$$\mathcal{B}_p(x,t) = \begin{cases} t^{-\frac{n}{\lambda}} \left\{ C - \frac{p-2}{2} \lambda^{\frac{1}{1-p}} \left(\frac{|x|}{t^{1/\lambda}} \right)^{\frac{p}{p-1}} \right\}_+^{\frac{p-1}{p-2}}, & t > 0, \\ 0, & t \leq 0, \end{cases}$$

when $(x,t) \neq (0,0)$. Here $\lambda = n(p-2) + p$, and C is a positive constant. With the definition $\mathcal{B}_p(0,0) = \infty$, the Barenblatt solution is p-superparabolic in the whole $\mathbb{R}^n \times \mathbb{R}$, although

$$\int_{-1}^{1} \int_{|x|<1} |\nabla \mathcal{B}_p(x,t)|^p \, dx \, dt = \infty.$$

Definition 4.2. *A function $u\ : \mathcal{O} \to \mathbb{R} \cup \{\infty\}$ is p-superparabolic if*

(i) *u is lower semicontinuous,*

(ii′) *u is finite in a dense subset of $\mathcal{O}$, and*

(iii) *u satisfies the comparison principle on each box Q_{t_1,t_2} with closure in $\mathcal{O}$: if $h \in C(\overline{Q}_{t_1,t_2})$ is p-parabolic in Q_{t_1,t_2} such that $h \leq u$ on the parabolic boundary of Q_{t_1,t_2}, then $h \leq u$ in Q_{t_1,t_2}.*

We refer to [KL] for a detailed discussion on the properties of the p-superparabolic functions.

Let us next turn to the definition of viscosity solutions of (4.1). Due to the presence of the time derivative u_t in the equation, we cannot exclude test-functions with vanishing spatial gradient $\nabla\varphi(x,t)$ at the point of touching like we did with the p-harmonic equation. As in the elliptic case, the equation is singular only in the range $1 < p < 2$, but we have chosen again not to distinguish between the two cases.

Definition 4.3. *A function $u\ : \mathcal{O} \to \mathbb{R} \cup \{\infty\}$ is a parabolic viscosity p-supersolution if*

(i) *u is lower semicontinuous,*

(ii′) *u is finite in a dense subset of $\mathcal{O}$, and*

(iv) *whenever $(x_0,t_0) \in \mathcal{O}$ and $\varphi \in C^2(\mathcal{O})$ are such that $u(x_0,t_0) = \varphi(x_0,t_0)$, $u(x,t) > \varphi(x,t)$ for $(x,t) \in \mathcal{O} \cap \{t < t_0\}$, and $\nabla\varphi(x,t) \neq 0$ if $x \neq x_0$, we have*

$$\limsup_{\substack{(x,t)\to(x_0,t_0) \\ t<t_0, x\neq x_0}} \Big(\varphi_t(x,t) - \Delta_p \varphi(x,t) \Big) \geq 0.$$

The concepts of *parabolic viscosity p-subsolution* and *parabolic viscosity p-solution* are defined analogously. Notice that the parabolic viscosity p-solutions are continuous by definition. As in the elliptic case, the precaution about $\nabla\varphi \neq 0$ can be ignored for $p \geq 2$.

What is to happen in the future will have no influence on the present time. This phenomenon, typical of parabolic equations, was taken into account in the definition above: the test-function is forced to be under the function u only up to the time t_0 of testing. This yields the same concept as a definition with no emphasis on the special role of the time variable; cf. [Ju].

THEOREM 4.4. *Let $1 < p < \infty$. In a given domain, the p-superparabolic functions and the parabolic viscosity p-supersolutions are the same.*

COROLLARY 4.5. *Let $1 < p < \infty$. A continuous function is a parabolic viscosity p-solution if and only if it is p-parabolic.*

The proof of Theorem 4.4 is virtually the same as its elliptic counterpart. To show that a p-superparabolic function is a parabolic viscosity p-supersolution, one needs to consider space-time boxes instead of balls and use the comparison principle for p-superparabolic and p-subparabolic functions; see [KL]. For the converse, the comparison principle for viscosity solutions is needed (Theorem 4.10 below).

LEMMA 4.6. *Every p-superparabolic function u is a parabolic viscosity p-supersolution.*

Proof. We argue by contradiction and assume that there exist $\varphi \in C^2(\mathcal{O})$ and $r > 0$ such that $u(0,0) = \varphi(0,0)$, $u(x,t) > \varphi(x,t)$ for all $(x,t) \in \mathcal{O} \cap \{t < 0\}$, $\nabla\varphi(x,t) \neq 0$ when $x \neq 0$, and

$$\varphi_t(x,t) - \Delta_p \varphi(x,t) < 0 \tag{4.3}$$

whenever $(x,t) \in Q_r \cup \{x \neq 0\}$, where $Q_r \equiv B_r(0) \times (-r, 0)$. Then for every nonnegative $\phi \in C_0^\infty(Q_r)$, we obtain using (4.3) and Gauss's theorem as in the proof of Lemma 3.4 that

$$\begin{aligned}
&- \iint_{Q_r} |\nabla\varphi|^{p-2} \langle \nabla\varphi, \nabla\phi \rangle \, dx\, dt \\
&= \lim_{\rho \to 0} \left[\iint_{Q_r \setminus \{|x| \leq \rho\}} \phi \left(\Delta_p \varphi \right) \, dx\, dt - \iint_{Q_r \setminus \{|x| \leq \rho\}} \operatorname{div}(\phi |\nabla\varphi|^{p-2} \nabla\varphi) \, dx\, dt \right] \\
&\geq \lim_{\rho \to 0} \left[\iint_{Q_r \setminus \{|x| \leq \rho\}} \phi \varphi_t \, dx\, dt + \int_{-r}^{0} \oint_{|x| = \rho} \phi |\nabla\varphi|^{p-2} \langle \nabla\varphi, \tfrac{x}{\rho} \rangle \, dS\, dt \right] \\
&= - \iint_{Q_r} \phi_t \varphi \, dx\, dt.
\end{aligned}$$

This implies that φ is p-subparabolic in Q_r; see [KL]. To conclude, we proceed as in the elliptic case, and apply the comparison principle for p-superparabolic and p-subparabolic functions from [KL] to the functions u and $\varphi + m$, where

$$m = \inf_{\partial_{par} Q_r} (u - \varphi) > 0.$$

This gives the desired contradiction. □

Due to the fact that the time derivative u_t appears as a linear term in (4.1), Theorem 4.7 below is easier to prove than the elliptic comparison principle, Theorem 2.7. In fact, the nonsingular case $p \geq 2$ follows from a very general result in [C]. Since the basic idea of the proof is quite similar to the one of the elliptic case, we will be somewhat sketchy.

THEOREM 4.7. *Let $\Omega_T = \Omega \times (0, T)$, where $\Omega \subset \mathbb{R}^n$ is a bounded domain, and assume that u is a parabolic viscosity p-subsolution and v is a parabolic viscosity p-supersolution in Ω_T. If $u \leq v$ on the parabolic boundary of Ω_T, then $u \leq v$ in Ω_T.*

Proof. For simplicity, we assume that u is bounded from above and v is bounded from below in $\overline{\Omega} \times [0,T]$. Since the proof is by contradiction, we assume that

$$\sup_{\Omega_T}(u-v) > \sup_{\partial_{par}\Omega_T}(u-v), \tag{4.4}$$

where $\partial_{par}\Omega_T$ denotes the parabolic boundary of Ω_T. By using the standard trick of replacing v by $v(x,t) + \frac{\varepsilon}{T-t}$ for small $\varepsilon > 0$, we may assume that v is a strict supersolution of (4.1) and $v(x,t) \to \infty$ as $t \to T$.

Let (x_j, y_j, t_j, s_j) be a maximum point of

$$w_j(x,y,t,s) = u(x,t) - v(y,s) - \Psi_j(x,y,t,s)$$

relative to $\overline{\Omega} \times \overline{\Omega} \times [0,T]$. Here

$$\Psi_j(x,y,t,s) = \frac{j}{q}|x-y|^q + \frac{j}{2}(t-s)^2, \quad q > \max\left\{\frac{p}{p-1}, 2\right\}.$$

By (4.4) and Proposition 3.7 in [CIL], we have that $(x_j, y_j, t_j, s_j) \in \Omega \times \Omega \times (0,T) \times (0,T)$ for j large enough. We distinguish between two cases.

Case 1. $x_j = y_j$.

By the choice of the point (x_j, y_j, t_j, s_j) we have

$$v(y,s) \geq -\Psi_j(x_j, y, t_j, s) + \Psi_j(x_j, y_j, t_j, s_j) + v(y_j, s_j)$$

for all $(y,s) \in \Omega \times [0,T]$; that is,

$$\phi(y,s) \equiv -\Psi_j(x_j, y, t_j, s) + \Psi_j(x_j, y_j, t_j, s_j) + v(y_j, s_j) - \frac{1}{q+1}|y-y_j|^{q+1}$$

is touching v from below at (y_j, s_j). Since v is a strict supersolution of (4.1) and $x_j = y_j$, we obtain after straightforward computations

$$0 < \frac{\varepsilon}{(T-s_j)^2} \leq \limsup_{\substack{(y,s)\to(y_j,s_j)\\ s<s_j, y\neq y_j}} \Big(\phi_s(y,s) - \Delta_p \phi(y,s)\Big) = j(t_j - s_j). \tag{4.5}$$

Similarly, we see that

$$\theta(x,t) \equiv \Psi_j(x, y_j, t, s_j) - \Psi_j(x_j, y_j, t_j, s_j) + u(x_j, t_j) + \frac{1}{q+1}|x-x_j|^{q+1}$$

is a good test-function for u at the point (x_j, t_j), and hence

$$0 \geq \liminf_{\substack{(x,t)\to(x_j,t_j)\\ t<t_j, x\neq x_j}} \Big(\theta_t(x,t) - \Delta_p \theta(x,t)\Big) = j(t_j - s_j). \tag{4.6}$$

Subtracting (4.6) from (4.5) gives

$$0 < \frac{\varepsilon}{(T-s_j)^2} \leq j(t_j - s_j) - j(t_j - s_j) = 0,$$

which is a contradiction.

Case 2. $x_j \neq y_j$.

As in the elliptic case, we may use the definition with jets. Using the maximum principle for semicontinuous functions and Lemma 3.5 from [OS], we infer that there exist $X_j, Y_j \in S_n$ such that

$$\begin{aligned}(D_t\Psi_j, D_x\Psi_j, X_j) &\in \overline{\mathcal{P}}^{2,+}u(x_j,t_j),\\ (-D_s\Psi_j, -D_y\Psi_j, Y_j) &\in \overline{\mathcal{P}}^{2,-}v(y_j,s_j),\end{aligned}$$

and

$$X_j \leq Y_j. \tag{4.7}$$

Here all the derivatives of Ψ_j are evaluated at the point (x_j, y_j, t_j, s_j). For the definition and properties of the parabolic jets $\mathcal{P}^{2,+}u$ and $\mathcal{P}^{2,-}v$ and their closures, we refer the reader to [C] and [CIL].

Let us now finish the proof. Since u is a subsolution and v is a strict supersolution, we obtain

$$0 < \frac{\varepsilon}{(T-s_j)^2} \leq -D_s\Psi_j + F(-D_y\Psi_j, Y_j) - D_t\Psi_j - F(D_x\Psi_j, X_j) \leq 0,$$

which is a contradiction. Here the last inequality follows from (4.7) after we notice that

$$\begin{aligned}D_t\Psi_j(x,y,t,s) &= -D_s\Psi_j(x,y,t,s),\\ D_x\Psi_j(x,y,t,s) &= -D_y\Psi_j(x,y,t,s),\end{aligned}$$

by the choice of Ψ_j. This shows that (4.4) cannot hold, and we are done. □

Remark 4.8. In [CGG], Chen, Giga, and Goto obtained a general comparison theorem for mean curvature flow-type equations. Those equations are singular at the points where the spatial gradient vanishes, but the nature of the singularity is different from that of the p-parabolic equation. Roughly speaking, the mean curvature flow equation has a bounded discontinuity at the points of singularity, whereas the p-parabolic equation behaves like $O(|\nabla u|^{p-2})$ near those points.

We finish the paper with a brief discussion on another possible definition for viscosity solutions of (4.1) in the singular case $1 < p < 2$. This approach is due to Ishii and Souganidis [IS], and in connection with the p-parabolic equation it has been used by Ohnuma and Sato; cf. [OS].

Let us introduce some notation. We set

$$\mathcal{F} = \Big\{ f \in C^2([0,\infty)) \;\; f(0) = f'(0) = f''(0) = 0,\; f''(r) > 0 \text{ for all } r > 0, \text{ and } \lim_{x\to 0_+}(-\Delta_p f(|x|)) = 0 \Big\}$$

and

$$\Sigma = \Big\{ \sigma \in C^1(\mathbb{R}) \;\; \sigma \text{ is even}, \sigma(0) = \sigma'(0) = 0, \text{ and } \sigma(r) > 0 \text{ for all } r \neq 0 \Big\}.$$

DEFINITION 4.9. *A function $\varphi \in C^2(\mathcal{O})$ is admissible if for any $(\hat{x}, \hat{t}) \in \mathcal{O}$ with $\nabla\varphi(\hat{x}, \hat{t}) = 0$ there are $\delta > 0$, $f \in \mathcal{F}$, and $\sigma \in \Sigma$ such that*

$$|\varphi(x,t) - \varphi(\hat{x},\hat{t}) - \varphi_t(\hat{x},\hat{t})(t-\hat{t})| \leq f(|x-\hat{x}|) + \sigma(t-\hat{t})$$

for all $(x,t) \in B_\delta(\hat{x}) \times (\hat{t}-\delta, \hat{t}+\delta)$.

Notice that if $\nabla\varphi \neq 0$, then φ is automatically admissible. The idea of introducing the admissible class is, roughly speaking, to have a good a priori control on the behavior of a test-function at the singular points. For lack of a better terminology, we call the solutions defined using the class of admissible test-functions relaxed viscosity solutions.

DEFINITION 4.10. *A function $u\ : \mathcal{O} \to \mathbb{R} \cup \{\infty\}$ is a relaxed viscosity p-supersolution if*

(i) *u is lower semicontinuous,*

(ii′) *u is finite in a dense subset of $\mathcal{O}$, and*

(v) *for all admissible $\varphi \in C^2(\mathcal{O})$ and all local minimum points (x,t) of $u-\varphi$ in $\mathcal{O}$*

$$\begin{cases} \varphi_t(x,t) - \Delta_p\varphi(x,t) \geq 0 & \textit{if } \nabla\varphi(x,t) \neq 0, \\ \varphi_t(x,t) \geq 0 & \textit{if } \nabla\varphi(x,t) = 0. \end{cases}$$

We have taken the liberty to modify the definition given in [IS], [OS] in order to make a comparison with Definition 4.3 easier. In particular, the original definition of Ishii and Souganidis was formulated without the semicontinuity assumption (i), and thus it does not imply continuity for the solutions.

LEMMA 4.11. *Every parabolic viscosity p-supersolution is a relaxed viscosity p-supersolution.*

Proof. We argue by contradiction and assume that there exist an admissible test-function $\varphi \in C^2(\mathcal{O})$ and $(x_0,t_0) \in \mathcal{O}$ such that $u-\varphi$ has a local minimum at (x_0,t_0), $\nabla\varphi(x_0,t_0) = 0$, and

$$\varphi_t(x_0,t_0) < 0. \tag{4.8}$$

Let $f \in \mathcal{F}$, $\sigma \in \Sigma$, and $\delta > 0$ be such that

$$|\varphi(x,t) - \varphi(x_0,t_0) - \varphi_t(x_0,t_0)(t-t_0)| \leq f(|x-x_0|) + \sigma(t-t_0) \tag{4.9}$$

for all $(x,t) \in B_\delta(x_0) \times (t_0-\delta, t_0+\delta)$. Following the ideas in [IS], we approximate σ by a sequence $\sigma_k \in C^2(\mathbb{R})$ satisfying

$$\begin{cases} \sigma_k(0) = \sigma_k'(0) = 0 \quad \text{for each } k = 1, 2, \ldots, \\ \sigma_k(r) \to \sigma(r), \ \sigma_k'(r) \to \sigma'(r) \quad \text{locally uniformly,} \end{cases}$$

and we denote

$$\begin{aligned} \phi(x,t) &= u(x_0,t_0) + \varphi_t(x_0,t_0)(t-t_0) - 2f(|x-x_0|) - 2\sigma(t-t_0), \\ \phi_k(x,t) &= u(x_0,t_0) + \varphi_t(x_0,t_0)(t-t_0) - 2f(|x-x_0|) - 2\sigma_k(t-t_0). \end{aligned}$$

Observe that (4.9) implies that $u-\phi$ has a strict local minimum at (x_0,t_0). Since $\sigma_k \to \sigma$ locally uniformly, we can find a sequence $(x_k,t_k) \to (x_0,t_0)$ such that $u-\phi_k$ has a local minimum at (x_k,t_k). Moreover, by modifying ϕ_k if necessary, we may assume that this local minimum is, in fact, strict. Hence ϕ_k can be used as a test-function in Definition 4.3, and we obtain

$$\limsup_{\substack{(x,t)\to(x_k,t_k) \\ t<t_k,\, x\neq x_0}} \Big((\phi_k)_t(x,t) - \Delta_p\phi_k(x,t) \Big) \geq 0$$

for each $k \in \mathbb{N}$. However, a direct computation yields

$$(\phi_k)_t(x,t) - \Delta_p \phi_k(x,t) = \varphi_t(x_0,t_0) - 2\sigma_k'(t-t_0) - 2^{p-1}\Delta_p f(|x-x_0|) < 0$$

if (x,t) is sufficiently close to (x_0,t_0) and $x \neq x_0$. Here we used (4.8), the definition of $\mathcal{F}$, and the fact that $\sigma_k'(0) = 0$. This contradiction shows that the antithesis was wrong, and the lemma is now proved. □

In [OS], Ohnuma and Sato proved a comparison principle for the relaxed viscosity p-supersolutions and subsolutions. In the light of Lemmas 4.6 and 4.11, this means that relaxed viscosity p-supersolutions satisfy (p-iii) in Definition 4.2, and hence they are precisely the parabolic viscosity p-supersolutions.

Acknowledgments. We are grateful to Eero Saksman for pointing out an error in an earlier version of the manuscript. We thank the anonymous referee for the careful reading of the manuscript and useful suggestions and comments.

THE LOCAL BEHAVIOR OF THE SOLUTION OF THE RADIOSITY EQUATION AT THE VERTICES OF POLYHEDRAL DOMAINS IN $\mathbb{R}^3$*

OLAF HANSEN†

Abstract. This article studies the regularity of the solution of the radiosity equation on polyhedral surfaces in $\mathbb{R}^3$. We examine the localized equation near the vertices and characterize the smoothness of its solution in terms of weighted Sobolev spaces. We also consider the effect of shadows and prove local $\mathcal{C}^1$-regularity in the case of a piecewise $\mathcal{C}^1$-emissivity function.

1. Introduction.

In this paper we study the properties of the solution of the radiosity equation over the boundary $S := \partial\Omega$ of a polyhedron $\Omega \subset \mathbb{R}^3$. This implies that the boundary S is a finite union of triangles.

The solution $\overline{u} : S \to \mathbb{R}$ of the radiosity equation describes the outgoing radiation at every point of the surface of S if the emissivity $E : S \to \mathbb{R}$, i.e., the sources of illumination and their brightness, on S is known. A further assumption is that the walls (S) behave like Lambertian diffuse reflectors. For many surfaces, i.e., paper or walls which are not glossy, this assumption is fulfilled. Even if there are mirrors or glossy surfaces, there exists a number of techniques for including their effects on the overall radiosity in a second computational step after the calculation of the radiosity solution; see [5, 20].

If one knows the solution of the radiosity equation and adds the glossy effects, one has the possibility of generating photo-realistic views into Ω, and one can study the appearance of rooms or the effect of different light sources before they are built; see [5, 20].

The radiosity equation is a transport equation, and it is mathematically a second kind of integral equation

$$(I - K)u(x) = E(x), \quad x \in S, \tag{1.1}$$

where the integral operator K is given by

$$(Ku)(x) := \frac{\rho(x)}{\pi} \int_S \beta(x,y) \frac{[\vec{n}_x \cdot (y-x)]\,[\vec{n}_y \cdot (x-y)]}{\|x-y\|^4}\, u(y)\, dy. \tag{1.2}$$

Here β is the visibility function, and ρ, $\rho(x) \in [0,1)$, $x \in S$, describes the reflectivity; see section 2. The vectors $\vec{n}_x$ and $\vec{n}_y$ are the inner normal vectors at point x, and y, $\vec{n}_y$ exist almost everywhere. We will shortly indicate the physical assumptions, which lead to (1.2). First, the radiosity $u : S \longrightarrow \mathbb{R}^+$, which has the physical unit $Watt/m^2$, does not depend on the wavelength, and so one has to solve this equation for different parts of the electromagnetic spectrum if this influence has to be considered. The outgoing radiance (see [12] for an exact definition of the radiance; here we will think

*Received by the editors September 14, 2000; accepted for publication (in revised form) June 8, 2001; published electronically October 11, 2001.
http://www.siam.org/journals/sima/33-3/37810.html

†Johannes Gutenberg–Universität Mainz, Mainz, Germany (hansen@mathematik.uni-mainz.de).

of a flux of radiative power, depending on the direction) at point $y \in S$ in the direction of $x \neq y$, $\vec{n}_y \cdot (x-y) > 0$ is given by

$$\frac{1}{\pi} \frac{[\vec{n}_y \cdot (x-y)]}{\|x-y\|} u(y) = \frac{1}{\pi} \cos(\angle(\vec{n}_y, x-y))\, u(y). \tag{1.3}$$

This very simple relation between the density of emitted power (radiosity) and the directed outgoing power density (radiance) is exactly fulfilled for black bodies. But in the theory of radiative transfer, this relation, known as the Lambertian cosine law, is often used as an approximation for nonblack bodies, so-called diffusive emitters. The factor $1/\pi$ in formula (1.3) is caused by an integration which relates the radiance with the radiosity; see [12, formula (2.8b)]. With respect to the distance r from y the radiance decays like

$$\frac{1}{r^2} \tag{1.4}$$

because of the conservation of energy. To get the power flux at the point x of the surface S we have to multiply the incoming radiance with the cosine of the angle between the surface normal and the direction of the incoming radiation

$$\cos(\angle(\vec{n}_x, y-x)) = \frac{[\vec{n}_x \cdot (y-x)]}{\|x-y\|} \tag{1.5}$$

to get the normal component of the flux. In our model the rays of light propagate along straight lines, so we have only to consider the visible part of the surface S if we calculate the total incoming flux at x

$$\int_S \beta(x,y) \frac{[\vec{n}_x \cdot (y-x)]}{\|x-y\|} \frac{1}{\|x-y\|^2} \frac{[\vec{n}_y \cdot (x-y)]}{\pi \|x-y\|} u(y) ds_y, \tag{1.6}$$

where we used (1.3)–(1.5). For the reflection we again consider the simplest possible case and assume that the fraction $\rho(x)$ of (1.6) is reflected. The reflected power should again be distributed according to the Lambertian cosine law (Lambertian diffuse reflection). So (1.1), written in the form

$$u(x) = E(x) + (Ku)(x), \tag{1.7}$$

states the fact that the radiosity (density of outgoing radiation) $u(x)$ at point x is caused by a source term $E(x)$ and reflected incoming radiation $(Ku)(x)$.

There are already a large number of publications on (1.1) in computer science; see the references in [5, 20]. The two dimensional case (cylindrical surfaces) (1.1) was analyzed by Atkinson [1], and Atkinson and Chandler [2] studied the three dimensional case. Rathsfeld [17] studied the behavior of the solution $\overline{u}$ of (1.1) in the three dimensional case along edges, and Qatanani [16] derived some mathematical properties of (1.1) in the case of smooth boundaries and studied different numerical methods for the two dimensional case. Investigations on different collocation methods for the three dimensional case and their performance can be found in the articles of Atkinson and Chien [3] and Atkinson, Chien, and Seol [4]. The Galerkin method is analyzed in the Master's thesis of Schon [19].

In the present article we follow closely the article of Elschner [8] on the double layer potential over polyhedral surfaces. But our direction is slightly different. Elschner's main result is the Fredholmness and the invertibility of the double layer operator on S. Our situation is different because the visibility function allows a very easy proof of the fact that the operator K of (1.2) is a contraction on $L^2(S)$; see also [16]. This already implies the invertibility of $I - K$, and Elschner's main result for our equation is proved. But we will use Elschner's Mellin transform techniques to study the local behavior of $\overline{u}$ near the vertices. On the other side, the visibility function introduces a number of regularity problems; these will be investigated in section 4.

In section 2 we formulate our problem and show the invertibility of $I - K$ in $L^2(S)$.

In section 3 we follow Elschner's analysis and study the equation and its solution locally near an arbitrary vertex of S. Our first main result is the invertibility of these local operators in a scale of weighted L^2-spaces; see Theorem 3.6. In Theorem 3.6 we describe in three steps a range of weighted L^2-spaces where the local operators are invertible. The explicit calculation of all suitable spaces seems to be impossible (see the formulas (3.32) and (3.34)) because the range depends on the zeros of some transcendental functions, but in the third part of this theorem it becomes clear that it is at least not an empty set. Figure 3 gives some impression of the fitting weights. The next important result in section 3 is the mapping property of the local operators between adjacent faces of S; see Lemmas 3.7–3.9. Again this result is very technical. But Corollary 3.11 shows an application for the case of a convex set Ω and a $\mathcal{C}^\infty$-function $E(x)$. In this case the regularity is close to the regularity results in [8] for the double layer potential. The reason is that for convex regions the visibility function $\beta(\cdot)$ is equal to one, and the local regularity results are not disturbed by nonlocal nonregular contributions. We hope that these two results will lead to error estimates for the boundary element method. The results of this section can also be used to derive the Fredholmness of (1.1), but this is already known from section 2. If the set Ω is not convex, one has to use discontinuity meshing in order to improve the convergence of the boundary element methods; see [10, 11, 9, 7]. But even then it is useful to know how the solution behaves near the lines of "discontinuity," and the present work is one step in this direction.

In section 3 we neglect the influence of the visibility function β. Now in section 4 we study its influence on the right-hand side of the localized equations of section 3. Even if the emissivity function is smooth on the faces of S, the right-hand sides of the local operators need not be smooth. This is a big difference from the case of the double layer potential and is caused by the shadow lines. By cutting down each face of S into smaller triangles we get a $\mathcal{C}^1$-regularity result, Lemma 4.1. In the proof of this lemma it becomes clear how these nonlocal effects create the nonregular contributions. Despite the fact that we have a lot of effects to consider, we try to summarize all contributions for a $\mathcal{C}^1$-function $E(x)$ in Corollary 4.2.

2. The radiosity equation and its localization near the vertices.

We consider a bounded domain $\Omega \subset \mathbb{R}^3$ with boundary $S := \partial\Omega$. The boundary S is assumed to be a polyhedron, and

$$S = \bigcup_{j=1}^{n} \Delta_j, \tag{2.1}$$

where Δ_j, $j = 1(1)n$, are closed triangles with

$$\dot{\Delta}_j \cap \dot{\Delta}_k = \emptyset, \quad j \neq k. \tag{2.2}$$

Here $\dot{\Delta}_j$ denotes the relative interior of Δ_j. We also use the following notation:

$$\dot{S} = \bigcup_{j=1}^{n} \dot{\Delta}_j. \tag{2.3}$$

For $x \in \dot{\Delta}_j$ the inner normal $\vec{n}(x)$ is well defined and by $\mathcal{E}_j$, $j = 1(1)n_E$, respectively, $\mathcal{V}_j$, $j = 1(1)n_V$, we denote the edges, respectively, the vertices of S. For $x \in \dot{\Delta}_j$ and $y \in \dot{\Delta}_k$ the visibility function $\beta(x, y)$ is given by

$$\beta(x,y) := \begin{cases} 1, & \{\lambda x + (1-\lambda)y \mid \lambda \in (0,1)\} \cap S = \emptyset \ \wedge \vec{n}(x) \cdot \vec{n}(y) < 0, \\ 0 & \text{otherwise.} \end{cases} \tag{2.4}$$

For the reflectivity function ρ we assume

$$\rho(x)|_{\Delta_j} = \rho_j \in [0, 1), \quad j = 1(1)n, \tag{2.5}$$

and at the beginning our assumption on the emissivity is

$$E \in L^2(S). \tag{2.6}$$

Now we can formulate the radiosity equation as

$$(I - K)u(x) = E(x), \qquad x \in S, \tag{2.7}$$

with the integral operator K given by

$$(Ku)(x) = \frac{\rho(x)}{\pi} \int_S \beta(x,y) \frac{[\vec{n}(x) \cdot (y-x)]\,[\vec{n}(y) \cdot (x-y)]}{\|x-y\|^4} u(y)dy. \tag{2.8}$$

Remark.

1. In the integration over S in (2.8) and in (2.7) we neglect the sets $\cup_{j=1}^{n_E} \mathcal{E}_j$ and $\cup_{j=1}^{n_V} \mathcal{V}_j$ which are of measure zero.

2. We can relax the assumptions on S. It is sufficient if S is the finite union of triangles (not necessary bounded) and on every triangle Δ_j there is a well defined normal $\vec{n}_j$. But we then also have to allow that pairs of triangles, for example Δ_j and Δ_{j+1}, are the same, because then we have to consider both sides and normals of every triangle.

A well-known fact for the radiosity equation is the following lemma.

LEMMA 2.1. *For $x \in \dot{S}$ we have*

$$(Ke)(x) = \rho(x) \ < \ 1, \tag{2.9}$$

where $e(x) = 1$, $x \in S$, is the unity function.

Proof. We will prove (2.9) for the case of a polyhedral surface S. The idea follows [5], and similar proofs can be found in [17] and [16].

Let $x \in \Delta_{j_0}$, and denote

$$\Delta_j(x) := \{y \in \Delta_j \mid \beta(x,y) = 1\},$$
$$S(x) := \bigcup_{j=1}^{n} \Delta_j(x).$$

We remark that each $\Delta_j(x)$ is a finite collection of smaller triangles because only the shadows of some other triangles are subtracted. This implies

$$S(x) = \bigcup_{j=1}^{\widetilde{n}} \delta_j(x),$$

with $\delta_j(x)$ a triangle for each j. The right-hand side of (2.8) can now be written in the following way:

$$\begin{aligned}
&\frac{\rho(x)}{\pi} \int_S \beta(x,y) \frac{[\vec{n}(x) \cdot (y-x)]\,[\vec{n}(y) \cdot (x-y)]}{\|x-y\|^4} dy \\
&= \frac{\rho(x)}{\pi} \int_{S(x)} \frac{[\vec{n}(x) \cdot (y-x)]\,[\vec{n}(y) \cdot (x-y)]}{\|x-y\|^4} dy \\
&= \frac{\rho(x)}{\pi} \sum_{j=1}^{\widetilde{n}} \int_{\delta_j(x)} \frac{[\vec{n}(x) \cdot (y-x)]\,[\vec{n}(y) \cdot (x-y)]}{\|x-y\|^4} dy.
\end{aligned}$$

Choose $\varepsilon > 0$ such that

$$\varepsilon < \min \left\{ \operatorname{dist}(x, \partial \Delta_{j_0}), \min_{j \neq j_0} \operatorname{dist}(x, \Delta_j) \right\}.$$

We assume that $x = 0$, $\Delta_{j_0} \subset \{(\xi_1, \xi_2, \xi_3) \,|\, \xi_3 = 0\}$, and we denote by

$$\partial B_\varepsilon^+(0) := \{(\xi_1, \xi_2, \xi_3) \,|\, \xi_1^2 + \xi_2^2 + \xi_3^2 = \varepsilon^2,\ \xi_3 \geq 0\}$$

the upper part of the sphere with radius ε. We further call $\widetilde{\delta}_j(x)$ the projection of $\delta_j(x)$ on $\partial B_\varepsilon^+(0)$,

$$\widetilde{\delta}_j(x) := \left\{ \varepsilon \frac{x}{\|x\|} \,|\, x \in \delta_j(x) \right\},$$

and $W_j(x)$ is the volume between these two surfaces (see Figure 1),

$$W_j(x) := \left\{ \lambda \frac{x}{\|x\|} \,|\, \lambda \in [\varepsilon, \|x\|],\ x \in \delta_j(x) \right\}.$$

We define

$$f(y) := \frac{\vec{n}(x) \cdot (y-x)}{\|x-y\|^4} (x-y)$$

and get by a short calculation

$$\operatorname{div}(f) = 0.$$

The Gaussian divergence theorem implies

$$\begin{aligned}
0 &= \int_{W_j(x)} \operatorname{div} f(y) dV(y) \\
&= \int_{\partial W_j(x)} f(y) \cdot \widetilde{\vec{n}}(y) dy \qquad \widetilde{\vec{n}} \text{ outer normal} \\
&= -\int_{\delta_j(x)} \frac{[\vec{n}(x) \cdot (y-x)]\,[\vec{n}(y) \cdot (x-y)]}{\|x-y\|^4} dy - \int_{\widetilde{\delta}_j(x)} \frac{[\vec{n}(x) \cdot (y-x)]\,[\vec{n}(y) \cdot (x-y)]}{\|x-y\|^4} dy.
\end{aligned}$$

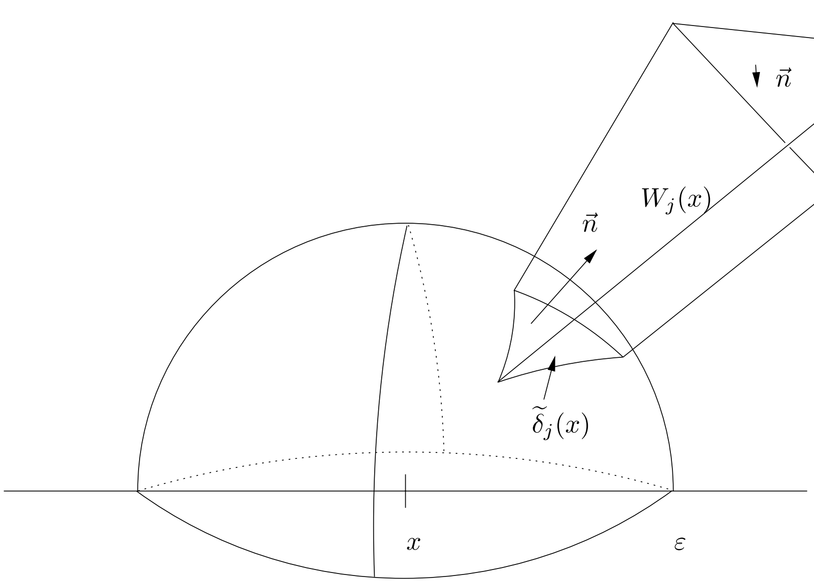

FIG. 1.

So we get

$$\int_{\delta_j(x)} \frac{[\vec{n}(x)\cdot(y-x)]\,[\vec{n}(y)\cdot(x-y)]}{\|x-y\|^4}dy = -\int_{\widetilde{\delta}_j(x)} \frac{[\vec{n}(x)\cdot(y-x)]\,[\vec{n}(y)\cdot(x-y)]}{\|x-y\|^4}dy$$

and finally

$$\begin{aligned} &\frac{\rho(x)}{\pi}\int_S \beta(x,y)\frac{[\vec{n}(x)\cdot(y-x)]\,[\vec{n}(y)\cdot(x-y)]}{\|x-y\|^4}dy \\ &= -\frac{\rho(x)}{\pi}\sum_{j=1}^{\widetilde{n}}\int_{\widetilde{\delta}_j(x)} \frac{[\vec{n}(x)\cdot(y-x)]\,[\vec{n}(y)\cdot(x-y)]}{\|x-y\|^4}dy \\ &= -\frac{\rho(x)}{\pi}\int_{\partial B_\varepsilon^+(0)} \frac{[\vec{n}(x)\cdot(y-x)]\,[\vec{n}(y)\cdot(x-y)]}{\|x-y\|^4}dy \\ &=: A(x), \end{aligned} \tag{2.10}$$

because the surface S is closed and in every direction of the upper half plane we meet the visible surface exactly one time. We neglect again sets of measure zero and remember $x = 0$, $\vec{n}(x) = (0,0,1)$, $\vec{n}(y) = y/\varepsilon$, $\|x-y\| = \varepsilon$. This gives us

$$\begin{aligned} A(x) &= -\frac{\rho(x)}{\pi}\int_0^{\pi/2}\int_0^{2\pi} \frac{\varepsilon\cos(\vartheta)(-1/\varepsilon)\varepsilon^2}{\varepsilon^4}\varepsilon\sin(\vartheta)d\varphi\,\varepsilon\,d\vartheta \\ &= \rho(x) \end{aligned}$$

and proves our result. □

Remark. The above proof shows that we get

$$(Ke)(x) \le \rho(x), \qquad x \in \dot{S}, \tag{2.11}$$

in the case in which S is not a closed surface. Then in (2.10) we get "$\leq$" instead of "$=$," because there may be a set of directions with measure greater than zero where x sees no part of S. One also has to consider the fact that the kernel function in (2.10) is positive.

We can copy the proof of [16, Lemma 2.3] and get the following theorem.

Theorem 2.2. *There exists a constant* $q_K < 1$,

$$q_K := \max_{j=1}^{n} \rho(x) \tag{2.12}$$

(see (2.5)*), such that*

$$\|K\|_{L^2(S)\to L^2(S)} \leq q_K. \tag{2.13}$$

The fixed point theorem of Banach shows the following corollary.

Corollary 2.3. *Equation* (2.7) *has exactly one solution* $\overline{u} \in L^2(S)$, *and for* $u_0 \in L^2(S)$ *the series* $(u_j)_{j\in\mathbb{N}}$ *given by*

$$u_j := E + Ku_{j-1}, \quad j \in \mathbb{N}, \tag{2.14}$$

converges linearly to $\overline{u}$.

We remark here that (2.14) is also of practical importance because it is used in computer graphics [5, 20] to solve (2.7) approximately. But then the function space $L^2(S)$ in (2.14) has to be replaced by some finite dimensional subspace.

The proper choice of these finite dimensional subspaces depends heavily on the smoothness of the solution $\overline{u}$. There are several reasons for the nonsmoothness of the solution $\overline{u}$. If the emissivity function is not smooth, along a line, for example, then $\overline{u}$ will also not be smooth along this line in general. This kind of singularity is very easy to handle because the right-hand side E of (2.7) is given and normally one knows its properties. The next reason is due to the visibility function; the solution along shadow lines may have some singularities. In section 4 we will study this effect in our context. Finally, along edges and near vertices, the smoothness of $\overline{u}$ is also not clear. The behavior of $\overline{u}$ along edges was studied in [17], and in the following section we will analyze the behavior of $\overline{u}$ near the vertices.

We choose one fixed vertex $\mathcal{V}_{j_0}$, $j_0 \in \{1, \dots, n_V\}$, and for simplicity we also assume

$$\mathcal{V}_{j_0} = 0. \tag{2.15}$$

For the localization we choose a function $\varphi \in \mathcal{C}^\infty(\mathbb{R}^3)$, $\varphi(x) \in [0,1]$, $x \in \mathbb{R}^3$, and

$$\varphi(x) = \begin{cases} 1, & \|x\| \leq \varepsilon, \\ 0, & \|x\| \geq 2\varepsilon, \end{cases} \tag{2.16}$$

where $\varepsilon > 0$ is so small that

$$\mathcal{V}_j \notin B_{3\varepsilon}(0), \quad j \neq j_0. \tag{2.17}$$

We get

$$\begin{aligned}[(1-\varphi+\varphi)\overline{u}](x) &= [(1-\varphi)+\varphi]K[[(1-\varphi)+\varphi]\overline{u}](x) + E(x) \\ &= [\varphi K\varphi\overline{u}](x) + [\varphi K(1-\varphi)\overline{u}](x) + [(1-\varphi)K\overline{u}](x) + E(x),\end{aligned}$$

and for $x \in B_\varepsilon(0)$ we have

$$(\varphi\overline{u})(x) = K(\varphi\overline{u})(x) + [K(1-\varphi)\overline{u}](x) + E(x). \tag{2.18}$$

From now on we assume, without loss of generality, that $\varepsilon = 1$; and by $\gamma = \gamma_{j_0}$ we denote

$$\gamma := S \cap \partial B_1(0), \tag{2.19}$$

with γ as a spherical polygon. The infinite polyhedral cone $\Gamma := \Gamma_{j_0}$ is defined by

$$\Gamma := \{r\omega \,|\, \omega \in \gamma,\ r \geq 0\}, \tag{2.20}$$

and the operator $\widetilde{K}$ on Γ is defined by

$$(\widetilde{K}u)(x) := \frac{\widetilde{\rho}(x)}{\pi} \int_\Gamma \beta(x,y) \frac{[\vec{n}(x)\cdot(y-x)]\,[\vec{n}(y)\cdot(x-y)]}{\|x-y\|^4} u(y)dy, \tag{2.21}$$

$u \in L^2(\Gamma)$ (in the next section we will see that $\widetilde{K}$ is well defined), $\widetilde{\rho}(x) := \rho(x/\|x\|)$, $x \neq 0$, and β is defined corresponding to (2.4).

By $\widetilde{u}$ and $\widetilde{E}$ we denote the extension by zero of the functions $\psi\overline{u}$ and ψE to Γ, where

$$\psi(x) := \varphi(3x), \tag{2.22}$$

$\text{supp}(\psi) \subset B_{2/3}(0)$. After some calculations we get

$$\begin{aligned}(I-\widetilde{K})\widetilde{u} &= \widetilde{E} + \psi K(1-\varphi)\overline{u} + (\psi\widetilde{K} - \widetilde{K}\psi)(\varphi\overline{u})\\ &=: f_1 + f_2 + f_3.\end{aligned} \tag{2.23}$$

We will study the equation

$$(I-\widetilde{K})v(x) = f(x), \quad x \in \Gamma, \tag{2.24}$$

in section 3, where we assume that f is sufficiently smooth. In section 4 we take a closer look at the functions f_2 and f_3 and recall some results of Rathsfeld [17].

3. The radiosity equation on an infinite polyhedral cone. Here we study (2.24), $\widetilde{K}$ given by (2.21), on the cone Γ of (2.20).

We assume that $(0,0,1)$ is a corner of the spherical polygon γ of (2.19), and we denote by F_1 and F_2 the two faces of Γ adjacent to edge $E_1 = \{(0,0,t)|t \geq 0\}$. After a suitable rotation, F_1 and F_2 have the following representation (see Figure 2):

$$\left\{\begin{aligned} F_1 &= \left\{ r\begin{pmatrix}\sin(\delta)\\ 0\\ \cos(\delta)\end{pmatrix} \,|\, \delta \in [0,\delta_1], \quad r \geq 0\right\},\\ F_2 &= \left\{ r\begin{pmatrix}\cos(\alpha)\sin(\delta)\\ \sin(\alpha)\sin(\delta)\\ \cos(\delta)\end{pmatrix} \,|\, \delta \in [0,\delta_2], \quad r \geq 0\right\}\end{aligned}\right. \tag{3.1}$$

with normals

$$\vec{n}_1 = \begin{pmatrix}0\\1\\0\end{pmatrix}, \quad \vec{n}_2 = \begin{pmatrix}\sin(\alpha)\\ -\cos(\alpha)\\ 0\end{pmatrix}. \tag{3.2}$$

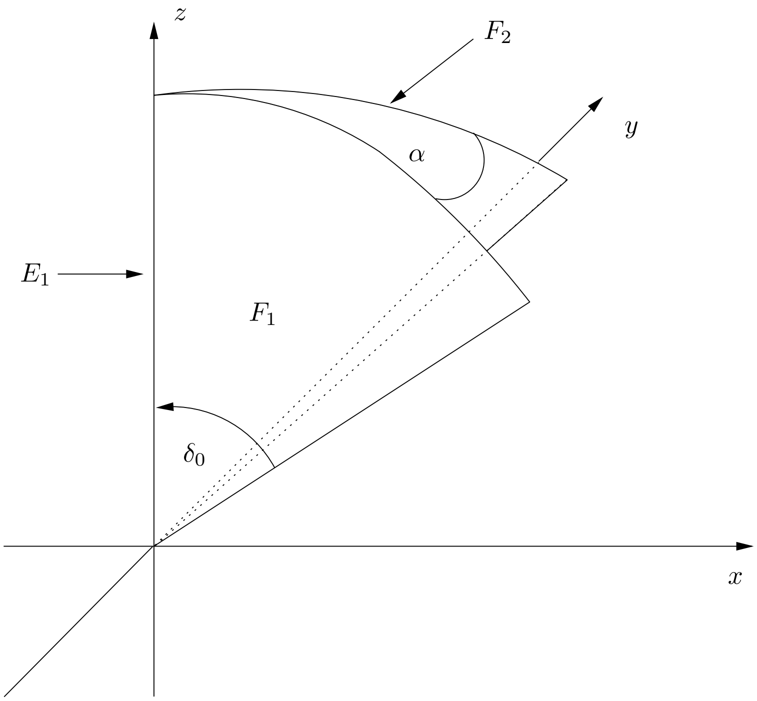

FIG. 2. *The two faces adjacent to edge E_1.*

Here $\alpha < \pi$ is the angle between F_1 and F_2. For $\alpha \geq \pi$ there would be no interaction between F_1 and F_2. We study the solution only local to the edge E_1, and so we assume $\delta_1 = \delta_2 = \delta_0 < \pi/2$. Further, δ_0 should be sufficiently small in order to guarantee that each part of F_1 can "see" each part of F_2. *This means that no occlusion occurs, and for the rest of this section we assume $\beta(x, y) = 1$.* Using the local coordinates from (3.1) and the notation $u_1 := v|_{F_1}$, respectively, $u_2 := v|_{F_2}$, we can rewrite (2.24) as

$$\text{(3.3)} \qquad \left\{ \begin{array}{lcl} u_1(r,\delta) - \dfrac{\rho_1}{\pi} \displaystyle\int_0^\infty \int_0^{\delta_0} k_1(r,\delta,r',\delta') u_2(r',\delta') d\delta' \, dr' & = & f_1(r,\delta), \\ u_2(r,\delta) - \dfrac{\rho_2}{\pi} \displaystyle\int_0^\infty \int_0^{\delta_0} k_1(r,\delta,r',\delta') u_1(r',\delta') d\delta' \, dr' & = & f_2(r,\delta) \end{array} \right.$$

with k_1 given by

$$\text{(3.4)} \qquad k_1(r,\delta,r',\delta') := \frac{\sin(\alpha)^2 \sin(\delta) \sin(\delta') r r'^2}{(r'^2 - 2\omega(\delta,\delta') r r' + r^2)^2},$$

and

$$\text{(3.5)} \qquad \omega(\delta,\delta') := \cos(\alpha)\sin(\delta)\sin(\delta') + \cos(\delta)\cos(\delta')$$

is the cosine of the angle between

$$\begin{pmatrix} \sin(\delta) \\ 0 \\ \cos(\delta) \end{pmatrix} \text{ and } \begin{pmatrix} \cos(\alpha)\sin(\delta') \\ \sin(\alpha)\sin(\delta') \\ \cos(\delta') \end{pmatrix}.$$

We also assume that the reflectivity functions ρ_1 and ρ_2 are constant on F_1, respectively, F_2. We will later often use the fact

$$\omega(\delta, \delta') \in [0, 1], \quad \delta \in [0, \delta_0], \tag{3.6}$$

where we used $\delta_0 < \pi/2$. We remark that the functions f_1 and f_2 also include the contributions of the integral over other parts of Γ. Using the new functions

$$v_1 := \frac{u_1 - \sqrt{\rho_1/\rho_2}u_2}{2} \text{ and } v_2 := \frac{u_1 + \sqrt{\rho_1/\rho_2}u_2}{2} \tag{3.7}$$

and multiplying (3.3) by the invertible matrix

$$\frac{1}{2}\begin{pmatrix} 1 & -\sqrt{\rho_1/\rho_2} \\ 1 & \sqrt{\rho_1/\rho_2} \end{pmatrix},$$

we see that (3.3) is equivalent to

$$\left.\begin{array}{rcl} v_1 - \overline{K}v_1 & = & \frac{1}{2}(f_1 - \sqrt{\rho_1/\rho_2}f_2) \\ v_2 - \overline{K}v_2 & = & \frac{1}{2}(f_1 + \sqrt{\rho_1/\rho_2}f_2) \end{array}\right\}, \tag{3.8}$$

where the integral operator $\overline{K}$ on $[0, \infty) \times [0, \delta_0]$ is given by

$$(\overline{K}v)(r, \delta) := \int_0^\infty \int_0^{\delta_0} \overline{k}(r, \delta, r', \delta')v(r', \delta')d\delta'\, dr', \tag{3.9}$$

and the kernel

$$\begin{aligned} \overline{k}(r, \delta, r', \delta') &:= \frac{\sqrt{\rho_1\rho_2}}{\pi} \frac{\sin(\alpha)^2 \sin(\delta) \sin(\delta')rr'^2}{(r'^2 - 2\omega(\delta, \delta')rr' + r^2)^2} \qquad (3.10) \\ &= \frac{\sqrt{\rho_1\rho_2}}{\pi} \sin(\alpha)^2 \frac{\sin(\delta) \sin(\delta')(r/r')}{((r/r')^2 - 2\omega(\delta, \delta')(r/r') + 1)^2} \frac{1}{r'} \\ &=: \overline{k}_1(\delta, \delta', r/r') \, \frac{1}{r'}. \qquad (3.11) \end{aligned}$$

For suitable v (for example, $v \in \mathcal{C}_0^\infty$) we can now write the integral operator $\overline{K}$ as a Mellin convolution operator with an operator valued kernel:

$$(\overline{K}v)(r, \delta) = \int_0^\infty \left(\int_0^{\delta_0} \overline{k}_1(\delta, \delta', r/r')v(r', \delta')d\delta' \right) \frac{dr'}{r'}. \tag{3.12}$$

Because the Mellin convolution is diagonalized by the Mellin transform $\mathcal{M}$, it is now natural to apply the Mellin transform with respect to r to the operator $\overline{K}$.

We summarize the definition and some properties of the Mellin transform $\mathcal{M}$:

$$(\mathcal{M}v)(z) := \int_0^\infty t^{z-1}v(t)\, dt; \tag{3.13}$$

see [13]. If we introduce the weighted L^2-space $L^2_\nu([0, \infty))$ with

$$\|v\|_{L^2_\nu} := \left(\int_0^\infty \left|t^{-\nu}v(t)\right|^2 dt \right)^{1/2}, \tag{3.14}$$

then we get that the function

$$x \longrightarrow (\mathcal{M}v)\left(\frac{1}{2} - \nu + ix\right), \quad v \in L^2_\nu([0,\infty)), \tag{3.15}$$

is well defined and $(\mathcal{M}v)(1/2 - \nu + i\cdot) \in L^2(\mathbb{R})$. We denote the mapping

$$v(x) \longrightarrow (\mathcal{M}v)\left(\frac{1}{2} - \nu + ix\right), \quad x \in \mathbb{R}, \tag{3.16}$$

by $\mathcal{M}_{Re(z)=1/2-\nu}$ and keep in mind

$$\mathcal{M}_{Re(z)=1/2-\nu} : \; L^2_\nu([0,\infty)) \xrightarrow{1:1} L^2(\mathbb{R}); \tag{3.17}$$

see [13, Theorem 3.2], where the restriction $\nu \le 1/2$ is caused by his definition of his set $\mathcal{E}$. We apply this Mellin transform to the operator $\overline{K}$ with respect to r and get

$$\begin{aligned} \mathcal{M}(\overline{K}v)(z,\delta) \; &= \int_0^{\delta_0} [\mathcal{M}\overline{k}_1(\delta,\delta',\cdot)](z)[\mathcal{M}v](z,\delta')d\delta' \\ &=: [\mathcal{A}(z)(\mathcal{M}v)(z)](\delta). \end{aligned} \tag{3.18}$$

This means that we get for all z in some area of the complex domain an integral operator $\mathcal{A}(z)$ on the interval $[0,\delta_0]$ with kernel

$$\left\{ \begin{array}{lcl} \overline{k}(z,\delta,\delta') & := & \dfrac{\sqrt{\rho_1\rho_2}}{\pi}\sin(\alpha)^2\sin(\delta)\sin(\delta')\kappa(z,\delta,\delta'), \\ \kappa(z,\delta,\delta') & := & (1-\omega(\delta,\delta'))^{-3/2}\kappa_1(z,\delta,\delta'), \\ \kappa_1(z,\delta,\delta') & := & 2^{3/2}B(1+z,3-z)\,{}_2F_1\left(\dfrac{3}{2}-z, z-\dfrac{1}{2}, \dfrac{5}{2}, \dfrac{1+\omega(\delta,\delta')}{2}\right). \end{array} \right. \tag{3.19}$$

Here B is the Beta function, and ${}_2F_1$ is the hypergeometric function; see [15]. Formula (3.19) follows from the integral table in [14, p. 310, formula 22], where the exponent $\nu - 0.5$ is corrected to $0.5 - \nu$. The above formula is correct for all $z \in \Sigma_{-1,3}$,

$$\Sigma_{\alpha,\beta} := \{z \in \mathbb{C} |\, \alpha < \mathrm{Re}(z) < \beta\}, \quad \alpha < \beta, \quad \alpha,\beta \in \mathbb{R}. \tag{3.20}$$

To analyze this operator we first estimate the function κ_1.

LEMMA 3.1. *The function $\kappa_1(z,\delta,\delta')$ is holomorphic in the strip $\Sigma_{-1,3}$. We have*

$$|\kappa_1(z,\delta,\delta')| \le \kappa_1(\mathrm{Re}(z),\delta,\delta'),$$

and for $s \in [-0.5, 2.5]$

$$0 \;\le\; \kappa_1(s,\delta,\delta') \le \left\{ \begin{array}{ll} \frac{\sqrt{2}}{8}\pi, & s \in [0.5, 1.5], \\ \frac{\sqrt{2}}{3}\Gamma(s+1)\Gamma(3-s), & s \in [-0.5, 0.5] \cup [1.5, 2.5]. \end{array} \right.$$

Proof. We have

$$\kappa(z,\delta,\delta') = \int_0^\infty \frac{t^{z-1}t}{(1-2\omega(\delta,\delta')+t^2)^2}dt.$$

This implies the following.

1. The function $\kappa(z)$ is holomorphic in $\Sigma_{-1,3}$ because of the convergence of the integral in this domain.

2.

$$\begin{aligned}|\kappa_1(z,\delta,\delta')| &\le (1-\omega(\delta,\delta'))^{3/2}\int_0^\infty \frac{|t^z|}{(1-2\omega(\delta,\delta')t+t^2)^2}dt\\ &= (1-\omega(\delta,\delta'))^{3/2}\int_0^\infty \frac{t^{\mathrm{Re}(z)}}{(1-2\omega(\delta,\delta')t+t^2)^2}dt\\ &= \kappa_1(\mathrm{Re}(z),\delta,\delta').\end{aligned}$$

For all $z \in \mathbb{C}$ we have

$$\mathrm{Re}\left(\frac{5}{2}-\left(\frac{3}{2}-z\right)-\left(z-\frac{1}{2}\right)\right) = \mathrm{Re}\left(\frac{3}{2}\right) \ > \ 0.$$

It is known from [21] that the following limit exists:

$$\lim_{w\to 1-} {}_2F_1(3/2-z, z-1/2, 5/2, w) = \frac{\Gamma(5/2)\Gamma(3/2)}{\Gamma(1+z)\Gamma(3-z)}.$$

By definition (see also [21])

$${}_2F_1(3/2-z,z-1/2,5/2,w) = \sum_{j=0}^\infty \underbrace{\frac{(3/2-z)_j(z-1/2)_j}{(5/2)_j j!}}_{=:a_j(z)} w^j.$$

If $s \in [1/2, 3/2]$, we get $a_j(s) \ge 0$. This implies that ${}_2F_1(3/2-s, s-1/2, 5/2, w)$ is monotone increasing with respect to w. By (3.6) we know

$$\frac{1+\omega(\delta,\delta')}{2} \in [1/2,1] \quad \forall \delta,\delta'.$$

So we estimate

$$\begin{aligned}\kappa_1(s,\delta,\delta') &\le 2^{3/2}B(1+s,3-s)_2F_1(3/2-s,s-1/2,5/2,1)\\ &= 2^{3/2}\frac{\Gamma(1+s)\Gamma(3-s)}{\Gamma(4)}\frac{\Gamma(5/2)\Gamma(3/2)}{\Gamma(1+s)\Gamma(3-s)}\\ &= 2^{3/2}\frac{1}{3!}\frac{3}{2}\Gamma(3/2)^2\\ &= \sqrt{2}\frac{\pi}{8}.\end{aligned}$$

If $s \in [-1/2, 1/2]$, we have

$$\begin{aligned}(s-1/2)_j &\le 0, \quad j \ge 1,\\ (3/2-s)_j &> 0, \quad j \ge 1,\\ \Longrightarrow a_j(s) &\le 0, \quad j \ge 1.\end{aligned}$$

So ${}_2F_1(3/2-s, s-1/2, 5/2, w)$ is monotone decreasing in w, and finally,

$$\begin{aligned}\kappa_1(s,\delta,\delta') &\le 2^{3/2}B(1+s,3-s)_2F_1(3/2-s,s-1/2,5/2,0)\\ &= 2^{3/2}\frac{\Gamma(1+s)\Gamma(3-s)}{\Gamma(4)}\,1\\ &= \frac{\sqrt{2}}{3}\Gamma(1+s)\Gamma(3-s).\end{aligned}$$

If $s \in [3/2, 5/2]$, it follows that

$$\begin{aligned}(s-1/2)_j &\geq 0, \quad j \geq 1,\\ (3/2-s)_j &\leq 0, \quad j \geq 1,\end{aligned}$$

and, similar to the above, we can estimate

$$\kappa_1(s,\delta,\delta') \leq \frac{\sqrt{2}}{3}\Gamma(1+s)\Gamma(3-s).$$

Now we have proved our estimates. □

In the proof we saw that it is sufficient to estimate ${}_2F_1(3/2-z, z-1/2, 5/2, w)$ in the vicinity of $w=1$. This proves the following corollary.

Corollary 3.2. *Let $\varepsilon, \varepsilon' > 0$. Then we get*

$$|\kappa_1(z,\delta,\delta')| \leq \frac{\sqrt{2}}{8}\pi + \varepsilon', \tag{3.21}$$

$z \in [-1+\varepsilon, 3-\varepsilon]$, $\delta, \delta' \in [0, \delta_0(\varepsilon,\varepsilon')]$, if $\delta_0(\varepsilon,\varepsilon')$ is sufficiently small.

Our next step is the study of the z-independent part of the integral operator $\mathcal{A}(z)$. We denote this operator by $\mathcal{B}$:

$$(\mathcal{B}v)(\delta) := \frac{\sqrt{\rho_1\rho_2}}{\pi}\sin(\alpha)^2\int_0^{\delta_0}\frac{\sin(\delta)\sin(\delta')}{(1-\omega(\delta,\delta'))^{3/2}}v(\delta')d\delta'. \tag{3.22}$$

The next lemma shows that $\mathcal{B}$ is closely connected to a Mellin operator (see also the proof of Theorem 2.1 in [8]).

Lemma 3.3. *We have*

$$\mathcal{B} = T_2^{-1} \circ T_1^{-1} \circ \mathcal{B}_2 \circ T_1 \circ T_2,$$

where $\mathcal{B}_2$ is a finite Mellin convolution on $[0, \vartheta_0]$, $\vartheta_0 := \tan(\delta_0/2)$,

$$(\mathcal{B}_2 w)(\vartheta) := \int_0^{\vartheta_0} l_2(\vartheta/\vartheta')w(\vartheta')\frac{d\vartheta'}{\vartheta'}, \tag{3.23}$$

and

$$l_2(t) := 2^{3/2}\frac{\sqrt{\rho_1\rho_2}}{\pi}\sin(\alpha)^2\frac{t}{(1-2\cos(\alpha)t+t^2)^{3/2}}. \tag{3.24}$$

The invertible operators T_1 and T_2 are given by

$$T_1 : L^2_\nu([0,\delta_0]) \longrightarrow L^2_\nu([0,\delta_0]), (T_1 v)(\delta) := v(\delta)/\cos(\delta/2) \tag{3.25}$$

and

$$T_2 : L^2_\nu([0,\delta_0]) \longrightarrow L^2_\nu([0,\vartheta_0]), (T_2 v)(\vartheta) := v(2\text{arctan}(\vartheta)). \tag{3.26}$$

Proof. In formula (3.22) we use the addition theorems for sine and cosine and get the following expressions for the numerator, respectively, the denominator, under the integral sign:

$$\begin{aligned}\sin(\delta)\sin(\delta') &= 4\sin(\delta/2)\sin(\delta'/2)\cos(\delta/2)\cos(\delta'/2),\\ 1-\omega(\delta,\delta') &= 2\cos(\delta/2)^2\sin(\delta'/2)^2 + 2\sin(\delta/2)^2\cos(\delta'/2)^2\\ &\quad - 4\cos(\alpha)\sin(\delta/2)\sin(\delta'/2)\cos(\delta/2)\cos(\delta'/2).\end{aligned}$$

Substituting this in (3.22) gives

$$\begin{aligned}
&\mathcal{B}w(\delta)\\
&= \sqrt{2}\frac{\sqrt{\rho_1\rho_2}}{\pi}\sin(\alpha)^2\frac{1}{\cos(\delta/2)}\int_0^{\delta_0}\frac{\tan(\delta/2)\tan(\delta'/2)}{(\tan(\delta/2)^2+\tan(\delta'/2)^2-2\cos(\alpha)\tan(\delta/2)\tan(\delta'/2))^{3/2}}\\
&\qquad\qquad\times\cos(\delta'/2)w(\delta')\frac{d\delta'}{\cos(\delta'/2)^2}\\
&= (T_1^{-1}\circ\mathcal{B}_1\circ T_1)w(\delta)
\end{aligned}$$

with T_1 defined in (3.25) and $\mathcal{B}_1$ defined according to

$$\begin{aligned}
&(\mathcal{B})_1 w(\delta)\\
&\quad := \sqrt{2}\frac{\sqrt{\rho_1\rho_2}}{\pi}\sin(\alpha)^2\int_0^{\delta_0}\frac{\tan(\delta/2)\tan(\delta'/2)}{(\tan(\delta/2)^2+\tan(\delta'/2)^2-2\cos(\alpha)\tan(\delta/2)\tan(\delta'/2))^{3/2}}\\
&\qquad\qquad\times w(\delta')\frac{d\delta'}{\cos(\delta'/2)^2}.
\end{aligned}$$

Substituting $\vartheta := \tan(\delta/2)$, respectively, $\vartheta' := \tan(\delta'/2)$, which implies

$$d\vartheta' = \frac{1}{2}\frac{1}{\cos(\delta'/2)^2}d\delta',$$

shows

$$\begin{aligned}
&\mathcal{B}_1 w(2\mathrm{arctan}(\vartheta))\\
&\quad = 2^{3/2}\frac{\sqrt{\rho_1\rho_2}}{\pi}\sin(\alpha)^2\int_0^{\vartheta_0}\frac{\vartheta\vartheta'}{(\vartheta^2+\vartheta'^2-2\cos(\alpha)\vartheta\vartheta')^{3/2}}w(2\mathrm{arctan}(\vartheta'))d\vartheta'\\
&\quad = 2^{3/2}\frac{\sqrt{\rho_1\rho_2}}{\pi}\sin(\alpha)^2\int_0^{\vartheta_0}\frac{\vartheta/\vartheta'}{((\vartheta/\vartheta')^2+1-2\cos(\alpha)\vartheta/\vartheta')^{3/2}}w(2\mathrm{arctan}(\vartheta'))\frac{d\vartheta'}{\vartheta'}.
\end{aligned}$$

The last equation implies

$$T_2\circ\mathcal{B}_1 = \mathcal{B}_2\circ T_2.$$

This proves the representation formula for $\mathcal{B}$, formula (3.23), and the invertibility of T_1 and T_2 is clear because of $\delta_0 < \pi/2$. □

Now we will give estimates for the operators in Lemma 3.3 to finally get a bound for the operator norm of $\mathcal{A}(z)$.

LEMMA 3.4. *The operators T_1 and T_2 and their inverses are continuous and fulfill the following estimates:*

$$(3.27)\quad \begin{cases} \|T_1\| \;\leq\; \dfrac{1}{\cos(\delta_0/2)}, & \|T_2\| \;\leq\; \dfrac{1}{\sqrt{2}\cos(\delta_0/2)}\max\limits_{\delta\in[0,\delta_0]}\left(\dfrac{\tan(\delta/2)}{\delta}\right)^{-\nu},\\[2ex] \|T_1^{-1}\| \;\leq\; 1, & \|T_2^{-1}\| \;\leq\; \sqrt{\dfrac{2^{1-2\nu}}{1+\vartheta_0^2}\max\limits_{\vartheta\in[0,\vartheta_0]}\left(\dfrac{\mathrm{arctan}(\vartheta)}{\vartheta}\right)^{-\nu}}. \end{cases}$$

Here we omit the domain of definition and the range of the operators.

Proof. The calculation of all of the above bounds is straightforward, and we give only the proof for $\|T_2\|_{L^2_\nu}$.

$$\begin{aligned}\|T_2 v\|_{L^2_\nu([0,\delta_0])^2\to L^2_\nu([0,\vartheta_0])} &= \int_0^{\vartheta_0} \vartheta^{-2\nu} v(2\mathrm{arctan}(\vartheta))\,d\vartheta \\ &= \int_0^{\delta_0} \tan(\delta/2)^{-2\nu} v(\delta)^2 \frac{d\delta}{2\cos(\delta/2)^2} \\ &= \int_0^{\delta_0} \delta^{-2\nu} v(\delta)^2 \underbrace{\left(\frac{1}{2\cos(\delta/2)^2}\left(\frac{\tan(\delta/2)}{\delta}\right)^{-2\nu}\right)}_{(*)} d\delta.\end{aligned}$$

The maximum over $\delta \in [0,\delta_0]$ of the $(*)$-term proves the bound for T_2. □

In the following we denote the product of all four bounds by $\sigma(\delta_0)$,

$$\sigma(\delta_0) := \|T_1\|_{L^2_\nu([0,\delta_0])}\|T_1^{-1}\|_{L^2_\nu([0,\delta_0])}\|T_2\|_{L^2_\nu([0,\delta_0])\to L^2_\nu([0,\vartheta_0])}\|T_2^{-1}\|_{L^2_\nu([0,\vartheta_0])\to L^2_\nu([0,\delta_0])}, \tag{3.28}$$

and it is easy to see that

$$\lim_{\delta_0\to 0}\sigma(\delta_0) = 1. \tag{3.29}$$

An upper bound for the norm of the operator $\mathcal{B}_2$ is given in the next lemma.

LEMMA 3.5. *The Mellin operator $\mathcal{B}_2$ is a bounded operator in $L^2_\nu([0,\infty))$, $\nu \in (-3/2, 3/2)$. We get*

$$\begin{aligned}&\|\mathcal{B}_2\|_{L^2_\nu} \\ &\quad\le 2^{5/2}\frac{\sqrt{\rho_1\rho_2}}{\pi}(1+\cos(\alpha))B(3/2-\nu, 3/2+\nu)\,{}_2F_1\left(1/2+\nu, 1/2-\nu, 2, \frac{1+\cos(\alpha)}{2}\right).\end{aligned} \tag{3.30}$$

This can be estimated further by

$$\begin{aligned}&\|\mathcal{B}_2\|_{L^2_\nu} \\ &\quad\le 2^{3/2}\frac{\sqrt{\rho_1\rho_2}}{\pi}(1+\cos(\alpha))\left\{\begin{array}{ll} 1, & \nu \in [-0.5, 0.5], \\ \Gamma(3/2-\nu)\Gamma(3/2+\nu), & \nu \in (-1.5, -.5)\cup(0.5, 1.5).\end{array}\right.\end{aligned} \tag{3.31}$$

Proof. The Mellin transform $\mathcal{M}_{Re(z)=1/2-\nu}$ transforms the operator $\mathcal{B}_2$ on L^2_ν into a multiplication operator with

$$\begin{aligned}\widehat{l}_2(w) = 2^{3/2}\frac{\sqrt{\rho_1\rho_2}}{\pi}\sin^2(\alpha)\,2B(w+1, 2-w)\frac{1}{1-\cos(\alpha)}\,{}_2F_1\left(1-w, w, 2, \frac{1+\cos(\alpha)}{2}\right),\\ \mathrm{Re}(w) = 1/2-\nu;\end{aligned}$$

see [14, p. 310, formula 22]. This transform exists for $w \in \Sigma_{-1,2}$. Because the function l_2 is positive, we again have the relation

$$\left|\widehat{l}_2(w)\right| \le \widehat{l}_2(\mathrm{Re}(w)).$$

This, together with the range for w, proves formula (3.30) because a multiplication operator is bounded by its essential maximum. For $\nu \in [-0.5, 0.5]$ the coefficients of the power series of ${}_2F_1$ are positive, so we get ($w = 1/2 - \nu$)

$$\begin{aligned} {}_2F_1\left(1/2+\nu, 1/2-\nu, 2, \frac{1+\cos(\alpha)}{2}\right) &\leq {}_2F_1(1/2+\nu, 1/2-\nu, 2, 1) \\ &= \frac{\Gamma(2)\Gamma(1)}{\Gamma(3/2-\nu)\Gamma(3/2+\nu)}. \end{aligned}$$

Together with

$$B(3/2-\nu, 3/2+\nu) = \frac{\Gamma(3/2-\nu)\Gamma(3/2+\nu)}{\Gamma(3)},$$

we get the upper bound in (3.31). For $\nu \in (-1.5, 0.5]$, respectively, $\nu \in [0.5, 1.5)$, the coefficients of the power series for ${}_2F_1(1/2+\nu, 1/2-\nu, 2, w)$ are negative (with the exception of the coefficient of w^0). This proves

$$\begin{aligned} {}_2F_1\left(1/2+\nu, 1/2-\nu, 2, \frac{1+\cos(\alpha)}{2}\right) &\leq {}_2F_1(1/2+\nu, 1/2-\nu, 2, 0) \\ &= 1, \end{aligned}$$

and now the second estimate in (3.31) is also proved. □

Theorem 3.6. *The operator $\overline{K}$ (see* (3.9)*) is a continuous operator on*

$$L^2_{\nu_1}([0,\infty)) \otimes L^2_{\nu_2}([0,\delta_0]), \quad \nu_1 \in (-2.5, 1.5),\ \nu_2 \in (-1.5, 1.5).$$

1. *The operator $(I - \overline{K})$ is invertible if*

$$B_0(\nu_1,\nu_2)\sigma_0(\delta_0) < 1 \tag{3.32}$$

holds, where

(3.33)$B_0(\nu_1,\nu_2)$

$$:= \sqrt{\rho_1\rho_2}(1+\cos(\alpha))B(3/2-\nu_2, 3/2+\nu_2){}_2F_1\left(1/2+\nu_2, 1/2-\nu_2, 2, \frac{1+\cos(\alpha)}{2}\right)$$
$$\times \begin{cases} 1, & (\nu_1,\nu_2) \in [-1,0] \times (-1.5, 1.5), \\ \frac{8}{3}\Gamma(3/2-\nu_1)\Gamma(5/2+\nu_1), & (\nu_1,\nu_2) \in [(-2,-1) \cup (0,1)] \times (-1.5, 1.5). \end{cases}$$

2. *$(I - \overline{K})$ is invertible if*

(3.34)$B_1(\nu_2)$

$$:= \sqrt{\rho_1\rho_2}(1+\cos(\alpha))B(3/2-\nu_2, 3/2+\nu_2){}_2F_1\left(1/2+\nu_2, 1/2-\nu_2, 2, \frac{1+\cos(\alpha)}{2}\right)$$
$$< 1,$$

$(\nu_1,\nu_2) \in (-2.5, 1.5) \times (-1.5, 1.5)$, *if δ_0 is sufficiently small.*

3. *If δ_0 is sufficiently small, the operator $I - \overline{K}$ is invertible on*

$$L^2_{\nu_1}([0,\infty)) \otimes L^2_{\nu_2}([0,\delta_0]), (\nu_1,\nu_2) \in [-1,0] \times [-0.5, 0.5]. \tag{3.35}$$

Proof.

1. After the application of the Mellin transform $\mathcal{M}_{Re(z)=1/2-\nu_1}$, the operator $\overline{K}$ is transformed into the parameter-dependent operator $\mathcal{A}(1/2-\nu_1+i\tau)$, $\tau \in \mathbb{R}$. For this operator we have

$$\begin{aligned}
&|[[\mathcal{A}(1/2-\nu_1+i\tau)]u](\delta)| \\
&\quad \le \frac{\sqrt{\rho_1\rho_2}}{\pi}\sin(\alpha)^2\int_0^{\delta_0}\frac{\sin(\delta)\sin(\delta')}{(1-\omega(\delta,\delta'))^{3/2}}\,|\kappa_1(1/2-\nu_1+i\tau,\delta,\delta')|\,|w(\delta')|\,d\delta' \\
&\quad \le C(\nu_1)[\mathcal{B}_2\,|w|](\delta).
\end{aligned}$$

Now using the bounds for $C(\nu_1)$, given in Lemmas 3.1 and 3.5 together with Lemmas 3.3 and 3.4, we get the above bound for $\mathcal{A}(1/2-\nu_1+i\tau)$ on $L^2_{\nu_2}$, independent of τ. This proves our result.

2. The proof of part 2 follows from Corollary 3.2.

3. For (ν_1,ν_2) in the above range we get by Lemmas 3.1 and 3.5 the bound

$$\begin{aligned}
B_0(\nu_1,\nu_2) &\le \frac{\sqrt{2}}{8}\pi \times \frac{\sqrt{\rho_1\rho_2}}{\pi}2^{3/2}(1+\cos(\alpha)) \\
&= \sqrt{\rho_1\rho_2}\frac{1+\cos(\alpha)}{2} \\
&< 1.
\end{aligned}$$

By (3.29) we know that we can choose δ_0 sufficiently small to guarantee

$$B_0(\nu_1,\nu_2)\sigma(\delta_0) < 1,$$

which proves part 3. □

Remark. The result in part 3 of the above theorem shows that the set of values (ν_1,ν_2) in parts 1 and 2 for which $(I-\overline{K})$ is an invertible operator is nonempty. The author knows no explicit formula which describes the boundary of the (ν_1,ν_2)-area, in dependence on α, where the operator $(I-\overline{K})$ is invertible. But the function B_1 in (3.34) depends only on ν_2, and one can calculate *numerically* $\overline{\nu}_2(\alpha)$ with $B_1(\overline{\nu}_2(\alpha)) = 1$. Because of the symmetry of B_1, this implies that

$$\begin{aligned}
(I-\overline{K}):\ L^2_{\nu_1}([0,\infty))\otimes L^2_{\nu_2}([0,\delta_0]) &\xrightarrow{1:1} L^2_{\nu_1}([0,\infty))\otimes L^2_{\nu_2}([0,\delta_0]), \\
&(\nu_1,\nu_2)\in(-2.5,1.5)\times(-\overline{\nu}_2(\alpha),\overline{\nu}_2(\alpha))
\end{aligned}$$

if δ_0 is small enough.

Here it is interesting that the range of suitable ν_2 values increases near $\alpha = 0$ (at least for the more realistic values $\sqrt{\rho_1\rho_2} < 1$) and has a minimum for some positive angle $\overline{\alpha} = \overline{\alpha}(\sqrt{\rho_1\rho_2})$. This is *different* than in the case of the classical double layer potential, where the singularities are getting stronger when the angle goes to zero. Here Figure 3 suggests that there exists some worst angle for the regularity, which is greater than zero. To the author this property is not clear and cannot be explained at the moment. But we would like to mention that this behavior can also be seen in Table 1 of [17], although Rathsfeld has not explicitly mentioned this phenomenon.

Now we want to study the smoothing properties of the operator $\overline{K}$. It is our aim to study the behavior of

$$\sin(\delta)^{m+k}\left(r\frac{\partial}{\partial r}\right)^k\left(\frac{\partial}{\partial\delta}\right)^m\overline{k}_1\left(\delta,\delta',\frac{r}{r'}\right); \tag{3.36}$$

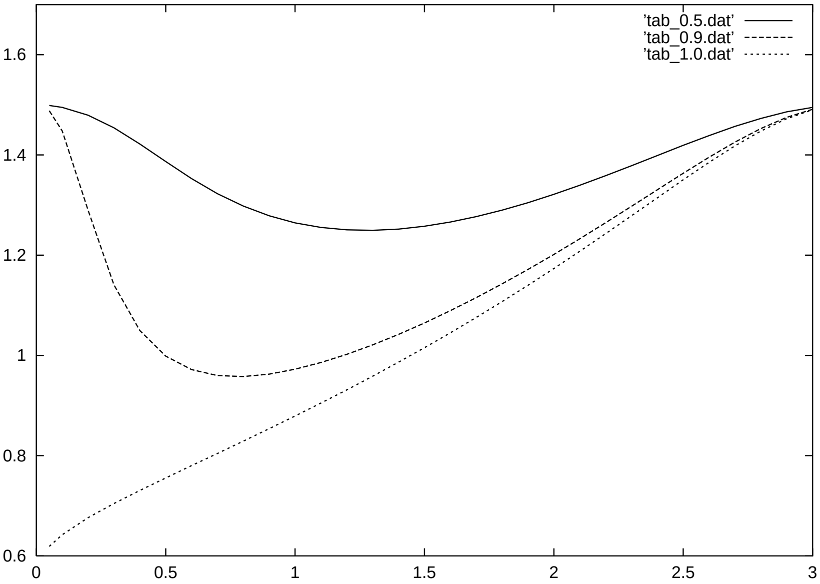

FIG. 3. *The curves* $\overline{\nu}_2(\alpha)$ *for three different values of* $\sqrt{\rho_1\rho_2}$: 0.5, 0.9, *and* 1.0.

see (3.11). Instead of $r\frac{\partial}{\partial r}$, we will write $t\frac{\partial}{\partial t}$ and consider $\overline{k}_1(\delta,\delta',t)$. We recall here that the function $\overline{k}_1$ is equivalent to k_1; see (3.4). We will see that an integral operator with kernel (3.36) behaves like the operator $\overline{K}$. But first we have to prove two technical lemmas. Instead of $\overline{k}_1$ we will use the equivalent but simpler kernel

$$\overline{k}_2(\delta,\delta',t) := \frac{\sin(\delta)t}{(1-2\omega(\delta,\delta')t+t^2)^2}. \tag{3.37}$$

LEMMA 3.7. *Let* $m \in \mathbb{N}_0$. *Then*

$$\begin{aligned}
&\left(\frac{\partial}{\partial\delta}\right)^m \overline{k}_2(\delta,\delta',t)\\
&= \sum_{n=0,2|n}^{m} \begin{pmatrix} m \\ n \end{pmatrix} \sin^{(m-n)}(\delta) \left(\sum_{j=1}^{n/2} \frac{t^{j+1} f_{n,j}}{(1-2\omega t+t^2)^{2+j}} + \sum_{j=n/2+1}^{n} \frac{t^{j+1}\omega'^{2j-n} f_{n,j}}{(1-2\omega t+t^2)^{2+j}} \right)\\
&\quad + \sum_{n=0,2\nmid n}^{m} \begin{pmatrix} m \\ n \end{pmatrix} \sin^{(m-n)}(\delta) \left(\sum_{j=1}^{(n+1)/2-1} \frac{t^{j+1} f_{n,j}}{(1-2\omega t+t^2)^{2+j}} + \sum_{j=(n+1)/2}^{n} \frac{t^{j+1}\omega'^{2j-n} f_{n,j}}{(1-2\omega t+t^2)^{2+j}} \right),
\end{aligned}$$

where we used the abbreviation ω *instead of* $\omega(\delta,\delta')$ *and* ω' *instead of* $\frac{\partial}{\partial\delta}\omega(\delta,\delta')$, *and* $f_{n,j}$ *are bounded* $\mathcal{C}^\infty$*-functions of* δ *and* δ'.

Proof. The proof is an easy consequence of the following two formulas:

1. n even:

$$\left(\frac{\partial}{\partial\delta}\right)^n \frac{1}{(1-2\omega t+t^2)^2} = \sum_{j=1}^{n/2} \frac{t^j f_{n,j}}{(1-2\omega t+t^2)^{2+j}} + \sum_{j=n/2+1}^{n} \frac{t^j\omega'^{2j-n} f_{n,j}}{(1-2\omega t+t^2)^{2+j}};$$

2. n odd:

$$\left(\frac{\partial}{\partial\delta}\right)^n \frac{1}{(1-2\omega t+t^2)^2} = \sum_{j=1}^{(n+1)/2-1} \frac{t^j f_{n,j}}{(1-2\omega t+t^2)^{2+j}} + \sum_{j=(n+1)/2}^{n} \frac{t^j \omega'^{2j-n} f_{n,j}}{(1-2\omega t+t^2)^{2+j}}.$$

We first look for $n=1$ and $n=2$ and get

$$\begin{aligned}
\frac{\partial}{\partial\delta}\frac{1}{(1-2\omega t+t^2)^2} &= \frac{4t\omega'}{(1-2\omega t+t^2)^{2+1}},\\
f_{1,1}(\delta,\delta') &= 4,\\
\left(\frac{\partial}{\partial\delta}\right)^2 \frac{1}{(1-2\omega t+t^2)^2} &= \frac{4t\omega''}{(1-2\omega t+t^2)^{2+1}} + \frac{24t^2\omega'^2}{(1-2\omega t+t^2)^{2+2}},\\
f_{2,1}(\delta,\delta') &= 4\omega''(\delta,\delta'),\\
f_{2,2}(\delta,\delta') &= 24.
\end{aligned}$$

This shows that our formula is correct for $n=1,2$. We proceed further by induction. We will show only that the formula is correct for $n+1$ if n is even. The other case is totally similar. So we assume that the formula is correct for an even n and get

$$\begin{aligned}
\left(\frac{\partial}{\partial\delta}\right)^{n+1} \frac{1}{(1-2\omega t+t^2)^2} &= \frac{\partial}{\partial\delta}\left(\sum_{j=1}^{n/2} \frac{t^j f_{n,j}}{(1-2\omega t+t^2)^{2+j}} + \sum_{j=n/2+1}^{n} \frac{t^j \omega'^{2j-n} f_{n,j}}{(1-2\omega t+t^2)^{2+j}}\right)\\
&= \sum_{j=1}^{n/2} \frac{t^{j+1}(4+2j)\omega' f_{n,j}}{(1-2\omega t+t^2)^{2+j+1}} + \sum_{j=1}^{n/2} \frac{t^j f'_{n,j}}{(1-2\omega t+t^2)^{2+j}}\\
&\quad + \sum_{j=n/2+1}^{n} \frac{t^{j+1}(4+2j)\omega'^{2j-n+1} f_{n,j}}{(1-2\omega t+t^2)^{2+j+1}}\\
&\quad + \sum_{j=n/2+1}^{n} \frac{t^j (2j-n)\omega'^{2j-n-1}\omega'' f_{n,j}}{(1-2\omega t+t^2)^{2+j}}\\
&\quad + \sum_{j=n/2+1}^{n} \frac{t^j \omega'^{2j-n} f'_{n,j}}{(1-2\omega t+t^2)^{2+j}}\\
&= \sum_{j=2}^{n/2} \frac{t^j (2+2j)\omega' f_{n,j-1}}{(1-2\omega t+t^2)^{2+j}} + \sum_{j=1}^{n/2} \frac{t^j f'_{n,j}}{(1-2\omega t+t^2)^{2+j}}\\
&\quad + \frac{t^{n/2+1=((n+1)+1)/2}(4+2n)\omega' f_{n,n/2}}{(1-2\omega t+t^2)^{2+((n+1)+1)/2}}\\
&\quad + \sum_{j=((n+1)+1)/2+1}^{n+1} \frac{(2+2j)\omega'^{2j-(n+1)} t^j f_{n,j-1}}{(1-2\omega t+t^2)^{2+j}}\\
&\quad + \sum_{j=((n+1)+1)/2}^{n} \frac{t^j \omega'^{2j-(n+1)}(\omega'' f_{n,j} + \omega' f_{n,j})}{(1-2\omega t+t^2)^{2+j}}.
\end{aligned}$$

Because $n/2 = (n+2)/2 - 1$, this proves the formula for $n+1$ if the functions $f_{n+1,j}$ are defined correspondingly. Here we see that $f_{n,j}$ is always a function of the sine and cosine of δ, respectively, δ'. □

The next lemma concerns the derivatives with respect to t.

LEMMA 3.8. *For $n \in \mathbb{N}_0$ we have*

$$\left(\frac{\partial}{\partial t}\right)^{2n} \frac{1}{(1-2\omega t+t^2)^{2+j}} = \sum_{l=0}^{n} a_l^{(j,2n)} \frac{(t-\omega)^{2l}}{((t-\omega)^2+(1-\omega^2))^{2+j+n+l}},$$

$$\left(\frac{\partial}{\partial t}\right)^{2n+1} \frac{1}{(1-2\omega t+t^2)^{2+j}} = \sum_{l=0}^{n} a_l^{(j,2n+1)} \frac{(t-\omega)^{2l+1}}{((t-\omega)^2+(1-\omega^2))^{2+j+n+l+1}}$$

with $a_l^{(j,n)} \in \mathbb{R}$.

An easy consequence is the following formula, which we need in the next lemma:

$$\left(t\frac{\partial}{\partial t}\right)^{k} \left(\frac{t^{j+1}}{(1-2\omega t+t^2)^{2+j}}\right) = \sum_{l=0}^{k} \sum_{i=0}^{\min\{j+1,l\}} b_{j,l,i} t^{j+1+l-i}$$

$$\times \begin{cases} \displaystyle\sum_{p=0}^{(l-i)/2} a_p^{(j,l-i)} \frac{(t-\omega)^{2p}}{((t-\omega)^2+(1-\omega^2))^{2+j+(l-i)/2+p}}, & l-i \textit{ even}, \\ \displaystyle\sum_{p=0}^{(l-i-1)/2} a_p^{(j,l-i)} \frac{(t-\omega)^{2p+1}}{((t-\omega)^2+(1-\omega^2))^{2+j+(l-i+1)/2+p}}, & l-i \textit{ odd}. \end{cases}$$

Proof. We first calculate the first two derivatives and get

$$\frac{\partial}{\partial t} \frac{1}{(1-2\omega t+t^2)^{2+j}} = \frac{-(2+j)2(t-\omega)}{((t-\omega)^2+(1-\omega^2))^{3+j}},$$

$$\left(\frac{\partial}{\partial t}\right)^{2} \frac{1}{(1-2\omega t+t^2)^{2+j}} = -\frac{(4+2j)}{((t-\omega)^2+(1-\omega^2))^{3+j}} + \frac{(4+2j)(6+2j)(t-\omega)^2}{((t-\omega)^2+(1-\omega^2))^{4+j}},$$

which proves our result with the corresponding definitions of $a_0^{(j,1)}, a_0^{(j,2)}$, and $a_1^{(j,2)}$. We proceed further by induction, but we again prove only one case. We assume that the formula is correct for $2n+1$ and prove it for $2(n+1)$. By our assumption we have

$$\begin{aligned} \left(\frac{\partial}{\partial t}\right)^{2(n+1)} \frac{1}{(1-2\omega t+t^2)^{2+j}} &= \sum_{l=0}^{n} \Bigg(\frac{a_l^{(j,2n+1)}(2l+1)(t-\omega)^{2l}}{((t-\omega)^2+(1-\omega^2))^{2+j+n+l+1}} \\ &\qquad - \frac{a_l^{(j,2n+1)} 2(t-\omega)^{2l+2}(2+j+n+1+l)}{((t-\omega)^2+(1-\omega^2))^{2+j+(n+1)+(l+1)}} \Bigg) \\ &= \sum_{l=0}^{n} \frac{a_l^{(j,2n+1)}(2l+1)(t-\omega)^{2l}}{((t-\omega)^2+(1-\omega^2))^{2+j+(n+1)+l}} \\ &\qquad - \sum_{l=1}^{n+1} \frac{a_{l-1}^{(j,2n+1)} 2(t-\omega)^{2l}(2+j+n+l)}{((t-\omega)^2+(1-\omega^2))^{2+j+(n+1)+l}}, \end{aligned}$$

and this proves our formula for $2(n+1)$ if the coefficients are defined correctly. For the proof of the last formula we use

$$\left(t\frac{\partial}{\partial t}\right)^{j} g(t) = \sum_{i=1}^{j} c_{j,i} t^i \left(\frac{\partial}{\partial t}\right)^{i} g(t), \quad c_{j,i} \in \mathbb{R},$$

and the formula

$$\left(\frac{\partial}{\partial t}\right)^j (fg)(t) = \sum_{i=0}^{j} \left(\begin{array}{c} j \\ i \end{array} \right) f^{(i)}(t) g^{(j-1)}(t). \qquad \square$$

Now we are ready to prove our main result on the kernel $\overline{k}_1$.

LEMMA 3.9. *For $m, k \in \mathbb{N}_0$ we have*

$$\sin(\delta)^{m+k} \left(t\frac{\partial}{\partial t}\right)^k \left(\frac{\partial}{\partial \delta}\right)^m \overline{k}_1(\delta, \delta', t) = g_{m,k}(\delta, \delta', t)\overline{k}_1(\delta, \delta', t)$$

with a bounded continuous function $g_{m,k}$ on $[0, \delta_0]^2 \times [0, \infty)$.

Proof. We have only to consider $\overline{k}_2$. By the previous two lemmas we get

$$\begin{aligned}
&\sin(\delta)^{m+k} \left(t\frac{\partial}{\partial t}\right)^k \left(\frac{\partial}{\partial \delta}\right)^m \overline{k}_2(\delta, \delta', t) \\
&= \sum_{n=0, 2|n}^{m} \left(\begin{array}{c} m \\ n \end{array} \right) \sum_{j=1}^{n/2} f_{n,j} \sum_{l=1}^{k} \sum_{i=0}^{\min\{j+1,l\}} b_{j,l,i}\alpha_{m,n,j,l,i} \\
&\quad + \sum_{n=0, 2|n}^{m} \left(\begin{array}{c} m \\ n \end{array} \right) \sum_{j=n/2+1}^{n} f_{n,j} \sum_{l=1}^{k} \sum_{i=0}^{\min\{j+1,l\}} b_{j,l,i}\omega'^{2j-n}\alpha_{m,n,j,l,i} \\
&= \sum_{n=0, 2\nmid n}^{m} \left(\begin{array}{c} m \\ n \end{array} \right) \sum_{j=1}^{(n+1)/2-1} f_{n,j} \sum_{l=1}^{k} \sum_{i=0}^{\min\{j+1,l\}} b_{j,l,i}\alpha_{m,n,j,l,i} \\
&\quad + \sum_{n=0, 2\nmid n}^{m} \left(\begin{array}{c} m \\ n \end{array} \right) \sum_{j=n/2+1}^{n} f_{n,j} \sum_{l=1}^{k} \sum_{i=0}^{\min\{j+1,l\}} b_{j,l,i}\omega'^{2j-n}\alpha_{m,n,j,l,i},
\end{aligned}$$

where

$$\begin{aligned}
\alpha_{m,n,j,l,i} &= \sin(\delta)^{m+k} \sin^{(m-n)}(\delta) t^{j+1+l-i} \\
&\quad \times \begin{cases} \displaystyle\sum_{p=0}^{(l-i)/2} \frac{a_p^{(j,l-i)}(t-\omega)^{2p}}{((t-\omega)^2 + (1-\omega^2))^{2+j+(l-i)/2+p}}, & l-i \text{ even}, \\ \displaystyle\sum_{p=0}^{(l-i-1)/2} \frac{a_p^{(j,l-i)}(t-\omega)^{2p+1}}{((t-\omega)^2 + (1-\omega^2))^{2+j+(l-i+1)/2+p}}, & l-i \text{ odd}. \end{cases}
\end{aligned}$$

Now one has to consider 16 different summands ($\alpha_{m,n,j,l,i}$ for m even/odd, $l-i$ even/odd). We will consider only the two cases m even, n even, $j \geq n/2+1$, and $l-i$ even and odd. This corresponds to the two cases in the second of the above sums. We have only to prove our lemma for small t because for large t the formula is clearly correct.

First, for $l-i$ even and p arbitrary,

$$\begin{aligned}
\alpha_{m,n,j,l,i}(\delta, \delta', t) &= \frac{\sin(\delta)^{m+k}(\pm\sin(\delta))t^{j+1+l-i}(t-\omega)^{2p}\omega'^{2j-n}}{((t-\omega)^2 + (1-\omega^2))^{2+j+(l-i)/2+p}} \\
&= \pm\overline{k}_2 \frac{\sin(\delta)^{m+k}t^{j+l-i}\omega'^{2j-n}}{((t-\omega)^2 + (1-\omega^2))^{j+(l-i)/2}} \frac{(t-\omega)^{2p}}{((t-\omega)^2 + (1-\omega^2))^p} \\
&\leq C_1\overline{k}_2 \frac{\sin(\delta)^{m+k}t^{j+l-i}\omega'^{2j-n}}{((t-\omega)^2 + (1-\omega^2))^{j+(l-i)/2}}
\end{aligned}$$

with some constant $C_1 > 0$. Now we remind the reader of

$$\begin{aligned} \omega'(\delta,\delta') &\leq C_2(\sin(\delta)+\sin(\delta')), && (3.38)\\ (1-2\omega t+t^2) &= (t-1)^2+2t(1-\omega) \\ &\geq 2t(1-\omega)\ \ldots \\ &\geq C_3 t(\sin(\delta)+\sin(\delta'))^2, && (3.39) \end{aligned}$$

where we have again used the addition theorems for sine and cosine in the last formula. We further estimate

$$\frac{\sin(\delta)^{m+k}t^{j+l-i}\omega'^{2j-n}}{((t-\omega)^2+(1-\omega^2))^{j+(l-i)/2}} \overset{(3.38),(3.39)}{\leq} C_4\frac{t^{(l-i)/2}\sin(\delta)^{m+k}}{(\sin(\delta)+\sin(\delta'))^{n+l-i}},$$

$C_4 > 0$, and for the exponent of the denominator we get

$$\begin{aligned} n+l-i &\leq n+l \\ &\leq m+k. \end{aligned}$$

This proves the result.

Second, for $l-i$ odd and p arbitrary,

$$\begin{aligned} \alpha_{m,n,j,l,i}(\delta,\delta',t) &= \frac{\sin(\delta)^{m+k}(\pm\sin(\delta))t^{j+1+l-i}(t-\omega)^{2p+1}\omega'^{2j-n}}{((t-\omega)^2+(1-\omega^2))^{2+j+(l-i+1)/2+p}} \\ &= \pm\bar{k}_2\frac{\sin(\delta)^{m+k}t^{j+l-i}\omega'^{2j-n}}{((t-\omega)^2+(1-\omega^2))^{j+(l-i)/2}}\frac{(t-\omega)^{2p+1}}{((t-\omega)^2+(1-\omega^2))^{p+1/2}} \\ &\leq C_5\bar{k}_2\frac{\sin(\delta)^{m+k}t^{j+l-i}\omega'^{2j-n}}{((t-\omega)^2+(1-\omega^2))^{j+(l-i)/2}} \end{aligned}$$

with some constant $C_5 > 0$. Now we are in the same situation as above, and our proof is finished. □

We will now introduce the function spaces $X^m_{\nu_1,\nu_2}$ for each face F_j of the cone Γ. After a suitable rotation we can assume that F_j has the following representation:

$$F_j = \left\{ r\begin{pmatrix} \sin(\delta) \\ 0 \\ \cos(\delta) \end{pmatrix} \mid 0 \leq r < \infty,\ \delta\in[0,\delta_0] \right\}, \quad \delta_0 \in (0,2\pi).$$

Then the norm on the function space $X^m_{\nu_1,\nu_2}(F_j)$ is defined by

$$(3.40)\quad \|u; X^m_{\nu_1,\nu_2}\|^2$$
$$:= \sum_{i+l\leq m}\int_0^\infty\int_0^{\delta_0} r^{-2\nu_1}\sin\left(\delta\frac{\pi}{\delta_0}\right)^{-2\nu_2}\left(\sin\left(\delta\frac{\pi}{\delta_0}\right)^{i+l}\left(r\frac{\partial}{\partial r}\right)^i\left(\frac{\partial}{\partial\delta}\right)^l u\right)^2 d\delta\, dr.$$

The above lemma implies the following corollary.

Corollary 3.10. *Let F_j and F_{j+1} be two adjacent faces of the infinite cone, and define L to be the integral operator*

$$Lu := \widetilde{K}u|_{F_{j+1}};$$

here the function u is given on F_j and extended by zero to the whole of Γ, *and* $\widetilde{K}$ *is the radiosity operator on the infinite cone; see* (2.21). *Then we get*

$$L:\, X^0_{\nu_1,\nu_2}(F_j) \longrightarrow X^m_{\nu_1,\nu_2}(F_{j+1})$$

for all $m \in \mathbb{N}$, *and* $(\nu_1, \nu_2) \in (-2.5, 1.5) \times (-1.5, 1.5)$.

Proof. The proof follows from the previous lemma and Theorem 3.6. □

To formulate a further application of Lemma 3.9, we introduce a weighted Sobolev space $X^m_{\nu_1,\nu_2}(S)$, $m \in \mathbb{N}$, on S in the following way. Every face Δ_j of S has three vertices, which we will denote by $v^{(j)}_i$, $i = 1, 2, 3$. There exists a linear transformation $\mathcal{T}_{j,i}$ (i.e., a rotation followed by a translation) with

$$\mathcal{T}_{j,i}(v^{(j)}_i) = 0,$$

and the infinite triangle $F_{j,i}$ generated by $\mathcal{T}_{j,i}\Delta_j$ fulfills

$$F_{j,i} = \left\{ r \begin{pmatrix} \sin(\delta) \\ 0 \\ \cos(\delta) \end{pmatrix} \mid 0 \le r < \infty,\, \delta \in [0, \delta_{j,i}] \right\}, \quad \delta_{j,i} \in (0, 2\pi). \tag{3.41}$$

For each S_j there exist three $\mathcal{C}^\infty$-functions $\varphi_{j,i}$, $i = 1, 2, 3$, which are nonnegative, and

$$\begin{aligned} \varphi_{j,1}(x) + \varphi_{j,2}(x) + \varphi_{j,3}(x) = 1, &\quad x \in \Delta_j, \\ \varphi_{j,i}|_{U_\varepsilon(v^{(j)}_i)} \equiv 1, &\quad \varepsilon > 0. \end{aligned}$$

Further, the support of $\varphi_{j,i}$ does not intersect the edge of Δ_j on the opposite side of $v^{(j)}_i$. Now $X^m_{\nu_1,\nu_2}(S)$ is defined by the norm

$$\|u :\, X^m_{\nu_1,\nu_2}(S)\|^2 := \sum_{j=1}^{n} \sum_{i=1}^{3} \|(\varphi_{j,i} u) \circ \mathcal{T}^{-1}_{j,i}; X^m_{\nu_1,\nu_2}(F_{j,i})\|^2. \tag{3.42}$$

Now we can formulate a special result which follows easily from Lemma 3.9 and shows its implications if the shadow lines do not disturb the regularity.

COROLLARY 3.11. *Let S be convex, $E \in L^2(S)$ with $E|_{\Delta_j} \in \mathcal{C}^\infty(\Delta_j)$, $j = 1(1)n$; then the solution $u \in L^2(S)$ of* (1.1) *fulfills*

$$u \in X^m_{\nu_1,\nu_2}(S), \quad m \in \mathbb{N}, \tag{3.43}$$

$\nu_1 \in (-2.5, -0.5]$, $\nu_2 \in (-1.5, 0]$.

Proof. We remark that the solution $u \in L^2(S)$ belongs to $X^0_{\nu_1,\nu_2}(S)$, (ν_1, ν_2) as above and $f \in X^m_{\nu_1,\nu_2}(S)$, (ν_1, ν_2) as above. The representation

$$u = f - Ku$$

for u and Lemma 3.9 prove the result. □

Remark. We mention here that it would be more interesting to get similar results for $\nu_1, \nu_2 > 0$. This seems to be possible. Because of Theorem 3.6, one gets the invertibility of the local operators for positive ν values, and by some localization techniques this shows that the operator $(I - K)$ is a Fredholm operator with index zero in $X^0_{\nu_1,\nu_2}(S)$, $\nu_1, \nu_2 > 0$, small enough. But because of $X^0_{\nu_1,\nu_2} \subset L^2(S)$ and kernel$(I-K)|_{L^2(S)} = \{0\}$ one gets the invertibility. This would show Corollary 3.11 also for some positive values of ν_1, ν_2.

However, Lemma 3.9 also makes it possible to get pointwise estimates for the solution of (1.1) if the assumptions of the above corollary are fulfilled; see [18, Lemma 5.2].[1]

COROLLARY 3.12. *Let S be convex, $E \in L^2(S)$, $E|_{\Delta_j} \in \mathcal{C}^\infty(\Delta_j)$, $j = 1(1)n$, and $u \in L^2(S)$ be the solution of* (1.1). *Let Δ_j, $j \in \{1,\dots,n\}$, be an arbitrary face with vertex $v_i^{(j)}$, $i \in \{1,2,3\}$, $D_{j,i} := [0,\infty) \times [0, \delta_{j,i}/2]$ (see* (3.41)*), and define*

$$u_{j,i} \;:=\; (\varphi_{j,i} u) \circ \mathcal{T}_{j,i}^{-1} \;:\; D_{j,i} \longrightarrow \mathbb{R}.$$

Then we get

$$\left.\begin{array}{lll} \sup_{(r,\delta)\in D_{j,i}} \left| \left(\sin(\delta)\frac{\partial}{\partial\delta}\right)^l u_{j,i}(r,\delta)\right| & \leq & c_l \\ \sup_{(r,\delta)\in D_{j,i}} \left| \left(r\frac{\partial}{\partial r}\right)^l u_{j,i}(r,\delta)\right| & \leq & c_l \end{array}\right\}, \qquad l \in \mathbb{N}_0,\ c_l > 0. \tag{3.44}$$

Proof. The proof is analogous to the proof of Rathsfeld's lemma. First, we notice that in the case of a convex domain the right-hand side of (2.24), and also of (3.8), is a $\mathcal{C}^\infty$-function. So we have to prove that

$$u_{j,i} := A^{-1}y,\ A \,:=\, I - \overline{K},$$

y a $\mathcal{C}^\infty$-function, fulfills (3.44). But the operator $\overline{K}$ fulfills the estimate (2.9) of Lemma 2.1. This also implies $\|\overline{K}\|_{L^\infty(D_{j,i})} < 1$; see [16]. But then we get

$$A^{-1} \;=\; \sum_{j=0}^{\infty} \overline{K}^j \;:\; L^\infty(D_{j,i}) \longrightarrow L^\infty(D_{j,i})$$

and

$$A^{-1} = I + \overline{K}A^{-1}.$$

The operator $\overline{K}$ is a Mellin convolution operator with respect to r, and so

$$\left(r\frac{\partial}{\partial r}\right)\overline{K}u = \overline{K}\left(r\frac{\partial}{\partial r}u\right).$$

Now

$$\left(r\frac{\partial}{\partial r}\right)^l u_{j,i} = A^{-1}\left(r\frac{\partial}{\partial r}y\right)$$

is bounded and

$$\left(\sin(\delta)\frac{\partial}{\partial\delta}\right)^l u_{j,i} = \left(\sin(\delta)\frac{\partial}{\partial\delta}\right)^l y + \underbrace{\left[\left(\sin(\delta)\frac{\partial}{\partial\delta}\right)^l \overline{K}\right]}_{=:\overline{K}_l} A^{-1}y.$$

The kernel of the $\overline{K}_l$ has the same structure as the kernel $\overline{k}_1$ of $\overline{K}$ by Lemma 3.9, so it maps $L^\infty(D_{j,i})$ into $L^\infty(D_{j,i})$, and we have proved our corollary. ∎

[1] The author would like to thank Dr. J. Elschner for the reference to this lemma.

4. The regularity near the vertices. Now we start to study the regularity of the right-hand sides of (3.3) and (2.23). The difference between these two equations is that the right-hand sides of (3.3) also contain some contributions from the local cone which come from the nonadjacent faces. But first we consider the function f_2 in (2.23).

For each triangle Δ_j, $j \in \{1, \ldots, N\}$ (see (2.1)) we denote by $\{v_1^{(j)}, v_2^{(j)}, v_3^{(j)}\}$ the vertices and by $\{e_1^{(j)}, e_2^{(j)}, e_3^{(j)}\}$ the edges of Δ_j. Given a triangle $\Delta \subset \mathbb{R}^3$, we denote by $E(\Delta)$ the plane which is spanned by Δ. If $x \in \mathbb{R}^3$ and $l \subset \mathbb{R}^3$ is a segment in $\mathbb{R}^3$, we denote

$$E(x,l) := \begin{cases} \text{the plane spanned by } l \text{ and } x & \text{if } x \text{ is not an element of the line} \\ & \text{spanned by } l, \\ \text{the line spanned by } l & \text{otherwise.} \end{cases}$$

For $j \in \{1, \ldots, N\}$ we denote by T_j the subset of S where the shadow lines created by Δ_j could cause problems for the regularity of the solution of the radiosity equation. To define T_j we need some preparations. Let

$$D_{j,m} := \begin{cases} E(\Delta_j) \cap \Delta_m & \text{if some parts of } \Delta_j \text{ are visible from } \Delta_m, \\ \emptyset & \text{otherwise,} \end{cases}$$

$m \in \{1, \ldots, N\} \setminus \{j\}$, and

$$\widetilde{D}_{j,m,k,l,i} := \begin{cases} E(e_k^{(j)}, v_l^{(i)}) \cap \Delta_m & \text{if } v_k^{(j)} \text{ or some parts of } e_l^{(i)} \text{ can be seen from } \Delta_m, \\ \emptyset & \text{otherwise,} \end{cases}$$

$k, l \in \{1, 2, 3\}$, $i \in \{1, \ldots, N\} \setminus \{j\}$. From a point $x \in D_{j,m} \subset \Delta_m$ one "sees" the set Δ_j only as a line. Assume $x \in D_{j,m,k,l,i} \subset \Delta_m$; if one "stands" at the point x and looks in the direction of the l vertex of Δ_i, the ray to the vertex also hits the edge number k of side Δ_j. So it is clear that in every neighborhood of x one finds points which see the vertex $v_l^{(i)}$ and others which do not see it. This indicates that the shape of the shadow (it is a polygon), seen from x, changes essentially (the number of vertices of the polygon) in the vicinity of x. In the above definitions the phrase "some parts of set A can be seen from Δ_m" means that $\vec{n}_A \cdot \vec{n}_{\Delta_m} < 0$, and there exists a point $y \in A$ and $x \in \Delta_m$ with $(y - x) \cdot \vec{n}_{\Delta_m} > 0$. Here the choice of the point x plays no role. Now T_j is given by

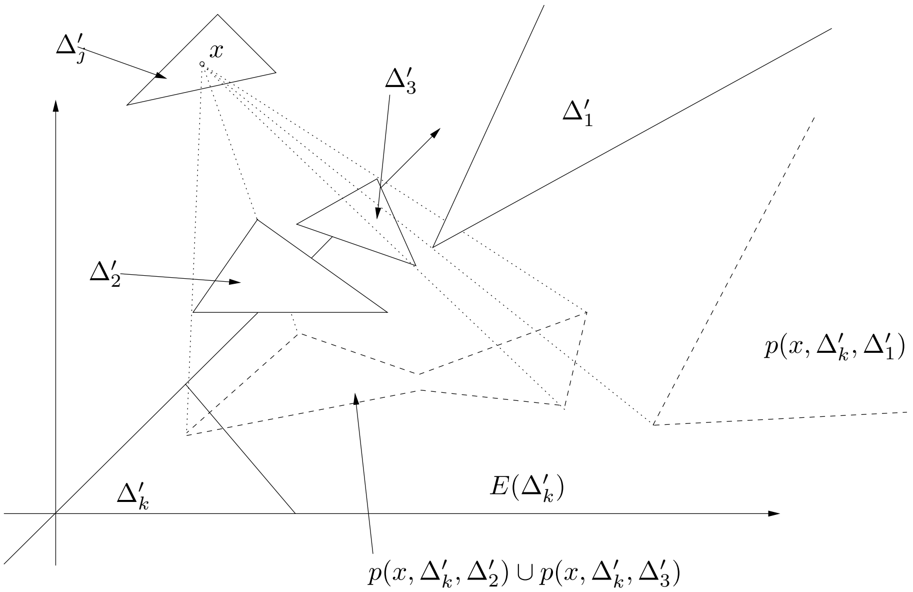
$$T_j := \bigcup_{m=1,\, m \neq j}^{N} \left(D_{j,m} \cup \left(\bigcup_{k,l=1}^{3} \bigcup_{i=1, i \notin \{m,j\}}^{N} \widetilde{D}_{j,m,k,l,i} \right) \right). \tag{4.1}$$

T_j is the set of points on S, where the shadows of Δ_j can cause problems, and T is the union of all these critical lines

$$T := \bigcup_{j=1}^{N} T_j. \tag{4.2}$$

Because T is the union of lines, we get

$$S' := \dot{S} \setminus T = \bigcup_{j=1}^{N'} \Delta'_j, \tag{4.3}$$



Δ'_j
x
Δ'_3
Δ'_1
Δ'_2
$p(x,\Delta'_k,\Delta'_1)$
Δ'_k
$E(\Delta'_k)$
$p(x,\Delta'_k,\Delta'_2)\cup p(x,\Delta'_k,\Delta'_3)$

FIG. 4. *The construction for projections* $p(x,\Delta'_k,\cdot)$.

where the triangles Δ'_j are open.

To explain the meaning of T we now fix $j,k\in\{1,\dots,N'\}$, $j\neq k$, and consider the shadows of S' seen from Δ'_j on $E(\Delta'_k)$. For $x\in\Delta'_j$ we denote by $p(x,\Delta'_k,\Delta'_i)$ the projection of the points $y\in\Delta'_i$ on $E(\Delta'_k)$. This means that if $\vec{n}_x\cdot\vec{n}_y<0$ and $(y-x)\cdot\vec{n}_x>0$ and if there is a $\lambda\geq 1$ such that $x+\lambda(y-x)\in E(\Delta'_k)$, then $x+\lambda(y-x)\in p(x,\Delta'_k,\Delta'_i)$. For each i, $p(x,\Delta'_k,\Delta'_i)$ is either empty, a triangle, or a triangle where one or two corners are in infinity. But it is never a line because of the definition of T. Now for $p(x,\Delta'_k,\Delta'_i)\neq\emptyset$ and $p(x,\Delta'_k,\Delta'_l)\neq\emptyset$, $i\neq l$, no vertex of $p(x,\Delta'_k,\Delta'_i)$ crosses the boundary of $p(x,\Delta' k,\Delta'_l)$ as x varies in Δ'_j. Also, no edge of $p(x,\Delta'_k,\Delta_i)$ crosses parallel to an edge of $p(x,\Delta' k,\Delta'_l)$. So $p(x,\Delta'_k,\Delta'_i)\cup p(x,\Delta'_k,\Delta'_l)$ are either two triangles or one polygonal domain in $E(\Delta'_k)$. This structure stays stable for all $x\in\Delta'_j$. The vertices of this triangle or polygonal domain are $\mathcal{C}^\infty$-functions on Δ'_j.

Now we can add in succession all shadows and get

$$\begin{aligned} P_{j,k} &:= \widetilde{\bigcup}_{i=1,i\notin\{j,k\}}^{N'} p(x,\Delta'_k,\Delta'_i) \\ &= \bigcup_{i=1}^{N'(j,k)} \widetilde{p}_{j,k,i}(x), \end{aligned} \tag{4.4}$$

where the union in the first line does not contain the Δ' which are adjacent to Δ'_j. Each $\widetilde{p}_{j,k,i}(x)$ is a polygonal domain in $E(\Delta'_k)$, the edges of $\widetilde{p}_{j,k,i}(x)$ are $\mathcal{C}^\infty$-functions on Δ'_j, and $\widetilde{p}_{j,k,i}(x)\cap\widetilde{p}_{j,k,i'}(x)=\emptyset$, $i\neq i'$. If we denote by $\widetilde{v}_{j,k,i}(x)$ an arbitrary vertex of $\widetilde{p}_{j,k,i}(x)$, we get for $x,y\in\Delta'_j$ that the curve

$$\lambda\longrightarrow\widetilde{v}_{j,k,i}(x+\lambda(y-x)),\quad \lambda\in[0,1],$$

moves along a straight line, and the velocity is always greater than zero (see Figure 4).

Lemma 4.1. *Let $u : S \to \mathbb{R}$, $u|_{\Delta'_j}$ be continuous, $j = 1(1)N'$. Let $j_0 \in \{1, \dots, N'\}$, and define S_{j_0} to be the union of all Δ'_j which are not equal or adjacent to Δ'_{j_0}. Define*

$$w(x) := \int_{S_{j_0}} \beta(x,y) \frac{\vec{n}_x \cdot (y-x)\, \vec{n}_y \cdot (x-y)}{\|x-y\|^4} u(y)dy;$$

then we get $w \in \mathcal{C}^1(\overline{\Delta'_{j_0}})$.

Proof. It is sufficient to prove that

$$w(x) = \int_{\Delta'_j} \beta(x,y) \frac{\vec{n}_x \cdot (y-x)\, \vec{n}_y \cdot (x-y)}{\|x-y\|^4} u(y)dy$$

is in $\mathcal{C}^1(\overline{\Delta'_{j_0}})$, where Δ'_j is one of the admissible triangles; therefore,

$$k(x,y) := \frac{\vec{n}_x \cdot (y-x)\, \vec{n}_y \cdot (x-y)}{\|x-y\|^4}$$

is a $\mathcal{C}^\infty$-function on $\Delta'_{j_0} \times \Delta'_j$. Define

$$\Delta'_j(x) := \Delta'_j \setminus \left(\bigcup_{k=1}^{N(j_0,j)} \widetilde{p}_{j_0,j,k}(x) \right).$$

Then

$$w(x) = \int_{\Delta'_j(x)} \frac{\vec{n}_x \cdot (y-x)\, \vec{n}_y \cdot (x-y)}{\|x-y\|^4} u(y)dy.$$

Because the corners of $\Delta'_j(x)$ are $\mathcal{C}^\infty$-functions of x, we find for every x a real $\delta > 0$ and a triangulation

$$\Delta'_j = \bigcup_{i=1}^{M_j} \Delta''_i$$

(see Figure 5), such that for all $z \in U_\delta(x) \cap \Delta'_{j_0}$ in every Δ''_i there is at most one corner point of $P_{j_0,j}$, and this point does not move out of Δ''_i when z varies in $U_\delta(x)$.

This implies that $\Delta''_i(z) := \Delta''_i \cap \Delta'_j(z)$ is either empty or has one of the following forms (see Figure 6).

If $\Delta''_i(z)$ is empty or has the form of case (a) for all $z \in U_\delta(x)$, it follows that

$$\int_{\Delta''_i(z)} k(z,y)u(y)dy$$

is a $\mathcal{C}^\infty$-function of z. The cases (b) and (d) and the cases (c) and (e) are complementary, and we have only to look for the cases (b) and (c). After some smooth transformation we can assume that we have the situation shown in Figure 7.

Here ξ_0, ξ_1, η_1, and η_2 are $\mathcal{C}^\infty$-functions of $z \in U_\delta(x)$. We will treat only the left case and give the result for the right case. We further consider z to be a real (one dimensional) variable because no direction has a special significance, and we will see that the first derivative is continuous.

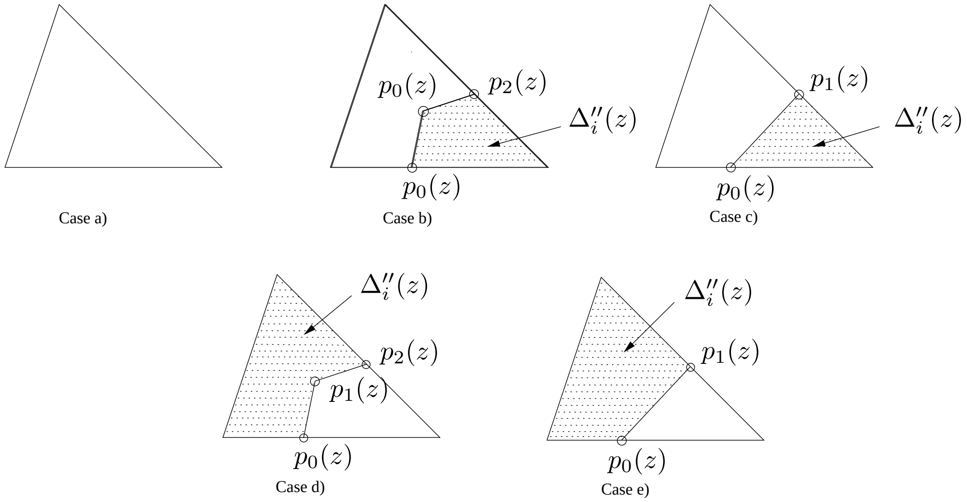
FIG. 5. *The partition of* $\Delta'_j(z)$.



Case a)

Case b)

Case c)

Case d)

Case e)

FIG. 6. *The possible shapes for* $\Delta''_i(z)$.

Define

$$\begin{aligned} F(z) &:= \int_{\Delta''_i(z)} k(z,\xi,\eta)u(\xi,\eta)d\xi d\eta \\ &= \int_0^{\xi_1(z)} \int_0^{s_1(z,\xi)} k(z,\xi,\eta)u(\xi,\eta)d\eta d\xi + \int_0^{\eta_1(z)} \int_{\eta_1(z)}^{s_2(z,\eta)} k(z,\xi,\eta)u(\xi,\eta)d\xi d\eta, \end{aligned}$$

where

$$\begin{aligned} s_1(z,\xi) &:= \eta_2(z) + \xi\frac{\eta_1(z)-\eta_2(z)}{\xi_1(z)}, \\ s'_1(z,\xi) &:= \frac{\partial}{\partial z} s_1(z,\xi) \end{aligned}$$

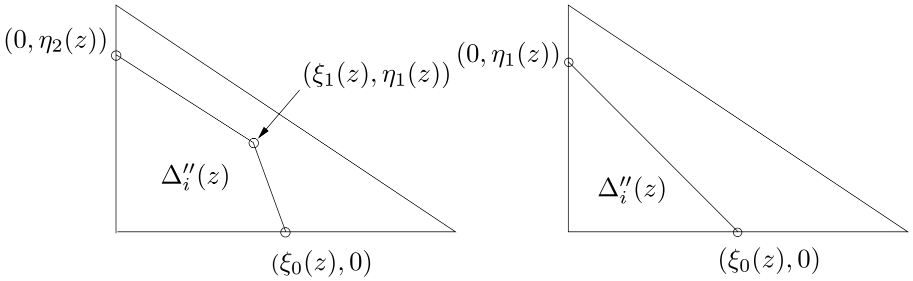


FIG. 7. *The two remaining possible shapes for* $\Delta_i''(z)$.

$$= \eta_2'(z) + \xi \frac{(\eta_1'(z)-\eta_2'(z))\xi_1(z) - \xi_1'(z)(\eta_1(z)-\eta_2(z))}{\xi_1^2(z)},$$

and

$$\begin{aligned} s_2(z,\eta) &:= \xi_0(z) + \eta \frac{\xi_1(z)-\xi_0(z)}{\eta_1(z)}, \\ s_2'(z,\eta) &= \frac{\partial}{\partial z} s_2(z,\eta) \\ &= \xi_0'(z) + \eta \frac{(\xi_1'(z)-\xi_0'(z))\eta_1(z) - \eta_1'(z)(\xi_1(z)-\xi_0(z))}{\eta_1^2(z)}. \end{aligned}$$

Now

$$\begin{aligned} F(z+h) - F(z) = &\int_0^{\xi_1(z)} \int_{s_1(z,\xi)}^{s_1(z+h,\xi)} k(z+h,\xi,\eta)u(\xi,\eta)d\eta d\xi \\ &+ \int_0^{\xi_1(z)} \int_0^{s_1(z,\xi)} (k(z+h,\xi,\eta) - k(z,\xi,\eta))u(\xi,\eta)d\eta d\xi \\ &+ \int_0^{\eta_1(z)} \int_{s_2(z,\eta)}^{s_2(z+h,\eta)} k(z+h,\xi,\eta)u(\xi,\eta)d\xi d\eta \\ &+ \int_0^{\eta_1(z)} \int_{\eta_1(z)}^{s_2(z,\eta)} (k(z+h,\xi,\eta) - k(z,\xi,\eta))u(\xi,\eta)d\xi d\eta \;+\; O(h^2). \end{aligned}$$

This implies

$$\begin{aligned} F'(z) = &\int_0^{\xi_1(z)} k(z,\xi,s_1(z,\xi))u(\xi,s_1(z,\xi))s_1'(z,\xi)d\xi \\ &+ \int_0^{\eta_1(z)} k(z,s_2(z,\eta))u(s_2(z,\eta),\eta)s_2'(z,\eta)d\eta \\ &+ \int_{\Delta_i''(z)} \frac{\partial k}{\partial z}(z,\xi,\eta)u(\xi,\eta)d\xi d\eta, \end{aligned}$$

and this function depends continuously on the variable z. But because of the appearance of $u(\xi,s_1(z,\xi))$ and $u(s_2(z,\eta),\eta)$ under the integral sign, we cannot expect that this function is differentiable if u is only continuous.

In the case of the right-hand side of the picture, we get

$$F'(z) = \int_0^{\xi_0(z)} k(z,\xi,s_1(z,\xi))u(\xi,s_1(z,\xi))s_1'(z,\xi)d\xi$$

$$+\int_{\Delta_i''(z)} \frac{\partial k}{\partial z}(z,\xi,\eta)u(\xi,\eta)d\eta d\xi,$$

and this shows the result for the second case. □

Remark. The previous lemma characterizes the smoothness of the function f_2 in (2.23) because the support of $(1-\varphi)\overline{u}$ is separated from the support of ψ, and we can apply Lemma 4.1 to derive the behavior of f_2. For a more thorough discussion and data structures for the calculation of the triangulation $\cup_{j=1}^{N'}\Delta_j'$, see [6].

Now we turn to f_3 in (2.23). For $x \in B_{2/3}(0)$ the function f_3 is given by

$$f_3(x) = \widetilde{K}[(1-\psi)\varphi u](x),$$

and the smoothness of f_3 follows from the above discussion. For $|x| \geq 2/3$ the smoothness of f_3 follows from the discussion of Rathsfeld [17, Lemma 4.1(ii)], where he showed that this term is in $\mathcal{C}^1$ for continuous u.

For the following we assume that either $T \cap B_1(0) = \emptyset$ (see (4.2)) or $0 \in T$, and then we assume that we introduce new faces on Γ (see (2.20)) to guarantee that each line of $T \cap \Gamma$ belongs to an edge. The last contribution to the right-hand side in (3.3) are the integrals of the faces of Γ, which are not adjacent, or the corresponding parts of the spherical γ are separated. Let F_1 and F_2 be two nonadjacent faces of Γ. We again assume that F_1 is given by

$$(4.5)\quad F_1 := \left\{ r\begin{pmatrix} \sin(\delta) \\ 0 \\ \cos(\delta) \end{pmatrix} =: p_1(r,\delta) \,|\, 0 \leq r \leq \infty,\ \delta \in [0,\delta_0] \right\} \text{with normal}\, \vec{n}_1 = \begin{pmatrix} 0 \\ 1 \\ 0 \end{pmatrix}.$$

For F_2 we assume that the normal is given by

$$(4.6)\qquad \vec{n}_2 := \begin{pmatrix} \sin(\alpha)\cos(\vartheta) \\ \sin(\alpha)\sin(\vartheta) \\ \cos(\alpha) \end{pmatrix}, \quad \alpha \in [0,\pi),\ \vartheta \in [-\pi,\pi).$$

To satisfy the visibility assumption, ϑ has to fulfill $\vartheta \in (-\pi, 0)$. For the plane perpendicular to $\vec{n}_2$ we have the two orthogonal vectors

$$\begin{pmatrix} \cos(\alpha)\cos(\vartheta) \\ \cos(\alpha)\sin(\vartheta) \\ -\sin(\alpha) \end{pmatrix}, \begin{pmatrix} -\sin(\vartheta) \\ \cos(\vartheta) \\ 0 \end{pmatrix}.$$

Therefore, we can assume

$$(4.7)\qquad F_2 = \left\{ r\left[\cos(\delta)\begin{pmatrix} \cos(\alpha)\cos(\vartheta) \\ \cos(\alpha)\sin(\vartheta) \\ -\sin(\alpha) \end{pmatrix} + \sin(\delta)\begin{pmatrix} -\sin(\vartheta) \\ \cos(\vartheta) \\ 0 \end{pmatrix}\right] =: p_2(r,\delta) \,|\, r \geq 0,\ \delta \in [\delta_1,\delta_2] \right\}.$$

Let $u \in \mathcal{C}([0,\infty) \times [\delta_1,\delta_2])$ with compact support, and define

$$(4.8)\ w(r,\delta) := \int_{F_2} \beta(r,\delta,r',\delta') \frac{\vec{n}_1 \cdot (p_2(r',\delta') - p_1(r,\delta))\, \vec{n}_2 \cdot (p_1(r,\delta) - p_2(r',\delta'))}{\|p_1(r,\delta) - p_2(r',\delta')\|^4} r' u(r',\delta') dr' d\delta'$$
$$= \int_0^\infty \int_{\delta_1}^{\delta_2} \beta(r,\delta,r',\delta') k(r,\delta,r',\delta') u(r',\delta') d\delta' dr',$$

where

$$(4.9)\ k(r,\delta,r',\delta') = r'^2 r \frac{(\cos(\delta)\cos(\alpha)\sin(\vartheta) + \sin(\delta)\cos(\vartheta))(\sin(\delta)\sin(\alpha)\cos(\vartheta) + \cos(\delta)\cos(\alpha))}{(r^2 + r'^2 - 2rr'\omega(\delta,\delta'))^2}$$

and

$$\omega(\delta,\delta') := \sin(\delta)(\cos(\delta')\cos(\alpha)\cos(\vartheta) - \sin(\delta')\sin(\vartheta)) - \cos(\delta)\cos(\delta')\sin(\alpha)$$
$$(4.10)\qquad \leq c < 1, \quad \delta \in [0,\delta_0], \quad \delta' \in [\delta_1,\delta_2],$$

because F_1 and F_2 are not adjacent. This implies

$$(4.11)\qquad k \in \mathcal{C}^\infty([0,\infty) \times [0,\delta_0] \times [0,\infty) \times [\delta_1,\delta_2]).$$

If we take into account shadow lines, then we get

$$(4.12)\qquad w(r,\delta) = \int_0^\infty \int_{\delta_1(r,\delta)}^{\delta_2(r,\delta)} k(r,\delta,r',\delta') u(r',\delta') d\delta' dr'.$$

This shows that

$$(4.13)\qquad w \in \mathcal{C}^1([0,\infty) \times [0,\delta]),$$

where we mention also that the first derivative is continuous up to the boundary.

If the right-hand side $E(x)$ of (1.1) is continuous differentiable on each closed face, then the right-hand side of (3.3) is a $\mathcal{C}^1$-function up to the edge with continuous first derivative. Therefore, the Mellin transform with respect to the δ variable of the right-hand side exists for $Re(z) > -1$, but there is eventually a pole at $z = 0$ which corresponds to the value at $\delta = 0$. The regularity of the solution with respect to the δ-variable is determined by Lemma 3.5. We denote by

$$(4.14)\qquad \overline{\nu}_2 = \overline{\nu}(\alpha, \sqrt{\rho_1\rho_2}) \in [0, 3/2)$$

the unique solution of

$$\sqrt{\rho_1\rho_2}(1+\cos(\alpha)) B\left(\frac{3}{2} - \nu_2, \frac{3}{2} + \nu_2\right) {}_2F_1\left(\frac{1}{2} + \nu_2, \frac{1}{2} - \nu_2, 2, \frac{1+\cos(\alpha)}{2}\right) = 1,$$

where α is the angle of Figure 2, and the uniqueness follows by [17, Lemma 3.1]. The next corollary collects the results from this section and the remark after Theorem 3.6.

COROLLARY 4.2. *Let $E : S \to \mathbb{R}$ be continuous differentiable on all faces $\overline{\Delta'_j}$ (see (4.3)) of S, and denote by $\overline{u}$ the solution of (1.1).*

1. *$\overline{u}|_{\Delta'_j}$ is a $\mathcal{C}^1$-function for all j. If the boundary of Δ'_j has no points in common with an edge of S, then we have $\overline{u}|_{\overline{\Delta'_j}} \in \mathcal{C}^1(\overline{\Delta'_j})$.*

2. *If $v \in S$ is a vertex of S and Δ'_j and Δ'_k are two adjacent faces with v as a common point, we denote by $\overline{u}_v$ the localization of $\overline{u}$ to the edge $\overline{\Delta'_j} \cap \overline{\Delta'_k}$. We introduce polar coordinates and denote by $\widehat{u}_v$ the Mellin transform of $\overline{u}_v$ with respect to the r variable. Then we get*

$$\widehat{u}(z,\delta) = \widehat{u}(z,0) + O_{\delta\to 0}(\delta^{\overline{\nu}_2 - 1/2}), \quad \mathrm{Re}(z) \in (0,3), \tag{4.15}$$

where $\overline{\nu}_2$ is given by (4.14); see also Figure 3 *for the shape of the function $\overline{\nu}_2(\cdot)$.*

3. *If Δ'_j is a triangle which gets only light from faces, which can be seen from every point of Δ'_j (even if these faces are adjacent), then we have*

$$\overline{u}|_{\Delta'_j} \in \mathcal{C}^\infty(\Delta'_j) \tag{4.16}$$

if $E \in \mathcal{C}^\infty(\Delta'_j)$.

Conclusion. In section 3 we proved regularity results for the solution $\overline{u}$ of the radiosity equation (2.7) in the vicinity of an arbitrary vertex $\mathcal{V}$ of S under the assumption that the set Ω is convex. So if Ω is convex or if the contributions from distant parts of S ($\psi K(1-\phi)\overline{u}$; see (2.23)) are negligible, then Theorem 3.6, especially formula (3.34), indicates how to grade the meshes for the numerical solution in the direction toward the edges in the vicinity of a vertex. In the case of a convex set, Corollaries 3.11–3.12 further show that the solution $\overline{u}$ is a $\mathcal{C}^\infty$-function if the right-hand side of the radiosity equation is a $\mathcal{C}^\infty$-function.

In section 4, we consider the nonconvex case and get the result that we can divide the surface S in smaller triangles, such that the solution is $\mathcal{C}^1$ on these smaller triangles if the given emissivity function is a $\mathcal{C}^1$-function. This partitioning into smaller triangles is related to the discontinuity meshing; see [10, 11, 7, 9]. On these finer triangulations we can also apply the results from section 3; see Corollary 4.2(2) and 4.2(3).

STABILITY OF ENTROPY SOLUTIONS TO THE CAUCHY PROBLEM FOR A CLASS OF NONLINEAR HYPERBOLIC-PARABOLIC EQUATIONS[*]

GUI-QIANG CHEN[†] AND EMMANUELE DIBENEDETTO[‡]

Abstract. Consider the Cauchy problem for the nonlinear hyperbolic-parabolic equation:

$$u_t + \frac{1}{2}\,\mathbf{a}\cdot\nabla_x u^2 = \Delta u_+ \qquad \text{for } t > 0, \tag{$*$}$$

where $\mathbf{a}$ is a constant vector and $u_+ = \max\{u, 0\}$. The equation is hyperbolic in the region $[u < 0]$ and parabolic in the region $[u > 0]$. It is shown that entropy solutions to $(*)$ that grow at most linearly as $|x| \to \infty$ are stable in a weighted $L^1(\mathbb{R}^N)$ space, which implies that the solutions are unique. The linear growth as $|x| \to \infty$ imposed on the solutions is shown to be optimal for uniqueness to hold. The same results hold if the Burgers nonlinearity $\frac{1}{2}\,\mathbf{a}u^2$ is replaced by a general flux function $\mathbf{f}(u)$, provided $\mathbf{f}'(u(x,t))$ grows in x at most linearly as $|x| \to \infty$, and/or the degenerate term u_+ is replaced by a nondecreasing, degenerate, Lipschitz continuous function $\beta(u)$ defined on $\mathbb{R}$. For more general $\beta(\cdot)$, the results continue to hold for bounded solutions.

1. Introduction and results.

Consider the Cauchy problem for the nonlinear hyperbolic-parabolic equation

$$\begin{aligned} &u_t + \frac{1}{2}\,\mathbf{a}\cdot\nabla_x u^2 = \Delta u_+ \qquad \text{in } \mathcal{D}'(S_T),\\ &u(\cdot,0) = u_0 \in L^\infty_{\text{loc}}(\mathbb{R}^N), \end{aligned} \tag{1.1}$$

where $\mathbf{a}$ is a constant vector, $u_+ = \max\{u, 0\}$, the set S_T is the strip

$$S_T = \mathbb{R}^N \times (0, T] \qquad \text{for some } T > 0,$$

and the initial data are taken in the sense of $L^1_{\text{loc}}(\mathbb{R}^N)$.

The equation in (1.1) could be regarded as a prototype model for the motion of an ideal fluid filling $\mathbb{R}^N$ and exhibiting both viscous and nonviscous phases. The set $[u > 0]$ can be identified with the viscous phase, the set $[u < 0]$ is the inviscid phase, and the set $[u = 0]$ is the free boundary interface separating these phases. Accordingly, the equation in (1.1) is of mixed type; i.e., it is hyperbolic in the inviscid phase and parabolic in the viscous phase. It can also be regarded as degenerate parabolic.

The main issues relating to the Cauchy problem (1.1) are its unique solvability and the local behavior of its solutions. Both issues are relatively well understood if

[‡] Department of Mathematics, Vanderbilt University, Nashville, TN 60208–2730 (dibe@math.vanderbilt.edu). This author's work was partially supported by NSF grants DMS-9706388 and DMS-9708261.

one removes the hyperbolic part $\mathbf{a}\cdot\nabla u^2$, thereby obtaining a degenerate parabolic equation (see, for example, the discussion and references of [6, 7, 8]). They are equally well understood if one removes the viscosity term Δu_+. This would give the N-dimensional Burgers equation (see, for example, [3, 4, 5]).

We establish that entropy solutions of (1.1) that grow at most linearly as $|x|\to\infty$ are stable, which implies that the solutions are unique. We also show that such a growth is optimal for uniqueness to hold.

For a smooth convex function $\eta(\cdot)$, let $\mathbf{q}(\eta;u)$ denote the flux function corresponding to the entropy $\eta(u)$, i.e.,

$$q(\eta;u) = \int_0^u s\eta'(s)ds, \qquad \mathbf{q}(\eta;u)\equiv q(\eta;u)\,\mathbf{a}. \tag{1.2}$$

A function $u\in L^\infty_{\rm loc}(S_T)$ is an entropy solution of the Cauchy problem (1.1) if

$$u_+ \in L^2\big(0,T;W^{1,2}_{\rm loc}(\mathbb{R}^N)\big) \tag{1.3}$$

and if, for every convex function $\eta\in C^2(\mathbb{R})$, for any nonnegative testing function $\psi\in C^1\big([0,T);C^2_0(\mathbb{R}^N)\big)$ with $\psi|_{t\geq T}=0$,

$$\begin{aligned}&\int_{S_T}\big\{\eta(u)\,\psi_t + \mathbf{q}(\eta;u)\cdot\nabla_x\psi - \eta'(u)\nabla_x u_+\cdot\nabla_x\psi\big\}\,dxdt\\ &-\int_{S_T}\eta''(u)\,|\nabla_x u_+|^2\,\psi\,dxdt + \int_{\mathbb{R}^N}\eta(u_0)\,\psi(x,0)\,dx\geq 0.\end{aligned}\tag{1.4}$$

Entropy solutions are distributional solutions. Since $u\in L^\infty_{\rm loc}(S_T)$, an adaptation of the results of [2] implies that $u_+\in C_{\rm loc}(S_T)$.

Main Theorem. *Let u and v be two entropy solutions of* (1.1) *in the sense of* (1.2)–(1.4) *for initial data u_0 and v_0. Assume, in addition, that they satisfy the growth condition*

$$|u(x,t)|+|v(x,t)| \leq \gamma(1+|x|) \tag{1.5}$$

for almost all $(x,t)\in\mathbb{R}^N\times[0,T]$, for some positive constant γ. Then there exists a smooth, positive weight $w(x,t)$ that can be determined a priori only in terms of γ and satisfying

$$w(x,t)\,\big(1+|x|\big)\in L^1(\mathbb{R}^N), \qquad \textit{uniformly in } t\in(0,T),$$

such that

$$\int_{\mathbb{R}^N} w(x,t)\,\big|u(x,t)-v(x,t)\big|\,dx \leq \int_{\mathbb{R}^N} w(x,0)\,\big|u_0(x)-v_0(x)\big|\,dx \tag{1.6}$$

for a.e. $t\in(0,T]$.

The theorem continues to hold if the Burgers nonlinearity $\frac{1}{2}\mathbf{a}u^2$ is replaced by a more general flux function $\mathbf{f}(u)$, provided $|\mathbf{f}'(u(x,t))|$ grows in x at most linearly as $|x|\to\infty$ for any fixed $t\in[0,T)$. Also, the degenerate term u_+ can be replaced by a nondecreasing, degenerate (possibly identically zero), Lipschitz continuous function $\beta(u)$ defined in $\mathbb{R}$. These generalizations follow, mutatis mutandis, from the arguments in sections 3–7. The Lipschitz requirement on $\beta(\cdot)$ would exclude degeneracies of the type $\beta(u) = u_+^m$ for some $m > 1$. For such a $\beta(\cdot)$, the theorem continues to hold for bounded solutions.

The stability theorem and the techniques we develop here may be useful to make error estimates for various approximate solutions, especially numerical methods, and to establish similar results for more general hyperbolic-parabolic equations, which model a wide variety of phenomena, ranging from porous media flow, via flow of glaciers and sedimentation processes, to traffic flow.

In section 2, we make some remarks to show that the linear growth as $|x| \to \infty$ imposed on the solutions in our main theorem is optimal; and the solutions in general are local, and if they exist, they blow up in finite time.

In order to prove the main theorem, in section 3, we first use the definition (1.4) of entropy solutions to derive two integral inequalities for a class of C^2 entropy-entropy flux pairs, depending on a parameter $\varepsilon > 0$. These two inequalities are written for two entropy solutions u and v of (1.1) with initial data u_0 and v_0, respectively.

In section 4, we first add these two integral inequalities and choose appropriate testing functions depending upon a parameter $h > 0$. These testing functions have a mollifier-type effect and serve to handle the possible irregularity of the solutions. Then we introduce a change of variables and employ the new variables in sections 5 and 6 to transform these integral inequalities into a form suitable to study the limits as $\varepsilon \to 0$ and then $h \to 0$ in the indicated order. This will produce a further more stringent integral inequality for u and v involving testing functions still to be chosen. In section 7, such testing functions are chosen to identify the weight $w(x,t)$ and the stability result (1.6).

2. Remarks on the stability.

Distributional solutions, which are not entropy solutions, are not unique and hence are not stable. For example, nonpositive solutions of (1.1) would be solutions of the inviscid Burgers equation, for which uniqueness fails outside the class of entropy solutions [3, 4, 5].

The growth condition (1.5) is optimal for uniqueness (hence stability) to hold. For this, consider locally bounded, nonnegative solutions of (1.1) for $N = 1$, i.e.,

$$\begin{aligned} &u_t + u\,u_x = u_{xx} \quad \text{in } \mathcal{D}'(S_T), \\ &u(\cdot,0) = u_0 \geq 0 \qquad \text{and smooth in } \mathbb{R}. \end{aligned} \tag{2.1}$$

Solutions of (2.1) are smooth and positive in S_T. Set

$$v(x,t) = \int_\alpha^x u(y,t)\,dy \qquad \text{for some } \alpha \in \mathbb{R}.$$

Then $u = v_x$, and u is a solution of (2.1) if and only if v is a classical solution of

$$\begin{aligned} &v_t + \frac{1}{2}(v_x)^2 - v_{xx} = c_\alpha(t), \\ &v(x,0) = \int_\alpha^x u_0(y)\,dy, \end{aligned} \tag{2.1$_v$}$$

where

$$c_\alpha(t) = \frac{1}{2}u^2(\alpha,t) - u_x(\alpha,t).$$

The Hopf-like transformation

$$w(x,t) \;=\; \exp\left\{-\frac{1}{2}\,v \,+\, \frac{1}{2}\int_0^t c_\alpha(\tau)\,d\tau\right\}$$

transforms $(2.1)_v$ into the equivalent formulation

$$(2.1)_w \qquad \begin{aligned} w_t \,-\, w_{xx} \;&=\; 0 \qquad \text{in } \; S_T, \\ w(x,0) \;&=\; \exp\left\{-\frac{1}{2}\,v(x,0)\right\}. \end{aligned}$$

Therefore, well-posedness for (2.1) is equivalent to well-posedness for $(2.1)_w$. The latter is well-posed if and only if

$$w(x,t) \;\leq\; \exp\left\{C\,\left(1 \,+\, x^2\right)\right\}$$

for some positive constant C and for all $t \in [0,T]$ (see [1, Chap. 5]). The constant C and the time T are linked by $4CT < 1$. By the Tychonov counterexample [1, p. 237], a faster growth would not guarantee uniqueness.

In terms of $u = -2(e^w)_x$, this implies that the stability theorem would be false for solutions growing faster than linearly as $|x| \to \infty$. This also implies that solutions of (1.1) are, in general, not global in time.

If the initial datum u_0 is bounded in $\mathbb{R}^N$ and in $BV(\mathbb{R}^N)$, then solutions of (1.1) can be constructed as in Volpert–Hudjaev [7, 8]. For such initial data, the authors also proved uniqueness. If the initial datum u_0 is bounded in $\mathbb{R}^N$ but not necessarily regular (i.e., not in $BV(\mathbb{R}^N)$), the existence of entropy solutions can be established as in Kruzhkov [3, 4], as indicated also in [6]. The same construction also implies $\nabla u_+ \in L^2_{\mathrm{loc}}(S_T)$. Attention to the uniqueness problem for parabolic-hyperbolic equations such as (1.1) has been drawn in [6].

If the initial datum is unbounded, then, by the previous remarks, solutions in general are local, and if they exist, they blow up in finite time. An existence theorem would have to involve an estimation of the blow-up time.

3. Proof of the stability theorem (i). In this section, we first use the definition (1.4) of entropy solutions to derive two integral inequalities for a class of C^2 entropy-entropy flux pairs, depending on a parameter $\epsilon > 0$.

To choose suitable entropy functions $\eta(u)$ in (1.4), introduce the regularizations of the Heaviside function:

$$H_\varepsilon(s) \equiv \begin{cases} 1 & \text{if } \; s > \varepsilon, \\ \sin\left(\dfrac{\pi}{2\varepsilon}\,s\right) & \text{if } \; |s| \leq \varepsilon, \\ -1 & \text{if } \; s < -\varepsilon. \end{cases}$$

Then, for each $k \in \mathbb{R}$, the functions

$$(3.1) \qquad u \longrightarrow \eta_\varepsilon(u-k) \equiv \int_0^{u-k} H_\varepsilon(s)\,ds, \qquad 0 < \varepsilon \ll 1,$$

are convex and of class C^2 in $\mathbb{R}$. Moreover,

$$(3.1)' \qquad \eta_\varepsilon(u-k) \longrightarrow |u-k| \qquad \text{as } \; \varepsilon \,\to\, 0.$$

For the corresponding flux functions defined in (1.2), we set

$$\mathbf{Q}_\varepsilon(u;k) \,=\, \mathbf{q}(\eta_\varepsilon;u) \,\equiv\, \left(\int_k^u s\,H_\varepsilon(s-k)\,ds\right)\mathbf{a}. \tag{3.2}$$

One verifies that

$$\mathbf{Q}_\varepsilon(u;k) \longrightarrow \frac{1}{2}\left|u^2-k^2\right|\mathbf{a} \qquad \text{as} \quad \varepsilon \to 0. \tag{3.2$'$}$$

In (1.4) we choose nonnegative testing functions $(x,t;y,\tau) \to \psi(x,t;y,\tau)$ depending upon two pairs of variables (x,t) and (y,τ) such that

$$\begin{aligned} &(x,t) \,\to\, \psi(x,t;y,\tau) \,\in\, C^1\big([0,T);C_0^2(\mathbb{R}^N)\big) \quad \text{ uniformly in } (y,\tau),\\ &(y,\tau) \,\to\, \psi(x,t;y,\tau) \,\in\, C^1\big([0,T);C_0^2(\mathbb{R}^N)\big) \quad \text{ uniformly in } (x,t). \end{aligned}$$

We also require that $\psi(x,t;y,\tau)=0$ for $t \ge T$ or $\tau \ge T$. With such a choice, (1.4) can be written interchangeably in terms of either pair of variables.

In (1.4), written in terms of (x,t), choose the entropy function

$$(x,t) \longrightarrow \eta_\varepsilon\big(u(x,t)-v(y,\tau)\big), \qquad (y,\tau)\in S_T \text{ fixed.} \tag{3.1$_{(x,t)}$}$$

For the choice of $k=v(y,\tau)$, the flux function introduced in (3.2) takes the form

$$\mathbf{Q}_\varepsilon\big(u(x,t);v(y,\tau)\big) \,=\, \left(\int_{v(y,\tau)}^{u(x,t)} s\,H_\varepsilon\big(s-v(y,\tau)\big)\,ds\right)\mathbf{a}. \tag{3.2$_{(x,t)}$}$$

We put these choices in (1.4) and then integrate over S_T in $dyd\tau$ to obtain

(3.3)$_{(x,t)}$

$$\begin{aligned} \int_{S_T}\int_{S_T}\Big\{\, &\eta_\varepsilon\big(u(x,t)-v(y,\tau)\big)\psi_t + \mathbf{Q}_\varepsilon\big(u(x,t);v(y,\tau)\big)\cdot\nabla_x\psi\\ &-H_\varepsilon\big(u(x,t)-v(y,\tau)\big)\nabla_x u_+(x,t)\cdot\nabla_x\psi\\ &-H'_\varepsilon\big(u(x,t)-v(y,\tau)\big)|\nabla_x u_+(x,t)|^2\,\psi\Big\}dxdt\,dyd\tau\\ &+\int_{S_T}\int_{\mathbb{R}^N}\eta_\varepsilon\big(u_0(x)-v(y,\tau)\big)\,\psi(x,0;y,\tau)\,dx\,dyd\tau \,\ge\, 0. \end{aligned}$$

Next we write the weak formulation (1.1) for the solution $(y,\tau)\to v(y,\tau)$, and in the resulting expression we take the entropy function

$$(y,\tau) \longrightarrow \eta_\varepsilon\big(v(y,\tau)-u(x,t)\big), \qquad (x,t)\in S_T \text{ fixed,} \tag{3.1$_{(y,\tau)}$}$$

and the corresponding flux function

$$\mathbf{Q}_\varepsilon\big(v(y,\tau);u(x,t)\big) = \left(\int_{u(x,t)}^{v(y,\tau)} s\,H_\varepsilon\big(s-u(x,t)\big)\,ds\right)\mathbf{a}. \tag{3.2$_{(y,\tau)}$}$$

Integrating over S_T in $dxdt$ yields

$(3.3)_{(y,\tau)}$
$$\int_{S_T}\int_{S_T}\Big\{\eta_\varepsilon\big(v(y,\tau)-u(x,t)\big)\psi_\tau + \mathbf{Q}_\varepsilon\big(v(y,\tau);u(x,t)\big)\cdot\nabla_y\psi$$
$$-H_\varepsilon\big(v(y,\tau)-u(x,t)\big)\nabla_y v_+(y,\tau)\cdot\nabla_y\psi$$
$$-H'_\varepsilon\big(v(y,\tau)-u(x,t)\big)|\nabla_y v_+(y,\tau)|^2\,\psi\Big\}dxdt\,dyd\tau$$
$$+\int_{S_T}\int_{\mathbb{R}^N}\eta_\varepsilon\big(v_0(y)-u(x,t)\big)\,\psi(x,t;y,0)dy\,dxdt \ \ge\ 0.$$

4. Proof of the stability theorem (ii). In this section, we first add the inequalities $(3.3)_{(x,t)}$–$(3.3)_{(y,\tau)}$ and choose appropriate testing functions depending upon a parameter $h>0$, and then we introduce a change of variables to transform these integral inequalities into a form suitable to study the limits as ϵ and h tend to zero.

We now add the inequalities $(3.3)_{(x,t)}$–$(3.3)_{(y,\tau)}$ and use the facts that η_ε and η''_ε are even functions and η'_ε is odd to obtain

$$I_{1,\varepsilon} + I_{2,\varepsilon} + I_{3,\varepsilon} \ge 0, \tag{4.1}$$

where we have set

$$I_{1,\varepsilon} = \int_{S_T}\int_{S_T}\Big\{\ \eta_\varepsilon\big(u(x,t)-v(y,\tau)\big)\,(\psi_t + \psi_\tau)$$
$$+\mathbf{Q}_\varepsilon\big(u(x,t);v(y,\tau)\big)\cdot\nabla_x\psi \tag{4.2}$$
$$+\mathbf{Q}_\varepsilon\big(v(y,\tau);u(x,t)\big)\cdot\nabla_y\psi\Big\}dxdt\,dyd\tau,$$

$$I_{2,\varepsilon} = -\int_{S_T}\int_{S_T}\Big\{H_\varepsilon\ \big(u(x,t)-v(y,\tau)\big)$$
$$\times\big[\nabla_x u_+(x,t)\cdot\nabla_x\psi\ -\ \nabla_y v_+(y,\tau)\cdot\nabla_y\psi\big]$$
$$+\ H'_\varepsilon\big(u(x,t)-v(y,\tau)\big) \tag{4.3}$$
$$\times\big[|\nabla_x u_+(x,t)|^2 + |\nabla_y v_+(y,\tau)|^2\big]\psi\Big\}dxdt\,dyd\tau,$$

and

$$I_{3,\varepsilon} = \int_{S_T}\int_{\mathbb{R}^N}\eta_\varepsilon\big(u_0(x)-v(y,\tau)\big)\psi(x,0;y,\tau)dx\,dyd\tau$$
$$+\int_{S_T}\int_{\mathbb{R}^N}\eta_\varepsilon\big(v_0(y)-u(x,t)\big)\psi(x,t;y,0)dy\,dxdt. \tag{4.4}$$

Next we choose the function $(x,t;y,\tau)\to\psi(x,t;y,\tau)$ of the form

$$\psi(x,t;y,\tau) = \varphi\left(\frac{1}{2}(x+y);\frac{1}{2}(t+\tau)\right) j_h\left(\frac{1}{2}(x-y);\frac{1}{2}(t-\tau)\right),$$

where $\varphi(\cdot;\cdot) \in C_0^\infty(S_T)$ is nonnegative and

$$j_h\left(\frac{1}{2}(x-y);\frac{1}{2}(t-\tau)\right) = \omega_h\left(\frac{1}{2}|x-y|\right)\omega_h\left(\frac{1}{2}(t-\tau)\right).$$

Here ω denotes the standard, symmetric mollifying kernel in $\mathbb{R}$, and

$$\omega_h(s) = \frac{1}{h}\,\omega\left(\frac{s}{h}\right), \quad \text{and} \quad \omega_h(s) = 0 \quad \text{for } |s| \geq h.$$

Consider the change of variables:

$$\begin{array}{llll} \xi = \frac{1}{2}(x+y), & \zeta = \frac{1}{2}(x-y), & s = \frac{1}{2}(t+\tau), & \sigma = \frac{1}{2}(t-\tau), \\ x = \xi+\zeta, & y = \xi-\zeta, & t = s+\sigma, & \tau = s-\sigma, \end{array} \tag{4.5}$$

whose Jacobian is 4. As $(x,t;y,\tau)$ range over $S_T \times S_T$, the new variables (ξ, s) range over S_T and (ζ,σ) range over S_T', where

$$S_T' = \mathbb{R}^N \times \left(-\frac{1}{2}T\,,\,\frac{1}{2}T\right).$$

Therefore, the change of variables in (4.5) maps $S_T \times S_T$ into $S_T \times S_T'$. In terms of the new variables, we compute

$$\begin{aligned} \psi(x,t;y,\tau) &= \varphi(\xi;s)\,j_h(\zeta;\sigma), \\ \nabla_x\psi &= \frac{1}{2}\left\{\nabla_\xi\varphi\,j_h + \varphi\,\nabla_\zeta j_h\right\}, \\ \nabla_y\psi &= \frac{1}{2}\left\{\nabla_\xi\varphi\,j_h - \varphi\,\nabla_\zeta j_h\right\}, \\ \nabla_x u_+(x,t) &= \frac{1}{2}\left\{\nabla_\xi u_+(\xi+\zeta\,,\,s+\sigma) + \nabla_\zeta u_+(\xi+\zeta\,,\,s+\sigma)\right\} \\ &= \nabla_\xi u_+(\xi+\zeta\,,\,s+\sigma), \\ \nabla_y v_+(y,\tau) &= \frac{1}{2}\left\{\nabla_\xi v_+(\xi-\zeta\,,\,s-\sigma) + \nabla_\xi v_+(\xi-\zeta\,,\,s-\sigma)\right\} \\ &= \nabla_\xi v_+(\xi-\zeta\,,\,s-\sigma), \\ \nabla_x j_h + \nabla_y j_h &= 0, \qquad j_{h,t} + j_{h,\tau} = 0, \\ \nabla_x\psi + \nabla_y\psi &= \nabla_\xi\varphi\,j_h, \qquad \psi_t + \psi_\tau = \varphi_s\,j_h, \\ \varphi_{\zeta_i} &= 0, \qquad j_{h,\xi_i} = 0, \quad i = 1,2,\ldots,N. \end{aligned}$$

In view of the dependence of u upon $(\xi+\zeta)$ and of v upon $(\xi-\zeta)$,

$$\begin{aligned} \nabla_\xi u_+(\xi+\zeta\,,\,s-\sigma) &= \nabla_\zeta u_+(\xi+\zeta\,,\,s-\sigma), \\ \nabla_\xi v_+(\xi-\zeta\,,\,s-\sigma) &= -\nabla_\zeta v_+(\xi-\zeta\,,\,s-\sigma). \end{aligned} \tag{4.6}$$

Next, using these new variables, we transform the various integrals in (4.1).

5. Transformation and limits of $I_{2,\varepsilon}$. We first use the new variables introduced in section 4 to transform $I_{2,\varepsilon}$ into a form suitable to study the limits as $\varepsilon \to 0$ and then $h \to 0$ in the indicated order, and we then estimate the limits.

With the indicated choices and change of variables, we have

$$\begin{aligned}
-\frac{1}{2}I_{2,\varepsilon} &= \int_{S'_T}\int_{S_T} H_\varepsilon\big(u(\xi+\zeta,s+\sigma)-v(\xi-\zeta,s-\sigma)\big)\\
&\quad\times\Big\{\,\nabla_\xi u_+(\xi+\zeta,s+\sigma)\cdot(\nabla_\xi\varphi\, j_h+\varphi\nabla_\zeta j_h)\\
&\qquad -\nabla_\xi v_+(\xi-\zeta,s-\sigma)\,(\nabla_\xi\varphi\, j_h-\varphi\nabla_\zeta j_h)\,\Big\}d\xi ds\,d\zeta d\sigma\\
&\qquad +2\int_{S'_T}\int_{S_T} H'_\varepsilon\big(u(\xi+\zeta,s+\sigma)-v(\xi-\zeta,s-\sigma)\big)\\
&\qquad \times\left\{|\nabla_\xi u_+|^2\,+\,|\nabla_\xi v_+|^2\right\}\,\varphi\, j_h\, d\xi ds\,d\zeta d\sigma\\
&= \int_{S'_T}\int_{S_T} H_\varepsilon(u-v)\nabla_\xi(u_+-v_+)\cdot\nabla_\xi\varphi\, j_h\, d\xi ds\,d\zeta d\sigma\\
&\quad +\int_{S'_T}\int_{S_T} H_\varepsilon(u-v)\nabla_\xi(u_++v_+)\cdot\varphi\,\nabla_\zeta j_h\, d\xi ds\,d\zeta d\sigma\\
&\quad +2\int_{S'_T}\int_{S_T} H'_\varepsilon\big(u(\xi+\zeta,s+\sigma)-v(\xi-\zeta,s-\sigma)\big)\\
&\quad \times\left\{|\nabla_\xi u_+|^2\,+\,|\nabla_\xi v_+|^2\right\}\,\varphi\, j_h\, d\xi ds\,d\zeta d\sigma\\
&= I^{(1)}_{2,\varepsilon}\,+\,I^{(2)}_{2,\varepsilon}\,+\,I^{(3)}_{2,\varepsilon}.
\end{aligned}$$

In transforming these integrals, we make use of the integrability of ∇u_+. In particular, $|\nabla u_+|$ vanishes a.e. on the set $[u\le 0]$, and a similar fact holds for v_+. Then, for a.e. $(\xi,s;\zeta,\sigma)\in S_T\times S'_T$, we write

$$\begin{aligned}
H_\varepsilon(u-v)\nabla_\xi(u_+-v_+) &= H_\varepsilon(u_+-v_+)\nabla_\xi(u_+-v_+)\\
&\quad +\nabla_\xi u_+\left\{H_\varepsilon(u_+-v)-H_\varepsilon(u_+-v_+)\right\}\\
&\quad +\nabla_\xi v_+\left\{H_\varepsilon(u_+-v_+)-H_\varepsilon(u-v_+)\right\}.
\end{aligned}$$

As $\varepsilon\to 0$, the last two terms tend to zero a.e. on every compact subset of $S_T\times S'_T$, and their modulus is dominated, uniformly in ε, by a locally integrable function. Thus, when they are put in the expression of $I^{(1)}_{2,\varepsilon}$ and after we take the limit as $\varepsilon\to 0$, they give no contribution. This process in $I^{(1)}_{2,\varepsilon}$ gives

$$\begin{aligned}
\lim_{\varepsilon\to 0} I^{(1)}_{2,\varepsilon} &= \lim_{\varepsilon\to 0}\int_{S'_T}\int_{S_T}\nabla_\xi\left(\int_0^{u_+-v_+} H_\varepsilon(\theta)d\theta\right)\cdot\nabla_\xi\varphi\, j_h\, d\xi ds\,d\zeta d\sigma\\
&= -\lim_{\varepsilon\to 0}\int_{S'_T}\int_{S_T}\eta_\varepsilon(u_+-v_+)\,\Delta_\xi\varphi\, j_h\, d\xi ds\,d\zeta d\sigma\\
&= -\int_{S'_T}\int_{S_T}|u_+-v_+|\,\Delta_\xi\varphi\, j_h\, d\xi ds\,d\zeta d\sigma.
\end{aligned}$$

In transforming $I^{(2)}_{2,\varepsilon}$, we first assume that u_+ and v_+ are regular, and we proceed formally. By a repeated formal integration by parts,

$$\begin{aligned}
I^{(2)}_{2,\varepsilon} &= -\int_{S'_T}\int_{S_T} H'_\varepsilon(u_+-v_+)\,\nabla_\xi(u_++v_+)\cdot\nabla_\zeta(u_+-v_+)\,\varphi\, j_h\, d\xi ds\, d\zeta d\sigma \\
&\quad -\int_{S'_T}\int_{S_T} H_\varepsilon(u_+-v_+)\,\mathrm{div}_\zeta\nabla_\xi(u_++v_+)\,\varphi\, j_h\, d\xi ds\, d\zeta d\sigma \\
&= -\int_{S'_T}\int_{S_T} H'_\varepsilon(u_+-v_+)\Big\{\nabla_\xi(u_++v_+)\cdot\nabla_\zeta(u_+-v_+) \\
&\qquad\qquad -\nabla_\xi(u_+-v_+)\cdot\nabla_\zeta(u_++v_+)\Big\}\,\varphi\, j_h\, d\xi ds\, d\zeta d\sigma \\
&\quad +\int_{S'_T}\int_{S_T} H_\varepsilon(u_+-v_+)\,\nabla_\zeta(u_++v_+)\cdot\nabla_\xi\varphi\, j_h\, d\xi ds\, d\zeta d\sigma.
\end{aligned}\tag{5.1}$$

From this, taking into account the differentiation formulae (4.6) and performing a further integration by parts, we have

$$\begin{aligned}
I^{(2)}_{2,\varepsilon} &= \int_{S'_T}\int_{S_T} H'_\varepsilon(u_+-v_+)\big\{|\nabla_\xi(u_+-v_+)|^2 \\
&\qquad\qquad -|\nabla_\xi(u_++v_+)|^2\big\}\,\varphi\, j_h\, d\xi ds\, d\zeta d\sigma \\
&\quad -\int_{S'_T}\int_{S_T}\left(\int_0^{(u_+-v_+)} H_\varepsilon(\theta)d\theta\right)\Delta_\xi\varphi\, j_h\, d\xi ds\, d\zeta d\sigma.
\end{aligned}\tag{5.2}$$

These calculations can be made rigorous by the following procedure. Denote by $u_{+,\nu}$ and $v_{+,\nu}$ the mollifications of u_+ and v_+ with respect to the variables ξ and ζ. Then

$$I^{(2)}_{2,\varepsilon} = o_\nu(1) + \int_{S'_T}\int_{S_T} H_\varepsilon(u_{+,\nu}-v_{+,\nu})\nabla_\xi(u_{+,\nu}+v_{+,\nu})\cdot\varphi\,\nabla_\zeta j_h\, d\xi ds\, d\zeta d\sigma,$$

where, for $\varepsilon > 0$ fixed, $o_\nu(1) \to 0$ as $\nu \to 0$. We perform integrations by parts in the integrals involving $u_{+,\nu}$ and $v_{+,\nu}$ to arrive at a formula analogous to (5.2). We then let $\nu \to 0$ to obtain (5.2), the various limits being justified, since ∇u_+ and ∇v_+ are in $L^2_{\mathrm{loc}}(S_T)$. Finally, letting $\varepsilon \to 0$ gives

$$\begin{aligned}
\liminf_{\varepsilon\to 0} I^{(2)}_{2,\varepsilon} &= -\int_{S'_T}\int_{S_T} |u_+-v_+|\,\Delta_\xi\varphi\, j_h\, d\xi ds\, d\zeta d\sigma \\
&\quad -4\liminf_{\varepsilon\to 0}\int_{S'_T}\int_{S_T} H'_\varepsilon(u_+-v_+)\,\nabla_\xi u_+\cdot\nabla_\xi v_+\,\varphi\, j_h\, d\xi ds\, d\zeta d\sigma.
\end{aligned}$$

We now combine these calculations in the expression of $I_{2,\varepsilon}$ and let $\varepsilon \to 0$ to obtain

$$\begin{aligned}
\limsup_{\varepsilon\to 0} I_{2,\varepsilon} &= 4\int_{S'_T}\int_{S_T} |u_+-v_+|\,\Delta_\xi\varphi\, j_h\, d\xi ds\, d\zeta d\sigma \\
&\quad -4\limsup_{\varepsilon\to 0}\int_{S'_T}\int_{S_T} H'_\varepsilon(u_+-v_+)|\nabla_\xi(u_+-v_+)|^2\varphi\, j_h\, d\xi ds\, d\zeta d\sigma \\
&\le 4\int_{S'_T}\int_{S_T} |u_+-v_+|\,\Delta_\xi\varphi\, j_h\, d\xi ds\, d\zeta d\sigma
\end{aligned}$$

since $\varphi \geq 0$ and $j_h \geq 0$. Finally, we let $h \searrow 0$ by following the same arguments as in Kruzhkov [3, 4] to obtain

$$\lim_{h \to 0} \limsup_{\varepsilon \to 0} I_{2,\varepsilon} \leq 4 \int_{S_T} \left|u_+(x,t) - v_+(x,t)\right| \Delta_x \varphi(x,t)\, dx\, dt.$$

6. Transformation and limits of $I_{1,\varepsilon}$ and $I_{3,\varepsilon}$. Now we continue to perform the change of variables to transform $I_{1,\varepsilon}$ and $I_{3,\varepsilon}$ into a form suitable to study the limits as $\varepsilon \to 0$ and then $h \to \varepsilon$.

In transforming $I_{1,\varepsilon}$, we use the definitions (3.1)–(3.1)$'$ of the entropy and the definitions (3.2)–(3.2)$'$ of the corresponding flux functions. Taking into account (4.5), we compute

$$\begin{aligned}\lim_{\varepsilon \to 0} I_{1,\varepsilon} = 4 \int_{S'_T} \int_{S_T} \Big\{ &|u(\xi+\zeta, s+\sigma) - v(\xi-\zeta, s-\sigma)|\, \varphi_s(\xi,s)\, j_h(\zeta,\sigma) \\ &+ \frac{1}{2}\left|u^2(\xi+\zeta, s+\sigma) - v^2(\xi-\zeta, s-\sigma)\right| \mathbf{a} \cdot \nabla_\xi \varphi(\xi,s)\, j_h(\zeta,\sigma) \Big\} d\xi ds\, d\zeta d\sigma.\end{aligned}$$

Letting now $h \to 0$, we find

$$\begin{aligned}\lim_{\varepsilon \to 0} I_{1,\varepsilon} = 4 \int_{S_T} \Big\{ &|u(x,t) - v(x,t)| \varphi_t(x,t) \\ &+ \frac{1}{2}\left|u^2(x,t) - v^2(x,t)\right| \mathbf{a} \cdot \nabla_x \varphi(x,t) \Big\}\, dx\, dt.\end{aligned}$$

In transforming $I_{3,\varepsilon}$, we perform the change of variables (4.5) involving only the space variables, whereas the time variables are left unchanged. The Jacobian of the transformation is 2. Analogous arguments and limiting processes yield

$$\begin{aligned}\lim\nolimits_{\varepsilon \to 0} I_{3,\varepsilon} = 2 &\int_{S_T} \int_{\mathbb{R}^N} |u_0(\xi+\zeta) - v(\xi-\zeta,\tau)| \varphi\left(\xi, \frac{1}{2}\tau\right) j_h\left(\zeta, -\frac{1}{2}\tau\right) d\xi\, d\zeta d\tau \\ &+2 \int_{S_T} \int_{\mathbb{R}^N} \left|v_0(\xi-\zeta) - u(\xi+\zeta,t)\right| \varphi\left(\xi, \frac{1}{2}t\right) j_h\left(\zeta, \frac{1}{2}t\right) d\xi\, d\zeta dt.\end{aligned}$$

Now letting $h \to 0$ gives

$$\lim_{h \to 0} \lim_{\varepsilon \to 0} I_{3,\varepsilon} = 4 \int_{\mathbb{R}^N} \left|u_0(x) - v_0(x)\right| \varphi(x,0)\, dx.$$

7. Proof of the stability theorem (iii). By combining these calculations in (4.1) and after taking the limit first for $\varepsilon \searrow 0$ and then for $h \searrow 0$, we arrive at

$$\begin{aligned}\int_{S_T} \Big\{ &\left|u(x,t) - v(x,t)\right| \varphi_t(x,t) + \frac{1}{2}\left|u^2(x,t) - v^2(x,t)\right| \mathbf{a} \cdot \nabla_x \varphi(x,t) \\ &+ \left|u_+(x,t) - v_+(x,t)\right| \Delta_x \varphi(x,t) \Big\} dxdt \\ &+ \int_{\mathbb{R}^N} \left|u_0(x) - v_0(x)\right| \varphi(x,0) dx \geq 0.\end{aligned} \tag{7.1}$$

In this more stringent integral inequality, the nonnegative testing function φ is still to be chosen.

In this section, we choose the testing function to identify the weight $w(x,t)$ and the stability result (1.6).

First we rewrite (7.1) in the form

$$\begin{aligned} &\int_{S_T} \big|u(x,\tau) - v(x,\tau)\big| \big\{\varphi_\tau + \mathbf{A}\cdot\nabla_x\varphi + b\,\Delta_x\varphi\big\}\,dx\,d\tau \\ &\qquad\qquad + \int_{\mathbb{R}^N} \big|u_0(x) - v_0(x)\big|\varphi(x,0)\,dx \,\geq\, 0, \end{aligned} \tag{7.2}$$

where we have set

$$\begin{aligned} \mathbf{A}(x,\tau) &\equiv \frac{1}{2}\frac{\big|u^2(x,\tau) - v^2(x,\tau)\big|}{|u(x,\tau) - v(x,\tau)|}\,\mathbf{a} \,=\, \frac{1}{2}\,|u(x,\tau) + v(x,\tau)|\,\mathbf{a}, \\ b(x,\tau) &\equiv \frac{\big|u_+(x,\tau) - v_+(x,\tau)\big|}{\big|u(x,\tau) - v(x,\tau)\big|} \end{aligned}$$

if $u \neq v$, and $A = b = 0$ if $u = v$. In (7.2) we choose the testing functions

$$\varphi_{\varepsilon,\delta}(x,\tau) \,=\, h_\delta(\tau)\,w(x,\tau)\,\zeta(x).$$

Here, for $0 < \delta \ll 1$, we have set

$$h_\delta(\tau) \,=\, \frac{1}{\delta}\int_{\tau - t}^{\infty} \omega\left(\frac{s}{\delta}\right) ds, \qquad 0 < t \leq T - \delta,$$

where $\omega(\cdot)$ is the standard, symmetric mollifier in $\mathbb{R}$. Moreover,

$$w(x,\tau) \,=\, e^{-\,(1 + \lambda_1\,\tau)\,|x|^2 \,-\, \lambda_2\,\tau}$$

for positive constants λ_1 and λ_2 to be chosen. Finally, $x \to \zeta(x)$ is a standard, nonnegative cutoff function in the ball $\{|x| < 2R\}$, satisfying

$$\begin{cases} \zeta(x) = 1 & \text{for } \ |x| < R, \\ |\nabla\zeta| \,\leq\, \dfrac{1}{R} & \text{for all } \ |x| < 2R, \\ |\Delta\zeta| \,\leq\, \dfrac{\text{const}}{R^2} & \text{for all } \ |x| < 2R. \end{cases}$$

These testing functions are admissible since both h_δ and $w\zeta$ are nonnegative and regular, and, by the properties of the mollifiers, $h_\delta(\tau) = 0$ for $\tau \geq t + \delta$. We compute

$$\begin{aligned} w_\tau(x,\tau) &\,=\, -\big(\lambda_2 \,+\, \lambda_1\,|x|^2\big)\; w(x,\tau), \\ \nabla_x w(x,\tau) &\,=\, -2\;(1 \,+ \lambda_1\,\tau)\;x\,w(x,\tau), \\ \Delta_x w(x,\tau) &\,=\; 2\,(1 \,+\, \lambda_1\,\tau)\,\big\{2\,(1 \,+\, \lambda_1\,\tau)\,|x|^2 \,-\, N\big\}\,w(x,\tau). \end{aligned}$$

By the structure of $x \to w(x,\tau)$ and $\zeta(x)$,

$$\lim_{R\to\infty}\int_{\{R<|x|<2R\}} \{w\,(\zeta + |\nabla\zeta| + |\Delta\zeta|) + |\nabla_x w\cdot\nabla\zeta|\}\,dx \,=\, 0,$$

uniformly in $\tau \in (0,T)$. Putting this testing function in (7.2) and letting $R \to \infty$ give

$$\begin{aligned} &- \int_{S_T} |u(x,\tau) - v(x,\tau)| \, \frac{1}{\delta} \, \omega\left(\frac{\tau - t}{\delta}\right) w(x,\tau)\, dx\, d\tau \\ (7.3) \qquad &+ \int_{S_T} |u(x,\tau) - v(x,\tau)| \, h_\delta(\tau) \left\{ w_\tau + \mathbf{A} \cdot \nabla_x w + b\Delta_x w \right\} dx\, d\tau \\ &+ \int_{\mathbb{R}^N} |u_0(x) - v_0(x)| \, h_\delta(0)\, w(x,0)\, dx \;\geq\; 0. \end{aligned}$$

The growth condition (1.5) implies that there exists a positive constant C, depending only upon γ, such that

$$\mathbf{A} \cdot x \;\leq\; C\left(1 + |x|^2\right) \qquad \text{for all } \; x \in \mathbb{R}^N.$$

Then

$$w_\tau + \mathbf{A} \cdot \nabla_x w + b\Delta_x w \leq w\left\{ C - \lambda_2 + \left[C + 4(1 + \lambda_1 \tau)^2 - \lambda_1 \right] |x|^2 \right\}.$$

Choose $\lambda_2 = C$ and $T_0 = \lambda_1^{-1}$. Then select λ_1 from

$$C \,+\, 4\,(1 \,+\, \lambda_1\,\tau)^2 \,-\, \lambda_1 \;\leq\; C \,+\, 16 \,-\, \lambda_1 \;\leq\; 0.$$

For such choices, we discard the second integral in (7.3) and let $\delta \to 0$ to obtain

$$\int_{\mathbb{R}^N} w(x,t) |u(x,t) - v(x,t)|\, dx \;\leq\; \int_{\mathbb{R}^N} w(x,0) |u_0 - v_0|\, dx$$

for a.e. $t \in (0, T_0)$. Since the weight w depends only upon γ, the process can be repeated to exhaust, in a finite number of steps, the time interval of existence.

In the case of general nonlinearities $\mathbf{f}(u)$ and $\beta(u)$, the weight w can be constructed depending only on the Lipschitz constant of $\beta(u)$ and $\sup_{(x,t)\in S_T} |\mathbf{f}'(u(x,t))|/(1 + |x|)$. □

Note added in proof. After we submitted this paper, we were aware of Carrillo's paper [9] dealing with bounded solutions for a similar problem in bounded domains.

ON EXISTENCE OF GLOBAL SOLUTIONS AND BLOW-UP TO A SYSTEM OF REACTION-DIFFUSION EQUATIONS MODELLING CHEMOTAXIS[*]

YIN YANG[†], HUA CHEN[†], AND WEIAN LIU[†]

Abstract. In this paper we investigate the properties of the solutions for some general reaction-diffusion systems due to Othmer–Stevens which arise in modelling chemotaxis, and we prove some results about collapse and finite-time action of certain local modifications of the environment.

Key words. chemotaxis, blow-up, collapse, subsuper solution

1. Introduction.

In biology, it is very important to investigate the movement of some cells or organisms in some given biological system (cf. [2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12]). The mechanism of communication between cells or organisms depends on the different ways they interact. In many biological systems, the movement occurs in response to a diffusible substance or otherwise transported signal. Other systems are modelled by so-called short-range interactions due to local modifications of the environment such as the production and release of nutrients. In this case, dispersal is not simply one of simple diffusion but rather one of correlated or reinforced random walks. In order to understand how the movement rules are affected by the effect of the chemo-attractant, Othmer and Stevens introduced in [4] several general classes of partial differential equations. In one of their models, they considered a master equation, i.e., barrier, and nearest neighbor lattice model. Following a limiting process, the model is described by the following system of partial differential equations:

$$\begin{cases} \dfrac{\partial p}{\partial t} = D\nabla\cdot\left(p\nabla\left(\ln\left(\dfrac{p}{w}\right)\right)\right) & \\ \dfrac{\partial w}{\partial t} = F(p,w) & \text{for } x\in\Omega,\quad t>0, \\ p\nabla\left(\ln\left(\dfrac{p}{w}\right)\right)\cdot\vec{n} = 0 & \text{for } x\in\partial\Omega,\quad t>0, \\ p(x,0) = p_0(x) > 0 & \\ w(x,0) = w_0(x) > 0 & \text{for } x\in\overline{\Omega}, \end{cases} \tag{1.1}$$

where $p(x,t)$ is the particle density of a particular species and $w(x,t)$ is the density of the local control species.

From the boundary condition and the first equation of (1.1), we can easily deduce that, for any solution $p(x,t)$ of (1.1), we have

$$\int_\Omega p(x,t)dx = \int_\Omega p(x,0)dx. \tag{1.2}$$

Through a large number of numerical experiments, Othmer and Stevens found that the asymptotic behavior of the solutions depends strongly on the dynamics of w. In particular, the growth of w determines whether or not blow-up occurs. In fact, from their numerical results in [4], Othmer and Stevens conjecture that, when w has linear growth, there is a global solution of the dynamics, and $p(x,t)$ collapses in some cases, where we say that the solution $p(x,t)$ collapses, which means when t tends to infinity, $p(x,t)$ could be controlled by the initial data, i.e., $\lim_{t\to\infty} \sup \|p(\cdot,t)\|_{L^\infty} < \|p_0(\cdot)\|_{L^\infty}$ (see Definition 2.1 below); whereas when w grows exponentially, $p(x,t)$ should blow up in finite time. For the case of w possessing exponential growth, Levine and Sleeman [2] have studied a special one-dimensional example under the additional boundary-value condition $p_x = w_x = 0$. In that situation they constructed an exact solution supporting the numerical observations of Othmer and Stevens.

In this paper, we extend some results of [2] to the case of general boundary conditions, general positive initial data, and higher dimensional spaces $\mathbb{R}^n$ $(n \geq 1)$. We concentrate on the two situations where w grows linearly and exponentially, respectively. We found that if w grows linearly, the conjectures suggested by numerical observations of Othmer and Stevens are true in general cases. When w possesses exponential growth, the numerical results lose a lot of information. We construct both global and blow-up in a finite-time solution, respectively, for the case Levine and Sleeman [2] considered. So even at the same growth rate the behavior of the biological systems can be very different just because they start their action in different conditions. That may be a very important fact in biological systems.

Our results are the following.

(1) When the production of w is proportional to the local density of p, i.e.,

$$\frac{\partial w}{\partial t} = \beta p - \mu w, \tag{1.3}$$

there exists a unique global solution that is bounded. Furthermore, when the initial data satisfy some additional conditions, in particular, when $w_0(x)$ is a constant, but not necessarily $p_0(x)$, then p collapses.

(2) When the control species grows exponentially, i.e.,

$$\frac{\partial w}{\partial t} = (\beta p - \mu) w, \tag{1.4}$$

both global and blow-up in finite-time solutions may exist dependent on their choice of initial data. We have constructed two families of solutions: global and blow-up in finite time. Also, we have proved that if blow-up occurs, $p(x,t)$, as well as $w(x,t)$, will blow up at the same points.

We discuss linear and exponential growth of w in sections 2–4, respectively. In section 5, we show how our method can be used to solve other dynamics which also arise from mathematical models in biology. We list without proof the main results we have obtained for these new systems.

The main tools we use here are the maximum principle, subsuper solutions, and function transformations.

2. The dynamics with *w* possessing linear growth. In this section, we consider the dynamics with w possessing linear growth. Thus we investigate the following problem:

$$
(2.1)\qquad \begin{cases} \dfrac{\partial p}{\partial t} = D\nabla\cdot\left(p\nabla\left(\ln\left(\dfrac{p}{w}\right)\right)\right) & \\ \dfrac{\partial w}{\partial t} = \beta p - \mu w & \text{for } x\in\Omega,\quad t>0, \\ p\nabla\left(\ln\left(\dfrac{p}{w}\right)\right)\cdot\vec{n} = 0 & \text{for } x\in\partial\Omega,\quad t>0, \\ p(x,0) = p_0(x) > 0 & \\ w(x,0) = w_0(x) > 0 & \text{for } x\in\Omega, \end{cases}
$$

where Ω is a bounded smooth domain in $\mathbb{R}^n$ $(n\geq 1)$, $\vec{n}$ is the outer normal on $\partial\Omega$, and $D>0$, $\beta>0$, $\mu\geq 0$ are all constants.

In their numerical results, Othmer and Stevens [4] suggest that when $\mu>0$, there is a global solution that might collapse. In the case $\mu=0$, the asymptotic behavior of the solution is still unknown, but it is conjectured that small amplitude stable solutions exist.

In order to prove their conjecture, we introduce a new function $u(x,t)=\frac{p(x,t)}{w(x,t)}$. It can be easily shown that $(p(x,t),w(x,t))$ is a solution of the dynamics (2.1) if and only if $(u(x,t),w(x,t))$ is a solution of the following dynamics:

$$
(2.2)\qquad \begin{cases} \dfrac{\partial u}{\partial t} = D\Delta u + D\dfrac{1}{w}(\nabla w)\cdot(\nabla u) + (\mu-\beta u)u & \\ w(x,t) = w_0(x)\exp\left\{\displaystyle\int_0^t(\beta u(x,\tau)-\mu)\,d\tau\right\} & \text{for } x\in\Omega,\quad t>0, \\ \dfrac{\partial u}{\partial n} = 0 & \text{for } x\in\partial\Omega,\quad t>0, \\ u(x,0) = u_0(x) \triangleq \dfrac{p_0(x)}{w_0(x)} > 0 & \\ w(x,0) = w_0(x) > 0 & \text{for} x\in\Omega \end{cases}
$$

and

$$
(2.3)\quad p(x,t) = w_0(x)u(x,t)\exp\left\{\int_0^t(\beta u(x,\tau)-\mu)\,d\tau\right\}\qquad \text{for } x\in\Omega,\quad t>0.
$$

Here we have used the fact that

$$
\begin{aligned} u_t &= \left(\frac{p}{w}\right)_t = \frac{1}{w}(p_t - uw_t), \\ p_t &= D\nabla\cdot\left(p\nabla\left(\ln\left(\frac{p}{w}\right)\right)\right) = D\nabla\cdot(w\nabla u) = Dw\Delta u + D(\nabla w)\cdot(\nabla u). \end{aligned}
$$

Since we can assert the local-in-time existence as well as the uniqueness of solutions by the result of [7] (also see [1, 2, 4]), we set

$$
(2.4)\qquad T = \sup\{\tilde{T}>0; (p,w) \text{ exists for } x\in\Omega, t\in[0,\tilde{T}]\}.
$$

So $T>0$ is well defined. Thus there exists a solution $(u(x,t),w(x,t))$ of the dynamics (2.2) for $x\in\Omega$, $t\in[0,T)$. For fixed w, we investigate the property of u. First we consider $\mu>0$.

LEMMA 2.1. *If $u_0(x)\leq\frac{\mu}{\beta}$, then $u(x,t)\leq\frac{\mu}{\beta}$ as long as the solution exists in time. Furthermore, if for any fixed $t\in(0,T)$, $u(\cdot,t)$ takes its minimum value at the point x_t, then $u_t(x_t,t)>0$ if $u(x_t,t)<\frac{\mu}{\beta}$.*

Proof. Assume that the result is false; then there exists $(x^*, t^*) \in \Omega \times (0, T)$ such that $u(x^*, t^*) > \frac{\mu}{\beta}$. Without loss of generality, we have

$$u(\bar{x}, \bar{t}) = \max_{\bar{\Omega} \times [0, t^*]} u(x, t) > \frac{\mu}{\beta}.$$

We know $\bar{t} > 0$ because of $u(\bar{x}, 0) = u_0(\bar{x}) \leq \frac{\mu}{\beta}$. Since at the point $(x, t) = (\bar{x}, \bar{t})$ we have

$$u_t - D\Delta u - D\frac{1}{w}(\nabla w) \cdot (\nabla u) = (\mu - \beta u)u < 0,$$

we get $(\bar{x}, \bar{t}) \notin \Omega \times (0, t^*]$ by the maximum principle. That means $\bar{x} \in \partial\Omega$. Again, by the maximum principle argument, we should have $\frac{\partial u}{\partial n}\big|_{(\bar{x}, \bar{t})} > 0$, which is a contradiction. That leads to $u(x, t) \leq \frac{\mu}{\beta}$ for all $(x, t) \in \bar{\Omega} \times (0, T)$.

For any fixed $t > 0$ we obtain from the maximum principle

$$-D\Delta u - D\frac{1}{w}(\nabla w) \cdot (\nabla u) = -u_t + (\mu - \beta u)u \leq 0$$

at the point (x_t, t). Since $(\mu - \beta u)u \geq 0$ for all $(x, t) \in \Omega \times (0, T)$, we have $u_t \geq 0$ at (x_t, t). When $u(x_t, t) < \frac{\mu}{\beta}$, we can get $u_t(x_t, t) > 0$ immediately. This completes the proof. □

It is easy to see that similar arguments lead to the following results.

Lemma 2.2. *If $u_0(x) \geq \frac{\mu}{\beta}$, then $u(x, t) \geq \frac{\mu}{\beta}$ for all $(x, t) \in \overline{\Omega} \times [0, T)$. If $u(\cdot, t)$ takes its maximum at the point $x = x^t$ for any fixed $t \in (0, T)$, then $u_t(x^t, t) < 0$ if $u(x^t, t) > \frac{\mu}{\beta}$.*

Lemma 2.3. *If $m \triangleq \min_{x \in \overline{\Omega}} u_0(x) < \frac{\mu}{\beta} < \max_{x \in \overline{\Omega}} u_0(x) \triangleq M$, then $m \leq u(x, t) \leq M$ for all $(x, t) \in \overline{\Omega} \times (0, T)$. Furthermore, $u_t(x^t, t) < 0$ if $u(x^t, t) > \frac{\mu}{\beta}$, and $u_t(x_t, t) > 0$ if $u(x_t, t) < \frac{\mu}{\beta}$, where x^t, x_t are the same as above.*

Remark 2.1. If $T = +\infty$, we can prove that $\lim_{t \to +\infty} u(x, t) = \frac{\mu}{\beta}$ for $\mu > 0$.

Theorem 2.1. *For arbitrary strictly positive initial data $(p_0(x), w_0(x))$, $x \in \overline{\Omega}$, compatible with the boundary condition along $x \in \partial\Omega$, there exists a unique global positive solution $(p(x, t), w(x, t))$ of the dynamics* (2.1) *when $\mu > 0$.*

Proof. We know that the dynamics (2.1) have a unique local positive solution. What we need to do is to prove $T = +\infty$.

Assume $T < +\infty$. From Lemmas 2.1–2.3 we know that the solution $u(x, t)$ of the related dynamics (2.2) is a bounded smooth function in $\Omega \times (0, T)$. So the function $w(x, t) = w_0(x) \exp\{\int_0^t (\beta u(x, \tau) - \mu)\, d\tau\}$ is not only well defined but also continuous on $\bar{\Omega} \times [0, T]$. This implies that both $u(x, t)$ and $p(x, t)$ are well defined and continuous on $\bar{\Omega} \times [0, T]$. Replacing the initial data $(p_0(x), w_0(x))$ of the dynamics (2.1) by $(p(x, T), w(x, T))$, we can obtain a new local positive solution $(\bar{p}(x, t), \bar{w}(x, t))$ defined in $\Omega \times [0, \delta)$ for some $\delta > 0$. It is obvious that $(P(x, t), W(x, t))$ is a positive solution of the dynamics (2.1) defined in $\Omega \times [0, T + \delta)$, where

$$P(x, t) = \begin{cases} p(x, t) & \text{for } (x, t) \in \Omega \times (0, T), \\ \bar{p}(x, t - T) & \text{for } (x, t) \in \Omega \times [T, T + \delta), \end{cases}$$

$$W(x, t) = \begin{cases} w(x, t) & \text{for } (x, t) \in \Omega \times (0, T), \\ \bar{w}(x, t - T) & \text{for } (x, t) \in \Omega \times [T, T + \delta). \end{cases}$$

This result is a contradiction to the definition of T. Thus $T = +\infty$, as required. $\square$

The uniqueness of the solution for (2.1) is trivial.

Remark 2.2. The problem (2.1) is actually a special case of the following Keller–Segel (KS) model with Neumann boundary conditions, i.e.,

$$\text{(KS)}\begin{cases} p_t = \nabla \cdot (d_1 \nabla p - \chi p \nabla \log w), \qquad w_t = d_2 \triangle w + \beta p - \mu w, \\ \text{Neumann boundary conditions,} \end{cases}$$

under the conditions of $d_1 = \chi = D,\ d_2 = 0$. From Theorem 2.1, we have proved, in this case, that the (KS) model has a unique global solution. However, the global existence of solutions for the general (KS) models depends on the parameters in (KS), the space dimensions, and initial functions (cf. [13, 14, 15]).

Based on their numerical results for a wide variety of initial data, Othmer and Stevens conjectured in [4] that $p(x,t)$ collapse when $\mu > 0$. In the case $\mu = 0$, this is unknown. Before discussing this problem, we introduce the concept of collapse used in [4].

DEFINITION 2.1. *Let $p(x,t)$ be the solution of the dynamics* (2.1) *for given initial distribution $p_0(x)$. Then if $\lim_{t\to\infty} \sup \|p(\cdot,t)\|_{L^\infty} < \|p_0(\cdot)\|_{L^\infty}$, we say there is collapse.*

In other words, if $p(x,t)$ denotes the particle density of a particular species and $p(x,t)$ collapses, what represents the species will not be aggregation (see [4] for details).

It is obvious that if $\mu > 0$, the dynamics (2.1) has a constant solution $(p, w) = (p_0, \beta p_0/\mu)$. So collapse does not occur. Furthermore, we can give a class of steady-state solutions for p which do not collapse at all.

Example 2.1. For any smooth function $\Phi(x) > 0$ defined on $\overline{\Omega}$,

$$(p, w) = \left(1, e^{-\mu t}\left(c - \frac{\beta}{\mu}\right) + \frac{\beta}{\mu}\right)\Phi(x)$$

is the solution of the dynamics (2.1) with initial data $(p_0(x), w_0(x)) = (1, c)\Phi(x)$ for all $c > 0$. It is obvious that we cannot expect collapse.

THEOREM 2.2. *Let $\mu > 0$. For the dynamics* (2.1) *the solution (p, w) is bounded. Furthermore, for all $(x,t) \in \overline{\Omega} \times [0, +\infty)$ we have $p(x,t) < w_0(x) \max_{\overline{\Omega}} u_0(x)$ if $w_0(x) \neq cp_0(x)$ for some $c > 0$.*

Proof. Let $c_0 = [\max_{x\in\bar{\Omega}} u_0(x)]^{-1}$ and $v(t) = e^{\mu t}[c_0 + \frac{\beta}{\mu}(e^{\mu t} - 1)]^{-1}$. We can easily find that $v(t)$ is a supersolution of the dynamics (2.2). From $u(x,t) \le v(t)$ for all $(x,t) \in \Omega \times (0 + \infty)$ we have

$$\begin{aligned} p(x,t) &= w_0(x) u(x,t) \exp\left\{\int_0^t (\beta u(x,\tau) - \mu)\, d\tau\right\} \\ &\le w_0(x) v(t) \exp\left\{\int_0^t (\beta v(\tau) - \mu)\, d\tau\right\} \\ &= w_0(x)/c_0 \\ &= w_0(x) \max_{x\in\bar{\Omega}} u_0(x) < +\infty. \end{aligned}$$

Next, from $(e^{\mu t} w)_t = \beta e^{\mu t} p$, we have

$$\begin{aligned} e^{\mu t}w(x,t) &= w(x,0) + \beta \int_0^t e^{\mu\tau} p(x,\tau)d\tau \\ &\leq w(x,0) + \beta \int_0^t w_0(x) \max_{x\in\bar{\Omega}} u_0(x) e^{\mu\tau} d\tau \\ &= w_0(x) + \frac{\beta}{\mu} w_0(x) \max_{x\in\bar{\Omega}} u_0(x)[e^{\mu t} - 1], \end{aligned}$$

which means

$$w(x,t) \leq e^{-\mu t}w_0(x) + \frac{\beta}{\mu} w_0(x) \max_{x\in\bar{\Omega}} u_0(x)[1 - e^{-\mu t}] < +\infty.$$

When $w_0(x) \neq cp_0(x)$, then $u(x,t) < v(t)$ for all $(x,t) \in \Omega \times (0,+\infty)$, which implies $p(x,t) < w_0(x) \max_{x\in\bar{\Omega}} u_0(x)$ for $(x,t) \in \Omega \times (0,+\infty)$. This completes the proof. □

Let $u_0(x)$ attain its maximum at the point x_1 and $p_0(x)$ its maximum at the point x_2. Denote $\sigma = p_0(x_2)/p_0(x_1)$. If $w_0(x) \leq \sigma w_0(x_1)$ for all $x \in \bar{\Omega}$, then $p(x,t) < p_0(x_2)$ when $w_0(x) \neq cp_0(x)$. This fact leads to the following result on the collapse.

COROLLARY 2.1. *Let $\mu > 0$, and suppose that $u_0(x)$ takes its maximum at the point x_1, and let $\sigma = [p_0(x_1)]^{-1} \max_{x\in\overline{\Omega}} p_0(x)$. If $w_0(x) \leq \sigma w_0(x_1)$ for $x \in \overline{\Omega}$ when $w_0(x) \neq cp_0(x)$ for some $c > 0$, then $p(x,t) < \max_{x\in\overline{\Omega}} p_0(x)$ for all $(x,t) \in \overline{\Omega} \times (0,+\infty)$. This means that there is collapse.*

Othmer and Stevens discuss in [4] the system

$$\begin{cases} \dfrac{\partial p}{\partial t} = D\dfrac{\partial}{\partial x}\left(p\dfrac{\partial}{\partial x}\left(\ln\left(\dfrac{p}{w}\right)\right)\right) & \text{for } x \in (0,1), \quad t > 0, \\ \dfrac{\partial w}{\partial t} = p - \mu w & \\ p\dfrac{\partial}{\partial x}\left(\ln\left(\dfrac{p}{w}\right)\right) = 0 & \text{for } x = 0, 1, \quad t > 0, \\ p(x,0) = p_0(x) > 0 & \text{for } x \in [0,1] \\ w(x,0) = w_0(x) > 0 & \end{cases}$$

and find that if $\mu = 0$, the space-independent solution $(p_0, w_0 + p_0 t)$ is unstable.

When $\mu > 0$, we have seen that there exists a solution

$$(p,w) = \left(1, e^{-\mu t}\left(c - \frac{\beta}{\mu}\right) + \frac{\beta}{\mu}\right)\Phi(x) \tag{2.5}$$

for the dynamics (2.1), where p is t-independent, with initial data $(p_0, w_0) = (1, c)\Phi(x)$. However, we can prove the solution (2.5) will be unstable asymptotically. In fact, if we choose a positive function $\psi(x)$, which takes its minimum at the maximum point of the function Φ, then both functions Φ and $\frac{\Phi}{1+\psi}$ attain their maxima at the same point. Thus, as a consequence of Theorems 2.1 and 2.2, we know that the dynamics (2.1) has a unique global solution $(p(x,t), w(x,t))$ with initial data $(p_0, w_0) = (\frac{1}{1+\psi(x)}, c)\Phi(x)$, which satisfies $\frac{p(x,t)}{w(x,t)} = u(x,t) < v(t)$ and

$$\begin{aligned} p(x,t) &< w_0(x) \max_{x\in\bar{\Omega}} u_0(x) = w_0(x) \max_{x\in\bar{\Omega}} \left(\frac{1}{c(1+\psi(x))} \right) \\ &= c\Phi(x) \max_{x\in\bar{\Omega}} \left(\frac{1}{c(1+\psi(x))} \right) \le \max_{x\in\bar{\Omega}} \Phi(x) \max_{x\in\bar{\Omega}} \left(\frac{1}{1+\psi(x)} \right) \\ &= \max_{x\in\bar{\Omega}} \left(\frac{\Phi(x)}{1+\psi(x)} \right). \end{aligned}$$

Let $\bar{x}$ be the maximum point of $p_0(x)$ (i.e., $\bar{x}$ is the maximum point of $\Phi(x)$ and the minimum point of $\psi(x)$); then we have

$$p(\bar{x},t) < p_0(\bar{x}) = \frac{\Phi(\bar{x})}{1+\psi(\bar{x})} < \Phi(\bar{x}).$$

That implies, for any $\psi(x) > 0$ but quite small, we have

$$\overline{\lim_{t\to+\infty}}\, p(\bar{x},t) \le p_0(\bar{x}) < \Phi(\bar{x}).$$

Therefore, we get the following result.

COROLLARY 2.2. *When $\mu > 0$, the solution*

$$(p,w) = \left(1, e^{-\mu t}\left(c - \frac{\beta}{\mu}\right) + \frac{\beta}{\mu}\right)\Phi(x)$$

with t-independent p is not asymptotically stable.

Next we consider the case $\mu = 0$.

THEOREM 2.3. *When $\mu = 0$, for any strictly positive initial data $(p_0(x), w_0(x))$ (satisfying the comparison condition similarly as above in Theorem* 2.1*), there exists a unique global positive solution $(p(x,t), w(x,t))$ of the dynamics* (2.1) *such that $p(x,t)$ is bounded and $w(x,t) \overset{t\to+\infty}{\longrightarrow} +\infty$. Furthermore,*

$$p(x,t) < w_0(x) \max_{\overline{\Omega}} u_0(x)$$

if $w_0(x) \neq cp_0(x)$ for some $c > 0$.

Proof. Let $u(x,t) = \frac{p(x,t)}{w(x,t)}$; we know that $(p(x,t), w(x,t))$ is a positive solution of the dynamics (2.1) if and only if $(u(x,t), w(x,t))$ is a positive solution of the following dynamics:

$$\begin{cases} \left.\begin{aligned} &\frac{\partial u}{\partial t} = D\Delta u + D\frac{1}{w}(\nabla w)\cdot(\nabla u) - \beta u^2 \\ &w(x,t) = w_0(x)\exp\left\{\int_0^t (\beta u(x,\tau))\,d\tau\right\} \end{aligned}\right\} & \text{for } x\in\Omega, \quad t>0, \\ \dfrac{\partial u}{\partial n} = 0 & \text{for } x\in\partial\Omega, \quad t>0, \\ \left.\begin{aligned} &u(x,0) = u_0(x) \triangleq \frac{p_0(x)}{w_0(x)} > 0 \\ &w(x,0) = w_0(x) > 0 \end{aligned}\right. & \text{for } x\in\overline{\Omega} \end{cases}$$

and

$$p(x,t) = w_0(x)u(x,t)\exp\left\{\int_0^t \beta u(x,\tau)\,d\tau\right\}$$

for $x \in \Omega$, $t > 0$. It can be easily found that

$$\left(\min_{x\in\bar\Omega} u_0(x)\right)\left[1+\beta \min_{x\in\bar\Omega} u_0(x)t\right]^{-1} \le u(x,t) \le \left(\max_{x\in\bar\Omega} u_0(x)\right)\left[1+\beta \max_{x\in\bar\Omega} u_0(x)t\right]^{-1},$$

which implies that there exists a global positive solution for the dynamics (2.1) by the method we use in the proof of Theorem 2.1. If $w_0(x) \ne cp_0(x)$ for some $c > 0$, we obtain

$$u(x,t) < \left(\max_{x\in\bar\Omega} u_0(x)\right)\left[1+\beta \max_{x\in\bar\Omega} u_0(x)t\right]^{-1}$$

and

$$\begin{aligned} p(x,t) &= w_0(x)u(x,t)\exp\left\{\int_0^t \beta u(x,\tau)\,d\tau\right\} \\ &< w_0(x)\frac{\max_{x\in\bar\Omega} u_0(x)}{1+\beta\max_{x\in\bar\Omega} u_0(x)t}\exp\left\{\int_0^t \frac{\beta\max_{x\in\bar\Omega} u_0(x)}{1+\beta\max_{x\in\bar\Omega} u_0(x)\tau}\,d\tau\right\} \\ &= w_0(x)\max_{x\in\bar\Omega} u_0(x), \end{aligned}$$

and $w(x,t) \ge w_0(x)[1+\beta\min_{x\in\bar\Omega} u_0(x)t] \overset{t\to+\infty}{\longrightarrow} +\infty$.

Similarly, we have the following result.

COROLLARY 2.3. *For $\mu = 0$, the statements of Corollaries* 2.1 *and* 2.2 *are also valid.*

3. One-dimensional case with w possessing exponential growth. The growth rate of w is very important to the characteristics of p, which determines whether or not blow-up occurs. Actually, Othmer and Stevens [4] conjectured that, when w grows exponentially, $p(x,t)$ should blow up in finite time. It is obvious that when both initial data $p(x,0)$ and $w(x,0)$ are positive constants, we can get a global solution immediately: $(p_0, w_0e^{(\beta p_0-\mu)t})$. What we are very interested in is the situation about nonconstant initial data. In a recent result of [2], Levine and Sleeman studied a special one-dimensional example under the additional boundary-value condition $p_x = w_x = 0$, and they constructed a class of solutions

$$\begin{aligned} p(x,t) &= 1 - 2Nc\varepsilon e^{Nct}\frac{\varepsilon e^{Nct}-\cos(Nx)}{1-2\varepsilon e^{Nct}\cos(Nx)+\varepsilon^2e^{2Nct}}, \\ w(x,t) &= \frac{e^t}{1-2\varepsilon e^{Nct}\cos(Nx)+\varepsilon^2e^{2Nct}} \end{aligned}$$

satisfying the problem, taking $D = \beta = 1, \mu = 0$,

$$\begin{cases} \dfrac{\partial p}{\partial t} = D\dfrac{\partial}{\partial x}\left(p\dfrac{\partial}{\partial x}\left(\ln\left(\dfrac{p}{w}\right)\right)\right) & \\ & \text{for } x \in (0,\pi), \quad t > 0, \\ \dfrac{\partial w}{\partial t} = (\beta p - \mu)w & \\ p_x = w_x = 0 & \text{for } x = 0, \pi; \quad t > 0, \\ p(x,0) = \dfrac{1-2\varepsilon(1-Nc)\cos(Nx)+(1-2Nc)\varepsilon^2}{1-2\varepsilon\cos(Nx)+\varepsilon^2} & \\ & \text{for } x \in [0,\pi], \\ w(x,0) = \dfrac{1}{1-2\varepsilon\cos(Nx)+\varepsilon^2} & \end{cases}$$

where $N > 0$ is an integer, $c = \frac{2}{N+\sqrt{N^2+4}}$, and $\varepsilon > 0$ sufficiently small. Levine and Sleeman's work confirms the conjecture of Othmer and Stevens. Unfortunately, combining the technique of [2] and the other technique, even we can find that, in the one-dimensional case, the blow-up conjecture is false. In fact, the situation in this case is more complicated; we can find two kinds of solutions. One would exist globally, and another one would blow up in finite time. In particular, the solution as obtained by Levine and Sleeman [2] is one of the special cases in our blow-up solutions family here.

At the beginning, let us follow the technique in Levine and Sleeman [2] and consider the special case of the dynamics:

$$(3.1)\qquad \begin{cases} \dfrac{\partial p}{\partial t} = \dfrac{\partial}{\partial x}\left(p\dfrac{\partial}{\partial x}\left(\ln\left(\dfrac{p}{w}\right)\right)\right) & \text{for } x \in (0,\pi), \quad t > 0, \\ \dfrac{\partial w}{\partial t} = pw & \\ p_x = w_x = 0 & \text{for } x = 0, \pi; \quad t > 0, \\ p(x,0) = p_0(x) > 0 & \\ w(x,0) = w_0(x) > 0 & \text{for } x \in [0,\pi]. \end{cases}$$

Let $\psi(x,t) = \ln w(x,t)$; we obtain the following initial boundary-value problem for ψ:

$$(3.2)\qquad \begin{cases} \psi_{tt} - \psi_{xxt} + (\psi_x\psi_t)_x = 0 & \text{for } x \in (0,\pi), \quad t > 0, \\ \psi_x = 0 & \text{for } x = 0, \pi; \quad t > 0, \\ \psi(x,0) = \psi_0(x) = \ln w_0(x) & \\ \psi_t(x,0) = p_0(x) > 0 & \text{for } x \in (0,\pi). \end{cases}$$

Let $\psi = \alpha t + \phi$. Then ϕ satisfies

$$(3.3)\qquad \begin{cases} \phi_{tt} + \alpha\phi_{xx} - \phi_{xxt} + \phi_t\phi_{xx} + \phi_x\phi_{xt} = 0 & \text{for } 0 < x < \pi, \quad t > 0, \\ \phi_x = 0 & \text{for } x = 0, \pi; \quad t > 0, \\ \phi(x,0) = \phi_0(x) & \\ \phi_t(x,0) = p_0(x) - \alpha & \text{for } x \in (0,\pi). \end{cases}$$

Let $\phi(x,t) = -\ln(c-u)$. Then

$$\phi_t = \frac{u_t}{c-u}, \quad \phi_x = \frac{u_x}{c-u}, \quad \phi_{tt} = \frac{(c-u)u_{tt} + u_t^2}{(c-u)^2},$$

$$\phi_{xx} = \frac{(c-u)u_{xx} + u_x^2}{(c-u)^2}, \quad \phi_{xt} = \frac{(c-u)u_{xt} + u_xu_t}{(c-u)^2},$$

and

$$\begin{aligned} \phi_{xxt} &= \frac{1}{(c-u)^4}\big\{(c-u)^2\big[(c-u)u_{xxt} - u_tu_{xx} + 2u_xu_{xt}\big] \\ &\quad +2(c-u)u_t\big[(c-u)u_{xx} + u_x^2\big]\big\} \\ &= \frac{1}{(c-u)}u_{xxt} + \frac{1}{(c-u)^2}\big[2u_xu_{xt} + u_tu_{xx}\big] + \frac{2u_tu_x^2}{(c-u)^3}. \end{aligned}$$

So we have

$$\begin{aligned}0 &= \phi_{tt} + \alpha\phi_{xx} - \phi_{xxt} + \phi_t\phi_{xx} + \phi_x\phi_{xt}\\ &= \frac{1}{(c-u)^2}\big(u_t^2 + \alpha u_x^2 - u_x u_{xt}\big) + \frac{1}{c-u}\big(u_{tt} + \alpha u_{xx} - u_{xxt}\big)\\ &= \frac{1}{(c-u)^2}\big(u_t^2 + \alpha u_x^2 - u_x u_{xt} + cu_{tt} + c\alpha u_{xx}\\ &\quad -cu_{xxt} - uu_{tt} - \alpha uu_{xx} + uu_{xxt}\big).\end{aligned}$$

If $u(x,t) < c$, the above equation is equivalent to the following equation:

$$cu_{tt} + c\alpha u_{xx} - cu_{xxt} + u_t^2 + \alpha u_x^2 - u_x u_{xt} - uu_{tt} - \alpha uu_{xx} + uu_{xxt} = 0.$$

Thus we have

$$\text{(3.4)}\quad \begin{cases} cu_{tt} + c\alpha u_{xx} - cu_{xxt} = & -\big(u_t^2 + \alpha u_x^2 - u_x u_{xt} - uu_{tt} - \alpha uu_{xx} + uu_{xxt}\big)\\ & \text{for } 0 < x < \pi, \quad t > 0,\\ u_x = 0 & \text{for } x = 0, \pi, \quad t > 0.\end{cases}$$

Next, let $u(x,t) = X(x)T(t) + g(t)$. Then

$$\begin{aligned}0 &= cXT'' + cg''(t) + c\alpha X''T - cX''T' + \big[XT' + g'(t)\big]^2 + \alpha X'^2T^2 - X'^2TT'\\ &\quad -\big(XT + g(t)\big)\big(XT'' + g''(t)\big) - \alpha\big[XT + g(t)\big]X''T + \big[XT + g(t)\big]X''T'\\ &= \big[cT'' + 2g'(t)T' - g''(t)T - g(t)T''\big]X + \big[c\alpha T - cT' - \alpha g(t)T + g(t)T'\big]X''\\ &\quad +\big[T'^2 - TT''\big]X^2 + \big[\alpha T^2 - TT'\big]X'^2 + \big[TT' - \alpha T^2\big]XX''\\ &\quad +[g'(t)]^2 - g(t)g''(t) + cg''(t).\end{aligned}$$

If $T'^2 = TT''$, we obtain $\frac{T'}{T} = \frac{T''}{T'}$, which implies $T(t) = c_2e^{c_1t}$. In this case, we can get

$$\begin{aligned}0 &= \big\{\big[cc_1^2 + 2c_1g'(t) - g''(t) - c_1^2g(t)\big]X + \big[\alpha c - cc_1 - \alpha g(t) + c_1g(t)\big]X''\\ &\quad +\big[\alpha - c_1\big](X')^2T + \big[c_1 - \alpha\big]TXX''\big\}T + cg''(t) - g(t)g''(t) + [g'(t)]^2.\end{aligned}$$

Choose $X(x) = \cos nx$. Then

$$\begin{aligned}0 &= \big[cc_1^2 + 2c_1g'(t) - g''(t) - c_1^2g(t) - \alpha cn^2 + cc_1n^2 + \alpha n^2g(t) - c_1n^2g(t)\big]XT\\ &\quad +\big\{n^2[\alpha - c_1]\sin^2 nx + n^2[\alpha - c_1]\cos^2 nx\big\}T^2 + cg''(t) - g(t)g''(t) + [g'(t)]^2\\ &= \big[cc_1^2 - \alpha cn^2 + cc_1n^2 + 2c_1g'(t) - g''(t) + (\alpha n^2 - c_1^2 - c_1n^2)g(t)\big]XT\\ &\quad +(\alpha n^2 - c_1n^2)T^2 + cg''(t) - g(t)g''(t) + [g'(t)]^2.\end{aligned}$$

Now let us consider the following equations:

$$\begin{cases} g''(t) - 2c_1g'(t) + (c_1^2 - \alpha n^2 + c_1n^2)g(t) = c(c_1^2 + c_1n^2 - \alpha n^2), & \text{(3.5)}\\ (c - g(t))g''(t) + (g'(t))^2 = n^2c_2^2(c_1 - \alpha)e^{2c_1t}. & \text{(3.6)}\end{cases}$$

From (3.5), it is obvious that $g(t) = Ae^{k_1 t} + Be^{k_2 t} + c$, where $c_1 < \alpha$, $k_1 = c_1 + n\sqrt{\alpha - c_1}$, and $k_2 = c_1 - n\sqrt{\alpha - c_1}$. Taking $g(t)$ into (3.6), we have

$$\begin{aligned} n^2 c_2^2 (c_1 - \alpha) e^{2c_1 t} &= \big[- Ae^{k_1 t} - Be^{k_2 t} \big] \big[Ak_1^2 e^{k_1 t} + Bk_2^2 e^{k_2 t} \big] + \big[Ak_1 e^{k_1 t} + Bk_2 e^{k_2} \big]^2 \\ &= -AB(k_1 - k_2)^2 e^{2c_1 t}, \end{aligned}$$

which implies

$$n^2 c_2^2 (\alpha - c_1) = AB(k_1 - k_2)^2 = 4n^2 AB(\alpha - c_1),$$

which leads to $4AB = c_2^2$. Replacing $2c_2$ by c_2, A by $-A$, and B by $-B$, we obtain

$$\psi(x,t) = \alpha t - \ln[\pm 2\sqrt{AB} e^{c_1 t} \cos nx + Ae^{k_1 t} + Be^{k_2 t}]$$

and

$$p(x,t) = \alpha - \frac{Ak_1 e^{k_1 t} + Bk_2 e^{k_2 t} \pm 2c_1 \sqrt{AB} e^{c_1 t} \cos nx}{Ae^{k_1 t} + Be^{k_2 t} \pm 2\sqrt{AB} e^{c_1 t} \cos nx}.$$

It is obvious that

$$w(x,t) = \frac{e^{\alpha t}}{\pm 2\sqrt{AB} e^{c_1 t} \cos nx + Ae^{k_1 t} + Be^{k_2 t}}.$$

(p, w) is the solution for the problem (3.1) with the initial data

$$(p_0(x), w_0(x)) = \left(\alpha - \frac{Ak_1 + Bk_2 \pm 2c_1 \sqrt{AB} \cos nx}{A + B \pm 2\sqrt{AB} \cos nx}, \frac{1}{\pm 2\sqrt{AB} \cos nx + A + B} \right).$$

THEOREM 3.1. *For the dynamics* (3.1), *we have the following kinds of solutions:*

(a) *Assume $A > B > 0$; if $c_1 < \alpha - n^2 \{ \frac{\sqrt{A}+\sqrt{B}}{\sqrt{A}-\sqrt{B}} \}^2$, then $(p(x,t), w(x,t))$ is the global solution for the dynamics* (3.1).

(b) *Assume $0 < A < B$; then for any $c_1 < \alpha$ there exists $T > 0$ such that $(p(x,t), w(x,t))$ is the solution of the dynamics* (3.1) *for $0 < t < T$, and the solution will blow up at the finite time $t = T$ at some point $x \in [0, \pi]$.*

Proof. (a) Since $A > B > 0$, we can choose a point x_0, satisfying $\cos nx_0 = -1$. Then, for $x \in [0, \pi], t > 0$, we have

$$\begin{aligned} Ae^{k_1 t} + Be^{k_2 t} \pm 2\sqrt{AB} e^{c_1 t} \cos nx &\geq Ae^{k_1 t} + Be^{k_2 t} + 2\sqrt{AB} e^{c_1 t} \cos nx_0 \\ &= e^{c_1 t} \left(\sqrt{A} e^{\frac{(n\sqrt{\alpha - c_1})t}{2}} - \sqrt{B} e^{-\frac{(n\sqrt{\alpha - c_1})t}{2}} \right)^2 \\ &\geq e^{c_1 t} (\sqrt{A} - \sqrt{B})^2 > 0, \end{aligned}$$

which implies that $p(x,t)$ and $w(x,t)$ are well defined and $w(x,t) > 0$ for all $t > 0$. Furthermore, because of $c_1 < \alpha$ and $c_1 < \alpha - n^2 \{ \frac{\sqrt{A}+\sqrt{B}}{\sqrt{A}-\sqrt{B}} \}^2$, which implies that

$\alpha - c_1 - n\sqrt{\alpha - c_1}\frac{\sqrt{A}+\sqrt{B}}{\sqrt{A}-\sqrt{B}} > 0$, we obtain that

$$
\begin{aligned}
p(x,t) &= \alpha - \frac{Ak_1e^{k_1t} + Bk_2e^{k_2t} \pm 2\sqrt{AB}c_1e^{c_1t}\cos nx}{Ae^{k_1t} + Be^{k_2t} \pm 2\sqrt{AB}e^{c_1t}\cos nx} \\
&= \alpha - \frac{Ak_1e^{n\sqrt{\alpha-c_1}t} + Bk_2e^{-n\sqrt{\alpha-c_1}t} \pm 2\sqrt{AB}c_1\cos nx}{Ae^{n\sqrt{\alpha-c_1}t} + Be^{-n\sqrt{\alpha-c_1}t} \pm 2\sqrt{AB}\cos nx} \\
&= \alpha - c_1 - n\sqrt{\alpha - c_1}\frac{Ae^{n\sqrt{\alpha-c_1}t} - Be^{-n\sqrt{\alpha-c_1}t}}{Ae^{n\sqrt{\alpha-c_1}t} + Be^{-n\sqrt{\alpha-c_1}t} \pm 2\sqrt{AB}\cos nx} \\
&\geq \alpha - c_1 - n\sqrt{\alpha - c_1}\frac{Ae^{n\sqrt{\alpha-c_1}t} - Be^{-n\sqrt{\alpha-c_1}t}}{\left\{\sqrt{A}e^{\frac{n\sqrt{\alpha-c_1}t}{2}} - \sqrt{B}e^{-\frac{n\sqrt{\alpha-c_1}t}{2}}\right\}^2} \\
&= \alpha - c_1 - n\sqrt{\alpha - c_1}\frac{\sqrt{A}e^{\frac{n\sqrt{\alpha-c_1}t}{2}} + \sqrt{B}e^{\frac{-n\sqrt{\alpha-c_1}t}{2}}}{\sqrt{A}e^{\frac{n\sqrt{\alpha-c_1}t}{2}} - \sqrt{B}e^{-\frac{n\sqrt{\alpha-c_1}t}{2}}} \\
&\geq \alpha - c_1 - n\sqrt{\alpha - c_1}\frac{\sqrt{A}+\sqrt{B}}{\sqrt{A}-\sqrt{B}} > 0.
\end{aligned}
$$

Furthermore, for any $x \in [0,\pi], t > 0$, we get that

$$
\begin{aligned}
p(x,t) &= \alpha - c_1 - n\sqrt{\alpha - c_1}\frac{Ae^{n\sqrt{\alpha-c_1}t} - Be^{-n\sqrt{\alpha-c_1}t}}{Ae^{n\sqrt{\alpha-c_1}t} + Be^{-n\sqrt{\alpha-c_1}t} \pm 2\sqrt{AB}\cos nx} \\
&\leq \alpha - c_1 - n\sqrt{\alpha - c_1}\frac{Ae^{n\sqrt{\alpha-c_1}t} - Be^{-n\sqrt{\alpha-c_1}t}}{\left\{\sqrt{A}e^{\frac{n\sqrt{\alpha-c_1}t}{2}} + \sqrt{B}e^{-\frac{n\sqrt{\alpha-c_1}t}{2}}\right\}^2} \\
&= \alpha - c_1 - n\sqrt{\alpha - c_1}\frac{\sqrt{A}e^{\frac{n\sqrt{\alpha-c_1}t}{2}} - \sqrt{B}e^{\frac{-n\sqrt{\alpha-c_1}t}{2}}}{\sqrt{A}e^{\frac{n\sqrt{\alpha-c_1}t}{2}} + \sqrt{B}e^{-\frac{n\sqrt{\alpha-c_1}t}{2}}} \\
&\leq \alpha - c_1 - n\sqrt{\alpha - c_1} < +\infty, \\
w(x,t) &= \frac{e^{\alpha t}}{\pm 2\sqrt{AB}e^{c_1t}\cos nx + Ae^{k_1t} + B^{k_2t}} \\
&\leq \frac{e^{(\alpha-c_1)t}}{-2\sqrt{AB} + Ae^{n\sqrt{\alpha-c_1}t} + Be^{-n\sqrt{\alpha-c_1}t}} \\
&= \frac{e^{(\alpha-c_1)t}}{\left\{\sqrt{A}e^{\frac{n\sqrt{\alpha-c_1}t}{2}} - \sqrt{B}e^{-\frac{n\sqrt{\alpha-c_1}t}{2}}\right\}^2} < +\infty.
\end{aligned}
$$

That leads to the global existence of the solution for the system (3.1).

(b) When $B > A > 0$, there exists a point $x_0 \in [0,\pi]$ such that $\cos nx_0 = \mp 1$

satisfying, for any $0 < t < T = \frac{1}{2n\sqrt{\alpha - c_1}} \ln \frac{B}{A}$,

$$\begin{aligned} p(x_0, t) &= \alpha - c_1 + n\sqrt{\alpha - c_1} \frac{Be^{-n\sqrt{\alpha - c_1}t} - Ae^{n\sqrt{\alpha - c_1}t}}{Be^{-n\sqrt{\alpha - c_1}t} + Ae^{n\sqrt{\alpha - c_1}t} \pm 2\sqrt{AB}\cos nx_0} \\ &= \alpha - c_1 + n\sqrt{\alpha - c_1} \frac{\sqrt{B}e^{\frac{-n\sqrt{\alpha - c_1}t}{2}} + \sqrt{A}e^{\frac{n\sqrt{\alpha - c_1}t}{2}}}{\sqrt{B}e^{\frac{-n\sqrt{\alpha - c_1}t}{2}} - \sqrt{A}e^{\frac{n\sqrt{\alpha - c_1}t}{2}}}, \\ w(x_0, t) &= \frac{e^{\alpha t}}{\pm 2\sqrt{AB}e^{c_1 t}\cos nx_0 + Ae^{k_1 t} + B^{k_2 t}} \\ &= \frac{e^{(\alpha - c_1)t}}{\left\{\sqrt{B}e^{\frac{-n\sqrt{\alpha - c_1}t}{2}} - \sqrt{A}e^{\frac{n\sqrt{\alpha - c_1}t}{2}}\right\}^2}. \end{aligned}$$

It is clear that $\lim_{t \to T^-} p(x_0, t) = +\infty, \lim_{t \to T^-} w(x_0, t) = +\infty$. We can also show that for any $x \in (0, \pi), 0 < t < T$,

$$\begin{aligned} p(x, t) &= \alpha - c_1 + n\sqrt{\alpha - c_1} \frac{Be^{-n\sqrt{\alpha - c_1}t} - Ae^{n\sqrt{\alpha - c_1}t}}{Be^{-n\sqrt{\alpha - c_1}t} + Ae^{n\sqrt{\alpha - c_1}t} \pm 2\sqrt{AB}\cos nx} \\ &\geq \alpha - c_1 + n\sqrt{\alpha - c_1} \frac{\sqrt{B}e^{\frac{-n\sqrt{\alpha - c_1}t}{2}} - \sqrt{A}e^{\frac{n\sqrt{\alpha - c_1}t}{2}}}{\sqrt{B}e^{\frac{-n\sqrt{\alpha - c_1}t}{2}} + \sqrt{A}e^{\frac{n\sqrt{\alpha - c_1}t}{2}}} > 0, \\ w(x, t) &= \frac{e^{\alpha t}}{\pm 2\sqrt{AB}e^{c_1 t}\cos nx + Ae^{k_1 t} + B^{k_2 t}} \\ &\geq \frac{e^{(\alpha - c_1)t}}{\left\{\sqrt{B}e^{\frac{-n\sqrt{\alpha - c_1}t}{2}} + \sqrt{A}e^{\frac{n\sqrt{\alpha - c_1}t}{2}}\right\}^2} > 0, \end{aligned}$$

and

$$\begin{aligned} p(x, t) &= \alpha - c_1 + n\sqrt{\alpha - c_1} \frac{Be^{-n\sqrt{\alpha - c_1}t} - Ae^{n\sqrt{\alpha - c_1}t}}{Be^{-n\sqrt{\alpha - c_1}t} + Ae^{n\sqrt{\alpha - c_1}t} \pm 2\sqrt{AB}\cos nx} \\ &\leq \alpha - c_1 + n\sqrt{\alpha - c_1} \frac{\sqrt{B}e^{\frac{-n\sqrt{\alpha - c_1}t}{2}} + \sqrt{A}e^{\frac{n\sqrt{\alpha - c_1}t}{2}}}{\sqrt{B}e^{\frac{-n\sqrt{\alpha - c_1}t}{2}} - \sqrt{A}e^{\frac{n\sqrt{\alpha - c_1}t}{2}}} < +\infty, \\ w(x, t) &= \frac{e^{\alpha t}}{\pm 2\sqrt{AB}e^{c_1 t}\cos nx + Ae^{k_1 t} + B^{k_2 t}} \\ &\leq \frac{e^{(\alpha - c_1)t}}{\left\{\sqrt{B}e^{\frac{-n\sqrt{\alpha - c_1}t}{2}} - \sqrt{A}e^{\frac{n\sqrt{\alpha - c_1}t}{2}}\right\}^2} < +\infty. \end{aligned}$$

That implies that the solution $(p(x, t), w(x, t))$ of the problem is well defined for $x \in (0, \pi), 0 < t < T$, the solution will blow up at the point $x = x_0$, and t tends to finite-time T.

Theorem 3.1 is proved. □

Remark 3.1. For the different cases corresponding to the different situations in Theorem 3.1, please see Figures 1–4 below.

Remark 3.2. We cannot respect the case $A = B$, because at this time the initial data $(p(x, 0), w(x, 0))$ cannot be well defined at the points x satisfying $\cos nx = \mp 1$.

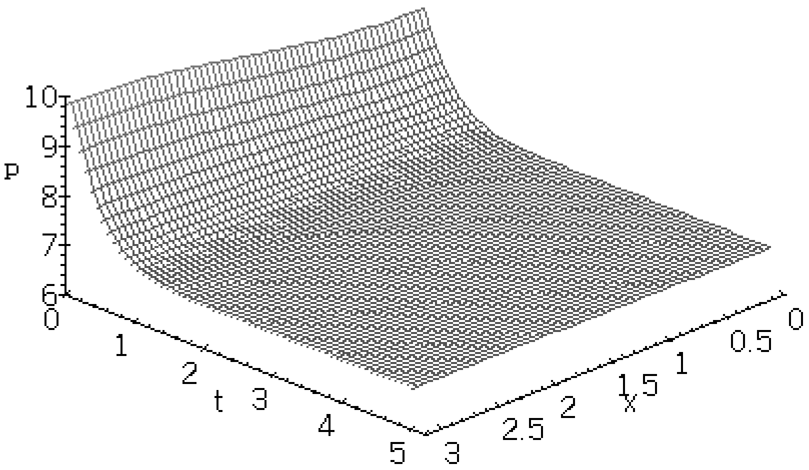

FIG. 1. *In the case of Theorem* 3.1(a)*, for the solution* $p(x,t)$*, where* $A = 4$*,* $B = 1$*,* $n = 1$*,* $c_1 = 1$*,* $\alpha = 11$.

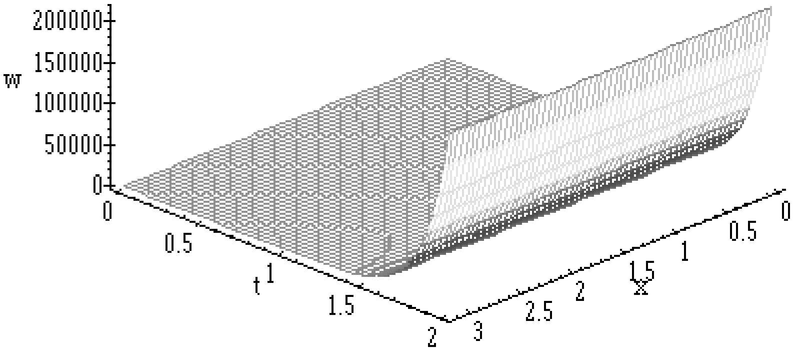

FIG. 2. *In the case of Theorem* 3.1(a)*, for the solution* $w(x,t)$*, where* $A = 4$*,* $B = 1$*,* $n = 1$*,* $c_1 = 1$*,* $\alpha = 11$.

