimensions, the curvelet transform provides optimal representations of smooth functions with twice differentiable singularities, a fact whose roots are grounded on the results presented in this paper.

Acknowledgments. I am especially grateful to David Donoho for many fruitful discussions. I would also like to thank one referee for some very helpful comments on the original version of the manuscript.

Some of the results were briefly described at the Royal Society meeting "Wavelets: a key to intermittent information?" held in London in February 1999.

AN APPROXIMATION SCHEME FOR MOTION BY MEAN CURVATURE WITH RIGHT-ANGLE BOUNDARY CONDITION*

HITOSHI ISHII† AND KATSUYUKI ISHII‡

Dedicated to the late Professor Yoshihito Tomita

Abstract. We show that the algorithm considered by Ishii [*GAKUTO Internat. Ser. Math. Sci. Appl.* 5, Gakkōtosho, Tokyo, 1995, pp. 111–127] and Ishii, Pires, and Souganidis [*J. Math. Soc. Japan,* 50 (1999), pp. 267–308] can be applied to motion by mean curvature with right-angle boundary condition.

Key words. motion by mean curvature, right-angle boundary condition, approximation scheme, viscosity solutions

1. Introduction.

In 1992, Bence, Merryman, and Osher proposed an algorithm for computing motion of a hypersurface by mean curvature (cf. [2]). It is described as follows. For a given closed set $C_0 \subset \mathcal{R}^N$, let u be a solution of the initial value problem for the heat equation

$$\left\{ \begin{array}{lll} u_t - \Delta u = 0 & \text{in} & (0, +\infty) \times \mathcal{R}^N, \\ u(0,x) = \chi_{C_0}(x) & \text{in} & \mathcal{R}^N, \end{array} \right. \tag{1.1}$$

where χ_{C_0} is the characteristic function of C_0. Fix a time step $h > 0$ and set

$$C_1 = \left\{ x \in \mathcal{R}^N \;\middle|\; u(h,x) \geqq \frac{1}{2} \right\}. \tag{1.2}$$

Next we solve (1.1) with C_0 replacing C_1 and define C_2 as the set in (1.2) with u replaced by the solution with the new initial data. Repeating this procedure, we obtain a sequence $\{C_k\}_{k \in \mathcal{N}}$ of closed subsets in $\mathcal{R}^N$. Then we set

$$C_t^h = C_k \qquad \text{if } kh \leqq t < (k+1)h \text{ and } k \in \mathcal{N} \cup \{0\}$$

for $t \geqq 0$. Letting $h \to 0$, we obtain in the limit a flow $\{M_t\}_{t \geqq 0}$ of closed subsets in $\mathcal{R}^N$ with $M_0 = C_0$, whose boundary moves by ($(n-1)$-times) mean curvature.

The convergence of this algorithm was proved by Evans [4] and Barles and Georgelin [1]. Noticing that the solution of (1.1) is given by taking the convolution with Gauss kernel and χ_{C_0}, Ishii [6] extended this algorithm to the case of general radially symmetric kernels. Ishii, Pires, and Souganidis [7] considered threshold dynamics type approximation schemes, which are also an extension of the above algorithm.

The main purpose of this paper is to show that the scheme introduced by [6] and [7] can be applied to the motion by mean curvature with right-angle boundary condition in a bounded domain. Our analysis is based on the level set approach as in [4], [6], and [7].

This paper is organized in the following way. In section 2 we recall briefly the level set approach to motion by mean curvature with right-angle boundary condition and introduce our scheme. Also, we state our main result in section 2. Section 3 is devoted to the estimates for the operator G_h. The key idea is to compare G_h with $\widetilde{G}_h$ defined in $\mathcal{R}^N$. However, our arguments are complicated because we need some estimates of the integration of $f_{\sqrt{h}}(\cdot - x)$ outside $B_N(x, \sqrt{h}R(\sqrt{h}))$. Thus we divide section 3 into two subsections. In section 3.1, we consider the case where the support of the kernel function f is compact. Thanks to the compactness of supp$f$, the arguments become easy and understandable. In section 3.2 we treat the noncompact case. We prove our main result in section 4.

2. Preliminaries and the main result.

First let us recall briefly the level set approach to motion by mean curvature with right-angle boundary condition. See Sato [8] and Giga and Sato [5] for the details.

Let $\Omega \subset \mathcal{R}^N$ be a bounded domain with C^2 boundary $\partial\Omega$ and let $g \in C(\overline{\Omega})$. We consider the initial-boundary value problem:

$$(2.1) \qquad \begin{cases} u_t + F(Du, D^2u) = 0 & \text{in} \quad (0, +\infty) \times \Omega, \\ \dfrac{\partial u}{\partial n} = 0 & \text{in} \quad (0, +\infty) \times \partial\Omega, \\ u(0, x) = g(x) & x \in \overline{\Omega}, \end{cases}$$

where $F(p, X) = -\mathrm{tr}\{(I - p \otimes p/|p|^2)X\}$ and n denotes the outer unit normal to $\partial\Omega$. Problem (2.1) is the level set equation of the mean curvature flow with right-angle boundary condition since each level set of (2.1) moves by its mean curvature in Ω and it intersects $\partial\Omega$ perpendicularly, at least formally. The above equation is degenerate parabolic and has singularities for $Du = 0$. In spite of the difficulties coming from these facts, problem (2.1) has a unique viscosity solution in $C([0, T) \times \overline{\Omega})$ for any $T > 0$. Moreover, it has been shown that, for the viscosity solution u of (2.1), the level set $\{x \in \overline{\Omega} \mid u(t, x) = c\}$ is determined by the set $\{x \in \overline{\Omega} \mid g(x) = c\}$ and is independent of the choice of g. Also, it has been shown that if $\{M_t\}_{0 \leqq t < T}$ is a flow of a closed subset of $\overline{\Omega}$ such that $\{\partial M_t\}_{0 \leqq t < T}$ is a smooth flow by mean curvature satisfying $\partial M_t \perp \partial\Omega$ for all $t \in [0, T)$ and if u is a viscosity solution of (2.1) with $\{x \in \overline{\Omega} \mid g(x) = c\} = \partial M_0$ (resp., $\{x \in \overline{\Omega} \mid g(x) \geqq c\} = M_0$), then $\{x \in \overline{\Omega} \mid u(t, x) = c\} = \partial M_t$ (resp., $\{x \in \overline{\Omega} \mid u(t, x) \geqq c\} = M_t$). Thus the family $\{x \in \overline{\Omega} \mid u(t, x) = c\}_{0 \leqq t < T}$ is often called a generalized motion by mean curvature with right-angle boundary condition.

Now we formulate an approximation scheme for motion by mean curvature with right-angle boundary condition, according to Ishii [6] and Ishii, Pires, and Souganidis [7]. Let f be a real-valued function on $\mathcal{R}^N$. We make the following assumptions.

(A.1) f is nonnegative, measurable, and radially symmetric.

(A.2) $\int_{\mathcal{R}^N} f(x)(1 + |x|^2)dx < +\infty$.

(A.3) $\int_{\mathcal{R}^{N-1}} f(\xi, 0)(1 + |\xi|^2)d\xi < +\infty$.

(A.4) Let $\{R(\rho)\}_{0<\rho<1}$ satisfy

$$R(\rho) \to +\infty, \rho R(\rho)^2 \to 0 \quad (\rho \to 0).$$

Then for any $g(\xi) = \langle A\xi, \xi\rangle + a$ ($A \in \mathcal{S}^{N-1}$, $a \in \mathcal{R}$),

$$\lim_{\rho\to 0} \sup_{0<r<\rho} \left| \int_{B_{N-1}(0,R(\rho))} f(\xi, rg(\xi))g(\xi)d\xi - \int_{\mathcal{R}^{N-1}} f(\xi, 0)g(\xi)d\xi \right| = 0.$$

We introduce the operator $G_h : C(\overline{\Omega}) \to C(\overline{\Omega})$ with $h > 0$ by

$$G_h g(x) = \sup\left\{ \lambda \in \mathcal{R} \;\middle|\; \int_\Omega f_{\sqrt{h}}(y-x)\chi_{\{g \geqq \lambda\}}(y)dy \geqq \frac{1}{2}\int_\Omega f_{\sqrt{h}}(y-x)dy \right\}$$

for $g \in C(\overline{\Omega})$. Here and in the sequel $f_{\sqrt{h}}(x) = h^{-N/2} f(x/\sqrt{h})$, $\{g \geqq \lambda\} = \{y \in \overline{\Omega} \mid g(y) \geqq \lambda\}$, and χ_A is the characteristic function of $A \subset \mathcal{R}^N$. It is easily seen that, for any g_1, g_2, $g \in C(\overline{\Omega})$,

$$G_h g_1 \leqq G_h g_2 \quad \text{if } g_1 \leqq g_2, \tag{2.2}$$

$$G_h(g+c) = G_h g + c, G_h c = c \quad \text{for all } c \in \mathcal{R}, \tag{2.3}$$

$$G_h(\theta \circ g) = \theta \circ G_h g \quad \text{for any nondecreasing function } \theta \in C(\mathcal{R}). \tag{2.4}$$

It follows from (2.2)–(2.4) that the operator G_h is contractive and nonexpansive on $C(\overline{\Omega})$.

Fix $T > 0$ and $m \in \mathcal{N}$. Let $h = T/m$ and let $g \in C(\overline{\Omega})$. Define $u^m \in C([0,T) \times \overline{\Omega})$ by

$$u^m(t,x) = G_{t-lh} \circ \underbrace{G_h \circ \cdots \circ G_h}_{l \text{ times}} g(x) \tag{2.5}$$
$$(lh \leqq t < (l+1)h, l = 0, \dots, m-1, x \in \overline{\Omega}),$$

where G_0 is the identity operator on $C(\overline{\Omega})$.

Set

$$c_N = \frac{\int_0^{+\infty} f(r)r^N dr}{2(N-1)\int_0^{+\infty} f(r)r^{N-2}dr}.$$

Under the above situation, our main result is the following.

THEOREM 2.1. *Let $g \in C(\overline{\Omega})$. Let $\{u^m\}_{m\in\mathcal{N}}$ be a sequence of functions defined by* (2.5). *Then $u^m \to u$ locally uniformly on $[0,T) \times \overline{\Omega}$ as $m \to +\infty$. Here u is a unique viscosity solution of*

$$\begin{cases} u_t + c_N F(Du, D^2u) = 0 & \text{in} \quad (0,+\infty) \times \overline{\Omega}, \\ \dfrac{\partial u}{\partial n} = 0 & \text{in} \quad (0,+\infty) \times \partial\Omega, \\ u(0,x) = g(x) & x \in \overline{\Omega}. \end{cases} \tag{2.6}$$

Examples. Let $R > 0$ and $f(r) = 1$ for $0 \leqq r \leqq R$ and $= 0$ for $r > R$. Then $c_N = R^2/\{2(N+1)\}$. Let $f(r) = \exp(-r^2/4)$. Then $c_N = 1$.

In what follows we simply denote $c_N F$ by F and set $B_M(x,r) = \{y \in \mathcal{R}^M \mid |x-y| < r\}$.

3. Estimates for G_h. To show Theorem 2.1, the following estimates play a crucial role. In what follows we always assume (A.1)–(A.4).

Lemma 3.1. *Let $\varphi \in C^2(\overline{\Omega})$, $z \in \overline{\Omega}$, and $\varepsilon > 0$.*

(1) *Assume $z \in \Omega$ and $D\varphi(z) \neq 0$. Then there exists a $\delta > 0$ such that, for all $x \in B_N(z,\delta)$ and $h \in (0,\delta]$,*

$$G_h\varphi(x) \leqq \varphi(x) + (-F(D\varphi(z), D^2\varphi(z)) + \varepsilon)h, \tag{3.1}$$

$$G_h\varphi(x) \geqq \varphi(x) + (-F(D\varphi(z), D^2\varphi(z)) - \varepsilon)h. \tag{3.2}$$

(2) *Assume $z \in \partial\Omega$ and $(\partial\varphi/\partial n)(z) > 0$. Then there exists a $\delta > 0$ such that, for all $x \in B_N(z,\delta) \cap \overline{\Omega}$ and $h \in (0,\delta]$, (3.1) holds.*

(3) *Assume $z \in \partial\Omega$ and $(\partial\varphi/\partial n)(z) < 0$. Then there exists a $\delta > 0$ such that, for all $x \in B_N(z,\delta) \cap \overline{\Omega}$ and $h \in (0,\delta]$, (3.2) holds.*

Roughly speaking, we prove this lemma as follows. For any function g in $\mathcal{R}^N$, define $\widetilde{G}_h g$ by

$$\widetilde{G}_h g(x) = \sup\left\{\lambda \in \mathcal{R} \;\middle|\; \int_{\mathcal{R}^N} f_{\sqrt{h}}(y-x)\chi_{\{g \geqq \lambda\}}(y)dy \geqq \frac{1}{2}\int_{\mathcal{R}^N} f_{\sqrt{h}}(y-x)dy\right\}.$$

Then we compare $G_h\varphi(x)$ with $\widetilde{G}_h\varphi(x)$ and use the following lemma.

Lemma 3.2 (see [6, Theorem 3.1], [7, Lemma 3.1]). *Let $\varphi \in C^2(\mathcal{R}^N)$, $z \in \mathcal{R}^N$, and $\varepsilon > 0$. Assume $D\varphi(z) \neq 0$. Then there exists a $\delta > 0$ such that, for all $x \in B_N(z,\delta)$ and $h \in (0,\delta]$,*

$$\widetilde{G}_h\varphi(x) \leqq \varphi(x) + (-F(D\varphi(z), D^2\varphi(z)) + \varepsilon)h,$$
$$\widetilde{G}_h\varphi(x) \geqq \varphi(x) + (-F(D\varphi(z), D^2\varphi(z)) - \varepsilon)h.$$

As mentioned in the introduction, we divide our consideration into two subsections. In section 3.1, we consider the case where supp$f$ is compact. In section 3.2, we treat the noncompact case.

3.1. The case where supp*f* is compact. We prove Lemma 3.1 in the case where supp$f$ is compact. For simplicity, we assume supp$f \subset \overline{B_N(0,1)}$ and that there exists a $\rho \in (0,1]$ such that

$$f(y) > 0 \quad \text{in} \quad \{y \in B_N(0,1) \mid \operatorname{dist}(y, \partial B_N(0,1)) \leqq \rho\}. \tag{3.3}$$

Let $\varphi \in C^2(\overline{\Omega})$ and $\varepsilon > 0$. Assume $z \in \Omega$ and $D\varphi(z) \neq 0$. Then there exists a $\delta > 0$ such that, for all $x \in B_N(z,\delta) \subset \Omega$ and $h \in (0,\delta]$,

$$G_h\varphi(x) = \widetilde{G}_h\varphi(x).$$

Thus Lemma 3.2 yields Lemma 3.1, part (1). In the following we assume $z \in \partial\Omega$ and $(\partial\varphi/\partial n)(z) > 0$ and prove Lemma 3.1, part (2). Lemma 3.1, part (3) can be proved similarly.

Since $\partial\Omega$ is C^2 and $\varphi \in C^2(\overline{\Omega})$, there exists an $r_0 > 0$ such that $\varphi \in C^2(B_N(z,r_0))$, and we can take a $\psi \in C^2(\mathcal{R}^{N-1})$ for which

$$y_N - z_N = \psi(y' - z') \quad \text{for all } y = (y', y_N) \in B_N(z,r_0) \cap \partial\Omega,$$
$$D'\psi(0) = 0, \quad y_N - z_N > \psi(y' - z') \quad \text{for all } y \in B_N(z,r_0) \cap \Omega,$$

where $D' = (\partial/\partial x_1, \dots, \partial/\partial x_{N-1})$. Taking r_0 smaller, if necessary, we observe

$$D_N\varphi(y) \leqq -\gamma, \quad |D'\varphi(y)| \leqq K, \quad |D'\psi(y'-z')| \leqq \varepsilon \quad \text{for all } y \in B_N(z,r_0), \tag{3.4}$$

where $D_N = \partial/\partial x_N$ and γ, $K > 0$, are independent of ε and r_0.

Moreover, we prepare some lemmas.

LEMMA 3.3. *Let $r > 0$ and let a, $b \in \mathcal{R}^{N-1}$ and $c \in \mathcal{R}$. Define*

$$P^+ = \{y \in B_N(0,r) \mid y_N > \langle b, y'\rangle + c, y_N > \langle a, y'\rangle\},$$
$$P^- = \{y \in B_N(0,r) \mid y_N > \langle b, y'\rangle + c, y_N < \langle a, y'\rangle\}.$$

Assume that $\langle a, b\rangle + 1 \neq 0$.

(1) *There exists a $\theta \in (0,1)$ depending only and continuously on a and b such that if*

$$\{y \in B_N(0,r) \mid y_N = \langle b, y'\rangle + c, y_N = \langle a, y'\rangle\} \neq \emptyset,$$

then

$$\frac{|c|}{\sqrt{|b|^2+1}} \leqq \theta r.$$

(2) *Let θ be the same as above. For each $\theta_1 \in [\theta, 1)$, if*

$$\frac{|c|}{\sqrt{|b|^2+1}} \leqq \theta_1 r,$$

then

$$\int_{P^+} f_{\sqrt{h}}(y)dy \geqq \int_{P^-} f_{\sqrt{h}}(y)dy + \int_{S^-} f_{\sqrt{h}}(y)dy,$$

where $S^- = \{y \in B_N(0,r) \mid \langle y, n\rangle > \theta_1 r\}$ and $n = (b,-1)/\sqrt{|b|^2+1}$.

Remark 3.1. If we write $n = (b,-1)/\sqrt{|b|^2+1}$, then the equation $y_N = \langle b, y'\rangle + c$ implies

$$\langle n, y\rangle + \frac{c}{\sqrt{|b|^2+1}} = 0,$$

and thus the value $-c/\sqrt{|b|^2+1}$ is the distance of the plane $y_N = \langle b, y'\rangle + c$ from the origin in the direction n, where n is the normal unit vector to the plane $y_N = \langle b, y'\rangle + c$.

Proof of Lemma 3.3. (1) Fix $\xi = (\xi', \xi_N) \in \{y \in B_N(0,r) \mid y_N = \langle a, y'\rangle, y_N = \langle b, y'\rangle + c\}$, and set

$$n = \frac{(b,-1)}{\sqrt{|b|^2+1}}, \quad t = \langle \xi, n\rangle, \quad v = \xi - tn. \tag{3.5}$$

Since $\langle \xi, (a,-1)\rangle = 0$, we get

$$0 = \langle (v+tn), (a,-1)\rangle = \langle v, (a,-1)\rangle + t\frac{\langle a, b\rangle + 1}{\sqrt{|b|^2+1}}.$$

It is seen by $|v|^2 + t^2 = |\xi|^2 \leqq r^2$ that

$$t^2 = \frac{|b|^2+1}{(\langle a, b\rangle + 1)^2}\langle v, (a,-1)\rangle^2 \leqq \frac{|b|^2+1}{(\langle a, b\rangle + 1)^2}(r^2 - t^2)(|a|^2+1)$$

and therefore,

$$t^2\left(1+\frac{(|b|^2+1)(|a|^2+1)}{(\langle a,b\rangle+1)^2}\right)\leqq r^2\frac{(|b|^2+1)(|a|^2+1)}{(\langle a,b\rangle+1)^2}.$$

Setting

$$\theta=\left(\frac{(|b|^2+1)(|a|^2+1)}{(\langle a,b\rangle+1)^2+(|b|^2+1)(|a|^2+1)}\right)^{1/2}\left(\geqq\frac{1}{\sqrt{2}}\right),$$

we have

$$0<\theta<1,\quad |t|\leqq\theta r.$$

Moreover, θ is a continuous function of a and b.

(2) For simplicity, set $h=1$. Let $\theta_1\in[\theta,1)$ and assume

$$\frac{|c|}{\sqrt{|b|^2+1}}\leqq\theta_1 r.$$

Define $S^{\pm}\subset B_N(0,r)$ by

$$S^+=\{y\in B_N(0,r)\mid\langle y,n\rangle<-\theta_1 r\},\quad S^-=\{y\in B_N(0,r)\mid\langle y,n\rangle>\theta_1 r\}.$$

Then we have

$$\mathcal{L}^N(S^+)=\mathcal{L}^N(S^-)=\alpha r^N \tag{3.6}$$

for some $\alpha>0$ depending only and continuously on θ_1. Here $\mathcal{L}^N(A)$ is the N-dimensional Lebesgue measure of a set $A\subset\mathcal{R}^N$. From part (1), we see

$$\{y\in B_N(0,r)\mid y_N=\langle a,y'\rangle, y_N=\langle b,y'\rangle+c\}\cap(S^+\cup S^-)=\emptyset.$$

Define n and t as in (3.5). By an orthogonal change of variables, we may assume that $n=(0,-1)$, so that $b=0$ and $t=-c$.

Case 1. $c\geqq 0$ (cf. Figure 3.1).

Set

$$Q^+=\{y\in B_N(0,r)\mid y_N>\langle a,y'\rangle, c<y_N<\theta_1 r\},$$
$$Q^-=\{y\in B_N(0,r)\mid y_N<\langle a,y'\rangle, c<y_N<\theta_1 r\},$$
$$R_s^+=\partial B_N(0,s)\cap Q^+,\ R_s^-\ =\partial B_N(0,s)\cap Q^-.$$

Then, by geometry it is easily observed that

$$\mathcal{S}(R_s^+)\geqq\mathcal{S}(R_s^-)\quad\text{for all } s\in(c,\theta_1 r),$$

where $\mathcal{S}(R_s^{\pm})$ denotes the surface area of $R_s^{\pm}$. Since f satisfies (A.1) and (A.2) and S^+ is congruent to S^-, using the change of variables $s=|y|$, we can compute

$$\int_{Q^+}f(y)dy=\int_c^{\theta_1 r}f(s)\mathcal{S}(R_s^+)ds\geqq\int_c^{\theta_1 r}f(s)\mathcal{S}(R_s^-)ds=\int_{Q^-}f(y)dy.$$

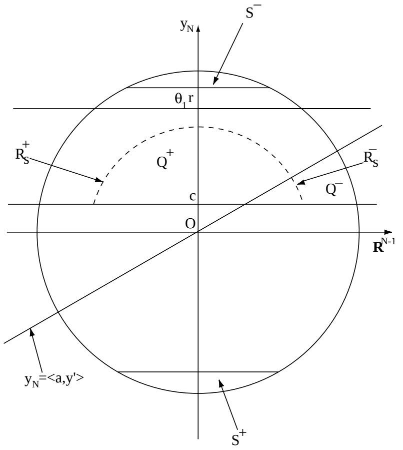

FIG. 3.1. *The case* $c \geqq 0$.

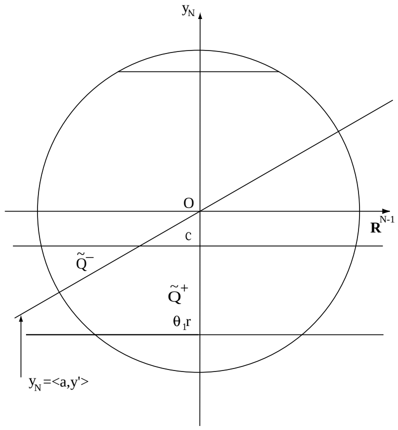

FIG. 3.2. *The case* $c < 0$.

Thus we obtain

$$\begin{aligned}\int_{P^+} f(y)dy &= \left(\int_{Q^+} + \int_{S^+}\right) f(y)dy \\ &\geqq \left(\int_{Q^-} + \int_{S^-}\right) f(y)dy = \left(\int_{P^-} + \int_{S^-}\right) f(y)dy.\end{aligned}$$

Case 2. $c < 0$ (cf. Figure 3.2).
Set

$$\begin{aligned}\widetilde{Q}^+ &= \{y \in B_N(0,r) \mid y_N > \langle a, y' \rangle, -\theta_1 r < y_N < c\}, \\ \widetilde{Q}^- &= \{y \in B_N(0,r) \mid y_N < \langle a, y' \rangle, -\theta_1 r < y_N < c\}.\end{aligned}$$

We easily see, as above, that

$$\begin{aligned}\int_{P^+} f(y)dy &= \frac{1}{2}\int_{B_N(0,1)} f(y)dy - \int_{\widetilde{Q}^+} f(y)dy \\ &\geqq \frac{1}{2}\int_{B_N(0,1)} f(y)dy - \int_{\widetilde{Q}^-} f(y)dy.\end{aligned}$$

Since

$$\int_{P^-} f(y)dy = \frac{1}{2}\int_{B_N(0,1)} f(y)dy - \int_{S^-} f(y)dy - \int_{\widetilde{Q}^-} f(y)dy,$$

we get

$$\int_{P^+} f(y)dy \geqq \int_{P^-} f(y)dy + \int_{S^-} f(y)dy. \qquad \square$$

Let $\widetilde{\lambda} = \widetilde{G}_h \varphi(x)$. Since $\varphi \in C^2(B_N(z, r_0))$, we can easily prove the following lemma.

Lemma 3.4. *There exist an $h_1 \in (0, r_0]$ and a $C_1 > 0$ independent of $x \in B_N(z, r_0)$ such that if $0 < h \leqq h_1$ and $x \in B_N(z, r_0)$, then $|\widetilde{\lambda} - \varphi(x)| \leqq C_1 h$.*

To continue, fix $C_2 > 0$ so that

$$\max_{B_{N-1}(0,r_0)} \|{D'}^2\psi\| \leqq C_2, \quad \max_{B_N(0,r_0)} \|D^2\varphi\| \leqq C_2.$$

Lemma 3.5. *There exist an $h_2 \in (0, r_0]$ and a $\theta_1 \in (0, 1)$ depending only on K, γ, C_1, and C_2 such that if $h \in (0, h_2)$ and*

$$\xi \in \{y \in B_N(x, \sqrt{h}) \mid \varphi(y) = \widetilde{\lambda}, y_N = \psi(y')\},$$

then $|\xi_N - x_N| \leqq \theta_1 \sqrt{h}$.

Proof. Using Lemma 3.4, we have

$$|\varphi(\xi) - \varphi(x)| = |\widetilde{\lambda} - \varphi(x)| \leqq C_1 h \quad (\text{for all } h \in (0, h_1)).$$

Since

$$|\varphi(\xi) - \varphi(x) - \langle D'\varphi(x), \xi' - x'\rangle - D_N\varphi(x)(\xi_N - x_N)| \leqq C_2 h, \quad D_N\varphi(x) \leqq -\gamma,$$

we get

$$\begin{aligned}\gamma|\xi_N - x_N| &\leqq |\varphi(\xi) - \varphi(x)| + |D'\varphi(x)||\xi' - x'| + C_2 h\\ &\leqq C_1 h + K\sqrt{h - |\xi_N - x_N|^2} + C_2 h.\end{aligned}$$

Hence, we see that

$$\gamma^2|\xi_N - x_N|^2 \leqq K^2(h - |\xi_N - x_N|^2) + (C_1 + C_2)^2 h^2 + 2(C_1 + C_2)h^{3/2}.$$

Thus

$$|\xi_N - x_N| \leqq \sqrt{\frac{K^2}{K^2 + \gamma^2} h + (C_1 + C_2)^2 h^2 + 2(C_1 + C_2)h^{3/2}}.$$

From this we complete the proof. □

Lemma 3.6. *There exists a $C_3 > 0$ depending only on γ, C_1, and C_2 such that if $y \in B_N(x, \sqrt{h})$ satisfies $\varphi(y) = \widetilde{\lambda}$, $h \in (0, h_1)$, and if $a = D'\varphi(x)/D_N\varphi(x)$, then $|(y_N - x_N) - \langle a, y' - x'\rangle| \leqq C_3 h$.*

Proof. Using Lemma 3.4, we observe that

$$C_1 h \geqq |\varphi(y) - \varphi(x)| = |\langle D'\varphi(x), y' - x'\rangle + D_N\varphi(x)(y_N - x_N) + O(h)|,$$

where $|O(h)| \leqq C_2 h$. Hence we have

$$|(y_N - x_N) - \langle a, y' - x'\rangle| \leqq (C_1 + C_2)h/\gamma. \qquad □$$

We are now in a position to prove Lemma 3.1, part (2). Set $\lambda = G_h\varphi(x)$ and $a \wedge b = \min\{a, b\}$.

Proof of Lemma 3.1, *part* (2). We show that there exists an $h_0 > 0$ such that $\lambda \leqq \widetilde{\lambda}$ for all $x \in B_N(z, r_0) \cap \overline{\Omega}$ and $h \in (0, h_0)$. Then we use Lemma 3.2, part (2) to obtain our desired result.

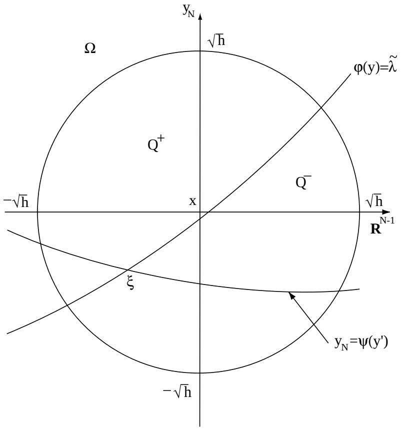

FIG. 3.3. *Case* 1.

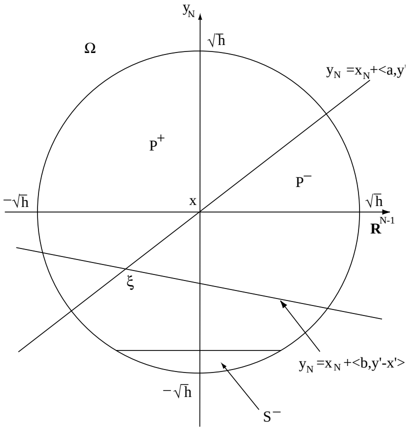

FIG. 3.4. *The sets* $P^{\pm}$ *and* S.

Define

$$Q^+ = \{y \in B_N(x, \sqrt{h}) \mid \varphi(y) < \widetilde{\lambda}, y_N > \psi(y')\},$$
$$Q^- = \{y \in B_N(x, \sqrt{h}) \mid \varphi(y) > \widetilde{\lambda}, y_N > \psi(y')\},$$
$$\widetilde{Q}^+ = \{y \in B_N(x, \sqrt{h}) \mid \varphi(y) < \widetilde{\lambda}\}, \widetilde{Q}^- = \{y \in B_N(x, \sqrt{h}) \mid \varphi(y) > \widetilde{\lambda}\}.$$

Note that $Q^{\pm} = \widetilde{Q}^{\pm} \cap \Omega$ for small $h > 0$. Here and in what follows we denote $\psi(y' - z') - z_N$ by $\psi(y')$ for simplicity. We observe

$$\int_{B_N(x,\sqrt{h})} f_{\sqrt{h}}(y-x)\chi_{\{\varphi \geqq \widetilde{\lambda}\}}(y)dy = \frac{1}{2}\int_{B_N(x,\sqrt{h})} f_{\sqrt{h}}(y-x)dy,$$

and thus

$$\int_{\widetilde{Q}^+} f_{\sqrt{h}}(y-x)dy = \int_{\widetilde{Q}^-} f_{\sqrt{h}}(y-x)dy. \tag{3.7}$$

Case 1. $\{y \in B_N(x, \sqrt{h}) \mid \varphi(y) = \widetilde{\lambda}, y_N = \psi(y')\} \neq \emptyset$ (cf. Figure 3.3).

Let $h_0 \leqq h_1 \wedge h_2$ and assume that $h \in (0, h_0)$. Fix $\xi \in \{y \in B_N(x, \sqrt{h}) \mid \varphi(y) = \widetilde{\lambda}, y_N = \psi(y')\}$. For $y' \in B_{N-1}(x', \sqrt{h})$,

$$\psi(y') = \psi(\xi') + \langle D'\psi(\xi'), y' - \xi'\rangle + O(h),$$

where $|O(h)| \leqq C_2 h$. Hence, if $y \in B_N(x, \sqrt{h})$ satisfies $y_N = \psi(y')$, then

$$|(y_N - \xi_N) - \langle D'\psi(\xi'), y' - \xi'\rangle| \leqq C_2 h. \tag{3.8}$$

Set

$$a(x) = \frac{D'\varphi(x)}{D_N\varphi(x)}, \quad b(\xi') = D'\psi(\xi'), \quad c(x;\xi) = \xi_N - x_N - \langle b(\xi'), \xi' - x'\rangle$$

for $x \in B_N(z, r_0)$ and $\xi \in \{y \in B_N(x, \sqrt{h}) \mid \varphi(y) = \widetilde{\lambda}, y_N = \psi(y')\}$. We observe that if $h \in (0, h_0)$, then

$$|\langle a(x), b(\xi')\rangle + 1| \geqq 1 - \frac{\varepsilon K}{\gamma}, \quad \frac{|c(x;\xi)|}{\sqrt{|b(\xi')|^2 + 1}} \leqq (\theta_1 + \varepsilon)\sqrt{h},$$

where θ_1 is from Lemma 3.5. We have used $|b(\xi')| = |D'\psi(\xi')| \leqq \varepsilon$ in (3.4). Letting $\theta_2 = (1+\theta_1)/2$ and $\varepsilon_0 = \min\{\gamma/K, \theta_2 - \theta_1\}/2$, for any $\varepsilon \in (0, \varepsilon_0)$, we get

$$|\langle a(x), b(\xi')\rangle + 1| \geqq \frac{1}{2}, \quad \frac{|c(x;\xi)|}{\sqrt{|b(\xi')|^2+1}} \leqq \theta_2\sqrt{h}.$$

For any $x \in B_N(z, r_0)$ and $\xi \in \{y \in B_N(x, \sqrt{h}) \mid \varphi(y) = \widetilde{\lambda}, y_N = \psi(y')\}$, put

$$a = a(x), \quad b = b(\xi'), \quad c = c(x;\xi), \quad \widetilde{n} = \frac{(b,-1)}{\sqrt{|b|^2+1}}.$$

In view of Lemma 3.3, part (2), we have

$$\int_{P^+} f_{\sqrt{h}}(y-x)dy \geqq \int_{P^-} f_{\sqrt{h}}(y-x)dy + \int_{S^-} f_{\sqrt{h}}(y-x)dy,$$

where

$$\begin{aligned}
P^+ &= \{y \in B_N(x,\sqrt{h}) \mid y_N > x_N + \langle b, y'-x'\rangle + c, y_N > x_N + \langle a, y'-x'\rangle\},\\
P^- &= \{y \in B_N(x,\sqrt{h}) \mid y_N > x_N + \langle b, y'-x'\rangle + c, y_N < x_N + \langle a, y'-x'\rangle\},\\
S^- &= \{y \in B_N(x,\sqrt{h}) \mid \langle y-x, \widetilde{n}\rangle > \theta_1\sqrt{h}\}
\end{aligned}$$

(cf. Figure 3.4). Note that the estimate of $\int_{S^-} f_{\sqrt{h}}(y-x)dy$ is independent of $x \in B_N(z, r_0)$, $\varepsilon \in (0, \varepsilon_0)$, and $h > 0$ because of (3.3) and (3.6) with $r = \sqrt{h}$. We easily see, by Lemma 3.6 and (3.8), that

$$\begin{aligned}
&\{y \in B_N(x,\sqrt{h}) \mid \varphi(y) = \widetilde{\lambda}\}\\
&\quad \subset \{y \in B_N(x,\sqrt{h}) \mid |y_N - x_N - \langle a, y'-x'\rangle| \leqq C_3 h\} \equiv T_1,\\
&B_N(x,\sqrt{h}) \cap \partial\Omega\\
&\quad \subset \{y \in B_N(x,\sqrt{h}) \mid |y_N - x_N - \langle b, y'-x'\rangle - c| \leqq C_2 h\} \equiv T_2.
\end{aligned}$$

Moreover, we compute

$$\begin{aligned}
\int_{Q^+} f_{\sqrt{h}}(y-x)dy = \int_{\widetilde{Q}^+\cap\Omega} f_{\sqrt{h}}(y-x)dy \geqq \int_{P^+} f_{\sqrt{h}}(y-x)dy - \int_{T_1} f_{\sqrt{h}}(y-x)dy,\\
\int_{Q^-} f_{\sqrt{h}}(y-x)dy = \int_{\widetilde{Q}^-\cap\Omega} f_{\sqrt{h}}(y-x)dy \leqq \int_{P^-} f_{\sqrt{h}}(y-x)dy + \int_{T_2} f_{\sqrt{h}}(y-x)dy,
\end{aligned}$$

and therefore we have

$$\int_{Q^+} f_{\sqrt{h}}(y-x)dy \geqq \int_{Q^-} f_{\sqrt{h}}(y-x)dy + \int_{S^-} f_{\sqrt{h}}(y-x)dy - \left(\int_{T_1} + \int_{T_2}\right) f_{\sqrt{h}}(y-x)dy.$$

By Lemma 3.6 we have $\mathcal{L}^N(T_1) \leqq C_4 h^{(N+1)/2}$ for some $C_4 > 0$. The smoothness of $\partial\Omega$ yields $\mathcal{L}^N(T_2) \leqq C_5 h^{(N+1)/2}$ for some $C_5 > 0$. Changing the variables $(y-x)/\sqrt{h} \to y$, we observe

$$\begin{aligned}
&\left(\int_{T_1} + \int_{T_2}\right) f_{\sqrt{h}}(y-x)dy = \left(\int_{T_1(h,x)} + \int_{T_2(h,x)}\right) f(y)dy,\\
&\mathcal{L}^N(T_1(h,x)) \leqq C_4\sqrt{h}, \quad \mathcal{L}^N(T_2(h,x)) \leqq C_5\sqrt{h},\\
&(T_i(h,x) = \{(y-x)/\sqrt{h} \mid y \in T_i\}, i = 1, 2).
\end{aligned}$$

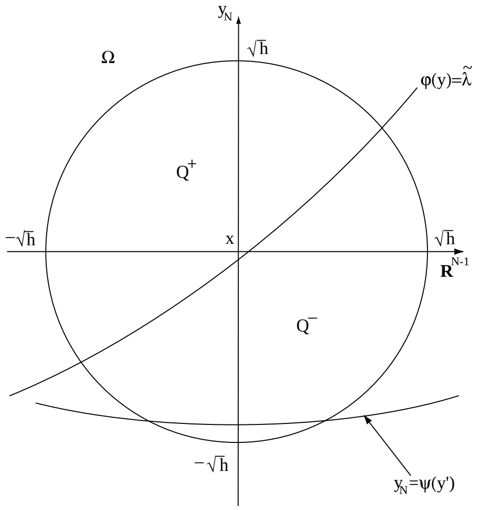

FIG. 3.5. *Case* 2.

Hence, taking $h_0 > 0$ smaller, if necessary, we obtain $\lambda \leqq \widetilde{\lambda}$ for any $x \in B_N(z, r_0)$ and $h \in (0, h_0)$.

Case 2. $\{y \in B_N(x, \sqrt{h}) \mid \varphi(y) = \widetilde{\lambda}\} \subset \Omega$ (cf. Figure 3.5).

In this case we have

$$\widetilde{Q}^+ = Q^+, \quad Q^- \subset \widetilde{Q}^-,$$

and hence we get $\lambda \leqq \widetilde{\lambda}$ by (3.7).

Case 3. $\{y \in B_N(x, \sqrt{h}) \mid \varphi(y) = \widetilde{\lambda}\} \subset \Omega^c$.

In this case we have $Q^- = \emptyset$, and hence $\lambda \leqq \widetilde{\lambda}$ is trivial.

Therefore, we have completed the proof. □

Remark 3.2. The assumptions we have actually used are only (A.1) and $\int_{\mathcal{R}^N} f(y)dy < +\infty$ because we have assumed that supp$f$ is compact. The other assumptions play important roles in the next subsection.

3.2. The case where supp*f* is not compact. By (A.2) there exist a $\rho_1 > 0$, $\{R(\rho)\}_{0<\rho<\rho_1}$ and an $\omega \in C(\mathcal{R}^+; \mathcal{R}^+)$ such that

$$\begin{aligned} &\int_{B_N(0,R(\sqrt{h}))^c} f(y)dy \leqq \sqrt{h}\omega(R(\sqrt{h})) \quad (h \in (0, \rho_1)), \\ &\omega(R) \to 0 \ (R \to +\infty), \quad R(\rho) \to +\infty, \quad \rho R(\rho)^2 \to 0 \quad (\rho \to 0) \end{aligned} \tag{3.9}$$

(cf. Ishii, Pires, and Souganidis [7]).

Moreover, (A.4) implies that, for each $\varepsilon > 0$, there exists an $\rho_2 = \rho_2(\varepsilon) > 0$ such that for any $g(\xi) = \langle A\xi, \xi \rangle + a$ $(A \in \mathcal{S}^{N-1},\ a \in \mathcal{R})$,

$$\sup_{0<r<\rho_2} \left| \int_{B_{N-1}(0,R(\rho_2))} f(y', rg(y'))g(y')dy' - \int_{\mathcal{R}^{N-1}} f(y', 0)g(y')dy' \right| < \varepsilon. \tag{3.10}$$

For $r > 0$, define

$$\widetilde{S}_h^r\varphi(x) = \int_{B_N(x,\sqrt{h}r)} f_{\sqrt{h}}(x-y)\varphi(y)dy,$$
$$\widetilde{G}_h^r\varphi(x) = \sup\left\{\lambda \in \mathcal{R} \;\middle|\; \widetilde{S}_h^r\chi_{\{\varphi \geqq \lambda\}}(x) \geqq \frac{1}{2}\int_{B_N(x,\sqrt{h}r)} f_{\sqrt{h}}(y-x)dy\right\},$$

and let $\widetilde{\mu}(r) = \widetilde{G}_h^r\varphi(x)$.

Fix $\varphi \in C^2(\overline{\Omega})$ and $\varepsilon > 0$. Assume $z \in \overline{\Omega}$ and $D\varphi(z) \neq 0$. Then there exists an $r_1 > 0$ such that $\varphi \in C^2(B_N(z,r_1))$ and $D\varphi \neq 0$ in $B_N(z,r_1)$. We can easily verify

$$\int_{B_N(x,\sqrt{h}r)} f_{\sqrt{h}}(y-x)\chi_{\{\varphi \geqq \widetilde{\mu}(r)\}}(y)dy = \frac{1}{2}\int_{B_N(x,\sqrt{h}r)} f_{\sqrt{h}}(y-x)dy \tag{3.11}$$

for all $r > 0$ satisfying $\sqrt{h}r < r_1$.

For any $h \in (0,\rho_1)$, set $\widetilde{\mu} = \widetilde{\mu}(R(\sqrt{h}))$. As to the estimates for $\widetilde{\mu}$ and $\widetilde{\lambda}$, we have the following lemmas.

LEMMA 3.7. *There exist an $h_1 \in (0,r_1]$ and a $C_1 > 0$ independent of $x \in B_N(z,r_1) \cap \overline{\Omega}$ such that if $x \in B_N(z,r_1)$ and $h \in (0,h_1)$, then $|\widetilde{\lambda} - \varphi(x)|$, $|\widetilde{\mu} - \varphi(x)| \leqq C_1 h$.*

This lemma can be shown easily, so we omit the proof.

LEMMA 3.8. *There exist an $\varepsilon_1 > 0$ and a $C_2 > 0$ such that, for any $\varepsilon \in (0,\varepsilon_1)$, there exists an $h_2 > 0$ such that $|\widetilde{\lambda} - \widetilde{\mu}| \leqq C_2\varepsilon h$ for all $h \in (0,h_2)$.*

Proof. It is easily seen by the change of variables $(y-x)/\sqrt{h} \to y$, (3.11), and (3.9) that

(3.12)
$$\begin{aligned}
&\int_{\mathcal{R}^N} f_{\sqrt{h}}(y-x)\chi_{\{\varphi \geqq \widetilde{\mu} - C_2\varepsilon h\}}(y)dy \\
&\quad = \int_{\mathcal{R}^N} f(y)\chi_{\{\varphi \geqq \widetilde{\mu} - C_2\varepsilon h\}}(x - \sqrt{h}y)dy \\
&\quad \geqq \int_{B_N(0,\sqrt{h}R(\sqrt{h}))} f(y)\chi_{\{\varphi \geqq \widetilde{\mu}\}}(x - \sqrt{h}y)dy \\
&\qquad + \int_{B_N(0,\sqrt{h}R(\sqrt{h}))} f(y)\chi_{\{\mu > \varphi \geqq \widetilde{\mu} - C_2\varepsilon h\}}(x - \sqrt{h}y)dy \\
&\quad = \frac{1}{2}\int_{B_N(0,\sqrt{h}R(\sqrt{h}))} f(y)dy + \int_{B_N(0,\sqrt{h}R(\sqrt{h}))} f(y)\chi_{\{\mu > \varphi \geqq \widetilde{\mu} - C_2\varepsilon h\}}(x - \sqrt{h}y)dy \\
&\quad \geqq \frac{1}{2}\int_{\mathcal{R}^N} f(y)dy - \sqrt{h}\omega(R(\sqrt{h})) \\
&\qquad + \int_{B_N(0,\sqrt{h}R(\sqrt{h}))} f(y)\chi_{\{\mu > \varphi \geqq \widetilde{\mu} - C_2\varepsilon h\}}(x - \sqrt{h}y)dy
\end{aligned}$$

for all $h \in (0,\rho_1 \wedge \rho_2)$.

We take a continuous family $\{U(x)\}_{x \in B_N(z,r_1)} \subset \mathcal{O}(N)$ satisfying

$$U(x)\left(\frac{D\varphi(x)}{|D\varphi(x)|}\right) = e_N \quad \text{for all } x \in B_N(z,r_1).$$

By the same calculations as in [7], we observe that there exists a $\delta_1 > 0$ such that if

$$\varphi(x - \sqrt{h}U^*(x)y) \geqq \widetilde{\mu} \text{ (resp., } \varphi(x - \sqrt{h}U^*(x)y) \leqq \widetilde{\mu}),$$

then

$$y_N \leqq \frac{\sqrt{h}}{|D\varphi(z)|}\left(\frac{\varphi(x)-\widetilde{\mu}}{h} + \varepsilon + \frac{1}{2}\langle P^*U(z)D^2\varphi(z)PU^*(z)Py', y'\rangle + \varepsilon|y'|^2\right)$$

$$\Bigg(\text{resp.,}$$

$$y_N \geqq \frac{\sqrt{h}}{|D\varphi(z)|}\left(\frac{\varphi(x)-\widetilde{\mu}}{h} + \varepsilon + \frac{1}{2}\langle P^*U(z)D^2\varphi(z)PU^*(z)Py', y'\rangle + \varepsilon|y'|^2\right)\Bigg)$$

for $\sqrt{h}y \in B_N(0,\delta_1)$ and $x \in B_N(z,r_1)$. Here P denotes the $N \times (N-1)$ matrix, whose (i,j)th entries are 1 if $i = j$ and 0 if $i \neq j$. A similar inequality to the one above holds for $\varphi(x - \sqrt{h}U^*(x)y) \leqq (\geqq)\widetilde{\mu} - C_2\varepsilon h$. Here we take δ_1 and r_1 smaller, if necessary.

For simplicity, set $U(z) = I$ and $|D\varphi(z)| = 1$. Then we see

$$\begin{aligned}
&\int_{B_N(0,R(\sqrt{h}))} f(y)\chi_{\{\widetilde{\mu}>\varphi\geqq\widetilde{\mu}-C_2\varepsilon h\}}(x-\sqrt{h}y)dy \\
&\geqq \int_{B_{N-1}(0,R(\rho_2))}\int_{\sqrt{h}(\psi_1(y')+\varepsilon(1+|y'|^2))}^{\sqrt{h}(\psi_1(y')-\varepsilon(1+|y'|^2)+C_2\varepsilon)} f(y',y_N)dy_Ndy' \\
&\equiv J,
\end{aligned}$$

where $\psi_1(y') = \langle P^*D^2\varphi(z)Py', y'\rangle/2$.

By (3.10) we observe

$$J \geqq \varepsilon\sqrt{h}\left(-2 - 2\int_{\mathcal{R}^{N-1}} f(y',0)|y'|^2dy' + (C_2 - 2)\int_{\mathcal{R}^{N-1}} f(y',0)dy'\right).$$

Thus, taking a $C_2 > 0$ large and an $h_2 \in (0, \rho_1 \wedge \rho_2)$ small, we have

$$\int_{B_N(0,R(\sqrt{h}))} f(y)\chi_{\{\widetilde{\mu}>\varphi\geqq\widetilde{\mu}-C_2\varepsilon h\}}(x-\sqrt{h}y)dy \geqq \varepsilon\sqrt{h} \geqq \sqrt{h}\omega(R(\sqrt{h}))$$

for all $h \in (0, h_2)$. Thus, from (3.12), we conclude $\widetilde{\lambda} \geqq \widetilde{\mu} - C_2\varepsilon h$. Since we can show $\widetilde{\lambda} \leqq \widetilde{\mu} + C_2\varepsilon h$ by a similar argument to the above, we have completed the proof. □

Consider the case $z \in \Omega$. Then there exists a $\delta_2 > 0$ such that

$$B_N(z,\delta_2) \subset\subset \Omega,\ D\varphi(x) \neq 0 \quad (\text{for all } x \in B_N(z,\delta_2)).$$

Replacing ε_1, $h_2 > 0$ with smaller ones, if necessary, we see that $|\widetilde{\lambda} - \widetilde{\mu}|$, $|\lambda - \widetilde{\mu}| \leqq C_2\varepsilon h$, for all $\varepsilon \in (0,\varepsilon_1)$ and $h \in (0,h_2)$. Hence we have $|\lambda - \widetilde{\lambda}| \leqq 2C_4\varepsilon h$, and using Lemma 3.2 and this, we can prove Lemma 3.1, part (1). Therefore, we assume $z \in \partial\Omega$ and $(\partial\varphi/\partial n)(z) > 0$ and show Lemma 3.1, part (2). Lemma 3.1, part (3) can be proved similarly. We use the same notations r_0, ψ, D', ..., as those in the previous subsection.

It is easily seen that Lemma 3.3 holds. Moreover, we have the following lemmas by similar arguments to the proofs of Lemmas 3.5 and 3.6. Let $C_3 > 0$ satisfy $\max_{B_{N-1}(0,r_0)} \|D'^2\psi\| \leqq C_3$ and $\max_{B_N(0,r_0)} \|D^2\varphi\| \leqq C_3$.

Lemma 3.9. *There exist an $h_3 > 0$ and a $\theta_1 \in (0,1)$ depending only on γ, K, C_2, and C_3 such that if $h \in (0, h_3)$ and*

$$\xi \in \{y \in B_N(x, \sqrt{h}R(\sqrt{h})) \mid \varphi(y) = \widetilde{\mu}, y_N = \psi(y')\},$$

then $|\xi_N - x_N| \leqq \theta_1 \sqrt{h}R(\sqrt{h})$.

Lemma 3.10. *There is a $C_4 > 0$ depending only on γ, C_1, and C_3 such that if $\widetilde{\mu} = \widetilde{G}_h\varphi(x)$, $y \in B_N(x, \sqrt{h}R(\sqrt{h}))$, satisfies $\varphi(y) = \widetilde{\mu}$, $h \in (0, h_1)$, and $a = D'\varphi(x)/D_N\varphi(x)$, then $|(y_N - x_N) - \langle a, y' - x'\rangle| \leqq C_4 hR(\sqrt{h})^2$.*

To estimate the integration of $f_{\sqrt{h}}(\cdot - x)$ in Ω^c, we need the following lemmas.

Lemma 3.11. *There exists a $C_5 > 0$ depending only on γ, C_1, and C_3 for which*

$$\sup_{\substack{y \in B_N(x, \sqrt{h}R(\sqrt{h})) \cap \{\varphi(y) = \widetilde{\mu}\} \\ x \in B_N(z, r_0)}} \left\langle \frac{D\varphi(x)}{|D\varphi(x)|}, y - x \right\rangle \leqq C_5 hR(\sqrt{h})^2 \quad \textit{for all } h \in (0, h_1).$$

This lemma can be shown easily, so we omit the proof.

Lemma 3.12. *Let $0 < s < r$. Let $a \in \mathcal{R}^N$ satisfy $\langle a, e_N\rangle < 0$ and let $b \in \mathcal{R}^N$ be the projection of a to $\{y \in \mathcal{R}^N \mid \langle y, e_N\rangle = 0\}$. Assume $b \neq 0$. For $\alpha > 0$, define*

$$\begin{aligned} Q &= \{y \in B_N(0, r) \mid \langle a, y\rangle \leqq 0, |y_N - s| \leqq \alpha\}, \\ R &= \{y \in B_N(0, r) \cap B_N(0, s + \alpha)^c \mid \langle a, y\rangle \geqq 0, \langle b, y\rangle \leqq 0\}. \end{aligned}$$

Then there exists an $\alpha_0 > 0$ such that, for any $\alpha \in (0, \alpha_0)$,

$$\int_Q f(y)dy \leqq \int_R f(y)dy.$$

Proof. Take $\alpha_0 > 0$ so small that, for $\alpha \in (0, \alpha_0)$,

$$\{y \in Q \mid \langle y, e_N\rangle \geqq -\alpha\} = \emptyset, \quad \operatorname{dist}(0, Q \cup R) \geqq \frac{1}{2}s.$$

We introduce the polar coordinate system

$$y = \frac{t}{\sqrt{1 + \eta^2}}(\xi, \eta) \quad (t \geqq 0, \eta \in \mathcal{R}, \xi \in S^{N-2}).$$

Take $\xi_0 \in S^{N-2}$ and define $\eta_0 < 0$ by $\langle a, (\xi_0, \eta_0)\rangle = 0$. Let $s_1 \in (s + \alpha, r)$ such that $\frac{s_1\eta_0}{\sqrt{1+\eta_0^2}} - s = \alpha$. Moreover, define η_1, $\eta_2 < 0$, $(\eta_0 < \eta_2 < \eta_1 < 0)$, by

$$\frac{t\eta_1}{\sqrt{1 + \eta_1^2}} - s = \alpha, \quad \frac{t\eta_2}{\sqrt{1 + \eta_2^2}} - s = -\alpha$$

for each $t \in [s_1, r]$. By the choice of a and α_0, we get $\sup_{t \in [s_1, r]} |\eta_1 - \eta_2| \leqq C_6\alpha$ for $C_6 > 0$ independent of $\alpha \in (0, \alpha_0)$. Therefore,

$$\begin{aligned} \int_Q f(y)dy &= \int_{s_1}^{r} \int_{S_1^{N-2}} \int_{\eta_2}^{\eta_1} f(t)t^{N-1} \frac{1}{(1 + \eta^2)^{N/2}} d\eta d\xi dt \\ &\leqq C_6\alpha \int_{s_1}^{r} \int_{S_1^{N-2}} f(t)t^{N-1} d\xi dt, \end{aligned} \tag{3.13}$$

where $S_1^{N-2} = \{y \in S^{N-2} \mid \langle a, y\rangle \leqq 0\}$.

On the other hand, it is easily observed that

$$\int_R f(y)dy = \int_{s+\alpha}^{r} \int_{S_1^{N-2}} \int_{-\infty}^{\eta_0} f(t)t^{N-1} \frac{1}{(1+\eta^2)^{N/2}} d\eta d\xi dt.$$

Thus, taking $\alpha_0 > 0$ smaller, if necessary, by (3.13) and this equality, we obtain our desired result for all $\alpha \in (0, \alpha_0)$. □

LEMMA 3.13. *Let $0 < s < r$ and let a, $b \in \mathcal{R}^N$, be the same as in the above lemma. Define*

$$\widetilde{Q} = \{y \in B_N(0,r) \mid \langle a, y\rangle \leqq 0, y_N \leqq -(s+\alpha)\},$$
$$\widetilde{R} = \{y \in B_N(0,r) \mid \langle a, y\rangle \geqq 0, \langle b, y\rangle \geqq 0, y_N \leqq -(s+\alpha)\}.$$

Then

$$\int_{\widetilde{Q}} f(y)dy \leqq \int_{\widetilde{R}} f(y)dy$$

for all $\alpha > 0$.

Proof. Let $\widetilde{Q}_t = \partial B_N(0,t) \cap \widetilde{Q}$ and $\widetilde{R}_t = \partial B_N(0,t) \cap \widetilde{R}$. Then it is easily seen that $\mathcal{S}(\widetilde{Q}_t) \leqq \mathcal{S}(\widetilde{R}_t)$ for all $t \in [s+\alpha, r]$. Here $\mathcal{S}(A)$ denotes the area for a surface $A \subset \mathcal{R}^N$. Thus, changing the variables $t = |y|$, we have

$$\int_{\widetilde{Q}} f(y)dy = \int_{s+\alpha}^{r} f(t)\mathcal{S}(\widetilde{Q}_t)dt \leqq \int_{s+\alpha}^{r} f(t)\mathcal{S}(\widetilde{R}_t)dt = \int_{\widetilde{R}} f(y)dy. \qquad \square$$

We are now in a position to prove Lemma 3.1, part (2).

Proof of Lemma 3.1, *part* (2). It suffices to show that there exist a $C > 0$ and an $\varepsilon_0 > 0$ such that, for any $\varepsilon \in (0, \varepsilon_0)$, there exists an $h_0 > 0$ such that

$$\lambda \leqq \widetilde{\lambda} + C\varepsilon h \quad (\text{for all } x \in B_N(z, r_0) \cap \overline{\Omega}, h \in (0, h_0)).$$

Once we have the above inequality, by using Lemma 3.2 and this inequality, we obtain our desired result.

Case 1. $\{y \in B_N(x, \sqrt{h}R(\sqrt{h})) \mid \varphi(y) = \widetilde{\mu}\} \cap \partial\Omega \neq \emptyset$.

We may assume $R(\sqrt{h}) \geqq R_1 = R(\rho_1/2)$ for all $h \in (0, \rho_1^2/4)$.

Subcase 1-1. $\mathrm{dist}(x, \partial\Omega) \leqq \sqrt{h}R_1$.

Lemma 3.3 holds with $r = \sqrt{h}R(\sqrt{h})$. Let θ_1 and S^- be the same as in Lemma 3.3. By a similar argument in Case 1 in section 3.1, there exists an $\varepsilon_1 > 0$ such that

$$\int_{S^-} f_{\sqrt{h}}(y-x)dy \geqq \int_{B_N(x, \sqrt{h_1/2}R_1 \cap \{\langle y,n\rangle \geqq \theta_1 R(\rho_1/2)\}} f(y)dy > 0$$

for all $h \in (0, \rho_1^2/4)$, $x \in B_N(z, r_0)$, and $\varepsilon \in (0, \varepsilon_1)$. Thus we have

$$\begin{aligned} &\int_\Omega f_{\sqrt{h}}(y-x)\chi_{\{\varphi \geqq \widetilde{\mu}\}}(y)dy - \sqrt{h}\omega(R(\sqrt{h})) + \int_{S^-} f_{\sqrt{h}}(y-x)dy \\ &\quad \leqq \int_{\Omega \cap B_N(x, \sqrt{h}R(\sqrt{h}))} f_{\sqrt{h}}(y-x)\chi_{\{\varphi \geqq \widetilde{\mu}\}}(y)dy + \int_{S^-} f_{\sqrt{h}}(y-x)dy = *. \end{aligned}$$

A similar argument in the previous subsection yields

$$\begin{aligned} * &\leqq \int_{\Omega \cap B_N(x, \sqrt{h}R(\sqrt{h}))} f_{\sqrt{h}}(y-x)\chi_{\{\varphi < \widetilde{\mu}\}}(y)dy + \left(\int_{T_1} + \int_{T_2}\right) f_{\sqrt{h}}(y-x)dy \\ &\leqq \int_\Omega f_{\sqrt{h}}(y-x)\chi_{\{\varphi < \widetilde{\mu}\}}(y)dy + \left(\int_{T_1} + \int_{T_2}\right) f_{\sqrt{h}}(y-x)dy, \end{aligned}$$

where T_1 and T_2 are defined by

$$T_1 = \{y \in B_N(x, \sqrt{h}R(\sqrt{h})) \mid |y_N - x_N - \langle a, y' - x' \rangle| \leqq C_3 h R(\sqrt{h})^2\},$$
$$T_2 = \{y \in B_N(x, \sqrt{h}R(\sqrt{h})) \mid |y_N - x_N - \langle b, y' - x' \rangle - c| \leqq C_2 h R(\sqrt{h})^2\},$$
$$\left(a = \frac{D'\varphi(x)}{D_N\varphi(x)}, b = D'\psi(\xi'), c = \xi_N - x_N - \langle b, \xi' - x' \rangle \right).$$

By similar calculations to the proof of Lemma 3.8, we get

$$\int_{T_1} f_{\sqrt{h}}(y - x)dy \leqq C_6 \sqrt{h} R(\sqrt{h})^2$$

for some $C_6 > 0$. On the other hand, we easily see that

$$\int_{T_2 \cap B_N(x, \sqrt{h}R_1)} f_h(y - x)dy \leqq \widetilde{\omega}(h)$$

for some $\widetilde{\omega} \in C(\mathcal{R}^+; \mathcal{R}^+)$ with $\widetilde{\omega}(0) = 0$. Using a similar argument to the proof of Lemma 3.12, we have

$$\int_{T_2 \cap B_N(x, \sqrt{h}R_1)^c} f_h(y - x)dy \leqq C_7 \sqrt{h} R(\sqrt{h})^2$$

for some $C_7 > 0$. Note that C_6, C_7 are independent of ε, $h > 0$, and $x \in B_N(z, r_0)$ and that $\widetilde{\omega}$ is independent of $\varepsilon > 0$ and $x \in B_N(z, r_0)$. Therefore, we can take $h_4 \in (0, \rho_1^2/4)$ to satisfy

$$\int_{S^-} f_{\sqrt{h}}(y - x)dy \geqq \sqrt{h}\omega(R(\sqrt{h})) + \left(\int_{T_1} + \int_{T_2} \right) f_{\sqrt{h}}(y - x)dy$$

for all $h \in (0, h_4)$. Then we have $\lambda \leqq \widetilde{\mu} \leqq \widetilde{\lambda} + C_2 \varepsilon h$ for all $h \in (0, h_4)$.

Subcase 1-2. $\operatorname{dist}(x, \partial\Omega) > \sqrt{h}R_1$.

Lemma 3.11 yields that, for some $h_5 = h_5(R_1, \gamma) > 0$,

$$\{y \in \Omega^c \mid \varphi(y) \leqq \widetilde{\mu}\} \subset \left\{ y \in \mathcal{R}^N \;\middle|\; \left\langle \frac{D\varphi(x)}{|D\varphi(x)|}, y - x \right\rangle \leqq 1 \right\}$$

for all $x \in B_N(z, r_0) \cap \overline{\Omega}$ and $h \in (0, h_5)$). Then, for each $x \in B_N(z, r_0) \cap \overline{\Omega}$, we can choose a unit vector $a = a(x, R_1) \in \mathcal{R}^N$ such that

$$\langle a, n(z_x) \rangle \geqq \frac{1}{2} \inf_{y \in B_N(z, r_0) \cap \overline{\Omega}} \left\langle \frac{D\varphi(y)}{|D\varphi(y)|}, n(z_y) \right\rangle,$$
$$\{y \in \Omega^c \mid \varphi(y) \leqq \widetilde{\mu}\} \subset \{y \in \mathcal{R}^N \mid \langle a, y - x \rangle \leqq 0\},$$

where $z_x \in \partial\Omega$ is a unique point satisfying $\operatorname{dist}(x, \partial\Omega) = |x - z_x|$. On the other hand, we observe that there exists an $h_6 > 0$ such that

$$\partial\Omega \cap B_N(x, \sqrt{h}R(\sqrt{h})) \subset \{y \in B_N(x, \sqrt{h}R(\sqrt{h})) \mid \langle a, y - x \rangle \leqq 0, |y_N - z_{x,N}| \leqq C_8 h R(\sqrt{h})^2\}$$

for all $h \in (0, h_6)$, and $C_8 > 0$ is independent of $x \in B_N(z, r_0)$, ε, $h > 0$, and $x \in B_N(z, r_0)$. Define

$$\begin{aligned}
Q &= \{y \in B_N(x, \sqrt{h}R(\sqrt{h})) \mid \langle a, y-x\rangle \leqq 0, |y_N - z_{x,N}| \leqq C_8 hR(\sqrt{h})^2\},\\
R &= \{y \in B_N(x, \sqrt{h}R(\sqrt{h})) \cap B_N(x, \operatorname{dist}(x, \partial\Omega) + C_8\sqrt{h}R(\sqrt{h}))^c\\
&\qquad \mid \langle a, y-x\rangle \geqq 0, \langle b, y-x\rangle \leqq 0\},\\
\widetilde{Q} &= \{y \in B_N(x, \sqrt{h}R(\sqrt{h})) \cap B_N(x, \operatorname{dist}(x, \partial\Omega) + C_8\sqrt{h}R(\sqrt{h}))^c\\
&\qquad \mid \langle a, y-x\rangle \leqq 0\},\\
\widetilde{R} &= \{y \in B_N(x, \sqrt{h}R(\sqrt{h})) \cap B_N(x, \operatorname{dist}(x, \partial\Omega) + C_8\sqrt{h}R(\sqrt{h}))^c\\
&\qquad \mid \langle a, y-x\rangle \geqq 0, \langle b, y-x\rangle \geqq 0\}.
\end{aligned}$$

Then applying Lemmas 3.12 and 3.13, we have, for some $h_7 > 0$,

$$\begin{aligned}
&\int_{\Omega^c \cap B_N(x, \sqrt{h}R(\sqrt{h}))} f_{\sqrt{h}}(y-x)\chi_{\{\varphi < \widetilde{\mu}\}}(y)dy \leqq \left(\int_Q + \int_{\widetilde{Q}}\right) f(y)dy\\
&\quad \leqq \left(\int_R + \int_{\widetilde{R}}\right) f(y)dy = \int_{\Omega^c \cap B_N(x, \sqrt{h}R(\sqrt{h}))} f_{\sqrt{h}}(y-x)\chi_{\{\varphi \geqq \widetilde{\mu}\}}(y)dy
\end{aligned}$$

for all $h \in (0, h_7)$. Therefore, there exists a $C_9 > 0$ independent of ε, $h > 0$, and $x \in B_N(z, r_0)$ such that

$$\begin{aligned}
&\int_\Omega f_{\sqrt{h}}(y-x)\chi_{\{\varphi \geqq \widetilde{\mu} + C_9\varepsilon h\}}(y)dy + \varepsilon\sqrt{h} - \sqrt{h}\omega(R(\sqrt{h}))\\
&\quad \leqq \int_{\Omega \cap B_N(x, \sqrt{h}R(\sqrt{h}))} f_{\sqrt{h}}(y-x)\chi_{\{\varphi \geqq \widetilde{\mu}\}}(y)dy\\
&\quad = \int_{B_N(x, \sqrt{h}R(\sqrt{h}))} f_{\sqrt{h}}(y-x)\chi_{\{\varphi \geqq \widetilde{\mu}\}}(y)dy\\
&\qquad - \int_{\Omega^c \cap B_N(x, \sqrt{h}R(\sqrt{h}))} f_{\sqrt{h}}(y-x)\chi_{\{\varphi \geqq \widetilde{\mu}\}}(y)dy\\
&\quad \leqq \int_{B_N(x, \sqrt{h}R(\sqrt{h}))} f_{\sqrt{h}}(y-x)\chi_{\{\varphi < \widetilde{\mu}\}}(y)dy\\
&\qquad - \int_{\Omega^c \cap B_N(x, \sqrt{h}R(\sqrt{h}))} f_{\sqrt{h}}(y-x)\chi_{\{\varphi < \widetilde{\mu}\}}(y)dy\\
&\quad = \int_{\Omega \cap B_N(x, \sqrt{h}R(\sqrt{h}))} f_{\sqrt{h}}(y-x)\chi_{\{\varphi < \widetilde{\mu}\}}(y)dy\\
&\quad < \int_\Omega f_{\sqrt{h}}(y-x)\chi_{\{\varphi < \widetilde{\mu} + C_9\varepsilon h\}}(y)dy.
\end{aligned}$$

Hence taking $\varepsilon_2 > 0$ small and $0 < h_8 \leqq \min\{h_i \mid i = 5, 6, 7\}$, we get $\lambda \leqq \widetilde{\mu} + C_9\varepsilon h \leqq \widetilde{\lambda} + (C_2 + C_9)\varepsilon h$ for all $\varepsilon \in (0, \varepsilon_2)$ and $h \in (0, h_8)$.

Case 2. $\{y \in B_N(x, \sqrt{h}R(\sqrt{h})) \mid \varphi(y) = \widetilde{\mu}\} \cap \partial\Omega = \emptyset$.

Subcase 2-1. $\{y \in B_N(x, \sqrt{h}R(\sqrt{h})) \mid \varphi(y) = \widetilde{\mu}\} \subset \Omega^c$.

It follows from Lemma 3.7 that for some $C_{11} > 0$ independent of ε, $h > 0$, and $x \in B_N(z, r_0)$,

$$\operatorname{dist}(x, \partial\Omega) \leqq C_{10}h \quad \text{for all } h \in (0, h_1). \tag{3.14}$$

It is easily seen that

$$\int_\Omega f_{\sqrt{h}}(y-x)\chi_{\{\varphi\geqq\widetilde{\mu}\}}(y)dy \leqq \sqrt{h}\omega(R(\sqrt{h})),$$
$$\int_{\Omega\cap B_N(x,\sqrt{h}R(\sqrt{h}))} f_{\sqrt{h}}(y-x)\chi_{\{\varphi<\widetilde{\mu}\}}(y)dy = \int_{\Omega\cap B_N(x,\sqrt{h}R(\sqrt{h}))} f_{\sqrt{h}}(y-x)dy.$$

By the smoothness of $\partial\Omega$ we can show that

$$\partial\Omega\cap B_N(x,\sqrt{h}R(\sqrt{h}))\subset\{y\in B_N(x,\sqrt{h}R(\sqrt{h}))\mid |y_N-z_{x,N}|\leqq C_{11}hR(\sqrt{h})^2\},$$

where $C_{11}>0$ is independent of ε, $h>0$, and $x\in B_N(z,r_0)$, and z_x is a unique point satisfying $\operatorname{dist}(x,\partial\Omega)=|x-z_x|$. Thus it follows from (3.9), (3.14), and (A.4) that there exists an $h_9>0$ such that, for all $h\in(0,h_9)$, we observe

$$\begin{aligned}
&\int_{\Omega\cap B_N(x,\sqrt{h}R(\sqrt{h}))} f_{\sqrt{h}}(y-x)dy\\
&\quad\geqq\frac{1}{2}\int_{B_N(0,\sqrt{h}R(\sqrt{h}))} f(y)dy-\int_{-C_{11}\sqrt{h}(R(\sqrt{h})+1)}^{C_{11}\sqrt{h}(R(\sqrt{h})+1)}\int_{B_{N-1}(0,R(\sqrt{h}))} f(y',y_N)dy'dy_N\\
&\quad\geqq\frac{1}{2}\int_{\mathcal{R}^N} f(y)dy-\sqrt{h}\omega(R(\sqrt{h}))-\int_{-C_{11}\sqrt{h}(R(\sqrt{h})+1)}^{C_{11}\sqrt{h}(R(\sqrt{h})+1)}\left(\int_{\mathcal{R}^{N-1}} f(y',0)dy'+1\right)dy_N\\
&\quad\geqq\sqrt{h}\omega(R(\sqrt{h})).
\end{aligned}$$

Therefore, we obtain $\lambda\leqq\widetilde{\mu}\leqq\widetilde{\lambda}+C_2\varepsilon h$ for all $\varepsilon\in(0,\varepsilon_1)$ and $h\in(0,h_1\wedge h_9)$.

Subcase 2-2. $\{y\in B_N(x,\sqrt{h}R(\sqrt{h}))\mid\varphi(y)=\widetilde{\mu}\}\subset\Omega$ and $\operatorname{dist}(x,\partial\Omega)\leqq\sqrt{h}R_1$.

As in Subcase 1-1, we observe that there exist a $C_{12}>0$ and an $h_{10}>0$ such that

$$\int_{\Omega\cap B_N(x,\sqrt{h}R(\sqrt{h}))} f_{\sqrt{h}}(y-x)\chi_{\{\varphi\geqq\widetilde{\mu}\}}(y)dy\leqq\frac{1}{2}\int_{B_N(x,\sqrt{h}R(\sqrt{h}))} f_{\sqrt{h}}(y-x)dy-C_{12}$$

for all $h\in(0,h_{10})$. It follows from this inequality that

$$\begin{aligned}
\int_\Omega f_{\sqrt{h}}(y-x)\chi_{\{\varphi\geqq\widetilde{\mu}\}}(y)dy&\leqq\frac{1}{2}\int_{B_N(x,\sqrt{h}R(\sqrt{h}))} f_{\sqrt{h}}(y-x)dy-C_{12}+\sqrt{h}\omega(R(\sqrt{h}))\\
&\leqq\int_\Omega f_{\sqrt{h}}(y-x)\chi_{\{\varphi<\widetilde{\mu}\}}(y)dy
\end{aligned}$$

for any $h\in(0,h_{10})$. Thus $\lambda\leqq\widetilde{\mu}\leqq\widetilde{\lambda}+C_2\varepsilon h$.

Subcase 2-3. $\{y\in B_N(x,\sqrt{h}R(\sqrt{h}))\mid\varphi(y)=\widetilde{\mu}\}\subset\Omega$ and $\operatorname{dist}(x,\partial\Omega)>\sqrt{h}R_1$.

Note that

$$\begin{aligned}
&\int_{\Omega\cap B_N(x,\sqrt{h}R(\sqrt{h}))} f_{\sqrt{h}}(y-x)\chi_{\{\varphi\geqq\widetilde{\mu}\}}(y)dy\\
&\quad\leqq\int_{\Omega\cap B_N(x,\sqrt{h}R(\sqrt{h}))} f_{\sqrt{h}}(y-x)\chi_{\{\varphi<\widetilde{\mu}\}}(y)dy.
\end{aligned}$$

Then computing as in Subcase 1-2, we have

$$\begin{aligned}
&\int_\Omega f_{\sqrt{h}}(y-x)\chi_{\{\varphi\geqq\widetilde{\mu}+C_{13}\varepsilon h\}}(y)dy\\
&\quad\leqq\int_\Omega f_{\sqrt{h}}(y-x)\chi_{\{\varphi<\widetilde{\mu}+C_{13}\varepsilon h\}}(y)dy+\sqrt{h}\omega(R(\sqrt{h}))-\varepsilon\sqrt{h}
\end{aligned}$$

for some $C_{13} > 0$ independent of ε, $h > 0$, and $x \in B_N(z, r_0)$. Taking $h_{11} > 0$ small, we have $\lambda \leqq \widetilde{\mu} + C_{13}\varepsilon h \leqq \widetilde{\lambda} + (C_2 + C_{13})\varepsilon h$ for all $h \in (0, h_{11})$.

Consequently, taking $C > 0$ large and ε_0, $h_0 > 0$, small enough, we complete the proof. □

4. Proof of Theorem 2.1. Before proving our main result, we prepare some lemmas.

LEMMA 4.1. *Let $\varepsilon > 0$ and $g \in C^2(\overline{\Omega})$. Assume $\partial g/\partial n > 0$ (resp., $\partial g/\partial n < 0$) on $\partial\Omega$. Then there exists a $\omega \in C(\mathcal{R}^+; \mathcal{R}^+)$, $\omega(0) = 0$, such that*

$$\sup_{x\in\overline{\Omega}, m\in\mathcal{N}} (u^m(t,x) - g(x)) \leqq \omega(t), \left(\text{resp., } \inf_{x\in\overline{\Omega}, m\in\mathcal{N}} (u^m(t,x) - g(x)) \geqq -\omega(t)\right)$$

for all $x \in \overline{\Omega}$ and $t \geqq 0$.

Proof. We may assume $\partial g/\partial n > 0$ on $\partial\Omega$ because we can prove the result similarly in the case $\partial g/\partial n < 0$ on $\partial\Omega$.

We prove that there exist a $C > 0$ and an $h_0 > 0$ such that

$$G_h g(x) \leqq g(x) + Ch \quad \text{for all } x \in \overline{\Omega},\ h \in (0, h_0). \tag{4.1}$$

Once we have this inequality, we use it iteratively to obtain our desired result with $\omega(t) = Ct$. Fix $z \in \overline{\Omega}$.

Case 1. $Dg(z) \neq 0$.

By using Lemma 3.1 with $\varepsilon = 1$, we see that there exists a $\delta_1 > 0$ such that

$$G_h g(x) \leqq g(x) + (-F(Dg(z), D^2g(z)) + 1)h$$

for all $x \in B_N(z, \delta_1) \cap \overline{\Omega}$ and $h \in (0, \delta_1)$.

Case 2. $Dg(z) = 0$.

Note that $z \in \Omega$ because we assume $\partial g/\partial n > 0$ on $\partial\Omega$. Since $g \in C^2(\overline{\Omega})$, we can find a $\delta_2 > 0$ such that

$$|g(x) - g(z)| \leqq \frac{1}{2}\|D^2g\|_\infty |x - z|^2 \quad \text{for all } x \in B_N(z, \delta_2) \subset \Omega. \tag{4.2}$$

Moreover, taking $C_1 = 2\|g\|_\infty/\delta_2^2 + \|D^2g\|_\infty/2$, we get

$$g(x) \leqq g(z) + C_1|x - z|^2 \quad \text{for all } x \in \overline{\Omega}.$$

Thus we have

$$G_h g(x) \leqq g(z) + C_1 G_h(|x - z|^2) \quad \text{for all } x \in \overline{\Omega}.$$

By a similar argument in Ishii [6] and Ishii, Pires, and Souganidis [7], we obtain

$$G_h(|x - z|^2) \leqq |x - z|^2 + C_2 h \quad \text{for all } x \in B_N(z, \delta_3),\ h \in (0, \delta_3),$$

for some $C_2 > 0$ and $\delta_3 > 0$. Hence, by (4.2) we get

$$\begin{aligned} G_h g(x) &\leqq g(z) + C_1(|x - z|^2 + C_2 h) \\ &\leqq g(x) + \left(C_1 + \frac{1}{2}\|D^2g\|_\infty\right)(|x - z|^2 + C_2 h) \\ &\qquad \text{for all } x \in B_N(z, \delta_2 \wedge \delta_3),\ h \in (0, \delta_2 \wedge \delta_3). \end{aligned}$$

Consequently, for any $z \in \overline{\Omega}$, there exist C_3, $\delta_4 > 0$ such that

$$G_h g(x) \leqq g(x) + C_3 h \quad \text{for all } x \in B_N(z, \delta_4),\ h \in (0, \delta_4).$$

Since $\overline{\Omega}$ is compact, we have (4.1). Thus the proof is completed. □

Define $\overline{u}(t,x)$ and $\underline{u}(t,x)$ by

$$\overline{u}(t,x) = \lim_{\varepsilon \to 0} \sup\{u^m(s,y) \mid m \geqq 1/\varepsilon, y \in \overline{\Omega}, 0 \leqq s < T, |s-t| + |y-x| \leqq \varepsilon\},$$
$$\underline{u}(t,x) = \lim_{\varepsilon \to 0} \inf\{u^m(s,y) \mid m \geqq 1/\varepsilon, y \in \overline{\Omega}, 0 \leqq s < T, |s-t| + |y-x| \leqq \varepsilon\}.$$

LEMMA 4.2. *Let $g \in C(\overline{\Omega})$. Then $\overline{u}(0,x) = \underline{u}(0,x) = g(x)$ for all $x \in \overline{\Omega}$.*

Proof. Take a sequence $\{g_k\} \subset C^2(\overline{\Omega})$ satisfying

$$\|g_k - g\|_{C(\overline{\Omega})} \leqq \frac{1}{k}, \quad \frac{\partial g_k}{\partial n} > 0 \quad \text{on} \quad \partial\Omega.$$

Define $u^{m,k}$ as (2.5) with g replacing g_k. Then Lemma 4.1 implies that, for each $n \in \mathcal{N}$, there exists an $\omega_k \in C(\mathcal{R}^+; \mathcal{R}^+)$, $\omega_k(0) = 0$, such that

$$u^{m,k}(t,y) - g_n(y) \leqq \omega_k(t) \quad \text{for all } y \in \overline{\Omega},\ t \geqq 0.$$

Since G_h is nonexpansive and $\|g_k - g\|_{C(\overline{\Omega})} \leqq 1/k$, we observe that

$$|u^m(t,y) - u^{m,k}(t,y)| \leqq \frac{1}{k} \quad \text{for all } y \in \overline{\Omega},\ t \geqq 0,\ k \in \mathcal{N}.$$

Hence we get

$$u^m(t,y) - g(y) \leqq \omega_k(t) + \frac{2}{k}.$$

Fix $x \in \overline{\Omega}$. Letting $m \to +\infty$, $y \to x$, $t \to 0$, and then $k \to +\infty$, we have

$$\overline{u}(0,x) \leqq g(x).$$

Since we can show $\underline{u}(0,x) \geqq g(x)$ by a similar argument and $\underline{u}(0,x) \leqq \overline{u}(0,x)$, we have the result. □

Proof of Theorem 2.1. By using Lemma 3.1, we can show that, for any $\varphi \in C^2(\overline{\Omega})$, if $x \in \Omega$ and $D\varphi(x) \neq 0$ or $x \in \partial\Omega$ and $(\partial\varphi/\partial n)(x) > 0$, then

$$\limsup_{h \to 0}{}^{*} \frac{G_h\varphi(x) - \varphi(x)}{h} \leqq -F_*(D\varphi(x), D^2\varphi(x)), \tag{4.3}$$

and if $x \in \Omega$ and $D\varphi(x) \neq 0$ or $x \in \partial\Omega$ and $(\partial\varphi/\partial n)(x) < 0$, then

$$\lim_{h \to 0}{}_{*} \frac{G_h\varphi(x) - \varphi(x)}{h} \geqq -F^*(D\varphi(x), D^2\varphi(x)),$$

where

$$\lim_{h \to 0}{}^{*} \psi_h(x) = \lim_{r \to 0} \sup\{\psi_h(y) \mid 0 < h < r, |y-x| < r\},$$
$$\lim_{h \to 0}{}_{*} \psi_h(x) = -\lim_{h \to 0}{}^{*}(-\psi_h(x)).$$

We prove $\overline{u}$ is a viscosity subsolution of (2.1). Fix $\varphi \in C^2((0,T) \times \overline{\Omega})$ and assume $\overline{u} - \varphi$ takes its maximum at (t_0, x_0). If $x_0 \in \partial\Omega$ and $(\partial\varphi/\partial n)(t_0, x_0) \leqq 0$, then we have nothing to prove. Thus we assume $x_0 \in \Omega$ or $x_0 \in \partial\Omega$ and $(\partial\varphi/\partial n)(t_0, x_0) > 0$. Then, by (4.3) and the same argument as in Ishii [6] or Ishii, Pires, and Souganidis [7], we conclude that $\overline{u}$ is a viscosity subsolution of (2.1). It can be proved similarly that $\underline{u}$ is a viscosity supersolution of (2.1). Therefore, Lemma 4.2 and the comparison principle due to Giga and Sato [5] yield $\overline{u} = \underline{u}$ in $[0,T) \times \overline{\Omega}$. Hence, by the results in Crandall, Ishii, and Lions [3, section 6], the proof is completed. □

ZERO VISCOSITY LIMIT OF THE OSEEN EQUATIONS IN A CHANNEL*

MARIA CARMELA LOMBARDO[†] AND MARCO SAMMARTINO[†]

Abstract. Oseen equations in the channel are considered. We give an explicit solution formula in terms of the inverse heat operators and of projection operators. This solution formula is used for the analysis of the behavior of the Oseen equations in the zero viscosity limit. We prove that the solution of Oseen equations converges in $W^{1,2}$ to the solution of the linearized Euler equations outside the boundary layer and to the solution of the linearized Prandtl equations inside the boundary layer.

Key words. Oseen equations, solution formula, zero viscosity limit, boundary layer, asymptotic expansion

1. Introduction.

In this paper we shall be concerned with the zero viscosity limit of the time dependent incompressible Oseen type equations in a two-dimensional channel.

Oseen equations are a simplified mathematical model in treating incompressible viscous fluids and their study should shed some light on the much more complicated physical phenomena described by the nonlinear Navier–Stokes equations.

The system we shall be concerned with is the following:

$$(\partial_t - \nu\Delta + U\partial_x)\boldsymbol{u} + \boldsymbol{\nabla} p = \boldsymbol{f}, \tag{1.1}$$

$$\boldsymbol{\nabla}\cdot\boldsymbol{u} = 0, \tag{1.2}$$

$$\gamma^-\boldsymbol{u} = \mathbf{g}^-, \tag{1.3}$$

$$\gamma^+\boldsymbol{u} = \mathbf{g}^+, \tag{1.4}$$

$$\boldsymbol{u}(t=0) = \boldsymbol{u}_0. \tag{1.5}$$

In the above equations $\boldsymbol{u} = (u(x,y,t), v(x,y,t))$ is the unknown vector field, p is the unknown pressure, $x \in \mathbb{R}$ denotes the tangential variable, $-1 \le y \le 1$ is the normal variable, $t \ge 0$ is the time, γ is the trace operator, i.e., $\gamma^-\boldsymbol{u} = \boldsymbol{u}(x,-1,t)$ and $\gamma^+\boldsymbol{u} = \boldsymbol{u}(x,1,t)$, ν is the viscosity coefficient, and $\mathbf{g}^-, \mathbf{g}^+$, and $\boldsymbol{u}_0$ are the boundary and the initial data, respectively.

Equation (1.1) is obtained by linearizing the Navier–Stokes equation around the velocity flow $(U,0)$, where U is assumed to be constant. Equation (1.2) is the incompressibility condition. Equations (1.3) and (1.4) are the boundary conditions, while (1.5) is the initial condition.

The analysis of the zero viscosity limit of (1.1)–(1.5) (with homogeneous boundary data $\mathbf{g}^+ = \mathbf{g}^- = 0$) was performed by Temam and Wang in [4], [5], and [6]. In [6] the authors considered the more general case of the three-dimensional Navier–Stokes equations linearized around the flow $(U_1(z), U_2(z), 0)$. Without explicitly solving the

[†]Dipartimento di Matematica, University of Palermo, Via Archirafi 34, 90123 Palermo, Italy (lombardo@dipmat.math.unipa.it, marco@dipmat.math.unipa.it). The research of the first author was partially supported by the INDAM. The research of the second author was partially supported by the GNFM-INDAM.

equations and under the assumption of sufficient smoothness of the initial data, they proved that the solution can be decomposed in the following form:

$$\boldsymbol{u} = \boldsymbol{u}^0 + \tilde{\boldsymbol{\theta}}^{\boldsymbol{\varepsilon}} + \nu^{1/4}\boldsymbol{w} \qquad \text{with} \qquad \boldsymbol{w} \in L^2\left([0,T];\ \left(W^{1,2}(\Omega)\right)^3\right),$$

where $\boldsymbol{u}^0$ is the inviscid solution and $\tilde{\boldsymbol{\theta}}^{\boldsymbol{\varepsilon}}$ is a corrector which takes into account the mismatch of the boundary conditions between the inviscid part and the overall solution.

In this paper we shall write the solution of (1.1)–(1.5) as the sum of an inviscid part, two Prandtl parts, and an error term, i.e.,

$$\boldsymbol{u} = \boldsymbol{u}^E + \boldsymbol{u}^{P(-)} + \boldsymbol{u}^{P(+)} + \nu^{1/2}\boldsymbol{w}\ . \tag{1.6}$$

In the above decomposition $\boldsymbol{u}^E$ is the inviscid (Euler) part describing the flow away from boundaries; $\boldsymbol{u}^{P(-)}$ and $\boldsymbol{u}^{P(+)}$ are the Prandtl parts describing the flow close to the two boundaries and decaying exponentially away from the two boundaries. Our main result is the following theorem.

Theorem 1.1 (informal statement). *Let $\boldsymbol{u}$ be the solution of* (1.1)–(1.6)*. If the initial data $\boldsymbol{u}_0$ is in H^4, and if the boundary data $\boldsymbol{g}^{\pm}$ are sufficiently regular and are such that the normal components are integrable (in the sense specified by Definition* 2.3 *below), then*

$$\nu^{1/4}\boldsymbol{w} \in L^\infty\left([0,T]\,; W^{1,2}\right)$$

with norm independent of ν.

Therefore the main advantage with respect to the results of [6] is that here we prove that the norm of the correction term is $O(\nu^{1/4})$ in $L^\infty\left([0,T]; W^{1,2}\right)$, while there an analogous estimate is proved with a nondivergence-free boundary layer corrector. We also allow nonzero boundary data.

We shall achieve this result through the explicit solution formula for the Oseen equation. This explicit representation formula is, we believe, of independent interest.

The paper is organized as follows: in section 2 we shall introduce the functional setting. In section 3 the convection-diffusion operators in the channel are defined and we shall give some estimate in the appropriate function spaces. In section 4 we shall solve the Oseen equations with boundary data, zero initial data, and zero source term. The solution will be written in the form of an infinite series: the norm of the generic term of the series will be shown to be exponentially decaying. Convergence of the series will follow and the norm of the solution will be proved to be bounded in terms of the norm of the boundary data. In section 5 the complete Oseen system is solved introducing the projection operator onto the divergence-free function space and estimates of the solution in terms of the data are given. In section 6 we shall finally analyze the vanishing viscosity limit of the Oseen equations. The main results of this paper are formally stated in Theorem 6.5 and Corollary 6.1.

2. The function spaces.

In this section we define some function spaces we shall be using throughout the paper. We introduce the notation $\boldsymbol{\Omega} \equiv \mathbb{R} \times [-1,1]$. Here and in the rest of the paper $l \geq 2$.

Definition 2.1. *$H^l(\mathbb{R})$ is the set of all functions $f(x)$ such that*

(i) $\frac{d^j}{dx^j} f \in L^2(\mathbb{R})$*, where $j \leq l$.*

We shall denote the usual norm in $H^l(\mathbb{R})$ with $|f|_l$.

Definition 2.2. *H'^{l}_T is the set of all functions $f(x,t)$ such that*

(i) *$\partial_t^j f(x,t) \in L^\infty([0,T], H^{l-j}(\mathbb{R}))$ and $j \le l$.*

The norm of $f \in H'^{l}_T$ is given by

$$|f|_{l,T} = \sum_{j_1+j_2 \le l} \sup_{0 \le t \le T} \|\partial_t^{j_1} \partial_x^{j_2} f(\cdot,t)\|_{L^2(\mathbb{R})} \ .$$

Definition 2.3. *$\boldsymbol{H}'^{l}_T$ is the set of all functions $\boldsymbol{f} = (f_\tau, f_N)$ such that*

(i) *$f_\tau \in H'^{l}_T$;*

(ii) *$|\xi|^{-1} f_N \in H'^{l+1}_T$.*

The norm of $\boldsymbol{f} \in \boldsymbol{H}'^{l}_T$ is given by

$$\boldsymbol{|}\, \boldsymbol{f} \,\boldsymbol{|}_{\,l,T} = |f_\tau|_{l,T} + ||\xi|^{-1} f_N|_{l,T} \ .$$

In the above definition ξ is the dual Fourier variable of x, and $|\xi|^{-1}$ has to be understood as a pseudodifferential operator. The space $\boldsymbol{H}'^{l}_T$ is the space to which all boundary data we shall deal with in the rest of the paper will belong. The hypothesis on the normal component is an *integrability* hypothesis.

Definition 2.4. *H^l is the set of all functions $f(x,y)$ such that*

(i) *$\partial_x^i \partial_y^j f(x,y) \in L^2(\boldsymbol{\Omega})$ for $i+j \le l$.*

The norm of f is given by

$$|f|_l = \sum_{i+j \le l} \|\partial_x^i \partial_y^j f(\cdot,\cdot)\|_{L^2(\boldsymbol{\Omega})} \ .$$

Definition 2.5.

H^l_T is the set of all functions $f(x,y,t)$ such that

- *$\partial_t^j f(x,y,t) \in L^\infty([0,T], H^{l-j})$ for $j \le l$.*

The norm of $f \in H^l_T$ is given by

$$|f|_{l,T} = \sum_{j_1+j_2+j_3 \le l} \sup_{0 \le t \le T} \|\partial_t^{j_1} \partial_x^{j_2} \partial_y^{j_3} f(\cdot,\cdot,t)\|_{L^2(\boldsymbol{\Omega})}.$$

All the above spaces are the natural ambient spaces for the Euler equations. We now introduce the ambient spaces for Prandtl equations. All the functions belonging to these spaces depend on the normal scaled variable $Y = y/\varepsilon$. We require differentiability with respect to this variable only up to the second order. We first introduce the spaces $K^{l,\mu(+)}$ and $K^{l,\mu(-)}$. The functions in these spaces are defined in the half plane $Y \le 1/\varepsilon$ and $Y \ge -1/\varepsilon$, respectively, and decay exponentially fast away from $Y = 1/\varepsilon$ and $Y = -1/\varepsilon$, respectively. In what follows $\mu > 0$.

Definition 2.6. *$K^{l,\mu(\pm)}$ is the set of all functions $f^\pm(x,Y)$ defined for $-\infty < \pm Y \le 1/\varepsilon$, and such that*

(i) *$\partial_x^{j_1} \partial_Y^{j_2} f^\pm(x,Y) \in L^2(\mathbb{R})$, with $j_2 \le 2$ and $j_1 + j_2 \le l$,*

(ii) *$\sup_{-\infty < \pm Y \le \frac{1}{\varepsilon}} e^{\mu(\frac{1}{\varepsilon} \mp Y)} \|\partial_x^{j_1} \partial_Y^{j_2} f^\pm(\cdot,Y)\|_{L^2} < \infty$, where $j_2 \le 2$ and $j_1 + j_2 \le l$.*

The norm is given by

$$|f|_{l,\mu(\pm)} = \sum_{j_2 \le 2} \sum_{j_1+j_2 \le l} \sup_{-\infty < \pm Y \le \frac{1}{\varepsilon}} e^{\mu(\frac{1}{\varepsilon} \mp Y)} \|\partial_x^{j_1} \partial_Y^{j_2} f^\pm(\cdot,Y)\|_{L^2} \ .$$

Definition 2.7. *$K^{l,\mu}$ is the set of functions $f(x,Y)$, defined for $-1/\varepsilon \le Y \le 1/\varepsilon$, such that*

$$f = f^+ + f^-,$$

where f^+ and f^- are restrictions to $-1/\varepsilon \le Y \le 1/\varepsilon$ of functions in $K^{l,\mu(+)}$ and $K^{l,\mu(-)}$, respectively. The norm is given by

$$|f|_{l,\mu}=\sum_{j_2\le 2}\sum_{j_1+j_2\le l}\left[\sup_{0<Y\le\frac{1}{\varepsilon}} e^{\mu(\frac{1}{\varepsilon}-Y)}\|\partial_x^{j_1}\partial_Y^{j_2}f(\cdot,Y)\|_{L^2}+\sup_{-\frac{1}{\varepsilon}<Y\le 0} e^{\mu(\frac{1}{\varepsilon}+Y)}\|\partial_x^{j_1}\partial_Y^{j_2}f(\cdot,Y)\|_{L^2}\right].$$

We now introduce the dependence on time. We require differentiability with respect to time only up to the first order: one time derivative is equivalent to two space derivatives.

Definition 2.8.
$K_T^{l,\mu(\pm)}$ is the set of all functions $f^\pm(x,Y,t)$ such that
(i) *$f \in L^\infty([0,T],K^{l,\mu(\pm)})$,*
(ii) *$\partial_t\partial_x^j f \in L^\infty([0,T],K^{0,\mu(\pm)})$ with $j \le l-2$.*
The norm is given by

$$\begin{aligned}|f|_{l,\mu,T(\pm)} = &\sum_{0\le j_2\le 2}\sum_{j_1\le l-2}\sup_{0\le t\le T}\sup_{-\infty<\pm Y\le\frac{1}{\varepsilon}} e^{\mu(\frac{1}{\varepsilon}\mp Y)}\|\partial_x^{j_1}\partial_Y^{j_2}f^\pm(\cdot,Y,t)\|_{L^2}\\ &+\sum_{j\le l-2}\sup_{0\le t\le T}\sup_{-\infty<\pm Y\le\frac{1}{\varepsilon}} e^{\mu(\frac{1}{\varepsilon}\mp Y)}\|\partial_t\partial_x^j f^\pm(\cdot,Y,t)\|_{L^2}\ .\end{aligned}$$

Definition 2.9. *$K_T^{l,\mu}$ is the set of functions $f(x,Y,t)$, defined for $-1/\varepsilon \le Y \le 1/\varepsilon$, such that*

$$f = f^+ + f^-\ ,$$

where f^+ and f^- are restrictions to $-1/\varepsilon \le Y \le 1/\varepsilon$ of functions in $K_T^{l,\mu(+)}$ and $K_T^{l,\mu(-)}$, respectively. The norm is given by

$$\begin{aligned}|f|_{l,\mu,T} = &\sum_{0\le j_2\le 2}\sum_{j_1\le l-2}\sup_{0\le t\le T}\sup_{0<Y\le\frac{1}{\varepsilon}} e^{\mu(\frac{1}{\varepsilon}-Y)}\|\partial_x^{j_1}\partial_Y^{j_2}f(\cdot,Y,t)\|_{L^2}\\ &+\sum_{j\le l-2}\sup_{0\le t\le T}\sup_{0<Y\le\frac{1}{\varepsilon}} e^{\mu(\frac{1}{\varepsilon}-Y)}\|\partial_t\partial_x^j f(\cdot,Y,t)\|_{L^2}\\ &+\sum_{0\le j_2\le 2}\sum_{j_1\le l-2}\sup_{0\le t\le T}\sup_{-\frac{1}{\varepsilon}<Y\le 0} e^{\mu(\frac{1}{\varepsilon}+Y)}\|\partial_x^{j_1}\partial_Y^{j_2}f(\cdot,Y,t)\|_{L^2}\\ &+\sum_{j\le l-2}\sup_{0\le t\le T}\sup_{-\frac{1}{\varepsilon}<Y\le 0} e^{\mu(\frac{1}{\varepsilon}+Y)}\|\partial_t\partial_x^j f(\cdot,Y,t)\|_{L^2}\ .\end{aligned}$$

We now introduce the ambient spaces for the error equation. All functions belonging to the following spaces are functions L^2 with respect to both tangential and normal variables. Notice that, due to the presence in the error equation of the rapidly varying terms arising from the Prandtl solution, the solution of the error equation will have a fast dependence on y. Therefore, in the following spaces, all the derivatives of order j with respect to y are weighted with $\varepsilon^j \equiv \nu^{j/2}$.

Definition 2.10. *L^l is the set of all functions $f(x,y)$ such that*

(i) *$\partial_x^{j_1}\varepsilon^{j_2}\partial_y^{j_2}f \in L^2(\mathbf{\Omega})$ with $j_2 \leq 2$ and $j_1 + j_2 \leq l$.*

The norm of $f \in L^l$ is given by

$$\|f\|_l = \sum_{j_1 \leq l} \|\partial_x^{j_1} f\|_{L^2(\mathbf{\Omega})} + \sum_{0\leq j_2 \leq 2}\sum_{j_1 \leq l-2} \|\partial_x^{j_1}\varepsilon^{j_2}\partial_y^{j_2} f\|_{L^2(\mathbf{\Omega})} \ .$$

Definition 2.11. *$L_T'^l$ is the set of all functions $f(x,t)$ such that*

(i) *$\partial_t\partial_x^j f \in L^\infty([0,T], H^l(\mathbb{R}))$ for $j \leq l-2$.*

The norm of $f \in L_T'^l$ is given by

$$\|f\|_{l,T} = \sum_{j \leq l-2} \sup_{0\leq t\leq T} \|\partial_t\partial_x^j f(\cdot,t)\|_{L^2(\mathbf{\Omega})} \ .$$

Definition 2.12. *L_T^l is the set of all functions f(x,y,t) such that*

(i) *$f \in L^\infty([0,T], L^l)$,*

(ii) *$\partial_t\partial_x^j f \in L^\infty([0,T], L^0)$ with $j \leq l-2$.*

The norm of $f \in L_T^l$ is given by

$$\|f\|_{l,T} = \sum_{0\leq j_2\leq 2}\sum_{j_1\leq l-2} \sup_{0\leq t\leq T} \|\partial_x^{j_1}\varepsilon^{j_2}\partial_y^{j_2} f(\cdot,\cdot,t)\|_{L^2(\mathbf{\Omega})} + \sum_{j\leq l-2}\sup_{0\leq t\leq T}\|\partial_t\partial_x^j f(\cdot,\cdot,t)\|_{L^2(\mathbf{\Omega})} \ .$$

3. The convection-diffusion operators in the channel. In this section we shall give an explicit representation of the convection-diffusion operators F_0, F_1, and F_2. These operators solve the convection-diffusion equation in the channel with initial data, boundary data, and source term, respectively. Our explicit representation is given in terms of the action on the Fourier transform in the tangential variable. These operators will be used in the construction of the explicit solution of the Oseen equations. In what follows ξ will always denote the dual Fourier variable of x:

$$\hat{f}(\xi') = \frac{1}{(2\pi)^{1/2}}\int_{-\infty}^{+\infty} dx\, f(x) e^{-i\xi' x} \ .$$

In the rest of the paper we shall not distinguish between a function and its Fourier transform.

The convection-diffusion equation in the channel writes as follows:

$$(\partial_t - \nu\Delta + U\partial_x)u = f \ , \tag{3.1}$$

$$\gamma^+ u = g^+ \ , \tag{3.2}$$

$$\gamma^- u = g^- \ , \tag{3.3}$$

$$u|_{t=0} = u_0 \ . \tag{3.4}$$

The operator F_0 solves the above equations with initial data and zero boundary data and zero source term. If we now introduce the θ-function (see [8, Chapter V]),

$$\theta(y,t) = \sum_{n=-\infty}^{\infty} k(y+4n,t), \qquad -\infty < y < \infty \ ,$$

where

$$k(y,t) = \frac{e^{-y^2/4\nu t}}{(4\pi\nu t)^{1/2}} \ ,$$

one can easily see that the explicit expression of F_0 is given by

$$F_0 u_0 \quad = e^{-[\nu\xi^2 + i\xi U]t} \int_{-1}^{+1} dy' \, [\theta(y-y',t) - \theta(y+y'+2,t)] \, u_0(\xi,y') \, . \tag{3.5}$$

The operator F_1 solves the convection-diffusion equations in the channel with boundary data, zero initial data, and zero source term: If we introduce the φ-function (see [8])

$$\varphi(y,t) = \sum_{n=-\infty}^{+\infty} h(y+4n,t), \qquad -\infty < y < \infty \, ,$$

where

$$h(y,t) = \frac{y}{t} \frac{e^{-y^2/(4\nu t)}}{\sqrt{4\pi t\nu}} \, ,$$

one can easily verify that the operator F_1 has the following expression:

$$\begin{aligned} F_1(g^+,g^-) = & \int_0^t ds \, e^{-(\nu\xi'^2 + i\xi' U)(t-s)} \varphi(y+1,t-s) g^-(\xi',s) \\ & + \int_0^t ds \, e^{-(\nu\xi'^2 + i\xi' U)(t-s)} \varphi(1-y,t-s) g^+(\xi',s) \, . \end{aligned} \tag{3.6}$$

Finally, the operator F_2 solves the convection-diffusion equations with source term, zero initial data, and zero boundary data. One can give the following explicit expression for F_2:

$$F_2 f = \int_0^t ds e^{-[\nu\xi^2 + i\xi U](t-s)} \int_{-1}^{+1} dy' \, [\theta(y-y',t-s) - \theta(y+y'+2,t-s)] \, f(\xi,y',s) \, . \tag{3.7}$$

We now give some estimates on the above operators. In the propositions below c is a constant that does not depend on ν. The proofs of the proposition below are standard and can be achieved using the explicit representation formulas (3.5), (3.6), and (3.7) and the same arguments of [3], where the heat operators in the half plane are considered.

Proposition 3.1. *Let $u_0 \in L^l$ with $\gamma^\pm u_0 = 0$. Then $F_0 u_0 \in L^l_T$ and the following estimate holds:*

$$\|F_0 u_0\|_{l,T} \le c \|u_0\|_l \, .$$

Proposition 3.2. *Let $g^+ \in L'^l_T$, $g^- \in L'^l_T$ satisfy the compatibility condition $g^+(t=0) = g^-(t=0) = 0$. Then $F_1(g^+,g^-) \in L^l_T$ and the following estimate holds:*

$$\|F_1(g^+,g^-)\|_{l,T} \le c[\|g^+\|_{l,T} + \|g^-\|_{l,T}] \, .$$

Proposition 3.3. *Let $g^+ \in L'^l_T$, $g^- \in L'^l_T$, and $g^+(t=0) = g^-(t=0) = 0$; then $F_1(g^+,g^-) \in K^{l,\mu}_T$ and the following estimate holds:*

$$|F_1(g^+,g^-)|_{l,\mu,T} \le c[\|g^+\|_{l,T} + \|g^-\|_{l,T}] \, .$$

Proposition 3.4. *Let $f \in L^l_T$; then $F_2 f \in L^l_T$ and the following estimate holds:*

$$\|F_2 f\|_{l,T} \le c \|f\|_{l,T}.$$

The following estimate on the operator F_2 says that, if the source term is of the same order of the square root of ν, then one can use the heat kernel to increase the regularity of the solution.

PROPOSITION 3.5. *Let $f = \sqrt{\nu}h$ with $h \in L_T^{l-1}$; then $F_2 f \in L_T^l$ and the following estimate holds:*

$$\|F_2 f\|_{l,T} \leq c\|h\|_{l-1,T}.$$

4. The Oseen equations with boundary data: The explicit solution.

In this section we shall derive the explicit solution of the Oseen equations in the channel with boundary data, zero source term, and zero initial data, namely,

$$(\partial_t - \nu\Delta + U\partial_x)\boldsymbol{u} + \boldsymbol{\nabla} p = 0, \tag{4.1}$$

$$\boldsymbol{\nabla} \cdot \boldsymbol{u} = 0, \tag{4.2}$$

$$\gamma^- \boldsymbol{u} = \mathbf{g}^-, \tag{4.3}$$

$$\gamma^+ \boldsymbol{u} = \mathbf{g}^+, \tag{4.4}$$

$$\boldsymbol{u}|_{t=0} = 0\ , \tag{4.5}$$

where $\mathbf{g}^+ = (g_\tau^+, g_N^+)$ and $\mathbf{g}^- = (g_\tau^-, g_N^-)$.

We shall express the solution of the above equations as a series. The nth (n even) term of the series solves Oseen equations in the channel with the *right* (in the sense that it cancels the boundary datum created at $y = -1$ by the $(n-1)$th term) boundary condition at $y = -1$. On the other hand, the nth term of the series creates a boundary datum at $y = +1$, which will be canceled by the $(n+1)$th term, which therefore has the *right* boundary condition at $y = +1$. Of course the main concern will be to show that this series is convergent. In fact we shall prove that, for a time T_α, this series is geometric with parameter $\alpha < 1$. Our representation for the solution of (4.1)–(4.5) will therefore be valid only up to time T_α. Notice, however, that $T_\alpha \to \infty$ when $\nu \to 0$.

The plan of the section is the following. First we introduce some pseudodifferential operators: (1) the operators $U^\pm$ (that we call the Ukai operators) that are projection operators, (2) the operator $\mathcal{L}$ solving Dirichlet problem in the strip, and (3) the projection-convection-diffusion operators $\mathcal{M}^+$ and $\mathcal{M}^-$. All these operators are the ingredients to construct, in section 4.4, the operators $\mathcal{O}^-$ and $\mathcal{O}^+$. These are operators that solve Oseen equations with the right boundary condition only at $y = -1$ and at $y = +1$, respectively. Finally, through these operators, in section 4.5 we construct the explicit solution formula.

4.1. The Ukai operators.

Here we define the following operators which are a modification of the operator U introduced in [7]:

$$U^- f = \int_{-1}^{y} dy' e^{-|\xi|(y-y')} f(y', \xi), \tag{4.6}$$

$$U^+ f = -\int_{y}^{1} dy' e^{|\xi|(y-y')} f(y', \xi). \tag{4.7}$$

These operators solve the problems

$$(\partial_y + |\xi|)U^- f = f, \tag{4.8}$$

$$\gamma^- U^- f = 0\ , \tag{4.9}$$

and

$$(\partial_y - |\xi|)U^+ f = f, \tag{4.10}$$

$$\gamma^+ U^+ f = 0\,. \tag{4.11}$$

The following proposition holds.

Proposition 4.1. *Let f be of the form $f = |\xi'|\tilde{f}$ with $\tilde{f} \in H_T^{l+1}$. Then $U^+ f \in H_T^l$, $U^- f \in H_T^l$, and the following estimates hold:*

$$\|U^+ f\|_{l,T} \leq c\|\tilde{f}\|_{l+1,T},$$
$$\|U^- f\|_{l,T} \leq c\|\tilde{f}\|_{l+1,T}.$$

The proof of the above proposition is a straightforward modification of the proof of a similar statement given in [1].

The following lemmas are crucial for our analysis.

Lemma 4.2. *Suppose $g_\tau^+ \in H_T^{\prime l}$ with $g_\tau^+|_{t=0} = 0$. Then $\gamma^- U^+ F_1(g_\tau^+, 0) \in H_T^{\prime l}$. Moreover, there exists $\alpha < 1$ and $T_\alpha > 0$, independent of g_τ^+, such that*

$$\|\gamma^- U^+ F_1(g_\tau^+, 0)\|_{l,T_\alpha} \leq \alpha\|g_\tau^+\|_{l,T}.$$

Lemma 4.3. *Suppose $g_\tau^- \in H_T^{\prime l}$ with $g_\tau^-|_{t=0} = 0$. Then $\gamma^- U^- F_1(0\,, g_\tau^-) \in H_T^{\prime l}$. Moreover, there exists $\alpha < 1$ and $T_\alpha > 0$, independent of g_τ^-, such that*

$$\|\gamma^+ U^- F_1(0, g_\tau^-)\|_{l,T_\alpha} \leq \alpha\|g_\tau^-\|_{l,T}.$$

The meaning of the estimate on the operator $U^+ F_1$ given in Lemma 4.2 is the following. Give to $U^+ F_1$ a boundary datum which is different from zero only at $y = +1$, and evaluate the norm of the trace at $y = -1$. Then, up to the (sufficiently small) time T_α, one has that this norm is strictly less than the norm of the boundary datum at $y = +1$. Lemma 4.3 admits a similar interpretation. It is natural to expect that the time T_α up to which the estimates are valid grows to infinity when the diffusivity goes to zero. This will show up clearly during the proof of the above lemmas, which are given in the appendix.

4.2. The inverse elliptic operators. We introduce the following operator $\mathcal{L} = (\mathcal{L}_\tau, \mathcal{L}_N)$:

$$\mathcal{L}_N(g_N^+, g_N^-) = \frac{\sinh[|\xi|(y+1)]}{\sinh[2|\xi|]} g_N^+ + \frac{\sinh[|\xi|(1-y)]}{\sinh[2|\xi|]} g_N^-, \tag{4.12}$$

$$\mathcal{L}_\tau(g_N^+, g_N^-) = \frac{\cosh[|\xi|(y+1)]}{\sinh[2|\xi|]} N' g_N^+ - \frac{\cosh[|\xi|(1-y)]}{\sinh[2|\xi|]} N' g_N^-, \tag{4.13}$$

where $N' = i\xi/|\xi|$. This operator has the property of being divergence-free and harmonic; moreover, one can easily see that it is the gradient of a scalar function. Therefore, it solves Oseen equations. Finally, it has the property that its normal component has g_N^+ and g_N^- as boundary conditions at $y = +1$ and $y = -1$, respectively.

We now give some estimates on this operator. In these estimates we shall always suppose that the boundary data $g_N^\pm$ are such that $|\xi|^{-1} g_N \in H_T^{\prime l+1}$. This hypothesis, which we shall refer to as *integrability* of the normal influx (in fact it is related to assuming that the total influx from the boundary is bounded), is necessary to handle the fact that the operator $\mathcal{L}$ is singular when $\xi \to 0$.

The proposition below gives an estimate of $\mathcal{L}$ in the spaces L^l_T and H^l_T. The estimate in the space L^l_T will be used in the next subsections in the construction of the Oseen operator. The estimate in the space H^l_T will be used in section 6 in the analysis of the Euler equations.

Proposition 4.4. *Let $g^\pm_N$ be such that $|\xi|^{-1}g^\pm_N \in H'^{l+1}_T$. Then $\mathcal{L}(g^+_N, g^-_N) \in L^l_T \bigcap H^l_T$. The following estimates hold:*

$$\begin{aligned}\|\mathcal{L}(g^+_N, g^-_N)\|_{l,T} &\le c\left[\||\xi|^{-1}g^+_N\|_{l+1,T} + \||\xi|^{-1}g^-_N\|_{l+1,T}\right],\\ |\mathcal{L}(g^+_N, g^-_N)|_{l,T} &\le c\left[\||\xi|^{-1}g^+_N\|_{l+1,T} + \||\xi|^{-1}g^-_N\|_{l+1,T}\right].\end{aligned}$$

The following lemmas will be useful in the estimates of the Oseen operator.

Lemma 4.5. *Let g^+_N be such that $|\xi|^{-1}g^+_N \in H'^{l+1}_T$. Then $\gamma^-\mathcal{L}_\tau(g^+_N, 0) \in L^l_T$, and the following estimate holds:*

$$\|\gamma^-\mathcal{L}_\tau(g^+_N, 0)\|_{l,T} \le \frac{1}{2}\||\xi|^{-1}g^+_N\|_{l+1,T}.$$

Lemma 4.6. *Let g^-_N be such that $|\xi|^{-1}g^-_N \in H'^{l+1}_T$. Then $\gamma^+\mathcal{L}_\tau(0, g^-_N) \in L^l_T$, and the following estimate holds:*

$$\|\gamma^+\mathcal{L}_\tau(0, g^-_N)\|_{l,T} \le \frac{1}{2}\||\xi|^{-1}g^-_N\|_{l+1,T}.$$

The meaning of Lemma 4.5 is the following. Give to the operator $\mathcal{L}_\tau$ a boundary datum which is nonzero only at $y = +1$. Then its trace at $y = -1$ is strictly less (half) than the datum at $y = +1$. A similar interpretation can be given to Lemma 4.6. The proof of the above two lemmas is a straightforward consequence of the fact that $\left|\frac{|\xi'|}{\sinh 2|\xi'|}\right| \le \frac{1}{2}$.

4.3. The projection-convection-diffusion operator. Through the operators we have introduced in the previous sections, we can define the operator $\mathcal{M}^-$. The tangential and normal component are defined as follows:

$$\begin{aligned}\mathcal{M}^-_\tau(g^-_\tau, g^-_N) &= U^-|\xi|F_1\left(0, g^-_\tau - \gamma^-\mathcal{L}_\tau(0, g^-_N)\right) + F_1\left(0, g^-_\tau - \gamma^-\mathcal{L}_\tau(0, g^-_N)\right),\\ \mathcal{M}^-_N(g^-_\tau, g^-_N) &= U^-|\xi|N'F_1\left(0, g^-_\tau - \gamma^-\mathcal{L}_\tau(0, g^-_N)\right).\end{aligned}$$

One can verify that the operator $\mathcal{M}^-$ is divergence-free, satisfies the Oseen equations, and has zero normal boundary condition at $y = -1$:

$$\begin{aligned}(\partial_t - \nu\Delta + U\partial_x)\,\mathcal{M}^-(g^-_\tau, g^-_N) + \boldsymbol{\nabla} p &= 0,\\ \boldsymbol{\nabla}\cdot\mathcal{M}^-(g^-_\tau, g^-_N) &= 0,\\ \gamma^-\mathcal{M}^-(g^-_\tau, g^-_N) &= \left(g^-_\tau - \gamma^-\mathcal{L}_\tau(0, g^-_N), 0\right),\\ \mathcal{M}^-(g^-_\tau, g^-_N)|_{t=0} &= 0.\end{aligned}$$

One can analogously define the operator $\mathcal{M}^+$:

$$\begin{aligned}\mathcal{M}^+_\tau(g^+_\tau, g^+_N) &= U^+|\xi|F_1\left(g^+_\tau - \gamma^+\mathcal{L}_\tau(g^+_N, 0), 0\right) + F_1\left(g^+_\tau - \gamma^+\mathcal{L}_\tau(g^+_N, 0), 0\right),\\ \mathcal{M}^+_N(g^+_\tau, g^+_N) &= U^+|\xi|N'F_1\left(g^+_\tau - \gamma^+\mathcal{L}_\tau(g^+_N, 0), 0\right).\end{aligned}$$

It has the property of being divergence-free and of solving Oseen equations with zero normal boundary condition at $y = 1$, namely,

$$\begin{aligned}(\partial_t - \nu\Delta + U\partial_x)\mathcal{M}^+(g_\tau^+, g_N^+) + \boldsymbol{\nabla} p &= 0,\\ \boldsymbol{\nabla}\cdot\mathcal{M}^+(g_\tau^+, g_N^+) &= 0,\\ \gamma^+\mathcal{M}^+(g_\tau^+, g_N^+) &= \left(g_\tau^+ - \gamma^+\mathcal{L}_\tau(g_N^+, 0), 0\right),\\ \mathcal{M}^-(g_\tau^+, g_N^+)|_{t=0} &= 0.\end{aligned}$$

4.4. The half space Oseen operators. One can finally define the half space Oseen operators $\mathcal{O}^+$ and $\mathcal{O}^-$. These operators solve the Oseen equations, are divergence-free, and have the right boundary condition at $y = +1$ and $y = -1$, respectively. Moreover, the trace of these operators, evaluated at $y = -1$ and $y = +1$, respectively, has norm strictly less than the boundary datum. This property, expressed in Propositions 4.5 and 4.6 below, makes them suitable for the iterative procedure of the next section.

The operator $\mathcal{O}^+$ is defined as

$$\begin{aligned}\mathcal{O}_N^+(g_\tau^+, g_N^+) &= \mathcal{L}_N(g_N^+, 0) + \mathcal{M}_N^+(g_\tau^+, g_N^+)\ ,\\ \mathcal{O}_\tau^+(g_\tau^+, g_N^+) &= \mathcal{L}_\tau(g_N^+, 0) + \mathcal{M}_\tau^+(g_\tau^+, g_N^+)\ .\end{aligned}$$

The operator $\mathcal{O}^-$ is defined as

$$\begin{aligned}\mathcal{O}_\tau^-(g_\tau^-, g_N^-) &= \mathcal{L}_\tau(0, g_N^-) + \mathcal{M}_\tau^-(g_\tau^-, g_N^-)\ ,\\ \mathcal{O}_N^-(g_\tau^-, g_N^-) &= \mathcal{L}_N(0, g_N^-) + \mathcal{M}_N^-(g_\tau^-, g_N^-)\ .\end{aligned}$$

These operators have the property of solving the Oseen equations in the channel: $\mathcal{O}^+$ with the *right* boundary condition at $y = +1$; $\mathcal{O}^-$ with the *right* boundary condition at $y = -1$.

$$\begin{aligned}(\partial_t - \nu\Delta + U\partial_x)\mathcal{O}^\pm(g_\tau^\pm, g_N^\pm) + \boldsymbol{\nabla} p &= 0,\\ \boldsymbol{\nabla}\cdot\mathcal{O}^\pm(g_\tau^\pm, g_N^\pm)\ &= 0,\\ \gamma^\pm\mathcal{O}^\pm(g_\tau^\pm, g_N^\pm) &= (g_\tau^\pm, g_N^\pm),\\ \mathcal{O}^\pm(g_\tau^-, g_N^-)|_{t=0} &= 0\ .\end{aligned}$$

We now give some estimates on these operators. In the next section these estimates will allow us to construct the solution of the Oseen equation in the channel. In these estimates we shall always suppose that the normal component of the datum is such that $|\xi|^{-1}g_N \in H_T^{\prime l+1}$, i.e., that $\boldsymbol{g} \in \boldsymbol{H}_T^{\prime l}$.

PROPOSITION 4.7. *Let $\boldsymbol{g}^+ \in \boldsymbol{H}_T^{\prime l}$ with $\boldsymbol{g}^+|_{t=0} = 0$. Then $\mathcal{O}^+(\boldsymbol{g}^+) \in L_T^l$ and the following estimate holds:*

$$\|\mathcal{O}^+(\boldsymbol{g}^+)\|_{l,T} \leq c\ \boldsymbol{|}\,\boldsymbol{g}^+\,\boldsymbol{|}_{\,l,T}\ .$$

PROPOSITION 4.8. *Let $\boldsymbol{g}^- \in \boldsymbol{H}_T^{\prime l}$ with $\boldsymbol{g}^-|_{t=0} = 0$. Then $\mathcal{O}^-(\boldsymbol{g}^-) \in \boldsymbol{H}_T^l$ and the following estimate holds:*

$$\|\mathcal{O}^-(\boldsymbol{g}^-)\|_{l,T} \leq c\ \boldsymbol{|}\,\boldsymbol{g}^-\,\boldsymbol{|}_{\,l,T}\ .$$

The proof of these propositions can be easily achieved by using Propositions 4.4, 4.1, and 3.3.

We now give the estimates on the trace of the operators $\mathcal{O}^+$ and $\mathcal{O}^-$. We shall also prove that the trace at $y = -1$ (at $y = +1$, respectively) of $\mathcal{O}^+$ (of $\mathcal{O}^-$, respectively) has the integrability property for the normal influx.

Proposition 4.9. *Let $\boldsymbol{g}^+ \in \boldsymbol{H}'^{l}_{T}$ with $\boldsymbol{g}^+|_{t=0} = 0$. Then $\gamma^-\mathcal{O}^+ \in \boldsymbol{H}'^{l}_{T}$. Moreover, for any $0 < \alpha < 1$ there exists $T_\alpha > 0$ such that*

$$\left| \gamma^-\mathcal{O}^+(\boldsymbol{g}^+) \right|_{l,T_\alpha} \leq \alpha \left| \boldsymbol{g}^+ \right|_{l,T} . \tag{4.14}$$

Proposition 4.10. *Let $\boldsymbol{g}^- \in \boldsymbol{H}'^{l}_{T}$ with $\boldsymbol{g}^-|_{t=0} = 0$. Then $\gamma^+\mathcal{O}^-(\boldsymbol{g}^-) \in \boldsymbol{H}'^{l}_{T}$. Moreover, for any $0 < \alpha < 1$ there exists $T_\alpha > 0$ such that*

$$\left| \gamma^+\mathcal{O}^-(\boldsymbol{g}^-) \right|_{l,T_\alpha} \leq \alpha \left| \boldsymbol{g}^- \right|_{l,T} . \tag{4.15}$$

The proof of Propositions 4.9 and 4.10 is given in the appendix.

4.5. The Oseen operator with boundary data. We now have to solve the Oseen equations (4.1)–(4.5). We shall construct the solution as an infinite sum:

$$\boldsymbol{u} = \sum_{i=0}^{\infty} \boldsymbol{u}^{(i)} . \tag{4.16}$$

Each term of the series solves the Oseen equations. The zeroth term $\boldsymbol{u}^{(0)}$ has the right boundary condition at $y = -1$:

$$\boldsymbol{u}^{(0)} = \mathcal{O}^-(\boldsymbol{g}^-) . \tag{4.17}$$

As the boundary condition for the first term of the series we choose $\gamma^+\boldsymbol{u}^{(1)} = \boldsymbol{g}^+ - \gamma^+\boldsymbol{u}^{(0)}$. Therefore, one has the following expression for $\boldsymbol{u}^{(1)}$:

$$\boldsymbol{u}^{(1)} = \mathcal{O}^+\left(\boldsymbol{g}^+ - \gamma^+\boldsymbol{u}^{(0)}\right) . \tag{4.18}$$

In fact this choice will fix the boundary condition at $y = +1$; on the other end it generates a boundary datum at $y = -1$. We define the second term of the series $\boldsymbol{u}^{(2)}$ so that it cancels this boundary datum at $y = -1$:

$$\boldsymbol{u}^{(2)} = \mathcal{O}^-\left(-\gamma^-\boldsymbol{u}^{(1)}\right) . \tag{4.19}$$

Recursively we define the generic even and odd term of the series:

$$\boldsymbol{u}^{(2m)} = \mathcal{O}^-\left(-\gamma^-\boldsymbol{u}^{(2m-1)}\right) , \qquad m > 1 , \tag{4.20}$$

$$\boldsymbol{u}^{(2m+1)} = \mathcal{O}^+\left(-\gamma^+\boldsymbol{u}^{(2m)}\right) , \qquad m > 1 . \tag{4.21}$$

To prove the convergence of the series we prove the following proposition.

Proposition 4.11. *Let $\boldsymbol{g}^\pm \in \boldsymbol{H}'^{l}_{T}$ with $\boldsymbol{g}^\pm|_{t=0} = 0$. Then for any $0 < \alpha < 1$ there exists $T_\alpha > 0$ such that for each $\boldsymbol{u}^{(i)}$ the following estimate holds:*

$$\|\boldsymbol{u}^{(i)}\|_{l,T_\alpha} \leq c\alpha^{i-2}\left(\left| \boldsymbol{g}^+ \right|_{l,T} + \left| \boldsymbol{g}^- \right|_{l,T} \right) . \tag{4.22}$$

Proof. We prove the proposition when $i = 2m$. The proof is analogous when i is odd:

$$\begin{aligned}\boldsymbol{u}^{(2m)} &= \mathcal{O}^-(-\gamma^-\boldsymbol{u}^{(2m-1)})\\ &= \mathcal{O}^-(-\gamma^-\mathcal{O}^+(-\gamma^+\boldsymbol{u}^{(2m-2)}))\\ &= \cdots\\ &= \mathcal{O}^-\underbrace{(-\gamma^-\mathcal{O}^+(-\gamma^+\mathcal{O}^-(-\gamma^-\mathcal{O}^+(\cdots(-\gamma^-\mathcal{O}^+}_{2m-2\text{ times}}(\boldsymbol{g}^+-\gamma^+\mathcal{O}^-\boldsymbol{g}^-))\ldots)))).\end{aligned}$$

Hence, first using Proposition 4.8, then using Propositions 4.9 and 4.10, one has

$$\begin{aligned}\|\boldsymbol{u}^{(2m)}\|_{l,T_\alpha} &= \|\mathcal{O}^-(-\gamma^-\boldsymbol{u}^{(2m-1)})\|_{l,T_\alpha}\\ &\le c\,\left|\,\gamma^-\boldsymbol{u}^{(2m-1)}\,\right|_{l,T_\alpha} = c\,\left|\,\gamma^-\mathcal{O}^+(\gamma^+\boldsymbol{u}^{(2m-2)})\,\right|_{l,T_\alpha}\\ &\le c\alpha\,\left|\,\gamma^+\boldsymbol{u}^{(2m-2)}\,\right|_{l,T_\alpha}\\ &\le\cdots\\ &\le c\alpha^{2m-2}\left(\left|\,\boldsymbol{g}^+\,\right|_{l,T}+\left|\,\boldsymbol{g}^-\,\right|_{l,T}\right)\;.\end{aligned}$$

Therefore the series (4.16) with $\boldsymbol{u}^{(i)}$ given by (4.17)–(4.21) is convergent, and we can define the operator $\mathcal{O}_b$, solving Oseen equations with boundary data:

$$\mathcal{O}_b(\boldsymbol{g}^-,\boldsymbol{g}^+) = \sum_{i=0}^{\infty}\boldsymbol{u}^{(i)}\;. \tag{4.23}$$

The following theorem is the main result of this section.

THEOREM 4.12. *Let* $\boldsymbol{g}^\pm = (g_\tau^\pm, g_N^\pm)$ *such that* $\boldsymbol{g}_N^\pm \in \boldsymbol{H}_T'^{l}$ *and* $\boldsymbol{g}^\pm|_{t=0} = 0$. *Then there exists* T_α, *independent of* $\boldsymbol{g}^\pm$, *such that the operator* $\mathcal{O}_b$, *defined by* (4.23) *with* $\boldsymbol{u}^{(i)}$ *given by* (4.17)–(4.21), *represents the solutions of the Oseen equations* (4.1)–(4.5). *Moreover,* $\mathcal{O}_b(\boldsymbol{g}^-,\boldsymbol{g}^+) \in L^l_{T_\alpha}$ *and the following estimate holds:*

$$\|\mathcal{O}_b(\boldsymbol{g}^-,\boldsymbol{g}^+)\|_{l,T_\alpha} \le c\left[\left|\,\boldsymbol{g}^+\,\right|_{l,T}+\left|\,\boldsymbol{g}^-\,\right|_{l,T}\right]\;.$$

5. The explicit solution of the Oseen equations.

We now solve the Oseen equations with source term, boundary data, and initial data (1.1)–(1.5). To accomplish this task first we introduce the projection operator onto the divergence-free part of a vector function. We shall write this projection operator so that its normal component evaluated at the boundary is identically zero. Then we shall use this projection operator to project the convection-diffusion operator F_0 and F_2 to get the operators $\mathcal{O}_i$ and $\mathcal{O}_s$. These operators solve the Oseen equation with initial datum and source term, respectively. On the other hand, they generate *wrong* boundary data. Finally, in the last subsection we shall use the operator $\mathcal{O}_b$ to cancel the wrong boundary data and get the representation of the solution of (1.1)–(1.5).

5.1. The projection operator.

We introduce the following projection operator:

$$P = 1 - \boldsymbol{\nabla}\Delta_N^{-1}\boldsymbol{\nabla}\cdot\;\;. \tag{5.1}$$

In the above expression with Δ_N^{-1} we have denoted the operator that solves the Poisson equation with Neumann boundary conditions. We give the explicit expression of this projection operator:

$$\begin{aligned}
P_\tau\ \boldsymbol{w} = w_\tau &+ \frac{N'}{\sinh(2|\xi'|)}\left[\gamma^+ w_N \cosh[|\xi'|(y+1)] - \gamma^- w_N \cosh[|\xi'|(y-1)]\right] \\
&- \frac{|\xi'|}{2\sinh(2|\xi'|)}\left\{\int_{-1}^{y} dy' \left[\cosh(|\xi'|(y-y'-2)) + \cosh(|\xi'|(y+y'))\right] w_\tau(|\xi'|, y')\right. \\
&- \int_{-1}^{y} dy' \left[\sinh(|\xi'|(y-y'-2)) - \sinh(|\xi'|(y+y'))\right] N' w_N(|\xi'|, y') \\
&+ \int_{y}^{1} dy' \left[\cosh(|\xi'|(y-y'+2)) + \cosh(|\xi'|(y+y'))\right] w_\tau(|\xi'|, y') \\
&\left. - \int_{y}^{1} dy' \left[\sinh(|\xi'|(y-y'+2)) - \sinh(|\xi'|(y+y'))\right] N' w_N(|\xi'|, y')\right\}, \\
P_N \boldsymbol{w} = &\frac{1}{\sinh(2|\xi'|)}\left\{\gamma^+ w_N \sinh[|\xi'|(y+1)] - \gamma^- w_N \sinh[|\xi'|(y-1)]\right\} \\
&+ \frac{|\xi'|}{2\sinh(2|\xi'|)}\left\{\int_{-1}^{y} dy'\ \left[\sinh(|\xi'|(y-y'-2)) + \sinh(|\xi'|(y+y'))\right]\ N' w_\tau\right. \\
&+ \int_{-1}^{y} dy'\ \left[\cosh(|\xi'|(y-y'-2)) - \cosh(|\xi'|(y+y'))\right]\ w_N \\
&+ \int_{y}^{1} dy'\ \left[\sinh(|\xi'|(y-y'+2)) + \sinh(|\xi'|(y+y'))\right]\ N' w_\tau \\
&\left. + \int_{y}^{1} dy'\ \left[\cosh(|\xi'|(y-y'+2)) - \cosh(|\xi'|(y+y'))\right]\ w_N\right\}.
\end{aligned}$$

It is not difficult to see that the following proposition holds.

Proposition 5.1. *Let $\boldsymbol{w} \in L^l_T$. Then $P\boldsymbol{w} \in L^l_T$ and*

$$\|P\boldsymbol{w}\|_{l,T} \le c\,\|\boldsymbol{w}\|_{l,T}\ .$$

It is important to notice that, if $\gamma^\pm w_N = 0$, then the normal component of the projection operator evaluated at the boundary is identically zero:

$$\text{if} \quad \gamma^\pm w_N = 0, \qquad \text{then} \quad \gamma^\pm P_N \boldsymbol{w} = 0\ . \tag{5.2}$$

5.2. The projected convection-diffusion operators. We can now introduce the operators $\mathcal{O}_i$ and $\mathcal{O}_s$, defined as

$$\mathcal{O}_i = PF_0\ , \qquad \mathcal{O}_s = PF_2\ .$$

Supposing that $\boldsymbol{\nabla}\cdot\boldsymbol{u}_0 = 0$, one therefore has that $\mathcal{O}_i\boldsymbol{u}_0$ satisfies

$$\begin{aligned}
\left(\partial_t - \partial_{YY} - \varepsilon^2\partial_{xx}\right)\mathcal{O}_i\boldsymbol{u}_0 + \boldsymbol{\nabla}p &= 0, \\
\boldsymbol{\nabla}\cdot\mathcal{O}_i\boldsymbol{u}_0 &= 0, \\
\mathcal{O}_i\boldsymbol{u}_0|_{t=0} &= \boldsymbol{u}_0\ .
\end{aligned}$$

On the other hand, $\mathcal{O}_s\boldsymbol{w}$ satisfies

$$\begin{aligned}
\left(\partial_t - \partial_{YY} - \varepsilon^2\partial_{xx}\right)\mathcal{O}_s\boldsymbol{w} + \boldsymbol{\nabla}p &= \boldsymbol{w}, \\
\boldsymbol{\nabla}\cdot\mathcal{O}_s\boldsymbol{w} &= 0, \\
\mathcal{O}_s\boldsymbol{w}|_{t=0} &= 0\ .
\end{aligned}$$

The following estimates are a consequence of the properties of P, expressed in Proposition 5.1, and of the properties of F_0 and F_2, expressed in Propositions 3.1 and 3.4.

PROPOSITION 5.2. *Let $\boldsymbol{u}_0 \in L^l$. Then $\mathcal{O}_i \boldsymbol{u}_0 \in L^l_T$ and*

$$\|\mathcal{O}_i \boldsymbol{u}_0\|_{l,T} \le \|\boldsymbol{u}_0\|_l \, .$$

PROPOSITION 5.3. *Let $\boldsymbol{w} \in L^l_T$. Then $\mathcal{O}_s \boldsymbol{w} \in L^l_T$ and*

$$\|\mathcal{O}_s \boldsymbol{w}\|_{l,T} \le c \, \|\boldsymbol{w}\|_{l,T} \, .$$

The normal components of the operators $\mathcal{O}_i$ and $\mathcal{O}_s$ evaluated at the boundary are zero (because of (5.2)). This readily gives the following estimates on the traces of $\mathcal{O}_i$ and $\mathcal{O}_s$.

PROPOSITION 5.4. *Let $\boldsymbol{u}_0 \in L^l$. Then $\gamma^\pm \mathcal{O}_i \boldsymbol{u}_0 \in \boldsymbol{H}'^l_T$ and*

$$\bigl|\, \gamma^\pm \mathcal{O}_i \boldsymbol{u}_0 \,\bigr|_{l,T} \le c \|\boldsymbol{u}_0\|_l \, .$$

PROPOSITION 5.5. *Let $\boldsymbol{w} \in L^l_T$. Then $\gamma^\pm \mathcal{O}_s \boldsymbol{w} \in \boldsymbol{H}'^l_T$ and*

$$\bigl|\, \gamma^\pm \mathcal{O}_s \boldsymbol{w} \,\bigr|_{l,T} \le c \|\boldsymbol{w}\|_{l,T} \, .$$

5.3. The solution of the Oseen equations. We can finally introduce the operator $\mathcal{O}$ that solves (1.1)–(1.5):

$$\begin{aligned} &\mathcal{O}(\boldsymbol{f}, \boldsymbol{u}_0, \boldsymbol{g}^-, \boldsymbol{g}^+) \\ &\quad = \mathcal{O}_s \boldsymbol{f} + \mathcal{O}_i \boldsymbol{u}_0 + \mathcal{O}_b(\boldsymbol{g}^+ - \gamma^+ \mathcal{O}_s \boldsymbol{f} - \gamma^+ \mathcal{O}_i \boldsymbol{u}_0, \boldsymbol{g}^- - \gamma^- \mathcal{O}_s \boldsymbol{f} - \gamma^- \mathcal{O}_i \boldsymbol{u}_0) \, . \end{aligned} \tag{5.3}$$

Therefore, if one defines

$$\boldsymbol{u} = \mathcal{O}(\boldsymbol{f}, \boldsymbol{u}_0, \boldsymbol{g}^+, \boldsymbol{g}^-) \, , \tag{5.4}$$

then one has that $\boldsymbol{u}$ solves the system (1.1)–(1.5).

Remark 5.1. The representation of the solution given by the operator $\mathcal{O}$ is valid only up to the time T_α. In fact the series which defines the operator $\mathcal{O}_b$ converges only up to the time T_α. On the other hand, given that T_α does not depend on the boundary data, one can take the value of the solution at the time T_α as the initial datum and solve the corresponding Oseen problem up to the time $2T_\alpha$. One can therefore construct the solution up to the time T. Moreover, we also notice that the time $T_\alpha = O(\nu^{-1})$. Therefore, in the zero viscosity limit, the representation (5.4) is valid for an arbitrarily long time. The following theorem holds.

THEOREM 5.6. *Suppose $\boldsymbol{f} \in L^l_T$, $\boldsymbol{u}_0 \in L^l$, and $\boldsymbol{g}^\pm \in \boldsymbol{H}'^l_T$. Suppose the following compatibility conditions are verified:*

$$\boldsymbol{\nabla} \cdot \boldsymbol{u}_0 = 0 \, , \tag{5.5}$$

and

$$\boldsymbol{g}^\pm|_{t=0} = \gamma^\pm \boldsymbol{u}_0 \, . \tag{5.6}$$

Then the solution of the Oseen equations (1.1)–(1.5) *is represented, for a time T_α, by* (5.4). *Moreover, the following estimate holds:*

$$\|\mathcal{O}(\boldsymbol{f}, \boldsymbol{u}_0, \boldsymbol{g}^-, \boldsymbol{g}^+)\|_{l,T} \le c \Bigl[\|\boldsymbol{f}\|_{l,T} + \|\boldsymbol{u}_0\|_l + \bigl|\, \boldsymbol{g}^+ \,\bigr|_{l,T} + \bigl|\, \boldsymbol{g}^- \,\bigr|_{l,T} \Bigr] \, .$$

The proof of this theorem is a consequence of Propositions 5.2, 5.3, 5.4, and 5.5 and Theorem 4.12.

We finally give a proposition which will be useful in the solution of the error equation, given in the next section. It says that if the forcing term in (1.1) is of the same order of the square root of the viscosity, then one can use the heat kernel to increase the regularity of the solution.

PROPOSITION 5.7. *Suppose* $\boldsymbol{f} = \sqrt{\nu}\boldsymbol{h}$ *with* $\boldsymbol{h} \in L_T^{l-1}$, $\boldsymbol{g}^{\pm} \in \boldsymbol{H}_T'^{l}$, *and* $\boldsymbol{u}_0 \in L'^{l}$. *Suppose that the compatibility conditions* (5.5) *and* (5.6) *are satisfied. Then* $\mathcal{O}_s(\boldsymbol{f}, \boldsymbol{g}^-, \boldsymbol{g}^+) \in L_T^l$, *and the following estimate holds:*

$$\|\mathcal{O}(\boldsymbol{f}, \boldsymbol{u}_0, \boldsymbol{g}^+, \boldsymbol{g}^-)\|_{l,T} \leq c\left[\|\boldsymbol{h}\|_{l-1,T} + \|\boldsymbol{u}_0\|_l + \left|\!\left|\!\left| \boldsymbol{g}^+ \right|\!\right|\!\right|_{l,T} + \left|\!\left|\!\left| \boldsymbol{g}^- \right|\!\right|\!\right|_{l,T}\right].$$

The proof of this proposition can be easily achieved using the analogous estimate for the operator F_2 given in Proposition 3.5, and the estimates for P, $\mathcal{O}_s$, $\mathcal{O}_i$, and $\mathcal{O}_b$, given in Propositions 5.1, 5.2, 5.3, 5.4, and 5.5 and Theorem 4.12.

6. The asymptotic analysis. We are now ready to introduce the boundary layer analysis for the Oseen equations (1.1)–(1.5). For simplicity we shall suppose that the source term is not present. In a remark at the end of section 6.1 we shall sketch the procedure that allows us to handle a source term.

We shall impose the initial condition $\boldsymbol{u}_0 \in H^l$ and show that the solution is the sum of an inviscid (Euler) part, two boundary layers (Prandtl) parts exponentially decaying outside a region of size $\varepsilon = \sqrt{\nu}$ close to the two boundaries $y = -1$ and $y = +1$, and a correction term.

We seek a solution of the form

$$u = u^E + u^P + \varepsilon w_\tau, \tag{6.1}$$

$$v = v^E + \varepsilon v^P + \varepsilon w_N, \tag{6.2}$$

$$p = p^E + \varepsilon p^w\ , \tag{6.3}$$

where (u^E, v^E) represents the inviscid solution, $(u^P, \varepsilon v^P)$ represents the Prandtl part which describes the behavior of the fluid in the boundary layers close to $y = \pm 1$, and (w_τ, w_N) is the correction term. They solve the following equations.

1. The convective equations

$$(\partial_t + U\partial_x)\boldsymbol{u}^E + \boldsymbol{\nabla} p^E = 0, \tag{6.4}$$

$$\boldsymbol{\nabla} \cdot \boldsymbol{u}^E = 0, \tag{6.5}$$

$$\gamma^- v^E = g_N^-, \tag{6.6}$$

$$\gamma^+ v^E = g_N^+, \tag{6.7}$$

$$\boldsymbol{u}^E(t = 0) = \boldsymbol{u}_0\ . \tag{6.8}$$

2. The boundary layer equations

$$(\partial_t - \varepsilon^2\Delta + U\partial_x)u^P = 0, \tag{6.9}$$

$$\partial_x u^P + \partial_Y v^P = 0, \tag{6.10}$$

$$\gamma^- u^P = g_\tau^- - \gamma^- u^E, \tag{6.11}$$

$$\gamma^+ u^P = g_\tau^+ - \gamma^+ u^E, \tag{6.12}$$

$$u^P(t = 0) = 0\ . \tag{6.13}$$

3. The correction equations

$$(\partial_t - \varepsilon^2\Delta + U\partial_x)\boldsymbol{w} + \boldsymbol{\nabla} p^w = \varepsilon\Delta \boldsymbol{u}^E, \tag{6.14}$$
$$\boldsymbol{\nabla}\cdot\boldsymbol{w} = 0, \tag{6.15}$$
$$\gamma^-\boldsymbol{w} = (0,\, -\gamma^- v^P\ ), \tag{6.16}$$
$$\gamma^+\boldsymbol{w} = (0,\, -\gamma^+ v^P\ ), \tag{6.17}$$
$$\boldsymbol{w}(t=0) = 0\ . \tag{6.18}$$

We require to hold the compatibility conditions between the boundary and the initial data:

$$\gamma^\pm v_0 = g_N^\pm(x, t=0), \tag{6.19}$$
$$g_\tau^\pm(t=0) = -\gamma^\pm u_0. \tag{6.20}$$

We require to hold the incompressibility condition for the initial data:

$$\boldsymbol{\nabla}\cdot\boldsymbol{u}_0 = 0. \tag{6.21}$$

Moreover, the incompressibility condition requires that

$$\int_{-\infty}^{\infty} (g_N^+ - g_N^-)\, dx = 0.$$

Notice the absence of the pressure term in (6.9)–(6.13). This is due to the introduction of a boundary layer corrector which differs from the usual Prandtl velocity for the value of the Euler velocity at the boundary. Namely, $\tilde{\boldsymbol{u}}^P = \boldsymbol{u}^P - \gamma\boldsymbol{u}^E$. Then, using the Euler equation at the boundary, one gets (6.9). For more details, see [2].

We now solve the above equations.

6.1. The Euler equations. One can see that the solution of (6.4)–(6.8) is

$$\begin{aligned} v^E &= \mathcal{L}_N\left(g_N^+ - v_0^E(x-Ut,1), g_N^- - v_0^E(x-Ut,-1)\right) \\ &\quad + v_0(x-Ut,y), \end{aligned} \tag{6.22}$$

$$\begin{aligned} u^E &= \mathcal{L}_\tau\left(g_N^+ - v_0^E(x-Ut,1), g_N^- - v_0^E(x-Ut,-1)\right) \\ &\quad + u_0(x-Ut,y), \end{aligned} \tag{6.23}$$

where the operator $\mathcal{L}$ was introduced in section 4.2. We now give an estimate on the above solution.

PROPOSITION 6.1. *Let* $\boldsymbol{g} \in \boldsymbol{H}'^l_T$. *Moreover, let* $\boldsymbol{u}_0 \in H^l$ *satisfy the compatibility conditions* (6.19) *and* (6.20) *and the incompressibility condition* (6.21). *Then* $\boldsymbol{u}^E \in H^l_T$ *and the following estimate holds:*

$$|\boldsymbol{u}^E|_{l,T} \le c(\,\big|\,\boldsymbol{g}^-\,\big|_{l,T} + \big|\,\boldsymbol{g}^+\,\big|_{l,T} + |\boldsymbol{u}_0|_l).$$

The proof is based on Proposition 4.4.

Remark 6.1. If a source term $\boldsymbol{f}$ is present in (6.4) one can solve the inviscid equation using the integrated (with respect to time) projection operator onto the divergence-free part.

6.2. The Prandtl equations. Equations (6.9) and the boundary conditions (6.11) and (6.12) and the initial condition (6.13) are convection-diffusion equations with boundary data and zero initial datum and no source. We have already solved these equations through the operator F_1 introduced in section 3. The solution is, therefore,

$$u^P = F_1(g_\tau^+ - \gamma^+ u^E, g_\tau^- - \gamma^- u^E) \; . \tag{6.24}$$

The normal component can be found using the incompressibility condition (6.10):

$$v^P = \int_Y^0 dY' \partial_x u^P \; . \tag{6.25}$$

Therefore, we conclude with the following proposition.

Proposition 6.2. *Let* $\mathbf{g}^\pm \in \boldsymbol{H}'^l_T$ *satisfy the compatibility conditions* (6.19)–(6.20) *and the incompressibility condition* (6.21). *Then* $u^P \in K_T^{l,\mu}$, $v^P \in K_T^{l-1,\mu}$, *and the following estimates hold:*

$$|u^P|_{l,\mu,T} \le c \left(\boldsymbol{|}\, \mathbf{g}^- \,\boldsymbol{|}_{l,T} + \boldsymbol{|}\, \mathbf{g}^+ \,\boldsymbol{|}_{l,T} + |\boldsymbol{u}_0|_l \right) ,$$
$$|v^P|_{l-1,\mu,T} \le c \left(\boldsymbol{|}\, \mathbf{g}^- \,\boldsymbol{|}_{l,T} + \boldsymbol{|}\, \mathbf{g}^+ \,\boldsymbol{|}_{l,T} + |\boldsymbol{u}_0|_l \right) .$$

6.3. The error equation. Let us now consider the correction term $\boldsymbol{w}$ satisfying (6.14)–(6.18).

One can see that (6.14)–(6.18) are of the same form as (1.1)–(1.5), namely, they are the Oseen equations with source term and boundary and initial data satisfying the hypotheses of Proposition 5.7. In fact the source term in (6.14) is $\varepsilon \Delta e^{i\xi U t} \boldsymbol{u}_0$, which is of the form $\varepsilon \boldsymbol{h}$ with $\boldsymbol{h} \in H_T^{l-2}$. Moreover, the boundary data $-\gamma^\pm v^P$ are of the form

$$-\gamma^\pm v^P = \partial_x \beta^\pm = -|\xi| N' \beta^\pm, \qquad \text{where} \qquad \beta^\pm = \int_0^{\pm 1/\varepsilon} dY' \, u^{P(\pm)} \in H'^l_T \; .$$

Therefore, $\gamma^\pm \boldsymbol{w} \in \boldsymbol{H}'^{l-1}_T$.

Hence the solution has the form given by (5.4) and we can give the estimate on the error $\boldsymbol{w}$.

Proposition 6.3. *Let us suppose that* $\boldsymbol{g}^\pm \in \boldsymbol{H}'^l_T$ *and* $\boldsymbol{u}_0 \in H^l$, *satisfying the compatibility conditions* (6.19)–(6.20) *and the incompressibility condition* (6.21). *Then the solution of* (6.14)–(6.18) $\boldsymbol{w} \in L_T^{l-1}$, *and the following estimate hold:*

$$\|w\|_{l-1,T} \le c \left[\boldsymbol{|}\, \boldsymbol{g}^+ \,\boldsymbol{|}_{l,T} + \boldsymbol{|}\, \boldsymbol{g}^- \,\boldsymbol{|}_{l,T} + |\boldsymbol{u}_0|_l \right] \; .$$

The above estimate is not enough to get the convergence of the solution of the Oseen equations to $\boldsymbol{u}^E + \boldsymbol{u}^P$ in a space where first derivatives are considered. A more refined analysis of the structure of the error is needed.

6.4. The structure of the error. We divide the error in the following way:

$$\boldsymbol{w} = \boldsymbol{w}^E + \boldsymbol{w}^{BL} + \varepsilon \boldsymbol{e}. \tag{6.26}$$

The Eulerian part of the error $\boldsymbol{w}^E$ satisfies convective equations, of the type (6.4)–(6.8), with $\varepsilon \Delta u^E$ as source term and with prescribed normal boundary data $-\gamma^\pm v^P$.

The boundary layer part of the error $\boldsymbol{w}^{BL}$ satisfies the boundary layer equations, of the type (6.9)–(6.13), with prescribed tangential component $-\gamma^{\pm}\boldsymbol{w}^{E}$.

Finally the overall correction $\boldsymbol{e}$ satisfies the correction equations, of the type (6.14)–(6.18), with zero source term and with prescribed boundary data $(0, -\gamma^{\pm} w_N^{BL})$, where with w_N^{BL} we have denoted the normal component of $\boldsymbol{w}^{BL}$.

One can therefore state the following proposition.

PROPOSITION 6.4. *Suppose the hypotheses of Proposition* 6.3 *hold true. Then the correction* $\boldsymbol{w}$ *admits a decomposition of the form* (6.26) *with* $\boldsymbol{w}^E \in H_T^{l-1}$, $w_\tau^{BL} \in K_T^{l-1,\mu}$, $w_N^{BL} \in K_T^{l-2,\mu}$, $\boldsymbol{e} \in L_T^{l-2}$, *and the following estimate holds:*

$$|\boldsymbol{w}^E|_{l-1,T} + |w_\tau^{BL}|_{l-1,\mu,T} + |w_N^{BL}|_{l-2,\mu,T} + \|\boldsymbol{e}\|_{l-2,T} \leq c\Big(|\!|\!| \boldsymbol{g}^+ |\!|\!|_{l,T} + |\!|\!| \boldsymbol{g}^- |\!|\!|_{l,T} + |\boldsymbol{u}_0|_l \Big) . \tag{6.27}$$

6.5. The main results. We can summarize the results of this section in the following theorem which is the main result of this paper.

THEOREM 6.5. *Let* $\boldsymbol{g}^{\pm} \in \boldsymbol{H}_T^{\prime l}$ *and* $\boldsymbol{u}_0 \in H^l$ *satisfy the compatibility conditions* (6.19)–(6.20) *and the incompressibility condition* (6.21). *Then the solution of Oseen equations* (1.1)–(1.5) *can be written in the form*

$$\boldsymbol{u} = \boldsymbol{u}^E + \boldsymbol{u}^P + \varepsilon \boldsymbol{w} \ , \tag{6.28}$$

where $\boldsymbol{u}^E$ *satisfies* (6.4)–(6.8), $\boldsymbol{u}^P$ *satisfies* (6.9)–(6.13), *and* $\boldsymbol{w}$ *satisfies* (6.14)–(6.18). *Moreover,* $\boldsymbol{u}^E \in H_T^l$, $u^P \in K_T^{l,\mu}$, $v^P \in K_T^{l-1,\mu}$, *and* $\boldsymbol{w} \in L_T^{l-1}$. *Moreover, the correction can be decomposed as*

$$\boldsymbol{w} = \boldsymbol{w}^E + \boldsymbol{w}^{BL} + \varepsilon \boldsymbol{e} \tag{6.29}$$

with $\boldsymbol{w}^E \in H_T^{l-1}$, $w_\tau^{BL} \in K_T^{l-1,\mu}$, $w_N^{BL} \in K_T^{l-2,\mu}$, *and* $\boldsymbol{e} \in L_T^{l-2}$. *The following estimates hold:*

$$\begin{aligned}
|\boldsymbol{u}^E|_{l,T} &\leq c\Big(|\!|\!| \boldsymbol{g}^+ |\!|\!|_{l,T} + |\!|\!| \boldsymbol{g}^- |\!|\!|_{l,T} + |\boldsymbol{u}_0|_l \Big) , \\
|u^P|_{l,\mu,T} &\leq c\Big(|\!|\!| \boldsymbol{g}^+ |\!|\!|_{l,T} + |\!|\!| \boldsymbol{g}^- |\!|\!|_{l,T} + |\boldsymbol{u}_0|_l \Big) , \\
|v^P|_{l-1,\mu,T} &\leq c\Big(|\!|\!| \boldsymbol{g}^+ |\!|\!|_{l,T} + |\!|\!| \boldsymbol{g}^- |\!|\!|_{l,T} + |\boldsymbol{u}_0|_l \Big) , \\
|\boldsymbol{w}^E|_{l-1,T} &\leq c\Big(|\!|\!| \boldsymbol{g}^+ |\!|\!|_{l,T} + |\!|\!| \boldsymbol{g}^- |\!|\!|_{l,T} + |\boldsymbol{u}_0|_l \Big) , \\
|w_\tau^{BL}|_{l-1,\mu,T} &\leq c\Big(|\!|\!| \boldsymbol{g}^+ |\!|\!|_{l,T} + |\!|\!| \boldsymbol{g}^- |\!|\!|_{l,T} + |\boldsymbol{u}_0|_l \Big) , \\
|w_N^{BL}|_{l-2,\mu,T} &\leq c\Big(|\!|\!| \boldsymbol{g}^+ |\!|\!|_{l,T} + |\!|\!| \boldsymbol{g}^- |\!|\!|_{l,T} + |\boldsymbol{u}_0|_l \Big) , \\
\|\boldsymbol{e}\|_{l-2,T} &\leq c\Big(|\!|\!| \boldsymbol{g}^+ |\!|\!|_{l,T} + |\!|\!| \boldsymbol{g}^- |\!|\!|_{l,T} + |\boldsymbol{u}_0|_l \Big) .
\end{aligned}$$

From the above theorem the following estimate on the convergence of the Oseen equation to $\boldsymbol{u}^E + \boldsymbol{u}^P$ easily follows.

COROLLARY 6.1. *Let* $\boldsymbol{u}_0 \in H^4$ *and* $\boldsymbol{g}^{\pm} \in L^{\infty}([0,T], H^4)$ *satisfy the compatibility conditions* (6.19)–(6.20) *and the incompressibility condition* (6.21). *Moreover, suppose that the inflows at the boundaries* $g_N^{\pm}$ *are such that* $|\xi|^{-1} g_N^{\pm} \in L^{\infty}\big([0,T], L^2\big)$. *If* $\boldsymbol{u}$, $\boldsymbol{u}^E$, *and* $\boldsymbol{u}^P$ *denote the solutions of* (1.1)–(1.5), (6.4)–(6.8), *and* (6.9)–(6.13), *respectively, then one has the following estimate:*

$$\|\boldsymbol{u} - (\boldsymbol{u}^E + \boldsymbol{u}^P)\|_{L^{\infty}([0,T],H^2)} \leq c\varepsilon^{1/2} \left[\|\boldsymbol{u}_0\|_{H^4} + \|\boldsymbol{g}^+\|_{L^{\infty}([0,T],H^4)} + \|\boldsymbol{g}^-\|_{L^{\infty}([0,T],H^4)} \right] . \tag{6.30}$$

The factor $\varepsilon^{1/2}$ comes from the fact that the correction $\boldsymbol{w}$ also has a boundary layer structure, i.e., its derivative with respect to y is $O(\varepsilon^{-1})$ in a region of size $O(\varepsilon^{1/2})$.

Remark 6.2. With minor formal modifications in the definitions of the function spaces H^l given in section 2, which allow l to be equal to 1, Corollary 6.1 could be stated for initial data belonging to H^3.

Appendix.

Proof of Lemma 4.2. Let us consider first the L^2 norm.

$$
\begin{aligned}
&\sup_{0\le t\le T} \|\gamma^- U^+ F_1(g_\tau^+,0)\|^2_{L^2(\xi')} \\
&= \sup_{0\le t\le T}\left\| \int_{-1}^{1} dy' e^{-|\xi'|(1+y')} \int_0^t ds\, e^{-[\nu\xi'^2 + i\xi' U](t-s)} \sum_{n=-\infty}^{\infty} \frac{y'-1-4n}{(t-s)} \frac{e^{-\frac{(y'-1-4n)^2}{4\nu(t-s)}}}{\sqrt{4\pi\nu(t-s)}} g_\tau^+(\xi',s) \right\|^2_{L^2(\xi')} \\
&\le \sup_{0\le t\le T}\left\| \int_0^t ds g_\tau^+ \sum_{n=0}^{\infty} e^{-|\xi'|(4n+2)} \int_{-1}^{1} dy' \frac{y'-1-4n}{(t-s)} \frac{e^{-\left[\frac{y'-1-4n}{\sqrt{4\nu(t-s)}} + \sqrt{\nu}|\xi'|(t-s)^{1/2}\right]^2}}{\sqrt{4\pi\nu(t-s)}} \right\|^2 \\
&\quad + \sup_{0\le t\le T}\left\| \int_0^t ds\, g_\tau^+ \sum_{n=-\infty}^{-1} \int_{-1}^{1} dy' e^{|\xi'|(-2y'+4n)} \frac{y'-1-4n}{(t-s)} \frac{e^{-\left[\frac{y'-1-4n}{\sqrt{4\nu(t-s)}} - \sqrt{\nu}|\xi'|(t-s)^{1/2}\right]^2}}{\sqrt{4\pi\nu(t-s)}} \right\|^2 \\
&\le \sup_{0\le t\le T}\left\| \int_0^t ds g_\tau^+ \sum_{n=0}^{\infty} e^{-|\xi'|(4n+2)} \int_{-1}^{1} dy' 2\sqrt{\nu} \frac{d}{dy'} \frac{e^{-\left[\frac{y'-1-4n}{\sqrt{4\nu(t-s)}} + \sqrt{\nu}|\xi'|(t-s)^{1/2}\right]^2}}{\sqrt{4\pi(t-s)}} \right\|^2 \\
&\quad + \sup_{0\le t\le T}\left\| \int_0^t ds g_\tau^+ \sum_{n=0}^{\infty} e^{-|\xi'|(4n+2)} \int_{-1}^{1} dy'\, 2\sqrt{\nu}|\xi'| \frac{e^{-\left[\frac{y'-1-4n}{\sqrt{4\nu(t-s)}} + \sqrt{\nu}|\xi'|(t-s)^{1/2}\right]^2}}{\sqrt{4\pi(t-s)}} \right\|^2 \\
&\quad + \sup_{0\le t\le T}\left\| \int_0^t ds g_\tau^+ \sum_{n=-\infty}^{-1} \int_{-1}^{1} dy' e^{|\xi'|(-2y'+4n)} 2\sqrt{\nu} \frac{d}{dy'} \frac{e^{-\left[\frac{y'-1-4n}{\sqrt{4\nu(t-s)}} - \sqrt{\nu}|\xi'|(t-s)^{1/2}\right]^2}}{\sqrt{4\pi(t-s)}} \right\|^2 \\
&\quad + \sup_{0\le t\le T}\left\| \int_0^t ds g_\tau^+ \sum_{n=-\infty}^{-1} \int_{-1}^{1} dy' e^{|\xi'|(-2y'+4n)} 2\sqrt{\nu}|\xi'| \frac{e^{-\left[\frac{y'-1-4n}{\sqrt{4\nu(t-s)}} - \sqrt{\nu}|\xi'|(t-s)^{1/2}\right]^2}}{\sqrt{4\pi(t-s)}} \right\|^2 \\
&= I_1 + I_2 + I_3 + I_4\ .
\end{aligned}
$$

We now consider the four terms separately. We begin from I_1:

$$
I_1 = \sup_{0\le t\le T}\left\| \int_0^t ds\, g_\tau^+ \sqrt{\nu} \sum_{n=0}^{\infty} e^{-|\xi'|(4n+2)} \right.
$$

$$\times \left[\frac{e^{-\left[\frac{4n}{\sqrt{4\nu(t-s)}}-\sqrt{\nu}|\xi'|(t-s)^{1/2}\right]^2}}{\sqrt{\pi(t-s)}} - \frac{e^{-\left[\frac{4n+2}{\sqrt{4\nu(t-s)}}-\sqrt{\nu}|\xi'|(t-s)^{1/2}\right]^2}}{\sqrt{\pi(t-s)}} \right] \Bigg\|^2$$

$$\leq \sup_{0\leq t\leq T} \left\| \int_0^t ds\ g_\tau^+ 2\sqrt{\nu} \sum_{n=0}^{\infty} e^{-|\xi'|(4n+2)} \frac{e^{-\left[\frac{4n}{\sqrt{4\nu(t-s)}}-\sqrt{\nu}|\xi'|(t-s)^{1/2}\right]^2}}{\sqrt{\pi(t-s)}} \right\|^2$$

$$\leq \sup_{0\leq t\leq T} \left\| \int_0^t ds\ 2\sqrt{\nu}\, e^{-\nu|\xi'^2|(t-s)}\, e^{-2|\xi|} g_\tau^+ \sum_{n=0}^{\infty} \frac{e^{-\frac{(4n)^2}{4\nu(t-s)}}}{\sqrt{\pi(t-s)}} \right\|^2$$

$$\leq \sup_{0\leq t\leq T} \left\| \int_0^t ds 4\sqrt{\nu} \frac{1}{\sqrt{\pi(t-s)}} g_\tau^+ \right\|^2$$

$$\leq \frac{16\nu T}{\pi} \sup_{0\leq t\leq T} \|g_\tau^+\|^2.$$

The estimate of the terms with the derivatives with respect to x and t is the same. Let us now pass to I_2. Introducing the variable $\eta = (y' - 1 - 4n)/\sqrt{4\nu(t-s)} + \sqrt{\nu}|\xi|(t-s)^{1/2}$, we get

$$I_2$$

$$= \sup_{0\leq t\leq T} \frac{1}{\pi} \left\| \int_0^t ds\, g_\tau^+(\xi', s)\, 4\nu|\xi'| \sum_{n=0}^{\infty} e^{-|\xi'|(4n+2)} \int_{\frac{-4n-2}{\sqrt{4\nu(t-s)}}+\sqrt{\nu}|\xi'|(t-s)^{1/2}}^{\frac{-4n}{\sqrt{4\nu(t-s)}}+\sqrt{\nu}|\xi'|(t-s)^{1/2}} d\eta\, e^{-\eta^2} \right\|^2$$

$$\leq \sup_{0\leq t\leq T} \left\| \int_0^t ds\, g_\tau^+\, 8\nu|\xi'| \left(e^{-2|\xi|} \frac{1}{2} T\nu|\xi| + \sum_{n>\frac{1}{2}T\nu|\xi|} e^{-|\xi'|(4n+2)} e^{-\left[\frac{4n}{\sqrt{4\nu(t-s)}}-\sqrt{\nu}|\xi'|(t-s)^{1/2}\right]} \right) \right\|^2$$

$$\leq \left(16\nu^4 T^4 + 4\nu^2 T^2\right) \sup_{0\leq t\leq T} \left\| g_\tau^+(\xi', s) \right\|^2.$$

The estimate of I_3 is analogous to the estimate of I_1, while the estimate of I_4 is analogous to the estimate of I_2. From the above estimates it is apparent that, choosing T_α small enough, one can make $\|\gamma^- U^+ F_1(g_\tau^+, 0)\|_{l.T_\alpha} < \alpha |g_\tau^+|_{l,T}$ with $\alpha < 1$. □

Remark A.1. It is interesting to notice that, in the zero viscosity limit, the time T_α up to which the above estimate is valid grows to infinity: $T_\alpha \sim \nu^{-1}$.

Proof of Proposition 4.9. The trace at $y = -1$ of the operator $\mathcal{O}^+$ is made of three terms: (1) the trace γ^- of $\mathcal{L}_\tau(\cdot, 0)$, which is estimated in Lemma 4.5; (2) the trace γ^- of $U^+ F_1(\cdot, 0)$, which is estimated in Lemma 4.2; (3) the trace γ^- of the operator $F_1(\cdot, 0)$, which can be estimated as follows:

$$\sup_{0\leq t\leq T} \left\| \gamma^- F_1(f_\tau^+, 0) \right\|_{L^2(\xi')}^2$$

$$= \sup_{0\leq t\leq T} \left\| \int_0^t ds\, e^{-[\nu\xi'^2 + i\xi' U](t-s)} \sum_{n=-\infty}^{\infty} \frac{2+4n}{\varepsilon(t-s)} \frac{e^{-\frac{(2+4n)^2}{4\nu(t-s)}}}{\sqrt{4\pi(t-s)}} g_\tau^+(\xi', s) \right\|_{L^2(\xi')}^2$$

$$
\begin{aligned}
&\leq \frac{4}{\pi} \sup_{0\leq t\leq T} \left\| \int_0^t ds\, e^{-\nu {\xi'}^2 (t-s)} \sum_{n=0}^{\infty} \frac{1+2n}{\varepsilon(t-s)} \frac{e^{-\frac{(1+2n)^2}{\nu(t-s)}}}{\sqrt{(t-s)}}\, g_\tau^+(\xi', s) \right\|^2_{L^2(\xi')} \\
&\leq \frac{\nu}{\pi} \sup_{0\leq t\leq T} \left\| \int_0^t ds\, \frac{e^{-\nu {\xi'}^2 (t-s)}}{(t-s)^{1/2}}\, g_\tau^+(\xi', s) \int_0^\infty d\eta\, \eta\, e^{-\eta^2} \right\|^2_{L^2(\xi')} \\
&\leq \frac{\nu T}{\pi} \sup_{0\leq t\leq T} \left\| g_\tau^+ \right\|^2_{L^2(\xi')} .
\end{aligned}
$$

As far as the term $\sup_{0\leq t\leq T} \|\gamma^- U^+ |\xi'| F_1(f_\tau^+ - \gamma^+ \mathcal{L}_\tau(f_N^+, 0), 0)\|^2_{L^2(\xi')}$ is concerned, the estimate is analogous to the one given in the proof of Lemma 4.2. The only things one has to use are the fact that $\sqrt{\nu(t-s)}|\xi'|e^{-\nu {\xi'}^2(t-s)}$ is bounded and the regularizing property of the integration with respect to time of the factor $\frac{1}{\sqrt{t-s}}$. The estimate in (4.14) is thus achieved. □

Proof of Proposition 4.10. The proof of Proposition 4.10 is analogous to the proof of Proposition 4.9. □

Acknowledgments. The authors thank Professor Giga and an anonymous referee for the useful comments that helped to improve the paper and the presentation of the results.

L^1 STABILITY FOR SYSTEMS OF CONSERVATION LAWS WITH A NONRESONANT MOVING SOURCE*

SEUNG-YEAL HA†

Abstract. In this paper, we study L^1 stability for systems of conservation laws with a moving source $u_t + f(u)_x = g(x - ct, u)$. The source is assumed to be nonresonant in that its speed c is different from the characteristic speeds of the system. We show that weak solutions are globally L^1 stable. Based on the modified Glimm scheme, we construct a robust nonlinear functional $H(t) = H[u(\cdot, t), v(\cdot, t)]$ which is equivalent to the L^1 distance of two solutions u, v and is nonincreasing in time t. This functional $H[u, v]$ consists of a linear part $L[u, v]$ measuring the L^1 distance, a quadratic part $Q_d[u, v]$ measuring nonlinear couplings between waves of different characteristic fields, a generalized entropy functional $E[u, v]$ capturing the nonlinearity of characteristic fields, and a new functional $Q_{so}[u, v]$ measuring the source effect on the L^1 distance.

Key words. conservation laws, L^1 stability, nonlinear functional

1. Introduction.

The purpose of this paper is to establish the L^1 stability of the initial value problem for systems of hyperbolic conservation laws with a moving source:

$$
\begin{aligned}
u_t + f(u)_x &= g(x - ct, u), \quad (x, t) \in R \times R_+, \\
u(x, 0) &= u_0(x), \quad x \in R,
\end{aligned} \tag{1.1}
$$

where $u \in \mathcal{N} \subset R^n$, $f : \mathcal{N} \to R^n$, and $g : R \times \mathcal{N} \to R^n$ denote the conserved quantities, the C^2 flux function, and the source, respectively. This system is assumed to be strictly hyperbolic. It is well known [15] that in general the system (1.1) does not admit classical solutions even for smooth initial data because of the nonlinearity of the flux function. Therefore, one needs to consider weak solutions.

DEFINITION 1.1. *A bounded measurable function $u(x, t)$ is a weak solution of (1.1) with given initial data $u_0(x)$ if and only if for $\phi \in C_c^1(R \times R_+)$,*

$$
\int_0^\infty \int_{-\infty}^\infty [u\phi_t + f(u)\phi_x + g(x - ct, u)\phi](x, t)dxdt + \int_{-\infty}^\infty u_0(x)\phi(x, 0)dx = 0.
$$

Several physical situations can be modeled as systems of hyperbolic conservation laws with a source such as a nozzle flow [7], [17], [19], [20], [21] and a moving magnetic field for magneto-hydrodynamics (MHD) [12]. As a prototype for systems of hyperbolic conservation laws with a source, we consider a quasi–one-dimensional nozzle flow model:

$$
\begin{aligned}
\frac{\partial \rho}{\partial t} + \frac{\partial(\rho u)}{\partial x} &= -\frac{A'(x)}{A(x)}(\rho u), \quad (x, t) \in R \times R_+, \\
\frac{\partial(\rho u)}{\partial t} + \frac{\partial(\rho u^2 + P)}{\partial x} &= -\frac{A'(x)}{A(x)}(\rho u^2),
\end{aligned}
$$

†Department of Mathematics, Serra Mall, Building 380, Stanford University, Stanford, CA, 94305 (syha@math.stanford.edu).

$$\frac{\partial(\rho E)}{\partial t} + \frac{\partial(\rho u E + P u)}{\partial x} = -\frac{A'(x)}{A(x)}(\rho u E + P u),$$
$$P = P(e, \rho),$$

where $A(x)$ is the cross sectional area of a nozzle, ρ the density, u the velocity, P the pressure, e the internal energy, and $E = e + \frac{u^2}{2}$ the total energy of a gas. The existence theory of a global weak solution for the system (1.1) was first established in [19] based on the modified Glimm scheme and the wave tracing method, and recently the global existence of weak solutions for L^∞ initial data was proved by using the compensated compactness in [7]. The basic idea for the construction of approximate solutions is to alternately use the Riemann solutions for a corresponding homogeneous system ($g(x, u) = 0$) and solutions traveling with a speed c. So far, most stability analyses for (1.1) have been carried out in bounded variation context [17], [19], [20], [21]. On the other hand, L^1 stability has been studied for scalar conservation laws [13], [14], [25].

Recently, there was a breakthrough for L^1 stability for systems of homogeneous conservation laws. So far, there are two different approaches. Bressan's approach is based on comparison and homotopy of two infinitesimally close solutions [2], [3], [4], [5]. In contrast, Liu and Yang's approach uses a robust nonlinear functional [23], [24]. In this paper, we adopt the latter approach which is based on the construction of a robust nonlinear functional $H[u, v]$ equivalent to the L^1 distance of u and v and nonincreasing in time. Without loss of generality, we may assume that the source has speed $c = 0$, i.e.,

$$u_t + f(u)_x = g(x, u).$$

As shown in [19], the stability of the Glimm solutions for (1.1) is subject to the following three essential mechanisms:

1. the genuine nonlinearity;
2. the nonresonance between hyperbolic waves and stationary waves;
3. the localization of the source in x, i.e., $\mathrm{supp}_x\{g(x, u)\}$ is compact.

Because of the above three mechanisms, hyperbolic waves are subsonic or supersonic; therefore, eventually, they will be away from the support of source. So they will be stabilized as hyperbolic waves for homogeneous systems. For the resonance case,[1] the interaction between hyperbolic waves and stationary waves will be quite complicated. In this case, the geometry of a nozzle is very important, as is shown for (1.1) with respect to special data [17], [20] and for a scalar model with respect to general data [21].

Based on the above three main mechanisms, we impose the following conditions on (1.1).

Main assumptions.

1. The system (1.1) is strictly hyperbolic.
   Let $\lambda_i(u), (i \in \{1, \dots, n\})$ be distinct real eigenvalues of $f'(u)$ and let $r_i(u)$ ($l_i(u)$) be corresponding right (left) eigenvectors of $f'(u)$, i.e.,

$$f'(u) r_i(u) = \lambda_i(u) r_i(u), \quad \lambda_1(u) < \cdots < \lambda_n(u),$$
$$l_i(u) f'(u) = \lambda_i(u) l_i(u), \quad l_i \cdot r_j = \delta_{ij}.$$

[1] One of the characteristic speeds is close to that of the source.

2. The source is not resonant with the conservation laws, that is, there exists $j_0 \in \{1, \dots, n-1\}$ such that

$$\lambda_1(u) < \cdots < \lambda_{j_0}(u) < 0 < \lambda_{j_0+1}(u) < \cdots < \lambda_n(u) \text{ for all } u \in \mathcal{N}.$$

3. Each characteristic field $(\lambda_j(u), r_j(u))$ is either genuinely nonlinear (g.n.l.) or linearly degenerate (l.d.g.) in the sense of [15]:

$$\begin{aligned}(\lambda_j(u), r_j(u)) \quad &\text{is g.n.l.} \iff \nabla\lambda_j(u) \cdot r_j(u) \neq 0 \quad \text{for all } u \in \mathcal{N},\\ (\lambda_j(u), r_j(u)) \quad &\text{is l.d.g.} \iff \nabla\lambda_j(u) \cdot r_j(u) \equiv 0.\end{aligned}$$

4. The total variation of initial data $u_0(x)$ is sufficiently small,

$$T.V_x(u_0(x)) \leq T.V << 1,$$

for a positive constant $T.V$ depending only on (1.1).

5. $g(x,p)$ is piecewise differentiable in x and continuously differentiable in p, and has compact support in x, and is sufficiently weak:

$$\begin{aligned}&g(x,p) \equiv 0, \quad x \notin [0,1] \ \text{ and } g(x,p) \neq 0, \quad x \in (0,1),\\ &G(x) \equiv \sup_{p\in\mathcal{N}} \left\{ |g(x,p)| + \left\| \frac{\partial g(x,p)}{\partial p} \right\| \right\}, \quad G_1 \equiv \|G(\cdot)\|_{L^1(R)},\\ &G_0 \equiv \|G(\cdot)\|_{L^\infty(R)}, \ G_0 + G_1 << 1.\end{aligned}$$

For (1.1) without a smallness assumption on the source, local L^1 stability in time was studied in [9], and when the source $g(x,u)$ depends only on u, under the dissipation condition on the source, L^1 stability was studied in [1]. The main theorem of this paper is as follows.

Theorem 1.2. *Let $u(x,t)$ and $v(x,t)$ be two weak solutions obtained by the Glimm scheme corresponding to initial data u_0 and v_0, respectively. Then under the main assumptions, we have*

$$||u(\cdot,t) - v(\cdot,t)||_{L^1(R)} \leq C||u_0(\cdot) - v_0(\cdot)||_{L^1(R)}, \quad t \geq 0,$$

where C is a generic constant which is independent of t.

The paper is organized as follows. In section 2, we review the basic theory of hyperbolic conservation laws and in section 3, we briefly discuss the simplified wave patterns [24] on which a nonlinear functional will be explicitly defined. In section 4, we study scalar conservation laws with a moving source. This section illustrates the necessity of a new functional which takes care of a source effect on the L^1 distance and treats an entropy functional. In section 5, we construct a nonlinear functional which contains a new functional measuring a source effect on the L^1distance and by using this functional, we prove L^1 stability for Glimm solutions.

2. Preliminaries. In this section, we review some of the basics for systems of hyperbolic conservation laws,

$$\begin{aligned}u_t + f(u)_x = 0, &\quad (x,t) \in R \times R_+,\\ u(x,0) = u_0(x), &\quad x \in R.\end{aligned} \tag{2.1}$$

The Riemann problem for (2.1) is the initial value problem with simple jump initial data

$$u(x,0) = \begin{cases} u_l, & x < 0,\\ u_r, & x > 0.\end{cases}$$

It is well known [15] that the Riemann solution is a function of $\frac{x}{t}$ and consists of $n+1$ intermediate constant states $\{u_l = u_0, u_1, u_2, \dots, u_n = u_r\}$ which are connected by shock waves, rarefaction waves, or contact discontinuities.

In the following, we define an ith rarefaction curve $R_i(u_0)$ and an ith shock curve $H_i(u_0)$.

$$\begin{aligned} R_i(u_0) &\equiv \text{ the integral curve of a vector field } r_i \cdot \nabla_u \text{ passing through } u_0, \\ H_i(u_0) &\equiv \{u \in R^n : \lambda_i(u_0, u)(u - u_0) = f(u) - f(u_0), \text{ for some scalar } \lambda_i(u_0, u)\}. \end{aligned}$$

For a l.d.g. characteristic field $(\lambda_i(u), r_i(u))$, it is well known [15] that $H_i(u_0) = R_i(u_0)$. We parameterize these curves by the arc length ξ and we divide the ith shock curve $H_i(u_0)$ and the ith rarefaction curve $R_i(u_0)$ as follows:

$$\begin{aligned} H_i^+(u_0) &\equiv \{u \in H_i(u_0) : \lambda_i(u) > \lambda(u_0, u) > \lambda_i(u_0)\}, \\ H_i^-(u_0) &\equiv \{u \in H_i(u_0) : \lambda_i(u) < \lambda(u_0, u) < \lambda_i(u_0)\}, \\ R_i^+(u_0) &\equiv \{u \in R_i(u_0) : \lambda_i(u) > \lambda_i(u_0)\}, \\ R_i^-(u_0) &\equiv \{u \in R_i(u_0) : \lambda_i(u) < \lambda_i(u_0)\}; \end{aligned}$$

moreover, we define an ith wave curve as follows:

$$W_i(u_0) \equiv \begin{cases} H_i^-(u_0) \cup R_i^+(u_0) & \text{if } i\text{th characteristic field is g.n.l.,} \\ H_i(u_0) = R_i(u_0) & \text{if } i\text{th characteristic field is l.d.g.} \end{cases}$$

Then by the second order contact of the ith shock curve and the ith rarefaction curve at u_0, the ith wave curve $W_i(u_0)$ is a C^2-curve [15].

THEOREM 2.1 (see [15]). *Suppose that* (2.1) *is strictly hyperbolic and each characteristic field is g.n.l. or l.d.g. If u_l and u_r are sufficiently close, then the Riemann problem for* (2.1) *has a unique solution in the class of elementary waves* $(u_{i-1}, u_i), u_i \in W_i(u_{i-1}), i = 1, 2, \dots, n, u_0 = u_l, u_n = u_r$.

For any i-wave $\alpha_i = (u_{i-1}, u_i)$, a signed strength $[\alpha_i]$ is defined as follows:

$$[\alpha_i] \equiv \mu_i(u_i) - \mu_i(u_{i-1}),$$

where μ_i is any nonsingular parameter along the ith wave curve $W_i(u_0)$ such that a shock wave has negative signed strength, whereas a rarefaction wave has positive signed strength. Approximate solutions for (1.1) are constructed by Riemann solutions for the corresponding homogeneous system and local steady solutions of (1.1) as building blocks [10], [18], [19]. For the details, we refer to [19].

DEFINITION 2.2. *Let $\{a_j\}_0^\infty$ be a sequence in* $(0, 1)$.

$$\{a_j\}_0^\infty \textit{ is equidistributed or (uniformly distributed)} \iff \lim_{N\to\infty} \frac{B(a_j, N, I)}{N} = |I|,$$

where $B(a_j, N, I) = |\{j : a_j \in I, 0 \le j \le N\}|$, for any subinterval I of $(0, 1)$ and $|I|$ denotes the length of the interval.

DEFINITION 2.3. *Let α_i and β_j be two i, j waves, respectively, such that α_i is located to the left of β_j.*

α_i and β_j are approaching if and only if $i > j$ or $i = j$ and at least one of them is a shock.

For later use, we state the approximate Rankine–Hugoniot condition for the approximate solutions.

Theorem 2.4 (see [19]). *Let (u_l, u_r) be a shock wave issued from (hr, ks) in the construction of approximate solutions and let $u_l(x,t)$ and $u_r(x,t)$ be two steady solutions with initial data u_l and u_r, respectively, along the $\frac{x-hr}{t-ks} = \lambda(u_l, u_r), ks < t < (k+1)s$. Then*

$$\lambda(u_l, u_r)(u_r(x,t) - u_l(x,t)) = f(u_r(x,t)) - f(u_l(x,t)) + \mathcal{O}(1)\left(\int_{hr}^{x} G(\xi)d\xi\right)|u_r - u_l|.$$

3. Known results. In this section, we study simplified wave patterns which will be used for the construction of a nonlinear functional $H(t)$ in section 5. These simplified wave patterns are a sort of generalization of those in [24], and we review the modified Glimm functional in [19].

3.1. Simplified wave patterns. Unlike linear waves, nonlinear waves change their strengths and speeds due to interactions and cancellations. The wave tracing is a book-keeping scheme of subdividing elementary waves in the approximate solution $u_r(x,t)$ so that the evolution of each subwave can be studied more definitely. After partitioning the waves in the approximate solutions [18], [19], we replace $u_r(x,t)$ by a simplified wave pattern $\bar{u}_r(x,t)$ consisting of nonlinear waves with deterministic speeds in each small time zone. Let us set

$$\begin{aligned}
&\text{time zone } \Lambda(t_1,t_2) \equiv \{(x,t) : -\infty < x < \infty, t_1 \le t < t_2\},\\
&\text{interaction measure } Q(t_1,t_2) \equiv \sum_{\Delta_{mn}\in\Lambda(t_1,t_2)} Q(\Delta_{mn}),\\
&\text{cancellation measure } C(t_1,t_2) \equiv \sum_{\Delta_{mn}\in\Lambda(t_1,t_2)} C(\Delta_{mn}),
\end{aligned}$$

where a local interaction measure $Q(\Delta_{mn})$ and a cancellation measure $C(\Delta_{mn})$ are defined as follows. Let Δ_{mn} be a diamond whose vertices are $((m-1)r + a_j r, ns)$, $(mr + a_j r, ns)$, $(mr, (n+\frac{1}{2})s)$, and $(mr, (n-\frac{1}{2})s)$.

$$\begin{aligned}
Q(\Delta_{mn}) &\equiv \sum_{(\alpha_i,\beta_j):app} \{|\alpha_i||\beta_j| : \ \alpha_i \text{ and } \beta_j \text{ pass through } \Delta_{mn}\},\\
C(\Delta_{mn}) &\equiv \sum_{(\alpha_i,\beta_j):app} \left\{\frac{|\alpha_i| + |\beta_i| - |\alpha_i + \beta_j|}{2} : \ \alpha_i \text{ and } \beta_i \text{ pass through } \Delta_{mn}\right\},
\end{aligned}$$

where (α_i, β_j) : *opp* denotes the approaching pair (α_i, β_j) defined in Definition 2.3. Without confusion, (u_{i-1}, u_i) denotes the i-wave or sometimes the difference of its end states. For the details and the motivation for the wave partition and tracing, we refer to [18], [19], [24]. The waves in $u_r(x,t), (x,t) \in \Lambda(t_1,t_2)$ consist of two different types of past history, i.e., the primitive waves issued from $t = t_1$ or waves which are generated by nonlinear interactions. Moreover, the waves also have two different futures (surviving in the future or cancelled in the future). Therefore, by refining waves in the approximate solutions in each small time zone, we can make waves into subwaves which will completely survive or be cancelled completely in the time zone $\Lambda(t_1,t_2)$ so that we can study the evolution of its subwaves definitely.

Let $\{a_j\}_0^\infty$ be an equidistributed sequence. Let ϵ be small and T be given; then let us set $N = \frac{1}{\epsilon}$, and let us choose M such that

$$(N-1)Ms < T \le NMs.$$

Without loss of generality, we may assume that N and M are integers; then it is easy to see that for a fixed N, as $s \to 0+$,

$$M \to \infty, \quad Ms \leq \frac{T\epsilon}{1-\epsilon}, \quad NMs \leq \frac{T}{1-\epsilon}.$$

We divide the interval $(0,1)$ into N equal subintervals with length ϵ. Let $\{I_i\}_1^{2^N}$ be the power set of such subintervals. Let us set

$$\delta = \sup_{1\leq p\leq N, 1\leq i\leq 2^N} \left\{ \frac{B(a_{m+(p-1)M}, M, I_i)}{M} - |I_i| \right\},$$

where $|I_i|$ denotes the Lebesgue measure of I_i. Then by the equidistributedness of $\{a_j\}$,

$$\lim_{M\to\infty} \delta = 0 \quad \text{ for any } \epsilon.$$

We partition the elementary waves in an approximate solution $u_r(x,t)$ into subwaves so that a rarefaction wave consists of rarefaction shocks whose maximal strength is ϵ [6], [18], [19], [23], [24]. In what follows, let us set

$$\Lambda_p \equiv \Lambda((p-1)Ms, pMs), \quad p = 1, \dots, N.$$

Based on the partitioned approximate solutions, we define a simplified wave pattern which consists of surviving nonlinear waves with fixed speeds in each small time zone Λ_p. This simplified wave pattern is a generalization of that in [24]. In [24], the simplified wave pattern consists of piecewise constant states, whereas our simplified wave pattern consists of piecewise stationary solutions. The construction of our simplified wave patterns is reviewed below.

Since $u_r(x,t)$ is of bounded variation, for a given small number ϵ, we can find E such that $T.V\{u_r(x,t) : |x| > E\} < \epsilon$. Next, we replace the $u_r(x,t)$ on $x < -E$ or $x > E$ by the values $\lim_{x\to-\infty} u(x,t)$ or $\lim_{x\to\infty} u(x,t)$, respectively. Hence we have a finite number of surviving waves on $[-E, E]$. Let us denote surviving i-waves by $v_i^1, \dots, v_i^N$. For each i-wave v_i^k, the location of it which is randomly determined by the sequence $\{a_j\}$ is now replaced by the line connecting its locations at time $t = (p-1)Ms+$ and $t = pMs-$. Let us denote its speed by $\lambda^*(v_i^k)$. As with the approximate solutions, the waves are connected to each other by stationary waves. Then it is noted that no i-waves do not cross each other in Λ_p. With regard to the secondary waves such as nonsurviving waves in $u_r(x,t)$ and generated waves from the nonlinear interactions in Λ_p, we do not keep track of them inside Λ_p. This generates an error in the L^1-norm which vanishes eventually, but in the beginning of the next time zone Λ_{p+1}, we consider those secondary waves. Therefore, the waves in the simplified wave pattern $\bar{u}_r(x,t)$ move in a deterministic way, but their end states evolve according to the stationary solution.

As a generalization of Theorem 5.3 in [24], we have the following theorem.

THEOREM 3.1 (see [24]). *There exists a simplified wave pattern $\bar{u}_r(x,t)$ consisting of a finite number of nonlinear waves $\{\bar{\alpha}\}$ in each time zone Λ_p and a large constant E such that the following hold.*

There exists a one-to-one correspondence $\alpha \to \bar{\alpha}$ between the surviving waves in $|x| < E$ and $K = \{\bar{\alpha}\}$ such that

1. $\sum_\alpha |\alpha - \bar{\alpha}| = \mathcal{O}(1)\{(Q_0 + Q_1 + C)(\Lambda_p) + \epsilon\}$,

2. $\sum_\alpha |\alpha||\lambda(\alpha) - \lambda^*(\bar{\alpha})| = \mathcal{O}(1)\{(Q_0 + Q_1 + C)(\Lambda_p) + \delta + \epsilon\}$,
3. $\sum\{|\alpha| : \alpha$ *is a secondary wave* $\} = \mathcal{O}(1)(Q_0 + Q_1 + C)(\Lambda_p)$,
4. $\bar{u}_r(x, (p-1)Ms) - u_r(x, (p-1)Ms) = 0$ *for* $|x| < E$,
5. $\int_{|x|>E} |\bar{u}_r(x, (p-1)Ms) - u_r(x, (p-1)Ms)|dx + \sum\{|\alpha| : \alpha \in u_r(x, (p-1)Ms), |x| > E\} < (T.V + G_1)\epsilon$.

3.2. The modified Glimm functional. Let $u_r(x,t)$ be a given approximate Glimm solution [19]. For such $u_r(x,t)$, we define the modified Glimm functional $F(u_r : t)$ as follows:

$$\begin{aligned} F(u_r : t) &= L(u_r : t) + KQ(u_r : t), \\ L(u_r : t) &= \sum\{|\alpha(t)| : \alpha \text{ is an elementary wave at time } t\}, \\ Q(u_r : t) &= Q_0(u_r : t) + Q_1(u_r : t), \\ Q_0(u_r : t) &= \sum\{|\alpha(t)||\beta(t)| : \alpha \text{ and } \beta \text{ are approaching }\}, \\ Q_1(u_r : t) &= \sum_{\lambda(\alpha(t))>0} \left\{ |\alpha(t)| \int_{hr}^{\infty} G(x)dx : \alpha \text{ is issued from } (hr, ks) \right\} \\ &\quad + \sum_{\lambda(\alpha(t))<0} \left\{ |\alpha(t)| \int_{-\infty}^{hr} G(x)dx : \alpha \text{ is issued from } (hr, ks) \right\}, \end{aligned}$$

where K is a large positive constant to be determined later.

Remark. The linear part $L(u_r : t)$ measures the strength of the waves at time t; therefore, $L(u_r : t)$ is equivalent to the total variation of the approximate solution at time t, and the quadratic part $Q(u_r : t)$ measures the potential interaction between waves. $Q_0(u_r : t)$ measures the potential interaction between hyperbolic waves, and $Q_1(u_r : t)$ measures the potential interaction between hyperbolic waves and stationary waves.

Then by the local interaction estimates of waves [19], we have the following decay estimates of the modified Glimm functional.

LEMMA 3.2 (see [19]). *Suppose that the total variation of initial data is sufficiently small and G_0 and G_1 are small enough. Then*

$$\begin{aligned} Q(u_r : \Lambda(0,t)) &\le 2(Q(u_r : 0) - Q(u_r : t)), \\ F(u_r : t+) - F(u_r : t-) &\le -\frac{1}{2}Q(u_r : t), \\ F(u_r : t) &\le F(u_r : 0) \quad \textit{for } t \ge 0. \end{aligned}$$

4. Scalar conservation laws with a source. In this section, in order to illustrate a functional which takes care of a source effect and an entropy functional in [22], we consider the scalar nozzle flow model which was introduced in [21]. We study time change of the L^1 distance between two solutions and a generalized entropy functional for scalar convex conservation laws with a source:

$$\begin{aligned} &u_t + f(u)_x = g(x,u), \quad (x,t) \in R \times R_+, \\ &f'(u) > 0,\ f''(u) > 0, \quad \mathrm{supp}_x(g(x,u)) = [0,1]. \end{aligned} \tag{4.1}$$

Unlike homogeneous scalar conservation laws, because of the source, the L^1 distance between two weak solutions may not be a contraction. Under the above assumptions of the source, we verify that in general, the L^1 distance is not a contraction. Moreover, we show that the $H(t) = ||u(\cdot,t) - v(\cdot,t)||_{L^1(R)}$ for the homogeneous case is not applicable to a nonhomogeneous case (Theorem 4.3). Hereafter, we will use the following notations:

$u_r(x,t)$: the approximate solution by the modified Glimm scheme
with a space mesh size r,
$\bar{u}_r(x,t)$: the simplified wave pattern corresponding to $u_r(x,t)$,
$\alpha_j^i(t)$: the jth i-wave at time t, $x(\alpha(t))$: the location of the wave $\alpha(t)$,
$\lambda(\alpha(t))$: the exact speed of $\alpha(t)$, $\dot{x}(\alpha(t))$: the approximate speed of $\alpha(t)$,
$J(\bar{u}_r)$: the set of all waves in $\bar{u}_r$, $J(\bar{v}_r)$: the set of all waves in $\bar{v}_r$,
$J \equiv J(\bar{u}_r) \cup J(\bar{v}_r)$, $q^{\pm}(\alpha) \equiv v(x(\alpha)\pm,t) - u(x(\alpha)\pm,t)$,
$\lambda(q^{\pm}(\alpha)) \equiv$ the speed of $(u(x(\alpha)\pm,t), v(x(\alpha)\pm,t))$.

We will also use the abbreviated notations $\bar{u}_r(x)$ and $\bar{v}_r(x)$ instead of $\bar{u}_r(x,t)$ and $\bar{v}_r(x,t)$, respectively. Let $u(x,t)$ and $v(x,t)$ be two solutions constructed by the modified Glimm scheme [19] corresponding to initial data $u_0(x)$ and $v_0(x)$, respectively, such that

$$\lim_{r\to 0} u_r(x,t) = u(x,t), \ \lim_{r\to 0} v_r(x,t) = v(x,t) \ \text{ in } L^1_{loc}(R \times R_+),$$
$$\text{and } \|u_0(x) - v_0(x)\|_{L^1(R)} < \infty.$$

For a given noninteraction time t, let us denote the set of all waves by $\{\alpha_i\}_1^m$ such that

$$-\infty < x(\alpha_1) < x(\alpha_2) < \cdots < x(\alpha_m) < \infty.$$

Then it is easy to see that

$$\text{(4.2a)} \qquad \frac{d}{dt}|\bar{u}_r(x) - \bar{v}_r(x)| = 0 \text{ on } (x(\alpha_i), x(\alpha_{i+1})), \ i = 1, \ldots, m-1,$$
$$\text{(4.2b)} \qquad \bar{u}_r(x) = \bar{v}_r(x) \text{ on } (-\infty, x(\alpha_1)) \ \text{ and } (x(\alpha_m), \infty).$$

On the other hand, we have

$$\begin{aligned}\text{(4.3)} \ \ \frac{d}{dt}\int_{x(\alpha_i)}^{x(\alpha_{i+1})} |\bar{u}_r(x) - \bar{v}_r(x)|dx &= \int_{x(\alpha_i)}^{x(\alpha_{i+1})} \frac{d}{dt}|\bar{u}_r(x) - \bar{v}_r(x)|dx \\ &+ \dot{x}(\alpha_{i+1})|\bar{u}_r(x(\alpha_{i+1})-) - \bar{v}_r(x(\alpha_{i+1})-)| - \dot{x}(\alpha_i)|\bar{u}_r(x(\alpha_i)+) - \bar{v}_r(x(\alpha_i)+)| \\ &= \dot{x}(\alpha_{i+1})|q^-(\alpha_{i+1})| - \dot{x}(\alpha_i)|q^+(\alpha_i)| \ \text{ by } (4.2a).\end{aligned}$$

It follows from (4.2b) and (4.4) that

$$
\begin{aligned}
&\frac{d}{dt}\|\bar{u}_r(\cdot,t)-\bar{v}_r(\cdot,t)\|_{L^1(R)} = \sum_{i=1}^{m-1}\frac{d}{dt}\int_{x(\alpha_i)}^{x(\alpha_{i+1})}|\bar{u}_r(x)-\bar{v}_r(x)|dx\\
&=\sum_{i=1}^{m}\{\dot{x}(\alpha_i)(|q^-(\alpha_i)|-|q^+(\alpha_i)|)\}\\
&=\sum_{i=1}^{m}\lambda(\alpha_i)(|q^-(\alpha_i)|-|q^+(\alpha_i)|)+\mathcal{O}(1)MsG_0\sum_{i=1}^{m}|\alpha_i|\\
&=\sum_{i=1}^{m-1}\{\lambda(\alpha_{i+1})|q^-(\alpha_{i+1})|-\lambda(\alpha_i)|q^+(\alpha_i)|\}+\mathcal{O}(1)MsG_0\sum_{1}^{m}|\alpha_i|\\
&=\sum_{i=1}^{m-1}\{(\lambda(\alpha_{i+1})-\lambda(q^-(\alpha_{i+1})))|q^-(\alpha_{i+1})|-(\lambda(\alpha_i)-\lambda(q^+(\alpha_i)))|q^+(\alpha_i)|\}\\
&+\sum_{i=1}^{m-1}\{\lambda(q^-(\alpha_{i+1}))|q^-(\alpha_{i+1})|-\lambda(q^+(\alpha_i))|q^+(\alpha_i)|\}+\mathcal{O}(1)MsG_0\sum_{1}^{m}|\alpha_i|\\
&\equiv I+II+\mathcal{O}(1)MsG_0\sum_{1}^{m}|\alpha_i|,
\end{aligned}
$$

where

$$
\begin{aligned}
I &\equiv \sum_{i=1}^{m-1}\{(\lambda(\alpha_{i+1})-\lambda(q^-(\alpha_{i+1})))|q^-(\alpha_{i+1})|-(\lambda(\alpha_i)-\lambda(q^+(\alpha_i)))|q^+(\alpha_i)|\},\\
II &\equiv \sum_{i=1}^{m-1}\{\lambda(q^-(\alpha_{i+1}))|q^-(\alpha_{i+1})|-\lambda(q^+(\alpha_i))|q^+(\alpha_i)|\},
\end{aligned}
$$

and we have used the fact that $\dot{x}(\alpha_i)-\lambda(\alpha_i)=\mathcal{O}(1)MsG_0$ and $|q^-(\alpha_i)|-|q^+(\alpha_i)|\leq|\alpha_i|$. Let us recall that for scalar convex conservation laws, unlike for systems, nonlinear interactions do not generate new waves. For simplicity, we assume that the initial data is constant outside a bounded interval. Then at time $t=0$, since there are only a finite number of waves in $\bar{u}_r(x,0)$ and $\bar{v}_r(x,0)$ and each wave has a positive speed, there exists a finite time T_{es} such that

$$x(\alpha_i(t))>1 \quad \text{for all } i=1,\dots,m \text{ and } t\geq T_{es}.$$

In the following two lemmas, we estimate I and II separately.

LEMMA 4.1. *The quantity I satisfies the following estimate:*

$$I\leq -C_1\sum\{|q^-(\alpha_i)||q^+(\alpha_i)|\}+|\mathcal{O}(1)|\epsilon(T.V+G_1),$$

where $|\mathcal{O}(1)|$ and C_1 depend only on (4.1), ϵ is the upper bound of the strength of rarefaction shocks in the simplified wave pattern, and the summation is over all waves in J which cross the other solution.

Proof. Since I is a finite sum, by rearrangement, we can rewrite I as follows:

$$\begin{aligned} I &= \sum_{i=1}^{m}\{(\lambda(\alpha_i)-\lambda(q^-(\alpha_i)))|q^-(\alpha_i)| - (\lambda(\alpha_i)-\lambda(q^+(\alpha_i)))|q^+(\alpha_i)|\} \\ &= \sum_{i=1}^{m} A(\alpha_i), \end{aligned}$$

where $A(\alpha_i) = (\lambda(\alpha_i)-\lambda(q^-(\alpha_i)))|q^-(\alpha_i)| - (\lambda(\alpha_i)-\lambda(q^+(\alpha_i)))|q^+(\alpha_i)|$.

We consider a generic case (the locations of discontinuities in $\bar{v}_r$ and $\bar{u}_r$ are not coincident).

Case 1. $\alpha_i = (v_-, v_+) \in J(\bar{v}_r)$, and assume that $\bar{u}_r$ is continuous at $x = x(\alpha_i)$. We claim that

$$A(\alpha_i) = \begin{cases} 0, & q^-(\alpha_i)q^+(\alpha_i) \geq 0, \\ -|\mathcal{O}(1)||q^+(\alpha_i)||q^-(\alpha_i)|, & q^-(\alpha_i) \geq 0,\ q^+(\alpha_i) \leq 0, \\ |\mathcal{O}(1)|\epsilon|\alpha_i|, & q^-(\alpha_i) \leq 0, q^+(\alpha_i) \geq 0. \end{cases} \tag{4.4}$$

By the Rankine–Hugoniot condition and definition of $q^{\pm}(\alpha_i)$,

$$\lambda(\alpha_i)[\alpha_i] + \lambda(q^-(\alpha_i))q^-(\alpha_i) = \lambda(q^+(\alpha_i))q^+(\alpha_i). \tag{4.5}$$

Subcase 1.1. $q^-(\alpha_i) \geq 0,\ q^+(\alpha_i) \geq 0$. We have

$$\begin{aligned} A(\alpha_i) &= (\lambda(\alpha_i)-\lambda(q^-(\alpha_i)))|q^-(\alpha_i)| - (\lambda(\alpha_i)-\lambda(q^+(\alpha_i)))|q^+(\alpha_i)| \\ &= \lambda(\alpha_i)(q^-(\alpha_i)-q^+(\alpha_i)) - \lambda(q^-(\alpha_i))q^-(\alpha_i) + \lambda(q^+(\alpha_i))q^+(\alpha_i) \\ &= -\lambda(\alpha_i)[\alpha_i] - \lambda(q^-(\alpha_i))q^-(\alpha_i) + \lambda(q^+(\alpha_i))q^+(\alpha_i) = 0 \text{ by (4.5)}. \end{aligned}$$

Subcase 1.2. $q^-(\alpha_i) \leq 0,\ q^+(\alpha_i) \leq 0$. By the same analysis as Subcase 1.1, we have $A(\alpha_i) = 0$.

Subcase 1.3. $q^-(\alpha_i) \geq 0, q^+(\alpha_i) \leq 0$. By the convexity of the flux function, we have

$$\begin{aligned} &\lambda(\alpha_i) - \lambda(q^-(\alpha_i)) = -|\mathcal{O}(1)||q^+(\alpha_i)|, \\ &\lambda(\alpha_i) - \lambda(q^+(\alpha_i)) = |\mathcal{O}(1)||q^-(\alpha_i)|, \\ &A(\alpha_i) = (\lambda(\alpha_i)-\lambda(q^-(\alpha_i)))|q^-(\alpha_i)| - (\lambda(\alpha_i)-\lambda(q^+(\alpha_i)))|q^+(\alpha_i)| \\ &\qquad = -|\mathcal{O}(1)||q^+(\alpha_i)||q^-(\alpha_i)|. \end{aligned}$$

Subcase 1.4. $q^-(\alpha_i) \leq 0,\ q^+(\alpha_i) \geq 0$. In this case, since the upper bound of a rarefaction shock is ϵ, we have

$$\max\{|q^+(\alpha_i)|, |q^-(\alpha_i)|\} \leq |\alpha_i| < \epsilon.$$

Again, by the convexity of the flux function, we have

$$\begin{aligned} &\lambda(\alpha_i) - \lambda(q^-(\alpha_i)) = |\mathcal{O}(1)||q^+(\alpha_i)|, \\ &\lambda(\alpha_i) - \lambda(q^+(\alpha_i)) = -|\mathcal{O}(1)||q^-(\alpha_i)|, \\ &A(\alpha_i) \leq |\mathcal{O}(1)||q^+(\alpha_i)||q^-(\alpha_i)| \leq |\mathcal{O}(1)|\epsilon|\alpha_i|. \end{aligned}$$

Case 2. $\alpha_i = (u_-, u_+) \in J(\bar{u}_r)$, and $\bar{v}_r$ is continuous at $x = x(\alpha_i)$. We claim that

$$A(\alpha_i) = \begin{cases} 0, & q^-(\alpha_i)q^+(\alpha_i) \geq 0, \\ |\mathcal{O}(1)|\epsilon|\alpha_i|, & q^-(\alpha_i) \geq 0,\ q^+(\alpha_i) \leq 0, \\ -|\mathcal{O}(1)||q^+(\alpha_i)||q^-(\alpha_i)|, & q^-(\alpha_i) \leq 0, q^+(\alpha_i) \geq 0. \end{cases} \tag{4.6}$$

By the Rankine–Hugoniot condition and definition of $q^{\pm}(\alpha_i)$,

$$\lambda(\alpha_i)[\alpha_i] + \lambda(q^+(\alpha_i))q^+(\alpha_i) = \lambda(q^-(\alpha_i))q^-(\alpha_i). \tag{4.7}$$

By the same analysis using (4.7) as in Case 1, we get (4.6). From (4.3) and (4.6), we conclude that

$$I \leq -C_1 \sum \{|q^-(\alpha_i)||q^+(\alpha_i)|\} + |\mathcal{O}(1)|\epsilon(T.V + G_1),$$

where the summation is over all waves in J which cross the other solution. □

Lemma 4.2. *The quantity II satisfies the following estimate:*

$$II \leq \chi_{[0,T_{es}]}(t) \int_0^1 G(x)|\bar{u}_r(x) - \bar{v}_r(x)|dx,$$

where $\chi_{[0,T_{es}]}(t)$ is the characteristic function of the interval $[0, T_{es}]$.

Proof. By the construction of a simplified wave pattern, if $q(x_0, t) = 0$ for some $x_0 \in ((x(\alpha_i), x(\alpha_{i+1}))$, then $q(x, t) = 0$ on $(x(\alpha_i), x(\alpha_{i+1}))$. Therefore, we need to consider only two cases:

$$\text{either } q^+(\alpha_i) \geq 0,\ q^-(\alpha_{i+1}) \geq 0,\ \text{ or } q^+(\alpha_i) \leq 0,\ q^-(\alpha_{i+1}) \leq 0.$$

Let us set $II(\alpha_i, \alpha_{i+1}) \equiv \lambda(q^-(\alpha_{i+1}))|q^-(\alpha_{i+1})| - \lambda(q^+(\alpha_i))|q^+(\alpha_i)|$.

Case 1. $q^+(\alpha_i) \geq 0, q^-(\alpha_{i+1}) \geq 0$.

$$\begin{aligned} II(\alpha_i, \alpha_{i+1}) &= \lambda(q^-(\alpha_{i+1}))q^-(\alpha_{i+1}) - \lambda(q^+(\alpha_i))q^+(\alpha_i) \\ &= f(\bar{v}_r(x(\alpha_{i+1})-)) - f(\bar{u}_r(x(\alpha_{i+1})-)) \\ &\quad - \{f(\bar{v}_r(x(\alpha_i)-)) - f(\bar{u}_r(x(\alpha_i)))\} \\ &= \int_{x(\alpha_i)}^{x(\alpha_{i+1})} \{f(\bar{v}_r(x))_x - f(\bar{u}_r(x))_x\}dx \\ &= \int_{x(\alpha_i)}^{x(\alpha_{i+1})} \{g(x, \bar{v}_r(x)) - g(x, \bar{u}_r(x))\}dx. \end{aligned} \tag{4.8}$$

Case 2. $q^+(\alpha_i) \leq 0, q^-(\alpha_{i+1}) \leq 0$. By the same calculation as Case 1, we have

$$II(\alpha_i, \alpha_{i+1}) = \int_{x(\alpha_i)}^{x(\alpha_{i+1})} \{g(x, \bar{u}_r(x)) - g(x, \bar{v}_r(x))\}dx. \tag{4.9}$$

For $t \geq T_{es}$, since $g(x, \bar{v}_r(x)) = g(x, \bar{u}_r(x)) = 0$ on $(x(\alpha_i(t)), x(\alpha_{i+1}(t)))$, $II(\alpha_i, \alpha_{i+1}) = 0$. For $t < T_{es}$, $|g(x, \bar{v}_r(x)) - g(x, \bar{u}_r(x))| \leq G(x)|\bar{u}_r(x) - \bar{v}_r(x)|$ on $(x(\alpha_i), x(\alpha_{i+1}))$. Thus, in (4.8) and (4.9) we have

$$II \leq \chi_{[0,T_{es}]}(t) \int_0^1 G(x)|\bar{u}_r(x) - \bar{v}_r(x)|dx.$$

This completes the proof. □

By combining Lemmas 4.1 and 4.2, we have the following estimates on the L^1 distance between two simplified wave patterns.

Theorem 4.3. *There exists a positive constant C_1 depending on* (4.1) *such that*

$$\frac{d}{dt}\|\bar{u}_r(\cdot, t) - \bar{v}_r(\cdot, t)\|_{L^1(R)} \leq -C_1 \sum \{|q^-(\alpha_i)||q^+(\alpha_i)|\} + |\mathcal{O}(1)|\epsilon(T.V + G_1)$$

$$+ \chi_{[0,T_{es}]}(t) \int_0^1 G(x)|\bar{u}_r(x) - \bar{v}_r(x)|dx$$
$$+ \mathcal{O}(1)MsG_0 \sum_1^m |\alpha_i|,$$

where the summation is over all genuine shock waves in one of the solutions which cross the other solution.

Remark 4.1. 1. For the two exact solutions $u(x,t)$ and $v(x,t)$, we have

$$\frac{d}{dt}\|u(\cdot,t) - v(\cdot,t)\|_{L^1(R)} \leq -C_1 \sum\{|q^-(\alpha_i)||q^+(\alpha_i)|\} + \chi_{[0,T_{es}]}(t) \int_0^1 G(x)|u(x) - v(x)|dx.$$

2. $\chi_{[0,T_{es}]}(t) \int_0^1 G(x)|\bar{u}_r(x) - \bar{v}_r(x)|dx$ implies the source effect on the L^1 distance.

In the following lemma, we estimate the time-variation of a shock strength.

LEMMA 4.4. *Let $\alpha(t) = (u_-(t), u_+(t))$, $(p-1)Ms \leq t < pMs$ be a discontinuity in $\bar{u}_r(x,t)$. Then*

$$\frac{d|\alpha(t)|}{dt} = \mathcal{O}(1)G(x(\alpha(t)))|\alpha(t)|,$$

where $\mathcal{O}(1)$ depends only on the system (4.1).

Proof. Let $\gamma(t) = (x(t), t)$ be the locus of $\alpha(t)$ in $x - t$ plane. Then the curve $\gamma(t)$ is differentiable at a.e. $t \in ((p-1)Ms, pM)$. Since the shock has a constant speed and strength in the region $[0,1]^c$ by the construction, we consider only the case $x(t) \in [0,1]$. Let us set

$$u_-(t) \equiv u(x(t)-, t), \quad u_+(t) \equiv u(x(t)+, t).$$

For definiteness, assume that $u_-((p-1)Ms) > u_+((p-1)Ms)$; then $u_-(t) > u_+(t), t \in ((p-1)Ms, pMs)$ and $|\alpha(t)| = u_-(t) - u_+(t)$. Since $u_-(t)$ and $u_+(t)$ are local steady solutions of (4.1), we have

$$\frac{du_-(t)}{dt} = \frac{\partial u_-(t)}{\partial x}\dot{x}(t) = \frac{\dot{x}(t)}{f'(u_-(t))}g(x(t), u_-(t)), \tag{4.10a}$$

$$\frac{du_+(t)}{dt} = \frac{\partial u_+(t)}{\partial x}\dot{x}(t) = \frac{\dot{x}(t)}{f'(u_+(t))}g(x(t), u_+(t)). \tag{4.10b}$$

It follows from (4.10a)–(4.10b) that

$$\begin{aligned}\frac{d|\alpha(t)|}{dt} &= \frac{du_-(t)}{dx} - \frac{du_+(t)}{dx} = \frac{\dot{x}(t)}{f'(u_-(t))}g(x(t), u_-(t)) - \frac{\dot{x}(t)}{f'(u_+(t))}g(x(t), u_+(t)) \\ &= \dot{x}(t)\frac{\partial}{\partial p}\left(\frac{g(x,p)}{f'(p)}\right)\Bigg|_{(x(t),\theta(t))}(u_-(t) - u_+(t)) = \mathcal{O}(1)G(x(\alpha))|\alpha(t)|,\end{aligned}$$

where $\theta(t)$ is between $u_-(t)$ and $u_+(t)$, and we have used the fact that $\frac{\partial}{\partial p}(\frac{g(x,p)}{f'(p)}) = \mathcal{O}(1)G(x(\alpha)), \dot{x}(t) = \mathcal{O}(1)$. This completes the proof. ∎

Next we define an entropy functional $E[\bar{u}_r, \bar{v}_r]$ to obtain the third order decay estimate for two simplified wave patterns $\bar{u}_r$ and $\bar{v}_r$. This entropy functional will be used to capture the nonlinearity of a characteristic field. From now on, without confusion we rewrite $\bar{u}_r, \bar{v}_r$ as u, v, respectively, and define

$$(u-v)_+ \equiv \max\{u-v, 0\}, \qquad (u-v)_- \equiv \max\{-(u-v), 0\}.$$

Let us set

$$\begin{aligned} E(\alpha) &\equiv |\alpha| \cdot \begin{cases} \int_{x(\alpha)}^{\infty}(u-v)_+(x,t)dx + \int_{-\infty}^{x(\alpha)}(u-v)_-(x,t)dx, & \alpha \in J(u), \\ \int_{x(\alpha)}^{\infty}(v-u)_+(x,t)dx + \int_{-\infty}^{x(\alpha)}(v-u)_-(x,t)dx, & \alpha \in J(v), \end{cases} \\ E(t) &\equiv E[u(\cdot,t), v(\cdot,t)] = \sum_{\alpha \in J} E(\alpha). \end{aligned}$$

In the following theorem, we study the time-variation of the entropy functional.

Theorem 4.5. *Let $u(x,t)$ and $v(x,t)$ be two simplified wave patterns of* (4.1) *whose total variations are bounded by $\mathcal{O}(1)(T.V + G_1)$. Then the entropy functional $E(t)$ satisfies*

$$\begin{aligned} &\frac{d}{dt}E(t) \le -C_2 \sum_{\alpha \in J} |\alpha| \max\{q^+(\alpha)q^-(\alpha), 0\} + \mathcal{O}(1) \sum_{\alpha \in J} G(x(\alpha))E(\alpha) \\ &+ \chi_{[0,T_{es}]}(t) \sum_{\alpha \in J(v)} |\alpha| \left\{ \int_{x(\alpha)}^{\infty} G(x)(v-u)_+(x,t)dx + \int_{-\infty}^{x(\alpha)} G(x)(v-u)_-(x,t)dx \right\} \\ &+ \chi_{[0,T_{es}]}(t) \sum_{\alpha \in J(u)} |\alpha| \left\{ \int_{x(\alpha)}^{\infty} G(x)(u-v)_+(x,t)dx + \int_{-\infty}^{x(\alpha)} G(x)(u-v)_-(x,t)dx \right\} \\ &+ \mathcal{O}(1)(T.V + G_1)^2\epsilon + \mathcal{O}(1)MsG_0 \sum_1^m |\alpha_i|, \quad \text{a.e. } t \in ((p-1)Ms, pMs), \end{aligned}$$

where C_2 is a positive constant depending only on (4.1).

Proof. Let us assume that $\alpha \in J(v)$, and u is continuous at $x = x(\alpha)$. Then by the definition of $E(\alpha)$,

$$\begin{aligned} \frac{dE(\alpha)}{dt} &= \frac{d}{dt}\left[|\alpha| \left\{ \int_{-\infty}^{x(\alpha)} (v-u)_-(x,t)dx + \int_{x(\alpha)}^{\infty} (v-u)_+(x,t)dx \right\} \right] \\ &= |\alpha| \left\{ \frac{d}{dt}\int_{-\infty}^{x(\alpha)} (v-u)_-(x,t)dx + \frac{d}{dt}\int_{x(\alpha)}^{\infty} (v-u)_+(x,t)dx \right\} \\ &+ \frac{d|\alpha|}{dt} \left\{ \int_{-\infty}^{x(\alpha)} (v-u)_-(x,t)dx + \int_{x(\alpha)}^{\infty} (v-u)_+(x,t)dx \right\} \\ &\equiv I(\alpha) + II(\alpha). \end{aligned}$$

From Lemma 4.4, we have

$$II(\alpha) = \mathcal{O}(1)G(x(\alpha))E(\alpha). \tag{4.11}$$

Let $\{x_j(t)\}$ be the partition of R such that

$$\begin{aligned} v(x,t) > u(x,t), &\quad x_{2i}(t) < x < x_{2i+1}(t), \\ v(x,t) < u(x,t), &\quad x_{2i-1}(t) < x < x_{2i}(t). \end{aligned}$$

Then by the construction of simplified wave patterns, either $u(x,t)$ or $v(x,t)$ has a discontinuity at $x = x_j(t)$. In the following, $q^{\pm}(x_j(t))$ denotes a wave $(u(x_j(t)\pm, t)$, $v(x_j(t)\pm, t))$ or a difference $v(x_j(t)\pm, t) - u(x_j(t)\pm, t)$.

By the same analysis as in [24], we get the following estimate:

$$\begin{aligned}
&\frac{d}{dt}\sum_{\alpha\in J(v)} E(\alpha) \le -C_2 \sum_{\alpha\in J(v)} |\alpha| \max\{q^+(\alpha)q^-(\alpha),0\} + \mathcal{O}(1)(T.V + G_1)^2\epsilon \\
&+ \chi_{[0,T_{es}]}(t) \sum_{\alpha\in J(v)} |\alpha| \left\{ \int_{x(\alpha)}^{\infty} G(x)(v-u)_+(x,t)dx + \int_{-\infty}^{x(\alpha)} G(x)(v-u)_-(x,t)dx \right\} \\
&+ \mathcal{O}(1)MsG_0 \sum_1^m |\alpha_i| + \mathcal{O}(1) \sum_{\alpha\in J(v)} G(x(\alpha))E_2(\alpha).
\end{aligned}$$

Similar estimates hold for $\sum_{\alpha\in J(u)} E(\alpha)$. Hence, we have

$$\begin{aligned}
\frac{dE(t)}{dt} \le\ & -C_2 \sum_{\alpha\in J} |\alpha| \max\{q^+(\alpha)q^-(\alpha),0\} + \mathcal{O}(1)(T.V + G_1)^2\epsilon \\
&+ \chi_{[0,T_{es}]}(t) \sum_{\alpha\in J(v)} |\alpha| \left\{ \int_{x(\alpha)}^{\infty} G(x)(v-u)_+(x,t)dx + \int_{-\infty}^{x(\alpha)} G(x)(v-u)_-(x,t)dx \right\} \\
&+ \chi_{[0,T_{es}]}(t) \sum_{\alpha\in J(u)} |\alpha| \left\{ \int_{x(\alpha)}^{\infty} G(x)(u-v)_+(x,t)dx + \int_{-\infty}^{x(\alpha)} G(x)(u-v)_-(x,t)dx \right\} \\
&+ \mathcal{O}(1)MsG_0 \sum_1^m |\alpha_i| + \mathcal{O}(1) \sum_{\alpha\in J(v)} G(x(\alpha))E_2(\alpha).
\end{aligned}$$

This completes the proof. □

5. Systems of hyperbolic conservation laws with a moving source.

In this section, we construct a nonlinear functional which is equivalent to the L^1 distance between two Glimm solutions and nonincreasing in time. By using this nonlinear functional, we establish the L^1 stability of the Glimm solutions.

5.1. A nonlinear functional. We define a nonlinear functional $H(t)$ which is equivalent to the L^1 distance and nonincreasing in time. Our analysis makes use of the strict hyperbolicity and the genuine nonlinearity, the fact that the source has a compact support in x, and the nonresonance condition of the system (1.1). Let us set

$$\begin{aligned}
&\mathcal{G} \equiv \{u(x,t) \in BV(R\times R_+) : u \ \text{ is a solution corresponding to initial data } \ u_0\}, \\
&\mathcal{D} \equiv \{(u,v) \in \mathcal{G}\times\mathcal{G} : u_0 - v_0 \in L^1(R)\}.
\end{aligned}$$

Let $u(x,t)$ and $v(x,t)$ be two weak solutions of (1.1) such that

$$\lim_{r\to 0} u_r(x,t) = u(x,t), \quad \lim_{r\to 0} v_r(x,t) = v(x,t) \quad \text{in } L^1_{loc}(R\times R_+).$$

Let $\bar{u}_r(x,t)$ and $\bar{v}_r(x,t)$ be the simplified wave patterns corresponding to $u_r(x,t)$ and $v_r(x,t)$, respectively. For the time being, we will fix r and without confusion, we rewrite $\bar{u}_r(x,t)$ and $\bar{v}_r(x,t)$ as $u(x,t)$ and $v(x,t)$. For given $(x,t)\in R\times R_+$, we solve the Riemann problem for the corresponding homogeneous conservation laws of (1.1) with initial data $(u(x,t),v(x,t))$ by shock waves or rarefaction shocks, i.e.,

$$\omega_0(x,t) = u(x,t), \ \ \omega_n(x,t) = v(x,t), \ \ \omega_i(x,t) \in H_i(\omega_{i-1}(x,t)), \ i = 0,1,\dots,n.$$

Moreover, if necessary, by a linear transformation of $u = (u^1,\dots,u^n)$, we may assume that each coordinate function u^i is strictly increasing along the ith wave curve

$W_i(u)$. Let us define $q_i(x,t)$, the strength of ith wave $(\omega_{i-1}(x,t), \omega_i(x,t))$, by the ith component of $\omega_i(x,t) - \omega_{i-1}(x,t)$, i.e.,

$$q_i(x,t) \equiv (\omega_i(x,t) - \omega_{i-1}(x,t))^i, \quad i = 1, \ldots, n.$$

Since $\mathcal{N} \subset$ compact subset of R^n, it is easy to see that

$$\frac{1}{C_3}|u(x,t) - v(x,t)| \leq \sum_1^n |q_i(x,t)| \leq C_3|u(x,t) - v(x,t)|,$$

where C_3 is a large positive constant which is independent of t.

Let us consider i-wave $\alpha^i \in J$, and define the location of the i-wave α^i and the waves generated by the difference of u and v at both sides of the wave as follows:

$$\begin{aligned} x(\alpha^i) \equiv & \quad \text{the location of } i\text{-wave } \alpha^i, \\ q_j^{\pm}(\alpha^i) \equiv q_j(x(\alpha^i)&\pm, t), \quad \lambda_j^{\pm}(\alpha^i) \equiv \lambda_j(\omega_{j-1}(x(\alpha^i)\pm, t), \omega_j(x(\alpha^i)\pm, t)). \end{aligned}$$

For $j = i$, we use abbreviated notations $q^{\pm}(\alpha^i), \lambda^{\pm}(\alpha^i)$. The nonlinear functional $H(t)$ is the weighted linear combination of four component functionals: $L(t)$ measuring the L^1 distance between two solutions $u(x,t)$ and $v(x,t)$, $Q_d(t)$ measuring nonlinear couplings between waves of different characteristic families, $E(t)$ capturing the nonlinearity of the characteristic field due to the bifurcation of a shock curve and a rarefaction curve, and $Q_{so}(t)$ measuring the source effect on the L^1 distance.

In contrast with the Liu–Yang functional [24], our modified nonlinear functional is defined to capture the effect of the source on the L^1 distance. For this, we need to consider the potential interaction between the imaginary wave [2] $q_i(x,t)$ and stationary waves. Recall that the strength of the stationary waves is measured by the function $G(x)$. In order to fix the idea, let us consider an imaginary wave $q_j(x_0,t), j > j_0$. Since this wave has a positive speed, it will propagate to ∞; in doing so, it will interact with the stationary waves lying $x \geq x_0$. The same argument holds for $q_j(x_0,t), j \leq j_0$. So potential interactions between imaginary waves located at $x = x_0$ and stationary waves are

$$\sum_{j \leq j_0} |q_j(x_0,t)| \int_{-\infty}^{x(q_j)} G(\xi) d\xi + \sum_{j \geq j_0+1} |q_j(x_0,t)| \int_{x(q_j)}^{\infty} G(\xi) d\xi.$$

Based on this observation, we define a nonlinear functional which contains a new component functional $Q_{so}(t)$ in the following. First we define a nonlinear functional for two simplified wave patterns $u(x,t)$ and $v(x,t)$.

$$L(t) \equiv \sum_{j=1}^n L_j(t) \equiv \sum_{j=1}^n \int_{-\infty}^{\infty} |q_j(x,t)| dx,$$

$$Q_d(t) \equiv \sum_{\alpha^i \in J} Q_d(\alpha^i(t)) \equiv \sum_{\alpha^i \in J} |\alpha^i(t)| \left\{ \sum_{j>i} \int_{-\infty}^{x(\alpha^i)} |q_j(x,t)| dx + \sum_{j<i} \int_{x(\alpha^i)}^{\infty} |q_j(x,t)| dx \right\},$$

$$E(t) \equiv \sum_{\alpha^i \in J} E(\alpha^i(t)) \equiv \sum_{\alpha^i \in J} |\alpha^i(t)| \cdot \begin{cases} \int_{-\infty}^{x(\alpha^i)} q_i(x,t)_+ dx + \int_{x(\alpha^i)}^{\infty} q_i(x,t)_- dx, & \alpha^i \in J(u), \\ \int_{x(\alpha^i)}^{\infty} q_i(x,t)_+ dx + \int_{-\infty}^{x(\alpha^i)} q_i(x,t)_- dx, & \alpha^i \in J(v), \end{cases}$$

[2] These waves are not the real hyperbolic waves in weak solutions but virtual waves generated by the difference between two weak solutions.

$$
\begin{aligned}
Q_{so}(t) \equiv \sum_{j\le j_0}\int_{-\infty}^{\infty}|q_j(x,t)|\left(\int_{-\infty}^{x(q_j)}G(\xi)d\xi\right)dx+\sum_{j\ge j_0+1}\int_{-\infty}^{\infty}|q_j(x,t)|\left(\int_{x(q_j)}^{\infty}G(\xi)d\xi\right)dx,\\
H(t)\equiv[1+K_1F((p-1)Ms)]L(t)+K_2[Q_d(t)+E(t)+Q_{so}(t)],\ t\in[(p-1)Ms,pMs),\\
1\le p\le N,
\end{aligned}
$$

where K_1 and K_2 are positive constants to be determined later, and $F(t)=F(u:t)+F(v:t)$ is the modified Glimm functional which was introduced in section 3.

5.2. Basic estimates. In this subsection, we study basic estimates which are necessary for the decay analysis of the nonlinear functional $H(t)$. In the following, the first three lemmas are direct consequences of the smoothness of the shock curves. See [6] and [24].

LEMMA 5.1. *Let $\bar u\in\mathcal{N}$ and $k\in\{1,2,\dots,n\}$. Let us define the states and wave speeds as follows:*

$$
\begin{aligned}
&u=H_k(\xi)(\bar u),\quad u'=H_k(\xi')(u),\quad u''=H_k(\xi+\xi')(\bar u),\\
&\lambda=\lambda_k(\bar u,u),\quad \lambda'=\lambda_k(u,u'),\quad \lambda''=\lambda_k(\bar u,u'').
\end{aligned}
$$

Then we have

$$
\begin{aligned}
|(\xi+\xi')\lambda''-(\xi\lambda+\xi'\lambda')|&=|(\xi+\xi')(\lambda''-\lambda')-\xi(\lambda-\lambda')|\\
&=\mathcal{O}(1)|\xi||\xi'|(|\xi|+|\xi'|).
\end{aligned}
$$

Let us set

$\{\omega_0^+,\omega_1^+,\dots,\omega_n^+\}$: the resolution of a discontinuity $(u(x(\alpha^i)+,t),v(x(\alpha^i)+0,t))$,
$\{\omega_0^-,\omega_1^-,\dots,\omega_n^-\}$: the resolution of a discontinuity $(u(x(\alpha^i)-,t),v(x(\alpha^i)-0,t))$,

$$
q_j^{\pm}(\alpha^i)=(\omega_j^{\pm}-\omega_{j-1}^{\pm})^j,\quad j=1,\dots,n.
$$

LEMMA 5.2. *Suppose that ξ_j,ξ_j', and ξ_j'' satisfy*

$$
H_n(\xi_n)\circ\cdots\circ H_1(\xi_1)(u)=H_n(\xi_n')\circ\cdots\circ H_1(\xi_1')\circ H_n(\xi_n'')\circ\cdots\circ H_1(\xi_1'')(u).
$$

Then, we get

$$
\sum_{i=1}^n|\xi_i-\xi_i'-\xi_i''|=\mathcal{O}(1)\left\{\sum_i|\xi_i'||\xi_i''|(|\xi_i'|+|\xi_i''|)+\sum_{j>i}|\xi_j''||\xi_i'|\right\}.
$$

If the values ξ_i' and ξ are related by

$$
R_i(\xi)(u^*)=H_n(\xi_n')\circ\cdots\circ H_1(\xi_1')(u^*),
$$

then we have

$$
|\xi-\xi_i|+\sum_{j\ne i}|\xi_j'|=\mathcal{O}(1)\left\{|\xi||\xi_i'|(|\xi|+|\xi_i'|)+\sum_{j\ne i}|\xi_j'||\xi|\right\}.
$$

Suppose $\alpha^i=(v_-,v_+)\in J(v)$ is an i-wave in v and u is continuous at $x=x(\alpha^i)$. Recall $\Lambda_p=\{(x,t):-\infty<x<\infty,(p-1)Ms\le t<pMs\},\quad p\in\{1,\dots,N\}$.

Let us set

$$\begin{aligned}
&e(\Lambda_p) \equiv (Q(\Lambda_p) + C(\Lambda_p) + \delta + \epsilon + MsG_0),\\
&\Gamma_s(\alpha^i) \equiv |\alpha^i||q^-(\alpha^i)|(|q^-(\alpha^i)| + |\alpha^i|) \text{ or } |\alpha^i||q^+(\alpha^i)|(|q^+(\alpha^i)| + |\alpha^i|),\\
&\Gamma_d(\alpha^i) \equiv |\alpha^i|\sum_{j>i} |q_j^-(\alpha^i)| \text{ or } |\alpha^i|\sum_{j<i} |q_j^+(\alpha^i)|.
\end{aligned}$$

Then it is easy to see that

$$(\Gamma_s + \Gamma_d)(\alpha^i) = \mathcal{O}(1)\sum_{j=1}^{n} |\alpha^i||q_j^-(\alpha^i)| = \mathcal{O}(1)\sum_{j=1}^{n} |\alpha^i||q_j^+(\alpha^i)|.$$

Remark. If $\alpha^i = (u_-, u_+) \in J(u)$ and v is continuous at $x = x(\alpha^i)$, then we have

$$\begin{aligned}
&\Gamma_s(\alpha^i) \equiv |\alpha^i||q^+(\alpha^i)|(|q^+(\alpha^i)| + |\alpha^i|) \text{ or } |\alpha^i||q^-(\alpha^i)|(|q^-(\alpha^i)| + |\alpha^i|),\\
&\Gamma_d(\alpha^i) \equiv |\alpha^i|\sum_{j<i} |q_j^+(\alpha^i)| \text{ or } |\alpha^i|\sum_{j>i} |q_j^-(\alpha^i)|.
\end{aligned}$$

In the following, we study the variation of $q_j(x,t)$ across the wave.

LEMMA 5.3. *Let $\alpha^i = (v_-, v_+) \in J(v)$ be an i-wave in the time zone Λ_p. Then*

$$q_j^+(\alpha^i) = \begin{cases} q^-(\alpha^i) + [\alpha^i] + \mathcal{O}(1)(\Gamma_s + \Gamma_d)(\alpha^i) + \mathcal{O}(1)|\alpha^i|e(\Lambda_p), & j = i,\\ q_j^-(\alpha^i) + \mathcal{O}(1)(\Gamma_s + \Gamma_d)(\alpha^i) + \mathcal{O}(1)|\alpha^i|e(\Lambda_p), & j \neq i, \end{cases}$$

where $[\alpha^i] = (v_+ - v_-)^i$.

Remark. If $\alpha^i = (u_-, u_+) \in J(u)$, then the same estimates hold by a straightforward calculation.

In the following, we estimates the time-variation of a shock strength as given in Lemma 4.4.

LEMMA 5.4. *Let $\alpha^i(t) = (u_-(t), u_+(t))$, $t \in [(p-1)Ms, pMs)$ be an i-wave issued from $(hr, (p-1)Ms)$ in the simplified wave pattern $u(x,t)$. Then*

$$\frac{d|\alpha^i(t)|}{dt} = \mathcal{O}(1)G(x(\alpha^i))|\alpha^i(t)|,$$

where $\mathcal{O}(1)$ depends only on (1.1).

Proof. The same argument as in Lemma 4.4 holds for this case. □

For a given noninteracting time t, let us denote $J = \{\alpha_i\}_1^m$ by the set of all waves in u and v, and assume that

$$-\infty < x(\alpha_1) < \cdots < 0 \le x(\alpha_k) < x(\alpha_{k+1}) < \cdots < 1 \le x(\alpha_l) < \cdots < x(\alpha_m) < \infty.$$

Without loss of generality, we may assume that $x(\alpha_k(t)) = 0$ and $x(\alpha_l(t)) = 1$.

LEMMA 5.5. *For a given time t and $j \in \{1, 2, \ldots, n\}$,*

$q_j(x,t)$ is differentiable a.e $x \in R$ and $\dfrac{\partial q_j(x,t)}{\partial x} = \mathcal{O}(1)G(x)\displaystyle\sum_{k=1}^{n} q_k(x,t)$, *a.e. $x \in R$.*

Proof. By the construction of a simplified wave pattern, $q_j(x,t)$ is piecewise differentiable in x and $\frac{\partial q_j(x,t)}{\partial x} = 0$ a.e $x \notin [0,1]$. Let $x \in (x(\alpha_i), x(\alpha_{i+1}))$, $i \in \{k, \ldots, l-1\}$. Since $u(x,t)$ and $v(x,t)$ are local steady solutions of (1.1),

$$u_x = (f'(u))^{-1}g(x,u), \quad v_x = (f'(v))^{-1}g(x,v).$$

Therefore, we have

$$v(y) = v(x) + \int_x^y (f'(v))^{-1} g(\xi, v) d\xi, \quad u(y) = u(x) + \int_x^y (f'(u))^{-1} g(\xi, u) d\xi,$$

$$(5.1) v(y) - u(y) = v(x) - u(x) + \int_x^y (f'(v))^{-1} g(\xi, v) - (f'(u))^{-1} g(\xi, u) d\xi.$$

Let us set $h(\xi, p) = f'(p))^{-1} g(\xi, p)$. Then

$$\begin{aligned} &\int_x^y \{(f'(v))^{-1} g(\xi, v) - (f'(u))^{-1} g(\xi, u)\} d\xi = \int_x^y (h(\xi, v) - h(\xi, u)) d\xi \\ &= \int_x^y \left\{ \int_0^1 \frac{\partial}{\partial s} h(\xi, u + s(v-u)) ds \right\} d\xi \\ &= \int_x^y \left\{ \int_0^1 \sum_{i=1}^n \frac{\partial h}{\partial p^i} |_{(\xi, u+s(v-u))} \cdot (v^i - u^i) ds \right\} d\xi \\ &= \mathcal{O}(1) \left(\int_x^y G(\xi) d\xi \right) |v(x) - u(x)|, \end{aligned}$$

where we have used that fact that $\frac{\partial h}{\partial p^i}|_{(\xi, u+s(v-u))} = \mathcal{O}(1) G(\xi)$ and $\sum_1^n |v^i(\xi, t) - u^i(\xi, t)| = \mathcal{O}(1)|v(x,t) - u(x,t)|$. Therefore, in (5.1), we have

$$v(y) - u(y) = v(x) - u(x) + \mathcal{O}(1) \left(\int_x^y G(\xi) d\xi \right) |v(x) - u(x)|.$$

This implies that

$$(v(x) - u(x))_x = \mathcal{O}(1) G(x) \sum_{k=1}^n |q_k(x,t)|.$$

Since $q_i(x,t) = \mathcal{O}(1) l_i(u(x)) \cdot (v(x) - u(x))$, by a direct calculation, we have the following estimate:

$$\frac{\partial q_i(x,t)}{\partial x} = \mathcal{O}(1) G(x) \sum_{k=1}^n |q_k(x,t)|.$$

This completes the proof. □

LEMMA 5.6. *For each $j \in \{1, \dots, n\}$,*

$$\sum_{\alpha^i \in J} \{\lambda(q_j^-(\alpha^i)) |q_j^-(\alpha^i)| - \lambda(q_j^+(\alpha^i)) |q_j^+(\alpha^i)|\} = \mathcal{O}(1) \sum_{k=1}^n \int_0^1 G(x) |q_k(x,t)| dx.$$

Proof. By the construction, the simplified wave pattern is piecewise constant outside an interval $[0,1]$. Therefore,

$$\lambda(q_j^-(\alpha_{i+1})) |q_j^-(\alpha_{i+1})| - \lambda(q_j^+(\alpha_i)) |q_j^+(\alpha_i)| = 0, \quad i \in \{1, \dots, k-1, l, \dots, m-1\},$$

$$\sum_{i=1}^{m-1} \{\lambda(q_j^-(\alpha_{i+1})) |q_j^-(\alpha_{i+1})| - \lambda(q_j^+(\alpha_i)) |q_j^+(\alpha_i)|\}$$

$$
\begin{aligned}
&= \sum_{1}^{k-1} \{\lambda(q_j^-(\alpha_{i+1}))|q_j^-(\alpha_{i+1})| - \lambda(q_j^+(\alpha_i))|q_j^+(\alpha_i)|\} \\
&+ \sum_{k}^{l-1} \{\lambda(q_j^-(\alpha_{i+1}))|q_j^-(\alpha_{i+1})| - \lambda(q_j^+(\alpha_i))|q_j^+(\alpha_i)|\} \\
&+ \sum_{l}^{m-1} \{\lambda(q_j^-(\alpha_{i+1}))|q_j^-(\alpha_{i+1})| - \lambda(q_j^+(\alpha_i))|q_j^+(\alpha_i)|\} \\
&= \sum_{k}^{l-1} \{\lambda(q_j^-(\alpha_{i+1}))|q_j^-(\alpha_{i+1})| - \lambda(q_j^+(\alpha_i))|q_j^+(\alpha_i)|\} \\
&= \sum_{k}^{l-1} II(\alpha_i, \alpha_{i+1}).
\end{aligned}
$$

Let us consider

$$II(\alpha_i, \alpha_{i+1}) = \lambda(q_j^-(\alpha_{i+1}))|q_j^-(\alpha_{i+1})| - \lambda(q_j^+(\alpha_i))|q_j^+(\alpha_i)|,\ i \in \{k, \dots, l-1\}.$$

Case 1. $q_j^+(\alpha_i) \geq 0, q_j^-(\alpha_{i+1}) \geq 0.$

$$
\begin{aligned}
(5.2) \qquad II(\alpha_i, \alpha_{i+1}) &= \lambda(q_j^-(\alpha_{i+1}))|q_j^-(\alpha_{i+1})| - \lambda(q_j^+(\alpha_i))|q_j^+(\alpha_i)| \\
&= f^j(\omega_j(x(\alpha_{i+1})-, t)) - f^j(\omega_{j-1}(x(\alpha_{i+1})-, t)) \\
&- \{f^j(\omega_j(x(\alpha_i)+, t)) - f^j(\omega_{j-1}(x(\alpha_i)+, t))\} \\
&= \int_{x(\alpha_i)}^{x(\alpha_{i+1})} \{f^j(\omega_j(x,t))_x - f^j(\omega_{j-1}(x,t))_x\} dx \\
&= \int_{x(\alpha_i)}^{x(\alpha_{i+1})} \{\nabla_p f^j(\theta_j(x,t)) \cdot (\omega_j(x,t) - \omega_{j-1}(x,t))\}_x dx,
\end{aligned}
$$

where $\theta_j(x,t) = (\theta_j^1(x,t), \dots, \theta_j^n(x,t))$ is on the line segment connecting $\omega_{j-1}(x,t)$ and $\omega_j(x,t)$. By the chain rule, we have

$$
\begin{aligned}
\{\nabla_p f^j(\theta_j(x,t)) \cdot (\omega_j(x,t) - \omega_{j-1}(x,t))\}_x &= (\nabla_p f^j(\theta_j(x,t)))_x \cdot (\omega_j(x,t) - \omega_{j-1}(x,t)) \\
&+ \nabla_p f^j(\theta_j(x,t)) \cdot (\omega_j(x,t) - \omega_{j-1}(x,t))_x.
\end{aligned}
$$

We claim the following:

$$
\begin{aligned}
&\text{(i)} \quad (\nabla_p f^j(\theta_j(x,t)))_x = \mathcal{O}(1)G(x), \\
&\text{(ii)} \quad (\omega_j(x,t) - \omega_{j-1}(x,t))_x = \mathcal{O}(1)G(x) \sum_{k=1}^{n} |q_k(x,t)|.
\end{aligned}
$$

(i) By the chain rule,

$$(\nabla_p f^j(\theta_j(x,t)))_x = \left(\sum_{l=1}^{n} \frac{\partial^2 f^j(\theta_j(x,t))}{\partial p^l \partial p^1} \cdot \theta_j^l(x,t)_x, \dots, \sum_{l=1}^{n} \frac{\partial^2 f^j(\theta_j(x,t))}{\partial p^l \partial p^n} \cdot \theta_j^l(x,t)_x \right).$$

Since $\nabla_p f^j(\theta_j(x,t)) = \mathcal{O}(1)$, $\frac{\partial^2 f^j(\theta_j(x,t))}{\partial p^l \partial p^s} = \mathcal{O}(1)$ and $\theta_j^l(x,t)_x = \mathcal{O}(1)G(x)$, we have

$$(\nabla_p f^j(\theta_j(x,t)))_x = \mathcal{O}(1)G(x).$$

(ii) By definition of $q_j(x,t)$, $\omega_j(x,t) - \omega_{j-1}(x,t) = \mathcal{O}(1)q_j(x,t)$. Therefore, we have

$$(\omega_j(x,t) - \omega_{j-1}(x,t))_x = \mathcal{O}(1)_x q_j(x,t) + \mathcal{O}(1)q_j(x,t)_x.$$

Lemma 5.5 yields

$$(\omega_j(x,t) - \omega_{j-1}(x,t))_x = \mathcal{O}(1)G(x)\sum_{k=1}^{n}|q_k(x,t)|.$$

From the above claim, in (5.2) we have

$$II(\alpha_i,\alpha_{i+1}) = \mathcal{O}(1)\sum_{k=1}^{n}\int_{x(\alpha_i)}^{x(\alpha_{i+1})} G(x)|q_k(x,t)|dx.$$

Case 2. $q_j^+(\alpha_i) \le 0, q_j^-(\alpha_{i+1}) \le 0$. By the same analysis as Case 1, we have

$$II(\alpha_i,\alpha_{i+1}) = \mathcal{O}(1)\sum_{k=1}^{n}\int_{x(\alpha_i)}^{x(\alpha_{i+1})} G(x)|q_k(x,t)|dx.$$

Case 3. $q_j^+(\alpha_i) > 0$, $q_j^-(\alpha_{i+1}) < 0$. Since $q_j(x,t)$ is continuous on $[x(\alpha_i), x(\alpha_{i+1})]$, by the intermediate value theorem, $q_j(x_0(t),t) = 0$ for some $x_0(t) \in (x(\alpha_i), x(\alpha_{i+1}))$. Using this fact, one has

$$|q_j^+(\alpha_i)| = |q_j(x_0) - q_j^+(\alpha_i)| = \left|\int_{x(\alpha_i)}^{x_0} q_j(x,t)_x dx\right| = \mathcal{O}(1)\sum_{k=1}^{n}\int_{x(\alpha_i)}^{x_0} G(x)|q_k(x,t)|dx.$$

On the other hand,

$$\begin{aligned}|q_j^-(\alpha_{i+1})| = |q_j^-(\alpha_{i+1}) - q_j(x_0)| &= \left|\int_{x_0}^{x(\alpha_{i+1})} q_j(x,t)_x dx\right| \\ &= \mathcal{O}(1)\sum_{k=1}^{n}\int_{x_0}^{x(\alpha_{i+1})} G(x)|q_k(x,t)|dx.\end{aligned}$$

Since $|\lambda(q_j^-(\alpha_{i+1}))| = \mathcal{O}(1)$, $|\lambda(q_j^+(\alpha_i))| = \mathcal{O}(1)$,

$$II(\alpha_i,\alpha_{i+1}) = \mathcal{O}(1)\sum_{k=1}^{n}\int_{x(\alpha_i)}^{x(\alpha_{i+1})} G(x)|q_k(x,t)|dx.$$

Case 4. $q_j^+(\alpha_i) < 0, q_j^-(\alpha_{i+1}) > 0$. By the same analysis as Case 3, we have

$$II(\alpha_i,\alpha_{i+1}) \le \mathcal{O}(1)\sum_{k=1}^{n}\int_{x(\alpha_i)}^{x(\alpha_{i+1})} G(x)|q_k(x,t)|dx.$$

This completes the proof. □

5.3. L^1 stability and uniqueness. Recall that the open interval $I_p = ((p-1)Ms, pMs), p \in \{1, \dots, N\}$ is the union of two disjoint sets $I_p = I_p^1 \cup I_p^2$, where I_p^1 is the set of all countable interaction times such that $H(t)$ is simply continuous, and I_p^2 is the set of all differentiable points of $H(t)$.

Lemma 5.7. *The nonlinear functional $H(t)$ is "almost decreasing" for the simplified wave patterns in the sense that*

$$H(pMs+) \leq H((p-1)Ms+) + \mathcal{O}(1)e(\Lambda_p)Ms,$$

where $\mathcal{O}(1)$ depends only on (1.1) *and $e(\Lambda_p) = Q(\Lambda_p) + C(\Lambda_p) + (\epsilon + \delta + MsG_0)$.*

Proof. We will study the time rate of a change for each component functional separately. Set

$$\Gamma \equiv \Gamma_s + \Gamma_d + \Gamma_{so}, \qquad \Gamma_s \equiv \sum_\beta \Gamma_s(\beta),$$
$$\Gamma_d \equiv \sum_\beta \Gamma_d(\beta), \qquad \Gamma_{so} \equiv \sum_1^n \int_0^1 G(x)|q_j(x,t)|dx.$$

In the following proof, we will use a similar analysis to that in Lemma 5.1 of [24].

Step 1. $\frac{dL(t)}{dt} \leq \mathcal{O}(1)\Gamma + \mathcal{O}(1)(T.V + G_1)e(\Lambda_p), t \in I_p^2$. By definition of $L(t)$,

$$\frac{dL(t)}{dt} = \sum_{j=1}^n \frac{dL_j(t)}{dt} = \sum_{j=1}^n \frac{d}{dt}\int_{-\infty}^\infty |q_j(x,t)|dx.$$

Let $j \in \{1, 2, \dots, n\}$. Then it follows from Lemma 5.6 that

$$\begin{aligned}(5.3) \qquad & \sum_{\alpha^i \in J} \{\lambda(q_j^-(\alpha^i))|q_j^-(\alpha^i)| - \lambda(q_j^+(\alpha^i))|q_j^+(\alpha^i)|\} \\ &= \sum_{i=1}^m \{\lambda(q_j^-(\alpha_i))|q_j^-(\alpha_i)| - \lambda(q_j^+(\alpha_i))|q_j^+(\alpha_i)|\} \\ &= \mathcal{O}(1)\sum_{l=1}^n \int_0^1 G(x)|q_l(x,t)|dx.\end{aligned}$$

Let us consider $\frac{d}{dt}\int_{-\infty}^\infty |q_j(x,t)|dx$; then by a direct calculation, we have

$$\begin{aligned}(5.4) \qquad & \frac{d}{dt}\int_{-\infty}^\infty |q_j(x,t)|dx = \sum_{\alpha^i \in J} \dot{x}(\alpha^i)(|q_j^-(\alpha^i)| - |q_j^+(\alpha^i)|) \\ &= \sum_{\alpha^i \in J} \{(\dot{x}(\alpha^i) - \lambda(q_j^-(\alpha^i)))|q_j^-(\alpha^i)| - (\dot{x}(\alpha^i) - \lambda(q_j^+(\alpha^i)))|q_j^+(\alpha^i)|\} \\ &+ \sum_{\alpha^i \in J} \{\lambda(q_j^-(\alpha^i))|q_j^-(\alpha^i)| - \lambda(q_j^+(\alpha^i))|q_j^+(\alpha^i)|\} \\ &= \sum_{\alpha^i \in J} I_j(\alpha^i) + \mathcal{O}(1)\sum_{l=1}^n \int_0^1 G(x)|q_l(x,t)|dx \quad \text{by (5.3)}.\end{aligned}$$

Let us set $I_j(\alpha^i) \equiv (\dot{x}(\alpha^i) - \lambda(q_j^-(\alpha^i)))|q_j^-(\alpha^i)| - (\dot{x}(\alpha^i) - \lambda(q_j^+(\alpha^i)))|q_j^+(\alpha^i)|$. Then, it follows from [24] that

$$I_j(\alpha^i) = \mathcal{O}(1)(\Gamma_s(\alpha^i) + \Gamma_d(\alpha^i)) + \mathcal{O}(1)|\alpha^i|e(\Lambda_p).$$

From (5.4), we get

$$\frac{d}{dt}\int_{-\infty}^{\infty}|q_j(x,t)|dx \le \mathcal{O}(1)\sum_{\beta\in J}(\Gamma_s+\Gamma_d)(\beta)+\mathcal{O}(1)(T.V+G_1)e(\Lambda_p)$$
$$+\,\mathcal{O}(1)\sum_{l=1}^{n}\int_0^1 G(x)|q_j(x,t)|dx.$$

Therefore, we have

$$\frac{dL(t)}{dt}\le \mathcal{O}(1)\Gamma+\mathcal{O}(1)(T.V+G_1)e(\Lambda_p).$$

Step 2. $\frac{dQ_d(t)}{dt}\le -\lambda_0\Gamma_d+\mathcal{O}(1)(T.V+G_1)\Gamma+\mathcal{O}(1)\left(\sum_\alpha G(x(\alpha))|\alpha|\right)L(t)$ $+\mathcal{O}(1)(T.V+G_1)e(\Lambda_p)$. By definition of $Q_d(t)$,

$$\text{(5.5)}\quad \frac{dQ_d(\alpha^i)}{dt}=|\alpha^i|\left\{\sum_{j>i}\frac{d}{dt}\int_{-\infty}^{x(\alpha^i)}|q_j(x,t)|dx+\sum_{j<i}\frac{d}{dt}\int_{x(\alpha^i)}^{\infty}|q_j(x,t)|dx\right\}$$
$$+\,\frac{d|\alpha^i|}{dt}\left\{\sum_{j>i}\int_{-\infty}^{x(\alpha^i)}|q_j(x,t)|dx+\sum_{j<i}\int_{x(\alpha^i)}^{\infty}|q_j(x,t)|dx\right\}$$
$$\le |\alpha^i|\left\{\sum_{j>i}\frac{d}{dt}\int_{-\infty}^{x(\alpha^i)}|q_j(x,t)|dx+\sum_{j<i}\frac{d}{dt}\int_{x(\alpha^i)}^{\infty}|q_j(x,t)|dx\right\}$$
$$+\,\mathcal{O}(1)G(x(\alpha^i))|\alpha^i|\sum_{j\ne i}L_j(t).$$

By the strict hyperbolicity of (1.1), for some positive constant λ_0,

$$\begin{aligned}&\lambda_j(u)-\lambda(\alpha^i)>\lambda_0,\quad j>i,\\&\lambda_j(u)-\lambda(\alpha^i)<-\lambda_0,\quad j<i.\end{aligned}$$

Then by the same calculation as in [24], from (5.5) we have the following estimate:

$$\frac{dQ_d(\alpha^i)}{dt}\le -\lambda_0\Gamma_d(\alpha^i)+\mathcal{O}(1)|\alpha^i|\Gamma+\mathcal{O}(1)|\alpha^i|(T.V+G_1)e(\Lambda_p)$$
$$+\,\mathcal{O}(1)G(x(\alpha))|\alpha^i|\sum_{j\ne i}L_j(t).$$

Hence, we have

$$\frac{dQ_d(t)}{dt}\le -\lambda_0\sum_{\beta\in J}\Gamma_d(\beta)+\mathcal{O}(1)(T.V+G_1)\Gamma+\mathcal{O}(1)(T.V+G_1)e(\Lambda_p)$$
$$+\,\mathcal{O}(1)\left(\sum_\alpha G(x(\alpha))|\alpha|\right)L(t).$$

Step 3. $\frac{dE(t)}{dt}\le -C_4\Gamma_s+\mathcal{O}(1)(T.V+G_1)\Gamma+\mathcal{O}(1)(T.V+G_1)e(\Lambda_p)$ $+\mathcal{O}(1)(\sum_\alpha G(x(\alpha))|\alpha|)L(t)$, where C_4 is a positive constant depending only on (1.1). By definition of $E(t)$,

$$\frac{dE(t)}{dt}=\sum_{\alpha^i\in J}\frac{d}{dt}\left[|\alpha^i|\left\{\int_{-\infty}^{x(\alpha^i)}(q_i(x,t))_-dx+\int_{x(\alpha^i)}^{\infty}(q_i(x,t))_+dx\right\}\right]$$

$$= \sum_{\alpha^i \in J} \frac{dE(\alpha^i)}{dt}.$$

Let us assume that $\alpha^i \in J(v)$, and u is continuous at $x = x(\alpha^i)$. The other case ($\alpha^i \in J(u)$) is treated similarly.

$$\begin{aligned}
\frac{dE(\alpha^i)}{dt} &= \frac{d|\alpha^i|}{dt}\left\{\int_{-\infty}^{x(\alpha^i)} (q_i(x,t))_- dx + \int_{x(\alpha^i)}^{\infty} (q_i(x,t))_+ dx\right\} \\
&\quad + |\alpha^i|\left\{\frac{d}{dt}\int_{-\infty}^{x(\alpha^i)} (q_i(x,t))_- dx + \frac{d}{dt}\int_{x(\alpha^i)}^{\infty} (q_i(x,t))_+ dx\right\} \\
&= \mathcal{O}(1)G(x(\alpha^i))|\alpha^i|\left\{\int_{-\infty}^{x(\alpha^i)} (q_i(x,t))_- dx + \int_{x(\alpha^i)}^{\infty} (q_i(x,t))_+ dx\right\} \\
&\quad + |\alpha^i|\left\{\frac{d}{dt}\int_{-\infty}^{x(\alpha^i)} (q_i(x,t))_- dx + \frac{d}{dt}\int_{x(\alpha^i)}^{\infty} (q_i(x,t))_+ dx\right\} \\
&\le \mathcal{O}(1)G(x(\alpha^i))|\alpha^i|L_i(t) \\
&\quad + |\alpha^i|\left\{\frac{d}{dt}\int_{-\infty}^{x(\alpha^i)} (q_i(x,t))_- dx + \frac{d}{dt}\int_{x(\alpha^i)}^{\infty} (q_i(x,t))_+ dx\right\},
\end{aligned}$$

where we have used the fact that $\frac{d|\alpha^i|}{dt} = \mathcal{O}(1)G(x(\alpha^i))|\alpha^i|$. By the same analysis as in Lemma 5.1 of [24], we have

$$\begin{aligned}
\frac{dE(\alpha^i)}{dt} &\le -C_4|\alpha^i|(|q^-(\alpha^i)| + |\alpha^i|)|q^-(\alpha^i)| + \mathcal{O}(1)(|\alpha^i|\Gamma(\alpha^i) + |\alpha^i|e(\Lambda_p)) \\
&\quad + \mathcal{O}(1)|\alpha^i|\left\{\sum_{\beta\in J}\Gamma(\beta) + (T.V + G_1)e(\Lambda_p) + \sum_{j=1}^{n}\int_0^1 G(x)|q_j(x,t)|dx\right\} \\
&\quad + \mathcal{O}(1)G(x(\alpha^i))|\alpha^i|L_i(t).
\end{aligned}$$

Hence, we have

$$\frac{dE(t)}{dt} \le -C_4\Gamma_s + \mathcal{O}(1)(T.V + G_1)\Gamma + \mathcal{O}(1)\left(\sum_{\alpha} G(x(\alpha))|\alpha|\right)L(t)$$

$$+\mathcal{O}(1)(T.V + G_1)e(\Lambda_p),$$

where C_4 is a positive constant depending only on (1.1).

Step 4. $\frac{dQ_{so}(t)}{dt} \le -\lambda_0\Gamma_{so} + \mathcal{O}(1)G_1\{\Gamma + (T.V + G_1)e(\Lambda_p)\}$.

By definition of $Q_{so}(t)$, we have

$$\begin{aligned}
Q_{so}(t) &= \sum_{j\le j_0}\int_{-\infty}^{\infty}|q_j(x,t)|\left(\int_{-\infty}^{x(q_j)} G(\xi)d\xi\right)dx \\
&\quad + \sum_{j\ge j_0+1}\int_{-\infty}^{\infty}|q_j(x,t)|\left(\int_{x(q_j)}^{\infty} G(\xi)d\xi\right)dx \\
&= \sum_{j\le j_0} I_j + \sum_{j\ge j_0+1} II_j.
\end{aligned}$$

For a given t, let us denote the locations of waves as follows:

$$\begin{aligned}-\infty < x(\alpha_1) < \cdots < x(\alpha_k) &= 0 < x(\alpha_{k+1}) < \cdots < x(\alpha_l)\\ &= 1 < x(\alpha_{l+1}) < \cdots < x(\alpha_m) < \infty.\end{aligned}$$

For notational convenience, let us denote $x(\alpha_0) \equiv -\infty$ and $x(\alpha_{m+1}) \equiv \infty$.

Case 1. $j \le j_0$.

Since $\int_{-\infty}^0 G(\xi)d\xi = 0$,

$$\begin{aligned}I_j &= \int_{-\infty}^{\infty} |q_j(x,t)| \left(\int_{-\infty}^{x(q_j)} G(\xi)d\xi\right) dx\\ &= \int_{x(\alpha_k)}^{x(\alpha_{k+1})} |q_j(x,t)| \left(\int_{-\infty}^{x(q_j)} G(\xi)d\xi\right) dx + \int_{x(\alpha_{k+1})}^{x(\alpha_{k+2})} |q_j(x,t)| \left(\int_{-\infty}^{x(q_j)} G(\xi)d\xi\right) dx\\ &+ \cdots + \int_{x(\alpha_{l-1})}^{x(\alpha_l)} |q_j(x,t)| \left(\int_{-\infty}^{x(q_j)} G(\xi)d\xi\right) dx + G_1 \int_{x(\alpha_l)}^{x(\alpha_{l+1})} |q_j(x,t)|dx\\ &+ \cdots + G_1 \int_{x(\alpha_{m-1})}^{x(\alpha_m)} |q_j(x,t)|dx.\end{aligned}$$

Then by a direct calculation, we have

$$\begin{aligned}\frac{dI_j}{dt} &\le \sum_{i=k}^{l-1} \left(\int_{-\infty}^{x(q_j(\alpha_i))} G(\xi)d\xi\right) \dot{x}(\alpha_i)(|q_j^-(\alpha_i)| - |q_j^+(\alpha_i)|)\\ &+ G_1 \sum_{i=l}^{m} \dot{x}(\alpha_i)(|q_j^-(\alpha_i)| - |q_j^+(\alpha_i)|) + \int_0^1 |q_j(x,t)|\dot{x}(q_j)G(x(q_j))dx\\ &\le \mathcal{O}(1)G_1 \left\{\sum_{i=k}^{m} (\Gamma_s + \Gamma_d)(\alpha_i) + \Gamma_{so} + (T.V + G_1)e(\Lambda_p)\right\} - \lambda_0 \int_0^1 G(x)|q_j(x,t)|dx.\end{aligned}$$

In the above calculation, we have used $\dot{x}(q_j) \le -\lambda_0$. Hence, we have

$$\begin{aligned}\frac{dI}{dt} = \sum_{j\le j_0} \frac{dI_j}{dt} &\le j_0 \mathcal{O}(1)G_1 \left\{\sum_{i=k}^{m} (\Gamma_s + \Gamma_d)(\alpha_i) + \Gamma_{so} + (T.V + G_1)e(\Lambda_p)\right\}\\ &- \lambda_0 \sum_{j\le j_0} \int_0^1 G(x)|q_j(x,t)|dx\\ &\le \mathcal{O}(1)G_1 \left\{\sum_{i=k}^{m} (\Gamma_s + \Gamma_d)(\alpha_i) + \Gamma_{so} + (T.V + G_1)e(\Lambda_p)\right\}\\ &- \lambda_0 \sum_{j\le j_0} \int_0^1 G(x)|q_j(x,t)|dx.\end{aligned}$$

Case 2. $j \ge j_0 + 1$. Since $\int_1^\infty G(\xi)d\xi = 0$,

$$\begin{aligned}II_j &= \int_{-\infty}^{\infty} |q_j(x,t)| \left(\int_{x(q_j)}^{\infty} G(\xi)d\xi\right) dx\\ &= G_1 \int_{x(\alpha_1)}^{x(\alpha_2)} |q_j(x,t)|dx + \cdots + G_1 \int_{x(\alpha_{k-1})}^{x(\alpha_k)} |q_j(x,t)|dx\end{aligned}$$

$$+\int_{x(\alpha_k)}^{x(\alpha_{k+1})} |q_j(x,t)| \left(\int_{x(q_j)}^{\infty} G(\xi)d\xi\right) dx + \cdots + \int_{x(\alpha_{l-1})}^{x(\alpha_l)} |q_j(x,t)| \left(\int_{x(q_j)}^{\infty} G(\xi)d\xi\right) dx.$$

Then by a direct calculation, we have

$$\begin{aligned}
&\frac{dII_j}{dt} = G_1 \sum_{i=1}^{k-1} \dot{x}(\alpha_i)(|q_j^-(\alpha_i)| - |q_j^+(\alpha_i)|) \\
&+ \sum_k^l \left(\int_{x(\alpha_i)}^{\infty} G(\xi)d\xi\right) \dot{x}(\alpha_i)(|q_j^-(\alpha_i)| - |q_j^+(\alpha_i)|) + \int_0^1 |q_j(x,t)|(-\dot{x}(q_j))G(x(q_j))dx \\
&\leq \mathcal{O}(1)G_1 \left\{\sum_{i=1}^l (\Gamma_s + \Gamma_d)(\alpha_i) + \Gamma_{so} + (T.V + G_1)e(\Lambda_p)\right\} - \lambda_0 \int_0^1 G(x)|q_j(x,t)|dx.
\end{aligned}$$

In the above calculations, we have used the fact that $\dot{x}(q_j) \geq \lambda_0$. Hence we have

$$\begin{aligned}
\frac{dII}{dt} \leq \sum_{j\geq j_0+1} \frac{dII_j}{dt} &= \mathcal{O}(1)G_1(n-j_0)\sum_1^l \{(\Gamma_s + \Gamma_d)(\alpha_i) + \Gamma_{so} \\
&+ (T.V + G_1)e(\Lambda_p)\} - \lambda_0 \sum_{j\geq j_0+1} \int_0^1 G(x)|q_j(x,t)|dx.
\end{aligned}$$

By combining Cases 1 and 2, we have

$$\frac{dQ_{so}(t)}{dt} \leq \mathcal{O}(1)G_1\{\Gamma + (T.V + G_1)e(\Lambda_p)\} - \lambda_0\Gamma_{so}.$$

Step 5. Let us choose $\tilde{c}$ such that $0 < \tilde{c} < \min\{\lambda_0, C_4\}$, where C_4 is the positive constant in Step 3. From definition of $H(t)$ and Steps 1–4, for $t \in I_p^2$, we have

$$\begin{aligned}
\frac{dL(t)}{dt} &\leq \mathcal{O}(1)\Gamma + \mathcal{O}(1)(T.V + G_1)e(\Lambda_p), \\
\frac{dQ_d(t)}{dt} &\leq -\tilde{c}\Gamma_d + \mathcal{O}(1)(T.V + G_1)\Gamma + \mathcal{O}(1)\left(\sum G(x(\alpha))|\alpha|\right)L(t) \\
&\quad + \mathcal{O}(1)(T.V + G_1)e(\Lambda_p), \\
\frac{dE(t)}{dt} &\leq -\tilde{c}\Gamma_s + \mathcal{O}(1)(T.V + G_1)\Gamma + \mathcal{O}(1)\left(\sum G(x(\alpha))|\alpha|\right)L(t) \\
&\quad + \mathcal{O}(1)(T.V + G_1)e(\Lambda_p), \\
\frac{dQ_{so}(t)}{dt} &\leq -\tilde{c}\Gamma_{so} + \mathcal{O}(1)G_1\Gamma + \mathcal{O}(1)G_1(T.V + G_1)e(\Lambda_p),
\end{aligned}$$

$$\begin{aligned}
\frac{dH(t)}{dt} &= (1 + K_1F((p-1)Ms))\frac{dL(t)}{dt} + K_2\left(\frac{dQ_d(t)}{dt} + \frac{dE(t)}{dt} + \frac{dQ_{so}(t)}{dt}\right) \\
&\leq [\mathcal{O}(1)\{1 + K_1F((p-1)Ms)\} + \mathcal{O}(1)K_2(T.V + G_1) + \mathcal{O}(1)K_2G_1 - \tilde{c}K_2]\Gamma \\
&+ [\mathcal{O}(1)(T.V + G_1)(1 + K_1F((p-1)Ms)) + \mathcal{O}(1)K_2(T.V + G_1) \\
&+ \mathcal{O}(1)K_2G_1(T.V + G_1)]e(\Lambda_p) + \mathcal{O}(1)K_2\left(\sum G(x(\alpha))|\alpha|\right)L(t).
\end{aligned} \tag{5.6}$$

Since $L(t)$ is Lipschitz continuous on $((p-1)Ms, pMs)$, we have

$$L(t) \leq \mathcal{O}(1)Ms + L(pMs-). \tag{5.7}$$

By definition of $H(t)$, there is a jump across the $t = pMs, p \in \{1, \dots, N\}$. Next, we estimate the size of this jump.

$$\begin{aligned} H(pMs+) - H(pMs-) = {} & [(1 + K_1 F(pMs))L(pMs+) \\ & + K_2(Q_d(pMs+) + E(pMs+) + Q_{so}(pMs+))] \\ & - [(1 + K_1 F((p-1)Ms)))L(pMs-) + K_2(Q_d(pMs-) \\ & + E(pMs-) + Q_{so}(pMs-))] = \sum_{i=1}^{5} I_i, \end{aligned}$$

where

$$\begin{aligned} I_1 &\equiv K_1(F(pMs) - F((p-1)Ms))L(pMs-), \\ I_2 &\equiv (1 + K_1 F(pMs))(L(pMs+) - L(pMs-)), \\ I_3 &\equiv K_2(Q_d(pMs+) - Q_d(pMs-)), \\ I_4 &\equiv K_2(E(pMs+) - E(pMs-)), \\ I_5 &\equiv K_2(Q_{so}(pMs+) - Q_{so}(pMs-)). \end{aligned}$$

By Lemma 3.2

$$F(pMs) - F((p-1)Ms) \leq -\frac{1}{2}\left(Q(\Lambda_p) + C(\Lambda_p)\right).$$

Therefore, we have

$$I_1 \leq -\frac{K_1}{2}\left(Q(\Lambda_p) + C(\Lambda_p)\right) L(pMs-). \tag{5.8}$$

On the other hand, the difference of a wave pattern at time $t = pNs+$ and $t = pMs-$ is due to interactions, cancellations, and errors by the scheme, so we have

$$L(pMs+) - L(pMs-) \leq \mathcal{O}(1)e(\Lambda_p)Ms.$$

Hence,

$$I_2 \leq \mathcal{O}(1)(1 + K_1 F(pMs))e(\Lambda_p)Ms. \tag{5.9}$$

By definition of $Q_d(t)$, I_3 can be estimated by considering the following two terms: one term is the product of change of the wave strengths and the L^1 norm at $t = pMs-$, and the other term is the product of change of the L_1 norm times the wave strengths. Therefore, we have

$$I_3 \leq C_5 K_2(T.V + G_1)e(\Lambda_p)Ms + C_5 K_2(Q(\Lambda_p) + C(\Lambda_p))L(pMs-). \tag{5.10}$$

By the same argument as above, we have

$$I_4 \leq C_5 K_2(T.V + G_1)e(\Lambda_p)Ms + C_5 K_2(Q(\Lambda_p) + C(\Lambda_k))L(pMs-). \tag{5.11}$$

Similarly, we have

$$Q_{so}(pMs+) - Q_{so}(pMs-) \leq \mathcal{O}(1)G_1 e(\Lambda_p)Ms,$$

i.e.,

$$I_5 \leq C_5 K_2 G_1 e(\Lambda_p)Ms. \tag{5.12}$$

Summing up all I_k's (5.8)–(5.12), we have

$$\begin{aligned}(5.13)\quad H(pMs+) - H(pMs-) &\leq \left(2C_5K_2 - \frac{K_1}{2}\right)(Q(\Lambda_p) + C(\Lambda_p))L(pMs-)\\ &+ [\mathcal{O}(1)(1+K_1F(pMs)) + \mathcal{O}(1)K_2(T.V + G_1) + \mathcal{O}(1)K_2G_1]\, e(\Lambda_p)Ms.\end{aligned}$$

If we integrate (5.6) from $(p-1)Ms$ to pMs, then by using (5.7) we have

$$\begin{aligned}(5.14)\qquad H(pMs-) - H((p-1)Ms+) &\leq [\mathcal{O}(1)(1+K_1F((p-1)Ms))\\ &+ \mathcal{O}(1)K_2(T.V + G_1) + \mathcal{O}(1)K_2G_1 - \tilde{c}K_2]\int \Gamma(t)dt\\ &+ [\mathcal{O}(1)(T.V + G_1)(1+K_1F((p-1)Ms)) + \mathcal{O}(1)K_2(T.V+G_1)\\ &+ \mathcal{O}(1)K_2G_1(T.V+G_1)]e(\Lambda_p)Ms + \mathcal{O}(1)K_2Q_1(\Lambda_p)Ms\\ &+ \mathcal{O}(1)K_2Q_1(\Lambda_p)L(pMs-),\end{aligned}$$

where the integral is over $((p-1)Ms, pMs)$, and we have used the fact that

$$\int \sum_{\alpha} G(x(\alpha))|\alpha| dt = \mathcal{O}(1)Q_1(\Lambda_p).$$

From (5.13) and (5.14), we have

$$\begin{aligned}H(pMs+) - H((p-1)Ms+) &\leq [\mathcal{O}(1)(1+K_1F((p-1)Ms))\\ &+ \mathcal{O}(1)K_2(T.V+G_1) + \mathcal{O}(1)K_2G_1 - \tilde{c}K_2]\int \Gamma(t)dt\\ &+ [\mathcal{O}(1)(T.V+G_1)(1+K_1F((p-1)Ms)) + \mathcal{O}(1)K_2(T.V+G_1)\\ &+ \mathcal{O}(1)K_2G_1(T.V+G_1) + \mathcal{O}(1)(1+K_1F(pMs+))\\ &+ \mathcal{O}(1)K_2G_1 + \mathcal{O}(1)K_2]e(\Lambda_p)Ms\\ &+ \left[2C_5K_2 + \mathcal{O}(1)K_2 - \frac{K_1}{2}\right](Q(\Lambda_p) + C(\Lambda_p))L(pMs-).\end{aligned}$$

Since $F(t), G_0, G_1$, and $T.V$ are sufficiently small, we can choose positive constants K_1 and K_2 so that

$$\begin{aligned}&\mathcal{O}(1)(1+K_1F((p-1)Ms)) + \mathcal{O}(1)K_2(T.V+G_1) + \mathcal{O}(1)K_2G_1 - \tilde{c}K_2 < 0,\\ &2C_5K_2 + \mathcal{O}(1)K_2 - \frac{K_1}{2} < 0.\end{aligned}$$

Then for such K_1 and K_2, we have

$$H(pMs+) \leq H((p-1)Ms+) + \mathcal{O}(1)e(\Lambda_p)Ms.$$

This completes the proof. □

Using Lemma 5.7 successively, we obtain the following estimate.

LEMMA 5.8. *Let $\bar{u}_r(x,t)$ and $\bar{v}_r(x,t)$ be two simplified wave patterns of* (1.1) *corresponding to initial data $u_0(x)$ and $v_0(x)$, respectively. If $u_0(x) - v_0(x) \in L^1(R)$, then we have*

$$H(T) \leq H(0) + \mathcal{O}(1)(Q(\Lambda_T) + C(\Lambda_T))Ms + \mathcal{O}(1)(\epsilon + \delta + MsG_0)T.$$

Proof. Let $\bar{u}_r(x,t)$ and $\bar{v}_r(x,t)$ be the simplified wave patterns and $T = NMs$. By Lemma 5.7, we have

$$H(NMs+) \leq H((N-1)Ms+) + \mathcal{O}(1)e(\Lambda_N)Ms.$$

If we use Lemma 5.7 successively in p, we obtain

$$H(T) \leq H(0) + \mathcal{O}(1)(Q(\Lambda_T) + C(\Lambda_T))Ms + \mathcal{O}(1)(\epsilon + \delta + MsG_0)T.$$

This completes the proof. □

Let us define the nonlinear functional $H(t) = H[u(\cdot,t), v(\cdot,t)]$ for two Glimm solutions $u(x,t)$ and $v(x,t)$ by

$$H[u(\cdot,t), v(\cdot,t)] = \lim_{r,\epsilon,\delta\to 0} H[\bar{u}_r(\cdot,t), \bar{v}_r(\cdot,t)],$$

where $\bar{u}_r(x,t)$ and $\bar{v}_r(x,t)$ are the simplified wave patterns of $u(x,t)$ and $v(x,t)$, respectively. Next, we establish L^1 stability as a direct consequence of the above lemma.

Theorem 5.9. *Let $u(x,t)$ and $v(x,t)$ be two weak solutions corresponding to initial data $u_0(x)$ and $v_0(x)$, respectively. If $u_0(x) - v_0(x) \in L^1(R)$, then we have*

$$H(t) \leq H(0),$$
$$\|u(\cdot,t) - v(\cdot,t)\|_{L^1(R)} \leq C\|u_0(\cdot) - v_0(\cdot)\|_{L^1(R)} \quad \textit{for } t \geq 0,$$

where C is independent of t.

Proof. (1) Let $\bar{u}_r(x,t)$ and $\bar{v}_r(x,t)$ be two simplified wave patterns of (1.1) such that

$$\lim_{r,\epsilon,\delta\to 0} \bar{u}_r(x,t) = u(x,t), \qquad \lim_{r,\epsilon,\delta\to 0} \bar{v}_r(x,t) = v(x,t) \quad \text{in } L^1_{loc}(R \times R_+).$$

Since $H[u(\cdot,t), v(\cdot,t)] = \lim_{r,\epsilon,\delta\to 0} H[\bar{u}_r, \bar{v}_r]$, it follows from Lemma 5.8 that

$$H(t) \leq H(0).$$

(2) Since $H[u(\cdot,t), v(\cdot,t)]$ is equivalent to $\|u(\cdot,t) - v(\cdot,t)\|_{L^1(R)}$ (see section 5.1), i.e.,

$$\frac{1}{C_3}\|u(\cdot,t) - v(\cdot,t)\|_{L^1(R)} \leq H(t) \leq 2C_3\|u(\cdot,t) - v(\cdot,t)\|_{L^1(R)}$$

for some positive constant C_3. Therefore, we have

$$\|u(\cdot,t) - v(\cdot,t)\|_{L^1(R)} \leq C_3 H(t) \leq C_3 H(0) \leq 2C_3^2\|u_0(x) - v_0(x)\|_{L^1(R)}.$$

Let us set $C = 2C_3^2$; then we have the desired result. □

Remark. As an immediate consequence of Theorem 5.9, we have the uniqueness of the Glimm solutions.

Acknowledgments. The author wishes to thank to Professor Tai-Ping Liu and Professor Tong Yang for helpful discussions.

A RESULT ON THE BLOW-UP RATE FOR THE ZAKHAROV SYSTEM IN DIMENSION 3[*]

VINCENT MASSELIN[†]

Abstract. We consider a blow-up solution (u, n, v) of the Zakharov system in $\mathbb{R}^3$:

$$\begin{cases} iu_t = -\Delta u + nu, \\ n_t = -\nabla \cdot v, \\ v_t = -\nabla(n + |u|^2). \end{cases}$$

If T is the finite blow-up time, we show the following integral estimate for n:

$$\int_0^T \left(\int_{\mathbb{R}^3} |n(x,t)|^q dx \right)^{\frac{\gamma}{q}} dt = +\infty,$$

where $\epsilon \in]0, \frac{1}{4}]$, $q = \frac{3}{2(1-\epsilon)} \in \left]\frac{3}{2}, 2\right]$, and $\gamma > \frac{1}{\epsilon}$. In particular, this implies that, for $a < 1$,

$$\sup_{t \in [O,T)} \left((T-t)^{a\epsilon} \left(\int_{\mathbb{R}^3} |n(x,t)|^q dx \right)^{\frac{1}{q}} \right) = +\infty.$$

1. Introduction.

In this paper, we consider the three-dimensional (3D) Zakharov system

$$\begin{cases} iu_t = -\Delta u + nu, \\ n_{tt} = \Delta n + \Delta |u|^2, \\ u(0) = u_0, \ n(0) = n_0, \ n_t(0) = n_1, \end{cases} \tag{1.1}$$

where $u : [0, T) \times \mathbb{R}^3 \to \mathbb{C}, n : [0, T) \times \mathbb{R}^3 \to \mathbb{R}$ and u_0, n_0, n_1 are initial data.

In fact, we consider the system (1.1) in the Hamiltonian case. That is, we assume that there is a $w_0 : \mathbb{R}^3 \to \mathbb{R}$ such that

$$n_t(0) = n_1 = -\Delta w_0.$$

Then, for all t, there is a $w(t)$ such that

$$n_t(t) = -\Delta w(t) = -\nabla \cdot v(t),$$

where $v(t) = \nabla w(t)$. In this case, (1.1) can be written in the form

$$\begin{cases} iu_t = -\Delta u + nu, \\ n_t = -\nabla \cdot v, \\ v_t = -\nabla(n + |u|^2), \\ u(0) = u_0, \ n(0) = n_0, \ v(0) = v_0. \end{cases} \tag{1.2}$$

The Cauchy problem for (1.1) or (1.2) has been studied in several papers. In [7], Ozawa and Tsutsumi proved that (1.1) is locally (in time) well-posed for initial data $(u_0, n_0, v_0) \in H^2 \times H^1 \times H^1$. With a method introduced by Bourgain for nonlinear dispersive equations, Bourgain and Colliander [1] and Ginibre, Tsutsumi, and Velo [3] have improved this result. The last authors have proved that (1.1) is locally (in time) well-posed for initial data $(u_0, n_0, n_1) \in H^k \times H^l \times H^{l-1}$ provided $l \geq 0$ and $2k - (l+1) \geq 0$; the solution satisfies

$$(u, n, n_t) \in \mathcal{C}\left([0,T), H^k \times H^l \times H^{l-1}\right).$$

Moreover, $\forall t \in [0,T)$,

$$\int_{\mathbb{R}^3} |u(x,t)|^2 dx = \int_{\mathbb{R}^3} |u_0(x)|^2 dx \tag{1.3}$$

and, if $k = 1$,

$$H(t) = H(0), \tag{1.4}$$

where

$$H(t) = \int_{\mathbb{R}^3} |\nabla u|^2 + n|u|^2 + \frac{1}{2}|v|^2 + \frac{1}{2}n^2 \, dx$$

is the Hamiltonian.

Here, we consider a blow-up solution of (1.2) in $\mathcal{C}([0,T), H_1)$, where $H_1 = H^1 \times L^2 \times L^2$: we assume that

$$\begin{cases} T < +\infty, \\ \lim\limits_{t \to T} |(u,n,v)(t)|_{H_1} = +\infty. \end{cases} \tag{1.5}$$

There is no general result for the existence of a blow-up solution but, in [6], Merle proved the following blow-up theorem:

Assume that for all time, $(u,n,v)(t)$ are radially symmetric functions. Moreover, assume that $H(0) < 0$. Then, $(u,n,v)(t)$ blows up. More precisely, we have the following alternatives:

(i) *$(u,n,v)(t)$ blows up in finite time;*

(ii) *$(u,n,v)(t)$ blows up in infinite time in H_1: $(u,n,v)(t)$ is defined for all t and* $\lim_{t \to +\infty} |(u,n,v)(t)|_{H_1} = +\infty$.

We will use the following notations. B is the ball $\{x \in \mathbb{R}^3;\ |x| < 1\}$. For $p \in [1, +\infty]$ and u a function of x or of (x,t), $|u|_p$ will be the L^p-norm in x on $\mathbb{R}^3$. We fix $\epsilon \in (0, \frac{1}{4}]$, $q = \frac{3}{2(1-\epsilon)} \in \left(\frac{3}{2}, 2\right]$ and $p \in [4,6)$ defined by the relation

$$\frac{2}{p} + \frac{1}{q} = 1. \tag{1.6}$$

In particular, if $\epsilon = \frac{1}{4}$, $q = 2$ and $p = 4$. C will represent any constant which depends on ϵ and $|(u_0, n_0, v_0)|_{H_1}$.

In this paper, we prove the following integral estimate on space and time for n.

THEOREM 1.1. *Let $(u,n,v) \in \mathcal{C}([0,T); H_1)$ be a blow-up solution of the Zakharov system* (1.2). *We assume that when $T < \infty$ that (u,n,v) blows up at time T. If $\gamma > \frac{1}{\epsilon}$, then*

$$\int_0^T \left(\int_{\mathbb{R}^3} |n(x,t)|^q dx \right)^{\frac{\gamma}{q}} dt = +\infty. \tag{1.7}$$

With this result, we can easily prove the following estimate.

THEOREM 1.2. *Let $(u,n,v) \in \mathcal{C}([0,T);H_1)$ be a blow-up solution of the Zakharov system* (1.2). *We assume that when $T<\infty$ that (u,n,v) blows up at time T. If $a<1$, then*

$$\sup_{t\in[0,T)} \Big((T-t)^{a\epsilon}|n(t)|_q\Big) = +\infty. \tag{1.8}$$

Assuming the radial symmetry for (u,n,v), we prove an estimate of n in $L^q(B)$ as follows.

THEOREM 1.3. *Let us assume that $(u,n,v) \in \mathcal{C}([0,T);H_1)$ is a radially symmetric solution of* (1.2). *We assume that when $T<\infty$ that (u,n,v) blows up at time T. If $a \in (0,\frac{1}{3})$, then*

$$\sup_{t\in[0,T)} \Big((T-t)^{a\epsilon}\,|n(t)|_{L^q(B)}\Big) = +\infty. \tag{1.9}$$

In [4], Landman et al. have worked out a numerical computation which suggests there is solution of (1.2) which blows up with the profile

$$\begin{cases} \tilde{u}(x,t) = \dfrac{2}{3(T-t)}P\Big(\dfrac{x}{\sqrt{3}(T-t)^{\frac{2}{3}}}\Big)e^{i(T-t)^{-\frac{1}{3}}}, \\ \tilde{n}(x,t) = \dfrac{1}{3(T-t)^{\frac{4}{3}}}N\Big(\dfrac{x}{\sqrt{3}(T-t)^{\frac{2}{3}}}\Big), \\ \tilde{v}(x,t) = \dfrac{2}{3}\dfrac{1}{(T-t)^{\frac{5}{3}}}w\Big(\dfrac{x}{\sqrt{3}(T-t)^{\frac{2}{3}}}\Big)\dfrac{x}{r}, \end{cases} \tag{1.10}$$

where (P,N,w) are radially symmetric and the solution of the system

$$\begin{cases} \Delta P = P + NP, \\ 5w + 2rw_r = -(P^2)_r, \\ 4w + 2rw_r = -(r^2N)_r \end{cases} \tag{1.11}$$

with $r=|x|$. This system is equivalent to

$$\begin{cases} \Delta P = P + NP, \\ \frac{1}{2}(2r^2N_{rr} + 13rN_r + 14N) = \Delta P^2. \end{cases} \tag{1.12}$$

In [5], we prove that there exist infinitely many radial and $\mathcal{C}^\infty$ solutions of (1.11), (1.12) such that P is positive decreasing and satisfying $\lim_{r\to+\infty} P(r) = 0$. Moreover, for such a solution

$$\lim_{r\to+\infty} 3r^2N(r) = -2P^2(0) \neq 0.$$

Then, when t tends to T, $|\tilde{n}(t)|_{L^q(B)}$ is equivalent to $(T-t)^{-\frac{4\epsilon}{3}}|N|_{L^q(\mathbb{R}^3)}$, and for all $\gamma > \frac{3}{4\epsilon}$

$$\int_0^T \Big(\int_{\mathbb{R}^3} |\tilde{n}(x,t)|^q dx\Big)^{\frac{\gamma}{q}} dt = +\infty.$$

Therefore, the result of Theorem 1.1 is not exactly optimal: we prove this for $\gamma > \frac{1}{\epsilon}$ instead of $\gamma > \frac{3}{4\epsilon}$. Moreover, we don't know if there exists $c>0$ such that $|n(t)|_{L^q(B)} \geq c(T-t)^{\frac{4}{3}\epsilon}$. We can prove only the following:

$$\lim_{t\to T} |n(t)|_{L^q(B)} = +\infty.$$

(See the end of the proof of Theorem 1.3.)

In the second part of this paper we prove the results. First, we recall some useful results. Then, we use the conservation of the Hamiltonian, the dispersion effect of the Schrödinger group $e^{it\Delta}$, and a Gronwall lemma to prove the space-time estimate (see Theorem 1.1). Finally, we prove Theorem 1.3.

2. Proofs of the theorems.

2.1. Some general results. First, let us state some inequalities with our notations, as follows.

LEMMA 2.1.

- *If* $\phi \in H^1(\mathbb{R}^3)$ *is radially symmetric, then* $\phi \in L^\infty(\mathbb{R}^3 \setminus B)$ *and*

$$|\phi|^2_{L^\infty(\mathbb{R}^3\setminus B)} \leq C|\nabla\phi|_2|\phi|_2. \tag{2.1}$$

- *If* Ω *is a domain in* $\mathbb{R}^3$ *and* $\phi \in H^1(\Omega)$, *then* $\phi \in L^p(\Omega)$ *and*

$$|\phi|_{L^p(\Omega)} \leq C|\nabla\phi|^{1-\epsilon}_{L^2(\Omega)}|\phi|^{\epsilon}_{L^2(\Omega)}, \tag{2.2}$$

in particular, $\phi \in L^4(\Omega)$ *and*

$$|\phi|_{L^4(\Omega)} \leq C|\nabla\phi|^{\frac{3}{4}}_{L^2(\Omega)}|\phi|^{\frac{1}{4}}_{L^2(\Omega}. \tag{2.3}$$

- *Let* $S(t) = e^{it\Delta}$ *and* $p' = \frac{p}{p-1}$. *There exists a constant* $C > 0$ *such that* $\forall\phi \in L^{p'}(\mathbb{R}^3)$ *and* $\forall t > 0$,

$$|S(t)\phi|_p \leq \frac{C}{t^{1-\epsilon}}|\phi|_{p'}. \tag{2.4}$$

For a blow-up solution, we have the following limits, which are more precise than (1.5).

LEMMA 2.2. *If* (u, n, v) *is a blow-up solution in* H_1 *and* T *is the finite blow-up time, then*

$$\lim_{t\to T}|u(t)|_4 = +\infty, \tag{2.5}$$

$$\lim_{t\to T}|\nabla u(t)|_2 = +\infty. \tag{2.6}$$

Proof. If (2.5) is false, then there is a sequence (t_k) and a constant c such that $\lim t_k = T$ and $\forall\ k$

$$|u(t_k)|_4 \leq c.$$

Then, according to the conservation of the Hamiltonian and Hölder inequalities,

$$\begin{aligned}\frac{1}{2}\int_{\mathbb{R}^3} n^2(x,t_k)dx &\leq H + \left|\int_{\mathbb{R}^3} n(x,t_k)|u|^2(x,t_k)dx\right| \\ &\leq H + |n(t_k)|_2|u(t_k)|_4^2.\end{aligned}$$

Therefore, $(|n(t_k)|_2)$ is bounded. Then, using again the conservation of H, we get

$$\int_{\mathbb{R}^3}|\nabla u(x,t_k)|^2dx + \frac{1}{2}\int_{\mathbb{R}^3} n^2(x,t_k) + |v(x,t_k)|^2dx \leq H + |n(t_k)|_2|u(t_k)|_4^2 \leq C,$$

which contradicts the blow-up assumption. □

Now (2.6) comes from the inequality (2.3) and the conservation of the L^2-norm.

We prove an integral inequality on $|u(t)|_p$ and $|n(t)|_q$ as follows.

LEMMA 2.3. *There exists a positive constant C such that $\forall t \in [0, T)$,*

$$|u(t)|_p \leq C\left(1 + \int_0^t \frac{1}{(t-s)^{1-\epsilon}} |n(s)|_q |u(s)|_p ds\right) \tag{2.7}$$

and, in particular,

$$|u(t)|_4 \leq C\left(1 + \int_0^t \frac{1}{(t-s)^{\frac{3}{4}}} |n(s)|_2 |u(s)|_4 ds\right). \tag{2.8}$$

Proof. We write the equation $iu_t = -\Delta u + nu$ on the integral form:

$$u(t) = S(t)u_0 - i\int_0^t S(t-s)n(s)u(s)ds.$$

Then, according to the Minkowski inequality,

$$|u(t)|_p \leq |S(t)u_0|_p + \int_0^t |S(t-s)n(s)u(s)|_p ds.$$

On the one hand, by (2.4), we have

$$|S(t-s)n(s)u(s)|_p \leq \frac{c}{(t-s)^{1-\epsilon}} |n(s)u(s)|_{p'}.$$

But, $1/p + 1/q = 1 - 1/p = 1/p'$, so according to the Hölder inequality,

$$|n(s)u(s)|_{p'} \leq |n(s)|_q |u(s)|_p$$

and

$$|S(t-s)n(s)u(s)|_p \leq \frac{1}{(t-s)^{1-\epsilon}} |n(s)|_q |u(s)|_p.$$

On the other hand, according to (2.2),

$$\begin{aligned} |S(t)u_0|_p &\leq c|S(t)u_0|_2^{\epsilon} |\nabla(S(t)u_0)|_2^{1-\epsilon} \\ &\leq c|u_0|_2^{\epsilon} |\nabla u_0|_2^{1-\epsilon} \end{aligned}$$

and (2.7) comes. In the particular case $\epsilon = 1/4,\ p = 4,\ q = 2$, we obtain (2.8). □

2.2. Proof of the integral estimate. By contradiction, let us assume there exists $\gamma_0 > \frac{1}{\epsilon}$ such that

$$\int_0^T \left(\int_{\mathbb{R}^3} |n(x,t)|^q dx\right)^{\frac{\gamma_0}{q}} dt < +\infty. \tag{2.9}$$

By Lemma 2.3, we have

$$|u(t)|_p \leq C\left(1 + \int_0^t \frac{1}{(t-s)^{1-\epsilon}} |n(s)|_q |u(s)|_p ds\right),$$

where $1-\epsilon+\frac{1}{\gamma}<1$ and $|n(s)|_q \in L^{\gamma}(0,T)$. Therefore, a Gronwall lemma (see, for example, [2, Lemma 8.1.1]) implies that there exists a constant $c>0$ such that $\forall\, t \in [0,T)$,

$$|u(t)|_p \leq C. \tag{2.10}$$

Now we display two cases. At first, if $\epsilon = \frac{1}{4}$, then $p=4$ and (2.10) contradicts Lemma 2.2. Also, we have shown that $\forall \gamma > 4$,

$$\int_0^T \left(\int_{\mathbb{R}^3} |n(x,t)|^2 dx \right)^{\frac{\gamma}{2}} dt = +\infty. \tag{2.11}$$

Now we return to the general case. By the conservation of the Hamiltonian,

$$\frac{1}{2}|n(t)|_2^2 \leq H + \left| \int_{\mathbb{R}^3} n(x,t)|u(x,t)|^2 dx \right|.$$

But $\frac{1}{q}+\frac{1}{p/2}=1$, so, by the Hölder inequality,

$$\begin{aligned} \frac{1}{2}|n(t)|_2^2 &\leq H + |n(t)|_q |u(t)|_p^2 \\ &\leq H + C|n(t)|_q. \end{aligned}$$

Therefore,

$$\int_0^T \left(\int_{\mathbb{R}^3} |n(x,t)|^2 dx \right)^{\frac{2\gamma_0}{2}} dt < +\infty$$

with $2\gamma_0 > \frac{2}{\epsilon} \geq 8$. So this contradicts the previous case $\epsilon = \frac{1}{4}$ and concludes the proof of the space-time estimate.

2.3. The radial case. We consider $a \in (0, \frac{1}{3})$ and we assume that (u,n,v) is a radially symmetric blow-up solution such that $\forall\, t$, $(u,n,v)(t) \in H^1 \times L^2 \times L^2$ and

$$|n(t)|_{L^q(B)} \leq \frac{c}{(T-t)^{a\epsilon}}. \tag{2.12}$$

First, we show the following estimate of $n(t)$ in L^2:

$$|n(t)|_2 \leq \frac{C}{(T-t)^{\frac{3a}{4}}}. \tag{2.13}$$

According to the conservation of the Hamiltonian, we have

$$\begin{aligned} \int_{\mathbb{R}^3} |\nabla u(x,t)|^2 dx + \frac{1}{2}\int_{\mathbb{R}^3} n(x,t)^2 dx \leq H &+ \left| \int_B n(x,t)|u(x,t)|^2 dx \right| \\ &+ \left| \int_{\mathbb{R}^3 \setminus B} n(x,t)|u(x,t)|^2 dx \right|, \end{aligned}$$

but $\frac{1}{q}+\frac{1}{p/2}=1$, so by the Hölder inequality, (2.2), and (2.12),

$$\begin{aligned} \left| \int_B n(x,t)|u(x,t)|^2 dx \right| &\leq \left(\int_B |n(x,t)|^q dx \right)^{\frac{1}{q}} \left(\int_B |u(x,t)|^p dx \right)^{\frac{2}{p}} \\ &\leq C \frac{1}{(T-t)^{a\epsilon}} \left| \nabla u(t) \right|_2^{2(1-\epsilon)}. \end{aligned}$$

On the other hand,

$$\begin{aligned}\left|\int_{\mathbb{R}^3\setminus B} n(x,t)|u(x,t)|^2dx\right| &\leq \frac{1}{2}\int_{\mathbb{R}^3\setminus B} n(x,t)^2dx + \frac{1}{2}\int_{\mathbb{R}^3\setminus B} |u(x,t)|^4dx\\ &\leq \frac{1}{2}\int_{\mathbb{R}^3\setminus B} n(x,t)^2dx + \frac{1}{2}|u(t)|^2_{L^\infty(\mathbb{R}^3\setminus B)}|u(t)|_2^2\\ &\leq \frac{1}{2}\int_{\mathbb{R}^3\setminus B} n(x,t)^2dx + C|\nabla u(t)|_2\end{aligned}$$

by the inequality (2.1). Then

$$\left(\int_{\mathbb{R}^3} |\nabla u(x,t)|^2dx\right)^{\epsilon} \leq H + \left(\int_{\mathbb{R}^3} |\nabla u(x,t)|^2dx\right)^{\epsilon-1} + \frac{c}{(T-t)^{a\epsilon}}.$$

However, by Lemma 2.2 (see (2.6)), $\lim \left(\int |\nabla u|^2\right)^{\epsilon-1} = 0$, so

$$\int_{\mathbb{R}^3} |\nabla u(x,t)|^2dx \leq \frac{c}{(T-t)^{\frac{a}{2}}}.$$

Then, by (2.3), we get

$$|u(t)|_4 \leq \frac{C}{(T-t)^{\frac{3a}{8}}}.$$

By the conservation of the Hamiltonian,

$$\frac{1}{2}\int_{\mathbb{R}^3} n^2(x,t)dx \leq H + |n(t)|_2|u(t)|_4^2$$

and (2.13) follows. Then, for $\gamma \in]4, \frac{4}{3a}[$ $(a < \frac{1}{3})$,

$$\int_0^T |n(t)|_2^\gamma dt < +\infty,$$

which contradicts Theorem 1.2 and concludes the proof. To show that $|n(t)|_{L^q(B)} \to +\infty$ as $t \to T$, we use the same method: if there exists $t_k \to T$ such that $|n(t_k)|_{L^q(B)} \leq c$, then we prove as above that $\int_{\mathbb{R}^3} |\nabla u(x,t_k)|^2dx \leq c$.

Acknowledgment. The author is grateful to Frank Merle for his direction and help during the preparation of this work.

THE STABILITY OF SUBDIVISION OPERATOR AT ITS FIXED POINT*

VLADIMIR PROTASOV†

Abstract. We consider the univariate two-scale refinement equation $\varphi(x) = \Sigma_{k=0}^{N} c_k \varphi(2x-k)$, where $c_0, \dots, c_N$ are complex values and $\Sigma c_k = 2$.

This paper analyzes the correlation between the existence of smooth compactly supported solutions of this equation and the convergence of the corresponding cascade algorithm/subdivision scheme. We introduce a criterion that expresses this correlation in terms of the mask of the equation. We show that the convergence of the subdivision scheme depends on values that the mask takes at the points of its *generalized cycles.* This means in particular that the stability of shifts of refinable function is not necessary for the convergence of the subdivision process. This also leads to some results on the degree of convergence of subdivision processes and on factorizations of refinable functions.

1. Introduction.

Refinement equations have been studied by many authors in great detail in connection with their role in the study of wavelets and of subdivision schemes in approximation theory and the design of curves and surfaces. In this paper we study the correlation between the existence of smooth solutions of refinement equations and the convergence of the corresponding subdivision schemes. We restrict ourselves to univariate equations having compactly supported mask. We obtain a criterion for the convergence of subdivision process under the condition that the associated refinement equation has a smooth solution.

Throughout the paper we denote by $\mathbb{T} = \mathbb{R}/2\pi\mathbb{Z}$ the unit circle, by $\mathcal{H}$ the space of entire functions on $\mathbb{C}$, by $\mathcal{C}^l$ the space of l times continuously differentiable functions on $\mathbb{R}$, by $\mathcal{C}^0 = \mathcal{C}$ the space of continuous functions, by $\mathcal{C}_0^l$ the space of compactly supported functions from $\mathcal{C}^l$, and by $\mathcal{C}_0$ the space of compactly supported continuous functions on $\mathbb{R}$. A sequence $\{f_k\}$ converges to zero in $\mathcal{C}_0^l$ if it converges to zero in $\mathcal{C}^l$ and the supports of $f_k,\ k \in \mathbb{N}$ are uniformly bounded.

Consider a refinement equation

$$\varphi(x) = \sum_{k=0}^{N} c_k \varphi(2x-k), \tag{1.1}$$

where $c_k \in \mathbb{C}$, $\sum_k c_k = 2$. It is well known that a $\mathcal{C}_0$-solution of this equation (*refinable function*), if it exists at all, is unique up to normalization, has its support on the

segment $[0, N]$, and can be represented in the frequency domain by the formula

$$\widehat{\varphi}(\xi) = \widehat{\varphi}(0) \prod_{r=1}^{\infty} m\left(\frac{\xi}{2^r}\right), \tag{1.2}$$

where $m(\xi) = \frac{1}{2}\sum_{k=0}^{N} c_k e^{-ik\xi}$ is the *mask* of (1.1) (as usually we denote $\hat{f}(\xi) = \int f(x)e^{-i\xi x}dx$). For a given mask $a(\xi)$ let us denote by $[a]$ the corresponding refinement equation. Let us also define the subspaces of the space $\mathcal{C}_0$ as

$$\mathcal{M}^l = \{f \in \mathcal{C}_0 \mid \widehat{f}(\xi)(1 - e^{-i\xi})^{-l-1} \in \mathcal{H}\}, \quad l \geq 0, \tag{1.3}$$

and the subspaces of $\mathcal{C}_0^l$ as

$$\mathcal{L}^l = \{f \in \mathcal{C}_0^l \mid \widehat{f^{(l)}} \in \mathcal{M}^l\}, \quad l \geq 0.$$

In other words the Fourier transform of a function from M^l has zeros of order $\geq l+1$ at all the points $2\pi k,\ k \in \mathbb{Z}$. The Fourier transform of a function from $\mathcal{L}^l$ has zero at the point $\xi = 0$ and has zeros of order $\geq l+1$ at all the points $2\pi k,\ k \in \mathbb{Z} \setminus \{0\}$.

Let us also denote $\mathcal{L} = \mathcal{L}^0 = \mathcal{M}^0$. By Poisson summation formula we have

$$f \in \mathcal{L} \ \Leftrightarrow\ f \in \mathcal{C}_0,\ \sum_k f(x-k) \equiv 0.$$

The *cascade algorithm* for refinement equations was introduced in [D]. A single iteration of that algorithm is $f_n = Tf_{n-1}$, where f_0 is an initial function from $\mathcal{C}_0$ and $Tf(x) = \sum_k c_k f(2x-k)$ is the *subdivision operator* associated to (1.1). This operator is defined on the space $\mathcal{C}_0$ and has the form

$$\widehat{Tf}(\xi) = m(\xi/2)\widehat{f}(\xi/2) \tag{1.4}$$

in the frequency domain. If f_n converges in the space $\mathcal{C}^l$ to a function $\varphi \in \mathcal{C}_0^l$ $(l \geq 0)$, then obviously it converges in $\mathcal{C}_0^l$ and φ is the solution of (1.1). Moreover, in that case the function $g = f_0 - \varphi$ necessarily belongs to $\mathcal{L}^l$ (see [CDM], [Du1]). The cascade algorithm *converges in* $\mathcal{C}^l$ if $T^n g \to 0,\ n \to \infty$ for any $g \in \mathcal{L}^l$. Properties of the cascade algorithms have been studied by many authors in various contexts. This algorithm gives a simple way for approximation of refinable functions. In particular, this was put to good use in the study of wavelets [D],[DL1], [Du2]. On the other hand, the convergence of the cascade algorithm is equivalent to the convergence of the corresponding *subdivision scheme* (see [RS] for many references). For a given mask $m(\xi)$, we say that the *subdivision process* $\{m\}$ *converges in* $\mathcal{C}^l$ if the corresponding cascade algorithm or the corresponding subdivision scheme converges in that space.