Remark 3.3. If we choose $c_1 = \alpha$, we can obtain $g(t) = (A + Bt)e^t$, and B must be 0 in this case. Then we get $(p(x,t), w(x,t)) = (0, \frac{1}{A+c_2 \cos nx})$ for any $|A| > |c_2|$, which is not permitted in our problem because we want only a positive solution.

Remark 3.4. Assume that $c_1 > \alpha$; we can get the solution

$$\begin{cases} p(x,t) & = \alpha - c_1 + \dfrac{\sqrt{c_1-\alpha}[A \sin n\sqrt{c_1-\alpha}t - B \cos n\sqrt{c_1-\alpha}t]}{A \cos n\sqrt{c_1-\alpha}t + B \sin n\sqrt{c_1-\alpha}t \pm \sqrt{A^2+B^2}\cos nx}, \\ w(x,t) & = \dfrac{e^{(\alpha-c_1)t}}{A \cos n\sqrt{c_1-\alpha}t + B \sin\ n\sqrt{c_1-\alpha}t \pm \sqrt{A^2+B^2}\cos\ nx}. \end{cases}$$

It can be easily found that the initial data $(p(x,0), w(x,0))$ cannot be well defined.

Remark 3.5. Let $c_1 = \frac{-n^2+n\sqrt{n^2+4}}{2}$. Then $k_1 = 2c_1, k_2 = 0$, and

$$p(x,t) = \alpha - 2c_1 \frac{Ae^{2c_1t} + 2\sqrt{AB}e^{c_1t}\cos nx}{B + 2\sqrt{AB}e^{c_1t}\cos nx + Ae^{2c_1t}}.$$

If we take $\alpha = B = 1$, $A = \epsilon^2$, and $n = N$, then we get the same solution as obtained

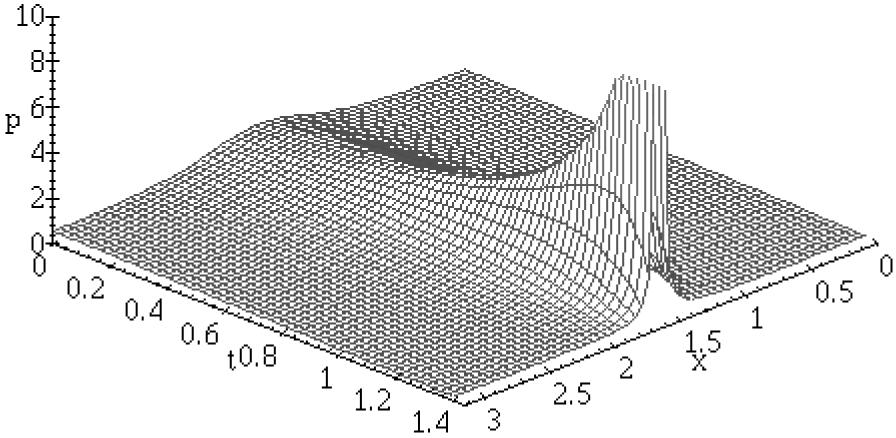

FIG. 3. *In the case of Theorem* 3.1(b)*, for the solution* $p(x,t)$*, where* $A = 0.1$*,* $B = 1$*,* $c_1 = 0.84$*,* $\alpha = 1$*,* $n = 2$*.*

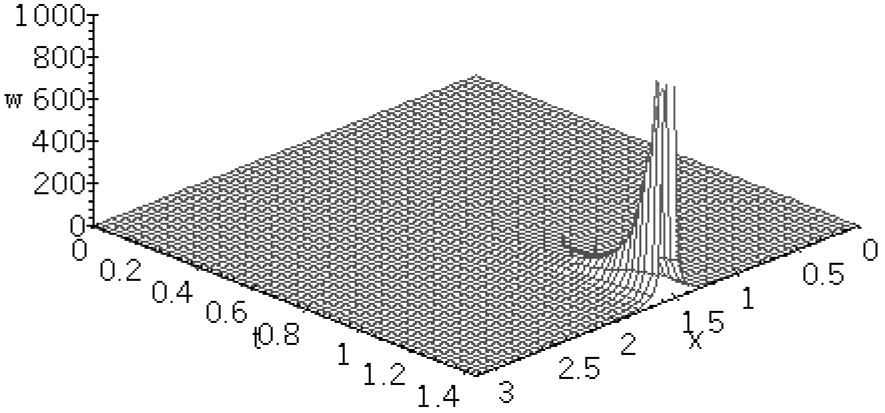

FIG. 4. *In the case of Theorem* 3.1(b)*, for the solution* $w(x,t)$*, where* $A = 0.1$*,* $B = 1$*,* $c_1 = 0.84$*,* $\alpha = 1$*,* $n = 2$*.*

by Levine and Sleeman [2].

Remark 3.6. For the problem (3.2), we can consider $\psi(x,t) = -\ln(c - \phi(x,t))$ directly, and so we get

$$\begin{cases} p(x,t) = k_1 - \mu \dfrac{Ae^{\mu t} - Be^{-\mu t}}{Ae^{\mu t} + Be^{-\mu t} \pm 2\sqrt{AB}\cos nx}, \\ w(x,t) = \dfrac{e^{k_1 t}}{Ae^{\mu t} + Be^{-\mu t} \pm 2\sqrt{AB}\cos nx}, \end{cases}$$

where $\mu = n\sqrt{k_1}$. It is clear that the solution $(p(x,t), w(x,t))$ blows up if $B > A > 0$. Furthermore, the blow-up time is $T = \frac{1}{\mu}\ln(\sqrt{\frac{B}{A}})$, and the blow-up point is $x_0 \in [0,\pi]$ satisfying $\cos nx_0 = \mp 1$. $(p(x,t), w(x,t))$ is global if $A > B > 0$ and $k_1 > n^2\{\frac{\sqrt{A}+\sqrt{B}}{\sqrt{A}-\sqrt{B}}\}^2$.

By the arguments above, we know that the maximal existence time of the solution for the system (3.1) is strongly dependent on the choice for their initial data. Also, we can investigate the asymptotic behavior of the solution and find something very interesting: First, we can get two pairs of solutions $(p_i(x,t), w_i(x,t))(i = 1, 2)$ such that even though the difference of their initial data is relatively large, they still have very similar asymptotic behavior:

$$\lim_{t\to+\infty}(p_1(x,t) - p_2(x,t)) = 0, \qquad \lim_{t\to+\infty}(w_1(x,t) - w_2(x,t)) = 0 \qquad \text{for } x \in \bar{\Omega}.$$

Second, even if the difference of their initial data is very small, we can also find two solutions $(p_i(x,t), w_i(x,t))$, $i = 1, 2$, in which one solution exists globally and another one will blow up in finite time. This means that these biological systems are unstable.

We have following result.

THEOREM 3.2. *For any positive spatial independent solution of the dynamics* (3.1) $(p_0, w_0e^{p_0t})$, *we have the following results.*

(a) *There exists a family of positive solutions for the dynamics* (3.1)

$$\begin{cases} p(x,t) &= k - \mu\dfrac{Ae^{\mu t} - Be^{-\mu t}}{Ae^{\mu t} + Be^{-\mu t} \pm 2\sqrt{AB}\cos Nx}, \\ w(x,t) &= \dfrac{e^{kt}}{Ae^{\mu t} + Be^{-\mu t} \pm 2\sqrt{AB}\cos Nx}, \end{cases}$$

where $\mu = N\sqrt{k}$, *satisfying*

$$\lim_{t\to+\infty}(p(x,t) - p_0) = 0, \quad \lim_{t\to+\infty}\left(\frac{w_0e^{p_0t}}{w(x,t)}\right) = 1.$$

(b) *For any positive constant* $\varepsilon > 0$ *small enough, we can find a positive solution* $(p(x,t), w(x,t))$ *with the initial data* $p_0 - \varepsilon < p(x,0) < p_0 + \varepsilon$ *and* $0 < w(x,0) < \varepsilon$, *and* $(p(x,t), w(x,t))$ *will blow up at finite-time* T.

Proof. (a) For any $p_0 > 0, w_0 > 0$, and positive integer $N > 0$ fixed, denote by $\sqrt{k}$ the positive solution of the equation

$$\lambda^2 - N\lambda - p_0 = 0.$$

Then we have $k - N\sqrt{k} = p_0 > 0$. Since the function $\frac{\sqrt{A}+x}{\sqrt{A}-x}$ is strictly increasing continuous for $0 < x < \sqrt{A}$, satisfying

$$\lim_{x\to0^+}\frac{\sqrt{A}+x}{\sqrt{A}-x} = 1, \quad \lim_{x\to\sqrt{A}^-}\frac{\sqrt{A}+x}{\sqrt{A}-x} = +\infty$$

for any positive constant A, we can find $B > 0$ sufficiently small such that

$$k > N^2\left\{\frac{\sqrt{A}+\sqrt{B}}{\sqrt{A}-\sqrt{B}}\right\}^2.$$

According to Theorem 3.1, the solution of the dynamics (3.1)

$$\begin{aligned} p(x,t) &= k - N\sqrt{k}\frac{Ae^{N\sqrt{k}t} - Be^{-N\sqrt{k}t}}{Ae^{N\sqrt{k}t} + Be^{-N\sqrt{k}t} \pm 2\sqrt{AB}\cos Nx}, \\ w(x,t) &= \frac{e^{kt}}{Ae^{N\sqrt{k}t} + Be^{-N\sqrt{k}t} \pm 2\sqrt{AB}\cos Nx} \end{aligned}$$

exists globally, and

$$\lim_{t\to+\infty} p(x,t) = k - N\sqrt{k} = p_0, \quad \lim_{t\to+\infty}\left[\frac{w_0 e^{p_0 t}}{w(x,t)}\right] = Aw_0.$$

If we choose $A = \frac{1}{w_0}$, we can get the result as mentioned in (a).

(b) For any $\varepsilon > 0$, we can find a positive constant $B_0 > 0$ sufficiently large such that for any $B \geq B_0$, $|p_0(\frac{\sqrt{B}-\sqrt{A}}{\sqrt{B}+\sqrt{A}} - 1)| < \varepsilon$, $|p_0(\frac{\sqrt{B}+\sqrt{A}}{\sqrt{B}-\sqrt{A}} - 1)| < \varepsilon$ for some positive constant A, where we suppose $B_0 > A$. Let $k = \frac{(\sqrt{N^2+4p_0}-N)^2}{4}$; then we have

$$k + N\sqrt{k} = p_0.$$

Choose $T > 0$ satisfying

$$T = \frac{1}{N[\sqrt{N^2+4p_0} - N]}\ln\frac{B}{A} > 0.$$

It is well known that the solution $(p(x,t), w(x,t))$, denoting $N\sqrt{k}$ by μ, where

$$\begin{aligned} p(x,t) &= k + \mu\frac{Be^{-\mu t} - Ae^{\mu t}}{Be^{-\mu t} + Ae^{\mu t} \pm 2\sqrt{AB}\cos Nx}, \\ w(x,t) &= \frac{e^{kt}}{Be^{-\mu t} + Ae^{\mu t} \pm 2\sqrt{AB}\cos Nx}, \end{aligned}$$

is a solution for the system (3.1) with the initial data

$$p_0 - \varepsilon < k + \mu\frac{\sqrt{B}-\sqrt{A}}{\sqrt{B}+\sqrt{A}} \leq p(x,0) \leq k + \mu\frac{\sqrt{B}+\sqrt{A}}{\sqrt{B}-\sqrt{A}} < p_0 + \varepsilon$$

that will blow up in finite-time T at the point x_0 chosen above.

The proof is completed. □

Remark 3.7. According to the statement above, we know that the maximum existence of the solution for the dynamics (3.1) is very sensitive to the initial data. Even close to the constant initial data, we can find both global and blow-up in finite-time solutions, respectively.

Remark 3.8. We can find from the argument in the proof of (b) of Theorem 3.2 that the blow-up time is

$$T = \frac{1}{N[\sqrt{N^2+4p_0} - N]}\ln\frac{B}{A} = \frac{[\sqrt{N^2+4p_0} + N]}{4p_0 N}\ln\frac{B}{A} = \frac{\sqrt{1+\frac{4p_0}{N^2}} + 1}{4p_0}\ln\frac{B}{A}.$$

It is obvious that T is increasing with B.

4. High dimensional case with *w* possessing exponential growth. In section 3, we knew that even in the special case, when w has exponential growth, the behavior of the solutions is very complicated. Let us consider the following general case:

$$
(4.1)\qquad \begin{cases} \dfrac{\partial p}{\partial t} = D\nabla\left(p\nabla\left(\ln\left(\dfrac{p}{w}\right)\right)\right) & \text{for } x \in \Omega \subseteq R^n, \quad t > 0,\\ \dfrac{\partial w}{\partial t} = (\beta p - \mu)w & \\ p\nabla\left(\ln\left(\dfrac{p}{w}\right)\right)\cdot \vec{n} = 0 & \text{for } x \in \partial\Omega, \quad t > 0,\\ p(x,0) = p_0(x) > 0 & \text{for } x \in \overline{\Omega},\\ w(x,0) = w_0(x) > 0 & \end{cases}
$$

where $\Omega, \vec{n}, D, \beta$, and μ are all the same as in the preceding section and $n \geq 1$. Let $u(x,t) = \frac{p(x,t)}{e^{\mu t}w(x,t)}$. Since $(e^{\mu t}w)_t = \beta e^{\mu t}wp$, $u = \frac{p}{e^{\mu t}w} = \frac{(e^{\mu t}w)_t}{\beta(e^{\mu t}w)^2}$, we have

$$
(4.2)\quad w(x,t) = \frac{w_0(x)e^{-\mu t}}{1 - \beta w_0(x)\displaystyle\int_0^t u(x,\tau)\,d\tau}, \qquad p(x,t) = \frac{w_0(x)u(x,t)}{1 - \beta w_0(x)\displaystyle\int_0^t u(x,\tau)\,d\tau}.
$$

Also, we easily find that $(p(x,t), w(x,t))$ is a solution of the dynamics (4.1) if and only if $(u(x,t), w(x,t))$ is a solution of the following initial boundary-value problem:

$$
\begin{cases} \dfrac{\partial u}{\partial t} = D\Delta u + D\dfrac{1}{w}(\nabla w)\cdot(\nabla u) - \dfrac{\beta w_0 u^2}{1 - \beta w_0\displaystyle\int_0^t u(x,\tau)\,d\tau} & \text{for } x \in \Omega, \quad t > 0,\\ w(x,t) = \dfrac{w_0(x)e^{-\mu t}}{1 - \beta w_0(x)\displaystyle\int_0^t u(x,\tau)\,d\tau} & \\ \dfrac{\partial u}{\partial n} = 0 & \text{for } x \in \partial\Omega, \quad t > 0,\\ u(x,0) = u_0(x) = \dfrac{p_0(x)}{w_0(x)} > 0 & \text{for } x \in \overline{\Omega}.\\ w(x,0) = w_0(x) > 0 & \end{cases}
$$
(4.3)

Similarly as in the preceding section, we know that there is a unique smooth positive solution for smooth initial data locally in time. What we want to discuss is the solutions of the systems (4.1) that do not exist globally. It is worthwhile to point out that the space-independent solution $(p_0, w_0e^{(\beta p_0 - \mu)_t})$, p_0, w_0 both positive constants, is a global solution of the dynamics (4.1). In the following, we consider only the solution (p, w) that is not independent of the spatial variable. In fact, let

$$
T = \sup\{\tilde{T} > 0;\ (p(x,t), w(x,t)) \text{ exists in } \Omega \times (0, \tilde{T}]\};
$$

then by using the maximum principle, for the solution $(u(x,t), w(x,t))$ of the dynamics (4.3), we can easily obtain

$$
(4.4)\qquad 0 < u(x,t) < \max_{x\in\overline{\Omega}} u_0(x), \quad w(x,t) > 0.
$$

Also observe that, for $x \in \Omega$, $0 < t < T$, we have

$$
(4.5)\qquad 0 < \beta w_0(x)\int_0^t u(x,\tau)d\tau \leq \max_{x\in\overline{\Omega}}\left[\beta w_0(x)\int_0^t u(x,\tau)d\tau\right] < 1.
$$

Let us define

$$\underline{w}_0 \overset{\triangle}{=} \min_{x\in\overline{\Omega}} w_0(x), \quad \overline{w}_0 \overset{\triangle}{=} \max_{x\in\overline{\Omega}} w_0(x),$$

$$\underline{u}_0 \overset{\triangle}{=} \min_{x\in\overline{\Omega}} u_0(x), \quad \overline{u}_0 \overset{\triangle}{=} \max_{x\in\overline{\Omega}} u_0(x),$$

$$m(t) \overset{\triangle}{=} 1 - \max_{x\in\overline{\Omega}} \left[\beta w_0(x) \int_0^t u(x,\tau)d\tau\right]$$

and

$$0 < \phi(t) \overset{\triangle}{=} \min_{x\in\overline{\Omega}} u(x,t) \le \max_{x\in\o verline\Omega} u(x,t) \overset{\triangle}{=} \psi(t) \text{ for } 0 < t < T.$$

Thus if $(p(x,t), w(x,t))$ is a global solution of (4.1), then we have the following necessary condition.

THEOREM 4.1. *If $T = +\infty$, then $m(+\infty) = 0$, which implies that*

$$\max_{x\in\overline{\Omega}} \left[\beta w_0(x) \int_0^\infty u(x,\tau)d\tau\right] = 1.$$

Proof. Since $T = +\infty$, the dynamics (4.1) has a unique global positive solution $(p(x,t), w(x,t))$ with positive initial data $p(x,0) = p_0(x)$, $w(x,0) = w_0(x)$ on $\overline{\Omega}$, which implies that the function transformation, given by (4.2), is well defined for all time and that $1/w$ is positive and finite for all time. Because $u(x,t)$ is a solution of the dynamics (4.3), we have

$$\frac{\partial u}{\partial t} - D \triangle u - D\frac{1}{w}(\nabla w)\cdot(\nabla u) = -\frac{\beta w_0(x)u^2}{1-\beta w_0(x)\displaystyle\int_0^t u(x,\tau)d\tau} \ge -\frac{\beta\overline{w}_0 u^2}{m(t)}$$

for $x \in \Omega,\ t > 0$. This implies that $u(x,t)$ is a supersolution of the following dynamics:

$$(4.6) \quad \begin{cases} \dfrac{\partial v}{\partial t} - D\triangle v - D\dfrac{1}{w}(\nabla w)\cdot(\nabla v) = -\dfrac{\beta\overline{w}_0 v^2}{m(t)} & \text{for } x\in\Omega, \quad t>0, \\ \dfrac{\partial v}{\partial \mathbf{n}} = 0 & \text{for } x \in \partial\Omega, \quad t > 0, \\ v(x,0) = \underline{u}_0 & \text{for } x \in \overline{\Omega}. \end{cases}$$

We can solve the dynamics (4.6), which has a unique solution as follows:

$$v(x,t) = v(t) = \frac{\underline{u}_0}{1+\displaystyle\int_0^t \frac{\beta\overline{w}_0\underline{u}_0}{m(t_1)}dt_1}, \quad x\in\Omega, \quad t>0;$$

thus we obtain

$$(4.7) \quad u(x,t) \ge \phi(t) \ge v(t) = \frac{\underline{u}_0}{1+\displaystyle\int_0^t \frac{\beta\overline{w}_0\underline{u}_0}{m(t_1)}dt_1}, \quad x\in\Omega, \quad t>0.$$

Observe that for all $t > 0$ we have

$$\begin{aligned}
1 &> \max_{x\in\overline{\Omega}}\left[\beta w_0\int_0^t u(x,\tau)d\tau\right] \geq \beta\overline{w}_0\int_0^t \phi(\tau)d\tau \geq \beta\overline{w}_0\int_0^t v(\tau)d\tau\\
&= \int_0^t \frac{\beta\overline{w}_0\underline{u}_0}{1+\displaystyle\int_0^{t_1}\frac{\beta\overline{w}_0\underline{u}_0}{m(t_2)}dt_2}dt_1\\
&= \int_0^t \frac{\beta\overline{w}_0\underline{u}_0}{m(t_1)}\cdot\frac{m(t_1)}{1+\displaystyle\int_0^{t_1}\frac{\beta\overline{w}_0\underline{u}_0}{m(t_2)}dt_2}dt_1\\
&\geq m(t)\int_0^t \frac{\beta\overline{w}_0(x)\underline{u}_0}{m(t_1)}\cdot\frac{1}{1+\displaystyle\int_0^{t_1}\frac{\beta\overline{w}_0\underline{u}_0}{m(t_2)}dt_2}dt_1\\
&= m(t)\ln\left(1+\int_0^t\frac{\beta\overline{w}_0\underline{u}_0}{m(t_1)}dt_1\right).
\end{aligned}$$

Keeping in mind that $\max_{x\in\overline{\Omega}}[\beta w_0(x)\int_0^t u(x,\tau)d\tau] < 1$ and $u(x,t) > 0$ for $x \in \Omega$ and $t > 0$, we can obtain, from the estimate above, that

$$m(+\infty) = 0, \text{ which implies that } \max_{x\in\overline{\Omega}}\left[\beta w_0(x)\int_0^{+\infty}u(x,\tau)d\tau\right] = 1,$$

as required. □

Theorem 4.2. *For the dynamics* (4.1), *if* (p, w) *does not exist globally, which means that* $T < +\infty$, *then the solution* $(p(x,t), w(x,t))$ *will blow up as* t *tends to* T. *Furthermore, we can find an* $x^* \in \overline{\Omega}$ *such that*

$$\lim_{t\to T^-} w(x^*,t) = +\infty \textit{ and } \lim_{t\to T^-} p(x^*,t) = +\infty.$$

Proof. Let $u(x,t) = \frac{p(x,t)}{w(x,t)e^{\mu t}}$. Then $(u(x,t), w(x,t))$ is the solution of the following system:

$$\begin{cases}
\dfrac{\partial u}{\partial t} = D\Delta u + D\dfrac{1}{w}(\nabla w)\cdot(\nabla u) - \dfrac{\beta w_0 u^2}{1-\beta w_0\displaystyle\int_0^t u(x,\tau)\,d\tau} & \\
 & \text{for } x\in\Omega, \quad 0<t<T,\\
w(x,t) = \dfrac{w_0(x)e^{-\mu t}}{1-\beta w_0(x)\displaystyle\int_0^t u(x,\tau)\,d\tau} & \\
\dfrac{\partial u}{\partial n} = 0 & \text{for } x\in\partial\Omega, \quad 0<t<T,\\
u(x,0) = u_0(x) = \dfrac{p_0(x)}{w_0(x)} > 0 & \\
 & \text{for } x\in\overline{\Omega}.\\
w(x,0) = w_0(x) > 0 &
\end{cases}$$

Let $f(x,t,u) = \frac{\beta w_0(x)}{1-\beta w_0(x)\int_0^t u(x,\tau)\,d\tau}$, and let $f_k(x,t,u) = \min\{f, k\}$. For w fixed, we denote $u_{(k)}(x,t)$ the solution of the following dynamics:

$$\text{(4.8)}\quad \begin{cases} \dfrac{\partial u}{\partial t} - D \bigtriangleup u - D\dfrac{1}{w}(\nabla w)\cdot(\nabla u) + f_k(x,t,u)u^2 = 0 & \text{for } (x,t)\in\Omega\times(0,T),\\ \dfrac{\partial u}{\partial \mathbf{n}} = 0 & \text{for } (x,t)\in\partial\Omega\times(0,T),\\ u(x,0) = u_0(x) & \text{for } x\in\overline{\Omega}. \end{cases}$$

We know that the dynamics (4.8) has a unique solution $u_{(k)}(x,t)$ in $\Omega\times(0,T)$ and $u(x,t)\le u_{(k)}(x,t)$ for all $(x,t)\in\Omega\times(0,T)$.

For any fixed k we can show that $u(x,t)\not\equiv u_{(k)}(x,t)$. Assume it is false, and assume we can find some k satisfying $u(x,t)\equiv u_{(k)}(x,t)$ for $(x,t)\in\Omega\times(0,T)$. Then $f(x,t,u)=f_k(x,t,u)\le k$. Since $w(x,t)=\frac{1}{\beta e^{\mu t}}f(x,t,u)=\frac{1}{\beta e^{\mu t}}f_k(x,t,u)$, $p(x,t)=\frac{1}{\beta}f(x,t,u)u=\frac{1}{\beta}f_k(x,t,u)u$, $w(x,T)$, $p(x,T)$ can be well defined for all $x\in\bar{\Omega}$. Replace the initial data $(p_0(x),w_0(x))$ of the dynamics (4.1) by $(p(x,T),w(x,T))$; we can extend the domain of the existence of the solution for the dynamics (4.1) from $\Omega\times(0,T)$ to $\Omega\times(0,T+\delta)$ for some $\delta>0$. That is in contradiction with the definition of T. So $u(x,t)\not\equiv u_{(k)}(x,t)$ for all k.

Notice that $w(x,t)=\frac{1}{\beta e^{\mu t}}f(x,t,u)$ for $(x,t)\in\bar{\Omega}\times(0,T)$, and for all k there is $(x_k,t_k)\in\bar{\Omega}\times(0,T)$ such that $f(x_k,t_k,u)>k$. Then $\lim_{k\to\infty}w(x_k,t_k)=+\infty$. It is obvious that $t_k\to T^-$. We can choose $\{x_{k_j}\}$ such that $x_{k_j}\to x^*\in\bar{\Omega}$; then $\lim_{t\to T^-}w(x^*,t)=+\infty$.

Since $\beta p=\frac{(e^{\mu t}w)_t}{e^{\mu t}w}$, we have

$$\beta\int_0^t p(x^*,\tau)\,d\tau=\int_0^t\frac{(e^{\mu t}w)_\tau}{e^{\mu\tau}w}\,d\tau=\ln\left(\frac{e^{\mu t}w(x^*,t)}{w_0(x^*)}\right)\overset{t\to T^-}{\longrightarrow}+\infty.$$

Noticing $T<+\infty$, we have $\lim_{t\to T^-}p(x^*,t)=+\infty$. This completes our proof. □

COROLLARY 4.1. *If the solution $(p(x,t),w(x,t))$ of the systems* (4.1) *blows up in finite time, then both $p(x,t)$ and $w(x,t)$ will blow up in the same point in the same time.*

Proof. If the solution of the systems (4.1) will blow up in finite time, say, in the time $t=T$, then at least one of functions $p(x,t)$ and $w(x,t)$ blows up at time T. If $w(x,t)$ blow up at the point $x=x_0$, we know that $p(x,t)$ will blow up at the point $x=x_0$ at the same time from the proof of Theorem 4.2 directly. Assume that $p(x,t)$ blows up. From the fact that $u(x,t)=\frac{p(x,t)}{w(x,t)e^{\mu t}}$ and

$$\begin{aligned} 0= {} & \frac{\partial u}{\partial t}-D\bigtriangleup u-D\frac{1}{w}(\nabla w)\cdot(\nabla u)-\mu u+\frac{\beta w_0(x)u^2}{1-\beta w_0(x)\displaystyle\int_0^t u(x,\tau)d\tau}\\ \ge {} & \frac{\partial u}{\partial t}-D\bigtriangleup u-D\frac{1}{w}(\nabla w)\cdot(\nabla u)-\mu u, \end{aligned}$$

and $\frac{\partial u}{\partial n}=0, u(x,0)=u_0(x)<\bar{u}_0$, we know that for the time $t=T$, there exist positive constants $M>m>0$, such that $m<u(x,t)<M$ for every $x\in\bar{\Omega}$. So we must have that $w(x_0,t)$ will blow up as time t tends to T. By the argument above, we know that the statement in the corollary is true. □

Remark 4.1. Levine and Sleeman [2] discuss the boundary condition $p_x(0,t)=p_x(\pi,t)=0$ (which is the same as the boundary conditions $w_x(0,t)=w_x(\pi,t)=0$), which is somewhat stronger than the original boundary conditions. They find that for their model (3.1), if $w_x = 0$ initially at an end point, then both w and p have to satisfy the zero-flux boundary condition on the entire existence interval.

According to our results in this paper, since $w = \frac{w_0(x)e^{-\mu t}}{1-\beta w_0(x)\int_0^t u(x,\tau)\,d\tau}$, we have

$$\begin{aligned}(\nabla w)\cdot\vec{n} &= \left\{ \frac{e^{-\mu t}}{1-\beta w_0(x)\displaystyle\int_0^t u\,d\tau}(\nabla w_0) - \frac{w_0 e^{-\mu t}}{\left(1-\beta w_0(x)\displaystyle\int_0^t u\,d\tau\right)^2} \right.\\ &\qquad \left. \times\left[-\beta(\nabla w_0)\int_0^t u\,d\tau - \beta w_0\int_0^t(\nabla u)\,d\tau\right]\right\}\cdot\vec{n}\\ &= \frac{e^{-\mu t}}{1-\beta w_0(x)\displaystyle\int_0^t u\,d\tau}\left[1+\frac{\beta w_0\displaystyle\int_0^t u\,d\tau}{1-\beta w_0\displaystyle\int_0^t u\,d\tau}\right](\nabla w_0)\cdot\vec{n}\\ &\quad + \frac{\beta w_0^2 e^{-\mu t}}{\left(1-\beta w_0\displaystyle\int_0^t u\,d\tau\right)^2}\int_0^t(\nabla u)\cdot\vec{n}\,d\tau\\ &= \frac{e^{-\mu t}}{1-\beta w_0(x)\displaystyle\int_0^t u\,d\tau}\left[1+\frac{\beta w_0\displaystyle\int_0^t u\,d\tau}{1-\beta w_0\displaystyle\int_0^t u\,d\tau}\right](\nabla w_0)\cdot\vec{n}.\end{aligned}$$

This implies that even for the original dynamics (4.1), at any point on $\partial\Omega$, $(\nabla w_0)\cdot\vec{n} = 0$ if and only if $(\nabla w(x,t))\cdot\vec{n} = 0$ on the entire existence interval. This situation also occurs for the dynamics (4.1).

5. Some results for other biological models. Othmer and Stevens have also constructed some other biological model:

$$(5.1)\qquad \begin{cases} \dfrac{\partial p}{\partial t} = D\nabla\cdot(p\nabla(\ln(pw))) & \text{for } x\in\Omega,\quad t>0,\\ \dfrac{\partial w}{\partial t} = F(p,w) & \\ p\nabla\left(\ln\left(pw\right)\right)\cdot\vec{n} = 0 & \text{for } x\in\partial\Omega,\quad t>0,\\ p(x,0) = p_0(x) > 0 & \\ w(x,0) = w_0(x) > 0 & \text{for } x\in\overline{\Omega}. \end{cases}$$

For this system we can also consider the growth rate of w as (i) $F(p,w) = \beta p - \mu w$ and (ii) $F(p,w) = (\beta p - \mu)w$; respectively. Here we introduce function transformations $u(x,t) = pw$, $u(x,t) = pwe^{\mu t}$, respectively; then we can prove the following results.

(i) When $F(p,w) = \beta p - \mu w$ and if the initial data satisfy the boundary conditions in (5.1), then there exists a unique global solution (p,w) of the dynamics (5.1) in which $p(x,t)$ is bounded. If $w_0(x) =$ constant, then there is collapse, except for the constant solution $(p,w) = (1,\frac{\beta}{\mu})c$.

(ii) When $F(p,w) = (\beta p - \mu)w$ and if the initial data satisfy the boundary conditions in (5.1), then there exists a unique global solution (p,w) of the dynamics

(5.1), and $p(x,t)$ is bounded. If $w_0(x) \leq 1$, then there is collapse, except for the constant solution $(p,w) = (\frac{\mu}{\beta}, c)$.

Since the processes of the proofs for these results are very similar to the above work in sections 2 and 4, we omit them here.

Acknowledgments. We thank B. D. Sleeman and H. A. Levine for having sent us the paper of their recent results and for many valuable and fruitful discussions. We also thank H. F. Weinberger for the comments.

The final version of the paper was completed while H. Chen was a visiting professor in the School of Mathematics, University of Leeds during September–October 1999; he also would like to thank the institute for the invitation and hospitality.

POTATO CHIP SINGULARITIES OF 3D FLOWS*

DIEGO CORDOBA† AND CHARLES FEFFERMAN†

Abstract. A “potato chip singularity” forms when two distinct surfaces moving with a three-dimensional (3D) fluid coincide at a finite time. Potato chip singularities were suggested by a numerical study of 3D ideal magnetohydrodynamics. We prove that an incompressible flow satisfying a mild assumption on velocity growth cannot form a potato chip singularity.

Key words. incompressible flow, singularity, potato chip, magnetohydrodynamics

AMS subject classification. 76B03

PII. S0036141001384995

In this note, we show that the technique we developed in [2, 3, 4] applies to a problem posed by Grauer and Marliani [5] on the possible formation of current sheet singularities in three-dimensional (3D) ideal incompressible magnetohydrodynamics (3D MHD). Numerical simulations in [5] show rapid initial increase of the current density, leading to a large current density in a thin neighborhood of a curved surface, called a “potato chip” in [5]. If the thickness of the potato chip becomes zero in finite time, then one has a breakdown for an initially smooth 3D MHD solution. That is, the initially smooth solution cannot be continued to a smooth 3D MHD solution beyond some finite “breakdown time” T. The numerics in [5] indicate that the initial rapid growth of current density changes to a merely exponential growth. Grauer and Marliani suggest in [5] that the technique of Cordoba [1] might be used to rule out a potato chip singularity for 3D MHD. This contrasts with earlier work of Kerr and Brandenburg [6], who reported observing a breakdown for a 3D MHD solution with an initial condition similar to that of [5].

The purpose of this note is to rule out finite-time potato chip singularities for general 3D incompressible flows, under a mild assumption on the velocity growth. We begin by giving a precise definition of a potato chip singularity. Our definition applies in particular to the scenario contemplated by Grauer and Marliani [5].

Let $U = \{(x_1, x_2, x_3) \in \mathbb{R}^3 : x_1^2 + x_2^2 < a^2, -\frac{H}{2} < x_3 < \frac{H}{2}\}$ be a cylinder, and let $[0, T)$ be an interval $(a, H, T > 0)$. We denote the closure of U by $\bar{U}$. A *moving surface* in $U \times [0, T)$ is defined as $S(t) = \{(x_1, x_2, x_3) \in U : x_3 = f(x_1, x_2, t)\}$ for $t \in [0, T)$, where f is a C^1 function from $\{(x_1, x_2, t) : x_1^2 + x_2^2 < a^2, 0 \le t < T\}$ to $\left(-\frac{H}{2}, \frac{H}{2}\right)$. Suppose we are given a velocity field $u(x, t) = (u_1(x, t), u_2(x, t), u_3(x, t))$, defined for $x \in \bar{U}$, $t \in [0, T)$. The moving surface $S(t)$ is said to *move with the velocity field* u if the equation

$$\frac{\partial f}{\partial t}(x_1, x_2, t) = u_1(x_1, x_2, x_3, t)\frac{\partial f}{\partial x_1}(x_1, x_2, t) + u_2(x_1, x_2, x_3, t)\frac{\partial f}{\partial x_2}(x_1, x_2, t) + u_3(x_1, x_2, x_3, t)$$

holds for all $x \in S(t)$, $t \in [0, T)$.

The velocity field u is said to form a *potato chip singularity* at time T if there exists a pair of moving surfaces

$$S_\pm(t) = \{(x_1, x_2, x_3) \in U : x_3 = f_\pm(x_1, x_2, t)\} \text{ in } U \times [0, T),$$

both moving with the velocity field u and satisfying the following two conditions:

- $f_-(x_1, x_2 t) < f_+(x_1, x_2, t)$ for $x_1^2 + x_2^2 < a^2$, $t \in [0, T)$,
- $\lim_{t \to T-} [f_+(x_1, x_2, t) - f_-(x_1, x_2, t)] = 0$ for $x_1^2 + x_2^2 < a^2$.

Our result on potato chip singularities is as follows.

THEOREM. *Let $u(x, t)$ be a C^1, divergence-free velocity field, defined on $\bar{U} \times [0, T)$. If we have $\int_0^T \sup_{x \in \bar{U}} |u(x, t)| dt < \infty$, then u cannot form a potato chip singularity at time T.*

This places an added burden on anyone alleging potato chip singularity formation in a numerical simulation: The velocity must be seen to grow so rapidly as to suggest the divergence of $\int_0^T \sup_{x \in U} |u(x, t)| \, dt$.

The rest of this note gives the proof of this theorem. We assume that a potato chip singularity forms at time T, and we derive a contradiction. By analogy with [3, 4], we introduce a time-varying region

$$\Omega(t) = \{(x_1, x_2, x_3) \in \mathbb{R}^3 : x_1^2 + x_2^2 < (R(t))^2, \ f_-(x_1, x_2, t) < x_3 < f_+(x_1, x_2, t)\}$$

for $t \in [t_0, T)$.

Here, $0 < R(t) < a$ is an increasing C^1 function on the interval $[t_0, T)$. Both the function $R(t)$ and the initial time $t_0 \in (0, T)$ will be specified later. We will derive an obvious formula for the time derivative of the volume of $\Omega(t)$. To do so, we first note that the boundary $\partial\Omega(t)$ consists of the top and bottom,

$$E_\pm(t) = \{(x_1, x_2, x_3) \in \mathbb{R}^3 : x_1^2 + x_2^2 \leq (R(t))^2, x_3 = f_\pm(x_1, x_2, t)\},$$

and the side

$$\mathcal{S}(t) = \{(x_1, x_2, x_3) \in \mathbb{R}^3 : x_1^2 + x_2^2 = (R(t))^2, \ f_-(x_1, x_2, t) \leq x_3 \leq f_+(x_1, x_2, t)\}.$$

The outward-pointing unit normal ν to $\partial\Omega(t)$ is given on $E_\pm(t)$ by

$$\nu = \nu_\pm = \pm \left(1, \frac{\partial f_\pm}{\partial x_1}, \frac{\partial f_\pm}{\partial x_2}\right) \Bigg/ \sqrt{1 + \left(\frac{\partial f_\pm}{\partial x_1}\right)^2 + \left(\frac{\partial f_\pm}{\partial x_2}\right)^2}$$

and on $\mathcal{S}(t)$ by

$$\nu = \nu_0 = (x_1, x_2, 0) \Big/ \sqrt{x_1^2 + x_2^2}.$$

The derivative of the volume of $\Omega(t)$ with respect to t is given by

$$\frac{d}{dt} \text{Vol}\, \Omega(t) = \int_{x_1^2 + x_2^2 < (R(t))^2} \left(\frac{\partial f_+}{\partial t} - \frac{\partial f_-}{\partial t}\right) dx_1 dx_2 + R'(t) \int_{x_1^2 + x_2^2 = (R(t))^2} (f_+ - f_-) \, d\,(\text{length}).$$

Now we bring in the fact that the surfaces $S_\pm(t)$ move with the velocity field. We have

$$\pm\int_{x_1^2+x_2^2<(R(t))^2}\frac{\partial f_\pm}{\partial t}dx_1dx_2 = \pm\int_{E_\pm(t)}\left(u_1\frac{\partial f_\pm}{\partial x_1}+u_2\frac{\partial f_\pm}{\partial x_2}+u_3\right)dx_1dx_2$$
$$= \int_{E_\pm(t)}(u_1,u_2,u_3)\cdot\left[\pm\left(1,\,\frac{\partial f_\pm}{\partial x_1},\frac{\partial f_\pm}{\partial x_2}\right)\Big/\sqrt{1+\left(\frac{\partial f_\pm}{\partial x_1}\right)^2+\left(\frac{\partial f_\pm}{\partial x_2}\right)^2}\,\right]$$
$$\cdot\sqrt{1+\left(\tfrac{\partial f_\pm}{\partial x_1}\right)^2+\left(\tfrac{\partial f_\pm}{\partial x_2}\right)^2}\,dx_1dx_2$$
$$= \int_{E_\pm} u\cdot\nu\, d\,(\text{Area}).$$

Therefore, our previous formula for the time derivative of Vol $\Omega(t)$ may be rewritten in the form

$$\frac{d}{dt}\operatorname{Vol}\Omega(t) = \int_{E_+(t)\cup E_-(t)} u\cdot\nu d\,(\text{Area})\; +\; R'(t)\int_{\mathcal{S}(t)} d\,(\text{Area}).$$

We can rewrite this again because the velocity field u is divergence-free. In fact, the divergence theorem for $\Omega(t)$ yields

$$0 = \int_{\Omega(t)}(\nabla\cdot u)\,d\,(\text{Vol})\; = \int_{E_\pm(t)\cup E_-(t)} u\cdot\nu d\,(\text{Area})\; + \int_{\mathcal{S}(t)} u\cdot\nu\, d\,(\text{Area}).$$

Consequently, we have the following proposition.

Proposition.

$$\frac{d}{dt}\operatorname{Vol}\Omega(t)\; = \int_{\mathcal{S}(t)}[R'(t)-u\cdot\nu]\,d\,(\text{Area}).$$

This is our basic formula for the time derivative of Vol $\Omega(t)$.

Now we pick the function $R(t)$ and the starting time $t_0\in(0,T)$. We take

$$R(t)=\frac{1}{2}\,a\; - \int_t^T \sup_{y\in\bar{U}}|u(y,\tau)|\,d\tau \quad\text{for}\quad t_0\le t<T.$$

Our assumptions on u show that $R(t)$ is a C^1 function on $[t_0,T)$, with $R'(t) = \sup_{y\in\bar{U}}|u(y,t)|$, and also that $0<R(t)<a$ for all $t\in[t_0,T)$, provided t_0 is taken close enough to T. We pick t_0 to make this happen. For this particular $R(t)$, the above proposition gives

$$\frac{d}{dt}\operatorname{Vol}\Omega(t)\; = \int_{x\in\mathcal{S}(t)}\left[\sup_{y\in\bar{U}}|u(y,t)| - u(x,t)\,\cdot\,\nu(x,t)\right]d(\text{Area})\;\ge\;0$$

for all $t\in[t_0,T)$, since $\mathcal{S}(t)\subset\bar{U}$.

Since Vol $\Omega(t_0)>0$, it follows that $\liminf_{t\to T-}$ Vol $\Omega(t)>0$, and consequently

$$\liminf_{t\to T-}\int_{x_1^2+x_2^2<a^2}(f_+(x_1,x_2,t)\,-f_-(x_1,x_2,t))\,dx_1dx_2\;>\;0. \tag{1}$$

On the other hand, if a potato chip singularity forms at time T, then

$$\lim_{t\to T-}(f_+(x_1,x_2,t)\,-f_-(x_1,x_2,t))\;=\;0\quad\text{for}\quad x_1^2+x_2^2<a^2,$$

with

$$0 < f_+(x_1, x_2, t) - f_-(x_1, x_2, t) < H.$$

Therefore, the Lebesgue dominated convergence theorem implies

$$\lim_{t \to T-} \int_{x_1^2 + x_2^2 < a^2} (f_+(x_1, x_2, t) - f_-(x_1, x_2, t))\, dx_1 dx_2 = 0. \tag{2}$$

The contradiction between (1) and (2) shows that a potato chip singularity cannot form at time T. The proof of the theorem is complete.

ON THE DIFFUSIVE PROFILES FOR THE SYSTEM OF COMPRESSIBLE ADIABATIC FLOW THROUGH POROUS MEDIA*

PIERANGELO MARCATI[†] AND RONGHUA PAN[‡]

Abstract. We study the Cauchy problem for the system of one dimensional compressible adiabatic flow through porous media and the related diffusive problem. We introduce a new approach which combines the usual energy methods with special L^1-estimates and use the weighted Sobolev norms to prove the global existence and large time behavior for the solutions of the problems. The asymptotic states for the solutions are given by either stationary solutions or similarity solutions depending on the behavior of the initial data when $|x| \to \infty$. Our estimates provide asymptotic time decay rates.

Key words. damping mechanism, diffusive profile, L^1-estimates, weighted energy estimates, decay rates

AMS subject classifications. 35L45, 76S05, 35Q35, 35K55

PII. S0036141099364401

1. Introduction.

The motion of the adiabatic gas flow through porous media can be modeled by the following damped hyperbolic system:

$$\begin{cases} v_t - u_x = 0, \\ u_t + p(v,s)_x = -\alpha u, \ \alpha > 0, \\ (e(v,s) + \frac{1}{2}u^2)_t + (pu)_x = -\alpha u^2. \end{cases} \tag{1.1}$$

Where v denotes the specific volume, u is the velocity, s stands for entropy, p denotes the gas pressure with $p_v(v,s) < 0$ for $v > 0$, and e is the specific internal energy for which one has $e_s \neq 0$ and $e_v + p = 0$ (due to the second law of thermodynamics). For smooth solutions, the system (1.1) is equivalent to the following one:

$$\begin{cases} v_t - u_x = 0, \\ u_t + p(v,s)_x = -\alpha u, \ \alpha > 0, \\ s_t = 0. \end{cases} \tag{1.2}$$

It is strictly hyperbolic with characteristic speeds $-\lambda_1 = \lambda_3 = \sqrt{-p_v}$ and $\lambda_2 = 0$.

In this paper, we are interested in the influence of the damping mechanism to the smoothness and the large time behavior of the solutions. We study the Cauchy problem for the system (1.2) with the following initial data:

$$(v,u,s)(x,0) = (v_0(x), u_0(x), s_0(x)), \quad x \in R, \tag{1.3}$$

satisfying the limit conditions

$$(v_0, u_0, s_0)(x) \to (v_\pm, u_\pm, s_\pm) \text{ as } x \to \pm\infty,$$

with $v_\pm > 0$. For the sake of simplicity, from now on, we take $\alpha = 1$ and $p(v, s) = (\gamma - 1)v^{-\gamma}e^s$, with $\gamma > 1$, which is the case for the polytropic gas dynamics.

The global existence with small initial data of smooth solutions for the Cauchy problem (1.2)–(1.3) has been studied first in [10] and [11] and later by [22]. Then a natural problem is the large time behavior of the solutions. From asymptotic analysis, it is known that the first term of $(1.2)_2$ decays to zero, as $t \to \infty$, faster than others. Therefore it is natural to expect that the problem (1.2)–(1.3) is time-asymptotically equivalent to the following reduced problem:

$$\begin{cases} \tilde{v}_t = -p(\tilde{v}, s)_{xx}, \\ \tilde{u} = -p(\tilde{v}, s)_x, \\ s_t = 0, \\ \tilde{v}(x, 0) = \tilde{v}_0(x), \ s(x, 0) = s_0(x), \\ \tilde{v}_0(\pm\infty) = v_\pm, \ s_0(\pm\infty) = s_\pm. \end{cases} \tag{1.4}$$

The system in (1.4) is obtained from (1.2) by approximating the momentum equation in (1.2) with Darcy's law. Since the first equation of (1.4) is parabolic, the damping mechanism in (1.2) creates some diffusive effects when t tends to infinity.

For the isentropic flow, namely, $s =$ const, (1.2) takes the following form:

$$\begin{cases} v_t - u_x = 0, \\ u_t + p(v)_x = -u. \end{cases} \tag{1.5}$$

The diffusive effect created by the damping mechanism has been investigated for the Cauchy problem of (1.5) with the initial data

$$(v(x, 0), u(x, 0)) = (v_*(x), u_*(x)) \tag{1.6}$$

such that

$$\lim_{x\to\pm\infty}(v_*(x), u_*(x)) = (v_\pm, u_\pm).$$

It has been proved in [5] that the smooth solution of (1.5)–(1.6) can be described time-asymptotically by the solution of the following parabolic problem:

$$\begin{cases} \tilde{v}_t = -p(\tilde{v})_{xx}, \\ \tilde{u} = -p(\tilde{v})_x, \\ \tilde{v}(x, 0) = \tilde{v}_*(x + d_0). \end{cases} \tag{1.7}$$

Where $\tilde{v}_*$ is the similarity solution of $(1.7)_1$ with $\tilde{v}_*(\pm\infty) = v_\pm$. For other results, we refer to [3], [4], [6], and [19] for smooth solutions and to [1], [4], [8], [12], [13], [14], [15], [17], [18], and [21] for weak solutions. For the initial boundary value problems on a quarter plane, we refer to [16] and [20].

There are few results in the literature for the case $s \neq$ const. Partial answers are given in [11] and [7] for the Cauchy problem and in the recent paper of Hsiao and Pan [9] concerning the initial boundary value problem. The case $v_- = v_+ = \bar{v}$ and $s_- = s_+ = \bar{s}$ was investigated in [11] and the case $v_- \neq v_+$ and $s_- = s_+ = \bar{s}$ was treated in [7] by using a technical condition (that they refer to in [7] as condition V) which requires us to solve the following parabolic problem

$$\begin{cases} \tilde{v}_t = -p(\tilde{v}, s)_{xx}, \\ \tilde{v}_0(x) = e^{\frac{1}{\gamma}(s(x)-\bar{s})}\tilde{v}_*(x + x_0) \end{cases} \tag{1.8}$$

and to control the behavior of its solutions by means of the similarity solutions of

$$\begin{cases} \tilde{v}_{*t} = -p(\tilde{v}_*, \bar{s})_{xx}, \\ \tilde{v}_*(\pm\infty) = v_\pm. \end{cases} \tag{1.9}$$

The purpose of this paper is to deal with the following two cases:

Case 1: $s_- = s_+ = \bar{s}$;

Case 2: $(v_\pm, s_\pm)$ satisfy $p(v_-, s_-) = p(v_+, s_+) = \bar{p}$.

In Case 1, namely, $s_- = s_+ = \bar{s}$, we cannot use the methods of [7] and we need new techniques. In particular we shall combine the usual energy methods with special L^1-estimates and with the use of weighted Sobolev norms to solve the problems in detail. This is the only case where $p(v_-, s_-) \neq p(v_+, s_+)$ that we can treat in this paper. In this case, the asymptotic states will be the similarity solution of (1.9) given by the scaling invariance with respect to the transformation $x \to \sigma x$, $t \to \sigma^2 t$. Our results strongly improved those in [7]. Indeed, we remove the technical condition V and we describe the asymptotic states both for the diffusion problem and the hyperbolic one by using the similarity solutions. Thanks to our new approach, it is possible to get a decay rate which did not exist in the previous results (see [7]). Our results on the parabolic problem generalize the result of [2] to the adiabatic case, and also obtain better decay rates.

In Case 2, we can determine a special solution $v_3(x)$ to $(1.4)_1$ by solving the equation $p(v_3, s) = \bar{p}$. Then in this case we establish results similar to those obtained in [11] with, in addition, some decay rates.

Before stating the main results, we describe the plan of this paper. In section 2, the parabolic problem (1.4) is studied in detail for both cases by using our new approach. Then sections 3 and 4 are devoted to the hyperbolic problem (1.2)–(1.3) for Case 1 and Case 2, respectively.

We now state our main results.

1.1. Main results: Parabolic equation. Since in (1.2) or (1.4) $s_t = 0$, then $s(x,t) = s(x) = s_0(x)$. Let us denote

$$\begin{aligned} a(x) &= (\gamma-1)^{-\frac{1}{\gamma}} e^{-\frac{1}{\gamma}s(x)}, \\ a_1 &= (\gamma-1)^{-\frac{1}{\gamma}} e^{-\frac{1}{\gamma}\bar{s}}, \\ w &\equiv a(x)\tilde{v} = p(\tilde{v}, s)^{-\frac{1}{\gamma}}, \end{aligned} \tag{1.10}$$

then (1.4) is equivalent to the following:

$$\begin{cases} w_t + a(x)(w^{-\gamma})_{xx} = 0, \\ \tilde{u} = -(w^{-\gamma})_x, \\ s(x,t) = s_0(x), \\ w(x,0) = w_0(x) = a(x)\tilde{v}_0(x), \\ w(\pm\infty) = w_\pm > 0. \end{cases} \tag{1.11}$$

Moreover, we will denote by $\tilde{w}(\eta)$ (with $\eta = \frac{x}{\sqrt{t+1}}$) the similarity solution of the following problem:

$$\begin{cases} \tilde{w}_t + a_1(\tilde{w}^{-\gamma})_{xx} = 0, \\ \tilde{w}(\pm\infty) = w_\pm. \end{cases} \tag{1.12}$$

By combining the weighted energy method and L^1-estimate, we can prove the following theorem for Case 1.

Theorem 1.1. *Assume that $w_0(x)$ and $s_0(x)$ are C^2 functions and*

$$w_0(x) - \tilde{w}(x,0) \in H^2(R) \cap L^1(R), \quad x(s_0(x) - \bar{s}) \in L^1(R).$$

There exists $\delta_0 > 0$ such that, if $0 < \delta < \delta_0$ and

$$|w_+ - w_-| + \|w_0(x) - \tilde{w}(x,0)\|_{H^2} \le \delta,$$

then (1.11) *has a unique global smooth solution $(w, \tilde{u}, s)(x,t)$ satisfying*

$$w(x,t) - \tilde{w} \in C^0([0,t]; H^2) \ for \ all \ t > 0.$$

Moreover, there exist positive constants $C > 0$, $\beta_1 > \frac{1}{3}$, and $\beta_2 > \frac{1}{2}$ such that

$$\|w(x,t) - \tilde{w}\|_{L^\infty} \le C(1+t)^{-\frac{1}{2}}(1 + \log(1+t))^{\beta_1},$$
$$\|\tilde{u} + (\tilde{w}^{-\gamma})_x\|_{L^\infty} \le C(1+t)^{-1}(1 + \log(1+t))^{\beta_2}.$$

Thus, by setting $\tilde{v} = a^{-1}w$, $\hat{v} = a^{-1}\tilde{w}$, and $\hat{u} = -(\tilde{w}^{-\gamma})_x$, one obtains the (unique) global smooth solution $(\tilde{v}, \tilde{u}, s)$ to (1.4) *which satisfies*

$$\|\tilde{v} - \hat{v}\|_{L^\infty} \le C(1+t)^{-\frac{1}{2}}(1 + \log(1+t))^{\beta_1},$$
$$\|\tilde{u} - \hat{u}\|_{L^\infty} \le C(1+t)^{-1}(1 + \log(1+t))^{\beta_2}.$$

Remark 1. (a) Our results in Theorem 1.1 generalize the ones in [2] to the adiabatic case and extend to a larger class of initial data. The decay rate here is better than in [2] and is almost optimal.

(b) The condition $x(s(x) - \bar{s}) \in L^1(R)$ can be replaced by the weaker one:

$$|x|^\beta (s(x) - \bar{s}) \in L^1(R)$$

for $\beta > 0$. This is clear from our proof below.

For Case 2, where $w_- = w_+ = \bar{w}$ in (1.11), it is clear that $(\bar{w}, 0, s_0(x))$ is a special solution for the system in (1.11). Let us denote $v_1(x) = a^{-1}\bar{w}$ and we have the following.

Theorem 1.2. *Assume that $w_0(x)$ and $s_0(x)$ are C^2 functions and $w_0 - \bar{w} \in H^2$. There exists $\delta_0 > 0$ such that if $0 < \delta < \delta_0$ and $\|w_0 - \bar{w}\|_{H^2} \le \delta$, then* (1.11) *has a unique global smooth solution $(w, \tilde{u}, s)(x,t)$ satisfying*

$$\lim_{t\to\infty} \|w(x,t) - \bar{w}\|_{L^\infty} = 0.$$

Furthermore, if $w_0(x) - \bar{w} \in L^1$, then

$$\|w(x,t) - \bar{w}\|_{L^\infty} \le C(1+t)^{-\frac{1}{2}}(1 + \log(1+t))^{\beta_1},$$
$$\|\tilde{u}\|_{L^\infty} \le C(1+t)^{-1}(1 + \log(1+t))^{\beta_2}.$$

Thus, by setting $v_2 = a^{-1}w$ and $u_2 = \tilde{u}$, one has a unique global smooth solution (v_2, u_2, s) to (1.4) *such that*

$$\|v_2 - v_1\|_{L^\infty} \le C(1+t)^{-\frac{1}{2}}(1 + \log(1+t))^{\beta_1},$$
$$\|u_2\|_{L^\infty} \le C(1+t)^{-1}(1 + \log(1+t))^{\beta_2}.$$

1.2. Main results: Hyperbolic problems. Based on the results in the previous theorems, we can solve (1.2)–(1.3) in detail for both cases, respectively.

Following [5], we define

$$\begin{aligned} &m(x,t) \equiv -(u_+ - u_-)m_0(x)e^{-t}, \\ &u_m(x,t) \equiv u_- e^{-t} + \int_{-\infty}^{x} m_t(\xi,t)\, d\xi, \end{aligned} \tag{1.13}$$

where $m_0(x)$ is a smooth function with compact support such that

$$\int_{-\infty}^{+\infty} m_0(x)\, dx = 1.$$

We first treat Case 1, where $s_- = s_+ = \bar{s}$. Denote by $(\tilde{v}, \tilde{u}, s)$ the solution to (1.4) obtained in Theorem 1.1. In addition, we assume

$$\int_{-\infty}^{+\infty} (v_0(x) - \tilde{v}_0(x))\, dx = -(u_+ - u_-). \tag{1.14}$$

A special choice of $\tilde{v}_0$ is given in Remark 2 below. Let us denote $y(x,t) = \int_{-\infty}^{x}(v - \tilde{v} - m)(\xi,t)\, d\xi$, then y satisfies

$$\begin{cases} y_{tt} + [p(y_x + \tilde{v} + m, s) - p(\tilde{v}, s)]_x + y_t = p(\tilde{v}, s)_{xt}, \\ y(x,0) = y_0(x) = \displaystyle\int_{-\infty}^{x} (v_0(\xi) - \tilde{v}_0(\xi) - m(\xi,0))\, d\xi, \\ y_t(x,0) = y_1(x) = u_0(x) - \tilde{u}(x,0) - u_m(x,0). \end{cases} \tag{1.15}$$

Theorem 1.3. *Under the conditions of Theorem* 1.1, *there exists $\varepsilon_0 > 0$ such that for all $0 < \varepsilon < \varepsilon_0$ and $\|y_0\|_{H^3} + \|y_1\|_{H^2} \le \varepsilon$, the system* (1.15) *admits a unique global smooth solution y such that*

$$y \in C^0([0,t]; H^3), \quad y_t \in C^0([0,t]; H^2)$$

for all $t > 0$. Moreover, there exists $C = C(\varepsilon) > 0$ such that

$$\|y_x\|_{L^\infty} \le C(1+t)^{-\frac{3}{4}}, \ \|y_t\|_{L^\infty} \le C(1+t)^{-\frac{5}{4}}.$$

Hence, by setting $v(x,t) = \tilde{v} + m + y_x$ and $u(x,t) = \tilde{u} + u_m + y_t$, one has the (unique) global smooth solution (v,u,s) to (1.2)–(1.3), *such that*

$$\|v - \tilde{v}\|_{L^\infty} \le C(1+t)^{-\frac{3}{4}}, \ \|u - \tilde{u}\|_{L^\infty} \le C(1+t)^{-\frac{5}{4}}.$$

Furthermore, in view of Theorem 1.1, *one has*

$$\begin{aligned} \|v - \hat{v}\|_{L^\infty} &\le C(1+t)^{-\frac{1}{2}}(1 + \log(1+t))^{\beta_1}, \\ \|u - \hat{u}\|_{L^\infty} &\le C(1+t)^{-1}(1 + \log(1+t))^{\beta_2}, \end{aligned}$$

where β_1 and β_2 are the same as before.

Remark 2. (a) The global existence for the smooth solution to (1.2)–(1.3) has been proved in [22], via characteristic method, provided that the initial data are small. We present here an alternative version in H^2 spaces by the energy estimate method.

(b) (1.14) is the restriction on the initial data which comes from (1.2)–(1.3) and (1.4). This is also the case for (1.16) and (1.18) below. There is a large class of functions $\tilde{v}_0(x)$ which can be chosen (for any given $v_0(x)$ in (1.3)). A special choice is $\tilde{v}_0(x) = a^{-1}\tilde{w}(x + x_0, 0)$, where x_0 is uniquely determined by

$$\int_{-\infty}^{+\infty} (v_0(x) - a^{-1}\tilde{w}(x + x_0, 0))\ dx = -(u_+ - u_-),$$

which is the special case discussed in [7]. Since Theorem 1.1 is obviously valid for $w_0(x) = \tilde{w}(x + x_0, 0)$, we include the results of [7].

(c) A similar condition was used in [9] for the initial boundary problem related to (1.2), where it was proved that both the solutions to the damped hyperbolic problem and those of the related diffusive problem have the same time asymptotic states if the initial total excessive mass is zero.

Let us now consider Case 2. Assume that

$$\int_{-\infty}^{+\infty} (v_0(x) - v_2(x, 0))\ dx = -(u_+ - u_-), \tag{1.16}$$

and denote by $\tilde{y}(x, t) = \int_{-\infty}^{x} (v - v_2 - m)(\xi, t)\ d\xi$, then we have

$$\begin{cases} \tilde{y}_{tt} + [(p(\tilde{y}_x + v_2 + m, s) - p(v_2, s)]_x = p(v_2, s)_{xt}, \\ \tilde{y}(x, 0) = \tilde{y}_0(x) = \int_{-\infty}^{x} (v_0(\xi) - v_2(\xi, 0) - m(\xi, 0))\ d\xi, \\ \tilde{y}_t(x, 0) = \tilde{y}_1(x) = u_0(x) - u_2(x, 0) - u_m(x, 0). \end{cases} \tag{1.17}$$

Similarly to Theorem 1.3, we have the following.

THEOREM 1.4. *Under the hypotheses of the Theorem* 1.2*, there exists* $\varepsilon_0 > 0$ *such that if* $0 < \varepsilon < \varepsilon_0$ *and* $\|\tilde{y}_0\|_{H^3} + \|\tilde{y}_1\|_{H^2} \le \varepsilon$*, then* (1.17) *has a unique global smooth solution* $\tilde{y}$ *such that*

$$\tilde{y} \in C^0([0, t]; H^3),\ \ \tilde{y}_t \in C^0([0, t]; H^2)$$

for all $t > 0$*. Moreover, there exists* $C = C(\varepsilon) > 0$ *such that*

$$\|\tilde{y}_x\|_{L^\infty} \le C(1 + t)^{-\frac{3}{4}},\ \ \|\tilde{y}_t\|_{L^\infty} \le C(1 + t)^{-\frac{5}{4}}.$$

Hence, by setting $v(x, t) = v_2 + m + \tilde{y}_x$ *and* $u(x, t) = u_2 + u_m + \tilde{y}_t$*, one has the (unique) global smooth solution* (v, u, s) *to* (1.2)–(1.3)*; moreover,*

$$\|v - v_2\|_{L^\infty} \le C(1 + t)^{-\frac{3}{4}},\ \ \|u - u_2\|_{L^\infty} \le C(1 + t)^{-\frac{5}{4}}.$$

Furthermore, in view of Theorem 1.2*, one has*

$$\begin{aligned} &\|v - v_1\|_{L^\infty} \le C(1 + t)^{-\frac{1}{2}}(1 + \log(1 + t))^{\beta_1}, \\ &\|u\|_{L^\infty} \le C(1 + t)^{-1}(1 + \log(1 + t))^{\beta_2}. \end{aligned}$$

Since $(v_1(x), 0, s(x))$ is a special solution to both (1.2) and (1.4), if we assume

$$\int_{-\infty}^{+\infty} (v_0 - v_1)(x)\ dx = -(u_+ - u_-) \tag{1.18}$$

and denote by $z(x,t) = \int_0^x (v - v_1 - m)(\xi, t)\ d\xi$, we have

$$(1.19) \qquad \begin{cases} z_{tt} + [p(z_x + v_1 + m, s) - p(v_1, s)]_x + z_t = 0, \\ z(x,0) = z_0(x) = \displaystyle\int_{-\infty}^{x} (v_0(\xi) - v_1(\xi) - m(\xi, 0))\ d\xi, \\ z_t(x,0) = z_1(x) = u_0(x) - u_m. \end{cases}$$

Then in this special case, we have the following result, which includes the paper [11].

Theorem 1.5. *There exists $\varepsilon_0 > 0$ such that if $0 < \varepsilon < \varepsilon_0$ and $\|z_0\|_{H^3} + \|z_1\|_{H^2} \leq \varepsilon$, then* (1.19) *has a unique global smooth solution z such that*

$$z \in C^0([0,t]; H^3),\ \ z_t \in C^0([0,t]; H^2)$$

for all $t > 0$. Moreover,

$$\|z_x\|_{L^\infty} \leq C(1+t)^{-\frac{3}{4}},\ \ \|z_t\|_{L^\infty} \leq C(1+t)^{-\frac{5}{4}}.$$

Hence, by setting $v(x,t) = v_1 + m + z_x$ and $u(x,t) = u_m + z_t$, one has the (unique) global smooth solution (v, u, s) to (1.2)–(1.3) *such that*

$$\|v - v_1\|_{L^\infty} \leq C(1+t)^{-\frac{3}{4}},\ \ \|u\|_{L^\infty} \leq C(1+t)^{-\frac{5}{4}}.$$

We will end this introduction by making a reduction. In fact, in sections 3 and 4, we will only prove Theorems 1.3–1.5 for the case $u_- = u_+ = 0$, where $m(x,t) = 0$ and $u_m = 0$. The general case can be treated in the similar way since $m(x,t)$ and u_m decay to zero exponentially fast.

2. Nonlinear diffusion equation.

This section is devoted to studing the diffusive problem (1.4). Clearly one has $s(x,t) = s_0(x) \equiv s(x)$ for all $t > 0$, which then is sufficient to solve the following equation:

$$(2.1) \qquad \begin{cases} \tilde{v}_t = -p(\tilde{v}, s)_{xx}, \\ \tilde{v}(x,0) = \tilde{v}_0(x),\ \tilde{v}_0(\pm\infty) = v_\pm > 0. \end{cases}$$

The equation (2.1) is equivalent to the following porous media type equation:

$$(2.2) \qquad \begin{cases} w_t + a(x)(w^{-\gamma})_{xx} = 0, \\ w(x,0) = w_0(x) = a(x)\tilde{v}_0(x), \\ w(\pm\infty) = w_\pm > 0, \end{cases}$$

where $a(x) = (\gamma - 1)^{-\frac{1}{\gamma}} e^{-\frac{1}{\gamma} s(x)}$, $w \equiv a(x)\tilde{v} = p(\tilde{v}, s)^{-\frac{1}{\gamma}}$. We will study the equation (2.2) instead of (2.1) for the following two cases, which are equivalent to those stated in the introduction.

Case 1: $s_- = s_+ = \bar{s}$.

Case 2: $(v_\pm, s_\pm)$ are chosen such that $w_- = w_+ = \bar{w}$, where we set $w_\pm = w(v_\pm, s_\pm)$.

We will concentrate our main efforts on Case 1 which is the most difficult part.

2.1. Case 1: $s_- = s_+ = \bar{s}$. In this subsection, (2.2) will be solved near the similarity solution for the related isentropic problem.

Now let us recall some results on the similarity solution for $(2.2)_1$ with $s(x) = \mathrm{const} = \bar{s}$. In this case, $(2.2)_1$ takes the form

$$w_t + a_1(w^{-\gamma})_{xx} = 0, \tag{2.3}$$

with $a_1 = (\gamma-1)^{-\frac{1}{\gamma}}e^{-\frac{1}{\gamma}\bar{s}}$. It is well known that (2.3) has a unique (up to a shift) similarity solution $\tilde{w}(\eta)$ (where $\eta = \frac{x}{\sqrt{1+t}}$) satisfying the limiting conditions $\tilde{w}(\pm\infty) = w_\pm$. Some properties of $\tilde{w}(\eta)$ are listed in the following lemma (see, for instance, [5]).

LEMMA 2.1. *Let $\tilde{w}(\eta)$ be the similarity solution to* (2.3) *with $\tilde{w}(\pm\infty) = w_\pm$ and $\eta = \frac{x}{\sqrt{1+t}}$. It follows that*

$$|\tilde{w}'(\eta)| + |\tilde{w}''(\eta)| \le C_1|w_+ - w_-|\exp\{-C_2\eta^2\},$$

$$|\tilde{w}(\eta) - w_-|_{\eta<0} + |\tilde{w}(\eta) - w_+|_{\eta>0} \le C_1|w_+ - w_-|\exp\{-C_2\eta^2\},$$

$$\tilde{w}_x = (1+t)^{-\frac{1}{2}}\tilde{w}'(\eta),\ \tilde{w}_t = -\frac{1}{2}(1+t)^{-1}\eta\tilde{w}'(\eta),\ (\tilde{w}^{-\gamma})_{xx} = -a_1^{-1}\tilde{w}_t,$$

$$\|D_t^iD_x^j\tilde{w}(\cdot,t)\|^2 \le C|w_+ - w_-|^2(1+t)^{-(2i+j)+\frac{1}{2}},$$

$$\|D_t^iD_x^j\tilde{w}(\cdot,t)\|_{L^\infty} \le C_1|w_+ - w_-|(1+t)^{-(i+\frac{1}{2}j)}$$

for $i+j \ge 1$ and $i \ge 0,\ j \ge 0$.

We now prove Theorem 1.1 by comparing $w(x,t)$ with $\tilde{w}(\eta)$.

Let us denote $\phi = w - \tilde{w}$; then from (2.2) and (2.3) we have the following equation:

$$\begin{cases}\phi_t + a(x)(\psi(\tilde{w})\phi)_{xx} + (a-a_1)(\tilde{w}^{-\gamma})_{xx} + a(x)(g(\phi,\tilde{w})\phi^2)_{xx} = 0,\\ \phi(x,0) = \phi_0(x) = w_0(x) - \tilde{w}(x,0).\end{cases} \tag{2.4}$$

Here

$$\psi(\tilde{w}) = -\gamma\tilde{w}^{-(\gamma+1)}$$

$$g(\phi,\tilde{w})\phi^2 = (\phi+\tilde{w})^{-\gamma} - \tilde{w}^{-\gamma} - \psi(\tilde{w})\phi.$$

Now let $F = -\psi(\tilde{w})\phi$; the corresponding problem on F is given by

$$\begin{cases}F_t + a(x)\psi(\tilde{w})F_{xx} - \psi(\tilde{w})(a-a_1)(\tilde{w}^{-\gamma})_{xx}\\ \quad -\psi_1(\tilde{w})F\tilde{w}_t - a\psi(\tilde{w})(fF^2)_{xx} = 0,\\ F(x,0) = F_0(x) = -\psi(\tilde{w}(x,0))\phi_0(x),\end{cases} \tag{2.5}$$

where

$$-\psi_1(\tilde{w})F = \psi'(\tilde{w})\phi,\ fF^2 = g\phi^2.$$

We will establish the global existence and large time behavior, for the solution F to (2.5), in the Banach space $X(0,T)$ defined for all $T > 0$ by

$$X(0,t) = \{F \in C^0([0,t];H^2),\quad 0 \le t \le T\}$$

and equipped with the norm

$$N^2(t) = \sup_{0 \le \tau \le t} \|F(\tau)\|_{H^2}^2.$$

The main result of this subsection is the following theorem.

THEOREM 2.2. *Assume that* $F_0(x)$ *and* $s(x) = s_0(x)$ *are* C^2 *functions such that* $F_0 \in H^2(R) \cap L^1(R)$ *and*

$$x(s(x) - \bar{s}) \in L^1(R). \tag{2.6}$$

Then there exist constants $\varepsilon_0 > 0$ *and* $\delta > 0$ *such that if* $|w_+ - w_-| \le \delta$ *and* $\|F_0\|_{H^2} \le \varepsilon_0$*, then* (2.5) *has a unique global smooth solution* F *satisfying*

$$\sum_{j=0}^{2} w_{j+1}(t) \|\partial_x^j F(\cdot, t)\|^2 + \int_0^t \sum_{j=1}^{3} w_j(\tau) \|\partial_x^j F(\cdot, \tau)\|^2 \, d\tau \le C,$$

where the weight functions $w_j(t)$ *are given by*

$$w_1(t) = (1+t)^{\frac{1}{2}} (1 + \log(1+t))^{-k}, \ w_j(t) = (1+t)^{j-1} w_1(t)$$

for $j, k > 1$.

Remark 3. (a) The condition (2.6) plays an important role in our proof of Theorem 2.2 (see Lemmas 2.3–2.7, 2.9–2.10 below). This condition enables us to bound the L^1-norm of F for all time. In [7], $s(x) - \bar{s}$ is assumed to be compact support besides the technical condition V; our condition (2.6) is much weaker. In fact, (2.6) asks only some decay properties on $s(x) - \bar{s}$ as $x \to \pm\infty$.

(b) The condition (2.6) can be replaced by the weaker one such as

$$|x|^{\beta} (s(x) - \bar{s}) \in L^1(R) \tag{2.6$'$}$$

for some $\beta > 0$. This is clear following our proof.

(c) In general, we could not bound the L^1-norm of F for all time without the conditions on the decay properties of $s(x) - \bar{s}$ as $x \to \pm\infty$ such as (2.6′). One cannot even bound the total mass of F uniformly in time under the condition $s(x) - \bar{s} \in L^1$. From this point of view, (2.6′) is optimal.

The local existence and uniqueness of the solution to (2.5) in $X(0, T)$ is standard, so to get the global existence, we will prove uniform estimates on the solution of (2.5). Hence, from now on, we assume the local existence in $X(0, T)$ for some $T > 0$.

The following L^1-estimate follows from the standard contraction property of the porous media type equation and will play a fundamental role in the rest of this section.

LEMMA 2.3. *Under the conditions of Theorem* 2.2*, as long as the solution exists in* $X(0, T)$*, there exist positive constants* C_1 *and* C_2*, such that*

$$\|\phi(\cdot, t)\|_{L^1} \le C_1 \|F(\cdot, t)\|_{L^1} \le C_2 (\|\phi_0\|_{L^1} + \delta). \tag{2.7}$$

Proof. We present here a formal argument which can easily be made rigorous by using any sequence approximating the sign function and passing into the limit by means of the *Lebesgue dominated convergence theorem*. Observe that $h = sign(\phi) = sign(F)$. Let us multiply the equation in (2.4) by $a^{-1}h$, then by integrating over

$[0,t]\times(-\infty,+\infty)$, it follows that

$$\begin{aligned}&\int_{-\infty}^{+\infty}a^{-1}|\phi|(x,t)dx+\int_0^t\int_{-\infty}^{+\infty}sign'(F)F_x^2dxd\tau\\&\le C\int_{-\infty}^{+\infty}a^{-1}|\phi_0|(x)dx+C\left|\int_0^t\int_{-\infty}^{+\infty}(a-a_1)\tilde{w}_tsign(F)dxd\tau\right|\\&+\left|\int_0^t\int_{-\infty}^{+\infty}(fF^2)_xF_xsign'(F)dxd\tau\right|\\&\le C(\|\phi_0\|_{L^1}+\delta).\end{aligned}\tag{2.8}$$

Here, we have used the following facts:

$$\begin{aligned}&\left|\int_0^t\int_{-\infty}^{+\infty}(a-a_1)\tilde{w}_tsign(F)dxd\tau\right|\\&\le C\int_0^t\int_{-\infty}^{+\infty}|s-\bar{s}||\tilde{w}_t|dxd\tau\\&\le C\int_0^t\int_{-\infty}^{+\infty}(1+t)^{-\frac{3}{2}}|x(s-\bar{s})||\tilde{w}'(\eta)|dxd\tau\\&\le C\delta,\end{aligned}\tag{2.9}$$

$$\begin{aligned}&\int_0^t\int_{-\infty}^{+\infty}(fF^2)_xF_xsign'(F)dxd\tau\\&=\int_0^t\int_{-\infty}^{+\infty}F_x(2fF_x+f_FFF_x+f_{\tilde{w}}F\tilde{w}_x)F\delta_{\{F=0\}}dxd\tau\\&=0.\end{aligned}\tag{2.10}$$

Hence (2.8) gives the proof of (2.7). □

With the help of Lemma 2.3, we can make the energy estimates on F.

Lemma 2.4. *Under the hypotheses of Theorem 2.2, there exists $\varepsilon_*>0$ such that if $0<\varepsilon<\varepsilon_*$ and $N(T)\le\varepsilon$, then we have*

$$\|F(\cdot,t)\|^2+\int_0^t\|F_x(\cdot,\tau)\|^2d\tau\le C(\|F_0\|^2+\delta)\tag{2.11}$$

for $0\le t\le T$.

Proof. Let us multiply (2.4) by $a^{-1}F$ and integrate the result over $[0,t]\times(-\infty,+\infty)$; we then get

$$\begin{aligned}&\int_{-\infty}^{+\infty}\frac{1}{2}a^{-1}F\phi(x,t)dx+\int_0^t\int_{-\infty}^{+\infty}F_x^2dxd\tau\\&\le\int_{-\infty}^{+\infty}\frac{1}{2}a^{-1}F_0\phi_0dx+\left|\int_0^t\int_{-\infty}^{+\infty}a^{-1}(a-a_1)(\tilde{w}^{-\gamma})_{xx}Fdxd\tau\right|\\&+\left|\int_0^t\int_{-\infty}^{+\infty}\frac{1}{2}a^{-1}\psi_2(\tilde{w})F^2\tilde{w}_tdxd\tau\right|+\left|\int_0^t\int_{-\infty}^{+\infty}(fF^2)_xF_xdxd\tau\right|\\&\equiv\int_{-\infty}^{+\infty}\frac{1}{2}a^{-1}F_0\phi_0dx+I_1+I_2+I_3,\end{aligned}\tag{2.12}$$

with $\psi_2(\tilde{w})F^2 = \phi^2\psi'(\tilde{w})$.

We use I_1, I_2, and I_3 step-by-step as follows:

$$\begin{aligned} I_1 &= \left| \int_0^t \int_{-\infty}^{+\infty} a^{-1}(a-a_1)(\tilde{w})^{-\gamma}_{xx} F dx d\tau \right| \\ &\le C\delta\varepsilon \int_0^t (1+\tau)^{-\frac{3}{2}} \|x(s-\bar{s})\|_{L^1}\ d\tau \\ &\le C\delta\varepsilon, \end{aligned} \tag{2.13}$$

$$\begin{aligned} I_2 &= \left| \int_0^t \int_{-\infty}^{+\infty} \frac{1}{2} a^{-1}\psi_2(\tilde{w})F^2 \tilde{w}_t dx d\tau \right| \\ &\le C \int_0^t \|F\|_{L^\infty} \|\tilde{w}_t\|_{L^\infty} \|F\|_{L^1} dx d\tau \\ &\le C\delta \int_0^t \|F\|^{\frac{1}{2}} \|F_x\|^{\frac{1}{2}} (1+\tau)^{-1} d\tau \\ &\le C\delta \left(\int_0^t \|F\|^2 \|F_x\|^2 d\tau + \int_0^t (1+\tau)^{-\frac{4}{3}} d\tau \right) \\ &\le C\delta \left(1 + \varepsilon^2 \int_0^t \|F_x\|^2\ d\tau \right), \end{aligned} \tag{2.14}$$

$$\begin{aligned} I_3 &= \left| \int_0^t \int_{-\infty}^{+\infty} (fF^2)_x F_x dx d\tau \right| \\ &\le \left(\frac{1}{2} + C\varepsilon \right) \int_0^t \|F_x\|^2\ d\tau + C\delta^2 \int_0^t \|F\|^4_{L^\infty}\ d\tau \\ &\le \left(\frac{1}{2} + C\varepsilon \right) \int_0^t \|F_x\|^2\ d\tau + C\delta^2 \int_0^t \|F\|^2 \|F_x\|^2\ d\tau \\ &\le \left(\frac{1}{2} + C\varepsilon \right) \int_0^t \|F_x\|^2\ d\tau. \end{aligned} \tag{2.15}$$

Due to the smallness of δ and ε, we conclude from (2.12)–(2.15) that

$$\|F(\cdot,t)\|^2 + \int_0^t \|F_x(\cdot,\tau)\|^2 d\tau \le C(\|F_0\|^2 + \delta), \tag{2.16}$$

which completes the proof of Lemma 2.4. □

For higher order estimates, we use the problem (2.5) to obtain the following results.

LEMMA 2.5. *Under the same conditions of Lemma* 2.4, *we have*

$$\|F_x(\cdot,t)\|^2 + \int_0^t \|F_{xx}(\cdot,\tau)\|^2\ d\tau \le C(\|F_0\|^2_{H^1} + \delta). \tag{2.17}$$

Proof. Let us multiply the equation in (2.5) by F_{xx}, then

$$\begin{aligned}&\int_{-\infty}^{+\infty} F_x^2(x,t)dx + \int_0^t \int_{-\infty}^{+\infty} F_{xx}^2(x,\tau)\ dxd\tau \\ &\le C\left(\|F_{0x}\|^2 + \left|\int_0^t \int_{-\infty}^{+\infty} \tilde{w}_t F_{xx}\ dxd\tau\right|\right. \\ &\qquad \left. + \left|\int_0^t \int_{-\infty}^{+\infty} (fF^2)_{xx} F_{xx}\ dxd\tau\right|\right),\end{aligned} \tag{2.18}$$

which implies, with the help of the Cauchy–Schwarz inequality and Lemma 2.1, that

$$\begin{aligned}&\int_{-\infty}^{+\infty} F_x^2(x,t)dx + \int_0^t \int_{-\infty}^{+\infty} F_{xx}^2(x,\tau)\ dxd\tau \\ &\le C(\|F_{0x}\|^2 + \delta^2) + C\int_0^t \int_{-\infty}^{+\infty} (fF^2)_{xx}^2\ dxd\tau.\end{aligned} \tag{2.19}$$

We bound the last term in (2.19) as follows:

$$\begin{aligned}&\int_0^t \int_{-\infty}^{+\infty} (fF^2)_{xx}^2\ dxd\tau \\ &\le C\int_0^t \int_{-\infty}^{+\infty} [(|F| + |F_x| + |w_x|)^2 F_x^2 + F^2 F_{xx}^2 + F^4(\tilde{w}_{xx}^2 + \tilde{w}_x^4)]\ dxd\tau \\ &\le C\varepsilon^2\delta^2 + C\varepsilon \int_0^t \int_{-\infty}^{+\infty} F_{xx}^2(\tau, x)\ dxd\tau.\end{aligned} \tag{2.20}$$

Then, by (2.19)–(2.20) and the estimates in Lemma 2.4, we get (2.17). □

We now turn to the third order estimates. For this purpose, we differentiate the equation in (2.5) with respect to x

$$\begin{aligned}&F_{tx} + a\psi(\tilde{w})F_{xxx} + (a\psi(\tilde{w}))_x F_{xx} - (\psi(\tilde{w})(a - a_1)(\tilde{w}^{-\gamma})_{xx})_x \\ &\quad + (\psi_1(\tilde{w})F\tilde{w}_t)_x - (a\psi(\tilde{w})(fF^2)_{xx})_x = 0.\end{aligned} \tag{2.21}$$

Multiplying (2.21) by F_{xxx} and then integrating it over $[0,t] \times (-\infty, +\infty)$, one has

$$\begin{aligned}&\int_{-\infty}^{+\infty} F_{xx}^2(\cdot,t)dx + \int_0^t \int_{-\infty}^{+\infty} F_{xxx}^2(\tau,x)\ dxd\tau \\ &\le C\left(\|F_{0xx}\|^2 + \int_0^t \int_{-\infty}^{+\infty} ((a\psi)_x F_{xx})^2\ dxd\tau + \int_0^t \int_{-\infty}^{+\infty} (\psi_1 \tilde{w} F \tilde{w}_t)_x^2\ dxd\tau \right. \\ &\qquad \left. + \int_0^t \int_{-\infty}^{+\infty} [((\psi(\tilde{w})(a - a_1)(\tilde{w}^{-\gamma})_{xx})_x^2 + (a\psi(\tilde{w})(fF^2)_{xx})_x^2]\ dxd\tau \right) \\ &\le C(\|F_0\|_{H^2}^2 + \delta^2) + C\varepsilon \int_0^t \int_{-\infty}^{+\infty} F_{xxx}^2(\tau,x)\ dxd\tau,\end{aligned} \tag{2.22}$$

which can be summarized as follows.

LEMMA 2.6. *Under the same conditions as Lemma 2.4, one has*

$$\|F_{xx}(\cdot,t)\|^2 + \int_0^t \|F_{xxx}(\cdot,\tau)\|^2\ d\tau \le C(\|F_0\|_{H^2}^2 + \delta). \tag{2.23}$$

From Lemma 2.4–2.6, we can conclude the following.

Lemma 2.7. *Under the same conditions as Theorem* 2.2, *there exists* $\varepsilon_* > 0$ *such that if* $0 < \varepsilon < \varepsilon_*$ *and* $N(T) \leq \varepsilon$, *then it follows that*

$$\|F(t)\|_{H^2}^2 + \int_0^t (\|F_t\|_{H^1}^2 + \|F_x\|_{H^2}^2)(\tau)\ d\tau \leq C_0(\|F_0\|_{H^2}^2 + \delta)$$

for all $0 \leq t \leq T$, *where* C_0 *is a positive constant independent of* t.

With the help of the previous lemmas we obtain the global existence of the solution $F(x,t)$ to (2.5).

Theorem 2.8. *Under the same conditions as Theorem* 2.2, (2.5) *has a unique global smooth solution* $F(x,t)$ *which tends to zero uniformly in* H^1 *as* t *goes to infinity.*

Proof. We choose δ, ε_0, and ε small such that $C_0(\varepsilon_0^2 + \delta) \leq \varepsilon^3$, $\varepsilon \leq \frac{1}{4}$ so that all the previous arguments are valid. Then, due to the local results, there exists a positive t_1 such that the solution $F(x,t)$ exists in $(-\infty, +\infty) \times [0, t_1]$ and satisfies

$$N(t)^2 \leq 4N^2(0) \text{ for all } t \in [0, t_1].$$

We can apply the L^1-estimate for F of Lemma 2.3 and then Lemma 2.7 in $0 \leq t \leq t_1$. Therefore, it follows that

$$N^2(t) \leq C_0(\|F_0\|_{H^2}^2 + \delta) \leq \varepsilon^3 \text{ for all } t \in [0, t_1].$$

By iterating the above procedure, a standard continuity argument allows us to establish the global existence in time for the solution to (2.5).

Now, from Lemma 2.7 and the above argument, we have

$$\|F(t)\|_{H^2}^2 + \int_0^t (\|F_x\|_{H^2}^2 + \|F_t\|_{H^1}^2)(\tau)\ d\tau \leq C_0(\|F_0\|_{H^2}^2 + \delta) \ \text{ for all } t > 0. \tag{2.24}$$

From (2.24) we know that

$$\|F_x(t)\|^2 + \int_0^{+\infty} \left| \frac{d}{dt} \|F_x(t)\|^2 \right|\ dt \leq C,$$

which implies

$$\lim_{t \to +\infty} \|F_x(t)\|^2 = 0.$$

Then, the Sobolev inequality implies

$$\begin{aligned} \lim_{t \to +\infty} \|F(t)\|^2 &\leq \lim_{t \to +\infty} \|F(t)\|_{L^\infty} \|F(t)\|_{L^1} \\ &= O(1) \lim_{t \to +\infty} \|F_x(t)\|^{\frac{1}{2}} \\ &= 0, \end{aligned}$$

which completes the proof of this theorem. □

By using the weighted energy method, we can prove the following decay estimates.

Lemma 2.9. *Let* F *be the solution to* (2.5) *obtained in Theorem* 2.8, *then*

$$\begin{aligned} &w_1(t)\|F(t)\|^2 + w_2(t)\|F_x(t)\|^2 \\ &+ \int_0^t (w_1(\tau)\|F_x(\tau)\|^2 + w_2(\tau)\|F_{xx}(\tau)\|^2)\ d\tau \leq C. \end{aligned} \tag{2.25}$$

Proof. Let us multiply (2.5) by $w_2(t)F_{xx}$, then we get

$$\begin{aligned}&\left(\frac{1}{2}w_2(t)F_x^2\right)_t - a\psi(\tilde{w})w_2(t)F_{xx}^2 - \frac{1}{2}w_2'(t)F_x^2 - \psi_1(\tilde{w})FF_{xx}\tilde{w}_t w_2(t)\\ &= -w_2(t)\psi(\tilde{w})(a-a_1)(\tilde{w}^{-\gamma})_{xx}F_{xx} - a\psi(\tilde{w})(fF^2)_{xx}F_{xx}w_2(t) + (\cdots)_x,\end{aligned}\tag{2.26}$$

where $(\cdots)_x$ denotes the term which does not need to be computed explicitly since it will disappear by integrating in x. Then one has

$$\begin{aligned}&w_2(t)\|F_x(\cdot,t)\|^2 + \int_0^t w_2(\tau)\|F_{xx}(\cdot,\tau)\|^2\ d\tau\\ &\le C_1\left(\|F_{0x}\|^2 + \left|\int_0^t\int_{-\infty}^{+\infty} w_2'(\tau)F_x^2 dxd\tau\right|\right.\\ &\qquad + \left|\int_0^t\int_{-\infty}^{+\infty} \tilde{w}_t^2 w_2(\tau)(a-a_1)^2\ dxd\tau\right|\\ &\qquad \left.+ \left|\int_0^t\int_{-\infty}^{+\infty} F^2\tilde{w}_t^2 w_2(\tau)\ dxd\tau\right| + \int_0^t\int_{-\infty}^{+\infty} w_2(\tau)(fF^2)_{xx}^2\ dxd\tau\ \right)\\ &\equiv C_1(\|F_{0x}\|^2 + J_1 + J_2 + J_3 + J_4).\end{aligned}\tag{2.27}$$

On the other hand, if we multiply (2.4) by $a^{-1}w_1(t)F$, we get

$$\begin{aligned}&\left(\frac{1}{2}F\phi a^{-1}w_1(t)\right)_t + w_1(t)F_x^2 - \frac{1}{2}w_1'(t)a^{-1}\psi_1(\tilde{w})F^2\\ &= \frac{1}{2}a^{-1}w_1(t)F^2\tilde{w}_t - a^{-1}w_1(t)(a-a_1)F(\tilde{w}^{-\gamma})_{xx}\\ &+ w_1(t)F_x(fF^2)_x + (\cdots)_x,\end{aligned}\tag{2.28}$$

which, integrated on $[0,t]\times(-\infty,+\infty)$, yields

$$\begin{aligned}&w_1(t)\|F(\cdot,t)\|^2 + \int_0^t w_1(t)\|F_x(\tau)\|^2 d\tau\\ &\le C_2\left(\|F_0\|^2 + \left|\int_0^t\int_{-\infty}^{+\infty} w_1'(\tau)F^2\ dxd\tau\right|\right.\\ &\qquad + \left|\int_0^t\int_{-\infty}^{+\infty} w_1(\tau)F^2\tilde{w}_t\ dxd\tau\right| + \left|\int_0^t\int_{-\infty}^{+\infty} w_1(\tau)\tilde{w}_t F(a-a_1)\ dxd\tau\right|\\ &\qquad \left.+ \left|\int_0^t\int_{-\infty}^{+\infty} w_1(\tau)F_x(fF^2)_x\ dxd\tau\right|\ \right)\\ &\equiv C_2(\|F_0\|^2 + J_5 + J_6 + J_7 + J_8).\end{aligned}\tag{2.29}$$

By calculating $K\times(2.29)+(2.27)$ with a $K>0$ to be determined later, we have

$$\begin{aligned}&Kw_1(t)\|F(t)\|^2 + w_2(t)\|F_x(t)\|^2\\ &+ \int_0^t (Kw_1(\tau)\|F_x(\tau)\|^2 + w_2(\tau)\|F_{xx}(\tau)\|^2)\ d\tau\\ &\le (C_1\|F_{0x}\|^2 + KC_2\|F_0\|^2)\\ &+ C_1(J_1+J_2+J_3+J_4) + KC_2(J_5+J_6+J_7+J_8).\end{aligned}\tag{2.30}$$

The following inequalities will be used to estimate the terms on $J_i (i = 1, \dots, 8)$:

$$\begin{aligned} |w_1'(t)| &= \left| \frac{1}{2}(1+t)^{-1}w_1(t) - k(1+\log(1+t))^{-1}(1+t)^{-1}w_1(t) \right| \\ &\le C(1+t)^{-1}w_1(t), \end{aligned} \tag{2.31}$$

$$|w_2'(t)| \le C(1+t)^{-1}w_2(t) = Cw_1(t). \tag{2.32}$$

Then, by choosing K large enough, one has

$$C_1 J_1 \le \frac{1}{2}K \int_0^t w_1(\tau)\|F_x(\tau)\|^2 \, d\tau, \tag{2.33}$$

$$J_2 \le C\delta^2 \int_0^t (1+\tau)^{-3} w_2(\tau) \, d\tau \le C\delta^2. \tag{2.34}$$

To estimate J_3, observe that the following inequality on F holds:

$$\|F\|_{L^\infty} \le C\|F_x\|^{\frac{2}{3}} \tag{2.35}$$

since

$$\begin{aligned} \|F\|_{L^\infty} &\le C\|F\|^{\frac{1}{2}}\|F_x\|^{\frac{1}{2}} \\ &\le C\|F\|_{L^\infty}^{\frac{1}{4}}\|F_x\|^{\frac{1}{2}}\|F\|_{L^1}^{\frac{1}{4}}. \end{aligned}$$

Then we see that

$$\begin{aligned} C_1 J_3 &= C_1 \left| \int_0^t \int_{-\infty}^{+\infty} F^2 \tilde{w}_t^2 w_2(\tau) \, dx d\tau \right| \\ &\le C \int_0^t w_2(\tau)\|\tilde{w}_t\|_{L^\infty}\|F\|_{L^\infty}\|F\|_{L^1} \, d\tau \\ &\le C\delta^2 \int_0^t (1+\tau)^{-2} w_2(\tau)\|F_x\|^{\frac{2}{3}} d\tau \\ &\le C\delta^2 + \frac{1}{4}K \int_0^t w_1(\tau)\|F_x(\cdot,\tau)\|^2 \, d\tau. \end{aligned} \tag{2.36}$$

Similarly, we can estimate J_5, J_6, and J_7 as follows:

$$\begin{aligned} C_2 K J_5 &= C_2 K \left| \int_0^t \int_{-\infty}^{+\infty} w_1'(\tau) F^2 \, dx d\tau \right| \\ &\le CK \int_0^t (1+\tau)^{-1} w_1(\tau)\|F_x\|^{\frac{2}{3}} d\tau \\ &\le CK + \frac{1}{8}K \int_0^t w_1(\tau)\|F_x(\cdot,\tau)\|^2 \, d\tau, \end{aligned} \tag{2.37}$$

$$\begin{aligned} C_2 K J_6 &= C_2 K \left| \int_0^t \int_{-\infty}^{+\infty} w_1(\tau) F^2 \tilde{w}_t \; dx d\tau \right| \\ &\leq CK\delta + \frac{1}{16} K \int_0^t w_1(\tau) \|F_x(\cdot,\tau)\|^2 \; d\tau, \end{aligned} \tag{2.38}$$

$$\begin{aligned} C_2 K J_7 &= C_2 K \left| \int_0^t \int_{-\infty}^{+\infty} w_1(\tau) \tilde{w}_t F(a-a_1) \; dx d\tau \right| \\ &\leq CK\delta + \frac{1}{32} K \int_0^t w_1(\tau) \|F_x(\cdot,\tau)\|^2 \; d\tau. \end{aligned} \tag{2.39}$$

To estimate J_8, we have

$$\begin{aligned} & C_2 K J_8 \\ &= C_2 K \left| \int_0^t \int_{-\infty}^{+\infty} w_1(\tau) F_x (fF^2)_x \; dx d\tau \right| \\ &\leq C \left| \int_0^t \int_{-\infty}^{+\infty} w_1(\tau) F_x (2fFF_x + f_F F^2 F_x + f_{\tilde{w}} \tilde{w}_x F^2) \; dx d\tau \right| \\ &\leq C\varepsilon K \int_0^t w_1(\tau) \|F_x(\cdot,\tau)\|^2 d\tau + CK \int_0^t \int_{-\infty}^{+\infty} w_1(\tau) \tilde{w}_x^2 F^2 \; dx d\tau \\ &\leq CK(\delta+\varepsilon) \int_0^t w_1(\tau) \|F_x(\cdot,\tau)\|^2 d\tau + CK\delta. \end{aligned} \tag{2.40}$$

We now deal with the term J_4. Noting that

$$\begin{aligned} (fF^2)_{xx} &= (2FF_x f + f_F F^2 F_x + f_{\tilde{w}} \tilde{w}_x F^2)_x \\ &= (2fF + f_F F^2) F_{xx} + (2f + 4f_F F + f_{FF} F^2) F_x^2 \\ &\quad + (4 f_{\tilde{w}} F + 2 f_{F\tilde{w}} F^2) F_x \tilde{w}_x + (f_{\tilde{w}} \tilde{w}_{xx} + f_{\tilde{w}\tilde{w}} \tilde{w}_x^2) F^2, \end{aligned}$$

we have

$$\begin{aligned} J_4 &= \left| \int_0^t \int_{-\infty}^{+\infty} w_2(\tau) (fF^2)_{xx}^2 \; dx d\tau \right| \\ &\leq C\varepsilon \int_0^t w_2(\tau) \|F_{xx}(\cdot,\tau)\|^2 \; d\tau + C \int_0^t \int_{-\infty}^{+\infty} F_x^4 w_2(\tau) \; dx d\tau \\ &\quad + C \left| \int_0^t \int_{-\infty}^{+\infty} w_2(\tau) F_x^2 \tilde{w}_x^2 F \; dx d\tau \right| \\ &\quad + C \int_0^t \int_{-\infty}^{+\infty} w_2(\tau) F^4 (\tilde{w}_{xx}^2 + \tilde{w}_x^4) \; dx d\tau \\ &\equiv C\varepsilon \int_0^t w_2(\tau) \|F_{xx}(\cdot,\tau)\|^2 \; d\tau + C(J_9 + J_{10} + J_{11}). \end{aligned} \tag{2.41}$$

We can estimate J_{10} and J_{11} in the following way:

$$\begin{aligned} J_{10} &= \left| \int_0^t \int_{-\infty}^{+\infty} w_2(\tau) F_x^2 \tilde{w}_x^2 F \ dx d\tau \right| \\ &\leq C\varepsilon\delta^2 \int_0^t w_1(\tau) \|F_x(\cdot,\tau)\|^2 \ d\tau, \end{aligned} \tag{2.42}$$

$$\begin{aligned} J_{11} &= \int_0^t \int_{-\infty}^{+\infty} w_2(\tau) F^4 (\tilde{w}_{xx}^2 + \tilde{w}_x^4) \ dx d\tau \\ &\leq C\delta^2\varepsilon^2 \int_0^t w_1(\tau) \|F_x(\cdot,\tau)\|^2 \ d\tau, \end{aligned} \tag{2.43}$$

while J_9 can be bounded as follows:

$$\begin{aligned} J_9 &= \int_0^t \int_{-\infty}^{+\infty} F_x^4 w_2(\tau) \ dx d\tau \\ &\leq C\varepsilon^2 \int_0^t w_2(\tau) \|F_{xx}\|^2 \ d\tau + C \int_0^t w_2(\tau) \|F_x(\tau)\|^2 \|F_x(\tau)\|^2 \ d\tau. \end{aligned} \tag{2.44}$$

Due to the smallness of δ and ε, by choosing K large enough, we deduce

$$\begin{aligned} & w_1(t)\|F(t)\|^2 + w_2(t)\|F_x(t)\|^2 \\ & + \int_0^t (w_1(\tau)\|F_x(\tau)\|^2 + w_2(\tau)\|F_{xx}(\tau)\|^2) \ d\tau \\ & \leq C \left(1 + \int_0^t w_2(\tau)\|F_x(\tau)\|^2 \|F_x(\tau)\|^2 \ d\tau \right). \end{aligned} \tag{2.45}$$

Therefore, from (2.45), it follows that

$$w_2(t)\|F_x(t)\|^2 \leq C \left(1 + \int_0^t w_2(\tau)\|F_x(\tau)\|^2 \|F_x(\tau)\|^2 \ d\tau \right),$$

which implies, with the help of Gronwall inequality, that

$$w_2(t)\|F_x(t)\|^2 \leq C$$

and

$$\int_0^t w_2(\tau)\|F_x(\tau)\|^2 \|F_x(\tau)\|^2 \ d\tau \leq C. \tag{2.46}$$

Hence, (2.45) and (2.46) give the proof of this lemma. □

The following lemma contains the decay rates for the derivatives of F, which will be useful in the next section.

Lemma 2.10. *The solution F to* (2.5)*, obtained in Theorem* 2.8*, satisfies*

$$\begin{aligned} w_3(t)\|F_t(t)\|^2 + w_4(t)\|F_{tx}\|^2 + \int_0^t (w_3(\tau)\|F_{tx}(\tau)\|^2 + w_4(\tau)\|F_{txx}(\tau)\|^2) \ d\tau & \\ \leq C\delta, & \end{aligned} \tag{2.47}$$

$$\|F_t\|_{L^\infty} \leq C w_3(t)^{-\frac{1}{4}} w_4(t)^{-\frac{1}{4}}.$$

Proof. It is sufficient to prove (2.47), since the estimate for $\|F_t\|_{L^\infty}$ can be derived from (2.47) by using Sobolev inequality.

Let us differentiate $(2.5)_1$ in t, then

$$\begin{aligned}&F_{tt} + a\psi(\tilde{w})F_{txx} + a\psi'(\tilde{w})\tilde{w}_t F_{xx} - [\psi(\tilde{w})(a-a_1)(\tilde{w}^{-\gamma})_{xx}]_t\\&-(\psi_1(\tilde{w})F\tilde{w}_t)_t - [a\psi(\tilde{w})(fF^2)_{xx}]_t = 0.\end{aligned} \tag{2.48}$$

If we multiply (2.48) by $a^{-1}w_3(t)F_t$, we get

$$\begin{aligned}&\left(\frac{1}{2}a^{-1}w_3(t)F_t^2\right)_t - \psi(\tilde{w})w_3(t)F_{tx}^2 + \frac{1}{2}F_t^2\psi(\tilde{w})_{xx}w_3(t) - \frac{1}{2}F_t^2a^{-1}w_3'(t)\\&+\psi'(\tilde{w})\tilde{w}_tF_{xx}w_3(t)F_t - a^{-1}[\psi(\tilde{w})(a-a_1)(\tilde{w}^{-\gamma})_{xx}]_tw_3(t)F_t\\&-a^{-1}(\psi_1(\tilde{w})F\tilde{w}_t)_tw_3(t)F_t - [\psi(\tilde{w})(fF^2)_{xx}]_tw_3(t)F_t + \{\cdots\}_x = 0.\end{aligned} \tag{2.49}$$

From the proof of Lemma 2.9 and $(2.5)_1$ it is clear that

$$\begin{aligned}&\int_0^t w_2(\tau)\|F_t(\cdot,\tau)\|^2\ d\tau\\&\le C\left(\int_0^t w_2(t)\|F_{xx}(\tau)\|^2 d\tau + \int_0^t\int_{-\infty}^{+\infty}(a-a_1)^2\tilde{w}_t^2w_2(\tau)\ dxd\tau\right.\\&\qquad\left.+\int_0^t\int_{-\infty}^{+\infty}F^2\tilde{w}_t^2w_2(\tau)\ dxd\tau + \int_0^t\int_{-\infty}^{+\infty}(fF^2)_{xx}^2w_2(\tau)\ dxd\tau\right)\\&\le C.\end{aligned} \tag{2.50}$$

Moreover, we have

$$a^{-1}(\psi_1(\tilde{w})F\tilde{w}_t)_tw_3(t)F_t = O(1)[\tilde{w}_tw_3(t)F_t^2 + (\tilde{w}_t^2+\tilde{w}_{tt})w_3(t)FF_t],$$

$$a^{-1}[\psi(\tilde{w})(a-a_1)(\tilde{w}^{-\gamma})_{xx}]_tw_3(t)F_t = O(1)(a-a_1)(\tilde{w}_t^2+\tilde{w}_{tt})w_3(t)F_t,$$

$$[\psi(\tilde{w})(fF^2)_{xx}]_tw_3(t)F_t = O(1)\tilde{w}_t(fF^2)_{xx}w_3(t)F_t - \psi(\tilde{w})(fF^2)_{xxt}w_3(t)F_t.$$

Now, integrating (2.49) and integrating by parts, we have

$$\begin{aligned}&w_3(t)\|F_t(t)\|^2 + \int_0^t w_3(\tau)\|F_{tx}(\tau)\|^2\ d\tau\\&\le C + C\int_0^t\int_{-\infty}^{+\infty}F_t^2w_2(\tau)\ dxd\tau + \int_0^t\int_{-\infty}^{+\infty}\tilde{w}_tw_3(\tau)F_{xx}^2\ dxd\tau\\&\quad+\int_0^t\int_{-\infty}^{+\infty}[(a-a_1)^2+F^2](\tilde{w}_t^2+\tilde{w}_{tt})^2w_3(\tau)(1+\tau)\ dxd\tau\\&\quad+\int_0^t\int_{-\infty}^{+\infty}w_2(\tau)(fF^2)_{xx}^2\ dxd\tau + \left|\int_0^t\int_{-\infty}^{+\infty}\psi(\tilde{w})(fF^2)_{xxt}w_3(\tau)F_t\ dxd\tau\right|\\&\le C\left(1+\left|\int_0^t\int_{-\infty}^{+\infty}w_3(\tau)(fF^2)_{xt}(F_{tx}+F_t\tilde{w}_x)\ dxd\tau\right|\right).\end{aligned} \tag{2.51}$$

To bound the previous terms, we observe that

$$\begin{aligned}&\left|\int_0^t \int_{-\infty}^{+\infty} w_3(\tau)(fF^2)_{xt} F_t \tilde{w}_x \ dxd\tau\right| \\ &\le C + C\int_0^t \int_{-\infty}^{+\infty} w_3(\tau)(fF^2)^2_{xt} \ dxd\tau\end{aligned}$$

and

$$\begin{aligned}&\left|\int_0^t \int_{-\infty}^{+\infty} w_3(\tau)(fF^2)_{xt} F_{tx} \ dxd\tau\right| \\ &\le \varepsilon_3 \int_0^t \int_{-\infty}^{+\infty} w_3(\tau)F^2_{tx} \ dxd\tau + C(\varepsilon_3)\int_0^t \int_{-\infty}^{+\infty} w_3(\tau)(fF^2)^2_{xt} \ dxd\tau.\end{aligned}$$

Then choosing ε_3 sufficient small, we have

$$\begin{aligned}&w_3(t)\|F_t(t)\|^2 + \int_0^t w_3(\tau)\|F_{tx}(\tau)\|^2 \ d\tau \\ &\le C\left(1 + \int_0^t \int_{-\infty}^{+\infty} w_3(\tau)(fF^2)^2_{xt} \ dxd\tau\right).\end{aligned} \tag{2.52}$$

Moreover, since

$$\begin{aligned}(fF^2)^2_{xt} &= [2fFF_x, f_F F^2 F_x + f_{\tilde{w}} \tilde{w}_x F^2]^2_t \\ &= O(1)(|F|F^2_{xt} + F^2_t F^2_x + \tilde{w}^2_t F^2_x F^2 \\ &\quad + F^2 F^2_t \tilde{w}^2_x + (\tilde{w}^2_{tx} + \tilde{w}^2_t \tilde{w}^2_x)F^4),\end{aligned}$$

it follows that

$$\begin{aligned}&\int_0^t \int_{-\infty}^{+\infty} w_3(\tau)(fF^2)^2_{xt} \ dxd\tau) \\ &\le C\left(\varepsilon \int_0^t w_3(\tau)\|F_{tx}\|^2 d\tau + A_1 + A_2 + A_3 + A_4\right),\end{aligned} \tag{2.53}$$

where, as in the previous estimates we get

$$A_1 = \int_0^t \int_{-\infty}^{+\infty} w_3(\tau) F^2_t F^2_x \ dxd\tau \le C, \tag{2.54}$$

$$A_2 = \int_0^t \int_{-\infty}^{+\infty} w_3(\tau) \tilde{w}^2_t F^2_x F^2 \ dxd\tau \le C\delta^2\varepsilon^2, \tag{2.55}$$

$$A_3 = \int_0^t \int_{-\infty}^{+\infty} w_3(\tau) F^2 F^2_t \tilde{w}^2_x \ dxd\tau \le C\delta^2\varepsilon^2, \tag{2.56}$$

and

$$A_4 = \int_0^t \int_{-\infty}^{+\infty} w_3(\tau)(\tilde{w}^2_{tx} + \tilde{w}^2_t \tilde{w}^2_x)F^4 \ dxd\tau \le C\delta^2. \tag{2.57}$$

Thus, we conclude from (2.52)—(2.57) that

$$w_3(t)\|F_t(t)\|^2 + \int_0^t w_3(\tau)\|F_{tx}(\tau)\|^2 \, d\tau \le C, \tag{2.58}$$

which completes the proof of the first part of (2.47).

Let us turn to the second part of (2.47). For this purpose, we multiply (2.48) by $w_4(t)F_{txx}$. After similar calculations as before, by virtue of (2.58), we get

$$\begin{aligned} & w_4(t)\|F_{tx}(t)\|^2 + \int_0^t w_4(\tau)\|F_{txx}(\tau)\|^2 \, d\tau \\ & \le C(1 + B_1 + B_2 + B_3 + B_4), \end{aligned} \tag{2.59}$$

where

$$B_1 = \int_0^t \int_{-\infty}^{+\infty} \tilde{w}_t^2 w_4(\tau) F_{xx}^2 \, dx d\tau \le C\delta^2,$$

$$B_2 = \int_0^t \int_{-\infty}^{+\infty} (\tilde{w}_t^2 + \tilde{w}_{tt})^2 w_4(\tau)(a - a_1)^2 \, dx d\tau \le C\delta^2,$$

$$B_3 = \int_0^t \int_{-\infty}^{+\infty} w_4(\tau)[\psi_1(\tilde{w}) F \tilde{w}_t]_t^2 \, dx d\tau \le C\delta^2,$$

and

$$\begin{aligned} B_4 &= \int_0^t \int_{-\infty}^{+\infty} w_4(\tau)[\psi(\tilde{w}(fF^2)_{xx}]_t^2 \, dx d\tau \\ & \le C\delta^2 + C\int_0^t \int_{-\infty}^{+\infty} w_4(\tau)(fF^2)_{txx}^2 \, dx d\tau. \end{aligned}$$

Hence, one has

$$\begin{aligned} & w_4(t)\|F_{tx}(t)\|^2 + \int_0^t w_4(\tau)\|F_{txx}(\tau)\|^2 \, d\tau \\ & \le C\left(1 + \int_0^t \int_{-\infty}^{+\infty} w_4(\tau)(fF^2)_{txx}^2 \, dx d\tau\right). \end{aligned} \tag{2.60}$$

In order to bound the last term in (2.60), we use the following identity:

$$\begin{aligned} & (fF^2)_{txx}^2 \\ & = O(1)[F^2F_{txx}^2 + F_x^2F_{tx}^2 + F^2\tilde{w}_x^2F_{tx}^2 \\ & \qquad + (\tilde{w}_{xx}^2 + \tilde{w}_x^4)F^2F_t^2 + \tilde{w}_{tx}^2F^2F_x^2] \\ & \qquad\qquad + O(1)[(F_t^2F_{xx}^2 + F_{xx}^2F^2\tilde{w}_t^2) + (F_x^4F_t^2 + \tilde{w}_t^2F_x^4) \\ & \qquad\qquad + (F_t^2F_x^2\tilde{w}_x^2 + F^2\tilde{w}_t^2\tilde{w}_x^2F_x^2) \\ & \qquad\qquad + (F^4F_t^2(\tilde{w}_{xx}^2 + \tilde{w}_x^4) + (\tilde{w}_{txx}^2 + \tilde{w}_x^2\tilde{w}_{tx}^2)F^4)] \\ & = [\Gamma_1 + \Gamma_2 + \Gamma_3 + \Gamma_4 + \Gamma_5] + [\Delta_1 + \Delta_2 + \Delta_3 + \Delta_4]. \end{aligned}$$

Then we bound each of these terms. Therefore, we have

$$\begin{aligned}&\int_0^t\int_{-\infty}^{+\infty} w_4(\tau)\Gamma_1\ dxd\tau\\ &\le C\int_0^t\int_{-\infty}^{+\infty} w_4(\tau)F^2F_{txx}^2\ dxd\tau\\ &\le C\varepsilon^2\int_0^t w_4(\tau)\|F_{txx}\|^2\ d\tau,\end{aligned}\tag{2.61}$$

$$\begin{aligned}&\int_0^t\int_{-\infty}^{+\infty} w_4(\tau)\Gamma_2\ dxd\tau\\ &\le C\int_0^t w_4(\tau)\|F_{tx}\|^2\|F_x\|^2\ d\tau + C\varepsilon^2\int_0^t w_4(\tau)\|F_{txx}\|^2 d\tau,\end{aligned}\tag{2.62}$$

$$\int_0^t\int_{-\infty}^{+\infty} w_4(\tau)\Gamma_3\ dxd\tau \le C\varepsilon^2,\tag{2.63}$$

$$\int_0^t\int_{-\infty}^{+\infty} w_4(\tau)\Gamma_4\ dxd\tau \le C\delta^2\varepsilon^2,\tag{2.64}$$

$$\int_0^t\int_{-\infty}^{+\infty} w_4(\tau)\Gamma_5\ dxd\tau \le C\delta^2\varepsilon^2,\tag{2.65}$$

$$\int_0^t\int_{-\infty}^{+\infty} w_4(\tau)\Delta_1\ dxd\tau \le C(1+\delta^2\varepsilon^2),\tag{2.66}$$

$$\int_0^t\int_{-\infty}^{+\infty} w_4(\tau)\Delta_2\ dxd\tau \le C,\tag{2.67}$$

$$\begin{aligned}&\int_0^t\int_{-\infty}^{+\infty} w_4(\tau)\Delta_3\ dxd\tau\\ &\le C\delta^2\int_0^t(\|F_x\|^2+\|F_{xx}\|^2)(w_3(\tau)\|F_t\|^2)\ d\tau + C\delta^2\varepsilon^2\int_0^t w_1(\tau)\|F_x\|^2\ d\tau\\ &\le C,\end{aligned}\tag{2.68}$$

$$\begin{aligned}&\int_0^t\int_{-\infty}^{+\infty} w_4(\tau)\Delta_4\ dxd\tau\\ &\le C\delta^2\int_0^t\|F_t\|^2 w_2(\tau)\ d\tau + C\delta^2\int_0^t w_1(\tau)\|F\|^2\|F_x\|^2\ d\tau\\ &\le C\delta^2.\end{aligned}\tag{2.69}$$

Thus, we see from (2.60)–(2.69) that

$$\begin{aligned} &w_4(t)\|F_{tx}(t)\|^2 + \int_0^t w_4(\tau)\|F_{txx}(\tau)\|^2\ d\tau \\ &\leq C + C\int_0^t w_4(\tau)\|F_{tx}\|^2\|F_x\|^2\ d\tau. \end{aligned} \tag{2.70}$$

Then the Gronwall inequality implies that

$$w_4(t)\|F_{tx}(t)\|^2 + \int_0^t w_4(\tau)\|F_{txx}(\tau)\|^2\ d\tau \leq C. \tag{2.71}$$

Equation (2.47) follows from (2.58) and (2.71). □

COROLLARY 2.11. *The solution F to* (2.5)*, obtained in Theorem* 2.8*, satisfies*

$$w_3(t)\|F_{xx}\|^2 \leq C,\ \|F_{xx}\|_{L^\infty} \leq C(w_3(t)w_4(t))^{-\frac{1}{4}},$$

$$\|F_x\|^2_{L^\infty} \leq Cw_3(t)^{-\frac{1}{2}}w_2(t)^{-\frac{1}{2}}.$$

Proof. From (2.5), we see that

$$\begin{aligned} F_{xx} &= O(1)(F_t + (a-a_1)\tilde{w}_t + F\tilde{w}_t + F_x^2 \\ &\quad + FF_x\tilde{w}_x + (\tilde{w}_{xx} + \tilde{w}_x^2)F^2). \end{aligned} \tag{2.72}$$

Taking the L^2-norm in (2.72), we have

$$\begin{aligned} w_3(t)\|F_{xx}\|^2 &\leq Cw_3(t)(\|F_t\|^2 + \|(a-a_1)\tilde{w}_t\|^2 + \|F\tilde{w}_t\|^2 + \|F_x^2\|^2 \\ &\quad + \|FF_x\tilde{w}_x\|^2 + \|(\tilde{w}_{xx} + \tilde{w}_x^2)F^2\|^2) \\ &\leq C(1 + w_3(t)\|F_x^2\|^2) \\ &\leq C(1 + w_3(t)\|F_x\|^2(\|F_x\|^2 + \|F_{xx}\|^2)) \\ &\leq C + Cw_3(t)\|F_x\|^2\|F_{xx}\|^2 \end{aligned}$$

which implies

$$w_3(t)\|F_{xx}\|^2 \leq C.$$

Then

$$\|F_x\|^2_{L^\infty} \leq Cw_3(t)^{-\frac{1}{2}}w_2(t)^{-\frac{1}{2}}.$$

Last, if we take the L^∞-norm in (2.72), we obtain

$$\begin{aligned} \|F_{xx}\|_{L^\infty} &\leq C(\|F_t\|_{L^\infty} + \|(a-a_1)\tilde{w}_t\|_{L^\infty} + \|F_x\|^2_{L^\infty} \\ &\quad + \|FF_x\tilde{w}_x\|_{L^\infty} + \|F^2(\tilde{w}_{xx} + \tilde{w}_x^2)\|_{L^\infty}) \\ &\leq C(w_3(t)w_4(t))^{-\frac{1}{4}}. \end{aligned}$$

□

Then Theorem 2.2 follows from Theorem 2.8, Lemmas 2.9–2.10, and Corollary 2.11.

Now, from F it is easy to obtain the solution ϕ of (2.4) and from ϕ the unique smooth solution w of (2.2). By defining $\tilde{v} = a^{-1}(x)w$ and $\tilde{u} = -(w^{-\gamma})_x$, we obtain the solution of (1.4). Theorem 1.1 then follows from Theorem 2.2 and the decay estimates follow from the interpolation inequality and (2.35).

2.2. Case 2: $\boldsymbol{w_- = w_+ = \mathrm{const} = \bar{w}}$. Observe that $w = \bar{w}$ is a stationary solution to (2.2). We will prove Theorem 1.2 by solving the Cauchy problem (2.2) near $\bar{w}$.

Let us denote by $\tilde{\phi} = w - \bar{w}$, then $\tilde{\phi}$

$$\begin{cases} \tilde{\phi}_t - ba(x)\tilde{\phi}_{xx} + a(x)(f_1(\tilde{\phi})\tilde{\phi}^2)_{xx} = 0, \\ \tilde{\phi}(x,0) = \tilde{\phi}_0(x) = w_0(x) - \bar{w}, \end{cases} \tag{2.73}$$

where

$$b = \gamma \bar{w}^{-(\gamma+1)}, \ f_1\tilde{\phi}^2 = (\bar{w} + \tilde{\phi})^{-\gamma} - \bar{w}^{-\gamma} - b\tilde{\phi}.$$

Then we have the following.

Theorem 2.12. *Suppose $\tilde{\phi}_0(x)$ and $s(x) = s_0(x)$ are C^2 functions and $\tilde{\phi}_0 \in H^2(R)$. There exists $\varepsilon_0 > 0$ such that if $0 < \varepsilon < \varepsilon_0$ and $\|\tilde{\phi}_0\|_{H^2} \le \varepsilon$, then* (2.73) *has a unique global smooth solution $\tilde{\phi}(x,t)$ satisfying*

$$\|\tilde{\phi}(\cdot,t)\|_{H^2}^2 + \int_0^t \|\tilde{\phi}_x(\cdot,\tau)\|_{H^2}^2 \, d\tau \le C\varepsilon^2 \tag{2.74}$$

and

$$\lim_{t\to\infty} \|\tilde{\phi}(\cdot,t)\|_{L^\infty} = 0.$$

Furthermore, if $\tilde{\phi}_0 \in L^1(R)$, then

$$\sum_{j=0}^{2} w_{j+1}(t)\|\partial_x^j \tilde{\phi}(\cdot,t)\|^2 + \int_0^t \sum_{j=1}^{3} w_j(\tau)\|\partial_x^j \tilde{\phi}(\cdot,\tau)\|^2 \, d\tau \le C.$$

Proof. Since the local result for (2.73) is classical, to prove the first part of Theorem 2.12, it is sufficient to derive the uniform estimate (2.74) under the a priori assumption $\|\tilde{\phi}\|_{H^2} \le \delta_0$ for δ_0 suitably small.

Multiply $(2.73)_1$ by $a^{-1}\tilde{\phi}$, integrate it over $(-\infty,+\infty) \times [0,t]$, and one then has

$$\begin{aligned} &\|\tilde{\phi}(\cdot,t)\|^2 + \int_0^t \|\tilde{\phi}_x(\cdot,\tau)\|^2 \, d\tau \\ &\le C\varepsilon_0^2 + C\left|\int_0^t \int_{-\infty}^{+\infty} (f_1(\tilde{\phi})\tilde{\phi}^2)_x \tilde{\phi}_x \, dxd\tau\right| \\ &\le C\varepsilon_0^2 + C\delta_0 \int_0^t \|\tilde{\phi}_x\|^2 \, d\tau, \end{aligned}$$

which implies

$$\|\tilde{\phi}(\cdot,t)\|^2 + \int_0^t \|\tilde{\phi}_x(\cdot,\tau)\|^2 \, d\tau \le C\varepsilon_0^2. \tag{2.75}$$

Next, multiplying $(2.73)_1$ by $\tilde{\phi}_{xx}$ and integrating over $(-\infty,+\infty)\times[0,t]$, one has

$$\begin{aligned}&\|\tilde{\phi}_x(\cdot,t)\|^2+\int_0^t\|\tilde{\phi}_{xx}(\cdot,\tau)\|^2\ d\tau\\&\leq C\varepsilon_0^2+C\left|\int_0^t\int_{-\infty}^{+\infty}(f_1(\tilde{\phi})\tilde{\phi}^2)_{xx}\tilde{\phi}_{xx}\ dxd\tau\right|\\&\leq C\varepsilon_0^2+\frac{1}{2}\int_0^t\|\tilde{\phi}_{xx}(\cdot,\tau)\|^2\ d\tau+C\int_0^t\int_{-\infty}^{+\infty}(f_1(\tilde{\phi})\tilde{\phi}^2)_{xx}^2\ dxd\tau\\&\leq C\varepsilon_0^2+\left(\frac{1}{2}+C\delta_0\right)\int_0^t\|\tilde{\phi}_{xx}(\cdot,\tau)\|^2\ d\tau.\end{aligned}$$

Thus we get

$$\|\tilde{\phi}_x(\cdot,t)\|^2+\int_0^t\|\tilde{\phi}_{xx}(\cdot,\tau)\|^2\ d\tau\leq C\varepsilon_0^2. \tag{2.76}$$

Finally, by differentiating $(2.73)_1$ in x and by repeating the previous procedure, one can derive

$$\|\tilde{\phi}_{xx}(\cdot,t)\|^2+\int_0^t\|\tilde{\phi}_{xxx}(\cdot,\tau)\|^2\ d\tau\leq C\varepsilon_0^2. \tag{2.77}$$

The estimate (2.74) follows from (2.75)–(2.77) and then (2.73) has a unique smooth solution $\tilde{\phi}$ such that

$$\lim_{t\to\infty}\|\tilde{\phi}(\cdot,t)\|_{L^\infty}=0.$$

We proceed now to prove the second part of Theorem 2.12. In this framework, we can develop a theory similar to what we did in the previous sections. Actually, it is less complicated since $\bar{w}$ is a constant.

Observe that if $\tilde{\phi}_0(x)\in L^1$, we can use the same argument used in Lemma 2.3 to prove

$$\|\tilde{\phi}(\cdot,t)\|_{L^1}\leq\|\tilde{\phi}_0\|_{L^1}. \tag{2.78}$$

Then we can employ the same argument used in subsection 2.1 to complete the proof of the decay estimates. We perform here just the first two orders estimates.

For the first order estimates, we multiply $(2.73)_1$ by $w_1(t)a^{-1}\tilde{\phi}$ then integrate it by parts over $(-\infty,+\infty)\times[0,t]$. We have

$$\begin{aligned}&w_1(t)\|\tilde{\phi}(\cdot,t)\|^2+\int_0^t w_1(\tau)\|\tilde{\phi}_x(\cdot,\tau)\|^2\ d\tau\\&\leq C+C\int_0^t(1+\tau)^{-1}w_1(\tau)\|\tilde{\phi}(\cdot,\tau)\|_{L^\infty}\|\tilde{\phi}(\cdot,\tau)\|_{L^1}\ d\tau\\&\quad+C\delta_0\int_0^t w_1(\tau)\|\tilde{\phi}_x(\cdot,\tau)\|^2\ d\tau,\end{aligned}\tag{2.79}$$

where

$$\begin{aligned}&\int_0^t(1+\tau)^{-1}w_1(\tau)\|\tilde{\phi}(\cdot,\tau)\|_{L^\infty}\|\tilde{\phi}(\cdot,\tau)\|_{L^1}\ d\tau\\&\leq C(\varepsilon_1)\int_0^t w_1(\tau)(1+t)^{-\frac{3}{2}}\ d\tau+\varepsilon_1\int_0^t w_1(\tau)\|\tilde{\phi}_x(\cdot,\tau)\|^2\ d\tau.\end{aligned}\tag{2.80}$$

By choosing ε_1 small, we see from (2.79)–(2.80)

$$w_1(t)\|\tilde{\phi}(\cdot,t)\|^2 + \int_0^t w_1(\tau)\|\tilde{\phi}_x(\cdot,\tau)\|^2\,d\tau \le C. \tag{2.81}$$

For the second order estimates, we multiply $(2.73)_1$ by $w_2(t)\tilde{\phi}_{xx}$, integrate it by parts over $(-\infty,+\infty)\times[0,t]$, then

$$\begin{aligned}
&w_2(t)\|\tilde{\phi}_x(\cdot,t)\|^2 + \int_0^t w_2(\tau)\|\tilde{\phi}_{xx}(\cdot,\tau)\|^2\,d\tau\\
&\le C + \frac{1}{2}\int_0^t w_2(\tau)\|\tilde{\phi}_{xx}(\cdot,\tau)\|^2\,d\tau\\
&\quad + C\int_0^t\int_{-\infty}^{+\infty} w_2(\tau)(f_1(\tilde{\phi})\tilde{\phi}^2)_{xx}^2\,dxd\tau,
\end{aligned} \tag{2.82}$$

where

$$\begin{aligned}
&\int_0^t\int_{-\infty}^{+\infty} w_2(\tau)(f_1(\tilde{\phi})\tilde{\phi}^2)_{xx}^2\,dxd\tau\\
&\le C\delta_0\int_0^t w_2(\tau)\|\tilde{\phi}_{xx}(\cdot,\tau)\|^2\,d\tau\\
&\quad + C\int_0^t w_2(\tau)\|\tilde{\phi}_x(\tau)\|^2(\|\tilde{\phi}_x\|^2+\|\tilde{\phi}_{xx}\|^2)\,d\tau\\
&\le C\delta_0\int_0^t w_2(\tau)\|\tilde{\phi}_{xx}(\cdot,\tau)\|^2\,d\tau + C\int_0^t w_2(\tau)\|\tilde{\phi}_x(\tau)\|^4\,d\tau.
\end{aligned} \tag{2.83}$$

We conclude from (2.82)–(2.83) that

$$\begin{aligned}
&w_2(t)\|\tilde{\phi}_x(\cdot,t)\|^2 + \int_0^t w_2(\tau)\|\tilde{\phi}_{xx}(\cdot,\tau)\|^2\,d\tau\\
&\le C + C\int_0^t w_2(\tau)\|\tilde{\phi}_x(\tau)\|^4\,d\tau,
\end{aligned}$$

which, together with the help of Gronwall inequality, implies that

$$w_2(t)\|\tilde{\phi}_x(\cdot,t)\|^2 + \int_0^t w_2(\tau)\|\tilde{\phi}_{xx}(\cdot,\tau)\|^2\,d\tau \le C. \qquad \square \tag{2.84}$$

In the following, we denote by $v_2(x,t)=a^{-1}w(x,t)$ the solution to (2.1) obtained in Theorem 1.2, and $u_2(x,t)=-p(v_2,s)_x$. Theorem 1.2 then follows from Theorem 2.12.

3. Convergence to similarity solutions. In this section, we will study (1.2)–(1.3) for Case 1, namely, we assume that $s_-=s_+=\bar{s}$. We shall prove Theorem 1.3 by comparing the solutions of (1.2)–(1.3) with those of (1.4) obtained in Theorem 2.2. Since the result for $s(x,t)$ is clear, in the following part we only deal with $(v,u)(x,t)$.

Let $(\tilde{v},\tilde{u},s(x))$ be the solution of (1.4) with the initial data $(\tilde{v}_0(x),s_0(x))$. As pointed in introduction, we will only prove Theorem 1.3 for the case where $u_-=$

$u_+ = 0$ and thus (1.14) turns into

$$\int_{-\infty}^{+\infty} (v_0(x) - \tilde{v}_0(x))\ dx = 0. \tag{3.1}$$

Let us denote

$$v_e = v - \tilde{v},\ u_e = u - \tilde{u}, \tag{3.2}$$

then it follows from (1.2) and (1.4) that

$$\begin{cases} v_{et} - u_{ex} = 0, \\ u_{et} + [p(\tilde{v} + v_e, s) - p(\tilde{v}, s)]_x = -u_e + p(\tilde{v}, s)_{xt}. \end{cases} \tag{3.3}$$

As usual let us consider

$$y = \int_{-\infty}^{x} v_e(\xi)\ d\xi, \tag{3.4}$$

which satisfies the following nonlinear wave equation:

$$\begin{cases} y_{tt} + [p(y_x + \tilde{v}, s) - p(\tilde{v}, s)]_x + y_t = p(\tilde{v}, s)_{xt}, \\ y(x, 0) = y_0(x) = \displaystyle\int_{-\infty}^{x} (v_0 - \tilde{v}_0)(\xi)\ d\xi, \\ y_t(x, 0) = y_1(x) = u_0(x) - \tilde{u}(x, 0) \end{cases}$$

since $y_x = v_e$ and $y_t = u_e$. Therefore

$$\begin{cases} y_{tt} + (p_v(\tilde{v}, s)y_x)_x + y_t = p(\tilde{v}, s)_{xt} - (F_1(\tilde{v}, y_x, s)y_x^2)_x, \\ y(x, 0) = y_0(x) = \displaystyle\int_{-\infty}^{x} (v_0 - \tilde{v}_0)(\xi)\ d\xi, \\ y_t(x, 0) = y_1(x) = u_0(x) - \tilde{u}(x, 0), \end{cases} \tag{3.5}$$

where

$$p(y_x + \tilde{v}, s) - p(\tilde{v}, s) = p_v(\tilde{v}, s)y_x + F_1(\tilde{v}, y_x, s)y_x^2.$$

The main result of this section is the following.

THEOREM 3.1. *There exists $\delta_0 > 0$ such that if $0 < \delta < \delta_0$ and*

$$\|y_0\|_{H^3} + \|y_1\|_{H^2} + |v_+ - v_-| \le \delta,$$

then (3.5) has a unique smooth solution $y \in H^3$ and $y_t \in H^2$ satisfying

$$\|y(t)\|_{H^3}^2 + \|y_t(t)\|_{H^2}^2 + \int_0^t \|(y_x, y_t)(\tau)\|_{H^2}\ d\tau \le C\delta^2.$$

Moreover,

$$(1 + t)\|y_x(\cdot, t)\|^2 + (1 + t)^2\|y_t(\cdot, t)\|^2 \le C \tag{3.6}$$

and

$$\|y_x(\cdot,t)\|_{L^\infty} \le C(1+t)^{-\frac{3}{4}}, \ \|y_t(\cdot,t)\|_{L^\infty} \le C(1+t)^{-\frac{5}{4}}. \tag{3.7}$$

Then Theorem 1.3 follows from Theorem 2.2 and Theorem 3.1.

We now prove Theorem 3.1. First of all, we have the following.

THEOREM 3.2. *There exists* $\delta_0 > 0$ *such that if* $0 < \delta < \delta_0$ *and*

$$\|y_0\|_{H^3} + \|y_1\|_{H^2} + |v_+ - v_-| \le \delta,$$

then (3.5) *has a unique global smooth solution* $y \in H^3$ *and* $y_t \in H^2$ *satisfying*

$$\|y(t)\|_{H^3}^2 + \|y_t(t)\|_{H^2}^2 + \int_0^t \|(y_x, y_t)(\tau)\|_{H^2}\ d\tau \le C\delta^2. \tag{3.8}$$

Proof. It is sufficient to prove the uniform estimates (3.8) under the following a priori assumption:

$$\|y(t)\|_{H^3}^2 + \|y_t\|_{H^2}^2 \le \varepsilon$$

for $\varepsilon > 0$ suitably small.

Multiplying $(3.5)_1$ by $y + 2y_t$, we have

$$\begin{aligned}&\left[y_t^2 - p_v(\tilde{v}, s)y_x^2 + \frac{1}{2}y^2 + yy_t\right]_t + y_t^2 - p_v(\tilde{v}, s)y_x^2 \\ &= p_{vv}(\tilde{v}, s)\tilde{v}_t(y_x^2 - y_x - 2y_{xt}) + (F_1 y_x^2 - p(\tilde{v}, s)_t)(y_x + 2y_{tx}) + \{\cdots\}_x,\end{aligned} \tag{3.9}$$

where $\{\cdots\}_x$ denote the terms which disappear after integration with respect to x. Integrating (3.9) over $[0,t] \times (-\infty, +\infty)$, we get

$$\begin{aligned}&\|(y, y_t, y_x)(t)\|^2 + \int_0^t \|(y_t, y_x)(\tau)\|^2\ d\tau \\ &\le C\delta^2 + C\left|\int_0^t \int_{-\infty}^{+\infty} p_{vv}(\tilde{v}, s)\tilde{v}_t y_x^2 \right. \\ &\qquad \left. -p(\tilde{v}, s)_t(y_x + 2y_{xt}) + F_1 y_x^2(y_x + 2y_{tx})\ dxd\tau\right|.\end{aligned} \tag{3.10}$$

Due to the smallness of ε, we can reduce (3.10) into

$$\begin{aligned}&\|(y, y_t, y_x)(t)\|^2 + \int_0^t \|(y_t, y_x)(\tau)\|^2\ d\tau \\ &\le C\delta^2 + C\left|\int_0^t \int_{-\infty}^{+\infty} p(\tilde{v}, s)_t(y_x + 2y_{xt})\ dxd\tau\right|,\end{aligned} \tag{3.11}$$

while

$$\begin{aligned}&\left|\int_0^t \int_{-\infty}^{+\infty} p(\tilde{v}, s)_t(y_x + 2y_{xt})\ dxd\tau\right| \\ &\le C(\varepsilon_1)\int_0^t \int_{-\infty}^{+\infty} (p(\tilde{v}, s)_t^2 + p(\tilde{v}, s)_{tx}^2)\ dxd\tau + \varepsilon_1 \int_0^t \int_{-\infty}^{+\infty} (y_x^2 + y_t^2)\ dxd\tau\end{aligned} \tag{3.12}$$

and

$$\int_0^t \int_{-\infty}^{+\infty} p(\tilde{v},s)_t^2 + p(\tilde{v},s)_{tx}^2 \, dxd\tau \le C\delta^2. \tag{3.13}$$

Now, by taking ε_1 small, it reads from (3.11)–(3.13) that

$$\|(y,y_t,y_x)(t)\|^2 + \int_0^t \|(y_x,y_t)(\tau)\|^2 \, d\tau \le C\delta^2. \tag{3.14}$$

We now differentiate (3.5) in x and then

$$y_{ttx} + (p_v(\tilde{v},s)y_x)_{xx} + y_{tx} = p(\tilde{v},s)_{xtx} - (F_1(\tilde{v},y_x,s)y_x^2)_{xx}. \tag{3.15}$$

If we multiply (3.15) by y_x+2y_{tx} and integrate the resulting equation over $[0,1]\times[0,t]$, by using (3.14) we get

$$\begin{aligned}
&\|(y_x,y_{tx},y_{xx})(t)\|^2 + \int_0^t \|(y_{tx},y_{xx})(\tau)\|^2 \, d\tau \\
&\le C\delta^2 + C\int_0^t \int_{-\infty}^{+\infty} (F_1y_x^2)_x^2 \, dxd\tau \\
&\qquad + C\int_0^t \int_{-\infty}^{+\infty} [O(1)y_xy_{xx}^2]_t \, dxd\tau \\
&\qquad + C\delta\int_0^t \int_{-\infty}^{+\infty} (y_x^2+y_{tx}^2+y_{xx}^2) \, dxd\tau,
\end{aligned}$$

which implies

$$\|(y_x,y_{tx},y_{xx})(t)\|^2 + \int_0^t \|(y_{tx},y_{xx})(\tau)\|^2 \, d\tau \le C\delta^2.$$

Repeating the above procedure, we can easily obtain the third order estimates and complete the proof of this theorem. □

With the help of Theorem 3.2, it is easy to obtain the following convergence results by using an argument similar to the proof of Theorem 2.8.

THEOREM 3.3. *The solution y to* (3.5) *in the Theorem* 3.2 *satisfies*

$$\lim_{t\to\infty} (\|y(\cdot,t)\|_{L^\infty} + \|(y_t,y_x)(\cdot,t)\|_{H^1}) = 0.$$

We investigate now the problem of the decay rate. We will follow the approach introduced by [19] concerning the isentropic case. However, since the entropy $s(x)$ is not constant here, some modifications are necessary.

LEMMA 3.4. *Under the previous hypotheses, it follows that*

$$(1+t)\|(y_x,y_t)(t)\|^2 + \int_0^t (1+\tau)\|y_t(\tau)\|^2 \, d\tau \le C\delta^2.$$

Proof. First, we notice that $(3.5)_1$ is equivalent to

$$y_{tt} + y_t + [p(\tilde{v}+y_x,s) - p(\tilde{v},s)]_x = p(\tilde{v},s)_{xt}. \tag{3.16}$$

Multiplying (3.16) by $(1+t)y_t$, after some calculations we get

$$\begin{aligned}&\left[(1+t)\left(\frac{1}{2}y_t^2+q\right)\right]_t+(1+t)y_t^2-q\\ &-\int_0^{y_x}\left[p_v(\tilde{v}+\xi,s)-p_v(\tilde{v},s)\right]\,d\xi+\tilde{v}_t(1+t)y_x^2-\frac{1}{2}y_t^2\\ &=(1+t)y_tp(\tilde{v},s)_{xt}+\{\cdots\}_x.\end{aligned}\tag{3.17}$$

Integrating (3.17) over $[0,t]\times(-\infty,+\infty)$, with the help of (3.8), we have

$$\begin{aligned}&(1+t)\|(y_x,y_t)(t)\|^2+\int_0^t(1+\tau)\|y_t(\tau)\|^2\,d\tau\\ &\le C\delta^2+\frac{1}{2}\int_0^t(1+\tau)\|y_t(\tau)\|^2\,d\tau,\end{aligned}$$

which implies

$$(1+t)\|(y_t,y_x)(t)\|^2+\int_0^t(1+\tau)\|y_t(\tau)\|^2\,d\tau\le C\delta^2.\tag{3.18}$$

Here we have used the following properties:

$$\begin{aligned}&q=-\int_0^{y_x}\left[p(\tilde{v}+\xi,s)-p(\tilde{v},s)\right]\,d\xi=O(1)y_x^2,\\ &\int_0^{y_x}\left[p_v(\tilde{v}+\xi,s)-p_v(\tilde{v},s)\right]\,d\xi=O(1)y_x^2,\\ &\tilde{v}_t\le O(1)(F_t+\tilde{w}_t)\le O(1)(1+t)^{-1}.\qquad\square\end{aligned}$$

LEMMA 3.5. *Under the previous hypotheses, we have*

$$(1+t)^2\|(y_t,y_{tt},y_{tx})(t)\|^2+\int_0^t(1+\tau)^2\|(y_{tt},y_{tx})(\tau)\|^2\,d\tau\le C\delta^2.$$

Proof. Differentiating $(3.5)_1$ in t, we have

$$y_{ttt}+(p_v(\tilde{v},s)y_x)_{xt}+y_{tt}=p(\tilde{v},s)_{xtt}-(F_1y_x^2)_{xt}.\tag{3.19}$$

Let us multiply (3.19) by $(1+t)y_t$ and $(1+t)y_{tt}$, respectively, then we deduce

$$\begin{aligned}&\left[(1+t)\left(y_ty_{tt}+\frac{1}{2}y_t^2\right)\right]_t-p_v(\tilde{v},s)(1+t)y_{tx}^2-(1+t)y_{tt}^2-\frac{1}{2}y_t^2-y_ty_{tt}\\ &=p_{vv}\tilde{v}_t(1+t)y_xy_{tx}+(1+t)y_t(p(\tilde{v},s)_{xtt}-(F_1y_x^2)_{xt})+\{\cdots\}_x,\end{aligned}\tag{3.20}$$

$$\begin{aligned}&\left[\frac{1}{2}(1+t)(y_{tt}^2-p_vy_{tx}^2)\right]_t+(1+t)y_{tt}^2\\ &-\frac{1}{2}y_{tt}^2+\frac{1}{2}p_vy_{tx}^2+\frac{1}{2}(1+t)p_{vv}\tilde{v}_ty_{tx}^2+(1+t)y_{tt}(y_xp_{vv}\tilde{v}_t)_x\\ &=(1+t)y_{tt}(p(\tilde{v},s)_{xtt}-(F_1y_x^2)_{xt})+\{\cdots\}_x.\end{aligned}\tag{3.21}$$

By using Theorem 3.2 and Lemma 3.4 and by integrating $8 \times (3.21) + (3.20)$ one has

$$\begin{aligned}
&(1+t)\|(y_t, y_{tt}, y_{tx})\|^2 + \int_0^t (1+\tau)\|(y_{tt}, y_{tx})(\tau)\|^2 \, d\tau \\
&\le C\left(\delta^2 + \int_0^t \int_{-\infty}^{+\infty} (1+\tau) p(\tilde{v}, s)_{xtt}^2 \, dx d\tau \right. \\
&\qquad \left. + \left| \int_0^t \int_{-\infty}^{+\infty} (1+\tau)(y_{tx} + y_{ttx})(F_1 y_x^2)_t \, dx d\tau \right| \right) \\
&\le C\delta^2 + C\left| \int_0^t \int_{-\infty}^{+\infty} (1+\tau)(y_{tx} + y_{ttx})(F_1 y_x^2)_t \, dx d\tau \right|.
\end{aligned} \tag{3.22}$$

Moreover, one has

$$\begin{aligned}
&\left| \int_0^t \int_{-\infty}^{+\infty} (1+\tau) y_{tx} (F_1 y_x^2)_t \, dx d\tau \right| \\
&\le C \int_0^t \int_{-\infty}^{+\infty} (1+\tau)(|y_x| y_{tx}^2 + |\tilde{v}_t y_x^2 y_{tx}|) \, dx d\tau \\
&\le C\delta^2 + C\delta \int_0^t \int_{-\infty}^{+\infty} (1+\tau) y_{tx}^2 \, dx d\tau
\end{aligned} \tag{3.23}$$

and

$$\begin{aligned}
&\left| \int_0^t \int_{-\infty}^{+\infty} (1+\tau) y_{ttx} (F_1 y_x^2)_t \, dx d\tau \right| \\
&\le C\delta^2 + C\delta \left((1+t)\|y_{tx}(t)\|^2 + \int_0^t (1+\tau)\|y_{tx}\|^2 \, d\tau \right).
\end{aligned} \tag{3.24}$$

In view of the smallness of δ, from (3.22)–(3.24) we have

$$(1+t)\|(y_t, y_{tt}, y_{tx})(t)\|^2 + \int_0^t (1+\tau)\|(y_{tt}, y_{tx})(\tau)\|^2 \, d\tau \le C\delta^2. \tag{3.25}$$

Now we multiply (3.19) by $(1+t)^2 y_t$ and $(1+t)^2 y_{tt}$ and repeat the previous calculations to conclude Lemma 3.5. □

LEMMA 3.6. *The solution y to* (3.5) *in Theorem* 3.2 *satisfies*

$$(1+t)^2\|(V_t, V_x)(t)\|^2 + \int_0^t (1+\tau)\|(V_t, V_x)(\tau)\|^2 \, d\tau \le C\delta^2,$$

where $V = p_v(\tilde{v}, s) y_x$.

Proof. The estimate for V_t can be obtained from Lemma 3.5 and the following relation:

$$V_t = p_v(\tilde{v}, s) y_{tx} + p_{vv}(\tilde{v}, s) \tilde{v}_t y_x.$$

It is easy to see that

$$V_x = -(y_{tt} + y_t + p(\tilde{v}, s)_{xt} + (F_2 V^2)_x), \tag{3.26}$$

where $F_2V^2 = F_1y_x^2$. Then we calculate the decay rate for V_x by using (3.26). First of all, it is easy to see by taking the L^2-norm in (3.26) that

$$(1+t)\|V_x(t)\|^2 \le C\delta^2 \tag{3.27}$$

and

$$\begin{aligned}&(1+t)^2\|V_x\|^2\\ &\le C(1+t)^2(\|y_{tt}\|^2 + \|y_t\|^2 + \|(F_2V^2)_x\|^2)\\ &\le C\delta^2 + \frac{1}{2}(1+t)^2\|V_x\|^2 + C(1+t)(\|V\|^2 + \|V_x\|^2)\\ &\le C\delta^2 + \frac{1}{2}(1+t)^2\|V_x\|^2\end{aligned}$$

thus

$$(1+t)^2\|V_x\|^2 \le C\delta^2. \tag{3.28}$$

Then, multiplying (3.26) by $(1+t)V_x$ and integrating it, one has

$$\begin{aligned}&\int_0^t (1+\tau)\|V_x(\tau)\|^2\ d\tau\\ &\le C\int_0^t\int_{-\infty}^{+\infty}(1+\tau)(y_{tt}^2 + y_t^2 + p(\tilde{v},s)_{xt}^2 + (F_2V^2)_x^2)\ dxd\tau\\ &\le C\delta^2 + C\int_0^t\int_{-\infty}^{+\infty}(F_2V^2)_x^2(1+\tau)\ dxd\tau\\ &\le C\delta^2 + C\int_0^t\int_{-\infty}^{+\infty}(1+\tau)V^4\ dxd\tau\\ &\le C\delta^2 + C\int_0^t(\|y_x\|^2 + \|y_{xx}\|^2)(1+\tau)\|y_x\|^2\ d\tau\\ &\le C\delta^2. \quad \square\end{aligned} \tag{3.29}$$

The following result easily holds by repeating the previous arguments on the equation (3.19) differentiated with respect to x.

Lemma 3.7. *The solution y to* (3.5) *in Theorem* 3.2 *satisfies*

$$(1+t)^2\|(y_{ttx}, y_{txx})(t)\|^2 + \int_0^t (1+\tau)^2\|(y_{ttx}, y_{txx})(\tau)\|^2\ d\tau \le C\delta^2.$$

Now we can prove the desired estimates on y_{tx}.

Lemma 3.8. *Under the previous hypotheses, one has*

$$(1+t)^3\|(y_{tt}, y_{tx})(t)\|^2 + \int_0^t (1+\tau)^3\|y_{tt}(\tau)\|^2\ d\tau \le C\delta^2.$$

Proof. Multiply (3.19) by $(1+t)^3y_{tt}$, then we obtain

$$\begin{aligned}&(1+t)^3\|(y_{tt}, y_{tx})(t)\|^2 + \int_0^t (1+\tau)^3\|y_{tt}(\tau)\|^2\ d\tau\\ &\le C\delta^2 + C\left|\int_0^t\int_{-\infty}^{+\infty}(1+\tau)^3y_{ttx}(F_1y_x^2)_t\ dxd\tau\right|.\end{aligned} \tag{3.30}$$

We have that

$$\tag{3.31}\begin{aligned}&\left|\int_0^t\int_{-\infty}^{+\infty}(1+\tau)^3 y_{ttx}(F_1y_x^2)_t\ dxd\tau\right|\\&\le C\left|\int_0^t\int_{-\infty}^{+\infty}[O(1)(1+\tau)^3y_{tx}^2y_x]_t\ dxd\tau\right|\\&+C\left|\int_0^t\int_{-\infty}^{+\infty}((1+t)^2y_{tx}^2+(1+\tau)^3y_{tx}^3\ dxd\tau\right|\\&+C\left|\int_0^t\int_{-\infty}^{+\infty}(1+\tau)^3y_{tt}(F_3\tilde{v}_tV^2)_x\ dxd\tau\right|\\&\le C(\alpha_1)\delta^2+C\delta(1+t)^3\|y_{tx}(t)\|^2+\alpha_1\int_0^t(1+\tau)^3\|y_{tt}\|^2\ d\tau,\end{aligned}$$

where $F_3V^2 = F_{1v}y_x^2$.

By choosing α_1 suitable small, we conclude from (3.30)–(3.31) that

$$(1+t)^3\|(y_{tt},y_{tx})(t)\|^2+\int_0^t(1+\tau)^3\|y_{tt}\|^2\ d\tau\le C\delta^2. \qquad \square$$

Therefore, we obtain the following desired decay rates.

THEOREM 3.9. *The solution y to* (3.5) *in Theorem* 3.2 *satisfies*

$$\tag{3.32}\sum_{k=0}^{1}[(1+t)^{k+1}\|\partial_x^kV(\cdot,t)\|^2+(1+t)^{k+2}\|\partial_x^ky_t(\cdot,t)\|^2]\le C$$

and

$$\tag{3.33}\|y_x(\cdot,t)\|_{L^\infty}\le C(1+t)^{-\frac{3}{4}},\ \ \|y_t(\cdot,t)\|_{L^\infty}\le C(1+t)^{-\frac{5}{4}}.$$

Proof. (3.32) comes directly from Lemmas 3.4–3.8. (3.33) follows from the interpolation inequality and (3.32), where

$$\|y_x(\cdot,t)\|_{L^\infty}\le C\|V(\cdot,t)\|_{L^\infty}\le C(1+t)^{-\frac{3}{4}}. \qquad \square$$

Theorem 3.1 then follows from Theorem 3.2 and Theorem 3.9.

4. Convergence to stationary solution. This section is devoted to proving Theorem 4 and Theorem 5, where (v_-,v_+) and (s_-,s_+) are chosen so that $p(v_-,s_-) = p(v_+,s_+) = \bar{p} = \text{const}$.

Denote by $(v_2,u_2)(x,t)$ the solution of (1.4) obtained in Theorem 2.12. We solve (1.2)–(1.3) near $(v_2,u_2)(x,t)$ under $u_- = u_+ = 0$ and then (1.16) implies

$$\tag{4.1}\int_{-\infty}^{+\infty}(v_0(x)-v_2(x,0))\ dx=0.$$

Similarly to section 3, we set

$$\tilde{y}=\int_{-\infty}^{x}(v(\xi,t)-v_2(\xi,t))\ d\xi,$$

which satisfies

$$\begin{cases} \tilde{y}_{tt} + (p_v(v_2,s)\tilde{y}_x)_x + \tilde{y}_t = p(v_2,s)_{xt} - (F_1(v_2,\tilde{y}_x,s)\tilde{y}_x^2)_x, \\ \tilde{y}(x,0) = \tilde{y}_0(x) = \displaystyle\int_{-\infty}^{x} (v_0(\xi) - v_2(\xi,0))\, d\xi, \\ \tilde{y}_t(x,0) = \tilde{y}_1(x) = u_0(x) - u_2(x,0), \end{cases} \tag{4.2}$$

where

$$p(\tilde{y}_x + v_2, s) - p(v_2,s) = p_v(v_2,s)\tilde{y}_x + F_1(v_2,\tilde{y}_x,s)\tilde{y}_x^2.$$

From the results in subsection 2.2 and the argument used in section 3, it is clear that the same argument of the section 3 can be used here to prove the following results.

THEOREM 4.1. *There exists* $\delta_0 > 0$ *such that if* $0 < \delta < \delta_0$ *and*

$$\|\tilde{y}_0\|_3^2 + \|\tilde{y}_1\|_2^2 \le \delta,$$

then (4.2) *has a unique smooth solution* $\tilde{y}$ *satisfying*

$$\sum_{k=0}^{1}[(1+t)^{k+1}\|\partial_x^k V_1(\cdot,t)\|^2 + (1+t)^{k+2}\|\partial_x^k \tilde{y}_t(\cdot,t)\|^2] \le C, \tag{4.3}$$

with $V_1 = p_v(v_2,s)\tilde{y}_x$, *and*

$$\|\tilde{y}_x(\cdot,t)\|_{L^\infty} \le C(1+t)^{-\frac{3}{4}},\ \|\tilde{y}_t(\cdot,t)\|_{L^\infty} \le C(1+t)^{-\frac{5}{4}}. \tag{4.4}$$

It is clear that Theorem 1.4 comes from Theorem 1.2 and Theorem 4.1.

We turn to proving Theorem 1.5 next. Since $(v_1(x), 0, s_0(x))$ is the stationary solution of both (1.2) and (1.4), we can also solve (1.2)–(1.3) near v_1 instead of v_2, under the condition $u_- = u_+ = 0$ and (1.19), then

$$\int_{-\infty}^{+\infty} (v_0(x) - v_1(x))\, dx = 0. \tag{4.5}$$

Denote

$$z = \int_{-\infty}^{x} (v(\xi,t) - v_1(\xi))\, d\xi; \tag{4.6}$$

then it follows that

$$\begin{cases} z_{tt} + (p_v(v_1,s)z_x)_x + z_t = -(F_1(v_1,z_x,s)z_x^2)_x, \\ z(x,0) = z_0(x) = \displaystyle\int_{-\infty}^{x} (v_0(\xi) - v_1(\xi))\, d\xi, \\ z_t(x,0) = z_1(x) = u_0(x), \end{cases} \tag{4.7}$$

where

$$p(z_x + v_1, s) - p(v_1,s) = p_v(v_1,s)z_x + F_1(v_1,z_x,s)z_x^2.$$

We will prove the following theorem.

THEOREM 4.2. *There exists $\delta_0 > 0$ such that if $0 < \delta < \delta_0$ and*

$$\|z_0\|_{H^3} + \|z_1\|_{H^2} \leq \delta,$$

then (4.7) *has a unique global smooth solution z satisfying*

$$\sum_{k=0}^{1}[(1+t)^{k+1}\|\partial_x^k V_2(\cdot,t)\|^2 + (1+t)^{k+2}\|\partial_x^k z_t(\cdot,t)\|^2] \leq C,$$

where $V_2 = p_v(v_1,s)z_x$ and

$$\|z_x(\cdot,t)\|_{L^\infty} \leq C(1+t)^{-\frac{3}{4}},\ \|z_t(\cdot,t)\|_{L^\infty} \leq C(1+t)^{-\frac{5}{4}}.$$

Hence (1.2)–(1.3) *has a unique global smooth solution $(v,u,s)(x,t)$ such that*

$$\|(v-v_1)(\cdot,t)\|_{L^\infty} \leq C(1+t)^{-\frac{3}{4}},\ \|u(\cdot,t)\|_{L^\infty} \leq C(1+t)^{-\frac{5}{4}}.$$

We note that Theorem 4.2 implies Theorem 1.5.

Using the same proof as in Theorem 3.2, noting $p(v_1,s) = \text{const}$, we can deduce the following lemma.

LEMMA 4.3. *There exists $\delta_0 > 0$ such that if $0 < \delta < \delta_0$ and*

$$\|z_0\|_{H^3} + \|z_1\|_{H^2} \leq \delta,$$

then (4.7) *has a unique smooth solution z satisfying*

$$\|z(t)\|_{H^3}^2 + \|z_t(t)\|_{H^2}^2 + \int_0^t \|(z_x,z_t)(\tau)\|_{H^2}\ d\tau \leq C\delta^2. \tag{4.8}$$

The next result concerns the decay rates.

LEMMA 4.4. *The solution z of* (4.7)*, obtained in Lemma* 4.3*, satisfies*

$$\sum_{k=0}^{1}[(1+t)^{k+1}\|\partial_x^k V_2(\cdot,t)\|^2 + (1+t)^{k+2}\|\partial_x^k z_t(\cdot,t)\|^2] \leq C, \tag{4.9}$$

where $V_2 = p_v(v_1,s)z_x$ and

$$\|z_x(\cdot,t)\|_{L^\infty} \leq C(1+t)^{-\frac{3}{4}},\ \|z_t(\cdot,t)\|_{L^\infty} \leq C(1+t)^{-\frac{5}{4}}. \tag{4.10}$$

Proof. We multiply $(4.7)_1$ by $(1+t)z_t$ and integrate it by parts. Then by using (4.8), we obtain, by a calculation similar to that one in the proof of Lemma 3.4, that

$$(1+t)\|(z_x,z_t)(t)\|^2 + \int_0^t (1+\tau)\|z_t(\tau)\|^2\ d\tau \leq C\delta^2. \tag{4.11}$$

Now let us differentiate $(4.7)_1$ in t, then we have

$$z_{ttt} + (p_v(v_1,s)y_x)_{xt} + y_{tt} = -(F_1 z_x^2)_{xt}. \tag{4.12}$$

Multiplying (4.12) by $(1+t)z_t$ and $(1+t)z_{tt}$, respectively, we deduce

$$\begin{aligned}&\left[(1+t)\left(z_t z_{tt}+\frac{1}{2}z_t^2\right)\right]_t - p_v(v_1,s)(1+t)z_{tx}^2-(1+t)z_{tt}^2\\&=\frac{1}{2}z_t^2+z_t z_{tt}-(F_1 z_x^2)_t(1+t)z_{tx}+\{\cdots\}_x,\end{aligned}\tag{4.13}$$

$$\begin{aligned}&\left[\frac{1}{2}(1+t)(z_{tt}^2-p_v z_{tx}^2)\right]_t+(1+t)z_{tt}^2\\&=\frac{1}{2}z_{tt}^2-\frac{1}{2}p_v z_{tx}^2-(1+t)z_{ttx}(F_1 z_x^2)_t)+\{\cdots\}_x.\end{aligned}\tag{4.14}$$

Then by using (4.8) and (4.11), and by integrating $8\times(4.14)+(4.13)$, we have

$$\begin{aligned}&(1+t)\|(z_{tt},z_{tx})\|^2+\int_0^t(1+\tau)\|(z_{tt},z_{tx})(\tau)\|^2\,d\tau\\&\leq C+C\left|\int_0^t\int_{-\infty}^{+\infty}(1+\tau)(z_{tx}+z_{ttx})(F_1 z_x^2)_t\,dxd\tau\right|.\end{aligned}\tag{4.15}$$

We see that

$$\begin{aligned}&\left|\int_0^t\int_{-\infty}^{+\infty}(1+\tau)z_{tx}(F_1 z_x^2)_t\,dxd\tau\right|\\&\leq C\delta\int_0^t(1+\tau)\|z_{tx}(\tau)\|^2\,d\tau,\end{aligned}\tag{4.16}$$

and

$$\begin{aligned}&\left|\int_0^t\int_{-\infty}^{+\infty}(1+\tau)z_{ttx}(F_1 z_x^2)_t\,dxd\tau\right|\\&\leq C\left|\int_0^t\int_{-\infty}^{+\infty}[O(1)|z_x|(1+\tau)z_{tx}^2]_t\,dxd\tau\right|\\&\quad+C\delta\int_0^t\int_{-\infty}^{+\infty}(1+(1+\tau))z_{tx}^2\,dxd\tau.\end{aligned}\tag{4.17}$$

Due to the smallness of δ, from (4.15)–(4.17) we have

$$(1+t)\|(z_{tt},z_{tx})\|^2+\int_0^t(1+\tau)\|(z_{tt},z_{tx})(\tau)\|^2\,d\tau\leq C.\tag{4.18}$$

Now let us multiply (4.12) by $(1+t)^2 z_t$ and $(1+t)^2 z_{tt}$ and repeat the previous calculations, then

$$(1+t)^2\|(z_t,z_{tt},z_{tx})\|^2+\int_0^t(1+\tau)^2\|(z_{tt},z_{tx})(\tau)\|^2\,d\tau\leq C.\tag{4.19}$$

The same proof as used in Lemma 3.6 yields

$$(1+t)^2\|(V_{2t},V_{2x})\|^2+\int_0^t(1+\tau)\|(V_{2t},V_{2x})(\tau)\|^2\,d\tau\leq C.\tag{4.20}$$

By differentiating (4.12) in x, we get

$$(1+t)^2\|(z_{ttx}, z_{txx})\|^2 + \int_0^t (1+\tau)^2\|(z_{ttx}, z_{txx})(\tau)\|^2 \, d\tau \le C, \tag{4.21}$$

and finally, by multiplying (4.12) by $(1+t)^3 z_{tt}$, it follows that

$$\begin{aligned}
&(1+t)^3\|(z_{tt}, z_{tx})\|^2 + \int_0^t (1+\tau)^3\|z_{tt}(\tau)\|^2 \, d\tau \\
&\le C + C\left|\int_0^t \int_{-\infty}^{+\infty} [O(1)|z_x|(1+\tau)^3 z_{tx}^2]_t \, dxd\tau\right| \\
&\quad + C\delta \int_0^t \int_{-\infty}^{+\infty} (1+\tau)^2 z_{tx}^2 \, dxd\tau + C\left|\int_0^t \int_{-\infty}^{+\infty} (1+\tau)^3 z_{tx}^3 \, dxd\tau\right|,
\end{aligned}$$

which implies

$$\begin{aligned}
&(1+t)^3\|(z_{tt}, z_{tx})\|^2 + \int_0^t (1+\tau)^3\|z_{tt}(\tau)\|^2 \, d\tau \\
&\le C + C\left|\int_0^t \int_{-\infty}^{+\infty} (1+\tau)^3 z_{tx}^3 \, dxd\tau\right|.
\end{aligned} \tag{4.22}$$

We have

$$\begin{aligned}
&\left|\int_0^t \int_{-\infty}^{+\infty} (1+\tau)^3 z_{tx}^3 \, dxd\tau\right| \\
&\le C\int_0^t \int_{-\infty}^{+\infty} (1+\tau)^2 z_{tx}^2 + (1+\tau)^4 z_{tx}^4 \, dxd\tau \\
&\le C + C\int_0^t (1+\tau)^2(\|z_{tx}\|^2 + \|z_{txx}\|^2) \, d\tau \\
&\le C.
\end{aligned} \tag{4.23}$$

Then from (4.22)–(4.23), it follows that

$$(1+t)^3\|(z_{tt}, z_{tx})\|^2 + \int_0^t (1+\tau)^3\|z_{tt}(\tau)\|^2 \, d\tau \le C. \tag{4.24}$$

Hence, (4.9) follows from the combination of (4.11), (4.19)–(4.21), and (4.24). The estimate (4.10) follows from (4.9). □

By combining Lemmas 4.3 and 4.4, we complete the proof of the Theorem 4.2.

A REPRESENTATION FORMULA FOR THE MEAN CURVATURE MOTION*

R. BUCKDAHN[†], P. CARDALIAGUET[†], AND M. QUINCAMPOIX[†]

Abstract. The goal of this paper is to give a representation formula for the mean curvature motion in terms of the value function of some stochastic optimal control problem. This result is generalized to several geometric evolution equations.

Key words. stochastic optimal control, viability, viscosity solutions

Introduction. The main result of this paper is a representation formula for the solutions of the equation of the mean curvature motion (MCM). This equation is the following second order parabolic (degenerate and nonlinear) PDE:

$$\left\{ \begin{array}{ll} u_t = |Du| curv(u) & \text{on } (0,+\infty)\times\mathbb{R}^n, \\ u(0,\cdot) = g & \text{on } \mathbb{R}^n, \end{array} \right. \tag{1}$$

where $curv(u) = \text{div}(Du/|Du|) = (\Delta u - \frac{\langle D^2uDu, Du\rangle}{|Du|^2})/|Du|$. It is known (cf. [5], [7]) that this equation has a unique solution in the viscosity sense when $g : \mathbb{R}^n \to \mathbb{R}^n$ is bounded and uniformly continuous. We have obtained the following formula: For any $t > 0$,

$$u(t,x) = \inf_{v\in\mathcal{A}} \left(\text{ess-sup}_\Omega\, g(X^{x,v(\cdot)}(t))\right),$$

where "$\inf_{v\in\mathcal{A}}$" means the infimum over any complete stochastic basis $(\Omega, \mathcal{F}, P; (\mathcal{F}_s, s \in [0,T]))$ endowed with an n-dimensional standard $(\mathcal{F}_s)$-Brownian motion $W = (W(s),\, s \in [0,T])$, and over any $(\mathcal{F}_s)$-progressively measurable process $v(\cdot)$ taking its values in the set

$$\mathcal{V} = \{v \in \mathcal{S}_n \mid v \geq 0,\ I - v^2 \geq 0, \text{ and } \text{Tr}(I - v^2) = 1\}$$

(in brief: $v \in \mathcal{A}(\Omega, \mathcal{F}, P; W)$). The process $X^{x,v(\cdot)} = (X^{x,v(\cdot)}(s),\, s \in [0,T])$ is the solution of the associated stochastic control system

$$\left\{ \begin{array}{l} dX^{x,v(\cdot)}(s) = \sqrt{2}v(s)dW(s), \\ X^{x,v(\cdot)}(0) = x. \end{array} \right. \tag{2}$$

As a byproduct of this result we obtain a representation formula for the MCM. A family of moving hypersurfaces (Σ_t) of $\mathbb{R}^n$ (without boundary) is evolving by its mean curvature if its normal velocity is equal at each point to its mean curvature at that point. It is known that, in general, there is no regular solution of the MCM: the

[†] Département de Mathématiques, Université de Bretagne Occidentale, 6, avenue Victor-le-Gorgeu, B.P. 809, 29285 Brest cedex, France (Rainer.Buckdahn@univ-brest.fr, Pierre.Cardaliaguet@univ-brest.fr, Marc.Quincampoix@univ-brest.fr).

family of moving surfaces (Σ_t) usually develops singularities in finite time. Several definitions for the front after the apparitions of singularities have been proposed. Here we use, on the one hand, the level set method introduced in [5] and [7], and, on the other hand, the distance solutions of a front introduced in an equivalent way in [11] and [3].

In the level set method, the front (Σ_t) is defined as the 0-level set of the solution u of (1) for some uniformly continuous function g vanishing on Σ_0. The level set method gives a unique solution for the front (independent of g) but has to face the fattening problem: The set Σ_t may have a nonempty interior.

A distance solution of the MCM is a family of moving sets (Σ_t) such that the function $u(t,x) = \mathbf{1}_{\Sigma_t}(x)$ is a (discontinuous) solution to (1) with $g = \mathbf{1}_{\Sigma_0}(x)$. Compared with the level set method, this way of defining a solution is more intrinsic. Unfortunately, distance solutions are not unique in general. In fact, the fattening problem in the level method and the nonuniqueness problem of distance solutions are directly related: Indeed, the solution given by the level set method is always a distance solution, and fattening occurs if and only if this solution is not the unique one. The solution given by the level set method is sometimes called the biggest flow because it contains any distance solution.

Let us finally recall that if there is a smooth solution to the MCM on the interval $[0,T]$, then this solution is unique and the distance solutions—and therefore also the biggest flow—coincide with the smooth solution on $[0,T]$.

We obtain the following representation formula for the MCM: Let (Σ_t) be the biggest flow of the MCM. Then we have

$$\forall t \geq 0,\ \ \Sigma_t = \{x \in \mathbb{R}^n \mid \exists v(\cdot) \in \mathcal{A} \text{ such that } X^{x,v(\cdot)}(t) \in \Sigma_0 \text{ a.s.}\}, \tag{3}$$

where "$\exists v(\cdot) \in \mathcal{A}$" means that there is a complete stochastic basis $(\Omega, \mathcal{F}, P; (\mathcal{F}_s,\ s \in [0,T]))$ endowed with an n-dimensional standard $(\mathcal{F}_s)$-Brownian motion $W = (W(s),\ s \in [0,T])$ and that $v(\cdot)$ is some $\mathcal{V}$-valued and $(\mathcal{F}_s)$-progressively measurable process. The process $X^{x,v(\cdot)}$ is the solution to (2).

We actually prove that (Σ_t) satisfies a stronger property:

$$\forall t \geq 0,\ \ x \in \Sigma_t \ \Leftrightarrow\ \exists v(\cdot) \in \mathcal{A} \text{ such that } X^{x,v(\cdot)}(s) \in \Sigma_s \text{ for } s \in [0,t]. \tag{4}$$

This statement can be understood as a dynamic programming principle. In fact, (4) not only holds true for the solution of the MCM given by the level set method but also for the distance solutions of the MCM. This property even characterizes these distance solutions. Indeed, if (Σ_t) is a family of moving sets, we prove that (Σ_t) is a distance solution of the MCM if and only if both (Σ_t) and $(\mathbb{R}^n \backslash \Sigma_t)$ satisfy a dynamic programming principle similar to (4).

This characterization of distance solutions relies upon a viability theorem for moving sets. Similar viability results can be found in the literature: see, in particular, [1], [2], [4], [9].

Let us now explain how this paper is organized. In section 1, we establish the representation formula for the solution of (1). Section 2 is devoted to the solutions of the MCM given by the level set approach, while the study of the distance solutions is the aim of section 3. In section 4, we generalize these results to some more general geometric equations. We complete the paper by giving in the appendix a statement of the viability theorem for moving sets and its proof.

When this paper was almost complete, we learned that Soner and Touzi [12] had a representation result similar to ours. In fact, their result is applicable to the motion by mean curvature in any codimension. In codimension one (i.e., the case we consider here), they prove that the moving set (Σ_t) given by

$$\Sigma_t = \{x \in \mathbb{R}^n \mid \exists v(\cdot) \in \mathcal{A} \text{ such that } X^{x,v(\cdot)}(t) \in \Sigma_0 \text{ a.s.}\}$$

is a distance solution of the MCM. Our result is slightly more precise, since it shows that (Σ_t) is in fact the solution given by the level set method.

1. A control problem.

Let us first define the set of controls: Let $\mathcal{S}_n$ be the set of all $n \times n$ symmetric matrices, and let $\mathcal{V}$ be the following compact subset of $\mathcal{S}_n$:

$$\mathcal{V} = \{v \in \mathcal{S}_n \mid v \geq 0,\ I - v^2 \geq 0 \text{ and } \mathrm{Tr}(I - v^2) = 1\},$$

where I is the $n \times n$ identity matrix. Let us point out that we have the following equality:

$$\{v^2 \mid v \in \mathcal{V}\} = \{w \in \mathcal{S}_n \mid w \geq 0,\ I - w \geq 0,\ \mathrm{Tr}(I - w) = 1\}, \tag{5}$$

from which we deduce that $\{v^2 \mid v \in \mathcal{V}\}$ is a convex subset of $\mathcal{S}_n$ and that

$$\{v^2 \mid v \in \mathcal{V}\} = \mathrm{Co}\,\{(I - aa^*) \mid a \in \mathbb{R}^n,\ |a| = 1\}, \tag{6}$$

where $\mathrm{Co}(A)$ stands for the closed convex hull of a set A.

Let $W = (W(s),\ s \in [0,T])$ be an n-dimensional standard $(\mathcal{F}_s)$-Brownian motion on some complete stochastic basis $(\Omega, \mathcal{F}, P; (\mathcal{F}_s))$. We denote by $\mathcal{A} = \mathcal{A}(\Omega, \mathcal{F}, P; W)$ the set of all $\mathcal{V}$-valued $(\mathcal{F}_s)$-progressively measurable processes $v(\cdot)$. A process $v(\cdot) \in \mathcal{A}$ is called an admissible control.

Let us recall that, if $(\Omega, \mathcal{A}, P)$ is a probability space and if $Y : \Omega \to \mathbb{R}$ is a random variable, then the ess-sup of Y is defined by

$$\text{ess-sup}_\Omega\, Y = \sup\{\tau \in \mathbb{R} \mid P(Y \geq \tau) > 0\}.$$

Our aim is to prove the following result.

THEOREM 1.1. *Let $g : \mathbb{R}^n \to \mathbb{R}$ be a bounded uniformly continuous function. Let $T > 0$ be fixed, and let us set, for any initial position $(t,x) \in [0,T] \times \mathbb{R}^n$,*

$$V(t,x) = \inf_{v \in \mathcal{A}} \left(\text{ess-sup}_\Omega\, g(X^{t,x,v(\cdot)}(T)) \right), \tag{7}$$

where $X^{t,x,v(\cdot)}(\cdot)$ is the solution to

$$\left\{ \begin{array}{rcl} dX^{t,x,v(\cdot)}(s) & = & \sqrt{2} v(s) dW(s)\ , \\ X^{t,x,v(\cdot)}(t) & = & x. \end{array} \right. \tag{8}$$

Then V is the solution, in the viscosity sense, of the equation of the MCM (written here with a terminal condition):

$$\left\{ \begin{array}{ll} -V_t - \Delta V + \frac{\langle D^2 V DV, DV \rangle}{|DV|^2} = 0 & \text{in } (0,T) \times \mathbb{R}^n, \\ V(T,\cdot) = g(\cdot) & \text{in } \mathbb{R}^n. \end{array} \right. \tag{9}$$

Remarks.

1. In particular, the value function V, as the solution to (9), is continuous.

2. We prove below that, for any $(t,x) \in [0,T] \times \mathbb{R}^n$, there is an optimal control $v(\cdot) \in \mathcal{A}$ in the following sense: There is a complete stochastic basis $(\Omega, \mathcal{F}, P; (\mathcal{F}_s,\, s \in [0,T]))$ endowed with an n-dimensional standard $(\mathcal{F}_s)$-Brownian motion $W = (W(s),\, s \in [0,T])$, and some $(\mathcal{F}_s)$-progressively measurable process $v(\cdot)$ taking its values in the set $\mathcal{V}$, such that the solution $X^{t,x,v(\cdot)}$ of (8) satisfies

$$V(t,x) = \text{ess-sup}_\Omega\, g(X^{t,x,v(\cdot)}(T)).$$

Proof of Theorem 1.1. Since, for any constants $a > 0$ and $b \in \mathbb{R}$, the function $(t,x) \to aV(t,x) + b$ is the value function for the ess-sup equation (7) for the terminal cost $x \to ag(x) + b$, and since g is bounded, we can assume, without loss of generality, that

$$\forall x \in \mathbb{R}^n,\ 1 \leq g(x) \leq 2. \tag{10}$$

Let us set, for any $p \geq 1$ and any $(t,x) \in [0,T] \times \mathbb{R}^n$,

$$V_p(t,x) = \inf_{v \in \mathcal{A}} \left[E((g(X^{t,x,v(\cdot)}(T)))^p) \right]^{\frac{1}{p}} ,$$

where $X^{t,x,v(\cdot)}(\cdot)$ is the solution to (8). It is known (see [8]) that V_p^p is the solution, in the viscosity sense, of the following equation:

$$\left\{ \begin{array}{ll} -(V_p^p)_t + \mathcal{H}(D^2 V_p^p) = 0 & \text{in } (0,T) \times \mathbb{R}^n, \\ V_p^p(T,\cdot) = g^p(\cdot) & \text{in } \mathbb{R}^n, \end{array} \right. \tag{11}$$

where

$$\forall S \in \mathcal{S}_n,\ \mathcal{H}(S) = \sup_{v \in \mathcal{V}} \left[-\text{Tr}(vv^* S) \right].$$

Since, from (6), the elements of $\mathcal{V}$ are symmetric matrices v such that v^2 are convex combinations of matrices of the form $(I - aa^*)$, we get

$$\forall S \in \mathcal{S}_n,\ \mathcal{H}(S) = \sup_{|a|=1} \left[-\text{Tr}((I - aa^*)S) \right] = - \left[\text{Tr}(S) - \lambda_{max}(S) \right],$$

where $\lambda_{max}(S)$ is the largest eigenvalue of S because

$$\max_{|a|=1} \text{Tr}(aa^* S) = \max_{|a|=1} \langle Sa, a \rangle = \lambda_{max}(S).$$

We divide the proof of Theorem 1.1 in two steps. In the first step, we prove that (V_p) converges to V. In the second step, we deduce from (11), satisfied by the V_p^p, that V is the solution of (9).

First step. Let $(t,x) \in [0,T] \times \mathbb{R}^n$ be fixed. We claim that

$$\lim_{p \to +\infty} V_p(t,x) = V(t,x). \tag{12}$$

Proof of the first step. Since, for any $v(\cdot) \in \mathcal{A}$ and any $1 \leq p \leq q$, we have

$$\left[E((g(X^{t,x,v(\cdot)}(T)))^p) \right]^{\frac{1}{p}} \leq \left[E((g(X^{t,x,v(\cdot)}(T)))^q) \right]^{\frac{1}{q}} \leq \text{ess-sup}_\Omega\, g(X^{t,x,v(\cdot)}(T)),$$

we deduce that the sequence $(V_p(t,x))$ is nondecreasing and that

$$\lim_{p\to+\infty} V_p(t,x) \le V(t,x).$$

Let us now prove the converse inequality. For doing so, we consider, for any $p \ge 1$, a control $v_p(\cdot)$ such that

$$\Big[E((g(X^{t,x,v_p(\cdot)}(T)))^p)\Big]^{\frac{1}{p}} \le V_p(t,x) + \frac{1}{p}.$$

Recall that $\mathcal{V}$ is compact. From (6), the set $\{\frac{1}{2}(\sqrt{2}v)(\sqrt{2}v)^* \mid v \in \mathcal{V}\}$ is convex. Hence, from standard arguments,[1] there exist a probability space $(\Omega, \mathcal{F}, P)$, some n-dimensional Brownian motion W on this space, some process $v(\cdot) \in \mathcal{A}(\Omega, \mathcal{F}, P; W)$, and a subsequence p_k such that

$$\forall q \ge 1,\ \lim_{k\to+\infty} \Big[E((g(X^{t,x,v_{p_k}(\cdot)}(T)))^q)\Big]^{\frac{1}{q}} = \Big[E((g(X^{t,x,v(\cdot)}(T)))^q)\Big]^{\frac{1}{q}}.$$

We have, for any fixed $q \ge 1$ and k sufficiently large,

$$\Big[E((g(X^{t,x,v_{p_k}(\cdot)}(T)))^q)\Big]^{\frac{1}{q}} \le \Big[E((g(X^{t,x,v_{p_k}(\cdot)}(T)))^{p_k})\Big]^{\frac{1}{p_k}} \le V_{p_k}(t,x) + \frac{1}{p_k}.$$

Since the sequence $(V_p(t,x))$ has a limit when $p \to +\infty$, letting $k \to +\infty$, we get

$$\Big[E((g(X^{t,x,v(\cdot)}(T)))^q)\Big]^{\frac{1}{q}} \le \lim_{p\to+\infty} V_p(t,x).$$

Then, letting $q \to +\infty$, we obtain the desired result:

$$V(t,x) \le \text{ess-sup}_{\Omega}\, g(X^{t,x,v(\cdot)}(T)) \le \lim_{p\to+\infty} V_p(t,x).$$

In particular, we see that the admissible control $v(\cdot) \in \mathcal{A}$ is optimal.

Second step. We now prove that V is the solution of (9). For doing so, we use the fact that V can be approximated by the V_p. Let us point out that V is lower semicontinuous, as the supremum of the continuous maps V_p. We do not prove directly that V is a solution. Instead, we consider the half-relaxed upper-limit $V^\sharp$ of the V_p:

$$\forall (t,x) \in [0,T]\times\mathbb{R}^n,\ V^\sharp(t,x) = \limsup_{(t',x')\to(t,x),\ p\to+\infty} V_p(t',x').$$

We are going to prove that V is a supersolution and that $V^\sharp$ is a subsolution. Moreover, V and $V^\sharp$ satisfy the following boundary conditions: $V(T,\cdot) \ge g$ and $V^\sharp(T,\cdot) \le g$. Then we obtain the equality $V = V^\sharp$ by the comparison principle since clearly

$$\forall (t,x),\ V(t,x) \le V^\sharp(t,x).$$

Equation satisfied by $\boldsymbol{V_p}$. From (11), one can deduce easily that V_p is a solution to

$$\begin{cases} -pV_p^{p-1}(V_p)_t + \mathcal{H}(p(p-1)V_p^{p-2}DV_p(DV_p)^* + pV_p^{p-1}D^2V_p) = 0 & \text{in } (0,T)\times\mathbb{R}^n, \\ V_p(T,\cdot) = g(\cdot) & \text{in } \mathbb{R}^n. \end{cases}$$

[1] See, in particular, [6] or [13, Theorem 5.3, Chapter 2] and its proof, namely, relations (5.25) and (5.26) and the conclusion from (5.41) to (5.43).

Since, from assumption (10), we have $g \geq 1$, we also have $V_p \geq 1$. Thus we can divide the above equation by pV_p^{p-1} to get that V_p is in fact the solution to

$$(13) \qquad \left\{ \begin{array}{ll} -(V_p)_t + \mathcal{H}((p-1)V_p^{-1}DV_p(DV_p)^* + D^2V_p) = 0 & \text{in } (0,T) \times \mathbb{R}^n, \\ V_p(T,\cdot) = g(\cdot) & \text{in } \mathbb{R}^n \end{array} \right.$$

because $\mathcal{H}$ is positively homogeneous of degree one.

***V* is a supersolution**. We now prove that V is a supersolution of (9). Let ϕ be a test function such that $V - \phi$ has a strict local minimum at some point $(t,x) \in (0,T) \times \mathbb{R}^n$. We have to prove that, at the point (t,x), we have

$$-\phi_t + H^*(D\phi, D^2\phi) \geq 0,$$

where we have set

$$\forall d \in \mathbb{R}^n \backslash \{0\},\ \forall S \in \mathcal{S}_n,\ H(d,S) = -\mathrm{Tr}(S) + \frac{\langle Sd, d\rangle}{|d|^2}$$

and where H^* is an upper regularization of H when $d = 0$, namely,

$$\forall S \in \mathcal{S}_n,\ H^*(0,S) = -\mathrm{Tr}(S) + \lambda_{max}(S).$$

Standard arguments show that there is a sequence (t_p, x_p) converging to (t,x) such that $(V_p(t_p,x_p))$ converges to $V(t,x)$ and such that $V_p - \phi$ has a local minimum at (t_p,x_p). Therefore, we have, at the point (t_p,x_p),

$$(14) \qquad -\phi_t + \mathcal{H}((p-1)V_p^{-1}D\phi(D\phi)^* + D^2\phi) \geq 0$$

because V_p is a viscosity solution of (13).

First case. $D\phi(t,x) \neq 0$. In this case, we have to prove that, at the point (t,x), we have

$$-\phi_t - \Delta\phi + \frac{\langle D^2\phi D\phi, D\phi\rangle}{|D\phi|^2} \geq 0.$$

Let us compute $\mathcal{H}((p-1)V_p^{-1}D\phi(D\phi)^* + D^2\phi)$ at the point (t_p,x_p):

$$(15) \qquad \begin{array}{l} \mathcal{H}((p-1)V_p^{-1}D\phi(D\phi)^* + D^2\phi) \\ \quad = -(p-1)V_p^{-1}|D\phi|^2 - \Delta\phi + \lambda_{max}((p-1)V_p^{-1}D\phi(D\phi)^* + D^2\phi) \end{array}$$

from the definition of $\mathcal{H}$. At this stage, we need to recall the following classical result.

LEMMA 1.2. *Let $S \in \mathcal{S}_n$ be such that the space of eigenvectors associated with $\lambda_{max}(S)$ is of dimension one. Then, the map $S \to \lambda_{max}(S)$ is of class $\mathcal{C}^1$ in a neighborhood of S. Moreover, its derivative $D\lambda_{max}(S)$ at this point S is given by*

$$(16) \qquad \forall H \in \mathcal{S}_n,\ D\lambda_{max}(S)(H) = \langle Ha, a\rangle,$$

where $a \in \mathbb{R}^n$ is an eigenvector of S associated with $\lambda_{max}(S)$ and such that $|a| = 1$.

(The proof of the lemma is given at the end of the present section for the sake of completeness.)

We apply the lemma to the matrix

$$S = \frac{D\phi(t,x)(D\phi(t,x))^*}{V(t,x)}$$

for which $\lambda_{max}(S) = \frac{|D\phi(t,x)|^2}{V(t,x)}$, and where $a = D\phi(t,x)/|D\phi(t,x)|$ since $D\phi(t,x) \neq 0$. Let us also set

$$S_p = \frac{D\phi(t_p,x_p)(D\phi(t_p,x_p))^*}{V_p(t_p,x_p)},$$

and let us notice that S_p converges to S. Moreover, since the matrices S_p satisfy the conditions of Lemma 1.2, the Taylor formula states that there is some $\theta_p \in (0,1)$ such that

$$\lambda_{max}\left(S_p + \frac{D^2\phi_p}{p-1}\right) = \lambda_{max}(S_p) + \frac{1}{p-1} D\lambda_{max}\left(S_p + \frac{\theta_p}{p-1} D^2\phi_p\right)(D^2\phi_p),$$

where we have set, for simplicity, $D\phi_p = D\phi(t_p,x_p)$ and $D^2\phi_p = D^2\phi(t_p,x_p)$. We now use the fact that λ_{max} is $\mathcal{C}^1$ in a neighborhood of S and that $S_p \to S$ to get

$$\lambda_{max}\left(S_p + \frac{D^2\phi_p}{p-1}\right) = \lambda_{max}(S_p) + \frac{1}{p-1} D\lambda_{max}(S)(D^2\phi_p) + o(1/p),$$

where $p\,o(1/p) \to 0$ when $p \to +\infty$. Then formula (16) gives

$$\lambda_{max}\left(S_p + \frac{D^2\phi_p}{p-1}\right) = \lambda_{max}(S_p) + \frac{\langle D^2\phi_p D\phi(t,x), D\phi(t,x)\rangle}{(p-1)|D\phi(t,x)|^2} + o(1/p).$$

Using this last equality in (15), we get, at the point (t_p,x_p),

$$\mathcal{H}((p-1)V_p^{-1}D\phi(D\phi)^* + D^2\phi) = -\Delta\phi + \frac{\langle D^2\phi D\phi(t,x), D\phi(t,x)\rangle}{|D\phi(t,x)|^2} + p\,o(1/p),$$

which, combined with (14), gives the desired inequality when $p \to +\infty$:

$$-\phi_t - \Delta\phi + \frac{\langle D^2\phi D\phi, D\phi\rangle}{|D\phi|^2} \geq 0$$

at the point (t,x).

Second case. $D\phi(t,x) = 0$. In this case, we have to prove that, at the point (t,x), we have

$$-\phi_t - \Delta\phi + \lambda_{max}(D^2\phi) \geq 0.$$

In order to use inequality (14), we first compute the quantity

$$\mathcal{H}((p-1)V_p^{-1}D\phi(D\phi)^* + D^2\phi)$$

taken at the point (t_p,x_p). Let us notice that, since $S \to \lambda_{max}(S)$ is subadditive, we have

$$\lambda_{max}((p-1)V_p^{-1}D\phi(D\phi)^* + D^2\phi) \leq (p-1)V_p^{-1}|D\phi|^2 + \lambda_{max}(D^2\phi),$$

from which we deduce the following inequality, taken at the point (t_p,x_p):

$$\mathcal{H}((p-1)V_p^{-1}D\phi(D\phi)^* + D^2\phi) \leq -\Delta\phi + \lambda_{max}(D^2\phi).$$

Using this inequality in (14) and letting $p \to +\infty$ give the desired result:

$$-\phi_t - \Delta\phi + \lambda_{max}(D^2\phi) \geq 0.$$

***$V^\sharp$* is a subsolution.** We set, for any positive z, any $d \in \mathbb{R}\backslash\{0\}$, and $S \in \mathcal{S}_n$,

$$\mathcal{H}_p(z,d,S) = \mathcal{H}\left(\frac{p-1}{z}dd^* + S\right).$$

Let us notice that we have

$$\mathcal{H}_p(z,d,S) \geq -\mathrm{Tr}(S) + \frac{\langle Sd, d\rangle}{|d|^2}$$

because

$$\mathcal{H}_p(z,d,S) = -\frac{(p-1)}{z}|d|^2 - \mathrm{Tr}(S) + \lambda_{max}\left(\frac{(p-1)}{z}dd^* + S\right)$$

with

$$\lambda_{max}\left(\frac{(p-1)}{z}dd^* + S\right) \geq \frac{(p-1)}{z}|d|^2 + \frac{\langle Sd, d\rangle}{|d|^2}.$$

Thus the V_p, being the solutions of (13), are subsolutions of (9). Then, from standard argument, the half-relaxed upper-limit of the V_p, which is nothing but $V^\sharp$, is still a subsolution of (9).

***V* satisfies the terminal condition.** Since the V_p satisfy $V_p(T,\cdot) = g$ and since $V_p(T,\cdot) \to V(T,\cdot)$, we clearly have $V(T,\cdot) = g$.

***$V^\sharp$* satisfies the terminal condition.** We have to show that $V^\sharp(T,\cdot) \leq g$. We argue by contradiction, by assuming that there are some $x_0 \in \mathbb{R}^n$ and some $\epsilon > 0$ such that $V^\sharp(T,x_0) \geq g(x_0) + \epsilon$. Let $\beta > 0$ be sufficiently large such that

$$\forall x \in \mathbb{R}^n,\ \frac{\beta}{2}|x-x_0|^2 + g(x_0) + \frac{\epsilon}{2} \geq g(x) + \frac{\epsilon}{4}.$$

(There is such a β because g is bounded and continuous.) We now choose $\alpha > \beta(n-1)$ sufficiently large so that

$$\forall x \in \mathbb{R}^n,\ \alpha T + \frac{\beta}{2}|x-x_0|^2 + g(x_0) + \frac{\epsilon}{2} \geq 3.$$

Let us set

$$\phi(t,x) = \alpha(T-t) + \frac{\beta}{2}|x-x_0|^2 + g(x_0) + \frac{\epsilon}{2}.$$

From the construction of ϕ, we have

$$\forall x \in \mathbb{R}^n,\ \phi(0,x) \geq 3 \text{ and } \phi(T,x) \geq g(x) + \frac{\epsilon}{4}.$$

Hence we have, for any $p \geq 1$,

$$\forall x \in \mathbb{R}^n,\ \phi(0,x) \geq V_p(0,x) + 1 \text{ and } \phi(T,x) \geq V_p(T,x) + \frac{\epsilon}{4} \tag{17}$$

because $1 \leq V_p \leq 2$ and $V_p(T,\cdot) = g$. From our assumption, $V^\sharp(T,x_0) \geq g(x_0) + \epsilon$, we deduce that there are a subsequence p_k and some (t_k, x_k) converging to (T, x_0) such that

$$\lim_{k\to+\infty} V_{p_k}(t_k,x_k) = V^\sharp(T,x_0) \geq g(x_0) + \epsilon.$$

Hence, for k sufficiently large, we have

$$V_{p_k}(t_k, x_k) > \phi(t_k, x_k) \tag{18}$$

since $\phi(T, x_0) = g(x_0) + \epsilon/2$. Let us now notice that $V_{p_k} - \phi$ has a local maximum at some point $(s_k, y_k) \in [0, T] \times \mathbb{R}^n$ because $-(V_{p_k} - \phi)$ is coercive. From (18), this maximum is positive. Thus, from (17), we have $s_k \in (0, T)$. Since V_{p_k} is the solution to (13), we have

$$\alpha + \mathcal{H}((p_k - 1)V_{p_k}^{-1}(s_k, y_k)\beta^2(y_k - x_0)(y_k - x_0)^* + \beta I) \leq 0, \tag{19}$$

where

$$\mathcal{H}((p_k - 1)V_{p_k}^{-1}(s_k, y_k)\beta^2(y_k - x_0)(y_k - x_0)^* + \beta I) = -\beta(n - 1).$$

This is in contradiction with (19) since $\alpha > \beta(n - 1)$. Therefore, we have proved that $V^\sharp(T, \cdot) \leq g$.

Conclusion. From the previous steps, we know that $V^\sharp$ is a subsolution of (9) with $V^\sharp(T, \cdot) \leq g$, while V is a lower semicontinous supersolution of (9) with $V(T, \cdot) \geq g$. Let us also recall that

$$\forall (t, x) \in [0, T] \times \mathbb{R}^n, \ V(t, x) \leq V^\sharp(t, x).$$

Therefore,

$$\forall x \in \mathbb{R}^n, \ V(T, x) = V^\sharp(T, x) = g(x).$$

Since g is uniformly continuous and since V and $V^\sharp$ are globally bounded, the comparison principle of [10] states that $V^\sharp \leq V$. Therefore, we have proved that $V^\sharp = V$ is the solution to (9).

Remark. In particular, V is continuous.

Proof of Lemma 1.2. Let us recall that

$$\forall S \in \mathcal{S}_n, \quad \lambda_{max}(S) = \max_{|a|=1} \langle Sa, a \rangle.$$

Hence, if $\dim(\mathrm{Ker}(S - \lambda_{max}(S)I)) = 1$, standard argument show that λ_{max} is differentiable at S and that

$$\forall H \in \mathcal{S}_n, \quad D\lambda_{max}(S)(H) = \langle Ha(S), a(S) \rangle,$$

where $a(S)$ is an eigenvalue associated with $\lambda_{max}(S)$ with $|a(S)| = 1$. Moreover, the map $(\lambda, S') \to \dim(\mathrm{Ker}(S' - \lambda I))$ being upper semicontinuous, there is a neighborhood $\mathcal{O}$ of S on which $\dim(\mathrm{Ker}(S' - \lambda_{max}(S')I)) = 1$ for any $S' \in \mathcal{O}$. Hence λ_{max} is differentiable at S' for $S' \in \mathcal{O}$, and its derivative is again given by $D\lambda_{max}(S')(H) = \langle Ha(S'), a(S') \rangle$. This map is clearly continuous (because $\dim(\mathrm{Ker}(S' - \lambda_{max}(S')I)) = 1$), and we have proved that λ_{max} is $\mathcal{C}^1$ in a neighborhood of S. □

2. The representation formula. In this section, we briefly recall the level set method for the MCM, and we prove the representation formula given in the introduction.

Let Σ_0 be a closed subset of $\mathbb{R}^n$, and let $g : \mathbb{R}^n \to \mathbb{R}$ be a uniformly continuous bounded function vanishing on Σ_0:

$$\Sigma_0 = \{x \in \mathbb{R}^n \mid g(x) = 0\}. \tag{20}$$

Let us consider the solution (in the viscosity sense) to

$$\left\{ \begin{array}{ll} u_t = |Du| curv(u) & \text{on } (0,+\infty)\times\mathbb{R}^n, \\ u(0,\cdot) = g & \text{on } \mathbb{R}^n, \end{array} \right. \tag{21}$$

where $curv(u) = \mathrm{div}(Du/|Du|) = (\Delta u - \frac{\langle D^2uDu, Du\rangle}{|Du|^2})/|Du|$. It is known (see [5], [7]) that the set

$$\Sigma_t = \{x \in \mathbb{R}^n \mid u(t,x) = 0\}$$

does not depend on g but only on $\Sigma_0 = \{g = 0\}$: Namely, if g_1 and g_2 are two uniformly continuous, bounded functions, such that

$$\Sigma_0 = \{g_1 = 0\} = \{g_2 = 0\},$$

then the associated solutions u_1 and u_2 satisfy

$$\Sigma_t = \{u_1(t,\cdot) = 0\} = \{u_2(t,\cdot) = 0\}.$$

The moving sets (Σ_t) can be understood as a generalized motion by mean curvature. Indeed, if there is a classical solution to the MCM starting from Σ_0 on some interval $[0,T]$, then this classical solution coincides with (Σ_t) on $[0,T]$.

Let us recall that the front (Σ_t) built by this method is sometimes called the biggest flow because it contains any distance solution of the MCM. (See the next section for the definition of distance solution.)

Remark. The connection between (9) and (21) is the following: A function $u : \mathbb{R}_+ \times \mathbb{R}^n \to \mathbb{R}$ is a solution to (21) if and only if, for any $T > 0$, the function $u^T(s,y) = u(T-s,y)$ is a solution to (9).

THEOREM 2.1. *Let (Σ_t) be defined as above. Then*

$$\Sigma_t = \{x \in \mathbb{R}^n \mid \exists v(\cdot) \in \mathcal{A} \;\; \textit{such that } X^{x,v(\cdot)}(t) \in \Sigma_0 \;\textit{a.s.}\},$$

where $X^{x,v(\cdot)}(s)$ is the solution to

$$\left\{ \begin{array}{l} dX^{x,v(\cdot)}(s) = \sqrt{2}v(s)dW(s), \\ X^{x,v(\cdot)}(0) = x. \end{array} \right. \tag{22}$$

Proof of Theorem 2.1. Let $t > 0$ be fixed. Let g be a nonnegative, bounded, uniformly continuous function satisfying (20), and let u be the solution to (21). Let us set $V(s,y) = u(t-s,y)$. Then V is the solution to (9), with a terminal time $T = t$; hence it is equal to the value function defined by (7).

Therefore, a point x belongs to Σ_t if and only if $V(0,x) = u(t,x) = 0$, i.e., there is some optimal control $v(\cdot) \in \mathcal{A}$ for $V(0,x)$ (cf. the remark to Theorem 1.1) such that the solution $X^{0,x,v(\cdot)}$ of (8) satisfies

$$\text{ess-sup}_\Omega g(X^{0,x,v(\cdot)}(t)) = 0.$$

Since g is nonnegative and satisfies (20), this means that

$$X^{0,x,v(\cdot)}(t) \in \Sigma_0 \quad \text{a.s.}$$

Moreover, $X^{0,x,v(\cdot)}$ of (8) is nothing but the solution $X^{x,v(\cdot)}$ of (22). This shows that a point x belongs to Σ_t if and only if there is some control $v(\cdot) \in \mathcal{A}$ such that $X^{x,v(\cdot)}(t) \in \Sigma_0$ a.s. $\square$

3. Characterization of distance solutions of the MCM. We say that a family (Σ_t) of moving sets is a distance solution of the MCM if the function $u(t,x) = \mathbf{1}_{\Sigma_t}(x)$ is a discontinuous solution of the following equation:

$$\left\{\begin{array}{ll} u_t = |Du|curv(u) & \text{on } (0,+\infty)\times\mathbb{R}^n, \\ u(0,\cdot) = \mathbf{1}_{\Sigma_0} & \text{on } \mathbb{R}^n. \end{array}\right. \tag{23}$$

This means that the half-relaxed upper-limit u^* is a subsolution of (23), with $u^* \leq (\mathbf{1}_{\Sigma_0})^*$ at $t=0$, while the half-relaxed lower-limit u_* is a subsolution of (23), with $u_* \geq (\mathbf{1}_{\Sigma_0})_*$ at $t=0$. Let us point out that distance solutions are not unique in general. The biggest solution, i.e., the solution given by the level set method, is a distance solution.

Notation. If (Σ_t) is a family of moving sets, we set

$$\bar{\Sigma}_t = L_{t'\to t}\Sigma_{t'} = \{x\in\mathbb{R}^n \mid \exists t_k\to t,\ x_k\in\Sigma_{t_k} \text{ with } x_k\to x\}.$$

In the same way, we set

$$\widehat{\Sigma}_t = \mathrm{Limsup}_{t'\to t}\mathbb{R}^n\backslash\Sigma_t = \{x\in\mathbb{R}^n \mid \exists t_k\to t,\ x_k\notin\Sigma_{t_k} \text{ with } x_k\to x\}.$$

We characterize the fact that (Σ_t) is moving by the mean curvature in terms of the viability of (Σ_t) and $(\mathbb{R}^n\backslash\Sigma_t)$ for the stochastic control system (22).

PROPOSITION 3.1. *Let (Σ_t) be a family of moving sets satisfying the initial condition:*

$$\overline{\Sigma_0} = \bar{\Sigma}_0 \quad \text{and} \quad \overline{\mathbb{R}^n\backslash\Sigma_0} = \widehat{\Sigma}_0. \tag{24}$$

Then (Σ_t) is a distance solution of the MCM if and only if the two following properties are satisfied:

(i) *For any $t\geq 0$ and any $x\in\bar{\Sigma}_t$, there exists some $v(\cdot)\in\mathcal{A}$ such that the solution $X^{x,v(\cdot)}$ of* (22) *satisfies*

$$\forall s\in[0,t], \qquad X^{x,v(\cdot)}(s)\in\bar{\Sigma}_{t-s} \quad a.s.$$

(ii) *For any $t\geq 0$ and any $x\in\widehat{\Sigma}_t$, there exists some $v(\cdot)\in\mathcal{A}$ such that the solution $X^{x,v(\cdot)}$ of* (22) *satisfies*

$$\forall s\in[0,t], \qquad X^{x,v(\cdot)}(s)\in\widehat{\Sigma}_{t-s} \quad a.s.$$

Remarks.

1. Actually, property (i) is equivalent with the fact that u is a subsolution of (23), while property (ii) is equivalent with the fact that u is a supersolution.
2. Since the solution given by the level set method is a distance solution, this means that this solution satisfies (i) and (ii).

The proposition is an application of a stochastic viability theorem (Theorem A.1) given in the appendix.

Proof of Proposition 3.1. We are going to prove that the map $u(t,x) = \mathbf{1}_{\Sigma_t}(x)$ is a subsolution of (23) if and only if (Σ_t) satisfies (i). The proof that u is a supersolution of (23) if and only if (Σ_t) satisfies (ii) is similar, and so we omit it.

Let us notice that $u^*(t,x) = \mathbf{1}_{\bar{\Sigma}_t}(x)$. From Theorem A.1, (ii), applied to the control system (8), the fact that $u(t,x) = \mathbf{1}_{\Sigma_t}(x)$ is a subsolution of (23) means that, for any $T>0$, the family of moving sets $(K_t^T)_{t\in[0,T]}$ defined by

$$\forall t\in[0,T],\ \ K_t^T = \bar{\Sigma}_{T-t}$$

is a viability domain (cf. Definition A.2 below) for the stochastic control system (8).

Let us first assume that u is a subsolution of (23). Then, for any $t > 0$ and any $x \in \Sigma_t$, the viability theorem applied to the viability domain $(K_s^T)_{s\in[0,T]}$, for some $T > t$, together with Remark A.1 part 3, implies that there is some control $v \in \mathcal{A}$ such that the solution $X^{0,x,v(\cdot)}$ of (8) satisfies

$$\forall s \in [0,t],\ X^{0,x,v(\cdot)}(s) \in K_{T-t+s}^T = \bar{\Sigma}_{t-s},$$

because the point x belongs to $K_{T-t}^T = \bar{\Sigma}_t$. Therefore, part (i) of the proposition is satisfied since the solution $X^{0,x,v(\cdot)}$ is nothing but the solution $X^{x,v(\cdot)}$ of (22).

Conversely, let us now assume that assertion (i) of the proposition holds true. Then Remark A.1 part 3 implies that, for any $T > 0$, the family (K_t^T) is a viability domain for system (8). Hence u is a subsolution of (23). □

4. Representation formula for anisotropic flows. In this section we consider geometric equations of the form

$$u_t = F(Du, D^2u). \tag{25}$$

By geometric, we mean that the function $F : \mathbb{R}^n\backslash\{0\} \times \mathcal{S}_n \to \mathbb{R}$ is elliptic, i.e.,

$$F(p,A) \le F(p,B) \qquad \text{whenever } A \le B \tag{26}$$

and satisfies the following conditions: for all $a \in \mathbb{R}\backslash\{0\}$ and for all $\sigma \in \mathbb{R}$,

$$F(ap, aX) = aF(p,X) \text{ and } F(p, X + \sigma pp^*) = F(p,X). \tag{27}$$

A geometric equation enjoys the so-called invariance property: If u is a solution to (25) in the viscosity sense, then, for any continuous function $\theta : \mathbb{R} \to \mathbb{R}$, the function $\theta(u)$ also satisfies (25) (cf. [5], [7]). With such an equation, one can associate a geometric flow: If Σ_0 is a closed subset of $\mathbb{R}^n$, the flow (Σ_t) of Σ_0 by F is defined by

$$\forall t \ge 0,\ \ \Sigma_t = \{x \in \mathbb{R}^n \mid u(t,x) = 0\},$$

where $u : \mathbb{R}_+ \times \mathbb{R}^n \to \mathbb{R}$ is the viscosity solution to

$$\left\{ \begin{array}{ll} u_t = F(Du, D^2u) & \text{on } (0,+\infty) \times \mathbb{R}^n, \\ u(0,\cdot) = g & \text{on } \mathbb{R}^n, \end{array} \right. \tag{28}$$

and where $g : \mathbb{R}^n \to \mathbb{R}^n$ is some uniformly continuous and bounded function vanishing on Σ_0. If F satisfies (27) and the following regularity conditions:

$$\left\{ \begin{array}{rl} \text{(i)} & F \text{ is continuous on } (\mathbb{R}^n\backslash\{0\}) \times \mathcal{S}_n, \\ \text{(ii)} & F \text{ is bounded on bounded subset of } (\mathbb{R}^n\backslash\{0\}) \times \mathcal{S}_n, \\ \text{(iii)} & F^*(0,0) = F_*(0,0) = 0, \end{array} \right. \tag{29}$$

then the set Σ_t depends only on Σ_0 and not on g.

In this section, we give a representation formula for the solution of (28) and for the flow (Σ_t) when F satisfies (26), (27), (29), and the following additional conditions:

$$\left\{ \begin{array}{rl} \text{(i)} & S \to F(p,S) \text{ is concave for any } p \neq 0, \\ \text{(ii)} & \forall p \neq 0,\ \forall S \in \mathcal{S}_n,\ \forall \lambda \in (\mathbb{R}\backslash\{0\}),\ F(\lambda p, S) = F(p,S), \\ \text{(iii)} & \forall p \neq 0,\ \forall S \in \mathcal{S}_n,\ \forall x \notin \mathbb{R}p,\ F(p, S + xx^*) > F(p,S). \end{array} \right. \tag{30}$$

We comment upon these assumptions after the statement of the lemma.

LEMMA 4.1. *Let* $F : \mathbb{R}^n\backslash\{0\} \times \mathcal{S}_n \to \mathbb{R}$ *satisfy* (26), (27), (29), *and* (30). *There is some compact subset* $\mathcal{V}_F$ *of* $\mathcal{S}_n$ *such that*

$$\forall (p, S) \in \mathbb{R}^n\backslash\{0\} \times \mathcal{S}_n, \;\; F(p, S) = \min_{v\in\mathcal{V}_F,\, vp=0} \mathrm{Tr}(Sv^2), \tag{31}$$

and

$$\{v^2 \mid v \in \mathcal{V}_F\} \quad \textit{is convex and compact.} \tag{32}$$

Remarks.

1. The lemma still holds true if we assume that assumption (27) is satisfied only for $a > 0$. However, in this case, the geometric equation associated with (25) is orientation dependent. This means that the correct definition of the associated flow (Σ_t) by the level set method requires the function g in (28) to be positive in the interior of Σ_0 and negative outside. Then the second part of Theorem 4.2 does not hold true anymore.
2. Conditions (30) (i) and (ii) are clearly necessary for formula (31) to hold true. Although (30) (iii) does not seem necessary, it cannot be omitted. For instance, let us assume that F is of the form
$$F(p, S) = \phi(p/|p|)\left(\mathrm{Tr}(S) - \frac{\langle Sp, p\rangle}{|p|^2}\right),$$
where $\phi : \mathbb{R}^n\backslash\{0\} \to \mathbb{R}$ is a continuous nonnegative function which is homogeneous of degree zero, which vanishes at some point $p_0 \neq 0$ and is not identically zero. Then F satisfies all the assumptions of Lemma 4.1 but (30) (iii). We claim that there is no set $\mathcal{V}_F$ such that equality (31) holds true. Indeed, otherwise, the set $\mathcal{V}_F$ should contain 0 because $F(p_0, \cdot) = 0$. In that case, equality (31) implies that $F \leq 0$, which is impossible since we have assumed that ϕ is a nonnegative function and is not identically zero. Therefore, there is no set $\mathcal{V}_F$ such that the representation formula (31) holds true for F.
3. The set $\mathcal{V}_F$ can be constructed as follows: Let C_p be defined as
$$\forall p \neq 0, \;\; C_p = \{w \in \mathcal{S}_n \mid \forall S \in \mathcal{S}_n, \; \mathrm{Tr}(Sw) \geq F(p, S)\},$$
and $C = \bigcup_{p\neq 0} C_p$. Then we can take
$$\mathcal{V}_F = \{v \in \mathcal{S}_n^+ \mid v^2 \in Co(C)\},$$
where $\mathcal{S}_n^+$ is the set of all $n \times n$ symmetric nonnegative matrices and where $Co(C)$ stands for the convex hull of the set C.

Proof. Let us first notice that, for any $p \neq 0$, the map $S \to F(p, S)$ is positively homogeneous. Indeed, from (27) and (30) (ii), we have

$$\forall S \in \mathcal{S}_n, \; \forall \lambda > 0, \; F(p, \lambda S) = \lambda F(p/\lambda, S) = \lambda F(p, S).$$

Let C_p be defined as in the remark. From the separation theorem applied to $F(p, \cdot)$, which is concave from assumption (30) (i) and positively homogeneous, the set C_p is nonempty, and we have

$$\forall S \in \mathcal{S}_n, \;\; F(p, S) = \inf_{w\in C_p} \mathrm{Tr}(Sw). \tag{33}$$

Let us also notice that, from assumption (30) (ii), we have

$$\forall p \neq 0,\ \forall \lambda \in \mathbb{R}\backslash\{0\},\ C_{\lambda p} = C_p. \tag{34}$$

Hence, from the definition of C_p, the set $\bigcup_{p\neq 0} C_p = \bigcup_{|p|=1} C_p$ is closed. Let us also point out that C_p is convex for any $p \neq 0$.

We claim that

$$\forall p \neq 0,\ \forall w \in C_p,\ \text{we have } w \geq 0 \text{ and} \quad \mathrm{Ker}(w) = \mathbb{R}p, \tag{35}$$

where Ker(w) stands for the kernel of w.

Proof of the claim. Let $w \in C_p$. For any $x \in \mathbb{R}^n$, we have, from (26) and (33) applied with $S = xx^*$,

$$0 = F(p, 0) \ \leq\ F(p, xx^*) \ \leq\ \langle wx, x\rangle.$$

Hence $w \geq 0$. Using assumption (27), (30) (ii), and (33), we get, for any $\lambda \in \mathbb{R}\backslash\{0\}$,

$$0 = F(p, \lambda pp^*) \ \leq\ \lambda\langle wp, p\rangle,$$

from which we deduce that $\mathbb{R}p \subset \mathrm{Ker}(w)$. Finally, from (30) (iii), we have, for $x \notin \mathbb{R}p$,

$$0 = F(p, 0) \ <\ F(p, xx^*) \ \leq\ \langle wx, x\rangle,$$

which implies that $\mathrm{Ker}(w) \subset \mathbb{R}p$.

We now claim that C_p is bounded independently of $p \neq 0$. Let $p \neq 0$ and $w \in C_p$. From (33) applied to $S = -I_n$, we have

$$\mathrm{Tr}(Sw) = -\mathrm{Tr}(w) \geq F(p, -I_n) \geq \min_{|q|=1} F(q, -I_n) > -\infty,$$

because F is continuous on $\mathbb{R}^n\backslash\{0\} \times \mathcal{S}_n$ (assumption (29)). From this inequality, we deduce that

$$\forall p \in \mathbb{R}^n\backslash\{0\},\ \forall w \in C_p, \quad \mathrm{Tr}(w) \leq -\min_{|q|=1} F(q, -I_n),$$

which in turn implies that C_p, for $p \neq 0$, are uniformly bounded since the w are nonnegative matrices. In particular, this proves that the set $C = \bigcup_{p\neq 0} C_p$ is compact.

We now claim that

$$\forall p \neq 0,\ \{w \in Co(C) \mid wp = 0\} = C_p. \tag{36}$$

Proof. Let us first notice that (35) implies that C_p is contained in $\{w \in Co(C) \mid wp = 0\}$. Let w belong to $Co(C)$ with $wp = 0$. There are $w_i \in C_{p_i}$ for some $p_i \neq 0$ and $\lambda_i \geq 0$, $\sum_i \lambda_i = 1$, such that $w = \sum_i \lambda_i w_i$. Then $wp = 0$ implies that

$$0 = \left\langle \sum_i \lambda_i w_i p, p \right\rangle = \sum_i \lambda_i \langle w_i p, p\rangle.$$

From (35), $\langle w_i p, p\rangle \geq 0$ for any i, and thus $\langle w_i p, p\rangle = 0$. Then (35) again states that $p_i \in \mathbb{R}p$, which proves that, for any i, $w_i \in C_{p_i} = C_p$ from (34). Since C_p is convex, w belongs to C_p, and (36) is established.

Let us finally set

$$\mathcal{V}_F = \{v \in \mathcal{S}_n^+ \mid v^2 \in Co(C)\}.$$

Let us notice that

$$\{v^2 \mid v \in \mathcal{V}_F\} = Co(C)$$

because, for any $w \in Co(C)$, we have $w \geq 0$ from (35), and thus there is some $v \in \mathcal{S}_n^+$ with $v^2 = w$. Hence (32) is satisfied because $Co(C)$ is convex and compact. We now prove equality (31). We have

$$\forall (p, S) \in \mathbb{R}^n \backslash \{0\} \times \mathcal{S}_n, \quad \min_{v \in \mathcal{V}_F,\, vp=0} \mathrm{Tr}(Sv^2) = \min_{w \in Co(C),\, wp=0} \mathrm{Tr}(Sw) = \min_{w \in C_p} \mathrm{Tr}(Sw)$$

from (36). Thus we have, from (33),

$$\forall (p, S) \in \mathbb{R}^n \backslash \{0\} \times \mathcal{S}_n, \quad \min_{w \in C,\, vp=0} \mathrm{Tr}(Sv^2) = \min_{w \in C_p} \mathrm{Tr}(Sw) = F(p, S),$$

which proves (31). □

THEOREM 4.2. *Let us assume that F satisfies* (26), (27), (29), *and* (30). *Let $\mathcal{V}_F$ satisfy properties* (31) *and* (32) *of Lemma* 4.1, *and let us denote by $\mathcal{A}_F = \mathcal{A}_F(\Omega, \mathcal{F}, P; W)$ the set of all $\mathcal{V}_F$-valued $(\mathcal{F}_s)$-progressively measurable processes $v(\cdot)$. Then the following hold.*

1. *For any uniformly continuous, bounded function $g : \mathbb{R}^n \to \mathbb{R}^n$, the solution u of* (28) *can be represented as follows:*

$$\forall (t, x) \in \mathbb{R}_+ \times \mathbb{R}^n, \quad u(t, x) = \inf_{v(\cdot) \in \mathcal{A}_F} \text{ess-sup}_\Omega g(X^{x,v(\cdot)}(t)),$$

where $X^{x,v(\cdot)}$ is the solution to

$$\left\{ \begin{array}{l} dX^{x,v(\cdot)}(s) = \sqrt{2} v(s) dW(s), \\ X^{x,v(\cdot)}(0) = x. \end{array} \right. \tag{37}$$

2. *The front (Σ_t) associated with F can be represented as follows:*

$$\forall t \geq 0,\ \Sigma_t = \{x \in \mathbb{R}^n \mid \exists v(\cdot) \in \mathcal{A}_F \text{ such that } X^{x,v(\cdot)}(t) \in \Sigma_0 \text{ a.s.}\},$$

where $X^{x,v(\cdot)}$ is the solution to (37).

Remark. Distance solutions of the evolution equation associated with (25) can be characterized exactly as in Proposition 3.1.

Proof. It is the same proof as for Theorems 1.1 and 2.1. So we omit it. □

Appendix. A viability theorem. Let us consider a stochastic control system described by the following differential equation:

$$\left\{ \begin{array}{l} dX(s) = b(s, X(s), v(s))ds + \sigma(s, X(s), v(s))dW(s), \\ X(t) = x, \end{array} \right. \tag{38}$$

where $\mathcal{V}$ is a compact metric space, $b : [0, T] \times \mathbb{R}^n \times \mathcal{V} \to \mathbb{R}^n$, $\sigma : [0, T] \times \mathbb{R}^n \times \mathcal{V} \to \mathbb{R}^{n \times d}$, and W is now a d-dimensional standard Brownian motion. We denote by $X^{t,x,v(\cdot)}$ the solution of (38).

Let $(K_t)_{t \in [0,T]}$ be a family of moving sets. The aim of the following theorem is to give a necessary and sufficient condition for the existence of an admissible control $v(\cdot)$ that keeps $X^{t,x,v(\cdot)}(s)$ in K_s for $s \in [t, T]$, whenever $x \in K_t$.

In what follows, we assume that the control system satisfies the following conditions:

(H1) b and σ are uniformly continuous in (t,x,v);

(H2) $|\sigma(t,x,v)-\sigma(t,x',v)| \le C_0|x-x'|$ for all $t\in[0,T]$, for all $x,x'\in\mathbb{R}^n$, for all $v\in\mathcal{V}$;

(H3) $\langle b(t,x,v)-b(t,x',v),x-x'\rangle \le \mu|x-x'|^2$ for all $t\in[0,T]$, for all $x,x'\in\mathbb{R}^n$, for all $v\in\mathcal{V}$;

(H4) the set $\left\{\left(\frac{1}{2}\sigma\sigma^*(t,x,v),b(t,x,v)\right),\ v\in\mathcal{V}\right\}$ is convex and compact for all $t\in[0,T]$, for all $x\in\mathbb{R}^n$.

The following result is strongly inspired by several results already existing in the literature (see [1], [2], [4], [9]). We give here a version for time dependent sets.

THEOREM A.1. *Let $(K_t)_{t\in[0,T]}$ be a family of moving sets such that the set K defined by*

$$K=\bigcup_{t\in[0,T]}\{t\}\times K_t$$

is a closed subset of $[0,T]\times\mathbb{R}^n$. Let us assume that conditions (H1)$-$(H4) *are satisfied by the stochastic control system* (38)*. Then the following statements are equivalent:*

(i) *For any $t\in(0,T)$, for any $x\in K_t$, there is a control $v(\cdot)\in\mathcal{A}$ such that the solution $X^{t,x,v(\cdot)}$ to* (38) *satisfies*

$$\forall s\in[t,T],\ X^{t,x,v(\cdot)}(s)\in K_s \text{ a.s.}$$

(ii) *The map $u(t,x)=1-\mathbf{1}_{K_t}(x)$ is a supersolution to the following equation:*

$$u_t(t,x)+\inf_{v\in\mathcal{V},\ \sigma(t,x,v)^*Du(t,x)=0}\mathcal{L}_{t,x,v}u=0, \tag{39}$$

where $\mathcal{L}$ is the operator defined by

$$\mathcal{L}_{t,x,v}u=\langle b(t,x,v),Du(t,x)\rangle+\frac{1}{2}\mathrm{Tr}\left(D^2u\sigma\sigma^*\right)(t,x,v),$$

and where we use the convention $\inf_\emptyset=+\infty$.

(iii) *For any $\mathcal{C}^2$ function $\phi:[0,T]\times\mathbb{R}^n\to\mathbb{R}$ with a local maximum on K at (t,x), we have*

$$\phi_t(t,x)+\inf_{v\in\mathcal{V},\ \sigma(t,x,v)^*D\phi(t,x)=0}\left(\mathcal{L}_{t,x,v}\phi\right)\le 0.$$

Remark A.1.

1. The map $u(t,x)=1-\mathbf{1}_{K_t}(x)$ is lower semicontinuous (but not continuous in general) since the set K is closed.
2. Let us assume that the family (K_t) satisfies one of the above statements and the following regularity condition at time $t=0$:

$$\forall x\in K_0,\ \exists t_k\to 0,\ \exists x_k\in K_{t_k} \text{ with } x_k\to x. \tag{40}$$

Then (i) holds true up to time $t=0$.

3. The statements of Theorem A.1 are equivalent with the following assertion: For any $t\in(0,T)$, for any $x\in K_t$, there is a control $v(\cdot)\in\mathcal{A}$ such that the solution X of

$$\begin{cases} dX(s)=b(t+s,X(s),v(s))dt+\sigma(t+s,X(s),v(s))dW(s),\\ X(0)=x,\end{cases} \tag{41}$$

satisfies

$$\forall s\in[0,T-t],\ X(s)\in K_{t+s} \text{ a.s.}$$

Parts 2 and 3 of the remark are proved below.

Definition A.2. *If a family of moving sets* (K_t) *satisfies one of the equivalent conditions of Theorem* A.1, *we say that it is a viability domain for the controlled system* (38).

Proof of Theorem A.1. We are going to prove the following implications: (iii)⇒(ii) ⇒ (i)⇒(iii).

(iii)⇒(ii). This is straightforward, and we leave this proof to the reader.

(ii) ⇒ (i). Let us consider a uniformly continuous map $f : [0,T] \times \mathbb{R}^n \to \mathbb{R}$ such that

$$\forall (t,x) \in [0,T] \times \mathbb{R}^n,\ 0 \leq f(t,x) \leq 1, \quad \text{and} \quad f(t,x) = 0 \Leftrightarrow x \in K_t. \tag{42}$$

We introduce the following optimal control problem:

$$V(t,x) = \inf_{v \in \mathcal{A}} E \int_t^T f(s, X^{t,x,v(\cdot)}(s))ds.$$

It is known that $V(t,x)$ is the unique solution to the following equation:

$$V_t(t,x) + \inf_{v \in \mathcal{V}} (\mathcal{L}_{t,x,v} V)(t,x) + f(t,x) = 0 \tag{43}$$

with terminal condition $V(T,\cdot) = 0$ (cf. [8]). Moreover, the value function V is uniformly continuous and bounded. Finally, for any (t,x) there is at least one optimal control $v(\cdot)$, cf. [6]. Hence (i) holds true if and only if $V = 0$ on $K \cap (0,T)$.

Since u is a supersolution to (39), a straightforward computation shows that the map $w(t,x) = e^{(T-t)}u(t,x)$ satisfies (in the viscosity sense)

$$w_t + \inf_v \mathcal{L}_{t,x,v} w + w \leq 0.$$

Thus w is a supersolution of (43) because $f \leq w$ from (42). Moreover, w and V satisfy the following terminal conditions at time T:

$$w(T,\cdot) \geq 0 \quad \text{and} \quad V(T,\cdot) = 0.$$

Hence, from the comparison principle (see [8]), we have $w \geq V$ on $(0,T] \times \mathbb{R}^n$. Therefore, $V = 0$ on $K \cap (0,T)$, and implication (ii) ⇒ (i) is established.

(i) ⇒ (iii). Let ϕ be a test function with a local maximum on K at (t,x) with $t \in (0,T)$. This means that

$$\forall (s,y) \in K \cap B((t,x),r),\ \ \phi(s,y) \leq \phi(t,x) \tag{44}$$

for some $r > 0$, where $B((t,x),r) = [t-r, t+r] \times B(x,r)$ ($B(x,r)$ being the ball centered at x of radius r). From (i), there is some admissible control $v(\cdot) \in \mathcal{A}$ such that the solution $X^{t,x,v(\cdot)}$ satisfies

$$\forall s \in [t,T],\ \ X^{t,x,v(\cdot)}(s) \in K_s \quad \text{a.s.} \tag{45}$$

For any $\epsilon \in (0,r)$, let us introduce the stopping time τ_ϵ defined by

$$\tau_\epsilon = (t+\epsilon) \wedge \inf\{s \geq t\ ,\ |X^{t,x,v(\cdot)}(s) - x| > \epsilon\}.$$

Then, from (44) and (45), we have

$$\forall s > t,\ \ \phi(s \wedge \tau_\epsilon, X^{t,x,v(\cdot)}(s \wedge \tau_\epsilon)) \leq \phi(t,x).$$

From standard arguments, the fact that this inequality holds for any $s > t$ and any $\epsilon > 0$ implies that

$$\phi_t(t,x) + \inf_{v\in\mathcal{V}} (\mathcal{L}_{t,x,v}\phi)(t,x) \leq 0. \tag{46}$$

Let $\theta : \mathbb{R} \to \mathbb{R}$ be an increasing function such that $\theta'(\phi(t,x)) = 1$ and $\theta''(\phi(t,x)) = \alpha$, where $\alpha > 0$ is arbitrary. Since ϕ has a local maximum on K at (t,x), $\theta \circ \phi$ also has a local maximum on K at (t,x). Hence, from the definition of $\mathcal{L}$ and inequality (46), we have at the point (t,x)

$$\phi_t + \inf_{v\in\mathcal{V}} \left(\langle b, D\phi\rangle + \frac{1}{2}\mathrm{Tr}((\alpha D\phi D\phi^* + D^2\phi)\sigma\sigma^*) \right) \leq 0. \tag{47}$$

Let $v_\alpha \in \mathcal{V}$ be a minimum in the above expression. When $\alpha \to +\infty$, the expresssion

$$\mathrm{Tr}(\alpha D\phi(t,x)D\phi(t,x)^*\sigma(t,x,v_\alpha)\sigma^*(t,x,v_\alpha)) = \alpha|\sigma^*(t,x,v_\alpha)D\phi(t,x)|^2$$

remains bounded, which proves, since $\mathcal{V}$ is compact, that there are some $\alpha_k \to +\infty$ and some $v \in \mathcal{V}$ such that $v_{\alpha_k} \to v$ and $\sigma^*(t,x,v)D\phi(t,x) = 0$. Let us also point out that, for any k, inequality (47) implies that

$$\phi_t + \langle b(v_{\alpha_k}), D\phi\rangle + \frac{1}{2}\mathrm{Tr}(D^2\phi\sigma(v_{\alpha_k})\sigma^*(v_{\alpha_k})) \leq 0,$$

where we have omitted the dependence in (t,x) for simplicity. Letting $k \to +\infty$ gives

$$\phi_t + \langle b(v), D\phi\rangle + \frac{1}{2}\mathrm{Tr}(D^2\phi\sigma(v)\sigma^*(v)) \leq 0.$$

Since $\sigma^*(t,x,v)D\phi(t,x) = 0$, we have proved the desired result. □

Proof of Remark A.1. We first prove part 2. If (K_t) enjoys property (40), then the value function V, defined above in the proof of (ii)⇒(i), vanishes also on $\{0\} \times K_0$. Indeed, V is zero on $K \cap (0,T)$, and, from (40), any point of $\{0\} \times K_0$ can be approximated by a point of $K \cap (0,T)$. Hence (i) holds true up to time $t = 0$.

Let us now prove part 3 of the remark. We first assume that (K_t) is a viability domain for system (38). Let us fix some $t \in (0,T)$. Using characterization (ii) or (iii) of Theorem A.1, one can prove that the family $(\tilde{K}_s)_{s\in[0,T-t]}$ defined by

$$\forall s \in [0, T-t],\ \tilde{K}_s = K_{s+t}$$

is a viability domain for the stochastic control system

$$\begin{cases} d\tilde{X}(\tau) = \tilde{b}(\tau, \tilde{X}(\tau), v(\tau))d\tau + \tilde{\sigma}(\tau, \tilde{X}(\tau), v(\tau))dW(\tau), \\ \tilde{X}(s) = x, \end{cases} \tag{48}$$

where

$$\tilde{b}(\tau,y,v) = b(t+\tau,y,v) \quad \text{and} \quad \tilde{\sigma}(\tau,y,v) = \sigma(t+\tau,y,v).$$

We claim that $(\tilde{K}_s)_{s\in[0,T-t]}$ satisfies property (40). Indeed, for any $x \in \tilde{K}_0 = K_t$, there exists a control v for which the solution $X^{t,x,v}$ of (38) satisfies $X^{t,x,v}(s) \in K_s$ on $[t,T]$ a.s. Let us choose ω such that this property is satisfied and for which $s \to X^{t,x,v}_\omega(s)$ is continuous. Then, for any sequence $s_k \to t^+$, the sequence of points

$x_k = X_\omega^{t,x,v}(s_k)$ converges to x and belongs to K_{s_k}. Hence any point x of $\tilde{K}_0 = K_t$ can be approximated by a sequence of points x_k of $\tilde{K}_{s_k - t} = K_{s_k}$. This proves (40) for $\tilde{K}$. Now applying part 2 of Remark A.1 to the viability domain $(\tilde{K}_s)_{s\in[0,T-t]}$ gives, for any $x \in \tilde{K}_0$, the existence of some control $v(\cdot)$ such that the solution $\tilde{X}^{0,x,v(\cdot)}$ of (48) satisfies

$$\tilde{X}^{0,x,v(\cdot)}(\tau) \in \tilde{K}_\tau \quad \forall \tau \in [0, T-t] \text{ a.s.}$$

Since $\tilde{K}_\tau = K_{\tau+t}$ and since $\tilde{X}^{0,x,v(\cdot)}$ is nothing but the solution of (41), we have proved the desired result.

Let us now assume that the set (K_t) satisfies the conditions of part 3 of the remark. Let V be the value function defined in the above proof of (ii)⇒(i). Let us define V^t on $[0, T-t] \times \mathbb{R}^n$ by $V^t(s,y) = V(s+t, y)$. Then one easily checks that $V^t = \tilde{V}$, where $\tilde{V}$ is the value function of the following control problem:

$$\tilde{V}(s,y) = \inf_{v \in \mathcal{A}} E \int_s^{T-t} f(t+\tau, \tilde{X}^{s,y,v(\cdot)}(\tau))d\tau,$$

where $\tilde{X}^{s,y,v(\cdot)}$ is the solution to (48). Indeed, V^t and $\tilde{V}$ both satisfy the same equation on $(0, T-t) \times \mathbb{R}^n$ (namely, (43) with $\tilde{f}(s,\cdot) = f(s+t,\cdot)$ instead of f) and have the same terminal condition $V^t(T-t,\cdot) = \tilde{V}(T-t,\cdot) = 0$. Moreover, our assumption implies that $V^t = \tilde{V}$ vanishes on $\{0\} \times \tilde{K}_0$. This means that the value function V vanishes on $\{t\} \times K_t$. This in turn implies that, for any $x \in K_t$, there is an optimal control v for $V(t,x)$ (cf. [6]) such that the solution $X^{t,x,v}$ of (38) satisfies $X^{t,x,v}(s) \in K_s$ on $[t,T]$ a.s. Since this holds true for any $t \in (0,T)$, we have proved that (K_t) is a viability domain for (38). □

Acknowledgment. We would like to thank J.-P. Aubin for suggesting the characterization in terms of viability given in section 3.

MATHEMATICAL JUSTIFICATION OF THE HYDROSTATIC APPROXIMATION IN THE PRIMITIVE EQUATIONS OF GEOPHYSICAL FLUID DYNAMICS*

PASCAL AZÉRAD† AND FRANCISCO GUILLÉN‡

Abstract. Geophysical fluids all exhibit a common feature: their aspect ratio (depth to horizontal width) is very small. This leads to an asymptotic model widely used in meteorology, oceanography, and limnology, namely the hydrostatic approximation of the time-dependent incompressible Navier–Stokes equations. It relies on the hypothesis that pressure increases linearly in the vertical direction. In the following, we prove a convergence and existence theorem for this model by means of anisotropic estimates and a new time-compactness criterium.

Key words. Navier–Stokes equations, shallow domains, geophysical fluid dynamics, hydrostatic approximation, singular perturbation, compactness criterium, asymptotic analysis

1. Introduction.

Atmospheric flow in meteorology, water flow in oceanography, and limnology are all described by the Navier–Stokes equations. Due to the fact that the aspect ratio

$$\epsilon = \frac{\text{characteristic depth}}{\text{characteristic width}}$$

is very small in most geophysical domains, asymptotic models have been used; see, e.g., [9, 15, 22]. One such model is the primitive equations model; see, e.g., [11, 12], wherein the unknown flow variables are velocity, pressure, temperature, and salinity (in the case of an ocean). Besides, most geophysical fluids are stratified (i.e., density is a known function of the temperature (and salinity, if any)) and have a free surface. We shall not investigate these features in this paper, leaving it, rather, for forthcoming work.

Instead we shall focus on the assumption that the pressure is hydrostatic, i.e., increases linearly with respect to the depth, as in the static case. This law agrees well with experiment (as first observed by Blaise Pascal around 1650; see [14])) and is frequently taken as a hypothesis in geophysical fluid dynamics. We justify this assumption by means of asymptotic analysis (taking ϵ as the small parameter). Our derivation is made possible by the use of anisotropic eddy viscosities, namely $\nu = (\nu_x, \nu_y, \nu_z)$, relying on the fact that the ratio between the horizontal and vertical scales leads to very different sizes for the horizontal and vertical eddies (see [9, 15]). Specifically, if we assume that $\nu = (\nu_1, \nu_2, \epsilon^2 \nu_3)$ with $\nu_i = \mathrm{O}(1)$ for $i = 1, 2, 3$, then we will see that weak solutions of the Navier–Stokes equations converge to a weak solution of a limit problem with hydrostatic pressure.

The stationary case has already been studied (see [4] for the linear problem and [5] for the nonlinear one), whereas the linear time-dependent case was solved in [1]. The main task of this paper is then to solve the nonlinear time-dependent case. Our result was announced in [2], whereas numerical simulations stemming from it were discussed in [3].

Fluid flow in thin domains (flat, curved, and with various boundary conditions) has been extensively studied; see [7, 13, 16, 20, 21]. In these works, an isotropic viscosity is used, and the depth is constant. By averaging along the vertical direction, two-dimensional (2D) limit models are obtained, together with existence and global regularity results.

Our approach is different, because we neither eliminate the vertical velocity by averaging nor assume the depth of the domain to be constant. By making use of different horizontal and vertical eddy viscosities, we are able to derive a three-dimensional (3D) limit nonlinear model. Let us emphasize that the anisotropic viscosity hypothesis is fundamental for the derivation of the primitive equations: in the stationary case, keeping an isotropic viscosity, the asymptotic model is linear, with vanishing horizontal diffusion; see [6].

The paper is organized as follows. In section 2, we present the physical model and the scaling leading to the primitive equations. We state the main theorem in section 3. The functional setting and weak formulation are described in section 4. In the next section, we state and prove a time-compactness result, which we shall use in the proof of the main theorem in section 6. Finally, in section 7, we comment on the convergence of the pressure and the orders of magnitude of the vertical velocity with respect to the aspect ratio.

2. Equations governing the flow and scaling. Let us consider an incompressible homogeneous fluid filling a thin domain defined by

$$\Omega_\epsilon = \left\{(x,y,z) \in \mathbb{R}^3;\ (x,y) \in \omega, -\epsilon\, h(x,y) < z < 0\right\},$$

where ω is an open bounded Lipschitz domain in $\mathbb{R}^2$ and $h : \overline{\omega} \to \mathbb{R}$ is a nonnegative lipschitzian application, which is arbitrary provided that Ω_ϵ is lipschitzian. In particular, h may vanish, contrary to [12, 9], but in order that the domain Ω_ϵ has no cusps, the slope must not vanish on the shores.[1] We denote by $\Gamma_s = \overline{\omega} \times \{0\}$ the fluid surface and by $\Gamma_b^\epsilon = \partial\Omega_\epsilon \setminus \Gamma_s$ the basin bottom. The fluid flow in Ω_ϵ is generated by the wind traction on the surface Γ_s, influenced by the Coriolis and centrifugal forces and governed by the Navier–Stokes equations, in which we take different eddy viscosities according to the direction; see [5, 9, 15]. Finally, we take the density as identically equal to one. In a geophysical rotating frame (z pointing upwards, x east, and y north), the initial-boundary value problem reads as follows.

Find $\mathbf{v} = (v_1, v_2, v_3)$ (velocity) and q (pressure), such that

$$\partial_t \mathbf{v} + (\mathbf{v}\cdot\nabla)\mathbf{v} - \Delta_\nu \mathbf{v} + \nabla q + 2\mathbf{w} \times \mathbf{v} = \mathbf{g} \quad \text{in } \Omega_\epsilon \times (0, \mathrm{T}), \tag{2.1}$$

$$\operatorname{div} \mathbf{v} = 0 \quad \text{in } \Omega_\epsilon \times (0, T), \tag{2.2}$$

$$\mathbf{v} = 0 \quad \text{on } \Gamma_b^\epsilon \times (0, T), \tag{2.3}$$

$$\nu_z \partial_z v_1 = \tau_1, \quad \nu_z \partial_z v_2 = \tau_2, \quad v_3 = 0 \quad \text{on } \Gamma_s \times (0, T), \tag{2.4}$$

$$\mathbf{v}(\cdot, t = 0) = \mathbf{v}_0 \quad \text{in } \Omega_\epsilon. \tag{2.5}$$

[1] This is a technical hypothesis. One could probably dispense with it due to the specific shape of the domain.

In (2.1), $\nabla = (\partial_x, \partial_y, \partial_z)$ denotes the gradient vector, and Δ_ν denotes the anisotropic Laplacian defined by $\Delta_\nu = \nu_x \partial^2_{xx} + \nu_y \partial^2_{yy} + \nu_z \partial^2_{zz}$ with $\nu = (\nu_x, \nu_y, \nu_z)$ the eddy kinematic viscosity vector. Moreover, $\mathbf{w} = f\,(0, \cos(l(y)), \sin(l(y)))$ represents the earth rotation angular speed (f the module and $l(y)$ the latitude), $2\mathbf{w} \times \mathbf{v}$ represents the Coriolis acceleration ($\times$ denotes the cross-product in $\mathbb{R}^3$), and $\mathbf{g}$ represents the force due to gravity (which also includes the centrifugal effect). It is well known (cf. [15, p. 18]) that $\mathbf{g}$ is a potential, i.e., $\mathbf{g} = \nabla\varphi$. It is customary to incorporate the gravity potential in the pressure term; thus we set

$$p = q - \varphi.$$

Equation (2.2) represents the incompressibility condition, and (2.3) represents the no-slip condition on the bottom.

In (2.4), τ_i, $i = 1, 2$, stand for the horizontal tractions exerted by the wind on the (fixed) surface Γ_s of the fluid, and $w = 0$ on Γ_s comes from the rigid lid hypothesis. In (2.5), $\mathbf{v}_0 = (v_{01}, v_{02}, v_{03})$ designates the initial velocity.

Remark. We have neglected the earth's curvature, and hence our analysis is valid only locally, e.g., for lakes; for seas or oceans, spherical coordinates should be used [12], although this can be somewhat cumbersome.

As usual in asymptotic analysis, we perform a vertical scaling to make the domain independent of ϵ, that is,

$$x = x_1, \quad y = x_2, \quad z = \epsilon\, x_3,$$

so that $\Omega = \big\{(x_1, x_2, x_3) \in \mathbb{R}^3;\ (x_1, x_2) \in \omega,\ -h(x_1, x_2) < x_3 < 0\big\}$ is the new fixed domain.

The corresponding kinematic scaling is

$$v_1 = u_1^\epsilon, \quad v_2 = u_2^\epsilon, \quad v_3 = \epsilon\, u_3^\epsilon, \quad p = p^\epsilon, \tag{2.6}$$

so that $\mathbf{u}^\epsilon = (u_1^\epsilon, u_2^\epsilon, u_3^\epsilon)$ is the new unknown velocity and p^ϵ is the new pressure.

It is necessary to scale the mechanical quantities accordingly. First, it is only natural to assume $v_{01} = u_{01}, v_{02} = u_{02}$, and $v_{03} = \epsilon u_{03}$, where u_{0i} does not depend on ϵ, $i = 1, 2, 3$. Next we assume $\nu_x = \nu_1$, $\nu_y = \nu_2$, and $\nu_z = \epsilon^2 \cdot \nu_3$, where ν_1, ν_2, ν_3 are constants. As mentioned in the introduction, in oceanography the vertical eddy viscosity is usually very small compared to the horizontal one. We refer to [5] for a mathematical discussion of this assumption, and here we content ourselves with one heuristic comment. Basically, a kinematic viscosity has the dimension L^2/T, where L (resp., T) is a typical length (resp., time) scale so that ν_x and ν_y have the dimension L_H^2/T, whereas ν_z has the dimension L_V^2/T, where L_H (resp., L_V) denotes a typical horizontal (resp., vertical) length scale. It follows that the ratio ν_z/ν_x and $\nu_z/\nu_y = \mathrm{O}(\epsilon^2)$.[2]

Now (2.4) becomes

$$\nu_3 \partial_3 u_i^\epsilon = \tau_i^\epsilon/\epsilon, \quad i = 1, 2.$$

We see that in order to end up with an O(1)-wind force on the rescaled domain, we have to assume that $\tau_i^\epsilon = \epsilon \cdot \theta_i$, $i = 1, 2$, where the θ_i are functions independent of ϵ.

[2] We do not delude ourselves with this sketchy argument. As far as we know, up to now there has been no rigorous derivation of any eddy viscosity model.

Remark. This last assumption can also be motivated by dimensional analysis, as follows. From $\tau_i = \nu_z \partial_z v_i$, one derives that τ_i has the dimension of

$$\frac{L_V^2}{T} \cdot \frac{1}{L_V} \cdot \frac{L_H}{T} = \epsilon \frac{L_H^2}{T^2} = O(\epsilon).$$

With the above considerations, problem (2.1)–(2.5) transforms into the following anisotropic Navier–Stokes equations:

$$\partial_t u_1^\epsilon + \mathbf{u}^\epsilon \cdot \nabla u_1^\epsilon - \Delta_\nu u_1^\epsilon - \alpha\, u_2^\epsilon + \epsilon\, \beta\, u_3^\epsilon + \partial_1 p^\epsilon = 0 \quad \text{in } \Omega \times (0,T), \tag{2.7}$$

$$\partial_t u_2^\epsilon + \mathbf{u}^\epsilon \cdot \nabla u_2^\epsilon - \Delta_\nu u_2^\epsilon + \alpha\, u_1^\epsilon + \partial_2 p^\epsilon = 0 \quad \text{in } \Omega \times (0,T), \tag{2.8}$$

$$\epsilon^2 \left\{ \partial_t u_3^\epsilon + \mathbf{u}^\epsilon \cdot \nabla u_3^\epsilon - \Delta_\nu u_3^\epsilon \right\} - \epsilon\, \beta\, u_1^\epsilon + \partial_3 p^\epsilon = 0 \quad \text{in } \Omega \times (0,T), \tag{2.9}$$

$$\operatorname{div} \mathbf{u}^\epsilon = 0 \quad \text{in } \Omega \times (0,T), \tag{2.10}$$

$$\mathbf{u}^\epsilon = 0 \quad \text{on } \Gamma_b \times (0,T), \tag{2.11}$$

$$\nu_3 \partial_3 u_1^\epsilon = \theta_1, \quad \nu_3 \partial_3 u_2^\epsilon = \theta_2, \quad u_3^\epsilon = 0 \quad \text{on } \Gamma_s \times (0,T), \tag{2.12}$$

$$\mathbf{u}^\epsilon(\cdot, t=0) = \mathbf{u}_0 \quad \text{in } \Omega. \tag{2.13}$$

Now $\nabla = (\partial_1, \partial_2, \partial_3)$, $\Delta_\nu = \nu_1 \partial_{11}^2 + \nu_2 \partial_{22}^2 + \nu_3 \partial_{33}^2$, $\Gamma_b = \partial\Omega \setminus \Gamma_s$, $\alpha = 2f \sin(l(x_2))$, and $\beta = 2f \cos(l(x_2))$.

If we assume that $\mathbf{u}^\epsilon = O(1)$, then neglecting the ϵ^2 and ϵ terms in the first and third momentum equation, (2.7) and (2.9), we formally get the hydrostatic Navier–Stokes equations, also called the primitive equations:

$$\partial_t u_1 + \mathbf{u} \cdot \nabla u_1 - \Delta_\nu u_1 - \alpha\, u_2 + \partial_1 p = 0 \quad \text{in } \Omega \times (0, \mathrm{T}), \tag{2.14}$$

$$\partial_t u_2 + \mathbf{u} \cdot \nabla u_2 - \Delta_\nu u_2 + \alpha\, u_1 + \partial_2 p = 0 \quad \text{in } \Omega \times (0, \mathrm{T}), \tag{2.15}$$

$$\partial_3 p = 0 \quad \text{in } \Omega \times (0, \mathrm{T}), \tag{2.16}$$

$$\operatorname{div} \mathbf{u} = 0 \quad \text{in } \Omega \times (0,T), \tag{2.17}$$

$$u_1 \, = \, u_2 \, = u_3 n_3 = 0 \quad \text{on } \Gamma_b \times (0,T), \tag{2.18}$$

$$\nu_3 \partial u_1 = \theta_1, \quad \nu_3 \partial_3 u_2 = \theta_2, \quad u_3 = 0 \quad \text{on } \Gamma_s \times (0,T), \tag{2.19}$$

$$u_i(\cdot, t=0) = u_{0i} \quad \text{in } \Omega,\ i = 1, 2. \tag{2.20}$$

Remark. The boundary condition (2.18) differs from its counterpart (2.11) because u_3 is less regular than u_1, u_2 as we shall see below. Also, the initial condition (2.20) does not involve u_3, the time derivative of which is missing in the hydrostatic model. The problem is not in the Cauchy–Kowalevska form.[3]

Remark. If u_3 were to be computed directly from (2.17), which is a *first* order equation, it is not obvious at all that it would fulfill the *two* boundary conditions on the bottom (2.18) and the surface (2.19).

3. Main theorem. Let T be a fixed positive duration. We make the natural assumption of a wind of finite energy: θ_1, $\theta_2 \in L^2(0,T; H^{-1/2}(\Gamma_s))$. Our main result is the following theorem.

THEOREM 3.1. *Let* $\mathbf{u}_0 \in L^2(\Omega)^3$, *with* $\operatorname{div} \mathbf{u}_0 = 0$, $\mathbf{u}_0 \cdot \mathbf{n} = 0$ *on* $\partial\Omega$, *and* $\theta_1, \theta_2 \in L^2(0,T; H^{-1/2}(\Gamma_s))$*; there exists a weak solution* $\mathbf{u}$ *of the hydrostatic Navier–Stokes equations* (2.14)–(2.20)*, obtained as a limit of weak solutions* $\mathbf{u}^\epsilon$ *of the anisotropic Navier–Stokes equations* (2.7)–(2.13)*, as the aspect ratio* ϵ *tends to zero.*

[3] Meteorologists say that u_3 is no longer a prognostic variable (see [11, 12]).

The proof relies on a priori estimates in anisotropic spaces (Propositions 6.1 and 6.2), which are sufficient to take the limit in the linear terms (see [1]), whereas for the nonlinear terms, we establish a new time-compactness criterium (Theorem 5.1), which enables us to get strong convergence of the horizontal velocities; see Lemma 6.3. This theorem states essentially that a small perturbation of an L^p-equicontinuous family still possesses a strong convergent subsequence. Let us emphasize that this seemingly technical refinement is by no means superfluous. Indeed, the usual compactness estimate fails: as $(u_1^\epsilon, u_2^\epsilon, \epsilon^2 u_3^\epsilon)$ is not divergence free, even if it is easy from (2.7)–(2.9) to control $\partial_t(u_1^\epsilon, u_2^\epsilon, \epsilon^2 u_3^\epsilon)$ in some dual space of divergence free velocities, it is not possible to apply the Aubin–Lions lemma to get compactness.

Another major difficulty of the proof is the lack of regularity of the vertical velocity, which is determined only by the incompressibility equation (2.10).

Remark. It is possible to handle a general force (f_1, f_2, f_3) in problem (2.14)–(2.20), by simply adding $\mathbf{f} = (f_1, f_2, \frac{f_3}{\epsilon})$ to (2.1), in order to end up with (f_1, f_2, f_3) in (2.7)–(2.9).

4. Weak formulation and anisotropic spaces. We need the following Hilbert spaces:

$$H_b^1(\Omega) = \overline{C_b^\infty(\Omega)}^{H^1(\Omega)} = \left\{v \in H^1(\Omega);\ v = 0 \text{ on } \Gamma_b\right\}$$

(where $C_b^\infty(\Omega) = \left\{\varphi \in C^\infty(\bar{\Omega});\ \varphi = 0 \text{ in some neighborhood of } \Gamma_b\right\}$),

$$\mathbf{V} = \left\{\mathbf{v} \in H_b^1(\Omega) \times H_b^1(\Omega) \times H_0^1(\Omega);\ \operatorname{div} \mathbf{v} = 0 \text{ in } \Omega\right\},$$

$$H(\partial_3, \Omega) = \left\{v \in L^2(\Omega);\ \partial_3 v \in L^2(\Omega)\right\}$$

(endowed with the norm $\|v\|^2_{H(\partial_3,\Omega)} = \|v\|^2_{L^2(\Omega)} + \|\partial_3 v\|^2_{L^2(\Omega)}$),

$$H_0(\partial_3, \Omega) = \overline{C_0^\infty(\Omega)}^{H(\partial_3,\Omega)} = \{v \in H(\partial_3, \Omega);\ v\, n_3 = 0 \text{ on } \partial\Omega\}$$

(n_3 is the third component of the normal exterior vector on $\partial\Omega$, and $v\, n_3$ is understood in the $H^{-1/2}(\partial\Omega)$ sense (see [19] for these spaces)),

$$\mathbf{W} = \left\{\mathbf{u} \in H_b^1(\Omega) \times H_b^1(\Omega) \times H_0(\partial_3, \Omega);\ \operatorname{div} \mathbf{u} = 0 \text{ in } \Omega\right\}.$$

Let us denote that $u_H = (u_1, u_2)$, $\theta_H = (\theta_1, \theta_2)$, $b(u_H) = \alpha\,(-u_2, u_1)$, and $\nabla_\nu = (\nu_1^{1/2}\partial_1, \nu_2^{1/2}\partial_2, \nu_3^{1/2}\partial_3)$. The scalar product in $L^2(\Omega)^d$, or the duality $L^p(\Omega), L^{p'}(\Omega)$, is denoted by $(\cdot,\cdot)$, and the duality $H^{-1/2}(\Gamma_s)H^{1/2}(\Gamma_s)$, is denoted by $\langle\cdot,\cdot\rangle_{\Gamma_s}$.

The weak form of the hydrostatic Navier–Stokes equations (2.14)–(2.20) is then as follows.

Find $\mathbf{u} = (u_H, u_3) \in L^2(0, T; \mathbf{W})$, with $u_H \in L^\infty(0, T; L^2(\Omega)^2)$, such that

$$\begin{aligned} \int_0^T -(u_H, \partial_t v_H) - (u_H, (\mathbf{u}\cdot\nabla)v_H) + (b(u_H), v_H) + (\nabla_\nu u_H, \nabla_\nu v_H) \\ = -(u_{0H}, v_H(0)) + \int_0^T \langle\theta_H, v_H\rangle_{\Gamma_s} \end{aligned} \tag{4.1}$$

for all $\mathbf{v} = (v_H, v_3) \in H^1(0, T; \mathbf{W})$, with $v_H(T) = 0$ and $\partial_3 v_H \in L^\infty(0, T; L^3(\Omega)^2)$.

Remark. Notice that a weak solution of the Navier–Stokes equations verifies the following regularity:

$$\mathbf{u} \in L^2(0,T;\mathbf{V}) \cap L^\infty(0,T;L^2(\Omega)^3)$$

(cf. [8, 10, 18]). Now the lack of regularity of u_3 makes it necessary to change $\mathbf{V}$ to $\mathbf{W}$. Moreover, in general, $u_3 \notin L^\infty(0,T;L^2(\Omega))$.

Remark. The regularity $L^\infty(0,T;L^3(\Omega)^2)$ is required for $\partial_3 v_H$ to give a meaning to $\int_0^T (u_H, u_3\partial_3 v_H)\,\mathrm{dt}$. The regularity $L^2(0,T;L^\infty(\Omega)^2)$ or any interpolated one $L^{2/a}(0,T;L^{3/(1-a)}(\Omega)^2)$ with $0 \le a \le 1$ can also be considered.

5. Compactness by perturbation. We give a compactness criterium, new to our knowledge, which generalizes the well-known translation criterium of Riesz–Fréchet–Kolmogorov, extended to the vectorial case by Simon [17]. In the following, $\tau_h f(t)$ denotes $f(t+h)$.

THEOREM 5.1. *Let $T > 0$, and let the Banach spaces $\mathbf{X} \overset{compact}{\hookrightarrow} \mathbf{B} \hookrightarrow \mathbf{Y}$. Let $(f_\epsilon)_{\epsilon>0}$ be a family of functions of $L^p(0,T;\mathbf{X})$, $1 \le p \le \infty$, with the extra condition $(f_\epsilon)_{\epsilon>0} \subset \mathcal{C}(0,T;\mathbf{Y})$ if $p = \infty$, such that*
(H1) *$(f_\epsilon)_{\epsilon>0}$ is bounded in $L^p(0,T;\mathbf{X})$,*
(H2) *$\|\tau_h f_\epsilon - f_\epsilon\|_{L^p(0,T-h;\mathbf{Y})} \le \varphi(h) + \psi(\epsilon)$ with*

$$\begin{cases} \lim_{h\to 0}\varphi(h) = 0, \\ \lim_{\epsilon\to 0}\psi(\epsilon) = 0. \end{cases}$$

Then the family $(f_\epsilon)_{\epsilon>0}$ possesses a cluster point in $L^p(0,T;\mathbf{B})$ and also in $\mathcal{C}(0,T;\mathbf{B})$ if $p = \infty$, as $\epsilon \to 0$.

Proof. It is enough to prove that, for every sequence $(\epsilon_n)_n$ such as $\epsilon_n > 0$ and $\epsilon_n \to 0$, the family $(f_{\epsilon_n})_n$ is relatively compact in $L^p(0,T;\mathbf{B})$. We apply Theorem 5 of Simon [17, p. 84] to the sequence $(f_{\epsilon_n})_n$, while observing that hypothesis (H2) implies that

$$\|\tau_h f_{\epsilon_n} - f_{\epsilon_n}\|_{L^p(0,T-h;\mathbf{Y})} \to 0 \quad \text{as } h \to 0$$

uniformly with respect to n. Indeed, (H2) implies that

$$\forall n,\ \|\tau_h f_{\epsilon_n} - f_{\epsilon_n}\|_{L^p(0,T-h;\mathbf{Y})} \le \varphi(h) + \psi(\epsilon_n).$$

Let $\epsilon > 0$ and then $\exists\, N$, such that for all $n \ge N$, $\psi(\epsilon_n) \le \epsilon/2$. On the other hand, $\exists\, \delta > 0$, such that for all $h : 0 \le h < \delta$, $\varphi(h) \le \epsilon/2$. Therefore, we get the estimate

$$\forall\, n \ge N \text{ and } \forall\, h : 0 \le h < \delta, \quad \|\tau_h f_{\epsilon_n} - f_{\epsilon_n}\|_{L^p(0,T-h;\mathbf{Y})} \le \epsilon.$$

In addition, for each $k \le N$, $\exists\, \delta_k > 0$, such that for all $h : 0 \le h < \delta_k$

$$\|\tau_h f_{\epsilon_k} - f_{\epsilon_k}\|_{L^p(0,T-h;\mathbf{Y})} \le \epsilon.$$

This follows from the L^p-continuity by translation of an L^p function for $p < \infty$ and for $p = \infty$; this is precisely a hypothesis.

Defining $\eta = \min\{\delta, \delta_1, \dots, \delta_N\}$, we obtain the desired uniform estimate

$$\forall\, h : 0 \le h < \eta, \quad \|\tau_h f_{\epsilon_n} - f_{\epsilon_n}\|_{L^p(0,T-h;\mathbf{Y})} \le \epsilon \quad \forall n.$$

The family $(f_{\epsilon_n})_n$ fulfills the hypotheses of Simon's theorem. □

6. Proof of the main theorem.

For simplicity in the notation, from now on, unless we specify otherwise, we will denote $\mathbf{u} = \mathbf{u}^\epsilon$ as a weak solution of the anisotropic Navier–Stokes equations (2.7)–(2.13).

6.1. Energy estimates.

The usual energy inequality (cf. [10]) for the Navier–Stokes equations gives, for a.e. $t \in [0, T]$,

$$\begin{aligned} &\|u_H(t)\|_{L^2}^2 + \epsilon^2 \|u_3(t)\|_{L^2}^2 + \int_0^t \{\|\nabla_\nu u_H(\tau)\|_{L^2}^2 + \epsilon^2 \|\nabla_\nu u_3(\tau)\|_{L^2}^2\} \, d\tau \\ &\quad \le \|u_{0H}\|_{L^2}^2 + \epsilon^2 \|u_{03}\|_{L^2}^2 + \int_0^t \langle \theta_H, u_H \rangle_{\Gamma_s}. \end{aligned}$$

Hence we obtain as in the isotropic Navier–Stokes system (cf. [1]) the following proposition.

Proposition 6.1. *The sequences $u_1, u_2, \epsilon u_3$ are bounded in $L^\infty(0, T; L^2(\Omega)) \cap L^2(0, T; H^1(\Omega))$.*

For the vertical velocities, we prove the following.

Proposition 6.2. *The sequences u_3 and $\partial_3 u_3$ are bounded in $L^2(0, T; L^2(\Omega))$; i.e., u_3 is bounded in $L^2(0, T; H_0(\partial_3, \Omega))$.*

Proof. As $\operatorname{div} \mathbf{u} = 0$, $\partial_3 u_3 = -\partial_1 u_1 - \partial_2 u_2$ is bounded in $L^2(0, T; L^2(\Omega))$. Moreover, the Poincaré inequality in the vertical direction, owing to $u_3 = 0$ on Γ_s, yields

$$\|u_3\|_{L^2} \le h_{\max} \|\partial_3 u_3\|_{L^2}, \quad \text{where } h_{\max} = \max_{\overline{\omega}} h.$$

Therefore, we have proved the proposition. □

6.2. Fractional time derivatives in horizontal spaces.

First, we define the auxiliary Hilbert spaces

$$B_H = \overline{P_H \mathcal{U}}^{(L^2)^2}, \quad W_H = \overline{P_H \mathcal{U}}^{(H^1)^2}, \quad \text{and} \quad Y_H = \overline{P_H \mathcal{U}}^{(H^2)^2},$$

where

$$\mathcal{U} = \left\{\varphi \in C_b^\infty(\Omega)^2 \times C_0^\infty(\Omega); \ \operatorname{div} \varphi = 0\right\}$$

and P_H is the projection

$$P_H : (x_1, x_2, x_3) \in \mathbb{R}^3 \mapsto (x_1, x_2) \in \mathbb{R}^2.$$

Then, from the Sobolev–Rellich embeddings, one deduces easily that

$$Y_H \hookrightarrow W_H \hookrightarrow B_H \equiv B_H' \hookrightarrow W_H' \hookrightarrow Y_H', \tag{6.1}$$

where all are dense and compact embeddings. Here and henceforth, X' denotes the dual space of X.

Now, we have the following lemma.

Lemma 6.3. *The estimate $\|\tau_h u_H - u_H\|_{L^\infty(0, T-h; Y_H')} \le C(h^{1/4} + \epsilon)$ holds.*

Proof. The spatial weak form of the Navier–Stokes equation (2.7)–(2.13) is

$$\begin{aligned} &\frac{d}{dt}(u_H, v_H) - (u_H, (\mathbf{u} \cdot \nabla) v_H) + (b(u_H), v_H) + (\nabla_\nu u_H, \nabla_\nu v_H) \\ &\quad + \epsilon^2 \left\{ \frac{d}{dt}(u_3, v_3) + (\mathbf{u} \cdot \nabla u_3, v_3) + (\nabla_\nu u_3, \nabla_\nu v_3) \right\} \\ &\quad + \epsilon \left\{ (\beta u_3, v_1) - (\beta u_1, v_3) \right\} = \langle \theta_H, v_H \rangle_{\Gamma_s} \quad \text{in } \mathcal{D}'(0, T) \\ &\quad \forall \mathbf{v} = (v_H, v_3) \in \mathbf{V}. \end{aligned} \tag{6.2}$$

Letting $v_H \in Y_H$, there is a null divergence lifting $\mathbf{v} = (v_H, v_3) \in H^2_b(\Omega)^2 \times H^1_0(\partial_3, \Omega)$ such that

$$\|v_3\|_{H^1} + \|\partial_3\, v_3\|_{H^1} \le C\|v_H\|_{Y_H}. \tag{6.3}$$

Here, the spaces $H^2_b(\Omega)$ and $H^1_0(\partial_3, \Omega)$ are the natural extensions of the spaces $H^1_b(\Omega)$ and $H_0(\partial_3, \Omega)$:

$$H^2_b(\Omega) = \overline{C^\infty_b(\Omega)}^{H^2(\Omega)} = \left\{ v \in H^2(\Omega);\ v = \frac{\partial v}{\partial n} = 0 \text{ on } \Gamma_b \right\},$$

$$H^1(\partial_3, \Omega) = \left\{ v \in H^1(\Omega);\ \partial_3 v \in H^1 \Omega) \right\},$$

$$H^1_0(\partial_3, \Omega) = \overline{C^\infty_0(\Omega)}^{H^1(\partial_3,\Omega)} = \left\{ v \in H^1(\partial_3, \Omega);\ v = \partial_3 v = \ 0 \ \text{ on } \partial\Omega \right\}.$$

Indeed, as $v_H \in Y_H$, there exists a sequence $(\varphi^n_H, \varphi^n_3) \in \mathcal{U}$ such that $\varphi^n_H \to v_H$ in $H^2(\Omega)^2$. Then $\partial_3 \varphi^n_3 = -\partial_1 \varphi^n_1 - \partial_2 \varphi^n_2$ is a Cauchy sequence in $H^1(\Omega)$, and by vertical Poincaré inequality, φ^n_3 is also a Cauchy sequence in $H^1(\Omega)$. Therefore, φ^n_3, being a Cauchy sequence in $H^1(\partial_3, \Omega)$, converges to a function v_3, which provides the desired lifting function. The continuous dependence (6.3) results from the above construction.

Now we take this $\mathbf{v} = (v_H, v_3)$ as a test function in (6.2) and integrate over $(t, t+h)$; i.e.,

$$(\tau_h u_H(t) - u_H(t), v_H) + \epsilon^2\, (\tau_h u_3(t) - u_3(t), v_3) = \int_t^{t+h} g^\epsilon(s)\, \mathrm{ds}, \tag{6.4}$$

where

$$\begin{aligned} g^\epsilon(s) \ \ = \ \ & (u_H, (\mathbf{u} \cdot \nabla) v_H) - \epsilon^2\, (\mathbf{u} \cdot \nabla u_3, v_3) - (b(u_H), v_H) - (\nabla_\nu u_H, \nabla_\nu v_H) \\ & - \epsilon\, (\nabla_\nu(\epsilon u_3), \nabla_\nu v_3) - \epsilon\, \{(\beta u_3, v_1) - (\beta u_1, v_3)\} + \langle \theta_H, v_H \rangle_{\Gamma_s}. \end{aligned}$$

Now we prove that

$$\|g^\epsilon\|_{L^{4/3}(0,T)} \le C\|v_H\|_{Y_H}. \tag{6.5}$$

To this end, we estimate every piece of g^ϵ. For the nonlinear terms, we have

$$(u_H, (\mathbf{u} \cdot \nabla) v_H) \le \|u_H\|_{L^3} \|\mathbf{u}\|_{L^2} \|\nabla v_H\|_{L^6} \le C\, \|u_H\|_{L^3} \|\mathbf{u}\|_{L^2} \|v_H\|_{Y_H}$$

and

$$\epsilon^2\, (\mathbf{u} \cdot \nabla u_3, v_3) \le \|\epsilon \mathbf{u}\|_{L^3} \|\nabla(\epsilon u_3)\|_{L^2} \|v_3\|_{L^6} \le C\, \|\epsilon \mathbf{u}\|_{L^3} \|\epsilon u_3\|_{H^1} \|v_H\|_{Y_H}.$$

By interpolation between $L^\infty(0, T; L^2)$ and $L^2(0, T; L^6)$, u_H is bounded in $L^4(0, T; L^3)$; i.e., $\|u_H\|_{L^3}$ is bounded in $L^4(0, T)$. As $\|\mathbf{u}\|_{L^2}$ is bounded in $L^2(0, T)$, we have $(u_H, (\mathbf{u} \cdot \nabla) v_H)$ bounded in $L^{4/3}(0, T)$. Similarly, as $\|\epsilon \mathbf{u}\|_{L^3}$ is bounded in $L^4(0, T)$ and $\|\epsilon u_3\|_{H^1}$ is bounded in $L^2(0, T)$, we have $\epsilon^2\, (\mathbf{u} \cdot \nabla u_3, v_3)$ bounded in $L^{4/3}(0, T)$. The linear terms of g^ϵ are handled easily by the Cauchy–Schwarz inequality:

$$\begin{array}{rcll} (b(u_H), v_H) & \le & \|u_H\|_{L^2} \|v_H\|_{L^2} & \text{bounded in } L^\infty(0, T), \\ (\nabla_\nu u_H, \nabla_\nu v_H) & \le & \|u_H\|_{H^1} \|v_H\|_{H^1} & \text{bounded in } L^2(0, T), \\ \epsilon\, (\nabla_\nu(\epsilon u_3), \nabla_\nu v_3) & \le & \epsilon\, \|\epsilon u_3\|_{H^1} \|v_3\|_{H^1} & \text{bounded in } L^2(0, T), \\ \epsilon\beta\, \{(u_3, v_1) - (u_1, v_3)\} & \le & 2f \|\epsilon \mathbf{u}\|_{L^2} \|\mathbf{v}\|_{L^2} & \text{bounded in } L^\infty(0, T), \\ \langle \theta_H, v_H \rangle_{\Gamma_s} & \le & C\, \|\theta_H\|_{H^{-1/2}(\Gamma_s)} \|v_H\|_{H^1} & \text{bounded in } L^2(0, T). \end{array}$$

Therefore, taking into account (6.3), according to all previous bounds, (6.5) holds. Next, applying the Hölder inequality to (6.5), we see that

$$\int_t^{t+h} |g^\epsilon(s)|\,\mathrm{ds} \le C\, h^{1/4} \|v_H\|_{Y_H}.$$

On the other hand,

$$|\epsilon^2\,(\tau_h u_3(t) - u_3(t), v_3)| \le \epsilon\,\{\|\tau_h(\epsilon u_3)(t)\|_{L^2} + \|\epsilon u_3(t)\|_{L^2}\}\|v_3\|_{L^2} \le \epsilon\, C\,\|v_H\|_{Y_H}$$

by virtue of Proposition 6.1.

These last two estimates together with (6.4) yield the required result. □

6.3. Convergence. Here we come back to the notation $\mathbf{u}^\epsilon$. The space-time weak form of the anisotropic Navier–Stokes equations (2.7)–(2.13) is as follows.

Find $\mathbf{u}^\epsilon = (u_H^\epsilon, u_3^\epsilon) \in L^2(0,T;\mathbf{V}) \cap L^\infty(0,T;L^2(\Omega)^3)$ such that

$$\begin{aligned}
&\int_0^T -(u_H^\epsilon, \partial_t v_H) - (u_H^\epsilon, (\mathbf{u}^\epsilon\cdot\nabla)v_H) + (b(u_H^\epsilon), v_H) + (\nabla_\nu u_H^\epsilon, \nabla_\nu v_H)\\
&+\epsilon^2\int_0^T -(u_3^\epsilon, \partial_t v_3) + (\mathbf{u}^\epsilon\cdot\nabla u_3^\epsilon, v_3) + (\nabla_\nu u_3^\epsilon, \nabla_\nu v_3)\\
&+\epsilon\,\beta\int_0^T (u_3^\epsilon, v_1) - (u_1^\epsilon, v_3) = -(u_{0H}, v_H(0)) - \epsilon^2(u_{03}, v_3(0)) + \int_0^T \langle\theta_H, v_H\rangle_{\Gamma_s}\\
&\forall\,\mathbf{v} = (v_H, v_3) \in H^1(0,T;\mathbf{V}),\ \text{with}\ \mathbf{v}(T) = 0.
\end{aligned}\tag{6.6}$$

The purpose of the following is to take the limit as $\epsilon \to 0$ in (6.6) to come to (4.1). By Propositions 6.1 and 6.2, it follows that $\mathbf{u}^\epsilon$ is bounded in $L^2(0,T;\mathbf{W})$ and u_H^ϵ is bounded in $L^\infty(0,T;B_H)$, allowing us to extract a subsequence, still denoted by $\mathbf{u}^\epsilon$, such that

$$\mathbf{u}^\epsilon = (u_H^\epsilon, u_3^\epsilon) \rightharpoonup \mathbf{u} = (u_H, u_3) \quad \text{in}\, L^2(0,T;\mathbf{W})\,\text{weak},$$

$$u_H^\epsilon \overset{\star}{\rightharpoonup} u_H \quad \text{in}\, L^\infty(0,T;B_H)\,\text{weak} - \star.$$

These weak convergences are enough to take the limit in the linear terms of (6.6) (cf. [1]). In particular, the terms of $\mathrm{O}(\epsilon)$ associated with the Coriolis acceleration vanish as ϵ tends to zero. Indeed,

$$\epsilon\,\beta\int_0^T (u_3^\epsilon, v_1) - (u_1^\epsilon, v_3) \le \epsilon\,2f\int_0^T \|\mathbf{u}^\epsilon\|_{L^2}\|\mathbf{v}\|_{L^2}$$

$$\le\ \epsilon\,2f\,\|\mathbf{u}^\epsilon\|_{L^2(0,T;L^2)}\|\mathbf{v}\|_{L^2(0,T;L^2)}\ \le\ \epsilon\,C\,\|\mathbf{v}\|_{L^2(0,T;L^2)}\ \le\ C\,\epsilon.$$

On the other hand, combining (6.1), Proposition 6.1, and Lemma 6.3, we can apply Theorem 5.1 for $p=\infty$ and the spaces $B_H \overset{compact}{\hookrightarrow} W_H' \hookrightarrow Y_H'$. Therefore, there exists a subsequence $u_H^\epsilon \to u_H$ in $\mathcal{C}(0,T;W_H')$ strong. Thus we get the weak time-continuity $u_H \in \mathcal{C}(0,T;W_H')$, so that the initial condition (2.20) makes sense for the horizontal velocities. On the other hand, the term of $0(\epsilon^2)$ related to the initial condition for the vertical velocity vanishes as ϵ tends to zero. Indeed,

$$-\epsilon^2(u_{03}, v_3(0)) \le \epsilon^2\|u_{03}\|_{L^2}\|v_3(0)\|_{L^2} \le \epsilon^2\|\mathbf{u}_0\|_{L^2}\|v_3\|_{\mathcal{C}(0,T;L^2)}\ \le\ C\,\epsilon^2.\tag{6.7}$$

Now the nonlinear terms fall into four types:

$$\text{(I)}\quad \epsilon^2\int_0^T (u_i^\epsilon \partial_i u_3^\epsilon, v_3)\,\mathrm{dt},\quad 1\le i\le 2,$$

$$\text{(II)}\quad \epsilon^2\int_0^T (u_3^\epsilon \partial_3 u_3^\epsilon, v_3)\,\mathrm{dt},$$

$$\text{(III)}\quad \int_0^T (u_i^\epsilon u_j^\epsilon, \partial_j v_i)\,\mathrm{dt},\quad 1\le i,\ j\le 2,$$

$$\text{(IV)}\quad \int_0^T (u_i^\epsilon u_3^\epsilon, \partial_3 v_i)\,\mathrm{dt},\quad 1\le i\le 2.$$

Type (I) term:

$$\epsilon^2\int_0^T (u_i^\epsilon \partial_i u_3^\epsilon, v_3)\,\mathrm{dt} \le \epsilon\int_0^T \|u_i^\epsilon\|_{L^6}\|\partial_i(\epsilon u_3^\epsilon)\|_{L^2}\|v_3\|_{L^3}$$

$$\le C\,\epsilon\,\|u_i^\epsilon\|_{L^2(0,T;H^1)}\|\partial_i(\epsilon u_3^\epsilon)\|_{L^2(0,T;L^2)}\|v_3\|_{\mathcal{C}(0,T;H^1)} \le C\,\epsilon.$$

Type (II) term:

$$\epsilon^2\int_0^T (u_3^\epsilon \partial_3 u_3^\epsilon, v_3)\,\mathrm{dt} \le \epsilon\int_0^T \|\epsilon u_3^\epsilon\|_{L^6}\|\partial_3 u_3^\epsilon\|_{L^2}\|v_3\|_{L^3}$$

$$\le C\,\epsilon\,\|\epsilon u_3^\epsilon\|_{L^2(0,T;H^1)}\|\partial_3 u_3^\epsilon\|_{L^2(0,T;L^2)}\|v_3\|_{\mathcal{C}(0,T;H^1)} \le C\,\epsilon.$$

Consequently, the type (I) and (II) terms are $O(\epsilon)$ and vanish as ϵ tends to zero.

To handle the type (III) and (IV) terms, we need some strong convergences. From compactness by perturbation (Theorem 5.1 for $p = 2$ and the spaces $W_H \overset{compact}{\hookrightarrow} B_H \hookrightarrow Y'_H$), there exists a subsequence, still denoted by u_H^ϵ, such that

$$u_H^\epsilon \to u_H \quad \text{in}\, L^2(0,T;L^2(\Omega)^2) \equiv L^2((0,T)\times\Omega)^2\,\text{strong.}$$

By Proposition 6.1, we have u_H^ϵ bounded in $L^\infty(0,T;L^2(\Omega)^2)\cap L^2(0,T;L^6(\Omega)^2)$, which by interpolation ensures that

$$u_H^\epsilon \,\text{is bounded in}\, L^{10/3}(0,T;L^{10/3}(\Omega)^2) \equiv L^{10/3}((0,T)\times\Omega)^2.$$

By the interpolation inequality again, for all $q : 2 \le q < 10/3$ there exists $\alpha : 0 < \alpha \le 1$ such that

$$\|u_H^\epsilon - u_H\|_{L^q} \le \|u_H^\epsilon - u_H\|_{L^2}^{\alpha}\|u_H^\epsilon - u_H\|_{L^{10/3}}^{1-\alpha}.$$

Thus

$$u_H^\epsilon \to u_H \quad \text{in}\, L^q((0,T)\times\Omega)\,\text{strong} \quad \forall\, q : 2\le q < 10/3. \tag{6.8}$$

Type (III) term: By the Hölder inequality and (6.8), we have

$$u_i^\epsilon u_j^\epsilon \to u_i u_j \quad \text{in}\, L^r((0,T)\times\Omega)\,\text{strong} \quad \forall\, r : 1\le r < 5/3$$

and for all $i, j = 1, 2$. On the other hand, by interpolation between $L^\infty(0,T;L^2)$ and $L^2(0,T;L^6)$, u_i^ϵ (and u_j^ϵ) is bounded in $L^{8/3}(0,T;L^4)$, and hence $u_i^\epsilon u_j^\epsilon$ is bounded in $L^{4/3}(0,T;L^2)$, and finally,

$$u_i^\epsilon u_j^\epsilon \rightharpoonup u_i u_j \quad \text{in}\, L^{4/3}(0,T;L^2)\,\text{weak}, \quad 1 \le i, \quad j \le 2.$$

In particular, we get

$$\int_0^T (u_i^\epsilon u_j^\epsilon, \partial_j v_i) \to \int_0^T (u_i u_j, \partial_j v_i), \quad 1 \le i, \quad j \le 2.$$

Indeed, $v_i \in \mathcal{C}(0,T;H^1)$ so that

$$\partial_j v_i \in L^\infty(0,T,L^2) \subset L^4(0,T,L^2) \equiv (L^{4/3}(0,T,L^2))'.$$

Type (IV) term: We have

$$u_3^\epsilon \rightharpoonup u_3 \quad \text{in}\, L^2(0,T;L^2)\,\text{weak}.$$

So by the Hölder inequality and (6.8),

$$u_i^\epsilon u_3^\epsilon \rightharpoonup u_i u_3 \quad \text{in}\, L^s(0,T;L^s)\,\text{weak} \quad \forall\, s : 1 \le s < 5/4$$

and for all $i = 1, 2$. On the other hand, it is easy to see that $u_i^\epsilon u_3^\epsilon$ is bounded in $L^{8/7}(0,T;L^{4/3})$, and hence

$$u_i^\epsilon u_3^\epsilon \rightharpoonup u_i u_3 \quad \text{in}\, L^{8/7}(0,T;L^{4/3})\,\text{weak}, \quad 1 \le i \le 2.$$

Now we shall have to slightly increase the regularity of the test functions of (4.1) to finish the limit process in the Type (IV) terms. For instance, assuming the additional regularity for the test functions $\partial_3 v_i \in L^8(0,T;L^4)$, we get

$$\int_0^T (u_i^\epsilon u_3^\epsilon, \partial_3 v_i) \to \int_0^T (u_i u_3, \partial_3 v_i), \quad 1 \le i \le 2.$$

In conclusion, the limit function $\mathbf{u}$ is a solution of the variational formulation (4.1) for all $\mathbf{v} = (v_H, v_3) \in H^1(0,T,\mathbf{V})$ with $v_H(T) = 0$ and $\partial_3 v_H \in L^8(0,T;L^4)$. Finally, we can argue by density, taking advantage of the regularity of each term of (4.1), and obtain that (4.1) holds for all $\mathbf{v} = (v_H, v_3) \in H^1(0,T,\mathbf{W})$ with $v_H(T) = 0$ and $\partial_3 v_H \in L^\infty(0,T;L^3)$; hence the proof of Theorem 3.1 is finished.

7. Concluding remarks.

7.1. Convergence of the pressure. By using the De Rham lemma [18] in the formulation (6.6) (resp., (4.1)), we can recover the potentials p^ϵ (resp., p) as distributions

$$\nabla p^\epsilon = \begin{pmatrix} -\partial_t u_1^\epsilon - \mathbf{u}^\epsilon \cdot \nabla u_1^\epsilon + \Delta_\nu u_1^\epsilon + \alpha u_2^\epsilon - \epsilon\beta u_3^\epsilon \\ -\partial_t u_2^\epsilon - \mathbf{u}^\epsilon \cdot \nabla u_2^\epsilon + \Delta_\nu u_2^\epsilon - \alpha u_1^\epsilon \\ -\epsilon^2 \left\{\partial_t u_3^\epsilon + \mathbf{u}^\epsilon \cdot \nabla u_3^\epsilon - \Delta_\nu u_3^\epsilon\right\} + \epsilon\beta u_1^\epsilon \end{pmatrix}, \tag{7.1}$$

respectively,

$$\nabla p = \begin{pmatrix} -\partial_t u_1 - \mathbf{u} \cdot \nabla u_1 + \Delta_\nu u_1 + \alpha u_2 \\ -\partial_t u_2 - \mathbf{u} \cdot \nabla u_2 + \Delta_\nu u_2 - \alpha u_1 \\ 0 \end{pmatrix}. \tag{7.2}$$

Moreover, (7.1) is also verified in $H^{-1}(0,T;H^{-1}(\Omega)^3)$ (i.e., in the dual space of $H^1_0(0,T;H^1_0(\Omega)^3)$), whereas (7.2) holds in $H^{-1}(0,T;W^{-1,3/2}(\Omega)^3)$ (i.e., in the dual space of $H^1_0(0,T;W^{1,3}_0(\Omega)^3)$). Proceeding as in subsection 6.3, we may derive that

$$\partial_i p^\epsilon \overset{\star}{\rightharpoonup} \partial_i p \quad \text{in } H^{-1}(0,T;W^{-1,3/2}(\Omega)), \quad i=1,2,$$

and

$$\|\partial_3 p^\epsilon\|_{H^{-1}(0,T;H^{-1}(\Omega))} \leq C\epsilon.$$

In particular, we have the strong convergence of $\partial_3 p^\epsilon$ to $\partial_3 p$.

Remark. The strong convergence of $\partial_3 p^\epsilon$ takes place in a better space than the weak convergence of $\partial_i p^\epsilon$, $i=1,2$. In some sense, this means that the validity of the hydrostatic approximation is less demanding than the validity of the horizontal momentum equations.

Remark. The above convergences can be slightly improved with respect to time. They remain true, replacing the space $H^{-1}(0,T;W^{-1,3/2}(\Omega))$ (resp., $H^{-1}(0,T;H^{-1}(\Omega))$) with the space $W^{-1,\infty}(0,T;W^{-1,3/2}(\Omega))$ (resp., $W^{-1,\infty}(0,T;H^{-1}(\Omega))$).

7.2. Orders of magnitude of the vertical velocity in the original domain.

The purpose of this last subsection is to interpret the previous results in the original domain Ω_ϵ. Consequently, we are going to consider $\mathbf{v}=(v_1,v_2,v_3)$, the weak solution in Ω_ϵ of problem (2.1)–(2.5), related to $\mathbf{u}^\epsilon=(u_1^\epsilon,u_2^\epsilon,u_3^\epsilon)$, a weak solution of problem (2.7)–(2.13) in Ω; see (2.6). First, it is important to notice that the true vertical velocity $v_3=\epsilon u_3^\epsilon$ is small with respect to the horizontal velocities v_i, $i=1,2$. Indeed, taking into account the estimates in Proposition 6.1 for u_i^ϵ, $i=1,2$, and Proposition 6.2 for u_3^ϵ, scaling off Ω to Ω_ϵ, we obtain

$$\frac{\|v_3\|_{L^2(0,T;L^2(\Omega_\epsilon))}}{\|v_i\|_{L^2(0,T;L^2(\Omega_\epsilon))}} = 0(\epsilon), \quad i=1,2.$$

By the same argument, we obtain

$$\frac{\|\partial_z v_3\|_{L^2(0,T;L^2(\Omega_\epsilon))}}{\|\partial_z v_i\|_{L^2(0,T;L^2(\Omega_\epsilon))}} = 0(\epsilon), \quad i=1,2.$$

This phenomenon is actually observed in most geophysical flows, which, therefore, are quasi-horizontal. It is striking that the vertical velocity goes to zero even if the initial vertical velocity is not assumed to be small. Looking at (6.7) in the proof of convergence, we need only that $\epsilon^2\|u_{03}\|_{L^2(\Omega)} \to 0$, that is, $\|v_{03}\|_{L^2(\Omega_\epsilon)}/\|v_{0i}\|_{L^2(\Omega_\epsilon)} = O(\epsilon^{-\alpha})$, $\alpha<1$.

Whereas, for the horizontal gradient, we cannot avail ourselves of Proposition 6.2, and we obtain only

$$\frac{\|\nabla_{x,y}\, v_3\|_{L^2(0,T;L^2(\Omega_\epsilon))}}{\|\nabla_{x,y}\, v_i\|_{L^2(0,T;L^2(\Omega_\epsilon))}} = 0(1), \quad i=1,2.$$

A MATHEMATICAL MODEL OF THE WEARING PROCESS OF A NONCONVEX STONE*

HITOSHI ISHII† AND TOSHIO MIKAMI‡

Abstract. We formulate the wearing process of a nonconvex stone in terms of partial differential equations (PDEs). We establish a comparison theorem, an existence theorem, and some stability properties of solutions of this PDE.

Key words. geometric evolution equations, wearing process, nonconvex stone

1. Introduction.

In this paper we study a mathematical model of the wearing process of a stone rolling on beach.

In [6], Firey proposed a mathematical model of the wearing process of such a stone in the case when it has a convex shape. In his model, a stone evolves according to the Gauss curvature flow. See, for instance, [1, 3, 7] for the mathematical developments regarding the Gauss curvature flow.

We extend his arguments to the case when the stone does not necessarily have a convex shape. The idea of this extension is very simple, and it is explained as follows. Let $V_t \subset \mathbf{R}^{n+1}$ be a stone at time t being worn due to hits of the bottom of the sea (or beach). In Firey's and our model the bottom of the sea is supposed to be a hyperplane. We fix a coordinate system for which the stone does not rotate and translate, and, for each unit vector $p \in \mathbf{R}^{n+1}$, we associate the hyperplane

$$H_p = \{x \in \mathbf{R}^{n+1} \mid x \cdot p = 0\}.$$

The set V_t evolves by losing its volume near the point where it is hit by the hyperplane H_p. Here the meaning of the sentence "A point $Q \in V_t$ is hit by H_p" is that the half space

$$Q + \{x \in \mathbf{R}^{n+1} \mid x \cdot p > 0\}$$

does not intersect with V_t. Of course, if $Q \in V_t$ is hit by a hyperplane, then $Q \in \partial V_t$. Three assumptions in this model of this wearing process are as follows: (i) the probability of H_p hitting the stone V_t is uniform in the direction p; (ii) the volume loss near a point $Q \in \partial V_t$ is proportional to how often the point Q is hit by hyperplanes; and (iii) the total volume loss of the stone in a time period is proportional to the length of the time period. Of course, once V_t becomes empty at a time t_0, then, by definition, $V_t = \emptyset$ for all $t > t_0$.

In what follows, we restrict our study to the case when the boundary of the stone V_t at time t is given by the graph of an evolving function. That is, we study the case when V_t is given by

$$V_t = \{(x, y) \in \mathbf{R}^n \times \mathbf{R} \mid y \geq u(x, t)\}$$

for some function $u : \mathbf{R}^n \times [0, \infty) \to \mathbf{R}$. Restricting our study to this case is not realistic in applications to the wearing process of a stone, but we are so far forced to do so by technical difficulties. Despite this restriction, we believe that the results obtained here are of some interest at least from the mathematical viewpoint. A natural approach to a PDE model of the wearing process of a compact stone seems to be the level set approach. We refer to [2] for this approach to the Gauss curvature flow.

In the case of a convex stone, the PDE which the function u should satisfy is

$$u_t(x, t) = g(Du(x, t), D^2u(x, t)) \qquad \text{for } (x, t) \in \mathbf{R}^n \times (0, \infty),$$

where $g : \mathbf{R}^n \times \mathcal{S}^n \to \mathbf{R}$ is given by

$$g(p, X) = \frac{\det_+ X}{(1 + |p|^2)^{(n+1)/2}}.$$

Here and later we denote by $\mathcal{S}^n$ the space of all real $n \times n$ symmetric matrices, and, for $X \in \mathcal{S}^n$,

$$\det{}_+ X = \prod_{i=1}^{n} \max\{\lambda_i, 0\},$$

with λ_i denoting the eigenvalues of X.

The extension to the general case is straightforward, and, in the general case, the PDE for u to satisfy is

$$\text{(1.1)} \quad u_t(x, t) = \chi(u, Du(x, t), x, t)g(Du(x, t), D^2u(x, t)) \qquad \text{for } (x, t) \in \mathbf{R}^n \times (0, \infty),$$

where $\chi : \mathcal{F} \times \mathbf{R}^n \times \mathbf{R}^n \times (0, \infty) \to \{0, 1\}$ is given by

$$\chi(u, p, x, t) = \begin{cases} 1 & \text{if } u(y, t) \geq u(x, t) + p \cdot (y - x) \quad \text{for } y \in \mathbf{R}^n, \\ 0 & \text{otherwise,} \end{cases}$$

and $\mathcal{F}$ denotes the space of all real functions on $\mathbf{R}^n \times (0, \infty)$. The heuristic meaning of χ in (1.1) is that if $\chi(u, p, x, t) = 0$, then the point $(x, u(x, t))$ on the surface (of the stone) $y \geq u(x, t)$ is not hit by the hyperplane (the sea bottom) $H_{(p,-1)}$, and otherwise it is hit by $H_{(p,-1)}$. The precise meaning of (1.1) will be clarified in the next section.

One of the new features in the PDE (1.1) is its nonlocality due to the factor χ.

Our primary purposes are to establish a comparison result for solutions of (1.1) and an existence theorem of solutions of (1.1). We use the notion of viscosity solution adapted to (1.1), and some stability results are established as well. The comparison result is stated and proved in section 2, the existence result is treated in section 3, and stability properties of viscosity solutions of (1.1) are discussed in section 4.

Finally, we wish to pursue some properties of solutions of (1.1) in a future publication.

2. Comparison theorem. We first introduce a function which describes the asymptotic behavior of solutions we shall be concerned with. Let h_0 be a real-valued function on $\mathbf{R}^n$. Assume that

$$h_0 \in C(\mathbf{R}^n) \quad \text{and} \quad h_0(x) \geq \varepsilon_0 |x| \quad \forall x \in \mathbf{R}^n, \tag{2.1}$$

for some constant $\varepsilon_0 > 0$.

Let $u, v : \mathbf{R}^n \times [0, \infty) \to \mathbf{R}$. We make the following assumptions:

$$u \in \mathrm{USC}(\mathbf{R}^n \times [0, \infty)),\ v \in \mathrm{LSC}(\mathbf{R}^n \times [0, \infty)), \tag{2.2}$$

$$u(x, 0) \leq v(x, 0)\ \forall x \in \mathbf{R}^n. \tag{2.3}$$

For each $T > 0$,

$$\sup_{(x,t) \in \mathbf{R}^n \times [0,T]} (|u(x, t) - h_0(x)| + |v(x, t) - h_0(x)|) < \infty. \tag{2.4}$$

u satisfies

$$u_t(x, t) \leq \chi^+(u, Du(x, t), x, t) g(Du(x, t), D^2 u(x, t)) \quad \text{in } \mathbf{R}^n \times (0, \infty) \tag{2.5}$$

in the viscosity sense, where

$$\chi^+(u, p, x, t) = \chi(u, p, x, t).$$

To be more precise, we call $u \in \mathrm{USC}(\mathbf{R}^n \times (0, \infty))$ a viscosity subsolution of (1.1) if whenever $\varphi \in C^2(\mathbf{R}^n \times (0, \infty))$ and $u - \varphi$ attains its maximum at $(\hat{x}, \hat{t}) \in \mathbf{R}^n \times (0, \infty)$, then

$$\varphi_t(\hat{x}, \hat{t}) \leq \chi^+(u, D\varphi(\hat{x}, \hat{t}), \hat{x}, \hat{t}) g(D\varphi(\hat{x}, \hat{t}), D^2\varphi(\hat{x}, \hat{t})).$$

The condition (2.5) is now stated that u is a viscosity subsolution of (1.1). v satisfies

$$v_t(x, t) \geq \chi^-(v, Dv(x, t), x, t) g(Dv(x, t), D^2 v(x, t)) \quad \text{in } \mathbf{R}^n \times (0, \infty) \tag{2.6}$$

in the viscosity sense, where

$$\chi^- \equiv \chi^-(v, p, x, t) = 1$$

if

$$v(y, t) > v(x, t) + p \cdot (y - x) \quad \text{for } y \in \mathbf{R}^n \setminus \{x\},$$

and there is $\varepsilon > 0$ such that for all $(y, s) \in \mathbf{R}^n \times (0, \infty)$ satisfying $|y| > \varepsilon^{-1}$ and $|s - t| < \varepsilon$,

$$v(y, s) > p \cdot y + \varepsilon |y|,$$

and, otherwise,

$$\chi^- \equiv \chi^-(v, p, x, t) = 0.$$

Again, to be precise, we call a function $v \in \mathrm{LSC}(\mathbf{R}^n \times (0,\infty))$ a viscosity supersolution of (1.1) if whenever $\varphi \in C^2(\mathbf{R}^n \times (0,\infty))$ and $u-\varphi$ attains its minimum at $(\hat{x},\hat{t}) \in \mathbf{R}^n \times (0,\infty)$, then

$$\varphi_t(\hat{x},\hat{t}) \geq \chi^-(u, D\varphi(\hat{x},\hat{t}), \hat{x}, \hat{t}) g(D\varphi(\hat{x},\hat{t}), D^2\varphi(\hat{x},\hat{t})).$$

The exact meaning of (2.6) is that v is a viscosity supersolution of (1.1).

We call a function $u : \mathbf{R}^n \times (0,\infty) \to \mathbf{R}$ a viscosity solution of (1.1) if the function

$$u^*(x,t) := \lim_{r\downarrow 0} \sup\{u(y,s) \mid |y-x| + |s-t| \leq r\}$$

is a viscosity subsolution of (1.1) and the function

$$u_*(x,t) := \lim_{r\downarrow 0} \inf\{u(y,s) \mid |y-x| + |s-t| \leq r\}$$

is a viscosity supersolution of (1.1). We often suppress "viscosity" for the sake of simplicity of presentation.

THEOREM 1. *Assume that* (2.1)–(2.6) *hold.* (a) *For any $\theta \in (0,1)$, the inequality $u(x,\theta t) \leq v(x,t)$ holds for all $(x,t) \in \mathbf{R}^n \times [0,\infty)$.* (b) *Assume, in addition, that*

$$h_0 \in C^2(\mathbf{R}^n),$$

$$\det{}_+ D^2 h_0(x) \leq C\left(1 + |Dh_0(x)|^2\right)^{(n+1)/2} \quad \forall x \in \mathbf{R}^n,$$

for some constant $C > 0$ and that for each $\varepsilon > 0$ there is a constant $R \equiv R(\varepsilon) > 0$ such that for all $x \in \mathbf{R}^n$, if $|x| \geq R$, then

$$u(x,0) - \varepsilon \leq h_0(x) \leq v(x,0) + \varepsilon.$$

Then $u \leq v$ on $\mathbf{R}^n \times [0,\infty)$.

Remark. Note that under the assumptions of (b) above, the function

$$w(x,t) = Ct + h_0(x)$$

satisfies

$$w_t(x,t) \geq g(Dw(x,t), D^2 w(x,t)) \quad \forall (x,t) \in \mathbf{R}^n \times (0,\infty).$$

Proof. First, we prove part (a). We fix $\theta \in (0,1)$ and $T > 0$ and intend to prove that

$$u(x,\theta t) \leq v(x,t) \quad \forall (x,t) \in \mathbf{R}^n \times [0,T). \tag{2.7}$$

Define

$$u_\theta(x,t) := u(x,\theta t) \quad \forall (x,t) \in \mathbf{R}^n \times [0,\infty),$$

and observe that

$$u_{\theta,t} \leq \theta \chi^+ g(Du_\theta, D^2 u_\theta) \quad \text{in } \mathbf{R}^n \times [0,\infty).$$

In view of (2.4), we may assume, if necessary, by adding u and v a constant that $u \geq 0$ on $\mathbf{R}^n \times [0,T)$.

Let $\mu \in (0,1)$ be such that $\theta\mu^{1-n} \leq 1$. Noting that for $(p,x,t) \in \mathbf{R}^n \times \mathbf{R}^n \times (0,\infty)$, if

$$u_\theta(y,t) \geq u_\theta(x,t) + p \cdot (y-x) \quad \forall y \in \mathbf{R}^n,$$

then

$$\mu u_\theta(y,t) \geq \mu u_\theta(x,t) + \mu p \cdot (y-x) \quad \forall y \in \mathbf{R}^n,$$

and computing formally that, since $\theta\mu \leq \mu^n$,

$$\begin{aligned}\mu u_{\theta,t} &\leq \mu\theta u_t(x,\theta t) \leq \mu^n \chi^+(u_\theta, Du_\theta, x, t)\frac{\det_+ D^2 u_\theta}{(1+|Du_\theta|^2)^{(n+1)/2}} \\ &\leq \chi^+(\mu u_\theta, \mu Du_\theta, x, t)\frac{\det_+(\mu D^2 u_\theta)}{(1+|\mu Du_\theta|^2)^{(n+1)/2}},\end{aligned}$$

we see that μu_θ is a subsolution of

$$u_t \leq \chi^+ g(Du, D^2 u) \quad \text{ in } \mathbf{R}^n \times (0,\infty).$$

In order to prove (2.7), it is enough to show that for all $\mu \in (0,1)$ satisfying $\theta\mu^{1-n} \leq 1$, we have

$$\mu u_\theta \leq v \quad \text{ on } \mathbf{R}^n \times [0,T). \tag{2.8}$$

Fix $\mu \in (0,1)$ such that $\theta\mu^{1-n} \leq 1$. To see that (2.8) holds for this μ, we suppose to the contrary that

$$\sup_{\mathbf{R}^n \times [0,T)} (\mu u_\theta - v) > 0.$$

By assumption (2.4), there is a constant $C_0 > 0$ such that

$$|u(x,t) - h_0(x)| + |v(x,t) - h_0(x)| \leq C_0 \quad \forall (x,t) \in \mathbf{R}^n \times [0,T].$$

From this, we see that for all $x \in \mathbf{R}^n$ and $t, s \in [0,T]$,

$$\begin{aligned}\mu u_\theta(x,t) \leq\ & \mu(h_0(x) + C_0) \leq v(x,s) + C_0 + (\mu - 1)(h_0(x) + C_0) \\ \leq\ & v(x,s) - (1-\mu)\varepsilon_0|x| + 2C_0.\end{aligned} \tag{2.9}$$

In particular, we see that there is $R > 0$ such that, for all $(x,t) \in \mathbf{R}^n \times [0,T]$, if $|x| \geq R$, then

$$\mu u_\theta(x,t) \leq v(x,t).$$

For notational simplicity, we write $w := \mu u_\theta$.

Subtracting from w a function like

$$\frac{\alpha}{T + \alpha^2 - t},$$

where α is a small positive constant, we may assume that

$$w_t \leq \chi^+ g(Dw, D^2 w) - \delta \quad \forall (x,t) \in \mathbf{R}^n \times (0,T),$$

for some constant $\delta > 0$. Moreover, there is a constant $\gamma \in (0, T/2)$ such that

$$w \le v \quad \forall (x,t) \in B(0,R) \times ([0,\gamma] \cup [T-\gamma, T].$$

Set

$$Q := B(0, R+\gamma) \times [0,T]$$

and

$$M := \sup_Q (|w| + |v|).$$

We assume for the moment that for some $(\xi, \tau) \in Q$ and $p \in \mathbf{R}^n$,

$$w(x,\tau) \ge w(\xi,\tau) + p \cdot (x - \xi) \quad \forall x \in \mathbf{R}^n. \tag{2.10}$$

Then we observe by using (2.9) that for any $(\eta, \sigma) \in Q$,

$$\begin{aligned} v(x,\sigma) &\ge w(x,\tau) + (1-\mu)\varepsilon_0|x| - 2C_0 \ge w(\xi,\tau) + p\cdot(x-\xi) + (1-\mu)\varepsilon_0|x| - 2C_0 \\ &= v(\eta,\sigma) + p\cdot(x-\eta) + (1-\mu)\varepsilon_0|x| + p\cdot(\eta-\xi) + w(\xi,\tau) - v(\eta,\sigma) - 2C_0. \end{aligned}$$

Observe as well that

$$h_0(x) + C_0 \ge h_0(\xi) - C_0 + p \cdot (x-\xi) \quad \forall x \in \mathbf{R}^n$$

and hence that

$$|p| \le 2C_0 + h_0(\xi) - h_0(\xi + |p|^{-1}p) \le 2C_0 + 2 \sup_{B(0,R+\gamma+1)} |h_0|.$$

Now we choose a constant $L > 0$ so that

$$\frac{1}{2}(1-\mu)\varepsilon_0(R+L) > 2C_0 + 4(R+\gamma)\left(C_0 + \sup_{B(0,R+\gamma)} |h_0|\right) + M,$$

and, consequently, for all $x \in \mathbf{R}^n$ and $(\eta,\sigma) \in Q$, if $|x| \ge R + L$ and if (2.10) holds for some $(\xi,\tau) \in Q$ and $p \in \mathbf{R}^n$, then

$$v(x,\sigma) > v(\eta,\sigma) + p \cdot (x - \eta). \tag{2.11}$$

Set $Q_L := B(0, R+L+\gamma) \times [0,T]$. Let $\varepsilon \in (0,1)$ and

$$w^\varepsilon(x,t) = \max\left\{ w(y,s) - \frac{1}{2\varepsilon}(|x-y|^2 + |t-s|^2) \;\middle|\; (y,s) \in Q_L \right\},$$

and

$$v_\varepsilon(x,t) = \min\left\{ v(y,s) + \frac{1}{2\varepsilon}(|x-y|^2 + |t-s|^2) \;\middle|\; (y,s) \in Q_L \right\}.$$

It is well known that

$$w \le w^\varepsilon \quad \text{and} \quad v \ge v_\varepsilon \quad \text{on } Q_L$$

and that if $\varepsilon > 0$ is sufficiently small, then

$$w^\varepsilon(x,t) > w(y,s) - \frac{1}{2\varepsilon}(|x-y|^2 + |t-s|^2)$$

and

$$v_\varepsilon(x,t) < v(y,s) + \frac{1}{2\varepsilon}(|x-y|^2 + |t-s|^2)$$

hold for all $(x,t),(y,s) \in Q_L$ such that $|x-y|^2 + |t-s|^2 \geq (\gamma/2)^2$. Fix such a small $\varepsilon > 0$. Set $Q' := \mathrm{int}B(0, R+\gamma/2) \times (\gamma/2, T-\gamma/2)$. Again, it is well known that if $(x,t) \in Q'$ and $(p,q,X) \in J^{2,+}w^\varepsilon(x,t)$, then, for $y = x + \varepsilon p$ and $s = t + \varepsilon q$,

$$w^\varepsilon(x,t) = w(y,s) - \frac{1}{2\varepsilon}\left(|x-y|^2 + |t-s|^2\right)$$

and

$$(p,q,X) \in J^{2,+}w(y,s).$$

We refer to [4] for the definition of $J^{2,\pm}$. Similarly, if $(x,t) \in Q'$ and $(p,q,X) \in J^{2,-}v_\varepsilon(x,t)$, then, for $y = x - \varepsilon p$ and $s = t - \varepsilon q$,

$$v_\varepsilon(x,t) = v(y,s) + \frac{1}{2\varepsilon}\left(|x-y|^2 + |t-s|^2\right)$$

and

$$(p,q,X) \in J^{2,-}v(y,s).$$

Finally, as is well known, w^ε and $-v_\varepsilon$ are Lipschitz continuous and semiconvex on $\mathbf{R}^{n+1}$.

We maximize functions which are small perturbations of the function $w^\varepsilon - v_\varepsilon$ on Q_L. First, we note that

$$\max_{Q_L \setminus Q'}(w^\varepsilon - v_\varepsilon) \leq 0 < \max_{Q_L}(w^\varepsilon - v_\varepsilon). \tag{2.12}$$

By perturbed optimization techniques (see, e.g., [5, Corollary 3.8]), for each $n \in \mathbf{N}$ there is $(a_n, b_n) \in \mathbf{R}^n \times \mathbf{R}$ such that the function

$$w^\varepsilon(x,t) - v_\varepsilon(x,t) - a_n \cdot x - b_n t$$

on Q_L attains a strict maximum at a point $(x_n, t_n) \in Q_L$ and such that $|a_n| + |b_n| < 1/n$.

Focusing our attention on large $n \in \mathbf{N}$, in view of (2.12), we may assume that $(x_n, t_n) \in Q'$.

For each such $n \in \mathbf{N}$ there is a function $\psi_n \in C^2(\mathbf{R}^n)$ such that

$$\psi_n(x) > 0 \quad \forall x \neq x_n, \qquad \psi_n(x_n) = 0;$$

$$\psi_n(x) \text{ is strictly convex on } \mathbf{R}^n;$$

$$w^\varepsilon(x,t) - v_\varepsilon(x,t) - a_n \cdot x - b_n t + \psi_n(x) \text{ attains a strict maximum at } (x_n, t_n);$$

$$\|\psi_n\|_\infty + \|D\psi_n\|_\infty + \|D^2\psi_n\|_\infty < 1/n.$$

By Jensen's maximum principle (see, e.g., [4, Lemmas A.2 and A.3]), there are $(p_n, q_n) \in \mathbf{R}^n \times \mathbf{R}$ and $(y_n, s_n) \in Q_L$ such that $w^\varepsilon(x,t) - v_\varepsilon(x,t) + \psi_n(x) - (a_n + p_n)\cdot x - (b_n + q_n)t$ attains a maximum at (y_n, s_n) over Q_L, w^ε and v_ε are twice differentiable at (y_n, s_n), and $|p_n| + |q_n| < 1/n$. We may assume that $(y_n, s_n) \in Q'$.

By the elementary maximum principle, we have

$$P_n := Dw^\varepsilon(y_n, s_n) = Dv_\varepsilon(y_n, s_n) - D\psi_n(y_n) + a_n + p_n,$$

$$Q_n := w^\varepsilon_t(y_n, s_n) = v_{\varepsilon,t}(y_n, s_n) + b_n + q_n,$$

$$X_n := D^2 w^\varepsilon(y_n, s_n) \le D^2 v_\varepsilon(y_n, s_n) - D^2\psi_n(y_n).$$

By the semiconvexity of w^ε and $-v_\varepsilon$, we have

$$-\frac{1}{\varepsilon} I \le D^2 w^\varepsilon(y_n, s_n), \quad D^2 v_\varepsilon(y_n, s_n) \le \frac{1}{\varepsilon} I.$$

Moreover, w^ε and v_ε are Lipschitz continuous on Q. For example, there is a constant $C \equiv C(\varepsilon) > 0$ such that for $(x,t), (y,s) \in Q$,

$$|w^\varepsilon(x,t) - w^\varepsilon(y,s)| + |v_\varepsilon(x,t) - v_\varepsilon(y,s)| \le C(|x-y| + |t-s|).$$

As a consequence, we have

$$|Dw^\varepsilon(y_n, s_n)| + |Dv_\varepsilon(y_n, s_n)| + |w^\varepsilon_t(y_n, s_n)| + |v_{\varepsilon,t}(y_n, s_n)| \le 4C.$$

Let $(\xi_n, t_n) \in Q_L$ and $(\eta_n, \sigma_n) \in Q_L$ be the maximum and minimum points of functions

$$w(x,t) - \frac{1}{2\varepsilon}\left(|x - y_n|^2 + |t - s_n|^2\right)$$

and

$$v(x,t) + \frac{1}{2\varepsilon}\left(|x - y_n|^2 + |t - s_n|^2\right)$$

on Q_L, respectively. Recall that

$$|\xi_n - y_n|^2 + |\tau_n - \sigma_n|^2 < (\gamma/2)^2 \quad \text{and} \quad |\eta_n - y_n|^2 + |\sigma_n - s_n|^2 < (\gamma/2)^2$$

and hence that $(\xi_n, \tau_n),\ (\eta_n, \sigma_n) \in \text{int}Q$.

Now we have

$$Q_n \le \chi^+(w, P_n, \xi_n, \tau_n) g(P_n, X_n) - \delta;$$

$$\begin{aligned} Q_n - q_n - b_n \ge & \chi^-(v, P_n + D\psi_n(y_n) - a_n - p_n, \eta_n, \sigma_n) \\ & \cdot g(P_n + D\psi_n(y_n) - a_n - p_n, X_n + \psi_n(y_n)). \end{aligned}$$

If $\chi^+(w, P_n, \xi_n, \tau_n) = 0$, then

$$Q_n + \delta \le 0 \le Q_n - q_n - b_n. \tag{2.13}$$

Suppose instead that $\chi^+(w, P_n, \xi_n, \tau_n) = 1$. This yields

$$w(x, \tau_n) \geq w(\xi_n, \tau_n) + P_n \cdot (x - \xi_n) \quad \forall x \in \mathbf{R}^n. \tag{2.14}$$

We have from this

$$w(x, \tau_n) - \frac{1}{2\varepsilon}(|y_n - \xi_n|^2 + |s_n - \tau_n|^2) \geq w^\varepsilon(y_n, s_n) + P_n \cdot (x - \xi_n) \quad (x \in \mathbf{R}^n).$$

If $y \in B(0, R + L + \gamma/2)$, then $x := y + \xi_n - y_n \in B(0, R + L + \gamma)$, and we have

$$w^\varepsilon(y_n, s_n) + P_n \cdot (y - y_n) \leq w(y + \xi_n - y_n, \tau_n) - \frac{1}{2\varepsilon}(|y_n - \xi_n|^2 + |s_n - \tau_n|^2) \leq w^\varepsilon(y, s_n).$$

Since (y_n, s_n) is a maximum point of

$$w^\varepsilon(x, t) - v_\varepsilon(x, t) + \psi_n(x) - (a_n + p_n) \cdot x - (q_n + b_n)t$$

over Q_L, we have for any $x \in \mathbf{R}^n$, with $|x| \leq R + L + \gamma$,

$$\begin{aligned}
&w^\varepsilon(x, s_n) - v_\varepsilon(x, s_n) + \psi_n(x) - (a_n + p_n) \cdot x - (q_n + b_n)s_n \\
&\leq w^\varepsilon(y_n, s_n) - v_\varepsilon(y_n, s_n) + \psi_n(y_n) - (a_n + p_n) \cdot y_n - (q_n + b_n)s_n.
\end{aligned}$$

Thus, using the strict convexity of ψ_n, for any $x \neq y_n$ with $|x| \leq R + L + \gamma/2$, we have

$$\begin{aligned}
v_\varepsilon(x, s_n) &\geq v_\varepsilon(y_n, s_n) + w^\varepsilon(x, s_n) - w^\varepsilon(y_n, s_n) + \psi_n(x) - \psi_n(y_n) \\
&\quad - (a_n + p_n) \cdot (x - y_n) \\
&\geq v^\varepsilon(y_n, s_n) + (P_n - a_n - p_n) \cdot (x - y_n) + \psi_n(x) - \psi_n(y_n) \\
&> v_\varepsilon(y_n, s_n) + (P_n - a_n - p_n + D\psi_n(y_n)) \cdot (x - y_n).
\end{aligned}$$

Therefore, we have, for all $x \in B(0, R + L + \gamma/2)$ with $x \neq y_n$ and $(y, s) \in Q_L$,

$$\begin{aligned}
v(y, s) &+ \frac{1}{2\varepsilon}\left(|y - x|^2 + |s - s_n|^2\right) \\
&> v(\eta_n, \sigma_n) + \frac{1}{2\varepsilon}\left(|\eta_n - y_n|^2 + |\sigma_n - s_n|^2\right) \\
&\quad + (P_n - a_n - p_n + D\psi_n(y_n)) \cdot (x - y_n),
\end{aligned}$$

and hence, for $y \in B(0, R + L)$ with $y \neq \eta_n$, plugging $s = \sigma_n$, $x = y + y_n - \eta_n \in B(0, R + L + \gamma/2) \setminus \{y_n\}$, we get

$$v(y, \sigma_n) > v(\eta_n, \sigma_n) + (P_n - a_n - p_n + D\psi_n(y_n)) \cdot (y - \eta_n).$$

On the other hand, by our choice of L (see (2.11)), we have from (2.14)

$$v(y, \sigma_n) > v(\eta_n, \sigma_n) + P_n \cdot (y - \eta) + \frac{1}{2}(1 - \mu)\varepsilon_0|y| \tag{2.15}$$

for all $y \in \mathbf{R}^n$ satisfying $|y| \geq R + L$. Choosing n large enough, we may assume that for all $y \in \mathbf{R}^n$, if $|y| \geq R + L$, then

$$(|a_n| + |p_n| + |D\psi_n(y_n)|)(|y| + R + \gamma) \leq \frac{1}{2}(1 - \mu)\varepsilon_0|y|.$$

Then we have

$$v(x,\sigma_n) > v(\eta_n,\sigma_n) + (P_n - a_n - p_n + D\psi_n(y_n)) \cdot (x - \eta_n) \quad \forall x \in \mathbf{R}^n \setminus \{\eta_n\}.$$

This, together with (2.15), guarantees that

$$\chi^-(v, P_n + D\psi_n(y_n) - a_n - p_n, \eta_n, \sigma_n) = 1,$$

and we have

$$g(P_n + D\psi_n(y_n) - a_n - p_n, X_n + \psi_n(y_n)) \le Q_n - q_n - b_n \le g(P_n, X_n) - \delta.$$

This and (2.13) yield a contradiction as we send $n \to \infty$.

Next we prove part (b). Fix $\varepsilon > 0$. Select $R > 0$ so that

$$u(x,0) - \varepsilon \le h_0(x) \le v(x,0) + \varepsilon \quad \forall x \in \mathbf{R}^n \setminus B(0,R).$$

We note that there is a function $k_\varepsilon(x) \in C(B(0,R+1))$ such that

$$u(x,0) - \varepsilon/2 \le k_\varepsilon(x) \le v(x,0) + \varepsilon/2 \quad \forall x \in B(0,R+1). \tag{2.16}$$

Indeed, since $u(x,0)$ is upper semicontinuous on $B(0,R+1)$, we find a sequence of continuous functions j_n on $B(0,R+1)$ such that

$$j_n(x) \downarrow u(x,0) \quad \text{as } n \to \infty \quad \forall x \in B(0,R+1).$$

Then, noting that

$$(j_n(x) - v(x,0))_+ \downarrow 0 \quad \text{as } n \to \infty$$

and the functions $(j_n(x) - v(x,0))_+$ are upper semicontinuous on $B(0,R+1)$, by virtue of Dini's lemma, we see that

$$(j_n(x) - v(x,0))_+ \downarrow 0$$

uniformly on $B(0,R+1)$ as $n \to \infty$. Selecting n large enough, the function j_n satisfies (2.16) with $k_\varepsilon = j_n$. Now a simple argument based on the mollification of k_ε and on partition of unity, we see that there is a function $h_\varepsilon \in C^2(\mathbf{R}^n)$ such that

$$u(x,0) - \varepsilon \le h_\varepsilon(x) \le v(x,0) + \varepsilon \quad \forall x \in \mathbf{R}^n,$$

and, for some constant $C_\varepsilon > 0$,

$$\det{}_+ D^2 h_\varepsilon(x) \le C_\varepsilon (1 + |Dh_\varepsilon(x)|^2)^{(n+1)/2} \quad \forall x \in \mathbf{R}^n. \tag{2.17}$$

Set $z(x,t) := h_\varepsilon(x) + \varepsilon + C_\varepsilon t$ for $(x,t) \in \mathbf{R}^n \times [0,\infty)$. By (2.17) we see that z is a supersolution of

$$z_t \ge g(Dz, D^2 z) \quad \text{in } \mathbf{R}^n \times (0,\infty).$$

Moreover, z satisfies not only this property but also the other properties required for v in part (a). Hence we see that, for any $\theta \in (0,1)$,

$$u(x,\theta t) \le z(x,t) \quad \forall (x,t) \in \mathbf{R}^n \times [0,\infty),$$

i.e.,

$$u(x,t) \le z(x,\theta^{-1}t) \quad \forall (x,t) \in \mathbf{R}^n \times [0,\infty).$$

Since z is continuous, we get

$$u(x,t) \le z(x,t) \quad \forall (x,t) \in \mathbf{R}^n \times [0,\infty).$$

Now let $\delta > 0$, and observe that

$$u(x,\delta) \le z(x,\delta) = h_\varepsilon(x) + \varepsilon + C_\varepsilon\delta \le v(x,0) + 2\varepsilon + C_\varepsilon\delta \quad \forall x \in \mathbf{R}^n.$$

Define

$$w(x,t) := u(x,\delta+t) - 2\varepsilon - C_\varepsilon\delta \quad \forall (x,t) \in \mathbf{R}^n \times [0,\infty).$$

Then w satisfies all the properties required for u in part (a), and hence we have

$$w(x,\theta t) \le v(x,t) \quad \forall (x,t) \in \mathbf{R}^n \times [0,\infty),\ \forall \theta \in (0,1).$$

For example, we have

$$u(x,\delta+\theta t) \le v(x,t) + 2\varepsilon + C_\varepsilon\delta \quad ((x,t) \in \mathbf{R}^n \times [0,\infty)\ \forall \theta \in (0,1).$$

Therefore, for all $(x,t) \in \mathbf{R}^n \times (\delta,\infty)$, choosing $\theta = (t-\delta)/t \in (0,1)$ in the above, we have

$$u(x,t) \le v(x,t) + 2\varepsilon + C_\varepsilon\delta.$$

Letting $\delta \downarrow 0$, we see that $u(x,t) \le v(x,t) + 2\varepsilon$ for all $(x,t) \in \mathbf{R}^n \times (0,\infty)$. It is immediate to conclude that $u \le v$ in $\mathbf{R}^n \times [0,\infty)$. □

3. Existence theorem. Let $h \in C(\mathbf{R}^n)$ satisfy

$$\lim_{|x|\to\infty} \big|h(x) - h_0(x)\big| = 0, \tag{3.1}$$

where $h_0 \in C^2(\mathbf{R}^n)$ is a function satisfying (2.1) and

$$\det{}_+ D^2 h_0(x) \le C(1 + |Dh_0(x)|^2)^{(n+1)/2} \quad \forall x \in \mathbf{R}^n, \tag{3.2}$$

for some constant $C > 0$.

THEOREM 2. *Assume that* (3.1) *and* (3.2) *hold. Then there is a viscosity solution* $u \in C(\mathbf{R}^n \times [0,\infty))$ *of*

$$\begin{cases} u_t(x,t) = \chi(u, Du(x,t), x, t) g(Du(x,t), D^2u(x,t)) & \textit{in } \mathbf{R}^n \times (0,\infty), \\ u(x,0) = h(x) \qquad \textit{for } x \in \mathbf{R}^n \end{cases} \tag{3.3}$$

satisfying

$$\sup_{(x,t)\in\mathbf{R}^n\times[0,T]} |u(x,t) - h(x)| < \infty \quad \forall T > 0. \tag{3.4}$$

Proof of Theorem 2. *Step* 1. *Construction of a supersolution:* Let $\varepsilon \in (0,1)$, and let $h_\varepsilon \in C^2(\mathbf{R}^n)$ be a function such that

$$|h(x) - h_\varepsilon(x)| < \varepsilon \quad \forall x \in \mathbf{R}^n;$$

$$\det{}_+ D^2 h_\varepsilon(x) \le C_\varepsilon (1 + |Dh_\varepsilon(x)|^2)^{(n+1)/2} \quad \forall x \in \mathbf{R}^n,$$

for some constant $C_\varepsilon > 0$.

Set

$$w(x,t;\varepsilon) := \varepsilon + h_\varepsilon(x) + C_\varepsilon t \quad \forall (x,t) \in \mathbf{R}^n \times [0,\infty).$$

Then the function $w(x,t;\varepsilon)$ of (x,t) is a supersolution of

$$w_t \ge \chi^- g(Dw, D^2 w) \quad \text{in } \mathbf{R}^n \times (0,\infty)$$

and satisfies

$$h(x) \le w(x,t;\varepsilon) \le h(x) + 2\varepsilon + C_\varepsilon t \quad \forall (x,t) \in \mathbf{R}^n \times [0,\infty). \tag{3.5}$$

Define

$$v(x,t) := \inf_{\varepsilon \in (0,1)} w(x,t;\varepsilon) \quad \forall (x,t) \in \mathbf{R}^n \times [0,\infty).$$

Since the pointwise infimum of supersolutions is a supersolution, the function v_* is a supersolution of

$$v_t \ge \chi^- g(Dv, D^2 v) \quad \text{in } \mathbf{R}^n \times (0,\infty).$$

Moreover, v is USC on $\mathbf{R}^n \times [0,\infty)$, $v(x,0) = h(x)$ for all $x \in \mathbf{R}^n$ by (3.5), and, for each $T > 0$, $h(x) \le v(x,t) \le h(x) + C_T$ for all $(x,t) \in \mathbf{R}^n \times [0,T]$ and for some constant $C_T > 0$ by (3.5).

Step 2. *Construction of a subsolution.* We set

$$z(x,t) = h(x) \quad \forall (x,t) \in \mathbf{R}^n \times [0,\infty).$$

Then z is a subsolution of

$$z_t \le \chi^+ g(Dz, D^2 z) \quad \forall (x,t) \in \mathbf{R}^n \times (0,\infty)$$

and satisfies

$$z(x,0) = h(x) \quad \forall x \in \mathbf{R}^n;$$

$$z(x,t) \le h(x) \quad \forall x \in \mathbf{R}^n, \ \forall t \ge 0.$$

Step 3. *Perron's method.* We apply Perron's method (see Theorem 5) to obtain a solution u of (3.3) such that

$$h(x) \le u(x,t) \le v(x,t) \quad \forall (x,t) \in \mathbf{R}^n \times [0,\infty).$$

This inequality shows that

$$\sup_{(x,t) \in \mathbf{R}^n \times [0,T]} |u(x,t) - h(x)| < \infty \quad \forall T > 0$$

and that

$$\lim_{t \downarrow 0} \sup_{x \in \mathbf{R}^n} |u(x,t) - h(x)| = 0.$$

Now Theorem 1 yields that $u^* \le u_*$ on $\mathbf{R}^n \times [0,\infty)$ and therefore that $u \in C(\mathbf{R}^n \times [0,\infty))$. □

4. Stability properties. In this section, we establish some stability results for viscosity solutions of (1.1), the nature of which is rather standard in the theory of viscosity solutions [4]. Note that Theorem 5 has already been applied in the proof of Theorem 2.

Theorem 3. *Let* $\{u^\alpha\}$ *be a family of viscosity subsolutions of* (1.1). *Assume that the function*

$$u(x,t) := \Big(\sup_\alpha u^\alpha\Big)^*(x,t)$$

on $\mathbf{R}^n \times (0,\infty)$ *is locally bounded. Then* u *is a viscosity subsolution of* (1.1).

Theorem 4. *Let* $\{u^\alpha\}$ *be a family of viscosity supersolutions of* (1.1). *Assume that the function*

$$u(x,t) := \Big(\inf_\alpha u^\alpha\Big)_*(x,t)$$

on $\mathbf{R}^n \times (0,\infty)$ *is locally bounded. Then* u *is a viscosity supersolution of* (1.1).

Theorem 5. *Let* $f^- \in \mathrm{LSC}(\mathbf{R}^n \times [0,\infty))$ *and* $f^+ \in \mathrm{USC}(\mathbf{R}^n \times [0,\infty))$ *be a viscosity subsolution and a viscosity supersolution of* (1.1)*, respectively. Suppose that* $f^- \le f^+$ *on* $\mathbf{R}^n \times [0,\infty)$. *Let* $\mathcal{S}$ *be the set of viscosity subsolutions* v*, defined on* $\mathbf{R}^n \times [0,\infty)$*, of* (1.1) *such that* $f^- \le v \le f^+$ *on* $\mathbf{R}^n \times [0,\infty)$*, and set*

$$u(x,t) := \sup\{v(x,t) \mid v \in \mathcal{S}\} \quad \textit{for } (x,t) \in \mathbf{R}^n \times [0,\infty).$$

Then u *is a viscosity solution of* (1.1).

Proof of Theorem 3. Let $\varphi \in C^2(\mathbf{R}^n \times (0,\infty))$. Let $(\hat{x},\hat{t}) \in \mathbf{R}^n \times (0,\infty)$ be a maximum point of $u - \varphi$. We may assume that $(\hat{x},\hat{t})$ is a strict maximum point and that u^α is USC in $\mathbf{R}^n \times (0,\infty)$.

As usual, we can select sequences of α_n and of points $(x_n,t_n) \in \mathbf{R}^n \times (0,\infty)$ so that $u^{\alpha_n} - \varphi$ attains a local maximum at (x_n,t_n) and so that, as $n \to \infty$,

$$u^{\alpha_n}(x_n,t_n) \to u(\hat{x},\hat{t}) \quad \text{and} \quad (x_n,t_n) \to (\hat{x},\hat{t}).$$

In view of standard proofs, we need only to show that if

$$\chi^+\left(u^{\alpha_n}, D\varphi(x_n,t_n), x_n, t_n\right) = 1 \quad \forall n \in \mathbf{N}, \tag{4.1}$$

then

$$\chi^+(u, D\varphi(\hat{x},\hat{t}), \hat{x}, \hat{t}) = 1.$$

Let us assume that (4.1) holds. Then, by definition, we have

$$u^{\alpha_n}(y,t_n) \ge u^{\alpha_n}(x_n,t_n) + D\varphi(x_n,t_n)\cdot(y - x_n) \quad \forall y \in \mathbf{R}^n.$$

Hence we have

$$u(y,t_n) \ge u^{\alpha_n}(x_n,t_n) + D\varphi(x_n,t_n)\cdot(y - x_n) \quad \forall y \in \mathbf{R}^n.$$

Sending $n \to \infty$, we get

$$u(y,\hat{t}) \ge u(\hat{x},\hat{t}) + D\varphi(\hat{x},\hat{t})\cdot(y - \hat{x}) \quad \forall y \in \mathbf{R}^n,$$

i.e.,

$$\chi^+(u, D\varphi(\hat{x},\hat{t}), \hat{x},\hat{t}) = 1. \qquad \square$$

Proof of Theorem 4. Let $\varphi \in C^2(\mathbf{R}^n \times (0,\infty))$. Let $(\hat{x},\hat{t}) \in \mathbf{R}^n \times (0,\infty)$ be a minimum point of $u - \varphi$. We may assume that $(\hat{x},\hat{t})$ is a strict minimum point and that u^α is LSC in $\mathbf{R}^n \times (0,\infty)$.

As before, there are sequences of α_n and of points $(x_n, t_n) \in \mathbf{R}^n \times (0,\infty)$ so that $u^{\alpha_n} - \varphi$ attains a local minimum at (x_n, t_n) and, as $n \to \infty$,

$$u^{\alpha_n}(x_n,t_n) \to u(\hat{x},\hat{t}) \quad \text{and} \quad (x_n,t_n) \to (\hat{x},\hat{t}).$$

In view of standard proofs, we need only to show that if

$$\liminf_{n\to\infty} \chi^-\left(u^{\alpha_n}, D\varphi(x_n,t_n), x_n, t_n\right) = 0, \tag{4.2}$$

then

$$\chi^-(u, D\varphi(\hat{x},\hat{t}), \hat{x},\hat{t}) g(D\varphi(\hat{x},\hat{t}), D^2\varphi(\hat{x},\hat{t})) = 0. \tag{4.3}$$

We argue by contradiction and so assume that (4.2) holds and that (4.3) does not hold. By passing to a subsequence, we may assume that

$$\chi^-\left(u^{\alpha_n}, D\varphi(x_n,t_n), x_n, t_n\right) = 0 \quad \forall n \in \mathbf{N}. \tag{4.4}$$

We have

$$\chi^-(u, D\varphi(\hat{x},\hat{t}), \hat{x},\hat{t}) = 1; \tag{4.5}$$

$$g(D\varphi(\hat{x},\hat{t}), D^2\varphi(\hat{x},\hat{t})) > 0. \tag{4.6}$$

Then from (4.5) there is a constant $\varepsilon > 0$ such that, for $(x,t) \in \mathbf{R}^n \times (0,\infty)$, if $|x| > \varepsilon^{-1}$, $|t - \hat{t}| < \varepsilon$, then

$$u(x,t) > p \cdot x + 2\varepsilon|x|, \tag{4.7}$$

where $p := D\varphi(\hat{x},\hat{t})$. We write p_n for $D\varphi(x_n,t_n)$ as well. We may assume that $|t_n - \hat{t}| < \varepsilon/2$ and $|p_n - p| < \varepsilon$ for all $n \in \mathbf{N}$.

From (4.7), for all $n \in \mathbf{N}$ and $(x,t) \in \mathbf{R}^n \times (0,\infty)$, if $|x| > \varepsilon^{-1}$, $|t - t_n| < \varepsilon/2$, then we have

$$u^{\alpha_n}(x,t) > p_n \cdot x + \varepsilon|x|.$$

Therefore, we see from (4.4) that there is a sequence of points $y_n \in \mathbf{R}^n$ such that $y_n \neq x_n$ and such that

$$u^{\alpha_n}(y_n,t_n) \leq u^{\alpha_n}(x_n,t_n) + p_n \cdot (y_n - x_n), \tag{4.8}$$

which immediately yields

$$u(y_n,t_n) \leq u^{\alpha_n}(x_n,t_n) + p_n \cdot (y_n - x_n). \tag{4.9}$$

We see easily from (4.7) and (4.9) that there is a constant $R > 0$ such that

$$|y_n| \leq R \quad \forall n \in \mathbf{N}.$$

Thus there is a subsequence of $n \in \mathbf{N}$ such that along the subsequence, $\{y_n\}$ converges to a point $\hat{y} \in \mathbf{R}^n$. We have from (4.9)

$$u(\hat{y}, \hat{t}) \leq u(\hat{x}, \hat{t}) + p \cdot (\hat{y} - \hat{x}).$$

Now (4.6) implies that the matrix $D^2\varphi(\hat{x}, \hat{t})$ is positive definite. By continuity, there is a constant $\delta > 0$ such that

$$D^2\varphi(x,t) \geq \delta I \quad ((x,t) \in B(\hat{x}, \delta) \times [\hat{t} - \delta, \hat{t} + \delta]).$$

We may assume that $(x_n, t_n) \in B(\hat{x}, \delta/2) \times [\hat{t} - \delta/2, \hat{t} + \delta/2]$ for all $n \in \mathbf{N}$. By using Taylor's expansion, we see that, for all $n \in \mathbf{N}$ and $x \in B(x_n, \delta/2)$,

$$u^{\alpha_n}(x, t_n) \geq u^{\alpha_n}(x_n, t_n) + p_n \cdot (x - x_n) + \frac{\delta}{2}|x - x_n|^2.$$

This, together with (4.8), guarantees that $|y_n - x_n| > \delta/2$ for all $n \in \mathbf{N}$ and hence that $|\hat{y} - \hat{x}| \geq \delta/2$. Thus we see that

$$\chi^-(u, p, \hat{x}, \hat{t}) = 0,$$

which is a contradiction. □

Proof of Theorem 5. From Theorem 3, we know that u_* is a subsolution of

$$u_t \leq \chi^+ g(Du, D^2u) \quad \text{in } \mathbf{R}^n \times (0, \infty).$$

We must show that u_* is a supersolution of

$$u_t \geq \chi^- g(Du, D^2u) \quad \text{in } \mathbf{R}^n \times (0, \infty).$$

To do this, we argue by contradiction and so suppose that there are $\varphi \in C^2(\mathbf{R}^n \times (0, \infty))$ and $(\hat{x}, \hat{t}) \in \mathbf{R}^n \times (0, \infty)$ such that

$$\varphi_t(\hat{x}, \hat{t}) < \chi^-(u_*, D\varphi(\hat{x}, \hat{t}), \hat{x}, \hat{t}) g(D\varphi(\hat{x}, \hat{t}), D^2\varphi(\hat{x}, \hat{t}))$$

and such that $u_* - \varphi$ attains a strict minimum at $(\hat{x}, \hat{t})$. We may assume that $u_*(\hat{x}, \hat{t}) = \varphi(\hat{x}, \hat{t})$.

If

$$\chi^-(u_*, D\varphi(\hat{x}, \hat{t}), \hat{x}, \hat{t}) g(D\varphi(\hat{x}, \hat{t}), D^2\varphi(\hat{x}, \hat{t})) = 0,$$

then φ is a classical subsolution of

$$u_t < 0$$

in a neighborhood of $(\hat{x}, \hat{t})$, and the standard argument for Perron's method yields a contradiction.

Next consider the case where

$$\chi^-(u_*, D\varphi(\hat{x}, \hat{t}), \hat{x}, \hat{t}) g(D\varphi(\hat{x}, \hat{t}), D^2\varphi(\hat{x}, \hat{t})) > 0.$$

Let us write $\hat{u} = u_*(\hat{x}, \hat{t})$, $a = D\varphi(\hat{x}, \hat{t})$, and $b = \varphi_t(\hat{x}, \hat{t})$.

Fix $\eta > 0$ so that

$$D^2\varphi(x,t) > 0 \quad \forall (x,t) \in Q_\eta.$$

Here Q_η denotes the cylinder $\{(x,t) \in \mathbf{R}^n \times \mathbf{R} \mid |x-\hat{x}| < \eta,\ |t-\hat{t}| < \eta\}$, and η is chosen so small that $Q_\eta \subset \mathbf{R}^n \times (0,\infty)$.

Since

$$\chi^-(u_*, a, \hat{x}, \hat{t}) = 1,$$

we have

$$u_*(x,\hat{t}) > \hat{u} + a \cdot (x-\hat{x}) \quad \forall x \in \mathbf{R}^n \setminus \{\hat{x}\},$$

and

$$u_*(y,s) > a \cdot y + \delta|y| \quad \text{if } |y| > \delta^{-1},\ |s-\hat{t}| < \delta,$$

for some $\delta > 0$. From these, we deduce that there is $\gamma > 0$ such that if $|p-a| < \gamma$, $|t-\hat{t}| < \gamma$, and $|r-\hat{u}| < \gamma$, then

$$u_*(x,t) > r + p \cdot (x-\hat{x}) \quad \text{if } |x-\hat{x}| \geq \eta.$$

As usual in the proof of existence by Perron's method, we find $r > 0$ and $\varepsilon > 0$ such that

$$Q_{2r} \subset \mathbf{R}^n \times (0,\infty);$$

$$\varphi(x,t) + \varepsilon < u(x,t) \quad \text{if } (x,t) \in Q_{2r} \setminus \overline{Q}_r;$$

$$\varphi(x,t) + \varepsilon \leq g(x,t) \quad \text{if } (x,t) \in Q_{2r};$$

$$\varphi_t(x,t) < g(D\varphi(x,t), D^2\varphi(x,t)) \quad \text{if } (x,t) \in Q_{2r}.$$

We may assume that $Q_{2r} \subset Q_\eta$ and that

$$|\varphi(x,t) + \varepsilon - \hat{u}| < \gamma \quad \forall (x,t) \in Q_{2r},$$

$$|D\varphi(x,t) - a| < \gamma \quad \forall (x,t) \in Q_{2r},$$

and that $2r < \gamma$.

Note that for $(x,t) \in Q_{2r}$ and $y \in \mathbf{R}^n$, if $|y-\hat{x}| \geq \eta$, then we have

$$u_*(y,t) > \varphi(x,t) + \varepsilon + D\varphi(x,t) \cdot (y-x). \tag{4.10}$$

Define

$$v(x,t) := \begin{cases} u(x,t) & \text{for } (x,t) \in (\mathbf{R}^n \times (0,\infty)) \setminus \overline{Q}_r, \\ \max\{u(x,t), \varphi(x,t)+\varepsilon\} & \text{for } (x,t) \in \overline{Q}_r. \end{cases}$$

We intend to show that v^* is a subsolution in $\mathbf{R}^n \times (0,\infty)$. Let $\psi \in C^2(\mathbf{R}^n \times (0,\infty))$. Let $(y,s) \in \mathbf{R}^n \times (0,\infty)$ be a maximum point of the function $v^* - \psi$.

Noting that $v \geq u$ in $\mathbf{R}^n \times (0,\infty)$ and that $v = u$ on $\mathbf{R}^n \times (0,\infty) \setminus \overline{Q}_r$, we see that for $(p,x,t) \in \mathbf{R}^n \times \mathbf{R}^n \times (0,\infty)$, if $(x,t) \notin \overline{Q}_r$, then

$$\chi^+(v^*, p, x, t) \geq \chi^+(u^*, p, x, t).$$

Hence, if $(y,s) \notin \overline{Q}_r$, then

$$\psi_t(y,s) \le \chi^+(v^*, D\psi(y,s), y, s) g(D\psi(y,s), D^2\psi(y,s)).$$

Now assume that $(y,s) \in Q_{2r}$. If $v^*(y,s) = u^*(y,s)$, then, as above, we get

$$\psi_t(y,s) \le \chi^+(v^*, D\psi(y,s), y, s) g(D\psi(y,s), D^2\psi(y,s)).$$

If $v^*(y,s) = \varphi(y,s) + \varepsilon$, then $\varphi - \psi$ has a local maximum at (y,s). Hence we have

$$D\varphi(y,s) = D\psi(y,s), \quad \varphi_t(y,s) = \psi_t(y,s), \quad D^2\varphi(y,s) \le D^2\psi(y,s),$$

and, therefore,

$$\psi_t(y,s) \le g(D\psi(y,s), D^2\psi(y,s)).$$

Since $D^2\varphi(x,t) > 0$ in Q_{2r}, we have

$$\varphi(x,s) + \varepsilon \ge \varphi(y,s) + \varepsilon + D\varphi(y,s) \cdot (x-y) \quad \text{if } |x - \hat{x}| < 2r$$

and hence

$$v^*(x,s) \ge v^*(y,s) + D\varphi(y,s) \cdot (x-y) \quad \text{if } |x - \hat{x}| < 2r.$$

Furthermore, from (4.10) we have

$$v^*(x,s) \ge u^*(x,s) \ge \varphi(y,s) + \varepsilon + D\varphi(y,s) \cdot (x-y) \quad \text{if } x - \hat{x}| \ge 2r.$$

These together yield

$$v^*(x,s) \ge v^*(y,s) + D\psi(y,s) \cdot (x-y) \quad \text{if } x \in \mathbf{R}^n.$$

Thus we see that

$$\chi^+(v^*, D\psi(y,s), y, s) = 1$$

and conclude that

$$\psi_t(y,s) \le \chi^+(v^*, D\psi(y,s), y, s) g(D\psi(y,s), D^2\psi(y,s)),$$

which shows that v^* is a subsolution. Since $f^- \le v \le f^+$ and $v \not\le u$, this yields a contradiction. □

AN UP-TO-THE BOUNDARY VERSION OF FRIEDRICHS'S LEMMA AND APPLICATIONS TO THE LINEAR KOITER SHELL MODEL*

ADEL BLOUZA[†] AND HERVÉ LE DRET[‡]

Abstract. In this work, we introduce a variant of the standard mollifier technique that is valid up to the boundary of a Lipschitz domain in $\mathbb{R}^n$. A version of Friedrichs's lemma is derived that gives an estimate up to the boundary for the commutator of the multiplication by a Lipschitz function and the modified mollification. We use this version of Friedrichs's lemma to prove the density of smooth functions in the new function space introduced in our earlier work concerning the linear Koiter shell model for shells with little regularity. The density of smooth functions is in turn used to prove continuous dependence of the solution of Koiter's model on the midsurface. This provides a complete justification of our new formulation of the Koiter model.

1. Introduction.

Mollification is a basic technique in analysis. It is classically performed by convolution with a compactly supported mollifier. In order for the convolution to be defined, it is necessary either to work on the whole of $\mathbb{R}^n$ or in a compactly contained subdomain ω of the domain of interest Ω. For many classical function spaces on a domain Ω, approximation by smooth functions is quite straightforward if the boundary of the domain Ω is regular enough. In effect, in the latter case, there usually is a continuous extension operator that reduces the case of the domain to that of $\mathbb{R}^n$. It suffices to perform the mollification on the extended function and then restrict the mollifed function to the domain. See [1], [13], [14], [22], and [24] among others.

Our main field of application here is the linear Koiter shell model in elasticity (see [21]). In [5], [6], we introduced a new formulation of this model that makes sense and is well-posed for midsurfaces of class $W^{2,\infty}$ instead of C^3, as was customarily assumed earlier; see also [9] and [11] for shell models in the same context of regularity. The simplest and most natural examples of $W^{2,\infty}$-shells are given by globally C^1- and piecewise C^3-midsurfaces. Consider, for instance, a shell consisting of a planar part that is connected to a circular cylinder part or an egg-shaped shell made of a quarter of a sphere and a quarter of an ellipsoid glued together along a circle. Our new formulation entails the introduction of a new functional setting. The new function space involves multiplication of distributional partial derivatives of the functions by given Lipschitz functions related to the geometry of the midsurface. It is required that such quantities be square-integrable. To the best of our knowledge, this specific kind of function space was not studied before regarding such fundamental issues as the density or nondensity of smooth functions. There are relatively close ideas in

transport equation theory (see [2], [12], [10]) although the techniques used therein do not apply in our case. For the function space introduced in [5], there is no obvious extension operator, and it is not natural to work on the whole of $\mathbb{R}^2$. Thus different ideas were needed to address the density question.

One such idea was first put forth in [23], without mention of regularity for the domain, and was then rediscovered simultaneously later on by the authors and by [15] in a slightly different form. The idea consists in defining a new mollification technique in which the mollifier is simultaneously scaled and translated inside the domain. For the technique to work, it is necessary that the domain satisfy a uniform cone condition, which is practically equivalent to being Lipschitz; see [1], [16]. This simple but powerful idea yields mollified functions defined on the whole domain without any need for an extension operator to provide values for the function outside of its domain of definition.

It is a straightforward matter to reproduce the proof of Friedrichs's lemma using the above convolution-translation in place of the convolution itself. This gives an L^p estimate on the whole domain for the commutator of the convolution-translation and the multiplication by a Lipschitz function applied to partial derivatives of an L^p function.

This version of Friedrichs's lemma is the main tool in proving the density of smooth functions in the new function space for Koiter's model. This density has important consequences. For example, it shows that standard finite element methods actually approximate the solution of the newly formulated variational problem for Koiter's model; see [19] and [20]. Another consequence that we develop here is that if we consider a sequence of $W^{2,\infty}$-midsurfaces that converge in a natural sense toward a given midsurface and a sequence of loads that also converge, then the corresponding sequence of solutions to Koiter's model converges in a natural sense too. Since the new model coincides with the classical model for C^3-midsurfaces, taking a sequence of such C^3-midsurfaces converging to a midsurface that is only $W^{2,\infty}$ shows that our new formulation is an appropriate extension of the classical formulation to less regular midsurfaces from the mathematical point of view.

2. A modified mollification technique.

In this section, we develop the convolution-translation technique introduced in [23] (see also [15]) that allows for up-to-the-boundary mollification without requiring an extension operator. It is well known that the density of smooth functions in, for example, Sobolev spaces, may fail if the domain under consideration is not regular. It is thus natural that the regularity of the boundary should come into play.

First of all, let us recall the *uniform cone property* for a domain Ω in $\mathbb{R}^n$. We refer the reader to [1], [13], [16], and [24] for details.

DEFINITION 2.1. *An open set $\Omega \subset \mathbb{R}^n$ is said to satisfy the* cone property *if there exists an open cone*

$$C = \{x = (x', x_n) \in \mathbb{R}^n; 0 < x_n < h, |x'| < x_n \tan(\theta/2)\},$$

with $h > 0$ and $0 < \theta < \pi$, such that for every point x in $\bar{\Omega}$ there is a rotation R_x such that $\bar{C}_x = x + R_x\bar{C} \subset \bar{\Omega}$. In other words, any point x is the vertex of a cone congruent to C and included in $\bar{\Omega}$ (or Ω). Here $|\cdot|$ denotes the standard Euclidean norm either on $\mathbb{R}^{n-1}$ or on $\mathbb{R}^n$.

The set Ω is said to satisfy the uniform cone property *if there exists a locally finite open covering $\{U_i\}_{i\geq 1}$ of $\partial\Omega$, and a corresponding sequence $\{C_i\}$ of cones, each congruent to some fixed cone C, such that the following hold.*

(i) *There exists M such that every U_i has diameter less than M.*

(ii) *For some $\delta > 0$, $\Omega_\delta = \{x \in \Omega; \operatorname{dist}(x; \partial\Omega) < \delta\} \subset \bigcup_{i=1}^{\infty} U_i$.*

(iii) *For every $i \in \mathbb{N}$, $Q_i = \bigcup_{x \in \Omega \cap U_i} (x + C_i) \subset \Omega$.*

(iv) *There exists $N \in \mathbb{N}$ such that every collection of $N + 1$ of the sets Q_i has an empty intersection.*

Remark 2.2. Note that a bounded domain of $\mathbb{R}^n$ satisfies the uniform cone property if and only if its boundary is Lipschitz; see [7] or [16, Theorem 1.2.2.2]. □

Let us now introduce some notation for the convolution-translation operator, which is the basic tool for subsequent developments.

DEFINITION 2.3. *Let e be a unit vector in $\mathbb{R}^n$ and $\tau > 0$. For all $u, v \in L^1(\mathbb{R}^n)$, we define their convolution-translation (of amount τ in the direction e) $u \star_{\tau,e} v$ by*

$$u \star_{\tau,e} v(x) = u \star v(x - \tau e), \tag{2.1}$$

that is,

$$u \star_{\tau,e} v(x) = \int_{\mathbb{R}^n} u(x - \tau e - y) v(y)\, dy. \tag{2.2}$$

Obviously, $u \star_{\tau,e} v \in L^1(\mathbb{R}^n)$, $u \star_{\tau,e} v = v \star_{\tau,e} u$, and if v is C^∞, so is $u \star_{\tau,e} v$ with $\partial^\alpha(u \star_{\tau,e} v) = u \star_{\tau,e} \partial^\alpha v$ for any multi-index $\alpha \in \mathbb{N}^n$.

The interesting feature of this slightly modified convolution is that it can be used to define a mollification technique for Sobolev spaces that is valid up to the boundary of any domain in $\mathbb{R}^n$ that satisfies the uniform cone condition, without using any extension operator. Let us now describe how this can be achieved.

Let ρ be a standard mollifier, i.e., a positive C^∞ function on $\mathbb{R}^n$ supported in the unit ball and such that $\int_{\mathbb{R}^n} \rho(x)\, dx = 1$. Let Ω be a domain in $\mathbb{R}^n$ that satisfies the uniform cone condition, and denote by U_i the locally finite covering of the boundary from Definition 2.1. To entirely cover Ω, we let $U_0 = \{x \in \Omega; \operatorname{dist}(x; \partial\Omega) > \delta/2\}$. We denote by $(\varphi_i)_{i \in \mathbb{N}}$ an associated C^∞ partition of unity.

THEOREM 2.4. *For all $u \in W^{m,p}(\Omega)$, there exists a sequence u_ε in $C^\infty(\bar{\Omega})$ such that*

$$u_\varepsilon \to u \quad \text{in} \quad W^{m,p}(\Omega) \quad \text{when} \quad \varepsilon \to 0. \tag{2.3}$$

Proof. This is of course a very classical result. We only include it here to show how it can be proved using the convolution-translation instead of standard mollification together with an extension operator.

We begin by localizing $u = \sum_{i \in \mathbb{N}} u_i$ with $u_i = \varphi_i u$. Each u_i has compact support in $U_i \cap \bar{\Omega}$. The "interior" part u_0 does not pose any problem and can be approximated by standard mollification. Let us concentrate on what happens near the boundary.

From now on, we may thus assume that u has support in, say, $U_1 \cap \bar{\Omega} = U$ without loss of generality. As far as cones are concerned, we may as well assume that $C = C_1$.

We consider an open subset Ω' of $\mathbb{R}^n$ such that $U_1 \cap \bar{\Omega}' = U$ and that satisfies conditions (i), (ii), and (iii) of Definition 2.1 with just one cone equal to C. Such a set clearly exists. Indeed, in view of [16, Theorem 1.2.2.2], $\partial\Omega \cap U$ is the graph of a Lipschitz function Φ from a compact subset K of a hyperplane in $\mathbb{R}^n$ into $\mathbb{R}$ (using an appropriate coordinate system (x', x_n)). If M denotes the Lipschitz constant of Φ, the standard McShane, or Whitney, extension of Φ to the whole hyperplane defined by

$$\tilde{\Phi}(x') = \min_{y \in K} (\Phi(y) + M|x' - y|)$$

provides a globally defined Lipschitz extension of Φ with the same Lipschitz constant M. It is thus sufficient to set $\Omega' = \{x \in \mathbb{R}^n; x_n < \tilde{\Phi}(x')\}$. Now, the extension of u by zero to $\Omega' \setminus \Omega$ clearly yields a function in $W^{m,p}(\Omega')$.

It follows from the previous considerations that we may assume that Ω satisfies the uniform cone condition with just one cone equal to C. Let θ_C, e_C, and h_C be, respectively, the cone's angle, outward unit axis vector, and height.

For all $0 < \varepsilon$, we now define

$$\eta(\varepsilon) = \varepsilon \sin(\theta_C/2) \tag{2.4}$$

and

$$\rho_\varepsilon(y) = \eta(\varepsilon)^{-n}\rho(y/\eta(\varepsilon)). \tag{2.5}$$

Let $\varepsilon_C = \frac{h_C}{1+\sin(\theta_C/2)}$. For all $0 < \varepsilon < \varepsilon_C$ and all $x \in \bar{\Omega}$, we then let

$$u_\varepsilon(x) = \int_{B(0,\eta(\varepsilon))} u(x - \varepsilon e - y)\rho_\varepsilon(y)\,dy. \tag{2.6}$$

By construction, we have $x - \varepsilon e - B(0,\eta(\varepsilon)) \subset x + C \subset \Omega$; therefore, $u_\varepsilon(x)$ is well defined *up to the boundary.* Moreover, since ρ_ε has support in $\bar{B}(0,\eta(\varepsilon))$, we have that

$$u_\varepsilon(x) = \int_{\mathbb{R}^n} \tilde{u}(x - \varepsilon e - y)\rho_\varepsilon(y)\,dy = \tilde{u} \star_{\varepsilon,e} \rho_\varepsilon(x),$$

i.e., $u_\varepsilon = (\tilde{u} \star_{\varepsilon,e} \rho_\varepsilon)_{|\bar{\Omega}}$, where $\tilde{u}$ is *any* extension of u to $\mathbb{R}^n$—for instance, the extension by 0. It follows that $u_\varepsilon \in C^\infty(\bar{\Omega})$. Moreover, it is easy to see that, for any multi-index α and all $x \in \bar{\Omega}$, we also have

$$\partial^\alpha u_\varepsilon(x) = \int_{\mathbb{R}^n} \widetilde{\partial^\alpha u}(x - \varepsilon e - y)\rho_\varepsilon(y)\,dy = \widetilde{\partial^\alpha u} \star_{\varepsilon,e} \rho_\varepsilon(x).$$

To conclude, it is thus sufficient to show that $u_\varepsilon \to u$ in $L^p(\Omega)$ when $\varepsilon \to 0$. This follows from the same argument that is used in standard mollification by approximating u in $L^p(\Omega)$ by a compactly supported continuous function and performing the convolution-translation on this function. □

3. A generalized version of Friedrichs's lemma.

Friedrichs's lemma was introduced to deal with partial differential equations with varying coefficients. There are many different versions of the lemma. We are concerned here with the version that estimates the commutator of the multiplication by a Lipschitz function and the convolution by a mollifier on $\mathbb{R}^n$ or on a compactly contained subset of the domain Ω; see [17] and [18]. We replace here the usual convolution by the previously introduced up-to-the-boundary convolution-translation.

In what follows, Ω is a domain in $\mathbb{R}^n$ that satisfies the uniform cone condition with just one cone, as before. For all $v \in L^p(\Omega)$, we denote by $\partial_\alpha v$ its distributional partial derivative with respect to x_α. (We thus do not use the multi-index notation.) Therefore, $\partial_\alpha v \in W^{-1,p}(\Omega)$. We need to define the convolution-translation for such distributions:

$$\partial_\alpha v \star_{\varepsilon,e} \rho_\varepsilon(x) = \int_{B(0,\eta(\varepsilon))} v(x - \varepsilon e - y)\partial_\alpha \rho_\varepsilon(y)\,dy, \tag{3.1}$$

where $\eta(\varepsilon)$ and ρ_ε are defined as in formulas (2.4) and (2.5). Clearly, this definition agrees with (2.6) when v is C^∞. Moreover, the resulting function is in $C^\infty(\bar\Omega)$. Finally, if we take a sequence $v_k \in C^\infty(\bar\Omega)$ such that $v_k \to v$ in $L^p(\Omega)$ when $k \to +\infty$, then $\partial_\alpha v_k \star_{\varepsilon,e} \rho_\varepsilon \to \partial_\alpha v \star_{\varepsilon,e} \rho_\varepsilon$ in $L^p(\Omega)$.

Our version of Friedrichs's lemma is as follows.

Lemma 3.1. *Let $v \in L^p(\Omega)$ and $a \in W^{1,\infty}(\Omega)$; then there exists a constant M which depends only on ρ and on the cone angle such that*

$$\|(a\partial_\alpha v) \star_{\varepsilon,e} \rho_\varepsilon - a(\partial_\alpha v \star_{\varepsilon,e} \rho_\varepsilon)\|_{L^p(\Omega)} \le M\|a\|_{W^{1,\infty}(\Omega)}\|v\|_{L^p(\Omega)}. \tag{3.2}$$

Proof. Note first that if $v \in L^p(\Omega)$ and $a \in W^{1,\infty}(\Omega)$, then $a\partial_\alpha v \in W^{-1,p}(\Omega)$ so that all terms are well defined. Moreover, in view of the above remarks, it is sufficient to establish estimate (3.2) for functions v in $\mathcal{D}(\Omega)$, which is a dense subset of $L^p(\Omega)$. In this case, $a\partial_\alpha v$ belongs to $W^{1,\infty}(\Omega)$ with compact support.

Let us estimate the commutator. For all $x \in \bar\Omega$, we have

$$[(a\partial_\alpha v)\star_{\varepsilon,e}\rho_\varepsilon - a(\partial_\alpha v\star_{\varepsilon,e}\rho_\varepsilon)](x) = \int_{B(0,\eta(\varepsilon))}[a(x-\varepsilon e-y)-a(x)]\partial_\alpha v(x-\varepsilon e-y)\rho_\varepsilon(y)\,dy. \tag{3.3}$$

Integrating the right-hand side of (3.3) by parts in the ball, we obtain

$$\begin{aligned}[(a\partial_\alpha v) \star_{\varepsilon,e} \rho_\varepsilon - a(\partial_\alpha v \star_{\varepsilon,e} \rho_\varepsilon)](x) &= \int_{B(0,\eta(\varepsilon))} \partial_\alpha a(x-\varepsilon e-y)v(x-\varepsilon e-y)\rho_\varepsilon(y)\,dy\\ &\quad+\int_{B(0,\eta(\varepsilon))}[a(x-\varepsilon e-y)-a(x)]v(x-\varepsilon e-y)\partial_\alpha\rho_\varepsilon(y)\,dy.\end{aligned} \tag{3.4}$$

Note that both integral quantities vanish for x outside of a compact neighborhood K of the support of v that is independent of ε for $\varepsilon \le \varepsilon_C$. We denote by $\tilde{\tilde a}$ the McShane extension of the restriction of a to K, and by $\tilde v$ the extension of v by zero. It is then clear that for all $x \in \bar\Omega$,

$$[(a\partial_\alpha v) \star_{\varepsilon,e} \rho_\varepsilon - a(\partial_\alpha v \star_{\varepsilon,e} \rho_\varepsilon)](x) = f_1(x) + f_2(x), \tag{3.5}$$

where

$$f_1(x) = \int_{\mathbb{R}^n} \partial_\alpha\tilde{\tilde a}(x-\varepsilon e-y)\tilde v(x-\varepsilon e-y)\rho_\varepsilon(y)\,dy$$

and

$$f_2(x) = \int_{\mathbb{R}^n}[\tilde{\tilde a}(x-\varepsilon e-y)-\tilde{\tilde a}(x)]\tilde v(x-\varepsilon e-y)\partial_\alpha\rho_\varepsilon(y)\,dy$$

for all $x \in \mathbb{R}^n$. It is thus enough to estimate f_1 and f_2 in L^p separately.

For the first term, we have

$$\begin{aligned}|f_1(x)| &\le \int_{\mathbb{R}^n}|\partial_\alpha\tilde{\tilde a}(x-\varepsilon e-y)||\tilde v(x-\varepsilon e-y)|\rho_\varepsilon(y)\,dy\\ &\le \|\partial_\alpha\tilde{\tilde a}\|_{L^\infty(\mathbb{R}^n)}\int_{\mathbb{R}^n}|\tilde v(x-\varepsilon e-y)|\rho_\varepsilon(y)\,dy\\ &\le \|a\|_{W^{1,\infty}(\Omega)}(|\tilde v|\star\rho_\varepsilon)(x-\varepsilon e)\end{aligned}$$

for all $x \in \mathbb{R}^n$. Therefore,

$$\begin{aligned}\|f_1\|_{L^p(\Omega)} &\leq \|f_1\|_{L^p(\mathbb{R}^n)}\\ &\leq \|a\|_{W^{1,\infty}(\Omega)}\|(|\tilde{v}| \star \rho_\varepsilon)\|_{L^p(\mathbb{R}^n)}\\ &\leq \|a\|_{W^{1,\infty}(\Omega)}\|\tilde{v}\|_{L^p(\mathbb{R}^n)}\\ &= \|a\|_{W^{1,\infty}(\Omega)}\|v\|_{L^p(\Omega)}.\end{aligned}$$

Similarly, for the second term,

$$\begin{aligned}|f_2(x)| &\leq \int_{\mathbb{R}^n} |\tilde{\tilde{a}}(x-\varepsilon e-y) - \tilde{\tilde{a}}(x)|\,|\tilde{v}(x-\varepsilon e-y)|\,|\partial_\alpha\rho_\varepsilon(y)|\,dy\\ &\leq \|\nabla\tilde{\tilde{a}}\|_{L^\infty(\mathbb{R}^n)}\int_{\mathbb{R}^n} |\tilde{v}(x-\varepsilon e-y)|\,|\varepsilon e - y|\,|\partial_\alpha\rho_\varepsilon(y)|\,dy\\ &\leq \|a\|_{W^{1,\infty}(\Omega)}(|\tilde{v}| \star g_\varepsilon)(x-\varepsilon e)\end{aligned}$$

for all $x \in \mathbb{R}^n$, where

$$g_\varepsilon(y) = |\varepsilon e - y|\,|\partial_\alpha\rho_\varepsilon(y)|.$$

In view of definitions (2.4) and (2.5), it is easy to see that

$$\|g_\varepsilon\|_{L^1(\mathbb{R}^n)} \leq \left(\frac{1}{\sin(\theta_C/2)} + 1\right)\|\partial_\alpha\rho\|_{L^1(\mathbb{R}^n)}.$$

Therefore,

$$\|f_2\|_{L^p(\Omega)} \leq \left(\frac{1}{\sin(\theta_C/2)} + 1\right)\|\partial_\alpha\rho\|_{L^1(\mathbb{R}^n)}\|a\|_{W^{1,\infty}(\Omega)}\|v\|_{L^p(\Omega)},$$

hence the result with $M = 1 + \left(\frac{1}{\sin(\theta_C/2)} + 1\right)\|\partial_\alpha\rho\|_{L^1(\mathbb{R}^n)}$. □

The following corollary will be the basic tool for our density results in the context of the Koiter shell model.

COROLLARY 3.2. *For all $v \in L^p(\Omega)$ and $a \in W^{1,\infty}(\Omega)$,*

$$\|(a\partial_\alpha v) \star_{\varepsilon,e} \rho_\varepsilon - a(\partial_\alpha v \star_{\varepsilon,e} \rho_\varepsilon)\|_{L^p(\Omega)} \to 0 \quad \textit{when} \quad \varepsilon \to 0. \tag{3.6}$$

Proof. Proceed as in [18] by approximating v in $L^p(\Omega)$ by a sequence of functions in $\mathcal{D}(\Omega)$. □

4. Application to the Koiter shell model.

4.1. Formulation of the problem. In this section, we briefly recall the formulation of the linear Koiter shell model introduced in [5] and [6]. This formulation is much simpler than the classical formulation and is, furthermore, valid for midsurfaces that can have discontinuous curvatures. We refer to [3] and [8] for general elastic shell theory.

In what follows, Greek indices and exponents always belong to the set $\{1, 2\}$, while Latin indices and exponents belong to the set $\{1, 2, 3\}$. We use the Einstein summation convention unless otherwise specified.

Let ω denote a Lipschitz domain of $\mathbb{R}^2$. We consider a shell with midsurface $S = \varphi(\bar{\omega})$, where $\varphi \in W^{2,\infty}(\omega; \mathbb{R}^3)$ is a one-to-one mapping such that the two vectors $a_\alpha = \partial_\alpha\varphi$ are linearly independent at each point $x \in \bar{\omega}$. We let $a_3 = a_1 \wedge a_2/|a_1 \wedge a_2|$ be the unit normal vector on the midsurface at point $\varphi(x)$. The vectors a_i define the covariant basis at point $\varphi(x)$. The regularity of the midsurface chart and the hypothesis of linear independence on $\bar{\omega}$ imply that the vectors a_i belong to $W^{1,\infty}(\omega;\mathbb{R}^3)$. The contravariant basis a^i is defined by the relations

$$a^i(x)\cdot a_j(x)=\delta^i_j,$$

where δ^i_j is the Kronecker symbol. In particular, $a^3(x)=a_3(x)$. As before, $a^i\in W^{1,\infty}(\omega;\mathbb{R}^3)$. We let $a(x)=|a_1(x)\wedge a_2(x)|^2$ so that $\sqrt{a}$ is the area element of the midsurface in the chart φ.

The first fundamental form of the surface is given in covariant components by $a_{\alpha\beta}=a_\alpha\cdot a_\beta\in W^{1,\infty}(\omega)$. The Christoffel symbols of the midsurface are given by $\Gamma^\rho_{\alpha\beta}=\Gamma^\rho_{\beta\alpha}=a^\rho\cdot\partial_\beta a_\alpha$, and we have $\Gamma^\rho_{\alpha\beta}\in L^\infty(\omega)$.

Let us recall the new expressions for the various strain tensors that were introduced in [5] and [6]. Let $u\in H^1(\omega;\mathbb{R}^3)$ be a displacement of the midsurface, i.e., a regular mapping from $\bar{\omega}$ into $\mathbb{R}^3$. Its linearized strain tensor is given by $\gamma(u)=\gamma_{\alpha\beta}(u)a^\alpha\otimes a^\beta$ with

$$\gamma_{\alpha\beta}(u)=\frac{1}{2}(\partial_\alpha u\cdot a_\beta+\partial_\beta u\cdot a_\alpha)\in L^2(\omega), \tag{4.1}$$

and its linearized change of curvature tensor is given by $\Upsilon(u)=\Upsilon_{\alpha\beta}(u)a^\alpha\otimes a^\beta$ with

$$\Upsilon_{\alpha\beta}(u)=(\partial_{\alpha\beta}u-\Gamma^\rho_{\alpha\beta}\partial_\rho u)\cdot a_3\in H^{-1}(\omega). \tag{4.2}$$

See [6] for a comparison with the classical approach, in which the displacement is identified with the triple of its covariant components, and an explanation of why our new approach does not require φ to be of class at least C^3, which includes many interesting cases, as we mentioned earlier.

In [5] and [6], we introduced the function space

$$W=\Big\{v\in H^1(\omega;\mathbb{R}^3),\partial_{\alpha\beta}v\cdot a_3\in L^2(\omega)\Big\} \tag{4.3}$$

for shell displacements. Note that if $v\in H^1(\omega;\mathbb{R}^3)$, then $\partial_{\alpha\beta}v\cdot a_3$ is a priori in $H^{-1}(\omega)$. In view of formulas (4.1) and (4.2), it is apparent that displacements in W are such that their linearized strain and change of curvature tensors are square-integrable. When equipped with its natural norm

$$\|v\|_W=\left(\|v\|^2_{H^1(\omega;\mathbb{R}^3)}+\sum_{\alpha,\beta}\|\partial_{\alpha\beta}v\cdot a_3\|^2_{L^2(\omega)}\right)^{1/2}, \tag{4.4}$$

the space W is a Hilbert space. To formulate an equilibrium problem for the shell, we consider $e>0$ to be the thickness of the shell and an elasticity tensor $a^{\alpha\beta\rho\sigma}\in L^\infty(\omega)$, which we assume to satisfy the usual symmetries and to be uniformly strictly positive.

In terms of boundary conditions, the simplest case is that of a shell clamped on all of its boundaries. This corresponds to the space

$$V_1=\big\{v\in W;v=\partial_\alpha v\cdot a_3=0\text{ on }\partial\omega\big\}, \tag{4.5}$$

which is a closed subspace of W, endowed with the norm of W. In [6], we proved the following existence and uniqueness result for Koiter's model.

THEOREM 4.1. *Let $f \in L^2(\omega;\mathbb{R}^3)$ be a given force resultant density. Then there exists a unique solution to the variational problem: Find $u \in V_1$ such that*

$$\forall v \in V_1, \quad \int_\omega e a^{\alpha\beta\rho\sigma}\left(\gamma_{\alpha\beta}(u)\gamma_{\rho\sigma}(v) + \frac{e^2}{12}\Upsilon_{\alpha\beta}(u)\Upsilon_{\rho\sigma}(v)\right)\sqrt{a}\,dx = \int_\omega f\cdot v\sqrt{a}\,dx. \tag{4.6}$$

Remark 4.2. 1. The proof of this theorem relies on the new version of the rigid displacement lemma and the Korn inequality for surfaces with $W^{2,\infty}$ regularity; see [6] for details.

2. Also in [6], it is proved that the space W defines an extension of the classical framework of [4] to our case. Indeed, when $\varphi \in C^3$, the function space of [4] is canonically isomophic to the space V_1. Moreover, the new and classical expressions for the linearized strain and change of curvature tensors coincide under this isomorphism. Consequently, the solution given by Theorem 4.1 is in this case equal, modulo the isomorphism, to the solution found in [4].

3. The case of a shell clamped on a part of its boundary $\gamma_0 \subset \partial\omega$ and submitted to tractions and moments on the remaining part is also treated in [6]. The relevant function space is

$$V_{1,\gamma_0} = \{v \in W; v = \partial_\alpha v \cdot a_3 = 0 \text{ on } \gamma_0\}, \tag{4.7}$$

which is also a closed subspace of W. For a simply supported shell, the relevant space is simply

$$V_0 = \{v \in W; v = 0 \text{ on } \partial\omega\}. \tag{4.8}$$

We thus also obtain existence and uniqueness results in these cases. □

4.2. Density results. One fundamental issue that was not addressed in [6] is the density of smooth functions in the various function spaces introduced in our new formulation of the Koiter model. The density of smooth functions is, for instance, required in order to make sure that standard finite element methods will actually approximate the solution of the continuous problem. Another use of this density will be to show the continuous dependence of the solution of the model on the midsurface, in an appropriate sense. In [6], the consistency of our formulation with the classical formulation is an a priori consistency: we know that our formulation is more general than and coincides with the classical formulation when both are applicable. Continuous dependence is a way to prove a posteriori consistency via a convergence result.

It should be noted that such a density result cannot be taken for granted since these spaces are not of a standard kind. Similar questions arise in transport theory; see [2], [12], and [15], for example. In the case of the transport equation, the definition of the relevant function spaces involves a directional derivative of the form $a\nabla u$, with a a vector field and u a scalar unknown, that is required to satisfy some integrability condition. Although formally slightly reminiscent of this situation, our function space setting is different, since the quantities of interest in shell theory, $\partial_{\alpha\beta}u \cdot a_3$, are not directional derivatives—a_3 does not "live" in the same space as u—and we cannot adapt techniques based on this special structure to our case.

It should also be noted that if $\omega = \mathbb{R}^2$, then the density of smooth functions in W follows more or less readily from the classical version of Friedrichs's lemma (see [18]), as will be made clear in the ensuing proofs. However, from the point of view of the applications, a shell whose midsurface was described by a chart over $\mathbb{R}^2$ would be of little interest. Prescribing tractions and moments on the boundary would be difficult, and the shell would be diffeomorphic to an open disk, which is restrictive in terms of the topology of the shell since multiply connected shells would not be allowed. Thus there is no escaping the difficulties that arise at the boundary.

As we mentioned earlier, the standard way of performing mollification up to the boundary consists in using an extension operator and then mollifying over $\mathbb{R}^2$. This does not seem to be of much help here. Indeed, if $E_1(u)$ and $E_2(\varphi)$ denote, respectively, an H^1-extension operator for the displacement u and a $W^{2,\infty}$-extension operator for the chart φ to $\mathbb{R}^2$, there does not seem to be an easy way of devising E_1 and E_2 in a way that ensures that $\partial_{\alpha\beta}(E_1(u)) \cdot \tilde{a}_3$ will belong to $L^2(\mathbb{R}^2)$, where $\tilde{a}_3$ denotes the corresponding extended normal vector (assuming it is defined), whenever $\partial_{\alpha\beta} u \cdot a_3$ belongs to $L^2(\omega)$. The classical techniques using reflections or integral operators do not seem to work very well because of the product of two quantities. The same remark applies if we try to extend a_3 itself without any reference to the geometrical underpinnings of the situation.

It is this failure that prompted us to look for an alternative and eventually rediscover a mollification technique essentially already put forth in [23].

Let us start with the larger function space, without boundary conditions.

THEOREM 4.3. *Assume that ω satisfies the uniform cone condition. Then the space $C^\infty(\bar{\omega};\mathbb{R}^3)$ is dense in W.*

Proof. First, it is clear that $C^\infty(\bar{\omega};\mathbb{R}^3) \subset W$. Let $u \in W$. We want to construct a sequence u_ε of $C^\infty(\bar{\omega};\mathbb{R}^3)$-functions that converges to u in the norm of W, i.e., such that $u_\varepsilon \to u$ in $H^1(\omega;\mathbb{R}^3)$ and $\partial_{\alpha\beta} u_\varepsilon \cdot a_3 \to \partial_{\alpha\beta} u \cdot a_3$ in $L^2(\omega)$ for all indices α, β.

It is not difficult to check that the space W can be localized using a partition of unity that is adapted to the uniform cone condition satisfied by ω. We can thus assume that u is compactly supported in one of the sets $U_i \cap \bar{\omega}$ introduced in the proof of Theorem 2.4. We leave the case of the "interior" part in $U_0 \cap \bar{\omega}$ aside for the time being.

Let $U = U_1 \cap \bar{\omega}$. As in the proof of Theorem 2.4, we can assume that ω satisfies the uniform cone condition with just one cone and that u is compactly supported in U. Then introducing

$$u_\varepsilon = \tilde{u} \star_{\varepsilon,e} \rho_\varepsilon,$$

Theorem 2.4 shows that

$$u_\varepsilon \to u \quad \text{in} \quad H^1(\omega;\mathbb{R}^3).$$

Let u_i, $u_{\varepsilon,i}$, and $a_{3,i}$ denote the Cartesian components of u, u_ε, and a_3, respectively, so that $\partial_{\alpha\beta} u \cdot a_3 = (\partial_{\alpha\beta} u_i) a_{3,i}$. Applying Corollary 3.2 to $\partial_\beta u_i \in L^2(\omega)$, we obtain

$$\|(a_{3,i}\partial_{\alpha\beta} u_i) \star_{\varepsilon,e} \rho_\varepsilon - a_{3,i}((\partial_{\alpha\beta} u_i) \star_{\varepsilon,e} \rho_\varepsilon)\|_{L^2(\omega)} \longrightarrow 0 \text{ when } \varepsilon \to 0.$$

Now, since $u \in W$, we also have that $(a_{3,i}\partial_{\alpha\beta} u_i) \in L^2(\omega)$. Therefore, by Theorem 2.4, it follows that

$$\|a_{3,i}\partial_{\alpha\beta} u_i - (a_{3,i}\partial_{\alpha\beta} u_i) \star_{\varepsilon,e} \rho_\varepsilon\|_{L^2(\omega)} \longrightarrow 0 \text{ when } \varepsilon \to 0$$

as well. Since

$$\partial_{\alpha\beta} u_{i,\varepsilon} = (\partial_{\alpha\beta} u_i) \star_{\varepsilon,e} \rho_\varepsilon,$$

we have thus shown that

$$\|a_{3,i}\partial_{\alpha\beta} u_i - a_{3,i}\partial_{\alpha\beta} u_{i,\varepsilon}\|_{L^2(\omega)} \longrightarrow 0 \text{ when } \varepsilon \to 0,$$

which concludes the proof near the boundary.

Concerning the interior part of u, it is apparent that the same proof works using standard mollification and the classical Friedrichs lemma. □

Let us now consider the case of various boundary conditions. As before, we assume that ω satisfies the uniform cone condition.

THEOREM 4.4. *For a totally clamped shell, $\mathcal{D}(\omega;\mathbb{R}^3)$ is dense in V_1.*

Proof. Localize as before near the boundary. We claim that the extension $\tilde{u}$ of u by zero to the whole of $\mathbb{R}^2$ is such that $\tilde{u} \in H^1(\mathbb{R}^2;\mathbb{R}^3)$ and $\partial_{\alpha\beta}\tilde{u}\cdot\tilde{\tilde{a}}_3 \in L^2(\mathbb{R}^2)$. Indeed, both conditions are equivalent to having $\tilde{u} \in H^1(\mathbb{R}^2;\mathbb{R}^3)$ and $\partial_\alpha\tilde{u}\cdot\tilde{\tilde{a}}_3 \in H^1(\mathbb{R}^2)$. Since both functions are piecewise H^1 and have no jump on $\partial\omega$, the claim is true.

Instead of translating inside the domain as earlier, we translate here *outside* and let $u_\varepsilon = \tilde{u} \star_{\varepsilon,-e} \rho_\varepsilon$. The same proof as in Theorem 4.3 shows that $(u_\varepsilon)_{|\omega} \to u$ in W and that $u_\varepsilon \in C^\infty(\mathbb{R}^2;\mathbb{R}^3)$. Moreover, since $\tilde{u}$ is identically zero outside of ω, it is clear that u_ε has compact support in ω. It may be necessary to change the cone in such a way that the exterior cone condition is also satisfied to achieve this, which is possible since ω is locally Lipschitz. Hence the result. □

Theorem 4.4 above can be seen as an intermediary step for the following density result.

THEOREM 4.5. *Assume that γ_0 consists of a finite union of open arcs in $\partial\omega$, and let $C^\infty_{c,\gamma_0}(\bar{\omega};\mathbb{R}^3)$ denote the set of functions in $C^\infty(\bar{\omega};\mathbb{R}^3)$ that are equal to 0 in a neighborhood of γ_0. Then $C^\infty_{c,\gamma_0}(\bar{\omega};\mathbb{R}^3)$ is dense in V_{1,γ_0}.*

Proof. We localize as before around γ_0, the interior of its complement in $\partial\omega$, and the endpoints of γ_0. Clearly, for the parts localized around γ_0, the same argument as in the proof of Theorem 4.4 applies. Equally clearly, for the parts localized around the interior of the complement, the argument of the proof of Theorem 4.3 applies. What remains are the parts that are localized around the endpoints of γ_0.

Let us thus assume that 0 is such an endpoint, and let us localize u in a ball of radius ε around this point. To this end, we introduce a function $\theta \in \mathcal{D}(B(0,1))$ such that $\theta(x) = 1$ if $|x| \leq 1/2$ and $\theta(x) = 0$ for $|x| \geq 3/4$, and let $\theta_\varepsilon(x) = \theta(x/\varepsilon)$. We want to show that $\theta_\varepsilon u$ tends to zero strongly in W when $\varepsilon \to 0$, so that we can approximate u by 0 in $B(0,\varepsilon/2)$.

Since u and $\partial_\alpha u \cdot a_3$ vanish on an arc that has 0 as an endpoint, we can apply Poincaré's inequality to both quantities to deduce that

$$\|u\|^2_{L^2(B(0,\varepsilon);\mathbb{R}^3)} \leq \varepsilon^2 \|\nabla u\|^2_{L^2(B(0,\varepsilon);M_{32})} \tag{4.9}$$

and

$$\|\partial_\alpha u \cdot a_3\|^2_{L^2(B(0,\varepsilon))} \leq \varepsilon^2 \|\nabla(\partial_\alpha u \cdot a_3)\|^2_{L^2(B(0,\varepsilon);\mathbb{R}^2)}. \tag{4.10}$$

By estimate (4.9), we see that $\theta_\varepsilon u \to 0$ in $H^1(\omega;\mathbb{R}^3)$. Indeed, $\partial_\alpha(\theta_\varepsilon u) = (\partial_\alpha\theta_\varepsilon)u + \theta_\varepsilon\partial_\alpha u$, and

$$\|(\partial_\alpha\theta_\varepsilon)u\|^2_{L^2(B(0,\varepsilon);\mathbb{R}^3)} \leq \|\nabla u\|^2_{L^2(B(0,\varepsilon);M_{32})} \to 0 \text{ when } \varepsilon \to 0.$$

We now note that $u \cdot a_3$ also vanishes on the same arc so that by Poincaré's inequality

$$\|u \cdot a_3\|^2_{L^2(B(0,\varepsilon))} \leq \varepsilon^2 \|\nabla(u \cdot a_3)\|^2_{L^2(B(0,\varepsilon);\mathbb{R}^2)}. \tag{4.11}$$

Now $\partial_\alpha(u \cdot a_3) = \partial_\alpha u \cdot a_3 + u \cdot \partial_\alpha a_3$, and therefore

$$\|\partial_\alpha(u\cdot a_3)\|^2_{L^2(B(0,\varepsilon))} \leq 2\big(\|\partial_\alpha u\cdot a_3\|^2_{L^2(B(0,\varepsilon))}+\|u\cdot\partial_\alpha a_3\|^2_{L^2(B(0,\varepsilon))}\big) \leq C\varepsilon^2\|u\|^2_{W(B(0,\varepsilon))},$$

using estimate (4.10) for the first term and estimate (4.9) and the fact that $\partial_\alpha a_3 \in L^\infty(\omega)$ for the second term, where $\|\cdot\|_{W(B(0,\varepsilon))}$ denotes the local W-norm on $B(0,\varepsilon)$. Consequently, by estimate (4.11), we obtain

$$\|u \cdot a_3\|^2_{L^2(B(0,\varepsilon))} \leq C\varepsilon^4 \|u\|^2_{W(B(0,\varepsilon))}. \tag{4.12}$$

We have

$$\partial_{\alpha\beta}(\theta_\varepsilon u) \cdot a_3 = (\partial_{\alpha\beta}\theta_\varepsilon) u \cdot a_3 + (\partial_\alpha \theta_\varepsilon)(\partial_\beta u) \cdot a_3 + (\partial_\beta\theta_\varepsilon)(\partial_\alpha u) \cdot a_3 + \theta_\varepsilon(\partial_{\alpha\beta} u) \cdot a_3.$$

Therefore, putting estimates (4.10) and (4.12) together, we see that

$$\|\partial_{\alpha\beta}(\theta_\varepsilon u) \cdot a_3\|_{L^2(B(0,\varepsilon))} \leq C\|u\|_{W(B(0,\varepsilon))} \to 0 \text{ when } \varepsilon \to 0,$$

which shows that $\theta_\varepsilon u \to 0$ in W.

Finally, it is fairly clear that the elements of the sequence u_ε, which are reconstructed by patching together all the local approximations of u, belong to $C^\infty_{c,\gamma_0}(\bar{\omega};\mathbb{R}^3)$, and the theorem is proved. □

Remark 4.6. Note that the space $C^\infty_{c,\gamma_0}(\bar{\omega};\mathbb{R}^3)$ does not depend on the chart φ, whereas the space V_{1,γ_0} does. This is useful since one of the applications we have in mind is the dependence of the solution of Koiter's model on the midsurface. The space $C^\infty_{c,\gamma_0}(\bar{\omega};\mathbb{R}^3)$ is a common dense subspace of all possible V_{1,γ_0} spaces for all possible midsurfaces. □

The case of a simply supported shell actually seems to be more difficult. We only solve it here for a domain ω of class C^∞ and by resorting to classical techniques.

THEOREM 4.7. *Assume that ω is of class C^∞. Then $C^\infty(\bar{\omega};\mathbb{R}^3) \cap H^1_0(\omega;\mathbb{R}^3)$ is dense in V_0.*

Proof. We proceed in a classical fashion. First localize as before. For the parts near the boundary, we can thus assume that $\omega = \{(x_1,x_2) \in \mathbb{R}^2; x_2 < \Psi(x_1)\}$, where $\Psi\colon \mathbb{R} \to \mathbb{R}$ is of class C^∞. Next we flatten the boundary using the C^∞-diffeomorphism

$$\begin{cases} \Theta_1(x) = x_1, \\ \Theta_2(x) = x_2 - \Psi(x_1). \end{cases}$$

This obviously induces an isomorphism on the associated V_0 spaces so that we are reduced to the case $\omega = \mathbb{R} \times \mathbb{R}^*_-$. We now extend u and a_3 for $x_2 > 0$ by

$$\begin{cases} \tilde{u}(x_1,x_2) = -u(x_1,-x_2), \\ \tilde{a}_3(x_1,x_2) = a_3(x_1,-x_2), \end{cases}$$

respectively. Clearly, $\tilde{u} \in H^1(\mathbb{R}^2;\mathbb{R}^3)$, $\tilde{a}_3 \in W^{1,\infty}(\mathbb{R}^2;\mathbb{R}^3)$, and $\tilde{u}$ is odd with respect to x_2.

Let us show that $\partial_{\alpha\beta}\tilde{u}\cdot\tilde{a}_3$ belongs to $L^2(\mathbb{R}^2)$, or, equivalently, that $\partial_\alpha\tilde{u}\cdot\tilde{a}_3$ is in $H^1(\mathbb{R}^2)$. For $x_2>0$, we have

$$\begin{cases}\partial_1\tilde{u}\cdot\tilde{a}_3(x_1,x_2)=-\partial_1 u\cdot a_3(x_1,-x_2),\\ \partial_2\tilde{u}\cdot\tilde{a}_3(x_1,x_2)=\partial_2 u\cdot a_3(x_1,-x_2),\end{cases}$$

so that $(\partial_\alpha\tilde{u}\cdot\tilde{a}_3)_{|\mathbb{R}\times\mathbb{R}_+^*}$ belongs to $H^1(\mathbb{R}\times\mathbb{R}_+^*)$. It thus suffices to prove that the jump of both quantities across $x_2=0$ is zero. This is clear for the second one as the traces at $x_2=0$ of both sides of the equality obviously coincide. It can also be shown with a little more work that $\partial_1 u\cdot a_3$ considered as a function in the variable x_2 belongs to $C^0(\mathbb{R}_-;H^{-1}(\mathbb{R}))$ with $\partial_1 u\cdot a_3(0)=0$, and thus there is no jump either.

We can now introduce a radial mollifier ρ, define $\rho_\varepsilon=\varepsilon^{-2}\rho(\cdot/\varepsilon)$, and let $u_\varepsilon=\tilde{u}\star\rho_\varepsilon$. Clearly, $u_{\varepsilon|\omega}\in C^\infty(\bar{\omega};\mathbb{R}^3)$, $u_{\varepsilon|\omega}\to u$ in W as $\varepsilon\to 0$ by the classical Friedrichs lemma, and $u_\varepsilon(x_1,0)=0$ by the imparity of u and parity of ρ with respect to x_2.

We can go back to the original domain by composition with the C^∞-diffeomorphism Θ^{-1}. □

Remark 4.8. 1. Since we are mainly interested in finding a dense subspace that does not depend on the midsurface, the above proof shows that if ω is of class $W^{2,\infty}$, then $W^{2,\infty}(\omega;\mathbb{R}^3)\cap H_0^1(\omega;\mathbb{R}^3)$ is dense in V_0.

2. The above proof also works for piecewise C^∞ domains satisfying the uniform cone condition, for instance polygons, by performing adequate reflections at the angles. In this case, $C^\infty(\bar{\omega};\mathbb{R}^3)\cap H_0^1(\omega;\mathbb{R}^3)$ is also dense in V_0. □

4.3. Continuous dependence on the midsurface. Our goal in this section is to show that the formulation of Koiter's model we proposed in [5] and [6] provides an adequate extension of the classical formulation for C^3-midsurfaces to $W^{2,\infty}$-midsurfaces, at least from the mathematical point of view. The density results of the previous section were formulated for a domain that satisfies the uniform cone condition. For practical purposes in the case of shells, we will from now on consider only bounded Lipschitz domains.

Let us thus consider a sequence of midsurface charts φ^n that approximate a given chart φ in the sense that $\varphi^n\to\varphi$ in $W^{2,p}(\omega;\mathbb{R}^3)$ strong for all $1<p<+\infty$ and $\varphi^n\overset{*}{\rightharpoonup}\varphi$ in $W^{2,\infty}(\omega;\mathbb{R}^3)$ weak-$*$. (Note that for any $\varphi\in W^{2,\infty}(\omega;\mathbb{R}^3)$, it is possible to construct such a sequence with φ^n of class C^3.) All corresponding geometric quantities will from now on be indicated by an n superscript. For instance, the covariant basis vectors are denoted by a_i^n, the covariant components of the first fundamental form and the area element by $a_{\alpha\beta}^n$ and $\sqrt{a^n}$, respectively, and the Christoffel symbols by $\Gamma_{\alpha\beta}^{n,\rho}$. We assume for simplicity that all shells have the same thickness and the same Lamé moduli μ and λ and denote by $a^{n,\alpha\beta\rho\sigma}$ the contravariant components of the elasticity tensor

$$a^{n,\alpha\beta\rho\sigma}=2\mu(a^{n,\alpha\beta}a^{n,\rho\sigma}+a^{n,\alpha\sigma}a^{n,\beta\sigma})+\frac{4\lambda\mu}{\lambda+2\mu}a^{n,\alpha\beta}a^{n,\rho\sigma}, \tag{4.13}$$

where $a^{n,\alpha\beta}$ denote the contravariant components of the first fundamental form. Finally, for all displacements v of the shells, we denote by

$$\gamma_{\alpha\beta}^n(v)=\frac{1}{2}(\partial_\alpha v\cdot a_\beta^n+\partial_\beta v\cdot a_\alpha^n)$$

and

$$\Upsilon_{\alpha\beta}^n(v)=(\partial_{\alpha\beta}v-\Gamma_{\alpha\beta}^{n,\rho}\partial_\rho v)\cdot a_3^n$$

the covariant components of the strain and change of curvature tensors with explicit dependence on the charts.

Let us collect all the information on convergence properties of the various geometric and mechanical quantities that we will need later on in one lemma.

LEMMA 4.9. *Let φ^n be a sequence of charts such that $\varphi^n \to \varphi$ in $W^{2,p}(\omega;\mathbb{R}^3)$ strong for all $1 < p < +\infty$ and $\varphi^n \overset{*}{\rightharpoonup} \varphi$ in $W^{2,\infty}(\omega;\mathbb{R}^3)$ weak-$*$. Then*

$$a_i^n \to a_i \textit{ strongly in } W^{1,p}(\omega;\mathbb{R}^3)\ \forall\ 1 < p < +\infty \textit{ and weakly-}* \textit{ in } W^{1,\infty}(\omega;\mathbb{R}^3), \tag{4.14}$$

$$a_{\alpha\beta}^n \to a_{\alpha\beta}, \sqrt{a^n} \to \sqrt{a}, \textit{ and } a^{n,\alpha\beta\rho\sigma} \to a^{\alpha\beta\rho\sigma} \textit{ in } C^0(\bar{\omega}), \tag{4.15}$$

and

$$\Gamma_{\alpha\beta}^{n,\rho} \to \Gamma_{\alpha\beta}^{\rho} \textit{ strongly in } L^p(\omega)\ \forall\ 1 < p < +\infty \textit{ and weakly-}* \textit{ in } L^\infty(\omega). \tag{4.16}$$

Proof. The proof is clear, using Morrey's theorem and the fact that the covariant tangent vectors are assumed to be linearly independent. □

In what follows, we will concentrate on the case of a totally clamped shell submitted only to force resultants for brevity. All results remain true—with appropriate modifications—for a simply supported shell and a partially clamped shell submitted to edge tractions and moments on the free part of the boundary. Let us rewrite the spaces involved with explicit dependence on the charts. For all n, we thus let $W^n = \{v \in H^1(\omega;\mathbb{R}^3), \partial_{\alpha\beta} v \cdot a_3^n \in L^2(\omega)\}$, equipped with their natural norm $\|v\|_{W^n} = \big(\|v\|^2_{H^1(\omega;\mathbb{R}^3)} + \sum_{\alpha,\beta} \|\partial_{\alpha\beta} v \cdot a_3^n\|^2_{L^2(\omega)}\big)^{1/2}$, and $V_1^n = \{v \in W^n; v = \partial_\alpha v \cdot a_3^n = 0 \text{ on } \partial\omega\}$, which is a closed subspace of W^n for all n.

For $f^n \in L^2(\omega;\mathbb{R}^3)$ we let u^n be the unique solution to the variational formulation of Koiter's model: Find $u^n \in V_1^n$ such that

$$\forall v^n \in V_1^n,\ \int_\omega e a^{n,\alpha\beta\rho\sigma} \left(\gamma_{\alpha\beta}^n(u^n)\gamma_{\rho\sigma}^n(v^n) + \frac{e^2}{12}\Upsilon_{\alpha\beta}^n(u^n)\Upsilon_{\rho\sigma}^n(v^n) \right) \sqrt{a^n}\, dx$$
$$= \int_\omega f^n \cdot v^n \sqrt{a^n}\, dx. \tag{4.17}$$

Our main result is the following.

THEOREM 4.10. *Let φ^n be a sequence of charts such that $\varphi^n \to \varphi$ in $W^{2,p}(\omega;\mathbb{R}^3)$ strong for all $1 < p < +\infty$ and $\varphi^n \overset{*}{\rightharpoonup} \varphi$ in $W^{2,\infty}(\omega;\mathbb{R}^3)$ weak-$*$, and let f^n be a sequence of force resultant densities such that $f^n \to f$ in $L^2(\omega;\mathbb{R}^3)$. Then*

$$u^n \to u \textit{ in } H^1(\omega;\mathbb{R}^3) \quad \textit{and} \quad \Upsilon_{\alpha\beta}^n(u^n) \to \Upsilon_{\alpha\beta}(u) \textit{ in } L^2(\omega), \tag{4.18}$$

where u is the solution to Koiter's model for a clamped shell with midsurface chart φ and applied force resultant density f.

The proof is comprised of a series of lemmas.

LEMMA 4.11. *If $v^n \in H^1(\omega;\mathbb{R}^3)$ and $\varphi^n \in W^{2,\infty}(\omega;\mathbb{R}^3)$ are two sequences such that $v^n \rightharpoonup v$ weakly in $H^1(\omega;\mathbb{R}^3)$, $\varphi^n \to \varphi$ strongly in $W^{2,p}(\omega;\mathbb{R}^3)$ for all $p < +\infty$, and $\varphi^n \overset{*}{\rightharpoonup} \varphi$ weakly-$*$ in $W^{2,\infty}(\omega;\mathbb{R}^3)$, then $\gamma_{\alpha\beta}^n(v^n) \rightharpoonup \gamma_{\alpha\beta}(v)$ weakly in $L^2(\omega)$ and $\Upsilon_{\alpha\beta}^n(v^n) \rightharpoonup \Upsilon_{\alpha\beta}(v)$ weakly in $H^{-1}(\omega)$.*

Proof. First, since $a_\alpha^n \to a_\alpha$ strongly in $C^0(\bar{\omega};\mathbb{R}^3)$, it follows clearly that

$$\gamma_{\alpha\beta}^n(v^n) = \frac{1}{2}(\partial_\alpha v^n \cdot a_\beta^n + \partial_\beta v^n \cdot a_\alpha^n) \rightharpoonup \gamma_{\alpha\beta}(v) \text{ in } L^2(\omega).$$

The case of the change of curvature tensor is more intricate. We know that $\partial_{\alpha\beta} v^n \rightharpoonup \partial_{\alpha\beta} v$ in $H^{-1}(\omega;\mathbb{R}^3)$. Let θ be a test-function in $H_0^1(\omega)$. By the Sobolev embedding theorem, $\theta \in L^4(\omega)$, and, as $\partial_\alpha a_3^n \to \partial_\alpha a_3$ strongly in $L^4(\omega;\mathbb{R}^3)$ by (4.14) with $p = 4$, it follows that

$$\begin{cases} \theta a_3^n \to \theta a_3, \\ \partial_\alpha(\theta a_3^n) = (\partial_\alpha \theta) a_3^n + \theta \partial_\alpha a_3^n \to \partial_\alpha(\theta a_3), \end{cases} \text{strongly in } L^2(\omega;\mathbb{R}^3)$$

so that

$$\theta a_3^n \to \theta a_3 \text{ strongly in } H_0^1(\omega;\mathbb{R}^3).$$

Therefore,

$$\langle \partial_{\alpha\beta} v^n \cdot a_3^n, \theta\rangle = \langle \partial_{\alpha\beta} v^n, \theta a_3^n\rangle \to \langle \partial_{\alpha\beta} v \cdot a_3, \theta\rangle;$$

hence

$$\partial_{\alpha\beta} v^n \cdot a_3^n \rightharpoonup \partial_{\alpha\beta} v \cdot a_3 \text{ weakly in } H^{-1}(\omega).$$

Let us now deal with the other part of $\Upsilon^n_{\alpha\beta}(v^n)$. We have that $\partial_\rho v^n \rightharpoonup \partial_\rho v$ weakly in $L^2(\omega;\mathbb{R}^3)$, $\Gamma^{n,\rho}_{\alpha\beta} \to \Gamma^\rho_{\alpha\beta}$ strongly in $L^p(\omega)$, and $a_3^n \to a_3$ strongly in $W^{1,p}(\omega;\mathbb{R}^3)$ for all $p < +\infty$. It follows easily from this and Hölder's inequality that

$$\Gamma^{n,\rho}_{\alpha\beta} \partial_\rho v^n \cdot a_3^n \rightharpoonup \Gamma^\rho_{\alpha\beta} \partial_\rho v \cdot a_3 \text{ weakly in } L^q(\omega)\ \forall\ 1 < q < 2.$$

Now, by the two-dimensional Sobolev embedding theorem, we have $L^q(\omega) \hookrightarrow H^{-1}(\omega)$ for all $1 < q < 2$, hence the result. □

Let us now establish some uniform norm equivalence results.

Lemma 4.12. *There exist two constants* $0 < c < C < +\infty$ *independent of* n *such that for all* $v^n \in V_1^n$,

$$c\|v^n\|_{W^n} \le \left\{ \sum_{\alpha\beta} \left(\|\gamma^n_{\alpha\beta}(v^n)\|^2_{L^2(\omega;\mathbb{R}^3)} + \|\Upsilon^n_{\alpha\beta}(v^n)\|^2_{L^2(\omega;\mathbb{R}^3)} \right) \right\}^{1/2} \le C\|v^n\|_{W^n}. \tag{4.19}$$

Proof. The proof is essentially identical to that of Lemma 11 in [6] for a single chart. □

We also need uniform positive definiteness of the elasticity tensors. By assumption, for each midsurface, there exists a constant $\eta_n > 0$ such that for all symmetric tensors $\tau = (\tau_{\alpha\beta})$ and almost all $x \in \omega$, $a^{n,\alpha\beta\rho\sigma}(x)\tau_{\alpha\beta}\tau_{\rho\sigma} \ge \eta_n \tau_{\alpha\beta}\tau_{\alpha\beta}$. For instance, in the case of an isotropic material, this is a statement concerning the Lamé moduli μ and λ and not the geometry of the midsurface. We will concentrate here on the isotropic case.

Lemma 4.13. *There is constant* $\eta > 0$ *independent of* n *such that* $\eta_n \ge \eta$ *for all* n.

Proof. We know that $a^{n,\alpha\beta\rho\sigma}$ converge uniformly to $a^{\alpha\beta\rho\sigma}$. As η_n is the infimum of the quadratic form $a^{n,\alpha\beta\rho\sigma}(x)\tau_{\alpha\beta}\tau_{\rho\sigma}$ on the Cartesian product of the unit sphere of the space of symmetric tensors with $\bar{\omega}$, the result is clear. □

We now are in a position to establish uniform bounds for the various quantities of interest.

Lemma 4.14. *There is constant M independent of n such that*

$$\|u^n\|_{H^1(\omega;\mathbb{R}^3)} \le M, \qquad \|\partial_{\alpha\beta} u^n \cdot a_3^n\|_{L^2(\omega)} \le M. \tag{4.20}$$

Proof. Let us take $v^n = u^n$ as a test-function in the variational formulation of Koiter's problem (4.17). In view of Lemmas 4.12 and 4.13, we obtain

$$c\eta\sqrt{\delta}\min(e, e^3/12)\|u^n\|_{W^n}^2 \le \|\sqrt{a^n} f^n\|_{L^2(\omega;\mathbb{R}^3)}\|u^n\|_{L^2(\omega;\mathbb{R}^3)},$$

where δ is a uniform lower bound for $a^n(x)$. The lemma easily follows from the above estimate. □

Lemma 4.15. *There exists a subsequence* (*still denoted by*) u^n *and* $u \in V_1$ *such that*

$$u^n \rightharpoonup u \textit{ weakly in } H^1(\omega;\mathbb{R}^3) \quad \textit{and} \quad \partial_{\alpha\beta} u^n \cdot a_3^n \rightharpoonup \partial_{\alpha\beta} u \cdot a_3 \textit{ weakly in } L^2(\omega). \tag{4.21}$$

Proof. Because of the previous bounds, we can find a subsequence u^n, a function $u \in H_0^1(\omega;\mathbb{R}^3)$, and functions $\kappa_{\alpha\beta} \in L^2(\omega)$ such that

$$u^n \rightharpoonup u \text{ weakly in } H^1(\omega;\mathbb{R}^3) \quad \text{and} \quad \partial_{\alpha\beta} u^n \cdot a_3^n \rightharpoonup \kappa_{\alpha\beta} \text{ weakly in } L^2(\omega).$$

As in the proof of Lemma 4.11, we see that $\kappa_{\alpha\beta} = \partial_{\alpha\beta} u \cdot a_3$ so that $u \in W$. Moreover, $\partial_\alpha u^n \cdot a_3^n \rightharpoonup \partial_\alpha u \cdot a_3$ in $H^1(\omega)$ so that $\partial_\alpha u \cdot a_3 \in H_0^1(\omega)$ and therefore $u \in V_1$. □

Our next task is to identify the weak limit u of the above subsequence of solutions u^n as being the solution to the Koiter problem corresponding to the limit midsurface and loads.

Lemma 4.16. *The limit u is the unique solution to the following: Find $u \in V_1$ such that*

$$\forall v \in V_1, \quad \int_\omega e a^{\alpha\beta\rho\sigma}\left(\gamma_{\alpha\beta}(u)\gamma_{\rho\sigma}(v) + \frac{e^2}{12}\Upsilon_{\alpha\beta}(u)\Upsilon_{\rho\sigma}(v)\right)\sqrt{a}\,dx = \int_\omega f\cdot v\sqrt{a}\,dx. \tag{4.22}$$

The whole sequence is convergent.

Proof. By Theorem 4.4, we know that the spaces V_1^n and V_1 all share a common dense subspace, namely here, $\mathcal{D}(\omega;\mathbb{R}^3)$. Therefore, any $\psi \in \mathcal{D}(\omega;\mathbb{R}^3)$ is a legitimate test-function for all n, as well as for the eventual limit problem (4.22). Now

$$a^{n,\alpha\beta\rho\sigma}\gamma_{\rho\sigma}^n(\psi)\sqrt{a^n} \to a^{\alpha\beta\rho\sigma}\gamma_{\rho\sigma}(\psi)\sqrt{a} \text{ strongly in } L^2(\omega)$$

and

$$a^{n,\alpha\beta\rho\sigma}\Upsilon_{\rho\sigma}^n(\psi)\sqrt{a^n} \to a^{\alpha\beta\rho\sigma}\Upsilon_{\rho\sigma}(\psi)\sqrt{a} \text{ strongly in } L^2(\omega)$$

by Lemma 4.9. On the other hand,

$$\gamma_{\alpha\beta}^n(u^n) \rightharpoonup \gamma_{\alpha\beta}(u) \text{ weakly in } L^2(\omega)$$

and

$$\Upsilon_{\alpha\beta}^n(u^n) \rightharpoonup \Upsilon_{\alpha\beta}(u) \text{ weakly in } L^2(\omega)$$

by Lemma 4.11 and since Lemmas 4.12 and 4.14 imply that $\Upsilon_{\alpha\beta}^n(u^n)$ is bounded in $L^2(\omega)$. Therefore, we can pass to the limit as $n \to +\infty$ in problem (4.17) and obtain problem (4.22) for all test-functions $\psi \in \mathcal{D}(\omega;\mathbb{R}^3)$. The identification of u then follows from the fact that $\mathcal{D}(\omega;\mathbb{R}^3)$ is dense in V_1, viz. Theorem 4.4.

The solution of problem (4.22) is unique; therefore, the standard uniqueness argument shows that the whole sequence u^n converges, and not just a subsequence thereof. □

The final step in the proof of Theorem 4.10 consists in showing that all weak convergences are actually strong. This would be a straightforward matter if the test-function spaces did not depend on n. We would just take $u - u^n$ as a test-function. There is a slight twist here since $u \notin V_1^n$ and $u^n \notin V_1$ so that $u - u^n$ is a legitimate test-function neither for problem (4.17) nor for problem (4.22). We recast the problem in abstract form to circumvent this difficulty.

Let us be given a family of Hilbert spaces $(H^n, \|\cdot\|_n)_{n\in\mathbb{N}}$ and a Hilbert space $(H, \|\cdot\|)$ with the following properties:

(i) There is a subspace D common to all H^n and H such that D is dense in H.

(ii) For all $y \in D$, $\|y\|_n \to \|y\|$ as $n \to +\infty$.

Let us also be given a corresponding family of continuous (on their respective spaces) symmetric bilinear forms a^n and a and a family of continuous linear forms l^n and l with the following properties:

(iii) There exists a constant η independent of n such that

$$\forall y^n \in H^n, \quad a^n(y^n, y^n) \geq \eta \|y^n\|_n^2.$$

(iv) For all y, z in D, $a^n(y,z) \to a(y,z)$ and $l^n(y) \to l(y)$ when $n \to +\infty$.

Lemma 4.17. *Assume that hypotheses* (i)–(iv) *are satisfied, and let $x^n \in H^n$ and $x \in H$ be the solutions of the variational problems*

$$\forall y^n \in H^n, \quad a^n(x^n, y^n) = l^n(y^n) \quad \textit{and} \quad \forall y \in H, \quad a(x,y) = l(y).$$

If, in addition, $l^n(x^n) \to l(x)$, then

$$\|x^n\|_n \to \|x\| \quad \textit{when} \quad n \to +\infty. \tag{4.23}$$

Proof. For all $y \in D$, we have

$$a^n(x^n - y, x^n - y) = l^n(x^n - 2y) + a^n(y,y).$$

By assumption (iii), it follows that

$$\eta \|x^n - y\|_n^2 \leq l^n(x^n) - 2l^n(y) + a^n(y,y).$$

Letting n tend to $+\infty$, we obtain

$$\limsup_{n\to+\infty} \|x^n - y\|_n^2 \leq \frac{1}{\eta}(l(x) - 2l(y) + a(y,y))$$

by assumption (iv). Therefore,

$$\limsup_{n\to+\infty} \big| \|x^n\|_n - \|y\|_n \big| \leq \sqrt{\frac{1}{\eta}(l(x) - 2l(y) + a(y,y))}.$$

Now

$$\big| \|x^n\|_n - \|x\| \big| \leq \big| \|x^n\|_n - \|y\|_n \big| + \big| \|y\|_n - \|y\| \big| + \big| \|y\| - \|x\| \big|$$

so that, letting n tend to $+\infty$, we obtain

$$\limsup_{n\to+\infty}\big|\|x^n\|_n-\|x\|\big|\leq\sqrt{\frac{1}{\eta}(l(x)-2l(y)+a(y,y))}+\big|\|y\|-\|x\|\big|$$

for all $y\in D$, by assumption (ii). The lemma then results from assumption (i) and the fact that a and l are continuous on H. ∎

We can now apply Lemma 4.17 to our shell problem to complete the proof of Theorem 4.10.

Lemma 4.18. *We have*

(4.24) $u^n\to u$ *strongly in* $H^1(\omega;\mathbb{R}^3)$ *and* $\Upsilon^n_{\alpha\beta}(u^n)\to\Upsilon_{\alpha\beta}(u)$ *strongly in* $L^2(\omega)$.

Proof. By the weak convergence result of Lemma 4.15, we know that

$$\liminf_{n\to+\infty}\|u^n\|_{H^1(\omega;\mathbb{R}^3)}\geq\|u\|_{H^1(\omega;\mathbb{R}^3)}\quad\text{and}\quad\liminf_{n\to+\infty}\|\partial_{\alpha\beta}u^n\cdot a_3^n\|_{L^2(\omega)}\geq\|\partial_{\alpha\beta}u\cdot a_3\|_{L^2(\omega)}.$$

The Hilbert spaces V_1^n and V_1 and the bilinear and linear forms associated with the Koiter problems clearly satisfy the hypotheses of Lemma 4.17 with $D=\mathcal{D}(\omega;\mathbb{R}^3)$. Therefore,

$$\|u^n\|^2_{H^1(\omega;\mathbb{R}^3)}+\sum_{\alpha\beta}\|\partial_{\alpha\beta}u^n\cdot a_3^n\|^2_{L^2(\omega)}=\|u^n\|^2_{V_1^n}$$
$$\to\|u\|^2_{V_1}=\|u\|^2_{H^1(\omega;\mathbb{R}^3)}+\sum_{\alpha\beta}\|\partial_{\alpha\beta}u\cdot a_3\|^2_{L^2(\omega)},$$

which, together with the previous estimates, implies that

$$\|u^n\|_{H^1(\omega;\mathbb{R}^3)}\to\|u\|_{H^1(\omega;\mathbb{R}^3)}\quad\text{and}\quad\|\partial_{\alpha\beta}u^n\cdot a_3^n\|_{L^2(\omega)}\to\|\partial_{\alpha\beta}u\cdot a_3\|_{L^2(\omega)}.$$

The first convergence implies that $u^n\to u$ strongly in $H^1(\omega;\mathbb{R}^3)$, and the second convergence implies that $\partial_{\alpha\beta}u^n\cdot a_3^n\to\partial_{\alpha\beta}u\cdot a_3$ strongly in $L^2(\omega)$. Both facts imply that $\partial_\alpha u^n\cdot a_3^n\to\partial_\alpha u\cdot a_3$ strongly in $H^1(\omega)$; therefore, by the Sobolev embedding theorem and Lemma 4.9, $\Gamma^{n,\rho}_{\alpha,\beta}\partial_\rho u^n\cdot a_3^n\to\Gamma^{\rho}_{\alpha,\beta}\partial_\rho u\cdot a_3$ strongly in $L^2(\omega)$, which completes the proof. ∎

Remark 4.19. Note that the convergences established in Theorem 4.10 are quite natural in the sense that they imply the convergence of the displacements and of the associated strain and change of curvature tensors in their respective natural spaces. This in turn implies the strong L^2 convergence of the various stress resultants. ∎

Let us close the article with the final comparison between the classical formulation of Koiter's model and our formulation. Let us be given a sequence of charts φ^n as in Theorem 4.10. For any displacement $v\in V_1^n$, we denote by $v_i^n=v^n\cdot a_i^n$ the covariant components of v so that

$$v^n(x)=v_i^n(x)a^{n,i}(x).$$

Note that in some sense, in considering the covariant components as the basic unknown as is classically done, one mixes regularity issues concerning the displacement with regularity issues concerning the chart. This leads to the restrictive C^3 assumption that is made in the classical formulation. This remark may be illustrated by the following result.

THEOREM 4.20. *Let φ^n be a sequence of C^3-charts such that $\varphi^n \to \varphi$ in $W^{2,p}(\omega;\mathbb{R}^3)$ strong for all $1 < p < +\infty$ and $\varphi^n \overset{*}{\rightharpoonup} \varphi$ in $W^{2,\infty}(\omega;\mathbb{R}^3)$ weak-$*$ with φ piecewise C^3 and $\varphi \notin C^3(\omega;\mathbb{R}^3)$. Let f^n be a sequence of force resultant densities such that $f^n \to f$ in $L^2(\omega;\mathbb{R}^3)$. Let $(u_1^n, u_2^n, u_3^n) \in H_0^1(\omega) \times H_0^1(\omega) \times H_0^2(\omega)$ be the solution of the classical formulation of Koiter's problem as in* [4]. *Then, for all $n \in \mathbb{N}$,*

$$u^n(x) = u_i^n(x) a^{n,i}(x), \tag{4.25}$$

u^n tends to u in the sense of Theorem 4.10, *but u_3^n is generically unbounded in $H^2(\omega)$.*

Proof. The fact that (4.25) holds was already noted in [6]. Clearly, $u_3^n \to u_3$ in $L^2(\omega)$ by Theorem 4.10. If u_3^n was bounded in $H^2(\omega)$, this would thus imply that $u_3 \in H^2(\omega)$. This is not the case. As was already noted in [6], for a piecewise C^3-midsurface, the derivatives of the second fundamental form contain Dirac masses concentrated on the interfaces between the smooth parts of the shell. The condition $\partial_{\alpha\beta} u \cdot a_3 \in L^2(\omega)$ is equivalent to $\partial_\alpha u \cdot a_3 \in H^1(\omega)$, which means that the jump of $\partial_\alpha u \cdot a_3$ vanishes on each interface. In covariant components, this reads $[\partial_\alpha u_3 + b_\alpha^\rho u_\rho] = 0$, or, equivalently, $[\partial_\alpha u_3] = -[b_\alpha^\rho] u_\rho$, on each interface (with u_3 piecewise H^2), where b_α^ρ denote the mixed components of the second fundamental form. Since the jump of b_α^ρ is nonzero for some components, this will generically induce a jump on $\partial_\alpha u_3$. The normal component u_3 thus cannot be in $H^2(\omega)$. $\square$

Remark 4.21. The previous result indicates that a continuous dependence analysis similar to the present one would be difficult to carry out in the classical formulation. Some extra conditions would need to be imposed on the sequence of midsurfaces in order to obtain a uniform H^2-bound on u_3^n. $\square$

Example 4.22. Let us consider the example of a $W^{2,\infty}$-shell made of a plane part and a circular cylindrical part. We take $\omega = \{-\pi/2, \pi/2\} \times \{0, 1\}$ and

$$\varphi(x) = \begin{cases} (x_1, x_2, 0)^T & \text{for } x_1 \leq 0, \\ (\sin x_1, x_2, 1 - \cos x_1)^T & \text{for } x_1 > 0. \end{cases}$$

The midsurface of this shell is of class $W^{2,\infty}$ and has a curvature discontinuity across $x_1 = 0$. In particular, it is not C^3 and the classical formulation of Koiter's model is not applicable. It is easy to construct an explicit sequence of C^3-midsurfaces φ^n that converge in all $W^{2,p}$ and in $W^{2,\infty}$ weak-$*$ by using Hermite interpolation polynomials in the strip $\{0 \leq x_1 \leq 1/n\}$. The sequence of solutions associated with the sequence of interpolated midsurfaces falls into the classical framework. The limit midsurface is not of class C^3; thus the limit displacement requires our new formulation. The interface between the smooth parts is the line $\{x_1 = 0\}$. On this interface, all mixed components of the second fundamental form are continuous except b_1^1, and it is easy to see that $[b_1^1] = 1$. Therefore, we obtain that $[\partial_1 u_3] = -u_1$ (and $[\partial_2 u_3] = 0$). Since, in general, u_1 will not vanish on $\{x_1 = 0\}$, we see that u_3 is not in $H^2(\omega)$. This is not surprising if we remember that u_3 is a covariant component of u, hence a scalar product of u with the covariant basis vector a_3. The (lack of) regularity of a_3 is thus necessarily reflected in the degree of regularity of u_3. $\square$

Acknowledgments. The authors would like to thank V. Girault and L. R. Scott for fruitful discussions concerning Friedrichs's lemma and its extension up to the boundary.

REDUCTION AND A CONCENTRATION-COMPACTNESS PRINCIPLE FOR ENERGY-CASIMIR FUNCTIONALS[*]

GERHARD REIN[†]

Abstract. Energy-Casimir functionals are a useful tool for the construction of steady states and the analysis of their nonlinear stability properties for a variety of conservative systems in mathematical physics. Recently, Y. Guo and the author employed them to construct stable steady states for the Vlasov–Poisson system in stellar dynamics, where the energy-Casimir functionals act on number density functions on phase space. In the present paper we construct natural, reduced functionals which act on mass densities on space and study compactness properties and the existence of minimizers in this context. This puts the techniques developed by Y. Guo and the author into a more general framework. We recover the concentration-compactness principle due to P.-L. Lions [*Ann. Inst. H. Poincaré Anal. Non Linéaire*, 1 (1984), pp. 109–145] in a more specific setting and connect our stability analysis with that of G. Wolansky [*Ann. Inst. H. Poincaré Anal. Non Linéaire*, 16 (1999), pp. 15–48].

1. Introduction.

The purpose of the present paper is to investigate the compactness properties and existence of minimizers of certain functionals which appear naturally in the stability analysis of various systems in kinetic theory. Given a large ensemble of particles which interact by gravitational attraction we consider energy-Casimir functionals which are defined on the space of phase space density functions, and certain reduced versions of these which are defined on the space of spatial density functions. This reduction procedure should put the techniques developed in [1, 2, 3, 4, 5, 11, 12] into a more general framework and make them applicable to problems outside kinetic theory. However, to be specific we start by recalling the Vlasov–Poisson system which describes the time evolution of a large ensemble of particles interacting by the gravitational field which they create collectively:

$$\partial_t f + v \cdot \partial_x f - \partial_x U \cdot \partial_v f = 0,$$

$$\triangle U = 4\pi\,\rho, \qquad \lim_{|x|\to\infty} U(t,x) = 0,$$

$$\rho(t,x) = \int f(t,x,v)dv.$$

Here the dynamic variable is the number density $f = f(t,x,v)$ of the ensemble in phase space, $x, v \in \mathbb{R}^3$ denote position and velocity, $\rho = \rho(t,x)$ is the spatial mass

density induced by f, and $U = U(t,x)$ is the induced gravitational potential. It is straightforward to check that

$$\iint Q(f(t,x,v))\,dv\,dx + \frac{1}{2}\iint |v|^2 f(t,x,v)\,dv\,dx - \frac{1}{2}\iint \frac{\rho(t,x)\,\rho(t,y)}{|x-y|}\,dx\,dy$$

is conserved along solutions for any suitable scalar function Q. The first part, which is conserved by itself, is a so-called Casimir functional, the second is the kinetic, and the third part is the potential energy of the system. When viewed as a functional on phase space densities $f = f(x,v) \geq 0$ we denote this functional by $\mathcal{H}_{\mathcal{C}}$. It is fairly straightforward to see that any minimizer of this functional subject to the constraint

$$\iint f(x,v)\,dv\,dx = M$$

with prescribed total mass $M > 0$ is a steady state of the Vlasov–Poisson system. It is far less obvious that such minimizers exist and that they are nonlinearly stable. When analyzing the minimization problem

$$\mathcal{H}_{\mathcal{C}}(f_0) = \inf\left\{\mathcal{H}_{\mathcal{C}}(f) | f \geq 0, \iint f\,dv\,dx = M\right\}, \tag{1.1}$$

one needs to make sure that one can pass to the limit in the (quadratic) potential energy along a minimizing sequence. Obviously, the potential energy is not a functional of f itself but of the induced spatial density ρ, and the crucial question is how, along a minimizing sequence, the spatial density can or cannot split into parts or spread uniformly in space. This was analyzed in the context of the Vlasov–Poisson system and with various variations in [1, 2, 3, 4, 5, 11, 12].

In the present paper we want to bring out the basic mechanism more clearly and in a framework not restricted to kinetic theory. To this end we construct in the next section a reduced version $\mathcal{H}_{\mathcal{C}}^r$ of the energy-Casimir functional $\mathcal{H}_{\mathcal{C}}$, which will be defined on spatial densities ρ:

$$\mathcal{H}_{\mathcal{C}}^r(\rho) = \int \Phi(\rho(x))\,dx - \frac{1}{2}\iint \frac{\rho(x)\,\rho(y)}{|x-y|}\,dx\,dy$$

with Φ a function determined by Q, which is convex if Q is convex. Then we explore the relation between the variational problems

$$\mathcal{H}_{\mathcal{C}}^r(\rho_0) = \inf\left\{\mathcal{H}_{\mathcal{C}}^r(\rho) | \rho \geq 0, \int \rho\,dx = M\right\} \tag{1.2}$$

and (1.1); in particular we will show how a minimizer of the reduced problem (1.2) induces a minimizer of (1.1). In the third section we reformulate the techniques developed for (1.1) in the framework of (1.2) and obtain the existence of a minimizer ρ_0 under appropriate conditions on Φ. In particular, we prove the essential part of the concentration-compactness principle due to P.-L. Lions [9] by a more direct method based on scaling and splitting. In the last section we discuss the role of symmetries in the problem and point out some applications and extensions of our results. An example of a function Φ which satisfies all the necessary assumptions is $\Phi(\rho) = \rho^{1+1/n}$ with $0 < n < 3$. In this case the potential U_0 induced by a minimizer ρ_0 is a solution of the semilinear elliptic problem

$$\triangle U_0 = (E_0 - U_0)_+^n, \qquad \lim_{|x|\to\infty} U_0(x) = 0,$$

where $(\cdot)_+$ denotes the positive part and E_0 is some constant. This equation is sometimes referred to as the Emden–Fowler equation and appears naturally in the study of self-gravitating fluid balls. Throughout this paper we restrict ourselves to the case of space dimension 3; extending these techniques to other space dimensions by adjusting various exponents is easy. We remark that the use of energy-Casimir functionals for questions of stability was discussed in a very broad context in [7].

2. Reduction of energy-Casimir functionals. For a measurable function $f = f(x,v)$ we define

$$\rho_f(x) := \int f(x,v)\,dv, \qquad x \in \mathbb{R}^3,$$

and

$$U_f := -\rho_f * \frac{1}{|\cdot|}.$$

Next we define

$$E_{\rm kin}(f) := \frac{1}{2}\iint |v|^2 f(x,v)\,dv\,dx,$$
$$E_{\rm pot}(f) := -\frac{1}{8\pi}\int |\nabla U_f(x)|^2 dx = -\frac{1}{2}\iint \frac{\rho_f(x)\rho_f(y)}{|x-y|}dx\,dy$$

($E_{\rm pot}$ can equally well be viewed as a functional of ρ instead of f), and

$$\mathcal{H}_{\mathcal{C}}(f) := \mathcal{C}(f) + E_{\rm kin}(f) + E_{\rm pot}(f),$$

where

$$\mathcal{C}(f) := \iint Q(f(x,v))\,dv\,dx,$$

and Q is a given function satisfying the following assumption.

Assumption on Q. $Q \in C^1([0,\infty[)$ is strictly convex, $Q(0) = Q'(0) = 0$, and $Q(f)/f \to \infty,\ f \to \infty$.

In particular, this implies that $Q \geq 0$ and $Q' : [0,\infty[\to [0,\infty[$ is one-to-one and onto.

We study the following variational problem: Minimize $\mathcal{H}_{\mathcal{C}}$ over the set

$$(2.1)\ \mathcal{F}_M := \left\{ f \in L^1_+(\mathbb{R}^6) \mid \mathcal{C}(f) + E_{\rm kin}(f) < \infty,\ \rho_f \in L^{6/5}(\mathbb{R}^3),\ \iint f = M \right\},$$

where $M > 0$ is prescribed and $L^1_+(\mathbb{R}^6)$ denotes the set of a.e. nonnegative functions in $L^1(\mathbb{R}^6)$. Note that since $\rho_f \in L^{6/5}(\mathbb{R}^3)$ the convolution defining U_f exists in $L^6(\mathbb{R}^3)$ with $\nabla U_f \in L^2(\mathbb{R}^3)$ according to the extended Young's inequality, and the potential energy of ρ_f is finite.

In order to guarantee the existence of a minimizer we will require additional growth conditions on Q to be introduced later; at the moment $E_{\rm pot}(f)$ could be minus infinity for $f \in \mathcal{F}_M$. A typical example of a function for which there exists a minimizer is $Q(f) = f^{1+1/k}$ with $0 < k < 3/2$.

To obtain a reformulation in terms of spatial densities ρ which captures the essential properties of this variational problem we proceed as follows. For $r \geq 0$ we define

$$\mathcal{G}_r := \left\{ g \in L^1_+(\mathbb{R}^3) | \int \left(\frac{1}{2}|v|^2 g(v) + Q(g(v)) \right) dv < \infty, \ \int g(v)\, dv = r \right\} \tag{2.2}$$

and

$$\Phi(r) := \inf_{g \in \mathcal{G}_r} \int \left(\frac{1}{2}|v|^2 g(v) + Q(g(v)) \right) dv. \tag{2.3}$$

In addition to the variational problem of minimizing $\mathcal{H}_\mathcal{C}$ over the set $\mathcal{F}_M$ we consider the problem of minimizing the functional

$$\mathcal{H}^r_\mathcal{C}(\rho) := \int \Phi(\rho(x))\, dx + E_{\rm pot}(\rho) \tag{2.4}$$

over the set

$$\mathcal{F}^r_M := \left\{ \rho \in L^{6/5} \cap L^1_+(\mathbb{R}^3) \mid \int \Phi(\rho(x))\, dx < \infty, \ \int \rho(x)\, dx = M \right\}. \tag{2.5}$$

The relation between the minimizers of $\mathcal{H}_\mathcal{C}$ and $\mathcal{H}^r_\mathcal{C}$ is the main theme of this section, and a remark on how we passed from $\mathcal{H}_\mathcal{C}$ to $\mathcal{H}^r_\mathcal{C}$ can be found at the end of the section.

Theorem 2.1.

(a) *For every function $f \in \mathcal{F}_M$,*

$$\mathcal{H}_\mathcal{C}(f) \geq \mathcal{H}^r_\mathcal{C}(\rho_f),$$

and if $f = f_0$ is a minimizer of $\mathcal{H}_\mathcal{C}$ over $\mathcal{F}_M$, then equality holds.

(b) *Let $\rho_0 \in \mathcal{F}^r_M$ be a minimizer of $\mathcal{H}^r_\mathcal{C}$ with induced potential U_0. Then there exists a Lagrange multiplier $E_0 \in \mathbb{R}$ such that a.e.*

$$\rho_0 = \begin{cases} (\Phi')^{-1}(E_0 - U_0), & U_0 < E_0, \\ 0, & U_0 \geq E_0. \end{cases}$$

Denote by

$$E = E(x,v) := \frac{1}{2}|v|^2 + U_0(x)$$

the energy of a particle at position x with velocity v, and define

$$f_0 := \begin{cases} (Q')^{-1}(E_0 - E), & E < E_0, \\ 0, & E \geq E_0. \end{cases}$$

Then $f_0 \in \mathcal{F}_M$ is a minimizer of $\mathcal{H}_\mathcal{C}$.

(c) *Now* assume *that $\mathcal{H}^r_\mathcal{C}$ has at least one minimizer in $\mathcal{F}^r_M$. Then the following holds: If $f_0 \in \mathcal{F}_M$ is a minimizer of $\mathcal{H}_\mathcal{C}$, then $\rho_0 := \rho_{f_0} \in \mathcal{F}^r_M$ is a minimizer of $\mathcal{H}^r_\mathcal{C}$. This map is one-to-one and onto between the sets of minimizers of $\mathcal{H}_\mathcal{C}$ in $\mathcal{F}_M$ and of $\mathcal{H}^r_\mathcal{C}$ in $\mathcal{F}^r_M$, respectively, and is the inverse of the map $\rho_0 \mapsto f_0$ described in* (b).

Remark. This theorem does not exclude the possibility that $\mathcal{H}_\mathcal{C}$ has a minimizer but $\mathcal{H}_\mathcal{C}^r$ has none. In the next section we show that under appropriate assumptions on Φ the reduced functional $\mathcal{H}_\mathcal{C}^r$ does have a minimizer, and then the theorem guarantees that we recover all minimizers of $\mathcal{H}_\mathcal{C}$ in $\mathcal{F}_M$ by "lifting" the ones of $\mathcal{H}_\mathcal{C}^r$ as described in (b).

Before we prove this theorem, we investigate the relation between Q and Φ; for a function $h : \mathbb{R} \to]-\infty, \infty]$ we denote by

$$h^*(\lambda) := \sup_{r \in \mathbb{R}} (\lambda\, r - h(r))$$

its Legendre transform. Some of the results of the lemma below will be relevant for the next section.

Lemma 2.2. *Let Q be as specified above, let Φ be defined by* (2.2), (2.3), *and extend both functions by $+\infty$ to the interval* $]-\infty, 0[$.

(a) *For $\lambda \in \mathbb{R}$,*

$$\Phi^*(\lambda) = \int Q^*\left(\lambda - \frac{1}{2}|v|^2\right) dv,$$

and, in particular, $Q^*(\lambda) = 0 = \Phi^*(\lambda)$ for $\lambda < 0$.

(b) *$\Phi \in C^1([0,\infty[)$ is strictly convex, and $\Phi(0) = \Phi'(0) = 0$.*

(c) *Let $k > 0$ and $n = k + 3/2$. As in the rest of the paper, constants denoted by C are positive, may depend on Q or M, and may change from line to line (or within one line).*

(i) *If $Q(f) = C\, f^{1+1/k},\ f \geq 0$, then $\Phi(\rho) = C\, \rho^{1+1/n},\ \rho \geq 0$.*

(ii) *If $Q(f) \geq C\, f^{1+1/k},\ f \geq 0$ large, then $\Phi(\rho) \geq C\, \rho^{1+1/n},\ \rho \geq 0$ large.*

(iii) *If $Q(f) \leq C\, f^{1+1/k},\ f \geq 0$ small, then $\Phi(\rho) \leq C\, \rho^{1+1/n},\ \rho \geq 0$ small.*

If the restriction to large, respectively, small values of f can be dropped, then the corresponding restriction for ρ can be dropped as well.

Proof. By definition,

$$\begin{aligned}
\Phi^*(\lambda) &= \sup_{r \geq 0} \left[\lambda\, r - \inf_{g \in \mathcal{G}_r} \int \left(\frac{1}{2}|v|^2 g(v) + Q(g(v))\right) dv\right] \\
&= \sup_{r \geq 0} \sup_{g \in \mathcal{G}_r} \int \left[\left(\lambda - \frac{1}{2}|v|^2\right) g(v) - Q(g(v))\right] dv \\
&= \sup_{g \in L^1_+(\mathbb{R}^3)} \int \left[\left(\lambda - \frac{1}{2}|v|^2\right) g(v) - Q(g(v))\right] dv \\
&= \int \sup_{y \geq 0} \left[\left(\lambda - \frac{1}{2}|v|^2\right) y - Q(y)\right] dv = \int Q^*\left(\lambda - \frac{1}{2}|v|^2\right) dv.
\end{aligned}$$

As to the last-but-one equality, observe that both sides are obviously zero for $\lambda \leq 0$. If $\lambda > 0$ then for any $g \in L^1_+(\mathbb{R}^3)$,

$$\int \left[\left(\lambda - \frac{1}{2}|v|^2\right) g(v) - Q(g(v))\right] dv \leq \int \sup_{y \geq 0} \left[\left(\lambda - \frac{1}{2}|v|^2\right) y - Q(y)\right] dv.$$

If $|v| \geq \sqrt{2\lambda}$ then $\sup_{y \geq 0} [\cdots] = 0$, and for $|v| < \sqrt{2\lambda}$ the supremum of the term in brackets is attained at $y = y_v := (Q')^{-1}\left(\lambda - \frac{1}{2}|v|^2\right)$. Thus with

$$g_0(v) := \begin{cases} y_v, & |v| < \sqrt{2\lambda}, \\ 0, & |v| \geq \sqrt{2\lambda}, \end{cases}$$

we have

$$\begin{aligned}\int \sup_{y\geq 0}\left[\left(\lambda-\frac{1}{2}|v|^2\right)y-Q(y)\right]dv &= \int\left[\left(\lambda-\frac{1}{2}|v|^2\right)g_0(v)-Q(g_0(v))\right]dv\\ &\leq \sup_{g\in L^1_+(\mathbb{R}^3)}\int\left[\left(\lambda-\frac{1}{2}|v|^2\right)g(v)-Q(g(v))\right]dv,\end{aligned}$$

and part (a) is established.

Since Q is strictly convex and lower semicontinuous as a function on $\mathbb{R}$ with $\lim_{|f|\to\infty} Q(f)/|f|\to\infty$, $Q^*\in C^1(\mathbb{R})$; cf. [10, Prop. 2.4]. Obviously, $Q^*(\lambda)=0$ for $\lambda\leq 0$; in particular, $(Q^*)'(0)=0$. Also, $(Q^*)'$ is strictly increasing on $[0,\infty[$ since Q' is strictly increasing on $[0,\infty[$ with range $[0,\infty[$. Since for $|\lambda|<\lambda_0$ with $\lambda_0>0$ fixed the integral in the formula for Φ^* extends over a compact set we may differentiate under the integral sign to conclude that $\Phi^*\in C^1(\mathbb{R})$ with derivative strictly increasing on $[0,\infty[$. This in turn implies the assertion of part (b).

Finally, $Q(f)\geq C\,f^{1+1/k},\ f\geq 0$ large, implies that $Q(f)\geq C\,f^{1+1/k}-C',\ f\geq 0$. Thus

$$Q^*(\lambda)\leq C'+\sup_{f\geq 0}\left(f\lambda-C\,f^{1+1/k}\right)=C'+\frac{1}{1+k}\left(\frac{k}{C_Q\,(1+k)}\right)^k\lambda^{1+k},\qquad \lambda\geq 0,$$

and

$$\begin{aligned}\Phi^*(\lambda)&\leq C\lambda^{3/2}+C\int_{|v|\leq\sqrt{2\lambda}}\left(\lambda-\frac{1}{2}|v|^2\right)^{1+k}dv=C\lambda^{3/2}+C\int_0^\lambda E^{1+k}\sqrt{\lambda-E}\,dE\\ &=C'+C\,\lambda^{k+5/2}=C'+C\lambda^{1+n},\qquad \lambda\geq 0.\end{aligned}$$

This in turn yields the assertion on Φ in (c)(ii). The assertion in (c)(i) is now obvious. As to (c)(iii) note first that for $\lambda\geq 0$ and small the corresponding supremum is attained at small f's, and thus

$$Q^*(\lambda)\leq\sup_{f\geq 0}\left(\lambda\,f-C\,f^{1+1/k}\right)=C\lambda^{1+k}.$$

Thus still for $\lambda\geq 0$ small, $\Phi^*(\lambda)\geq C\lambda^{1+n}$, which in turn implies the assertion for Φ. □

We now prove the theorem above.

Proof of Theorem 2.1. *Proof of the inequality in part* (a). For $\rho\in\mathcal{F}^r_M$ define

$$\mathcal{F}_\rho:=\{f\in\mathcal{F}_M|\rho_f=\rho\}. \tag{2.6}$$

Clearly, for $\rho=\rho_f$ with $f\in\mathcal{F}_M$,

$$\begin{aligned}\mathcal{C}(f)+E_{\mathrm{kin}}(f)&\geq\inf_{\tilde f\in\mathcal{F}_\rho}(\mathcal{C}(\tilde f)+E_{\mathrm{kin}}(\tilde f))\\ &\geq\inf_{\tilde f\in\mathcal{F}_\rho}\int\left[\inf_{g\in\mathcal{G}_{\rho(x)}}\int\left(\frac{1}{2}|v|^2g(v)+Q(g(v))\right)dv\right]dx\\ &=\int\left[\inf_{g\in\mathcal{G}_{\rho(x)}}\int\left(\frac{1}{2}|v|^2g(v)+Q(g(v))\right)dv\right]dx\\ &=\int\Phi(\rho(x))\,dx,\end{aligned} \tag{2.7}$$

and the inequality in part (a) is established.

An intermediate assertion. We claim that if $f \in \mathcal{F}_M$ is such that up to sets of measure zero,

$$\left\{ \begin{array}{rl} Q'(f) = E_0 - E > 0, & \text{where } f > 0, \\ E_0 - E \leq 0, & \text{where } f = 0, \end{array} \right. \tag{2.8}$$

with E defined as in (b) but with U_f instead of U_0 and E_0 a constant, then equality holds in part (a).

To prove this, observe that since Q is convex, we have for a.e. $x \in \mathbb{R}^3$ and every $g \in \mathcal{G}_{\rho_f(x)}$,

$$\begin{aligned} \frac{1}{2}|v|^2 g(v) + Q(g(v)) \geq{}& \frac{1}{2}|v|^2 f(x,v) + Q(f(x,v)) \\ &+ \left(\frac{1}{2}|v|^2 + Q'(f(x,v))\right)(g(v) - f(x,v)) \text{ a.e.} \end{aligned}$$

Now by (2.8),

$$\begin{aligned} \int \left(\frac{1}{2}|v|^2 + Q'(f)\right)(g - f)\,dv &= \int_{\{f>0\}} \dots + \int_{\{f=0\}} \dots \\ &= (E_0 - U_f(x)) \int_{\{f>0\}} (g - f)\,dv + \int_{\{f=0\}} \frac{1}{2}|v|^2 g\,dv \\ &= -(E_0 - U_f(x)) \int_{\{f=0\}} (g - f)\,dv + \int_{\{f=0\}} \frac{1}{2}|v|^2 g\,dv \\ &= \int_{\{f=0\}} (E - E_0)\, g\,dv \geq 0; \end{aligned}$$

observe that $g \geq 0$ and $\int g\,dv = \int f\,dv$ so $\int (g - f)\,dv = 0$. Thus we see that

$$\begin{aligned} \Phi(\rho_f(x)) &\geq \int \left(\frac{1}{2}|v|^2 f + Q(f)\right) dv \\ &\geq \inf_{g \in \mathcal{G}_{\rho_f(x)}} \int \left(\frac{1}{2}|v|^2 g + Q(g)\right) dv = \Phi(\rho_f(x)) \text{ a.e.,} \end{aligned}$$

and the proof of our intermediate assertion is complete.

Proof of the equality assertion in (a). If $f_0 \in \mathcal{F}_M$ is a minimizer of $\mathcal{H}_\mathcal{C}$ then the Euler–Lagrange equation of the minimization problem implies that (2.8) holds for some Lagrange multiplier E_0; this can be proved as in [5, Thm. 2]. Thus equality holds in (a) by the intermediate assertion, and the proof of part (a) is complete.

Proof of part (b). Let $\rho_0 \in \mathcal{F}_M^r$ be a minimizer of $\mathcal{H}_\mathcal{C}^r$. Then the Euler–Lagrange equation yields the relation between ρ_0 and U_0. Let f_0 be defined as in (b). Then up to sets of measure zero,

$$\begin{aligned} \int f_0(x,v)\,dv &= \int_{|v| \leq \sqrt{2(E_0 - U_0(x))}} (Q')^{-1}\left(E_0 - U_0(x) - \frac{1}{2}|v|^2\right) dv \\ &= (\Phi^*)'(E_0 - U_0(x)) = (\Phi')^{-1}(E_0 - U_0(x)) = \rho_0(x), \end{aligned}$$

where $U_0(x) < E_0$, and both sides are zero where $U_0(x) \geq E_0$. Thus $\rho_0 = \rho_{f_0}$, in particular, $f_0 \in \mathcal{F}_M$. By definition, f_0 satisfies the Euler–Lagrange relation (2.8) and thus by our intermediate assertion $\mathcal{H}_\mathcal{C}(f_0) = \mathcal{H}_\mathcal{C}^r(\rho_0)$. Therefore, again by part (a),

$$\mathcal{H}_\mathcal{C}(f) \geq \mathcal{H}_\mathcal{C}^r(\rho_f) \geq \mathcal{H}_\mathcal{C}^r(\rho_0) = \mathcal{H}_\mathcal{C}(f_0), \qquad f \in \mathcal{F}_M,$$

so that f_0 is a minimizer of $\mathcal{H}_\mathcal{C}$, and the proof of part (b) is complete.

Proof of part (c). Assume that $\mathcal{H}^r_\mathcal{C}$ has a minimizer $\rho_0 \in \mathcal{F}^r_M$ and define f_0 as above. Then part (a), the fact that each $\rho \in \mathcal{F}^r_M$ can be written as $\rho = \rho_f$ for some $f \in \mathcal{F}_M$, and our intermediate assertion imply that

$$\begin{aligned}\inf_{f\in\mathcal{F}_M} \mathcal{H}_\mathcal{C}(f) &\geq \inf_{f\in\mathcal{F}_M} \mathcal{H}^r_\mathcal{C}(\rho_f) = \inf_{\rho\in\mathcal{F}^r_M} \mathcal{H}^r_\mathcal{C}(\rho)\\ &= \mathcal{H}^r_\mathcal{C}(\rho_0) = \mathcal{H}_\mathcal{C}(f_0) \geq \inf_{f\in\mathcal{F}_M} \mathcal{H}_\mathcal{C}(f).\end{aligned} \tag{2.9}$$

Now take any minimizer $g_0 \in \mathcal{F}_M$ of $\mathcal{H}_\mathcal{C}$. Then by (2.9) and part (a),

$$\inf_{\rho\in\mathcal{F}^r_M} \mathcal{H}^r_\mathcal{C}(\rho) = \inf_{f\in\mathcal{F}_M} \mathcal{H}_\mathcal{C}(f) = \mathcal{H}_\mathcal{C}(g_0) = \mathcal{H}^r_\mathcal{C}(\rho_{g_0}),$$

that is, $\rho_{g_0} \in \mathcal{F}^r_M$ minimizes $\mathcal{H}^r_\mathcal{C}$, and the proof of part (c) is complete. □

Remark. If we define an intermediate functional

$$\mathcal{P}(\rho) := \inf_{f\in\mathcal{F}_\rho} \iint \left(\frac{1}{2}|v|^2 f(x,v) + Q(f(x,v))\right) dv\, dx$$

with $\mathcal{F}_\rho$ as defined in (2.6), then (2.7) shows that

$$\mathcal{H}_\mathcal{C}(f) \geq \mathcal{P}(\rho_f) + E_{\mathrm{pot}}(\rho_f) \geq \int \Phi(\rho_f(x))\, dx + E_{\mathrm{pot}}(\rho_f) = \mathcal{H}^r_\mathcal{C}(\rho_f)$$

with equality for minimizers. Note that $\mathcal{P}(\rho)$ is obtained by minimizing the positive contribution to $\mathcal{H}_\mathcal{C}$, which also happens to be the part depending on phase space densities f directly, over all f's which generate a given spatial density ρ. Then in a second step one minimizes for each point x over all functions $g = g(v)$ which have as integral the value $\rho(x)$.

These constructions are borrowed from [14] where they appear for the special case $Q(f) = f^{1+1/k}$. In [14] the resulting functional of ρ is investigated under the assumption of spherical symmetry by rewriting it as a functional of $m_\rho(r) := 4\pi \int_0^r s^2 \rho(s)\, ds$ where $r := |x|$. While minimizers of the present variational problems are spherically symmetric a posteriori, the a priori restriction to spherical symmetry implies that any stability result derived from their minimizing property is restricted to spherically symmetric perturbations, which is undesirable. Moreover, in the last section we will comment on some extensions of the present techniques to situations where the minimizers are not spherically symmetric.

3. Concentration-compactness principle and existence of minimizers.

In this section we prove a concentration-compactness principle that will yield a solution to the following variational problem: Minimize the functional

$$\mathcal{H}^r_\mathcal{C}(\rho) := \int \Phi(\rho(x))\, dx + E_{\mathrm{pot}}(\rho)$$

over the set

$$\mathcal{F}^r_M := \left\{\rho \in L^1_+(\mathbb{R}^3) \mid \int \Phi(\rho) < \infty,\ \int \rho = M\right\} \tag{3.1}$$

for $M > 0$ given and Φ satisfying the following.

Assumptions on Φ. $\Phi \in C^1([0,\infty[)$, $\Phi(0) = 0 = \Phi'(0)$, and

($\Phi 1$) Φ is strictly convex;
($\Phi 2$) $\Phi(\rho) \geq C\rho^{1+1/n}$, $\rho \geq 0$ large, with $0 < n < 3$;
($\Phi 3$) $\Phi(\rho) \leq C\rho^{1+1/n'}$, $\rho \geq 0$ small, with $0 < n' < 3$.

Note that Lemma 2.2 tells us that the function Φ, which we constructed from a given Q in section 2, has these properties, provided Q satisfies the growth conditions corresponding to ($\Phi 2$) and ($\Phi 3$). The aim of this section is to prove the following result.

Theorem 3.1. *The functional $\mathcal{H}^r_\mathcal{C}$ is bounded from below on $\mathcal{F}^r_M$. Let $(\rho_i) \subset \mathcal{F}^r_M$ be a minimizing sequence of $\mathcal{H}^r_\mathcal{C}$. Then there exists a sequence of shift vectors $(a_i) \subset \mathbb{R}^3$ and a subsequence, again denoted by (ρ_i), such that for any $\epsilon > 0$ there exists $R > 0$ with*

$$\int_{a_i+B_R} \rho_i(x)\,dx \geq M - \epsilon, \qquad i \in \mathbb{N},$$

$$T\rho_i := \rho_i(\cdot + a_i) \rightharpoonup \rho_0 \text{ weakly in } L^{1+1/n}(\mathbb{R}^3), \qquad i \to \infty,$$

and

$$\int_{B_R} \rho_0 \geq M - \epsilon.$$

Finally,

$$\nabla U_{T\rho_i} \to \nabla U_0 \text{ strongly in } L^2(\mathbb{R}^3), \qquad i \to \infty,$$

and $\rho_0 \in \mathcal{F}^r_M$ is a minimizer of $\mathcal{H}^r_\mathcal{C}$.

Here and in the following we denote for $0 < R < S \leq \infty$,

$$B_R := \{x \in \mathbb{R}^3 | |x| \leq R\},$$
$$B_{R,S} := \{x \in \mathbb{R}^3 | R \leq |x| < S\}.$$

We split our argument into a series of lemmas. The first thing to note is that $\mathcal{H}^r_\mathcal{C}$ is bounded from below on $\mathcal{F}^r_M$.

Lemma 3.2. *Under the above assumptions on Φ,*

$$\mathcal{H}^r_\mathcal{C}(\rho) \geq \int \Phi(\rho)\,dx - C - C\left(\int \Phi(\rho)\,dx\right)^{n/3}, \qquad \rho \in \mathcal{F}^r_M,$$

in particular,

$$h^r_M := \inf_{\mathcal{F}^r_M} \mathcal{H}^r_\mathcal{C} > -\infty.$$

Proof. By the extended Young's inequality, interpolation, and assumption ($\Phi 2$),

$$-E_{\text{pot}}(\rho) \leq C\|\rho\|^2_{6/5} \leq C\|\rho\|_1^{(5-n)/3}\|\rho\|_{1+1/n}^{(n+1)/3}$$
$$\leq C + C\left(\int \Phi(\rho)\,dx\right)^{n/3}, \qquad \rho \in \mathcal{F}^r_M.$$

Since $n < 3$, $\mathcal{H}^r_\mathcal{C}$ is bounded from below on $\mathcal{F}^r_M$. $\square$

Corollary 3.3. *Any minimizing sequence of $\mathcal{H}_\mathcal{C}^r$ in $\mathcal{F}_M^r$ is bounded in $L^{1+1/n}(\mathbb{R}^3)$ and therefore has a subsequence which converges weakly in $L^{1+1/n}(\mathbb{R}^3)$.*

Proof. By Lemma 3.2, $\int \Phi(\rho)$ is bounded along any minimizing sequence. The assertion follows by (Φ2) and the fact that $\int \rho = M$ for $\rho \in \mathcal{F}_M^r$. □

Note that the estimates above show that the definition (3.1) coincides with our earlier definition for the set $\mathcal{F}_M^r$. We also see that the assumption (Φ2) is quite natural. Next we prove a splitting estimate which will show that along a minimizing sequence the mass cannot vanish.

Lemma 3.4. *Let $\rho \in \mathcal{F}_M^r$. Then*

$$\sup_{a\in\mathbb{R}^3} \int_{a+B_R} \rho(x)\,dx \geq \frac{1}{RM}\left(-2E_{\text{pot}}(\rho) - \frac{M^2}{R} - \frac{C\|\rho\|^2_{1+1/n}}{R^{(5-n)/(n+1)}}\right), \qquad R > 1.$$

Proof. We split the potential energy as follows:

$$\begin{aligned} -2E_{\text{pot}}(\rho) &= \iint_{|x-y|\leq 1/R} \frac{\rho(x)\,\rho(y)}{|x-y|}\,dx\,dy + \iint_{1/R<|x-y|<R} \cdots + \iint_{R\geq|x-y|} \cdots \\ &=: I_1 + I_2 + I_3. \end{aligned}$$

By Hölder's inequality and Young's inequality,

$$\begin{aligned} I_1 &\leq \|\rho\|_{1+1/n} \|\rho * (\mathbf{1}_{B_{1/R}} 1/|\cdot|)\|_{n+1} \leq \|\rho\|^2_{1+1/n} \|\mathbf{1}_{B_{1/R}} 1/|\cdot|\|_{(n+1)/2} \\ &\leq C\,\|\rho\|^2_{1+1/n} R^{-(5-n)/(n+1)}; \end{aligned}$$

here $\mathbf{1}_S$ denotes the indicator function of the set $S \subset \mathbb{R}^3$. The estimates for I_2 and I_3 are straightforward:

$$I_2 \leq R \iint_{|x-y|\leq R} \rho(x)\,\rho(y)\,dx\,dy \leq M\,R \sup_{a\in\mathbb{R}^3} \int_{a+B_R} \rho(x)\,dx,$$

and

$$I_3 \leq R^{-1} M^2.$$

Putting these estimates together yields the assertion. □

Note that to obtain this estimate we actually split the Green's function $1/|x|$. To exploit this estimate along minimizing sequences we need to know that $h_M^r < 0$. It is here that we need the assumption (Φ3).

Lemma 3.5.

(a) *For every $M > 0$ we have $h_M^r < 0$.*

(b) *For every $0 < \bar{M} \leq M$ we have $h_{\bar{M}}^r \geq (\bar{M}/M)^{5/3} h_M^r$.*

Proof. For $\rho \in \mathcal{F}_M^r$ and $a, b > 0$ we define $\bar{\rho}(x) := a\rho(bx)$. Then

$$\begin{aligned} \int \bar{\rho}\,dx &= ab^{-3} \int \rho\,dx, \\ E_{\text{pot}}(\bar{\rho}) &= a^2 b^{-5} E_{\text{pot}}(\rho), \\ \int \Phi(\bar{\rho}) &= b^{-3} \int \Phi(a\rho)\,dx. \end{aligned}$$

To prove part (a) we fix a bounded and compactly supported function $\rho \in \mathcal{F}^r_M$ and choose $a = b^3$ so that $\bar\rho \in \mathcal{F}^r_M$ as well. By (Φ3) and since $3/n' > 1$,

$$\mathcal{H}^r_\mathcal{C}(\bar\rho) = b^{-3} \int \Phi(b^3\rho)\, dx + b\, E_{\text{pot}}(\rho) \le C\, b^{3/n'} + b\, E_{\text{pot}}(\rho) < 0, \qquad b \to 0,$$

and part (a) is established. As to part (b), we take $a = 1$ and $b = (M/\bar M)^{1/3} \ge 1$. For $\rho \in \mathcal{F}^r_M$ and $\bar\rho \in \mathcal{F}^r_{\bar M}$ rescaled with these parameters we find that

$$\begin{aligned}\mathcal{H}^r_\mathcal{C}(\bar\rho) &= b^{-3} \int \Phi(\rho)\, dx + b^{-5} E_{\text{pot}}(\rho)\\ &\ge b^{-5} \left(\int \Phi(\rho)\, dx + E_{\text{pot}}(\rho) \right) = \left(\frac{\bar M}{M}\right)^{5/3} \mathcal{H}^r_\mathcal{C}(\rho).\end{aligned} \tag{3.2}$$

Since for the present choice of a and b the map $\rho \mapsto \bar\rho$ is one-to-one and onto between $\mathcal{F}^r_M$ and $\mathcal{F}^r_{\bar M}$, this estimate proves part (b). ∎

COROLLARY 3.6. *Let $(\rho_i) \subset \mathcal{F}^r_M$ be a minimizing sequence of $\mathcal{H}^r_\mathcal{C}$. Then there exist $\delta_0 > 0$, $R_0 > 0$, $i_0 \in \mathbb{N}$, and a sequence of shift vectors $(a_i) \subset \mathbb{R}^3$ such that*

$$\int_{a_i + B_R} \rho_i(x)\, dx \ge \delta_0, \qquad i \ge i_0,\ R \ge R_0.$$

Proof. By Corollary 3.3, $(\|\rho_i\|_{1+1/n})$ is bounded. By Lemma 3.5(a) we have

$$E_{\text{pot}}(\rho_i) \le \mathcal{H}^r_\mathcal{C}(\rho_i) \le \frac{1}{2} h^r_M < 0, \qquad i \ge i_0,$$

for a suitable $i_0 \in \mathbb{N}$. Thus by Lemma 3.4 there exist $\delta_0 > 0$, $R_0 > 0$, and a sequence of shift vectors $(a_i) \subset \mathbb{R}^3$ as required. ∎

Finally, we will also need to exploit the well-known compactness properties of the solution operator of the Poisson equation.

LEMMA 3.7. *Let $(\rho_i) \subset L^{1+1/n}(\mathbb{R}^3)$ be bounded and*

$$\rho_i \rightharpoonup \rho_0 \text{ weakly in } L^{1+1/n}(\mathbb{R}^3).$$

(a) *For any $R > 0$,*

$$\nabla U_{\mathbf{1}_{B_R}\rho_i} \to \nabla U_{\mathbf{1}_{B_R}\rho_0} \text{ strongly in } L^2(\mathbb{R}^3).$$

(b) *If in addition (ρ_i) is bounded in $L^1(\mathbb{R}^3)$, $\rho_0 \in L^1(\mathbb{R}^3)$, and for any $\epsilon > 0$ there exist $R > 0$ and $i_0 \in \mathbb{N}$ such that*

$$\int_{|x| \ge R} |\rho_i(x)|\, dx < \epsilon, \qquad i \ge i_0,$$

then

$$\nabla U_{\rho_i} \to \nabla U_{\rho_0} \text{ strongly in } L^2(\mathbb{R}^3).$$

Proof. As to part (a), take any $R' > R$. Since $1 + 1/n > 4/3 > 6/5$, the mapping

$$L^{1+1/n}(\mathbb{R}^3) \ni \rho \mapsto \mathbf{1}_{B_{R'}} \nabla U_{\mathbf{1}_{B_R}\rho} \in L^2(B_{R'})$$

is compact. Thus the asserted strong convergence holds on $B_{R'}$. On the other hand,

$$\int_{|x|\geq R'} |\nabla U_{\mathbf{1}_{B_R}\rho_i}|^2 dx \leq \frac{C}{R'-R}\|\mathbf{1}_{B_R}\rho_i\|_1^2 \leq \frac{C}{R'-R}, \qquad i \in \mathbb{N}\cup\{0\},$$

which is arbitrarily small for R' large. As to part (b), we have for any $R > 0$,

$$\|\nabla U_{\rho_i} - \nabla U_{\rho_0}\|_2 \leq \|\nabla U_{\mathbf{1}_{B_R}\rho_i} - \nabla U_{\mathbf{1}_{B_R}\rho_0}\|_2 + \|\nabla U_{\mathbf{1}_{B_{R,\infty}}\rho_i} - \nabla U_{\mathbf{1}_{B_{R,\infty}}\rho_0}\|_2.$$

Using the extended Young's inequality, interpolation, and the boundedness of the sequence in $L^{1+1/n}(\mathbb{R}^3)$, we find that

$$\begin{aligned}\|\nabla U_{\mathbf{1}_{B_{R,\infty}}\rho_i} - \nabla U_{\mathbf{1}_{B_{R,\infty}}\rho_0}\|_2 &\leq C\left(\|\mathbf{1}_{B_{R,\infty}}\rho_i\|_{6/5} + \|\mathbf{1}_{B_{R,\infty}}\rho_0\|_{6/5}\right)\\ &\leq C\left(\|\mathbf{1}_{B_{R,\infty}}\rho_i\|_1^{(5-n)/6} + \|\mathbf{1}_{B_{R,\infty}}\rho_0\|_1^{(5-n)/6}\right).\end{aligned}$$

Given $\epsilon > 0$ we now choose $R > 0$ and $i_0 \in \mathbb{N}$ such that this is less than $\epsilon > 0$ for $i \geq i_0$, and recalling (a) completes the proof. □

We are now ready to prove the main result of this section.