It is clear that the convergence of the subdivision process in $\mathcal{C}^l$ implies that the corresponding refinement equation has a $\mathcal{C}_0^l$-solution. In general, the converse is not true. (See [DL2] and [CDM] for many examples. See also [CH], [W], [RS] for general discussions of this aspect.) In this paper we analyze the correlation between the existence of smooth solutions of refinement equations and the convergence of the corresponding subdivision process. In other words, we study stability of the subdivision operator at its fixed point. Let us first formulate several previously known results on this problem.

2. Preliminary results. Necessary conditions for the convergence of subdivision processes were first introduced in the work [DGL2].

If a subdivision process $\{m\}$ converges in $\mathcal{C}^l$, then its mask can be factored as

$$m(\xi) = \left(\frac{1+e^{-i\xi}}{2}\right)^{l+1} a(\xi) \tag{2.1}$$

for some trigonometric polynomial $a(\xi)$. In particular, the condition

$$m(\xi) = \left(\frac{1+e^{-i\xi}}{2}\right) a(\xi) \tag{2.2}$$

is necessary for the convergence of the subdivision process in $\mathcal{C}$ [DGL2].

For a given mask m denote by $\mathbf{l}(m)$ the maximal integer l such that condition (2.1) is satisfied. So if a subdivision process $\{m\}$ converges in $\mathcal{C}^k$, then $k \le \mathbf{l}(m)$. Let us remark that condition (2.1) is not necessary for the existence of $\mathcal{C}_0^l$-solutions of the refinement equation [DL2], [P2].

Sufficient conditions for the convergence of the subdivision process in the space $\mathcal{C}$ (i.e., in the case $l = 0$) were introduced in [CDM].

If a refinement equation $[m]$ has a $\mathcal{C}_0$-solution and that solution is stable in the space $L^\infty(\mathbb{R})$ (i.e., its integer translates possess Riesz basis property in that space), then the subdivision process $\{m\}$ converges in $\mathcal{C}$ [CDM].

This condition is simplified by the criterion of stability of refinable functions proved in [JW] and [Z] and introduced independently in [He1]. To formulate it we need some notation. Let $p(\xi)$ be a trigonometric polynomial. If for some $\alpha \in \mathbb{T}$ we have $p(\alpha/2) = p(\pi + \alpha/2) = 0$, then the pair $\{\alpha/2, \pi + \alpha/2\}$ is a *pair of symmetric roots* for $p(\xi)$. In order to be defined, we set that for any $\alpha \in \mathbb{T}$ the value $\alpha/2 \in \mathbb{T}$ has the corresponding real value from the half-interval $[0, \pi)$. Further, a given set $\mathbf{b} = \{\beta_1, \dots, \beta_n\} \subset \mathbb{T}$, where $n \ge 2$, is called a *cycle* of the polynomial $p(\xi)$ if $2\beta_j = \beta_{j+1}$ for $j = 1, \dots, n$ (we set $\beta_{n+1} = \beta_1$) and $p(\beta_j + \pi) = 0$ for all $j = 1, \dots, n$. We consider only irreducible cycles, i.e., we suppose everywhere that all elements of a cycle are different. Now let us remember the criterion of stability of refinable functions.

The $\mathcal{C}_0$-solution of a refinement equation is stable in L^∞ if and only if its mask has neither symmetric roots nor cycles [JW], [Z], [He1].

Those two results can be summarized in the following theorem.

Theorem 2.1 (see [CDM],[JW],[Z],[He1]). *Suppose a mask m satisfying* (2.2) *has neither symmetric roots nor cycles; if the equation $[m]$ has a $\mathcal{C}_0$-solution, then the process $\{m\}$ converges in $\mathcal{C}$.*

Remark 1. The statement of Theorem 2.1 can also be formulated in terms of *Cohen's criterion* (see [D]). Namely, it was shown in [V, Proposition 2.4] that a mask satisfies Cohen's criterion if and only if it has neither symmetric roots nor cycles.

3. Statement of the fundamental theorems. In this paper we give a criterion of stability of subdivision operator at its fixed point (Theorem 3.1). We will see that symmetric roots of mask do not influence the convergence of subdivision process (Corollary 3). This means in particular that the stability of solutions is not necessary for the convergence of the subdivision process. The convergence depends on values of the mask at the points of cycles.

To formulate the criterion we need some further notation. Everywhere below we consider trigonometric polynomials without positive powers, i.e., polynomials of the form $p(\xi) = \sum_{k=0}^{N} a_k e^{-ik\xi}$. As usual we set deg $p = N$ (assuming $a_N \neq 0$).

To an arbitrary trigonometric polynomial p we associate a polynomial $R[p]$ as follows: suppose $r(\xi)$ is the polynomial of smallest degree such that the function $\frac{p(\xi)r(\xi)}{r(2\xi)}$ is a polynomial without symmetric roots; then we set $R[p](\xi) = \frac{p(\xi)r(\xi)}{r(2\xi)}$. The reader will have no difficulty in showing that the mapping $p \mapsto R[p]$ is well defined. For given p, the polynomial $R[p]$ can by easily found algorithmically. If p has no symmetric roots, then $R[p] = p$. If $\{\alpha/2, \pi + \alpha/2\}$ is a pair of symmetric roots of p, then we pass from $p(\xi)$ to the polynomial $p_\alpha(\xi) = \frac{p(\xi)(1-e^{i(\alpha-\xi)})}{1-e^{i(\alpha-2\xi)}}$. After several steps we obtain a polynomial $\tilde{p}(\xi)$ that has no symmetric roots. In general, there exist several different ways to realize each step of this algorithm: if there exist several pairs of symmetric roots, we can choose any of them to pass to the next polynomial. Nevertheless, *the result (i.e., the polynomial $\tilde{p}(\xi)$) does not depend on that choice and coincides with the polynomial $R[p]$*. The proof of this fact is left to the reader.

For any trigonometric polynomial p and any finite subset $Y = \{\alpha_1, \dots, \alpha_n\} \subset \mathbb{T}$, we denote $\rho_p(Y) = (\prod_{q=1}^{n} |p(\alpha_q)|)^{1/n}$. If the set Y is cyclic (i.e, $\alpha_{q+1} = 2\alpha_q$, $q = 1, \dots, n$, where $\alpha_{n+1} = \alpha_1$), then $\rho_p(Y) = \rho_{R[p]}(Y)$. (The proof is trivial.)

Now let us formulate the criterion of stability of subdivision process.

THEOREM 3.1. *Suppose a refinement equation $[m]$ has a $\mathcal{C}_0^l$-solution $l \geq 0$; then the process $\{m\}$ converges in $\mathcal{C}^l$ if and only if the mask m satisfies* (2.1) *and for any cycle $\mathbf{b}$ of the polynomial $R[m]$ we have $\rho_m(\mathbf{b}) < 2^{-l}$.*

The simplest corollary of this theorem is the following generalization of Theorem 2.1 from the case $l = 0$ to an arbitrary integer factor $l \geq 0$.

COROLLARY 1. *Suppose a mask m satisfying* (2.1) *has neither symmetric roots nor cycles; if the equation $[m]$ has a $\mathcal{C}_0^l$-solution, then the process $\{m\}$ converges in $\mathcal{C}^l$.*

Another problem is to explore the degree of convergence of the subdivision processes. For a given integer $l \geq 0$, a mask m, and a function $f \in \mathcal{L}^l$ denote

$$\nu_l(m, f) = -\lim_{n\to\infty} \frac{\log_2 \|T^n[f^{(l)}]\|_{\mathcal{C}}}{n},$$

where T is the subdivision operator associated to m. (We set $\log_2 0 = -\infty$.) Also for a subspace $\mathcal{V} \subset \mathcal{L}^l$ we denote $\nu_l(m, \mathcal{V}) = \inf_{f\in\mathcal{V}} \nu_l(m, f)$. The value $\nu_l(m) = \nu_l(m, \mathcal{L}^l)$ is the *degree of convergence of the process $\{m\}$ in the space $\mathcal{C}^l$*.

For any mask m we have $\nu_l(m) \leq l + 1$ (see [DL1]). Furthermore, it was shown in [DL1] and [HC] that a process $\{m\}$ converges in $\mathcal{C}^l$ if and only if $\nu_l(m) > l$. In particular, the inequality $\nu_0(m) > 0$ means that $\{m\}$ converges in $\mathcal{C}$. Let L be the maximal integer such that $\{m\}$ converges in $\mathcal{C}^L$. (If the process $\{m\}$ does not converge in $\mathcal{C}$, then we set $L = 0$.) The values $\nu_l(m)$, $l = 0, 1, \dots$ are connected as follows:

$$\nu_l(m) = l + 1 \quad \text{for} \quad l < L; \quad \nu_l(m) = \nu_L(m) \quad \text{for} \quad l \geq L. \tag{3.1}$$

The proof can be found in [DL2]. The value $\nu_L(m)$ is said to be the *degree of convergence of the process* $\{m\}$ and is denoted in what follows by $\nu(m)$. Thus, if $\nu(m_1) = \nu(m_2)$, then $\nu_l(m_1) = \nu_l(m_2)$ for any $l \geq 0$.

The degree of convergence of subdivision processes in various functional spaces was studied in [CDM], [W], [Du1], [Du2], [R3], [RS]. The following theorem reduces this problem (in the space $\mathcal{C}^l$) from general refinement equations to the case of refinement equations having stable solutions.

THEOREM 3.2. *For a given mask m satisfying* (2.1) *for some integer $l \geq 0$ denote $m_1(\xi) = R[m](\xi)/\prod_{k=1}^{q}\prod_{\beta\in\mathbf{b}_k}(1 + e^{i(\beta-\xi)})$, where $\{\mathbf{b}_1, \dots, \mathbf{b}_q\}$ is the set of cycles* *of the polynomial $R[m]$ (counting with multiplicity). Then we have the following: the equation $[m]$ has a $\mathcal{C}_0^l$-solution if and only if $[m_1]$ does; furthermore,*

$$\nu_l(m) = \min\{\nu_l(m_1), -\log_2 \rho_m(\mathbf{b}_1), \ldots, -\log_2 \rho_m(\mathbf{b}_q)\}.$$

COROLLARY 2. *Under the conditions of Theorem* 3.2 *we have*

$$\nu_k(m) = \min\{\nu_k(m_1), -\log_2 \rho_m(\mathbf{b}_1), \ldots, -\log_2 \rho_m(\mathbf{b}_q)\} \qquad \text{for any } k \le l.$$

Moreover, if $\mathbf{l}(m) = \mathbf{l}(m_1)$, *then*

$$\nu(m) = \min\{\nu(m_1), -\log_2 \rho_m(\mathbf{b}_1), \ldots, -\log_2 \rho_m(\mathbf{b}_q)\}.$$

Remark 2. Since the mask m_1 has neither symmetric roots nor cycles, it follows that the $\mathcal{C}_0^l$-solution of the equation $[m_1]$ is stable. Some previously known results on subdivision processes deal with the stable case (see, for instance, [CDM]). Theorem 3.2 makes it possible to extend those results to the case of general refinement equations.

COROLLARY 3. *For an arbitrary mask m satisfying* (2.1) *we have*

$$\nu_l(m) = \nu_l(R[m]).$$

Moreover, in the case $\mathbf{l}(m) = \mathbf{l}(R[m])$ *we have* $\nu(m) = \nu(R[m])$.

To prove this, it is sufficient to apply Theorem 3.2 to the masks m and $R[m]$ and note that $\rho_m(\mathbf{b}_i) = \rho_{R[m]}(\mathbf{b}_i)$.

Thus symmetric roots of the mask do not have influence on the degree of convergence of the subdivision process. So the sufficient conditions from Corollary 1 are not necessary for the convergence.

Remark 3. It can easily be shown that $\mathbf{l}(m) \le \mathbf{l}(R[m])$ for any mask m. There are masks such that $\mathbf{l}(m) < \mathbf{l}(R[m])$ and, moreover, $\nu(m) < \nu(R[m])$. That is why the condition $\mathbf{l}(m) = \mathbf{l}(R[m])$ is essential in the statement of Corollary 3 (see [P2]).

Remark 4. (The degree of convergence in various subspaces of $\mathcal{C}_0$). Consider the family of embedded subspaces $\{\mathcal{M}^l\}$ defined from (1.3). It was shown in [DL2],[Du1] that $f \in \mathcal{M}^l$ whenever $\nu_0(m, f) > l$. So the subspaces $\{\mathcal{M}^l\}$ can be considered as spaces of fast convergence of the subdivision processes. Moreover, if $\nu_0(m, \mathcal{M}^l) > l$, then the mask m satisfies (2.1) and hence all the subspaces $\mathcal{M}^k,\ k = 0, \cdots, l$, are invariant with respect to the corresponding subdivision operator. So it is natural to restrict a subdivision operator to suitable subspace $\mathcal{M}^l$ and consider the value $\nu_0(m, \mathcal{M}^l)$ instead of $\nu_l(m)$ (see, for instance, [CDM], [Du1], [Du2]). Theorems 3.1 and 3.2 of this paper can be reformulated in those terms without any change.

Theorems 3.1 and 3.2 will be proved in the next section. Then, in section 5, we introduce the notion of *generalized cycles* and establish a correlation between zeros of mask m and cycles of the polynomial $R[m]$. As a corollary we shall formulate the criterion of Theorem 3.1 in terms of zeros of the mask m (without the transfer to the polynomial $R[m]$).

4. Proof of the main results. To prove Theorems 3.1 and 3.2 let us first consider the case $l = 0$. The proof will be split into several lemmas and propositions.

For a finite family of real values $\Delta = \{\delta_1, \ldots, \delta_n\}$ (that may coincide), let

$$\mathcal{C}_0\{\Delta\} = \mathcal{C}_0\{\delta_1, \ldots, \delta_n\} = \left\{ f \in \mathcal{C}_0 \mid \widehat{f}(\xi) / \prod_{q=1}^{n} (1 - e^{i(\delta_q - \xi)}) \in \mathcal{H} \right\}.$$

It is clear that $\mathcal{M}^l = \mathcal{C}_0\{0, \cdots, 0\}$ ($l+1$ zeros). From the Poisson summation formula it follows that for any $f \in \mathcal{C}_0\{\Delta\}$ we have

$$\sum_{k\in\mathbb{Z}} e^{ik\delta_q} f(x-k) = 0, \quad q = 1, \dots, n. \tag{4.1}$$

Let us also denote

$$\mathcal{L}_\Delta = \mathcal{C}_0\{0, \Delta\} = \mathcal{C}_0\{0, \delta_1, \dots, \delta_n\} \text{ and } \mathcal{L}_\Delta[0, N] = \{f \in \mathcal{L}_\Delta \mid \operatorname{supp} f \in [0, N]\}.$$

For given $\delta \in \mathbb{R}$, consider the difference operator S_δ acting from the space $\mathcal{C}_0\{\Delta\}$ into the space $\mathcal{C}_0\{\Delta, \delta\} = \mathcal{C}_0\{\delta_1, \dots, \delta_n, \delta\}$ and defined by the formula $S_\delta \psi(x) = \psi(x) - e^{i\delta}\psi(x-1)$.

Lemma 4.1. *For any $\delta \in \mathbb{R}$ the operator S_δ is a homeomorphism of the spaces $\mathcal{C}_0\{\Delta\}$ and $\mathcal{C}_0\{\Delta, \delta\}$.*

Proof. For arbitrary $\varphi \in \mathcal{C}_0\{\Delta, \delta\}$ denote $\psi(x) = S_\delta^{-1}\varphi(x) = \sum_{k=0}^{+\infty} e^{ik\delta}\varphi(x-k)$. If $\operatorname{supp}\varphi \subset [a, b]$ for some integers a, b, then by (4.1) we have $\operatorname{supp}\psi \subset [a, b-1]$. Thus, $\psi \in \mathcal{C}_0$. It now follows that $\psi \in \mathcal{C}_0\{\Delta\}$. It remains to note that $S_\delta\psi = \varphi$ and the operators S_δ and S_δ^{-1} are obviously continuous. □

The following proposition is the first step in the proof of Theorems 3.1 and 3.2.

Proposition 1. *Suppose a mask $m(\xi)$ satisfying* (2.2) *possesses a pair of symmetric roots $\alpha/2$ and $\pi + \alpha/2$. Let $m_\alpha(\xi) = \frac{m(\xi)(1-e^{i(\alpha-\xi)})}{1-e^{i(\alpha-2\xi)}}$. Then the equation $[m]$ has a $\mathcal{C}_0$-solution if and only if $[m_\alpha]$ does. Furthermore, $\nu_0(m) = \nu_0(m_\alpha)$.*

Proof. Let T and T_α be the subdivision operators associated to the masks m and m_α, respectively.

Consider the operator $(P\psi)(x) = \sum_{k=0}^{N-2} p_k\psi(2x-k)$, where $p_0, \dots, p_{N-2}$ are the coefficients of the polynomial

$$p(\xi) = \sum_{k=0}^{N-2} p_k e^{-ik\xi} = \frac{m(\xi)}{1-e^{i(\alpha-2\xi)}}.$$

That is to say that in the frequency domain $\widehat{P\psi}(\xi) = \widehat{\psi}(\xi/2)p(\xi/2)$. It is clear that P is a continuous operator on $\mathcal{C}_0$. Furthermore, it preserves the subspace $\mathcal{L}$. Indeed, for any $\psi \in \mathcal{L}$ and $n \in \mathbb{Z}$ we have $\widehat{P\psi}(2\pi n) = \widehat{\psi}(\pi n)p(\pi n) = 0$. (If n is even, then $\widehat{\psi}(\pi n) = 0$; if n is odd, then $p(\pi n) = 0$, since the mask m satisfies (2.2).) Now observe that

$$PS_\alpha = T_\alpha, \quad S_\alpha P = T. \tag{4.2}$$

To prove this we apply (1.4) and get, consequently,

$$\widehat{PS_\alpha\psi}(\xi) = p(\xi/2)(1-e^{i(\alpha-\xi/2)})\widehat{\psi}(\xi/2) = m_\alpha(\xi/2)\widehat{\psi}(\xi/2) = \widehat{T_\alpha\psi}(\xi).$$

The equality $S_\alpha P = T$ can be proved in the same way.

Let $\psi \in \mathcal{C}_0$ be a solution of the equation $[m_\alpha]$. Since $T(S_\alpha\psi) = S_\alpha PS_\alpha\psi = S_\alpha T_\alpha\psi = S_\alpha\psi$, we see that the function $S_\alpha\psi$ is a solution of the equation $[m]$. Conversely, if a function $\varphi \in \mathcal{C}_0$ satisfies $T\varphi = \varphi$, then by (4.2) we have $\varphi \in \mathcal{C}_0\{\alpha\}$. Hence, by Lemma 4.1, the function $\psi = S_\alpha^{-1}\varphi$ is well defined and belongs to $\mathcal{C}_0$. Now, arguing as above, we obtain $T_\alpha\psi = \psi$.

From (4.2) it follows that $T^k = S_\alpha T_\alpha^{k-1}P$ for every $k \geq 1$. Therefore, since P and S_α are continuous and preserve the subspace $\mathcal{L}$, we see that $\nu_0(m) \geq \nu_0(m_\alpha)$.

Conversely, from the equality $T_{\alpha}^{k} = PT^{k-1}S_{\alpha}$ it follows that $\nu_0(m_{\alpha}) \geq \nu_0(m)$. Proposition 1 is proved. □

So using Proposition 1 we can consequently eliminate all symmetric roots and pass from the refinement equation with mask m to one with mask $R[m]$. The next step is to eliminate all cycles of the polynomial $R[m]$. In order to realize it we use the *matrix technique*, which was successfully applied in the study of subdivision processes [MP],[CDM], [DL1],[W],[E]. For a given refinement equation $[m]$ consider the two linear operators B_0 and B_1 acting on $\mathbb{C}^N$ and defined by $N \times N$ matrices as follows:

$$(B_0)_{ks} = c_{2k-s-1}, \quad (B_1)_{ks} = c_{2k-s}, \tag{4.3}$$

where c_j is the coefficient of (1.1) if $j \in \{0, 1, \ldots, N\}$, and $c_j = 0$ otherwise. As usual, we denote by *span* (M) the linear span of a given set M in $\mathbb{C}^N$, by A^* the conjugate operator for a given operator A, and by $V^{\perp}$ the orthogonal complement of a subspace V in Euclidean space. Let us recall the notion of the joint spectral radius of finite-dimensional linear operators:

$$\hat{\rho}(A_1, A_2) = \lim_{n\to\infty} \max_{(d_1,\ldots,d_n)\in\{0,1\}^n} .\|A_{d_1}\cdots A_{d_n}\|^{1/n}.$$

See [RoS], [BW], [CH], [LW], [P1] for more details about the joint spectral radius.

We need the following two lemmas. The first one is a direct corollary of results of the works [DL2] and [CH]. The proof of the second one can be found in [HC] or [P1].

Lemma 4.2 (see [DL2], [CH]). *Let Δ be a finite family of real values such that the space $\mathcal{L}_{\Delta}$ is invariant with respect to the subdivision operator T; then*

$$\nu_0(m, \mathcal{L}_{\Delta}) = -\log_2 \hat{\rho}(B_0|_V, B_1|_V),$$

where

$$V = span\ \{(f(x), \ldots, f(x+N-1))^T \in \mathbb{C}^N \mid f \in \mathcal{L}_{\Delta}[0, N],\ x \in [0,1]\}.$$

In particular,

$$\nu_0(m) = \hat{\rho}(B_0|_W, B_1|_W),\ \textit{where}\ W = \left\{(x_1, \cdots, x_N)^T \in \mathbb{C}^N \mid \sum x_j = 0\right\}.$$

Lemma 4.3 (see [HC], [P1]). *Let A_0 and A_1 be linear operators acting on a finite-dimensional Euclidean space E. Suppose E_0 is a nontrivial common invariant subspace of these operators; then*

$$\hat{\rho}(A_0, A_1) = \max\Big\{\hat{\rho}(A_0|_{E_0}, A_1|_{E_0}), \hat{\rho}(A_0^*|_{E_0^{\perp}}, A_1^*|_{E_0^{\perp}})\Big\}.$$

Now we are able to realize the second step of the proof of Theorems 3.1 and 3.2.

Proposition 2. *Suppose a mask $m(\xi)$ possesses a cycle $\mathbf{b} = \{\beta_1, \ldots, \beta_n\}$. Denote by $\tilde{m}(\xi)$ the polynomial $m(\xi)/\prod_{k=1}^{n}(1 + e^{i(\beta_k - \xi)})$. Then the equation $[m]$ has a $\mathcal{C}_0$-solution if and only if $[\tilde{m}]$ does. Furthermore, $\nu_0(m) = min\{\nu_0(\tilde{m}), -\log_2 \rho_m(\mathbf{b})\}$.*

Proof. Consider the polynomial $q(\xi) = \prod_{k=1}^{n}(1 - e^{i(\beta_k - \xi)})$ and the corresponding operator $Q = S_{\beta_1} \circ \cdots \circ S_{\beta_n}$, which has the form $\widehat{Q\psi}(\xi) = \widehat{\psi}(\xi)q(\xi)$ in the frequency domain. It follows from Lemma 4.1 that Q maps the space $\mathcal{C}_0$ one-to-one into $\mathcal{C}_0\{\mathbf{b}\}$ and Q^{-1} is well defined and continuous on $\mathcal{C}_0\{\mathbf{b}\}$. Let T and $\tilde{T}$ be the subdivision operators associated to the masks m and $\tilde{m}$, respectively. For an arbitrary function $f \in \mathcal{C}_0\{\mathbf{b}\}$ we have

$$\widehat{Tf}(\xi)/q(\xi) = m(\xi/2)\hat{f}(\xi/2)/q(\xi) = \tilde{m}(\xi/2)\hat{f}(\xi/2)/q(\xi/2) \in \mathcal{H}.$$

Consequently, Tf is in $\mathcal{C}_0\{\mathbf{b}\}$ whenever $f \in \mathcal{C}_0\{\mathbf{b}\}$. This yields that the operator equality

$$\tilde{T} = Q^{-1}TQ \tag{4.4}$$

holds on the space $\mathcal{C}_0$. If a function $\psi \in \mathcal{C}_0$ satisfies the equality $\tilde{T}\psi = \psi$, then $\varphi = Q\psi$ satisfies $T\varphi = \varphi$. Conversely, assume that a function $\varphi \in \mathcal{C}_0$ satisfies $T\varphi = \varphi$. First let us show that φ belongs to $\mathcal{C}_0\{\mathbf{b}\}$. Using (1.2) we get

$$\widehat{\varphi}(\xi) = \widehat{\varphi}(0)\prod_{r=1}^{\infty} m\left(\frac{\xi}{2^r}\right) = \widehat{\varphi}(0)\prod_{r=1}^{\infty} \frac{q(\xi/2^{r-1})}{q(\xi/2^r)}\tilde{m}\left(\frac{\xi}{2^r}\right) = \frac{q(\xi)\widehat{\varphi}(0)}{q(0)}\prod_{r=1}^{\infty}\tilde{m}\left(\frac{\xi}{2^r}\right).$$

Since the function $\prod_{r=1}^{\infty}\tilde{m}(\frac{\xi}{2^r})$ is entire, it follows that $\varphi \in \mathcal{C}_0\{\mathbf{b}\}$, whence the function $\psi = Q^{-1}\varphi$ is well defined and obviously satisfies $\tilde{T}\psi = \psi$.

Now in order to prove the equality $\nu_0(m) = \min\ \{\nu_0(\tilde{m}), -\log_2\rho_m(\mathbf{b})\}$ we are going to use Lemmas 4.2 and 4.3. Let B_0 and B_1 be the linear operators acting in $\mathbb{C}^N$ and defined from (4.3). For arbitrary $t \in \mathbb{T}$ let us denote the vector $u(t) = (1, e^{it}, e^{2it}, \dots, e^{i(N-1)t})^T \in \mathbb{C}^N$. Further, define the following subspaces:

$$U = span\ \{u(\beta_1), \dots, u(\beta_n)\}, \quad W = u(0)^{\perp} = \left\{(x_1, \dots, x_N) \in \mathbb{C}^N \mid \sum x_k = 0\right\},$$

and

$$\tilde{W} = \{u(0), u(\beta_1), \dots, u(\beta_n)\}^{\perp}.$$

Finally, denote $A_i = B_i|_W,\ \tilde{A}_i = B_i|_{\tilde{W}}, i = 0, 1.$

From (4.4) it follows that the equality $T^k = Q\tilde{T}^kQ^{-1}$ holds on the space $\mathcal{L}_{\mathbf{b}}$ for any $k \geq 1$. This yields that $\nu_0(\tilde{m}) = \nu_0(m, \mathcal{L}_{\mathbf{b}})$. If we combine this with Lemma 4.2, we get $\nu_0(\tilde{m}) = -\log_2\hat{\rho}(\tilde{A}_0, \tilde{A}_1)$. Now it remains to prove the equality

$$\hat{\rho}(A_0, A_1) = \max\{\hat{\rho}(\tilde{A}_0, \tilde{A}_1), \rho_m(\mathbf{b})\}. \tag{4.5}$$

To do this observe the following property of operators B_0 and B_1:

(4.6)

$$B_0^* u(t) = \overline{m\left(\frac{t}{2}\right)}u\left(\frac{t}{2}\right) + \overline{m\left(\frac{t}{2}+\pi\right)}u\left(\frac{t}{2}+\pi\right), \quad t \in \mathbb{T},$$

$$B_1^* u(t) = e^{-\frac{it}{2}}\overline{m\left(\frac{t}{2}\right)}u\left(\frac{t}{2}\right) + e^{-i(\frac{t}{2}+\pi)}\overline{m\left(\frac{t}{2}+\pi\right)}u\left(\frac{t}{2}+\pi\right), \quad t \in \mathbb{T}.$$

(This can be easily shown by a direct calculation; see also [P1] or [CD2].) Therefore, for arbitrary $\beta_k \in \mathbf{b}$ the following hold:

$$B_0^* u(\beta_k) = \overline{m(\beta_{k-1})}u(\beta_{k-1}), \quad B_1^* u(\beta_k) = e^{-i\beta_{k-1}}\overline{m(\beta_{k-1})}u(\beta_{k-1}).$$

Therefore, for any $\beta_k \in \mathbf{b}$ and any set of indices $\{d_1, \dots, d_n\} \in \{0, 1\}^n$ we have

$$B_{d_1}^* \cdots B_{d_n}^* u(\beta_k) = e^{i\mu}\left(\prod_{j=1}^{n}\overline{m(\beta_j)}\right)u(\beta_k),$$

where $\mu \in \mathbb{T}$ depends on β and $d_1, \dots, d_n$. Since the vectors $\{u(\beta_k)\}_{k=1}^n$ form a basis of the space U, it follows that the operator $B^*_{d_1} \cdots B^*_{d_n}|_U$ is expressed in that basis by a diagonal matrix and moreover, the modulus of each diagonal entry of that matrix is equal to $|\prod_{j=1}^n m(\beta_j)| = (\rho_m(\mathbf{b}))^n$. This implies immediately that

$$\hat{\rho}(B^*_0|_U, B^*_1|_U) = \rho_m(\mathbf{b}). \tag{4.7}$$

If we apply Lemma 4.3 to the space W, its subspace $\tilde{W}$, and operators A_0, A_1 defined above, we obtain

$$\hat{\rho}(A_0, A_1) = \max\Big\{\hat{\rho}(\tilde{A}_0, \tilde{A}_1), \hat{\rho}(A^*_0|_H, A^*_1|_H)\Big\},$$

where H is the orthogonal complement of the subspace $\tilde{W}$ in the space W. Let us finally note that $A^*_i|_H = P_H B^*_i|_U P_H^{-1}, i = 0, 1$, where P_H is the operator of orthogonal projection from U to H. (Since the vectors $u(0), u(\beta_1), \dots, u(\beta_n)$ are linearly independent, it follows that P_H^{-1} is well defined on the space H.) Combining this with (4.7), we get

$$\hat{\rho}(A^*_0|_H, A^*_1|_H) = \hat{\rho}(B^*_0|_U, B^*_1|_U) = \rho_m(\mathbf{b}),$$

which completes the proof of Proposition 2. □

Suppose we have a subdivision process $\{m_0\}$; then we pass to the process $\{R[m_0]\}$ and, using Proposition 2, consequently eliminate all cycles of the mask $R[m_0]$. As a result we obtain the mask m_1 that has neither symmetric roots nor cycles. So we prove the following statement, which is a weaker version of Theorem 3.2.

Proposition 3. *For a given mask m_0 satisfying* (2.2) *let us denote*

$$m_1(\xi) = R[m_0](\xi) / \prod_{k=1}^{q} \prod_{\beta \in \mathbf{b}_k} (1 + e^{i(\beta - \xi)}),$$

where $\{\mathbf{b}_1, \dots, \mathbf{b}_q\}$ is the set of cycles of the polynomial $R[m_0]$ (counting with multiplicity). Then we have the following: the equation $[m_0]$ has a $\mathcal{C}_0$-solution if and only if $[m_1]$ does; furthermore,

$$\nu_0(m_0) = \min\{\nu_0(m_1), -\log_2 \rho_{m_0}(\mathbf{b}_1), \dots, -\log_2 \rho_{m_0}(\mathbf{b}_q)\}.$$

Thus Theorem 3.2 is proved for the case $l = 0$. Combining this with Theorem 2.1 we obtain Theorem 3.1 for the case $l = 0$.

Now it remains to realize the third step of the proof, i.e., to extend the statements of Theorems 3.1 and 3.2 from the case $l = 0$ to the general integer factor $l \geq 0$. To do this we introduce Proposition 4, which gives a method of factorization of refinement equations. Proposition 4 reduces the study of refinable functions and subdivision processes from the space $\mathcal{C}^l$ to $\mathcal{C}$.

Let us first remember the definition of the *cardinal B-spline*:

$$B_0(x) = \chi_{[0,1]}(x); \quad B_k(x) = [\chi_{[0,1]} * \cdots * \chi_{[0,1]}](x) \quad (k \text{ convolutions}).$$

For any $k \geq 0$ the cardinal B-spline B_k is a solution of the refinement equation with mask $(\frac{1+e^{-i\xi}}{2})^{k+1}$ (see, for instance, [Sc] or [DL2]).

Proposition 4. *Suppose m and m_0 are masks of refinement equations such that $m(\xi) = (\frac{1+e^{-i\xi}}{2})^l m_0(\xi)$, $l \geq 1$; then*

(a) *the equation* $[m]$ *has a* $\mathcal{C}_0^l$*-solution if and only if* $[m_0]$ *has a* $\mathcal{C}_0$*-solution. Moreover,* $\psi = S_0^{-l}\varphi^{(l)}$ *and* $\varphi = B_{l-1} * \psi$*, where* φ *and* ψ *are solutions of* $[m]$ *and* $[m_0]$*, respectively;* S_0 *is the difference operator:* $S_0 f(x) = f(x) - f(x-1)$.

(b) *The subdivision process* $\{m\}$ *converges in* $\mathcal{C}^l$ *if and only if* $\{m_0\}$ *converges in* $\mathcal{C}$*. Moreover,* $\nu(m) = \nu(m_0) + l$.

Proof. It follows from Lemma 4.1 that the mapping $S_0^l : \mathcal{C}_0 \to \mathcal{M}^{l-1}$ is a homeomorphism. Furthermore, for any $k \geq 0$ the mapping $S_0^l : \mathcal{M}^k \to \mathcal{M}^{k+l}$ is a homeomorphism. Now observe that for any $f \in \mathcal{C}_0$ and $g \in \mathcal{M}^{l-1}$ we have

$$T_0 f = 2^l S_0^{-l} T S_0^l f, \quad f \in \mathcal{C}_0,$$

$$Tg = 2^{-l} S_0^l T_0 S_0^{-l} g, \quad g \in \mathcal{M}^{l-1}, \tag{4.8}$$

where T and T_0 are the subdivision operators associated to the masks m and m_0, respectively. This immediately implies item (a). Further, from (4.8) it follows that $\nu_0(m, \mathcal{M}^{k+l}) = \nu_0(m_0, \mathcal{M}^k) + l$ for any admissible $k \geq 0$, i.e. whenever $k \leq \mathbf{l}(m_0)$. Therefore, $\nu_{k+l}(m) = \nu_k(m_0) + l$. Combining this with (3.1) we obtain item (b), which completes the proof of Proposition 4. □

Now to extend Theorems 3.1 and 3.2 from the case $l = 0$ it is sufficient to pass from the mask m to m_0 (applying Proposition 4) and note that $\rho_m(\mathbf{b}) = 2^{-l}\rho_{m_0}(\mathbf{b})$ for any cycle $\mathbf{b}$. This concludes the proof of the main theorems. □

Remark 5. The statement of item (a) of Proposition 4 generalizes the result [E, Theorem 2.2], which was obtained for refinement equations satisfying Cohen's criterion (see Remark 1).

Remark 6. It follows from results of the work [P2] that the statement of item (a) of Proposition 4 can be extended to general refinement equations, i.e., equations without condition (2.1). Namely, the following hold.

If an equation $[m]$ *has a* $\mathcal{C}_0^l$*-solution* $\varphi(x)$, $(l \geq 1)$*, then there exist dyadic rational values* $\gamma_1, \ldots, \gamma_r$ *(perhaps coinciding) such that* $\varphi = B_{l-1} * (S_{\gamma_1} \circ \cdots \circ S_{\gamma_r}\psi)$ *(and correspondingly* $\psi = S_0^{-l} \circ S_{\gamma_1}^{-1} \circ \cdots \circ S_{\gamma_r}^{-1}\varphi^{(l)}$*), where* ψ *is the* $\mathcal{C}_0$*-solution of the equation having the mask*

$$m_0(\xi) = \frac{m(\xi)}{[(1+e^{-i\xi})/2]^l} \prod_{k=1}^{r} \frac{1 - e^{i(2\pi\gamma_k - \xi)}}{1 - e^{i(2\pi\gamma_k - 2\xi)}}.$$

So the study of smooth refinable functions can be reduced to the study of continuous refinable functions (see [P2] for more details; see also [R1] and [C] for similar factorization theorems).

5. Generalized cycles. Theorems 3.1 and 3.2 are formulated in terms of cycles of the polynomial $R[m]$. It is easy to see that in general the sets of cycles of the polynomials m and $R[m]$ are different. The question arises, How can cycles of $R[m]$ be characterized by roots of m? In other words, we are going to reformulate the criterion of stability of subdivision operator in terms of zeros of its mask.

Let $p(\xi)$ be a given trigonometric polynomial. (Let us remember that we consider polynomials without positive powers.) Assume that p possesses a pair of symmetric roots $\{\alpha/2, \pi + \alpha/2\}$. The transfer from $p(\xi)$ to the polynomial $p_\alpha(\xi) = \frac{p(\xi)(1-e^{i(\alpha-\xi)})}{1-e^{i(\alpha-2\xi)}}$ is said to be a *transfer to the previous level.* The inverse transfer from p_α to p is a *transfer to the next level.* So the polynomial $R[p]$ is obtained from p by a sequence of transfers to the previous level.

To a given value $\alpha \in \mathbb{T}$ we assign a binary tree denoted in what follows by $\mathcal{T}_\alpha$. To every vertex of this tree we associate a value from $\mathbb{T}$ as follows: put α at the root, then put $\alpha/2$ and $\pi + \alpha/2$ at the vertices of the first level. (The *level* of the vertex is the distance from this vertex to the root. The root has level 0.) If a value γ is associated to a vertex on the nth level, then the values $\gamma/2$ and $\pi + \gamma/2$ are associated to its neighbors on the $(n+1)$st level. Thus there are the values $\frac{\alpha}{2^n} + \frac{2k\pi}{2^n}$, $k = 0, \dots, 2^n - 1$ on the nth level of the tree $\mathcal{T}_\alpha$. A set of vertices $\mathcal{A}$ of the tree $\mathcal{T}_\alpha$ is called a *minimal cut set* if every infinite path (all the paths are without backtracking) starting at the root includes exactly one element of $\mathcal{A}$. For instance, the one-element set $\mathcal{A} = \{root\}$ is a minimal cut set.

Definition 5.1. *A set $\{\beta_1, \dots, \beta_n\} \subset \mathbb{T}$ is called a generalized cycle of the polynomial $p(\xi)$ if the following hold:*

(a) *this set is cyclic, i.e., $\beta_{j+1} = 2\beta_j$ for all $j = 1, \dots, n$ (we set $\beta_{n+1} = \beta_1$);*

(b) *for any $j = 1, \dots, n$, the tree $\mathcal{T}_{\beta_j + \pi}$ possesses a minimal cut set that consists of roots of the polynomial p.*

Any (regular) cycle of $p(\xi)$ is also a generalized cycle. Indeed, in this case each minimal cut set A_j is the root of the corresponding tree $\mathcal{T}_{\beta_j+\pi}$. Now we establish a correlation between generalized cycles of the polynomial $p(\xi)$ and (regular) cycles of $R[p]$.

Proposition 5. (a) *Every cycle of the polynomial $R[p]$ is a generalized cycle of p.*

(b) *Every generalized cycle $\mathbf{b}$ of the polynomial p such that $\rho_p(\mathbf{b}) \neq 0$ is a cycle of $R[p]$.*

Proof. (a) Let $\mathbf{b} = \{\beta_1, \dots, \beta_n\}$ be a cycle of the polynomial $R[p]$. The polynomial p is obtained from $R[p]$ by a sequence of transfers to the next level. That sequence takes the root of the tree $\mathcal{T}_{\beta_j+\pi}$ to some minimal cut set $\mathcal{A}_j$ of this tree. Since $\beta_j + \pi$ is a root of $R[p]$, it follows that all elements of $\mathcal{A}_j$ are roots of p. So the set $\mathbf{b}$ is a generalized cycle for $p(\xi)$.

(b) Let $\mathbf{b} = \{\beta_1, \dots, \beta_n\}$ be a generalized cycle of the polynomial $p(\xi)$. Applying a suitable sequence of transfers to the previous level, we pass from the minimal cut sets $\mathcal{A}_1, \dots, \mathcal{A}_n$ to the roots $\beta_1 + \pi, \dots, \beta_n + \pi$ of the corresponding trees. Then we continue applying transfers to the previous level until we obtain the polynomial $R[p]$. If at some step we involve an element $\beta_j + \pi$ in this process, then the polynomial $p_1(\xi)$, which is obtained from the polynomial $p(\xi)$ by this step, has the pair of symmetric roots $\{\beta_j, \beta_j + \pi\}$. This implies that $\rho_{p_1}(\mathbf{b}) = 0$, and hence $\rho_p(\mathbf{b}) = 0$. Consider the opposite case. If the elements $\beta_1 + \pi, \dots, \beta_n + \pi$ are not involved, then each of them is a root of $R[p]$. Therefore, $\mathbf{b}$ is a cycle of $R[p]$. This completes the proof. □

Corollary 4. *If a polynomial $p(\xi)$ has no symmetric roots, then the set of its generalized cycles coincides with the set of its (regular) cycles.*

Corollary 5. *The set of all generalized cycles of a polynomial $p(\xi)$ is a union of the following two sets: the first one is the set of all cycles of $R[p]$; the second one consists of generalized cycles $\mathbf{b}$ such that $\rho_p(\mathbf{b}) = 0$.*

It follows from Propositions 2 and 4 that any cycle $\mathbf{b}$ such that $\rho_m(\mathbf{b}) = 0$ does not have influence on the convergence of the subdivision process $\{m\}$, i.e., $\nu(m) = \nu(\tilde{m})$ in terms of Proposition 2. Hence the criterion of convergence for subdivision processes can be formulated in terms of generalized cycles of mask. As a corollary we obtain the following main result of this section.

Corollary 6. *The statement of Theorem 3.1 remains true if the notion "a cycle of the polynomial $R[m]$" is replaced by "a generalized cycle of the mask m."*

UNIQUENESS FOR ELASTIC WAVE SCATTERING BY ROUGH SURFACES*

T. ARENS†

Abstract. We consider a two-dimensional elastic wave scattering problem for an unbounded surface represented as the graph of a $C^{1,\alpha}$ function. The total displacement is assumed to vanish on the surface. We present a new radiation condition, the upwards propagating radiation condition, for such problems based on a similar condition recently introduced for acoustic scattering problems. The relation between this radiation condition and more commonly used conditions is discussed. Subsequently we prove uniqueness of solution to the scattering problem under this radiation condition for a general class of incident fields, including plane and cylindrical waves.

Key words. elastic waves, scattering theory, rough surfaces, radiation condition, uniqueness

1. Introduction.

To date there appears to be little rigorous mathematical study of scattering problems for time harmonic elastic waves involving infinite rough surfaces. This paper is a first contribution to close this gap by proposing a precisely formulated radiation condition for a class of two-dimensional such problems and proving uniqueness for a problem in this class under this radiation condition.

The propagation of time harmonic waves with circular frequency ω in an elastic solid with Lamé constants μ, λ ($\mu > 0$, $\lambda + \mu \geq 0$), is governed by Hooke's law

$$\tau_{jk} = \lambda \operatorname{div} \mathbf{u} \, \delta_{jk} + \mu \left(\frac{\partial u_j}{\partial x_k} + \frac{\partial u_k}{\partial x_j} \right), \qquad j,k = 1,2,3, \tag{1}$$

and by the equations of motion

$$\sum_{k=1}^{3} \frac{\partial \tau_{jk}}{\partial x_k} + \omega^2 u_j = 0, \qquad j = 1,2,3. \tag{2}$$

Here, the vector field $\mathbf{u}$ denotes the displacements and τ denotes the stress tensor. Inserting the components of τ as given by (1) into the equations of motion (2) yields the Navier equation

$$\mu \, \Delta \mathbf{u} + (\lambda + \mu) \text{ grad div} \, \mathbf{u} + \omega^2 \, \mathbf{u} = 0. \tag{3}$$

All waves are assumed to be traveling in a half-space bounded by a surface invariant in the x_3-direction, on which all displacements are assumed to vanish. Because of this special geometry, the system of equations (3) separates into two parts, one describing compressional and vertically polarized shear waves, and the other describing horizontally polarised shear waves. Here we will consider only the first part; the scattering problem is treated as a problem of plane strain. Thus the problem is two-dimensional

and, assuming that the boundary is the graph of a function f, the domain under consideration is $\Omega := \{\mathbf{x} \in \mathbb{R}^2 : x_2 > f(x_1)\}$. We will assume throughout this paper that f is bounded and that $\partial\Omega$ is Lyapunov.

This problem has many engineering applications, notably in seismology. In [10, 14, 15] the problem is considered in the case of a periodic traction-free surface and various numerical and analytical methods for computing the solution are presented. However, there appears to be no mathematically rigorous attempt to prove uniqueness and existence of solution until the author's recent work for the periodic case [1, 2].

In the case of acoustic waves, a lot of progress has been made lately in proving uniqueness and existence for both incident plane waves and incident cylindrical waves [4, 5, 6, 7, 8, 16]. The first step was to introduce a new radiation condition that will ensure uniqueness of solution for a wide range of incident fields, notably plane waves and cylindrical waves. In the present paper, these results will be generalized to the elastic wave case.

In section 2, we begin by introducing some notations and stating some results from linear elasticity theory used later in the paper. In section 3, we propose a new radiation condition for elastic wave scattering, suggested by the *upwards propagating radiation condition* (UPRC) for the Helmholtz equation [4], and we analyze its relation to other radiation conditions. In particular, we show that the new radiation condition is satisfied by solutions to the Navier equation satisfying Kupradze's radiation condition [13]. Finally, in section 4, a mathematical formulation of the scattering problem as a boundary value problem is given and uniqueness of solution to this problem is proved. Throughout the paper, reference will be made to some results on the regularity of solutions to the Navier equation that have been collected in the appendix.

2. Preliminaries. We will start by introducing notations and making some definitions that will be helpful subsequently. For any set $\mathcal{S} \subset \mathbb{R}^m$ ($m \in \mathbb{N}$) denote by $BC(\mathcal{S})$ the set of bounded and continuous, complex valued functions on $\mathcal{S}$, a Banach space under the supremum norm $\|\cdot\|_{\infty;\mathcal{S}}$. As an extension of the usual Hölder spaces $C^{k,\alpha}(\bar{D})$ ($k \in \mathbb{N} \cup \{0\}$) for bounded domains D with norm $\|\cdot\|_{k,\alpha;D}$, for unbounded domains $\mathcal{S} \subset \mathbb{R}^m$, we will introduce the sets

$$\mathcal{V}^{k,\alpha}(\mathcal{S}) := \{u : u \in C^{k,\alpha}(\bar{D}) \text{ for any domain } D \subset\subset \mathcal{S}\}$$

and

$$C^{k,\alpha}(\mathcal{S}) := \left\{ u \in \mathcal{V}^{k,\alpha}(\mathcal{S}) : \sup_{D \subset\subset \mathcal{S}} \|u\|_{k,\alpha;D} < \infty \right\}.$$

We also introduce a norm on $C^{k,\alpha}(\mathcal{S})$ by defining, for $u \in C^{k,\alpha}(\mathcal{S})$,

$$\|u\|_{k,\alpha;\mathcal{S}} := \sup_{D \subset\subset \mathcal{S}} \|u\|_{k,\alpha;D},$$

and we remark that $C^{k,\alpha}(\mathcal{S})$ is a Banach space with this norm.

The domain Ω under consideration is

$$\Omega := \{\mathbf{x} \in \mathbb{R}^2 : x_2 > f(x_1)\},$$

where we assume $f \in C^{1,\alpha}(\mathbb{R})$ to be real-valued.

We further let $S := \partial\Omega$ and, for any $A > 0$, $S(A) := \{\mathbf{x} \in S : |x_1| < A\}$. The normal $\mathbf{n}$ to S will always be assumed to be pointing out of Ω.

For $h \in \mathbb{R}$, define $U_h := \{\mathbf{x} \in \mathbb{R}^2 : x_2 > h\}$ and $T_h := \{\mathbf{x} \in \mathbb{R}^2 : x_2 = h\}$. Furthermore, let $D_h := \Omega \setminus \overline{U}_h$. We define $T_h(A)$ and $D_h(A)$ analogously to $S(A)$ and finally introduce $\gamma(h, A) := \{\mathbf{x} \in \Omega : |x_1| = A, x_2 < h\}$. Throughout, the normals on T_h and those on $T_h(A)$ and $\gamma(h, A)$ will be assumed to be pointing out of D_h and $D_h(A)$, as appropriate.

Throughout, all vectors and vector fields shall be denoted in bold print. For $\mathbf{y} = (y_1, y_2)^\top \in \mathbb{R}^2$ and $h \in \mathbb{R}$, define

$$\mathbf{y}'_h := (y_1, 2h - y_2)^\top \qquad \text{and} \qquad \mathbf{y}^\perp := (y_2, -y_1)^\top.$$

In addition to the usual differential operators grad$\cdot$ and div$\cdot$, we will make use of

$$\operatorname{grad}^\perp u := \left(\frac{\partial u}{\partial x_2}, -\frac{\partial u}{\partial x_1}\right)^\top \qquad \text{and} \qquad \operatorname{div}^\perp \mathbf{u} := \frac{\partial u_1}{\partial x_2} - \frac{\partial u_2}{\partial x_1}.$$

The differential operator in the Navier equation is abbreviated by Δ^* defined as

$$\Delta^* \mathbf{u} := \mu \, \Delta \, \mathbf{u} + (\lambda + \mu) \operatorname{grad} \operatorname{div} \mathbf{u}.$$

The fundamental solution in free-field conditions to the Helmholtz equation $\Delta \, u + k^2 u = 0$ will also play a role; it is given by

$$\Phi(\mathbf{x}, \mathbf{y}) := \frac{i}{4} H_0^{(1)}(k|\mathbf{x} - \mathbf{y}|), \qquad \mathbf{x}, \mathbf{y} \in \mathbb{R}^2,$$

where $H_0^{(1)}$ denotes the Hankel function of order 0 and of the first kind.

The rest of this section will be devoted to stating some results from the linear theory of elastic wave propagation. First, let us note that any solution $\mathbf{u}$ to the Navier equation can be decomposed into uniquely identified compressional (or longitudinal) and shear (or transversal) components as

$$\mathbf{u} = \mathbf{u}_p + \mathbf{u}_s,$$

where

$$\mathbf{u}_p := -\frac{1}{k_p^2} \operatorname{grad} \operatorname{div} \mathbf{u} \quad \text{and} \quad \mathbf{u}_s := -\frac{1}{k_s^2} \operatorname{grad}^\perp \operatorname{div}^\perp \mathbf{u},$$

and the wave numbers k_p and k_s satisfy

$$k_p^2 = \frac{\omega^2}{2\mu + \lambda}, \qquad k_s^2 = \frac{\omega^2}{\mu}. \tag{4}$$

We find that $\mathbf{u}_p$ ($\mathbf{u}_s$) is a solution to the vector Helmholtz equation with $k = k_p$ ($k = k_s$).

Recalling Hooke's law (1), we follow Kupradze [13] in introducing a *generalised stress tensor* $\mathcal{P} = (\pi_{jk})$ by

$$\pi_{jk} := \tilde{\lambda} \operatorname{div} \mathbf{u} \, \delta_{jk} + \mu \frac{\partial u_j}{\partial x_k} + \tilde{\mu} \frac{\partial u_k}{\partial x_j},$$

where $\tilde{\lambda}$, $\tilde{\mu}$ are real numbers satisfying $\tilde{\lambda} + \tilde{\mu} = \lambda + \mu$. Given a curve $\Lambda \subset \mathbb{R}^2$ with a normal $\mathbf{n}$, the *generalised stress vector* on Λ is defined by

$$\mathbf{P}\mathbf{u} := \mathcal{P} \, \mathbf{n} = (\mu + \tilde{\mu}) \frac{\partial \mathbf{u}}{\partial \mathbf{n}} + \tilde{\lambda} \, \mathbf{n} \operatorname{div} \mathbf{u} - \tilde{\mu} \, \mathbf{n}^\perp \operatorname{div}^\perp \mathbf{u}.$$

Where it is important to distinguish between derivatives taken with respect to $\mathbf{x}$ and $\mathbf{y}$, the notations $\mathbf{P}^{(\mathbf{x})}\cdot$ and $\mathbf{P}^{(\mathbf{y})}\cdot$ will be used.

Similarly to Green's identities, there hold the generalized Betti formulae as follows.

Lemma 2.1. *Let $B \subseteq \mathbb{R}^2$ be a domain in which the divergence theorem holds. The normal on ∂B will be assumed to be pointing out of B. Then for vector fields $\mathbf{v} \in C^1(\bar{B})$ and $\mathbf{w} \in C^2(\bar{B})$ the first generalized Betti formula holds:*

$$\int_B \mathbf{v} \cdot \Delta^* \mathbf{w}\, d\mathbf{x} = \int_{\partial B} \mathbf{v} \cdot \mathbf{P}\mathbf{w}\, ds - \int_B \mathcal{E}_{a,b}(\mathbf{v}, \mathbf{w})\, d\mathbf{x}, \tag{5}$$

where the symmetric bilinear form $\mathcal{E}_{\tilde{\mu},\tilde{\lambda}}$ is given by

$$\begin{aligned}\mathcal{E}_{\tilde{\mu},\tilde{\lambda}}(\mathbf{v}, \mathbf{w}) := (2\mu + \lambda) \left(\frac{\partial v_1}{\partial x_1} \frac{\partial w_1}{\partial x_1} + \frac{\partial v_2}{\partial x_2} \frac{\partial w_2}{\partial x_2} \right) + \mu \left(\frac{\partial v_1}{\partial x_2} \frac{\partial w_1}{\partial x_2} + \frac{\partial v_2}{\partial x_1} \frac{\partial w_2}{\partial x_1} \right) \\ + \tilde{\lambda} \left(\frac{\partial v_1}{\partial x_1} \frac{\partial w_2}{\partial x_2} + \frac{\partial v_2}{\partial x_2} \frac{\partial w_1}{\partial x_1} \right) + \tilde{\mu} \left(\frac{\partial v_1}{\partial x_2} \frac{\partial w_2}{\partial x_1} + \frac{\partial v_2}{\partial x_1} \frac{\partial w_1}{\partial x_2} \right).\end{aligned}$$

For $\mathbf{v}$, $\mathbf{w} \in C^2(\bar{B})$, the third generalized Betti formula holds:

$$\int_B (\mathbf{v} \cdot \Delta^*\, \mathbf{w} - \mathbf{w} \cdot \Delta^*\, \mathbf{v})\, d\mathbf{x} = \int_{\partial B} (\mathbf{v} \cdot \mathbf{P}\mathbf{w} - \mathbf{w} \cdot \mathbf{P}\mathbf{v})\, ds. \tag{6}$$

Proof. The proof is as in Kupradze [13] for the three-dimensional case. □

In the definition and analysis of the new radiation condition, we will make heavy use of the elastic Green's tensors for free-field conditions and for a half-space with rigid boundary. The matrix of fundamental solutions for the Navier equation (3) which is the Green's tensor for free-field conditions is given by

$$\begin{aligned}\Gamma(\mathbf{x}, \mathbf{y}) := &\frac{i}{4\mu} H_0^{(1)}(k_s |\mathbf{x} - \mathbf{y}|) \\ &+ \frac{i}{4\omega^2} \nabla_x \nabla_x^\top \left(H_0^{(1)}(k_s |\mathbf{x} - \mathbf{y}|) - H_0^{(1)}(k_p |\mathbf{x} - \mathbf{y}|) \right).\end{aligned} \tag{7}$$

The Green's tensor for the half-space U_h with a rigid surface (i.e., the first boundary value problem) is given by

$$\Gamma_{D,h}(\mathbf{x}, \mathbf{y}) := \Gamma(\mathbf{x}, \mathbf{y}) - \Gamma(\mathbf{x}, \mathbf{y}'_h) + \mathbf{U}(\mathbf{x}, \mathbf{y}), \qquad \mathbf{x}, \mathbf{y} \in \overline{U_h},\ \mathbf{x} \neq \mathbf{y}, \tag{8}$$

where

$$\begin{aligned}&\mathbf{U}(\mathbf{x}, \mathbf{y}) \\ &= -\frac{i}{2\pi\omega^2} \Bigg\{ \int_{-\infty}^{\infty} \frac{\mathrm{e}^{i\gamma_p(x_2+y_2-2h)} - \mathrm{e}^{i(\gamma_p(x_2-h)+\gamma_s(y_2-h))}}{\gamma_p\gamma_s + t^2} \begin{pmatrix} -t^2\gamma_s & t^3 \\ t\gamma_p\gamma_s & -t^2\gamma_p \end{pmatrix} \mathrm{e}^{-iX_1 t}\, dt \\ &\qquad - \int_{-\infty}^{\infty} \frac{\mathrm{e}^{i\gamma_s(x_2+y_2-2h)} - \mathrm{e}^{i(\gamma_s(x_2-h)+\gamma_p(y_2-h))}}{\gamma_p\gamma_s + t^2} \begin{pmatrix} t^2\gamma_s & t\gamma_p\gamma_s \\ t^3 & t^2\gamma_p \end{pmatrix} \mathrm{e}^{-iX_1 t}\, dt \Bigg\}\end{aligned}$$

and $X_1 := x_1 - y_1$,

$$\gamma_p := \begin{cases} \sqrt{k_p^2 - t^2}, & k_p^2 \geq t^2, \\ i\sqrt{t^2 - k_p^2}, & k_p^2 < t^2, \end{cases} \qquad \gamma_s := \begin{cases} \sqrt{k_s^2 - t^2}, & k_s^2 \geq t^2, \\ i\sqrt{t^2 - k_s^2}, & k_s^2 < t^2. \end{cases}$$

The following theorem, which was essentially proved in [1], establishes the properties of $\Gamma_{D,h}$.

THEOREM 2.2.

(i) *For* $\mathbf{y} \in U_h$ *fixed,* $\Gamma_{D,h}(\cdot,\mathbf{y}) - \Gamma(\cdot,\mathbf{y}) \in [C^\infty(U_h) \cap C^1(\overline{U_h})]^{2\times 2}$ *and its columns are solutions to the Navier equation* (3) *in* $U_h \setminus \{\mathbf{y}\}$*.*

(ii) *For* $\mathbf{y} \in U_h$, $\mathbf{x} \in \partial U_h$, *there holds* $\Gamma_{D,h}(\mathbf{x},\mathbf{y}) = 0$*.*

(iii) *Let* $\mathbf{x}$, $\mathbf{y} \in U_h$, $\mathbf{x} \neq \mathbf{y}$*. Then*

$$\Gamma_{D,h}(\mathbf{x},\mathbf{y}) = \Gamma_{D,h}(\mathbf{y},\mathbf{x})^\top.$$

(iv) *For any* $\varepsilon > 0$, *the estimate*

$$\max_{j,k=1,2} |\Gamma_{D,h,jk}(\mathbf{x},\mathbf{y})| \leq \frac{\mathcal{H}(x_2 - h, y_2 - h)}{|x_1 - y_1|^{3/2}}$$

holds for all $\mathbf{x},\mathbf{y} \in U_h$, $|x_1 - y_1| \geq \varepsilon$, *where* $\mathcal{H} \in C(\mathbb{R}^2)$*.*

(v) *Let* $\Gamma^{(p)}_{D,h} := -k_p^{-2}\, \mathrm{grad}_{\mathbf{x}}\, \mathrm{div}_{\mathbf{x}}\, \Gamma_{D,h}$ *denote the longitudinal and let* $\Gamma^{(s)}_{D,h} := \Gamma_{D,h} - \Gamma^{(p)}_{D,h}$ *denote the transversal part of* $\Gamma_{D,h}$*. Then, for* $\mathbf{x}$, $\mathbf{y} \in U_h$, *and* $r := |\mathbf{x}-\mathbf{y}|$,

$$\Gamma^{(p)}_{D,h}(\mathbf{x},\mathbf{y}) = O(r^{-1/2}), \quad \frac{\partial \Gamma^{(p)}_{D,h}}{\partial r}(\mathbf{x},\mathbf{y}) - ik_p \Gamma^{(p)}_{D,h}(\mathbf{x},\mathbf{y}) = o(r^{-1/2}),$$
$$\Gamma^{(s)}_{D,h}(\mathbf{x},\mathbf{y}) = O(r^{-1/2}), \quad \frac{\partial \Gamma^{(s)}_{D,h}}{\partial r}(\mathbf{x},\mathbf{y}) - ik_s \Gamma^{(s)}_{D,h}(\mathbf{x},\mathbf{y}) = o(r^{-1/2})$$

uniformly in $\mathbf{x}$ *and* $\mathbf{y}$ *as* $r \to \infty$*.*

Proof. The proof follows from Theorems 2.1, 2.4, and 2.5 and Lemma 3.3 in [1]. □

By applying $\mathbf{P}\cdot$ to $\Gamma_{D,h}$, the matrix functions $\Pi^{(1)}_{D,h}$ and $\Pi^{(2)}_{D,h}$, defined by

$$\begin{array}{rcl} \Pi^{(1)}_{D,h,jk}(\mathbf{x},\mathbf{y}) & := & \left(\mathbf{P}^{(\mathbf{x})}(\Gamma_{D,h,\cdot k}(\mathbf{x},\mathbf{y}))\right)_j, \\ \Pi^{(2)}_{D,h,jk}(\mathbf{x},\mathbf{y}) & := & \left(\mathbf{P}^{(\mathbf{y})}(\Gamma_{D,h,j\cdot}(\mathbf{x},\mathbf{y}))^\top\right)_k, \end{array} \qquad j,k = 1,2,$$

are obtained. For these matrices, similar results to those for $\Gamma_{D,h}$ hold as follows.

THEOREM 2.3.

(i) *For* $\mathbf{y} \in U_h$, *the columns of* $\Pi^{(2)}_{D,h}(\cdot,\mathbf{y})$ *are solutions to the Navier equation* (3) *in* $U_h \setminus \{\mathbf{y}\}$*.*

(ii) *For* $\mathbf{x} \in U_h$, *the rows of* $\Pi^{(1)}_{D,h}(\mathbf{x},\cdot)$ *are solutions to the Navier equation* (3) *in* $U_h \setminus \{\mathbf{x}\}$*.*

(iii) *Theorem* 2.2 (iv) *and* (v) *hold with* $\Gamma_{D,h}$ *replaced by* $\Pi^{(1)}_{D,h}$ *and* $\Pi^{(2)}_{D,h}$, *respectively.*

(iv) *For* $\mathbf{x}$, $\mathbf{y} \in U_h$, $\mathbf{x} \neq \mathbf{y}$, *there holds*

$$\Pi^{(2)}_{D,h}(\mathbf{x},\mathbf{y}) = \Pi^{(1)}_{D,h}(\mathbf{y},\mathbf{x})^\top.$$

(v) *Let* $B \subset U_h$ *be a bounded domain in which the divergence theorem holds. Then any solution* $\mathbf{u} \in [C^2(B) \cap C^1(\bar{B})]^2$ *to the Navier equation* (3) *can be represented as*

$$\mathbf{u}(\mathbf{x}) = \int_{\partial B} \left\{ \Gamma_{D,h}(\mathbf{x},\mathbf{y})\, \mathbf{P}\mathbf{u}(\mathbf{y}) - \Pi^{(2)}_{D,h}(\mathbf{x},\mathbf{y})\, \mathbf{u}(\mathbf{y}) \right\} ds(\mathbf{y})$$

for all $\mathbf{x} \in B$*.*

Proof. The proof follows from Theorems 3.1 and 3.4 in [1]. □

Remark 2.4. We also note that from a representation of Γ in terms of Hankel functions of order 0 and 1 [12, formula (2.6)] together with Theorem 2.2 and the fact that $\Gamma_{D,h} - \Gamma$ remains bounded for $\mathbf{x}$, $\mathbf{y} \in U_h$, we see that there exists some constant $C > 0$ such that

$$\max_{j,k=1,2} |\Gamma_{D,h,jk}(\mathbf{x},\mathbf{y})| \leq C \,|1 + \log|\mathbf{x}-\mathbf{y}|\,| \tag{9}$$

for $\mathbf{x}$, $\mathbf{y} \in U_h$. As a consequence, together with an application of Theorem 2.2 (iv), we have for $h < \inf f$ and $h' > \sup f$ that

$$\sup_{\mathbf{x}\in D_{h'}} \int_S \max_{j,k=1,2} |\Gamma_{D,h,jk}(\mathbf{x},\mathbf{y})|^2 \, ds(\mathbf{y}) < \infty.$$

Remark 2.5. Similarly to (9), we also prove that $\Pi^{(2)}_{D,h}(\mathbf{x},\mathbf{y})$ remains bounded for $|\mathbf{x}-\mathbf{y}| \geq \varepsilon > 0$. Thus, using Theorem 2.2 (iv) and Lemma A.1, we see for $H' > H > h$ and any derivative with respect to $\mathbf{x}$, $\mathcal{G}$, of $\Pi^{(2)}_{D,h}$ that

$$\sup_{\mathbf{x}\in U_H\setminus U_{H'}} \int_{T_h} \max_{j,k=1,2} |\mathcal{G}_{jk}(\mathbf{x},\mathbf{y})| \, ds(\mathbf{y}) < \infty.$$

3. Radiation conditions for rough surface scattering. We will start this section by reviewing the acoustic case. Consider the Helmholtz equation

$$\Delta\, u + k^2 u = 0 \tag{10}$$

in some domain $G \subset \mathbb{R}^2$ such that for some $H \in \mathbb{R}$, $U_H \subset G$.

The standard radiation condition employed in problems of scattering by bounded obstacles for the Helmholtz equation was introduced by Sommerfeld as follows.

Definition 3.1. *A solution $u \in C^2(U_H) \cap L^\infty(U_H)$ to the Helmholtz equation* (10) *in U_H will be said to be* radiating *if*

$$u(\mathbf{x}) = O(r^{-1/2}), \qquad \frac{\partial u}{\partial r} - iku = o(r^{-1/2}),$$

uniformly in $\mathbf{x}/r$ as $r := |\mathbf{x}| \to \infty$.

Recently, a new radiation condition, the *upward propagating radiation condition* (UPRC) was introduced and successfully employed in a wide range of problems of scattering by unbounded rough surfaces and inhomogeneous layers [4, 6, 7, 8, 16] as follows.

Definition 3.2. *A solution $u : G \to \mathbb{C}$ to the Helmholtz equation* (10) *in $G \subset \mathbb{R}^2$ is said to satisfy UPRC, if, for some $H \in \mathbb{R}$ and $\phi \in L^\infty(T_H)$, $U_H \subset G$ and*

$$u(\mathbf{x}) = 2\int_{T_H} \frac{\partial \Phi}{\partial y_2}(\mathbf{x},\mathbf{y})\,\phi(\mathbf{y})\,ds(\mathbf{y}), \qquad \mathbf{x} \in U_H.$$

Let us now turn back to the elastic case. The radiation condition for the Navier equation (3) corresponding to Sommerfeld's radiation condition in the Helmholtz equation case is Kupradze's radiation condition, as given in the following definition.

Definition 3.3. *A solution $\mathbf{u} \in \left[C^3(U_H) \cap L^\infty(U_H)\right]^2$ to the Navier equation* (3) *in U_h will be said to be* radiating *if*

$$\mathbf{u}_p = O(r^{-1/2}), \quad \frac{\partial \mathbf{u}_p}{\partial r} - ik_p\mathbf{u}_p = o(r^{-1/2}),$$
$$\mathbf{u}_s = O(r^{-1/2}), \quad \frac{\partial \mathbf{u}_s}{\partial r} - ik_s\mathbf{u}_s = o(r^{-1/2}),$$

uniformly in $\mathbf{x}/r$ *as* $r := |\mathbf{x}| \to \infty$*, i.e., if both compressional and shear components of* $\mathbf{u}$ *are radiating solutions to the Helmholtz equation in* U_H*.*

The idea of the UPRC can be extended to the elastic case through the following definition.

DEFINITION 3.4. *A solution* $\mathbf{u} : G \to \mathbb{C}^2$ *to the Navier equation* (3) *in* $G \subset \mathbb{R}^2$ *is said to satisfy the UPRC, if, for some* $H \in \mathbb{R}$ *and* $\phi \in [L^\infty(T_H)]^2$, $U_H \subset G$ *and*

$$\mathbf{u}(\mathbf{x}) = \int_{T_H} \Pi^{(2)}_{D,H}(\mathbf{x},\mathbf{y})\,\phi(\mathbf{y})\,ds(\mathbf{y}), \qquad \mathbf{x} \in U_H. \tag{11}$$

Remark 3.5. Note that from Theorem 2.3 (iii) it follows that for arbitrary $\phi \in [L^\infty(T_h)]^2$ the integral in (11) exists as an improper integral.

Remark 3.6. Apparently the definition of the UPRC depends on the choice of the parameters $\tilde{\lambda}$ and $\tilde{\mu}$ in the definition of the generalized stresses. However, Theorem 3.7 below shows that the definition and the density ϕ itself are in fact independent of these numbers.

The following theorem characterizes the UPRC further and also establishes that it is satisfied by any radiating solution (see also [6, Theorem 2.9]).

THEOREM 3.7. *Given* $a \in \mathbb{R}$ *and* $\mathbf{u} : U_a \to \mathbb{C}^2$*, the following statements are equivalent:*

(i) $\mathbf{u} \in \left[C^2(U_a)\right]^2$, $\mathbf{u} \in [L^\infty(U_a \setminus U_H)]^2$ *for all* $H > a$, $\Delta^* \mathbf{u} + \omega^2\mathbf{u} = 0$ *in* U_a*, and* $\mathbf{u}$ *satisfies the UPRC in* U_a*.*

(ii) $\mathbf{u} \in \left[C^2(U_a)\right]^2$, $\mathbf{u} \in [L^\infty(U_a \setminus U_H)]^2$ *for all* $H > a$, $\Delta^* \mathbf{u} + \omega^2\mathbf{u} = 0$ *in* U_a*, and for some* $H > a$ *and* ϕ_1, $\phi_2 \in L^\infty(T_H)$,

$$\mathbf{u}(\mathbf{x}) = 2\ \mathrm{grad} \int\limits_{T_H} \frac{\partial \Phi_p}{\partial y_2}(\mathbf{x},\mathbf{y})\,\phi_1(\mathbf{y})\,ds(\mathbf{y}) + 2\ \mathrm{grad}^\perp \int\limits_{T_H} \frac{\partial \Phi_s}{\partial y_2}(\mathbf{x},\mathbf{y})\,\phi_2(\mathbf{y})\,ds(\mathbf{y})$$

for all $\mathbf{x} \in U_H$*, where* Φ_p *and* Φ_s *denote the fundamental solutions for the Helmholtz equation with* k *replaced by* k_p *and* k_s*, respectively.*

(iii) $\mathbf{u} \in [L^\infty(U_a \setminus U_H)]^2$ *for all* $H > a$ *and there exists a sequence* $(\mathbf{u}_n)$ *of radiating solutions such that* $\mathbf{u}_n(\mathbf{x}) \to \mathbf{u}(\mathbf{x})$ *uniformly on compact subsets of* U_a *and*

$$\sup_{\mathbf{x} \in U_H \setminus U_{h'}, n \in N} |\mathbf{u}_n(\mathbf{x})| < \infty \tag{12}$$

for all $H, h' \in \mathbb{R}$ *satisfying* $h' > H > a$*.*

(iv) $\mathbf{u}$ *satisfies* (11) *for* $H = a$ *and some* $\phi \in [L^\infty(T_a)]^2$*.*

(v) $\mathbf{u} \in [L^\infty(U_a \setminus U_H)]^2$ *for some* $H > a$ *and* $\mathbf{u}$ *satisfies* (11) *for each* $H > a$ *with* $\phi = \mathbf{u}|_{T_H}$*.*

(vi) $\mathbf{u} \in \left[C^2(U_a)\right]^2$, $\mathbf{u} \in [L^\infty(U_a \setminus U_H)]^2$ *for all* $H > a$, $\Delta^* \mathbf{u} + \omega^2\mathbf{u} = 0$ *in* U_a*, and for every* $H > a$ *and radiating solution in* U_a, $\mathbf{w}$*, such that the restrictions of* $\mathbf{w}$ *and* $\mathbf{Pw}$ *to* T_H *are in* $\left[L^1(T_H)\right]^2$*, there holds*

$$\int_{T_H} (\mathbf{u} \cdot \mathbf{Pw} - \mathbf{w} \cdot \mathbf{Pu})\,ds = 0. \tag{13}$$

Proof. (i) ⇒ (ii): With H chosen so that (11) holds, we introduce the functions

$$\begin{array}{rcl} \Psi_{p,k}(\mathbf{x},\mathbf{y}) & := & -\frac{1}{k_p^2}\,\mathrm{div}_{\mathbf{x}}\,\Pi^{(2)}_{D,H,\cdot k}(\mathbf{x},\mathbf{y}), \\ \Psi_{s,k}(\mathbf{x},\mathbf{y}) & := & -\frac{1}{k_s^2}\,\mathrm{div}^\perp_{\mathbf{x}}\,\Pi^{(2)}_{D,H,\cdot k}(\mathbf{x},\mathbf{y}), \end{array} \qquad k = 1, 2,$$

and rewrite $\mathbf{u}(\mathbf{x})$ for $\mathbf{x} \in U_H$ as

$$\begin{aligned}\mathbf{u}(\mathbf{x}) &= \mathbf{u}_p(\mathbf{x}) + \mathbf{u}_s(\mathbf{x}) \\ &= \operatorname{grad} \int_{T_H} \sum_{k=1}^{2} \Psi_{p,k}(\mathbf{x},\mathbf{y})\, \phi_k(\mathbf{y})\, ds(\mathbf{y}) \\ &\quad + \operatorname{grad}^{\perp} \int_{T_H} \sum_{k=1}^{2} \Psi_{s,k}(\mathbf{x},\mathbf{y})\, \phi_k(\mathbf{y})\, ds(\mathbf{y}). \end{aligned} \tag{14}$$

Limiting our attention to the first integral for the moment, we define

$$\begin{aligned}\mathbf{v}_N(\mathbf{x}) &= \int_{T_H(N)} \sum_{k=1}^{2} \Psi_{p,k}(\mathbf{x},\mathbf{y})\, \phi_k(\mathbf{y})\, ds(\mathbf{y}), \\ \mathbf{v}(\mathbf{x}) &= \int_{T_H} \sum_{k=1}^{2} \Psi_{p,k}(\mathbf{x},\mathbf{y})\, \phi_k(\mathbf{y})\, ds(\mathbf{y}).\end{aligned}$$

For $H' > H$, the vector fields $\mathbf{v}_N$ are solutions to the Helmholtz equation $\Delta \mathbf{v}_N + k_p^2 \mathbf{v}_N = 0$ in $U_{H'}$. By Theorem 2.2 (v) and two applications of Lemma A.1, we see that they are furthermore radiating in $U_{H'}$. By Theorem 2.2 (iv) together with Lemma A.1, there also holds $\mathbf{v}_N(\mathbf{x}) \to \mathbf{v}(\mathbf{x})$ uniformly on compact subsets of $U_{H'}$. For $h' > H'$, by Remark 2.5, we finally see that

$$\sup_{\mathbf{x} \in U_{H'} \setminus U_{h'}, n \in \mathbb{N}} |\mathbf{v}_N(\mathbf{x})| < \infty.$$

So by Theorem 2.1 in [6], $\mathbf{v}$ satisfies the UPRC for the Helmholtz equation (see Definition 3.2), which is the assertion. The argument for the second integral in (14) is identical.

(ii) ⇒ (iii): Set $\Psi_1 := -1/k_p^2 \operatorname{div} \mathbf{u}$ and $\Psi_2 := -1/k_s^2 \operatorname{div}^{\perp} \mathbf{u}$. Then (ii) implies that for all $\mathbf{x} \in U_H$ there holds

$$\begin{aligned}\Psi_1(\mathbf{x}) &= 2 \int_{T_H} \frac{\partial \Phi_p}{\partial y_2}(\mathbf{x},\mathbf{y})\, \phi_1(\mathbf{y})\, ds(\mathbf{y}), \\ \Psi_2(\mathbf{x}) &= 2 \int_{T_H} \frac{\partial \Phi_s}{\partial y_2}(\mathbf{x},\mathbf{y})\, \phi_2(\mathbf{y})\, ds(\mathbf{y}).\end{aligned}$$

From the equivalence of (i) and (ii) in Theorem 2.9 in [6], it follows that there exist sequences $(\Psi_j^{(n)})$ $(j = 1, 2)$ of radiating solutions to the Helmholtz equation with $k = k_p$ and $k = k_s$, respectively, such that $\Psi_j^{(n)}(\mathbf{x}) \to \Psi_j(\mathbf{x})$ uniformly on compact subsets of U_a and

$$\sup_{\mathbf{x} \in U_a \setminus U_h, n \in N, j=1,2} |\Psi_j^{(n)}(\mathbf{x})| < \infty$$

for all $h > a$. Set

$$\mathbf{u}_n(\mathbf{x}) := \operatorname{grad}\, \Psi_1^{(n)}(\mathbf{x}) + \operatorname{grad}^{\perp}\, \Psi_2^{(n)}(\mathbf{x}).$$

Lemma A.1 then implies (12) and that $\mathbf{u}_n(\mathbf{x})$ converges to $\mathbf{u}(\mathbf{x})$ uniformly on compact subsets of U_a.

(iii) ⇒ (vi): Suppose $H > a$ and set $D := U_H \cap B_R(0)$ for some $R > H$, where $B_R(0)$ denotes the open ball with center 0 and radius R. Further assume $\mathbf{w}$ to be a radiating solution in U_a, such that the restrictions of $\mathbf{w}$ and $\mathbf{Pw}$ to T_H are in $\left[L^1(T_H)\right]^2$. Then

$$\int_{\partial D} \{\mathbf{u}_n \cdot \mathbf{Pw} - \mathbf{w} \cdot \mathbf{Pu}_n\}\, ds = 0$$

follows from the third generalized Betti formula (6). Letting $R \to \infty$ and using the fact that $\mathbf{w}$ and $\mathbf{u}_n$ are radiating solutions to the Navier equation, we conclude that

$$\int_{T_H} \{\mathbf{u}_n \cdot \mathbf{Pw} - \mathbf{w} \cdot \mathbf{Pu}_n\}\, ds = 0.$$

Taking the limit as $n \to \infty$, recalling (12) and using Theorem 2.2 (iv) and Lemma A.1, we see that (13) holds. The remaining assertion follows from Corollary A.2.

(vi) ⇒ (i),(v): It suffices to show that (11) holds for all $H > a$ with $\phi = \mathbf{u}|_{T_H}$.

Given $H > a$ and $\mathbf{x} \in U_H$, choose $h', A \in \mathbb{R}$, with $h' > x_2 > H$ and $A > |x_1|$. Set $B := \{\mathbf{y} \in U_H \setminus \overline{U}_{h'} : |y_1| < A\}$. Then, by Theorem 2.3 (v),

$$\mathbf{u}(\mathbf{x}) = \int_{\partial B} \left\{\Gamma_{D,H}(\mathbf{x},\mathbf{y})\, \mathbf{Pu}(\mathbf{y}) - \Pi^{(2)}_{D,H}(\mathbf{x},\mathbf{y})\, \mathbf{u}(\mathbf{y})\right\} ds(\mathbf{y}).$$

Letting $A \to \infty$ and recalling $\mathbf{u} \in [L^\infty(U_a \setminus U_{h'})]^2$ as well as Theorem 2.2 (ii) and (iv) and Theorem 2.3 (iii), we obtain that

$$\begin{aligned}\mathbf{u}(\mathbf{x}) = &\int_{T_{h'}} \left\{\Gamma_{D,H}(\mathbf{x},\mathbf{y})\, \mathbf{Pu}(\mathbf{y}) - \Pi^{(2)}_{D,H}(\mathbf{x},\mathbf{y})\, \mathbf{u}(\mathbf{y})\right\} ds(\mathbf{y})\\ &+ \int_{T_H} \Pi^{(2)}_{D,H}(\mathbf{x},\mathbf{y})\, \mathbf{u}(\mathbf{y})\, ds(\mathbf{y}).\end{aligned}$$

By applying (13) with $\mathbf{w}$ equal to each of the rows of $\Gamma_{D,H}(\mathbf{x},\cdot)$ in turn, the integral over $T_{h'}$ is seen to vanish.

(v) ⇒ (iv): Introducing, for $\alpha \in \mathbb{R}$, the mapping

$$\eta_\alpha(\mathbf{z}) := (z_1, z_2 + \alpha)^\top,$$

we have from (v) that

$$\mathbf{u}(\mathbf{x}) = \int_{T_a} \Pi^{(2)}_{D,H}(\mathbf{x}, \eta_{H-a}(\mathbf{z}))\, \mathbf{u}(\eta_{H-a}(\mathbf{z}))\, ds(\mathbf{z}), \qquad \mathbf{x} \in U_H. \tag{15}$$

As $\mathbf{u} \in [L^\infty(U_a \setminus U_H) \cap C(U_a)]^2$ for some $H > a$, the densities $\mathbf{u}(\eta_{H-a}(\cdot))$ are all in some ball in $[L^\infty(T_a)]^2$ for H close enough to a. Recalling that the unit ball in $[L^\infty(T_a)]^2$ is weak$*$ sequentially compact, there thus exists a sequence (H_n) with $H_n \to a$ and $\mathbf{u}(\eta_{H_n-a}(\cdot)) \to \phi \in [L^\infty(T_a)]^2$. Taking the limit as $H \to a$, through this sequence in (15) we now conclude that (11) holds for $H = a$ with this ϕ.

(iv) ⇒ (iii): As (11) is satisfied with $h = a$, it follows from Theorem 2.3 (iii) that

$$|\mathbf{u}(\mathbf{x})| \le \|\phi\|_\infty\, g(x_2), \qquad \mathbf{x} \in U_a, \tag{16}$$

where $g \in C(\mathbb{R})$. Setting

$$\mathbf{u}_n(\mathbf{x}) := \int_{T_a(n)} \Pi^{(2)}_{D,a}(\mathbf{x},\mathbf{y})\, \phi(\mathbf{y})\, ds(\mathbf{y}), \qquad \mathbf{x} \in U_a,$$

$\mathbf{u} \in [L^\infty(U_a \setminus U_h)]^2$ for all $h > a$ and (12) follows from (16). That $\mathbf{u}_n(\mathbf{x})$ converges to $\mathbf{u}(\mathbf{x})$ uniformly on compact subsets of U_a, and that $\mathbf{u}_n$ is radiating, is also easily seen from Theorem 2.3 (iii). $\square$

Remark 3.8. In the case of a periodic boundary, one usually imposes a radiation condition using the Rayleigh expansion [2, 10, 14, 15]. Assume f to be 2π-periodic. Then $\mathbf{u} \in BC(\Omega)$ is said to satisfy the Rayleigh expansion radiation condition (RERC) if, for $x_2 > \max f$, it has an expansion of the form

$$\mathbf{u}(\mathbf{x}) = \sum_{n\in\mathbb{Z}} \left\{ u_{p,n} \begin{pmatrix} \alpha_n \\ \beta_n \end{pmatrix} \mathrm{e}^{i(\alpha_n x_1 + \beta_n x_2)} + u_{s,n} \begin{pmatrix} \gamma_n \\ -\alpha_n \end{pmatrix} \mathrm{e}^{i(\alpha_n x_1 + \gamma_n x_2)} \right\},$$

where $\alpha \in \mathbb{R}$, $\alpha \neq 0$, $u_{p,n}$, $u_{s,n} \in \mathbb{C}$ $(n \in \mathbb{Z})$, $\alpha_n := \alpha + n$,

$$\beta_n := \begin{cases} \sqrt{k_p^2 - \alpha_n^2}, & \alpha_n^2 \le k_p^2, \\ i\sqrt{\alpha_n^2 - k_p^2}, & \alpha_n^2 > k_p^2, \end{cases} \qquad \gamma_n := \begin{cases} \sqrt{k_s^2 - \alpha_n^2}, & \alpha_n^2 \le k_s^2, \\ i\sqrt{\alpha_n^2 - k_s^2}, & \alpha_n^2 > k_s^2. \end{cases}$$

A field $\mathbf{u}$ satisfying the RERC is quasi-periodic with phase-shift α in $U_{\max f}$; that is, for all $\mathbf{x} = (x_1, x_2)^\top \in U_{\max f}$,

$$\mathbf{u}(x_1 + 2\pi, x_2) = \mathrm{e}^{i\alpha 2\pi}\, \mathbf{u}(x_1, x_2).$$

From Remark 2.14 in [6] and the equivalence of statements (i) and (ii) in Theorem 3.7, it follows that any bounded solution to the Navier equation $\mathbf{u}$ in Ω that satisfies the UPRC in Ω and is quasi-periodic in Ω with phase-shift α also satisfies the RERC. Conversely, by the same arguments, a bounded, quasi-periodic solution to the Navier equation in Ω, satisfying the RERC, also satisfies the UPRC.

4. Uniqueness for the scattering problem with a rigid rough surface.

We will now address the goal of this paper, to prove uniqueness of solution to the scattering problem for a rigid rough surface. Let $\mathbf{u}^{inc}$ denote the incident field. We require only that $\mathbf{u}^{inc}$ is a solution to the Navier equation in some neighborhood of $S = \partial\Omega$ and that $\mathbf{g} := \mathbf{u}^{inc}|_S \in BC(S)$. The problem is then to find the scattered field $\mathbf{u}$ so that the total field $\mathbf{u}^{inc} + \mathbf{u}$ vanishes on S. Mathematically, this scattering problem will be formulated as the following boundary value problem.

Problem 4.1. Find a vector field $\mathbf{u} \in [C^2(\Omega) \cap C(\overline{\Omega}) \cap H^1_{loc}(\bar{\Omega})]^2$ that satisfies

1. the Navier equation $\Delta^* \mathbf{u} + \omega^2 \mathbf{u} = 0$ in Ω,
2. the Dirichlet boundary condition $\mathbf{u} = \mathbf{g}$ on S for some vector field $\mathbf{g} \in [BC(S)]^2$,
3. the vertical growth rate condition

$$\sup_{\mathbf{x}\in\Omega} x_2^\beta \, |\mathbf{u}(\mathbf{x})| < \infty \tag{17}$$

for some $\beta \in \mathbb{R}$, and

4. the UPRC in Ω.

Remark 4.2. A solution of Problem 4.1 satisfies statement (i) of Theorem 3.7 with any $a > \sup f$.

From Remark 3.8 we see that, in the case when f is periodic and the Dirichlet data $\mathbf{g}$ is quasi-periodic, Problem 4.1 reduces to the diffraction grating problem considered in [1, 2], if we assume additionally that the solution $\mathbf{u}$ is quasi-periodic. The diffraction grating problem was shown in [1, 2] to be uniquely solvable. Thus we know that

Problem 4.1 admits solutions, at least in the case when f is periodic and $\mathbf{g}$ is quasi-periodic. We now show that Problem 4.1 has at most one solution in every case. This result implies for the diffraction grating problem that the additional assumption on the solution of being quasi-periodic can in fact be dropped.

In all of what follows, let h denote a real number with $h < \inf f$. The first step in the uniqueness proof will be the following representation theorem.

THEOREM 4.3. *Let* $\mathbf{u}$ *be a solution to Problem* 4.1 *with* $\mathbf{g} \equiv 0$. *Then* $\mathbf{u} \in [C^1(\bar{\Omega})]^2$, *its first derivatives are bounded in* D_H *for any* $H > \sup f$, *and*

$$\mathbf{u}(\mathbf{x}) = \int_S \Gamma_{D,h}(\mathbf{x},\mathbf{y})\, \mathbf{P}\mathbf{u}(\mathbf{y})\, ds(\mathbf{y})$$

for all $\mathbf{x} \in \Omega$.

Proof. That $\mathbf{u} \in [C^1(\bar{\Omega})]^2$ and its first derivatives are bounded in D_H, $H > \sup f$, is a consequence of Theorem A.3. For $\mathbf{x} \in \Omega$, choose $h', A \in \mathbb{R}$, with $h' > \max\{x_2, \sup f\}$ and $A > |x_1|$. Then, by Theorem 2.3 (v), there holds

$$\mathbf{u}(\mathbf{x}) = \int_{\partial D_{h'}(A)} \left\{ \Gamma_{D,h}(\mathbf{x},\mathbf{y})\, \mathbf{P}\mathbf{u}(\mathbf{y}) - \Pi^{(2)}_{D,h}(\mathbf{x},\mathbf{y})\, \mathbf{u}(\mathbf{y}) \right\} ds(\mathbf{y}).$$

By applying Lemma A.1, we see that the growth rate condition (17) for $\mathbf{u}$ also holds for any first derivative of $\mathbf{u}$. Letting $A \to \infty$ and recalling Theorems 2.2 (iv) and 2.3 (iii) then yields

$$\mathbf{u}(\mathbf{x}) = \int_{T_{h'}} \left\{ \Gamma_{D,h}(\mathbf{x},\mathbf{y})\, \mathbf{P}\mathbf{u}(\mathbf{y}) - \Pi^{(2)}_{D,h}(\mathbf{x},\mathbf{y})\, \mathbf{u}(\mathbf{y}) \right\} ds(\mathbf{y}) \\ + \int_S \Gamma_{D,h}(\mathbf{x},\mathbf{y})\, \mathbf{P}\mathbf{u}(\mathbf{y})\, ds(\mathbf{y}).$$

The proof is now completed by recalling Remark 4.2 and the equivalence of (i) and (vi) in Theorem 3.7, by which the integral over $T_{h'}$ vanishes. □

Let us now introduce some functionals that will be of importance in the following arguments. Let $h' > \sup f$, $A > 0$, and $\mathbf{u} \in C^1(\bar{\Omega})$. We define

$$\begin{aligned} I(h',A)[\mathbf{u}] &:= \int_{T_{h'}(A)} \Bigg\{ (2\mu+\lambda) \left(\left| \frac{\partial u_2}{\partial x_2} \right|^2 - \left| \frac{\partial u_1}{\partial x_1} \right|^2 \right) \\ &\qquad + \mu \left(\left| \frac{\partial u_1}{\partial x_2} \right|^2 - \left| \frac{\partial u_2}{\partial x_1} \right|^2 \right) + \omega^2 |\mathbf{u}|^2 \Bigg\} ds, \\ J_1(h',A)[\mathbf{u}] &:= 2\,\mathrm{Re} \int_{\gamma(h',A)} \frac{\partial \bar{\mathbf{u}}}{\partial x_2} \cdot \mathbf{P}\mathbf{u}\, ds, \\ J_2(h',A)[\mathbf{u}] &:= \mathrm{Im} \int_{\gamma(h',A)} \bar{\mathbf{u}} \cdot \mathbf{P}\mathbf{u}\, ds, \\ K(h',A)[\mathbf{u}] &:= \mathrm{Im} \int_{T_{h'}(A)} \bar{\mathbf{u}} \cdot \mathbf{P}\mathbf{u}\, ds. \end{aligned}$$

Recall the assumptions on the direction of the normal vectors in section 2. The following lemma is of fundamental importance.

LEMMA 4.4. *Suppose* $\mathbf{u}$ *satisfies statement* (ii) *in Theorem* 3.7 *with* $H > \sup f$ *and some densities* $\phi_j \in L^2(T_H) \cap L^\infty(T_H)$ $(j = 1, 2)$. *Then, for all* $h' > H$, *there* *holds*

$$I(h',\infty)[\mathbf{u}] \le 2k_s\, K(h',\infty)[\mathbf{u}].$$

Proof. Choose $H > \sup f$ so that the representation for $\mathbf{u}$ in U_H according to statement (ii) of Theorem 3.7 holds. Then the argument presented for the derivation of (29) in [4] yields

$$\mathbf{u}(\mathbf{x}) = \frac{i}{2\pi}\int_{-\infty}^{\infty} \tilde{\phi}_1(t)\begin{pmatrix} t \\ \gamma_p\end{pmatrix} \mathrm{e}^{i(tx_1+\gamma_p x_2)} + \tilde{\phi}_2(t)\begin{pmatrix}\gamma_s \\ -t\end{pmatrix}\mathrm{e}^{i(tx_1+\gamma_s x_2)}\, dt, \qquad \mathbf{x}\in U_H,$$

where $\tilde{\phi}_1(t) := \mathrm{e}^{-i\gamma_p H}\hat{\phi}_1(t)$, $\tilde{\phi}_2(t) := \mathrm{e}^{-i\gamma_s H}\hat{\phi}_2(t)$, and $\hat{\phi}_j$ denotes the Fourier transform of $\phi_j(y_1,y_2)$ with respect to y_1 $(j=1,2)$.

By an application of Parseval's theorem we derive from this representation, for any $h' > H$, by long but straightforward calculations that

$$I(h',\infty)[\mathbf{u}] = 2\omega^2\left\{\int_{-k_p}^{k_p} |\tilde{\phi}_1|^2\gamma_p^2\, dt + \int_{-k_s}^{k_s}|\tilde{\phi}_2|^2\gamma_s^2\, dt\right\}.$$

On the other hand, a similar calculation shows that

$$K(h',\infty)[\mathbf{u}] = \omega^2\left\{\int_{-k_p}^{k_p} |\tilde{\phi}_1|^2\gamma_p\, dt + \int_{-k_s}^{k_s}|\tilde{\phi}_2|^2\gamma_s\, dt\right\}.$$

The assertion is now proven by noting $k_p \ge \gamma_p$ on $[-k_p,k_p]$, $k_s\ge\gamma_s$ on $[-k_s,k_s]$, and $k_s > k_p$. □

Another, simpler relation involving these functionals is stated in the following lemma.

LEMMA 4.5. *Let* $\mathbf{u}$ *be a solution to Problem* 4.1 *with* $\mathbf{g}\equiv 0$. *Further assume* $h' > \max f$ *and* $A > 0$. *Then*

$$K(h',A)[\mathbf{u}] = -J_2(h',A)[\mathbf{u}].$$

Proof. For the proof apply the third generalized Betti formula (6) to $\mathbf{u}$ and $\bar{\mathbf{u}}$ in $D_{h'}(A)$. □

Assume now that $\mathbf{u}$ is a solution to Problem 4.1 with $\mathbf{g}\equiv 0$. As $\mathbf{u}$ and its tangential derivatives vanish on S, $\mathbf{Pu}$ has the simple form

$$\mathbf{Pu} = \mu\frac{\partial\mathbf{u}}{\partial\mathbf{n}} + (\lambda+\mu)\,\mathbf{n}\,\mathrm{div}\,\mathbf{u} \qquad \text{on } S. \tag{18}$$

We thus conclude that

$$\int_{S(A)} \frac{\partial\bar{\mathbf{u}}}{\partial x_2}\cdot\mathbf{Pu}\, ds = \int_{S(A)}\left\{\mu n_2\left|\frac{\partial\mathbf{u}}{\partial\mathbf{n}}\right|^2 + (\lambda+\mu)n_2|\mathrm{div}\,\mathbf{u}|^2\right\} ds \tag{19}$$

for any $A>0$. For any $h' > \sup f$, by the first Betti formula (5) there also holds

$$\int_{\partial D_{h'}(A)} \frac{\partial\bar{\mathbf{u}}}{\partial x_2}\cdot\mathbf{Pu}\, ds = \int_{D_{h'}(A)} \mathcal{E}_{\tilde{\mu},\tilde{\lambda}}\left(\frac{\partial\bar{\mathbf{u}}}{\partial x_2},\mathbf{u}\right) - \omega^2\frac{\partial\bar{\mathbf{u}}}{\partial x_2}\cdot\mathbf{u}\, d\mathbf{x}.$$

By an integration by parts we thus conclude that

$$2\,\mathrm{Re}\int_{\partial D_{h'}(A)}\frac{\partial\bar{\mathbf{u}}}{\partial x_2}\cdot\mathbf{P}\mathbf{u}\,ds=\int_{T_{h'}(A)}\mathcal{E}_{\tilde{\mu},\tilde{\lambda}}(\bar{\mathbf{u}},\mathbf{u})-\omega^2|\mathbf{u}|^2\,ds$$
$$+\int_{S(A)}\left\{\mu n_2\left|\frac{\partial\mathbf{u}}{\partial\mathbf{n}}\right|^2+(\lambda+\mu)n_2|\mathrm{div}\,\mathbf{u}|^2\right\}ds. \tag{20}$$

Combining (19) and (20) now yields

$$\int_{S(A)}\left\{\mu n_2\left|\frac{\partial\mathbf{u}}{\partial\mathbf{n}}\right|^2+(\lambda+\mu)n_2|\mathrm{div}\,\mathbf{u}|^2\right\}ds$$
$$=\mathrm{Re}\int_{T_{h'}(A)}\left\{\mathcal{E}_{\tilde{\mu},\tilde{\lambda}}(\bar{\mathbf{u}},\mathbf{u})-2\frac{\partial\bar{\mathbf{u}}}{\partial x_2}\cdot\mathbf{P}\mathbf{u}-\omega^2|\mathbf{u}|^2\right\}ds-J_1(h',A)[\mathbf{u}].$$

It is also not difficult to see that

$$\mathrm{Re}\int_{T_{h'}}\left\{\mathcal{E}_{\tilde{\mu},\tilde{\lambda}}(\bar{\mathbf{u}},\mathbf{u})-2\frac{\partial\bar{\mathbf{u}}}{\partial x_2}\cdot\mathbf{P}\mathbf{u}-\omega^2|\mathbf{u}|^2\right\}ds=-I(h',A)[\mathbf{u}],$$

so we finally conclude that

$$0\le-\int_{S(A)}\left\{\mu n_2\left|\frac{\partial\mathbf{u}}{\partial\mathbf{n}}\right|^2+(\lambda+\mu)n_2|\mathrm{div}\,\mathbf{u}|^2\right\}ds$$
$$=I(h',A)[\mathbf{u}]+J_1(h',A)[\mathbf{u}]. \tag{21}$$

The rest of the derivation of the uniqueness result is now a rather straightforward adaptation of the method presented in [7] for the Helmholtz equation case. Let us introduce the vector fields $\mathbf{v}_A$ defined for $A>0$ by

$$\mathbf{v}_A(\mathbf{x}):=\int_{S(A)}\Gamma_{D,h}(\mathbf{x},\mathbf{y})\,\mathbf{P}\mathbf{u}(\mathbf{y})\,ds(\mathbf{y}).$$

Using the Cauchy–Schwartz inequality and Theorem 2.2 (iv), we find that $\mathbf{v}_A|_{h'}\in[L^2(T_{h'})\cap BC(T_{h'})]^2$ for all $h'>\sup f$. As $\mathbf{v}_A$ is a radiating solution to the Navier equation for every $A\in\mathbb{R}$, it is seen to satisfy statement (iii) of Theorem 3.7 and thus also statement (ii) of that theorem. Thus, by Lemma 4.4,

$$I(h',\infty)[\mathbf{v}_A]\le 2k_s\,K(h',\infty)[\mathbf{v}_A]. \tag{22}$$

Now set $w(x_1):=|\mathbf{P}\mathbf{u}(x_1,f(x_1))|$ for $x_1\in\mathbb{R}$. Then

$$\int_{-A}^{A}|w(x_1)|^2\,dx_1\le\int_{S(A)}|\mathbf{P}\mathbf{u}|^2\,ds\le(1+\|f'\|^2_{\infty;\mathbb{R}})^{1/2}\int_{-A}^{A}|w(x_1)|^2\,dx_1 \tag{23}$$

follows. Using Theorem 2.2 (iv) and Lemma A.1 we obtain the estimates

$$|\Gamma_{D,h}(\mathbf{x},\mathbf{y})|,\ \left|\frac{\partial}{\partial x_j}\Gamma_{D,h}(\mathbf{x},\mathbf{y})\right|\le C(1+|x_1-y_1|)^{-3/2},\qquad j=1,2,$$

for $\mathbf{x} \in T_{h'}$, $\mathbf{y} \in S$, where C is some positive constant depending only on h' and h. This yields the estimates

$$\begin{aligned} |\mathbf{v}_A(\mathbf{x})|,\ \left|\tfrac{\partial \mathbf{v}_A}{\partial x_j}(\mathbf{x})\right| &\leq C\,W_A(x_1), \\ |\mathbf{u}(\mathbf{x}) - \mathbf{v}_A(\mathbf{x})| &\leq C\,(W_\infty(x_1) - W_A(x_1)), \\ \left|\tfrac{\partial \mathbf{u}}{\partial x_j}(\mathbf{x}) - \tfrac{\partial \mathbf{v}_A}{\partial x_j}(\mathbf{x})\right| &\leq C\,(W_\infty(x_1) - W_A(x_1)) \end{aligned} \tag{24}$$

for $\mathbf{x} \in T_{h'}$, $j = 1, 2$, with certain generic constants C, where

$$W_A(x_1) := \int_{-A}^{A} (1 + |x_1 - y_1|)^{-3/2}\, w(y_1)\, dy_1, \qquad x_1 \in \mathbb{R}.$$

Recalling (18), we can estimate by (21)–(23) and Lemma 4.5 that

$$\begin{aligned} \int_{-A}^{A} |w(x_1)|^2\, dx_1 \leq -C \int_{S(A)} &\left\{ \mu n_2 \left| \frac{\partial \mathbf{u}}{\partial \mathbf{n}} \right|^2 + (\lambda + \mu) n_2 |\operatorname{div} \mathbf{u}|^2 \right\} ds \\ \leq C \Big\{ &|I(h', A)[\mathbf{u}] - I(h', A)[\mathbf{v}_A]| \\ &+ |I(h', A)[\mathbf{v}_A] - I(h', \infty)[\mathbf{v}_A]| \\ &+ 2k_s \Big[|K(h', \infty)[\mathbf{v}_A] - K(h', A)[\mathbf{v}_A]| \\ &\qquad + |K(h', A)[\mathbf{v}_A] - K(h', A)[\mathbf{u}]| \Big] \\ &+ |J_1(h', A)[\mathbf{u}]| + 2k_s |J_2(h', A)[\mathbf{u}]| \Big\}. \end{aligned} \tag{25}$$

From (24) there now follows, with some positive constant C,

$$\left.\begin{array}{r} |I(h', A)[\mathbf{v}_A] - I(h', \infty)[\mathbf{v}_A|, \\ |K(h', \infty)[\mathbf{v}_A] - K(h', A)[\mathbf{v}_A]| \end{array}\right\} \leq C \int_{\mathbb{R} \setminus [-A, A]} W_A^2(x_1)\, dx_1$$

and

$$\left.\begin{array}{r} |I(h', A)[\mathbf{u}] - I(h', A)[\mathbf{v}_A]|, \\ |K(h', A)[\mathbf{v}_A] - K(h', A)[\mathbf{u}]| \end{array}\right\} \leq C \int_{-A}^{A} (W_\infty(x_1) - W_A(x_1))\, W_\infty(x_1)\, dx_1,$$

so that we finally conclude, for some constant $c > 0$ and all $A > 0$,

$$\begin{aligned} \int_{-A}^{A} |w(x_1)|^2\, dx_1 \leq c \Big\{ &\int_{\mathbb{R} \setminus [-A, A]} W_A^2(x_1)\, dx_1 \\ &+ \int_{-A}^{A} (W_\infty(x_1) - W_A(x_1))\, W_\infty(x_1)\, dx_1 \\ &+ |J_1(h', A)[\mathbf{u}]| + |J_2(h', A)[\mathbf{u}]| \Big\}. \end{aligned} \tag{26}$$

Since (26) holds and we also have from Theorem A.3 that $w \in L^\infty(\mathbb{R})$, we can apply Lemma A in [7] to obtain that $w \in L^2(\mathbb{R})$ and, noting (23), that for all $A_0 > 0$,

$$(1 + \|f'\|^2_{\infty;\mathbb{R}})^{-1/2} \int_S |\mathbf{Pu}|^2 \, ds \le \int_{-\infty}^{\infty} |w(x_1)|^2 \, dx_1$$
$$\le c \sup_{A > A_0} \{|J_1(h', A)[\mathbf{u}]| + |J_2(h', A)[\mathbf{u}]\}|. \tag{27}$$

For $x \in D_{h'}$ with $|x_1| > 0$, we now deduce by Theorem 2.2 (iv), Theorem 4.3, and the Cauchy–Schwartz inequality that

$$\begin{aligned} |\mathbf{u}(\mathbf{x})|^2 &\le 2 \left\{ \int_{S \setminus S(|x_1|/2)} |\Gamma_{D,h}(\mathbf{x}, \mathbf{y}) \, \mathbf{Pu}(\mathbf{y})| \, ds(\mathbf{y}) \right\}^2 \\ &\quad + 2 \left\{ \int_{S(|x_1|/2)} |\Gamma_{D,h}(\mathbf{x}, \mathbf{y}) \, \mathbf{Pu}(\mathbf{y})| \, ds(\mathbf{y}) \right\}^2 \\ &\le C_1 \int_{S \setminus S(|x_1|/2)} |\mathbf{Pu}|^2 \, ds + C_2 \left(\frac{|x_1|}{2} \right)^{-2}, \end{aligned}$$

where

$$C_1 = 16 \sup_{\mathbf{x} \in D_{h'}} \int_S \max_{j,k=1,2} |\Gamma_{D,h,jk}(\mathbf{x}, \mathbf{y})|^2 \, ds(\mathbf{y}) < \infty$$

by Remark 2.4 and

$$C_2 = 32 \, \|\mathcal{H}\|^2_{C([0,h'-h]^2)} \, (1 + \|f'\|_{\infty;\mathbb{R}})^{1/2} \, \|\mathbf{Pu}\|_{[L^2(S)]^2}.$$

Thus, $\mathbf{u}(\mathbf{x}) \to 0$ as $|x_1| \to \infty$ ($\mathbf{x} \in D_{h'}$), uniformly in x_2. From Lemma A.1 and Theorem A.3 it now follows that $J_j(A)[\mathbf{u}] \to 0$ as $A \to \infty$ ($j = 1, 2$), and consequently, by (27), that $\mathbf{Pu} = 0$ on S. Recalling Theorem 4.3 once more, we conclude that $\mathbf{u} \equiv 0$ in Ω. We have thus shown the following theorem.

THEOREM 4.6. *Let* $\mathbf{u}$ *and* $\mathbf{v}$ *be solutions of Problem* 4.1 *with the same Dirichlet data* $\mathbf{g}$. *Then* $\mathbf{u} \equiv \mathbf{v}$ *in* Ω.

Appendix. Regularity results. The following regularity results for solutions to the Navier equation, which are special cases of general results for systems of second order elliptic equations, are used in this paper.

LEMMA A.1. *Given a domain* $G \subset \mathbb{R}^2$, *let* $\mathbf{u} \in [L^\infty(G)]^2$ *be a solution to the Navier equation* (3) *in* G *in a distributional sense. Assume* $G' \subset\subset G$ *and set* $d := d(\partial G', \partial G)$. *Then* $\mathbf{u} \in [C^1(\overline{G'})]^2$ *and, for all* $\mathbf{x} \in G'$,

$$|\operatorname{grad} u_k(\mathbf{x})| \le C \, (1 + d^{-1}) \, \|\mathbf{u}\|_{\infty;G}, \qquad k = 1, 2,$$

where C *is only dependent on* μ, λ, *and* ω.

Proof. The proof follows from application of estimates in Fichera [9] and Sobolev's imbedding theorem. □

By applications of this result we immediately obtain the following corollary.

COROLLARY A.2. *Given a domain* $G \subset \mathbb{R}^2$, *let* $(\mathbf{v}_n) \subset [L^\infty(G)]^2$ *be a sequence of solutions to the Navier equation in* G *and, for some vector field* $\mathbf{v}$, *suppose that*

$\mathbf{v}_n(\mathbf{x}) \to \mathbf{v}(\mathbf{x})$ *uniformly on compact subsets of* G. *Then* $\mathbf{v} \in [C^2(G)]^2$ *and is a solution to the Navier equation in* G.

The next result can be obtained in a manner very similar to that employed for scalar elliptic equations (see, e.g., Gilbarg and Trudinger [11]). A detailed proof is given in [3, Theorem 2.7].

THEOREM A.3. *Let* $\mathbf{u} \in [C^2(\Omega) \cap C(\bar{\Omega}) \cap H^1_{loc}(\bar{\Omega})]^2$ *be a solution to the Navier equation in* Ω, *bounded in* D_H *for some* $H > \sup f$, *with* $\mathbf{u} = 0$ *on* S. *Then* $\mathbf{u} \in \mathcal{V}^{1,\alpha}(\bar{\Omega})$ *and, for any* $H > \sup f$, $u \in C^{1,\alpha}(\overline{D_H})$ *with*

$$\|\mathbf{u}\|_{1,\alpha;D_H} \leq C \, \|\mathbf{u}\|_{\infty;D_H}, \tag{28}$$

where C *is a constant dependent only on* λ, μ, ω, H, *and* $\|f\|_{1,\alpha;\mathbb{R}}$.

GLOBAL EXISTENCE FOR SYSTEMS OF NONLINEAR WAVE EQUATIONS IN 3D WITH MULTIPLE SPEEDS*

THOMAS C. SIDERIS† AND SHU-YI TU‡

Abstract. Global smooth solutions to the initial value problem for systems of nonlinear wave equations with multiple propagation speeds will be constructed in the case of small initial data and nonlinearities satisfying the null condition.

Key words. systems of nonlinear wave equations, global existence, null condition

AMS subject classification. 35L70

PII. S0036141000378966

1. Introduction.

This paper is concerned with the Cauchy problem for coupled systems of quasi-linear wave equations in three space dimensions of the form

$$\partial_t^2 u^k - c_k^2 \triangle u^k = C^{jk}_{\alpha\beta}(\partial u)\partial_\alpha\partial_\beta u^j, \quad k = 1, \ldots, m,$$

subject to suitably small initial conditions. We assume that the propagation speeds are distinct, and we refer to this situation as the nonrelativistic case. Here, ∂u stands for the full space-time gradient, and $C^{jk}_{\alpha\beta}(\xi) = O(|\xi|)$ are smooth functions near the origin in $\mathbb{R}^{4m}$. We shall construct a unique global classical solution, provided that the coefficients of the nonlinear terms satisfy the null condition, which permits only certain special nonlinear self-interactions of the kth component of the solution in the kth equation. This nonrelativistic system serves as a simplified model for wave propagation problems with different speeds, such as nonlinear elasticity, charged plasmas, and magneto-hydrodynamics.

The main difficulty in the nonrelativistic case is that the smaller symmetry group of the linear operator weakens the form of the invariant Klainerman inequality; see section 6. In order to obtain a viable $L^\infty - L^2$ estimate for solutions, we utilize an additional set of weighted L^2 estimates, as has been developed in [15], [19], [20]. The advantage of this method is the total avoidance of direct estimation of the fundamental solution for the linear problem as well as any type of asymptotic constructions. We treat nondivergence form nonlinearities which may contain both spatial and temporal derivatives.

In the three-dimensional (3D) relativistic (scalar) case, the null condition was first identified and shown to lead to global existence of small solutions by Christodoulou [3] and Klainerman [13]. Without it, small solutions remain smooth "almost globally" [8], [9], [12], but as examples show, arbitrarily small initial conditions can develop singularities in finite time [7], [18]. Small solutions always exist globally in higher dimensions [11], [17], [12]. The two-dimensional (2D) relativistic case is rather more complicated. The sharpest results are given in [1], [2], but other work appeared previously in [4], [10].

The case of nonrelativistic systems in 3D has also recently been considered by Yokoyama [21]. Under the same null condition as described below, Yokoyama establishes the existence of global small solutions. However, instead of expressing the smallness condition for the initial data in terms of a neighborhood of the origin in a Sobolev space, as we do here, Yokoyama considers only data of the form $(u, \partial_t u)|_{t=0} = \varepsilon(u_0, u_1)$ for fixed C^∞ functions with compact support. Another significant difference is that Yokoyama obtains decay of solutions through direct $L^\infty - L^\infty$ estimation of the fundamental solution for the linear wave equation. By avoiding such direct estimations, our $L^\infty - L^2$ approach is much simpler. Moreover, our estimates are sharper insofar as they do not require the logarithmic growth factors used in Proposition 3.1 in [21].

An early result for 3D nonrelativistic systems was obtained by Kovalyov [16] in the semilinear case under a strong *nonresonance condition* that ruled out all nonlinear self-interactions. The 2D case has been examined in [6] and [5] using an approach similar to [21].

The statement of the main result is given in section 3 after a summary of some standard notation. The rest of the paper presents the proof. To simplify the exposition, we truncate the nonlinearity at the quadratic level, but this entails no loss of generality since the higher-order terms do not affect the global behavior of small solutions [12].

2. Notation. Points in $\mathbb{R}^4$ will be denoted by $X = (x^0, x^1, x^2, x^3) = (t, x)$. Partial derivatives will be written as $\partial_k = \partial/\partial x^k$, $k = 0, \dots, 3$, with the abbreviations $\partial = (\partial_0, \partial_1, \partial_2, \partial_3) = (\partial_t, \nabla)$. The angular-momentum operators are defined as

$$\Omega = (\Omega_1, \Omega_2, \Omega_3) = x \wedge \nabla,$$

where $\wedge$ denotes the usual vector cross product in $\mathbb{R}^3$, and the scaling operator is defined by

$$S = t\partial_t + r\partial_r = x^\alpha \partial_\alpha. \tag{2.1}$$

The collection of these seven vector fields will be labeled as

$$\Gamma = (\Gamma_0, \dots, \Gamma_7) = (\partial, \Omega, S).$$

Instead of the usual multi-index notation, we will write $a = (a_1, \dots, a_\kappa)$ for a sequence of indices $a_i \in \{0, \dots, 7\}$ of length $|a| = \kappa$, and

$$\Gamma^a = \Gamma_{a_\kappa} \cdots \Gamma_{a_1}.$$

Suppose that b and c are disjoint subsequences of a. Then we will say $b + c = a$ if $|b| + |c| = |a|$, and $b + c < a$ if $|b| + |c| < |a|$.

The d'Alembertian will be used to denote the operator

$$\Box = \mathrm{Diag}(\Box_1, \dots, \Box_m) \quad \text{with} \quad \Box_k = \partial_t^2 - c_k^2 \triangle.$$

For convenience, we will assume that the speeds are distinct

$$c_1 > \cdots > c_m > 0.$$

It is also possible to treat the case where some of the speeds are the same; see the remark following the statement of Theorem 3.1. This operator acts on vector functions $u : \mathbb{R}^4 \to \mathbb{R}^m$. The standard energy is then defined as

$$E_1(u(t)) = \sum_{k=1}^m \int_{\mathbb{R}^3} [\, |\partial_t u^k(t,x)|^2 + c_k^2 \, |\nabla u^k(t,x)|^2 \,] \, dx,$$

and higher-order derivatives will be estimated through

$$E_\kappa(u(t)) = \sum_{|a|\le\kappa-1} E_1(\Gamma^a u(t)), \qquad \kappa = 2, 3, \ldots. \tag{2.2a}$$

In order to describe the solution space, we introduce the time-independent vector fields $\Lambda = (\Lambda_1, \ldots, \Lambda_7) = (\nabla, \Omega, r\partial_r)$. Define

$$H^\kappa_\Lambda(\mathbb{R}^3) = \{f \in L^2(\mathbb{R}^3; \mathbb{R}^m) : \Lambda^a f \in L^2,\ |a| \le \kappa\}$$

with the norm

$$\|f\|_{H^\kappa_\Lambda} = \sum_{|a|\le\kappa} \|\Lambda^a f\|_{L^2}. \tag{2.2b}$$

Solutions will be constructed in the space $\dot{H}^\kappa_\Gamma(T)$ obtained by closing the set $C^\infty([0,T); C^\infty_0(\mathbb{R}^3, \mathbb{R}^m))$ in the norm $\sup_{0\le t<T} E^{1/2}_\kappa(u(t))$. Thus,

$$\dot{H}^\kappa_\Gamma(T) \subset \left\{ u(t,x) : \partial u(t,\cdot) \in \bigcap_{j=0}^{\kappa-1} C^j([0,T); H^{\kappa-1-j}_\Lambda) \right\}.$$

By (6.1) it will follow that $\dot{H}^\kappa_\Gamma(T) \subset C^{\kappa-2}([0,T) \times \mathbb{R}^3; \mathbb{R}^m)$.

An important intermediate role will be played by the weighted norm

$$\mathcal{X}_\kappa(u(t)) = \sum_{k=1}^m \sum_{|a|=2} \sum_{|b|\le\kappa-2} \|\langle c_k t - |x|\rangle \partial^a \Gamma^b u^k(t)\|_{L^2(\mathbb{R}^3)}, \tag{2.2c}$$

where we use the notation $\langle\rho\rangle = (1 + |\rho|^2)^{1/2}$.

3. Main result. Consider the initial value problem for a coupled nonlinear system of the form

$$\Box u = N(u,u) \tag{3.1}$$

in which the components of the quadratic nonlinearity depend on the form

$$N^k(u,v) = C^{ijk}_{\alpha\beta\gamma} \partial_\alpha u^i \partial_\beta \partial_\gamma v^j. \tag{3.2a}$$

Summation is performed over repeated indices regardless of their position, up or down. Greek indices range from 0 to 3 and Latin indices from 1 to m.

Existence of solutions depends on the energy method which requires the system to be symmetric:

$$C^{ijk}_{\alpha\beta\gamma} = C^{ikj}_{\alpha\beta\gamma} = C^{ijk}_{\alpha\gamma\beta}. \tag{3.2b}$$

The key assumption necessary for global existence is the following *null* condition which says that the self-interaction of each wave family is nonresonant:

$$C^{kkk}_{\alpha\beta\gamma} X_\alpha X_\beta X_\gamma = 0 \quad \text{for all} \quad X \in \mathcal{N}_k, \quad k = 1, \ldots, m, \tag{3.2c}$$

with the null cones

$$\mathcal{N}_k = \{X \in \mathbb{R}^4 : x_0^2 - c_k^2(x_1^2 + x_2^2 + x_3^2) = 0\}.$$

Theorem 3.1. *Assume that the nonlinear terms in* (3.2a) *satisfy the symmetry and null conditions* (3.2b), (3.2c). *Then the initial value problem for* (3.1) *with initial data*

$$\partial_\alpha u(0) \in H^{\kappa-1}_\Lambda(\mathbb{R}^3), \quad \kappa \geq 9,$$

satisfying

$$E^{1/2}_{\kappa-2}(u(0)) \ \exp\ C E^{1/2}_{\kappa}(u(0)) < \varepsilon, \tag{3.3}$$

with ε sufficiently small, has a unique global solution $u \in \dot{H}^\kappa_\Gamma(T)$ for every $T > 0$. The solution satisfies the bounds

$$E^{1/2}_{\kappa-2}(u(t)) < 2\varepsilon \quad \text{and} \quad E_\kappa(u(t)) \leq 4E_\kappa(u(0))\langle t\rangle^{C\varepsilon}.$$

Remark. We briefly discuss the case when some of the speeds are repeated. Suppose that only $\ell < m$ of the speeds $c_1 = c_{k_1} > c_{k_2} > \cdots > c_{k_\ell}$ are distinct. For $p = 1, \ldots, \ell$, let $I_p = \{k : 1 \leq k \leq m,\ c_k = c_{k_p}\}$. The null condition is now extended to be

$$C^{ijk}_{\alpha\beta\gamma} X_\alpha X_\beta X_\gamma = 0 \quad \text{for all} \quad X \in \mathcal{N}_{k_p},\ (i,j,k) \in I^3_p,\ p = 1, \ldots, \ell.$$

The proof can easily be adjusted to handle this more general case.

4. Commutation and null forms. In preparation for the energy estimates, we need to consider the commutation properties of the vector fields Γ with respect to the nonlinear terms. It is necessary to verify that the null structure is preserved upon differentiation.

Lemma 4.1. *Let u be solution u of* (3.1) *in $\dot{H}^\kappa_\Gamma(T)$. Assume that the null condition* (3.2c) *holds for the nonlinearity in* (3.2a). *Then for $|a| \leq \kappa - 1$,*

$$\Box\Gamma^a u = \sum_{b+c+d=a} N_d(\Gamma^b u, \Gamma^c u)$$

in which each N_d is a quadratic nonlinearity of the form (3.2a) *satisfying* (3.2c). *Moreover, if $b + c = a$, then $N_d = N$.*

Proof. First we note the well-known facts that

$$[\partial, \Box] = 0, \quad [\Omega, \Box] = 0, \quad [S, \Box] = -2\Box.$$

Recalling the definition (3.2a), we set

$$[\Gamma, N](u, v) = \Gamma N(u, v) - N(\Gamma u, v) - N(u, \Gamma v).$$

This is a quadratic nonlinearity of the form (3.2a). Thus, if $[\Gamma, N]$ is null for each Γ, then the result follows by induction. In fact, if $d = (d_1, \ldots, d_k)$, then N_d is the k-fold commutator $N_d = [\Gamma_{d_k}, [\ldots, [\Gamma_{d_1}, N]]]$.

A simple calculation shows that

$$[\partial, N](u, v) = 0 \quad \text{and} \quad [S, N](u, v) = -3N(u, v).$$

Thus, these commutators are null if N is null.

We can express the angular momentum operators as $\Omega_\lambda = \varepsilon_{\lambda\mu\nu} x_\mu \partial_\nu$, $\lambda = 1, 2, 3$, where $\varepsilon_{\lambda\mu\nu}$ is the tensor with value $+1$, -1 if $\lambda\mu\nu$ is an even, respectively, odd, permutation of 123, and with value 0 otherwise. Using this, we find that the kth component of $[\Omega_\lambda, N]$ is

$$[\Omega_\lambda, N]^k(u,v) = \widetilde{C}^{ijk}_{\alpha\beta\gamma}\partial_\alpha u^j \partial_\beta\partial_\gamma v^k$$

with

$$\widetilde{C}^{ijk}_{\alpha\beta\gamma} = [C^{ijk}_{\alpha\beta\nu}\varepsilon_{\lambda\gamma\nu} + C^{ijk}_{\nu\beta\gamma}\varepsilon_{\lambda\alpha\nu} + C^{ijk}_{\alpha\nu\gamma}\varepsilon_{\lambda\beta\nu}].$$

To see that this commutator is also null, write

$$h^k(X) = C^{kkk}_{\alpha\beta\gamma}X_\alpha X_\beta X_\gamma \quad \text{and} \quad \tilde{h}^k(X) = \widetilde{C}^{kkk}_{\alpha\beta\gamma}X_\alpha X_\beta X_\gamma.$$

Then $\tilde{h}^k(X) = -Dh^k(X)Y^\lambda$ with $Y^\lambda_\mu = \varepsilon_{\lambda\mu\nu}X_\nu$. Now the null condition says that $h^k(X) = 0$ for $X \in \mathcal{N}_k$. But since Y^λ is tangent to $\mathcal{N}_k$ at X, we have $\tilde{h}^k(X) = 0$ for $X \in \mathcal{N}_k$. This implies that $[\Omega_\lambda, N]$ is null. □

5. Estimates for null forms. The utility of the null condition is captured in the next lemma. The presence of the terms with the weight $\langle c_k t - r\rangle$ in these inequalities is explained by the absence of the Lorentz rotations in our list of vector fields Γ.

LEMMA 5.1. *Suppose that the nonlinear form $N(u,v)$ defined in* (3.2a) *satisfies the null condition* (3.2c). *Set $c_0 = \min\{c_k/2 : k = 1,\dots,m\}$. For u, v, $w \in C^2([0,T]\times\mathbb{R}^3;\mathbb{R}^m)$, and $r \geq c_0 t$, we have at any point $X = (t,x)$*

$$\text{(5.1a)} \qquad |C^{kkk}_{\alpha\beta\gamma}\partial_\alpha u^k\partial_\beta\partial_\gamma v^k| \leq \frac{C}{\langle X\rangle}\Big[|\Gamma u^k||\partial^2 v^k| + |\partial u^k||\partial\Gamma v^k| + \langle c_k t - r\rangle|\partial u^k||\partial^2 v^k|\Big]$$

and

$$\text{(5.1b)} \; |C^{kkk}_{\alpha\beta\gamma}\partial_\alpha u^k\partial_\beta v^k\partial_\gamma w^k| \leq \frac{C}{\langle X\rangle}\Big[|\Gamma u^k||\partial v^k||\partial w^k| + |\partial u^k||\Gamma v^k||\partial w^k| + |\partial u^k||\partial v^k||\Gamma w^k| + \langle c_k t - r\rangle|\partial u^k||\partial v^k||\partial w^k|\Big]$$

in which $\langle X\rangle = (1+|X|^2)^{1/2}$.

Proof. Spatial derivatives have the decomposition

$$\nabla = \frac{x}{r}\partial_r - \frac{x}{r^2}\wedge\Omega.$$

So if we introduce the two operators $D^\pm_k = \frac{1}{2}(\partial_t \pm c_k\partial_r)$ and the null vectors $Y^\pm_k = (1, \pm x/c_k r) \in \mathcal{N}_k$, we obtain

$$\text{(5.2)} \qquad (\partial_t, \nabla) = (Y^-_k D^-_k + Y^+_k D^+_k) - \Big(0, \frac{x}{r^2}\wedge\Omega\Big).$$

On the other hand, if we write

$$D^+_k = \frac{c_k}{c_k t + r}S - \frac{c_k t - r}{c_k t + r}D^-_k,$$

the formula (5.2) can be transformed into

$$\partial = Y^-_k D^-_k - \frac{c_k t - r}{c_k t + r}Y^+_k D^-_k + \frac{c_k}{c_k t + r}Y^+_k S - \Big(0, \frac{x}{r^2}\wedge\Omega\Big).$$

Thus, we have

$$\partial \equiv Y_k^- D_k^- + R. \tag{5.3a}$$

Now, we may assume that $|X| \geq 1$, for otherwise the estimates are trivial. But then it follows that $1/r$ and $1/(c_k t + r)$ are bounded by $C/\langle X \rangle$, and as a consequence we have

$$|Ru| \leq C\langle X\rangle^{-1}[|\Gamma u| + \langle c_k t - r\rangle |\partial u|]. \tag{5.3b}$$

Using (5.3a), we have

$$\begin{aligned} C^{kkk}_{\alpha\beta\gamma}\partial_\alpha u^k \partial_\beta\partial_\gamma v^k = C^{kkk}_{\alpha\beta\gamma}[&Y^-_{k\alpha}Y^-_{k\beta}Y^-_{k\gamma}D^-_k u^k (D^-_k)^2 v^k + R_\alpha u^k \partial_\beta\partial_\gamma v^k \\ &+ Y^-_{k\alpha}D^-_k u^k R_\beta \partial_\gamma v^k + Y^-_{k\alpha}D^-_k u^k Y^-_{k\beta} D^-_k R_\gamma v^k]. \end{aligned} \tag{5.4}$$

The first term in (5.4) vanishes since N obeys the null condition, and by (5.3b) the remaining terms in (5.4) have the estimate (5.1a).

The proof of (5.1b) is similar. □

6. Sobolev inequalities. The following Sobolev inequalities involve only the angular momentum operators since we are in the nonrelativistic case. The weight $\langle ct - r\rangle$ compensates for this. We use the notation defined in (2.2a), (2.2b), (2.2c).

Lemma 6.1. *Let $u \in \dot H^\kappa_\Gamma(T)$ with $\mathcal{X}_\kappa(u(t)) < \infty$.*

$$\langle r\rangle^{1/2}|\Gamma^a u(t,x)| \leq C E^{1/2}_\kappa(u(t)), \quad |a| + 2 \leq \kappa, \tag{6.1}$$

$$\langle r\rangle|\partial\Gamma^a u(t,x)| \leq C E^{1/2}_\kappa(u(t)), \quad |a| + 3 \leq \kappa, \tag{6.2}$$

$$\langle r\rangle\langle c_i t - r\rangle^{1/2}|\partial\Gamma^a u^i(t,x)| \leq C\Big[E^{1/2}_\kappa(u(t)) + \mathcal{X}_\kappa(u(t))\Big], \quad |a| + 3 \leq \kappa, \tag{6.3}$$

$$\langle r\rangle\langle c_i t - r\rangle|\partial^2\Gamma^a u^i(t,x)| \leq C\mathcal{X}_\kappa(u(t)), \quad |a| + 4 \leq \kappa. \tag{6.4}$$

Proof. This result is essentially Proposition 3.3 in [20] (see also [14]). □

7. Weighted decay estimates. The main extra step in the nonrelativistic case is to control the weighted norm $\mathcal{X}_\kappa(u(t))$. This will be accomplished in this section by a type of bootstrap argument.

Lemma 7.1. *Let $u \in \dot H^\kappa_\Gamma(T)$. Then*

$$\mathcal{X}_\kappa(u(t)) \leq C\left[E^{1/2}_\kappa(u(t)) + \sum_{|a|\leq\kappa-2}\|(t+r)\,\Box\Gamma^a u(t)\|_{L^2}\right]. \tag{7.1}$$

Proof. Recall that the weighted norm involves derivatives in the form $\partial^2\Gamma^a u$. In the case when $\partial^2 = \nabla\partial$, the result was given in Lemma 3.1 of [15]. Otherwise, if $\partial^2 = \partial_t^2$, then the result is an immediate consequence of (2.10) in [15]. □

Now we assume that u solves the nonlinear PDE.

Lemma 7.2. *Let $u \in \dot H^\kappa_\Gamma(T)$ be a solution of* (3.1)*. Define $\kappa' = \left[\frac{\kappa-1}{2}\right] + 3$. Then for all $|a| \leq \kappa - 2$,*

$$\|(t+r)\Box\Gamma^a u(t)\|_{L^2} \leq C[\mathcal{X}_{\kappa'}(u(t))E^{1/2}_\kappa(u(t)) + \mathcal{X}_\kappa(u(t))E^{1/2}_{\kappa'}(u(t))]. \tag{7.2}$$

Proof. By Lemma 4.1, we must estimate terms of the form

$$\|(t+r)\partial\Gamma^b u^i \partial^2\Gamma^c u^j\|_{L^2},$$

but since $(t+r) \leq C\langle r\rangle\langle c_j t - r\rangle$, we will consider

$$\|\langle r\rangle\langle c_j t - r\rangle \partial\Gamma^b u^i \partial^2\Gamma^c u^j\|_{L^2} \tag{7.3}$$

with $b+c \leq a$ and $|a| \leq \kappa - 2$.

Let $m = \left[\frac{\kappa-1}{2}\right] = \kappa' - 3$. We separate two cases: either $|b| \leq m$ or $|c| \leq m-1$. In the first case, (7.3) is estimated as follows using (6.2):

$$\|\langle r\rangle \partial\Gamma^b u^i\|_{L^\infty} \|\langle c_j t - r\rangle \partial^2\Gamma^c u^j\|_{L^2} \leq C E_{\kappa'}^{1/2}(u(t))\mathcal{X}_\kappa(u(t)).$$

Otherwise, we use (6.4) to estimate (7.3) by

$$\|\partial\Gamma^b u^i\|_{L^2} \|\langle r\rangle\langle c_j t - r\rangle \partial^2\Gamma^c u^j\|_{L^\infty} \leq C E_\kappa^{1/2}(u(t))\mathcal{X}_{\kappa'}(u(t)). \qquad \square$$

The next result gains control of the weighted norm by the energy. We distinguish two different energies, the smaller of which must remain small. In the next section, we will allow the larger energy to grow polynomially in time.

LEMMA 7.3. *Let $u \in \dot{H}^\kappa_\Gamma(T)$, $\kappa \geq 8$, be a solution of* (3.1)*. Define $\mu = \kappa - 2$, and assume that*

$$\varepsilon_0 \equiv \sup_{0 \leq t < T} E_\mu^{1/2}(u(t))$$

is sufficiently small. Then for $0 \leq t < T$,

$$\mathcal{X}_\mu(u(t)) \leq C E_\mu^{1/2}(u(t)) \tag{7.4a}$$

and

$$\mathcal{X}_\kappa(u(t)) \leq C E_\kappa^{1/2}(u(t)). \tag{7.4b}$$

Proof. Let $\mu' = \left[\frac{\mu-1}{2}\right] + 3$, $\mu = \kappa - 2$. Since $\mu \geq 6$, we have $\mu' \leq \mu$. Thus, by Lemmas 7.1 and 7.2, we find using our assumption that

$$\mathcal{X}_\mu(u(t)) \leq C[E_\mu^{1/2}(u(t)) + \varepsilon_0 \mathcal{X}_\mu(u(t))].$$

Thus, if ε_0 is small enough, the bound (7.4a) results.

Again, since $\kappa \geq 8$, we have $\kappa' = \left[\frac{\kappa-1}{2}\right] + 3 \leq \mu = \kappa - 2$. From Lemmas 7.1 and 7.2 we now have

$$\mathcal{X}_\kappa(u(t)) \leq C[E_\kappa^{1/2}(u(t)) + \mathcal{X}_\mu(u(t))E_\kappa^{1/2}(u(t)) + \mathcal{X}_\kappa(u(t))E_\mu^{1/2}(u(t))].$$

If we apply (7.4a) and our assumption, then

$$\mathcal{X}_\kappa(u(t)) \leq C[E_\kappa^{1/2}(u(t)) + \varepsilon_0 \mathcal{X}_\kappa(u(t))],$$

from which (7.4b) follows. $\square$

8. Energy estimates.

General energy method. In this section we shall complete the proof of Theorem 3.1. Assume that $u(t) \in \dot{H}^\kappa_\Gamma(T)$ is a local solution of the initial value problem for (3.1). Our task will be to show that $E_\kappa(u(t))$ remains finite for all $t \geq 0$. To do so, we will derive a pair of coupled differential inequalities for (modifications of) $E_\kappa(u(t))$ and $E_\mu(u(t))$ with $\mu = \kappa - 2$. If (3.3) holds, then $E_\mu^{1/2}(u(0)) < \varepsilon$. Suppose that T_0 is the largest time such that $E_\mu^{1/2}(u(t)) < 2\varepsilon$ for $0 \leq t < T_0$ with ε small enough so that Lemma 7.3 is valid. All of the following computations will be valid on this time interval.

Following the energy method, we have for any $\nu = 1, \dots, \kappa$,

$$E_\nu'(u(t)) = \sum_{|a|\leq \nu-1} \int \langle \Box \Gamma^a u(t), \partial_t \Gamma^a u(t) \rangle dx,$$

and from Lemma 4.1, this takes the form

$$E_\nu'(u(t)) = \sum_{|a|\leq \nu-1} \sum_{b+c+d=a} \int \langle N_d(\Gamma^b u, \Gamma^c u), \partial_t \Gamma^a u \rangle dx. \tag{8.1}$$

Terms in (8.1) with $b = 0$, $c = a$, and $|a| = \nu - 1$ are handled with the aid of the symmetry condition (3.2b) which allows us to integrate by parts as follows. Recall that from Lemma 4.1, $N_d = N$ when $b + c = a$.

$$\begin{aligned}
\int \langle N(u, \Gamma^a u), \partial_t \Gamma^a u \rangle dx &= C^{ijk}_{\alpha\beta\gamma} \int \partial_\alpha u^i \partial_\beta \partial_\gamma \Gamma^a u^j \partial_t \Gamma^a u^k dx \\
&= C^{ijk}_{\alpha\beta\gamma} \int \partial_\gamma [\partial_\alpha u^i \partial_\beta \Gamma^a u^j \partial_t \Gamma^a u^k] dx \\
&\quad - C^{ijk}_{\alpha\beta\gamma} \int \partial_\alpha \partial_\gamma u^i \partial_\beta \Gamma^a u^j \partial_t \Gamma^a u^k dx \\
&\quad - C^{ijk}_{\alpha\beta\gamma} \int \partial_\alpha u^i \partial_\beta \Gamma^a u^j \partial_t \partial_\gamma \Gamma^a u^k dx \\
&= C^{ijk}_{\alpha\beta 0} \partial_t \int \partial_\alpha u^i \partial_\beta \Gamma^a u^j \partial_t \Gamma^a u^k dx \\
&\quad - C^{ijk}_{\alpha\beta\gamma} \int \partial_\alpha \partial_\gamma u^i \partial_\beta \Gamma^a u^j \partial_t \Gamma^a u^k dx \\
&\quad - \frac{1}{2} C^{ijk}_{\alpha\beta\gamma} \int \partial_\alpha u^i \partial_t [\partial_\beta \Gamma^a u^j \partial_\gamma \Gamma^a u^k] dx \\
&= \frac{1}{2} C^{ijk}_{\alpha\beta\gamma} \eta_{\gamma\delta}\ \partial_t \int \partial_\alpha u^i \partial_\beta \Gamma^a u^j \partial_\delta \Gamma^a u^k dx \\
&\quad - C^{ijk}_{\alpha\beta\gamma} \int \partial_\alpha \partial_\gamma u^i \partial_\beta \Gamma^a u^j \partial_t \Gamma^a u^k dx \\
&\quad + \frac{1}{2} C^{ijk}_{\alpha\beta\gamma} \int \partial_t \partial_\alpha u^i \partial_\beta \Gamma^a u^j \partial_\gamma \Gamma^a u^k dx,
\end{aligned}$$

using the symbol $\eta_{\gamma\delta} = \mathrm{Diag}[1, -1, -1, -1]$. The first term above can be absorbed into the energy as a lower order perturbation. Define

$$\widetilde{E}_\nu(u(t)) = E_\nu(u(t)) - \frac{1}{2} \sum_{|a|=\nu-1} C^{ijk}_{\alpha\beta\gamma} \eta_{\gamma\delta} \int \partial_\alpha u^i \partial_\beta \Gamma^a u^j \partial_\delta \Gamma^a u^k dx.$$

The perturbation is bounded by $C\|\partial u\|_{L^\infty} E_\nu(u(t))$, but by (6.2), the maximum norm $\|\partial u\|_{L^\infty}$ is controlled by $E_3^{1/2}(u(t)) \leq E_\mu^{1/2}(u(t)) < 2\varepsilon$. Thus, for small solutions we have

$$(1/2)E_\nu(u(t)) \leq \widetilde{E}_\nu(u(t)) \leq 2E_\nu(u(t)). \tag{8.2}$$

Returning to (8.1), we have derived the energy identity

$$\begin{aligned}\widetilde{E}'_\nu(u(t)) = &\sum_{|a|\leq \nu-1} \sum_{\substack{b+c+d=a \\ |a|\neq \nu-1}} \int \langle N_d(\Gamma^b u, \Gamma^c u), \partial_t \Gamma^a u\rangle dx \\ &+ \sum_{|a|=\nu-1} \Bigg[\sum_{\substack{b+c=a \\ c\neq a}} \int \langle N(\Gamma^b u, \Gamma^c u), \partial_t \Gamma^a u\rangle dx. \\ &\qquad - C^{ijk}_{\alpha\beta\gamma} \int \partial_\alpha \partial_\gamma u^i \partial_\beta \Gamma^a u^j \partial_t \Gamma^a u^k dx \\ &\qquad + \frac{1}{2} C^{ijk}_{\alpha\beta\gamma} \int \partial_t \partial_\alpha u^i \partial_\beta \Gamma^a u^j \partial_\gamma \Gamma^a u^k dx \Bigg].\end{aligned} \tag{8.3}$$

Higher energy. For the first series of estimates we take $\nu = \kappa$ in (8.3). We immediately obtain

$$\widetilde{E}'_\kappa(u(t)) \leq C \sum_{i,j,k} \sum_{|a|\leq \kappa-1} \sum_{\substack{b+c\leq a \\ |c|\leq \kappa-2}} \|\partial \Gamma^b u^i \partial^2 \Gamma^c u^j\|_{L^2} \|\partial \Gamma^a u^k\|_{L^2}. \tag{8.4}$$

In some cases, the indices i and j have been interchanged. In the sum on the right-hand side of (8.4), we have either $|b| \leq \kappa'$ or $|c| \leq \kappa' - 1$ with $\kappa' = \left[\frac{\kappa}{2}\right]$. Note that since $\kappa \geq 9$, we have $\kappa' + 3 \leq \kappa - 2 = \mu$. We will also use that $\langle t\rangle \leq C\langle r\rangle \langle c_j t - r\rangle$.

In the first case, we estimate using (6.2) and (7.4b) as follows:

$$\begin{aligned}\|\partial \Gamma^b u^i \partial^2 \Gamma^c u^j\|_{L^2} &\leq C\langle t\rangle^{-1} \|\langle r\rangle \partial \Gamma^b u^i\|_{L^\infty} \|\langle c_j t - r\rangle \partial^2 \Gamma^c u^j\|_{L^2} \\ &\leq C\langle t\rangle^{-1} E^{1/2}_{|b|+3}(u(t)) \mathcal{X}_\kappa(u(t)) \\ &\leq C\langle t\rangle^{-1} E^{1/2}_\mu(u(t)) E^{1/2}_\kappa(u(t)).\end{aligned}$$

In the second case, we use (6.4) and then (7.4a):

$$\begin{aligned}\|\partial \Gamma^b u^i \partial^2 \Gamma^c u^j\|_{L^2} &\leq C\langle t\rangle^{-1} \|\partial \Gamma^b u^i\|_{L^2} \|\langle r\rangle \langle c_j t - r\rangle \partial^2 \Gamma^c u^j\|_{L^\infty} \\ &\leq C\langle t\rangle^{-1} E^{1/2}_\kappa(u(t)) \mathcal{X}_{|c|+4}(u(t)) \\ &\leq C\langle t\rangle^{-1} E^{1/2}_\kappa(u(t)) \mathcal{X}_\mu(u(t)) \\ &\leq C\langle t\rangle^{-1} E^{1/2}_\kappa(u(t)) E^{1/2}_\mu(u(t)).\end{aligned}$$

Going back to (8.4) and recalling (8.2), we have established the inequality

$$\begin{aligned}\widetilde{E}'_\kappa(u(t)) &\leq C\langle t\rangle^{-1} E^{1/2}_\mu(u(t)) E_\kappa(u(t)) \\ &\leq C\langle t\rangle^{-1} \widetilde{E}^{1/2}_\mu(u(t)) \widetilde{E}_\kappa(u(t)).\end{aligned} \tag{8.5}$$

Lower energy. The second series of energy estimates will exploit the null condition. We return to (8.3) now with $\nu = \mu = \kappa - 2$. The resulting integrals on the right-hand side of (8.3) will be subdivided into separate integrals over the regions $r \leq c_0 t$ and $r \geq c_0 t$. Recall that the constant c_0 was defined in Lemma 5.1.

Inside the cones. On the region $r \leq c_0 t$, we have that the right-hand side of (8.3) is bounded above by

$$\sum_{i,j,k} \sum_{|a| \leq \mu - 1} \sum_{\substack{b+c \leq a \\ |c| \leq \mu - 2}} \|\partial \Gamma^b u^i \partial^2 \Gamma^c u^j \partial \Gamma^a u^k\|_{L^1(r \leq c_0 t)}.$$

Since $r \leq c_0 t$, we have that $\langle c_i t - r\rangle \geq C\langle t\rangle$ for each $i = 1, \ldots, m$. Thus, using (6.3), a typical term can be estimated by

$$\begin{aligned} C\langle t\rangle^{-3/2} &\|\langle c_i t - r\rangle^{1/2} \partial \Gamma^b u^i \langle c_j t - r\rangle \partial^2 \Gamma^c u^j \partial \Gamma^a u^k\|_{L^1(r \leq c_0 t)} \\ &\leq C\langle t\rangle^{-3/2} \|\langle c_i t - r\rangle^{1/2} \partial \Gamma^b u^i\|_{L^\infty} \|\langle c_j t - r\rangle \partial^2 \Gamma^c u^j\|_{L^2} \|\partial \Gamma^a u^k\|_{L^2} \\ &\leq C\langle t\rangle^{-3/2} \Big[E^{1/2}_{|b|+3}(u(t)) + \mathcal{X}_{|b|+3}(u(t))\Big] \mathcal{X}_{|c|+2}(u(t)) E^{1/2}_{\mu}(u(t)). \end{aligned}$$

In the preceding, we have $|b| + 3 \leq \kappa$, $|c| + 2 \leq \mu$, and $|a| + 1 \leq \mu$. With the aid of Lemma 7.3, we have achieved an upper bound of the form

$$C\langle t\rangle^{-3/2} E_\mu(u(t)) E^{1/2}_\kappa(u(t))$$

for the portion of the integrals over $r \leq c_0 t$ on the right of (8.3).

Away from the origin. It remains to estimate the right-hand side of (8.3) for $r \geq c_0 t$.

First, we consider the nonresonant terms, i.e., those for which $(i, j, k) \neq (k, k, k)$. If $i \neq j$ and $r \geq c_0 t$, then $\langle t\rangle^{3/2} \leq C\langle r\rangle \langle c_i t - r\rangle^{1/2} \langle c_j t - r\rangle$. Using (6.3) we have the estimate

$$\begin{aligned} \|\partial \Gamma^b u^i & \partial^2 \Gamma^c u^j \partial \Gamma^a u^k\|_{L^1(r \geq c_0 t)} \\ &\leq C\langle t\rangle^{-3/2} \|\langle r\rangle \langle c_i t - r\rangle^{1/2} \partial \Gamma^b u^i\|_{L^\infty} \|\langle c_j t - r\rangle \partial^2 \Gamma^c u^j\|_{L^2} \|\partial \Gamma^a u^k\|_{L^2} \\ &\leq C\langle t\rangle^{-3/2} \Big[E^{1/2}_{|b|+3}(u(t)) + \mathcal{X}_{|b|+3}(u(t))\Big] \mathcal{X}_{|c|+2}(u(t)) E^{1/2}_{|a|+1}(u(t)) \\ &\leq C\langle t\rangle^{-3/2} E_\mu(u(t)) E^{1/2}_\kappa(u(t)). \end{aligned}$$

Otherwise, if $j \neq k$, we pair the weight $\langle r\rangle \langle c_k t - r\rangle^{1/2}$ with $\partial \Gamma^a u^k$ in L^∞ to get the same upper bound.

We are left to consider the resonant terms in (8.3), i.e., $(i, j, k) = (k, k, k)$, in the region $r \geq c_0 t$. It is here, finally, where the null condition enters. An application of Lemma 5.1 yields the following upper bound for these terms:

$$\begin{aligned} C\langle t\rangle^{-1} \sum_k \sum_{\substack{b+c=a \\ |c| \leq \mu - 2}} \Big[&\|\Gamma^{b+1} u^k \partial^2 \Gamma^c u^k \partial \Gamma^a u^k\|_{L^1(r \geq c_0 t)} \\ &+ \|\partial \Gamma^b u^k \partial \Gamma^{c+1} u^k \partial \Gamma^a u^k\|_{L^1(r \geq c_0 t)} \\ &+ \|\langle c_k t - r\rangle \partial \Gamma^b u^k \partial^2 \Gamma^c u^k \partial \Gamma^a u^k\|_{L^1(r \geq c_0 t)} \Big]. \end{aligned}$$

We still need to squeeze out an additional decay factor of $\langle t\rangle^{-1/2}$.

Since $r \geq c_0 t$, we have $\langle r\rangle \geq C\langle t\rangle$. Thus, we have using (6.1) that

$$\begin{aligned}
&\|\Gamma^{b+1}u^k\partial^2\Gamma^c u^k\partial\Gamma^a u^k\|_{L^1(r\geq c_0t)}\\
&\quad\leq C\langle t\rangle^{-1/2}\|\langle r\rangle^{1/2}\Gamma^{b+1}u^k\|_{L^\infty(r\geq c_0t)}\|\partial^2\Gamma^c u^k\|_{L^2}\|\partial\Gamma^a u^k\|_{L^2}\\
&\quad\leq C\langle t\rangle^{-1/2}E^{1/2}_{|b|+3}(u(t))E_\mu(u(t))\\
&\quad\leq C\langle t\rangle^{-1/2}E^{1/2}_\kappa(u(t))E_\mu(u(t)).
\end{aligned}$$

In a similar fashion, the second term is handled using (6.2):

$$\begin{aligned}
&\|\partial\Gamma^b u^k\partial\Gamma^{c+1}u^k\partial\Gamma^a u^k\|_{L^1(r\geq c_0t)}\\
&\quad\leq C\langle t\rangle^{-1}\|\partial\Gamma^b u^k\|_{L^2}\|\langle r\rangle\partial\Gamma^{c+1}u^k\|_{L^\infty(r\geq c_0t)}\|\partial\Gamma^a u^k\|_{L^2}\\
&\quad\leq C\langle t\rangle^{-1}E^{1/2}_{|c|+3}(u(t))E_\mu(u(t))\\
&\quad\leq C\langle t\rangle^{-1}E^{1/2}_\kappa(u(t))E_\mu(u(t)).
\end{aligned}$$

The final set of terms are estimated using (6.2) again and (7.4a):

$$\begin{aligned}
&\|\langle c_kt{-}r\rangle\partial\Gamma^b u^k\partial^2\Gamma^c u^k\partial\Gamma^a u^k\|_{L^1(r\geq c_0t)}\\
&\quad\leq C\langle t\rangle^{-1}\|\langle r\rangle\partial\Gamma^b u^k\|_{L^\infty(r\geq c_0t)}\|\langle c_kt-r\rangle\partial^2\Gamma^c u^k\|_{L^2}\|\partial\Gamma^a u^k\|_{L^2}\\
&\quad\leq C\langle t\rangle^{-1}E^{1/2}_{|b|+3}(u(t))\mathcal{X}_{|c|+2}(u(t))E^{1/2}_\mu(u(t))\\
&\quad\leq C\langle t\rangle^{-1}E^{1/2}_\kappa(u(t))E_\mu(u(t)).
\end{aligned}$$

Combining all the estimates in this subsection, we obtain, thanks to (8.2), the following inequality for the lower energy:

$$\begin{aligned}
\widetilde{E}'_\mu(u(t)) &\leq C\langle t\rangle^{-3/2}E_\mu(u(t))E^{1/2}_\kappa(u(t))\\
&\leq C\langle t\rangle^{-3/2}\widetilde{E}_\mu(u(t))\widetilde{E}^{1/2}_\kappa(u(t)).
\end{aligned}\tag{8.6}$$

Conclusion of the proof. By (8.2), we have that the modified energy satisfies $\widetilde{E}^{1/2}_\mu(u(t)) \leq C\varepsilon$ for $0 \leq t < T_0$. So from (8.5), we find that

$$\widetilde{E}_\kappa(u(t)) \leq \widetilde{E}_\kappa(u(0))\langle t\rangle^{C\varepsilon},$$

provided ε is small. Inserting this bound into (8.6) and using (8.2), we obtain

$$\begin{aligned}
(1/2)E_\mu(u(t)) &\leq \widetilde{E}_\mu(u(t)) \leq \widetilde{E}_\mu(u(0))\exp CI\widetilde{E}^{1/2}_\kappa(u(0))\\
&\leq 2E_\mu(u(0))\exp 2CIE^{1/2}_\kappa(u(0)) < 2\varepsilon^2
\end{aligned}$$

with $I = \int_0^\infty\langle s\rangle^{-3/2+C\varepsilon}ds$. With this we see that $E^{1/2}_\mu(u(t))$ remains strictly less than 2ε throughout the closed interval $0 \leq t \leq T_0$. This shows that $E_\mu(u(t))$ is bounded for all time, which completes the proof of Theorem 3.1.

INVARIANT MANIFOLDS AND LONG-TIME ASYMPTOTICS FOR THE VLASOV–POISSON–FOKKER–PLANCK EQUATION*

YOSHIYUKI KAGEI†

Dedicated to Professors Takaaki Nishida and Masayasu Mimura on their 60*th birthdays.*

Abstract. We study the large time behavior of small solutions to the Cauchy problem for the Vlasov–Poisson–Fokker–Planck equation, which is a degenerate parabolic equation with nonlocal nonlinearity. We construct finite dimensional invariant manifolds in a neighborhood of the origin in polynomially weighted Sobolev spaces, which enables us to compute systematically the long-time asymptotics for small solutions. To construct invariant manifolds, we make use of the "similarity variables" transformation as in C. E. Wayne's work in 1997, where invariant manifolds for parabolic equations in unbounded domains are constructed.

Key words. Vlasov–Poisson–Fokker–Planck equation, long-time asymptotics, invariant manifold

1. Introduction.

Many nonlinear parabolic partial differential equations often exhibit some scale-invariant structures in large time behavior of their solutions; namely, their solutions asymptotically have some self-similar profiles in large times. Based on this viewpoint, Bricmont, Kupiainen, and Lin [4] developed the renormalization group method to study large time behavior of solutions of certain types of nonlinear parabolic equations and derived the long-time asymptotics of solutions up to the leading order.

On the other hand, for many dissipative systems, the large time behavior of solutions is recognized to be controlled by a finite number of degrees of freedom. To study this point, invariant manifold theory is a strong mathematical tool, and, actually, the large time behavior of solutions is described by a system of a finite number of ordinary differential equations when the dimension of the constructed invariant manifold is finite. However, the application of the theory had been restricted to systems of ordinary differential equations and some classes of partial differential equations on bounded domains, where the spectra of linearized problems are discrete. In 1997, Wayne [21] constructed invariant manifolds for the problem

$$\partial_t f - \Delta_x f + F(f) = 0, \quad f = f(x,t), \quad x \in \boldsymbol{R}^N, \quad t > 0, \tag{1.1}$$

where $F(f) = O(|f|^p)$ as $|f| \to 0$ for some $p > 1$. To construct the invariant manifold for (1.1), Wayne used the change of variables to the so-called "similarity variables" and showed the existence of finite dimensional invariant manifolds in some Sobolev spaces with polynomial weights. As a result, for suitable F, asymptotic profiles of solutions in large time were given, up to orders higher than that given in [4]. Wayne's method has been generalized in a few directions: to the study of the long-time behavior of solutions around spatially periodic steady solutions of the Swift–Hohenberg equation

[11]; to problems on cylindrical domains [22]; to higher-order dissipative systems [10]. See also [15] for an approach in the L^p-framework. All of these problems have linearized parts of essentially diffusive type or of the type $(-\Delta_x)^n$.

The purpose of this paper is to carry out the same kind of analysis initiated by Wayne [21] for a different type of problem to study the long-time asymptotics of solutions to such problems. The problem discussed in this paper is the Cauchy problem for the Vlasov–Poisson–Fokker–Planck equation (without friction term)

$$\begin{aligned} &\partial_t f + u\cdot\nabla_x f + E(f)\cdot\nabla_u f - \Delta_u f = 0, \quad (x,u)\in \boldsymbol{R}^N\times\boldsymbol{R}^N,\ t>0,\\ &f|_{t=0} = f_0. \end{aligned} \tag{1.2}$$

Here $N\geq 2$, $f=f(x,u,t)$ is the unknown function, which describes the density of particles with respect to position $x\in\boldsymbol{R}^N$ and velocity $u\in\boldsymbol{R}^N$ at time t; $\nabla_x = (\partial_{x_1},\dots,\partial_{x_N})$, $\nabla_u=(\partial_{u_1},\dots,\partial_{u_N})$; Δ_u is the Laplacian with respect to the variable u: $\Delta_u = \partial_{u_1}^2+\cdots\partial_{u_N}^2$. $E(f)$ is an integral operator defined by

$$E(f)=\omega\frac{x}{|x|^N} *_x \int_{R^N} f(x,u,t)\,du, \quad \omega = +\frac{1}{\sigma^2|S^{N-1}|} \text{ or } -\frac{1}{\sigma^2|S^{N-1}|},$$

where $|S^{N-1}|$ is the $(N-1)$ dimensional volume of the N dimensional unit sphere; σ is a positive constant (called a diffusion constant); $*_x$ denotes the convolution with respect to x. Thus the equation in (1.2) is a degenerate parabolic equation with nonlocal nonlinearity.

We will construct finite dimensional invariant manifolds for (1.2) in some Sobolev spaces with polynomial weights and give long-time asymptotics of small solutions to (1.2). To state our main result we introduce function spaces

$$\begin{aligned} X_r^{\ell,m} = \{f(x,u)\in L^2(\boldsymbol{R}^N\times\boldsymbol{R}^N) : (1+|x|^2+|u|^2)^{r/2}\partial_x^\alpha\partial_u^\beta f \in L^2(\boldsymbol{R}^N\times\boldsymbol{R}^N),\\ 0\leq|\alpha|\leq\ell,\ 0\leq|\beta|\leq m\}, \end{aligned}$$

where ℓ, m, and r are nonnegative integers. The norm of $X_r^{\ell,m}$ is defined by

$$\|f\|_{X_r^{\ell,m}} = \left(\int\sum_{|\alpha|\leq\ell,|\beta|\leq m}(1+|x|^2+|u|^2)^r|\partial_x^\alpha\partial_u^\beta f(x,u)|^2\,dxdu\right)^{1/2}.$$

We now give the asymptotics of small solutions up to the order n.

THEOREM 1.1. *Let n be an integer satisfying $0\leq n\leq 3N-5$, and let r be an integer satisfying $r\geq n+3N+\frac{1}{2}$. Also, let m be an integer satisfying $m>N$. Then for any $\varepsilon>0$, if $\|f_0\|_{X_r^{m,m}}$ is sufficiently small, there exists a unique global solution $f(t)$ of (1.2) in $C([0,\infty);X_r^{m,m})$, and $f(t)$ satisfies*

$$\lim_{t\to\infty} t^{\frac{n+1}{2}-\varepsilon}\Big\|t^{2N}f(t^{3/2}x,t^{1/2}u,t)-\sum_{k=0}^{n}t^{-\frac{k}{2}}\sum_{3|\alpha|+|\beta|=k}B_{\alpha,\beta}g_{\alpha,\beta}(x,u)\Big\|_{L^\infty_{x,u}}=0.$$

Here $g_{\alpha,\beta}(x,u)=c_{\alpha,\beta}\partial_x^\alpha(\partial_x+\partial_u)^\beta e^{-3|x-\frac{u}{2}|^2-\frac{1}{4}|u|^2}$ and $c_{\alpha,\beta}=(-\frac{1}{3})^{|\alpha|}\frac{1}{\alpha!\beta!}(\frac{\sqrt{3}}{2\pi})^N$ with α and β being multi-indices; and $B_{\alpha,\beta}$ are constants determined by f_0 and the nonlinearity. In particular, $B_{0,0}=\int f_0(x,u)\,dxdu$.

Remark 1.2. In Theorem 1.1 the range of n is restricted as $0 \leq n \leq 3N-5$. One can, however, obtain the asymptotics of f up to any nonnegative $n \in \mathbf{Z}$; in fact, the full dynamics have been reduced to those of the system of ordinary differential equations (2.6) below.

If n is beyond the range in Theorem 1.1, i.e., if $n \geq 3N-4$, then the effect of the nonlinearity becomes somewhat stronger, and logarithmic terms appear in the asymptotics. For example, if $n = 3N-4$, then we have

$$\begin{aligned}
&t^{2N} f(t^{3/2}x, t^{1/2}u, t) \\
&\quad \sim \sum_{k=0}^{n-1} \sum_{3|\alpha|+|\beta|=k} (B_{\alpha,\beta} t^{-\frac{k}{2}} + \widetilde{B}_{\alpha,\beta} t^{-\frac{n}{2}}) g_{\alpha,\beta}(x,u) \\
&\qquad + \sum_{3|\alpha|+|\beta|=n} (B_{\alpha,\beta} t^{-\frac{n}{2}} + \widetilde{B}_{\alpha,\beta} t^{-\frac{n}{2}} \log t)\, g_{\alpha,\beta}(x,u) \\
&\qquad + h(x,u,t) + O(t^{-\frac{n+1}{2}+\varepsilon}), \quad (n = 3N-4),
\end{aligned}$$

where $B_{\alpha,\beta}$ and $\widetilde{B}_{\alpha,\beta}$ are some constants and $h(x,u,t) = O(t^{-\frac{n}{2}})$. (For example, when $N = 2$, the constants $\widetilde{B}_{0,\beta}$ ($|\beta| = 2$) are given by $\widetilde{B}_{0,\beta} = -\frac{3}{8} {B_{0,0}}^2 \omega$ for $\beta = (2,0)$ and $(0,2)$, $\widetilde{B}_{0,\beta} = 0$ for $\beta = (1,1)$.) As for the function $h(x,u,t)$, see section 2.

The existence, uniqueness, and regularity of solutions to (1.2) have been widely studied; see, e.g., [1, 2, 3, 5, 7, 8, 9, 17, 18, 19, 20] and references therein. Among these works, this paper is closely related to those in [5, 9, 17]. The work [9] by Carrillo, Soler, and Vázquez is the first one among the works for (1.2) to make use of the scaling-invariant property of the fundamental solution of the linearized problem. It is shown in [9] that under some conditions the long-time asymptotics of weak solutions can be obtained up to the leading order when $N \geq 3$. An existence of solutions satisfying these conditions was shown in [8], and at least for initial data small enough in some sense, such solutions exist. Carpio [5] then studied large time behavior of small solutions when $N = 3$. In the analysis in [5] the fundamental solution of the linearized problem of (1.2) was investigated in detail and the long-time asymptotics was obtained up to the second order by using the rescaling technique. The result in [5] shows that the effect of the nonlinearity appears in the second order term of the asymptotics in a weak sense. Ono and Strauss [17] recently obtained sharp decay estimates for the difference of the solution to (1.2) and the solution of the corresponding linearized problem for any $N \geq 2$ if the initial value is sufficiently small. Our results extend these results to higher-order asymptotics and indicate the order in the asymptotics where the effect of the nonlinearity becomes strong.

We prove Theorem 1.1 and Remark 1.2 by constructing finite dimensional invariant manifolds as in [10, 11, 21, 22]. We change the variables into the "similarity" variables:

$$\begin{aligned}
&\tilde{t} = \log(t+1), \quad \tilde{x} = x/(t+1)^{3/2}, \quad \tilde{u} = u/(t+1)^{1/2}, \\
&f(x,u,t) = (t+1)^{-2N} \tilde{f}(x/(t+1)^{3/2}, u/(t+1)^{1/2}, \log(t+1))
\end{aligned}$$

(cf. [9]). Then the equation for $\tilde{f}$ is written, after omitting tildes, as

(1.3)
$$\begin{aligned}
&\partial_t f - (\tfrac{3}{2}x - u) \cdot \nabla_x f - \tfrac{1}{2} u \cdot \nabla_u f - 2Nf + e^{-(\frac{3}{2}N-2)t} E(f) \cdot \nabla_u f - \Delta_u f = 0, \\
&f|_{t=0} = f_0.
\end{aligned}$$

In [10, 11, 21] (see also [15]), to construct invariant manifolds in polynomially weighted spaces, the crucial step is, roughly speaking, to show that the linearized semigroup $T(t)$ in the similarity variables behaves as

$$\begin{cases} P_jT(t)f_0 = e^{\lambda_k t}P_jf_0, \quad k = 0, \dots, n, \\ \|Q_nT(t)f_0\| \le Ce^{\lambda_{n+1}t}\|f_0\| \end{cases} \tag{1.4}$$

in some spaces with polynomial weights. Here λ_k, $k = 0, 1, \dots, n$ are the first $n + 1$ eigenvalues of the linearized operator with $\lambda_n < \cdots < \lambda_0$; P_k denotes the eigenprojection associated with the eigenvalue λ_k; $Q_n = I - \sum_{k=0}^{n} P_k$; and λ_{n+1} is a number satisfying $\lambda_{n+1} < \lambda_n$. The proof of (1.4) in [10, 11, 21] is done by a skillful decomposition of the underlying domain $\boldsymbol{R}^N$ and a use of the fact that the growth bound for $Q_nT(t)$ in an exponentially weighted space can be estimated by the spectral bound of its generator. It is the same in [15]. The method in [10, 11, 21] also works in our case since the spectrum of our $T(t)$ in some exponentially weighted space consists only of discrete eigenvalues. (See the remarks in the appendix.) However, in this paper we will show (1.4) by directly analyzing the Fourier transform of our $T(t)$ in polynomially weighted spaces. The "similarity-variable" transformation plays an important role in bringing out clearly the discrete nature of the spectrum of $T(t)$, which can be seen more easily through the Fourier transform of $T(t)$. We derive a useful expression of a spectral representation of $T(t)f_0$ in terms of its Fourier transform. This expression naturally leads us to the behavior of the semigroup as in (1.4) without analysis of the linearized problem in the exponentially weighted space. The dissipative nature of the problem works well in controlling various quantitative estimates. The method is also applicable for the case (1.1). It is still unclear to the author what kind of structures of asymptotic self-similarity and dissipativity are needed for the analysis by the invariant manifold method on unbounded domains as initiated by Wayne [21].

The paper is organized as follows. In section 2 we reformulate the problem in the similarity variables. The existence theorem (Theorem 2.1) of invariant manifolds for (1.3) is then stated, and the proofs of Theorem 1.1 and Remark 1.2 are outlined. Some comments on the case $N = 1$ are given in Remark 2.2. In section 3 we investigate some spectral properties of the linearized operator and show the behavior of the linearized semigroup as in (1.4). In section 4 we derive some estimates for the nonlinearity, which, together with (1.4), implies Theorem 2.1. The appendix is devoted to a derivation of an integral formula of the linearized semigroup for (1.3).

2. Formulation of the problem in the similarity variables. In this section we reformulate the problem in the similarity variables. We then present the existence theorem of the invariant manifolds (Theorem 2.1), and the proofs of Theorem 1.1 and Remark 1.2 are outlined.

Let us transform the problem into the one in the similarity variables. We change the variables as

$$\begin{aligned} &\tilde{t} = \log(t+1), \quad \tilde{x} = x/(t+1)^{3/2}, \quad \tilde{u} = u/(t+1)^{1/2}, \\ &f(x,u,t) = (t+1)^{-\gamma}\tilde{f}(x/(t+1)^{3/2}, u/(t+1)^{1/2}, \log(t+1)), \end{aligned}$$

where $\gamma = \frac{1}{2}N + 2$. The change of variables here is slightly different from the ones written in the introduction. Since the nonlinearity in (1.2) is just quadratic, this transformation is convenient, and the transformed problem becomes autonomous. In fact, the nonlinearity is transformed as

$$E(f)\cdot\nabla_u f(x,u,t) = (t+1)^{-2\gamma+\frac{N}{2}+1}E(\tilde{f})\cdot\nabla_{\tilde{u}}\tilde{f}(x/(t+1)^{3/2}, u/(t+1)^{1/2}, \log(t+1)),$$

and the equation for $\tilde{f}$ is written, after omitting tildes, as

$$\begin{aligned}(2.1)\qquad &\partial_t f - \left(\frac{3}{2}x - u\right)\cdot\nabla_x f - \frac{1}{2}u\cdot\nabla_u f - \gamma f + E(f)\cdot\nabla_u f - \Delta_u f = 0,\\ &f|_{t=0} = f_0.\end{aligned}$$

We write the problem (2.1) in the form

$$\partial_t f = Lf - \mathcal{N}(f), \quad f(0) = f_0,$$

where $Lf = \Delta_u f + (\frac{3}{2}x - u)\cdot\nabla_x f + \frac{1}{2}u\cdot\nabla_u f + \gamma f$ and $\mathcal{N}(f) = E(f)\cdot\nabla_u f$.

We first consider the linear problem in the weighted space $X_r^{\ell,m}$. As we will see in section 3, the linearized operator has the following properties.

We are given a nonnegative integer n, and we fix this n hereafter. For this n we take the weight large enough in such a way that $r \geq n + 3N + \frac{1}{2}$. Then, as for the spectrum $\sigma(L)$ of L in $X_r^{0,0}$, we have

$$\sigma(L) \subset \{\lambda_k : k = 0, 1, \dots, n\} \cup \{\mathrm{Re}\lambda \leq \lambda_{n+1}\} \quad \left(\lambda_j = -(2N-\gamma) - \frac{j}{2}\right).$$

Here each of the λ_k $(k = 0, 1, \dots, n)$ is a semisimple eigenvalue; the associated eigenspace is spanned by functions $g_{\alpha,\beta}$'s with α and β satisfying $3|\alpha| + |\beta| = k$, where

$$\begin{aligned}&g_{\alpha,\beta}(x,u) = c_{\alpha,\beta}\partial_x^\alpha(\partial_x + \partial_u)^\beta e^{-\mu(x,u)}, \quad \mu(x,u) = 3\left|x - \frac{u}{2}\right|^2 + \frac{1}{4}|u|^2,\\ &c_{\alpha,\beta} = \left(-\frac{1}{3}\right)^{|\alpha|}\frac{1}{\alpha!\beta!}\left(\frac{\sqrt{3}}{2\pi}\right)^N.\end{aligned}$$

The eigenprojection P_k associated with λ_k is given by

$$P_k f = \sum_{3|\alpha|+|\beta|=k}\langle f, g^*_{\alpha,\beta}\rangle g_{\alpha,\beta}.$$

Here $g^*_{\alpha,\beta}(x,u) = (\partial_x + 3\partial_u)^\alpha(\partial_x + 2\partial_u)^\beta e^{-\mu(x,u)}$ denotes the adjoint eigenfunction, and the pairing $\langle\cdot,\cdot\rangle$ is defined by

$$\langle f, g\rangle = \int f(x,u)g(x,u)e^{\mu(x,u)}\,dxdu.$$

Note that $\langle g_{\alpha,\beta}, g^*_{\tilde{\alpha},\tilde{\beta}}\rangle = 1$ if $(\alpha,\beta) = (\tilde{\alpha},\tilde{\beta})$, and $\langle g_{\alpha,\beta}, g^*_{\tilde{\alpha},\tilde{\beta}}\rangle = 0$ if $(\alpha,\beta) \neq (\tilde{\alpha},\tilde{\beta})$. We denote by $\mathcal{P}_n = \sum_{k=0}^n P_k$ the projection onto the spectral subspace corresponding to discrete eigenvalues $\{\lambda_k\}_{k=0}^n$, and we define $\mathcal{Q}_n$ by $\mathcal{Q}_n = I - \mathcal{P}_n$.

By Proposition 3.3 below, $\mathcal{P}_n$ is a bounded operator in $X_r^{\ell,m}$ since $r \geq n + 3N + \frac{1}{2}$ and $X_r^{\ell,m}$ is decomposed into the direct sum

$$X_r^{\ell,m} = Y_n \oplus Z_{r,n}^{\ell,m}, \quad Y_n \equiv \mathcal{P}_n X_r^{\ell,m}, \quad Z_{r,n}^{\ell,m} \equiv \mathcal{Q}_n X_r^{\ell,m},$$

and the solution $T(t)f_0$ of the linear problem is decomposed as

$$\begin{aligned}&T(t)f_0 = \varphi_n(t) + \psi(t), \quad \varphi_n(t) \in Y_n, \quad \psi(t) \in Z_{r,n}^{\ell,m},\\ &\varphi_n(t) = \sum_{k=0}^n e^{\lambda_k t}P_k f_0, \quad \psi(t) = \mathcal{Q}_n T(t)f_0.\end{aligned}$$

As for the part $\psi(t) = \mathcal{Q}_n T(t) f_0$ on the subspace $Z^{\ell,m}_{r,n}$, the estimate

$$\|\mathcal{Q}_n T(t) f_0\|_{X^{\ell,m}_r} \leq C(1 + t^{-\frac{j}{2}}) e^{\lambda_{n+1} t} \|f_0\|_{X^{\ell,m-j}_r} \tag{2.2}$$

holds for $\ell \geq 0$, $m \geq j$, and $j = 0, 1$. Therefore, the large time behavior of solutions of the linear problem is described, up to $O(e^{\lambda_{n+1} t})$, by the behavior of solutions on the *finite dimensional invariant subspace* Y_n.

For the nonlinear problem we have the following theorem, from which the long-time asymptotics given in Theorem 1.1 and Remark 1.2 are obtained.

Theorem 2.1. *Let $n \geq 0$ be an integer, and let r be an integer satisfying $r \geq n + 3N + \frac{1}{2}$. Then for any fixed integers $m \geq 0$, $j \geq 1$, and $\ell = [\frac{N}{2} - 1] + 1$, there exists a finite dimensional invariant manifold $\mathcal{M}$ for* (2.1) *in a neighborhood of the origin of $X^{m+\ell,j}_r$, i.e., there exist $\Phi \in C^1(Y_n; Z^{m+\ell,j}_{r,n})$ and $R > 0$ such that $\Phi(0) = 0$, $D\Phi(0) = 0$, and*

$$\mathcal{M} = \{\varphi_n + \Phi(\varphi_n); \varphi_n \in Y_n, \|\varphi_n\|_{X^{m+\ell,j}_r} \leq R\},$$

where $Y_n = \mathcal{P}_n X^{m+\ell,j}_r$ and $Z^{m+\ell,j}_{r,n} = \mathcal{Q}_n X^{m+\ell,j}_r$; and $\mathcal{M}$ is invariant under semiflows defined by (2.1)*. Furthermore, solutions near the origin stay in a neighborhood of the origin for all times and approach to $\mathcal{M}$ at a rate $O(e^{(\lambda_{n+1}+\varepsilon)t})$ as $t \to \infty$. More precisely, if $\|f_0\|_{X^{m+\ell,j}_r}$ is sufficiently small, then there uniquely exists a solution $\bar{f}(t)$ of* (2.1) *on $\mathcal{M}$ such that*

$$\|f(t) - \bar{f}(t)\|_{X^{m+\ell,j}_r} \leq C e^{(\lambda_{n+1}+\varepsilon)t}. \tag{2.3}$$

Theorem 2.1 follows from Propositions 3.6 and 4.1 below by applying standard arguments of invariant manifold theory in [6, 16].

We now outline how to obtain the long-time asymptotics given in Theorem 1.1 and Remark 1.2.

Our starting point is the estimate (2.3) in Theorem 2.1. We can rewrite the estimate (2.3) in the form

$$\|\varphi_n(t) - \bar{\varphi}_n(t)\|_{X^{m+\ell,j}_r} \leq C e^{(\lambda_{n+1}+\varepsilon)t} \tag{2.4}$$

and

$$\|\psi(t) - \Phi(\bar{\varphi}_n(t))\|_{X^{m+\ell,j}_r} \leq C e^{(\lambda_{n+1}+\varepsilon)t}, \tag{2.5}$$

where

$$f(t) = \varphi_n(t) + \psi(t), \quad \bar{f}(t) = \bar{\varphi}_n(t) + \Phi(\bar{\varphi}_n(t)), \quad \varphi_n(t), \bar{\varphi}_n(t) \in Y_n, \quad \psi(t) \in Z^{m+\ell,j}_{r,n}.$$

From (2.4) and (2.5) we can see that to obtain the asymptotics of $f(t)$ up to $O(e^{(\lambda_{n+1}+\varepsilon)t})$, it suffices to investigate the behavior of $\bar{\varphi}_n(t)$, which is governed by a system of a finite number of ordinary differential equations. Since $\bar{\varphi}_n(t)$ can be written as

$$\bar{\varphi}_n(t) = \sum_{3|\alpha|+|\beta| \leq n} \varphi_{\alpha,\beta}(t) g_{\alpha,\beta}, \quad \varphi_{\alpha,\beta} \in \mathbf{R},$$

the problem is reduced to the analysis of the behavior of $\varphi_{\alpha,\beta}$'s.

We now derive a system of ordinary differential equations for $\varphi_{\alpha,\beta}$'s. Since $\bar{f}(t) = \bar{\varphi}_n(t) + \Phi(\bar{\varphi}_n(t))$ is a solution of (2.1) on $\mathcal{M}$, it satisfies

$$\partial_t \bar{f} = L\bar{f} - \mathcal{N}(\bar{f}), \quad \bar{f} = \bar{\varphi}_n + \Phi(\bar{\varphi}_n).$$

Taking the pairing $\langle\cdot,\cdot\rangle$ of this identity with $g^*_{\alpha,\beta}$, we have

$$\dot{\varphi}_{\alpha,\beta} = \lambda_k \varphi_{\alpha,\beta} + H_{\alpha,\beta}(\bar{\varphi}_n), \quad 3|\alpha| + |\beta| = k,\ 0 \le k \le n, \tag{2.6}$$

where $\dot{\varphi}_{\alpha,\beta} = \frac{d}{dt}\varphi_{\alpha,\beta}$ and $H_{\alpha,\beta}(\bar{\varphi}_n) = -\langle \mathcal{N}(\bar{\varphi}_n + \Phi(\bar{\varphi}_n)), g^*_{\alpha,\beta}\rangle$.

For $\alpha = \beta = 0$, one can easily verify that $H_{0,0}(\bar{\varphi}_n) = 0$. Hence

$$\dot{\varphi}_{0,0} = \lambda_0 \varphi_{0,0}, \quad \text{i.e.,} \quad \varphi_{0,0}(t) = e^{\lambda_0 t}\varphi_{0,0}(0).$$

Recall that $\lambda_0 = -(2N - \gamma) = -(\frac{3}{2}N - 2) < 0$. For $(\alpha, \beta) \neq (0, 0)$, we have, by the variation of constants formula,

$$\varphi_{\alpha,\beta}(t) = e^{\lambda_k t}\varphi_{\alpha,\beta}(0) + e^{\lambda_k t}\int_0^t e^{-\lambda_k s} H_{\alpha,\beta}(\bar{\varphi}_n(s))\, ds \tag{2.7}$$

with $k = 3|\alpha| + |\beta|$, $1 \le k \le n$. Since $\lambda_k = \lambda_0 - \frac{k}{2}$, one can expect that $\varphi_{\alpha,\beta}(t)$ decays strictly faster than $\varphi_{0,0}(t)$. Therefore, the slowest term in $H_{\alpha,\beta}(\bar{\varphi}_n(s))$ behaves like $e^{2\lambda_0 s}$, since the lowest order terms of $H_{\alpha,\beta}(\bar{\varphi}_n)$ are quadratic in $\{\varphi_{\alpha,\beta}\}$. As a result, the integrand in (2.7) behaves like $e^{(2\lambda_0 - \lambda_k)s}$.

Now let $n \le 3N - 5$. This is just equivalent to $|\lambda_n| < 2|\lambda_0|$ (and to $|\lambda_{n+1}| \le 2|\lambda_0|$). It then follows that for $3|\alpha| + |\beta| = k,\ 0 \le k \le n$,

$$\varphi_{\alpha,\beta}(t) \sim \text{const. } e^{\lambda_k t} + O(e^{2\lambda_0 t}),$$

where const. depends on $\varphi_{\alpha,\beta}(0)$ and $H_{\alpha,\beta}$. We can also obtain

$$\|\psi(t)\|_{X_r^{m+\ell,j}} \le C e^{(\lambda_{n+1}+\varepsilon)t}.$$

Therefore,

$$\tilde{f}(x, u, \tilde{t}) \sim \sum_{k=0}^{n} e^{\lambda_k \tilde{t}} \sum_{3|\alpha|+|\beta|=k} B_{\alpha,\beta}\, g_{\alpha,\beta}(x, u) + O(e^{(\lambda_{n+1}+\varepsilon)\tilde{t}}). \tag{2.8}$$

Here we write the solution of (2.1) and the time variable with tildes. Now, converting (2.8) to the original function f and the original time scale t, we obtain the asymptotics given in Theorem 1.1 for $n \le 3N - 5$ if we choose m and j as $m + l > N$ and $j > N$. Note that this choice of m and j implies that $X_r^{m+\ell,j} \subset L^\infty(dxdu)$ due to the Sobolev embedding.

We next consider higher-order asymptotics. In higher-order cases, the estimates (2.4), (2.5), and (2.6) for $\varphi_{\alpha,\beta}$'s, of course, take the same forms. Let $n \ge 3N - 4$. Then $|\lambda_n| \ge 2|\lambda_0|$ and $|\lambda_{n+1}| > 2|\lambda_0|$. Therefore, the integrand in (2.7) does not decay as $s \to \infty$ for some α and β, and the effect of the inhomogeneous term is no longer weak. Also, one must take the effect of $\Phi(\bar{\varphi}_n(t))$ into account, and thus the form of the asymptotics becomes complicated.

For example, if $n = 3N - 4$, then we have $\lambda_n = 2\lambda_0$, and, therefore, the integrand in (2.7) with $3|\alpha| + |\beta| = n$ is of $O(1)$. It then follows that for $3|\alpha| + |\beta| = n$,

$$\varphi_{\alpha,\beta}(t) \sim c_1 e^{\lambda_n t} + c_2\, t e^{\lambda_n t} + O(e^{\lambda_{n+1} t}),$$

where c_1 and c_2 are some constants. One can also see that $\Phi(\bar{\varphi}_n(t)) = O(e^{\lambda_n t})$. Combining these with (2.4) and (2.5) and converting to the original function f and the original time scale t, we see that

$$\begin{aligned}
&t^{2N} f(t^{3/2}x, t^{1/2}u, t) \\
&\sim \sum_{k=0}^{n-1} \sum_{3|\alpha|+|\beta|=k} (B_{\alpha,\beta} t^{-\frac{k}{2}} + \widetilde{B}_{\alpha,\beta} t^{-\frac{n}{2}}) g_{\alpha,\beta}(x,u) \\
&\quad + \sum_{3|\alpha|+|\beta|=n} (B_{\alpha,\beta} t^{-\frac{n}{2}} + \widetilde{B}_{\alpha,\beta} t^{-\frac{n}{2}} \log t)\, g_{\alpha,\beta}(x,u) \\
&\quad + h(x,u,t) + O(t^{-\frac{n+1}{2}+\varepsilon}) \quad (n = 3N-4),
\end{aligned}$$

where $B_{\alpha,\beta}$ and $\widetilde{B}_{\alpha,\beta}$ are some constants and $h(x,u,t) = O(t^{-\frac{n}{2}})$. This gives the asymptotics presented in Remark 1.2 for $n = 3N - 4$. (A direct calculation, for example, for $N = 2$ shows that the constants $\widetilde{B}_{0,\beta}$ ($|\beta| = 2$) are given by $\widetilde{B}_{0,\beta} = -\frac{3}{8} {B_{0,0}}^2 \omega$ for $\beta = (2,0)$ and $(0,2)$ and $\widetilde{B}_{0,\beta} = 0$ for $\beta = (1,1)$.) For $n \geq 3N - 3$, it is possible to obtain the asymptotics in a similar manner as above, but the form of the asymptotics becomes more complicated.

Remark 2.2. In the case when $N = 1$, the nonlinearity is relevant [4, 10]. However, as in [10], if $\int f_0 \, dxdu = 0$, one may obtain something about the dynamics of small solutions. But in this case the dynamics will strongly depend on the sign of ω (in $E(f)$), and we do not consider this case here.

In the remaining part of this paper we will prove Theorem 2.1. The strategy of the proof is similar to that in [10, 11, 21], and the theorem follows from Propositions 3.6 and 4.1 below by applying standard arguments of invariant manifold theory in [6, 16].

3. Some spectral properties of the linearized operator. In this section we deduce some spectral properties of the linearized operator, which is needed for the construction of invariant manifolds. We first investigate the spectrum of the operator A:

$$Af = \left(\frac{3}{2}x - u\right) \cdot \nabla_x f + \frac{1}{2} u \cdot \nabla_u f + 2Nf + \Delta_u f.$$

Note that the linearized operator L which appears in (2.1) is given by $L = A - (2N - \gamma)I$.

Let n be a nonnegative integer. We fix this n hereafter and take an integer r satisfying $r \geq n + 3N + \frac{1}{2}$. We discuss the spectrum of A in $X_r^{0,0}$. The Fourier transform of Af is given by

$$\hat{A}\hat{f} \equiv \widehat{Af} = -\frac{3}{2}\xi \cdot \nabla_\xi \hat{f} - \left(\frac{1}{2}w - \xi\right) \cdot \nabla_w \hat{f} - |w|^2 \hat{f},$$

where $\hat{f}(\xi, w)$ is the Fourier transform of $f(x,u)$:

$$\hat{f}(\xi, w) = \int e^{-ix\cdot\xi - iu\cdot w} f(x,u)\, dxdu.$$

Consider now the eigenvalue problem $\lambda \hat{f} - \hat{A}\hat{f} = 0$. Transforming the variables

$$\begin{aligned}
&\tilde{w} = w + \xi, \quad \tilde{\xi} = \xi, \\
&\hat{f}(\xi, w) = \hat{g}(\xi, w + \xi)\, e^{-\hat{\mu}(\xi,w)}, \quad \hat{\mu}(\xi, w) = |w + \tfrac{\xi}{2}|^2 + \tfrac{1}{12}|\xi|^2,
\end{aligned}$$

we reduce the problem to

$$\lambda\hat{g} + \frac{3}{2}\tilde{\xi}\cdot\nabla_{\tilde{\xi}}\hat{g} + \frac{1}{2}\tilde{w}\cdot\nabla_{\tilde{w}}\hat{g} = 0.$$

On can easily verify that each $\sigma_k = -\frac{k}{2}$ $(k = 0, 1, 2\cdots)$ is an eigenvalue, and the associated eigenfunctions are given by $\tilde{\xi}^\alpha \tilde{w}^\beta$ with multi-indices α and β satisfying $3|\alpha| + |\beta| = k$, and in the original variables, $\xi^\alpha(w+\xi)^\beta e^{-\hat{\mu}(\xi,w)}$. Therefore, taking the inverse Fourier transform, we have the following.

Proposition 3.1. *The spectrum $\sigma(A)$ of A in $X_r^{0,0}$ contains a set of eigenvalues $\{\sigma_k = -\frac{k}{2} : k = 0, 1, 2, \cdots\}$, and eigenfunctions associated with σ_k are given by $g_{\alpha,\beta}$ with multi-indices α and β satisfying $3|\alpha| + |\beta| = k$.*

We next consider the adjoint problem with respect to the pairing $\langle\cdot,\cdot\rangle$. The adjoint operator A^* of A with respect to the pairing $\langle\cdot,\cdot\rangle$ is given by

$$A^* = -\left(\frac{3}{2}x - u\right)\cdot\nabla_x + \left(\frac{7}{2}u - 6x\right)\cdot\nabla_u + 2N + \Delta_u.$$

As above, we have the following proposition.

Proposition 3.2. *The spectrum $\sigma(A^*)$ of A^* in $X_r^{0,0}$ contains a set of eigenvalues $\{\sigma_k = -\frac{k}{2} : k = 0, 1, 2, \cdots\}$, and eigenfunctions associated with σ_k are given by $g^*_{\alpha,\beta}$ with multi-indices α and β satisfying $3|\alpha| + |\beta| = k$.*

Since the linearized operator L of (2.1) is written as $L = A - (2N-\gamma)I$, we see that $\lambda_k = \sigma_k - (2N-\gamma)$ $(k = 0, 1, 2, \cdots)$ are eigenvalues of L. The projection $\mathcal{P}_n$ onto the eigenspaces of the first $n+1$ eigenvalues of L is formally given by

$$\mathcal{P}_n f = \sum_{k=0}^{n} P_k f = \sum_{k=0}^{n}\sum_{3|\alpha|+|\beta|=k}\langle f, g^*_{\alpha,\beta}\rangle g_{\alpha,\beta}.$$

As in [21], the following proposition shows that $\mathcal{P}_n$ is well defined in $X_r^{0,0}$ if r is suitably large.

Proposition 3.3. *If $r \geq n + \frac{1}{2}(2N+1)$, then $\mathcal{P}_n$ is well defined as a bounded operator in $X_r^{0,0}$.*

Proof. Let α and β satisfy $3|\alpha| + |\beta| \leq n$. Since $|g^*_{\alpha,\beta}(x,u)| \leq C(1+|x|+|u|)^n e^{-\mu(x,u)}$, we have

$$\begin{aligned}|\langle f, g^*_{\alpha,\beta}\rangle| &\leq C\int(1+|x|+|u|)^n|f|\,dxdu\\ &= C\int(1+|x|+|u|)^{-(2N+1)/2}(1+|x|+|u|)^{n+(2N+1)/2}|f|\,dxdu\\ &\leq C\left(\int(1+|x|+|u|)^{2n+(2N+1)}|f|^2\,dxdu\right)^{1/2},\end{aligned}$$

and the proposition follows. □

We next give a useful representation of the Fourier transform of $P_k f$.

Lemma 3.4. *Let k be a nonnegative integer, and let r be an integer satisfying $r \geq k + \frac{1}{2}(2N+1)$. Then*

$$\widehat{P_k f}(\xi,w) = \sum_{3|\alpha|+|\beta|=k}(3i)^{|\alpha|}(-i)^{|\beta|}[(\partial_\xi - \partial_w)^\alpha\partial_w^\beta(\hat{f}e^{\hat{\mu}})]\Big|_{\xi=w=0}\hat{g}_{\alpha,\beta}(\xi,w),$$

where $\hat{\mu} = \hat{\mu}(\xi,w) = |w+\frac{\xi}{2}|^2 + \frac{1}{12}|\xi|^2$.

The lemma can be shown by a simple application of the induction argument on α and β. So we omit the proof.

We next discuss the semigroup generated by A. As we will see in the appendix, the Fourier transform of the semigroup $S(t)$ generated by A takes the form

$$\widehat{S(t)f_0}(\xi,w)=\hat{f}(\xi,w,t)=\hat{f}_0(e^{-\frac{3}{2}t}\xi,e^{-\frac{1}{2}t}w+e^{-\frac{1}{2}t}a(t)\xi)e^{-a(t)|w+\frac{a(t)}{2}\xi|^2-\frac{a(t)^3}{12}|\xi|^2}.$$

Taking the inverse Fourier transform then gives an integral formula of the semigroup $S(t)f_0$:

$$S(t)f_0=\left(\tfrac{\sqrt{3}}{2\pi}\right)^N a(t)^{-2N}\int e^{-\frac{3|x-e^{-\frac{3}{2}t}y-\frac{a(t)}{2}(u+e^{-\frac{t}{2}}v)|^2}{a(t)^3}-\frac{|u-e^{-\frac{t}{2}}v|^2}{4a(t)}}f_0(y,v)dydv,$$

where $a(t)=1-e^{-t}$. See the appendix for the derivation of the formula of $S(t)f_0$.

Proposition 3.5. *Let r be an integer satisfying $r\geq n+\frac{1}{2}(2N+1)$. Then*

$$(\widehat{P_kS(t)}f)(\xi,w)=e^{-\hat{\mu}(\xi,w)}\sum_{3|\alpha|+|\beta|=k}\tfrac{1}{\alpha!\beta!}\partial_{\tilde{\xi}}^{\alpha}\partial_{\tilde{w}}^{\beta}F(0,0)(e^{-\frac{3}{2}t}\xi)^{\alpha}(e^{-\frac{t}{2}}(w+\xi))^{\beta}.$$

Here $F(\tilde{\xi},\tilde{w})=e^{\tilde{\mu}(\tilde{\xi},\tilde{w})}\hat{f}(\tilde{\xi},\tilde{w}-\tilde{\xi})$ and $\tilde{\mu}(\tilde{\xi},\tilde{w})=|\tilde{w}-\frac{\tilde{\xi}}{2}|^2+\frac{1}{12}|\tilde{\xi}|^2$.

Proof. Since $a(t)=1-e^{-t}$, we have

$$a(t)\left|w+\frac{a(t)}{2}\xi\right|^2+\frac{a(t)^3}{12}|\xi|^2=\hat{\mu}(\xi,w)-\tilde{\mu}(e^{-\frac{3}{2}t}\xi,e^{-\frac{1}{2}t}(w+\xi)),$$

and so

$$\widehat{S(t)f}=\hat{f}(e^{-\frac{3}{2}t}\xi,e^{-\frac{1}{2}t}(w+\xi)-e^{-\frac{3}{2}t}\xi)e^{\tilde{\mu}(e^{-\frac{3}{2}t}\xi,e^{-\frac{1}{2}t}(w+\xi))-\hat{\mu}(\xi,w)}.$$

Lemma 3.4 then applies to yield the desired formula since $\tilde{\mu}(\tilde{\xi},\tilde{w})=\hat{\mu}(\xi,w)$ and $\partial_{\tilde{w}}=\partial_w$, $\partial_{\tilde{\xi}}=\partial_\xi-\partial_w$ under the transformation $\tilde{\xi}=\xi$ and $\tilde{w}=w+\xi$. This completes the proof. □

Since the semigroup $T(t)$ generated by $L=A-(2N-\gamma)I$ is written as $T(t)=e^{-(2N-\gamma)t}S(t)$, Proposition 3.6 shows that $T(t)$ behaves as in (1.4) in $X_r^{0,0}$ if $r\geq n+3N+\frac{1}{2}$. In particular, for the spectrum $\sigma(L)$ of L in $X_r^{0,0}$, it holds that

$$\sigma(L)\subset\{\lambda_k\,:\,k=0,1,\dots,n\}\cup\{\operatorname{Re}\lambda\leq\lambda_{n+1}\}$$

if $r\geq n+3N+\frac{1}{2}$; each of λ_k $(k=0,1,\dots,n)$ is a semisimple eigenvalue; and the associated eigenspace is spanned by functions $g_{\alpha,\beta}$'s with α and β satisfying $3|\alpha|+|\beta|=k$.

Proposition 3.6. *Let n be a nonnegative integer, and let r be an integer satisfying $r\geq n+3N+\frac{1}{2}$. Then for any fixed integers $\ell\geq 0$, $m\geq 0$, and $j=0,1$,*

$$\|\mathcal{Q}_nT(t)f_0\|_{X_r^{\ell,m+j}}\leq C(1+t^{-\frac{j}{2}})e^{\lambda_{n+1}t}\|f_0\|_{X_r^{\ell,m}}.$$

Proof. Let $r\geq n+3N+\frac{1}{2}$. By the Plancherel theorem it suffices to estimate $\|\partial_\xi^\alpha\partial_w^\beta(\xi^{\gamma_1}w^{\gamma_2}\widehat{\mathcal{Q}_nS(t)}f)\|_{L^2}$ for any α, β, γ_1, and γ_2 with $|\alpha|+|\beta|\leq r$.

We first make some preliminary observations. As in Proposition 3.5, we set $F(\tilde{\xi},\tilde{w}) = e^{\tilde{\mu}(\tilde{\xi},\tilde{w})}\hat{f}(\tilde{\xi},\tilde{w}-\tilde{\xi})$ and $\tilde{\mu}(\tilde{\xi},\tilde{w}) = |\tilde{w}-\frac{\tilde{\xi}}{2}|^2 + \frac{1}{12}|\tilde{\xi}|^2$. Then direct calculations give the bounds

$$\begin{aligned} &|\partial_{\tilde{\xi}}^{\alpha}\partial_{\tilde{w}}^{\beta}F(\tau c_1\tilde{\xi},\tau c_2\tilde{w})| \\ &\quad\le\ C(1+|\tilde{\xi}|+|\tilde{w}|)^{|\alpha|+|\beta|}e^{\tilde{\mu}(\tau c_1\tilde{\xi},\tau c_2\tilde{w})} \\ &\qquad\times\sum_{\substack{\sigma\le\alpha,\\ \eta'\le\beta}}\left|(\partial_\xi-\partial_w)^{\sigma}\partial_w^{\eta}\hat{f}(\tau c_1\tilde{\xi},\tau(c_2\tilde{w}-c_1\tilde{\xi}))\right| \end{aligned}\tag{3.1}$$

uniformly in τ, c_1, $c_2\in[0,1]$, and $\tilde{\xi}$, $\tilde{w}\in\mathbf{R}^N$, and

$$\hat{\mu}(\xi,w)-\tilde{\mu}(\tau e^{-\frac{3}{2}t}\xi,\tau e^{-\frac{1}{2}t}(w+\xi))\ge\frac{1}{2}\hat{\mu}(\xi,w)\tag{3.2}$$

for all $\tau\in[0,1]$, ξ, $w\in\mathbf{R}^N$, and sufficiently large t, e.g., $t\ge\log 36$.

We next set

$$F_n(\tilde{\xi},\tilde{w},t)=F(c_1\tilde{\xi},c_2\tilde{w})-\sum_{3|\alpha|+|\beta|\le n}\frac{1}{\alpha!\beta!}\partial_{\tilde{\xi}}^{\alpha}\partial_{\tilde{w}}^{\beta}F(0,0)c_1^{|\alpha|}\tilde{\xi}^{\alpha}c_2^{|\beta|}\tilde{w}^{\beta},$$

where $c_1=e^{-\frac{3}{2}t}$ and $c_2=e^{-\frac{1}{2}t}$.

Then if we set $\tilde{\xi}=\xi$ and $\tilde{w}=w+\xi$, Proposition 3.5 implies that

$$\begin{aligned} (\widehat{\mathcal{Q}_nS(t)}f)(\xi,w) &= (\widehat{S(t)}f)(\xi,w)-\sum_{k=0}^{n}(\widehat{P_kS(t)}f)(\xi,w) \\ &= e^{-\hat{\mu}(\tilde{\xi},\tilde{w}-\tilde{\xi})}F_n(\tilde{\xi},\tilde{w},t), \end{aligned}$$

and it suffices to estimate

$$\begin{aligned} &(\partial_\xi-\partial_w)^{\alpha'}\partial_w^{\beta'}\left[\xi^{\gamma_1}w^{\gamma_2}(\widehat{\mathcal{Q}_nS(t)}f)(\xi,w)\right] \\ &\quad=\partial_{\tilde{\xi}}^{\alpha'}\partial_{\tilde{w}}^{\beta'}\left[\tilde{\xi}^{\gamma_1}\tilde{w}^{\gamma_2}e^{-\hat{\mu}(\tilde{\xi},\tilde{w}-\tilde{\xi})}F_n(\tilde{\xi},\tilde{w},t)\right] \\ &\quad=\sum_{\tilde{\alpha}\le\alpha',\,\tilde{\beta}\le\beta'}\begin{pmatrix}\alpha'\\ \tilde{\alpha}\end{pmatrix}\begin{pmatrix}\beta'\\ \tilde{\beta}\end{pmatrix}\partial_{\tilde{\xi}}^{\alpha'-\tilde{\alpha}}\partial_{\tilde{w}}^{\beta'-\tilde{\beta}}\left[\tilde{\xi}^{\gamma_1}\tilde{w}^{\gamma_2}e^{-\hat{\mu}(\tilde{\xi},\tilde{w}-\tilde{\xi})}\right]\partial_{\tilde{\xi}}^{\tilde{\alpha}}\partial_{\tilde{w}}^{\tilde{\beta}}F_n(\tilde{\xi},\tilde{w},t) \\ &\quad\equiv\sum_{\tilde{\alpha}\le\alpha',\,\tilde{\beta}\le\beta'}I_{\alpha',\beta',\tilde{\alpha},\tilde{\beta},n} \end{aligned}$$

for all α' and β' with $|\alpha'|+|\beta'|\le r$.

In what follows we set $\tilde{\xi}=\xi$ and $\tilde{w}=w+\xi$.

Applying Taylor's theorem to $\partial_{\tilde{\xi}}^{\tilde{\alpha}}\partial_{\tilde{w}}^{\tilde{\beta}}F_n(\tilde{\xi},\tilde{w},t)$, we see that for multi-indices $\tilde{\alpha}$, $\tilde{\beta}$ with $|\tilde{\alpha}|+|\tilde{\beta}|=j\le n$,

$$\begin{aligned} &\partial_{\tilde{\xi}}^{\tilde{\alpha}}\partial_{\tilde{w}}^{\tilde{\beta}}F_n(\tilde{\xi},\tilde{w}) \\ =\ &\sum_{\substack{|\alpha|+|\beta|\\ =n-j+1}}c_1^{|\alpha|+|\tilde{\alpha}|}c_2^{|\beta|+|\tilde{\beta}|}\int_0^1\tfrac{(n-j+1)(1-\tau)^{n-j+1}}{\alpha!\beta!}\partial_{\tilde{\xi}}^{\alpha}\partial_{\tilde{w}}^{\beta}F(\tau c_1\tilde{\xi},\tau c_2\tilde{w})\,\tilde{\xi}^{\alpha}\tilde{w}^{\beta}\,d\tau \\ &+\sum_{(\alpha,\beta)\in\Lambda_{\tilde{\alpha},\tilde{\beta}}}\frac{1}{\tilde{\alpha}!\tilde{\beta}!}\partial_{\tilde{\xi}}^{\alpha}\partial_{\tilde{w}}^{\beta}F(0,0)c_1^{|\alpha|}\tilde{\xi}^{\alpha-\tilde{\alpha}}c_2^{|\beta|}\tilde{w}^{\beta-\tilde{\beta}} \\ \equiv\ &G^{(1)}_{\tilde{\alpha},\tilde{\beta},n}(\tilde{\xi},\tilde{w},t)+G^{(2)}_{\tilde{\alpha},\tilde{\beta},n}(\tilde{\xi},\tilde{w},t), \end{aligned}\tag{3.3}$$

where $\Lambda_{\tilde{\alpha},\tilde{\beta}} = \{(\alpha,\beta) : \alpha \geq \tilde{\alpha}, \beta \geq \tilde{\beta}, |\alpha| + |\beta| \leq n, 3|\alpha| + |\beta| \geq n+1\}$; $\tilde{\xi} = \xi$, $\tilde{w} = w + \xi$, $c_1 = e^{-\frac{3}{2}t}$, and $c_2 = e^{-\frac{1}{2}t}$. For $|\tilde{\alpha}| + |\tilde{\beta}| = j \geq n+1$, we have

$$\partial_{\tilde{\xi}}^{\tilde{\alpha}} \partial_{\tilde{w}}^{\tilde{\beta}} F_n(\tilde{\xi}, \tilde{w}) = c_1^{|\tilde{\alpha}|} c_2^{|\tilde{\beta}|} \partial_{\tilde{\xi}}^{\tilde{\alpha}} \partial_{\tilde{w}}^{\tilde{\beta}} F(c_1\tilde{\xi}, c_2\tilde{w}), \tag{3.4}$$

where $\tilde{\xi} = \xi$, $\tilde{w} = w + \xi$, $c_1 = e^{-\frac{3}{2}t}$, and $c_2 = e^{-\frac{1}{2}t}$.

Since $c_1^{|\alpha|} c_2^{|\beta|} = e^{-(\frac{3}{2}|\alpha| + \frac{1}{2}|\beta|)t} \leq e^{-\frac{n+1}{2}t}$ for $3|\alpha| + |\beta| \geq n+1$, we see from (3.1) and (3.3) that for $|\tilde{\alpha}| + |\tilde{\beta}| = j \leq n$,

$$\begin{aligned} & |G^{(2)}_{\tilde{\alpha},\tilde{\beta},n}(\tilde{\xi}, \tilde{w}, t)| \\ \leq\ & Ce^{-\frac{n+1}{2}t}(1 + |\xi| + |w|)^{n-j} \sup_{\sigma \leq \tilde{\alpha},\, \eta \leq \tilde{\beta}} \sup_{\xi, w} \left| (\partial_\xi - \partial_w)^\sigma \partial_w^\eta \hat{f}(\xi, w) \right| \\ \leq\ & Ce^{-\frac{n+1}{2}t}(1 + |\xi| + |w|)^{n-j} \int (1 + |x-u| + |u|)^n |f| \, dx du \\ \leq\ & Ce^{-\frac{n+1}{2}t}(1 + |\xi| + |w|)^{n-j} \|f\|_{X^{0,0}_{n+\frac{1}{2}(2N+1)}}. \end{aligned} \tag{3.5}$$

We also see from (3.1) and (3.3) that for $|\tilde{\alpha}| + |\tilde{\beta}| = j \leq n$,

$$\begin{aligned} & |G^{(1)}_{\tilde{\alpha},\tilde{\beta},n}(\tilde{\xi}, \tilde{w}, t)| \\ \leq\ & C(1 + |\xi| + |w|)^{2(n+1)} \left(\int_0^1 e^{\tilde{\mu}(\tau c_1 \tilde{\xi}, \tau c_2 \tilde{w})} \, d\tau \right) \\ & \times \sum_{\substack{|\alpha|+|\beta| \\ = n-j+1}} e^{-\{\frac{3}{2}(|\alpha| + |\tilde{\alpha}|) + \frac{1}{2}(|\beta| + |\tilde{\beta}|)\}t} \sup_{\substack{\sigma \leq \alpha,\, \eta \leq \beta \\ \xi, w}} \left| (\partial_\xi - \partial_w)^\sigma \partial_w^\eta \hat{f}(\xi, w) \right| \\ \leq\ & Ce^{-\frac{n+1}{2}t} \|f\|_{X^{0,0}_{n+1+\frac{1}{2}(2N+1)}} (1 + |\xi| + |w|)^{2(n+1)} \int_0^1 e^{\tilde{\mu}(\tau c_1 \tilde{\xi}, \tau c_2 \tilde{w})} \, d\tau. \end{aligned} \tag{3.6}$$

It then follows from (3.2), (3.5), and (3.6) that for $|\tilde{\alpha}| + |\tilde{\beta}| = j \leq n$

$$|I_{\alpha',\beta',\tilde{\alpha},\tilde{\beta},n}| \leq Ce^{-\frac{n+1}{2}t} \|f\|_{X^{0,0}_r} e^{-\frac{1}{4}\hat{\mu}(\xi,w)},$$

provided that $t \geq \log 36$ since $r \geq n + 3N + \frac{1}{2} > n + 1 + \frac{1}{2}(2N+1)$. This implies that for $|\tilde{\alpha}| + |\tilde{\beta}| = j \leq n$

$$\|I_{\alpha',\beta',\tilde{\alpha},\tilde{\beta},n}\|_{L^2} \leq Ce^{-\frac{n+1}{2}t} \|f\|_{X^{0,0}_r},$$

provided that $t \geq \log 36$.

For $j = |\tilde{\alpha}| + |\tilde{\beta}| \geq n+1$, we apply (3.1), (3.2), and (3.4) to obtain

$$\begin{aligned} |I_{\alpha',\beta',\tilde{\alpha},\tilde{\beta},n}| \leq\ & Ce^{-(\frac{3}{2}|\tilde{\alpha}| + \frac{1}{2}|\tilde{\beta}|)t} e^{-\frac{1}{4}\hat{\mu}(\xi,w)} \\ & \times \sum_{|\sigma| + |\eta| \leq j} \left| (\partial_\xi - \partial_w)^\sigma \partial_w^\eta \hat{f}(e^{-\frac{3}{2}t}\xi, e^{-\frac{1}{2}t}(w + \xi) - e^{-\frac{3}{2}t}\xi) \right| \end{aligned}$$

for $t \geq \log 36$. Thus we have, for $t \geq \log 36$ and $j = |\tilde{\alpha}| + |\tilde{\beta}| \geq n+1$,

$$\|I_{\alpha',\beta',\tilde{\alpha},\tilde{\beta},n}\|_{L^2} \leq C \left\{ \begin{array}{l} e^{-(\frac{3}{2}|\tilde{\alpha}| + \frac{1}{2}|\tilde{\beta}|)t} \|f\|_{X^{0,0}_{j+\frac{1}{2}(2N+1)}}, \\ e^{Nt - (\frac{3}{2}|\tilde{\alpha}| + \frac{1}{2}|\tilde{\beta}|)t} \|f\|_{X^{0,0}_j}. \end{array} \right. \tag{3.7}$$

For $n+2N+1 \le j = |\tilde{\alpha}|+|\tilde{\beta}| \le r$ we apply the second inequality of (3.7) to obtain

$$\|I_{\alpha',\beta',\tilde{\alpha},\tilde{\beta},n}\|_{L^2} \le Ce^{-\frac{n+1}{2}t}\|f\|_{X_r^{0,0}},$$

since $N - (\frac{3}{2}|\tilde{\alpha}| + \frac{1}{2}|\tilde{\beta}|) \le -\frac{n+1}{2}$; while for $n+1 \le j = |\tilde{\alpha}|+|\tilde{\beta}| \le n+2N$ we apply the first inequality of (3.7) to obtain

$$\|I_{\alpha',\beta',\tilde{\alpha},\tilde{\beta},n}\|_{L^2} \le Ce^{-\frac{n+1}{2}t}\|f\|_{X_r^{0,0}},$$

since $j + \frac{1}{2}(2N+1) \le n+3N+\frac{1}{2} \le r$.

Now recall that $T(t) = e^{-(2N-\gamma)t}S(t)$. Then, for any nonnegative integers ℓ and m, we find from the above estimates that

$$\|\mathcal{Q}_n T(t)f\|_{X_r^{\ell,m}} \le Ce^{\lambda_{n+1}t}\|f\|_{X_r^{0,0}}$$

holds provided that $t \ge \log 36$.

For $t \le \log 36$, it is easy to see that

$$\|T(t)f\|_{X_r^{\ell,m+j}} \le C(1+t^{-\frac{j}{2}})\|f\|_{X_r^{\ell,m}}$$

for any nonnegative r, l, and m and $j=0,1$. Thus we have

$$\|\mathcal{Q}_n T(t)f\|_{X_r^{\ell,m+j}} \le C(1+t^{-\frac{j}{2}})\|f\|_{X_r^{\ell,m}}$$

for $t \le \log 36$. This, together with the estimate for $t \ge \log 36$, yields the desired result, and the proof is complete. □

Remark 3.7. One can also obtain

$$\|T(t)f\|_{X_r^{\ell+1,m}} \le C(1+t^{-3/2})\|f\|_{X_r^{\ell,m}}$$

for small t.

4. Estimates for the nonlinearity. Theorem 2.1 follows from Propositions 3.6 and 4.1 below as in [10, 21] by applying standard arguments of invariant manifold theory in [6, 16]. So our remaining task is to prove the following.

PROPOSITION 4.1. *Let $N \ge 2$. If $r > \frac{N}{2}$, then the following estimate holds for any fixed nonnegative m and k:*

$$\|E(f)\cdot\nabla_u g\|_{X_r^{m+\ell,k}} \le C\|f\|_{X_r^{m+\ell,k}}\|g\|_{X_r^{m+\ell,k+1}},$$

where $\ell = [\frac{N}{2}-1]+1$.

Proof. Here we prove the case $m=k=0$ only. The extension to general m and k is an easy task.

First, we observe that $\frac{x}{|x|^N}$ is homogeneous of degree $1-N$. Therefore,

$$\|\partial_x^\alpha E(f)\|_{L^q(dx)} \le C\|\int \partial_x^\alpha f(x,u)\,du\|_{L^p(dx)}$$

with $1<p<q<\infty$, $\frac{1}{q} = \frac{1}{p} - \frac{1}{N}$ [13, Cor. 5.15, pp. 137]. We thus obtain

$$\begin{aligned} \|\partial_x^\alpha E(f)\|_{L^q(dx)} &\le C\int \|\partial_x^\alpha f(x,u)\|_{L^p(dx)}\,du \\ &\le C_\varepsilon\left(\int (1+|u|^2)^{\frac{N+\varepsilon}{2}}\|\partial_x^\alpha f(x,u)\|_{L^p(dx)}^2\,du\right)^{1/2} \end{aligned} \tag{4.1}$$

for any $\varepsilon > 0$, where p and q are the same as above.

Second, we note that $\|f\|_{X_r^{\ell,0}}$ is equivalent with $\|\sum_{|\alpha|\leq\ell}\partial_x^\alpha(\rho_r f)\|_{L^2(dxdu)}$, where $\rho_r(x,u)=(1+|x|^2+|u|^2)^{r/2}$. Therefore, by the interpolation inequality,

$$\|\nabla_x^j f\|_{L^2(dx)}\leq C\|\nabla_x^\ell f\|_{L^2(dx)}^{\frac{j}{\ell}}\|f\|_{L^2(dx)}^{1-\frac{j}{\ell}},\quad 1\leq j\leq\ell,$$

it suffices to show that

$$\|\partial_x^\alpha(\rho_r E(f)\cdot\nabla_u g)\|_{L^2(dxdu)}\leq C\|f\|_{X_r^{\ell,0}}\|g\|_{X_r^{\ell,1}}$$

for $|\alpha|=\ell$ and 0.

For a multi-index β and $r\geq 0$ we set $\tilde g_{\beta,r}(x,u)=|\partial_x^\beta(\rho_r(x,u)\nabla_u g(x,u))|$. Then

$$\|\partial_x^\alpha(\rho_r E(f)\cdot\nabla_u g)\|_{L^2(dxdu)}\leq C\sum_{\beta\leq\alpha}\|\partial_x^{\alpha-\beta}E(f)\tilde g_{\beta,r}\|_{L^2(dxdu)}\equiv C\sum_{\beta\leq\alpha}J_{\alpha,\beta,r}$$

and

$$J_{\alpha,\beta,r}\leq\|\partial_x^{\alpha-\beta}E(f)\|_{L^q(dx)}\big\|\|\tilde g_{\beta,r}\|_{L^s(dx)}\big\|_{L^2(du)}\tag{4.2}$$

with $2\leq q,\ s\leq\infty$ satisfying $\frac{1}{q}+\frac{1}{s}=\frac{1}{2}$.

We consider the case $N=3$. Then $\ell=[\frac{N}{2}-1]+1=1$. We estimate each $J_{\alpha,\beta,r}$. For $|\alpha|=\ell(=1)$ and $|\beta|=0$ we take $\frac{1}{q}=\frac{1}{2}-\frac{1}{N}$ and $\frac{1}{s}=\frac{1}{N}$ in (4.2). Then by (4.1) with $p=2$ we have

$$\|\partial_x^\alpha E(f)\|_{L^q(dx)}\leq C_\varepsilon\|\partial_x^\alpha f\|_{X^{0,0}_{\frac{1}{2}(N+\varepsilon)}},$$

and by the Gagliardo–Nirenberg–Sobolev inequality (see, e.g., [14]), we see that

$$\|\tilde g_{\beta,r}\|_{L^s(dx)}\leq C\|\nabla_x^\ell\tilde g_{0,r}\|_{L^2(dx)}^{\delta}\|\tilde g_{0,r}\|_{L^2(dx)}^{1-\delta},$$

where $\frac{1}{s}=\delta(\frac{1}{2}-\frac{\ell}{N})+(1-\delta)\frac{1}{2}$ and $\delta\in[0,1]$. It then follows that for $|\alpha|=\ell(=1)$ and $|\beta|=0$

$$J_{\alpha,\beta,r}\leq C_\varepsilon\|f\|_{X^{\ell,0}_{\frac{1}{2}(N+\varepsilon)}}\|g\|_{X_r^{\ell,1}}.$$

We next estimate $J_{\alpha,\beta,r}$ with $|\beta|=\ell(=1)$. Note that in this case $\alpha=\beta$. Taking $q=\infty$ and $s=2$ in (4.2) and using (4.1) and the Gagliardo–Nirenberg–Sobolev inequality, we obtain

$$\|E(f)\|_{L^\infty(dx)}\leq C\|\nabla_x^\ell E(f)\|_{L^{q_1}(dx)}^{\delta}\|E(f)\|_{L^{q_1}(dx)}^{1-\delta}\leq C_\varepsilon\|f\|_{X^{\ell,0}_{\frac{1}{2}(N+\varepsilon)}},$$

where $\frac{1}{q_1}=\frac{1}{2}-\frac{1}{N}$, $0=\delta(\frac{1}{q_1}-\frac{\ell}{N})+(1-\delta)\frac{1}{q_1}$, and $\delta\in[0,1]$. Whence, for $|\alpha|=|\beta|=\ell(=1)$,

$$J_{\alpha,\beta,r}\leq C_\varepsilon\|f\|_{X^{\ell,0}_{\frac{1}{2}(N+\varepsilon)}}\|g\|_{X_r^{\ell,1}}.$$

In the case when $\alpha=0$, we take $q=\infty$ and $s=2$ in (4.2). Then, similarly as above, we see that

$$J_{\alpha,\beta,r}\leq C_\varepsilon\|f\|_{X^{\ell,0}_{\frac{1}{2}(N+\varepsilon)}}\|g\|_{X_r^{0,1}}$$

for $\alpha = \beta = 0$. Combining the above estimates, we obtain the desired estimate for $N = 3$.

We next consider the case when $N = 2$. In this case we also have $\ell = [\frac{N}{2} - 1] + 1 = 1$. We choose $1 < \tilde{p} < 2$ and set $\frac{1}{\tilde{q}} = \frac{1}{\tilde{p}} - \frac{1}{2}$. When $|\beta| = \ell (= 1)$, we take $q = \infty$ and $s = 2$ in (4.2). Then by (4.1) and the Gagliardo–Nirenberg–Sobolev inequality, we see that

$$\begin{aligned} \|E(f)\|_{L^\infty(dx)} &\leq C\|\nabla_x^\ell E(f)\|_{L^{\tilde{q}}(dx)}^\delta \|E(f)\|_{L^{\tilde{q}}(dx)}^{1-\delta} \\ &\leq \left(\sum_{|\alpha| \leq \ell} \int (1 + |u|^2)^{\frac{1}{2}(N+\varepsilon)} \|\partial_x^\alpha f\|_{L^{\tilde{p}}(dx)}^2 \, du \right)^{1/2} \\ &\leq C_\varepsilon \|f\|_{X^{\ell,0}_{\frac{1}{\tilde{p}}(N+\varepsilon)}}, \end{aligned}$$

where $0 = \delta(\frac{1}{\tilde{q}} - \frac{\ell}{N}) + (1 - \delta)\frac{1}{\tilde{q}}$ and $\delta \in [0, 1]$. Therefore, for $|\alpha| = |\beta| = \ell (= 1)$,

$$J_{\alpha,\beta,r} \leq C_\varepsilon \|f\|_{X^{\ell,0}_{\frac{1}{\tilde{p}}(N+\varepsilon)}} \|g\|_{X_r^{\ell,1}}.$$

For $\alpha = \beta = 0$ we obtain, in a similar manner,

$$J_{\alpha,\beta,r} \leq C_\varepsilon \|f\|_{X^{\ell,0}_{\frac{1}{\tilde{p}}(N+\varepsilon)}} \|g\|_{X_r^{0,1}}.$$

For $|\alpha| = \ell (= 1)$ and $|\beta| = 0$ we take $q = \tilde{q}$ and $\frac{1}{s} = \frac{1}{2} - \frac{1}{\tilde{q}}$ in (4.2). By (4.1) we have

$$\|\partial_x^\alpha E(f)\|_{L^{\tilde{q}}(dx)} \leq C_\varepsilon \|\partial_x^\alpha f\|_{X^{0,0}_{\frac{1}{\tilde{p}}(N+\varepsilon)}}.$$

By the Gagliardo–Nirenberg–Sobolev inequality, we have

$$\|\tilde{g}_{\beta,r}\|_{L^s(dx)} \leq C\|\nabla_x^\ell \tilde{g}_{0,r}\|_{L^2(dx)}^\delta \|\tilde{g}_{0,r}\|_{L^2(dx)}^{1-\delta},$$

where $\frac{1}{s} = \frac{1}{2} - \frac{1}{\tilde{q}}$, $\frac{1}{s} = \delta(\frac{1}{2} - \frac{\ell}{N}) + (1 - \delta)\frac{1}{2}$, and $\delta \in [0, 1]$. It then follows that for $|\alpha| = \ell (= 1)$ and $|\beta| = 0$

$$J_{\alpha,\beta,r} \leq C_\varepsilon \|f\|_{X^{\ell,0}_{\frac{1}{\tilde{p}}(N+\varepsilon)}} \|g\|_{X_r^{\ell,1}}.$$

Combining the above estimates, we obtain

$$\|E(f) \cdot \nabla_u g\|_{X_r^{\ell,0}} \leq C_{\varepsilon,\tilde{p}} \|f\|_{X^{\ell,0}_{\frac{1}{\tilde{p}}(N+\varepsilon)}} \|g\|_{X_r^{\ell,1}}.$$

Now, for a given $r > \frac{N}{2}$, choose $\tilde{p}$ and $\varepsilon > 0$ so that $r > \frac{1}{\tilde{p}}(N + \varepsilon)$. Then we obtain the desired estimate for the case when $N = 2$.

When N is odd and $N \geq 5$, $J_{\alpha,\beta,r}$ is estimated as follows. If $|\alpha| = 0$ or if $|\alpha| = \ell$ and $|\beta| = 0$, ℓ, then one can estimate $J_{\alpha,\beta,r}$ in the same way as in the case when $N = 3$ since $\ell = [\frac{N}{2} - 1] + 1$. For $|\alpha| = \ell$ and $1 \leq |\beta| \leq \ell - 1$, we can apply the Gagliardo–Nirenberg–Sobolev inequality to obtain

$$\|\partial_x^{\alpha-\beta} E(f)\|_{L^q(dx)} \leq C\|\nabla_x^\ell E(f)\|_{L^{q_1}(dx)}^{\delta_1} \|E(f)\|_{L^{q_1}(dx)}^{1-\delta_1}$$

and

$$\|\tilde{g}_{\beta,r}\|_{L^s(dx)} \leq C\|\nabla_x^\ell \tilde{g}_{0,r}\|_{L^2(dx)}^{\delta_2} \|\tilde{g}_{0,r}\|_{L^2(dx)}^{1-\delta_2}$$

for some $2 < q,\, q_1,\, s < \infty$, $\frac{\ell-|\beta|}{\ell} \le \delta_1 < 1$, and $\frac{|\beta|}{\ell} \le \delta_2 < 1$ with

$$\text{(4.3)} \qquad \begin{cases} \dfrac{1}{q} = \dfrac{\ell-|\beta|}{N} + \delta_1\left(\dfrac{1}{q_1} - \dfrac{\ell}{N}\right) + (1-\delta_1)\dfrac{1}{q_1}, \quad \dfrac{1}{q_1} = \dfrac{1}{2} - \dfrac{1}{N}, \\ \dfrac{1}{s} = \dfrac{|\beta|}{N} + \delta_2\left(\dfrac{1}{2} - \dfrac{\ell}{N}\right) + (1-\delta_2)\dfrac{1}{2}, \quad \dfrac{1}{s} = \dfrac{1}{2} - \dfrac{1}{q}. \end{cases}$$

In fact, this is possible since $\ell = [\frac{N}{2} - 1] + 1$. For example, take $\delta_1 = \frac{N-\frac{3}{2}}{N-1}$ in (4.3). We then verify that $2 < q < \infty$ and $\delta_2 = \delta_1$. Using (4.1), we can now obtain the desired estimate.

When N is even and $N \ge 4$, one can prove similarly to the case of odd N with a slight modification as we did for $N = 2$. Set q_1 and δ_1 in (4.3) such as $\frac{1}{q_1} = \frac{1}{\tilde{p}} - \frac{1}{N}$ and $\delta_1 = \frac{1}{\tilde{p}} - \frac{1}{2} + \frac{N-1}{N}$ for $1 < \tilde{p} < 2$. If $\tilde{p}$ is sufficiently close to 2, then we find that $2 < q < \infty$ and $\frac{\ell-|\beta|}{\ell} \le \delta_1 < 1$. The desired estimate then follows in a similar manner to the case when $N = 2$. This completes the proof. □

Appendix. In the appendix we outline a derivation of an integral formula of $S(t)f_0$.

Consider the linear problem

$$\text{(A.1)} \qquad \begin{aligned} &\partial_t f - \left(\frac{3}{2}x - u\right)\cdot\nabla_x f - \frac{1}{2}u\cdot\nabla_u f - 2Nf - \Delta_u f = 0, \\ &f|_{t=0} = f_0. \end{aligned}$$

Taking the Fourier transform of (A.1), we have

$$\text{(A.2)} \qquad \begin{aligned} &\partial_t \hat{f} + \frac{3}{2}\xi\cdot\nabla_\xi \hat{f} + \left(\frac{1}{2}w - \xi\right)\cdot\nabla_w \hat{f} + |w|^2\hat{f} = 0, \\ &\hat{f}|_{t=0} = \hat{f}_0. \end{aligned}$$

The problem (A.2) is reduced to the following two problems:

$$\text{(A.3)} \qquad \partial_t \hat{f} + \frac{3}{2}\xi\cdot\nabla_\xi \hat{f} + \left(\frac{1}{2}w - \xi\right)\cdot\nabla_w \hat{f} = 0, \quad \hat{f}|_{t=0} = \hat{f}_0,$$

and

$$\text{(A.4)} \qquad \partial_t \hat{f} + \frac{3}{2}\xi\cdot\nabla_\xi \hat{f} + \left(\frac{1}{2}w - \xi\right)\cdot\nabla_w \hat{f} = -|w|^2, \quad \hat{f}|_{t=0} = 0.$$

Let $\hat{f}^{(1)}(\xi, w, t)$ and $\hat{f}^{(2)}(\xi, w, t)$ be solutions of (A.3) and (A.4), respectively. Then the solution of (A.2) is given by

$$\hat{f}(\xi, w, t) = \hat{f}^{(1)}(\xi, w, t)\, e^{\hat{f}^{(2)}(\xi, w, t)}.$$

Solutions of (A.3) and (A.4) can be obtained easily by the characteristics. Let $(\Xi(t), W(t))$ be the solution of

$$\frac{d}{dt}\begin{pmatrix} \Xi \\ W \end{pmatrix} = \begin{pmatrix} -\frac{3}{2} & 0 \\ 1 & -\frac{1}{2} \end{pmatrix}\begin{pmatrix} \Xi \\ W \end{pmatrix}, \quad \begin{pmatrix} \Xi(0) \\ W(0) \end{pmatrix} = \begin{pmatrix} \xi \\ w \end{pmatrix},$$

which are explicitly given as

$$\Xi(t) = e^{-\frac{3}{2}t}\xi, \quad W(t) = e^{-\frac{1}{2}t}w + (e^{-\frac{1}{2}t} - e^{-\frac{3}{2}t})\xi.$$

Then solutions $\hat{f}^{(1)}(\xi, w, t)$ and $\hat{f}^{(2)}(\xi, w, t)$ take the forms

$$\hat{f}^{(1)}(\xi, w, t) = \hat{f}_0(\Xi(t), W(t)) = \hat{f}_0(e^{-\frac{3}{2}t}\xi, e^{-\frac{1}{2}t}w + e^{-\frac{1}{2}t}a(t)\xi)$$

and

$$\hat{f}^{(2)}(\xi, w, t) = -\int_0^t |W(t-s)|^2\, ds = -a(t)\left|w + \frac{a(t)}{2}\xi\right|^2 - \frac{a(t)^3}{12}|\xi|^2,$$

where $a(t) = 1 - e^{-t}$. Hence the solution of (A.2) is

$$\widehat{S(t)f_0}(\xi, w) = \hat{f}(\xi, w, t) = \hat{f}_0(e^{-\frac{3}{2}t}\xi, e^{-\frac{1}{2}t}w + e^{-\frac{1}{2}t}a(t)\xi)e^{-a(t)|w+\frac{a(t)}{2}\xi|^2 - \frac{a(t)^3}{12}|\xi|^2}.$$

The inverse Fourier transform now gives an integral formula of the semigroup $S(t)f_0$:

$$S(t)f_0 = \left(\frac{\sqrt{3}}{2\pi}\right)^N a(t)^{-2N} \int e^{-\frac{3|x-e^{-\frac{3}{2}t}y - \frac{a(t)}{2}(u+e^{-\frac{t}{2}}v)|^2}{a(t)^3} - \frac{|u-e^{-\frac{t}{2}}v|^2}{4a(t)}} f_0(y, v)dydv,$$

where $a(t) = 1 - e^{-t}$.

Remarks. (i) One can see that the semigroup $S(t)$ is compact for $t > 0$ in the space $X = L^2(e^{\mu(x,u)}dxdu)$ with $\mu(x, u) = 3|x - \frac{u}{2}|^2 + \frac{|u|^2}{4}$ (which implies that the spectrum of $S(t)$ consists only of discrete eigenvalues). This can be shown as follows. A straightforward calculation yields the identity

$$\begin{aligned} &\frac{3\left|x - e^{-\frac{3}{2}t}y - \dfrac{a(t)}{2}(u + e^{-\frac{t}{2}}v)\right|^2}{a(t)^3} + \frac{|u - e^{-\frac{t}{2}}v|^2}{4a(t)} + \frac{1}{2}\mu(y, v) - \frac{1}{2}\mu(x, u) \\ &= \frac{\nu_1(a(t))}{a(t)^3}\left|x - \frac{F_1(t, a(t), y, u, v)}{G_1(a(t))}\right|^2 + \frac{\nu_2(a(t))}{a(t)}\left|u - \frac{F_2(t, a(t), y, v)}{G_2(a(t))}\right|^2 \\ &\quad + a(t)\nu_3(a(t))|y - F_3(t, a(t), v)|^2 + a(t)^3\nu_4(a(t))|v|^2, \end{aligned}$$

where $\nu_j(a)$ $(j = 1, \dots, 4)$ are smooth in a with $\delta \le \nu_j(a) \le M$ for some $\delta > 0$ and $M > 0$ uniformly in $a \in [0, 1]$, F_j are polynomials in a whose coefficients are smooth in t and linear in y, u, v, and G_j are polynomials in a with $\inf_{0\le a\le 1} G_j(a) \ge \delta$ for some $\delta > 0$. Noting this identity and using the integral formula of $S(t)f_0$ above, one can see that

$$\|(1 + \nabla_x + \nabla_u)S(t)f_0\|_X \le Ce^{\eta t}(1 + a(t)^{-3/2} + a(t)^{-1/2})\|f_0\|_X$$

for $t > 0$ with some constants $\eta > 0$ and $C > 0$. This inequality shows that $S(t)$ is compact for $t > 0$ in X, since the embedding

$$\{f \in X : \nabla_x f, \nabla_u f \in X\} \hookrightarrow X$$

is compact [12, Proposition 1.1].

(ii) Noting remark (i) and the fact that $\hat{f}(\xi, w)$ is analytic in ξ and w for $f \in X$, one can deduce that the spectrum $\sigma(A)$ of A in X consists only of discrete eigenvalues $\sigma_k = -\frac{k}{2}$, $k = 0, 1, 2, \dots$, and the eigenspace associated with σ_k is spanned by functions $g_{\alpha,\beta}$ with $3|\alpha| + |\beta| = k$. The corresponding assertion holds for the adjoint A^*.

(iii) As for $\frac{d}{dt}S(t)$, the inequality

$$\left\| \frac{d}{dt} S(t) f_0 \right\|_X \leq C t^{-2} \|f_0\|_X$$

holds for small $t > 0$, and the behavior $\|\frac{d}{dt}S(t)f_0\|_X = O(t^{-2})$ as $t \to 0$ seems to be optimal. Thus $S(t)$ does not seem to be analytic in X.

Acknowledgments. The author is very grateful to the referees for their valuable comments. The author expresses his hearty thanks to Professor Takayuki Kobayashi for valuable discussions. The author also thanks Professor Takayoshi Ogawa for his interest in this work.

ON THE UNIQUENESS OF THE CONTINUATION FOR A THERMOELASTICITY SYSTEM[*]

VICTOR ISAKOV[†]

Abstract. We obtain new uniqueness of the continuation results for the thermoelasticity system on the plane. The crucial ingredient of the proofs is the use of Carleman-type estimates with two large parameters for basic second order partial differential operators with constant coefficients. We derive these estimates by applying differential quadratic forms. The proposed technique can be of value when studying similar questions for systems of partial differential equations of upper triangular principal structure. The results can be applied to control theory and inverse problems.

Key words. uniqueness of the continuation, Carleman estimates, the equations of thermoelasticity

AMS subject classifications. 35Bxx, 35Lxx

PII. S0036141000366509

We will consider the lateral Cauchy problem for a thermoelasticity system (1.1), (1.2). This system describes combined elastic and thermal effects in plates and is of current theoretical and applied interest. We observe that this system is strongly coupled and has an "upper triangular" principal structure. Many important questions including the fundamental one about uniqueness of the continuation are open. The system (1.1), (1.2) cannot be principally diagonalized like Maxwell's or elasticity systems in the recent work of Eller, Isakov, Nakamura, and Tataru [4] and Isakov [9]. In this paper we give sufficient conditions for uniqueness by combining new Carleman estimates with additional large parameter λ for the Laplace, wave, and heat equations. This additional parameter enables us to principally decouple the system. For wave operators such estimates were first introduced and used for the elasticity system in the paper of Isakov [7]. In section 3 of this paper we derive them with the same weight function for the wave and Laplace equations, and in section 4 we derive them for the heat operator. Finally, in section 5 we combine these estimates to obtain the main uniqueness result. In case of constant (or more generally, analytic) coefficients one can derive sharp uniqueness results from the Holmgren–John theorem, and we give this short derivation in section 2. But when coefficients are of finite smoothness, this argument cannot be applied as well as its recent generalization by Tataru [16] and the subsequent work of Robbiano and Zuily [15]. The paper of Lebeau and Zuazua [13] handles a thermoelasticity system in self-adjoint form (with variable principal part) because it requires use of eigenfunctions expansions and of the geometrical optics technique introduced by Bardos, Lebeau, and Rauch [3] with its restrictions of extra regularity of coefficients and absence of diffractive points of the lateral boundary.

We expect that the idea of the additional parameter λ can be used for other systems with "triangular" principal structure. Observe that the concept of the principal part depends on a particular equation or system. Some interesting cases are discussed in the book of Hörmander [5] as well as in the papers of Isakov [8] and Nirenberg [14].

Uniqueness of the continuation has immediate applications to inverse problems (see Isakov [10]) and to optimal control theory. In particular, by using uniqueness of the continuation, Avalos and Lasiecka [2] recently proved boundary stabilizability of the system (1.1), (1.2). The results of Lagnese [12] about exact-approximate controllability are applicable only to the system (1.1), (1.2) with constant coefficients when control is applied to the whole lateral boundary, and there is a good possibility that the results of this paper and their extensions to variable coefficients will be missing ingredients for proofs of controllability in a general situation, in particular from a part of the lateral boundary.

We use the standard notation $\partial_k = \partial/\partial x_k$, $\partial_t = \partial/\partial_t$, $D = -i\partial$. We let $\nabla = (\partial_1, \ldots, \partial_n)$, $\nabla_{x,t} = (\nabla, \partial_t)$. α and β are multi-indices of partial differentiations ∂^α, ∂^β. $B(a;r)$ is the ball of radius r centered at a. ν denotes the exterior unit normal to the boundary of a domain, C and δ denote constants depending only on operators P, the domain Q, the weight function ϕ, and the parameter $\epsilon > 0$. We will specify dependence on all other parameters. $\| \|_{(k)}(Q)$ is the norm in the Sobolev space $H_k(Q)$.

1. Main results. We are interested in the system of two strongly coupled partial differential equations

$$\partial_t^2 w - \gamma\Delta\partial_t^2 w + \Delta^2 w + b_1\Delta v + B_1 w + B_2 v = 0 \quad \text{in } Q = \Omega \times (0,T), \tag{1.1}$$

$$\partial_t v - b\Delta v + B_3 w + B_4 v = 0 \qquad \text{in } Q = \Omega \times (0,T), \tag{1.2}$$

where γ, b are positive constants, Ω is a domain in $\mathbb{R}^2$,

$$B_k w = b_k \partial_t \Delta w + \sum b_{j,k}\partial_j \Delta w + \sum b_{2+j,k}\partial_t^2 \partial_j w + \sum b_{k,\alpha}\partial^\alpha w, k = 1, 3,$$

and the sums in B_k are over $j = 1, 2, |\alpha| \leq 2$, with $\alpha_0 = 0$ for B_4, $B_k v = \sum b_{4+j,k}\partial_j v + b_{7,k} v$, $k = 2, 4$. Here b_k, $b_{j,k}$ are in $L^\infty(Q)$. In particular, when $B_1 = B_2 = 0$, $B_3 = b_3\partial_t\Delta$, $B_4 v = b_{7,4} v$, we obtain the simplest thermoelasticity system for (scalar) displacement w and temperature v. We are interested in the (lateral) Cauchy problem for this system when in addition to the equations we prescribe the Cauchy data

$$\partial_\nu^j w = w_j, \quad \partial_\nu^k v = v_k, \quad j = 0, \ldots, 3, \quad k = 0, 1 \quad \text{on } S = \Gamma \times (0,T), \tag{1.3}$$

where $\Gamma \subset \partial\Omega$, $\Gamma \in C^1$.

Let Q_- be a domain in $\mathbb{R}^2$ such that $S = \partial Q_- \cap \partial Q$, while Q_- and Q do not overlap. For any reasonable definition of a solution to the Cauchy problem (1.1)–(1.3), uniqueness in $Q_0 \subset Q$ will follow from the following uniqueness of the continuation principle: if (w, v) solves (1.1), (1.2) in $Q_- \cup S \cup Q$ and is zero on Q_-, then it is zero on Q_0. Observe that we generally cannot expect uniqueness in the whole Q due to finite speed of propagation of the hyperbolic component w.

First we consider a simple but important case of (real) analytic b_j, $b_{j,k}$ and show that the Holmgren–John theorem implies uniqueness in any subdomain Q_0 of Q formed of its points that can be reached by noncharacteristic (with respect to the operator $-\gamma\partial_t^2 + \Delta$) deformations of $\Gamma \times (0,T)$.

Theorem 1.1. *Let Q_* be a domain in $\mathbb{R}^3$. Let the coefficients b_j, $b_{j,k}$ be real analytic in Q_*. Let S_* be a C^2-surface inside Q_* which is time-like with respect to the wave operator $-\gamma\partial_t^2 + \Delta$ and which divides Q_* into two subdomains Q_- and Q_+. Let (w, v) be a (distribution) solution to the system* (1.1), (1.2) *in Q_*, which is zero in Q_+.*

Then (w, v) is zero near S_* in Q_*.

According to trace theorems, the Cauchy data for solutions with less regularity are in corresponding Sobolev spaces of negative order. Definition of the space $H_{(k-j-1/2)}(S)$ and applicability of the trace theorem for normal derivatives ∂_ν^j of functions from $H_{(k)}(\Omega)$ require $\Gamma \in C^{|k-j|}$.

Corollary 1.2. *Let $\Gamma \in C^2$. A solution $(w,v) \in C([0,T]; H_2(\Omega) \times L^2(\Omega))$ to the Cauchy problem* (1.1)–(1.3) *is uniquely determined at any point $(x,t) \in Q$ such that $\gamma^{1/2}d < t < T - \gamma^{1/2}d$, where d is the* (*Euclidean*) *distance in Q from x to Γ.*

We will prove these results in section 2. Meanwhile we observe that in Theorem 1.1 we consider more general domains Q_* than cylindrical Q and more general surfaces S_* than S. This generality is needed for noncharacteristic deformations to obtain Corollary 1.2. A C^1-surface in $\mathbb{R}^3$ with the unit normal ν is called time-like with respect to the wave operator $-\gamma\partial_t^2 + \Delta$ if $\nu_1^2 + \nu_2^2 > \gamma\nu_0^2$ at any point of this surface. d is the distance in Q, i.e., $d = \inf|\gamma|$ over all smooth curves $\gamma \subset Q$ joining x and a point of Γ; $|\gamma|$ is the Euclidean length of γ.

When coefficients are not analytic, this argument does not work and we will obtain uniqueness in a smaller (than in Corollary 1.2) domain Q_0 by using Carleman estimates. We let Q_ϵ be $Q \cap \{-\theta^2(t-T/2)^2 + |x-a|^2 - \rho > \epsilon\}$, where ρ is a parameter to be chosen later. We will give uniqueness results in two cases: (1) $\Gamma = \partial\Omega$, and (2) $\Omega \subset \{-h < x_2 < 0, |x_1| < r\}$, $\Gamma = \partial\Omega \cap \{x_2 < 0\}$. We will assume

$$\begin{aligned} &\Omega \subset B(0;\theta T/2), \quad \rho = 0 \quad \text{in case (1)}, \\ &4h(h+2a_2) < \theta^2 T^2, \quad \rho = a_2^2 + r^2, \quad a = (0,a_2) \quad \text{in case (2)}. \end{aligned} \tag{1.4}$$

Let $Q_\epsilon = Q \cap \{-\theta^2(t-T/2)^2 + |x-a|^2 - \rho > \epsilon\}$. Geometry of Q_ϵ (including illustrating figures) and the conditions (1.4) are discussed in Isakov [10, section 3.4]. In particular, choosing $\theta < \gamma^{-\frac{1}{2}}$ close to $\gamma^{-\frac{1}{2}}$ and $T > \frac{\mathrm{diam}\Omega}{\sqrt{\gamma}}$, one obtains a sharp uniqueness domain in case (1). In case (2) the uniqueness domain Q_0 is not optimal: the maximal space domain $Q_0 \cap \{t = T/2\}$ is never $\Omega \times \{T/2\}$, but it contains the domain $(\Omega \cap \{x_2 < -\frac{r^2}{2a_2}\}) \times \{T/2\}$, and selecting large a_2 and large T according to (1.4) (for example, greater than $2\sqrt{\gamma a_2}$), we can approximate Ω with any precision by uniqueness domains.

Theorem 1.3. *Let us assume that* (1.4) *is satisfied and that*

$$\gamma\theta^2 < 1. \tag{1.5}$$

Let the coefficients b_j, $b_{j,k}$, $b_{j,\alpha} \in L^\infty(Q)$.

Then any solution (w,v) to (1.1)–(1.3) *with lower order derivatives $\partial_t\Delta w$, $\partial_j\Delta w$, $\partial_t^2\partial_j w$, $\partial^\alpha w$, $|\alpha| \le 2$, $\partial_j v (j = 1,2)$ in $L^2(Q)$ is unique in Q_0.*

In the case of time independent coefficients, one can reduce regularity assumptions of Theorem 1.3 by using mollifying with respect to t and standard elliptic theory.

Corollary 1.4. *In addition to the conditions of Theorem* 1.3 *let us assume that the coefficients of* (1.1), (1.2) *do not depend on t and that the partial derivatives of first order of the coefficients $b_{1,k}$, $b_{2,k}$, $b_{5,k}$, $b_{6,k}$ are in $L^\infty(\Omega)$.*

Then any solution $(w,v) \in C([0,T]; H_2(\Omega) \times L^2(\Omega))$ to the Cauchy problem (1.1)–(1.3) *is unique in Q_0.*

We will prove these results in sections 2–5, where the following notation and known results are used.

We let $\zeta = \xi + i\tau\nabla_{t,x}\phi$, $\tau > 0$, $\xi = (\xi_0, \xi_1, \xi_2) \in \mathbb{R}^3$, and

$$\phi = e^{\lambda\psi}, \quad \psi(x,t) = -\theta^2(t-T/2)^2 + |x-a|^2 - \rho.$$

We have the following simple equalities:

$$
\begin{gathered}
\partial_0\phi = -\lambda\theta^2(t-T/2)\phi, \quad \partial_j\phi = \lambda(x-a)_j\phi,\\
\partial_0^2\phi = (\lambda^2\theta^4(t-T/2)^2 - \lambda\theta^2)\phi,\\
\partial_0\partial_j\phi = -\lambda^2\theta^2(t-T/2)(x-a)_j\phi, \quad j=1,2,\\
\partial_1\partial_2\phi = \lambda^2(x-a)_1(x-a)_2\phi, \quad \partial_j^2\phi = (\lambda^2(x-a)_j^2+\lambda)\phi.
\end{gathered} \tag{1.6}
$$

A differential quadratic from $\mathcal{G}v\overline{v}$ is the sum

$$\sum g^{\alpha\beta}(x,t)D^\alpha v\overline{D^\beta v},$$

and its symbol is

$$\sum g^{\alpha\beta}(x,t)\zeta^\alpha\overline{\zeta^\beta}.$$

In the next sections for a partial differential operator $P(x,t;D)$ with the principal symbol $p(x,t;\zeta)$ (which will be differently defined in sections 3 and 4), we will make use of the differential quadratic forms

$$\mathcal{F}(x,t;D,\overline{D},\tau) = |P(x,t;D+i\tau\nabla_{x,t}\phi(x,t))v|^2 - |\overline{P}(x,t;D-i\tau\nabla_{x,t}\phi(x,t))v|^2$$

and $\mathcal{G}$, which are obtained from $\mathcal{F}$ by integrating by parts and have the principal symbol

$$
\begin{aligned}
\mathcal{G}_{pr}(x,t;\xi,\xi,\tau) = 2\tau\sum\partial_j\partial_k\phi\partial p/\partial\zeta_j\overline{\partial p/\partial\zeta_k} - 2\mathcal{T}\sum\partial p/\partial\zeta_k\overline{\partial_k p}\\
- 2\mathcal{T}\sum\overline{p}(\partial^2 p/\partial x_k\partial\zeta_k + i\tau\partial^2 p/\partial\zeta_j\partial\zeta_k\partial_j\partial_k\phi),
\end{aligned} \tag{1.7}
$$

where $\partial p/\partial\zeta_j$, $\partial_k p\dots$ are calculated at the point $(x,t;\xi+i\tau\nabla_{x,t}\phi(x,t))$. For the operators Δ and $\partial_t-\Delta$, the sums are over $j,k=1,2$, and for the wave operator they are over j, $k=0,1,2$. The form $\mathcal{G}$ has the following useful property:

$$\int_Q \mathcal{G}v\overline{v} = \int_Q \mathcal{F}v\overline{v} \le \int_Q |P(\,;D+i\tau\nabla\phi)v|^2 \tag{1.8}$$

for all functions $v \in C_0^\infty(Q)$. As one can see from formula (1.7) and the similar formula for the symbol of $\mathcal{G}$ (where the principal symbol of P must be replaced by the complete symbol of P and for the heat operator the sum is over j, $k=0,1,2$),

$$\left|\int_Q(\mathcal{G}_{pr}-\mathcal{G})v\overline{v}\right| \le C\lambda\sum\|(\tau\lambda\phi)^{1-|\alpha|}\partial^\alpha v\|_{(0)}^2(Q), \tag{1.9}$$

where the sum is over $|\alpha|\le 1$ for the wave operator P with the additional condition $\alpha_0=0$ for the Laplace and heat operators.

We will use the abbreviation $\sigma = \lambda\tau\phi$.

2. Proof of uniqueness in the analytic case.

The proof of Theorem 1.1 is a reduction of the system (1.1), (1.2) to a first order system to which one can apply the Holmgren–John theorem.

Proof of Theorem 1.1. It suffices to show that a solution (w,v) is zero near any point of S_* which we can assume to be the origin. S_* near the origin is the graph of a C^2-function on its tangent plane, and Q_+ is the subgraph of this function. Replacing this function by its second order Taylor polynomial and subtracting the square of the distance to the origin, we can assume that S_* is analytic near the origin. Now one can find an analytic substitution with nonzero Jacobian at the origin transforming this surface into the surface $\{y_2 = 0\}$.

Expressing Δv from (1.2) and substituting into (1.1), we obtain a new system. Since S_* is time-like with respect to the wave operator, the new system in the new variables $y_0, \dots, y_2$ will have the form

$$\partial_2^4 W = A_4 W + A_1 V, \quad \partial_2^2 V = A_2 V + A_3 W \quad \text{near the origin,} \tag{2.1}$$

where A_j are linear partial differential operators of order j with coefficients analytic near the origin; moreover, A_4 does not contain the partial differentiation ∂_2^4 and A_2 does not contain the partial differentiation ∂_2^2. The new vector functions $\boldsymbol{W}$, $\boldsymbol{V}$ whose components are all partial derivatives of the function W up to order 3 and all partial derivatives of V up to order 1 satisfy the first order system of the Cauchy–Kowalevsky type

$$\partial_2 \boldsymbol{W} = \boldsymbol{A}(y; \boldsymbol{W}, \partial_0 \boldsymbol{W}, \partial_1 \boldsymbol{W}, \boldsymbol{V}), \quad \partial_2 \boldsymbol{V} = \boldsymbol{B}(y; \boldsymbol{W}, \boldsymbol{V}, \partial_0 \boldsymbol{V}, \partial_1 \boldsymbol{V})$$

near the origin. Here $\mathbf{A}$, $\mathbf{B}$ are matrices analytically depending on y near the origin. Indeed, if $W_j = \partial_2^k \partial^\alpha w$, where $k + |\alpha| = 3$, $k < 3$, $\alpha_2 = 0$, then $\partial^\alpha = \partial^{\alpha(*)} \partial_l$ for some $l < 2$ and $\partial_2 W_j = \partial_l W_m$, where $W_m = \partial_2^{k+1} \partial^{\alpha(*)} w$. If $W_j = \alpha_2^3 w$, then $\partial_2 W_j$ can be expressed from the first equation (2.1). Similarly, one obtains the equations for $\mathbf{V}$.

Since $\mathbf{W}$, $\mathbf{V}$ are zero on one side of S_*, by the Holmgren–John theorem [6], [11] we conclude that they are zero near the origin.

The proof is complete. □

Proof of Corollary 1.2. From the definition of the distance d it follows that there is a finite collection of intervals $I_1, \dots, I_m$ in Ω such that the starting point x^l of I_l is inside I_{l-1}, the starting point of I_1 is on Γ, the terminal point of I_m is x, and their total length $d^* = d_1 + \cdots + d_m$ satisfies the inequality $\gamma^{1/2} d_* < t < T - \gamma^{1/2} d_*$. We will use the "triangle lemma" 3.4.6 in [10] to propagate subsequently along these intervals. As one can see from its proof in [10] for scalar hyperbolic equations this lemma is valid for our system (1.1), (1.2) because in Theorem 1.1 we use time-like surfaces for the scalar hyperbolic operator. In our situation, this lemma says that if Tr is the triangle in the (x_2, t)-plane with the vertices $(0,0)$, $(-R, T_0)$, $(-R, T_0)$, and Tr_ϵ is the ϵ-perturbation $\{|x_1| < \epsilon\} \times Tr$ of Tr with respect to x_1 and $\gamma^{1/2} R < T_0$, then a solution to the Cauchy problem (1.1)–(1.3) with $\Gamma = \partial(Tr_\epsilon) \cap \{x_2 = -R\}$ is uniquely determined in the whole Tr_ϵ. Here ϵ is any positive number, so the triangle can be arbitrarily "thin."

We can choose ϵ so small that any ϵ-perturbation P_l of the rectangle $I_l \times (0, T)$ in the normal direction is still in Q. Using the triangle lemma for P_1 (with the choice of the x_2-axis parallel to I_1 and possible t-translations of triangles), we conclude that (w, v) is uniquely determined near the interval $\{(x^2, t) : \gamma^{1/2} d_1 < t < T - \gamma^{1/2} d_1\}$. Propagating along P_2 we conclude that (w, v) is unique near $\{(x^3, t) : \gamma^{1/2}(d_1 + d_2) < t < T - \gamma^{1/2}(d_1 + d_2)\}$. Repeating this step m times, we complete the proof. □

3. Carleman-type estimates with additional parameter for Laplace, wave, and plate operators.

Lemma 3.1. *There is C such that*

$$\lambda^{1/2} \| \sigma^{3/2 - |\alpha|} e^{\tau\phi} \partial^\alpha u_1 \|_{(0)}(Q) \le C \| e^{\tau\phi} \Delta u_1 \|_{(0)}(Q) \tag{3.1}$$

for all $u_1 \in C_0^\infty(Q_\epsilon)$ *provided* $|\alpha| \le 1$, $\alpha_0 = 0$, *and* $\tau > C(\lambda)$.

Proof. First we will derive Carleman estimates in $Q(s) = Q \cap \{t = s\}$ and then integrate them with respect to s over $(0, T)$.

We consider $p(\zeta) = \zeta \cdot \zeta$ and the corresponding form $\mathcal{G}$. Let $(x^0, t^0) \in \overline{Q_\epsilon}$. We will denote by ϕ^0, $\mathcal{G}^0, \ldots$ functions and forms at the point (x^0, t^0).

For brevity we will drop the index 0 until (3.5). We will prove that

$$|\zeta|^4 \le C(\lambda^{-1}\sigma\mathcal{G}_{pr} + C|p(\zeta)|^2). \tag{3.2}$$

Indeed, the equality $p(\zeta) = 0$ and the relations (1.6) imply that

$$|\xi|^2 = \tau^2|\nabla\phi|^2 = \sigma^2|x-a|^2, \quad \xi \cdot \nabla\phi = 0. \tag{3.3}$$

According to (1.6), (1.7)

$$\begin{aligned}\mathcal{G}_{pr}(\xi,\xi,\tau) &= 8\tau \sum \lambda^2\phi(x-a)_j(x-a)_k\zeta_j\overline{\zeta_k} + 8\lambda\phi\sum|\zeta_k|^2 \\ &\ge 8\tau\lambda^2\phi|(x-a)\cdot\zeta|^2 \ge 8\tau\lambda^4\phi^3\tau^2|x-a|^2 \ge \epsilon_1\lambda\sigma^3,\end{aligned}$$

where we kept only $\mathcal{T}\zeta$, and used (1.6) and the inequality $|x-a| > 0$ on $\overline{Q_\epsilon}$ due to the choice of the parameters s, a and to the definition of Q_ϵ. From (3.3) it follows that $|\zeta| \le C\sigma$, so we have

$$C\tau\phi\mathcal{G}_{pr}(\xi,\xi,\tau) \ge |\zeta|^4. \tag{3.4}$$

For continuity and homogeneity reasons, this inequality holds when $|p(\zeta)| \le \delta|\zeta|^2$ for some $\delta > 0$ not depending on λ, τ.

Indeed, using the notation $\tau^* = \lambda\tau(x-a)\phi$ from (1.7) as in the above computation we have

$$\begin{aligned}\tau\phi\mathcal{G}_{pr}(\xi,\xi,\tau) &\ge 8\sum\tau_j^*\tau_k^*\zeta_j\overline{\zeta_k} - 4\tau^2\phi\mathcal{T}(\overline{p}i\Delta\phi_0) \\ &= 8|\tau^*\cdot\zeta|^2 - 4\tau^2\lambda^2\phi^2\mathcal{T}(\overline{p}i(|x-a|^2 + 2/\lambda)) \ge 8|\tau^*|^4 - C|p|\,|\tau^*|^2,\end{aligned}$$

where we have used the formulae (1.6) and dropped the real part of $\tau^* \cdot \zeta$. The inequality $|p| \le \delta|\zeta|^2$ implies that $|\xi|^2 - |\tau^*|^2 \le \delta(|\xi|^2 + |\tau^*|^2)$, or $|\xi|^2 \le (1+\delta)/(1-\delta)|\tau^*|^2$, and hence $|\zeta|^2 \le 2/(1-\delta)|\tau^*|^2$. Choosing δ small and summing up, we obtain (3.4).

Consider the case $\delta|\zeta|^2 \le |p(\zeta)|$. The definition of $\mathcal{G}$ implies that in any event $\tau\phi\mathcal{G} \ge -C_1|\zeta|^4$. Using this inequality and choosing $C > 2C_1/\delta$, we complete the proof of (3.2).

From (3.2) and from the property (1.9), we conclude that

$$\begin{aligned}\sum\int_{Q(s)}\sigma_0^{4-2|\alpha|}|\partial^\alpha v|^2 \le C\Bigg(&\lambda^{-1}\sigma_0\int_{Q(s)}\mathcal{G}(x^0,t^0;D,\overline{D},\tau)v\overline{v} \\ &+ \int_{Q(s)}|P(D+i\tau\nabla\phi^0)v|^2\Bigg)\end{aligned} \tag{3.5}$$

provided $v \in C_0^\infty(Q_\epsilon)$, $|\alpha| \le 2$, $\alpha_0 = 0$, and $\tau > C$. From the definition of $\mathcal{G}$ and ϕ it follows that

(3.6)

$$\left|\int_{Q(s)}(\mathcal{G}(x,t;D,D,\tau) - \mathcal{G}(x^0,t^0;D,\overline{D},\tau))v\overline{v}\right| \le \omega(\delta,\lambda)\sum(\tau\phi)^{3-2|\alpha|}\int_{Q(s)}|\partial^\alpha v|^2,$$

where the sum is over $|\alpha| \leq 1$, $\alpha_0 = 0$,

(3.7)
$$\left| \int_{Q(s)} |P(D + i\tau\nabla\phi^0)v|^2 - |P(D + i\tau\nabla\phi)|^2 \right| \leq \omega(\delta, \lambda) \sum (\tau\phi^0)^{4-2|\alpha|} \int_{Q(s)} |\partial^\alpha v|^2,$$

where the sum is over $|\alpha| \leq 2$, $\alpha_0 = 0$, and $\omega(\delta, \lambda) \to 0$ as $\delta \to 0$ when λ is fixed, provided $v \in C_0^\infty(Q_\epsilon \cap B(x^0, t^0, \delta))$. Given $\lambda > 1$ we can use (3.6), (3.7) and choose $\delta > 0$ so small that differences between right sides of (3.5) with (x, t) and (x^0, t^0) are absorbed by the left side. This yields

$$\begin{aligned}
&\sum \int_{Q(s)} \sigma_0^{4-2|\alpha|} |\partial^\alpha v|^2 \\
&\quad \leq \; C\left(\lambda^{-1}\sigma_0 \int_{Q(s)} \mathcal{G}(x, t; D, \overline{D}, \tau)v\overline{v} + \int_{Q(x)} |P(D + i\tau\nabla\phi)v|^2 \right) \\
&\quad \leq \; C\lambda^{-1}\sigma_0 \int_{Q(s)} |P(D + i\tau\nabla\phi)v|^2 \qquad (3.8)
\end{aligned}$$

due to the property (1.8) of the form $\mathcal{G}$. Dividing (3.8) by σ_0 and using as above that $\sigma_0 = \sigma(1 + \omega(\delta, \lambda))$, we can replace σ_0 in the left side by σ. Returning to $u_1 = e^{\tau\phi}v$, we obtain the inequality

$$\lambda \sum \int_{Q(s)} \sigma^{3-2|\alpha|} e^{2\tau\phi} |\partial^\alpha u_1|^2 \leq C \int_{Q(s)} e^{2\tau\phi} |\Delta u_1|^2$$

for all $u_1 \in C_0^\infty(B(x^0, t^0; \delta))$ for some δ and $\lambda > C$, $\tau > C(\lambda)$. Here the sums are over $|\alpha| \leq 2$, $\alpha_0 = 0$. Integrating with respect to s over $(0, T)$, we obtain (3.1) for all u_1 with small support. Using the partition of the unity over $\overline{Q_\epsilon}$, we complete the proof. □

Lemma 3.2. *Assume that*

$$\gamma\theta^2 < 1. \qquad (3.9)$$

Then there is C such that

$$\|\sigma^{3/2-|\alpha|} e^{\tau\phi} \partial^\alpha u_2\|_{(0)}(Q) \leq C \|e^{\tau\phi}(-\gamma\partial_t^2 + \Delta)u_2\|_{(0)}(Q) \qquad (3.10)$$

for all functions $u_2 \in C_0^\infty(Q_\epsilon)$, $\tau > C(\lambda)$, $|\alpha| \leq 1$.

Proof. We will adjust the method of the proof of Lemma 3.1 to the wave operator with the symbol $p(\widetilde{\zeta}) = \gamma\zeta_0^2 - \zeta \cdot \zeta$. We let $\zeta_0 = \xi_0 + i\tau\partial_t\phi$, $\widetilde{\zeta} = (\zeta_0, \zeta)$, $X = (x, t)$ and will use most of the notation of Lemma 3.1. In particular, we will fix any $X^0 \in \overline{Q_\epsilon}$.

We claim that

$$|\zeta_0|^2 + |\zeta|^2 \leq C(\sigma_0^{-1} \mathcal{G}^0_{pr}(\widetilde{\xi}, \widetilde{\xi}, \tau) + C\lambda^2 |p(\widetilde{\zeta})|^2 |\widetilde{\zeta}|^{-2}). \qquad (3.11)$$

In the proof of (3.11), we will drop the index 0.

Let $p(\widetilde{\zeta}) = 0$. Using (1.6) we will have

$$\gamma\xi_0^2 - |\xi|^2 = \sigma(|x - a|^2 - \theta^4(t - T/2)^2), \qquad (3.12)$$

and the formulas (1.6), (1.7) give

$$\begin{aligned}\mathcal{G}_{pr}(\widetilde{\xi},\widetilde{\xi},\tau) &= 2\tau(\partial_0^2\phi 4|\zeta_0|^2 - 4\sum \partial_0\partial_j\phi(\zeta_0\overline{\zeta_j} + \overline{\zeta_0}\zeta_j) + 4\sum \partial_j\partial_k\phi\zeta_j\overline{\zeta_k})\\ &= 8\sigma(-\gamma^2\theta^2|\zeta_0|^2 + |\zeta|^2 + \lambda|\gamma\theta^2(t-T/2)\zeta_0 + (x-a)\cdot\zeta|^2).\end{aligned}$$

To obtain (3.11) we will again use homogeneity and continuity arguments assuming $|\widetilde{\zeta}|^2 = 1$.

When $\tau = 0$, we have $\xi_0^2 + |\xi|^2 = 1$, $\gamma\xi_0^2 = |\xi|^2$. So

$$-\gamma^2\theta^2\xi_0^2 + |\xi|^2 = \gamma(1-\gamma\theta^2)/(1+\gamma) > C^{-1}$$

according to assumption (3.9). Hence in this case

$$\sigma^{-1}\mathcal{G}_{pr}(\widetilde{\xi},\widetilde{\xi},\tau) \geq C^{-1}|\widetilde{\zeta}|^2.$$

As in Lemma 3.1, we generally have

$$\sigma^{-1}\mathcal{G}_{pr} \geq 8(-\gamma^2\theta^2|\zeta_0|^2 + |\zeta|^2 + \lambda|\gamma\theta^2(t-T/2)\zeta_0 + (x-a)\cdot\zeta|^2) - C\lambda|p(\widetilde{\zeta})|. \tag{3.13}$$

Let

$$|p(\widetilde{\zeta})| < \delta\lambda^{-1}|\widetilde{\zeta}|^2. \tag{3.14}$$

Then we have $-\delta\lambda^{-1}|\widetilde{\zeta}|^2 < \gamma\xi_0^2 - |\xi|^2 - (\gamma\tau_0^{*2} - |\tau^*|^2) < \delta\lambda^{-1}|\widetilde{\zeta}|^2$.

Consider the case $|\widetilde{\tau}^*|^2 < \delta|\widetilde{\zeta}|^2$. Using the above inequality we obtain $\gamma\xi_0^2 - ((\gamma+1)\delta + \delta\lambda^{-1})|\widetilde{\zeta}|^2 < |\xi|^2$. Using the last inequality, (3.9) and (3.14), we will have

$$\begin{aligned}-\gamma^2\theta^2|\zeta_0|^2 + |\zeta|^2 &\geq \gamma(1-\gamma\theta^2)\xi_0^2 - ((2\gamma+1)\delta + \delta\lambda^{-1})|\widetilde{\zeta}|^2\\ &\geq C^{-1}\xi_0^2 - (C\delta + \delta\lambda^{-1})|\widetilde{\zeta}|^2 > C^{-1}|\widetilde{\zeta}|^2 - (C\delta + \delta_0\lambda^{-1})|\widetilde{\zeta}|^2.\end{aligned}$$

So for some small δ, (3.13) and (3.14) imply (3.11). From now on we will fix such δ.

When $\delta|\widetilde{\zeta}|^2 \leq |\widetilde{\tau}^*|^2$, then $|\widetilde{\zeta}|^2 \leq C\sigma^2$. Using that $|\zeta| \geq |\mathcal{T}\zeta|$ and again using (1.6), we obtain

$$\begin{aligned}|\gamma\theta^2(t-T/2)\zeta_0 + (x-a)\cdot\zeta|^2 &\geq |-\gamma\theta^4\lambda(t-T/2)^2\tau\phi + \tau\lambda|x-a|^2\phi^2|^2\\ &= \sigma^2|-\gamma\theta^4(t-T/2)^2 + |x-a|^2| > \epsilon\sigma^2\end{aligned}$$

due to the condition (3.9) and to the definition of Q_ϵ. Hence from (3.13) and (3.14), we have

$$\sigma^{-1}\mathcal{G}^0_{pr} \geq -C|\widetilde{\zeta}|^2 + \lambda C^{-1}|\widetilde{\zeta}|^2 - C\delta|\widetilde{\zeta}|^2,$$

which implies (3.11) when $\lambda > C$.

Now we will consider the remaining case $|p(\widetilde{\zeta})| \geq \delta\lambda^{-1}|\widetilde{\zeta}|^2$. Using (3.13), we conclude that

$$\begin{aligned}\sigma^{-1}\mathcal{G}^0_{pr} + C_1\lambda^2|p(\widetilde{\zeta})|^2|\widetilde{\zeta}|^{-2} &\geq -C|\widetilde{\zeta}|^2 + \lambda|p(\widetilde{\zeta})|(C_1\lambda|p(\widetilde{\zeta})|\,|\widetilde{\zeta}|^{-2} - C)\\ &\geq -C|\widetilde{\zeta}|^2 + \delta|\widetilde{\zeta}|^2(C_1\delta - C),\end{aligned}$$

and choosing C_1 sufficiently large we complete the proof of (3.11).

The inequality (3.11) for the principal symbol of the differential quadratic form and the bound (1.9) as in the proof of Lemma 3.1 imply that

(3.15)

$$\sum_{|\alpha|\le 1}\int_Q \sigma_0^{2-2|\alpha|}|\partial^\alpha v|^2 \le C\left(\sigma_0^{-1}\int_Q \mathcal{G}^0_{pr}(D,\overline{D},\tau)v\overline{v} + \lambda^2\int |p(\widetilde{\zeta})|^2|\widetilde{\zeta}^0|^{-2}|\widehat{v}(\widetilde{\xi})|^2\,d\widetilde{\xi}\right).$$

As in Lemma 3.1,

$$\left|\int_Q (\mathcal{G}-\mathcal{G}^0)v\overline{v}\right| \le \omega(\delta,\lambda)\sum_{|\alpha|\le 1}\tau^{3-2|\alpha|}\int_Q |\partial^\alpha v|^2.$$

Letting

$$|||v|||_k = \left(\int |\widetilde{\zeta}^0|^{2k}|\widehat{v}(\widetilde{\xi})|^2\,d\widetilde{\xi}\right)^{1/2}$$

and using that by Lemma 8.4.1 in [5] and Lemma 2.1 in [7]

$$\begin{aligned}&|||P(D+i\tau(\nabla_{x,t}\phi)^0)v|||^2_{-1}\\ &\quad\le 2|||P(D+i\tau\nabla_{x,t}\phi)v|||^2_{-1} + \omega(\delta,\tau;\lambda)\sum_{|\alpha|\le 1}\int_Q \sigma_0^{2-2|\alpha|}|\partial^\alpha v|^2\end{aligned}$$

when $v \in C_0^\infty(B(X^0;\delta))$, where $\omega \to 0$ as $\delta \to 0$, $\tau \to 0$, and λ is fixed. Choosing δ small, absorbing the differences at X and X^0 as in the proof of Lemma 3.1, and observing that

$$\lambda^2|||P(D+i\tau\nabla_{x,t}\phi)v|||^2_{-1} \le C\tau^{-2}\|P(D+i\tau\nabla_{x,t}\phi)v\|^2_{(0)},$$

we derive from (3.15)

$$\begin{aligned}\sum_{|\alpha|\le 1}\int_Q \sigma_0^{2-2|\alpha|}|\partial^\alpha v|^2 &\le C\left(\sigma_0^{-1}\int_Q \mathcal{G}v\overline{v} + C\tau^{-2}\int_Q |P(D+i\tau\nabla_{x,t}\phi)v|^2\right)\\ &\le C(\sigma_0^{-1}+\tau^{-2})\int_Q |P(D+i\tau\nabla_{x,t}\phi)v|^2\end{aligned}$$

due to the property (1.8) of the form $\mathcal{G}$. Choosing $\tau > \lambda$ large we can achieve that $\sigma_0^{-1} > \tau^{-2}$, and therefore we can drop the term with τ in front of the last integral. Arguing as at the end of the proof of Lemma 3.1, we can replace σ_0 by σ, return to the function u_2, and use partition of the unity to complete the proof. □

A "substitution" of the estimate of Lemma 3.1 into the estimate of Lemma 3.2 gives the following lemma.

Lemma 3.3. *Under the condition* (3.9) *there is* C *such that*

(3.16)

$$\begin{aligned}&\|\sigma^{3-|\beta|}e^{\tau\phi}\partial^\beta w_0\|_{(0)}(Q) + \|\sigma^{1/2}e^{\tau\phi}\partial_t^2\partial^\alpha w_0\|_{(0)}(Q) + \|\sigma^{1/2}e^{\tau\phi}\partial_t\Delta w_0\|_{(0)}(Q)\\ &\qquad + \|\sigma^{1/2}e^{\tau\phi}\partial^\alpha\Delta w_0\|_{(0)}(Q) \le C\|e^{\tau\phi}(-\gamma\Delta\partial_t^2+\Delta^2)w_0\|_{(0)}(Q)\end{aligned}$$

for all $w_0 \in C_0^\infty(Q_\epsilon)$ *provided* $|\beta| \le 2$, $|\alpha| = 1$, $\alpha_0 = 0$, *and* $\tau > C(\lambda)$.

Proof. This lemma follows from Lemmas 3.1 and 3.2 by letting $u_1 = (-\gamma\partial_t^2 + \Delta)w_0$, $u_2 = \Delta w_0$, and choosing large τ to eliminate terms resulting from commuting multiplication by ϕ and the differential operators.

Indeed, letting $u_1 = (-\gamma\partial_t^2 + \Delta)w_0$ in (3.1), we obtain

(3.17)
$$\begin{aligned}&\|e^{\tau\phi}(-\gamma\partial_t^2 + \Delta)\Delta w_0\|_{(0)}(Q)\\ &\quad\ge\ \lambda/C \sum_{|\alpha^*|\le 1, \alpha_0^*=0} \|\sigma^{3/2-|\alpha^*|} e^{\tau\phi}\partial^{\alpha^*}(-\gamma\partial_t^2 + \Delta)w_0\|_{(0)}(Q).\end{aligned}$$

By Lemma 3.2 with $u_2 = \sigma^{3/2}w_0$ we have

$$(3.18)\ \sum_{|\alpha^{**}|\le 1} \|\sigma^{3/2-|\alpha^{**}|}e^{\tau\phi}\partial^{\alpha^{**}}(\sigma^{3/2}w_0)\|_{(0)} \le C\|e^{\tau\phi}(-\gamma\partial_t^2 + \Delta)(\sigma^{3/2}w_0)\|_{(0)}.$$

By the Leibniz formula

$$\begin{aligned}\partial_j(\sigma^{3/2}w_0) &= \tau^{3/2}b_j w_0 + \sigma^{3/2}\partial_j w_0,\\ (-\gamma\partial_t^2 + \Delta)(\sigma^{3/2}w_0) &= \sigma^{3/2}(-\gamma\partial_t^2 + \Delta)w_0 + \tau^{3/2}\sum_{|\beta|\le 1} b_\beta \partial^\beta w_0,\end{aligned}$$

where b are bounded functions determined only by ψ and λ. Using the triangle inequality, we obtain from (3.18) that

$$\begin{aligned}&\sum_{|\alpha^{**}|\le 1} \|\sigma^{3-|\alpha^{**}|}e^{\tau\phi}\partial^{\alpha^{**}}w_0\|_{(0)} - \tau^2 C(\lambda)\|e^{\tau\phi}w_0\|_{(0)}\\ &\quad\le\ C\|\sigma^{3/2}e^{\tau\phi}(-\gamma\partial_t^2 + \Delta)w_0\|_{(0)} + C(\lambda)\tau^{3/2}\sum_{|\beta|\le 1}\|e^{\tau\phi}\partial^\beta w_0\|_{(0)}.\end{aligned}$$

Choosing large τ will absorb the second terms of the left and right sides by the first term in the left side.

Similarly we have

$$\sum \|\sigma^{2-|\alpha^{**}|}e^{\tau\phi}\partial^{\alpha^*+\alpha^{**}}w_0\|_{(0)} \le C\sum \|\sigma^{1/2}e^{\tau\phi}(-\gamma\partial_t^2\partial^{\alpha^*} + \Delta\partial^{\alpha^*})w_0\|_{(0)},$$

where the sums are over $|\alpha^*| = 1$, $\alpha_0^* = 0$, $|\alpha^{**}| \le 1$, $\tau > C(\lambda)$.

The last two inequalities combined with (3.17) yield

$$\sum_{|\beta|\le 2} \|\sigma^{3-|\beta|}e^{\tau\phi}\partial^\beta w_0\|_{(0)} \le C/\lambda\|e^{\tau\phi}(-\gamma\partial_t^2 + \Delta)\Delta w_0\|_{(0)}.$$

Indeed, when $|\beta_0| \le 1$, it follows directly from these inequalities by letting $\beta = \alpha^* + \alpha^{**}$. When $\beta_0 = 2$, the partial derivative $\partial^\beta w_0 = 1/\gamma(\gamma\partial_t^2 - \Delta)w_0 + 1/\gamma\Delta w_0$ can be bounded from the right side of (3.17) ($\alpha^* = 0$) and the already obtained bounds on space derivatives of second order.

To complete the proof we similarly use Lemma 3.2 with $u_2 = \Delta w_0$ bounding the last two terms of the left side in (3.16). Expressing as above $\partial_t^2 w_0$ as the sum of the wave operator and the Laplacian and utilizing again the right side of (3.17) with $|\alpha^*| = 1$ and previous bounds of Δw_0, we obtain (3.16). □

4. Carleman estimates for the heat equation. In this section we consider $p(\widetilde{\zeta}) = i\zeta_0 + \zeta \cdot \zeta$ and will accordingly modify the proof of Lemma 3.1.

LEMMA 4.1. *There is C such that*

$$\lambda^{1/2}\|\sigma^{3/2-|\alpha|}e^{\tau\phi}\partial^\alpha u\|_{(0)}(Q) \le C\|e^{\tau\phi}(\partial_t - \Delta)u\|_{(0)}(Q) \tag{4.1}$$

for all $u \in C_0^\infty(Q_\epsilon)$, $|\alpha| \le 2$, $\alpha_0 = 0$, provided $\tau > C(\lambda)$.

Proof. As in Lemma 3.1, we first fix $X^0 \in \overline{Q_\epsilon}$ and obtain local estimates on functions supported near this point. As above, for a while we drop the index 0.

We claim that for some C

$$|\zeta_0|^2 + |\zeta|^4 \le C(\lambda^{-1}\sigma\mathcal{G}_{pr} + C|p(\widetilde{\zeta})|^2). \tag{4.2}$$

Indeed, the equality $p(\widetilde{\zeta}) = 0$ and the relations (1.6) imply that

$$\sigma\theta^2(t - T/2) + |\xi|^2 = \sigma^2|x-a|^2, \quad \xi_0 = 2\sigma\xi \cdot (x-a) \tag{4.3}$$

and

$$\begin{aligned}\mathcal{G}_{pr} &= 8\sigma\lambda\sum(x-a)_j(x-a)_j\zeta_j\overline{\zeta_k} + 8\lambda\phi\sum|\zeta_k|^2\\ &\ge 8\lambda\sigma|(x-a)\cdot\zeta|^2 \ge 8\lambda\sigma^3|x-a|^2 \ge 8C^{-1}\lambda\sigma^3,\end{aligned} \tag{4.4}$$

provided $X \in Q_\epsilon$. We can assume that $\sigma > C$; then the first equality of (4.3) implies that $|\xi| \le C\sigma$, and using in addition the second equality of (4.3), we conclude that $|\xi_0| \le C\sigma^2$, so $|\zeta_0| \le C\sigma^2$. Now, from (4.4) it follows that

$$\lambda^{-1}\sigma\mathcal{G}_{pr} \ge C^{-1}(|\zeta_0|^2 + |\zeta|^4). \tag{4.5}$$

Modifying the homogeneity and continuity arguments from the proof of Lemma 3.1, we conclude that (4.5) remains valid when $|p(\widetilde{\zeta})|^2 \le \delta(|\zeta_0|^2 + |\zeta|^4)$ for some small positive δ.

When $\delta(|\zeta_0|^2 + |\zeta|^4) \le |p(\widetilde{\zeta})|^2$, we can with no changes repeat the argument in the elliptic case and complete the proof of (4.2).

From (4.2) and from the property (1.9) of differential quadratic forms, we obtain

$$\sigma_0^{4-2|\alpha|}\int_Q |\partial^\alpha v|^2 + \int_Q |\partial_0 v|^2 \le C\left(\lambda^{-1}\sigma_0\int_Q \mathcal{G}^0 v\overline{v} + \int_Q |P(D + \tau i\nabla_{x,t}\phi^0)v|^2\right) \tag{4.6}$$

provided $\tau > C$, $|\alpha| \le 2$, $\alpha_0 = 0$, $v \in C_0^\infty(Q_\epsilon)$. As above, from the definition of $\mathcal{G}$ and from the regularity assumptions on ϕ, it follows that

$$\left|\int_Q (\mathcal{G} - \mathcal{G}^0)v\overline{v}\right| \le \omega(\delta;\lambda)\left(\sum_{|\alpha|\le 1}\tau^{3-2|\alpha|}\int_Q |\partial^\alpha v|^2\right),$$

$$\left|\int_Q\right| P(D + i\tau\nabla_{x,t}\phi)v|^2 - |P(D + i\tau\nabla_{x,t}\phi^0)v|^2| \le \omega(\delta;\lambda)\sum_{|\alpha|\le 2,\alpha_0=0}\tau^{4-2|\alpha|}\int_Q |\partial^\alpha v|^2$$

provided $v \in C_0^\infty(B(X^0;\delta))$, where $\omega(\delta;\lambda) \to 0$ as $\delta \to 0$ and λ is fixed. Using these inequalities, we can replace $\mathcal{G}^0$ and ϕ^0 in (4.6) by $\mathcal{G}$ and ϕ and remove $\mathcal{G}$ as in the elliptic case. Observe that in the parabolic case we handle all α with $|\alpha| \le 2$, $\alpha_0 = 0$.

Similarly, returning to $v_0 = e^{\tau\phi}v$ and using partition of the unity we complete the proof of Lemma 4.1. $\square$

Corollary 4.2. *Under the conditions of Lemma* 4.1*, we have*

$$\lambda^{1/2}\|\sigma^{2-|\alpha|}e^{\tau\phi}\partial^{\alpha}v_0\|_{(0)}(Q) \leq C\|\sigma^{1/2}e^{\tau\phi}(\partial_t - \Delta)v_0\|_{(0)}(Q) \tag{4.7}$$

for all $v_0 \in C_0^{\infty}(Q_{\epsilon})$*,* $|\alpha| \leq 2$*,* $\alpha_0 = 0$*, provided* $\tau > C(\lambda)$*.*

Proof. As in the proof of Lemma 3.3, letting in (4.1) $v_0 = \sigma^{1/2}v^*$ and using the Leibniz formula and the triangle inequality, we will have

$$\lambda^{1/2}\sum_{|\alpha|\leq 2}\|\sigma^{2-|\alpha|}e^{\tau\phi}\partial^{\alpha}v^*\|_{(0)} - C(\lambda)\sum_{|\alpha|\leq 1}\tau^{1-|\alpha|}\|e^{\tau\phi}\partial^{\alpha}v^*\|_{(0)}$$
$$\leq C\left(\|\sigma^{1/2}e^{\tau\phi}(\partial_t - \Delta)v^*\|_{(0)} + C(\lambda)\sum\tau^{1/2}\|e^{\tau\phi}\partial^{\alpha}v^*\|_{(0)}\right).$$

Choosing $\tau > C(\lambda)$, we absorb the second sums in the left and right sides by the first sum in the left side and complete the proof of Corollary 4.2. $\square$

5. Proofs of main results in the nonanalytic case. The Carleman-type estimates like (3.1), (3.10), (3.16), (4.1), and (4.7) are classical (and the only available) tools to prove uniqueness in the Cauchy problem for corresponding partial differential equations. Their introduction and use comes back to the pioneering work of T. Carleman of 1938. We refer to discussions of this method in Hörmander [5, sections 8.1–8.3] and Isakov [10, section 3.2]. Below we will use the Carleman method. The introduction of large parameter τ in the weight function $e^{\tau\phi}$ with ϕ decaying away from S is the crucial idea of this method. It helps to neglect parts of the boundary where no data are available. If we use Lemma 3.3 and Corollary 4.2 without the additional large parameter λ (which were known), we arrive at the inequalities (5.2), (5.3), but when bounding Δv_0 in the right side of (5.2) from (5.3) ($|\alpha| = 2$), we will lose the large parameter and will not be able to eliminate the terms with $\partial_t\Delta w$ in the right side and therefore complete the proof.

Proof of Theorem 1.3. We will introduce a cut-off function $\chi \in C_0^{\infty}(\mathbb{R}^3)$ such that it is 1 on $Q_{2\epsilon}$ and 0 on $Q\backslash Q_{\epsilon}$. Let $w_0 = \chi w$, $v_0 = \chi v$. By using the Leibniz formula, we derive from (1.1), (1.2) that

(5.1)

$$-\gamma\Delta\partial_t^2 w_0 + \Delta^2 w_0$$
$$= -\Delta v_0 + L_1(x,t;w,\partial_t w,\nabla w,\nabla^2 w,\nabla\partial_t w,\partial_t^2 w,\nabla\partial_t^2 w,\partial_t\Delta w,\nabla\Delta w,v,\nabla v),$$
$$\partial_t v_0 - b\Delta v_0 = L_2(x,t;w,\nabla w,\partial_t w,\nabla\partial_t w,\Delta w,\nabla\Delta w_0,\partial_t\Delta w_0,\nabla\partial_t^2 w_0,v,\nabla v),$$

where L_1, L_2 are linear functions of $w,\ldots,\nabla v$ with the coefficients in $L^{\infty}(Q)$.

Applying Lemma 3.3 and expressing the left side from the first equation through its right side, we will have the Carleman-type estimates

(5.2)

$$\sum(\|\sigma^{3-|\beta|}e^{\tau\phi}\partial^{\beta}w_0\|^2_{(0)}(Q_{\epsilon}) + \|\sigma^{1/2}e^{\tau\phi}\nabla\partial_t^2 w_0\|^2_{(0)}(Q_{\epsilon}) + \|\sigma^{1/2}e^{\tau\phi}\nabla_{x,t}\Delta w_0\|^2_{(0)}(Q_{\epsilon}))$$
$$\leq\ C(\|e^{\tau\phi}\Delta v_0\|^2_{(0)}(Q_{\epsilon}) + \sum(\|e^{\tau\phi}\partial^{\beta}w\|^2_{(0)}(Q_{\epsilon}) + \|e^{\tau\phi}\nabla_{x,t}\Delta w\|^2_{(0)}(Q_{\epsilon})$$
$$+\ \|e^{\tau\phi}\nabla\partial_t^2 w\|^2_{(0)}(Q_{\epsilon}) + \|e^{\tau\phi}\partial^{\alpha}v\|^2_{(0)}(Q_{\epsilon})))$$

when $\tau > C(\lambda)$, where the sums are over $|\beta| \leq 2$, $|\alpha| = 1$, $\alpha_0 = 0$. Similarly, from Corollary 4.2

$$\begin{aligned}\lambda \sum \|\sigma^{2-|\beta^*|} e^{\tau\phi} \partial^{\beta^*} v_0\|^2_{(0)}(Q_\epsilon) &\leq C \sum (\|\sigma^{1/2} e^{\tau\phi} \nabla_{x,t} \Delta w\|^2_{(0)}(Q_\epsilon) \\ &+ \|\sigma^{1/2} e^{\tau\phi} \nabla \partial_t^2 w\|^2_{(0)}(Q_\epsilon) + \|\sigma^{1/2} e^{\tau\phi} \partial^\beta w\|^2_{(0)}(Q_\epsilon) + \|\sigma^{1/2} e^{\tau\phi} \partial^\alpha v\|^2_{(0)}(Q_\epsilon))\end{aligned} \tag{5.3}$$

for the same τ, α, β, and $|\beta^*| \leq 2$, $b_0^* = 0$.

We will add (5.2) and (5.3) multiplied by $\lambda^{-1/2}$ to obtain

$$\begin{aligned}&\sum (\|\sigma^{3-|\beta|} e^{\tau\phi} \partial^\beta w_0\|^2_{(0)}(Q_\epsilon) + \|\sigma^{\frac{1}{2}} e^{\tau\phi} \nabla \partial_t^2 w_0\|^2_{(0)}(Q_\epsilon) + \|\sigma^{\frac{1}{2}} e^{\tau\phi} \nabla_{x,t} \Delta w_0\|^2_{(0)}(Q_\epsilon) \\ &\quad + \lambda^{\frac{1}{2}} \|\sigma^{2-|\beta^*|} e^{\tau\phi} \partial^{\beta^*} v_0\|^2_{(0)}(Q_\epsilon)) \leq C(\|e^{\tau\phi} \Delta v_0\|^2_{(0)}(Q_\epsilon) \\ &\quad + \sum (\|e^{\tau\phi} \partial^\beta w\|^2_{(0)}(Q_\epsilon) + \|e^{\tau\phi} \nabla_{x,t} \Delta w\|^2_{(0)}(Q_\epsilon) + \|e^{\tau\phi} \nabla \partial_t^2 w\|^2_{(0)}(Q_\epsilon) \\ &\quad + \|e^{\tau\phi} \partial^\alpha v\|^2_{(0)}(Q_\epsilon)) + C\lambda^{-\frac{1}{2}} \sum (\|\sigma^{\frac{1}{2}} e^{\tau\phi} \nabla_{x,t} \Delta w\|^2_{(0)}(Q_\epsilon) + \|\sigma^{\frac{1}{2}} e^{\tau\phi} \nabla \partial_t^2 w\|^2_{(0)}(Q_\epsilon) \\ &\quad + \|\sigma^{\frac{1}{2}} e^{\tau\phi} \partial^\beta w\|^2_{(0)}(Q_\epsilon) + \|\sigma^{\frac{1}{2}} e^{\tau\phi} \partial^\alpha v\|^2_{(0)}(Q_\epsilon)).\end{aligned}$$

We will break Q_ϵ into $Q_{2\epsilon}$ and its complement $Q_\epsilon \backslash Q_{2\epsilon}$ and choose sufficiently large λ to absorb the integral of Δv_0 in the right side by the last sum in the left side and to absorb the integrals of $\sigma^{\frac{1}{2}} \nabla_{x,t} \Delta w$, $\sigma^{\frac{1}{2}} \nabla \partial_t^2 w$ over $Q_{2\epsilon}$ (where $w_0 = w$, $v_0 = v$) in the right side by the corresponding integrals in the left side. Then we fix this λ, shrink the integration domain in the left side to $Q_{2\epsilon}$, and choose sufficiently large τ to absorb the integrals of the right side over $Q_{2\epsilon}$ by the integrals in the left side to obtain

$$\begin{aligned}&\tau(\|e^{\tau\phi} w\|^2_{(0)}(Q_{2\epsilon}) + \|e^{\tau\phi}\|^2_{(0)}(Q_{2\epsilon})) \leq C\tau^{1/2} \sum (\|e^{\tau\phi} \partial^\beta w\|^2_{(0)}(Q_\epsilon \backslash Q_{2\epsilon}) \\ &\quad + \|e^{\tau\phi} \nabla \Delta w\|^2_{(0)}(Q_\epsilon \backslash Q_{2\epsilon}) + \|e^{\tau\phi} \partial_t \Delta w\|^2_{(0)}(Q_\epsilon \backslash Q_{2\epsilon}) + \|e^{\tau\phi} \partial_t^2 \partial^\alpha w\|^2_{(0)}(Q_\epsilon \backslash Q_{2\epsilon}) \\ &\quad + \|e^{\tau\phi} \partial^\alpha v\|^2_{(0)}(Q_\epsilon \backslash Q_{2\epsilon})).\end{aligned}$$

Using that $\phi^* = \sup \phi$ over $Q_\epsilon \backslash Q_{2\epsilon}$ is equal to $\inf \phi$ over $Q_{2\epsilon}$, replacing ϕ by ϕ^* in both sides of the inequality, and dividing by $\tau^{1/2} e^{2\tau\phi^*}$, we arrive at

$$\tau^{1/2}(\|w\|^2_{(0)}(Q_{2\epsilon}) + \|v\|^2_{(0)}(Q_{2\epsilon})) \leq CM,$$

where M is the sum of $L^2(Q)$-norms of all partial derivatives of w and v entering the right side of the last inequality. Letting $\tau \to \infty$, we conclude that $w = v = 0$ on $Q_{2\epsilon}$ for any $\epsilon > 0$.

The proof is complete. □

Proof of Corollary 1.4. Let $\epsilon > 0$. The mollified functions $w_\delta = \chi_\delta * w$, $v_\delta * v$, where * denotes convolution with respect to t and χ_δ is the standard mollifying kernel [6, sections 1.2, 4.1–4.3], are well defined in $Q \cap \{\delta < t < T - \delta\}$ and solve there the Cauchy problem (1.1)–(1.3) with zero Cauchy data on S. From well-known properties of mollifiers and the assumptions on (w, v), we have $(\partial_t^k w_\delta, \partial_t^k v_\delta) \in C([0, T];$ $H_2(\Omega) \times L^2(\Omega))$. We can find small δ and a domain $\Omega^\bullet$ with $\overline{\Omega^\bullet} \subset \Omega \cup \Gamma$ so that $\overline{Q}_{\epsilon/2} \subset (\delta, T - \delta) \times \Omega^\bullet$. Transferring all terms of the equations (1.1), (1.2) except $\Delta^2 w$ and Δv into their right sides and considering these equations as elliptic ones on $\Omega^\bullet$ for fixed $t \in (\delta, T - \delta)$ from interior-type Schauder estimates for equations in variational form [1], we conclude that $(w_\delta, v_\delta) \in C(\delta, T - \delta;\ H_4(\Omega^\bullet) \times H_2(\Omega^\bullet))$. In addition, all terms of these equations involving ∂_t are in $L^2(Q_{\epsilon/2})$. By Theorem 1.3 we have $(w_\delta, v_\delta) = 0$ in Q_ϵ. Letting $\delta \to 0$, we obtain the same conclusion for w, v in any Q_ϵ, which concludes the proof. $\square$

This method of the proof implies conditional Hölder-type stability estimates for the Cauchy problem (1.1)–(1.3) (compare with [10, section 3.2]).

We think that it would be interesting to use the additional large parameter in Carleman estimates for boundary value problems considered by Tataru in [17] and to apply this method for a full (vector) system of thermoelasticity.

Acknowledgments. The author is grateful to Professor Irena Lasiecka who stimulated his work on uniqueness of the continuation for the von Karman and thermoelasticity systems, to Dr. Matthias Eller who helped to eliminate a number of flaws in the proofs, and to the referees for careful reading of the manuscript and helpful suggestions.

ASYMPTOTIC PROFILES OF NONSTATIONARY INCOMPRESSIBLE NAVIER–STOKES FLOWS IN THE WHOLE SPACE[*]

YOSHIKO FUJIGAKI[†] AND TETSURO MIYAKAWA[‡]

Dedicated to Professor Kiyoshi Asano

Abstract. Asymptotic profiles are deduced for weak and strong solutions of the incompressible Navier–Stokes equations in the whole space. It is shown that if the initial velocity satisfies a specific moment condition, the corresponding solution behaves like the first-order spatial derivatives of the heat kernel. Higher-order asymptotics are also deduced in case the initial data admit vector potentials with spatial decay of order $-n$. We further note that the results are not optimal and suggest by means of an example that there exist solutions with a more rapid (space-time) decay property if we require certain symmetry conditions to the initial data.

Key words. incompressible Navier–Stokes equations, initial value problem, asymptotic profiles, moment estimates

1. Introduction.

We consider the Navier–Stokes system in $\mathbb{R}^n$, $n \geq 2$, which will be treated in this paper in the form of the integral equation

$$u(t) = e^{-tA}a - \int_0^t \nabla \cdot e^{-(t-s)A} P(u \otimes u)(s)ds, \tag{1.1}$$

and we discuss asymptotic properties of weak and strong solutions. Here, $u = (u_1, \ldots, u_n)$ is unknown velocity, $a = (a_1, \ldots, a_n)$ is a given initial velocity, $\nabla = (\partial_1, \ldots, \partial_n)$ with $\partial_j = \partial/\partial x_j$, $A = -\Delta$ is the Laplacian, $\{e^{-tA}\}_{t\geq 0}$ is the heat semigroup, $P = (P_{jk})$ is the Fujita–Kato bounded projection [5] onto the spaces of solenoidal vector fields, and

$$(\nabla \cdot e^{-tA} P(u \otimes u))_j = \sum_{k,\ell=1}^{n} \partial_\ell E_t * P_{jk} * (u_\ell u_k),$$

where $E_t = (4\pi t)^{-\frac{n}{2}} \exp(-\frac{|x|^2}{4t})$ is the heat kernel and $*$ is the convolution of distributions over $\mathbb{R}^n$. In this paper we always assume that the initial data a are solenoidal, i.e., $\nabla \cdot a = 0$, and satisfy

$$\int (1 + |y|)|a(y)|dy < \infty. \tag{1.2}$$

Here, and in what follows, integration will be performed on $\mathbb{R}^n$ unless otherwise specified. The assumption (1.2) implies $a \in \boldsymbol{L}^1$; so the condition $\nabla \cdot a = 0$ ensures (see [7, 8])

$$\int a(y)dy = 0. \tag{1.3}$$

Most literature on the nonstationary Navier–Stokes system deals with solutions as curves in some L^p-like function spaces and only a few results are available concerning the space-time asymptotic behavior of the solutions. The weak solutions are treated as curves in the space $\boldsymbol{L}^2$ and the existence for all $t > 0$ is established for all initial data in $\boldsymbol{L}^2$, although its uniqueness still remains open when $n \geq 3$. As for the strong solutions, it is known (see [5, 8]) that a unique strong solution $u(t)$ exists for all $t > 0$ in general $\boldsymbol{L}^q$-spaces, satisfying

$$\|u(t)\|_q \leq Ct^{-\frac{1}{2}-\frac{n}{2}(1-\frac{1}{q})}, \quad \|\nabla u(t)\|_q \leq Ct^{-1-\frac{n}{2}(1-\frac{1}{q})} \qquad (1 \leq q \leq \infty, \quad t > 0), \tag{1.4}$$

if a is in $\boldsymbol{L}^n \cap \boldsymbol{L}^1$, is small in $\boldsymbol{L}^n$, and satisfies (1.2). Hereafter, $\| \cdot \|_r$ denotes the L^r-norm. On the other hand, the second author proved in [9] that given γ with $1 \leq \gamma \leq n+1$, problem (1.1) admits, under suitable assumptions on a, a unique strong solution u such that

$$|u(x,t)| \leq C(1+|x|)^{-\alpha}(1+t)^{-(\gamma-\alpha)/2} \qquad \text{for all } \alpha \text{ with } 0 \leq \alpha \leq \gamma, \tag{1.5}$$

and improved a similar result of Takahashi [17]. Inspired by [9], we deduce in this paper another kind of space-time asymptotic profile of u for weak and strong solutions. To be more precise, we first show that if a satisfies (1.2), the weak and strong solutions given by the standard method admit, as $t \to \infty$, an asymptotic expansion of the first order in terms of the spatial derivatives of Gaussian-like functions. As for the strong solutions, our result improves that of Carpio [1] which deduces the first-order asymptotics of two kinds, one in $\mathbb{R}^3$ and the other in $\mathbb{R}^2$. Our proof shows that one and the same result holds in all space dimensions $n \geq 2$. Moreover, contrary to [1], our argument requires neither the theory of Hardy spaces nor the Calderón–Zygmund kernels but utilizes only Taylor's formula for smooth functions and elementary results on the Fourier transform.

We next consider the strong solutions satisfying (1.5) in $\mathbb{R}^n$, $n \geq 2$, and the weak solutions in $\mathbb{R}^3$ and $\mathbb{R}^4$. We show that these solutions admit a higher-order asymptotic expansion in terms of the space-time derivatives of Gaussian-like functions if the initial data satisfy appropriate moment conditions. We prove this result with the aid of (an improvement of) the estimates for L^2-moments of solutions as given in [3, 14].

In section 2 we state our main results after some preliminaries. In particular, we prove there that the kernel function of the operator $\nabla \cdot e^{-tA}P$ belongs to $L^1 \cap L^\infty$ together with its derivatives and behaves like the first-order derivative of the heat kernel. Due to this nice property of the kernel function, we can avoid the use of Hardy spaces and Calderón–Zygmund kernels.

In section 3 we deduce the asymptotics for the linear term $e^{-tA}a$ and in section 4 we prove the first-order asymptotics for weak and strong solutions whose initial data satisfy (1.2). The weak solutions treated in this paper are those satisfying the energy inequality

$$\|u(t)\|_2^2 + 2\int_0^t \|\nabla u\|_2^2 ds \leq \|a\|_2^2 \qquad \text{for all } t \geq 0 \tag{1.6}$$

and the decay estimate

$$\|u(t)\|_2 \leq C(1+t)^{-\frac{n+2}{4}}. \tag{1.7}$$

It is now well known (see [4, appendix] and [18]) that such weak solutions exist in all space dimensions $n \geq 2$ whenever $a \in \boldsymbol{L}^2$, $\nabla \cdot a = 0$, and a satisfies (1.2). We shall deduce the first-order asymptotics for such weak solutions by slightly modifying the argument given for strong solutions.

In section 5 we deduce higher-order asymptotics for strong solutions satisfying (1.5) with $\gamma = n+1$ and for weak solutions whose initial data satisfy (1.2) and some additional moment conditions. It should be noticed here that our strong solutions admit the asymptotic expansion up to (and including) order n, the space dimension, while our weak solutions admit the same expansion only up to (and including) order $n-1$. This is because of the difference between the L^2-moment estimates which are satisfied by our strong or weak solutions (see (2.7) and (2.8) below). We also note that the moment estimate (2.8) for weak solutions is proved only when $n = 3, 4$, so our higher-order asymptotic result for weak solutions deals only with this case.

In section 6 we examine the solutions in $\mathbb{R}^2$ which decay exponentially in time and are rapidly decreasing in the spatial direction, and we give a slightly refined version of a result of Schonbek [12] (see also [15]). The result shows that our asymptotic results are by no means optimal. We refer the reader to [10, 11, 12, 13, 15] for the problem of the optimality of decay rates of solutions in connection with the classes of corresponding initial data.

In deducing the higher-order expansion for strong solutions, we have treated in this paper only those solutions which satisfy (1.5) with $\gamma = n+1$. It would be an interesting problem to find space-time asymptotic profiles in the case $1 \leq \gamma < n+1$. We also note that nothing is known about the space-time behavior for weak solutions if we drop assumption (1.2) on initial data.

Finally we note that our first-order asymptotic result is extended to weak and strong solutions of the Navier–Stokes system in the half-space $\mathbb{R}^n_+$. The result clarifies a difference of the behavior between the Navier–Stokes flows in $\mathbb{R}^n$ and $\mathbb{R}^n_+$ which is caused by the presence of the boundary of $\mathbb{R}^n_+$. The details are given in [2].

2. Preliminaries and the results.

We first recall that the Fujita–Kato projection P onto the solenoidal fields has the kernel function $P(x) = (P_{jk}(x))_{j,k=1}^n$ with the Fourier transform

$$\widehat{P}_{jk}(\xi) \equiv \int e^{-ix\cdot\xi} P_{jk}(x)dx = \delta_{jk} + \frac{i\xi_j i\xi_k}{|\xi|^2} \qquad \left(i = \sqrt{-1}, \quad x \cdot \xi = \sum_{j=1}^n x_j \xi_j \right).$$

Therefore, $\partial_\ell e^{-tA}P = F_\ell = (F_{\ell,jk})_{j,k=1}^n$ with

$$\widehat{F}_{\ell,jk}(\xi,t) = i\xi_\ell e^{-t|\xi|^2}\left(\delta_{jk} + \frac{i\xi_j i\xi_k}{|\xi|^2}\right) \equiv \widehat{F}^1_{\ell,jk}(\xi,t) + \widehat{F}^2_{\ell,jk}(\xi,t).$$

Thus, denoting the heat kernel by

$$E_t(x) = (4\pi t)^{-\frac{n}{2}} \exp(-\tfrac{|x|^2}{4t}),$$

we easily see that $F^1_{\ell,jk}(x,t) = (\partial_\ell E_t)(x)\delta_{jk}$, and so, writing $\partial_x^\beta = \partial_1^{\beta_1} \cdots \partial_n^{\beta_n}$ for any multi-index $\beta = (\beta_1, \ldots, \beta_n)$ of nonnegative integers,

$$\|\partial_t^p \partial_x^\beta F^1_{\ell,jk}(\cdot,t)\|_q \leq C_q t^{-\frac{1+|\beta|+2p}{2} - \frac{n}{2}(1-\frac{1}{q})} \qquad (1 \leq q \leq \infty).$$

To evaluate $F^2_{\ell,jk}$, we invoke the relation $|\xi|^{-2} = \int_0^\infty e^{-s|\xi|^2} ds$ and get

$$\widehat{F}^2_{\ell,jk}(\xi,t) = i\xi_\ell i\xi_j i\xi_k \int_t^\infty e^{-s|\xi|^2} ds \qquad \text{so that} \quad F^2_{\ell,jk}(x,t) = \int_t^\infty \partial_\ell\partial_j\partial_k E_s(x) ds.$$

From this we easily obtain

$$\|\partial_t^p \partial_x^\beta F^2_{\ell,jk}(\cdot,t)\|_q \le C_q t^{-\frac{1+|\beta|+2p}{2}-\frac{n}{2}(1-\frac{1}{q})} \qquad (1 \le q \le \infty).$$

Combining this with the estimate for $F^1_{\ell,jk}$ gives

$$\|\partial_t^p \partial_x^\beta F_{\ell,jk}(\cdot,t)\|_q \le C_q t^{-\frac{1+|\beta|+2p}{2}-\frac{n}{2}(1-\frac{1}{q})} \qquad (1 \le q \le \infty). \tag{2.1}$$

In this paper we employ the summation convention for repeated indices. Our results are then stated as follows.

THEOREM 2.1.