Proof of Theorem 3.1. We split $\rho \in \mathcal{F}_M^r$ into three different parts:

$$\rho = \mathbf{1}_{B_{R_1}}\rho + \mathbf{1}_{B_{R_1,R_2}}\rho + \mathbf{1}_{B_{R_2,\infty}}\rho =: \rho_1 + \rho_2 + \rho_3;$$

the parameters $R_1 < R_2$ of the split are yet to be determined. With

$$I_{lm} := \iint \frac{\rho_l(x)\,\rho_m(y)}{|x-y|}, \qquad l,m = 1,2,3,$$

we have

$$\mathcal{H}_\mathcal{C}^r(\rho) = \mathcal{H}_\mathcal{C}^r(\rho_1) + \mathcal{H}_\mathcal{C}^r(\rho_2) + \mathcal{H}_\mathcal{C}^r(\rho_3) - I_{12} - I_{13} - I_{23}.$$

If we choose $R_2 > 2R_1$, then

$$I_{13} \leq \frac{C}{R_2}.$$

Next, we use the Cauchy–Schwarz inequality, the extended Young's inequality, and interpolation to get

$$\begin{aligned}I_{12} + I_{23} = \frac{1}{4\pi}\left|\int \nabla(U_1 + U_3)\cdot\nabla U_2 dx\right| &\leq C\|\rho_1 + \rho_3\|_{6/5}\|\nabla U_2\|_2\\ &\leq C\|\rho\|_{1+1/n}^{(n+1)/6}\,\|\nabla U_2\|_2.\end{aligned}$$

Using the estimates above and Lemma 3.5(b), we find with $M_l = \int \rho_l,\ l = 1,2,3,$

$$\begin{aligned}h_M^r - \mathcal{H}_\mathcal{C}^r(\rho) &\leq \left(1 - \left(\frac{M_1}{M}\right)^{5/3} - \left(\frac{M_2}{M}\right)^{5/3} - \left(\frac{M_3}{M}\right)^{5/3}\right) h_M^r\\ &\quad + C\left(R_2^{-1} + \|\rho\|_{1+1/n}^{(n+1)/6}\,\|\nabla U_2\|_2\right)\\ &\leq \frac{C}{M^2}\left(M_1M_2 + M_1M_3 + M_2M_3\right) h_M^r\\ &\quad + C\left(R_2^{-1} + \|\rho\|_{1+1/n}^{(n+1)/6}\,\|\nabla U_2\|_2\right)\\ &\leq Ch_M^r\, M_1\, M_3 + C\left(R_2^{-1} + \|\rho\|_{1+1/n}^{(n+1)/6}\,\|\nabla U_2\|_2\right);\end{aligned} \tag{3.3}$$

observe that by Lemma 3.5(a) $h^r_M < 0$ and that constants denoted by C are positive and depend on M and Φ but not on R_1 or R_2. We want to use (3.3) to show that up to a subsequence and a shift M_3 becomes small along any minimizing sequence for i large provided the splitting parameters are suitably chosen.

The sequence $T\rho_i := \rho_i(\cdot + a_i),\ i \in \mathbb{N}$, is minimizing and bounded in $L^{1+1/n}(\mathbb{R}^3)$ so there exists a subsequence, denoted by $(T\rho_i)$ again, such that $T\rho_i \rightharpoonup \rho_0$ weakly in $L^{1+1/n}(\mathbb{R}^3)$; cf. Corollary 3.3. Now choose $R_0 < R_1$ so that by Corollary 3.6, $M_{i,1} \geq \delta_0$ for i large. By (3.3),

$$(3.4)\ -C\, h^r_M \delta_0 M_{i,3} \leq \frac{C}{R_2} + C\,\|\nabla U_{0,2}\|_2 + C\|\nabla U_{i,2} - \nabla U_{0,2}\|_2 + \mathcal{H}^r_{\mathcal{C}}(T\rho_i) - h^r_M,$$

where $U_{i,l}$ is the potential induced by $\rho_{i,l}$ which in turn has mass $M_{i,l},\ i \in \mathbb{N}\cup\{0\}$, and the index $l = 1, 2, 3$ refers to the splitting. Given any $\epsilon > 0$ we increase $R_1 > R_0$ such that the second term on the right-hand side of (3.4) is small, say less than $\epsilon/4$. Next choose $R_2 > 2R_1$ such that the first term is small. Now that R_1 and R_2 are fixed, the third term in (3.4) converges to zero by Lemma 3.7(a). Since $(T\rho_i)$ is minimizing the remainder in (3.4) follows suit. Therefore, for i sufficiently large,

$$(3.5)\qquad \int_{a_i + B_{R_2}} T\rho_i = M - M_{i,3} \geq M - (-C\, h^r_M \delta_0)^{-1}\epsilon.$$

Clearly, $\rho_0 \geq 0$ a.e. By weak convergence we have that for any $\epsilon > 0$ there exists $R > 0$ such that

$$M \geq \int_{B_R} \rho_0\, dx \geq M - \epsilon,$$

which in particular implies that $\rho_0 \in L^1(\mathbb{R}^3)$ with $\int \rho_0 dx = M$. The functional $\rho \mapsto \int \Phi(\rho)\, dx$ is convex, so by Mazur's lemma and Fatou's lemma

$$\int \Phi(\rho_0)\, dx \leq \limsup_{i\to\infty} \int \Phi(T\rho_i)\, dx.$$

The strong convergence of the gravitational fields now follows by Lemma 3.7(b), and in particular,

$$\mathcal{H}^r_{\mathcal{C}}(\rho_0) \leq \limsup_{i\to\infty} \mathcal{H}^r_{\mathcal{C}}(\rho_i) = h^r_M$$

so that ρ_0 is a minimizer of $\mathcal{H}^r_{\mathcal{C}}$. □

4. Applications, symmetries, extensions. Although the main purpose of the present paper is to get a more general understanding of the techniques developed in [1, 2, 3, 4, 5, 11, 12] we want to at least indicate some possible applications of these techniques. First we should mention that [5] differs from the other papers in so far as there the Casimir functional is used as part of the constraint under which then the total energy is minimized. This made it possible to relax the growth conditions on Q—$0 < k \leq 7/2$ is covered in [5]—but since in the reduction process we turn $\mathcal{C}(f)+E_{\rm kin}(f)$ into a new functional of ρ, [5] seems to be outside the present framework.

We start with the observation, already noted in Theorem 2.1, that if $\rho_0 \in \mathcal{F}^r_M$ is a minimizer of $\mathcal{H}^r_{\mathcal{C}}$ with induced potential U_0, then

$$(4.1)\qquad \rho_0 = (\Phi')^{-1}_+(E_0 - U_0) := \begin{cases} (\Phi')^{-1}(E_0 - U_0), & U_0 < E_0,\\ 0, & U_0 \geq E_0,\end{cases}$$

and thus

$$\triangle U_0 = 4\pi (\Phi')_+^{-1}(E_0 - U_0) \tag{4.2}$$

on $\mathbb{R}^3$. The corresponding minimizer of $\mathcal{H}_\mathcal{C}$,

$$f_0 = \begin{cases} (Q')^{-1}(E_0 - E), & E < E_0, \\ 0, & E \geq E_0, \end{cases}$$

is a steady state of the Vlasov–Poisson system, since $E = E(x,v) = \frac{1}{2}|v|^2 + U_0(x)$ is a conserved quantity for the characteristics of the Vlasov equation with potential U_0 induced by $\rho_0 = \rho_{f_0}$. Steady states obtained in this manner have finite mass M, which is a necessary property for physically relevant steady states. We remark that the ansatz $f_0 = \phi(E_0 - E)$ reduces the stationary Vlasov–Poisson system to the semilinear Poisson equation

$$\triangle U_0 = 4\pi \int \phi\left(E_0 - \frac{1}{2}|v|^2 - U_0\right) dv,$$

which is exactly (4.2), provided Q can be chosen such that $(Q')^{-1} = \phi$ on $\mathbb{R}_+$ and $\phi = 0$ on $\mathbb{R}_-$. As far as the existence of steady states is concerned, our "reduced" approach allows us to cover $f_0 = (E_0 - E)_+^k$ with $-1 < k < 3/2$ which leads to (4.2) with right-hand side $C\,(E_0 - U_0)_+^n$ with $n = k + 3/2$ in the permissible range $]0, 3[$; note that the lower bound $k > -1$ is necessary to make the v-integral above converge. With the direct approach working with $\mathcal{H}_\mathcal{C}$ we were restricted to $0 < k < 3/2$.

The main feature of steady states obtained as minimizers in this manner is that their nonlinear stability. Since this is the main point in the investigations cited above, we do not go into this here. Instead, we briefly look a the role of symmetries in our problem. First we note that for any $\rho_0 \in \mathcal{F}_M^r$ its spherically symmetric decreasing rearrangement, denoted by ρ_0^*, also lies in $\mathcal{F}_M^r$ and satisfies

$$\int \Phi(\rho_0) = \int \Phi(\rho_0^*), \qquad E_{\mathrm{pot}}(\rho_0) \geq E_{\mathrm{pot}}(\rho_0^*)$$

with equality if and only if $\rho_0 = \rho_0^*(\cdot - x^*)$ for some $x^* \in \mathbb{R}^3$; cf. [8, Thms. 3.7, 3.9]. In particular, any minimizer of $\mathcal{H}_\mathcal{C}^r$ must be spherically symmetric with respect to some point in $\mathbb{R}^3$. If we are interested only in solving (4.2) or the stationary Vlasov–Poisson system, we therefore lose nothing if we restrict ourselves to the set of spherically symmetric functions in $\mathcal{F}_M^r$. The crucial part of the concentration-compactness argument simplifies considerably under this restriction.

Lemma 4.1. *Define*

$$R_0 = -\frac{3}{5}\frac{M^2}{h_M^r} > 0.$$

Let $\rho \in \mathcal{F}_M^r$ be spherically symmetric, $R > 0$, and

$$m := \int_{\{|x| \geq R\}} \rho.$$

Then the following estimate holds:

$$\mathcal{H}_\mathcal{C}^r(\rho) \geq h_M^r + \left[\frac{1}{R_0} - \frac{1}{R}\right](M - m)\,m.$$

If $R > R_0$, then for any spherically symmetric minimizing sequence $(\rho_i) \subset \mathcal{F}^r_M$ of $\mathcal{H}^r_\mathcal{C}$,

$$\lim_{i\to\infty} \int_{|x|\geq R} \rho_i = 0.$$

Proof. Clearly,

$$\mathcal{H}^r_\mathcal{C}(\rho) = \mathcal{H}^r_\mathcal{C}(\rho_1) + \mathcal{H}^r_\mathcal{C}(\rho_2) - \int \frac{\rho_1(x)\,\rho_2(y)}{|x-y|}dx\,dy,$$

where $\rho_1 = \mathbf{1}_{B_R}\rho$, $\rho_2 = \rho - \rho_1$. Due to spherical symmetry,

$$\begin{aligned}\int \frac{\rho_1(x)\,\rho_2(y)}{|x-y|}dx\,dy &= \frac{1}{4\pi}\int \nabla U_{\rho_1}\cdot\nabla U_{\rho_2}dx\\ &= \int_0^\infty \frac{4\pi}{r^2}\int_0^r \rho_1(s)\,s^2ds\,\frac{4\pi}{r^2}\int_0^r \rho_2(s)\,s^2ds\,r^2dr\\ &= \int_R^\infty \cdots dr \leq \frac{(M-m)\,m}{R}.\end{aligned}$$

Thus by Lemma 3.5,

$$\begin{aligned}\mathcal{H}^r_\mathcal{C}(\rho) &\geq h^r_{M-m} + h^r_m - \frac{(M-m)\,m}{R}\\ &\geq \left[\left(\frac{M-m}{M}\right)^{5/3} + \left(\frac{m}{M}\right)^{5/3}\right] h^r_M - \frac{(M-m)\,m}{R}\\ &\geq \left[1 - \frac{5}{3}\frac{M-m}{M}\frac{m}{M}\right] h^r_M - \frac{(M-m)\,m}{R},\end{aligned}$$

which is the first assertion of the lemma; note that the scaling transformations in the proof of Lemma 3.5 preserve spherical symmetry. Now take $R > R_0$ and assume that the second assertion is false so that up to a subsequence,

$$\lim_{i\to\infty} \int_{|x|\geq R} \rho_i = m > 0.$$

Choose $R_i > R$ such that

$$m_i := \int_{|x|\geq R_i} \rho_i = \frac{1}{2}\int_{|x|\geq R} \rho_i.$$

By the already established splitting estimate,

$$\mathcal{H}^r_\mathcal{C}(\rho_i) \geq h^r_M + \left[\frac{1}{R_0} - \frac{1}{R_i}\right](M-m_i)\,m_i \geq h^r_M + \left[\frac{1}{R_0} - \frac{1}{R}\right](M-m_i)\,m_i,$$

and with $i \to \infty$,

$$h^r_M \geq h^r_M + \left[\frac{1}{R_0} - \frac{1}{R}\right](M - m/2)\,m/2 > h^r_M,$$

a contradiction. □

The lemma above now replaces Lemma 3.4, Corollary 3.6, and the proof of (3.5), which relied on the fairly lengthy argument via (3.3) and (3.4). In addition, we get a somewhat sharper result on the minimizer:

$$\operatorname{supp}\rho_0 \subset B_{R_0}.$$

That spherical symmetry helps with compactness issues was already noted in [13]. The a priori restriction to the spherically symmetric case is undesirable in view of resulting stability assertions: These would then be restricted to spherically symmetric perturbations. Moreover, the symmetry simplification cannot be used if one does not a priori know that the minimizers will be spherically symmetric. One example for this situation is the construction of steady states with axial symmetry, say with respect to the x_3-axis, by making Q in addition depend explicitly on $x_1 v_2 - x_2 v_1$, the angular momentum with respect to the axis of symmetry. The same reduction procedure as before now gives a function Φ that depends in addition on $r = r(x) = \sqrt{x_1^2 + x_2^2}$, and minimizers will not be spherically symmetric. An investigation of axially symmetric steady states and their stability will be the content of [6].

To illustrate the method explained in section 3 let $\Phi = \Phi(r,\rho)$ satisfy the assumptions (Φ1)–(Φ3) uniformly in $r \geq 0$, and assume in addition that $\Phi(\cdot,\rho)$ is nonincreasing for every $\rho > 0$. Then all the arguments in section 3 go through the following: That Φ is nonincreasing in r is needed in the scaling argument (3.2)—note that $b \geq 1$ so $r(x)/b \leq r(x)$ there—and all the other estimates remain unchanged. Thus we obtain a minimizer ρ_0 with induced potential U_0. Let us take the specific example

$$\Phi(r,\rho) := \frac{2+r}{1+r}\,\rho^2, \qquad r \geq 0,\ \rho \geq 0.$$

Then the variational equation (4.1) reads as

$$\rho_0(x) = \frac{1}{2}\,\frac{1+r(x)}{2+r(x)}\,(E_0 - U_0(x))$$

on the support of ρ_0, and due to the explicit dependence on $r(x)$ this minimizer is not spherically symmetric, and the simpler arguments stated above for the spherically symmetric case do not apply. If one wishes to study the minimization of $\mathcal{H}_\mathcal{C}^r$ with $\Phi(\rho)$ generalized to $\Phi(x,\rho)$ the crucial step in the analysis which restricts the possible dependence on x is the scaling in Lemma 3.5.

Another situation where the minimizers will in general not be spherically symmetric arises if one includes in the Vlasov–Poisson system an exterior gravitational field, say $U_e = U_{\rho_e}$ with some fixed $\rho_e \in L^1_+ \cap L^{1+1/n}(\mathbb{R}^3)$. It is quite easy to check that all the analysis carried out in this paper extends to this case; only the potential energy needs to be modified accordingly:

$$\begin{aligned} E_{\mathrm{pot}}(\rho) &= -\frac{1}{2}\iint \frac{\rho(x)\,\rho(y)}{|x-y|}dx\,dy - \iint \frac{\rho(x)\,\rho_e(y)}{|x-y|}dx\,dy \\ &= \frac{1}{2}\int \rho(x) U_\rho(x)\,dx + \int \rho(x) U_e(x)\,dx, \end{aligned}$$

and if ρ_e is not spherically symmetric, then neither are possible minimizers.

Acknowledgment. This paper originates from my collaboration with Y. Guo, Brown University, whom I would like to thank for many stimulating discussions.

STABILITY OF VISCOUS SHOCK WAVES FOR PROBLEMS WITH NONSYMMETRIC VISCOSITY MATRICES*

M. LIEFVENDAHL† AND G. KREISS†

Abstract. Sufficient conditions for nonlinear stability of viscous shock wave solutions of systems of conservation laws are given. The analysis applies to strong shocks of Lax type but is restricted to perturbations with zero mass. We use the Laplace transform and reduce the question of stability to a spectral condition for the resolvent equation of the linearized problem.

Key words. shock waves, nonlinear stability, conservation laws

1. Introduction.

Traveling wave solutions occur in systems modeling physical phenomena such as gas dynamics, magnetohydrodynamics, and phase transitions. To be able to simulate such a problem it is important to understand the dynamic properties of the system. In this paper we consider the stability of viscous shock waves satisfying a parabolic system of conservation laws

$$v_t + f(v)_x = Bv_{xx},$$

where v approaches asymptotic states U_R and U_L as $x \to \pm\infty$. We assume that in the corresponding inviscid case the asymptotic states can be connected by a so-called Lax shock (see Lax [10]). In the case of sufficiently weak shocks, that is, when the difference between the asymptotic states is sufficiently small, existence and stability is understood. See, for instance, Kopell and Howard [7], Liu [13], Goodman [4], and Szepessy and Xin [17]. In the latter three papers nonlinear stability under increasingly more general perturbations is established. Under general conditions on the nonlinearity only stable viscous shock waves are possible.

For strong shocks, however, we do not expect sufficient conditions for stability to be as general as in the weak shock case. In Freistühler and Zumbrun [3] and in Liefvendahl and Kreiss [12] viscous shock waves of Lax type are constructed such that the linearized problem has solutions that grow exponentially. An example of a stability result is the paper by Matsumura and Nishihara [16], where a stability theorem for strong shock waves of a model system for compressible viscous gases is proven. The system is of mixed hyperbolic-parabolic type.

In this paper we assume the existence of a strong viscous shock wave of Lax type and prove a theorem stating sufficient conditions for stability under zero mass perturbations. The result is presented in greater detail in Liefvendahl [11]. It is an extension of the results in Kreiss and Kreiss [9], where the case $B = I$ is treated. In our approach the conditions for stability involve the spectral properties of the linearized problem. The theorem proved here is a special case of the results stated in Zumbrun and Howard [18]. The latter apply also to general mass perturbations and to nonconstant B.

1.1. The main theorem. In this subsection we state the problem and all assumptions and formulate the main result. In the next subsection we outline the proof.

Consider the Cauchy problem for a system of n real conservation laws:

$$\begin{aligned} v_t + f(v)_x &= Bv_{xx}, \qquad t > 0, \quad x \in \mathbb{R}, \\ v(x,0) &= v_0(x). \end{aligned}$$

Here the matrix B is constant and has eigenvalues with positive real part and the function f is smooth.

We shall assume there is a traveling wave solution U, which without loss of generality can be assumed to be stationary. We make the following assumption concerning U.

Assumption 1. (i) There is a smooth solution $U(x)$ tending exponentially to constant states U_R, U_L as $x \to \pm\infty$; that is, there are constants $\beta > 0$ and K such that

$$\begin{aligned} |U(x) - U_R| &\le Ke^{-\beta x}, \\ |U(x) - U_L| &\le Ke^{\beta x}. \end{aligned}$$

(ii) The Jacobian matrix of f evaluated at U_R and U_L has real, distinct, nonzero eigenvalues. Let n_R denote the number of negative eigenvalues of $f'(U_R)$ and n_L the number of positive eigenvalues of $f'(U_L)$. Then $n_R + n_L = n + 1$.

(iii) Let $\alpha_i(\xi)$ denote the eigenvalues of the symbol $-i\xi A - \xi^2 B$, where $\xi \in \mathbb{R}$ and $A = A_R$ or A_L. Then there is a constant $\gamma > 0$ such that

$$\text{Re } \alpha_i(\xi) \le -\gamma\xi^2.$$

The last two conditions ensure that the shock wave is of Lax type and that the asymptotic states are stable; see Majda and Pego [15].

The zero mass of the perturbation enters in the following assumption on the initial data.

Assumption 2. Let the initial condition be of the form

$$v_0(x) = U(x) + \varepsilon \left(\tilde{v}_0(x)\right)_x, \quad |\varepsilon| << 1,$$

where $\tilde{v}_0$ and its derivatives have bounded L^1- and L^2-norms.

With $B = I$ the Assumptions 1 and 2 imply Assumption 1.1 in [9]. Also, note that our assumptions on f, A, and B are a special case of (H0)–(H4) in [18].

We shall use L^p-norms, for $p \in \{1, 2, \infty\}$, and the H^1-norm. For a function $f : \mathbb{R} \to \mathbb{R}^n$ with components $\{f_k\}_{k=1}^n$, these are defined by

$$\begin{aligned} \|f\|_{L^p(a,b)} &= \left(\sum_{k=1}^n \int_a^b |f_k(x)|^p dx\right)^{1/p}, \qquad p \in \{1,2\}, \\ \|f\|_{L^\infty(a,b)} &= \max_{1\le k\le n} \left(\text{ess sup}_{x\in(a,b)} |f_k(x)|\right), \\ \|f\|_{H^1(a,b)} &= \left(\|f\|^2_{L^2(a,b)} + \|f_x\|^2_{L^2(a,b)}\right)^{1/2}. \end{aligned}$$

When it is obvious which interval (a,b) to use or when it is the entire real axis we will not explicitly write it.

The aim of this paper is to supplement the above assumptions by structural conditions which imply nonlinear stability. We shall investigate stability by considering the equation for the perturbation from steady state. Since we will use the Laplace transform, we want to consider a problem with homogeneous initial data. Therefore we introduce

$$v(x,t) = U(x) + \varepsilon e^{-t}\left(\tilde{v}_0(x)\right)_x + \varepsilon u(x,t).$$

This leads to the following equation for the introduced function u:

$$u_t + (Au)_x + \varepsilon\left(Cu + g(u)\right)_x = Bu_{xx} - h_x, \tag{1}$$

with homogeneous initial data

$$u(x,0) = 0. \tag{2}$$

In (1) we introduced the following:

$$\begin{aligned} A(x) &= f'(U(x)),\\ C(x,t) &= f'(U + \epsilon e^{-t}\tilde{v}_{0x}) - f'(U),\\ h(x,t) &= \frac{1}{\epsilon}\left(f(U + \epsilon e^{-t}\tilde{v}_{0x}) - f(U)\right) - e^{-t}\left(\tilde{v}_0 + B\tilde{v}_{0xx}\right), \end{aligned}$$

and g, which is the rest term in the Taylor expansion of the nonlinearity, so it can be bounded according to $|g(u)| \le K|u|^2$.

Connected with (1) is the eigenvalue problem

$$B\varphi_{xx} - (A\varphi)_x = \mu\varphi, \quad \|\varphi\|_{L^2} < \infty. \tag{3}$$

Clearly zero is an eigenvalue with eigenfunction U_x. This eigensolution corresponds to the nonuniqueness of shock wave solutions (U can be shifted in space). A necessary condition for linear (and therefore also for nonlinear) stability is that there are no eigenvalues with positive real part.

Assumption 3. The only eigenvalue with $\operatorname{Re}\mu \ge 0$ is $\mu = 0$. The dimension of the corresponding eigenspace is 1.

The last assumption follows.

Assumption 4. The $n \times n$ matrix

$$M = \left(\, S_R^{II} \quad S_L^{I} \quad U_R - U_L \,\right)$$

is nonsingular. Here S_R^{II} consists of the eigenvectors of A_R corresponding to positive eigenvalues and S_L^{I} consists of the eigenvectors of A_L corresponding to negative eigenvalues.

The importance of the matrix M for shock wave stability has been known a long time. Assumption 4 appears as a condition for stability of viscous profiles in, for instance, [8], [9], [17], and [18]. It is shown to hold for all sufficiently weak shocks in [17] and to be necessary for stability in [18]. (Note the misprint concerning this in [18], first appearing on page 19; $\{r_j^{\pm} : a_j^{\pm} \lesseqgtr 0\}$ should be $\{r_j^{\pm} : a_j^{\pm} \gtreqless 0\}$.) For the inviscid problem the condition is necessary for stability; see Majda [14] and Erpenbeck [2]. This is also the situation for a corresponding discrete problem; see Bultelle, Grassin, and Serre [1].

We can now formulate our main result. We use the following concept of stability.

Definition 1. *Problem* (1), (2) *is nonlinearly stable under zero mass perturbations if the solution $u(x,t)$ remains smooth for all $t \geq 0$ and $||u(\cdot,t)||_{L^\infty}$ tends to zero for $t \to \infty$ for sufficiently small ϵ. In particular, we call the problem linearly stable if the convergence takes place for $\varepsilon = 0$.*

Our main theorem is as follows.

Theorem 1. *If Assumptions* 1–4 *are satisfied, then problems* (1)–(2) *are nonlinearly stable under zero mass perturbations.*

Note that we do not require the shock to be weak. Also, we give no temporal decay rate for the solution. This cannot be done without more severe requirements on the spatial decay of the initial perturbation.

1.2. Outline of the proof. Most parts of the proof of the theorem are identical with the proof of the corresponding theorem in [9]. In this paper we give details only of the parts that differ significantly, which of course concern the generalization $B \neq I$.

We will derive estimates for the corresponding linear problem. The linear problem is Laplace transformed in time, yielding the resolvent equation

$$B\hat{u}_{xx} - \Big(A(x)\hat{u}\Big)_x - s\hat{u} = \hat{h}_x, \quad \|\hat{u}(\cdot,s)\|_{L_2} < \infty. \tag{4}$$

As in [9], we want to prove the estimate

$$\|\hat{u}\|^2_{H^1} \leq K\left(\|\hat{h}\|^2_{L^2} + \|\hat{h}\|^2_{L^1}\right), \quad \operatorname{Re} s > 0. \tag{5}$$

From the estimate (5) nonlinear stability follows; see [9].

For sufficiently large $|s|$, (5) is obtained by integration by parts. This can be done since there is a constant matrix $H = H^*$ (a symmetrizer) which is positive definite and satisfies

$$\operatorname{Re}\ (\hat{u}_x, (HB + B^*H)\hat{u}_x) \geq \|\hat{u}_x\|^2_{L^2}.$$

Here $(\cdot,\cdot)$ denotes the complex L^2-inner product.

For $C \geq |s| \geq c > 0$ we need a result stating that for $A = A_R$ and A_L, all roots $\kappa(s)$ of the characteristic equation,

$$\det(sI - \kappa A - \kappa^2 B) = 0, \qquad \operatorname{Re}\, s > 0,$$

have real part bounded away from zero, and that there are precisely n roots with positive real part and n roots with negative real part. Then we can proceed as in [9], reducing the problem (4) to a bounded interval and deriving the estimate (5) by compactness arguments. The required result for the characteristic equation is given in section 2.1.

In [9] the treatment for the remaining part of the s plane relies heavily on the diagonalization of the constant coefficient problems obtained by letting $|x| \to \infty$ in the resolvent equation. In our case the method of proof must be modified, since only block-diagonalization is possible. The details of this part of the proof are given in this paper.

In section 2.1 we analyze the constant coefficient problems connected with the asymptotic states U_R and U_L. In the appendix we have collected some results for ODEs on a half-line that relate this analysis to the resolvent equation. In section 2.2 there is also a preliminary analysis of the resolvent equation when $s = 0$. In section 3 we use these results to prove the following result.

Lemma 1. *There exists constants K and $c > 0$ such that for $s \in \Omega_c := \{s \in \mathbb{C} : \operatorname{Re}\, s > 0, |s| \leq c\}$ the solution of* (4) *satisfies the estimate* (5).

2. Preliminary analysis. In the first part of this section we state properties of the limiting coefficients of the resolvent equation when $|x| \to \infty$. In the last part we analyze the resolvent equation for $s = 0$ in the case with forcing having bounded support.

2.1. Properties of the limiting coefficient matrices. The coefficients of the resolvent equation are nearly constant when $|x| \gg 1$. In this section we study the limiting coefficient matrices ($x \to \pm\infty$) when the resolvent equation is written as a first order system.

More precisely, we will study the eigenvalues and block-diagonalizing transformations for the matrix

$$D_0(s) := \begin{pmatrix} B^{-1}A_R & B^{-1} \\ sI & 0 \end{pmatrix}.$$

The treatment of the corresponding matrix when A_R is changed to A_L is completely analogous. Recall that A_R has distinct eigenvalues. Thus we can diagonalize it as

$$T_{1R}A_R S_{1R} = \begin{pmatrix} \Lambda^- & 0 \\ 0 & \Lambda^+ \end{pmatrix}.$$

Here the diagonal of Λ^- consists of $\lambda_1, \ldots, \lambda_{n_R}$, which are all negative. The diagonal of Λ^+ consists of $\lambda_{n_R+1}, \ldots, \lambda_n$, which are all positive.

We will now state a series of properties of the introduced matrices. Statements 1–4 below are established in [18] and play an equally fundamental role therein. Statement 5 is special to our approach and is new.

LEMMA 2. *Denote the eigenvalues of $B^{-1}A_R$ by $\{\tau_i\}_{i=1}^n$ and the eigenvalues of $D_0(s)$ by $\{\kappa_i(s)\}_{i=1}^{2n}$.*

1. *For $|s| \ll 1$ we have the expansions*

$$\kappa_i = \tau_i + \mathcal{O}(s^{1/n}), \qquad (6)$$

$$\kappa_{i+n} = -\frac{s}{\lambda_i} + \frac{s^2\tilde{b}_{ii}}{\lambda_i^3} + \mathcal{O}(s^3),$$

which hold for $i = 1, \ldots, n$. Here $\{\tilde{b}_{ii}\}_{i=1}^n$ denotes the diagonal elements of $T_{1R}BS_{1R}$.

2. *For $s \in \Omega := \{s \in \mathbb{C} : \mathrm{Re}\, s \geq 0, s \neq 0\}$, exactly n of the functions κ_i have positive real part and n have negative real part. We emphasize that for no $s \in \Omega$ is there a κ_i which is purely imaginary. Also, no κ_i crosses the imaginary axis when s varies in Ω.*

3. *The number of eigenvalues $\{\tau_i\}_{i=1}^n$ with positive real part is $n - n_R$ and the number with negative real part is n_R. We can block diagonalize $B^{-1}A_R$ according to*

$$T_{2R}B^{-1}A_R S_{2R} = \begin{pmatrix} A^+ & 0 \\ 0 & A^- \end{pmatrix},$$

where the τ_i with positive real part are eigenvalues of A^+ and those with negative real part are eigenvalues of A^-. We have $T_{2R} = S_{2R}^{-1}$.

4. $\mathrm{Re}\, \tilde{b}_{ii} > 0$ *for $i = 1, \ldots, n$.*

5. *In the region $\Omega_c := \{s \in \mathbb{C} : \text{Re } s > 0, |s| \leq c\}$, for a sufficiently small c, we have analytic matrices $S_R(s)$ and $T_R := S_R^{-1}$ such that*

$$T_R(s)D_0(s)S_R(s) = \begin{pmatrix} C^+(s) & 0 & 0 & 0 \\ 0 & C^-(s) & 0 & 0 \\ 0 & 0 & \mathcal{K}^+(s) & 0 \\ 0 & 0 & 0 & \mathcal{K}^-(s) \end{pmatrix}, \tag{7}$$

where

- *C^+ is an $(n-n_R)\times(n-n_R)$ matrix. The eigenvalues of C^+ are $\kappa_1, \ldots, \kappa_{n-n_R}$.*
- *C^- is an $n_R \times n_R$ matrix. The eigenvalues of C^- are $\kappa_{n-n_R+1}, \ldots \kappa_n$.*
- *$\mathcal{K}^+$ is an $n_R \times n_R$ diagonal matrix. The eigenvalues of $\mathcal{K}^+$ are $\kappa_{n+1}, \ldots, \kappa_{n+n_R}$.*
- *$\mathcal{K}^-$ is an $(n-n_R)\times(n-n_R)$ diagonal matrix. The eigenvalues of $\mathcal{K}^-$ are $\kappa_{n+n_R+1}, \ldots, \kappa_{2n}$.*
- *The block-diagonalizing transformations have the following form for $|s| \ll 1$:*

$$S_R(s) = \begin{pmatrix} S_{2R} & -A_R^{-1}S_{1R} \\ 0 & S_{1R} \end{pmatrix} + \mathcal{O}(s),$$
$$T_R(s) = \begin{pmatrix} T_{2R} & T_{2R}A_R^{-1} \\ 0 & T_{1R} \end{pmatrix} + \mathcal{O}(s). \tag{8}$$

Proof. Start with property 1. The κ_i are solutions of the characteristic equation $P(\kappa, s) := \det(\kappa^2 B - \kappa A_R - sI) = 0$. We see that P is a polynomial in κ and s, so the κ_i are algebraic functions. This means that the $\kappa_i(s)$ are functions which are analytic except at finitely many points; see [6, p. 119]. To determine the expansions we first solve $P(\kappa, 0) = 0$ and obtain the $\mathcal{O}(1)$ terms. For $\kappa_{n+1}, \ldots, \kappa_{2n}$ this term is zero. For $\kappa_1, \ldots, \kappa_n$ we do not need more information; the remainder is in the worst case $\mathcal{O}(s^{1/n})$. For $\kappa_{n+1}, \ldots, \kappa_{2n}$ we continue by grouping terms of $P(\gamma_i s, s)$ according to powers in s. We will determine $\{\gamma_i\}_{i=1}^n$; here γ_i correspond to κ_{i+n}. We neglect higher order terms and set the expression to zero, which gives γ_i. To obtain the $\mathcal{O}(s^2)$ terms we use the ansatz $\kappa_{i+n} = -s/\lambda_i + s^2\theta_i$ and determine θ_i. The details are given in [11].

To prove property 2, we first study the characteristic equation for $|s| \gg 1$,

$$\det(\kappa^2 B - sI) \approx 0,$$

which yields $\kappa_i \approx \pm\sqrt{s/\beta_i}$, where β_i are the eigenvalues of B. This means that for $|s| \gg 1$ and $s \in \Omega$ half of the κ_i have positive real part and half of them have negative real part. Now we assume that one of the κ_i crosses the imaginary axis when s varies in Ω. Then

$$\det(-\xi_0^2 B - i\xi_0 A_R - s_0 I) = 0 \tag{9}$$

for some $\xi_0 \in \mathbb{R}$. According to (9), s_0 is an eigenvalue of the symbol $-\xi_0^2 B - i\xi_0 A_R$. Assumption 1 then implies Re $s_0 < -\gamma\xi_0^2$, which contradicts $s_0 \in \Omega$. Thus the number of κ_i with positive and negative real part, respectively, is n for all $s \in \Omega$.

Property 3 follows by using the expansions of κ_i with a real s and counting the number of eigenvalues in the right and left complex half planes.

Property 4 follows from the expansion for $\kappa_{n+1}, \dots, \kappa_{2n}$ for a purely imaginary s and the requirement that no κ_i can be purely imaginary.

To prove property 5, we note that the information contained in the expansions in (6), concerning grouping of eigenvalues of with positive and negative real part, and the order of the branching of the $\mathcal{O}(s)$ eigenvalues, make Theorem 8, page 70, in [5] applicable. This theorem is stated in terms of eigenprojections corresponding to eigenvalues. Restating it in terms of block diagonal transformations we get the existence and analyticity of S_R and T_R. The expansions of the matrices S_R and T_R then follow by inspection; see [11] for details. This concludes the proof. □

Finally we introduce notation for submatrices of the block-diagonalizing transformations introduced in this section. We partition the matrices T_{1R} and T_{2R} according to

$$T_{1R} = \begin{pmatrix} T_{1R}^{I} \\ T_{1R}^{II} \end{pmatrix}, \qquad T_{2R} = \begin{pmatrix} T_{2R}^{I} \\ T_{2R}^{II} \end{pmatrix},$$

where T_{1R}^{I} contains the first n_R rows of T_{1R}, and T_{1R}^{II} contains the last $n - n_R$ rows. Correspondingly, T_{2R}^{I} contains the first $n - n_R$ rows of T_{2R}, and T_{2R}^{II} the last n_R rows.

We partition the matrix T_R into submatrices corresponding to the blocks on the diagonal of the matrix in the right-hand side of (7),

$$T_R(s) = \begin{pmatrix} T_R^{I}(s) \\ T_R^{II}(s) \\ T_R^{III}(s) \\ T_R^{IV}(s) \end{pmatrix}.$$

The partition is done so that T_R^I has $(n - n_R)$ rows, T_R^{II} has n_R rows, etc.

2.2. Solution at the zero eigenvalue when the forcing has bounded support. The resolvent equation (4), with $s = 0$ and forcing stemming from initial data with zero mass, can be integrated once. We then obtain the problem

$$u_x = B^{-1}Au + f, \tag{10}$$

where we have dropped the ˆ-notation for the Laplace-transformed function. The forcing f is not directly related to $\hat{h}$. Instead we assume supp $f \subset [-l_0, l_0]$ for some l_0 and $f \in L^1 \cap L^2$. Studying (10) on an interval $[l, \infty)$ with $l > l_0$, we can apply Lemma 4. According to the lemma there exists an l_1, which we take larger than l_0, such that for $l > l_1$ the following holds. For solutions of the ODE (10), the requirement that u is bounded is equivalent with the condition

$$R(l)u(l) = 0, \tag{11}$$

where $R(l)$ can be written as

$$R(l) = T_{2R}^{I} - e^{-\beta l} P(l) T_{2R}^{II}. \tag{12}$$

Here T_{2R}^{I} and T_{2R}^{II} were introduced in the preceding section and P satisfies $|P(l)| \leq K$.

The argument above can also be applied to (10) on an interval $(-\infty, -l]$ with $l > l_0$ and we obtain boundary conditions

$$R(-l)u(-l) = 0, \tag{13}$$

where we, in the same manner, have the expression $R(-l) = T_{2L}^{II} - e^{-\beta l} P(-l) T_{2L}^{I}$.

Now we consider (10) for $x \in [-l, l]$ with the boundary conditions (11) and (13). This problem consists of n first order ODEs together with $n-1$ boundary conditions. We also note that any solution of this problem is also a solution of (10) on the whole real axis, and vice versa. The reason for replacing the ODE on the real axis with that on a bounded interval is to make it possible to estimate the solutions via a "compactness" argument, which we describe below.

Next we derive a representation formula for the solution by introducing a fundamental matrix $\Psi(x)$ for the homogeneous version of (10). The n columns of Ψ are linearly independent solutions of (10) with $f = 0$. The solution of the inhomogeneous problem can now be written as

$$u(x) = \Psi(x) \left[u(0) + \int_0^x \Psi^{-1}(\xi) f(\xi) d\xi \right].$$

Inserting this into the boundary conditions at $x = \pm l$ we obtain the following system of $n - 1$ linear equations for the components of $u(0)$:

$$\text{(14)} \qquad \begin{pmatrix} R(l)\Psi(l) \\ R(-l)\Psi(-l) \end{pmatrix} u(0) = \begin{pmatrix} R(l)\Psi(l) \int_0^l \Psi^{-1}(\xi) f(\xi) d\xi \\ -R(-l)\Psi(-l) \int_{-l}^0 \Psi^{-1}(\xi) f(\xi) d\xi \end{pmatrix}.$$

For the homogeneous problem, $f = 0$, we have zero in the right-hand side of (14). According to Assumption 3, the solutions of the homogeneous problem have the form $u = \alpha\varphi_0$ for an arbitrary α, i.e., the eigenspace of zero has dimension one. This means that the solutions of (14) in the homogeneous case are $u(0) = \alpha\varphi_0(0)$.

The solutions of (14) are not unique. Our goal is to construct one solution which can be estimated in terms of the forcing function f. This is done by adding one more condition, which is that we choose the solution $u(0)$ of (14) that has minimal Euclidean length.

The above procedure gives a function $u(x)$, which can be written as

$$u(x) = \alpha\varphi_0 + \Psi(x) \left[u_0 + \int_0^x \Psi^{-1}(\xi) f(\xi) d\xi \right].$$

Here u_0 is any solution of (14) and α is determined by the requirement that $\alpha\varphi_0(0) + u_0$ be the minimal solution of (14). We have the estimate

$$|u(0)| \le K \left| \int_{-l}^{l} \Psi^{-1}(\xi) f(\xi) d\xi \right| \le K \max_{x \in [-l,l]} \left| \Psi^{-1}(x) \right| \|f\|_{L^1}.$$

We obtain the last inequality since $|\Psi^{-1}(x)|$ is a continuous function on a compact domain, and therefore is bounded. The same argument holds for $|\Psi(x)|$. We also need to use

$$\|f\|_{L^1[-l,l]} \le K\sqrt{l} \|f\|_{L^2[-l,l]}.$$

Using the solution formula it is now easy to derive

$$\text{(15)} \qquad \|u\|_{L^1[-l,l]} + \|u\|_{L^2[-l,l]} + \|u\|_{L^\infty[-l,l]} \le K\|f\|_{L^2}.$$

To extend the solution from $[-l, l]$ to the entire real axis we use Lemma 3 with the now-determined boundary values. This gives the estimate

$$\text{(16)} \qquad \|u\|_{L^1[l,\infty)} + \|u\|_{L^2[l,\infty)} + \|u\|_{L^\infty[l,\infty)} \le K|u(l)|$$

and the corresponding one to the left. Since the right-hand side in (16) can be estimated by the L^∞-norm of u, we can use (15) to get an estimate in terms of f. Combining the estimates and using the triangle inequality in (10) we get

$$\|u\|_{H^1} + \|u\|_{L^1} + \|u\|_{L^\infty} \le K\|f\|_{L^2}.$$

3. The resolvent estimate near the zero eigenvalue. In this section we prove Lemma 1. The proof proceeds by splitting the unknown into several terms which satisfies simpler problems. These auxiliary problems are treated in sections 3.1–3.3, then we complete the proof by summing the constructions in section 3.4.

3.1. Reduction of the forcing to $\mathcal{O}(s)$. In our procedure to solve and estimate the solution of (4), we start by splitting the unknown $\hat{u} = u_1 + u_2$, where u_1 solves the equation

$$u_{1x} = B^{-1}Au_1 + \hat{h}. \tag{17}$$

When u_1 has been determined, u_2 must satisfy the following equation, which is derived by inserting $\hat{u} = u_1 + u_2$ into (4):

$$su_2 + (Au_2)_x = Bu_{2xx} - su_1. \tag{18}$$

Here we see that u_1, multiplied by the small s, occurs as forcing. Equation (18) is treated in section 3.2. To solve (17) we split the unknown further:

$$u_1 = u_{1M} + \varphi_R u_{1R} + \varphi_L u_{1L}.$$

Here φ_R and φ_L are smooth monotone cut-off functions,

$$\varphi_R = \begin{cases} 1, & x > l, \\ 0, & x < l-1, \end{cases} \qquad \varphi_L = \begin{cases} 1, & x < -l, \\ 0, & x > -l+1, \end{cases}$$

where l will be given below. The function u_{1R} solves the problem

$$\begin{aligned} &u_{1Rx} = B^{-1}Au_{1R} + \hat{h}, \qquad && x \in [l-1, \infty), \\ &T^I_{2R} u_{1R}(l-1) = 0, && \end{aligned} \tag{19}$$

and u_{1L} solves the corresponding problem on the interval $(-\infty, -l+1]$ with T^{II}_{2L} as coefficient matrix in the linear homogeneous boundary conditions at $x = -l+1$.

The remaining part of u_1 must satisfy

$$u_{1Mx} = B^{-1}Au_{1M} + h_M, \tag{20}$$

where $h_M = (1-\varphi_R-\varphi_L)\hat{h} - \varphi_{Rx}u_{1R} - \varphi_{Lx}u_{1L}$. We note that $\operatorname{supp} h_M \subset [-l, l]$. The equation for u_{1M} will be considered below after we have determined u_{1R} and u_{1L}.

If l is chosen sufficiently large, the problems for u_{1R} and u_{1L} are of the type treated in Lemma 3. We thus have unique solutions u_{1R} and u_{1L} for the problems to the right and left, respectively. The function u_{1R} satisfies the estimate

$$\|u_{1R}\|_{L^1[l-1,\infty)} + \|u_{1R}\|_{H^1[l-1,\infty)} + \|u_{1R}\|_{L^\infty[l-1,\infty)} \le K\left(\|\hat{h}\|_{L^1} + \|\hat{h}\|_{L^2}\right). \tag{21}$$

The function u_{1L} satisfies the corresponding estimate, i.e., with all R-subscripts replaced by L-subscripts and the interval changed from $[l-1,\infty)$ to $(-\infty, -l+1]$.

Now we study the equation for u_{1M}. Combining the expression for h_M with the estimate of u_{1R} and u_{1L} in terms of $\hat{h}$, we obtain an estimate of h_M in terms of $\hat{h}$:

$$\|h_M\|_{L^1} + \|h_M\|_{L^2} \leq K\left(\|\hat{h}\|_{L^1} + \|\hat{h}\|_{L^2}\right).$$

Equation (20) is of the type treated in section 2.2. Using the construction described there, we obtain a function u_{1M}, which solves (20) and can be estimated in terms of h_M and thus also in terms of $\hat{h}$:

$$\|u_{1M}\|_{H^1} + \|u_{1M}\|_{L^1} \leq K\left(\|\hat{h}\|_{L^1} + \|\hat{h}\|_{L^2}\right).$$

The last step in this section is to combine the constructions and estimates of u_{1R}, u_{1L}, and u_{1M}. This yields the function u_1 and the following estimate for it:

$$\|u_1\|_{H^1} + \|u_1\|_{L^1} \leq K\left(\|\hat{h}\|_{L^1} + \|\hat{h}\|_{L^2}\right). \tag{22}$$

3.2. Cut-off of forcing to obtain bounded support. In this section we will study (18), where u_1 has the role of forcing. We rewrite the equation to a system of first order equations by introducing the variable $v_2 = Bu_{2x} - Au_2$. This leads to

$$\begin{pmatrix} u_2 \\ v_2 \end{pmatrix}_x = \begin{pmatrix} B^{-1}A & B^{-1} \\ sI & 0 \end{pmatrix}\begin{pmatrix} u_2 \\ v_2 \end{pmatrix} + s\begin{pmatrix} 0 \\ u_1 \end{pmatrix}.$$

To solve this problem we split the unknown:

$$\begin{pmatrix} u_2 \\ v_2 \end{pmatrix} = \begin{pmatrix} u_{2M} \\ v_{2M} \end{pmatrix} + \varphi_R\begin{pmatrix} u_{2R} \\ v_{2R} \end{pmatrix} + \varphi_L\begin{pmatrix} u_{2L} \\ v_{2L} \end{pmatrix}.$$

Here φ_R and φ_L are, as before, smooth and monotone cut-off functions for the right and left half-infinite intervals, respectively. The location where the cut-off is performed in this section is chosen independently of the cut-off location in section 3.1. For u_{2R} and v_{2R} we have the problem

$$\begin{pmatrix} u_{2R} \\ v_{2R} \end{pmatrix}_x = \begin{pmatrix} B^{-1}A & B^{-1} \\ sI & 0 \end{pmatrix}\begin{pmatrix} u_{2R} \\ v_{2R} \end{pmatrix} + s\begin{pmatrix} 0 \\ u_1 \end{pmatrix}, \qquad x \in [l-1, \infty), \tag{23}$$

where l remains to be fixed. We choose homogeneous boundary conditions

$$\begin{pmatrix} T_R^I(s) \\ T_R^{III}(s) \end{pmatrix}\begin{pmatrix} u_{2R}(l-1) \\ v_{2R}(l-1) \end{pmatrix} = 0,$$

where T_R^I and T_R^{III} were introduced in section 2.1. For u_{2L} and v_{2L} we have the corresponding problem on the interval $(-\infty, -l+1]$, with T_L^{II} and T_L^{IV} as submatrices in the homogeneous boundary conditions at $x = -l+1$.

The remaining parts of u_2 and v_2, u_{2M} and v_{2M}, must satisfy the equation

$$\begin{pmatrix} u_{2M} \\ v_{2M} \end{pmatrix}_x = \begin{pmatrix} B^{-1}A & B^{-1} \\ sI & 0 \end{pmatrix}\begin{pmatrix} u_{2M} \\ v_{2M} \end{pmatrix} + s\begin{pmatrix} g \\ h \end{pmatrix}, \tag{24}$$

where

$$\begin{cases} sg = -\varphi_{Rx}u_{2R} - \varphi_{Lx}u_{2L}, \\ sh = s(1-\varphi_R-\varphi_L)u_1 - \varphi_{Rx}v_{2R} - \varphi_{Lx}v_{2L}. \end{cases} \tag{25}$$

Equation (24) will be studied in section 3.3.

If l is chosen sufficiently large, the problems for $(u_{2R}, v_{2R})^T$ and $(u_{2L}, v_{2L})^T$ are of the type treated in Lemma 5. We thus have unique, bounded solutions of both problems. The functions u_{2R} and v_{2R} satisfy the estimates

$$\begin{aligned} &\|u_{2R}(\cdot,s)\|_{H^1[l-1,\infty)} + \|v_{2R}(\cdot,s)\|_{H^1[l-1,\infty)} \leq K\left(\|u_1\|_{L^1} + \|u_1\|_{L^2}\right), \\ &\|u_{2R}(\cdot,s)\|_{L^\infty[l-1,\infty)} + \|v_{2R}(\cdot,s)\|_{L^\infty[l-1,\infty)} \leq |s|K\left(\|u_1\|_{L^1} + \|u_1\|_{L^2}\right). \end{aligned} \tag{26}$$

Here the L^2 estimate follows from the lemma. The L^2 estimate of the derivative, and thereby the H^1 estimate, follows from the triangle inequality applied to (23). For the functions u_{2L} and v_{2L} we have the corresponding estimates on the interval $(-\infty, -l+1]$. We also observe that, using (22), we obtain an estimate in terms of the original forcing $\hat{h}$.

3.3. Approximation of the component in the zero eigenspace. We now study (24). Recall that the forcing is $\mathcal{O}(s)$ and has support in a bounded interval, for which we introduce the notation $[-l_0, l_0]$. The forcing functions g and h can, via (22), (25), and (26), be estimated in terms of the original forcing $\hat{h}$. For $|s| \ll 1$ the problem is nearly singular, and we expect the solution to have a large component in the zero eigenspace of (3). This motivates the following splitting of u_{2M}:

$$u_{2M} = u_3 + \alpha\tilde{\varphi}_0 + u_4, \tag{27}$$

where

$$\tilde{\varphi}_0(x) = \begin{cases} \varphi_0(x), & |x| \leq l, \\ 0, & |x| \geq l, \end{cases}$$

and l will be determined below. We introduce $v_3 := v_{2M}$ for notational convenience. We use $\tilde{\varphi}_0$ instead of φ_0 in the ansatz (27) because we want to retain the bounded support of the forcing in the equations for u_3 and v_3, which are

$$\begin{pmatrix} u_3 \\ v_3 \end{pmatrix}_x = \begin{pmatrix} B^{-1}A & B^{-1} \\ sI & 0 \end{pmatrix} \begin{pmatrix} u_3 \\ v_3 \end{pmatrix} + s\begin{pmatrix} g \\ h - \alpha\tilde{\varphi}_0 \end{pmatrix}. \tag{28}$$

We can apply Lemma 6 to (28) on an interval $[l, \infty)$. According to the lemma there exists an l_1, which we choose larger than l_0, such that for $l > l_1$ the following holds. For solutions of the ODE (28), the requirement that the solution is bounded is equivalent to the condition

$$\tilde{R}(l,s)\begin{pmatrix} u_3(l) \\ v_3(l) \end{pmatrix} = 0, \tag{29}$$

where $\tilde{R}$ is described in the lemma. Lemma 6 can also be applied to (24) on the interval $(-\infty, -l+1]$ and we obtain boundary conditions

$$\tilde{R}(-l,s)\begin{pmatrix} u_3(-l) \\ v_3(-l) \end{pmatrix} = 0. \tag{30}$$

We use an iteration to construct α, u_3, and v_3 on $[-l, l]$, so that estimates in terms of g and h are possible, and (28), (29), and (30) are satisfied. When u_3, v_3, and α have been determined we will, in section 3.4, consider the equation for u_4, which we introduced in (27). The iteration, which is described in detail below, is an L^∞-contraction for sufficiently small $|s|$. The limit is our solution u_3, v_3, and α.

The first iterate satisfies the problem

$$\begin{aligned}&\begin{pmatrix} u^{(1)} \\ v^{(1)} \end{pmatrix}_x = \begin{pmatrix} B^{-1}A & B^{-1} \\ 0 & 0 \end{pmatrix}\begin{pmatrix} u^{(1)} \\ v^{(1)} \end{pmatrix} + s\begin{pmatrix} g \\ h-\alpha^{(1)}\varphi_0 \end{pmatrix},\\ &\tilde{R}(l,0)\begin{pmatrix} u^{(1)}(l) \\ v^{(1)}(l) \end{pmatrix} = 0, \qquad \tilde{R}(-l,0)\begin{pmatrix} u^{(1)}(-l) \\ v^{(1)}(-l) \end{pmatrix} = 0.\end{aligned} \tag{31}$$

The nth iterate satisfies the problem

$$\begin{aligned}&\begin{pmatrix} u^{(n)} \\ v^{(n)} \end{pmatrix}_x = \begin{pmatrix} B^{-1}A & B^{-1} \\ 0 & 0 \end{pmatrix}\begin{pmatrix} u^{(n)} \\ v^{(n)} \end{pmatrix} + s\begin{pmatrix} 0 \\ u^{(n-1)}-\alpha^{(n)}\varphi_0 \end{pmatrix},\\ &\tilde{R}(l,0)\begin{pmatrix} u^{(n)}(l) \\ v^{(n)}(l) \end{pmatrix} = (\tilde{R}(l,s)-\tilde{R}(l,0))\begin{pmatrix} u^{(n-1)}(l) \\ v^{(n-1)}(l) \end{pmatrix},\\ &\tilde{R}(-l,0)\begin{pmatrix} u^{(n)}(-l) \\ v^{(n)}(-l) \end{pmatrix} = (\tilde{R}(-l,s)-\tilde{R}(-l,0))\begin{pmatrix} u^{(n-1)}(-l) \\ v^{(n-1)}(-l) \end{pmatrix}.\end{aligned} \tag{32}$$

First we determine $v^{(1)}$, $\alpha^{(1)}$. From (31), using the expression (47) for $\tilde{R}(l,0)$, we extract the following equations for $v^{(1)}$, $\alpha^{(1)}$:

$$v_x^{(1)} = sh - s\alpha^{(1)}\varphi_0, \qquad T_{1R}^{I}v^{(1)}(l) = 0, \qquad T_{1L}^{II}v^{(1)}(-l) = 0. \tag{33}$$

The last two expressions imply that we can write $v(l) = S_R^{II}c^{II}$ and $v(-l) = S_L^{I}c^{I}$, where S_R^{II} and S_L^{I} were introduced in Assumption 4. Here the components of c^I and c^{II} together comprise $n-1$ unknowns. Using these expressions and integrating the first equation in (33) we arrive at the following $n \times n$ system of linear equations:

$$\left(S_{1L}^{I};\, S_{1R}^{II};\, \int_{-l}^{l}\varphi_0\,dx\right)\begin{pmatrix} c^I \\ c^{II} \\ s\alpha^{(1)} \end{pmatrix} = s\int_{-l}^{l} h\,dx. \tag{34}$$

We have

$$\left|U_R - U_L - \int_{-l}^{l}\varphi_0\,dx\right| \le Ke^{-\beta l}$$

and thus, by Assumption 4, (34) is solvable for sufficiently large l. Since $v^{(1)}$ is expressed by an integral of h, it is easy to derive

$$\begin{aligned}\|v^{(1)}\|_{L^\infty[-l,l]} + \|v^{(1)}\|_{H^1[-l,l]} &\le |s|K\|h\|_{L^2},\\ |\alpha^{(1)}| &\le K\|h\|_{L^2}.\end{aligned} \tag{35}$$

Next we turn to the problem for $u^{(1)}$. The boundary conditions will be inhomogeneous; e.g., to the right, we have

$$R(l)u^{(1)}(l) = -\tilde{R}_{12}(l)v^{(1)}(l).$$

The standard procedure to make the boundary conditions homogeneous is to make an ansatz $u^{(1)} = w + \tilde{u}$ and choose w as a smoothly varying function which satisfies the boundary conditions. The problem for $\tilde{u}$ is

$$\begin{aligned}&\tilde{u}_x = B^{-1}A\tilde{u} + sg^{(1)},\\ &R(l)\tilde{u}(l) = 0, \qquad R(-l)\tilde{u}(-l) = 0,\end{aligned}$$

where $sg^{(1)} = sg - w_x + B^{-1}Aw$. The L^2-norm of the function $g^{(1)}$ can be estimated in terms of g and h via (35). The problem for $\tilde{u}$ is of the type treated in section 2.2, and using the construction described there, we obtain a function $\tilde{u}$ which solves the above problem. Using $u^{(1)} = w + \tilde{u}$ we get a solution of (31), which satisfies the estimate

$$\|u^{(1)}\|_{L^\infty[-l,l]} + \|u^{(1)}\|_{H^1[-l,l]} \le |s|K\left(\|g\|_{L^2} + \|h\|_{L^2}\right).$$

This completes the construction and estimate of the first iterate. The treatment of the nth iterate is similar, only the forcing functions in the equations are changed. First we determine $v^{(n)}$ and $\alpha^{(n)}$. The boundary conditions are now inhomogeneous. From (32) and (47) we have

$$T^I_{1R} v^{(n)}(l) = sQ_1(l,s)\begin{pmatrix} u^{(n-1)}(l) \\ v^{(n-1)}(l) \end{pmatrix}.$$

Thus

$$v^{(n)}(l) = S^{II}_{1R}c^{II} + b^{(n)}(l), \tag{36}$$

where

$$b^{(n)}(l) = sS^I_{1R}Q_1\begin{pmatrix} u^{(n-1)}(l) \\ v^{(n-1)}(l) \end{pmatrix}.$$

In the same manner we obtain the following expression to the left:

$$v^{(n)}(-l) = S^I_{1L}c^I + b^{(n)}(-l). \tag{37}$$

Thus we can express $v^{(n)}(l)$ and $v^{(n)}(-l)$ in terms of the $n-1$ unknowns, c^I and c^{II}. Next we integrate the equation for $v^{(n)}$ and use the expressions (36) and (37) to obtain

$$\left(S^I_{1L};\, S^{II}_{1R};\, \int_{-l}^{l}\varphi_0\,dx\right)\begin{pmatrix} c^I \\ c^{II} \\ s\alpha^{(n)} \end{pmatrix} = s\int_{-l}^{l} u^{(n-1)}\,dx + b^{(n)}(-l) + b^{(n)}(-l).$$

As before, the system can be solved for sufficiently large l, and the solution can be estimated as

$$\begin{aligned} &\|v^{(n)}\|_{L^\infty[-l,l]} + \|v^{(n)}\|_{H^1[-l,l]} + |s\alpha^{(n)}| \\ &\quad\le sK\left(\|u^{(n-1)}\|_{L^2[-l,l]} + \|u^{(n-1)}\|_{L^\infty[-l,l]} + \|v^{(n-1)}\|_{L^\infty[-l,l]}\right). \end{aligned} \tag{38}$$

The problem for $u^{(n)}$ also has inhomogeneous boundary conditions. They are treated with the standard procedure described above. Referring to the construction in section 2.2, we obtain a solution which satisfies

$$\begin{aligned} &\|v^{(n)}\|_{L^\infty[-l,l]} + \|v^{(n)}\|_{H^1[-l,l]} \\ &\le sK\left(\|u^{(n-1)}\|_{L^2[-l,l]} + \|v^{(n-1)}\|_{L^2[-l,l]} + \|u^{(n-1)}\|_{L^\infty[-l,l]} + \|v^{(n-1)}\|_{L^\infty[-l,l]}\right). \end{aligned} \tag{39}$$

The construction is now complete. We see that for sufficiently small $|s|$ the iteration defines a contraction. The solution of our original problem (28), (29), and (30) is given by the uniformly convergent sums

$$u_3 = \sum_{n=1}^{\infty} u^{(n)}, \qquad v_3 = \sum_{n=1}^{\infty} v^{(n)}, \qquad \alpha = \sum_{n=1}^{\infty} \alpha^{(n)}.$$

Summing the estimates for the iterates, we obtain

$$\begin{aligned} \|u_3\|_{H^1[-l,l]} &\le |s| K \left(\|h\|_{L^2} + \|g\|_{L^2} \right), \\ |\alpha| &\le K \left(\|h\|_{L^2} + \|g\|_{L^2} \right). \end{aligned} \tag{40}$$

3.4. Summary of the splittings. Before the summing of the splitting of $\hat{u}$ into terms, we extend the function u_3 to the intervals $[l, \infty)$ and $(-\infty, -l]$. Since (28) is homogeneous in these regions, we can apply Lemma 5. This gives estimates that together with (40) yield

$$\|u_3\|_{H^1} \le K \left(\|h\|_{L^2} + \|g\|_{L^2} \right).$$

Summing the splittings from the sections above, we have the following expression of the original unknown in terms of the introduced parts:

$$\hat{u} = u_1 + \varphi_R u_{2R} + \varphi_L u_{2L} + u_3 + \alpha \varphi_0 + u_4.$$

Here the function u_4 satisfies the equation

$$s u_4 + (A u_4)_x = B u_{4xx} + s\alpha(\varphi_0 - \tilde{\varphi}_0).$$

This means that the function u_4 satisfies the same type of problem as u_2; see (18). The difference is that the norms of the forcing has been reduced by a factor $\mathcal{O}(e^{-\beta l})$. This leads us to define an iteration to determine $\hat{u}$. The first iterate $\hat{u}^{(1)}$ is given by

$$\hat{u}^{(1)} = u_1 + \varphi_R u_{2R} + \varphi_L u_{2L} + u_3 + \alpha \tilde{\varphi}_0.$$

Then we repeat the process and split u_4 according to

$$u_4 = \varphi_R u_{2R}^{(2)} + \varphi_L u_{2L}^{(2)} + u_3^{(2)} + \alpha^{(2)} \varphi_0 + u_4^{(2)}$$

and define the second iterate by $\hat{u}^{(2)} = u_4 - u_4^{(2)}$. The process is continued, and we have

$$u_4^{(n-1)} = \varphi_R u_{2R}^{(n)} + \varphi_L u_{2L}^{(n)} + u_3^{(n)} + \alpha^{(n)} \varphi_0 + u_4^{(n)}.$$

For l large enough, the size of the forcing in the equation for $u_4^{(n)}$ is reduced in each step and we have

$$\lim_{n \to \infty} \|u_4^{(n)}\|_{L^\infty} = 0.$$

In conclusion, we have constructed a solution of the resolvent equation (4):

$$\hat{u} = \sum_{n=1}^{\infty} \hat{u}^{(n)}$$

for $s \in \Omega_c$. Summing the estimates of the iterates using (22), (26), and (40) we obtain

$$\|\hat{u}\|_{H^1} \le K \left(\|\hat{h}\|_{L^1} + \|\hat{h}\|_{L^2} \right),$$

which completes the proof of Lemma 1.

Appendix. Results for ODEs on a half-line. Here we derive four lemmas on systems of ODEs, with nearly constant coefficients, on a half-infinite interval. These results are used in sections 2.2 and 3. In section A.1 we introduce the ODE and state all assumptions on the coefficients and forcing in the section. In section A.2, on the other hand, we state the results for exactly the problem treated in the main body of the article. Consequently we refer to objects defined in earlier sections.

In this appendix we state the results without proof. The proofs are rather straightforward. Similar results are given in [9], and in [11] these results are given with very minor changes. Proofs can be found in both these references.

A.1. Systems without a parameter. Consider the ODE

$$u_x = Au + f, \qquad x \in [0, \infty), \tag{41}$$

where the coefficient matrix converges to a constant matrix

$$\lim_{x\to\infty} A(x) = A_0.$$

The limiting matrix has no purely imaginary eigenvalues, so we can block-diagonalize it according to

$$TA_0S = \begin{pmatrix} A^+ & 0 \\ 0 & A^- \end{pmatrix},$$

where A^+ is a $k \times k$ matrix. We denote by T^I the first k rows of T and by T^{II} the last $n-k$ rows. We have the following measure of the difference between the coefficient matrix and the limiting matrix:

$$\gamma = \int_0^\infty |A(x) - A_0| dx.$$

We are now in position to state two lemmas.

LEMMA 3. *Consider* (41) *with the boundary conditions*

$$T^{II}u(0) = u_0^{II} \tag{42}$$

and assume $f \in L^1$. Then there exists a γ_0, determined by A_0, such that, if $\gamma \leq \gamma_0$, there exists a unique solution of the problem (41), (42). *This solution satisfies the following estimate:*

$$\|u\|_{L^\infty} + \|u\|_{L^1} + \|u\|_{L^2} \leq K\left(|u_0^{II}| + \|f\|_{L^1}\right),$$

where the constant K depends only on A_0.

LEMMA 4. *Consider* (41) *with $f = 0$. Then there is a γ_0 such that, if $\gamma < \gamma_0$, there is a matrix P such that all bounded solutions u of* (41) *satisfy*

$$(T^I - PT^{II})u(0) = 0.$$

We also have $|P| \leq K\gamma$. The constants γ_0 and K depend only on A_0.

A.2. Systems with a parameter. We consider

$$\begin{pmatrix} u \\ v \end{pmatrix}_x = D(x,s)\begin{pmatrix} u \\ v \end{pmatrix} + f, \qquad x \in [l,\infty), \quad s \in \Omega_c, \tag{43}$$

where

$$D(x,s) = \begin{pmatrix} B^{-1}A & B^{-1} \\ sI & 0 \end{pmatrix},$$

and B, A, and Ω_c denote the same matrices and region, respectively, as in the main body of the article. For this problem we have the following difference between the coefficient matrix and the limiting matrix D_0:

$$\int_l^\infty |D(x,s) - D_0(s)|dx \le Ke^{-\beta l}.$$

This is because the shock profile approaches the left and right states exponentially in x.

We now state two lemmas for the system (43), corresponding to the two lemmas in the preceding section.

Lemma 5. *Consider* (43) *with* $f \in L^1$ *and boundary conditions*

$$\begin{pmatrix} T^{II}(s) \\ T^{IV}(s) \end{pmatrix}\begin{pmatrix} u(l) \\ v(l) \end{pmatrix} = \begin{pmatrix} u_0^{II} \\ v_0^{II} \end{pmatrix}.$$

Then there is an l_0*, independent of* s*, such that for* $l > l_0$*, there is a unique bounded solution. This solution satisfies the estimates*

$$\|u\|_{L^\infty} + \|v\|_{L^\infty} \le K\left(|u_0^{II}| + |v_0^{II}| + \|f\|_{L^1}\right), \tag{44}$$

$$\|u\|_{H^1} + \|v\|_{H^1} \le \frac{K}{|s|}\left(|u_0^{II}| + |v_0^{II}| + \|f\|_{L^1}\right). \tag{45}$$

The constant K *in these inequalities depends only on* B *and* A_R*. The norms are taken over the interval* $[l,\infty)$*.*

Remark. The estimates for the H^1-norm of the solution break down in the limit $s \to 0$ (for $s \in \Omega_c$). This is a consequence of the fact that some of the eigenvalues κ_i of D_0 tend to zero as $s \to 0$ (see (6)), so the decay rate is not uniform in s. When this lemma is applied in the derivation of the resolvent estimate, it is possible to get, an s-independent estimate because we have first reduced the forcing to $\mathcal{O}(s)$.

Lemma 6. *Consider* (43) *with* $f = 0$*. Then there is an* l_0 *such that, for all* $l > l_0$*, all bounded solutions of* (43) *satisfy*

$$\tilde{R}(l,s)\begin{pmatrix} u(l) \\ v(l) \end{pmatrix} = 0, \tag{46}$$

where $\tilde{R}$ *can be written*

$$\tilde{R}(l,s) = \begin{pmatrix} T_R^I(s) \\ T_R^{III}(s) \end{pmatrix} - e^{-\beta l}\tilde{Q}(l,s)\begin{pmatrix} T_R^{II}(s) \\ T_R^{IV}(s) \end{pmatrix}.$$

$\tilde{Q}$ *is analytic in* s *and can be written*

$$\tilde{Q}(l,s) = \begin{pmatrix} P(l) & Q_{12}(l) \\ 0 & 0 \end{pmatrix} + \mathcal{O}(s),$$

where P was introduced in (12) *and Q_{12} is a bounded function of l. Conversely, any function $(u, v)^T$ which satisfies* (43) *and* (46) *is bounded.*

Remark. Using the expression (8) for $T_R(s)$ we obtain

$$\tilde{R}(l, s) = \begin{pmatrix} T^I_{2R} - e^{-\beta l} P(l) T^{II}_{2R} & \tilde{R}_{12}(l) \\ 0 & T^I_{1R} \end{pmatrix} + sQ_1(s, l), \tag{47}$$

where $\tilde{R}_{12}$ is a bounded function of l and Q_1 is a bounded function of s and l, for $l > l_0$ and $s \in \Omega_c$. We observe that the submatrix in the upper left corner is just the matrix $R(l)$ from (11).

CRITICAL THRESHOLDS IN A CONVOLUTION MODEL FOR NONLINEAR CONSERVATION LAWS*

HAILIANG LIU† AND EITAN TADMOR†

Abstract. In this work we consider a convolution model for nonlinear conservation laws. Due to the delicate balance between the nonlinear convection and the nonlocal forcing, this model allows for narrower shock layers than those in the viscous Burgers' equation and yet exhibits the conditional finite time breakdown as in the damped Burgers' equation. We show the critical threshold phenomenon by presenting a lower threshold for the breakdown of the solutions and an upper threshold for the global existence of the smooth solution. The threshold condition depends only on the relative size of the minimum slope of the initial velocity and its maximal variation. We show the exact blow-up rate when the slope of the initial profile is below the lower threshold. We further prove the L^1 stability of the smooth shock profile, provided the slope of the initial profile is above the critical threshold.

Key words. wave breakdown, critical threshold, shock profile, stability

1. Introduction.

Consider the scalar equation of the form

$$u_t + uu_x = Q * u - u, \tag{1.1}$$

where Q is a regular symmetric kernel, monotonically decreasing on $\mathbb{R}^+$, subject to initial data

$$u(0,x) = u_0(x), \quad u_0 \in C_b^1(\mathbb{R}). \tag{1.2}$$

We are concerned with the critical threshold phenomenon supported by the balance between the nonlinear convection and the nonlocal source term in (1.1).

For the kernel Q, we make the following assumption:

(H1) $Q \in C^1(\mathbb{R})$, $Q(-r) = Q(r) \geq 0$, $\int Q(y)dy = 1$, $\int Q(y)|y|dy < \infty$, and $Q'(x) \leq 0$ for $x \geq 0$.

To clarify the effect of the nonlocal term on the right-hand side of (1.1), we make a hyperbolic scaling

$$(t,x) \to \left(\frac{t}{\epsilon}, \frac{x}{\epsilon}\right), \quad \epsilon > 0,$$

which leads to

$$u_t + uu_x = \frac{1}{\epsilon}[Q_\epsilon * u - u], \tag{1.3}$$

where $Q_\epsilon := \frac{1}{\epsilon}Q(\frac{x}{\epsilon})$ and is converging to a delta function $\delta(x)$ as the scaled parameter ϵ tends to zero.

A typical example of the kernel Q is $\frac{1}{2}e^{-|x|}$; with this specific kernel, (1.3) can be written as

$$u_t + uu_x = \mathcal{F}^{-1}\left[\frac{-\epsilon\xi^2}{1+\epsilon^2\xi^2}\hat{u}(t,\xi)\right] = \epsilon\mathcal{F}^{-1}\left[\frac{1}{1+\epsilon^2\xi^2}\hat{u}(t,\xi)\right]_{xx}, \tag{1.4}$$

which is called an R-C-E model after Rosenau's regularized version of the Chapman–Enskog expansion for hydrodynamics [17]. The operator on the right-hand side of (1.4) looks like the usual viscosity term ϵu_{xx} at low wave-number ξ, while for higher wave numbers it is intended to model a bounded approximation of a linearized collision operator, thereby avoiding the artificial instabilities that occur when the Chapman–Enskog expansion is truncated after a finite number of terms [17]. This idea has been greatly advanced recently by Slemrod and his collaborators. A renormalization procedure was introduced in [19] to eliminate the truncation instability and to produce the desired dissipation; the corresponding applications can be found in [20, 21, 22]. The regularization of the Burnett equations via relaxation was investigated by Jin and Slemrod [5, 6]. The rigorous analysis of the model (1.4), including the existence of the shock profiles, the smoothness, as well as the upper-Lipschitz continuity, has been studied by Schochet and Tadmor [23]. We remark that, as observed in [23], the solution sequence $\{u^\epsilon\}$ of (1.4) does not satisfy the Kružkov entropy inequality. The convergence of the solution u^ϵ of (1.4) to the entropy solution of the inviscid Burgers' equation was proved in [23] via the L^1 contraction argument.

(1.3) with $Q = \frac{1}{2}e^{-|x|}$ can also be written as a hyperbolic-elliptic system

$$u_t + uu_x = \phi_x, \quad x \in \mathbb{R}, \quad t > 0, \tag{1.5}$$

$$\epsilon^2\phi_{xx} - \phi + \epsilon u_x = 0. \tag{1.6}$$

It is easy to see that (1.6) enables one to express ϕ in terms of u formally as

$$\phi = (1-\epsilon^2\partial_x^2)^{-1}\epsilon u_x = \epsilon Q_\epsilon * u_x,$$

which in turn gives the right-hand side of (1.3),

$$\phi_x = \epsilon Q_\epsilon * u_{xx} = \frac{1}{\epsilon}[Q_\epsilon * u - u].$$

The system of equations (1.5)–(1.6) is derived as the third-order approximation of the full system describing the motion of radiating gas in therm-nonequilibrium, while the second-order approximation gives the viscous Burgers' equation $u_t + uu_x = \epsilon u_{xx}$, and the first-order approximation gives the inviscid Burgers' equation $u_t + uu_x = 0$. Hamer [4] studied these equations in the physical respect, especially for the steady progressive shock wave solutions. Noting that if ϵ in (1.6) is small, one has $\phi \sim \epsilon u_x$, which leads to the usual viscous Burgers' equation. The viscous Burgers' equation admits smooth shock wave profiles but does not allow the finite time breakdown. On the other hand, if the parameter ϵ is large, one finds from (1.6) that $\epsilon\phi_{xx} + u_x \sim 0$, which when combined with (1.5) gives the damped Burgers' equation $u_t + uu_x = -u/\epsilon$. This damped equation reflects the conditional breakdown in finite time but does not support monotone traveling waves (shock profiles).

The parameter ϵ in (1.3) does not play a role in our analysis and so will be set to 1 for convenience. Equation (1.3) with $\epsilon = 1$, i.e., (1.1), is a physical model that allows for the shock wave profile and yet exhibits the finite time breakdown. For stability of shock profiles via energy method we refer to [11, 8]. The global weak solution to (1.1) was studied in [23].

As is known, the typical well-posedness result asserts that either a solution of a time-dependent PDE exists for all time (global existence of the smooth solution) or else there is a finite time (called life span) such that some norm of the solution becomes unbounded as the life span is approached (called finite time breakdown). The natural question is whether there is a critical threshold for the initial data such that the global existence of the smooth solution or the finite time breakdown depends only on crossing such a critical threshold. This remarkable critical threshold phenomenon was first observed and studied in [3] for a class of Euler–Poisson equations. In this paper we confirm such a critical threshold phenomenon for (1.1)–(1.2) by giving an upper threshold for the global existence of the smooth solution and a lower threshold for the finite time breakdown. We also show the exact blow-up rate as the life span is approached.

In this paper we shall use the following notation for $g \in L^\infty(\mathbb{R})$ to denote the maximal variation:

$$V(g) := \max_{x\in\mathbb{R}} g(x) - \min_{x\in\mathbb{R}} g(x).$$

The first result tells us the critical threshold phenomenon in (1.1).

THEOREM 1.1. *Consider the Cauchy problem* (1.1)–(1.2) *with initial data* $u_0 \in C_b^1(\mathbb{R})$. *Let the kernel* Q *satisfy* (H_1); *then we have the following:*

- *If* $V(u_0) < \frac{1}{4Q(0)}$ *and*

$$\inf_{x\in\mathbb{R}} \partial_x u_0(x) > -\frac{1}{2}\left[1 + \sqrt{1 - 4Q(0)V(u_0)}\right],$$

then the smooth solution exists for all time.

- *If*

$$\inf_{x} \partial_x u_0(x) < -\frac{1}{2}\left[1 + \sqrt{1 + 4Q(0)V(u_0)}\right],$$

then the solution u *must break down at finite time* T. *Moreover,*

$$\lim_{t\to T}(\min_{x\in\mathbb{R}}\{u_x(t,x)\}) = -\infty$$

and the exact blow-up rate is

$$\lim_{t\to T}((T-t)\min_{x\in\mathbb{R}}\{u_x(t,x)\}) = -1.$$

Concerning this theorem, several remarks are in order.

Remarks. 1. The above results show that the solution behavior of (1.1)–(1.2) depends on the relative size of the minimum slope of the initial profile and its maximal variation. If either the maximal variation is too large or the initial velocity slope is too negative, the solution would lose smoothness in finite time. This peculiar phenomenon explains the result obtained in [23], in which additional constraints on the shock strength are imposed to ensure the smoothness of the shock profiles. Further relation between the smoothness of the shock profiles and the shock strength are given in [8]. The critical threshold phenomenon was already partially observed in previous studies; see [23] and [9].

2. As an example, we take $u_0^\theta(x) = \exp(-x^2/\theta)$ for $\theta > 0$. Note that

$$\inf_{x\in\mathbb{R}} [\partial_x u_0^\epsilon(x)] = -\sqrt{\frac{2}{e\theta}}, \quad V(u_0^\theta) = 1.$$

Therefore, choosing θ so small that

$$\theta < \frac{4}{e(1 + 2Q(0) + \sqrt{1 + 4Q(0)})},$$

we see that $\partial_x u_0^\theta$ is below the lower threshold, and thereby the corresponding solution $u^\theta(t, x)$ breaks down in finite time.

3. Note that at the blow-up time, the solution is still bounded, and the gradient of the solution becomes unbounded from below. Such a breakdown is referred to as wave breaking in the context of the shallow water waves. In [25] Whitham emphasized that wave breaking phenomena are some of the most intriguing long-standing problems of water theory. This issue was first settled recently in [15] for Whitham's equation. Another shallow water equation derived recently by Camassa and Holm [2] can be written as (1.5) coupled with the following equation:

$$\phi_{xx} - \phi - u^2 - \frac{1}{2}u_x^2 = 0.$$

This equation as a completely integrable system has a soliton solution and yet exhibits finite time breakdown phenomena for a large class of initial data, which has been observed and justified by Holm [2], Constantin and Escher [1], and McKean [14]. The main tool used in the above papers is to trace the solution gradient along a curve on which the minimum of the gradient is obtained. In this work we trace the dynamics of the solution gradient along the characteristics, which are well known in the context of the hyperbolic equations; see, e.g., [12, 7, 13]. For the global weak solution to the above shallow water equation, we refer to [24] and references therein.

4. From the results above we see that if the magnitude of the initial profile is small, both thresholds given in Theorem 1.1 are close to $\inf_{x\in\mathbb{R}} \partial_x u_0(x) = -1$, which is exactly the critical threshold for the damped Burgers' equation:

$$u_t + uu_x = -u.$$

Indeed, along the particle path $x(\alpha, t)$ defined by

$$\frac{d}{dt}x(\alpha, t) = u(t, x(\alpha, t)), \quad x(\alpha, 0) = \alpha, \quad \alpha \in \mathbb{R},$$

the gradient of the solution to the damped Burgers' equation above can be written explicitly as

$$u_x(t, x) = [e^t(1 + (\partial_x u_0(\alpha))^{-1}) - 1]^{-1},$$

which is bounded from below for all time if and only if

$$\inf_{x\in\mathbb{R}} \partial_x u_0(x) \geq -1.$$

This remarkable critical threshold phenomenon explains why (1.1) admits narrower shock layers than those in the viscous Burgers' equation. We now turn to discussing the asymptotic behavior of solutions, as the initial data are above the critical threshold. We shall concentrate on the case $u_0(-\infty) = u_- > u_+ = u_0(+\infty)$. As shown in [23], (1.1) with $Q = \frac{1}{2}e^{-|x|}$ admits a smooth shock profile $U(x-st)$ connecting u_+ to u_- if and only if the strength $|V(U)| = |u_+ - u_-| \leq \sqrt{2}$. Considering the conservative form of the equation, the natural question is whether this shock profile is stable in $L^1(\mathbb{R})$.

Our stability result is summarized below.

Theorem 1.2. *Let $U(x - st)$ be a continuous shock profile of* (1.1) *and $S(t)u_0$ be a solution to* (1.1)–(1.2) *with initial data $u_0 \in U + L^1(\mathbb{R})$ and $u_0 \in [\inf U, \sup U]$. If $\partial_x u_0 \geq -\frac{1}{2}[1 + \sqrt{1 - 4Q(0)V(u_0)}]$, then there exists a constant k such that*

$$\lim_{t\to\infty} \|S(t)u_0 - U(\cdot - st + k)\|_{L^1} = 0.$$

Remarks. 1. The $L^p (1 \leq p < \infty)$ stability is immediate from the above L^1 stability result and the L^∞ boundedness of $S(t)u_0$. Consult [8] for the stability of traveling waves via the energy principle.

2. We assume that the initial data are above the upper critical threshold to ensure the regularity of the ω-limit set of the solution. This condition is expected to be relaxed since our upper threshold is not sharp.

We now conclude this section by outlining the rest of the paper. In section 2, we recall several properties of (1.1) and give the estimate of the nonlocal term in (1.1), which paves the way for the next sections. The lower threshold for finite time breakdown is given in section 3, in which we also prove the exact blow-up rate. The upper threshold for global existence of the smooth solution is carried out in section 4. The final section is devoted to the L^1 stability of the shock profiles.

2. Preliminaries.

This section is devoted to some estimates which will be used in the next two sections.

In order to formulate the problem, we denote the solution operator of (1.1) as $S(t)$, indexed with $t \in [0, \infty)$,

$$S(t) : L^\infty(\mathbb{R}) \to L^\infty(\mathbb{R}), \quad t \geq 0,$$

such that the solution $u(t, x)$ of (1.1) with initial data a can be expressed as

$$u(t) = S(t)a.$$

We recall from [23] that the solution operator $S(t)$ satisfies the following properties:

- (translate invariance) $S(t)a(x + k) = (S(t)a)(x + k)$ for any $k \in \mathbb{R}$;
- (conservative) if $a - b \in L^1(\mathbb{R})$, then for all $t > 0$, $S(t)a - S(t)b \in L^1(\mathbb{R})$ and $\int(S(t)a - S(t)b) = \int(a - b)$;
- (L^1 contraction) if $a - b \in L^1(\mathbb{R})$, then $S(t)a - S(t)b \in L^1(\mathbb{R})$ and $\|S(t)a - S(t)b\|_1$ is nonincreasing for $t > 0$;
- (monotonicity) if $a(x) \geq b(x)$ for $x \in \mathbb{R}$, then $S(t)a \geq S(t)b$ for all $t > 0$.

The above monotonicity immediately gives us the following maximum principle.

Lemma 2.1. *Let $u_0 \in L^\infty(\mathbb{R})$. Then the solution $u(t, \cdot)$ is also bounded with*

$$\min_{x\in\mathbb{R}} u_0(x) \leq u(t, \cdot) \leq \max_{x\in\mathbb{R}} u_0(x).$$

This maximum principle leads to the following bounds, which will be used in figuring out our threshold conditions.

Lemma 2.2. *Let u be the smooth solution in $[0,T]$. Then it holds that*

$$\min_{x\in\mathbb{R}} u_0(x) \le Q * u(t,\cdot) \le \max_{x\in\mathbb{R}} u_0(x), \quad t\in[0,T], \tag{2.1}$$

$$-Q(0)V(u_0) \le Q * u_x(t,\cdot) \le Q(0)V(u_0). \tag{2.2}$$

Proof. The first inequality follows from the fact $Q*1=1$ and the L^∞ bound $\min_{x\in\mathbb{R}} u_0(x) \le u(t,\cdot) \le \max_{x\in\mathbb{R}} u_0(x)$. We shall prove the second inequality as follows:

$$\begin{aligned} Q * u_x &= \int_{\mathbb{R}} Q(x-y)u_y(t,y)dy \\ &= \int_{\mathbb{R}} Q_x(x-y)u(t,y)dy \\ &= \left[\int_{-\infty}^{x} Q_x(x-y)u(t,y)dy + \int_{x}^{+\infty} Q_x(x-y)u(t,y)dy\right] \\ &\le \min_{x\in\mathbb{R}} u_0(x)\int_{-\infty}^{x} Q_x(x-y)dy + \max_{x\in\mathbb{R}} u_0(x)\int_{x}^{+\infty} Q_x(x-y)dy \\ &\le Q(0)\left[-\min_{x\in\mathbb{R}} u_0(x) + \max_{x\in\mathbb{R}} u_0(x)\right] = Q(0)V(u_0). \end{aligned}$$

The lower bound $-Q(0)V(u_0)$ is clear from the above estimate. □

The existence of T is ensured by the local existence theorem stated in the following lemma.

Lemma 2.3. *Consider the Cauchy problem* (1.1)–(1.2) *with initial data $u_0 \in C_b^1(\mathbb{R})$. Then there exists a positive constant T, depending only on $\|u_0\|_{C_b^1(\mathbb{R})}$, such that* (1.1)–(1.2) *has a unique smooth solution in $C_b^1(\mathbb{R}\times[0,T])$.*

The proof of this local existence is standard via an iteration scheme; the details are omitted. This local existence provides a base for extending the solution or justifying the finite time breakdown.

3. Blow-up criterion—lower threshold.

This section is devoted to a general discussion of wave breaking criteria.

Theorem 3.1. *Consider the Cauchy problem* (1.1)–(1.2). *The maximal existence time T is finite if and only if the gradient of the solution becomes unbounded from below in finite time.*

Proof. From the local existence in Lemma 2.3 it follows that if the gradient of the solution becomes unbounded from below in finite time, then $T<\infty$.

Let the life span $T<\infty$ and assume that for some constant $M>0$ we have

$$u_x(t,x) \ge -M, \quad (t,x)\in[0,T)\times\mathbb{R}. \tag{3.1}$$

On the other hand, by [23, Theorem 5.1] the solution $u(t,x)$ satisfies the one-sided Lipschitz condition, i.e.,

$$u_x(t,x) \le \frac{1}{(\max_{x\in\mathbb{R}} u_{0x})^{-1}+t} \le \max_{x\in\mathbb{R}} u_{0x} < \infty.$$

Therefore the standard continuation argument enables us to extend the solution to $[0,T+\delta)$ with $\delta>0$, and thereby one must have $T=\infty$. This contradiction ensures that

$$\lim_{t\to T-}(\min_{x\in\mathbb{R}} u_x(t,x)) = -\infty. \qquad □$$

The lower threshold is given in the following theorem.

THEOREM 3.2. *Consider the Cauchy problem* (1.1)–(1.2) *with the initial profile* $u_0 \in C_b^1(\mathbb{R})$*. If* u_0 *is bounded and its gradient is negative with*

$$\inf_{x\in\mathbb{R}} \partial_x u_0(x) < -\frac{1}{2}\big[1+\sqrt{1+4Q(0)V(u_0)}\big],$$

then the life span T *must be finite. Moreover,*

$$T \le \left[-\frac{1}{2}\big(1+\sqrt{1+4Q(0)V(u_0)}\big) - \inf_{x\in\mathbb{R}} \partial_x u_0(x)\right]^{-1}$$

and

$$\lim_{t\to T}(\min_{x\in\mathbb{R}}\{u_x(t,x)\}) = -\infty.$$

Proof. Differentiation of (1.1) with respect to x leads to

$$d_t + ud_x + d^2 = Q * u_x - d, \quad t \in (0,T),$$

where $d := u_x(t,x)$. The smoothness of u ensures that there exists a smooth curve $x(\alpha,t)$ satisfying

$$\frac{d}{dt}x(\alpha,t) = u(t,x(\alpha,t)), \quad x(\alpha,0)=\alpha, \quad \alpha \in \mathbb{R}.$$

Evaluating the above $d-$ equation at $x(\alpha,t)$ and using $Q * u_x \le A := Q(0)V(u_0)$ stated in Lemma 2.2, we have

$$d' + d^2 = Q * u_x(t,x(\alpha,t)) - d \le A - d, \quad ' := \partial_t + u\partial_x$$

for $t \in (0,T)$. That is,

$$d' \le -(d-M_1)(d-M_2), \quad t \in (0,T), \tag{3.2}$$

with

$$M_1 := -\frac{1}{2}[1+\sqrt{1+4A}], \quad M_2 := -\frac{1}{2}[1-\sqrt{1+4A}].$$

For a fixed $\alpha \in \mathbb{R}$, if $d_0(\alpha) := u_0'(\alpha) < M_1$, then we claim that

$$d(t) < d_0(\alpha), \quad t \in (0,T). \tag{3.3}$$

If this would not be true, there is some $t_0 \in (0,T)$ with $d(t) < d_0$ on $[0,t_0)$ and $d(t_0) = d_0$ by the continuity of $d = u_x$ in time. But in this case

$$d' \le -(d_0 - M_1)(d_0 - M_2) < 0, \quad t \in (0,t_0).$$

An integration over $(0,t_0)$ yields

$$d(t_0) < d_0,$$

which contradicts our assumption that $d(t_0) = d_0$ for $t_0 < T$. This implies that (3.3) holds.

Combining (3.3) with (3.2), we obtain

$$d' \leq -(d - M_1)^2, \quad t \in (0, T),$$

and integration yields

$$d(t) \leq M_1 + \left[t - \frac{1}{M_1 - d_0}\right]^{-1}.$$

From this we find that $d(t) \to -\infty$ before t reaches $\frac{1}{M_1 - d_0}$. This proves that the solution breaks down in finite time once $\partial_x u_0 \geq M_1$ fails. □

The blow-up rate at the breaking time is summarized in the next theorem.

THEOREM 3.3. *Let T be the maximal existence time of* (1.1)–(1.2). *If the life span T is finite, then*

$$\lim_{t \to T} \left((T - t) \left(\min_{x \in \mathbb{R}} \{u_x(t, x)\} \right) \right) = -1.$$

Proof. By Theorem 3.1 one has

$$\lim_{t \to T} \left(\min_{x \in \mathbb{R}} \{u_x(t, x)\} \right) = -\infty.$$

For $t \in [0, T)$ the solution u is smooth and the curve $x(\alpha, t)$ is well defined by

$$\frac{d}{dt} x(\alpha, t) = u(t, x(\alpha, t)), \quad x(\alpha, 0) = \alpha, \quad \alpha \in \mathbb{R}.$$

This implies

$$\frac{\partial}{\partial \alpha} x(\alpha, t) = \exp\left(\int_0^t u_x(\tau, x(\alpha, \tau)) d\tau \right) > 0, \quad t \in (0, T),$$

and hence $x(\alpha, t)$ is a one-to-one mapping from $\mathbb{R}$ to $\mathbb{R}$. From these facts it follows that there exists an $\alpha \in \mathbb{R}$ such that

$$\min_{x \in \mathbb{R}} \{u_x(t, x)\} = u_x(t, x(\alpha, t)).$$

As done previously, we consider dynamics of $d = u_x$ along the curve $x(\alpha, t)$, using $-A \leq Q * u_x \leq A = Q(0)V(u_0)$ to obtain

$$-A - d \leq d' + d^2 \leq A - d, \quad t \in (0, T).$$

Let $\epsilon \in (0, 1)$ be suitably small. Since $\lim_{t \to T} d(t) = -\infty$, there exists $t_0 \in (0, T)$ such that

$$d(t) < B^-(\epsilon), \quad t \in [t_0, T), \tag{3.4}$$

with

$$B^-(\epsilon) = \frac{-2A}{\sqrt{1 + 4A\epsilon(2 - \epsilon)} - 1}$$

being the smaller root of $(\epsilon^2 - 2\epsilon)d^2 - d + A = 0$. Otherwise there exists $\delta > 0$ such that

$$d(t) < B^-(\epsilon), \quad t \in (t_0, t_0 + \delta),$$

and for $\delta < T - t_0$

$$d(t_0 + \delta) = B^-(\epsilon).$$

Hence for $d(t) < B^-(\epsilon)$ on $(t_0, t_0 + \delta)$,

$$\frac{d}{dt} d(t) \le A - d - d^2 \le -(1-\epsilon)^2 d^2 < 0, \quad t \in (t_0, t_0 + \delta).$$

Integration gives

$$d(t_0 + \delta) < d(t_0) < B^-(\epsilon).$$

This contradiction shows that

$$d \le B^-(\epsilon), \quad t \in [t_0, T);$$

therefore

$$d' \le -(1-\epsilon)^2 d^2, \quad t \in [t_0, T). \tag{3.5}$$

On the other hand, let

$$B^+(\epsilon) = \frac{-2A}{\sqrt{1 + 4A\epsilon(2+\epsilon)} + 1},$$

which is the bigger root of $(\epsilon^2 + 2\epsilon)d^2 - d - A = 0$. We find that $B^-(\epsilon) < B^+(\epsilon)$ and

$$d(t) < B^+(\epsilon), \quad t \in (t_0, T).$$

This gives $(\epsilon^2 + 2\epsilon)d^2 - d - A > 0$, yielding

$$d' \ge -(d^2 + d + A) \ge -(1+\epsilon)^2 d^2, \quad t \in (t_0, T). \tag{3.6}$$

A combination of (3.5) with (3.6) gives

$$-(1+\epsilon)^2 d^2 \le d' \le -(1-\epsilon)^2 d^2, \quad t \in (t_0, T).$$

Note that d is locally Lipschitz on (t_0, T) and so is $1/d$ on (t_0, T). The above inequality leads to

$$(1-\epsilon)^2 \le \left(\frac{1}{d}\right)' \le (1+\epsilon)^2, \quad t \in (t_0, T).$$

For $t \in (t_0, T)$, integrate the above over (t, T) to obtain

$$-(1-\epsilon)^2 (T - t) \le \frac{1}{d(t)} \le -(1+\epsilon)^2 (T - t), \quad t \in (t_0, T).$$

Optimizing the above in terms of ϵ, one then has

$$\lim_{t \to T} (T - t) d(t) = -1.$$

This completes the proof. □

4. Global smoothness—upper threshold. With the breakdown criterion in section 2, we are ready to discuss the upper threshold for the global existence of the smooth solution to (1.1)–(1.2).

THEOREM 4.1. *Consider the Cauchy problem* (1.1)–(1.2) *with the initial profile* $u_0 \in C_b^1(\mathbb{R})$. *If* u_0 *is bounded with the maximal variation* $V(u_0) \leq \frac{1}{4Q(0)}$ *and its gradient is above an upper threshold, i.e.,*

$$\inf_{x\in\mathbb{R}} \partial_x u_0(x) \geq -\frac{1}{2}\left[1+\sqrt{1-4Q(0)V(u_0)}\right],$$

then the smooth solution exists for all time and satisfies

$$\partial_x u(t,x) \geq -\frac{1}{2}\left[1+\sqrt{1-4Q(0)V(u_0)}\right].$$

Proof. To show the global existence of the smooth solution it suffices to establish an a priori lower bound for the gradient of solution u_x. As argued earlier, we evaluate $d := u_x$ along the particle path $x(\alpha, t)$ to obtain

$$d' + d^2 = Q * u_x(t, x(\alpha,t)) - d(t).$$

Noting that the lower bound of Qu_x is $-A = -V(u_0)Q(0)$, we find that

$$d' \geq -A - d - d^2 = -(d-A_1)(d-A_2),$$

where

$$A_1 = -\frac{1}{2}[1+\sqrt{1-4A}], \quad A_2 = -\frac{1}{2}[1-\sqrt{1-4A}].$$

Now let q solve the following problem:

$$\frac{d}{dt}q(t) = -(q-A_1)(q-A_2), \quad q(0) = d_0.$$

Then the comparison of the above differential relations yields

$$d - q \geq (d_0 - q(0)) \exp\left(-\int_0^t (d+q+1)d\tau\right) = 0, \quad t > 0.$$

However, q can be solved explicitly as

$$q(t) = \left[A_1 - A_2\frac{d_1 - A_1}{d_0 - A_2}\exp(A_2 - A_1)t\right]\left[1 - \frac{d_1 - A_1}{d_0 - A_2}\exp(A_2 - A_1)t\right]^{-1}.$$

Therefore for $A_2 > d_0 \geq A_1$ one has $d(t) \geq q(t) \geq A_1$; for $d_0 \geq A_2$ one has $d(t) \geq q(t) \geq A_2$. The possible breakdown occurs only when $d_0 < A_1$ because

$$q(t^*) = -\infty, \qquad t^* = \frac{1}{A_2 - A_1}\log\frac{d_1 - A_2}{d_0 - A_1} > 0.$$

The lower bound of d cannot be ensured for $d_0 < A_1$. However, $d_0 \geq A_1$ is sufficient to ensure the global existence of the smooth solution. □

5. L^1 stability of shock profiles. Let us rewrite (1.1) as

$$u_t + f(u)_x = Q * u - u, \quad f = u^2/2. \tag{5.1}$$

A shock wave with speed $s \in \mathbb{R}$ is a solution of (5.1) of the form $U(x - st)$, with U approaching two different shock states $u_\pm$ at far field. The function U formally satisfies the equation

$$-sU' + f(U)' = Q * U - U, \quad U(\pm\infty) = u_\pm.$$

The critical threshold phenomenon revealed in the previous sections suggests that the smooth shock profile is possibly subject to some constraints on the shock strength.

Indeed the existence of the shock profiles for (5.1) with convex flux function f has been proved [23, Theorem 3.1], which we state below, for $Q = \frac{1}{2}e^{-|x|}$, for the reader's convenience.

THEOREM 5.1. *Assume $f'' > 0$. Then the Lax shock condition*

$$f'(u_+) < s < f'(u_-) \tag{5.2}$$

and the Rankine–Hugoniot shock condition

$$H(u_+) = 0, \quad H(u) \equiv -s(u - u_-) + f(u) - f(u_-), \tag{5.3}$$

are necessary conditions for the existence of a traveling wave solution

$$U(z \equiv x - st), \quad \lim_{z\to\pm\infty} U(z) = u_\pm,$$

for (5.1). *Conversely, if* (5.2) and (5.3) *hold, then a sufficient condition for the existence of such a traveling wave is*

$$4 \sup_{u_+<u<u_-} \{-f''(u)H(u)\} \le 1,$$

and a necessary condition is

$$4\{-f''(u^*)H(u^*)\} \le 1.$$

Here u^* is defined by

$$f'(u^*) = s.$$

Note that for the Burgers' flux $f = u^2/2$, the shock speed by the Rankine–Hugoniot relation (5.3) becomes $s = \frac{u_+ + u_-}{2}$. If the shock condition (5.2), i.e.,

$$u_+ < u_-$$

holds, then there exists such a traveling wave if and only if

$$|u_+ - u_-| \le \sqrt{2}. \tag{5.4}$$

This shows that the traveling wave solutions of the R-C-E equation give narrower shock layers than those of the viscous Burgers' equation.

Recall that the solution operator

$$S(t) : L^\infty(\mathbb{R}) \to L^\infty(\mathbb{R}), \quad t \ge 0,$$

satisfies the nice properties listed in section 2, which ensures that $S(t)$ can be well extended to $L^1(\mathbb{R}) + L^\infty(\mathbb{R})$ and preserves all those properties.

To reformulate the stability problem, we introduce the following set:

$$A := U + L^1(\mathbb{R}),$$

which is a complete metric space with the metric

$$\rho(a_1, a_2) = \|a_1 - a_2\|_1.$$

We also set two subspaces of A,

$$A_1 := \{U(\cdot + k), \quad k \in \mathbb{R}\}$$

and

$$A_2 = \{a \in A : \lim_{t\to\infty} S(t)a \quad \text{exists and} \lim_{t\to\infty} S(t)a \in A_1\}.$$

Equipped with the above notations, we see that proving the stability result in Theorem 1.2 reduces to proving the relation

$$A \cap [u+, u_-] \subset A_2, \tag{5.5}$$

provided $S(t)a$ is smooth.

We introduce the ω-limit set of a as

$$\omega(a) = \cap_{s\geq 0}\overline{\cup_{t\geq s}\{S(t)a\}}.$$

This ω-limit set is invariant for $S(t)$. In fact, the definition implies that $b \in \omega(a)$ if and only if there is a sequence $\{t_k\} \to \infty$ such that

$$\rho(S(t_k)a, b) \to 0.$$

The following lemma plays a critical role in proving (5.5).

LEMMA 5.2. *If $a, b \in A \cap [u_+, u_-]$ and $a - b$ does not keep same sign on $\mathbb{R}$, then*

$$\|S(t)a - S(t)b\|_1 < \|a - b\|_1, \quad t > 0.$$

Proof. By Kružkov's argument [10] we have

$$\int_0^T \int_{\mathbb{R}} \{|u - v|\phi_t + sgn(u - v)[f(u) - f(v)]\phi_x\} dxdt$$
$$\geq \int_0^T \int_{\mathbb{R}} \{|u - v| - sgn(u - v)G * (u - v)\}\phi dxdt,$$

where ϕ is an arbitrary nonnegative test function. Thus, by taking $\phi(x, t) = \chi(t)\psi(x, t)$, letting $\psi = 1 - g_\epsilon(|x - x_0| - M(T - t))$ with $M = sup|f'|$ tend to the function that is identically one, and letting $\chi(t)$ approximate the indicator function of the interval $[0, t]$, we conclude

$$\|a - b\|_1 - \|S(t)a - S(t)b\|_1 \geq \int_{\mathbb{R}} |S(t)a - S(t)b| - sgn(a - b)G * (S(t)a - S(t)b)dx. \tag{5.6}$$

Using the monotonicity of $S(t)$ we see that if $a-b$ changes sign on $\mathbb{R}$, then so does $S(t)a - S(t)b$. Note that since $\|Q\|_1 = 1$, we find that

$$\int_{\mathbb{R}} |u| - sign(u) Q * u dx = 0$$

if and only if u does not change sign or $u \equiv 0$. This shows that the right-hand side of (5.6) is positive if $a-b$ changes sign on $\mathbb{R}$. □

Armed with the above lemma we proceed to complete the stability proof via the following steps, which have become standard since the work by Osher and Ralston [16] and Serre [18].

First we restrict our stability proof to the initial data in

$$N(U,k_1,k_2) := \{a \in A, \quad U(x+k_1) \le a(x) \le U(x+k_2), \quad \text{for some} \quad k_1, k_2 \in \mathbb{R}\},$$

and we can later extend our argument to a larger class using the following dense lemmas.

Step 1 (dense argument). We first show that both A_1 and A_2 are complete subspaces of A.

Lemma 5.3. *Let U be the monotone shock profile; then A_i, $i = 1, 2$, are close in A.*

Proof. We first show the closeness of A_1. It is easy to see that for any $k \in \mathbb{R}$, $U(x+k) \in A$ since

$$\|U(\cdot + k) - U(\cdot)\|_1 = |k(u_+ - u_-)| < \infty.$$

We assume $U(x+k_n)$ converges in A; then it is a Cauchy sequence. Note that

$$\|U(\cdot + k_n) - U(\cdot + k_m)\|_{L^1} = |(k_n - k_m)(u_+ - u_-)|$$

implies k_n is also a Cauchy sequence in $\mathbb{R}$. Let its limit be k; then by letting $m \to \infty$ in the above equation, one finds that the limit of $U(x+k_n)$ is $U(x+k) \in A_1$.

We now turn to showing the closeness of A_2. Let $a_k \in A_2$ be a Cauchy sequence with its limit being $a \in A$. We need to show $a \in A_2$. Note that for each $a_k \in A_2$ we have that $\lim_{t\to\infty} S(t)a_k = \tilde{a}_k \in A_1$ exists. Hence $\tilde{a}_k$ is a Cauchy sequence in the complete metric space A_1, for

$$\|\tilde{a}_k - \tilde{a}_l\|_1 = \lim_{t\to\infty} \|S(t)a_k - S(t)a_l\|_1 \le \|a_k - a_l\|_1.$$

We denote the limit of $\tilde{a}_k$ by $\tilde{a}$ as $k \to \infty$, which, when combined with the closeness of A_1, implies that $\tilde{a} \in A_1$. Therefore $a \in A_2$ since

$$\|S(t)a - \tilde{a}\|_1 \le \|S(t)a - S(t)a_k\|_1 + \|S(t)a_k - \tilde{a}_k\|_1 + \|\tilde{a}_k - \tilde{a}\|_1 \to 0$$

as $k \to \infty$ and $t \to \infty$. □

Lemma 5.4. *For any given $k_1, k_2 \in \mathbb{R}$, the set $N(U, k_1, k_2)$ is dense in $A \cap [u_+, u_-]$.*

The proof can be done as in [16]; the details are omitted.

Step 2 (compact criteria).

Lemma 5.5. *For any $k_1, k_2 \in \mathbb{R}$, the ω-limit set $\omega(N(U, k_1, k_2))$ is not empty.*

Proof. It suffices to show that $\cup_{t\ge0}\{S(t)a\}$ is precompact for any $a \in N(U, k_1, k_2)$. Indeed, due to $a - U \in L^1$ and the L^1 contraction of $S(t)$ we have

$$\|S(t)a - U\|_1 = \|S(t)a - S(t)U\|_1 \le \|a - U\|_1 < \infty, \quad t \ge 0.$$

The L^1 equicontinuity follows from the fact that

$$\|S(t)a(x+h) - S(t)a(x)\|_1 \le \|a(x+h) - a(x)\|_1 \to 0$$

uniformly in time as h goes to zero. Using the semigroup property of $S(t)$, we have

$$U(x+k_1) \le S(t)a \le U(x+k_2), \quad t \ge 0.$$

Hence

$$||S(t)a - U(x)||_{L^1(|x|>M)} \le \max\{\|U(\cdot + k_1) - U\|_{L^1(|x|>M)}, \|U(\cdot + k_2) - U\|_{L^1(|x|>M)}\} \to 0$$

uniformly in t as M goes to ∞.

When recalling the Frechet–Kolmogorov–Riesz compactness theorem, the above facts yield that $\cup_{t\ge 0}\{S(t)a\}$ is precompact. □

Step 3 (time-invariance).

LEMMA 5.6. *Let $b \in \omega(N(U,k_1,k_2))$. Then for any given $k \in \mathbb{R}$*

$$\|b - U(\cdot + k)\|_1 = \|S(t)b - U(\cdot + k)\|_1.$$

Proof. Since $b \in \omega(N(U,k_1,k_2))$, we see that there exists $a \in N(U,k_1,k_2)$ and a sequence $\{t_n\}$ such that $t_n \to \infty$ as $n \to \infty$ and

$$\lim_{n\to\infty} \|S(t_n)a - b\|_1 = 0.$$

Given any $k \in \mathbb{R}$, by contraction of $S(t)$ we know that

$$\|S(t)a - U(x+k)\|_1 = \|S(t)a - S(t)U(x+k)\|_1$$

is decreasing in time and thus admits a limit $c_k \ge 0$ as $t \to \infty$, i.e.,

$$\lim_{t\to\infty} \|S(t)a - U(x+k)\|_1 = c_k \ge 0.$$

Letting $t = t_n$ in the above equation and passing to the limit, we have

$$\|b - U(\cdot + k)\|_1 = c_k.$$

Note that if $b \in \omega(a)$, then $S(t)b \in \omega(a)$ (ω is invariant under the flow); thereby

$$\|S(t)b - U(\cdot + k)\|_1 = c_k.$$

Therefore

$$\|S(t)b - U(\cdot + k)\|_1 = \|b - U(\cdot + k)\|_1 \quad \forall t > 0, \quad k \in \mathbb{R}. \qquad \square$$

We are now ready to prove (5.5). We first prove

$$N(U,k_1,k_2) \subset A_2.$$

By Lemma 5.5 we know that $\omega(N(U,k_1,k_2))$ is not empty. For $a \in N(U,k_1,k_2)$ and $b \in \omega(a)$, we need to show that there exists a $k \in \mathbb{R}$ such that

$$b = U(x+k).$$

Lemma 5.6 shows that

$$\|b - U(\cdot + k)\|_1 = \|S(t)b - U(\cdot + k)\|_1 = c_k.$$

Noting that $U(x+k)$ is the fixed point of $S(t)$, Lemma 5.2 shows that $b - U(x+k)$ must stay with one sign.

Therefore, choosing

$$k = \int_{\mathbb{R}} (a - U)dx/(u_+ - u_-)$$

gives

$$c_k = \int_{\mathbb{R}} [b - U(\cdot + k)] = \int_{\mathbb{R}} [a - U(\cdot + k)] = 0.$$

On the other hand, since the initial data a are assumed to be above the critical threshold, $\partial_x(S(t)a)$ is uniformly bounded with respect to t, and hence b is Lipschitz continuous. This regularity combined with the above fact yields

$$b = U(x+k).$$

We now conclude the proof of (5.5). Let $a \in A \cap [u_+, u_-]$. We need to show $a \in A_2$.

Using Lemma 5.4 shows that there exists $a_n \in N(U, k_1, k_2) \in A$ such that $\|a_n - a\|_1 \to 0$ as $n \to \infty$. By the above proved fact we see that there exists k_n such that

$$\lim_{t\to\infty} \|S(t)a_n - U(\cdot + k_n)\|_1 = 0.$$

This tells us that $a_n \in A_2$. Due to the closeness of A_2, the limit a also belongs to A_2. Therefore there exists a k such that

$$\lim_{t\to\infty} \|S(t)a - U(\cdot + k)\|_1 = 0;$$

as argued above, the constant k as the limit of $\int_{\mathbb{R}}(a_n - U)dx/(u_+ - u_-)$ is

$$\int_{\mathbb{R}} (a - U)dx/(u_+ - u_-)$$

since $|\int (a_n - a)dx| \le \|a_n - a\| \to 0$ as $n \to \infty$. This completes the proof of (5.5) and thereby of Theorem 1.2.

SPECTRAL APPROXIMATION ORDERS OF RADIAL BASIS FUNCTION INTERPOLATION ON THE SOBOLEV SPACE[*]

JUNGHO YOON[†]

Abstract. In this study, we are mainly interested in error estimates of interpolation, using smooth radial basis functions such as multiquadrics. The current theories of radial basis function interpolation provide optimal error bounds when the basis function ϕ is smooth and the approximand f is in a certain reproducing kernel Hilbert space $\mathcal{F}_\phi$. However, since the space $\mathcal{F}_\phi$ is very small when the function ϕ is smooth, the major concern of this paper is to prove approximation orders of interpolation to functions in the Sobolev space. For instance, when ϕ is a multiquadric, we will observe the error bound $o(h^k)$ if the function to be approximated is in the Sobolev space of smoothness order k.

Key words. radial basis function, interpolation, Sobolev space, positive definite function, multiquadric, "shifted" surface spline

1. Introduction.

Radial basis function interpolation is a very useful and convenient tool for multivariate scattered data approximation problems. Its strengths are as follows: (i) it facilitates the evaluation of the approximant; (ii) the accuracy of approximation is usually very satisfactory provided the approximand f is reasonably smooth; (iii) there is enough flexibility in the choice of basis functions. A function $\phi : \mathbb{R}^d \to \mathbb{R}$ is radial in the sense that $\phi(x) = \Phi(|x|)$, where $|\cdot|$ is the usual Euclidean norm.

Let Π_m denote the subspace of $C(\mathbb{R}^d)$ consisting of all algebraic polynomials of degree less than m on $\mathbb{R}^d$. Suppose that a continuous function $f : \mathbb{R}^d \to \mathbb{R}$ is known only at a set of discrete points $X := \{x_1, \ldots, x_N\}$ in $\Omega \subset \mathbb{R}^d$. Radial basis function interpolation to f on X starts with choosing a basis function ϕ, and then it defines an interpolant by

$$a_{f,X}(x) := \sum_{i=1}^{\ell} \beta_i p_i(x) + \sum_{j=1}^{N} \alpha_j \phi(x - x_j), \tag{1.1}$$

where $p_1, \ldots, p_\ell$ is a basis for Π_m and the coefficients α_j $(j = 1, \ldots, N)$ and β_i $(i = 1, \ldots, \ell)$ are chosen to satisfy the linear system

$$\begin{aligned} a_{f,X}(x_j) &= f(x_j), \quad && j = 1, \ldots, N, \\ \sum_{j=1}^{N} \alpha_j p_i(x_j) &= 0, && i = 1, \ldots, \ell. \end{aligned} \tag{1.2}$$

Here, the set of scattered points X has the nondegeneracy property for Π_m; that is, if $p \in \Pi_m$ and $p(x_j) = 0$, $j = 1, \ldots, N$, then $p = 0$. It guarantees that the interpolation

method reproduces the polynomial space Π_m, i.e., $a_{p,X} = p$ for any $p \in \Pi_m$. For a wide choice of functions ϕ and polynomial orders m, the existence and uniqueness of the solution of the linear system (1.2) is ensured when ϕ is a conditionally positive definite function (see [M]).

DEFINITION 1.1. *Let $\phi : \mathbb{R}^d \to \mathbb{R}$ be a continuous function. We say that ϕ is conditionally positive definite of order $m \in \mathbb{N} := \{1, 2, \ldots\}$ if for every finite set of pairwise distinct points $X = \{x_1, \ldots, x_N\} \subset \mathbb{R}^d$ and for every $\alpha = (\alpha_1, \ldots, \alpha_N) \in \mathbb{R}^N \setminus 0$ satisfying*

$$\sum_{j=1}^{N} \alpha_j p(x_j) = 0, \quad p \in \Pi_m,$$

the quadric form

$$\sum_{i=1}^{N} \sum_{j=1}^{N} \alpha_i \alpha_j \phi(x_i - x_j)$$

is positive definite.

In what follows, we assume $\phi = \Phi(|\cdot|)$ to be conditionally positive definite of order m. Also, the function ϕ is considered as a tempered distribution in $\mathcal{D}'(\mathbb{R}^d)$, and we assume that its Fourier transform $\hat{\phi}$ coincides on $\mathbb{R}^d \setminus 0$ with some continuous function while having a certain type of singularity (necessarily of a finite order) at the origin, i.e., $\hat{\phi}$ is of the form

$$|\cdot|^n \hat{\phi} = F > 0, \quad n \geq 0, \quad \text{and } F \in L_\infty(\mathbb{R}^d).$$

Among many radial basis functions, our major concern is with smooth functions ϕ such as multiquadrics $\phi(x) := c_{m,d}(|x|^2 + \lambda^2)^{m-d/2}$, d odd, $m > d/2$, where $c_{m,d}$ is a suitable constant.

For a given basis function ϕ, there arises a function space

$$\mathcal{F}_\phi := \left\{ f : |f|_\phi := \int_{\mathbb{R}^d} \frac{|\hat{f}(\theta)|^2}{\hat{\phi}(\theta)} d\theta < \infty \right\}, \tag{1.3}$$

which is called reproducing kernel Hilbert space (or "native" space) for ϕ ([MN2] and [WS]). For all $x \in \Omega$, $f \in \mathcal{F}_\phi$, bounds for the interpolation error are usually of the form

$$|f(x) - a_{f,X}(x)| \leq P_{\phi,X}(x)|f|_\phi. \tag{1.4}$$

Here $P_{\phi,X}$ is the *power function* that evaluates the norm of the error functional at x:

$$P_{\phi,X}(x) = \sup_{|f|_\phi \neq 0} \frac{|f(x) - a_{f,X}(x)|}{|f|_\phi}.$$

In fact, when the basis function ϕ is smooth, the interpolation method provides optimal asymptotic decay of errors, but the space $\mathcal{F}_\phi$ is very small. The approximands f need to be extremely smooth for effective error estimates. However, practically, most multivariate scattered data are not arising from extremely smooth functions. An error analysis for the case that the underlying function is reasonably smooth needs to be provided. Thus, the main objective of this paper is to prove asymptotic error bounds of interpolation (by using smooth basis function ϕ) to functions in a larger space, especially in the Sobolev space.

Asymptotic approximation properties are usually quantified by the notion of approximation order. In order to make this notion feasible, we measure the "density" of X (in Ω) by

$$h := h(X;\Omega) := \sup_{x\in\Omega} \min_{x_j\in X} |x - x_j|. \tag{1.5}$$

Here we assume that $\Omega \subset \mathbb{R}^d$ is an open bounded domain with both cone property and Lipschitz boundary. In particular, for a given set X, we adopt the scaled basis functions $\phi_\omega := \phi(\cdot/\omega)$, where

$$\omega := \omega(h)$$

is a parameter depending on h such that $h/\omega \to 0$ as $h \to 0$, and we use the notation

$$s_{f,X}(x) := \sum_{i=1}^{\ell} \beta_i p_i(x) + \sum_{j=1}^{N} \alpha_j \phi_\omega(x - x_j) \tag{1.6}$$

to differentiate from the notation $a_{f,X}$ in (1.1). Then our goal is to provide error estimates of $f - s_{f,X}$ of the following form: Let ϕ be a smooth basis function (e.g., multiquadric). Under some suitable conditions of the parameter ω (e.g., $\omega = h^r$ with $r \in [0,1)$), we will show the asymptotic property

$$\|f - s_{f,X}\|_{L_\infty(\Omega)} = o(h^k), \quad h \to 0,$$

provided that $f \in W_\infty^k(\Omega)$, the L_∞-Sobolev space of smoothness order k. To the writer's knowledge, this is the first paper dedicated to the study of spectral approximation order of interpolation to the functions in the Sobolev space $W_\infty^k(\Omega)$. Indeed, Buhmann and Dyn also explored the spectral convergence order of multiquadric interpolation in the paper [BuD]. However, this result considers interpolants on $h \cdot \mathbb{Z}^d$ under some conditions of the underlying function f, while we work with a finite subset X in Ω.

The reader who is interested in knowing more about the state of the art in the area of radial basis function methods may find it useful to consult with the surveys [Bu], [D], and [P]. Other important sources are the works of Wu and Schaback [WS] and especially those of Madych and Nelson [MN1], [MN2], who developed a theory of interpolation based on reproducing kernel Hilbert spaces. Interpolation by compactly supported basis functions has been studied by Wendland [W].

The following notations will be used throughout this paper. For any $k \in \mathbb{N}$, the Sobolev space is defined by

$$W_p^k(\Omega) := \left\{ f : \|f\|_{k,L_p(\Omega)} := \left(\sum_{|\alpha|_1 \le k} \|D^\alpha f\|_{L_p(\Omega)}^p \right)^{1/p} < \infty \right\}$$

with $1 \le p \le \infty$. Several different function norms are used. When $\mathbf{g}$ is a matrix or a vector, $\|\mathbf{g}\|_p$ indicates its p-norm with $1 \le p \le \infty$. For $x \in \mathbb{R}^d$, $|x| := (x_1^2 + \cdots + x_d^2)^{1/2}$ stands as its Euclidean norm. The Fourier transform of $f \in L_1(\mathbb{R}^d)$ is defined as

$$\hat{f}(\theta) := \int_{\mathbb{R}^d} f(t) \exp(-i\theta \cdot t)\, dt.$$

Also, for a function $f \in L_1(\mathbb{R}^d)$ we use the notation $f^\vee$ for the inverse Fourier transform. In particular, the Fourier transform can be uniquely extended to the space of tempered distributions on $\mathbb{R}^d$.

2. The extension of a function f in $W^k_\infty(\Omega)$. Our analysis in this paper requires the construction of a suitable extension of a given function $f \in W^k_\infty(\Omega)$ to a function on $\mathbb{R}^d$. Indeed, the lengthy assumptions on Ω in section 1 assure the existence of a function on $\mathbb{R}^d$ whose restriction to Ω agrees with f. The following result is cited from literature.

THEOREM 2.1 (Brenner and Scott [BrS]). *Suppose that Ω has a Lipschitz boundary. Then for every function $f \in W^k_p(\Omega)$, there is an extension mapping $E : W^k_p(\Omega) \to W^k_p(\mathbb{R}^d)$ defined for all nonnegative integer k and real numbers p in the range $1 \le p \le \infty$ satisfying $Ef|_\Omega = f$ for all $f \in W^k_p(\Omega)$ and*

$$\|Ef\|_{k,L_p(\mathbb{R}^d)} \le c\|f\|_{k,L_p(\Omega)},$$

where the constant c is independent of f.

The construction of our suitable extension of $f \in W^k_\infty(\Omega)$ to a function on $\mathbb{R}^d$ can be done in two steps. First, according to Theorem 2.1, there exists a function $Ef \in W^k_\infty(\mathbb{R}^d)$ such that $Ef|_\Omega = f$. Second, we let σ_Ω be a C^∞-cutoff function such that $\sigma_\Omega(x) = 1$ for $x \in \Omega$ and $\sigma_\Omega(x) = 0$ for $|x| > r$ with a sufficiently large $r > 0$. Then we define an extension f^o by

$$f^o := \sigma_\Omega Ef.$$

Of course, f^o is compactly supported and $f^o(x) = f(x)$ for $x \in \Omega$. Indeed, for a large part of this paper, we wish to work with f^o and not f. For convenience, we will henceforth write f for f^o. Therefore, here and in what follows, *without great loss*, we assume that an approximand $f \in W^k_\infty(\Omega)$ is supported in a sufficiently large compact set in $\mathbb{R}^d$ such that $f \in W^k_\infty(\mathbb{R}^d)$.

3. Error bounds. In this section, we will provide a (modified) method of error analysis of interpolation to functions in the Sobolev space $W^k_\infty(\Omega)$. In addition, we obtain a sufficient condition for the optimal convergence order $\|f - s_{f,X}\|_{L_\infty(\Omega)} = o(h^k)$ with $f \in W^k_\infty(\Omega)$. For this purpose, we start with finding a mollified function (say, f_H) of a given (underlying) function f. The function f_H is supposed to be in the space $\mathcal{F}_{\phi_\omega}$ in (1.3) and should be a good approximation to f in some sense. In order to define a mollification f_H of f, we use a nonnegative C^∞-cutoff function

$$\sigma : \mathbb{R}^d \to [0,1]. \tag{3.1}$$

Here, for convenience, we assume that the function σ is radially symmetric and supp σ lies in the Euclidean ball $B_1 = \{x \in \mathbb{R}^d : |x| \le 1\}$, and we assume that $\sigma = 1$ on $B_{1/2}$ and $\|\sigma\|_{L_\infty(\mathbb{R}^d)} = 1$. Then, letting $\sigma_\delta := \sigma(\cdot/\delta)$ with $\delta > 0$, we construct two functions f_H and f_T by

$$\begin{aligned} f_H &:= \sigma_\delta(h\cdot)^\vee * f, \\ f_T &:= f - \sigma_\delta(h\cdot)^\vee * f. \end{aligned} \tag{3.2}$$

It clearly follows that

$$f = f_H + f_T.$$

Also, due to the fact that the interpolation operator $s_{f,X}$ is linear, it is useful to split the error $f - s_{f,X}$ as follows:

$$f - s_{f,X} = (f_H - s_{f_H,X}) + (f_T - s_{f_T,X}).$$

Accordingly, this section falls naturally into two parts. In the first, since $f_H \in \mathcal{F}_{\phi_\omega}$, we estimate the term $f_H - s_{f_H,X}$ by applying the well-known method in (1.4). The second part of the section deals with $f_T - s_{f_T,X}$. Our main tool for this case is to use stability results on the interpolation process. Afterward, the final result is stated in Theorem 3.6

From the papers (see, e.g., [WS], [MN2]), we cite the following lemma.

LEMMA 3.1. *Let $a_{X,f}$ in (1.1) be an interpolant to f on $X = \{x_1, \ldots, x_N\}$. Given ϕ and m, for all functions f in the space $\mathcal{F}_\phi$, there is an error bound of the form*

$$|f(x) - a_{f,X}(x)| \le |f|_\phi P_{\phi,X}(x),$$

where $P_{\phi,X}(x)$ is the norm of the error functional at x, i.e.,

$$P_{\phi,X}(x) = \sup_{|f|_\phi \neq 0} \frac{|f(x) - a_{f,X}(x)|}{|f|_\phi}. \tag{3.3}$$

The following lemma estimates the error $f_H - s_{f_H,X}$.

LEMMA 3.2. *Let $f_H := \sigma_\delta(h\cdot)^\vee * f$ with $\sigma_\delta(h\cdot)$ as the cutoff function in (3.1), and let $s_{f_H,X}$ in (1.6) be the interpolant to f_H on X using the basis function ϕ_ω. Let ω be a parameter depending on h, i.e., $\omega = \omega(h)$. Then, for every $f \in L_2(\mathbb{R}^d)$, we have an estimate of the form*

$$|f_H(x) - s_{f_H,X}(x)| \le P_{\phi,X/\omega}(x/\omega) M_{\phi,\omega}(\delta/h) \|f\|_{L_2(\mathbb{R}^d)}, \quad x \in \Omega,$$

where $M_{\phi,\omega}(r)$, $r > 0$, is defined by

$$M_{\phi,\omega}(r) := \sup_{\theta \in B_r} |\hat{\phi}_\omega(\theta)|^{-1/2}. \tag{3.4}$$

Proof. Recalling the definition of $s_{f_H,X}$ in (1.6), one simply notes that the function $s_{f_H,X}(\omega\cdot)$ can be considered as an interpolant (employing the shifts of ϕ) to the scaled function $f_H(\omega\cdot)$ on X/ω, i.e.,

$$s_{f_H,X}(\omega\cdot) = \sum_{i=1}^{\ell} \beta_i p_i(x) + \sum_{j=1}^{N} \alpha_j \phi(\cdot - x_j/\omega) = a_{f_H(\omega\cdot),X/\omega},$$

with $a_{f,X}$ in (1.1). Then, since $f_H(\omega\cdot)$ belongs to the space $\mathcal{F}_\phi$, Lemma 3.1 can be used directly to derive the bound

$$\begin{aligned} |f_H(x) - s_{f_H,X}(x)| &= |f_H(\omega\cdot) - a_{f_H(\omega\cdot),X/\omega}|(x/\omega) \\ &\le P_{\phi,X/\omega}(x/\omega)|f_H(\omega\cdot)|_\phi. \end{aligned} \tag{3.5}$$

Now, in order to estimate the term $|f_H(\omega\cdot)|_\phi$, we find from the definition of f_H in (3.2) that

$$\widehat{f_H(\omega\cdot)}(\theta) = \omega^{-d} \sigma_\delta(h\theta/\omega) \hat{f}(\theta/\omega).$$

Then the explicit formula of the norm $|\cdot|_\phi$ in (1.3) induces by change of variables that

$$|f_H(\omega\cdot)|_\phi^2 = \omega^{-d}\int_{\mathbb{R}^d} \left|\sigma_\delta(h\theta)\hat{f}(\theta)\right|^2 \hat{\phi}^{-1}(\omega\theta)d\theta$$
$$\leq \sup_{\theta\in B_{\delta/h}} |\hat{\phi}_\omega(\theta)|^{-1}\|f\|_{L_2(\mathbb{R}^d)}^2.$$

Due to the expression (3.5), we finish the proof. □

Now, we are going to turn to the estimate of the error $f_T - s_{f_T,X}$ with f_T in (3.2). Since there is no guarantee that the function f_T belongs to the space $\mathcal{F}_\phi$, the classical method of the error analysis of interpolation is not applicable to this case. Hence, in order to make the estimate $f_T - s_{f_T,X}$ feasible, we employ the stability results on interpolation process. To this end, we define the separation distance within X by

$$q := q_X := \min_{1\leq i\neq j\leq N} |x_i - x_j|/2. \tag{3.6}$$

It is well known from literature (e.g., [NSW2], [S1]) that as q is getting smaller, the condition number of the interpolation matrix becomes larger. Also, the irregularity of a set X can be measured by the ratio h/q. In particular, we assume that the sets of scattered points considered in this study are sets of quasi-uniformly distributed points. These sets satisfy the following property: There exists a constant $\eta > 0$ independent of X such that

$$2q \leq h \leq \eta q. \tag{3.7}$$

This condition implies that the number of the scattered points in the set X is bounded above by a quantity that depends on the density of X, i.e., $N = O(h^{-d})$. On the other hand, we particularly introduce a function φ defined by

$$\varphi := \sigma_\epsilon^\vee = \sigma(\cdot/\epsilon)^\vee, \tag{3.8}$$

where σ_ϵ is the cutoff function in (3.1). For the purpose of simplifying the following analysis, we assume $\epsilon > 0$ to be any fixed number satisfying the condition

$$\epsilon < \delta/\eta \tag{3.9}$$

with δ in (3.2). It is obvious that the Fourier transform of φ is $\hat{\varphi} = \sigma_\epsilon$, which is supported in the ball B_ϵ. Furthermore, since σ is a C^∞-cutoff function, $\varphi(x)$ decays fast as x tends to ∞. Indeed, the function φ is employed to use the stability results on the interpolation process. It first requires us to show that φ is a conditionally positive definite radial function. For this proof, we find the following identity:

$$\sum_{i=1}^N\sum_{j=1}^N \alpha_i\alpha_j\varphi(x_i - x_j) = \int_{\mathbb{R}^d} \hat{\varphi}(\theta)\left|\sum_{j=1}^N \alpha_j e^{ix_j\cdot\theta}\right|^2 d\theta$$

for any $\alpha = (\alpha_1,\ldots,\alpha_N) \in \mathbb{R}^N \setminus 0$. Since the map $\theta \mapsto \sum_{j=1}^N \alpha_j e^{ix_j\cdot\theta}$, $\theta \in \mathbb{R}^d$, has zeros at most on a set of measure zero, we see that the integral in the right-hand side of the above identity is always positive. It is asserted from Definition 1.1 that the function φ is conditionally positive definite of order $m = 0$. Also, since the cutoff function σ_ϵ is radially symmetric, its inverse Fourier transform φ is also a radial function (see [S3]). Then an interpolant to f on X using the (scaled) function

$$\varphi_q(x) := \varphi(x/q)$$

is of the form

$$g_{f,X}(x) = \sum_{j=1}^{N} \beta_j \varphi_q(x - x_j). \tag{3.10}$$

One simply notes that the matrix $\mathbf{A}_{\varphi_q} := (\varphi_q(x_i - x_j))_{i,j=1,\ldots,N}$ is positive definite.

Proposition 3.3. *Let X be a q-separated set with q in equation* (3.6). *Let $\mathbf{b}_f := (\beta_1, \ldots, \beta_N)^T$, and let $\mathbf{A}_{\varphi_q} := (\varphi_q(x_i - x_j))_{i,j=1,\ldots,N}$ be the interpolation matrix by φ_q. Then we have the following properties:*

(a) $\|\mathbf{A}_{\varphi_q}^{-1}\|_2 \le c_1$ *for some* $c_1 > 0$.

(b) $\|\mathbf{A}_{\varphi_q}^{-1}\|_1 = \|\mathbf{A}_{\varphi_q}^{-1}\|_\infty \le c_2 \|\mathbf{A}_{\varphi_q}^{-1}\|_2$ *for some* $c_2 > 0$.

(c) $\|\mathbf{b}_f\|_\infty \le c_3 \|f\|_{L_\infty(\mathbb{R}^d)}$ *for some* $c_3 > 0$.

Proof. Since the interpolation matrix $\mathbf{A}_{\varphi_q}$ has the separation distance 1, the matrix norm $\|\mathbf{A}_{\varphi_q}^{-1}\|_2$ is bounded by a constant (see [NSW2]). Furthermore, the basis function φ_q decays fast around ∞, and the inequality in (b) is proved by a direct application of Theorem 3.11 in the paper [BSW]. The identity $\|\mathbf{A}_{\varphi_q}^{-1}\|_1 = \|\mathbf{A}_{\varphi_q}^{-1}\|_\infty$ is an obvious consequence of symmetry. Finally, to prove (c), we find that the matrix $\mathbf{b}_f$ can be written as

$$\mathbf{b}_f = \mathbf{A}_{\varphi_q}^{-1}\mathbf{f}$$

with $\mathbf{f} := (f(x_1), \ldots, f(x_N))^T$. After some direct calculations, one can prove the inequality $\|\mathbf{b}_f\|_\infty \le \|\mathbf{A}_{\varphi_q}^{-1}\|_1 \|f\|_{L_\infty(\mathbb{R}^d)}$. Hence, by using (b), the relation in (c) is immediate. □

Before estimating the error $f_T - s_{f_T,X}$, we cite the following result.

Lemma 3.4 (Yoon [Y1]). *Let $f_T = f - \sigma_\delta(h\cdot)^\vee * f$ with $\sigma_\delta(h\cdot)$ the cutoff function in* (3.1). *Then, for every $f \in W_\infty^k(\mathbb{R}^d)$ with k a positive integer, we have the following decaying property:*

$$\|f_T\|_{L_\infty(\mathbb{R}^d)} = \|f - f_H\|_{L_\infty(\mathbb{R}^d)} = o(h^k).$$

Lemma 3.5. *Let X be a set of scattered points with the condition* (3.7), *and let $s_{f_T,X}$ in* (1.6) *be the interpolant to f_T on X using ϕ_ω, where $f_T = f - \sigma_\delta(h\cdot)^\vee * f$ and $\omega = \omega(h)$. Then, for every $f \in W_\infty^k(\Omega)$ with k a positive integer, there is an error bound of the form*

$$|f_T(x) - s_{f_T,X}(x)| \le o(h^k)(1 + P_{\phi,X/\omega}(x/\omega) M_{\phi,\omega}(\delta/h)), \quad x \in \Omega,$$

as $h \to 0$, with $M_{\phi,\omega}(r)$, $r > 0$, in (3.4).

Proof. Let us first define a function $\tilde{f}$ by

$$\tilde{f} := h^{-k} f_T.$$

It is clear that $h^{-k} s_{f_T,X} = s_{\tilde{f},X}$. Then, we employ the interpolant $g_{\tilde{f},X}$ in (3.10) to derive the following bound:

$$h^{-k}|f_T(x) - s_{f_T,X}(x)| \le |\tilde{f}(x)| + |g_{\tilde{f},X}(x)| + |g_{\tilde{f},X}(x) - s_{\tilde{f},X}(x)|.$$

The convergence property $\|f_T\|_{L_\infty(\mathbb{R}^d)} = o(h^k)$ in Lemma 3.4 yields that $\|\tilde{f}\|_{L_\infty(\mathbb{R}^d)} = o(1)$ as h tends to 0. Also, by applying Proposition 3.3, we get

$$\begin{aligned} |g_{\tilde{f},X}(x)| &\le \|\mathbf{b}_{\tilde{f}}\|_\infty \sum_{j=1}^N \varphi_q(x - x_j) \\ &\le c\,\|\tilde{f}\|_{L_\infty(\mathbb{R}^d)} = o(1). \end{aligned}$$

Here, since X is a q-separated set and the function φ_q decays fast around ∞, we can easily check that $\sum_{j=1}^N \varphi_q(\cdot - x_j)$ is uniformly bounded on Ω. Therefore, it remains to show that the term $g_{\tilde{f},X} - s_{\tilde{f},X}$ is bounded by $o(1)P_{\phi,X/\omega}(x/\omega)M_{\phi,\omega}(\delta/h)$ as $h \to 0$. For this, we claim that

$$s_{\tilde{f},X} = s_{g_{\tilde{f},X},X}.$$

In fact, this identity is immediate from the interpolation property $\tilde{f}(x_j) = g_{\tilde{f},X}(x_j)$ for any $j = 1, \dots, N$. Then, applying the same technique as in the proof of Lemma 3.2 gives us the bound

$$(3.11) \qquad |s_{\tilde{f},X}(x) - g_{\tilde{f},X}(x)| \le P_{\phi,X/\omega}(x/\omega)|g_{\tilde{f},X}(\omega\cdot)|_\phi, \quad x \in \Omega.$$

Moreover, according to the definition of the norm $|\cdot|_\phi$, we get

$$(3.12) \qquad \begin{aligned} |g_{\tilde{f},X}(\omega\cdot)|_\phi^2 &= \int_{\mathbb{R}^d} \left| \sum_{j=1}^N \beta_j e^{ix_j\cdot\theta} \right|^2 \sigma_\epsilon^2(q\theta)\hat{\phi}_\omega^{-1}(\theta) q^{2d} d\theta \\ &\le M_{\phi,\omega}^2(\epsilon/q) \int_{\mathbb{R}^d} \left| \sum_{j=1}^N \beta_j \varphi_q(x - x_j) \right|^2 dx. \end{aligned}$$

Remembering the relations $\frac{1}{q} \le \frac{\eta}{h}$ in (3.7) and $\epsilon < \frac{\delta}{\eta}$ in (3.9), we easily find that $\frac{\epsilon}{q} \le \frac{\eta\epsilon}{h} \le \frac{\delta}{h}$. Then since $M_{\phi,\omega}(r)$ is monotonically increasing as r grows, it follows that

$$(3.13) \qquad M_{\phi,\omega}(\epsilon/q) \le M_{\phi,\omega}(\delta/h).$$

Also, since $\sum_{j=1}^N \varphi_q(\cdot - x_j)$ is uniformly bounded, we have

$$(3.14) \qquad \begin{aligned} \int_{\mathbb{R}^d} \left| \sum_{j=1}^N \beta_j \varphi_q(x - x_j) \right|^2 dx &\le c\|\mathbf{b}_{\tilde{f}}\|_\infty^2 \int_{\mathbb{R}^d} \left| \sum_{j=1}^N \varphi_q(x - x_j) \right| dx \\ &\le c'\|\tilde{f}\|_{L_\infty(\mathbb{R}^d)} = o(1) \end{aligned}$$

by Proposition 3.3 and the condition $N = O(h^{-d})$. Hence, inserting (3.13) and (3.14) into (3.12), we arrive at the bound

$$|g_{f,X}|_\phi \le M_{\phi,\omega}(\delta/h)o(1).$$

Together with (3.11), we complete the proof of this lemma. □

From Lemma 3.2 and Lemma 3.5, we realize that one of the important ingredients for the estimate $f - s_{f,X}$ is the term $M_{\phi,\omega}(\delta/h)$, $\delta > 0$. Observing the definition of

f_H in (3.2) carefully, we find that the number δ can be chosen arbitrarily. Of course, a certain choice of δ should induce a suitable bound of $P_{\phi,X/\omega}(x/\omega)M_{\phi,\omega}(\delta/h)$, which leads to a desirable estimate of $f - s_{f,X}$. We are now ready to describe the main result of this section.

THEOREM 3.6. *Let X be a set of scattered points with the condition* (3.7), *and let $s_{f,X}$ in* (1.6) *be an interpolant to f on X using the basis function $\phi_\omega = \phi(\cdot/\omega)$. Let $M_{\phi,\omega}(r)$, $r > 0$, be defined as in* (3.4). *Assume that there exists a constant $\delta_0 > 0$ such that*

$$P_{\phi,X/\omega}(x/\omega)M_{\phi,\omega}(\delta_0/h) \le o(h^k).$$

Then, for every function $f \in W_\infty^k(\Omega)$ with k a positive integer, we have an error bound of the form

$$\|f - s_{f,X}\|_{L_\infty(\Omega)} = o(h^k).$$

4. Applications to special radial basis functions. We now turn to applications to special radial basis functions. Employing some known basis functions ϕ, we will show that the interpolant $s_{f,X}$ provides optimal approximation orders for $f \in W_\infty^k(\Omega)$. All the examples here are based on Theorem 3.6.

Example 4.1. Let the radial basis function ϕ be chosen to be one of the following:

(a) $\phi_\lambda(x) := (-1)^{\lceil m-d/2\rceil}(|x|^2+\lambda^2)^{m-d/2}$, d odd, $m > d/2$ (multiquadrics),

(b) $\phi_\lambda(x) := (-1)^{m-d/2+1}(|x|^2+\lambda^2)^{m-d/2}\log(|x|^2+\lambda^2)^{1/2}$, $m > d/2$, d even ("shifted" surface splines).

(c) $\phi_\lambda(x) := (|x|^2+\lambda^2)^{m-d/2}$, $0 < m < d/2$ (inverse multiquadrics),

where $d,\ m \in \mathbb{N}$ and $\lambda > 0$, and where $\lceil s\rceil$ indicates the smallest integer greater than s. Note that we stress the parameter λ by using the notation ϕ_λ. We find (see [GS]) that the Fourier transform of ϕ_λ is of the form

$$\hat{\phi}_\lambda = c(m,d)\tilde{K}_m(\lambda\cdot)|\cdot|^{-2m},$$

where $c(m,d)$ is a positive constant depending on m and d, and $\tilde{K}_\nu(|t|) := |t|^\nu K_\nu(|t|) \neq 0$, $t \ge 0$, with $K_\nu(|t|)$ the modified Bessel function of order ν. It is well known from literature (e.g., [AS]) that

$$\tilde{K}_\nu \sim (1 + |\cdot|^{(2\nu-1)/2})\exp(-|\cdot|).$$

Then, for all $\theta \in B_{\delta/h}$, we have the bound $\hat{\phi}_\lambda(\omega\theta)^{-1/2} \le c|\omega\delta/h|^m \exp(\lambda\omega\delta/2h)$ for a constant $c > 0$. It leads to the inequality

$$M_{\phi_\lambda,\omega}(\delta/h) \le c(\delta)\omega^{-d/2}|\omega/h|^m \exp(\lambda\omega\delta/2h),$$

where $c(\delta)$ is a constant depending on δ. On the other hand, due to Madych and Nelson [MN3], we see that there exists a constant $c' > 0$ independent of X such that

$$P_{\phi_\lambda,X/\omega}(x/\omega) \le c\exp(-c'\lambda\omega/h)$$

for a sufficiently small $h > 0$. Since $\omega^{m-d/2} \le o(h^{-d/2})$ (see section 1), from the above two inequalities, we arrive at the expression

$$M_{\phi_\lambda,\omega}(\delta/h)P_{\phi_\lambda,X/\omega}(x/\omega) \le c(\delta)h^{-m-d/2}\exp\left(-\frac{\lambda\omega}{h}(c'-\delta/2)\right). \tag{4.1}$$

Here, we can choose a sufficiently small $\delta_0 > 0$ such that $c' - \delta/2 > 0$ for any $\delta \leq \delta_0$. In particular, we assume ω to satisfy the relation

$$h|\log h|^{1+r} \leq \omega$$

for any fixed $r > 0$. Then, it follows that

$$\exp\left(-\frac{\lambda\omega}{h}\left(c' - \delta_0/2\right)\right) \leq \exp\big(-\lambda|\log h|^{1+r}(c' - \delta_0/2)\big) \\ = h^{\lambda(c'-\delta_0/2)|\log h|^r}. \tag{4.2}$$

Indeed, as h tends to 0, the number $\lambda(c' - \delta_0/2)|\log h|^r > 0$ becomes arbitrarily large. Hence, for any given $k \in \mathbb{N}$, there exists a sufficiently small $h_0 > 0$ such that $h^{\lambda(c'-\delta/2)|\log h|^r} \leq o(h^{k+m+d/2})$ for any $h \leq h_0$. Consequently, together with (4.1) and (4.2), we conclude that

$$M_{\phi_\lambda,\omega}(\delta_0/h)P_{\phi_\lambda,X/\omega}(x/\omega) \leq o(h^k), \quad h \leq h_0.$$

According to Theorem 3.6, we have the following result.

THEOREM 4.1. *Let ϕ_λ be one of the radial basis functions: multiquadrics, inverse multiquadrics, and "shifted" surface splines. Let X be a set of scattered points with the condition* (3.7)*, and let $s_{f,X}$ in* (1.6) *be an interpolant to f on X using $\phi_\lambda(\cdot/\omega)$. Assume that $\omega = \omega(h)$ is chosen to satisfy the relation*

$$h|\log h|^{1+r} \leq \omega$$

for any fixed $r > 0$. Then, for every $f \in W^k_\infty(\Omega)$ with k a positive integer, we have an error estimate of the form

$$\|f - s_{f,X}\|_{L_\infty(\Omega)} = o(h^k) \quad \text{as} \quad h \to 0.$$

COROLLARY 4.2. *Let ϕ_λ be one of the radial basis functions: multiquadrics, inverse multiquadrics, and "shifted" surface splines. Let X be a set of scattered points with the condition* (3.7)*, and let $s_{f,X}$ in* (1.6) *be an interpolant to f on X using $\phi_\lambda(\cdot/\omega)$. Assume that $\omega(h) = h^s$ with $s \in [0, 1)$ or $\omega(h) = h|\log h|^{1+r}$ with $r > 0$. Then, for every $f \in W^k_\infty(\Omega)$ with k a positive integer,*

$$\|f - s_{f,X}\|_{L_\infty(\Omega)} = o(h^k) \quad \text{as} \quad h \to 0.$$

Remark. Recalling that the interpolant $a_{f,X}$ in (1.1) uses the original (nonscaled) basis function, we make an observation concerning the interpolants $a_{f,X}$ in relation to $s_{f,X}$. Given a set X, assume that the interpolant $a_{f,X}$ employs the basis function $\phi_{\omega\lambda}$ instead of ϕ_λ. Then, one should realize that the interpolant $a_{f,X}$ is identically equal to $s_{f,X}$, which uses ϕ_λ. The equality can be verified by the uniqueness of the solution of the linear system (1.2). The reader is referred to the paper [Y2] for the details of the proof.

Example 4.2. Let us consider the basis function ϕ whose Fourier transform $\hat{\phi}$ is of the form

$$\hat{\phi}(\theta) = \exp(-|\theta|^a)$$

with $0 < a \leq 1$. In the case $a = 1$, the basis function ϕ becomes the so-called Poisson kernel

$$\phi = \frac{c_d}{(1 + |\cdot|^2)^{(d+1)/2}}$$

with a suitable constant c_d. For any $\theta \in B_{\delta/h}$, we get $\hat{\phi}(\omega\theta)^{-1} \leq \exp((\omega\delta/h)^a)$. It leads to the inequality

$$M_{\phi,\omega}(\delta/h) \leq \omega^{-d/2} \exp((\omega\delta)^a/h^a).$$

Also, due to Madych and Nelson (see [MN3]), there exists a constant $c' > 0$ independent of X such that

$$P_{\phi,X/\omega}(x/\omega) \leq c \exp(-c'\omega^a/h^a)$$

for sufficiently small $h > 0$. Invoking the condition $\omega^{-d/2} \leq o(h^{-d/2})$, we derive from the above inequalities that

$$M_{\phi,\omega}(\delta/h)P_{\phi,X/\omega}(x/\omega) \leq ch^{-d/2} \exp\left(-\frac{\omega^a}{h^a}(c' - \delta^a)\right). \tag{4.3}$$

Now, in a similar fashion to the case of Example 4.1, we can choose a sufficiently small $\delta_0 > 0$ such that $c' - \delta^a > 0$ for any $\delta \leq \delta_0$. In particular, we assume ω to satisfy

$$h^a |\log h|^{1+r} \leq \omega^a$$

for any fixed $r > 0$. Then, it follows that

$$\begin{aligned}\exp\left(-\frac{\omega^a}{h^a}(c' - \delta_0^a)\right) &\leq \exp\big(-|\log h|^{1+r}(c' - \delta_0^a)\big)\\ &= h^{|\log h|^r(c'-\delta_0^a)}.\end{aligned}$$

Here, $|\log h|^r(c' - \delta_0^a)$ becomes arbitrarily large as h tends to 0. Thus, for any given $k \in \mathbb{N}$, there exists a sufficiently small $h_0 > 0$ such that $h^{|\log h|^r(c'-\delta^a)} \leq o(h^{k+d/2})$ if $h \leq h_0$. Therefore, together with (4.3), we conclude that

$$M_{\phi_\lambda,\omega}(\delta/h)P_{\phi_\lambda,X/\omega}(x/\omega) \leq o(h^k), \quad h \leq h_0.$$

According to Theorem 3.6, we have the following result.

THEOREM 4.3. *Let ϕ be the basis function whose Fourier transform $\hat{\phi}$ is defined by $\hat{\phi} = \exp(-|x|^a)$ with $a \leq 1$. Let X be a set of scattered points with the condition (3.7), and let $s_{f,X}$ in (1.6) be an interpolant to f on X using $\phi_\lambda(\cdot/\omega)$. Assume that $\omega = \omega(h)$ is chosen to satisfy the relation*

$$h|\log h|^{(1+r)/a} \leq \omega$$

with a fixed number $r > 0$. Then, for every $f \in W_\infty^k(\Omega)$ with k a positive integer, we have an error bound of the form

$$\|f - s_{f,X}\|_{L_\infty(\Omega)} = o(h^k) \quad \textit{as} \quad h \to 0.$$

COROLLARY 4.4. *Let ϕ be the function whose Fourier transform $\hat{\phi}$ is of the form $\hat{\phi} = \exp(-|x|^a)$ with $0 < a \leq 1$. Let X be a set of scattered points with the condition (3.7), and let $s_{f,X}$ in (1.6) be an interpolant to f on X using $\phi_\lambda(\cdot/\omega)$. Assume that $\omega = h^s$ with $s \in [0, 1)$ or $\omega = h|\log h|^{(1+r)/a}$ with $r > 0$. Then, for every $f \in W_\infty^k(\Omega)$ with k a positive integer,*

$$\|f - s_{f,X}\|_{L_\infty(\Omega)} = o(h^k) \quad \textit{as} \quad h \to 0.$$

Remark. The Gaussian function $\phi := \exp(-\alpha|\cdot|^2)$, $\alpha > 0$, is not included in the examples of section 4. Indeed, the "quadratic exponential" error bound $\exp(-c/h^2)$, $c > 0$, of its power function $P_{\phi,X}$ is necessary to obtain the condition

$$P_{\phi,X/\omega}(x/\omega)M_{\phi,\omega}(\delta_0/h) \leq o(h^k)$$

for some $\delta_0 > 0$. However, it is not yet proven in the bounded domain case, but it is shown only on all of $\mathbb{R}^d$ under certain circumstances. The reader is referred to the manuscript [S3] for the details. More generally, for any given basis function ϕ, there would be a general theorem on the bounds of $P_{\phi,X}$ in terms of $\hat{\phi}$. In fact, we can easily check that $P_{\phi,X}$ is dependent only on the Fourier transform $\hat{\phi}$, more precisely, on the decaying property of $\hat{\phi}$ (see [WS] and [MN2] for the details).

STABILITY OF L^∞ SOLUTIONS FOR HYPERBOLIC SYSTEMS WITH COINCIDING SHOCKS AND RAREFACTIONS*

STEFANO BIANCHINI†

Abstract. We consider a hyperbolic system of conservation laws

$$\begin{cases} u_t + f(u)_x = 0, \\ u(0, \cdot) = u_0, \end{cases}$$

where each characteristic field is either linearly degenerate or genuinely nonlinear. Under the assumption of coinciding shock and rarefaction curves and the existence of a set of Riemann coordinates w, we prove that there exists a semigroup of solutions $u(t) = \mathcal{S}_t u_0$, defined on initial data $u_0 \in L^\infty$. The semigroup $\mathcal{S}$ is continuous w.r.t. time and the initial data u_0 in the L^1_{loc} topology. Moreover, $\mathcal{S}$ is unique and its trajectories are obtained as limits of wave front tracking approximations.

Key words. hyperbolic systems, conservation laws, well posedness

AMS subject classification. 35L65

1. Introduction.

Consider the Cauchy problem for a strictly hyperbolic system of conservation laws

$$\begin{cases} u_t + f(u)_x = 0, \\ u(0, \cdot) = u_0, \end{cases} \tag{1.1}$$

where $u \in \mathbb{R}^n$ and $f : \Omega \mapsto \mathbb{R}^n$ is sufficiently smooth, Ω open. If the initial data u_0 are of small total variation, the global existence was proved first in [18]. Moreover, a series of papers [6, 7, 9, 10, 15] establishes the uniqueness and well posedness of the Cauchy problem (1.1). However, when u_0 has large total variation or, even more generically, u_0 belongs to L^∞, the solution u may not exist globally in L^∞ [20]: only for special systems it is possible to consider initial data with large total variation. We recall some of the results available in this direction.

(1) For scalar conservation laws, the entropy solution to (1.1) generates a contracting semigroup w.r.t the L^1 distance on a domain of L^∞ data [21].

(2) For a general Temple class system, in [3, 5, 24] the existence and stability of the entropy solution for initial data with arbitrarily large but bounded total variation are proved.

(3) If all characteristic families are genuinely nonlinear and the system is Temple class, the existence and stability for initial data in L^∞ are proved in [12].

(4) For special 2×2 systems, in which one of the equations is autonomous, various results have been proved in [4, 16], with initial data with unbounded total variation.

An open question is whether the semigroup of solutions to the systems of case (2), defined on all the initial data u_0 with total variation arbitrary large but bounded, can be extended to data in L^∞. In many systems, in fact, some of the characteristic fields are linearly degenerate, so that the results of [12] do not apply.

†S.I.S.S.A.-I.S.A.S., via Beirut 2-4, 34014 Trieste, Italy (bianchin@sissa.it, http://www.sissa.it/bianchin).

An example is the 2×2 traffic model considered in [2],

$$\left\{ \begin{array}{rcl} \rho_t + \big(\rho v\big)_x & = & 0, \\ \big(\rho(v+p(v))\big)_t + \big(\rho v(v+p(\rho))\big)_x & = & 0, \end{array} \right. \tag{1.2}$$

where $\rho(t,x)$ is the density of cars in the point (t,x) and $v(t,x)$ is their velocity. In this model, the first eigenvalue is genuinely nonlinear and the integral curves of the corresponding right eigenvector are straight lines. The second eigenvector is linearly degenerate, so that the assumption of coinciding shock and rarefaction curves is verified for this system. The existence of a set of Riemann coordinates follows by the fact that the system is 2×2.

Another example is a simple 2×2 model for chromatography,

$$\left\{ \begin{array}{rcl} u^1_t + \left(\dfrac{u^1}{1+u^1+u^2} \right)_x & = & 0, \\ u^2_t + \left(\dfrac{u^2}{1+u^1+u^2} \right)_x & = & 0, \end{array} \right.$$

where all characteristic fields are linearly degenerate and the integral curves of the eigenvalues are straight lines. The major difficulty here in applying the results of [12] is the fact that the total variation of the solution does not decay in time.

The aim of this paper is to prove that, at least in the case where the eigenvalues are genuinely nonlinear or linearly degenerate and shocks and rarefactions coincide, the solution to (1.1) can be defined for $u_0 \in L^\infty$.

This result is particularly interesting from the point of view of control theory. Consider for example the traffic model (1.2) in the quarter plane $t \geq 0$, $x \geq 0$: this system describes the flow of cars in a highway, given a boundary condition $\tilde{u}(t)$ on the line $x = 0$. The function $\tilde{u}$ can be thought of as a control on the system: we are allowed to choose $\tilde{u}$ in order to minimize some prescribed cost functional, for example, the average time spent by a car to arrive from $x = 0$ to $x = \bar{x}$. As shown in [1], in general the compactness of the attainable set can be obtained only with L^∞ boundary data.

To illustrate the heart of the matter, we assume that the system (1.1) admits a system of Riemann coordinates $w \in \mathbb{R}^n$, and that shock and rarefaction curves coincide in Ω. Moreover, we assume that each characteristic field is linearly degenerate or genuinely nonlinear. Differently from [11], we do not assume that rarefaction curves are straight lines. We consider a set E of the form

$$E \doteq \Big\{ u \in \Omega : \ w(u) \in [a_i, b_i], \ i = 1, \dots, n \Big\}.$$

With $L^\infty(\mathbb{R}; E)$ we denote the space of L^∞ functions with values in E. The main result of this paper is the following.

THEOREM 1.1. *There exists a unique semigroup $\mathcal{S} : [0, +\infty) \times L^\infty(\mathbb{R}; E) \longmapsto L^\infty(\mathbb{R}; E)$ such that the following properties are satisfied:*

(i) *for all $u_n, u \in L^\infty(\mathbb{R}; E)$, $t_n, t \in [0, +\infty)$, with $u_n \to u$ in L^1_{loc}, $|t - t_n| \to 0$ as $n \to +\infty$,*

$$\lim_{n \to +\infty} \mathcal{S}_{t_n} u_n = \mathcal{S}_t u \quad \textit{in } L^1_{\mathrm{loc}};$$

(ii) *the trajectory $\mathcal{S}_t u_0$ is a weak entropy solution to the Cauchy problem* (1.1) *for every $u_0 \in L^\infty(\mathbb{R}; E)$;*

(iii) *if u_0 is piecewise constant, then, for t sufficiently small, $\mathcal{S}_t u_0$ coincides with the function obtained by piecing together the solutions of the corresponding Riemann problems.*

From the results of [11, 14], any solution to (1.1) satisfying Lax entropy conditions and a weak regularity assumption is unique. Theorem 1.1 proves that it is possible to define a weak solution $u(t)$ when the initial data are in L^∞ so that $u(t)$ depends continuously w.r.t. the initial data u_0. The uniqueness follows because $\mathcal{S}$ satisfies (iii) and it is the limit of wave front approximations.

As is shown in the last example of [12], the semigroup $\mathcal{S}$ cannot be uniformly continuous; thus we cannot apply any compactness argument to construct the solution $u(t) \doteq \mathcal{S}_t u_0$. The fundamental problem is that, differently from [12], the total variation of the Riemann invariants corresponding to linearly degenerate families does not decrease in time.

The main idea of this paper is to study how the solution to the characteristic equation

$$\dot{x}(t) = \lambda_i(u(t,x(t))), \quad x(0) = y, \tag{1.3}$$

depends on the solution u of (1.1). Denote with $x(t,y)$ the solution of (1.3).

It will be shown that, for a fixed time τ, the map $y \mapsto x(\tau,y)$ depends Lipschitz continuously on the initial data u_0, and, moreover, the Lipschitz constant is independent of the total variation of u_0. Since the Riemann invariant w_i is the broad solution to

$$(w_i)_t + \lambda_i(u(t,x))(w_i)_x = 0, \tag{1.4}$$

a simple argument gives the convergence of the wave front tracking approximations. We recall that a broad solution of (1.4) with initial data $\bar{w}_i(\cdot)$ is given by $w_i(x(t,y)) = \bar{w}_i(y)$, where $x(t,x)$ is the solution to (1.3). In other words, the value of w_i is constant along the integral lines of (1.3).

We note that the stability of the map $y \mapsto x(t,y)$ implies also the well posedness of the ODE (1.3) when $u(t,x)$ is an L^∞ solution of the system (1.1). This result is quite surprising because, as noted in [16], for general hyperbolic systems the solution to (1.3) does not exist or it is not unique. In our case, the assumption on the existence of Riemann invariants and the conservation form of (1.1) implies the continuous dependence of $x(t,y)$ on the initial data u_0, and then we can extend the notion of solutions to (1.3) when u_0 is in L^∞.

The paper is organized as follows. Section 2 contains the basic assumptions on system (1.1). Moreover, we construct the wave front approximation of the solution $u(t)$. In section 3 we carefully analyze the shift differential map, i.e., the evolution of a perturbation in u_0 in which only the position of the initial jumps has changed. The method we use is essentially the one in [12], with slight modifications due to the fact that in our system the rarefaction curves do not need to be straight lines. The main result here is the explicit computation of the shift differential map.

Section 4 is concerned with the equation for characteristics (1.3). We prove the Lipschitz dependence of the map $y \mapsto x(t)$ w.r.t. both the initial data u_0 and y. Moreover, we will show that the Lipschitz constant is independent from the total variation of u_0. Finally, in section 5, we prove Theorem 1.1.

2. Basic assumptions and wave front approximations.

We consider a strictly hyperbolic system of conservation laws

$$u_t + f(u)_x = 0, \tag{2.1}$$

where $f : \Omega \to \mathbb{R}^n$ is a smooth vector field defined on some open set $\Omega \subseteq \mathbb{R}^n$. Let $A(u) \doteq Df(u)$ be the Jacobian matrix of f and denote with $\lambda_i(u)$ its eigenvalues and with $r_i(u)$, $l^i(u)$ its right and left eigenvectors, respectively. We assume that the eigenvalues λ_i can be either genuinely nonlinear or linearly degenerate. In the following the ith rarefaction curve through $u \in \Omega$ will be written as $R_i(s)u$, with $R_i(0)u = u$, while the ith shock curve will be denoted by $S_i(s)u$, and its speed by $\sigma_i(s,u)$. The directional derivative of a function $\phi(u)$ in the direction of $r_i(u)$ will be denoted as

$$r_i \bullet \phi(u) \doteq \lim_{h\to 0} \frac{\phi(u + hr_i(u)) - \phi(u)}{h},$$

while the left and right limit of a bounded variation function f in a point x will be written as

$$f(x-) = \lim_{y\to x-} f(y), \qquad f(x+) = \lim_{y\to x+} f(y).$$

We assume that the rarefaction curves R_i generate a system of Riemann coordinates $w(u)$. We recall that a necessary and sufficient condition for the local existence of Riemann coordinates is the Frobenius involutive condition: if $[X,Y]$ denotes the Lie bracket of the vector fields X,Y, the condition is

$$[r_i, r_j] \in \operatorname{span}\{r_i, r_j\} \quad \text{for all } i, j = 1, \dots, n.$$

In the following we will use indifferently the conserved coordinates u or the Riemann coordinates w.

Fix a domain

$$E \doteq \Big\{ u \in \Omega : \ w(u) \in [a_i, b_i], \ i = 1, \dots, n \Big\}. \tag{2.2}$$

Since E is compact, there is a constant $c > 0$ such that

$$r_i \bullet \lambda_i(u) > c \quad \text{for all } u \in E \quad \text{if } \lambda_i \text{ is genuinely nonlinear.} \tag{2.3}$$

We suppose that the system (2.1) is uniformly strictly hyperbolic in Ω: this means that there exists a constant d such that

$$\lambda_{i+1}(u) - \lambda_i(v) \geq d \quad \text{for all } u, v \in E, \ i = 1, \dots, n-1. \tag{2.4}$$

We also assume that in the system (2.1) shock and rarefaction curves coincide: this implies [27] that either the rarefaction curve $R_i(s)u$ is a straight line or the eigenvalue is linearly degenerate. In fact, one can prove that

$$\frac{d^2}{ds^2}\sigma_i(s,u)\bigg|_{s=0} = \frac{1}{6}(r_i \bullet \lambda_i(u))\langle l^i(u), r_i \bullet r_i(u)\rangle + \frac{1}{3} r_i \bullet (r_i \bullet \lambda_i(u)), \tag{2.5}$$

and for the shock curve $S_i(s)u$ we have

$$\langle l^j(u), S'''(0)u - R'''(0)u\rangle = \frac{1}{2(\lambda_j(u) - \lambda_i(u))}(r_i \bullet \lambda_i(u))\langle l^j(u), r_i \bullet r_i(u)\rangle. \tag{2.6}$$

If λ_i is genuinely nonlinear, the left-hand side of (2.6) is zero if and only if the rarefaction curve is a straight line, because $r_i \bullet r_i(u)$ is orthogonal to $r_i(u)$.

The flux function f thus satisfies the following assumptions:

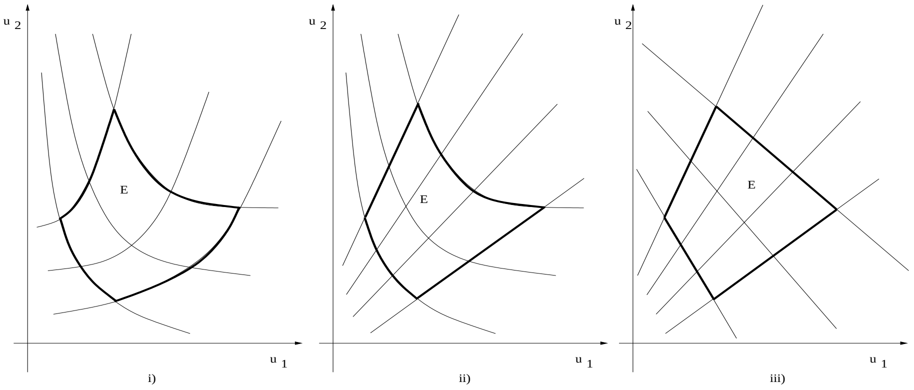

FIG. 1. *The various situations for a* 2×2 *system considered in Remark* 2.1.

(H1) the eigenvalues λ_i of Df are linearly degenerate or genuinely nonlinear;

(H2) the rarefaction curves form a system of coordinates;

(H3) shock and rarefaction curves coincide.

The system (2.1) thus has n_{ld} linearly degenerate fields λ_i, corresponding to the Riemann invariants w_i, and $n_{gnl} = n - n_{ld}$ genuinely nonlinear fields λ_k, corresponding to the Riemann invariants w_k. In the latter case we have $r_k \bullet r_k(u) = 0$ for all $u \in E$.

REMARK 2.1. *If* $\Omega \subseteq \mathbb{R}^2$*, then the rarefaction curves* $R_i(s)u$ *always generate a system of Riemann coordinates. Thus our assumptions are satisfied by the following classes of systems:*

(i) *both eigenvalues are linearly degenerate;*

(ii) *one eigenvalue is linearly degenerate, the other genuinely nonlinear, and the rarefaction curves of the latter are straight lines;*

(iii) *both eigenvalues are genuinely nonlinear and the system is of Temple class.*

The various situations are shown in Figure 1. *Case* (ii) *corresponds to the traffic model considered in* [2]*, while case* (i) *corresponds to* 2×2 *chromatography.*

Given the two points $u^-, u^+ \in E$, with coordinates $u^- = u(w_1^-, \dots, w_n^-)$ and $u^+ = u(w_1^+, \dots, w_n^+)$, with $w_i^+ \neq w_i^-$, consider the intermediate states $u(\omega_i)$, where

$$\omega_0 = w(u^-), \quad \omega_i = (w_1^+, \dots, w_i^+, w_{i+1}^-, \dots, w_n^-), \quad i = 1, \dots, n. \tag{2.7}$$

For all $i = 1, \dots, n$, we denote with $v_i(u^-, u^+)$ the vectors defined as

$$v_i(u^-, u^+) = u(\omega_i) - u(\omega_{i-1}), \tag{2.8}$$

and we define $r_i(u^-, u^+)$ as

$$r_i(u^-, u^+) = \begin{cases} \dfrac{v_i(u^-, u^+)}{|v_i(u^-, u^+)|} = \dfrac{u(\omega_i) - u(\omega_{i-1})}{|u(\omega_i) - u(\omega_{i-1})|} & \text{if } w_i^- \neq w_i^+, \\ r_i(\omega_{i-1}) = r_i(\omega_i) & \text{if } w_i^- = w_i^+, \end{cases} \tag{2.9}$$

where $r_i(u)$ is the ith eigenvector of $DF(u)$. We assume that the vectors $r_i(u^-, u^+)$ are linearly independent for all $u^-, u^+ \in E$. This condition is satisfied for data in a sufficiently small neighborhood of a given point $\bar{u} \in \Omega$. We denote also with $\{l^i(u^-, u^+), i = 1, \dots, n\}$ the dual base.

We now define an approximated semigroup of solutions $\mathcal{S}^\nu$ on a set $E^\nu \subseteq E$. The construction is similar to the one in [3]. For any integer $\nu \in \mathbb{N}$, set

$$E^\nu \doteq \Big\{ u \in E : w_i(u) \in 2^{-\nu}\mathbb{Z}, i = 1, \dots, n \Big\}, \tag{2.10}$$

and let $D^{\nu,M}$ be the domain defined as

$$(2.11)\quad D^{\nu,M} \doteq \Big\{ u : \mathbb{R} \longmapsto E^\nu : u \text{ piecewise constant and Tot.Var.}(u) \leq M \Big\}.$$

Given $\bar{u} \in E^\nu$, we construct a solution $u(t)$ by wave front tracking. We first define how to solve the Riemann problem $[u^-, u^+]$, with $u^-, u^+ \in E^\nu$.

The solution to the Riemann problem u^-, u^+ is constructed by piecing together the solutions to the simple Riemann problems $[\omega_{i-1}, \omega_i]$, where ω_i is defined in (2.7). If the ith field is linearly degenerate, then $[\omega_{i-1}, \omega_i]$ is solved by a contact discontinuity traveling with speed $\lambda_i(\omega_i)$. If the ith field is genuinely nonlinear and $w_i^+ < w_i^-$, then $[\omega_{i-1}, \omega_i]$ is solved by a shock traveling with the Rankine–Hugoniot speed $\sigma_i(\omega_{i-1}, \omega_i)$. Finally, if the ith field is genuinely nonlinear and $w_i^+ > w_i^-$, then $[\omega_{i-1}, \omega_i]$ is solved by a rarefaction fan: if $w_i^+ = w_i^- + p_i 2^{-\nu}$, $p_i \in \mathbb{N}$, consider the states

$$\omega_{i,0} = \omega_{i-1}, \quad \omega_{i,l} = (w_1^+, \dots, w_{i-1}^+, w_i^- + \ell 2^{-\nu}, w_{i+1}^-, \dots, w_n^-), \quad \ell = 1, \dots, p_i.$$

The solution will consist of p_i shock waves $[\omega_{i,l-1}, \omega_{i,l}]$, traveling with the corresponding shock speed $\sigma_i(\omega_{i,l-1}, \omega_{i,l})$.

At time $t = 0$ we solve the initial Riemann problems of $\bar{u}$. Note that the number of wave fronts is bounded by $2^\nu \cdot \text{Tot.Var.}(\bar{u})$. When two or more fronts interact, we again solve the Riemann problem they generate, and so on. It is easy to show that at each interaction at least one of the following alternatives holds:

(i) the number of waves decreases at least by 1;

(ii) the total variation of the solution $u(t)$ decreases by $2^{1-\nu}$;

(iii) the interaction potential $Q(t)$, defined as

$$(2.12)\qquad Q(t) \doteq \sum_{\alpha,\beta \text{ approaching}} |\sigma_\alpha||\sigma_\beta| \leq M^2,$$

decreases by $2^{-\nu}$. We recall that two waves σ_α, σ_β of the families k_α, k_β, located at points x_α, X_β, are considered as *approaching* if $x_\alpha < x_\beta$ and $k_\alpha > k_\beta$.

This implies that there are at most a finite number of interactions, so that we can construct our approximate solution for all $t \geq 0$. Note that $\mathcal{S}_t^\nu u = u(t)$ is a semigroup of solutions, but not entropic due to the presence of rarefaction fronts.

If the ith family is linearly degenerate, the ith Riemann coordinate $w_i(t, \cdot)$ of the solution can be constructed by solving the semilinear system

$$(2.13)\qquad \begin{cases} (w_i)_t + \lambda_i(u(t,x))(w_i)_x = 0, \\ \qquad w_i(0,x) = w_{i,0}(x). \end{cases}$$

Since u is a piecewise constant solution, with a finite number of jumps, the broad solution to (2.13) is well defined [8]: If we denote with $x(t,y)$ the solution to the ODE

$$(2.14)\qquad \dot{x} = \lambda_i(u(t,x)), \qquad x(0) = y,$$

then the solution to (2.13) is given by

$$(2.15)\qquad w_i(t, x(t,y)) = w_{i,0}(y).$$

In the following sections we will consider the dependence on the initial data u_0 of the genuinely nonlinear Riemann coordinates $w_k(t, \cdot)$ and the map $h_i^t(y)$ defined as

$$(2.16)\qquad h_i^t(y) \doteq x_i(t,y),$$

where $x_i(t,y)$ is the solution to (2.14).

3. Estimates on the shift differential map. In this section we prove some properties of the shift differential map. These properties are closely related to the structure of (2.1), i.e., the conservation form, the coinciding shock and rarefaction assumption, which prevents the creation of shock when two jumps of the same family collide, and the existence of Riemann invariants, which prevents the creation of shock when two jumps of different families interact.

Consider a wave front solution $u(t, \cdot)$ of (2.1), and assume that the initial datum $u(0, \cdot)$ has a finite number N of jumps σ_α, located in y_α:

$$u(0,x) = \sum_{\alpha=1}^{N} \sigma_\alpha \chi_{[y_\alpha,+\infty)}(x).$$

If ξ_α is the shift rate of the jump σ_α, define $u^\theta(t, \cdot)$ as the front tracking solution with initial datum

$$u^\theta(0,x) = \sum_{\alpha=1}^{N} \sigma_\alpha \chi_{[y_\alpha+\theta\xi_\alpha,+\infty)}(x). \tag{3.1}$$

In the following, we will use the integral shift function, defined by

$$v(t,x) \doteq \lim_{\theta\to 0} \left\{ -\frac{1}{\theta} \int_{-\infty}^{x} u^\theta(t,y) - u(t,y)dy \right\}. \tag{3.2}$$

If $u(t, \cdot)$ has a shock σ_β, located in y_β, and if ξ_β is its shift rate, it is clear that the following relation holds:

$$\sigma_\beta \xi_\beta = v(t, y_\beta+) - v(t, y_\beta-). \tag{3.3}$$

We first recall the following result in [12], obtained using the conservation form of the equations.

LEMMA 3.1. *Consider a bounded, open region Γ in the t-x plane. Call σ_α, $\alpha = 1, \ldots, N$, the fronts entering Γ, and let ξ_α be their shifts. Assume that the fronts leaving Γ, say σ'_β, $\beta = 1, \ldots, N'$, are linearly independent. Then their shifts ξ'_β are uniquely determined by the linear relation*

$$\sum_{\beta=1}^{N'} \xi'_\beta \sigma'_\beta = \sum_{\alpha=1}^{N} \xi_\alpha \sigma_\alpha. \tag{3.4}$$

REMARK 3.2. *As observed in* [12], (3.4) *implies that the shift rates of the outgoing fronts depend only on the shift rates of the incoming ones, and not on the order in which these wave fronts interact inside Γ. In particular, we can perform the following operations, without changing the shift rates of the outgoing fronts:*

(O1) *switch the order of which three or more fronts interact;*

(O2) *invert the order of two fronts at time 0, if they have zero shift rate.*

The second lemma is concerned with a configuration where a sequence of contact discontinuities interacts with a wave of another family.

LEMMA 3.3. *Consider a family of parallel contact discontinuities σ_α of the ith linearly degenerate family, $\alpha = 1, \ldots, N$, and a single wave front σ of the kth family, $k \neq i$. Let ξ_α and ξ be their initial shifts, respectively, and let ξ'_α, ξ' be their shifts*

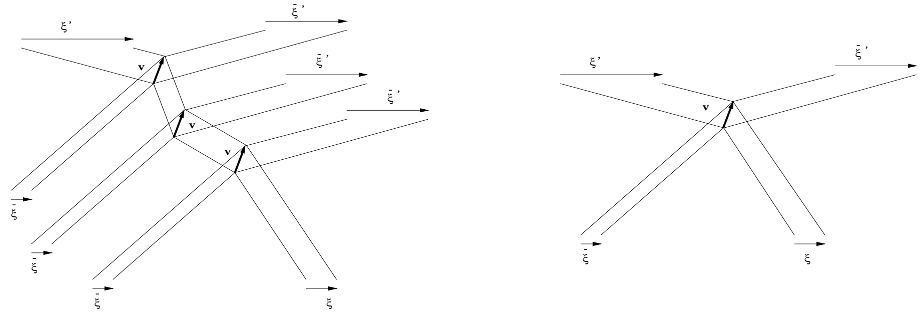

FIG. 2. *Interaction with a sheaf of contact discontinuities.*

after interaction. Assume that $\xi_\alpha = \bar\xi$ for all α. Then after the interactions all the shift rates ξ'_α of the ith family have the same value $\bar\xi'$ and

$$\xi'_\alpha = \bar\xi' = \frac{\bar\xi(\bar\Lambda' - \Lambda) - \xi(\bar\Lambda' - \bar\Lambda)}{\Lambda - \bar\Lambda}, \qquad \xi' = \frac{\bar\xi(\Lambda' - \Lambda) - \xi(\bar\Lambda' - \bar\Lambda)}{\Lambda - \bar\Lambda}, \tag{3.5}$$

where $\bar\Lambda$, Λ and $\bar\Lambda'$, Λ' are the speeds of the shocks σ_α and σ before and after interaction, respectively.

Proof. Define the vector $\mathbf{v}$ in the t-x plane as the shift of the first collision point. By a direct computation one finds

$$\mathbf{v} = \left(\frac{\xi - \bar\xi}{\bar\Lambda - \Lambda}, \frac{\bar\Lambda\xi - \Lambda\bar\xi}{\bar\Lambda - \Lambda} \right). \tag{3.6}$$

Since all the incoming shocks of the linearly degenerate family have the same speed $\bar\Lambda$, by simple geometrical considerations it follows that the vector $\mathbf{v}$ is constant during all interactions (Figure 2). Formula (3.5) follows easily. □

REMARK 3.4. *Note that this lemma allows us to perform the following new operation, without changing the shift rates:*

(O3) *replace a family of contact discontinuities σ_α of a linearly degenerate family, all with the same shift rate $\bar\xi$, by a single wave $\sigma = \sum \sigma_\alpha$ with shift rate $\bar\xi$.*

In the next lemma we will show that the existence of Riemann coordinates w implies a strong relation among shocks of different families.

LEMMA 3.5. *Consider two adjacent jumps belonging to different families, σ_i and σ_j, $i < j$, located at $x_i > x_j$. Let σ'_i, σ'_j be their strength after interaction. Then the following holds:*

$$\operatorname{span}\{\sigma_i, \sigma_j\} = \operatorname{span}\{\sigma'_i, \sigma'_j\}. \tag{3.7}$$

Proof. If ξ_i, ξ_j are the shift rates before interaction, and ξ'_i, ξ'_j after interaction, then (3.7) follows easily from the conservation relation

$$\sigma_i\xi_i + \sigma_j\xi_j = \sigma'_i\xi'_i + \sigma'_j\xi'_j \qquad \text{for all } \xi_i, \xi_j \in \mathbb{R}, \tag{3.8}$$

because, by assumption, no waves of other families are generated. □

REMARK 3.6. *Note that the previous lemma implies that the conservation relation (3.8) is bidimensional, i.e., the shocks σ_i, σ_j and σ'_i, σ'_j lie on a two dimensional*

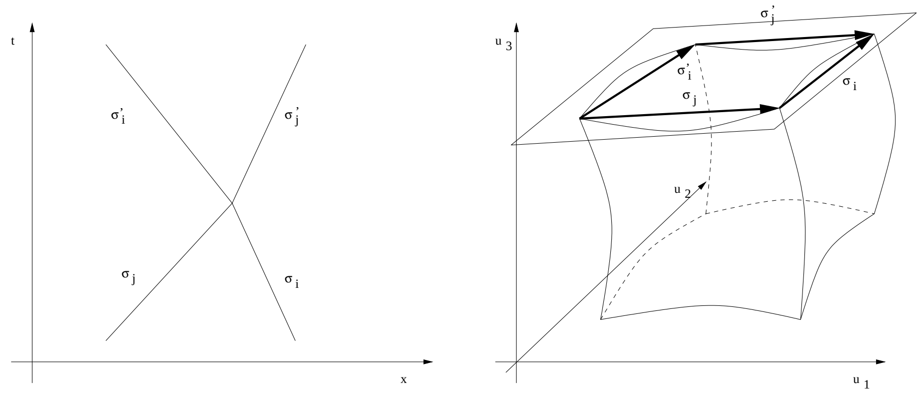

FIG. 3. *Vector relations among shocks.*

plane (Figure 3*). We can then obtain an identity which relates the strengths σ with the speeds Λ: substituting* (3.5) *into* (3.8)*, since $\bar{\xi}$, ξ are arbitrary, we get*

$$\begin{aligned} \sigma_i(\Lambda_j - \Lambda_i) &= \sigma'_i(\Lambda'_i - \Lambda_j) + \sigma'_j(\Lambda'_j - \Lambda_j), \\ \sigma_j(\Lambda_i - \Lambda_j) &= \sigma'_i(\Lambda'_i - \Lambda_i) + \sigma'_j(\Lambda'_j - \Lambda_i). \end{aligned} \tag{3.9}$$

One can show that if a Riemann solver verifies (3.9) *for all pairs of waves i, j, then there exists a flux function f such that the wave front approximation is a weak solution to* (2.1).

An important property of the shift differential map for Temple class systems is the fact that a perturbation to the initial data, initially localized in $[a, b]$, remains in the neighborhood of the set $\cup_i[x_i(t, a), x_i(t, b)]$, where $x_i(t, y)$ is the solution of the ith characteristic equation starting at y. We now extend this property to hyperbolic systems satisfying the hypotheses (H1), (H2), (H3) of section 2.

Consider N jumps σ_α, $\alpha = 1, \dots, N$, of some linearly degenerate family i, located at x_α and corresponding to the jumps $c(\alpha)e_i$ in the Riemann coordinates w:

$$\sigma_\alpha = u(w(x_\alpha-) + c(\alpha)e_i) - u(w(x_\alpha-)) \tag{3.10}$$

for some constants $c(\alpha)$, $\alpha = 1, \dots, N$.

DEFINITION 3.7. *We say that the jumps σ_α defined in* (3.10) *are in involution if*

$$\sum_{\alpha=1}^{N} c(\alpha) = 0, \tag{3.11}$$

i.e., the initial and final Riemann coordinate w_i is the same: $w_i(x_1-) = w_i(x_N+)$.

Note that, by the existence of Riemann coordinates, this relation does not depend on the positions and strength of the shocks of the other families. We can now extend Lemma 2 in [12] to our systems.

LEMMA 3.8. *Consider a wave front tracking solution u. Assume that there are N shocks σ_α either*

(i) *of the ith linearly degenerate family in involution, or*

(ii) *of the kth genuinely nonlinear family,*

and let $x_\alpha(t)$, $0 \leq t \leq T$, be the position of the shock σ_α, $\alpha = 1, \dots, N$. Then it is possible to assign at time $t = 0$ shift rates to all shocks such that $\xi_1 = 1$ and the shift of all fronts outside the strip $\Gamma \doteq \{(t, x); t \in [0, T], x_1(t) \leq x \leq x_N(t)\}$ is zero.

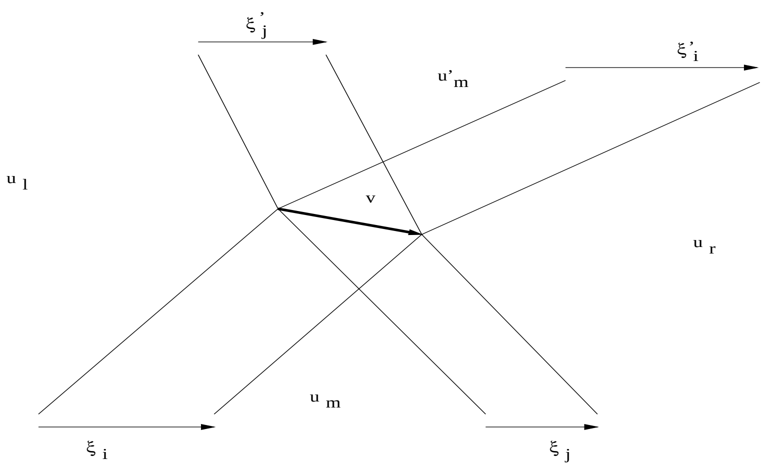

FIG. 4. *Computation of the shift rate.*

Proof. We consider only the case of linearly degenerate family i, since in the other case the proof is exactly the one given in [12].

Let $x_\alpha(t)$, $\alpha = 1, \dots, N$, be the position of the shock σ_α of the ith family in involution, and let $\bar{w}_i$ be the value of the Riemann coordinate at $x_1(t)- = x_1(0)-$. For $w \in E$, define $\tilde{w}$ as the projection of w on the hyperplane $\{w_i = \bar{w}_i\}$, and $\tilde{u} = u(\tilde{w})$.

We choose the shift rates such that

$$-\frac{d}{d\theta} \int_{-\infty}^{x} u^\theta dy = \sum_{x_i(t) \leq x} \xi_i(t)\sigma_i(t) = c(t,x)(u(t,x) - \tilde{u}(t,x)), \tag{3.12}$$

where $c(t,x)$ is a scalar function different from 0 only in $[x_1(t), x_N(t)]$, and we recall that $\tilde{u}(t,x) = u(\tilde{w}(t,x))$.

By imposing the value $\xi_1 = 1$, i.e., $c(0, x_1(0)-) = 0$, $c(0, x_1(0)+) = 1$, we need to prove that (3.12) can be satisfied at time $t = 0$. We have two cases.

(1) If the jump σ_i belongs to the ith family and is inside $[x_0(0), x_N(0)]$, then set $\xi = c(t, x_i-)$.

(2) If the jump σ_i belong to the kth family with $k \neq i$, then by assumption (2.8) and by (3.7) there exists a unique shift ξ_i and a unique constant $c(0,x+)$ such that

$$\xi_i\sigma_i + c(0,x-)(u(0,x-) - \tilde{u}(0,x-)) = c(0,x+)(u(0,x+) - \tilde{u}(0,x)).$$

Since we assume that the shocks are in involution, setting $\xi_N = c(0, x_n-)$ we have that (3.12) holds at time $t = 0$: in fact, the last jump has size $\tilde{u}(0, x_N(0)-) - u(0, x_N(0)-)$.

We now show that this property is conserved for all $t \geq 0$. This follows easily from conservation and Lemma 3.5. The proof is exactly the same as in [12]; we repeat it for completeness. Consider the interaction between two shocks σ_i and σ_j in the point (τ, y); see Figure 4. By inductive assumption, we have for the states u_l, u_m, and u_l that

$$\sum_{x_\gamma(\tau) < y} \sigma_\gamma(\tau)\xi_\gamma(\tau) = c_l(u_l - \tilde{u}_l), \tag{3.13}$$

$$c_l(u_l - \tilde{u}_l) + \sigma_i \xi_i = c_m(u_m - \tilde{u}_m),$$
$$c_m(u_m - \tilde{u}_m) + \sigma_j \xi_j = c_r(u_r - \tilde{u}_r).$$

Using conservation we have

$$\xi_i \sigma_i + \xi_j \sigma_j = \xi_j' \sigma_j' + \xi_i' \sigma_i', \tag{3.14}$$

so that for the new middle state u_m' we have

$$c_l(u_l - \tilde{u}_l) + \sigma_j' \xi_j' = c_m'(u_m' - \tilde{u}_m') = c_r(u_r - \tilde{u}_r) - \sigma_i' \xi_i', \tag{3.15}$$

and using Lemma 3.5 we conclude

$$\operatorname{span}\Big\{u_l - \tilde{u}_l, \sigma_j'\Big\} \bigcap \operatorname{span}\Big\{u_r - \tilde{u}_r, \sigma_i'\Big\} = \operatorname{span}\{u_m - \tilde{u}_m'\}.$$

The same relation proves that they vanish outside Γ. In fact, assume for example that $c_l = 0$ and $j < i$. Then from (3.15) we get

$$\sigma_j' \xi_j' = c_m'(u_m' - \tilde{u}_m'),$$

which implies that $c_m' = 0$. This concludes the proof. □

REMARK 3.9. *Note that for discontinuities of a linearly degenerate family all shift rates have the same sign. Note, moreover, that if no waves of other families are present, then we shift all jumps σ_α by unit rate* 1. *This corresponds to the case considered in Lemma* 3.3*, i.e., to the substitution of a family of contact discontinuities with a single jump, whose strength in this case is* 0 *by the involution assumption.*

Using conservation and the previous lemmas, we obtain explicitly the shift differential map at a given time τ. We recall that, given the states $u^-, u^+ \in E$, we denote with $r_i(u^-, u^+)$ the vectors defined in (2.9), and with $l^i(u^-, u^+)$ its dual base. Let $P_j(u^-, u^+)$ be the projection operator on $\operatorname{span}\{r_i(u^-, u^+), i = 1, \dots, j\}$:

$$P_j(u^-, u^+) v \doteq \sum_{i=1}^{j} \langle l^i(u^-, u^+), v \rangle r_i(u^-, u^+), \tag{3.16}$$

where $\langle \cdot, \cdot \rangle$ denotes the scalar product in $\mathbb{R}^n$.

Given a point (t, x), with $u(t, x)$ continuous in x, define x_i to be the intersection of the backward ith characteristics starting at (t, x) with the real axis $\{(0, x)\}$, and for all $(0, y)$ let $j(y)$ be the index such that $x_{j(y)} \le y < x_{j(y)-1}$, $j(y) = 1, \dots, n+1$, with $x_0 = +\infty$ and $x_{n+1} = -\infty$. Without any loss of generality, we can assume that in $(0, y)$ there is a jump σ of the kth family.

Define the points $w_l, w_r \in E$ by

$$\begin{aligned} &w_l(x,y) \\ &\doteq \begin{cases} w(t,x), & j(y) = 1, \\ (w_1(0,y-), \dots, w_{j(y)-1}(0,y-), w_{j(y)}(t,x), \dots, w_n(t,x)), & 2 \le j(y) \le n, \\ w(0,y-), & j(y) = n+1, \end{cases} \\ &w_r(x,y) \\ &\doteq \begin{cases} w(0,y+), & j(y) = 1, \\ (w_1(t,x), \dots, w_{j(y)-1}(t,x), w_{j(y)}(0,y+), \dots, w_n(0,y+)), & 2 \le j(y) \le n, \\ w(t,x), & j(y) = n+1. \end{cases} \end{aligned} \tag{3.17}$$

Moreover, for $2 \leq j(y) \leq n$, define the point $w_m \in E$ by

$$\begin{aligned}(3.18)\quad & w_m(x,y) \\ & \doteq (w_1(t,x), \dots, w_k(0,y+), \dots, w_{j(y)-1}(t,x), w_{j(y)}(0,y+), \dots, w_n(0,y+))\end{aligned}$$

if $k < j(y)$. In a similar way, if $k \geq j(y)$,

$$\begin{aligned}(3.19)\quad & w_m(x,y) \\ & \doteq (w_1(t,x), \dots, w_{j(y)-1}(t,x), w_{j(y)}(0,y+), \dots, w_k(0,y-), \dots, w_n(0,y+)).\end{aligned}$$

Define $P(x,y)$ as the vector

$$(3.20)\qquad P(x,y) \doteq \begin{cases} 0, & j(y) = 1, \\ P_{j(y)-1}(w_l, w_m)\sigma + P_{j(y)-1}(w_m, w_r)\big(\sigma - P_{j(y)-1}(w_l, w_m)\sigma\big), & \\ \qquad 2 \leq j(y) \leq n+1, k < j(y), & \\ P_{j(y)-1}(w_l, w_m)\big(P_{j(y)-1}(w_m, w_r)\sigma\big), & 2 \leq j(y) \leq n, k \geq j(y), \end{cases}$$

where $w_l = w_l(x,y)$, $w_m = w_m(x,y)$, $w_r = w_r(x,y)$, and σ is the initial jump in $(0,y)$. Consider now a front tracking solution u^θ, obtained by shifting the initial jumps σ_α in y_α with rates ξ_α.

THEOREM 3.10. *If $v(t,x)$ is the integral shift function of $u^\theta(t,\cdot)$, defined in* (3.2), *then*

$$(3.21)\qquad v(t,x) = \lim_{\theta \to 0} \left\{ -\frac{1}{\theta} \int_{-\infty}^{x} u^\theta(t,y) - u(t,y) dy \right\} = \sum_\alpha P(x, y_\alpha)\xi_\alpha.$$

Proof. The theorem will be proved outside the times of interaction, because the Lipschitz dependence in L^1 of the approximate semigroup implies the validity of (3.21) for all $t \geq 0$.

If is sufficient to show that $\sum_{y_\alpha} P(x, y_\alpha)\xi_\alpha$ is piecewise constant, with jumps only at the points x_β where $u(t,\cdot)$ has a shock σ_β, and the following relation holds:

$$(3.22)\ \sum_{y_\alpha} \big(P(x_\beta+, y_\alpha) - P(x_\beta-, y_\alpha)\big)\xi_\alpha = \sigma_\beta \xi_\beta, \qquad \lim_{x \to -\infty} \sum_{y_\alpha} P(x, y_\alpha)\xi_\alpha = 0,$$

where ξ_β is the shift rate of σ_β, located in x. Note that by (3.20) the second equality of (3.22) is trivially satisfied.

By linearity in the shift rates ξ_α, we can consider the case in which a single shock is shifted, let us say σ at y; (3.21) becomes

$$(3.23)\qquad v(t,x) = P(x,y)\xi.$$

Formula (3.16) follows from the following considerations: Consider a wave front pattern, Figure 5, where for simplicity we assume that $k < j(y)$. The states w_l, w_m are computed considering the Riemann problem generated by adding to the k-jump σ in $(0,y)$ all the i-waves starting from the left of $(0,y)$ and ending in the right of (t,x) and all the i-waves, with $i \neq k$, starting from the right of $(0,y)$ and ending in the left of (t,x). The jump w_m, w_r is a single wave of the kth family formed by adding all the k-waves between $(0,y)$ and (t,x). Using the definition of $v(t,x)$ given (3.2), one obtains easily the second case of (3.20). In fact

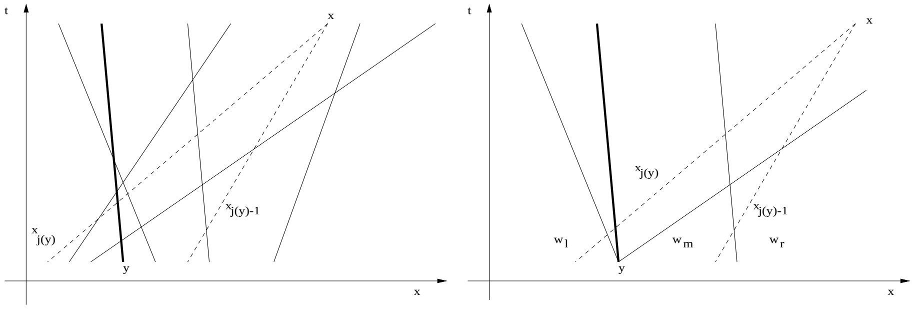

FIG. 5. *Wave pattern for the computation of formula* (3.16).

the shift rates of the shocks in the left of (t, x) are given by the shift rates of the jumps of the Riemann problem w_l, w_m ending in the left of (t, x), $P_{j(y)-1}(w_l, w_m)\sigma$, plus the shift rate of the shock w_m, w_r, $P_k(w_m, w_r)(\sigma - P_{j(y)-1}(w_l, w_m)\sigma)$. Since only the i-waves with $i \geq j(y) > k$ are present in $\sigma - P_{j(y)-1}(w_l, w_m)\sigma$, then $P_k(w_m, w_r)(\sigma - P_{j(y)-1}(w_l, w_m)\sigma) = P_{j(y)-1}(w_m, w_r)(\sigma - P_{j(y)-1}(w_l, w_m)\sigma)$. The other cases can be computed in a similar way: in this case one solves the Riemann problem w_m, w_r in $(0, y)$ and considers the k-wave w_l, w_m starting in the left of $(0, y)$ and ending in the right of (t, x).

From the above considerations, it is clear that $P(x, y)$ is piecewise constant with jumps only when there is an i-shock σ' in (t, x). In fact, otherwise, the wave front pattern used to compute $P(x, y)$ remains the same. Let $\{z_p : p = 1, \dots, M\}$ be the set of the starting points of all shocks arriving in (t, x), and define

$$z^- = \min_p z_p, \qquad z^+ = \max_p z_p. \tag{3.24}$$

We consider two cases:

(1) The shocks arriving in (t, x) start on both sides of $(0, y)$: $z^- \leq y \leq z^+$. In this case, $(P(x+, y) - P(x-, y))\xi$ is the shift rate of the i-shock starting in the Riemann problem $w_l(x-, y), w_m(x+, y)$ if $i > k$ ($w_m(x-, y), w_r(x+, y)$ if $i < k$), which collides with a k-shock $w_m(x+, y), w_r(x+, y)$ (w_l, w_m if $i < k$). In fact, the only difference is that in $w_m(x-, y), w_m(x+, y)$ there is a shock of the ith family starting in $(0, y)$, and i is genuinely nonlinear. Finally, using $r_i \bullet r_i(u) = 0$ and Lemma 3.5, one can change position to the i-wave and the remaining k-wave w_m, w_r, whose strength does not change.
If $i = k$, there are no k-shocks starting on the right (left) of $(0, y)$ and ending on the right (left) of (t, x), so that $(P(x+, y) - P(x-, y))\xi$ is the shift rate of the i-shock of the Riemann problem $w_l(x-, y), w_r(x+, y)$.

(2) The shocks of the ith family arriving in (t, x) start either in $(-\infty, y)$ or $(y, +\infty)$. Assume for definiteness that $y < z^-$. In this case the difference $(P(x+, y) - P(x-, y))\xi$ is the shift rate of the shock σ' colliding with the shifted shocks of the Riemann problem $w_l(x-, y), w_m(x-, y)$ in $(0, y)$, crossing the jump $w_m(x-, y), w_r(x-, y)$, and finally overtaking σ'. In fact one can use Lemma 3.5 (and $r_i \bullet r_i(u) = 0$ if i is genuinely nonlinear) to obtain the wave pattern of Figure 6.

The various cases will be proved in the following lemmas.

LEMMA 3.11. *Assume that $z^- \leq y \leq z^+$, i.e., case* (1). *If the shock σ' is of the*

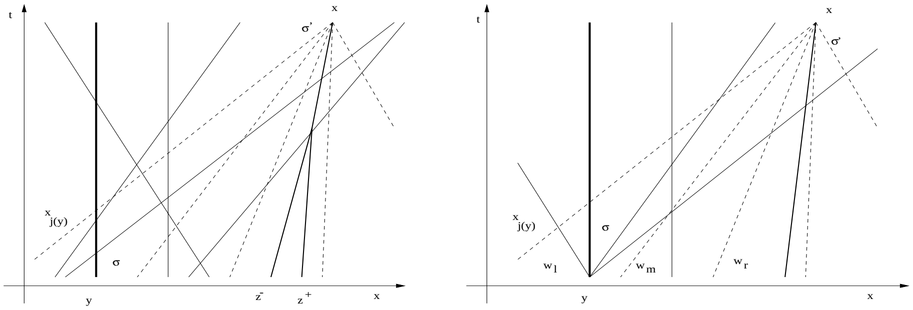

FIG. 6. *Computation of the shift rate in the case of Lemma* 3.12.

ith family, then its shift ξ' is

$$\xi'\sigma' = \big(P(x+,y) - P(x-,y)\big)\xi. \tag{3.25}$$

Proof. We follow closely the method of [12]. Assume for definiteness $k < j(y)$, the other cases being similar. The basic idea is to reduce the computation to the single Riemann problem $w_l(x-,y), w_m(x+,y)$, with eventually a single k-wave w_m, w_r.

Consider Figure 7. By Lemma 3.1, we can simplify the wave configuration considering only the fronts crossing starting in the right of $(0,y)$ and ending in the left of (t,x). In fact we can move the other fronts to $\pm\infty$ without changing the shift rate of σ'.

We can now shift the initial position of the waves of the ith family merging in x such that their initial position coincides with y, without changing the shift rate ξ'. This operation can be repeated for all shocks of genuinely nonlinear families.

Finally, we can move the shocks of the linearly degenerate families such that they have the same sequence of interaction with the other shocks. This means that, if x_i^j is the position of the jth shock of the ith linearly degenerate family, the only interactions among shocks occurring in the sector $[x_i^1(t), x_i^n(t)]$ are those involving one ith wave and one kth wave, with $k \neq i$. Using Lemma 3.3, we can at this point substitute them with a single shock, whose strength is the sum of the strengths of the i-waves. Finally we move their position at $t = 0$ such that it coincides with y; we obtain the wave patterns of Figure 7. To conclude, we just need to prove that the Riemann problem obtained in this way is exactly $w_l(x-,y), w_m(x+,y)$ and that the remaining k-wave is $w_m(x+,y), w_r(x+,y)$.

By the previous argument, the strength of the shock of the jth family, $j < i$, $j \neq k$, is given by the j-waves starting in the right of y and ending in the left of x. Since they are the only j-wave crossing the segment $[(0,y-),(t,x+)]$, it follows that

$$w_{l,j}(x,y) = w_j(0,y-), \qquad w_{r,j}(x,y) = w_j(t,x+).$$

The other relations for $j = k$ and $j > i$ follow in the same way. Finally, for $j = i$ the jump is $w_i(t,x+) - w_i(t,x-)$. Note that the wave pattern is the same as that obtained in case (1). □

We consider only the case $y < z^-$, since the other is entirely similar.

LEMMA 3.12. *Assume that $y < z^-$. Then the shift ξ' of σ' is given by*

$$\xi'\sigma' = \big(P(x+,y) - P(x-,y)\big)\xi. \tag{3.26}$$

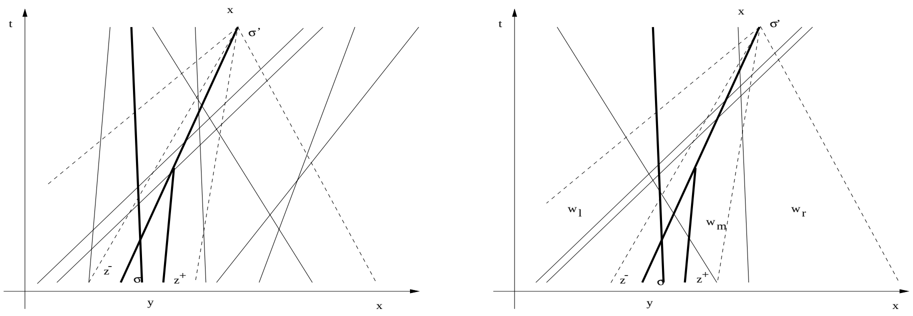

FIG. 7. *Computation of the shift rate in the case of Lemma* 3.11.

Proof. The hypothesis implies that the ith shock ending at x starts in the right of y. With the same simplification considered in Lemma 3.11, we reduce to the Riemann problem $w_l(x,y), w_r(x,y)$ in $\bar{y}$, such that the waves of the jth families, $j > i$, generated at $\bar{y}$ collide with the i-wave in x_α (see Figure 6) after overtaking the k-wave w_m, w_r. The conclusion follows easily, since the wave pattern is the same as that considered in (2). □

This concludes the proof of Theorem 3.10. □

Finally we extend to our case the following result proved in [12].

PROPOSITION 3.13. *Let u be a wave front tracking solution, and consider two wave fronts, $x(t)$ and $y(t)$, $t \in [0,T]$. Then there exists a second front tracking solution $\tilde{u}$ such that the initial and final positions of the two shocks are the same, and* Tot.Var.$(\tilde{u})$ *is uniformly bounded.*

Proof. For genuinely nonlinear fields, the proof is the same as in [12]. We then restrict the proof to the case of linearly degenerate fields i.

Assume that there exist two jumps σ_1, σ_2 of the ith family, with positions $z_1(t) < z_2(t)$, such that

$$\begin{aligned} x(0) \notin [z_1(0), z_2(0)] \text{ and } y(0) \notin [z_1(0), z_2(0)], \\ x(T) \notin [z_1(T), z_2(T)] \text{ and } y(T) \notin [z_1(T), z_2(T)]. \end{aligned} \tag{3.27}$$

For definiteness, assume $w_i(0, z_1-) < w_i(0, z_1+)$, and the following condition is satisfied:

$$w_i(0, z_1-) \in [w_i(0, z_2-), w(0, z_2+)]. \tag{3.28}$$

Let σ_α, $\alpha = 1, \dots, N$, be the jumps of linearly degenerate family i in the strip $[z_1(0), z_2(0))$. If we define

$$\sigma_{N+1} = u(w_i(0, z_1-)) - u(w_i(0, z_2-)),$$

it is easy to verify that the shocks σ_α, $\alpha = 1, \dots, N+1$, are in involution. By Lemma 3.8, we can then move the jumps to the left until either $z_1(t)$ meets the wave fronts $x(t)$, or $z_1(t)$ coincides with another shock of the ith family (Figure 8). It is clear that we can repeat the same procedure also in the following cases:

(i) $w_i(0, z_1-) > w_i(0, z_1+)$ and $w_i(0, z_1-) \in [w_i(0, z_2+), w(0, z_2-)]$;

(ii) $w_i(0, z_2-) < w_i(0, z_2+)$ and $w_i(0, z_2+) \in [w_i(0, z_1+), w(0, z_1-)]$;

(iii) $w_i(0, z_2-) > w_i(0, z_2+)$ and $w_i(0, z_2+) \in [w_i(0, z_1-), w(0, z_1+)]$.

It is now easy to prove that the total variation of the jumps of the ith family satisfying (3.27) can be at most $3\|w\|_\infty$. Since $x(t)$, $y(t)$ divide the lines $t = 0$ and $t = \tau$ in three regions, the total variation of w_i is bounded by $27\|w\|_\infty$. □

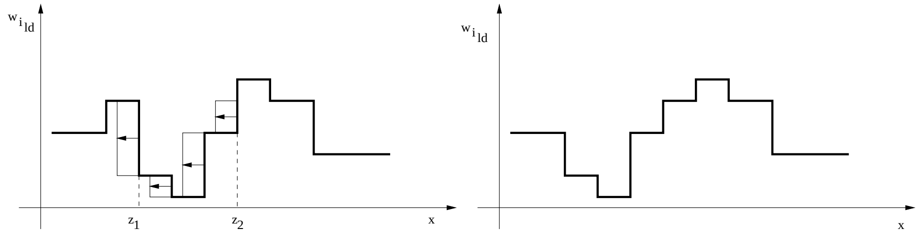

FIG. 8. *Cancellation among contact discontinuities.*

4. Estimates on characteristics. In this section we prove some estimates on the solution $x_i(t,y)$ of the characteristic equation

$$\begin{cases} \dot{x}_i = \lambda_i(u(t,x_i)), \\ x_i(0) = y. \end{cases} \tag{4.1}$$

We assume for simplicity that the ith family is linearly degenerate; however, the same results are valid for characteristics of a genuinely nonlinear family if the following condition holds: for all τ there exists an ϵ such that in the strip $\{(t,x); \tau \leq t \leq T, x_i(t,y) - \epsilon \leq x \leq x_i(t,y) + \epsilon\}$ there are no shock waves of the ith family. Given front tracking, approximation u, $x_i(t,y)$ is unique, since it crosses only a finite number of transversal jumps, and it depends Lipschitz continuously on the initial data y (see [8]).

We want to give uniform estimates on this dependence. The idea is to suppose that in y there is a shock σ^ϵ of the i-family of size ϵ: $w_i(0,y+) - w_i(0,y-) = \epsilon$. Since by assumption no shocks of the i-family collide with σ^ϵ, it is easy to construct a wave front solution. For $x < x(t,y)$, the solution $u^\epsilon(t,\cdot)$ takes values in

$$E^{\nu,-} \doteq \Big\{u : w_j(u) \in [a_j, b_j] \cap 2^{-\nu}\mathbb{Z}, j = 1,\ldots,n\Big\},$$

while for $x > x(t,y)$, enlarging E and assuming ϵ sufficiently small,

$$E^{\nu,+} \doteq \Big\{u : w_j(u) \in [a_j,b_j] \cap 2^{-\nu}\mathbb{Z}, j \neq i, w_i(u) \in [a_i,b_i] \cap \big\{2^{-\nu}\mathbb{Z} + \epsilon\big\}\Big\}.$$

The following lemma proves the continuous dependence of the solution $u^\epsilon(t)$ and the position $x_i^\epsilon(t,y)$ of the shock σ^ϵ w.r.t. ϵ.

LEMMA 4.1. *Consider a front tracking solution u, with initial data u_0 and the characteristic lines $x_i(t,y_1) < x_i(t,y_2)$, defined in* (4.1) *for a linearly degenerate family i. Let u^ϵ be the wave front solution with initial data $u(w_0^\epsilon)$, where w_0^ϵ is defined as*

$$w_0^\epsilon(x) \doteq \begin{cases} w(u_0(x)), & x \leq y_1, \\ w(u_0(x)) + \epsilon e_i, & y_1 < x \leq y_2, \\ w(u_0(x)), & x > y_2. \end{cases} \tag{4.2}$$

Then there exist constants L, L', depending only on the total variation of the initial data u_0, such that for all $t \geq 0$

$$\begin{aligned} &\int_{\mathbb{R}} \big|u(t,x) - u^\epsilon(t,x)\big| dx \leq L\epsilon\big|y_1 - y_2\big| \quad \textit{and} \\ &\big|x_i^\epsilon(t,y_j) - x_i(t,y_j)\big| \leq L'\epsilon t\big|y_1 - y_2\big|, \quad j = 1,2, \end{aligned} \tag{4.3}$$

where $x_i^\epsilon(t, y_j)$ is the position of the shock σ_j^ϵ starting in $(0, y_j)$.

Proof. The first inequality is an easy consequence of the L^1 continuous dependence for front tracking solutions; see [3]. For the second one, note that all the shocks different from σ^ϵ have size uniformly bigger than 0, so that their position is shifted of the order ϵ. Thus the second inequality follows by standard ODE perturbation estimates; see [8]. □

An easy application of the previous lemma together with Proposition 3.13 implies that to compute $x_1(t, y_1)$ and $x_2(t, y_2)$ we can actually consider in (4.1) a solution $\tilde{u}$ with uniformly bounded total variation, so that the constant L' in (4.3) is independent on the total variation of u_0.

We now estimate the dependence of $x_i(t, y)$ w.r.t. u.

PROPOSITION 4.2. *Let ξ_α be the shift rate of the jump σ_α in $u(0, \cdot)$, and denote with x_i^θ the solution to*

$$\begin{cases} \dot{x}_i^\theta = \lambda_i(u^\theta(t, x_i^\theta)), \\ x_i^\theta(0) = y, \end{cases}$$

where $u^\theta(t)$ is the shifted front tracking solution. Then there exists a constant D independent of the total variation of u such that

$$\left|\lim_{\theta \to 0} \frac{x_i^\theta(t, y) - x_i(t, y)}{\theta}\right| \leq D \sum_\alpha \Big|\sigma_\alpha \xi_\alpha\Big|. \tag{4.4}$$

Proof. If ϵ is the size of the shock σ^ϵ located in $(0, y)$, then we can apply Theorem 3.10 to compute its shift ξ^ϵ. By formula (3.21) we obtain

$$\xi^\epsilon \sigma^\epsilon = \sum_\alpha \big(P(x+, y_\alpha) - P(x-, y_\alpha)\big)\xi_\alpha. \tag{4.5}$$

If θ is sufficiently small, then we have

$$\xi^\epsilon = \frac{x_i^{\theta,\epsilon}(t, y) - x_i^\epsilon(t, y)}{\theta},$$

where $x_i^{\theta,\epsilon}(t, y)$ is the position of the shifted shock and $x_i^\epsilon(t, y)$ is its original position. Note that $(P(x+, y_\alpha) - P(x-, y_\alpha))\xi_\alpha$ is the shift rate of the shock σ^ϵ after colliding with the shocks of the Riemann problems w_l, w_m and w_m, w_r. Their total shift is proportional to $|\sigma_\alpha \xi_\alpha|$, and after the interaction with σ^ϵ, the shift of the latter is proportional to $|\sigma^\epsilon||\sigma_\alpha \xi_\alpha|$. Thus taking the limit as ϵ tends to 0 of (4.5), we obtain for ϵ sufficiently small

$$\left|\frac{x_i^\theta(t, y) - x_i(t, y)}{\theta}\right| \leq D \sum_\alpha \Big|\sigma_\alpha \xi_\alpha\Big|,$$

which implies (4.4). □

We now prove the uniform Lipschitz continuity of the map $y \longmapsto x_i(t, y)$ for all $t \geq 0$.

PROPOSITION 4.3. *Consider two characteristic lines $x_i(t, y_1)$, $x_i(t, y_2)$, solutions to (4.1). There exists $C > 0$, depending only on the system and the set E, such that*

$$\frac{1}{C} \leq \frac{x_i^2(t, y_2) - x_i^1(t, y_1)}{y_2 - y_1} \leq C. \tag{4.6}$$

Proof. As in the previous proposition, let ϵ be the size of the shock $\sigma^\epsilon(t)$ located in $(0,y)$ in Riemann coordinates. If $\xi(t)$ is its shift rate, then for θ sufficiently small by Theorem 3.10 we obtain

$$\frac{x_i^\epsilon(t,y+\theta\xi)-x_i^\epsilon(t,y)}{\theta}\sigma^\epsilon(t)=\xi^\epsilon(t)\sigma^\epsilon(t)=r_i(w_l,w_r)\bigl\langle l^i(w_l,w_r),\sigma(0)\bigr\rangle\xi(0). \tag{4.7}$$

In fact, by assumption, in the simplified wave patterns to compute the shift rate of σ^ϵ, there are no waves of the ith family different from σ^ϵ. Dividing by ϵ and taking the limit as ϵ tends to 0, we obtain

$$\frac{x_i(t,y+\theta\xi)-x_i(t,y)}{\theta}\frac{\partial}{\partial w_i}u(t,x)=\frac{\partial}{\partial w_i}u(0,y)\bigl\langle l^i(w_l,w_r),r_i(0,y)\bigr\rangle\xi(0),$$

which implies

$$\frac{d}{dy}x_i(t,y)=\frac{\partial u(0,y)/\partial w_i}{\partial u(t,x)/\partial w_i}\bigl\langle l^i(w_l,w_r),r_i(0,y)\bigr\rangle. \tag{4.8}$$

We use the fact that $\sigma^\epsilon(t)/\epsilon$ tends to $\partial u(0,y)/\partial w_i\cdot r_i(w_l,w_r)$ as $\epsilon\to 0$. Since E is compact, the conclusion (4.6) follows easily. $\square$

Remark 4.4. *The above proposition implies that the map h_i^t defined in* (2.16) *is uniformly Lipschitz, independent on the total variation of u_0, together with its inverse map $(h_i^t)^{-1}$.*

To end this section, we give a different proof of the following result given in [12].

Proposition 4.5. *If $x(t)$, $y(t)$ are the positions of two adjacent k-rarefaction waves, then for some constant $\kappa>0$ one has*

$$y(\tau)-x(\tau)\geq\kappa\tau 2^{-\nu}, \tag{4.9}$$

where $c>0$ is the constant defined in (2.3). *Thus for all $\tau>0$ the total variation of the Riemann invariant w_k of the kth genuinely nonlinear family with N shocks at $t=0$ is bounded by*

$$\text{Tot.Var.}\{w_k(\tau,\cdot);[a,b]\}\leq\frac{2(b-a)}{\kappa\tau}+\bigl\|w_k\bigr\|_{L^\infty}+(N+1)2^{1-\nu}. \tag{4.10}$$

Proof. Consider two adjacent k-rarefaction fronts $x(t)$ and $y(t)$, and let t_α, $\alpha=1,\dots,N$, be the interaction times of $x(t)$, $y(t)$ with other waves in the interval $[0,\tau]$. Fix $t_i\in(t_{\bar\alpha},t_{\bar\alpha+1})$ for some $\bar\alpha$ and let $z(t,x(t_i))$ be the characteristic line of the kth genuinely nonlinear family starting in $(t_i,x(t_i))$ (see Figure 9). Assume $t_{i+1}>t_i$ sufficiently close to t_i such that $t_{i+1}\in(t_{\bar\alpha},t_{\bar\alpha+1})$ and $z(t,x(t_i))$ does not collide with shocks of other families for $t\in[t_i,t_{i+1}]$. Let $z(t,x(t_{i+1}))$ be the characteristic curve starting in $(t_{i+1},x(t_{i+1}))$. By the assumption of genuine nonlinearity, at time t_{i+1} we have

$$z(t_{i+1},x(t_i))-z(t_{i+1},x(t_{i+1}))\geq c(t_{i+1}-t_i)2^{-\nu-1}$$

for some constant c, depending only on E. Using Proposition 4.3, at time τ we have

$$z(\tau,x(t_i))-z(\tau,x(t_{i+1}))\geq\frac{c}{C}(t_{i+1}-t_i)2^{-\nu-1}. \tag{4.11}$$

Repeating the process, it is possible to find a countable number of times t_i such that

$$\lim_{i\to-\infty}t_i=t_{\bar\alpha},\qquad\lim_{i\to+\infty}t_i=t_{\bar\alpha+1},$$

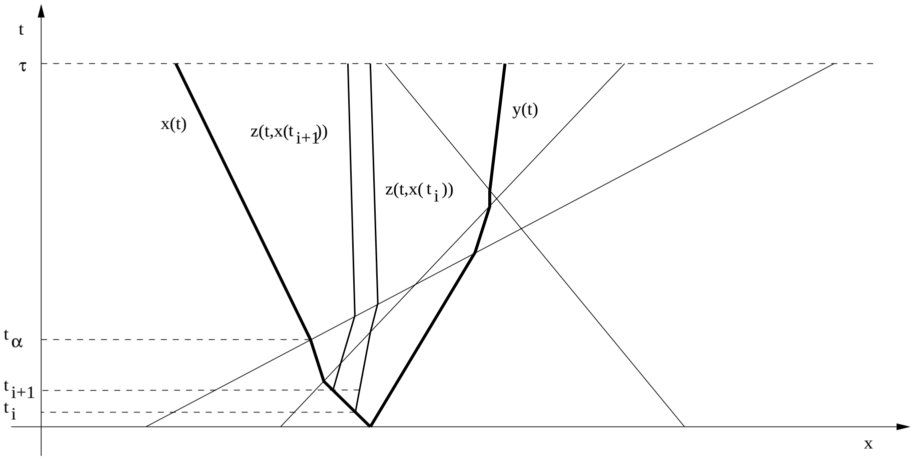

FIG. 9. *Decay of positive waves.*

and using (4.11) we get

$$z(\tau, x(t_{\bar\alpha})) - z(\tau, x(t_{\bar\alpha+1})) \geq \frac{c}{C}(t_{\bar\alpha+1} - t_{\bar\alpha})2^{-\nu-1}. \tag{4.12}$$

Repeating the process for $y(t)$ and for all intervals $(t_{\alpha+1}, t_\alpha)$, we obtain (4.9), where $\kappa = c/C$.

The second equation follows, noticing that the total amount of positive jumps in the interval $[a, b]$ is bounded by $(1 + N)2^{-\nu} + (b - a)/\kappa\tau$. □

5. Proof of the main theorem. In this section we construct the semigroup $\mathcal{S}$ on $L^\infty(\mathbb{R}; E)$. In [3] it is shown that for all M there exists a semigroup $\mathcal{S}^M$ defined on the domain

$$D^M \doteq \Big\{u : \mathbb{R} \mapsto E : \text{Tot.Var.}(u) \leq M\Big\}, \tag{5.1}$$

which is the only limit of the wave front tracking approximations constructed in section 2. We now study the dependence of the solution on the initial data $u \in D^M$. We consider separately the case for genuinely nonlinear and linearly degenerate families.

PROPOSITION 5.1. *Consider a front tracking solution u, such that $u(0, \cdot)$ has N jumps σ_α, $\alpha = 1, \ldots, N$, and let ξ_α be their shift rates. Given $\tau \geq 0$, denote with σ_β the jumps in the Riemann invariant $w_k(\tau, \cdot)$ of the kth genuinely nonlinear family. Then there exists a constant K, depending only on the system and the domain E, such that*

$$\sum_\beta \big|\xi_\beta \sigma_\beta\big| \leq K(1 + N2^{-\nu}) \sum_{\alpha=1}^N \big|\xi_\alpha \sigma_\alpha\big|. \tag{5.2}$$

Proof. The proof follows by Theorem 3.10 and Proposition 4.5. In fact, given a fixed shock $\sigma_{\bar\alpha}$, using Theorem 3.10, we have that at time τ for a shock σ_β of the ith family there exist D' such that

$$\big|\xi_\beta \sigma_\beta\big| \leq D' \big|\xi_{\bar\alpha} \sigma_{\bar\alpha}\big| \tag{5.3}$$

if the shock σ_β starts on both sides of $\sigma_{\bar\alpha}$, or, using the same estimate of Proposition 4.2,

$$|\xi_\beta| \leq D|\sigma_{\bar\alpha}\xi_{\bar\alpha}| \tag{5.4}$$

if σ_β starts on one side of $\sigma_{\bar\alpha}$. Since there is at most 1 shock such that (5.3) holds, and the interval of influence is $[x_{\bar\alpha} - \hat\lambda\tau, x_{\bar\alpha} + \hat\lambda\tau]$, using Proposition 4.5 together with (5.3) and (5.4) we obtain

$$\sum_\beta |\xi_\beta\sigma_\beta| \leq D'|\xi_{\bar\alpha}\sigma_{\bar\alpha}| + D|\sigma_{\bar\alpha}\xi_{\bar\alpha}| \cdot \text{Tot.Var.}\Big\{w_k, [x_{\bar\alpha} - \hat\lambda\tau, x_{\bar\alpha} + \hat\lambda\tau]\Big\} \leq F(1+2^{-\nu})|\xi_{\bar\alpha}\sigma_{\bar\alpha}|.$$

The conclusion follows the linearity of the shift differential map. □

Using the results of the previous section, the following result is trivial.

Proposition 5.2. *Consider a wave front solution u, such that $u(0,\cdot)$ has N jumps σ_α, $\alpha = 1,\dots,N$, and let ξ_α be their shifts. Consider* (4.1), *with the eigenvalue λ_i linearly degenerate. For fixed $\tau \geq 0$, the shift ξ_i of $x_i(\tau, y)$ is then bounded by*

$$|\xi_i| \leq D\sum_{\alpha=1}^N |\xi_\alpha\sigma_\alpha|. \tag{5.5}$$

Proof. This is a corollary of Proposition 4.2. □

Using the above propositions, we can prove the following theorem.

Theorem 5.3. *Consider two initial data u_1 and u_2, and denote with $w_{j,k}(t,\cdot)$ the kth Riemann coordinate of $\mathcal{S}^M u_j$, $j = 1,2$, corresponding to the kth genuinely nonlinear family. Moreover, let $h^\tau_{j,i}$, $j = 1,2$, be the map defined in* (4.1) *for the ith linearly degenerate family. Then there exists a constant K', independent of M, such that the following estimates hold:*

$$\int_{\mathbb{R}} |w_{1,k}(t,x) - w_{2,k}(t,x)|dx \leq K' \int_{\mathbb{R}} |u_1(x) - u_2(x)|dx, \tag{5.6}$$

$$\sup_{t\geq 0, x\in\mathbb{R}} |h^t_{1,i}(x) - h^t_{2,i}(x)| \leq K' \int_{\mathbb{R}} |u_1(x) - u_2(x)|dx. \tag{5.7}$$

Proof. Consider two piecewise constant initial data u^ν_1, u^ν_2 in $D^{M,\nu}$, and construct a pseudopolygonal path $\gamma_0 : \theta \longmapsto u^\nu_\theta$, connecting u_1 and u_2, such that

$$\|\gamma_0\|_{L^1} \leq E\|u^\nu_1 - u^\nu_2\|_{L^1}.$$

We can assume that u^ν_θ has a finite number N of jumps. If we denote with γ^ν_τ the path $\theta \longmapsto \mathcal{S}^\nu_\tau u^\nu_\theta$, we have by Proposition 5.1

$$\begin{aligned} \|w^\nu_{2,k}(\tau) - w^\nu_{1,k}(\tau)\|_{L^1} &\leq \left\|(\gamma^\nu_\tau)_k\right\|_{L^1} \leq K(1 + N2^{-\nu})\|\gamma_0\|_{L^1} \\ &\leq K'(1 + N2^{-\nu})\|u_2 - u_1\|_{L^1}. \end{aligned} \tag{5.8}$$

Now if $\nu \to +\infty$, since $w^\nu_{j,k}(\tau)$ converges to $w_{j,k}(\tau)$, we obtain (5.6). Since this estimate does not depend on the number of initial jumps N, we can extend it uniformly on D^M.

Using the same pseudopolygonal path, in a similar way we can prove that

$$\left|x^\nu_{2,i}(\tau,y)-x^\nu_{1,i}(\tau,y)\right|\le K'\left\|u_2-u_1\right\|_{L^1}.$$

This shows that $x^\nu_i(\tau,\cdot)$ converges uniformly to the solution $x_i(\tau,\cdot)$ as $\nu\to+\infty$ and $u^\nu\to u$. It also implies that

$$\left|x_{2,i}(\tau,y)-x_{1,i}(\tau,y)\right|\le K'\left\|u_2-u_1\right\|_{L^1}.$$

This concludes the proof. □

We can now define $\mathcal{S}$ on the domain $L^\infty(\mathbb{R};E)$.