(i) *Let $a \in \boldsymbol{L}^n \cap \boldsymbol{L}^1$ be solenoidal and satisfy* (1.2). *Let $u = (u_1, \dots, u_n)$ be the corresponding strong solution of* (1.1) *which exists for all $t \ge 0$ if a is small in $\boldsymbol{L}^n$. Then for $1 \le q \le \infty$ and $j = 1, \dots, n$, we have*

$$\begin{aligned} \lim_{t\to\infty} t^{\frac{1}{2}+\frac{n}{2}(1-\frac{1}{q})} \Big\| u_j(t) + (\partial_k E_t)(\cdot) \int y_k a_j(y) dy \\ + F_{\ell,jk}(\cdot,t) \int_0^\infty \int (u_\ell u_k)(y,s) dy ds \Big\|_q = 0. \end{aligned} \tag{2.2}$$

(ii) *For every $a \in \boldsymbol{L}^2$ which is solenoidal and satisfies* (1.2), *there exists a weak solution u which admits the expansion* (2.2) *with $1 \le q \le 2$. The result below concerns higher-order asymptotics of weak and strong solutions.*

THEOREM 2.2.

(iii) *Let a satisfy the assumption of Theorem* 2.1(i) *and the following additional conditions:*

$$\begin{aligned} &\int |y|^m |a(y)| dy < \infty, && |a(y)| \le c_0(1+|y|)^{-n-1}, && \\ &a_j = \sum_{k=1}^n \partial_k b_{jk}, && |b_{jk}(y)| \le c_0(1+|y|)^{-n}, && b_{jk} \in L^1, \end{aligned} \tag{2.3}$$

for some integer m such that $1 \le m \le n$. If $c_0 > 0$ and the norms $\|b_{jk}\|_1$ are small, there exists a global strong solution u which satisfies (1.5) *with $\gamma = n+1$. Furthermore, for $1 \le q \le \infty$ and $j = 1, \dots, n$, we have*

$$\begin{aligned} \lim_{t\to\infty} t^{\frac{m}{2}+\frac{n}{2}(1-\frac{1}{q})} \Big\| u_j(t) - \sum_{1\le|\alpha|\le m} \frac{(-1)^{|\alpha|}}{\alpha!} (\partial_x^\alpha E_t)(\cdot) \int y^\alpha a_j(y) dy \\ + \sum_{|\beta|+2p\le m-1} \frac{(-1)^{|\beta|+p}}{p!\beta!} (\partial_t^p \partial_x^\beta F_{\ell,jk})(\cdot,t) \\ \times \int_0^\infty \int s^p y^\beta (u_\ell u_k)(y,s) dy ds \Big\|_q = 0. \end{aligned} \tag{2.4}$$

(iv) *Let $n = 3, 4$, and suppose that*

$$\int (1+|y|)^{n-1}|a(y)|dy < \infty, \qquad \int (1+|y|)^n|a(y)|^2 dy < \infty. \tag{2.5}$$

Then there exists a weak solution u satisfying (2.4) *for* $1 \le q \le 2$ *and* $1 \le m \le n-1$.

Remarks.

(i) Notice that (1.4) implies

$$\|u(s)\|_2^2 \le C(1+s)^{-1-\frac{n}{2}}, \tag{2.6}$$

so the last integral in (2.2) is finite. On the other hand, (1.2) and (1.3) together imply

$$\|e^{-tA}a\|_2^2 \le C(1+t)^{-1-\frac{n}{2}}.$$

So a result of Wiegner [18] ensures the existence of a weak solution u satisfying (2.6).

(ii) Theorem 2.1 improves an asymptotic result of Carpio [1] in the following sense. First, the result of [1] ignores the vanishing of the average (1.3) and so contains the trivial term $E_t(x)\int a(y)dy \equiv 0$. Second, [1] deals only with the case discussed in assertion (i) of Theorem 2.1, and the results given there are incomplete in the two-dimensional case.

(iii) The existence of a strong solution treated in Theorem 2.2(iii) is proved in [9], and convergence of the integrals in the second sum of (2.4) is ensured by the estimate

$$\int |y|^m|u(y,s)|^2 dy \le C(1+s)^{-\frac{n-m}{2}-1} \qquad (0 \le m \le n+1). \tag{2.7}$$

This estimate will be proved in section 5.

(iv) The proofs of Theorems 2.1 and 2.2 will be carried out in almost the same way for weak and strong solutions. They differ only in estimating the nonlinear convolution integral of (1.1) in a neighborhood of $s = t$. The restriction $m \le n-1$ in Theorem 2.2(iv) arises from the fact that for weak solutions we know only the estimate

$$\int |y|^m|u(y,s)|^2 dy \le C(1+s)^{-(1+\frac{n}{2})(1-\frac{m}{n})} \qquad (0 \le m \le n, \quad n = 3, 4), \tag{2.8}$$

which is weaker than (2.7). This estimate is due to [3, 14], and a detailed proof will be given in the appendix for the reader's convenience. Since (2.8) seems to be valid for general weak solutions only when $n = 3, 4$, Theorem 2.2(iv) would be valid only for $n = 3$, 4. This point will be discussed at the end of section 5.

It should be emphasized here that Theorems 2.1 and 2.2 are by no means optimal. Indeed, the following result is known.

THEOREM 2.3. *If $n = 2$, a solution u exists satisfying*

$$\|u(t)\|_q \le C_q e^{-\gamma_q t} \qquad \textit{and} \qquad |u(x,t)| \le C_m e^{-\gamma t}(1+|x|)^{-m}$$

for all $1 \le q \le \infty$ and $m = 0, 1, 2, \dots$, with some positive constants C_q, C_m, γ, γ_q, and γ_m.

This result is proved in [12] for $2 \le q \le \infty$ and $n = 2$, and it is extended in [15] to the case when n is even. Our Theorem 2.3 covers the case $1 \le q < 2$ and contains a pointwise decay result. We give a detailed proof in section 6 for the reader's convenience.

In [11, 12, 13] Schonbek and in [15] Schonbek, Schonbek, and Süli discuss the problem of finding lower bounds of rates of decay in time for weak solutions to the Navier–Stokes system which do not belong to the class of solutions as described in Theorem 2.3. We note that Theorem 2.1(ii) can be applied to characterizing weak solutions satisfying the lower bound estimate $\|u(t)\|_2 \geq ct^{-\frac{n+2}{4}}$ for large $t > 0$. The details are given in [10].

3. Asymptotics for the linear term. This section proves the following theorem.

THEOREM 3.1. *Suppose a is solenoidal and satisfies*

$$\int (1+|y|)^m |a(y)| dy < \infty \tag{3.1}$$

for an integer $m \geq 1$. Then for $1 \leq q \leq \infty$,

$$\lim_{t\to\infty} t^{\frac{m}{2}+\frac{n}{2}(1-\frac{1}{q})} \left\| e^{-tA}a - \sum_{1\leq|\alpha|\leq m} \frac{(-1)^{|\alpha|}}{\alpha!} (\partial_x^\alpha E_t)(\cdot) \int y^\alpha a(y)dy \right\|_q = 0. \tag{3.2}$$

Proof. Recall that (see [7, 8]) since a is solenoidal and integrable, it satisfies (1.3). Thus, applying Taylor's formula gives

$$\begin{aligned}(e^{-tA}a)(x) &\equiv \int E_t(x-y)a(y)dy = \int [E_t(x-y) - E_t(x)]a(y)dy \\ &= \sum_{1\leq|\alpha|\leq m-1} \frac{(-1)^{|\alpha|}}{\alpha!} (\partial_x^\alpha E_t)(x) \int y^\alpha a(y)dy + \int R_m(x,y)a(y)dy,\end{aligned}$$

where

$$\begin{aligned}R_m(x,y) &= \frac{1}{(m-1)!}\int_0^1 (1-\theta)^{m-1} \left(\frac{d}{d\theta}\right)^m E_t(x-y\theta)d\theta \\ &= \sum_{|\alpha|=m} \frac{(-1)^{|\alpha|}}{\alpha!}(\partial_x^\alpha E_t)(x)y^\alpha \\ &\quad + \frac{(-1)^m}{(m-1)!}\int_0^1 (1-\theta)^{m-1} \sum_{|\alpha|=m} \frac{m!}{\alpha!}[(\partial_x^\alpha E_t)(x-y\theta) - (\partial_x^\alpha E_t)(x)]y^\alpha d\theta.\end{aligned}$$

Therefore, via the change of variables $xt^{-\frac{1}{2}} \to x$ we obtain

$$\begin{aligned}&\left\| e^{-tA}a - \sum_{1\leq|\alpha|\leq m} \frac{(-1)^{|\alpha|}}{\alpha!} (\partial_x^\alpha E_t)(\cdot) \int y^\alpha a(y)dy \right\|_q \\ &\qquad \leq C_m t^{-\frac{m}{2}-\frac{n}{2}(1-\frac{1}{q})} \sum_{|\alpha|=m} \int_0^1 \int \varphi_t(y,\theta)|y|^m |a(y)|dyd\theta,\end{aligned}$$

where

$$\varphi_t(y,\theta) = \sum_{|\alpha|=m} \|(\partial_x^\alpha E_1)(\cdot - y\theta t^{-\frac{1}{2}}) - (\partial_x^\alpha E_1)(\cdot)\|_q.$$

This function is bounded in t, θ, and y, and we have

$$\lim_{t\to\infty} \varphi_t(y,\theta) = 0 \qquad \text{for fixed } y \text{ and } \theta. \tag{3.3}$$

Since $|y|^m|a(y)|$ is integrable on $\mathbb{R}^n$ by (3.1), the dominated convergence theorem yields

$$\lim_{t\to\infty} \int_0^1 \int \varphi_t(y,\theta)|y|^m|a(y)|dyd\theta = 0.$$

This implies (3.2) and so the proof of Theorem 3.1 is complete. □

Remark. Convergence (3.3) is valid for $q = \infty$ since the function $\partial_x^\alpha E_1$ is bounded and uniformly continuous on $\mathbb{R}^n$.

4. Proof of Theorem 2.1. Let

$$\begin{aligned} w(t) &= (w_1(t),\dots,w_n(t)) = -\int_0^t \nabla\cdot e^{-(t-s)A}P(u\otimes u)(s)ds \\ &= -\left(\int_0^t F_{\ell,jk}(t-s) * (u_\ell u_k)(s)ds\right)_{j=1}^n . \end{aligned} \tag{4.1}$$

Due to Theorem 3.1, it suffices to prove the following theorem.

THEOREM 4.1.

(i) *Under the assumption of Theorem* 2.1(i), *we have*

$$\lim_{t\to\infty} t^{\frac12+\frac n2(1-\frac1q)} \left\| w_j(t) + F_{\ell,jk}(\cdot,t)\int_0^\infty\int (u_\ell u_k)(y,s)dyds\right\|_q = 0 \tag{4.2}$$

for all $1 \le q \le \infty$ *and* $j = 1,\dots,n$.

(ii) *Under the assumption of Theorem* 2.1(ii), *the weak solution* u *satisfies* (4.2) *for all* $1 \le q \le 2$ *and* $j = 1,\dots,n$.

Proof. We write (4.1) as

$$w_j(t) = -\left(\int_0^{t/2} + \int_{t/2}^t\right) F_{\ell,jk}(t-s) * (u_\ell u_k)(s)dyds \equiv J_1 + J_2.$$

Direct calculation gives

$$\begin{aligned} w_j(t) &+ F_{\ell,jk}(x,t)\int_0^\infty\int (u_\ell u_k)dyds \\ &= F_{\ell,jk}(x,t)\int_{t/2}^\infty\int (u_\ell u_k)dyds \\ &\quad - \int_0^{t/2}\int [F_{\ell,jk}(x-y,t-s) - F_{\ell,jk}(x,t-s)](u_\ell u_k)dyds \\ &\quad + \int_0^{t/2}\int\int_0^1 s(\partial_t F_{\ell,jk})(x,t-s\tau)(u_\ell u_k)dydsd\tau + J_2 \\ &\equiv J_{11} + J_{12} + J_{13} + J_2. \end{aligned}$$

We see from (2.1) and (2.6) that

$$t^{\frac12+\frac n2(1-\frac1q)}\|J_{11}\|_q \le C_q \int_{t/2}^\infty \|u(s)\|_2^2 ds \le Ct^{-\frac n2} \to 0 \qquad \text{as } t\to\infty \tag{4.3}$$

for all $1 \le q \le \infty$. Similarly, applying (2.1) and (2.6) gives

$$\|J_{13}\|_q \le C_q \int_0^1 \int_0^{t/2} s(t-s\tau)^{-\frac{3}{2}-\frac{n}{2}(1-\frac{1}{q})} \|u(s)\|_2^2 ds d\tau$$

$$\le C_q t^{-\frac{3}{2}-\frac{n}{2}(1-\frac{1}{q})} \int_0^{t/2} s\|u(s)\|_2^2 ds \le C_q t^{-\frac{3}{2}-\frac{n}{2}(1-\frac{1}{q})} \int_0^t (1+s)^{-\frac{n}{2}} ds$$

so that, for all $1 \le q \le \infty$,

$$t^{\frac{1}{2}+\frac{n}{2}(1-\frac{1}{q})} \|J_{13}\|_q \le Ct^{-1} \int_0^t (1+s)^{-\frac{n}{2}} ds \to 0 \qquad \text{as } t \to \infty. \tag{4.4}$$

Next, we write $F_{\ell,jk}(x,t) = t^{-\frac{1+n}{2}} K(xt^{-\frac{1}{2}})$ in terms of a smooth, bounded, integrable, and uniformly continuous function K. Applying Minkowski's inequality for the integral yields, after a change of variables,

$$\|J_{12}\|_q \le C_q \int_0^{t/2} \int (t-s)^{-\frac{1}{2}-\frac{n}{2}(1-\frac{1}{q})} \|K(\cdot - y(t-s)^{-\frac{1}{2}}) - K(\cdot)\|_q |u(y,s)|^2 dy ds$$

$$\le C_q t^{-\frac{1}{2}-\frac{n}{2}(1-\frac{1}{q})} \int_0^{t/2} \int \|K(\cdot - y(t-s)^{-\frac{1}{2}}) - K(\cdot)\|_q |u(y,s)|^2 dy ds.$$

Therefore,

$$t^{\frac{1}{2}+\frac{n}{2}(1-\frac{1}{q})} \|J_{12}\|_q \le C_q \int_0^{t/2} \int \varphi_t(y,s) |u(y,s)|^2 dy ds = C_q \int_0^{t/2} \psi_t(s) ds,$$

where $\varphi_t(y,s) = \|K(\cdot - y(t-s)^{-\frac{1}{2}}) - K(\cdot)\|_q$ and $\psi_t(s) = \int \varphi_t(y,s)|u(y,s)|^2 dy$. Note that $\varphi_t(y,s) \le C_q$, that $\varphi_t(y,s) \to 0$ as $t \to \infty$ for fixed y and s, and that $|u(y,s)|^2 dy$ is a finite measure on $\mathbb{R}^n$ for fixed s. The bounded convergence theorem now implies $\psi_t(s) \to 0$ as $t \to \infty$ for each fixed s. However, $\psi_t(s) \le C_q \|u(s)\|_2^2$, and the right-hand side is bounded and integrable over $[0,\infty)$ due to (2.6). Applying again the bounded convergence theorem gives

$$\lim_{t\to\infty} \int_0^M \psi_t(s) ds = 0 \qquad \text{for any fixed } M > 0. \tag{4.5}$$

Now, given $\varepsilon > 0$, choose $M > 0$ so that $\int_M^\infty \|u(s)\|_2^2 ds < \varepsilon$. Then for $t > 2M$, we have

$$\int_0^{t/2} \psi_t(s) ds \le \int_0^M \psi_t(s) ds + C_q \int_M^\infty \|u(s)\|_2^2 ds \le \int_0^M \psi_t(s) ds + C_q \varepsilon.$$

This, together with (4.5), gives $\lim_{t\to\infty} \int_0^{t/2} \psi_t(s) ds = 0$; and we have deduced

$$\lim_{t\to\infty} t^{\frac{1}{2}+\frac{n}{2}(1-\frac{1}{q})} \|J_{12}\|_q = 0 \qquad \text{for all } 1 \le q \le \infty. \tag{4.6}$$

Observe that we have so far invoked only (2.6) for estimating u, so (4.3), (4.4), and (4.6) hold for both of the weak and strong solutions.

We next estimate J_2. It is here where we have to deal with weak and strong solutions separately. Consider first the strong solutions. By (1.4) we get

$$\|J_2\|_q \le \int_{t/2}^{t} \|F_{\ell,jk}(\cdot, t-s)\|_1 \|u(s)\|_{2q}^2 ds$$
$$\le C_q \int_{t/2}^{t} (t-s)^{-\frac{1}{2}}(1+s)^{-1-(n-\frac{n}{2q})} ds \le C_q (1+t)^{-\frac{1}{2}-(n-\frac{n}{2q})}$$

for all $1 \le q \le \infty$, and so

$$t^{\frac{n}{2}+\frac{n}{2}(1-\frac{1}{q})}\|J_2\|_q \le C_q(1+t)^{-\frac{1}{2}} \to 0 \qquad \text{as } t \to \infty. \tag{4.7}$$

This completes the proof of Theorem 4.1(i). □

Next consider the weak solutions. We first show that

$$\lim_{t\to\infty} t^{\frac{n}{2}}\|J_2\|_1 = 0. \tag{4.8}$$

We apply (2.1) and (2.6) to get

$$\|J_2\|_1 \le \int_{t/2}^{t} \|F(t-s)\|_1 \|u(s)\|_2^2 ds \le C \int_{t/2}^{t} (t-s)^{-\frac{1}{2}} s^{-1-\frac{n}{2}} ds \le Ct^{-\frac{n+1}{2}},$$

so that $t^{\frac{n}{2}}\|J_2\|_1 \le Ct^{-\frac{1}{2}} \to 0$ as $t \to \infty$, which proves (4.8). Second, we show that

$$\lim_{t\to\infty} t^{\frac{n}{2}+\frac{n}{4}}\|J_2\|_2 = 0. \tag{4.9}$$

The argument below is due to [4] (see also [11, 18]). Let

$$v(t) = -\int_{\tau}^{t} F(t-s) * (u \otimes u)(s) ds = u(t) - e^{-(t-\tau)A}u(\tau)$$

with $0 < \tau < t$, and assume that v is smooth. (This situation is realized if we replace u by approximate solutions u_N as given in [4, 11].) Then v solves the initial value problem

$$\partial_t v + Av = -P(u \cdot \nabla u) \quad (t > \tau), \qquad v(\tau) = 0.$$

Multiplying the above equation by $2v$ and integrating by parts gives, since $(u\cdot\nabla v, v) = 0$,

$$\partial_t \|v\|_2^2 + 2\|A^{1/2}v\|_2^2 = -2(u\cdot\nabla u, v) = 2(u\cdot\nabla v, u) = 2(u\cdot\nabla v, u_0),$$

where $u_0(t) = e^{-(t-\tau)A}u(\tau)$. By the standard L^p-L^q estimates for e^{-tA} and (2.6), we get

$$\|u_0(t)\|_\infty \le C(t-\tau)^{-\frac{n}{4}}\|u(\tau)\|_2 \le C(t-\tau)^{-\frac{n}{4}}\tau^{-\frac{n}{4}-\frac{1}{2}}.$$

Since $\|\nabla v\|_2 = \|A^{1/2}v\|_2$ and $\|u\|_2 \le \|a\|_2$, we have

$$2|(u\cdot\nabla v, u_0)| \le C\|u\|_2\|\nabla v\|_2\|u_0\|_\infty = C\|A^{1/2}v\|_2\|u\|_2\|u_0\|_\infty$$
$$\le C\|A^{1/2}v\|_2(t-\tau)^{-\frac{n+1}{2}}\tau^{-\frac{n}{4}-\frac{1}{2}}$$
$$\le \|A^{1/2}v\|_2^2 + C(t-\tau)^{-n-1}\tau^{-\frac{n}{2}-1},$$

which implies

$$\partial_t\|v\|_2^2 + \|A^{1/2}v\|_2^2 \le C(t-\tau)^{-n-1}\tau^{-\frac{n}{2}-1}.$$

Let $\{E_\lambda\}_{\lambda\ge 0}$ be the spectral measure associated with the positive self-adjoint operator A. Applying $\|A^{1/2}v\|_2^2 \ge \varrho(\|v\|_2^2 - \|E_\varrho v\|_2^2)$ yields

$$\partial_t\|v\|_2^2 + \varrho\|v\|_2^2 \le \varrho\|E_\varrho v\|_2^2 + C(t-\tau)^{-n-1}\tau^{-\frac{n}{2}-1}.$$

However, we know that (see [4, 11, 18])

$$\|E_\varrho v\|_2^2 \le C\varrho^{\frac{n+2}{2}}\left(\int_\tau^t \|u\|_2^2 ds\right)^2$$

and so

$$\partial_t\|v\|_2^2 + \varrho\|v\|_2^2 \le C\varrho^{\frac{n+4}{2}}\left(\int_\tau^t \|u\|_2^2 ds\right)^2 + C(t-\tau)^{-n-1}\tau^{-\frac{n}{2}-1}.$$

Here we put $\varrho = m(t-\tau)^{-1}$, $m>0$; then we multiply both sides by $(t-\tau)^m$ to get

$$\partial_t((t-\tau)^m\|v\|_2^2) \le C(t-\tau)^{m-\frac{n}{2}-2}\left(\int_\tau^t \|u\|_2^2 ds\right)^2 + C(t-\tau)^{m-n-1}\tau^{-\frac{n}{2}-1}.$$

Choosing m so that $m > n/2+2$ and $m > n+1$, we obtain

$$\begin{aligned}\|v(t)\|_2^2 &\le C(t-\tau)^{-m}\int_\tau^t (s-\tau)^{m-\frac{n}{2}-2}\left(\int_\tau^s \|u\|_2^2 d\sigma\right)^2 ds + C(t-\tau)^{-n}\tau^{-\frac{n}{2}-1}\\ &\le C(t-\tau)^{-2-\frac{n}{2}}\int_\tau^t\left(\int_\tau^s \|u\|_2^2 d\sigma\right)^2 ds + C(t-\tau)^{-n}\tau^{-1-\frac{n}{2}}.\end{aligned}$$

Inserting $\tau = t/2$ yields $v(t) = J_2$, and so

$$t^{n+\frac{n}{2}}\|J_2\|_2^2 \le Ct^{n-1}\left(\int_{t/2}^\infty \|u\|_2^2 ds\right)^2 + Ct^{-1} \le Ct^{-1} \to 0 \qquad \text{as } t\to\infty.$$

This proves (4.9). Interpolating between (4.8) and (4.9) now gives

$$\lim_{t\to\infty} t^{\frac{n}{2}+\frac{n}{2}(1-\frac{1}{q})}\|J_2\|_q = 0 \qquad \text{for all } 1\le q\le 2. \tag{4.10}$$

This completes the proof of Theorem 4.1(ii). □

5. Proof of Theorem 2.2. This section proves Theorem 2.2. Recall that, as shown in [9], our strong solutions satisfy pointwise estimate (1.5) with $\gamma = n+1$, i.e.,

$$|u(x,t)| \le C_\alpha(1+|x|)^{\alpha-n-1}(1+t)^{-\alpha/2} \qquad \text{for all } 0\le\alpha\le n+1. \tag{5.1}$$

Choosing $\alpha = n+1$ and then $\alpha = 1$, we get

$$\|u(t)\|_\infty \le C(1+t)^{-\frac{1+n}{2}}, \qquad \|u(t)\|_{1,w} \le C(1+t)^{-\frac{1}{2}}, \tag{5.2}$$

where $\|\cdot\|_{1,w}$ is the quasi norm of the weak L^1-space (see [16]). Hence, we get (2.6), i.e.,

$$\|u(t)\|_2 \le C\|u(t)\|_\infty^{1/2}\|u(t)\|_{1,w}^{1/2} \le C(1+t)^{-\frac{n+2}{4}}.$$

Using (1.2), (1.3), (2.1), and (2.6), we can estimate (1.1) to get $\|u(t)\|_1 \le C(1+t)^{-\frac{1}{2}}$. Combining this with the first estimate of (5.2), we conclude that

$$\|u(t)\|_q \le C(1+t)^{-\frac{1}{2}-\frac{n}{2}(1-\frac{1}{q})} \qquad \text{for all } 1 \le q \le \infty. \tag{5.3}$$

We also invoke estimate (2.7) for our strong solutions, i.e.,

$$\int |y|^m |u(y,s)|^2 dy \le C_m(1+s)^{-1-\frac{n-m}{2}} \qquad \text{for all } 0 \le m \le n+1. \tag{5.4}$$

This is deduced as follows. Note that (5.1) implies $|y|^{n+1}|u(y,s)| \le C$, and so

$$\int |y|^{n+1}|u(y,s)|^2 dy \le C\int |u(y,s)|dy \le C(1+s)^{-\frac{1}{2}}.$$

Combining this with (5.3) gives, via Hölder's inequality,

$$\int |y|^m|u(y,s)|^2 dy \le \left(\int |y|^{n+1}|u|^2 dy\right)^{\frac{m}{n+1}} \left(\int |u|^2 dy\right)^{1-\frac{m}{n+1}} \le C_m(1+s)^{-1-\frac{n-m}{2}}.$$

On the other hand, under the assumptions of Theorem 2.2(iv), we know (see [3, 14]) the existence of a weak solution u satisfying the energy inequality and (2.8), i.e.,

$$\int |y|^m |u(y,s)|^2 dy \le C(1+s)^{-(1+\frac{n}{2})(1-\frac{m}{n})} \qquad \text{for all } 0 \le m \le n. \tag{5.5}$$

The proof of (5.5) will be given in the appendix.

Now define the function $w(t)$ by (4.1). Since we have Theorem 3.1, in order to prove Theorem 2.2 we need only show the following.

THEOREM 5.1.

(i) *Under the asumption of Theorem* 2.2(iii), *we have*

$$\begin{aligned}\left\| w_j(t) + \sum_{|\beta|+2p\le m-1} \frac{(-1)^{|\beta|+p}}{p!\beta!}(\partial_x^\beta \partial_t^p F_{\ell,jk})(\cdot,t)\int_0^\infty\int s^p y^\beta (u_\ell u_k)dyds\right\|_q \\ = o(t^{\frac{m}{2}+\frac{n}{2}(1-\frac{1}{q})}) \qquad \textit{as } t\to\infty\end{aligned} \tag{5.6}$$

for all $1 \le q \le \infty$ *and all integers* m *such that* $1 \le m \le n$.

(ii) *Under the assumption of Theorem* 2.2(iv), *the function* w *satisfies* (5.6) *for all* $1 \le q \le 2$ *and all integers* m *such that* $1 \le m \le n-1$.

To prove Theorem 5.1, we again invoke the notation

$$w_j(t) = -\left(\int_0^{t/2} + \int_{t/2}^t\right) F_{\ell,jk}(t-s) * (u_\ell u_k)(s)ds \equiv J_1 + J_2.$$

The integral J_2 is already estimated in section 4, and we know that (4.7) holds for strong solutions and (4.10) for weak solutions. It thus suffices to find the desired expansion for J_1. As in section 4, J_1 is estimated in the same way for both weak and strong solutions.

We begin by noticing the following version of Taylor's formula.

LEMMA 5.2. *Let F denote any of the functions $F_{\ell,jk}$ and let $m \geq 1$ be an arbitrary integer. Then,*

$$F(x-y,t-s) = \sum_{|\beta|+2p\leq m-1} \frac{(-y)^\beta(-s)^p}{p!\beta!}(\partial_x^\beta \partial_t^p F)(x,t) + S^m.$$

Here, denoting $N_m = [(m-1)/2]$, the greatest integer in $(m-1)/2$,

$$\begin{aligned} S^m = &\sum_{|\beta|+2p=m-1,|\beta|\geq 2} |\beta| \int_0^1 (1-\theta)^{|\beta|-1} \frac{(-y)^\beta(-s)^p}{p!\beta!} \\ &\qquad\qquad \times[(\partial_x^\beta\partial_t^p F)(x-y\theta,t) - (\partial_x^\beta\partial_t^p F)(x,t)]d\theta \\ &+\frac{(-s)^{N_m}}{N_m!}[(\partial_t^{N_m}F)(x-y,t) - (\partial_t^{N_m}F)(x,t)] \\ &+\frac{(-s)^{N_m+1}}{N_m!}\int_0^1 (1-\tau)^{N_m}(\partial_t^{N_m+1}F)(x-y,t-s\tau)d\tau \end{aligned}$$

if m is odd, and

$$\begin{aligned} S^m = &\sum_{|\beta|+2p=m-1} |\beta| \int_0^1 (1-\theta)^{|\beta|-1} \frac{(-y)^\beta(-s)^p}{p!\beta!} \\ &\qquad\qquad \times[(\partial_x^\beta\partial_t^p F)(x-y\theta,t) - (\partial_x^\beta\partial_t^p F)(x,t)]d\theta \\ &+\frac{(-s)^{N_m+1}}{N_m!}\int_0^1 (1-\tau)^{N_m}(\partial_t^{N_m+1}F)(x-y,t-s\tau)d\tau \end{aligned}$$

if m is even.

The proof of Lemma 5.2 is straightforward, and so it is omitted here.

Proof of Theorem 5.1. We apply Lemma 5.2 to get

$$\begin{aligned} J_1 + &\sum_{|\beta|+2p\leq m-1} \frac{(-1)^{|\beta|+p}}{p!\beta!}(\partial_t^p\partial_x^\beta F_{\ell,jk})(x,t)\int_0^\infty\!\!\int s^p y^\beta (u_\ell u_k)(y,s)dyds \\ &= \sum_{|\beta|+2p\leq m-1} \frac{(-1)^{|\beta|+p}}{p!\beta!}(\partial_t^p\partial_x^\beta F_{\ell,jk})(x,t)\int_{t/2}^\infty\!\!\int s^p y^\beta (u_\ell u_k)(y,s)dyds \\ &\qquad - \int_0^{t/2}\!\!\int S^m_{\ell,jk}(x,y,t,s)(u_\ell u_k)(y,s)dyds \\ &\equiv J_{11} + J_{12}. \end{aligned}$$

Suppose u is a strong solution and recall (2.1) and (2.7), i.e., that

$$\|(\partial_t^p\partial_x^\beta F_{\ell,jk})(\cdot,t)\|_q \leq C_q t^{-\frac{1+|\beta|+2p}{2}-\frac{n}{2}(1-\frac{1}{q})},$$

$$\int s^p|y|^{|\beta|}|u(y,s)|^2dy \leq C(1+s)^{-\frac{n-(|\beta|+2p)}{2}-1}.$$

If $|\beta| + 2p \le m-1$, each term of J_{11} behaves in L^q like $t^{-\frac{n+1}{2}-\frac{n}{2}(1-\frac{1}{q})}$ as $t \to \infty$; hence

$$t^{\frac{m}{2}+\frac{n}{2}(1-\frac{1}{q})}\|J_{11}\|_q \le Ct^{-\frac{n-m+1}{2}} \le Ct^{-\frac{1}{2}} \to 0 \qquad \text{as } t \to \infty$$

for $1 \le q \le \infty$ and $1 \le m \le n$. So we need only estimate J_{12}, using the concrete expression of functions $S^m_{\ell,jk}$ as given in Lemma 5.2. Let S^m_2 be the last term in the definition of S^m which involves the integral in τ, and write

$$S^m = S^m_1 + S^m_2.$$

Since $0 \le s \le t/2$, straightforward estimation shows that

$$\|(\partial_t^{N_m+1}F)(\cdot - y, t - s\tau)\|_q \le ct^{-\frac{3}{2}-N_m-\frac{n}{2}(1-\frac{1}{q})} = \begin{cases} ct^{-1-\frac{m}{2}-\frac{n}{2}(1-\frac{1}{q})} & (m : \text{odd}), \\ ct^{-\frac{1}{2}-\frac{m}{2}-\frac{n}{2}(1-\frac{1}{q})} & (m : \text{even}), \end{cases}$$

and

$$\begin{aligned} \int_0^{t/2} s^{N_m+1}\|u(s)\|_2^2 ds &\le c\int_0^{t/2} s^{N_m+1}(1+s)^{-1-\frac{n}{2}}ds \\ &\le \begin{cases} c\displaystyle\int_0^{t/2}(1+s)^{-\frac{n-m+1}{2}}ds & (m : \text{odd}), \\ c\displaystyle\int_0^{t/2}(1+s)^{-1-\frac{n-m}{2}}ds & (m : \text{even}). \end{cases} \end{aligned}$$

Therefore, the contribution from S^m_2 is estimated as

$$\le Ct^{-\frac{m}{2}-\frac{n}{2}(1-\frac{1}{q})} \times t^{-1}\int_0^t (1+s)^{-\frac{1}{2}}ds = o(t^{-\frac{m}{2}-\frac{n}{2}(1-\frac{1}{q})}) \qquad \text{if } m \text{ is odd,}$$

and

$$\le Ct^{-\frac{m}{2}-\frac{n}{2}(1-\frac{1}{q})} \times t^{-\frac{1}{2}}\int_0^t (1+s)^{-1}ds = o(t^{-\frac{m}{2}-\frac{n}{2}(1-\frac{1}{q})}) \qquad \text{if } m \text{ is even.}$$

To estimate the contribution from S^m_1, we write

$$(\partial_x^\beta \partial_t^p F)(x,t) = t^{-\frac{1+n+|\beta|+2p}{2}}K(xt^{-\frac{1}{2}}),$$

and, when m is odd,

$$(\partial_t^{N_m}F)(x,t) = t^{-\frac{m+n}{2}}K(xt^{-\frac{1}{2}})$$

in terms of some functions K which are smooth, bounded, integrable, and uniformly continuous on $\mathbb{R}^n$. We easily see that

$$\|(\partial_x^\beta \partial_t^p F)(\cdot - y\theta, t) - (\partial_x^\beta \partial_t^p F)(\cdot, t)\|_q \le Ct^{-\frac{m}{2}-\frac{n}{2}(1-\frac{1}{q})}\|K(\cdot - yt^{-\frac{1}{2}}\theta) - K(\cdot)\|_q$$

when $|\beta| + 2p = m-1$, and

$$\|(\partial_t^{N_m}F)(\cdot - y, t) - (\partial_t^{N_m}F)(\cdot, t)\|_q \le Ct^{-\frac{m}{2}-\frac{n}{2}(1-\frac{1}{q})}\|K(\cdot - yt^{-\frac{1}{2}}) - K(\cdot)\|_q.$$

Using these estimates as well as (2.7), we can proceed in exactly the same way as in section 4 to conclude that the contribution from S_1^m is $o(t^{-\frac{m}{2}-\frac{n}{2}(1-\frac{1}{q})})$. We have thus deduced

$$\lim_{t\to\infty} t^{\frac{m}{2}+\frac{n}{2}(1-\frac{1}{q})}\|J_1\|_q = 0 \tag{5.7}$$

for $1 \le m \le n$ and $1 \le q \le \infty$ when u is a strong solution.

When u is a weak solution, we can estimate J_{11} and J_{12} in the same way as above, using (2.8) instead of (2.7), and conclude that (5.7) holds for $1 \le m \le n-1$ and $1 \le q \le \infty$. This completes the proof of Theorem 5.1. □

Remarks.

(i) In this section we could treat higher-order expansions of weak solutions only in space dimensions $n = 3, 4$ because the moment estimate (2.8) is known only in this case. It should be noticed that in Theorem 2.1(ii), we could treat weak solutions in general space dimensions $n \ge 2$ because we then needed (2.8) only with $m = 0$ which is valid in all space dimensions. As will be seen from the argument in the appendix, it seems impossible to deduce (2.8) for $m \ge 1$ when $n \ge 5$. Indeed, the desired boundedness is first deduced for approximate solutions and then for the weak solutions by passing to the limit. However, if the boundedness were true for the approximate solutions on $\mathbb{R}^n$, $n \ge 5$, we could then deduce the precompactness of the approximate solutions in $L^2(0, T : \boldsymbol{L}^2)$ for any fixed $T > 0$. This precompactness readily implies that the weak solutions obtained by passing to the limit satisfy the so-called *strong energy inequality* of Leray [6]:

$$\|u(t)\|_2^2 + 2\int_s^t \|\nabla u\|_2^2 d\tau \le \|u(s)\|_2^2 \qquad \text{for } s = 0, \text{ a.e. } s > 0, \text{ and all } t \ge s.$$

However, the existence of weak solutions satisfying this inequality remains open when $n \ge 5$ and seems in general not to be valid, as is remarked in [5].

(ii) From the argument in this section, we see that if our weak solutions should satisfy the moment estimate (2.7) under suitable conditions on the initial data a, then we could deduce the asymptotic expansion (2.4) with $1 \le q \le 2$ and $1 \le m \le n$ also for the weak solutions. Indeed, we needed moment estimates, which are different between the cases of weak and strong solutions, only in dealing with the integral J_1, and our estimates for J_2 (given in section 4) are independent of the moment estimates.

6. Proof of Theorem 2.3. In this section we prove Theorem 2.3. The case $2 \le q \le \infty$ is treated in [12, 15] by an elementary method. Our main purpose is to extend the result to the case $1 \le q < 2$ by employing the Hardy space theory. Consider the solution ω of the linear heat equation

$$\partial_t \omega = \Delta\omega, \qquad \omega(0) = \omega_0,$$

where $\omega_0(y) = \omega_0(|y|) \in \mathcal{S}(\mathbb{R}^2)$, $\widehat{\omega_0} \in C_c^\infty(\mathbb{R}^2)$, and $\widehat{\omega_0} \equiv 0$ in a neighborhood of $\xi = 0$. Note that $\widehat{\omega_0}$ is also radial, and so both ω_0 and $\widehat{\omega_0}$ can be chosen as real-valued functions. Thus, $\widehat{\omega}(\xi, t) = e^{-t|\xi|^2}\widehat{\omega_0}(\xi)$ is radial, and so $\omega(x, t)$ is also radial. Moreover, $\omega(t) \in \mathcal{S}(\mathbb{R}^2)$ and

$$\int x^\alpha \omega(x, t)dx = \int y^\alpha \omega_0(y)dy = 0 \qquad \text{for all multi-indices } \alpha.$$

This implies that $\omega(t)$ belongs to the Hardy space $\mathcal{H}^p$ for all $0 < p < \infty$ and all $t \geq 0$ ([16, p. 128]), and

$$\|\omega(t)\|_{H^q} \leq Ct^{-(\frac{1}{p}-\frac{1}{q})}\|\omega_0\|_{H^p} \qquad \text{whenever } 0 < p \leq q < \infty. \tag{6.1}$$

See [7] for a proof of (6.1). Consider now

$$u(x,t) = (u_1(x,t), u_2(x,t)) = \frac{1}{2\pi}\int \frac{(-x_2+y_2, x_1-y_1)}{|x-y|^2}\omega(y,t)dy,$$

where $x = (x_1, x_2)$ and $y = (y_1, y_2)$. Then

$$\nabla \times u \equiv \partial_1 u_2 - \partial_2 u_1 = \omega \qquad \text{and} \qquad u \cdot \nabla\omega = 0,$$

so $\partial_t\omega - \Delta\omega + u \cdot \nabla\omega = 0$, and therefore,

$$\nabla \times (\partial_t u - \Delta u + u \cdot \nabla u) = 0.$$

Thus, there exists a scalar function p such that

$$\partial_t u - \Delta u + u \cdot \nabla u + \nabla p = 0.$$

Since $\nabla \cdot u = 0$, it follows that u solves the Navier–Stokes system. Applying the Fourier transform gives

$$\widehat{u}(\xi,t) = \frac{(-i\xi_2, i\xi_1)}{|\xi|^2}\widehat{\omega}(\xi,t) = \frac{(-i\xi_2, i\xi_1)}{|\xi|^2}e^{-t|\xi|^2}\widehat{\omega_0}(\xi).$$

This shows that for each fixed t, the function $\widehat{u}(\xi,t)$ is in $C_c^\infty(\mathbb{R}^2)$ and vanishes in a fixed neighborhood of $\xi = 0$ independent of t. The Hausdorff–Young inequality for the Fourier transform shows that if $2 \leq q \leq \infty$, then

$$\|u(t)\|_q \leq C_q\|\widehat{u}(t)\|_{q'} \leq C_q\left(\int e^{-q't|\xi|^2}|\widehat{\omega_0}(\xi)|^{q'}d\xi\right)^{1-1/q} \leq C_q e^{-\gamma_q t},$$

with $1/q' = 1 - 1/q$, since $\widehat{\omega_0} \equiv 0$ in a neighborhood of $\xi = 0$. We thus conclude that

$$\|u(t)\|_q \leq C_q e^{-\gamma_q t} \qquad \text{for all } 2 \leq q \leq \infty. \tag{6.2}$$

We next write $\widehat{u}$ in the form $\widehat{u}(\xi,t) = |\xi|^{-1}(-i\xi_2|\xi|^{-1}, i\xi_1|\xi|^{-1})\widehat{\omega}(\xi,t)$ so that

$$u = (-\Delta)^{-1/2}(-R_2, R_1)\omega,$$

where R_j are the Riesz transforms. Since R_j are bounded in Hardy spaces, it follows by the Hardy–Littlewood–Sobolev inequality in Hardy spaces [16, p. 136] and (6.1) that $\|u(t)\|_{H^{6/7}} \leq C\|\omega(t)\|_{H^{3/5}} \leq C\|\omega_0\|_{H^{3/5}}$, and therefore

$$\|u(t)\|_1 \leq C\|u(t)\|_{H^1} \leq C\|u(t)\|_2^{1/4}\|u(t)\|_{H^{6/7}}^{3/4} \leq C_1 e^{-\gamma_1 t}.$$

This, together with (6.2), implies

$$\|u(t)\|_q \leq C_q e^{-\gamma t} \qquad \text{for all } 1 \leq q \leq \infty \tag{6.3}$$

with another constant $\gamma > 0$ independent of q. To see the behavior with respect to the space variables, we fix a function $M = (M_1, M_2)$ so that $\widehat{M} \in C_c^\infty(\mathbb{R}^2)$, $\widehat{M} \equiv 0$, in a neighborhood of $\xi = 0$, and

$$\widehat{M}(\xi) = \frac{(-i\xi_2, i\xi_1)}{|\xi|^2} \qquad \text{in a neighborhood of supp}\, \widehat{\omega_0}.$$

Since $\widehat{u}(\xi, t) = \widehat{M}(\xi)e^{-t|\xi|^2}\widehat{\omega_0}(\xi)$, the relation

$$x^\beta u(x,t) = (2\pi)^{-2} \int e^{ix\cdot\xi}(i\partial_\xi)^\beta[\widehat{M}(\xi)e^{-t|\xi|^2}\widehat{\omega_0}(\xi)]d\xi$$

and the fact that $\widehat{\omega_0} \equiv 0$ in a neighborhood of $\xi = 0$ together imply

$$|x^\beta u(x,t)| \le C_\beta \sum_{\eta\le\beta} \int e^{-t|\xi|^2}|\partial_\xi^\eta \widehat{\omega_0}(\xi)|d\xi \le C_\beta e^{-\gamma t} \sum_{\eta\le\beta} \int |\partial_\xi^\eta \widehat{\omega_0}(\xi)|d\xi \le C_\beta e^{-\gamma t}$$

for all multi-indices β. Hence

$$|u(x,t)| \le C_m e^{-\gamma t}(1 + |x|)^{-m} \qquad \text{for all integers } m \ge 0. \tag{6.4}$$

By (6.3) and (6.4) the proof of Theorem 2.3 is complete. □

Appendix. On boundedness of L^2-moments of weak solutions. We shall prove the following, which was employed in the proof of Theorem 2.2(iv).

PROPOSITION A.1. *Let $n = 3$ or 4 and suppose that*

$$\int (1 + |x|)|a(x)|dx < \infty, \qquad \int (1 + |x|)^n |a(x)|^2 dx < \infty.$$

Then the corresponding weak solution u obtained via the methods of [3, 4] *satisfies*

$$\int |x|^n |u(x,t)|^2 dx \le C \qquad \text{for all } \ t \ge 0.$$

Consequently,

$$\int |x|^m |u(x,t)|^2 dx \le C(1+t)^{-(1+\frac{n}{2})(1-\frac{m}{n})} \qquad (m = 0, 1, \dots, n). \tag{A.1}$$

The above result is due to [3, 14]. We here give a detailed proof, modifying slightly the argument of [3], since [3] and [14] are not yet published.

Proof of Proposition A.1. Note that (see [18]) (A.1) is known for $m = 0$. The Navier–Stokes system is

$$\begin{aligned} \partial_t u - \Delta u + u\cdot\nabla u + \nabla p = 0,\\ \nabla\cdot u = 0. \end{aligned} \tag{NS}$$

Assuming, as we may (see [4]), that u is smooth, we multiply (NS) by $2|x|u$ and integrate by parts to get

$$\partial_t \int |x||u|^2 dx + 2\int |x||\nabla u|^2 dx = -2\int \nabla u \cdot \frac{x}{|x|} u dx - 2\int u\cdot\nabla u |x| u dx$$
$$+2\int p\frac{x}{|x|} u dx.$$

Direct calculation gives

$$\int u\cdot\nabla u|x|udx = -\int u|x|u\cdot\nabla udx - \int uu\cdot\frac{x}{|x|}udx$$

so that

$$\int u\cdot\nabla u|x|udx = -\frac{1}{2}\int uu\cdot\frac{x}{|x|}udx.$$

Therefore,

$$\text{(A.2)}\qquad \left|\int u\cdot\nabla u|x|udx\right| \le \frac{1}{2}\|u\|_3^3 \le \begin{cases} C\|u\|_2^{3/2}\|\nabla u\|_2^{3/2} & (n=3),\\ C\|u\|_2\|\nabla u\|_2^2 & (n=4).\end{cases}$$

Furthermore, since

$$\text{(A.3)}\qquad p = R_jR_k(u_ju_k)$$

with $R=(R_1,\dots,R_n)$ the Riesz transforms (see [16]), applying the L^p-boundedness of singular integrals [16] gives

$$\|p\|_2 \le C\|u\|_4^2 \le \begin{cases} C\|u\|_2^{1/2}\|\nabla u\|_2^{3/2} & (n=3),\\ C\|\nabla u\|_2^2 & (n=4).\end{cases}$$

It follows that

$$\text{(A.4)}\qquad \left|\int p\frac{x}{|x|}udx\right| \le \|p\|_2\|u\|_2 \le \begin{cases} C\|u\|_2^{3/2}\|\nabla u\|_2^{3/2} & (n=3),\\ C\|u\|_2\|\nabla u\|_2^2 & (n=4).\end{cases}$$

Finally,

$$\left|\int u\frac{x}{|x|}\nabla udx\right| \le \|u\|_2\|\nabla u\|_2 \le C(\|u\|_2^2+\|\nabla u\|_2^2).$$

Since $\|u\|_2^{3/2}\|\nabla u\|_2^{3/2} \le C(\|u\|_2^6+\|\nabla u\|_2^2) \le C(\|u\|_2^2+\|\nabla u\|_2^2)$, we see from (A.2) and (A.4) that

$$\partial_t\int|x||u|^2dx + \int|x||\nabla u|^2dx \le C(\|u\|_2^2+\|\nabla u\|_2^2)$$

and the right-hand side is integrable in $t\in[0,\infty)$ by (1.6) and (1.7). Hence we get

$$\text{(A.5)}\qquad \int|x||u(x,t)|^2dx \le C.$$

We next multiply (NS) by $2|x|^2|u|$ and integrate by parts to get

$$\partial_t\int|x|^2|u|^2dx + 2\int|x|^2|\nabla u|^2dx = -4\int\nabla u\cdot x\cdot udx - 2\int u\cdot\nabla u|x|^2udx$$
$$+4\int px\cdot udx.$$

We have

$$\left|\int \nabla u\cdot x\cdot udx\right| \le \left(\int |x|^2|\nabla u|^2dx\right)^{1/2}\left(\int |u|^2dx\right)^{1/2}$$
$$\le \varepsilon \int |x|^2|\nabla u|^2dx + C_\varepsilon \int |u|^2dx$$

for all $\varepsilon > 0$. Furthermore,

$$\int u\cdot\nabla u|x|^2udx = -\int uu\cdot x\cdot udx$$

and so

$$\left|\int u\cdot\nabla u|x|^2udx\right| \le \int |x||u|^3dx \le \left(\int |x|^2|u|^2dx\right)^{1/2}\|u\|_4^2$$
$$\le \begin{cases} C\left(\int |x|^2|u|^2dx\right)^{1/2}(\|u\|_2^2+\|\nabla u\|_2^2) & (n=3),\\ C\left(\int |x|^2|u|^2dx\right)^{1/2}\|\nabla u\|_2^2 & (n=4).\end{cases}$$

Similarly,

$$\left|\int px\cdot udx\right| \le \|p\|_2\left(\int |x|^2|u|^2dx\right)^{1/2} \le C\|u\|_4^2\left(\int |x|^2|u|^2dx\right)^{1/2}$$
$$\le \begin{cases} C\left(\int |x|^2|u|^2dx\right)^{1/2}(\|u\|_2^2+\|\nabla u\|_2^2) & (n=3),\\ C\left(\int |x|^2|u|^2dx\right)^{1/2}\|\nabla u\|_2^2 & (n=4).\end{cases}$$

We thus obtain

$$\partial_t\int |x|^2|u|^2dx + \int |x|^2|\nabla u|^2dx \le C\|u\|_2^2 + C(\|u\|_2^2+\|\nabla u\|_2^2)$$
$$+ C(\|u\|_2^2+\|\nabla u\|_2^2)\int |x|^2|u|^2dx.$$

Since $\|u\|_2^2+\|\nabla u\|_2^2$ is integrable in $t\in[0,\infty)$ by (1.6) and (1.7), we get

$$\int |x|^2|u(x,t)|^2dx \le C \tag{A.6}$$

by Gronwall's lemma. Consequently,

$$\int |x||u(x,t)|^2dx \le C(1+t)^{-\frac{1}{2}-\frac{n}{4}}. \tag{A.7}$$

We next multiply (NS) by $2|x|^3u$ and integrate by parts to get

$$\partial_t\int |x|^3|u|^2dx + 2\int |x|^3|\nabla u|^2dx = -6\int \nabla u|x|x\cdot udx$$
$$-2\int u\cdot\nabla u|x|^3udx + 6\int p|x|x\cdot udx.$$

We easily see that

$$\left|\int \nabla u|x|x\cdot u dx\right| \le \left(\int |x|^3|\nabla u|^2 dx\right)^{1/2}\left(\int |x||u|^2 dx\right)^{1/2}$$
$$\le \varepsilon\int |x|^3|\nabla u|^2dx + C_\varepsilon\int |x||u|^2dx$$

for all $\varepsilon > 0$. Furthermore,

$$2\int u\cdot\nabla u|x|^3 u dx = -3\int uu\cdot|x|x\cdot udx$$

and so by (A.6),

$$\left|\int u\cdot\nabla u|x|^3udx\right| \le \left(\int |x|^2|u|^2dx\right)^{1/2}\left(\int |x|^2|u|^4dx\right)^{1/2} \le C\left(\int |x|^2|u|^4dx\right)^{1/2}.$$

Similarly, from

$$\int |x|^2|p|^2dx \le C\int |x|^2|u|^4dx,$$

which shows the boundedness of operators R_j in weighted L^q-spaces [16, p. 218], we see by (A.6) that

$$\left|\int p|x|x\cdot udx\right| \le \left(\int |x|^2|p|^2dx\right)^{1/2}\left(\int |x|^2|u|^2dx\right)^{1/2} \le C\left(\int |x|^2|u|^4dx\right)^{1/2}.$$

When $n = 3$,

$$\begin{aligned}\||x|uu\|_2 &\le \||x|u\|_{24/5}\|u\|_{24/7} \le \|u\|_{24/7}\||x|^{3/2}u\|_6^{2/3}\|u\|_{24/7}^{1/3}\\ &\le C\|u\|_{24/7}^{4/3}\|\nabla(|x|^{3/2}u)\|_2^{2/3}\\ &\le C\|u\|_{24/7}^{4/3}(\||x|^{1/2}u\|_2 + \||x|^{3/2}\nabla u\|_2)^{2/3}\\ &\le C\|u\|_2^{1/2}\|\nabla u\|_2^{5/6}(\||x|^{1/2}u\|_2 + \||x|^{3/2}\nabla u\|_2)^{2/3}\\ &\le C\|u\|_2^{1/2}\|\nabla u\|_2^{5/6}\||x|^{1/2}u\|_2^{2/3} + C\|u\|_2^{1/2}\|\nabla u\|_2^{5/6}\||x|^{3/2}\nabla u\|_2^{2/3}\\ &\le \varepsilon\||x|^{3/2}\nabla u\|_2^2 + C_\varepsilon(\||x|^{1/2}u\|_2^2 + \|u\|_2^2 + \|\nabla u\|_2^2)\end{aligned}$$

for all $\varepsilon > 0$. When $n = 4$, we get

$$\begin{aligned}\||x|uu\|_2 &\le \||x|^{3/2}u\|_4^{2/3}\|u\|_4^{4/3} \le C\|\nabla(|x|^{3/2}u)\|_2^{2/3}\|\nabla u\|_2^{4/3}\\ &\le C(\||x|^{1/2}u\|_2^{2/3} + \||x|^{3/2}\nabla u\|_2^{2/3})\|\nabla u\|_2^{4/3}\\ &\le C_\varepsilon(\|\nabla u\|_2^2 + \||x|^{1/2}u\|_2^2) + \varepsilon\||x|^{3/2}\nabla u\|_2^2\end{aligned}$$

for all $\varepsilon > 0$. Therefore,

$$\partial_t\int |x|^3|u|^2dx + \int |x|^3|\nabla u|^2dx \le C(\||x|^{1/2}u\|_2^2 + \|u\|_2^2 + \|\nabla u\|_2^2).$$

By (1.6), (1.7), and (A.7) the right-hand side is integrable in $t \in [0, \infty)$, and we obtain

$$\int |x|^3 |u(x,t)|^2 dx \le C. \tag{A.8}$$

Consequently,

$$\int |x|^j |u(x,t)|^2 dx \le C(1+t)^{-(1+\frac{n}{2})(1-\frac{j}{3})} \qquad (j = 0, 1, 2, 3, \quad n = 3, 4). \tag{A.9}$$

Assume finally that $n = 4$, multiply (NS) by $2|x|^4 u$, and integrate by parts to get

$$\partial_t \int |x|^4 |u|^2 dx + 2\int |x|^4 |\nabla u|^2 dx = -8 \int \nabla u |x|^2 \cdot x \cdot u dx - 2\int u \cdot \nabla u |x|^4 u dx$$
$$+8 \int p|x|^2 x \cdot u dx.$$

We have

$$\left|\int \nabla u |x|^2 \cdot x \cdot u dx\right| \le \left(\int |x|^4 |\nabla u|^2 dx\right)^{1/2} \left(\int |x|^2 |u|^2 dx\right)^{1/2}$$
$$\le \varepsilon \int |x|^4 |\nabla u|^2 dx + C_\varepsilon \int |x|^2 |u|^2 dx$$

for all $\varepsilon > 0$. Furthermore,

$$2\int u \cdot \nabla u |x|^4 u dx = -4 \int uu|x|^2 x \cdot u dx$$

so that by (A.8)

$$\left|\int u \cdot \nabla u |x|^4 u dx\right| \le C \left(\int |x|^3 |u|^4 dx\right)^{1/2} \left(\int |x|^3 |u|^2 dx\right)^{1/2}$$
$$\le C \left(\int |x|^3 |u|^4 dx\right)^{1/2}.$$

Similarly, from

$$\int |x|^3 |p|^2 dx \le C \int |x|^3 |u|^4 dx,$$

it follows by (A.8) that

$$\left|\int p|x|^2 x \cdot u dx\right| \le C \left(\int |x|^3 |u|^4 dx\right)^{1/2} \left(\int |x|^3 |u|^2 dx\right)^{1/2} \le C \left(\int |x|^3 |u|^4 dx\right)^{1/2}.$$

However,

$$\left(\int |x|^3 |u|^4 dx\right)^{1/2} \le \||x|^2 u\|_4^{3/4} \|u\|_4^{5/4} \le C \|\nabla(|x|^2 u)\|_2^{3/4} \|\nabla u\|_2^{5/4}$$
$$\le C(\||x|u\|_2^{3/4} + \||x|^2 \nabla u\|_2^{3/4}) \|\nabla u\|_2^{5/4}$$
$$\le \varepsilon \||x|^2 \nabla u\|_2^2 + C_\varepsilon (\|\nabla u\|_2^2 + \||x|u\|_2^2)$$

for all $\varepsilon > 0$. We thus have

$$\partial_t \int |x|^4|u|^2 dx + \int |x|^4|\nabla u|^2 dx \le C(\||x|u\|_2^2 + \|\nabla u\|_2^2). \tag{A.10}$$

Since $\||x|u\|_2^2 \le C(1+t)^{-1}$ by (A.9), it follows from (A.10) that

$$\int |x|^4|u(x,t)|^2 dx \le C \log(1+t).$$

However, this implies

$$\||x|u\|_2^2 \le \left(\int |u(x,t)|^2 dx\right)^{1/2} \left(\int |x|^4|u(x,t)|^2 dx\right)^{1/2} \le C(1+t)^{-3/2}[\log(1+t)]^{1/2},$$

and the right-hand side is integrable in $t \in [0,\infty)$. So we conclude from (A.10) that

$$\int |x|^4|u(x,t)|^2 dx \le C \qquad (n=4).$$

This completes the proof of Proposition A.1. □

Remarks.

(i) The above argument also shows that

$$\int_0^\infty \int |x|^n |\nabla u|^2 dx dt < \infty \qquad (n=3,4).$$

(ii) We have omitted discussing the finiteness of L^2-moments. Actually, this is verified first for approximate solutions and the desired boundedness result is then deduced for weak solutions by passing to the limit. The details are described in [3, 14].

(iii) It is impossible to apply the argument of this section to estimating the moments $\int |x|^{n+k}|u|^2 dx$, $k \ge 1$. The main reason is that the pressure p is represented in (A.3) in terms of singular integrals R_j, and one cannot apply in the present situation the weighted L^q-estimates, which were crucial in the above argument, in such a way that the resulting terms are estimated in the Sobolev space $H^1 = W^{1,2}$. To avoid this difficulty, we need some additional integrability conditions on weak solutions; however, conditions of this kind imply that the solutions must be strong solutions. For the details, we refer the reader to [3, 14].

ON FULLY NONLINEAR PDEs DERIVED FROM VARIATIONAL PROBLEMS OF L^p NORMS[*]

TOSHIHIRO ISHIBASHI[†] AND SHIGEAKI KOIKE[†]

In memory of Professor Yoshihito Tomita

Abstract. The p-Laplace operator arises in the Euler–Lagrange equation associated with a minimizing problem which contains the L^p norm of the gradient of functions. However, when we adapt a different L^p norm equivalent to the standard one in the minimizing problem, a different p-Laplace-type operator appears in the corresponding Euler–Lagrange equation. First, we derive the limit PDE which the limit function of minimizers of those, as $p \to \infty$, satisfies in the viscosity sense. Then we investigate the uniqueness and existence of viscosity solutions of the limit PDE.

Key words. viscosity solution, fully nonlinear equation, ∞-Laplacian, comparison principle, concave solution

1. Introduction.

We consider the following variational problem:

$$\inf\left\{ \|Dv\|^p_{L^p(\Omega)} - \int_\Omega fv dx \;\middle|\; v \in W^{1,p}_0(\Omega) \right\}, \tag{1.1}$$

where $p > 1$, $\Omega \subset \mathbf{R}^n$ is a bounded domain with smooth boundary $\partial\Omega$ for simplicity, $f : \Omega \to \mathbf{R}$ is a given (smooth) function, Du denotes the gradient of u (i.e., $(u_{x_1}, \ldots, u_{x_n})$), and $\|Du\|^p_{L^p(\Omega)} = \int_\Omega |Du|^p dx$. Here and later, for $\xi = (\xi_1, \ldots, \xi_n) \in \mathbf{R}^n$, we denote $|\xi|$ by the Euclidean norm of ξ; $|\xi|^2 = \sum_{k\in I} \xi_k^2$, where $I = \{1, 2, \ldots, n\}$.

It is well known that the minimizer $u^p \in W^{1,p}_0(\Omega)$ of the variational problem (1.1) is a weak solution (in the distribution sense) of

$$-\sum_{k\in I} p \left(|Du|^{p-2} u_{x_k}\right)_{x_k} = f \quad \text{in } \Omega.$$

In order to deal with a perfect plastic torsion model, it is important to study the limit function of u^p, as $p \to \infty$, when $f \equiv 1$. In fact, in this case, Kawohl in [12] showed that

$$\lim_{p\to\infty} u^p(x) = \operatorname{dist}(x, \partial\Omega) \quad \text{uniformly in } \Omega.$$

We also refer to Bhattacharya, DiBenedetto, and Manfredi [3].

On the other hand, initiated by Aronsson's works [1] and [2], for a given (Lipschitz continuous) function $g : \overline{\Omega} \to \mathbf{R}$, Jensen in [9] characterized the limit function $u := \lim_{p\to\infty} u^p$, where u^p is a minimizer of the variational problem

$$\inf\left\{ \|Dv\|^p_{L^p(\Omega)} \;\middle|\; v - g \in W^{1,p}_0(\Omega) \right\},$$

as a unique viscosity solution of

$$\begin{cases} -\triangle_\infty u = 0 & \text{in } \Omega, \\ u = g & \text{on } \partial\Omega, \end{cases} \tag{1.2}$$

where

$$\triangle_\infty u = \sum_{k,l\in I} u_{x_k} u_{x_l} u_{x_k x_l}.$$

In fact, to show the uniqueness of viscosity solutions of (1.2), Jensen introduced variational problems (1.1) with $f = \pm\varepsilon^{p-1}$ (for $\varepsilon > 0$) but under the Dirichlet condition $u = g$ on $\partial\Omega$. Following his argument, we can verify that $\hat{u} := \lim_{p\to\infty} \hat{u}^p \in C(\overline{\Omega})$, where $\hat{u}^p$ is a minimizer of (1.1) when $f \equiv 1$, is a (unique) viscosity solution of

$$\begin{cases} \min\{|Du| - 1, -\triangle_\infty u\} = 0 & \text{in } \Omega, \\ u = 0 & \text{on } \partial\Omega. \end{cases}$$

We refer to [3], [5], [6], [10], [11], and [15] for related topics on the L^∞-Laplace equation (1.2).

In this paper, we are interested in the following questions.

(i) If we take other equivalent norms in (1.1) to $\|\cdot\|_{L^p(\Omega)}$, which PDEs are expected to be solved by $\hat{u} := \lim_{p\to\infty} \hat{u}^p$?

(ii) Under which condition can we characterize $\hat{u}$ as a unique (viscosity) solution of the expected PDE?

Let us consider two typical examples.

Example 1.1. If we use the equivalent norm

$$\|Dv\|_{1,p} := \left(\sum_{k\in I} \|v_{x_k}\|^p_{L^p(\Omega)} \right)^{\frac{1}{p}}$$

in (1.1), then we easily verify that the unique minimizer u^p is a weak solution of

$$-p\sum_{k\in I} \left(|u_{x_k}|^{p-2} u_{x_k}\right)_{x_k} = -p(p-1)\sum_{k\in I} |u_{x_k}|^{p-2} u_{x_k x_k} = f \quad \text{in } \Omega. \tag{1.3}$$

In the case when $\min_{\overline{\Omega}} f > 0$ in (1.3), we will observe that $u := \lim_{p\to\infty} u^p$ is a viscosity solution of

$$\min\left\{ \max_{j\in I} |u_{x_j}| - 1, -\sum_{k\in \hat{I}[Du(x)]} u^2_{x_k} u_{x_k x_k} \right\} = 0 \quad \text{in } \Omega, \tag{1.4}$$

where for $\xi = (\xi_1, \ldots, \xi_n) \in \mathbf{R}^n$ we set

$$\hat{I}[\xi] = \left\{ k \in I \;\middle|\; \max_{j\in I} |\xi_j| = |\xi_k| \right\}.$$

We notice that the PDE (1.4) has serious discontinuity with respect to Du-variables.

We note that if we suppose that $\max_{\overline{\Omega}} f < 0$, then the limit function satisfies the following PDE:

$$\max\left\{1 - \max_{j\in I}|u_{x_j}|, -\sum_{k\in\hat{I}[Du(x)]} u_{x_k}^2 u_{x_k x_k}\right\} = 0 \quad \text{in } \Omega.$$

Example 1.2. Next, if we use the equivalent norm

$$\|Dv\|_{\infty,p} := \left(\max_{k\in I}\|v_{x_k}\|_{L^p(\Omega)}^p\right)^{\frac{1}{p}}$$

in (1.1), then it turns out that the minimizer u^p of (1.1) satisfies

$$\max_{k\in I}\int_\Omega \left(p|u_{x_k}|^{p-2}u_{x_k}\phi_{x_k} - f\phi\right)dx \geq 0 \quad \forall\phi\in W_0^{1,p}(\Omega).$$

Hence it holds that

$$\min_{k\in I}\int_\Omega \left(p|u_{x_k}|^{p-2}u_{x_k}\phi_{x_k} - f\phi\right)dx \leq 0 \quad \forall\phi\in W_{0,+}^{1,p}(\Omega) \tag{1.5}$$

and

$$\max_{k\in I}\int_\Omega \left(p|u_{x_k}|^{p-1}u_{x_k}\phi_{x_k} - f\phi\right)dx \geq 0 \quad \forall\phi\in W_{0,+}^{1,p}(\Omega), \tag{1.6}$$

where $W_{0,+}^{1,p}(\Omega) = \{\phi\in W_0^{1,p}(\Omega) \mid \phi\geq 0 \text{ in } \Omega\}$. Thus, if u^p is smooth enough, then it holds that

$$\min_{k\in I}\left\{-p\left(|u_{x_k}|^{p-2}u_{x_k}\right)_{x_k}\right\} = \min_{k\in I}\left\{-p(p-1)|u_{x_k}|^{p-2}u_{x_k x_k}\right\} \leq f \tag{1.7}$$

and

$$\max_{k\in I}\left\{-p\left(|u_{x_k}|^{p-2}u_{x_k}\right)_{x_k}\right\} = \max_{k\in I}\left\{-p(p-1)|u_{x_k}|^{p-2}u_{x_k x_k}\right\} \geq f. \tag{1.8}$$

Therefore, we may call u^p a weak subsolution of (1.7) (resp., a weak supersolution of (1.8)) if u^p satisfies (1.5) (resp., (1.6)).

Let us consider the case when $\min_{\overline{\Omega}} f > 0$ as in Example 1.1.

We will observe that $u := \lim_{p\to\infty} u^p$ is, respectively, a viscosity subsolution and a viscosity supersolution of

$$\min\left\{\max_{j\in I}|u_{x_j}| - 1, F^-(Du, D^2u)\right\} \leq 0 \quad \text{in } \Omega \tag{1.9}$$

and

$$\min\left\{\max_{j\in I}|u_{x_j}| - 1, F^+(Du, D^2u)\right\} \geq 0 \quad \text{in } \Omega, \tag{1.10}$$

where, for $(q, X)\in\mathbf{R}^n\times S^n$,

$$F^-(q,X) = \begin{cases} \min_{k\in I}(-q_k^2 X_{kk}), & \text{provided } \hat{I}[q] = I, \\ \min_{k\in\hat{I}[q]}(-q_k^2 X_{kk})\wedge 0 & \text{otherwise} \end{cases}$$

and

$$F^+(q,X) = \begin{cases} \max\limits_{k\in I}(-q_k^2 X_{kk}), & \text{provided } \hat{I}[q] = I, \\ \max\limits_{k\in \hat{I}[q]}(-q_k^2 X_{kk}) \vee 0 & \text{otherwise.} \end{cases}$$

Here S^n denotes the set of $n \times n$ symmetric matrices equipped with the standard order.

We remark that if $u \in C^2(\Omega)$ satisfies $\hat{I}[Du(x)] \neq I$ for all $x \in \Omega$, then it is a viscosity subsolution of (1.9). Thus we cannot expect the comparison principle for viscosity subsolutions of (1.9) and viscosity supersolutions of (1.10) in general.

We note that in the case when $\min_{\overline{\Omega}} f < 0$, the corresponding limit function satisfies the following inequalities in the viscosity sense:

$$\max\left\{1 - \max_{j\in I}|u_{x_j}|, F^-(Du, D^2u)\right\} \leq 0$$

and

$$\max\left\{1 - \max_{j\in I}|u_{x_j}|, F^+(Du, D^2u)\right\} \geq 0.$$

This paper is organized as follows. In section 2, we recall the definition of viscosity solutions for second-order degenerate elliptic PDEs and its equivalent definitions. We also show that minimizers of variational problems are viscosity solutions of the associated Euler–Lagrange equations.

We verify that the limit function (as $p \to \infty$) of minimizers of our variational problems is indeed a viscosity solution of the corresponding limit PDE in section 3. This verification result immediately gives the existence of viscosity solutions of the limit PDE.

In section 4, we show a comparison result between a viscosity subsolution u and a viscosity supersolution v of the limit PDE, assuming that u or $-v$ is "locally" convex. This comparison principle yields a uniqueness result for locally concave viscosity solutions.

Section 5 is devoted to the existence of concave viscosity solutions when the domain Ω is convex.

In the final section, we study some typical examples.

2. Preliminaries.

2.1. Notations. We shall briefly recall the definition of viscosity solutions of fully nonlinear second-order (degenerate elliptic) PDEs:

$$F(Du, D^2u) = 0 \quad \text{in } \Omega, \tag{2.1}$$

where $F : \mathbf{R}^n \times S^n \to \mathbf{R}$ is given. Although we could deal with more general PDEs (e.g., PDEs having x and $u(x)$ variables), we restrict our attention here to the above PDEs for the sake of simplicity.

We denote by F^* and F_*, respectively, the upper and lower semicontinuous envelopes of F; for $(q, X) \in \mathbf{R}^n \times S^n$,

$$F^*(q,X) = \lim_{\varepsilon\to 0}\sup\{F(q',X') \mid |q'-q| + |X'-X| < \varepsilon\},$$

and $F_*(q,X) = -(-F)^*(q,X)$.

Definition. We call $u \in C(\Omega)$ a viscosity subsolution (resp., supersolution) of (2.1) if

$$F_*(D\phi(x), D^2\phi(x)) \le 0 \quad \big(\text{resp., } F^*(D\phi(x), D^2\phi(x)) \ge 0\big)$$

whenever $u - \phi$ attains its maximum (resp., minimum) at $x \in \Omega$ for $\phi \in C^2(\Omega)$.

We call $u \in C(\Omega)$ a viscosity solution of (2.1) if it is a viscosity subsolution and a viscosity supersolution of (2.1).

Remark. In the above definition, we can change "maximum (resp., minimum)" to "strict maximum (resp., strict minimum)." We refer to [4] for the general theory of viscosity solutions of fully nonlinear second-order degenerate elliptic PDEs.

Since we will use a definition equivalent to the one above, we prepare some notation. For a function $u : \Omega \to \mathbf{R}$ and $x \in \Omega$, we define semijets $J^{2,\pm}u(x)$ in the following manner:

$$J^{2,+}u(x) = \left\{ (q, X) \in \mathbf{R}^n \times S^n \;\middle|\; \begin{array}{ll} u(y) \le & u(x) + \langle q, y - x\rangle \\ & +\langle X(y-x), y-x\rangle/2 \\ & +o(|y-x|^2) \text{ as } y \in \Omega \to x \end{array} \right\},$$

and $J^{2,-}u(x) = -J^{2,+}(-u)(x)$.

For $x \in \Omega$, we denote by $\overline{J}^{2,\pm}u(x)$ the following sets:

$$\left\{ (q, X) \in \mathbf{R}^n \times S^n \;\middle|\; \begin{array}{c} \exists x^m \in \Omega \text{ and } \exists (q^m, X^m) \in J^{2,\pm}u(x^m) \text{ such that} \\ \lim\limits_{m\to\infty} (x^m, u(x^m), q^m, X^m) = (x, u(x), q, X) \end{array} \right\}.$$

PROPOSITION 2.1 (see [4]). *A function $u \in C(\Omega)$ is a viscosity subsolution* (*resp., supersolution*) *of* (2.1) *if and only if*

$$F_*(q, X) \le 0 \quad \forall x \in \Omega \textit{ and } \forall (q, X) \in \overline{J}^{2,+}u(x)$$
$$\left(\textit{resp., } F^*(q, X) \ge 0 \quad \forall x \in \Omega \textit{ and } \forall (q, X) \in \overline{J}^{2,-}u(x)\right).$$

When u is a viscosity subsolution (resp., supersolution) of (2.1), we will often call u a viscosity solution of $F(Du, D^2u) \le 0$ (resp., $F(Du, D^2u) \ge 0$).

In what follows, we shall omit the term "viscosity" since we discuss only viscosity solutions.

For later convenience, we introduce some terminology: First, we denote by $B_r(x)$ the standard open ball in $\mathbf{R}^n$ with radius $r > 0$ and center $x \in \mathbf{R}^n$; $B_r(x) = \{y \in \mathbf{R}^n \mid |x - y| < r\}$. We will write B_r for $B_r(0)$.

Definition. We call a function $u : \Omega \to \mathbf{R}$ locally convex (resp., locally concave) if for each $x \in \Omega$, there is $r > 0$ such that u is convex (resp., concave) in $B_r(x) \subset \Omega$.

We remark that if Ω is a convex domain in $\mathbf{R}^n$, then the local convexity is equivalent to the convexity. However, this equivalence does not hold for general domains. In general, even if $u : \Omega \to \mathbf{R}$ is locally convex in a nonconvex domain, we cannot extend u to the convex-hull of Ω by a convex function.

In section 4, we will use the following basic lemma.

LEMMA 2.2. *Assume that $u : \Omega \to \mathbf{R}$ is locally convex. If $(q, X) \in \overline{J}^{2,+}u(x)$ for $x \in \Omega$, then we have $X \ge 0$.*

Proof. It suffices to show that if $(q, X) \in J^{2,+}u(x)$ for $x \in \Omega$, then $X \ge 0$.

Fix any $(q, X) \in J^{2,+}u(x)$ for $x \in \Omega$.

Since for any $\xi \in \mathbf{R}^n$ with $|\xi| = 1$ and small $t > 0$, the definition yields

$$u(x \pm t\xi) \leq u(x) \pm t\langle q, \xi\rangle + \frac{t^2}{2}\langle X\xi, \xi\rangle + o(t^2),$$

the local convexity implies that

$$0 \leq t^2\langle X\xi, \xi\rangle + o(t^2). \qquad \square$$

2.2. Verification for fixed $p > n$. In this subsection, we fix $p > n$.

In order to treat the examples in section 1 at the same time, throughout this paper we shall consider the norm $\|\cdot\|$ of a function $h = (h_1, \ldots, h_n) \in L^p(\Omega; \mathbf{R}^n)$; for fixed sets $I_j \subset I$ $(j = 1, 2, 3)$,

$$\|h\| := \left(\|P_1[h]\|^p_{L^p(\Omega)} + \sum_{k \in I_2} \|h_k\|^p_{L^p(\Omega)} + \max_{k \in I_3} \|h_k\|^p_{L^p(\Omega)}\right)^{\frac{1}{p}}.$$

Here $P_1[h] = \sum_{k \in I_1} h_k e_k$, where e_k is the standard kth unit vector.

We shall suppose that

$$I_1 \cup I_2 \cup I_3 = I := \{1, 2, \ldots, n\}. \tag{A1}$$

Although there are (infinitely) many other equivalent norms, we have decided to choose the above one in this paper since it contains three typical seminorms.

We consider the variational problem

$$\inf\left\{\|Dv\|^p - \int_\Omega fv dx \;\middle|\; v \in W_0^{1,p}(\Omega)\right\}. \tag{2.2}$$

It is well known that if we suppose that $f \in C(\overline{\Omega})$, for instance, then under (A1), there is a (unique) minimizer $u^p \in W_0^{1,p}(\Omega)$ of this variational problem since this norm is equivalent to the standard one, which is $\|\cdot\|_{W^{1,p}(\Omega)}$.

We introduce continuous functions $F_p^\pm : \mathbf{R}^n \times S^n \to \mathbf{R}$ for $p > 1$, which arise in the Euler–Lagrange equation associated with the variational problem (2.2):

$$\begin{aligned} F_p^-(q, X) = \; & -p|P_1[q]|^{p-4} \sum_{k,l \in I_1} \left(\delta_{kl} q_k^2 + (p-2) q_k q_l\right) X_{kl} \\ & + p(p-1)\left(-\sum_{k \in I_2} |q_k|^{p-2} X_{kk} + \min_{k \in I_3}\left(-|q_k|^{p-2} X_{kk}\right)\right) \end{aligned}$$

and

$$\begin{aligned} F_p^+(q, X) = \; & -p|P_1[q]|^{p-4} \sum_{k,l \in I_1} \left(\delta_{kl} q_k^2 + (p-2) q_k q_l\right) X_{kl} \\ & + p(p-1)\left(-\sum_{k \in I_2} |q_k|^{p-2} X_{kk} + \max_{k \in I_3}\left(-|q_k|^{p-2} X_{kk}\right)\right). \end{aligned}$$

PROPOSITION 2.3. *Assume that* (A1) *holds. Then, for any $f \in C(\overline{\Omega})$, the minimizer u^p of the above variational problem* (2.2) *is, respectively, a sub- and a supersolution of*

$$F_p^-(Du, D^2u) - f \leq 0 \tag{2.3}$$

and

$$F_p^+(Du, D^2u) - f \geq 0. \tag{2.4}$$

Remarks. (1) If $I_2 = I_3 = \emptyset$, then $F_p^- = F_p^+$ becomes the standard p-Laplace operator;

$$F_p^\pm(q, X) = -p \sum_{k,l \in I} \left(\delta_{kl}|q|^{p-2} + (p-2)|q|^{p-4} q_k q_l\right) X_{kl}.$$

(2) If $I_1 = I_3 = \emptyset$, then $F_p^- = F_p^+$ becomes the PDE part of (1.3) in Example 1.1.

(3) If $I_1 = I_2 = \emptyset$, then we have that $F_p^\pm$ are the PDE parts of (1.7) and (1.8) in Example 1.2.

Proof. We shall show only the assertion for subsolutions since the proof for supersolutions can be done in a symmetric way.

Suppose that there is $\phi \in C^2(\Omega)$ such that $u^p(\hat{x}) = \phi(\hat{x})$ for some $\hat{x} \in \Omega$, $u^p(x) < \phi(x)$ for $x \in \Omega \setminus \{\hat{x}\}$, and

$$F_p^-(D\phi(\hat{x}), D^2\phi(\hat{x})) \geq f(\hat{x}) + 2\theta \quad \text{for some } \theta > 0.$$

Then we will get a contradiction.

We may suppose that $\hat{x} = 0 \in \Omega$. Let us simply write u for the minimizer u^p.

Choosing smaller $\theta > 0$ if necessary, we can find small $r > t > 0$ such that $B_r \subset \Omega$,

$$F_p^-(D\phi(x), D^2\phi(x)) \geq f(x) + \theta \quad \text{in } B_r,$$
$$\min_{B_t}(u - \phi) \geq -\theta \quad \text{and} \quad \max_{\partial B_r}(u - \phi) \leq -3\theta.$$

Hence, for any $\psi \in W_{0,+}^{1,p}(B_r)$, by integration by parts, we have

$$\begin{aligned} &\sum_{k \in I_1} \int_{B_r} |P_1[D\phi]|^{p-2} \phi_{x_k} \psi_{x_k} dx + \sum_{k \in I_2} \int_{B_r} |\phi_{x_k}|^{p-2} \phi_{x_k} \psi_{x_k} dx \\ &\qquad + \min_{k \in I_3} \int_{B_r} |\phi_{x_k}|^{p-2} \phi_{x_k} \psi_{x_k} dx \geq \frac{1}{p} \int_{B_r} (f + \theta) \psi dx. \end{aligned} \tag{2.5}$$

On the other hand, since u is a minimizer of (2.2), for any $\psi \in W_{0,+}^{1,p}(\Omega)$, we have

$$\begin{aligned} &\sum_{k \in I_1} \int_\Omega |P_1[Du]|^{p-2} u_{x_k} \psi_{x_k} dx + \sum_{k \in I_2} \int_\Omega |u_{x_k}|^{p-2} u_{x_k} \psi_{x_k} dx \\ &\qquad + \min_{k \in I_3} \int_\Omega |u_{x_k}|^{p-2} u_{x_k} \psi_{x_k} dx \leq \frac{1}{p} \int_\Omega f \psi dx. \end{aligned} \tag{2.6}$$

Setting

$$\psi(x) = \begin{cases} (u(x) - \phi(x) + 2\theta)^+ & \text{for } x \in B_r, \\ 0 & \text{for } x \in \Omega \setminus B_r, \end{cases}$$

if $I_3 \neq \emptyset$, by (2.5) and (2.6) we can find $j_0 \in I_3$ such that

$$\begin{aligned} -\theta^2 \int_{B_t} dx \geq &\sum_{k \in I_1} \int_{B_r} \left(|P_1[Du]|^{p-2} u_{x_k} - |P_1[D\phi]|^{p-2}\right) \psi_{x_k} dx \\ &+ \sum_{k \in I_2} \int_{B_r} \left(|u_{x_k}|^{p-2} u_{x_k} - |\phi_{x_k}|^{p-2} \phi_{x_k}\right) \psi_{x_k} dx \\ &+ \int_{B_r} \left(|u_{x_{j_0}}|^{p-2} u_{x_{j_0}} - |\phi_{x_{j_0}}|^{p-2} \phi_{x_{j_0}}\right) \psi_{x_{j_0}} dx, \end{aligned}$$

which is a contradiction.

In the case when $I_3 = \emptyset$, we need only to delete the third term above. □

3. Verification. In this section, we seek the PDEs which, as $p \to \infty$, the limit of minimizers of (2.2) satisfies in the viscosity sense when f is positive. In fact, the "limit" PDEs will be derived from (2.3) and (2.4).

3.1. The limit PDEs. We introduce some notation: for $q = (q_1, \ldots, q_n) \in \mathbf{R}^n$, we set

$$q_0 = |P_1[q]| \quad \text{and} \quad G(q) = \max\{|q_j| \mid j \in \{0\} \cup I_2 \cup I_3\}.$$

Moreover, we set

$$I[q] = \{k \in \{0\} \cup I_2 \cup I_3 \mid G(q) = |q_k|\},$$
$$I_1[q] = \begin{cases} I_1, & \text{provided } G(q) = q_0, \\ \emptyset, & \text{provided } G(q) > q_0, \end{cases}$$

and

$$I_k[q] = \{j \in I_k \mid G(q) = |q_j|\} \quad \text{for } k = 2, 3.$$

For $J \subset I_3$, we set

$$F^-_J(q, X) = \begin{cases} 0, & \text{provided } J = \emptyset, \\ \min\limits_{k \in I_3}(-q_k^2 X_{kk}), & \text{provided } J = I_3, \\ \min\limits_{k \in J}(-q_k^2 X_{kk}) \wedge 0 & \text{otherwise} \end{cases}$$

and

$$F^+_J(q, X) = \begin{cases} 0, & \text{provided } J = \emptyset, \\ \max\limits_{k \in I_3}(-q_k^2 X_{kk}), & \text{provided } J = I_3, \\ \max\limits_{k \in J}(-q_k^2 X_{kk}) \vee 0 & \text{otherwise.} \end{cases}$$

Using this notation, we define (possibly discontinuous) functions $F^\pm_\infty : \mathbf{R}^n \times S^n \to \mathbf{R}$ in the following way: for $(q, X) \in \mathbf{R}^n \times S^n$, we set

$$F^\pm_\infty(q, X) = -\sum_{k,l \in I_1[q]} q_k q_l X_{kl} - \sum_{k \in I_2[q]} q_k^2 X_{kk} + F^\pm_{I_3[q]}(q, X).$$

Here and later, whenever $I_k[q] = \emptyset$ for $k \in \{1, 2\}$, we regard the terms containing $I_k[q]$ as zero.

THEOREM 3.1. *Assume that* (A1) *holds. Assume also that $f \in C(\overline{\Omega})$ satisfies*

$$\min_{x \in \overline{\Omega}} f(x) > 0.$$

Let $u^p \in W^{1,p}_0(\Omega)$ be the minimizer of the variational problem (2.2). *Then there exists a subsequence u^{p_i} such that u^{p_i} converges to a $u \in W^{1,\infty}(\Omega)$ uniformly in $\overline{\Omega}$. Moreover, we see that $u = 0$ on $\partial\Omega$ and u is a solution of*

$$\begin{cases} \min\{G(Du) - 1, F^-_\infty(Du, D^2u)\} \leq 0 & \text{in } \Omega, \\ \min\{G(Du) - 1, F^+_\infty(Du, D^2u)\} \geq 0 & \text{in } \Omega. \end{cases}$$

Before giving a proof of Theorem 3.1, we present representation formulas of $(F_\infty^+)^*$ and $(F_\infty^-)_*$, which will be proved after the proof of Theorem 3.1.

LEMMA 3.2. *$(F_\infty^+)^*(q,X)$ and $(F_\infty^-)_*(q,X)$ are, respectively, represented by*

$$\max\left\{ -\sum_{k,l\in I_1} 1_J q_k q_l X_{kl} - \sum_{k\in I_2\cap J} q_k^2 X_{kk} + F^+_{I_3\cap J}(q,X) \;\middle|\; \emptyset \neq J \subset I[q] \right\}$$

and

$$\min\left\{ -\sum_{k,l\in I_1} 1_J q_k q_l X_{kl} - \sum_{k\in I_2\cap J} q_k^2 X_{kk} + F^-_{I_3\cap J}(q,X) \;\middle|\; \emptyset \neq J \subset I[q] \right\},$$

where

$$1_J = \begin{cases} 1, & \textit{provided } 0 \in J, \\ 0 & \textit{otherwise.} \end{cases}$$

In our proof of Theorem 3.1, we will use the following proposition.

PROPOSITION 3.3. (1) *Assume that $(F_\infty^+)^*(q,X) \le -\theta$ for $\theta > 0$. Then we have the following properties:*

$$\text{(i)} \qquad \textit{If } G(q) = q_0, \textit{ then } -\sum_{k,l\in I_1} q_k q_l X_{kl} \le -\frac{\theta}{2}.$$

$$\text{(ii)} \qquad -q_k^2 X_{kk} \le -\theta \textit{ for } k \in I_2[q] \cup I_3[q].$$

(2) *Assume that $(F_\infty^-)_*(q,X) \ge \theta$ for $\theta > 0$. Then we have the following properties:*

$$\text{(i}'\text{)} \qquad \textit{If } G(q) = q_0, \textit{ then } -\sum_{k,l\in I_1} q_k q_l X_{kl} \ge \frac{\theta}{2}.$$

$$\text{(ii}'\text{)} \qquad -q_k^2 X_{kk} \ge \theta \textit{ for } k \in I_2[q] \cup I_3[q].$$

The proof of Proposition 3.3 will also be given in the end this section.

Proof of Theorem 3.1. First, we note that we may suppose that I_1 consists of at least two integers if it is not empty. In fact, if I_1 has only one element, we can follow the argument below replacing I_1 and I_2, respectively, by $\emptyset$ and $I_1 \cup I_2$. Moreover, we may suppose that $I_1 \neq \emptyset$, $I_2 \neq \emptyset$, and $I_3 \neq \emptyset$ since the argument below becomes easier if some of them are empty.

By Proposition 2.3, for $p > n$, we verify that u^p is a solution of

$$\begin{cases} F_p^-(Du, D^2u) - f \le 0 & \text{in } \Omega, \\ F_p^+(Du, D^2u) - f \ge 0 & \text{in } \Omega. \end{cases}$$

Moreover, since $0 \in W_0^{1,p}(\Omega)$, we find a constant $C > 0$ independent of $p > n$ such that

$$\|Du^p\|_{L^p(\Omega)} \le C\|Du^p\| \le C\|u^p\|_{L^1(\Omega)}^{\frac{1}{p}}.$$

Since $\|u^p\|_{L^1(\Omega)} \le |\Omega|^{(p-1)/p}\|u^p\|_{L^p(\Omega)}$ by the Hölder inequality, the Poincaré inequality (e.g., [7, p. 164]) implies that

$$\|Du^p\|_{L^p(\Omega)} \le C^{\frac{p}{p-1}} |\Omega|^{\frac{1}{p}+\frac{1}{n(p-1)}} |B_1|^{\frac{-1}{n(p-1)}}.$$

Thus, by the Poincaré inequality again, there is a constant $C' > 0$ independent of $p > n$ such that

$$\|u^p\|_{W^{1,p}(\Omega)} \leq C'.$$

Hence, by the Hölder inequality again, we can find a constant $C_0 > 0$ such that

$$\|u^p\|_{W^{1,\hat{p}}(\Omega)} \leq C_0 \quad \forall p \geq \hat{p} > n.$$

Therefore, the Sobolev imbedding implies that there exists $u \in \cap_{p>1} W^{1,p}(\Omega)$ such that u^p converges to u uniformly in $\overline{\Omega}$ by taking a subsequence $\{p^i\}$ such that $\lim_{i\to\infty} p^i = \infty$.

Moreover, from the above inequality, we have $u \in W^{1,\infty}(\Omega)$.

We shall first verify that u is a supersolution of

$$\min\{G(Du) - 1, F^+_\infty(Du, D^2u)\} \geq 0 \quad \text{in } \Omega.$$

Suppose that, for $\phi \in C^2(\Omega)$, $u(\hat{x}) = \phi(\hat{x})$ for $\hat{x} \in \Omega$, $u(x) > \phi(x)$ for $x \in \Omega \setminus \{\hat{x}\}$, and

$$\lim_{\varepsilon\to 0} \sup \left\{ \min\{G(q') - 1, F^+_\infty(q', X')\} \mid |q' - q| + |X' - X| < \varepsilon \right\} \leq -\theta \tag{3.1}$$

for some $\theta > 0$, where $q = D\phi(\hat{x})$ and $X = D^2\phi(\hat{x})$. We will get a contradiction.

In view of the uniform convergence of u^p to u, we may choose $x^p \in \Omega$ such that $u^p - \phi$ attains its minimum at x^p and that $x^p \to \hat{x}$ as $p \to \infty$. Let us simply write (q^p, X^p) for $(D\phi(x^p), D^2\phi(x^p))$.

Consider the case when

$$G(q) < 1.$$

We may suppose that there is $\alpha \in (0,1)$ such that

$$G(q^p) < 1 - \alpha \quad \text{for large } p > 2 \vee n.$$

By Proposition 2.3, we see that

$$\begin{aligned} \frac{f(x^p)}{p(p-2)} \leq & -|q^p_0|^{p-4} \sum_{k,l\in I_1} \left(\frac{\delta_{kl}}{p-2}(q^p_k)^2 + q^p_k q^p_l \right) X^p_{kl} \\ & - \frac{p-1}{p-2} \sum_{k\in I_2} |q^p_k|^{p-2} X^p_{kk} + \frac{p-1}{p-2} \max_{k\in I_3}(-|q^p_k|^{p-2} X^p_{kk}) \\ =: & \, A_1 + A_2 + A_3. \end{aligned} \tag{3.2}$$

From (3.2), we see that $G(q^p) > 0$. Thus, dividing (3.2) by $G(q^p)^{p-4}$, we observe that the left-hand side of the resulting inequality tends to ∞, as $p \to \infty$, while the right-hand side of it is finite.

Thus we may suppose that

$$G(q) \geq 1.$$

Hence, by (3.1), we may suppose that

$$(F^+_\infty)^*(q, X) \leq -\theta. \tag{3.3}$$

Now we shall estimate $\hat{A}_k := A_k/G(q^p)^{p-4}$ $(k=1,2,3)$ from above.

We point out here that

$$\lim_{p\to\infty}\left(\frac{|q^p_k|}{G(q^p)}\right)^{p-4}=0 \quad \text{for } k\in\{0\}\cup I_2\cup I_3, \text{ provided } G(q)>|q_k|. \tag{3.4}$$

Taking a subsequence of $\{q^p\}_{p>n}$ if necessary, we may suppose that there is a nonempty set $\hat{I}\subset\{0\}\cup I_2\cup I_3$ such that $\hat{I}=I[q^p]$ for all $p>n$. We note that $\hat{I}\subset I[q]$ since G is continuous.

Estimate for $\hat{A}_1$. We first remark that for large $p>2\vee n$,

$$\sum_{k\in I_1}\left|\frac{q^p_0}{G(q^p)}\right|^{p-4}\frac{|q^p_k|^2|X_{kk}|}{p-2}\le O(p^{-1}). \tag{3.5}$$

In the case when $0\in\hat{I}$, by (i) of Proposition 3.3, (3.5) implies that for large $p>n$,

$$\hat{A}_1\le-\sum_{k,l\in I_1}q^p_kq^p_lX^p_{kl}+O(p^{-1})=-\sum_{k,l\in I_1}q_kq_lX_{kl}+O(p^{-1})\le-\frac{\theta}{3}.$$

In the case when $0\notin\hat{I}$ and $G(q)=q_0$, since $-\sum_{k,l\in I_1}q^p_kq^p_lX^p_{kl}<0$ by (i) of Proposition 3.3, (3.4) yields that for large $p>n$,

$$\hat{A}_1\le O(p^{-1}).$$

Also, if $G(q)>q_0$, (3.4) yields the same inequality as above.

Therefore, we may suppose that

$$\hat{A}_1\le\begin{cases}-\dfrac{\theta}{3}, & \text{provided } 0\in\hat{I},\\ O(p^{-1}), & \text{provided } 0\notin\hat{I}.\end{cases} \tag{3.6}$$

Estimate for $\hat{A}_2$. We set

$$\begin{aligned}\frac{p-2}{p-1}\hat{A}_2 &= -\sum_{k\in I_2[q]}\left(\frac{|q^p_k|}{G(q^p)}\right)^{p-4}(q^p_k)^2X^p_{kk}-\sum_{k\in I_2\setminus I_2[q]}\left(\frac{|q^p_k|}{G(q^p)}\right)^{p-4}(q^p_k)^2X^p_{kk}\\ &=: C_1+C_2.\end{aligned}$$

In the case when $I_2[q]=\emptyset$ (resp., $I_2\setminus I_2[q]\neq\emptyset$), the above equality holds by taking $C_1=0$ (resp., $C_2=0$).

We note that $-(q^p_k)^2X^p_{kk}<0$ for $k\in I_2[q]$ and large $p>n$ by (ii) of Proposition 3.3.

If there is $k\in\hat{I}\cap I_2$, then we have

$$C_1\le-\sum_{k\in\hat{I}\cap I_2}q_k^2X_{kk}+O(p^{-1})\le-\frac{\theta}{2}.$$

In the case when $\hat{I}\cap I_2=\emptyset$ and $I_2[q]\neq\emptyset$, since $-(q^p_k)^2X^p_{kk}<0$ for $k\in I_2[q]$, we see that for large $p>n$, $C_1\le 0$.

On the other hand, if $I_2\setminus I_2[q]\neq\emptyset$, then (3.4) yields that

$$C_2\le O(p^{-1}).$$

Hence, if $\hat{I}\cap I_2[q]\neq\emptyset$ for large $p>n$, we have

$$\hat{A}_2\leq\frac{p-2}{p-1}\left(-\frac{\theta}{2}+O(p^{-1})\right)\leq-\frac{\theta}{3}.$$

Therefore, we may suppose that

$$\hat{A}_2\leq\begin{cases}-\dfrac{\theta}{3}, & \text{provided } \hat{I}\cap I_2\neq\emptyset,\\ O(p^{-1}), & \text{provided } \hat{I}\cap I_2=\emptyset.\end{cases}\tag{3.7}$$

Estimate for $\hat{A}_3$. If $I_3[q]=\emptyset$, we see that $\hat{A}_3\leq O(p^{-1})$ for large $p>n$.

Hence by (ii) of Proposition 3.3, we see that for large $p>n$,

$$\hat{A}_3\leq\begin{cases}-\dfrac{\theta}{3}, & \text{provided } \hat{I}\cap I_3=I_3,\\ O(p^{-1}), & \text{provided } \hat{I}\cap I_3\neq I_3.\end{cases}\tag{3.8}$$

Let us get a contradiction to (3.3).

First, suppose that $0\in\hat{I}$. Using the estimates (3.6), (3.7), and (3.8) in (3.2), we have

$$0<\frac{f(x^p)}{p(p-1)G(q^p)^{p-4}}\leq-\frac{\theta}{3}+O(p^{-1}),$$

which is a contradiction for large $p>n$.

Next, suppose that $0\notin\hat{I}$ and $\hat{I}\cap I_2\neq\emptyset$. Then, using (3.6), (3.7), and (3.8) in (3.2) again, we get the same contradiction as above.

Finally, if we suppose that $0\notin\hat{I}$ and $\hat{I}\cap I_2=\emptyset$, then $\emptyset\neq\hat{I}\subset I_3$.

Hence, using (3.6), (3.7), and (3.8) in (3.2), we have

$$0\leq F^+_{\hat{I}}(q^p,X^p)+O(p^{-1}).$$

Thus, sending $p\to\infty$ in the above, by Lemma 3.2 we get

$$0\leq F^+_{\hat{I}}(q,X)\leq(F^+_\infty)^*(q,X),$$

which is a contradiction to (3.3).

Next, we shall verify that u is a subsolution of

$$\min\{G(Du)-1,F^-_\infty(Du,D^2u)\}\leq 0\quad\text{in }\Omega.$$

Suppose that, for $\phi\in C^2(\Omega)$, $u(\hat{x})=\phi(\hat{x})$ for $\hat{x}\in\Omega$, $u(x)<\phi(x)$ for $x\in\Omega\setminus\{\hat{x}\}$, and

$$\lim_{\varepsilon\to 0}\inf\left\{\min\{G(q')-1,F^-_\infty(q',X')\}\mid|q'-q|+|X'-X|<\varepsilon\right\}\geq\theta\tag{3.9}$$

for some $\theta>0$, where $q=D\phi(\hat{x})$ and $X=D^2\phi(\hat{x})$. We will get a contradiction again.

As before, we may choose $x^p\in\Omega$ such that $u^p-\phi$ attains its maximum at x^p and $\lim_{p\to\infty}x^p=\hat{x}$. By Proposition 2.3, we see that

$$\begin{aligned}\frac{f(x^p)}{p(p-2)}\ \geq\ &-|q^p_0|^{p-4}\sum_{k,l\in I_1}\left(\frac{\delta_{kl}}{p-2}(q^p_k)^2+q^p_kq^p_l\right)X^p_{kl}\\ &-\frac{p-1}{p-2}\left(\sum_{k\in I_2}(q^p_k)^{p-2}X^p_{kk}-\min_{k\in I_3}(-(q^p_k)^{p-2}X^p_{kk})\right)\\ =:&\ A_1+A_2+A_3,\end{aligned}\tag{3.10}$$

where $(q^p, X^p) = (D\phi(x^p), D^2\phi(x^p))$.

In view of (3.10), we see that $G(q^p) > 1$ for large $p > n$ since $G(q) > 1$. Moreover, we have

$$(F_\infty^-)_*(q, X) \geq \theta. \tag{3.11}$$

Following the argument for supersolutions with (2) of Proposition 3.3, we can estimate $\hat{A}_k := A_k/G(q^p)^{p-4}$ from below in the following manner:

$$\hat{A}_1 \geq \begin{cases} \dfrac{\theta}{3}, & \text{provided } 0 \in \hat{I}, \\ O(p^{-1}), & \text{provided } 0 \notin \hat{I}, \end{cases}$$

$$\hat{A}_2 \geq \begin{cases} \dfrac{\theta}{3}, & \text{provided } \hat{I} \cap I_2 \neq \emptyset, \\ O(p^{-1}), & \text{provided } \hat{I} \cap I_2 = \emptyset, \end{cases}$$

and

$$\hat{A}_3 \geq \begin{cases} \dfrac{\theta}{3}, & \text{provided } \hat{I} \cap I_3 = I_3, \\ O(p^{-1}), & \text{provided } \hat{I} \cap I_3 \neq I_3. \end{cases}$$

Here we use the same nonempty set $\hat{I} \subset I[q]$ as before.

If $0 \in \hat{I}$ or if $0 \notin \hat{I}$ and $\hat{I} \cap I_2 \neq \emptyset$, then, using these estimates in (3.10), we have

$$\frac{f(x^p)}{p(p-2)G(q^p)^{p-4}} \geq \frac{\theta}{3} + O(p^{-1}),$$

which is a contradiction for large $p > n$ since $G(q^p) > 1$.

On the other hand, in the case when $0 \notin \hat{I}$ and $\hat{I} \cap I_2 = \emptyset$, we see that $\emptyset \neq \hat{I} \subset I_3$. Thus, since $0 \geq F_{\hat{I}}^-(q^p, X^p) + O(p^{-1})$, Lemma 3.2 yields that

$$0 \geq F_{\hat{I}}^-(q, X) \geq (F_\infty^-)_*(q, X),$$

which contradicts (3.11). □

3.2. Proof of Lemma 3.2 and Proposition 3.3.

Proof of Lemma 3.2. We give only a proof of the representation formula for $(F_\infty^+)^*$ since we can show the other assertion similarly.

We may suppose that $G(q) > 0$ since the assertion is trivial if $G(q) = 0$; $q = 0$ by (A1).

For $(q, X) \in \mathbf{R}^n \times S^n$, we fix any nonempty set $J \subset I[q]$. We shall see that

$$(F_\infty^+)^*(q, X) \geq -\sum_{k,l \in I_1} 1_J q_k q_l X_{kl} - \sum_{k \in I_2 \cap J} q_k^2 X_{kk} + F_{I_3 \cap J}^+(q, X).$$

Case 1: $0 \in J$. First, we shall consider the case when $I_1 \cap (I_2[q] \cup I_3[q]) \neq \emptyset$.

In this case, we note that there is $k \in I_1$ such that $\{k\} = I_1 \cap (I_2[q] \cup I_3[q])$ and $q_j = 0$ for $j \in I_1 \setminus \{k\}$. Thus, taking $q^\varepsilon = (q_1^\varepsilon, \ldots, q_n^\varepsilon)$, where

$$q_j^\varepsilon = \begin{cases} q_j, & \text{provided } j \in I_1 \cup (J \cap I), \\ q_j - \varepsilon \operatorname{sgn}(q_j) & \text{otherwise,} \end{cases}$$

we have

$$\lim_{\varepsilon\downarrow 0} F_\infty^+(q^\varepsilon, X) = -\sum_{k,l\in I_1} q_k q_l X_{kl} - \sum_{j\in I_2\cap J} q_j^2 X_{jj} + F^+_{I_3\cap J}(q,X). \tag{3.12}$$

Even when $I_1 \cap (I_2[q] \cup I_3[q]) = \emptyset$, using the same q^ε as above, we get (3.12).

Case 2: $0 \notin J$. Let $q^\varepsilon = (q_1^\varepsilon, \dots, q_n^\varepsilon)$ be given by

$$q_k^\varepsilon = \begin{cases} q_k - \varepsilon \operatorname{sgn}(q_k), & \text{provided } k \in I \setminus J, \\ q_k, & \text{provided } k \in J. \end{cases}$$

Noting that $I[q^\varepsilon] = J$ for small $\varepsilon > 0$, we have

$$\lim_{\varepsilon\downarrow 0} F_\infty^+(q^\varepsilon, X) = -\sum_{k\in I_2\cap J} q_k^2 X_{kk} + F^+_{I_3\cap J}(q,X).$$

In order to show the opposite inequality, we choose $(q^m, X^m) \in \mathbf{R}^n \times S^n$ so that

$$\lim_{m\to\infty} (q^m, X^m) = (q, X) \quad \text{and} \quad \lim_{m\to\infty} F_\infty^+(q^m, X^m) = (F_\infty^+)^*(q,X).$$

By taking a subsequence if necessary, we may suppose that there is a nonempty set $J \subset \{0\} \cup I_2 \cup I_3$ such that $J = I[q^p]$ for all $p > n$. Hence we have

$$\begin{aligned}(F_\infty^+)^*(q,X) &= \lim_{m\to\infty} F_\infty^+(q^m, X^m) \\ &= -\sum_{k,l\in I_1} 1_J q_k q_l X_{kl} - \sum_{k\in I_2\cap J} q_k^2 X_{kk} + F^+_{I_3\cap J}(q,X). \qquad \square\end{aligned}$$

Next, using Lemma 3.2, we shall prove Proposition 3.3.

Proof of Proposition 3.3. We give only a proof for assertions of (1) since those for (2) can be proved similarly.

We introduce the notation: for $k \in I$, $\varepsilon > 0$, and $q = (q_1, \dots, q_n) \in \mathbf{R}^n$, we set

$$q_j^{k,\varepsilon} = \begin{cases} q_k & \text{for } j = k, \\ q_j - \varepsilon \operatorname{sgn}(q_j) & \text{otherwise.} \end{cases}$$

Proof of (i). Assume that $0 \in I[q]$. As noted in the proof of Lemma 3.2, we see that if $I_1 \cap I_j[q] \neq \emptyset$ for $j = 2$ or 3, then $q_j = 0$ for $j \in I_1 \setminus \{k\}$. Moreover, $I_1 \cap I_j[q]$ consists of a single point. Thus we remark that if $I_1 \cap I_j[q] = \{k\}$ for $j = 2$ or 3, then

$$-\sum_{j,l\in I_1} q_j q_l X_{jl} = -q_k^2 X_{kk}.$$

Thus we easily see that

$$-\theta \geq \lim_{\varepsilon\downarrow 0} F_\infty^+(q^{k,\varepsilon}, X) \geq \begin{cases} -2\displaystyle\sum_{k,l\in I_1} q_k q_l X_{kl}, & \text{provided } I_1 \cap I_2[q] \neq \emptyset, \\ -\displaystyle\sum_{k,l\in I_1} q_k q_l X_{kl}, & \text{provided } I_1 \cap I_2[q] = \emptyset \\ & \text{and } I_1 \cap I_3[q] \neq \emptyset. \end{cases}$$

In the remaining case (i.e., $I_1 \cap I_j[q] = \emptyset$ for $j = 2, 3$), we have

$$-\theta \geq \lim_{\varepsilon\downarrow 0} F_\infty^+(q^{0,\varepsilon}, X) = -\sum_{k,l\in I_1} q_k q_l X_{kl},$$

where $q^{0,\varepsilon} = (q_1^{0,\varepsilon}, \dots, q_n^{0,\varepsilon})$ is given by

$$q_k^{0,\varepsilon} = \begin{cases} q_k, & \text{provided } k \in I_1, \\ q_k - \varepsilon \mathrm{sgn}(q_k), & \text{provided } k \in I \setminus I_1. \end{cases}$$

Proof of (ii). If there is $k \in I_3[q] \setminus I_2[q]$, then as before, we have

$$-\theta \geq \lim_{\varepsilon \to 0} F_\infty^+(q^{k,\varepsilon}, X) = (-q_k^2 X_{kk}) \vee 0 \geq 0.$$

Thus we may suppose that $I_3[q] \setminus I_2[q] = \emptyset$.

Choose $k \in I_2[q]$. Then, as before, we have

$$-\theta \geq \lim_{\varepsilon \to 0} F_\infty^+(q^{k,\varepsilon}, X) \geq -q_k^2 X_{kk}. \qquad \square$$

4. Comparison principle. When we try to establish the comparison principle, we immediately meet some difficulties.

First, $F_\infty^\pm$ contains serious discontinuity with respect to Du-variables. Moreover, if $I_3 \neq \emptyset$, then F_∞^+ does not coincide with F_∞^-. Thus, to our knowledge, we cannot apply the standard argument in the theory of viscosity solutions to show that the comparison principle holds for sub- and supersolutions of the limit PDEs.

Therefore, we will impose the local convexity of subsolutions or the local concavity of supersolutions for our comparison result below. In the next section, we will present a sufficient condition for the existence of (locally) concave solutions.

As explained in Example 1.2, if $I_3 = I$ and $I_1 = I_2 = \emptyset$, then we cannot expect that the comparison principle holds in general.

To avoid this difficulty, we suppose that

$$\text{(A2)} \qquad I_3 \subset I_2.$$

We note that (A1) is not necessary for the comparison result below, but we have to suppose that

$$\text{(A3)} \qquad I_1 \cup I_2 \neq \emptyset.$$

THEOREM 4.1. *Assume that* (A2) *and* (A3) *hold. Let u and $v \in C(\overline{\Omega})$ be, respectively, a subsolution and a supersolution of*

$$\min\{G(Du) - 1, F_\infty^-(Du, D^2u)\} \leq 0 \quad \textit{in } \Omega$$

and

$$\min\{G(Dv) - 1, F_\infty^+(Dv, D^2v)\} \geq 0 \quad \textit{in } \Omega.$$

If we assume that either u or $-v$ is locally convex, then we have

$$\max_{\overline{\Omega}}(u - v) \leq \max_{\partial\Omega}(u - v).$$

Remark. In our proof, we modify Jensen's argument in [9] for the case when $I_2 \cup I_3 = \emptyset$ since the limit PDEs are possibly discontinuous.

We give two approximations for sub- and supersolutions in Lemma 4.2. The approximations in Lemma 4.2 were obtained in [9], but our lemma contains more precise information.

To demonstrate Theorem 4.1, we will use the approximation of supersolutions and a property from Lemma 4.2. However, we can prove our comparison result more easily using both approximations with no use of the precise information. See the remark after the proof.

Lemma 4.2. *Under the assumptions in Theorem* 4.1, *for any* $\varepsilon > 0$, *there are functions* $\bar{u}$ *and* $\bar{v} \in C(\overline{\Omega})$ *and a constant* $\tau > 0$ *satisfying the following properties:*

(i) $\max_{\overline{\Omega}}(|u-\bar{u}| + |v-\bar{v}|) < \varepsilon$.

(ii) $\bar{u}$ *and* $\bar{v}$ *are, respectively, a subsolution and a supersolution of*

$$\min\{G(D\bar{u}) - 1, F_\infty^-(D\bar{u}, D^2\bar{u})\} + \tau \le 0 \tag{4.1}$$

and

$$\min\{G(D\bar{v}) - 1, F_\infty^+(D\bar{v}, D^2\bar{v})\} - \tau \ge 0. \tag{4.2}$$

(iii) *If* u (*resp.,* v) *is convex* (*resp., concave*), *then so is* $\bar{u}$ (*resp.,* $\bar{v}$).

(iv) *For any* $x \in \Omega$, *there are constants* $\alpha_k, \beta_k \ge \tau$ ($k = 1, 2$) *such that for any* $(q, X) \in \overline{J}^{2,+}\bar{u}(x)$ (*resp.,* $(q, X) \in \overline{J}^{2,-}\bar{v}(x)$), *there is* $(\bar{q}, \bar{X}) \in \overline{J}^{2,+}u(x)$ (*resp.,* $(\bar{q}, \bar{X}) \in \overline{J}^{2,-}v(x)$) *satisfying the following property:*

$$\bar{q} = \alpha_1 q \text{ and } \bar{X} = \alpha_1 X - \beta_1 q \otimes q \quad (\text{resp., } \bar{q} = \alpha_2 q \text{ and } \bar{X} = \alpha_2 X + \beta_2 q \otimes q).$$

Proof of Theorem 4.1. Suppose that there is $\theta > 0$ such that

$$\max_{\overline{\Omega}}(u - v) - \max_{\partial\Omega}(u - v) \ge 2\theta.$$

In view of Lemma 4.2, we choose a supersolution $\bar{v} \in C(\overline{\Omega})$ (for small $\varepsilon > 0$) of (4.2) with a positive constant $\tau > 0$. Thus we may suppose that

$$\max_{\overline{\Omega}}(u - \bar{v}) - \max_{\partial\Omega}(u - \bar{v}) \ge \theta. \tag{4.3}$$

We set $\Phi(x, y) = u(x) - \bar{v}(y) - \alpha|x - y|^2/2$. Because of (4.3), by the standard argument (see [4], for instance), we may find $(x^\alpha, y^\alpha) \in \Omega \times \Omega$ such that

$$\max_{\overline{\Omega}\times\overline{\Omega}} \Phi = \Phi(x^\alpha, y^\alpha) \quad \text{and} \quad \lim_{\alpha\to\infty}(x^\alpha, y^\alpha) = (z, z),$$

where $z \in \Omega$ satisfies $\max_{\overline{\Omega}}(u - \bar{v}) = (u - \bar{v})(z)$.

In view of Theorem 3.2 in [4], for instance, we find X^α and $Y^\alpha \in S^n$ such that

$$\begin{pmatrix} X^\alpha & 0 \\ 0 & -Y^\alpha \end{pmatrix} \le 3\alpha \begin{pmatrix} I & -I \\ -I & I \end{pmatrix}, \tag{4.4}$$

$$(\alpha(x^\alpha - y^\alpha), X^\alpha) \in \overline{J}^{2,+}u(x^\alpha) \quad \text{and} \quad (\alpha(x^\alpha - y^\alpha), Y^\alpha) \in \overline{J}^{2,-}\bar{v}(y^\alpha).$$

We note that (4.4) implies

$$X^\alpha \le Y^\alpha. \tag{4.5}$$

Hence, setting $q^\alpha = \alpha(x^\alpha - y^\alpha)$, we have

$$\lim_{\varepsilon\to 0} \sup\left\{\min\{G(q) - 1, F_\infty^+(q, Y)\} \;\middle|\; |q - q^\alpha| + |Y - Y^\alpha| < \varepsilon\right\} \ge \tau \tag{4.6}$$

and

$$\lim_{\varepsilon\to 0}\inf\left\{\min\{G(q)-1, F_\infty^-(q,X)\}\ \big|\ |q-q^\alpha|+|X-X^\alpha|<\varepsilon\right\}\le 0. \tag{4.7}$$

In view of (4.6), we find a sequence $(q^m, Y^m)\in \mathbf{R}^n\times S^n$ such that $\lim_{m\to\infty}(q^m, Y^m)=(q^\alpha, Y^\alpha)$ and that

$$\lim_{m\to\infty}\min\{G(q^m)-1, F_\infty^+(q^m,Y^m)\}\ge\tau. \tag{4.8}$$

Since G is continuous, we have

$$G(q^\alpha)-1\ge\tau. \tag{4.9}$$

Let us first consider the case when u is locally convex.

Lemma 2.2, together with (4.5), yields that $Y^\alpha\ge 0$ since u is locally convex. Hence, if $G(q^m)=q_0^m$ (≥ 1) for $m\ge 1$, then we have

$$\lim_{m\to\infty}F_\infty^+(q^m,Y^m)\le-\lim_{m\to\infty}\sum_{k,l\in I_1}q_k^m q_l^m Y_{kl}^m\le 0,$$

which contradicts (4.8).

Thus we may suppose that $G(q^m)>q_0^m$ for all $m\ge 1$. In this case, due to (A3), we find $k\in I_2$ such that $G(q^m)=|q_k^m|\ge 1$. Hence we have

$$\lim_{m\to\infty}F_\infty^+(q^m,Y^m)\le 0,$$

which contradicts (4.8) again.

Next, let us suppose that v is locally concave.

In view of (iv) in Lemma 4.2, we find $(\bar q,\bar Y)\in\overline{J}^{2,-}v(y^\alpha)$ such that $\bar q=\alpha_2 q^\alpha$ and

$$\bar Y=\alpha_2 Y^\alpha+\beta_2 q^\alpha\otimes q^\alpha\quad\text{for some }\alpha_2,\beta_2\ge\tau.$$

Hence, since $G(q^\alpha)\ge 1$, by Lemma 2.2, we find $\sigma>0$ such that

$$\langle X^\alpha q^\alpha, q^\alpha\rangle\le\langle Y^\alpha q^\alpha, q^\alpha\rangle\le-\sigma. \tag{4.10}$$

Now we choose $(\hat q^m, X^m)\in\mathbf{R}^n\times S^n$ such that $\lim_{m\to\infty}(\hat q^m, X^m)=(q^\alpha, X^\alpha)$ and that

$$\lim_{m\to\infty}\min\{G(\hat q^m)-1, F_\infty^-(\hat q^m, X^m)\}\le 0. \tag{4.11}$$

We note that (4.10) implies

$$\langle X^m\hat q^m,\hat q^m\rangle\le-\frac{\sigma}{2}. \tag{4.12}$$

Since we may suppose $G(\hat q^m)-1>0$ by (4.9), (4.11) yields that

$$\lim_{m\to\infty}F_\infty^-(\hat q^m, X^m)\le 0.$$

However, as before, by (A2), this implies a contradiction to (4.12). ∎

Remark. If we also approximate u by $\bar u$ by Lemma 4.2, then (4.7) becomes

$$\lim_{\varepsilon\to 0}\inf\{\min\{G(q)-1, F_\infty^-(q,X)\}\ |\ |q-q^\alpha|+|X-X^\alpha|<\varepsilon\}\le-\tau. \tag{4.7$'$}$$

Then, in the case when v is locally concave, we directly get a contradiction from (4.7′) with no use of (iv) of Lemma 4.2.

Since in the proof of Theorem 4.1 we need only to suppose that v is a supersolution of

$$G(Du) - 1 \geq 0 \quad \text{in } \Omega,$$

we have the following corollary, which will be useful to show that u^p converges to the corresponding distance function from $\partial\Omega$ in a typical example.

COROLLARY 4.3. *Assume that* (A2) *and* (A3) *hold. Let u and $v \in C(\overline{\Omega})$ be, respectively, a subsolution and a supersolution of*

$$\min\{G(Du) - 1, F_\infty^-(Du, D^2u)\} \leq 0 \quad \textit{in } \Omega$$

and

$$G(Dv) - 1 \geq 0 \quad \textit{in } \Omega.$$

If we assume that v is locally concave, then we have

$$\max_{\overline{\Omega}}(u - v) \leq \max_{\partial\Omega}(u - v).$$

Remark. If u is a subsolution of $G(Du) - 1 \leq 0$ in the above, then we do not need to suppose that u (or $-v$) is locally convex to show the assertion. See the proof of the comparison principle for the eikonal equation in [8].

Proof of Lemma 4.2. Set $C_0 := \max_{\overline{\Omega}}(|u| + |v|) + 1$. We shall first construct $\bar{u}$. We set $w = u + \delta u^2$, where $\delta := \min\{1/(4C_0), \varepsilon/C_0^2\}$. We note that $-3/(16\delta) \leq w$. We notice that w is convex if u is convex. Thus, because we will take $\bar{u} = \rho w$ for some $\rho > 0$, we verify that (iii) holds.

Suppose that for $\phi \in C^2(\Omega)$, $w(\hat{x}) = \phi(\hat{x})$ for $\hat{x} \in \Omega$, and $w \leq \phi$ in Ω. We may suppose that $-3/(16\delta) \leq \phi$.

Choose $\psi \in C^2(\Omega)$ such that $|\psi| \leq C_0$, $\phi = \psi + \delta\psi^2$, and $u - \psi$ attains its maximum at x^0. Hence we can find $(q^m, X^m) \in \mathbf{R}^n \times S^n$ such that

$$\lim_{m\to\infty}(q^m, X^m) = (D\psi(\hat{x}), D^2\psi(\hat{x}))$$

and

$$\min\{G(q^m) - 1, F_\infty^-(q^m, X^m)\} \leq \frac{1}{m}.$$

We note that

$$D\psi = \frac{D\phi}{1 + 2\delta\psi} \quad \text{and} \quad D^2\psi = \frac{D^2\phi}{1 + 2\delta\psi} - \frac{2\delta D\phi \otimes D\phi}{(1 + 2\delta\psi)^3}.$$

If there is a subsequence of $\{q^m\}$ (denoted by the same symbol) such that

$$G(q^m) - 1 \leq \frac{1}{m},$$

then we have

$$G(D\phi(\hat{x})) \leq \frac{1}{1 + 2\delta\psi(\hat{x})} \leq \frac{1}{1 - \delta C_0}. \tag{4.13}$$

On the other hand, if there is no such a subsequence of $\{q^m\}$, then we may suppose that

$$G(q^m) \geq 1,$$

and, moreover,

$$-\sum_{k,l\in I_1[q^m]} q_k^m q_l^m X_{kl}^m - \sum_{k\in I_2[q^m]} (q_k^m)^2 X_{kk}^m + f_{I_3[q^m]}^-(q^m, X^m) \leq \frac{1}{m}.$$

Setting $\alpha = 1 + 2\delta\psi(\hat{x}) \in [1/2, 2]$, $\hat{q}^m = \alpha q^m$, and $\hat{X}^m = \alpha X^m + 2\delta\alpha^{-2}\hat{q}^m \otimes \hat{q}^m$, we have

$$\begin{aligned}\frac{8}{m} \geq & -\sum_{k,l\in I_1[\hat{q}^m]} \hat{q}_k^m \hat{q}_l^m \left(\hat{X}_{kl}^m - 2\delta\alpha^{-2}\hat{q}_k^m \hat{q}_l^m\right) \\ & - \sum_{k\in I_2[\hat{q}^m]} (\hat{q}_k^m)^2 \left(\hat{X}_{kk}^m - 2\delta\alpha^{-2}(\hat{q}_k^m)^2\right) + f_{I_3[q^m]}^-(q^m, X^m).\end{aligned}$$

Hence, in the case when $G(\hat{q}^m) = \hat{q}_0^m$, we can choose a constant $\hat{\tau} > 0$ such that for any $m \geq 1$,

$$\begin{aligned}-\hat{\tau} + \frac{8}{m} \geq & -\sum_{k,l\in I_1} \hat{q}_k^m \hat{q}_l^m \hat{X}_{kl}^m - \sum_{k\in I_2[\hat{q}^m]} (\hat{q}_k^m)^2 \hat{X}_{kk}^m + f_{I_3[\hat{q}^m]}^-(\hat{q}^m, \hat{X}^m) \\ = & F_\infty^-(\hat{q}^m, \hat{X}^m).\end{aligned}$$

If $G(\hat{q}^m) > \hat{q}_0^m$, then, noting (A2), we find $k \in I_2$ such that $G(\hat{q}^m) = |\hat{q}_k^m|$. Thus we can find a constant $\hat{\tau} > 0$ satisfying the above inequality. (Notice that the first term does not exist in this case.)

Finally, in view of (4.13), taking $\bar{u} = \rho w$, where $\rho = 1 - 2\delta C_0$, we verify easily that $\bar{u}$ is a subsolution of

$$\min\left\{G(D\bar{u}) - 1 + \frac{\delta C_0}{1 - 2\delta C_0}, F_\infty^-(D\bar{u}, D^2\bar{u}) + \hat{\tau}(1 - 2\delta C_0)^3\right\} \leq 0 \quad \text{in } \Omega.$$

Therefore, taking $\tau := \min\{\delta C_0/(1 - 2\delta C_0), \hat{\tau}(1 - 2\delta C_0)^3\}$, we verify that (4.1) holds for $\bar{u}$.

In order to check (iv), we let $(q, X) \in \overline{J}^{2,+}\bar{u}(x)$ for $x \in \Omega$. Choose $(q^m, X^m) \in J^{2,+}\bar{u}(x^m)$ so that $\lim_{m\to\infty}(x^m, u(x^m), q^m, X^m) = (x, u(x), q, X)$. For each $m \geq 1$, we can choose $\phi^m \in C^2(\Omega)$ such that $\bar{u} \leq \phi^m$ in Ω, $\bar{u}(x^m) = \phi^m(x^m)$, and $(D\phi^m(x^m), D^2\phi(x^m)) = (q^m, X^m)$.

We can select $\psi^m \in C^2(\Omega)$ such that $\phi^m = \rho\psi^m(1 + \delta\psi^m)$, $u \leq \psi^m$ in Ω, $u(x^m) = \psi^m(x^m)$, and $(D\psi^m(x^m), D^2\psi(x^m)) \in J^{2,+}u(x^m)$. Hence we have

$$\hat{q}^m := D\psi^m(x^m) = \frac{q^m}{\rho(1 + 2\delta\psi(x^m))}$$

and

$$X^m := D^2\psi^m(x^m) = \frac{X^m}{\rho(1 + 2\delta\psi^m(x^m))} - \frac{2\delta q^m \otimes q^m}{\rho(1 + 2\delta\psi^m(x^m))^3}.$$

By taking $(\bar{q}, \bar{X}) = \lim_{m\to\infty}(\hat{q}^m, \hat{X}^m)$ with $\alpha_1 = \rho^{-1}(1 + 2\delta u(x))^{-1}$ and $\beta_1 = 2\delta\rho^{-1}(1 + 2\delta u(x))^{-3}$, we get (iv) for smaller $\tau > 0$ if necessary.

To construct $\bar{v}$, at the first stage in the above, we use the transformation $\hat{w} = v - \delta v^2$. We can follow the argument for $\bar{u}$. We also refer to [9]. □

5. Existence of concave solutions. In the case when $I_3 \neq \emptyset$, we do not know nice approximate PDEs, which implies the "power concavity" of solutions. Therefore, in this section, we suppose that

$$\text{(A4)} \qquad I_3 = \emptyset.$$

We also suppose that

$$\text{(A5)} \qquad \Omega \quad \text{is convex.}$$

THEOREM 5.1 (cf. Theorem 2 in [16]). *Assume that* (A1), (A4), *and* (A5) *hold. Let* $u \in W_0^{1,p}(\Omega)$ *be the* (*unique*) *minimizer of*

$$\inf\left\{ \|Dv\|^p - \int_\Omega v dx \;\Big|\; v \in W_0^{1,p}(\Omega) \right\}.$$

Then $u^{\frac{p-1}{p}}$ *is concave for* $p > n$.

Remark. For the conclusion in Theorem 5.1, we do not have to suppose $p > n$. However, for the existence of concave solutions of the limit PDEs, we need only the power concavity for large $p > 1$.

Since $(u^p)^{(p-1)/p}$ converges $\lim_{p\to\infty} u^p$ uniformly in $\overline{\Omega}$, where u^p is the unique minimizer of the above variational problem, Theorem 5.1 yields the following.

COROLLARY 5.2. *Assume that* (A1), (A4), *and* (A5) *hold. Then there exists a unique concave solution* $u \in W^{1,\infty}(\Omega)$, *which satisfies that* $u = 0$ *on* $\partial\Omega$ *of*

$$\begin{cases} \min\{G(Du) - 1, F_\infty^-(Du, D^2u)\} \leq 0 & \textit{in } \Omega, \\ \min\{G(Du) - 1, F_\infty^+(Du, D^2u)\} \geq 0 & \textit{in } \Omega. \end{cases}$$

Since our proof is a modification of that by Sakaguchi in [16], we give only a sketch of proof.

Sketch of proof of Theorem 5.1. For $\varepsilon > 0$, we shall consider the following regularized variational problem:

$$\text{(5.1)} \qquad \inf\left\{ \int_\Omega g_\varepsilon^p(v, Dv)dx - \int_\Omega v dx \;\Big|\; v \in W_0^{1,p}(\Omega) \right\},$$

where

$$g_\varepsilon^p(r,p) = \left(\varepsilon|r|^{\frac{2}{p}} + |P_1[p]|^2\right)^{\frac{p}{2}} + \sum_{k\in I_2} \left(\varepsilon|r|^{\frac{2}{p}} + |p_k|^2\right)^{\frac{p}{2}}.$$

It is easy to see that a (unique) minimizer $u_\varepsilon \in W_0^{1,p}(\Omega)$ of (5.1) exists. Moreover, by the standard argument (see [16] for example), we see that

$$\text{(5.2)} \qquad \begin{cases} \text{(i)} & u_\varepsilon \to u \text{ in } W^{1,p}(\Omega) \text{ as } \varepsilon \to 0, \\ \text{(ii)} & u_\varepsilon \geq 0 \text{ in } \Omega, \end{cases}$$

where $u \in W_0^{1,p}(\Omega)$ is the unique minimizer of the variational problem (5.1) with $\varepsilon = 0$.

According to the weak Harnack inequality in [17], we see that

$$\text{(5.3)} \qquad u > 0 \quad \text{in } \Omega.$$

Hence (5.3) and the uniform convergence of u_ε to u imply that for any $\delta > 0$, there are $\varepsilon(\delta), \tau(\delta) > 0$ such that

$$u_\varepsilon \geq \tau(\delta) \quad \text{in } \Omega_\delta \quad \text{for } \varepsilon \in (0, \varepsilon(\delta)), \tag{5.4}$$

where

$$\Omega_\delta = \{x \in \Omega \mid \operatorname{dist}(x, \partial\Omega) > \delta\}.$$

We may suppose that Ω_δ is strictly convex and $\partial\Omega_\delta$ is smooth.

From now on, for simplicity, we shall write u for u_ε. Also, we write $D_1 u$ for $P_1[Du]$.

It is obvious that u is a weak solution (in the distribution sense) of

$$-\sum_{k \in I_1} \left[\left(\varepsilon u^{\frac{2}{p}} + |D_1 u|^2 \right)^{\frac{p-2}{p}} u_{x_k} \right]_{x_k} - \sum_{k \in I_2} \left[\left(\varepsilon u^{\frac{2}{p}} + |u_{x_k}|^2 \right)^{\frac{p-2}{2}} u_{x_k} \right]_{x_k} = G_\varepsilon(u, Du),$$

where

$$G_\varepsilon(u, Du) = \frac{1}{p} - \frac{\varepsilon}{p} u^{\frac{2-p}{p}} \left\{ \left(\varepsilon u^{\frac{2}{p}} + |D_1 u|^2 \right)^{\frac{p-2}{p}} + \sum_{k \in I_2} \left(\varepsilon u^{\frac{2}{p}} + |u_{x_k}|^2 \right)^{\frac{p-2}{p}} \right\}.$$

We remark that $u \in C^\infty(\Omega_\delta)$ (see [16] for example). Thus, setting $v = u^{\frac{p-1}{p}}$, we observe that v is a classical solution of

$$-\sum_{k \in I_1} A(|D_1 v|)_{x_k} - \sum_{k \in I_2} A(v_{x_k})_{x_k} = \hat{G}_\varepsilon(v, Dv), \tag{5.5}$$

where for $r \in \mathbf{R}$,

$$A(r) = \left(\varepsilon + \left(\frac{p}{p-1} \right)^2 r^2 \right)^{\frac{p-2}{2}},$$

and for $(r, q) \in \mathbf{R} \times \mathbf{R}^n$,

$$\hat{G}_\varepsilon(r, q) = \frac{p-1}{vp^2} \left\{ 1 + \left(\frac{|P_1[q]|^2}{p-1} - \varepsilon \right) A(|P_1[q]|) + \sum_{k \in I_2} \left(\frac{q_k^2}{p-1} - \varepsilon \right) A(q_k) \right\}.$$

We note that the left-hand side of (5.5) can be written in the following way:

$$-\sum_{k,l \in I} a_\varepsilon^{kl}(Dv) v_{x_k x_l},$$

where $(a_\varepsilon^{kl}(q))$ is positive semidefinite.

In order to apply the concave maximum principle by Kennington in [13] to (5.5), we first remark that the right-hand side of (5.5) is positive in Ω_δ for small $\varepsilon > 0$.

Setting $w(x, y; t) = (1-t)v(x) + (1-t)v(y) - v((1-t)x + ty)$ for $x, y \in \Omega$ and $t \in (0, 1)$, we also remark that Korevaar's Lemma 2.1 in [14] yields that w does not attain its positive maximum on $\partial(\Omega_\delta \times \Omega_\delta) \times [0, 1]$. Therefore, Theorem 3.1 in [13] implies that $w \leq 0$ in $\overline{\Omega}_\delta \times \overline{\Omega}_\delta \times [0, 1]$.

Since $(u_\varepsilon)^{(p-1)/p}$ is concave in Ω_δ for small $\varepsilon > 0$, so is $u^{(p-1)/p}$ in Ω_δ. Therefore, $u^{(p-1)/p}$ is concave in the whole domain Ω. □

6. Some remarks and examples.

6.1. Convergence to a distance function. In this subsection, for simplicity, we shall consider only the case when

$$\text{(A6)} \qquad I_2 = I \quad \text{and} \quad I_1 = I_3 = \emptyset.$$

In contrast with the result in [12] and [3], we show that the minimizer u^p of the variational problem (2.2) converges to the following distance function from $\partial\Omega$:

$$d_1(x, \partial\Omega) = \inf \left\{ \sum_{k\in I} |x_k - y_k| \ \middle|\ y \in \partial\Omega \right\}.$$

We first give a remark which was informed by Ishii.

Proposition 6.1. *We see that* $d_1(\cdot, \partial\Omega)$ *is a supersolution of*

$$\text{(6.1)} \qquad G(Du) - 1 = 0 \quad \textit{in } \Omega.$$

Proof. Due to the well-known fact in the theory of viscosity solutions, it is enough to show that for each $y = (y_1, \ldots, y_n) \in \partial\Omega$,

$$h(x) := \sum_{k\in I} |x_k - y_k|$$

is a supersolution of (6.1).

For any $x^0 \in \Omega$, we let $p \in \mathbf{R}^n$ satisfy that $(p, X) \in J^{2,-}u(x^0)$ for some $X \in S^n$. We may suppose that $x^0 = 0$. We notice that $y \neq 0$. Thus we have

$$u(x) \geq u(0) + \langle p, x\rangle + o(|x|).$$

Hence it is easy to see that

$$|p_k| \leq 1 \quad \text{provided } y_k = 0 \quad \text{and} \quad |p_k| = 1 \quad \text{provided } y_k \neq 0.$$

Therefore, we verify that $G(p) = 1$. □

Next we prepare the following lemma.

Lemma 6.2. *Assume that* (A5) *holds. Then* $d_1(\cdot, \partial\Omega)$ *is concave in* Ω.

Proof. Fix $x^j = (x^j_1, \ldots, x^j_n) \in \Omega$ for $j = 1, 2$. Since $Q_j := \{y \in \mathbf{R}^n \mid \sum_{k\in I} |x^j_k - y_k| \leq d_1(x^j, \partial\Omega)\}$ for $j = 1, 2$ are in $\overline{\Omega}$, by (A5), we see that for $t \in [0, 1]$,

$$tQ_1 + (1-t)Q_2 = \{tx + (1-t)y \in \mathbf{R}^n \mid x \in Q_1,\ y \in Q_2\} \subset \overline{\Omega}.$$

Therefore, in view of a simple observation, we see that

$$d_1(tx^1 + (1-t)x^2, \partial\Omega) \geq td_1(x^1, \partial\Omega) + (1-t)d_1(x^2, \partial\Omega). \qquad □$$

We shall show that $d_1(\cdot, \partial\Omega)$ is indeed a solution of (6.1) when Ω is convex.

Proposition 6.3. *Assume that* (A5) *holds. Then* $d_1(\cdot, \partial\Omega)$ *is a solution of* (6.1).

Proof. In view of Proposition 6.1, it is sufficient to show that d_1 is a subsolution of (6.1).

For any $x^0 \in \Omega$, we fix $p \in \mathbf{R}^n$ such that $(p, X) \in J^{2,+}d_1(x^0, \partial\Omega)$ for some $X \in S^n$. We may suppose $x^0 = 0$.

We shall show that $G(p) \leq 1$. To this end, we consider the function $\phi(x) = -\sum_{k\in I} |x_k| + d_1(0, \partial\Omega)$ for $x \in \overline{\Omega}$.

We claim that ϕ is a subsolution of $G(D\phi) - 1 \leq 0$ in Ω. Indeed, for any $x \in \Omega$ and $\hat{p} \in \mathbf{R}^n$ such that $(\hat{p}, \hat{X}) \in J^{2,+}\phi(x)$ for some $\hat{X} \in S^n$, as in the proof of Proposition 6.2, we easily see that

$$|\hat{p}_k| \leq 1, \quad \text{provided } x_k = 0, \quad \text{and} \quad |\hat{p}_k| = 1, \quad \text{provided } x_k \neq 0.$$

Thus, noting that $\phi \leq 0$ on $\partial\Omega$, by Corollary 4.3 together with Proposition 6.1 and Lemma 6.2, we see that $\phi \leq d_1$ in $\overline{\Omega}$. Therefore, we have

$$\begin{aligned}\phi(x) \leq d_1(x, \partial\Omega) &\leq d_1(0, \partial\Omega) + \langle p, x\rangle + \frac{\langle Xx, x\rangle}{2} + o(|x|^2)\\ &= \phi(0) + \langle p, x\rangle + \frac{\langle Xx, x\rangle}{2} + o(|x|^2).\end{aligned}$$

Hence we have $(p, X) \in J^{2,+}\phi(0)$, which concludes the proof. □

Finally, combining Proposition 6.3 with Corollary 4.3, we obtain the following.

COROLLARY 6.4. *Assume that* (A5) *and* (A6) *hold. Assume also that*

$$\min_{x\in\overline{\Omega}} f(x) > 0.$$

Let u^p *be the minimizer of* (2.2).

Then we have

$$\lim_{p\to\infty} u^p(x) = d_1(x, \partial\Omega) \quad \textit{uniformly in } x \in \overline{\Omega}.$$

Proof. In view of Theorems 4.1 and 5.1, we may choose a subsequence u^{p_i} so that $u := \lim_{i\to\infty} u^{p_i}$ is a concave solution of

$$\min\left\{G(Du) - 1, -\sum_{k\in I[Du]} u_{x_k}^2 u_{x_k x_k}\right\} = 0 \quad \text{in } \Omega.$$

Hence Proposition 6.3 and Theorem 4.1 yield that $d_1 \leq u$ in $\overline{\Omega}$.

In view of Lemma 6.2 and Proposition 6.3, we see that d_1 is a concave supersolution of $G(Du) - 1 \geq 0$ in Ω. Thus Corollary 4.3 and Theorem 5.1 yield that $u \leq d_1$ in $\overline{\Omega}$. □

6.2. Examples. We consider three typical domains in $\mathbf{R}^2$; $I = \{1, 2\}$. For each domain, we deal with three cases:

$$\left\{\begin{aligned}\min\left\{|Du| - 1, -\sum_{k,l\in I} u_{x_k} u_{x_l} u_{x_k x_l}\right\} &= 0 \quad \text{in } \Omega,\\ u &= 0 \quad \text{on } \partial\Omega,\end{aligned}\right. \tag{6.2}$$

$$\left\{\begin{aligned}\min\left\{\max_{j\in I} |u_{x_j}| - 1, -\sum_{k\in I[Du(x)]} (u_{x_k})^2 u_{x_k x_k}\right\} &= 0 \quad \text{in } \Omega,\\ u &= 0 \quad \text{on } \partial\Omega,\end{aligned}\right. \tag{6.3}$$

and

$$(6.4)\qquad \begin{cases} \min\Big\{\max\limits_{j\in I}|u_{x_j}|-1, F^{+}_{I[Du]}(Du,D^2u)\Big\}\geq 0 & \text{in } \Omega,\\ \min\Big\{\max\limits_{j\in I}|u_{x_j}|-1, F^{+}_{I[Du]}(Du,D^2u)\Big\}\leq 0 & \text{in } \Omega,\\ \hfill u=0 & \text{on } \partial\Omega. \end{cases}$$

Here we use the notation $F^{\pm}_J$ for $J\subset I$ from section 3.

We notice that (6.2), (6.3), and (6.4), respectively, correspond to the cases when $I_2=I_3=\emptyset$, $I_1=I_3=\emptyset$, and $I_1=I_2=\emptyset$.

According to [12] and [3], we know that

$$\lim_{p\to\infty} u^p(x)=d(x,\partial\Omega)\quad\text{uniformly in } \overline{\Omega},$$

where u^p is the minimizer of the variational problem (2.2) for $I_2=I_3=\emptyset$.

Also, by Corollary 6.4, we see that

$$\lim_{p\to\infty} u^p(x)=d_1(x,\partial\Omega)\quad\text{uniformly in } \overline{\Omega},$$

where u^p is the minimizer of the variational problem (2.2) for $I_1=I_3=\emptyset$.

In Examples 6.1–6.3 below, although $d_1(\cdot,\partial\Omega)$ is a solution of (6.4), it does not imply that the corresponding u^p converges to $d_1(\cdot,\partial\Omega)$ because we do not know the uniqueness of (concave) solutions of (6.4).

Example 6.1. Let us consider $\Omega=\{x=(x_1,x_2)\in\mathbf{R}^2 \mid |x_k|<1 \text{ for } k\in I\}$.

Then we easily see that the following function is a solution of (6.2), (6.3), and (6.4):

$$u(x_1,x_2)=\begin{cases} 1-|x_1| & \text{for } |x_2|\leq |x_1|,\\ 1-|x_2| & \text{otherwise.}\end{cases}$$

Notice that $u(x)=d(x,\partial\Omega)=d_1(x,\partial\Omega)$.

We note that u is the unique solution of (6.2) and that it is the unique concave solution of (6.3).

Example 6.2. We next deal with $\Omega=\{(x_1,x_2)\in\mathbf{R}^2 \mid |x_1|+|x_2|<1\}$.

It is easy to see that the distance function $d(\cdot,\partial\Omega)$ is given by

$$d_1(x,\partial\Omega)=1-|x_1|-|x_2|\quad\text{for } x=(x_1,x_2)\in\Omega$$

and that it is the unique concave solution of (6.3).

Also, we see that the distance function $d(x,\partial\Omega)=d_1(x,\partial\Omega)/\sqrt{2}$ is the unique solution of (6.2).

Example 6.3. We shall treat $\Omega=B_1$. It is immediately seen that the unique solution of (6.2) is given by the distance function

$$d(x,\partial\Omega)=1-|x|\quad\text{for } x\in\Omega.$$

By an elementary calculation, we can show that the distance function $d_1(\cdot,\partial\Omega)$ is given by

$$d_1(x,\partial\Omega)=\begin{cases} \sqrt{1-x_2^2}-|x_1| & \text{for } |x_2|\leq|x_1|,\\ \sqrt{1-x_1^2}-|x_2| & \text{otherwise.}\end{cases}$$

Hence, by Corollary 6.4, we see that $d_1(\cdot, \partial\Omega)$ is the unique concave solution of (6.3).

We note that for $r \in (0,1)$, the level set $\Omega(r) := \{x \in \mathbf{R}^2 \mid d_1(x, \partial\Omega) > r\}$ strictly contains B_r. More precisely, we have

$$\Omega(r) = \bigcap_{k=1}^{4} B_1(\hat{x}^k),$$

where

$$\hat{x}^1 = (r-1, 0), \quad \hat{x}^2 = (0, r-1), \quad \hat{x}^3 = (1-r, 0), \quad \text{and} \quad \hat{x}^4 = (0, 1-r).$$

Acknowledgments. The authors thank Professor H. Ishii for his suggestions on the first draft.

A MATHEMATICAL MODEL OF THE SPREAD OF FELINE LEUKEMIA VIRUS (FeLV) THROUGH A HIGHLY HETEROGENEOUS SPATIAL DOMAIN[*]

W. E. FITZGIBBON[†], M. LANGLAIS[‡], AND J. J. MORGAN[§]

Abstract. We are concerned with a system of partial differential equations modeling the spread of feline leukemia virus (FeLV) through highly heterogeneous habitats or spatial domains. Our differential equations may feature discontinuities in the coefficients of divergence from differential operators and discontinuities in the coupling terms. Global well posedness, long term behavior, approximation, and homogenization results are provided.

Key words. compartmental or diffractive diffusion, mass action, proportionate mixing, spatial heterogeneity, homogenization

1. Introduction.

We shall be concerned with the development and analysis of diffusive models describing the spread of feline leukemia virus (FeLV) through the domestic cat population, *Felis catus.* The domestic cat population provides excellent examples or test cases for validating epidemic models and calibrating the effects of various factors such as spatial structure and social organization on the dynamics of the transmission of disease; see Courchamp et al. [3] and Fromont et al. [11], [12].

FeLV is an oncogenic and immunosuppressive retrovirus of the domestic cat population which can have a severe impact on population growth via direct mortality and the reduction of female fertility. An excellent review of the disease is given by Hardy [14]. Although its transmission mode may be epigenic (vertical from mother to feotus during pregnancy) (see Hoover [16]), most pregnancies abort or the newborns die quickly [16]. Consequently, we shall assume no vertical transmission. The horizontal transmission from cat to cat results from pathogens contained mainly in the saliva and occurs from biting, grooming, copulating, and sharing of food sources.

The clinical course of FeLV begins with a latent period lasting on average from three weeks to four months. Although the virus is present, this phase of the disease is asymptomatic, and because their viremia is low the cats are minimally infectious [14]. The latent phase of the disease ends with two possible outcomes. Approximately two thirds of the infected cats cease viral replication and become immune to subsequent infection. These cats are considered to be clinically recovered and appear to maintain immunity for the rest of their lives. We should, however, point out that the issue of permanent immunity is somewhat problematic and open to discussion. About one third of the infected cats become persistently viremic and develop prolif-

erative and immunosupressive disorders which lead to death within a few weeks to several years.

Neglecting spatial considerations for the moment, we shall assume that the feline population, in the absence of infection, satisfies a basic logistic growth described by the ordinary differential equation

$$\dot{p} = (b - m)p - kp^2, \tag{1.1}$$

where the linear term accounts for the natural growth rate, b the birth rate and m the death rate, and the quadratic term accounts for the damping of growth due to resource limitations of the habitat or environment. Our basic FeLV circulation model subdivides the population into three distinct groups: susceptibles or individuals who are not infected but are capable of being infected will be denoted by u; the infective class consisting of individuals who are infected and are capable of transmitting the disease will be denoted by v; and finally, we use the variable w to denote the recovered or immune class which is made up of individuals who have been exposed to the disease but who at the conclusion of the period of recovery have gained complete immunity as a consequence of their exposure.

The following coupled system of ordinary differential equations will describe the epidemiology described heretofore:

$$\begin{aligned} du/dt &= -f(u, v, w) + b(u + w) - (m + kp)u, \\ dv/dt &= \pi f(u, v, w) - \alpha v - (m + kp)v, \\ dw/dt &= (1 - \pi)f(u, v, w) - (m + kp)w, \end{aligned} \tag{1.2}$$

with initial conditions $u(0) = u_0 > 0,\ v(0) = v_0 > 0,\ w(0) = w_0 > 0$. We set the total population $p = u + v + w$. Here some remarks are clearly in order. The linear term $b(u + w)$ represents the birth process into the susceptible class. Our model system assumes there are no births from the infective class. This represents an approximation of the underlying biological reality. We also postulate that individuals born from the recovered or immune class are born into the susceptible class and do not have immunity. This is also consistent with what actually happens: kittens born to immune females are initially passively protected by maternal antibodies but shortly become susceptible [16]. We have also collapsed the exposed class and assumed direct passage from the susceptible class to either the fully infected and infectious class or to the recovered and immune class. In all three classes we assume the logistic damping of (1.1). We account for disease-induced mortality with the term αv in the fully infected class. Last, π is the proportion of infected cats becoming infective.

The remaining term to be discussed is the incidence $f(u, v, w)$, and the rationale for the proper definition of the incidence term is an ongoing subject of discussion in the literature; see Busenberg and Cooke [2] and Diekmann et al. [4]. Two different incidence terms are commonly proposed: mass action and proportionate mixing. In the case of FeLV, field studies indicate that each of the two models can be appropriate depending on the nature of the habitat [12]: proportionate mixing appears most appropriate for rural to semiurban environments with large host population densities, and mass action is most appropriate for rural environments with smaller host population densities. We can also discuss the effects of vaccination against FeLV. However, this shall be taken up in future work treating more complete models; see also Lubkin et al. [21] and Fromont et al. [11], [12].

2. Spatially heterogeneous models. In this section we wish to include the spatial distribution of our populations and, in particular, account for the effects of spatial heterogeneity. We consider a bounded two dimensional habitat or spatial domain $\Omega \subset \mathbb{R}^2$. Because we shall not be interested in special quantitative effects contributed by boundary irregularity, we shall assume that $\partial\Omega$ is smooth with Ω lying locally on one side of $\partial\Omega$. Our state variables u, v, w no longer represent populations but rather population densities $u(x,t), v(x,t), w(x,t)$ for the susceptible, infected and infectious, and the immune/recovered populations, respectively. The time dependent populations $u(t), v(t), w(t)$ may be computed by integration over the habitat, i.e.,

$$\begin{aligned} u(t) &= \int_\Omega u(x,t)dx, \\ v(t) &= \int_\Omega v(x,t)dx, \qquad t > 0, \\ w(t) &= \int_\Omega w(x,t)dx. \end{aligned} \tag{2.1}$$

We shall account for the assumption that our populations remain confined to Ω for all time by the imposition of standard no flux boundary conditions.

The heterogeneity of the habitat will be reflected by our designation of open subregions $\{\Omega_1, \ldots, \Omega_K\} \subset \Omega$ having the properties that

$$\begin{aligned} &\overline{\Omega}_l \subset \Omega && \text{for } l = 1, \ldots, K, \\ &\overline{\Omega}_l \cap \overline{\Omega}_k = \emptyset && \text{if } l \neq k, \end{aligned} \tag{2.2}$$

and the same smoothness properties as Ω. For convenience we let

$$\Omega^* = \bigcup_{l=1}^{K} \Omega_l$$

and

$$\Omega_0 = \Omega - \overline{\Omega}^*.$$

For the purpose at hand we can consider $\Omega_1, \ldots, \Omega_K$ to be urban areas of habitat Ω with large cat population densities and the ambient region Ω_0 to be the rural part of Ω with smaller cat population densities.

The feline population will be assumed to disperse via a diffusive mechanism. However, we shall assume a sharp transition between each Ω_l and the ambient region. We model this with a compartmental or diffractive operator on Ω. A diffusion advection operator,

$$\partial u/\partial t = \operatorname{div}(d(x)\nabla u - u\bar{c}(x)),$$

is said to be compartmental or diffractive if the following conditions hold: there exist positive numbers $\underline{d}, \overline{d}$ such that

$$0 < \underline{d} \leq d(x) \leq \overline{d} \qquad \text{for } x \in \Omega, \tag{2.3}$$

and

$$d(x) = \begin{cases} d_l(x) & \text{for } x \in \Omega_l,\ l = 1 \text{ to } K, \\ d_0(x) & \text{for } x \in \Omega_0, \end{cases} \tag{2.4}$$

with $d_l(\ ) \in C(\overline{\Omega}_l)$ for $l = 1$ to K and $d_0(\ ) \in C(\overline{\Omega}_0)$. We allow for discontinuity of $d(\ )$ across the interface of Ω_l with Ω_0. We shall assume that the transport vector field $\overline{c}(\ )$ is continuous on $\overline{\Omega}$, and we impose compatibility conditions on the interface of Ω_l with Ω_0, namely, that

$$\text{(2.5)} \qquad \begin{cases} [u]_{\partial\Omega_l} = 0, \\ [d\ \partial u/\partial\eta_l]_{\partial\Omega_l} = 0, \end{cases} \qquad l = 1 \text{ to } K,$$

where $[\rho]_{\partial\Omega_l}$ denotes the saltus of the function ρ on $\partial\Omega_l$ and η_l is a unit normal vector to $\partial\Omega_l$. We point out that if u represents a concentration density, (2.5) insures continuity of the state variable u and the flux $d\ \partial u/\partial\eta_l - u\overline{c}\cdot\eta_l$ across the interface of Ω_l with Ω_0. However, a discontinuity of $d(\ )$ across $\partial\Omega_l$ will force a jump discontinuity of the normal derivative $\partial u/\partial\eta_l$ on $\partial\Omega_l$. Thus we cannot expect the smoothness from compartmental diffusive operators that we expect from normal diffusion processes. Finally, we impose boundary conditions on $\partial\Omega$; in our case we shall have homogeneous Neumann boundary conditions

$$\text{(2.6)} \qquad d(x)\partial u/\partial\eta - u\overline{c}(x)\cdot\eta = 0 \quad \text{on } \partial\Omega.$$

We point out that compartmental or diffractive diffusion operators arose in nuclear reactor engineering, and they have been studied both in Russia and the United States by Ladyzhenskaya, Rivkind, and Ural'ceva [19], Seftel [25], and Stewart [27], [28], [29]. Recently they were the subject of a throughgoing study in Horton [17]; see also Fitzgibbon and Morgan [6] and Fitzgibbon, Hollis, and Morgan [7].

We shall also want to consider reaction diffusion equations (as well as systems) with compartmental diffusion. A compartmental reaction diffusion model has the form

$$\text{(2.7)} \qquad \partial u/\partial t - \operatorname{div}(d(x)\nabla u - u\overline{c}(x)) = g(x, u)$$

for $x \in \Omega^* \bigcup \Omega_0$ and $t > 0$, where we assume that the piecewise continuity conditions on $d(\ )$, the continuity conditions on $\overline{c}(\ )$, the compatibility conditions on $\partial\Omega_l$, and the exterior homogeneous Neumann condition on $\partial\Omega$ are satisfied. We assume that $g \in C^1(\Omega_i \times \mathbb{R}_+)$ for each i, and there exists $L \in L_\infty(\Omega)$ such that L can be extended to a continuous function on each of $\overline{\Omega}_0, \overline{\Omega}_1, \ldots, \overline{\Omega}_K$ and

$$\mid g(x, u) - g(x, v) \mid \leq L(x) \mid u - v \mid, \qquad u, v \in \mathbb{R},\ x \in \Omega.$$

A strong solution to the initial value problem with $u(\ , 0) = u_0 \in C(\overline{\Omega})$ is a continuous mapping $u(\ , t)$ from $[0, \infty)$ to $L_p(\Omega)$ having the properties that $u \in W_p^{2,1}(X \times (\tau, \infty))$ for every open set Q with $\overline{Q} \subset \Omega^* \bigcup \Omega_0$ for every $\tau > 0$, and such that u satisfies the differential equation, the boundary and compatibility are continuous almost everywhere (a.e.) on Ω and $\partial\Omega$. A classical solution is one with $u(\ , t)$ as a continuous mapping of $[0, \infty)$ to $C(\overline{\Omega})$ with $u(\ ,\ ) \in C^{2,1}(\Omega_l \times (0, \infty))$ for $l = 0, 1, 2, \ldots, K$ such that the compatibility conditions (2.5) on $\partial\Omega_l$, the exterior boundary condition (2.6), and the differential equation are satisfied.

It is known that the infinitesimal generator A_p of an analytic semigroup $\{T_p(t) \mid t \geq 0\}$ on L_p can be associated with $\operatorname{div}(d(x)\nabla u - u\overline{c}(x))$ (and the given compatability conditions and boundary conditions), and it can also be shown that this differential operator can be used to obtain the infinitesimal generator A of an analytic semigroup

$\{T(t) \mid t \geq 0\}$ on $C(\overline{\Omega})$; c.f. [17], [29]. Moreover, strong L_p solutions exist and are represented by

$$u(t) = T_p(t)u(0) + \int_0^t T_p(t-s)g(\cdot, u(s))ds,\ u(0) \in L_p(\Omega), \tag{2.8}$$

and classical solutions are given by

$$u(t) = T(t)u(0) + \int_0^t T(t-s)g(\cdot, u(s))ds,\ u(0) \in C(\overline{\Omega}). \tag{2.9}$$

The regularity theory for parabolic equations with discontinuous coefficients will insure that strong $L_p(\Omega)$ solutions are regularized to classical solutions on $C(\overline{\Omega})$ (see [19]). If for each $x \in \Omega$ the forcing term $g(x,)$ is only locally Lipschitz continuous in the state variable, then we are guaranteed local classical solutions on maximal intervals $[0, T_0)$, and the key to extending these solutions will be finding continuous functions $M(t)$ on $[0, \infty)$ which bound the $L_\infty(\Omega)$ norm of the state variable $u(t)$. These results immediately extend to systems of reaction diffusion equations with compartmental diffusion.

We let $\chi(x)$ be the characteristic function of Ω^* and assume $\sigma(x)$ is a bounded strictly positive function which is piecewise continuous on $\overline{\Omega}_0, \overline{\Omega}_1, \ldots, \overline{\Omega}_K$. We obtain a heterogeneous incidence term by specifying

$$f(x, u, v, w) = \chi(x)\sigma(x)\frac{uv}{u+v+w} + (1 - \chi(x))\sigma(x)uv. \tag{2.10}$$

A moment's reflection will convince the reader that for fixed $x \in \Omega$, $f(x, , ,)$ can be made to be continuous on $\mathbb{R}^3_+$ by defining $f(x, 0, 0, 0) = 0$ and that $f(, , ,)$ is piecewise continuous on $\Omega \times \mathbb{R}^3_+$. Moreover, when $x \in \Omega^*$ we have a proportionate mixing term, and when $x \in \Omega_0$ we have mass action.

We assume that our population disperses via a compartmental diffusion system of partial differential equations of the form

(2.11)

$$\begin{aligned}
\partial u/\partial t &= \operatorname{div}(d^{(1)}(x)\nabla u - u\bar{c}^{(1)}(x)) - f(x, u, v, w) + b(x)(u + w) - (m(x) + k(x)p)u,\\
\partial v/\partial t &= \operatorname{div}(d^{(2)}(x)\nabla v - v\bar{c}^{(2)}(x)) + \pi f(x, u, v, w) - \alpha(x)v - (m(x) + k(x)p)v,\\
\partial w/\partial t &= \operatorname{div}(d^{(3)}(x)\nabla w - w\bar{c}^{(3)}(x)) + (1 - \pi)f(x, u, v, w) - (m(x) + k(x)p)w,
\end{aligned}$$

where $p = u + u + w$. We impose standard no flux boundary conditions on $\partial\Omega$,

$$\begin{aligned}
&d^{(1)}(x)\partial u/\partial\eta - u\bar{c}^1(x) \cdot \eta = 0,\\
&d^{(2)}(x)\partial v/\partial\eta - v\bar{c}^2(x) \cdot \eta = 0, \quad x \in \partial\Omega, \quad t > 0,\\
&d^{(3)}(x)\partial w/\partial\eta - w\bar{c}^3(x) \cdot \eta = 0,
\end{aligned} \tag{2.12}$$

and we impose compatibility conditions on the interface of Ω_l $(l = 1, \ldots, K)$ with Ω_0,

$$[u]_{\partial\Omega_l} = [v]_{\partial\Omega_l} = [w]_{\partial\Omega_l} = 0, \tag{2.13}$$

and

$$[d^{(1)}\partial u/\partial\eta_l]_{\partial\Omega_l} = [d^{(2)}\partial v/\partial\eta_l]_{\partial\Omega_l} = [d^{(3)}\partial w/\partial\eta_l]_{\partial\Omega_l} = 0. \tag{2.14}$$

The initial data is assumed to be continuous and nonnegative on $\overline{\Omega}$:

$$u(x, 0) = u_0(x), \quad v(x, 0) = v_0(x), \quad w(x, 0) = w_0(x). \tag{2.15}$$

Throughout what follows we shall assume that the diffusitivities $d^{(i)}(x),\ i=1,2,3,$ satisfy the conditions outlined at the beginning of the section and that the transport vector fields $\overline{c}^{(i)}(x),\ i=1,2,3,$ are continuous on $\overline{\Omega}$. The spatially dependent birth rate $b(x)$, death rate $m(x)$, logistic coefficient $k(x)$, and disease-induced mortality rate $\alpha(x)$ should all be continuous and strictly positive on $\overline{\Omega}$. The proportion π of infected cats becoming infective is constant, $0<\pi<1$ (see [11] and [21]).

In what follows we shall need to make use of b_0, b_1, k_0, k_1 such that

$$\left\{\begin{array}{l} 0<b_0<b(x)\le b_1<\infty \\ 0<k_0\le k(x)\le k_1<\infty \end{array}\right. \quad \text{for } x\in\overline{\Omega}, \tag{2.16}$$

and the following estimates.

Lemma 1. *If $u(x,t), v(x,t), w(x,t)$ are nonnegative classical solutions to* (2.11)–(2.15) *on $\Omega\times[0,T_1)$ and $p(x,t)=u(x,t)+v(x,t)+z(x,t)$, then*

$$\parallel p(\ ,t)\parallel_{1,\Omega}\le \max(\parallel p_0\parallel_{1,\Omega},(b_1/k_0)\mid\Omega\mid)=C_1; \tag{2.17}$$

if $T_1=\infty$, then

$$\lim_{t\to\infty}\sup\parallel p(\ ,t)\parallel_{1,\Omega}\le (b_1/k_0)\mid\Omega\mid. \tag{2.18}$$

Moreover, if τ,τ^* are such that $(\tau,\tau+\tau^*)\subset[0,T_1)$, then there exists a constant $C_{\tau,\tau^*}=C_{\tau,\tau^*}(b_1,k_0,\parallel p_0\parallel_{1,\Omega})$ so that for $Q(\tau,\tau+\tau^*)=\Omega\times(\tau,\tau+\tau^*)$ we have

$$\parallel p(\ ,\ )\parallel_{2,Q(\tau,\tau+\tau^*)}\le C_{\tau,\tau^*}. \tag{2.19}$$

If τ is sufficiently large, then C_{τ,τ^*} can be chosen independent of $\parallel p_0\parallel_{1,\Omega}$.

Proof. The first two estimates (2.17) and (2.18) are essentially the substance of Proposition 2 in Fitzgibbbon and Langlais [5]. To obtain the third estimate we add the components of our system to obtain

$$\frac{d}{dt}\int_\Omega p(x,t)dx\le b_1\int_\Omega p(x,t)dx-k_0\int_\Omega p^2(x,t)dx. \tag{2.20}$$

Applying the Hölder inequality and then Young's inequality to the first term on the right-hand side of (2.20), we obtain

$$\frac{d}{dt}\int_\Omega p(x,t)dx\le\tilde{b}-\tilde{k}\int_\Omega p^2(x,t)dx \tag{2.21}$$

for appropriately chosen $\tilde{b}$ and $\tilde{k}$, from which the desired result follows. □

We now turn our attention to the global well posedness and uniform boundedness of solutions to (2.11)–(2.15). We remark that if the functions d_i and c_i are in $C^1(\overline{\Omega})$, then these results can be obtained by application of the intermediate sum argument of Morgan [10], [22], [23]. However, the estimates obtained in this manner require control of the modulus of continuity of the coefficients of the differential operators, and for what follows we shall need estimates which are independent of the modulus of continuity of the coefficients. Toward this end, we have the following two theorems.

Theorem 1. *If the initial data (u_0,v_0,w_0) is nonnegative and continuous on $\overline{\Omega}$, then* (2.11)–(2.15) *have globally defined unique classical solutions $u(x,t), v(x,t), w(x,t)$ on $Q(0,\infty)=\Omega\times(0,+\infty)$ which are nonnegative.*

Proof. In light of the previous discussion concerning local well posedness, we shall be content with establishing a priori $L_\infty(\Omega)$ estimates on the state variables u, v, w. We refer the reader to Horton [17] for a careful development of the local theory. Because the vector field defined by the epidemiological kinetics and written as

$$F(x,u,v,w) = \begin{pmatrix} -f(x,u,v,w) + b(x)(u+w) - (m(x)+k(x)p)u, \\ \pi f(x,u,v,w) - \alpha(x)v - (m(x)+k(x)p)v, \\ (1-\pi)f(x,u,v,w) - (m(x)+k(x)p)w \end{pmatrix} \tag{2.22}$$

does not point out $\mathbb{R}^3_+$ on the coordinate hyperplane, $\mathbb{R}^3_+$ may be shown to be an invariant rectangle by the maximum principle arguments in [26]. To extend our local results globally we follow standard parabolic methodology and construct an $M(t) \geq 0$ which is continuous on $\mathbb{R}_+$ so that

$$\max\{\| u(\ ,t) \|_{\infty,\Omega}, \| v(\ ,t) \|_{\infty,\Omega}, \| w(\ ,t) \|_{\infty,\Omega}\} \leq M(t) \tag{2.23}$$

on the maximal interval of existence $[0, T_{\max})$. These time dependent a priori L_∞ bounds will guarantee that $T_{\max} = \infty$. We shall use energy-type arguments to bootstrap the estimates of Lemma 1 to sufficiently high L_p estimates. We will use these estimates to obtain L_p estimates of the coupling terms of (2.11). This will allow us to apply the regularity theorem of parabolic equations with discontinuous coefficients to obtain the desired function $M(t)$.

We begin with the first equation of (2.11). If we multiply by u and integrate on Ω, we obtain

$$\begin{aligned} &\frac{1}{2}\frac{d}{dt}\int_\Omega u^2(x,t)dx + \int_\Omega d^{(1)}(x)|\nabla u|^2(x,t)dx + \int_\Omega k(x)u^3(x,t)dx \\ &\leq \int_\Omega b(x)u^2(x,t)dx + \int_\Omega b(x)w(x,t)u(x,t)dx + \int_\Omega u(x,t)\overline{c}^{(1)}(x)\cdot\nabla u(x,t)dx \\ &\qquad \leq b_1\left[\int_\Omega u^2(x,t)dx + \left[\int_\Omega w^2(x,t)dx\right]^{\frac{1}{2}}\left[\int_\Omega u^2(x,t)dx\right]^{\frac{1}{2}}\right] \\ &\qquad + \| \overline{c}^{(1)} \|_{\infty,\Omega}\left[\left(\int_\Omega u^2(x,t)dx\right)^{\frac{1}{2}}\left(\int_\Omega |\nabla u|^2(x,t)dx\right)^{\frac{1}{2}}\right]. \end{aligned} \tag{2.24}$$

We recall that Lemma 1 guarantees space time cylinder estimates in L_2. Integration and Young's inequality yield

$$\begin{matrix} u(\ ,t) \in L_2(\Omega) \\ u \in L_3(Q(0,T)) \\ |\nabla u| \in L_2(Q(0,T)) \end{matrix} \qquad \text{for } T < T_{\max}, \tag{2.25}$$

and the existence of functions $C_2, C_3 \in C(\mathbb{R}_+)$ so that

$$\begin{matrix} \| u(\ ,t) \|_{2,\Omega} \leq C_2(t) & \text{for } t < T_{\max}, \\ \| u \|_{3,Q(0,T)} \leq C_3(T) & \text{for } [0,T] \subset [0,T_{\max}), \\ \| |\nabla u| \|_{2,Q(\tau,T)} \leq C_3(T) & \text{for } [\tau,T] \subset [0,T_{\max}). \end{matrix} \tag{2.26}$$

We now multiply the first equation of (2.11) by u^2 and integrate on Ω to obtain

$$\frac{1}{3}\frac{d}{dt}\int_\Omega u^3(x,t)dx + 2\int_\Omega d^{(1)}(x)u(x,t)\mid\nabla u\mid^2(x,t) + \int_\Omega k(x)u^4(x,t)dx \tag{2.27}$$

$$= \int_\Omega b(x)u^3(x,t)dx + \int_\Omega b(x)w(x,t)u^2(x,t)dx + 2\int_\Omega u^2(x,t)\overline{c}^{(1)}(x).\nabla u(x,t)dx$$

$$\leq b_1\left[\int_\Omega u^3(x,t)dx + \left(\int_\Omega w^2(x,t)\right)^{\frac{1}{2}}\left(\int_\Omega u^4(x,t)\right)^{1/2}\right]$$

$$+2\parallel \overline{c}^{(1)}\parallel_{\infty,\Omega}\left[\left(\int_\Omega u^4(x,t)\right)^{1/2}\left(\int_\Omega\mid\nabla u\mid^2(x,t)dx\right)^{1/2}\right].$$

From this we may obtain

$$\begin{array}{l} u(\ ,t)\in L_3(\Omega) \text{ for } t\in[0,T_{\max}),\\ u\in L_4(Q(0,T)) \text{ for } T\in[0,T_{\max}),\end{array} \tag{2.28}$$

and $C_4, C_5 \in C(\mathbb{R}_+)$ so that

$$\begin{array}{l} \parallel u(\ ,t)\parallel_{3,\Omega}\leq C_4(t) \text{ for } t\in[0,T_{\max})\\ \parallel u\parallel_{4,Q(0,T)}\leq C_5(T) \text{ for } T\in[0,T_{\max})\end{array}, \tag{2.29}$$

We now consider the second equation of (2.11): multiply by v to obtain

$$\frac{1}{2}\frac{d}{dt}\int_\Omega v^2(x,t)dx + \int_\Omega d^{(2)}(x)\mid\nabla v\mid^2(x,t)dx + k_0\int_\Omega v^3(x,t)dx \tag{2.30}$$

$$\leq \pi\parallel\sigma\parallel_{\infty,\Omega}\left[\int_\Omega v^2(x,t)dx + \int_\Omega u(x,t)v^2(x,t)dx\right]$$

$$+\parallel\overline{c}^{(2)}\parallel_{\infty,\Omega}\left[\int_\Omega v^2(x,t)dx\right]^{1/2}\left[\int_\Omega\mid\nabla v\mid^2(x,t)dx\right]^{1/2},$$

and integrate and apply Young's inequality to obtain $d_0>0, \tilde{k}>0, \tilde{c}>0$ so that

$$\frac{1}{2}\int_\Omega v^2(x,t)dx + d_0\int_0^t\int_\Omega\mid\nabla v\mid^2(x,t)dxdt + \tilde{k}\int_0^t\int v^3(x,t)dxdt \tag{2.31}$$

$$\leq \pi\parallel\sigma\parallel_{\infty,\Omega}\left[\int_0^t\int_\Omega v^2(x,t)dxdt + \int_0^t\int_\Omega u^3(x,t)dxdt\right]$$

$$+\tilde{c}\int_0^t\int_\Omega v^2(x,t)dxdt + \frac{1}{2}\int_\Omega v_0^2(x)dx.$$

We thereby obtain time dependent estimates for $\|v(\ ,t)\|_{2,\Omega}$, $\|v\|_{3,Q(0,T)}$, and $\||\nabla v|\|_{2,Q(0,T)}$ in the same manner as these estimates were obtained for u. Estimates for $\|v(\ ,t)\|_{3,\Omega}$ and $\|v\|_{4,Q(0,T)}$ can be obtained by multiplying the second equation of (2.11) by v^2. We now multiply the third equation of (2.11) by w and use the estimates already obtained to produce estimates for $w(,t)$ in $L_3(\Omega)$ and $\mid \nabla w \mid$ in $L_2(Q(0,T))$. With these estimates in hand one proceeds to multiplying the third equation of (2.11) by w^2 to obtain estimates for $w(\ ,t)$ in $L_4(\Omega)$ and w in $L_4(Q(0,T))$.

We can now return to the first and second equations of (2.11) and multiplying by u^4 and v^4, respectively, to produce estimates on $u(\ ,t)$ in $L_5(\Omega)$ and u in $L_6(Q(0,T))$ and on $v(\ ,t)$ in $L_5(\Omega)$ and $v \in L_6(Q(0,T))$. We now have the requisite bound on u,v,w to ensure that each of three components of $F(x,u,v,w)$ is bounded in $L_3(Q(0,T))$. This allows us to apply the powerful regularity theory for parabolic equations with discontinuous coefficients in Ladyzhenskaya, Solonnikov, and Ural'ceva [20] to guarantee the existence of our desired $M(t)$ and complete our argument since $\Omega \subset \mathbb{R}^2$.

We point out that the discontinuity in the diffusitivities $d^{(i)}(x)$ prevented us from applying standard regularity theorems for reaction diffusion systems.

We find that we can also obtain uniform $L_\infty(\Omega)$ estimates.

THEOREM 2. *If* $u_0, v_0, w_0 \in C(\overline{\Omega})$ *are nonnegative and* $u(x,t), v(x,t)$*, and* $w(x,t)$ *are globally defined solutions to* (2.11)–(2.15), *then there exists a positive constant* $M_0 = M_0(u_0,v_0,w_0)$ *(independent of t) so that*

$$\max_{t>0}\{\| u(\ ,t) \|_{\infty,\Omega}, \| v(\ ,t) \|_{\infty,\Omega}, \| w(\ ,t) \|_{\infty,\Omega}\} \leq M_0.$$

Proof. If we examine the arguments of the previous global existence results and Lemma 1, we may observe that these arguments can be adapted to produce estimates for u,v,w in $L_2(Q(\tau,\tau+\tau^*))$ for any $(\tau,\tau+\tau^*) \subset [0,\infty)$ and that if τ is chosen sufficiently large, then these estimates can be chosen independent of the initial data. More specifically, we can find a uniform constant $C(2,\tau^*)$ so that

$$\max\{\| u \|_{2,Q(\tau,\tau+\tau^*)}, \| v \|_{2,Q(\tau,\tau+\tau^*)}, \| w \|_{2,Q(\tau,\tau+\tau^*)}\} \leq C(2,\tau^*).$$

Moreover, these estimates can be bootstrapped to uniform space time cylinder estimates for $u, v \in L_6(Q(\tau,\tau+\tau^*))$ and $w \in L_3(Q(\tau,\tau+\tau^*))$, i.e., we will have constants $C(6,\tau^*)$ and $C(3,\tau^*)$ so that

$$\max\{\| u \|_{6,Q(\tau,\tau+\tau^*)}, \| v \|_{6,Q(\tau,\tau+\tau^*)}\} \leq C(6,\tau^*) \tag{2.32}$$

and

$$\| w \|_{3,Q(\tau,\tau+\tau^*)} \leq C(3,\tau^*). \tag{2.33}$$

We can now use (2.10) and (2.22) to find a uniform constant $K(3,\tau^*)$ so that each component

$$\| F_i(\ ,u,v,w) \|_{3,Q(\tau,\tau+\tau^*)} \leq K(3,\tau^*) \qquad \text{for } i = 1 \text{ to } 3.$$

The regularity results of [20] for parabolic equations of the form

$$\partial z/\partial t = \operatorname{div}(d(x)\nabla z + z\overline{a}(x)) + f(x,t)$$

having discontinuous coefficients in $\Omega \subset \mathbb{R}^2$ are dependent upon the L_3 space time cylinder norm of f and the $L_\infty(\Omega)$ norm of the initial data as well as the time height of space time cylinder.

We shall solve initial value problems on short time intervals and avoid the difficulty of needing to use the $L_\infty(\Omega)$ norm of initial values using the legerdomain of constructing an auxiliary function which agrees with our unknowns on intervals but cuts off the initial value. To be more precise, we let $\varphi(t)$ be a continuously differentiable nonnegative function defined on $\mathbb{R}$ having the properties that

$$\begin{aligned} &\varphi(s) = 0 \qquad \text{for } s \leq 0,\\ &\varphi(s) = 1 \qquad \text{for } s > 1,\\ &\varphi'(s) \geq 0 \qquad \text{for } s \in (0,1). \end{aligned} \tag{2.34}$$

We shall confine our attention to the first equation. We define

$$\rho(x,t) = \varphi(t-\tau)u(x,t)$$

and observe that if $\tau \geq 0$, then the function $\rho(x,t) = u(x,t)$ for $t \in [\tau+1, \tau+2]$ and that $\rho(x,\tau) = 0$. If we differentiate ρ with respect to t, we obtain

$$\begin{aligned} \partial\rho/\partial t &= \varphi'(t-\tau)u + \operatorname{div}(d^{(1)}(x)\nabla\rho - \rho\bar{c}^{(1)}(x)) + \varphi(t-\tau)F_1(x,u,v,w)\\ &= \operatorname{div}(d^{(1)}(x)\nabla\rho - \rho\bar{c}^{(1)}(x)) + g(x,t) \end{aligned}$$

with

$$d^{(1)}(x)\partial\rho/\partial\eta - \rho c^{(1)} \cdot \eta = 0, \qquad x \in \partial\Omega, t \geq 0,$$

and

$$\rho(x,\tau) = 0.$$

Moreover, we clearly have uniform estimates for $u, v \in L_6(Q(\tau,\tau+2))$ and $w \in L_3(Q(\tau,\tau+2))$. These yield $L_\infty(Q(\tau,\tau+2))$ estimates for $\rho(x,t)$ and hence uniform $L_\infty(Q(\tau+1,\tau+2))$ estimates for $u(x,t)$. Hence, since

$$\| u \|_{\infty,Q(0,\infty)} \leq \max\left[\| u \|_{\infty,Q(0,1)}, \| u \|_{\infty,Q(1,\infty)}\right],$$

we have a uniform sup norm bound for u. Identical arguments work for v and w.

3. Long term behavior. Given the high degree of spatial heterogeneity of these systems, we cannot expect to obtain explicit statements describing the long term asymptotic behavior of solutions. Nevertheless, some results along these lines are possible. We begin by obtaining a priori gradient estimates.

LEMMA 2. *If u, v, w are classical nonnegative solutions to* (2.11)–(2.15), *then there exist a q $(2 < q < \infty)$ and a constant $C^*(q)$ so that for $t \in (\varepsilon, \infty)$*

$$\max_{t>\varepsilon}\{\| |\nabla u|(,t) \|_{q,\Omega},\ \| |\nabla v|(,t) \|_{q,\Omega},\ \| |\nabla w|(,t) \|_{q,\Omega}\} \leq C^*(q). \tag{3.1}$$

Proof. We return to (2.11) and use the uniform a priori estimates on the L_∞ norms of the state variables u, v, w together with the uniform cylinder estimates for $p(x,t)$ in $L_2(Q(\tau,\tau+\tau^*))$ to obtain uniform estimates for the nonlinear terms $F_i(x,u,v,w)$ in $L_2(Q(\tau,\tau+\tau^*))$. The application of Meyer's lemma for parabolic equations with discontinuous coefficients (see Bensoussan, Lions, and Papanicolaou [1]) will guarantee the existence of a q $(2 < q < \infty)$ so that $|\nabla u|, |\nabla v|$, and $|\nabla w|$ are uniformly bounded in $W_q^1(Q(\tau,\tau+\tau^*)$. Hence there exists a $C_q(\tau^*)$ so that

$$\max\{\| |\nabla u| \|_{q,Q(\tau,\tau+\tau^*)}, \| |\nabla v| \|_{q,Q(\tau,\tau+\tau^*)}, \| |\nabla w| \|_{q,Q(\tau,\tau+\tau^*)}\} \leq C_q(\tau^*). \tag{3.2}$$

We now differentiate our equations with respect to t. Setting $\theta = \partial u/\partial t$, $\varphi = \partial v/\partial t$, and $\psi = \partial w/\partial t$, we obtain

(3.3)

$$\begin{aligned}
\partial\theta/\partial t \; &= \operatorname{div}(d^{(1)}\nabla\theta - \theta\overline{c}^{(1)}) - \chi\sigma(1/p)(v\theta + u\varphi) + \chi\sigma(uv/p^2)(\theta + \varphi + \psi) \\
&\quad -(1-\chi)\sigma(v\theta + u\varphi) + b(\theta + \psi) - (m + kp)\theta - k(\theta + \varphi + \varphi)u, \\
\partial\varphi/\partial t \; &= \operatorname{div}(d^{(2)}\nabla\varphi - \varphi\overline{c}^{(2)}) + \pi\chi\sigma(1/p)(v\theta + u\varphi) - \pi\chi\sigma(uv/p^2)(\theta + \varphi + \psi) \\
&\quad +\pi(1-\chi)\sigma(v\theta + u\varphi) - (m + kp)\varphi - k(\theta + \varphi + \psi)v - \alpha\varphi, \\
\partial\psi/\partial t \; &= \operatorname{div}(d^{(3)}\nabla\psi - \psi\overline{c}^{(3)}) + (1-\pi)\chi\sigma(1/p)(v\theta + u\varphi) \\
&\quad -(1-\pi)\chi\sigma(uv/p^2)(\theta + \varphi + \psi)) + (1-\pi)(1-\chi)\sigma(v\theta + u\varphi) \\
&\quad -(m + kp)\psi - k(\theta + \varphi + \psi)v.
\end{aligned}$$

For notational convenience we let $\mathcal{L}_j(\rho) = \operatorname{div}(d^{(j)}\nabla\rho - \rho\overline{c}^{(j)})$. If we multiply the first equation of (2.11) through by $\partial u/\partial t$, we obtain

$$(\partial u/\partial t)^2 = \mathcal{L}_1(u)\partial u/\partial t + F_1(, u, v, w)\partial u/\partial t,$$

implying

$$(\partial u/\partial t)^2 \leq \mathcal{L}_1(u)\partial u/\partial t + K/\delta + \delta\left(\frac{\partial u}{\partial t}\right)^2 \tag{3.4}$$

for any $\delta > 0$ and appropriately chosen $K > 0$. Integration of this inequality and use of routine calculations will produce a uniform constant $C(\tau^*)$ so that for $\tau > \varepsilon$

$$\| \theta \|_{2,Q(\tau,\tau+\tau^*)} \leq C(\tau^*).$$

Analogous arguments produce uniform $L_2(Q(\tau, \tau + \tau^*))$ estimates for φ and ψ. We now return to (3.3) and observe that θ, φ, ψ satisfy

$$\begin{aligned}
\partial\theta/\partial t &= \mathcal{L}_1(\theta) + g_1(x, t), \\
\partial\varphi/\partial t &= \mathcal{L}_2(\varphi) + g_2(x, t), \\
\partial\psi/\partial t &= \mathcal{L}_3(\psi) + g_3(x, t),
\end{aligned} \tag{3.5}$$

with $g_i(,)$ uniformly bounded in $L_2(Q(\tau, \tau + \tau^*))$. We may again apply Meyer's lemma [1] to observe that φ, θ, ψ are uniformly bounded in $W_q^1(Q(\tau, \tau + \tau^*))$ for some $2 < q < \infty$. Therefore, there exists a constant $C_q(\tau^*)$ so that

$$\max\{\| \, |\nabla\theta| \, \|_{q,Q(\tau,\tau+\tau^*)}, \; \| \, |\nabla\varphi| \, \|_{q,Q(\tau,\tau+\tau^*)}, \; \| \, |\nabla\psi| \, \|_{q,Q(\tau,\tau+\tau^*)}\} \leq C_q(\tau^*). \tag{3.6}$$

We now take the minimum of the two q's for (3.2) and (3.6) and obtain uniform estimates for $|\nabla u|, |\nabla\partial u/\partial t|, |\nabla v|, |\nabla\partial v/\partial t|, |\nabla w|, |\nabla\partial w/\partial t|$ in $L_q(Q(\tau, \tau + \tau^*))$ for some $q > 2$.

It is now a simple matter to construct a priori bounds for $|\nabla u|(t)$, $|\nabla v|(t)$, and $|\nabla w|(t)$ in $L_q(\Omega)$. To see this, define

$$g(t) = \int_\Omega |\nabla u(x, t)|^q dx.$$

Then the estimates above imply $g \in W_q^1(\tau, \tau + 1)$ for every $\tau > 0$. Therefore, from the Sobolev imbedding theorem g is bounded. The same arguments can be applied to v and w. □

Each of the differential operators $\partial/\partial t - \mathcal{L}_i(\ )$, $i = 1$ to 3, can be used to define an analytic semigroup $\{T_p^i(t)/t \geq 0\}$ with infinitesimal generator A_p^i. Although the semigroup $\{T_p^i(t)/t \geq 0\}$ does not make initial data infinitely smooth, we do have the property that $T_p^i(t) : L_p(\Omega) \to D(A_p)$ for $t > 0$. Since our unknowns u, v, and w are bounded, the mappings $F_i(,)$ defining the epidemiological kinetics can be shown to be Lipschitz in $L_p(\Omega)$, and we can realize solutions to our systems as strong $L_p(\Omega)$ solutions to

$$\begin{aligned}
du/dt - A_p^1 u &= F_1(\cdot, v, v, w),\\
dv/dt - A_p^2 v &= F_2(\cdot, u, v, w),\\
dw/dt - A_p^3 w &= F_3(\cdot, u, v, w),
\end{aligned}\tag{3.7}$$

which have a variation of parameters representation:

$$\begin{aligned}
u(t) &= T_p^1(t)u_0 + \int_0^t T_p^1(t-s)F_1(\cdot, u(s), v(s), w(s))ds,\\
v(t) &= T_p^2(t)w_0 + \int_0^t T_p^2(t-s)F_2(\cdot, u(x), v(s), w(s))ds,\\
w(t) &= T_p^3(t)w_0 + \int_0^t T_p^3(t-s)F_3(\cdot, u(s), v(s), w(s))ds.
\end{aligned}\tag{3.8}$$

We can use standard semigroup theory to guarantee the local existence of nonnegative strong solutions for (3.7) if our initial data (u_0, v_0, w_0) lies in the positive cone of any $L_p(\Omega)$. We can use the regularity of the theory of parabolic equations with discontinuous coefficients [19] to argue that these local strong solutions are classical solutions which can be extended globally by use of a priori estimates.

Moreover, we can define a semidynamical system on the positive cone of any $(L_p(\Omega))^+$ by defining

$$U^p(t)[u_0, v_0, w_0]^T = [u(\ ,t), v(\ ,t), w(\ ,t)]^T,$$

where $u(\ ,t), v(\ ,t), w(\ ,t)$ are solutions to (3.7) and

$$u(x,0) = u_0(x), v(x,0) = v_0(x), w(x,0) = w_0(x).$$

We recall that a compact subset $\mathcal{A}$ is said to be a global attractor for a semidynamical system $U(t)$ defined on the positive cone X^+ of a Banach space X if $\mathcal{A}$ is forward invariant under the action of $U(t)$ and if for all $z_0 \in X^+$ we have

$$\lim_{t\to\infty} \delta(U(t)z_0, \mathcal{A}) = 0,$$

where $\delta(\ ,\ )$ is the Hausdorff metric on compact subsets of X.

We have the following result.

THEOREM 3. *If* $(u_0, v_0, w_0) \in (L_2(\Omega))^3_+$ *and* $u(\ ,t), v(\ ,t), w(\ ,t)$ *are the corresponding solutions to* (2.11)–(2.15), *then the trajectories* $\Theta = \{u(\ ,t), v(\ ,t), w(\ ,t) \mid t \geq 0\}$ *are precompact in* $L_2(\Omega)$, *and each triple of initial data* $(u_0, v_0, w_0) \in (L_2(\Omega))^3_+$ *has a compact connected forward invariant* ω*-limit set* $\omega(u_0, v_0, w_0)$. *Moreover, the semidynamical system defined as* $U(t)(u_0, v_0, w_0)^T = (u(,t), v(,t), w(,t))$ *has a global attractor* $\mathcal{A}$ *in* $(L_2(\Omega))^3_+$.

Proof. The existence of the ω-limit set is an immediate consequence of the fact that the trajectory Θ is contained in a bounded subset of $(W_q^1(\Omega))^3, q > 2$, which is compactly embedded in $(L_2(\Omega))^3$. Here we are applying standard results from the theory of semidynamical systems in functions spaces (see Hale [13]); the existence of a global attractor follows from compactness and the fact that eventually solution trajectories are uniformly bounded in $L_\infty(\Omega)$ (see Fitzgibbon, Langlais, and Morgan [8]). $\square$

4. Approximations. It is possible to approximate the compartmental model (2.11)–(2.15) by a sequence of traditional reaction diffusion models of the form

$$\begin{aligned} &\partial u_n/\partial t = \operatorname{div}(d_n^{(1)}(x)\nabla u_n - u_n\overline{c}_n^{(1)}(x)) + F_1^n(x,u_n,v_n,w_n),\\ &\partial v_n/\partial t = \operatorname{div}(d_n^{(2)}(x)\nabla v_n - v_n\overline{c}_n^{(2)}(x)) + F_2^n(x,u_n,v_n,w_n), \qquad x\in\Omega, t>0,\\ &\partial w_n/\partial t = \operatorname{div}(d_n^{(3)}(x)\nabla w_n - w_n\overline{c}_n^{(3)}(x)) + F_3^n(x,u_n,v_n,w_n), \end{aligned} \tag{4.1}$$

with homogeneous Neumann boundary conditions

$$\begin{aligned} &d_n^{(1)}\partial u_n/\partial\eta - u_n\overline{c}_n^{(1)}\cdot\eta = 0,\\ &d_n^{(2)}\partial v_n/\partial\eta - v_n\overline{c}_n^{(2)}\cdot\eta = 0, \quad x\in\partial\Omega, t>0,\\ &d_n^{(3)}\partial w_n/\partial\eta - w_n\overline{c}_n^{(3)}\cdot\eta = 0, \end{aligned} \tag{4.2}$$

and initial conditions (nonnegative and continuous on $\overline{\Omega}$)

$$u_n(x,0) = u_0(x), \quad v_n(x,0) = v_0(x), \quad w_n(x,0) = w_0(x), \quad x\in\Omega. \tag{4.3}$$

The diffusitivities $d_n^{(i)}(x)$ are assumed to be continuous on $\overline{\Omega}$ with

$$0 < \underline{d} \le d_n^{(i)}(x) \le \overline{d} \ \text{ for } i = 1 \text{ to } 3,\ x\in\Omega,\ n\in\mathbb{Z}^+,$$

and we assume that advection fields $\overline{c}_n^{(i)}(x)$ are continuous on $\overline{\Omega}$. The kinetic terms have the form

$$F^n(x,u,v,w) = \begin{pmatrix} -f_n(x,u,v,w) + b(x)(u+w) - (m(x)+k(x)p)u,\\ \pi f_n(x,u,v,w) - \alpha(x)v - (m(x)+k(x)p)v,\\ (1-\pi)f_n(x,u,v,w) - (m(x)+k(x)p)w \end{pmatrix} \tag{4.4}$$

with incidence term

$$f_n(x,u,v,w) = \chi_n(x)\sigma_n(x)uv/(u+v+w) + (1-\chi_n(x))\sigma_n(x)uv, \tag{4.5}$$

where $\chi_n(\ )$ and $\sigma_n(\ )$ belong to $C(\overline{\Omega})$, $\sigma_n(\ )$ being strictly positive and $0\le\chi_n(\ )\le 1$ on $\overline{\Omega}$.

We shall assume the following:

(A$_1$) The approximating terms $d_n^{(i)}(\ )$, $\chi_n(\ )$, and $\sigma_n(\ )$ are uniformly bounded in $L_\infty(\Omega)$;

(A$_2$) $\lim\limits_{n\to\infty} d_n^{(i)}(x) = d^{(i)}(x)$ for a.e. $x\in\Omega$, $i = 1$ to 3,

$\lim\limits_{n\to\infty} \overline{c}_n^{(i)} = \overline{c}^{(i)}$ in $C(\overline{\Omega})$, $i = 1$ to 3,

$\lim\limits_{n\to\infty} \sigma_n(x) = \sigma(x)$ for a.e. $x\in\Omega$,

$\lim\limits_{n\to\infty} \chi_n(x) = \chi(x)$ for a.e. $x\in\Omega$.

The elliptic operators $\mathrm{div}(d_n^{(i)}(x)\nabla z - z\overline{c}_n^{(i)}(x))$ can be used to specify infinitesimal generators A_n^i of analytic semigroups $\{T_n^i(t) \mid t \geq 0\}$ in the spaces $L_p(\Omega)$ $(p > 1)$ and $C(\overline{\Omega})$. Here we shall with some abuse of notation suppress the particular function space dependence of the generators and semigroups. Solutions to (4.1)–(4.3) may be represented as

$$\begin{aligned} u_n(\cdot,t) &= T_n^1(t)u_0 + \int_0^t T_n^1(t-s)F_n^1(\cdot,u_n(,s),v_n(,s),w_n(,s))ds,\\ v_n(\cdot,t) &= T_n^2(t)v_0 + \int_0^t T_n^2(t-s)F_n^2(\cdot,u_n(,s),v_n(,s),w_n(,s))ds, \qquad (4.6)\\ w_n(\cdot,t) &= T_n^3(t)w_0 + \int_0^t T_n^3(t-s)F_n^3(\cdot,u_n(,s),v_n(,s),w_n(,s))ds. \end{aligned}$$

We have pointed out that solutions to (2.11)–(2.15) can be represented by the Duhamel formulae

$$\begin{aligned} u(\cdot,t) &= T^1(t)u_0 + \int_0^t T^1(t-s)F^1(\cdot,u(,s),v(,s),w(,s))ds,\\ v(\cdot,t) &= T^2(t)v_0 + \int_0^t T^2(t-s)F^2(\cdot,u(,s),v(,s),w(,s))ds, \qquad (4.7)\\ w(\cdot,t) &= T^3(t)w_0 + \int_0^t T^3(t-s)F^3(\cdot,u(,s),v(,s),w(,s))ds. \end{aligned}$$

We have the following approximation theorem.

Theorem 4. *If the approximation conditions* (A_1) *and* (A_2) *hold and the solutions to* (4.1)–(4.3) *are given by* $u_n(x,t)$, $v_n(x,t)$, *and* $w_n(x,t)$ *and the solution to the compartmental system is given by* $u(x,t)$, $v(x,t)$, $w(x,t)$, *then on any interval* $[0,T]$

$$\begin{aligned} &\lim_{n\to\infty} \| u_n(\cdot,t) - u(\cdot,t) \|_{2,\Omega} = 0,\\ &\lim_{n\to\infty} \| v_n(\cdot,t) - v(\cdot,t) \|_{2,\Omega} = 0,\\ &\lim_{n\to\infty} \| w_n(\cdot,t) - w(\cdot,t) \|_{2,\Omega} = 0 \qquad \textit{for } t \in [0,T]. \end{aligned}$$

Proof. We shall establish subsequence convergence which will show that any sequence has a subsequence converging to a solution of (2.11)–(2.15). However, uniqueness of the limit guarantees that the subsequential convergence is in fact convergence. If we return to estimates producing Lemma 1, we see that our estimates guarantee a priori $L_\infty(\Omega)$ bounds and $L_2(\Omega)$ gradient bounds which depend only upon the size of the diffusion coefficients and the initial data, and the bounds for the birth rate and logistic coefficients.

Therefore, we can obtain uniform bounds for $\| |\nabla u_n|(,t) \|_{2,\Omega}, \| |\nabla v_n|(,t) \|_{2,\Omega}$, and $\| |\nabla w_n|(,t) \|_{2,\Omega}$, and hence for each $t \in [0,T]$ the solutions lie in a bounded subset of $H^1(\Omega)$. Because $H^1(\Omega)$ is compactly embedded in $L_2(\Omega)$, a standard application of the Arzela–Ascoli lemma will guarantee the convergence of a subsequence $u_{n'}(,t), v_{n'}(,t), w_{n'}(,t)$ in $L_2(\Omega)$ to a limiting function $(u^*(\ ,t), v^*(\ ,t), w^*(\ ,t))$. This subsequence has a subsequence $(u_{n''}(\ ,t), v_{n''}(\ ,t), w_{n''}(\ ,t))$ which converges pointwise a.e. to $(u^*(\ ,t), v^*(\ ,t), w^*(\ ,t))$. Standard semigroup approximation theory (see Pazy [24]) will insure the strong convergence of $T_n^1(t), T_n^2(t)$, and $T_n^3(t)$ to $T^1(t), T^2(t)$, and $T^3(t)$.

Moreover, we have pointwise a.e. convergence of $F_n^i(x, u_n(x,t), v_n(x,t), w_n(x,t))$ to the corresponding $F^i(x, u^*(x,t), v^*(x,t), w^*(x,t))$, and we can apply the Lebesgue convergence theorem to ensure convergence of $(u_{n''}, v_{n''}, w_{n''})$ to a solution of (4.7). The regularity theory of analytic semigroups guarantees that a solution to (4.7) is indeed a solution to (2.11)–(2.15). Because these solutions are unique, our proof is complete. □

5. Complex habitats with repeated microstructure. A different approximation is realized by averaging the effects of the complex local structure over the whole domain; by virtue of this approximation endeavor we obtain a global picture of the dynamics. More precisely, many habitats consist of more or less repeatedly interspersed fragmented subpatches. Here we shall attempt to isolate a subpatch $\Omega_\#$ of Ω and consider the fragmentation of Ω as being produced by a periodic reproduction of $\Omega_\#$. Although the scale of the microstructure of $\Omega_\#$ may be small in comparison with the scale of Ω, this microstructure can have a profound effect upon the global dynamics. Theoretically this situation can be described by the methods presented heretofore. However, from a practical computational point of view, the microstructure of the domain may be far too fine to track, and it becomes reasonable to implement homogenization techniques which average the effects of the local structure and predict the overall dynamics.

We commence with a mathematical formulation. We introduce a basic cell

$$\hat{\Omega} = \prod_{j=1}^{2} [0, Y_j^0] \subset \mathbb{R}^2. \tag{5.1}$$

A function $\varphi(\,) : \mathbb{R}^2 \to \mathbb{R}$ is said to be $\hat{\Omega}$ periodic if it admits a period Y_j^0 in the direction y_j, $j = 1, 2$. We let $d^{(1)}(y), d^{(2)}(y), d^{(3)}(y)$, $\chi(y), \sigma(y), \alpha(y), b(y), m(y), k(y)$ be functions satisfying the conditions of section 2 on $\hat{\Omega}$ with corresponding subregions $\hat{\Omega}_0, \hat{\Omega}_1, \ldots, \hat{\Omega}_K$. We extend $d^{(1)}(\,), d^{(2)}(\,), d^{(3)}(\,), \chi(\,), \sigma(\,), \alpha(\,), b(\,), m(\,), k(\,)$ periodically to $\mathbb{R}^2$ with the distinguished subregions being reproduced as well. We define

$$\begin{aligned} &d_\varepsilon^{(i)}(x) = d^{(i)}(x/\varepsilon), \\ &\overline{c}_\varepsilon^{(i)}(x) = \overline{c}^{(i)}(x/\varepsilon) \qquad \text{for } i = 1 \text{ to } 3,\ x \in \Omega, \end{aligned} \tag{5.2}$$

and

$$\begin{aligned} &\chi_\varepsilon(x) = \chi(x/\varepsilon), \quad \sigma_\varepsilon(x) = \sigma(x/\varepsilon), \\ &b_\varepsilon(x) = b(x/\varepsilon), \quad m_\varepsilon(x) = m(x/\varepsilon),\ k_\varepsilon(x) = k(x/\varepsilon), \\ &\alpha_\varepsilon(x) = \alpha(x/\varepsilon), \quad f_\varepsilon(x,u,v,w) = f(x/\varepsilon, u, v, w). \end{aligned} \tag{5.3}$$

In the same manner we get corresponding subregions $\Omega_{0,\varepsilon}, \Omega_{1,\varepsilon}, \ldots, \Omega_{K,\varepsilon}$.

For small ε we consider the system of partial differential equations

(5.4)

$$\begin{aligned} \partial u_\varepsilon/\partial t &= \operatorname{div}(d_\varepsilon^{(1)} \nabla u_\varepsilon - u_\varepsilon \overline{c}_\varepsilon^{(1)}) - f_\varepsilon(u_\varepsilon, v_\varepsilon, w_\varepsilon) + b_\varepsilon(u_\varepsilon + w_\varepsilon) - (m_\varepsilon + k_\varepsilon p_\varepsilon) u_\varepsilon, \\ \partial v_\varepsilon/\partial t &= \operatorname{div}(d_\varepsilon^{(2)} \nabla v_\varepsilon - v_\varepsilon \overline{c}_\varepsilon^{(2)}) + \pi f_\varepsilon(u_\varepsilon, v_\varepsilon, w_\varepsilon) - \alpha_\varepsilon v_\varepsilon - (m_\varepsilon + k_\varepsilon p_\varepsilon) v_\varepsilon, \\ \partial w_\varepsilon/\partial t &= \operatorname{div}(d_\varepsilon^{(3)} \nabla w_\varepsilon - w_\varepsilon \overline{c}_\varepsilon^{(3)}) + (1-\pi) f_\varepsilon(u_\varepsilon, v_\varepsilon, w_\varepsilon) - (m_\varepsilon + k_\varepsilon p_\varepsilon) w_\varepsilon \end{aligned}$$

with no flux boundary conditions

$$\begin{aligned} &d_\varepsilon^{(1)}\partial u_\varepsilon/\partial\eta - u_\varepsilon \bar{c}_\varepsilon^{(1)}\cdot\eta = 0,\\ &d_\varepsilon^{(2)}\partial v_\varepsilon/\partial\eta - v_\varepsilon \bar{c}_\varepsilon^{(2)}\cdot\eta = 0, \qquad x\in\partial\Omega,\\ &d_\varepsilon^{(3)}\partial w_\varepsilon/\partial\eta - w_\varepsilon \bar{c}_\varepsilon^{(3)}\cdot\eta = 0, \end{aligned} \tag{5.5}$$

and compatibility conditions

$$[u_\varepsilon]_{\partial\Omega_{l,\varepsilon}} = [v_\varepsilon]_{\partial\Omega_{l,\varepsilon}} = [w_\varepsilon]_{\partial\Omega_{l,\varepsilon}} = 0, \qquad l = 1,\dots,K, \tag{5.6}$$

$$[d_\varepsilon^{(1)}\partial u_\varepsilon/\partial\eta]_{\partial\Omega_{l,\varepsilon}} = [d_\varepsilon^{(2)}\partial v_\varepsilon/\partial\eta]_{\partial\Omega_{l,\varepsilon}} = [d_\varepsilon^{(3)}\partial w_\varepsilon/\partial\eta]_{\partial\Omega_{l,\varepsilon}} = 0$$

with $\partial\Omega_{l,\varepsilon}$ the interface between $\Omega_{l,\varepsilon}$ and $\Omega_{0,\varepsilon}$, $l = 1,\dots,K$.

We have initial conditions

$$u_\varepsilon(x,0) = u_0(x), \quad v_\varepsilon(x,0) = v_0(x), \quad w_\varepsilon(x,0) = w_0(x) \qquad \text{for } x\in\Omega. \tag{5.7}$$

A simple prototype of this scenario has been considered in Fitzgibbon, Langlais, and Morgan [9] and Heiser, Langlais, and Pontier [15]. We are guaranteed the existence of solutions to (5.4)–(5.7) by our existing theory, and our present concern shall be the behavior as $\varepsilon \downarrow 0$. A partial answer to this question is given by the following result.

Theorem 5. *For each $\varepsilon > 0$ and $T > 0$ there exists a globally defined unique classical solution triple to (5.4)–(5.7), $u_\varepsilon(x,t), v_\varepsilon(x,t), w_\varepsilon(x,t)$. There exist positive definite symmetric constant matrices $D_h^{(j)}$ and constant vector fields $\bar{c}_h^{(j)}$ depending solely on $d^{(j)}, \bar{c}^{(j)}, \Omega$, and $\hat{\Omega}$ for $j = 1$ to 3, constants*

$$\sigma = \frac{1}{|\,\hat{\Omega}\,|}\int_{\hat{\Omega}} \sigma(y)dy, \qquad \chi^\sharp = \frac{1}{\sigma}\frac{1}{|\,\hat{\Omega}\,|}\int_{\hat{\Omega}} \chi(y)\sigma(y)dy,$$

$$b = \frac{1}{|\,\hat{\Omega}\,|}\int_{\hat{\Omega}} b(y)dy, \qquad m = \frac{1}{|\,\hat{\Omega}\,|}\int_{\hat{\Omega}} m(y)dy, \qquad k = \frac{1}{|\,\hat{\Omega}\,|}\int_{\hat{\Omega}} k(y)dy,$$

and a function

$$f(u,v,w) = \chi^\sharp\sigma\frac{uv}{u+v+w} + (1-\chi^\sharp)\sigma uv$$

such that, as $\varepsilon \to 0$, $u_\varepsilon(\,,t), v_\varepsilon(\,,t), w_\varepsilon(\,,t)$ converges strongly in $L_2(0,T)$ to the classical solution $u(\,,t), v(\,,t), w(\,,t)$ of the homogenized system

$$\begin{aligned} &\partial u/\partial t = \operatorname{div}(D_h^{(1)}\nabla u - u\bar{c}_h^{(1)}) - f(u,v,w) + b(u+w) - (m+kp)u,\\ &\partial v/\partial t = \operatorname{div}(D_h^{(2)}\nabla v - v\bar{c}_h^{(2)}) + \pi f(u,v,w) - \alpha v - (m+kp)v,\\ &\partial w/\partial t = \operatorname{div}(D_h^{(3)}\nabla w - w\bar{c}_h^{(3)}) + (1-\pi) f(u,v,w) - (m+kp)w, \end{aligned} \tag{5.8}$$

with no flux boundary conditions

$$\begin{aligned} &\sum_{i,j=1}^{2} D_{h,ij}^{(1)}\frac{\partial u}{\partial x_i}\cos(\eta,x_j) - uc_h^{(1)}\cdot\eta = 0,\\ &\sum_{i,j=1}^{2} D_{h,ij}^{(2)}\frac{\partial v}{\partial x_i}\cos(\eta,x_j) - vc_h^{(2)}\cdot\eta = 0, \qquad x\in\partial\Omega, \quad t>0,\\ &\sum_{i,j=1}^{2} D_{h,ij}^{(3)}\frac{\partial w}{\partial x_i}\cos(\eta,x_j) - wc_h^{(3)}\cdot\eta = 0, \end{aligned} \tag{5.9}$$

and initial conditions

$$u(x,0)=u_0(x),\ v(x,0)=v_0(x),\ w(x,0)=w_0(x)\ \ \textit{for } x\in\Omega.$$

Proof. This result is obtained via applications of standard techniques developed in, e.g., Bensoussan, Lions, and Papanicolaou [1] and Jikov, Kozlov, and Oleinik [18]. We point out that standard arguments will yield the existence and uniqueness of solutions of the homogenized problem (c.f. Theorem 1).

The crucial step lies in using the result in Theorem 2 stating that

$$\max_{t>0}\{\parallel u_\varepsilon(,t)\parallel_{\infty,\Omega},\parallel v_\varepsilon(,t)\parallel_{\infty,\Omega},\parallel w_\varepsilon(,t)\parallel_{\infty,\Omega}\}\le M_0,$$

M_0 being a constant independent of ε for $0<\varepsilon\le 1$. Then it follows from integration by parts that for any fixed $T>0$ the solution triples $(u_\varepsilon,v_\varepsilon,w_\varepsilon)$ are bounded in the Sobolev space of order one $H^1(\Omega\times(0,T))$, independently of ε for $0<\varepsilon\le 1$. A compactness argument yields that they lie in a relatively compact subset of $L_2(\Omega\times(0,T))$. Hence there exists a sequence $(u_{\varepsilon'},v_{\varepsilon'},w_{\varepsilon'})$ converging to some limit (u,v,w) strongly in $L_2(\Omega\times(0,T))$ and weakly in $H^1(\Omega\times(0,T))$ as $\varepsilon'\to 0$.

Next it is well known that for any function $\varphi(\,):\mathbb{R}^2\to\mathbb{R}$ and $\hat\Omega$ periodic

$$\varphi_\varepsilon(\,)\rightharpoonup\mathcal{M}(\varphi)=\frac{1}{\mid\hat\Omega\mid}\int_{\hat\Omega}\varphi(y)dy,\quad\text{as }\varepsilon\to 0,$$

in a weak-star $L^\infty(\Omega)$ sense, i.e., for any $\psi\in L^1(\Omega)$

$$\int_\Omega\varphi_\varepsilon(x)\psi(x)dx\to\mathcal{M}(\varphi)\int_\Omega\psi(x)dx,\quad\text{as }\varepsilon\to 0.$$

From these two facts the convergence as $\varepsilon'\to 0$ of the kinetics on the right-hand sides of (5.4) toward the corresponding kinetics of (5.8) follows, weakly in $L_2(\Omega\times(0,T))$ and strongly in the dual space $[H^1(\Omega\times(0,T))]'$.

The goal of homogenization techniques is to handle the behavior of such quantities as $-\text{div}(d_\varepsilon^{(1)}\nabla u_\varepsilon-u_\varepsilon\overline{c}_\varepsilon^{(1)})$ when $\varepsilon\to 0$. Then one can show that there exist a positive definite symmetric matrix $D_h^{(1)}$ and a vector $\overline{c}_h^{(1)}$ depending solely on $d^{(1)},\overline{c}^{(1)},\Omega$, and $\hat\Omega$ such that upon extracting further subsequences

$$d_{\varepsilon''}^{(1)}\nabla u_{\varepsilon''}-u_{\varepsilon''}\overline{c}_{\varepsilon''}^{(1)}\rightharpoonup D_h^{(1)}\nabla u-u\overline{c}_h^{(1)}$$

weakly in $L_2(\Omega\times(0,T))$ as ε" $\to 0$; see [1] and [18]. Identical arguments work for the equations for v_ε and w_ε.

At this point the convergence of a suitable subsequence of $(u_\varepsilon,v_\varepsilon,w_\varepsilon)_{0<\varepsilon\le 1}$ toward a solution of (5.8) is established. A uniqueness argument ensures that this subsequential convergence is indeed convergence. □

Homogenized operators. We point out that computation of the homogenized diffusion operators is complicated. However, an algorithm using asymptotic expansions appears in [1] and [18].

In the one dimensional case some simplifications occur, and one has

$$D_h^{(j)}=\left[\mathcal{M}\left(\frac{1}{d^{(j)}}\right)\right]^{-1}\quad\text{and}\quad\overline{c}_h^{(j)}=D_h^{(j)}\left[\mathcal{M}\left(\frac{\overline{c}^{(j)}}{d^{(j)}}\right)\right],\ j=1\cdots 3.$$

In the two dimensional case one must first compute a set of auxiliary functions, namely, $\chi_l^{(j)}$ and $\xi^{(j)}$, $\hat{\Omega}$ periodic members of $H^1(\hat{\Omega})$ and solutions of

$$\begin{aligned} &-\operatorname{div}(d^{(j)}(y)\nabla\chi_l^{(j)}) = \frac{\partial d^{(j)}(y)}{\partial y_l},\\ &-\operatorname{div}(d^{(j)}(y)\nabla\xi^{(j)}) = -\operatorname{div}(\overline{c}^{(j)}), \qquad j = 1\cdots 3, \quad l = 1, 2. \end{aligned}$$

These nine functions are uniquely defined up to a constant; note that $\xi^{(j)}$ is a constant when $\operatorname{div}(\overline{c}^{(j)}) = 0$. The entries of the three matrices $D_h^{(j)}$ are

$$D_{h,il}^{(j)} = \begin{cases} \mathcal{M}(d^{(j)}) + \mathcal{M}\left(d^{(j)}\dfrac{\partial\chi_i^{(j)}}{\partial y_i}\right) & \text{for } l = i,\\ \mathcal{M}\left(d^{(j)}\dfrac{\partial\chi_l^{(j)}}{\partial y_i}\right) & \text{for } l \neq i, \end{cases}$$

for $j = 1$ to 3; hence these matrices may not be diagonal. The entries of the three constant vectors $c_h^{(j)}$ are

$$\overline{c}_{h,i}^{(j)} = \mathcal{M}(\overline{c}_i^{(j)}) - \mathcal{M}\left(d^{(j)}\frac{\partial\xi^{(j)}}{\partial y_i}\right), \ i = 1, 2, \quad j = 1\cdots 3.$$

Note that $\overline{c}_h^{(j)} = \mathcal{M}(\overline{c}^{(j)})$ when $\operatorname{div}(\overline{c}^{(j)}) = 0$.

6. Concluding consideration. We feel that the notions of compartmental diffusion and homogenization are important for the spatial spread of infectious disease within complex highly spatially heterogeneous habitats. Heretofore, standard Fickian diffusion has been used to describe the space time evolution or progation within homogeneous habitats supporting spatially distributed habitats. Indeed, one can incorporate heterogeneity in diffusion and transport terms; however, one expects diffusion smoothing to regularize these effects. We also feel that diffractive or compartmental diffusion offers many other interesting applications within the reaction diffusion context.

THE NISHIURA–OHNISHI FREE BOUNDARY PROBLEM IN THE 1D CASE*

PAUL C. FIFE† AND DANIELLE HILHORST‡

Abstract. A free boundary problem due to Nishiura and Ohnishi is solved in one space dimension. That problem was derived, during their study of phase separation phenomena in diblock copolymers, as an asymptotic limit of pattern-forming PDEs generalizing that of Cahn and Hilliard. The free boundary problem in one dimension reduces to a linear system of ODEs for the lengths of the intervals between interfaces. This system also arises in a completely different context as the spatial discretization of a simple heat equation in a medium with periodic properties. (The medium is homogeneous in an important special case.) The initial-value problem for this system is completely solved, and global stability results for stationary solutions (in which the interfaces are regularly spaced) are obtained. Nucleation phenomena are briefly discussed.

Key words. discrete heat equation, free boundary problem, diblock copolymers, global stability

1. Introduction.

Pattern-forming phenomena in block copolymer melts have been the subject of a number of field-theoretic models and analyses. Equilibrium models based on a free energy functional were given by Leibler [4], Ohta and Kawasaki [7], and Kawasaki, Ohta, and Kohrogui [3]. Bahiana and Oono [1] suggested a phenomenological cell dynamical system leading to an evolutionary PDE for the composition $u(x,t)$ of the melt as a function of space and time. In [5], a similar PDE was proposed by Nishiura and Ohnishi as a gradient (steepest descent) flow for a free energy functional $E^\epsilon[u]$, generalizing that of Ginzburg and Landau, of the type appearing in [7, 3]. This PDE was investigated in [5, 6].

In [5] the authors also derived formally a limit free boundary problem (FBP) as a parameter ϵ in the equation approaches zero. This limiting process was investigated rigorously by Henry [2] for radial solutions in three dimensions. The local and global minimizers of E^ϵ and of related functionals in one space dimension were considered by Ren and Wei [9, 10] and by Ohnishi et al. [8]. In [9], the local minimizers for small ϵ were found to be close, in the L^2 sense, to piecewise constant functions whose intervals of constancy alternated in length. Among them, the global minimizers were specified. In [8, 10], the global minimizers of a rescaled free energy functional were characterized.

In this paper we concentrate on the evolution the FBP and show that in one dimension it reduces to a linear homogeneous system of ODEs of a particularly simple type. The variables in this system are the interval lengths between the discrete interfaces. The system is the same as that which arises as spatial discretization of a heat equation. The role of the space variable in the heat equation is taken, in

the context of the FBP, by the index ordering the positions of the intervals. Thus although the FBP is in general difficult and nonlinear, in one dimension it reduces in a remarkable way to a linear spatially discrete heat equation. This suggests that the FBP provides a very efficient way to "uniformize" a given set $\{x_n\}$ of interfaces. This point is discussed at the end of section 3.

The conversion of the FBP to a system of ODEs is given in section 3 after background considerations in section 2. The same problem for a finite interval can be reformulated as a periodic problem on the whole line. The problem on the whole real line with an infinite number of interfaces, periodic or not, is solved explicitly in section 4. In the periodic (i.e., finite interval) case the solution simplifies somewhat; this is shown in section 4.7. Since we wish the interval lengths to be positive, it is important to know whether any can collapse to zero, and it is shown in section 5 that collapsing is not possible.

All stationary solutions are found in section 6, where it is also shown how to construct certain other similarity solutions. Of special interest is a one-parameter family of stationary solutions with positive bounded interval lengths for each given average value $\bar{u}$ of the concentration variable. These solutions are those which were identified in [9] as approximating the local minimizers of the free energy when ϵ is small. The stability of stationary solutions is addressed in sections 7 (for the whole line) and 8 (for a bounded interval). In the latter case, unrestricted global stability is proved, and in the former it is shown that a wide class of initial data (not necessarily small) generate solutions converging to stationary solutions.

A kind of nucleation procedure (outside the context of the given FBP) is described in section 9, and a discussion related to various kinds of energy is given in section 10. The paper ends with some further remarks in section 11.

2. The FBP. The PDE model consists of the following equations for functions $u = u^\epsilon(x,t),\ v = v^\epsilon(x,t),\ w = w^\epsilon(x,t)$:

$$u_t = \Delta w, \tag{1}$$

$$w = -\left(\epsilon\Delta u - \frac{1}{\epsilon}f(u) - v\right), \tag{2}$$

$$-\Delta v = u - \bar{u}. \tag{3}$$

These equations are to hold in a bounded domain Ω, and Neumann boundary conditions for v, u, and w are prescribed on $\partial\Omega$. The quantity $\bar{u}$ is the average value of u; it can be seen by integrating (1) to be independent of time. Finally, the function $f(u) = F'(u)$, where typically $F(u) = \frac{1}{2}(1-u^2)^2$, although with little change it can be taken to be any C^1 function with minima of 0 assumed only at $u = \pm 1$. The actual system studied in [5, 6, 8, 10] was like (1)–(3), but with (2) replaced by

$$w = -(\hat{\epsilon}^2\Delta u - f(u) - \sigma v), \tag{4}$$

$\sigma = O(1)$. This system can be reduced to (1)–(3) by rescaling space, time, v, and w and by defining $\epsilon = \hat{\epsilon}^{2/3}$.

As mentioned before, there is an FBP obtained in [5] as an asymptotic approximation to (1)–(3) in some sense for small ϵ. It takes the following form in two dimensions; these equations extend immediately to any other dimension.

FBP. Given a curve Γ_0 separating the planar domain Ω into two parts $\Omega_0^\pm$, find $\Gamma(t)$, $w(x,t)$, and $v(x,t)$ for $t \geq 0$, with $\Gamma(t)$ separating the plane into domains $\Omega^\pm(t)$ satisfying

$$\Delta w = 0 \quad \text{in } \Omega^\pm(t), \tag{5}$$

$$\frac{\partial w}{\partial n} = 0 \quad \text{on } \partial\Omega, \tag{6}$$

$$V = -\frac{1}{2}\left[\frac{\partial w}{\partial n}\right] \quad \text{on } \Gamma(t), \tag{7}$$

$$K = \frac{3}{2}(w - v) \quad \text{on } \Gamma(t), \tag{8}$$

$$-\Delta v = u - \bar{u} \quad \text{in } \Omega, \tag{9}$$

$$\frac{\partial v}{\partial n} = 0 \quad \text{on } \partial\Omega, \tag{10}$$

$$u = \pm 1 \text{ in } \Omega^\pm(t), \tag{11}$$

and initial condition $\Gamma(0) = \Gamma_0$, where V is the normal velocity of Γ, K is its curvature (counted positive if the center of curvature lies on the Ω^+ side), and $\bar{u}$ is the average value of u over Ω.

The directional derivative in (7) is in the direction toward Ω^+, V is considered to be positive if motion is in that same direction, and the jump indicated there is the derivative on the positive (Ω^+) side minus that on the Ω^- side.

The rigorous connection between (1)–(3) and (5)–(11) was studied by Henry [2] in the case of radial solutions in three dimensions. Among other things, beginning with a sequence of energy-bounded solutions of (1)–(3) corresponding to a sequence of values of ϵ approaching 0, Henry showed that a subsequence converges to a weak solution of the FBP. This weak solution satisfies (8) at any point where there is a spatial jump in the limit function u between -1 and 1.

3. The one-dimensional (1D) case.

In one dimension the left side of (8) vanishes, and the problem is invariant under the scaling $x \to \gamma x, t \to t, w \to \gamma^2 w,\ v \to \gamma^2 v,\ u \to u$ for arbitrary γ. This implies that any stationary spatial solution of the FBP (pattern) filling the whole line can be expanded or contracted at will, and it will still be a stationary solution with the same stability properties. This appears to contradict the selection of a preferred spacing on the basis of energy minimization, as in [9] and in [8], but does not because the FBP does not allow the creation or deletion of interfaces, so that the spacing is usually predetermined from the initial data. See sections 8 and 11 for more on this issue.

Now let Ω be the interval $(0, L)$, and let $\Gamma(t)$ consist of N distinct ordered moving points $\{x_n(t)\}$, $n = 1, 2, \ldots, N$ contained in Ω.

Let $\nu_n = 1$ if u jumps from -1 to $+1$ as x_n is traversed from left to right (so that $(x_n, x_{n+1}) \in \Omega^+$), and let $\nu_n = -1$ if the jump is from $+1$ to -1. Note that ν_n is the value of u in (x_n, x_{n+1}); since $u = \pm 1$ in alternate intervals, $-\nu_n$ is the value of u in (x_{n-1}, x_n).

Let space derivatives be denoted by " $'$ " and time derivatives by " $\dot{}$ ". We also use the notation

$$v_n = v(x_n), \quad p_n = v'(x_n).$$

The equations corresponding to (5)–(10) are

$$w'(x) = \text{ const on } (x_n, x_{n+1}) \text{ for each } n = 1, \dots, N-1, \tag{12}$$

$$w'(x) = 0 \text{ on } (0, x_1) \text{ and } (x_N, L), \tag{13}$$

$$-2\nu_n \dot{x}_n = w'(x_n + 0) - w'(x_n - 0),\ n = 1, \dots, N, \tag{14}$$

$$w(x_n) = v(x_n) \quad \text{for all } n = 1, \dots, N, \tag{15}$$

$$v'' = \bar{u} - u, \tag{16}$$

$$v'(0) = v'(L) = 0. \tag{17}$$

Note that in (14), $\dot{x}_n$ represents ν_n times the velocity V in (7), $\frac{\partial}{\partial n} = \nu_n \frac{d}{dx}$, and $\left[\frac{\partial w}{\partial n}\right] = \nu_n \left[\frac{\partial w}{\partial n}|_{x_n+0} - \frac{\partial w}{\partial n}|_{x_n-0}\right] = w'(x_n + 0) - w'(x_n - 0)$.

It will be convenient to extend this problem by reflection to the entire real line. Namely, we extend the functions $u,\ v,\ w$ to be $2L$-periodic functions which are even with respect to the points $x = 0$ and L.

In this periodic extension, each of the original points x_n (which we shall call interfacial points) has a counterpart $-x_n$ (in fact, many counterparts, by periodicity). The point $x = 0$ is not interfacial because $u = -\nu_1$ on the entire interval $(-x_1, x_1)$. A similar statement holds at $x = L$.

We must check whether the extended functions (u, v, w) continue to satisfy the above equations. It is immediate that $w' = $ const (12) in each of the new intervals between interfacial points. As for (14), we note that in going from x_n to $-x_n$, we must replace ν_n by $-\nu_n$, V by $-V$, and $\frac{\partial}{\partial n}$ by $-\frac{\partial}{\partial n}$. Making these replacements changes (14) into

$$-2(-\nu_n)(-\dot{x}_n) = -[w'(-x_n - 0) - w'(-x_n + 0)],$$

which is still seen to be the form that (7) takes at the interfacial point $-x_n$. Therefore, (7) continues to be satisfied by the extended functions. Finally, (15) and (16) are still valid.

Thus each solution of the problem on $(0, L)$ gives rise to a $2L$-periodic solution on the whole line, even with respect to 0 and L. Conversely, any such solution on the whole line, when restricted to $(0, L)$, is a solution of the finite interval problem; in fact, the evenness implies the boundary conditions (13) and (17). Thus the two problems are equivalent.

In view of this, we shall usually confine our attention in the following to problems on the whole line. In fact we no longer necessarily assume periodicity. The interfacial points $\{x_n\}$ will have indices n ranging over all positive and negative integers: $-\infty < n < \infty$.

Integrating (16), we have, for all n,

$$v'(x) = p_n + (\bar{u} - \nu_n)(x - x_n), \quad x \in [x_n, x_{n+1}], \tag{18}$$

$$v(x) = v_n + p_n(x - x_n) + \frac{1}{2}(\bar{u} - \nu_n)(x - x_n)^2. \tag{19}$$

We now denote the interval lengths by $\xi_n = x_{n+1} - x_n$. From (18) and (19),

$$\frac{v(x_{n+1}) - v(x_n)}{\xi_n} = p_n + \frac{1}{2}(\bar{u} - \nu_n)\xi_n, \tag{20}$$

$$p_{n+1} - p_n = (\bar{u} - \nu_n)\xi_n. \tag{21}$$

And from (12) and (15),

$$w'(x) = \frac{v(x_{n+1}) - v(x_n)}{\xi_n}, \quad x \in (x_n, x_{n+1}). \tag{22}$$

Hence from (22), (20), and (14),

$$-2\nu_n \dot{x}_n = p_n - p_{n-1} + \frac{1}{2}\left[(\bar{u} - \nu_n)\xi_n - (\bar{u} - \nu_{n-1})\xi_{n-1}\right]. \tag{23}$$

Substituting (21) into (23) and multiplying by $\nu_n/2$, we find

$$-\dot{x}_n = \frac{1}{4}[(\nu_n\bar{u} - 1)\xi_n + (\nu_n\bar{u} + 1)\xi_{n-1}], \tag{24}$$

and hence

$$\dot{\xi}_n = \frac{1}{4}\left[(\nu_n\bar{u} + 1)\xi_{n+1} + 2(\nu_n\bar{u} - 1)\xi_n + (\nu_n\bar{u} + 1)\xi_{n-1}\right]. \tag{25}$$

Our main effort will be devoted to solving the initial-value problem associated with (25). After the solution is found, it is straightforward to obtain $x_0(t)$ by solving (from (24))

$$\dot{x}_0 = -\frac{1}{4}\left[(\nu_0\bar{u} - 1)\xi_0 + (\nu_0\bar{u} + 1)\xi_{-1}\right], \tag{26}$$

and hence

$$x_n(t) = x_0(t) + \sum_0^{n-1} \xi_j(t) \tag{27}$$

for all $n > 0$, a similar representation holding for $n < 0$.

The evolution (25) is especially revealing in the case when $\bar{u} = 0$, for then it is a space-discretization of the ordinary heat equation

$$\dot{\xi}_n = \frac{1}{4}\left[\xi_{n+1} - 2\xi_n + \xi_{n-1}\right], \tag{28}$$

in which the index n plays the role of space, and ξ_n plays the role of temperature at location n.

In the general case when $\bar{u} \neq 0$, the coefficients on the right side of (25) depend on n, which in a sense represents the discretization of a heat equation for an inhomogeneous medium, the diffusivity being a function of the grid point which alternates between one positive value and another.

If one thinks of the heat equation $U_t = U_{xx}$ as being an efficient way to evolve an initial function $U(x, 0)$ of x toward a constant function equal to the spatial average of $U(x, 0)$ (and it is, in the sense of being a steepest-descent rule for decreasing $\int U_x(x, t)^2 dx$), then (28) is the analogous efficient way to evolve a sequence of interfacial points $\{x_n(0)\}$ to a configuration in which they are equally spaced, so that the ξ_n are independent of n. A similar interpretation can be given to the case when $\bar{u} \neq 0$. The outcome of this evolution process is studied carefully in sections 7 and 8.

Returning to problems on a finite interval $[0, L]$ with N interfaces, we note that the even extension to the whole line described above generates a solution of (25), defined for all n, such that ξ_n is periodic in n of period $2N$. In fact each interval length $\xi_n = x_{n+1} - x_n$ for $n = 1, 2, \dots, N - 1$ has by reflection its counterpart $(-x_n) - (-x_{n+1})$ (the length of a subinterval of $[-L, 0]$), which we may rename ξ_{-n}. In addition, there is the interval $-x_1, x_1$ (whose length we rename ξ_0) spanning the origin, and the interval length ξ_N spanning the point $x = L$. This makes a total of $2N$ subintervals covering a basic period interval $(-x_{N-1}, 2L - x_{N-1})$ of length $2L$. The periodic extension simply involves translating the basic period interval, with its $2N$ subintervals, periodically to cover the whole line.

In section 4.7 we prove the existence, given initial data $\xi_n(0)$ which are $2N$-periodic in n, of a solution which remains $2N$-periodic as time evolves. This, together with the uniqueness of solutions of the general initial-value problem, implies that periodic initial data always generate periodic solutions.

4. General solution. The purpose of this section is to provide an explicit solution of the initial-value problem for (25).

The number $\bar{u}$ in (25) was originally introduced in (3) as the spatial average of u in a bounded domain. However, the system (25) has meaning independently of the significance of $\bar{u}$, and we consider its solution for arbitrary $\bar{u} \in (-1, 1)$. It will be seen in (68) that stationary solutions are such that $\bar{u}$ is indeed the average of u, and for solutions on a finite interval, we see in section 8 that the evolution leads to a final state with this same property.

For definiteness, we take

$$\nu_n = (-1)^n$$

throughout the rest of the paper, so that $u = 1$ on (x_n, x_{n+1}) for n even.

4.1. Formal solution in the case $\bar{u} = 0$. This case is straightforward and involves solving (28) by Fourier transform. We first derive the solution in a formal manner; the justification, along with that of section 4.2, will follow in section 4.5.

We represent

$$\xi_n(t) = \frac{1}{2\pi} \int_{-\pi}^{\pi} \tilde{\alpha}(k, t) e^{ink} dk, \tag{29}$$

the inverse transform being

$$\tilde{\alpha}(k,t) = \sum_{n=-\infty}^{\infty} \xi_n(t) e^{-ikn}. \tag{30}$$

The system (28) becomes

$$\frac{\partial \tilde{\alpha}}{\partial t} = \frac{1}{2}(\cos k - 1)\tilde{\alpha}, \tag{31}$$

whose solution is

$$\tilde{\alpha}(k,t) = \tilde{A}(k) \exp\left[-\frac{1}{2}(1-\cos k)t\right], \tag{32}$$

and the spectral function $\tilde{A}(k)$ can be obtained from the initial data $\{\xi_n(0)\}$. We therefore have

$$\xi_n(t) = \frac{1}{2\pi}\int_{-\pi}^{\pi} \tilde{A}(k) \exp\left[-\frac{1}{2}(1-\cos k)t\right] e^{ink} dk. \tag{33}$$

Conditions under which these equations, and those given below, have meaning in the distribution sense will be given in section 4.5.

4.2. Formal solution in the case $\bar{u} \neq 0$. We split the numbers ξ_n into two sets, corresponding to even and odd n, and then rescale, so defining

$$\zeta_n = (1-\bar{u})\xi_{2n}, \qquad \eta_n = (1+\bar{u})\xi_{2n+1}. \tag{34}$$

From (25) we have

$$\frac{1}{1-\bar{u}}\dot{\zeta}_n = \dot{\xi}_{2n} = \frac{1}{4}\left[(\bar{u}+1)\xi_{2n+1} - 2(1-\bar{u})\xi_{2n} + (1+\bar{u})\xi_{2n-1}\right]$$

$$= \frac{1}{4}(\eta_n - 2\zeta_n + \eta_{n-1}). \tag{35}$$

Similarly,

$$\frac{1}{1+\bar{u}}\dot{\eta}_n = \frac{1}{4}(\zeta_{n+1} - 2\eta_n + \zeta_n). \tag{36}$$

Again, the system (35), (36) may be solved by Fourier transform. We represent

$$\zeta_n(t) = \frac{1}{2\pi}\int_{-\pi}^{\pi} \alpha(k,t) e^{ink} dk, \quad \eta_n(t) = \frac{1}{2\pi}\int_{-\pi}^{\pi} \beta(k,t) e^{ink} dk, \tag{37}$$

the inverse transforms being

$$\alpha(k,t) = \sum_{n=-\infty}^{\infty} \zeta_n(t) e^{-ikn}, \quad \beta(k,t) = \sum_{n=-\infty}^{\infty} \eta_n(t) e^{-ikn}. \tag{38}$$

The system (35), (36) becomes

$$\frac{1}{1-\bar{u}}\dot{\alpha} = \frac{1}{4}\left[\beta(1+e^{-ik}) - 2\alpha\right],$$

$$\frac{1}{1+\bar{u}}\dot{\beta} = \frac{1}{4}\left[\alpha(1+e^{ik}) - 2\beta\right]. \tag{39}$$

The general solution of this linear system is

$$\begin{aligned}\alpha(k,t) &= A(k)e^{\sigma_+(k)t} + \lambda_-(k)B(k)e^{\sigma_-(k)t},\\ \beta(k,t) &= \lambda_+(k)A(k)e^{\sigma_+(k)t} + B(k)e^{\sigma_-(k)t}\end{aligned} \tag{40}$$

for arbitrary $A,\ B$, which will be allowed to be distributions (see section 4.4 below), where

$$\sigma_\pm(k) = \frac{1}{2}\left[-1 \pm \sqrt{\bar{u}^2 + (1-\bar{u}^2)\cos^2(k/2)}\right], \tag{41}$$

$$\lambda_\pm(k) = \frac{2(2\sigma_\pm + 1 \mp \bar{u})}{(1\mp\bar{u})(1+e^{\mp ik})}. \tag{42}$$

It is seen, since $\bar{u} \neq 0$, that the $\sigma_\pm$ and $\lambda_\pm$ are real, C^∞ is periodic in k with period 2π, and for $-\pi < k \leq \pi$,

$$\sigma_-(k) \leq -\frac{1}{2},\ \sigma_+(k) < 0 \text{ when } k \neq 0, \quad \sigma_+(0) = 0. \tag{43}$$

For small k, we have

$$\sigma_+(k) \sim -\frac{1}{16}(1-\bar{u}^2)k^2. \tag{44}$$

Note that the numerator and denominator in (42) both vanish when $k \to \pm\pi$, but the ratio remains bounded.

In all, we have

$$\zeta_n(t) = \frac{1}{2\pi}\int_{-\pi}^{\pi}\left[A(k)e^{\sigma_+(k)t} + \lambda_-(k)B(k)e^{\sigma_-(k)t}\right]e^{ink}dk, \tag{45}$$

$$\eta_n(t) = \frac{1}{2\pi}\int_{-\pi}^{\pi}\left[\lambda_+(k)A(k)e^{\sigma_+(k)t} + B(k)e^{\sigma_-(k)t}\right]e^{ink}dk. \tag{46}$$

The distributions A and B can be found from initial values $\xi_n(0)$ by setting $t=0$ in (40), (37) and inverting. Specifically,

$$A(k) = (1-\lambda_-(k)\lambda_+(k))^{-1}\sum_n\left[\zeta_n(0) - \lambda_-(k)\eta_n(0)\right]e^{-ikn}, \tag{47}$$

$$B(k) = (1-\lambda_-(k)\lambda_+(k))^{-1}\sum_n\left[\eta_n(0) - \lambda_+(k)\zeta_n(0)\right]e^{-ikn}. \tag{48}$$

4.3. Real solutions. If we should wish to consider all complex-valued solutions of (35) and (36), $A(k)$ and $B(k)$ are arbitrary. However, our motivation dictates that the solution be real and positive. Of course, the real and imaginary parts of any complex solution of (35), (36) are also solutions, so we shall be justified in studying complex ones. Apart from that, it may be of interest to characterize those distributions A and B which generate real solutions.

We shall show that ζ_n and η_n are real for all n if and only if

$$\overline{A(-k)} = A(k), \quad \overline{B(-k)} = B(k) \tag{49}$$

for all k. Taking the complex conjugate of (45), we obtain

$$\overline{\zeta_n(t)} = \frac{1}{2\pi}\int_{-\pi}^{\pi}\left[\overline{A(k)}e^{-ink}e^{\sigma_+(k)t} + \overline{\lambda_-(k)B(k)}e^{-ink}e^{\sigma_-(k)t}\right]dk. \tag{50}$$

By transforming the integration variable $k\rightarrow -k$, noting that $\sigma_\pm(-k) = \sigma_\pm(k)$ and $\lambda_\pm(-k) = \overline{\lambda_\pm(k)}$, we obtain

$$\overline{\zeta_n(t)} = \frac{1}{2\pi}\int_{-\pi}^{\pi}\left[\overline{A(-k)}e^{ink}e^{\sigma_+(k)t} + \lambda_-(k)\overline{B(-k)}e^{ink}e^{\sigma_-(k)t}\right]dk.$$

The condition that ζ_n must be real is that $\overline{\zeta_n(t)} = \zeta_n(t)$. Comparing this last representation to (45), we see that the condition reduces to (49). The same analysis can be applied to show that the reality of the η_n is also equivalent to (49).

By the use of (49), we have the representation

$$\zeta_n(t) = \frac{1}{\pi}\int_0^{\pi} \operatorname{Re}\left[e^{ink}\left(A(k)e^{\sigma_+(k)t} + \lambda_-(k)B(k)e^{\sigma_-(k)t}\right)\right]dk, \tag{51}$$

$$\eta_n(t) = \frac{1}{\pi}\int_0^{\pi} \operatorname{Im}\left[e^{ink}\left(\lambda_+(k)A(k)e^{\sigma_+(k)t} + B(k)e^{\sigma_-(k)t}\right)\right]dk. \tag{52}$$

This time the distributions A and B, defined only for $k \in [0,\pi]$, need only satisfy (49) when $k = 0$; otherwise, they are arbitrary.

4.4. Periodic distributions. We shall show (Theorem 1) that if the initial values $\xi_n(0)$ satisfy a growth condition with respect to n, then the above formal analysis is justified, i.e., a global solution of the initial-value problem exists in the form (45)–(48).

But first, we briefly review the Fourier transform theory for distributions.

We define a 2π-periodic distribution α to be a linear functional on the space of C^∞ 2π-periodic functions (test functions) $\phi(k)$, its value being denoted by $\langle\alpha,\phi\rangle$, which is continuous in the sense that if $\{\phi_j\}$ is a sequence of test functions such that for each $m = 0, 1, \ldots$

$$\lim_{j\to\infty}\left(\frac{d}{dk}\right)^m \phi_j(k) = \left(\frac{d}{dk}\right)^m \phi(k)$$

uniformly in k, then

$$\lim_{j\to\infty}\langle\alpha,\phi_j\rangle = \langle\alpha,\phi\rangle.$$

When $\alpha(k)$ is an integrable function, we use the convention that $\langle\alpha,\phi\rangle = \frac{1}{2\pi}\int_{-\pi}^{\pi}\alpha(k)$ $\phi(k)\,dk$.

Thus the right side of (45) is to be interpreted as

$$\langle A, \exp[\sigma_+(k)t + ink]\rangle + \langle B, \lambda_-(k)\exp[\sigma_-(k)t + ink]\rangle$$

if A and B are distributions. The right side of (46) is interpreted similarly.

The continuity of distributions implies that if $\phi(k,t)$ is a test function for each t such that for all m, $\frac{\partial^m \phi}{\partial k^m}$ is continuously differentiable in t, then

$$\frac{d}{dt}\langle A, \phi(\cdot,t)\rangle = \left\langle A, \frac{\partial \phi}{\partial t}(\cdot,t)\right\rangle. \tag{53}$$

In fact, we just express the t-derivatives as limits of difference quotients.

It is this property (53) that ensures, for any distributions A and B, that the functions $\zeta_n(t)$, $\eta_n(t)$ given by (45), (46) satisfy (35), (36). We just differentiate (45), (46) and use (39), (40).

4.5. Justification.

THEOREM 1. *Assume that for some* $p > 0$, $C > 0$ *the initial data satisfy* $|\xi_n(0)| \le C(1+|n|^p)$ *for all* n. *Then* (47), (48) *define distributions A, B, and* (45), (46) *provide the solution of the initial-value problem for* (35), (36) *for all* $t \ge 0$.

Proof. We have just seen that if A and B are any distributions, then (45), (46) provide a solution of (35), (36). It remains only to show (i) that the distributions A and B can be obtained in terms of the initial conditions by the expressions (47), (48) provided the right sides of those equations really are distributions, and (ii) that the right sides are distributions provided that the initial data satisfy the growth condition. The first task (i) is simply a consequence of the inversion formula. Therefore, we recall the proof of that formula, which takes this form: If we set $e_n(k) = e^{ink}$ and, for any given distribution α, set $\alpha_n = \langle \alpha, e_n\rangle$, then α can be reconstituted as

$$\alpha = \sum_n \alpha_n \overline{e_n}. \tag{54}$$

The meaning of (54) is simply that for every test function ϕ,

$$\langle \alpha, \phi\rangle = \sum_n \alpha_n \langle \overline{e_n}, \phi\rangle. \tag{55}$$

The proof of this follows from the standard inversion formula for smooth functions: Let ϕ be any test function. If we set $\phi_n = \langle \overline{e_n}, \phi\rangle$, then

$$\phi(k) = \sum_n \phi_n e_n(k), \tag{56}$$

and the convergence is uniform. Applying the distribution α to (56) with use of the continuity property of α, we get precisely (55), which completes the proof of (i).

Finally, we show (ii) that the stated growth condition implies that the right sides of (47) and (48) are distributions. We do this for (47), as the argument for (48) is the same. First, the growth condition on the $\xi_n(0)$ implies

$$|\zeta_n(0)| + |\eta_n(0)| \le C(1+|n|^{2p}). \tag{57}$$

(Here C is a generic constant.) Now let ϕ be any test function, and let R_n be the nth term on the right of (47). We have the estimate

$$|\langle R_n, \phi\rangle| \le C(1+|n|^{2p})|\langle \phi, \overline{e_n}\rangle|. \tag{58}$$

But $|\langle \overline{e_n}, \phi\rangle|$ decays as $|n|\to\infty$ faster than any negative power of $|n|$, by virtue of the infinite differentiability of ϕ (integrate by parts any number of times). Therefore, using (58), we see that the series $[1-\lambda_-(k)\lambda_+(k)]^{-1}\sum[\zeta_n(0)-\lambda_-(k)\eta_n(0)]\langle\overline{e_n},\phi\rangle$ corresponding to the right side of (47) converges uniformly in k. We call the limit $\langle A,\phi\rangle$. We omit the proof that this linear functional is continuous in the right sense, so that it defines a distribution A. □

4.6. Monochromatic solutions. By way of example, consider the case when the initial data are

$$\xi_n(0) = e^{i\gamma n} \tag{59}$$

for some real number γ, which (since $e^{i\gamma n}$ is 2π-periodic in γ) we may and shall confine to the interval $0 \le \gamma < 2\pi$. Then

$$\zeta_n(0) = (1-\bar{u})e^{i2\gamma n}, \quad \eta_n(0) = (1+\bar{u})e^{i\gamma}e^{i2\gamma n}. \tag{60}$$

We can then find A and B from (47), (48) and the solution from (45), (46). However, we take a more direct approach, supposing that the solution, in its dependence on n, remains monochromatic, proportional to $e^{i2\gamma n}$. Thus in the spectral representation (45), (46), only the value $k = 2\gamma$ appears. (It of course may happen that 2γ lies outside the range of integration $[-\pi,\pi]$ in (45), (46). However, $\sigma_\pm$, A, B, and $\lambda_\pm$ are all 2π-periodic functions of k, so we really mean the value of k (mod 2π) which does lie in $[-\pi,\pi]$.) The distributions A and B will be delta-functions.

Prompted by these considerations, we propose to find a solution in the form

$$\zeta_n(t) = a_+(\gamma)\exp\left(\sigma_+(2\gamma)t + 2in\gamma\right) + \lambda_-(2\gamma)a_-(\gamma)\exp\left(\sigma_-(2\gamma)t + 2in\gamma\right), \tag{61}$$

$$\eta_n(t) = \lambda_+(2\gamma)a_+(\gamma)\exp\left(\sigma_+(2\gamma)t + 2in\gamma\right) + a_-(\gamma)\exp\left(\sigma_-(2\gamma)t + 2in\gamma\right) \tag{62}$$

for some constants $a_\pm(\gamma)$. We set $t = 0$ and replace the left sides of (61), (62) by the right sides of (60). The resulting equations can be solved for a_+ and a_-:

$$\begin{aligned} a_+(\gamma) &= [1-\lambda_+(2\gamma)\lambda_-(2\gamma)]^{-1}[(1-\bar{u}) - \lambda_-(2\gamma)(1+\bar{u})e^{i\gamma}], \\ a_-(\gamma) &= [1-\lambda_+(2\gamma)\lambda_-(2\gamma)]^{-1}[(1+\bar{u}))e^{i\gamma} - \lambda_+(2\gamma)(1-\bar{u})]. \end{aligned} \tag{63}$$

It is now straightforward to verify that (61), (62) is indeed the desired solution.

4.7. The solution for a finite interval. It was shown in section 3 that the problem with N interfacial points on a finite interval is equivalent to a problem on the whole real line, with the solution ξ_n required to be periodic in n of period $2N$.

First of all, we represent the $2N$-periodic initial data $\xi_n(0)$ in the form

$$\xi_n(0) = \sum_{m=0}^{2N-1} c_m e^{i\frac{2\pi}{2N}mn}. \tag{64}$$

These are $2N$ equations ($n = 0,\ldots,2N-1$) for the $2N$ unknowns c_m. They can be solved by forming the combination $\sum_{n=0}^{2N-1}\xi_n(0)e^{-i\frac{2\pi}{2N}nm}$ and observing the relation

$$\sum_{n=0}^{2N-1} e^{i\frac{2\pi}{2N}np} = \begin{cases} 2N, & p = 0, \\ 0, & p = 1,2,\ldots,2N-1. \end{cases} \tag{65}$$

We find that (64) holds with

$$c_m = \frac{1}{2N} \sum_{n=0}^{2N-1} \xi_n(0) e^{-i\frac{2\pi}{2N}nm}. \tag{66}$$

From (64) and the linearity property, we conclude that the solution $\xi_n(t)$ is a linear combination of monochromatic solutions as in (61), (62), (63) with $\gamma = \frac{2\pi m}{2N} = \frac{\pi m}{N} \equiv \gamma_m$, $m = 0, \ldots, 2N-1$, and coefficients c_m (66).

5. Positivity of the $\boldsymbol{\xi_n}$. Suppose $\xi_n(0) > 0$ for all n. We show that it is impossible for a finite number of these interval lengths to vanish at some finite positive $t = T > 0$, the surrounding ones remaining positive. Specifically, given some finite nonempty sequence $S = \{n : n_1 \le n \le n_2\}$ (the simplest case is when $n_1 = n_2$), we say that this set collapses at time $T > 0$ if (i) $\lim_{t\uparrow T} \xi_n(t) = 0$ and $\xi_n(t) > 0$ for $t < T$ close to T for $n \in S$, and (ii) $\xi_n(t) > 0$ for $t \le T$ close to T for $n = n_1 - 1$ or $n_2 + 1$.

THEOREM 2. *If* $\xi_n(t)$ *satisfy* (25)*, no finite sequence collapses at any finite time.*

Proof. If S collapses at time T, then for $t < T$ close to T, ξ_{n_2} is arbitrarily small, but ξ_{n_2+1} is bounded away from zero. Therefore, it follows from (25) with $n = n_2$ that $\dot{\xi}_{n_2} > 0$, contradicting its approach to 0. □

This leads to the following global existence result.

COROLLARY 1. *Any positive initial data satisfying the hypotheses of Theorem* 1 *give rise to a global positive solution of* (25) or (35), (36).

6. Stationary and similarity solutions. First, we exhibit the stationary solutions on the whole line. From (35), (36) with the left side set equal to 0, we derive the result that $\zeta_{n+1} - \zeta_n \equiv \alpha$ and $\eta_{n+1} - \eta_n \equiv \beta$ are independent of n. Therefore, $\zeta_n = \zeta_0 + n\alpha$, $\eta_n = \eta_0 + n\beta$. But, again using (35), we find $\alpha = \beta$ and $\eta_0 = \zeta_0 - \frac{\alpha}{2}$, so that

$$\zeta_n = \zeta_0 + n\alpha, \quad \eta_n = \zeta_0 + \left(n - \frac{1}{2}\right)\alpha. \tag{67}$$

This provides a two-parameter family of solutions, the parameters being α and ζ_0. But since we want solutions which are positive for each n, we should select $\alpha = 0$.

In the case when $\alpha = 0$, we obtain constant solutions

$$(1 - \bar{u})\xi_{2n} = \zeta_n = \eta_n = (1 + \bar{u})\xi_{2n+1} \equiv \zeta_0 \quad \text{for all } n.$$

For these constant solutions, the interval lengths alternate between $\frac{\zeta_0}{1-\bar{u}}$ and $\frac{\zeta_0}{1+\bar{u}}$. The "average" value of u can then be verified to be

$$\frac{\xi_{2n} - \xi_{2n+1}}{\xi_{2n} + \xi_{2n+1}} = \frac{\frac{1}{1-\bar{u}} - \frac{1}{1+\bar{u}}}{\frac{1}{1-\bar{u}} + \frac{1}{1+\bar{u}}} = \bar{u}. \tag{68}$$

It may be checked that these stationary solutions correspond to the choice

$$A(k) = 2\pi\zeta_0\delta(k), \quad B(k) = 0 \tag{69}$$

in (45), (46). The stationary solutions shown above, which grow linearly in n and which we had to reject, correspond to $A(k)$ being an imaginary constant times $\delta'(k)$ and $B(k) = 0$. Positive solutions which grow quadratically in n may also be constructed; they are not stationary, but rather they grow linearly in t. For them, the function $A(k)$ is a constant times $\delta''(k)$. This process may be continued to obtain similarity solutions corresponding to any derivative of $\delta(k)$.

7. Stability for problems on the whole line. Given a stationary solution $\{\xi_n^0\}$ (or any other solution, for that matter), we now endeavor to characterize initial data $\xi_n(0)$ such that the resulting evolution $\xi_n(t)$ will converge to $\{\xi_n^0\}$ as $t\to\infty$. After that, we consider conditions under which the corresponding result holds for the interface locations $x_n(t)$.

Since our basic problem (25) is linear and homogeneous, it suffices to find solutions which decay to 0 as $t\to\infty$; those solutions (which could now be negative) will then be considered as perturbations of the basic solution $\{\xi_n^0\}$, and the only additional restriction we might wish to impose is that the basic solution plus the perturbation be real and positive initially (hence at all later times).

We give two characterizations of decaying solutions.

THEOREM 3. *Let* $\xi_n(0)\to 0$ *as* $|n|\to\infty$. *Then*

$$\max_n |\xi_n(t)|\to 0 \text{ as } t\to\infty. \tag{70}$$

Remark. Part of the proof is a simple comparison argument for the system (35), (36), which is quasi-monotone. More detailed results based on monotonicity arguments can be derived.

THEOREM 4. *Assume the spectral pair* $A(k)$, $B(k)$, *obtained from the initial data by* (47), (48), *satisfies any one of the following, or is a linear combination of pairs, each satisfying one of the following. Then* $\lim_{t\to\infty}\xi_n(t) = 0$ *uniformly in* n. *In case* 1, *the convergence is exponential; in the second case, it may be algebraic of order* $t^{(\alpha-1)/2}$.

1. $A(k) = c_1\delta(k-k_0)$ *and* $B(k) = c_2\delta(k-k_1)$ *for some constants* c_i *and* k_i *with* $k_0 \neq 0$.
2. $|A(k)| + |B(k)| \le c|k|^{-\alpha}$ *for some constants* c *and* $\alpha < 1$.

Remark. In case 2, Theorem 3 applies, because it can be shown that the initial values decay as $|n|\to\infty$. Theorem 4 gives the rate of decay.

We prove Theorem 4 first and then Theorem 3.

Proof of Theorem 4. In the first case, we get from (45) that $\zeta_n(t) = \frac{c_1}{2\pi}e^{\sigma_+(k_0)t}e^{ink_0} + \frac{c_2\lambda_-(k_1)}{2\pi}e^{\sigma_-(k_1)t}e^{ink_1}$, and the conclusion follows for the ζ_n because, by hypothesis, $\sigma_+(k_0)$ and $\sigma_-(k_1)$ are negative. The same argument works for the η_n as well.

This result shows that for time decay it is not necessary for the initial values of the ξ_n to approach 0 as $|n|\to\infty$; examples are the monochromatic solutions in section 4.6 with $\gamma\neq 0$.

In the second case, we again use (45), and (44) as well, to obtain for some $c, \beta > 0$

$$|\zeta_n(t)| < c\int_{-\infty}^{\infty} |k|^{-\alpha}e^{-\beta k^2 t}dk$$

$$= [\text{setting } \kappa = k\sqrt{t}] \quad c\int_{-\infty}^{\infty} t^{(\alpha-1)/2}|\kappa|^{-\alpha}e^{-\beta\kappa^2}d\kappa = ct^{(\alpha-1)/2}, \tag{71}$$

and the conclusion again follows.

LEMMA 1. *Let* $\xi_n(0)\to 0$ *as* $|n|\to\infty$. *Then for all* $t \ge 0$, $X(t) \equiv \max_n \max[|\zeta_n(t)|, |\eta_n(t)|] \le X(0)$.

Proof. Defining

$$z_n = \begin{cases} (1-\bar{u})\xi_n, & n \text{ even}, \\ (1+\bar{u})\xi_n, & n \text{ odd}, \end{cases}$$

we represent $X(t) = \max_n |z_n(t)|$ and write (35), (36) (or (25)) in the form

$$\frac{4}{1-(-1)^n\bar{u}}\dot{z}_n = z_{n+1} - 2z_n + z_{n-1}. \tag{72}$$

For any $\epsilon > 0$, let $y_n = z_n - \epsilon n^2 - 2\epsilon t$, so that from (72)

$$\frac{4}{1-(-1)^n\bar{u}}\dot{y}_n = y_{n+1} - 2y_n + y_{n-1} + 2\epsilon - \frac{8\epsilon}{1-(-1)^n\bar{u}}. \tag{73}$$

We have $y_n(0) \le X(0)$ for all n and (since the z_n are bounded) $y_n(t) < 0$ for large n. If $y_n(t^*) > X(0)$ for some $n,\ t^* > 0$, $\max_{n,t\in[0,t^*]} y_n(t)$ is achieved at some $n = n_1,\ t = t_1$, where $\dot{y}_{n_1}(t_1) \ge 0,\ \ y_{n_1+1}(t_1) - 2y_{n_1}(t_1) + y_{n_1-1}(t_1) \le 0$. Substituting these inequalities into (73), we obtain that the left side is ≥ 0 and the right side is $\le -2\epsilon < 0$. This contradiction implies that $y_n(t) \le X(0)$ for all $n,\ t$.

Since this is true for every choice of $\epsilon > 0$, we conclude that $z_n(t) \le X(0)$. Similarly, we get that $z_n(t) \ge -X(0)$, so that $X(t) \le X(0)$. □

LEMMA 2. *If $\xi_n(0) = 0$ for $|n|$ large enough, then $\xi_n(t)\to 0$ as $t\to\infty$, uniformly in n.*

Proof. In (47) and (48) there are only a finite number of terms in the summations on the right. Therefore, $A(k)$ and $B(k)$ are bounded functions of k, and the second hypothesis of Theorem 4 holds with $\alpha = 0$. □

Proof of Theorem 3. Given any $\epsilon > 0$, let $N(\epsilon)$ be such that $|\xi_n(0)| < \epsilon$ for $|n| > N(\epsilon)$. Write $\xi_n(t) = \xi_n^1(t) + \xi_n^2(t)$, where $\xi_n^1(t)$ is the evolution starting from

$$\xi_n^1(0) = \begin{cases} \xi_n(0), & |n| \le N(\epsilon), \\ 0, & |n| > N(\epsilon). \end{cases}$$

By Lemma 2, $\xi_n^1(t)\to 0$ as $t\to\infty$, so let $T(\epsilon)$ be such that $|\xi_n^1(t)| < \epsilon$ for $t > T(\epsilon)$, for all n. Since $|\xi_n^2(0)| < \epsilon$, we have from Lemma 1 that $|\xi_n^2(t)| < \epsilon$ for all n and t. Therefore, $|\xi_n(t)| < 2\epsilon$ for $t > T(\epsilon)$ and all n. This establishes the convergence.

THEOREM 5. *Assume condition* 2 *of Theorem* 4 *holds with $\alpha < 0$. Then for each m, the limit $\lim_{t\to\infty} x_m(t) = x_m(\infty)$ exists. The limit is a stationary configuration.*

Proof. We may use (26), (34), (37), (40), (44) to obtain an integral representation of $\dot{x}_0(t)$ in terms of A and B. For the convergence of $x_0(t)$ to a limit, it suffices that $\int_1^\infty |\dot{x}_0(t)|\,dt < \infty$.

Proceeding as in the proof of Theorem 4 leads to the estimate $|\dot{x}_0(t)| \le ct^{\frac{\alpha}{2}-1}$. This is integrable as required if $\alpha < 0$. □

8. Global stability in the case of a finite interval. We showed in section 4.7 that in this case, the evolution reduces to that of a finite linear combination of monochromatic evolutions. So we briefly return to the question of the decay of monochromatic solutions considered in section 4.6. We give the argument only for the more difficult case $\bar{u} \ne 0$.

In view of (43), it is seen from (61), (62) that every monochromatic solution decays exponentially to zero unless $\sigma_+(2\gamma) = 0$, i.e., $\gamma = 0$ or π. The rate is $e^{\sigma_+(2\gamma)t}$. We now consider these two exceptional cases in more detail, beginning with the case $\gamma = 0$. We calculate from (41), (42)

$$\sigma_+(0) = 0,\quad \sigma_-(0) = -1,\quad \lambda_+(0) = 1,\quad \lambda_-(0) = -\frac{1-\bar{u}}{1+\bar{u}}. \tag{74}$$

Thus from (63)

$$a_+ = 1 - \bar{u}^2, \quad a_- = \bar{u}(1+\bar{u}), \tag{75}$$

and by (61), (62)

$$\begin{aligned} \zeta_n(t) &= (1-\bar{u}^2) - \tfrac{1-\bar{u}}{1+\bar{u}} e^{-t}, \\ \eta_n(t) &= (1-\bar{u}^2) + \bar{u}(1+\bar{u})e^{-t}. \end{aligned} \tag{76}$$

In the limit as $t \to \infty$, therefore, ζ_n and η_n approach the limit $1-\bar{u}^2$ exponentially, independently of n; hence

$$\xi_{2n}(\infty) = 1+\bar{u}, \quad \xi_{2n+1}(\infty) = 1-\bar{u}, \tag{77}$$

so that the limiting sizes of the intervals alternate between $1+\bar{u}$ and $1-\bar{u}$. It is easily verified (section 6) that the average value of u in this configuration is $\bar{u}$. (Note again that we have not assumed that the initial data for this solution have this value for their average; the number $\bar{u}$ is, for the purpose of the above calculations, just a parameter in the differential equations.)

Finally, consider the last case, $\gamma = \pi$. We have $\sigma_+(2\pi) = 0$. By periodicity, the values of the σ's and λ's are the same as in (74), but the factor $e^{i\gamma}$ in (63) is now -1. It follows that $a_+ = 0$ and $a_- = -(1+\bar{u})$. Because $a_+ = 0$, this monochromatic solution decays to 0 exponentially.

Therefore, the only one which does not is the one with $\gamma = 0$.

Therefore, in the linear combination of monochromatic solutions giving the solution of the problem on a finite interval, arising from the representation (64) of the initial data, all terms decay to zero except the one with $m = 0$. That case was analyzed in (76) above. We conclude that if (64) holds, then

$$\xi_{2n}(\infty) = c_0(1+\bar{u}), \quad \xi_{2n+1}(\infty) = c_0(1-\bar{u}). \tag{78}$$

Finally, by (66), $c_0 = \frac{1}{2N}\sum_{n=0}^{2N-1} \xi_n(0) = \frac{L}{N} \equiv \bar{\xi}$, where L is the length of the finite interval we are considering and $\bar{\xi}$ is the initial (and also final) average of the ξ_n.

In short, we have found that, irrespective of the initial values of the N intervals making up the basic x-interval of length L, the lengths of the intervals evolve to become semiuniform, i.e., the even ones all have the same length $\bar{\xi}(1+\bar{u})$, and the odd ones as well, with lengths $\bar{\xi}(1-\bar{u})$. Those two lengths are such that the average value of u is $\bar{u}$, and the total length is L. This final stationary solution is therefore globally stable.

Theorem 6. *Given any finite N and any initial data* (64), *the solution of the initial-value problem on a finite interval satisfies*

$$\xi_{2n}(\infty) = \bar{\xi}(1+\bar{u}), \quad \xi_{2n+1}(\infty) = \bar{\xi}(1-\bar{u}).$$

In view of the exponential convergence of the ξ's and the proof of Theorem 5, we also have convergence of the interfaces $x_n(t)$, although not necessarily to the locations of the original unperturbed locations; generally there will be a shift.

9. Nucleation. Nucleation in this context is the opposite of collapsing (see section 5). It involves inserting two (or more) new spurious interfaces enclosing a spurious interval of 0 length which then grows. Given a solution $\{x_n(t)\}$, an arbitrary time $t^* > 0$, and an arbitrary point x^* in the interior of one of the intervals (say, (x_0, x_1)

for definiteness) at time t^*, one may consider a new initial-value problem for interval lengths $\xi_n^*(t)$ starting at t^* with initial values of $\xi_n^*(t^*)$ obtained as follows. Set $\xi_0^*(t^*) = 0$; this corresponds to beginning with an interval of 0 length located at the point x^*. Also set $\xi_1^*(t^*) = x_1 - x^*$ and $\xi_{-1}^*(t^*) = x^* - x_0$, and require the remaining $\xi_n^*(t^*)$ to match with some $\xi_m(t^*)$ for the appropriate m, depending on n.

An argument similar to that in the proof of Theorem 2 shows that at the initial time, the derivative $\dot{\xi}_0^*(t^*) > 0$, so that the "ghost interval" ξ_0^* immediately develops positive length, making it a real interval. The new initial-value problem then has a global positive solution.

In an easy generalization of this procedure, one can think of the point x^* as representing a collection of any positive odd number of ghost intervals; then again, they all immediately become intervals of positive length. Finally, any interface located at position x^* at time t^* can be considered to be an interface abutting an even number of ghost interfaces on one side, which again move apart to generate an even number of new intervals.

10. Energy considerations. We consider the FBP on a finite interval $(0, L)$ with N interfacial points and with $\bar{u}$ denoting the average value of u constant in time.

For any $\epsilon > 0$, the energy

$$E^\epsilon[u] = \frac{1}{L}\int_0^L \left(\frac{\epsilon}{2}|u'|^2 + \frac{1}{\epsilon}F(u) + \frac{1}{2}(v')^2\right) dx \tag{79}$$

is a Lyapunov functional [5] for the original model problem (1)–(3). (Recall that v is given in terms of u by (3).)

The local minima of (79) were considered by Ren and Wei [9]; they showed that they are approximated by the local minima of the Gamma-limit functional

$$E^0[N, \xi] = \frac{\mu N}{L} + E_*[N, \xi], \tag{80}$$

where $\mu = \int_{-1}^1 \sqrt{2F(u)}du$, $\xi = (\xi_1, \dots, \xi_N)$, and

$$E_*[N, \xi] = \frac{1}{L}\int_0^L \frac{1}{2}(v'(x))^2 dx. \tag{81}$$

The domain of (79) consists of L^2 functions $u(x)$ on $(0, L)$ with prescribed average $\bar{u}$; the value of the functional may be $+\infty$. The reduced energy (81) can also be interpreted as a functional of functions u, but we write it as depending on N and the ξ_n. It is calculated as follows. Let ξ_n be given. Setting $p_0 = 0$, one calculates in succession the numbers p_n from (21) and then the function $v'(x)$ from (18). The fact that $\bar{u}$ is the average of u guarantees that $v' = 0$ at $x = 0, L$. This function is then used in the definition (81).

It can also be shown that in our 1D scenario, $E_*[N, \xi]$ is a Lyapunov functional for the FBP (12)–(17). Since the first part of (80) depends only on N and N doesn't change, $E^0[N, \xi]$ is also a Lyapunov functional.

If one allows N to be variable, then the global minimum of $E^0[N, \xi]$ is attained when $N = N_m$, a value which depends only on L and can be calculated, and when the numbers ξ_n, $n = 0, \dots, N_m$ form a stationary solution (section 6).

Calculations show (see e.g. [9]) that N_m is an integer differing from

$$\left(\frac{1}{24\mu}\right)^{1/3} L \tag{82}$$

by no more than unity.

The spacing which minimizes this energy is then approximately $(24\mu)^{1/3}$, which is independent of L.

However, this global minimum has little relevance for the 1D dynamical FBP because N remains constant. The artificial nucleation process described in section 9 allows for only an increase, not a decrease, in N. It is likely that when $\epsilon \ll 1$, layered solutions of the original PDEs (1)–(3) follow the evolving solution of the FBP, so that the global minimum will not be very important for their evolution either.

There remains the question as to whether solutions of the original problem that begin without layers will naturally develop layers with the preferred spacing. In this connection it is important to look at the dominant modes arising from initial data which are a small perturbation of the constant solution $u \equiv \bar{u}$, according to the evolution (1)–(3). It turns out that the dominant modes have wavelength of the order $O(\epsilon)$, rather than $O(1)$, which is characteristic of the optimal spacing.

11. Discussion. The energy-conserving, mass-preserving (if u is interpreted as a scaled mass density) pattern-forming system of PDEs (1)–(3) proposed by Bahiana and Oono and by Nishiura and Ohnishi has, as the latter authors showed, a formal limiting FBP, and this connection was justified in a weak sense for radial solutions by Henry. In the 1D case, this latter problem is shown to reduce to a discretized heat equation. These equations have an explicit solution. In fact, we have the representation (45)–(48) (or (33) if $\bar{u} = 0$) for the solution in terms of its initial data.

Generally, it is shown that stationary configurations (in which the intervals where $u = 1$ all have the same length, and the same is true where $u = -1$) have a large basin of stability. When, for example, the initial data $\xi_n(0)$ approach a stationary solution as $|n| \to \infty$, the evolution approaches that same configuration uniformly in n as $t \to \infty$.

The system (35), (36), being quasi-monotone, enjoys a maximum principle, which we have in effect used in Lemma 1. It can be used to prove other properties of the solutions not considered here, such as comparison principles.

By the nature of the FBP, interfaces in one dimension are neither created nor destroyed. (However, an artificial nucleation process was described in section 9.) Therefore, when the domain is a finite interval, stability is of course within the class of evolutions with a given number of interfaces. Ren and Wei [9] considered, for the original problem ($\epsilon > 0$) in one dimension, the question of which configurations minimize the energy E^ϵ (79). Here the minimization is over all functions, so in a sense the number of interfaces (which appear as transition layers in this case) can be varied. They obtained an "optimal" spacing of the order $O(1)$ with the spacing given in accordance with (82). In [8, 10], the same analysis was done for a free energy corresponding to the alternative evolution (1), (4), (3). Similar results were obtained, but their optimal spacing was $O(\hat{\epsilon}^{1/3})$ (as $\hat{\epsilon} \to 0$). If we invoke the scaling procedure connecting their energy functional with ours, their spacing of order $O(\hat{\epsilon}^{1/3})$ corresponds to our spacing of $O(1)$ as $\epsilon \to 0$.

The role of global (as opposed to local) minimizers is much more important for problems in higher dimensions than in one dimension, because in one dimension there is no mechanism for changing the number of interfaces once that number has been established by the initial data. Therefore, there is no mechanism for adjusting the spacing to achieve energy optimality.

DIFFUSIVE N-WAVES AND METASTABILITY IN THE BURGERS EQUATION[*]

YONG JUNG KIM[†] AND ATHANASIOS E. TZAVARAS[‡]

Abstract. We study the effect of viscosity on the large time behavior of the viscous Burgers equation by using a transformed version of Burgers (in self-similar variables) that captures efficiently the mechanism of transition to the asymptotic states and allows us to estimate the time of evolution from an N-wave to the final stage of a diffusion wave. Then we construct certain special solutions of diffusive N-waves with unequal masses. Finally, using a set of similarity variables and a variant of the Cole–Hopf transformation, we obtain an integrated Fokker–Planck equation. The latter is solvable and provides an explicit solution of the viscous Burgers equation in a series of Hermite polynomials. This format captures the long-time–small-viscosity interplay, as the diffusion wave and the diffusive N-waves correspond, respectively, to the first two terms in the Hermite polynomial expansion.

Key words. diffusion waves, diffusive N-waves, convection-diffusion, metastability

1. Introduction.

The Cauchy problem for the viscous Burgers equation

$$\begin{gathered} u_t + uu_x = \mu u_{xx}, \qquad x \in \mathbb{R}\,,\ \mu, t > 0, \\ u(x,0) = u_0(x), \qquad x \in \mathbb{R}, \end{gathered} \tag{1.1}$$

has, since the pioneering work of Hopf [7], served as a paradigm for the development of the theory of shock waves (see [4] and references therein).

In the limit as the viscosity $\mu \to 0$, the solution u^μ of (1.1) converges to the entropy weak solution u of the inviscid Burgers

$$\begin{gathered} u_t + uu_x = 0, \qquad x \in \mathbb{R}\,,\ t > 0, \\ u(x,0) = u_0(x), \quad x \in \mathbb{R}, \end{gathered} \tag{1.2}$$

satisfying the Oleinik condition [16]

$$u(x+,t) \le u(x-,t)\,.$$

The asymptotic behavior of (1.2) is an N-wave, whose positive and negative masses are determined by the positive and negative invariants

$$\begin{gathered} p_0 = -\inf_x \int_{-\infty}^x u_0 dy\,, \quad q_0 = \sup_x \int_x^\infty u_0 dy\,, \\ \text{where} \quad -p_0 + q_0 = M_0 = \int_{\mathbb{R}} u_0(x)dx, \end{gathered} \tag{1.3}$$

of the initial data [7, 12]. On the other hand, the large time behavior of u^μ for fixed μ is characterized by the well-known diffusion wave of mass M_0 (see [7]). Therefore, the reversal of order in the successive limit passages $t \to \infty$, $\mu \to 0$ leads to different results; in other words, the long-time response of the viscous Burgers equation exhibits sensitive dependence on the viscosity.

The objective of the present article is to provide a quantitative understanding of the long-time–small-viscosity interplay for the Burgers equation. To place the problem in context, the reader is referred to the numerical runs of section 4 for the evolution of solutions to (1.1), when the viscosity $\mu \ll 1$. These indicate that at an initial stage u^μ evolves from the initial state u_0 into a saw-tooth profile; at a second stage, the waves interact eventually producing an approximate N-wave; this last structure persists for a very long time, but eventually the smallest of the positive and negative masses is consumed, and thereafter u^μ looks like the final asymptotic state of a diffusion wave.

The Burgers equation is invariant under the group of scaling transformations $x \to cx$, $t \to c^2 t$, $u \to u/c$, and under time and space translations, $t \to t + a$ and $x \to x + b$. This property suggests a transformation to similarity variables,

$$s = \ln(t)\,, \quad \xi = x/\sqrt{t}\,, \quad w(\xi, s) = \sqrt{t}\, u(x,t)\,, \tag{1.4}$$

which puts (1.1) in the form

$$w_s + \left(\frac{1}{2}w^2 - \frac{1}{2}\xi w\right)_\xi = \mu w_{\xi\xi}, \qquad \xi\,, s \in \mathbb{R}, \quad \mu > 0\,. \tag{1.5}$$

The diffusion waves (see (2.6)) are the steady states of (1.5) and determine its large time behavior (see [7] and sections 2 and 3). In the limit $\mu \to 0$, solutions of (1.5) satisfy the (self-similar variant of the) inviscid Burgers equation

$$w_s + \left(\frac{1}{2}w^2 - \frac{1}{2}\xi w\right)_\xi = 0, \tag{1.6}$$

subject to the Oleinik entropy condition

$$w(\xi+, s) \le w(\xi-, s). \tag{1.7}$$

The admissible steady states of (1.6)–(1.7) are the two parameter family

$$\mathcal{N}_{p,q}(\xi) = \begin{cases} \xi, & -\sqrt{2p} < \xi < \sqrt{2q}, \\ 0, & \text{otherwise,} \end{cases}$$

with p, q positive constants. They are precisely the self-similar form of the N-waves, and p, q measure, respectively, the negative and positive mass of the N-wave.

The similarity forms (1.5) and (1.6)–(1.7) provide a convenient formulation for performing long-time numerical runs as well as a framework for a qualitative explanation of the various regimes of the problem. In the first stage the solution evolves from u_0 to a saw-tooth profile via the usual compression-attenuation mechanism of hyperbolic equations. In the next stage the waves interact and produce an approximate N-wave. In both of these stages the effect of diffusion lies only in selecting admissible discontinuities, and the evolution is essentially governed by the convection equation (1.6)–(1.7). The N-waves are steady states for (1.6), but, due to the presence of small diffusion, they are only approximate solutions for (1.5). This discrepancy drives the evolution in the last stage from an approximate N-wave to the steady state of (1.5), a diffusion wave. This stage is a very slow transition and a manifestation of metastability driven by the small diffusion.

A number of techniques have been developed for treating asymptotic behavior problems for nonlinear convection (see, e.g., [2, 3, 13]) or convection-diffusion equations (see, e.g., [5, 6, 14]). Here we exploit the similarity structure based on the invariances of the Burgers equation. This perspective is initiated in Hopf [7] and is developed in Tartar [20], Liu–Pierre [13] (for convection equations), and Escobedo–Vazques–Zuazua [5, 6] (for various multidimensional convection-diffusion equations with power laws). The aim is to pursue quantitative explanations of the various regimes; the simplicity of the equation allows us to obtain a complete picture, including the interesting regime of small-viscosity long-time interaction.

We begin, in sections 2–3, with a review of some of the standard hyperbolic theory of L^1-contraction and Oleinik inequality for the self-similar Burgers (1.5). We show how to use a special Lyapunov function to establish the asymptotic in time profile (for μ fixed) of a diffusion wave (see Theorem 3.3). The results in sections 2–3 can be established with different methods, but we draw attention to the fact that the study of (1.5) provides optimal convergence results with little effort. They also set the stage for section 4, where we provide explanations and predictions for the numerical runs based on heuristic arguments and theoretical results.

In the last two sections we turn our attention to the issue of metastability. In section 5, we generalize a construction of Whitham [21] and provide a special solution corresponding to a diffusive N-wave with unequal positive and negative masses. This solution reads

$$\begin{aligned} &u_{p,q}(x,t+1) = \sqrt{\frac{\mu}{t+1}}\, v_{p,q}\left(\frac{x}{\sqrt{4\mu(t+1)}}, t\right), \\ &\qquad \text{where} \quad v_{p,q}(\xi,t) = \frac{\frac{B}{\sqrt{\pi}} e^{-\xi^2} + 2A\frac{1}{\sqrt{t+1}}\xi e^{-\xi^2}}{1 - \frac{B}{\sqrt{\pi}}\int_{-\infty}^{\xi} e^{-\zeta^2} d\zeta + A\frac{1}{\sqrt{t+1}} e^{-\xi^2}}, \end{aligned} \tag{1.8}$$

where $B = 1 - e^{(p-q)/2\mu}$ and $A = e^{p/2\mu} + O(B)$ are constants determined via the positive and negative masses p, q of the initial data. The solution $u_{p,q}$ converges to an N-wave as $\mu \to 0$, which suggests the terminology diffusive N-wave for $u_{p,q}$. It captures, in an explicit manner, the slow transition from an approximate N-wave to the final stage of a diffusion wave.

Motivated by the format of (1.8), we use in section 6 appropriate similarity variables and a variant of the Cole–Hopf transformation to transform the Burgers equation into an integrated version of a Fokker–Planck equation. Unlike the Laplace operator on the real line, the present operator (6.7) has a discrete spectrum. The process yields an explicit formula for the solution of the Burgers equations in terms of Hermite polynomials:

$$\begin{aligned} &u(x,t) = \sqrt{\frac{\mu}{t+1}}\, v\left(\frac{x}{\sqrt{4\mu(t+1)}}, t\right), \\ &\qquad \text{where} \quad v(\xi,t) = -\frac{\partial_\xi \psi_M^\infty + \sum_{n=0}^{\infty} a_n (t+1)^{-\frac{n+1}{2}} \partial_\xi\left(H_n(\xi) e^{-\xi^2}\right)}{\psi_M^\infty + \sum_{n=0}^{\infty} a_n (t+1)^{-\frac{n+1}{2}} H_n(\xi) e^{-\xi^2}}, \end{aligned} \tag{1.9}$$

where ψ_M^∞ is the potential of a diffusion wave of mass M (see (6.16)), H_n are the Hermite polynomials, and the Fourier–Hermite coefficients a_n are computed explicitly from the data (see (6.18)). The asymptotic profile of the diffusion wave corresponds to keeping only the first term in the expansion, $-\frac{\partial_\xi \psi_M^\infty}{\psi_M^\infty}$, while the diffusive N-wave (1.8) corresponds to keeping the first two terms in the expansion and describes the first order correction of the general solution beyond the diffusion wave.

2. Self-similar Burgers—preliminaries.

Some of the basic properties of the viscous Burgers equations are directly linked to the self-similar Burgers equation

$$w_s + \left(\frac{1}{2}w^2 - \frac{1}{2}\xi w\right)_\xi = \mu w_{\xi\xi}. \tag{2.1a}$$

This problem is obtained from (1.1) in two different ways. If the similarity transformation (1.4) is used, then one obtains (2.1a) set in the interval $(\xi, s) \in \mathbb{R} \times \mathbb{R}$, and the initial data are projected back to $-\infty$. Alternatively, and due to the invariance $t \to t+1$, one may use the transformation

$$s = \ln(t+1)\,, \quad \xi = x/\sqrt{t+1}\,, \quad w(\xi, s) = \sqrt{t+1}\,u(x,t)$$

and obtain the initial value problem consisting of (2.1a) set on $(\xi, s) \in \mathbb{R}\times\mathbb{R}^+$ subject to data

$$w(\xi, 0) = w_0(\xi). \tag{2.1b}$$

In either case the total mass remains invariant under the transformation, and the initial mass is preserved:

$$\int_{\mathbb{R}} w(\xi, s) d\xi = M_0 < \infty.$$

Let w^μ be the solution of (2.1). In the limit $\mu \to 0$, $w^\mu \to w$ a.e., where w is a weak solution of the initial value problem

$$\begin{aligned} w_s + \left(\frac{1}{2}w^2 - \frac{1}{2}\xi w\right)_\xi &= 0, \\ w(\xi, 0) &= w_0(\xi), \end{aligned} \tag{2.2}$$

that satisfies the Oleinik (entropy) condition

$$w(\xi+, s) \le w(\xi-, s). \tag{2.3}$$

2.1. Steady states.

The admissible steady states of (2.2) are given by the two parameter family

$$\mathcal{N}_{p,q}(\xi) = \begin{cases} \xi, & -\sqrt{2p} < \xi < \sqrt{2q}, \\ 0, & \text{otherwise}, \end{cases} \tag{2.4}$$

parametrized by the positive constants p and q measuring, respectively, the mass of the negative and positive parts of the steady state. These solutions are precisely the N-waves, when viewed on the self-similar coordinates, and are denoted by $\mathcal{N}_{p,q}$. If the total mass M is prescribed, there is a one parameter family $\mathcal{N}_{p,p+M}$ corresponding to the mass M.

The equilibria of (2.1a) (for $\mu > 0$) satisfy the equation

$$\left(\frac{1}{2}\mathcal{G}^2 - \frac{1}{2}\xi\mathcal{G}\right)' = \mu\mathcal{G}'' \tag{2.5}$$

and are computed by the formula

$$\mathcal{G}_M(\xi) = \frac{\sqrt{\mu}\,(1 - e^{-M/2\mu})\,e^{-\xi^2/4\mu}}{1 - (1 - e^{-M/2\mu})\frac{1}{\sqrt{\pi}}\int_{-\infty}^{\xi/\sqrt{4\mu}} e^{-\zeta^2}d\zeta}, \qquad M \in \mathbb{R}. \tag{2.6}$$

The denominator in (2.6) does not vanish, and the total mass of $\mathcal{G}_M$ is computed by

$$\int_{-\infty}^{\infty} \mathcal{G}_M d\xi = -2\mu \int_{-\infty}^{\infty} \partial_\xi \ln\left(1 - (1 - e^{-M/2\mu})\frac{1}{\sqrt{\pi}}\int_{-\infty}^{\xi/\sqrt{4\mu}} e^{-\zeta^2}d\zeta\right) d\xi = M. \tag{2.7}$$

The steady states of the viscous problem are thus determined by the total mass M and correspond to the well-known diffusion waves in self-similar coordinates. We summarize some of their properties below.

Lemma 2.1. *Let $\mathcal{G}_M$ be a diffusion wave given by* (2.6). *Then*

(i) $\mathcal{G}_0(\xi) = 0$ *and* $\int_{-\infty}^{\infty} \mathcal{G}_M d\xi = M$*;*

(ii) $\mathcal{G}_M(\xi) > \mathcal{G}_{M'}(\xi)$ *for* $M > M'$*;*

(iii) *for any bounded function $f(\xi)$ with a compact support, there exists $M > 0$ such that $\mathcal{G}_{-M}(\xi) \leq f(\xi) \leq \mathcal{G}_M(\xi)$;*

(iv) $\mathcal{G}_M \to \mathcal{N}_{0,M}$ *as $\mu \to 0$ for $M > 0$ and $\mathcal{G}_M \to \mathcal{N}_{|M|,0}$ as $\mu \to 0$ for $M < 0$.*

2.2. Oleinik inequality. We present a quick derivation of some well-known properties viewed from the perspective of (2.1a). Recall that (2.1a) arises from the transformation (1.4) and is set on $\mathbb{R} \times \mathbb{R}$. The derived estimates are independent of μ and s. We begin with the analogue of the Oleinik estimate [16].

Lemma 2.2. *The solution $w(\xi, s)$ of* (2.1a) *satisfies*

$$w_\xi(\xi, s) \leq 1, \qquad s, \xi \in \mathbb{R}. \tag{2.8}$$

Proof. The quantity $z = w_\xi$ satisfies

$$z_s + \left(w - \frac{1}{2}\xi\right) z_\xi + z(z-1) = \mu z_{\xi\xi}. \tag{2.9}$$

If z has an interior maximum, then the value at the maximum is between 0 and 1. Since

$$w_\xi(\xi, \ln t) = t u_x(\sqrt{t}\xi, t)\,, \tag{2.10}$$

for smooth data u_0 we have $\lim_{s\to-\infty} w_\xi(\xi, s) = 0$, and (2.8) follows. If the data are not smooth, they may be approximated by smooth data in a standard way, and we conclude (2.8) by a density argument. □

Consider the functions

$$\begin{aligned} W(\xi, s) = W_-(\xi, s) &= \int_{-\infty}^{\xi} w(\zeta, s)d\zeta, \\ W_+(\xi, s) &= \int_{\xi}^{\infty} w(\zeta, s)d\zeta = M_0 - W(\xi, s) \end{aligned} \tag{2.11}$$

and the quantities

$$(2.12)\qquad \begin{aligned} p(s) &= -\inf_{\xi} W(\xi,s)\,,\\ q(s) &= \sup_{\xi} W_+(\xi,s) = M_0 + p(s)\,. \end{aligned}$$

$p(s)$ and $q(s)$ are time-invariants for solutions of the inviscid problem [12], but for the viscous problem they do not remain constant anymore. W satisfies a viscous Hamilton–Jacobi equation

$$(2.13)\qquad W_s + \frac{1}{2}(W_\xi - \xi)W_\xi = \mu W_{\xi\xi}.$$

As a simple implication of the maximum principle and Lemma 2.2, we have the following lemma.

Lemma 2.3. *Let $w(\xi,s;\mu)$ be the solution of* (2.1a), *let W be its integral given by* (2.11), *and let $A = -\inf W(\xi,0)$ and $B = \sup W(\xi,0) \geq 0$. Then W and w are uniformly bounded by*

$$(2.14)\qquad -A \leq W(\xi,s) \leq B,$$

$$(2.15)\qquad |w(\xi,s)| \leq \sqrt{2(A+B)}.$$

Proof. The estimate (2.14) follows from the maximum principle. To show (2.15), suppose that $w(\xi_1,s) > \sqrt{2(A+B)}$ for some s,ξ_1. Let $\xi_0 < \xi_1$ be such that $w(\xi_0) = 0$ and $w(\xi,s) > 0$ on (ξ_0,ξ_1). (If $w > 0$ on $(-\infty,\xi_1)$, we take $\xi_0 = -\infty$.) Since $w_\xi \leq 1$, we have $\int_{\xi_0}^{\xi_1} w(\xi,s)d\xi > A+B$ and

$$W(\xi_1,s) = W(\xi_0,s) + \int_{\xi_0}^{\xi_1} w(\xi,s)d\xi > B,$$

thus violating (2.15). If it is assumed that $w(\xi_1,s) < -\sqrt{2(A+B)}$, then similar arguments lead to a contradiction. □

2.3. L^1-contraction theory. From now on, consider the initial value problem (2.1) consisting of (2.1a) and (2.1b) and set $(\xi,s) \in \mathbb{R}\times\mathbb{R}^+$. For data $w_0 \in L^\infty \cap L^1$ this problem has a unique smooth solution. Let w_1, w_2 be two solutions; their difference $v = w_1 - w_2$ satisfies the linear parabolic equation

$$(2.16)\qquad \begin{aligned} v_s + \frac{1}{2}((w_1+w_2-\xi)v)_\xi &= \mu v_{\xi\xi},\\ v(\xi,0) &= w_1(\xi,0) - w_2(\xi,0). \end{aligned}$$

The integral

$$V(\xi,s) = \int_{-\infty}^{\xi} v(\zeta,s)d\zeta = \int_{-\infty}^{\xi} w_1(\zeta,s) - w_2(\zeta,s)d\zeta$$

satisfies

$$(2.17)\qquad V_s + \frac{1}{2}(w_1+w_2-\xi)V_\xi - \mu V_{\xi\xi} = 0.$$

Let $v^+ = \max\{v, 0\} = (v + |v|)/2$.

THEOREM 2.4. *Let* w_1, w_2 *be classical solutions of* (2.1) *with initial data* $w_1(\xi, 0)$ *and* $w_2(\xi, 0)$*. Then*

$$\int_{-\infty}^{\infty} |w_1(\xi, s) - w_2(\xi, s)| d\xi \le \int_{-\infty}^{\infty} |w_1(\xi, 0) - w_2(\xi, 0)| d\xi, \tag{2.18}$$

$$\int_{-\infty}^{\infty} (w_1(\xi, s) - w_2(\xi, s))^{\pm} d\xi \le \int_{-\infty}^{\infty} (w_1(\xi, 0) - w_2(\xi, 0))^{\pm} d\xi. \tag{2.19}$$

Furthermore, the quantity

$$\int_{-\infty}^{\infty} (w_1(\xi, s) - w_2(\xi, s))^{\pm} d\xi \tag{2.20}$$

decreases strictly in s*, unless either* $w_1(\xi, s) \le w_2(\xi, s)$ *or* $w_2(\xi, s) \le w_1(\xi, s)$ *for all* $\xi \in \mathbb{R}$.

Proof. The first part is a direct consequence of the standard contraction theory for convection-diffusion equations; see [8, 18]. We present a proof of the second part, which is based on a detailed analysis of a linear equation

$$v_s + (a(\xi, s)v)_\xi = \mu v_{\xi\xi}, \tag{2.21}$$

with $a(\xi, s)$ continuously differentiable and $|a_\xi| \le M$.

Step 1. Let $v^+ = \max\{v, 0\} = \frac{v+|v|}{2}$. Then $\partial_\xi v^+ = v_\xi \chi_{\{v>0\}}$, $\partial_s v^+ = v_s \chi_{\{v>0\}}$, and $v^+ \in W^{1,\infty}(\mathbb{R} \times \mathbb{R}^+)$. Also set

$$V^+(\xi, s) = \int_{-\infty}^{\xi} v^+(\zeta, s) d\zeta = \int_{-\infty}^{\xi} (w_1 - w_2)^+(\zeta, s) d\zeta, \tag{2.22}$$

which (due to the integrability of v and v_s) enjoys the regularity $W^{2,\infty}$ in ξ and $W^{1,\infty}$ in s. We show in this step that v^+ and V^+ satisfy

$$(v^+)_s + (a(\xi, s)v^+)_\xi \le \mu(v^+)_{\xi\xi}, \tag{2.23}$$

$$(V^+)_s + a(\xi, s)(V^+)_\xi \le \mu(V^+)_{\xi\xi} \tag{2.24}$$

in the sense of distributions.

To see that, consider the functions

$$\psi_n(v) = \begin{cases} 0, & v \le 0, \\ nv, & 0 \le v \le 1/n, \\ 1, & v \ge 1/n, \end{cases} \qquad \Psi_n(v) = \int_{-\infty}^{v} \psi_n(\tau) d\tau = \begin{cases} 0, & v \le 0, \\ \dfrac{nv^2}{2}, & 0 \le v \le 1/n, \\ v - \dfrac{1}{2n}, & v \ge 1/n. \end{cases}$$

Then $\Psi_n(v)$ satisfies

$$\begin{aligned} (\Psi_n(v))_s + (a\Psi_n(v))_\xi + a_\xi(v\psi_n(v) - \Psi_n(v)) &= \mu(\Psi_n(v))_{\xi\xi} - \mu\psi_n'(v)v_\xi^2 \\ &\le \mu(\Psi_n(v))_{\xi\xi}. \end{aligned} \tag{2.25}$$

Using the properties

$$\Psi_n(v) \to v^+, \quad 0 \le \Psi_n(v) \le v^+, \tag{2.26}$$

$$v\psi_n(v) - \Psi_n(v) \to 0\,, \quad |v\psi_n(v) - \Psi_n(v)| \le \frac{1}{2}v^+, \tag{2.27}$$

we pass to the limit $n \to \infty$ in (2.25) and obtain (2.23).

Next we consider the integrated version of (2.25),

$$\begin{aligned} \partial_s \int_{-\infty}^{\xi} \Psi_n(v) d\zeta + a\Psi_n(v) + \int_{-\infty}^{\xi} a_\xi (v\psi_n(v) - \Psi_n(v)) d\zeta \\ = \mu \partial_\xi \Psi_n(v) - \mu \int_{-\infty}^{\xi} \psi_n'(v) v_\xi^2 d\zeta \le \mu \partial_\xi \Psi_n(v), \end{aligned} \tag{2.28}$$

and use the properties (2.25), $|a_\xi| \le M$, and

$$\int_{-\infty}^{\xi} \Psi_n(v) d\zeta \to \int_{-\infty}^{\xi} v^+ d\zeta\,, \quad \int_{-\infty}^{\xi} \Psi_n(v) d\zeta \le V^+$$

$$\left| \int_{-\infty}^{\xi} a_\xi (v\psi_n(v) - \Psi_n(v)) d\zeta \right| \le \frac{M}{2} \int_{-\infty}^{\xi} v^+ d\zeta$$

to pass to the limit $n \to \infty$ and derive (2.24).

Step 2. From (2.23) we derive the inequality

$$\frac{d}{ds} \int \varphi(\xi) v^+(\xi, s) d\xi - \int \big(a v^+ - \mu (v^+)_\xi \big)(\xi, s) \varphi_\xi(\xi) d\xi \le 0 \tag{2.29}$$

for any positive test function $\varphi \in C_c^\infty(\mathbb{R})$. In turn, this yields that $\int v^+(\xi, s) d\xi$ is decreasing in s. Since $\int v(\xi, s) d\xi$ is a conserved quantity, this implies (2.18) and (2.19).

We may obtain a more detailed variant of (2.19) as follows. Fix $s > 0$ and consider a decomposition of the open set $\{\xi : v(\xi, s) > 0\} = \cup_k (\alpha_k, \beta_k)$ into countably many subintervals such that $v(\cdot, s) > 0$, and C^1 on (α_k, β_k), $v_\xi(\alpha_k, s) \ge 0$, and $v_\xi(\beta_k, s) \le 0$. Consider a test function φ_n such that

$$\varphi_n(\xi) = \begin{cases} 0, & \xi \le \alpha_k \ \text{ or } \ \xi \ge \beta_k, \\ 1, & \alpha_k + \dfrac{1}{n} \le \xi \le \beta_k - \dfrac{1}{n}, \\ \text{linear}, & \alpha_k < \xi < \alpha_k + \dfrac{1}{n} \ \text{ or } \ \beta_k - \dfrac{1}{n} < \xi < \beta_k. \end{cases}$$

We apply (2.29) for this test function and pass to the limit $n \to \infty$ to obtain

$$\frac{d}{ds} \int_{\alpha_k}^{\beta_k} v^+(\xi, s) d\xi \le \mu \big(v_\xi(\beta_k, s) - v_\xi(\alpha_k, s) \big) \le 0\,,$$

$k = 1, 2, \dots$; that is, the area under any component of v^+ is decreasing in size.

Step 3. The second part of the theorem, which is a stronger version of the first part, is obtained from the strong maximum principle. Consider $V^+(\xi, s)$ in (2.22), fix $\bar{s} > 0$, and suppose there exists $\xi_0 < \xi_1$ such that $v(\xi_0, \bar{s}) > 0$ and $v(\xi_1, \bar{s}) < 0$. Consider a restriction of V^+ defined by

$$Z^+(\xi, s) = \int_{-\infty}^{\xi} v^+(\zeta, s) \chi_{(-\infty, \xi_1)}(\zeta)\, d\zeta = \begin{cases} V^+(\xi, s) & \text{if } \xi < \xi_1, \\ V^+(\xi_1, s) & \text{if } \xi > \xi_1, \end{cases} \quad |s - \bar{s}| < \delta,$$

where

$$\chi_{(-\infty,\xi_1)} = \begin{cases} 1, & \xi \in (-\infty, \xi_1), \\ 0, & \xi \notin (-\infty, \xi_1). \end{cases}$$

We can take $\delta > 0$ so small that Z^+ has the same regularity as V^+ and compute

$$\begin{aligned} \partial_s Z^+ + a\partial_\xi Z^+ - \mu\partial_\xi^2 Z^+ \\ &= \big(\partial_s V^+ + a\partial_\xi V^+ - \mu\partial_\xi^2 V^+\big)\chi_{(-\infty,\xi_1)} - \mu v^+(\xi_1, s)\delta(\xi - \xi_1) \\ &\quad + \partial_s V^+(\xi_1, s)\chi_{(-\infty,\xi_1)} = I_1 + I_2 + I_3 \le 0, \end{aligned} \tag{2.30}$$

where the last inequality follows from (2.24) and the properties $v^+(\xi_1, s) = 0$ (hence $I_2 = 0$) and (from step 2)

$$\frac{d}{ds}\int_{-\infty}^{\xi_1} v^+(\zeta, s)d\zeta = \frac{d}{ds}V^+(\xi_1, s) \le 0.$$

Therefore, Z^+ satisfies the parabolic inequality (2.30) in the interval $0 < s - \bar{s} < \delta$.

If $Z^+(\xi_1, s)$ is strictly decreasing at $\bar{s}$, then (2.20) follows. On the other hand, if $Z^+(\xi_1, s)$ remains constant in the small time interval, then $Z^+(\cdot, s)$ has a strictly positive maximum at the interior point $\xi = \xi_1$ for a time interval $0 < s - \bar{s} < \delta$ which contradicts the strong maximum principle (see, e.g., [11]). □

Remark 2.5 (the lap-number). For semilinear parabolic equations there exists a literature concerning the number of zeroes of a solution, sometimes called the lap-number (see, e.g., Matano [15] and Angenent [1]). Such results hinge on analysis of the linear equation

$$u_t = u_{xx} + q(x, t)u, \qquad x \in \mathbb{R}\,,\ t > 0\,, \tag{2.31}$$

when $q(x, t) \in L^\infty$ and for solutions satisfying the bound $|u(x, t)| \le Ae^{Bx^2}$. It is shown in [1] that the number of zeroes

$$\mathbb{Z}_t = \{x \in \mathbb{R} : u(x, t) = 0\}$$

becomes immediately (at time $t = 0+$) a discrete set, and thereafter the number of zeroes is decreasing in time. The basis of the last result is the property that if $u(x, t)$ and $u_x(x, t)$ vanish simultaneously at (x_0, t_0) (i.e., u has a multiple zero at (x_0, t_0)), then, roughly speaking, $u(\cdot, t)$ has more zeroes for $t < t_0$ than for $t > t_0$ (see Angenent [1, Theorem B] for the precise statement).

These results apply to various semilinear parabolic equations that can (through transformations of variables) be put in the form (2.31) [1]. They also apply to quasilinear equations when linear variants of them can be put into this framework. In particular, the viscous Burgers equation shares this property (along solutions that the wave speed $u(x, t)$ and its first derivatives are uniformly bounded). Finally, the same property is transferred to solutions $w(\xi, s)$ of (2.1) through the similarity transformations.

3. Evolution of the viscous problem. Here we study the long-time convergence of solutions to a diffusion wave.

3.1. Convergence to a diffusion wave. Consider the difference $w(\xi,s)-\mathcal{G}_M(\xi)$, and note that the L^1-contraction implies

$$\int_{-\infty}^{\infty}(w(\xi,s)-\mathcal{G}_M(\xi))^{\pm}d\xi \le \int_{-\infty}^{\infty}(w(\xi,0)-\mathcal{G}_M(\xi))^{\pm}d\xi. \tag{3.1}$$

First, we prove a technical lemma, indicating that if the solution stabilizes, then the mass of the solution stabilizes.

Lemma 3.1. *Let w be the solution of* (2.1) *emanating from initial data $w_0 \in L^1\cap L^\infty$. If along a time sequence $\{s_k\}$ we have $w(\xi,s_k)\to\bar{w}(\xi)$ a.e. ξ as $s_k\to\infty$, then*

$$\lim_{s_k\to\infty}\int_{-\infty}^{\infty} w(\zeta,s_k)d\zeta = \int_{-\infty}^{\infty}\lim_{s_k\to\infty} w(\zeta,s_k)d\zeta\,. \tag{3.2}$$

Proof. Assume first that the data satisfy

$$\mathcal{G}_{-M}(\xi)\le w_0(\xi)\le\mathcal{G}_M(\xi).$$

Then from the comparison estimate (2.19)

$$\mathcal{G}_{-M}(\xi)\le w(\xi,s)\le\mathcal{G}_M(\xi)$$

and the dominated convergence theorem implies the desired result.

Now let $w_0\in L^1\cap L^\infty$. For $\varepsilon>0$ choose $M>0$ so that

$$\int_{-\infty}^{\infty}(w_0(\zeta)-\mathcal{G}_M(\zeta))^+ + (w_0(\zeta)-\mathcal{G}_{-M}(\zeta))^- d\zeta<\varepsilon. \tag{3.3}$$

Let

$$w_M(\xi,s)=\begin{cases}\mathcal{G}_M(\xi) & \text{if } w>\mathcal{G}_M,\\ w(\xi,s) & \text{if } \mathcal{G}_{-M}<w<\mathcal{G}_M,\\ \mathcal{G}_{-M}(\xi) & \text{if } w<\mathcal{G}_{-M},\end{cases} \tag{3.4}$$

and define $\bar{w}_M(\xi)$ in a similar fashion using the limit function $\bar{w}(\xi)$ in the place of $w(\xi,s)$. Observe that $w_M(\zeta,s_k)\to\bar{w}_M(\zeta)$ and that

$$\begin{aligned}&\left|\int_{-\infty}^{\infty}\big(w(\zeta,s_k)-w_M(\zeta,s_k)\big)d\zeta\right|\\ &\qquad=\left|\int_{w>\mathcal{G}_M}\big(w(\zeta,s_k)-\mathcal{G}_M(\zeta)\big)d\zeta+\int_{w<\mathcal{G}_{-M}}\big(w(\zeta,s_k)-\mathcal{G}_{-M}(\zeta)\big)d\zeta\right|\le 2\varepsilon\end{aligned}$$

from (2.19), (3.1), and (3.3). Now $\int_{\mathbb{R}} w_M(\cdot,s_k)d\zeta\to\int_{\mathbb{R}}\bar{w}_M d\zeta$, and we conclude by (3.3)

$$\left|\lim_{s_k\to\infty}\int_{-\infty}^{\infty}w(\zeta,s_k)d\zeta-\int_{-\infty}^{\infty}\bar{w}(\zeta)d\zeta\right|\le 4\varepsilon,$$

which gives (3.2). □

In the following theorem we show that the solution of (2.1) converges to a diffusion wave preserving the initial total mass.

THEOREM 3.2 (convergence in time). *Let w be the solution to the Cauchy problem* (2.1) *with $\mu > 0$ and $w_0 \in L^1 \cap L^\infty$, $\partial_\xi w_0 \in L^2$, and total mass $\int w_0(\xi) d\xi = M_0$. Then*

$$w(\xi, s) \to \mathcal{G}_{M_0}(\xi) \quad \text{as } s \to \infty, \tag{3.5}$$

a.e. and in $L^1(\mathbb{R})$, where $\mathcal{G}_{M_0}$ is the diffusion wave given by (2.6).

Proof. Consider the quantity $\Phi = e^{-\frac{1}{2\mu}W}$ motivated by the Cole–Hopf transformation. Then Φ satisfies

$$\Phi_s - \frac{1}{2}\xi\Phi_\xi = \mu\Phi_{\xi\xi}. \tag{3.6}$$

We differentiate (3.6) with respect to s and multiply by Φ_s. After rearranging the terms, we obtain

$$\partial_s\Phi_s^2 - \frac{1}{2}\partial_\xi\big(\xi\Phi_s^2\big) + \frac{1}{2}\Phi_s^2 + 2\mu\Phi_{\xi s}^2 = \mu\partial_{\xi\xi}\Phi_s^2.$$

Therefore, the quantity

$$g(s) = \int_{\mathbb{R}} \Phi_s^2(\xi, s) d\xi = \int_{\mathbb{R}} \frac{1}{4\mu^2} e^{-\frac{1}{\mu}W} W_s^2 \, d\xi$$

satisfies the differential inequality $\frac{dg}{ds} + \frac{1}{2}g \le 0$. We conclude that

$$\int_{\mathbb{R}} e^{-\frac{1}{\mu}W} W_s^2 \, d\xi \le \left(\int_{\mathbb{R}} e^{-\frac{1}{\mu}W(\xi,0)} W_s^2(\xi, 0) \, d\xi \right) e^{-\frac{s}{2}}$$

and, from (2.14) and (2.13), that

$$\int_{\mathbb{R}} W_s^2(\xi, s) \, d\xi \le O(1) e^{-\frac{s}{2}}, \tag{3.7}$$

where $O(1)$ depends on μ and the H^1-norm of the data w_0. (The last dependence may be relaxed by using the regularizing effect of (2.1), but we will not pursue the details here.)

From (2.8) and (2.15), the function $(w(\xi, s) - \xi)$ is decreasing and for any $[a, b] \subset \mathbb{R}$ we have

$$TV_{\xi\in[a,b]} w(\cdot, s) \le \sup_\xi w_0 - \inf_\xi w_0 + 2(b - a).$$

From Helly's theorem and a diagonal argument we can extract a subsequence $s_n \to \infty$ and a function $\bar{w}$ of locally bounded variation so that

$$w(\xi, s_n) \to \bar{w}(\xi) \quad \text{as } s_n \to \infty. \tag{3.8}$$

Let $\theta(\xi)$ be a C^∞-function with compact support. From (2.13) we obtain

$$\int_{\mathbb{R}} W_s(\cdot, s)\theta d\xi + \int_{\mathbb{R}} \frac{1}{2}\big(w^2 - \xi w\big)\theta d\xi + \int_{\mathbb{R}} \mu w \theta_\xi d\xi = 0.$$

We use (3.7), (3.8), and Lemma 3.1 to pass to the limit along s_n and deduce that $\bar{w}$ satisfies

$$\begin{gathered} \frac{1}{2}\bar{w}^2 - \frac{1}{2}\xi\bar{w} = \mu\bar{w}_\xi, \\ \int_{\mathbb{R}} \bar{w} d\xi = \int_{\mathbb{R}} w_0 d\xi = M_0 \, . \end{gathered} \tag{3.9}$$

Therefore, $\bar{w} = \mathcal{G}_{M_0}$, and, as the limit is uniquely determined by (3.9), we conclude that the family $w(\xi, s) \to \mathcal{G}_{M_0}(\xi)$ as $s \to \infty$. □

3.2. Convergence to a diffusion wave via the invariance principle. Next we provide a proof of the time-convergence to a diffusion wave from the viewpoint of the LaSalle invariance principle, in the spirit of [3, 6]. Recall that the solution operator of the viscous Burgers defines a contraction semigroup in $L^1(\mathbb{R})$ defined by $T(s)w_0 = w(\cdot, s)$, where $w_0 \in L^1(\mathbb{R}) \cap L^\infty(\mathbb{R})$ is the initial datum.