Definition 5.4. *For all $u\in L^\infty(\mathbb{R},E)$, let $u^M\in D^M$ be such that*

$$\lim_{M\to+\infty}u^M=u\quad in\ L^1_{\mathrm{loc}}. \tag{5.9}$$

Define $\mathcal{S}_tu$ as

$$\mathcal{S}_tu=\lim_{M\to+\infty}\mathcal{S}^M_tu, \tag{5.10}$$

where the limit is in L^1_{loc}.

It is easy to prove that the right-hand side of (5.10) is a Cauchy sequence in every compact set $[a,b]$. In fact, using the finite speed of propagation, we can consider u with compact support $[a-\hat\lambda t,b+\hat\lambda t]$. For the components w_k of the kth genuinely nonlinear family, it follows directly from (5.6), while for a linearly degenerate component w_i, let $\tilde w$ be a Lipschitz continuous function such that

$$\int_{\mathbb{R}}\left|w_i(0,x)-\tilde w(x)\right|dx\le\epsilon.$$

By Theorem 5.3 we have for $u_1,u_2\in D^M$ such that $\|u-u_i\|_{L^1}<\delta$, $i=1,2$,

$$\sup_{t\ge0,x\in\mathbb{R}}\left|h^t_{1,i}(x)-h^t_{2,i}(x)\right|<K'\delta,$$

and it follows by easy computations that

$$\begin{aligned}\left\|w_{1,i}(t)-w_{2,i}(t)\right\|_{L^1}&\le\left\|w_{1,i}(t)-\tilde w\circ\left(h^t_{1,i}\right)^{-1}\right\|_{L^1}\\&\quad+\left\|w_{2,i}(t)-\tilde w\circ\left(h^t_{2,i}\right)^{-1}\right\|_{L^1}\\&\quad+\left\|\tilde w\circ\left(h^t_{1,i}\right)^{-1}-\tilde w\circ\left(h^t_{2,i}\right)^{-1}\right\|_{L^1}\\&\le C\left\|w_{1,i}(0)-\tilde w\right\|_{L^1}+C\left\|w_{2,i}(0)-\tilde w\right\|_{L^1}\\&\quad+L(b-a)G\left\|u_2-u_1\right\|_{L^1}\\&\le2C(\epsilon+\delta)+L(b-a)G\delta,\end{aligned} \tag{5.11}$$

where L is the Lipschitz constant of $\tilde w$. This shows that $w^M_i(t)$ is a Cauchy sequence for all $t\ge0$, because the right-hand side of (5.11) can be made arbitrarily small. We can now prove the main theorem.

Theorem 5.5. *The semigroup $\mathcal{S}:[0,+\infty)\otimes L^\infty(\mathbb{R};E)\longmapsto L^\infty(\mathbb{R};E)$ defined in* (5.10) *is the only continuous semigroup on $L^\infty(\mathbb{R};E)$ such that the following properties are satisfied:*

(i) *for all* $\bar{u}^n, \bar{u} \in L^\infty(\mathbb{R}; E)$, $t_n, t \in [0, +\infty)$, *with* $\bar{u}_n \to \bar{u}$ *in* L^1_{loc}, $|t - t_n| \to 0$ *as* $n \to +\infty$,

$$\lim_{n \to +\infty} \mathcal{S}_{t_n} \bar{u}_n = \mathcal{S}_t \bar{u} \quad \textit{in } L^1_{\mathrm{loc}}; \tag{5.12}$$

(ii) *each trajectory* $t \mapsto \mathcal{S}_t u_0$ *is a weak entropic solution to the Cauchy problem*

$$\begin{cases} u_t + f(u)_x = 0, \\ u(0, x) = u_0(x) \end{cases} \tag{5.13}$$

with $u_0 \in L^\infty(\mathbb{R}; E)$;

(iii) *if* u_0 *is piecewise constant, then, for* t *sufficiently small,* $\mathcal{S}_t u_0$ *coincides with the function obtained by piecing together the solutions of the corresponding Riemann problems.*

Proof. The statement follows easily, since we proved that $\mathcal{S}_t u$ is the unique limit of wave front approximations, and for data with bounded total variation we can apply the results in [3]. □

Remark 5.6. *Note that we also proved that the characteristic equation* (4.1) *is well posed for* L^∞ *data: the solution* $x_i(t, y)$ *is Lipschitz continuous w.r.t. both variables. In fact, if* u_0^n *converges to* u_0 *in* L^1_{loc}, *Proposition* 4.2 *implies that* $x_i^n(t, y)$, *solution to the* i *characteristic equation, tends to* $x(t, y)$ *uniformly for all* t, y. *It is then easy to prove that* $x(t, y)$ *satisfies the equation*

$$x_i(t, y) = y + \int_0^t \lambda_i\big(s, x_i(s, y)\big) ds.$$

The above equation implies uniqueness of $x_i(t, y)$ *in the sense of Carathéodory, and Proposition* 4.3 *prove continuous dependence on* y.

This is not trivial, since even for 2×2 *systems not in conservation form the dependence is Hölder continuous, while for general* $n \times n$ *the solution does not exist* [16].

Note, moreover, that semigroup $\mathcal{S}$ *is continuous but not uniformly continuous. However, if the initial data takes values in a compact set of* $L^1 \cap L^\infty$, *then the semigroup becomes uniformly continuous. This extends the Lipschitz continuity when the initial data have bounded total variation.*

Acknowledgment. I wish to thank Prof. Alberto Bressan for having suggested the problem and his careful reading of the manuscript.

ILL-POSEDNESS ISSUES FOR THE BENJAMIN–ONO AND RELATED EQUATIONS[*]

L. MOLINET[†], J. C. SAUT[‡], AND N. TZVETKOV[‡]

Abstract. We establish that the Cauchy problem for the Benjamin–Ono equation and for a rather general class of nonlinear dispersive equations with dispersion slightly weaker than that of the Korteweg–de Vries equation cannot be solved by an iteration scheme based on the Duhamel formula. As a consequence, the flow map fails to be smooth.

Key words. Benjamin–Ono equation, internal long waves, Cauchy problem, ill-posedness

1. Introduction.

The Benjamin–Ono equation is one of the fundamental equations describing the evolution of weakly nonlinear dispersive internal long waves. It has been derived by Benjamin [4] as an approximate model for long-crested unidirectional waves at the interface of a two-layer system of incompressible inviscid fluids; the top layer is assumed to be infinitely deep, while the heavier bottom layer has finite depth. In nondimensional variables, the Benjamin–Ono equation writes as

$$u_t - Hu_{xx} + uu_x = 0, \quad u = u(t,x), \quad (t,x) \in \mathbb{R}^2, \tag{1}$$

where $u(t,x)$ is proportional to the vertical deviation of the interface from its rest position at the point x at time t, and H is the Hilbert transform applied in the spatial variable.

The Benjamin–Ono equation has attracted a considerable number of papers during the last 20 years, particularly because it is completely integrable, at least formally [3]. Actually, rigorous results concerning the inverse scattering transform method require a certain small norm condition that excludes solitary waves [8].

We now review the state of the art concerning the Cauchy problem for the Benjamin–Ono equation, which turns out to be more delicate than expected.

First, (1) possesses two conservation laws:[1]

$$\int_{-\infty}^{\infty} u^2(t,x)dx = \int_{-\infty}^{\infty} u^2(0,x)dx \qquad \text{(momentum)}, \tag{2}$$

$$\begin{aligned}\int_{-\infty}^{\infty} \left[\frac{1}{2}||D_x|^{\frac{1}{2}}u|^2 - \frac{1}{6}u^3\right](t,x)dx \\ = \int_{-\infty}^{\infty} \left[\frac{1}{2}||D_x|^{\frac{1}{2}}u|^2 - \frac{1}{6}u^3\right](0,x)dx \qquad \text{(energy)}.\end{aligned} \tag{3}$$

[1] In fact, (1) possesses an infinite number due to the integrability.

This suggests that the space $L^2(\mathbb{R})$ or the energy space $H^{1/2}(\mathbb{R})$ are good candidates for a global well-posedness theory of the Cauchy problem. This problem is open and one aim of this paper is to present some obstructions to its solvability by iteration methods. On the other hand, some positive results are known. The Benjamin–Ono equation has global weak solutions in the energy space (see [19]) and even global weak solutions for data in L^2 (see [10, 11, 22]). This last result is based on smoothing properties of the underlying linear group. It has also been shown that the Cauchy problem is globally well-posed in H^s, $s > 3/2$ (see [9, 2]).[2] This result has been extended to $s = 3/2$ by Ponce (see [18]) by using dispersive estimates on the linear group. It is worth noticing that all the results summarized above are based on a compactness method: one passes to the limit by compactness arguments on some approximate solutions. Another natural way of solving the Cauchy problem is to perform an iterative method on the integral equation corresponding to the Benjamin–Ono equation with initial data ϕ:

$$u(t) = S(t)\phi - \int_0^t S(t-t')(u_x(t')u(t'))dt',$$

where $S(t) = \exp(tH\partial_x^2)$ is the generator of the free evolution.

Our results are negative ones and are inspired by a previous work of the authors on the Kadomtsev-Petviashvili-I equation (see [17]). They show that one cannot solve the Cauchy problem for the Benjamin–Ono equation by a Picard iterative method implemented on the integral formulation of (1) for initial data in the Sobolev space $H^s(\mathbb{R})$, $s \in \mathbb{R}$. In particular the methods introduced by Bourgain [6] and Kenig, Ponce, and Vega [13] for the Korteweg–de Vries (KdV) equation cannot be used for the Benjamin–Ono equation. Note that scaling arguments imply that the Cauchy problem should be ill-posed in $H^s(\mathbb{R})$, $s < -1/2$, and actually this has been recently proved in [5].

As a consequence, there does not exist a $T > 0$ such that (1) admits a unique local solution defined on the interval $[-T, T]$ and such that the flow-map data-solution $\phi \longmapsto u(t),\ t \in [-T, T]$, is C^2 differentiable at the origin from $H^s(\mathbb{R})$ to $H^s(\mathbb{R})$. This implies in particular that the flow map for the Cauchy problem solved in [2, 9, 18] is not smooth (C^2) at the origin, a fact which would be difficult to establish from the compactness theory alone.

We note that the situation is radically different for the generalized Benjamin–Ono equation

$$u_t + u^k u_x - Hu_{xx} = 0, \tag{4}$$

which has been studied by Kenig, Ponce, and Vega [14]. Actually, they establish by an iterative method (thus the corresponding flow is smooth) that (4) is locally well-posed for small data in a Sobolev space $H^{s_k}(\mathbb{R})$ ($s_k > 1$ if $k = 2$, $s_k > 5/6$ if $k = 3$, $s_k \geq 3/4$ if $k \geq 4$).

The rest of the paper is organized as follows. In the next section we state and prove our main results for the Benjamin–Ono equation. Section 3 is devoted to a natural extension of our arguments to a general class of nonlinear dispersive equations with dispersion slightly weaker than that of the KdV equation. This includes, for instance, the intermediate long wave equation (ILW), the Smith equation, and equations describing waves in rotating fluids.

[2] This result uses the next conservation law.

Notations. Different numerical constants are denoted by c and may change from line to line. For any positive A and B the notation $A \lesssim B$ (resp., $A \gtrsim B$) means that there exists a positive constant c such that $A \leq cB$ (resp., $A \geq cB$). The notation $A \sim B$ means that $A \lesssim B \lesssim A$. We denote the Fourier transform by $\widehat{\cdot}$ or $\mathcal{F}$.

2. The Benjamin–Ono equation. Consider the Cauchy problem

$$\left\{\begin{array}{l} u_t - Hu_{xx} + uu_x = 0,\ (t,x) \in \mathbb{R}^2, \\ u(0,x) = \phi(x). \end{array}\right. \tag{5}$$

Write (5) as an integral equation:

$$u(t) = S(t)\phi - \int_0^t S(t-t')(u_x(t')u(t'))dt'. \tag{6}$$

Our main results follow.

THEOREM 1. *Let $s \in \mathbb{R}$ and T be a positive real number. Then there does not exist a space X_T continuously embedded in $C([-T,T], H^s(\mathbb{R}))$ such that there exists $C > 0$ with*

$$\|S(t)\phi\|_{X_T} \leq C\|\phi\|_{H^s(\mathbb{R})}, \quad \phi \in H^s(\mathbb{R}), \tag{7}$$

and

$$\left\| \int_0^t S(t-t')\,[u(t')u_x(t')]\,dt' \right\|_{X_T} \leq C\|u\|^2_{X_T}, \quad u \in X_T. \tag{8}$$

Note that (7) and (8) would be needed to implement a Picard iterative scheme on (6), in the space X_T. As a consequence of Theorem 1 we can obtain the following result.

THEOREM 2. *Fix $s \in \mathbb{R}$. Then there does not exist a $T > 0$ such that* (5) *admits a unique local solution defined on the interval $[-T,T]$ and such that the flow-map data-solution*

$$\phi \longmapsto u(t), \quad t \in [-T,T],$$

for (5) *is C^2 differentiable at zero from $H^s(\mathbb{R})$ to $H^s(\mathbb{R})$.*

We note that in [23] the failure of C^2 regularity of the flow map of the KdV equation on $H^s(\mathbb{R})$ for $s < -3/4$ is studied, motivated by work of Bourgain [7]. A direct corollary of Theorem 2 is the next statement.

THEOREM 3. *The flow map in the existing results for the Benjamin–Ono equation is not C^2 from $H^s(\mathbb{R})$ to $H^s(\mathbb{R})$.*

2.1. Proof of Theorem 1. Suppose that there exists a space X_T such that (7) and (8) hold. Take $u = S(t)\phi$ in (8). Then

$$\left\| \int_0^t S(t-t')\,[(S(t')\phi)(S(t')\phi_x)]\,dt' \right\|_{X_T} \leq C\|S(t)\phi\|^2_{X_T}.$$

Now using (7) and that X_T is continuously embedded in $C([-T,T], H^s(\mathbb{R}))$ we obtain for any $t \in [-T,T]$ that

$$\left\| \int_0^t S(t-t')\,[(S(t')\phi)(S(t')\phi_x)]\,dt' \right\|_{H^s(\mathbb{R})} \lesssim \|\phi\|^2_{H^s(\mathbb{R})}. \tag{9}$$

We show that (9) fails by choosing an appropriate ϕ.

Take ϕ defined by its Fourier transform as[3]

$$\widehat{\phi}(\xi) = \alpha^{-\frac{1}{2}} \mathbb{1}_{I_1}(\xi) + \alpha^{-\frac{1}{2}} N^{-s} \mathbb{1}_{I_2}(\xi), \quad N \gg 1, \quad 0 < \alpha \ll 1,$$

where I_1, I_2 are the intervals

$$I_1 = [\alpha/2, \alpha], \quad I_2 = [N, N+\alpha].$$

Note that $\|\phi\|_{H^s} \sim 1$. We will use the next lemma.

LEMMA 1. *The following identity holds:*

$$\int_0^t S(t-t')\Big[(S(t')\phi)(S(t')\phi_x)\Big]\,dt'$$
$$= c\int_{\mathbb{R}^2} e^{ix\xi+itp(\xi)}\,\xi\,\hat{\phi}(\xi_1)\hat{\phi}(\xi-\xi_1)\frac{e^{it(p(\xi_1)+p(\xi-\xi_1)-p(\xi))}-1}{p(\xi_1)+p(\xi-\xi_1)-p(\xi)}d\xi d\xi_1,$$

where $p(\xi) = \xi|\xi|$.

Proof of Lemma 1. The proof is very similar to that of Lemma 4 in [17]. We give it for the sake of completeness. Taking the inverse Fourier transform with respect to x, it is easily seen that

$$\int_0^t S(t-t')\Big[(S(t')\phi)(S(t')\phi_x)\Big]\,dt'$$
$$= c\int_0^t\int_{\mathbb{R}} e^{ix\xi+itp(\xi)}e^{-it'p(\xi)}\xi\Big[(e^{it'p(\cdot)}\hat{\phi}(\cdot)) * (e^{it'p(\cdot)}\hat{\phi}(\cdot))\Big](\xi)\,d\xi\,dt'$$
$$= c\int_{\mathbb{R}^2} e^{ix\xi+itp(\xi)}\,\xi\,\hat{\phi}(\xi_1)\hat{\phi}(\xi-\xi_1)\int_0^t e^{it'(p(\xi_1)+p(\xi-\xi_1)-p(\xi))}\,dt'\,d\xi_1 d\xi$$
$$= c\int_{\mathbb{R}^2} e^{ix\xi+itp(\xi)}\,\xi\,\hat{\phi}(\xi_1)\hat{\phi}(\xi-\xi_1)\frac{e^{it(p(\xi_1)+p(\xi-\xi_1)-p(\xi))}-1}{p(\xi_1)+p(\xi-\xi_1)-p(\xi)}\,d\xi_1 d\xi. \qquad \square$$

According to the above lemma,

$$\int_0^t S(t-t')\,[(S(t')\phi)(S(t')\phi_x)]\,dt' = c(f_1(t,x)+f_2(t,x)+f_3(t,x)),$$

where, from the definition of ϕ, we have the following representations for f_1, f_2, f_3:

$$f_1(t,x) = \frac{c}{\alpha}\int_{\substack{\xi_1\in I_1\\ \xi-\xi_1\in I_1}} \xi\, e^{ix\xi+it\xi|\xi|}\frac{e^{it(\xi_1|\xi_1|+(\xi-\xi_1)|\xi-\xi_1|-\xi|\xi|)}-1}{\xi_1|\xi_1|+(\xi-\xi_1)|\xi-\xi_1|-\xi|\xi|}d\xi d\xi_1,$$

$$f_2(t,x) = \frac{c}{\alpha N^{2s}}\int_{\substack{\xi_1\in I_2\\ \xi-\xi_1\in I_2}} \xi\, e^{ix\xi+it\xi|\xi|}\frac{e^{it(\xi_1|\xi_1|+(\xi-\xi_1)|\xi-\xi_1|-\xi|\xi|)}-1}{\xi_1|\xi_1|+(\xi-\xi_1)|\xi-\xi_1|-\xi|\xi|}d\xi d\xi_1,$$

$$f_3(t,x) = \frac{c}{\alpha N^{s}}\int_{\substack{\xi_1\in I_1\\ \xi-\xi_1\in I_2}} \xi\, e^{ix\xi+it\xi|\xi|}\frac{e^{it(\xi_1|\xi_1|+(\xi-\xi_1)|\xi-\xi_1|-\xi|\xi|)}-1}{\xi_1|\xi_1|+(\xi-\xi_1)|\xi-\xi_1|-\xi|\xi|}d\xi d\xi_1$$

$$+ \quad \frac{c}{\alpha N^{s}}\int_{\substack{\xi_1\in I_2\\ \xi-\xi_1\in I_1}} \xi\, e^{ix\xi+it\xi|\xi|}\frac{e^{it(\xi_1|\xi_1|+(\xi-\xi_1)|\xi-\xi_1|-\xi|\xi|)}-1}{\xi_1|\xi_1|+(\xi-\xi_1)|\xi-\xi_1|-\xi|\xi|}d\xi d\xi_1.$$

[3] The analysis below works as well for $\mathcal{R}e\,\phi$ instead of ϕ (some new harmless terms appear).

Set

$$\chi(\xi,\xi_1) := \xi_1|\xi_1| + (\xi-\xi_1)|\xi-\xi_1| - \xi|\xi|.$$

Then clearly

$$\mathcal{F}_{x\mapsto\xi}(f_1)(t,\xi) = \frac{c\,\xi e^{it\xi|\xi|}}{\alpha}\int_{\substack{\xi_1\in I_1\\ \xi-\xi_1\in I_1}} \frac{e^{it\chi(\xi,\xi_1)}-1}{\chi(\xi,\xi_1)}d\xi_1,$$

$$\mathcal{F}_{x\mapsto\xi}(f_2)(t,\xi) = \frac{c\,\xi e^{it\xi|\xi|}}{\alpha N^{2s}}\int_{\substack{\xi_1\in I_2\\ \xi-\xi_1\in I_2}} \frac{e^{it\chi(\xi,\xi_1)}-1}{\chi(\xi,\xi_1)}d\xi_1,$$

$$\mathcal{F}_{x\mapsto\xi}(f_3)(t,\xi) = \frac{c\,\xi e^{it\xi|\xi|}}{\alpha N^{s}}\left(\int_{\substack{\xi_1\in I_1\\ \xi-\xi_1\in I_2}} \frac{e^{it\chi(\xi,\xi_1)}-1}{\chi(\xi,\xi_1)}d\xi_1 + \int_{\substack{\xi_1\in I_2\\ \xi-\xi_1\in I_1}} \frac{e^{it\chi(\xi,\xi_1)}-1}{\chi(\xi,\xi_1)}d\xi_1\right).$$

Since the supports of $\mathcal{F}_{x\mapsto\xi}(f_j)(t,\xi)$, $j=1,2,3$, are disjoint, we have

$$\left\|\int_0^t S(t-t')\left[(S(t')\phi)(S(t')\phi_x)\right]dt'\right\|_{H^s(\mathbb{R})} \geq \|f_3(t,\cdot)\|_{H^s(\mathbb{R})}.$$

We now give a lower bound for $\|f_3(t,\cdot)\|_{H^s(\mathbb{R})}$. Note that for $(\xi_1,\xi-\xi_1)\in I_1\times I_2$ or $(\xi_1,\xi-\xi_1)\in I_2\times I_1$ one has $|\chi(\xi,\xi_1)| = 2|\xi_1(\xi-\xi_1)| \sim \alpha N$. Hence it is natural to choose α and N so that $\alpha N = N^{-\epsilon}$, $0<\epsilon\ll 1$. Then

$$\left|\frac{e^{it\chi(\xi,\xi_1)}-1}{\chi(\xi,\xi_1)}\right| = |t| + O(N^{-\epsilon})$$

for $\xi_1\in I_1$, $\xi-\xi_1\in I_2$ or $\xi_1\in I_2$, $\xi-\xi_1\in I_1$. Hence for $t\neq 0$,

$$\|f_3(t,\cdot)\|_{H^s(\mathbb{R})} \gtrsim \frac{N\,N^s\,\alpha\,\alpha^{\frac{1}{2}}}{\alpha N^s} = \alpha^{\frac{1}{2}}N.$$

Therefore we arrive at

$$1\sim\|\phi\|^2_{H^s(\mathbb{R})} \geq \|f_3(t,\cdot)\|_{H^s(\mathbb{R})} \geq \alpha^{\frac{1}{2}}N \sim N^{\frac{1-\epsilon}{2}},$$

which is a contradiction for $N\gg 1$ and $\epsilon\ll 1$. This completes the proof of Theorem 1. □

2.2. Proof of Theorem 2. Consider the Cauchy problem

$$\begin{cases} u_t - Hu_{xx} + uu_x = 0, \\ u(0,x) = \gamma\phi, \quad \gamma\ll 1, \quad \phi\in H^s(\mathbb{R}). \end{cases} \tag{10}$$

Suppose that $u(\gamma,t,x)$ is a local solution of (10) and that the flow map is C^2 at the origin from $H^s(\mathbb{R})$ to $H^s(\mathbb{R})$. We have

$$\frac{\partial^2 u}{\partial\gamma^2}(0,t,x) = -2\int_0^t S(t-t')\left[(S(t')\phi)(S(t')\phi_x)\right]dt'.$$

The assumption of C^2 regularity yields

$$\left\|\int_0^t S(t-t')\left[(S(t')\phi)(S(t')\phi_x)\right]dt'\right\|_{H^s(\mathbb{R})} \lesssim \|\phi\|^2_{H^s(\mathbb{R})}.$$

But the above estimate is (9), which has been shown to fail in section 2.1. □

3. A class of nonlinear dispersive equations. We consider now the class of equations

$$u_t + uu_x - Lu_x = 0, \quad u(0,x) = \phi(x), \quad (t,x) \in \mathbb{R}^2, \tag{11}$$

where L is defined via the Fourier transform

$$\widehat{Lf}(\xi) = \omega(\xi)\hat{f}(\xi).$$

Here $\omega(\xi)$ is a continuous real-valued function. Set $p(\xi) = \xi\,\omega(\xi)$. We assume that $p(\xi)$ is differentiable and such that, for some $\gamma \in \mathbb{R}$,

$$|p'(\xi)| \lesssim |\xi|^\gamma, \quad \xi \in \mathbb{R}. \tag{12}$$

The next theorem shows that (11) shares the bad behavior of the Benjamin–Ono equation with respect to iterative methods.

Theorem 4. *Assume that* (12) *holds with* $\gamma \in [0, 2[$. *Then the conclusions of Theorems* 1, 2, *and* 3 *are valid for the Cauchy problem* (11).

The proof follows the considerations of the previous section. The main point in the analysis is that for $\xi_1 \in I_1$, $\xi - \xi_1 \in I_2$ one has

$$|p(\xi_1) + p(\xi - \xi_1) - p(\xi)| \lesssim \alpha N^\gamma, \qquad \alpha \ll 1, \quad N \gg 1.$$

We choose α and N such that $\alpha N^\gamma = N^{-\epsilon}$, $0 < \epsilon \ll 1$. We take the same ϕ as in the proof of Theorem 1 and arrive at the lower bound

$$1 \sim \|\phi\|^2_{H^s(\mathbb{R})} \geq \alpha^{\frac{1}{2}} N = N^{1-\frac{\gamma+\epsilon}{2}},$$

which fails for $0 < \epsilon \ll 1$, $\gamma \in [0, 2[$.

Here we give several examples where Theorem 4 applies.

- Pure power dispersion:

$$\omega(\xi) = |\xi|^\gamma, \quad 0 \leq \gamma < 2.$$

This dispersion corresponds to a class of models for vorticity waves in the coastal zone (see [20]). It is interesting to notice that the case $\gamma = 2$ corresponds to the KdV equation which can be solved by iterative methods (see [6, 13]). Therefore Theorem 4 is sharp for a pure power dispersion. However, the Cauchy problem corresponding to $1 \leq \gamma < 2$ has been proven in [12, Theorem 1.3] to be locally well-posed by a compactness method combined with sharp estimates on the linear group for initial data in $H^s(\mathbb{R})$, $s \geq (9 - 3\gamma)/4$.

- Perturbations of the Benjamin–Ono equation:

$$\omega(\xi) = (|\xi|^2 + 1)^{\frac{1}{2}} \quad \text{(see [21])},$$

$$\omega(\xi) = \xi \coth(\xi) \quad \text{(the ILW equation; see [15, 1, 2])}.$$

- Equations describing waves in rotating fluids:

$$\omega(\xi) = \xi^2 K_0(|\xi|) \quad \text{(where } K_0 \text{ is the Bessel function of order zero; see [16])}.$$

A LOCAL INVERSION PRINCIPLE OF THE NASH–MOSER TYPE*

ALFONSO CASTRO† AND J. W. NEUBERGER‡

Abstract. We prove an inverse function theorem of the Nash–Moser type. The main difference between our method and that of [J. Moser, *Proc. Nat. Acad. Sci. USA,* 47 (1961), pp. 1824–1831] is that we use continuous steepest descent while Moser uses a combination of Newton-type iterations and approximate inverses. We bypass the *loss of derivatives problem* by working on finite dimensional subspaces of infinitely differentiable functions.

Key words. Nash–Moser methods, inverse function theorem, continuous steepest descent

AMS subject classifications. Primary, 34B15; Secondary, 35J65

PII. S0036141099357690

1. Introduction.

Inverse function theorems are fundamental tools for the study of solutions to nonlinear equations. Proofs depend on iteration arguments. When a nonlinear equation comes from a partial differential equation, it often happens that the operators under consideration do not have enough *regularity* and the iteration process is defined only for a few steps. This is known as loss of derivatives. In order to overcome this difficulty, iteration techniques have been designed to allow the iteration to lead to a limit. These are known as generalized inverse function theorems. They generally depend on having a *scale* of intermediate spaces between the domain and the range of the nonlinear operator under consideration. Most notable of such results is the one proven by J. Moser in [5] and [6] (see also [2]). The reader is referred to [3] for a sharper version of the results of [5].

Here we prove an inverse function theorem (Theorem 2.1 below) using finite dimensional subspaces of infinitely differentiable functions, which makes the phenomenon of loss of derivatives immaterial. In addition we only assume the operators to have a first order derivative. This is in contrast with the results of [5] and [3] where Newton-like iteration techniques require extensive use of the properties of the *quadratic remainder* (see (10)). In [12] another inverse function theorem is proven without assumptions on the quadratic remainder. Our use of continuous steepest descent has roots in [1], [7], [8], and [9]. For applications of generalized inverse function theorems to elliptic systems the reader is referred to [4] and [11].

2. Main result.

For the sake of simplicity we present our main result in the context of a particular class of Sobolev spaces. However, the general principle applies to many other *scales* of spaces sharing the general properties of the Sobolev spaces that are defined in the next paragraph. The reader is referred to [2] for various other scales of spaces.

Let each of m and n denote a positive integer. For each nonnegative integer ρ let C^ρ denote the set of ρ-differentiable functions $u : R^n \to R^m$ that are 2π-periodic in each of its n independent real variables. The norm in C^ρ is given by

$$|u|_\rho = \max\{|u(x)|; x \in R^n\} + \max\{|D^\alpha u(x)|; x \in R^n, |\alpha| = \rho\}; \tag{1}$$

here, $\alpha = (\alpha_1, \dots, \alpha_n)$ is an n-tuple of nonnegative integers and $|\alpha| = \alpha_1 + \cdots + \alpha_n$. Similarly for $r \geq 0$ we define H^r as the Sobolev space of functions $u : R^n \to R^m$ of the form

$$u(x) = \sum_{j \in \mathbf{Z}^n} c_j e^{ij \cdot x} \tag{2}$$

such that

$$\|u\|_r^2 \equiv \sum_{j \in \mathbf{Z}^n} |c_j|^2 \ + \sum_{j \in \mathbf{Z}^n} |j|^{2r} |c_j|^2 < \infty, \tag{3}$$

where $|(j_1, \dots, j_n)|^2 = j_1^2 + \cdots + j_n^2$. Actually H^r is also defined for $r < 0$ provided that the expression in (2) is understood in the sense of distributions and

$$\|u\|_r^2 \equiv |c_0|^2 \ + \sum_{j \in \mathbf{Z}^n - \{0\}} |j|^{2r} |c_j|^2 < \infty. \tag{4}$$

For $r \geq 0$ the inner product in H^r is given by

$$\left\langle \sum_{j \in \mathbf{Z}^n} c_j e^{ij \cdot x}, \sum_{j \in \mathbf{Z}^n} d_j e^{ij \cdot x} \right\rangle_r = \sum_{j \in \mathbf{Z}^n} (1 + |j|^{2r}) c_j \bar{d}_j. \tag{5}$$

Let $\epsilon > 0$ and $F : \{x \in C^1; |x|_1 < \epsilon\} \to C^0$ be a continuous function such that $F(0) = 0$. Typically F is a first order differential operator. We assume that for $u, v \in C^1$, with $|u|_1 < \epsilon$, the limit

$$\lim_{t \to 0} \frac{F(u + tv) - F(u)}{t} \equiv F'(u)v \tag{6}$$

exists and is a continuous function of v and that $F'(\cdot)v$ defines a continuous function from C^1 into C^0, for each $v \in C^1$. We also assume that there exist $\lambda \in R$, positive constants k_1, k_2, k_3, and $l > (n/2) + 1$ with

$$\langle F'(u)v, v \rangle_0 \geq k_1 \|v\|_0^2 \tag{7}$$

for all $u, v \in C^1$;

$$\langle F'(u)v, v \rangle_l \geq k_2 \|v\|_\lambda^2 - k_3 \|v\|_0^2 \tag{8}$$

for $u \in C^1$, $|u|_l \leq \epsilon$, $v \in H^l$; and for each positive integer ρ there exists M_ρ such that

$$\|F(u)\|_\rho \leq M_\rho \|u\|_{\rho+1} \quad \text{for} \quad |u|_1 < \epsilon. \tag{9}$$

Without loss of generality we may assume that $k_1 < k_2$.

In [6], it is shown that the equation $F(u) = g$ has a solution when the operators $F'(u)$ have *approximate inverses*, and

$$\|F(u + v) - F(u) - F'(u)v\|_0 \leq M \|v\|_0^{2-\beta} \|v\|_l^\beta \ \text{ for } \ |u|_1 < \epsilon, \ |u + v|_1 < \epsilon, \tag{10}$$

where M is a constant independent of u, v and $0 \leq \beta < 1$. In addition, it is shown that (7) and (8) with $l = \lambda$ are sufficient for $F'(u)$ to have an approximate inverse.

Here we prove the following theorem.

THEOREM 2.1. *If (6)–(9) hold and $l > (n/2) + 1$, then there exist $\delta > 0$ such that, if $\|g\|_l < \delta$, then the equation*

$$F(y) = g \tag{11}$$

has a solution.

Proof. For each positive integer k, let X_k denote the linear subspace of H^l of functions of the form

$$u(x) = \sum_{\|j\|^2 \leq k^2} c_j e^{ij\cdot x}. \tag{12}$$

Let $P_k \equiv P$ denote the orthogonal projection of H^l onto X_k. An elementary Fourier series argument shows that P is also an orthogonal projection of H^0 onto X_k and

$$\langle Pu, v\rangle_0 = \langle u, Pv\rangle_0 \ \text{ for all } \quad u, v \in H^l. \tag{13}$$

Now let $\Lambda \in (n/2+1, l)$. Since X_k is finite dimensional and a subset of C^1, by (6) there exists a bounded differentiable function $\tilde{F} : X_k \to X_k$ such that $PF(u) = \tilde{F}(u)$ if $\|u\|_\Lambda < \epsilon/2$, $u \in X_k$. Hence the initial value problem

$$z'(t) = -\tilde{F}(z(t)) + P(g),\ t \geq 0, \quad z(0) = 0, \tag{14}$$

has a solution defined on $[0, \infty)$.

Let us see that, for $\|g\|_l$ small enough, $|z(t)|_1 < \epsilon/2$ for all $t \geq 0$. In fact, let $w(t) = P(\tilde{F}(z(t)) - g)$. Thus

$$\begin{aligned}(\|w(t)\|_0^2)' &= 2\langle w(t), P\tilde{F}'(z(t))z'(t)\rangle_0 \\ &= -2\langle Pw(t), \tilde{F}'(z(t))(P(w(t))\rangle_0 \\ &\leq -2k_1\|w(t)\|_0^2.\end{aligned} \tag{15}$$

In particular we see that the quantity $\|w(t)\|_0$ is a decreasing function of t. In addition, from (15) we have

$$\|w(t)\|_0 \leq \|w(0)\|_0 e^{-k_1 t} = \|g\|_0 e^{-k_1 t}. \tag{16}$$

Now we estimate the H^l norm of $w(t)$. In order to do so we observe that for each (k, λ) there exists a positive constant $C(k, \lambda)$ such that

$$\|x\|_\lambda^2 \geq C(k, \lambda)\|x\|_l^2 \ \text{ for all } \quad x \in X_k. \tag{17}$$

We note that $C(k, \lambda) \to 0$ as $k \to \infty$ when $\lambda < l$; otherwise $C(k, \lambda)$ can be taken to be equal to 1. From now on we restrict ourselves to the case $\lambda < l$; the case $\lambda \geq l$ is simpler. Thus we may assume that

$$C(k, \lambda) \to 0 \ \text{ as } \quad k \to \infty. \tag{18}$$

From (8), (13), (16), (17), and (18) we infer that for k sufficiently large

$$\begin{aligned}(\|w(t)\|_l^2)' &= 2\langle w(t), P\tilde{F}'(z(t))z'(t)\rangle_l \\ &= -2\langle Pw(t), \tilde{F}'(z(t))(P(w(t))\rangle_l \\ &\leq -2(k_2\|w(t)\|_\lambda^2 - k_3\|w(t)\|_0^2) \\ &\leq -2(k_2 C(k, \lambda)\|w(t)\|_l^2 - k_3\|g\|_0^2 e^{-2k_1 t}).\end{aligned} \tag{19}$$

Thus for k sufficiently large

$$\begin{aligned} \|w(t)\|_l^2 &\le (\|g\|_l^2 + k_3\|g\|_0^2/(k_1 - k_2C(k,\lambda)))e^{-2k_2C(k,\lambda)t} \\ &\le (\|g\|_l^2 + 2k_3\|g\|_0^2/k_1)e^{-2k_2C(k,\lambda)t} \\ &\equiv M(\|g\|_l)e^{-2k_2C(k,\lambda)t}, \end{aligned} \tag{20}$$

where $M(\|g\|_l) \to 0$ as $\|g\|_l \to 0$. By interpolation properties of Sobolev space (see section I.2 in [6]) one has

$$\|w(t)\|_\Lambda \le \|w(t)\|_0^{(1-\Lambda/l)}\|w(t)\|_l^{\Lambda/l} \le M(\|g\|_l)^{\Lambda/(2l)}\|g\|_0^{(1-\Lambda/l)}e^{-k_1(1-\Lambda/l)t}. \tag{21}$$

Integrating (14) by (20) and (21), we see that there exist $\delta > 0$ such that if $\|g\|_l \le \delta$, then

$$\|z(t)\|_\Lambda < \epsilon/3 \quad \text{for all} \quad t \ge 0. \tag{22}$$

Now letting $x_k \in X_k$ be an element in the w-limit set of the orbit defined by z, we see that $\|x_k\|_\Lambda \le \epsilon/3$ and $\tilde{F}(x_k) = PF(x_k) = P(g)$. Therefore by the Sobolev imbedding theorem we may assume that it converges to some element $x \in H^{\lambda_1}$, with $\lambda_1 \in ((N/2)+1, l)$. By (9), $F(x_k)$ is bounded in $H^{\lambda_1 - 1}$. Using again that bounded sequences in H^s have converging subsequences in H^t if $s > t$, we may further assume that $\{F(x_k)\}$ converges in H^{λ_2} with $\lambda_2 \in (n/2, \lambda_1 - 1)$. Recalling that, by Poincaré's inequality,

$$\|z\|_{\lambda_2 - 1} \le C_k\|z\|_{\lambda_2} \quad \text{for all} \quad z \in X_k^{\perp}, \tag{23}$$

with C_k converging to zero as $k \to \infty$, we conclude that $\|(I-P)F(x_k)\|_{\lambda_2 - 1} \to 0$ as $k \to \infty$. This and the fact that $\{F(x_k)\}$ converges to $F(x)$ imply that $\{P(F(x_k))\}$ converges to $F(x)$ in H^{λ_2}. Hence in H^{λ_2} we have

$$g = \lim P_k(g) = \lim P_k(F(x_k)) = F(x), \tag{24}$$

and this proves the theorem. □

ON THE CONCEPT OF VERY WEAK L^2 SOLUTIONS TO EULER'S EQUATIONS[*]

HAMID BELLOUT[†], EMIL CORNEA[†], AND JINDŘICH NEČAS[‡]

Abstract. We propose a new concept of very weak solutions to Euler's equations. We show global existence of such solutions.

Key words. incompressible, fluid, Euler equations

AMS subject classifications. Primary, 35Q30, 35Q35; Secondary, 76B03

PII. S0036141000384290

1. Introduction.

The question of existence of global L^2 weak solutions in $\mathbf{R}^3$ to the initial boundary value problem for inviscid, incompressible fluids, governed by Euler equations

$$\rho \frac{\partial v_i}{\partial t} + \rho v_j \frac{\partial v_i}{\partial x_j} + \frac{\partial p}{\partial x_i} = 0 \quad \text{in } (0,T)\times\Omega, \quad i = 1,2,3, \tag{1.1}$$

$$\operatorname{div} \boldsymbol{v} = 0 \quad \text{in } (0,T)\times\Omega, \tag{1.2}$$

$$\boldsymbol{v}\cdot\boldsymbol{\nu} = 0 \quad \text{in } (0,T)\times\partial\Omega, \tag{1.3}$$

with initial condition

$$\boldsymbol{v}(0,\boldsymbol{x}) = \boldsymbol{v}^0(\boldsymbol{x}), \qquad \boldsymbol{x}\in\Omega, \tag{1.4}$$

where ρ is a positive constant (which will be assumed to be 1), is still open. A very nice and informative discussion of this question and related issues can be found in [4].

A concept of measure-valued solutions was proposed by DiPerna, Majda, Tartar, and others. See [4] and [5] and the references therein. This latter concept seems to be much too large a class of solutions. To quote Lions in [4, p. 153], *A very weak notion (relying on relaxed Young measures or relaxed measure valued solutions) is proposed by R.J. DiPerna and A. Majda* [129] *but the relevance of this notion is not entirely clear since it is not known that "solutions" in the sense of* [129] *coincide with smooth solutions as long as the latter do exist.* Another concept of solutions, called dissipative solutions, was introduced by Lions in [4].

For other results on this problem see also [1], [6], and the references therein.

We shall present here a straightforward concept, based on the *fixed point* for the map $\gamma : \boldsymbol{u} \to \boldsymbol{v}$, where $\boldsymbol{u}$ and $\gamma(\boldsymbol{u}) = \boldsymbol{v}$ are related by the Oseen equations

$$\frac{\partial v_i}{\partial t} + u_j \frac{\partial v_i}{\partial x_j} + \frac{\partial p}{\partial x_i} = 0 \quad \text{in } (0,T)\times\Omega, \quad i = 1,2,3, \tag{1.5}$$

where the fixed point is understood in the sense of the closure of the graph $(\boldsymbol{u}, \boldsymbol{v})$ in the topology of $L^{\infty}_{weak-star}((0,T); L^2_{weak}(\Omega)^3)$. Obviously any L^2 weak solution is a very weak solution in our sense.

We would like to make a few comments on the relation between the very weak solutions we introduce and other concepts of solutions.

1. It is not excluded that nonsmooth, very weak solutions coexist with classical solutions.
2. If a smooth classical solution exists on a time interval $[0, T_c)$, then the very weak solution provided by our method of construction will coincide with this classical solution over the time interval $[0, T_c)$.
3. If a very weak solution is known to be smooth in a time interval $[0, T_w)$, it will coincide with the classical solution over the time interval $[0, T_w)$.
4. Our very weak solutions and the dissipative solutions of Lions are in L^2, a space strictly smaller than the set where Young-measure solutions, whose existence was proved by Diperna and Majda, live.

We will prove items 2 and 3. In the proof of item 3 we will show that if an element $(\boldsymbol{u}, \boldsymbol{u})$ is in the closure of the graph for the topology of $L^{\infty}_{weak-star}((0,T); L^2_{weak}(\Omega)^3)$ and $\boldsymbol{u}$ is smooth, then, in fact, $(\boldsymbol{u}, \boldsymbol{u})$ will be in the smaller set, which is the closure of the graph for the strong topology of $L^{\infty}((0,T); L^2(\Omega)^3)$.

At this stage the possible relations between Young-measure solutions, dissipative solutions, or our very weak solutions remain an open question.

2. Main results.

Let $0 < T < \infty$. We assume that Ω is a smooth bounded domain in $\mathbf{R}^3$, and $\Omega_t = \{t\} \times \Omega$. We will denote by $\boldsymbol{\nu}$ the outward unit normal vector to Ω.

We introduce the spaces $\mathcal{V}$ and V defined by

$$\mathcal{V} = \left\{ \boldsymbol{v} \in L^2(\Omega)^3 : \frac{\partial v_i}{\partial x_i} = 0 \text{ in } \Omega,\ \boldsymbol{v} \cdot \boldsymbol{\nu} = 0 \text{ on } \partial\Omega \right\} \tag{2.1}$$

and

$$V = L^{\infty}((0,T); \mathcal{V}). \tag{2.2}$$

Let $\boldsymbol{v}^0 \in \mathcal{V}$. We recall the definition of a weak solution.

Definition 1. *A* $\boldsymbol{v} \in V$ *is a weak solution to* (1.1)–(1.4) *with* $\rho = 1$ *if*

$$-\int\int_Q v_i \frac{\partial \phi_i}{\partial t}\, dt d\boldsymbol{x} - \int\int_Q v_j v_i \frac{\partial \phi_i}{\partial x_j}\, dt d\boldsymbol{x} - \int_{\Omega} v_i^0 \phi_i \, d\boldsymbol{x} = 0 \tag{2.3}$$

for all $\boldsymbol{\phi} \in C^1([0,T]; W^{3,2}(\Omega)^3) \cap V$ *with* $\boldsymbol{\phi}(T, \cdot\,) = 0$, *where* $Q = (0,T) \times \Omega$.

Let $\boldsymbol{u} \in V$ be given. We are looking for a function $\boldsymbol{v} \in V$ such that for any $\boldsymbol{\phi}$ as described above

$$-\int\int_Q v_i \frac{\partial \phi_i}{\partial t}\, dt d\boldsymbol{x} - \int\int_Q u_j v_i \frac{\partial \phi_i}{\partial x_j}\, dt d\boldsymbol{x} - \int_{\Omega} v_i^0 \phi_i \, d\boldsymbol{x} = 0. \tag{2.4}$$

Proposition 1. *For any given* $\boldsymbol{u} \in V$ *and any given* $\boldsymbol{v}_0 \in \mathcal{V}$ *there exists a weak solution to Oseen equation* (2.4).

Proof. We will use the Galerkin method to show existence. Since $\mathcal{V}$ is separable, there exists a basis $\{\boldsymbol{w}^k\}_{k \geq 1}$ of $\mathcal{V}$. It is well known that $\{\boldsymbol{w}^k\}_{k \geq 1}$ can be chosen to be an orthonormal basis in $\mathcal{V}$. Also, since $\mathcal{D}(\Omega)$ is dense in $\mathcal{V}$, we can assume that this basis is made of smooth functions (C^{∞}, for example; cf. [3]).

We look for a function $\boldsymbol{v}^n(t,\boldsymbol{x}) = \sum_{1\le k\le n} a_k(t)\boldsymbol{w}^k(\boldsymbol{x})$, such that $a_k(\cdot) \in C^1([0,T])$, and

$$\int_{\Omega_t} \frac{\partial v_i^n}{\partial t} w_i^k \, d\boldsymbol{x} + \int_{\Omega_t} u_j \frac{\partial v_i^n}{\partial x_j} w_i^k \, d\boldsymbol{x} = 0 \tag{2.5}$$

and

$$\int_\Omega v_i^n(0) w_i^k \, d\boldsymbol{x} = \int_\Omega v_i^0 w_i^k \, d\boldsymbol{x} \tag{2.6}$$

for all $1 \le k \le n$.

Putting $\boldsymbol{v}^n$ in (2.5), we get

$$\frac{1}{2}\int_\Omega \frac{\partial}{\partial t}|\boldsymbol{v}^n|^2 d\boldsymbol{x} = 0; \tag{2.7}$$

hence

$$\frac{1}{2}\int_\Omega |\boldsymbol{v}^n|^2 \, d\boldsymbol{x} = \frac{1}{2}\int_\Omega |\boldsymbol{v}^n(0)|^2 \, d\boldsymbol{x}. \tag{2.8}$$

Since the functions $\sum_{1\le k\le m} b_k(t)\boldsymbol{w}^k(x)$, with $b_k(t) \in C^1([0,T])$ and $b_k(T) = 0$, are dense in $C^1([0,T]; W^{3,2}(\Omega)^3) \cap V$ (with $\boldsymbol{\phi}(T,\cdot) = 0$), the $L^\infty_{weak-star}((0,T); L^2_{weak}(\Omega)^3)$ limit $\boldsymbol{v}$ of (a subsequence of) $\boldsymbol{v}^n$ satisfies (2.4) and $\operatorname{div}\boldsymbol{v} = 0$. We also note that $\boldsymbol{v}^n \cdot \boldsymbol{\nu} = 0$ on the boundary Ω_t for all $t \ge 0$. Since $\boldsymbol{v}^n$ converges in the topology of $L^\infty_{weak-star}((0,T); L^2_{weak}(\Omega)^3)$, it follows by the trace theorem that $\boldsymbol{v}\cdot\boldsymbol{\nu} = \lim_{n\to\infty} \boldsymbol{v}^n \cdot \boldsymbol{\nu} = 0$, where the convergence is taking place within the topology of $L^\infty_{weak-star}((0,T); W^{-1/2,2}_{weak}(\partial\Omega)^3)$ (e.g., see Temam [7, p. 9]). Therefore, $\boldsymbol{v} \in V$, and so $\boldsymbol{v}$ is a weak solution to (2.4). □

REMARK 1. *It is easy to prove that, if* $\boldsymbol{u} \in L^\infty((0,T); W^{3,2}(\Omega)^3)$*, then so is* $\boldsymbol{v}$*, and the solution is unique, assuming that* $\boldsymbol{v}^0 \in W^{3,2}(\Omega)^3$.

DEFINITION 2. *Let* $\boldsymbol{u}^n \in V$ *be given, and let* $\boldsymbol{v}^n \in V$ *be the corresponding solution to the Oseen problem* (2.4). *If* $\boldsymbol{u}^n$ *converges to a function* $\boldsymbol{u}$ *and* $\boldsymbol{v}^n$ *converges to a function* $\boldsymbol{v}$ *in the topology of* $L^\infty_{weak-star}((0,T); L^2_{weak}(\Omega)^3)$ *and* $\boldsymbol{u} = \boldsymbol{v}$*, then* $\boldsymbol{u}$ *is called a very weak solution to the problem* (1.1)–(1.4).

REMARK 2. *Obviously, a weak solution is a very weak solution.*

2.1. Existence of very weak solutions to the Dirichlet problem for Euler's equations on bounded domains.

Let Ω be a bounded domain in $\mathbf{R}^3$ with smooth boundary. Let $\omega \in \mathcal{D}(\mathbf{R}^3)$, $\omega(\boldsymbol{x}) \ge 0$, $\int \omega(\boldsymbol{x})\, d\boldsymbol{x} = 1$, $\omega(\boldsymbol{x}) = \omega(-\boldsymbol{x})$. This is a classical mollifier whose existence can be found in most textbooks. We define $\omega_h(\boldsymbol{x}) := h^{-3}\omega(\boldsymbol{x}/h)$, $h > 0$, and

$$\boldsymbol{u}^h(t,\boldsymbol{x}) := (\omega_h * \boldsymbol{u}(t,\cdot))(\boldsymbol{x}) = \frac{1}{h^3}\int_\Omega \omega\left(\frac{\boldsymbol{x}-\boldsymbol{y}}{h}\right)\boldsymbol{u}(t,\boldsymbol{y})\, d\boldsymbol{y}. \tag{2.9}$$

Clearly, if $\boldsymbol{u}$ is divergence-free, then so is $\boldsymbol{u}^h$. Also, $\int_\Omega |\boldsymbol{u}^h|^2 d\boldsymbol{x} \le c\int_\Omega |\boldsymbol{u}|^2 d\boldsymbol{x}$, where c is a constant independent of h.

We choose the same basis, $\{\boldsymbol{w}^k\}_{k\ge 1}$, of $\mathcal{V}$ as before. They are orthogonal functions in $L^2(\Omega)^3$, and they are smooth (cf. [3]). We denote by $\mathcal{P}$ the L^2-orthogonal projection onto $\mathcal{V}$, $E_n := span\{\boldsymbol{w}^1, \ldots, \boldsymbol{w}^n\}$, and we denote by $\mathcal{P}_n$ the L^2-orthogonal projection onto E_n.

Theorem 1. *Let Ω be a bounded domain in $\mathbf{R}^3$ with smooth boundary. For any $\boldsymbol{v}^0 \in \mathcal{V}$ there exists a very weak solution to the problem* (1.1)–(1.4).

Proof. For a fixed $h > 0$, let us first look for a solution to the problem $\boldsymbol{v} \in V$, and

$$-\int_Q v_i \frac{\partial \phi_i}{\partial t}\, dt d\boldsymbol{x} - \int_Q \mathcal{P}(\boldsymbol{v}^h)_j v_i \frac{\partial \phi_i}{\partial x_j}\, dt d\boldsymbol{x} - \int_\Omega v_i^0 \phi_i \, d\boldsymbol{x} = 0 \tag{2.10}$$

for all $\boldsymbol{\phi} \in C^1([0,T]; W^{3,2}(\Omega)^3) \cap V$ with $\boldsymbol{\phi}(T,\cdot) = 0$. Here $\mathcal{P}(\boldsymbol{v}^h)(t,\cdot)$ means $\mathcal{P}(\boldsymbol{v}^h(t,\cdot))$.

As in the above, we will use the Galerkin method to show the existence of solutions to (2.10). Let $\boldsymbol{v}^n$ be the Galerkin approximation to (2.10). That is, $\boldsymbol{v}^n(t,\boldsymbol{x}) = \sum_{1\le k\le n} a_k(t)\boldsymbol{w}^k(\boldsymbol{x}) \in E_n$ with $a_k(\cdot) \in C^1([0,T])$, and $\boldsymbol{v}^n$ satisfies

$$\int_{\Omega_t} \frac{\partial v_i^n}{\partial t} w_i^k \, d\boldsymbol{x} + \int_{\Omega_t} \mathcal{P}(\boldsymbol{v}^{h,n})_j \frac{\partial v_i^n}{\partial x_j} w_i^k \, d\boldsymbol{x} = 0 \tag{2.11}$$

and

$$\int_\Omega v_i^n(0) w_i^k \, d\boldsymbol{x} = \int_\Omega v_i^0 w_i^k \, d\boldsymbol{x} \tag{2.12}$$

for all $1 \le k \le n$. Since $\mathcal{P}(\boldsymbol{v}^{h,n})$ is linear in $a_1, a_2, \dots, a_n$, the second term in the left-hand side of (2.11) is quadratic in $a_1, a_2, \dots, a_n$. Therefore, the existence and uniqueness of $\boldsymbol{v}^n$ follows immediately from the Picard theorem. Clearly, we have

$$\int_\Omega |\boldsymbol{v}^n(t,\boldsymbol{x})|^2 \, d\boldsymbol{x} \le c < \infty \qquad \forall t \in [0,T]. \tag{2.13}$$

We remark that

$$\boldsymbol{v}^{h,n}(t,\boldsymbol{x}) := \frac{1}{h^3} \int_{\mathbf{R}^3} \omega\left(\frac{\boldsymbol{x}-\boldsymbol{y}}{h}\right) \boldsymbol{v}^n(t,\boldsymbol{y}) d\boldsymbol{y}, \qquad \boldsymbol{x} \in \mathbf{R}^3, \tag{2.14}$$

where $\boldsymbol{v}^n(t,\cdot)$ is extended by 0 outside of Ω. From (2.13) and properties of the mollifiers, it follows that $\boldsymbol{v}^{h,n}(t,\cdot) \in C^\infty(\mathbf{R}^3)^3$, and for all $r \ge 0$

$$||\boldsymbol{v}^{h,n}(t,\cdot)||_{C^r(\mathbf{R}^3)} \le c < \infty, \quad t \in [0,T], \tag{2.15}$$

where $c = c(r)$ is a constant.

In order to estimate $\frac{\partial \boldsymbol{v}^n}{\partial t}$, we need the following technical lemma.

Lemma 1.[1] *Let $s \ge 1$ and $p \ge 2$. Assume that $\partial\Omega$ is of class C^∞. Every function $\boldsymbol{\phi} \in W^{s,p}(\Omega)^3$ has the $L^2(\Omega)^3$-orthogonal decomposition*

$$\boldsymbol{\phi} = \boldsymbol{\psi} + \mathbf{grad}(q), \tag{2.16}$$

where $\boldsymbol{\psi} \in W^{s,p}(\Omega)^3 \cap \mathcal{V}$, $q \in W^{s+1,p}(\Omega)/R$. Moreover,

$$||\boldsymbol{\psi}||_{W^{s,p}(\Omega)^3} \le C\, ||\boldsymbol{\phi}||_{W^{s,p}(\Omega)^3}, \tag{2.17}$$

where $C = C(s,p,\Omega)$ is a constant independent of $\boldsymbol{\phi}$.

[1] This should be a well-known classical result about the Helmholtz decomposition. But since we were unable to find a easy source to reference, we decided to provide a quick proof for the reader's convenience.

Proof of Lemma 1. Let $\boldsymbol{\phi} \in W^{s,p}(\Omega)^3$. As $p \geq 2$, $\boldsymbol{\phi} \in L^2(\Omega)^3$, and the Helmholtz decomposition yields (2.16), where $\boldsymbol{\psi} \in L^2(\Omega)^3$, $\operatorname{div}\boldsymbol{\psi} = 0$ in Ω, $\boldsymbol{\psi}\cdot\boldsymbol{\nu} = 0$ on $\partial\Omega$ (i.e., $\boldsymbol{\psi} \in \mathcal{V}$), $q \in W^{1,2}(\Omega)/R$, and $\boldsymbol{\psi}$, $\mathbf{grad}(q)$ are mutually orthogonal in $L^2(\Omega)^3$ (cf. [7, Theorem 1.4., p. 15] or [2, Corollary 3.4, p. 50]). As $\boldsymbol{\phi} \in W^{s,p}(\Omega)^3$, with $s \geq 1$, we have $\boldsymbol{\phi}\cdot\boldsymbol{\nu} \in W^{s-1/p,p}(\partial\Omega)$. It then follows that $\Delta q = \operatorname{div}(\boldsymbol{\phi}-\boldsymbol{\psi}) = \operatorname{div}\boldsymbol{\phi} \in W^{s-1,p}(\Omega)$ and $\frac{\partial q}{\partial \boldsymbol{\nu}} = \mathbf{grad}(q)\cdot\boldsymbol{\nu} = (\boldsymbol{\phi}-\boldsymbol{\psi})\cdot\boldsymbol{\nu} = \boldsymbol{\phi}\cdot\boldsymbol{\nu} \in W^{s-1/p,p}(\partial\Omega)$. The regularity of the solution to the Neumann problem for the Laplace equation implies (cf. [2, Theorem 1.10, p. 15]) that $q \in W^{s+1,p}(\Omega)/R$ and there is a constant $C = C(s,p,\Omega)$ (independent of $\boldsymbol{\phi}$) such that $||q||_{W^{s+1,p}(\Omega)^3/R} \leq C\left(||\operatorname{div}\boldsymbol{\phi}||_{W^{s-1,p}(\Omega)} + ||\boldsymbol{\phi}\cdot\boldsymbol{\nu}||_{W^{s-1/p,p}(\partial\Omega)}\right) \leq C\,||\boldsymbol{\phi}||_{W^{s,p}(\Omega)^3}$. Thus $\boldsymbol{\psi} = \boldsymbol{\phi} - \mathbf{grad}(q) \in W^{s,p}(\Omega)^3$ and $||\boldsymbol{\psi}||_{W^{s,p}(\Omega)^3} \leq ||\boldsymbol{\phi}||_{W^{s,p}(\Omega)^3} + ||q||_{W^{s+1,p}(\Omega)^3/R}$, which yields (2.17). □

COROLLARY 1. *If $s, p, \Omega, \boldsymbol{\phi}$, and $\boldsymbol{\psi}$ are as in Lemma* 1, *then $\boldsymbol{\psi} = \mathcal{P}(\boldsymbol{\phi})$. Therefore, the operator $\mathcal{P}$ maps $W^{s,p}(\Omega)^3$ onto $W^{s,p}(\Omega)^3 \cap \mathcal{V}$, and $\mathcal{P}$ is a bounded operator.*

Proof of Corollary 1. In (2.16) $\boldsymbol{\psi} \in \mathcal{V}$ and $\mathbf{grad}(q)$ is in the $L^2(\Omega)^3$-orthogonal of $\mathcal{V}$, so $\mathcal{P}(\boldsymbol{\phi}) = \boldsymbol{\psi}$. Equation (2.17) implies that $\mathcal{P}$ is a bounded operator. □

Proof of Theorem 1 (cont.). Let $\boldsymbol{\phi} \in W_0^{1,2}(\Omega)^3$ and $\boldsymbol{\psi}$ be as in (2.16). That is, $\boldsymbol{\psi} = \mathcal{P}(\boldsymbol{\phi})$. Since $\boldsymbol{v}^n(t,\cdot) \in E_n$, and so $\frac{\partial \boldsymbol{v}^n}{\partial t}(t,\cdot) \in E_n$, using (2.11), we have

$$\begin{aligned}\int_{\Omega_t} \frac{\partial v_i^n}{\partial t}\phi_i\,d\boldsymbol{x} = \int_{\Omega_t} \frac{\partial v_i^n}{\partial t}\psi_i\,d\boldsymbol{x} \;&=\; \int_{\Omega_t} \frac{\partial v_i^n}{\partial t}\mathcal{P}_n(\boldsymbol{\psi})_i\,d\boldsymbol{x}\\ &= \int_{\Omega_t} \mathcal{P}(v^{h,n})_j v_i^n \frac{\partial}{\partial x_j}\left(\mathcal{P}_n\left(\boldsymbol{\psi}\right)_i\right)\,d\boldsymbol{x}.\end{aligned} \tag{2.18}$$

As $\boldsymbol{v}^{h,n} \in C^\infty(\mathbf{R}^3)$, then $\boldsymbol{v}^{h,n} \in W^{1,4}(\Omega)$. The embedding theorem, Corollary 1, (2.15), and the properties of mollifiers imply that

$$\begin{aligned}\left|\left|\mathcal{P}(\boldsymbol{v}^{h,n})\right|\right|_{L^\infty(\Omega)^3} &\leq c\,\left|\left|\mathcal{P}(\boldsymbol{v}^{h,n})\right|\right|_{W^{1,4}(\Omega)^3}\\ &\leq c\,\left|\left|\boldsymbol{v}^{h,n}\right|\right|_{W^{1,4}(\Omega)^3} \leq c\,||\boldsymbol{v}^n||_{L^2(\Omega)^3} \leq c.\end{aligned} \tag{2.19}$$

Since $E_n \subset \mathcal{V}$, it follows that $\mathcal{P}_n(\boldsymbol{\psi}) = \mathcal{P}_n(\boldsymbol{\phi})$. However, $\boldsymbol{\phi} \in W_0^{1,2}(\Omega)^3$, and (for an appropriate choice of the basis $\{\boldsymbol{w}^k\}_{k\geq 1}$ of $\mathcal{V}$) a direct calculation yields that $\mathcal{P}_n(\boldsymbol{\phi})$ is also the $W^{1,2}(\Omega)^3$-orthogonal projection of $\boldsymbol{\phi}$ on E_n. Therefore,

$$||\mathcal{P}_n(\boldsymbol{\psi})||_{W^{1,2}(\Omega)^3} = ||\mathcal{P}_n(\boldsymbol{\phi})||_{W^{1,2}(\Omega)^3} \leq c\,||\boldsymbol{\phi}||_{W_0^{1,2}(\Omega)^3}\,. \tag{2.20}$$

Using (2.19), (2.13), and (2.20) in (2.18), we obtain

$$\left|\int_{\Omega_t} \frac{\partial v_i^n}{\partial t}\phi_i\,d\boldsymbol{x}\right| \leq\; c\,||\boldsymbol{\phi}||_{W_0^{1,2}(\Omega)^3} \tag{2.21}$$

for any $\boldsymbol{\phi} \in W_0^{1,2}(\Omega)^3$. Thus

$$\left|\left|\frac{\partial \boldsymbol{v}^n}{\partial t}\right|\right|_{L^\infty((0,T);W^{-1,2}(\Omega)^3)} \leq\; c. \tag{2.22}$$

From (2.14) and (2.22), it follows from classical properties of mollifiers that

$$\left|\left|\frac{\partial \boldsymbol{v}^{h,n}}{\partial t}\right|\right|_{L^\infty((0,T);W^{1,2}(\Omega)^3)} \leq\; c. \tag{2.23}$$

Note that in (2.19)–(2.23) the constant c depends on h.

Let $h > 0$ be fixed. From (2.13) and classical compactness arguments it follows that there exist a subsequence n_k and a function $\boldsymbol{v} \in V$ such that $\boldsymbol{v} = \lim_{n_k \to \infty} \boldsymbol{v}^{n_k}$ in the topology of $L^\infty_{weak-star}((0,T); L^2_{weak}(\Omega)^3)$. It then follows from (2.23) and (2.15) that $\boldsymbol{v}^{h,n_k}$ converges strongly in $L^2((0,T); L^2(\Omega)^3)$ to $\boldsymbol{v}^h$ as $k \to \infty$, and so $\mathcal{P}(\boldsymbol{v}^{h,n_k}) \to \mathcal{P}(\boldsymbol{v}^h)$ strongly in $L^2((0,T); L^2(\Omega)^3)$. Therefore, $\mathcal{P}(\boldsymbol{v}^{h,n_k})_j v_i^{n_k}$ converges in the topology of $L^\infty_{weak-star}((0,T); L^2_{weak}(\Omega))$ to $\mathcal{P}(\boldsymbol{v}^h)_j v_i$. Hence $\boldsymbol{v}$ is a solution to the problem (2.10).

We will now let h go to zero and finish the proof of the theorem.

Let us consider a subsequence $h_m \to 0$, and let $\boldsymbol{v}^m$ be the corresponding solution to (2.10) with $h = h_m$. It can easily be seen that $\boldsymbol{v}^m$ and $\boldsymbol{v}^{h_m,m}$ are uniformly bounded in $L^\infty((0,T); L^2(\Omega))$. Therefore, without loss of generality, we can assume that $\boldsymbol{v}^m \to \boldsymbol{v}$ and $\boldsymbol{v}^{h_m,m} \to \boldsymbol{w}$, and so $\mathcal{P}(\boldsymbol{v}^{h_m,m}) \to \mathcal{P}(\boldsymbol{w})$, in the topology of $L^\infty_{weak-star}((0,T); L^2_{weak}(\Omega)^3)$. Clearly, we will have that $\boldsymbol{v} \in V$. To finish the proof of the theorem we need simply to show that $\mathcal{P}(\boldsymbol{w}) = \boldsymbol{v}$.

First we will show that $\boldsymbol{w} = \boldsymbol{v}$. Letting $\boldsymbol{\chi} \in C(\bar{I}; L^2(\Omega)^3)$, we have

$$\begin{aligned}
&\int_0^T \int_\Omega v_i^{h_m,m}(t,\boldsymbol{x})\chi_i(t,\boldsymbol{x})\, d\boldsymbol{x}\, dt \\
&\qquad = \int_0^T dt \int_\Omega \chi_i(t,\boldsymbol{x}) d\boldsymbol{x} \int_{\mathbf{R}^3} \omega\left(\frac{\boldsymbol{x}-\boldsymbol{y}}{h_m}\right) v_i^m(t,\boldsymbol{y})\, d\boldsymbol{y} \\
&\qquad = \int_0^T dt \int_{\mathbf{R}^3} v_i^m(t,\boldsymbol{y}) \frac{d\boldsymbol{y}}{h_m^3} \int_{\mathbf{R}^3} \omega\left(\frac{\boldsymbol{x}-\boldsymbol{y}}{h_m}\right) \chi_i(t,\boldsymbol{x})\, d\boldsymbol{x}
\end{aligned} \tag{2.24}$$

(with $\chi_i(t,\cdot) = 0$ on $\mathbf{R}^3 \setminus \Omega$). Since

$$\frac{1}{h^3} \int_{\mathbf{R}^3} \omega\left(\frac{\boldsymbol{y}-\boldsymbol{x}}{h}\right) \chi_i(t,\boldsymbol{x})\, d\boldsymbol{x} \to \chi_i(t,\boldsymbol{y}) \qquad \text{in } C(\bar{I} \times \Omega)$$

as $h \to 0$ and $\omega(\boldsymbol{x}) = \omega(-\boldsymbol{x})$, we get from (2.24) that

$$\int_0^T \int_\Omega v_i^{h_m,m}(t,\boldsymbol{x})\chi_i(t,\boldsymbol{x})\, d\boldsymbol{x}\, dt \to \int_0^T \int_\Omega v_i(t,\boldsymbol{y})\chi_i(t,\boldsymbol{y})\, d\boldsymbol{y}\, dt. \tag{2.25}$$

It follows that $\boldsymbol{w} = \boldsymbol{v}$.

Since $\boldsymbol{v} \in V$, it follows that $\boldsymbol{w} \in V$, and therefore $\mathcal{P}(\boldsymbol{w}) = \boldsymbol{w}$. Hence $\mathcal{P}(\boldsymbol{w}) = \boldsymbol{v}$, and so $\boldsymbol{v}$ is a very weak solution. □

2.2. Existence of space-periodic very weak solutions to Euler's equation. We shall now consider the space-periodic solutions to (1.1)–(1.4). The proof here is similar to that of the previous subsection. But since in the periodic case we can work with an explicit basis and an explicit decomposition (2.16), we will present some of the details.

We set $\Omega = (-\pi,\pi)^3$ and $Q = (0,T) \times (-\pi,\pi)^3$. There is an obvious identification between functions on Ω and the functions 2π-periodic in each variable on $\mathbf{R}^3$. Throughout this subsection we will use this identification. We consider the spaces $\mathcal{V}_{per}$ and V_{per} defined by

$$\mathcal{V}_{per} = \mathcal{V}_{per}(\mathbf{R}^3) = \left\{ \boldsymbol{v} \in L^2((-\pi,\pi)^3)^3 : \frac{\partial v_i}{\partial x_i} = 0 \text{ in } (-\pi,\pi)^3,\ \int_{(-\pi,\pi)^3} \boldsymbol{v}\, d\boldsymbol{x} = 0 \right\}$$

and

$$V_{per} = L^\infty((0,T); \mathcal{V}_{per}). \tag{2.26}$$

We set $\boldsymbol{w}^{\boldsymbol{k}} = \boldsymbol{c}_{\boldsymbol{k}} e^{I(\boldsymbol{x}\cdot\boldsymbol{k})} + \bar{\boldsymbol{c}}_{\boldsymbol{k}} e^{-I(\boldsymbol{x}\cdot\boldsymbol{k})}$ with $c^j_{\boldsymbol{k}} k_j = 0$, $\boldsymbol{k} \neq (0,0,0)$, where $I^2 = -1$, $\bar{\boldsymbol{c}}_{\boldsymbol{k}} = (\bar{c}^1_{\boldsymbol{k}}, \bar{c}^2_{\boldsymbol{k}}, \bar{c}^3_{\boldsymbol{k}})$, and $\bar{c}^j_{\boldsymbol{k}}$ is the complex conjugate of $c^j_{\boldsymbol{k}}$.

Thus $\{\boldsymbol{w}^{\boldsymbol{k}}\}_{|\boldsymbol{k}|>0}$ is an orthogonal basis in $\mathcal{V}_{per}$, where $|\boldsymbol{k}| = \max_i |k_i|$. We denote $E_n := span\{\boldsymbol{w}^{\boldsymbol{k}} : 0 < |\boldsymbol{k}| \le n\}$.

A function $\boldsymbol{v} \in V_{per}$ is a *space-periodic weak solution* to (1.1)–(1.4), with $\rho = 1$, if $\boldsymbol{v}$ satisfies (2.3) for all $\boldsymbol{\phi}$ as above with $\boldsymbol{\phi}$ 2π-periodic in each spatial variable.

PROPOSITION 2. *For any $\boldsymbol{u} \in V_{per}$ and any given $\boldsymbol{v}^0 \in \mathcal{V}_{per}$, there exists a space-periodic weak solution to Oseen equation* (2.4).

Proof. The proof is similar to that of Proposition 1. □

A function $\boldsymbol{u} \in V_{per}$ is called a *space-periodic very weak solution* to the problem (1.1), (1.2), and (1.4) if Definition 2 holds for $\boldsymbol{u}$ with $\boldsymbol{u}^n, \boldsymbol{v}^n \in V_{per}$.

THEOREM 2. *For any $\boldsymbol{v}^0 \in \mathcal{V}_{per}$ there exists a space-periodic very weak solution to the problem* (1.1)*,* (1.2)*, and* (1.4).

Proof. As in the proof of Theorem 1, for a fixed $h > 0$, we consider the equation for $\boldsymbol{v} \in V_{per}$

$$-\int_Q v_i \frac{\partial \phi_i}{\partial t}\, dt\, d\boldsymbol{x} - \int_Q v^h_j v_i \frac{\partial \phi_i}{\partial x_j}\, dt\, d\boldsymbol{x} - \int_\Omega v^0_i \phi_i\, d\boldsymbol{x} = 0 \tag{2.27}$$

for all $\boldsymbol{\phi} \in C^1([0,T]; W^{3,2}(\Omega)^3) \cap V_{per}$, $\boldsymbol{\phi}$ 2π-periodic in each spatial variable, with $\boldsymbol{\phi}(T, \cdot\,) = 0$. Note that $\boldsymbol{v}^h(t, \cdot\,) \in C^\infty(\mathbf{R}^3) \cap \mathcal{V}_{per}$, 2π-periodic function in each spatial variable, with $\int_{\Omega_t} \boldsymbol{v}^h\, d\boldsymbol{x} = 0$, for all t. That is, $\boldsymbol{v}^h \in V_{per}$.

As above, let $\boldsymbol{v}^n(t,x) = \sum_{0<|\boldsymbol{k}|\le n} a_{\boldsymbol{k}}(t) \boldsymbol{w}^{\boldsymbol{k}}(x)$ be the Galerkin approximation in E_n to (2.27), and let $\boldsymbol{v}^{h,n}$ be defined by (2.14), where $\boldsymbol{v}^n$ is considered as a 2π-periodic function on $\mathbf{R}^3$. Clearly, $\boldsymbol{v}^{h,n} \in C^\infty(\mathbf{R}^3)^3$, and $\boldsymbol{v}^{h,n}$ is 2π-periodic in each spatial variable. The function $\boldsymbol{v}^n$ satisfies

$$\int_{\Omega_t} \frac{\partial v^n_i}{\partial t} w^{\boldsymbol{k}}_i\, d\boldsymbol{x} + \int_{\Omega_t} v^{h,n}_j \frac{\partial v^n_i}{\partial x_j} w^{\boldsymbol{k}}_i\, d\boldsymbol{x} = 0 \tag{2.28}$$

and

$$\int_\Omega v^n_i(0) w^{\boldsymbol{k}}_i\, d\boldsymbol{x} = \int_\Omega v^0_i w^{\boldsymbol{k}}_i\, d\boldsymbol{x} \tag{2.29}$$

for all $1 \le k \le n$. The existence and uniqueness of such a function follows immediately from the Picard theorem. We have

$$||\boldsymbol{v}^n||_{L^\infty((0,T), L^2(\Omega)^3)} \le c. \tag{2.30}$$

Let $\boldsymbol{\phi} = (\phi_1, \phi_2, \phi_3) \in W^{1,2}(\Omega)^3$ be a 2π-periodic function in each variable. Thus $\phi_i(\boldsymbol{x}) = \sum_{\boldsymbol{\ell}} \phi_{i,\boldsymbol{\ell}} e^{I(\boldsymbol{\ell},\boldsymbol{x})}$ with $\sum_{\boldsymbol{\ell}} |\phi_{i,\boldsymbol{\ell}}|^2 |\boldsymbol{\ell}|^2_2 < \infty$ and $|\boldsymbol{\ell}|^2_2 = \ell^2_1 + \ell^3_1 + \ell^2_3$. We define

$$q_{\boldsymbol{\ell}} = -I \frac{\ell_i\, \phi_{i,\boldsymbol{\ell}}}{|\boldsymbol{\ell}|^2_2}, \quad \psi_{i,\boldsymbol{\ell}} = \phi_{i,\boldsymbol{\ell}} - I \ell_i\, q_{\boldsymbol{\ell}}$$

and set $\psi_i(\boldsymbol{x}) = \sum_{\boldsymbol{\ell}} \psi_{i,\boldsymbol{\ell}} e^{I(\boldsymbol{\ell},\boldsymbol{x})}$, $\boldsymbol{\psi} = (\psi_1, \psi_2, \psi_3)$, and $q(\boldsymbol{x}) = \sum_{\boldsymbol{\ell}} q_{\boldsymbol{\ell}} e^{I(\boldsymbol{\ell},\boldsymbol{x})}$. It is easy to verify that $\boldsymbol{\psi} \in W^{1,2}(\Omega)^3$, $\operatorname{div} \boldsymbol{\psi} = 0$ in Ω, $||\mathbf{grad}(q)||_{W^{1,2}(\Omega)^3} \le c||\boldsymbol{\phi}||_{W^{1,2}(\Omega)^3}$,

$\boldsymbol{\psi}, \mathbf{grad}(q)$ are orthogonal in both $L^2(\Omega)^3$ and $\boldsymbol{\phi} = \boldsymbol{\psi} + \mathbf{grad}(q)$. This is exactly the analogue of (2.16). Using this decomposition and (2.28), we immediately get (2.21) and then

$$\left|\left|\frac{\partial \boldsymbol{v}^n}{\partial t}\right|\right|_{L^\infty((0,T);W^{-1,2}(\Omega)^3)} \leq c. \tag{2.31}$$

Let $h > 0$ be fixed. It follows from (2.30) that there exist a subsequence $\boldsymbol{v}^{n_k}$ and a function $\boldsymbol{v} \in V_{per}$ such that $\boldsymbol{v}^{n_k} \to \boldsymbol{v}$ in $L^\infty_{weak-star}((0,T); L^2_{weak}(\Omega)^3)$. Since $L^2(\Omega)^3 \subset\subset W^{-1,2}(\Omega)^3 \subset W^{-1,2}(\Omega)^3$, using (2.30) and (2.31), the convergence $\boldsymbol{v}^{n_k} \to \boldsymbol{v}$ holds in $L^2((0,T); W^{-1,2}(\Omega)^3)$ (cf. [3, Theorem 5.1, p. 58] or [7, Theorem 2.1, p. 271]). Using properties of mollifiers, it then follows that $\boldsymbol{v}^{h,n_k} \to \boldsymbol{v}^h$ strongly in $L^2((0,T); W^{2,2}(\Omega)^3)$. For a function $\boldsymbol{\chi} \in L^2((0,T); W^{2,2}(\Omega)^3)$, $v_j^{h,n_k} \frac{\partial \chi_i}{\partial x_j} \to v_j^h \frac{\partial \chi_i}{\partial x_j}$ in $L^2((0,T); W^{1,2}(\Omega))$, and so $\int_0^T \int_\Omega v_j^{h,n_k} v_i^{n_k} \frac{\partial \chi_i}{\partial x_j}\, d\boldsymbol{x}dt \to \int_0^T \int_\Omega v_j^h v_i \frac{\partial \chi_i}{\partial x_j}\, d\boldsymbol{x}dt$. Therefore, $\boldsymbol{v}$ is a solution to the problem (2.27).

Proceeding as in the last part of the proof of Theorem 1, by letting h go to zero, we obtain (2.25). Therefore, $\boldsymbol{v}$ is a space-periodic very weak solution, and the proof is complete. □

3. Regularity. Here we state some regularity results and shed some light on the relation between very weak solutions and traditional classical solutions. The first result we prove is that if a smooth solution exists, which implicitly assumes that the initial condition is smooth, then the very weak solution constructed by our method will coincide with the classical solution. This does not preclude the existence of other, nonsmooth, very weak solutions.

The second theorem we prove in this section is less obvious and is more significant. We prove that *any* smooth very weak solution is actually a classical solution. This is achieved by showing that smooth elements of the form $(\boldsymbol{u}, \boldsymbol{u})$, which are in the closure, for the weak topology, of the graph of the map γ described in the introduction are in fact in the *smaller* set, which is the closure for the strong topology of the same set.

For simplicity of notation we prove these results in the space-periodic case. The generalization to the other case is immediate.

We begin by clarifying our terminology.

DEFINITION 3. *A function $\boldsymbol{u} \in V_{per}$ is said to be a smooth classical solution to the problem* (1.1), (1.2), *and* (1.4) *in* $[0,T) \times \Omega$ *if it is in the space* $C^0([0,T); W^{3,2}(\Omega)^3)$ *and it satisfies* (1.1), (1.2), *and* (1.4).

LEMMA 2. *Assume that $\boldsymbol{v}^0 \in \mathcal{V} \cap W^{3,2}(\Omega)^3$ and $h > 0$ is a fixed number. Then there exist a time $T > 0$ and a constant C, both independent of h, such that the solution $\boldsymbol{v}(t, \boldsymbol{x}, h)$ of problem* (2.27) *satisfies*

$$||\boldsymbol{v}(\cdot, \cdot, h)||_{C^0([0,T), W^{3,2}(\Omega)^3)} \leq C. \tag{3.1}$$

Proof. This proof follows the same outline as the existence proof used in [6]. Using $\boldsymbol{\phi} = D^{\boldsymbol{l}} \boldsymbol{v}^n$ for all $|\boldsymbol{l}| \leq 3$ as a test function in (2.28), we deduce as in [6, section 2.1] that

$$\frac{d}{dt} ||\boldsymbol{v}^n(t, \cdot)||^2_{W^{3,2}(\Omega)^3} \leq c ||\boldsymbol{v}^n(t, \cdot)||^3_{W^{3,2}(\Omega)^3}, \tag{3.2}$$

where c is a constant independent of n and h. It then easily follows that by letting $n \to \infty$, we get that the solution $\boldsymbol{v}(t, \boldsymbol{x}, h)$ of problem (2.27) satisfies

$$\frac{d}{dt} ||\boldsymbol{v}(t, \cdot, h)||^2_{W^{3,2}(\Omega)^3} \leq c ||\boldsymbol{v}(t, \cdot, h)||^3_{W^{3,2}(\Omega)^3} \tag{3.3}$$

for all $t \geq 0$ and all h.

Choose T such that $0 < T < \frac{2}{c \cdot ||\boldsymbol{v}^0||_{W^{3,2}(\Omega)^3}}$. From the previous estimate it easily follows (see [6, Appendix 2.1], for example) that for $0 \leq t \leq T$

$$||\boldsymbol{v}(\cdot, \cdot, h)||_{C^0([0,T);W^{3,2}(\Omega)^3)} \leq \frac{2||\boldsymbol{v}^0||_{W^{3,2}(\Omega)^3}}{2 - T \cdot c \cdot ||\boldsymbol{v}^0||_{W^{3,2}(\Omega)^3}}, \tag{3.4}$$

where c (the same constant as in the estimate (3.3)) is independent of h and of the initial condition. □

PROPOSITION 3. *Assume that $\boldsymbol{v}^0 \in \mathcal{V}_{per} \cap W^{3,2}(\Omega)^3$. Then there exists a time $T > 0$ such that the space-periodic very weak solution $\boldsymbol{v}(t, \boldsymbol{x})$ to problem* (1.1), (1.2), (1.4) *obtained as a limit of solutions $\boldsymbol{v}(t, \boldsymbol{x}, h)$ to the problem* (2.27) *is a smooth classical solution on $[0, T) \times \Omega$, and it satisfies estimates* (3.3)–(3.4).

Proof. Let $T > 0$ be small enough so that the right-hand side of (3.4) is finite. Since the very weak solution $\boldsymbol{v}$ is the weak limit in L^2 of a sequence of functions which satisfy the estimates (3.3)–(3.4) uniformly, it easily follows that this sequence of functions converges strongly to the weak solution $\boldsymbol{v}$. It follows from this and the Oseen equation that such a limit is a weak solution of the Euler system of equations.

From (3.3)–(3.4) it follows that this weak solution satisfies the same estimates, and we can then deduce that such a weak solution is in fact a classical solution on $[0, T) \times \Omega$. □

Next we prove a continuation-type technical lemma.

LEMMA 3. *Let $M > 0$ be a given number, and let $\boldsymbol{v}(t, \boldsymbol{x})$ be the space-periodic very weak solutions to problem* (1.1), (1.2), (1.4) *obtained as a limit of solutions $\boldsymbol{v}(t, \boldsymbol{x}, h)$ to the problem* (2.27). *Assume that $\boldsymbol{v}^0 \in \mathcal{V}_{per} \cap W^{3,2}(\Omega)^3$ and that there exists a finite time $T_M > 0$ such that $||\boldsymbol{v}(t, \cdot)||_{W^{3,2}(\Omega)^3} \leq M$ for all $t \leq T_M$. Then there exists a number $\alpha > 0$ such that $\boldsymbol{v}(t, \boldsymbol{x})$ is a smooth classical solution on $[0, T_M + \alpha) \times \Omega$.*

Proof. Here c is the same constant as in estimate (3.3). We have already proved in the proposition above that this very weak solution is a smooth classical solution in the region $[0, \sigma) \times \Omega$ with $\sigma = \frac{2}{c \cdot ||\boldsymbol{v}^0||_{W^{3,2}(\Omega)^3}}$.

Now we will consider the remaining case $T_M \geq \sigma$. Let $\sigma_{M+1} = \frac{2}{c \cdot (M+1)} > \sigma_{M+2} = \frac{2}{c \cdot (M+2)}$. Assume that $0 < t_0 < T_M$ is such that $\boldsymbol{v}(t, \boldsymbol{x})$ is a smooth classical solution on $[0, t_0] \times \Omega$ and that $\boldsymbol{v}(t_0, \boldsymbol{x}, h)$ converges weakly in $W^{3,2}(\Omega)^3$ to $\boldsymbol{v}(t_0, \boldsymbol{x})$ as $h \to 0$. From the previous proposition it follows that the set of such t_0 is not empty.

We will show that in fact $\boldsymbol{v}(t, \boldsymbol{x})$ is a smooth classical solution on $[0, t_0 + \sigma_{M+2}] \times \Omega$ and that $\boldsymbol{v}(t_0 + \sigma_{M+2}, \boldsymbol{x}, h)$ converges weakly in $W^{3,2}(\Omega)^3$ to $\boldsymbol{v}(t_0 + \sigma_{M+2}, \boldsymbol{x})$.

Since $||\boldsymbol{v}(t_0, \cdot)||_{W^{3,2}(\Omega)^3} \leq M$, it follows from the weak convergence that for h small enough $||\boldsymbol{v}(t_0, \cdot, h)||_{W^{3,2}(\Omega)^3} \leq (M + 1)$. Dividing both sides of (3.3) by $||\boldsymbol{v}(t, \cdot, h)||^3_{W^{3,2}(\Omega)^3}$ and integrating with respect to time from t_0 to $t_0 + s$, we find that

$$||\boldsymbol{v}(t_0 + s, \cdot, h)||_{W^{3,2}(\Omega)^3} \leq \frac{2||\boldsymbol{v}(t_0, \cdot, h)||_{W^{3,2}(\Omega)^3}}{2 - s \cdot c \cdot ||\boldsymbol{v}(t_0, \cdot, h)||_{W^{3,2}(\Omega)^3}}, \tag{3.5}$$

from which it easily follows that

$$\sup_{s \leq \sigma_{M+2}} ||\boldsymbol{v}(t_0 + s, \cdot, h)||_{W^{3,2}(\Omega)^3} \leq \frac{2(M+1)}{2 - \sigma_{M+2} \cdot c \cdot (M+1)}. \tag{3.6}$$

This, in conjunction with (3.3), will allow us to conclude that the sequence $\boldsymbol{v}(t, \boldsymbol{x}, h)$ converges weakly in $W^{1,2}((t_0, t_0 + \sigma_{M+2}); W^{3,2}(\Omega)^3)$ to $\boldsymbol{v}(t, \boldsymbol{x})$. It then holds that

$\boldsymbol{v}(t,\boldsymbol{x})$ is now a smooth classical solution on $[0, t_0 + \sigma_{M+2}] \times \Omega$. We also have that $\boldsymbol{v}(t_0 + \sigma_{M+2}, \boldsymbol{x}, h)$ converges weakly in $W^{3,2}(\Omega)^3$ to $\boldsymbol{v}(t_0 + \sigma_{M+2}, \boldsymbol{x})$.

The procedure described above can be repeated as long as $t_0 + \sigma_{M+2} \leq T_M$. Repeating the previous procedures enough times, we will, in a finite number of steps, reach the time $T_M + \frac{\sigma_{M+2}}{2}$. We can then take $\alpha = \frac{\sigma_{M+2}}{2}$. □

Next we will prove the uniqueness result we alluded to in point 2 of the introduction.

THEOREM 3. *Assume that* $\boldsymbol{v}^0 \in \mathcal{V}_{per} \cap W^{3,2}(\Omega)^3$ *and that* $\boldsymbol{v}(t,\boldsymbol{x})$ *is the space-periodic very weak solution to problem* (1.1)*,* (1.2)*,* (1.4) *obtained as a limit of solutions* $\boldsymbol{v}(t,\boldsymbol{x},h)$ *to the problem* (2.27)*. Assume that there exist a positive time* T_c *and a function* $\boldsymbol{u}$ *which is a smooth classical solution on* $[0,T_c) \times \Omega$ *to the problem* (1.1)*,* (1.2)*, and* (1.4) *in the sense of the Definition* 3*. Assume also that* $\boldsymbol{v}(0,\boldsymbol{x}) = \boldsymbol{u}(0,\boldsymbol{x})$*. Then* $\boldsymbol{v}(t,\boldsymbol{x}) \in C^0([0,T_c); W^{3,2}(\Omega)^3)$*. Moreover,* $\boldsymbol{v}(t,\boldsymbol{x}) = \boldsymbol{u}(t,\boldsymbol{x})$ *for all* $t \in [0,T_c)$*.*

Proof. Let T^* be a positive finite number such that $T^* < T_c$. Assume that $\boldsymbol{v}(t,\boldsymbol{x}) \in C^0([0,T^*]; W^{3,2}(\Omega)^3)$. It then follows from Lemma 3 that $\boldsymbol{v}(t,\boldsymbol{x})$ is a smooth classical solution over the region $[0,T^*] \times \Omega$. In this case, it is an easy exercise (see [6, p. 78], for example) to show that $\boldsymbol{v}(t,\boldsymbol{x}) = \boldsymbol{u}(t,\boldsymbol{x})$ for all $t \in [0, T*)$. If this can be done for all $T^* < T_c$, then the solutions coincide for all $t \in [0,T_c)$.

Alternatively, there exists a $T_b < T_c$ such that $\boldsymbol{v}(t,\boldsymbol{x}) \notin C^0([0,T_b]; W^{3,2}(\Omega)^3)$. In this case it can easily be seen, using Lemma 3, that there exists a positive time $T_{cr} \leq T_b$ such that $\boldsymbol{v}(t,\boldsymbol{x}) \in C^0([0,T_{cr}); W^{3,2}(\Omega)^3)$ and such that

$$\lim_{t\to {T_{cr}}^-} ||\boldsymbol{v}(t,\cdot)||_{W^{3,2}(\Omega)^3} = \infty. \tag{3.7}$$

From the discussion above we will have that $\boldsymbol{v}(t,\boldsymbol{x}) = \boldsymbol{u}(t,\boldsymbol{x})$ for all $t \in [0,T_{cr})$. This with (3.7) would contradict the fact that $\boldsymbol{u}(t,\boldsymbol{x}) \in C^0([0,T_c); W^{3,2}(\Omega)^3)$. □

THEOREM 4. *Let* $\boldsymbol{w} \in V_{per} \cap C^0([0,T_w); W^{3,2}(\Omega)^3)$ *be any space-periodic very weak solution. Then* $\boldsymbol{w}$ *is a classical solution over the time interval* $[0,T_w)$*.*

Proof. Let $\boldsymbol{w}$ be a very weak smooth solution. Then, by definition, there exist a sequence $\boldsymbol{u}^n \in V$ and a sequence $\boldsymbol{v}^n \in V$ such that $\frac{\partial v_i^n}{\partial t} + u_j^n \frac{\partial v_i^n}{\partial x_j} + \frac{\partial p^n}{\partial x_i} = 0$ in $(0,T_w) \times \Omega$, $i = 1,2,3$, and such that $\boldsymbol{v}^n$ and $\boldsymbol{u}^n$ converge to $\boldsymbol{w}$ in $L^\infty_{weak-star}((0,T_w); L^2_{weak}(\Omega)^3)$.

Fix T such that $0 < T < T_w$. We will show next that $\boldsymbol{w}$ is a classical solution in $[0,T) \times \Omega$ in the sense of Definition 3.

Now we introduce the sequence of functions $\boldsymbol{u}^{h,n}$ defined by mollifying the sequence $\boldsymbol{u}^n$ as in (2.14), we let $\boldsymbol{\psi}^{h,n} \in V$ be the unique solution of the Oseen problem obtained by taking $\boldsymbol{u} = \boldsymbol{u}^{h,n}$ in (2.4), and we let the initial condition $\boldsymbol{v}^{h,n}(0,\boldsymbol{x})$ be the mollification of $\boldsymbol{v}^n(0,\boldsymbol{x})$. Taking the difference of the equations satisfied by $\boldsymbol{\psi}^{h,n}$ and $\boldsymbol{v}^n$, multiplying by $\boldsymbol{\psi}^{h,n} - \boldsymbol{v}^n$, and integrating by parts in space, we find

$$\frac{1}{2}\int_\Omega \frac{\partial}{\partial t}|\boldsymbol{\psi}^{h,n} - \boldsymbol{v}^n|^2 d\boldsymbol{x} = \int_\Omega (u^n - u^{h,n})_j \left(\frac{\partial}{\partial x_j}\psi_i^{h,n}\right)(\psi_i^{h,n} - v_i^n) d\boldsymbol{x}.$$

From this, we deduce in a standard fashion that

$$\begin{aligned}\int_{\Omega_t} |\boldsymbol{\psi}^{h,n} - \boldsymbol{v}^n|^2 d\boldsymbol{x} &\leq c_1 \int_{\Omega_0} |\boldsymbol{\psi}^{h,n} - \boldsymbol{v}^n|^2 d\boldsymbol{x} \\ &\quad + c_2 \int_0^T \int_\Omega |\boldsymbol{u}^n - \boldsymbol{u}^{h,n}|^2 \left|\frac{\partial}{\partial x}\boldsymbol{\psi}^{h,n}\right|^2 d\boldsymbol{x}dt,\end{aligned} \tag{3.8}$$

where c_1 and c_2 are independent of h and n.

For a fixed $h > 0$, $\boldsymbol{u}^{h,n} \in L^\infty((0,T);C^\infty(\Omega)^3)$, $\boldsymbol{\psi}^{h,n}(0,\boldsymbol{x}) \in W^{4,2}(\Omega)^3$, and their norms in these spaces are bounded independently of n. From this and the fact that $\boldsymbol{\psi}^{h,n}$ is a solution of a linear partial differential equation with smooth coefficients, we deduce in a standard way that $\boldsymbol{\psi}^{h,n}$ is bounded uniformly in $W^{1,2}((0,T);W^{4,2}(\Omega)^3)$. Therefore, we have that for h fixed and $n \to \infty$ the sequence $\boldsymbol{\psi}^{h,n}$ will converge in $C^0([0,T];W^{4,2}(\Omega)^3)$ to a function $\boldsymbol{\psi}^h$. From this and the weak convergence in L^2 of the sequence $|\boldsymbol{u}^n - \boldsymbol{u}^{h,n}|$ to $|\boldsymbol{w} - \boldsymbol{w}^h|$, it follows that

$$\lim_{n\to\infty} \int_0^T \int_\Omega |\boldsymbol{u}^n - \boldsymbol{u}^{h,n}|^2 \left|\frac{\partial}{\partial x}\boldsymbol{\psi}^{h,n}\right|^2 d\boldsymbol{x}dt \le \int_0^T \int_\Omega |\boldsymbol{w} - \boldsymbol{w}^h|^2 \left|\frac{\partial}{\partial x}\boldsymbol{\psi}^h\right|^2 d\boldsymbol{x}dt,$$

where $\boldsymbol{w}^h$ is the mollification of $\boldsymbol{w}$.

This, together with (3.8), yields in the limit that

$$\begin{aligned}\int_{\Omega_t} |\boldsymbol{\psi}^h - \boldsymbol{w}|^2 d\boldsymbol{x} \le c_1 &\int_{\Omega_0} |\boldsymbol{\psi}^h - \boldsymbol{w}|^2 d\boldsymbol{x}\\ &+ c_2 \int_0^T \int_\Omega |\boldsymbol{w} - \boldsymbol{w}^h|^2 \left|\frac{\partial}{\partial x}\boldsymbol{\psi}^h\right|^2 d\boldsymbol{x}dt.\end{aligned} \tag{3.9}$$

From the definition of $\boldsymbol{\psi}^{h,n}$ and the fact that $\boldsymbol{u}^{h,n}$ converges strongly to $\boldsymbol{w}^h$ as $n \to \infty$, it is easy to see that $\boldsymbol{\psi}^h \equiv \lim_{n\to\infty} \boldsymbol{\psi}^{h,n}$ is the solution to the problem $\frac{\partial \psi_i^h}{\partial t} + w_j^h \frac{\partial \psi_i^h}{\partial x_j} + \frac{\partial p^h}{\partial x_i} = 0$ in $(0,T) \times \Omega$, $i = 1,2,3$, and satisfies $\boldsymbol{\psi}^h(0,\boldsymbol{x}) = \boldsymbol{w}^h(0,\boldsymbol{x})$.

From the uniform regularity of $\boldsymbol{w}^h$, it can be deduced in a standard way that $\boldsymbol{\psi}^h$, the solutions of the associated Oseen equation, will also be uniformly bounded in $W^{1,2}((0,T);W^{3,2}(\Omega)^3)$, for example.

It can then easily be seen that at least for a subsequence of the sequence, $\boldsymbol{\psi}^h$ will converge in $W^{1,2}((0,T);W^{3,2}(\Omega)^3)$ when $h \to 0$. Since the right-hand side of (3.9) goes to zero as $h \to 0$, it follows that, in fact, $\boldsymbol{\psi}^h$ converges to $\boldsymbol{w}$ as $h \to 0$.

Therefore, the sequence $(\boldsymbol{w}^h, \boldsymbol{\psi}^h)$, which is in the graph of the map γ, converges strongly in $C^0([0,T];W^{3,2}(\Omega)^3)$ to $(\boldsymbol{w},\boldsymbol{w})$. Hence $(\boldsymbol{w},\boldsymbol{w})$ is in the strong closure of the graph.

Also, it follows from $\frac{\partial \psi_i^h}{\partial t} + w_j^h \frac{\partial \psi_i^h}{\partial x_j} + \frac{\partial p^h}{\partial x_i} = 0$ and the strong convergence of $(\boldsymbol{w}^h, \boldsymbol{\psi}^h)$ that $\boldsymbol{w}$ is a classical solution of (1.1) in $[0,T) \times \Omega$.

Since T was a generic number less than T_w, it follows that $\boldsymbol{w}$ is a smooth classical solution in $[0,T_w) \times \Omega$. □

Acknowledgments. We would like to thank Professor W. Strauss, whose pointed questions prompted us to write the regularity section, which has strengthened the philosophy of the paper. We would also like to thank Professor V. Sverak for valuable discussions.

SOME NEW VELOCITY AVERAGING RESULTS*

MICHAEL WESTDICKENBERG†

Abstract. Let (R, μ) be a nonatomic finite measure space, and let $E = L^{\underline{r}}(R, \mu)$ be a Lebesgue space over R. Then we consider tempered distributions f and g (depending on $x \in \mathbb{R}^n$ and $v \in R$), for which $\mathrm{div}_{\mathrm{x}}(\mathbf{a}\mathrm{f}) = \mathrm{g}$ in $\mathcal{S}'(\mathbb{R}^n, E)$. Here $\mathbf{a} : R \longrightarrow \mathbb{R}^n$ is a bounded function of v (a velocity field) satisfying a nondegeneracy condition. We study the regularity of the average $\bar{f} = \int_R f(\cdot, v)\psi(v)\, d\mu(v) \in \mathcal{S}'(\mathbb{R}^n)$ (with $\psi \in L^{\underline{r}'}(R, \mu)$ a suitable weight function) when f and g are bounded in Banach space valued Besov spaces. We also present some compactness results for sequences of averages.

Key words. kinetic equations, velocity averaging, regularity, compactness

AMS subject classifications. 35B65, 35L65, 76P05

1. Introduction.

The subject of velocity averaging is the regularity of moments of solutions of transport equations. Let us consider a typical situation: Assume functions f and g are given, depending on $x \in \mathbb{R}^n$ (space) and $v \in \mathbb{R}^n$ (velocity), for which the relation

$$v \cdot \nabla_x f = g \quad \text{in } \mathcal{D}'(\mathbb{R}^n \times \mathbb{R}^n) \tag{1.1}$$

holds. Assume further that we know the regularity of the two functions, e.g., f and g bounded in $L_p(\mathbb{R}^n \times \mathbb{R}^n)$. What can be said about the velocity average

$$\bar{f}(x) = \int_{\mathbb{R}^n} f(x, v)\psi(v)\, dv?$$

Here $\psi \in \mathcal{D}(\mathbb{R}^n)$ is a suitable weight function. It turns out that $\bar{f}$ is somewhat smoother than f and g. Agoshkov [1] showed that if f and g are in $L_2(\mathbb{R}^n \times \mathbb{R}^n)$ and if the weight function is chosen suitably, then the average is bounded in the Sobolev space $W^{1/2,2}(\mathbb{R}^n)$. Hence we have a gain of one half derivative here. Golse, Lions, Perthame, and Sentis [13] proved that $\bar{f} \in W^{1/2,2}(\mathbb{R}^n)$ for all $\psi \in \mathcal{D}(\mathbb{R}^n)$. Their proof is based on a v-dependent decomposition of the Fourier space. Using interpolation, the authors also obtain a result for $1 < p < \infty$: If $f, g \in L_p(\mathbb{R}^n \times \mathbb{R}^n)$, then $\bar{f} \in W^{s,p}(\mathbb{R}^n)$ for all s strictly less than $\min\{1/p, 1/p'\}$.

DiPerna, Lions, and Meyer [10] gave a further improvement. They proved that $\bar{f} \in B^s_{p,\max\{p,2\}}(\mathbb{R}^n)$ with $s = \min\{1/p, 1/p'\}$. Here $B^s_{p,q}(\mathbb{R}^n)$ is a Besov space (cf. section 3.3). Bézard [3] showed that for $1 < p \leq 2$ the average is contained in the (slightly smaller) generalized Sobolev space $H^s_p(\mathbb{R}^n)$. Finally, DeVore and Petrova [7] made clear that $\bar{f} \in B^s_{p,p}(\mathbb{R}^n)$. They also proved that no further improvement with respect to the secondary index q of the Besov norm is possible.

There are several generalizations to the results given. One can assume different integrability for f and g, i.e., $f \in L_p(\mathbb{R}^n \times \mathbb{R}^n)$ and $g \in L_q(\mathbb{R}^n \times \mathbb{R}^n)$ for suitable p, q.

*Received by the editors November 13, 2000; accepted for publication (in revised form) August 22, 2001; published electronically January 16, 2002. This work was supported by Deutsche Forschungsgemeinschaft, SFB 256, at Bonn University.

†Institut für Angewandte Mathematik, Wegelerstrasse 10, D-53115 Bonn, Germany (mwest@iam.uni-bonn.de).

DiPerna, Lions, and Meyer [10] show for this case that the average is contained in a Besov space built on Lorentz spaces instead of $L_p(\mathbb{R}^n)$-spaces as usual. Bézard [3] claims that $\bar{f}$ is even contained in some Sobolev space $H^s_r(\mathbb{R}^n)$, but there is a mistake in his proof.

One can consider also the situation $f, g \in L_q(\mathbb{R}^n_v, L_p(\mathbb{R}^n_x))$ with $1 < q \leq p$. Then it is shown in [10] that $\bar{f} \in B^s_{p,t}(\mathbb{R}^n)$ with $s = \min\{1/q, 1/q'\}$ and suitable t. Note that s depends only on q and that the integrability of $\bar{f}$ is the same as that of f and g, namely, $L_p(\mathbb{R}^n)$. Bézard [3] also studies this situation for $q \leq 2$ and claims that $\bar{f} \in H^s_q(\mathbb{R}^n)$ with $s = 1/p'$; i.e., the roles of p and q are exchanged. But his proof is incorrect.

One can admit derivatives in v or even in x on the right-hand side (RHS) of the transport equation. This was first studied by DiPerna and Lions [9]. But consult also DiPerna, Lions, and Meyer [10]. More general transport operators such as the relativistic streaming operator or transport equations arising from a kinetic formulation of scalar conservation laws can also be considered, cf. Golse, Lions, Perthame, and Sentis [13], DiPerna and Lions [8, 9], Gérard [12], DiPerna, Lions, and Meyer [10], and Lions, Perthame, and Tadmor [16].

The velocity averaging technique can also be used to study compactness. Assume that sequences $f^{(k)}, g^{(k)}$ that satisfy the transport equation (1.1) and are uniformly bounded or precompact in some function space are given; what can be said about the convergence of the sequence $\bar{f}^{(k)}$? It is clear that the regularity results given above imply compactness. However, we refer also to Golse, Perthame, and Sentis [14], Golse, Lions, Perthame, and Sentis [13], DiPerna and Lions [8], Lions, Perthame, and Tadmor [16], Perthame and Souganidis [18], Bouchut [5], and Westdickenberg and Noelle [23].

Finally, let us mention that there is also a relationship between velocity averaging and results known as moments lemmas or dispersion lemmas. Here one considers solutions of the free transport equation $\partial_t f + v \cdot \nabla_x f = 0$ for suitable initial data $f(0, \cdot) = f_0$ with given integrability with respect to x and v. Then one asks what integrability f has in t, x, and v. In particular, one is interested to find decay estimates for f in time. We refer to Perthame [17], Castella and Perthame [6], Bouchut [5], and the references given there.

In this paper, we present some new velocity averaging results. The starting point of our investigation was the question of whether one can gain more than half a derivative in regularity by assuming more integrability in the kinetic variable v. In a sense, our results give an affirmative answer to this question, cf. section 2. We were also interested to find out what the weakest assumptions on f and g are that would still guarantee strong precompactness. We give some answers to that question below.

This paper is organized as follows: In section 2 we first develop a new view on velocity averaging and state our regularity and compactness results. In section 3 we then collect some facts from the theory of Banach space valued tempered distributions. Sections 4 and 5 contain the proofs of our results.

We will assume in the following the space dimension $n \geq 2$. We denote by $\mathcal{D}(\mathbb{R}^n)$ the space of C^∞-functions with compact support, equipped with the usual topology of test functions. $\mathcal{D}'(\mathbb{R}^n)$ is the corresponding dual, the space of distributions.

2. Main results. We want to make an attempt here to develop a somewhat different, less pragmatic view on velocity averaging than is usual in the literature. Therefore, we go back to the transport equation $\operatorname{div}_x(\mathbf{a}f) = g$ and make precise in what sense this equation should hold. We will use notions and results from the theory of Banach space valued tempered distributions. The reader is referred to section 3, where we put together some information relevant to our discussion.

Let (R,μ) be a nonatomic finite measure space, and let $E = L_{\underline{r}}(R,\mu)$, $1 \le \underline{r} \le \infty$, be a Lebesgue space over (R,μ). Then we consider distributions f and g in $\mathcal{S}'(\mathbb{R}^n, E)$, i.e., linear mappings of the Schwartz class $\mathcal{S}(\mathbb{R}^n)$ (x-dependance) into E (v-dependance), that are continuous with respect to the Fréchet topology of $\mathcal{S}(\mathbb{R}^n)$. We assume that a function $\mathbf{a}\colon R \longrightarrow \mathbb{R}^n$ (velocity field) in $L_\infty(R,\mu)$ is given and that the following relation holds for f and g:

$$\operatorname{div}_x(\mathbf{a}f) = g \qquad \text{in } \mathcal{S}'(\mathbb{R}^n, E). \tag{2.1}$$

By the definition of $\mathcal{S}'(\mathbb{R}^n, E)$, this means that for all test functions $\varphi \in \mathcal{S}(\mathbb{R}^n)$

$$-\sum_{j=1}^{n} \mathbf{a}_j \langle f, \partial_j \varphi\rangle = \langle g, \varphi\rangle \qquad \text{in } E, \tag{2.2}$$

i.e., μ-almost everywhere (μ-a.e.). We use brackets to denote the dual pairing of distributions and test functions. Note that multiplication with $\mathbf{a} \in L_\infty(R,\mu)$ maps E continuously into itself. If both f and g are regular, we may also write

$$-\sum_{j=1}^{n} \mathbf{a}_j \int_{\mathbb{R}^n} f(x,\cdot)\partial_j\varphi(x)\,dx = \int_{\mathbb{R}^n} g(x,\cdot)\varphi(x)\,dx \qquad \text{in } E.$$

Now let ψ be an element of the conjugate space $E' = L_{\underline{r}'}(R,\mu)$ with $1/\underline{r} + 1/\underline{r}' = 1$. Then we can define the average $\bar{f}$ to be that distribution in $\mathcal{S}'(\mathbb{R}^n)$ for which

$$\langle \bar{f}, \varphi\rangle = \int_R \langle f(\cdot, v), \varphi\rangle\, \psi(v)\, d\mu(v) \quad \forall \varphi \in \mathcal{S}(\mathbb{R}^n). \tag{2.3}$$

Hence the average is the pairing of $f \in \mathcal{S}'(\mathbb{R}^n, E)$ with some $\psi \in E'$. Assume now that boundedness of f and g in suitable function spaces is given. Then we may ask for the regularity of $\bar{f}$.

2.1. Regularity. We will use Banach space valued Besov spaces $B^s_{p,q}(\mathbb{R}^n, E)$ with $s \in \mathbb{R}$ and $0 < p,\, q \le \infty$. Assume that we are given two tempered distributions

$$f \in B^s_{p,q}(\mathbb{R}^n, E_1) \quad \text{and} \quad g \in B^{s-\tau}_{p,q}(\mathbb{R}^n, E_2)$$

for suitable numbers $s, \tau \in \mathbb{R}$ and spaces $E_1 = L_{r_1}(R,\mu)$ and $E_2 = L_{r_2}(R,\mu)$. We will consider two different cases: $0 < p \le 1$ (Case I) and $1 < p < \frac{n}{n-1}$ (Case II). We put $E = L_{\underline{r}}(R,\mu)$ with $\underline{r} = \min\{r_1, r_2\}$ and assume that (2.1) holds.

Now let $F = L_r(R,\mu)$ be another Lebesgue space with $1/r \le \min\{1/r_1', 1/r_2'\}$. Then multiplication by some $\psi \in F$ maps E_1 continuously into $L_{\rho_1}(R,\mu)$, where $1/\rho_1 = 1/r + 1/r_1$, and analogously maps E_2 into some $L_{\rho_2}(R,\mu)$. We fix a weight $\psi \in F$ and define the average $\bar{f}$ as in (2.3).

We will assume further that the velocity field $\mathbf{a}$ is nondegenerate in the following sense: There are numbers $C > 0$ and $\alpha \in (0,1]$ s.t. for all $\delta \in (0,1]$

$$\sup_{\xi \in \mathbb{R}^n} \mu\{v \in R \colon |\mathbf{a}(v)\cdot \xi/|\xi|| \le \delta\} \le C\delta^\alpha. \tag{2.4}$$

Remark 2.1. This condition was first used in [16]. Let us give an example. If R is a compact subset of $\mathbb{R}^n$ and μ is the Lebesgue measure, then, for $\mathbf{a}(v) = v$, (2.4) is satisfied with $\alpha = 1$. This velocity field appears, e.g., in the Boltzmann equations.

THEOREM 2.2. *Let $0 < q \le \infty$, $0 < \tau \le 1$, and $\alpha/\rho_2' < 1$. With the assumptions above, $\bar{f}$ is bounded in $B^S_{P,q}(\mathbb{R}^n)$ for numbers P and $S = s - \kappa + \Delta S$ given by*

Case I	$0 < p \le 1$	$P = 2$	$\kappa = n\left(\frac{1}{p} - \frac{1}{2}\right)$
Case II	$1 < p < \frac{n}{n-1}$	$P = \left[\frac{1}{p} - \frac{n-1}{n}\right]^{-1}$	$\kappa = n - 1$

and

$$\Delta S = (1-\tau)\frac{\alpha}{\rho_1'}\left[1 + \alpha\left(\frac{1}{\rho_2} - \frac{1}{\rho_1}\right)\right]^{-1}. \tag{2.5}$$

More precisely, there exists some constant $C > 0$ s.t. for all f, g, and ψ in the respective function spaces the following inequality holds:

$$\|\bar{f}\|_{B^S_{P,q}(\mathbb{R}^n)} \le C\|\psi\|_F \left\{\|f\|_{B^s_{p,q}(\mathbb{R}^n,E_1)} + \|g\|_{B^{s-\tau}_{p,q}(\mathbb{R}^n,E_2)}\right\} \tag{2.6}$$

whenever f and g satisfy the transport equation (2.1).

Remark 2.3. The regularity of the average differs from that of f (i.e., s) by two terms. First, we lose $n(\frac{1}{p} - \frac{1}{P})$ derivatives. More precisely, we change regularity for integrability: Instead of $L_p(\mathbb{R}^n)$-boundedness we now have $L_P(\mathbb{R}^n)$. This is simply a Sobolev imbedding. Second, we gain some regularity ΔS, which is a nonnegative number. This regularizing effect is an outcome of the nondegeneracy of $\mathbf{a}$. Note that ΔS does not depend on p and q. It is a function of α, τ, ρ_1, and ρ_2 only.

Let us discuss a few special cases. If $\alpha = 1$, $\tau = 0$, and $r = \infty$, then $\Delta S \to 1$ for r_1 and r_2 getting large. In other words, we gain almost a full derivative if we have much integrability with respect to the kinetic variable v. (Remember that (R, μ) is a finite measure space.) For $r_1 = r_2 = 2$ we find $\Delta S = 1/2$. Now suppose that g is a full derivative less regular than f, i.e., $\tau = 1$; then $\Delta S = 0$. This is obvious since in that case the transport equation contains no nontrivial regularity information. Note also that ΔS is getting smaller if r is chosen small: For more general (less integrable) weights $\psi \in L_r(R, \mu)$ we pay with a smaller gain of regularity.

Here is an example: If we consider the transport equation $v \cdot \nabla_x f = g$, for which the nondegeneracy condition (2.4) holds with $\alpha = 1$, and if both f and g are contained in $B^0_{1,1}(\mathbb{R}^n, L_\infty(R, \mu))$, then for $\psi \in L_\infty(R, \mu)$ the average $\bar{f}$ is in the negative Sobolev space $H^\epsilon_2(\mathbb{R}^n)$ for all $\epsilon < -\frac{n}{2} + 1$. In the particular case $n = 2$, this means that the average is almost in $L_2(\mathbb{R}^n)$. We cannot reach $\epsilon = 0$ because α/ρ_2' has to be strictly less than 1 (i.e., although the velocity field $\mathbf{a}$ would admit $\alpha = 1$, in our estimates we have to use an $\alpha < 1$). This is an improvement over the results mentioned in section 1 since in section 1 at most quadratic integrability in v could be handled, giving a maximal gain of regularity of one half derivative. Note that for an arbitrary Banach space E the following embedding holds:

$$B^0_{1,1}(\mathbb{R}^n, E) \hookrightarrow L_1(\mathbb{R}^n, E) \hookrightarrow B^0_{1,\infty}(\mathbb{R}^n, E). \tag{2.7}$$

(This follows immediately from the definitions.) Therefore, if we start with f and g in $L_1(\mathbb{R}^n, L_\infty(R, \mu))$, we obtain $\bar{f} \in B^\epsilon_{2,\infty}(\mathbb{R}^n)$ with ϵ as above. The latter space is slightly larger than the corresponding Sobolev space $H^\epsilon_2(\mathbb{R}^n)$.

Remark 2.4. Clearly, it would be nice to get rid of the Sobolev embedding at least partially. And it is also a little bit disappointing that the two cases do not match for $p = 1$ unless $n = 2$: The P for $p > 1$ is considerably larger than that for $p \le 1$. (Hence we lose more derivatives in the Sobolev embedding.) The reason for this discrepancy is that we employ different methods of proof for the two cases of our theorem: for the first case we use a decomposition of f and g into simple building blocks, which gives a decoupling of the x- and v-dependance; for the second case we use the Radon transform and its regularizing properties (cf. section 4). We are not aware of a straightforward way to connect these two methods and thereby fill the gap in P mentioned above. Nevertheless, we hope that our methods are interesting for their own sake.

2.2. Compactness. We now want to discuss a few compactness results and start with a generalization of what was said in section 2.1. Let (R, μ) again be a nonatomic finite measure space, and let E_1 and E_2 be two arbitrary rearrangement-invariant Banach function spaces (cf. section 5.1). Then we consider sequences of distributions bounded in Banach space valued Besov spaces,

$$f^{(k)} \in B^s_{p,q}(\mathbb{R}^n, E_1) \quad \text{and} \quad g^{(k)} \in B^{s-\tau}_{p,q}(\mathbb{R}^n, E_2), \tag{2.8}$$

that satisfy the transport equation (2.1) in $\mathcal{S}'(\mathbb{R}^n, E)$ with $E = E_1 + E_2$. Assume there exists a subset F of the associated space E' of E and two further Banach function spaces G_1 and G_2 such that multiplication with $\psi \in F$ maps E_1 continuously into G_1, and E_2 into G_2. We are interested in the precompactness of the sequence of averages $\bar{f}^{(k)}$ (cf. definition (2.3)) in local Besov spaces $B^{S,\text{loc}}_{P,q}(\mathbb{R}^n)$.

More precisely, we want to identify circumstances under which the sequence of products $\chi \bar{f}^{(k)}$ contains a subsequence converging in $B^S_{P,q}(\mathbb{R}^n)$, where $\chi \in \mathcal{D}(\mathbb{R}^n)$ is an arbitrary test function with compact support. Again we must assume nondegeneracy of the velocity field $\mathbf{a}$, which now takes the form

$$\lim_{\delta \to 0} \eta(\delta) = 0, \qquad \text{where } \eta(\delta) = \sup_{\xi \in \mathbb{R}^n} \mu \left\{ v \in R \colon |\mathbf{a}(v) \cdot \xi / |\xi|| \le \delta \right\}. \tag{2.9}$$

Note that this assumption is weaker than condition (2.4). Again we consider two different situations: $0 < p \le 1$ and $1 < p < \frac{n}{n-1}$. Then we have the following theorem.

THEOREM 2.5. *Let $0 < q \le \infty$ and $0 < \tau < 1$. Assume that the fundamental function of the associated space G_1' of G_1 is continuous at zero. Then the sequence of averages $\bar{f}^{(k)}$ is precompact in $B^{S,\text{loc}}_{P,q}(\mathbb{R}^n)$, where $S = s_1 - \kappa$ with the following.*

Case I	$0 < p \le 1$	$P = 2$	$\kappa = n \left(\frac{1}{p} - \frac{1}{2} \right)$
Case II	$1 < p < \frac{n}{n-1}$	$P = \left[\frac{1}{p} - \frac{n-1}{n} \right]^{-1}$	$\kappa = n - 1$

If $\tau = 1$, we still have precompactness if we assume that the sequence $g^{(k)}$ is not only bounded in $B^{s-\tau}_{p,q}(\mathbb{R}^n, E_2)$ but strongly precompact.

For the definition of the fundamental function we refer to section 5.1.

Remark 2.6. The gain of regularity due to the averaging process depends primarily on the nondegeneracy of the velocity field $\mathbf{a}$ and the integrability of f with respect to the kinetic variable v: the higher α and ρ_1 are in Theorem 2.2, the bigger ΔS becomes. Here we consider a situation where $\mathbf{a}$ is only weakly nondegenerate (i.e., we assume only that $\eta(\delta) \to 0$ for $\delta \to 0$; nothing is said about a polynomial rate) and where also the v-integrability of $f^{(k)}$ is only slightly better than $L_1(R, \mu)$. Then we still have precompactness, but there is no gain of regularity at all. Of course, if we strengthen our assumptions, we will get more: If instead of (2.9) we have (2.4) and if E_1, E_2 are Lebesgue spaces as above, then we can combine the proofs of Theorems 2.2 and 2.5 to show precompactness in $B^{S,\mathrm{loc}}_{P,q}(\mathbb{R}^n)$ with regularity S strictly less than $s - n(\frac{1}{p} - \frac{1}{P}) + \Delta S$ and ΔS given by (2.5).

Remark 2.7. Let us discuss a few examples. The choice $E_1 = L^1(R, \mu)$ forces $F = L^\infty(R, \mu)$ and hence $G_1 = L^1(R, \mu)$ because $L^1(R, \mu)$ is the largest of all rearrangement-invariant Banach function spaces over (R, μ). The fundamental function of the corresponding associated space $G'_1 = L^\infty(R, \mu)$ is discontinuous at zero (cf. section 5.1). Therefore, Theorem 2.5 does not apply: You need more than simple L^1-integrability in the kinetic variable v to obtain strong compactness.

A sufficient condition would be, for example, $E_1 = L \log L(R, \mu)$ and $F = L^\infty(R, \mu)$. Then $G_1 = L \log L(R, \mu)$, and the fundamental function of $G'_1 = \exp L(R, \mu)$ is continuous at zero. $L \log L$-integrability plays an important role for the Boltzmann equations: If f is a solution of this system, then $f \log f$ is the entropy density, and the famous H-theorem tells us that the global entropy does not increase in time.

Note, finally, that the choice $F = E'_1$ does not work either, since from the Hölder inequality (5.1) we again obtain only L^1-integrability for the product.

Concretely, if $f^{(k)}$ and $g^{(k)}$ are bounded in the Besov spaces $B^0_{1,1}(\mathbb{R}^n, L \log L(R, \mu))$ and $B^{-\tau}_{1,1}(\mathbb{R}^n, L_1(R, \mu))$ with $\tau < 1$, then for $\psi \in L_\infty(R, \mu)$ the average $\bar{f}^{(k)}$ is locally precompact in the Sobolev space $H^\epsilon_2(\mathbb{R}^n)$ with $\epsilon = -\frac{n}{2}$. We can admit $\tau = 1$ if we assume strong precompactness instead of mere boundedness for $g^{(k)}$. If $f^{(k)}$ is only bounded in $L_1(\mathbb{R}^n, L \log L(R, \mu))$ instead, then we can use the embedding (2.7) to obtain local precompactness of $\bar{f}^{(k)}$ in $B^\epsilon_{2,\infty}(\mathbb{R}^n)$ with ϵ as above.

Remark 2.8. To prove precompactness of $\bar{f}^{(k)}$ it is sufficient to have boundedness of $f^{(k)}$ and $g^{(k)}$ in local Besov spaces only, cf. Remark 5.9.

3. Preliminaries.

We collect here some results we will need later in the proofs. We start with a few remarks about Banach space valued distributions.

3.1. Banach space valued tempered distributions.

If E is some arbitrary Banach space, we define the Schwartz class $\mathcal{S}(\mathbb{R}^n, E)$ to be the space of infinitely differentiable, rapidly decreasing functions on $\mathbb{R}^n$ taking their values in E. This space is locally convex and complete with respect to the Fréchet topology defined by the family of seminorms

$$p_N(\varphi) = \sup_{|\alpha| \le N} \sup_{x \in \mathbb{R}^n} (1 + |x|)^N \|\partial^\alpha \varphi(x)\|_E \quad \text{with } N \in \mathbb{N}_0.$$

We abbreviate $\mathcal{S}(\mathbb{R}^n) = \mathcal{S}(\mathbb{R}^n, \mathbb{C})$. Now let $\mathcal{O}_M(\mathbb{R}^n, E)$ be the space of smooth E-valued functions with at most polynomial growth at infinity (also called slowly increasing). Again the topology is defined by a family of seminorms

$$\psi \longmapsto \sup_{x \in \mathbb{R}^n} \|\varphi(x) \partial^\alpha \psi(x)\|_E \quad \text{for } \varphi \in \mathcal{S}(\mathbb{R}^n), \alpha \in \mathbb{N}^n_0. \tag{3.1}$$

We denote by $\mathcal{S}'(\mathbb{R}^n, E)$ the space of linear mappings from $\mathcal{S}(\mathbb{R}^n)$ into E that are continuous with respect to the strong topology of the Schwartz class. The dual pairing of some $f \in \mathcal{S}'(\mathbb{R}^n, E)$ with a test function $\varphi \in \mathcal{S}(\mathbb{R}^n)$ is expressed using brackets: $\langle f, \varphi \rangle$. Note that this quantity is an element of E. Therefore, equality in $\mathcal{S}'(\mathbb{R}^n, E)$ means equality in E after testing against $\varphi \in \mathcal{S}(\mathbb{R}^n)$. If $f \in L^1_{\mathrm{loc}}(\mathbb{R}^n, E)$, the pairing is just an integral. As we did for $\mathcal{S}(\mathbb{R}^n)$, we will simply write $\mathcal{O}_M(\mathbb{R}^n)$ and $\mathcal{S}'(\mathbb{R}^n)$ whenever $E = \mathbb{C}$.

Exactly as in the scalar case, we can define derivatives of E-valued tempered distributions $f \in \mathcal{S}'(\mathbb{R}^n, E)$ or the product of f with a slowly increasing function in $\mathcal{O}_M(\mathbb{R}^n)$. Additionally, the notions of support $\operatorname{supp} f$ of f, Fourier transform $\hat{f} = \mathbf{F}f$ and its inverse $\check{f} = \mathbf{F}^{-1}f$, and convolution $f \star \rho$ for $\rho \in \mathcal{S}(\mathbb{R}^n)$ can be carried over from the scalar theory. Again we have the identity $f \star \rho = \mathbf{F}^{-1}[\hat{\rho}\mathbf{F}f]$ in $\mathcal{S}'(\mathbb{R}^n, E)$. Instead of going into details here, we refer to Amann [2] or Hörmander [15].

Let us assume now that besides E there exist two more Banach spaces F and G and a bilinear continuous mapping $\cdot \colon F \times E \longrightarrow G$ with a norm not bigger than one. We call this mapping a multiplication. Then we can define the product $a \bullet f$ of some E-valued tempered distribution $f \in \mathcal{S}'(\mathbb{R}^n, E)$ with a function $a = \psi \otimes \chi$, where $\psi \in \mathcal{O}_M(\mathbb{R}^n)$ and $\chi \in F$, to be that distribution in $\mathcal{S}'(\mathbb{R}^n, G)$ for which

$$\langle a \bullet f, \varphi \rangle = \chi \cdot \langle f, \psi\varphi \rangle \quad \forall \varphi \in \mathcal{S}(\mathbb{R}^n). \tag{3.2}$$

Note that $\langle f, \psi\varphi \rangle \in E$. Then we can ask whether that definition can be extended to a class of functions more general than $a = \psi \otimes \chi$.

Theorem 3.1. *There exists a uniquely defined bilinear mapping*

$$\begin{aligned} \bullet \colon \mathcal{O}_M(\mathbb{R}^n, F) \times \mathcal{S}'(\mathbb{R}^n, E) &\longrightarrow \mathcal{S}'(\mathbb{R}^n, G), \\ (a, f) &\longmapsto a \bullet f, \end{aligned}$$

with (3.2) *for all $a = \psi \otimes \chi$. The mapping $\bullet$ is uniformly continuous with respect to each variable if the respective other one is confined to bounded subsets.*

Remark 3.2. This is a special case of the Schwartz kernel theorem (cf. Theorem 2.1 in Amann [2]). The idea of the proof is the following: Choose some test function $\eta \in \mathcal{D}(\mathbb{R}^n)$ with $\eta \geq 0$ and $\int_{\mathbb{R}^n} \eta(x)\, dx = 1$. For $\epsilon > 0$ define

$$\eta_\epsilon(x) = \epsilon^{-n}\eta(x/\epsilon) \quad \forall x \in \mathbb{R}^n.$$

Then the convolution $f_\epsilon = f \star \eta_\epsilon$ is a function in $\mathcal{O}_M(\mathbb{R}^n, E)$ with $\lim_{\epsilon \to 0} f_\epsilon = f$ in $\mathcal{S}'(\mathbb{R}^n, E)$. If $a \in \mathcal{O}_M(\mathbb{R}^n, F)$ is given, we can define the product $a \bullet f_\epsilon$ pointwise by $a \bullet f_\epsilon(x) = a(x) \cdot f_\epsilon(x) \in G$ for all $x \in \mathbb{R}^n$. Then we put

$$a \bullet f = \lim_{\epsilon \to 0} a \bullet f_\epsilon \quad \text{in } \mathcal{S}'(\mathbb{R}^n, G).$$

Of course, a little work is necessary to show that this definition makes sense. If there is no danger of confusion, we will abbreviate $a \bullet f$ by af.

Remark 3.3. We also need the following fact. Assume there exist Banach spaces E, F_1, F_2, G, H_1, H_2 and multiplications (all denoted by $\cdot$)

$$\begin{tikzcd}
F_1 & \times \arrow[d] & F_2 & & & & F_2 & \times \arrow[d] & E \\
& H_1 & \times & E \arrow[r] & G & F_1 \arrow[l] & \times & H_2 &
\end{tikzcd}$$

that are associative; i.e., $(\chi_1 \cdot \chi_2) \cdot e = \chi_1 \cdot (\chi_2 \cdot e)$ in G for all $\chi_j \in F_j$ and $e \in E$. Then the pointwise multiplication of Theorem 3.1 is associative as well. More precisely,

$$(M_1 \bullet M_2) \bullet f = M_1 \bullet (M_2 \bullet f) \quad \text{in } \mathcal{S}'(\mathbb{R}^n, G)$$

for all $M_j \in \mathcal{O}_M(\mathbb{R}, F_j)$ and $f \in \mathcal{S}'(\mathbb{R}^n, E)$ (cf. Amann [2]).

3.2. L_p-spaces of Banach space valued entire functions. Let $f \in \mathcal{S}'(\mathbb{R}^n, E)$ be a distribution with the property that the support of its Fourier transform $\mathbf{F}f$ is contained in a compact subset $K \subset \mathbb{R}^n$. If $\rho \in \mathcal{S}(\mathbb{R}^n)$ with $\operatorname{supp} \hat{\rho}$ compact and $\hat{\rho}(\xi) = 1$ for all $\xi \in K$, then the identity $f = \mathbf{F}^{-1}[\hat{\rho}\mathbf{F}f] = f \star \rho$ in $\mathcal{S}'(\mathbb{R}^n, E)$ follows immediately from the definitions. Now ρ is an entire analytic function on $\mathbb{R}^n$ that can be extended to $\mathbb{C}^n$. This is the famous Payley–Wiener–Schwartz theorem. For any $N \in \mathbb{N}$ there exists some constant $C_N > 0$ s.t.

$$|\rho(z)| \le C_N(1+|z|)^{-N} e^{c|\mathrm{Im} z|} \quad \forall z \in \mathbb{C}^n. \tag{3.3}$$

From this estimate one derives, completely analogous to the scalar valued case, that $f \in \mathcal{S}'(\mathbb{R}^n, E)$ with $\operatorname{supp} \mathbf{F}f$ compact is an entire analytic E-valued function too. We refer to [15, Theorem 7.3.1] for the argument with $E = \mathbb{C}$.

Definition 3.4. *Let E be some Banach space with $K \subset \mathbb{R}^n$ compact and $0 < p \le \infty$. Then we define the L_p-space of E-valued entire analytic functions*

$$L_{p,K}(\mathbb{R}^n, E) = \Big\{ f \in \mathcal{S}'(\mathbb{R}^n, E) \colon \operatorname{supp} \hat{f} \subset K, \|f\|_{L_p(\mathbb{R}^n,E)} < \infty \Big\}$$

$$\textit{with} \quad \|f\|_{L_p(\mathbb{R}^n,E)} = \left(\int_{\mathbb{R}^n} \|f(x)\|_E^p \, dx \right)^{1/p}.$$

The space $L_{p,K}(\mathbb{R}^n, E)$ is complete with respect to $\|\cdot\|_{L_p(\mathbb{R}^n,E)}$.

Theorem 3.5. *Let E be some Banach space with $K \subset \mathbb{R}^n$ compact, $0 < p \le \infty$, and $0 < w < \infty$. Then there exists a constant $C > 0$ s.t. for all $f \in L_{p,K}(\mathbb{R}^n, E)$*

$$\sup_{y \in \mathbb{R}^n} \|f(x-y)\|_E \, (1+|y|)^{-n/w} \le C \left(\mathbf{M}\|f\|_E^w \right)^{1/w}(x) \quad \forall x \in \mathbb{R}^n.$$

Here $\mathbf{M}$ is the usual Hardy–Littlewood maximal operator

$$\mathbf{M}g(x) = \sup \left\{ \frac{1}{|Q|} \int_Q |g(y)| \, dy \colon \textit{all cubes } Q \textit{ containing } x \right\}.$$

Now if $0 < w < p$ (hence $p/w > 1$), we obtain as an immediate consequence of the Hardy–Littlewood maximal inequality (cf. Stein [20])

$$\begin{aligned} \left\| \sup_{y \in \mathbb{R}^n} \frac{\|f(\cdot - y)\|_E}{(1+|y|)^{n/w}} \right\|_{L^p(\mathbb{R}^n)} &\le C \, \|\mathbf{M}\|f\|_E^w\|_{L^{p/w}(\mathbb{R}^n)}^{1/w} \\ &\le C \, \|\|f\|_E^w\|_{L^{p/w}(\mathbb{R}^n)}^{1/w} = C\|f\|_{L_p(\mathbb{R}^n,E)}. \end{aligned}$$

The constant $C = C(n, p, K, w)$ does not depend on f.

Theorem 3.6 (Nikol'skij inequality). *Let E and K be as above with $0 < p \le q \le \infty$ and $\alpha \in \mathbb{N}_0^n$. Then there exists a constant $C > 0$ s.t. for all $f \in L_{p,K}(\mathbb{R}^n, E)$*

$$\|\partial^\alpha f\|_{L_q(\mathbb{R}^n,E)} \le C\|f\|_{L_p(\mathbb{R}^n,E)}. \tag{3.4}$$

We refer to Triebel [22, Chapter III/15] and to the literature cited there.

3.3. Banach space valued Besov spaces. Let φ_0 be a radially symmetric test function in $\mathcal{S}(\mathbb{R}^n)$ supported in $B_2(0) \subset \mathbb{R}^n$ with $\varphi_0(\xi) = 1$ for all $|\xi| \le 1$. Then define $\varphi_1(\xi) = \varphi_0(2^{-1}\xi) - \varphi_0(\xi)$ and $\varphi_\nu(\xi) = \varphi_1(2^{-\nu+1}\xi)$ for $\nu \in \mathbb{N}$. We obtain a dyadic decomposition of unity $\sum_{\nu \in \mathbb{N}_0} \varphi_\nu(\xi) = 1$ for all $\xi \in \mathbb{R}^n$.

DEFINITION 3.7. *Let E be an arbitrary Banach space with $0 < p,\, q \leq \infty$, and $s \in \mathbb{R}$. Then the Banach space valued Besov space $B^s_{p,q}(\mathbb{R}^n, E)$ is defined as the space of all E-valued distributions $f \in \mathcal{S}'(\mathbb{R}^n, E)$ for which the Besov (quasi) norm*

$$\|f\|_{B^s_{p,q}(\mathbb{R}^n,E)} = \Big\| \big\{ 2^{\nu s} \|f_\nu\|_{L_p(\mathbb{R}^n,E)} \big\}_\nu \Big\|_{\ell_q(\mathbb{N}_0)} \tag{3.5}$$

is finite. Here $f_\nu = \mathbf{F}^{-1}[\varphi_\nu \hat{f}]$ in $\mathcal{S}'(\mathbb{R}^n, E)$. For $1 \leq p, q \leq \infty$, (3.5) is a norm.

Remark 3.8. We stress that the Banach space is completely arbitrary. Assumptions like the unconditionality of Martingale differences (UMD) property, separability, or reflexivity are not necessary. If $E = \mathbb{C}$, we will simply write $B^s_{p,q}(\mathbb{R}^n)$.

Remark 3.9. Assume $t \in \mathbb{R}$, $0 < r \leq \infty$, and let F be a second Banach space continuously embedded into E. As an immediate consequence of definition (3.5), the following inclusions hold:

$$\begin{aligned} &B^s_{p,q}(\mathbb{R}^n, E) \hookrightarrow B^s_{p,r}(\mathbb{R}^n, E) \quad \text{if } q \leq r,\\ &B^s_{p,q}(\mathbb{R}^n, E) \hookrightarrow B^t_{p,q}(\mathbb{R}^n, E) \quad \text{if } t \leq s, \text{ and}\\ &B^s_{p,q}(\mathbb{R}^n, E) \hookrightarrow B^s_{p,q}(\mathbb{R}^n, F). \end{aligned}$$

For any $\sigma \in \mathbb{R}$ the operator $\mathcal{J}_\sigma$, defined by

$$\widehat{\mathcal{J}_\sigma \varphi}(\xi) = \left(1 + |\xi|^2\right)^{\sigma/2} \hat{\varphi}(\xi) \quad \forall \xi \in \mathbb{R}^n,$$

maps the Schwartz class $\mathcal{S}(\mathbb{R}^n)$ injectively onto itself. A posteriori then, the same is true for the space $\mathcal{S}'(\mathbb{R}^n, E)$ because the product of $\mathbf{F}f \in \mathcal{S}'(\mathbb{R}^n, E)$ with a function $(1 + |\cdot|^2)^{\sigma/2} \in \mathcal{O}_M(\mathbb{R}^n)$ is well defined. We have $\mathcal{J}_\sigma \circ \mathcal{J}_{-\sigma} = \mathrm{Id}$ in $\mathcal{S}'(\mathbb{R}^n, E)$.

THEOREM 3.10. *For numbers $s \in \mathbb{R}$ and $0 < p, q \leq \infty$, the two spaces $B^{pq}_{s-\sigma}(\mathbb{R}^n, E)$ and $\mathcal{J}_\sigma B^s_{p,q}(\mathbb{R}^n, E) = \big\{ \mathcal{J}_\sigma f \colon f \in B^s_{p,q}(\mathbb{R}^n, E) \big\}$ coincide. The quantity*

$$\|f\|^*_{B^s_{p,q}(\mathbb{R}^n,E)} = \|\mathcal{J}_\sigma f\|_{B^{s-\sigma}_{p,q}(\mathbb{R}^n,E)}$$

is an equivalent (quasi) norm on $B^s_{p,q}(\mathbb{R}^n, E)$.

Remark 3.11. So Besov spaces of different regularity (with the same p, q, of course) are isomorphic to each other. The mapping $\mathcal{J}_\sigma$ is called a lifting. Let us also recall the closely related estimate

$$\|\partial^\alpha f\|_{B^s_{p,q}(\mathbb{R}^n,E)} \leq C \|f\|_{B^{s+|\alpha|}_{p,q}(\mathbb{R}^n,E)} \quad \forall \alpha \in \mathbb{N}^n_0.$$

We will not give here the proof of Theorem 3.10 nor that of the next one, Theorem 3.12. In both cases, it is an easy adaptation of the corresponding result for the scalar case. We refer to Triebel [21].

THEOREM 3.12. *Let $s \in \mathbb{R}$, $0 < p, q \leq \infty$, and $\psi \in \mathcal{O}_M(\mathbb{R}^n)$. Then for large M*

$$\|\psi f\|_{B^s_{p,q}(\mathbb{R}^n,E)} \leq C \sum_{|\alpha| \leq M} \|\partial^\alpha \psi\|_{L_\infty(\mathbb{R}^n)} \|f\|_{B^s_{p,q}(\mathbb{R}^n,E)} \quad \forall f \in \mathcal{S}'(\mathbb{R}^n, E). \tag{3.6}$$

4. Proofs—regularity. We briefly repeat the assumptions made in section 2.1. Let (R, μ) be a nonatomic finite measure space, and fix Lebesgue spaces $E_1 = L_{r_1}(R, \mu)$ and $E_2 = L_{r_2}(R, \mu)$ with $1 \leq r_1, r_2 \leq \infty$. Assume we are given $f \in B^s_{p,q}(\mathbb{R}^n, E_1)$ and $g \in B^{s-\tau}_{p,q}(\mathbb{R}^n, E_2)$ for some $0 < p, q \leq \infty$ and $s, \tau \in \mathbb{R}$ satisfying a transport equation $\mathrm{div}_x(\mathbf{a}f) = g$ in $\mathcal{S}'(\mathbb{R}^n, E)$, where $E = L_{\underline{r}}(R, \mu)$ and

$\underline{r} = \min\{r_1, r_2\}$. For an arbitrary $\psi \in F = L_r(R,\mu)$ with $1/r \leq \min\{1/r_1', 1/r_2'\}$ define the average $\bar{f} \in \mathcal{S}'(\mathbb{R}^n)$ by

$$\langle \bar{f}, \phi \rangle = \int_R \langle f(\cdot, v), \phi \rangle \, \psi(v) \, d\mu(v) \quad \forall \phi \in \mathcal{S}(\mathbb{R}^n).$$

We will prove that if the velocity field $\mathbf{a}$ satisfies a nondegeneracy condition (2.4), and provided that suitable assumptions on the various parameters hold (which we will repeat in the course of the proof as they are needed), then the average $\bar{f}$ is bounded in the Besov space $\bar{f} \in B^S_{P,q}(\mathbb{R}^n)$ for numbers P, S given in section 2.1.

Without restriction of generality we may fix some s large because of a simple lifting argument: The operator $\mathcal{J}_\sigma$ introduced in section 3.3 is an isomorphism between Banach space valued Besov spaces, $\mathcal{J}_\sigma B^s_{p,q}(\mathbb{R}^n, E) \approx B^{s-\sigma}_{p,q}(\mathbb{R}^n, E)$, and it commutes with the transport operator. We may therefore consider the distributions $F = \mathcal{J}_\sigma f$, respectively, $G = \mathcal{J}_\sigma g$. They satisfy the same transport equation $\operatorname{div}_x(\mathbf{a}F) = G$. Then $\bar{F}$ is equal to $\mathcal{J}_\sigma \bar{f}$, which means that the regularity is simply shifted by σ.

The average $\bar{f}$ is a tempered distribution and can therefore be decomposed into its dyadic components $\bar{f} = \sum_{\nu=0}^\infty \bar{f}_\nu$ in $\mathcal{S}'(\mathbb{R}^n)$ with $\bar{f}_\nu = \mathbf{F}^{-1}[\varphi_\nu \mathbf{F} \bar{f}]$ as usual. It is then sufficient to estimate each block separately: We will show that there exists a constant $C > 0$ independent of f and g s.t. for all $\nu \geq 0$

$$(4.1) \qquad 2^{\nu S} \|\bar{f}_\nu\|_{L_P(\mathbb{R}^n)} \leq C \|\psi\|_F \left\{ 2^{\nu s} \|f_\nu\|_{L_p(\mathbb{R}^n, E_1)} + 2^{\nu(s-\tau)} \|g_\nu\|_{L_p(\mathbb{R}^n, E_2)} \right\}.$$

Here f_ν and g_ν are the dyadic components of f and g. We take the $\ell_q(\mathbb{N}_0)$-norm of the sequence $\left\{2^{\nu S} \|\bar{f}_\nu\|_{L_P(\mathbb{R}^n)}\right\}_{\nu=0}^\infty$, use the q-triangle inequality, and are done.

To prove inequality (4.1) for $\nu = 0$ is a simple matter. Note that for all $\nu \geq 0$

$$\left\langle \bar{f}_\nu, \phi \right\rangle = \int_R \langle f_\nu(\cdot, v), \phi \rangle \, \psi(v) \, d\mu(v) \quad \forall \phi \in \mathcal{S}(\mathbb{R}^n).$$

This follows easily from the definitions. Now each f_ν is an entire analytic function because of the Payley–Wiener–Schwartz theorem (cf. section 3.1). We estimate

$$(4.2) \ \|\bar{f}_0\|_{L_P(\mathbb{R}^n)} = \left\| \int_R f_0(\cdot, v) \psi(v) \, d\mu(v) \right\|_{L_P(\mathbb{R}^n)} \leq \mu(R)^{1/\rho_1'} \|\psi\|_F \|f_0\|_{L_P(\mathbb{R}^n, E_1)}$$

and then use the Nikol'skij inequality (3.4) with $\alpha = 0$ and $q = P$. Recall that R has finite μ-measure and that the exponent ρ_1 was defined by $1/\rho_1 = 1/r + 1/r_1$. This gives (4.1) for $\nu = 0$. So we will assume in the following that $\nu \geq 1$. Then both f_ν and g_ν are smooth functions, and the support of their Fourier transforms lies in a compact set strictly bounded away from the origin.

Since f and g satisfy the transport equation (2.1), the following identity holds:

$$(4.3) \qquad (i\mathbf{a}(v) \cdot \xi) \, \hat{f}(\xi, v) = \hat{g}(\xi, v) \quad \text{in } \mathcal{S}'(\mathbb{R}^n, E).$$

As explained in Theorem 3.1, the left-hand side (LHS) must be understood as a product of the symbol $i\mathbf{a} \cdot \xi \in \mathcal{O}_M(\mathbb{R}^n, L_\infty(R,\mu))$ with the tempered distribution $\hat{f} \in \mathcal{S}'(\mathbb{R}^n, E)$. More precisely, the LHS is that distribution for which

$$\left\langle (i\mathbf{a} \cdot \xi) \, \hat{f}, \phi \right\rangle = \sum_{j=1}^n \mathbf{a}_j \left\langle \hat{f}, i\xi_j \phi \right\rangle \quad \forall \phi \in \mathcal{S}(\mathbb{R}^n).$$

Note that multiplication with $\mathbf{a} \in L_\infty(R,\mu)$ maps E continuously into itself. Then identity (4.3) follows immediately from the definitions, and it still holds when we multiply both sides with φ_ν. So we may replace $\hat{f}$ and $\hat{g}$ with $\hat{f}_\nu$ and $\hat{g}_\nu$.

One might be tempted to divide by the symbol $i\mathbf{a} \cdot \xi$ and express $\hat{f}_\nu$ by $\hat{g}_\nu$. However, products of distributions are defined only for smooth functions. And since $(i\mathbf{a} \cdot \xi)^{-1}$ becomes unbounded for all $\xi \in \mathbb{R}^n$ orthogonal to $\mathbf{a}(v)$, we must be a little more careful. We introduce a splitting and use (4.3) only for that part of Fourier space that is bounded away from the set of points where the symbol vanishes. This is the classical approach. We choose an arbitrary nonnegative test function $\Pi \in \mathcal{D}(\mathbb{R})$, vanishing outside the interval $[-1,1]$, with $\Pi(\xi) = 1$ for all $|\xi| \le \frac{1}{2}$. Then we can define functions

$$\chi_{\mathbf{s}}(\xi,v) = \Pi\left(\delta^{-1}\mathbf{a}(v)\cdot\xi/|\xi|\right) \quad \text{and} \quad \chi_{\mathbf{r}}(\xi,v) = 1 - \chi_{\mathbf{s}}(\xi,v) \tag{4.4}$$

for $(\xi,v) \in \mathbb{R}^n \times R$ and $\delta \ge 0$. Note that the support of $\chi_{\mathbf{s}}$ is contained in the set

$$A_\delta = \{(\xi,v) \in \mathbb{R}^n \times R\colon |\mathbf{a}(v)\cdot\xi/|\xi|| \le \delta\}\,. \tag{4.5}$$

We claim now that both $\varphi_\nu\chi_{\mathbf{s}}$ and $\varphi_\nu\chi_{\mathbf{r}}(i\mathbf{a}\cdot\xi)^{-1}$ are bounded in $\mathcal{O}_M(\mathbb{R}^n, L_\infty(R,\mu))$ for any $\nu \ge 1$. If that is true, we obtain an identity

$$\hat{f}_\nu(\xi,v) = \chi_{\mathbf{s}}(\xi,v)\hat{f}_\nu(\xi,v) + \chi_{\mathbf{r}}(\xi,v)\frac{\hat{g}_\nu(\xi,v)}{i\mathbf{a}(v)\cdot\xi} \quad \text{in } \mathcal{S}'(\mathbb{R}^n,E) \tag{4.6}$$

for $\nu \ge 1$. In fact, note that the second term on the RHS of (4.6) is well defined in $\mathcal{S}'(\mathbb{R}^n,E)$ because of Theorem 3.1. Then we may use the relation (4.3) together with Remark 3.3 to eliminate $\hat{g}_\nu$, and (4.6) follows from the definition of $\chi_{\mathbf{s}}$ and $\chi_{\mathbf{r}}$.

To prove our claim, let us start with $\chi_{\mathbf{s}}$. This function is homogeneous of degree zero in ξ. Hence ξ-derivatives of it of order k are homogeneous in ξ of degree $-k$ for $k \ge 0$. More precisely, if $\alpha \in \mathbb{N}_0^n$ is some multi-index, $|\xi|^{|\alpha|}\partial_\xi^\alpha\chi_{\mathbf{s}}(\xi)$ is a linear combination of products of the following terms:

- derivatives of Π taken at $\delta^{-1}\mathbf{a}(v)\cdot\xi/|\xi|$,
- powers of $\delta^{-1}\mathbf{a}(v)\cdot\xi/|\xi|$ with positive exponent,
- polynomials in $\mathbf{a}(v) \in \mathbb{R}^n$, and
- polynomials in $\xi/|\xi| \in \mathbb{R}^n$.

This follows easily from an induction argument. We assumed that $\mathbf{a} \in L_\infty(R,\mu)$. Therefore, all of these terms are uniformly bounded with respect to v for any $\xi \in \mathbb{R}^n$ fixed. And since φ_ν vanishes in a neighborhood of zero for $\nu \ge 1$, the functions $\varphi_\nu\chi_{\mathbf{s}}$ are bounded in $\mathcal{O}_M(\mathbb{R}^n, L_\infty(R,\mu))$. We can proceed in the same manner for $\varphi_\nu\chi_{\mathbf{r}}$.

To prove that even $\varphi_\nu\chi_{\mathbf{r}}(i\mathbf{a}\cdot\xi)^{-1}$ is bounded in $\mathcal{O}_M(\mathbb{R}^n, L_\infty(R,\mu))$, note first that this function is homogeneous of degree -1 in ξ. Taking derivatives with respect to ξ, we obtain the same terms we already had for $\chi_{\mathbf{s}}$, but now there are also powers of $\mathbf{a}(v)\cdot\xi/|\xi|$ with negative exponent. Still, these terms are uniformly bounded in v because $\chi_{\mathbf{r}}$ vanishes in $A_{\delta/2}$ by construction. This proves our claim.

Summing up, we have a decomposition $\bar{f}_\nu = \bar{f}_{\mathbf{s},\nu} + \bar{f}_{\mathbf{r},\nu}$ for $\nu \ge 1$ with

$$\left\langle \bar{f}_{\mathbf{s},\nu}, \phi \right\rangle = \int_R \left\langle \left[\chi_{\mathbf{s}}\hat{f}_\nu\right](\cdot,v), \check{\phi} \right\rangle \psi(v)\,d\mu(v) \quad \text{and} \tag{4.7}$$

$$\left\langle \bar{f}_{\mathbf{r},\nu}, \phi \right\rangle = \int_R \left\langle \left[|\cdot|^{-1}\bar{\chi}_{\mathbf{r}}\hat{g}_\nu\right](\cdot,v), \check{\phi} \right\rangle \psi(v)\,d\mu(v) \quad \forall \phi \in \mathcal{S}(\mathbb{R}^n). \tag{4.8}$$

We put $\bar{\chi}_{\mathbf{r}}(\xi,v) = \chi_{\mathbf{r}}(\xi,v)\left(i\mathbf{a}(v)\cdot\xi/|\xi|\right)^{-1}$. While up to now the argument was the same for both cases of Theorem 2.2, we must now specialize a bit.

4.1. Regularity—Case I. We will use the fact that each $f \in B^s_{p,q}(\mathbb{R}^n, E)$ can be decomposed into an infinite sum of simple building blocks of the form $\lambda\mathbf{Q}$, where $\mathbf{Q}$ is a scalar function with nice properties and λ is an element of E.

4.1.1. The subatomic decomposition. Let $Q_{\nu m}$ be a cube in $\mathbb{R}^n$ centered at $2^{-\nu}m$ with sides parallel to the coordinate axes and side length $2^{-\nu}$, where $m \in \mathbb{Z}^n$ and $\nu \in \mathbb{N}_0$. If Q is a cube in $\mathbb{R}^n$ and $c > 1$ is a number, we will write cQ for the cube concentric with Q but with sides c times as long as those of Q. Now choose a nonnegative function $\psi \in \mathcal{S}(\mathbb{R}^n)$ with compact support in some cQ_{00} and

$$\sum_{m\in\mathbb{Z}^n} \psi(x-m) = 1 \quad \forall x \in \mathbb{R}^n. \tag{4.9}$$

Let $s \in \mathbb{R}, 0 < p \leq \infty, \frac{L+1}{2} \in \mathbb{N}_0, \gamma \in \mathbb{N}_0^n$, and $\psi^\gamma(x) = x^\gamma\psi(x)$. Then the function

$$(\gamma qu)^L_{\nu m}(x) = 2^{-\nu(s-\frac{n}{p})}\left((-\Delta)^{\frac{L+1}{2}}\psi^\gamma\right)(2^\nu x - m) \tag{4.10}$$

is called an $(s,p)_L - \gamma$-quark over the cube $Q_{\nu m}$.

Remark 4.1. This definition is taken from [22, section 14.1]. In the following, we will need only the case $L = -1$. Then the Laplace operator in (4.10) drops out.

Before stating the subatomic decomposition for $B^s_{p,q}(\mathbb{R}^n, E)$, we show the following.

THEOREM 4.2. *Let $K \subset \mathbb{R}^n$ be a compact set, and let $0 < p \leq \infty$. Then there exists a number $\kappa > 0$ with the following property: for any $\mu \in \mathbb{N}$ with $\mu > \kappa$ the entire analytic function $g \in L_{p,K}(\mathbb{R}^n, E)$ can be written as*

$$g(x) = \sum_{m\in\mathbb{Z}^n}\sum_{\gamma\in\mathbb{N}_0^n} \lambda^\gamma_m \psi^\gamma(2^\mu x - m), \tag{4.11}$$

where the sum converges in $L_q(\mathbb{R}^n, E)$ for all $q \in [p,\infty]$ with $\lambda^\gamma_m \in E$ s.t.

$$\sup_{\gamma\in\mathbb{N}_0^n} 2^{\mu|\gamma|}\left(\sum_{m\in\mathbb{Z}^n} \|\lambda^\gamma_m\|^p_E\right)^{1/p} \leq C\|g\|_{L_p(\mathbb{R}^n,E)}. \tag{4.12}$$

The constant $C = C(K,\mu,n,p)$ does not depend on g.

Proof. Our proof somewhat simplifies a similar argument in Triebel [22, section 14.15]. Choose $\rho \in \mathcal{S}(\mathbb{R}^n)$ with $\operatorname{supp}\hat{\rho}$ contained in some compact neighborhood of K and $\hat{\rho}(\xi) = 1$ for all $\xi \in K$. From the Paley–Wiener–Schwartz theorem we infer that ρ is an entire analytic function. Moreover,

$$g(x) = \int_{\mathbb{R}^n} g(y)\rho(x-y)\,dy \quad \forall x \in \mathbb{R}^n \tag{4.13}$$

(cf. section 3.2). Note that as a consequence of the Nikol'skij inequality (3.4) the function g is bounded and hence locally integrable. We now expand $\rho(\cdot - y)$ into a Taylor series around the point $2^{-\mu}m$ with $m \in \mathbb{Z}^n$ and $\mu \in \mathbb{N}$ fixed. Then

$$\begin{aligned}\psi(2^\mu x - m)\rho(x-y) &= \psi(2^\mu x - m)\sum_{\gamma\in\mathbb{N}_0^n}\frac{D^\gamma\rho(2^{-\mu}m - y)}{\gamma!}\left(x - 2^{-\mu}m\right)^\gamma \\ &= \sum_{\gamma\in\mathbb{N}_0^n} 2^{-\mu|\gamma|}\frac{D^\gamma\rho(2^{-\mu}m-y)}{\gamma!}\psi^\gamma(2^\mu x - m). \end{aligned} \tag{4.14}$$

Since $\operatorname{supp}\psi \subset cQ_{00}$ with $c > 1$, we have $|\psi^\gamma(2^\mu x - m)| \leq (\frac{c}{2}\sqrt{2}^n)^{|\gamma|}$. We apply the Cauchy integral formula componentwise to ρ. Then we obtain for all $z \in \mathbb{C}^n$

$$\rho(z_1, \dots, z_n) = (2\pi i)^{-n} \int_{|w_1 - z_1| = 1} \cdots \int_{|w_n - z_n| = 1} \frac{\rho(w_1, \dots, w_n)\, dw_1 \cdots dw_n}{(z_1 - w_1) \cdots (z_n - w_n)}$$

(integration over $\mathbb{C}^n$). Differentiation gives

$$\begin{aligned} &D^\gamma \rho(z_1, \dots, z_n) \\ &= (-1)^{|\gamma|} \gamma! (2\pi i)^{-n} \int_{|w_1 - z_1| = 1} \cdots \int_{|w_n - z_n| = 1} \frac{\rho(w_1, \dots, w_n)\, dw_1 \cdots dw_n}{(z_1 - w_1)^{\gamma_1 + 1} \cdots (z_n - w_n)^{\gamma_n + 1}} \end{aligned}$$

for $z \in \mathbb{C}^n$ and $\gamma \in \mathbb{N}_0^n$. Using (3.3), we now obtain for arbitrary $N \in \mathbb{N}$ the estimate

$$|D^\gamma \rho(z)| \leq C_N \gamma! (2\pi)^{-n} \int_{|w_1 - z_1| = 1} \cdots \int_{|w_n - z_n| = 1} (1 + |w|)^{-N} e^{c|\mathrm{Im} w|}\, dw_1 \cdots dw_n.$$

If $z \in \mathbb{R}^n$, then $|\mathrm{Im} w| \leq 1$ in the domain of integration. Using

$$1 + |z| \leq (1 + |w|)(1 + |z - w|) \leq (1 + |w|)(1 + |z_1 - w_1| + \cdots + |z_n - w_n|),$$

we can find some constant $C = C(K, N, n)$ s.t.

$$|D^\gamma \rho(z)| \leq C \gamma! (1 + |z|)^{-N} \quad \forall z \in \mathbb{R}^n,\ \gamma \in \mathbb{N}_0^n. \tag{4.15}$$

The number of multi-indices $\gamma \in \mathbb{N}_0^n$ with $|\gamma| = k$ grows polynomially in k. We conclude that the expansion (4.14) is absolutely convergent for μ large enough:

$$\begin{aligned} &\left| \psi(2^\mu x - m) \rho(x - y) - \sum_{|\gamma| \leq K} 2^{-\mu|\gamma|} \frac{D^\gamma \rho(2^{-\mu} m - y)}{\gamma!} \psi^\gamma(2^\mu x - m) \right| \\ &\leq C \mathbf{1}_{cQ_{\mu m}}(x) \left(1 + |2^{-\mu} m - y|\right)^{-N} \underbrace{\sum_{k = K+1}^\infty k^n 2^{-\mu k} \left(\frac{c}{2}\sqrt{2}^n\right)^k}_{c_K} \end{aligned} \tag{4.16}$$

and $c_K \to 0$ for $K \to \infty$. This estimate implies (4.11) with

$$\lambda_m^\gamma = 2^{-\mu|\gamma|} \int_{\mathbb{R}^n} g(y) \frac{(D^\gamma \rho)(2^{-\mu} m - y)}{\gamma!} dy \in E. \tag{4.17}$$

To see that, note first that the sum in m does not cause any harm: For $x \in \mathbb{R}^n$ fixed only finitely, many terms contribute to the sum because ψ is compactly supported. Using (4.9), we can write for any $x \in \mathbb{R}^n$

$$\begin{aligned} &\left\| g(x) - \sum_{m \in \mathbb{Z}^n} \sum_{|\gamma| \leq K} \lambda_m^\gamma \psi^\gamma(2^\mu x - m) \right\|_E \\ &\leq \sum_{m \in \mathbb{Z}^n} \left\| \psi(2^\mu x - m) g(x) - \sum_{|\gamma| \leq K} \lambda_m^\gamma \psi^\gamma(2^\mu x - m) \right\|_E . \end{aligned}$$

Consider one single term of this sum. If $g(x)$ is replaced with (4.13) and λ_m^γ with (4.17), then we obtain the following:

$$\left\|\int_{\mathbb{R}^n} g(y)\left(\psi(2^\mu x-m)\rho(x-y)\right.\right.$$
$$\left.\left.-\sum_{|\gamma|\le K}2^{-\mu|\gamma|}\frac{(D^\gamma\rho)\,(2^{-\mu}m-y)}{\gamma!}\psi^\gamma(2^\mu x-m)\right)dy\right\|_E.$$

The integrand is smooth and hence strongly measurable: g is an entire analytic function, and the terms in brackets are in $\mathcal{S}(\mathbb{R}^n)$. Note that the sum in γ is finite here. Then the Bochner theorem allows us to push the E-norm inside the integral. We apply (4.16) and estimate

$$\int_{R^n}\|g(y)\|_E\left|\psi(2^\mu x-m)\rho(x-y)\right.$$
$$\left.-\sum_{|\gamma|\le K}2^{-\mu|\gamma|}\frac{(D^\gamma\rho)\,(2^{-\mu}m-y)}{\gamma!}\psi^\gamma(2^\mu x-m)\right|dy$$
$$\le Cc_K\mathbf{1}_{cQ_{\mu m}}(x)\int_{\mathbb{R}^n}\|g(y)\|_E\left(1+|2^{-\mu}m-y|\right)^{-N}dy.$$

Recall that N can be made arbitrarily large. Moreover,

$$1+|x-y|\le\left(1+|x-2^{-\mu}m|\right)\left(1+|2^{-\mu}m-y|\right)\le\left(1+c2^{-\mu}\right)\left(1+|2^{-\mu}m-y|\right)$$

for all $x\in cQ_{\mu m}$. Using Theorem 3.5, we find some constant $C>0$ s.t. for $w<p$

$$\int_{\mathbb{R}^n}\|g(y)\|_E\left(1+|2^{-\mu}m-y|\right)^{-N}dy$$
$$\le C\sup_{y\in\mathbb{R}^n}\|g(y)\|_E\,(1+|x-y|)^{-\frac{n}{w}}\cdot\int_{\mathbb{R}^n}(1+|x-y|)^{-N+\frac{n}{w}}\,dy$$
$$\le C\left(\mathbf{M}\|g\|_E^w\right)^{1/w}(x)\quad\forall x\in cQ_{\mu m}. \tag{4.18}$$

The constant $C=C(\mu,n,p,w,K,N)$ does not depend on g. We obtain

$$\left\|g(x)-\sum_{m\in\mathbb{Z}^n}\sum_{|\gamma|\le K}\lambda_m^\gamma\psi^\gamma(2^\mu x-m)\right\|_E\le Cc_K\left(\mathbf{M}\|g\|_E^w\right)^{1/w}(x)\cdot\sum_{m\in\mathbb{Z}^n}\mathbf{1}_{cQ_{\mu m}}(x)$$

for all $x\in\mathbb{R}^n$. Note that the m-sum on the RHS is uniformly bounded because only finitely many cubes $cQ_{\mu m}$ overlap. Now we take $L_q(\mathbb{R}^n)$ (quasi) norms on both sides. Since $w<p\le q$ (hence $q/w>1$) we apply the Hardy–Littlewood maximal inequality (cf. Stein [20]) and obtain

$$\left\|g(x)-\sum_{m\in\mathbb{Z}^n}\sum_{|\gamma|\le K}\lambda_m^\gamma\psi^\gamma(2^\mu x-m)\right\|_{L_q(\mathbb{R}^n,E)}\le Cc_K\left\|\mathbf{M}\|g\|_E^w\right\|_{L_{q/w}(\mathbb{R}^n)}^{1/w}$$
$$\text{and}\quad\left\|\mathbf{M}\|g\|_E^w\right\|_{L_{q/w}(\mathbb{R}^n)}^{1/w}\le C\|g\|_{L_q(\mathbb{R}^n,E)}\le C\|g\|_{L_p(\mathbb{R}^n,E)}.$$

In the last step we used the Nikol'skij inequality (3.4). Now c_K vanishes if $K \to \infty$. Therefore, (4.11) converges strongly in $L_q(\mathbb{R}^n, E)$ for any $q \geq p$ as claimed.

To prove (4.12) we need only to modify this argument a little. Note first that the $\ell_p(\mathbb{Z}^n)$ (quasi) norm in m can also be realized like this:

$$\begin{aligned}\sum_{m\in\mathbb{Z}^n} \|\lambda_m^\gamma\|_E^p &= \sum_{m\in\mathbb{Z}^n} \|\lambda_m^\gamma\|_E^p \cdot 2^{\mu n} \int_{\mathbb{R}^n} \mathbf{1}_{Q_{\mu m}}(x)\,dx \\ &= 2^{\mu n} \int_{\mathbb{R}^n} \sum_{m\in\mathbb{Z}^n} \|\lambda_m^\gamma\|_E^p \mathbf{1}_{Q_{\mu m}}(x)\,dx \\ &= 2^{\mu n} \int_{\mathbb{R}^n} \left(\sum_{m\in\mathbb{Z}^n} \|\lambda_m^\gamma\|_E \mathbf{1}_{Q_{\mu m}}(x) \right)^p dx\end{aligned}$$

because the $Q_{\mu m}$ are pairwise disjoint. On the other hand, we find with (4.15)

$$2^{\mu|\gamma|} \|\lambda_m^\gamma\|_E \leq C \int_{\mathbb{R}^n} \|g(y)\|_E \left(1 + |2^{-\mu}m - y|\right)^{-N} dy.$$

If we now continue with (4.18), we obtain (4.12). The proof is complete. □

Now we can present the subatomic decomposition for $B^s_{p,q}(\mathbb{R}^n, E)$.

THEOREM 4.3. *Let $0 < p, q \leq \infty$, and $s > \sigma_p = \max\{n\,(1/p - 1)\,, 0\}$. Then there exists a number $\kappa > 0$ s.t. for any $\mu \in \mathbb{N}$ with $\mu > \kappa$ any $f \in B^s_{p,q}(\mathbb{R}^n, E)$ can be decomposed into an infinite sum*

$$f(x) = \sum_{\nu=0}^{\infty} \sum_{m\in\mathbb{Z}^n} \sum_{\gamma\in\mathbb{N}_0^n} \lambda^\gamma_{\nu m} \mathbf{Q}^\gamma_{\nu m}(x) \qquad \text{in } \mathcal{S}'(\mathbb{R}^n, E). \tag{4.19}$$

The $\mathbf{Q}^\gamma_{\nu m}$ are $(s,p)_{-1} - \gamma$-quarks and the $\lambda^\gamma_{\nu m} \in E$ coefficients with

$$\sup_{\gamma\in\mathbb{N}_0^n} 2^{\mu|\gamma|} \left(\sum_{\nu=0}^{\infty} \left(\sum_{m\in\mathbb{Z}^n} \|\lambda^\gamma_{\nu m}\|_E^p \right)^{q/p} \right)^{1/q} < \infty. \tag{4.20}$$

Vice versa, if coefficients $\lambda^\gamma_{\nu m} \in E$ are given with (4.20)*, then the sum* (4.19) *converges in $\mathcal{S}'(\mathbb{R}^n, E)$ and defines an element in $B^s_{p,q}(\mathbb{R}^n, E)$. The* inf *in* (4.20) *over all admissible representations* (4.19) *is an equivalent (quasi) norm in $B^s_{p,q}(\mathbb{R}^n, E)$.*

Remark 4.4. This is Corollary 15.9 in Triebel [22].

One direction of the proof is straightforward: For $f \in \mathcal{S}'(\mathbb{R}^n, E)$ we apply Theorem 4.2 to the dyadic parts f_ν. Let us consider the family $g_\nu(y) = f_\nu(2^{-\nu}y)$ for $y \in \mathbb{R}^n$. From the definition of the Fourier transform we easily find that $\operatorname{supp} \hat{g}_\nu \subset B_2(0)$ for all $\nu \in \mathbb{N}_0$. Hence the supports of $\hat{g}_\nu$ are all contained in one single fixed compact subset $K \subset \mathbb{R}^n$. Then there exists some $\kappa > 0$ s.t. for each $\mu > \kappa$ and all $\nu \in \mathbb{N}_0$ the entire analytic function g_ν can be decomposed into

$$g_\nu(y) = \sum_{m\in\mathbb{Z}^n} \sum_{\gamma\in\mathbb{N}_0^n} \tilde{\lambda}^\gamma_{\nu m} \psi^\gamma(2^\mu y - m),$$

with strong convergence in $L^q(\mathbb{R}^n, E)$ for all $q \geq p$, and coefficients $\tilde{\lambda}^\gamma_{\nu m} \in E$ with

$$\sup_{\gamma\in\mathbb{N}_0^n} 2^{\mu|\gamma|} \left(\sum_{m\in\mathbb{Z}^n} \|\tilde{\lambda}^\gamma_{\nu m}\|_E^p \right)^{1/p} \leq C\|g_\nu\|_{L_p(\mathbb{R}^n,E)} = C 2^{\nu\frac{n}{p}} \|f_\nu\|_{L_p(\mathbb{R}^n,E)}. \tag{4.21}$$

The constant C can be chosen independent of ν. Renormalizing, we can write

$$f_\nu(x) = g_\nu(2^\nu x) = 2^{\mu(s-\frac{n}{p})} \sum_{m\in\mathbb{Z}^n} \sum_{\gamma\in\mathbb{N}_0^n} \underbrace{2^{\nu(s-\frac{n}{p})}\tilde{\lambda}^\gamma_{\nu m}}_{=\lambda^\gamma_{\nu m}} \underbrace{(\gamma q u)^{-1}_{\mu+\nu,m}(x)}_{=\mathbf{Q}^\gamma_{\nu m}(x)} \tag{4.22}$$

for $x \in \mathbb{R}^n$. This is (4.19). Now the proof of (4.20) is easy. From (4.21) we obtain

$$\begin{aligned}
&\sup_{\gamma\in\mathbb{N}_0^n} 2^{\mu|\gamma|} \left(\sum_{\nu=0}^\infty \left(\sum_{m\in\mathbb{Z}^n} \|\lambda^\gamma_{\nu m}\|^p_E \right)^{q/p} \right)^{1/q} \\
&\quad \le C \left(\sum_{\nu=0}^\infty \left(2^{\nu s} 2^{-\nu\frac{n}{p}} \sup_{\gamma\in\mathbb{N}_0^n} 2^{\mu|\gamma|} \left(\sum_{m\in\mathbb{Z}^n} \|\tilde{\lambda}^\gamma_{\nu m}\|^p_E \right)^{1/p} \right)^q \right)^{1/q} \\
&\quad \le C \left(\sum_{\nu=0}^\infty 2^{\nu s q} \|f_\nu\|^q_{L_p(\mathbb{R}^n,E)} \right)^{1/q} = C\|f\|_{B^s_{p,q}(\mathbb{R}^n,E)}.
\end{aligned}$$

We used the Minkowski inequality. Proving the reverse direction is more elaborate, and we do not want to give the details here. We refer again to Triebel [22].

4.1.2. Proof of Theorem 2.2, Case I. Let us consider first the term $\bar{f}_{\mathbf{s},\nu}$ in (4.7). If we assume for the moment that $f_\nu(x,v) = \lambda(v)\mathbf{Q}(x)$ for suitable $\mathbf{Q} \in L_2(\mathbb{R}^n)$ and $\lambda \in E_1$, then $\hat{f}_\nu = \lambda\hat{\mathbf{Q}}$ is a measurable function, and we find

$$\langle \bar{f}_{\mathbf{s},\nu}, \phi \rangle = \int_{\mathbb{R}^n} M(\xi)\hat{\mathbf{Q}}(\xi)\check{\phi}(\xi)\,d\xi \quad \text{with} \quad M(\xi) = \int_R \chi_{\mathbf{s}}(\xi,v)\,(\psi\lambda)\,(v)\,d\mu(v).$$

In that situation, we obtain $\bar{f}_{\mathbf{s},\nu}$ by simply applying the Fourier multiplier operator M to $\mathbf{Q}$. We can use Plancherel's theorem to estimate

$$\left|\langle \bar{f}_{\mathbf{s},\nu}, \phi \rangle\right| \le \|M\|_{L_\infty(\mathbb{R}^n)} \|\mathbf{Q}\|_{L_2(\mathbb{R}^n)} \|\phi\|_{L_2(\mathbb{R}^n)}.$$

By assumption, the product $\psi\lambda$ is bounded in $L_{\rho_1}(R,\mu)$. Therefore, we may use the Hölder inequality to estimate

$$\|M\|_{L_\infty(\mathbb{R}^n)} = \sup_{\xi\in\mathbb{R}^n} \left| \int_R \chi_{\mathbf{s}}(\xi,v)\,(\psi\lambda)\,(v)\,d\mu(v) \right| \le \|\psi\|_F \|\lambda\|_{E_1} \sup_{\xi\in\mathbb{R}^n} \|\mathbf{1}_{A_\delta(\xi)}\|_{L_{\rho_1'}(R,\mu)},$$

where $A_\delta(\xi) = \{v \in R\colon (\xi,v) \in A_\delta\}$. However, the nondegeneracy condition (2.4) for the velocity field $\mathbf{a}$ bounds the measure of the set A_δ uniformly in $\xi \in \mathbb{R}^n$. Therefore,

$$\|\bar{f}_{\mathbf{s},\nu}\|_{L_2(\mathbb{R}^n)} = \sup_{\phi\in\mathcal{S}(\mathbb{R}^n)} \|\phi\|^{-1}_{L_2(\mathbb{R}^n)} \left|\langle \bar{f}_{\mathbf{s},\nu}, \phi \rangle\right| \le C\delta^{\alpha/\rho_1'} \|\psi\|_F \|\lambda\|_{E_1} \|\mathbf{Q}\|_{L_2(\mathbb{R}^n)}. \tag{4.23}$$

The conclusion is that $\bar{f}_{\mathbf{s},\nu}$ becomes small in $L_2(\mathbb{R}^n)$ for $\delta \to 0$ if $\mathbf{Q} \in L_2(\mathbb{R}^n)$, $\lambda \in E_1$, and $\rho_1 > 1$. If $\rho_1 = 1$, the estimate does not depend on δ anymore.

We now consider the second term $\bar{f}_{\mathbf{r},\nu}$ in (4.8). If we assume again for the moment that $g_\nu(x,v) = \lambda(v)\mathbf{Q}(x)$ for suitable $\mathbf{Q} \in L_2(\mathbb{R}^n)$ and $\lambda \in E_2$, then $\hat{g}_\nu = \lambda\hat{\mathbf{Q}}$ is a measurable function, and we can write

$$\langle \bar{f}_{\mathbf{r},\nu}, \phi \rangle = \int_{\operatorname{supp}\varphi_\nu} |\xi|^{-1} \bar{M}(\xi)\hat{\mathbf{Q}}(\xi)\check{\phi}(\xi)\,d\xi \quad \text{with } \bar{M}(\xi) = \int_R \bar{\chi}_{\mathbf{r}}(\xi,v)\,(\psi\lambda)\,(v)\,d\mu(v).$$

To estimate $\bar{f}_{\mathbf{r},\nu}$ in $L_2(\mathbb{R}^n)$, we need to find an L_∞-bound for the multiplier. We have $|\xi|^{-1} \le c2^{-\nu}$ in the domain of integration by the construction of φ_ν. Moreover,

$$\|\bar{M}\|_{L_\infty(\mathbb{R}^n)} \le \|\psi\|_F \|\lambda\|_{E_2} \sup_{\xi\in\mathbb{R}^n} \left\| (i\mathbf{a}\cdot\xi/|\xi|)^{-1} \mathbf{1}_{R\setminus A_{\delta/2}(\xi)} \right\|_{L_{\rho_2'}(R,\mu)}.$$

Now we can use the following result.

Lemma 4.5. *Assume* (2.4). *Then for every $\rho \ge 1$ with $\alpha < \rho$*

$$\sup_{\xi\in\mathbb{R}^n} \int_{R\setminus A_\delta(\xi)} |i\mathbf{a}(v)\cdot\xi/|\xi||^{-\rho}\, d\mu(v) \le C\delta^{\alpha-\rho}.$$

Remark 4.6. Here $C = C(\alpha,\rho)$ does not depend on δ. Estimates of this kind appear in many papers on velocity averaging, e.g., in [13], [16], [5].

We use Lemma 4.5 with $\rho = \rho_2'$ under the assumption that $\alpha/\rho_2' < 1$. By testing $\bar{f}_{\mathbf{r},\nu}$ against all functions $\phi \in \mathcal{S}(\mathbb{R}^n)$, we obtain

$$\|\bar{f}_{\mathbf{r},\nu}\|_{L_2(\mathbb{R}^n)} \le C2^{-\nu}\delta^{-1+\alpha/\rho_2'}\|\psi\|_F\|\lambda\|_{E_2}\|\mathbf{Q}\|_{L_2(\mathbb{R}^n)}.$$

We conclude that the dyadic elements $\bar{f}_{\mathbf{r},\nu}$ of the average vanish in $L_2(\mathbb{R}^n)$ like $2^{-\nu}$ if $\nu\to\infty$. This corresponds to a gain of regularity of one derivative (cf. Definition 3.7). Note, however, that $\delta^{-1+\alpha/\rho_2'}$ becomes large as $\delta\to 0$.

Now we use Theorem 4.2, which tells us that the dyadic blocks of f_ν and g_ν can be realized as tensor products. Recall (4.22) from section 4.1.1: For suitable coefficients $\lambda_{\nu m}^\gamma \in E_1$ and $(s_1,p)_{-1} - \gamma$-quarks $\mathbf{Q}_{\nu m}^\gamma$, we have

$$f_\nu(x,v) = 2^{\mu(s-\frac{n}{p})} \sum_{m\in\mathbb{Z}^n}\sum_{\gamma\in\mathbb{N}_0^n} \lambda_{\nu m}^\gamma(v)\mathbf{Q}_{\nu m}^\gamma(x).$$

To control $\bar{f}_{\mathbf{s},\nu}$ in $L_2(\mathbb{R}^n)$, we can now use the triangle inequality and obtain

$$\|\bar{f}_{\mathbf{s},\nu}\|_{L_2(\mathbb{R}^n)} \le C\delta^{\alpha/\rho_1'}\|\psi\|_F \sum_{m\in\mathbb{Z}^n}\sum_{\gamma\in\mathbb{N}_0^n} \|\lambda_{\nu m}^\gamma\|_{E_1}\|\mathbf{Q}_{\nu m}^\gamma\|_{L_2(\mathbb{R}^n)}. \tag{4.24}$$

Here the constant $C = C(\mu,n,p)$ does not depend on f or ν. Note now that quarks are normalized, i.e., there exists a constant $C = C(\mu)$ s.t.

$$\|\mathbf{Q}_{\nu m}^\gamma\|_{L_2(\mathbb{R}^n)} \le C2^{\sigma|\gamma|}2^{-\nu s_1+\nu n(\frac{1}{p}-\frac{1}{2})} \qquad \text{for some } \sigma>0 \text{ and } \gamma\in\mathbb{N}_0^n, m\in\mathbb{Z}^n.$$

One nice feature of the subatomic decomposition in Theorem 4.2 is that we can choose the parameter $\mu\in\mathbb{N}$ as large as we want (at the expense of enlarging the constants, of course). For suitable μ and with $\kappa = n(\frac{1}{p}-\frac{1}{2})$, we therefore obtain the following estimate:

$$\begin{aligned}
\|\bar{f}_{\mathbf{s},\nu}\|_{L_2(\mathbb{R}^n)} &\le C\delta^{\alpha/\rho_1'}2^{-\nu s_1}2^{\nu\kappa}\|\psi\|_F \\
&\qquad\cdot \sup_{\gamma\in\mathbb{N}_0^n} 2^{\mu|\gamma|}\left(\sum_{m\in\mathbb{Z}^n}\|\lambda_{\nu m}^\gamma\|_{E_1}^p\right)^{1/p} \cdot \sum_{\gamma\in\mathbb{N}_0^n} 2^{-(\mu-\sigma)|\gamma|} \\
&\le C\delta^{\alpha/\rho_1'}2^{\nu\kappa}\|\psi\|_F\|f_\nu\|_{L_p(\mathbb{R}^n,E_1)}. \qquad (4.25)
\end{aligned}$$

Consult (4.21)–(4.22). Here we used the fact that $\ell_p(\mathbb{Z}^n) \hookrightarrow \ell_1(\mathbb{Z}^n)$ if $p\le 1$. A similar argument works for $\bar{f}_{\mathbf{r},\nu}$ with $\nu\ge 1$. We have

$$\|\bar{f}_{\mathbf{r},\nu}\|_{L_2(\mathbb{R}^n)} \le C\delta^{-1+\alpha/\rho_2'}2^{-\nu}2^{\nu\kappa}\|\psi\|_F\|g_\nu\|_{L_p(\mathbb{R}^n,E_2)}.$$

The rest of the proof is only a matter of matching: For all $\nu \geq 1$, we want

$$\begin{aligned} &2^{\nu S}\|\bar{f}_{\mathbf{s},\nu}\|_{L_2(\mathbb{R}^n)} \leq C\|\psi\|_F \cdot 2^{\nu s}\|f_\nu\|_{L_p(\mathbb{R}^n,E_1)} \quad \text{and} \\ &2^{\nu S}\|\bar{f}_{\mathbf{r},\nu}\|_{L_2(\mathbb{R}^n)} \leq C\|\psi\|_F \cdot 2^{\nu(s-\tau)}\|g_\nu\|_{L_p(\mathbb{R}^n,E_2)}. \end{aligned} \tag{4.26}$$

To provide this, we choose the ansatz $\delta = 2^{-\nu\sigma}$ and solve the system of equations

$$\begin{aligned} S - \sigma\frac{\alpha}{\rho_1'} &= s - \kappa, \\ S - \sigma\left(-1 + \frac{\alpha}{\rho_2'}\right) &= 1 + s - \tau - \kappa \end{aligned}$$

for (σ, S). We find

$$\begin{aligned} \sigma &= (1-\tau)\left[1 + \alpha\left(\frac{1}{\rho_2} - \frac{1}{\rho_1}\right)\right]^{-1} \quad \text{and} \\ S &= s - n\left(\frac{1}{p} - \frac{1}{2}\right) + (1-\tau)\frac{\alpha}{\rho_1'}\left[1 + \alpha\left(\frac{1}{\rho_2} - \frac{1}{\rho_1}\right)\right]^{-1}. \end{aligned}$$

S is just the regularity of the average $\bar{f}$ we seek. Note also that $\sigma \geq 0$ and hence $\delta \leq 1$ because $\tau \leq 1$. Using (4.26), we obtain the estimate (4.1) for all $\nu \geq 1$.

4.2. Regularity—Case II.

To prove estimate (4.1) for $1 < p < \frac{n}{n-1}$, we use the fact that the action of some homogeneous Fourier multiplier operator on smooth functions can be rewritten in terms of the well-known Radon transform.

4.2.1. Some remarks on the Radon transform.

The Radon transform $\mathbf{R}$ maps a function $\Phi \in \mathcal{S}(\mathbb{R}^n)$ to the average of Φ over all $n-1$-dimensional hyperplanes in $\mathbb{R}^n$. Every such hyperplane is characterized by (1) the unit normal vector $\omega \in S^{n-1}$ and (2) the distance $r \geq 0$ between hyperplane and origin. We therefore define

$$\mathbf{R}\Phi(\omega, r) = \int_{\omega\cdot x = r} \Phi(x)\,dS(x) \qquad \text{for } (\omega, r) \in S^{n-1} \times [0,\infty). \tag{4.27}$$

Here dS is the induced Lebesgue measure. As a synonym we will also write $\tilde{\Phi} = \mathbf{R}\Phi$. Putting $\tilde{\Phi}(\omega, r) = \tilde{\Phi}(-\omega, -r)$, the Radon transform can be extended to a function on $S^{n-1} \times \mathbb{R}$. We have the following relationship with the Fourier transform:

$$\begin{aligned} (2\pi)^n\check{\Phi}(s\omega) &= \int_{\mathbb{R}^n} e^{is\omega\cdot x}\Phi(x)\,dx = \int_{\mathbb{R}} e^{isr}\left(\int_{\omega\cdot x = r}\Phi(x)\,dS(x)\right)dr \\ &= \int_{\mathbb{R}} e^{isr}\tilde{\Phi}(\omega, r)\,dr = 2\pi\mathbf{F}^{-1}\tilde{\Phi}(\omega, s) \qquad \text{for } (\omega, s) \in S^{n-1} \times \mathbb{R}. \end{aligned} \tag{4.28}$$

Let $m \in L_\infty(\mathbb{R}^n)$ be an even homogeneous function of degree zero. For simplicity we assume $m \in C^\infty(S^{n-1})$. Choose $\varphi \in \mathcal{S}(\mathbb{R}^n)$ with $\operatorname{supp}\check{\varphi} \subset \mathbb{R}^n \backslash B_1(0)$. Then

$$\begin{aligned} \mathbf{F}[m\check{\varphi}](x) &= \int_{\mathbb{R}^n} e^{-ix\cdot\xi} m(\xi)\check{\varphi}(\xi)\,d\xi \\ &= \int_{S^{n-1}} m(\omega)\int_0^\infty e^{-ix\cdot s\omega}s^{n-1}\check{\varphi}(s\omega)\,ds\,d\omega. \end{aligned} \tag{4.29}$$

Note that $m\check{\varphi} \in \mathcal{S}(\mathbb{R}^n)$. Now we define $\Phi \in \mathcal{S}(\mathbb{R}^n)$ by $\check{\Phi}(\xi) = |\xi|^{n-1}\check{\varphi}(\xi)$ for all $\xi \in \mathbb{R}^n$. Since m is even, we obtain after a substitution $t = -s$ and $\sigma = -\omega$

$$\int_{S^{n-1}} m(\omega) \int_0^\infty e^{-ix\cdot s\omega} \check{\Phi}(s\omega)\, ds\, d\omega = \int_{S^{n-1}} m(\sigma) \int_{-\infty}^0 e^{-ix\cdot t\sigma} \check{\Phi}(t\sigma)\, dt\, d\sigma.$$

We may therefore extend the s-integral in (4.29) to the whole real line if we allow for an extra factor 1/2. If we now use equality (4.28), we find

$$\begin{aligned} \mathbf{F}[m\check{\varphi}](x) &= \frac{1}{2(2\pi)^{n-1}} \int_{S^{n-1}} m(\omega) \int_{\mathbb{R}} e^{-isx\cdot\omega} \mathbf{F}^{-1}\tilde{\Phi}(\omega, s)\, ds\, d\omega \\ &= \frac{1}{2(2\pi)^{n-1}} \int_{S^{n-1}} m(\omega) \tilde{\Phi}(\omega, x\cdot\omega)\, d\omega. \end{aligned} \tag{4.30}$$

The RHS is simply the average of $\tilde{\Phi}$ over all hyperplanes containing a given point $x \in \mathbb{R}^n$. Now $\mathbf{F}[|\cdot|^{n-1}\check{\varphi}]$ is just a power of the Laplacian, $\Delta^{\frac{n-1}{2}}\varphi$, times some constant (cf. Stein [20]). Hence we obtain for $m(\xi) = 1$ the following identity:

$$\varphi(x) = c\Delta^{\frac{n-1}{2}} \int_{S^{n-1}} \tilde{\varphi}(\omega, x\cdot\omega)\, d\omega.$$

This gives an inversion formula for the Radon transform.

4.2.2. Proof of Theorem 2.2, Case II. Consider first $\hat{f}_{\mathbf{s},\nu}$ in (4.7). Following the proof of Theorem 3.1, we obtain for $\chi_{\mathbf{s}}\hat{f}_\nu \in \mathcal{S}'(\mathbb{R}^n, E)$ and $\phi \in \mathcal{S}(\mathbb{R}^n)$

$$\left\langle \chi_{\mathbf{s}}\hat{f}_\nu, \check{\phi} \right\rangle = \lim_{\epsilon\to 0} \left\langle \chi_{\mathbf{s}}\hat{f}_{\nu,\epsilon}, \check{\phi} \right\rangle \quad \text{with } \hat{f}_{\nu,\epsilon} = \hat{f}_\nu \star \eta_\epsilon,$$

with η_ϵ as in section 3.1. Since $\hat{f}_\nu = \varphi_\nu \hat{f}$ is compactly supported, $\hat{f}_{\nu,\epsilon} \in \mathcal{S}(\mathbb{R}^n, E)$. We choose now some $\rho_1 \in \mathcal{S}(\mathbb{R}^n)$ with $\operatorname{supp}\rho_1 \subset B_5(0)\backslash B_{1/5}(0)$ and $\rho_1(\xi) = 1$ for $\xi \in \operatorname{supp}\varphi_1$, and we put $\rho_\nu(\xi) = \rho_1(2^{-\nu+1}\xi)$ for $\nu \geq 1$. Then we have for all $\epsilon > 0$

$$\left\langle \chi_{\mathbf{s}}\hat{f}_{\nu,\epsilon}, \check{\phi} \right\rangle = \int_{\mathbb{R}^n} \left(\chi_{\mathbf{s}}\rho_\nu\check{\phi}\right)(\xi) \cdot \hat{f}_{\nu,\epsilon}(\xi)\, d\xi = \int_{\mathbb{R}^n} \mathbf{F}[\chi_{\mathbf{s}}\rho_\nu\check{\phi}](x) \cdot \check{\eta}(\epsilon x) f_\nu(x)\, dx$$

in E. Note here that $f_\nu \in \mathcal{O}_M(\mathbb{R}^n, E)$ and $\mathbf{F}[\chi_{\mathbf{s}}\rho_\nu\check{\phi}] \in \mathcal{S}(\mathbb{R}^n, L_\infty(R,\mu))$. Using the dominated convergence theorem, we may let $\epsilon \to 0$ to find

$$\left\langle \chi_{\mathbf{s}}\hat{f}_\nu, \check{\phi} \right\rangle = \int_{\mathbb{R}^n} \mathbf{F}[\chi_{\mathbf{s}}\rho_\nu\check{\phi}](x) \cdot f_\nu(x)\, dx \quad \forall\phi \in \mathcal{S}(\mathbb{R}^n).$$

Now let us consider averages again. Since $\chi_{\mathbf{s}}(\xi, v)$ for fixed $v \in R$ is even and homogeneous in ξ, we can use (4.30). We obtain with $\Phi_\nu = \mathbf{F}[|\cdot|^{n-1}\rho_\nu\check{\phi}]$, $\nu \geq 1$,

$$\langle \bar{f}_{\mathbf{s},\nu}, \phi\rangle = \frac{1}{2(2\pi)^{n-1}} \int_R \int_{\mathbb{R}^n} \left(\int_{S^{n-1}} \chi_{\mathbf{s}}(\omega, v)\tilde{\Phi}_\nu(\omega, x\cdot\omega)\, d\omega \right) f_\nu(x, v)\psi(v)\, dx\, d\mu(v). \tag{4.31}$$

We must show that the integral exists (absolute integrability). We first do the integration in v. Then the Hölder inequality and our assumptions give us an estimate

$$\int_R |\psi(v) f_\nu(x, v)\chi_{\mathbf{s}}(\omega, v)|\, d\mu(v) \leq \|\psi\|_F \|f_\nu(x)\|_{E_1} \|\chi_{\mathbf{s}}(\omega)\|_{L_{\rho_1'}(R,\mu)} \tag{4.32}$$
$$\text{for } (x, \omega) \in \mathbb{R}^n \times S^{n-1}.$$

Since $\chi_{\mathbf{s}}(\omega, v) \leq \mathbf{1}_{A_\delta(\omega)}(v)$ for all $v \in R$, where

$$A_\delta(\omega) = \{v \in R\colon |\mathbf{a}(v) \cdot \omega| \leq \delta\} \quad \text{with } \omega \in S^{n-1},$$

assumption (2.4) on the nondegeneracy of the velocity field yields a bound $C\delta^{\alpha/\rho_1'}$ uniformly in ω for the last term on the RHS of (4.32). Now we integrate over the sphere S^{n-1}. Recall that the Radon transform is defined as an integral over hyperplanes. Therefore, we may write

$$|\mathbf{R}\Phi_\nu(\omega, r)| = \left| \int_{\omega \cdot x = r} \Phi_\nu(x)\, dS(x) \right| \leq \int_{\omega \cdot x = r} |\Phi_\nu(x)|\, dS(x) = \mathbf{R}|\Phi_\nu|(\omega, r)$$

for $(\omega, r) \in S^{n-1} \times \mathbb{R}$. That is, the Radon transform of some function can be estimated in absolute value by the Radon transform of the absolute value of that function. Now we use the following result (cf. Ramm and Katsevich [19, Lemma 2.1.1]):

$$\int_{S^{n-1}} \mathbf{R}|\Phi_\nu|(\omega, x \cdot \omega)\, d\omega = \frac{2\pi^{\frac{n-1}{2}}}{\Gamma(\frac{n-1}{2})} \int_{\mathbb{R}^n} \frac{|\Phi_\nu(y)|}{|x-y|}\, dy$$

for all $x \in \mathbb{R}^n$. The operator on the RHS is a fractional integration of order $n-1$. We refer to Stein [20, Kapitel VIII/4.2]. Finally, we do the integration in x and use the Hölder inequality again. Then we can estimate

$$\left|\left\langle \bar{f}_{\mathbf{s},\nu}, \phi \right\rangle\right| \leq C\delta^{\alpha/\rho_1'} \|\psi\|_F \|f_\nu\|_{L_p(\mathbb{R}^n, E_1)} \left\| \int_{\mathbb{R}^n} \frac{|\Phi_\nu(y)|}{|\cdot - y|}\, dy \right\|_{L_{p'}(\mathbb{R}^n)}.$$

Let $1 < P < \infty$ be given with $\frac{1}{P} = \frac{1}{p} - \frac{n-1}{n}$. Then (cf. Stein [20])

$$\left\| \int_{\mathbb{R}^n} \frac{|\Phi_\nu(y)|}{|\cdot - y|}\, dy \right\|_{L_{p'}(\mathbb{R}^n)} \leq C \|\Phi_\nu\|_{L_{P'}(\mathbb{R}^n)}.$$

The constant does not depend on Φ_ν. Since $|\cdot|^{n-1}\rho_\nu = 2^{(\nu-1)(n-1)}[|\cdot|^{n-1}\rho_1](2^{-\nu+1}\cdot)$,

$$\|\Phi_\nu\|_{L_{P'}(\mathbb{R}^n)} \leq C 2^{(\nu-1)(n-1)} \|\phi\|_{L_{P'}(\mathbb{R}^n)}$$

for $\nu \geq 1$ with $C = \|\mathbf{F}[|\cdot|^{n-1}\rho_1]\|_{L_1(\mathbb{R}^n)}$ (the Young inequality). This proves absolute integrability for (4.31). We test $\bar{f}_{\mathbf{s},\nu}$ against all $\phi \in \mathcal{S}(\mathbb{R}^n)$ and use the fact that the Schwartz class is dense in $L_{P'}(\mathbb{R}^n)$. We obtain the following estimate:

$$\begin{aligned} \|\bar{f}_{\mathbf{s},\nu}\|_{L_P(\mathbb{R}^n)} &= \sup_{\phi \in \mathcal{S}(\mathbb{R}^n)} \|\phi\|_{L_{P'}(\mathbb{R}^n)}^{-1} \left|\left\langle \bar{f}_{\mathbf{s},\nu}, \phi \right\rangle\right| \\ &\leq C 2^{\nu(n-1)} \delta^{\alpha/\rho_1'} \|\psi\|_F \|f_\nu\|_{L_p(\mathbb{R}^n, E_1)}. \end{aligned} \tag{4.33}$$

Of course, we now want to apply a similar argument to g_ν. As above, we obtain

$$\left\langle \chi_{\mathbf{r}} \hat{g}_\nu / (i\mathbf{a} \cdot \xi), \check{\phi} \right\rangle = 2^{-\nu+1} \int_{\mathbb{R}^n} \mathbf{F}[\bar{\chi}_{\mathbf{r}} \bar{\rho}_\nu \check{\phi}](x) \cdot g_\nu(x)\, dx \quad \forall \varphi \in \mathcal{S}(\mathbb{R}^n).$$

Here, $\bar{\rho}_1(\xi) = \rho_1(\xi)/|\xi|$ and $\bar{\rho}_\nu(\xi) = \bar{\rho}_1(2^{-\nu+1}\xi)$ for all $\xi \in \mathbb{R}^n$ and $\nu \in \mathbb{N}$. But now we have a problem: for v fixed the function $\bar{\chi}_{\mathbf{r}}$ is homogeneous but not even in ξ. To circumvent this difficulty we use the Riesz transforms $\mathcal{R}_j$ with $j = 1, \ldots, n$. These mappings are defined, e.g., for all $\phi \in \mathcal{S}(\mathbb{R}^n)$ s.t. $\operatorname{supp} \check{\phi} \subset \mathbb{R}^n \backslash B_1(0)$ by

$$\mathbf{F}^{-1}[\mathcal{R}_j \phi](\xi) = i\xi_j |\xi|^{-1} \check{\phi}(\xi) \quad \forall \xi \in \mathbb{R}^n.$$

Applying these operators twice gives the following identity: $\phi = -\sum_{j=1}^n \mathcal{R}_j^2\phi$. The $\mathcal{R}_j$ are $L_p(\mathbb{R}^n)$-continuous for $1 < p < \infty$. We refer again to Stein [20] for more information and proofs. Let us define now $\Phi_{\nu,j} \in \mathcal{S}(\mathbb{R}^n)$ and $\bar{\chi}_{\mathbf{r},j}$ as follows:

$$\check{\Phi}_{\nu,j}(\xi) = i\xi_j|\xi|^{n-2}\bar{\rho}_\nu(\xi)\check{\phi}(\xi) \qquad \text{and} \qquad \bar{\chi}_{\mathbf{r},j}(\xi,v) = i\xi_j|\xi|^{-1}\bar{\chi}_{\mathbf{r}}(\xi,v)$$

for all $(\xi,v) \in \mathbb{R}^n \times R$, $j = 1,\dots,n$, and $\nu \geq 1$. Then we obtain

$$\langle \bar{f}_{\mathbf{r},\nu}, \phi\rangle = C\sum_{j=1}^n \int_R\int_{\mathbb{R}^n}\left(\int_{S^{n-1}} \bar{\chi}_{\mathbf{r},j}(\omega,v)\tilde{\Phi}_{\nu,j}(\omega, x\cdot\omega)\,d\omega\right) g_\nu(x,v)\psi(v)\,dx\,d\mu(v).$$

Note that $\bar{\chi}_{\mathbf{r},j}$ for $v \in R$ fixed is an even function in ξ. Again, we do the integration in v first and obtain for all $(x,\omega) \in \mathbb{R}^n \times S^{n-1}$ the following estimate:

$$\int_R |\psi(v)g_\nu(x,v)\bar{\chi}_{\mathbf{r}}(\omega,v)|\,d\mu(v) \leq \|\psi\|_F\|g_\nu(x)\|_{E_2}\left(\int_R \frac{\mathbf{1}_{R\setminus A_{\delta/2}(\omega)}(v)}{|i\mathbf{a}(v)\cdot\omega|^{\rho_2'}}d\mu(v)\right)^{1/\rho_2'}.$$

Using the nondegeneracy of the velocity field and Lemma 4.5 again, it is easy to show that the last factor is bounded by $C\delta^{-1+\alpha/\rho_2'}$ uniformly in ω. Proceeding as we did above, we find a constant C s.t.

$$\|\bar{f}_{\mathbf{r},\nu}\|_{L_P(\mathbb{R}^n)} \leq C2^{\nu(n-2)}\delta^{-1+\alpha/\rho_2'}\|\psi\|_F\|g_\nu\|_{L_p(\mathbb{R}^n,E_2)} \tag{4.34}$$

for $\nu \geq 1$. We used $\|\mathcal{R}_j\phi\|_{L_{P'}(\mathbb{R}^n)} \leq C\|\phi\|_{L_{P'}(\mathbb{R}^n)}$ for all $\phi \in \mathcal{S}(\mathbb{R}^n)$ and j.

5. Proofs—compactness.

First we must introduce some terminology.

5.1. Rearrangement-invariant Banach function spaces.

The Lebesgue spaces $L_p(R,\mu)$ over the finite measure space (R,μ) are just instances of more general so-called rearrangement-invariant Banach function spaces. We collect here some basic facts about these spaces but refer to Bennett and Sharpley [4] for more details.

Consider the vector space $\mathcal{M}(R,\mu)$ of μ-measurable mappings from R into $\mathbb{R}$ (or $\mathbb{C}$), where, as usual, functions which coincide μ-a.e. are identified. Denote by $\mathcal{M}^+(R,\mu)$ the set of all $f \in \mathcal{M}(R,\mu)$ with $f \geq 0$, and for some μ-measurable subset $A \subset R$ let $\mathbf{1}_A$ be its characteristic function.

Definition 5.1. *A mapping $\rho\colon \mathcal{M}^+(R,\mu) \to [0,\infty]$ is called a Banach function norm if for all $f, f_n \in \mathcal{M}^+(R,\mu)$, $a \geq 0$, and μ-measurable sets $A \subset R$ we have*

(P1) $\rho(f) = 0 \Leftrightarrow f = 0$ *μ-a.e.,*
$\rho(af) = a\rho(f)$, *and*
$\rho(f_1 + f_2) \leq \rho(f_1) + \rho(f_2)$;
(P2) $0 \leq f_1 \leq f_2$ *μ-a.e.* $\Rightarrow \rho(f_1) \leq \rho(f_2)$;
(P3) $0 \leq f_n \nearrow f_0$ *μ-a.e.* $\Rightarrow \rho(f_n) \nearrow \rho(f_0)$;
(P4) $\mu(A) < \infty \Rightarrow \rho(\mathbf{1}_A) < \infty$;
(P5) $\mu(A) < \infty \Rightarrow \int_A f\,d\mu < C\rho(f)$.

Here $C = C(\rho, A)$ is a constant not depending on f.

Definition 5.2. *Let ρ be a Banach function norm. Then the Banach function space $E = E(\rho)$ is defined as the space of all $f \in \mathcal{M}(R,\mu)$ s.t. $\|f\|_E = \rho(|f|) < \infty$.*

For each Banach function norm ρ we can define an associated norm ρ' via

$$\rho'(g) = \sup\left\{\int_R fg\,d\mu \colon f \in \mathcal{M}^+(R,\mu), \rho(f) \leq 1\right\}$$

for all $g \in \mathcal{M}^+(R,\mu)$. The associated norm ρ' also has all the properties (P1)–(P5) in Definition 5.1 and therefore generates a Banach function space $E' = E(\rho')$ associated to E. The generalized Hölder inequality holds.

Theorem 5.3. *Let E be a Banach function space, and let E' be the space associated to E. If $f \in E$ and $g \in E'$, then the product fg is absolutely integrable, and we have*

$$\int_R |fg|\, d\mu \leq \|f\|_E \|g\|_{E'}. \tag{5.1}$$

Definition 5.4. *The distribution function μ_f of $f \in \mathcal{M}(R,\mu)$ is defined by*

$$\mu_f(\lambda) = \mu\,\{x \in R\colon |f(x)| > \lambda\} \quad \forall \lambda \geq 0.$$

Note that μ_f depends only on $|f|$. If a second finite measure space (S,ν) is given, then two functions $f \in \mathcal{M}(R,\mu)$ and $g \in \mathcal{M}(S,\nu)$ are called equimeasurable if their distribution functions are identical, i.e., if $\mu_f(\lambda) = \nu_g(\lambda)$ for all $\lambda \geq 0$.

Definition 5.5. *For $f \in \mathcal{M}(R,\mu)$ let f^* be the function on $[0,\infty)$ defined by*

$$f^*(t) = \inf\,\{\lambda\colon \mu_f(\lambda) \leq t\} \quad \forall t \geq 0.$$

f^* is called the decreasing rearrangement of f.

In other words, f^* is a decreasing function on $[0,\infty)$ with the same distribution function as f itself. Here we use the convention $\inf \emptyset = \infty$; i.e., if $\mu_f(\lambda) > t$ for all $\lambda \geq 0$, then $f^*(t) = \infty$. For a finite measure space (R,μ) the distribution function μ_f is always bounded. Then f^* is a function on the interval $[0,\mu(R)]$.

Definition 5.6. *Let ρ be a Banach function norm over some finite measure space (R,μ). Then ρ is called rearrangement-invariant if $\rho(f) = \rho(g)$ for all pairs of equimeasurable functions $f,g \in \mathcal{M}(R,\mu)$. In that case we also call the Banach function space $E = E(\rho)$ defined by ρ rearrangement-invariant.*

Let us now assume that the finite measure space (R,μ) is also nonatomic, i.e., no single point carries a positive measure. This excludes Dirac measures.

Definition 5.7. *Let E be a rearrangement-invariant Banach function space over some finite nonatomic measure space (R,μ). For every t inside the interval $[0,\mu(R)]$ let A be a μ-measurable subset of R with $\mu(A) = t$. Then the function*

$$\varphi_E\colon t \mapsto \|\mathbf{1}_A\|_E \tag{5.2}$$

is called the fundamental function of E.

Since for every $B \subset R$ with $\mu(B) = t$ the functions $\mathbf{1}_A$ and $\mathbf{1}_B$ are equimeasurable, and since E is assumed rearrangement-invariant, φ_E is well defined.

The fundamental function φ_E of a rearrangement-invariant Banach function space E is quasi-concave, i.e., φ_E is increasing, $\varphi_E(t) = 0$ iff $t = 0$, and $\varphi_E(t)/t$ is decreasing. From the quasi concavity of the function, continuity in $(0,\mu(R)]$ follows. Nevertheless, a discontinuity at zero is still possible.

Theorem 5.8. *Let E be a rearrangement-invariant Banach function space over the finite nonatomic measure space (R,μ), and let E' be the associated space. Then*

$$\varphi_E(t)\varphi_{E'}(t) = t \quad \forall t \in [0,\mu(R)].$$

We refer to section II.5 in [4]. Let us discuss two examples. The fundamental function of the Lebesgue space $L^p(R,\mu)$ with $1 \leq p < \infty$ is given by $\varphi_{L^p}(t) = t^{1/p}$ for

$t \in [0, \mu(R)]$. However, if $p = \infty$, then

$$\varphi_{L^\infty}(t) = \begin{cases} 0 & \text{for } t = 0, \\ 1 & \text{for } t \in (0, \mu(R)], \end{cases}$$

since the characteristic function of a null set is equivalent to the zero function. In that case, the fundamental function is discontinuous at zero.

In applications, the Orlicz space $L \log L(R, \mu)$ plays an important role. That is the rearrangement-invariant Banach function space defined by the norm

$$\|f\|_{L \log L(R,\mu)} = -\int_0^{\mu(R)} f^*(t) \log\left(t/\mu(R)\right)\, dt.$$

For the fundamental function we have

$$\varphi_{L \log L}(t) = t\left(1 - \log\left(t/\mu(R)\right)\right) \quad \forall t \in [0, \mu(R)].$$

The space associated to $L \log L(R, \mu)$ is the space $\exp L(R, \mu)$ of exponentially integrable functions. The corresponding fundamental function is given by

$$\varphi_{\exp L}(t) = \frac{1}{1 - \log\left(t/\mu(R)\right)} \quad \forall t \in [0, \mu(R)].$$

Note that $\varphi_{\exp L}$ is continuous at zero (but not differentiable). That is remarkable because for all $1 < p < \infty$ the following inclusions hold (since $\mu(R) < \infty$):

$$L^\infty(R, \mu) \hookrightarrow \exp L(R, \mu) \hookrightarrow L^p(R, \mu) \hookrightarrow L \log L(R, \mu) \hookrightarrow L^1(R, \mu).$$

Although $\exp L$ and L^∞ are so close that no other L^p-space fits between them, there is a considerable difference in their respective fundamental functions.

5.2. Proof of Theorem 2.5. Again, we briefly recall our assumptions. Let E_1 and E_2 be two rearrangement-invariant Banach function spaces over some nonatomic finite measure space. Assume we are given a sequence of pairs

$$f^{(k)} \in B^s_{p,q}(\mathbb{R}^n, E_1) \quad \text{and} \quad g^{(k)} \in B^{s-\tau}_{p,q}(\mathbb{R}^n, E_2)$$

satisfying the transport equation (2.1) in $\mathcal{S}'(\mathbb{R}^n, E)$ for $E = E_1 + E_2$. We fix a weight ψ in some subset $F \subset E'$ s.t. multiplication with ψ maps E_1 continuously into some rearrangement-invariant Banach function space G_1 and, similarly, E_2 into some G_2. If the velocity field now satisfies a nondegeneracy condition and if the fundamental function of G_1' is continuous at zero, we will show that the sequence of averages $\bar{f}^{(k)}$ is precompact in a suitable local Besov space $B^{S,\mathrm{loc}}_{P,q}(\mathbb{R}^n)$.

To simplify notation, we will drop the index k in the following. We already know that there exists a decomposition of the average $\bar{f}$ into $\bar{f} = \sum_{\nu=0}^\infty \bar{f}_\nu$ in $\mathcal{S}'(\mathbb{R}^n)$ and $\bar{f}_\nu = \bar{f}_{\mathbf{s},\nu} + \bar{f}_{\mathbf{r},\nu}$ for $\nu \geq 1$. In contrast to our approach in section 4, we will now choose the splitting parameter δ independent of ν. Then we can write $\bar{f} = \bar{f}_0 + \bar{F}_{\mathbf{s}} + \bar{F}_{\mathbf{r}}$ with $\bar{F}_{\mathbf{s}} = \sum_{\nu=1}^\infty \bar{f}_{\mathbf{s},\nu}$ and $\bar{F}_{\mathbf{r}} = \sum_{\nu=1}^\infty \bar{f}_{\mathbf{r},\nu}$. We claim that $\bar{f}_0 \in B^\sigma_{P,q}(\mathbb{R}^n)$ for arbitrary $\sigma \in \mathbb{R}$ and P as given above. Moreover,

$$\bar{F}_{\mathbf{s}} \in B^S_{P,q}(\mathbb{R}^n) \quad \text{and} \quad \bar{F}_{\mathbf{r}} \in B^{S+\epsilon}_{P,q}(\mathbb{R}^n)$$

with the S from above and $\epsilon = 1 - \tau > 0$. To see that, let us first consider the dyadic components $\bar{F}_{\mathbf{s},\nu}$. As an immediate consequence of the support properties of the family φ_ν with $\nu \geq 0$, we realize that

$$\bar{F}_{\mathbf{s},\nu} = \mathbf{F}^{-1}[\varphi_\nu \mathbf{F}\bar{F}_{\mathbf{s}}] = \begin{cases} \mathbf{F}^{-1}[\varphi_0 \mathbf{F}\bar{f}_{\mathbf{s},1}] & \text{if } \nu = 0, \\ \mathbf{F}^{-1}[\varphi_1 \mathbf{F}(\bar{f}_{\mathbf{s},1} + \bar{f}_{\mathbf{s},2})] & \text{if } \nu = 1, \\ \bar{f}_{\mathbf{s},\nu} & \forall \nu \geq 2. \end{cases}$$

Since $P \geq 1$, we can now apply the Young inequality to obtain the estimates

$$\begin{aligned} &\|\bar{F}_{\mathbf{s},0}\|_{L_P(\mathbb{R}^n)} \leq C\|\bar{f}_{\mathbf{s},1}\|_{L_P(\mathbb{R}^n)}, \\ &\|\bar{F}_{\mathbf{s},1}\|_{L_P(\mathbb{R}^n)} \leq C\left\{\|\bar{f}_{\mathbf{s},1}\|_{L_P(\mathbb{R}^n)} + \|\bar{f}_{\mathbf{s},2}\|_{L_P(\mathbb{R}^n)}\right\}, \quad \text{and} \\ &\|\bar{F}_{\mathbf{s},\nu}\|_{L_P(\mathbb{R}^n)} = \|\bar{f}_{\mathbf{s},\nu}\|_{L_P(\mathbb{R}^n)} \quad \forall \nu \geq 2. \end{aligned}$$

However, the L_P-norm of $\bar{f}_{\mathbf{s},\nu}$ has already been estimated in the last sections. Using the generalized Hölder inequality for the Banach function space G_1, we obtain the following analogue of the estimates (4.25) and (4.33):

$$\|\bar{f}_{\mathbf{s},\nu}\|_{L_P(\mathbb{R}^n)} \leq C2^{\nu(\frac{1}{p}-\frac{1}{P})} \sup_{\xi \in \mathbb{R}^n} \|\mathbf{1}_{A_\delta(\xi)}\|_{G_1'} \|\psi\|_F \|f_\nu\|_{L_p(\mathbb{R}^n,E_1)}.$$

The constant does not depend on f or ν. But the G_1'-norm of the characteristic function of some set A with measure $s \geq 0$ is just the fundamental function $\varphi_{G_1'}(s)$. And since this function is increasing, we can use the nondegeneracy condition for $\mathbf{a}$ to obtain the following estimate (cf. (2.9)):

$$\|\bar{F}_{\mathbf{s}}\|_{B^S_{P,q}(\mathbb{R}^n)} \leq C\varphi_{G_1'}(\eta(\delta))\,\|\psi\|_F \|f\|_{B^s_{p,q}(\mathbb{R}^n,E_1)}. \tag{5.3}$$

Again, the constant C does not depend on f or δ. In the same way, we can find a bound for the second term $\bar{F}_{\mathbf{r}}$. We use the generalized Hölder inequality for G_2, estimate $|i\mathbf{a}\cdot\omega|^{-1}\mathbf{1}_{R\setminus A_{\delta/2}(\omega)}$ by $C\delta^{-1}$, and obtain

$$\|\bar{F}_{\mathbf{r}}\|_{B^{S+\epsilon}_{P,q}(\mathbb{R}^n)} \leq C\delta^{-1}\|\psi\|_F \|g\|_{B^{s-\tau}_{p,q}(\mathbb{R}^n,E_2)}. \tag{5.4}$$

Finally, note that most dyadic parts of $\bar{f}_0$ vanish by the construction of φ_ν. Using the Young, the Nikol'skij, and the Hölder inequalities (3.4)–(5.1), we then obtain

$$\|\bar{f}_0\|_{B^\sigma_{P,q}(\mathbb{R}^n)} \leq C\|\psi\|_F \|f\|_{B^s_{p,q}(\mathbb{R}^n,E_1)} \quad \forall \sigma \in \mathbb{R}.$$

Let us now consider sequences $f^{(k)}, g^{(k)}$ with (2.8), satisfying a transport equation (2.1). Let $\chi \in \mathcal{D}(\mathbb{R}^n)$ be some test function with compact support. Then we may decompose $\chi\bar{f}^{(k)}$ into three parts, $\chi\bar{F}_{\mathbf{s}}^{(k)}, \chi\bar{F}_{\mathbf{r}}^{(k)}$, and $\chi\bar{f}_0^{(k)}$, and estimate as follows.

I. By assumption, the fundamental function of the rearrangement-invariant Banach function space G_1' is continuous at zero, and $\lim_{\delta\to 0}\eta(\delta) = 0$. Therefore,

$$\|\chi\bar{F}_{\mathbf{s}}^{(k)}\|_{B^S_{P,q}(\mathbb{R}^n)} \leq C\|\bar{F}_{\mathbf{s}}^{(k)}\|_{B^S_{P,q}(\mathbb{R}^n)} \leq C\varphi_{G_1'}(\eta(\delta))\,\|\psi\|_F \|f^{(k)}\|_{B^s_{p,q}(\mathbb{R}^n,E_1)} \longrightarrow 0$$

uniformly in k if $\delta \to 0$: The sequence $f^{(k)}$ is uniformly bounded, and the constants are independent of k and δ. We also used Theorem 3.12 and (5.3). We conclude that the first part of $\bar{f}^{(k)}$ becomes small, choosing the parameter δ suitably.

II. Because of Theorem 3.12 and (5.4), there exists a number $C > 0$ s.t.

$$\|\chi\bar{F}_{\mathbf{r}}^{(k)}\|_{B^{S+\epsilon}_{P,q}(\mathbb{R}^n)} \leq C\|\bar{F}_{\mathbf{r}}^{(k)}\|_{B^{S+\epsilon}_{P,q}(\mathbb{R}^n)} \leq C\delta^{-1}\|\psi\|_F\|g^{(k)}\|_{B^{s-\tau}_{p,q}(\mathbb{R}^n,E_2)} \tag{5.5}$$

with C independent of δ, k and $g^{(k)}$. Therefore, for every fixed $\delta > 0$, the sequence $\chi\bar{F}_{\mathbf{r}}^{(k)}$ is uniformly bounded in $B^{S+\epsilon}_{P,q}(\mathbb{R}^n)$ for some $\epsilon > 0$. And since the supports of all functions of the sequence are contained in one single compact subset of $\mathbb{R}^n$, we can use, e.g., Theorem 3.3.2/1 in Edmunds and Triebel [11] to conclude that $\chi\bar{F}_{\mathbf{r}}^{(k)}$ is precompactly contained in $B^S_{P,q}(\mathbb{R}^n)$. Similarly, we proceed for $\chi\bar{f}_0^{(k)}$.

Therefore, the sequence of averages $\chi\bar{f}^{(k)}$ can be decomposed into three parts, two of which are precompact in $B^S_{P,q}(\mathbb{R}^n)$, while the third goes to zero uniformly with respect to k, as $\delta \to 0$. Hence $\chi\bar{f}^{(k)}$ itself is precompact as claimed. The proof is complete.

Remark 5.9. Note that the fine structure of G_2 plays no role in the proof of Theorem 2.5. If $\epsilon = 0$, precompactness of $\chi\bar{F}_{\mathbf{r}}^{(k)}$ in $B^S_{P,q}(\mathbb{R}^n)$ follows from estimate (5.5) and the assumed precompactness of $g^{(k)}$ in $B^{s-1}_{p,q}(\mathbb{R}^n, E_2)$.

Remark 5.10. We return to Remark 2.8. Assume that

$$f^{(k)} \in B^{s,\mathrm{loc}}_{p,q}(\mathbb{R}^n, E_1) \quad \text{and} \quad g^{(k)} \in B^{s-\tau,\mathrm{loc}}_{p,q}(\mathbb{R}^n, E_2)$$

are uniformly bounded; i.e., for all test functions $\chi \in \mathcal{D}(\mathbb{R}^n)$ the sequence $\chi f^{(k)}$ is bounded in $B^s_{p,q}(\mathbb{R}^n, E_1)$, etc. Then we have the following equality:

$$\mathrm{div}_x(\mathbf{a}\chi f^{(k)}) = \chi g^{(k)} - f^{(k)}\mathrm{div}_x(\mathbf{a}\chi).$$

The RHS is uniformly bounded in $B^{s-\tau}_{p,q}(\mathbb{R}^n, E)$ with $E = E_1 + E_2$. From Theorem 2.5 we therefore conclude that the sequence $\chi\bar{f}^{(k)}$ is precompact in $B^S_{P,q}(\mathbb{R}^n)$. Hence it is also possible to choose $f^{(k)}$ and $g^{(k)}$ in local Besov spaces only.

TIME EVOLUTION OF NEMATIC LIQUID CRYSTALS WITH VARIABLE DEGREE OF ORIENTATION*

M. C. CALDERER[†], D. GOLOVATY[‡], F.-H. LIN[§], AND C. LIU[†]

Abstract. We consider an evolution system, describing the time-dependent behavior of nematic liquid crystals with variable degree of orientation within the continuum model of Ericksen. We establish a dissipation relation and prove both the global existence of weak solutions and the local existence of classical solutions. Furthermore, we investigate the stability and long-time behavior of solutions and obtain an exact solution of the corresponding stationary system in a one-dimensional case.

Key words. nematic liquid crystals, reaction-diffusion mechanism, weak solutions, free energy functional

1. Introduction.

In this paper, we study the system of partial differential equations governing the evolution of uniaxially nematic liquid crystals with variable degree of orientation in the absence of either flow or electromagnetic field.

A typical nematic liquid crystal consists of the rigid, rodlike molecules with one molecular axis being much longer than the other two. As a consequence of the highly anisotropic molecular shape, there is a higher probability that the axes of any two neighboring molecules point in a similar direction. The resulting molecular structure is then commonly characterized as having some orientational order.

Within the standard continuum theory of Ericksen [4], the local molecular orientation is described through the second moments of the appropriate local orientational distribution functions. For a uniaxial nematic, the second moment is fully specified by a unit vector $\mathbf{n}$, called the director, and a scalar s, called the order parameter. Given a point $\mathbf{x}$, a simple interpretation of these characteristics is that, on average, the molecules tend to be oriented along the director $\mathbf{n}(\mathbf{x})$ in a vicinity of $\mathbf{x}$. Since the majority of the molecules actually point in the directions close to, but different than $\mathbf{n}(\mathbf{x})$, the quality of the intermolecular alignment has to be described by an additional parameter $s(\mathbf{x})$. It can be shown that the values of s are restricted to the interval $(-\frac{1}{2}, 1)$, where all molecules align perfectly with the director as s approaches 1 and align perpendicular to it as s approaches $-\frac{1}{2}$. The special case of $s = 0$ corresponds to the isotropic state with randomly oriented molecules in which the director $\mathbf{n}$ is meaningless. The important consequence of the isotropy for the analysis of the Ericksen model is that the underlying partial differential equations become singular when $s = 0$.

The two-parameter approach of Ericksen is a generalization of the earlier Oseen–Frank theory in which a liquid crystal configuration is described by the director field alone. The well-known flaw of the Oseen–Frank approach is its inability to predict some observable liquid crystal configurations. In particular, for the appropriately chosen material constants, the energy minimizing configuration $\mathbf{n}$ is a harmonic map into S^2 with a singular set consisting at most of isolated points [13]. This, however, contradicts the experimental observations [8] of both line and surface defects in various materials, including liquid crystals. The Ericksen model was introduced, in part, in order to address this deficiency of the Oseen–Frank theory.

When s is bounded away from zero and the gradient of the director can be controlled, the evolution equation for the order parameter (2.9) exhibits a reaction-diffusion mechanism normally responsible for the dynamics of the domain structures. This mechanism, however, might be suppressed when s is small and, therefore, the size of the term involving the gradient of the director is very large. The evolution and the interactions of the structural defects corresponding to vanishing s constitutes, in fact, a difficult mathematical problem, especially for the defects of codimension one or two (surface and line defects). From the practical point of view, the understanding of the defect dynamics plays an important role in the industrial applications of liquid crystals, such as the design of efficient display devices.

The main goal of this paper is to establish both the existence and the regularity results for the system of partial differential equations comprising the Ericksen model. Here, the biggest challenge is to find the framework within which a degenerate parabolic equation is guaranteed to have a solution. Our approach is to approximate the set of the governing equations by a system of nonsingular PDEs and to show that the approximate solutions converge, in a weak sense, to a solution of the Ericksen system.

Following [4] and [10], we consider a free energy functional with the density having a quadratic dependence on both $s\nabla\mathbf{n}$ and ∇s. Furthermore, we assume that the free energy density depends on the order parameter through the double-well potential $W(s)$. The locations of the extrema for W and their corresponding energy values are physically determined by the temperature in thermotropic liquid crystals and by the concentration in lyotropic liquid crystals. In particular, a minimum of W can be moved into the isotropic state $s = 0$ either by raising the temperature, or by lowering the concentration of a polymer in a given solvent.

In the stationary case, the model for nematic liquid crystals with variable degree of orientation was studied by Leslie [10] and by Virga [15]. Some aspects of the time dependent behavior in modeling of patterns, associated with flow relaxation, have been investigated by Calderer [1]. Recently, the plane Poiseuille flow was considered by Calderer and Liu [2] to show that the order parameter allows for the modeling of new types of defects.

The outline of the paper is as follows. The governing equations and the constitutive properties of the model are outlined in section 2. In section 3 we use the dissipative relation to obtain some a priori estimates. These relations, in turn, allow us to prove the global existence of weak solutions in section 4. Next, using the semigroup methods, we prove the local in time existence of classical solutions (section 5) and then, in section 6, discuss both the stability and the long time behavior of solutions. Finally, an exact solution of the corresponding stationary system is obtained in section 7 in order to illustrate the singular behavior of the Ericksen system in the one-dimensional case.

2. Governing equations. In the absence of a flow, the evolution for s and $\mathbf{n}$ is governed by the following system of partial differential equations [4]:

$$\beta(s)\dot{s} = \operatorname{div}\left\{\frac{\partial W_1}{\partial \nabla s}\right\} - \frac{\partial W_1}{\partial s} - W'(s), \tag{2.1}$$

$$\gamma(s)\dot{\mathbf{n}} \times \mathbf{n} = \left(\operatorname{div}\left\{\frac{\partial W_1}{\partial \nabla \mathbf{n}}\right\} - \frac{\partial W_1}{\partial \mathbf{n}}\right) \times \mathbf{n}, \tag{2.2}$$

$$|\mathbf{n}|^2 = 1, \tag{2.3}$$

where $\mathcal{W}(s, \mathbf{n}, \nabla s, \nabla \mathbf{n}) = W(s) + W_1(s, \mathbf{n}, \nabla s, \nabla \mathbf{n})$ denotes the Helmholtz free energy. As in the Oseen–Frank theory [16], the term W_1 is a quadratic function of the gradients of $\mathbf{n}$ and s. The absence of the first order term in free energy is due to the invariance of $\mathcal{W}$ with respect to the transformation $\mathbf{n} \to -\mathbf{n}$. From now on we will assume that

(2.4) $W_1 = \dfrac{1}{2}k_1|\nabla s|^2 + \dfrac{1}{2}k_2 s^2 |\nabla \mathbf{n}|^2$, where k_1 and k_2 are positive constants,

(2.5) $W(s)$ is a smooth double-well potential satisfying $\lim\limits_{s \to -\frac{1}{2}, 1} W(s) = \infty$.

Using the molecular theory predictions [4] on the asymptotic behavior of the constitutive functions near $s = 0$ and rescaling we set

$$\gamma(s) = \frac{k_2}{k_3} s^2, \tag{2.6}$$

$$\beta(s) \equiv 1, \tag{2.7}$$

where k_3 is a positive constant.

Suppose that the material occupies a bounded domain $\Omega \in \mathbf{R}^n$ with the smooth boundary $\partial\Omega$, where $n \leq 3$. We denote the points in Ω by $x = (x_1, \ldots, x_n)$ and consider the planar director configurations

$$\mathbf{n} = (\cos\phi, \sin\phi, 0). \tag{2.8}$$

Then (2.1)–(2.2) reduce to

$$s_t = k_1 \triangle s - k_2 s |\nabla \phi|^2 - W'(s), \tag{2.9}$$

$$s^2 \phi_t = k_3 \operatorname{div}\left(s^2 \nabla \phi\right), \tag{2.10}$$

where $x \in \Omega$ and $t > 0$. This system will be supplemented by the following initial and boundary data:

$$s(x,0) = g(x), \quad \phi(x,0) = h(x), \qquad x \in \Omega, \tag{2.11}$$

$$s(x,t) = g(x), \quad \phi(x,t) = h(x), \qquad x \in \partial\Omega, \quad t \geq 0, \tag{2.12}$$

where g and h are the given smooth functions of x.

Remark 2.1. It has been shown by several authors [11], [15] that, in the stationary case, the introduction of s into the energy allows for the modeling of new types of defects. Consider, for example, the Oseen–Frank free energy for $\mathbf{n}(x)$ with $x \in \mathbf{R}$. Then the corresponding Euler–Lagrange equation is

$$-\mathbf{n}'' = |\mathbf{n}'|^2 \mathbf{n}.$$

Multiplying this equation by $\mathbf{n}'$ and using the fact that $|\mathbf{n}| = 1$, we have

$$(|\mathbf{n}'|^2)' = 0, \text{ and } -\mathbf{n}'' = a\mathbf{n},$$

where $a \geq 0$ is a constant. Therefore, $\mathbf{n}$ is a smooth, defect-free vector field. On the other hand, when the order parameter and the corresponding energy contribution are included into the model, the defects can exist in one-dimensional geometries [2].

3. A priori estimates and the Lyapunov function.

In this section we construct a Lyapunov function and obtain some a priori estimates on the solutions of (2.9)–(2.10).

THEOREM 3.1. *Suppose that the pair* $(s(x\,,\,t),\,\phi(x\,,\,t))$ *is a classical solution of the system* (2.9)–(2.10) *for* $x \in \Omega$ *and* $t \in (0\,,\,T)$. *Set*

$$E(t) := E[s(\cdot,t),\,\phi(\cdot,t)] = \int_\Omega \left[\frac{k_1}{2}|\nabla s|^2 + \frac{k_2}{2}s^2|\nabla\phi|^2 + W(s)\right] dx. \tag{3.1}$$

Then $E(t)$ *is a Lyapunov function for the system* (2.9)–(2.10)*, that is,*

$$E(t) \geq m\,|\Omega| > -\infty, \tag{3.2}$$

$$E\,'(t) \leq 0 \textit{ for all } t \in (0,T), \tag{3.3}$$

where $|\Omega|$ *denotes the Lebesgue measure of* Ω *and* $m := \min_{s\in(-\frac{1}{2},1)} W(s)$.

Proof. First, we calculate

$$E\,'(t) = \int_\Omega \left[\Big(k_2 s|\nabla\phi|^2 + W'(s)\Big)\, s_t + k_1\nabla s\cdot\nabla s_t + k_2 s^2\nabla\phi\cdot\nabla\phi_t\right] dx. \tag{3.4}$$

Integrating the mixed derivatives terms in (3.4) by parts and using the boundary conditions (2.12) along with the governing equations (2.9)–(2.10), we have

$$\begin{aligned} E\,'(t) &= \int_\Omega \left\{ \Big(-k_1\Delta s + k_2 s|\nabla\phi|^2 + W'(s)\Big)\; s_t - k_2\phi_t \operatorname{div}\left(s^2\nabla\phi\right) \right\} dx \\ &= -\int_\Omega \left\{ s_t^2 + \frac{k_2}{k_3}s^2{\phi_t}^2 \right\} dx \leq 0\,. \end{aligned} \tag{3.5}$$

Therefore, $E(t) \leq E(0)$ for all $t \in [0,T]$. The proof of the assertion (3.2) follows immediately from nonnegativity of the gradient terms in (3.1). □

Note that, from the previous theorem, one can obtain the following bound on the gradient of the director:

$$\int_\Omega s^2|\nabla\phi|^2\,dx \leq 2k_2^{-1}\left\{E(0) - m\,|\Omega|\right\} \tag{3.6}$$

for all $t \in [0,T]$.

LEMMA 3.2. *Let* Ω *be a domain with the smooth boundary and* (s,ϕ) *be a smooth solution of the system* (2.9)–(2.10). *Suppose that* $g(x) \in \left(-\frac{1}{2},1\right)$ *for all* $x \in \bar\Omega$*; then there exist two constants,* s_- *and* s_+*, such that* $-\frac{1}{2} < s_- < 0 < s_+ < 1$ *and* $s(x,t) \in (s_-,\,s_+)$ *for all* $x \in \Omega$ *and* $t > 0$.

Proof. This result follows from the maximum principle [12] by taking into account the property (2.5) of the function W. By our assumptions on the function g, there exist

$$g_- := \min_{x\in\bar\Omega} g(x) \text{ and } g_+ := \max_{x\in\bar\Omega} g(x),$$

where $-\frac{1}{2} < g_- \leq g_+ < 1$. Moreover, since W' is continuous and $\lim_{s\to -\frac{1}{2},1} W(s) = \infty$, we can find

$$s_- \in (-1/2, \min\{0, g_-\}),$$

such that $W'(s_-) < 0$, and

$$s_+ \in (\max\{0, g_+\}, 1),$$

such that $W'(s_+) > 0$.

Next, suppose that $t^* > 0$ is the smallest time for which $s(x^*, t^*) = s_+$ for some $x^* \in \Omega$. Then $W'(s(x^*, t^*)) = W'(s_+) > 0$, $s_t(x^*, t^*) \geq 0$, and $\triangle s(x^*, t^*) \leq 0$. This, however, contradicts (2.9); hence $s(x, t) < s_+$ for all $x \in \Omega$ and $t > 0$. A similar argument can be used to show that $s > s_-$ as well. □

By slightly modifying the proof of the previous lemma one can also prove the following lemma.

LEMMA 3.3. *Suppose that s_1 and s_2 are the wells of the potential W; that is, both s_1 and s_2 are the strict local minima of W. Let Ω be a domain with the smooth boundary and (s, ϕ) be the smooth solution of the system* (2.9)–(2.10). *Suppose that $g(x) \in (s_1, s_2)$ for all $x \in \bar{\Omega}$; then $s(x, t) \in (s_1, s_2)$ for all $x \in \Omega$ and $t > 0$.*

In the next two sections we discuss the solvability of the problem (2.9)–(2.10).

4. Global existence of weak solutions. The system (2.9)–(2.10) for the nematic liquid crystals with variable degree of orientation was originally introduced by Ericksen to model the line singularities. However, the obvious drawback of (2.9)–(2.10) is that the problem loses its parabolicity whenever the order parameter s is allowed to vanish. In order to overcome the degeneracy in the stationary version of (2.9)–(2.10), Lin [11] introduced a variable $\mathbf{u} = s\mathbf{n}$ and recast the problem in terms of s and $\mathbf{u}$. Within the new formulation, the constraint $|\mathbf{n}|^2 = 1$ has to be replaced by $s^2 = |\mathbf{u}|^2$, and the flow for $(s, \mathbf{u})$ is from Ω into a circular cone. The corresponding problem is then nonsingular, but since the target manifold itself is not smooth, the solution of the reformulated problem is, in general, only Lipschitz continuous.

Here, in order to overcome the degeneracy in (2.10) at $s = 0$, we introduce the modified system of equations

$$s_{\epsilon t} = k_1 \triangle s_\epsilon - k_2 s_\epsilon |\nabla \phi_\epsilon|^2 - W'(s_\epsilon), \tag{4.1}$$

$$\left(s_\epsilon^2 + \epsilon^2\right) \phi_{\epsilon t} = k_3 \operatorname{div}\left(\left(s_\epsilon^2 + \epsilon^2\right) \nabla \phi_\epsilon\right), \tag{4.2}$$

where $\epsilon > 0$ is small. Suppose that $(s_\epsilon, \phi_\epsilon)$ satisfy the initial and boundary data (2.11)–(2.12). Then the proof of the following lemma is the same as that of Theorem 3.1.

LEMMA 4.1. *Suppose that $(s_\epsilon, \phi_\epsilon)$ is a smooth solution of* (4.1)–(4.2). *Then it satisfies the following dissipative relation:*

$$E'_\epsilon(t) = -\int_\Omega \left[\left(s_{\epsilon t}^2 + \frac{k_2}{k_3}\left(s_\epsilon^2 + \epsilon^2\right)\phi_{\epsilon t}^2\right)\right] dx \leq 0, \tag{4.3}$$

where

$$E_\epsilon(t) = \int_\Omega \left[\frac{k_1}{2}|\nabla s_\epsilon|^2 + \frac{k_2}{2}\left(s_\epsilon^2 + \epsilon^2\right)|\nabla \phi_\epsilon|^2 + W(s_\epsilon)\right] dx. \tag{4.4}$$

Theorem 4.2. *There exists a unique global classical solution* $(s_\epsilon, \phi_\epsilon)$ *of the system* (4.1)–(4.2)*, corresponding to the initial and boundary data* (2.11)–(2.12).

Here the existence follows from the standard results for parabolic systems, along with a priori estimates derived in Lemma 4.1 [9, Chapter 10], [5, Chapter 3]. The regularity of solutions follows from Sobolev imbedding result, combined with a bootstrap argument.

Note that, for any $\epsilon > 0$, the conclusion of the Lemma 3.2 can be applied to the solutions of (4.1)–(4.2), since (4.1) for s_ϵ is the same as (2.9) for s. Then s_ϵ is bounded in $L^\infty(\Omega_T)$ uniformly in ϵ, where $\Omega_T = \Omega \times (0, T)$. Moreover, for any $\epsilon > 0$ and $0 < T < \infty$, the solutions of (4.1)–(4.2) belong to the following functional spaces:

$$\begin{gathered} s_\epsilon \in L^\infty\left(0,T;H^1(\Omega)\right) \cap H^1\left(0,T;L^2(\Omega)\right), \\ s_\epsilon \nabla\phi_\epsilon \in L^\infty\left(0,T;L^2(\Omega)\right), \\ s_\epsilon \phi_{\epsilon t} \in L^2\left(0,T;L^2(\Omega)\right). \end{gathered}$$

In particular, s_ϵ is uniformly bounded with respect to ϵ in $L^\infty\left(0,T;H^1(\Omega)\right)$, while $s_\epsilon\nabla\phi_\epsilon$ is uniformly bounded with respect to ϵ in $L^\infty\left(0,T;L^2(\Omega)\right)$, and $s_{\epsilon t}$ is uniformly bounded with respect to ϵ in $L^2\left(0,T;L^2(\Omega)\right)$. Furthermore, ϕ_ϵ is uniformly bounded with respect to ϵ in $L^\infty(\Omega_T)$ by the standard version of the maximum principle [12] for (4.2) and the assumptions on h in (2.11)–(2.12).

Theorem 4.3. *There exists a global weak solution,* (s, ϕ)*, of the system*

$$\frac{1}{2}\left(s^2\right)_t = \frac{k_1}{2}\triangle\left(s^2\right) - k_1|\nabla s|^2 - k_2 s^2|\nabla\phi|^2 - W'(s)\,s, \tag{4.5}$$

$$s^2\phi_t = k_3\,\mathrm{div}\left(s^2\nabla\phi\right). \tag{4.6}$$

Moreover,

$$\begin{gathered} s \in L^\infty\left(0,T;H^1(\Omega)\right) \cap H^1\left(0,T;L^2(\Omega)\right), \\ s\nabla\phi \in L^\infty\left(0,T;L^2(\Omega)\right), \\ s,\, \phi \in L^\infty(\Omega_T). \end{gathered}$$

Proof. We multiply (4.1) and (4.2) by smooth test functions, $s_\epsilon\xi_1(t)\xi_2(x)$ and $\eta_1(t)\eta_2(x)$, respectively, and pass to the limit as $\epsilon \to 0$. First, we carry out several integrations by parts:

$$\begin{aligned} &-\int_0^T\int_\Omega \frac{1}{2}s_\epsilon^2\xi_{1t}(t)\,\xi_2(x)\,dx\,dt \\ &= \int_0^T\int_\Omega \Big\{ \frac{k_1}{2}s_\epsilon^2\xi_1(t)\triangle\xi_2(x) - k_1|\nabla s_\epsilon|^2\xi_1(t)\,\xi_2(x) \\ &\qquad - k_2 s_\epsilon^2|\nabla\phi_\epsilon|^2\xi_1(t)\,\xi_2(x) - W'(s_\epsilon)\,s_\epsilon\xi_1(t)\,\xi_2(x) \Big\}\,dx\,dt \end{aligned} \tag{4.7}$$

and

$$\begin{aligned} &-\int_0^T\int_\Omega \left\{ \left(s_\epsilon^2+\epsilon^2\right)\phi_\epsilon\eta_{1t}(t)\,\eta_2(x) + 2s_\epsilon\phi_\epsilon s_{\epsilon t}\eta_1(t)\,\eta_2(x) \right\}\,dx\,dt \\ &= \int_0^T\int_\Omega -k_3\left(s_\epsilon^2+\epsilon^2\right)\nabla\phi_\epsilon\cdot\nabla\eta_2(x)\,\eta_1(t)\,dx\,dt \\ &= \int_0^T\int_\Omega \left\{ -k_3 s_\epsilon^2\nabla\phi_\epsilon\cdot\nabla\eta_2(x)\,\eta_1(t) + k_3\epsilon^2\phi_\epsilon\eta_1(t)\triangle\eta_2(x) \right\}\,dx\,dt. \end{aligned} \tag{4.8}$$

By letting $\epsilon \to 0$, we can find a subsequence, $\{\epsilon_j\}_{j\in\mathbf{N}}$, such that s_{ϵ_j} converges to s weakly in $H^1\left(0,T;L^2\left(\Omega\right)\right)$, weakly-$*$ in $L^\infty\left(0,T;H^1\left(\Omega\right)\right)$ and in $L^\infty\left(\Omega_T\right)$, while ϕ_{ϵ_j} converges to a limit ϕ weakly- $*$ in $L^\infty\left(\Omega_T\right)$. Moreover, on the same subsequence, $s_{\epsilon_j}\nabla\phi_{\epsilon_j}$ converges to $s\nabla\phi$ weakly- $*$ in $L^\infty\left(0,T;L^2\left(\Omega\right)\right)$.

Now, by the uniform bounds on s_{ϵ_j}, ϕ_{ϵ_j}, and $s_{\epsilon_j}\nabla\phi_{\epsilon_j}$, every term in (4.7)–(4.8) converges to the corresponding term for s and ϕ. Note that, by Lemma 3.2, the term $s_\epsilon W'\left(s_\epsilon\right)$ is bounded uniformly in ϵ in $L^\infty\left(\Omega_T\right)$. Then, since the terms involving ϵ^2 all vanish in the limit $\epsilon \to 0$, the resulting limiting equations are the weak forms of (4.5) and (4.6). □

Remark 4.4. The equation (4.5) for the order parameter s can be obtained by multiplying the governing equation (2.9) by s. Hence, when $s \neq 0$, (2.9) and (4.5) are equivalent. On the other hand, $s \equiv 0$ is a solution of both equations.

Remark 4.5. The energy law (3.5) holds in a form of the inequality

$$E(t) + \int_0^t \int_\Omega \left\{ \left(s_t^2 + \frac{k_2}{k_3} s^2 {\phi_t}^2 \right) \right\} dx\, dt \le E(0) \tag{4.9}$$

for the weak solutions of (4.5)–(4.6) constructed in this section.

Remark 4.6. Let $s \ge 0$ (or $s \le 0$) and $0 < k_2 < k_1$. As in [11], the target space for (2.9)–(2.10) (a half of a metric cone over $\mathbf{S}^2$) can be approximated by nonpositively curved smooth manifolds. Following the arguments of [3] and taking the appropriate limit we find that the solutions of (2.9)–(2.10) are Lipschitz continuous.

5. Local existence of strong solutions. In this section we will use the semigroup approach to study the existence of strong solutions of the governing system of equations (2.9)–(2.10). Assuming that $f = (f_1, f_2)$ and $u = (s, \phi)$ we introduce the notation

$$\begin{aligned} f_1(s,\phi) &= -k_2 s |\nabla\phi|^2 - W'(s), \\ f_2(s,\phi) &= 2k_3 s^{-1} \nabla s \cdot \nabla\phi. \end{aligned} \tag{5.1}$$

In addition, we define the functional space

$$X = L^2(\Omega) \times L^2(\Omega),$$

with the norm

$$\|f\|_X^2 = \|f_1\|_{L^2(\Omega)}^2 + \|f_2\|_{L^2(\Omega)}^2.$$

We begin by rewriting the system (2.9)–(2.10) in the form

$$u_t + \mathcal{A}u = f(u, \nabla u), \qquad u = (s,\phi), \tag{5.2}$$

where f is given by (5.1) and $\mathcal{A}$ represents the linear operator

$$(\mathcal{A}u, v) = \int_\Omega (k_1 \nabla s \cdot \nabla v_1 + k_2 \nabla\phi \cdot \nabla v_2)\, dx\,.$$

Here $v = (v_1, v_2) \in H^1(\Omega) \times H^1(\Omega)$ satisfies the same boundary conditions as in (2.12). Clearly, $\mathcal{A}$ is a self-adjoint and positive definite operator. If $u \in C^2(\Omega)$ and $u = u_0$ on $\partial\Omega$, then $\mathcal{A}u = -\mathrm{div}\,(K\,\nabla u)$, where $K = \left(\begin{smallmatrix} k_1 & 0 \\ 0 & k_2 \end{smallmatrix}\right)$. Therefore,

$$\mathcal{D}(\mathcal{A}) = \left\{ u \in W^{2,2}(\Omega) \times W^{2,2}(\Omega) : u(x) = u_0,\, x \in \partial\Omega \right\}.$$

For $\alpha \geq 0$, we define

$$X^\alpha = \mathcal{D}(\mathcal{A}^\alpha), \quad \|u\|_\alpha = \|\mathcal{A}^\alpha u\|, \quad u \in X^\alpha.$$

Then we have the following lemma.

LEMMA 5.1. *Suppose that $\partial\Omega$ is a C^2-hypersurface separating $\Omega \subset \mathbf{R}^n$ from $\mathbf{R}^n \backslash \bar{\Omega}$. For $0 \leq \alpha \leq 1$, the following continuous imbedding results hold* [6]*:*

(1) $X^\alpha \subset W^{k,q},\ k - \frac{n}{q} < 2\alpha - \frac{n}{2},\ q \geq 2,$

(2) $X^\alpha \subset C^\nu,\ 0 \leq \nu < 2\alpha - \frac{n}{2},$

(3) $X^\alpha \subset L^q,\ \frac{1}{q} > \frac{1}{2} - \frac{2\alpha}{n},\ q \geq 2.$

For $\alpha \geq \frac{n}{4}$ and $\epsilon > 0$, let

$$\mathcal{U}_\epsilon = \{u \in X^\alpha : \epsilon < s < 1\}. \tag{5.3}$$

For a given $u_0 \in \mathcal{U}_\epsilon$, set

$$\mathcal{V}_\delta = \{u \in \mathcal{U}_\epsilon : \|u - u_0\|_\alpha \leq \delta\}$$

to be a δ-neighborhood of u_0 where $\delta > 0$ is fixed.

Remark 5.2. Suppose that $u \in \mathcal{V}_\delta$ for a given u_0. It follows from part (2) of Lemma 5.1 that

$$\max_{x \in \Omega \cup \partial\Omega} |s(x) - s_0(x)| \leq C(\delta),$$

where $C(\delta) \to 0$ as $\delta \to 0$. Therefore, $s(x) > s_0(x) - C(\delta) > \epsilon - C(\delta) > 0$ holds for a sufficiently small $\delta > 0$; that is, the order parameter s is uniformly bounded away from zero.

Define

$$\mu = \mu(u_0) = \epsilon - C(\delta) > 0, \qquad a = \sup\nolimits_{(s,\phi) \in \mathcal{V}_\delta} |W''(s)|;$$

then we have the following lemma.

LEMMA 5.3. *Suppose that n and α satisfy one of the following three conditions:*

$$n = 3,\ \alpha > \frac{7}{8},\ \text{ or } n = 2,\ \alpha > \frac{3}{4},\ \text{ or } n = 1,\ \alpha > \frac{5}{8}.$$

Then $F(u) = f(u, \nabla u)$ is locally Lipschitz continuous in $\mathcal{U}_\epsilon$; that is, there exists a $\delta > 0$ such that

$$\|F(u_1) - F(u_2)\|_X \leq K(\delta) \|u_1 - u_2\|_\alpha \tag{5.4}$$

for every $u_0 \in \mathcal{U}_\epsilon$ and $u_1, u_2 \in \mathcal{V}_\delta$.

Proof. For n and α satisfying the conditions of the lemma, the imbedding results of Lemma 5.1 imply

$$X^\alpha \subset W^{1,4} \cup L^\infty \quad \text{and} \quad X^\alpha \in C^\nu,$$

where

$$0 < \nu < 2\alpha - \frac{1}{2} \text{ if } n = 1,$$
$$0 < \nu < 2\alpha - 1 \text{ if } n = 2,$$
$$0 < \nu < 2\alpha - \frac{3}{2} \text{ if } n = 3.$$

Then the following estimates on (f_1, f_2) hold for every $u_1, u_2 \in \mathcal{V}_\delta$:

$$\begin{aligned}
&\left\|s_1|\nabla\phi_1|^2 - s_2|\nabla\phi_2|^2\right\|_{L^2}\\
&\quad\le \left\|(s_1 - s_2)\,|\nabla\phi_1|^2\right\|_{L^2} + \left\|s_2\left(|\nabla\phi_1|^2 - |\nabla\phi_2|^2\right)\right\|_{L^2}\\
&\quad\le \|\nabla\phi_1\|_{L^4}^2\|s_1 - s_2\|_\infty + K'\|s_2\|_\infty(\|\nabla\phi_1\|_{L^4} + \|\nabla\phi_2\|_{L^4})\|\nabla\phi_1 - \nabla\phi_2\|_{L^4}\\
&\quad\le K\|u_1 - u_2\|_\alpha
\end{aligned}$$

for some constant $K = K(\delta, u_0)$ and $K' = K'(\delta, u_0)$. Moreover,

$$\|W'(s_1) - W'(s_2)\|_{L^2} \le a\|u_1 - u_2\|_\alpha$$

and

$$\begin{aligned}
&\left\|s_1^{-1}\nabla s_1\cdot\nabla\phi_1 - s_2^{-1}\nabla s_2\cdot\nabla\phi_2\right\|_{L^2}\\
&\qquad\qquad\le \left\|s_1^{-1}\nabla s_1\cdot(\nabla\phi_1 - \nabla\phi_2)\right\|_{L^2} + \left\|\nabla\phi_2\cdot\left(s_1^{-1}\nabla s_1 - s_2^{-1}\nabla s_2\right)\right\|_{L^2}.
\end{aligned}$$

Finally, we observe that

$$\begin{aligned}
\left\|s_1^{-1}\nabla s_1\cdot(\nabla\phi_1 - \nabla\phi_2)\right\|_{L^2} &\le \mu^{-1}\|s_1\|_{W^{1,4}}\|\nabla\phi_1 - \nabla\phi_2\|_{W^{1,4}}\\
&\le \mu^{-1}K\|u_1 - u_2\|_\alpha
\end{aligned}$$

and

$$\begin{aligned}
\left\|\nabla\phi_2\cdot\left(s_1^{-1}\nabla s_1 - s_2^{-1}\nabla s_2\right)\right\|_{L^2} &\le \mu^{-2}\|\nabla\phi_2\|_{L^4}\|s_2\nabla s_1 - s_1\nabla s_2\|_{L^4}\\
&\le K\mu^{-2}\|u_2 - u_1\|_\alpha.
\end{aligned}$$

Hence we conclude that (5.4) holds. □

Remark 5.4. The estimates, similar to the ones in the proof of the previous lemma, can be used to show that

$$\|F(u)\|_X \le K(\|u\|_\infty)\|u\|_{W^{1,2k}}^k, \qquad k \ge 2, \tag{5.5}$$

where $u \in \mathcal{U}_\epsilon$ and $\|\cdot\|_\infty$ is the L^∞-norm in Ω.

THEOREM 5.5. *Let $\epsilon > 0$ and $\alpha < 1$ be as in Lemma 5.3. For any $u_0 = (s_0, \phi_0) \in \mathcal{U}_\epsilon$ there exists $T_\epsilon = T_\epsilon(u_0) > 0$ such that the boundary-value problem (2.9)–(2.12) has a unique, maximally defined solution $u(t) = (s(t), \phi(t)) \in \mathcal{D}(A)$, as long as $t \in (0, T_\epsilon)$. The solution $u(t)$ satisfies the initial conditions $s(x, 0) = s_0$ and $\phi(x, 0) = \phi_0$ for every $x \in \Omega$ and $u_i(t) \in W^{2,2}(\Omega) \cap W^{1,4}(\Omega) \cap L^\infty(\Omega)$ for $i = 1, 2$ and $t \in (0, T_\epsilon)$. Furthermore, either $T_\epsilon = \infty$ or there exists a sequence $\{t_n\} \to T_\epsilon$ such that $s(t_n) \to s_\epsilon \in \partial\mathcal{U}_\epsilon$ as $t_n \to T_\epsilon$.*

Remark 5.6. It follows from the definition of $\mathcal{U}_\epsilon$ in (5.3) that the condition $s_\epsilon \in \partial\mathcal{U}_\epsilon$ corresponds to either $\lim_{t_n\to T_\epsilon} s_\epsilon(x_0, t_n) = \epsilon$ or $\lim_{t_n\to T_\epsilon} s_\epsilon(x_0, t_n) = 1$ for some $x_0 \in \Omega$.

Remark 5.7. The preceding existence results are also valid for the initial data $s_0 \in (-\frac{1}{2}, 0)$. However, they do not apply in the case when $s_0(x) \to 0$ as $x \to \bar{x}$, where $\bar{x} \in \bar{\Omega} := \Omega \cup \partial\Omega$.

Remark 5.8. Additional regularity properties of a solution of the abstract equation (5.2) can be inferred from its definition [6]. In particular, one can show that the original equation is satisfied by this solution in a classical sense. In fact, since

$u \in D(A)$ and $u_t(\cdot, t) \in X^\alpha$ is locally Hölder continuous for $t > 0$ [6, Theorem 3.5.2], the functions u and u_t are continuous on $(0, T_\epsilon) \times \bar{\Omega}$. The inclusion $u \in D(A)$ guarantees that $\nabla u_i \in W^{1,2}(\Omega) \subset L^6(\Omega)$; hence $Au \in L^3(\Omega)$. Therefore, $u_i \in W^{2,3}(\Omega)$ and $\nabla u_i \in W^{1,3}(\Omega) \subset L^q$ for all $q > 3$. By repeating this argument, we conclude that $u_i \in W^{2,q}$ for $q > 3$ and $\nabla u(t, \cdot)$ is Hölder continuous. Then $F_i(u) \in C^\beta(\Omega)$ and $u_i(t, \cdot) \in C^{2+\beta}(\Omega)$ for some $\beta > 0$. Moreover, for $t > 0$, the function $u(x, t)$ is continuously differentiable in t and twice continuously differentiable in x; hence $u(x, t)$ is a classical solution of the governing system (2.9)–(2.10).

6. Long-time behavior and stability of solutions.

Suppose that a solution (s, ϕ) of (2.9)–(2.10) is sufficiently smooth to satisfy the energy law (cf. Theorem 3.1)

$$E'(t) + \int_\Omega \left\{ \left(s_t^2 + \frac{k_2}{k_3} s^2 {\phi_t}^2 \right) \right\} dx = 0 \tag{6.1}$$

or, in a more general case, the energy inequality (4.9)

$$E(t) + \int_0^t \int_\Omega \left\{ \left(s_t^2 + \frac{k_2}{k_3} s^2 {\phi_t}^2 \right) \right\} dx\, dt \le E(0) \tag{6.2}$$

for every $t \in (0, \infty)$. Then both terms $s_t = k_1 \triangle s - k_2 s |\nabla \phi|^2 - W'(s)$ and $s\phi_t = k_3 s^{-1} \mathrm{div}\left(s^2 \nabla \phi\right)$ are in the space $L^2\left(0, \infty; L^2(\Omega)\right)$. By using Fubini's theorem we can prove the following.

THEOREM 6.1. *Suppose that* (s, ϕ) *is a weak solution of* (2.9)–(2.12) *obtained in Theorem* 4.3. *Given any sequence* $\{t_i\}_{i \in \mathbf{N}}$ *such that* $t_i \to \infty$, *there exists a subsequence* $\{t_{i_j}\}_{j \in \mathbf{N}}$ *satisfying* $s(t_{i_j}, \cdot) \to s^*$ *in* $H^1(\Omega)$ *and* $\phi(t_{i_j}, \cdot) \overset{*}{\rightharpoonup} \phi^*$ *in* $L^\infty(\Omega)$ *weak-*$*$, *where* (s^*, ϕ^*) *is a solution of the stationary problem*

$$k_1 \triangle s - k_2 s |\nabla \phi|^2 - W'(s) = 0, \tag{6.3}$$

$$k_3 \mathrm{div}\left(s^2 \nabla \phi\right) = 0, \tag{6.4}$$

with (2.12) *as the boundary condition.*

Remark 6.2. When $0 < k_2 < k_1$ and $W \equiv 0$, one can apply the argument of R. Schoen [7], [14], [11] to show the uniqueness of the stationary minimizing solution. Then, the result of Theorem 6.1 holds not just on a subsequence but as $t \to \infty$. The same conclusion is valid when $W \neq 0$ is small in comparison with the size of the domain.

Note that there is no global (up to the boundary) uniqueness of the stationary solution when $k_2 > k_1$.

7. The exact solution in the one-dimensional case.

We now restrict Ω to lie in $\mathbf{R}$ and suppose that $\Omega := [-a, a]$. Then the system (6.3)–(6.4) can be written as

$$K^2\, s_{xx} - s\phi_x^2 - \frac{1}{\kappa^2} W'(s) = 0, \tag{7.1}$$

$$\left(s^2 \phi_x\right)_x = 0. \tag{7.2}$$

Here $K = \sqrt{k_1/k_2}$ and $\kappa = \sqrt{K_2}$. The system (7.1)–(7.2) can be decoupled by setting the angle ϕ to a constant value in Ω. Then the second equation is satisfied automatically and the first one reduces to a stationary Ginzburg–Landau equation in one dimension. We, however, will be interested in solutions of the full system with a nonconstant angular part. Therefore, we will require that $\phi(-a) < \phi(a)$. We will not impose any additional boundary conditions on s and ϕ, except for the technical restriction that $s(-a) = s(a)$. Note that, lacking uniqueness, we do not claim that we can identify the exact asymptotic limit of (2.9)–(2.10) as $t \to \infty$. In this section we will merely be interested in discussing the possible features of such a limit.

By integrating (7.2), substituting the result into (7.1), and integrating once, we obtain

$$K^2 S_x^2 + 4\alpha^2 - \frac{8}{\kappa^2} S W_1(S) = \beta S, \tag{7.3}$$

$$\phi_x = \frac{\alpha}{S}, \tag{7.4}$$

where $S := s^2$, the function $W_1(S) := W(\sqrt{S})$, and both α and β are the constants of integration. For the remainder of this section we will also assume that the potential function has a special form $W(s) = \left(1 - s^2\right)^2/8$ and, hence, $W_1(S) = (1 - S)^2/8$. This apparent relaxation of the assumptions on W from section 2 can be justified on the basis of the maximum principle result of Lemma 3.2. Then

$$(\kappa\, K\, S_x)^2 = S^3 - 2S^2 + \left(1 + \kappa^2\beta\right) S - 4\kappa^2\alpha^2. \tag{7.5}$$

The general solution of this ODE can be expressed in terms of elliptic integrals. However, for a certain combination of the constants β and α, there is a particular explicit solution of (7.5) in terms of elementary functions. To find this solution we will suppose that

$$\kappa^2\alpha^2 = \frac{1}{54}\left[1 + 9\kappa^2\beta - \left(1 - 3\kappa^2\beta\right)^{\frac{3}{2}}\right]. \tag{7.6}$$

Then (7.5) transforms into

$$(\kappa\, K\, S_x)^2 = (S - S_0(\lambda))^2\,(S - S_1(\lambda))\,, \tag{7.7}$$

where

$$S_0(\lambda) = \frac{2 + \lambda}{3}, \quad S_1(\lambda) = \frac{2(1 - \lambda)}{3},$$

and

$$\lambda = \sqrt{1 - 3\,\kappa^2\beta}. \tag{7.8}$$

Integrating (7.7) and using the restriction on the boundary values of s, we obtain

$$S(x) = S_1(\lambda) + \lambda \tanh^2\left(\frac{\sqrt{2\,\lambda}\,x}{\kappa\, K}\right). \tag{7.9}$$

We can now use (7.9) to solve (7.4):

$$\begin{aligned} \phi(x) &= \phi(-a) + \alpha \int_{-a}^{x} \frac{1}{S(p)}\, dp \\ &= \phi(-a) + \frac{\kappa\, K\, \alpha}{S_0(\lambda)\sqrt{2 S_1(\lambda)}} \left[\arctan\left\{\sqrt{\frac{\lambda}{S_1(\lambda)}} \tanh\left(\frac{\sqrt{2\,\lambda}\,x}{\kappa\, K}\right)\right\}\right. \\ &\quad \left. + \arctan\left\{\sqrt{\frac{\lambda}{S_1(\lambda)}} \tanh\left(\frac{\sqrt{2\,\lambda}\,a}{\kappa\, K}\right)\right\}\right] + \frac{\alpha}{S_0(\lambda)}(x + a) \end{aligned} \tag{7.10}$$

for every $\lambda \in (0\,,1)$. Moreover, (7.6) can be rewritten in terms of α and λ:

$$\alpha = \frac{2}{3\sqrt{3}\,\kappa}\,(2+\lambda)\,\sqrt{1-\lambda} = \frac{S_0(\lambda)\sqrt{2S_1(\lambda)}}{\kappa}. \tag{7.11}$$

Then (7.10) simplifies to

$$\begin{aligned}\phi(x) = \phi(-a) + K &\left[\arctan\left\{\sqrt{\frac{\lambda}{S_1(\lambda)}}\tanh\left(\frac{\sqrt{2\,\lambda}\,x}{\kappa\,K}\right)\right\}\right.\\ &\left.+\arctan\left\{\sqrt{\frac{\lambda}{S_1(\lambda)}}\tanh\left(\frac{\sqrt{2\,\lambda}\,a}{\kappa\,K}\right)\right\}\right] + \frac{\sqrt{2S_1(\lambda)}}{\kappa}(x+a).\end{aligned} \tag{7.12}$$

Finally, introducing a new parameter $\mu^2 = \lambda$, assuming that

$$\nu^2(\mu) = \frac{S_1(\mu^2)}{\mu^2} = \frac{2\,(1-\mu^2)}{3\,\mu^2}, \tag{7.13}$$

and using the definition of S, we have for every $\mu \in (0\,,1)$ that

$$s(x) = \mu\,\sqrt{\nu^2 + \tanh^2\left(\frac{\sqrt{2}\,\mu\,x}{\kappa\,K}\right)}, \tag{7.14}$$

$$\begin{aligned}\phi(x) = \phi(-a) + K &\left[\arctan\left\{\frac{1}{\nu}\tanh\left(\frac{\sqrt{2}\,\mu\,x}{\kappa\,K}\right)\right\}\right.\\ &\left.+\arctan\left\{\frac{1}{\nu}\tanh\left(\frac{\sqrt{2}\,\mu\,a}{\kappa\,K}\right)\right\}\right] + \frac{\sqrt{2}\,\nu\,\mu}{\kappa}\,(x+a).\end{aligned} \tag{7.15}$$

The only remaining free parameter in these equations is μ, and it can be determined by imposing the boundary conditions either on s or on ϕ. The former boundary-value problem would have a solution in the form (7.14) only if $s(-a) = s(a)$. If the boundary conditions on ϕ are given, $\phi(-a) = \phi_0$ and $\phi(a) = \phi_1$, for example, then μ can be determined from the equation

$$\phi_1 - \phi_0 = 2K\,\arctan\left\{\frac{1}{\nu(\mu)}\tanh\left(\frac{\sqrt{2}\,\mu\,a}{\kappa\,K}\right)\right\} + \frac{2\sqrt{2}\,\nu(\mu)\,\mu\,a}{\kappa}. \tag{7.16}$$

We do not claim that (7.16) would always have a solution—indeed, (7.14)–(7.15) represent a one-parameter family of solutions of the system (7.1)–(7.2) and not its general solution. However, (7.14)–(7.15) can still be used to describe some of the basic types of solutions of (7.1)–(7.2).

First, we observe that, by the definitions of λ and μ, the inequality $0 \le \mu \le 1$ always holds. Using the Maple computer algebra system [17], we will illustrate four different cases of possible singular behavior of the liquid crystal system.

(1) Suppose that $\mu = 0$. Then (7.9) and (7.12) reduce to

$$s(x) = \sqrt{\frac{2}{3}}, \tag{7.17}$$

$$\phi(x) = \phi(-a) + \frac{2}{\sqrt{3}\kappa}(x+a). \tag{7.18}$$

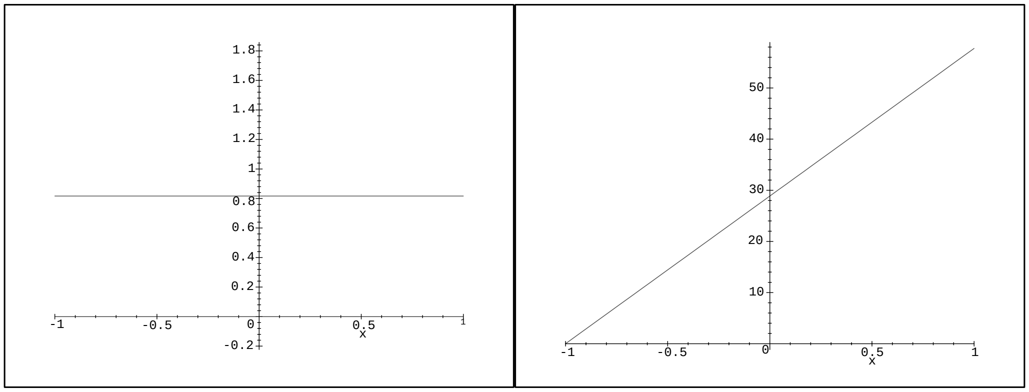

FIG. 7.1. *The graphs of s and ϕ when $K = 1$, $\mu = 0$, $\kappa = 0.04$, and $a = 1$.*

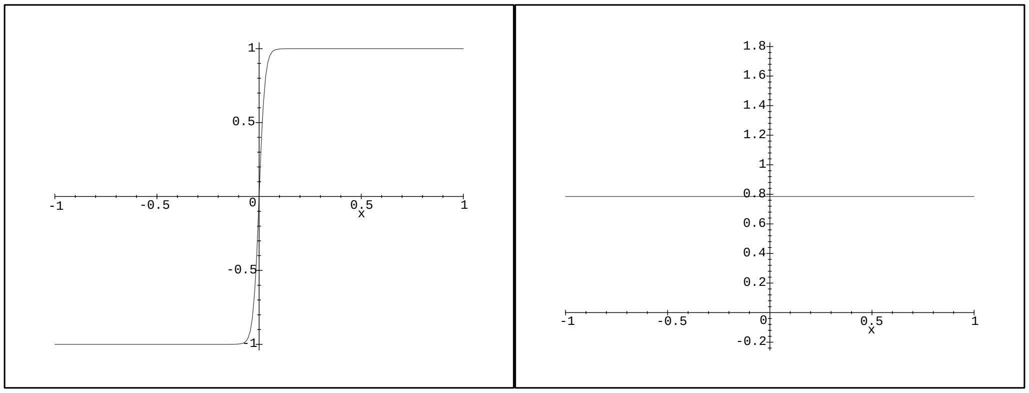

FIG. 7.2. *The graphs of s and ϕ when $K = 1$, $\mu = 1$, $\kappa = 0.04$, and $a = 1$.*

This solution (Figure 7.1) is independent of K and corresponds to a rotation of the director vector of a constant length. No structural defects are observed in this state.

(2) Now let $\mu = 1$. Then $\lambda = 1$, and by (7.11), one can see that $\alpha = 0$ holds. It follows as a consequence of (7.4) that $\phi(x)$ is constant on $(-a\,, a)$. In addition, by (7.9), we have that

$$s(x) = \tanh\left(\frac{\sqrt{2}\,x}{\kappa\,K}\right) \tag{7.19}$$

is a solution of a stationary Ginzburg–Landau equation. Typical profiles of the angle and order parameter for small values of κ are shown on Figure 7.2. Here the value of the order parameter abruptly changes at $x = 0$, while the director remains constant throughout the domain. This picture corresponds to an interface between two regions with different degrees of orientation.

(3) Here we suppose that κ is large and $\mu \to 1$. As one can observe on Figure 7.3, the corresponding physical situation can be described as a combination of the defect (wall) at $x = 0$ and the gradually changing order parameter in the bulk.

(4) We now let $\mu \to 1$ and κ be small. As μ approaches 1, the structure of the solutions changes as shown on Figures 7.4 and 7.5. The situation on Figure 7.4 can be characterized as a combination of the defect (wall) at $x = 0$ and some additional

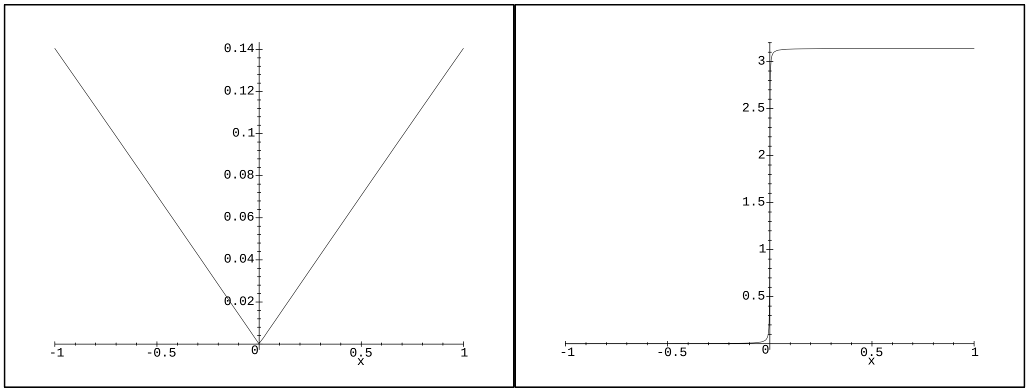

Fig. 7.3. *The graphs of s and ϕ when $K = 1$, $\mu = 0.8$, $\kappa = 10$, and $a = 1$.*

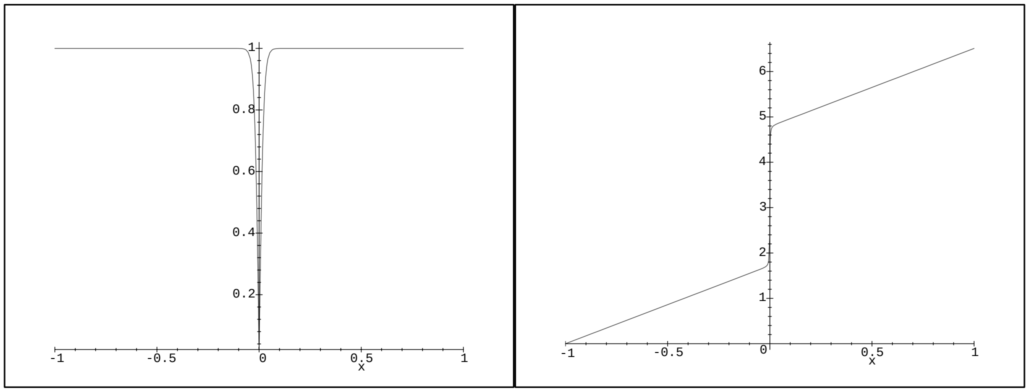

Fig. 7.4. *The graphs of s and ϕ when $K = 1$, $\mu = 99.9 \times 10^{-2}$, $\kappa = 0.04$, and $a = 1$.*

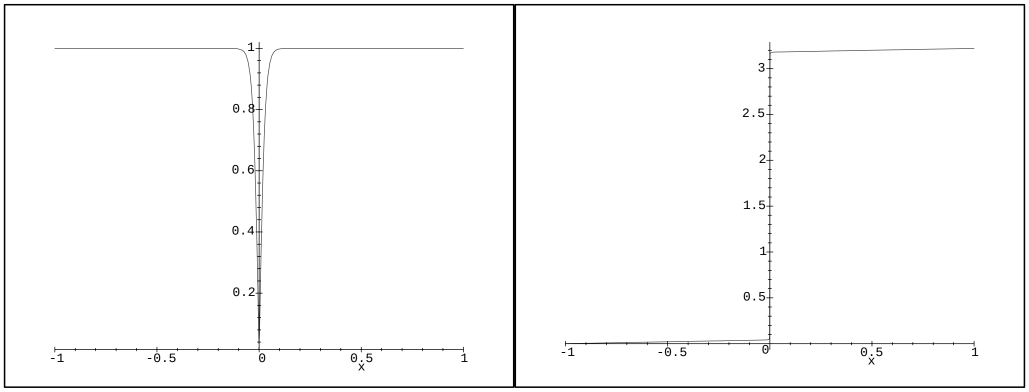

Fig. 7.5. *The graphs of s and ϕ when $K = 1$, $\mu = 99.9999 \times 10^{-2}$, $\kappa = 0.04$, and $a = 1$.*

rotation of the director in the bulk. When μ is closer to 1 (Figure 7.5), almost all of the director rotation is concentrated exclusively within the core of the defect.

We conclude, therefore, that for $\mu \in [0\,,1)$, the solution (6.14)–(6.15) is similar to a twisted nematic in which the director rotates either in the bulk or inside the defect (wall) at the center of the domain. The smallness of parameters $\frac{\kappa}{\mu}$ and $\frac{\nu}{\kappa}$ induces sharp interfaces and defects inside the domain, respectively.

8. Conclusion. We have presented the analysis of the evolution system modeling the behavior of nematic liquid crystals with variable degree of orientation. By introducing the order parameter, the system allows for the presence of structural defects in a material. This, however, creates mathematical difficulties and leads to a degenerate problem when the liquid crystal is in an isotropic state. The existence of weak solutions of the governing equations has been shown in a general case; their regularity can be established subject to certain restrictions on the order parameter. In particular, the regularity of solutions when the minima of the potential function lie on both sides of zero is still open. Using the appropriate smoothness of the director-order parameter configuration, one can then determine its asymptotic behavior and, therefore, describe the dynamics of new types of defects.

PERMANENCE OF WEAKLY COUPLED VECTOR FIELDS*

SEBASTIAN J. SCHREIBER†

Abstract. Let $F^1, \dots, F^k$ be k dissipative vector fields on finite dimensional Euclidean spaces that preserve the skeleton of the positive orthant. Permanence of all sufficiently weak couplings of these vector fields corresponds to robust permanence of the uncoupled vector field $F^1 \times \cdots \times F^k$. A sufficient condition for robust permanence of $F^1 \times \cdots \times F^k$ involving unsaturated Morse decompositions is provided. In the case of coupled food chain vector fields and coupled two-dimensional vector fields, this sufficient condition is shown to be necessary. As an illustration, these results are applied to weakly coupled logistic-Holling predator-prey systems.

Key words. permanence, weak coupling, population dynamics

1. Introduction.

Ecological communities are bound together by a web of complex relationships. Data on interaction strengths between species in natural food webs indicate that these interaction strengths are characterized by many weak interactions and a few strong interactions [2, 19, 21, 30]. Consequently, food webs are often viewed as modular [22] in which modules of strongly interacting species are weakly interconnected. Because of this modularity, theoretical ecologists often develop ordinary differential equation models that include strong interactions and ignore weak interactions [11, 24, 25]. One justification for this approach is the belief that weak interactions play a small role on the models dynamics and therefore can be ignored. More recently, however, theoretical ecologists have considered the effects of weak interactions and have found that weak interactions can play important stabilizing and "noise" dampening roles [2, 19, 21] and can magnify spatiotemporal variation in community structure [2]. Furthermore, weak couplings of predator-prey systems with periodic orbits exhibit phase locking and entrainment [28]. To better understand their global dynamics, we investigate permanence of weakly coupled systems.

Population dynamics are frequently modeled by vector fields on the positive orthant of Euclidean space that leave the boundary of this orthant invariant. Stated loosely, such a vector field is permanent provided that the boundary of the positive orthant is repelling [3, 4, 9, 13, 14, 27]. Ecologically this is interpreted as the long-term coexistence of the interacting populations. Reviews of the mathematical progress on studying permanence and its applications can be found in [10, 15, 29]. If we have k-vector fields $F^1, \dots, F^k$ representing k uncoupled systems of interacting populations, then weak couplings of these vector fields correspond to vector fields that are close to the product vector field $F^1 \times \cdots \times F^k$. The goal of this article is to find conditions that ensure all vector fields sufficiently close to the uncoupled vector field $F^1 \times \cdots \times F^k$ are permanent. In other words, determine under what conditions $F^1 \times \cdots \times F^k$ is robustly permanent. After defining these concepts more precisely in section 2, we conjecture that $F^1 \times \cdots \times F^k$ is robustly permanent if and only if for each $1 \le i \le k$ the vector field F^i is robustly permanent. If this conjecture is indeed true, then it reduces a

†Department of Mathematics, Western Washington University, Bellingham, WA 98225 (sschreib@cc.wwu.edu).

potentially high-dimensional problem (i.e., determining whether $F^1 \times \cdots \times F^k$ has a robustly repelling boundary) to k lower-dimensional problems (i.e., determining for each $1 \leq i \leq k$ whether F^i has a robustly repelling boundary). To prove such a conjecture requires an appropriate characterization of robust permanence and extending it to product vector fields. Results in this direction include the recent work of the author [26] in which it is shown that a vector field is robustly permanent provided that it admits an unsaturated Morse decomposition of its boundary dynamics, and a generalization of this criterion by Hirsch, Smith, and Zhao [8] to semiflows. Recall that a Morse decomposition of an invariant set K is a collection of isolated invariant subsets of K such that collapsing these sets to distinct points results in a gradient-like quotient flow on K. On the other hand, an unsaturated equilibrium in a population model is in effect one which can be invaded by some population entering the system at low density. Thus an unsaturated Morse decomposition is one in which the invariant subsets in the decomposition, which may be more complicated than just equilibria, have the analogous property of invasibility by at least one population not already present. In section 3, we discuss these results and prove that if $F^1, \ldots, F^k$ are vector fields that admit an unsaturated Morse decomposition, then $F^1 \times \cdots \times F^k$ admits an unsaturated Morse decomposition and, consequently, is robustly permanent. In section 4, we use the main result of section 3 to prove our conjecture for couplings of two-dimensional vector fields and for couplings of food chain vector fields. In section 5, we prove a technical proposition to make our results more applicable and illustrate our approach with coupled predator-prey systems of the logistic-Holling type.

2. Preliminaries and a conjecture.

DEFINITION 2.1. *Let $\mathcal{P}^r(n)$ be the space of C^r vector fields $F = (F_1, \ldots, F_n) : \mathbf{R}^n_+ \to \mathbf{R}^n$ that satisfy $F_i(x) = 0$ whenever $x_i = 0$.*

The extra condition on F corresponds to the fact that in the absence of population i, the growth rate of population i is zero. We view $\mathcal{P}^r(n)$ as the space of all possible models of n-interacting populations and endow $\mathcal{P}^r(n)$ with the C^r Whitney topology [7, Chapter 2].

DEFINITION 2.2. *Let $F = (F_1, \ldots, F_n) \in \mathcal{P}^r(n)$ with $r \geq 1$. The* per capita growth functions *$f = (f_1, \ldots, f_n) : \mathbf{R}^n_+ \to \mathbf{R}^n$ associated with F are the continuous functions defined by*

$$f_i(x) = \begin{cases} \frac{F_i(x)}{x_i} & \text{if } x_i \neq 0, \\ \frac{\partial F_i}{\partial x_i}(x) & \text{if } x_i = 0 \end{cases} \tag{2.1}$$

for any $x = (x_1, \ldots, x_n) \in \mathbf{R}^n_+$.

We recall several definitions from dynamical systems theory. Assume $F : \mathbf{R}^n_+ \to \mathbf{R}^n$ is C^1 and that $\dot{x} = F(x)$ generates a global flow $\phi : \mathbf{R} \times \mathbf{R}^n_+ \to \mathbf{R}^n_+$. Let $\phi_t x = \phi(t, x)$. Given sets $I \subseteq \mathbf{R}$ and $K \subseteq \mathbf{R}^n_+$, let $\phi_I K = \{\phi_t x : t \in I, x \in K\}$. A set $K \subseteq \mathbf{R}^n_+$ is called *invariant* if $\phi_t K = K$ for all $t \in \mathbf{R}$. The *omega limit set* of a set $K \subseteq \mathbf{R}^n_+$ equals $\omega(F, K) = \cap_{t \geq 0} \overline{\phi_{[t,\infty)} K}$. The *alpha limit set* of a set $K \subseteq \mathbf{R}^n_+$ equals $\alpha(F, K) = \cap_{t \leq 0} \overline{\phi_{(-\infty,t]} K}$. $A \subset \mathbf{R}^n_+$ is called an *attractor* for ϕ provided there exists an open neighborhood $U \subseteq \mathbf{R}^n_+$ of A such that $\omega(F, U) = A$. The *basin of attraction* of A is the set of points $x \in \mathbf{R}^n_+$ such that $\omega(F, x) \subseteq A$. The flow ϕ is *dissipative* if there exists a compact attractor $A \subset \mathbf{R}^n_+$ for ϕ whose basin of attraction is $\mathbf{R}^n_+$.

DEFINITION 2.3. *$F \in \mathcal{P}^r(n)$ is* permanent *provided that $\dot{x} = F(x)$ generates a dissipative flow ϕ and there exists a compact attractor $A \subset \text{int}\mathbf{R}^n_+$ for ϕ whose basin of attraction is $\text{int}\mathbf{R}^n_+$.*

Permanence was originally introduced in [27] and for dissipative vector fields is equivalent to uniform persistence [4]. To talk about permanence of weakly coupled vector fields, the following definition is useful.

DEFINITION 2.4. *$F \in \mathcal{P}^r(n)$ is C^r* robustly permanent *if there exists a neighborhood $\mathcal{N} \subseteq \mathcal{P}^r(n)$ of F such that every vector field $G \in \mathcal{N}$ is permanent.*

Now suppose that $F^1 \in \mathcal{P}^r(n_1), \ldots, F^k \in \mathcal{P}^r(n_k)$ are vector fields. Define the product vector field $F^1 \times \cdots \times F^k \in \mathcal{P}^r(n_1 + \cdots + n_k)$ by

$$F^1 \times \cdots \times F^k(x^1, \ldots, x^k) = (F^1(x^1), \ldots, F^k(x^k)),$$

where $x^1 \in \mathbf{R}_+^{n_1}, \ldots, x^k \in \mathbf{R}_+^{n_k}$. If $F^1 \times \cdots \times F^k$ is C^r robustly permanent, then all sufficiently weak C^r couplings of $F^1, \ldots, F^k$ are permanent.

We make the following conjecture.

CONJECTURE 1. *Let $F^1 \in \mathcal{P}^r(n_1), \ldots, F^k \in \mathcal{P}^r(n_k)$ with $r \geq 1$ be vector fields that generate dissipative flows. If F^i is C^r robustly permanent for each $1 \leq i \leq k$, then $F^1 \times \cdots \times F^k$ is C^r robustly permanent.*

The converse of this conjecture—namely, robust permanence of $F^1 \times \cdots \times F^k$ implies robust permanence of F^i for each $1 \leq i \leq k$—follows immediately from the definitions. The utility of this conjecture, provided that it is true, is that it reduces checking robust permanence of a $n_1 + \cdots + n_k$-dimensional vector field to checking robust permanence of n_i-dimensional vector fields for $1 \leq i \leq k$.

3. Unsaturated Morse decompositions. In previous work [26], the author developed a sufficient condition for robust permanence. This condition involves the notion of unsaturated Morse decompositions that we discuss now. Let $F \in \mathcal{P}^r(n)$ with $r \geq 1$ generate the dissipative flow ϕ and let $f = (f_1, \ldots, f_n)$ denote the per capita growth rate functions associated with F. Given a compact invariant set K, let $\mathcal{M}_{\text{inv}}(F, K)$ denote the set of ϕ-invariant Borel probability measures with support in K. A compact invariant set K for ϕ is *unsaturated* if

$$\min_{\mu \in \mathcal{M}_{\text{inv}}(F,K)} \max_{1 \leq i \leq n} \int_K f_i \, d\mu > 0.$$

Recall that a compact invariant set K is *isolated* if there exists a neighborhood V of K such that K is the maximal compact invariant set in V. A collection of sets $\{M_1, \ldots, M_k\}$ is a *Morse decomposition* for a compact invariant set K if $M_1, \ldots, M_k$ are pairwise disjoint, compact isolated invariant sets for $\phi|K$ with the property that for each $x \in K$ there are integers $l = l(x) \leq m = m(x)$ such that $\alpha(F, x) \subseteq M_m$ and $\omega(F, x) \subseteq M_l$ and if $l = m$, then $x \in M_l = M_m$. Let K be a compact invariant set. We say that $\{M_1, \ldots, M_k\}$ is an *unsaturated Morse decomposition for K* if $\{M_1, \ldots, M_k\}$ is a Morse decomposition for K and each M_j is unsaturated. The following sufficient condition for C^r robust permanence was proven by the author.

THEOREM 3.1 (Schreiber [26]). *Let $F \in \mathcal{P}^r(n)$ with $r \geq 1$ be such that $\dot{x} = F(x)$ generates a dissipative flow ϕ. Let $\Lambda \subset \partial \mathbf{R}_+^n$ be the maximal compact invariant set for $\phi|\partial \mathbf{R}_+^n$. If Λ admits an unsaturated Morse decomposition, then F is C^r robustly permanent.*

As a step toward our conjecture, we prove a direct product of flows that admit unsaturated Morse decompositions admits an unsaturated Morse decomposition.

THEOREM 3.2. *If $F^1 \in \mathcal{P}^r(n_1), \ldots, F^k \in \mathcal{P}^r(n_k)$ with $r \geq 1$ are vector fields such that for each $1 \leq i \leq k$*

1. *F^i generates a dissipative flow,*

2. *F^i admits an unsaturated Morse decomposition of the maximal compact invariant set of $\partial\mathbf{R}_+^{n_i}$,*

then $F^1 \times \cdots \times F^k$ is C^r robustly permanent.

The proof of this theorem follows from induction, the following proposition, and the fact that dissipative vector fields are open in the C^1 Whitney topology.

PROPOSITION 3.3. *Let $F \in \mathcal{P}^r(n)$ and $G \in \mathcal{P}^r(m)$ with $r \geq 1$ generate dissipative flows ϕ_t and ψ_t, respectively. Let $\Lambda_1 \subset \mathbf{R}_+^n$ and $\Lambda_2 \subset \mathbf{R}_+^m$ be the maximal compact invariant sets for ϕ and ψ, respectively. If $\Lambda_1 \cap \partial\mathbf{R}_+^n$ admits an unsaturated Morse decomposition for ϕ and $\Lambda_2 \cap \partial\mathbf{R}_+^m$ admits an unsaturated Morse decomposition for ψ, then $\Lambda_1 \times \Lambda_2 \cap \partial\mathbf{R}_+^{n+m}$ admits an unsaturated Morse decomposition for $\phi \times \psi$.*

Proof. Let $\{N_1, \ldots, N_k\}$ and $\{M_1, \ldots, M_l\}$ be unsaturated Morse decompositions for $\phi|\Lambda_1 \cap \partial\mathbf{R}_+^n$ and $\psi|\Lambda_2 \cap \partial\mathbf{R}_+^m$, respectively. Theorem 3.1 implies that ϕ and ψ are permanent. Hence there exist compact attractors $N_0 \subset \mathrm{int}\mathbf{R}_+^n$ and $M_0 \subset \mathrm{int}\mathbf{R}_+^m$ for ϕ and ψ, respectively, whose basins of attraction are $\mathrm{int}\mathbf{R}_+^n$ and $\mathrm{int}\mathbf{R}_+^m$, respectively. Hence $\{N_0, \ldots, N_k\}$ and $\{M_0, \ldots, M_l\}$ define Morse decompositions for $\phi|\Lambda_1$ and $\psi|\Lambda_2$, respectively.

Define the collection of sets $\{V_i\}_{i=0}^{l(k+1)+k}$ by

$$V_{j(k+1)+i} = N_i \times M_j, \qquad i = 0, \ldots, k, \quad j = 0, \ldots, l.$$

We claim that this collection of sets is a Morse decomposition for $\phi \times \psi$ restricted to $\Lambda_1 \times \Lambda_2$. Given any $1 \leq i \leq k$ and $1 \leq j \leq k$, N_i and M_j have isolating neighborhoods for $\phi|\Lambda_1$ and $\psi|\Lambda_2$. The product of these isolating neighborhoods is an isolating neighborhood of $N_i \times M_j$ for $\phi \times \psi|\Lambda_1 \times \Lambda_2$. Hence, $\{V_i\}_{i=0}^{l(k+1)+k}$ is a collection of isolated invariant sets for $\phi \times \psi|\Lambda_1 \times \Lambda_2$. Given $z = (x, y) \in \Lambda_1 \times \Lambda_2$, there exist $0 \leq i \leq k$ and $0 \leq j \leq l$ such that $\alpha(F, x) \subset N_i$ and $\alpha(G, y) \subset M_j$. Hence, $\alpha(F \times G, z) \subset V_{j(k+1)+i}$. Since $\{N_1, \ldots, N_k\}$ and $\{M_1, \ldots, M_l\}$ are Morse decompositions for F and G, respectively, there exist $i' \leq i$ and $j' \leq j$ such that $\omega(F, x) \subset M_{i'}$ and $\omega(G, y) \subset N_{j'}$. Furthermore, $i' = i$ only if $x \in N_i$ and $j' = j$ only if $y \in M_j$. Consequently, $\omega(F \times G, z) \subset N_{i'} \times M_{j'} = V_{j'(k+1)+i'}$ with $j'(k+1) + i' \leq j(k+1) + i$. Furthermore, $j'(k+1) + i' = j(k+1) + i$ only if $z \in V_{j(k+1)+i}$. Hence, $\{V_i\}_{i=0}^{l(k+1)+k}$ is a Morse decomposition for $\phi \times \psi|\Lambda_1 \times \Lambda_2$.

Since $V_0 \subset \mathrm{int}\mathbf{R}_+^{n+m}$ is an attractor for $\phi \times \psi$ with basin of attraction $\mathrm{int}\mathbf{R}_+^{n+m}$, $\{V_i\}_{i=1}^{l(k+1)+k}$ defines a Morse decomposition for $\phi \times \psi$ restricted to $\Lambda = (\Lambda_1 \times \Lambda_2) \cap \partial\mathbf{R}_+^{n+m}$. We claim that this Morse decomposition is unsaturated. Let $(f_1, \ldots, f_n)$ and $(g_1, \ldots, g_l)$ be the per capita growth rate functions of F and G, respectively. The per capita growth rate functions for $H = F \times G$ are given by

$$(h_1(x,y), \ldots, h_n(x,y), h_{n+1}(x,y), \ldots, h_{n+m}(x,y)) = (f_1(x), \ldots, f_n(x), g_1(y), \ldots, g_m(y)).$$

Let $V_{j(k+1)+i} = N_i \times M_j$ with $0 \leq i \leq k$ and $0 \leq j \leq l$ be a component of this Morse decomposition. Due to the fact that $j(k+1)+i \geq 1$, we have that either $i \neq 0$ or $j \neq 0$. Assume that $i \neq 0$ as the case $j \neq 0$ can be treated similarly. Since $\mathcal{M}_{\mathrm{inv}}(H, N_i \times M_j)$ is compact in the weak* topology, to show that $V_{j(k+1)+i}$ is unsaturated reduces to verifying that

$$\max_{1 \leq l \leq n+m} \int_{N_i \times M_j} h_l \, d\mu > 0$$

for every $\mu \in \mathcal{M}_{\mathrm{inv}}(H, N_i \times M_j)$. Let $\mu \in \mathcal{M}_{\mathrm{inv}}(H, N_i \times M_j)$. Define $\pi : \mathbf{R}^n \times \mathbf{R}^m \to \mathbf{R}^n$ by $\pi(x, y) = x$. Let $\pi_*\mu$ be the Borel probability measure on N_i defined by

$\pi_*\mu(A) = \mu(\pi^{-1}(A))$ for all Borel sets $A \subset N_i$. $\pi_*\mu$ is invariant for ϕ as for any continuous function $c : N_i \to \mathbf{R}$ and $t \in \mathbf{R}$,

$$\int_{N_i} c \circ \phi_t \, d\pi_*\mu = \int_{N_i \times M_j} c \circ \phi_t \circ \pi \, d\mu = \int_{N_i \times M_j} c \circ \pi \circ \phi_t \times \psi_t \, d\mu$$
$$= \int_{N_i \times M_j} c \circ \pi \, d\mu = \int_{N_i} c \, d\pi_*\mu$$

where the third equality is given by the invariance of μ. Since M_i is unsaturated for ϕ,

$$\max_{1 \le l \le n} \int_{N_i} f_l \, d\pi_*\mu > 0. \tag{3.1}$$

Since $\int_{N_i \times M_j} h_l \, d\mu = \int_{N_i} f_l \, d\pi_*\mu$ for $1 \le l \le n$, (3.1) implies that

$$\max_{1 \le l \le n+m} \int_{N_i \times M_j} h_l \, d\mu > 0.$$

Hence $N_i \times M_j$ is unsaturated for $\phi \times \psi$. □

4. Two corollaries.

In the next two subsections, we derive two corollaries of Theorem 3.2.

4.1. Weakly coupled two-dimensional systems.

The basic building blocks of ecological theory are two-species interactions that include competition, mutualism, and predator-prey interactions [1]. The following corollary of Theorem 3.2 implies that our conjecture is true for couplings of two-dimensional vector fields.

COROLLARY 4.1. *Let $F^1 \in \mathcal{P}^r(2), \dots, F^k \in \mathcal{P}^r(2)$ with $r \ge 1$ be vector fields that generate dissipative flows. If (f_1^i, f_2^i) denote the per capita growth rates of F^i for $1 \le i \le k$, then $F^1 \times \cdots \times F^k$ is robustly permanent if and only if for each $1 \le i \le k$*

1. *$f_1^i(0) > 0$ or $f_2^i(0) > 0$,*
2. *$f_2^i(x) > 0$ for all $x = (x_1, 0) \in \mathbf{R}_+^2 \backslash \{0\}$ such that $f_1^i(x) = 0$, and*
3. *$f_1^i(x) > 0$ for all $x = (0, x_2) \in \mathbf{R}_+^2 \backslash \{0\}$ such that $f_2^i(x) = 0$.*

Remark. Since two-dimensional vector fields can exhibit periodic orbits as well as equilibria, the boundary dynamics of the direct product of several two-dimensional vector fields may exhibit periodic and quasi-periodic orbits. Despite these complications, the corollary implies that robust permanence of uncoupled two-dimensional vector fields is determined by easily verified conditions at equilibria.

Proof. First, suppose that each F^i for $1 \le i \le k$ satisfies the three conditions of the corollary. For each $1 \le i \le k$, we will show that F^i admits an unsaturated Morse decomposition. Let Λ^i be the global attractor for F^i. Condition 1 implies that either $f_1^i(0) > 0$ or $f_2^i(0) > 0$. Without loss of generality, assume that $f_1^i(0) > 0$. Define $M_1 = \Lambda^i \cap \{(x_1, 0) : x_1 > 0\}$ and $M_2 = \Lambda^i \cap \{(0, x_2) : x_2 \ge 0\}$. Since $f_1^i(0) > 0$, M_1 and M_2 are disjoint isolated invariant sets for $\partial\mathbf{R}_+^2$. Invariance of $\{(0, x_2) : x_2 \ge 0\}$ implies that every point $x = (0, x_2) \in \Lambda^i$ satisfies $\alpha(F^i, x) \cup \omega(F^i, x) \subset M_2$. Invariance of $\{(x_1, 0) : x_1 \ge 0\}$ and the fact that $f_1^i(0) > 0$ implies that every point $x = (x_1, 0) \in \mathbf{R}_+^2$ with $x_1 > 0$ satisfies $\omega(F^i, x) \subset M_1$. Hence, $\{M_1, M_2\}$ is a Morse decomposition for F^i restricted to $\Lambda^i \cap \partial\mathbf{R}_+^2$. Since all invariant measures for F^i restricted to $\partial\mathbf{R}_+^2$ are convex combinations of Dirac measures based at equilibria, conditions 1–3 imply that $\{M_1, M_2\}$ is an unsaturated Morse decomposition for F^i restricted to $\Lambda^i \cap \partial\mathbf{R}_+^2$. Theorem 3.2 implies that $F_1 \times \cdots \times F_k$ is C^r robustly permanent.

On the other hand, suppose that one of the conditions is not met for one of the vector fields F^i. We will show that for every C^r neighborhood $\mathcal{N} \subset \mathcal{P}^r(2)$ of F^i contains a vector field that is not permanent. It follows that $F^1 \times \cdots \times F^k$ is not C^r robustly permanent. If condition 1 is not met for F^i, then there is a $G \in \mathcal{N}$ such that the origin is linearly stable for G. If condition 2 is not met for F^i, then there is an equilibrium $x^* = (x_1^*, 0)$ such that $f_2^i(x^*) \leq 0$. An appropriate perturbation of F^i yields a $G \in \mathcal{P}^r(2)$ such that x^* is an equilibrium for G and $g_2(x^*) < 0$, where (g_1, g_2) are the per capita growth rate functions for G. The stable manifold theorem implies there is a point $y \in \text{int}\mathbf{R}_+^2$ such that $\omega(y) = x^*$. Hence G is not permanent. Similarly, if condition 3 is not met for F^i, then we can find $G \in \mathcal{N}$ such that G is not permanent. □

4.2. Weakly coupled food chains. Using Theorem 3.2, we can prove our conjecture for food chain vector fields that represent a collection of populations where the ith population consumes the $(i-1)$st population and is consumed by the $(i+1)$st population [1]. Food chain models represent a fundamental ecological unit whose dynamics have been studied extensively [5, 6, 16, 17, 18, 20, 23].

Definition 4.2. *Let $F \in \mathcal{P}^r(n)$ with $r \geq 1$ and $f = (f_1, \ldots, f_n)$ denote the per capita growth rate functions. F is a* food chain vector field *provided that F generates a dissipative flow and for all $2 \leq i \leq n$, $f_i(x) < 0$ whenever $x_{i-1} = 0$.*

The definition of a food chain vector field asserts that in the absence of the $(i-1)$st population for $i \geq 2$, the ith population has a negative per capita growth rate and is doomed to extinction. Population 1 plays a special role under this assumption as $f_1(0)$ is permitted to be positive. Population 1 in food chain models typically represents an auto-trophic population (e.g., a population of plants) whose resources are not explicitly modeled.

Given a vector field F, recall a point $x \in \mathbf{R}_+^n$ is *recurrent* if $x \in \omega(F, x)$. The *Birkhoff center* for a compact invariant set K, denoted $BC(F, K)$, is the closure of the recurrent points of K. The following characterization of C^r robust permanence for food chain models was proven by the author.

Theorem 4.3 (Schreiber [26]). *Let $F \in \mathcal{P}^r(n)$ with $r \geq 1$ be a food chain vector field with $r \geq 1$ that generates a dissipative flow ϕ. Let Λ be the maximal compact invariant set for $\phi|\partial\mathbf{R}_+^n$. Then the following are equivalent:*

1. *F is C^r robustly permanent.*
2. *There exist compact sets $A_0 = \{0\} = \mathbf{R}_+^0, A_1 \subset \text{int}\mathbf{R}_+^1, \ldots, A_{n-1} \subset \text{int}\mathbf{R}_+^{n-1}$ and $t > 0$ such that for each $m \in \{0, 1, \ldots, n-1\}$, A_m is an attractor for $\phi|\mathbf{R}_+^m$ with basin of attraction $\text{int}\mathbf{R}_+^m$ and*

$$\min_{x \in BC(F, A_m)} \int_0^t f_{m+1}(\phi_s x)\,ds > 0, \tag{4.1}$$

where $BC(F, A_m)$ is the Birkhoff center of $\phi|A_m$. In particular, $\{A_0, \ldots, A_{n-1}\}$ defines an unsaturated Morse decomposition for $\phi|\Lambda$.

With this characterization in hand, we immediately get the following corollary.

Corollary 4.4. *If $F^1 \in \mathcal{P}^r(n_1), \ldots, F^k \in \mathcal{P}^r(n_k)$ are food chain vector fields with $r \geq 1$, then $F^1 \times \cdots \times F^k$ is C^r robustly permanent if and only if F^i is robustly permanent for each $1 \leq i \leq k$.*

5. Using the results. Although the C^r Whitney topology on $\mathcal{P}^r(n)$ is natural from a theoretical perspective, the perturbations considered in most models are not

C^r close in this strong sense. Fortunately, a means to bypass this issue is contained in the following proposition.

PROPOSITION 5.1. *Let $F \in \mathcal{P}^r(n)$ with $r \geq 1$ be C^r robustly permanent. Let $\Lambda \subset \mathbf{R}^n_+$ be the maximal compact invariant set for F. Let V_1 be a compact neighborhood of Λ and V_2 a compact neighborhood of V_1. Then there exists $\epsilon > 0$ such that if $G \in \mathcal{P}^r(n)$ satisfies*

1. *G generates a dissipative flow,*
2. *the maximal compact invariant set for G is contained in V_1, and*
3. *$\|G(x) - F(x)\| + \|DG(x) - DF(x)\| + \cdots + \|D^rG(x) - D^rF(x)\| \leq \epsilon$ for all $x \in V_2$,*

then G is permanent.

Proof. Let F be C^r robustly permanent and have maximal compact invariant set Λ. Since F is C^r robustly permanent, there exists a C^r neighborhood $\mathcal{N} \subset \mathcal{P}^r(n)$ of F such that every $G \in \mathcal{N}$ is permanent. Without loss of generality, we may assume that this neighborhood is given by

$$\{G \in \mathcal{P}^r(n) : \|G(x) - F(x)\|_r < c(x) \text{ for all } x \in \mathbf{R}^n_+\},$$

where $c : \mathbf{R}^n_+ \to (0,1]$ is a continuous function and

$$\|G(x) - F(x)\|_r = \|G(x) - F(x)\| + \|DG(x) - DF(x)\| + \cdots + \|D^rG(x) - D^rF(x)\|.$$

Let $\rho : \mathbf{R}^n_+ \to [0,1]$ be a smooth function such that $\rho(x) = 1$ for all $x \in V_1$ and $\rho(x) = 0$ for all $x \in \mathbf{R}^n_+ \setminus V_2$. Define

$$\epsilon = \min_{x \in V_2} \frac{c(x)}{(r+2)!(1 + \|\rho(x)\|_r)}.$$

Let $G \in \mathcal{P}^r(n)$ be a vector field that satisfies conditions in the statement of the proposition. Define $\tilde{G}(x) = F(x) + \rho(x)(G(x) - F(x))$. We claim that $\tilde{G}$ lies in $\mathcal{N}$. To this end, we need to make estimates for $\|D^i\tilde{G}(x) - D^iF(x)\| = \|D^i(\rho(x)(G(x) - F(x))\|$ for all $x \in \mathbf{R}^n_+$ and $0 \leq i \leq r$. The product rule implies that for $x \in V_2$ and $0 \leq i \leq r$,

$$\begin{aligned}\|D^i\left(\rho(x)(G(x) - F(x))\right)\| &\leq i! \sum_{j=0}^{i} \|D^{j-i}\rho(x) D^j(G(x) - F(x))\| \\ &\leq (i+1)! \|\rho(x)\|_r\, \epsilon.\end{aligned}$$

Consequently, for $x \in V_2$,

$$\|\tilde{G}(x) - F(x)\|_r \leq (r+2)! \|\rho(x)\|_r\, \epsilon \leq c(x).$$

On the other hand, for $x \in \mathbf{R}^n_+ \setminus V_2$, $\|F(x) - \tilde{G}(x)\|_r = 0$. Hence $\tilde{G}$ lies in $\mathcal{N}$ and is permanent. Since $\tilde{G} = G$ on the maximal compact invariant set for G, it follows that G is permanent. □

Now we illustrate how these results can be used for coupled predator-prey systems similar to those considered by Vandermeer [28]. Vandermeer used MacArthur predator-prey equations, but we choose not to use these equations as they exhibit some pathological properties (i.e., the equations are not continuous on the boundary of phase space). Instead we assume that the prey exhibits logistic dynamics in the absence of the predator, and the predator has a Holling type II function response [1]. Coupling these equations only through the predators, we get

$$\begin{aligned}
&\frac{dx_i}{dt} = r_i x_i\left(1-\frac{x_i}{K_i}\right) - \frac{a_i x_i y_i}{1+b_i x_i+\epsilon c_i x_j} - \frac{\epsilon d_j y_j x_i}{1+b_j x_j+\epsilon c_j x_i},\\
&\frac{dy_i}{dt} = \frac{e_i x_i y_i}{1+b_i x_i+\epsilon c_i x_j} + \frac{\epsilon f_i y_i x_j}{1+b_i x_i+\epsilon c_i x_j} - m_i y_i, \qquad (5.1)\\
&i,j\in\{1,2\},\quad i\neq j,
\end{aligned}$$

where x_i and y_i are the densities of prey species i and predator species i, respectively. The parameters have the following interpretation: r_i is the intrinsic rate of growth of prey species i; K_i is the carrying capacity of prey species i; a_i and ϵd_i correspond to the rates at which the predators encounter prey species; $\frac{b_i}{a_i}$ and $\frac{c_i}{d_i}$ correspond to prey handling times for predator species i; $\frac{e_i}{a_i}$, $\frac{f_i}{d_i}$ correspond to the conversion rate of prey numbers to predator numbers; and m_i is the per capita mortality rate of predator species i. $\epsilon = 0$ corresponds to the uncoupled system. The fact that this coupling is somewhat complex follows from the fact that the predators are handling both prey species when $\epsilon > 0$.

THEOREM 5.2. *Let $r_i, K_i, a_i, b_i, c_i, d_i, e_i, f_i$, and m_i be positive reals. There exists an $\tilde{\epsilon} > 0$ such that* (5.1) *is permanent for all* $0 \le \epsilon < \tilde{\epsilon}$ *if and only if* $K_i > \frac{m_i}{e_i - b_i m_i} > 0$ *for* $i = 1, 2$.

Proof. Consider the uncoupled system (i.e., $\epsilon = 0$ in (5.1)) that is given by

$$\begin{aligned}
&\frac{dx_i}{dt} = r_i x_i\left(1-\frac{x_i}{K_i}\right) - \frac{a_i x_i y_i}{1+b_i x_i},\\
&\frac{dy_i}{dt} = \frac{e_i x_i y_i}{1+b_i x_i} - m_i y_i, \qquad i = 1,2. \qquad (5.2)
\end{aligned}$$

The only boundary equilibria for the predator-prey subsystem $x_i - y_i$ of (5.2) are given by the origin $(x_i, y_i) = (0, 0)$ and $(x_i, y_i) = (K_i, 0)$. These equilibria satisfy the conditions of Corollary 4.1 if and only if $K_i > \frac{m_i}{e_i - b_i m_i} > 0$. Alternatively, if $K_i \le \frac{m_i}{e_i - b_i m_i}$ or $\frac{m_i}{e_i - b_i m_i} \le 0$ for some $i \in \{1, 2\}$, it can be shown [12, Lemma 3.2] that predator i is driven to extinction in the uncoupled system and (5.2) is not permanent. Hence (5.2) is C^1 robustly permanent if and only if $K_i > \frac{m_i}{e_i - b_i m_i} > 0$ for $i = 1, 2$.

To deduce that (5.1) is permanent for sufficiently small $\epsilon \ge 0$ when (5.2) is C^1 robustly permanent, we invoke Proposition 5.1. To this end, let $\alpha = \min\{\frac{a_1}{e_1}, \frac{a_2}{e_2}, \frac{d_1}{f_1}, \frac{d_2}{f_2}\}$ and $\beta = \min\{m_1, m_2\}$. Define $S : \mathbf{R}^4_+ \to \mathbf{R}$ by $S(x_1, y_1, x_2, y_2) = x_1 + \alpha y_1 + x_2 + \alpha y_2$. Our choice of α and β imply that any solution $(x_1(t), y_1(t), x_2(t), y_2(t))$ to (5.1) with $x_i(0) \ge 0$, $y_i(0) \ge 0$, and $\epsilon \ge 0$ satisfies

$$\begin{aligned}
&\frac{d}{dt}S(x_1(t), y_1(t), x_2(t), y_2(t)) + \beta S(x_1(t), y_1(t), x_2(t), y_2(t))\\
&\le r_1 x_1(t)\left(1-\frac{x_1(t)}{K_1}\right) + r_2 x_2(t)\left(1-\frac{x_2(t)}{K_2}\right) + \beta(x_1(t)+x_2(t)) \le C,
\end{aligned}$$

where $C = \frac{(r_1+\beta)^2 K_1}{4r_1} + \frac{(r_2+\beta)^2 K_2}{4r_2}$. It follows that

$$\limsup_{t\to\infty} S(x_1(t), y_1(t), x_2(t), y_2(t)) \le \frac{C}{\beta}.$$

Therefore, the maximal compact invariant set of (5.1) restricted to $\mathbf{R}^4_+$ for any $\epsilon \geq 0$ lies in the compact set

$$V_1 = \left\{ (x_1, y_1, x_2, y_2) \in \mathbf{R}^4_+ : S(x_1, x_2, x_3, x_4) \leq \frac{C}{\beta} \right\}.$$

Choosing any compact neighborhood V_2 of V_1, Proposition 5.1 implies that whenever (5.2) is C^1 robustly permanent, there exists a $\tilde{\epsilon} > 0$ such that (5.1) is permanent for all $0 \leq \epsilon \leq \tilde{\epsilon}$. □

CRITICAL THRESHOLD AND STABILITY OF CLUSTER SOLUTIONS FOR LARGE REACTION-DIFFUSION SYSTEMS IN R^1*

JUNCHENG WEI[†] AND MATTHIAS WINTER[‡]

Abstract. We study a large reaction-diffusion system which arises in the modeling of catalytic networks and describes the emerging of cluster states. We construct single cluster solutions on the real line and then establish their stability or instability in terms of the number N of components and the connection matrix. We provide a rigorous analysis around the single cluster solutions, which is new for systems of this kind. Our results show that for $N \leq 4$ the hypercycle system is linearly stable, while for $N \geq 5$ the hypercycle system is linearly unstable.

Key words. pattern formation, stability, cluster solutions, reaction-diffusion system, catalytic network, hypercycle

1. Introduction: The model.

In this paper, we continue our study [61] on the cluster solutions for large reaction-diffusion systems. A typical example is the hypercyclical reaction-diffusion system which arises as a spatial model concerning the origin of life similar to the one introduced by Eigen and Schuster [18], [19], [20], [21]. For more background on the concept of the hypercycle, see also [35], [36]. It arises in the modeling of catalytic networks in the case that a number of RNA-like polymers ("components") catalyze the replication of each other in a cyclic way. Examples in nature include the Krebs cycle for biosynthesis in the living cell and the Bethe–Weizsäcker cycle for high rate energy production in massive stars. Eigen and Schuster argue that the hypercycle satisfies important criteria of natural selection: (1) selective stability of each component due to favorable competition with error copies, (2) cooperative behavior of the components integrated into the hypercycle, and (3) favorable competition of the hypercycle unit with other less efficient systems.

We show rigorously that this may lead to compartmentation (i.e., the build-up of spatially small and essentially closed subsystems) due to spontaneous formation of clusters (also called "spots" or "spikes").

We first study a general system of $N + 1$ equations, where N may be any fixed positive integer representing the number of components. For this general system we first prove the existence of solutions with clusters which, for the different components, have the same location and different heights.

Then we study the stability question for some particularly important examples. At this point, we should like to emphasize that we provide a rigorous analysis around cluster solutions—not around *constant states.* We also establish a threshold size for the system such that smaller systems are stable and larger ones are unstable. This type of result is new for the kind of $(N + 1)$-systems under investigation.

Now we proceed to write down the reaction-diffusion system explicitly and define the biological terms in a mathematically rigorous way. As suggested in [8], [9] we study the following:

$$(1.1)\begin{cases} \frac{\partial X_i}{\partial t} = D_X \Delta X_i - g_X X_i + M \sum_{j=1}^N k_{ij} X_i X_j, \quad i = 1, 2, \dots, N, \quad x \in R, \\ \frac{\partial M}{\partial t} = D_M \Delta M + k_M - g_M M - LM \sum_{i,j=1}^N k_{ij} X_i X_j, \quad x \in R, \end{cases}$$

where N is the number of different polymer species, X_i denotes the concentration of the polymers, and M is the concentration of activated monomers. The replication of each polymer X_i is catalyzed by each X_j at a nonnegative rate constant k_{ij}. Linear (noncatalytic) growth terms are neglected. The activated monomers are produced at a constant rate k_M; g_X and g_M are decay rate constants. L is the number of monomers in each polymer, and D_X and D_M are constant diffusion coefficients.

A typical example of the matrix k_{ij} is a hypercyclical $N \times N$ matrix, namely

$$(1.2) \qquad (k_{ij}^{hyper}) = \begin{pmatrix} 0 & 0 & 0 & ... & k_0 \\ k_0 & 0 & 0 & ... & 0 \\ 0 & k_0 & 0 & ... & 0 \\ ... & ... & ... & ... & 0 \\ 0 & 0 & ... & k_0 & 0 \end{pmatrix}_{N \times N}, \quad k_0 > 0.$$

The system (1.1) with the matrix (k_{ij}^{hyper}) is called "elementary hypercycle" by Eigen and Schuster [21] as the polymers interact in pairs only. There are more complex hypercycles if the polymers interact in triples, quadruples, etc. However, more complex hypercycles are likely to be of less importance for an efficient start of evolution than elementary hypercycles since they are more difficult to form in the first place.

While Eigen and Schuster [21] use an assumption of constant organization, meaning that the total sum of all polymer concentrations is kept constant, in system (1.1) another mechanism for bounding the polymer concentrations is present: Since each polymer consists of L monomers, the polymer concentrations are bounded by the limited supply of activated monomers. This is a nonlocal coupling in contrast to the local coupling in the model of Eigen and Schuster.

We pose the problem in one-dimensional space, which, on the one hand, allows a rigorous analysis and, on the other hand, is relevant if the early biochemical reactions take place in very thin lines, like, for example, on the edges of rocks.

A cluster may loosely be defined as a region of high concentrations X_i of the polymers and low concentration M of the monomer, as monomers are consumed by the replication of polymers. A rigorous definition of a cluster is given by the solution in the existence theorem (Theorem 2.1).

In this paper, we study the existence and stability of a single-cluster solution in R^1. Let us first reduce the system (1.1) to standard form. Dividing by g_X and g_M, respectively, gives

$$\frac{1}{g_X} \partial_t X_i = \frac{D_X}{g_X} \Delta X_i - X_i + \frac{M}{g_X} \sum_{j=1}^N k_{ij} X_i X_j,$$

$$\frac{1}{g_M} \partial_t M = \frac{D_M}{g_M} \Delta M + \frac{k_M}{g_M} - M - \frac{LM}{g_M} \sum_{ji,=1}^N k_{ij} X_i X_j.$$

Rescaling $M = (k_M/g_M)\hat{M}$, $X_i = \sqrt{g_M/L}\hat{X}_i$, we get

$$\frac{1}{g_X}\partial_t \hat{X}_i = \frac{D_X}{g_X}\Delta \hat{X}_i - \hat{X}_i + \frac{1}{g_X}\frac{k_M}{g_M}\hat{M}\sqrt{\frac{g_M}{L}}\sum_{j=1}^N k_{ij}\hat{X}_i\hat{X}_j,$$

$$\frac{1}{g_M}\partial_t \hat{M} = \frac{D_M}{g_M}\Delta \hat{M} + 1 - \hat{M} - \hat{M}\sum_{i,j=1}^N k_{ij}\hat{X}_i\hat{X}_j.$$

Rescaling space variables x and time variable t:

$$x = \sqrt{\frac{D_M}{g_M}}\hat{x}, \quad t = \frac{1}{g_X}\hat{t},$$

renaming constants:

$$A = \frac{k_M}{g_X g_M}\sqrt{\frac{g_M}{L}}, \quad \epsilon^2 = \frac{D_X}{D_M}\frac{g_M}{g_X}, \quad \tau = \frac{g_X}{g_M},$$

and dropping the hats, we finally arrive at the following standard form:

$$\left\{ \begin{array}{c} \partial_t X_i = \epsilon^2 \Delta X_i - X_i + AM\sum_{j=1}^N k_{ij}X_iX_j, \\ \tau\partial_t M = \Delta M + 1 - M - M\sum_{i,j=1}^N k_{ij}X_iX_j. \end{array} \right. \tag{1.3}$$

We shall study (1.3) on the real line R for $\epsilon > 0$ small. Different choices of A and τ might distinguish between stability and instability. Therefore, we will treat them as parameters. We look for solutions of (1.3) which are even:

$$X_i = X_i(|x|) \in H^1(R), \quad i = 1, \dots, N,$$

$$1 - M = 1 - M(|x|) \in H^1(R).$$

The stationary equation corresponding to (1.3) becomes

$$\left\{ \begin{array}{c} \epsilon^2 \Delta X_i - X_i + AM\sum_{j=1}^N k_{ij}X_iX_j = 0, \quad i = 1, \dots, N, \\ \Delta M + 1 - M - M\sum_{i,j=1}^N k_{ij}X_iX_j = 0, \\ X_i(|x|) > 0, \, 0 < M(|x|) < 1, \quad x \in R. \end{array} \right. \tag{1.4}$$

From now on, we shall concentrate on (1.3) and (1.4).

2. Main results: Existence and stability. Now we state our main results of this paper. First we construct cluster solutions to (1.4). To this end, we need to introduce some assumptions and notation.

Let w be the unique solution [26], [31] of the following problem:

$$\left\{ \begin{array}{l} \Delta w - w + w^2 = 0, \quad w > 0 \text{ in } R, \\ w(0) = \max_{y\in R} w(y), \quad w(y) \to 0 \text{ as } |y| \to +\infty. \end{array} \right. \tag{2.1}$$

Since (2.1) is an ODE, we can write w explicitly:

$$w(y) = \frac{3}{2\cosh^2 \frac{y}{2}}. \tag{2.2}$$

Now we state the existence result. In fact, this is quite easy. We search for solutions of the following type:

$$X_i = \xi_i X_0, \quad \xi_i > 0, \quad i = 1, \ldots, N, \tag{2.3}$$

where ξ_i are positive constants which satisfy

$$\sum_{j=1}^{N} k_{ij}\xi_j = 1, \quad i = 1, \ldots, N. \tag{2.4}$$

Our first assumption is that

(H1) there exists a unique solution $(\xi_1, \ldots, \xi_N)$ of (2.4).

Suppose (H1) holds true. Substituting (2.3) into (1.4), we see that (X_0, M) must satisfy

$$\begin{cases} \epsilon^2 \Delta X_0 - X_0 + AMX_0^2 = 0 \text{ in } R, \\ \Delta M + 1 - M - M(\sum_{i=1}^{N} \xi_i) X_0^2 = 0 \text{ in } R. \end{cases} \tag{2.5}$$

In the case in which $N = 1$, (2.5) becomes the standard Gray–Scott model [23], [24], [58]. The existence of single-pulse solutions for the Gray–Scott model in one dimension has been studied in [14] and in two dimensions in [58].

Following the same proof as in Theorem 2.1 of [58], we define

$$L = L(A, \epsilon) := \frac{1}{2A^2 \sum_{i=1}^{N} \xi_i} \epsilon \int_R (w(y))^2 dy. \tag{2.6}$$

If $0 < L < \frac{1}{4}$, then the following equation has two solutions:

$$\eta(1 - \eta) = L. \tag{2.7}$$

We denote the smaller one by η^s, where $0 < \eta^s < \frac{1}{2}$, and the larger one by η^l, where $1 > \eta^l > \frac{1}{2}$.

Now we have the following theorem.

Theorem 2.1. *Suppose that* (H1) *holds.*

Assume that

$$\epsilon << 1 \tag{2.8}$$

and

$$\epsilon << L < \frac{1}{4} - \delta_0; \tag{2.9}$$

more precisely, for $L = L(A, \epsilon)$ there are positive numbers δ_0, δ_1, and ϵ_0 such that, for all ϵ and A with $0 < \epsilon < \epsilon_0$, we have $L < \frac{1}{4} - \delta_0$ and $\epsilon / L(A, \epsilon) < \delta_1$.

Then (1.4) *admits two "single-cluster" solutions $(X_\epsilon^s, M_\epsilon^s) = (X_{\epsilon,1}^s, \ldots, X_{\epsilon,N}^s, M_\epsilon^s)$ and $(X_\epsilon^l, M_\epsilon^l) = (X_{\epsilon,1}^l \ldots, X_{\epsilon,N}^l, M_\epsilon^l)$ with the following properties:*

(1) *All components are even functions.*

(2) $X_{\epsilon,i}^s = \frac{\xi_i}{AM_\epsilon^s(0)}(1 + o(1)) w(\frac{|x|}{\epsilon})$, $X_{\epsilon,i}^l = \frac{\xi_i}{AM_\epsilon^l(0)}(1 + o(1)) w(\frac{|x|}{\epsilon})$, $i = 1, \ldots, N$, *where w is the unique solution of* (2.1).

(3) *$M_\epsilon^s(x) \to 1$ $M_\epsilon^l(x) \to 1$ for all $x \neq 0$ and $M_\epsilon^s(0)$, $M_\epsilon^l(0)$ satisfy*

$$\begin{gathered} M_\epsilon^s(0) \sim \eta^s, \quad M_\epsilon^l(0) \sim \eta^l, \\ 0 < M_\epsilon^s(0) < M_\epsilon^l(0) < 1. \end{gathered} \tag{2.10}$$

(4) *There exist $a > 0, b > 0$ such that*

$$\begin{gathered} 0 < 1 - M_\epsilon^s(x) \le Ce^{-a|x|}, \quad 0 < 1 - M_\epsilon^l(x) \le Ce^{-a|x|}, \\ 0 < X_{\epsilon,i}^s(x) \le C(AM_\epsilon^s(0))^{-1} e^{-b\frac{|x|}{\epsilon}}, \quad 0 < X_{\epsilon,i}^l(x) \le C(AM_\epsilon^l(0))^{-1} e^{-b\frac{|x|}{\epsilon}}. \end{gathered} \tag{2.11}$$

Finally, if ϵ is small enough and $L > \frac{1}{4} + \delta_0$ (in the same sense as in (2.9)), then there are no single-cluster solutions.

The proof of Theorem 2.1 is exactly the same as the proof of Theorem 2.1 of [58] or Theorem 1.1 of [61]. We omit the details here.

The main goal of this paper is to study the stability and instability of the cluster solution constructed in Theorem 2.1. To this end, we first linearize (1.3) around $(X_\epsilon^s, M_\epsilon^s)$ or $(X_\epsilon^l, M_\epsilon^l)$, respectively. From now on, we omit the superscripts s or l where this is possible without confusing the reader. The linearized operator is as follows:

$$\mathcal{L}_\epsilon \begin{pmatrix} \phi_{\epsilon,i} \\ \\ \psi_\epsilon \end{pmatrix} = \begin{pmatrix} \epsilon^2 \Delta\phi_{\epsilon,i} - \phi_{\epsilon,i} + AM_\epsilon \sum_{j=1}^N k_{ij}(\phi_{\epsilon,j} X_{\epsilon,i} + X_{\epsilon,j}\phi_{\epsilon,i}) \\ +A\psi_\epsilon \sum_{j=1}^N k_{ij} X_{\epsilon,i} X_{\epsilon,j}, \\ \Delta\psi_\epsilon - \psi_\epsilon - \psi_\epsilon \sum_{i,j=1}^N k_{ij} X_{\epsilon,i} X_{\epsilon,j} \\ -M_\epsilon \sum_{i,j=1}^N k_{ij}(\phi_{\epsilon,j} X_{\epsilon,i} + \phi_{\epsilon,i} X_{\epsilon,j}) \end{pmatrix}, \tag{2.12}$$

where $i = 1, \ldots, N$. The eigenvalue problem becomes

$$\mathcal{L}_\epsilon \begin{pmatrix} \phi_{\epsilon,i} \\ \psi_\epsilon \end{pmatrix} = \begin{pmatrix} \lambda_\epsilon \phi_{\epsilon,i} \\ \tau\lambda_\epsilon \psi_\epsilon \end{pmatrix}, \quad i = 1, \ldots, N. \tag{2.13}$$

We assume that the domain of $\mathcal{L}_\epsilon$ is $(H^2(R))^N$ and $\lambda_\epsilon \in \mathcal{C}$ is the set of complex numbers.

Certainly 0 is an eigenvalue of $\mathcal{L}_\epsilon$. We say that a cluster solution is *linearly stable* if the spectrum $\sigma(\mathcal{L}_\epsilon)$ of $\mathcal{L}_\epsilon$ (except for 0) lies in a left half-plane $\{\lambda \in \mathcal{C} : \text{ Re }(\lambda) < -c_0\}$, where $c_0 > 0$, and that 0 is a simple eigenvalue. A cluster solution is called *linearly unstable* if there exists an eigenvalue λ_ϵ of $\mathcal{L}_\epsilon$ with Re $(\lambda_\epsilon) > 0$. (From now on, we use the terms linearly stable and linearly unstable as defined above.)

Before we state our results on the stability, we introduce two more assumptions on the connection matrix (k_{ij}).

The second assumption is the following:

$$\sum_{i=1}^N k_{ij}\xi_i = 1, \quad j = 1, \ldots, N, \tag{H2}$$

where ξ_j is given (2.4).

Note that assumption (H2) imposes a certain symmetry on the connection matrix (k_{ij}).

The last assumption concerns the following eigenvalue problem:

$$\begin{cases} \Delta\phi - \phi + \mu w\phi = 0, \\ \phi \in H^1(R). \end{cases} \tag{EVP}$$

By Lemma 4.1 of [51], (EVP) admits the following set of eigenvalues:

$$\mu_1 = 1,\ \mu_2 = 2,\ 2 < \mu_3 \leq \mu_4 \leq \cdots . \tag{2.14}$$

(In fact, we have the following explicit values of μ_n (see Appendix A):

$$\mu_n = \frac{(1+n)(2+n)}{6}, \quad n = 1, 2, 3, \dots, .\Big) \tag{2.15}$$

Put

$$\mathcal{B} = (b_{ij}), \quad \text{where } b_{ij} = (\xi_i k_{ij}). \tag{2.16}$$

Observe that by (2.4) and (H1) the matrix $\mathcal{B}$ has an eigenvalue 1, and the associated eigenvector is $\xi = (\xi_1, \xi_2, \dots, \xi_N)^\tau$; i.e., we have $\mathcal{B}\xi = \xi$.

We take the Jordan decomposition of $\mathcal{B}$,

$$\mathcal{B} = \mathcal{P}\mathcal{D}\mathcal{P}^{-1}, \tag{2.17}$$

where $\mathcal{P}$ is an invertible matrix and $\mathcal{D}$ is the Jordan form. Namely, we have

$$b_{ij} = \sum_{k,l=1}^{N} p_{ik} d_{kl} p_{lj}^{-1},$$

where d_{kl} has Jordan form (i.e., it is composed of Jordan blocks

$$\begin{pmatrix} \sigma_k & 1 & 0 & \cdots & 0 \\ 0 & \sigma_k & 1 & \cdots & 0 \\ 0 & 0 & \sigma_k & \cdots & \vdots \\ \vdots & \vdots & \vdots & \vdots & 1 \\ 0 & 0 & 0 & \cdots & \sigma_k \end{pmatrix}$$

with eigenvalues $\sigma_k \in \mathcal{C}$) and $\sum_{k=1}^{N} p_{ik} p_{kj} = \delta_{ij}$.

We now assume that

$$\begin{cases} [1 + \operatorname{spec}(\mathcal{B})] \cap \operatorname{spec}(\mathrm{EVP}) = \{2\}, \\ \ \ 1 \text{ is a simple eigenvalue of } \mathcal{B}. \end{cases} \tag{H3}$$

Assumption (H3) means the following: Let us denote the eigenvalues of $\mathcal{B}$ by

$$\sigma_1 = 1, \sigma_2, \dots, \sigma_N, \tag{2.18}$$

where σ_j may be complex. Then assumption (H3) is equivalent to

$$\sigma_j \neq \frac{(1+n)(2+n)}{6} - 1 \quad \text{for } j \geq 2, n = 1, 2, \dots . \tag{2.19}$$

Since $\xi = (\xi_1, \dots, \xi_N)^\tau$ is an eigenvector of $\mathcal{B}$ with eigenvalue 1, by assumption (H3) we may assume that

$$\mathcal{P} = (\mathbf{p}_1, \dots, \mathbf{p}_N), \quad \mathbf{p}_1 = \frac{1}{\|\xi\|}\xi, \quad \|\xi\| = \sqrt{\sum_{i=1}^{N} \xi_i^2}. \tag{2.20}$$

The following is our main result on stability.

THEOREM 2.2. *Suppose that the matrix* (k_{ij}) *satisfies* (H1), (H2), *and* (H3).

Assume that

$$\epsilon << 1, \quad \epsilon << L < \frac{1}{4} - \delta_0, \tag{2.21}$$

in the same sense as in (2.9).

Let $(X^s_\epsilon, M^s_\epsilon)$ *and* $(X^l_\epsilon, X^l_\epsilon)$ *be the solutions constructed in Theorem* 2.1.

Let $\sigma = \sigma_R + i\sigma_I$ *be an eigenvalue of* $\mathcal{B}$*, and let*

$$f(\sigma) := (12\sigma_R + 5)^2(3\sigma_R^2 + 2\sigma_R) - 3\sigma_I^2. \tag{2.22}$$

Then we have the following:

(1) *(Stability) Suppose that* $0 \leq \tau < \tau_0$*, where* $\tau_0 > 0$ *may be chosen independent of* ϵ*. Assume that for all eigenvalues* σ *of* $\mathcal{B}$ *with* $\sigma \neq 1$ *and* $\sigma_R > 0$*, we have* $f(\sigma) < 0$*. Then* $(X^s_\epsilon, M^s_\epsilon)$ *is linearly stable.*

(2) *(Instability) Assume that there exists an eigenvalue* σ *of* $\mathcal{B}$ *with* $\sigma \neq 1$ *and* $\sigma_R > 0$ *such that* $f(\sigma) > 0$*. Then* $(X^s_\epsilon, M^s_\epsilon)$ *is linearly unstable for all* $\tau > 0$.

(3) *(Instability)* $(X^l_\epsilon, M^l_\epsilon)$ *is linearly unstable for all* $\tau > 0$.

Theorem 2.2 applies to many matrices. In section 4, we shall apply Theorem 2.2 to some specific examples which include the N-hypercycle case, $(k_{ij}) = (k_{ij}^{hyper})$, where (k_{ij}^{hyper}) is given by (1.2). In this case, we have the following theorem.

THEOREM 2.3. *Consider the hypercycle case, i.e., let* (k_{ij}) *be given in* (1.2).

Assume that (2.21) *holds. Let* $(X^s_\epsilon, M^s_\epsilon)$ *and* $(X^l_\epsilon, X^l_\epsilon)$ *be the solutions constructed in Theorem* 2.1.

Then we have the following:

(1) *(Stability) Assume that* $N \leq 4$ *and* $0 < \tau < \tau_0$ *for some small* $\tau_0 > 0$ *which is independent of* ϵ*. Then* $(X^s_\epsilon, M^s_\epsilon)$ *is linearly stable.*

(2) *(Instability) Assume that* $N > 4$*. Then* $(X^s_\epsilon, M^s_\epsilon)$ *is linearly unstable for all* $\tau > 0$.

(3) *(Instability)* $(X^l_\epsilon, M^l_\epsilon)$ *is linearly unstable for all* $\tau > 0$.

The proof of Theorem 2.3 is based on Theorem 2.2 and will be given in section 4.

Some remarks on the stability results—Theorems 2.2 and 2.3—are in order.

Remarks.

(1) For existence (Theorem 2.1), only assumption (H1) is needed. For the stability results (Theorem 2.2), we need all three assumptions (H1)–(H3). Conditions (H2) and (H3) are needed in the reduction process (section 6, Lemma 6.4) and in the study of the vectorial nonlocal eigenvalue problem (NLEP) (section 7). These conditions enable us to *decouple* the system. It is an interesting open problem to study the case when assumptions (H2) and (H3) are dropped.

Note also that it is allowed that $\xi_i \neq \xi_j$ for $i \neq j$. So we may have clusters with *different heights.*

(2) In (1) of Theorem 2.2, we have assumed that τ is small. In the case in which τ is large, we can show that the stability of $(X^s_\epsilon, M^s_\epsilon)$ can be reduced to the study of an algebraic equation (section 5). More precisely, one can use hypergeometric functions and generalized hypergeometric functions to reduce the stability of the NLEP given in (5.2) to the algebraic equation which is given in Lemma 5.4 and derived in Appendix B.

(3) The threshold of stability at $N = 4$ for the hypercycle system (Theorem 2.3) has far-reaching consequences for biological applications. It implies that the underlying biological system can be stable only if it does not have too many constituents. This shows that prebiotic evolution might fail if the system becomes too large.

This is qualitatively the same result as has been established by the authors in the two-dimensional system. However, in two dimensions we were not able to establish the exact threshold [61].

Knowing the exact threshold size for stability is also important in verifying the validity of our model by experiments: Now the question can be studied of whether the thresholds given by theory and the one determined by experiments are the same. Furthermore, the agreement between theoretical values and numerically calculated ones for related models plays an important role in deciding which model to choose. (We refer to the works quoted at the end of the introduction for related numerical investigations, in particular in [7], where, among others, multicluster states in one space dimension have been computed numerically.)

Our critical threshold is in correspondence with the result of Eigen and Schuster [21] that the *constant* nontrivial steady state for the hypercycle is stable if and only if $N \leq 4$.

To see quickly how the magic number 4 comes into play, we have to study an eigenvalue problem with complex coefficients:

$$\Delta\phi - \phi + (1 + e^{\sqrt{-1}\theta})w\phi = \lambda\phi, \quad \phi \in H^2(R), \tag{2.23}$$

where $\theta = \frac{2\pi}{N}$. By using hypergeometric functions, we show (in section 5) that problem (2.23) is stable if and only if $\theta > \theta^h \sim \arccos(0.0455)$. Substituting the expression for $\theta = \frac{2\pi}{N}$, we see that $N \leq 4$.

Let us conclude this section by mentioning some related results.

In [8] the parameter dependence of the stability of clusters and spirals against parasites (i.e., rival polymers which receive catalytic support from the hypercycle but do not contribute to the catalysis of any other polymer) is studied numerically. Mathematically speaking, the occurrence of a parasite means that there exists $i_0 \in \{1, 2, \ldots, N\}$ such that $k_{i_0,j} > 0$ for some $j \neq i_0$ but $k_{j,i_0} = 0$ for all j. A parasite may or may not destroy the hypercycle depending on the rate constants. In [9] clusters (for $N = 5$) are established numerically for the elementary N-hypercycle system in two space dimensions.

It is known numerically [8], [9] that parasites may destroy stable cluster states. Our results complement the picture by the rigorously proved fact that even pure cluster states may turn unstable if they become too large. This implies that the hypercycle, although it has some very preferable properties (see the beginning of the introduction), it has an inherent instability behavior which may act as an obstruction to the evolution of large biological systems.

In [7], for a closely related reaction-diffusion model in one and two space dimensions, the dependence of various properties of cluster states on diffusivities is shown numerically, including the cluster size, their shape, and the distance between different clusters.

The effect of faulty replication on the hypercycle has been studied by an analysis of the geometry of bifurcations around steady states and numerical computations in the framework of an ODE reaction model [1].

For a cellular automata model it was shown numerically that a spiral wave structure may be stable against parasites [5]. The chaotic dynamics for this type of model has been investigated numerically in [34], [46].

There are many recent results on the Gray–Scott model which we would like to recall here. In [14], by using the Mel'nikov method, Doelman, Kaper, and Zegeling constructed single- and multiple-pulse solutions for (1.1) in the one-dimensional case with $D_M = 1, D_X = \delta^2 << 1$, where $X_i = X$. In their paper [14], it is assumed that $k_M = g_M = \delta^2, g_X = \delta^{2\alpha/3}$, $k_{11} = 1$, $L = 1$, where $\alpha \in [0, \frac{3}{2})$. In this case, they showed that $M = O(\delta^\alpha), X = O(\delta^{-\frac{\alpha}{3}})$. Later the stability of single- and multiple-pulse solutions in one dimension are obtained in [12], [13]. (The techniques are extended to other reaction-diffusion equations in [15].) We note that, in their scaling, $\tau = \delta^{\frac{2\alpha}{3}-2}$. Their scaling is chosen in order to obtain $X = O(1), M = O(1)$. Since they choose two scaling parameters accordingly, they can achieve their goal. In our standard formulation of the system (1.3), we have only the scaling parameter A so that we cannot obtain $X = O(1), M = O(1)$. On the other hand, the homoclinic solution in their scaling corresponds exactly to our cluster solution in (1.3), which is given in Theorem 1.1. For the stability results it is important to notice that the results of the system for the general N case are much more complicated than for $N = 1$. The main reason is that the behavior for the N-system cannot be reduced to the case $N = 1$ in contrast to the existence issue, and therefore a new analysis is needed.

Some related results on the existence and stability of solutions to the Gray–Scott model in one dimension can be found in [16], [29], [30], [42], [43], [47], and [48].

In R^2 and R^3, Muratov and Osipov [37] have given some formal asymptotic analysis on the construction and stability of spiky solution. In [57], the system (1.1) for $N = 1$ is studied on the real axis in the shadow system case, namely, $D_M >> 1, D_X << 1$, and $k_M = g_M = O(1), g_X = O(1)$, $k_{11} = 1$, $L = 1$. The shadow system can be reduced to a single equation. For spike solutions for single equations as well as other systems, please see [3], [4], [11], [22], [25], [27], [28], [32], [33], [38], [39], [40], [41], [44], [45], [50], [51], [52], [53], [54], [55], [56], [59], [60], and the references therein.

In the two-dimensional case, rigorous existence and stability results on the Gray–Scott system have been established in [58]. The existence of one-spike solutions is proved. Their stability is established and rests upon the derivation and analysis of a related NLEP.

3. Outline of the proof of Theorem 2.2.

We outline the proof of Theorem 2.2, which is our main theorem. It is divided into four steps. We need to analyze the eigenvalue problem (2.12). We consider two cases: small eigenvalues ($\lambda_\epsilon = o(1)$) and large eigenvalues ($|\lambda_\epsilon| \geq C > 0$ for some positive constant $C > 0$).

Step 1 (small eigenvalue case). We show that in the small eigenvalue case, λ_ϵ must be zero, and the corresponding eigenfunction must be translations of (X_ϵ, M_ϵ). This is done in Theorem 6.1 (1).

Step 2 (large eigenvalue case). We show that in the large eigenvalue case, (2.12) can be reduced to a vectorial NLEP. This is done in Theorem 6.1 (2) and (3).

Step 3 (study of the vectorial NLEP). We show, under the assumptions (H2) and (H3), that the study of the vectorial NLEP can be decoupled to the study of two eigenvalue problems—one is a scalar eigenvalue problem but with complex coefficients, and the other one is a scalar NLEP. This is done in section 7.

Step 4 (study of two eigenvalue problems). We study the two reduced eigenvalue problems in section 5. This analysis provides the key estimates in this paper.

The structure of the paper is as follows.

In section 4, we consider the applications of Theorem 2.2. In particular, we consider several interesting matrices (k_{ij}), including the hypercycle matrix and symmetric matrices.

In section 5, we study some scalar local and nonlocal eigenvalue problems associated with w.

In section 6, we separate the eigenvalue problem into two cases: small eigenvalues and large eigenvalues. The case of large eigenvalues is then linked to a vectorial NLEP given in (6.9).

In section 7, we reduce the vectorial NLEP given in (6.9) to a local eigenvalue problem with complex coefficients given in (5.1) and a scalar NLEP given in (5.2).

Throughout this paper, the letter C will always denote various generic constants which are independent of ϵ for ϵ sufficiently small. The notation $A \sim B$ means that $\lim_{\epsilon \to 0} \frac{A}{B} = 1$, and $A = O(B)$ is defined as $|A| \leq C|B|$ for some $C > 0$.

4. Effect of the connection matrix (k_{ij}).

In this section, we apply the stability results of Theorem 2.2 to some specific examples. We would like to point out that there are many matrices which satisfy assumptions (H1)–(H3) in Theorem 2.2.

Example 1 (proof of Theorem 2.3). For the hypercyclical network, we have

$$\xi_1 = \cdots = \xi_N = \frac{1}{k_0},$$

$$b_{ij}^{hyper} = \delta_{i,j+1} \quad \text{modulo } N.$$

The eigenvalues are $\sigma = e^{2\pi j\sqrt{-1}/N}$, $j = 1, \ldots, N$, and they are all simple. In this case, it is easy to see that (H1)—(H3) are satisfied. By Theorem 2.2, we just need to find the zeroes of the following function:

$$f(\sigma) := (12\sigma_R + 5)^2(3\sigma_R^2 + 2\sigma_R) - 3\sigma_I^2, \quad \sigma_R^2 + \sigma_I^2 = 1, \quad 0 < \sigma_R < 1. \tag{4.1}$$

It is easy to check that the solution to (4.1) is

$$\sigma_R^0 = 0.0455\ldots.$$

Note that $\cos(\frac{2\pi}{5}) > \sigma_R^0$.

By Theorem 2.2 (1), we obtain the stability of the small cluster solution for $N = 1, 2, 3, 4$. By Theorem 2.2 (2), we obtain the instability of small solutions for $N \geq 5$.

We conclude that the critical threshold size for the hypercycle system is 4. When the system size exceeds 4, then a parasite appears: there is an eigenvector $c = (c_1, \ldots, c_N)^\tau$ of (k_{ij}) such that $\sum_{j=1}^N c_j X_j$ vanishes quickly.

Example 2. We consider the case when the connection matrix (k_{ij}) is symmetric, i.e.,

$$k_{ij} = k_{ji}.$$

In this case, it is easy to see that the matrix $\mathcal{B} = (k_{ij}\xi_i)$ has only real eigenvalues. Let the eigenvalues of $\mathcal{B}$ be

$$\sigma_1 = 1, \sigma_2, \ldots, \sigma_N.$$

The first eigenvalue $\sigma_1 = 1$ is guaranteed by (2.4).

Assumption (H2) is satisfied if we further assume that $\xi_1 = \cdots = \xi_N$.

Assumption (H3) says that

$$\sigma_j \neq \frac{(1+k)(2+k)}{6} - 1, \quad j = 2, \ldots, N, \quad k = 1, 2, \ldots. \tag{4.2}$$

Since $f(\sigma) > 0$ if $\sigma = \sigma_R > 0$, Theorem 2.2 shows that $(X_\epsilon^s, M_\epsilon^s)$ is linearly stable if

$$\sigma_j < 0, \quad j = 2, \ldots, N. \tag{4.3}$$

On the other hand, if there exists $\sigma_j > 0$ for some $j \geq 2$, we have instability. (Assumption (H3) implies that $\sigma_j \neq 0$.)

Example 3. For the (cyclical) bidiagonal matrix

$$(k_{ij}) = k_0 \begin{pmatrix} 1-\alpha & \alpha & 0 & \ldots & 0 \\ 0 & 1-\alpha & \alpha & \ldots & 0 \\ 0 & 0 & 1-\alpha & \ldots & 0 \\ \ldots & \ldots & \ldots & \ldots & \alpha \\ \alpha & 0 & \ldots & 0 & 1-\alpha \end{pmatrix}_{N \times N}, \quad k_0 > 0,$$

with $0 \leq \alpha < 1$, it is easy to see that conditions (H1)–(H3) are satisfied. In this case, $\xi_1 = \cdots = \xi_N = \frac{1}{k_0}$. The eigenvalues are computed as $\sigma = 1 - \alpha(1 - e^{2\pi j\sqrt{-1}/N})$, $j = 1, \ldots, N$, and are all simple.

We substitute σ into the polynomial and compute the critical threshold $N_{critical}$. It turns out that $N_{critical}$ depends on the value of α: $N_{critical}$ will increase of the order α as α increases. The following is a table of $N_{critical}$ for small α:

α	$N_{critical}$
0.5	3
1	4
1.5	5
2	6

From all of the previous examples, we see as a general trend that, if the system is not dominated too much by diagonal terms, we have stability. Otherwise, a parasite emerges. This means that cooperative behavior and not self-enhancement is needed to stabilize the cluster.

We point to the last example, where the stability is especially strong if the parameter α gets large. In the case in which $\alpha > 1$ (which means that the diagonal becomes negative and the off-diagonal elements are positive and bigger than the diagonal), this describes self-inhibition coupled with cooperative enhancement and leads to particularly good stability.

5. Two eigenvalue problems. In this section, we study two eigenvalue problems. The first is a local eigenvalue problem with complex coefficients

$$\begin{cases} \Delta\phi - \phi + w\phi + \sigma w\phi = \lambda\phi, \\ \sigma = \sigma_R + i\sigma_I = |\sigma|e^{i\theta}, |\sigma| > 0, \quad \theta \in (-\pi, \pi], \quad \phi \in H^1(R), \end{cases} \tag{5.1}$$

where w is defined by (2.1).

The second is a scalar NLEP

$$\Delta\phi - \phi + 2w\phi - \frac{2(1-\eta)}{\eta\sqrt{1+\tau\lambda} + 1 - \eta} \frac{\int_R w\phi}{\int_R w^2} w^2 = \lambda\phi, \quad \phi \in H^2(R), \tag{5.2}$$

where

$$0<\eta<1,\ \tau\geq 0,\ \lambda\in\mathcal{C},\ \lambda=\lambda_R+i\lambda_I,\ \lambda_R\geq 0,$$

and we take the principal branch for $\sqrt{1+\tau\lambda}$.

The analysis presented in this section provides the key estimates for this paper.

To study (5.1) and (5.2), we first collect some important properties associated with the function w.

LEMMA 5.1. (1) *The linear operator*

$$\begin{cases} L_0\phi := \Delta\phi-\phi+2w\phi, \\ \qquad \phi\in H^1(R), \end{cases}$$

has the kernel

$$\text{Ker }(L_0)=\text{span }\left\{w^{'}(y)\right\}.$$

(2) *The eigenvalue problem*

$$(EVP) \qquad \begin{cases} \Delta\phi-\phi+\mu w\phi=0, \\ \qquad \phi\in H^1(R), \end{cases}$$

admits the following set of eigenvalues:

$$\mu_1=1,\ v_1=\text{span }\{w\},$$

$$\mu_2=2,\ v_2=\text{Ker }(L_0),$$

$$\mu_n=\frac{(1+n)(2+n)}{6}>2 \textit{ for } n\geq 3.$$

(3) *If $\mu_R>0$, then the eigenvalue problem*

$$\begin{cases} \Delta\phi-\phi+w\phi+\mu_R w\phi=\lambda\phi, \\ \qquad \mu_R>0,\ \phi\in H^1(R), \end{cases}$$

admits a positive (principal) eigenvalue λ_1 such that

$$-\lambda_1=\inf_{\phi\in H^1(R)\setminus\{0\}}\frac{\int_R(\phi')^2+\phi^2-(1+\mu_R)w\phi^2}{\int_R\phi^2}<0.$$

Moreover, when $\mu_R=1$, there is only one positive eigenvalue (which is the principal one).

(4) *Let ϕ (complex-valued) satisfy the following eigenvalue problem:*

$$\begin{cases} \Delta\phi-\phi+w\phi+\sigma w\phi=\lambda\phi, \\ \text{Re }(\sigma)\leq 0, \quad \phi\in H^1(R), \quad \lambda\neq 0. \end{cases}$$

Then

$$\text{Re }(\lambda)\leq -c_0<0.$$

Proof. The proof will be given in Appendix A. The proof of (2) follows the method of Lemma 5.2. Some of the results have been proved in previous work. For the convenience of the reader we recall the proofs of (3) and (4). □

We are ready to study the first eigenvalue problem (5.1). By symmetry, we may assume that $\theta \in [0, \frac{\pi}{2}]$. We consider θ as a parameter. By Lemma 5.1 (3) and a perturbation argument, for $|\theta|$ near 0, there is an unstable eigenvalue λ for (5.1), i.e., $\lambda = \lambda_R + i\lambda_I$, where $\lambda_R > 0$. On the other hand, by Lemma 5.1 (4), for $|\theta| \geq \frac{\pi}{2}$, (5.1) has only stable eigenvalues, i.e., $\lambda = \lambda_R + i\lambda_I$, where $\lambda_R < 0$. Now, if we vary θ, then there must be a point $\theta^h \in (0, \frac{\pi}{2})$ such that, for $\theta = \theta^h$, (5.1) has a Hopf bifurcation, i.e., there is an eigenvalue $\lambda = \sqrt{-1}\lambda_I$. Let us now compute θ^h. It turns out that, unlike in the two-dimensional case [61], we can now obtain the exact value for θ^h in one domension.

LEMMA 5.2. *Let ϕ (complex-valued) satisfy the eigenvalue problem* (5.1) *with $\sigma = \sigma_R + \sqrt{-1}\sigma_I, \sigma_R > 0$. Then the following hold.*

(1) *If $f(\sigma) < 0$, then* (5.1) *is stable.*

(2) *If $f(\sigma) > 0$, then* (5.1) *is unstable.*

(3) *If $f(\sigma) = 0$, then there exists an eigenvalue λ with $\lambda = \sqrt{-1}\lambda_I$.*

Here $f(\sigma) := (12\sigma_R + 5)^2(3\sigma_R^2 + 2\sigma_R) - 3\sigma_I^2$.

Proof. We are looking for a Hopf bifurcation for (5.1). Therefore, we have to solve

$$\Delta\phi - \phi + (1 + \sigma)w\phi = \lambda\phi \tag{5.3}$$

with

$$\lambda = \sqrt{-1}\lambda_I$$

(i.e., the real part λ_R of λ vanishes) and

$$\sigma = \sigma_R + i\sigma_I.$$

As in [12], let

$$\gamma = \sqrt{1 + \lambda}, \quad \mu = 1 + \sigma, \quad \phi = w^\gamma F.$$

Then F satisfies

$$F^{''} + 2\gamma\frac{w^{'}}{w}F^{'} + \left(\mu - \left(\gamma + \frac{2}{3}\gamma(\gamma - 1)\right)\right) w^{p-1}F = 0. \tag{5.4}$$

Next we introduce the following new variable:

$$z = \frac{1}{2}\left(1 - \frac{w^{'}}{w}\right). \tag{5.5}$$

Then

$$\frac{w^{'}}{w} = 1 - 2z, \quad w = 6z(1 - z), \quad \frac{dz}{dx} = z(1 - z).$$

This yields the following equation for F as a function of z:

$$z(1 - z)F^{''} + (c - (a + b + 1)z)F^{'} - abF = 0, \tag{5.6}$$

where

$$a+b+1=2+4\gamma, \quad ab=2(2\gamma(\gamma-1)-3(\mu-\gamma)), \quad c=1+2\gamma. \tag{5.7}$$

The solutions to (5.6) are standard hypergeometric functions. See [49] for more details. Now there are two solutions to (5.6):

$$F(a,b;c;z), \quad z^{1-c}F(a-c+1,b-c+1;2-c;z).$$

By our construction F is regular at $z=0$. At $z=1$, $F(a,b;c;z)$ has a singularity

$$\lim_{z\to 1}(1-z)^{-(c-a-b)}F(a,b;c;z)=\frac{\Gamma(c)\Gamma(a+b-c)}{\Gamma(a)\Gamma(b)},$$

where $c-a-b=-2\gamma<0$. Note that since $\gamma=\sqrt{1+\sqrt{-1}\lambda_I}$, the real part of γ is positive. So a solution that is regular at both $z=0$ and $z=1$ can exist only if $\Gamma(x)$ has a pole at a or b, respectively. In other words, $a,b=0,-1,-2,\ldots$.

From (5.7), we compute that

$$a=2\gamma-\alpha \text{ or } b=2\gamma-\alpha,$$

where α satisfies

$$\alpha^2+\alpha-6\mu=0. \tag{5.8}$$

By symmetry we may assume that $a=2\gamma-\alpha=-l,\ l\geq 0$, and $\alpha=\alpha_R+\sqrt{-1}\alpha_I$. So we have to solve the system

$$\begin{cases} \alpha_R^2+\alpha_R-\alpha_I^2-6(1+\sigma_R)=0, \\ 2\gamma=\alpha-l, \quad l=0,1,2,\ldots. \end{cases} \tag{5.9}$$

Since we take the principal branch for $\gamma=\sqrt{1+\sqrt{-1}\lambda_I}$, it follows that

$$\alpha_R>l.$$

Moreover, we have

$$4=(\alpha_R-l)^2-\alpha_I^2,$$

which implies that

$$\alpha_R\geq l+2. \tag{5.10}$$

On the other hand, we have

$$4=(\alpha_R-l)^2-\alpha_I^2=\alpha_R^2-\alpha_I^2-2l\alpha_R+l^2$$

$$=-(2l+1)\alpha_R+l^2+6(1+\sigma_R).$$

So we obtain

$$\alpha_R=\frac{1}{2l+1}(l^2+2+6\sigma_R).$$

By (5.10), we have

$$\frac{1}{2l+1}(l^2+2+6\sigma_R) \geq l+2,$$

which is impossible unless $l=0$ or $l=1$. For $l=1$ we just recover the case $\lambda=0$ with the eigenfunction w' given by Lemma 5.1 (1). This clearly does not correspond to a Hopf bifurcation.

In conclusion, for a Hopf bifurcation we must have $a=0$ or $b=0$. In this case, we have

$$\alpha_R = 2+6\sigma_R, \quad \alpha_I = \frac{6}{(2\alpha_R+1)}\sigma_I. \tag{5.11}$$

Substituting this relation into (5.9), we obtain that (σ_R, σ_I) must be a zero of the polynomial f defined by (2.22).

In summary, a Hopf bifurcation can occur only at the point (σ_R^h, σ_I^h) such that $f(\sigma)=0$.

Note that the set $\{f(\sigma)=0\}$ defines a monotone curve within the set $\{(\sigma_R,\sigma_I)|\sigma_R > 0, \sigma_I>0\}$. Since $f(0,\sigma_I)<0$ for $\sigma_I>0$ and $f(\sigma_R,0)>0$ for $\sigma_R>0$, we see that if $f(\sigma)<0$, then (5.1) is stable, and if $f(\sigma)>0$, then (5.1) is unstable. □

Next we study the scalar NLEP (5.2). First we state the following lemma.

LEMMA 5.3. *Consider the NLEP* (5.2).

(1) *Suppose that* $0 \leq \tau < \tau_0$, *where* τ_0 *is sufficiently small and* $0<\eta<\frac{1}{2}$. *Let* $\lambda_0 \neq 0$ *be an eigenvalue of* (5.2). *Then we have* $\mathrm{Re}(\lambda_0) \leq -c_1$ *for some* $c_1>0$.

(2) *Suppose that* $\tau>0$ *and* $\frac{1}{2}<\eta<1$; *then* (5.2) *admits a real eigenvalue* λ_0 *with* $\lambda_0 \geq c_2 > 0$ *for some* $c_2>0$.

Proof. (1) When $\tau=0$, we have

$$\frac{2(1-\eta)}{\eta\sqrt{1+\tau\lambda}+1-\eta} = 2(1-\eta) > 1$$

if $0<\eta<\frac{1}{2}$. By Theorem 2.1 of [57], we have that $\lambda_R < -c_1 < 0$.

To show that the same thing is true when τ is small, we have to show that if $\lambda_R \geq 0$ and $0<\tau<1$, then $|\lambda| \leq C$, where C is a generic constant (independent of τ). In fact, multiplying (5.2) by $\bar{\phi}$, the conjugate of ϕ, and integrating by parts, we obtain that

$$\int_R (|\nabla\phi|^2+|\phi|^2-2w|\phi|^2) = -\lambda\int_R |\phi|^2 - f(\tau\lambda)\frac{\int_R w\phi}{\int_R w^2}\int_R w^2\bar{\phi}, \tag{5.12}$$

where $f(\tau\lambda)=\frac{2(1-\eta)}{\eta\sqrt{1+\tau\lambda}+1-\eta}$. From the imaginary part of (5.12), we obtain that

$$|\lambda_I| \leq C_1|f(\tau\lambda)|,$$

where $\lambda=\lambda_R+\sqrt{-1}\lambda_I$ and C_1 is a positive constant (independent of τ). Note that the real part of $\sqrt{1+\tau\lambda}$ is positive. Hence $|f(\tau\lambda)| \leq 2$, and so $|\lambda_I| \leq 2C_1$. Taking the real part of (5.12), we obtain that $\lambda_R \leq C_2$, where C_2 is a positive constant (independent of $\tau>0$). Therefore, we have that $|\lambda|$ is uniformly bounded, and hence a perturbation argument gives the desired conclusion.

(2) Assume that $\frac{1}{2}<\eta<1$. Now we show that (5.2) admits a positive eigenvalue for all $\tau>0$.

By Lemma 5.1 (3), L_0 has only one positive eigenvalue $\lambda_1 > 0$. Consider the following function:

$$h(\alpha) = \int_R ((L_0 - \alpha)^{-1} w) w, \quad 0 < \alpha < \lambda_1. \tag{5.13}$$

It is easy to see that

$$h^{'}(\alpha) = \int_R ((L_0 - \alpha)^{-2} w) w = \int_R [(L_0 - \alpha)^{-1} w]^2 > 0,$$

and

$$\lim_{\alpha \to \lambda_1} h(\alpha) = +\infty.$$

Next we consider the following function:

$$\rho(\lambda) = \frac{\eta\sqrt{1 + \tau\lambda} + 1 - \eta}{2(1 - \eta)} - 1 - \left(\int_R w^2\right)^{-1} \lambda h(\lambda). \tag{5.14}$$

Note that

$$\rho(0) = \frac{1}{2(1 - \eta)} - 1 > 0$$

since $\frac{1}{2} < \eta < 1$. On the other hand,

$$\lim_{\lambda \to \lambda_1 -} \rho(\lambda) = -\infty.$$

Hence there must exist an $\lambda_0 \in (0, \lambda_1)$ such that $\rho(\lambda_0) = 0$. It is easy to see that this $\lambda_0 > 0$ is an eigenvalue of (5.2), which proves (2) of Lemma 5.3. □

In the general case when τ is large and $0 < \eta < \frac{1}{2}$, there are no analytic results for (5.2) available. Fortunately, we can use hypergeometric functions and generalized hypergeometric functions to reduce (5.2) to a computable problem. Such an idea has already been used in [12]. However, our transformation is different, and the eigenvalue problem becomes computable more easily. We recall that by Lemma 5.3 (1) for $\tau = 0$ all eigenvalues are stable. So, if we vary τ, we obtain either stability or a Hopf bifurcation. All we need is to compute when a Hopf bifurcation occurs.

Let us first introduce the so-called generalized Gauss function. Let $a_1, a_2, \dots, a_A$ and $b_1, b_2, \dots, b_B$ be two sequences of numbers. Consider the following series:

$$1 + \frac{a_1 a_2 \cdots a_A}{b_1 b_2 \cdots b_B} \frac{z}{1!} + \frac{(a_1 + 1)(a_2 + 1) \cdots (a_A + 1)}{(b_1 + 1)(b_2 + 1) \cdots (b_B + 1)} \frac{z^2}{2!} + \cdots \tag{5.15}$$

$$\equiv {}_A F_B \left\{ \begin{array}{ccccc} a_1, & a_2, & \dots, & a_A & ; \\ & & & & z \\ b_1, & b_2, & \dots, & b_B & ; \end{array} \right\}.$$

${}_A F_B$ is called a generalized Gauss function or a generalized hypergeometric function. For more details on such functions, we refer to [49].

Now we have the following lemma, whose proof is technical and is thus delayed to Appendix B.

Lemma 5.4. *Let $\lambda=\sqrt{-1}\lambda_I$ be an eigenvalue of* (5.2). *Then λ is a solution of the following algebraic equation:*

$$\frac{5}{6}(3-\lambda)\frac{\eta\sqrt{1+\tau\lambda}+1-\eta}{2(1-\eta)}$$

$$= {}_4F_3\left\{\begin{array}{ccccc} 1, & \frac{1}{2}, & 4, & 3 & ; \\ & & & & 1 \\ & 3-\sqrt{1+\lambda}, & 3+\sqrt{1+\lambda}, & \frac{7}{2} & ; \end{array}\right\}. \tag{5.16}$$

By Lemma 5.4, (5.2) can be solved by using Mathematica. We will not produce any numerical results here. The readers are referred to [12] for some numerical results for the case in which $N=1$.

6. Derivation of the vectorial NLEP and reduction process. In this section, we study the eigenvalue problem (2.12) and show that it can be reduced to a vectorial NLEP.

Let (X_ϵ, M_ϵ) be one of the two solutions constructed in section 2. Now we study the eigenvalue problem associated with (X_ϵ, M_ϵ). We assume that

$$\epsilon << L < \frac{1}{4}-\delta_0$$

(in the same sense as in (2.9)), where $\delta_0>0$ is a small but fixed constant, and that $0\le\tau<\tau_0$, where τ_0 is given by Lemma 5.3 and is independent of ϵ.

We need to analyze the following eigenvalue problem (letting $x=\epsilon y$):

$$\begin{cases} \Delta_y\phi_{\epsilon,i}-\phi_{\epsilon,i}+AM_\epsilon\sum_{j=1}^N k_{ij}(X_{\epsilon,j}\phi_{\epsilon,i}+\phi_{\epsilon,j}X_{\epsilon,i}) \\ +A\psi_\epsilon\sum_{j=1}^N k_{ij}X_{\epsilon,i}X_{\epsilon,j}=\lambda_\epsilon\phi_{\epsilon,i},\ y\in R, i=1,\dots,N, \\ \Delta_x\psi_\epsilon-\psi_\epsilon-\psi_\epsilon\sum_{i,j=1}^N k_{ij}X_{\epsilon,i}X_{\epsilon,j} \\ -M_\epsilon\sum_{i,j=1}^N k_{ij}(X_{\epsilon,j}\phi_{\epsilon,i}+X_{\epsilon,i}\phi_{\epsilon,j})=\tau\lambda_\epsilon\psi_\epsilon, \quad x\in R, \\ \lambda_\epsilon\in\mathcal{C}. \end{cases} \tag{6.1}$$

We assume that $(\phi_{\epsilon,1},\dots,\phi_{\epsilon,N},\psi_\epsilon)\in(H^2(R))^N\oplus H^2(R)$. Here we equip $(H^2(R))^N\oplus H^2(R)$ with the following norm:

$$\|(X,u)\|^2_{(H^2(R))^N\oplus H^2(R)}=\|X(y)\|^2_{(H^2(R))^N}+\|u(x)\|^2_{H^2(R)}.$$

Since $X_{\epsilon,i}=\xi_iX_{0,\epsilon}$, (6.1) becomes

$$\begin{cases} \Delta_y\phi_{\epsilon,i}-\phi_{\epsilon,i}+AM_\epsilon X_{0,\epsilon}\sum_{j=1}^N k_{ij}(\xi_i\phi_{\epsilon,j}+\xi_j\phi_{\epsilon,i}) \\ +A\psi_\epsilon\xi_iX_{0,\epsilon}^2=\lambda_\epsilon\phi_{\epsilon,i}, \\ \Delta\psi_\epsilon-\psi_\epsilon-\psi_\epsilon(\sum_{i=1}^N\xi_i)X_{0,\epsilon}^2 \\ -M_\epsilon\sum_{i,j=1}^N k_{ij}(\xi_i\phi_{\epsilon,j}+\xi_j\phi_{\epsilon,i})X_{0,\epsilon}=\tau\lambda_\epsilon\psi_\epsilon. \end{cases} \tag{6.2}$$

First let us formally derive the limiting eigenvalue problems.

Since $(X_{0,\epsilon}, M_\epsilon)$ satisfies (2.5), we have

$$X_{0,\epsilon}(y)\sim(AM_\epsilon(0))^{-1}(1+o(1))w(y) \tag{6.3}$$

and

$$M_\epsilon(0)(1-M_\epsilon(0)) \sim L := \frac{1}{2A^2(\sum_{i=1}^N \xi_i)}\epsilon \int_R w(y)^2 dy. \tag{6.4}$$

By the assumptions (H1) and (H2), $\sum_{j=1}^N k_{ij}\xi_j = \sum_{i=1}^N k_{ij}\xi_i = 1$, the eigenvalue problem is changed into

$$\begin{cases} \Delta_y \phi_{\epsilon,i} - \phi_{\epsilon,i} + w\phi_{\epsilon,i} + w\sum_{j=1}^N b_{ij}\phi_{\epsilon,j} \\ +\frac{1}{AM_\epsilon(0)^2}\xi_i \psi_\epsilon w^2 = \lambda_\epsilon \phi_{\epsilon,i}, \quad i=1,\ldots,N, \\ \Delta_x \psi_\epsilon - \psi_\epsilon - \frac{1}{A^2M_\epsilon(0)^2(\sum_{i=1}^N \xi_i)}\psi_\epsilon w^2 \\ -\frac{M_\epsilon}{AM_\epsilon(0)}2\sum_{j=1}^N \phi_{\epsilon,j} w = \tau\lambda_\epsilon \psi_\epsilon. \end{cases} \tag{6.5}$$

Let $\beta_\epsilon = \sqrt{1+\tau\lambda_\epsilon}$. Here we take the principal branch of $1+\tau\lambda_\epsilon$. Since we are interested only in the unstable eigenvalues of λ_ϵ (otherwise it is stable), we may assume that $\mathrm{Re}(\lambda_\epsilon) \geq -a_0$ for some small number $a_0 > 0$ so that $1+\tau a_0 > \frac{1}{2}$. Following the same proof as for (1) of Lemma 5.3 (that is, multiplying the equations for $\phi_{\epsilon,i}$ by $\bar{\phi}_{\epsilon,i}$, integrating by parts, and summing up), we see that

$$|\lambda_\epsilon| \leq C \quad \text{if } \mathrm{Re}(\lambda_\epsilon) \geq -a_0, \tag{6.6}$$

where $C > 0$ is a positive constant (independent of $\epsilon > 0$).

From the second equation in (6.5), we calculate using the fact that Green's function of

$$\Delta G(x,\xi) - \beta^2 G(x,\xi) + \delta(\xi) = 0 \quad \text{in } R$$

is

$$G(x,\xi) = \frac{1}{2\beta}e^{-\beta|x-\xi|},$$

the relation

$$\psi_\epsilon(0) = \frac{1}{2\beta_\epsilon}\int_R e^{-\beta_\epsilon |x|}$$

$$\times\left(-\frac{1}{A^2M_\epsilon(0)^2(\sum_{i=1}^N \xi_i)}\psi_\epsilon w^2 - \frac{M_\epsilon}{AM_\epsilon(0)}2\sum_{j=1}^N \phi_{\epsilon,j} w\right) dx$$

$$= \frac{1}{2\beta_\epsilon}\epsilon\Bigg[-\frac{\psi_\epsilon(0)}{A^2M_\epsilon(0)^2(\sum_{i=1}^N \xi_i)}\int_R w^2(y)\,dy$$

$$-\frac{1}{A}\sum_{j=1}^N \int_R \left(\sum_{j=1}^N \phi_j\right) w\,dy + o(\epsilon)\Bigg], \tag{6.7}$$

where

$$\phi_{\epsilon,i}(x) = \phi_i\left(\frac{x}{\epsilon}\right), \quad x = \epsilon y, \quad i = 1,\ldots,N. \tag{6.8}$$

By (6.4) and (6.7), we have

$$
\begin{aligned}
&\frac{\psi_\epsilon(0)}{AM_\epsilon^2(0)}\\
&\quad= -\frac{\epsilon}{\beta_\epsilon A^2 M_\epsilon(0)^2}\int_R \left(\sum_{j=1}^N \phi_j\right) w \left[1+\frac{\epsilon}{2\beta_\epsilon(\sum_{i=1}^N \xi_i)A^2M_\epsilon(0)^2}\int_R w^2(y)\,dy\right]^{-1}\\
&\quad= -\int_R \left(\sum_{j=1}^N \phi_j\right) w \left[\frac{\beta_\epsilon A^2 M_\epsilon(0)^2}{\epsilon}+\frac{1}{2(\sum_{i=1}^N \xi_i)}\int_R w^2(y)\,dy\right]^{-1}\\
&\quad= -\int_R \left(\sum_{j=1}^N \phi_j\right) w \left[\frac{\beta_\epsilon M_\epsilon(0)(\sum_{i=1}^N \xi_i)}{2(1-M_\epsilon(0))}\int_R w^2(y)\,dy+\frac{(\sum_{i=1}^N \xi_i)}{2}\int_R w^2(y)\,dy\right]^{-1}\\
&\quad= -\frac{2(1-M_\epsilon(0))}{1-M_\epsilon(0)+\beta_\epsilon M_\epsilon(0)}\frac{\int_R(\sum_{j=1}^N \phi_j)w}{(\sum_{i=1}^N \xi_i)\int_R w^2(y)\,dy}.
\end{aligned}
$$

Substituting this relation into the first equation in (6.5) and taking the limit $\epsilon \to 0$, we obtain the following NLEP:

$$
\begin{aligned}
(6.9)\qquad &\Delta\phi_i - \phi_i + \phi_i w + \sum_{j=1}^N b_{ij}\phi_j - \xi_i \frac{2(1-\eta)}{\eta\beta_0+1-\eta}\frac{\sum_{j=1}^N \int_R \phi_j w}{(\sum_{i=1}^N \xi_i)\int_R w^2} w^2\\
&= \lambda_0\phi_i, \phi_i \in H^2(R), i=1,\dots,N,
\end{aligned}
$$

where $\eta = \lim_{\epsilon\to 0} M_\epsilon(0), \lambda_0 = \lim_{\epsilon\to 0}\lambda_\epsilon, \beta_0 = \lim_{\epsilon\to 0}\beta_\epsilon = \sqrt{1+\tau\lambda_0}$. (Here, we have assumed that all the limits exist. Otherwise, we take a subsequence $\epsilon_n \to 0$.)

Though the derivations above are formal, we can rigorously prove the following separation of eigenvalues.

THEOREM 6.1. *Suppose that the assumptions* (H1)–(H3) *are satisfied.*

Let λ_ϵ be an eigenvalue of (6.2) *such that* $\mathrm{Re}(\lambda_\epsilon) > -a_0$.

(1) *Suppose that (for suitable sequences $\epsilon_n \to 0$) we have $\lambda_{\epsilon_n} \to 0$ as $n \to \infty$. Then for n sufficiently large, it follows that $\lambda_{\epsilon_n} = 0$ and*

$$(\phi_{\epsilon_n,1},\dots,\phi_{\epsilon_n,N},\psi_{\epsilon_n}) \in \text{span}\,\{(X'_{\epsilon_n}, M'_{\epsilon_n})\}.$$

(2) *Suppose that (for suitable sequences $\epsilon_n \to 0$) we have $\lambda_{\epsilon_n} \to \lambda_0 \neq 0$. Then λ_0 is an eigenvalue of the NLEP given in* (6.9).

(3) *Let $\lambda_0 \neq 0$ be an eigenvalue of the NLEP given in* (6.9). *Then for ϵ sufficiently small, there is an eigenvalue λ_ϵ of* (6.2) *with $\lambda_\epsilon \to \lambda_0$ as $\epsilon \to 0$.*

From Theorem 6.1 (1) and (3), we see that (6.2) is reduced to the study of the vectorial NLEP (6.9).

In the rest of this section, we prove Theorem 6.1.

Proof of Theorem 6.1. For (1), the proof is very delicate. We can proceed as in the proof of Theorem 2.2 (3) in section 6 of [58], where existence and stability of a single-cluster state for the Gray–Scott system in two dimensions are studied. First we prove the analogies of Lemmas 3.1 and 3.2 of [58] in one dimension. We begin with the following lemma.

LEMMA 6.2. *Let $g(y)$ be a function in $L^2(R^1)$ such that*

$$|g(y)| \le Ce^{-c|y|},$$

where c is a positive constant. Then we have

$$\left|\int_R (|y-z|-|z|)|g(z)|dz\right| \le C|y|, \tag{6.10}$$

where C depends on $\int_R |z||g(z)|dz$.

Proof. This follows from standard potential analysis. □

Next we study the asymptotic behavior of ψ_ϵ. We have the following lemma.

Lemma 6.3. *Let $(\phi_{\epsilon,1},\dots,\phi_{\epsilon,N},\psi_\epsilon)$ satisfy* (6.5). *Then we have*

$$\frac{1}{AM_\epsilon(0)^2}\psi_\epsilon(0) = -\frac{1-M_\epsilon(0)}{\beta_\epsilon M_\epsilon(0)+1-M_\epsilon(0)}\,\frac{2\sum_{j=1}^N\int_R\sum_{j=1}^N\phi_{\epsilon,j}w}{(\sum_{i=1}^N\xi_i)\int_R w^2}+o(1) \tag{6.11}$$

and

$$\frac{1}{AM_\epsilon(0)^2(\sum_{i=1}^N\xi_i)}(\psi_\epsilon(x)-\psi_\epsilon(0))$$

$$= O\left(\frac{2}{\epsilon(1-\sqrt{1-4L})}\left(1+\sum_{i=1}^N\|\phi_{\epsilon,i}\|_{L^2_y}\right)\left(1+\frac{|x|}{\epsilon}\right)\right), \tag{6.12}$$

where $x=\epsilon y$ and

$$\|\phi\|^2_{L^2_y}=\int_R\phi^2(y)dy.$$

Proof. Relation (6.11) follows from the representation formula. To prove (6.12), we note that by the representation formula we calculate

$$\psi_\epsilon(x)-\psi_\epsilon(0)=\frac{1}{2\beta}\int_R(e^{-\beta_\epsilon|z-x|}-e^{-\beta_\epsilon|z|})$$

$$\times\left(-\frac{\psi_\epsilon X_{0,\epsilon}^2}{(\sum_{i=1}^N\xi_i)}-2M_\epsilon\left(\sum_{j=1}^N\phi_{\epsilon,j}\right)X_{0,\epsilon}\right)dz.$$

Let $x=\epsilon y$ and $z=\epsilon\tilde z$. It is easy to see that

$$e^{-\beta_\epsilon|z-x|}-e^{-\beta_\epsilon|z|}=e^{-\beta_\epsilon\epsilon|y-\tilde z|}-e^{-\beta_\epsilon\epsilon|\tilde z|}$$

$$=-\beta_\epsilon\epsilon(|y-\tilde z|-|\tilde z|)+O(\beta_\epsilon^2\epsilon^2(|y|^2+|\tilde z|^2)).$$

Equation (6.12) now follows from Lemma 6.2. □

Finally, we need the analogue of Lemma 4.2 of [58].

Let us denote the linear operator on the left-hand side of (6.9) as $\mathcal{L}$, where $\mathcal{L}:(H^2(R))^N\to(L^2(R))^N$. Then we have the following lemma.

Lemma 6.4. *Assume that assumptions* (H1)–(H3) *hold true.*

(1) *Let ϕ be an eigenfunction of* (6.9) *with $\lambda_0=0$. Then we have*

$$\phi\in\mathcal{K}_0:=\text{span }\{w^{'}(y)\vec e_0\}, \tag{6.13}$$

where $\vec{e_0} = (1, \ldots, 1)^\tau$. *(This implies that* Ker $(\mathcal{L}) = \mathcal{K}_0$.*)*

(2) *The operator* $\mathcal{L}$ *is an invertible operator if restricted as follows:*

$$\mathcal{L} : \mathcal{K}_0^{\perp,1} \to \mathcal{K}_0^{\perp,2},$$

where

$$\mathcal{K}_0^{\perp,1} = \left\{ u \in (H^2(R))^N | \int_R uw^{'}(y)\vec{e_0} = 0 \right\},$$

$$\mathcal{K}_0^{\perp,2} = \left\{ u \in (L^2(R))^N | \int_R uw^{'}(y)\vec{e_0} = 0 \right\}.$$

The proof of Lemma 6.4 is technical and is delayed to Appendix C.

Now Theorem 6.1 (1) follows from Lemma 6.4 by the same proof as for Theorem 2.2 (3) of [58].

Item (2) of Theorem 6.1 follows the asymptotic analysis done at the beginning of this section.

To prove (3) of Theorem 6.1, we use the same argument as given in section 2 of [10], where the following eigenvalue problem was studied:

$$(6.14) \qquad \begin{cases} \epsilon^2 \Delta h - h + p u_\epsilon^{p-1} h - \frac{qr}{s+1+\tau\lambda_\epsilon} \frac{\int_\Omega u_\epsilon^{r-1} h}{\int_\Omega u_\epsilon^r} u_\epsilon^p = \lambda_\epsilon h \text{ in } \Omega, \\ h = 0 \text{ on } \partial\Omega, \end{cases}$$

where u_ϵ is a solution of the single equation

$$\begin{cases} \epsilon^2 \Delta u_\epsilon - u_\epsilon + u_\epsilon^p = 0 \text{ in } \Omega, \\ u_\epsilon > 0 \text{ in } \Omega, \; u_\epsilon = 0 \text{ on } \partial\Omega. \end{cases}$$

Here $1 < p < \frac{n+2}{n-2}$ if $n \geq 3$, and $1 < p < +\infty$ if $n = 1, 2$, $\frac{qr}{(s+1)(p-1)} > 1$, and $\Omega \subset R^n$ is a smooth bounded domain. If u_ϵ is a single interior peak solution, then it can be shown [56] that the limiting eigenvalue problem is an NLEP

$$(6.15) \qquad \Delta\phi - \phi + p w^{p-1}\phi - \frac{qr}{s+1+\tau\lambda_0} \frac{\int_{R^N} w^{r-1}\phi}{\int_{R^N} w^r} w^p = \lambda_0 \phi,$$

where w is the corresponding ground state solution in R^n:

$$\Delta w - w + w^p = 0, \quad w > 0 \text{ in } R^n, \quad w = w(|y|) \in H^1(R^n).$$

Dancer in [10] showed that if $\lambda_0 \neq 0$, $\text{Re}(\lambda_0) > 0$ is an unstable eigenvalue of (6.15), then there exists an eigenvalue λ_ϵ of (6.14) such that $\lambda_\epsilon \to \lambda_0$.

Now we follow his idea. Let $\lambda_0 \neq 0$ be an eigenvalue of (6.9) with $\text{Re}(\lambda_0) > 0$. First we note that, from the equation for ψ_ϵ, we can express ψ_ϵ in terms of $(\phi_{\epsilon,1}, \ldots, \phi_{\epsilon,N})$. Now we write the first equation for $(\phi_{\epsilon,1}, \phi_{\epsilon,2}, \ldots, \phi_{\epsilon,N})$ as follows:

$$(6.16) \quad \phi_{\epsilon,i} = -R_\epsilon(\lambda_\epsilon) \left[A M_\epsilon \sum_{j=1}^N k_{ij}(X_{\epsilon,j}\phi_{\epsilon,i} + \phi_{\epsilon,j} X_{\epsilon,i}) + A\psi_\epsilon \sum_{j=1}^N k_{ij} X_{\epsilon,i} X_{\epsilon,j} \right],$$
$$i = 1, \ldots, N,$$

where $R_\epsilon(\lambda)$ is the inverse of $-\Delta + (1 + \lambda_\epsilon)$ in $H^2(R)$ (which exists if $\text{Re}(\lambda_\epsilon) > -1$ or $\text{Im}(\lambda_\epsilon) \neq 0$). The important thing is that $R_\epsilon(\lambda_\epsilon)$ is a compact operator if ϵ is sufficiently small. The rest of the argument exactly follows that in [10]. For the sake of limited space, we omit the details here. □

7. Analysis of the vectorial NLEP and the proof of Theorem 2.2. In this section, we analyze the vectorial NLEP which we have obtained in (6.9):

$$\Delta\phi_i - \phi_i + \phi_i w + \sum_{j=1}^N b_{ij}\phi_j - \frac{\xi_i}{\sum_{i=1}^N \xi_i}\frac{2(1-\eta)}{1-\eta+\eta\beta_0}\frac{\sum_{j=1}^N \int_R \phi_j w}{\int_R w^2} w^2 \tag{7.1}$$
$$= \lambda_0\phi_i, \quad i = 1, \dots, N, \quad \phi_i \in H^2(R).$$

We will decouple it to a local eigenvalue problem with complex coefficients given in (5.1) and a scalar NLEP given in (5.2). Here assumptions (H2) and (H3) play a very important role. By Lemma 5.2, Lemma 5.3, and Theorem 6.1, we finish the proof of Theorem 2.2.

Proof of (1) *of Theorem* 2.2. Consider the case for $(X_\epsilon^s, M_\epsilon^s)$ and τ small. In this case, $0 \le \eta = \lim_{\epsilon\to 0} M_\epsilon(0) < \frac{1}{2}$. By Theorem 6.1 (1), if $\lambda_\epsilon = o(1)$, then $\lambda_\epsilon = 0$ and 0 is a simple eigenvalue. (The eigenspace is one-dimensional.) We need only to consider large eigenvalues. Let us assume that for a subsequence $\epsilon_n \to 0$ we have $\lambda_{\epsilon_n} \to \lambda_0$, where $\mathrm{Re}(\lambda_0) \ge 0$ and $\lambda_0 \ne 0$. We shall derive a contradiction.

By Theorem 6.1 (2), λ_0 is an eigenvalue of (7.1). First we take care of the nonlocal terms in (7.1). Adding the equations for $i = 1, \dots, N$ (using the assumption (H2)), we get

$$\Delta\left(\sum_{i=1}^N \phi_i\right) - \left(\sum_{i=1}^N \phi_i\right) + 2w\left(\sum_{i=1}^N \phi_i\right)$$
$$-\frac{2(1-\eta)}{\beta_0\eta + 1 - \eta}\frac{\int_R(\sum_{i=1}^N \phi_i)w}{\int_R w^2}w^2 = \lambda_0\sum_{i=1}^N \phi_i.$$

From Lemma 5.3 (1) we know that for $0 < \eta = \lim_{\epsilon\to 0} M_\epsilon(0) < \frac{1}{2}$ and τ small we have

$$\sum_{i=1}^N \phi_i = 0 \qquad \text{if } \mathrm{Re}\ (\lambda_0) \ge 0, \quad \lambda_0 \ne 0. \tag{7.2}$$

Therefore, the nonlocal terms in (7.1) all vanish, and (7.1) reduces to the following vectorial local eigenvalue problem:

$$\Delta\phi_i - \phi_i + w\phi_i + w\sum_{j=1}^N b_{ij}\phi_j = \lambda_0\phi_i, \quad \phi_i \in H^1(R), \quad i = 1, \dots, N. \tag{7.3}$$

To finish the proof, we have to transform this to Jordan form; we decompose

$$b_{ij} = \sum_{k,l=1}^N p_{ik}d_{kl}p_{lj}^{-1},$$

as in (2.17) of section 2, where d_{kl} has Jordan form.

Set

$$\Phi_i = \sum_{j=1}^N p_{ij}^{-1}\phi_j. \tag{7.4}$$

Then (7.3) can be expressed in terms of Φ as follows:

$$\Delta\Phi_i - \Phi_i + w\Phi_i + \sum_{j=1}^{N} d_{ij}\Phi_j w = \lambda_0\Phi_i, \quad i = 1, \dots, N. \tag{7.5}$$

We have to study the eigenvalue problems for each Jordan block separately.

Let σ be an eigenvalue of $\mathcal{B}$. By assumption (H3), $\sigma = 1$ is a simple eigenvalue of $\mathcal{B}$. Assume also that for those $\sigma \neq 1$ with $\sigma_R > 0$, it holds that $f(\sigma) < 0$.

For those eigenvalues $\sigma_k \neq 1, k > 1$, the corresponding ith component Φ_i of the eigenfunction satisfies

$$\Delta\Phi_i - \Phi_i + (1+\sigma_k)w\Phi_i = \lambda_0\Phi_i \tag{7.6}$$

with Re $(\lambda_0) \geq 0$.

By Lemma 5.2 (1), $\Phi_i = 0$ by our assumption on σ_k. Substituting this into the $(i-1)$th equation, we get (for the eigenfunction Φ_{i-1})

$$\Delta\Phi_{i-1} - \Phi_{i-1} + (1+\sigma_k)w\Phi_{i-1} = \lambda_0\Phi_{i-1}, \tag{7.7}$$

and by Lemma 5.2 (1) again we conclude that $\Phi_{i-1} = 0$. Continuing in this way, we see that those components of Φ corresponding to the Jordan block of σ_k all vanish.

Since $\sigma_1 = 1$ is a simple eigenvalue, we are left with the only possibility that $\Phi_1 \neq 0$. On the other hand, we have that

$$\sum_{j=1}^{N} \phi_j = \sum_{j=1}^{N} c_j\Phi_j, \tag{7.8}$$

where $c_j = \langle \vec{e}_0, \mathbf{p}_j \rangle$, where $\vec{e}_0 = (1, \dots, 1)^\tau$ and $\mathbf{p}_j$ is the jth column of $\mathcal{P}$. Note that $c_1 = \frac{\sum_{i=1}^{N} \xi_i}{\|\xi\|} > 0$.

Since $\sum_{j=1}^{N} \phi_j = 0$ and $\Phi_j = 0$, $j = 2, \dots, N$, we conclude from (7.8) that $\sum_{j=1}^{N} \phi_j = c_1\Phi_1 = 0$, and hence $\Phi_1 = \cdots = \Phi_N = 0$, which is a contradiction.

Therefore, Re $(\lambda_0) \geq 0$ is not possible. Thus we have Re $(\lambda_0) \leq -c_0 < 0$.

This proves (1) of Theorem 2.2. □

Proofs of (2) *and* (3) *of Theorem* 2.2. As before, we decompose $\mathcal{B} = \mathcal{P}\mathcal{D}\mathcal{P}^{-1}$ and let $\phi = \mathcal{P}\Phi$. The problem (7.1) is equivalent to the following:

$$\Delta\Phi - \Phi + w\Phi + w\mathcal{D}\Phi - \mathcal{P}^{-1}\xi \frac{2(1-\eta)}{(\beta_0\eta + 1 - \eta)(\sum_{i=1}^{N}\xi_i)} \frac{\sum_{i=1}^{N}\int_R w\phi_i}{\int_R w^2} w^2 = \lambda_0\Phi. \tag{7.9}$$

Note that

$$\mathcal{P}^{-1}\xi = \|\xi\|\vec{e}_1 \tag{7.10}$$

since ξ is the first eigenvector of $\mathcal{B}$, where $\vec{e}_1 = (1, 0, \dots, 0)^\tau$.

Therefore, (7.9) is decoupled into

$$\Delta\Phi_1 - \Phi_1 + 2w\Phi_1 - \frac{2\|\xi\|(1-\eta)}{(\beta_0\eta + 1 - \eta)(\sum_{i=1}^{N}\xi_i)} \frac{\sum_{i=1}^{N}\int_R w\phi_i}{\int_R w^2} w^2 = \lambda_0\Phi_1, \tag{7.11}$$

and

$$\Delta\Phi_i - \Phi_i + w\Phi_i + \sum_{j=1}^{N} d_{ij}\Phi_j w = \lambda_0\Phi_i, \quad i = 2, \ldots, K. \tag{7.12}$$

By (7.8) we have that

$$\int_R \sum_{i=1}^{N} w\phi_i = \sum_{j=1}^{N} c_j \int_R w\Phi_j. \tag{7.13}$$

We first prove (3) of Theorem 2.2. We consider $(X_\epsilon^l, M_\epsilon^l)$. In this case, $2(1-\eta) < 1$. By Lemma 5.3 (2), for any $\tau > 0$, there exist an eigenvalue $\lambda_0 > 0$ and an eigenfunction Φ_0 such that

$$\Delta\Phi_0 - \Phi_0 + 2w\Phi_0 - \frac{2(1-\eta)}{(\beta_0\eta + 1 - \eta)} \frac{\int_R w\Phi_0}{\int_R w^2} w^2 = \lambda_0\Phi_0, \quad \lambda_0 > 0.$$

Now we choose

$$\Phi_1 = \Phi_0, \quad \Phi_j = 0, \quad j = 2, \ldots, K. \tag{7.14}$$

Then $\mathbf{\Phi} = (\Phi_1, \ldots, \Phi_N)$ is a solution of (7.9) with $\lambda_0 > 0$. The corresponding $\phi = \mathcal{P}\Phi$ is a solution of (7.1) with $\lambda_0 > 0$. By Theorem 6.1 (3), we have the instability of $(X_\epsilon^l, M_\epsilon^l)$ for any $\tau > 0$.

This proves (3) of Theorem 2.2.

Finally, we prove (2) of Theorem 2.2. Consider $(X_\epsilon^s, M_\epsilon^s)$. Assume that there exist $\sigma_k \neq 1$ with $\mathrm{Re}(\sigma_k) > 0$ such that $f(\sigma_k) > 0$. By Lemma 5.2 (2), there exist an eigenvalue λ_0 with $\mathrm{Re}(\lambda_0) > 0$ and an eigenfunction Φ_0 such that

$$\Delta\Phi_0 - \Phi_0 + (1 + \sigma_k)w\Phi_0 = \lambda_0\Phi_0. \tag{7.15}$$

If σ_k is positive, we may choose λ_0 to be the principal eigenvalue given by Lemma 5.1 (3).

We choose $\Phi_k = \Phi_0$ and $\Phi_j = 0$ for $j \neq k$, $j \neq 1$. To choose Φ_1, we see that we have to solve (7.11), which becomes

$$\Delta\Phi_1 - \Phi_1 + 2w\Phi_1 - \frac{2(1-\eta)}{(\beta_0\eta + 1 - \eta)} \frac{\int_R w\Phi_1}{\int_R w^2} w^2 - \lambda_0\Phi_1 \tag{7.16}$$

$$= c_k \frac{2\|\xi\|(1-\eta)}{(\beta_0\eta + 1 - \eta)(\sum_{i=1}^{N} \xi_i)} \frac{\int_R w\Phi_0}{\int_R w^2} w^2.$$

To see that (7.16) is solvable, we note that (7.16) is equivalent to

$$\Delta\tilde{\Phi}_1 - \tilde{\Phi}_1 + 2w\tilde{\Phi}_1 - \lambda_0\tilde{\Phi}_1 = -\Lambda\lambda_0 w, \tag{7.17}$$

where

$$\tilde{\Phi}_1 = \Phi_1 - \Lambda w,$$

$$\Lambda = \frac{2(1-\eta)}{(\beta_0\eta+1-\eta)}\frac{\int_R w\Phi_1}{\int_R w^2} + c_k \frac{2\|\xi\|(1-\eta)}{(\beta_0\eta+1-\eta)(\sum_{i=1}^N \xi_i)}\frac{\int_R w\Phi_0}{\int_R w^2}.$$

If σ_k is not real, then $\mathrm{Im}(\lambda_0) \neq 0$, and so $L_0 - \lambda_0$ is invertible, where $L_0 = \Delta - 1 + 2w$. If σ_k is positive, then $\sigma_k \neq 1$ and $L_0 - \lambda_0$ is invertible. Thus (7.17) is solvable, and hence (7.16) is solvable. Going backward, we see that there exists a solution to (7.1) with $\mathbf{\Phi} = (\Phi_1, 0, \ldots, 0, \Phi_0, 0, \ldots, 0)$ and $\mathrm{Re}(\lambda_0) > 0$. Hence $(X_\epsilon^s, M_\epsilon^s)$ is unstable.

Item (2) of Theorem 2.2 is thus proved. □

Appendix A. Proof of Lemma 5.1. For (1), please see Lemma 4.1 of [51].

For (2), the fact that $\mu_1 = 1, \mu_2 = 2$ has already been proved in Lemma 4.1 of [51]. The exact value of μ_n can be computed using the same method as in the proof of Lemma 5.2. In fact, in this case, $\lambda = 0, \gamma = 1$, and hence the eigenvalues are given by

$$a = 2\gamma - \alpha = -(n-1),\, n = 1, 2, 3 \ldots,$$

where $\alpha^2 + \alpha - 6\mu = 0$. Thus $\mu_n = \frac{\alpha^2+\alpha}{6}, \alpha = n+1$.

Item (3) follows by the variational characterization of the eigenvalues:

$$-\lambda_1 = \inf_{\phi \in H^1(R), \phi \not\equiv 0} \frac{\int_R (\phi')^2 + \phi^2 - (1+\mu_R)w\phi^2}{\int_R \phi^2} < 0$$

since by the last inequality for $\phi = w$

$$-\lambda_1 \le -\mu_R \frac{\int_R w^3}{\int_R w^2} < 0.$$

This is the same analysis as in [61].

When $\mu_R = 1$, there exists only one positive eigenvalue (which is the principal one). See Lemma 1.2 of [56].

To prove (4), note that

$$\sigma = \sigma_R + i\sigma_I, \quad \phi = \phi_R + i\phi_I, \quad \lambda = \lambda_R + i\lambda_I,$$

and write the eigenvalue problem for real and imaginary parts separately:

$$\Delta\phi_R - \phi_R + (1+\sigma_R)w\phi_R - \sigma_I w\phi_I = \lambda_R\phi_R - \lambda_I\phi_I, \tag{A.1}$$

$$\Delta\phi_R - \phi_I + (1+\sigma_R)w\phi_I + \sigma_I w\phi_R = \lambda_R\phi_I + \lambda_I\phi_R. \tag{A.2}$$

Multiplying (A.1) by ϕ_R and (A.2) by ϕ_I, integrating over R, and adding, we get

$$\int_R [-({\phi_R}')^2 - \phi_R^2 + (1+\sigma_R)w\phi_R^2] + \int_R [-|{\phi_I}'|^2 - \phi_I^2 + (1+\sigma_R)w\phi_I^2]$$

$$= \lambda_R \int_R \phi_R^2 + \phi_I^2.$$

Since, in the last equation, the left-hand side is ≤ 0, we also get that the right-hand side is ≤ 0. Therefore, $\lambda_R \le 0$. Now assume that $\lambda_R = 0$. Then by (2) we get

$\phi_R = c_1 w$, $\phi_I = c_2 w$ (with $c_1, c_2 \in R$), and $\sigma_R = 0$. But this implies $\lambda_I = 0$, $\sigma_I = 0$, and we get $\lambda = 0$, contrary to what we assumed. Therefore, λ_R cannot be zero, and we conclude that Re $(\lambda) \leq -c_0 < 0$.

Appendix B. Proof of Lemma 5.4. In this appendix, we show how problem (5.2) can be reduced to (5.16).

Let ${}_AF_B$ be defined by (5.15). An important property of ${}_AF_B$ is the following integral property, whose proof can be found in [49]:

$$\text{(B.1)} \qquad {}_{A+1}F_{B+1}\left\{\begin{matrix} a_1, & a_2, & \ldots, & a_A, & c, & ; & \\ & & & & & & z \\ b_1, & b_2, & \ldots, & b_B, & d & ; & \end{matrix}\right\}$$

$$= \frac{\Gamma(d)}{\Gamma(c)\Gamma(d-c)} \int_0^1 t^{c-1}(1-t)^{d-c-1} {}_AF_B \left\{\begin{matrix} a_1, & a_2, & \ldots, & a_A & ; & \\ & & & & & tz \\ b_1, & b_2, & \ldots, & b_B & ; & \end{matrix}\right\} dt.$$

Let

$$f(\lambda) = \frac{2(1-\eta)}{\eta\sqrt{1+\tau\lambda}+1-\eta},$$

and let w be the unique solution of (2.1). Integrating (2.1), we have that

$$w^{'} = -\sqrt{w^2 - \frac{2}{3}w^3}.$$

First let us solve the following problem:

$$\text{(B.2)} \qquad \Delta\phi_0 - \phi_0 + 2w\phi_0 = w^2 + \lambda\phi_0, \quad \phi_0 \in H^2(R).$$

Since w is an even function, we may assume that ϕ_0 is also an even function. Let us denote the variable by t. Note that ϕ_0 is unique.

Set

$$\gamma = \sqrt{1+\lambda},$$

where we take the principal branch of $\sqrt{1+\lambda}$.

Then it is easy to see that problem (5.2) becomes

$$\text{(B.3)} \qquad \frac{1}{f(\lambda)} = \frac{\int_R w\phi_0}{\int_R w^2} = \frac{\int_0^{+\infty} w\phi_0 dt}{\int_0^{+\infty} w^2 dt}.$$

First let us set

$$\phi_0 = w^\gamma G.$$

Then, by some simple computations, G satisfies

$$\text{(B.4)} \qquad \frac{d^2G}{dt^2} + 2\gamma\frac{w^{'}}{w}\frac{dG}{dt} + \left(2 - \frac{\gamma}{3}(1+2\gamma)\right) wG = w^{1-\gamma}.$$

Next we perform the following change of variables:

$$z=\frac{2}{3}w. \tag{B.5}$$

Note that $w(0)=\frac{3}{2}$, and so z is a homeomorphism from $[0,+\infty]$ to $[0,1]$.

(We remark that here we take a different transformation as in [12]. Our transformation can be considered as a quadratic transformation for hypergeometric functions.)

By some lengthy computations, we obtain the following equation for $G(z)$:

$$z(1-z)G^{''}+(c-(a+b+1)z)G^{'}-abG=\left(\frac{3}{2}\right)^{2-\gamma}z^{1-\gamma}, \tag{B.6}$$

where

$$a=2+\gamma,\quad b=\gamma-\frac{3}{2},\quad c=1+2\gamma. \tag{B.7}$$

To solve (B.6), we take a power series

$$G(z)=z^s\sum_{k=0}^{+\infty}c_kz^k,$$

and, substituting it into (B.6), we obtain that

$$\sum_{k=0}^{+\infty}c_kz^{s+k-1}(s+k)(s+k-1+c)-\sum_{k=1}^{+\infty}c_kz^{s+k}(s+k+a)(s+k+b)=\left(\frac{3}{2}\right)^{2-\gamma}z^{1-\gamma}.$$

So

$$s-1=1-\gamma,\quad c_0s(s-1+c)=\left(\frac{3}{2}\right)^{2-\gamma},$$

$$c_k(s+k)(s+k-1+c)=c_{k-1}(s+k-1+a)(s+k-1+b).$$

By regrouping the coefficients, we have that

$$G(z)=\left(\frac{3}{2}\right)^{2-\gamma}(4-\gamma^2)^{-1}z^{2-\gamma}{}_3F_2\left\{\begin{matrix}1, & \frac{1}{2}, & 4 & ; & \\ & & & & z\\ & 3-\gamma, & 3+\gamma & ; & \end{matrix}\right\}. \tag{B.8}$$

Now we can compute

$$\begin{aligned}\int_0^{+\infty}w\phi_0dt&=\frac{3}{2}\int_0^1w^{1+\gamma}G(z)\frac{dz}{-w^{'}}\\&=\left(\frac{3}{2}\right)^{1+\gamma}\int_0^1z^{\gamma}(1-z)^{-\frac{1}{2}}G(z)dz\\&=\left(\frac{3}{2}\right)^{3}(4-\gamma^2)^{-1}\int_0^1z^2(1-z)^{-\frac{1}{2}}{}_3F_2\left\{\begin{matrix}1, & \frac{1}{2}, & 4 & ; & \\ & & & & z\\ & 3-\gamma, & 3+\gamma & ; & \end{matrix}\right\}dz.\end{aligned}$$

By (B.1), we obtain that

$$\int_0^{+\infty} w\phi_0 dt$$

$$= \left(\frac{3}{2}\right)^3 (4-\gamma^2)^{-1} \frac{\Gamma(3)\Gamma(\frac{1}{2})}{\Gamma(\frac{7}{2})} {}_4F_3 \left\{ \begin{matrix} 1, & \frac{1}{2}, & 4, & 3 & ; & \\ & & & & & 1 \\ & 3-\gamma, & 3+\gamma, & \frac{7}{2} & ; & \end{matrix} \right\}. \tag{B.9}$$

On the other hand, it is easy to compute that

$$\int_0^{+\infty} w^2 dt = \left(\frac{3}{2}\right)^2 \int_0^1 z^2(1-z)^{-\frac{1}{2}} dz = \left(\frac{3}{2}\right)^2 \frac{\Gamma(2)\Gamma(\frac{1}{2})}{\Gamma(2+\frac{1}{2})}. \tag{B.10}$$

By (B.9), (B.10), and (B.3), we obtain (5.16).

Appendix C. Proof of Lemma 6.4. We prove Lemma 6.4 in this appendix. We assume that the assumptions (H1)–(H3) are satisfied.

Proof of Lemma 6.4 (1). Recall that $L_0 = \Delta - 1 + 2w$. It is easy to check that $w^{'}\vec{e}_0 \in \text{Ker } (\mathcal{L})$. All we need to show is that the dimension of Ker $(\mathcal{L})$ is at most 1. To this end, let $\phi \in \text{Ker } (\mathcal{L})$. We first show that the nonlocal term vanishes. In fact, summing up all the equations and using the assumptions (H1) and (H2), we obtain

$$\Delta\left(\sum_{j=1}^N \phi_j\right) - \left(\sum_{j=1}^N \phi_j\right) + 2w\left(\sum_{j=1}^N \phi_j\right) - 2(1-\eta)\frac{\int_R w(\sum_{j=1}^N \phi_j)}{\int_R w^2} w^2 = 0$$

since $\beta_0 = \sqrt{1+\tau\lambda_0} = 1$.

That is,

$$\Delta\left(\sum_{j=1}^N \phi_j - cw\right) - \left(\sum_{j=1}^N \phi_j - cw\right) + 2w\left(\sum_{j=1}^N \phi_j - cw\right) = 0, \tag{C.1}$$

where

$$c = 2(1-\eta)\frac{\int_R w(\sum_{j=1}^N \phi_j)}{\int_R w^2}. \tag{C.2}$$

By Lemma 5.1 (1)

$$\sum_{j=1}^N \phi_j - cw \in \text{Ker } (L_0) = \text{span}\{w'\}.$$

So we have

$$\int_R w\left(\sum_{j=1}^N \phi_j - cw\right) = 0.$$

Substituting this relation into (C.2), we get

$$\int_R w\sum_{j=1}^N \phi_j = 0$$

since

$$2(1-\eta) \neq 1.$$

Thus in $\mathcal{L}$ the nonlocal term vanishes, and we obtain the following system of equations:

$$\Delta\phi_i - \phi_i + w\phi_i + \sum_{j=1}^{N} b_{ij} w\phi_j = 0, \quad i = 1, \dots, N.$$

We decompose

$$\mathbf{B} = \mathcal{P}\mathcal{D}\mathcal{P}^{-1}$$

as in (2.17) of section 2.

Set

$$\Phi_i = \sum_{j=1}^{N} p_{ij}^{-1} \phi_j.$$

Then the operator L can be expressed in terms of Φ as follows:

$$\Delta\Phi_i - \Phi_i + w\Phi_i + \sum_{j=1}^{N} d_{ij}\Phi_j w = 0.$$

If $1+\sigma \notin$ spec (EVP) (recall that (EVP) was defined in Lemma 5.1 (2)), then by the last line of the Jordan block corresponding to σ we get $\Phi_i = 0$ using Lemma 5.1. Using this in the previous line, we get $\Phi_{i-1} = 0$, etc. This implies that all components of Φ in the Jordan block corresponding to σ vanish.

If $1+\sigma \in$ spec (EVP), then by hypothesis (H3) we have $\sigma = 1$. By assumption (H3), the eigenvalue $\sigma = 1$ is simple. Since $\Phi_j = 0, j = 2, \dots, K$, we are left with Φ_1 only.

Now by Lemma 5.1 (1) we get $\Phi_1 \in \text{Ker } (L_0) = \text{span}\{w'\}$.

In conclusion, we have proved that except for $i = 1$, where $\Phi_1 = cw'$, $c \in R$, for all other $i = 2, \dots, N$, it holds that $\Phi_i = 0$. This implies that the dimension of Ker$\mathcal{L}$ is at most 1.

This finishes the proof of Lemma 6.4 (1). □

Proof of Lemma 6.4 (2). To show that $\mathcal{L}$ is invertible from $\mathcal{K}_0^{\perp,1} \to \mathcal{K}_0^{\perp,2}$, we need only to show that the conjugate operator of $\mathcal{L}$, denoted by $\mathcal{L}^*$, has the kernel $\mathcal{K}_0$. In fact, let $\phi \in \text{Ker}(\mathcal{L}^*)$. Then we have

$$\Delta\phi_i - \phi_i + \phi_i w + \sum_{j=1}^{N} b_{ji}\phi_j w$$

$$-2(1-\eta)\frac{\int_R w^2 \sum_{i=1}^{N} \xi_i\phi_i}{\int_R w^2 (\sum_{i=1}^{N} \xi_i)} w = 0, \quad i = 1, \dots, N.$$

Multiplying the ith equation by ξ_i and summing up all the equations, by (H1) we have the following:

$$\text{(C.3)}\ \Delta\left(\sum_{i=1}^{N} \xi_i\phi_i\right) - \left(\sum_{i=1}^{N} \xi_i\phi_i\right) + 2w\left(\sum_{i=1}^{N} \xi_i\phi_i\right) - 2(1-\eta)\frac{\int_R w^2 (\sum_{i=1}^{N} \xi_i\phi_i)}{\int_R w^2} w = 0.$$

Multiplying (C.3) by w and then integrating over R, we obtain

$$(1-2(1-\eta))\int_R w^2 \sum_{i=1}^N \xi_i\phi_i = 0.$$

Since $2(1-\eta) \neq 1$, it is easy to deduce that

$$\int_R w^2 \sum_{i=1}^N \xi_i\phi_i = 0.$$

This means that the nonlocal term vanishes. The rest of the proof of Lemma 6.4 (2) is similar to that of Lemma 6.4 (1), since spec $(\mathcal{B})$ = spec $(\mathcal{B}^\tau)$, and may be omitted. □

MEMORY DRIVEN INSTABILITY IN A DIFFUSION PROCESS*

BRIAN R. DUFFY[†], PEDRO FREITAS[‡], AND MICHAEL GRINFELD[†]

Abstract. We consider the n-dimensional version of a model proposed by Olmstead et al. [*SIAM J. Appl. Math.*, 46 (1986), pp. 171–188] for the flow of a non-Newtonian fluid in the presence of memory. We prove the existence of a global attractor and obtain conditions for the existence of a Lyapunov functional, which allows us to give a full description of this attractor in a certain region of the parameter space in the bistable case. We then study the stability and bifurcation of stationary solutions and, in particular, prove that for certain values of the parameters it is not possible to stabilize the flow by increasing a Rayleigh-type number. The existence of periodic and homoclinic orbits is also shown by studying the Bogdanov–Takens singularity obtained from a center manifold reduction.

Key words. parabolic systems, memory effects, non-Newtonian fluids

1. Introduction.

In [14] Olmstead et al. studied the following equation as a model for the flow of a viscoelastic fluid:

$$u_t = \int_{-\infty}^{t} K(t,\ s) u_{xx}(x,s) ds + Rf(u), \tag{1.1}$$

on $x \in I = (0, \pi)$ and $t > 0$, subject to the Dirichlet boundary conditions

$$u(0,\ t) = u(\pi, t) = 0$$

and the initial condition $u(x, s) = u_0(x, s),\ s \leq 0$. Here $u(x, t)$ is the velocity of the fluid, R is a Rayleigh-type number, and f is taken to be cubic-like.

It is not hard to see (consulting [15], for example) that this equation cannot realistically describe the behavior of viscoelastic fluids. However, it is worth studying as it describes a reaction-diffusion process in a medium with memory (see [16] for a discussion of the diffusion processes in such media). In addition, it turns out to be an interesting mathematical object.

The bulk of [14] considers the case of the Jeffreys kernel

$$K(t,\ s) = \frac{1-\alpha}{\lambda} e^{-(t-s)/\lambda} + 2\alpha\delta(t-s),$$

with $\alpha \in [0,\ 1]$ and where δ denotes the Dirac delta function. Here λ has the physical meaning of relaxation time, and α is the ratio of retardation to relaxation times. If $\alpha = 0$, we have the Maxwell kernel, while if $\alpha = 1$ we recover the standard reaction-diffusion case. This case is also recovered in the limit $\lambda \to 0$, as is easily seen, for example, from (2.2).

One of the characteristics of the Jeffreys kernel is that the stationary solutions depend only on the Rayleigh number. However, their stability does depend on the values taken by α and λ as well as R. This is, of course, due to the existence of other solutions, such as periodic solutions, which may bifurcate from the stationary solutions.

The stability and bifurcation analysis carried out in [14] was mainly based on the study of a set of ordinary differential equations obtained by a truncated Fourier series expansion. It is known that systems obtained by such procedures may display a behavior which is different from that of the original equation.

The purpose of the present paper is to carry out, in a rigorous way, the same type of study as in [14], but now for the n-dimensional version of (1.1), that is,

$$u_t = \int_{-\infty}^{t} K(t,s)\Delta u(x,s)ds + Rf(u), \quad x \in \Omega. \tag{1.2}$$

Here K is as before, Ω is a bounded domain in $\mathbb{R}^n$, and we consider Dirichlet boundary conditions. The function f is typically cubic-like, and whenever it will be necessary to be specific we will take f to be $u(1-u^2)$, although most of the results hold for more general classes of functions.

We begin by rewriting (1.2) as a strongly damped wave equation and then go on to show the existence of a Lyapunov functional for a certain region in parameter space. We then prove the existence of a global attractor with the help of invariant rectangles. This allows us to completely describe the attractor in the case where the Lyapunov functional exists, provided a bistable bifurcation diagram is assumed.

We then consider the stability and bifurcation of stationary solutions in terms of the parameters α, λ, and R. We relate the stability of the stationary solutions to that of the stationary solutions of a scalar parabolic equation and then go on to prove that there exist unbounded regions $\mathcal{Q}_1$ and $\mathcal{Q}_2$ in parameter space such that stable solutions of the parabolic equation remain stable in $\mathcal{Q}_1$, while in $\mathcal{Q}_2$ all stationary solutions of (1.1) become unstable. In particular, $\mathcal{Q}_2$ allows for R to be unbounded, which means that for certain values of α and λ it is not possible to stabilize the stationary solutions by increasing the value of the Rayleigh-type parameter R.

We remark that the results obtained in [14] for the finite-dimensional approximation actually state that for all positive α there exists a value of R, say R^*, such that for all $R > R^*$ there exists a nontrivial stable stationary solution. Thus, apart from the interest of this result as far as the behavior of solutions of (1.2) is concerned—large Rayleigh numbers do not necessarily stabilize the flow—it also illustrates the fact that finite-dimensional approximations, such as those considered in [14], may not represent the behavior of the infinite-dimensional system faithfully in this case. See section 7 for details.

The proof of these results relies on a careful analysis of the spectrum of the linearized operator around the stationary solutions and is based on the methods developed in [2, 3] and on the asymptotics of the stationary solution for large R. This enables us to reduce the problem to the study of a simpler self-adjoint operator, and we actually show that under certain conditions the linearization of (1.2) around a stationary solution always has positive *real* eigenvalues. This analysis also enables us to show that, by decreasing α and increasing λ, stationary solutions undergo a series of bifurcations due to pairs of complex eigenvalues crossing the imaginary axis from left to right, thus increasing the instability indices of these solutions; for a more precise statement, see Proposition 5.3.

Regarding the study of the bifurcations occurring in (1.2), we finally consider the linearized operator around the trivial solution for the values of the parameters for which there exists a double zero eigenvalue, and we make a center manifold reduction. This enables us to make a rigorous study of the behavior of solutions near that point. In particular, we show that this double zero eigenvalue corresponds to a Bogdanov–Takens singularity of the type studied in [7], and we obtain a complete description of the bifurcations occurring near this point. In the last section, the results obtained are then compared with those from [14].

2. The associated wave equation. As in [14], we begin by transforming the integro-differential equation (1.2) into a pair of coupled partial differential equations by introducing the auxiliary variable

$$v(x,t) = \frac{1-\alpha}{\lambda}\int_{-\infty}^{t} e^{-(t-s)/\lambda}u(x,s)\,ds. \tag{2.1}$$

This leads to the following system of equations:

$$\begin{cases} u_t = \alpha\Delta u + \Delta v + Rf(u), \\ \lambda v_t = (1-\alpha)u - v, \end{cases} \tag{2.2}$$

subject to homogeneous Dirichlet conditions in Ω and initial conditions at $t = 0$ derived from $u_0(x,s)$ in an obvious way. Note that, except in the case where α is one, we have from

$$v(x,0) = \frac{1-\alpha}{\lambda}\int_{-\infty}^{0} e^{s/\lambda}u(x,s)\,ds$$

that by taking

$$u(x,t) = e^{t/\lambda}\left[\left(1+\frac{2t}{\lambda}\right)u_0(x) - \frac{4t}{(1-\alpha)\lambda}v_0(x)\right], \quad t \leq 0,$$

for instance, it is possible to choose the initial conditions at $t = 0$ to be any given pair (u_0, v_0).

For the study below, it is convenient to rewrite (2.2) as a scalar equation

$$\lambda u_{tt} + \left[1-\lambda Rf'(u)\right]u_t = \Delta u + \alpha\lambda\Delta u_t + Rf(u), \tag{2.3}$$

together with Dirichlet boundary conditions and initial conditions of the form $u(x,0) = u_0(x)$ and $u_t(x,0) = u_1(x)$. In particular, keeping in mind that when α is one v vanishes identically, we now see that, as the parameter α goes from 0 to 1, we go from a damped wave equation to a reaction-diffusion equation, namely,

$$u_t = \Delta u + Rf(u). \tag{2.4}$$

It now becomes relatively simple to obtain conditions for the existence of a Lyapunov functional, and it will also be possible to apply the results from [3] directly—see sections 3 and 5, respectively.

This form of the equation also shows that nonzero values of α actually have the effect of adding a strong damping term to the wave equation corresponding to the Maxwell kernel ($\alpha = 0$).

Existence, uniqueness, and continuous dependence of solutions for (2.2) in the space $Z = \left[H^2(\Omega) \cap H_0^1(\Omega)\right] \times L^2(\Omega)$ now follow from standard results—see [12, 8], for instance.

3. Existence of a Lyapunov functional. Multiplying (2.3) by u_t and integrating over Ω gives

$$\begin{aligned}\frac{d}{dt}\int_\Omega \frac{\lambda}{2}u_t^2 dx &= -\int_\Omega \left[1-\lambda R f'(u)\right] u_t^2 dx + \int_\Omega u_t \Delta u dx \\ &\qquad + \alpha\lambda\int_\Omega u_t\Delta u_t dx + R\int_\Omega f(u)u_t dx \\ &= -\int_\Omega \left[1-\lambda R f'(u)\right] u_t^2 dx - \int_\Omega \nabla u\cdot\nabla u_t dx \\ &\qquad -\alpha\lambda\int_\Omega |\nabla u_t|^2 dx + R\frac{d}{dt}\int_\Omega F(u)dx,\end{aligned}$$

where F is a primitive of f and we have used integration by parts. By Poincaré's inequality, we thus have

$$\begin{aligned}\frac{d}{dt}\int_\Omega \frac{\lambda}{2}u_t^2 + \tfrac{1}{2}|\nabla u|^2 - RF(u)dx &= -\int_\Omega \left[1-\lambda R f'(u)\right] u_t^2 dx - \alpha\lambda\int_\Omega |\nabla u_t|^2 dx \\ &\le -\int_\Omega \left[1-\lambda R f'(u)+\alpha\lambda\sigma_p\right] u_t^2 dx,\end{aligned}$$

where σ_p is the principal eigenvalue of the Dirichlet Laplacian for the domain Ω.

Defining

$$M = \sup_{u\in\mathbb{R}}\left[f'(u)\right] \quad \text{and} \quad \Theta = \lambda(\alpha\sigma_p - MR)+1,$$

we have proven the following theorem.

THEOREM 3.1. *If Θ is positive, then the functional*

$$\mathcal{L}(u) = \int_\Omega \frac{\lambda}{2}u_t^2 + \frac{1}{2}|\nabla u|^2 - RF(u)dx$$

is strictly decreasing along trajectories of (2.3), *except at stationary solutions.*

If, for instance, F is bounded from above, then $\mathcal{L}$ is bounded from below, and, provided that all equilibria are isolated, we have that solutions converge to an equilibrium as t goes to infinity. In particular, this gives the following corollary.

COROLLARY 3.2. *Assume that $f(0)$ is zero, F is bounded from above, and both $\sigma_p - MR$ and Θ are positive. Then all solutions of* (2.3) *converge to zero.*

Proof. Since Θ is assumed to be positive and F is bounded from above, if we prove that there are no stationary solutions other than the trivial solution, we must have all solutions converging to zero.

The stationary solutions satisfy

$$\left\{\begin{array}{l}\Delta u + Rf(u) = 0,\\ v = (1-\alpha)u,\end{array}\right. \tag{3.1}$$

together with Dirichlet boundary conditions. If we multiply the first of these equations by Δu and integrate over Ω, we obtain

$$\int_\Omega (\Delta u)^2 dx = -R\int_\Omega f(u)\Delta u dx = R\int_\Omega f'(u)|\nabla u|^2 dx,$$

where in the integration by parts it was taken into account that $f(0)$ vanishes. We thus have that

$$\int_\Omega (\Delta u)^2 dx - MR\int_\Omega |\nabla u|^2 dx \leq 0.$$

On the other hand, using an argument similar to that used in [4] for the case of a compact manifold, we have that the functional

$$\int_\Omega (\Delta u)^2 dx - \xi\int_\Omega |\nabla u|^2 dx$$

is nonnegative for ξ less than or equal to σ_p. Hence, if $MR < \sigma_p$, it follows that u must vanish. ▯

4. Existence and structure of the attractor. In this section, we assume for simplicity that $f(u) = u(1-u^2)$, but clearly the results described are true for more general functions, as long as the necessary dissipativity conditions hold. We begin by showing the existence of invariant rectangles for α in $(0,1]$. This together with the results from [11] imply the existence of a compact connected attractor in $L^2 \times L^2$ for (2.2). For the parameter region where a Lyapunov functional exists, it is then possible to apply Mischaikow's results [13] to obtain the following theorem.

THEOREM 4.1. *The semigroup associated with* (2.3) *(and hence that associated with* (1.2)*) has a global attractor* $\mathcal{A}_{R,\lambda,\alpha}$ *in* L^2 *for* α *in* $(0,1]$. *Furthermore, if* Θ *is positive and the bifurcation diagram of stationary solutions is bistable, the flow on the attractor is semiconjugate to the flow on the Chaffee–Infante attractor* $\mathcal{A}_{R,\lambda,1}$.

Proof. We begin by rewriting system (2.2) so that the diffusion matrix is in diagonal form. For α in $(0,1]$, let

$$\begin{bmatrix} u \\ v \end{bmatrix} = \begin{bmatrix} 1 & 1 \\ 0 & -\alpha \end{bmatrix} \begin{bmatrix} w \\ z \end{bmatrix}.$$

This yields

$$\begin{cases} w_t = \alpha\Delta w + h(w,z), \\ z_t = -\dfrac{1}{\alpha\lambda}\left[(1-\alpha)w + z\right], \end{cases}$$

where

$$h(w,z) = g(w+z) + \frac{1}{\lambda}z \quad\text{and}\quad g(t) = Rf(t) + \frac{1-\alpha}{\alpha\lambda}t.$$

Now consider the "kinetic equations" associated to this system, that is,

$$\begin{cases} w' = h(w,z), \\ z' = -\dfrac{1}{\alpha\lambda}\left[(1-\alpha)w + z\right]. \end{cases} \tag{4.1}$$

To prove the existence of invariant rectangles, we now proceed as in [18] and show that there are arbitrarily large rectangles in the (w,z) plane on the boundary of which the vector field of the "kinetic system" (4.1) points inward.

Let ℓ_1, ℓ_2, and ℓ_3 denote the lines in the plane wz defined by (see Figure 4.1)

$$z = (\alpha-1)w,\ z = -w - \sqrt{\frac{1}{3} + \frac{1}{3\alpha\lambda R}},\ \text{ and }\ z = -w + \sqrt{\frac{1}{3} + \frac{1}{3\alpha\lambda R}}.$$

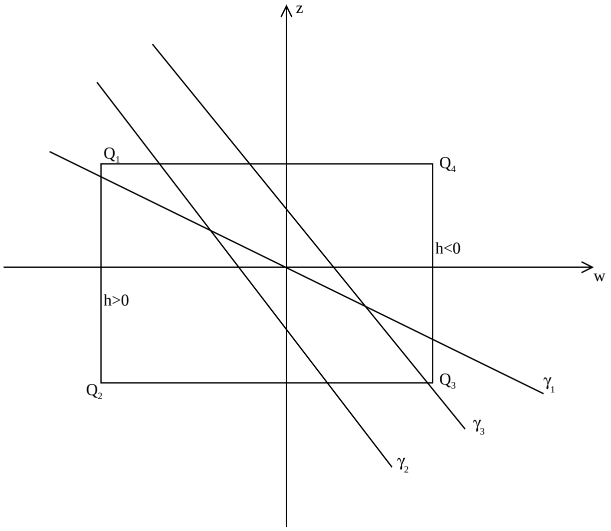

FIG. 4.1. *Invariant rectangles.*

First, note that for α in $(0, 1)$, γ_1 always intersects γ_2 and γ_3 and that z' is positive below γ_1 and negative above this line.

We have that

$$\frac{\partial h(w,z)}{\partial z} = g'(w+z) + \frac{1}{\lambda} = R(1-3(w+z)^2) + \frac{1}{\alpha\lambda}$$

is positive between γ_2 and γ_3 and negative otherwise. Furthermore, note that on γ_1 we have that $wh(w,z) = wh(w,(\alpha-1)w) = Rwf(\alpha w)$ is negative for $|w|$ large enough. It is thus possible to pick a point slightly above γ_1 (but still below γ_2) with negative w coordinate and such that h is positive at this point. In a similar way, it is possible to pick a point slightly below γ_1 (but above γ_3) with positive w coordinate and such that h is negative there. Denote these points by Q_1 and Q_3, respectively.

Now choose a point $Q_2 = -(w_1, z_1)$ in the third quadrant such that $-w_1$ is equal to the w coordinate of Q_1 and $-z_1$ is less than the z coordinate of Q_3. Then $h(Q_2)$ is positive on the segment Q_1Q_2 since $\partial h/\partial z$ is negative on that segment.

Now let Q_4 be a point in the first quadrant with z coordinate equal to that of Q_1 and w coordinate equal to that of Q_3. Then, since $h(Q_3)$ is negative and $\partial h/\partial z$ is negative above γ_3, it follows that h remains negative on the line segment Q_3Q_4.

In this way, we have that the rectangle $R = Q_1Q_2Q_3Q_4$ is such that $w' = h$ is positive on the left vertical side and negative on the right vertical side, and z' is positive on the lower horizontal side and negative on the upper horizontal side. Since the same construction starting from points Q_1 and Q_3 with more negative and more positive w coordinates, respectively, will still give a rectangle with these properties, we have shown the existence of arbitrarily large invariant rectangles for this equation. Verification of conditions (4.5)–(4.7) of [11] is now immediate, and we obtain the existence of a compact attractor in the space H of L^2 functions u and v taking almost all values in the invariant rectangle.

Hence, if the bifurcation diagram is bistable, as in the case considered in [14], under the conditions of Theorem 3.1 we can apply Mischaikow's results to conclude that the dynamics on the attractor of (2.3) (and thus of (1.2)) is semiconjugate to that of the Chaffee–Infante attractor corresponding to $\alpha = 1$. □

5. Stability of stationary solutions. In the specific case of a cubic-like function, such as that described in the introduction, the stationary problem (3.1) has been exhaustively studied in the literature—see, for instance, [10] for a survey of results regarding the existence of positive solutions for the elliptic problem associated with (2.4). In particular, we have that for $f(u) = u(1 - u^2)$ there is a branch of stable positive solutions bifurcating from the trivial solution and existing for all R larger than σ_p.

Linearizing (2.3) around a stationary solution corresponding to $(\bar{u}, (1-\alpha)\bar{u})$, we obtain the following eigenvalue problem in μ:

$$(1 + \alpha\lambda\mu)\Delta\phi + R(\lambda\mu + 1)a(x)\phi = \mu(\lambda\mu + 1)\phi \tag{5.1}$$

in Ω with Dirichlet boundary conditions and where $a(x) = f'(\bar{u})$. Methods that enable us to deal with problems of this type have been considered by the second author in [3]. From the results there, we immediately obtain the following proposition.

Proposition 5.1. *Let T be the operator obtained by linearizing* (2.2) *around a stationary solution. Then the spectrum of T consists of eigenvalues of finite multiplicity and exactly one point of the essential spectrum, $\mu = -1/(\alpha\lambda)$. Furthermore, there exist real numbers $\rho_0 > 0$ and $\pi/2 < \theta_0 < \pi$ such that the whole spectrum is contained inside a sector of the form $\{\lambda \in \mathbb{C} : \lambda = \rho_0 + \rho e^{i\theta}, |\theta| > \theta_0\}$.*

The idea behind the methods used in [3]—see also [2]—is to relate the eigenvalue problem (5.1) to a simpler self-adjoint problem. In order to do this, we rewrite (5.1) in the more familiar form

$$L_p\phi := \Delta\phi + pRa(x)\phi = \gamma\phi \tag{5.2}$$

by letting

$$\gamma = \frac{\mu(\lambda\mu + 1)}{\lambda\alpha\mu + 1} \quad \text{and} \quad p = \frac{\lambda\mu + 1}{\lambda\alpha\mu + 1}.$$

Consequently, we have that a real number $\mu \neq -1/(\alpha\lambda)$ will be a real eigenvalue of (5.1) provided that

$$\begin{cases} \mu = \dfrac{p - 1}{\lambda(1 - \alpha p)}, \\ \gamma = \dfrac{p(p - 1)}{\lambda(1 - \alpha p)}. \end{cases} \tag{5.3}$$

From the first of these equations we see that the values of the auxiliary parameter p that correspond to positive values of μ are $p \in (1, 1/\alpha)$. We thus look for intersections of the curve Γ defined by the second equation with the eigencurves of L_p, $\gamma_k(p)$, for $p \in (1, 1/\alpha)$. Note that, in particular, $\gamma_k(1)$ are the eigenvalues of the linearization of the reaction-diffusion equation (2.4).

A straightforward result is that for each positive eigenvalue $\gamma_j(1)$ of the operator L_1 there must exist at least one intersection between Γ and $\gamma_j(p)$ for p in $(1, 1/\alpha)$, and thus there corresponds at least a positive eigenvalue of problem (5.1). By noting that L_1 is precisely the operator associated with the linearization of (2.4) around the same stationary solution, we have the following theorem.

Theorem 5.2. *Let (u, v) be a stationary solution of* (2.2). *Then the dimension of the unstable manifold of (u, v) as a solution of this equation is greater than or equal to the dimension of the unstable manifold of u as a solution of* (2.4). *In particular, in the case where Ω is a ball, the only stationary solutions that may be stable are those which do not change sign.*

If Θ is positive, then the stability of the stationary solution is the same in both cases.

Proof. The first part is a simple consequence of the results in [3]. For the second part, multiply (5.1) by $\overline{\phi}$, and integrate by parts to obtain

$$-(1+\alpha\lambda\mu)\int_\Omega |\nabla\phi|^2 dx + R(\lambda\mu+1)\int_\Omega a(x)|\phi|^2 dx = \mu(\lambda\mu+1), \tag{5.4}$$

where it is assumed that ϕ has been normalized. Now separating μ into real and imaginary parts, we have from the equation for the imaginary parts that

$$-\alpha\lambda \mathrm{Im}(\mu)\int_\Omega |\nabla\phi|^2 dx + \lambda R \mathrm{Im}(\mu)\int_\Omega a(x)|\phi|^2 dx = \mathrm{Im}(\mu)\left[2\lambda\mathrm{Re}(\mu)+1\right].$$

It thus follows that either

$$-\alpha\lambda\int_\Omega |\nabla\phi|^2 dx + \lambda R\int_\Omega a(x)|\phi|^2 dx = 2\lambda\mathrm{Re}(\mu)+1$$

or $\mathrm{Im}(\mu)$ is zero. In the first case, we have that

$$2\lambda\mathrm{Re}(\mu) = -\alpha\lambda\int_\Omega |\nabla\phi|^2 dx + \lambda R\int_\Omega a(x)|\phi|^2 dx - 1 \le -\Theta,$$

and thus there are no nonreal eigenvalues with nonnegative real part when Θ is positive. This means that in this case the instability of a solution is determined only by the real eigenvalues.

Now assume that $\mathrm{Im}(\mu) = 0$. Then, for any positive eigenvalue of the linearization of the scalar parabolic equation (2.4) around the stationary solution, we have that the eigencurve γ of L_p passes through that point when p equals one. By continuity it must intersect the curve Γ defined by the second equation in (5.3) at some point $p \in (1, 1/\alpha)$. This shows that the same stationary solution is also unstable as a stationary solution of (2.3).

If, on the other hand, the stationary solution is asymptotically stable when considered as a stationary solution of (2.4), while it is unstable as a solution of (2.3), this means that there are at least two intersection points (counting multiplicities) of the eigencurve with the curve Γ from (5.3) for $p \in [1, 1/\alpha)$. There are now two cases to consider. First assume that the two intersections take place for p strictly larger than one. Since changing either of the two parameters α or λ does not affect the stationary solutions (and hence does not affect the eigencurve), it would now be possible, by making λ sufficiently small, or α sufficiently close to one, to change the curve Γ without changing the sign of Θ in such a way that no intersection takes place. This implies that the real eigenvalues have come together and become complex, which is not possible since we have seen that for positive values of Θ there are no nonreal eigenvalues with nonnegative real parts.

Now assume that one of the intersections takes place when p equals one. Then, again making λ sufficiently small or α sufficiently close to one, it is possible to make the positive eigenvalue cross zero and become negative, which would imply the existence of a bifurcation from a real eigenvalue giving rise to a stationary solution and contradicting the fact that the existence of stationary solutions does not depend on the parameters α or λ.

Finally, note that zero eigenvalues can occur only for intersections at p equal to one, and thus there exists a zero eigenvalue for (2.3) if and only if there exists one for (2.4). Also, if the stationary solution is stable for (2.4), then a zero eigenvalue must be simple as it is the first eigenvalue. Thus if there existed a zero eigenvalue with a higher multiplicity for (2.3), this would mean that a slight increase of the parameter λ would cause an eigenvalue to cross zero and become positive, while keeping Θ positive. This would again imply the existence of a bifurcation from a real eigenvalue, giving a contradiction. $\square$

From what has been seen, it seems likely that increasing λ and picking α close to zero will have a destabilizing effect on stationary solutions. This is indeed the case, as the following result shows.

Proposition 5.3. *Fix R, and let $(\bar{u}, (1-\alpha)\bar{u})$ be a stationary solution of* (2.2). *There exists a decreasing sequence of positive numbers α_k, $k = 1, \ldots,$ with $\alpha_1 < 1$, and an increasing sequence λ_k, $k = 1, \ldots,$ depending on α, such that for all $\alpha \in (\alpha_{k+1}, \alpha_k)$, if $\lambda > \lambda_k$, then there are at least $2k$ positive real eigenvalues of the linearized operator around the stationary solution $(\bar{u}, (1-\alpha)\bar{u})$.*

Proof. Denote by p_k^* the intersection point of the kth eigencurve for L_p with the positive part of the horizontal axis. From Proposition 2.3 in [2] we have that

$$\gamma_k(p) \geq \frac{\gamma_k(p_k^*) - \gamma_1(0)}{p_k^*} p + \gamma_1(0) = -\frac{\gamma_1(0)}{p_k^*} p + \gamma_1(0) \quad (p > p_k^*),$$

as $\gamma_k(p) > 0$ for all $p > p_k^*$. Thus, if $1/\alpha_k > p_k^*$, it follows that the eigencurve γ_k will have a portion above a straight line with positive inclination which is also above the p-axis on some subinterval of $(1, 1/\alpha_k)$. If we now take λ_k to be large enough, it follows that the graphs of γ_k and Γ must intersect at least twice for $p \in (1, 1/\alpha_k)$, giving rise to at least one pair of real positive eigenvalues. $\square$

Since, for α equal to one, the point spectrum coincides with that of the reaction-diffusion equation and the point of the essential spectrum is situated at $-1/\lambda$, we might expect that by making α close to one, solutions which are stable for the scalar equation (2.4) will remain stable.

Theorem 5.4. *Assume that $\bar{u}$ is a stable stationary solution of* (2.4), *and define*

$$\alpha_* = \frac{RM - 1/\lambda}{RM - \gamma_1(1)}.$$

If $\alpha > \alpha_*$, then $(\bar{u}, (1-\alpha)\bar{u})$ is a stable stationary solution of (2.3).

Proof. From (5.4) we have that μ satisfies the quadratic equation

$$\lambda\mu^2 + \left(1 + \alpha\lambda \int_\Omega |\nabla\phi|^2 dx - \lambda R \int_\Omega a(x)|\phi|^2 dx\right)\mu \\ + \int_\Omega |\nabla\phi|^2 dx - R\int_\Omega a(x)|\phi|^2 dx = 0,$$

and thus the stationary solution will be stable if and only if

$$\int_\Omega |\nabla\phi|^2 dx - R\int_\Omega a(x)|\phi|^2 dx > 0 \tag{5.5}$$

and

$$1 + \alpha\lambda \int_\Omega |\nabla\phi|^2 dx - \lambda R \int_\Omega a(x)|\phi|^2 dx > 0. \tag{5.6}$$

Since $\bar{u}$ is a stable solution of (2.4), we have that

$$\gamma_1(1) = \sup\left[-\int_\Omega |\nabla u|^2 dx + R\int_\Omega a(x)|u|^2 dx\right] < 0,$$

where the supremum is taken over all functions u in $H_0^1(\Omega)$ with $L^2(\Omega)$ norm 1. In particular,

$$\int_\Omega |\nabla\phi|^2 dx - R\int_\Omega a(x)|\phi|^2 dx \geq -\gamma_1(1) > 0,$$

showing that (5.5) is satisfied.

On the other hand, multiplying this last inequality by λ and adding 1 to both sides give

$$1 + \lambda\int_\Omega |\nabla\phi|^2 dx - \lambda R\int_\Omega a(x)|\phi|^2 dx \geq 1 - \gamma_1(1)\lambda,$$

and so

$$1 + \alpha\lambda\int_\Omega |\nabla\phi|^2 dx - \lambda R\int_\Omega a(x)|\phi|^2 dx \geq 1 - \gamma_1(1)\lambda + \lambda(\alpha - 1)\int_\Omega |\nabla\phi|^2 dx. \tag{5.7}$$

There are now two cases to consider. If

$$\int_\Omega |\nabla\phi|^2 dx < \frac{1 - \lambda\gamma_1(1)}{(1-\alpha)\lambda},$$

then the right-hand side of (5.7) is positive for all values of α, and we are done. Assume thus that

$$\int_\Omega |\nabla\phi|^2 dx \geq \frac{1 - \lambda\gamma_1(1)}{(1-\alpha)\lambda}.$$

Then

$$1 + \alpha\lambda\int_\Omega |\nabla\phi|^2 dx - \lambda R\int_\Omega a(x)|\phi|^2 dx \geq 1 + \frac{\alpha(1 - \lambda\gamma_1(1))}{1-\alpha} - \lambda RM,$$

and this last expression is positive for α in $(\alpha_*, 1)$. □

A straightforward consequence of this result is that for each stable solution of (2.4) there exists a value of α strictly smaller than 1, say α_{**}, such that the corresponding solution of (2.3) is stable for all α in $(\alpha_{**}, 1]$ and all λ. The following corollary gives precise details.

COROLLARY 5.5. *If $\bar{u}$ is as above and α is larger than $RM/(RM - \gamma_1(1))$, then $(\bar{u}, (1-\alpha)\bar{u})$ is stable for all positive values of λ.*

Note that both here and in Theorem 5.4 the term $\gamma_1(1)$ depends on the parameter R.

5.1. Positive solutions in balls. Theorem 5.2 states that only stationary solutions which are stable for the reaction-diffusion equation (2.4) may be stable for the wave equation (2.3). In this section, we show that there are regions in parameter space (α, λ) for which there are no stable solutions for any values of the parameter R. The proof uses estimates for the first eigencurve $\gamma_1(p)$ for large values of the parameter R.

In order to be able to obtain these estimates, we now restrict ourselves to the case where Ω is a ball and consider the specific case of $f(u) = u(1-u^2)$, although similar results could be obtained by the same methods for other types of functions, such as $f(u) = u(1-u^{p-1})$ for other values of p larger than one. Because Ω is a ball, only solutions which do not change sign can be stable when considered as stationary solutions of (2.4), and thus we now concentrate on branches of positive solutions. For this type of function, it is known that there exists a value of R, say R^*, such that for all R larger than R^* there exists one (and only one) positive stationary solution which is stable for (2.4).

THEOREM 5.6. *Assume that Ω is a ball. There exists α_0 in $(0,1)$, such that for all $0 \leq \alpha < \alpha_0$ there exists λ_0, depending on α, with the property that for all $\lambda > \lambda_0$ all stationary solutions of* (2.3) *are unstable for all values of R.*

By looking at the second equation in (5.3), we see that solutions (in p) corresponding to positive eigenvalues μ can exist only if the eigencurve $\gamma_k(p)$ is positive for some $p \in (1, 1/\alpha)$. As, in this case, all eigencurves are below the p-axis for $p \in (0,1)$, it becomes important to study the point $p_1^*(R)$ where the eigencurve $\gamma_1(p)$ intersects the real axis for positive p. Regarding this, we have the following lemma.

LEMMA 5.7. *Let Ω be the unit ball in $\mathbb{R}^n$. For each $k = 1, \ldots,$ there exists a unique positive value p_k^*, depending on R, such that $\gamma_k(p_k^*) = 0$ and $\gamma_k(p) > 0$ for all $p > p_k^*$. Furthermore, there exists an increasing sequence P_k, such that $p_k^*(R) < P_k$ for all $R > 1$. Furthermore, these values P_k can be chosen to be independent of $n \geq 1$.*

To establish the existence of, say, a value P_1 such that for all R the first eigencurve $\gamma_1(p)$ crosses the p-axis at values of $p < P_1$ requires two different pieces of information. The first ingredient is a uniformly valid matched asymptotics approximation of the (positive) solution u_R of the boundary value problem

$$\Delta u + Rf(u) = 0, \quad x \in \Omega, \ u = 0 \text{ on } \partial\Omega, \tag{5.8}$$

where $f(u) = u - u^3$. Note that by results of [10] such a positive solution exists for all $n \geq 1$ for sufficiently large R; furthermore, by the results of [5] this solution is radially symmetric.

The second ingredient of the proof is just the classical variational characterization of eigenvalues.

Matched asymptotics [9] give us the following representation:

$$u_R(r) \sim \tanh\left(\sqrt{\frac{R}{2}}(1-r)\right) + O(1/\sqrt{R}). \tag{5.9}$$

As $R \to \infty$, this solution is asymptotically equal to one everywhere in the ball far from the boundary, and it has a boundary layer close to $r = 1$ required to meet the boundary condition at $r = 1$. Note that the radially symmetric solution of (5.8) satisfies the boundary value problem

$$u_{rr} + \frac{n-1}{r}u_r + Rf(u) = 0, \quad u_r(0) = u(1) = 0, \tag{5.10}$$

and thus the term involving $(n-1)$ plays no role in the principal terms of either the outer or the inner expansions.

Now, by the variational characterization of eigenvalues, the eigenvalue $\gamma_1(p)$ of the problem

$$\Delta\phi + pRf'(u_R)\phi = \gamma\phi, \quad x \in \Omega,\ \phi = 0 \text{ on } \partial\Omega, \tag{5.11}$$

satisfies

$$\gamma_1(p) = \sup\left\{-\int_\Omega |\nabla\psi|^2 dx + pR\int_\Omega f'(u_R)\psi^2 dx\right\},$$

where the supremum is taken over all functions ψ in $H_0^1(\Omega)$ with $L^2(\Omega)$ norm 1. Hence if we show that for all arbitrarily large R there exist a function ψ_R and a value p^* independent of R such that

$$A = -\int_\Omega |\nabla\psi_R|^2 dx + p^*R\int_\Omega f'(u_R)\psi_R^2 dx > 0,$$

we have established the existence of P_1 and moreover $P_1 \le p^*$.

Consider the solution u_R with the asymptotic representation (5.9). Clearly, the function $f'(u_R)$ changes sign when $u_R = 1/\sqrt{3}$, that is, at the point

$$\overline{r} = 1 - \sqrt{\frac{2}{R}}\tanh^{-1}\left(1/\sqrt{3}\right) + O(1/R).$$

Consider the function $v_R(r)$ defined for $r \in [0,1]$ as follows:

$$v_R(r) = \begin{cases} \sin\frac{\pi(1-r)}{1-\overline{r}} & \text{if } r \in [\overline{r},\, 1], \\ 0 & \text{otherwise.} \end{cases}$$

Now let $\psi_R(r) = v_R(r)/\|v_R\|_2$.

Denoting by σ_n the surface area of the unit sphere, we have then

$$\frac{1}{\sigma_n}\|v_R\|^2 A = -\frac{\pi^2}{(1-\overline{r})^2}\int_{\overline{r}}^1 \cos^2\left[\frac{\pi(1-r)}{1-\overline{r}}\right] r^{n-1}dr$$
$$+pR\int_{\overline{r}}^1 \left[1 - 3\tanh^2\left(\sqrt{\frac{R}{2}}(1-r)\right) + O\left(\frac{1}{\sqrt{R}}\right)\right]\sin^2\left[\frac{\pi(1-r)}{1-\overline{r}}\right] r^{n-1}dr.$$

This can be rewritten as follows:

$$\frac{1}{\sigma_n}\|v_R\|^2 A = -\frac{\pi^2}{1-\overline{r}}\int_0^1 \cos^2(\pi y)(\overline{r} + y(1-\overline{r}))^{n-1}dy + pR(1-\overline{r})$$
$$\times\int_0^1 \left[1 - 3\tanh^2\left((1-y)\tanh^{-1}(1/\sqrt{3})\right) + O(1/\sqrt{R})\right](\overline{r} + y(1-\overline{r}))^{n-1}\sin^2(\pi y)dy.$$

Since $1-\overline{r} = O(1/\sqrt{R})$, this means that

$$\frac{1}{\sigma_n}\|v_R\|^2 A = \sqrt{R}\left[-\frac{\pi^2}{2\sqrt{2}\tanh^{-1}(1/\sqrt{3})} + p\sqrt{2}\tanh^{-1}(1/\sqrt{3})\beta + O(1/\sqrt{R})\right],$$

where

$$\beta = \int_0^1 \left[1 - 3\tanh^2\left((1-y)\tanh^{-1}(1/\sqrt{3})\right)\right] \sin^2(\pi y) dy \approx 0.3353.$$

Hence, if we choose $p > p^* = \pi^2/(4\beta(\tanh^{-1}(1/\sqrt{3}))^2) \approx 16.972$, we are guaranteed that, for all R sufficiently large, A is positive and so will be the eigenvalue $\gamma_1(p)$ for that value of p.

For P_k, $k > 1$, we use the same argument but employ functions

$$v_R^k(r) = \begin{cases} \sin\left[\dfrac{k\pi(1-r)}{1-\overline{r}}\right] & \text{if } r \in [\overline{r},\, 1], \\ 0 & \text{otherwise.} \end{cases}$$

Clearly, v_R^k and v_R^l are orthogonal if $k \neq l$.

Remark 5.1. Numerically, the limiting value P_1 is approximately 10.8 in the one-dimensional case. We present a rough argument to approximate this value. By WKB reasoning we expect for large R the nonnegative eigenfunction to behave as our functions $\psi_R(v)$ above. In fact, we expect the sinusoidal part to be of the form $\sin\left[\sqrt{pR}(1-r)\right]$. On the other hand, we also expect from the variational formulation the sinusoidal part to be $\sin[\pi(1-r)/(1-\overline{r})]$. Thus in the limit we should have $\sqrt{P_1 R} = \pi/(1-\overline{r})$ as $R \to \infty$. But this implies that $P_1 = \pi^2/(2\tanh^{-1}(1/\sqrt{3})^2) \approx 11.38$.

Proof of Theorem 5.6. Let u_R be a stable stationary solution of the system (2.3). By Lemma 5.7 we have that, for any value of R on the interval $(R^*, +\infty)$, there exists a value P_1 such that the eigencurve $\gamma_1(p)$ intersects the horizontal axis at a value p_1^* smaller than P_1 and becomes positive for all values of p larger than p_1^*. This means that it is always possible to choose α_0^1 sufficiently small such that $1/\alpha$ is larger than p_1^*, independently of R, for α smaller than α_0^1. From the proof of Proposition 5.3, we know that the eigencurve is above the straight line joining $\gamma_1(0)$ and P_1. We may then pick λ_0^1 sufficiently large (and again independently of R) such that the curves γ_1 and Γ intersect at a point $(\overline{p}, \overline{\gamma}_1)$ with $\overline{p}$ in the interval $(1, 1/\alpha)$. This implies that the solution u_R is unstable.

Since the number of stable stationary solutions for the parabolic problem (2.4) with the nonlinearity f considered is finite for each value of R, we may now apply the above argument to all of these solutions and obtain values of α_0 and λ_0 for which all solutions are unstable when $\alpha \leq \alpha_0$ and $\lambda \geq \lambda_0$. □

6. The double zero eigenvalue. In this section, we consider a center manifold reduction for the double zero eigenvalue of the linearized equations around the trivial solution. We take $f(u) = u(1-u^2)$, but again it is clear that the argument holds for a much more general class of functions. In order to obtain a projection on the center manifold corresponding to a known form for the Bogdanov–Takens singularity, we rewrite (2.3) as

$$\begin{cases} u_t = w, \\ w_t = \dfrac{1}{\lambda}\Delta u + \alpha\Delta w + \dfrac{R}{\lambda} f(u) + \left[R f'(u) - \dfrac{1}{\lambda}\right] w. \end{cases}$$

This is equivalent to

$$\begin{bmatrix} u_t \\ w_t \end{bmatrix} = C \begin{bmatrix} u \\ w \end{bmatrix} + N(u,w), \tag{6.1}$$

where

$$C = \begin{bmatrix} 0 & 1 \\ \frac{1}{\lambda}(\Delta + R) & \alpha\Delta + \left(R - \frac{1}{\lambda}\right) \end{bmatrix} \quad \text{and} \quad N(u,w) = \begin{bmatrix} 0 \\ -\frac{R}{\lambda}u^3 - 3Ru^2w \end{bmatrix}.$$

The eigenvalue problem corresponding to the linearization around the trivial solution, which corresponds to the eigenvalues of the operator C, is given by

$$\begin{cases} \psi = \mu\phi, \\ \frac{1}{\lambda}\Delta\phi + \frac{R}{\lambda}\phi + \alpha\Delta\psi + \left(R - \frac{1}{\lambda}\right)\psi = \mu\psi. \end{cases}$$

In this case, it is possible to obtain an explicit expression for the eigenvalues, namely,

$$\mu_k^{\pm} = \frac{-\alpha\lambda\sigma_k + R\lambda - 1 \pm \sqrt{(1 - R\lambda + \alpha\lambda\sigma_k)^2 + 4(R - \sigma_k)\lambda}}{2\lambda}, \tag{6.2}$$

where, as before, σ_k denotes an eigenvalue of the Dirichlet Laplacian in Ω, that is,

$$\begin{cases} -\Delta v_k = \sigma_k v_k, & x \in \Omega, \\ v_k = 0, & x \in \partial\Omega. \end{cases}$$

As before, we shall denote the principal eigenvalue by σ_p and the corresponding normalized eigenfunction by v_p. It follows that there exists a double zero eigenvalue if and only if

$$\begin{cases} R = \sigma_k, \ k = 1, 2, \dots, \\ \alpha = 1 - \frac{1}{\lambda\sigma_k}. \end{cases}$$

Note that if α is 1, then it is not possible to satisfy the second equation, and thus there is no double zero eigenvalue in this case. On the other hand, for any α on $[0,1)$ it is possible to choose the remaining parameters R and λ so that zero is, in fact, a double eigenvalue.

Because of stability, we are interested in the case in which $k = 1$, which corresponds to

$$C_1 = \begin{bmatrix} 0 & 1 \\ \frac{1}{\lambda}(\Delta + \sigma_p) & \alpha\Delta + \left(\sigma_p - \frac{1}{\lambda}\right) \end{bmatrix}.$$

An eigenfunction for this operator and which corresponds to the zero eigenvalue is given by $\psi_1 = (v_p, 0)$. The other (generalized) eigenfunction is a solution of

$$C_1 \begin{bmatrix} u \\ w \end{bmatrix} = \begin{bmatrix} v_p \\ 0 \end{bmatrix}.$$

We thus obtain $\psi_2 = (0, v_p)$.

We now make the decomposition of the phase space Z into

$$X = \{rv_p, \ r = (r_1, r_2) \in \mathbb{R}^2\}$$

and $Y = X^{\perp}$. The linear space X is invariant by C, and, with respect to the canonical basis, it can be represented in X by

$$C = \begin{bmatrix} 0 & 1 \\ \epsilon_1 & \epsilon_2 \end{bmatrix},$$

where

$$\text{(6.3)}\qquad \begin{cases} \epsilon_1 = \dfrac{R-\sigma_p}{\lambda}, \\ \epsilon_2 = R - \dfrac{1}{\lambda} - \alpha\sigma_p. \end{cases}$$

In this case, M is equal to 1, and thus ϵ_2 is equal to $-\Theta/\lambda$. To see that it is possible to unfold the singularity by means of the parameters R and λ, for any value of α in $[0,1)$, we have to prove that the map taking (R,λ) to (ϵ_1,ϵ_2) is surjective near $(R^*,\lambda^*) = (\sigma_p, 1/(1-\alpha)\sigma_p)$. This follows from the fact that the Jacobian matrix for this map is given by

$$\begin{bmatrix} \dfrac{1}{\lambda} & \dfrac{\sigma_p - R}{\lambda^2} \\ 1 & \dfrac{1}{\lambda^2} \end{bmatrix},$$

and thus its determinant at (R^*,λ^*) is equal to $1/\lambda_*^3$, which is nonzero.

When $\epsilon \equiv (\epsilon_1,\, \epsilon_2) = 0$, the invariant subspace corresponding to the double eigenvalue is spanned by ψ_1 and ψ_2. In this case, $X = \operatorname{span}\{\psi_1,\psi_2\}$, and an element z of Z can be decomposed as $z = rv_p + y$, $r \in \mathbb{R}^2$, $y \in Y$. Following [1], we write (6.1) as

$$\begin{cases} \dot{r} = C(\epsilon)r + \overline{N}(rv_p + y), \\ \dot{y} = D(\epsilon)y + (I-\mathcal{P})N(rv_p+y), \\ \dot{\epsilon} = 0, \end{cases}$$

where $\mathcal{P}$ is the projection from Z on X, defined by

$$\mathcal{P}\begin{bmatrix} u \\ w \end{bmatrix} \;=\; \begin{bmatrix} \displaystyle\int_\Omega uv_p dx \\ \displaystyle\int_\Omega wv_p dx \end{bmatrix} v_p,$$

$D = (I-\mathcal{P})C$, and $\overline{N} : Z \to \mathbb{R}^2$ is given by

$$\overline{N}(u,w) \;=\; \langle \mathcal{P}N(u,w), v_p\rangle \;=\; \begin{bmatrix} 0 \\ -\dfrac{R}{\lambda}\displaystyle\int_\Omega (u^3 + 3\lambda u^2 w)v_p dx \end{bmatrix}.$$

The equation on the center manifold is given by

$$\dot{r} = C(\epsilon)r + \overline{N}(rv_p + h(r,\epsilon)),$$

where $h(r,\epsilon) = (h_1(r,\epsilon), h_2(r,\epsilon)) = O(r^2 + |\epsilon r|)$. The nonzero term in $\overline{N}$ can then be evaluated to give

$$-R\int_\Omega v_p^4 dx \left(\frac{1}{\lambda}r_1^3 + 3r_1^2 r_2\right) + h.o.t.$$

Hence

$$\begin{bmatrix} \dot{r_1} \\ \dot{r_2} \end{bmatrix} \;=\; \begin{bmatrix} 0 & 1 \\ \epsilon_1 & \epsilon_2 \end{bmatrix}\begin{bmatrix} r_1 \\ r_2 \end{bmatrix} \;+\; \begin{bmatrix} 0 \\ -R\displaystyle\int_\Omega v_p^4 dx \left(\frac{1}{\lambda}r_1^3 + 3r_1^2 r_2\right) \end{bmatrix} + h.o.t.$$

Comparing this with the case in section 7.3 of [7], we see that this situation corresponds to having both parameters a_3 and b_3 in there equal to -1. The corresponding behavior is shown in Figures 7.3.7 and 7.3.9 in that section.