Theorem 3.3 (convergence in time). *Let w be the solution to the Cauchy problem* (2.1) *with $\mu > 0$ and $w_0 \in L^1 \cap L^\infty$ with total mass $\int w_0(\xi)d\xi = M_0$. Then*

$$w(\xi, s) \to \mathcal{G}_{M_0}(\xi) \quad \text{as } s \to \infty, \tag{3.10}$$

pointwise and in $L^p(\mathbb{R})$, $1 \le p < \infty$, where $\mathcal{G}_{M_0}$ is the diffusion wave given by (2.6).

Proof. Consider the ω-limit set

$$\omega(w_0) = \left\{ \psi \in L^1(\mathbb{R}) : \psi = \lim_{k\to\infty} T(s_k)w_0 \text{ for a subsequence } s_k \right\}. \tag{3.11}$$

From (3.8) we have a convergent subsequence $T(s_k)w_0 = w(\cdot, s_k)$ and thus $\omega(w_0)$ is not empty. Moreover, T is positively invariant; that is, if $\psi \in \omega(w_0)$, then $T(s)\psi \in \omega(w_0)$. This follows from the semigroup property and the observation

$$T(s)\psi = \lim_{k\to\infty} T(s)T(s_k)w_0 = \lim_{k\to\infty} T(s + s_k)w_0. \tag{3.12}$$

Consider the distance functional $V : L^1(\mathbb{R}) \to \mathbb{R}$ defined by

$$V(\chi) = ||\chi - \mathcal{G}_{M_0}||_{L^1}, \tag{3.13}$$

which is continuous in $L^1(\mathbb{R})$. The diffusion wave $\mathcal{G}_{M_0}$ is a special solution of (2.1). Due to the contraction theory (2.18), V satisfies

$$V(T(s)w_0) = ||w(\cdot, s) - \mathcal{G}_{M_0}||_{L^1} \le ||w_0 - \mathcal{G}_{M_0}||_{L^1} = V(w_0) \tag{3.14}$$

for any $s > 0, w_0 \in L^1(\mathbb{R})$. Since $V(T(s)w_0)$ is decreasing in time, it converges $V(T(s)w_0) \to c$ to a limit $c \ge 0$. From the continuity of V, we obtain

$$V(T(s)\psi) = V\left(\lim_{k\to\infty} T(s + s_k)w_0\right) = \lim_{k\to\infty} V(T(s + s_k)w_0) = c \tag{3.15}$$

for any $\psi \in \omega(w_0)$ and $s \ge 0$.

We shall assume there is $\psi \in \omega(w_0)$ such that $\psi \neq \mathcal{G}_{M_0}$ and establish a contradiction. For such a ψ we have $V(\psi) = c > 0$, $T(s)\psi \in \omega(w_0)$, and $V(T(s)\psi) = c$ from (3.15). Since

$$\int \psi(\xi) - \mathcal{G}_{M_0}(\xi)d\xi = 0\,,$$

there exist ξ_0, ξ_1 such that $\mathcal{G}_{M_0}(\xi_0) > \psi(\xi_0)$ and $\mathcal{G}_{M_0}(\xi_1) < \psi(\xi_1)$. Theorem 2.4 then implies that $V(T(s)\psi) < V(\psi) = c$, which contradicts (3.15). So the nonempty ω-limit set should be $\omega(w_0) = \{\mathcal{G}_{M_0}\}$. □

4. Diffusion driven interfaces and metastability. The asymptotic behavior of the inviscid Burgers equation is an N-wave [12]. By contrast, solutions of the viscous Burgers equation approach diffusion waves asymptotically in time. That indicates a sensitive dependence of the long-time asymptotics for the viscous Burgers equation on the viscosity that we begin analyzing from this section.

Numerical computations for solutions of the viscous Burgers equation were performed using the self-similar version (1.5). This framework has two advantages: first, the solution does not spread in time (thus a smaller computational domain is needed), and second, the time variable $s = \ln(t)$ allows us to compute for long times. The results are presented in Figure 1 for a viscosity $\mu = 0.01$ (see section 4.3 for information on the numerical scheme). It is seen that initially w^{μ} evolves from "oscillatory" initial data w_0 into a saw-tooth profile. This transition occurs relatively quickly ($s \sim 0.5$) and is driven by the usual compression-attenuation mechanism of hyperbolic equations. At the next stage the waves interact and eventually produce an approximate N-wave. This takes a longer time ($s \sim 2$), and this stage is also governed by the convection mechanism mainly (see section 4.3). Once the latter stage is reached, it appears as if there is no dynamical change. A more careful look, though, shows that the negative and positive masses of the solution decrease slowly until eventually the smaller one disappears. This evolution occurs at a far slower time scale. In Figure 1 the negative mass disappears at $s \sim 100$, which, considering that the original time variable is $t = e^s$, is an exceptionally long time.

We next analyze the role of diffusion at the intermediate stage driven by wave interactions and then transition from an N-wave to a diffusion wave (for small $s \sim 0.5$ and large $s > 2$ for the numerical run of Figure 1). Then, in sections 5 and 6, we provide a quantitative description of the metastable stage of the evolution.

4.1. Wave interactions. We provide a heuristic analysis valid for solutions emanating from data that at time $s = 0$ intersect the axis at finitely many points

$$\{\xi \in \mathbb{R} : w(\xi, s) = 0\} = \{g_1(s) < g_2(s) < \cdots < g_n(s)\}, \quad s = 0, \tag{4.1}$$

and the intersections occur transversally

$$w_\xi(g_i(s), s) \neq 0, \qquad i = 1, 2, \ldots, n, \quad s = 0. \tag{4.2}$$

For notational convenience, let $g_0(s) = -\infty$ and $g_{n+1}(s) = +\infty$. (This is the generic form of solutions that appears in numerical runs after the initial stage ($s \sim 0.5$ in Figure 1); we refer to Figure 2 for such a profile.) Our goal is to track the mechanism of motion of the intersection points.

The points of intersection g_i satisfy $w(g_i(0), 0) = 0$. Using the implicit function theorem, the curves $g_i(s)$ are each defined on a maximal interval $s \in [0, S_i)$ and move with the speed

$$g_i'(s) = -\frac{w_s(g_i(s), s)}{w_\xi(g_i(s), s)}. \tag{4.3}$$

On the interval $[0, S_i)$ we have $w_\xi(g_i(s), s) > 0$, but at the maximal time S_i it is $w_\xi(g_i(S_i), S_i) = 0$. Typically, at such times two of the curves will come together and disappear.

Consider the functions

$$p_i(s) = -\int_{-\infty}^{g_i(s)} w(\zeta, s) d\zeta = -W(g_i(s), s), \tag{4.4}$$

where $-p_i(s)$ measures the total mass of $w(\cdot, s)$ to the left of $g_i(s)$. Here we define $p_i(s)$ with a negative sign since it should represent the invariance variable p_0 in (1.3)

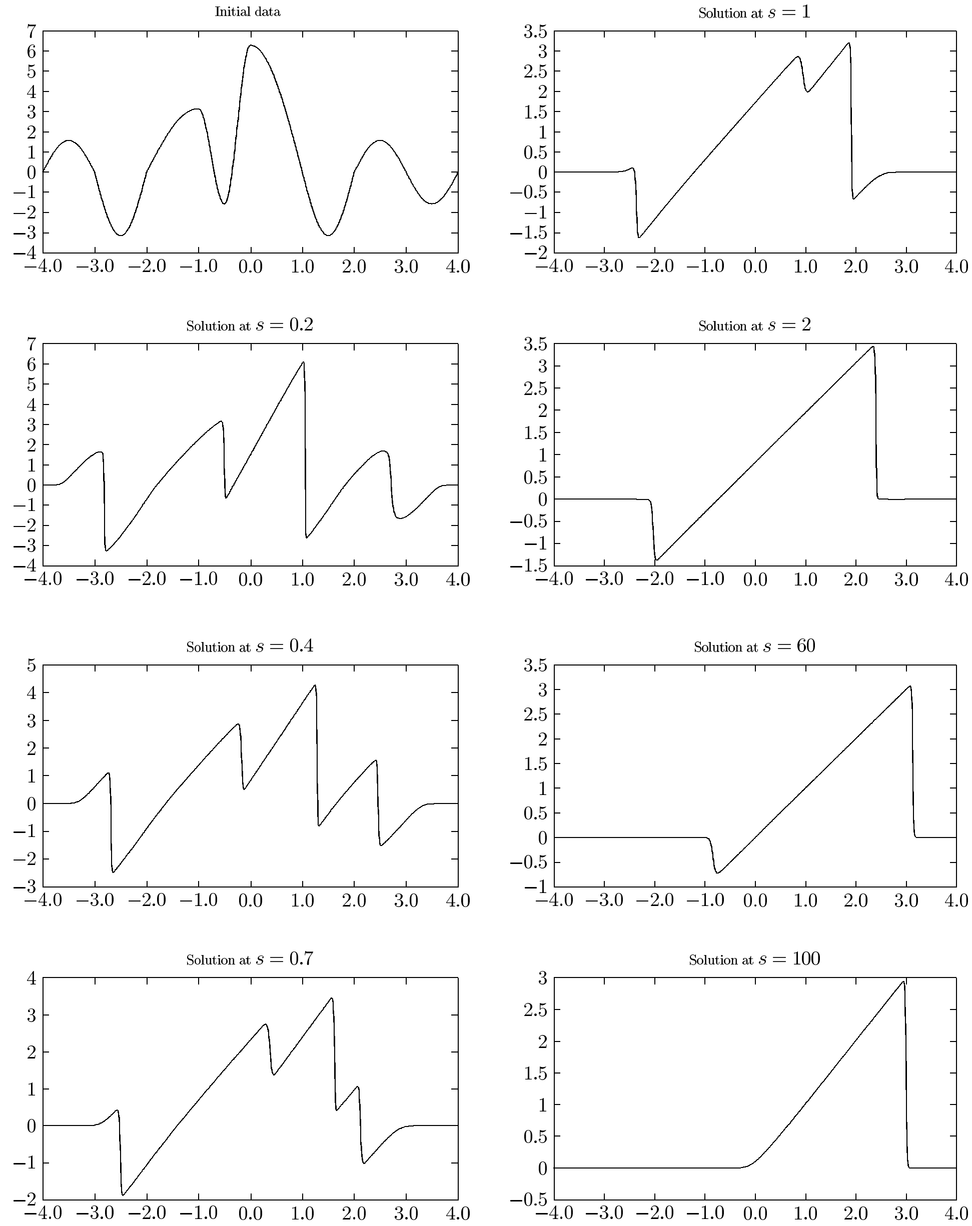

FIG. 1. *Numerical solution of transformed Burgers* (2.1): *This numerical solution is generated by the Godunov scheme with discretized viscosity and* $\Delta\xi = 0.01, \Delta s = 0.001, \mu = 0.01$.

or $p(s)$ in (2.12). Using (2.13) and the fact that $w(g_i(s), s) = 0$, we obtain

$$-p_i'(s) = W_\xi(g_i(s), s)g_i'(s) + W_s(g_i(s), s) = \mu w_\xi(g_i(s), s), \tag{4.5}$$

which pinpoints the effect of the diffusion on the mass change across a zero curve $\xi = g_i(s)$.

The remainder of our analysis is heuristic in nature. In numerical runs, after an initial transient stage, the usual compression-attenuation mechanism of Burgers

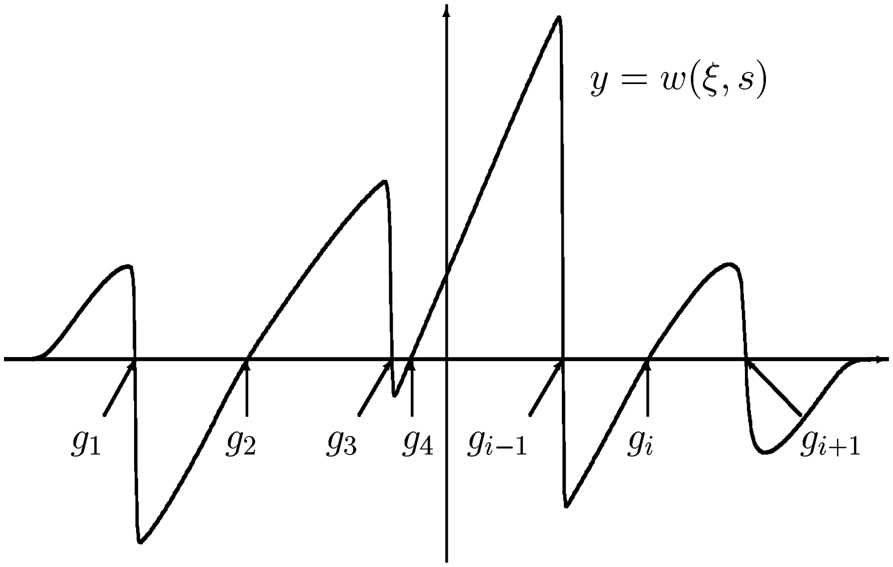

FIG. 2. *A profile of the solution at $s = 0.5$.*

produces solutions that consist entirely of shocks and rarefactions. We will operate under this condition, analyzing solutions whose time sections (s = constant) consist entirely of shocks and rarefactions and look like that in Figure 2.

The area between two zero curves $g_i(s) < g_{i+1}(s)$ (see Figure 2) is given by $A(s) = -(p_{i+1}(s) - p_i(s))$ and changes in time at a rate

$$A'(s) = -p'_{i+1}(s) + p'_i(s) = \mu w_\xi(g_{i+1}(s), s) - \mu w_\xi(g_i(s), s) < 0. \tag{4.6}$$

The positive slope at $g_i(s)$ represents an approximate rarefaction and may be estimated using the Oleinik estimate, by $0 < w_\xi(g_i(s), s) \leq 1$. Hence the change of mass across the zero curve $\xi = g_i(s)$ satisfies

$$-p'_i(s) = \mu w_\xi(g_i(s), s) \leq \mu \tag{4.7}$$

and is controlled by the diffusion. On the other hand, the negative slope at $g_{i+1}(s)$ will correspond (for μ small) to a shock profile, and the lower bound for w_ξ is of order $O(1/\mu)$. Hence the mass change across the zero curve $\xi = g_{i+1}(s)$, representing a shock, is of order $O(1)$. This points out the distinct roles of shock and rarefaction profiles: When w is increasing near a zero point, the mass change across the point is controlled by the diffusion and tends to zero as $\mu \to 0$. By contrast, near a shock profile the mass change is fast and independent of μ. The above estimations remain valid until near the time that two of the curves g_i merge and the enclosed area $A(s)$ vanishes.

4.2. Transition from N-wave to diffusion wave. Consider now a solution that emanates from N-wave like data: $w(\xi, 0) < 0$ for $\xi < \xi_0$ and $w(\xi, 0) > 0$ for $\xi > \xi_0$ with $w_\xi(\xi_0, 0) \neq 0$. We consider the zero-curve $\xi = g(s)$ emanating from the point $g(0) = \xi_0$ and satisfying $w(g(s), s) = 0$. From the implicit function theorem, the curve $g(s)$ is defined on a maximal interval $[0, S), S > 0$. As noted in Remark 2.5, the number of zeroes is nonincreasing, and for N-wave-like data, as above, it cannot happen that w and w_ξ vanish at the same point $(\bar{\xi}, \bar{s})$. This implies that either $S = \infty$ or (if S is finite) $g(s) \to \pm\infty$ as $s \to S$. In either case the solution retains its N-wave-like form in the interval $[0, S)$.

The infimum $p(s)$ of (2.12) is given by

$$p(s) = -\int_{-\infty}^{g(s)} w(\zeta, s) d\zeta. \tag{4.8}$$

From (4.7) we see that

$$p(s) \geq p(0) - \mu s \quad \text{for } 0 < s < S. \tag{4.9}$$

We next show that $S \geq \frac{1}{\mu} \min\{p(0), q(0)\}$, which provides an estimate of the transition-time to a diffusion wave. For simplicity, we assume $q(0) > p(0)$ and show that $S \geq p(0)/\mu$. Indeed, if $S < p(0)/\mu$, then from (4.9) we see that $p(s) > 0$, which implies that the mass of the negative part of the solution is still present at the time S. This contradicts the definition of S. The same argument can be made for the positive part of the solution, and we conclude that

$$\begin{array}{l} p(s) > p(0) - \mu s, \\ q(s) > q(0) - \mu s, \end{array} \qquad s < \frac{1}{\mu} \min(p(0), q(0)), \tag{4.10}$$

where $p(s), q(s)$ are the invariant variables defined in (2.12).

4.3. Comparison of the inviscid and viscous problems. We compare the evolution between the inviscid and the viscous problem for initial data consisting of two separated N-waves

$$w_0(x) = \begin{cases} x + 10, & -12 < x < -8, \\ x, & -\sqrt{2} < x < \sqrt{6}, \\ 0, & \text{otherwise}; \end{cases} \tag{4.11}$$

see Figure 3. The method of characteristics gives the exact solution of the inviscid problem: In the original variables (x, t) the solution starts to spread out, and then two inside shocks interact until a single N-wave emerges. In terms of the self-similar variables (ξ, s), one N-wave moves into the origin without changing shape until it collides with the other N-wave, and the interaction results in a new N-wave. The exact solution of the inviscid problem with initial data (4.11) is obtained by tracking the characteristics and is displayed in Figure 3 with solid lines.

The viscous problem (2.1) is solved numerically by the following scheme: Consider a uniform space $\xi_{j+1/2} = (j + 1/2)\Delta\xi$ and time $s_n = n\Delta s$ mesh, where $j \in \mathbb{Z}, n \in \mathbb{Z}^+$. The approximation of a cell-average U_j^n,

$$U_j^n \sim \frac{1}{\Delta\xi} \int_{\xi_{j-1/2}}^{\xi_{j+1/2}} w(\xi, s_n) d\xi\,,$$

is generated by a three-step explicit method,

(4.12)
$$U_j^{n+1} = U_j^n - \frac{\Delta s}{\Delta\xi}(F(U_j^n, U_{j+1}^n) - F(U_{j-1}^n, U_j^n)) + \mu \frac{\Delta s}{(\Delta\xi)^2} D(U_{j-1}^n, U_j^n, U_{j+1}^n),$$

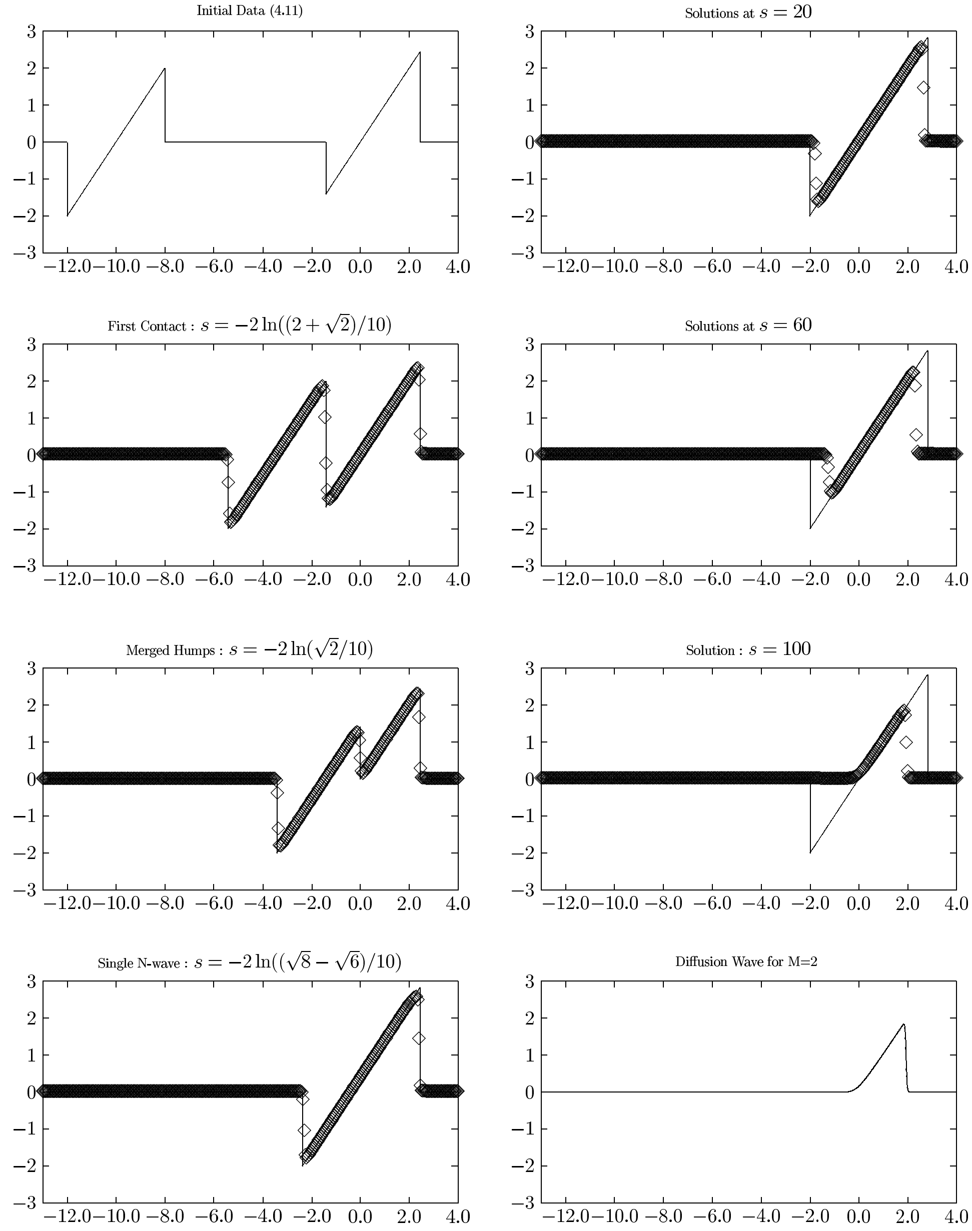

FIG. 3. *Comparison of the inviscid and viscous problems: Solid lines are exact solutions of inviscid problem* (2.2)*, and diamond dots are numerical solutions of viscous problem* (2.1) *using the Godunov scheme with* $\Delta\xi = 0.01, \Delta s = 0.0005, \mu = 0.02$*. Solutions are plotted at every other* 4 *mesh points.*

where the numerical flux F is an approximation of

$$F(U_j^n, U_{j+1}^n) \sim \frac{1}{\Delta s}\int_{s_n}^{s_{n+1}} \frac{1}{2}(w^2 - \xi_{j+1/2}w)ds, \tag{4.13}$$

and the diffusion term is discretized by

$$D(U_{j-1}^n, U_j^n, U_{j+1}^n) = U_{j-1}^n - 2U_j^n + U_{j+1}^n. \tag{4.14}$$

Since the flux of the self-similar Burgers (2.1) depends on the space variable, the solution of the Riemann problem increases exponentially along the characteristics $w(\xi(s), s) = w(\xi(0), 0)e^{s/2}$. The characteristics are not straight lines, and schemes using Riemann solver, like the Godunov scheme (see [10]), should take that into account. Here we consider a numerical flux

$$F(U_j^n, U_{j+1}^n) = \begin{cases} I(U_{j+1}^n, \bar{\xi}) & \text{if } \lambda(U_j^n, \bar{\xi}) + \lambda(U_{j+1}^n, \bar{\xi}) \le 0, \lambda(U_{j+1}^n, \bar{\xi}) \le 0, \\ I(U_j^n, \bar{\xi}) & \text{if } \lambda(U_j^n, \bar{\xi}) + \lambda(U_{j+1}^n, \bar{\xi}) > 0, \lambda(U_j^n, \bar{\xi}) > 0, \\ -3\bar{\xi}^2/8 & \text{if } \lambda(U_j^n, \bar{\xi}) < 0, \lambda(U_{j+1}^n, \bar{\xi}) > 0, \end{cases} \tag{4.15}$$

where $\bar{\xi} = \xi_{j+1/2}$ and λ is the wave speed

$$\lambda(U, \xi) = U - \xi/2. \tag{4.16}$$

$I(U, \xi)$ is an approximation of the line integral of (4.13) for a shock wave which is given by

$$I(U, \xi) = \frac{1}{2}U^2(e^{\Delta s} - 1) - \xi U(e^{\Delta s/2} - 1), \tag{4.17}$$

and we can easily check that the rarefaction wave centered at $\bar{\xi}$ has constant value $w = -3\bar{\xi}^2/8$ along the vertical line $\xi = \bar{\xi}$.

In the computation of Figure 3 the mesh size is $\Delta\xi = 0.01$, the time step is $\Delta s = 0.0005$, and the viscosity $\mu = 0.02$. The numerical solution is displayed with diamond dots. The first column indicates that the solution of the viscous problem with small viscosity is close to the solution of the inviscid problem, until the solution reaches the state of single N-wave (which is a steady state for the inviscid problem (1.6)). This stage of the evolution is dominated by convection. Subsequently, the diffusion becomes dominant, and the solution evolves slowly until it reaches the asymptotic state of a diffusion wave (a steady state for (1.5)).

Remark 4.1 (monitoring the viscosity of a numerical scheme). Numerical schemes for inviscid problems introduce numerical viscosity. A classical example is the first order Lax–Friedrich scheme for the linear equation $u_t + Au_x = 0$, which is actually a second order scheme for $u_t + Au_x = \varepsilon u_{xx}$ with a numerical viscosity

$$\varepsilon = \left(1 - \frac{(\Delta t)^2}{(\Delta x)^2}A^2\right)\frac{(\Delta x)^2}{2\Delta t}. \tag{4.18}$$

For nonlinear equations it is hard to have such an explicit control of the numerical viscosity. For that reason we opted to use a scheme based on the parabolic equation, using Godunov for the convection term and a discretization for the diffusion term.

Nevertheless, it is possible that the numerical viscosity ε can be different from the purported one μ. Under the assumption that numerical viscosity is the only factor that causes the area change of numerically approximate N-waves (an assumption clearly valid at the level of the differential equation), we can measure the numerical viscosity, using the formula (4.7), by measuring the area change and the slope at the zero point. Consider, for example, the initial data

$$w_0(\xi) = \begin{cases} x, & -2 < x < 2, \\ 0, & \text{otherwise.} \end{cases} \tag{4.19}$$

TABLE 1

Numerical viscosity of (4.12): *Initial data* (4.19), $\mu = 0.05$, $\Delta\xi = 0.01$, $\Delta s = 0.000667$.

$s^n - 1 < s < s^n$	$\max(U^n)$	$P(s^n) = \sum_{j<0} U_j^n$	$P(s^n) - P(s^n\text{-}1)$	$\Delta P/\bar{w}_\xi \sim \varepsilon$

$90 < s < 91$	1.812541e-12	-9.858833e-13	5.406505e-13	0.048895

As the area of the negative part is $\int_{-\infty}^{0} w(\zeta, s)d\zeta$, we consider $P(s^n) = \sum_{j<0} \Delta\xi U_j^n$. From (4.7) it is natural to define the numerical viscosity as

$$\varepsilon(s^n) = \frac{P(s^n) - P(s^{n-1})}{\Delta s\, \bar{w}_\xi}, \tag{4.20}$$

where the slope at the zero point is approximated by $\bar{w}_\xi = \frac{U_1^n - U_{-1}^n}{2\Delta\xi}$. In Table 1 we present the measured numerical viscosity for the scheme (4.12) with initial data (4.19) and viscosity $\mu = 0.05$. It is seen that the numerical viscosity represents the purported viscosity very well, $\varepsilon \sim \mu$, but as the solution decreases (in the second part of the table), the viscosity also decreases slightly. In the last part the solution is almost zero, and the numerical viscosity remains constant at the value around $\varepsilon \sim 0.049$.

5. Diffusive N-waves. The Cole–Hopf transformation implies that $u(x, t)$ is a solution of (1.1) if and only if

$$\varphi(x, t) = e^{-\frac{1}{2\mu}\int_{-\infty}^{x} u(x,t)dx} \tag{5.1}$$

solves the heat equation

$$\varphi_t = \mu\varphi_{xx}. \tag{5.2}$$

Note that (5.1) implies

$$\varphi(-\infty, t) = 1, \quad u = -2\mu\frac{\varphi_x}{\varphi}, \quad \int_a^b u(x,t)dx = -2\mu\ln(\varphi(b,t)/\varphi(a,t)) \tag{5.3}$$

and allows us to compute the mass of u. Whitham [21] uses the transformation to produce a special solution of a diffusive N-wave with equal positive and negative mass. In this section we give an extension to this construction and compute a special solution of a diffusive N-wave with possibly unequal positive and negative masses. This solution characterizes the transition from a diffusive N-wave to a diffusion wave, observed during the late-time response of Burgers.

We consider the special potential

$$\varphi_{p,q}(x, t) = 1 + A\sqrt{\frac{t_0}{t}}e^{-x^2/4\mu t} - B\frac{1}{\sqrt{\pi}}\int_{-\infty}^{\frac{x}{\sqrt{4\mu t}}} e^{-\zeta^2}d\zeta \tag{5.4}$$

and the corresponding solution of Burgers

$$u_{p,q}(x,t) = -2\mu\frac{(\varphi_{p,q})_x}{\varphi_{p,q}} = \frac{\frac{x}{t}A\sqrt{\frac{t_0}{t}}e^{-x^2/4\mu t} + \sqrt{\frac{\mu}{t}}\frac{B}{\sqrt{\pi}}e^{-x^2/4\mu t}}{1 + A\sqrt{\frac{t_0}{t}}e^{-x^2/4\mu t} - B\frac{1}{\sqrt{\pi}}\int_{-\infty}^{\frac{x}{\sqrt{4\mu t}}} e^{-\zeta^2}d\zeta}\,. \tag{5.5}$$

Recall that the positive and negative mass of the solution u are computed by

$$p(t) = -\inf_x \int_{-\infty}^{x} u_{p,q}(y,t)dy, \quad q(t) = \sup_x \int_x^{\infty} u_{p,q}(y,t)dy\,. \tag{5.6}$$

$p(t)$, $q(t)$ are not invariant for the viscous Burgers, but the total mass $(q(t) - p(t))$ is. The constants $A > 0$ and B in (5.4) will be determined so that the positive and negative masses at a given time t_0 are prescribed positive constants p and q, that is, $p(t_0) = p$ and $q(t_0) = q$.

This takes a lengthy computation that we outline below. To fit the total mass $M = \int u_{p,q}(y,t)dy = q - p$, we use (5.3) and obtain

$$\int_{-\infty}^{\infty} u_{p,q}(y,t)dy = -2\mu\ln(1-B) = q - p\,.$$

Hence $B = 1 - e^{(p-q)/2\mu}$. Note that $B > 0$ for $p < q$ and $B < 0$ for $q < p$; in either case $1 - B > 0$.

Clearly, $u < 0$ for $x < x_0(t) = -t\sqrt{\mu}B/\sqrt{t_0\pi}A$, and $u > 0$ for $x > x_0(t)$. The negative mass is computed from (5.3):

$$\begin{aligned} p(t) &= -\inf_x \int_{-\infty}^{x} u_{p,q}(y,t)dy = 2\mu\ln\frac{\varphi(x_0(t),t)}{\varphi(-\infty,t)} \\ &= 2\mu\ln\left(1 + A\sqrt{\frac{t_0}{t}}\,e^{-\frac{t}{t_0}(\frac{B}{\sqrt{4\pi A}})^2} - \frac{B}{\sqrt{\pi}}\int_{-\infty}^{-\sqrt{\frac{t}{t_0}}\frac{B}{\sqrt{4\pi A}}} e^{-\zeta^2}d\zeta\right). \end{aligned} \tag{5.7}$$

The requirement $p(t_0) = p$ gives the equation

$$Ae^{-(\frac{B}{\sqrt{4\pi A}})^2} = e^{p/2\mu} - 1 + \frac{B}{\sqrt{\pi}}\int_{-\infty}^{-\frac{B}{\sqrt{4\pi A}}} e^{-\zeta^2}d\zeta. \tag{5.8}$$

We give an approximate solution of (5.8). Note that $A > e^{p/2\mu} - 1 + cB$ for some $0 < c < 1$, which in turn gives the estimates

$$A = O(e^{\frac{p}{2\mu}})\,, \quad \frac{B}{A} = O(e^{-\frac{p}{2\mu}} + e^{-\frac{q}{2\mu}})\,, \quad \text{as } \mu \to 0.$$

Now we can rewrite (5.8) and use Taylor expansion to obtain

$$\begin{aligned} e^{p/2\mu} - 1 &= A\left(e^{-\rho^2} - 2\rho\int_{-\infty}^{-\rho} e^{-\zeta^2}d\zeta\right)\Big|_{\rho=\frac{B}{\sqrt{4\pi A}}} \\ &= A\Big(1 - \sqrt{\pi}\rho + O(\rho^2)\Big)\Big|_{\rho=\frac{B}{\sqrt{4\pi A}}} = A\left(1 - \frac{1}{2}\frac{B}{A} + O\left((\frac{B}{A})^2\right)\right). \end{aligned}$$

We conclude that

$$B = 1 - e^{(p-q)/2\mu}\,, \quad A = e^{p/2\mu} - 1 + B\left[\frac{1}{2} + O(e^{-\frac{p}{2\mu}} + e^{-\frac{q}{2\mu}})\right] \tag{5.9}$$

and that $A = e^{p/2\mu} + O(B)$ as $\mu \to 0$.

Next we consider the behavior of $u_{p,q}$ as the viscosity $\mu \to 0$. We write this $u_{p,q}$ in the form

$$u_{p,q}(x,t) = \frac{\frac{x}{t} + \frac{B}{A}\sqrt{\frac{\mu}{\pi t_0}}}{1 + \sqrt{\frac{t}{t_0}}\frac{e^{\frac{x^2}{4\mu t}}}{A}\left(1 - B\frac{1}{\sqrt{\pi}}\int_{-\infty}^{x/\sqrt{4\mu t}} e^{-y^2}dy\right)}.$$

It is clear that

$$\frac{x}{t} + \frac{B}{A}\sqrt{\frac{\mu}{\pi t_0}} \to 0\,,$$

$$\frac{1}{A}e^{\frac{x^2}{4\mu t}}\left(1 - B\frac{1}{\sqrt{\pi}}\int_{-\infty}^{x/\sqrt{4\mu t}} e^{-y^2}dy\right) \sim \begin{cases} \frac{1}{A}e^{\frac{x^2}{4\mu t}}\,, & x < 0, \\ \frac{1-B}{A}e^{\frac{x^2}{4\mu t}}\,, & x > 0, \end{cases}$$
$$\sim \begin{cases} e^{\frac{1}{4\mu t}(x^2 - 2pt)}\,, & x < 0, \\ e^{\frac{1}{4\mu t}(x^2 - 2qt)}\,, & x > 0, \end{cases}$$

and, as a result,

$$u_{p,q}(x,t) \sim \begin{cases} 0, & x < -\sqrt{2pt}, \\ x/t, & -\sqrt{2pt} < x < \sqrt{2qt}, \\ 0, & x > \sqrt{2qt}, \end{cases} \tag{5.10}$$

as $\mu \to 0$. This validates the terminology diffusive N-wave for $u_{p,q}$.

The long-time behavior of $u_{p,q}(x,t)$ is also easily computed. A simple inspection shows that as $t \to \infty$

$$\varphi_{p,q}(x,t) \sim 1 - \frac{B}{\sqrt{4\pi\mu t}}\int_{-\infty}^{x} e^{-y^2/4\mu t}dy\,,$$

within leading order, and that $u_{p,q}$ has the structure of a diffusion wave of mass M.

If $M > 0$, the area of the negative part of the solution diminishes as $t \to \infty$. The time at which most of the negative area has almost disappeared can be estimated as follows: First, (5.7) is written in the form

$$e^{p(t)/2\mu} = 1 + A\sqrt{\frac{t_0}{t}}e^{-\frac{t}{t_0}\frac{B^2}{4\pi A^2}} - \frac{B}{\sqrt{\pi}}\int_{-\infty}^{-\sqrt{\frac{t}{t_0}}\frac{B}{\sqrt{4\pi}A}} e^{-\zeta^2}d\zeta. \tag{5.11}$$

We substitute $t = t_0A^2/B^2$ and obtain

$$e^{p(t)/2\mu} = 1 + |B|e^{-\frac{1}{4\pi}} - \frac{B}{\sqrt{\pi}}\int_{-\infty}^{-\frac{\mathrm{sign(B)}}{\sqrt{4\pi}}} e^{-\zeta^2}d\zeta. \tag{5.12}$$

If $q > p$, then $B \sim 1$, and we get

$$e^{p(t)/2\mu} \sim 1 + e^{-\frac{1}{4\pi}} - \frac{1}{\sqrt{\pi}}\int_{-\infty}^{-\frac{1}{\sqrt{4\pi}}} e^{-\zeta^2}d\zeta \sim 1.579$$

so that

$$p(t_0A^2/B^2) \sim 2\mu \ln(1.579) \sim 0.913\,\mu.$$

On the other hand, if $M < 0$ (equivalently, $p > q$), it is the area of the positive part of the solution that diminishes. The critical time is now estimated as follows: For $p > q$ and $\mu \ll 1$, we have $B \sim -e^{(p-q)/2\mu} < 0$. Dividing both sides of (5.12) by $|B|$, we obtain

$$e^{p(t)/2\mu}/|B| = 1/|B| + e^{-\frac{1}{4\pi}} + \frac{1}{\sqrt{\pi}} \int_{-\infty}^{\frac{1}{\sqrt{4\pi}}} e^{-\zeta^2} d\zeta.$$

In turn,

$$e^{q(t)/2\mu} = e^{(p(t)-(p-q))/2\mu} \sim e^{-\frac{1}{4\pi}} + \frac{1}{\sqrt{\pi}} \int_{-\infty}^{\frac{1}{\sqrt{4\pi}}} e^{-\zeta^2} d\zeta \sim 1.579,$$

and

$$q(t_0A^2/B^2) \sim 0.913\,\mu.$$

Remark 5.1. Because of the invariance of Burgers under translations $t \to t + a$, the functions $\varphi_{p,q}(x, t+1)$ and $u_{p,q}(x, t+1)$ are also special solutions associated to diffusive N-waves. The latter can be expressed (for $t_0 = 1$) in the form

$$\begin{aligned} \varphi_{p,q}(x, t+1) &= \psi_{p,q}\left(\frac{x}{\sqrt{4\mu(t+1)}}, t\right), \\ u_{p,q}(x, t+1) &= \sqrt{\frac{\mu}{t+1}}\, v_{p,q}\left(\frac{x}{\sqrt{4\mu(t+1)}}, t\right), \end{aligned} \tag{5.13}$$

where

$$\begin{aligned} \psi_{p,q}(\xi, t) &= 1 - \frac{B}{\sqrt{\pi}} \int_{-\infty}^{\xi} e^{-\zeta^2} d\zeta + A\frac{1}{\sqrt{t+1}} e^{-\xi^2}, \\ v_{p,q}(\xi, t) &= \frac{\frac{B}{\sqrt{\pi}} e^{-\xi^2} + 2A\frac{1}{\sqrt{t+1}} \xi e^{-\xi^2}}{1 - \frac{B}{\sqrt{\pi}} \int_{-\infty}^{\xi} e^{-\zeta^2} d\zeta + A\frac{1}{\sqrt{t+1}} e^{-\xi^2}}. \end{aligned} \tag{5.14}$$

The form (5.13) of the diffusive N-waves motivates an explicit solution for the Cauchy problem of the viscous Burgers equation, which is carried out in section 6. A survey of this solution and comparison with $v_{p,q}$ indicates that while the diffusion wave is the $t \to \infty$ asymptotic profile for the viscous Burgers, the diffusive N-wave $u_{p,q}$ gives a more accurate description of the behavior in the large time regime, which encompasses the very long-time behavior and the leading order correction and is valid for a substantially longer time interval.

6. An explicit solution of the viscous Burgers equation.

The objective of this section is to derive an explicit solution of the Cauchy problem for the viscous Burgers equation

$$\begin{aligned} &u_t + uu_x = \mu u_{xx}, \quad x \in \mathbb{R}, \quad \mu, t > 0, \\ &u(x, 0) = u_0(x), \qquad x \in \mathbb{R}. \end{aligned} \tag{6.1}$$

Our approach hinges on the invariance properties of the viscous Burgers equation, a self-similar variant of the Cole–Hopf transformation, and the exact solvability of a Fokker–Planck-type of equation. It yields an explicit solution of (6.1) in terms of Hermite polynomials.

Step 1. First, we apply to (6.1) the change of variables

$$u(x,t) = \sqrt{\frac{\mu}{t+1}}\, v\left(\frac{x}{\sqrt{4\mu(t+1)}}, t\right). \tag{6.2}$$

Then the function $v(\xi, t)$ of the similarity variable $\xi = \frac{x}{\sqrt{4\mu(t+1)}}$ satisfies the Cauchy problem

$$\begin{aligned} &(t+1)v_t + \left(-\tfrac{1}{2}\xi v + \tfrac{1}{4}v^2 \right)_\xi = \tfrac{1}{4}v_{\xi\xi}, \qquad && \xi \in \mathbb{R}, \quad t > 0, \\ &v(\xi, 0) = v_0(\xi), && \xi \in \mathbb{R}, \end{aligned} \tag{6.3}$$

with initial data

$$v_0(\xi) = \frac{1}{\sqrt{\mu}} u_0(\sqrt{4\mu}\xi). \tag{6.4}$$

The transformation is motivated by the invariance properties of the viscous Burgers equation and the form of the special solutions termed diffusive N-waves in section 5. Despite their similarity, the transformation (1.4) used in sections 2–4 differs in the dependence on viscosity and should not be confused with (6.2). In problem (6.3) the sole dependence on viscosity is through the initial data.

Step 2. We apply to (6.3) a variant of the Cole–Hopf transformation. Let

$$V(\xi, t) = \int_{-\infty}^{\xi} v(\zeta, t)\, d\zeta,$$

and introduce $\psi(\xi, t)$ so that

$$V = -\ln\psi, \qquad v = -\frac{\psi_\xi}{\psi}. \tag{6.5}$$

A calculation shows that V satisfies

$$(t+1)V_t - \frac{1}{2}\xi V_\xi + \frac{1}{4}V_\xi^2 = \frac{1}{4}V_{\xi\xi}, \tag{6.6}$$

and ψ satisfies the initial value problem

$$4(t+1)\psi_t = \psi_{\xi\xi} + 2\xi\psi_\xi, \qquad \xi \in \mathbb{R},\ t > 0, \tag{6.7}$$

with data

$$\begin{aligned} &\psi(\xi, 0) = \bar{\psi}(\xi) := e^{-V_0(\xi)}, \\ &\text{where} \quad V_0(\xi) = \int_{-\infty}^{\xi} v_0(\zeta) d\zeta = \frac{1}{2\mu}\int_{-\infty}^{\sqrt{4\mu}\xi} u_0(y)dy \\ &\qquad\qquad = \frac{M}{2\mu} - \frac{1}{2\mu}\int_{\sqrt{4\mu}\xi}^{\infty} u_0(y)dy. \end{aligned} \tag{6.8}$$

Step 3. Next we solve the initial value problem consisting of (6.7) with initial data

$$\psi(\xi,0) = \psi_0(\xi)\,, \qquad \text{with} \qquad e^{\frac{\xi^2}{2}}\psi_0 \in L^2(\mathbb{R}) \tag{6.9}$$

via separation of variables. This leads to the issue of finding the eigenvalues and eigenfunctions of the boundary value problem

$$g'' + 2\xi g' = \lambda g\,, \qquad -\infty < \xi < \infty. \tag{6.10}$$

The problem (6.10) turns out to have a discrete spectrum, associated with the Hermite polynomials.

The Hermite polynomials (see Szegö [19, Chapter V]) are the solutions $y = H_n(\xi)$, $n = 0, 1, 2, \dots$, of the boundary value problem

$$y'' - 2\xi y' + 2ny = 0\,, \qquad -\infty < \xi < \infty.$$

H_n are polynomials of degree n and are generated from the relation

$$H_n(\xi) = (-1)^n e^{\xi^2} \frac{d^n}{d\xi^n}\big(e^{-\xi^2}\big)\,.$$

The first few of them are $H_0 = 1$, $H_1 = 2\xi$, $H_2 = 4\xi^2 - 2$, and so on. They satisfy the orthogonality conditions

$$\int_{-\infty}^{\infty} H_m(\xi)\, H_n(\xi)\, e^{-\xi^2}\, d\xi = 2^n\, n!\, \sqrt{\pi}\, \delta_{nm}\,,$$

and the system $\{H_n(\xi)e^{-\frac{\xi^2}{2}}\}_{n=0}^{\infty}$ is a complete orthogonal system in $L^2(\mathbb{R})$.

Using these properties, it can be seen that the eigenvalues and eigenfunctions of (6.10) are $\lambda_n = -2(n+1)$ and $g_n(\xi) = e^{-\xi^2}H_n(\xi)$, $n = 0, 1, 2, \dots$. Moreover, the solution of (6.7)–(6.9) is given in the form of a series

$$\psi(\xi,t) = \sum_{n=0}^{\infty} a_n (t+1)^{-\frac{n+1}{2}} H_n(\xi) e^{-\xi^2}, \tag{6.11}$$

where a_n are determined by

$$\psi_0(\xi)\, e^{\frac{\xi^2}{2}} = \sum_{n=0}^{\infty} a_n H_n(\xi) e^{-\frac{\xi^2}{2}}\,.$$

For $\psi_0 e^{\frac{\xi^2}{2}} \in L^2(\mathbb{R})$ this problem is solvable, and the Fourier–Hermite coefficients are determined by the formula

$$a_n = \frac{1}{2^n\, n!\, \sqrt{\pi}} \int_{-\infty}^{\infty} \psi_0(\xi) H_n(\xi) d\xi\,. \tag{6.12}$$

Remark 6.1. The Hermite polynomials also appear in the eigenfunctions of the eigenvalue problem (sometimes called Hermite functions)

$$z'' + (2n+1-\xi^2)z = 0\,, \quad z_n(\xi) = H_n(\xi)e^{-\frac{\xi^2}{2}}\,, \quad n = 0, 1, 2, \dots\,,$$

which is associated with the problem of the harmonic oscillator in quantum mechanics. The eigenfunctions of the problem at hand are different from the ones above. The operator in (6.10) can be thought of as the integrated version of a Fokker–Planck-type operator.

Now consider the problem (6.7) with initial data

$$\psi(\xi,0)=\bar{\psi}(\xi)\,,\qquad \bar{\psi}(\xi)\to a \text{ as } \xi\to-\infty,\qquad \bar{\psi}(\xi)\to b \text{ as } \xi\to\infty. \tag{6.13}$$

The steady states $\psi^\infty(\xi)$ of (6.7)–(6.13) solve

$$\psi^\infty_{\xi\xi}+2\xi\psi^\infty_\xi=0\,,\qquad \psi^\infty(-\infty)=a\,,\ \ \psi^\infty(\infty)=b\,,$$

and are given by

$$\psi^\infty(\xi)=a+\frac{b-a}{\sqrt{\pi}}\int_{-\infty}^{\xi}e^{-\zeta^2}d\zeta\,. \tag{6.14}$$

By superposition, it is possible to solve (6.7) with initial data

$$\bar{\psi}(\xi)=\psi^\infty(\xi)+\psi_0(\xi)\,,\qquad \text{where}\quad \psi_0 e^{\frac{\xi^2}{2}}\in L^2(\mathbb{R}).$$

Its solution is given in the form

$$\psi(\xi,t)=\psi^\infty(\xi)+\sum_{n=0}^{\infty}a_n(t+1)^{-\frac{n+1}{2}}H_n(\xi)e^{-\xi^2}, \tag{6.15}$$

where the Fourier coefficients a_n are computed from (6.12).

Step 4. Returning now to Burgers, we assume that $u_0(x)=O(e^{-x^2})$ as $|x|\to\infty$. Then $v_0(\xi)=O(e^{-\xi^2})$ as $|\xi|\to\infty$. (The orders will, in general, depend on the viscosity.) The initial data $\bar{\psi}$ are given in (6.8) and satisfy $\bar{\psi}(-\infty)=1$ and $\bar{\psi}(\infty)=e^{-\frac{M}{2\mu}}$. We define the associated diffusion wave

$$\begin{aligned}\psi^\infty_M&=1-\frac{1-e^{-\frac{M}{2\mu}}}{\sqrt{\pi}}\int_{-\infty}^{\xi}e^{-\zeta^2}d\zeta\\ &=e^{-\frac{M}{2\mu}}+\frac{1-e^{-\frac{M}{2\mu}}}{\sqrt{\pi}}\int_{\xi}^{\infty}e^{-\zeta^2}d\zeta.\end{aligned} \tag{6.16}$$

Consider

$$\psi_0=\bar{\psi}-\psi^\infty_M=e^{-V_0}-\psi^\infty_M,$$

and note that ψ_0 can be expressed as

$$\begin{aligned}\psi_0(\xi)&=e^{-\int_{-\infty}^{\xi}v_0d\zeta}-1+\frac{1-e^{-\frac{M}{2\mu}}}{\sqrt{\pi}}\int_{-\infty}^{\xi}e^{-\zeta^2}d\zeta\\ &=e^{-\frac{M}{2\mu}+\int_{\xi}^{\infty}v_0d\zeta}-e^{-\frac{M}{2\mu}}-\frac{1-e^{-\frac{M}{2\mu}}}{\sqrt{\pi}}\int_{\xi}^{\infty}e^{-\zeta^2}d\zeta.\end{aligned}$$

Using the inequalities $|e^x-1|\le 2x$ for $|x|\ll 1$ and the decay $v_0(\xi)=O(e^{-\xi^2})$ as $|\xi|\to\infty$, we see that $\psi_0(\xi)=O(e^{-\xi^2})$ as $|\xi|\to\infty$. We apply the results of the previous section and see that ψ is given by (6.15). As a result, the solution of (6.1) is given by the formula

$$u(x,t) = \sqrt{\frac{\mu}{t+1}}\, v\left(\frac{x}{\sqrt{4\mu(t+1)}}, t\right),$$

$$\text{where}\quad v(\xi,t) = -\frac{\partial_\xi \psi_M^\infty + \displaystyle\sum_{n=0}^{\infty} a_n (t+1)^{-\frac{n+1}{2}} \partial_\xi \left(H_n(\xi) e^{-\xi^2}\right)}{\psi_M^\infty + \displaystyle\sum_{n=0}^{\infty} a_n (t+1)^{-\frac{n+1}{2}} H_n(\xi) e^{-\xi^2}}. \tag{6.17}$$

ψ_M^∞ is given in (6.16), and the coefficients a_n are computed by

$$a_n = \frac{1}{2^n\, n!\, \sqrt{\pi}} \int_{-\infty}^{\infty} \left(e^{-V_0} - \psi_M^\infty\right) H_n d\xi\,. \tag{6.18}$$

In view of the form of the Hermite polynomials, the coefficients a_n may also be expressed in terms of moments of the function $\psi_0 = e^{-V_0} - \psi_M^\infty$.

An inspection of (6.17) shows that as $t \to \infty$

$$v \sim -\frac{\partial_\xi \psi_M^\infty}{\psi_M^\infty},$$

which is the asymptotic profile of a diffusion wave of mass M. The next order approximation is (recall that $H_0 = 1$)

$$v(\xi,t) \sim -\frac{\partial_\xi \psi_M^\infty - 2a_0 (t+1)^{-\frac{1}{2}} \xi e^{-\xi^2}}{\psi_M^\infty + a_0 (t+1)^{-\frac{1}{2}} e^{-\xi^2}},$$

which is that of a diffusive N-wave (compare with (5.14)). The coefficient a_0 is computed by the formula

$$a_0 = \frac{1}{\sqrt{\pi}} \int_{-\infty}^{\infty} e^{-V_0} - \psi_M^\infty \, d\xi\,.$$

ARE NATURAL IMAGES OF BOUNDED VARIATION?*

YANN GOUSSEAU† AND JEAN-MICHEL MOREL†

Abstract. The bounded variation assumption is the starting point of many methods in image analysis and processing. However, one common drawback of these methods is their inability to handle textures and small structures properly. Here we precisely show why natural images are incompletely represented by BV functions. Through an experimental study of the distribution of bilevels of natural images, we show that their total variation blows up to infinity with the increasing of resolution. To reach these conclusions, we compute bounds on the total variation, and we model convolution and sampling under quite general assumptions.

Key words. natural images, bounded variation, total variation, bilevels, power laws, size distribution, wavelets

1. Introduction.

This paper addresses the question of whether natural images may be represented as functions of bounded variation. The question is of relevance because of the wide use of the space BV in image modeling. Roughly speaking, the space BV is the space of functions whose weak derivative is a measure with finite total variation and is a straightforward space for images since it contains characteristic functions of simple sets, thus enabling the representation of edges. The BV assumption is the starting point of different approaches in image restoration [Rud87], [ROF92], [CW98], [Mal99a], image segmentation [Amb89], image deconvolution [RO94], [KMR99], optical flow computation [ADK99], or image compression. These methods have proven very efficient, especially in dealing with one-dimensional discontinuity in images. However, one common drawback is their inability to handle textures properly. In particular, restoration or deconvolution in BV leads to the smoothing out of textures, and segmentation procedures in BV fail to isolate textured areas. A recent paper [Nik00] yields mathematical proofs of the stair-casing effect, according to which BV minimization tends to create constant patches in images, thus eliminating textural effects.

In this paper, we show that this phenomenon can be explained by the fact that natural images are not of bounded variation. Our approach combines an experimental program we performed on the distribution of homogeneous and connected regions in images, the sections, and a theoretical result bounding from below the BV norm of two-dimensional functions according to the distribution of their sections. We formalize the link between experiments on discrete images and the mathematical results by using a simple model of convolution and sampling for the formation of numerical images. We point out here that another method to estimate the BV norm of images relies on the study of wavelet coefficients. In order to study locally the (ir)regularity of a signal, one may investigate the decay of wavelet coefficients at a certain location (see [Mey93], [Mal99b] for an introduction to wavelet decompositions). More recently,

the link between the global decay of wavelet coefficients and the BV norm has been studied so that, in some cases, this decay permits us to decide whether or not a function belongs to the space BV; see [CDPX99], [Oru98]. We shall compare our method and the wavelet method to decide whether an image is in BV or not. As we shall see, the geometric measurements we perform seem more accurate and permit us to show that natural images are not of bounded variation.

The paper is organized as follows: in section 2, we recall our results about the power law distribution of sections' area and perimeter. In section 3, we recall basic definitions and properties related to the space BV of functions with bounded variation. In section 4, we establish a link between the distribution of section size and the BV norm of functions of $\mathbb{R}^2$; in section 5, we show that by combining the experimental results of section 2 and the theoretical results of section 4, we can conclude that natural images are not of bounded variation. Eventually, in section 6, we compare our conclusions with recent results on the decay of wavelet coefficients.

2. The distribution of bilevels in natural images. In previous papers (see [AGM99], [Gou00]), we explored the statistics of homogeneous and connected regions of natural images. The most remarkable fact is that the distributions of their area and perimeter are very well approximated by a power law. More precisely, we consider a digital image I, whose gray levels are between 0 and N. For an integer k, we call a k-bilevel of I any of the binary images defined by

$$I_l(i,j) = \begin{cases} 1 & \text{if } I(i,j) \in \left[(l-1)\frac{N}{k}, l\frac{N}{k}\right), \\ 0 & \text{otherwise} \end{cases}$$

for l varying from 1 to k. We then define a section to be a connected component of a set $\{(i,j)/I_l(i,j) = 1\}$ for some l. For each integer a, we define $f(a)$ to be the number

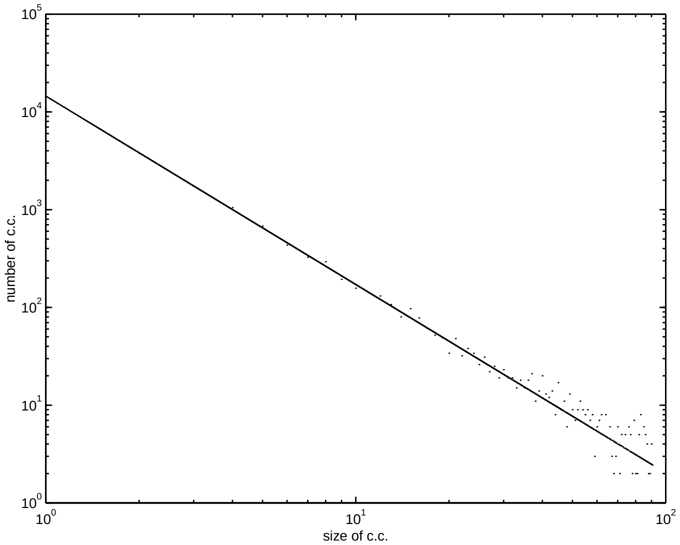

FIG. 2. *Function f (section area distribution) for the airport image, Figure* 1, *in* log-log *coordinates.*

TABLE 1

Average results for the distribution of area of sections on 100 *images from the van Hateren database. We denote by $\langle\alpha\rangle$ and $\langle E\rangle$ the mean values of α and E respectively, std α is the standard deviation of α;* min*(α) and* max*(α) are the minimum and maximum values for α.*

k	$\langle\alpha\rangle$	std α	max α	min α	$\langle E\rangle$	max E
16	1.85	0.19	2.20	1.39	0.37	0.49
14	1.83	0.19	2.18	1.36	0.37	0.54
12	1.83	0.19	2.15	1.37	0.37	0.54
10	1.81	0.18	2.12	1.27	0.37	0.50
8	1.80	0.17	2.26	1.32	0.38	0.59

of sections with area a (in pixels). Our experiments show that

$$f(a) \approx \frac{C}{a^{\alpha}}, \tag{2.1}$$

where C and α are image dependent constants. Moreover, in most images, α is close to 2.

We will not recall here all the experimental results, and we refer to the previously mentioned papers for more details, but we will give some examples. For each image, we fit a straight line with slope α to the function f in log-log coordinate, minimizing the least squares distance. We also compute the least squares error E. In Figure 1, we display a digital image and some of its sections, and in Figure 2 we display the corresponding fit for f. Similar graphics are obtained for all considered digital images (either from a digital camera, scanned images, or calibrated images). In Table 1, we display results averaged over 100 calibrated images from a database collected by van Hateren, freely available at http://hlab.phys.rug.nl/imlib/; see [vHvdS98]. The most noticeable fact here is the proximity of α to 2, and the fact that for all images and some value of k, α is larger than 1.5, a fact that will be proven relevant in what follows for estimating the BV norm of images.

Table 2

Average results for the distribution of perimeter of sections on 100 *images from the van Hateren database. Notations are the same as for Table* 1.

k	$\langle\beta\rangle$	std β	max β	min β	$\langle E\rangle$	max E
16	2.35	0.28	2.57	2.04	0.36	0.42
14	2.42	0.29	2.60	2.10	0.29	0.35
12	2.38	0.33	2.63	1.99	0.42	0.51
10	2.46	0.15	2.62	2.10	0.31	0.39
8	2.36	0.14	2.49	2.04	0.37	0.41

In [AGM99], [Gou00], we also studied the distribution of the perimeters of sections, which are also distributed according to a power law with an exponent β usually between 2 and 3. In Table 2, we display results similar to those in Table 1 for the values of β (still computed by minimizing the least squares error in log-log coordinates) on the previously mentioned images database.

Are small sections due to noise or microtextures? In Figure 1, we have shown some of the small sections from which the size statistics are estimated. We do that for the following purpose: it might be objected to the observed size laws that their small scale behavior is due to the caption device and not to the underlying "natural" image. Thus it is very relevant to look at the sections and decide whether they are due to digitization noise, to some microtexture, or to the inherent geometric structure of the image. In Figure 1, we can check that most small sections arise on contrasted parts of the image (the so called "edges") and that their shape coincides with those edges. We can also rule out a Gibbs phenomenon: it multiplies the edge contribution to the bounded variation norm by a fixed constant factor. We have shown only one example, but we have chosen a kind of example for which the BV model should be very likely, since the whole scene is a geometric human-made scene with as little texture as possible. All other images we have checked confirm this interpretation: small sections correspond to objects or pieces of objects, or pieces of contours. They are not at all uniformly distributed over the image, as would happen with noise.

3. Functions of bounded variation and sets of finite perimeter.

In this section, we recall some basic facts about functions of bounded variation. Let I be a bounded function defined on a domain (e.g., rectangular) $\Omega \subset \mathbb{R}^2$. I is in $BV(\Omega)$, the space of functions with bounded variations, if

$$||I||_{BV} \overset{\text{def}}{=} \int_\Omega |DI| < +\infty,$$

where the gradient DI is to be understood in a weak sense (see [Zie89]):

$$\int_\Omega |DI| = \sup\left\{\int_\Omega I \text{div}\phi \mid \phi \in C_c^1(\Omega), |\phi| < 1\right\},$$

where $C_c^1(\Omega)$ is the space of continuously differentiable functions with compact support, defined from Ω to $\mathbb{R}^2$. Actually the usual BV norm is defined as the sum of $\int |DI|$, the total variation, and the L^1 norm, $\int |I|$. We consider only the total variation (which is not a norm), and write it $||.||_{BV}$.

We will be interested in a more geometric characterization of $BV(\Omega)$. For $\lambda \in \mathbb{R}$, define the level set of I with level λ by

$$\chi_\lambda I = \{x, I(x) \geq \lambda\}.$$

Now (see [EG92]) recall that a set $E \in \Omega$ is of finite perimeter per(E) if

$$\mathrm{per}(E) \overset{\mathrm{def}}{=} ||\mathbb{1}_E||_{BV} \leq +\infty,$$

where $\mathbb{1}_E$ is the characteristic function of the set E. This definition generalizes the usual definition of the boundary length, in the sense that both definitions are equivalent in the case of a set with piecewise regular boundary. If a function has bounded variation, then, for almost every $\lambda \in \mathbb{R}$, $\chi_\lambda I$ is a set with finite perimeter and (coarea formula (see [EG92])),

$$||I||_{BV} = \int_{\mathbb{R}} \mathrm{per}(\chi_\lambda I) d\lambda. \tag{3.1}$$

Conversely, if per$(\chi_\lambda I)$ is finite (for almost all λ) and the preceding integral is finite, then I has bounded variation. We also recall that, by the classical isoperimetric inequality, we have for every set O with finite perimeter,

$$\mathrm{per}(O) \geq 2\pi^{\frac{1}{2}} \nu(O)^{\frac{1}{2}}, \tag{3.2}$$

where $\nu(O)$ denotes the Lebesgue measure of O.

The BV space is a very straightforward space for images. First, if images are neither continuous nor strictly differentiable, it seems reasonable to assume them to be in a space where they are weakly differentiable. Moreover, the occlusion phenomenon is responsible for one-dimensional discontinuities which prevent the weak derivatives of images from being integrable, thus forcing images out of any Sobolev space. Such a simple image as a white disk on a black background belongs to the space BV, which is the natural space to perform calculus of variations on functions whose one-dimensional discontinuities have finite length (see [Amb89]). Now, a first way for an image not to be in this space is to have level lines with infinite length. For instance, the characteristic functions of two-dimensional sets with fractal boundaries will not be of bounded variation. There is also another way for a function not to be in BV. Each of its level lines may be of finite perimeter, while the sum of these level lines' perimeters is infinite. As we will see in the next two sections, this is what happens for natural images, in which, in a precise sense, small objects are too numerous for the function to be of bounded variation.

4. A lower bound for the *BV* norm.

In the following, we shall consider sections of the image. We always assume that the image I satisfies $0 \leq I(x) \leq C$. We first fix two parameters γ, λ, with $0 \leq \lambda \leq \gamma$. For any $n \in \mathbb{N}$, we consider the bilevel sets of I

$$\{x, \lambda + (n-1)\gamma \leq I(x) < \lambda + n\gamma\} = \chi_{\lambda+(n-1)\gamma} I \setminus \chi_{\lambda+n\gamma} I.$$

We call the (γ, λ)-section of I any set which is a connected component of a bilevel set $\chi_{\lambda+(n-1)\gamma} I \setminus \chi_{\lambda+n\gamma} I$ for some n. We denote each one of the components by $S_{\gamma,\lambda,i}$ for $i \in J(\gamma, \lambda)$, a set of indices. Notice that the (γ, λ)-sections are disjoint, and their union is the image domain Ω,

$$\bigcup_{i \in J(\gamma,\lambda)} S_{\gamma,\lambda,i} = \Omega. \tag{4.1}$$

There are several ways to define the connected components of a set with finite perimeter, since such a set is defined up to a set with zero Lebesgue measure. One can prove [ACMM99] that a definition of connected components for a set with finite perimeter permits the following statements. (Recall that ν is the two-dimensional Lebesgue measure and per is the perimeter.)

Definition 4.1. *Let X be a set with finite perimeter in $\mathbb{R}^2$. We say that X is not decomposable if we cannot write it as $X = Y \cup Z$ with $\nu(Y) > 0$, $\nu(Z) > 0$, $\nu(X) = \nu(Y) + \nu(Z)$, and $per(X) = per(Y) + per(Z)$.*

Theorem 4.2. *Each set of finite perimeter X admits a unique decomposition*

$$X = \cup_n X_n,$$

where the union is finite or countable, and such that

(i) *each X_n is not decomposable,*
(ii) *for each n, $\nu(X_n) > 0$,*
(iii) *$per(X) = \sum_n per(X_n)$.*

This definition matches the usual requirements of connectivity, in particular, if for $x \in X$, cc(x,X) is the component relative to X that contains x, $X \subset Y$ implies $\mathrm{cc}(x, X) \subset \mathrm{cc}(x, Y)$.

We need this definition because (iii) will enable us to use the distribution of sections, as experimentally observed in section 2, to bound the BV norm of images from below. We denote by $J(n) \subset J(\gamma, \lambda)$ the set of indices of sections which are connected components of $\chi_{\lambda+(n-1)\gamma} I \setminus \chi_{\lambda+n\gamma} I$. Note that by classical results on BV functions, for each γ, $\chi_{\lambda+(n-1)\gamma} I \setminus \chi_{\lambda+n\gamma} I$ has finite perimeter for almost every λ. As an obvious consequence of Proposition 4.2, we have the following corollary.

Corollary 4.3. *Let I belong to BV. Then for almost every λ,*

$$per(\chi_{\lambda+(n-1)\gamma} I \setminus \chi_{\lambda+n\gamma} I) = \sum_{i \in J(n)} per(S_{\lambda,\gamma,i}).$$

In order to estimate the BV norm of I, we shall need the following lemma.

Lemma 4.4. *If $B \subset A$ are two sets with finite perimeter, then*

$$per(A \setminus B) \leq per(A) + per(B).$$

Proof. Recall that $\mathrm{per}(A) = ||\mathbb{1}_A||_{BV}$. Then by the subadditivity of the BV norm, we deduce from

$$\mathbb{1}_{A \setminus B} = \mathbb{1}_A - \mathbb{1}_B$$

that

$$\mathrm{per}(A \setminus B) \leq \mathrm{per}(A) + \mathrm{per}(B). \qquad \square$$

In the following theorem, we analyze the statistics of sizes of sections as follows. We fix γ, that is, the overall contrast of considered sections, and for each $0 \leq \lambda \leq \gamma$, we count all sections $S_{\gamma,\lambda,i}$ which have an area between s_1 and s_2 with $0 < s_1 < s_2$. That is, we consider the integer

$$\mathrm{Card}\{i, s_1 \leq \nu(S_{\gamma,\lambda,i}) < s_2\}.$$

Note that this number is bounded since Ω is bounded and the sections are disjoint. We average this number over all λ's in $[0,\gamma]$ to obtain the function

$$f(\gamma, s_1, s_2) = \int_0^\gamma \mathrm{Card}\{i, s_1 \le |S_{\gamma,\lambda,i}| < s_2\} d\lambda.$$

Remark. To be able to define f, we made the assumption that

$$\mathrm{Card}\{i, s_1 \le \nu(S_{\gamma,\lambda,i}) < s_2\} \text{ is a measurable function of } \lambda. \tag{4.2}$$

We will suppose that for some $\gamma > 0$, this average number has a density $f(\gamma, s)$ with respect to s. That is,

$$\forall s > 0 \qquad \lim_{s_1 \uparrow s, s_2 \downarrow s} \frac{f(\gamma, s_1, s_2)}{s_1 - s_2} = f(\gamma, s). \tag{4.3}$$

Then we have the following bound for the BV norm of I.

THEOREM 4.5. *Let I be in $BV(\Omega)$. Assume that there exists some $\gamma > 0$ such that (4.2) and (4.3) hold (i.e., the average number of sections with area s, for $0 \le \lambda \le \gamma$, has a density $f(\gamma, s)$); then*

$$||I||_{BV} \ge \pi^{\frac{1}{2}} \int_0^{\nu(\Omega)} s^{\frac{1}{2}} f(\gamma, s) ds. \tag{4.4}$$

Proof. Applying Corollary 4.3 and Lemma 4.4,

$$\begin{aligned}
||I||_{BV} &= \int_{\mathbb{R}} \mathrm{per}\{x, I(x) \ge \lambda\} d\lambda \\
&= \frac{1}{2}\left(\int_{\mathbb{R}} \mathrm{per}\{x, I(x) \ge \lambda\} d\lambda + \int_{\mathbb{R}} \mathrm{per}\{x, I(x) \ge \lambda - \gamma\} d\lambda\right) \\
&\ge \frac{1}{2} \int_{\mathbb{R}} \mathrm{per}(\chi_{\lambda-\gamma} I \setminus \chi_\lambda I) d\lambda \\
&= \frac{1}{2} \sum_{n \in \mathbb{Z}} \int_{n\gamma}^{(n+1)\gamma} \mathrm{per}(\chi_{\lambda-\gamma} I \setminus \chi_\lambda I) d\lambda \\
&= \frac{1}{2} \int_0^\gamma \sum_{n \in \mathbb{Z}} \mathrm{per}(\chi_{\lambda+(n-1)\gamma} I \setminus \chi_{\lambda+n\gamma} I) d\lambda \\
&= \frac{1}{2} \int_0^\gamma \sum_{i \in J(\gamma,\lambda)} \mathrm{per}(S_{\gamma,\lambda,i}) d\lambda.
\end{aligned}$$

By the isoperimetric inequality (3.2), we therefore obtain

$$||I||_{BV} \ge \pi^{\frac{1}{2}} \int_0^\gamma \sum_{i \in J(\gamma,\lambda)} \nu(S_{\gamma,\lambda,i})^{\frac{1}{2}} d\lambda.$$

Then, for any $n \in \mathbb{N}^*$

$$||I||_{BV} \ge \pi^{\frac{1}{2}} \sum_{k=1}^{n-1} \left(\frac{\nu(\Omega)}{n} k\right)^{\frac{1}{2}} f\left(\gamma, \frac{\nu(\Omega)}{n} k, \frac{\nu(\Omega)}{n}(k+1)\right). \tag{4.5}$$

We introduce the functions

$$f_n = \sum_{k=1}^{n-1} \left(\frac{\nu(\Omega)}{n}k\right)^{\frac{1}{2}} f\left(\gamma, \frac{\nu(\Omega)}{n}k, \frac{\nu(\Omega)}{n}(k+1)\right) \frac{n}{\nu(\Omega)} \mathbb{1}_{\left[\frac{\nu(\Omega)}{n}k, \frac{\nu(\Omega)}{n}(k+1)\right)}.$$

We have

$$||I||_{BV} \geq \pi^{\frac{1}{2}} \int_0^{\nu(\Omega)} f_n(s)ds$$

and

$$\forall s_0 > 0 \qquad f_n(s_0) \underset{n\to+\infty}{\longrightarrow} (s_0)^{\frac{1}{2}} \gamma f(\gamma, s_0),$$

thanks to hypothesis (4.3). Therefore, by Fatou's lemma,

$$||I||_{BV} \geq \pi^{\frac{1}{2}} \int_0^{\nu(\Omega)} s^{\frac{1}{2}} f(\gamma, s)ds. \qquad \square$$

We can repeat the preceding analysis by assuming now that

$$g(\gamma, p_1, p_2) = \int_0^{\gamma} \text{Card}\{i, p_1 \leq \text{per}(S_{\gamma,\lambda,i}) \leq p_2\} d\lambda$$

has an average density $g(\gamma, p)$ with respect to p (once more assuming the cardinal we integrate is measurable). That is,

$$(4.6) \qquad \lim_{p_1\uparrow p, p_2\downarrow p} \frac{g(\gamma, p_1, p_2)}{p_2 - p_1} = g(\gamma, p).$$

Then we have the analogue of Theorem 4.5 for the perimeters of sections.

THEOREM 4.6. *Let I be in $BV(\Omega)$. Assume that there exists some $\gamma > 0$ such that* (4.6) *holds, i.e., the average number of sections with perimeter s, for $0 \leq \lambda \leq \gamma$, has a density $g(\gamma, p)$. Then*

$$(4.7) \qquad ||I||_{BV} \geq \frac{1}{2} \int_0^{+\infty} pg(\gamma, p)dp.$$

Proof. In the same way as before (without using the isoperimetric inequality) and fixing some $p_m > 0$,

$$\begin{aligned} ||I||_{BV} &\geq \frac{1}{2} \int_0^{\gamma} \sum_{i\in J(\gamma,\lambda)} \text{per}(S_{\gamma,\lambda,i}) d\lambda \\ &\geq \frac{1}{2} \sum_{k=1}^{n-1} \left(\frac{p_m}{n}k\right) g\left(\gamma, \frac{p_m}{n}k, \frac{p_m}{n}(k+1)\right). \end{aligned}$$

As before, this implies

$$||I||_{BV} \geq \frac{1}{2} \int_0^{+\infty} pg(\gamma, p)dp. \qquad \square$$

5. Application: Natural images are not of bounded variation.

5.1. The continuous framework. In this section, we draw the consequences of Theorems 4.5 and 4.6 for the images analyzed in section 2 by assuming that the observed distribution of sections approximates the distribution in continuous images. According to our experimental results, we suppose that the considered images satisfy

$$f(\gamma, s) = \frac{C}{s^{\alpha}}, \tag{5.1}$$

$$g(\gamma, p) = \frac{C}{p^{\beta}} \tag{5.2}$$

for some constants $\alpha > 0$, $\beta > 0$, where f is the density for the area distribution of the sections, and g is the density for the perimeters. This law has been experimentally checked for several values of $\gamma = \frac{256}{k}$ (the grey level width of the sections) and k ranging from 8 to 20; see section 2 and [Gou00]. We also checked that the value of α was almost unchanged when the bilevels were not defined from gray level 0, but from some gray level less than $\frac{256}{k}$ (that is, in the continuous model for different values of λ), and that when averaging the experimental density function over integer values of λ between 0 and $\gamma = \frac{256}{k}$, f and g still are power laws with the same exponent. Thus hypotheses (5.1) and (5.2) are valid. We emphasized here that the shapes and locations of small sections indicate that these are not due to noise, but to small structures and objects clearly present in the image, particularly, pieces of edges; see Figure 1. Moreover, Gaussian white noise leads to quite different statistics; see [Gou00].

Then, by Theorem 4.5, we have

$$||I||_{BV} \geq c \int_0^{\nu(\Omega)} \frac{Cs^{\frac{1}{2}}}{s^{\alpha}} ds$$

and, in the same way,

$$||I||_{BV} \geq c \int_0^{+\infty} \frac{Cp}{p^{\beta}} dp.$$

Thus, if we admit that (5.1) and (5.2) indeed hold for natural images when $s \to 0$, as is indicated by the experiments recalled in section 2, we obtain that the considered images are not in BV if $\alpha > \frac{3}{2}$ or $\beta > 2$, since the corresponding integrals are not finite. These values of α and β have been checked for all images of the database studied in section 2, for some value of k, except for some (3 out of 100) blurred images. The assumption that formulae (5.1) and (5.2) hold for small scales, below the scale of pixelization, is a strong one, but the experiment of section 2 indicates that the distribution is the same at all scales. Moreover, the next section will analyze the effect of pixelisation on the BV norm. Of course, there exists a cut-off scale in images, but the lower bounds we found for the BV norm indicate that the contribution of small scales to the value of this norm is unexpectedly large compared to the contribution of larger scales. As mentioned in the introduction, this should be related to the problem of the erasing of textures by variational methods minimizing the total variation of images. Indeed, the BV norm gives a large weight to small-scale textures that are known to disappear in the process of restoration (deblurring or denoising, for instance) by such variational methods; see [ROF92], [Mal99a].

5.2. Convolution and sampling. In this section, we draw the same conclusions as in the previous one about the BV norm of natural images, with a more rigorous interpretation of our experimental results. We give a practical application of the method of Theorem 4.5 in a case where its hypotheses are satisfied. We assume that discrete images, on which we performed the analysis of section 2, are obtained from continuous ones through convolution and sampling. We first show that when we compute the BV norm of a function after convolution with a rescaled smoothing kernel (under some regularity conditions) and sampling, we underestimate the actual value of the BV norm of the initial function. We write G for a two-dimensional function and C for the square whose lower left corner is (0,0) and whose upper right corner (1,1); n is an integer, and for a real number x, $[x]_n = [nx]/n$, $[nx]$ is the integer part of nx.

LEMMA 5.1. *Let I be a function in $BV(C)$, let $G_n(x,y) = G(nx, ny)$, define*

$$I_c = I * G_n,$$

and for $(x,y) \in C$

$$I_n(x,y) = I_c\left([x]_n + \frac{1}{2n}, [y]_n + \frac{1}{2n}\right).$$

Assume that there exist some functions a and b such that

$$\forall x, y \in C \qquad |G(x,y)| \leq a(x)b(y), \tag{5.3}$$

and assume there exists a constant K such that

$$\sup_{x,y} \sum_{i,j} a(x+i)b(y+j) \leq K. \tag{5.4}$$

Then

$$||I_n||_{BV(C)} \leq \sqrt{2}K||I||_{BV(C)}.$$

Proof. For i, j integer in $[0,n)$, define

$$I_{i,j} = I_c\left(\frac{i}{n} + \frac{1}{2n}, \frac{j}{n} + \frac{1}{2n}\right).$$

We have

$$||I_n||_{BV} = \sum_{i,j} \left(|I_{i,j} - I_{i-1,j}| + |I_{i,j} - I_{i,j-1}|\right).$$

Now, for all i, j,

$$\begin{aligned}
|I_{i,j} - I_{i-1,j}| &= \left|\int \left(I\left(\frac{i+1}{n} - x, \frac{j}{n} - y\right) - I\left(\frac{i}{n} - x, \frac{j}{n} - y\right)\right) G(nx, ny)\right| \\
&= \left|\int \int_0^1 \frac{\partial}{\partial x} I\left(\frac{i+t}{n} - x, \frac{j}{n} - y\right) G(nx, ny)\right| \\
&\leq \int \int_0^1 \left|\frac{\partial}{\partial x} I\left(\frac{i+t}{n} - x, \frac{j}{n} - y\right)\right| a(nx)b(ny) \\
&\leq \int \int_0^1 \left|\frac{\partial}{\partial x} I\left(\frac{t}{n} - x, -y\right)\right| a(nx+i)b(ny+j)
\end{aligned}$$

so that

$$\sum_{i,j} |I_{i+1,j} - I_{i,j}| \leq \sup_{x,y} \sum_{i,j} a(x+i)b(y+j) \int \left| \frac{\partial}{\partial x} I \right|,$$

and thus

$$||I_n||_{BV} \leq K \int \left| \frac{\partial}{\partial x} I \right| + \left| \frac{\partial}{\partial y} I \right| \leq \sqrt{2} K ||I||_{BV},$$

the last inequality resulting from $|u| + |v| \leq \sqrt{2}(u^2 + v^2)^{1/2}$. □

This theorem enables us to reformulate the fact that natural images do not belong to BV in a slightly different way. Suppose that the continuous image I is represented by the discrete function I_n of the previous theorem. Assume, moreover, that the distribution of the area of the discrete connected components of bilevels for I_n is $f_{n,\gamma}(k)$ for values of k from 1 to n^2. Then reasoning as in Theorem 4.5 leads to the following theorem.

THEOREM 5.2. *Let I be a function in $BV(C)$ and I_n a sampling of I, defined as in Lemma* 5.1*, the kernel G satisfying hypotheses* (5.3) *and* (5.4)*. Then there is a constant C such that*

$$||I||_{BV} \geq C \sum_{k=1}^{n^2} \left(\frac{1}{n^2} k \right)^{\frac{1}{2}} f_n(\gamma, k), \tag{5.5}$$

where $f_n(\gamma, k)$ is the number of connected components of I_n of area k for values of k from 1 *to n^2.*

Proof. Since I_n is a step function, all measurability conditions of Theorem 4.5 are satisfied, and we obtain formula (4.5), which yields

$$||I_n||_{BV} \geq C \sum_{k=1}^{n^2} \left(\frac{1}{n^2} k \right)^{\frac{1}{2}} f_n(\gamma, k).$$

By Lemma 5.1, we obtain formula (5.5). □

We now come to the consequences of our experiments.

COROLLARY 5.3. *If for all n there is a constant C_n such that*

$$f_n(\gamma, k) \geq \frac{C_n}{\left(\frac{1}{n^2} k\right)^{\alpha}} \tag{5.6}$$

with $\alpha < 2$, then

$$||I_n||_{BV} \geq C \sum_{k=1}^{n^2} \frac{1}{n^2} \left(\frac{k}{n^2} \right)^{\frac{1}{2} - \alpha}. \tag{5.7}$$

Proof. We have (computing the area of the unit square)

$$\sum_{k=1}^{n^2} f_n(\gamma, k) \frac{k}{n^2} = 1$$

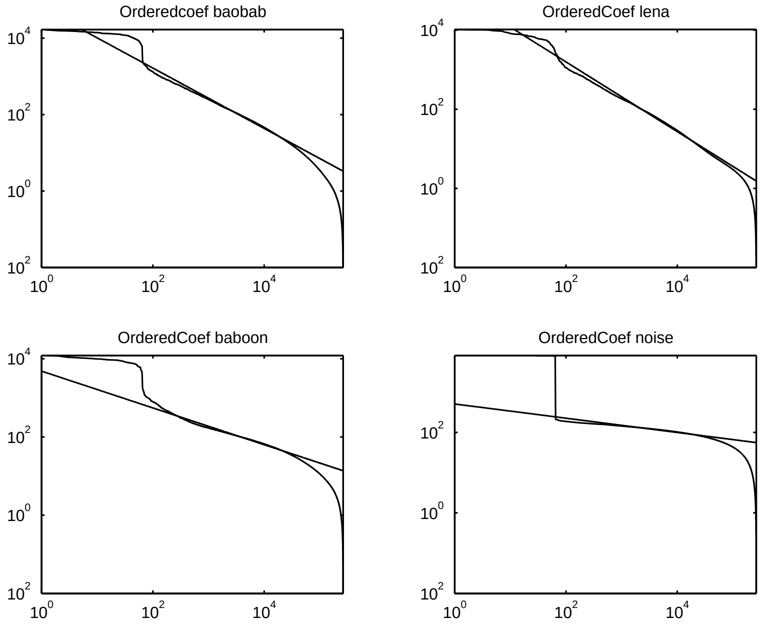

FIG. 3. *Ordered wavelet coefficients (modulus against the rank in* log-log *coordinates) and least squares fit for four images.*

so that

$$C_n \sum_{k=1}^{n^2} \frac{1}{n^2} \left(\frac{k}{n^2} \right)^{1-\alpha} \geq \frac{1}{n^2}.$$

Now if $\alpha < 2$, the preceding Riemann sum converges, and

$$C_n \geq \frac{(2-\alpha)}{n^2}.$$

Eventually, replacing expression (5.6) into formula (5.5) yields the result. □

Now the same conclusions as before hold, since the right side of formula (5.7) tends to infinity as soon as $\alpha > 1.5$. We have thus proved that if the distribution of the (discrete) sections of the (piecewise constant) function which is obtained by convolving I with a rescaled filter and sampling at n^2 points follows formula (5.6) with $1.5 < \alpha < 2$, then I is not of bounded variation.

Remark. The assumptions of Corollary 5.3 correspond exactly to our numerical experiments on natural images. Notice that we observed a variation of the constant C_n, and that the preceding proof shows that the blow-up result for the BV norm of images is independent of this variation.

6. Wavelets and the space BV. As mentioned in the introduction, recent results concerning the link between the global decay of wavelet coefficients and the total variation of images permit us to address the main question of this paper in a wavelet framework. Let (c_k) be the wavelet coefficients of the image I, ordered in a nonincreasing sequence. We say that the c_k's are in l^1 if $\sum |c_k| < +\infty$, and that they are in weak-l^1 if there exists a constant C such that $c_k \leq \frac{C}{k}$. Obviously, l^1 is included

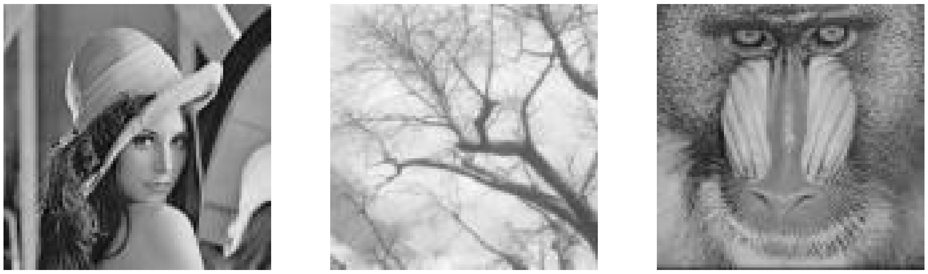

FIG. 4. *Lena, baobab, and baboon images, on which we study the decay of wavelet coefficients as shown in Figure* 3.

in weak-l^1. It is well known that if the c_k are in l^1, then I is in a Besov space included in BV. In the other direction, Cohen, DeVore, Petrushev, and Xu [CDPX99] recently proved that if I is in BV, then the c_k's are in weak-l^1 for the Haar wavelets. Cohen, Meyer, and Oru then generalized the result to any compactly supported wavelet basis; see [Oru98].

Thus it is possible to decide whether an image belongs to BV or not by looking at its wavelet coefficients decay, except if they decrease as $\frac{C}{k}$, which happens to be the case quite often. We present in Figure 3 the ordered coefficients for four images: the well-known Lena image, a part of a baobab image, a baboon image (Figure 4), and a Gaussian white noise. We used Daubechies's wavelets (using filters of length 8 provided by Wavelab), and found very similar results with Haar's wavelets. As we see, there is a fairly linear part in those graphs but only for intermediate scales. Assuming the small scales' behavior is perturbed by sampling and that the decay observed for most of the coefficients is characteristic of what happens at small scales, we may use the preceding results. We fitted a line to those values according to a least squares error so that an image should be in BV when the slope of this line is (strictly) greater than 1, and out of BV if the slope is (strictly) smaller than 1. In the case of the baobab and baboon images (Figure 4), we, respectively, found slopes of 0.76 and 0.45, and values of α (the exponent of the power law distribution of sections area), respectively, equal to 1.9 and 2.38 (for $k = 16$) so that both methods agree: those images are not in BV. For the well-known image of Lena, our approach gives an α of 1.9 (for $k = 16$), which suggests that Lena is clearly out of BV, whereas from the wavelet approach, a slope of .95 indicates the image is not BV. Now this result is close to the uncertainty zone. Of course, the decay of the coefficients for the noise image is very slow (0.16) so that this image is not in BV, whereas the distribution of the area of sections does not follow a power law (but an exponential distribution). Note that in all four cases, the inference of the distribution at small scales is less clear than in the morphological approach of the previous sections.

To understand the nature of the uncertainty when the slope is 1, it is worth noticing that the wavelet coefficients produced by the characteristic function of a simple shape already decrease as $\frac{1}{k}$ so that the simple presence of edges in the image implies this type of decay. In a sense, the wavelet coefficients look at the smoothness of the edges of the image, whereas, by investigating the sections' size distribution, we investigate the number and the cumulated length of those sections. Thus, as we mentioned already, it is not surprising that we get more precise estimates of the image oscillations at small scales and can therefore decide, for instance, that Lena is not BV while the wavelet coefficient analysis is ambiguous [Mal99b].

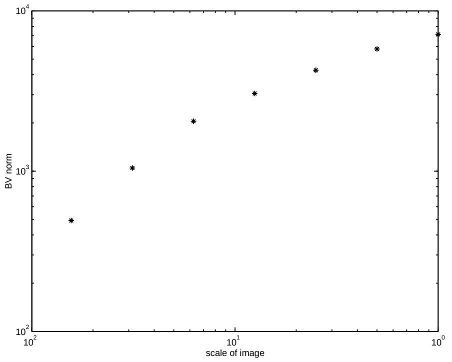

FIG. 5. *Simple plot of the BV norm as a function of the scale for the image of the airport. The BV norm is directly computed on the image which is successively downsampled. Abscissa equals a half means the image has been subsampled by a factor of* 2.

Clearly, our proposed procedure and the wavelet experiments imply that the scale behavior of the image needs some sophisticated statistics to be correctly extrapolated at fine scales. Thus it is necessary to point out that less sophisticated statistics can yield uninterpretable results on images for which the formerly mentioned methods yield clearcut answers. By one of the referee's suggestions, we performed the following experiment (Figure 5). We simulated a zoom backward at six dyadic scales of a natural image and computed the resulting BV norm. In several images where the section statistics are conclusive, we get no clear scaling behavior, as can be seen in Figure 5. Actually, even if the dots in the recently mentioned experiment had been aligned, we could not have made any strong statement. The number of obtainable samples is simply too small.

7. Conclusion. Combining experimental results about the distribution of sections in natural images and a result about the total variation of functions of $\mathbb{R}^2$, we have shown that natural images are not of bounded variation. This conclusion relies on the assumption that the observed images are obtained from continuous ones through fairly arbitrary convolution and sampling. This shows precisely that even if they are well-adapted to the large scale geometric structures of images, modeling them as functions with bounded variation does not account for the intricate nature of their small details.

GLOBAL WELL-POSEDNESS FOR SCHRÖDINGER EQUATIONS WITH DERIVATIVE*

J. COLLIANDER[†], M. KEEL[‡], G. STAFFILANI[§], H. TAKAOKA[¶], AND T. TAO[‖]

Abstract. We prove that the one-dimensional Schrödinger equation with derivative in the nonlinear term is globally well-posed in H^s for $s > 2/3$, for small L^2 data. The result follows from an application of the "I-method." This method allows us to define a modification of the energy norm H^1 that is "almost conserved" and can be used to perform an iteration argument. We also remark that the same argument can be used to prove that any quintic nonlinear defocusing Schrödinger equation on the line is globally well-posed for large data in H^s, for $s > 2/3$.

Key words. Schrödinger equations, global well-posedness

1. Introduction.

We consider the derivative nonlinear Schrödinger initial value problem (IVP)

$$(1)\qquad \begin{cases} i\partial_t u + \partial_x^2 u = i\lambda\partial_x(|u|^2 u), \\ u(x,0) = u_0(x), \qquad\qquad x \in \mathbb{R}, \quad t \in \mathbb{R}, \end{cases}$$

where $\lambda \in \mathbb{R}$. The equation in (1) is a model for the propagation of circularly polarized Alfvén waves in magnetized plasma with a constant magnetic field [18, 19, 23].

It is natural to impose the smallness condition

$$(2)\qquad \|u_0\|_{L^2} < \sqrt{\frac{2\pi}{\lambda}}$$

on the initial data, as this will force the energy to be positive via the sharp Gagliardo–Nirenberg inequality. Note that the L^2 norm is conserved by the evolution.

Well-posedness for the Cauchy problem (1) has been studied by many authors [10, 11, 12, 20, 21, 22, 26, 27]. The best local well-posedness result is due to Takaoka [22], who used a gauge transformation and the Fourier restriction method is used to obtain local well-posedness in $H^s,\ s \geq 1/2$. In [24], Takaoka showed that this result is sharp in the sense that the data map fails to be C^3 or uniformly C^0 for $s < 1/2$ (cf. Bourgain [4] and Biagioni–Linares [1]).

In [20], global well-posedness is obtained for (1) in H^1, assuming the smallness condition (2). The argument there is based on two gauge transformations performed in order to remove the derivative in the nonlinear term. This was improved by Takaoka [24], who proved global well-posedness in H^s for $s > \frac{32}{33}$, assuming (2). The method of proof is based on the idea of Bourgain [3, 5] of estimating separately the evolution of low frequencies and of high frequencies of the initial data.

In this paper we improve the global well-posedness result further.

Theorem 1.1. *The Cauchy problem* (1) *is globally well-posed in* H^s *for* $s > 2/3$, *assuming the smallness condition* (2).

The proof of Theorem 1.1 is based on the "I-method" used by the authors in other nonlinear Cauchy problems in [15, 7, 8, 9] (see also [14]). The basic idea is as follows. After a rescaling, we define a new energy $E_N(u)(t)$ for the solution u that depends on a parameter $N \gg 1$. We prove a local well-posed result in the norm associated to E_N on intervals of length ~ 1, and finally we perform an iteration on the time intervals. The reason why this iteration can be globally extended is that the increment of the energy $E_N(u)(t)$ over each time interval is very small. In other words, the argument is successful because the energy $E_N(u)(t)$ is *almost conserved*.

After the proof of Theorem 1.1 is completed, we will briefly remark that, using the same techniques, one can also show that the one-dimensional defocusing quintic nonlinear Schrödinger is globally well-posed for initial data in $H^s, s > 2/3$. The details of the proof of this fact will appear in a different paper.

The restriction $s > 2/3$ is probably not sharp and might be improvable either by more sophisticated multilinear estimates and better estimates on the symbols M_4, M_6, M_8 which appear in our argument, or by using the "correction term" strategy of [8]. In fact, one may reasonably conjecture that one could extend the global well-posedness result to match the local result at $s > 1/2$. We will not pursue these matters here.

2. Notation.

To prove Theorem 1.1, we may assume $2/3 < s < 1$, since for $s \geq 1$ the result is contained in [20, 24]. Henceforth $2/3 < s < 1$ shall be fixed. Also, by rescaling u, we may assume $\lambda = 1$.

We use C to denote various constants depending on s; if C depends on other quantities as well, this will be indicated by explicit subscripting, e.g., $C_{\|u_0\|_2}$ will depend on both s and $\|u_0\|_2$. We use $A \lesssim B$ to denote an estimate of the form $A \leq CB$. We use $a+$ and $a-$ to denote expressions of the form $a + \varepsilon$ and $a - \varepsilon$, where $0 < \varepsilon \ll 1$ depends only on s.

We use $\|f\|_p$ to denote the $L^p(\mathbb{R})$ norm and $L^q_t L^r_x$ to denote the mixed norm

$$\|f\|_{L^q_t L^r_x} := \left(\int \|f(t)\|_r^q \, dt \right)^{1/q}$$

with the usual modifications when $q = \infty$.

We define the spatial Fourier transform of $f(x)$ by

$$\hat{f}(\xi) := \int_{\mathbb{R}} e^{-ix\xi} f(x) \, dx$$

and the spacetime Fourier transform $u(t, x)$ by

$$\tilde{u}(\tau, \xi) := \int_{\mathbb{R}} \int_{\mathbb{R}} e^{-i(x\xi + t\tau)} u(t, x) \, dt dx.$$

Note that the derivative ∂_x is conjugated to multiplication by $i\xi$ by the Fourier transform.

We shall also define D_x to be the Fourier multiplier with symbol $\langle\xi\rangle := 1 + |\xi|$. We can then define the Sobolev norms H^s by

$$\|f\|_{H^s} := \|D_x^s f\|_2 = \|\langle\xi\rangle^s \hat{f}\|_{L^2_\xi}.$$

We also define the spaces $X^{s,b}(\mathbb{R} \times \mathbb{R})$ (first introduced in [2]) on $\mathbb{R} \times \mathbb{R}$ by

$$\|u\|_{X^{s,b}(\mathbb{R}\times\mathbb{R})} := \|\langle\xi\rangle^s \langle\tau - |\xi|^2\rangle^b \hat{u}(\xi,\tau)\|_{L^2_\tau L^2_\xi}.$$

We often use $\|u\|_{s,b}$ to abbreviate $\|u\|_{X^{s,b}(\mathbb{R}\times\mathbb{R})}$. For any time interval I, we define the restricted spaces $X^{s,b}(I \times \mathbb{R})$ by

$$\|u\|_{X^{s,b}(I\times\mathbb{R})} := \inf\{\|U\|_{s,b} : U|_{I\times\mathbb{R}} = u\}.$$

We shall take advantage of the Strichartz estimates

$$\|u\|_{L^6_t L^6_x} \lesssim \|u\|_{0,1/2+} \tag{3}$$

and

$$\|u\|_{L^\infty_t L^2_x} \lesssim \|u\|_{0,1/2+} \tag{4}$$

(see, e.g., [2]). From (4) and Sobolev embedding we observe

$$\|u\|_{L^\infty_t L^\infty_x} \lesssim \|u\|_{1/2+,1/2+}. \tag{5}$$

In our arguments we shall be using the trivial embedding

$$\|u\|_{s_1,b_1} \lesssim \|u\|_{s_2,b_2} \text{ whenever } s_1 \leq s_2, b_1 \leq b_2$$

so frequently that we will not mention this embedding explicitly.

We now give some useful notation for multilinear expressions. If $n \geq 2$ is an even integer, we define a *(spatial) multiplier of order* n to be any function $M_n(\xi_1, \ldots, \xi_n)$ on the hyperplane

$$\Gamma_n := \{(\xi_1, \ldots, \xi_n) \in \mathbb{R}^n : \xi_1 + \cdots + \xi_n = 0\},$$

which we endow with the standard measure $\delta(\xi_1 + \cdots + \xi_n)$, where δ is the Dirac delta.

If M_n is a multiplier of order n and $f_1, \ldots, f_n$ are functions on $\mathbb{R}$, we define the quantity $\Lambda_n(M_n; f_1, \ldots, f_n)$ by

$$\Lambda_n(M_n; f_1, \ldots, f_n) := \int_{\Gamma_n} M_n(\xi_1, \ldots, \xi_n) \prod_{j=1}^{n} \hat{f}_j(\xi_j).$$

We adopt the notation

$$\Lambda_n(M_n; f) := \Lambda_n(M_n; f, \bar{f}, f, \bar{f}, \ldots, f, \bar{f}).$$

Observe that $\Lambda_n(M_n; f)$ is invariant under permutations of the even ξ_j indices or of the odd ξ_j indices.

If M_n is a multiplier of order n, $1 \le j \le n$ is an index, and $k \ge 1$ is an even integer, we define the *elongation* $\mathbf{X}_j^k(M_n)$ of M_n to be the multiplier of order $n+k$ given by

$$\mathbf{X}_j^k(M_n)(\xi_1, \dots, \xi_{n+k}) := M_n(\xi_1, \dots, \xi_{j-1}, \xi_j + \cdots + \xi_{j+k}, \xi_{j+k+1}, \dots, \xi_{n+k}).$$

In other words, $\mathbf{X}_j^k$ is the multiplier obtained by replacing ξ_j by $\xi_j + \cdots + \xi_{j+k}$ and advancing all the indices after ξ_j accordingly.

We shall often write ξ_{ij} for $\xi_i + \xi_j$, ξ_{ijk} for $\xi_i + \xi_j + \xi_k$, etc. We also write ξ_{i-j} for $\xi_i - \xi_j$, ξ_{ij-klm} for $\xi_{ij} - \xi_{klm}$, etc.

3. The Gauge transformation and the conservation laws. In this section we apply the gauge transform used in [20] in order to improve the derivative nonlinearity.

DEFINITION 3.1. *We define the nonlinear map* $\mathcal{G} : L^2(\mathbb{R}) \to L^2(\mathbb{R})$ *by*

$$\mathcal{G}f(x) := e^{-i\int_{-\infty}^{x} |f(y)|^2 dy} f(x).$$

The inverse transform $\mathcal{G}^{-1}f$ *is then given by*

$$\mathcal{G}^{-1}f(x) := e^{i\int_{-\infty}^{x} |f(y)|^2 dy} f(x).$$

This transform is well behaved on H^s.

LEMMA 3.2. *The map* $\mathcal{G}$ *is a bicontinuous map from* H^s *to* H^s.

A similar statement holds for $0 \le s \le 1/2$, but we shall not need it here.

Proof. We shall just prove the continuity of $\mathcal{G}$, as the continuity of $\mathcal{G}^{-1}$ is proven similarly.

Define *Lip* to be the space of functions with norm

$$\|f\|_{Lip} := \|f\|_\infty + \|f'\|_{L^\infty}.$$

Since $s > 1/2$, we see from Sobolev embedding that the nonlinear map $f \mapsto e^{-i\int_{-\infty}^{x} |f(y)|^2 dy}$ continuously maps H^s to *Lip*. It therefore suffices to show the product estimate

$$\|fg\|_{H^s} \lesssim \|f\|_{H^s} \|g\|_{Lip}.$$

But this estimate follows immediately from the Leibniz rule and Hölder when $s = 0$ or $s = 1$, and the intermediate cases then follow by interpolation. □

Set $w_0 := \mathcal{G}u_0$ and $w(t) := \mathcal{G}u(t)$ for all times t. A straightforward calculation shows that the IVP (1) can be transformed to

$$\begin{cases} i\partial_t w + \partial_x^2 w = -iw^2 \partial_x \bar{w} - \frac{1}{2}|w|^4 w, \\ w(x,0) = w_0(x), \qquad x \in \mathbb{R}, \quad t \in \mathbb{R}. \end{cases} \tag{6}$$

Also, the smallness condition (2) becomes

$$\|w_0\|_{L^2} < \sqrt{2\pi}. \tag{7}$$

By Lemma 3.2 we thus see that global well-posedness of (1) in H^s is equivalent to that of (6). From [20, 22, 24], we know that both Cauchy problems are locally well-posed in H^s and globally well-posed in H^1, assuming (7). By standard limiting arguments, we thus see that Theorem 1.1 will follow if we can show the following.

Proposition 3.3. *Let w be a global H^1 solution to* (6) *obeying* (7). *Then for any $T > 0$ we have*

$$\sup_{0\leq t\leq T} \|w(t)\|_{H^s} \lesssim C_{\|w_0\|_{H^s}, \|w_0\|_2, T},$$

where the right-hand side does not depend on the H^1 norm of w.

Just by looking at the equation in (6) it is not easy to understand why this should be better than the equation in (1). In fact, we still see a derivative, and, moreover, a quintic nonlinearity has been introduced. But it was made clear in [20, 13, 22] how a derivative of the complex conjugate of the solution w can be handled while a derivative of w cannot. Also, the quintic term is not going to introduce any extra trouble.

Let $n \geq 2$ be an even integer, and let M_n be a multiplier of order n. From (6) we have

$$\partial_t w = i w_{xx} - w\bar{w}_x w + \frac{i}{2} w\bar{w}w\bar{w}w$$

and

$$\partial_t \bar{w} = -i w_{xx} - \bar{w} w_x \bar{w} - \frac{i}{2} \bar{w}w\bar{w}w\bar{w}.$$

Taking the Fourier transform of these identities, we obtain the useful differentiation law

$$\begin{aligned}\partial_t \Lambda_n(M_n; w(t)) = {} & i\Lambda_n\left(M_n \sum_{j=1}^{n} (-1)^j \xi_j^2; w(t)\right)\\ & - i\Lambda_{n+2}\left(\sum_{j=1}^{n} \mathbf{X}_j^2(M_n)\xi_{j+1}; w(t)\right)\\ & + \frac{i}{2}\Lambda_{n+4}\left(\sum_{j=1}^{n} (-1)^{j-1}\mathbf{X}_j^4(M_n); w(t)\right)\end{aligned} \tag{8}$$

for any even integer $n \geq 2$ and any multiplier M_n of order n.

We now turn to the conservation laws that the solution w of (6) enjoys. What follows in this section was originally described by Ozawa in [20]; however, we have redone the computations in our own notation, as this will prove useful later.

Definition 3.4. *If $f \in H^1(\mathbb{R})$, we define the energy $E(f)$ by*

$$E(f) := \int \partial_x f \partial_x \overline{f}\; dx - \frac{1}{2}\mathrm{Im}\int f\overline{f} f \partial_x \overline{f}\; dx.$$

By Plancherel, we may write $E(f)$ using the Λ notation as

$$E(f) = -\Lambda_2(\xi_1\xi_2; f) - \frac{1}{2}\mathrm{Im}\Lambda_4(i\xi_4; f).$$

Expanding the second term using $\mathrm{Im}(z) = (z - \bar{z})/2i$ and using symmetry, we may rewrite this as

$$E(f) = -\Lambda_2(\xi_1\xi_2; f) + \frac{1}{8}\Lambda_4(\xi_{13-24}; f). \tag{9}$$

Lemma 3.5 (see [20]). *If w is an H^1 solution to (6) for times $t \in [0,T]$, then we have*

$$\|w(t)\|_2 = \|w_0\|_2$$

and

$$E(w(t)) = E(w_0)$$

for all $t \in [0,T]$.

Proof. These conservation laws are proven in [20]; however, we give a proof based on the identity (8), as the proof here will be needed later on.

We of course have

$$\|w(t)\|_2^2 = \Lambda_2(1; w(t)).$$

In the rest of this proof we shall drop the $w(t)$ from the Λ notation. Differentiating the previous equation and applying (8), we obtain

$$\partial_t \|w(t)\|_2^2 = -i\Lambda_2(\xi_1^2 - \xi_2^2) - i\Lambda_4(\xi_2 + \xi_3) + \frac{i}{2}\Lambda_6(1 - 1 + 1 - 1 + 1 - 1).$$

The first term vanishes since $\xi_{12} = 0$. The second term can be symmetrized to $-\frac{i}{2}\Lambda_4(\xi_{1234})$, which vanishes. The third term clearly vanishes. This proves the L^2 conservation.

Now we prove energy conservation. From (9) we have

$$\partial_t E(t) = -\partial_t \Lambda_2(\xi_1\xi_2) + \frac{1}{8}\partial_t \Lambda_4(\xi_{13-24}), \tag{10}$$

and from (8) we have

$$\partial_t \Lambda_2(\xi_1\xi_2) = -i\Lambda_2(\xi_1\xi_2(\xi_1^2 - \xi_2^2)) - i\Lambda_4(\xi_{123}\xi_4\xi_2 + \xi_1\xi_{234}\xi_3) + \frac{i}{2}\Lambda_6(\xi_{12345}\xi_6 - \xi_1\xi_{23456}).$$

The Λ_2 term vanishes since $\xi_{12} = 0$. To simplify the Λ_4 term we write $\xi_{123} = -\xi_4$ and $\xi_{234} = -\xi_1$ and then symmetrize. To simplify the Λ_6 term we write $\xi_{12345} = -\xi_6$ and $\xi_{23456} = -\xi_1$ and then symmetrize to obtain

$$\partial_t \Lambda_2(\xi_1\xi_2) = \frac{i}{2}\Lambda_4(\xi_1^2\xi_3 + \xi_2^2\xi_4 + \xi_3^2\xi_1 + \xi_4^2\xi_2) + \frac{i}{6}\Lambda_6(\xi_1^2 - \xi_2^2 + \xi_3^2 - \xi_4^2 + \xi_5^2 - \xi_6^2).$$

We may simplify the Λ_4 term further, using the identity

$$\begin{aligned}
\xi_1^2\xi_3 + \xi_2^2\xi_4 + \xi_3^2\xi_1 + \xi_4^2\xi_2 &= \xi_1\xi_3\xi_{13} + \xi_2\xi_4\xi_{24} \\
&= \xi_{13}(\xi_1\xi_3 - \xi_2\xi_4) \\
&= \xi_{13}(-\xi_1\xi_{124} - \xi_2\xi_4) \\
&= -\xi_{13}(\xi_1 + \xi_2)(\xi_1 + \xi_4) \\
&= -\xi_{12}\xi_{13}\xi_{14}
\end{aligned}$$

to obtain

$$\partial_t \Lambda_2(\xi_1\xi_2) = -\frac{i}{2}\Lambda_4(\xi_{12}\xi_{13}\xi_{14}) + \frac{i}{6}\Lambda_6(\xi_1^2 - \xi_2^2 + \xi_3^2 - \xi_4^2 + \xi_5^2 - \xi_6^2). \tag{11}$$

We now consider the second component of the energy. From (8) we have

$$\begin{aligned}\partial_t \Lambda_4(\xi_{13-24}) &= i\Lambda_4(\xi_{13-24}(\xi_1^2 - \xi_2^2 + \xi_3^2 - \xi_4^2)) \\ &\quad - i\Lambda_6(\xi_{1235-46}\xi_2 + \xi_{15-2346}\xi_3 + \xi_{1345-26}\xi_4 + \xi_{13-2456}\xi_5) \\ &\quad + \frac{i}{2}\Lambda_8(\xi_{123457-68} - \xi_{17-234568} + \xi_{134567-28} - \xi_{13-245678}).\end{aligned}$$

The Λ_8 term symmetrizes to $i\Lambda_8(\xi_{12345678})$, which vanishes. The Λ_6 term can be rewritten as

$$2i\Lambda_6(\xi_{46}\xi_2 - \xi_{15}\xi_3 + \xi_{26}\xi_4 - \xi_{13}\xi_5),$$

which we rewrite as

$$2i\Lambda_6(\xi_{246}\xi_2 - \xi_{135}\xi_3 + \xi_{246}\xi_4 - \xi_{135}\xi_5) - 2i\Lambda_6(\xi_2^2 - \xi_3^2 + \xi_4^2 - \xi_5^2).$$

The first term symmetrizes to $\frac{4i}{3}\Lambda_6(\xi_{246}^2 - \xi_{135}^2)$, which vanishes. The second term symmetrizes to

$$\frac{4i}{3}\Lambda_6(\xi_1^2 - \xi_2^2 + \xi_3^2 - \xi_4^2 + \xi_5^2 - \xi_6^2).$$

Finally, consider the Λ_4 term. We may factorize

$$\xi_{13-24}(\xi_1^2 - \xi_2^2 + \xi_3^2 - \xi_4^2) = \xi_{13-24}(\xi_{1-2}\xi_{12} + \xi_{3-4}\xi_{34}).$$

Since $\xi_{12} = \xi_{-34}$ and $\xi_{13} = -\xi_{24}$, we may simplify this as

$$2\xi_{13}\xi_{12}(\xi_{1-2} - \xi_{3-4}) = 4\xi_{12}\xi_{13}\xi_{14}.$$

Combining all these identities, we thus have

$$\frac{1}{8}\partial_t \Lambda_4(\xi_{13-24}) = -\frac{1}{2}i\Lambda_4(\xi_{12}\xi_{13}\xi_{14}) - \frac{i}{6}\Lambda_6(\xi_1^2 - \xi_2^2 + \xi_3^2 - \xi_4^2 + \xi_5^2 - \xi_6^2).$$

Combining this with (11) and (10), we obtain

$$\partial_t E(w(t)) = 0,$$

and the claim follows. □

Heuristically, the energy $E(w(t))$ has the same strength as $\|w(t)\|_{H^1}^2$. We can make this precise as follows.

Lemma 3.6. *Let f be an H^1 function on $\mathbb{R}$ such that $\|f\|_2 < \sqrt{2\pi}$. Then we have*

$$\|\partial_x f\|_2 \le C_{\|f\|_2} E(f)^{1/2}, \tag{12}$$

where $C_{\|f\|_2}$ depends only on $\|f\|_2$.

Proof. Define the function

$$g(x) := \exp\left(i\frac{3}{4}\int_{-\infty}^{x} |f(y)|^2\, dy\right) f(x).$$

A routine computation shows that

$$\|g\|_2 = \|f\|_2 < \sqrt{2\pi}$$

and

$$E(f) = \|\partial_x g\|_2^2 - \frac{1}{16}\|g\|_6^6.$$

From the sharp Gagliardo–Nirenberg inequality [28]

$$\|g\|_6^6 \leq \frac{4}{\pi^2}\|g\|_2^4\|\partial_x g\|_2^2, \tag{13}$$

we therefore have

$$\|\partial_x g\|_2 \lesssim C_{\|f\|_2} E(f)^{1/2}.$$

From the definition of g we have

$$f(x) = \exp\left(-i\frac{3}{4}\int_{-\infty}^{x} |g(y)|^2 \; dy\right) g(x),$$

and so we have

$$\|\partial_x f\|_2 \lesssim \|\partial_x g\|_2 + \|g^3\|_2.$$

By another application of (13) we thus obtain (12). □

4. The almost conserved energy norm. It remains to prove Proposition 3.3. Fix w, T. We also let $N \gg 1$ be a large parameter depending on T, $\|w_0\|_2$, and $\|w_0\|_{H^s}$ which we shall choose later.

Because we do not want to use the H^1 norm of w, we cannot directly use the energy $E(w(t))$ defined above. So we are looking for a substitute notion of "energy" that can be defined for a less regular solution and that has a very slow increment in time. In the frequency space let us consider an even C^∞ monotone multiplier $m(\xi)$ taking values in $[0, 1]$ such that

$$m(\xi) := \begin{cases} 1 \quad \text{if } |\xi| < N, \\ \left(\frac{|\xi|}{N}\right)^{s-1} \quad \text{if } |\xi| > 2N. \end{cases} \tag{14}$$

We define the multiplier operator $I : H^s \longrightarrow H^1$ such that $\widehat{Iw}(\xi) := m(\xi)\widehat{w}(\xi)$. This operator is smoothing of order $1 - s$; indeed, we have

$$\|u\|_{s_0,b_0} \lesssim \|Iu\|_{s_0+1-s,b_0} \lesssim N^{1-s}\|u\|_{s_0,b_0} \tag{15}$$

for any $s_0, b_0 \in \mathbb{R}$.

Our substitute energy will be defined by

$$E_N(w) := E(Iw).$$

Note that this energy makes sense even if w is in only H^s.

In general the energy $E_N(w(t))$ is not conserved in time, but we will show that the increment is very small in terms of N. This will be accomplished in three stages. First, in Proposition 4.1 below, we write the increment of $E_N(w(t))$ as a multilinear expression in w. Then, in Lemma 6.1, we estimate these multilinear expressions in terms of the norm $\|Iw\|_{1,1/2+}$, gaining a power of N^{-1+} in the process. Finally, in

Theorem 5.1 (and Lemma 3.6), we control the norm $\|Iw\|_{1,1/2+}$ back in terms of $E_N(w(t))$.

Proposition 4.1. *Let w be an H^1 global solution to* (6). *Then for any $T \in \mathbb{R}$ and $\delta > 0$ we have*

$$E_N(w(T+\delta)) - E_N(w(T)) = \int_T^{T+\delta} [\Lambda_4(M_4; w(t)) + \Lambda_6(M_6; w(t)) + \Lambda_8(M_8; w(t))]\, dt,$$

where the multipliers M_4, M_6, M_8 are given by

$$\begin{aligned} M_4 &:= C_1 m_1 m_2 m_3 m_4 \xi_{12}\xi_{13}\xi_{14} + C_2(m_1^2\xi_1^2\xi_3 + m_2^2\xi_2^2\xi_4 + m_3^2\xi_3^2\xi_1 + m_4^2\xi_4^2\xi_2),\\ M_6 &:= C_3 \sum_{j=1}^{6} (-1)^{j-1} m_j^2 \xi_j^2 + C_4 \sum_{\{a,c,e\}=\{1,3,5\},\{b,d,f\}=\{2,4,6\}} m_a m_b m_c m_{def} \xi_{ac} \xi_e\\ &\quad - \ m_{abc} m_d m_e m_f \xi_{df} \xi_b,\\ M_8 &:= C_5 \sum_{\{a,c,e,g\}=\{1,3,5,7\};\{b,d,f,h\}=\{2,4,6,8\}} m_a m_b m_c m_{defgh} \xi_{ac-bdefgh}\\ &\quad - \ m_{abcde} m_f m_g m_h \xi_{abcdeg-fh}, \end{aligned}$$

where $C_1, \dots, C_5$ are absolute constants and we adopt the abbreviations m_i for $m(\xi_i)$, m_{ij} for $m(\xi_{ij})$, etc. Furthermore, if $|\xi_j| \ll N$ for all j, then the multipliers M_4, M_6, M_8 all vanish.

Proof. From (9) we have

$$E_N(w(t)) = -\Lambda_2(m_1\xi_1 m_2\xi_2; w(t)) + \frac{1}{8}\Lambda_4(\xi_{13-24} m_1 m_2 m_3 m_4; w(t)).$$

Henceforth we omit the $w(t)$ from the Λ notation. By (8) we have

$$\begin{aligned} \partial_t \Lambda_2(m_1\xi_1 m_2\xi_2) &= -i\Lambda_2(m_1\xi_1 m_2\xi_2(\xi_1^2 - \xi_2^2))\\ &\quad - i\Lambda_4(m_{123}\xi_{123} m_4\xi_4\xi_2 + m_1\xi_1 m_{234}\xi_{234}\xi_3)\\ &\quad + \frac{i}{2}\Lambda_6(m_{12345}\xi_{12345} m_6\xi_6 - m_1\xi_1 m_{23456}\xi_{23456}). \end{aligned}$$

The Λ_2 term vanishes since $\xi_{12} = 0$. To simplify the Λ_4 term, we use $\xi_{123} = -\xi_4$ and $\xi_{234} = -\xi_1$ and then symmetrize to obtain the second term of M_4. To simplify the Λ_6 term, we use $\xi_{12345} = -\xi_6$ and $\xi_{23456} = -\xi_1$ and then symmetrize to get the first term of M_6.

In a similar vein, we have

$$\begin{aligned} \partial_t \Lambda_4(\xi_{13-24} m_1 m_2 m_3 m_4) &= -i\Lambda_4(\xi_{13-24} m_1 m_2 m_3 m_4 (\xi_1^2 - \xi_2^2 + \xi_3^2 - \xi_4^2))\\ &\quad - i\Lambda_6(\xi_{1235-46} m_{123} m_4 m_5 m_6 \xi_2 + \xi_{15-2346} m_1 m_{234} m_5 m_6 \xi_3\\ &\qquad + \xi_{1345-26} m_1 m_2 m_{345} m_6 \xi_4 + \xi_{13-2456} m_1 m_2 m_3 m_{456} \xi_5)\\ &\quad + \frac{i}{2}\Lambda_8(\xi_{123457-68} m_{12345} m_6 m_7 m_8 - \xi_{17-234568} m_1 m_{23456} m_7 m_8\\ &\qquad + \xi_{134567-28} m_1 m_2 m_{34567} m_8 - \xi_{13-245678} m_1 m_2 m_3 m_{45678}). \end{aligned}$$

The Λ_4 term is of the form of the first term of M_4 by the argument used to prove (11). To simplify the Λ_6 term, we use $\xi_{1235-46} = -2\xi_{46}$ and similarly for the other four terms and then symmetrize to obtain the second term of M_6. Finally, if we symmetrize the Λ_8 term, we obtain M_8. The first part of the proposition then follows from the fundamental theorem of calculus applied to the function $t \longrightarrow E_N(w(t))$.

If all the frequencies are $\ll N$, then all the m_i, m_{ij}, etc. terms are equal to 1. In this case our calculations are identical to those in Lemma 3.5, and so our symbols M_4, M_6, M_8 will vanish by the computations given in that lemma. □

5. Local estimates. In Lemma 6.1 we shall estimate the expression in Proposition 4.1. It turns out that one cannot estimate this expression effectively just by using spatial norms such as $\|Iw\|_{H^1}$ (as is done for some simple equations in [5]), but one must use spacetime norms such as $\|Iw\|_{1,1/2+}$. The purpose of this section is to obtain the required control on these spacetime norms.

Theorem 5.1. *Let w be an H^1 global solution to* (6), *and let $T \in \mathbb{R}$ be such that*

$$\|Iw(T)\|_{H^1} \leq C_0$$

for some $C_0 > 0$. Then we have

$$\|Iw\|_{X^{1,1/2+}([T,T+\delta]\times\mathbb{R})} \lesssim 1$$

for some $\delta > 0$ depending on C_0.

We now prove Theorem 5.1. We shall be able to exploit the estimates in [22]. By standard iteration arguments (see, e.g., [2, 16, 17, 22, 24, 25]) it suffices to prove the following lemma.

Lemma 5.2. *We have*

$$\|I(w_1\partial_x\overline{w_2}w_3)\|_{X_{1,b-1}(\mathbb{R}\times\mathbb{R})} \lesssim \prod_{i=1}^{3}\|Iw_i\|_{X_{1,1/2+}(\mathbb{R}\times\mathbb{R})}, \tag{16}$$

$$\|I(w_1\overline{w_2}w_3\overline{w_4}w_5)\|_{X_{1,b-1}(\mathbb{R}\times\mathbb{R})} \lesssim \prod_{i=1}^{5}\|Iw_i\|_{X_{1,1/2+}(\mathbb{R}\times\mathbb{R})} \tag{17}$$

for all Schwarz functions w_i and some $b > 1/2$ (in fact, we may take any $1/2 < b < 5/8$).

Proof. By Plancherel and duality it suffices to show

$$\left|\int_* \frac{m(\xi_4)\langle\xi_4\rangle\langle\tau_4+\xi_4^2\rangle^{b-1}\xi_2}{\prod_{j=1}^{3} m(\xi_j)\langle\xi_j\rangle\langle\tau_j-(-1)^{j-1}\xi_j^2\rangle^{1/2+}}\prod_{j=1}^{4}F_j(\tau_j,\xi_j)\right| \lesssim \prod_{j=1}^{4}\|F_j\|_{L^2_{\tau_j}L^2_{\xi_j}}$$

and

$$\left|\int_{**} \frac{m(\xi_6)\langle\xi_6\rangle\langle\tau_6+\xi_6^2\rangle^{b-1}}{\prod_{j=1}^{5} m(\xi_j)\langle\xi_j\rangle\langle\tau_j-(-1)^{j-1}\xi_j^2\rangle^{1/2+}}\prod_{j=1}^{6}F_j(\tau_j,\xi_j)\right| \lesssim \prod_{j=1}^{6}\|F_j\|_{L^2_{\tau_j}L^2_{\xi_j}}$$

for all functions $F_1, \ldots, F_6$, where $\int_*$, $\int_{**}$ denote integration over the measure $\delta(\tau_1 + \cdots + \tau_4)\delta(\xi_1 + \cdots + \xi_4)$ and $\delta(\tau_1 + \cdots + \tau_6)\delta(\xi_1 + \cdots + \xi_6)$, respectively.

We may assume that the F_j are all real and nonnegative. We now observe the pointwise estimate

$$\frac{m(\xi_n)\langle\xi_n\rangle^{1-s}}{\prod_{j=1}^{n-1} m(\xi_j)\langle\xi_j\rangle^{1-s}} \lesssim 1$$

for $n = 4, 6$ and all $\xi_1, \dots, \xi_n$ such that $\xi_1 + \cdots + \xi_n = 0$. To see this, we use symmetry to assume that $|\xi_1| \geq \cdots \geq |\xi_{n-1}|$ so that $|\xi_n| \lesssim |\xi_1|$. Since $m(\xi)\langle\xi\rangle^{1-s}$ is essentially increasing in $|\xi|$, we thus see that

$$\frac{m(\xi_n)\langle\xi_n\rangle^{1-s}}{\prod_{j=1}^{n-1} m(\xi_j)\langle\xi_j\rangle^{1-s}} \lesssim \frac{1}{\prod_{j=2}^{n-1} m(\xi_j)\langle\xi_j\rangle^{1-s}}.$$

Since $m(\xi)\langle\xi\rangle^{1-s} \gtrsim 1$ for all ξ, the claim follows.

Because of this estimate, we need only to show the estimates

$$\left|\int_* \frac{\langle\xi_4\rangle^s\langle\tau_4 + \xi_4^2\rangle^{b-1}\xi_2}{\prod_{j=1}^3 \langle\xi_j\rangle^s\langle\tau_j - (-1)^{j-1}\xi_j^2\rangle^{1/2+}} \prod_{j=1}^4 F_j(\tau_j, \xi_j)\right| \lesssim \prod_{j=1}^4 \|F_j\|_{L^2_{\tau_j} L^2_{\xi_j}} \tag{18}$$

and

$$\left|\int_{**} \frac{\langle\xi_6\rangle^s\langle\tau_6 + \xi_6^2\rangle^{b-1}}{\prod_{j=1}^5 \langle\xi_j\rangle^s\langle\tau_j - (-1)^{j-1}\xi_j^2\rangle^{1/2+}} \prod_{j=1}^6 F_j(\tau_j, \xi_j)\right| \lesssim \prod_{j=1}^6 \|F_j\|_{L^2_{\tau_j} L^2_{\xi_j}}. \tag{19}$$

The estimate (18) is equivalent to the first estimate of Lemma 3.1 in [24] after undoing the duality and Plancherel, so it suffices to prove (19). By undoing the duality we can write this as

$$\|w_1\overline{w_2}w_3\overline{w_4}w_5\|_{s,b-1} \lesssim \prod_{j=1}^5 \|w_j\|_{s,1/2+}.$$

We may assume that the Fourier transforms $\tilde{w}_j$ are all real and nonnegative. By using $|\xi_1 + \xi_2 + \xi_3 + \xi_4 + \xi_5|^s \lesssim \sum_{i=1}^5 |\xi_i|^s$, it suffices to prove estimates of the form

$$\|(D_x^s w_1)\overline{w_2}w_3\overline{w_4}w_5\|_{0,b-1} \lesssim \prod_{j=1}^5 \|w_j\|_{s,1/2+}$$

in addition to similar estimates when D_x^s falls on one of the other functions. We shall prove only the displayed estimate, as the others are similar. We may estimate the $X^{0,b-1}$ norm by the $L_t^2 L_x^2$ norm. But then the claim follows from three applications of (3), two applications of (5), and Hölder (ensuring that the term with the D_x^s is estimated using (3)). □

6. Proof of Proposition 3.3. We can now prove Proposition 3.3, which as remarked before will give Theorem 1.1. Let T, w be as in the proposition. Our constants may depend on $\|w_0\|_2$ and $\|w_0\|_{H^s}$.

We start by rescaling the solution w. Let $\mu > 0$ be chosen later. We observe that w is a solution for the IVP (6) if and only if

$$w^\mu(t, x) = \frac{1}{\mu^{1/2}} w\left(\frac{t}{\mu^2}, \frac{x}{\mu}\right)$$

is a solution for the IVP (6) with initial data $w_0^\mu = \mu^{-1/2}w(\mu^{-1}x)$. From Plancherel's theorem and a simple computation we see that

$$\|I\partial_x w_0^\mu\|_2 \lesssim \frac{N^{1-s}}{\mu^s}\|w_0\|_{H^s},$$

while

$$\|Iw_0^\mu\|_2 \le \|w_0^\mu\|_2 = \|w_0\|_2 < \sqrt{2\pi}.$$

We now choose $\mu := N^{\frac{1-s}{s}}$. From the previous we see that $\|Iw_0^\mu\|_{H^1} \lesssim 1$, so from Sobolev embedding (or Gagliardo–Nirenberg) we obtain

$$E(Iw_0^\mu) \le C_1$$

for some constant $C_1 > 0$.

Now suppose inductively that we have a time T such that

$$E(Iw^\mu(T)) \le C_1 + C_2 N^{-1+} T,$$

where $C_2 > 0$ is a constant depending on C_1 to be chosen later. If $T \ll N^{1-}$, we then have $E(Iw^\mu(T)) \le 2C_1$, which implies from Lemma 3.6 that

$$\|Iw^\mu(T)\|_{H^1} \le C_3,$$

where C_3 depends on C_1. By Theorem 5.1 we thus have

$$\|Iw^\mu\|_{X^{1,1/2+}([T,T+\delta]\times\mathbb{R})} \le C_4,$$

where C_4, δ depend on C_3.

In the next four sections we shall prove the following key estimate.

Lemma 6.1. *For any Schwartz function w, we have*

$$\left| \int_T^{T+\delta} \Lambda_n(M_n; w(t))\, dt \right| \lesssim N^{-1+} \|Iw\|^n_{X^{1,1/2+}([T,T+\delta]\times\mathbb{R})} \tag{20}$$

for $n = 4, 6, 8$, where M_4, M_6, M_8 are as defined in Proposition 4.1.

Assuming this estimate for the moment, we see from the previous and Proposition 4.1 that

$$E(Iw^\mu(T+\delta)) \le E(Iw^\mu(T)) + C_5 N^{-1+},$$

where C_5 depends on δ and C_4. This allows us to close the induction hypothesis by setting $C_2 := C_5$. As a consequence, we have thus shown that[1]

$$\|Iw^\mu(T)\|_{H^1} \lesssim 1$$

for all $T \ll N^{1-}$. From the definition of I this implies that

$$\|w^\mu(T)\|_{H^s} \lesssim C_N$$

for all $T \ll N^{1-}$. Undoing the scaling, this implies that

$$\|w(T)\|_{H^s} \lesssim C_{N,\mu}$$

for all $T \ll N^{1-}/\mu^2$. However, if $s > 2/3$, then $N^{1-}/\mu^2 = N^{\frac{3s-2-}{s}}$ goes to infinity as $N \to \infty$, and Proposition 3.3 follows.

Remark 6.2. An examination of the above argument shows also that the H^s norm of w (and of u) grows at most polynomially in time; however, the order of the growth obtained by this argument goes to infinity as $s \to 2/3$.

[1] Strictly speaking, we have shown this only for T being an integer multiple of δ; however, this can be easily remedied, e.g., by using the fact that the $X^{1,1/2+}$ norm controls the $L_t^\infty H_x^1$ norm on $[T, T+\delta] \times \mathbb{R}$.

7. Proof of Lemma 6.1: Preliminaries. To prove Lemma 6.1 we shall treat the cases $n = 4$, $n = 6$, and $n = 8$ separately. The idea will be first to obtain some good estimates on M_n in terms of $m(\xi_i)$ and $\langle \xi_i \rangle$ and then to bound the resulting multilinear expression using standard tools such as the Strichartz estimates (3), (5), the trivial estimate

$$\|u\|_{L_t^2 L_x^2} \lesssim \|u\|_{0,0}, \tag{21}$$

and Hölder's inequality. In addition to the above linear estimates, we shall also take advantage of the following bilinear improvement to Strichartz's estimate in the case of differing frequencies (cf. [3, 21]).

Lemma 7.1. *For any Schwartz functions u, v with Fourier support in $|\xi| \sim R$, $|\xi| \ll R$, respectively, we have that*

$$\|uv\|_{L_t^2 L_x^2} = \|u\bar{v}\|_{L_t^2 L_x^2} \lesssim R^{-1/2} \|u\|_{0,1/2+} \|v\|_{0,1/2+}.$$

Proof. This is an improved Strichartz estimate of the type considered in [3]. In fact, the desired estimate is contained in Theorem 2 of [21]. We present the short proof for the sake of completeness.

It is enough to show that if u and v are solutions of the free Schrödinger equation, that is, $u = e^{it\partial_x^2}\phi$ and $v = e^{it\partial_x^2}\psi$, then

$$\|D_x^{1/2}(uv)\|_{L^2} \lesssim \|\phi\|_{L^2} \|\psi\|_{L^2}, \tag{22}$$

where D_x is the operator such that $\widehat{D_x f}(\xi) = \langle \xi \rangle \hat{f}(\xi)$. If we use duality and the change of variable $\xi_1 + \xi_2 = s$ and $|\xi_1|^2 + |\xi_2|^2 = r$, the left-hand side of (22) becomes

$$\begin{aligned} \sup_{\|F\|_{L^2} \le 1} &\int R^{1/2} F(\xi_1 + \xi_2, |\xi_1|^2 + |\xi_2|^2) \hat{\phi}(\xi_1) \hat{\psi}(\xi_2) d\xi_1 d\xi_2 \\ &\lesssim \int R^{1/2} F(s, r) \frac{H(s, r)}{R} ds dr, \end{aligned}$$

where $H(s, r)$ denotes the product of $\hat{\phi}$ and $\hat{\psi}$ in the new variables. Notice that the change of variables introduced above has a Jacobian of size R. Now if we use Cauchy–Schwarz and if we change the variables back to ξ_1 and ξ_2, then we obtain (22). □

In one of our subcases, we shall also take advantage of a trick (originally due to Bourgain [2]) of splitting the symbol $|\xi_1|^2 - \cdots + |\xi_n|^2$ as a sum of $\tau_j \mp |\xi_j|^2$.

Our estimates are not the best possible, and it is likely that one can improve the N^{-1+} gain in our estimates, probably to $N^{-3/2+}$. However, this will fall short of the N^{-2+} gain needed to push the global well-posedness down to match the local well-posedness theory at $s > 1/2$. However, one can recover this by adding higher-order correction terms to the energy $E_N(w(t))$, as in [8]. If one does this, one will end up estimating the Λ_6 and Λ_8 expressions rather than Λ_4. This will be beneficial because such expressions will have fewer derivatives in their symbol and can therefore enjoy better decay in N. The details of this argument will appear in a later paper.

We set out some notation. Let $n = 4$, 6, or 8, and let $\xi_1, \ldots, \xi_n$ be frequencies such that $\xi_1 + \cdots + \xi_n = 0$. Define $N_i := |\xi_i|$ and $N_{ij} := |\xi_{ij}|$. We adopt the notation that

$$1 \le \mathit{soprano}, \mathit{alto}, \mathit{tenor}, \mathit{baritone} \le n$$

are the distinct indices such that

$$N_{soprano} \geq N_{alto} \geq N_{tenor} \geq N_{baritone}$$

are the highest, second highest, third highest, and fourth highest values of the frequencies $N_1, \ldots, N_n$, respectively. (If there is a tie in frequencies, we break the tie arbitrarily.)

Since $\xi_1 + \cdots + \xi_n = 0$, we must have $N_{soprano} \sim N_{alto}$. Also, from Proposition 4.1 we see that M_n vanishes unless $N_{soprano} \gtrsim N$.

8. Proof of Lemma 6.1 when $n = 4$. We now estimate the Λ_4 expression. We begin by estimating the multiplier M_4.

LEMMA 8.1. *Let $\xi_1, \xi_2, \xi_3, \xi_4$ be such that $\xi_{1234} = 0$.*

- *If $N_{tenor} \sim N_{soprano}$, then*

$$|M_4(\xi_1, \xi_2, \xi_3, \xi_4)| \lesssim N^{-1}(N/N_{soprano})^{1/10}\langle \xi_{12}\xi_{14}\rangle^{1/2} \prod_{j=1}^{4} \langle \xi_j \rangle m(\xi_j). \tag{23}$$

- *If $N_{tenor} \ll N_{soprano}$, then*

$$|M_4(\xi_1, \xi_2, \xi_3, \xi_4)| \lesssim N^{-1}(N/N_{soprano})^{1/10} N_{soprano} \prod_{j=1}^{4} \langle \xi_j \rangle m(\xi_j). \tag{24}$$

Proof. Fix $\xi_1, \ldots, \xi_4$. If $N_{soprano} \ll N$, then M_4 vanishes by the second part of Proposition 4.1, and so we will assume that $N_{soprano} \gtrsim N$.

We split $M_4 = C_1 M_4' + C_2 M_4''$, where

$$M_4' := m_1 m_2 m_3 m_4 \xi_{12}\xi_{13}\xi_{14}$$

and

$$M_4'' := m_1^2 \xi_1^2 \xi_3 + m_2^2 \xi_2^2 \xi_4 + m_3^2 \xi_3^2 \xi_1 + m_4^2 \xi_4^2 \xi_2.$$

In the $N_{soprano} \gtrsim N$ case we will not need to exploit cancellation between M_4' and M_4'' (although such cancellation certainly exists) and shall estimate them separately.

Let us first prove (23). We begin with estimating M_4'. We have

$$\begin{aligned}
|M_4'| &= N_{12}N_{13}N_{14} m(N_1)m(N_2)m(N_3)m(N_4) \\
&\lesssim N_{12}N_{14}N_{soprano} m(N_{soprano})^3 \\
&\lesssim \langle N_{12}N_{14}\rangle^{1/2} N_{soprano}^2 m(N_{soprano})^3 \\
&\lesssim \langle N_{12}N_{14}\rangle^{1/2} \frac{1}{N}(N/N_{soprano})^{1/10} \langle N_{soprano}\rangle^3 m(N_{soprano})^3 \\
&\sim N^{-1}(N/N_{soprano})^{1/10}\langle N_{12}N_{14}\rangle^{1/2} \langle N_{soprano}\rangle m(N_{soprano}) \langle N_{alto}\rangle m(N_{alto}) \langle N_{tenor}\rangle m(N_{tenor}) \\
&\lesssim N^{-1}(N/N_{soprano})^{1/10}\langle N_{12}N_{14}\rangle^{1/2} \prod_{j=1}^{4} \langle N_j \rangle m(N_j),
\end{aligned}$$

as desired.

It remains to estimate M_4''. We divide it into two cases: $N_{baritone} \sim N_{soprano}$ and $N_{baritone} \ll N_{soprano}$.

Case 1. $N_{baritone} \sim N_{soprano}$.

In this case all the frequencies are comparable to each other. By symmetry we may assume that $N_{12} \leq N_{14}$, in which case it suffices to show

$$|M_4''| \lesssim N^{-1}(N/N_1)^{1/10} N_{12} N_1^4 m(N_1)^4.$$

We can rewrite $M_4'' = f(0) - f(h)$, where

$$f(h) := m(\xi_1 - h)^2(\xi_1 - h)^2(\xi_3 + h) + m(\xi_3 + h)^2(\xi_3 + h)^2(\xi_1 - h)$$

and $h := \xi_1 + \xi_2$. A routine calculation shows that

$$|f'(x)| \lesssim m(N_1)^2 N_1^2$$

for all $x = O(N_1)$, so by the mean value theorem and the assumption $N_1 \gtrsim N$ we have

$$|M_4''| = |f(0) - f(h)| \lesssim N_{12} m(N_1)^2 N_1^2 \lesssim N^{-1}(N/N_1)^{1/10} N_{12} N_1^4 m(N_1)^4,$$

as desired (in fact, we gain an additional power of N).

Case 2. $N_{baritone} \ll N_{soprano}$.

By symmetry we may assume that *baritone* $= 4$, and thus $N_1 \sim N_2 \sim N_3 \gg N_4$. In this case $N_{14} \sim N_1$, $N_{12} = N_{34} \sim N_1$, and $\langle N_4 \rangle m(N_4) \gtrsim 1$, so it suffices to show

$$|M_4''| \lesssim N^{-1}(N/N_1)^{1/10} N_1^4 m(N_1)^3.$$

But we may crudely estimate the left-hand side by

$$|M_4''| \lesssim m(N_1)^2 N_1^3 + m(N_4)^2 N_4^2 N_1 \lesssim m(N_1)^2 N_1^3,$$

which suffices since $N_1 \gtrsim N$. This proves (23).

Now we show (24). Observe that

$$N_{12} N_{13} N_{14} \lesssim N_{soprano}^2 N_{tenor},$$

and hence

$$\begin{aligned} |M_4'| &\lesssim N_{soprano}^2 N_{tenor} m(N_{soprano}) m(N_{alto}) m(N_{tenor}) m(N_{baritone}) \\ &\lesssim \prod_{j=1}^4 \langle N_j \rangle m(N_j) \\ &\lesssim N^{-1+} N_{soprano}^{1-} \prod_{j=1}^4 \langle N_j \rangle m(N_j). \end{aligned}$$

Thus it remains only to estimate M_4''. Since $\langle N_{baritone} \rangle m(N_{baritone})$ and $m(N_{tenor}) N^{-1}(N/N_{soprano})^{1/10} N_{soprano}$ are both $\gtrsim 1$, it suffices to show

$$|M_4''| \lesssim m(N_{soprano})^2 N_{soprano}^2 N_{tenor}.$$

By symmetry we may reduce to one of two cases.

Case 1. $N_3 = N_{tenor}$ and $N_4 = N_{baritone}$.

We crudely estimate

$$\begin{aligned}|M_4''(\xi_1,\xi_2,\xi_3,\xi_4)| &\lesssim m(N_1)^2 N_1^2 N_3 + m(N_2)^2 N_2^2 N_4 \\ &\quad + m(N_3)^2 N_3^2 N_1 + m(N_4)^2 N_4^2 N_2 \lesssim m(N_1)^2 N_1^2 N_3,\end{aligned}$$

as desired.

Case 2. $N_2 = N_{tenor}$ and $N_4 = N_{baritone}$.

In this case we estimate

$$\begin{aligned}|M_4''| &\lesssim |m_1^2\xi_1^2\xi_3 + m_3^2\xi_3^2\xi_1| + m(N_2)^2 N_2^2 N_4 + m(N_4)^2 N_4^2 N_2 \\ &= N_1 N_3 |m(\xi_1)^2\xi_1 - m(\xi_1+\xi_2+\xi_4)^2(\xi_1+\xi_2+\xi_4)| + O(m(N_1)^2 N_1^2 N_2).\end{aligned}$$

The function $m(\xi_1 + h)^2(\xi_1 + h)$ has a derivative of $O(m(N_1)^2)$ whenever $|h| \ll N_1$; thus by the mean value theorem we have

$$|M_4'(\xi_1,\xi_2,\xi_3,\xi_4)| \lesssim N_1 N_3 N_{24} m(N_1)^2 + O(m(N_1)^2 N_1^2 N_2) \lesssim m(N_1)^2 N_1^2 N_2,$$

as desired. □

We now prove (20) in the $n = 4$ case. It suffices to show that

$$\int_T^{T+\delta} \Lambda_4(M_4; w_1(t), \overline{w_2(t)}, w_3(t), \overline{w_4(t)})\, dt \lesssim N^{-1+} \prod_{j=1}^4 \|Iw_j\|_{1,1/2+}$$

for all Schwartz functions $w_1, \dots, w_4$ on $\mathbb{R} \times \mathbb{R}$. Since M_4 vanishes for $N_{soprano} \ll N$, it suffices by dyadic decomposition to show that

$$\begin{aligned}&\int_T^{T+\delta} \Lambda_4(M_4 \chi_{N_{soprano} \sim 2^k}; w_1(t), \overline{w_2(t)}, w_3(t), \overline{w_4(t)})\, dt \\ &\qquad \lesssim N^{-1+} 2^{(0+)k} (N/2^k)^{1/10} \prod_{j=1}^4 \|Iw_j\|_{1,1/2+}\end{aligned}$$

for all integers k for which $2^k \gtrsim N$. (The exact choice of the cutoff $\chi_{N_{soprano} \sim 2^k}$ is not important as we shall soon be taking absolute values everywhere anyway.)

Fix k. Without loss of generality we may assume that the Fourier transforms $\tilde{w}_j$ are real and nonnegative. We divide the Λ_4 integral into the regions $N_{tenor} \sim N_{soprano}$ and $N_{tenor} \ll N_{soprano}$.

Case 1. $N_{tenor} \sim N_{soprano}$.

We first perform some manipulations to eliminate the cutoff $\chi_{[T,T+\delta]}(t)$. Write $\chi_{[T,T+\delta]}(t) = a(t) + b(t)$, where $a(t)$ is $\chi_{[T,T+\delta]}(t)$ convolved with a smooth approximation to the identity of width 2^{-100k}, and $b(t) = \chi_{[T,T+\delta]}(t) - a(t)$.

Let us first consider the contribution of $b(t)$. We crudely estimate $M_4 = O(2^{10k})$ and estimate this contribution by

$$2^{10k} \int\int |b(t)||w_1(t,x)||w_2(t,x)||w_3(t,x)||w_4(t,x)|\, dxdt.$$

By Hölder, three applications of (3), one application of (4), and four applications of (15), we can bound this by

$$2^{10k} \|b\|_2 \prod_{j=1}^4 \|Iw_j\|_{1,1/2+}.$$

Since $\|b\|_2 \lesssim 2^{-50k}$, the claim then follows.

Now consider the contribution of $a(t)$. We use the following lemma.

LEMMA 8.2. *We have*

$$\|a(t)w_1\|_{1,1/2+} \lesssim 2^{(0+)k}\|w_1\|_{1,1/2+}.$$

Proof. By applying Plancherel, restricting to a single frequency ξ, and then undoing Plancherel, we see that it suffices to show that

$$\|a(t)f\|_{H_t^{1/2+}} \lesssim 2^{(0+)k}\|f\|_{H_t^{1/2+}}$$

for all functions f. However, this follows from the routine calculation

$$\|a(t)\|_{H_t^{1/2+}} \lesssim 2^{(0+)k}$$

and the fact that $H_t^{1/2+}$ is closed under multiplication. □

It therefore suffices to show

$$\left|\int \Lambda_4(M_4\chi_{N_{tenor}\sim N_{soprano}\sim 2^k}; w_1(t), \overline{w_2(t)}, w_3(t), \overline{w_4(t)})\ dt\right|$$
$$\lesssim N^{-1}(N/2^k)^{1/10}\prod_{j=1}^{4}\|Iw_j\|_{1,1/2+}.$$

Without loss of generality we may assume that the Fourier transforms $\tilde{w}_j$ are real and nonnegative. By Plancherel and (23) we estimate the left-hand side by

$$N^{-1}(N/2^k)^{1/10}\left|\int_* \langle\xi_{12}\xi_{14}\rangle^{1/2}\widetilde{ID_xw_1}(\tau_1,\xi_1)\widetilde{\overline{ID_xw_2}}(\tau_2,\xi_2)\widetilde{ID_xw_3}(\tau_3,\xi_3)\widetilde{\overline{ID_xw_4}}(\tau_4,\xi_4)\right|.$$

From the identity (cf. Bourgain [2] and Kenig–Ponce–Vega [17])

$$\begin{aligned}\sum_{j=1}^{4}(\tau_j-(-1)^{j-1}\xi_j^2) &= -\xi_1^2+\xi_2^2-\xi_3^2+\xi_4^2\\ &= \xi_{12}\xi_{2-1}+\xi_{34}\xi_{4-3}\\ &= \xi_{12}(\xi_{2-1}-\xi_{4-3})\\ &= -2\xi_{12}\xi_{14}\end{aligned}$$

we see that

$$\langle\xi_{12}\xi_{14}\rangle \lesssim \langle\tau_j-(-1)^{j-1}\xi_j^2\rangle$$

for some $j=1,2,3,4$. We shall assume $j=1$; the argument for other values of j is similar. We can then use duality and Plancherel to estimate the previous by

$$N^{-1}(N/2^k)^{1/10}\|Iw_1\|_{1,1/2+}\|\overline{ID_xw_2}ID_xw_3\overline{ID_xw_4}\|_{L_t^2L_x^2}.$$

However, this is acceptable by Hölder and three applications of (3).

Case 2. $N_{tenor} \ll N_{soprano}$.

We shall assume that *soprano* $=1$ and *alto* $=2$; the reader may verify that the other cases follow by the same argument. We may then restrict w_1, w_2 to have Fourier support in $|\xi|\sim 2^k$ and w_3, w_4 to have Fourier support in the region $|\xi|\ll 2^k$.

By (24) we have

$$|M_4| \lesssim N^{-1}(N/2^k)^{1/10}2^k\prod_{j=1}^{4}\langle\xi_i\rangle m(\xi_i).$$

The claim then follows from Hölder and two applications of Proposition 7.1.

9. Proof of Lemma 6.1 when $n = 6$. We begin with the analogue of Lemma 8.1.

LEMMA 9.1. *Let $\xi_1, \ldots, \xi_6$ be such that $\xi_{123456} = 0$.*

- *If $N_{tenor} \sim N_{soprano}$, then*

$$(25) \quad |M_6(\xi_1, \xi_2, \xi_3, \xi_4, \xi_5, \xi_6)| \lesssim N^{-1} \langle \xi_{soprano} \rangle m(\xi_{soprano}) \langle \xi_{alto} \rangle m(\xi_{alto}) \langle \xi_{tenor} \rangle m(\xi_{tenor}).$$

- *If $N_{tenor} \ll N_{soprano}$, then*

$$(26) \quad |M_6(\xi_1, \xi_2, \xi_3, \xi_4, \xi_5, \xi_6)| \lesssim N^{-1+} \langle N_{soprano} \rangle^{1-} \langle \xi_{soprano} \rangle m(\xi_{soprano}) \langle \xi_{alto} \rangle m(\xi_{alto}).$$

One can improve these estimates by exploiting further cancellation in the expression M_6, but we shall not need to do so because of the good smoothing properties of (6).

Proof. Since $\xi_{123456} = 0$, we have $N_{alto} \sim N_{soprano}$. We may also assume that $N_{soprano} \gtrsim N$ since M_6 vanishes otherwise.

We have the very crude estimate

$$|M_6| \lesssim N_{soprano}^2.$$

If $N_{tenor} \sim N_{soprano}$, we then have

$$|M_6| \lesssim N_{soprano}^2 \lesssim N^{-1} m(N_{soprano}) N_{soprano} m(N_{alto}) N_{alto} m(N_{tenor}) N_{tenor}$$

(using the hypothesis $s > 2/3$), and (25) follows.

Now suppose that $N_{tenor} \ll N_{soprano}$. Then

$$|M_6| \lesssim N_{soprano}^2 \lesssim N^{-1+} \langle N_{soprano} \rangle^{1-} m(N_{soprano}) N_{soprano} m(N_{alto}) N_{alto}$$

(since $s > 1/2$), and (26) follows. □

We now prove (20) for $n = 6$. As in the previous section, it suffices to show

$$\int_T^{T+\delta} \Lambda_6(M_6; w_1(t), \overline{w_2(t)}, w_3(t), \overline{w_4(t)}, w_5(t), \overline{w_6(t)})\ dxdt \lesssim N^{-1+} \prod_{j=1}^{6} \|Iw_j\|_{1,1/2-}$$

for all Schwartz functions $w_1, \ldots, w_6$ on $\mathbb{R} \times \mathbb{R}$. Without loss of generality we may assume that the Fourier transforms $\tilde{w}_i$ of w_i are real and nonnegative.

We again divide the analysis into the cases $N_{tenor} \sim N_{soprano}$ and $N_{tenor} \ll N_{soprano}$.

Case 1. $N_{tenor} \sim N_{soprano}$.

By (25) and symmetry it suffices to show

$$\int_T^{T+\delta} \int \prod_{j=1}^{3} |D_x I w_j| \prod_{j=4}^{6} |w_j|\ dxdt \lesssim \prod_{j=1}^{6} \|Iw_j\|_{1,1/2+}.$$

However, this follows from Hölder, six applications of (3) first, and three applications of (15) later.

Case 2. $N_{tenor} \ll N_{soprano}$.

We shall assume that *soprano* = 1 and *alto* = 2; the reader may verify that the other cases follow by the same argument.

First suppose that $N_{soprano} \sim 2^k$ for some integer k. Then w_1, w_2 have Fourier support on $|\xi| \sim 2^k$, while w_3, w_4, w_5, w_6 have Fourier support on $|\xi| \ll 2^k$.