We have thus shown the following theorem.

THEOREM 6.1. *In a neighborhood of the double zero eigenvalue of the linearization of* (2.2) *around the trivial solution corresponding to* $(R^*, \lambda^*) = (\sigma_p, 1/((1-\alpha)\sigma_p))$, *the parameters R and λ unfold a Bogdanov–Takens singularity of the type*

$$\begin{cases} \dot{x} = y, \\ \dot{y} = \mu_1 x + \mu_2 y - x^3 - x^2 y \end{cases}$$

for (μ_1, μ_2) *in a neighborhood of* $(0, 0)$. *In particular, in a neighborhood of* (R^*, λ^*), *there are curves of homoclinic solutions of* (2.2) *and of blue sky bifurcations of periodic solutions.*

7. Conclusions. It remains to compare our results with those from [14] and the conclusions derived there.

First, note that the mechanism of restabilization of convection by increasing R, as seen in Figures 5 and 6 of [14, p. 185], cannot be correct, as the branches of stationary solutions that are stable for large R are spurious: these are branches of secondary bifurcations, which do not exist in the infinite-dimensional problem. Furthermore, Theorem 5.6 shows that there are values of λ and α for which there are no stable stationary solutions, independently of the value of R.

On the other hand, we have shown in Theorem 6.1 that the progression (as we increase R) of (a) Hopf bifurcation from the (stable) trivial (conduction) state followed by (b) a pitchfork bifurcation of unstable nontrivial (convection) states, (c) Hopf bifurcation from these nontrivial states (which leads the states without internal zeros to become stable), and (d) the blue sky annihilation of periodic solutions, which is clearly seen in Figures 5 and 6 of [14], persists in the infinite-dimensional system as well. This progression is consistent with the observations of [17] on the transition from conduction to steady convection in viscoelastic fluids via oscillatory convection.

The methods used in this paper were not able to determine whether or not another feature of the truncated dynamics of [14] persists in (2.2), namely, the loss of stability of a *stable* branch of equilibria due to an increase in R. This feature of the truncated dynamics leads to a conjecture that is stronger than the statement of Theorem 5.6, namely, that for any λ and $\alpha < 1$, increasing R will destabilize convection. Clearly, increasing R would eventually make Θ negative. Such a conjecture is also consistent with (again, finite-dimensional) numerics of [6].

Finally, we point out that the case corresponding to the Maxwell kernel ($\alpha = 0$) poses some interesting open problems. In particular, we see from (6.2) that along the line defined by $\lambda R = 1$ there is an infinite-dimensional center manifold.

QUADRILATERAL MACROELEMENTS*

MING-JUN LAI† AND LARRY L. SCHUMAKER‡

Abstract. Macroelements of smoothness C^r depending only on natural derivative information are constructed on triangulated quadrilaterals for all $r \geq 1$.

Key words. bivariate splines, approximation order, quadrangulation, scattered data interpolation

AMS subject classifications. 41A15, 41A63, 41A25, 65D10

PII. S0036141000377134

1. Introduction. Suppose that Q is a convex quadrilateral and that $\triangle_Q$ is the triangulation obtained by splitting Q into four triangles by drawing in the two diagonals. Let v_Q be the intersection of the diagonals.

The first macroelement on $\triangle_Q$ was the C^1 piecewise cubic macroelement constructed in [8, 17]; see also [6]. Later, a class of C^r macroelements on $\triangle_Q$ was constructed in [14, 15]; see also [5]. The aim of this paper is to improve these higher smoothness macroelements by removing unnatural degrees of freedom.

The macroelements in [15] are based on the superspline spaces

$$\begin{aligned} &\mathcal{S}_{6m+1}^{2m+1,3m}(\triangle_Q), \qquad r = 2m, \\ &\mathcal{S}_{6m+3}^{2m+1,3m+1}(\triangle_Q), \qquad r = 2m+1, \end{aligned} \tag{1.1}$$

where, in general, if $\triangle$ is a triangulation of a domain Ω,

$$\mathcal{S}_d^{r,\rho}(\triangle) := \{s \in C^r(\Omega) \ : \ s \text{ is a piecewise polynomial of degree } d \text{ on } \triangle, \ s \in C^\rho(v) \text{ for all vertices } v\}. \tag{1.2}$$

As usual, $C^\rho(v)$ means that all polynomials on triangles sharing the vertex v have common derivatives up to order ρ at that vertex.

In this paper, we will make use of certain subspaces of the superspline spaces (1.1) which satisfy additional supersmoothness at the vertex v_Q as well as some other special smoothness conditions.

The paper is organized as follows. In section 2, we review some well-known Bernstein–Bézier notation and state a key lemma. In section 3, we discuss the case where r is even, and in section 4, we illustrate it with several examples. The case where r is odd is treated in section 5 and illustrated in section 6. Section 7 contains results on the corresponding global spline spaces, including their approximation power. Concluding remarks can be found in section 8.

2. Notation and preliminaries. We make use of standard Bernstein–Bézier techniques. Given a triangle $T := \langle u_1, u_2, u_3 \rangle$ and an integer d, let

$$\xi^T_{ijk} := \frac{(iu_1 + ju_2 + ku_3)}{d}, \qquad i + j + k = d,$$

be the corresponding *domain points*. We will work with the usual rings and disks of domain points defined by

$$R^T_n(u_1) := \{\xi^T_{ijk} \ : \ i = d - n\},$$
$$D^T_n(u_1) := \{\xi^T_{ijk} \ : \ i \geq d - n\},$$

with similar definitions at the other vertices of T. It is well known (see [10] for explicit formulae) that specifying the B-coefficients in the disk $D^T_n(u_1)$ of a polynomial p is equivalent to specifying the derivatives $D^\nu_x D^\mu_y p(u_1)$ for $0 \leq \nu + \mu \leq n$.

Given a triangulation $\triangle$, we are interested in spline spaces which are subsets of the space $\mathcal{S}^0_d(\triangle)$ of splines which are globally C^0 and are piecewise polynomials of degree d. The corresponding set of domain points is defined to be the union of the $\{\xi^T_{ijk}\}$ as T runs over the triangles of $\triangle$, where points on edges are not repeated. We recall that a *minimal determining set (MDS)* for a spline space $\mathcal{S} \subseteq \mathcal{S}^0_d(\triangle)$ is a subset $\mathcal{M}$ of the domain points associated with $\mathcal{S}^0_d(\triangle)$ such that every spline $s \in \mathcal{S}$ is uniquely determined by the set of B-coefficients which are identified with the points of $\mathcal{M}$.

We shall make extensive use of certain linear functionals defined by smoothness conditions between polynomials of degree d on adjoining triangles. These were introduced in [2], but we repeat their definition here for convenience. Suppose that $T := \langle u_1, u_2, u_3 \rangle$ and $\tilde{T} := \langle u_4, u_3, u_2 \rangle$ are two adjoining triangles which share the edge $e := \langle u_2, u_3 \rangle$. Let s be a function whose restrictions to T and $\tilde{T}$ are polynomials of degree d. Let c_{ijk} and $\tilde{c}_{ijk}$ be the coefficients of the B-representations of s_T and $s_{\tilde{T}}$, respectively. Then, for any $n \leq m \leq d$, we define

$$\tau^n_{m,e} s := \tilde{c}_{n,m-n,d-m} - \sum_{i+j+k=n} c_{i,j+d-m,k+m-n} B^n_{ijk}(u_4), \tag{2.1}$$

where B^n_{ijk} are the Bernstein polynomials of degree n on the triangle T.

The following lemma [2] can be used to compute certain coefficients of s on the ring $R_m(u_2)$ assuming that an appropriate set of smoothness conditions across the edge e is satisfied.

LEMMA 2.1. *Suppose s is a piecewise polynomial of degree d defined on $T \cup \tilde{T}$ and that $d, m, p, q, \tilde{q}$ are integers with $0 \leq q, \tilde{q}$, $-1 \leq p \leq q, \tilde{q}$, and $q + \tilde{q} - p \leq m \leq d$. Suppose that*

$$\tau^n_{m,e} s = 0, \qquad p + 1 \leq n \leq q + \tilde{q} - p, \tag{2.2}$$

and that all of the coefficients c_{ijk} involved in these smoothness conditions are known except for

$$\begin{aligned} c_\nu &:= c_{\nu,d-r,r-\nu}, \qquad && \nu = p+1, \ldots, q, \\ \tilde{c}_\nu &:= \tilde{c}_{\nu,r-\nu,d-r}, \qquad && \nu = p+1, \ldots, \tilde{q}. \end{aligned} \tag{2.3}$$

Then the coefficients (2.3) *are uniquely determined by* (2.2).

3. The case $r = 2m$. Let Q be a quadrilateral with vertices $v_1, \dots, v_4$ in counterclockwise order. We define the triangles $T^{[i]} := \langle v_Q, v_i, v_{i+1}\rangle$ and edges $e_i := \langle v_i, v_Q\rangle$ for $i = 1, 2, 3, 4$, where $v_5 = v_1$ and v_Q is the point where the two diagonals of Q intersect.

THEOREM 3.1. *Given $r = 2m$, let $\mathcal{S}_r(\triangle_Q)$ be the linear subspace of all splines s in $\mathcal{S}_{6m+1}^{2m+1,3m}(\triangle_Q)$ that satisfy the following set of additional smoothness conditions:*

$$s \in C^{4m}(v_Q), \tag{3.1}$$

$$\tau_{3m+i+1,e_l}^{2m+1+j} s = 0, \qquad 1 \le j \le 2i, \quad 1 \le i \le m-1, \quad l = 1, 2, 3, 4, \tag{3.2}$$

and

$$\tau_{4m+1,e_1}^{2m+1+j} s = 0, \qquad 1 \le j \le 2m. \tag{3.3}$$

Then

$$\dim \mathcal{S}_r(\triangle_Q) = 26m^2 + 22m + 4.$$

Moreover, the following set $\mathcal{M}_r$ of domain points is an MDS:

(1) $D_{3m}^{T^{[i]}}(v_i)$ *for $i = 1, 2, 3, 4$,*

(2) $\{\xi_{j,3m,3m-j+1}^{T^{[i]}}, \dots, \xi_{j,3m-j+1,3m}^{T^{[i]}}\}$ *for $j = 1, \dots, 2m$ and $i = 1, 2, 3, 4$.*

Proof. First, we show that $\mathcal{M}_r$ is a determining set. Suppose that $s \in \mathcal{S}_r(\triangle_Q)$ and that we have set the coefficients of s corresponding to all domain points in $\mathcal{M}_r$. Then, using the usual smoothness conditions, we solve for the unset coefficients corresponding to domain points in the disks $D_{3m}(v_i)$ for $i = 1, 2, 3, 4$.

We now make use of Lemma 2.1. First, we compute the coefficients on the rings $R_{3m+i+1}(v_l)$ for $i = 0, \dots, m-1$ and $l = 1, 2, 3, 4$. On the ring $R_{3m+i+1}(v_l)$, this involves solving a system of $2(m+i)+1$ linear equations. Note that the spline satisfies all of the smoothness conditions required for the lemma since they either are already implicit in the supersmoothness of the space or have been explicitly enforced in the definition of $\mathcal{S}_r(\triangle_Q)$.

Using the lemma, we now compute the coefficients on $R_{4m+1}(v_1)$. We now start a sequence of calculations. First, we compute the $4m$ unset coefficients corresponding to points on the edge E_0, where, in general, E_i is the set of domain points in $T^{[1]} \cup T^{[2]}$ at a distance i from the edge $\langle v_1, v_3\rangle$. Then we compute the $4m$ coefficients corresponding to points in the set $\tilde{E}_0$, where $\tilde{E}_i$ is the set of domain points in $T^{[2]} \cup T^{[3]}$ at a distance i from the edge $\langle v_2, v_4\rangle$. The remaining coefficients in $T^{[1]} \cup T^{[2]} \cup T^{[3]}$ are computed by alternately working on the sets E_i and $\tilde{E}_i$ for $i = 1, \dots, r$. Finally, we compute the remaining coefficients in $T^{[4]}$ from the C^r smoothness conditions.

We have shown that all coefficients of s are determined by those corresponding to the domain points in the set $\mathcal{M}_r$. This shows that $\mathcal{M}_r$ is a determining set.

To see that $\mathcal{M}_r$ is an MDS, we consider $\mathcal{S}_{6m+1}^{2m+1}(\triangle_Q) \cap C^{4m}(v_Q)$. By Theorem 2.2 in [18] the dimension of this space is $32m^2+18m+4$. Our space $\mathcal{S}_r(\triangle_Q)$ is the subspace which satisfies the $4m^2 - 2m$ special conditions (3.2)–(3.3) and the supersmoothness $C^{3m}(v_i)$ for $i = 1, 2, 3, 4$. Enforcing the supersmoothness requires an additional $2m^2 - 2m$ conditions. Thus

$$\begin{aligned}(32m^2 + 18m + 4) - (4m^2 - 2m) - (2m^2 - 2m)& \\ \le \dim \mathcal{S}_r(\triangle_Q) \le \#\mathcal{M}_r = 26m^2 + 22m + 4.&\end{aligned}$$

Since the expression on the left equals the one on the right, we conclude that it is equal to the dimension of $\mathcal{S}_r(\triangle_Q)$, and $\mathcal{M}_r$ is an MDS. □

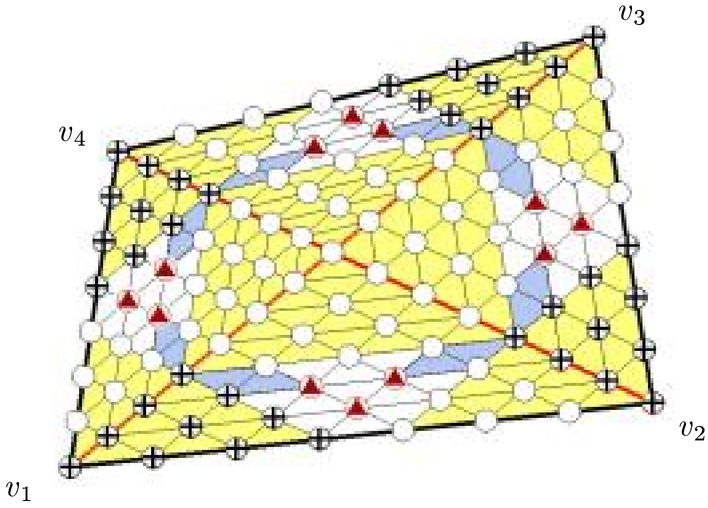

Fig. 1. *The C^2 macroelement.*

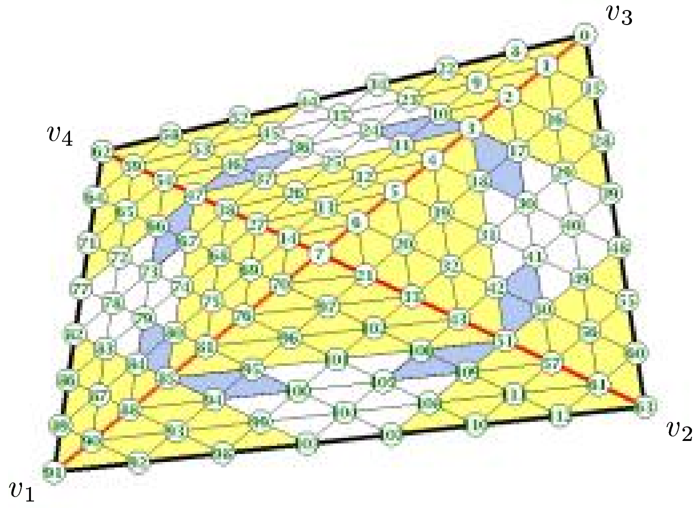

Fig. 2. *Domain points for the C^2 macroelement.*

4. Examples. In this section, we illustrate the construction of section 3.

Example 4.1. *The space $\mathcal{S}_2(\triangle_Q)$ is the subspace of $\mathcal{S}_7^3(\triangle_Q) \cap C^4(v_Q)$ that satisfies the two special smoothness conditions corresponding to τ_{5,e_1}^4 and τ_{5,e_1}^5.*

Discussion. The dimension of $\mathcal{S}_2(\triangle_Q)$ is 52, and the MDS for this macroelement is shown in Figure 1. It consists of 10 points in each of the disks $D_3(v_i)$ (marked with crosses) and 3 points corresponding to item (2) of Theorem 3.1 for each edge of Q (marked with triangles). After setting the coefficients in the MDS, the remaining coefficients are computed in the following order. First, we use C^3 smoothness to compute

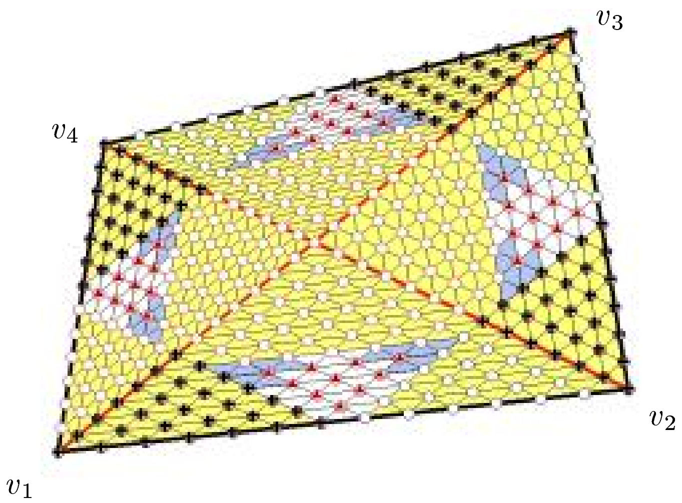

Fig. 3. *The C^4 macroelement.*

the coefficients numbered 80,81,95 in Figure 2, followed by those numbered 106,43,42, then 18,4,11, and 37,38,67. Using the two special smoothness conditions, we can now compute the coefficients numbered 74,75,76,96,101. Then, using C^4 smoothness, we compute the coefficients numbered 70,7,6,5 (lying in the set E_0) and 33,21,14,27 (lying in the set $\tilde{E}_0$). Next we compute coefficients numbered 97,20,19, then 32,13,26, then 102,31, and 12,25. Finally, the coefficients numbered 68,69 are computed by standard smoothness conditions. □

Example 4.2. *The space $\mathcal{S}_4(\triangle_Q)$ is the subspace of $\mathcal{S}_{13}^{5,6}(\triangle_Q) \cap C^8(v_Q)$ that satisfies the twelve special smoothness conditions corresponding to $\{\tau_{8,e_i}^6, \tau_{8,e_i}^7\}_{i=1}^4$ and $\tau_{9,e_1}^6, \tau_{9,e_1}^7, \tau_{9,e_1}^8, \tau_{9,e_1}^9$.*

Discussion. The dimension of $\mathcal{S}_4(\triangle_Q)$ is 152, and the MDS for this macroelement is shown in Figure 3. It consists of 28 points in each of the disks $D_3(v_i)$ (marked with crosses) and 10 points corresponding to item (2) of Theorem 3.1 for each edge of Q (marked with triangles). □

5. The case $r = 2m + 1$.

Theorem 5.1. *Given $r = 2m + 1$, let $\mathcal{S}_r(\triangle_Q)$ be the linear subspace of all splines s in $\mathcal{S}_{6m+3}^{2m+1,3m+1}(\triangle_Q)$ that satisfy the following set of additional smoothness conditions:*

$$s \in C^{4m+1}(v_Q), \tag{5.1}$$

$$\tau_{3m+i+2,e_l}^{2m+1+j} s = 0, \qquad 1 \le j \le 2i, \quad 1 \le i \le m-1, \quad l = 1,2,3,4, \tag{5.2}$$

$$\tau_{4m+2,e_l}^{2m+1+j} s = 0, \qquad 1 \le j \le 2m, \quad l = 1,2,3. \tag{5.3}$$

Then

$$\dim \mathcal{S}_r(\triangle_Q) = 26m^2 + 42m + 16.$$

Moreover, the following set $\mathcal{M}_r$ of domain points is an MDS:

(1) $D^{T^{[i]}}_{3m+1}(v_i)$ *for* $i = 1, 2, 3, 4,$

(2) $\{\xi^{T^{[i]}}_{j,3m+1,3m-j+2}, \dots, \xi^{T^{[i]}}_{j,3m-j+2,3m+1}\}$ *for* $j = 1, \dots, 2m+1$ *and* $i = 1, 2, 3, 4.$

Proof. First, we show that $\mathcal{M}_r$ is a determining set. Suppose that $s \in \mathcal{S}_r(\triangle_Q)$ and that we have set the coefficients of s corresponding to all domain points in $\mathcal{M}_r$. Then, using the usual smoothness conditions, we solve for the unset coefficients corresponding to domain points in the disks $D_{3m+1}(v_i)$ for $i = 1, 2, 3, 4$.

Next we use Lemma 2.1 to compute the coefficients corresponding to points on the rings $R_{3m+i+2}(v_l)$ for $i = 0, \dots, m-1$ and $l = 1, 2, 3, 4$. On the ring $R_{3m+i+2}(v_l)$, this involves solving a system of $2(m+i)+1$ linear equations. Then we compute coefficients on the rings $R_{4m+2}(v_l)$ for $l = 1, 2, 3$.

Using the lemma, we now compute the $4m+1$ unset coefficients corresponding to the sets E_0 and $\tilde{E}_0$ defined in the proof of Theorem 3.1. The remaining coefficients in $T^{[1]} \cup T^{[2]} \cup T^{[3]}$ are computed by alternately working on the sets E_i and $\tilde{E}_i$ for $i = 1, \dots, r-1$. Finally, we compute the remaining coefficients in $T^{[4]}$ from the C^r smoothness conditions.

We have shown that all coefficients of s are determined by those corresponding to the domain points in the set $\mathcal{M}_r$. This shows that $\mathcal{M}_r$ is a determining set.

To see that $\mathcal{M}_r$ is an MDS, consider $\mathcal{S}^{2m+1}_{6m+3}(\triangle_Q) \cap C^{4m+1}(v_Q)$. By Theorem 2.2 in [18] the dimension of this space is $32m^2 + 46m + 16$. Our space $\mathcal{S}_r(\triangle_Q)$ is the subspace which satisfies the $4m^2 + 2m$ special conditions (5.2)–(5.3) and the supersmoothness $C^{3m+1}(v_i)$ for $i = 1, 2, 3, 4$. Enforcing the supersmoothness requires an additional $2m^2 + 2m$ conditions. Thus

$$\begin{aligned}(32m^2 + 46m + 16) - (4m^2 + 2m) - (2m^2 + 2m)&\\ \le \dim \mathcal{S}_r(\triangle_Q) \le \#\mathcal{M}_r = 26m^2 + 42m + 16.&\end{aligned}$$

Since the expression on the left equals the one on the right, we conclude that it is equal to the dimension of $\mathcal{S}_r(\triangle_Q)$, and $\mathcal{M}_r$ is an MDS. □

6. Examples. In this section, we illustrate the construction of section 5.

EXAMPLE 6.1. *The space $\mathcal{S}_3(\triangle_Q)$ is the subspace of $\mathcal{S}^{3,4}_9(\triangle_Q) \cap C^5(v_Q)$ that satisfies the six special smoothness conditions corresponding to $\tau^4_{6,e_i}, \tau^5_{6,e_i}$ for $i = 1, 2, 3$.*

Discussion. The dimension of $\mathcal{S}_3(\triangle_Q)$ is 84, and the MDS for this macroelement is shown in Figure 4. It consists of 15 points in each of the disks $D_4(v_i)$ (marked with crosses) and 6 points corresponding to item (2) of Theorem 5.1 along each edge of Q (marked with triangles). □

EXAMPLE 6.2. *The space $\mathcal{S}_5(\triangle_Q)$ is the subspace of $\mathcal{S}^{5,7}_{15}(\triangle_Q) \cap C^9(v_Q)$ that satisfies the twenty special smoothness conditions corresponding to $\{\tau^6_{9,e_i}, \tau^7_{9,e_i}\}^4_{i=1}$ and $\{\tau^6_{10,e_i}, \tau^7_{10,e_i}, \tau^8_{10,e_i}, \tau^9_{10,e_i}\}^3_{i=1}$.*

Discussion. The space $\mathcal{S}_5(\triangle_Q)$ has dimension 204, and the MDS for this macroelement is shown in Figure 5. It consists of 36 points in each of the disks $D_5(v_i)$ (marked with crosses) and 15 points corresponding to item (2) in Theorem 5.1 along each edge of Q (marked with triangles). □

7. Superspline spaces with stable bases. Let $\Diamond$ be a quadrangulation of a domain Ω with vertices $\{v_i\}^V_{i=1}$. Suppose E is the number of edges. Let $\diamondplus$ be the triangulation obtained by inserting both diagonals in each quadrilateral Q in $\Diamond$. Let

$$\mathcal{S}_r(\diamondplus) := \{s \in C^r(\Omega) \;:\; s|_Q \in \mathcal{S}_r(\triangle_Q) \text{ for all } Q \in \Diamond\}, \tag{7.1}$$

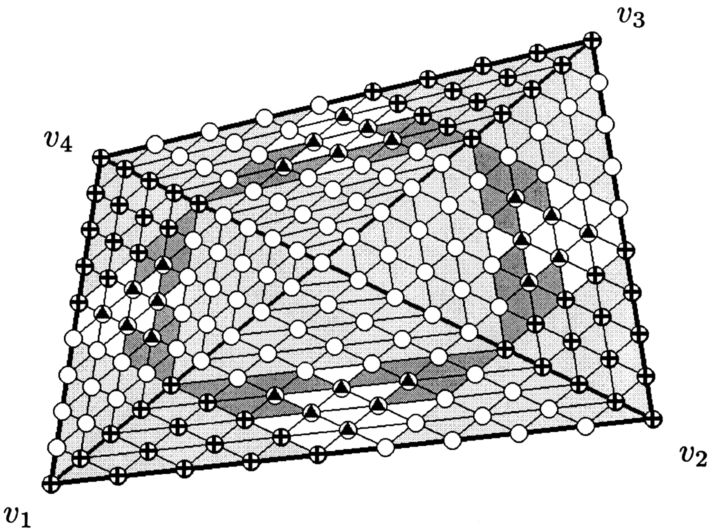

FIG. 4. *The C^3 macroelement.*

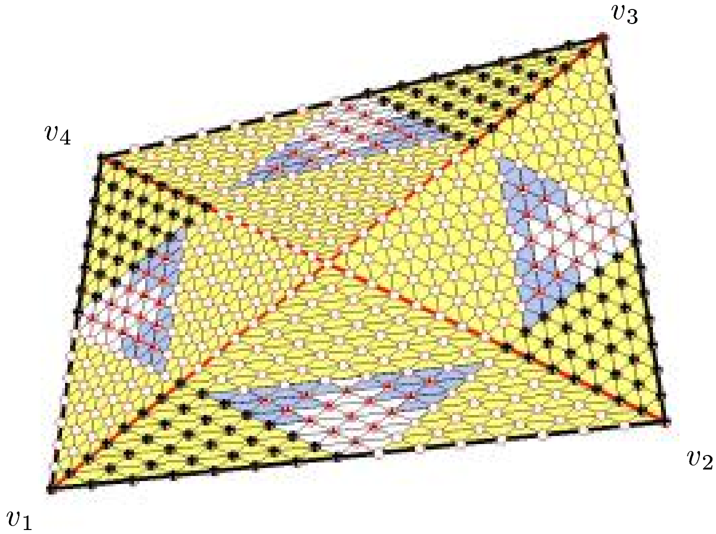

FIG. 5. *The C^5 macroelement.*

where $\mathcal{S}_r(\triangle_Q)$ are the spaces defined in Theorems 3.1 and 5.1. Let

$$d_r = \begin{cases} 6m+1, & r = 2m, \\ 6m+3, & r = 2m+1, \end{cases} \tag{7.2}$$

and

$$\rho_r = \begin{cases} 3m, & r = 2m, \\ 3m+1, & r = 2m+1. \end{cases} \tag{7.3}$$

THEOREM 7.1. *For all $r \geq 1$,*

$$\dim \mathcal{S}_r(\diamondplus) = \binom{\rho_r + 2}{2} V + \binom{r+1}{2} E. \tag{7.4}$$

Moreover, the following set $\mathcal{M}_r$ of domain points forms an MDS:

(1) *For each vertex $v \in \Diamond$, choose $D^T_{\rho_r}(v)$, where T is some triangle in $\diamondplus$ with vertex at v;*

(2) *for each edge $e \in \Diamond$, choose $\{\xi^T_{j,\rho_r,d_r-\rho_r-j}, \ldots, \xi^T_{j,d_r-\rho_r-j,\rho_r}\}$ for $j = 1, \ldots, r$, where T is some triangle in $\diamondplus$ sharing the edge e.*

Proof. First, we show that $\mathcal{M}_r$ is a determining set. For each vertex $v \in \Diamond$, using the smoothness conditions, item (1) determines all coefficients corresponding to points in the disk $D_{\rho_r}(v)$. Similarly, if $\tilde{T}$ is a second triangle sharing the edge e, then item (2) determines the corresponding coefficients in both T and $\tilde{T}$. The claim then follows from Theorems 3.1 and 5.1.

To show that $\mathcal{M}_r$ is an MDS, we now construct the dual basis corresponding to $\mathcal{M}_r$. For each $\xi \in \mathcal{M}_r$, let B_ξ be the unique spline in $\mathcal{S}_r(\diamondplus)$ such that

$$\lambda_\eta B_\xi = \delta_{\xi,\eta}, \qquad \eta \in \mathcal{M}_r, \tag{7.5}$$

where λ_η is the linear functional which picks off the B-coefficient corresponding to the domain point η.

In view of (7.5), the splines in $\mathcal{B} := \{B_\xi\}_{\xi \in \mathcal{M}_r}$ are linearly independent, and thus $\mathcal{B}$ forms a basis for $\mathcal{S}_r(\diamondplus)$. It follows that $\dim \mathcal{S}_r(\diamondplus) = \#\mathcal{M}_r$, which is the number in (7.4). □

It is easy to see that the dual basis functions constructed in the above proof have local support. In particular,

(1) if ξ is a point as in item (1) of Theorem 7.1, then $\operatorname{supp}(B_\xi)$ is contained in the union of all quadrilaterals of $\diamondplus$ sharing the vertex v;

(2) if ξ is a point as in item (2) of Theorem 7.1, then $\operatorname{supp}(B_\xi)$ is contained in $Q \cup \tilde{Q}$, where e is the edge between Q and $\tilde{Q}$. (If e is a boundary edge of a quadrilateral Q, then the support is simply Q.)

LEMMA 7.2. *Let $\{B_\xi\}_{\xi \in \mathcal{M}}$ be the set of dual basis splines constructed in the proof of Theorem 7.1. Then there exists a constant K depending only on the smallest angle in $\diamondplus$ such that $\|B_\xi\| \leq K$ for all $\xi \in \mathcal{M}_r$.*

Proof. Fix $\xi \in \mathcal{M}_r$, and let B_ξ be the corresponding dual basis spline. We examine the size of its B-coefficients. By definition, $c_\xi = 1$ and $c_\eta = 0$ for all other $\eta \in \mathcal{M}_r$. The remaining B-coefficients of B_ξ are computed by using smoothness conditions or solving the linear systems of equations appearing in Lemma 2.1 of [2]. These involve matrices whose inverses are bounded in norm by a constant depending only on the smallest angle in $\diamondplus$. This shows that all of the B-coefficients of B_ξ are bounded by a constant K, and the result follows. □

THEOREM 7.3. *The dual basis $\{B_\xi\}_{\xi \in \mathcal{M}_r}$ is a stable basis in the sense that there exist constants K_1, K_2 depending only on the smallest angle in $\diamondplus$ such that, for all choices of the coefficient vector $c = (c_\xi)_{\xi \in \mathcal{M}_r}$,*

$$K_1 \|c\|_\infty \;\leq\; \Big\| \sum_{\xi \in \mathcal{M}_r} c_\xi B_\xi \Big\|_\infty \;\leq\; K_2 \|c\|_\infty. \tag{7.6}$$

Proof. The proof follows in the same way as the proof of Theorem 2.3 of [7]. □

We conclude this section with an approximation result. Given a function f in $L_1(\Omega)$ and an integer $0 \le k \le d_r$, let

$$Q_k f := \sum_{\xi \in \mathcal{M}_r} \lambda_{\xi,k} f \, B_\xi,$$

where $\lambda_{\xi,k}$ is the linear functional defined in section 10 of [11].

THEOREM 7.4. *Fix $1 \le p \le \infty$. Suppose f lies in the Sobolev space $W_p^{k+1}(\Omega)$ for some $0 \le k \le d_r$. Then*

$$\|D_x^\alpha D_y^\beta (f - Q_k f)\|_p \le K |\diamondplus|^{k+1-\alpha-\beta} |f|_{k+1,p} \tag{7.7}$$

for $0 \le \alpha + \beta \le k$, where $|\diamondplus|$ is the mesh size of $\diamondplus$ (i.e., the diameter of the largest triangle), and $|f|_{k+1,p}$ is the usual Sobolev seminorm. If Ω is convex, then the constant K depends only on d_r, p, k, and the smallest angle in $\diamondplus$. If Ω is nonconvex, it also depends on the Lipschitz constant $L_{\partial\Omega}$ associated with the boundary of Ω.

Proof. The proof follows in the same way as the proof of Theorem 1.1 of [11]. □

8. Remarks.

Remark 8.1. We used the java code described in [1] to check the macroelements described in this paper and to generate the figures. The code can be used or downloaded from http://www.math.utah.edu/~alfeld.

Remark 8.2. Theorem 10.1 of [13] implies that, in order to obtain macroelements on $\triangle_Q$ which will join with C^r smoothness when constructed on the individual quadrilaterals of a quadrangulation, we must require supersmoothness of order ρ_r at the vertices of Q, where ρ_r is defined in (7.3). This implies that we cannot use polynomials of degree lower than the d_r given in (7.2).

Remark 8.3. While there is a unique choice of minimal degree and minimal supersmoothness at the vertices of Q, our choice of extra smoothness conditions is not the only choice which leads to macroelements based on the natural set of degrees of freedom, i.e., other sets of τ's will also work.

Remark 8.4. In view of the connection between derivatives and B-coefficients, Theorem 7.1 immediately implies that, given $f \in C^{\rho_r}(\Omega)$, there exists a unique spline $s \in \mathcal{S}_r(\diamondplus)$ which solves the Hermite interpolation problem

$$D_x^\nu D_y^\mu s(v) = D_x^\nu D_y^\mu f(v), \qquad 0 \le \nu + \mu \le \rho_r, \qquad v \in \Diamond, \tag{8.1}$$

and

$$D_e^j s(\eta_{e,i}^j) = D_e^j f(\eta_{e,i}^j), \qquad 1 \le i \le j, \quad 1 \le j \le r, \tag{8.2}$$

for all edges e of $\Diamond$. Here D_e denotes the perpendicular derivative to the edge $e := \langle u_1, u_2 \rangle$, and

$$\eta_{e,i}^j s := \frac{(j+1-i)u_1 + iu_2}{j+1}, \qquad i = 1, \dots, j.$$

A simple application of the Bramble–Hilbert lemma shows that this interpolant satisfies the error bounds of Theorem 7.4 with $p = \infty$. For error bounds for other bivariate spline spaces, see [4].

Remark 8.5. In view of Remark 8.2, it is clear that the natural set of degrees of freedom for a C^r macroelement on $\triangle_Q$ are precisely the derivative information described in (8.1)–(8.2). For a comparison with the natural degrees of freedom for smooth macroelements defined on Clough–Tocher and Powell–Sabin splits, see [2, 3, 12, 13].

EDGE BIFURCATIONS FOR NEAR INTEGRABLE SYSTEMS VIA EVANS FUNCTION TECHNIQUES*

TODD KAPITULA† AND BJÖRN SANDSTEDE‡

Abstract. When studying the linear stability of waves for near integrable systems, a fundamental problem is the location of the point spectrum of the linearized operator. Internal modes may be created upon the perturbation, i.e., eigenvalues may bifurcate out of the continuous spectrum, even if the corresponding eigenfunction is not initially localized. This phenomenon is also known as an *edge bifurcation*. It has recently been shown that the Evans function is a powerful tool when one wishes to detect an edge bifurcation and track the resulting eigenvalues. It has been an open question as to the role played by the solutions to the Lax pair, associated with the integrable problem, in the construction of the Evans function and the detection of edge bifurcations. Using the Zakharov–Shabat eigenvalue problem and the massive Thirring model as illustrations, we show the connection between the inverse scattering formalism and the linear stability analysis of waves. In particular, we show a direct connection between the scattering coefficients and the Evans function. Last, using perturbations of the massive Thirring model, we show how the Evans function can be used to predict the location of bifurcating edge eigenvalues.

Key words. travelling waves, stability, Evans function, inverse scattering theory

1. Introduction.

Much work has been done recently on the detection of edge bifurcations, or internal modes, for perturbed integrable systems (see, for instance, [15, 16, 17, 25, 27, 31]). When considering the stability of solitons for an integrable system, it is typically a straightforward problem to locate the spectrum associated with the operator which arises from linearizing about the soliton. This is possible primarily due to the fact that the integrable problem has so much structure. The basic issue is then to try to determine the spectrum for the perturbed problem when this structure is no longer available.

In order to illustrate the issues involved, consider the following well-studied example, the perturbed focusing nonlinear Schrödinger equation (NLS):

$$\mathrm{i}q_t + \frac{1}{2}q_{xx} - \omega q + |q|^2 q = \mathrm{i}\epsilon R(q, q^*) \qquad (+\text{complex conjugate (c.c.)}),$$

where $q(x,t) \in \mathbb{C}$ for any $(x,t) \in \mathbb{R} \times \mathbb{R}^+$ and where $\omega \in \mathbb{R}^+$ and $0 \leq \epsilon \leq 1$. When $\epsilon = 0$, the NLS has the soliton solution

$$\phi(x,\omega) = \sqrt{2\omega}\,\mathrm{sech}(\sqrt{2\omega}\,x).$$

After linearizing the unperturbed NLS about ϕ, we obtain

$$\mathrm{i}q_t + \frac{1}{2}q_{xx} - \omega q + \phi^2(2q + q^*) = 0 \qquad (+\text{c.c.}),$$

and the associated eigenvalue problem is therefore

$$\mathrm{i}\lambda q + \frac{1}{2}q_{xx} - \omega q + \phi^2(2q + q^*) = 0. \qquad (+\text{c.c.})$$

Upon computing the spectrum of the linearized operator, one finds that $\lambda = 0$ is an isolated eigenvalue of geometric multiplicity two and algebraic multiplicity four, and the rest of the spectrum is a continuous spectrum which resides on the imaginary axis in the bands $|\operatorname{Im}\lambda| \geq \omega$ [21, 39]. Thus, when $\epsilon = 0$, the wave is linearly stable in that there exists no unstable spectrum (i.e., no spectral elements λ with $\operatorname{Re}\lambda > 0$). Here, to fix notation, we divide the spectrum of a given operator into two disjoint sets. The point spectrum consists of all isolated eigenvalues with finite multiplicity, while the essential (or continuous) spectrum is the complement of the point spectrum in the spectrum.

A fundamental question is: If the wave persists, what happens to its linear stability for $\epsilon > 0$? There are two issues to consider. The first is the fate of the point eigenvalues at $\lambda = 0$. Depending on the type of perturbation and what invariances of the NLS are preserved under the perturbation, some of these eigenvalues will generally move. This issue comes up in general in the study of perturbed Hamiltonian systems (see [14] and references therein). The perturbed eigenvalues can be tracked, for instance, by using the Evans function [13, 14] or via a Lyapunov-Schmidt reduction. There has also been a great deal of formal work using adiabatic and variational ideas. (A small subset is [3, 21, 40, 26, 35].) The idea behind these methods is that the effect of radiation on the evolution of the perturbed wave is of higher order and can thus be neglected at first order in a perturbation expansion. For the focusing NLS, the rigorous eigenvalue analysis and formal work are in agreement; however, this is not always the case, for it has recently been shown in [15] that the results disagree for the defocusing NLS.

The second issue, and the primary focus of this paper, is to locate the rest of the spectrum. The location of the continuous spectrum is straightforward (see Henry [11]), and one typically assumes that the perturbation is such that the continuous spectrum remains in the closed left-half plane. A more troublesome problem is determining the location of the rest of the point spectrum. Under the perturbation of the PDE, it is possible for point eigenvalues to move out of the continuous spectrum. If this occurs, then one says that an edge bifurcation has occurred or an internal mode has been created. It must be emphasized that an edge bifurcation can happen even if the corresponding eigenfunctions for the unperturbed problem are not localized. Indeed, the recent work of [16, 17, 25, 31] has shown this to be the case for the perturbed NLS. For the NLS, it turns out that an edge bifurcation can happen only at the edge of the continuous spectrum, i.e., at the points $\lambda = \pm\mathrm{i}\omega$; furthermore, at most one eigenvalue can pop out of the continuous spectrum at each of these two points. A priori, however, this fact is not obvious, as it appears to be possible for an edge bifurcation to occur along any point in the continuous spectrum: since it is known that the eigenfunctions associated with the continuous spectrum are all bounded but nondecaying, it seems to be plausible that a small perturbation of the PDE can cause these bounded eigenfunctions to decay as $|x| \to \infty$ and therefore to become true eigenfunctions.

This idea naturally leads to the question: What is the underlying mechanism that determines where an edge bifurcation may take place? We investigate this question for integrable PDEs. Thus consider a Lax pair

$$\mathbf{v}_x = L\mathbf{v}, \qquad \mathbf{v}_t = M\mathbf{v},$$

where $\mathbf{v} \in \mathbb{C}^n$, and L and M are 2×2 matrices that depend on (x, t). The associated integrable PDE

$$\mathbf{u}_t = \mathcal{K}(\mathbf{u}) \tag{1.1}$$

is derived from the compatibility condition $\mathbf{v}_{xt} = \mathbf{v}_{tx}$, i.e., from $L_t - M_x + [L, M] = 0$. The direct scattering problem consists of finding the solutions to $\mathbf{v}_x = L\mathbf{v}$ that are oscillatory as $|x| \to \infty$. These solutions are called Jost functions, and they can be parametrized by their asymptotic spatial wavenumber, or frequency, k for $x \to -\infty$. Associated with the Jost function with wavenumber k is the transmission coefficient $a(k)$, which measures the amplitude of the Fourier mode with wavenumber k as $x \to \infty$. Roughly speaking,

$$\phi(k, x) \sim \mathrm{e}^{-\mathrm{i}kx} \text{ as } x \to -\infty, \qquad \phi(k, x) \sim a(k)\mathrm{e}^{-\mathrm{i}kx} \text{ as } x \to \infty,$$

where $\phi(k, x)$ is the Jost function with wavenumber k.

We are interested in finding solutions to the eigenvalue problem which arises from linearizing (1.1) about the soliton. It turns out that certain quadratic combinations of the Jost functions, the so-called adjoint squared eigenfunctions, satisfy this linearized problem [21, 22]. Thus one can recover asymptotically oscillatory solutions to the linearized problem which correspond to eigenmodes in the continuous spectrum. Furthermore, if one knows the transmission coefficient $a(k)$, then one can determine the precise behavior of these solutions as $|x| \to \infty$. Of course, not all of the solutions here will be known; however, as will be seen, this will be unimportant as long as one has sufficient information about $a(k)$. As we shall see, the transmission coefficient actually encodes all the information needed to predict edge bifurcations.

We use the Evans function, $E(\lambda)$, to study edge bifurcations. The Evans function $E(\lambda)$ is an analytic function of the spectral parameter λ which has the property that $E(\lambda) = 0$ if and only if λ is a point eigenvalue; furthermore, the order of the zero is the algebraic multiplicity of the eigenvalue [4, 6, 7, 8, 9, 30]. Originally, the Evans function was defined only away from the continuous spectrum. We showed in [16, 17] (see also [10]) that the Evans function can actually be extended across the essential spectrum. Edge bifurcations manifest themselves as zeros of the Evans function that move out of the continuous spectrum. Thus, by locating the zeros of $E(\lambda)$ embedded in the continuous spectrum, one can determine where an edge bifurcation will take place and can also track these zeros under the perturbation.

In order to finish the problem, one must then be able to calculate the Evans function on the continuous spectrum. For the class of problems under consideration in this paper, this calculation is possible. It is found that for integrable PDEs arising from the Zakharov–Shabat eigenvalue problem, the Evans function restricted to the continuous spectrum vanishes precisely at branch points of the continuous spectrum and at points where the transmission coefficient $a(k)$ vanishes for some real k (see section 3.3 for details). For simplicity, we exclude the second possibility (see Assumption 2.1) and focus instead on edge bifurcations at branch points. In this situation, the total number of bifurcating eigenvalues depends on the order of the branch point (see section 3 for details). To illustrate the effects of perturbations, we consider the massive Thirring model, where an edge bifurcation can happen at four branch points—two are at the edge of the continuous spectrum, and two are contained within the continuous spectrum. The reason for this phenomenon is that the massive Thirring model possesses *two* dispersion relationships which are used to describe the continuous spectrum, while the PDEs arising from the Zakharov–Shabat eigenvalue problem contain only one. We then utilize the resulting Evans function to present a perturbation expansion for the bifurcating eigenvalues.

Pelinovsky and Sulem [32, 33] have recently considered a problem which is complementary to that presented herein. They consider an integrable PDE (such as the focusing NLS) which possesses a soliton solution and ask the question about the evolution of small perturbations of this soliton. Since the system is integrable, the question can be answered by performing a detailed analysis of the associated scattering problem. Using a different technique than that presented herein, they study edge bifurcations of simple eigenvalues for the scattering problem (and not for the integrable PDE itself as we do). They show that if an edge bifurcation occurs, then a certain matching condition must hold. (Note, however, that their approach does not appear to prove the converse.) In addition, they show that an edge bifurcation leads to the creation of new solitons.

The paper is organized as follows. In section 2, we discuss the Zakharov–Shabat eigenvalue problem as the prototypical example. In section 3, we show how the squared eigenfunctions of the scattering problem are related to the linear stability problem of the underlying integrable PDE. Furthermore, we calculate the Evans function for the integrable PDE. Last, in section 4, we use the massive Thirring model to illustrate what happens when several branch points collide and to present a perturbation analysis of the Evans function that predicts the location of eigenvalues that move out of the continuous spectrum upon adding perturbation to the PDE.

NOTATION 1.1. *Throughout this paper, we denote the complex conjugate of a complex number q by q^*; we emphasize that $\bar{q}$ does not denote the complex conjugate of q.*

2. Direct and inverse scattering for the Zakharov–Shabat problem.

Much of the following discussion follows that given in [2, 24] (see also [1]) and is included to set up the notation and for the sake of completeness.

2.1. The evolution equation.

We begin by choosing complex-valued functions r and q that depend on (x,t) such that $\mathbf{u}(x,t) = (r,q)(x,t)$ decays to zero exponentially as $|x| \to \infty$ for every t. Consider the 2×2 scattering problem given by

$$\mathbf{v}_x = \begin{pmatrix} -\mathrm{i}k & q(x,t) \\ r(x,t) & \mathrm{i}k \end{pmatrix} \mathbf{v}, \tag{2.1}$$

where $\mathbf{v} = (v_1, v_2)$ again depends on (x,t). We assume that the time-dependence of $\mathbf{v}$ is governed by the linear equation

$$\mathbf{v}_t = \begin{pmatrix} A & B \\ C & D \end{pmatrix} \mathbf{v}, \tag{2.2}$$

where A, B, C, and D are complex-valued functions that depend on $\mathbf{u} = (r,q)$ and on k. The compatibility condition $\mathbf{v}_{tx} = \mathbf{v}_{xt}$ is satisfied provided we have that $D = -A$ and

$$\begin{aligned} A_x + rB - qC &= 0, \\ B_x - q_t + 2Aq + 2\mathrm{i}kB &= 0, \\ C_x - r_t - 2Ar - 2\mathrm{i}kC &= 0. \end{aligned} \tag{2.3}$$

One way of solving the compatibility condition (2.3) is to assume an ansatz of the form

$$A = \Omega(k) + \sum_{j=0}^{n-1} A_j k^j, \qquad B = \sum_{j=0}^{n-1} B_j k^j, \qquad C = \sum_{j=0}^{n-1} C_j k^j,$$

so that A, B, and C are polynomial functions of the eigenvalue parameter k for a given dispersion relation

$$\Omega(k) = \sum_{j=0}^{n} d_j k^j. \tag{2.4}$$

Here the coefficients d_j are given complex numbers, while the coefficients A_j, B_j, and C_j depend on (r, q) in such a fashion that they decay to zero as $|x| \to \infty$. Substituting the above ansatz into (2.3), solving recursively starting at $j = n - 1$, and working down to $j = 0$, we obtain

$$A_j = \int_{-\infty}^{x} (qC_j - rB_j)\, \mathrm{d}y, \qquad \begin{pmatrix} C_j \\ B_j \end{pmatrix} = \sum_{\ell=j+1}^{n} \mathrm{i} d_\ell (\mathcal{L}^A(\mathbf{u}))^{\ell-1-j} \mathbf{u} \tag{2.5}$$

for $j = 0, \ldots, n - 1$. The operator $\mathcal{L}^A(\mathbf{u})$ that appears in (2.5) arises naturally when solving (2.3) inductively and is given by

$$\mathcal{L}^A(\mathbf{u})\mathbf{v} := -\frac{1}{2}\mathrm{i}\sigma_3 \partial_x \mathbf{v} + \mathrm{i}\mathbf{u} \int_{-\infty}^{x} (qv_1 - rv_2)\, \mathrm{d}y, \tag{2.6}$$

where $\mathbf{u} = (r, q)$, $\mathbf{v} = (v_1, v_2)$, and σ_3 is the Pauli spin matrix

$$\sigma_3 = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}.$$

In addition, as part of the compatibility condition on the level $j = 0$, we obtain the evolution equation

$$\sigma_3 \mathbf{u}_t + 2\Omega(\mathcal{L}^A(\mathbf{u}))\mathbf{u} = 0 \tag{2.7}$$

for $\mathbf{u}(x, t) = (r, q)(x, t)$.

In summary, for any given polynomial dispersion relation $\Omega(k)$, we can construct the evolution equation (2.7) by means of the Zakharov–Shabat scattering problem (2.1) and (2.2). The class of equations that can be realized by (2.7), upon using an appropriate dispersion relation $\Omega(k)$, includes KdV, mKdV, and NLS (see [2, p. 258]). Direct and inverse scattering theory allow us to actually solve (2.7).

2.2. The direct scattering problem. First, we describe how the scattering data are obtained from the functions (r, q). This map involves certain solutions, the so-called Jost functions, to (2.1). For any k with $\operatorname{Im} k > 0$, there are unique solutions $\phi(k, x)$ and $\psi(k, x)$ to (2.1) that satisfy

$$\lim_{x \to -\infty} \phi(k, x)\mathrm{e}^{\mathrm{i}kx} = \begin{pmatrix} 1 \\ 0 \end{pmatrix}, \qquad \lim_{x \to \infty} \psi(k, x)\mathrm{e}^{-\mathrm{i}kx} = \begin{pmatrix} 0 \\ 1 \end{pmatrix}.$$

The solutions $\mathrm{e}^{\mathrm{i}kx}\phi(k, x)$ and $\mathrm{e}^{-\mathrm{i}kx}\psi(k, x)$ are analytic in k for $\operatorname{Im} k > 0$. We emphasize that these solutions also depend on t; we will, however, suppress this dependence in our notation. The first piece of the scattering data, the transmission coefficient $a(k)$, is given by

$$a(k) := \phi(k,x) \wedge \psi(k,x) := \det \begin{pmatrix} \phi_1(k,x) & \psi_1(k,x) \\ \phi_2(k,x) & \psi_2(k,x) \end{pmatrix}.$$

Note that we have

$$\lim_{x\to\infty} \phi(k,x)\mathrm{e}^{\mathrm{i}kx} = a(k)\begin{pmatrix}1\\0\end{pmatrix}$$

for $\operatorname{Im} k > 0$ since the trace of the matrix in (2.1) is zero. It is desirable to analytically extend the transmission coefficient $a(k)$ across the real axis $\operatorname{Im} k = 0$. This extension has been carried out in [2, p. 268] under the assumption that the potentials $(r,q)(x,t)$ decay exponentially to zero as $|x| \to \infty$. The gap lemma [10, 17] deals with this issue in more generality. Roughly speaking, in this context, it states that if the system (2.1) approaches a constant system exponentially fast as $|x| \to \infty$, which is guaranteed by the assumption on r and q, then the solutions ϕ and ψ can be analytically extended. After extending the coefficient $a(k)$, we have that, when $k \in \mathbb{R}$,

$$\lim_{x\to\infty} \left[\phi(k,x) - a(k)\mathrm{e}^{-\mathrm{i}kx}\begin{pmatrix}1\\0\end{pmatrix} - b(k)\mathrm{e}^{\mathrm{i}kx}\begin{pmatrix}0\\1\end{pmatrix}\right] = 0$$

for some function $b(k)$, the so-called reflection coefficient, which may not be analytic in k. In a similar fashion, one can construct solutions $\bar\phi(k,x)$ and $\bar\psi(k,x)$ to (2.1) for $\operatorname{Im} k < 0$ that satisfy

$$\lim_{x\to-\infty} \bar\phi(k,x)\mathrm{e}^{-\mathrm{i}kx} = \begin{pmatrix}0\\-1\end{pmatrix}, \qquad \lim_{x\to\infty} \bar\psi(k,x)\mathrm{e}^{\mathrm{i}kx} = \begin{pmatrix}1\\0\end{pmatrix}.$$

Recall that $\bar\phi$ does not denote the complex conjugate of ϕ. The above solutions are analytic in k for $\operatorname{Im} k < 0$ and can again be extended across $\operatorname{Im} k = 0$ in an analytic fashion. The associated transmission coefficient $\bar a(k)$ is given by

$$\bar a(k) = \bar\phi(k,x) \wedge \bar\psi(k,x)$$

and is analytic for $\operatorname{Im} k \le 0$. For $\operatorname{Im} k < 0$, we have

$$\lim_{x\to\infty} \bar\phi(k,x)\mathrm{e}^{-\mathrm{i}kx} = \bar a(k)\begin{pmatrix}0\\-1\end{pmatrix},$$

while, for $\operatorname{Im} k = 0$, we have

$$\lim_{x\to\infty} \left[\bar\phi(k,x) - \bar a(k)\mathrm{e}^{\mathrm{i}kx}\begin{pmatrix}0\\-1\end{pmatrix} - \bar b(k)\mathrm{e}^{-\mathrm{i}kx}\begin{pmatrix}1\\0\end{pmatrix}\right] = 0$$

for some function $\bar b(k)$ that may not be analytic.

2.3. The adjoint squared eigenfunctions. Next we use the Jost functions to define the squared eigenfunctions $\Psi(k,x)$ and $\bar\Psi(k,x)$ as well as the adjoint squared eigenfunctions $\Psi^A(k,x)$ and $\bar\Psi^A(k,x)$. The functions Ψ and $\bar\Psi$ are given by

$$\Psi(k,x) = \begin{pmatrix}\psi_1(k,x)^2\\ \psi_2(k,x)^2\end{pmatrix}, \qquad \bar\Psi(k,x) = \begin{pmatrix}\bar\psi_1(k,x)^2\\ \bar\psi_2(k,x)^2\end{pmatrix}$$

for $\operatorname{Im} k \geq 0$ and $\operatorname{Im} k \leq 0$, respectively, while Ψ^A and $\bar{\Psi}^A$ are defined via

$$\Psi^A(k,x) = \begin{pmatrix} \phi_2(k,x)^2 \\ -\phi_1(k,x)^2 \end{pmatrix}, \qquad \bar{\Psi}^A(k,x) = \begin{pmatrix} \bar{\phi}_2(k,x)^2 \\ -\bar{\phi}_1(k,x)^2 \end{pmatrix}$$

again for $\operatorname{Im} k \geq 0$ and $\operatorname{Im} k \leq 0$, respectively. All of these functions are analytic in k in their domain of definition. The adjoint squared eigenfunctions satisfy

$$\begin{aligned} &\lim_{x\to-\infty} \Psi^A(k,x)\mathrm{e}^{2\mathrm{i}kx} = \begin{pmatrix} 0 \\ -1 \end{pmatrix}, \qquad \lim_{x\to\infty} \Psi^A(k,x)\mathrm{e}^{2\mathrm{i}kx} = a(k)^2 \begin{pmatrix} 0 \\ -1 \end{pmatrix}, \\ &\lim_{x\to-\infty} \bar{\Psi}^A(k,x)\mathrm{e}^{-2\mathrm{i}kx} = \begin{pmatrix} 1 \\ 0 \end{pmatrix}, \qquad \lim_{x\to\infty} \bar{\Psi}^A(k,x)\mathrm{e}^{-2\mathrm{i}kx} = \bar{a}(k)^2 \begin{pmatrix} 1 \\ 0 \end{pmatrix} \end{aligned} \tag{2.8}$$

for $\operatorname{Im} k > 0$ and $\operatorname{Im} k < 0$, respectively. If $b(k) = \bar{b}(k) = 0$ for all $k \in \mathbb{R}$, then (2.8) is also true for $\operatorname{Im} k = 0$; otherwise, additional terms that involve the reflection coefficients have to be added in a straightforward fashion using the asymptotics of the Jost functions. We remark that the (adjoint) squared eigenfunctions also depend on t. A straightforward computation that uses (2.1) shows that

$$(\mathcal{L}^A(\mathbf{u}) - k)\Psi^A(k,x) = (\mathcal{L}^A(\mathbf{u}) - k)\bar{\Psi}^A(k,x) = 0$$

for any $k \in \mathbb{R}$. For 1-soliton solutions with $r = -q^*$, the adjoint squared eigenfunctions can be calculated explicitly (see [20, section 3]).

2.4. The inverse scattering problem. In the previous sections, we started with a solution $(r,q)(x,t)$ to (2.7) and then associated with that solution the scattering data, the Jost functions, and eventually the squared eigenfunctions. Inverse scattering allows us to, at least in principle, find solutions to (2.7) for a given set of scattering data. In other words, the inverse scattering problem consists of mapping given scattering data to solutions $\mathbf{u} = (r,q)$ of (2.7). We briefly describe the procedure and refer to [2, section IV.B and Appendix 5] and [20, p. 124] for more details and proofs.

Recall that $\Omega(k)$ denotes the polynomial dispersion relation that we chose earlier. We begin with the so-called primordial scattering data

$$\left\{ \frac{\bar{b}_0(k)}{a_0(k)},\ \frac{b_0(k)}{\bar{a}_0(k)};\ k \in \mathbb{R} \right\}, \qquad \left\{ (k_j, \beta_j)_{j=1,N},\ (\bar{k}_j, \bar{\beta}_j)_{j=1,\bar{N}} \right\} \tag{2.9}$$

consisting of the functions a_0, $\bar{a}_0$, b_0, and $\bar{b}_0$, where we assume that the fractions appearing in (2.9) are bounded uniformly in $k \in \mathbb{R}$ and pairs of complex numbers with $\Omega(k_j) = 0 = \Omega(\bar{k}_j)$ for all j. Thus the primordial scattering data involve fractions of the scattering data. We remark that the scattering data can be reconstructed from the primordial scattering data [2, Appendix 5]. We evolve the primordial scattering data by defining

$$\frac{\bar{b}(k,t)}{a(k,t)} = \mathrm{e}^{2\Omega(k)t}\frac{\bar{b}_0(k)}{a_0(k)}, \qquad \frac{b(k,t)}{\bar{a}(k,t)} = \mathrm{e}^{-2\Omega(k)t}\frac{b_0(k)}{\bar{a}_0(k)}. \tag{2.10}$$

Using these data, one can, at least in principle, reconstruct the Jost functions $\phi(k,x)$ and $\bar{\phi}(k,x)$ by solving certain integral equations [2, section IV.B]. Using the Jost functions, we obtain the adjoint squared eigenfunctions and from these a solution

$(r,q)(x,t)$ of (2.7) via

$$\begin{aligned}\begin{pmatrix} r \\ q \end{pmatrix} = \frac{1}{\pi}\int_{-\infty}^{\infty} \left[\frac{\bar{b}(k)}{a(k)}\Psi^A(k,x) + \frac{b(k)}{\bar{a}(k)}\bar{\Psi}^A(k,x)\right] \mathrm{d}k \\ -2\mathrm{i}\sum_{j=1}^{N}\beta_j\Psi^A(k_j,x) + 2\mathrm{i}\sum_{j=1}^{\bar{N}}\bar{\beta}_j\bar{\Psi}^A(\bar{k}_j,x).\end{aligned}$$

In the next section, we restrict our analysis to transmission coefficients $a(k)$ and $\bar{a}(k)$ that are nonzero for $k \in \mathbb{R}$ and that have a finite number of zeros off the real axis $\operatorname{Im} k = 0$. For transmission coefficients with these properties, it was shown by Kaup [19] that the adjoint squared eigenfunctions formed by the Jost functions ϕ and $\bar{\phi}$ form a basis for $L^2(\mathbb{R},\mathbb{C}) \cap L^1(\mathbb{R},\mathbb{C})$.

2.5. Spectral stability of 1-solitons. We consider 1-solitons which are solutions to (2.7) whose scattering data are rather simple [1, 2]. The precise requirements on the scattering data of 1-solitons are summarized in the following assumption.

Assumption 2.1. Assume that $\mathbf{u}_0$ is a stationary, i.e., time-independent, 1-soliton. More precisely, we assume that the following is true: we have $N = \bar{N} = 1$ in (2.9), the associated reflection coefficients $b(k)$ and $\bar{b}(k)$ are identically zero for $k \in \mathbb{R}$, and the associated transmission coefficients $a(k)$ and $\bar{a}(k)$ are nonzero for any $k \in \mathbb{R}$ and have each precisely one simple zero off the real axis $\operatorname{Im} k = 0$.

We remark that the simple zeros of $a(k)$ and $\bar{a}(k)$ are given by $k = k_1$ and $k = \bar{k}_1$, respectively, which are defined in (2.9) [2, Appendix 5].

Note that 1-solitons typically arise as rotating waves $\mathbf{u}(x,t) = \mathrm{e}^{\mathrm{i}\omega t}\mathbf{u}_0(x)$ or as travelling waves $\mathbf{u}(x,t) = \mathbf{u}_0(x - ct)$ (or a combination of both) for suitable real numbers ω and c. Upon changing the coefficients d_0 and d_1 of the dispersion relation $\Omega(k)$ in (2.4), we can always arrange to have $\omega = 0$ and $c = 0$. The change in the dispersion relation amounts to transforming (2.7) into a corotating and comoving coordinate frame (see [2, (2.7)] for an explicit example).

We are interested in the stability of soliton solutions to (2.7) upon adding perturbations that destroy the integrability of (2.7). To investigate this question, we need to have information about the spectrum and the associated eigenfunctions of the integrable PDE (2.7) linearized about a soliton. Thus define

$$\mathcal{K}(\mathbf{u}) := -2\sigma_3\Omega(\mathcal{L}^A(\mathbf{u}))\mathbf{u} \tag{2.11}$$

so that (2.7) is given by $\mathbf{u}_t = \mathcal{K}(\mathbf{u})$ and such that its linearization about the soliton $\mathbf{u}_0$ is

$$\mathbf{v}_t = \mathcal{K}'(\mathbf{u}_0)\mathbf{v}. \tag{2.12}$$

Upon seeking solutions to (2.12) of the form $\mathbf{v}(x,t) = \mathrm{e}^{\lambda t}\mathbf{v}(x)$, we get the associated eigenvalue problem

$$[\mathcal{K}'(\mathbf{u}_0) - \lambda]\mathbf{v} = 0. \tag{2.13}$$

We then have the following lemma.

Lemma 2.2. *Suppose that Assumption* 2.1 *is met. The adjoint squared eigenfunctions* $\Psi^A(k,x)$ *and* $\bar{\Psi}^A(k,x)$ *then satisfy*

$$\begin{aligned} &[\mathcal{K}'(\mathbf{u}_0) - 2\Omega(k)]\sigma_3\Psi^A(k,x) = 0 \quad \textit{for any } k \textit{ with } \operatorname{Im} k \geq 0, \\ &[\mathcal{K}'(\mathbf{u}_0) + 2\Omega(k)]\sigma_3\bar{\Psi}^A(k,x) = 0 \quad \textit{for any } k \textit{ with } \operatorname{Im} k \leq 0. \end{aligned} \tag{2.14}$$

In other words, $\sigma_3\Psi^A(k,x)$ and $\sigma_3\bar{\Psi}^A(k,x)$ are eigenfunctions of the linear operator $\mathcal{K}'(\mathbf{u}_0)$. We remark that the adjoint squared eigenfunctions do not depend on t, since we assumed that the underlying solution $\mathbf{u}_0 = (r_0, q_0)$ is time-independent.

Proof. The claim is a consequence of results by Kaup and Newell (see [24, Appendix B] or [29, section 6.4]). The idea is to compute the variation of (2.7) with respect to one of the primordial scattering data. Hence we fix $\ell \in \mathbb{R}$ and replace the original scattering data by the fractions

$$(1+\epsilon\delta(k-\ell))\frac{\bar{b}(k)}{a(k)},$$

where δ denotes the δ-distribution and ϵ is a small perturbation parameter. The following arguments are formal but can be made rigorous by approximating the δ-distribution with localized bump functions. Upon calculating the derivative of (2.7) with respect to ϵ, we conclude that

$$\frac{\mathrm{d}}{\mathrm{d}\epsilon}\begin{pmatrix} r_t \\ q_t \end{pmatrix} = \mathcal{K}'(\mathbf{u}_0)\frac{\mathrm{d}}{\mathrm{d}\epsilon}\begin{pmatrix} r \\ q \end{pmatrix}$$

so that

$$\sigma_3\frac{\mathrm{d}}{\mathrm{d}\epsilon}\begin{pmatrix} r_t \\ -q_t \end{pmatrix} = \mathcal{K}'(\mathbf{u}_0)\sigma_3\frac{\mathrm{d}}{\mathrm{d}\epsilon}\begin{pmatrix} r \\ -q \end{pmatrix}. \tag{2.15}$$

From [29, (6.55)], we know that

$$\begin{aligned}\frac{\mathrm{d}}{\mathrm{d}\epsilon}\begin{pmatrix} r \\ -q \end{pmatrix} &= -\frac{1}{\pi}\int_{-\infty}^{\infty}\left[\frac{\mathrm{d}}{\mathrm{d}\epsilon}\left(\frac{\bar{b}(k)}{a(k)}\right)\Psi^A(k,x) - \frac{\mathrm{d}}{\mathrm{d}\epsilon}\left(\frac{b(k)}{\bar{a}(k)}\right)\bar{\Psi}^A(k,x)\right]\mathrm{d}k \\ &\quad +2\mathrm{i}\frac{\mathrm{d}\beta_1}{\mathrm{d}\epsilon}\Psi^A(k_1,x) + 2\mathrm{i}\frac{\mathrm{d}\bar{\beta}_1}{\mathrm{d}\epsilon}\bar{\Psi}^A(\bar{k}_1,x).\end{aligned}$$

Upon taking the time derivative of this expression and using (2.10), we obtain

$$\begin{aligned}\frac{\mathrm{d}}{\mathrm{d}\epsilon}\begin{pmatrix} r_t \\ -q_t \end{pmatrix} &= -\frac{1}{\pi}\int_{-\infty}^{\infty}\left[\frac{\mathrm{d}}{\mathrm{d}\epsilon}\left(\frac{\bar{b}(k)}{a(k)}\right)(2\Omega(k)\Psi^A(k,x) + \partial_t\Psi^A(k,x))\right. \\ &\quad \left. -\frac{\mathrm{d}}{\mathrm{d}\epsilon}\left(\frac{b(k)}{\bar{a}(k)}\right)(-2\Omega(k)\bar{\Psi}^A(k,x) + \partial_t\bar{\Psi}^A(k,x))\right]\mathrm{d}k \\ &\quad +2\mathrm{i}\frac{\mathrm{d}\beta_1}{\mathrm{d}\epsilon}\partial_t\Psi^A(k_1,x) + 2\mathrm{i}\frac{\mathrm{d}\bar{\beta}_1}{\mathrm{d}\epsilon}\partial_t\bar{\Psi}^A(\bar{k}_1,x).\end{aligned}$$

Evaluating these expressions at $b = \bar{b} = 0$ and using that the adjoint squared eigenfunctions of the 1-soliton do not depend on time, we get

$$\frac{\mathrm{d}}{\mathrm{d}\epsilon}\begin{pmatrix} r \\ -q \end{pmatrix} = -\frac{1}{\pi}\Psi^A(\ell,x), \qquad \frac{\mathrm{d}}{\mathrm{d}\epsilon}\begin{pmatrix} r_t \\ -q_t \end{pmatrix} = -\frac{2\Omega(\ell)}{\pi}\Psi^A(\ell,x).$$

Substituting this result into (2.15), we obtain

$$2\Omega(\ell)\sigma_3\Psi^A(\ell,x) = \mathcal{K}'(\mathbf{u}_0)\sigma_3\Psi^A(\ell,x),$$

which is the desired result. Using $(1+\epsilon\delta(k-\ell))b(k)/\bar{a}(k)$ and following the steps above, we see that

$$-2\Omega(\ell)\sigma_3\bar{\Psi}^A(\ell,x) = \mathcal{K}'(\mathbf{u}_0)\sigma_3\bar{\Psi}^A(\ell,x)$$

for any $\ell \in \mathbb{R}$. Since the adjoint squared eigenfunctions Ψ^A and the dispersion relation are analytic in ℓ, we conclude that Ψ^A satisfies the above equation for any ℓ with $\operatorname{Im} \ell \geq 0$. This completes the argument. □

The following lemma shows that the only element in the point spectrum Σ_{pt} of the linearized operator $\mathcal{K}'(\mathbf{u}_0)$ is $\lambda = 0$.

LEMMA 2.3. *Suppose that Assumption* 2.1 *is met. If* $\mathbf{v}(x)$ *is a solution of* (2.13) *such that* $\mathbf{v}(x)$ *decays to zero exponentially as* $|x| \to \infty$*, then* $\lambda = 0$ *or* $\mathbf{v} = 0$.

Proof. Suppose that $\mathbf{v}(x)$ is a solution of (2.13) such that $\mathbf{v}(x)$ decays to zero exponentially as $|x| \to \infty$. Owing to the completeness result in [19], we then have

$$\begin{aligned}(2.16)\quad \sigma_3 \mathbf{v}(x) = \int_{-\infty}^{\infty} &\left[\alpha(k)\Psi^A(k,x) + \bar{\alpha}(k)\bar{\Psi}^A(k,x)\right] \mathrm{d}k \\ &+\beta\Psi^A(k_1,x) + \bar{\beta}\bar{\Psi}^A(\bar{k}_1,x) + \gamma\frac{\mathrm{d}}{\mathrm{d}k}\Psi^A(k_1,x) + \bar{\gamma}\frac{\mathrm{d}}{\mathrm{d}k}\bar{\Psi}^A(\bar{k}_1,x)\end{aligned}$$

for certain exponentially decaying functions $\alpha(k), \bar{\alpha}(k)$ and complex numbers $\beta, \bar{\beta}, \gamma$, and $\bar{\gamma}$. Here, the derivatives of Ψ^A and $\bar{\Psi}^A$ with respect to k, evaluated at k_1, are generalized eigenfunctions of $\mathcal{K}'(\mathbf{u}_0)$, belonging to the eigenvalue $\lambda = 0$, that need to be added to the set introduced in section 2.3 to make it complete [19]. Multiplying (2.16) by σ_3, applying the operator $[\mathcal{K}'(\mathbf{u}_0) - \lambda]$ to both sides of the above equation, and exploiting the properties of the adjoint squared eigenfunctions established in [19] and in Lemma 2.2, we obtain

$$\begin{aligned}0 = \int_{-\infty}^{\infty} &\left[(2\Omega(k) - \lambda)\alpha(k)\Psi^A(k,x) - (2\Omega(k) + \lambda)\bar{\alpha}(k)\bar{\Psi}^A(k,x)\right] \mathrm{d}k \\ &+\lambda(\gamma - \beta)\Psi^A(k_1,x) + \lambda(\bar{\gamma} - \bar{\beta})\bar{\Psi}^A(\bar{k}_1,x) - \lambda\gamma\frac{\mathrm{d}\Psi^A}{\mathrm{d}k}(k_1,x) - \lambda\bar{\gamma}\frac{\mathrm{d}\bar{\Psi}^A}{\mathrm{d}k}(\bar{k}_1,x).\end{aligned}$$

We conclude that necessarily $\alpha(k) = \bar{\alpha}(k) = 0$ for all k. Furthermore, we have either $\lambda = 0$ or the coefficients $\beta, \bar{\beta}, \gamma$, and $\bar{\gamma}$ vanish. In the latter case, we have $\mathbf{v} = 0$. □

Note that, as a consequence of the results in [19], $\lambda = 0$ has geometric multiplicity two, and each of the geometric eigenvalues admits a maximal Jordan block of length two. In fact, the eigenfunctions are given by $\Psi^A(k_1,x)$ and $\bar{\Psi}^A(\bar{k}_1,x)$, where k_1 and $\bar{k}_1$ are defined in (2.9), and the associated generalized eigenfunctions are $\frac{\mathrm{d}}{\mathrm{d}k}\Psi^A(k_1,x)$ and $\frac{\mathrm{d}}{\mathrm{d}k}\bar{\Psi}^A(\bar{k}_1,x)$, respectively. This can be confirmed by taking derivatives of (2.14) with respect to k, evaluated at $k = k_1$ and $k = \bar{k}_1$, using that $\Omega(k_1) = \Omega(\bar{k}_1) = 0$, and exploiting (2.8) together with the assumption that $k = k_1$ and $k = \bar{k}_1$ are simple zeros of $a(k)$ and $\bar{a}(k)$, respectively.

It is straightforward to compute the essential spectrum Σ_{ess} of $\mathcal{K}'(\mathbf{u}_0)$. The operator $\mathcal{K}'(\mathbf{u}_0)$ is a relatively compact perturbation of the linearization $\mathcal{K}'(0)$ about the asymptotic rest state $\mathbf{u} = 0$ which is given by

$$\mathcal{K}'(0) = -2\sigma_3\Omega\left(-\frac{1}{2}\mathrm{i}\sigma_3\partial_x\right)$$

on account of (2.6) and (2.11). As a consequence, the essential spectrum of $\mathcal{K}'(\mathbf{u}_0)$ is

$$(2.17)\qquad \Sigma_{\mathrm{ess}} = \{\lambda \in \mathbb{C};\ \lambda = \pm 2\Omega(k) \text{ for some } k \in \mathbb{R}\}.$$

More precisely, the radiation modes are given by $\exp(\lambda t + \mathrm{i}kx)\mathbf{v}_0$, where λ and k are related via $\lambda = 2\Omega(-k/2)$ for $\mathbf{v}_0 = (1,0)$ and $\lambda = -2\Omega(k/2)$ for $\mathbf{v}_0 = (0,1)$. In particular, the essential spectrum is (marginally) stable, i.e., lies on the imaginary axis, if and only if the coefficients in (2.7) are purely imaginary. Since the soliton is certainly unstable if the essential spectrum is unstable, we assume henceforth that the above condition on the coefficients is met.

Assumption 2.4. We assume that the coefficients d_j of the dispersion relation $\Omega(k)$, introduced in (2.4), are purely imaginary; i.e., we have $d_j \in \mathrm{i}\mathbb{R}$ for $j = 0, \ldots, n$.

3. The Evans function.

Now that those aspects of the inverse scattering formalism that will be necessary for the following analysis have been addressed, we will proceed to show how Assumption 2.1 yields precise information as to how one can locate those points in the continuous spectrum at which discrete eigenvalues may move out upon adding a perturbation to the integrable PDE (2.7). The tool we choose to use is the Evans function, $E(\lambda)$. Thus, consider the eigenvalue problem (2.13)

$$[\mathcal{K}'(\mathbf{u}_0) - \lambda]\mathbf{v} = 0. \tag{3.1}$$

We assume that this eigenvalue problem can be rewritten as the first-order system

$$\frac{\mathrm{d}}{\mathrm{d}x}\mathbf{Y} = [M(\lambda) + R(x)]\mathbf{Y}, \qquad \mathbf{Y}(x) \in \mathbb{C}^{2n}, \tag{3.2}$$

where n is the degree of the polynomial dispersion relation (2.4) and therefore of the linearized PDE (3.1). The matrix $R(x)$ converges to zero exponentially fast as $|x| \to \infty$. Note that $\mathbf{v}$ satisfies (3.1) if and only if $Y = (1, \frac{\mathrm{d}}{\mathrm{d}x}, \ldots, \frac{\mathrm{d}^{n-1}}{\mathrm{d}x^{n-1}})\mathbf{v}$ satisfies (3.2).

3.1. The construction of the Evans function.

We briefly recall the construction of the Evans function following the approach in [36] that avoids differential forms and refer to [4] for the original approach via differential forms. We begin by defining the Evans function for values of $\lambda \in \mathbb{C}$ such that λ is not in the essential spectrum given in (2.17). For such values of λ, the matrix $M(\lambda)$ is hyperbolic, i.e., its spectrum contains no points on the imaginary axis. We are interested in locating isolated eigenvalues which correspond to those values of λ for which (3.2) or, equivalently, (3.1) has a nonzero localized solution. We accomplish this by constructing all solutions to (3.2) that decay as $x \to -\infty$ and all solutions that decay as $x \to \infty$. The associated initial data at a given value of x then define two subspaces such that λ is an eigenvalue if and only if those two subspaces have a nontrivial intersection, leading to a solution of (3.2) that decays as $x \to \pm\infty$. Therefore, assuming that $M(\lambda)$ has n_u eigenvalues with positive real part and $n_s = 2n - n_u$ eigenvalues with negative real part, choose two sets $\{\mathbf{Y}_j(\lambda, x)\}_{j=1,\ldots,n_u}$ and $\{\mathbf{Y}_j(\lambda, x)\}_{j=n_u+1,\ldots,2n}$ of linearly independent solutions of (3.2) with the following properties: the above solutions depend analytically on λ, $\mathbf{Y}_j(\lambda, x)$ converges to zero exponentially as $x \to -\infty$ for $j = 1, \ldots, n_u$, and $\mathbf{Y}_j(\lambda, x)$ converges to zero exponentially as $x \to \infty$ for $j = n_u + 1, \ldots, 2n$. Note that such a choice is always possible (see, e.g., [36]). The Evans function $E(\lambda)$ is the complex-valued function defined by

$$E(\lambda) = \exp\left(-\int_0^x \mathrm{tr}[M(\lambda) + R(s)]\,\mathrm{d}s\right) \det(\mathbf{Y}_1(\lambda, x) \ldots \mathbf{Y}_{2n}(\lambda, x)),$$

where we consider the $2n$ vectors $\mathbf{Y}_j(\lambda, x)$ as column vectors in a $2n \times 2n$ matrix. By construction, λ is in the point spectrum Σ_{pt} if and only if $E(\lambda) = 0$, as this then leads to a solution (the eigenfunction) of (3.2) that decays exponentially as $|x| \to \infty$.

In fact, the algebraic multiplicity of λ, considered as an eigenvalue of $\mathcal{K}'(\mathbf{u}_0)$, is equal to the order of λ, considered as a zero of $E(\lambda)$; see [4]. As we shall see now, the set $\{\mathbf{Y}_j(\lambda,x)\}_{j=1,\ldots,n_\mathrm{u}}$ can be constructed from the adjoint squared eigenfunctions $\sigma_3\Psi^A(k,x)$ and $\sigma_3\bar{\Psi}^A(k,x)$.

To see this, fix again λ with $\operatorname{Re}\lambda \geq 0$ such that $\lambda \notin \Sigma_{\mathrm{ess}}$. For any such fixed λ, solve the equation $\lambda = 2\Omega(k)$ subject to the constraint $\operatorname{Im} k > 0$, and denote the corresponding roots by $k_1, \ldots, k_\ell$, counted with their order.[1] Analogously, solve $\lambda = -2\Omega(k)$ subject to the constraint $\operatorname{Im} k < 0$, and denote the solutions by $\bar{k}_1, \ldots, \bar{k}_{\bar{\ell}}$, again counted with their order. Note that ℓ and $\bar{\ell}$ are independent of λ, since ℓ and $\bar{\ell}$ can change only when one of the k's becomes real, which can happen only for $\lambda \in \Sigma_{\mathrm{ess}}$. We exclude those values of λ, however. We remark that the solutions $k_1, \ldots, k_\ell$ and $\bar{k}_1, \ldots, \bar{k}_{\bar{\ell}}$ depend continuously on λ.

The roots k_j and $\bar{k}_j$ of the dispersion relation and the eigenvalues ν_j and $\bar{\nu}_j$ of the matrix $M(\lambda)$ are related via

$$\nu_j = -2\mathrm{i}k_j, \qquad \bar{\nu}_j = 2\mathrm{i}\bar{k}_j \tag{3.3}$$

for $j = 1, \ldots, n$. Note that the unstable eigenvalues of $M(\lambda)$ are those that correspond to $k_1, \ldots, k_\ell$ and $\bar{k}_1, \ldots, \bar{k}_{\bar{\ell}}$, so that $\ell + \bar{\ell} = n_u$.

Consider the eigenvalue problem (3.1). Suppose first that λ is such that $k_1, \ldots, k_\ell$ are ℓ distinct numbers, while $\bar{k}_1, \ldots, \bar{k}_{\bar{\ell}}$ are $\bar{\ell}$ distinct numbers. As a consequence of Lemma 2.2, $\sigma_3\Psi^A(k_j,x)$ for $j = 1, \ldots, \ell$ and $\sigma_3\bar{\Psi}^A(\bar{k}_j,x)$ for $j = 1, \ldots, \bar{\ell}$ are solutions to the eigenvalue problem (3.1). Furthermore, on account of (2.8) and the above discussion, these solutions are linearly independent, they decay exponentially as $x \to -\infty$, and any solution to (3.1) with this property is, in fact, a linear combination of the above adjoint squared eigenfunctions. Again, due to (2.8), any linear combination of the $\Psi^A(k_1,x), \ldots, \Psi^A(k_\ell,x)$ and $\bar{\Psi}^A(\bar{k}_1,x), \ldots, \bar{\Psi}^A(\bar{k}_{\bar{\ell}},x)$ grows exponentially as $x \to \infty$ except for those λ for which $a(k_j)$ or $\bar{a}(\bar{k}_j)$ vanishes for some j. Assumption 2.1 precludes this except when $\lambda = 0$.

Next suppose that one of the $k_1, \ldots, k_\ell$ has order $m > 1$ as a zero of $\lambda = 2\Omega(k)$. In other words, assume that, possibly after relabeling the roots, $k_1 = \cdots = k_m$ and $k_j \neq k_1$ for $j = m+1, \ldots, \ell$, so that

$$\frac{\mathrm{d}^j}{\mathrm{d}k^j}\Omega(k)\Big|_{k=k_1, j=1,\ldots,m-1} = 0, \qquad \frac{\mathrm{d}^m}{\mathrm{d}k^m}\Omega(k)\Big|_{k=k_1} \neq 0.$$

Differentiating (2.14) and (2.8) with respect to k shows that $\sigma_3 \frac{\mathrm{d}^j}{\mathrm{d}k^j}\Psi^A(k_1,x)$ satisfies (3.1) with

$$\lim_{x\to-\infty} \frac{\mathrm{e}^{2\mathrm{i}k_1 x}}{(-2\mathrm{i}x)^j} \frac{\mathrm{d}^j\Psi^A}{\mathrm{d}k^j}(k_1,x) = \begin{pmatrix} 0 \\ -1 \end{pmatrix}, \quad \lim_{x\to\infty} \frac{\mathrm{e}^{2\mathrm{i}k_1 x}}{(-2\mathrm{i}x)^j} \frac{\mathrm{d}^j\Psi^A}{\mathrm{d}k^j}(k_1,x) = a(k_1)^2 \begin{pmatrix} 0 \\ -1 \end{pmatrix}$$

for $j = 0, \ldots, m-1$. Furthermore, these solutions together with the remaining functions $\Psi^A(k_{m+1},x), \ldots, \Psi^A(k_\ell,x)$ and $\bar{\Psi}^A(\bar{k}_1,x), \ldots, \bar{\Psi}^A(\bar{k}_{\bar{\ell}},x)$ form a linearly independent set of solutions upon multiplying them by σ_3. Again, linear combinations of these functions generate all solutions to (3.1) that decay as $x \to -\infty$, and any such combination grows exponentially as $x \to \infty$ except when $\lambda = 0$.

The above discussion provides a different proof of Lemma 2.2. The crucial assumption is that $a(k)\bar{a}(k) \neq 0$ except for those k for which $\Omega(k) = 0$ so that $\lambda = 0$.

[1] Note that we abuse notation: the roots $k_1, \ldots, k_\ell$ are not related to the numbers appearing in (2.9).

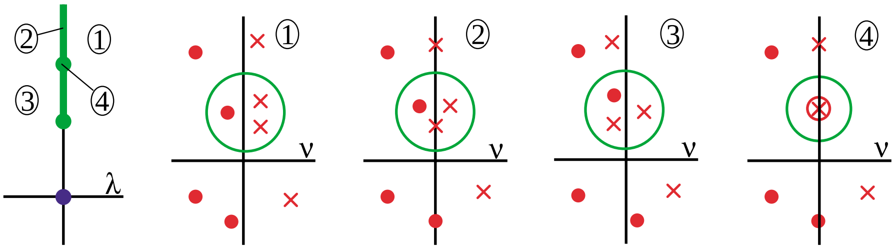

FIG. 3.1. *The leftmost plot shows the spectrum of the integrable PDE in the complex λ-plane with the upper bullet labeled 4 being the branch point λ_*. The other four plots, numbered 1–4, show the eigenvalues ν and $\bar{\nu}$ (related via (3.3) to the roots k and $\bar{k}$ of the dispersion relation) of the matrix $M(\lambda)$ for λ to the right (1), on (2), and to the left (3) of the essential spectrum. The inset with label 4 shows these eigenvalues at the branch point, where the three spatial eigenvalues ν inside the circle collapse. In the plots labeled 1–4, bullets and crosses denote the eigenvalues in the stable and unstable sets.*

An extension of the above calculation will allow us to address the issue of locating edge-bifurcation points.

In the last step, we concentrate on the essential spectrum. The idea is to analytically extend the solutions $\mathbf{Y}_j(\lambda, x)$ that we constructed above for $\lambda \notin \Sigma_{\text{ess}}$ into the essential spectrum. Hence again fix λ with $\operatorname{Re}\lambda \geq 0$ such that $\lambda \notin \Sigma_{\text{ess}}$. Define the sets

$$K^u(\lambda) := \{k_1(\lambda), \dots, k_\ell(\lambda)\}, \qquad \bar{K}^u(\lambda) := \{\bar{k}_1(\lambda), \dots, \bar{k}_{\bar{\ell}}(\lambda)\},$$

which depend continuously on λ. Analogously, denote by $k_{\ell+1}, \dots, k_n$ the roots of $\lambda = 2\Omega(k)$ that satisfy $\operatorname{Im} k < 0$ and by $\bar{k}_{\bar{\ell}+1}, \dots, \bar{k}_n$ the roots of $\lambda = -2\Omega(k)$ with $\operatorname{Im} k > 0$, and define

$$K^s(\lambda) := \{k_{\ell+1}(\lambda), \dots, k_n(\lambda)\}, \qquad \bar{K}^s(\lambda) := \{\bar{k}_{\bar{\ell}+1}(\lambda), \dots, \bar{k}_n(\lambda)\}.$$

We then continue these sets of roots into the essential spectrum, which is possible since the roots k of $\lambda = 2\Omega(k)$ and $\lambda = -2\Omega(k)$ depend continuously on λ. Note that the sets $K^u(\lambda)$ and $K^s(\lambda)$ have a nonempty intersection precisely when $\lambda = 2\Omega(k)$ and $\Omega'(k) = 0$ for some $k \in \mathbb{R}$. In fact, $K^u(\lambda) \cap K^s(\lambda)$ consists exactly of all elements k with the above property. The analogous statement is, of course, true for $\bar{K}^u(\lambda)$ and $\bar{K}^s(\lambda)$. We say that λ is a branch point of the essential spectrum if $K^u(\lambda) \cap K^s(\lambda)$ or $\bar{K}^u(\lambda) \cap \bar{K}^s(\lambda)$ are nonempty. This is also illustrated in Figure 3.1.

On account of [17] and the above discussion, the Evans function $E(\lambda)$ vanishes for $\lambda \in \Sigma_{\text{ess}}$ if and only if there are coefficients $b_j, \bar{b}_j \in \mathbb{C}$, with $j = 1, \dots, n$ such that the function

$$v(x) = \sum_{j=1}^{\ell} b_j \Psi^A(k_j(\lambda), x) + \sum_{j=1}^{\bar{\ell}} \bar{b}_j \bar{\Psi}^A(\bar{k}_j(\lambda), x) \tag{3.4}$$

has the asymptotic behavior

$$v(x) = \sum_{j=\ell+1}^{n} b_j \mathrm{e}^{-2\mathrm{i}k_j(\lambda)x} \begin{pmatrix} 0 \\ 1 \end{pmatrix} + \sum_{j=\bar{\ell}+1}^{n} \bar{b}_j \mathrm{e}^{-2\mathrm{i}\bar{k}_j(\lambda)x} \begin{pmatrix} 1 \\ 0 \end{pmatrix} + \mathrm{O}(x^{-1}) \tag{3.5}$$

as $x \to \infty$. Of course, at least one of the coefficients b_j and $\bar{b}_j$ has to be nonzero. In other words, we seek solutions to (3.1) or, equivalently, (3.2) that have wavenumbers in K^u or $\bar{K}^u$ as $x \to -\infty$ and wavenumbers in K^s or $\bar{K}^s$ as $x \to \infty$. Comparing (3.4) and (3.5) with (2.8), we see that this occurs exactly when $a(k)\bar{a}(k) = 0$ for some $k \in \mathbb{C}$ with $\lambda = 2\Omega(k)$ or $\lambda = -2\Omega(k)$ or else if λ is a branch point of the essential spectrum. Indeed, if $k \in K^u(\lambda) \cap K^s(\lambda)$, then $k = k_1(\lambda) = k_{\ell+1}(\lambda)$, possibly after relabeling the roots, and $v(x) = \Psi^A(k, x)$ satisfies (3.5).

In summary, we have proved the following theorem.

Theorem 3.1. *Assume that Assumptions* 2.1 *and* 2.4 *are met. The Evans function $E(\lambda)$ vanishes only at $\lambda = 0$ and at points λ for which there is a $k \in \mathbb{R}$ such that $\lambda = 2\Omega(k)$ (or $\lambda = -2\Omega(k)$) and $\Omega'(k) = 0$.*

Recall our original motivation: we wanted to locate all points in the essential spectrum where discrete eigenvalues may move out upon adding a perturbation to the original PDE. Any such point corresponds to a zero of the Evans function, and the above theorem indeed gives all zeros of the Evans function: apart from $\lambda = 0$, these zeros are in one-to-one correspondence with the branch points of the essential spectrum, i.e., with any point λ such that there is a $k \in \mathbb{R}$ with $\lambda = 2\Omega(k)$, or $\lambda = -2\Omega(k)$ and $\Omega'(k) = 0$. The remaining issues are to predict how many eigenvalues may move out of the essential spectrum and to locate those eigenvalues for a given perturbation. In the next section, we discuss the first issue.

3.2. The Evans function at branch points.

We want to compute the Evans function $E(\lambda)$ for λ close to a fixed branch point $\lambda_* \in \Sigma_{\text{ess}}$. We assume that λ_* is a branch point of $\lambda = 2\Omega(k)$; the case of branch points of $\lambda = -2\Omega(k)$ can, of course, be handled in the same fashion. Thus we assume that there is a number $k_* \in \mathbb{R}$ such that $\lambda_* = 2\Omega(k_*)$ and $\Omega'(k_*) = 0$. In addition, we assume that the following nondegeneracy condition is met. At the end of this section, we shall comment on the situation where the following assumption is not met.

Assumption 3.2. Assume that λ_* is a nondegenerate branch point, i.e., we have $\Omega'(k) \neq 0$ for any $k \in \mathbb{R}$ such that $\lambda_* = -2\Omega(k)$, or else $\lambda_* = 2\Omega(k)$ with $k \neq k_*$.

Throughout this section, we assume that λ is close to λ_*. Denote by $m \in \mathbb{N}$ the order of k_* as a root of $\lambda_* = 2\Omega(k)$. Note that $m > 1$. As a consequence of Assumption 3.2, we therefore have

$$\lambda = 2\Omega(k) = \lambda_* + (k - k_*)^m \tilde{\Omega}(k), \qquad \tilde{\Omega}(k_*) \in \mathrm{i}\mathbb{R} \setminus \{0\}. \tag{3.6}$$

In particular, if we continue the m roots of (3.6) near k_*, then, upon tracing out one revolution on a circle in λ that is centered at λ_*, these roots undergo a cyclic permutation of length m. After m full revolutions, the roots are labeled as before [18, section II.1.2]. Following [15, 16, 17], we will wish to define the Evans function on an appropriate Riemann surface. We therefore set

$$\lambda = \lambda_* + \gamma^m, \tag{3.7}$$

so that $\arg(\gamma) \in [-\pi/2m, \pi/2m)$ corresponds to the principal sheet of the Riemann surface. The m roots of (3.6) near k_* are then given by

$$k_* + \gamma \exp\left(\frac{2\pi \mathrm{i} j}{m}\right)(\tilde{\Omega}(k_*)^{\frac{1}{m}} + \mathrm{O}(\gamma)), \qquad j = 0, \ldots, m-1. \tag{3.8}$$

For $\operatorname{Re}\lambda > 0$, i.e., for $\arg(\gamma) \in (-\pi/2m, \pi/2m)$, none of the roots in (3.8) is real. (Otherwise, λ would be in the continuous spectrum.) Thus there are numbers m_u and $m_s = m - m_u$ such that m_u of the roots k in (3.8) have $\operatorname{Im} k > 0$ and m_s of them have $\operatorname{Im} k < 0$. We denote these roots by $k_1(\gamma), \dots, k_{m_u}(\gamma)$ and $k_{\ell+1}(\gamma), \dots, k_{\ell+m_s}(\gamma)$, where ℓ is as in section 3.1. Note that these roots are analytic in γ.

The remaining $n-m$ roots k of (3.6) that are not close to k_* can also be divided into roots with $\operatorname{Im} k > 0$ and $\operatorname{Im} k < 0$. We denote those roots by $k_{m_u+1}(\gamma), \dots, k_\ell(\gamma)$ and $k_{\ell+m_s+1}(\gamma), \dots, k_n(\gamma)$, respectively. The roots $\bar{k}_1, \dots, \bar{k}_{\bar{\ell}}$ and $\bar{k}_{\bar{\ell}+1}, \dots, \bar{k}_n$ of $\lambda = -2\Omega(k)$ with $\operatorname{Im} k < 0$ and $\operatorname{Im} k > 0$, respectively, are defined as in section 3.1. As before, the collections of stable and unstable roots define the sets $K^u(\gamma)$ and $K^s(\gamma)$ as well as $\bar{K}^u(\gamma)$ and $\bar{K}^s(\gamma)$.

The key is that these sets are well defined for any γ close to zero. Indeed, we had seen earlier that the sets K^u and K^s (or $\bar{K}^u$ and $\bar{K}^s$) have a nonempty intersection only at branch points with the elements in the intersection given by the roots of the dispersion relation that cause the branch points. Due to Assumption 3.2, those roots are the ones of (3.6) near k_*. These critical roots, however, depend analytically on the new spectral parameter γ.

Figure 3.1 illustrates the situation. Plotted there is the spectrum of the operator $\mathcal{K}'(\mathbf{u}_0)$ and the spectra of the matrix $M(\lambda)$ that appears in (3.2). Note that the eigenvalues of $M(\lambda)$ are related via (3.3) to the roots of the dispersion relation.

The Evans function $E(\gamma)$ is now defined as before except that we count the eigenspaces associated with the roots $k_1(\gamma), \dots, k_\ell(\gamma)$ and $\bar{k}_1(\gamma), \dots, \bar{k}_{\bar{\ell}}(\gamma)$ as unstable and the eigenvalues associated with $k_{\ell+1}, \dots, k_n$ and $\bar{k}_{\bar{\ell}+1}, \dots, \bar{k}_n$ as stable. Again, linearly independent solutions to (3.1) and (3.2) can be computed as in the previous section using the adjoint squared eigenfunctions. The crucial contribution comes from the critical roots $k_1(\gamma), \dots, k_{m_u}(\gamma)$ and $k_{\ell+1}(\gamma), \dots, k_{\ell+m_s}(\gamma)$. First, note that the adjoint squared eigenfunctions $\Psi^A(k_1(\gamma), x), \dots, \Psi^A(k_{m_u}(\gamma), x)$ and $\Psi^A(k_{\ell+1}(\gamma), x), \dots, \Psi^A(k_{\ell+m_s}(\gamma), x)$ are well defined and analytic in γ due to the analytic extension of the Jost function ϕ across $\operatorname{Im} k = 0$. We can therefore use the adjoint squared eigenfunctions to construct solutions of (3.2) in the unstable and stable eigenspaces via

$$\mathbf{Y}_j(x) = \left(1, \frac{\mathrm{d}}{\mathrm{d}x}, \dots, \frac{\mathrm{d}^{n-1}}{\mathrm{d}x^{n-1}}\right) \Psi^A(k_j(\gamma), x).$$

Note, however, that the functions $\mathbf{Y}_1, \dots, \mathbf{Y}_{m_u}$, and likewise $\mathbf{Y}_{\ell+1}, \dots, \mathbf{Y}_{\ell+m_s}$, are linearly independent only for $\gamma \neq 0$. At $\gamma = 0$, all of these functions coincide. It is certainly possible to construct from the $\mathbf{Y}_j$ a set of linearly independent solutions. Before we do that, note that, due to (3.8), we have

$$\det \begin{pmatrix} 1 & \dots & 1 & 1 & \dots & 1 \\ k_1 & \dots & k_{m_u} & k_{\ell+1} & \dots & k_{\ell+m_s} \\ \vdots & \dots & \vdots & \vdots & \dots & \vdots \\ k_1^{m-1} & \dots & k_{m_u}^{m-1} & k_{\ell+1}^{m-1} & \dots & k_{\ell+m_s}^{m-1} \end{pmatrix} = C_{\mathrm{vmd}} \gamma^{m(m-1)/2}(1 + \mathrm{O}(\gamma)),$$

where

$$C_{\mathrm{vmd}} = \tilde{\Omega}(k_*)^{\frac{m-1}{2}} \prod_{j>l} \left[\exp\left(\frac{2\pi \mathrm{i} j}{m}\right) - \exp\left(\frac{2\pi \mathrm{i} l}{m}\right)\right] \neq 0$$

is a nonzero Vandermonde determinant. Thus, upon exploiting once more the asymptotics (2.8) of the squared eigenfunctions together with the expression (3.8), we see that the minor of the determinant of the matrix with columns $\mathbf{Y}_1(x), \dots, \mathbf{Y}_{m_u}(x)$ is given by $C_u\gamma^{m_u(m_u-1)/2}$ as $x \to \infty$ for some nonzero number C_u. Analogously, the minor of the determinant of the matrix with columns $\mathbf{Y}_{\ell+1}(x), \dots, \mathbf{Y}_{\ell+m_s}(x)$ is given by $C_s\gamma^{m_s(m_s-1)/2}$ as $x \to \infty$ for some $C_s \neq 0$. Thus we may still use the solutions $\mathbf{Y}_1, \dots, \mathbf{Y}_{m_u}$ and $\mathbf{Y}_{\ell+1}, \dots, \mathbf{Y}_{\ell+m_s}$ but must divide the determinant in the definition of the Evans function by the product $C_uC_s\gamma^{m_u(m_u-1)/2}\gamma^{m_s(m_s-1)/2}$ to account for the degeneracy of these solutions. Thus we can finally calculate the Evans function. We obtain

$$\begin{aligned} E(\gamma) &= \exp\left(-\int_0^x \operatorname{tr}[M(\lambda)+R(s)]\,\mathrm{d}s\right)\det(\mathbf{Y}_1(\gamma,x)\dots\mathbf{Y}_{2n}(\gamma,x)) \\ &= \tilde{C}_*(1+\mathrm{O}(\gamma))\gamma^{-m_u(m_u-1)/2}\gamma^{-m_s(m_s-1)/2} \\ &\quad \times \det\begin{pmatrix} 1 & \dots & 1 & 1 & \dots & 1 \\ k_1 & \dots & k_{m_u} & k_{\ell+1} & \dots & k_{\ell+m_s} \\ \vdots & \dots & \vdots & \vdots & \dots & \vdots \\ k_1^{m-1} & \dots & k_{m_u}^{m-1} & k_{\ell+1}^{m-1} & \dots & k_{\ell+m_s}^{m-1} \end{pmatrix} \\ &= C_*(1+\mathrm{O}(\gamma))\gamma^{-m_u(m_u-1)/2}\gamma^{-m_s(m_s-1)/2}\gamma^{m(m-1)/2} \\ &= C_*(1+\mathrm{O}(\gamma))\gamma^{m_um_s}, \end{aligned} \tag{3.9}$$

where the coefficient $C_* \in \mathbb{C}$ is a nonzero number that involves a product of transmission coefficients. Note that we used in (3.9) that the only nonzero contribution to the determinant is from the critical solutions that we constructed above. Indeed, the analysis in section 3.1 applies to all the other solutions. Thus we proved the following theorem.

Theorem 3.3. *Suppose that Assumptions* 2.1, 2.4, *and* 3.2 *are met. Recall the definitions of* m_u *and* $m_s = m - m_u$ *introduced after* (3.8)*. The Evans function* $E(\gamma)$ *is then given by*

$$E(\gamma) = C_*\gamma^{m_um_s} + \mathrm{O}(\gamma^{m_um_s+1}),$$

where $C_* \neq 0$ *and* $\lambda = \lambda_* + \gamma^m$*. Only roots of the Evans function* $E(\gamma)$ *that satisfy* $-\pi/2m < \arg(\gamma) < \pi/2m$ *correspond to eigenvalues of the operator* $\mathcal{K}'(\mathbf{u}_0)$.

As a consequence of Theorem 3.3, upon adding a perturbation of the integrable PDE, there will be m_um_s zeros of the Evans function near $\lambda = \lambda_*$ on the Riemann surface. It is then of interest to understand how many of these zeros correspond to true eigenvalues of the linearized PDE operator and if any oscillatory instabilities arise as a result of the perturbation. This computation involves a Taylor expansion of the Evans function with respect to γ and the perturbation parameter ϵ. The generic case $m = 2$ (with $m_u = m_s = 1$) was considered by Kivshar et al. [25] for conservative perturbations and independently by Kapitula and Sandstede [16, 17] for arbitrary perturbations. Additional applications can be found [27]. Combining the results in [13] and [36], one can derive Taylor expansions of the Evans function also for $m > 1$. Since the expansion depends strongly on m and m_u, we decided not to give any details pertaining to the Zakharov–Shabat problem, and we refer instead to section 4 for an example that involves a branch point of higher order for the massive Thirring model.

3.3. Discussion. We briefly comment on degenerate branch points that violate Assumption 3.2. In this case, there would be several wavenumbers $k_*^{(1)}, \dots, k_*^{(l)} \in \mathbb{R}$ with associated orders $m^{(1)}, \dots, m^{(l)}$ for some $l > 1$. It is then tempting to guess that $E(\gamma) \sim \prod_{j=1}^{l} \gamma^{m_u^{(j)}m_s^{(j)}}$. This is *not* the case, however. The reason is that we need to find the correct scaling for γ in (3.7) that allows us to extend the Evans function to an appropriate Riemann surface. The $m^{(j)}$ roots associated with $k_*^{(j)}$ form a permutation cycle of length $m^{(j)}$. Thus, in (3.7), we need to choose m to be the least common multiple of the numbers $m^{(1)}, \dots, m^{(l)}$. Proceeding as in this section, we see that the order of the Evans functions at degenerate branch points is typically larger than our guess predicts. On the other hand, since only zeros with $-\pi/2m < \arg(\gamma) < \pi/2m$ correspond to true eigenvalues, we also see that less of these zeros are actually meaningful for the original eigenvalue problem.

Last, note that the proof of Theorem 3.1 uses, in a crucial way, the hypothesis that the transmission coefficients $a(k)$ and $\bar{a}(k)$ do not vanish for $k \in \mathbb{R}$ (see Assumption 2.1). In fact, if this assumption is violated so that $a(k_*) = 0$ for some $k_* \in \mathbb{R}$, then the Evans function $E(\lambda)$ vanishes also for $\lambda = 2\Omega(k_*) \in \Sigma_{\text{ess}}$, which may not be a branch point.

4. The massive Thirring model. In the previous two sections, a class of problems was considered in which the PDE had a single dispersion relation associated with it. In this section, a PDE which has two dispersion relations will be discussed. Each will generate a single branch point of the Evans function; furthermore, near each branch point, $E(\gamma) \sim \gamma$ on the appropriate Riemann surface. As a consequence, when doing perturbation expansions, the work presented in [15, 17] will directly apply. However, as a certain parameter is varied, the two branch points will collide so that now $E(\gamma) \sim \gamma^2$. We will perform a perturbation expansion in this case and show that the collision of the branch points can induce an oscillatory instability for the underlying wave.

A light pulse that propagates in a nonlinear grating with a quadratic nonlinearity may generate pulses at higher frequencies via second-harmonic generation. In the case of a longitudinal periodic variation of the linear susceptibility which couples two linearly polarized envelopes at the fundamental frequency, a second-harmonic field is generated through type II second-harmonic generation. The normalized equations which describe this phenomenon are given by

$$\begin{aligned} &\mathrm{i}\partial_t a_1 + \mathrm{i}\partial_x a_1 - \beta a_1 + a_2 + a_3 a_2^* = 0, \\ &\mathrm{i}\partial_t a_2 - \mathrm{i}\partial_x a_2 + a_1 + \beta a_2 + a_3 a_1^* = 0, \\ &\mathrm{i}\partial_t a_3 + \mathrm{i}v\partial_x a_3 + \delta k\, a_3 + a_1 a_2 = 0 \end{aligned} \tag{4.1}$$

(see Trillo [38]). In the above equation, a_j represents the normalized polarized envelope, δk is the second-harmonic generation wave-vector mismatch, and β represents the coupling of the grating to the second-harmonic beam. In the derivation of (4.1), $|\beta| \ll 1$ has been assumed. The parameter v represents the walk-off of the generated second harmonic: when $v = 0$, the second-harmonic velocity is identical with the group velocity, at the fundamental frequency, of the material. Here, we consider only the case $v = 0$ that occurs when the second-harmonic velocity is close to the fundamental frequency of the material [38].

Note that (4.1) is equivariant with respect to phase rotations

$$(a_1, a_2, a_3) \longmapsto (a_1 \mathrm{e}^{\mathrm{i}\alpha}, a_2 \mathrm{e}^{\mathrm{i}\alpha}, a_3 \mathrm{e}^{2\mathrm{i}\alpha}), \qquad \alpha \in \mathbb{R}.$$

Thus we seek rotating waves of the form

$$a_1 = \tilde{a}_1 \mathrm{e}^{-\mathrm{i}\beta x}, \qquad a_2 = \tilde{a}_2 \mathrm{e}^{-\mathrm{i}\beta x}, \qquad a_3 = \tilde{a}_3 \mathrm{e}^{-2\mathrm{i}\beta x}.$$

Substituting this ansatz into (4.1) and dropping the tildes, we obtain

$$\begin{aligned} \mathrm{i}(\partial_t+\partial_x)a_1+a_2+a_3a_2^*&=0,\\ \mathrm{i}(\partial_t-\partial_x)a_2+a_1+a_3a_1^*&=0,\\ \mathrm{i}\partial_t a_3+\delta k\, a_3+a_1a_2&=0. \end{aligned} \tag{4.2}$$

(Recall that we set $v=0$.) Note that (4.2) is Hamiltonian

$$\mathrm{i}\partial_\xi a_j=\frac{\delta H}{\delta a_j^*}\qquad (j=1,2,3),$$

where the Hamiltonian is given by [37]

$$\begin{aligned} H=\int_{-\infty}^{\infty}\Bigg[&\frac{\mathrm{i}}{2}(a_2\partial_x a_2^*-a_1\partial_x a_1^*)+\text{c.c.}\\ &-\delta k|a_3|^2-a_1a_2^*-a_1^*a_2-a_1^*a_2^*a_3-a_1a_2a_3^*\Bigg]\,\mathrm{d}x. \end{aligned}$$

We assume that the mismatch is large and negative, i.e., that $|\delta k|\gg 1$ and $\delta k<0$. Let $\epsilon=-1/\delta k$ so that $0<\epsilon\ll 1$. Upon defining $u_j=a_j/\sqrt{\epsilon}$ for $j=1,2$, (4.2) becomes

$$\begin{aligned} \mathrm{i}(\partial_t+\partial_x)u_1+u_2+a_3u_2^*&=0,\\ \mathrm{i}(\partial_t-\partial_x)u_2+u_1+a_3u_1^*&=0,\\ \mathrm{i}\epsilon\partial_t a_3-a_3+u_1u_2&=0. \end{aligned}$$

We are interested in stationary solutions of the above PDE. For $0<Q<\pi$, we set

$$\begin{aligned} u_j&=\tilde{u}_j\sqrt{1-2\epsilon\cos Q}\exp(-2\mathrm{i}\cos(Q)t),\qquad j=1,2,\\ a_3&=\tilde{a}_3\sqrt{1-2\epsilon\cos Q}\exp(-4\mathrm{i}\cos(Q)t). \end{aligned}$$

Upon substituting and dropping the tildes, we get

$$\begin{aligned} \mathrm{i}\partial_t u_1+\mathrm{i}\partial_x u_1+u_2+\cos(Q)u_1+a_3u_2^*&=0,\\ \mathrm{i}\partial_t u_2-\mathrm{i}\partial_x u_2+u_1+\cos(Q)u_2+a_3u_1^*&=0,\\ \mathrm{i}\epsilon\partial_t a_3-(1-2\epsilon\cos Q)(a_3-u_1u_2)&=0. \end{aligned} \tag{4.3}$$

4.1. Existence of pulses. We seek localized steady-states of (4.3), i.e., solutions to the ODE

$$\begin{aligned} u_1'&=\ \ \mathrm{i}[u_2+\cos(Q)u_1+a_3u_2^*],\\ u_2'&=-\mathrm{i}[u_1+\cos(Q)u_2+a_3u_1^*],\\ 0&=-\mathrm{i}(1-2\epsilon\cos Q)(a_3-u_1u_2), \end{aligned}$$

where $'=\mathrm{d}/\mathrm{d}x$. In particular, a_3 is slaved to the other two variables via $a_3=u_1u_2$, and we arrive at the reduced equation

$$\begin{aligned} u_1'&=\ \ \mathrm{i}[u_2+\cos(Q)u_1+u_1|u_2|^2],\\ u_2'&=-\mathrm{i}[u_1+\cos(Q)u_2+u_2|u_1|^2]. \end{aligned} \tag{4.4}$$

It is important to note that (4.4) is the steady-state problem associated with the massive Thirring model, which after suitable scalings is given by

$$\begin{aligned} \mathrm{i}\partial_t u_1+\mathrm{i}\partial_x u_1+u_2+(\cos Q+|u_2|^2)u_1&=0,\\ \mathrm{i}\partial_t u_2-\mathrm{i}\partial_x u_2+u_1+(\cos Q+|u_1|^2)u_2&=0. \end{aligned} \tag{4.5}$$

The massive Thirring model is an integrable PDE that describes the propagation of optical gap solitons in a periodically modulated nonlinear fiber [5, 22, 23, 28, 34, 38], and its steady-states are known.

LEMMA 4.1. *With* $\Phi(x) = \sin(Q)\,\mathrm{sech}(x\sin Q - \mathrm{i}Q/2)$*, the function* $(u_1, u_2, a_3) = (\Phi, -\Phi^*, -|\Phi|^2)$ *is a stationary solitary pulse to* (4.3) *for each* $|v| < 1$*.*

4.2. The reduced eigenvalue problem. Now that the existence question has been settled, it is desirable to determine the stability of the pulse found in Lemma 4.1. Recall that the pulse is that of the massive Thirring model. In fact, comparing (4.3) and (4.5), we might expect that the linear stability problem associated with (4.3) can be thought of as a perturbation of that associated with the massive Thirring model (4.5). This will be seen to indeed be the case. As a consequence, much of the theory developed in [12, 13, 15, 16, 17] will be applicable. However, as shall be seen, some extensions of the theory are necessary in order to fully understand the problem.

We wish to linearize (4.3) about the wave given in Lemma 4.1. Thus, denoting the perturbation by $\mathbf{Y} = (u_1, u_1^*, u_2, u_2^*, a_3, a_3^*)^T \in \mathbb{C}^6$ and using the ansatz $\mathbf{Y}(x,t) = \mathbf{Y}(x)\mathrm{e}^{\mathrm{i}\lambda t}$ (so that the wave is unstable for $\mathrm{Im}\,\lambda < 0$), we obtain the eigenvalue problem

$$\begin{aligned} \mathrm{i}\partial_x u_1 + u_2 - (\lambda - \cos Q)u_1 - |\Phi|^2 u_2^* - \Phi a_3 &= 0,\\ \mathrm{i}\partial_x u_1^* - u_2^* - (\lambda + \cos Q)u_1^* + |\Phi|^2 u_2 + \Phi^* a_3^* &= 0,\\ -\mathrm{i}\partial_x u_2 + u_1 - |\Phi|^2 u_1^* - (\lambda - \cos Q)u_2 + \Phi^* a_3 &= 0,\\ -\mathrm{i}\partial_x u_2^* - u_1^* + |\Phi|^2 u_1 - (\lambda + \cos Q)u_2^* - \Phi a_3^* &= 0,\\ -(1 - 2\epsilon\cos Q)(\Phi^* u_1 - \Phi u_2) - (1 + \epsilon(\lambda - 2\cos Q))a_3 &= 0,\\ (1 - 2\epsilon\cos Q)(\Phi u_1^* - \Phi^* u_2^*) + (1 - \epsilon(\lambda + 2\cos Q))a_3^* &= 0. \end{aligned} \tag{4.6}$$

LEMMA 4.2. *If* λ *is an eigenvalue, then so is* $-\lambda$ *and* $\pm\lambda^*$*.*

Proof. The statement is a consequence of the fact that the system is Hamiltonian, which implies that eigenvalues appear as quadruples. A direct proof goes as follows: (4.6) is invariant under $(u_1, u_1^*, u_2, u_2^*, a_3, a_3^*) \mapsto (u_1^*, u_1, u_2^*, u_2, a_3^*, a_3)$ and $\lambda \to -\lambda$. Furthermore, these equations are invariant after taking the complex conjugate and then setting $\lambda \to -\lambda$. □

We investigate eigenvalues λ in bounded regions of $\mathbb{C}$ that are chosen independently of ϵ. For such λ, we can solve (4.6) directly for a_3 and a_3^*. Upon substituting the resulting expressions

$$a_3 = -\frac{1 - 2\epsilon\cos Q}{1 + \epsilon(\lambda - 2\cos Q)}(\Phi^* u_1 - \Phi u_2), \qquad a_3^* = -\frac{1 - 2\epsilon\cos Q}{1 - \epsilon(\lambda + 2\cos Q)}(\Phi u_1^* - \Phi^* u_2^*)$$

into the first four equations in (4.6), one gets the reduced eigenvalue problem

$$\begin{aligned} \partial_x u_1 &= \mathrm{i}\left[(\cos Q - \lambda + |\Phi|^2)u_1 + (1 - \Phi^2)u_2 - |\Phi|^2 u_2^*\right]\\ &\quad + \mathrm{i}\epsilon\lambda\left[-|\Phi|^2 u_1 + \Phi^2 u_2\right] + \mathrm{O}(\epsilon^2),\\ \partial_x u_1^* &= \mathrm{i}\left[-(\cos Q + \lambda + |\Phi|^2)u_1^* + |\Phi|^2 u_2 - (1 - (\Phi^*)^2)u_2^*\right]\\ &\quad + \mathrm{i}\epsilon\lambda\left[-|\Phi|^2 u_1^* + (\Phi^*)^2 u_2^*\right] + \mathrm{O}(\epsilon^2),\\ \partial_x u_2 &= \mathrm{i}\left[-(1 - (\Phi^*)^2)u_1 + |\Phi|^2 u_1^* - (\cos Q - \lambda + |\Phi|^2)u_2\right]\\ &\quad + \mathrm{i}\epsilon\lambda\left[-(\Phi^*)^2 u_1 + |\Phi|^2 u_2\right] + \mathrm{O}(\epsilon^2),\\ \partial_x u_2^* &= \mathrm{i}\left[-|\Phi|^2 u_1 + (1 - \Phi^2)u_1^* + (\cos Q + \lambda + |\Phi|^2)u_2^*\right]\\ &\quad + \mathrm{i}\epsilon\lambda\left[-\Phi^2 u_1^* + |\Phi|^2 u_2^*\right] + \mathrm{O}(\epsilon^2). \end{aligned} \tag{4.7}$$

Resetting $\mathbf{Y} = (u_1, u_1^*, u_2, u_2^*)^T \in \mathbb{C}^4$, we use the shortcut

$$\frac{\mathrm{d}\mathbf{Y}}{\mathrm{d}x} = M_0(\lambda, x)\mathbf{Y} + \epsilon M_\epsilon(\lambda, x)\mathbf{Y} \tag{4.8}$$

for the above system. Alternatively, we may write (4.7) in operator form as

$$[L_0 + \epsilon L_\epsilon]\mathbf{Y} = \lambda \mathbf{Y}, \tag{4.9}$$

where L_ϵ depends on λ.

4.3. The adjoint squared eigenfunctions of the massive Thirring model. The first step is to understand the eigenvalue problem for $\epsilon = 0$. Note that, when $\epsilon = 0$, the eigenvalue problem (4.9) is exactly that associated with the massive Thirring model. When $\epsilon = 0$, by exploiting integrability, we can conclude that the spectrum consists of an isolated eigenvalue at $\lambda = 0$ of geometric multiplicity two and algebraic multiplicity four, and continuous spectrum on the real axis with branch points at $\lambda = -1 \pm \cos Q$ and $\lambda = 1 \pm \cos Q$ (see [22, 23]). Since the spatial and rotational invariance associated with (4.3) persists under the perturbation, and since the problem is Hamiltonian, the eigenvalue at $\lambda = 0$ continues to have geometric multiplicity two and algebraic multiplicity four, even for $\epsilon \neq 0$. Any unstable eigenvalue must therefore bifurcate out of the continuous spectrum. The purpose of the rest of this section is to locate all bifurcating eigenvalues satisfying $|\lambda| \ll 1/\epsilon$.

The proof of the following lemma will be left to the interested reader, as it can easily be verified.

LEMMA 4.3. *Let*

$$\mathbf{Y}(\lambda, x) = [p_1(\lambda, x), p_2(\lambda, x), p_3(\lambda, x), p_4(\lambda, x)]^T$$

be a solution of (4.8) *for* $\epsilon = 0$. *Another solution is then given by*

$$\tilde{\mathbf{Y}}(\lambda, x) = [p_2^*(-\lambda, x), p_1^*(-\lambda, x), p_4^*(-\lambda, x), p_3^*(-\lambda, x)]^T.$$

Furthermore, if $\lambda \in \mathbb{R}$, *then*

$$\mathbf{Z}(\lambda, x) = [p_1(\lambda, x), -p_2(\lambda, x), -p_3(\lambda, x), p_4(\lambda, x)]^T$$

is a solution to the adjoint equation $\mathbf{Z}' = -M_0^*(\lambda, x)\mathbf{Z}$.

Edge bifurcations for the perturbed problem can be located by computing the Evans function for the unperturbed eigenvalue problem (4.8). Thus, as in section 3, we need to find solutions to the eigenvalue problem of the integrable massive Thirring model, i.e., to (4.8) or, equivalently, to (4.9). As shown in [22, 23], these solutions are given by the adjoint squared eigenfunctions of the scattering problem that is associated with the massive Thirring model. Hence we state only the result proved in [22, 23]. We emphasize, however, that it is again inverse scattering theory as outlined in section 2 that provides these solutions via the scattering problem, the Jost functions, and eventually the adjoint squared eigenfunctions.

PROPOSITION 4.4. *Let*

$$\Omega_f(k) = \cos Q + \sqrt{1 + k^2}, \qquad \Omega_s(k) = \cos Q - \sqrt{1 + k^2}.$$

When $\epsilon = 0$, *the eigenvalue problem* (4.9) *has two linearly independent solutions* $\Psi_s^A(k, x)$ *and* $\Psi_f^A(k, x)$ *such that*

$$L_0 \Psi_s^A(k, x) = \Omega_s(k)\Psi_s^A(k, x), \qquad L_0 \Psi_f^A(k, x) = -\Omega_f(k)\Psi_f^A(k, x).$$

Furthermore, these eigenfunctions have the asymptotics

$$\Psi_s^A(k,x)\mathrm{e}^{-\mathrm{i}kx} \longrightarrow \begin{cases} [1,0,-r(-k),0]^T, & x\to-\infty, \\ a_s^2(k)[1,0,-r(-k),0]^T, & x\to\infty, \end{cases}$$

$$\Psi_f^A(k,x)\mathrm{e}^{\mathrm{i}k^*x} \longrightarrow \begin{cases} [0,1,0,r(k)^*]^T, & x\to-\infty, \\ a_f^2(k)[0,1,0,r(k)^*]^T, & x\to\infty, \end{cases}$$

where the transmission coefficients

$$a_s(k) = \frac{r(-k)-\mathrm{e}^{\mathrm{i}Q}}{r(-k)-\mathrm{e}^{-\mathrm{i}Q}}\,\mathrm{e}^{-\mathrm{i}Q}, \qquad a_f(k) = \frac{r(k)^*+\mathrm{e}^{-\mathrm{i}Q}}{r(k)^*+\mathrm{e}^{\mathrm{i}Q}}\,\mathrm{e}^{\mathrm{i}Q},$$

with $r(k) = k+\sqrt{1+k^2}$, are such that $|a_s(k)| = |a_f(k)| = 1$ for real k.

Due to the simple relationship between (4.9) and (4.8), these eigenfunctions are also solutions to (4.8). Note that, as a consequence of Lemma 4.3, one also has eigenfunctions for $\lambda = -\Omega_f(k)$ and $\lambda = -\Omega_s(k)$. One should also note that the fact that there are two transmission coefficients for this problem is a reflection of the existence of two dispersion relationships $\lambda = \pm\Omega_s(k)$ and $\lambda = \pm\Omega_f(k)$.

4.4. Edge bifurcations for $Q \neq \pi/2$. In this section, it will be shown that the perturbed wave is linearly stable for $\cos Q \neq 0$. If $\cos Q = 0$, then additional technical difficulties are introduced which will be handled in the next section. Thus, throughout this section, we assume that $\cos Q \neq 0$. Let

$$M_\infty(\lambda) = \lim_{|x|\to\infty}(M_0(\lambda,x)+\epsilon M_\epsilon(\lambda,x)).$$

A routine calculation shows that the eigenvalues of $M_\infty(\lambda)$ are given by

$$\mu_s^\pm(\lambda) = \pm\sqrt{1-(\lambda-\cos Q)^2}, \qquad \mu_f^\pm(\lambda) = \pm\sqrt{1-(\lambda+\cos Q)^2}, \tag{4.10}$$

and the associated eigenvectors are

$$\mathbf{v}_s^\pm(\lambda) = [1,0,(\lambda-\cos Q)+\mathrm{i}\mu_s^\pm(\lambda),0]^T \tag{4.11}$$

$$\mathbf{v}_f^\pm(\lambda) = [0,1,0,-(\lambda+\cos Q)+\mathrm{i}\mu_f^\pm(\lambda)]^T. \tag{4.12}$$

The branch cuts for $\mu_{s,f}^\pm(\lambda)$ are taken so that the functions are analytic in the region $\operatorname{Im}\lambda \le 0$ except at the branch points $\lambda = \pm1\pm\cos Q$. For example, if $\operatorname{Re}\lambda < 0$, then

$$\arg(1-(\lambda-\cos Q)^2) \in (-\pi,\pi], \tag{4.13}$$

$$\arg(1-(\lambda+\cos Q)^2) \in (-\pi,\pi]. \tag{4.14}$$

Define solutions $\mathbf{Y}_{s,f}^+(\lambda,x)$ and $\mathbf{Y}_{s,f}^-(\lambda,x)$ such that

$$\lim_{x\to\infty}\mathbf{Y}_{s,f}^+(\lambda,x)\mathrm{e}^{-\mu_{s,f}^-(\lambda)x} = \mathbf{v}_{s,f}^-(\lambda), \qquad \lim_{x\to-\infty}\mathbf{Y}_{s,f}^-(\lambda,x)\mathrm{e}^{-\mu_{s,f}^+(\lambda)x} = \mathbf{v}_{s,f}^+(\lambda). \tag{4.15}$$

Note that, for $\operatorname{Im}\lambda < 0$, $\mathbf{Y}_{s,f}^-(\lambda,x)$ decays exponentially fast as $x\to-\infty$, while $\mathbf{Y}_{s,f}^+(\lambda,x)$ decays exponentially fast as $x\to\infty$. The Evans function is then given by

$$E(\lambda) = (\mathbf{Y}_s^-\wedge\mathbf{Y}_f^-\wedge\mathbf{Y}_s^+\wedge\mathbf{Y}_f^+)(\lambda,x). \tag{4.16}$$

To calculate the Evans function explicitly, we have to relate the information given in Proposition 4.4 to the solutions $\mathbf{Y}^{\pm}_{s,f}(\lambda, x)$. First consider the solution $\Psi^A_s(k, x)$. Inverting the relation $\lambda = \Omega_s(k)$ yields that Proposition 4.4 applies when $k = k_s(\lambda)$, where

$$k_s(\lambda) = \sqrt{(\lambda - \cos Q)^2 - 1}, \qquad \arg((\lambda - \cos Q)^2 - 1) \in (-2\pi, 0].$$

The restriction on the argument is so that the above expressions are consistent with (4.13). Note that, since $\Omega_s(k)$ is even in k, $\Psi^A_s(-k, x)$ is also a solution to the eigenvalue problem. An examination of the relations (4.10) and (4.11), as well as of the asymptotics given in (4.15), then reveals that

$$\mathbf{Y}^-_s(\lambda, x) = \Psi^A_s(k_s(\lambda), x), \qquad \mathbf{Y}^+_s(\lambda, x) = \frac{1}{a^2_s(-k_s(\lambda))}\,\Psi^A_s(-k_s(\lambda), x).$$

Now consider the solution $\Psi^A_f(k, x)$. As before, upon inverting $\lambda = \Omega_s(k)$, we see that Proposition 4.4 applies when $k = k_f(\lambda)$, where

$$k_f(\lambda) = \sqrt{(\lambda + \cos Q)^2 - 1}, \qquad \arg((\lambda + \cos Q)^2 - 1) \in (-2\pi, 0],$$

to make it consistent with (4.14). As above, $\Psi^A_f(-k, x)$ is also a solution to the eigenvalue problem since $\Omega_f(k)$ is even is k. Inspecting (4.10), (4.12), and (4.15), we obtain

$$\mathbf{Y}^-_f(\lambda, x) = \Psi^A_f(k_f(\lambda), x), \qquad \mathbf{Y}^+_f(\lambda, x) = \frac{1}{a^2_f(-k_f(\lambda))}\,\Psi^A_f(-k_f(\lambda), x).$$

We now have the following lemma, which follows immediately from the definition of the Evans function and the asymptotics of the squared eigenfunctions.

Lemma 4.5. *Assume that* $\cos Q \neq 0$. *The Evans function of* (4.8) *with* $\epsilon = 0$ *is given by*

$$E(\lambda) = -4k_s(\lambda)k_f(\lambda)\left[\frac{a_s(k_s(\lambda))}{a_s(-k_s(\lambda))}\right]^2\left[\frac{a_f(k_f(\lambda))}{a_f(-k_f(\lambda))}\right]^2.$$

Since $a_s(k_s(0)) = a_f(k_f(0)) = 0$, with each zero being simple, $\lambda = 0$ is a zero of multiplicity four for the Evans function. Furthermore, note that the Evans function has zeros at the branch points $\lambda = \pm 1 \pm \cos Q$. Assume that $\cos Q \neq 0$ so that the branch points of the Evans function do not coincide. As in [15], the Evans function can then be defined on a Riemann surface by setting

$$\gamma^2_s(\lambda) = 1 - (\lambda - \cos Q)^2 \qquad \text{or} \qquad \gamma^2_f(\lambda) = 1 - (\lambda + \cos Q)^2. \tag{4.17}$$

On each of these surfaces, the Evans function is analytic, and its zero at the branch point is simple. Therefore, the zero remains simple under perturbation. However, since the zero is simple and the system is Hamiltonian, the perturbed zero must either lie on the real axis or not correspond to an eigenvalue (i.e., it lies on the wrong sheet of the Riemann surface). In either case, it does not contribute to a linear instability.

4.5. Edge bifurcations for $Q = \pi/2$. The above conclusion of linear stability was predicated upon the fact that the branch points of the Evans function were separated. If $Q = \pi/2$, then the branch points, and hence the pair of simple zeros, coincide. It is then possible that complex zeros exist on the appropriate Riemann surface, which will necessarily lead to an unstable wave. We show in this section that the wave is indeed linearly unstable for $0 < Q - \pi/2 < 4\epsilon^2$, with the location of the unstable eigenvalues arising from the edge bifurcation being given by

$$\lambda = -1 + \epsilon^2 \left[2 - A - \mathrm{i}\sqrt{4A - A^2}\right], \tag{4.18}$$

where $Q - \pi/2 = A\epsilon^2$ with $0 < A < 4$. Otherwise, the wave is linearly stable, and only real eigenvalues arise from the edge bifurcation.

To calculate the Taylor expansion for the Evans function on the appropriate Riemann surface, the theory presented in [15, 17] must be slightly modified. First, rewrite the Evans function given in (4.16) as

$$E(\lambda) = ((\mathbf{Y}_s^- - \mathbf{Y}_s^+) \wedge (\mathbf{Y}_f^- - \mathbf{Y}_f^+) \wedge \mathbf{Y}_s^+ \wedge \mathbf{Y}_f^+)(\lambda, 0).$$

We wish to write the Evans function on the Riemann surface. The idea will be to look on the surface defined by $\gamma_s(\lambda)$, which is defined in (4.17). As a consequence, all expressions must be written in terms of this variable. Set

$$\nu^2 = 4\cos Q, \qquad \arg(\nu) \in (-\pi/2, \pi/2].$$

Expression (4.10) can now be rewritten as

$$\mu_s^\pm(\gamma_s) = \pm\gamma_s, \qquad \mu_f^\pm(\gamma_s) = \pm\sqrt{\gamma_s^2 + \nu^2\sqrt{1-\gamma_s^2} - \nu^4/4},$$

and expressions (4.11) and (4.12) have similar modifications. Note that when $\gamma_s = 0$ one has

$$\mu_f^\pm = \pm\nu\sqrt{1-\nu^2/4}, \qquad \mathbf{v}_f^\pm = \left(0, 1, 0, \sqrt{1-(\mu_f^\pm)^2} + \mathrm{i}\mu_f^\pm\right)^T,$$

and that the restriction on the argument of ν is consistent with that of (4.14).

We can now proceed to compute the Taylor expansion of the Evans function on the Riemann surface and, in particular, to get exact expressions for the coefficients in the expansion. The theory presented in [13, 15] will be heavily used and will not be rederived here. However, we will give the most important intermediate calculations. As an application of the gap lemma, the solutions $\mathbf{Y}_{s,f}^\pm(\lambda, x)$ can be written on the Riemann surface defined by $\gamma_s(\lambda)$. This will now be done implicitly, with the observation that $\lambda = -1$ corresponds to $\gamma_s = 0$. Let $\mathbf{u}_j(x)$, $j = 1, \ldots, 4$ be solutions to (4.8) with $(\epsilon, \nu) = (0, 0)$ such that $\mathbf{u}_1(x) = \mathbf{Y}_s^\pm(0, x)$, $\mathbf{u}_2(x) = \mathbf{Y}_f^\pm(0, x)$, and $\mathbf{u}_3(x)$ and $\mathbf{u}_4(x)$ are such that

$$(\mathbf{u}_1 \wedge \cdots \wedge \mathbf{u}_4)(x) = 1.$$

Let the adjoint solutions $\mathbf{u}_j^A(x)$ satisfy $\mathbf{u}_j(x) \cdot \mathbf{u}_k^A(x) = \delta_{jk}$. For $(\gamma_s, \nu) = (0, 0)$, the relevant eigenfunctions are given by

$$\tag{4.19} \begin{aligned} \mathbf{Y}_s^\pm(0, x) &= \begin{bmatrix} \tanh(2x)\tanh(x - \mathrm{i}\pi/4) \\ \mathrm{i}\,\mathrm{sech}(2x)\tanh(x + \mathrm{i}\pi/4) \\ -\tanh(2x)\tanh(x + \mathrm{i}\pi/4) \\ \mathrm{i}\,\mathrm{sech}(2x)\tanh(x - \mathrm{i}\pi/4) \end{bmatrix}, \\ \mathbf{Y}_f^\pm(0, x) &= \begin{bmatrix} \mathrm{i}\,\mathrm{sech}(2x)\tanh(x - \mathrm{i}\pi/4) \\ \tanh(2x)\tanh(x + \mathrm{i}\pi/4) \\ -\mathrm{i}\,\mathrm{sech}(2x)\tanh(x + \mathrm{i}\pi/4) \\ \tanh(2x)\tanh(x - \mathrm{i}\pi/4) \end{bmatrix}, \end{aligned}$$

while the relevant adjoint eigenfunctions $\mathbf{Z}_{s,f}(0,x)$ can be found by using the result of Lemma 4.3. It is important to note that the adjoint eigenfunctions are orthogonal to $\mathbf{Y}^{\pm}_{s,f}(0,x)$. Thus there exist constants c_{jk} such that

$$\mathbf{u}_3^A(x) = c_{11}\mathbf{Z}_s(0,x) + c_{12}\mathbf{Z}_f(0,x), \qquad \mathbf{u}_4^A(x) = c_{21}\mathbf{Z}_s(0,x) + c_{22}\mathbf{Z}_f(0,x).$$

Furthermore, the matrix $C = [c_{jk}] \in \mathbb{C}^{2\times 2}$ is invertible. As will be seen, the exact values for the entries c_{jk} are unimportant. The expressions in (4.19) will be implicitly used in the subsequent calculations.

When performing the perturbation expansion on the Riemann surface, the parameters that will be varied are γ_s, ν, and ϵ. It is important to keep in mind that $\gamma_f = \gamma_s$ when $\nu = 0$ so that in this case we will not distinguish between the two. For $j = 3, 4$, set

$$\alpha_j^{s,f} = \partial_{\gamma_s}\mathbf{v}^-_{s,f}\cdot\mathbf{u}_j^A(-\infty) - \partial_{\gamma_s}\mathbf{v}^+_{s,f}\cdot\mathbf{u}_j^A(+\infty).$$

Following [15], one has that

$$\partial_{\gamma_s}(\mathbf{Y}^-_{s,f} - \mathbf{Y}^+_{s,f})(0,0) = \sum_{j=3}^{4}\alpha_j^{s,f}\mathbf{u}_j(0) + \sum_{j=1}^{2}c^j_{s,f}\mathbf{u}_j(0)$$

on the Riemann surface. Using the fact that

$$\partial^2_{\gamma_s}E(0) = 2(\partial_{\gamma_s}(\mathbf{Y}^-_s - \mathbf{Y}^+_s)\wedge\partial_{\gamma_s}(\mathbf{Y}^-_f - \mathbf{Y}^+_f)\wedge\mathbf{Y}^+_s\wedge\mathbf{Y}^+_f)(0,0)$$

at $\gamma_s = 0$ and also utilizing the definition of the solutions $\mathbf{u}_j(0)$, we obtain

$$\partial^2_{\gamma_s}E(0) = 2\begin{vmatrix} \alpha_3^s & \alpha_4^s \\ \alpha_3^f & \alpha_4^f \end{vmatrix} = 8\det(C).$$

We must now get expressions for the lower-order derivatives in the Taylor expansion for $E(\gamma_s)$. Following [13], we have

$$\partial_\epsilon(\mathbf{Y}^-_{s,f} - \mathbf{Y}^+_{s,f})(0,0) = \sum_{j=3}^{4}\langle M_\epsilon\mathbf{Y}_{s,f},\mathbf{u}_j^A\rangle\mathbf{u}_j(0) + \sum_{j=1}^{2}c^j_{s,f}\mathbf{u}_j(0),$$

where $\langle\cdot,\cdot\rangle$ represents that standard L^2 inner product. Since

$$\partial^2_\epsilon E(0) = 2(\partial_\epsilon(\mathbf{Y}^-_s - \mathbf{Y}^+_s)\wedge\partial_\epsilon(\mathbf{Y}^-_f - \mathbf{Y}^+_f)\wedge\mathbf{Y}^+_s\wedge\mathbf{Y}^+_f)(0,0),$$

this then yields that

$$\partial^2_\epsilon E(0) = 2\begin{vmatrix} \langle M_\epsilon\mathbf{Y}_s,\mathbf{u}_3^A\rangle & \langle M_\epsilon\mathbf{Y}_s,\mathbf{u}_4^A\rangle \\ \langle M_\epsilon\mathbf{Y}_f,\mathbf{u}_3^A\rangle & \langle M_\epsilon\mathbf{Y}_f,\mathbf{u}_4^A\rangle \end{vmatrix} = -32\det(C).$$

Also, $\mathbf{Y}^-_s = \mathbf{Y}^+_s$ for all ν, while

$$\partial_\nu(\mathbf{Y}^-_f - \mathbf{Y}^+_f)(0,0) = \beta_3^f\mathbf{u}_3(0) + \beta_4^f\mathbf{u}_4(0) + c_f^1\mathbf{u}_1(0) + c_f^2\mathbf{u}_2(0),$$

where

$$\beta_j^f = \partial_\nu\mathbf{v}^-_f\cdot\mathbf{u}_j^A(-\infty) - \partial_\nu\mathbf{v}^+_f\cdot\mathbf{u}_j^A(+\infty).$$

This yields that $\partial_\nu^k E(0) = 0$ for all $k \geq 0$, while

$$\begin{aligned}
\partial^2_{\epsilon\gamma_s} E(0) &= (\partial_\epsilon(\mathbf{Y}_s^- - \mathbf{Y}_s^+) \wedge \partial_{\gamma_s}(\mathbf{Y}_f^- - \mathbf{Y}_f^+) \wedge \mathbf{Y}_s^+ \wedge \mathbf{Y}_f^+)(0,0) \\
&\quad + (\partial_{\gamma_s}(\mathbf{Y}_s^- - \mathbf{Y}_s^+) \wedge \partial_\epsilon(\mathbf{Y}_f^- - \mathbf{Y}_f^+) \wedge \mathbf{Y}_s^+ \wedge \mathbf{Y}_f^+)(0,0) \\
&= \begin{vmatrix} \langle M_\epsilon \mathbf{Y}_s, \mathbf{u}_3^A \rangle & \langle M_\epsilon \mathbf{Y}_s, \mathbf{u}_4^A \rangle \\ \alpha_3^f & \alpha_4^f \end{vmatrix} + \begin{vmatrix} \alpha_3^s & \alpha_4^s \\ \langle M_\epsilon \mathbf{Y}_f, \mathbf{u}_3^A \rangle & \langle M_\epsilon \mathbf{Y}_f, \mathbf{u}_4^A \rangle \end{vmatrix} \;=\; 0, \\
\partial^2_{\epsilon\nu} E(0) &= (\partial_\epsilon(\mathbf{Y}_s^- - \mathbf{Y}_s^+) \wedge \partial_\nu(\mathbf{Y}_f^- - \mathbf{Y}_f^+) \wedge \mathbf{Y}_s^+ \wedge \mathbf{Y}_f^+)(0,0) \\
&= \begin{vmatrix} \langle M_\epsilon \mathbf{Y}_s, \mathbf{u}_3^A \rangle & \langle M_\epsilon \mathbf{Y}_s, \mathbf{u}_4^A \rangle \\ \beta_3^f & \beta_4^f \end{vmatrix} \;=\; 0, \\
\partial^2_{\gamma_s\nu} E(0) &= (\partial_{\gamma_s}(\mathbf{Y}_s^- - \mathbf{Y}_s^+) \wedge \partial_\nu(\mathbf{Y}_f^- - \mathbf{Y}_f^+) \wedge \mathbf{Y}_s^+ \wedge \mathbf{Y}_f^+)(0,0) \\
&= \begin{vmatrix} \alpha_3^s & \alpha_4^s \\ \beta_3^f & \beta_4^f \end{vmatrix} \;=\; 4\det(C).
\end{aligned}$$

Thus, on the Riemann surface, the Evans function has the Taylor expansion

$$E(\gamma_s) = 4\det(C)\,(\gamma_s^2 + \nu\gamma_s - 4\epsilon^2),$$

and the zeros of the Evans function on the Riemann surface are given by

$$\gamma_s = \frac{1}{2}\left(-\nu \pm \sqrt{\nu^2 + 16\epsilon^2}\right).$$

Only zeros on the correct Riemann sheet, given by $\arg(\gamma_s) \in (-\pi/2, \pi/2]$, correspond to eigenvalues. Suppose that $\nu = 2\sqrt{\cos Q}$, i.e., $0 < \pi/2 - Q \ll 1$. The zeros are then real; furthermore, only one lies on the correct sheet. Upon inverting the relationship in (4.17), i.e., by setting

$$\lambda = \cos Q - \sqrt{1 - \gamma_s^2},$$

it is then seen that the real eigenvalue is, to lowest order, given by

$$\lambda = -1 + 2\cos Q + 2\epsilon^2 - \sqrt{\cos^2 Q + 4\epsilon^2 \cos Q}.$$

Next suppose that $0 < Q - \pi/2 \ll 1$, i.e., $\nu = 2\mathrm{i}\sqrt{-\cos Q}$. The zeros on the Riemann surface are then given by

$$\gamma_s = -\mathrm{i}\sqrt{-\cos Q} \pm \sqrt{4\epsilon^2 + \cos Q}.$$

The root lies on the correct sheet only for $0 < -\cos Q < 4\epsilon^2$, in which case it is given by

$$\gamma_s = -\mathrm{i}\sqrt{-\cos Q} + \sqrt{4\epsilon^2 + \cos Q}.$$

Upon setting $\cos Q = -A\epsilon^2$ for $A > 0$, i.e., $Q = \pi/2 + A\epsilon^2$, we see that the corresponding complex eigenvalue is, to lowest order, given by

$$\lambda = -1 + \epsilon^2\left[2 - A - \mathrm{i}\sqrt{4A - A^2}\right]. \tag{4.20}$$

Thus the wave is unstable.

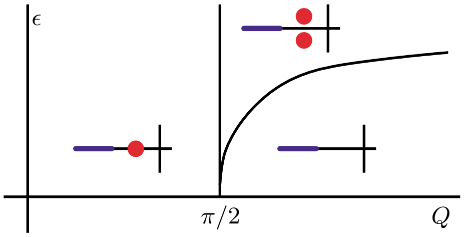

Fig. 4.1. *The insets show the eigenvalue structure near $\lambda = -1$ of the perturbed wave for Q close to $\pi/2$. The thick solid line in each inset denotes the essential spectrum, while bullets correspond to eigenvalues λ (i.e., to zeros of the Evans function on the correct Riemann sheet). Note that eigenvalues λ with $\operatorname{Im}\lambda < 0$ are unstable. The region of instability in the (Q, ϵ)-plane is bounded, to leading order, by the line $Q = \pi/2$ and the parabola $Q = \pi/2 + 4\epsilon^2$.*

In conclusion, the wave is linearly stable if $\cos Q < 0$ or if $\cos Q > -4\epsilon^2$. If $0 < -\cos Q < 4\epsilon^2$, then the wave is linearly unstable, and the location of the unstable eigenvalue is given to lowest order by (4.18). Note that, since the system is Hamiltonian, there is another unstable eigenvalue at $-\lambda^*$ with λ given by (4.20). This fact can be verified directly by computing the Taylor expansion of the Evans function about $\gamma_f = 0$. Our results near $Q = \pi/2$ are summarized in Figure 4.1.

Remark 4.6. Barashenkov, Pelinovsky, and Zemlyanaya [5] analyzed a different perturbation of the massive Thirring model and through the use of solvability conditions realized a different type of edge-bifurcation scenario as Q passed through $\pi/2$. (Compare Figure 4.1 with [5, Figure 1].) The results presented herein can be thought of as a theoretical justification for the calculations in [5].

Acknowledgments. We thank Alejandro Aceves for asking the question which led to this work and acknowledge helpful discussions with James Alexander in an early stage of this work.

GEOMETRIC STABILITY SWITCH CRITERIA IN DELAY DIFFERENTIAL SYSTEMS WITH DELAY DEPENDENT PARAMETERS*

EDOARDO BERETTA† AND YANG KUANG‡

Abstract. In most applications of delay differential equations in population dynamics, the need of incorporation of time delays is often the result of the existence of some stage structure. Since the through-stage survival rate is often a function of time delays, it is easy to conceive that these models may involve some delay dependent parameters. The presence of such parameters often greatly complicates the task of an analytical study of such models. The main objective of this paper is to provide practical guidelines that combine graphical information with analytical work to effectively study the local stability of some models involving delay dependent parameters. Specifically, we shall show that the stability of a given steady state is simply determined by the graphs of some functions of τ which can be expressed explicitly and thus can be easily depicted by Maple and other popular software. In fact, for most application problems, we need only look at one such function and locate its zeros. This function often has only two zeros, providing thresholds for stability switches. The common scenario is that as time delay increases, stability changes from stable to unstable to stable, implying that a large delay can be stabilizing. This scenario often contradicts the one provided by similar models with only delay independent parameters.

Key words. delay differential equations, stability switch, characteristic equations, stage structure, population models

1. Introduction.

Due to the fact that actions and reactions take time to take effect in real-life problems, one often introduces time delays in the variables being modeled. This often yields delay differential and delay difference models [11], [21], [19]. Some of these models have delay dependent parameters (for example, [1], [2], [3], [4], [9], [10], [22]), while most of them contain only parameters that are independent of time delays.

In most applications of delay differential equations in population dynamics, the need of incorporation of a time delay is often the result of the existence of some stage structure [1], [3], [10], [11], [12], [15]. Indeed, just about every population goes through some distinct life stages [23], [18]. Since the through-stage survival rate is often a function of a time delay, it is thus easy to conceive that these models will inevitably involve some delay dependent parameters.

In view of the fact that it is often difficult to analytically study models with delay dependent parameters even if only a single discrete delay is present, it is natural to resort to the help of computer programs. The main objective of this paper is to provide practical guidelines that combine graphical information with analytical work to effectively study the local stability of models involving delay dependent parameters. To apply our results, one need only perform some routine computation (using our analytical criteria) and generate some simple graphs which can be easily produced by popular software such as Maple. The results also can be readily confirmed by some

selective simulations using the freely available and user friendly software XPP. No other programming skill is required.

Specifically, we shall show that the stability of a given steady state is simply determined by the graphs of some functions of τ which can be expressed explicitly and thus can be easily depicted by Maple and other popular software. In fact, for most application problems, we need only look at one such function and locate its zeros. This function often has only two zeros, providing thresholds for stability switches. The common scenario is that as time delay increases, stability changes from stable to unstable to stable. We hope this work will show that it is important and possible to systematically study local stability aspects of some models with delay dependent parameters.

In the next section, we present a general geometric criterion that, theoretically speaking, can be applied to models with many delays, or even distributed delays [5], [7]. This is followed by a section dealing with the simple case of a first order characteristic equation, providing more user friendly geometric and analytic criteria for stability switches. In section 4, we accomplish the same for the second order case. The analytical criteria provided for the first and second order cases can be used to obtain some insightful analytical statements and can be helpful for conducting simulations. Examples are provided for both first and second order cases to illustrate the applications of our criteria. A discussion section concludes the paper.

2. A general geometric criterion.

In this section we study the occurrence of any possible stability switching *resulting from the increase of value of the time delay* τ for the general characteristic equation

$$D(\lambda,\tau)=0. \tag{2.1}$$

Here

$$D(\lambda,\tau)=P_n(\lambda,\tau)+Q_m(\lambda,\tau)e^{-\lambda\tau} \tag{2.2}$$

and

$$P_n(\lambda,\tau)=\sum_{k=0}^{n}p_k(\tau)\lambda^k, \quad Q_m(\lambda,\tau)=\sum_{k=0}^{m}q_k(\tau)\lambda^k. \tag{2.3}$$

In (2.3), $n,m\in\mathbf{N}_0$, $n>m$, and $p_k(\cdot),q_k(\cdot):\mathbf{R}_{+0}\to\mathbf{R}$ are continuous and differentiable functions of τ such that

$$P_n(0,\tau)+Q_m(0,\tau)=p_0(\tau)+q_0(\tau)\neq 0 \quad \forall\tau\in\mathbf{R}_{+0}, \tag{2.4}$$

i.e., $\lambda=0$ is not a characteristic root of (2.1).

In the following "—" denotes complex and conjugate. $P_n(\lambda,\tau)$, $Q_m(\lambda,\tau)$ are analytic functions in λ and differentiable in τ for which we assume ([21, p. 83]; see also [8] and [6]) the following:

(i) If $\lambda=i\omega,\omega\in\mathbf{R}$, then $P_n(i\omega,\tau)+Q_m(i\omega,\tau)\neq 0,\tau\in\mathbf{R}$;

(ii) $\limsup\{|Q_m(\lambda,\tau)/P_n(\lambda,\tau)|:|\lambda|\to\infty,\mathrm{Re}\ \lambda\geq 0\}<1$ for any τ;

(iii) $F(\omega,\tau):=|P_n(i\omega,\tau)|^2-|Q_m(i\omega,\tau)|^2$ for each τ has at most a finite number of real zeros.

(iv) Each positive root $\omega(\tau)$ of $F(\omega,\tau)=0$ is continuous and differentiable in τ whenever it exists.

Assumption (i) implies that $P_n(\lambda, \tau)$ and $Q_m(\lambda, \tau)$ have no common imaginary roots. This is needed to ensure that threshold time delays can be explicitly expressed (see the comment after (2.10)). Assumption (ii) is needed to ensure that there are no roots bifurcating from infinity. Assumption (iii) is needed to ensure that there are only finite "gates" for roots to cross the imaginary axis for any given τ. Assumption (iv) is needed to compute the derivative of the imaginary roots with respect to τ. We remark also that, since P_n, Q_m have real coefficients, then

$$\overline{P_n(-i\omega, \tau)} = P_n(i\omega, \tau), \qquad \overline{Q_m(-i\omega, \tau)} = Q_m(i\omega, \tau) \tag{2.5}$$

for each τ and any real ω, thus ensuring that if $\lambda = i\omega$ for some real ω is a characteristic root of (2.1), then also $\lambda = -i\omega$ is a characteristic root. In the following, we will drop the indices n, m from P_n, Q_m. Furthermore, we will denote by P_R, Q_R the real parts of P and Q, respectively, and by P_I, Q_I the imaginary parts of P and Q, respectively. Hence, we can write

$$P(\lambda, \tau) = P_R(\lambda, \tau) + iP_I(\lambda, \tau), \quad Q(\lambda, \tau) = Q_R(\lambda, \tau) + iQ_I(\lambda, \tau), \tag{2.6}$$

where P_R, P_I, Q_R, Q_I are real functions. In the following we will use this nomenclature for derivatives. The total derivative, say of $P(\lambda, \tau)$, with respect to τ will be denoted by

$$D_\tau P(\lambda, \tau) := P'_\lambda(\lambda, \tau)\frac{d\lambda}{d\tau} + P'_\tau(\lambda, \tau), \tag{2.7}$$

where $P'_\lambda(\lambda, \tau) := \partial_\lambda P(\lambda, \tau)$, $P'_\tau(\lambda, \tau) := \partial_\tau P(\lambda, \tau)$ are the partial derivatives with respect to λ, τ, respectively. Of course, after the partial derivation of $P(\lambda, \tau)$ with respect to λ, its real part can be separated from its imaginary one. We then have

$$P'_\lambda(\lambda, \tau) = P'_{R_\lambda}(\lambda, \tau) + iP'_{I_\lambda}(\lambda, \tau) \tag{2.8}$$

and the same nomenclature applies for derivatives of $Q(\lambda, \tau)$. Similarly, $F'_\omega(\omega, \tau) = \partial_\omega F(\omega, \tau)$ denotes the partial derivative of $F(\omega, \tau)$ with respect to ω, and so on. This stated, let us consider the general problem. Since for increasing τ the imaginary axis cannot be crossed by $\lambda(\tau) = 0$ for some $\tau > 0$ (see (2.4)), we look for the occurrence of a pair of simple and conjugate imaginary roots $\lambda = \pm i\omega(\tau)$, $\omega(\tau)$ real and positive, which crosses the imaginary axis at some positive τ value, say τ^*. Because of (2.5), without loss of generality, we can consider just $\lambda = i\omega(\tau)$, $\omega(\tau) > 0$, and the possibility that it is a root of the characteristic equation (2.1). Then $\omega(\tau)$ must satisfy the following:

$$\begin{cases} Q_I(i\omega, \tau)\sin\omega\tau + Q_R(i\omega, \tau)\cos\omega\tau = -P_R(i\omega, \tau), \\ -Q_R(i\omega, \tau)\sin\omega\tau + Q_I(i\omega, \tau)\cos\omega\tau = -P_I(i\omega, \tau), \end{cases} \tag{2.9}$$

which gives

$$\begin{cases} \sin\omega\tau = \dfrac{-P_R(i\omega, \tau)Q_I(i\omega, \tau) + P_I(i\omega, \tau)Q_R(i\omega, \tau)}{|Q(i\omega, \tau)|^2}, \\ \cos\omega\tau = -\dfrac{P_R(i\omega, \tau)Q_R(i\omega, \tau) + P_I(i\omega, \tau)Q_I(i\omega, \tau)}{|Q(i\omega, \tau)|^2}, \end{cases} \tag{2.10}$$

where $|Q(i\omega, \tau)|^2 \neq 0$ because of assumption (i) (since $D(i\omega, \tau) = Q(i\omega, \tau) = 0$ together imply $P(i\omega, \tau) = 0$).

On the other hand, since (2.10) can be written as

$$\sin\omega\tau = \operatorname{Im}\left(\frac{P(i\omega,\tau)}{Q(i\omega,\tau)}\right), \qquad \cos\omega\tau = -\operatorname{Re}\left(\frac{P(i\omega,\tau)}{Q(i\omega,\tau)}\right),$$

if ω satisfies (2.10), then $\omega(\tau)$ must satisfy that

$$|P(i\omega,\tau)|^2 = |Q(i\omega,\tau)|^2, \tag{2.11}$$

i.e., $\omega(\tau)$ must be a (positive) root of

$$F(\omega,\tau) := |P(i\omega,\tau)|^2 - |Q(i\omega,\tau)|^2. \tag{2.12}$$

Assume that $I \subseteq \mathbf{R}_{+0}$ is the set where $\omega(\tau)$ is a positive root of (2.12) and for $\tau \notin I$, $\omega(\tau)$ is not definite. Then for all τ in I, $\omega(\tau)$ satisfies that

$$F(\omega,\tau) = 0. \tag{2.13}$$

Hence, differentiating (2.13) with respect to τ we get

$$F'_\omega(\omega,\tau)\omega' + F'_\tau(\omega,\tau) = 0, \quad \tau \in I, \tag{2.14}$$

where

$$\begin{cases} F'_\omega = 2[(P'_{R_\omega}P_R + P'_{I_\omega}P_I) - (Q'_{R_\omega}Q_R + Q'_{I_\omega}Q_I)], \\ F'_\tau = 2[(P'_{R_\tau}P_R + P'_{I_\tau}P_I) - (Q'_{R_\tau}Q_R + Q'_{I_\tau}Q_I)]. \end{cases} \tag{2.15}$$

Now it is important to notice that if $\tau \notin I$, then there are no positive $\omega(\tau)$ solutions of (2.13), and we cannot have stability switches. Furthermore, for any $\tau \in I$ where $\omega(\tau)$ is a positive solution of (2.13), we can define the angle $\theta(\tau) \in [0, 2\pi]$ as the solution of (2.10):

$$\begin{cases} \sin\theta(\tau) = \dfrac{-P_R(i\omega,\tau)Q_I(i\omega,\tau) + P_I(i\omega,\tau)Q_R(i\omega,\tau)}{|Q(i\omega,\tau)|^2}, \\ \cos\theta(\tau) = -\dfrac{P_R(i\omega,\tau)Q_R(i\omega,\tau) + P_I(i\omega,\tau)Q_I(i\omega,\tau)}{|Q(i\omega,\tau)|^2}, \end{cases} \tag{2.16}$$

and the relation between the arguments "$\theta(\tau)$" in (2.16) and "$\omega(\tau)\tau$" in (2.10) for $\tau \in I$ must be

$$\omega(\tau)\tau = \theta(\tau) + n2\pi, \quad n \in \mathbf{N}_0. \tag{2.17}$$

Hence, we can define the maps $\tau_n : I \to \mathbf{R}_{+0}$ given by

$$\tau_n(\tau) := \frac{\theta(\tau) + n2\pi}{\omega(\tau)}, \quad n \in \mathbf{N}_0, \quad \tau \in I, \tag{2.18}$$

where $\omega(\tau)$ is a positive root of (2.13). Let us introduce the functions $I \to \mathbf{R}$,

$$S_n(\tau) := \tau - \tau_n(\tau), \quad \tau \in I, \quad n \in \mathbf{N}_0, \tag{2.19}$$

that are continuous and differentiable in τ as shown in the following lemma.

LEMMA 2.1. *Assume that $\omega(\tau)$ is a positive real root of* (2.13) *defined for $\tau \in I$, which is continuous and differentiable. Assume further that* (i) *holds true. Then the functions $S_n(\tau), n \in \mathbf{N}_0$, are continuous and differentiable on I.*

Proof. Assume that $\theta(\tau)$ is, for example, a monotone increasing function in a neighborhood $I_\delta(\tau')$ of $\tau' \in I$, where $\theta(\tau') = 2\pi$. Since $\theta(\tau)$ must belong to $[0, 2\pi]$ at τ', $\theta(\tau)$ may have a jump of height 2π down to 0 at τ'. This will give rise to the first kind of discontinuity for $\tau_n(\tau)$ and $S_n(\tau)$ with a jump of height $2\pi/\omega(\tau')$ at τ'. Without such a discontinuity, Remark 4.1 (see below) implies that $\theta(\tau)$ is continuous and differentiable on I and so are $\tau_n(\tau)$ and $S_n(\tau)$. Thus it is enough to prove that $\theta(\tau) \neq 0, 2\pi$ on I, and hence $\theta(\tau) \in (0, 2\pi)$ on I. Assumption (i) implies that either

(a) $P_R(i\omega, \tau) + Q_R(i\omega, \tau) \neq 0$, or

(b) $P_I(i\omega, \tau) + Q_I(i\omega, \tau) \neq 0$.

Assume first that (a) holds true. Then either

(a1) $P_R(i\omega, \tau) \neq 0$, or

(a2) $Q_R(i\omega, \tau) \neq 0$.

Assume now that (a1) is true. If $\theta(\tau) = 0, 2\pi$, then $\sin\theta(\tau) = 0$ and $\cos\theta(\tau) = 1$. From the first of (4.16), we have

$$Q_I = P_I Q_R / P_R.$$

Substituting this into the second equation of (4.16) yields (since ω is a root of $F(\omega, \tau) = 0$)

$$\cos\theta(\tau) = -Q_R/P_R.$$

Hence $\cos\theta(\tau) = 1$ implies that $P_R + Q_R = 0$, contradicting (a). The proof for case (a2) is similar and so is the proof for (b). This proves the lemma. □

We can also prove the following theorem.

THEOREM 2.2. *Assume that $\omega(\tau)$ is a positive real root of* (2.13) *defined for $\tau \in I$, $I \subseteq \mathbf{R}_{+0}$, and at some $\tau^* \in I$,*

$$S_n(\tau^*) = 0 \quad \textit{for some } n \in \mathbf{N}_0. \tag{2.20}$$

Then a pair of simple conjugate pure imaginary roots $\lambda_+(\tau^*) = i\omega(\tau^*), \lambda_-(\tau^*) = -i\omega(\tau^*)$ of (2.1) *exists at $\tau = \tau^*$ which crosses the imaginary axis from left to right if $\delta(\tau^*) > 0$ and crosses the imaginary axis from right to left if $\delta(\tau^*) < 0$, where*

$$\delta(\tau^*) = \operatorname{sign}\left\{\left.\frac{d\mathrm{Re}\ \lambda}{d\tau}\right|_{\lambda = i\omega(\tau^*)}\right\} = \operatorname{sign}\{F'_\omega(\omega(\tau^*), \tau^*)\}\operatorname{sign}\left\{\left.\frac{dS_n(\tau)}{d\tau}\right|_{\tau = \tau^*}\right\}. \tag{2.21}$$

Proof. The existence part of the theorem follows from the requirement (2.17) which ensures that if and only if $\tau^* \in I$ is a zero of $S_n(\tau)$ for some $n \in \mathbf{N}_0$, $\lambda = \pm i\omega(\tau^*)$ together with $\omega(\tau^*) > 0$, a solution of (2.13), are characteristic roots of (2.1).

To prove the geometric criterion (2.21) we remark that

$$\operatorname{sign}\left\{\frac{d\mathrm{Re}\lambda}{d\tau}\right\} = \operatorname{sign}\left\{\mathrm{Re}\left(\frac{d\lambda}{d\tau}\right)^{-1}\right\}.$$

Then differentiating (2.1) with respect to τ we obtain that

$$\begin{aligned}&\left(\frac{d\lambda}{d\tau}\right)[P'_\lambda(\lambda, \tau) + (Q'_\lambda(\lambda, \tau) - \tau Q(\lambda, \tau))e^{-\lambda\tau}]\\ &= \lambda Q(\lambda, \tau)e^{-\lambda\tau} - [P'_\tau(\lambda, \tau) + Q'_\tau(\lambda, \tau)e^{-\lambda\tau}].\end{aligned} \tag{2.22}$$

From (2.2), we have

$$e^{\lambda\tau} = -\frac{Q(\lambda,\tau)}{P(\lambda,\tau)}. \tag{2.23}$$

Hence, we obtain

$$\left(\frac{d\lambda}{d\tau}\right)^{-1} = \left(-\frac{P'_\lambda(\lambda,\tau)}{P(\lambda,\tau)} + \frac{Q'_\lambda(\lambda,\tau)}{Q(\lambda,\tau)} - \tau\right) \Big/ \left(\lambda + \frac{P'_\tau(\lambda,\tau)}{P(\lambda,\tau)} - \frac{Q'_\tau(\lambda,\tau)}{Q(\lambda,\tau)}\right), \tag{2.24}$$

where $P(i\omega,\tau)$, $Q(i\omega,\tau) \neq 0$ due to assumption (i). Assume that $\lambda = i\omega(\tau)$, where $\omega(\tau) > 0$ is a root of (2.13). Then from (2.24) we obtain

$$\begin{aligned}&\operatorname{sign}\left\{\left.\frac{d\mathrm{Re}\,\lambda}{d\tau}\right|_{\lambda=i\omega}\right\}\\ &\quad = \operatorname{sign}\,\mathrm{Re}\left\{\frac{-P'_\lambda(i\omega,\tau)\overline{P(i\omega,\tau)} + Q'_\lambda(i\omega,\tau)\overline{Q(i\omega,\tau)} - \tau|P(i\omega,\tau)|^2}{P'_\tau(i\omega,\tau)\overline{P(i\omega,\tau)} - Q'_\tau(i\omega,\tau)\overline{Q(i\omega,\tau)} + i\omega|P(i\omega,\tau)|^2}\right\}.\end{aligned} \tag{2.25}$$

Now we remark that

$$iP'_\lambda(i\omega,\tau) = P'_\omega(i\omega,\tau), \qquad iQ'_\lambda(i\omega,\tau) = Q'_\omega(i\omega,\tau). \tag{2.26}$$

Hence, in (2.25) we have

$$\begin{aligned}&-P'_\lambda(i\omega,\tau)\overline{P(i\omega,\tau)} + Q'_\lambda(i\omega,\tau)\overline{Q(i\omega,\tau)}\\ &\quad = i[(P'_{R_\omega}P_R + P'_{I_\omega}P_I) - (Q'_{R_\omega}Q_R + Q'_{I_\omega}Q_I)]\\ &\qquad -[(P'_{I_\omega}P_R - P_IP'_{R_\omega}) - (Q'_{I_\omega}Q_R - Q_IQ'_{R_\omega})],\end{aligned} \tag{2.27}$$

which due to (2.15) becomes

$$\begin{aligned}&-P'_\lambda(i\omega,\tau)\overline{P(i\omega,\tau)} + Q'_\lambda(i\omega,\tau)\overline{Q(i\omega,\tau)}\\ &\quad = i\frac{F'_\omega(\omega,\tau)}{2} - [(P_RP'_{I_\omega} - P_IP'_{R_\omega}) - (Q_RQ'_{I_\omega} - Q_IQ'_{R_\omega})].\end{aligned} \tag{2.28}$$

Similarly, in (2.25) we have

$$\begin{aligned}&P'_\tau(i\omega,\tau)\overline{P(i\omega,\tau)} - Q'_\tau(i\omega,\tau)\overline{Q(i\omega,\tau)}\\ &\quad = \frac{1}{2}F'_\tau(\omega,\tau) + i[(P_RP'_{I_\tau} - P_IP'_{R_\tau}) - (Q_RQ'_{I_\tau} - Q_IQ'_{R_\tau})].\end{aligned} \tag{2.29}$$

Furthermore, remember that from (2.14)

$$F'_\tau(\omega,\tau) = -F'_\omega(\omega,\tau)\omega'. \tag{2.30}$$

Hence, from (2.28)–(2.30) in (2.25) we obtain

$$\operatorname{sign}\left\{\left.\frac{d\mathrm{Re}\,\lambda}{d\tau}\right|_{\lambda=i\omega}\right\} = \operatorname{sign}\,\mathrm{Re}\left\{\frac{-2\{U + \tau|P(i\omega,\tau)|^2\} + iF'_\omega(\omega,\tau)}{F'_\tau(\omega,\tau) + i2\{V + \omega|P(i\omega,\tau)|^2\}}\right\},$$

where

$$U := (P_RP'_{I_\omega} - P_IP'_{R_\omega}) - (Q_RQ'_{I_\omega} - Q_IQ'_{R_\omega}), \quad V := (P_RP'_{I_\tau} - P_IP'_{R_\tau}) - (Q_RQ'_{I_\tau} - Q_IQ'_{R_\tau}).$$

Simple computation yields

$$\text{sign}\left\{\left.\frac{d\text{Re }\lambda}{d\tau}\right|_{\lambda=i\omega}\right\} = \text{sign }\{F'_\omega(\omega,\tau)\}\text{ sign }\left\{\tau\omega' + \omega + \frac{U\omega'+V}{|P(i\omega,\tau)|^2}\right\}. \tag{2.31}$$

Now observe that if $S_n(\tau^*) = 0$, then $S'_n(\tau^*) = (\omega(\tau^*) + \tau^*\omega'(\tau^*) - \theta'(\tau^*))/\omega(\tau^*)$, which gives

$$\text{sign }\{S'_n(\tau^*)\} = \text{sign }\{\omega(\tau^*) + \tau^*\omega'(\tau^*) - \theta'(\tau^*)\}, \tag{2.32}$$

where $\theta'(\tau^*)$ can be computed with the help of (2.16). Let

$$\begin{cases} \psi(\tau) = -P_R(i\omega,\tau)Q_I(i\omega,\tau) + P_I(i\omega,\tau)Q_R(i\omega,\tau), \\ \varphi(\tau) = P_R(i\omega,\tau)Q_R(i\omega,\tau) + P_I(i\omega,\tau)Q_I(i\omega,\tau); \end{cases} \tag{2.33}$$

then for all $\tau \in I$, $\theta'(\tau)$ is defined as (see Remark 2.1)

$$\theta'(\tau) = \frac{\psi(\tau)\varphi'(\tau) - \psi'(\tau)\varphi(\tau)}{|P(i\omega,\tau)|^4}, \tag{2.34}$$

where

$$\begin{cases} \varphi'(\tau) = (P'_{R_\omega}Q_R + P_RQ'_{R_\omega} + P'_{I_\omega}Q_I + P_IQ'_{I_\omega})\omega' \\ \quad +(P'_{R_\tau}Q_R + P_RQ'_{R_\tau} + P'_{I_\tau}Q_I + P_IQ'_{I_\tau}), \\ \psi'(\tau) = (-P'_{R_\omega}Q_I - P_RQ'_{I_\omega} + Q'_{R_\omega}P_I + Q_RP'_{I_\omega})\omega' \\ \quad +(-P'_{R_\tau}Q_I - P_RQ'_{I_\tau} + Q'_{R_\tau}P_I + Q_RP'_{I_\tau}). \end{cases} \tag{2.35}$$

Hence, from (2.34), (2.35) we have

$$\begin{aligned} |P(i\omega,\tau)|^4\theta'(\tau) = \omega'\{&(P'_{R_\omega}Q_R + P_RQ'_{R_\omega} + P'_{I_\omega}Q_I + P_IQ'_{I_\omega})(-P_RQ_I + Q_RP_I) \\ &(-P'_{R_\omega}Q_I - P_RQ'_{I_\omega} + Q'_{R_\omega}P_I + Q_RP'_{I_\omega})(P_RQ_R + P_IQ_I)\} \\ &+(P'_{R_\tau}Q_R + P_RQ'_{R_\tau} + P'_{I_\tau}Q_I + P_IQ'_{I_\tau})(-P_RQ_I + Q_RP_I) \\ &-(-P'_{R_\tau}Q_I - P_RQ'_{I_\tau} + Q'_{R_\tau}P_I + Q_RP'_{I_\tau})(P_RQ_R + P_IQ_I) \\ &\equiv \omega'A + B. \end{aligned} \tag{2.36}$$

It can be shown that

$$\begin{aligned} A &= -(P_R^2 + P_I^2)Q'_{R_\omega}Q_I - (Q_R^2 + Q_I^2)P_RP'_{I_\omega} + P'_{R_\omega}P_I(Q_R^2 + Q_I^2) \\ &\quad +(P_R^2 + P_I^2)Q_RQ'_\omega \\ &= (P'_{R_\omega}P_I - P_RP'_{I_\omega})|P(i\omega,\tau)|^2 - (Q'_{R_\omega}Q_I - Q_RQ'_{I_\omega})|P(i\omega,\tau)|^2 \end{aligned} \tag{2.37}$$

and

$$\begin{aligned} B &= -(P_R^2 + P_I^2)(Q'_{R_\tau}Q_I - Q_RQ'_{I_\tau}) + (Q_R^2 + Q_I^2)(P'_{R_\tau}P_I - P_RP'_{I_\tau}) \\ &= |P(i\omega,\tau)|^2(Q_RQ'_{I_\tau} - Q'_{R_\tau}Q_I) - |P(i\omega,\tau)|^2(P_RP'_{I_\tau} - P'_{R_\tau}P_I). \end{aligned} \tag{2.38}$$

Hence, from (2.36)–(2.38) we obtain

$$\begin{aligned} \theta'(\tau) &= -\frac{\omega'[(P'_{I_\omega}P_R - P'_{R_\omega}P_I) - (Q_RQ'_{I_\omega} - Q'_{R_\omega}Q_I)]}{|P(i\omega,\tau)|^2} \\ &\quad -\frac{[(P_RP'_{I_\tau} - P'_{R_\tau}P_I) - (Q_RQ'_{I_\tau} - Q'_{R_\tau}Q_I)]}{|P(i\omega,\tau)|^2} = -\frac{U\omega'+V}{|P(i\omega,\tau)|^2}. \end{aligned} \tag{2.39}$$

Therefore, if we substitute (2.39) evaluated at τ^* in (2.32), and we compare the result with (2.31), we find that

$$\operatorname{sign}\left\{\frac{d\mathrm{Re}\ \lambda}{d\tau}\bigg|_{\lambda=i\omega(\tau^*)}\right\} = \operatorname{sign}\ \{F'_\omega(\omega,\tau^*)\}\operatorname{sign}\ \{S'_n(\tau^*)\},$$

thus completing the proof. □

Remark 2.1. Assume that $\theta(\tau)\in(0,2\pi), \tau\in I$, where $\theta(\tau)$ is defined by (2.16). According to (2.35), we can rewrite (2.16) as

$$\sin\theta(\tau) = \frac{\psi(\tau)}{|Q(i\omega,\tau)|^2}, \qquad \cos\theta(\tau) = -\frac{\varphi(\tau)}{|Q(i\omega,\tau)|^2}, \qquad \tau\in I, \tag{2.40}$$

where ψ,φ are continuous and differentiable functions of τ such that $\psi^2+\varphi^2 = |P(i\omega,\tau)|^4$ and $|Q(i\omega,\tau)|^2 = |P(i\omega,\tau)|^2$ for $\tau\in I$. Hence, we have

$$\begin{aligned}
&\theta(\tau) = \arctan(-\psi(\tau)/\varphi(\tau)) \quad \text{if} \quad \sin\theta(\tau)>0, \cos\theta(\tau)>0;\\
&\theta(\tau) = \pi/2 \quad \text{if} \quad \sin\theta(\tau)=1, \cos\theta(\tau)=0;\\
&\theta(\tau) = \pi+\arctan(-\psi(\tau)/\varphi(\tau)) \quad \text{if} \quad \cos\theta(\tau)<0;\\
&\theta(\tau) = 3\pi/2 \quad \text{if} \quad \sin\theta(\tau)=-1, \cos\theta(\tau)=0;\\
&\theta(\tau) = 2\pi+\arctan(-\psi(\tau)/\varphi(\tau)) \quad \text{if} \quad \sin\theta(\tau)<0, \cos\theta(\tau)>0.
\end{aligned} \tag{2.41}$$

It is easy to see that the function $\theta(\tau)$ defined above is continuous on I. Furthermore $\theta'(\tau)$ is well defined for $\theta(\tau)\in(0,2\pi)$ and it is indeed given by (2.34). Observe that if $\theta(\tau)\neq\pi/2, 3\pi/2$, then $\varphi(\tau)\neq 0$, and (2.34) simply follows from (2.41). When $\theta(\tau)=\pi/2, 3\pi/2$, we have $\varphi(\tau)=0$. In this case, we compute $\theta'(\tau)$ directly from (2.40) and obtain

$$-(\sin(\theta(\tau)))\theta'(\tau) = (-\varphi(\tau)/(\psi^2(\tau)+\varphi^2(\tau))^{1/2})'. \tag{2.42}$$

Since $\sin\theta(\tau)\neq 0$ (i.e., $\psi(\tau)\neq 0$), it is easy to see that (2.42) implies (2.34) as well.

Therefore, if $\theta(\tau)\in(0,2\pi), \tau\in I$, then $\theta(\tau)$ is continuous and differentiable. If in addition, $\omega(\tau)$ is positive, continuous, and differentiable on I, then functions $\tau_n(\tau)$ and $S_n(\tau), n\in\mathbf{N}_0$, are all continuous and differentiable.

Remark 2.2. Instead of looking for zeros of S_n, we can look for the zeros of, say, $Z_n = \omega S_n = \omega\tau - \theta(\tau) - 2n\pi = Z_0 - 2n\pi$. Since $\omega>0$, they have the same zeros, and all the functions Z_n have the same shape as Z_0 (they are simply shifted down by $2n\pi$). Furthermore it is easy to check that $\operatorname{sign}(S'_n) = \operatorname{sign}(Z'_n)$ when considering the derivative with respect to τ at the same zero as S_n and Z_n. In most cases of applications, we can assume that $I=[0,\tau_1)$ with $\omega(0)>0$ and $\omega(\tau)\to 0$ as $\tau\to\tau_1$. Then clearly $Z_n(0)<0$ and $Z_n(\tau)<0$ as $\tau\to\tau_1$. Hence either Z_n is negative or it has an even number of zeros (taking into account multiplicity of the zeros).

3. First order characteristic equation.

In this section, we consider the first order characteristic equation

$$D(\lambda,\tau)=0, \tag{3.1}$$

where

$$D(\lambda,\tau) = a(\tau)\lambda + b(\tau) + c(\tau)e^{-\lambda\tau}, \tag{3.2}$$

which belongs to the general class

$$D(\lambda,\tau) = P_n(\lambda,\tau) + Q_m(\lambda,\tau)e^{-\lambda\tau}, \tag{3.3}$$

where P_n, Q_m are polynomials in λ with $n > m$. In our case $P(\lambda,\tau) := P_n(\lambda,\tau) = a(\tau)\lambda + b(\tau)$ is a first order polynomial in λ, $Q(\lambda,\tau) := Q_m(\lambda,\tau) = c(\tau)$. The coefficients a, b, c are real smooth functions of τ assumed to have continuous derivatives in τ and

$$b(\tau) + c(\tau) \neq 0 \quad \forall\tau \geq 0. \tag{3.4}$$

Due to assumption (3.4), $\lambda = 0$ cannot be a root of (3.1) and a stability switch (or a cross of the imaginary axis) necessarily occurs with $\lambda = \pm i\omega$ with $\omega > 0$. Without loss of generality assume $\lambda = i\omega$, $\omega > 0$, as a root of (3.2). Hence at $\lambda = i\omega$ we have

$$P(i\omega,\tau) = b(\tau) + i\omega a(\tau), \quad Q(i\omega,\tau) = c(\tau), \tag{3.5}$$

i.e.,

$$F(\omega,\tau) = |P(i\omega,\tau)|^2 - |Q(i\omega,\tau)|^2 = \omega^2a^2 + b^2 - c^2, \tag{3.6}$$

from which $F(\omega,\tau) = 0$ gives a solution for $\omega(\tau) > 0$:

$$\omega(\tau) = \left(\frac{c^2(\tau) - b^2(\tau)}{a^2(\tau)}\right)^{1/2}, \tag{3.7}$$

which is defined if $|c(\tau)| > |b(\tau)|$ and $a(\tau) \neq 0$. Furthermore, since $P_R(i\omega,\tau) = b(\tau)$, $P_I(i\omega,\tau) = \omega a(\tau)$, $Q_R(i\omega,\tau) = c(\tau)$, $Q_I(i\omega,\tau) = 0$, (2.16) give

$$\sin\theta(\tau) = \frac{\omega(\tau)a(\tau)}{c(\tau)}, \quad \cos\theta(\tau) = -\frac{b(\tau)}{c(\tau)}. \tag{3.8}$$

Let

$$I = \{\tau : \tau \geq 0, a(\tau) \neq 0 \quad \text{and} \quad |b(\tau)| < |c(\tau)|\}.$$

Let $\theta(\tau) \in I$ be the solution of (3.8). Then a stability switch may occur, through the roots $\lambda = \pm i\omega(\tau)$, where $\omega(\tau) > 0$ is given by (3.7), at the τ values

$$\tau_n = \frac{\theta(\tau) + n2\pi}{\omega(\tau)} \tag{3.9}$$

for $n \in \mathbf{N}_0 := \{0, 1, 2, \ldots\}$. Then for each $n \in \mathbf{N}_0$ (3.9) defines the maps $\tau_n : I \rightarrow \mathbf{R}_{+0}$, and the stability switch may occur only for the τ values at which

$$\tau_n(\tau) = \tau \quad \text{for some} \quad n \in \mathbf{N}_0. \tag{3.10}$$

Hence (3.7), (3.8) define the maps (3.9), and the occurrence of stability switches takes place at the zeros of the functions

$$S_n(\tau) := \tau - \tau_n(\tau), \quad n \in \mathbf{N}_0. \tag{3.11}$$

Remark 3.1. We remark here that for $\tau \in I, \theta(\tau)$ is continuous and differentiable in τ. To see this, we observe that due to (3.4), we have $\cos\theta(\tau) \neq 1$ for $\tau \in I$. Hence for $\tau \in I,\ \theta(\tau) \neq 0, 2\pi$. This shows that $\theta(\tau)$ is continuous and differentiable. As a result, we see that $\tau_n(\tau)$ are also continuous and differentiable for $\tau \in I$. Now we want to see if it is possible to determine the direction in which the pair of imaginary roots $\lambda = \pm i\omega(\tau^*)$ (where τ^* is such that $S_n(\tau^*) = 0$ for some n) crosses the imaginary axis as τ increases. In view of the fact that it is now quite straightforward to generate the graphs of $S_n(\tau)$ by popular software such as Maple, we want to connect the rather abstract value of

$$R(\tau) := \text{sign}\left\{\left.\frac{d\text{Re}\lambda}{d\tau}\right|_{\lambda = i\omega(\tau^*)}\right\}$$

with the intuitive and easy to use one

$$S(\tau) := \text{sign}\left\{\left.\frac{dS_n(\tau)}{d\tau}\right|_{\tau=\tau^*}\right\} = \text{sign}\left\{1 - \left.\frac{d\tau_n(\tau)}{d\tau}\right|_{\tau=\tau^*}\right\}. \tag{3.12}$$

Observe that

$$F'_\omega(\omega, \tau) = 2\omega a^2 > 0 \tag{3.13}$$

since $\omega(\tau) > 0$. Therefore, (2.21) in Theorem 2.2 becomes

$$\text{sign}\left\{\left.\frac{d\text{Re }\lambda}{d\tau}\right|_{\lambda=i\omega(\tau^*)}\right\} = \text{sign}\left\{\left.\frac{dS_n(\tau)}{d\tau}\right|_{\tau=\tau^*}\right\}. \tag{3.14}$$

Hence, we have the following.

Theorem 3.1. *The characteristic equation* (3.1) *admits a pair of simple and conjugate roots* $\lambda_+(\tau^*) = i\omega(\tau^*), \lambda_-(\tau^*) = -i\omega(\tau^*)$, $\omega(\tau^*) > 0$, *at* $\tau^* \in I$ *if* $S_n(\tau^*) = 0$, *for some* $n \in \mathbf{N}_0$. *This pair of simple conjugate pure imaginary roots crosses the imaginary axis from left to right if* $\delta(\tau^*) > 0$ *and crosses the imaginary axis from right to left if* $\delta(\tau^*) < 0$, *where*

$$\delta(\tau^*) = \text{sign}\left\{\left.\frac{d\text{Re}\lambda}{d\tau}\right|_{\lambda=i\omega(\tau^*)}\right\} = \text{sign}\left\{\left.\frac{dS_n(\tau)}{d\tau}\right|_{\tau=\tau^*}\right\}. \tag{3.15}$$

The following analytical result on $R(\tau)$ is useful for determining analytically the τ values at which a stability switch occurs.

Theorem 3.2. *For the characteristic equation* (3.1),

$$\text{sign}\left\{\left.\frac{d\text{Re}\lambda}{d\tau}\right|_{\lambda=i\omega(\tau^*)}\right\} = \text{sign}\,\{a^2(\tau)\omega(\tau)\omega'(\tau)(a(\tau)b(\tau) + c(\tau)^2\tau) + \omega^2(\tau)a^2(\tau)(a'(\tau)b(\tau) - a(\tau)b'(\tau) + c^2(\tau))\}. \tag{3.16}$$

Proof. Denote by a', b', c' the derivatives of $a(\tau), b(\tau), c(\tau)$ with respect to τ. Differentiating (3.1) with respect to τ we obtain

$$\frac{d\lambda}{d\tau} = \frac{\lambda c(\tau)e^{-\lambda\tau} - (a'(\tau)\lambda + b'(\tau) + c'(\tau)e^{-\lambda\tau})}{a(\tau) - c(\tau)\tau e^{-\lambda\tau}}. \tag{3.17}$$

It is convenient to consider $(d\lambda/d\tau)^{-1}$. Hence, from (3.17) we have

$$\left(\frac{d\lambda}{d\tau}\right)^{-1} = \frac{a(\tau)e^{\lambda\tau} - c(\tau)\tau}{\lambda c(\tau) - (a'(\tau)\lambda + b'(\tau))e^{\lambda\tau} - c'(\tau)}, \tag{3.18}$$

where, due to (3.1)

$$e^{\lambda\tau} = -\frac{c(\tau)}{a(\tau)\lambda + b(\tau)}. \tag{3.19}$$

Therefore, substituting (3.19) in (3.18), we have

$$\left(\frac{d\lambda}{d\tau}\right)^{-1} = \frac{-\frac{a(\tau)c(\tau)}{a(\tau)\lambda+b(\tau)} - c(\tau)\tau}{\lambda c(\tau) + \frac{c(\tau)(a'(\tau)\lambda+b'(\tau))}{a(\tau)\lambda+b(\tau)} - c'(\tau)}. \tag{3.20}$$

Now, we compute (3.20) at $\lambda = i\omega(\tau)$. We have

$$\left(\frac{d\lambda}{d\tau}\right)^{-1}\Bigg|_{\lambda=i\omega(\tau)} = \frac{-\frac{ac(b-i\omega a)}{(\omega^2a^2+b^2)} - c\tau}{i\omega c + \frac{c(i\omega a'+b')(b-i\omega a)}{\omega^2a^2+b^2} - c'}. \tag{3.21}$$

Since $\omega^2(\tau)a^2(\tau) + b^2(\tau) = c^2(\tau)$ for any $\tau \in I$, we obtain

$$\left(\frac{d\lambda}{d\tau}\right)^{-1}\Bigg|_{\lambda=i\omega(\tau)} = \frac{-(ab + c^2\tau) + i\omega a^2}{\omega^2aa' + bb' - cc' + i\omega(a'b - ab' + c^2)}. \tag{3.22}$$

Since $F(\omega,\tau) = 0$ for all $\tau \in I$, we obtain

$$-\omega\omega' a^2 = \omega^2 aa' + bb' - cc' \tag{3.23}$$

for all $\tau \in I$, which substituted in (3.22) provides

$$\left(\frac{d\lambda}{d\tau}\right)^{-1}\Bigg|_{\lambda=i\omega(\tau)} = \frac{-(a(\tau)b(\tau) + c(\tau)^2\tau) + i\omega(\tau)a(\tau)^2}{-a^2(\tau)\omega(\tau)\omega'(\tau) + i\omega(\tau)(a'(\tau)b(\tau) - a(\tau)b'(\tau) + c^2(\tau))}. \tag{3.24}$$

Therefore, we have

$$\begin{aligned} R(\tau) = \operatorname{sign}\ \{&a^2(\tau)\omega(\tau)\omega'(\tau)(a(\tau)b(\tau) + c(\tau)^2\tau) + \omega^2(\tau)a^2(\tau)(a'(\tau)b(\tau) \\ &-a(\tau)b'(\tau) + c^2(\tau))\}, \end{aligned} \tag{3.25}$$

proving the theorem. □

Example. As an example of first order characteristic equations with delay dependent coefficients, we consider the first model with time delay (simpler one) introduced by Bence and Nisbet [3] for a population of sessile invertebrates. (This population was previously studied by Roughgarden, Iwasa, and Baxter [25] and Roughgarden and Iwasa [24] in terms of different mathematical models.) This model is a two-stage model in which the population is divided into an adult population, which is explicitly modeled, and a juvenile population which is modeled implicitly. The model takes the form

$$\frac{dA}{dt} = se^{-m_J\tau}\max\{0, 1 - a_AA(t-\tau)\} - m_AA(t), \tag{3.26}$$

where $A(t)$ represents the adult population, s is the settlement rate of juveniles, $e^{-m_J\tau}$ is the through-stage survival probability of juveniles, m_A is the mortality rate of adults, and τ is the fixed time delay between settlement and recruitment into the adult population. Finally $a_A > 0$ is the amount of space occupied by an adult individual. The characteristic equation at steady state takes the form (3.1) with

$$a(\tau) = 1, \quad b(\tau) = m_A, \quad c(\tau) = a_A s e^{-m_J \tau}, \tag{3.27}$$

and $\tau \in \mathbf{R}_{+0}$. Furthermore,

$$b(0) + c(0) = m_A + a_A s > 0,$$

thus ensuring that at $\tau = 0$ we have one negative eigenvalue.

Let $\omega(\tau)$ be the positive solution of

$$\omega^2(\tau) = a_A^2 s^2 e^{-2m_J \tau} - m_A^2 \tag{3.28}$$

which exists provided that

$$a_A s > m_A, \quad \tau < \tau_1 := \frac{1}{m_J} \log\left(\frac{a_A s}{m_A}\right). \tag{3.29}$$

Then, eigenvalues $\lambda_+ = i\omega(\tau), \lambda_- = -i\omega(\tau)$, $\omega(\tau) > 0$, can only occur for delays τ in the interval $I = (0, \tau_1)$. No stability switches for $\tau \geq \tau_1$. It is interesting to determine the values of τ at which $R(\tau) = 1$ and those at which $R(\tau) = -1$. To this end we can use formula (3.16)

$$R(\tau) = \operatorname{sign}\,\{a^2 \omega\omega'(ab + c^2\tau) + \omega^2 a 2(a'b - ab') + \omega^2 c^2\},$$

where a, b, c are coefficients in (3.27) and ω is defined by (3.28). From (3.27) we see that $a' = b' = 0$, $ab = m_A$,

$$\omega\omega' = -m_J a_A^2 s^2 e^{-2m_J\tau} = -m_J c^2. \tag{3.30}$$

Substituting (3.30) in (3.16) we obtain

$$\begin{aligned} R(\tau) &= \operatorname{sign}\,\{-m_J c^2(m_A + c^2\tau) + \omega^2 c^2\} \\ &= \operatorname{sign}\,\{-m_A(m_J + m_A) - c^2(m_J\tau - 1)\}. \end{aligned} \tag{3.31}$$

Then if $(1/m_J) < \tau_1$, (3.31) shows that in the interval $((1/m_J), \tau_1)$ we have $R(\tau) = -1$, i.e., possible stability switches can only occur toward stability. Assume that $\tau < \min\{(1/m_J), \tau_1\}$. Then (3.31) takes the form

$$R(\tau) = \operatorname{sign}\,\{(1 - m_J\tau) a_A^2 s^2 e^{-2m_J\tau} - m_A(m_J + m_A)\}, \tag{3.32}$$

which yields the following conclusions:

(i) If the parameters satisfy

$$m_A < a_A s < m_A \left(1 + \frac{m_J}{m_A}\right)^{1/2}, \tag{3.33}$$

then for all $\tau \in [0, \tau_1)$ we have $R(\tau) = -1$. In such cases, a stability switch from unstable to stable may occur. Since at $\tau = 0$ the steady state is asymptotically stable, then it remains asymptotically stable for all $\tau \in [0, \tau_1)$.

(ii) Assume that the parameters satisfy

$$a_A s > m_A \left(1 + \frac{m_J}{m_A}\right)^{1/2}. \tag{3.34}$$

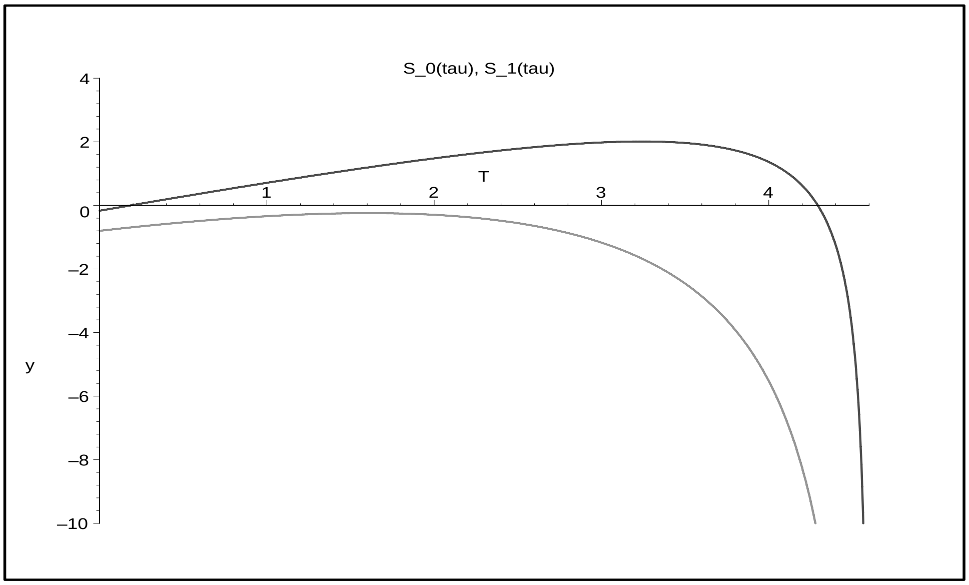

FIG. 1. *Graph of stability switch in terms of time delay for the first model of Bence and Nisbet* [3]. *The top curve is* $S_0(\tau)$.

Then there exists a τ_c, $0 < \tau_c < \tau_1$, such that

$$\operatorname{sign}\left\{ \frac{d\mathrm{Re}\,\lambda}{d\tau}\bigg|_{\lambda=i\omega(\tau)} \right\} > 0$$

in $(0, \tau_c)$, vanishes at τ_c, and is negative in (τ_c, τ_1). τ_c is the unique zero of

$$\varphi(\tau) := (1 - m_J\tau)a_A^2 s^2 e^{-2m_J\tau} - m_A(m_J + m_A), \quad \tau \in (0, \tau_1). \tag{3.35}$$

The statements of (i), (ii) are helpful in choosing the parameters to perform relevant numerical simulations. In Figure 1, we plot the graph of the map $S_0(\tau)$ versus τ in the interval $I = [0, \tau_1)$ for the following set of parameters satisfying (3.34):

$$a_A = 1, \quad m_A = 1, \quad m_J = 0.5, \quad s = 10,$$

with $\tau_1 = 4.605$. The graph of $S_0(\tau)$ versus τ in Figure 1 shows that $S_0(\tau)$ has two zeros, the first at the value $\tau_{01} = 0.20$, the second at the value $\tau_{02} = 4.24$, and $S_1(\tau) < 0$ on $(0, \tau_1)$. According to Theorem 3.1 at τ_{01} a stability switch occurs toward instability whereas at τ_{02} the stability switch occurs toward stability. Hence, for the model by Bence and Nisbet [3], as confirmed by other computer simulations, intermediate delays ($\tau \in (0.2, 4.24)$) show a destabilizing effect on the steady state, whereas large delays ($\tau > 4.24$) have a stabilizing one. For $\tau \in (\tau_{01}, \tau_{02})$, the steady state is unstable whereas it is asymptotically stable for $0 \le \tau < \tau_{01}$ and for any $\tau > \tau_{02}$. These results are in agreement with our computer simulations using XPP.

4. Second order characteristic equation. In this section, we consider the characteristic equation

$$D(\lambda, \tau) := \lambda^2 + a(\tau)\lambda + b(\tau)\lambda e^{-\lambda\tau} + c(\tau) + d(\tau)e^{-\lambda\tau} = 0; \tag{4.1}$$

$\tau \in \mathbf{R}_{+0}$ and $a(\tau), b(\tau), c(\tau), d(\tau) : \mathbf{R}_{+0} \to \mathbf{R}$ are differentiable functions of class $C^1(\mathbf{R}_{+0})$ such that $c(\tau) + d(\tau) \neq 0$ for all $\tau \in \mathbf{R}_{+0}$, and for any τ, $b(\tau), d(\tau)$ are not simultaneously zero. We have

$$P(\lambda, \tau) := P_n(\lambda, \tau) = \lambda^2 + a(\tau)\lambda + c(\tau), \qquad Q(\lambda, \tau) := Q_m(\lambda, \tau) = b(\tau)\lambda + d(\tau).$$

We assume that $P_n(\lambda, \tau)$ and $Q_m(\lambda, \tau)$ cannot have common imaginary roots. That is, for any real number ω,

$$P_n(i\omega, \tau) + Q_m(i\omega, \tau) \neq 0. \tag{4.2}$$

We have

$$F(\omega, \tau) = |P(i\omega, \tau)|^2 - |Q(i\omega, \tau)|^2 = (c - \omega^2)^2 + \omega^2 a^2 - (\omega^2 b^2 + d^2). \tag{4.3}$$

Hence, $F(\omega, \tau) = 0$ implies

$$\omega^4 - \omega^2(b^2 + 2c - a^2) + (c^2 - d^2) = 0, \tag{4.4}$$

and its roots are given by

$$\omega_+^2 = \frac{1}{2}\{(b^2 + 2c - a^2) + \Delta^{1/2}\}, \quad \omega_-^2 = \frac{1}{2}\{(b^2 + 2c - a^2) - \Delta^{1/2}\}, \tag{4.5}$$

where

$$\Delta = (b^2 + 2c - a^2)^2 - 4(c^2 - d^2). \tag{4.6}$$

Therefore, the following holds:

$$2\omega_\pm^2 - (b^2 + 2c - a^2) = \pm\Delta^{1/2}. \tag{4.7}$$

Furthermore, $P_R(i\omega, \tau) = c(\tau) - \omega^2(\tau)$, $P_I(i\omega, \tau) = \omega(\tau)a(\tau)$, $Q_R(i\omega, \tau) = d(\tau)$, $Q_I(i\omega, \tau) = \omega(\tau)b(\tau)$. Hence (2.16) becomes

$$\sin\theta(\tau) = \frac{-(c - \omega^2)\omega b + \omega a d}{\omega^2 b^2 + d^2}, \quad \cos\theta(\tau) = -\frac{(c - \omega^2)d + \omega^2 ab}{\omega^2 b^2 + d^2}, \tag{4.8}$$

which jointly with (4.4) defines the maps (2.19). Now, from (4.3) we have

$$\begin{aligned} F'_\omega(\omega, \tau) &= 2(c - \omega^2)(-2\omega) + 2\omega a^2 - 2\omega b^2 \\ &= 2\omega[2\omega^2 - (b^2 + 2c - a^2)] \\ &= 2\omega_\pm[\pm\Delta^{1/2}], \end{aligned} \tag{4.9}$$

where $\omega_\pm(\tau) > 0$. Hence (2.21) in Theorem 2.2 becomes

$$\operatorname{sign}\left\{\left.\frac{d\mathrm{Re}\,\lambda}{d\tau}\right|_{\lambda = i\omega_\pm}\right\} = \operatorname{sign}\{\pm\Delta^{1/2}\}\operatorname{sign}\left\{\left.\frac{dS_n(\tau)}{d\tau}\right|_{\tau = \tau^*}\right\}. \tag{4.10}$$

This proves the following theorem.

THEOREM 4.1. *The characteristic equation* (4.1) *has a pair of simple and conjugate pure imaginary roots $\lambda = \pm i\omega(\tau^*)$, $\omega(\tau^*)$ real, at $\tau^* \in I$ if $S_n(\tau^*) = \tau^* - \tau_n(\tau^*) = 0$ for some $n \in \mathbf{N}_0$. If $\omega(\tau^*) = \omega_+(\tau^*)$, this pair of simple conjugate pure imaginary* *roots crosses the imaginary axis from left to right if* $\delta_+(\tau^*) > 0$ *and crosses the imaginary axis from right to left if* $\delta_+(\tau^*) < 0$, *where*

$$\delta_+(\tau^*) := \operatorname{sign}\left\{ \left.\frac{d\mathrm{Re}\ \lambda}{d\tau}\right|_{\lambda = i\omega_+(\tau^*)} \right\} = \operatorname{sign}\left\{ \left.\frac{dS_n(\tau)}{d\tau}\right|_{\tau=\tau^*} \right\}. \tag{4.11}$$

If $\omega(\tau^*) = \omega_-(\tau^*)$, *this pair of simple conjugate pure imaginary roots crosses the imaginary axis from left to right if* $\delta_-(\tau^*) > 0$ *and crosses the imaginary axis from right to left if* $\delta_-(\tau^*) < 0$, *where*

$$\delta_-(\tau^*) := \operatorname{sign}\left\{ \left.\frac{d\mathrm{Re}\ \lambda}{d\tau}\right|_{\lambda = i\omega_-(\tau^*)} \right\} = -\operatorname{sign}\left\{ \left.\frac{dS_n(\tau)}{d\tau}\right|_{\tau=\tau^*} \right\}. \tag{4.12}$$

We remark that if $\omega_+(\tau^*) = \omega_-(\tau^*) = \omega(\tau^*)$, then $\Delta(\tau^*) = 0$ and

$$\operatorname{sign}\left\{ \left.\frac{d\mathrm{Re}\ \lambda}{d\tau}\right|_{\lambda = i\omega(\tau^*)} \right\} = 0. \tag{4.13}$$

The same is true when $S_n'(\tau^*) = 0$. The following result can be useful in identifying values of τ where stability switches may take place. (In using this theorem, the plus or minus signs are to be used consistently on both sides of the equations.)

THEOREM 4.2. *Assume that for all* $\tau \in I$, $\omega(\tau)$ *is defined as a solution of* (4.4). *Then*

$$\delta_\pm(\tau) = \operatorname{sign}\{\pm\Delta^{1/2}(\tau)\}\operatorname{sign}D_\pm(\tau), \tag{4.14}$$

where

$$\begin{aligned} D_\pm(\tau) = {} & \omega_\pm^2[(\omega_\pm^2 b^2 + d^2) + a'(c - \omega_\pm^2) + bd' - b'd - ac'] \\ & + \omega_\pm\omega_\pm'[\tau(\omega_\pm^2 b^2 + d^2) - bd + a(c - \omega_\pm^2) + 2\omega_\pm^2 a] \end{aligned}$$

for all $\tau \in I$.

Proof. Let us differentiate with respect to τ the characteristic equation (4.1). We obtain

$$\left(\frac{d\lambda}{d\tau}\right)^{-1} = \frac{-\frac{2\lambda + a}{\lambda^2 + a\lambda + c} + \frac{b}{b\lambda + d} - \tau}{\lambda + \frac{a'\lambda + c'}{\lambda^2 + a\lambda + c} - \frac{b'\lambda + d'}{b\lambda + d}}. \tag{4.15}$$

Now, let $\lambda = i\omega(\tau)$ where $\omega(\tau) > 0$ satisfies (4.4). Hence, we have

$$\begin{aligned} \mathrm{Re}\left(\frac{d\lambda}{d\tau}\right)^{-1}\Bigg|_{\lambda = i\omega} &= \mathrm{Re}\left\{ \frac{-\frac{(2i\omega + a)((c-\omega^2) - i\omega a)}{(c-\omega^2)^2 + \omega^2 a^2} + \frac{b(d - i\omega b)}{d^2 + \omega^2 b^2} - \tau}{i\omega + \frac{(i\omega a' + c')((c-\omega^2) - i\omega a)}{(c-\omega^2)^2 + \omega^2 a^2} - \frac{(i\omega b' + d')(d - i\omega b)}{d^2 + \omega^2 b^2}} \right\} \\ &= \mathrm{Re}\left\{ \frac{[bd - \tau(d^2 + \omega^2 b^2) - 2\omega^2 a - a(c - \omega^2)] + i[\omega(2\omega^2 - (b^2 + 2c - a^2))]}{[\omega^2 aa' + c'(c - \omega^2) - \omega^2 bb' - dd'] + i[\omega((d^2 + \omega^2 b^2) + a'(c - \omega^2) - ac' + bd' - b'd)]} \right\}. \end{aligned} \tag{4.16}$$

Therefore, from (4.16) we have

$$\begin{aligned} \operatorname{sign}\left\{ \mathrm{Re}\left(\frac{d\lambda}{d\tau}\right)^{-1}\Bigg|_{\lambda = i\omega} \right\} = \operatorname{sign}\{ & [\tau(d^2 + \omega^2 b^2) - bd + a(c - \omega^2) + 2\omega^2 a] \\ & \times[-\omega^2 aa' - c'(c - \omega^2) + \omega^2 bb' + dd'] \\ & + \omega^2[2\omega^2 - (b^2 + 2c - a^2)] \\ & \times[(\omega^2 b^2 + d^2) + a'(c - \omega^2) + bd' - b'd - ac']\}. \end{aligned} \tag{4.17}$$

Differentiating both sides of (4.4) with respect to τ we obtain

$$\omega\omega'[2\omega^2 - (b^2 + 2c - a^2)] = -\omega^2 aa' - c'(c - \omega^2) + \omega^2 bb' + dd'. \tag{4.18}$$

Furthermore, $\omega(\tau)$ must be one of the two roots $\omega_\pm(\tau)$ given by (4.5); therefore,

$$2\omega_\pm^2 - (b^2 + 2c - a^2) = \pm\Delta^{1/2}. \tag{4.19}$$

Combining (4.18) and (4.19) in (4.17), we obtain

$$\begin{aligned} &\operatorname{sign}\left\{\operatorname{Re}\left(\frac{d\lambda}{d\tau}\right)^{-1}\bigg|_{\lambda=i\omega_\pm(\tau)}\right\} \\ &= \operatorname{sign}\,\{\pm\Delta^{1/2}(\tau)\} \\ &\quad \times\operatorname{sign}\,\{\omega_\pm^2[(\omega_\pm^2 b^2 + d^2) + a'(c - \omega_\pm^2) + bd' - b'd - ac'] \\ &\qquad + \omega_\pm\omega_\pm'[\tau(\omega_\pm^2 b^2 + d^2) - bd + a(c - \omega_\pm^2) + 2\omega_\pm^2 a]\}. \end{aligned}$$

Since

$$\operatorname{sign}\left\{\frac{d\mathrm{Re}\ \lambda}{d\tau}\right\} = \operatorname{sign}\left\{\mathrm{Re}\ \left(\frac{d\lambda}{d\tau}\right)^{-1}\right\},$$

the proof is completed. □

Remark 4.1. In almost all the application problems that we have encountered so far that have characteristic equations of the form (4.1), often only ω_+ is feasible. In these cases, stability switches occur only at the roots of $S_0^+(\tau) = \tau - \tau_0^+(\tau) = 0$, where

$$\tau_0^+(\tau) = \theta_+(\tau)/\omega_+(\tau), \qquad \tau \in I, \tag{4.20}$$

and $\theta_+(\tau)$ is the solution of (4.8) when $\omega = \omega_+$.

However, if both ω_+ and ω_- are feasible for $\tau \in I$, then we have the following two sequences of functions on I:

$$S_n^+(\tau) = \tau - (\theta_+(\tau) + 2n\pi)/\omega_+(\tau), \quad S_n^-(\tau) = \tau - (\theta_-(\tau) + 2n\pi)/\omega_-(\tau), \tag{4.21}$$

where the notations are self-evident. Clearly $S_n^+(\tau) > S_{n+1}^+(\tau)$ and $S_n^-(\tau) > S_{n+1}^-(\tau)$ for all $n \in \mathbf{N}_0, \tau \in I$. In addition to this, we have the following simple statement.

THEOREM 4.3. *Assume that $S_0^+(\tau) > S_0^-(\tau)$ on I. Then $S_n^+(\tau) > S_n^-(\tau)$ on I for all $n \in \mathbf{N}_0$.*

Proof. It is easy to see that $S_0^+(\tau) > S_0^-(\tau)$ on I implies that

$$\theta_+(\tau)/\omega_+(\tau) < \theta_-(\tau)/\omega_-(\tau), \qquad \tau \in I. \tag{4.22}$$

Note that $\omega_+(\tau) > \omega_-(\tau)$ on I; the theorem follows from (4.21). □

Remark 4.2. When both ω_+ and ω_- are feasible for $\tau \in I$, it is easy to imagine that the stability switches may depend on all real roots of $S_n^+(\tau) = 0$ and $S_n^-(\tau) = 0$. In such situations, one must examine all these possible real roots in order to determine the stability of the equilibrium. To illustrate this, let us consider such a scenario. Assume that Theorem 4.3 holds true and the equilibrium is asymptotically stable when $\tau = 0$. Assume further that $S_0^+(\tau) = 0$ at $t_1 = \tau_{01}^+$ and $t_4 = \tau_{02}^+$, $S_0^-(\tau) = 0$ at $t_2 = \tau_{01}^-$ and $t_3 = \tau_{02}^-$, and no real roots for $S_n^+(\tau) = 0$ and $S_n^-(\tau) = 0$ when $n > 0$. Then it is easy to see (Figure 2) that $t_1 < t_2 < t_3 < t_4$. Careful but simple examination shows

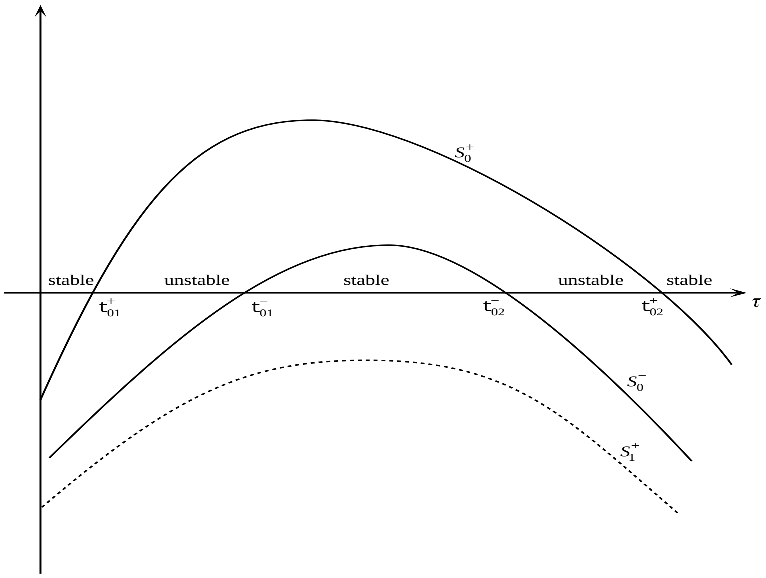

FIG. 2. *Illustration for Remark* 4.2.

that the equilibrium is asymptotically stable for $\tau \in [0, t_1) \cup (t_2, t_3) \cup ((t_4, \infty) \cap I)$ and is unstable for $\tau \in (t_1, t_2) \cup (t_3, t_4)$. More complicated scenarios are clearly conceivable.

Example. As an example for the second order characteristic equations with delay dependent coefficients, we consider the second model with time delay and stage structure introduced by Bence and Nisbet [3] for a population of sessile invertebrates. Again, the model is a two-stage model in which population is divided into adult and juvenile populations, both of which are explicitly modeled. The model takes the form

$$J'(t) = s[F(t) - e^{-m_J\tau} F(t-\tau)] - m_J J(t), \tag{4.23}$$

$$A'(t) = se^{-m_J\tau} F(t-\tau) - m_A A(t), \tag{4.24}$$

$$F(t) = \max\{0, 1 - a_J J(t) - a_A A(t)\}, \tag{4.25}$$

where $sF(t)$ represents the newly settled juveniles and $se^{-m_J\tau}F(t-\tau)$ the ones that become adults. When $a_J = 0$, this model reduces to (3.26). Here, s, m_g, m_A, a_A are positive constants and a_J is a nonnegative constant. This model was systematically studied by Kuang and So in [22]. It should be mentioned here that the last statement of their Theorem 4.1, which says that $S_0^+(\tau) > 0$ (with respect to the positive steady state) implies that the positive steady state is unstable, is not fully justified. To be accurate, it requires the assumption that ω_- is not feasible. The analysis and simulation (with both Maple and XPP) we conducted so far, however, indeed suggest that this assumption may in fact hold for all biologically meaningful parameters.

Let J^*, A^*, F^* denote equilibrium population sizes of juveniles, adults, and equilibrium free space, respectively. We have

$$J^* = \frac{sF^*}{m_J}(1 - e^{-m_J\tau}), \qquad A^* = \frac{sF^*}{m_A}e^{-m_J\tau}. \tag{4.26}$$

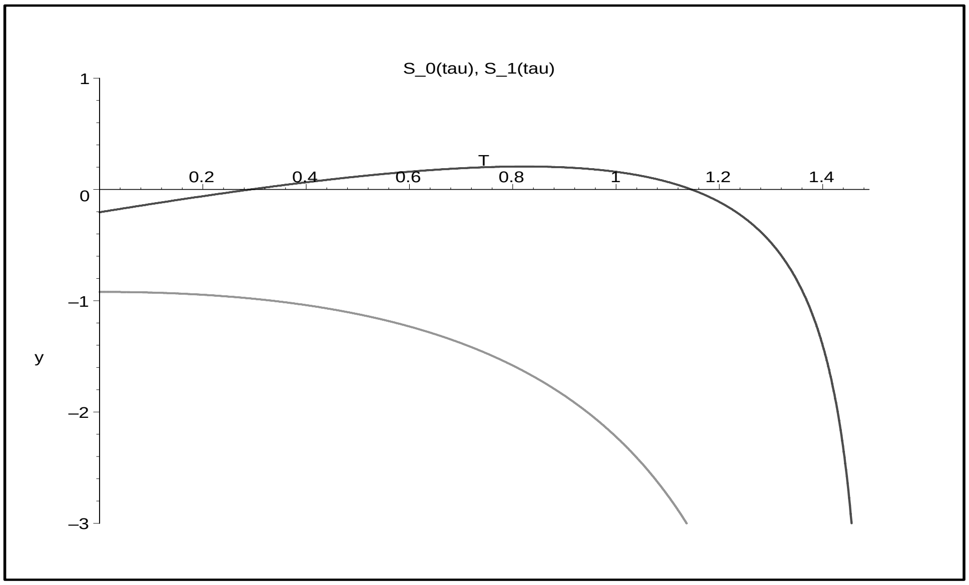

FIG. 3. *Graph of stability switch in terms of time delay for the second model of Bence and Nisbet* [3]*. The top curve is* $S_0(\tau)$*.*

It follows that $F^* \neq 0$ and

$$F^* = 1 - sF^* \left[\frac{a_J}{m_J}(1 - e^{-m_J\tau}) + \frac{a_A}{m_A} e^{-m_J\tau} \right]. \tag{4.27}$$

Following the notation of Bence and Nisbet [3], $\sigma_J = sa_J/m_J, \sigma_A = sa_A/m_A$, we have

$$F^* = [1 + \sigma_J + (\sigma_A - \sigma_J)e^{-m_J\tau}]^{-1}.$$

Thus, system (4.23)–(4.25) has a unique positive steady state (J^*, A^*) and $F^* < 1$. Its characteristic equation at the positive steady state takes the form

$$\lambda^2 + a\lambda + b\lambda e^{-\lambda\tau} + c + de^{-\lambda\tau} = 0, \tag{4.28}$$

where

$$a = m_J + m_A + a_J s, \qquad b = b(\tau) = (a_A - a_J)se^{-m_J\tau}, \tag{4.29}$$

$$c = m_A m_J + a_J m_A s, \qquad d = d(\tau) = (a_A m_J - a_J m_A)se^{-m_J\tau}. \tag{4.30}$$

Clearly, $c + d > 0$, which implies $\lambda = 0$ can never be a root of (4.28). When $\tau = 0$, (4.28) reduces to

$$\lambda^2 + (a + b)\lambda + c + d = 0,$$

which has roots with negative real parts, implying that (J^*, A^*) is locally asymptotically stable when $\tau = 0$.

In Figure 3, we plot the graph of the map $S_0^+(\tau)$ versus τ in the interval $I = [0, \tau_1)$ for the set of parameters satisfying

$$a_A = 1, \quad m_A = 1, \quad a_J = 0.1, \quad m_J = 1, \quad s = 10,$$

with $\tau_1 = 1.49$. It can be shown that for this set of parameters, ω_- is not feasible for $\tau \in I$. The graph of $S_0^+(\tau)$ versus τ in Figure 3 shows that $S_0^+(\tau)$ has two zeros, the first at the value $\tau_{01} = 0.29$, the second at the value $\tau_{02} = 1.14$, whereas $S_1^+(\tau) < 0$ on I. According to Theorem 4.1 and Remark 4.1, we see that at τ_{01} a stability switch occurs toward instability whereas at τ_{02} the stability switch occurs toward stability. Again, we see that intermediate delays show a destabilizing effect on the steady state, whereas large delays have a stabilizing one. For $\tau \in (\tau_{01}, \tau_{02})$, the steady state is unstable, whereas it is asymptotically stable for $0 \le \tau < \tau_{01}$ and for any $\tau > \tau_{02}$. These results are in agreement with our computer simulations using XPP.

5. Discussion.

It is well known that for nonlinear delay systems (including many neutral delay systems) the occurrence of characteristic roots crossing the imaginary axis from left to right as the result of changing certain parameters often ensures the emergence of nontrivial periodic solutions near the steady state as it becomes unstable (Hale and Verduyn Lunel [17]). For well-constructed population models, this scenario is to be expected. XPP simulation can easily confirm this.

We would like to stress here that the geometric criterion presented in the previous section may also be applicable to models with several discrete delays or distributed delays.

Consider, for an example, the following Lotka–Volterra predator prey model with two discrete delays:

$$\begin{cases} x'(t) = x(t)[e_1 - a_1 x(t) - a_2 y(t-\sigma)], \\ y'(t) = y(t)[-e_2 + a_3 x(t-\tau) - a_4 y(t)], \end{cases} \tag{5.1}$$

where all parameters are positive constants. Assume further that it has a positive steady state $E^* = (x^*, y^*)$. Let $r = \sigma/\tau$. The system can be reduced to the following one with dimensionless time t/τ, which, for simplicity, we again denote by t:

$$\begin{cases} x'(t) = \tau x(t)[e_1 - a_1 x(t) - a_2 y(t-r)], \\ y'(t) = \tau y(t)[-e_2 + a_3 x(t-1) - a_4 y(t)]. \end{cases} \tag{5.2}$$

At E^*, the characteristic equation is

$$\lambda^2 + \lambda a^* \tau + b^* \tau^2 + c^* \tau^2 e^{-\lambda(r+1)} = 0, \tag{5.3}$$

where $a^* = a_1 x^* + a_4 y^*,\ b^* = a_1 a_4 x^* y^*,\ c^* = a_2 a_3 x^* y^*$. Since $\tau = \sigma/r$, we see that the characteristic equation takes the form

$$\lambda^2 + \lambda A(r,\sigma) + B(r,\sigma) + C(r,\sigma) e^{-\lambda(r+1)} = 0, \tag{5.4}$$

where $A(r,\sigma) = a^*\sigma/r,\ B(r,\sigma) = b^*\sigma^2/r^2,\ C(r,\sigma) = c^*\sigma^2/r^2$, and r may vary in $\mathbf{R}_+$. Clearly, for each fixed value of delay σ, we have a characteristic equation with parameters dependent on r. Notice that all coefficients of (5.4) are positive, and hence all its real roots must be negative. Stability switching may occur when imaginary roots $\lambda = i\omega$ exist and cross the imaginary axis.

It is straightforward to find that ω must be the solution of

$$F(\omega, r) := \omega^4 + \omega^2(A^2(r) - 2B(r)) + B^2(r) - C^2(r). \tag{5.5}$$

(For simplicity, we drop the dependence of σ.) This gives

$$\omega_\pm^2 = \frac{1}{2}\{2B(r) - A^2(r) \pm [(2B(r) - A^2(r))^2 + 4(C^2(r) - B^2(r))]^{1/2}\}. \tag{5.6}$$

Let $\theta(r) \in [0, 2\pi]$ be the solution of

$$\cos\theta(r) = \frac{\omega^2(r) - B(r)}{C(r)}, \qquad \sin\theta(r) = \frac{\omega(r)A(r)}{C(r)}. \tag{5.7}$$

The imaginary roots $\lambda = \pm i\omega, \omega(r) > 0$ will appear at the r values which are zeros r^* of

$$S_n(r) = r + 1 - \frac{\theta(r) + 2n\pi}{\omega(r)}, \qquad n \in \mathbf{N}_0. \tag{5.8}$$

Hence, once we know such r^*, we know $\tau^* = \sigma/r^*$. This will give us a pair of delay values (τ^*, σ) at which the stability switch may be possible when increasing the value of $r = \sigma/\tau$ while keeping σ fixed. Of course, such analysis can be performed for each σ for which the solutions (5.6) are feasible. A similar procedure can be applied to σ while keeping τ fixed.

As an example for the applicability of our geometric criterion to models with distributed delays, we consider the following model of single species growth:

$$x'(t) = f\left(\int_{-\tau}^{0} e^{ds}x(t+s)ds\right) - g(x(t)), \tag{5.9}$$

where τ is the maximum stage delay and d is the through-stage death rate, both positive constants. The first term accounts for the births due to all the age groups and the second term represents the death rate. Typical assumptions on f and g are given in [20]. This model can also be viewed as a direct extension of the models studied in [10]. Assume that it admits a positive steady state of $x(t) = x^*$. Then

$$f\left(\frac{1}{d}(1 - e^{-d\tau})x^*\right) = g(x^*).$$

Let

$$a := f'\left(\frac{1}{d}(1 - e^{-d\tau})x^*\right), \qquad b := g'(x^*).$$

Then the linearized equation of (5.9) takes the form

$$u'(t) = a\int_{-\tau}^{0} e^{ds}u(t+s)ds - bu(t). \tag{5.10}$$

By differentiating the above equation one more time and making some simple substitution, we have

$$u''(t) + (b+d)u'(t) + (db - a)u(t) + ae^{-d\tau}u(t-\tau) = 0. \tag{5.11}$$

Clearly, this is a special case of (4.1) and our criteria are applicable.

There are several factors that may have contributed to the current prevalence of models containing only delay independent parameters. These include the following: (1) the authors fail to recognize the need to have some of the parameters become delay dependent; (2) the authors think that delay independent parameters can provide a good enough description or approximation of the dynamics; (3) there is simply a lack of mathematical results and methods to deal with models involving delay dependent parameters.

To see why it is easy to overlook the need of introducing delay dependent parameters in a model, let us consider the well-studied Nicholson's blowfly model proposed in [16]:

$$N' = R - D = R(N(t-\tau)) - \delta N = pN(t-\tau)e^{-N(t-\tau)} - \delta N, \tag{5.12}$$

where N is the sexually mature adult blowfly population density, δ is its individual death rate, and R is the recruitment rate. In arriving at the above form of R, Gurney, Blythe, and Nisbet [16] argued that (1) the rate at which eggs are produced depends only on the current size of adult population, (2) each egg takes about τ units of time to become a sexually mature adult, and (3) the probability of a given egg maturing into a viable adult depends only on the number of competitors of the same age. However, since an individual larva will die at a constant or average rate of d, the through-stage survival rate for a larva to adulthood is $e^{-d\tau}$. Thus a more plausible model should take the form (Cooke et al. [10])

$$N' = e^{-d\tau}R(N(t-\tau)) - \delta N = pe^{-d\tau}N(t-\tau)\exp\{-N(t-\tau)\} - \delta N. \tag{5.13}$$

Now, this equation has a parameter $e^{-d\tau}$ that depends on the time delay τ.

To see the importance of introducing delay dependent parameters, we again use models (5.12) and (5.13). It is well known [21] that for (5.12), if a positive steady state exists and this steady state is unstable for $\tau = \tau_0$, then it remains unstable for $\tau > \tau_0$. That is, a large time delay plays a destabilizing role. However, for model (5.13), one sees the opposite [10]. What is often observed (which can be easily verified by XPP) is that there are two threshold values $0 < \tau_0 < \tau_1$ such that the positive steady state is unstable only when $\tau \in [\tau_0, \tau_1]$. Dramatic differences in dynamics provided by models with delay dependent parameters and models with delay independent parameters like that above seem to be the rule rather than the exception. It is also worth mentioning here that applying existing criteria designed for models with delay independent parameters can lead to speculative or even erroneous statements.

Acknowledgments. The authors would like to thank the two referees for their constructive comments and suggestions.

BLOCH APPROXIMATION IN HOMOGENIZATION AND APPLICATIONS[*]

CARLOS CONCA[†], RAFAEL ORIVE[‡], AND MUTHUSAMY VANNINATHAN[§]

Abstract. The classical problem of homogenization of elliptic operators with periodically oscillating coefficients is revisited in this paper. As is well known, the homogenization process in a classical framework is concerned with the study of asymptotic behavior of solutions u^ε of boundary value problems associated with such operators when the period $\varepsilon > 0$ of the coefficients is small. In a previous work by C. Conca and M. Vanninathan [*SIAM J. Appl. Math.*, 57 (1997), pp. 1639–1659], a new proof of weak convergence as $\varepsilon \to 0$ towards the homogenized solution was furnished using Bloch wave decomposition.

Following the same approach here, we go further and introduce what we call *Bloch approximation*, which will provide energy norm approximation for the solution u^ε. We develop several of its main features. As a simple application of this new object, we show that it contains both the first and second order correctors. Necessarily, the Bloch approximation will have to capture the oscillations of the solution in a sharper way. The present approach sheds new light and offers an alternative for viewing classical results.