We apply (26) and bound the contribution of this case by

$$N^{-1+}2^{(1-)k} \int_T^{T+\delta} \int \prod_{j=1}^{2} |D_x I w_j| \prod_{j=3}^{6} |w_j| \; dxdt,$$

which we bound using Hölder by

$$N^{-1+}2^{(1-)k} \|(D_x I w_1) w_3\|_{L_t^2 L_x^2} \|(D_x I w_2) w_4\|_{L_t^2 L_x^2} \|w_5\|_{L_t^\infty L_x^\infty} \|w_6\|_{L_t^\infty L_x^\infty}.$$

By Lemma 7.1, (5), and (15) we can bound this by

$$N^{-1+}2^{(0-)k} \prod_{j=1}^{6} \|I w_j\|_{1,1/2+}.$$

The claim then follows by summing in k.

10. Proof of Lemma 6.1 when n = 8. We begin with the analogue of Lemma 8.1.

LEMMA 10.1. *For any* $\xi_1, \dots, \xi_6$ *with* $\xi_{123456} = 0$*, we have*

$$|M_8(\xi_1, \xi_2, \xi_3, \xi_4, \xi_5, \xi_6, \xi_7, \xi_8)| \lesssim N^{-1} \langle \xi_{soprano} \rangle m(\xi_{soprano}) \langle \xi_{alto} \rangle m(\xi_{alto}). \tag{27}$$

Proof. As usual, we may assume that $N_{soprano} \sim N_{alto} \gtrsim N$. We crudely estimate

$$|M_8| \lesssim N_{soprano} \lesssim N^{-1} N_{soprano} m(N_{soprano}) N_{alto} m(N_{alto}),$$

and the claim follows. □

To prove (20) for $n = 8$ it suffices to show

$$\int_T^{T+\delta} \Lambda_8(M_8; w_1(t), \dots, \overline{w_8(t)}) \; dt \lesssim N^{-1} \prod_{j=1}^{8} \|I w_j\|_{1,1/2+}$$

for all Schwartz functions $w_1, \dots, w_8$ on $\mathbb{R} \times \mathbb{R}$. Without loss of generality, we may assume that the Fourier transforms $\tilde{w_i}$ of w_i are real and nonnegative. By Lemma 10.1 and symmetry it thus suffices to show

$$\int_T^{T+\delta} \int |D_x I w_1| |D_x I w_2| \prod_{j=3}^{8} |w_j| \; dxdt \lesssim N^{-1} \prod_{j=1}^{8} \|I w_j\|_{1,1/2+}.$$

However, this follows from Hölder, six applications of (3), and two applications of (5) and (15).

Remark 10.2. As was shown in section 3, the gauge transform in Definition 3.1 introduces a quintic term in the IVP (6). Then one can ask if the same arguments we proposed above can be used in order to study the global well-posedness of the quintic nonlinear Schrödinger IVP

$$\begin{cases} i\partial_t v + \partial_x^2 v + \lambda |v|^4 v = 0, & \\ v(x,0) = v_0(x), & x \in \mathbb{R}, \quad t \in \mathbb{R}, \end{cases} \tag{28}$$

where $\lambda \in \mathbb{R}$. In this case we define the energy

$$H(f) := \int |\partial_x f(x)|^2 \, dx - \frac{\lambda}{6} \int |f|^2 \, dx.$$

By Plancherel, we may write $H(f)$ using the Λ notation as

$$H(f) = \Lambda_2(\xi_1\xi_2; f) - \frac{\lambda}{6}\Lambda_6(1; f).$$

As in Lemma 3.5, one can prove that the energy $H(v(t))$ of the solution v for (28) is constant. Now let us define the new energy

$$H_N(v) = H(Iv) = \Lambda_2(\xi_1\xi_2 m_1 m_2; v) - \frac{\lambda}{6}\Lambda_6\left(\prod_{i=1}^{6} m_i; v\right)$$

just like we did in section 4. Then, by the analogue of (8), $\partial_t H_N(v(t))$ will involve terms of type Λ_2, Λ_6, and Λ_{10}. Using the same ideas presented in the proof of Lemma 6.1, we can also estimate in the appropriate way the term involving Λ_{10}. If in (28) we assume that $\lambda < 0$ (defocusing) or that the L^2 norm of the initial data is small (so that the Gagliardo–Niremberg inequality can be applied), then the energy $H(v)(t)$ stays positive for all times, and global well-posedness in H^s for $s > 2/3$ will follow. We will present the details of the proof in a future paper. It has to be said here that global results for "small data" are already available for (28) through more standard arguments [6].

NEW STABILITY ESTIMATES FOR THE INVERSE ACOUSTIC INHOMOGENEOUS MEDIUM PROBLEM AND APPLICATIONS[*]

PETER HÄHNER[†] AND THORSTEN HOHAGE[‡]

Abstract. This paper is concerned with the scattering of time-harmonic acoustic waves by inhomogeneous media. We study the problem to recover the refractive index from far field measurements and from near field mesurements. We establish logarithmic stability estimates for these problems using a priori information with respect to Sobolev norms and a priori information about the support of the inhomogeneity. Our results improve previous estimates due to Stefanov by giving an explicit exponent in the logarithmic estimate, by using the L^2-norm for far field patterns, and by dropping the assumption that the refractive indices are close together. These improvements make it possible to prove convergence rates for iterative regularization methods.

1. Introduction.

The scattering of time-harmonic acoustic waves in an inhomogeneous medium with refractive index n is described by the differential equation

$$\Delta u + k^2 n u = 0. \tag{1.1}$$

Here the real part of the complex valued function u describes the space-dependent part of a velocity potential, and $k > 0$ is the wave number. We assume that the refractive index n is a complex valued function in $\mathbb{R}^3$ satisfying $\mathrm{Im}(n(x)) \geq 0$ for all $x \in \mathbb{R}^3$ and supp $(1 - n) \subset B_1$. (For $R > 0$ we use the notation $B_R := \{x \in \mathbb{R}^3 \colon |x| < R\}$.) We will also assume throughout that $1 - n$ belongs to the Sobolev space $H^s(\mathbb{R}^3)$ for some fixed $s > 3/2$. Due to Sobolev's imbedding theorem, this implies that n is uniformly Hölder continuous in $\mathbb{R}^3$ with Hölder exponent $s - 3/2$. Since by rescaling we can always obtain that $\mathrm{supp}(1 - n) \subset B_1$, this is not a severe restriction.

The following problem will be referred to as the *direct scattering problem*: Given an incident wave $u^{\mathrm{i}} \in C^2(B_1)$ satisfying the Helmholtz equation $\Delta u^{\mathrm{i}} + k^2 u^{\mathrm{i}} = 0$ in B_1 and k and n as above, find a scattered wave $u^{\mathrm{s}} \in C^2(\mathbb{R}^3)$ satisfying the differential equation

$$\Delta u^{\mathrm{s}} + k^2 n u^{\mathrm{s}} = k^2 (1 - n) u^{\mathrm{i}} \quad \text{in } \mathbb{R}^3 \tag{1.2a}$$

and the Sommerfeld radiation condition

$$\lim_{|x| \to \infty} |x| \left(\frac{\partial u^{\mathrm{s}}}{\partial r}(x) - iku^{\mathrm{s}}(x) \right) = 0 \tag{1.2b}$$

uniformly for all directions $\hat{x} = (1/r)x$, where $r := |x|$. The right-hand side of (1.2a) is defined to be zero outside of B_1. It can be shown that this problem has a unique solution (cf. [3, Chapter 8]). Note that the total field $u := u^{\mathrm{i}} + u^{\mathrm{s}}$ satisfies (1.1).

To formulate our first inverse problem, let us introduce point sources $u^{\mathrm{i}}(x) = \Phi(x, y)$, located at $y \in \mathbb{R}^3$, $|y| > 1$, as incident fields. Here

$$\Phi(x, y) := \frac{1}{4\pi} \frac{e^{ik|x-y|}}{|x-y|}, \quad x, y \in \mathbb{R}^3, \quad x \neq y,$$

denotes the fundamental solution to the Helmholtz equation. The corresponding scattered fields u^{s} satisfying (1.2a) and (1.2b) for $u^{\mathrm{i}}(x) = \Phi(x, y)$ are denoted by $w_n^{\mathrm{s}}(x, y)$. The total field $w_n(x, y) := \Phi(x, y) + w_n^{\mathrm{s}}(x, y)$ is the Green function for our scattering problem. It is actually defined for all x, $y \in \mathbb{R}^3$, $x \neq y$, but we shall need it only for points $|y| > 1$. We consider the inverse problem to determine the refractive index n from a knowledge of its corresponding Green function w_n on $\partial B_R \times \partial B_R$ with some $R > 1$. This means we are probing the medium using point sources located on ∂B_R and measure the scattered waves on ∂B_R in order to recover the inhomogeneity. We will show the following logarithmic stability estimate.

Theorem 1.1. *Let $C_n > 0$ and $R > 1$ be given constants. Then, there exists a positive constant C (depending only on s, k, R, and C_n) such that for all refractive indices n, $\tilde{n}$ satisfying $\|1 - n\|_{H^s}, \|1 - \tilde{n}\|_{H^s} \leq C_n$, $\operatorname{supp}(1 - n)$, $\operatorname{supp}(1 - \tilde{n}) \subset B_1$, the estimates*

$$\|n - \tilde{n}\|_{L^2(B_1)} \leq C \left[-\ln^- \left(\|w_n^{\mathrm{s}} - w_{\tilde{n}}^{\mathrm{s}}\|_{L^2(\partial B_R \times \partial B_R)} \right) \right]^{-\frac{s}{s+3}} \tag{1.3}$$

and

$$\|n - \tilde{n}\|_{\infty} \leq C \left[-\ln^- \left(\|w_n^{\mathrm{s}} - w_{\tilde{n}}^{\mathrm{s}}\|_{L^2(\partial B_R \times \partial B_R)} \right) \right]^{-\frac{2s-3}{2s+3}} \tag{1.4}$$

hold true. Here $\ln^-(t) := \ln(t)$ for $t \leq \exp(-1)$, and $\ln^-(t) := -1$ else.

This theorem implies that if one uses point sources located on ∂B_R to probe the medium and if one measures the scattered waves on ∂B_R, then the refractive index depends continuously on these data under the a priori assumptions $\|1 - n\|_{H^s} \leq C_n$ and $\operatorname{supp}(1 - n) \subset B_1$. The logarithmic estimates (1.3) and (1.4) reflect the exponentially ill-posed nature of the problem. Let us point out that Theorem 1.1 also implies a global uniqueness result for the inverse scattering problem to determine the refractive index from measurements of the scattered fields on ∂B_R using point sources located on ∂B_R. Namely, two refractive indices from H^s having the same Green function on $\partial B_R \times \partial B_R$ must be identical.

Another interesting inverse problem results from using far field data instead of near field data. A solution v to the Helmholtz equation in an exterior domain satisfying (1.2b) is known to obey

$$v(x) = \frac{e^{ik|x|}}{|x|} \left(v^{\infty}\left(\frac{x}{|x|} \right) + \mathrm{O}\left(\frac{1}{|x|} \right) \right)$$

(cf. [3, Section 2.2]). The function $v^{\infty} : S^2 \to \mathbb{C}$, $S^2 := \{x \in \mathbb{R}^3 : |x| = 1\}$ is called *the far field pattern* of v. In this context we will consider plane incident waves $u^{\mathrm{i}}(x) = u^{\mathrm{i}}(x, d) = \exp(ikx \cdot d)$, $d \in S^2$. The corresponding scattered fields are denoted by $u_n^{\mathrm{s}}(\cdot, d)$, and their far field patterns are denoted by $u_n^{\infty}(\cdot, d)$. Probing the medium with plane incident waves from all directions and measuring the corresponding far field patterns lead to the problem to recover n from a knowledge of u_n^∞ on $S^2 \times S^2$. We will prove the following result.

THEOREM 1.2. *Let $C_n > 0$ and $0 < \epsilon < \frac{s}{s+3}$ be given constants. Then there exists a positive constant C (depending only on s, ϵ, k, and C_n) such that for all refractive indices n, $\tilde{n}$ satisfying $\|1-n\|_{H^s}, \|1-\tilde{n}\|_{H^s} \le C_n$, and $\operatorname{supp}(1-n)$, $\operatorname{supp}(1-\tilde{n}) \subset B_1$, the estimate*

$$\|n - \tilde{n}\|_{L^2(B_1)} \le C \left[-\ln^- \left(\|u_n^\infty - u_{\tilde{n}}^\infty\|_{L^2(S^2\times S^2)}\right)\right]^{-\frac{s}{s+3}+\epsilon} \tag{1.5}$$

holds true.

Moreover, for $0 < \epsilon < \frac{2s-3}{2s+3}$ the maximum norm of $n - \tilde{n}$ can be estimated by

$$\|n - \tilde{n}\|_\infty \le C \left[-\ln^- \left(\|u_n^\infty - u_{\tilde{n}}^\infty\|_{L^2(S^2\times S^2)}\right)\right]^{-\frac{2s-3}{2s+3}+\epsilon}. \tag{1.6}$$

The main idea for the proof of Theorem 1.1 goes back to Alessandrini [1], who examined the continuous dependence of the conductivity on its corresponding Dirichlet-to-Neumann map. In [17] Stefanov applied this idea to potential scattering problems and proved that the potential depends continuously on the corresponding Dirichlet-to-Neumann map. Both articles employ a lemma about holomorphic functions in several variables which prevents the exponent in the inequalities from being known explicitly. In order to obtain the explicit exponents $-s/(s+3)$ and $-(2s-3)/(2s+3)$, we present a modified and simpler proof. Moreover, contrary to Stefanov, who establishes his result only for refractive indices n and $\tilde{n}$ sufficiently close to each other, we shall need only the assumption that the H^s norms of $1-n$ and $1-\tilde{n}$ are bounded by a constant C_n. Stefanov's paper [17] also contains a stability estimate involving far field data. However, instead of the L^2 norm, a very strong norm involving exponentially increasing weights for the Fourier coefficients of the far field patterns is used. Since no estimate on the measurement error with respect to this norm will be available in practice, Stefanov's result is primarily of theoretical interest.

Let us point out that the function $[-\ln t]^{-1}$ is converging very slowly to 0 as $t \to 0$. The power $0 < p < 1$ in the function $[-\ln t]^{-p}$ is even deteriorating the convergence. However, since it is possible to prove convergence rates for iterative regularization methods which are based on stability estimates and since our numerical example indicates that the convergence of an iterative regularization method is not much faster than predicted by our estimate, we have strong evidence that our stability estimate cannot be significantly improved.

We also want to emphasize that assuming high regularity for n, i.e., using the a priori information $1 - n \in H_0^s(B_1)$ with a very large s, will improve the estimate somewhat but not very much.

In the next section we briefly collect the necessary results for the Green function. The following two sections are dedicated to the proofs of the two main theorems. In the final section of this paper we show how Theorem 1.2 can be used to obtain convergence rates for iterative regularization methods, and we present numerical computations comparing the actual speed of convergence to our estimates.

2. The Green function.

In this section we want to briefly review the properties of the Green function that we shall use in what follows for our stability estimates.

Let us first introduce the *Lippmann–Schwinger equation*, which is an equivalent formulation of (1.2a), (1.2b) as an integral equation of the second kind:

$$u(x) + k^2 \int_{B_1} \Phi(x,y)\,(1-n(y))\,u(y)\,\mathrm{d}y = u^{\mathrm{i}}(x), \quad x \in B_1. \tag{2.1}$$

If $u \in C(B_1)$ is a solution to (2.1), then

$$u^{\mathrm{s}}(x) := -k^2 \int_{B_1} \Phi(x,y)\,(1-n(y))\,u(y)\,\mathrm{d}y, \quad x \in \mathbb{R}^3, \tag{2.2}$$

is the solution to (1.2a), (1.2b), and vice versa (cf. [3, Section 8.2]). Using the incident waves $u^{\mathrm{i}}(x) = \Phi(x,y)$, we find that w_n^s is infinitely smooth for $|x|, |y| > 1$, $x \neq y$. From (2.2) and the asymptotic behavior of $\Phi(x,y)$ we obtain

$$u^\infty(\hat{x}) = -\frac{k^2}{4\pi} \int_{B_1} e^{-ik\hat{x}\cdot y}\,(1-n(y))\,u(y)\,\mathrm{d}y, \quad \hat{x} \in S^2.$$

Hence the far field u^∞ is C^∞ on $S^2 \times S^2$.

For a fixed radius $R > 1$ let us introduce the single layer potential having the Green function $w_n(x,y) = \Phi(x,y) + w_n^s(x,y)$ as kernel, that is, the function

$$u(x) := \int_{\partial B_R} w_n(x,y)\,\varphi(y)\;\mathrm{d}s(y), \quad x \in \mathbb{R}^3. \tag{2.3}$$

Here we assume that the density φ is a continuous function on ∂B_R. For convenience we also introduce the operator S_n which maps φ to $u|_{\partial B_R}$, i.e.,

$$(S_n\varphi)(x) := \int_{\partial B_R} w_n(x,y)\,\varphi(y)\;\mathrm{d}s(y), \quad x \in \partial B_R. \tag{2.4}$$

Lemma 2.1. *Suppose $1 < R$. Then*

(a) *The Green function satisfies $w_n(x,y) = w_n(y,x)$. In particular, the operator S_n is symmetric: $\int_{\partial B_R} g\,(S_n f)\;\mathrm{d}s = \int_{\partial B_R} (S_n g) f\;\mathrm{d}s$ for all f, $g \in C(\partial B_R)$.*

(b) *The mapping $1 - n \mapsto w_n|_{\partial B_R \times \partial B_R}$, regarded as a mapping from $H_0^s(B_1)$ to $L^2(\partial B_R \times \partial B_R)$, is completely continuous. In particular, bounded sets are mapped into bounded sets.*

Proof. The symmetry of w_n^{s} and then of the Green function w_n can be shown with the help of Green's theorem (cf. [16, Section 8, Chapter 1.2.2 and Section 3, Chapter 1.2.3]). This immediately implies the symmetry of S_n by interchanging the order of integration.

For part (b) we observe that the embedding $H_0^s(B_1) \to H_0^{s'}(B_1)$ with $s > s' > 3/2$ is a compact linear mapping. Since the mapping $H_0^{s'}(B_1) \to L^2(\partial B_R \times \partial B_R)$, $1 - n \mapsto w_n|_{\partial B_R \times \partial B_R}$ is continuous, the composition is completely continuous and maps bounded sets into bounded sets. □

The next lemma states that the single layer potential having as kernel the Green function w_n is the unique solution to a certain transmission problem.

Lemma 2.2. *For $f \in C(\partial B_R)$ the function*

$$u(x) := \int_{\partial B_R} w_n(x,y)\,f(y)\;\mathrm{d}s(y), \quad x \in \mathbb{R}^3, \tag{2.5}$$

is the unique solution to the boundary value problem

$$\Delta u + k^2 n u = 0 \quad \text{in } \mathbb{R}^3 \setminus \partial B_R, \tag{2.6a}$$

$$\frac{\partial u_-}{\partial \nu} - \frac{\partial u_+}{\partial \nu} = f \quad \text{on } \partial B_R, \tag{2.6b}$$

$$\lim_{r\to\infty} r\left(\frac{\partial u}{\partial r} - iku\right) = 0 \tag{2.6c}$$

in $C(\mathbb{R}^3)\cap C^2(\mathbb{R}^3\backslash\partial B_R)$*. Here,* ν *denotes the unit normal vector on* ∂B_R *directed into the exterior of* B_R*.*

Proof. In order to prove that the boundary value problem (2.6) has at most one solution, we assume that u is a solution of (2.6) with $f=0$. Then we can follow the first part of the reasoning for the uniqueness proof of (1.2a), (1.2b) [3, Theorem 8.7], and we obtain $u=0$ in the exterior of B_R, whence $u=\frac{\partial u_-}{\partial\nu}=0$ on ∂B_R. Now Green's representation formula (cf. [3, Theorem 2.1]),

$$u(x)=\int_{\partial B_R}\left\{\frac{\partial u}{\partial\nu}(y)\,\Phi(x,y)-u(y)\,\frac{\partial\Phi(x,y)}{\partial\nu(y)}(x,y)\right\}\,\mathrm{d}s(y)$$
$$-\int_{B_R}(\Delta u(y)+k^2u(y))\,\Phi(x,y)\,\mathrm{d}y,\quad x\in B_R,$$

together with the differential equation (2.6a), implies that u is a solution of the homogeneous Lippmann–Schwinger equation. Thus we also have $u=0$ in B_R.

Since u defined as in (2.5) is a superposition of the solutions $w_n(\cdot,y)$ to $\Delta_x w_n+k^2nw_n=0$, u itself also satisfies this differential equation in $\mathbb{R}^3\setminus\partial B_R$. Moreover, u is a radiating solution. Finally, we can conclude from the regularity properties of the single layer potential with kernel Φ (cf. [3, Section 3.1]) that u as defined in (2.5) satisfies the boundary conditions. Hence it is the solution of (2.6). □

Our final lemma of this section states a series representation of w_n^s and of u_n^∞ in terms of spherical harmonics. For convenience we want to use the notation

$$\mathcal{M}:=\{(l_1,m_1,l_2,m_2)\in\mathbb{N}_0\times\mathbb{Z}\times\mathbb{N}_0\times\mathbb{Z}:|m_1|\le l_1\text{ and }|m_2|\le l_2\},$$

and Y_l^m, $l=0,1,2,\ldots$, $-l\le m\le l$, are a basis of the spherical harmonics. $h_l^{(1)}$ denotes the spherical Hankel of the first kind and of order l (cf., e.g., [3, Section 2.4]).

LEMMA 2.3.

(a) *For* $|x|,\ |y|>1$ *the scattered part of the Green function can be represented as*

$$w_n^s(x,y)=-\frac{k^2}{4\pi}\sum_{(l_1,m_1,l_2,m_2)\in\mathcal{M}} i^{l_1-l_2}\,\alpha_{l_1,m_1,l_2,m_2}\,h_{l_1}^{(1)}(k|x|)\,h_{l_2}^{(1)}(k|y|)$$
$$\times\,Y_{l_1}^{m_1}\left(\frac{x}{|x|}\right)Y_{l_2}^{m_2}\left(\frac{y}{|y|}\right)$$

with suitable constants α_{l_1,m_1,l_2,m_2}*. The series converges absolutely and uniformly on compact subsets of* $\mathbb{R}^3\setminus\overline{B_1}$ *and can be differentiated termwise.*

(b) *The far field* $u_n^\infty(\hat{x},d)$ *has the expansion*

$$u_n^\infty(\hat{x},d)=\sum_{(l_1,m_1,l_2,m_2)\in\mathcal{M}}\alpha_{l_1,m_1,l_2,m_2}\,Y_{l_1}^{m_1}(\hat{x})\,Y_{l_2}^{m_2}(d),$$

where the coefficients α_{l_1,m_1,l_2,m_2} *are the same as in part* (a)*.*

For a proof we refer to Stefanov [17, Proposition 2.2].

3. Estimating the refractive index with the help of near field data (proof of Theorem 1.1). The main idea for the stability estimate is to estimate the Fourier coefficients in the Fourier expansion of $n-\tilde{n}$ with the help of special solutions to (1.1) which depend in a particular way on a complex parameter vector $\zeta\in\mathbb{C}^3$. We call these solutions *geometrical optics solutions.*

LEMMA 3.1. *Suppose $k > 0$, $1 < R'$, a positive constant C_n, and a refractive index n with $\|1-n\|_{H^s} \leq C_n$ are given. Then there are constants $M_1, M_2 > 0$, depending only on s, k, R', and C_n with the following property. For all $\zeta \in \mathbb{C}^3$ satisfying*

$$|\operatorname{Im}(\zeta)| \geq M_1 \quad \textit{and} \quad \zeta \cdot \zeta = k^2$$

there exists a function $v(\cdot\,,\zeta) \in C^2(B_{R'})$ such that

$$U(x,\zeta) := e^{i\zeta\cdot x}(1+v(x,\zeta)), \quad x \in B_{R'}, \tag{3.1}$$

is a solution to $\Delta u + k^2 n u = 0$ in $B_{R'}$, and the estimate

$$\|v(\cdot\,,\zeta)\|_{L^2(B_{R'})} \leq \frac{M_2}{|\operatorname{Im}(\zeta)|} \tag{3.2}$$

holds.

These solutions have a long history and were employed by different authors dealing with inverse scattering problems. We refer the reader to [15] for a brief overview. A proof of the above lemma for the equation $\Delta u + qu = 0$ can be found in [18]. For our case we refer the reader to Lemma 5 in [6].

We have

$$n(x) - \tilde{n}(x) = \sum_{\gamma\in\mathbb{Z}^3} \widehat{(n-\tilde{n})}(\gamma)\, \frac{1}{(2\pi)^{3/2}}\, \exp(i\gamma\cdot x), \quad x \in B_1, \tag{3.3}$$

where $\hat{f}(\gamma)$ denotes the Fourier coefficients of a function $f \in L^2((-\pi,\pi)^3)$ with respect to the orthonormal bases $(2\pi)^{-3/2}\exp(i\gamma\cdot x)$, $x \in (-\pi,\pi)^3$, $\gamma \in \mathbb{Z}^3$. We first bound the sum (3.3) over those multi-indices γ whose norm is larger than a given constant $\rho \geq 2$. It is immediately seen that

$$\begin{aligned}\sum_{|\gamma|>\rho} |\widehat{(n-\tilde{n})}(\gamma)|^2 &\leq \frac{1}{(1+\rho^2)^s} \sum_{|\gamma|>\rho} (1+\gamma\cdot\gamma)^s |\widehat{(n-\tilde{n})}(\gamma)|^2 \\ &\leq \frac{c^2}{\rho^{2s}} \end{aligned} \tag{3.4}$$

because the second factor can be bounded with the help of $\|1-n\|_{H^s} \leq C_n$, $\|1-\tilde{n}\|_{H^s} \leq C_n$. For the estimate of $\|n-\tilde{n}\|_\infty$ we use the Cauchy–Schwarz inequality and obtain

$$\begin{aligned}&\sum_{|\gamma|>\rho} |\widehat{(n-\tilde{n})}(\gamma)| \\ &\leq \left(\sum_{|\gamma|>\rho} (1+\gamma\cdot\gamma)^s |\widehat{(n-\tilde{n})}(\gamma)|^2\right)^{1/2} \left(\sum_{|\gamma|>\rho} \frac{1}{(1+\gamma\cdot\gamma)^s}\right)^{1/2} \\ &\leq \frac{c}{\rho^{s-3/2}}. \end{aligned} \tag{3.5}$$

Here for the second factor we have employed the inequality

$$\sum_{|\gamma|>\rho} \frac{1}{(1+\gamma\cdot\gamma)^s} \leq \frac{c}{\rho^{2s-3}}.$$

Note that c may denote different constants in what follows.

Next, we study the remaining sum of (3.3) over those multi-indices γ with $|\gamma| \leq \rho$. To this end we need the following lemma, which, together with the geometrical optics solutions, is the main tool used to establish a relation between the Fourier coefficients and the operator $S_n - S_{\tilde{n}}$.

LEMMA 3.2. *Assume* $1 < R < R'$. *Moreover,* n, $\tilde{n}$ *are refractive indices with* $\operatorname{supp}(1-n)$, $\operatorname{supp}(1-\tilde{n}) \subset B_1$. *Then, there exists a positive constant* M_3 *(depending only on* k, R, *and* R'*) such that for all solutions* $u \in C^2(B_{R'}) \cap L^2(B_{R'})$ *to* $\Delta u + k^2 n u = 0$ *and all solutions* $\tilde{u} \in C^2(B_{R'}) \cap L^2(B_{R'})$ *to* $\Delta \tilde{u} + k^2 \tilde{n} \tilde{u} = 0$ *in* $B_{R'}$ *the estimate*

$$\left| \int_{B_1} (n - \tilde{n})\, u\, \tilde{u}\, dx \right| \leq M_3 \, \|S_n - S_{\tilde{n}}\|_{L^2(\partial B_R)} \, \|u\|_{L^2(B_{R'})} \, \|\tilde{u}\|_{L^2(B_{R'})} \tag{3.6}$$

holds.

Proof. Given u as in the lemma, we first define a function v by extending $u|_{\overline{B_R}}$ continuously as a radiating solution to the Helmholtz equation in the exterior of B_R, i.e., we set $v|_{\overline{B_R}} = u|_{\overline{B_R}}$ in B_R and $v|_{\mathbb{R}^3 \setminus B_R}$ to be the radiating solution to the Helmholtz equation $\Delta v + k^2 v = 0$ in $\mathbb{R}^3 \setminus \overline{B_R}$ with Dirichlet data $v|_{\partial B_R} = u|_{\partial B_R}$. From Lemma 2.2 we obtain

$$v = S_n \left(\frac{\partial v_-}{\partial \nu} - \frac{\partial v_+}{\partial \nu} \right) \quad \text{on } \partial B_R. \tag{3.7}$$

Proceeding analogously with $\tilde{u}$ to define a function $\tilde{v}$ and establishing the analogue of relation (3.7) for $\tilde{v}$, we use Green's second integral theorem to compute

$$\begin{aligned} &\int_{\partial B_R} \left(\frac{\partial v_-}{\partial \nu} - \frac{\partial v_+}{\partial \nu} \right) (S_n - S_{\tilde{n}}) \left(\frac{\partial \tilde{v}_-}{\partial \nu} - \frac{\partial \tilde{v}_+}{\partial \nu} \right) \, \mathrm{d}s \\ &= \int_{\partial B_R} v \left(\frac{\partial \tilde{v}_-}{\partial \nu} - \frac{\partial \tilde{v}_+}{\partial \nu} \right) \, \mathrm{d}s - \int_{\partial B_R} \tilde{v} \left(\frac{\partial v_-}{\partial \nu} - \frac{\partial v_+}{\partial \nu} \right) \, \mathrm{d}s \\ &= k^2 \int_{B_1} (n - \tilde{n})\, u\, \tilde{u} \, \mathrm{d}x, \end{aligned}$$

and, therefore,

$$\begin{aligned} &\left| \int_{B_1} (n - \tilde{n})\, u\, \tilde{u} \; \mathrm{d}x \right| \\ &\leq \frac{1}{k^2} \, \|S_n - S_{\tilde{n}}\|_{L^2(\partial B_R)} \left\| \frac{\partial v_-}{\partial \nu} - \frac{\partial v_+}{\partial \nu} \right\|_{L^2(\partial B_R)} \left\| \frac{\partial \tilde{v}_-}{\partial \nu} - \frac{\partial \tilde{v}_+}{\partial \nu} \right\|_{L^2(\partial B_R)} . \end{aligned} \tag{3.8}$$

In order to bound the norms of the normal derivatives in (3.8), we apply standard regularity results (Weyl's lemma) for the Helmholtz equation in the shells

$$\Gamma_1 := \left\{ x \in \mathbb{R}^3 \colon \frac{1+R}{2} < |x| < \frac{R'+R}{2} \right\} \subset \Gamma_2 := \{ x \in \mathbb{R}^3 \colon 1 < |x| < R' \}$$

to obtain $\|u\|_{C^2(\Gamma_1)} \leq c \|u\|_{L^2(\Gamma_2)} \leq c \|u\|_{L^2(B_{R'})}$. Hence $\|\partial v_- / \partial \nu\|_{L^2(\partial B_R)}$ can be bounded by $\|u\|_{L^2(B_{R'})}$. Regularity properties for the solution to the exterior boundary value problem for the Helmholtz equation with smooth boundary data $u|_{\partial B_R}$ imply that $\|\partial v_+ / \partial \nu\|_{L^2(\partial B_R)}$ can also be bounded by $\|u\|_{L^2(B_{R'})}$. The same reasoning applies to $\tilde{v}$. Now the lemma follows from inequality (3.8). □

We are now in a position to estimate the Fourier coefficients for the multi-indices $|\gamma| \leq \rho$.

LEMMA 3.3. *Assume $\rho \geq 2$ and C_n are positive constants and n, $\tilde{n}$ are refractive indices satisfying $\|1 - n\|_{H^s}, \|1 - \tilde{n}\|_{H^s} \leq C_n$ and* supp$(1 - n)$, supp$(1 - \tilde{n}) \subset B_1$. *Moreover, suppose $1 < R$ and define $t_0 := \sqrt{M_1^2 + k^2}$ (M_1 being the constant from Lemma* 3.1 *for $R' = 2R$). Then there exists a positive constant M_4 (depending only on s, k, R, and C_n) such that for all $\gamma \in \mathbb{Z}^3$ with $|\gamma| \leq \rho$ and all $t > t_0$ the estimate*

$$\left|\widehat{(n - \tilde{n})}(\gamma)\right| \leq M_4 \left(e^{4R(t+\rho)} \|S_n - S_{\tilde{n}}\|_{L^2(\partial B_R)} + \frac{1}{t} \right) \tag{3.9}$$

holds true.

Proof. For $t > t_0 > k$ and a fixed multi-index $\gamma \in \mathbb{Z}^3$ we choose unit vectors d_1, $d_2 \in \mathbb{R}^3$ such that $d_1 \cdot d_2 = d_1 \cdot \gamma = d_2 \cdot \gamma = 0$ and define the complex vectors

$$\zeta_t := -\frac{1}{2}\, \gamma + i \sqrt{t^2 - k^2 + \frac{|\gamma|^2}{4}}\; d_1 + t\, d_2 \in \mathbb{C}^3, \tag{3.10}$$

$$\tilde{\zeta}_t := -\frac{1}{2}\, \gamma - i \sqrt{t^2 - k^2 + \frac{|\gamma|^2}{4}}\; d_1 - t\, d_2 \ \in \mathbb{C}^3. \tag{3.11}$$

Then the relations $\zeta_t + \tilde{\zeta}_t = -\gamma$, $\zeta_t \cdot \zeta_t = \tilde{\zeta}_t \cdot \tilde{\zeta}_t = k^2$ are satisfied. Furthermore, $t > t_0 = \sqrt{M_1^2 + k^2}$ implies $|\operatorname{Im}(\zeta_t)|, |\operatorname{Im}(\tilde{\zeta}_t)| \geq M_1$. Therefore, according to Lemma 3.1, there exist the geometrical optics solutions

$$U(x, \zeta_t) = e^{i\zeta_t \cdot x}(1 + v(x, \zeta_t)), \quad x \in B_{2R},$$

to $\Delta u + k^2 n u = 0$ and

$$\tilde{U}(x, \tilde{\zeta}_t) = e^{i\tilde{\zeta}_t \cdot x}(1 + \tilde{v}(x, \tilde{\zeta}_t)), \quad x \in B_{2R},$$

to $\Delta \tilde{u} + k^2 \tilde{n} \tilde{u} = 0$. Using Lemma 3.1 once more, we infer

$$U(x, \zeta_t)\, \tilde{U}(x, \tilde{\zeta}_t) = e^{-i\gamma \cdot x}(1 + p(x, t)),$$

where the L^1 norm of the remainder

$$p(x, t) = v(x, \zeta_t) + \tilde{v}(x, \tilde{\zeta}_t) + v(x, \zeta_t)\, \tilde{v}(x, \tilde{\zeta}_t)$$

is bounded by

$$\int_{B_1} |p(x, t)| \ \mathrm{d}x \leq \frac{c}{t} \tag{3.12}$$

with a suitable constant c. Then we compute

$$\begin{aligned}
&\left|\widehat{(n - \tilde{n})}(\gamma)\right| \\
&= \frac{1}{(2\pi)^{3/2}} \left| \int_{B_1} (n - \tilde{n})(x)\, e^{-i\gamma \cdot x} \ \mathrm{d}x \right| \\
&= \frac{1}{(2\pi)^{3/2}} \left| \int_{B_1} (n - \tilde{n})(x)\, U(x, \zeta_t)\, \tilde{U}(x, \tilde{\zeta}_t) \ \mathrm{d}x \right. \\
&\qquad\qquad \left. - \int_{B_1} (n - \tilde{n})(x)\, e^{-i\gamma \cdot x}\, p(x, t) \ \mathrm{d}x \right| \\
&\leq c' \, \|S_n - S_{\tilde{n}}\|_{L^2(\partial B_R)}\, \|U(\cdot, \zeta_t)\|_{L^2(B_{2R})}\, \|\tilde{U}(\cdot, \tilde{\zeta}_t)\|_{L^2(B_{2R})} + \frac{c''}{t} \\
&\leq M_4 \left(e^{4R(t+\rho)} \|S_n - S_{\tilde{n}}\|_{L^2(\partial B_R)} + \frac{1}{t} \right),
\end{aligned} \tag{3.13}$$

where we have used the estimates (3.6) and (3.12) for the first inequality. For the last line in (3.13) we note that

$$\begin{aligned}\|U(\cdot,\zeta_t)\|_{L^2(B_{2R})} &= \|e^{i\zeta_t\cdot x}\,(1+v(\cdot,\zeta_t))\|_{L^2(B_{2R})}\\ &\le \|e^{i\zeta_t\cdot x}\|_{\infty,B_{2R}}\|1+v(\cdot,\zeta_t)\|_{L^2(B_{2R})}\\ &\le c'''e^{2R(t+\rho)}\end{aligned}$$

for all $t \ge t_0$ and all $\gamma \in \mathbb{Z}^3$ with $|\gamma| \le \rho$ because of $|\operatorname{Im}(\zeta_t)| \le t + |\gamma| \le t+\rho$. Together with the analogous estimate for $\|\tilde{U}(\cdot,\tilde{\zeta}_t)\|_{L^2(B_{2R})}$, we obtain (3.13), i.e., we have proved inequality (3.9). □

Finally, we can prove Theorem 1.1 by choosing the parameters ρ and t in (3.4), (3.5), and (3.9) appropriately.

Proof of Theorem 1.1. In view of the Fourier expansion (3.3) for $n-\tilde{n}$, Parseval's equation, the inequalities (3.4) and (3.9), and the fact that there are less than $c\rho^3$ multi-indices $\gamma \in \mathbb{Z}^3$ with $|\gamma| \le \rho$, we have

$$\begin{aligned}\|n-\tilde{n}\|^2_{L^2(B_1)} &\le \frac{c^2}{\rho^{2s}} + \left(\sum_{|\gamma|\le\rho} |\widehat{(n-\tilde{n})}(\gamma)|\right)^2\\ &\le \frac{c^2}{\rho^{2s}} + \left(c\rho^3\left[e^{4R(t+\rho)}\|S_n - S_{\tilde{n}}\|_{L^2(\partial B_R)} + \frac{1}{t}\right]\right)^2\\ &\le c\left(e^{(4R+1)(t+\rho)}\|S_n - S_{\tilde{n}}\|_{L^2(\partial B_R)} + \frac{\rho^3}{t} + \frac{1}{\rho^s}\right)^2, \qquad (3.14)\end{aligned}$$

where we have also used $\rho^3 e^{4R(t+\rho)} \le e^{(4R+1)(t+\rho)}$ (due to $\rho^3 \le 6e^\rho$) in the last line. Note that the value of the constants c will change during the proof. For the maximum norm, in view of (3.3) and (3.5), we compute

$$\begin{aligned}\|n-\tilde{n}\|_\infty &\le c\sum_{|\gamma|\le\rho} |\widehat{(n-\tilde{n})}(\gamma)| + \frac{c}{\rho^{s-3/2}}\\ &\le c\rho^3\left(e^{4R(t+\rho)}\|S_n - S_{\tilde{n}}\|_{L^2(\partial B_R)} + \frac{1}{t}\right) + \frac{c}{\rho^{s-3/2}}\\ &\le c\left(e^{(4R+1)(t+\rho)}\|S_n - S_{\tilde{n}}\|_{L^2(\partial B_R)} + \frac{\rho^3}{t} + \frac{1}{\rho^{s-3/2}}\right). \qquad (3.15)\end{aligned}$$

For $t > t_0 + 2^{s+3}$ (t_0 from Lemma 3.3) and $\rho := t^{1/(s+3)}$ the condition $\rho \ge 2$ is satisfied and inequality (3.14) becomes

$$\|n-\tilde{n}\|_{L^2(B_1)} \le c\left(e^{(8R+2)t}\|w^{\mathrm{s}}_n - w^{\mathrm{s}}_{\tilde{n}}\|_{L^2(\partial B_R\times\partial B_R)} + \frac{2}{t^{s/(s+3)}}\right) \qquad (3.16)$$

because of $\rho = t^{1/(s+3)} \le t$ and $\|S_n - S_{\tilde{n}}\|_{L^2(\partial B_R)} \le \|w^{\mathrm{s}}_n - w^{\mathrm{s}}_{\tilde{n}}\|_{L^2(\partial B_R\times\partial B_R)}$.

We may restrict our attention to the case that $\|w^{\mathrm{s}}_n - w^{\mathrm{s}}_{\tilde{n}}\|_{L^2}$ is sufficiently small such that

$$t := -\frac{1}{s+3}\;\frac{3}{8R+2}\;\ln\left(\|w^{\mathrm{s}}_n - w^{\mathrm{s}}_{\tilde{n}}\|_{L^2}\right) > t_0 + 2^{s+3}.$$

Otherwise, the bound on $\|n-\tilde{n}\|_\infty$ from the a priori information about n and $\tilde{n}$ and the monotonicity of $[-\ln^-(t)]^{-p}$, $0<p<1$, imply

$$\|n-\tilde{n}\|_{L^2(B_1)} \le c\,\frac{[-\ln^-(\|w^{\mathrm{s}}_n - w^{\mathrm{s}}_{\tilde{n}}\|_{L^2})]^{-p}}{[(t_0+2^{s+3})\,\frac{s+3}{3}\,(8R+2)]^{-p}}.$$

Inserting t into (3.16) yields the inequality

$$\begin{aligned}\|n-\tilde{n}\|_{L^2(B_1)} &\leq c\left\{\|w_n^{\mathrm{s}}-w_{\tilde{n}}^{\mathrm{s}}\|_{L^2}^{s/(s+3)}+(-\ln\|w_n^{\mathrm{s}}-w_{\tilde{n}}^{\mathrm{s}}\|_{L^2})^{-s/(s+3)}\right\}\\ &\leq c\left[-\ln\left(\|w_n^{\mathrm{s}}-w_{\tilde{n}}^{\mathrm{s}}\|_{L^2}\right)\right]^{-s/(s+3)}\end{aligned}$$

because $x\leq(-\ln(x))^{-1}$ for $0<x<1$.

The analogous analysis with $\rho:=t^{2/(2s+3)}$ and

$$t:=-\frac{1}{2s+3}\,\frac{3}{4R+1}\,\ln\left(\|w_n^{\mathrm{s}}-w_{\tilde{n}}^{\mathrm{s}}\|_{L^2}\right)>t_0+2^{s+3}$$

reveals

$$\begin{aligned}\|n-\tilde{n}\|_\infty &\leq c\left\{\|w_n^{\mathrm{s}}-w_{\tilde{n}}^{\mathrm{s}}\|_{L^2}^{(2s-3)/(2s+3)}+(-\ln\|w_n^{\mathrm{s}}-w_{\tilde{n}}^{\mathrm{s}}\|_{L^2})^{-(2s-3)/(2s+3)}\right\}\\ &\leq c\left[-\ln\left(\|w_n^{\mathrm{s}}-w_{\tilde{n}}^{\mathrm{s}}\|_{L^2}\right)\right]^{-(2s-3)/(2s+3)}.\end{aligned}$$

This finishes the proof. □

4. Estimating the refractive index with the help of far field data (proof of Theorem 1.2). Our proof of Theorem 1.2 is based on the following abstract linear stability result. It has been proved in [11, 14] for bounded operators. For the convenience of the reader we include the short proof for compact operators which is sufficient for our purposes.

LEMMA 4.1. *Let X,Y be Hilbert spaces, and let $T:X\to Y$ be a compact linear operator. Moreover, assume that $f\in C([0,\|T^*T\|])$ is monotonically increasing with $f(0)=0$ and that the function*

$$\phi_f:[0,f(\|T^*T\|)^2]\to[0,\|T^*T\|f(\|T^*T\|)^2]$$

defined by $\phi_f(\xi):=\xi\cdot(f\cdot f)^{-1}(\xi)$ is convex. Then the source condition

$$w=f(T^*T)v,\qquad\|v\|\leq\rho,\tag{4.1}$$

implies the stability estimate

$$\|w\|^2\leq\rho^2\phi_f^{-1}\left(\frac{\|Tw\|^2}{\rho^2}\right).\tag{4.2}$$

Proof. We can assume that x_μ, $\mu\in\mathcal{M}$, is a Hilbert basis of X with $T^*Tx_\mu=\lambda_\mu x_\mu$, and $\lambda_\mu\geq0$ for all $\mu\in\mathcal{M}$. Replacing w by $(1/\rho)w$, we see that we can also assume that $\rho=1$. If $v=\sum_{\mu\in\mathcal{M}}\alpha_\mu x_\mu$, then $w=\sum_{\mu\in\mathcal{M}}f(\lambda_\mu)\alpha_\mu x_\mu$. We first assume that $\|v\|^2=\sum_{\mu\in\mathcal{M}}|\alpha_\mu|^2=1$. Then Jensen's inequality yields

$$\begin{aligned}\phi_f(\|w\|^2)=\phi_f\left(\sum_{\mu\in\mathcal{M}}(f(\lambda_\mu))^2|\alpha_\mu|^2\right)&\leq\sum_{\mu\in\mathcal{M}}\phi_f((f\cdot f)(\lambda_\mu))\,|\alpha_\mu|^2\\ =\sum_{\mu\in\mathcal{M}}(f\cdot f)(\lambda_\mu)\,\lambda_\mu\,|\alpha_\mu|^2&=\|Tw\|^2.\end{aligned}$$

Since ϕ_f is convex and $\phi_f(0)=0$, this inequality is also valid for $\|v\|<1$. Applying ϕ_f^{-1} to both sides of the inequality yields the assertion since ϕ_f^{-1} is increasing under the given assumptions. □

We want to apply this result to the operator T which maps the difference $w_n - w_{\tilde{n}} = w_n^{\mathrm{s}} - w_{\tilde{n}}^{\mathrm{s}}$ of two Green functions on $\partial B_{2R} \times \partial B_{2R}$ to the corresponding difference of far field patterns $u_n^\infty - u_{\tilde{n}}^\infty$. For the function f we choose $f = g_\theta$, $0 < \theta < 1$, defined by

$$g_\theta(\lambda) := \begin{cases} \exp(-\frac{1}{2}(-\ln\lambda)^\theta), & 0 < \lambda \le \exp(-1), \\ 0, & \lambda = 0. \end{cases} \tag{4.3}$$

The corresponding functions $\phi_\theta := \phi_{g_\theta}$ and their second derivatives are given by

$$\begin{aligned} \phi_\theta(\xi) &= \xi \exp(-(-\ln\xi)^{\frac{1}{\theta}}), \qquad 0 < \xi \le \exp(-1), \\ \phi_\theta''(\xi) &= \exp\left(-(-\ln\xi)^{\frac{1}{\theta}}\right)\left(\frac{(-\ln\xi)^{\frac{1}{\theta}-2}}{\theta\xi}\right)\left(1 - \ln\xi + \frac{(-\ln\xi)^{\frac{1}{\theta}}-1}{\theta}\right). \end{aligned}$$

It is obvious that the functions g_θ are continuous and monotonically increasing and that $\phi_\theta''(\xi) > 0$ for $0 < \xi < \exp(-1)$ and $0 < \theta < 1$.

With the help of the orthonormal basis

$$Y_{r,\mu}(x,y) = \frac{1}{r^2}\, Y_{l_1}^{m_1}\left(\frac{x}{|x|}\right) Y_{l_2}^{m_2}\left(\frac{y}{|y|}\right), \quad \mu = (l_1, m_1, l_2, m_2) \in \mathcal{M},$$

of $L^2(\partial B_r \times \partial B_r)$ and the basis $Y_\mu := Y_{1,\mu}$ in $L^2(S^2 \times S^2)$, we infer from the series expansions in Lemma 2.3 that T defined by

$$Y_{2R,\mu} \mapsto -\frac{\pi}{k^2R^2}\, i^{l_2-l_1}\, \frac{1}{h_{l_1}^{(1)}(2kR) h_{l_2}^{(1)}(2kR)}\, Y_\mu \tag{4.4}$$

maps $(w_n - w_{\tilde{n}})|_{\partial B_{2R} \times \partial B_{2R}}$ to $u_n^\infty - u_{\tilde{n}}^\infty$. Because g_θ is defined only on $[0, \exp(-1)]$, we introduce the scaling factor $\omega := \|T\| \exp(1/2)$ and use the operator $\omega^{-1}T$. In order to apply Lemma 4.1, we must check that a function $w_n - w_{\tilde{n}}$ from which it is known a priori that it originates from refractive indices n, $\tilde{n}$ such that $\|1-n\|_{H^s}, \|1-\tilde{n}\|_{H^s} \le C_n$, $\operatorname{supp}(1-n)$, $\operatorname{supp}(1-\tilde{n}) \subset B_1$, satisfies the source condition, i.e., there is a constant $\rho > 0$ such that $(w_n - w_{\tilde{n}})|_{\partial B_{2R} \times \partial B_{2R}} = g_\theta(\omega^{-2}T^*T)v$ for an appropriate $v \in L^2(\partial B_{2R} \times \partial B_{2R})$ with $\|v\| \le \rho$. We do this in the following lemma.

Lemma 4.2. *Let $1 < R$, $C_n > 0$, and $0 < \theta < 1$ be given. Furthermore, define $\omega := \|T\| \exp(1/2)$, where T denotes the operator from* (4.4). *Then there exists a constant $\rho > 0$ such that all $(w_n - w_{\tilde{n}})|_{\partial B_{2R} \times \partial B_{2R}}$ originating from refractive indices n, $\tilde{n}$ such that $\|1-n\|_{H^s}, \|1-\tilde{n}\|_{H^s} \le C_n$, $\operatorname{supp}(1-n)$, $\operatorname{supp}(1-\tilde{n}) \subset B_1$, satisfy the source condition $(w_n - w_{\tilde{n}})|_{\partial B_{2R} \times \partial B_{2R}} = g_\theta(\omega^{-2}T^*T)v$ for an appropriate $v \in L^2(\partial B_{2R} \times \partial B_{2R})$ with $\|v\| \le \rho$.*

Proof. We know from Lemma 2.3 that

$$(w_n - w_{\tilde{n}})(r\hat{x}, r\hat{y}) = \sum_{\mu \in \mathcal{M}} \alpha_\mu\, r^2\, h_{l_1}^{(1)}(kr)\, h_{l_2}^{(1)}(kr)\, Y_{r,\mu}(r\hat{x}, r\hat{y})$$

for all $r \ge R$ with suitable coefficients α_μ. For convenience we set

$$\gamma_\mu := -\pi(kR\, i^{l_1} h_{l_1}^{(1)}(2kR))^{-1}(kR(-i)^{l_2}\, h_{l_2}^{(1)}(2kR))^{-1}$$

and

$$\delta_\mu = 4\, \frac{h_{l_1}^{(1)}(2kR)}{h_{l_1}^{(1)}(kR)}\, \frac{h_{l_2}^{(1)}(2kR)}{h_{l_2}^{(1)}(kR)}.$$

Note that $|\gamma_\mu|$ are the singular values of T. If we can verify that the function

$$v := \sum_{\mu\in\mathcal{M}} \alpha_\mu \; R^2 \, h^{(1)}_{l_1}(kR) \, h^{(1)}_{l_2}(kR) \; \frac{\delta_\mu}{g_\theta(|\gamma_\mu|^2/\omega^2)} \; Y_{2R,\mu}$$

belongs to $L^2(\partial B_{2R} \times \partial B_{2R})$ and $\|v\| \leq \rho$, a straightforward computation shows $g_\theta(\omega^{-2}T^*T)v = w_n - w_{\tilde{n}}$ on $\partial B_{2R} \times \partial B_{2R}$, and we have proved the source condition.

Since we know from Lemma 2.1(b) that

$$\sum_{\mu\in\mathcal{M}} \left|\alpha_\mu \; R^2 \, h^{(1)}_{l_1}(kR) \, h^{(1)}_{l_2}(kR)\right|^2 = \|(w_n - w_{\tilde{n}})|_{\partial B_R \times \partial B_R}\|^2 \leq c^2$$

for all refractive indices satisfying the assumptions, it suffices to prove

$$\sup_{\mu\in\mathcal{M}} \frac{|\delta_\mu|}{g_\theta(|\gamma_\mu/\omega|^2)} \leq c, \tag{4.5}$$

or in other words that the supremum in (4.5) is finite. (The variable c denotes various constants during the proof.)

To see this, we use the asymptotic formulae

$$\begin{aligned} \frac{1}{c}\left(\frac{l}{kRe}\right)^l \leq |h^{(1)}_l(2kR)| \leq c\left(\frac{l}{kRe}\right)^l, \qquad l \to \infty, \\ \frac{h^{(1)}_l(2kR)}{h^{(1)}_l(kR)} = \frac{1}{2^{l+1}}\;\left(1 + \mathrm{O}\left(\frac{1}{l}\right)\right), \qquad l \to \infty, \end{aligned} \tag{4.6}$$

which follow from the series representation of the spherical Hankel functions (cf. [3]). Therefore, we have

$$|\delta_\mu| \leq c\, 2^{-l_1-l_2}. \tag{4.7}$$

Using the monotonicity of g_θ from (4.6) and the inequality $(a+b)^\theta \leq a^\theta + b^\theta$, which holds for $a, b \geq 0$ and $0 \leq \theta \leq 1$ (for a proof consider the case $a + b = 1$), we obtain the estimate

$$\begin{aligned} g_\theta(|\gamma_\mu/\omega|^2)^{-2} &\leq g_\theta\left(c^2\left(\frac{ekR}{l_1}\right)^{2l_1}\left(\frac{ekR}{l_2}\right)^{2l_2}\right)^{-2} \\ &= \exp\left(\left\{\ln\left(c^2\left(\frac{l_1}{ekR}\right)^{2l_1}\left(\frac{l_2}{ekR}\right)^{2l_2}\right)\right\}^\theta\right) \\ &\leq \exp\left(\left\{\ln c + 2l_1 \ln\frac{l_1}{ekR}\right\}^\theta + \left\{\ln c + 2l_2 \ln\frac{l_2}{ekR}\right\}^\theta\right). \end{aligned}$$

Since $\lim_{l\to\infty}(\{\ln c + 2l\ln(l/(ekR))\}^\theta - 2l\ln 2) = -\infty$, it follows from (4.7) that

$$\frac{|\delta_\mu|^2}{g_\theta(|\gamma_\mu/\omega|^2)^2} \leq c$$

for all $\mu \in \mathcal{M}$. This shows (4.5) and finishes the proof. $\square$

Proof of Theorem 1.2. Lemma 4.2 yields

$$(w_n - w_{\tilde n})|_{\partial B_{2R}\times\partial B_{2R}} = g_\theta(\omega^{-2}T^*T)v, \quad \|v\| \le \rho.$$

Hence, using $T((w_n - w_{\tilde n})|_{\partial B_{2R}\times\partial B_{2R}}) = u_n^\infty - u_{\tilde n}^\infty$, according to Lemma 4.1 we have

$$\begin{aligned}\|(w_n - w_{\tilde n})|_{\partial B_{2R}\times\partial B_{2R}}\|^2 &\le \rho^2\phi_\theta^{-1}\left(\frac{\|T((w_n - w_{\tilde n})|_{\partial B_{2R}\times\partial B_{2R}})\|^2}{\omega^2\rho^2}\right)\\ &= \rho^2\phi_\theta^{-1}\left(\frac{\|u_n^\infty - u_{\tilde n}^\infty\|^2}{\omega^2\rho^2}\right).\end{aligned}$$

To estimate ϕ_θ^{-1}, we write $\phi_\theta(\xi) = \exp(-\psi(-\ln\xi))$ with $\psi(x) := x + x^{\frac{1}{\theta}}$. Obviously, $\psi(x) \le 2x^{\frac{1}{\theta}}$ for $x \ge 1$, so $\psi^{-1}(y) \ge \left(\frac{y}{2}\right)^\theta$ for $y \ge 2$. It follows that

$$\phi_\theta^{-1}(\lambda) = \exp(-\psi^{-1}(-\ln\lambda)) \le \exp\left(-\left(\frac{-\ln\lambda}{2}\right)^\theta\right)$$

for $0 < \lambda \le \exp(-2)$, and we get

$$\|w_n^{\mathrm{s}} - w_{\tilde n}^{\mathrm{s}}\|^2_{L^2(\partial B_{2R}\times\partial B_{2R})} \le \rho^2\exp\left(-\left(-\ln\frac{\|u_n^\infty - u_{\tilde n}^\infty\|_{L^2(S^2\times S^2)}}{\omega\rho}\right)^\theta\right)$$

for sufficiently small $\|u_n^\infty - u_{\tilde n}^\infty\|_{L^2(S^2\times S^2)}$. Inserting this into (1.3) and choosing θ such that $\theta\frac{s}{s+3} = \frac{s}{s+3} - \epsilon$ yield the assertion. By adjusting the constant, similarly to the proof of Theorem 1.1, this inequality holds for all refractive indices satisfying the assumptions. The estimate for $\|n - \tilde n\|_\infty$ is derived analogously. ∎

5. Applications. In this final section we discuss the numerical solution of the inverse problem to recover the refractive index $n(x) = 1 - a(x)$ from measurements of the far field pattern $u^\infty(\hat x, d)$ by iterative regularization methods. Introducing the Hilbert spaces $X = H_0^s(B_1)$, $Y = L^2(S^2\times S^2)$ and the operator $F : X \to Y$, $F(a) := u_{1-a}^\infty$, this problem can be formulated as a nonlinear operator equation:

$$F(a) = u^\infty. \tag{5.1}$$

Usually the measured data will be contaminated by noise. We use the notation $u^{\infty,\delta}$ with $\|u^{\infty,\delta} - u^\infty\| \le \delta$ for noisy data with noise level δ.

A number of methods have been developed to solve general problems of the form (5.1). Among the most popular are the *Landweber iteration*

$$a_{j+1}^\delta := a_j^\delta + \mu F'[a_j^\delta]^*(u^{\infty,\delta} - F(a_j^\delta)) \tag{5.2}$$

($\mu \le \|F'[a]\|^{-1}$ for a in a neighborhood of the exact solution $a^\dagger$), the *Levenberg–Marquardt algorithm*

$$a_{j+1}^\delta := a_j^\delta + (\alpha_j I + F'[a_j^\delta]^*F'[a_j^\delta])^{-1}F'[a_j^\delta]^*(u^{\infty,\delta} - F(a_j^\delta)), \tag{5.3}$$

and the *iteratively regularized Gauß–Newton method* (IRGNM)

(5.4)
$$a_{j+1}^\delta := a_0 + (\alpha_j I + F'[a_j^\delta]^*F'[a_j^\delta])^{-1}F'[a_j^\delta]^*\left(u^{\infty,\delta} - F(a_j^\delta) + F'[a_j^\delta](a_j^\delta - a_0)\right).$$

For the last two methods there are different strategies for choosing the regularization parameters α_j, e.g., $\alpha_j = 2^{-j}\alpha_0$.

An important issue is the choice of the stopping index. The most well-known stopping rule is *Morozov's discrepancy principle*, which consists in stopping the iteration at the first index $J = J(\delta, u^{\infty,\delta})$ such that

$$\|F(a_J^\delta) - u^{\infty,\delta}\| \leq \tau\delta \tag{5.5}$$

with some fixed constant $\tau \geq 1$.

We call an iterative method $a_{j+1}^\delta := \Psi_j(a_j, \ldots, a_0, u^{\infty,\delta})$ together with a stopping rule $J(\delta, u^{\infty,\delta})$ an *iterative regularization method* for F if for all initial guesses a_0 in a neighborhood of $a^\dagger$ the iterates a_{j+1}^δ, $j \leq J(\delta, u^{\infty,\delta})$ are well defined and

$$\lim_{j\to\infty} a_j^0 = a^\dagger, \tag{5.6}$$

$$\lim_{\delta\to 0} \sup_{\|u^{\infty,\delta}-u^\infty\|\leq\delta} \|a_{J(\delta,u^{\infty,\delta})}^\delta - a^\dagger\| = 0. \tag{5.7}$$

It has been shown that under certain conditions restricting the degree of nonlinearity of the operator F, the Landweber iteration (Hanke, Neubauer, and Scherzer [9]), the Levenberg–Marquardt algorithm (Hanke [8]), and the IRGNM (Blaschke/Kaltenbacher, Neubauer, Scherzer [2]), together with the discrepancy principle (5.5), are regularization methods in the sense of the definition above. It must be mentioned that none of these nonlinearity conditions has been verified for the inverse acoustic medium scattering problem yet.

Since it is well known that the convergence in (5.7) can be *arbitrarily slow* for any ill-posed problem (cf. [5, Proposition 3.11]), one is interested in proving estimates on the convergence rate under additional a priori assumptions. In the literature, assumptions of the form

$$a^\dagger - a_0 = f(F'[a^\dagger]^* F'[a^\dagger])v, \qquad \|v\| \leq \rho, \tag{5.8}$$

have been studied intensively. These conditions, called *nonlinear source conditions*, are nonlinear analogues to (4.1). It turns out that for many exponentially ill-posed problems source conditions (5.8) with $f = f_p$ $(p > 0)$

$$f_p(\lambda) := \begin{cases} (-\ln\lambda)^{-p}, & 0 < \lambda \leq \exp(-1), \\ 0, & \lambda = 0 \end{cases} \tag{5.9}$$

(so-called *logarithmic source conditions*), have natural interpretations as smoothness conditions in Sobolev spaces (cf. [11, 13]). The usual Hölder-type source conditions (5.8) with $f(\lambda) = \lambda^\mu$, $\mu > 0$, are appropriate for mildly ill-posed problems but typically far too restrictive for exponentially ill-posed problems. Under the logarithmic source condition (5.8), (5.9), convergence rates of the form

$$\|a_{J(\delta,u^{\infty,\delta})}^\delta - a^\dagger\| = \mathrm{O}\left(f_p(\delta)\right)$$

have been established for the IRGNM [10] and for the Landweber iteration [4].

Unfortunately, it seems that logarithmic source conditions for the inverse acoustic medium scattering problem do not have an equivalent formulation with the help of known Sobolev spaces. However, Theorem 1.2 gives us a sufficient condition for convergence rates under the simple assumption that the exact solution $n^\dagger = 1 - a^\dagger$ and the initial guess $n_0 := 1 - a_0$ belong to $H_0^s(B_1)$.

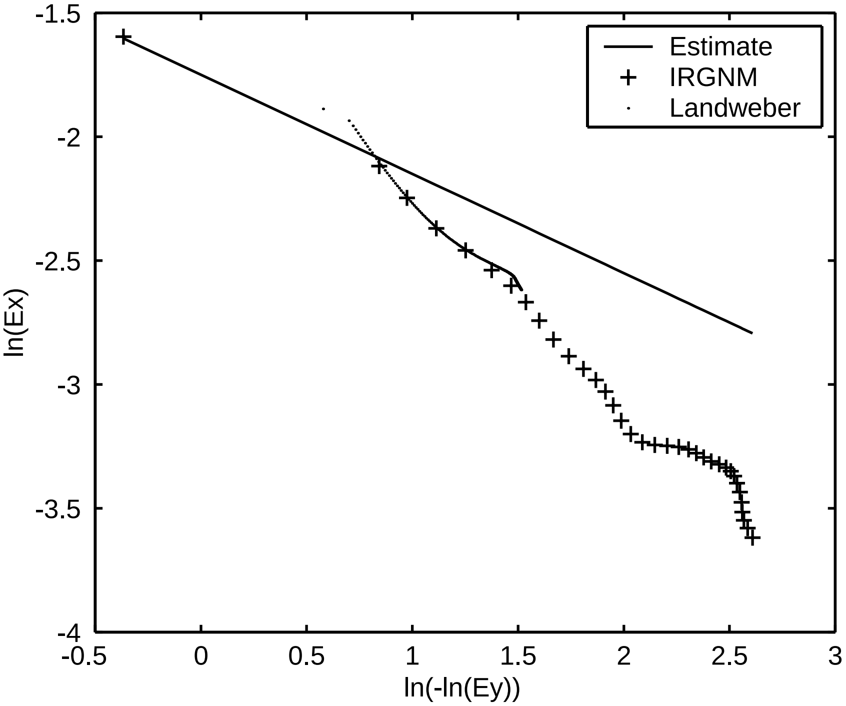

FIG. 5.1. *Plot of* $Ex := \|a_j^0 - a^\dagger\|_{L^2}$ *on a logarithmic scale over* $Ey := \|u^\infty_{1-a_j^0} - u^\infty_{1-a^\dagger}\|_{L^2}$ *on a double logarithmic scale.*

COROLLARY 5.1. *Assume that* $a^\dagger, a_0 \in H^s(B_1)$. *Let* a_j^δ *denote the iterates generated by an iterative regularization method for* F *which converges for the initial guess* a_0, *and assume that the stopping index* J *is chosen according to* (5.5). *Then for any* $\epsilon > 0$

$$\|a_j^0 - a^\dagger\|_{L^2(B_1)} = \mathrm{O}\left(-\ln\|u^\infty_{1-a_j^0} - u^\infty_{1-a^\dagger}\|\right)^{-\frac{s}{s+3}+\epsilon}, \qquad j \to \infty, \tag{5.10}$$

$$\|a^\delta_{J(\delta,u^{\infty,\delta})} - a^\dagger\|_{L^2(B_1)} = \mathrm{O}\left((-\ln\delta)^{-\frac{s}{s+3}+\epsilon}\right), \qquad \delta \to 0. \tag{5.11}$$

Proof. Due to (5.6) we know that there is a constant C_n such that $\|a_j^0\|_{H^s} \le C_n$ for all j. Hence Theorem 1.2 with $n = 1 - a^\dagger$ and $\tilde{n} = 1 - a_j^0$ yields (5.10). Analogously, (5.11) follows from (5.7), (5.5), and Theorem 1.2. □

In Figure 5.1 the actual values of $\|a_j^0 - a^\dagger\|_{L^2}$ and $\|u^\infty_{1-a_j^0} - u^\infty_{1-a^\dagger}\|_{L^2}$ for the IRGNM and the Landweber iteration are compared to the estimate (5.10). We used the Hilbert space $X = H_0^2(B_1)$, i.e., $s = 2$. To implement the IRGNM we solved the equation system involving $\alpha_j I + F'[a_j^\delta]^* F'[a_j^\delta]$ by the conjugate gradient method using a special preconditioner (cf. [12]; our test problem is taken from section 3 of this paper). We performed 500 Landweber iterations and 20 Newton iterations using exact synthetic data, which were created using a modified algorithm with a much finer discretization in order to avoid an inverse crime. The constant in (5.10) was chosen to fit the data. The picture shows that our estimate is of the right form. The exponent $-\frac{s}{s+3} = -\frac{2}{5}$ is fairly close to our experimental results, but it seems to be a little too pessimistic. In fact, using (3.9), we cannot get an exponent greater than 1 even for a single Fourier coefficient. As long as estimate (3.9) is used, we cannot expect to obtain a better stability result than

$$\|n-\tilde{n}\|_{L^2(B_1)} \leq C\left[-\ln^-\left(\|w_n^{\mathrm{s}}-w_{\tilde{n}}^{\mathrm{s}}\|_{L^2(\partial B_R\times\partial B_R)}\right)\right]^{-1}.$$

To our knowledge it is still open whether there is an example which shows that no better estimate is possible or whether new ideas could improve (3.9) and then the stability estimate.

INEQUALITIES OF DUFFIN–SCHAEFFER TYPE[*]

GENO NIKOLOV[†]

Abstract. We prove here that if an algebraic polynomial f of degree at most n has smaller absolute values than T_n (the nth Chebyshev polynomial of the first kind) at arbitrary $n+1$ points in $[-1,1]$, which interlace with the zeros of T_n, then the uniform norm of f' in $[-1,1]$ is smaller than n^2. This is an extension of a classical result obtained by Duffin and Schaeffer.

Key words. Chebyshev polynomial, Markov inequality, numerical differentiation

1. Introduction and statement of the result.

Denote by π_n the class of algebraic polynomials of degree at most n and by $\|\cdot\|$ the supremum norm in $[-1,1]$. The classical inequality of the brothers Markov [8], [9] asserts that, among all $f \in \pi_n$ satisfying

$$\|f\| \le 1, \tag{1}$$

the Chebyshev polynomial of the first kind $T_n(x) = \cos n \arccos x$ has the greatest norm of its kth derivative ($k = 1, \dots, n$). For more than one century the inequality of the Markov brothers has been a challenge for many mathematicians and an object of various generalizations (see, e.g., [3], [4, Chapter 4], [7, Chapter 2]). Inequalities of the Markov type, relating norms of a polynomial and its derivatives, have found numerous applications in both approximation theory and numerical analysis.

One of the most striking extensions of the classical Markov inequality was found by Duffin and Schaeffer [5], who showed that the extremal property of T_n persists under a weaker assumption than (1). Namely, Duffin and Schaeffer proved that T_n still has the largest uniform norm of its kth derivative in the wider class of polynomials from π_n, satisfying

$$|f(\cos(\nu\pi/n))| \le 1,\ \ \nu = 0, \dots, n. \tag{2}$$

(Actually, Duffin and Schaeffer proved a more general result, including an inequality on a strip in the complex plane, but it does not fall in the frame of the present paper.) Let us mention that (2) is a more natural restriction than (1) since to bound a norm of a polynomial of degree n it suffices to impose restrictions on its absolute value at $n+1$ points only.

The points

$$\eta_\nu := \cos(\nu\pi/n),\ \ \nu = 0, \dots, n,$$

are the local extremum points for T_n in $[-1,1]$ and $|T_n(\eta_\nu)| = 1$. Thus the result of Duffin and Schaeffer may be viewed as a comparison-type theorem: the inequality

$|f| \le |T_n|$ at the points of local extrema for T_n induces the inequalities $\|f^{(k)}\| \le \|T_n^{(k)}\|$ for $k = 1, \dots, n$. This suggests the following definition.

DEFINITION. *A polynomial $Q \in \pi_n$ and a mesh $\Delta = \{t_\nu\}_{\nu=0}^n$, $(1 \ge t_0 > t_1 > \cdots > t_n \ge -1)$ are said to admit the Duffin- and Schaeffer-type inequality (DS-inequality) if for every $f \in \pi_n$ the assumption $|f(t_\nu)| \le |Q(t_\nu)|$ for $\nu = 0, \dots, n$ implies $\|f'\| \le \|Q'\|$, or, more generally, $\|f^{(k)}\| \le \|Q^{(k)}\|$ for $k = 1, \dots, n$.*

Note that in our definition the comparison points $\{t_\nu\}_{\nu=0}^n$ are not necessarily assumed to be extremum points for Q.

In 1992, Shadrin [16] proposed a simple proof of the Markov inequality under the assumption (2). Based on a theorem of Shadrin, Bojanov and Nikolov [2] proved a DS-inequality for $Q = P_n^{(\lambda)}$, the ultraspherical polynomials, when the mesh Δ consists of the local extremum points of $P_n^{(\lambda)}$.

THEOREM A. *Let $Q := P_n^{(\lambda)}$ $(\lambda > -1/2)$ and $\{t_\nu\}_{\nu=0}^n$ be the zeros of $(1-x^2)Q'(x)$. If $f \in \pi_n$ satisfies*

$$|f(t_\nu)| \le |Q(t_\nu)| \quad \textit{for} \quad \nu = 0, \dots, n,$$

then

$$\|f^{(k)}\| \le \|Q^{(k)}\|$$

for all $k \in \{1, \dots, n\}$ if $\lambda \ge 0$, and for $k \ge 2$ if $\lambda \in (-1/2, 0)$. Equality is possible if and only if $f = cQ$ with $|c| = 1$.

The special case $\lambda = 0$ comes down to the classical inequality of Duffin and Schaeffer.

For some other DS-inequalities, we refer the reader to [6], [10], [11], [12], [13], [14]. In particular, the following result has been proved in [12].

THEOREM B. *If $f \in \pi_n$ satisfies $|f(\pm 1)| \le 1$ and*

$$|f(x)| \le \sqrt{1 - x^2} \quad \textit{at the zeros of } T_{n-1},$$

then

$$\|f^{(k)}\| \le \|T_n^{(k)}\| \quad \textit{for} \quad k = 1, \dots, n.$$

Moreover, equality is possible if and only $f = cT_n$ with $|c| = 1$.

Theorems A and B show that for $Q = T_n$ the DS-inequality holds at least for two choices of “check points,” namely, for those formed by the zeros of $(1 - x^2)T_n'(x)$ and by the zeros of $(1 - x^2)T_{n-1}(x)$. We naturally come to the question, What are the meshes Δ admitting the DS-inequality with $Q = T_n$? The aim of this paper is to show that for $k = 1$ each mesh $\Delta = \{t_\nu\}_{\nu=0}^n$ whose points interlace with the zeros of T_n is admissible.

THEOREM 1. *Let $\{t_\nu\}_{\nu=0}^n$ satisfy $1 \ge t_0 > \xi_1 > t_1 > \cdots > \xi_n > t_n \ge -1$, where $\{\xi_\nu\}_{\nu=1}^n$ are the zeros of T_n, i.e., $\xi_\nu = \cos((2\nu - 1)\pi/(2n))$. If $f \in \pi_n$ and*

$$|f(t_\nu)| \le |T_n(t_\nu)| \quad \textit{for} \quad \nu = 0, \dots, n,$$

then

$$\|f'\| \le n^2. \tag{3}$$

Moreover, equality in (3) is possible if and only if $f = cT_n$ with $|c| = 1$.

Note that the set of all admissible meshes Δ (i.e., such that DS-inequality holds with $Q = T_n$) cannot be substantially larger than the one described in Theorem 1. In fact, the points of any admissible mesh must separate the zeros of T_n (see section 4).

The proof of Theorem 1 relies on a pointwise inequality given by the next theorem, which was suggested to the author by Shadrin [18].

Theorem 2. *Let $Q \in \pi_n$ have n distinct zeros $\{x_\nu\}_{\nu=1}^n$, all located in $(-1, 1)$. Let $\{t_j\}_{j=0}^n$ satisfy $1 \geq t_0 > x_1 > t_1 > \cdots > x_n > t_n \geq -1$. If $f \in \pi_n$ and*

$$|f(t_j)| \leq |Q(t_j)| \quad \textit{for } j = 0, \ldots, n,$$

then for each $k \in \{1, \ldots, n\}$ and for every $x \in [-1, 1]$ there holds

$$|f^{(k)}(x)| \leq \max\{|Q^{(k)}(x)|, |Q_\nu^{(k)}(x)|,\ \nu = 1, \ldots, n\},$$

where

$$Q_\nu(x) = Q(x)\frac{1 - x_\nu x}{x - x_\nu}.$$

The paper is organized as follows. In section 2, we summarize some results from V. Markov's paper and prove Theorem 2. The proof of Theorem 1 is given in section 3. Section 4 contains some concluding remarks and points out a possible application of Theorem 1 to the estimation of the round-off error in the Lagrange differentiation formula.

2. Proof of Theorem 2.

We start with an observation from the original work of Markov [9] concerning polynomial interpolation and pointwise estimates for polynomial derivatives. We formulate it in two lemmas.

Definition. *Let $p \in \pi_n$ or $p \in \pi_{n+1}$, $q \in \pi_n$, and p, q have only real and simple zeros, say, $\{t_j\}_{j=1}^{n(+1)}$ and $\{\tau_j\}_{j=1}^n$. The zeros of p and q are said to interlace if*

$$t_1 \leq \tau_1 \leq t_2 \leq \cdots \leq t_{n-1} \leq \tau_n (\leq t_{n+1}).$$

If only strict inequalities appear above, then the zeros of p and q are said to interlace strictly.

The first of Markov's lemmas reveals a simple (and, as a matter of fact, very useful) property of the zeros of algebraic polynomials.

Lemma 3. *Let p and q be algebraic polynomials ($p \not\equiv q$), which have only real and simple zeros. If the zeros of p and q interlace, then the zeros of p' and q' interlace strictly.*

A proof of Lemma 3 can be found in [15, Lemma 2.7.1] or in [16]. Note that for polynomials of the same degree the claim of Lemma 3 can be viewed as a monotone dependence of the zeros of the derivative with respect to the zeros of the polynomial [1, p. 39].

Given a mesh $\Delta = \{t_j\}_{j=0}^n$ $(1 \geq t_0 > t_1 > \cdots > t_n \geq -1)$ and $\epsilon := \{\epsilon_j\}_{j=0}^n$ $(\epsilon_j > 0,\ j = 0, \ldots, n)$, we define the set of polynomials

$$\Omega_n(\Delta, \epsilon) := \{f \in \pi_n : |f(t_j)| \leq \epsilon_j,\ j = 0, \ldots, n\}.$$

Clearly, $\Omega_n(\Delta, \epsilon)$ is a compact set.

Define real valued polynomials $\{P_\nu\}_{\nu=0}^n = \{P_\nu(\Delta, \epsilon; \cdot)\}_{\nu=0}^n \in \Omega_n(\Delta, \epsilon)$ by

$$|P_\nu(t_j)| = \epsilon_j \quad \text{for } j, \nu = 0, \ldots, n,$$
$$P_0(t_{j-1})P_0(t_j) < 0 \quad \text{for } j = 1, \ldots, n,$$

and, for each $\nu = 1, \dots, n$,

$$P_\nu(t_{\nu-1})P_\nu(t_\nu) > 0, \quad P_\nu(t_{j-1})P_\nu(t_j) < 0 \text{ for } j \neq \nu.$$

Evidently, the above conditions determine $\{P_\nu\}_{\nu=0}^n$ uniquely up to a multiplier -1. Theorem 2 follows easily from the next lemma.

LEMMA 4. *For each $x \in [-1,1]$ and for every $k \in \{1,\dots,n\}$,*

$$\sup\{|f^{(k)}(x)| : f \in \Omega_n(\Delta,\epsilon)\} = \max\{|P_\nu^{(k)}(x)|, \nu = 0,\dots,n\}.$$

Proof. Note first that the sup is attainable since $\Omega_n(\Delta,\epsilon)$ is compact. Set $\omega(t) := (t-t_0)\cdots(t-t_n)$, $\omega_\nu(t) := \omega(t)/(t-t_\nu)$ $(\nu = 0,\dots,n)$; then for $f \in \Omega_n(\Delta,\epsilon)$ and a fixed $x \in [-1,1]$ the Lagrange interpolation formula yields

$$|f^{(k)}(x)| = \left|\sum_{j=0}^n \frac{\omega_j^{(k)}(x)}{\omega_j(t_j)} f(t_j)\right| \leq \sum_{j=0}^n \left|\frac{\omega_j^{(k)}(x)}{\omega_j(t_j)}\right| \epsilon_j. \tag{4}$$

The upper bound is attained if $|f(t_j)| = \epsilon_j$ for $j = 0,\dots,n$ and f has a suitable sign pattern at the points $\{t_j\}$. Next we show that the polynomials $\{P_\nu\}_{\nu=0}^n$ provide a complete set of appropriate sign patterns. For any pair of indices $i,j \in \{0,\dots,n\}$, $i<j$, the zeros of ω_i and ω_j interlace (though not strictly); therefore, in view of Lemma 3, the zeros $\{\gamma_{i,\mu}\}_{\mu=1}^{n-k}$ of $\omega_i^{(k)}$ and the zeros $\{\gamma_{j,\mu}\}_{\mu=1}^{n-k}$ of $\omega_j^{(k)}$ interlace strictly. Furthermore, since the zeros of ω_i are less than or equal to the corresponding zeros of ω_j, we have the following arrangement:

$$\gamma_{0,n-k} < \cdots < \gamma_{n,n-k} < \gamma_{0,n-k-1} < \cdots < \gamma_{n,n-k-1} < \cdots < \gamma_{0,1} < \cdots < \gamma_{n,1}.$$

Since $\omega_{j-1}(t_{j-1})\omega_j(t_j) < 0$ for $j = 1,\dots,n$, the above inequalities show that for $x \in [-1,1] \setminus \{\gamma_{\nu,j}\}_{\nu=0,j=1}^{n\;\;n-k}$, the quantities $\{\omega_j^{(k)}(x)/\omega_j(t_j)\}_{j=0}^n$ either change their signs alternatively if

$$x \in I_{n,k}^0, \quad I_{n,k}^0 = I_{n,k}^0(\Delta) := [-1,\gamma_{0,n-k}) \bigcup_{j=n-k}^{1} (\gamma_{n,j},\gamma_{0,j-1}) \bigcup (\gamma_{n,1},1]$$

or change signs alternatively with only one exception: $\frac{\omega_{\nu-1}^{(k)}(x)}{\omega_{\nu-1}(t_{\nu-1})}\frac{\omega_\nu^{(k)}(x)}{\omega_\nu(t_\nu)} > 0$ for some $\nu \in \{1,\dots,n\}$. The latter situation occurs when $x \in I_{n,k}^\nu$, where

$$I_{n,k}^\nu = I_{n,k}^\nu(\Delta) := \bigcup_{j=1}^{n-k} (\gamma_{\nu-1,j},\gamma_{\nu,j}).$$

Correspondingly, if $x \in I_{n,k}^\nu$ for some $\nu \in \{0,\dots,n\}$, then (4) holds with equality sign for $f = P_\nu$. If $x = \gamma_{\nu,j}$, then $\omega_\nu^{(k)}(x) = 0$, and equality in (4) holds for $f = P_\nu$ as well as for any $f \in \pi_n$ which coincides with P_ν at the points $\{t_j : j \neq \nu\}$.

Thus, in (4), equality holds for $f = P_\nu$ if $x \in \overline{I}_{n,k}^\nu$ $(\nu = 0,\dots,n)$, and since $\cup_{\nu=0}^n \overline{I}_{n,k}^\nu = [-1,1]$, the proof of Lemma 4 is complete. □

Remark. It follows from the proof of Lemma 4 that if for some $f \in \Omega_n(\Delta,\epsilon)$ we have equality in (4) for some $x \in I_{n,k}^\nu$ $(\nu \in \{0,\dots,n\})$, then necessarily $f = cP_\nu$, where c is a constant with $|c| = 1$. Thus, for $x \in [-1,1] \setminus \{\gamma_{\nu,j}\}_{\nu=0,j=1}^{n\;\;n-k}$, any extremal polynomial in Lemma 4 is of the form $f = cP_\nu$, where $\nu \in \{0,\dots,n\}$ and $|c| = 1$.

Proof of Theorem 2. Set $\epsilon_j := |Q(t_j)|$, $j = 0, \dots, n$, and define polynomials $\{P_\nu\}_{\nu=0}^n$ as above. Based on the interlacing assumption, we conclude that $P_0 = Q$ or $P_0 = -Q$, while for $\nu = 1, \dots, n$ the sign patterns of P_ν and Q_ν coincide. Moreover, we have

$$|Q_\nu(t_j)| = \epsilon_j \frac{1 - x_\nu t_j}{|t_j - x_\nu|} \geq \epsilon_j \text{ for } j = 0, \dots, n \quad \text{and} \quad \nu = 1, \dots, n.$$

In the proof of Lemma 4, we deduced that for any $f \in \Omega_n(\Delta, \epsilon)$

$$|f^{(k)}(x)| \leq |P_\nu^{(k)}(x)| \text{ if } x \in \overline{I}_{n,k}^{\nu}, \quad \nu = 0, \dots, n. \tag{5}$$

For $\nu = 0$ (5) reads as $|f^{(k)}(x)| \leq |Q^{(k)}(x)|$, while for $x \in \overline{I}_{n,k}^{\nu}$ ($\nu \in \{1, \dots, n\}$) we have

$$|P_\nu^{(k)}(x)| = \sum_{j=0}^{n} \left| \frac{\omega_j^{(k)}(x)}{\omega_j(t_j)} \right| \epsilon_j \leq \sum_{j=0}^{n} \left| \frac{\omega_j^{(k)}(x)}{\omega_j(t_j)} \right| |Q_\nu(t_j)| = |Q_\nu^{(k)}(x)|.$$

(For the last equality we used that P_ν and Q_ν have the same sign pattern.) The claim of Theorem 2 now follows from Lemma 4. □

As an immediate consequence of Theorem 2 we get the following corollary.

Corollary 5. *If, in addition to the assumptions of Theorem* 2, *for a* $k \in \{1, \dots, n\}$

$$\max_{1 \leq \nu \leq n} \|Q_\nu^{(k)}\| \leq \|Q^{(k)}\|,$$

then

$$\|f^{(k)}\| \leq \|Q^{(k)}\|.$$

3. Proof of Theorem 1.

The proof of Theorem 1 follows from Corollary 5, applied to $Q = T_n$ with $k = 1$. The application of Corollary 5 is possible because of the following lemma.

Lemma 6. *Let the polynomials* $\{P_\nu\}_{\nu=1}^n$ *be defined by*

$$P_\nu(x) := T_n(x) \frac{1 - \xi_\nu x}{x - \xi_\nu}.$$

Then, for $n \geq 2$,

$$\|P_\nu'\| < n^2 \quad (\nu = 1, \dots, n). \tag{6}$$

For $n = 2, 3$ the validity of (6) is verified directly; therefore, we assume in what follows that $n \geq 4$. The proof of Lemma 6 goes through a number of lemmas.

Lemma 7. *For every* $x \in [-1, 1]$ *and for* $\nu = 1, \dots, n$

$$|P_\nu'(x)| \leq R_\nu(x),$$

where

$$R_\nu(x) = \left[\frac{(1 - \xi_\nu^2)^2}{(x - \xi_\nu)^4} + \frac{n^2 (1 - \xi_\nu x)^2}{(1 - x^2)(x - \xi_\nu)^2} \right]^{1/2}.$$

Proof. The result is immediate from

$$P_\nu'(x) = T_n'(x)\frac{1-\xi_\nu x}{x-\xi_\nu} - T_n(x)\frac{1-\xi_\nu^2}{(x-\xi_\nu)^2}, \tag{7}$$

the identity $[T_n(x)]^2 + (1-x^2)[T_n'(x)]^2/n^2 = 1$, and Cauchy's inequality. □

LEMMA 8. *$R_\nu(x)$ is a strictly convex function on each of the intervals $(-1,\xi_\nu)$ and $(\xi_\nu,1)$.*

Proof. We suppress the index ν, writing

$$R(x) = \left[\frac{(1-\xi^2)^2}{(x-\xi)^4} + \frac{n^2(1-\xi x)^2}{(1-x^2)(x-\xi)^2}\right]^{1/2} =: (g_1^2(x) + g_2^2(x))^{1/2},$$

where

$$g_1(x) := \frac{1-\xi^2}{(x-\xi)^2},\ g_2(x) := \frac{n(1-\xi x)}{(1-x^2)^{1/2}(x-\xi)}.$$

Since

$$R'' = \frac{(g_1g_2' - g_1'g_2)^2 + R^2(g_1g_1'' + g_2g_2'')}{R^3},$$

the lemma will be proved if we show that $g_1(x)g_1''(x)$ and $g_2(x)g_2''(x)$ are positive in $(-1,\xi)$ and in $(\xi,1)$. This is easily seen for the first term, while for the second term a short calculation yields

$$\begin{aligned}&\frac{(x-\xi)^4(1-x^2)^3}{n^2}g_2(x)g_2''(x)\\ &\quad = 2(1-\xi^2)(1-x^2)^2 - 2x(x-\xi)(1-\xi^2)(1-x^2) + (1-\xi x)(x-\xi)^2(2x^2+1).\end{aligned}$$

The positivity of the right-hand side is easily verified with the help of the inequality

$$\begin{aligned}&2(1-\xi^2)(1-x^2)^2 + (1-\xi x)(x-\xi)^2(2x^2+1)\\ &\quad \ge 2(1-x^2)|x-\xi|[2(1-\xi^2)(1-\xi x)(2x^2+1)]^{1/2}.\end{aligned}$$ □

We now examine the polynomials $\{P_\nu\}_{\nu=1}^n$. Due to symmetry, we may (and shall) consider only half of them, say, those with indices $1 \le \nu \le [(n+1)/2]$. Recall that the zeros of P_ν coincide with the zeros $\{\xi_j\}_{j=1}^n$ of T_n with the exception of ξ_ν which is replaced by $1/\xi_\nu$. (In the case where n is odd and $\nu = (n+1)/2$, $1/\xi_\nu$ is interpreted as a zero at ∞.) With this last convention, we observe that for $1 \le \nu \le [(n+1)/2]$ the zeros of P_ν are located to the right with respect to the zeros $\{\xi_i\}$ of T_n and interlace with them. In view of Lemma 3, the same relation holds between the zeros of the derivatives of P_ν and T_n. We are interested in the behavior of $P_\nu'(x)$ and, in particular, its critical points. To this end, we shall exploit (7) and the explicit form of P_ν'',

$$P_\nu''(x) = T_n''(x)\frac{1-\xi_\nu x}{x-\xi_\nu} - 2T_n'(x)\frac{1-\xi_\nu^2}{(x-\xi_\nu)^2} + 2T_n(x)\frac{1-\xi_\nu^2}{(x-\xi_\nu)^3}. \tag{8}$$

In the proof of the next lemmas we shall use the differential equation

$$(1-x^2)T_n''(x) - xT_n'(x) + n^2T_n(x) = 0 \tag{9}$$

as well as the following simple facts:

$$\{n\sin(\alpha/n)\}_{n=1}^{\infty}\nearrow\alpha, \tag{10}$$

$$\cot\alpha\le\frac{1}{\alpha}, \tag{11}$$

where $0<\alpha\le\pi/2$.

Lemma 9. *The polynomials* P_ν' $(\nu=1,\dots,[(n+1)/2])$ *satisfy the following:*

(i) *if* $2\le\nu<\frac{n+1}{2}$, *then* P_ν' *has exactly one local extremum to the right of* 1;

(ii) P_ν' *has exactly one local extremum in* $(\xi_{\nu+1},\eta_\nu)$;

(iii) P_ν' *is strictly monotone in* $[\eta_\nu,\eta_{\nu-1}]$;

(iv) P_ν' *is strictly monotone in* $[-1,\eta_{n-1}]$ *and in* $[\eta_1,1]$.

Proof. The first claim in (iv) follows trivially since, as was already mentioned, the zeros of P_ν are located to the right with respect to $\{\xi_j\}_{j=1}^n$. In view of Lemma 3, the same is true for the zeros of P_ν'' and T_n''. Since the leftmost zero of T_n'' is located to the right of η_{n-1}, so is the smallest zero of P_ν''.

Substituting $x=1$ in (8), we get

$$P_\nu''(1)=\frac{n^2(n^2-1)}{3}-2n^2\cot^2\frac{(2\nu-1)\pi}{4n}+\frac{\cot^2\frac{(2\nu-1)\pi}{4n}}{\sin^2\frac{(2\nu-1)\pi}{4n}}.$$

With the help of (10) and (for $\nu=2$) (11), it is easy to see that $P_\nu''(1)>0$ for $2\le\nu\le[(n+1)/2]$. Since P_ν' has a negative leading coefficient and at most one critical point to the right of $x=1$, this proves part (i) of the lemma.

Now we find the sign of P_ν'' at the points $\xi_{\nu+1}$, η_ν, and $\eta_{\nu-1}$. First, we shall show that

$$\operatorname{sign}\{P_\nu''(\xi_{\nu+1})\}=(-1)^{\nu+1}. \tag{12}$$

Putting $x=\xi_{\nu+1}$ in (8) and using that $T_n''(\xi_{\nu+1})=\xi_{\nu+1}T_n'(\xi_{\nu+1})/(1-\xi_{\nu+1}^2)$ and $\operatorname{sign}\{T_n'(\xi_{\nu+1})\}=(-1)^\nu$, we get

$$\operatorname{sign}\{P_\nu''(\xi_{\nu+1})\}=(-1)^{\nu+1}\operatorname{sign}\{2(1-\xi_\nu^2)(1-\xi_{\nu+1}^2)+\xi_{\nu+1}(\xi_\nu-\xi_{\nu+1})(1-\xi_\nu\xi_{\nu+1})\}.$$

Now (12) is obvious if $\xi_{\nu+1}\ge0$. The only possibility where $\xi_{\nu+1}<0$ is $\nu=m$ and $n=2m$ or $n=2m-1$. An easy calculation shows that for $n\ge4$ (12) is true in this case, too.

Next we prove both (ii) and (iii) by showing that

$$\operatorname{sign}\{P_\nu''(\eta_\mu)\}=(-1)^\nu\quad\text{for } \mu=\nu,\ \nu-1,\ \mu\ne0. \tag{13}$$

Using (8) and (9), we obtain

$$P_\nu''(\eta_\mu)=\frac{T_n(\eta_\mu)}{(\xi_\nu-\eta_\mu)^3(1-\eta_\mu^2)}[n^2(1-\xi_\nu\eta_\mu)(\xi_\nu-\eta_\mu)^2-2(1-\xi_\nu^2)(1-\eta_\mu^2)]. \tag{14}$$

Since $\operatorname{sign}\{T_n(\eta_\mu)\}=(-1)^\mu$, it suffices to prove that the term in the square brackets is positive. Using the inequality $(1-\xi_\nu^2)(1-\eta_\mu^2)<(1-\xi_\nu\eta_\mu)^2$, we obtain

$$n^2(1-\xi_\nu\eta_\mu)(\xi_\nu-\eta_\mu)^2-2(1-\xi_\nu^2)(1-\eta_\mu^2)>(1-\xi_\nu\eta_\mu)[n^2(\xi_\nu-\eta_\mu)^2-2(1-\xi_\nu\eta_\mu)].$$

After simple manipulations, using the trigonometric representation of ξ_ν and η_μ, we find that the inequality $n^2(\xi_\nu - \eta_\mu)^2 - 2(1 - \xi_\nu\eta_\mu) \geq 0$ is equivalent to

$$\frac{1}{n^2 \sin^2 \frac{\pi}{4n}} + \frac{1}{n^2 \sin^2 \frac{(2\nu+2\mu-1)\pi}{4n}} \leq 2.$$

This last inequality will hold for all $\nu \in \{1, \ldots, [(n+1)/2]\}$ and $\mu = \nu$, $\nu - 1$, $(\mu \neq 0)$ if it is true for $\nu = \mu = 1$, i.e., if

$$\frac{1}{n^2 \sin^2 \frac{\pi}{4n}} + \frac{1}{n^2 \sin^2 \frac{3\pi}{4n}} \leq 2.$$

Since the left-hand side is a decreasing function of n (see (10)), and for $n = 3$ it is $(\sin^{-2}(\pi/12) + 2)/9 = (4\sqrt{3} + 10)/9 < 2$, (13) is proved. Now we conclude from (12) and (13) (with $\mu = \nu$) that P''_ν has a zero in $(\xi_{\nu+1}, \eta_\nu)$ for $\nu = 1, \ldots, [(n+1)/2]$. In addition, (13) implies that this zero is unique, and no zeros of P''_ν exist in $[\eta_\nu, \eta_{\nu-1}]$ $(\nu \geq 2)$; otherwise, there would be at least three zeros in $(\xi_{\nu+1}, \xi_{\nu-1})$, which is a contradiction. For the same reason, P''_1 has a simple zero in (ξ_2, η_1), and no zeros of P''_1 exist in $[\eta_1, 1]$. This is exactly the claim of (iii) for $\nu = 1$ and of the second part of (iv) for $\nu = 1$.

To prove the second part of (iv) for $2 \leq \nu < (n+1)/2$, we shall show that

$$P''_\nu(\eta_1) > 0. \tag{15}$$

Having established (15), the second part of (iv) will follow immediately. Indeed, we found in the beginning of this proof that $P''_\nu(1) > 0$ for $2 \leq \nu < (n+1)/2$, and if P'_ν was not monotone in $[\eta_1, 1]$, then P''_ν would have at least three zeros (two zeros if $\nu = (n+1)/2$)) to the right of η_1, which is impossible. The proof of (15) goes along the lines of the proof of (13). Equation (14) with $\mu = 1$ shows that (15) follows if

$$n^2(1 - \xi_\nu\eta_1)(\xi_\nu - \eta_1)^2 - 2(1 - \xi_\nu^2)(1 - \eta_1^2) > 0$$

or, in view of $(1 - \xi_\nu^2)(1 - \eta_1^2) \leq (1 - \xi_\nu\eta_1)^2$, if

$$n^2(\xi_\nu - \eta_1)^2 - 2(1 - \xi_\nu\eta_1) > 0.$$

The latter inequality is equivalent to the inequality

$$\frac{1}{n^2 \sin^2 \frac{(2\nu-3)\pi}{4n}} + \frac{1}{n^2 \sin^2 \frac{(2\nu+1)\pi}{4n}} \leq 2,$$

whose validity is easily verified with the help of (10). Lemma 9 is proved. □

LEMMA 10. *The following estimates for* $\|P'_\nu\|$ *hold true:*

(i) *for* $\nu = 1, 2$,

$$\|P'_\nu\| \leq \max\{|P'_\nu(-1)|, |P'_\nu(1)|, R_\nu(\eta_{n-1}), R_\nu(\eta_\nu)\};$$

(ii) *for* $\nu = 3, \ldots, [(n+1)/2]$,

$$\|P'_\nu\| \leq \max\{|P'_\nu(-1)|, |P'_\nu(1)|, R_\nu(\eta_{n-1}), R_\nu(\eta_\nu), R_\nu(\eta_{\nu-1}), R_\nu(\eta_1)\}.$$

Proof. According to Lemma 9, P'_1 is monotone in $[-1, \eta_{n-1}]$ and $[\eta_1, 1]$; therefore, on these intervals,

$$|P'_1(x)| \leq \max\{|P'_1(-1)|, |P'_1(\eta_{n-1})|, |P'_1(\eta_1)|, |P'_1(1)|\}.$$

On the complementary interval $[\eta_{n-1},\eta_1]$, we have $|P_1'(x)|\le R_1(x)$ (Lemma 7), and since R_1 is convex there (Lemma 8), it follows that $R_1(x)\le\max\{R_1(\eta_{n-1}),R_1(\eta_1)\}$ for $x\in[\eta_{n-1},\eta_1]$. This proves (i) for $\nu=1$.

The proof of (i) for $\nu=2$ relies on the observation that, by Lemma 9, P_2' is monotone in $[-1,\eta_{n-1}]$ and in $[\eta_2,1]$, while $|P_2'(x)|\le\max\{R_2(\eta_{n-1}),R_2(\eta_2)\}$ in $[\eta_{n-1},\eta_2]$, by virtue of Lemmas 7 and 8.

Part (ii) can be proved in the same fashion, exploiting the monotonicity of P_ν' on the intervals $[-1,\eta_{n-1}]$, $[\eta_\nu,\eta_{\nu-1}]$, and $[\eta_1,1]$ and the convexity of R_ν on $[\eta_{n-1},\eta_\nu]$ and $[\eta_{\nu-1},\eta_1]$. We leave the details to the reader. □

Our last lemma estimates the quantities appearing in Lemma 10.

Lemma 11. *The following inequalities hold true:*

(i) $|P_\nu'(\pm1)|<n^2$ $(\nu=1,\dots,[(n+1)/2])$;

(ii) $R_\nu(\eta_1)<n^2$ $(\nu=1,3,4,\dots,[(n+1)/2])$;

(iii) $R_\nu(\eta_\nu)<n^2$ $(\nu=1,\dots,[(n+1)/2])$;

(iv) $R_\nu(\eta_{\nu-1})<n^2$ $(\nu=3,\dots,[(n+1)/2])$;

(v) $R_\nu(\eta_{n-1})<n^2$ $(\nu=1,\dots,[(n+1)/2])$.

Proof. Substituting $x=\pm1$ in (7), we get

$$P_\nu'(1)=n^2-\cot^2\frac{(2\nu-1)\pi}{4n},\quad |P_\nu'(-1)|=n^2-\tan^2\frac{(2\nu-1)\pi}{4n}.$$

Then (10) and $0<(2\nu-1)\pi/(2n)\le\pi/4$ show the validity of slightly sharper inequalities than (i), namely,

$$n^2-1\le|P_\nu'(-1)|<n^2-\frac{\pi}{4n}$$

and

$$(1-16/\pi^2)n^2<P_\nu'(1)<n^2-1.$$

Now we prove (ii). A short calculation yields

$$R_\nu(\eta_1)=\left[\frac{(1-\xi_\nu^2)^2}{(\eta_1-\xi_\nu)^4}+\frac{n^2(1-\xi_\nu\eta_1)^2}{(1-\eta_1^2)(\eta_1-\xi_\nu)^2}\right]^{1/2}=:\{[A(\nu)]^2+[B(\nu)]^4\}^{1/2},$$

where

$$A(\nu)=\frac{n}{2}\left|2\cot\frac{\pi}{n}+\cot\frac{(2\nu-3)\pi}{4n}-\cot\frac{(2\nu+1)\pi}{4n}\right|,$$
$$B(\nu)=\frac{1}{2}\left|\cot\frac{(2\nu-3)\pi}{4n}+\cot\frac{(2\nu+1)\pi}{4n}\right|.$$

Assume first that $3\le\nu\le[(n+1)/2]$; then it is easy to see that $A(\nu)\le A(3)$ and $B(\nu)\le B(3)$. We use (11) to obtain

$$\begin{aligned}B(3)&=\frac12\left[\cot\frac{3\pi}{4n}+\cot\frac{7\pi}{4n}\right]<\frac{20n}{21\pi},\\ A(3)&=\frac{n}{2}\left[\cot\frac{3\pi}{4n}+2\cot\frac{\pi}{n}-\cot\frac{7\pi}{4n}\right]\\ &<\frac{n}{2}\left[\cot\frac{3\pi}{4n}+2\cot\frac{\pi}{n}\right]\\ &<\frac{5n^2}{3\pi}.\end{aligned}$$

Therefore, for $3 \leq \nu \leq [(n+1)/2]$,

$$R_\nu(\eta_1) < \left[\left(\frac{5n^2}{3\pi}\right)^2 + \left(\frac{20n}{21\pi}\right)^4\right]^{1/2} < 0.54n^2 < n^2.$$

Similarly, for $\nu = 1$, we find

$$\begin{aligned} A(1) &= \frac{n}{2}\left[\cot\frac{\pi}{4n} - 2\cot\frac{\pi}{n} + \cot\frac{3\pi}{4n}\right] < \frac{n}{2}\left[\cot\frac{\pi}{4n} + \cot\frac{3\pi}{4n}\right] < \frac{8n^2}{3\pi}, \\ B(1) &= \frac{1}{2}\left[\cot\frac{\pi}{4n} - \cot\frac{3\pi}{4n}\right] < \frac{1}{2}\cot\frac{\pi}{4n} < \frac{2n}{\pi}. \end{aligned}$$

Hence

$$R_1(\eta_1) < \left[\left(\frac{8n^2}{3\pi}\right)^2 + \left(\frac{2n}{\pi}\right)^4\right]^{1/2} < 0.95n^2 < n^2.$$

Thus (ii) is proved.

Next we prove (iii). For $1 \leq \nu \leq [(n+1)/2]$, we have

$$R_\nu(\eta_\nu) = \left[\frac{(1-\xi_\nu^2)^2}{(\xi_\nu - \eta_\nu)^4} + \frac{n^2(1-\xi_\nu\eta_\nu)^2}{(1-\eta_\nu^2)(\xi_\nu - \eta_\nu)^2}\right]^{1/2} =: \{[C(\nu)]^2 + [D(\nu)]^4\}^{1/2},$$

where

$$\begin{aligned} C(\nu) &= \frac{n}{2}\left[\cot\frac{\pi}{4n} + \cot\frac{(4\nu-1)\pi}{4n} - 2\cot\frac{\nu\pi}{n}\right], \\ D(\nu) &:= \frac{1}{2}\left[\cot\frac{\pi}{4n} - \cot\frac{(4\nu-1)\pi}{4n}\right]. \end{aligned}$$

Unlike the situation with $A(\nu)$ and $B(\nu)$, we observe that $C(\nu)$ and $D(\nu)$ increase with ν, and for $n \geq 3$

$$\begin{aligned} D(\nu) \leq D((n+1)/2) &= \frac{n}{n\sin\frac{\pi}{2n}} \leq \frac{2n}{3}, \\ C(\nu) \leq C((n+1)/2) &= \frac{n}{2}\left[\cot\frac{\pi}{4n} + 2\tan\frac{\pi}{2n} - \tan\frac{\pi}{4n}\right] \\ &= \frac{n}{\sin\frac{\pi}{2n}} + n\left[\tan\frac{\pi}{2n} - \tan\frac{\pi}{4n}\right] \\ &< \frac{n^2}{n\sin\frac{\pi}{2n}} + \frac{\pi}{4}\frac{1}{\cos^2\frac{\pi}{2n}} \\ &\leq \frac{1}{3}(2n^2 + \pi). \end{aligned}$$

With this (iii) is proved since

$$R_\nu(\eta_\nu) < n^2\left[\left(\frac{2}{3} + \frac{\pi}{3n^2}\right)^2 + \left(\frac{2}{3}\right)^4\right]^{1/2} < 0.91n^2 < n^2.$$

The same arguments as above lead to the proof of (iv): $R_\nu(\eta_{\nu-1}) = [(\tilde{C}(\nu))^2 + (\tilde{D}(\nu))^4]^{1/2}$, where

$$\begin{aligned}\tilde{C}(\nu) &= \frac{n}{2}\left[\cot\frac{\pi}{4n} + 2\cot\frac{(\nu-1)\pi}{n} - \cot\frac{(4\nu-3)\pi}{4n}\right],\\ \tilde{D}(\nu) &= \frac{1}{2}\left[\cot\frac{\pi}{4n} + \cot\frac{(4\nu-3)\pi}{4n}\right].\end{aligned}$$

Observing that $\tilde{C}(\nu)$ and $\tilde{D}(\nu)$ decrease with ν, for $3 \le \nu \le [(n+1)/2]$ we find the estimates

$$\begin{aligned}\tilde{D}(\nu) \le \tilde{D}(3) &= \frac{1}{2}\left[\cot\frac{\pi}{4n} + \cot\frac{9\pi}{4n}\right] < \frac{20n}{9\pi},\\ \tilde{C}(\nu) \le \tilde{C}(3) &= \frac{n}{2}\left[\cot\frac{\pi}{4n} + 2\cot\frac{2\pi}{n} - \cot\frac{9\pi}{4n}\right]\\ &< \frac{n}{2}\left[\cot\frac{\pi}{4n} + \cot\frac{7\pi}{4n}\right]\\ &< \frac{16n^2}{7\pi},\end{aligned}$$

and hence

$$R_\nu(\eta_{\nu-1}) < \left[\left(\frac{16n^2}{7\pi}\right)^2 + \left(\frac{20n}{9\pi}\right)^4\right]^{1/2} < 0.89n^2 < n^2.$$

Finally, (v) can be proved in the same way as (i)–(iv). Alternatively, one can use the inequality

$$\frac{1-\xi\eta}{|\xi-\eta|} \ge \frac{1+\xi\eta}{\xi+\eta} \quad (0 \le \xi, \eta < 1,\ \xi \ne \eta)$$

to compare pairwise $A(\nu)$ and $B(\nu)$ with the corresponding terms in $R_\nu(\eta_{n-1}) = R_\nu(-\eta_1)$. The result is $R_\nu(\eta_{n-1}) \le R_\nu(\eta_1) < n^2$. We omit the details. □

Proof of Lemma 6. The inequality follows from Lemmas 10 and 11. □

Proof of Theorem 1. Inequality (3) follows immediately from Corollary 5 and Lemma 6. It remains to clarify in which cases an equality is possible. Let $\Delta = \{t_j\}_{j=0}^n$ be a fixed mesh satisfying the assumptions of Theorem 1. Let $\epsilon = (\epsilon_0, \dots, \epsilon_n) =: (|T_n(t_0)|, \dots, |T_n(t_n)|)$, and let the polynomials $P_0 = T_n,\ P_\nu\ (\nu = 1, \dots, n)$ be defined as in section 2. Suppose that $f \in \Omega(\Delta, \epsilon)$ is an extremal polynomial, i.e., $\|f'\| = n^2$. According to Lemma 6 and the remark following the proof of Lemma 4, for $x \in \cup_{\nu=1}^n \overline{I}_{n,1}^\nu$ there holds

$$|f'(x)| \le \max_{1\le\nu\le n} \|P'_\nu\| < n^2;$$

therefore, $\|f'\|$ is attained for $x \in I_{n,1}^0$. However, when $x \in I_{n,1}^0$ we have

$$|f'(x)| \le |P'_0(x)| = |T'_n(x)| \le T'_n(1) = n^2,$$

and equality holds only for $x = \pm 1$ and $f = cT_n$ with $|c| = 1$. Theorem 1 is proved. □

4. Concluding remarks.

1. The requirement in Theorem 1 that the points $\Delta = \{t_j\}_{j=0}^n$ interlace strictly with the zeros of T_n was imposed only in order to avoid unimportant complications in the proof. Actually, Theorem 1 is valid under the weaker assumption that $\{t_j\}_{j=0}^n$ interlace with $\{\xi_j\}_{j=1}^n$. If a comparison point t_j coincides with a zero of T_n, then the polynomials from the corresponding class $\Omega_n(\Delta, \epsilon)$ must vanish at that point. In the case when all $\{\xi_\nu\}_{\nu=1}^n$ belong to Δ, Theorem 1 holds trivially since in that case $\Omega_n(\Delta, \epsilon) = \{cT_n(x) : |c| \le 1\}$.

2. So far, we cannot extend Theorem 1 to higher order derivatives, i.e., to prove $\|f^{(k)}\| \le \|T_n^{(k)}\|$ for all $k \ge 2$. However, it should be pointed out that this inequality holds true for $k = n-1$ and for $k = n$. This is easily seen from the proof of Lemma 4: for any polynomial $f \in \Omega_n(\Delta, \epsilon)$ and for $k = n-1, n$ we have $\|f^{(k)}\| = |f^{(k)}(-1)|$ or $\|f^{(k)}\| = |f^{(k)}(1)|$, and for $x = \pm 1$ the extremal polynomials in Lemma 4 are of the form $cP_0 = \pm cT_n$, $|c| = 1$.

3. According to Lemma 4, a necessary condition for a mesh $\Delta = \{t_j\}_{j=0}^n$ to admit DS-inequality with an extremal polynomial $Q = T_n$ is for the sign pattern of $(T_n(t_0), \ldots, T_n(t_n))$ to coincide (up to a factor -1) with the sign pattern of some of the polynomials $\{P_\nu\}_{\nu=0}^n$. Theorem 1 asserts DS-inequality for all meshes Δ having the sign structure of P_0. One may think that DS-inequality also holds for any other mesh $\Delta = \{t_j\}_{j=0}^n$ for which the sign pattern of $(T_n(t_0), \ldots, T_n(t_n))$ coincides with the sign pattern of some P_ν, $\nu \in \{1, \ldots, n\}$. However, the example below shows that this is not true in general.

Let $t_j = \eta_{j+1}$ for $j = 0, 1, \ldots, n-2$, $t_n = \eta_n$, and $t_{n-1} = \zeta$, where $\zeta \in (-1, \xi_n)$. Define the polynomial

$$q(x) = \begin{cases} T_n(x) & \text{for } x = t_j, \quad j = 0, \ldots, n-2, n, \\ \\ -T_n(x) & \text{for } x = t_{n-1}. \end{cases}$$

Clearly, q has the same sign structure as P_{n-1}, and $|q(t_j)| = |T_n(t_j)|$ $(j = 0, \ldots, n)$. The explicit form of q is

$$q(x) = T_n(x) + a(1+x)T_n'(x), \quad \text{where } a = -2T_n(\zeta)/((1+\zeta)T_n'(\zeta)) > 0,$$

and for $k = 1, \ldots, n$ we have

$$\|q^{(k)}\| \ge q^{(k)}(1) > T_n^{(k)}(1) = \|T_n^{(k)}\|.$$

4. As was mentioned in [11, p. 174], inequalities of Duffin–Schaeffer type may be viewed as exact estimates for the round-off error in Lagrange differentiation formulas. We describe below briefly a possible application of the result of Theorem 1.

Let $\Delta = \{t_j\}_{j=0}^n$ be a mesh whose points interlace strictly with the zeros of T_n. Suppose that inaccurate data $\{\tilde{f}(t_j)\}_{j=0}^n$ for a function $f \in C^{n+1}[-1, 1]$ is given, where

$$|f(t_j) - \tilde{f}(t_j)| \le \delta_j \quad (j = 0, \ldots, n).$$

If $f'(x) \approx L_n'(\tilde{f}; x)$ is the Lagrange differentiation formula based on this information, then for the error $R(f; x) := f'(x) - L_n'(\tilde{f}; x)$ there holds

$$R(f; x) = R^{\text{round}}(f; x) + R^{\text{trunc}}(f; x)$$

with $R^{\text{round}}(f;x) = L_n'(\tilde{f} - f;x)$ being the error caused by inaccuracy of the data and $R^{\text{trunc}}(f;x)$ being the error caused by the fact that f is not necessarily a polynomial (truncation error). We have the estimate

$$\|R(f;\cdot)\| \le \|R^{\text{round}}(f;\cdot)\| + \|R^{\text{trunc}}(f;\cdot)\|.$$

The exact bound for the truncation error in the Lagrange differentiation formula in the general case has been obtained by Shadrin [17] (in our case $\|R^{\text{trunc}}(f;\cdot)\| \le \|f^{(n+1)}\|\|\omega'\|/(n+1)!$). For the round-off error, Theorem 1 provides the following exact upper bound:

$$\|R^{\text{round}}(f;\cdot)\| \le Mn^2, \quad \text{where} \quad M = \max_{0\le j\le n} \frac{\delta_j}{|T_n(t_j)|}.$$

This upper bound is attained when $\delta_j/|T_n(t_j)| = M$ for $j = 0,\dots,n$.

ON THE EQUIVALENCE OF VISCOSITY SOLUTIONS AND WEAK SOLUTIONS FOR A QUASI-LINEAR EQUATION*

PETRI JUUTINEN[†], PETER LINDQVIST[‡], AND JUAN J. MANFREDI[§]

Abstract. We discuss and compare various notions of weak solution for the p-Laplace equation

$$-\mathrm{div}(|\nabla u|^{p-2}\nabla u) = 0$$

and its parabolic counterpart

$$u_t - \mathrm{div}(|\nabla u|^{p-2}\nabla u) = 0.$$

In addition to the usual Sobolev weak solutions based on integration by parts, we consider the p-superharmonic (or p-superparabolic) functions from nonlinear potential theory and the viscosity solutions based on generalized pointwise derivatives (jets). Our main result states that in both the elliptic and the parabolic case, the viscosity supersolutions coincide with the potential-theoretic supersolutions.

Key words. p-Laplacian, viscosity solutions, p-superharmonic functions

1. Introduction.

The objective of this paper is to prove that the viscosity solutions of the p-Laplace equation

$$-\,\mathrm{div}\left(|\nabla u|^{p-2}\nabla u\right) = 0 \tag{1.1}$$

and its parabolic analogue coincide with the usual weak solutions, defined with the aid of test-functions under the integral sign. Our main result is that the viscosity supersolutions are the same as the so-called p-harmonic functions, which are defined through a comparison principle in nonlinear potential theory. In the linear case $p = 2$ the viscosity supersolutions of the Laplace equation $-\Delta u = 0$ are merely the superharmonic functions in classical potential theory. This result and its parabolic counterpart are due to Lions and can be found, for example, in [FIT]. For related results for equations with measurable coefficients see [Je2], and for certain classes of nonlinear equations see [CKSS].

The p-Laplace equation is the Euler–Lagrange equation for the variational integral

$$\int_\Omega |\nabla u(x)|^p\,dx.$$

Here $1 < p < \infty$ is a fixed exponent, the function u is scalar valued, and Ω is a domain in the n-dimensional Euclidean space. Notice that in the case $p = 2$ (the linear case) we have the Dirichlet integral and the Laplace equation

$$-\Delta u = 0.$$

The p-harmonic equation is the prototype of a class of quasi-linear equations in the form

$$-\operatorname{div} \mathcal{A}_p(x, \nabla u(x)) = 0,$$

and it is fundamental in the nonlinear potential theory; cf. [HKM]. The p-harmonic operator $\operatorname{div}(|\nabla u|^{p-2}\nabla u)$ also appears in many contexts in physics: non-Newtonian fluids (dilatant fluids have $p > 2$, and pseudoplastics have $1 < p < 2$), reaction-diffusion problems, nonlinear elasticity (torsional creep), glaceology ($p = 4/3$), and the thermal radiation of a hydrogen bomb (see [B]), just to mention a few applications.

We will study the mere notion of solutions, subsolutions, and supersolutions. There is something new to be said about this much-investigated basic topic in connection with the so-called viscosity solutions, a modern concept originating in the theory of Hamilton–Jacobi equations. The viscosity solutions have turned out to be indispensable in the case $p = \infty$ (not treated here; see [Je], [JLM]) and quite useful for p finite when it comes to the pointwise interpretation of expedient identities involving second derivatives; cf. [LMS]. We begin with a brief discussion about different definitions of solution.

The solutions with continuous second derivatives (classical solutions) have the advantage of being easy to define: the equation

$$|\nabla u|^2 \Delta u + (p-2) \sum_{i,j=1}^{n} \frac{\partial u}{\partial x_i} \frac{\partial u}{\partial x_j} \frac{\partial^2 u}{\partial x_i \partial x_j} = 0$$

has to hold at each point in the domain Ω. However, when $p \neq 2$ this class of solutions is too restricted for the solvability of the Dirichlet problem. Roughly speaking, this is due to the fact that solutions may not, in general, be of class C^2 at points where $\nabla u = 0$.

To assure the solvability of the Dirichlet boundary value problem, the *p-harmonic functions* are usually defined as (continuous) weak solutions in the Sobolev space $W^{1,p}$. This is the familiar situation with test-functions under the integral sign; see Definition 2.1 below. The uniqueness comes almost for free here. In other words, one has both existence and uniqueness for the Dirichlet boundary value problem.

The definition of *viscosity solutions* is based on pointwise evaluation of the p-harmonic operator

$$\Delta_p u = \operatorname{div}\left(|\nabla u|^{p-2}\nabla u\right),$$

though only for smooth test-functions φ; see section 2 below. The underlying phenomenon is that the classical (of class C^2) sub- and supersolutions are enough to determine the p-harmonic functions, although the latter often are less smooth. This is the content of Corollary 2.6, which states that the viscosity solutions[1] are the p-harmonic functions. To the best of our knowledge, this is a new result.

[1] To indicate the dependence on the exponent p, they are called viscosity p-solutions below.

We have also included a section on the so-called p-parabolic equation

$$u_t - \operatorname{div}(|\nabla u|^{p-2}\nabla u) = 0.$$

According to Corollary 4.5, its viscosity solutions[2] are the p-parabolic functions (continuous weak solutions in a parabolic Sobolev space). The interpretation of this result requires some caution in the range $1 < p < \frac{2n}{n+2}$, because discontinuous "solutions" have to be ruled out. The proof of the equivalence of the parabolic definitions is simpler than in the elliptic situation. We end the paper with a brief discussion of an alternative definition, due to Ishii and Souganidis [IS], for parabolic viscosity solutions in the singular case $1 < p < 2$.

Finally, let us briefly indicate an application. It is to be expected that, at least under suitable conditions, the limit

$$\lim_{t\to\infty} u(x,t)$$

of a p-parabolic function is p-harmonic. Such a theorem has been proved in [Ju] with the viscosity technique, which is advantageous for convergence problems. Our Corollary 2.6 complements the result, making it possible to conclude that the viscosity p-solution, obtained as limit function, is p-harmonic.

2. Definitions. Let Ω denote a domain in $\mathbb{R}^n$. The Sobolev space $W^{1,p}(\Omega)$ consists of all functions $u\,\Omega \to [-\infty,\infty]$ that together with their distributional first derivatives

$$\nabla u = \left(\frac{\partial u}{\partial x_1}, \frac{\partial u}{\partial x_2}, \dots, \frac{\partial u}{\partial x_n}\right)$$

are p-summable. The corresponding local space is denoted by $W^{1,p}_{\mathrm{loc}}(\Omega)$.

Definition 2.1. *We say that a continuous function $u \in W^{1,p}_{\mathrm{loc}}(\Omega)$ is p-harmonic in Ω if*

$$\int_\Omega |\nabla u|^{p-2}\langle \nabla u, \nabla\varphi\rangle\, dx = 0$$

for every $\varphi \in C_0^\infty(\Omega)$. Here $1 < p < \infty$.

By elliptic regularity theory the continuity is redundant in the definition. According to a theorem of Ural'tseva, in the case $p > 2$, later extended by DiBenedetto and Lewis to all $p > 1$, $u \in C^{1,\alpha}_{\mathrm{loc}}(\Omega)$; cf. [Ur], [DB], [Le].

Next we will define the p-superharmonic functions via a comparison principle as in [Li]. Notice immediately that the "fundamental solution"

$$V(x) = |x|^{\frac{p-n}{p-1}}$$

if $1 < p < n$ and

$$V(x) = \log\left(\frac{1}{|x|}\right)$$

[2] To indicate the dependence on the exponent p, they are called parabolic viscosity p-solutions later.

if $p = n$ is, indeed, p-superharmonic in $\mathbb{R}^n$ according to the definition below, although

$$\int_{|x|<1} |\nabla V(x)|^p \, dx = \infty.$$

Any reasonable definition has to include this example. This is taken into account in the following potential-theoretic definition.

Definition 2.2. *The function* $u\,\Omega \to (-\infty, \infty]$ *is called p-superharmonic if*

(i) *u is lower semicontinuous,*

(ii) $u \not\equiv \infty$*, and*

(iii) *u satisfies the comparison principle on each subdomain* $D \Subset \Omega$*: if* $h \in C(\overline{D})$ *is p-harmonic in D and* $u \geq h$ *on* ∂D*, then* $u \geq h$ *in D.*

We have used the notation $D \Subset \Omega$ to indicate that the closure of the domain D is contained in Ω. For $p = 2$, this is the classical definition of superharmonic functions due to Riesz. Note that there are no requirements for the gradient ∇u in Definition 2.2. However, a locally bounded p-superharmonic function u is actually in $W^{1,p}_{\text{loc}}(\Omega)$ and satisfies the inequality

$$\int_\Omega |\nabla u|^{p-2} \langle \nabla u, \nabla \varphi \rangle \, dx \geq 0 \tag{2.1}$$

for every nonnegative test-function $\varphi \in C_0^\infty(\Omega)$. Moreover, the converse is also true for a lower semicontinuous function u in $W^{1,p}_{\text{loc}}(\Omega)$. We refer the reader to [Li] for this fact and more information about the definition and properties of p-superharmonic functions.

Needless to say, *p-subharmonic* functions are defined in an analogous way, so that u is p-subharmonic if and only if $-u$ is p-superharmonic. A function u is p-harmonic if and only if it is both p-superharmonic and p-subharmonic. For the sake of completeness, we mention the *comparison principle* in nonlinear potential theory; see [HKM], [Li].

Comparison principle for p-subharmonic and p-superharmonic functions. Suppose that Ω is a bounded domain, that u is p-subharmonic, and that v is p-superharmonic in Ω. If

$$\limsup_{x \to z} u(x) \leq \liminf_{x \to z} v(x)$$

for all $z \in \partial\Omega$ and if both sides of the inequality are not simultaneously $+\infty$ or $-\infty$, then $u \leq v$ in Ω.

Let us now turn our attention to viscosity solutions. The notion of viscosity solutions requires that the expression

$$\begin{aligned} \Delta_p \varphi &= \operatorname{div}\left(|\nabla \varphi|^{p-2} \nabla \varphi\right) \\ &= |\nabla \varphi|^{p-4} \left[|\nabla \varphi|^2 \Delta \varphi + (p-2) \sum_{i,j=1}^n \frac{\partial \varphi}{\partial x_i} \frac{\partial \varphi}{\partial x_j} \frac{\partial^2 \varphi}{\partial x_i \partial x_j} \right] \end{aligned}$$

be evaluated pointwise for smooth functions φ. This is not a problem when $\nabla \varphi \neq 0$, but the critical points pose additional difficulties, especially in the range $1 < p < 2$. A standard way to deal with singular equations in the theory of viscosity solutions is to use suitable semicontinuous extensions of the operator; cf. [CGG], [CIL]. For the p-Laplacian this approach would allow some false "solutions." For example, $u \equiv$ *constant* would then solve

$$-\Delta_p u(x) = f(x)$$

in the viscosity sense for any continuous function f.

In the following definition, the pointwise evaluation of $\Delta_p \varphi$ is avoided when $\nabla\varphi = 0$. This precaution has no bearing if $p \geq 2$. (Observe that the difficulty with critical points cannot be just defined away, and, in connection with the approximating equation $-\Delta_p v = \varepsilon$, isolated critical points have to be dealt with; see Lemma 3.2 below.) To further motivate the definition, we remark that a function $\varphi \in C^2(\Omega)$ that satisfies $-\Delta_p \varphi(x) = 0$ when $\nabla\varphi(x) \neq 0$ (nothing being said about the possible critical points) is p-harmonic in Ω. This new result is an immediate consequence of Corollary 2.6 below.

DEFINITION 2.3. *The function $u\,\Omega \to (-\infty, \infty]$ is called a viscosity p-supersolution if*

(i) *u is lower semicontinuous,*

(ii) *$u \not\equiv \infty$, and*

(iv) *whenever $x_0 \in \Omega$ and $\varphi \in C^2(\Omega)$ are such that $u(x_0) = \varphi(x_0)$, $u(x) > \varphi(x)$ for $x \neq x_0$, and $\nabla\varphi(x_0) \neq 0$, we have*

$$-\Delta_p \varphi(x_0) \geq 0.$$

Each point x_0 requires its own family of test-functions touching from below, which may very well be empty. It is not difficult to see that condition (iv) can be replaced by the following condition.

(v) The following comparison holds for each subdomain $D \Subset \Omega$: let $\varphi \in C^2(\Omega)$ be such that $\nabla\varphi(x) \neq 0$ and $-\Delta_p \varphi(x) < 0$ in D. If $u \geq \varphi$ on ∂D, then $u \geq \varphi$ in D.

In other words, the comparison is with respect to "smooth strict subsolutions" in Definition 2.3 and with respect to p-harmonic functions in Definition 2.2. Our main result, Theorem 2.5 below, guarantees that both definitions yield the same class of u's. We have come to a fundamental issue about the difference between conditions (iii) and (v). At first sight, condition (v) looks like (iii) in Definition 2.2, especially if one replaces the strict inequality $-\Delta_p \varphi(x) < 0$ by $-\Delta_p \varphi(x) \leq 0$, which is possible a posteriori due to our results. The point is that the comparison in (iii) is with respect to p-harmonic functions that are not necessarily of class C^2, the regularity being merely $C^{1,\alpha}$, while (v) is restricted to C^2-functions. It is in doubt whether one can further restrict the comparison in (iii) to p-harmonic functions h having continuous second derivatives.

An upper semicontinuous function u is a viscosity p-subsolution if $-u$ is a viscosity p-supersolution. A viscosity solution of the equation $-\Delta_p u = 0$ is both a viscosity p-supersolution and p-subsolution.

Remark 2.4. If $p \geq 2$, then $-\Delta_p \varphi(x)$ is well defined also at the critical points of φ, and there is no need to require in (iv) that the gradient of a test-function does not vanish at the point of touching. However, since it turns out that both versions of the definition give the same class of solutions, we have decided to use the one that works also in the singular case $1 < p < 2$.

THEOREM 2.5. *Let $1 < p < \infty$. In a given domain the p-superharmonic functions and the viscosity p-supersolutions are the same.*

COROLLARY 2.6. *Let $1 < p < \infty$. A function is p-harmonic if and only if it is a viscosity p-solution.*

The proof of Theorem 2.5 has two parts. First, we must prove that p-superharmonic functions are viscosity p-supersolutions. This is a rather immediate consequence of the classical comparison principle for p-superharmonic and p-subharmonic functions. Second, we must show that viscosity p-supersolutions are p-superharmonic, that is, they satisfy the comparison principle with respect to p-harmonic functions. This is more delicate since the points at which the gradient vanishes present difficulties in the degenerate as well as in the singular case. Since this comparison principle may be of independent interest, we have stated it by itself. The proof is presented in section 3 below.

THEOREM 2.7 (the comparison principle). *Let $\Omega \subset \mathbb{R}^n$ be a bounded domain, and assume that u is a viscosity p-subsolution and v is a viscosity p-supersolution in Ω. If*

$$\limsup_{x\to z} u(x) \le \liminf_{x\to z} v(x) \tag{2.2}$$

for all $z \in \partial\Omega$ and if both sides of (2.2) *are not simultaneously ∞ or $-\infty$, then $u \le v$ in Ω.*

Proof of Theorem 2.5. Let us first assume that u is p-superharmonic. To show that u is a viscosity p-supersolution, we argue by contradiction and assume that there exists $x_0 \in \Omega$ and $\varphi \in C^2(\Omega)$ such that $u(x_0) = \varphi(x_0)$, $u(x) > \varphi(x)$ for all $x \neq x_0$, $\nabla\varphi(x_0) \neq 0$, and

$$-\Delta_p \varphi(x_0) < 0.$$

By continuity, there exists a radius $r > 0$ such that

$$\begin{cases} -\Delta_p \varphi(x) < 0, \\ \quad \nabla\varphi(x) \neq 0 \end{cases}$$

for every $x \in B_r(x_0)$. Let

$$m = \inf_{|x-x_0|=r} (u(x) - \varphi(x)) > 0,$$

and define $\tilde\varphi = \varphi + m$. Then $\tilde\varphi$ is p-subharmonic in the open set $B_r(x_0)$. Since $\tilde\varphi \le u$ on $\partial B_r(x_0)$, we obtain from the comparison principle for p-superharmonic and p-subharmonic functions that $\tilde\varphi \le u$ in $B_r(x_0)$. However,

$$\tilde\varphi(x_0) = \varphi(x_0) + m > u(x_0),$$

which is a contradiction. Therefore, u must be a viscosity p-supersolution.

For the converse implication, it is enough to check that (iii) holds for viscosity p-supersolutions. This, however, follows immediately from Theorem 2.7 after noticing that by the first half of the proof, every p-harmonic function is a viscosity p-solution. □

3. Proof of the comparison principle. Let the functions u and v satisfy the assumptions in Theorem 2.7. We begin with some simplifications of the general situation.

First reduction (approximation by smooth domains). We may assume, without loss of generality, that the bounded domain Ω is smooth, the function $v \in C^{1,\alpha}(\overline{\Omega})$ is p-harmonic, and $u \le v$ on $\partial\Omega$.

To see this, let us first observe that by (2.2) we can find for any $\epsilon > 0$ a smooth domain $D \Subset \Omega$ such that $u < v + \epsilon$ in $\Omega \setminus D$. By semicontinuity there is a function $\varphi \in C^\infty(\Omega)$ such that

$$u < \varphi < v + \epsilon$$

on ∂D. Next, let h be the unique weak solution to the Dirichlet problem

$$\begin{cases} -\Delta_p h = 0 & \text{in } D, \\ h = \varphi & \text{on } \partial D. \end{cases}$$

In other words, $h \in C(\bar{D}) \cap W^{1,p}(D)$ is p-harmonic in D. Since D is regular, h takes its prescribed continuous boundary values φ in the classical sense.

We have

$$u \le h \le v + \epsilon$$

on ∂D. In fact, it is known that $h \in C^{1,\alpha}(\bar{D})$ (see [Lie]), but we prefer to give an argument which avoids this difficult boundary regularity result. The weaker local regularity $h \in C^{1,\alpha}_{\mathrm{loc}}(D)$ will suffice. To this end, we construct a regular domain $D_1 \Subset D$ such that

$$u - \epsilon \le h \le v + 2\epsilon$$

on ∂D_1 and $u < v + 2\epsilon$ in $\Omega \setminus D_1$. Notice that now we have $h \in C^{1,\alpha}(\overline{D}_1)$, because $h \in C^{1,\alpha}_{\mathrm{loc}}(D)$. If we assume the theorem for regular domains, we get

$$u - \epsilon \le h \le v + 2\epsilon$$

in the whole D_1. Therefore, we conclude that $u \le v + 3\epsilon$ in Ω. Since $\epsilon > 0$ was arbitrary, this is the desired situation. Moreover, since the two cases $u - \epsilon \le h$ and $h \le v + 2\epsilon$ are symmetric, it suffices to prove that $u - \epsilon \le h$ in D_1.

Second reduction (approximation by "regularized" equations). It is enough to prove the comparison principle in the case when v is a weak solution of the equation

$$-\Delta_p v = \varepsilon, \qquad \varepsilon > 0. \tag{3.1}$$

More precisely, suppose that v is a weak solution of (3.1) with smooth boundary values ($v - w \in W^{1,p}_0(\Omega)$ for some $w \in C^{1,\alpha}(\overline{\Omega})$) and Ω is a bounded smooth domain. If u is a viscosity p-subsolution in Ω such that $u(x) \le v(x)$ for all $x \in \partial\Omega$, then we have $u(x) \le v(x)$ for $x \in \Omega$.

Indeed, let us assume that the comparison principle holds in the setting described above, and let u and v be as in the first reduction. If v_ε is the unique weak solution of (3.1) with the boundary condition $v_\varepsilon = v$ on $\partial\Omega$, then by the assumed comparison $u \le v_\varepsilon$ in Ω for every $\varepsilon > 0$. On the other hand, by Lemma 3.1 below, $v_\varepsilon \to v$ locally uniformly. This, in turn, means that $u \le v$ in Ω, which is exactly what we want to prove.

LEMMA 3.1. *Let $v \in W^{1,p}(\Omega)$ be p-harmonic in a bounded domain Ω, and let v_ε be the unique weak solution of the Dirichlet problem*

$$\begin{cases} -\Delta_p v_\varepsilon = \varepsilon & \text{in } \Omega, \\ \quad v_\varepsilon = v & \text{on } \partial\Omega. \end{cases}$$

Then $v_\varepsilon \to v$ locally uniformly in Ω as $\varepsilon \to 0$.

Proof. Take $v - v_\varepsilon \in W_0^{1,p}(\Omega)$ as a test-function in (1.1) and (3.1), and subtract the resulting equations. This yields

$$\begin{aligned}\int_\Omega \big\langle |\nabla v|^{p-2}\nabla v - |\nabla v_\varepsilon|^{p-2}\nabla v_\varepsilon, \nabla v - \nabla v_\varepsilon\big\rangle\, dx &= \varepsilon \int_\Omega (v_\varepsilon - v)\, dx \\ &\le \varepsilon |\Omega|^{\frac{p-1}{p}} \left(\int_\Omega |v - v_\varepsilon|^p\, dx\right)^{\frac{1}{p}} \\ &\le K\varepsilon \left(\int_\Omega |\nabla v - \nabla v_\varepsilon|^p\, dx\right)^{\frac{1}{p}},\end{aligned}$$

where we have used the inequalities of Hölder and Sobolev, and $K = K(p, n, \Omega)$ is some constant depending only on p, n, and Ω.

For $p \ge 2$, it follows easily from the elementary vector inequality [DB, Chapter I]

$$|a - b|^p \le 2^{p-1}\langle |a|^{p-2}a - |b|^{p-2}b, a - b\rangle$$

that

$$\int_\Omega |\nabla v - \nabla v_\varepsilon|^p\, dx \le K\varepsilon^{\frac{p}{p-1}}, \tag{3.2}$$

where $K = K(p, n, \Omega)$. The singular case $1 < p < 2$ is slightly more delicate. Start with the vector inequality [DB, Chapter I]

$$\frac{|a - b|^2}{(|a| + |b|)^{2-p}} \le \gamma \langle |a|^{p-2}a - |b|^{p-2}b, a - b\rangle,$$

where γ depends only on p and n and $a, b \in \mathbb{R}^n$. By Hölder's inequality

$$\int_\Omega |\nabla v - \nabla v_\varepsilon|^p\, dx \le \left(\int_\Omega \frac{|\nabla v - \nabla v_\varepsilon|^2}{(|\nabla v| + |\nabla_\varepsilon|)^{2-p}}\, dx\right)^{\frac{p}{2}} \left(\int_\Omega (|\nabla v| + |\nabla v_\varepsilon|)^p\, dx\right)^{\frac{2-p}{2}},$$

and this time

$$\int_\Omega \frac{|\nabla v - \nabla v_\varepsilon|^2}{(|\nabla v| + |\nabla_\varepsilon|)^{2-p}}\, dx \le \gamma K \varepsilon \left(\int_\Omega |\nabla v - \nabla v_\varepsilon|^p\, dx\right)^{\frac{1}{p}}.$$

Therefore, we have the inequality

$$\int_\Omega |\nabla v - \nabla v_\varepsilon|^p\, dx \le K\varepsilon^p \left(\int_\Omega (|\nabla v| + |\nabla v_\varepsilon|)^p\, dx\right)^{2-p}.$$

Since $\int_\Omega |\nabla v_\varepsilon|^p\, dx$, on the other hand, can be estimated in terms of $\int_\Omega |\nabla v|^p\, dx$ independently of ε for ε small, this implies

$$\int_\Omega |\nabla v - \nabla v_\varepsilon|^p\, dx \le C\,\varepsilon^p \left(1 + \int_\Omega |\nabla v|^p\, dx\right)^{2-p}. \tag{3.3}$$

By estimates (3.2), (3.3), it follows that we have a uniform bound for

$$\int_\Omega |\nabla v_\varepsilon|^p\, dx$$

independent of ε. It then follows from the interior regularity estimates for solutions of (3.1) (cf. [Le], [DB2]) that if we fix a compact set $K \subset \Omega$, we have a uniform bound for $\|v_\varepsilon\|_{C^\alpha(K)}$ for any $1 < p < \infty$. By Ascoli–Arzelà's theorem, there exists a subsequence $\varepsilon_i \to 0$ for which $v_{\varepsilon_i} \to w$ uniformly in K. It follows again from (3.2), (3.3) that indeed $w = v$ and that the full sequence $v_\varepsilon \to v$ locally uniformly in Ω as $\varepsilon \to 0$. □

The weak solutions of (3.1) can be seen as strict supersolutions of (1.1), and this property is of great importance in the proof below of the reduced version of Theorem 2.7. A similar type of approximation argument has been used by Jensen [Je] in connection with the ∞-Laplace equation.

We will need the following result on the "viscosity properties" of weak solutions of (3.1).

Lemma 3.2. *Let $v_\varepsilon \in W^{1,p}(\Omega)$ be a continuous weak solution of the equation $-\Delta_p v_\varepsilon = \varepsilon$ in Ω, and let $x_0 \in \Omega$ and $\varphi \in C^2(\Omega)$ be such that $v_\varepsilon - \varphi$ has a strict local minimum at x_0. Then*

$$\limsup_{\substack{x \to x_0 \\ x \neq x_0}} \left(-\Delta_p \varphi(x)\right) \geq \varepsilon,$$

provided that $\nabla\varphi(x_0) \neq 0$ or x_0 is an isolated critical point.

Remark. We have come to a decisive point. In the case $p \geq 2$ the proof yields that $-\Delta_p\varphi(x_0) \geq \varepsilon$ and that $\nabla\varphi(x) \neq 0$ in some neighborhood of x_0. It is the case $1 < p < 2$ that requires caution, because $-\Delta_p\varphi(x)$ is undetermined at the critical points (which may be encountered).

Proof. Suppose that the assertion is not true, that is, there is $r > 0$ such that

$$\nabla\varphi(x) \neq 0 \quad \text{and} \quad -\Delta_p\varphi(x) < \varepsilon,$$

when $0 < |x - x_0| < r$. After a translation, we may assume that $x_0 = 0$. Take any nonnegative test-function $\phi \in C_0^\infty(B_r)$, and integrate over the annulus $\rho < |x| < r$. (The auxiliary $\rho > 0$ can be skipped if $\nabla\varphi(0) \neq 0$.) According to Gauss's theorem,

$$\begin{aligned} -\oint_{|x|=\rho} \phi|\nabla\varphi|^{p-2}\langle\nabla\varphi, \tfrac{x}{\rho}\rangle\, dS &= \int_{\rho<|x|<r} \operatorname{div}(\phi|\nabla\varphi|^{p-2}\nabla\varphi)\, dx \\ &= \int_{\rho<|x|<r} |\nabla\varphi|^{p-2}\langle\nabla\varphi, \nabla\phi\rangle\, dx + \int_{\rho<|x|<r} \phi(\Delta_p\varphi)\, dx. \end{aligned}$$

The flux approaches 0 as $\rho \to 0_+$. Indeed,

$$\left| \oint_{|x|=\rho} \phi|\nabla\varphi|^{p-2}\langle\nabla\varphi, \tfrac{x}{\rho}\rangle\, dS \right| \leq \|\phi\|_\infty \|\nabla\varphi\|_\infty^{p-1}\omega_{n-1}\rho^{n-1},$$

where $\omega_{n-1}\rho^{n-1}$ is the area of the sphere of radius ρ. By the antithesis we have

$$\int_{\rho<|x|<r} \phi(\Delta_p\varphi)\, dx \geq -\varepsilon \int_{\rho<|x|<r} \phi\, dx \geq -\varepsilon \int_{B_r} \phi\, dx.$$

Therefore, we obtain

$$\int_{B_r} |\nabla\varphi|^{p-2}\langle\nabla\varphi, \nabla\phi\rangle\, dx = \lim_{\rho\to 0} \int_{\rho<|x|<r} |\nabla\varphi|^{p-2}\langle\nabla\varphi, \nabla\phi\rangle\, dx \leq \varepsilon \int_{B_r} \phi\, dx.$$

Thus φ is a weak subsolution of (3.1). We finish by using the comparison principle as in the proof of Theorem 2.5 presented in section 2. $\square$

After the reductions made above, it suffices to prove the following version of the comparison principle [see (3.4) below]. In the proof we use the notation

$$F(\eta, X) = -|\eta|^{p-2}\left[\operatorname{trace}(X) + (p-2)\left\langle X\frac{\eta}{|\eta|}, \frac{\eta}{|\eta|}\right\rangle\right] \tag{3.4}$$

when $\eta \neq 0$ is a vector in $\mathbb{R}^n$ and $X \in S_n$, where S_n denotes the class of real symmetric $n \times n$ matrices. For a smooth function φ we clearly have

$$F(\nabla\varphi(x), D^2\varphi(x)) = -\operatorname{div}(|\nabla\varphi(x)|^{p-2}\nabla\varphi(x))$$

when $\nabla\varphi(x) \neq 0$. Here $D^2\varphi = (\frac{\partial^2\varphi}{\partial x_i \partial x_j})_{n\times n}$ is the Hessian matrix of φ.

PROPOSITION 3.3. *Suppose that $\Omega \subset \mathbb{R}^n$ is a smoothly bounded domain, u is a viscosity p-subsolution, and $v \in C^{1,\alpha}(\overline{\Omega})$ is a weak solution of $-\Delta_p v = \varepsilon$ in Ω such that $u \leq v$ on $\partial\Omega$. Then $u \leq v$ in Ω.*

Proof. Without loss of generality, we may assume that $\varepsilon = 1$. We argue by contradiction and assume that $u - v$ has an interior maximum, that is,

$$\sup_{\Omega}(u-v) > \sup_{\partial\Omega}(u-v). \tag{3.5}$$

Consider the functions

$$w_j(x,y) = u(x) - v(y) - \Psi_j(x,y), \quad j = 1, 2, \ldots,$$

where

$$\Psi_j(x,y) = \tfrac{j}{q}|x-y|^q, \qquad q > \max\left\{\frac{p}{p-1}, 2\right\},$$

and let (x_j, y_j) be a maximum of w_j relative to $\overline{\Omega} \times \overline{\Omega}$. By (3.5) and Proposition 3.7 in [CIL], we see that for j sufficiently large, (x_j, y_j) is an interior point. Since

$$u(x) - v(y) - \Psi_j(x,y) \leq u(x_j) - v(y_j) - \Psi_j(x_j, y_j)$$

for all $x, y \in \Omega$, we obtain by choosing $x = x_j$ that

$$v(y) \geq -\Psi_j(x_j, y) + v(y_j) + \Psi_j(x_j, y_j)$$

for all $y \in \Omega$. Let us denote

$$\phi_j(y) = -\Psi_j(x_j, y) + v(y_j) + \Psi_j(x_j, y_j) - \frac{1}{q+1}|y - y_j|^{q+1}.$$

Then, clearly, $v - \phi_j$ has a strict local minimum at y_j, and thus

$$\limsup_{\substack{y \to y_j \\ y \neq y_j}} (-\Delta_p \phi_j(y)) \geq 1$$

by Lemma 3.2. This implies that $x_j \neq y_j$. Indeed, if $x_j = y_j$, then a direct computation shows that $-\Delta_p \phi_j(y) \to 0$ as $y \to y_j$, which is a contradiction.

The rest of the proof is now a rather standard application of the maximum principle for semicontinuous functions (also known as the theorem on sums) in [CIL]. Since (x_j, y_j) is a local maximum point of $w_j(x, y)$, we conclude that there exist symmetric $n \times n$ matrices X_j, Y_j such that

$$\begin{aligned}(D_x\Psi_j(x_j, y_j), X_j) &\in \overline{J}^{2,+}u(x_j),\\ (-D_y\Psi_j(x_j, y_j), Y_j) &\in \overline{J}^{2,-}v(y_j),\end{aligned}$$

and

$$\begin{pmatrix} X_j & 0 \\ 0 & -Y_j \end{pmatrix} \le D^2\Psi_j(x_j, y_j) + \frac{1}{j}\left[D^2\Psi_j(x_j, y_j)\right]^2. \tag{3.6}$$

Here $\overline{J}^{2,+}u(x_j)$ and $\overline{J}^{2,-}v(y_j)$ are the closures of the second order superjet of u at x_j and the second order subjet of v at y_j, respectively. We refer the reader to [C] and [CIL] for the definition and properties of jets.

Observe that since $D^2\Psi_j$ annihilates vectors of the form $\binom{\xi}{\xi}$, we obtain from (3.6) that

$$X_j \le Y_j$$

in the sense of matrices, that is, $\langle (Y_j - X_j)\xi, \xi\rangle \ge 0$ for all $\xi \in \mathbb{R}^n$.

Let us now finish the proof. It is well known (see [CIL]) that for equations that are continuous in each variable, viscosity solutions can be defined using jets instead of test-functions as in Definition 2.3. Since $x_j \neq y_j$, we have that

$$\eta_j \equiv D_x\Psi_j(x_j, y_j) = -D_y\Psi_j(x_j, y_j) \neq 0.$$

This means that

$$(\eta, X) \mapsto F(\eta, X),$$

where F is given by (3.4) and is continuous in a neighborhood of the points (η_j, X_j) and (η_j, Y_j), and we may use the equivalent definition involving jets. Since u is a subsolution of (1.1), we obtain that

$$-|\eta_j|^{p-2}\left[\operatorname{trace}(X_j) + (p-2)\left\langle X_j\frac{\eta_j}{|\eta_j|}, \frac{\eta_j}{|\eta_j|}\right\rangle\right] \le 0.$$

On the other hand, since $\eta_j \neq 0$, by the definition of $\overline{J}^{2,-}$ Lemma 3.2 implies that

$$-|\eta_j|^{p-2}\left[\operatorname{trace}(Y_j) + (p-2)\left\langle Y_j\frac{\eta_j}{|\eta_j|}, \frac{\eta_j}{|\eta_j|}\right\rangle\right] \ge 1.$$

Hence

$$\begin{aligned}0 < 1 \le &- |\eta_j|^{p-2}\left[\operatorname{trace}(Y_j) + (p-2)\left\langle Y_j\frac{\eta_j}{|\eta_j|}, \frac{\eta_j}{|\eta_j|}\right\rangle\right]\\ &+ |\eta_j|^{p-2}\left[\operatorname{trace}(X_j) + (p-2)\left\langle X_j\frac{\eta_j}{|\eta_j|}, \frac{\eta_j}{|\eta_j|}\right\rangle\right]\\ \le&\ 0,\end{aligned}$$

where the last inequality follows from the fact $X_j \leq Y_j$. This contradiction means that our initial assumption (3.5) cannot hold, and, therefore,

$$\sup_{\Omega}(u - v) = \sup_{\partial\Omega}(u - v) \leq 0$$

as claimed. □

4. The parabolic case. The p-parabolic equation

$$u_t - \operatorname{div}\left(|\nabla u|^{p-2}\nabla u\right) = 0, \tag{4.1}$$

where $u = u(x,t)$, has the p-harmonic equation as its stationary equation. Let us introduce some notation. Let

$$Q = (a_1, b_1) \times (a_2, b_2) \times \cdots \times (a_n, b_n)$$

denote a parallelepiped, and consider the "space-time box"

$$Q_{t_1,t_2} = Q \times (t_1, t_2)$$

in the (x,t)-space. Its parabolic boundary is

$$\partial_{par} Q = \left(\overline{Q} \times \{t_1\}\right) \cup \left(\partial Q \times (t_1, t_2]\right).$$

It consists of the bottom and the lateral sides, but the interior points of the top are excluded.

In order to describe the appropriate function space, we introduce the abbreviation

$$V^p(t_1, t_2; Q) = C\left(t_1, t_2; L^2(Q)\right) \cap L^p\left(t_1, t_2; W^{1,p}(Q)\right).$$

Thus $u \in V^p(t_1, t_2; Q)$ implies that the mapping

$$t \mapsto \int_Q |u(x,t)|^2 \, dx$$

is continuous in $[t_1, t_2]$, the Sobolev derivative

$$\nabla u(x,t) = \left(\frac{\partial u(x,t)}{\partial x_1}, \ldots, \frac{\partial u(x,t)}{\partial x_n}\right)$$

exists for almost every t in $[t_1, t_2]$, and the integral

$$\int_{t_1}^{t_2} \int_Q \left(u^2 + |\nabla u|^p\right) \, dt \, dx$$

is finite.

Definition 4.1. *Let $\mathcal{O}$ be a domain in $\mathbb{R}^n \times \mathbb{R}$, and suppose that the function $u\, \mathcal{O} \to \mathbb{R}$ is continuous and belongs to $V^p(t_1, t_2; Q)$ whenever the closure of Q_{t_1,t_2} is comprised in $\mathcal{O}$. We say that u is p-parabolic in $\mathcal{O}$ if*

$$\int\int_{\mathcal{O}} (-u\varphi_t + |\nabla u|^{p-2}\langle \nabla u, \nabla \varphi \rangle) \, dt \, dx = 0 \tag{4.2}$$

for all test-functions $\varphi \in C_0^\infty(\mathcal{O})$.

By parabolic regularity theory, the continuity is a redundant requirement in the definition if $p > \frac{2n}{n+2}$. The case $1 < p \leq \frac{2n}{n+2}$ is not fully understood. It is known that there exist locally unbounded u's satisfying (4.1) in a weaker sense than described above. We refer to [DB, Chapter XII]. Such weak solutions cannot be viscosity solutions, since the latter are both upper and lower semicontinuous by definition and hence locally bounded. Thus our characterization of the p-parabolic viscosity solutions discards such discontinuous weak solutions.

The definition below includes the celebrated Barenblatt solution, which for $p > 2$ is given as