1. Introduction.

In this paper, the classical problem of homogenization of elliptic operators with periodically oscillating coefficients is revisited. As is well known, the homogenization process is concerned with the study of the behavior of solutions u^ε of boundary value problems associated with such operators when the coefficients are periodic with small period $\varepsilon > 0$. For an excellent introduction to this subject, the reader is referred to the book of A. Bensoussan, J.-L. Lions, and G. Papanicolaou [5]. In a previous work by C. Conca and M. Vanninathan [11], a new proof of weak convergence of u^ε towards the homogenized solution u^* was furnished using Bloch wave decomposition. Following the same approach, we go further and introduce what we call *Bloch approximation* of the solution u^ε. As a simple application of this new object, we treat the problem of correctors in homogenization. At this point, it is worthwhile to remark that the homogenized solution u^* is merely the weak limit of solutions u^ε as $\varepsilon \to 0$. The idea behind introducing correctors is to look for terms (called *first order correctors*) which, when added to the homogenized solution, provide an approximation in the energy norm for all ε sufficiently small. *Second order correctors* yield an error estimate in the energy norm of order $O(\varepsilon)$. The main feature of Bloch approximation is that it contains both the first and second order corrector terms. Another important feature is that it is easily computable in principle.

Historically, a classical way of obtaining such correctors is to work in the physical space and use multiscale expansion of the solution, which was first introduced in the basic book just cited. As we will see, the method of Bloch waves sheds new light and offers an alternative for viewing the classical results. This method naturally leads us to work in the Fourier space, and thus in a framework dual to the one used in L. Tartar [21], whose method is very general and justifies, in particular, the first term obtained via the multiscale expansion. (There are also other methods of justification based on the analysis in physical space; cf. G. Nguetseng [17] and G. Allaire [1].) However, it is important to mention that the Bloch wave method does not presuppose any multiscale structure of the solution; on the contrary, such a structure of the solution will be a consequence of the present method. Although correctors are generally not unique, our approach yields a posteriori the same ones as those obtained in [5].

Bloch waves and their applications are not by any means new. It is a classical tool which has been in use in solid state physics since the pioneering paper of F. Bloch [6]. However, the basic idea was introduced in the mathematical literature much earlier by G. Floquet [13]. For later developments, let us cite the works of F. Odeh and J. Keller [18] and M. Reed and B. Simon [19]. A deep analysis concerning the partial regularity of the spectrum of Schrödinger's equation with periodic potential was carried out by C. Wilcox [22]. Our point of view regards periodic medium as a perturbation of homogeneous ones. In this context, the book by T. Kato [15] provides excellent analysis when the parameter of perturbation is a scalar. We end this rather incomplete list by citing G. Allaire and C. Conca [2], [3], and P. Gérard et al. [14]. We feel it is also appropriate to cite a recent work by M. Avellaneda, L. Berlyand, and J.-F. Clouet [4], in which the Bloch–Floquet approach is used to provide new homogenization results and handles the boundary layer terms for frequency dependent problems. To conclude, let us refer the reader to C. Conca [8] for a more complete general survey on Bloch waves.

Before proceeding further, we mention a word about the notations adopted in what follows. Unless mentioned explicitly, the usual summation convention with respect to the repeated indices is understood. The constants appearing in various estimates independent of ε are generically denoted by c, c_1, c_2, etc. Apart from the usual norms in Sobolev spaces H^1, H^2, we will also use the following seminorms:

$$|v|_{H^1} = \left\{ \sum_{j=1}^{N} \left\| D_j v \right\|_{L^2}^2 \right\}^{\frac{1}{2}}, \quad |v|_{H^2} = \left\{ \sum_{j,k=1}^{N} \left\| D_{j,k}^2 v \right\|_{L^2}^2 \right\}^{\frac{1}{2}}.$$

Now let us introduce the problem to be studied in this work. We consider the operator

$$A \overset{\text{def}}{=} -\frac{\partial}{\partial y_k}\left(a_{k\ell}(y) \frac{\partial}{\partial y_\ell} \right), \quad y \in \mathbb{R}^N, \tag{1.1}$$

where the coefficients satisfy

$$\begin{cases} a_{k\ell} \in L^\infty_\#(Y), \quad \text{where} \quad Y =]0, 2\pi[^N, \text{ i.e., each } a_{k\ell} \text{ is a} \\ Y\text{-periodic bounded measurable function defined on } \mathbb{R}^N, \text{ and} \\ \exists \alpha > 0 \quad \text{such that} \quad a_{k\ell}(y)\eta_k\eta_\ell \geq \alpha|\eta|^2 \quad \forall \eta \in \mathbb{R}^N, \ y \in Y \text{ a.e.}, \\ a_{k\ell} = a_{\ell k} \quad \forall k, \ell = 1, \ldots, N. \end{cases} \tag{1.2}$$

For each $\varepsilon > 0$, we consider also the operator A^ε, where

$$A^\varepsilon \overset{\text{def}}{=} -\frac{\partial}{\partial x_k}\left(a^\varepsilon_{k\ell}(x)\frac{\partial}{\partial x_\ell}\right) \quad \text{with} \quad a^\varepsilon_{k\ell}(x) = a_{k\ell}\left(\frac{x}{\varepsilon}\right), \quad x \in \mathbb{R}^N. \tag{1.3}$$

In homogenization theory, it is usual to refer to x and y, the slow and the fast variables, respectively. They are related by $y = \frac{x}{\varepsilon}$. Associated with A^ε, let us consider the boundary value problem

$$A^\varepsilon u^\varepsilon = f \quad \text{in} \quad \Omega, \quad u^\varepsilon \in H^1_0(\Omega), \tag{1.4}$$

which is posed in an arbitrary bounded domain Ω in $\mathbb{R}^N$ and where f is a given element in $L^2(\Omega)$. It is classical that the above problem admits one and only one solution.

From the classical work [5], it is known that one can associate to A^ε a homogenized operator A^* given by

$$A^* \overset{\text{def}}{=} -\frac{\partial}{\partial x_k}\left(q_{k\ell}\frac{\partial}{\partial x_\ell}\right). \tag{1.5}$$

The homogenized coefficients $q_{k\ell}$ are constants and their definition is given below. The solution u^ε of (1.4) converges weakly in $H^1_0(\Omega)$ to the so-called homogenized solution u^* characterized by

$$A^* u^* = f \quad \text{in} \quad \Omega, \quad u^* \in H^1_0(\Omega). \tag{1.6}$$

In the present paper, we do not consider the effects of boundaries, postponing them to a subsequent article [9]. In the case of $\mathbb{R}^N$, it is natural to replace the operator A^ε by $(A^\varepsilon + I)$. In that case, if w^ε satisfies

$$\left\{\begin{array}{rll} (A^\varepsilon + I)w^\varepsilon = g & \text{in} & \mathbb{R}^N, \\ w^\varepsilon \rightharpoonup w^* & \text{in} & H^1(\mathbb{R}^N)\text{-weak}, \end{array}\right. \tag{1.7}$$

where g is a given function in $L^2(\mathbb{R}^N)$, then it can be seen that (see Proposition 6.1 below)

$$w^\varepsilon \to w^* \quad \text{in} \quad L^2(\mathbb{R}^N)\text{-strong}. \tag{1.8}$$

In view of the above result, there is no concentration of L^2-energy at infinity, and therefore throughout this paper we will consider a sequence u^ε and a function $f \in L^2(\mathbb{R}^N)$ satisfying

$$\left\{\begin{array}{rll} A^\varepsilon u^\varepsilon = f & \text{in} & \mathbb{R}^N, \\ u^\varepsilon \rightharpoonup u^* & \text{in} & H^1(\mathbb{R}^N)\text{-weak}, \\ u^\varepsilon \to u^* & \text{in} & L^2(\mathbb{R}^N)\text{-strong}. \end{array}\right. \tag{1.9}$$

The central issue in the analysis of the first order correctors is to obtain functions $u^\varepsilon_1 \in H^1(\mathbb{R}^N)$, which can be easily constructed and have the following characteristic property:

$$\|u^\varepsilon - u^* - \varepsilon u^\varepsilon_1\|_{H^1(\mathbb{R}^N)} \to 0 \quad \text{as} \quad \varepsilon \to 0. \tag{1.10}$$

By definition, second order correctors $u_2^\varepsilon \in H^1(\mathbb{R}^N)$ will enjoy the property

$$\|u^\varepsilon - u^* - \varepsilon u_1^\varepsilon - \varepsilon^2 u_2^\varepsilon\|_{H^1(\mathbb{R}^N)} \leq c\varepsilon. \tag{1.11}$$

One of the purposes of this article is to carry out a more general construction than the classical one for correctors, namely, Bloch approximation θ^ε, which contains all the above correctors and justifies the procedure. Apart from this, θ^ε contains a lot of information about the periodic medium which will be amply demonstrated in this paper.

1.1. Survey of the previous results. In the classical book [5] the authors obtain an asymptotic expansion (with $y = \frac{x}{\varepsilon}$) of the form

$$\begin{aligned} u^\varepsilon(x) = \quad & u^*(x) + \varepsilon\left\{\chi_k(y)\frac{\partial u^*}{\partial x_k}(x) + \widetilde{u}_1(x)\right\} \\ & + \varepsilon^2\left\{\chi_{k\ell}(y)\frac{\partial^2 u^*}{\partial x_k x_\ell}(x) + \chi_\ell(y)\frac{\partial \widetilde{u}_1}{\partial x_\ell}(x) + \widetilde{u}_2(x)\right\} + \cdots . \end{aligned} \tag{1.12}$$

Here, χ_k is the unique solution of the cell problem

$$\begin{cases} A\chi_k = \dfrac{\partial a_{k\ell}}{\partial y_\ell} \qquad \text{in} \quad \mathbb{R}^N, \\ \chi_k \in H^1_\#(Y), \quad \mathcal{M}_Y(\chi_k) \overset{\text{def}}{=} \dfrac{1}{|Y|}\displaystyle\int_Y \chi_k dy = 0. \end{cases} \tag{1.13}$$

The function $\chi_{k\ell}$ is characterized as the unique solution of

$$\begin{cases} A\chi_{k\ell} = a_{k\ell} + a_{km}\dfrac{\partial \chi_\ell}{\partial y_m} - \dfrac{\partial}{\partial y_m}(a_{mk}\chi_\ell) - \mathcal{M}_Y(a_{k\ell}) - \mathcal{M}_Y\left(a_{km}\dfrac{\partial\chi_\ell}{\partial y_m}\right) \text{ in } \mathbb{R}^N, \\ \chi_{k\ell} \in H^1_\#(Y), \quad \mathcal{M}_Y(\chi_{k\ell}) = 0. \end{cases} \tag{1.14}$$

Further, $\widetilde{u}_1(x), \widetilde{u}_2(x), \ldots$ are independent of ε and satisfy equations of the type $A^*\widetilde{u}_j = \widetilde{g}_j$ in $\mathbb{R}^N$, where, for instance, $\widetilde{g}_1(x) = b_{jk\ell}D^3_{jk\ell}u^*$, where $b_{jk\ell}$ are constants:

$$b_{jk\ell} = \mathcal{M}_Y\left(a_{jm}\frac{\partial \chi_{k\ell}}{\partial y_m} + a_{k\ell}\chi_j\right) \quad \forall j, k, \ell = 1, \ldots, N.$$

With these notations, the classical formula of the homogenized coefficients is as follows:

$$q_{k\ell} = \mathcal{M}_Y\left(a_{k\ell} + a_{km}\frac{\partial\chi_\ell}{\partial y_m}\right) \quad \forall k, \ell = 1, \ldots, N.$$

(Another characterization of $q_{k\ell}$ is given in Proposition 1.5 below.) Using the above expansion, the first order corrector term is obtained in [5]. More precisely, we have the following.

Theorem 1.1. *We assume that the coefficients $a_{k\ell}$ satisfy assumptions* (1.2), *$f \in L^2(\mathbb{R}^N)$, and the solution $\chi_k \in W^{1,\infty}(Y)$, $k = 1, \ldots, N$. Then the first order corrector is defined by*

$$u_1^\varepsilon(x) = \chi_k\left(\frac{x}{\varepsilon}\right)\frac{\partial u^*}{\partial x_k}(x),$$

which means that

$$\|u^\varepsilon - u^* - \varepsilon u_1^\varepsilon\|_{H^1(\mathbb{R}^N)} \to 0 \quad \textit{as} \quad \varepsilon \to 0. \qquad \square$$

In this paper, we obtain a more general result using a different approach introduced in [11]. The basic tool of this new approach is Bloch waves ψ associated with A which we define now. Let us consider the following spectral problem parameterized by $\eta \in \mathbb{R}^N$: find $\lambda = \lambda(\eta) \in \mathbb{R}$ and $\psi = \psi(y;\eta)$ (not identically zero) such that

$$(1.15) \quad \begin{cases} A\psi(\cdot;\eta) = \lambda(\eta)\psi(\cdot;\eta) \quad \text{in} \quad \mathbb{R}^N, \quad \psi(\cdot;\eta) \text{ is } (\eta;Y)\text{-periodic, i.e.,} \\ \psi(y + 2\pi m;\eta) = e^{2\pi i m\cdot\eta}\psi(y;\eta) \quad \forall m \in \mathbb{Z}^N,\ y \in \mathbb{R}^N. \end{cases}$$

Next, we define $\phi(y;\eta) = e^{-iy\cdot\eta}\psi(y;\eta)$, and (1.15) can be rewritten in terms of ϕ as follows:

$$(1.16) \qquad A(\eta)\phi = \lambda\phi \quad \text{in} \quad \mathbb{R}^N, \quad \phi \text{ is } Y\text{-periodic.}$$

Here, the operator $A(\eta)$ is defined by

$$(1.17) \qquad A(\eta) \overset{\text{def}}{=} -\left(\frac{\partial}{\partial y_k} + i\eta_k\right)\left[a_{k\ell}(y)\left(\frac{\partial}{\partial y_\ell} + i\eta_\ell\right)\right],$$

which can be rewritten as

$$(1.18) \qquad A(\eta) = A + i\eta_k C_k + \eta_k\eta_\ell a_{k\ell}(y)$$

with

$$(1.19) \qquad C_k\phi \overset{\text{def}}{=} -a_{kj}(y)\frac{\partial\phi}{\partial y_j} - \frac{\partial}{\partial y_j}(a_{kj}(y)\phi).$$

It is clear from (1.15) that the (η, Y) periodicity condition is unaltered if we replace η by $(\eta + q)$ with $q \in \mathbb{Z}^N$, and η can therefore be confined to the *dual cell* $\eta \in Y' = [-\frac{1}{2}, \frac{1}{2}[^N$. It is well known (C. Conca, J. Planchard, and M. Vanninathan [10]) that for each $\eta \in Y'$, the above spectral problem admits a discrete sequence of eigenvalues with the following properties:

$$\begin{cases} 0 \le \lambda_1(\eta) \le \cdots \le \lambda_m(\eta) \le \cdots \to \infty \\ \forall m \ge 1,\ \lambda_m(\eta) \text{ is a Lipschitz function of } \eta \in Y'. \end{cases}$$

Besides, the corresponding eigenfunctions denoted by $\psi_m(\cdot;\eta)$ and $\phi_m(\cdot;\eta)$ form orthonormal bases in the spaces of all $L^2_{loc}(\mathbb{R}^N)$-functions which are $(\eta;Y)$-periodic and Y-periodic, respectively; these spaces are denoted by $L^2_\#(\eta;Y)$ and $L^2_\#(Y)$. It is worthwhile to remark that these eigenfunctions in fact belong to the spaces $H^1_\#(\eta;Y)$ and $H^1_\#(Y)$, respectively, where

$$H^1_\#(\eta;Y) = \left\{\psi \in L^2_\#(\eta;Y) \;\middle|\; \frac{\partial\psi}{\partial y_k} \in L^2_\#(\eta;Y) \quad \forall k = 1,\dots,N\right\},$$

$$H^1_\#(Y) = \left\{\phi \in L^2_\#(Y) \;\middle|\; \frac{\partial\phi}{\partial y_k} \in L^2_\#(Y) \quad \forall k = 1,\dots,N\right\}.$$

The functions $\psi_m(\cdot;\eta)$ and $\phi_m(\cdot;\eta)$ (referred to as *Bloch waves*) introduced above enable us to describe the spectral resolution of A (an unbounded self-adjoint operator in $L^2(\mathbb{R}^N)$) in the orthogonal basis $\{e^{iy\cdot\eta}\phi_m(y;\eta)|m \geq 1, \eta \in Y'\}$. More precisely, we have the following.

THEOREM 1.2. *Let $g \in L^2(\mathbb{R}^N)$. The mth Bloch coefficient of g is defined as follows:*

$$(B_m g)(\eta) = \int_{\mathbb{R}^N} g(y)e^{-iy\cdot\eta}\bar{\phi}_m(y;\eta)dy \quad \forall m \geq 1,\ \eta \in Y'.$$

Then the following inverse formula holds:

$$g(y) = \int_{Y'} \sum_{m=1}^{\infty} (B_m g)(\eta)e^{iy\cdot\eta}\phi_m(y;\eta)d\eta.$$

Further, we have Parseval's identity:

$$\int_{\mathbb{R}^N} |g(y)|^2 dy = \int_{Y'} \sum_{m=1}^{\infty} |(B_m g)(\eta)|^2 d\eta.$$

Finally, for all g in the domain of A, we have

$$Ag(y) = \int_{Y'} \sum_{m=1}^{\infty} \lambda_m(\eta)(B_m g)(\eta)e^{iy\cdot\eta}\phi_m(y;\eta)d\eta. \qquad \square$$

To obtain the spectral resolution of A^ε in an analogous manner, let us introduce Bloch waves at the ε-scale:

$$\lambda_m^\varepsilon(\xi) = \varepsilon^{-2}\lambda_m(\eta), \quad \phi_m^\varepsilon(x;\xi) = \phi_m(y;\eta), \quad \psi_m^\varepsilon(x;\xi) = \psi_m(y;\eta),$$

where the variables (x,ξ) and (y,η) are related by $y = \frac{x}{\varepsilon}$ and $\eta = \varepsilon\xi$. Observe that $\phi_m^\varepsilon(x;\xi)$ is εY-periodic (in x) and $\varepsilon^{-1}Y'$-periodic with respect to ξ. In the same manner, $\psi_m^\varepsilon(\cdot;\xi)$ is $(\varepsilon\xi;\varepsilon Y)$-periodic because of the relation $\psi_m^\varepsilon(x;\xi) = e^{ix\cdot\xi}\phi_m^\varepsilon(x;\xi)$. Note that the dual cell at ε-scale is $\varepsilon^{-1}Y'$ and hence we take ξ to vary in $\varepsilon^{-1}Y'$ in what follows. With these notations, we have the following result analogous to Theorem 1.2.

THEOREM 1.3. *Let $g \in L^2(\mathbb{R}^N)$. The mth Bloch coefficient of g at the ε-scale is defined as follows:*

$$(B_m^\varepsilon g)(\xi) = \int_{\mathbb{R}^N} g(x)e^{-ix\cdot\xi}\bar{\phi}_m^\varepsilon(x;\xi)dx \quad \forall m \geq 1,\ \xi \in \varepsilon^{-1}Y'.$$

Then the following inverse formula and Parseval's identity hold:

$$g(x) = \int_{\varepsilon^{-1}Y'} \sum_{m=1}^{\infty} (B_m^\varepsilon g)(\xi)e^{ix\cdot\xi}\phi_m^\varepsilon(x;\xi)d\xi,$$

$$\int_{\mathbb{R}^N} |g(x)|^2 dx = \int_{\varepsilon^{-1}Y'} \sum_{m=1}^{\infty} |(B_m^\varepsilon g)(\xi)|^2 d\xi.$$

Finally, for all g in the domain of A^ε, we get

$$A^\varepsilon g(x) = \int_{\varepsilon^{-1}Y'} \sum_{m=1}^{\infty} \lambda_m^\varepsilon(\xi)(B_m^\varepsilon g)(\xi)e^{ix\cdot\xi}\phi_m^\varepsilon(x;\xi)d\xi. \qquad \square$$

Using the above theorem, the classical homogenization result was deduced in [11]. Let us recall the main steps. The first one consists of considering a sequence $u^\varepsilon \in H^1(\mathbb{R}^N)$ satisfying (1.9). We can express the equation $A^\varepsilon u^\varepsilon = f$ in $\mathbb{R}^N$ in the equivalent form

$$\lambda_m^\varepsilon(\xi)(B_m^\varepsilon u^\varepsilon)(\xi) = (B_m^\varepsilon f)(\xi) \quad \forall m \geq 1,\ \xi \in \varepsilon^{-1}Y'. \tag{1.20}$$

In the homogenization process, one can neglect all the relations for $m \geq 2$. More precisely, it is proved in [11] that the following result holds.

PROPOSITION 1.4. *Let*

$$v^\varepsilon(x) = \int_{\varepsilon^{-1}Y'} \sum_{m=2}^{\infty} (B_m^\varepsilon u^\varepsilon)(\xi) e^{ix\cdot\xi} \phi_m^\varepsilon(x;\xi) d\xi. \tag{1.21}$$

Then $\|v^\varepsilon\|_{L^2(\mathbb{R}^N)} \leq c\varepsilon$. □

Thus we can concentrate our attention only on the relation corresponding to the first Bloch wave:

$$\lambda_1^\varepsilon(\xi)(B_1^\varepsilon u^\varepsilon)(\xi) = (B_1^\varepsilon f)(\xi) \quad \forall \xi \in \varepsilon^{-1}Y'. \tag{1.22}$$

The homogenized equation in the Fourier space

$$q_{k\ell}\xi_k\xi_\ell \widehat{u*}(\xi) = \widehat{f}(\xi) \quad \forall \xi \in \mathbb{R}^N \tag{1.23}$$

is obtained from (1.22) by passing to the limit as $\varepsilon \to 0$. Here, the symbol $\widehat{\ }$ stands for the classical Fourier transformation

$$\widehat{f}(\xi) = \frac{1}{(2\pi)^{N/2}} \int_{\mathbb{R}^N} f(x) e^{-ix\cdot\xi} dx.$$

To this end, the following results were established and applied in [11].

PROPOSITION 1.5. *We assume that* $a_{k\ell}$ *satisfies* (1.2). *Then there exists* $\delta > 0$ *such that the first eigenvalue* $\lambda_1(\eta)$ *is an analytic function on* $B_\delta \overset{\text{def}}{=} \{\eta \mid |\eta| < \delta\}$, *and there is a choice of the first eigenvector* $\phi_1(y;\eta)$ *satisfying*

$$\begin{cases} \eta \to \phi_1(\cdot;\eta) \in H^1_\#(Y) \text{ is analytic on } B_\delta, \\ \phi_1(y;0) = p^{(0)} \ (= |Y|^{-1/2} = \frac{1}{(2\pi)^{N/2}}). \end{cases}$$

Moreover, we have the relations

$$\lambda_1(0) = 0, \quad D_k\lambda_1(0) = \frac{\partial \lambda_1}{\partial \eta_k}(0) = 0 \quad \forall k = 1, \ldots, N,$$

$$\frac{1}{2} D^2_{k\ell}\lambda_1(0) = \frac{1}{2}\frac{\partial^2 \lambda_1}{\partial \eta_k \partial \eta_\ell}(0) = q_{k\ell} \quad \forall k, \ell = 1, \ldots, N,$$

and there exist constants c *and* $\widetilde{c}$ *such that*

$$c|\eta|^2 \leq \lambda_1(\eta) \leq \widetilde{c}|\eta|^2 \quad \forall \eta \in Y', \tag{1.24}$$

$$0 < \lambda_2^{(N)} \leq \lambda_m(\eta) \quad \forall m \geq 2,\ \eta \in Y', \tag{1.25}$$

where $\lambda_2^{(N)}$ *is the second eigenvalue of the spectral problem for* A *in the cell* Y *with Neumann boundary conditions on* ∂Y. □

Apart from the above result of regularity on the Bloch spectrum, we need to prove that the first Bloch transform is an approximation to the Fourier transform. This result is naturally expected from the fact that $\phi_1^\varepsilon(x;\xi) \to (2\pi)^{-N/2}$, as $\varepsilon \to 0$, $\forall \xi \in \mathbb{R}^N$.

PROPOSITION 1.6. *Let g^ε and g be in $L^2(\mathbb{R}^N)$. Then*

(i) *if $g^\varepsilon \rightharpoonup g$ weakly in $L^2(\mathbb{R}_x^N)$, then $\chi_{\varepsilon^{-1}Y'} B_1^\varepsilon g^\varepsilon \rightharpoonup \widehat{g}$ weakly in $L^2_{loc}(\mathbb{R}_\xi^N)$ provided there is a fixed compact set K such that* $\operatorname{supp}(g^\varepsilon) \subset K \, \forall \varepsilon$;

(ii) *if $g^\varepsilon \to g$ in $L^2(\mathbb{R}_x^N)$, then $\chi_{\varepsilon^{-1}Y'} B_1^\varepsilon g^\varepsilon \to \widehat{g}$ in $L^2_{loc}(\mathbb{R}_\xi^N)$.* □

These results easily lead us to the following homogenization theorem in $\mathbb{R}^N$.

THEOREM 1.7. *We consider a sequence u^ε satisfying* (1.9). *Then*

$$a_{k\ell}^\varepsilon \frac{\partial u^\varepsilon}{\partial x_\ell} \rightharpoonup q_{k\ell} \frac{\partial u^*}{\partial x_\ell} \quad \text{in} \quad L^2(\mathbb{R}^N) \quad \forall k = 1, \dots, N.$$

In particular, u^* satisfies $A^* u^* = f$ in $\mathbb{R}^N$. □

Once the homogenization result in $\mathbb{R}^N$ is established, it is an easy matter to deduce the corresponding result in a bounded domain Ω by localization techniques using a cut-off function $\phi \in \mathcal{D}(\Omega)$ (see [11]).

1.2. Presentation of new results: The Bloch approximation. Let us consider the sequence u^ε satisfying hypotheses (1.9). The *Bloch approximation* of u^ε is defined by the following formula:

$$\theta^\varepsilon(x) \overset{\text{def}}{=} \int_{\varepsilon^{-1}Y'} \widehat{u^*}(\xi) e^{ix\cdot\xi} \phi_1^\varepsilon(x;\xi) d\xi, \quad x \in \mathbb{R}^N. \tag{1.26}$$

First of all, let us remark that this object is not difficult to be computed in principle. Our goal throughout this paper is to study properties of this function and particularly its relations with various correctors terms. It is worth noticing that θ^ε is defined only in terms of the first Bloch mode ϕ_1^ε. We will see in section 3 that higher Bloch modes ϕ_m^ε, $m \geq 2$, do not contribute at all in the analysis of the correctors of first and second order in the energy norm. (It will be interesting to know whether these higher order modes play a part in the analysis of correctors in stronger norms $H^2, \dots,$ etc. For H^2-estimates, we refer to our work in [12].) Thus we are motivated to introduce the projection onto the first Bloch mode: for all $g \in L^2(\mathbb{R}^N)$, we define

$$P_1^\varepsilon g(x) = \int_{\varepsilon^{-1}Y'} B_1^\varepsilon g(\xi) e^{ix\cdot\xi} \phi_1^\varepsilon(x;\xi) d\xi, \quad x \in \mathbb{R}^N. \tag{1.27}$$

We note by the item (ii) of Proposition 1.6 that the Fourier transform $\widehat{u*}$ is an approximation of $B_1^\varepsilon u^\varepsilon$. Therefore, heuristically speaking, the Bloch approximation θ^ε is close to $P_1^\varepsilon u^\varepsilon$ and hence to u^ε. With these notations, we will prove the following theorem.

THEOREM 1.8. *Assume that the coefficients $a_{k\ell}$ satisfy* (1.2). *Let u^ε be the sequence introduced in* (1.9). *Then if $f \in L^2(\mathbb{R}^N)$, we have*

$$(u^\varepsilon - \theta^\varepsilon) \to 0 \quad \text{in} \quad H^1(\mathbb{R}^N). \tag{1.28}$$

Furthermore, we have the estimate

$$|u^\varepsilon - \theta^\varepsilon|_{H^1(\mathbb{R}^N)} \leq c\varepsilon \|f\|_{L^2(\mathbb{R}^N)}. \tag{1.29}$$ □

It is worth remarking that even though error estimates of the type (1.29) are sometimes found in the literature, they are usually obtained using the maximum principle with more regularity hypotheses on $a_{k\ell}$ and f. Here, we obtain these natural estimates under optimal hypotheses.

Thanks to the above result, we are reduced to expanding θ^ε in terms of ε in order to be able to compare it with the classical correctors for u^ε. To fulfill this task, it is clear from the definition of θ^ε that it is necessary to obtain asymptotic expansions of the first eigenvalue $\lambda_1^\varepsilon(\xi)$ and the first Bloch mode $\phi_1^\varepsilon(\cdot;\xi)$. (In addition, for our purposes below, we need an asymptotic expansion of the first Bloch transform $B_1^\varepsilon g(\xi)$ for which we refer the reader to section 5. These results strengthen earlier results, particularly those of Proposition 1.6.) We now state results in this direction, and their proofs will be taken up in the following sections along with other auxiliary results. First, we introduce some test functions $\chi_{k\ell}$, $\chi_{k\ell m}$, $\chi_{k\ell mn}$ defined by the following cell problems (observe that the first ones are nothing but the functions already introduced in (1.14)):

$$(1.30)\qquad \begin{cases} A\chi_{k\ell} = (a_{k\ell} - q_{k\ell}) - \dfrac{1}{2}\left(C_k\chi_\ell + C_\ell\chi_k\right) \quad \text{in} \quad \mathbb{R}^N, \\ \chi_{k\ell} \in H^1_\#(Y), \quad \mathcal{M}_Y(\chi_{k\ell}) = 0. \end{cases}$$

$$(1.31)\qquad \begin{cases} A\chi_{k\ell m} = \dfrac{1}{3}\Big[(a_{k\ell} - q_{k\ell})\chi_m + (a_{\ell m} - q_{\ell m})\chi_k + (a_{mk} - q_{mk})\chi_\ell \\ \qquad\qquad -C_k\chi_{\ell m} - C_\ell\chi_{mk} - C_m\chi_{k\ell}\Big] \quad \text{in} \quad \mathbb{R}^N, \\ \chi_{k\ell m} \in H^1_\#(Y), \quad \mathcal{M}_Y(\chi_{k\ell m}) = 0. \end{cases}$$

$$(1.32)\qquad \begin{cases} A\chi_{k\ell mn} = \dfrac{1}{4!}D^4_{k\ell mn}\lambda_1(0) - \dfrac{1}{4}\left(C_n\chi_{k\ell m} + C_k\chi_{\ell mn} + C_\ell\chi_{mnk} + C_m\chi_{nk\ell}\right) \\ \qquad + \dfrac{1}{3!}\Big[(a_{k\ell} - q_{k\ell})\chi_{mn} + (a_{\ell m} - q_{\ell m})\chi_{kn} + (a_{km} - q_{km})\chi_{\ell n} \\ \qquad + (a_{mn} - q_{mn})\chi_{k\ell} + (a_{\ell n} - q_{\ell n})\chi_{km} + (a_{kn} - q_{kn})\chi_{\ell m}\Big] \text{ in } \mathbb{R}^N, \\ \chi_{k\ell mn} \in H^1_\#(Y), \quad \mathcal{M}_Y(\chi_{k\ell mn}) = 0. \qquad \square \end{cases}$$

Proposition 1.9. *All odd order derivatives of λ_1 at $\eta = 0$ vanish, i.e.,*

$$D^\beta\lambda_1(0) = 0 \quad \forall\beta \in \mathbb{Z}^N_+,\ |\beta| \text{ odd.}$$

All even order derivatives of λ_1 at $\eta = 0$ can be calculated in a systematic fashion. For instance, the fourth order derivatives have the following expressions: for all $k, \ell, m, n = 1, \ldots, N$

$$\frac{1}{4!}D^4_{k\ell mn}\lambda_1(0) = \frac{1}{4}\frac{1}{|Y|}\int_Y \left\{C_n\chi_{k\ell m} + C_k\chi_{\ell mn} + C_\ell\chi_{mnk} + C_m\chi_{nk\ell}\right\} dy$$

$$- \frac{1}{3!}\frac{1}{|Y|}\int_Y \Big\{ (a_{k\ell} - q_{k\ell})\chi_{mn} + (a_{\ell m} - q_{\ell m})\chi_{nk} + (a_{mn} - q_{mn})\chi_{k\ell}$$

$$+ \ (a_{nk} - q_{nk})\chi_{\ell m} + (a_{km} - q_{km})\chi_{\ell n} + (a_{\ell n} - q_{\ell n})\chi_{km} \Big\}\, dy. \qquad \square$$

Various derivatives of ϕ_1 at $\eta = 0$ can also be calculated in a systematic fashion.

PROPOSITION 1.10. *We have the following expressions:*

$$D_k\phi_1(y;0) = ip^{(0)}\chi_k(y),$$

$$\frac{1}{2!}D^2_{k\ell}\phi_1(y;0) = -\, p^{(0)}\chi_{k\ell}(y) - \beta^{(2)}_{k\ell}p^{(0)},$$

$$\frac{1}{3!}D^3_{k\ell m}\phi_1(y;0) = -\, ip^{(0)}\chi_{k\ell m}(y) - \frac{i}{3}\left(\beta^{(2)}_{k\ell}\chi_m(y) + \beta^{(2)}_{\ell m}\chi_k(y) + \beta^{(2)}_{mk}\chi_\ell(y)\right)p^{(0)},$$

$$\frac{1}{4!}D^4_{k\ell mn}\phi_1(y;0) = p^{(0)}\chi_{k\ell mn}(y) - \frac{1}{3!}\Big(\beta^{(2)}_{k\ell}\chi_{mn}(y) + \beta^{(2)}_{\ell m}\chi_{nk}(y) + \beta^{(2)}_{mn}\chi_{k\ell}$$

$$+ \beta^{(2)}_{nk}\chi_{\ell m}(y) + \beta^{(2)}_{km}\chi_{n\ell}(y) + \beta^{(2)}_{\ell n}\chi_{km}(y)\Big)p^{(0)} + \beta^{(4)}_{k\ell mn}p^{(0)}$$

with

$$\beta^{(2)}_{k\ell} = \frac{1}{2!}\frac{1}{|Y|}\int_Y \chi_\ell\chi_k dy,$$

$$\beta^{(4)}_{k\ell mn} = \frac{1}{|Y|}\int_Y \frac{1}{4}\left[\chi_{\ell mn}\chi_k + \chi_{kmn}\chi_\ell + \chi_{n\ell k}\chi_m + \chi_{k\ell n}\chi_n\right]dy$$

$$- \frac{1}{|Y|}\int_Y \frac{1}{6}\left[\chi_{\ell m}\chi_{kn} + \chi_{km}\chi_{n\ell} + \chi_{\ell k}\chi_{nm}\right]dy$$

$$+ \frac{1}{|Y|}\frac{1}{2}\left(\beta^{(2)}_{k\ell}\beta^{(2)}_{mn} + \beta^{(2)}_{km}\beta^{(2)}_{n\ell} + \beta^{(2)}_{kn}\beta^{(2)}_{m\ell}\right). \qquad \square$$

We note that all odd order derivatives of ϕ_1 at $\eta = 0$ are purely imaginary and all even order derivatives are real.

Since $\phi_1(\cdot;\eta)$ is proved to be analytic for $|\eta| \le \delta$, we can expand it and thus give rise to an asymptotic expansion of θ^ε which is as follows:

$$(1.33)\quad \theta^\varepsilon(x) = u^*(x) + \varepsilon\chi_k\left(\frac{x}{\varepsilon}\right)\frac{\partial u^*}{\partial x_k}(x) - \varepsilon^2\left(\chi_{k\ell}\left(\frac{x}{\varepsilon}\right) + \beta^{(2)}_{k\ell}\right)\frac{\partial^2 u^*}{\partial x_k \partial x_\ell}(x) + \cdots.$$

This can be rigorously proved. Our next result is a sample where we specify the precise hypotheses needed to justify the above expansion up to three terms.

THEOREM 1.11. *Assume that the hypotheses of Theorem* 1.8 *hold.*

(i) *If* $u^* \in H^1(\mathbb{R}^N)$, *then*

$$\|\theta^\varepsilon - u^*\|_{L^2(\mathbb{R}^N)} \le c\varepsilon\|u^*\|_{H^1(\mathbb{R}^N)}.$$

(ii) *If* $f \in L^2(\mathbb{R}^N)$ *and* $\chi_k \in W^{1,\infty}_{\#}(Y)$, *where* χ_k *is the solution of* (1.13) *and* $\chi^\varepsilon_k(x) = \chi_k\left(\frac{x}{\varepsilon}\right)$, *then we have*

$$\left\|\theta^\varepsilon - u^* - \varepsilon\chi^\varepsilon_k\frac{\partial u^*}{\partial x_k}\right\|_{H^1(\mathbb{R}^N)} \le c\varepsilon\|f\|_{L^2(\mathbb{R}^N)}.$$

(iii) *If* $f \in H^1(\mathbb{R}^N)$ *and* χ_k, $\chi_{k\ell} \in W^{1,\infty}_{\#}(Y)$, *where* $\chi_{k\ell}$ *is the solution of* (1.30), $\beta^{(2)}_{k\ell}$ *are constants defined in Proposition* 1.10, *and* $\chi^\varepsilon_{k\ell}(x) = \chi_{k\ell}\left(\frac{x}{\varepsilon}\right)$, *then*

$$\left\| \theta^\varepsilon - u^* - \varepsilon \chi^\varepsilon_k \frac{\partial u^*}{\partial x_k} + \varepsilon^2 \left(\chi^\varepsilon_{k\ell} + \beta^{(2)}_{k\ell}\right) \frac{\partial^2 u^*}{\partial x_k \partial x_\ell} \right\|_{H^1(\mathbb{R}^N)} \leq c\varepsilon^2 \|f\|_{H^1(\mathbb{R}^N)}. \qquad \square$$

It is important to note that these above expansions are of Taylor type owing to the analyticity of $\lambda_1(\eta)$ and $\phi_1(\cdot;\eta)$. This is the main difference between this approach and the classical one found in [5], where the expansion has a multiscale structure.

Concerning the hypotheses on the smoothness of functions χ_k and $\chi_{k\ell}$ in statements (ii) and (iii), it is worth mentioning from regularity theory of elliptic boundary value problems that $W^{1,\infty}$-estimates are hard to come by. This is why they are usually assumed in homogenization theory. However, several numerical studies with simple fibers show that these assumptions are valid. Thus they are reasonable hypotheses to work with as far as certain applications are concerned.

The expansions of $\lambda_1(\eta)$, $\phi^\varepsilon_1(\cdot;\eta)$, and $B^\varepsilon_1 g(\xi)$ obtained in Propositions 1.5 and 1.9 and Propositions 5.1, 5.2, and 5.3 below have further interesting consequences which will be developed in a forthcoming paper. For the time being, we will be content with a few remarks. Since higher order modes can be neglected, the first eigenvalue $\lambda_1(\eta)$ along with the first eigenvector $\phi_1(\cdot;\eta)$ represent the periodic medium under consideration. Their contributions occur somewhat separately without interaction at the levels of homogenized equation and correctors. More precisely, the first eigenvalue $\lambda_1(\eta)$ contributes at various levels through its derivatives at $\eta = 0$. The first eigenvector $\phi_1(\cdot;\eta)$ and its first derivatives contribute through the first Bloch transform $B^\varepsilon_1 g(\xi)$ and its expansion described in Propositions 5.2 and 5.3.

In the homogenized equation, for instance, we see the product of the second order derivatives of $\lambda_1(\eta)$ at $\eta = 0$ with the 0th order term of $B^\varepsilon_1 g(\xi)$, namely, $\widehat{g}(\xi)$. We see a similar structure in the correctors, too. There seem to be situations where both interact and contribute jointly in a manner different from the above. One example of such a situation is the study of the propagation of waves in a periodic medium. It appears that the homogenized medium is not good enough to provide an approximation to the propagation for large times because of the appearance of dispersion effects shown numerically in F. Santosa and W. W. Symes [20]. We feel that this is an appropriate place to highlight the improvements achieved in this work with respect to [20]. Apart from the mathematical rigor, the main point is that the third order derivatives of $\lambda_1(\eta)$ at $\eta = 0$ are shown to be zero even in the multidimensional case. (In fact all odd order derivatives vanish.) Moreover, our arguments are more general compared with the one-dimensional case covered in [20]. This will have consequences in the propagation of waves in periodic media. We plan to cover these aspects in a future publication.

We conclude this introduction by saying how the rest of this paper is organized. Section 2 is devoted to certain fundamental lemmas which are indispensable. As an immediate application, we prove in section 3 that the higher order Bloch modes are negligible. Taylor expansions for λ_1 and ϕ_1 are obtained in section 4 which proves Propositions 1.9 and 1.10. Section 5 is devoted to the description of the asymptotic behavior of the first Bloch transform B^ε_1 whose definition is given in Theorem 1.2. Finally, in section 6, we present the proofs of the main results, namely, Theorems 1.8 and 1.11.

2. Fundamental lemmas. In this section, we prove a series of results which generalize Parseval's identity stated in Theorem 1.3. These estimates will be useful later for the analysis of correctors. The following two lemmas are easily seen to be generalizations of well-known classical results for $-\Delta$.

LEMMA 2.1. *For all $g \in H^1(\mathbb{R}^{\mathbb{N}})$, we have*

$$c_1 |g|^2_{H^1(\mathbb{R}^N)} \le \int_{\varepsilon^{-1}Y'} \sum_{m=1}^{\infty} \lambda_m^\varepsilon(\xi) |B_m^\varepsilon g(\xi)|^2 d\xi \le c_2 |g|^2_{H^1(\mathbb{R}^N)},$$

where c_1 and c_2 are constants independent of ε and g.

Proof. First of all, by uniform ellipticity of A^ε, we have

$$\alpha \int_{\mathbb{R}^N} |\nabla g|^2 dx \le \int_{\mathbb{R}^N} A^\varepsilon g \bar{g} dx \le \beta \int_{\mathbb{R}^N} |\nabla g|^2 dx.$$

We can rewrite the middle term by applying the Plancherel identity:

$$\int_{\mathbb{R}^N} g(x)\overline{h(x)} dx = \int_{\varepsilon^{-1}Y'} \sum_{m=1}^{\infty} B_m^\varepsilon g(\xi) \overline{B_m^\varepsilon h(\xi)} d\xi \quad \forall g, h \in L^2(\mathbb{R}^N). \tag{2.1}$$

Indeed, using the spectral resolution of A^ε, we get

$$\int_{\mathbb{R}^N} A^\varepsilon g \bar{g} dx = \int_{\varepsilon^{-1}Y'} \sum_{m=1}^{\infty} \lambda_m^\varepsilon(\xi) |B_m^\varepsilon g(\xi)|^2 d\xi.$$

This completes the proof. □

By using the duality between $H^1(\mathbb{R}^N)$ and $H^{-1}(\mathbb{R}^N)$, we deduce the following.

LEMMA 2.2. *For all $g \in H^{-1}(\mathbb{R}^N)$, there exist c_1 and c_2 which are independent of ε and g, such that*

$$c_1 \|g\|^2_{H^{-1}(\mathbb{R}^N)} \le \int_{\varepsilon^{-1}Y'} \sum_{m=1}^{\infty} \frac{1}{1+\lambda_m^\varepsilon(\xi)} |B_m^\varepsilon g(\xi)|^2 d\xi \le c_2 \|g\|^2_{H^{-1}(\mathbb{R}^N)}.$$

Proof. It is well known that $(A^\varepsilon + I)\colon H^1(\mathbb{R}^N) \to H^{-1}(\mathbb{R}^N)$ is an isomorphism. For every $g \in H^{-1}(\mathbb{R}^N)$ there exists a unique solution $u \in H^1(\mathbb{R}^N)$ of $A^\varepsilon u + u = g$ in $\mathbb{R}^N$. We can express the previous equation in the equivalent form

$$(\lambda_m^\varepsilon(\xi) + 1) B_m^\varepsilon u(\xi) = B_m^\varepsilon g(\xi) \quad \forall m \ge 1,\ \xi \in \varepsilon^{-1}Y'.$$

Therefore, an application of the Cauchy–Schwarz inequality yields

$$\begin{aligned}
\langle g, v\rangle &= \int_{\varepsilon^{-1}Y'} \sum_{m=1}^{\infty} (\lambda_m^\varepsilon(\xi)+1) B_m^\varepsilon u B_m^\varepsilon v d\xi \\
&\le \left(\int_{\varepsilon^{-1}Y'} \sum_{m=1}^{\infty} (\lambda_m^\varepsilon(\xi)+1) |B_m^\varepsilon u|^2 d\xi \right)^{1/2} \left(\int_{\varepsilon^{-1}Y'} \sum_{m=1}^{\infty} (\lambda_m^\varepsilon(\xi)+1) |B_m^\varepsilon v|^2 d\xi \right)^{1/2} \\
&\le \left(\int_{\varepsilon^{-1}Y'} \sum_{m=1}^{\infty} \frac{|B_m^\varepsilon g|^2}{(\lambda_m^\varepsilon(\xi)+1)} d\xi \right)^{1/2} \left(\int_{\varepsilon^{-1}Y'} \sum_{m=1}^{\infty} (\lambda_m^\varepsilon(\xi)+1) |B_m^\varepsilon v|^2 d\xi \right)^{1/2}
\end{aligned}$$

for all $v \in H^1(\mathbb{R}^N)$, $g \in H^{-1}(\mathbb{R}^N)$. Here, $\langle \cdot, \cdot \rangle$ denotes the $H^1(\mathbb{R}^N)$ and $H^{-1}(\mathbb{R}^N)$ duality pairing. By virtue of Lemma 2.1 and Parseval's identity, the second term in the right-hand side is equivalent to the H^1-norm of v. Thus we deduce the existence of a constant c_1 such that

$$c_1 \|g\|^2_{H^{-1}(\mathbb{R}^N)} \leq \int_{\varepsilon^{-1}Y'} \sum_{m=1}^{\infty} \frac{1}{1+\lambda_m^\varepsilon(\xi)} |B_m^\varepsilon g(\xi)|^2 d\xi,$$

which is the lower estimate in Lemma 2.2. To prove the upper estimate is enough to use the continuity of the solution $u \in H^1(\mathbb{R}^N)$ with respect to the right-hand side $g \in H^{-1}(\mathbb{R}^N)$. □

In our next lemma, we consider $g^\varepsilon = g^\varepsilon(\xi)$ a measurable function defined on $\varepsilon^{-1}Y'$, and another function $\rho = \rho(y;\eta)$ measurable with respect to $(y;\eta)$ and Y-periodic in y. We then introduce

$$G^\varepsilon(x) = \int_{\varepsilon^{-1}Y'} g^\varepsilon(\xi) e^{ix\cdot\xi} \rho\left(\frac{x}{\varepsilon};\varepsilon\xi\right) d\xi, \quad x \in \mathbb{R}^N. \tag{2.2}$$

The following result estimates its $L^2(\mathbb{R}^N)$ and $H^1(\mathbb{R}^N)$ norms.

LEMMA 2.3. *We assume $g^\varepsilon \in L^2(\varepsilon^{-1}Y')$ and $\rho \in L^\infty(Y'; H^1_\#(Y))$. Then we have*

$$\|G^\varepsilon\|^2_{L^2(\mathbb{R}^N)} = \int_{\varepsilon^{-1}Y'} |g^\varepsilon(\xi)|^2 \|\rho(\cdot;\varepsilon\xi)\|^2_{L^2(Y)} d\xi,$$

$$|G^\varepsilon|^2_{H^1(\mathbb{R}^N)} = \int_{\varepsilon^{-1}Y'} |g^\varepsilon(\xi)|^2 \|i\xi\rho(\cdot;\varepsilon\xi) + \varepsilon^{-1}\nabla_y\rho(\cdot;\varepsilon\xi)\|^2_{L^2(Y)^N} d\xi.$$

Proof. We expand $\rho(y;\eta)$ as a function of y in the orthonormal basis $\{\phi_m(y;\eta)\}_{m=1}^\infty$ where η is a parameter:

$$\rho(y;\eta) = \sum_{m=1}^{\infty} a_m(\eta)\phi_m(y;\eta).$$

Introducing this expression in (2.2), we get

$$G^\varepsilon(x) = \int_{\varepsilon^{-1}Y'} g^\varepsilon(\xi) \sum_{m=1}^{\infty} a_m(\varepsilon\xi) e^{ix\cdot\xi} \phi_m^\varepsilon(x;\xi) d\xi.$$

Applying Parseval's identity of Theorem 1.3, we get

$$\|G^\varepsilon\|^2_{L^2(\mathbb{R}^N)} = \int_{\varepsilon^{-1}Y'} |g^\varepsilon(\xi)|^2 \sum_{m=1}^{\infty} |a_m(\varepsilon\xi)|^2 d\xi.$$

This completes the proof of the first part of the lemma if we use Parseval's identity in $L^2(Y)$:

$$\|\rho(\cdot;\eta)\|^2_{L^2(Y)} = \sum_{m=1}^{\infty} |a_m(\eta)|^2 \quad \forall \eta \in Y'. \tag{2.3}$$

For the second part of the lemma, we formally differentiate $G^\varepsilon(x)$ with respect to x. We obtain

$$\nabla_x G^\varepsilon(x) = \int_{\varepsilon^{-1}Y'} g^\varepsilon(\xi) e^{ix\cdot\xi} \left(i\xi\rho\left(\frac{x}{\varepsilon};\varepsilon\xi\right) + \varepsilon^{-1}\nabla_y\rho\left(\frac{x}{\varepsilon};\varepsilon\xi\right)\right) d\xi.$$

We remark that the above integral is of the same type as the one analyzed in the first part. This completes the proof. □

The next lemma presents H^1-estimates on the Bloch modes.

LEMMA 2.4. *We suppose that the coefficients $a_{k\ell}$ satisfy* (1.2). *Then there exists a constant c depending on $\|a_{k\ell}\|_{L^\infty(Y)}$ such that*

$$\left\|\frac{\partial\phi_m}{\partial y_k}(\cdot;\eta)\right\|_{L^2(Y)} \leq c_1\lambda_m(\eta)^{1/2} \quad \forall\eta\in Y',\ m\geq 1,\ k=1,\dots,N. \tag{2.4}$$ □

To prove this, let us introduce the bilinear forms associated with the operators $A(\eta)$ and A, respectively.

$$a(\eta;\phi,\psi) = \int_Y a_{k\ell}(y)\left(\frac{\partial\phi}{\partial y_\ell}+i\eta_\ell\phi\right)\overline{\left(\frac{\partial\psi}{\partial y_k}+i\eta_k\psi\right)}dy,$$

$$a(\phi,\psi) = \int_Y a_{k\ell}(y)\frac{\partial\phi}{\partial y_\ell}\overline{\frac{\partial\psi}{\partial y_k}}dy.$$

The basic estimates on them are obtained in [10, p. 190]: There exist constants c, $\widetilde{c}$ which are independent of $\eta\in Y'$ such that for all $\phi\in H^1_\#(Y)$,

$$c\ (\|\nabla\phi\|^2_{L^2(Y)^N}+|\eta|^2\|\phi\|^2_{L^2(Y)}) \leq a(\eta;\phi,\phi) \leq \widetilde{c}\ (\|\nabla\phi\|^2_{L^2(Y)^N}+|\eta|^2\|\phi\|^2_{L^2(Y)}), \tag{2.5}$$

$$c\ \|\nabla\phi\|^2_{L^2(Y)^N} \leq\ a(\phi,\phi)\ \leq \widetilde{c}\ \|\nabla\phi\|^2_{L^2(Y)^N}. \tag{2.6}$$

Proof of Lemma 2.4. For simplicity, we denote $\phi_m(\cdot;\eta)$ by $\phi_m(\eta)$. We recall that it satisfies

$$a(\eta;\phi_m(\eta),\psi) = \lambda_m(\eta)(\phi_m(\eta),\psi) \quad \forall\psi\in H^1_\#(Y). \tag{2.7}$$

To deduce (2.4), it is enough to take $\psi=\phi_m(\eta)$ and use (2.5). □

Our next result concerns the estimation of expressions which are inverse to (2.2). We define

$$J^\varepsilon g(\xi) = \int_{\mathbb{R}^N} g(x)e^{-ix\cdot\xi}\rho\left(\frac{x}{\varepsilon};\varepsilon\xi\right)dx \quad \text{for} \quad \xi\in\varepsilon^{-1}Y', \tag{2.8}$$

where $g=g(x)$ is a measurable function defined on $\mathbb{R}^N$ and $\rho=\rho(y;\eta)$ is a measurable function defined on $Y\times Y'$. We assume that ρ is Y-periodic in y. The required hypotheses on these functions will depend on the estimate deduced on $J^\varepsilon g$. This is illustrated in the results that follow which are analogous to classical estimates on the Fourier transform.

LEMMA 2.5.

(i) *If $g\in L^2(\mathbb{R}^N)$ and $\rho\in L^\infty(Y';L^2_\#(Y))$, then we have*

$$\|J^\varepsilon g\|_{L^2(\varepsilon^{-1}Y')} \leq \|g\|_{L^2(\mathbb{R}^N)}\|\rho\|_{L^\infty(Y';L^2_\#(Y))}.$$

(ii) *If $g\in H^1(\mathbb{R}^N)$ and $\rho\in L^\infty(Y';H^1_\#(Y))$, then we have*

$$\|(1+|\xi|^2)^{1/2}J^\varepsilon g(\xi)\|_{L^2(\varepsilon^{-1}Y')} \leq c\left\{\|\nabla g\|_{L^2(\mathbb{R}^N)}\|\rho\|_{L^\infty(Y';L^2(Y))}\right.$$
$$\left.+\ \varepsilon^{-1}\|g\|_{L^2(\mathbb{R}^N)}\|\nabla_y\rho\|_{L^\infty(Y';L^2(Y)^N)}\right\}.$$

Proof. The idea is to consider the product space $L^2(Y'; L^2_\#(Y))$ and expand $\rho(y;\eta)$ in two steps. First using the fact that $\{\bar{\phi}_m(\cdot;\eta)\}_{m=1}^\infty$ is an orthonormal basis in $L^2_\#(Y)$, we get

$$\rho(y;\eta) = \sum_{m=1}^\infty a_m(\eta)\bar{\phi}_m(y;\eta) \quad \forall y \in Y,\ \eta \in Y'.$$

Next, for each m, we can expand $a_m(\eta)$ in the usual Fourier series:

$$a_m(\eta) = \sum_{n\in\mathbb{Z}^N} a_{mn} e^{2\pi i n\cdot\eta} \quad \forall \eta \in Y'.$$

The corresponding Parseval's identities are as follows:

$$\|\rho(\cdot;\eta)\|^2_{L^2(Y)} = \sum_m |a_m(\eta)|^2 \quad \forall \eta \in Y',$$
$$\int_{Y'} |a_m(\eta)|^2 d\eta = \sum_{n\in\mathbb{Z}^N} |a_{mn}|^2 \quad \forall m \in \mathbb{N}.$$

Using this expansion, we can rewrite $J^\varepsilon g$ as follows:

$$J^\varepsilon g(\xi) = \sum_{m=1}^\infty \sum_{n\in\mathbb{Z}^N} a_{mn} e^{2\pi i \varepsilon n\cdot\xi} \int_{\mathbb{R}^N} g(x) e^{-ix\cdot\xi} \bar{\phi}_m\left(\frac{x}{\varepsilon};\varepsilon\xi\right) dx,$$

which, according to the definition of $B^\varepsilon_m g(\xi)$, is equal to

$$J^\varepsilon g(\xi) = \sum_{m=1}^\infty \sum_{n\in\mathbb{Z}^N} a_{mn} e^{2\pi i \varepsilon n\cdot\xi} B^\varepsilon_m g(\xi) = \sum_{m=1}^\infty a_m(\varepsilon\xi) B^\varepsilon_m g(\xi).$$

By the Cauchy–Schwarz inequality,

$$\begin{aligned}|J^\varepsilon g(\xi)|^2 &\le \left(\sum_{m=1}^\infty |a_m(\varepsilon\xi)|^2\right)\left(\sum_{m=1}^\infty |B^\varepsilon_m g(\xi)|^2\right)\\ &= \|\rho(\cdot;\varepsilon\xi)\|^2_{L^2(Y)} \left(\sum_{m=1}^\infty |B^\varepsilon_m g(\xi)|^2\right)\\ &\le \|\rho\|^2_{L^\infty(Y';L^2_\#(Y))} \left(\sum_{m=1}^\infty |B^\varepsilon_m g(\xi)|^2\right).\end{aligned}$$

The proof of (i) is complete if we integrate the above inequality with respect to $\xi \in \varepsilon^{-1}Y'$ and apply Theorem 1.3. For the proof of (ii), we multiply (2.8) by $(-i\xi_k)$ and obtain

$$(-i\xi_k) J^\varepsilon g(\xi) = \int_{\mathbb{R}^N} g(x)(-i\xi_k) e^{-ix\cdot\xi} \rho\left(\frac{x}{\varepsilon};\varepsilon\xi\right) dx,$$

which, by integration by parts, can be rewritten as

$$(-i\xi_k) J^\varepsilon g(\xi) = -\int_{\mathbb{R}^N} \frac{\partial g}{\partial x_k}(x) e^{-ix\cdot\xi} \rho\left(\frac{x}{\varepsilon};\varepsilon\xi\right) dx - \varepsilon^{-1} \int_{\mathbb{R}^N} g(x) e^{-ix\cdot\xi} \frac{\partial \rho}{\partial y_k}\left(\frac{x}{\varepsilon};\varepsilon\xi\right) dx.$$

It is now sufficient to apply (i) to each of the terms on the right-hand side of the above relation. □

Next, we will need some properties of the classical *discrete Fourier transform* in our asymptotic description of the first Bloch transform. In particular, we are interested in the relation between discrete and continuous Fourier transforms. To this end, let us begin by introducing some necessary notations. Let $\{Y_\ell^\varepsilon\}_{\ell\in\mathbb{Z}^N}$ be the mesh of $\mathbb{R}^N$ generated by the cell εY. More precisely, $Y_\ell^\varepsilon = x_\ell^\varepsilon + \varepsilon Y$ where $x_\ell^\varepsilon = 2\pi\varepsilon\ell$ is the origin of the cell Y_ℓ^ε. We recall the definition of the discrete Fourier transform of a function corresponding to this mesh: Let $p > N$ be given. For $g \in W^{1,p}(\mathbb{R}^N)$ with compact support we define

$$F^\varepsilon g(\xi) = \sum_{\ell\in\mathbb{Z}^N} g(x_\ell^\varepsilon) e^{-ix_\ell^\varepsilon\cdot\xi} \quad \forall \xi \in \varepsilon^{-1}Y'. \tag{2.9}$$

It is worthwhile to recall that $W^{1,p}(\mathbb{R}^N)$ is embedded in $\mathcal{C}^0(\mathbb{R}^N)$ when $p > N$, and so $g(x_\ell^\varepsilon)$ is well defined.

Lemma 2.6. *For $g \in W^{1,p}(\mathbb{R}^N)$ $(p > N)$ with compact support K, we have*

(i) $\varepsilon^N(\chi_{\varepsilon^{-1}Y'} F^\varepsilon g)(\xi) \to \frac{1}{(2\pi)^{N/2}}\widehat{g}(\xi)$ *for* $\xi \in \mathbb{R}^N$.

(ii) $\|\varepsilon^N F^\varepsilon g\|_{L^2(\varepsilon^{-1}Y')} \le c|K|^{\frac{p-2}{2p}}\{\|g\|_{L^p(\mathbb{R}^N)} + \varepsilon\|\nabla g\|_{L^p(\mathbb{R}^N)^N}\}$, $|K|$ *denotes the measure of* K.

(iii) $\varepsilon^N\chi_{\varepsilon^{-1}Y'} F^\varepsilon g \to \frac{1}{(2\pi)^{N/2}}\widehat{g}$ *in* $L^2(\mathbb{R}^N)$.

Proof. To prove (i), we multiply (2.9) by ε^N to get

$$\varepsilon^N F^\varepsilon g(\xi) = \frac{1}{(2\pi)^N}\sum_{\ell\in\mathbb{Z}^N} g(x_\ell^\varepsilon)e^{-ix_\ell^\varepsilon\cdot\xi}|Y_\ell^\varepsilon|.$$

We regard the right-hand side of the above equality as a Riemann sum of the integral

$$\frac{1}{(2\pi)^N}\int_{\mathbb{R}^N} g(x)e^{-ix\cdot\xi}dx$$

which converges to it as $\varepsilon \to 0$.

To prove (ii), we observe that the right-hand side of (2.9) is nothing but the Fourier series in the variable $\xi \in \varepsilon^{-1}Y'$. Therefore, by Parseval's identity, we get

$$\varepsilon^N\int_{\varepsilon^{-1}Y'} |F^\varepsilon g(\xi)|^2 d\xi = \sum_{\ell\in\mathbb{Z}^N} |g(x_\ell^\varepsilon)|^2.$$

We multiply this relation by ε^N and rewrite it as

$$\varepsilon^{2N}\int_{\varepsilon^{-1}Y'} |F^\varepsilon g(\xi)|^2 d\xi = \frac{1}{(2\pi)^N}\sum_{\ell\in\mathbb{Z}^N} |g(x_\ell^\varepsilon)|^2|Y_\ell^\varepsilon|. \tag{2.10}$$

To estimate the right-hand side of the above equality, we integrate the inequality

$$|g(x_\ell^\varepsilon)|^2 \le 2\left\{|g(x)|^2 + |g(x) - g(x_\ell^\varepsilon)|^2\right\}, \quad x \in Y_\ell^\varepsilon,$$

over Y_ℓ^ε to obtain

$$|g(x_\ell^\varepsilon)|^2|Y_\ell^\varepsilon| \le 2\left\{\int_{Y_\ell^\varepsilon} |g(x)|^2 dx + \int_{Y_\ell^\varepsilon} |g(x) - g(x_\ell^\varepsilon)|^2 dx\right\}. \tag{2.11}$$

Since $p > N$, we can use the classical Morrey's inequality (see Brezis [7, p. 167]) to deduce

$$|g(x) - g(x^\varepsilon_\ell)| \leq c\varepsilon^{1-\frac{N}{p}} |\nabla g|_{L^p(Y^\varepsilon_\ell)^N}.$$

Using both the above estimate in (2.11) and the Hölder inequality and summing over $\ell \in \mathbb{Z}^N$, we complete the proof of (ii).

To prove the statement (iii) we first use (i) and (ii) to deduce that

$$\varepsilon^N \chi_{\varepsilon^{-1}Y'}(\xi) F^\varepsilon g(\xi) \rightharpoonup \frac{1}{(2\pi)^{N/2}} \widehat{g}(\xi) \quad \text{in } L^2(\mathbb{R}^N)\text{-weak.}$$

Let us now expand

$$\begin{aligned} \left\| \varepsilon^N \chi_{\varepsilon^{-1}Y'} F^\varepsilon g - \tfrac{1}{(2\pi)^{N/2}} \widehat{g} \right\|^2_{L^2(\mathbb{R}^N)} &= \varepsilon^{2N} \|F^\varepsilon g\|^2_{L^2(\mathbb{R}^N)} - \tfrac{2\varepsilon^N}{(2\pi)^{N/2}} (\chi_{\varepsilon^{-1}Y'} F^\varepsilon g, \widehat{g}) \\ &\quad + \tfrac{1}{(2\pi)^N} \|\widehat{g}\|^2_{L^2(\mathbb{R}^N)}. \end{aligned}$$

Now relation (2.10) shows that

$$\varepsilon^{2N} \|F^\varepsilon g\|^2_{L^2(\mathbb{R}^N)} \to \frac{1}{(2\pi)^N} \int_{\mathbb{R}^N} |g|^2 dx = \frac{1}{(2\pi)^N} \|\widehat{g}\|^2_{L^2(\mathbb{R}^N)}.$$

Thanks to the above weak convergence, the second term converges to

$$-\frac{2}{(2\pi)^{N/2}} \frac{1}{(2\pi)^{N/2}} \|\widehat{g}\|^2_{L^2(\mathbb{R}^N)}.$$

This simple computation establishes the strong convergence in $L^2(\mathbb{R}^N)$. □

3. Higher Bloch modes are negligible. In this section, we consider a sequence of solutions u^ε of the equation with $f \in H^{-1}(\mathbb{R}^N)$:

$$A^\varepsilon u^\varepsilon = f \quad \text{in} \quad \mathbb{R}^N, \quad u^\varepsilon \in H^1(\mathbb{R}^N). \tag{3.1}$$

Let us recall that the above equation is equivalent to (1.20) in the Bloch space. In what follows, we present a systematic method of obtaining estimates on the solution in Sobolev spaces L^2 and H^1. In particular, we show that the component of u^ε in the higher Bloch modes does not play any role in the analysis of correctors of first and second order provided f is sufficiently smooth. Thus we consider v^ε defined in (1.21), which is nothing but the projection of u^ε corresponding to all higher Bloch modes. Estimates on v^ε derived in this section improve Proposition 1.4.

PROPOSITION 3.1. *We have the following estimates for $f \in L^2(\mathbb{R}^N)$:*

(i) $|v^\varepsilon|_{H^1(\mathbb{R}^N)} \leq c\varepsilon \|f\|_{L^2(\mathbb{R}^N)}$,

(ii) $\|v^\varepsilon\|_{L^2(\mathbb{R}^N)} \leq c\varepsilon \|f\|_{H^{-1}(\mathbb{R}^N)}$.

Proof. To show (i), we apply Lemma 2.1 with $g = v^\varepsilon$ and use (1.20). We obtain

$$\begin{aligned} \|\nabla v^\varepsilon\|^2_{L^2(\mathbb{R}^N)^N} &\leq c \int_{\varepsilon^{-1}Y'} \sum_{m=2}^{\infty} \frac{1}{\lambda^\varepsilon_m(\xi)} |B^\varepsilon_m f(\xi)|^2 d\xi \\ &\leq c \sup_{m \geq 2,\ \xi \in \varepsilon^{-1}Y'} \frac{1}{\lambda^\varepsilon_m(\xi)} \|f\|^2_{L^2(\mathbb{R}^N)}. \end{aligned}$$

Proof of (i) is complete since we have (cf. (1.25))

$$\sup_{m\geq 2,\ \xi\in\varepsilon^{-1}Y'} \frac{1}{\lambda_m^\varepsilon(\xi)} \leq \frac{1}{\lambda_2^{(N)}}\varepsilon^2. \tag{3.2}$$

For the proof of (ii), we apply Lemma 2.2 with $g = f$ and (1.20). We have

$$\begin{aligned}\|v^\varepsilon\|^2_{L^2(\mathbb{R}^N)} &= \int_{\varepsilon^{-1}Y'} \sum_{m=2}^\infty |B_m^\varepsilon u^\varepsilon(\xi)|^2 d\xi \\ &= \int_{\varepsilon^{-1}Y'} \sum_{m=2}^\infty \frac{1}{\lambda_m^\varepsilon(\xi)^2} |B_m^\varepsilon f(\xi)|^2 d\xi.\end{aligned}$$

Writing

$$\frac{1}{\lambda_m^\varepsilon(\xi)^2}|B_m^\varepsilon f(\xi)|^2 = \frac{1+\lambda_m^\varepsilon(\xi)}{\lambda_m^\varepsilon(\xi)^2}\frac{|B_m^\varepsilon f(\xi)|^2}{1+\lambda_m^\varepsilon(\xi)}$$

and using (3.2), we deduce that

$$\frac{1}{\lambda_m^\varepsilon(\xi)^2}|B_m^\varepsilon f(\xi)|^2 \leq c\varepsilon^2 \frac{|B_m^\varepsilon f(\xi)|^2}{1+\lambda_m^\varepsilon(\xi)}.$$

The proof is complete if we use Lemma 2.2. □

While the above proposition shows that v^ε can be neglected at the level of the first order correctors (cf. (1.10)), the next result will demonstrate that v^ε can be neglected at the level of correctors of first and second order. These finer estimates require naturally higher order regularity of f but not of the coefficients $a_{k\ell}(y)$. Let us state the following proposition, whose proof is similar to the previous one and hence will not be repeated.

Proposition 3.2. *We have the following estimates for $f \in H^1(\mathbb{R}^N)$:*

(i) $|v^\varepsilon|_{H^1(\mathbb{R}^N)} \leq c\varepsilon^2\|f\|_{H^1(\mathbb{R}^N)}$,

(ii) $\|v^\varepsilon\|_{L^2(\mathbb{R}^N)} \leq c\varepsilon^2\|f\|_{L^2(\mathbb{R}^N)}$. □

Assuming $a_{k\ell}$ are in $W^{1,\infty}_\#(Y)$ and further assumptions, we can obtain H^2-estimates on the solution. This is difficult as it involves more subtleties (see [12]).

4. Taylor expansion of the first Bloch eigenvalue and eigenvector. The purpose of this section is to indicate a systematic method to compute derivatives of the first Bloch eigenvalue $\lambda_1(\eta)$ and the first Bloch eigenvector $\phi_1(\cdot;\eta)$ at $\eta = 0$. In particular, we will prove Propositions 1.9 and 1.10. Recall that $\lambda_1(\eta)$ and $\phi_1(\cdot;\eta)$ depend analytically on η in a small neighborhood B_δ of $\eta = 0$. At the cost of reducing this neighborhood, we claim that the branch $\eta \mapsto \phi_1(\cdot;\eta)$ can be chosen so that the following conditions are satisfied simultaneously:

$$\eta \in B_\delta \mapsto \phi_1(\cdot;\eta) \in H^1_\#(Y) \quad \text{is analytic,} \tag{4.1}$$

$$\|\phi_1(\cdot;\eta)\|_{L^2(Y)} = 1 \quad \forall \eta \in B_\delta, \tag{4.2}$$

$$\mathfrak{Im}\int_Y \phi_1(y;\eta)dy = 0 \quad \forall \eta \in B_\delta. \tag{4.3}$$

In what follows, we will see that the above conditions uniquely fix the eigenvector $\phi_1(\cdot;\eta)$. We remark that the condition (4.2) is classical, whereas the condition (4.3) is somewhat unusual and can be achieved as indicated below. The idea consists of multiplying $\phi_1(\cdot;\eta)$ by a complex number $(\alpha_1(\eta)+i\alpha_2(\eta))$ where $\alpha_1(\eta)$ and $\alpha_2(\eta)$ are real analytic with respect to η and are chosen such that

$$\mathfrak{Im}\int_Y (\alpha_1(\eta)+i\alpha_2(\eta))\phi_1(y;\eta)dy = 0.$$

If we define

$$d(\eta) = (d_1(\eta), d_2(\eta)) \overset{\text{def}}{=} \left(\mathfrak{Im}\int_Y \phi_1(y;\eta)dy, \mathfrak{Re}\int_Y \phi_1(y;\eta)dy\right),$$

then the above condition is equivalent to

$$\alpha_1(\eta)d_1(\eta) + \alpha_2(\eta)d_2(\eta) = 0 \quad \forall \eta \in B_\delta.$$

Obviously, one such choice which is analytic is as follows:

$$\alpha_1(\eta) = -d_2(\eta), \quad \alpha_2(\eta) = d_1(\eta).$$

Of course, the above procedure has destroyed condition (4.2) (but not condition (4.1)). However, it can be regained by dividing by $|d(\eta)|$. This is possible because $d(0) \neq 0$ by our choice of $\phi_1(\cdot;0)$ (see Proposition 1.5).

Thanks to our choice of the branch satisfying (4.1)–(4.3), we will now draw some consequences which will simplify the computations below. In fact, differentiating (4.2) with respect to η, we successively get for all $k,\ell,m,n = 1,\ldots,N$

$$\mathfrak{Re}\langle D_k\phi_1(\cdot;\eta), \phi_1(\cdot;\eta)\rangle = 0, \tag{4.4}$$

$$\mathfrak{Re}\langle D^2_{k\ell}\phi_1(\cdot;\eta), \phi_1(\cdot;\eta)\rangle + \mathfrak{Re}\langle D_k\phi_1(\cdot;\eta), D_\ell\phi_1(\cdot;\eta)\rangle = 0, \tag{4.5}$$

$$\left\{\begin{aligned} &\mathfrak{Re}\langle D^3_{k\ell m}\phi_1(\cdot;\eta), \phi_1(\cdot;\eta)\rangle + \mathfrak{Re}\langle D^2_{k\ell}\phi_1(\cdot;\eta), D_m\phi_1(\cdot;\eta)\rangle \\ &\quad + \mathfrak{Re}\langle D^2_{km}\phi_1(\cdot;\eta), D_\ell\phi_1(\cdot;\eta)\rangle + \mathfrak{Re}\langle D_k\phi_1(\cdot;\eta), D^2_{\ell m}\phi_1(\cdot;\eta)\rangle = 0,\end{aligned}\right. \tag{4.6}$$

$$\left\{\begin{aligned} &\mathfrak{Re}\langle D^4_{k\ell mn}\phi_1(\cdot;\eta), \phi_1(\cdot;\eta)\rangle + \mathfrak{Re}\langle D^3_{k\ell m}\phi_1(\cdot;\eta), D_n\phi_1(\cdot;\eta)\rangle \\ &\quad + \mathfrak{Re}\langle D^3_{k\ell n}\phi_1(\cdot;\eta), D_m\phi_1(\cdot;\eta)\rangle + \mathfrak{Re}\langle D^2_{k\ell}\phi_1(\cdot;\eta), D^2_{mn}\phi_1(\cdot;\eta)\rangle \\ &\quad\quad + \mathfrak{Re}\langle D^3_{kmn}\phi_1(\cdot;\eta), D_\ell\phi_1(\cdot;\eta)\rangle + \mathfrak{Re}\langle D^2_{km}\phi_1(\cdot;\eta), D^2_{\ell n}\phi_1(\cdot;\eta)\rangle \\ &\quad\quad\quad + \mathfrak{Re}\langle D^2_{kn}\phi_1(\cdot;\eta), D^2_{\ell m}\phi_1(\cdot;\eta)\rangle + \mathfrak{Re}\langle D_k\phi_1(\cdot;\eta), D^3_{\ell mn}\phi_1(\cdot;\eta)\rangle = 0,\end{aligned}\right. \tag{4.7}$$

where $\langle\cdot;\cdot\rangle$ denotes the scalar product in $L^2_\#(Y)$. On the other hand, differentiation of (4.3) yields

$$\mathfrak{Im}\int_Y D^\beta\phi_1(y;\eta)dy = 0 \quad \forall\ \beta \in \mathbb{Z}^N_+. \tag{4.8}$$

From these sets of relations, it follows that

$$\int_Y D^\beta\phi_1(y;0)dy = 0 \quad \forall\ \beta \in \mathbb{Z}^N_+ \text{ with } |\beta| \text{ odd.} \tag{4.9}$$

4.1. First order derivatives. If we differentiate the eigenvalue equation $(A(\eta) - \lambda_1(\eta))\phi_1(\cdot;\eta) = 0$ once with respect to η_k, we obtain

$$D_k(A(\eta) - \lambda_1(\eta))\phi_1(\cdot;\eta) + (A(\eta) - \lambda_1(\eta))D_k\phi_1(\cdot;\eta) = 0. \tag{4.10}$$

Taking the scalar product with $\phi_1(\cdot;\eta)$, we get

$$\langle [D_k(A - \lambda_1)]\phi_1, \phi_1\rangle = 0, \tag{4.11}$$

where we have suppressed the dependence on η for ease of writing. We will continue with this convention in what follows provided there is no ambiguity. It follows from (1.18) that

$$D_kA(0) = iC_k \quad \forall \eta \in Y', \tag{4.12}$$

where the operator C_k is defined in (1.19).

If we evaluate the relation (4.11) at $\eta = 0$ and use the structure of C_k, we immediately get that

$$D_k\lambda_1(0) = 0 \quad \forall k = 1, \ldots, N. \tag{4.13}$$

The next step is to compute the first order derivatives of ϕ_1 at $\eta = 0$. To this end, we go back to (4.10) and use (4.13). We obtain

$$AD_k\phi_1(\cdot;0) = -D_kA(0)\phi_1(\cdot;0) = -iC_k\phi_1(\cdot;0).$$

Taking into account (4.9) and the above equation, we can solve for $D_k\phi_1(y;0)$ and obtain

$$D_k\phi_1(y;0) = i\phi_1(y;0)\chi_k(y) = ip^{(0)}\chi_k(y), \tag{4.14}$$

where, we recall, χ_k satisfies (1.13) and the constant $p^{(0)}$ was fixed in Proposition 1.5. Thus, the first order derivative is completely determined and

$$D_k\phi_1(y;0) \quad \text{is purely imaginary.} \tag{4.15}$$

4.2. Second order derivatives. Our starting point is the relation (4.10), which we differentiate once with respect to η. We obtain

$$[D^2_{k\ell}(A - \lambda_1)]\phi_1 + [D_k(A - \lambda_1)]D_\ell\phi_1 + [D_\ell(A - \lambda_1)]D_k\phi_1 + (A - \lambda_1)D^2_{k\ell}\phi_1 = 0. \tag{4.16}$$

Taking the scalar product with ϕ_1, we get

$$\langle [D^2_{k\ell}(A - \lambda_1)]\phi_1, \phi_1\rangle + \langle [D_k(A - \lambda_1)]D_\ell\phi_1, \phi_1\rangle + \langle [D_\ell(A - \lambda_1)]D_k\phi_1, \phi_1\rangle = 0 \tag{4.17}$$

for all $\eta \in B_\delta$. If we use the information obtained in section 4.1 on $D_k\lambda_1(0)$, $D_k\phi_1(\cdot;0)$, $D_kA(0)$, and

$$D^2_{k\ell}A(\eta) = 2a_{k\ell}(y) \quad \forall k, \ell = 1, \ldots, N, \ \eta \in Y', \tag{4.18}$$

we obtain

$$\frac{1}{2!}D^2_{k\ell}\lambda_1(0) = \frac{1}{|Y|}\int_Y a_{k\ell}(y)dy - \frac{1}{2|Y|}\int_Y (C_k\chi_\ell(y) + C_\ell\chi_k(y))dy$$

$$= \frac{1}{2}(q_{k\ell} + q_{\ell k}) = q_{k\ell} \quad \forall k,\ell = 1,\dots,N. \tag{4.19}$$

As before, the next step is to compute $D^2_{k\ell}\phi_1(\cdot;0)$. For this purpose, we go back to (4.16) and rewrite it with $\eta = 0$ as follows:

$$AD^2_{k\ell}\phi_1(\cdot;0) = \left\{-2(a_{k\ell} - q_{k\ell}) + C_k\chi_\ell + C_\ell\chi_k\right\}\phi_1(\cdot;0).$$

By comparing the above equation with (1.30) and using the simplicity of the eigenvalue under consideration, we see that $D^2_{k\ell}\phi_1(\cdot;0)$ is of the form

$$\frac{1}{2!}D^2_{k\ell}\phi_1(y;0) = -p^{(0)}\chi_{k\ell}(y) - \beta^{(2)}_{k\ell}p^{(0)}$$

for some constant $\beta^{(2)}_{k\ell}$. Thanks to (4.5) and (4.8), we can infer that

$$\beta^{(2)}_{k\ell} \quad \text{and} \quad D^2_{k\ell}\phi_1(\cdot;0) \quad \text{are real.} \tag{4.20}$$

Moreover, $\beta^{(2)}_{k\ell}$ admits the expression given in Proposition 1.10.

4.3. Third order derivatives. From the calculations done so far, it is now clear how to proceed further to calculate higher order derivatives. Therefore we will be brief here. Differentiating (4.16), we get

$$\begin{cases}[D^3_{k\ell m}(A-\lambda_1)]\phi_1 + [D^2_{k\ell}(A-\lambda_1)]D_m\phi_1 + [D^2_{\ell m}(A-\lambda_1)]D_k\phi_1 \\ \quad + [D^2_{km}(A-\lambda_1)]D_\ell\phi_1 + [D_k(A-\lambda_1)]D^2_{\ell m}\phi_1 + [D_\ell(A-\lambda_1)]D^2_{km}\phi_1 \\ \quad\quad + [D_m(A-\lambda_1)]D^2_{k\ell}\phi_1 + (A-\lambda_1)D^3_{k\ell m}\phi_1 = 0.\end{cases} \tag{4.21}$$

Taking the scalar product with ϕ_1, we get

$$\begin{cases}\langle[D^3_{k\ell m}(A-\lambda_1)]\phi_1,\phi_1\rangle + \langle[D^2_{k\ell}(A-\lambda_1)]D_m\phi_1,\phi_1\rangle + \langle[D^2_{\ell m}(A-\lambda_1)]D_k\phi_1,\phi_1\rangle \\ \quad + \langle[D^2_{km}(A-\lambda_1)]D_\ell\phi_1,\phi_1\rangle + \langle[D_k(A-\lambda_1)]D^2_{\ell m}\phi_1,\phi_1\rangle \\ \quad\quad + \langle[D_\ell(A-\lambda_1)]D^2_{km}\phi_1,\phi_1\rangle + \langle[D_m(A-\lambda_1)]D^2_{k\ell}\phi_1,\phi_1\rangle = 0.\end{cases} \tag{4.22}$$

To conclude that $D^3_{k\ell m}\lambda_1(0) = 0$, it is enough to use the following information in the above relation:

$$\begin{cases} D_kA \text{ is purely imaginary}, \quad D^2_{k\ell}A \text{ is real}, \quad D^3_{k\ell m}A = 0, \\ \phi_1(0), D^2_{k\ell}\phi_1(0) \text{ are real}, \quad D_k\phi_1(0) \text{ is purely imaginary.}\end{cases} \tag{4.23}$$

It is evident that the above argument is very general and so can be used to establish that all odd order derivatives of λ_1 at $\eta = 0$ vanish. This proves the first part of Proposition 1.9.

To find the third order derivatives of ϕ_1 at $\eta = 0$, we realize that (4.21) defines a periodic problem for $D^3_{k\ell m}\phi_1(\cdot;0)$ which can be compared with (1.31). Further, the relation (4.9) says that its average vanishes. These observations are enough to get the expression of $D^3_{k\ell m}\phi_1(\cdot;0)$ given in Proposition 1.10. We conclude by observing the following important property:

$$D^3_{k\ell m}\phi_1(y;0) \quad \text{is purely imaginary.} \tag{4.24}$$

4.4. Fourth order derivatives. To arrive at the expressions for the fourth order derivatives of λ_1 and ϕ_1 at $\eta = 0$ given in Propositions 1.9 and 1.10, we follow the same arguments as in section 4.3.

5. Convergence of the first Bloch transform to the Fourier transform.

This section is devoted to the proof of the next proposition which shows the sense in which the Fourier transform is approximated by the first Bloch transform.

PROPOSITION 5.1.

(i) *For every $g \in L^2(\mathbb{R}^N)$ with compact support, we have*

$$\chi_{\varepsilon^{-1}Y'}(\xi)B_1^\varepsilon g(\xi) \to \widehat{g}(\xi) \quad \textit{in} \quad L^\infty_{loc}(\mathbb{R}^N_\xi).$$

(ii) *If $g \in L^2(\mathbb{R}^N)$, we have*

$$\chi_{\varepsilon^{-1}Y'}(\xi)B_1^\varepsilon g(\xi) \to \widehat{g}(\xi) \quad \textit{in} \quad L^2(\mathbb{R}^N_\xi).$$

This will be a consequence of a more general result. In order to state it, we need to introduce some new notations. We associate with every function $\rho = \rho(y;\eta)$ defined on $Y \times Y'$ which is Y-periodic in y the following function:

$$\widetilde{\rho}^{(0)}(\eta) = \frac{1}{|Y|}\int_Y \rho(y;\eta)e^{-iy\cdot\eta}dy, \quad \eta \in Y'. \tag{5.1}$$

With this notation, we have the following proposition.

PROPOSITION 5.2. *We suppose $\rho \in L^\infty(Y';L^2_\#(Y))$. Then for all $g \in W^{1,p}(\mathbb{R}^N)$ with compact support K and with $p > N$, we have*

$$\chi_{\varepsilon^{-1}Y'}(\xi)\left(J^\varepsilon g(\xi) - (2\pi)^{N/2}\tilde{\rho}^{(0)}(\varepsilon\xi)\widehat{g}(\xi)\right) \to 0 \quad \textit{in} \quad L^2(\mathbb{R}^N_\xi), \tag{5.2}$$

where, we recall, $J^\varepsilon g$ was defined in (2.8).

The proof will be taken up later. Admitting it for the moment, we turn our attention to the following proof.

Proof of Proposition 5.1. If $g \in L^2(\mathbb{R}^N)$ with compact support K, we have for all $\xi \in \mathbb{R}^N$

$$\begin{aligned}|\chi_{\varepsilon^{-1}Y'}(\xi)B_1^\varepsilon g(\xi) - \widehat{g}(\xi)| &\le |\chi_{\varepsilon^{-1}Y'}(\xi)(B_1^\varepsilon g(\xi) - \widehat{g}(\xi))| + |(\chi_{\varepsilon^{-1}Y'}(\xi) - 1)\widehat{g}(\xi)| \\ &\le c|K|\|g\|_{L^2(\mathbb{R}^N)}\|\phi_1(\cdot;\varepsilon\xi) - \phi_1(\cdot;0)\|_{L^2(Y)} + |(\chi_{\varepsilon^{-1}Y'}(\xi) - 1)\widehat{g}(\xi)|.\end{aligned}$$

If $|\xi|$ is bounded, then by using the fact that the map $\eta \mapsto \phi_1(\cdot;\eta) \in L^2_\#(Y)$ is Lipschitz near $\eta = 0$, we deduce

$$||\phi_1(\cdot;\varepsilon\xi) - \phi_1(\cdot;0)\|_{L^2(Y)} \le c\varepsilon.$$

This completes the proof of (i).

The proof of (ii) is more involved. First, according to Theorem 1.3, we have the uniform estimate

$$\int_{\varepsilon^{-1}Y'} |B_1^\varepsilon g(\xi)|^2 d\xi \leq \int_{\mathbb{R}^N} |g(x)|^2 dx,$$

and so, by the usual density arguments, it is enough to prove (ii) with $g \in \mathcal{D}(\mathbb{R}^N)$. We can now complete the proof using Proposition 5.2. Indeed, with $\rho = \bar{\phi}_1$, we see that

$$\tilde{\rho}^{(0)}(\varepsilon\xi) \to p^{(0)} \quad \text{and} \quad B_1^\varepsilon g(\xi) = J^\varepsilon g(\xi) \quad \forall \xi \in \mathbb{R}^N,$$

which implies, by Lebesgue's dominated convergence theorem, that

$$(2\pi)^{N/2} \chi_{\varepsilon^{-1}Y'}(\xi) \tilde{\rho}^{(0)}(\varepsilon\xi) \widehat{g}(\xi) \to \widehat{g}(\xi) \quad \text{in} \quad L^2(\mathbb{R}^N_\xi). \qquad \square$$

Proof of Proposition 5.2. The key point is that the variation of $\rho(\frac{x}{\varepsilon}; \varepsilon\xi)$ with respect to x is faster than that of g. To exploit this, we consider the ε-mesh $\{Y_\ell^\varepsilon\}_{\ell \in \mathbb{Z}^N}$ generated by the cell εY which was already introduced at the end of section 2. We decompose

$$\begin{aligned} J^\varepsilon g(\xi) &= \sum_{\ell \in \mathbb{Z}^N} \int_{Y_\ell^\varepsilon} g(x) e^{-ix\cdot\xi} \rho\left(\frac{x}{\varepsilon}; \varepsilon\xi\right) dx \\ &= \sum_{\ell \in \mathbb{Z}^N} g(x_\ell^\varepsilon) \int_{Y_\ell^\varepsilon} e^{-ix\cdot\xi} \rho\left(\frac{x}{\varepsilon}; \varepsilon\xi\right) dx + r_1^\varepsilon(\xi), \end{aligned} \tag{5.3}$$

where

$$r_1^\varepsilon(\xi) = \sum_{\ell \in \mathbb{Z}^N} \int_{Y_\ell^\varepsilon} (g(x) - g(x_\ell^\varepsilon)) e^{-ix\cdot\xi} \rho\left(\frac{x}{\varepsilon}; \varepsilon\xi\right) dx. \tag{5.4}$$

The first term on the right-hand side of (5.3) can be, by means of the change of variables $x = x_\ell^\varepsilon + \varepsilon y$, transformed into

$$|Y| \varepsilon^N F^\varepsilon g(\xi) \widetilde{\rho}^{(0)}(\varepsilon\xi),$$

where $F^\varepsilon g$ is the discrete Fourier transform of g and $\tilde{\rho}^{(0)}$ is defined in (5.1). Since we know that $\chi_{\varepsilon^{-1}Y'}(\xi) \varepsilon^N F^\varepsilon g(\xi) \to \frac{1}{(2\pi)^{N/2}} \hat{g}(\xi)$ in $L^2(\mathbb{R}^N)$ (cf. Lemma 2.6), our hypothesis on ρ ensures that

$$\left\| \chi_{\varepsilon^{-1}Y'}(\xi) \left\{ |Y| \varepsilon^N F^\varepsilon g(\xi) - (2\pi)^{N/2} \widehat{g}(\xi) \right\} \tilde{\rho}^{(0)}(\varepsilon\xi) \right\|_{L^2(\mathbb{R}^N)} \to 0. \tag{5.5}$$

Thus, to complete the proof, it is enough to show that

$$\|r_1^\varepsilon\|_{L^2(\varepsilon^{-1}Y')} \leq \frac{c(K)}{(1 - \frac{N}{p})} \varepsilon \|\rho\|_{L^\infty(Y'; L^2_\#(Y))} \|\nabla g\|_{L^p(\mathbb{R}^N)}. \tag{5.6}$$

To this end, we rewrite r_1^ε in a slightly different form, namely,

$$r_1^\varepsilon(\xi) = \int_{\mathbb{R}^N} \widetilde{g}_1^\varepsilon(x) e^{-ix\cdot\xi} \rho\left(\frac{x}{\varepsilon}; \varepsilon\xi\right) dx, \tag{5.7}$$

where

$$\widetilde{g}_1^\varepsilon(x) = \sum_{\ell\in\mathbb{Z}^N} (g(x) - g(x_\ell^\varepsilon))\chi_{Y_\ell^\varepsilon}(x). \tag{5.8}$$

We already know how to estimate integrals of the type (5.7) in $L^2(\mathbb{R}^N)$ (see Lemma 2.5), and so we can deduce (5.6) provided we have the estimate

$$\|\widetilde{g}_1^\varepsilon\|_{L^2(\mathbb{R}^N)} \le \frac{c(K)}{(1-\frac{N}{p})}\varepsilon\|\nabla g\|_{L^p(\mathbb{R}^N)}. \tag{5.9}$$

Thanks to our hypothesis, we can deduce a stronger estimate, namely,

$$\|\widetilde{g}_1^\varepsilon\|_{L^p(\mathbb{R}^N)} \le \frac{c}{(1-\frac{N}{p})}\varepsilon\|\nabla g\|_{L^p(\mathbb{R}^N)}, \tag{5.10}$$

where c is a constant independent of K, the support of g. We note that (5.10) is a simple consequence of Morrey's estimate (see [7, p. 167]).

Finally, we note that (5.9) can be obtained from (5.10) with $c(K) = c|K|^{1-\frac{2}{p}}$ and a simple application of the Hölder inequality. □

The proof of Proposition 5.2 shows that the result can be strengthened by assuming suitable smoothness on g. Our next result is an example in this direction. It introduces naturally the following quantities:

$$\widetilde{\rho}^{(k)}(\eta) = \frac{1}{|Y|}\int_Y \rho(y;\eta)y_k e^{-iy\cdot\eta}dy \quad \forall k = 1,\dots,N, \quad \eta\in Y'. \tag{5.11}$$

Then we have the following corrector result for $J^\varepsilon g$.

PROPOSITION 5.3. *We suppose $\rho\in L^\infty(Y';L^2_\#(Y))$. Then for all $g\in W^{2,p}(\mathbb{R}^N)$ with compact support K and with $p>N$, we have*

$$\chi_{\varepsilon^{-1}Y'}(\xi)\left\{J^\varepsilon g(\xi) - (2\pi)^{N/2}\big[\tilde{\rho}^{(0)}(\varepsilon\xi) + i\varepsilon\xi_k\tilde{\rho}^{(k)}(\varepsilon\xi)\big]\widehat{g}(\xi)\right\} \to 0 \quad \text{in} \quad L^2(\mathbb{R}^N_\xi).$$

Proof. We follow the idea of the proof of Proposition 5.2. We decompose $J^\varepsilon g(\xi)$ as

$$J^\varepsilon g(\xi) = \sum_{\ell\in\mathbb{Z}^N}\int_{Y_\ell^\varepsilon}\{g(x_\ell^\varepsilon) + \nabla g(x_\ell^\varepsilon)\cdot(x - x_\ell^\varepsilon)\}\,e^{-ix\cdot\xi}\rho\left(\frac{x}{\varepsilon};\varepsilon\xi\right)dx + r_2^\varepsilon(\xi), \tag{5.12}$$

where

$$r_2^\varepsilon(\xi) = \sum_{\ell\in\mathbb{Z}^N}\int_{Y_\ell^\varepsilon}\{g(x) - g(x_\ell^\varepsilon) - \nabla g(x_\ell^\varepsilon)\cdot(x - x_\ell^\varepsilon)\}\,e^{-ix\cdot\xi}\rho\left(\frac{x}{\varepsilon};\varepsilon\xi\right)dx. \tag{5.13}$$

We can estimate $r_2^\varepsilon(\xi)$ as follows:

$$\|r_2^\varepsilon\|_{L^2(\varepsilon^{-1}Y')} \le \frac{c(K)}{(2-\frac{N}{p})}\varepsilon^2\|\rho\|_{L^\infty(Y';L^2_\#(Y))}\,|g|_{W^{2,p}(\mathbb{R}^N)}. \tag{5.14}$$

This, in fact, will be a consequence of Lemma 2.5, because we can represent r_2^ε as follows:

$$r_2^\varepsilon(\xi) = \int_{\mathbb{R}^N}\widetilde{g}_2^\varepsilon(x)e^{-ix\cdot\xi}\rho\left(\frac{x}{\varepsilon};\varepsilon\xi\right)dx \tag{5.15}$$

with

$$\widetilde{g}_2^\varepsilon(x) = \sum_{\ell\in\mathbb{Z}^N} \left(g(x) - g(x_\ell^\varepsilon) - \nabla g(x_\ell^\varepsilon)\cdot(x - x_\ell^\varepsilon)\right)\chi_{Y_\ell^\varepsilon}(x), \tag{5.16}$$

which admits the following estimates:

$$\|\widetilde{g}_2^\varepsilon\|_{L^2(\mathbb{R}^N)} \le \frac{c(K)}{(2-\frac{N}{p})}\varepsilon^2|g|_{W^{2,p}(\mathbb{R}^N)}, \tag{5.17}$$

$$\|\widetilde{g}_2^\varepsilon\|_{L^p(\mathbb{R}^N)} \le \frac{c}{(2-\frac{N}{p})}\varepsilon^2|g|_{W^{2,p}(\mathbb{R}^N)}. \tag{5.18}$$

As before, (5.17) will be a consequence of (5.18) with $c(K) = c|K|^{1-\frac{2}{p}}$.

To establish (5.18), what we need is a generalization of Morrey's inequality for $W^{2,p}$ functions, namely,

$$|g(x)-g(x_\ell^\varepsilon)-\nabla g(x_\ell^\varepsilon)\cdot(x-x_\ell^\varepsilon)| \le \frac{c}{(2-\frac{N}{p})}|x-x_\ell^\varepsilon|^{2-\frac{N}{p}}|g|_{W^{2,p}(Y_\ell^\varepsilon)} \ \forall x\in Y_\ell^\varepsilon. \tag{5.19}$$

Admitting the above estimate, it is an easy matter to prove (5.18). But the above estimate is a consequence of Morrey's inequality for the gradient $\nabla g \in W^{1,p}(\mathbb{R}^N)$ and the following representation: for all $x \in Y_\ell^\varepsilon$,

$$g(x) - g(x_\ell^\varepsilon) - \nabla g(x_\ell^\varepsilon)\cdot(x - x_\ell^\varepsilon) = \int_0^1 \{\nabla g((1-t)x_\ell^\varepsilon + tx) - \nabla g(x_\ell^\varepsilon)\}\cdot(x - x_\ell^\varepsilon)dt.$$

This completes the proof of the estimate (5.14) on r_2^ε. Thus, as expected, r_2^ε tends to zero more rapidly. The same cannot be said for the first term on the right-hand side of (5.12). Indeed, it is equal to

$$|Y|\left[\varepsilon^N(F^\varepsilon g)(\xi)\tilde{\rho}^{(0)}(\varepsilon\xi) + \varepsilon^{N+1}\left(F^\varepsilon\frac{\partial g}{\partial x_k}\right)(\xi)\tilde{\rho}^{(k)}(\varepsilon\xi)\right]. \tag{5.20}$$

According to Lemma 2.6, we have the following convergence (apart from (5.5)):

$$\chi_{\varepsilon^{-1}Y'}\left\{|Y|\left[\varepsilon^N\left(F^\varepsilon\frac{\partial g}{\partial x_k}\right)(\xi) - \frac{1}{(2\pi)^{N/2}}i\xi_k\widehat{g}(\xi)\right]\tilde{\rho}^{(k)}(\varepsilon\xi)\right\} \to 0 \text{ in } L^2(\mathbb{R}_\xi^N). \tag{5.21}$$

This clearly allows us to complete the proof. □

6. Proof of the main convergence results. Applying the previously developed techniques and results, we are now in a position to prove the main convergence results stated in section 1.2 of the introduction (namely, Theorems 1.8 and 1.11 and the statement (1.8)). We begin by recalling briefly the set-up. We take $f \in L^2(\mathbb{R}^N)$ and consider a sequence u^ε satisfying (1.9), i.e.,

$$\begin{cases} A^\varepsilon u^\varepsilon = f & \text{in} \quad \mathbb{R}^N, \\ u^\varepsilon \rightharpoonup u^* & \text{in} \quad H^1(\mathbb{R}^N)\text{-weak}, \\ u^\varepsilon \to u^* & \text{in} \quad L^2(\mathbb{R}^N)\text{-strong}. \end{cases} \tag{6.1}$$

6.1. No concentration of energy at infinity. Our hypothesis that $u^\varepsilon \to u^*$ in $L^2(\mathbb{R}^N)$-strong may, at first sight, look artificial. But this in not the case. If Ω is bounded and smooth, then it is classical that the weak convergence in $H^1(\Omega)$ will automatically imply the strong convergence in $L^2(\Omega)$. This is not the case in $\mathbb{R}^N$. To make comparisons, the correct operator to consider is $(A^\varepsilon + I)$ instead of A^ε in $\mathbb{R}^N$. In that case, we have the following.

PROPOSITION 6.1. *Assume that w^ε satisfies*

$$\left\{ \begin{array}{rll} (A^\varepsilon + I)w^\varepsilon = g & \textit{in} & \mathbb{R}^N, \\ w^\varepsilon \rightharpoonup w^* & \textit{in} & H^1(\mathbb{R}^N)\textit{-weak}, \end{array} \right. \tag{6.2}$$

where g is a given function in $L^2(\mathbb{R}^N)$. Then

$$w^\varepsilon \to w^* \quad \textit{in} \quad L^2(\mathbb{R}^N)\textit{-strong}.$$

Proof. First of all, following the idea of Proposition 3.1, we can neglect higher Bloch modes of w^ε and w^*. More precisely, we can show

$$\int_{\varepsilon^{-1}Y'} \sum_{m=2}^{\infty} |B_m^\varepsilon w^\varepsilon(\xi)|^2 d\xi \le c\varepsilon^4,$$

$$\int_{\varepsilon^{-1}Y'} \sum_{m=2}^{\infty} |B_m^\varepsilon w^*(\xi)|^2 d\xi \le c\varepsilon^2.$$

Therefore, it remains to prove

$$\int_{\varepsilon^{-1}Y'} |B_1^\varepsilon w^\varepsilon(\xi) - B_1^\varepsilon w^*(\xi)|^2 d\xi \to 0. \tag{6.3}$$

Equation (6.2) gives the relation

$$(1 + \lambda_1^\varepsilon(\xi))B_1^\varepsilon w^\varepsilon(\xi) = B_1^\varepsilon g(\xi), \quad \xi \in \varepsilon^{-1}Y'.$$

We use it to write

$$\begin{aligned} \chi_{\varepsilon^{-1}Y'}(\xi)(B_1^\varepsilon w^\varepsilon(\xi) - B_1^\varepsilon w^*(\xi)) = \chi_{\varepsilon^{-1}Y'}(\xi)&\frac{B_1^\varepsilon g(\xi)}{1 + \lambda_1^\varepsilon(\xi)} \\ &-\widehat{w}^*(\xi) - (\chi_{\varepsilon^{-1}Y'}(\xi)B_1^\varepsilon w^*(\xi) - \widehat{w}^*(\xi)). \end{aligned}$$

According to Proposition 5.1, the last term tends to zero in $L^2(\mathbb{R}^N)$. It suffices to show

$$\chi_{\varepsilon^{-1}Y'}(\xi)\frac{B_1^\varepsilon g(\xi)}{1 + \lambda_1^\varepsilon(\xi)} - \widehat{w}^*(\xi) \to 0 \quad \text{in} \quad L^2(\mathbb{R}_\xi^N). \tag{6.4}$$

Note that w^* satisfies the homogenized equation $A^* w^* + w^* = g$ in $\mathbb{R}^N$, which is equivalent to

$$\left(\frac{1}{2}D_{k\ell}^2 \lambda_1(0)\xi_k \xi_\ell + 1\right) \widehat{w}^*(\xi) = \widehat{g}(\xi), \quad \xi \in \mathbb{R}^N.$$

So, (6.4) is reduced to

$$\chi_{\varepsilon^{-1}Y'}(\xi)\frac{B_1^\varepsilon g(\xi)}{1+\lambda_1^\varepsilon(\xi)} - \frac{\widehat{g}(\xi)}{1+\frac{1}{2}D^2_{k\ell}\lambda_1(0)\xi_k\xi_\ell} \to 0 \quad \text{in} \quad L^2(\mathbb{R}^N_\xi). \tag{6.5}$$

The above expression can be written in the form

$$\frac{a^\varepsilon + b^\varepsilon}{c^\varepsilon},$$

where

$$a^\varepsilon = \left(1 + \frac{1}{2}\ D^2_{k\ell}\lambda_1(0)\xi_k\xi_\ell\right)\left[\chi_{\varepsilon^{-1}Y'}(\xi)B_1^\varepsilon g(\xi) - \widehat{g}(\xi)\right],$$

$$b^\varepsilon = -\left(\lambda_1^\varepsilon(\xi) - \frac{1}{2}D^2_{k\ell}\lambda_1(0)\xi_k\xi_\ell\right)\widehat{g}(\xi),$$

$$c^\varepsilon = (1+\lambda_1^\varepsilon(\xi))\left(1 + \frac{1}{2}\ D^2_{k\ell}\lambda_1(0)\xi_k\xi_\ell\right).$$

Now we have the convergence

$$\frac{a^\varepsilon}{c^\varepsilon} = \frac{\chi_{\varepsilon^{-1}Y'}(\xi)B_1^\varepsilon g(\xi) - \widehat{g}(\xi)}{1+\lambda_1^\varepsilon(\xi)} \to 0 \text{ in } L^2(\mathbb{R}^N_\xi)$$

because $[1+\lambda_1^\varepsilon(\xi)] \geq 1$ and by the virtue of Proposition 5.1.

The convergence of $\frac{b^\varepsilon}{c^\varepsilon}$ is not immediate. To show this, we split the energy into three parts, taking $\gamma > 0$ as a fixed constant:

$$\int_{\substack{|\xi|\leq\delta\varepsilon^{-1}\\|\xi|\leq\gamma}} \left(\frac{b^\varepsilon}{c^\varepsilon}\right)^2 d\xi + \int_{\substack{|\xi|\leq\delta\varepsilon^{-1}\\|\xi|>\gamma}} \left(\frac{b^\varepsilon}{c^\varepsilon}\right)^2 d\xi + \int_{|\xi|>\delta\varepsilon^{-1}} \left(\frac{b^\varepsilon}{c^\varepsilon}\right)^2 d\xi.$$

In the first two parts, we use the estimate

$$\left|\lambda_1^\varepsilon(\xi) - \frac{1}{2}D^2_{k\ell}\lambda_1(0)\xi_k\xi_\ell\right| \leq c|\xi|^3\varepsilon \quad \text{for} \quad |\xi| \leq \delta\varepsilon^{-1}, \tag{6.6}$$

which holds since $\lambda_1(0) = D\lambda_1(0) = 0$ (see Proposition 1.5). In the first integral, we have $c^\varepsilon \geq 1$ and $|b^\varepsilon(\xi)| \leq c\gamma^3\varepsilon|\widehat{g}(\xi)|$, and consequently it is less than

$$c\varepsilon^2 \int_{\mathbb{R}^N} |\widehat{g}(\xi)|^2 d\xi$$

and hence converges to zero. In the second integral, we have

$$c^\varepsilon \geq \frac{1}{2}\lambda_1^\varepsilon(\xi)D^2_{k\ell}\lambda_1(0)\xi_k\xi_\ell \geq c|\xi|^4 \geq c\gamma|\xi|^3 \quad \text{since} \quad |\xi| \geq \gamma > 0.$$

With regards to b^ε, we still have $|b^\varepsilon(\xi)| \leq c|\xi|^3\varepsilon|\widehat{g}(\xi)|$, and so the second integral also converges to zero.

In the third integral, we use the bounds

$$|b^\varepsilon| \leq \left(\lambda_1^\varepsilon(\xi) + \frac{1}{2}D^2_{k\ell}\lambda_1(0)\xi_k\xi_\ell\right)|\widehat{g}(\xi)|,$$

$$c^\varepsilon \geq \lambda_1^\varepsilon(\xi) + \frac{1}{2}D^2_{k\ell}\lambda_1(0)\xi_k\xi_\ell.$$

Thus the third integral is estimated from above by

$$\int_{|\xi|>\delta\varepsilon^{-1}} |\widehat{g}(\xi)|^2 d\xi.$$

Obviously, this tends to zero as $\varepsilon \to 0$ since $g \in L^2(\mathbb{R}^N)$. □

6.2. Corrector result in $\mathbb{R}^N$. This section is devoted to the proof of Theorem 1.8 concerning the Bloch approximation θ^ε. The proof consists of several steps which correspond to estimations of the required energy in different regions in the Fourier space (in a neighborhood of the origin $|\eta| \leq \delta$ and in its complement $|\eta| > \delta$).

Step 1. We decompose u^ε as follows:

$$u^\varepsilon = v^\varepsilon + P_1^\varepsilon u^\varepsilon,$$

where v^ε and $P_1^\varepsilon u^\varepsilon$ are defined in (1.21) and (1.27), respectively. Thanks to Proposition 3.1, it is enough to prove

$$\|P_1^\varepsilon u^\varepsilon - \theta^\varepsilon\|_{L^2(\mathbb{R}^N)} \to 0, \tag{6.7}$$

$$|P_1^\varepsilon u^\varepsilon - \theta^\varepsilon|_{H^1(\mathbb{R}^N)} \leq c\varepsilon \|f\|_{L^2(\mathbb{R}^N)}. \tag{6.8}$$

Step 2. We estimate the energies in the region $|\xi| > \delta\varepsilon^{-1}$. To this end, we introduce the quantities

$$\theta^{\varepsilon,\delta}(x) = \int_{\substack{\xi\in\varepsilon^{-1}Y' \\ |\xi|>\delta\varepsilon^{-1}}} \widehat{u}^*(\xi) e^{ix\cdot\xi} \phi_1^\varepsilon(x;\xi) d\xi, \tag{6.9}$$

$$P_1^{\varepsilon,\delta} u^\varepsilon(x) = \int_{\substack{\xi\in\varepsilon^{-1}Y' \\ |\xi|>\delta\varepsilon^{-1}}} B_1^\varepsilon u^\varepsilon(\xi) e^{ix\cdot\xi} \phi_1^\varepsilon(x;\xi) d\xi. \tag{6.10}$$

We will obtain the estimates

$$\|\theta^{\varepsilon,\delta}\|_{L^2(\mathbb{R}^N)} \leq c\varepsilon \|f\|_{H^{-1}(\mathbb{R}^N)}, \tag{6.11}$$

$$|\theta^{\varepsilon,\delta}|_{H^1(\mathbb{R}^N)} \leq c\varepsilon \|f\|_{L^2(\mathbb{R}^N)}, \tag{6.12}$$

$$\|P_1^{\varepsilon,\delta} u^\varepsilon\|_{L^2(\mathbb{R}^N)} \leq c\varepsilon \|f\|_{H^{-1}(\mathbb{R}^N)}, \tag{6.13}$$

$$|P_1^{\varepsilon,\delta} u^\varepsilon|_{H^1(\mathbb{R}^N)} \leq c\varepsilon \|f\|_{L^2(\mathbb{R}^N)}. \tag{6.14}$$

We start with (6.14). Using Lemma 2.3 with $\rho = \phi_1$ and inequalities (2.5), we get

$$|P_1^{\varepsilon,\delta} u^\varepsilon|^2_{H^1(\mathbb{R}^N)} \leq c \int_{\substack{\xi\in\varepsilon^{-1}Y' \\ |\xi|>\delta\varepsilon^{-1}}} |B_1^\varepsilon u^\varepsilon(\xi)|^2 \lambda_1^\varepsilon(\xi) d\xi.$$

Now (6.14) easily follows if we use (1.22) and (1.24). Next, we prove (6.12). Following the above procedure, we get

$$|\theta^{\varepsilon,\delta}|^2_{H^1(\mathbb{R}^N)} \leq c \int_{\substack{\xi\in\varepsilon^{-1}Y' \\ |\xi|>\delta\varepsilon^{-1}}} |\widehat{u}^*(\xi)|^2 |\xi|^2 d\xi. \tag{6.15}$$

If $f \in L^2(\mathbb{R}^N)$, then it is well known that $u^* \in H^2(\mathbb{R}^N)$ and

$$\int_{\mathbb{R}^N} |\xi|^4 |\widehat{u}^*(\xi)|^2 d\xi \leq c \int_{\mathbb{R}^N} |\widehat{f}(\xi)|^2 d\xi. \tag{6.16}$$

Combining (6.15) and (6.16), we easily get (6.12). We now show (6.11). By Parseval's identity, we have

$$\|\theta^{\varepsilon,\delta}\|^2_{L^2(\mathbb{R}^N)} = \int_{\substack{\xi \in \varepsilon^{-1}Y' \\ |\xi| > \delta\varepsilon^{-1}}} |\widehat{u}^*(\xi)|^2 d\xi \leq c_\delta \varepsilon^2 \int_{\substack{\xi \in \varepsilon^{-1}Y' \\ |\xi| > \delta\varepsilon^{-1}}} |\xi|^{-2} |\widehat{f}(\xi)|^2 d\xi,$$

since u^* and f are related by the homogenized equation $A^* u^* = f$ in $\mathbb{R}^N$. This clearly implies

$$\|\theta^{\varepsilon,\delta}\|^2_{L^2(\mathbb{R}^N)} \leq c_\delta \varepsilon^2 \int_{\substack{\xi \in \varepsilon^{-1}Y' \\ |\xi| > \delta\varepsilon^{-1}}} (1 + |\xi|^2)^{-1} |\widehat{f}(\xi)|^2 d\xi = c_\delta \varepsilon^2 \|f\|^2_{H^{-1}(\mathbb{R}^N)}.$$

The proof of (6.13) is completely analogous.

Step 3. Now, we consider the energies in $|\xi| \leq \delta\varepsilon^{-1}$. To this end, let us define

$$\omega^\varepsilon(x) = \int_{|\xi| \leq \delta\varepsilon^{-1}} (B_1^\varepsilon u^\varepsilon(\xi) - \widehat{u}^*(\xi)) e^{ix\cdot\xi} \phi_1^\varepsilon(x;\xi) d\xi \tag{6.17}$$

and show that

$$\|\omega^\varepsilon\|_{L^2(\mathbb{R}^N)} \to 0, \tag{6.18}$$

$$|\omega^\varepsilon|_{H^1(\mathbb{R}^N)} \leq c\varepsilon \|f\|_{L^2(\mathbb{R}^N)}. \tag{6.19}$$

To prove (6.18), we decompose the integrand as follows:

$$B_1^\varepsilon u^\varepsilon - \widehat{u}^* = B_1^\varepsilon (u^\varepsilon - u^*) + (B_1^\varepsilon u^* - \widehat{u}^*).$$

By Parseval's equality, the first term in the L^2-norm is bounded above by $\|u^\varepsilon - u^*\|_{L^2(\mathbb{R}^N)}$ which, by our hypothesis, converges to zero. That the second term converges to zero in $L^2(\mathbb{R}^N)$ is proved in Proposition 5.1.

Next, we turn are attention to the proof of (6.19). By Lemma 2.1, we have

$$|\omega^\varepsilon|^2_{H^1(\mathbb{R}^N)} \leq c \int_{|\xi| \leq \delta\varepsilon^{-1}} \lambda_1^\varepsilon(\xi) |B_1^\varepsilon u^\varepsilon(\xi) - \widehat{u}^*(\xi)|^2 d\xi. \tag{6.20}$$

To estimate the above integral, we write the integrand as

$$B_1^\varepsilon u^\varepsilon(\xi) - \widehat{u}^*(\xi) = \lambda_1^\varepsilon(\xi)^{-1} (B_1^\varepsilon f(\xi) - \widehat{f}(\xi)) + \Big[\lambda_1^\varepsilon(\xi)^{-1} - \Big(\frac{1}{2} D^2_{k\ell} \lambda_1(0) \xi_k \, \xi_\ell\Big)^{-1}\Big] \widehat{f}(\xi).$$

Thus we get, using (1.24), that

$$\begin{cases} |\omega^\varepsilon|^2_{H^1(\mathbb{R}^N)} \;\leq\; c \displaystyle\int_{|\xi| \leq \delta\varepsilon^{-1}} \frac{|B_1^\varepsilon f(\xi) - \widehat{f}(\xi)|^2}{|\xi|^2} d\xi \\ \qquad\qquad\quad + \; c \displaystyle\int_{|\xi| \leq \delta\varepsilon^{-1}} \lambda_1^\varepsilon(\xi) \Big| \lambda_1^\varepsilon(\xi)^{-1} - \Big(\frac{1}{2} D^2_{k\ell} \lambda_1(0) \xi_k \xi_\ell\Big)^{-1} \Big|^2 |\widehat{f}(\xi)|^2 d\xi. \end{cases} \tag{6.21}$$

To estimate the first term on the right-hand side of (6.21), we represent the integrand as

$$\frac{B_1^\varepsilon f(\xi) - \widehat{f}(\xi)}{|\xi|} = \int_{\mathbb{R}^N} f(x) e^{-ix\cdot\xi} \frac{(\phi_1^\varepsilon(x;\xi) - \phi_1^\varepsilon(x;0))}{|\xi|} dx.$$

Applying Lemma 2.5 and using $\|\phi_1(\cdot;\eta) - \phi_1(\cdot;0)\|_{L^2(Y)} \leq c|\eta|$ for $|\eta| \leq \delta$, we get

$$\int_{|\xi|\leq\delta\varepsilon^{-1}} \frac{|B_1^\varepsilon f(\xi) - \widehat{f}(\xi)|^2}{|\xi|^2} d\xi \leq c\varepsilon^2 \|f\|^2_{L^2(\mathbb{R}^N)}.$$

The second term on the right-hand side of (6.21) can be rewritten, using the homogenized equation, as

$$\int_{|\xi|\leq\delta\varepsilon^{-1}} \frac{|\lambda_1^\varepsilon(\xi) - \frac{1}{2}D^2_{k\ell}\lambda_1(0)\xi_k\xi_\ell|^2}{\lambda_1^\varepsilon(\xi)} |\widehat{u}^*(\xi)|^2 d\xi.$$

Using (6.6) and (1.24), we see that the above integral is estimated from above by

$$c\varepsilon^2 \int_{|\xi|\leq\delta\varepsilon^{-1}} |\xi|^4 |\widehat{u}^*(\xi)|^2 d\xi \leq c\varepsilon^2 \|f\|^2_{L^2(\mathbb{R}^N)}.$$

This establishes (6.19) and hence the result. □

6.3. Asymptotic expansion of the Bloch approximation. In this concluding section, we prove Theorem 1.11.

Proof of (i). We have the following decomposition:

$$\theta^\varepsilon(x) - u^*(x) = z^\varepsilon(x) + \theta^{\varepsilon,\delta}(x) + u^{*,\delta}(x), \tag{6.22}$$

where

$$z^\varepsilon(x) = \int_{\substack{\xi\in\varepsilon^{-1}Y' \\ |\xi|\leq\delta\varepsilon^{-1}}} \widehat{u}^*(\xi) e^{ix\cdot\xi} (\phi_1^\varepsilon(x;\xi) - \phi_1^\varepsilon(x;0)) d\xi, \tag{6.23}$$

$$u^{*,\delta}(x) = \frac{1}{(2\pi)^{N/2}} \int_{|\xi|>\delta\varepsilon^{-1}} \widehat{u}^*(\xi) e^{ix\cdot\xi} d\xi, \tag{6.24}$$

and $\theta^{\varepsilon,\delta}$ is defined in (6.9).

The second term has already been estimated in the L^2-norm (see (6.11)). The same proof shows that the third term admits a bound

$$\|u^{*,\delta}\|_{L^2(\mathbb{R}^N)} \leq c\varepsilon \|f\|_{H^{-1}(\mathbb{R}^N)} \leq c\varepsilon \|u^*\|_{H^1(\mathbb{R}^N)}. \tag{6.25}$$

To estimate the first term on the right-hand side of (6.22), we must proceed differently. In fact, it is essential to use Lemma 2.3. We see then that

$$\|z^\varepsilon\|^2_{L^2(\mathbb{R}^N)} = \int_{\substack{\xi\in\varepsilon^{-1}Y' \\ |\xi|\leq\delta\varepsilon^{-1}}} |\widehat{u}^*(\xi)|^2 \|\phi_1^\varepsilon(\cdot;\xi) - \phi_1^\varepsilon(\cdot;0)\|^2_{L^2(Y)} d\xi.$$

Using the Lipschitz continuity of the map $\eta \mapsto \phi_1(\cdot;\eta) \in L^2(Y)$ for $|\eta| \leq \delta$, we see that the above integral can be majorized, and we obtain

$$\|z^\varepsilon\|^2_{L^2(\mathbb{R}^N)} \leq c\varepsilon^2 \int_{|\xi|\leq\delta\varepsilon^{-1}} |\widehat{u}^*(\xi)|^2 |\xi|^2 d\xi \leq c\varepsilon^2 |u^*|^2_{H^1(\mathbb{R}^N)}. \tag{6.26}$$

This finishes the proof of (i). We note that we cannot, in general, assert that

$$|u^*|_{H^1(\mathbb{R}^N)} \leq c\|f\|_{H^{-1}(\mathbb{R}^N)}$$

as we are working on the entire space $\mathbb{R}^N$.

Proof of (ii). Because of (i), it suffices to prove

$$\left|\theta^\varepsilon - u^* - \varepsilon\chi_k^\varepsilon \frac{\partial u^*}{\partial x_k}\right|_{H^1(\mathbb{R}^N)} \leq c\varepsilon\|f\|_{L^2(\mathbb{R}^N)}. \tag{6.27}$$

To this end, we use once again the decomposition (6.22) for $(\theta^\varepsilon - u^*)$ in terms of z^ε, $\theta^{\varepsilon,\delta}$, and $u^{*,\delta}$. For $\theta^{\varepsilon,\delta}$, we have the estimate (6.12). For $u^{*,\delta}$, we can easily derive the estimate

$$|u^{*,\delta}|^2_{H^1(\mathbb{R}^N)} \leq c\int_{|\xi|>\delta\varepsilon^{-1}} |\xi|^2|\widehat{u}^*(\xi)|^2 d\xi \leq c_\delta\varepsilon^2\|f\|^2_{L^2(\mathbb{R}^N)}. \tag{6.28}$$

Thus, we are reduced to obtaining the estimate

$$\left|z^\varepsilon - \varepsilon\chi_k^\varepsilon \frac{\partial u^*}{\partial x_k}\right|_{H^1(\mathbb{R}^N)} \leq c\varepsilon\|f\|_{L^2(\mathbb{R}^N)}. \tag{6.29}$$

To this end, we use the representation

$$\frac{\partial u^*}{\partial x_k}(x) = \frac{1}{(2\pi)^{N/2}}\int_{\mathbb{R}^N}(i\xi_k)\widehat{u}^*(\xi)e^{ix\cdot\xi}d\xi,$$

and combine it with the representation (6.23) for z^ε. We get

$$\begin{aligned} z^\varepsilon(x) - \varepsilon\chi_k^\varepsilon(x)\frac{\partial u^*}{\partial x_k}(x) = &\int_{|\xi|\leq\delta\varepsilon^{-1}} \widehat{u}^*(\xi)e^{ix\cdot\xi}\left(\phi_1^\varepsilon(x;\xi) - \phi_1^\varepsilon(x;0) - ip^{(0)}\chi_k^\varepsilon(x)\varepsilon\xi_k\right)d\xi \\ &-\int_{|\xi|>\delta\varepsilon^{-1}} ip^{(0)}\chi_k^\varepsilon(x)\varepsilon\xi_k\widehat{u}^*(\xi)e^{ix\cdot\xi}d\xi. \end{aligned} \tag{6.30}$$

To estimate the first term on the right-hand side of (6.30), we appeal to Lemma 2.3. Further, we use

$$\left\|\phi_1(\cdot;\eta) - \phi_1(\cdot;0) - ip^{(0)}\chi_k(\cdot)\eta_k\right\|_{H^1(Y)} \leq c|\eta|^2 \quad \text{for} \quad |\eta|\leq\delta. \tag{6.31}$$

The estimate on the second term on the right-hand side of (6.30) is more straightforward. We finally get

$$\left|z^\varepsilon - \varepsilon\chi_k^\varepsilon\frac{\partial u^*}{\partial x_k}\right|^2_{H^1(\mathbb{R}^N)} \leq c\varepsilon^2\int_{\mathbb{R}^N}|\xi|^4|\widehat{u}^*(\xi)|^2 d\xi.$$

This completes the proof of (6.29) and hence (ii).

Proof of (iii). Consider again the decomposition (6.22). Thanks to (6.9) and (6.15), we have the estimates

$$\|\theta^{\varepsilon,\delta}\|_{L^2(\mathbb{R}^N)} \leq c\varepsilon^2\|f\|_{L^2(\mathbb{R}^N)}, \tag{6.32}$$

$$|\theta^{\varepsilon,\delta}|_{H^1(\mathbb{R}^N)} \leq c\varepsilon^2|f|_{H^1(\mathbb{R}^N)}. \tag{6.33}$$

Similar techniques imply

$$\|u^{*,\delta}\|_{L^2(\mathbb{R}^N)} \le c\varepsilon^2 \|f\|_{L^2(\mathbb{R}^N)}, \tag{6.34}$$

$$|u^{*,\delta}|_{H^1(\mathbb{R}^N)} \le c\varepsilon^2 |f|_{H^1(\mathbb{R}^N)}. \tag{6.35}$$

On the other hand, it is clear from the representation (6.30) that

$$\Big\| z^\varepsilon - \varepsilon \chi^\varepsilon_k \frac{\partial u^*}{\partial x_k} \Big\|_{L^2(\mathbb{R}^N)} \le c\varepsilon^2 \|f\|_{L^2(\mathbb{R}^N)}. \tag{6.36}$$

Thus, it is enough to obtain the estimate

$$\Big| \theta^\varepsilon - u^* - \varepsilon \chi^\varepsilon_k \frac{\partial u^*}{\partial x_k} + \varepsilon^2 (\chi^\varepsilon_{k\ell} + \beta^{(2)}_{k\ell}) \frac{\partial^2 u^*}{\partial x_k \partial x_\ell} \Big|_{H^1(\mathbb{R}^N)} \le c\varepsilon^2 |f|_{H^1(\mathbb{R}^N)}. \tag{6.37}$$

Thanks to (6.33) and (6.35), we are reduced to showing that

$$\Big| z^\varepsilon - \varepsilon \chi^\varepsilon_k \frac{\partial u^*}{\partial x_k} + \varepsilon^2 (\chi^\varepsilon_{k\ell} + \beta^{(2)}_{k\ell}) \frac{\partial^2 u^*}{\partial x_k \partial x_\ell} \Big|_{H^1(\mathbb{R}^N)} \le c\varepsilon^2 |f|_{H^1(\mathbb{R}^N)}. \tag{6.38}$$

We can write

$$\begin{aligned} z^\varepsilon(x) - \varepsilon \chi^\varepsilon_k(x) \frac{\partial u^*}{\partial x_k}(x) &+ \varepsilon^2 (\chi^\varepsilon_{k\ell}(x) + \beta^{(2)}_{k\ell}) \frac{\partial^2 u^*}{\partial x_k \partial x_\ell}(x) \\ &= \int_{|\xi| \le \delta\varepsilon^{-1}} \widehat{u}^*(\xi) e^{ix\cdot\xi} [\phi^\varepsilon_1(x;\xi) - \phi^\varepsilon_1(x;0) - ip^{(0)} \chi^\varepsilon_k(x) \varepsilon \xi_k i \\ &\qquad + p^{(0)} (\chi^\varepsilon_{k\ell}(x) + \beta^{(2)}_{k\ell}) \varepsilon^2 \xi_k \xi_\ell] d\xi \\ &\quad - \int_{|\xi| > \delta\varepsilon^{-1}} ip^{(0)} \chi^\varepsilon_k(x) \varepsilon \xi_k \widehat{u}^*(\xi) e^{ix\cdot\xi} d\xi \\ &\quad + \int_{|\xi| > \delta\varepsilon^{-1}} p^{(0)} (\chi^\varepsilon_{k\ell}(x) + \beta^{(2)}_{k\ell}) \varepsilon^2 \xi_k \xi_\ell \widehat{u}^*(\xi) e^{ix\cdot\xi} d\xi. \end{aligned} \tag{6.39}$$

The analysis of the right-hand side of (6.39) is similar to that of (6.30). The new information needed is the following:

$$\Big\| \phi_1(\cdot;\eta) - \phi_1(\cdot;0) - ip^{(0)} \chi_k(\cdot) \eta_k + p^{(0)} (\chi_{k\ell}(\cdot) + \beta^{(2)}_{k\ell}) \eta_k \eta_\ell \Big\|_{H^1(Y)} \le c|\eta|^3 \tag{6.40}$$

for $|\eta| \le \delta$, which is a simple consequence of Proposition 1.10. The proof is concluded via a simple application of Lemma 2.3. □

ON THE HARDY–LITTLEWOOD THEOREM FOR FUNCTIONS OF BOUNDED VARIATION[*]

PAULO R. ZINGANO[†] AND STANLY L. STEINBERG[‡]

Abstract. We derive here an improved version of the well-known Hardy–Littlewood theorem for functions of bounded variation in the classical sense of Jordan. Results for the positive and negative variations are also discussed.

Key words. functions of bounded variation, Hardy–Littlewood theorem, essential bounded variation, positive and negative variations, absolutely continuous functions

1. Introduction. In this paper we will point out a fundamental property of functions of bounded variation (in the classical sense of C. Jordan [15], [16]) which has apparently not been noticed in the well-developed theory of such functions. We recall that $f : [a, b] \to R$ is of bounded (or finite) variation on the interval $[a, b]$, written $f \in \mathrm{BV}(a, b)$, if its total variation given by

$$\mathrm{TV}[f; a, b] = \sup_{\pi} \sum_{i=1}^{n} |f(x_i) - f(x_{i-1})| \tag{1.1}$$

is finite, where the supremum is taken over all possible partitions $\pi = \{x_0 < x_1 < \cdots < x_n\}$ of $[a, b]$. Given $f \in \mathrm{BV}(a, b)$, its positive and negative variations are similarly defined by

$$\mathrm{PV}[f; a, b] = \sup_{\pi} \sum_{i=1}^{n} \big(f(x_i) - f(x_{i-1}) \big)_+, \tag{1.2a}$$

$$\mathrm{NV}[f; a, b] = \sup_{\pi} \sum_{i=1}^{n} \big(f(x_i) - f(x_{i-1}) \big)_-, \tag{1.2b}$$

where, for an arbitrary $\theta \in R$, θ_+ and θ_- denote the positive and negative parts of θ, i.e.,

$$\theta_+ = \frac{1}{2}(|\theta| + \theta), \qquad \theta_- = \frac{1}{2}(|\theta| - \theta). \tag{1.3}$$

The concept of bounded variation plays a key role in many important topics in the theory of functions [14], [22], [35], measure and integration [5], [6], [14], [26], partial differential equations [10], [20], [28], [29], numerical analysis [10], [11], [19], applied

mathematics [3], [18], [27], and other disciplines. It has been generalized with many fruitful applications to higher dimensions [9], [14], [20], [28], [33], [34], functions with values in normed or metric spaces and set-valued functions [1], [23], [24], [26], and more general notions such as pth-variations [31], [32], harmonic and Λ-variations [30], Φ-variations [21], [30], [32], and other classes of functions; see, e.g., [2], [7], and the recent literature. In this respect, e.g., we should observe that, taking into account [5, section 2.9], the results of the present paper can be carried over to mappings of bounded variation with values in a reflexive Banach space.

Our concern here is certain equivalent characterizations for the space $\mathrm{BV}(a,b)$. It is well known that any $f \in \mathrm{BV}(a,b)$ is bounded and has finite side limits $f(x^-)$, $f(x^+)$ at every $x \in \,]\, a,\, b\,[$; also, $f(a^+)$, $f(b^-)$ are well defined so that all discontinuities of f (if any) are simple and, by the finiteness of (1.1), are at most denumerable. Changing the value of $f \in \mathrm{BV}(a,b)$ at a single point may change its total variation; by the remarks just made, it is natural to assume that f has no external saltus, i.e., one has $f(a) = f(a^+)$, $f(b) = f(b^-)$, and

$$f(x) \;\in\; [\![\, f(x^-)\,,\, f(x^+)\,]\!] \qquad \forall\, x \,\in\,]\, a,\, b\,[, \tag{1.4}$$

where, for real α , β, $[\![\, \alpha, \beta\,]\!]$ denotes the smallest closed interval containing the points α, β, that is, $[\![\, \alpha, \beta\,]\!] = [\, \min(\alpha,\beta), \max(\alpha,\beta)\,]$. Following [22], we call $f \in \mathrm{BV}(a,b)$ *normal* if it has no external saltus on $[\, a,\, b\,]$. It is easy to see that if f, $g \in \mathrm{BV}(a,b)$ are equal a.e. and f is normal in the sense just given, then

$$\mathrm{TV}\,[\, f\,;\, a,b\,] \;\leq\; \mathrm{TV}\,[\, g\,;\, a,b\,] \tag{1.5}$$

and similarly for the positive and negative variations; moreover, if g is also normal on $[\, a,b\,]$, then these quantities are the same. This motivates the following definition: given an arbitrary f in the space $L^1(a,b)$ of Lebesgue measurable functions which are integrable on $[\, a,\, b\,]$, we say that f is of (essential) bounded variation on $[\, a,\, b\,]$ when there exists some $g \in \mathrm{BV}(a,b)$ such that $f = g$ a.e., and, modifying g if necessary so as to make g normal, the quantities $\mathrm{TV}\,[\, g\,;\, a,b\,]$, $\mathrm{PV}\,[\, g\,;\, a,b\,]$, $\mathrm{NV}\,[\, g\,;\, a,b\,]$ are said to be the *essential variations* of f, so that

$$\mathrm{TV}_{\mathrm{ess}}\,[\, f\,;\, a,b\,] \;=\; \mathrm{TV}\,[\, g\,;\, a,b\,] \tag{1.6}$$

when $f \;=\; g$ a.e. with $g \;\in\; \mathrm{BV}(a,b)$ normal; likewise, one has $\mathrm{PV}_{\mathrm{ess}}\,[\, f\,;\, a,b\,] \;=\; \mathrm{PV}\,[\, g\,;\, a,b\,]$ and $\mathrm{NV}_{\mathrm{ess}}\,[\, f\,;\, a,b\,] \;=\; \mathrm{NV}\,[\, g\,;\, a,b\,]$ in this case. This is equivalent to setting

$$\mathrm{TV}_{\mathrm{ess}}\,[\, f\,;\, a,b\,] \;=\; \inf_{\substack{u \,\in\, \mathrm{BV}(a,b) \\ u \,=\, f \;\; a.e.}} \mathrm{TV}\,[\, u\,;\, a,b\,] \tag{1.7}$$

and similarly for the essential positive and negative variations; other slightly different (but equivalent) characterizations are given in [2], [4], [12], [23]. Clearly, (1.6), (1.7) provide the appropriate notions when we do not want to distinguish functions which are equal a.e., as in the case of L^p spaces. In particular, it is convenient for the following well-known result. *Given $f \in L^1(a,b)$, the statements below are equivalent* *to one another:*

$$\mathrm{TV}_{\mathrm{ess}}\,[\,f\,;\,a,b\,]\;=\;C, \tag{1.8a}$$

$$\sup_{h>0}\;\frac{1}{h}\int_a^{b-h}|\,f(x+h)-f(x)\,|\,dx\;=\;C, \tag{1.8b}$$

$$\limsup_{h\to 0^+}\;\frac{1}{h}\int_a^{b-h}|\,f(x+h)-f(x)\,|\,dx\;=\;C, \tag{1.8c}$$

where C stands for a nonnegative quantity (possibly infinite). Other equivalent assertions can be found in, e.g., [4], [9], [20], [25], [26], [28], [34], but there will be no need of them here. The equivalence of (1.8a) and (1.8c) is the essence of the Hardy–Littlewood theorem [13]; see also [2], [23], [35], and section 3 below. It readily gives (1.8b) once we observe that

$$\frac{1}{h}\int_a^{b-h}|\,f(x+h)-f(x)\,|\,dx\;\leq\;\mathrm{TV}_{\mathrm{ess}}\,[\,f\,;\,a,b\,]\qquad\forall\;h>0. \tag{1.9}$$

We now state our main result: when C is finite, another statement equivalent to (1.8a), (1.8c) above is that

$$\lim_{h\to 0^+}\;\frac{1}{h}\int_a^{b-h}|\,f(x+h)-f(x)\,|\,dx\;=\;C. \tag{1.10}$$

In other words, given $f\in L^1(a,b)$, *whenever the limit superior given in* (1.8c) *is finite, the corresponding limit inferior has necessarily the same value*, so that the limit (1.10) is well defined. This will be established in section 3, along with other results which come naturally in the analysis. When f is absolutely continuous on $[\,a,b\,]$, these properties are easily obtained (see, e.g., [5], [25], [26]), and we find it convenient to review this case first, which forms the subject of section 2.

2. Absolutely continuous functions. We start the analysis with an important subclass of the space $\mathrm{BV}(a,b)$, namely, the space $AC(a,b)$ of absolutely continuous functions on $[\,a,b\,]$, i.e., integrals of functions in $L^1(a,b)$. These functions share a number of properties which are well known for mappings in $C^1([\,a,b\,])$, the space of continuously differentiable functions, as the following result illustrates. One should recall that an (arbitrary) function $\varphi\in\mathrm{BV}(a,b)$ of bounded variation has a finite derivative at almost every point in the interval concerned; moreover, its derivative φ' belongs to $L^1(a,b)$; see, e.g., [5], [6], [14], [17].

THEOREM 2.1. *Let $\varphi\in\mathrm{AC}(a,b)$. Then $\varphi\in\mathrm{BV}(a,b)$ and its total, positive, and negative variations on $[\,a,b\,]$* are given by

$$\mathrm{TV}\,[\,\varphi\,;\,a,b\,]\;=\;\int_a^b|\,\varphi'(x)\,|\,dx, \tag{2.1a}$$

$$\mathrm{PV}\,[\,\varphi\,;\,a,b\,]\;=\;\int_a^b\big(\,\varphi'(x)\,\big)_+\,dx, \tag{2.1b}$$

$$\mathrm{NV}\,[\,\varphi\,;\,a,b\,]\;=\;\int_a^b\big(\,\varphi'(x)\,\big)_-\,dx, \tag{2.1c}$$

where $\varphi' \in L^1(a,b)$ is the a.e. derivative of φ, and $(\cdot)_+$, $(\cdot)_-$ denote the positive and negative parts of $(\cdot)$; cf. (1.3).

Proof. For any partition $\{ x_0 < x_1 < \cdots < x_n \}$ of $[a,b]$, we have

$$\sum_{i=1}^{n} | \varphi(x_i) - \varphi(x_{i-1}) | = \sum_{i=1}^{n} \left| \int_{x_{i-1}}^{x_i} \varphi'(x)\, dx \right| \le \int_a^b | \varphi'(x) | \, dx$$

so that $\varphi \in \mathrm{BV}(a,b)$ and

$$\mathrm{TV}[\varphi;\, a,b] \le \int_a^b |\varphi'(x)|\, dx. \tag{2.2}$$

Similarly, using (1.3), we obtain

$$\mathrm{PV}[\varphi;\, a,b] \le \int_a^b \big(\varphi'(x)\big)_+ \, dx, \qquad \mathrm{NV}[\varphi;\, a,b] \le \int_a^b \big(\varphi'(x)\big)_- \, dx.$$

To show that equality holds, let (ψ_ℓ) be a sequence of smooth (C^1) functions compactly supported in $]\,a, b\,[$ (i.e., $\psi_\ell \in C_0^1(a,b)$) and such that

$$\| \psi_\ell - \varphi' \|_{L^1(a,b)} \to 0 \quad \text{as} \quad \ell \to \infty.$$

For each ℓ, we set

$$\varphi_\ell(x) = \varphi(a) + \int_a^x \psi_\ell(s)\, ds, \quad x \in [a,b].$$

Now, given $\varepsilon > 0$, let $L(\varepsilon) > 0$ be such that $\| \psi_\ell - \varphi' \|_{L^1(a,b)} \le \frac{\varepsilon}{2}$ for all $\ell \ge L(\varepsilon)$ and, for each ℓ, let $a = x_0^{(\ell)} < x_1^{(\ell)} < \cdots < x_{n_\ell}^{(\ell)} = b$ be chosen so that

$$\sum_{i=1}^{n_\ell} | \varphi_\ell(x_i^{(\ell)}) - \varphi_\ell(x_{i-1}^{(\ell)}) | \ge \mathrm{TV}[\varphi_\ell;\, a,b] - \frac{\varepsilon}{2}.$$

Then, for each $\ell \ge L(\varepsilon)$, we have

$$\begin{aligned}
\mathrm{TV}[\varphi_\ell;\, a,b] - \frac{\varepsilon}{2} &\le \sum_{i=1}^{n_\ell} \left| \int_{x_{i-1}^{(\ell)}}^{x_i^{(\ell)}} \varphi_\ell'(s)\, ds \right| \\
&\le \sum_{i=1}^{n_\ell} \left| \int_{x_{i-1}^{(\ell)}}^{x_i^{(\ell)}} \varphi'(s)\, ds \right| + \sum_{i=1}^{n_\ell} \left| \int_{x_{i-1}^{(\ell)}}^{x_i^{(\ell)}} \big(\psi_\ell(s) - \varphi'(s)\big)\, ds \right| \\
&\le \sum_{i=1}^{n_\ell} | \varphi(x_i^{(\ell)}) - \varphi(x_{i-1}^{(\ell)}) | + \sum_{i=1}^{n_\ell} \int_{x_{i-1}^{(\ell)}}^{x_i^{(\ell)}} | \psi_\ell(s) - \varphi'(s) |\, ds \\
&\le \mathrm{TV}[\varphi;\, a,b] + \| \psi_\ell - \varphi' \|_{L^1(a,b)}
\end{aligned}$$

so that

$$\mathrm{TV}\,[\,\varphi_\ell\,;\,a,b\,]\;-\;\frac{\varepsilon}{2}\;\le\;\mathrm{TV}\,[\,\varphi\,;\,a,b\,]\;+\;\|\,\psi_\ell\;-\;\varphi'\,\|_{L^1(a,b)}.$$

Hence, for every $\ell \ge L(\varepsilon)$, we have

$$\mathrm{TV}\,[\,\varphi\,;\,a,b\,]\;\ge\;\mathrm{TV}\,[\,\varphi_\ell\,;\,a,b\,]\;-\;\varepsilon, \tag{2.3}$$

and, because

$$\mathrm{TV}\,[\,\varphi_\ell\,;\,a,b\,]\to\int_a^b|\,\varphi'(s)\,|\,ds$$

as $\ell\to\infty$, in view of the fact that, due to the smoothness of φ_ℓ,

$$\mathrm{TV}\,[\,\varphi_\ell\,;\,a,b\,]\;=\;\int_a^b|\,\varphi_\ell'(s)\,|\,ds\;=\;\int_a^b|\,\psi_\ell(s)\,|\,ds,$$

we then obtain from (2.3) that

$$\mathrm{TV}\,[\,\varphi\,;\,a,b\,]\;\ge\;\int_a^b|\,\varphi'(s)\,|\,ds\;-\;\varepsilon.$$

Since $\varepsilon > 0$ is arbitrary, this gives (2.1a) if we recall (2.2). Finally, using (1.3), we derive (2.1b) and (2.1c) in an entirely similar way. □

It is interesting to note that the converse to Theorem 2.1 is also true, that is, given $\varphi \in \mathrm{BV}(a,b)$ such that (2.1a) holds, then φ must be absolutely continuous on $[\,a,b]$; see [5, p. 165]. To complete this section, we will now derive the property (1.10) for functions in $AC(a,b)$. Clearly, it will be sufficient to establish the following result.

Theorem 2.2. *Let* $\varphi \in \mathrm{AC}(a, b+h_0)$ *for some* $h_0 > 0$. *Then*

$$\mathrm{TV}\,[\,\varphi\,;\,a,b\,]\;=\;\lim_{h\to 0^+}\;\frac{1}{h}\int_a^b\big|\,\varphi(x+h)\;-\;\varphi(x)\,\big|\,dx, \tag{2.4a}$$

$$\mathrm{PV}\,[\,\varphi\,;\,a,b\,]\;=\;\lim_{h\to 0^+}\;\frac{1}{h}\int_a^b\big(\,\varphi(x+h)\;-\;\varphi(x)\,\big)_+\,dx, \tag{2.4b}$$

$$\mathrm{NV}\,[\,\varphi\,;\,a,b\,]\;=\;\lim_{h\to 0^+}\;\frac{1}{h}\int_a^b\big(\,\varphi(x+h)\;-\;\varphi(x)\,\big)_-\,dx. \tag{2.4c}$$

Proof. By Fatou's lemma [5], [6], we have

$$\liminf_{h\to 0^+}\;\frac{1}{h}\int_a^b\big|\,\varphi(x+h)\;-\;\varphi(x)\,\big|\,dx\;\ge\;\int_a^b|\,\varphi'(x)\,|\,dx$$

so that, by (2.1a) of the previous result, we obtain

$$\liminf_{h\to 0^+}\;\frac{1}{h}\int_a^b\big|\,\varphi(x+h)\;-\;\varphi(x)\,\big|\,dx\;\ge\;\mathrm{TV}\,[\,\varphi\,;\,a,b\,]. \tag{2.5}$$

On the other hand, since

$$\begin{aligned}\int_a^b \big|\,\varphi(x+h)\,-\,\varphi(x)\,\big|\,dx \;&\le\; \int_a^b \mathrm{TV}\,[\,\varphi\,;\,x,x+h\,]\,dx\\ &=\; \int_a^b \big(\,\mathrm{TV}\,[\,\varphi\,;\,a,x+h\,]\,-\,\mathrm{TV}\,[\,\varphi\,;\,a,x\,]\,\big)\,dx\\ &=\; \int_b^{b+h} \mathrm{TV}\,[\,\varphi\,;\,a,x\,]\,dx\,-\,\int_a^{a+h} \mathrm{TV}\,[\,\varphi\,;\,a,x\,]\,dx,\end{aligned}$$

we obtain

$$\int_a^b \big|\,\varphi(x+h)\,-\,\varphi(x)\,\big|\,dx \;\le\; \int_b^{b+h} \mathrm{TV}\,[\,\varphi\,;\,a,x\,]\,dx$$

so that

$$\limsup_{h\,\to\,0^+}\;\frac{1}{h}\int_a^b \big|\,\varphi(x+h)\,-\,\varphi(x)\,\big|\,dx \;\le\; \mathrm{TV}\,[\,\varphi\,;\,a,b\,]. \tag{2.6}$$

This, together with (2.5) above, gives (2.4a). Recalling (1.3), we obtain (2.4b), (2.4c) in a completely similar way. □

In what follows, we will show that (2.4a), (2.4c) are also valid for (normal) functions of bounded variation on some interval $[\,a,\,b+h_0\,]$ containing $[\,a,b\,]$. Note that this clearly gives (1.10) for functions in $\mathrm{BV}(a,b)$, as stated in the introduction.

3. Functions with bounded variation: General case. We now turn to the main results. Let $f\in\mathrm{BV}(a,b+h_0)$ for some $h_0>0$ be given, which we assume to be normal on every point of $[\,a,b\,]$, and let $\mathrm{TV}\,[\,f\,;\,a,b+\,]$ denote the right-side limit

$$\mathrm{TV}\,[\,f\,;\,a,b+\,]\;=\;\lim_{\varepsilon\,\to\,0^+}\mathrm{TV}\,[\,f\,;\,a,b+\varepsilon\,], \tag{3.1}$$

and similarly for $\mathrm{PV}\,[\,f\,;\,a,b+\,]$ and $\mathrm{NV}\,[\,f\,;\,a,b+\,]$; these limiting quantities are simply $\mathrm{TV}\,[\,f\,;\,a,b\,]$, $\mathrm{PV}\,[\,f\,;\,a,b\,]$, and $\mathrm{NV}\,[\,f\,;\,a,b\,]$, respectively, when f is right-continuous at the point b. With this notation, we now give the following generalization of Theorem 2.2 above.

THEOREM 3.1. *Let $f\in\mathrm{BV}(a,b+h_0)$ for some $h_0>0$ with f normal on $[\,a,b\,]$. Then*

$$\lim_{h\,\to\,0^+}\;\frac{1}{h}\int_a^b \big|\,f(x+h)\,-\,f(x)\,\big|\,dx \;=\; \mathrm{TV}\,[\,f\,;\,a,b+\,], \tag{3.2a}$$

$$\lim_{h\,\to\,0^+}\;\frac{1}{h}\int_a^b \big(\,f(x+h)\,-\,f(x)\,\big)_+\,dx \;=\; \mathrm{PV}\,[\,f\,;\,a,b+\,], \tag{3.2b}$$

$$\lim_{h\,\to\,0^+}\;\frac{1}{h}\int_a^b \big(\,f(x+h)\,-\,f(x)\,\big)_-\,dx \;=\; \mathrm{NV}\,[\,f\,;\,a,b+\,]. \tag{3.2c}$$

Proof. Starting with (3.2a), we have, as observed above,

$$\int_a^b |\,f(x+h)-f(x)\,|\,dx \;\le\; h\,\mathrm{TV}\,[\,f\,;\,a,b+h\,]$$

for all $h > 0$, $h < h_0$, so that we obtain

$$\limsup_{h \to 0^+} \frac{1}{h} \int_a^b |\, f(x+h) - f(x)\,|\, dx \;\leq\; \mathrm{TV}\,[\, f\,;\, a, b+]. \tag{3.3}$$

To finish the argument, it remains to show that

$$\liminf_{h \to 0^+} \frac{1}{h} \int_a^b \big|\, f(x+h) - f(x)\,\big|\, dx \;\geq\; \mathrm{TV}\,[\, f\,;\, a, b+]. \tag{3.4}$$

For convenience, let us assume from now on that f is right-continuous at b, since setting $f(b) = f(b^+)$ does not change the values of the integrals above or the normality of f on $[\,a, b\,]$. We may then proceed as follows. Given $h > 0$, $h < h_0$, set $a_j^h \equiv a + jh$ for each $j = 0, 1, 2, \ldots$, and let $J = J_h$ be the value of j such that $a_{J-1}^h < b$ and $a_J^h \geq b$. For every $j = 1, 2, \ldots, J_h$, we divide the interval $[\,a_{j-1}^h, a_j^h\,]$ in $K \geq 1$ subintervals $[\,x_j^{k-1}, x_j^k\,]$, $1 \leq k \leq K$, where

$$x_j^k \;=\; a_{j-1}^h \,+\, k\,\frac{h}{K}.$$

We then have, as $K \to \infty$,

$$\sum_{j=1}^{J_h} \frac{1}{K} \sum_{k=1}^{K} |\, f(x_j^k + h) - f(x_j^k)\,| \;\overset{K\to\infty}{\longrightarrow}\; \frac{1}{h} \int_a^{a_{J_h}^h} \big|\, f(x+h) - f(x)\,\big|\, dx.$$

On the other hand,

$$\begin{aligned}
\frac{1}{h} \int_a^{a_{J_h}^h} \big|\, f(x+h) - f(x)\,\big|\, dx &= \sum_{j=1}^{J_h} \lim_{K\to\infty} \frac{1}{K} \sum_{k=1}^{K} \big|\, f(x_{j+1}^k) - f(x_j^k)\,\big| \\
&\geq \sum_{j=1}^{J_h} \lim_{K\to\infty} \left|\, \frac{1}{K} \sum_{k=1}^{K} f(x_{j+1}^k) \;-\; \frac{1}{K} \sum_{k=1}^{K} f(x_j^k) \,\right| \\
&= \sum_{j=1}^{J_h} \left|\, M_{j+1}^h - M_j^h \,\right|,
\end{aligned}$$

where, for each $j = 1, 2, \ldots, J_h, J_h + 1, \ldots$, we set M_j^h to be the average values

$$M_j^h \;\equiv\; \frac{1}{h} \int_{a_{j-1}^h}^{a_j^h} f(x)\, dx\ .$$

In particular, defining $\mathcal{M}_h[\,f\,] : [\,a, b + h_0 - h\,] \mapsto R$ by putting, for $j = 1, 2, \ldots, J_h$, $J_h + 1, \ldots$, the values

$$\mathcal{M}_h[\,f\,](x) \;=\; \begin{cases} M_j^h & \text{if} \quad a_{j-1}^h < x < a_j^h, \\[2ex] \dfrac{M_j^h + M_{j+1}^h}{2} & \text{if} \quad x = a_j^h \end{cases}$$

and $\mathcal{M}_h[\,f\,](a) = M_1^h$, we get

$$\frac{1}{h}\int_a^{a^h_{J_h}} \big|\, f(x+h) - f(x)\,\big|\, dx \;\;\geq\;\; \mathrm{TV}\,[\,\mathcal{M}_h[\,f\,]\,;\, a, a^h_{J_h}+]. \tag{3.5}$$

Thus, (3.4) will be obtained if we show that

$$\liminf_{h\to 0^+}\; \mathrm{TV}\,[\,\mathcal{M}_h[\,f\,]\,;\, a, a^h_{J_h}+] \;\;\geq\;\; \mathrm{TV}\,[\,f\,;\, a, b+], \tag{3.6}$$

and this can be done as follows. Given $\eta > 0$ arbitrary, let $a = x_0 < x_1 < \cdots < x_{N-1} < x_N = b$ be such that

$$\text{(i)}\qquad \sum_{j=1}^{N} \big|\, f(x_j) - f(x_{j-1})\,\big| \;\;\geq\;\; \mathrm{TV}\,[\,f\,; a, b\,] \;-\; \eta,$$

$$\text{(ii)}\qquad f(b^-) \;-\; \eta \;\;\leq\;\; f(x) \;\;\leq\;\; f(b^-) \;+\; \eta \qquad \forall\, x \,\in\, [\,x_{N-1}, b\,[\;\;.$$

Since f is normal on $[\,a, b\,]$, we may also assume that

$$\text{(iii)}\qquad f \;\text{ is continuous at }\; x_1, x_2, \ldots, x_{N-1}.$$

Let then $\delta > 0$ be such that

$$\text{(iv)}\qquad f(x_j) \;-\; \frac{\eta}{N} \;\;\leq\;\; f(x) \;\;\leq\;\; f(x_j) \;+\; \frac{\eta}{N} \qquad \text{for each }\; x \,\in\, [\,x_j - \delta,\; x_j + \delta\,]$$

for every $j = 1, 2, \ldots, N-1$, and

$$\text{(v)}\qquad f(a) \;-\; \frac{\eta}{N} \;\;\leq\;\; f(x) \;\;\leq\;\; f(a) \;+\; \frac{\eta}{N} \qquad \text{for every }\; x \,\in\,]\,a,\; a+\delta\,],$$

$$\text{(vi)}\qquad f(b) \;-\; \frac{\eta}{N} \;\;\leq\;\; f(x) \;\;\leq\;\; f(b) \;+\; \frac{\eta}{N} \qquad \text{for every }\; x \,\in\,]\,b,\; b+2\,\delta\,],$$

$$\text{(vii)}\qquad \delta \;\;\leq\;\; \frac{b - x_{N-1}}{2}.$$

In particular, we get

$$\text{(a)}\qquad \mathcal{M}_h[\,f\,](x_j) \,\in\, \Big[\, f(x_j) - \frac{\eta}{N}\,,\; f(x_j) + \frac{\eta}{N}\,\Big] \quad \text{for }\; j = 1, 2, \ldots, N-1,$$

$$\text{(b)}\qquad \mathcal{M}_h[\,f\,](a) \,\in\, \Big[\, f(a) - \frac{\eta}{N}\,,\; f(a) + \frac{\eta}{N}\,\Big],$$

$$\text{(c)}\qquad \mathcal{M}_h[\,f\,]\bigg(a^h_{J_h} + \frac{h}{2}\bigg) \,\in\, \Big[\, f(b) - \frac{\eta}{N}\,,\; f(b) + \frac{\eta}{N}\,\Big],$$

and, by (ii), (iv), and (vi),

$$\text{(d)}\qquad \mathcal{M}_h[\,f\,](x_{N-1}) \,\in\, \Big[\, f(b^-) - \eta - \frac{\eta}{N}\,, f(b^-) + \eta + \frac{\eta}{N}\Big],$$

so that, for each $j = 1, 2, \ldots, N-1$,

$$\left|\, \mathcal{M}_h[\,f\,](x_j) \,-\, \mathcal{M}_h[\,f\,](x_{j-1}) \,\right| \;\geq\; \left|\, f(x_j) \,-\, f(x_{j-1}) \,\right| - \frac{2\,\eta}{N}$$

and

$$\left|\mathcal{M}_h[\,f\,]\left(a^h_{J_h} + \frac{h}{2}\right) - \mathcal{M}_h[\,f\,](x_{N-1})\right| \;\geq\; \left|\, f(x_N) \,-\, f(x_{N-1}) \,\right| - \frac{2\,\eta}{N} - \eta.$$

Hence, we obtain

$$\begin{aligned} &\mathrm{TV}\,[\,\mathcal{M}_h[\,f\,]\,;\, a, a^h_{J_h}+] \\ &\geq \left|\mathcal{M}_h[\,f\,]\left(a^h_{J_h} + \frac{h}{2}\right) - \mathcal{M}_h[\,f\,](x_{N-1})\right| + \sum_{j=1}^{N-1} \left|\, \mathcal{M}_h[\,f\,](x_j) \,-\, \mathcal{M}_h[\,f\,](x_{j-1}) \,\right| \\ &\geq \sum_{j=1}^{N} \left|\, f(x_j) \,-\, f(x_{j-1}) \,\right| \,-\, 3\,\eta\;, \end{aligned}$$

so that

$$\mathrm{TV}\,[\,\mathcal{M}_h[\,f\,]\,;\, a, a^h_{J_h}+] \;\geq\; \mathrm{TV}\,[\,f\,; a, b\,] \,-\, 4\,\eta$$

in view of (i). Since $\eta > 0$ is arbitrary, we then obtain

$$\liminf_{h \to 0^+} \, \mathrm{TV}\,[\,\mathcal{M}_h[\,f\,]\,;\, a, a^h_{J_h}+] \;\geq\; \mathrm{TV}\,[\,f\,;\, a, b\,],$$

which concludes the derivation of (3.6). Recalling (3.5), this gives (3.4). Finally, using (1.3), the inequalities (3.2b), (3.2c) are proved in a similar way. □

Clearly, this result establishes (1.10) at once. An easy way to see this is as follows: Given $f \in \mathrm{BV}(a,b)$, we extend it to $[\,a, +\infty\,[$ by setting $f(x) = f(b^-)$ for all $x > b$, and we redefine f on $[\,a, b\,]$ if necessary so that it be normal everywhere. Writing the integral in (3.2a) as a sum of two integrals corresponding to the intervals $[\,a, b-h\,]$ and $[\,b-h, b\,]$, we immediately get (1.10) from the limit (3.2a) and the fact that

$$\frac{1}{h} \int_{b-h}^{b} \left|\, f(x+h) - f(x) \,\right| dx \;\to\; 0 \qquad \text{as} \quad h \;\to\; 0$$

due to the continuity of f at the point b. Doing the same with the integrals (3.2b) and (3.2c), we then obtain the following result.

THEOREM 3.2. *Let $f \in \mathrm{BV}(a,b)$ be normal on $[\,a, b\,]$. Then*

$$\lim_{h \to 0^+} \frac{1}{h} \int_a^{b-h} \left|\, f(x+h) \,-\, f(x) \,\right| dx \;=\; \mathrm{TV}\,[\,f\,;\, a, b\,], \tag{3.7a}$$

$$\lim_{h \to 0^+} \frac{1}{h} \int_a^{b-h} \big(\, f(x+h) \,-\, f(x) \,\big)_+ \, dx \;=\; \mathrm{PV}\,[\,f\,;\, a, b\,], \tag{3.7b}$$

$$\lim_{h \to 0^+} \frac{1}{h} \int_a^{b-h} \big(\, f(x+h) \,-\, f(x) \,\big)_- \, dx \;=\; \mathrm{NV}\,[\,f\,;\, a, b\,]. \tag{3.7c}$$

As stated in the introduction, there is a converse to the result above, which we formulate as the following well-known property; see, e.g., [2], [13], [23], [35].

Theorem 3.3. *Let $f \in L^1(a,b)$ be such that*

$$\limsup_{h \to 0^+} \frac{1}{h} \int_a^{b-h} \big|\, f(x+h) - f(x) \,\big| \, dx \;=\; C \;<\; \infty. \tag{3.8}$$

Then f is of essential bounded variation on $[\,a,b\,]$ and $\mathrm{TV}_{ess}\,[\,f\,;\,a,b\,] \,=\, C$.

Proof. For the sake of completeness, we will provide a quick derivation of this result along the lines of the proof given in [2]; see also [8] for an alternative argument.

For each integer $n \geq 1$, let $h = (b-a)/n$ and $a_j^h = a + jh$, $0 \leq j \leq n$. We then construct the step function $\mathcal{M}_h[\,f\,] \in \mathrm{BV}(a,b)$ as in the proof of Theorem 3.1, i.e., we set

$$\mathcal{M}_h[\,f\,](x) \;=\; M_j^h \;=\; \frac{1}{h} \int_{a_{j-1}^h}^{a_j^h} f(s)\,ds \qquad \text{if} \quad a_{j-1}^h \,<\, x \,<\, a_j^h$$

for $j = 1, 2, \ldots, n$, extending it to the nodal points $\{\, a_0^h,\, a_1^h,\, \ldots\, , a_n^h \,\}$ in any way so as to become normal everywhere on $[\,a,b\,]$. Then

$$\mathrm{TV}\,[\,\mathcal{M}_h[\,f\,]\,;\,a,b\,] \;=\; \sum_{j=1}^{n} \big|\, M_j^h - M_{j-1}^h \,\big| \;\leq\; \frac{1}{h} \int_a^b \big|\, f(x+h) - f(x) \,\big| \, dx$$

so that, by (3.8), we obtain

$$\limsup_{h \to 0^+} \; \mathrm{TV}\,[\,\mathcal{M}_h[\,f\,]\,;\,a,b\,] \;\leq\; C, \tag{3.9}$$

from which we get that the total variation on $[\,a,b\,]$ of the family of functions $\mathcal{M}_h[\,f\,]$ is uniformly bounded as $h \,\to\, 0^+$. Moreover, it is well known that

$$\|\, \mathcal{M}_h[\,f\,] \,-\, f \,\|_{L^1(a,b)} \;\to\; 0 \tag{3.10}$$

as $h \,\to\, 0^+$; see, e.g., [2, Lemma 1.2.2]. This implies that some subsequence of the functions $\mathcal{M}_h[\,f\,]$ must converge pointwise to f a.e. on $[\,a,b\,]$ as $h \,\to\, 0^+$, say the sequence $\mathcal{M}_{h'}[\,f\,]$, and, because of (3.9), these functions $\mathcal{M}_{h'}[\,f\,]$ are then uniformly bounded on $[\,a,b\,]$. Thus, we can apply Helly's principle [22] and select a subsequence of $\mathcal{M}_{h'}[\,f\,]$, say $\mathcal{M}_{h''}[\,f\,]$, which converges pointwise to some function $g \in \mathrm{TV}(a,b)$ everywhere on $[\,a,b\,]$ as $h \to 0^+$. From (3.9), we immediately obtain that $\mathrm{TV}\,[\,g\,;\,a,b\,] \leq C$, while we also have $f = g$ a.e. on $[\,a,b\,]$ because of (3.10)—in fact, f is the a.e. pointwise limit of the whole sequence $\mathcal{M}_{h'}[\,f\,]$ as $h \to 0^+$. This is still true if we redefine g on $[\,a,b\,]$ so that it be normal everywhere on this interval. Now, from Theorem 3.2 and (3.8), we then have

$$\mathrm{TV}\,[\,g\,;\,a,b\,] \;=\; \lim_{h \to 0^+} \; \frac{1}{h} \int_a^{b-h} \big|\, g(x+h) - g(x) \,\big| \, dx \;=\; C,$$

since $g = f$ a.e. on $[\,a,b\,]$. This gives $\mathrm{TV}_{\mathrm{ess}}\,[\,f\,;\,a,b\,] \,=\, C$, as stated. $\square$

In fact, the proof given above establishes more, if we only recall Theorem 3.2. Given $f \in L^1(a,b)$ satisfying the condition (3.8), it follows that

$$\text{(3.11a)} \qquad \mathrm{TV}_{\mathrm{ess}}\,[\,f\,;\,a,b\,] \;=\; \lim_{h \to 0^+} \frac{1}{h} \int_a^{b-h} \big|\, f(x+h) - f(x) \,\big| \, dx,$$

$$\text{(3.11b)} \qquad \mathrm{PV}_{\mathrm{ess}}\,[\,f\,;\,a,b\,] \;=\; \lim_{h \to 0^+} \frac{1}{h} \int_a^{b-h} \big(\, f(x+h) - f(x) \,\big)_+ \, dx,$$

$$\text{(3.11c)} \qquad \mathrm{NV}_{\mathrm{ess}}\,[\,f\,;\,a,b\,] \;=\; \lim_{h \to 0^+} \frac{1}{h} \int_a^{b-h} \big(\, f(x+h) - f(x) \,\big)_- \, dx.$$

A note of caution should be given here. Given $f \in L^1(a, b + h_0)$ for some $h_0 > 0$, we observe that the property

$$\text{(3.12)} \qquad \limsup_{h \to 0^+} \frac{1}{h} \int_a^{b} \big|\, f(x+h) - f(x) \,\big| \, dx \;=\; C \;<\; \infty$$

does *not* imply that $\mathrm{TV}_{\mathrm{ess}}\,[\,f\,;\,a, b+\,] \,=\, C$ or the existence of the limit

$$\text{(3.13)} \qquad \lim_{h \to 0^+} \frac{1}{h} \int_a^{b} \big|\, f(x+h) - f(x) \,\big| \, dx \;=\; C.$$

We can ascertain from (3.12) only that f is of essential bounded variation on $[\,a,b\,]$ and that (3.11a), (3.11c) hold. In fact, the following example will illustrate this. Taking $0 < \varepsilon < 1$ and setting

$$\text{(3.14a)} \qquad f(x) \;=\; \begin{cases} 1 & \text{if} \quad \varepsilon^n \dfrac{1+\varepsilon}{1-\varepsilon} \;\le\; x \;\le\; \varepsilon^n \dfrac{2}{1-\varepsilon} \quad \text{for some } n \,\ge\, 1, \\[2ex] 0 & \text{otherwise,} \end{cases}$$

we obtain $f \in L^1(-1,1) \cap \mathrm{BV}(-1,0)$ with $\mathrm{TV}_{\mathrm{ess}}\,[\,f\,;\,-1\,,\,0+\,] = \infty$, and

$$\text{(3.14b)} \qquad \limsup_{h \to 0^+} \frac{1}{h} \int_{-1}^{0} \big|\, f(x+h) - f(x) \,\big| \, dx \;=\; \frac{1}{2}$$

while

$$\text{(3.14c)} \qquad \liminf_{h \to 0^+} \frac{1}{h} \int_{-1}^{0} \big|\, f(x+h) - f(x) \,\big| \, dx \;=\; \frac{\varepsilon}{1+\varepsilon} \;<\; \frac{1}{2}.$$

We conclude this discussion with one final remark. The results given above have been stated in terms of the differences $f(x+h) - f(x)$, but of course could have been written in terms of $f(x) - f(x-h)$ instead, with only some minor obvious changes in the statements or the analysis. Thus, for example, Theorem 3.1 could have been given as follows: given $f \in \mathrm{BV}(a - h_0, b)$ for some $h_0 > 0$,

$$\text{(3.15)} \qquad \lim_{h \to 0^+} \frac{1}{h} \int_a^{b} \big|\, f(x) - f(x-h) \,\big| \, dx \;=\; \mathrm{TV}_{\mathrm{ess}}\,[\,f\,;\,a-\,,b\,],$$

where

$$\mathrm{TV}_{\mathrm{ess}}\,[\,f\,;\,a-\,,b\,] \;=\; \lim_{\varepsilon \to 0^+} \mathrm{TV}_{\mathrm{ess}}\,[\,f\,;\,a-\varepsilon\,,b\,]$$

and similarly for the other left-side limits $\mathrm{PV}_{\mathrm{ess}}\,[\,f\,;\,a-\,,b\,]$ and $\mathrm{NV}_{\mathrm{ess}}\,[\,f\,;\,a-\,,b\,]$.

ON THE STOCHASTIC EULER EQUATIONS IN A TWO-DIMENSIONAL DOMAIN[*]

JONG UHN KIM[†]

Abstract. In this paper, we discuss an initial-boundary value problem associated with the Euler equations with a random noise in a simply connected two-dimensional bounded domain. We present two different results according to the space regularity of the random noise. When the random noise is regular in the space variables, we prove the existence of a unique solution as a Banach space-valued continuous stochastic process. If the noise is less regular in the space variables, we establish the existence of solutions defined over a given probability space under the assumption that the noise is given in terms of a standard Brownian motion.

Key words. Euler equations, vorticity, existence, pathwise solutions, measurability, Brownian motion

Introduction. In this paper we will discuss an initial-boundary value problem for the Euler equations with a random noise in a two-dimensional simply connected domain. The problem is formulated as follows:

$$\frac{\partial u}{\partial t} + u \cdot \nabla u + \nabla p = \frac{\partial W}{\partial t} \qquad \text{for } (t,x) \in (0,T) \times G, \tag{0.1}$$

$$\nabla \cdot u = 0 \qquad \text{for } (t,x) \in (0,T) \times G, \tag{0.2}$$

$$u \cdot n = 0 \qquad \text{for } (t,x) \in [0,T] \times \partial G, \tag{0.3}$$

$$u(0,x) = u_0(x) \qquad \text{for } x \in G, \tag{0.4}$$

where $u = (u_1, u_2)$ is the velocity vector, p is the pressure, G is a simply connected bounded domain in R^2 with smooth boundary ∂G, and $u \cdot n$ stands for the normal component of u on ∂G. The right-hand side of (0.1) represents an external random noise. A Wiener process with values in a Hilbert space is a typical example for W.

The deterministic Euler equations have been extensively investigated. For a complete survey of known results for the deterministic Euler equations, see Lions [8] and references therein. We will recall only the results on the existence of solutions that are directly relevant to our investigation. The fundamental result on the existence and uniqueness of solutions for a two-dimensional domain is due to Yudovich [12]. The approach in [12] is to start with the vorticity equation in terms of the stream function. By the method of parabolic regularization, the existence of vorticity was established with the L^∞-estimate. This leads to the existence and uniqueness of the velocity vector. The case of a simply connected domain was analyzed first, and the analysis was extended to a multiply connected domain by introducing some auxiliary functions. Bardos [1] employed a different approach for a similar result. The method of [1] is to approximate the Euler equations directly by the Navier–Stokes equations

with special boundary conditions. The solution of the Euler equations was obtained as the zero viscosity limit. The method does not require geometric conditions on the space domain other than some smoothness of the boundary.

For the stochastic Euler equations, there are rather a limited number of results that include Bessaih [3], Bessaih and Flandoli [4], Brzezniak and Peszat [5], Capinski and Cutland [6], and Mikulevicius and Valiukevicius [9]. These works present results on the existence of solutions, which are different from each other. In particular, the issues raised in [4] have motivated our work. They [4] used the same approximation scheme as in [1] for the proof of existence. In fact, they could have relaxed regularity conditions on W in the space variables for the uniqueness of solutions if the viscosity term had been modified to contain W. But the boundary conditions are still required. This is due to the introduction of the viscosity term in (0.1). Here we propose to use a different method in the case of a simply connected domain. We will mainly work with the vorticity equation as in [12], but our approximation scheme is different. By virtue of this new scheme, we cannot only relax conditions on the regularity of $W(t,x)$ in the space variables x but also dispense with any boundary condition on W for the existence and uniqueness of solutions. One could imitate the procedure in [12] with some modification for the existence of solutions. But then the measurability of solutions as random variables is difficult to come by because a fixed point theorem was used. For a multiply connected domain, we can modify the system of approximate equations to include several unknown scalar functions corresponding to the inner boundaries following the idea of [12], and proceed in the same way as in the case of a simply connected domain. But the analysis will be far more lengthy, and we will not pursue this.

We will also discuss the case where W is less regular in the space variables and the solution is not known to be unique. This is the case where martingale solutions were obtained in [3]. Our goal is to find solutions over a given probability space with less regular W. We will show that this is possible if W is given in terms of a standard Brownian motion. When W is less regular in the space variables, we can still obtain pathwise solutions. But the uniqueness of solution is not known, and this causes difficulty in the measurability of pathwise solutions. For the stochastic Navier–Stokes equations, Bensoussan and Temam [2] overcame this difficulty by making a special assumption on the probability space and using a selection theorem. Here we use a general probability space, but W has to be expressed in terms of a Brownian motion. We will first work on the completion of the canonical probability space, from which the general case follows. Our crucial tool is a selection theorem proved in [2]. However, our approach is quite different because of insufficient regularity of W in the space variables. In fact, our procedure can relax the regularity condition on the example (3.38) in [2].

Our results are stated in section 1 and proved in sections 2 and 3.

1. Notation and statement of the results.

Throughout this paper, $T > 0$ is a given positive number, G is a simply connected bounded domain in R^2 with smooth boundary ∂G, and $H^\alpha(G)$ denotes the usual Sobolev space of order $\alpha \in R$. We will use the same notation for both vector-valued function classes and scalar-valued function classes. The function spaces $\mathcal{V}$ and $\mathcal{H}$ are defined by

$$\mathcal{V} = \big\{ f = (f_1, f_2) \,\big|\, f \in H^1(G),\ \nabla \cdot f = 0 \text{ in } G, \text{and } f \cdot n = 0 \text{ on } \partial G \big\},$$

$$\mathcal{H} = \big\{ f = (f_1, f_2) \,\big|\, f \in L^2(G),\ \nabla \cdot f = 0 \text{ in } G, \text{and } f \cdot n = 0 \text{ on } \partial G \big\}.$$

We will also use the notation $\nabla \times f = \partial f_2/\partial x_1 - \partial f_1/\partial x_2$.

$(\Omega, \mathcal{F}, \mathcal{F}_t, P)$ is a given stochastic basis, where P is a probability measure, $\mathcal{F}$ is a σ-algebra, and $\{\mathcal{F}_t\}_{t\geq 0}$ is a right-continuous filtration on $(\Omega, \mathcal{F})$ such that $\mathcal{F}_0$ contains all P-negligible subsets. When $\mathcal{X}$ is a metric space, the mapping $f : \Omega \to \mathcal{X}$ is said to be $\mathcal{X}$-valued $\mathcal{F}$-measurable if $f^{-1}(\mathcal{O}) \in \mathcal{F}$ for every open subset $\mathcal{O} \subset \mathcal{X}$.

We will present two results under different assumptions.

1.1. The first result. We suppose that the random vector function $W = (W_1(t,x;\omega), W_2(t,x;\omega))$ satisfies the following conditions:

$$\text{For } P\text{-almost all } \omega \in \Omega,\ W(\cdot,\cdot\,;\omega) \in C([0,T]; H^{3+\alpha}(G)) \text{ for some } \alpha > 0. \tag{1.1}$$

$$\text{For each } t \in [0,T],\ W(t,\cdot\,;\cdot) \text{ is } H^{3+\alpha}(G)\text{-valued } \mathcal{F}_t\text{-measurable.} \tag{1.2}$$

Definition 1.1. *A random function $u(t,x;\omega)$ is said to be a solution of* (0.1)–(0.4) *if u is a $\mathcal{V}$-valued continuous stochastic process adapted to $\{\mathcal{F}_t\}_{0\leq t\leq T}$, and for P-almost all ω,* (0.1) *is satisfied with some distribution p in the sense of distribution over $(0,T)\times G$ and* (0.4) *holds.*

Under the above assumptions, our result is the following.

Theorem 1.2. *Suppose u_0 is $\mathcal{V}$-valued $\mathcal{F}_0$-measurable such that $\nabla \times u_0(\cdot\,;\omega) \in L^\infty(G)$ for P-almost all ω. Then, there is a unique solution to* (0.1)–(0.4).

Here uniqueness means pathwise uniqueness, and Definition 1.1 is used only for Theorem 1.2.

1.2. The second result.

1.2.1. A general probability space. We assume that W is given by

$$W(t,x;\omega) = g(x)B_t(\omega), \tag{1.3}$$

where g is R^2-valued and belongs to $H^1(G)$, and $B_t(\cdot)$ is a standard one-dimensional Brownian motion over $(\Omega, \mathcal{F}, \mathcal{F}_t, P)$.

Theorem 1.3. *Suppose u_0 is deterministic and belongs to $\mathcal{V}$. Let $\delta \in (1/2, 0)$. Then, there is a random function u defined over Ω such that u is $L^2(0,T;\mathcal{V}) \cap C([0,T]; \mathcal{H}\cap H^\delta(G))$-valued $\mathcal{F}$-measurable and such that* (0.1)–(0.4) *are satisfied with some distribution p for P-almost all ω.*

This result will be first proved in the following special case.

1.2.2. The canonical probability space. Here we choose $\Omega = C([0,\infty))$, which is a Polish space under a standard metric. Let $\mathcal{B}(\Omega)$ be the σ-algebra of all Borel subsets of $C([0,\infty))$. Let P be the Wiener measure on $(\Omega, \mathcal{B}(\Omega))$ such that the coordinate mapping process

$$X_t : \omega \mapsto \omega(t) \tag{1.4}$$

is the standard Brownian motion under P. Then, $\big(\Omega,\, \mathcal{B}(\Omega), P\big)$ is called the canonical probability space. Following Karatzas and Shreve [7], we define

$$\mathcal{N} = \left\{ A \subset \Omega \,\middle|\, \text{there is a } B \in \mathcal{B}(\Omega) \text{ with } A \subset B \text{ and } P(B) = 0 \right\}, \tag{1.5}$$

$$\mathcal{F}_t = \text{the } \sigma\text{-algebra generated by } X_s,\ 0 \leq s \leq t, \text{ and } \mathcal{N}, \tag{1.6}$$

$$\mathcal{F} = \text{the completion of } \mathcal{B}(\Omega) \text{ under } P. \tag{1.7}$$

Then, $\{\mathcal{F}_t\}$ is a right-continuous filtration on $(\Omega, \mathcal{F})$ (see [7, p. 90]), and $\mathcal{F}_0$ contains all P-negligible subsets. Furthermore, X_t is again a Brownian motion on $(\Omega, \mathcal{F}, \mathcal{F}_t, P)$. We assume that

$$W(t,x;\omega) = g(x)X_t(\omega), \tag{1.8}$$

where g is R^2-valued and belongs to $H^1(G)$.

2. Proof of Theorem 1.2. We first choose a $\mathcal{F}_0$-measurable set $\tilde{\Omega} \subset \Omega$ with $P(\tilde{\Omega}) = 1$ such that for each $\omega \in \tilde{\Omega}$, $W(\cdot,\, \cdot;\omega) \in C([0,T]; H^{3+\alpha}(G))$, $\nabla \times u_0(\cdot\,;\omega) \in L^\infty(G)$, and $u_0(\cdot\,;\omega) \in \mathcal{V}$ hold. We consider the following initial-boundary value problem for a scalar random function $\zeta_\epsilon(t,x;\omega)$ with parameter $\epsilon > 0$:

$$\frac{\partial \zeta_\epsilon}{\partial t} + (\nabla^\perp \Psi_\epsilon)\cdot\nabla\zeta_\epsilon = -(\nabla^\perp\Psi_\epsilon)\cdot\nabla(\nabla\times W_\epsilon(t,x;\omega)) \quad \text{for } (t,x) \in (0,T)\times G, \tag{2.1}$$

$$\zeta_\epsilon(0,x;\omega) = \nabla\times u_{0,\epsilon}(x;\omega) - \nabla\times W_\epsilon(0,x;\omega) \quad \text{for } x \in G, \tag{2.2}$$

where $\nabla^\perp = (\partial/\partial x_2, -\partial/\partial x_1)$, and Ψ_ϵ is the solution of

$$\begin{cases} -(1-\epsilon\Delta)\Delta\Psi_\epsilon = \zeta_\epsilon + \nabla\times W_\epsilon(t,\cdot;\omega) \quad \text{in } G, \\ \Psi_\epsilon = \Delta\Psi_\epsilon = 0, \quad \text{on } \partial G. \end{cases} \tag{2.3}$$

Equation (2.1) is a regularized vorticity equation. Here W_ϵ is defined by

$$W_\epsilon = r_G\left((\mathcal{L}W)\star\rho_\epsilon\right), \tag{2.4}$$

where r_G denotes restriction to G, $\mathcal{L}$ is a continuous extension: $H^{3+\alpha}(G) \to H^{3+\alpha}(R^2)$ such that $r_G\,\mathcal{L}h = h$ for all $h \in H^{3+\alpha}(G)$, and ρ_ϵ is the Friedrichs mollifier. For $\mathcal{L}$, it is sufficient that ∂G is C^m-smooth with $m \geq 3+\alpha$. The convolution is taken with respect to the space variables $x \in R^2$. Then, for each $\omega \in \tilde{\Omega}$, $W_\epsilon \in C([0,T]; C^3(\overline{G}))$ and

$$W_\epsilon \to W \text{ strongly in } C([0,T]; H^{3+\alpha}(G)) \text{ as } \epsilon \to 0. \tag{2.5}$$

In the meantime, $u_{0,\epsilon}$ in (2.2) is an approximation of u_0 such that $u_{0,\epsilon} \in C^2(\overline{G}) \cap \mathcal{V}$ and, for each $\omega \in \tilde{\Omega}$, as $\epsilon \to 0$,

$$\nabla\times u_{0,\epsilon} \;\to\; \nabla\times u_0 \qquad \begin{cases} \text{weak-star in } L^\infty(G), \\ \text{strongly in } L^2(G). \end{cases} \tag{2.6}$$

We will sketch a procedure to construct such approximations. Let us define

$$h(x;\omega) = \begin{cases} \nabla\times u_0(x;\omega) \quad \text{for } x \in G, \\ 0 \quad \text{for } x \notin G \end{cases} \tag{2.7}$$

and

$$h_\epsilon = \rho_\epsilon \star h. \tag{2.8}$$

Then $h_\epsilon \in C^\infty(R^2)$, and as $\epsilon \to 0$, $h_\epsilon \to h$ weak-star in $L^\infty(G)$ and strongly in $L^2(R^2)$ for each $\omega \in \tilde{\Omega}$. We then find Φ_ϵ satisfying

$$\begin{cases} -\Delta\Phi_\epsilon = h_\epsilon \quad \text{in } G, \\ \Phi_\epsilon = 0 \quad \text{on } \partial G. \end{cases} \tag{2.9}$$

We now choose $u_{0,\epsilon} = \nabla^{\perp}\Phi_{\epsilon}$. Since $h_{\epsilon} \in C^{\infty}(\overline{G})$, it follows that $\Phi_{\epsilon} \in C^{\infty}(\overline{G})$. We also note that $\nabla \times (\nabla^{\perp}\Phi_{\epsilon}) = -\Delta\Phi_{\epsilon} = h_{\epsilon}$ in G and that $n \cdot \nabla^{\perp}\Phi_{\epsilon} = \partial\Phi_{\epsilon}/\partial s = 0$ on ∂G. Here n is a normal vector and $\partial/\partial s$ is tangential differentiation on ∂G. Hence, $u_{0,\epsilon}$ satisfies all the required properties.

LEMMA 2.1. *For each $\omega \in \tilde{\Omega}$, there is a unique solution $\zeta_{\epsilon}(\cdot\,,\cdot\,;\omega) \in C^1([0,T] \times \overline{G})$ of (2.1)–(2.3). Furthermore, for each $0 < s \leq T$, $\zeta_{\epsilon}(s,\cdot)$ is $L^2(G)$-valued $\mathcal{F}_s$-measurable, and it holds that*

$$\|\zeta_{\epsilon}\|_{C([0,T]\times\overline{G})} \leq M(\omega), \tag{2.10}$$

$$\left\|\frac{\partial\zeta_{\epsilon}}{\partial t}\right\|_{C([0,T];H^{-1}(G))} \leq M(\omega) \tag{2.11}$$

for some positive constants $M(\omega)$ independent of ϵ.

Proof. For approximate solutions, we use a complete orthonormal system of the eigenfunctions $\{e_m\}_{m=1}^{\infty}$ of

$$\begin{cases} -\Delta e_m = \lambda_m e_m & \text{in } G, \\ e_m = 0 \quad \text{on } \partial G. \end{cases} \tag{2.12}$$

Let us write

$$\zeta_{\epsilon,m}(t,x;\omega) = \sum_{k=1}^{m} c_{m,k}(t;\omega)e_k(x) \tag{2.13}$$

and define $\Psi_{\epsilon,m}$ to be the solution of

$$\begin{cases} -(1-\epsilon\Delta)\Delta\Psi_{\epsilon,m} = \zeta_{\epsilon,m} + \displaystyle\sum_{k=1}^{m} \langle\nabla \times W_{\epsilon}(t,\cdot\,;\omega),\, e_k\rangle_{L^2(G)}\, e_k & \text{in } G, \\ \Psi_{\epsilon,m} = \Delta\Psi_{\epsilon,m} = 0, \quad \text{on } \partial G, \end{cases} \tag{2.14}$$

where $\langle\cdot\,,\,\cdot\rangle_{L^2(G)}$ is the inner product in $L^2(G)$. We then consider the following system of ordinary differential equations:

$$\begin{aligned} \frac{dc_{m,k}}{dt} &+ \langle(\nabla^{\perp}\Psi_{\epsilon,m}) \cdot \nabla\zeta_{\epsilon,m},\, e_k\rangle_{L^2(G)} \\ &= \langle-(\nabla^{\perp}\Psi_{\epsilon,m}) \cdot \nabla(\nabla \times W_{\epsilon}(t,\cdot\,;\omega)),\, e_k\rangle_{L^2(G)}, \quad k = 1,\ldots,m, \end{aligned} \tag{2.15}$$

$$c_{m,k}(0;\omega) = \langle\nabla \times u_{0,\epsilon}(\cdot\,;\omega) - \nabla \times W_{\epsilon}(0,\cdot\,;\omega),\, e_k\rangle_{L^2(G)}, \quad k = 1,\ldots,m. \tag{2.16}$$

The system (2.15) can be put in the form

$$\frac{dz}{dt} = h(t,z;\omega), \tag{2.17}$$

where $z = (c_{m,1},\ldots,c_{m,m})$, and all the components of the vector function h are polynomials in $c_{m,k}$'s with coefficients depending on t, ω. For each $\omega \in \tilde{\Omega}$, the coefficients belong to $C([0,T])$. Thus, the existence and uniqueness of local solutions follow immediately. For the existence on the whole interval $[0,T]$, we need some a priori estimates. We first note that, for each t,

$$\langle(\nabla^{\perp}\Psi_{\epsilon,m}) \cdot \nabla\zeta_{\epsilon,m},\, \zeta_{\epsilon,m}\rangle_{L^2(G)} = 0 \tag{2.18}$$

and

$$\|\nabla^\perp \Psi_{\epsilon,m}\|_{L^2(G)} \le M\Big(\|\zeta_{\epsilon,m}\|_{L^2(G)} + \|\nabla \times W_\epsilon\|_{L^2(G)} \Big), \tag{2.19}$$

which implies

$$\begin{aligned} &\Big| \langle -(\nabla^\perp \Psi_{\epsilon,m}) \cdot \nabla(\nabla \times W_\epsilon),\, \zeta_{\epsilon,m}\rangle_{L^2(G)} \Big| \\ &\quad \le M \|\nabla^\perp \Psi_{\epsilon,m}\|_{L^2(G)} \|\zeta_{\epsilon,m}\|_{L^2(G)} \|\nabla(\nabla \times W_\epsilon)\|_{L^\infty(G)} \\ &\quad \le M\Big(\|\zeta_{\epsilon,m}\|^2_{L^2(G)} + \|\nabla \times W_\epsilon\|^2_{L^2(G)} \Big) \|W_\epsilon\|_{H^{3+\alpha}(G)}, \end{aligned} \tag{2.20}$$

where M denotes positive constants independent of t, m, and ϵ. We multiply (2.15) by $c_{m,k}$, sum over $1 \le k \le m$, and apply Gronwall's inequality to obtain bounds for $c_{m,k}$'s. It follows that for each $\omega \in \tilde{\Omega}$, the above system has a unique solution in $C^1([0,T])$, and

$$\sup_{0\le t\le T} \|\zeta_{\epsilon,m}(t)\|_{L^2(G)} \le M(\omega), \tag{2.21}$$

where $M(\omega)$ is a positive constant independent of ϵ and m. Later, we will need the estimates of the time derivative of $\zeta_{\epsilon,m}$. For this, we note that

$$\begin{aligned} &\Big\| \sum_{k=1}^m \langle (\nabla^\perp \Psi_{\epsilon,m}) \cdot \nabla \zeta_{\epsilon,m},\, e_k \rangle_{L^2(G)}\, e_k \Big\|_{L^\infty(0,T;H^{-1}(G))} \\ &\le K \|(\nabla^\perp \Psi_{\epsilon,m}) \cdot \nabla \zeta_{\epsilon,m}\|_{L^\infty(0,T;H^{-1}(G))} = K \|\nabla \cdot \big((\nabla^\perp \Psi_{\epsilon,m})\zeta_{\epsilon,m}\big)\|_{L^\infty(0,T;H^{-1}(G))} \\ &\le K \|(\nabla^\perp \Psi_{\epsilon,m})\zeta_{\epsilon,m}\|_{L^\infty(0,T;L^2(G))} \le M(\epsilon,\omega), \end{aligned} \tag{2.22}$$

where K denotes a positive constant depending only on G, and $M(\epsilon, \omega)$ is a positive constant independent of m. Here we have used the fact that $H^{-1}(G)$ can be characterized by

$$H^{-1}(G) = \left\{ \sum_{k=1}^\infty a_k e_k \,\middle|\, \sum_{k=1}^\infty |a_k|^2/\lambda_k < \infty \right\}.$$

We also find that

$$\begin{aligned} &\Big\| \sum_{k=1}^m \langle (\nabla^\perp \Psi_{\epsilon,m}) \cdot \nabla(\nabla \times W_\epsilon),\, e_k \rangle_{L^2(G)}\, e_k \Big\|_{L^\infty(0,T;L^2(G))} \\ &\le K \|\nabla^\perp \Psi_{\epsilon,m}\|_{L^2(G)} \|W_\epsilon\|_{H^{3+\alpha}(G)} \le M(\omega), \end{aligned} \tag{2.23}$$

where K and $M(\omega)$ are positive constants independent of ϵ and m. It follows from (2.15) and the above estimates that

$$\left\| \frac{\partial \zeta_{\epsilon,m}}{\partial t} \right\|_{L^\infty(0,T;H^{-1}(G))} \le M(\epsilon,\omega). \tag{2.24}$$

For the measurability of $c_{m,k}$'s, we recall that the components of h in (2.17) are polynomials in $c_{m,k}$'s, where all the coefficients belong to $C([0,T])$ for each $\omega \in \tilde{\Omega}$, and depend continuously on W_ϵ in the sense that the mapping $W_\epsilon(\cdot,\cdot;\omega) \mapsto$ each coefficient is continuous from $C\big([0,T]; H^{3+\alpha}(G)\big)$ to $C([0,T])$ for each $\omega \in \tilde{\Omega}$. Since $W_\epsilon(s,\cdot;\cdot)$ is $H^{3+\alpha}(G)$-valued $\mathcal{F}_s$-measurable, it follows that $c_{m,k}(s;\cdot)$'s are $\mathcal{F}_s$-measurable for each $s \in (0,T]$. Now we proceed to construct pathwise solutions. Let us fix $\omega \in \tilde{\Omega}$. By virtue of (2.21) and (2.24), we can extract a subsequence still denoted by $\{\zeta_{\epsilon,m}\}_{m=1}^{\infty}$ such that as $m \to \infty$,

$$\zeta_{\epsilon,m} \to \zeta_\epsilon \quad \text{weak-star in } L^\infty(0,T;L^2(G)), \tag{2.25}$$

and

$$\zeta_{\epsilon,m} \to \zeta_\epsilon \quad \text{strongly in } C([0,T];H^{-\beta}(G)) \text{ for any } \beta \in (0,1/2) \tag{2.26}$$

for some $\zeta_\epsilon \in L^\infty(0,T;L^2(G))$ with $\partial\zeta_\epsilon/\partial t \in L^\infty(0,T;H^{-1}(G))$. For compactness in $C\big([0,T];H^{-\beta}(G)\big)$, see Corollary 8 of Simon [10]. This together with (2.14) yields

$$\Psi_{\epsilon,m} \to \Psi_\epsilon \quad \text{strongly in } C([0,T];H^{-\beta+4}(G)), \tag{2.27}$$

where Ψ_ϵ satisfies

$$\begin{cases} -(1-\epsilon\Delta)\Delta\Psi_\epsilon = \zeta_\epsilon + \nabla\times W_\epsilon(t,\cdot;\omega) \quad \text{in } G, \\ \Psi_\epsilon = \Delta\Psi_\epsilon = 0 \quad \text{on } \partial G. \end{cases} \tag{2.28}$$

It is easy to see that as $m \to \infty$,

$$(\nabla^\perp\Psi_{\epsilon,m})\cdot\nabla\zeta_{\epsilon,m} \to \nabla^\perp\Psi_\epsilon\cdot\nabla\zeta_\epsilon \quad \text{weak-star in } L^\infty(0,T;H^{-1}(G)). \tag{2.29}$$

Hence, ζ_ϵ is a solution of (2.1) and (2.2) for each $\omega \in \tilde{\Omega}$. We now show that this ζ_ϵ is necessarily in $C^1([0,T]\times\overline{G})$. For this, we consider the following linear deterministic problem:

$$\frac{\partial\zeta}{\partial t} + \Phi\cdot\nabla\zeta = F, \tag{2.30}$$

$$\zeta(0,\cdot) = \zeta_0. \tag{2.31}$$

Here Φ, F, and ζ_0 are given functions that satisfy the following conditions:

(i) Φ is R^2-valued and belongs to $C\big([0,T];C^1(\overline{G})\big)$.

(ii) Φ is tangential on the boundary ∂G for all t, and $\nabla\cdot\Phi = 0$ for all (t,x).

(iii) $F \in C\big([0,T];C^1(\overline{G})\big)$ and $\zeta_0 \in C^1(\overline{G})$.

Under these conditions, we have the following lemma.

Lemma 2.2. *Suppose that $\zeta \in L^\infty(0,T;L^2(G))$ is a solution of* (2.30)–(2.31). *Then $\zeta \in C^1([0,T]\times\overline{G})$.*

Proof. Since $\zeta \in L^\infty(0,T;L^2(G))$ satisfies (2.30) in the sense of distribution over $(0,T)\times G$, it holds that $\zeta \in C([0,T];H^{-\gamma}(G))$ for any $\gamma > 0$. Thus, (2.31) makes sense. By virtue of the conditions (i) and (ii), the flow associated with

$$\begin{cases} \dfrac{dx}{dt} = \Phi(t,x), \\ x(0) = y \in \overline{G} \end{cases} \tag{2.32}$$

exists on $[0,T]$ and gives rise to a volume preserving C^1-diffeomorphism $y \mapsto x = \eta(t,y)$ for each $t \in [0,T]$. Choose any arbitrary $\phi \in C_0^1((0,T)\times G)$. It follows from (2.30) and the divergence-free condition of Φ that

$$\int_0^T \int_G \zeta\Big(\frac{\partial \phi}{\partial t} + \Phi\cdot\nabla\phi\Big)\,dx\,dt = -\int_0^T\int_G F\phi\,dx\,dt. \tag{2.33}$$

We now express the integrals in terms of the new variables (s,y), where $t = s$ and $x = \eta(s,y)$:

$$\begin{aligned}\int_0^T \int_G \zeta(t,x)\Big(\frac{\partial \phi}{\partial t}(t,x) + \Phi(t,x)\cdot\nabla\phi(t,x)\Big)\,dx\,dt \\ = \int_0^T\int_G \zeta(s,\eta(s,y))\frac{\partial\phi}{\partial s}(s,\eta(s,y))\,dy\,ds,\end{aligned} \tag{2.34}$$

$$\int_0^T\int_G F(t,x)\phi(t,x)\,dx\,dt = \int_0^T\int_G F(s,\eta(s,y))\phi(s,\eta(s,y))\,dy\,ds. \tag{2.35}$$

Thus, it holds that

$$\frac{\partial\zeta}{\partial s}(s,\eta(s,y)) = F(s,\eta(s,y)) \tag{2.36}$$

in the sense of distribution over $(0,T)\times G$. We note that as a function of (s,y), $\zeta(s,\eta(s,y))$ belongs to $L^\infty\big(0,T;L^2(G)\big)$ because $y\mapsto\eta(s,y)$ is volume preserving for each s. Meanwhile,

$$\zeta(0,\eta(0,y)) = \zeta(0,y) = \zeta_0(y). \tag{2.37}$$

Since the initial value problem

$$\begin{cases}\dfrac{\partial z}{\partial s}(s,y) = F(s,\eta(s,y)), \quad (s,y)\in(0,T)\times G,\\ z(0,y) = \zeta_0(y), \quad y\in G,\end{cases}$$

has at most one solution in the space of distributions over $(0,T)\times G$, ζ is necessarily represented by

$$\zeta(t,x) = \zeta_0(y) + \int_0^t F(s,\eta(s,y))\,ds \tag{2.38}$$

for each $(t,x)\in(0,T)\times G$, where $x = \eta(t,y)$. Since the right-hand side belongs to $C^1([0,T]\times\overline{G})$, so does ζ. This completes the proof of the lemma. □

For each fixed $\omega\in\tilde\Omega$, we set $\Phi(t,x) = \nabla^\perp\Psi_\epsilon(t,x;\omega)$, $F(t,x) = -(\nabla^\perp\Psi_\epsilon)\cdot\nabla(\nabla\times W_\epsilon(t,x;\omega))$, and $\zeta_0(x) = \nabla\times u_{0,\epsilon}(x;\omega) - \nabla\times W_\epsilon(0,x;\omega)$. Then, the above conditions (i), (ii), and (iii) are satisfied, and $\zeta_\epsilon\in L^\infty(0,T;L^2(G))$ is a solution of (2.30)–(2.31). By Lemma 2.2, ζ_ϵ is necessarily in $C^1([0,T]\times\overline{G})$.

Next we will show that ζ_ϵ is a unique solution of (2.1)–(2.3). Fix $\epsilon>0$, and let ζ and $\tilde\zeta$ be two weak solutions in $C([0,T];L^2(G))$ of (2.1)–(2.3), and let Ψ and $\tilde\Psi$ be associated with ζ and $\tilde\zeta$, respectively, through (2.3). Then, both ζ and $\tilde\zeta$ belong to

$C^1([0,T]\times\overline{G})$ by the same argument as above. We denote the right-hand side of (2.1) by F and $\tilde{F}$ associated with Ψ and $\tilde{\Psi}$, respectively. We then have

$$\frac{\partial(\zeta-\tilde{\zeta})}{\partial t}+(\nabla^{\perp}\Psi)\cdot\nabla(\zeta-\tilde{\zeta})+\nabla^{\perp}(\Psi-\tilde{\Psi})\cdot\nabla\tilde{\zeta}=F-\tilde{F} \tag{2.39}$$

and

$$\|\nabla^{\perp}(\Psi-\tilde{\Psi})\|_{C(\overline{G})}\le M(\epsilon,\omega)\|\zeta-\tilde{\zeta}\|_{L^2(G)}\quad\text{for all } t. \tag{2.40}$$

By multiplying (2.39) by $\zeta-\tilde{\zeta}$ and integrating over G, we can easily find

$$\zeta\equiv\tilde{\zeta}, \tag{2.41}$$

which shows the uniqueness. Hence ζ_ϵ is determined independently of any subsequence $\{\zeta_{\epsilon,m}\}_{m=1}^{\infty}$. Consequently, the whole sequence $\{\zeta_{\epsilon,m}\}_{m=1}^{\infty}$ converges to ζ_ϵ for each $\omega\in\tilde{\Omega}$. Next we will establish the measurability of ζ_ϵ as a random function. Fix any $0<s\le T$. Each $\zeta_{\epsilon,m}(s,\cdot)$ is $H^{\mu}(G)$-valued $\mathcal{F}_s$-measurable for each $\mu\in R$, which follows from the measurability of $c_{m,k}$'s and the structure of $\zeta_{\epsilon,m}$. By virtue of (2.26), $\zeta_\epsilon(s,\cdot)$ is $H^{-\beta}(G)$-valued $\mathcal{F}_s$-measurable for $\beta\in(0,1/2)$. But each closed ball in $L^2(G)$ is a Borel subset of $H^{-\beta}(G)$, and thus $\zeta_\epsilon(s,\cdot)$ is $L^2(G)$-valued $\mathcal{F}_s$-measurable.

Next we will obtain a priori estimates independent of ϵ. By multiplying (2.1) by ζ_ϵ^3 and integrating over G, we find

$$\frac{d}{dt}\int_G\zeta_\epsilon^4\,dx=\frac{1}{4}\int_G F_\epsilon\,\zeta_\epsilon^3\,dx\quad\text{for all }\omega\in\tilde{\Omega}. \tag{2.42}$$

It follows from (2.3) that

$$\|\Delta\Psi_\epsilon\|_{L^4(G)}\le M\big(\|\zeta_\epsilon\|_{L^4(G)}+\|\nabla\times W_\epsilon\|_{L^4(G)}\big), \tag{2.43}$$

which yields

$$\|\nabla^{\perp}\Psi_\epsilon\|_{C(\overline{G})}\le M\big(\|\zeta_\epsilon\|_{L^4(G)}+\|\nabla\times W_\epsilon\|_{L^4(G)}\big), \tag{2.44}$$

where M denotes positive constants independent of t and ϵ. We can derive from (2.42) with help of (2.5) and (2.44):

$$\frac{d}{dt}\int_G\zeta_\epsilon^4\,dx\le M(\omega)\int_G\zeta_\epsilon^4\,dx+M(\omega), \tag{2.45}$$

which, together with (2.6), implies

$$\|\zeta_\epsilon\|_{C([0,T];L^4(G))}\le M(\omega), \tag{2.46}$$

where, here and below, $M(\omega)$ stands for positive constants independent of ϵ. It now follows from (2.5) and (2.44) that

$$\|F_\epsilon\|_{C([0,T]\times\overline{G})}\le M(\omega), \tag{2.47}$$

which, combined with (2.6) and (2.38), yields

$$\|\zeta_\epsilon\|_{C([0,T]\times\overline{G})}\le M(\omega). \tag{2.48}$$

We can also derive from (2.1) that

$$\left\| \frac{\partial \zeta_\epsilon}{\partial t} \right\|_{C([0,T];H^{-1}(G))} \leq M(\omega). \tag{2.49}$$

This ends the proof of Lemma 2.1. □

We now proceed to obtain a solution of

$$\frac{\partial \zeta}{\partial t} + (\nabla^\perp \Psi) \cdot \nabla \zeta = -(\nabla^\perp \Psi) \cdot \nabla(\nabla \times W(t,x;\omega)) \quad \text{for } (t,x) \in (0,T) \times G, \tag{2.50}$$

$$\zeta(0,x;\omega) = \nabla \times u_0(x;\omega) - \nabla \times W(0,x;\omega) \quad \text{for } x \in G, \tag{2.51}$$

where Ψ is the solution of

$$\begin{cases} -\Delta \Psi = \zeta + \nabla \times W(t,\cdot\,;\omega) & \text{in } G, \\ \Psi = 0 \quad \text{on } \partial G. \end{cases} \tag{2.52}$$

For the time being, we establish only the existence of a solution for each $\omega \in \tilde{\Omega}$.

Lemma 2.3. *For each* $\omega \in \tilde{\Omega}$, *there is a solution* ζ *of* (2.50)–(2.52) *such that* $\zeta \in L^\infty((0,T) \times G) \cap C([0,T]; H^{-\beta}(G))$ *for any* $\beta \in (0,1/2)$.

Proof. Let us fix $\omega \in \tilde{\Omega}$. By virtue of (2.48) and (2.49), we can use Corollary 8 of [10] to extract a subsequence still denoted by $\{\zeta_\epsilon\}$ and its companion $\{\Psi_\epsilon\}$ through (2.3) such that as $\epsilon \to 0$,

$$\zeta_\epsilon \to \zeta \quad \text{weak-star in } L^\infty(0,T;L^\infty(G)), \tag{2.53}$$

$$\zeta_\epsilon \to \zeta \quad \text{strongly in } C([0,T];H^{-\beta}(G)) \ \text{ for any } \beta \in (0,1/2), \tag{2.54}$$

and

$$\Psi_\epsilon \to \Psi \quad \text{strongly in } C([0,T];H^{2-\beta}(G)) \tag{2.55}$$

for some ζ and Ψ which satisfy

$$\begin{cases} -\Delta \Psi = \zeta + \nabla \times W & \text{in } G, \\ \Psi = 0 \quad \text{on } \partial G. \end{cases} \tag{2.56}$$

Since $\nabla^\perp \Psi_\epsilon$ is divergence-free, $(\nabla^\perp \Psi_\epsilon) \cdot \nabla \zeta_\epsilon = \nabla \cdot (\zeta_\epsilon \nabla^\perp \Psi_\epsilon)$ holds. Meanwhile, we use (2.53) and (2.55) to find that as $\epsilon \to 0$,

$$\nabla \cdot (\zeta_\epsilon \nabla^\perp \Psi_\epsilon) \to \nabla \cdot (\zeta \nabla^\perp \Psi) \quad \text{weak-star in } L^\infty(0,T;H^{-1}(G)). \tag{2.57}$$

It follows that ζ satisfies (2.50)–(2.52), and the proof of Lemma 2.3 is complete. □

For each $\omega \in \tilde{\Omega}$, we use the above Ψ to set

$$v = \nabla^\perp \Psi \tag{2.58}$$

so that

$$\nabla \times v = -\Delta \Psi = \zeta + \nabla \times W, \tag{2.59}$$

and (2.50) can be written as

$$\frac{\partial}{\partial t}(\nabla \times v) + \nabla \cdot \big((\nabla \times v)v\big) = \frac{\partial}{\partial t}\nabla \times W. \tag{2.60}$$

By straightforward differentiation, it is easy to see

$$\nabla \times \big((v \cdot \nabla)v\big) = \nabla \cdot \big((\nabla \times v)v\big), \tag{2.61}$$

and thus (2.60) reduces to

$$\nabla \times \left(\frac{\partial v}{\partial t} + (v \cdot \nabla)v - \frac{\partial W}{\partial t}\right) = 0. \tag{2.62}$$

Since G is a simply connected domain, there is a scalar distribution p over $(0,T) \times G$ such that

$$\frac{\partial v}{\partial t} + (v \cdot \nabla)v + \nabla p = \frac{\partial W}{\partial t}. \tag{2.63}$$

In the meantime, (2.51) and (2.59) yield

$$\nabla \times v(0,\cdot) = \nabla \times u_0(\cdot\,;\omega), \tag{2.64}$$

which implies

$$v(0,\cdot) = u_0(\cdot\,;\omega) + \nabla q \tag{2.65}$$

for some scalar distribution q over G. Since $v(0,\cdot) \in \mathcal{H}$ and $u_0(\cdot\,;\omega) \in \mathcal{V}$, it holds that $\nabla q \in \mathcal{H}$, which implies $\nabla q \equiv 0$. Hence, we have shown that for fixed $\omega \in \tilde{\Omega}$, v satisfies (0.1)–(0.4). It follows from (2.53), (2.55), (2.56), and (2.58) that for each $\omega \in \tilde{\Omega}$, $v \in C([0,T];\mathcal{H}) \cap L^\infty(0,T;\mathcal{V})$ and, by a result in [12],

$$\left\| \frac{\partial v}{\partial x_i} \right\|_{L^\infty(0,T;L^r(G))} \leq r\, M(\omega), \quad i = 1, 2, \tag{2.66}$$

for all $2 \leq r < \infty$. If there is another function $u \in C([0,T];\mathcal{H}) \cap L^\infty(0,T;\mathcal{V})$ that satisfies (0.1)–(0.4) for fixed $\omega \in \tilde{\Omega}$, then $\partial(v-u)/\partial t \in L^\infty(0,T;\mathcal{V}')$, where $\mathcal{V}'$ is the dual of $\mathcal{V}$, and we can use the same argument as in [4, pp. 50–51] with the help of (2.66) to find $v \equiv u$. Hence the above v is unique, and ζ is also unique. Thus, ζ is determined independently of any choice of the subsequence $\{\zeta_\epsilon\}$. Next we will show that $\zeta \in C([0,T];L^2(G))$. For this, one could follow the argument in [12], but there seems to be a gap in the argument because of some missing details. We proceed differently. It is already known that $\zeta \in L^\infty(0,T;L^\infty(G)) \cap C([0,T];H^{-\beta}(G))$ for any $\beta \in (0,1/2)$. Thus, $\zeta(t)$ is $L^2(G)$-weakly continuous on $[0,T]$; see Theorem 2.1 of Strauss [11]. Let us recall how ζ was constructed. The approximation ζ_ϵ satisfies the energy identity

$$\|\zeta_\epsilon(t)\|^2_{L^2(G)} = \|\zeta_\epsilon(0)\|^2_{L^2(G)} + 2\int_0^t \int_G F_\epsilon \zeta_\epsilon \, dx\, ds, \tag{2.67}$$

where F_ϵ converges to $-(\nabla^\perp \Psi)\cdot\nabla(\nabla \times W)$ strongly in $C([0,T];L^2(G))$ as $\epsilon \to 0$. We pause to emphasize that a formal computation such as multiplying (2.50) by ζ and integrating over G cannot be justified because ζ is only known to be in $L^\infty((0,T)\times G)$.

For each $t \in [0,T]$, $\zeta_\epsilon(t)$ converges to $\zeta(t)$ strongly in $H^{-\beta}(G)$ for any $\beta \in (0,1/2)$ and $\zeta(t) \in L^2(G)$. Hence, $\zeta_\epsilon(t)$ converges to $\zeta(t)$ weakly in $L^2(G)$. By (2.6), we pass $\epsilon \to 0$ to arrive at

$$\|\zeta(t)\|^2_{L^2(G)} \le \|\zeta(0)\|^2_{L^2(G)} - 2\int_0^t \int_G (\nabla^\perp \Psi)\cdot\nabla(\nabla\times W)\zeta\,dx\,ds, \tag{2.68}$$

from which it follows that

$$\overline{\lim_{t\to 0}}\, \|\zeta(t)\|^2_{L^2(G)} \le \|\zeta(0)\|^2_{L^2(G)}. \tag{2.69}$$

Consequently, we find that $\zeta(t)$ is right-continuous at $t = 0$ strongly in $L^2(G)$. Since $\zeta \in L^\infty(0,T;L^\infty(G)) \cap C([0,T];H^{-\beta}(G))$ for any $\beta \in (0,1/2)$ implies that $\zeta(t) \in L^\infty(G)$ and $v(t) \in \mathcal{V}$ for every $t \in [0,T]$, we can take any $0 < t < T$ as the initial time to repeat the above result. By virtue of the uniqueness of solutions, $\zeta(t)$ is right-continuous at each $t \in [0,T)$ strongly in $L^2(G)$. By change of variables $\zeta \mapsto -\zeta$, $W \mapsto -W$, and $t \mapsto T-t$ and applying the above result, we find that $\zeta(t)$ is also left-continuous, and $\zeta \in C([0,T];L^2(G))$. Thus, $v(t) \in C([0,T];\mathcal{V})$. By the same argument as in the proof of measurability of ζ_ϵ, we can easily find that for each $0 < s \le T$, $\zeta(s,\cdot)$ is $L^2(G)$-valued $\mathcal{F}_s$-measurable. Therefore, $v(s,\cdot)$ is $\mathcal{V}$-valued $\mathcal{F}_s$-measurable. Now the proof of Theorem 1.2 is complete.

3. Proof of Theorem 1.3. We proceed under the assumptions made in section 1.2.2. Let us define

$$W_\epsilon(t,x;\omega) = g_\epsilon(x)\,X_t(\omega), \tag{3.1}$$

where each $g_\epsilon \in C^4(\overline{G})$ and, as $\epsilon \to 0$,

$$g_\epsilon \to g \qquad \text{strongly in } H^1(G). \tag{3.2}$$

Let $\tilde\Omega \in \mathcal{F}_0$ with $P(\tilde\Omega) = 1$ such that for each $\omega \in \tilde\Omega$, $X_{(\cdot)}(\omega) \in C([0,T])$.

As in section 2, we choose $u_{0,\epsilon} \in C^2(\overline{G}) \cap \mathcal{V}$ such that

$$\nabla\times u_{0,\epsilon} \to \nabla\times u_0 \quad \text{strongly in } L^2(G). \tag{3.3}$$

According to Lemma 2.1, for each $\omega \in \tilde\Omega$ there is a unique $\xi_\epsilon(\cdot,\cdot;\omega) \in C\big([0,T];C^1(\overline{G})\big)$ that satisfies

(3.4)
$$\xi_\epsilon(t) = \nabla\times u_{0,\epsilon} - \int_0^t (\nabla^\perp\Psi_\epsilon)\cdot\nabla\xi_\epsilon\,ds + \nabla\times W_\epsilon(t) \qquad \text{for all } (t,x) \in [0,T]\times\overline{G}.$$

Here we have set $\xi_\epsilon = \zeta_\epsilon + \nabla\times W_\epsilon$, where ζ_ϵ satisfies (2.1)–(2.3). Next we need the fact that $H^1(G)$ is a Borel subset of $L^2(G)$. This follows easily from the fact that each closed ball of $H^1(G)$ of finite radius is a closed subset of $L^2(G)$. It is already known that $\xi_\epsilon(s,\cdot)$ is $L^2(G)$-valued $\mathcal{F}_s$-measurable for each $s \in [0,T]$. Since $\xi_\epsilon \in C([0,T];C^1(\overline{G}))$, for each $\omega \in \tilde\Omega$, $\xi_\epsilon(t,\cdot)$ is $H^1(G)$-valued continuous and adapted to $\{\mathcal{F}_t\}$. In the same way, $\nabla^\perp\Psi_\epsilon$ is $H^3(G)$-valued continuous and adapted to $\{\mathcal{F}_t\}$. We now apply Ito's formula to find that, for P-almost all ω,

$$\begin{aligned}\|\xi_\epsilon(t)\|^2_{L^2(G)} = {}& \|\nabla\times u_{0,\epsilon}\|^2_{L^2(G)} - 2\int_0^t \langle(\nabla^\perp\Psi_\epsilon\cdot\nabla)\xi_\epsilon,\,\xi_\epsilon\rangle_{L^2(G)}\,ds \\ &+ 2\int_0^t \langle\xi_\epsilon,\,\nabla\times g_\epsilon\rangle_{L^2(G)}\,dX_s + \int_0^t \|\nabla\times g_\epsilon\|^2_{L^2(G)}\,ds\end{aligned} \tag{3.5}$$

for all $0 \le t \le T$, where the second term in the right-hand side vanishes. By the Burkholder–Davis–Gundy inequality, it holds that, for all $t \in [0, T]$,

$$\begin{aligned} E\biggl(\sup_{0\le\eta\le t}\biggl|\int_0^\eta \langle \xi_\epsilon,\, \nabla\times g_\epsilon\rangle_{L^2(G)}\, dX_s\biggr|\biggr) &\\ \le M\, E\biggl(\biggl(\int_0^t |\langle \xi_\epsilon,\, \nabla\times g_\epsilon\rangle_{L^2(G)}|^2\, ds\biggr)^{1/2}\biggr) &\\ \le M\|\nabla\times g_\epsilon\|_{L^2(G)} E\biggl(\biggl(\int_0^t \|\xi_\epsilon\|^2_{L^2(G)}\, ds\biggr)^{1/2}\biggr). & \end{aligned} \tag{3.6}$$

Here and below, $E(\cdot)$ is the expectation with respect to P, and M denotes positive constants independent of ϵ. We can infer from (3.5) and (3.6) that

$$E\bigl(\|\xi_\epsilon\|^2_{C([0,T];L^2(G))}\bigr) \le M \tag{3.7}$$

and

$$E\bigl(\|\nabla^\perp\Psi_\epsilon\|^2_{C([0,T];H^1(G))}\bigr) \le M. \tag{3.8}$$

Consequently,

$$\begin{aligned} E\biggl(\|(\nabla^\perp\Psi_\epsilon)\cdot\nabla\xi_\epsilon\|_{C([0,T];H^{-1-\delta}(G))}\biggr) &\\ = E\biggl(\|\nabla\cdot((\nabla^\perp\Psi_\epsilon)\xi_\epsilon)\|_{C([0,T];H^{-1-\delta}(G))}\biggr) \le M & \end{aligned} \tag{3.9}$$

for any $\delta \in (0, 1/2)$. From now on, we fix a given $\delta \in (0, 1/2)$. In the meantime, we find from the well-known property of the Brownian motion

$$E\bigl(\|W_\epsilon\|^2_{C^\gamma([0,T];H^1(G))}\bigr) \le M \tag{3.10}$$

for some $0 < \gamma < 1/2$. It now follows from (3.4) and the above estimates that

$$E\bigl(\|\xi_\epsilon\|_{C^\gamma([0,T];H^{-1-\delta}(G))}\bigr) \le M. \tag{3.11}$$

Since it holds that, for all $t_1, t_2 \in [0, T]$ and all $\phi \in C([0, T]; L^2(G)) \cap C^\gamma([0, T]; H^{-1-\delta}(G))$,

$$\begin{aligned} \|\phi(t_2) - \phi(t_1)\|_{H^{-\delta}(G)} &\\ \le M\|\phi(t_2) - \phi(t_1)\|^{1/(1+\delta)}_{L^2(G)}\, \|\phi(t_2) - \phi(t_1)\|^{\delta/(1+\delta)}_{H^{-1-\delta}(G)}, & \end{aligned} \tag{3.12}$$

we can apply the Ascoli theorem to conclude that the injection

$$C([0, T]; L^2(G)) \cap C^\gamma([0, T]; H^{-1-\delta}(G)) \;\to\; C([0, T]; H^{-\delta}(G)) \tag{3.13}$$

is compact. Combining all these, we are now ready to extract a suitably convergent subsequence.

Since the injection

(3.14)
$$L^p\biggl(\Omega; \Bigl[C([0, T]; L^2(G)) \cap C^\gamma([0, T]; H^{-1-\delta}(G))\Bigr]\biggr) \;\to\; L^p\biggl(\Omega; \Bigl[C([0, T]; H^{-\delta}(G))\Bigr]\biggr)$$

is not compact for any $1 \leq p \leq \infty$, we will use a measure-theoretic argument. Let us set $\epsilon = 1/k,\ k = 1, 2, \dots$. It follows from (3.7) and (3.11) that

$$P\biggl(\|\xi_{1/k}\|_{C([0,T];L^2(G))} + \|\xi_{1/k}\|_{C^\gamma([0,T];H^{-1-\delta}(G))} \geq L\biggr) \leq M/L \quad \text{for all } k, \tag{3.15}$$

which yields

$$P\left(\bigcup_{L=1}^{\infty}\bigcap_{m=1}^{\infty}\bigcup_{k=m}^{\infty}\{\|\xi_{1/k}\|_{C([0,T];L^2(G))} + \|\xi_{1/k}\|_{C^\gamma([0,T];H^{-1-\delta}(G))} \leq L\}\right) = 1. \tag{3.16}$$

Hence there is a subset $\Omega^\dagger \subset \tilde{\Omega}$ such that $P(\Omega^\dagger) = 1$ and, for each $\omega \in \Omega^\dagger$, there is a positive integer L and a subsequence $\{\xi_{1/k_j}\}_{j=1}^{\infty}$ satisfying

$$\|\xi_{1/k_j}\|_{C([0,T];L^2(G))} + \|\xi_{1/k_j}\|_{C^\gamma([0,T];H^{-1-\delta}(G))} \leq L \quad \text{for all } j. \tag{3.17}$$

We now fix $\omega \in \Omega^\dagger$, and make a choice of L and a subsequence satisfying (3.17). By virtue of (3.13) and (3.17), we can further extract a subsequence $\{\xi_\nu\}$ such that, as $\nu \to 0$,

$$\xi_\nu \to \xi \quad \text{weak-star in } L^\infty(0,T;L^2(G)), \tag{3.18}$$

$$\xi_\nu \to \xi \quad \text{strongly in } C([0,T];H^{-\delta}(G)) \tag{3.19}$$

for some function ξ. It follows from (2.3) and (3.19) that, as $\nu \to 0$,

$$\Psi_\nu \to \Psi \quad \text{strongly in } C([0,T];H^{2-\delta}(G)), \tag{3.20}$$

where Ψ satisfies

$$\begin{cases} -\Delta\Psi = \xi & \text{in } G, \\ \Psi = 0 & \text{on } \partial G. \end{cases} \tag{3.21}$$

Hence, ξ satisfies, for each $t \in [0,T]$,

$$\xi(t) = \nabla \times u_0 - \int_0^t (\nabla^\perp\Psi)\cdot\nabla\xi\, ds + \nabla \times W \tag{3.22}$$

in the sense of distribution over G. Hence, for each $\omega \in \Omega^\dagger$, we have constructed a function $\xi \in L^\infty(0,T;L^2(G)) \cap C([0,T];H^{-\delta}(G))$ that satisfies (3.22). We will use the following result of Bensoussan and Temam [2, pp. 220–221].

THEOREM. *Let X be a Polish space and Y be a separable Banach space. Suppose that Λ is a multivalued mapping from X to the set of nonempty closed subsets of Y such that its graph is closed. Then, Λ admits a universally Radon measurable selection; i.e., there is a mapping L from X to Y such that $L(x) \in \Lambda(x)$ for all $x \in X$, and L is measurable for any Radon measure defined on the Borel sets of X.*

Since Ω is a Polish space and $\mathcal{F}$ is the completion of $\mathcal{B}(\Omega)$ under P, P is inner regular. Thus, there is a compact subset $K_1 \subset \Omega^\dagger$ such that $P(\Omega^\dagger \setminus K_1) < 1/2$. Let us define a separable Banach space $\mathcal{S} = L^2(0,T;L^2(G)) \cap C\bigl([0,T];H^{-\delta}(G)\bigr)$ and a multivalued mapping

$$\Lambda:\ K_1 \to \mathcal{S}, \tag{3.23}$$

where

$$\Lambda(\omega) = \big\{ \xi \in \mathcal{S} \,\big|\; \xi \text{ satisfies (3.22) with } W = g(x)\,\omega(t) \text{ for all } t \in [0,T] \big\}. \tag{3.24}$$

We will show that the graph of Λ is closed in $K_1 \times \mathcal{S}$. Let $\omega_n \in K_1$ and $\xi_n \in \Lambda(\omega_n)$ for $n = 1, 2, \dots$ such that, as $n \to \infty$,

$$(\omega_n, \xi_n) \;\to\; (\omega^\star, \xi^\star) \quad \text{in } K_1 \times \mathcal{S}. \tag{3.25}$$

For each $n,$ it holds that

$$\xi_n(t) = \nabla \times u_0 - \int_0^t (\nabla^\perp \Psi_n) \cdot \nabla \xi_n \, ds + \nabla \times g(x)\omega_n(t) \tag{3.26}$$

in the sense of distribution over G for all $t \in [0,T]$. Here, Ψ_n is determined from

$$\begin{cases} -\Delta \Psi_n = \xi_n & \text{in } G, \\ \Psi_n = 0 & \text{on } \partial G. \end{cases} \tag{3.27}$$

Since ξ_n converges to $\xi^\star$ in $\mathcal{S},$ and ω_n converges to $\omega^\star$ in $C([0,T]),$ it is apparent that $\xi^\star$ satisfies (3.22) with $\omega^\star$. Hence, $\xi^\star \in \Lambda(\omega^\star)$. By the same argument, the set $\Lambda(\omega)$ is a nonempty closed subset of $\mathcal{S}$ for each $\omega \in K_1$.

Since K_1 is also a Polish space, we apply the above theorem to find a function

$$\Xi_1 \, : K_1 \;\to\; \mathcal{S} \tag{3.28}$$

such that

$$\Xi_1(\omega) \in \Lambda(\omega) \qquad \text{for each } \omega \in K_1 \tag{3.29}$$

and Ξ_1 is measurable for every radon measure defined on the Borel subsets of K_1. Since K_1 is a compact subset of $\Omega,$ it is apparent that

$$\Xi_1^{-1}(\mathcal{O}) \in \mathcal{F} \qquad \text{for every open subset } \mathcal{O} \text{ of } \mathcal{S}. \tag{3.30}$$

Let us proceed by induction. After $K_1, \dots, K_m$ and $\Xi_1, \dots, \Xi_m$ have been chosen, we choose a compact subset $K_{m+1} \subset \Omega^\dagger \backslash \bigcup_{j=1}^m K_j$ such that $P(\Omega^\dagger \backslash \bigcup_{j=1}^{m+1} K_j) < 1/2^{m+1}$ and the corresponding Ξ_{m+1} as above. By piecing up all Ξ_j's, we can construct a $\mathcal{S}$-valued $\mathcal{F}$-measurable function Ξ such that for P-almost all $\omega,$ $\Xi(\omega)$ satisfies, for all $t \in [0,T],$

$$\Xi(t, \cdot\,; \omega) = \nabla \times u_0 - \int_0^t (\nabla^\perp \Psi) \cdot \nabla \Xi \; ds + \nabla \times W \tag{3.31}$$

in the sense of distribution over G, where Ψ is obtained from (3.21) with ξ replaced by Ξ. By setting $v = \nabla^\perp \Psi,$ we repeat the same argument as before to arrive at

$$\frac{\partial v}{\partial t} + (v \cdot \nabla) v + \nabla p = \frac{\partial W}{\partial t} \tag{3.32}$$

in the sense of distribution over $(0,T) \times G$ with some scalar distribution $p,$ for P-almost all $\omega,$ and

$$v(0, \cdot\,; \omega) = u_0 \quad \text{for } P\text{-almost all } \omega. \tag{3.33}$$

From the regularity of Ξ, we have

$$v \in L^2(0,T;\mathcal{V}) \cap C\big([0,T]; H^{1-\delta}(G) \cap \mathcal{H}\big), \quad \text{for } P\text{-almost all } \omega, \tag{3.34}$$

and the measurability of v also follows from that of Ξ. This completes the proof of Theorem 1.3 under the assumptions in section 1.2.2.

It remains to link this special case to a general case. Let $B_t(\cdot)$ be a given standard Brownian motion over $(\Omega, \mathcal{F}, \mathcal{F}_t, P)$. Let $\tilde{\Omega}$ be a subset of Ω with $P(\tilde{\Omega}) = 1$ such that for each $\omega \in \tilde{\Omega}$, $B_{(\cdot)}(\omega) \in C([0,\infty))$. We consider a mapping Θ from $\tilde{\Omega}$ into $C([0,\infty))$ defined by

$$\Theta : \omega \mapsto B_{(\cdot)}(\omega). \tag{3.35}$$

Then Θ is $C([0,\infty))$-valued $\mathcal{F}$-measurable, and Θ induces a probability measure P^* on $\big(C([0,\infty)), \mathcal{B}\big(C([0,\infty))\big)\big)$ such that

$$P^*(\mathcal{G}) = P(\Theta^{-1}(\mathcal{G})) \quad \text{for each } \mathcal{G} \in \mathcal{B}\big(C([0,\infty))\big). \tag{3.36}$$

Then the coordinate mapping process X_t becomes a standard Brownian motion over $\big(C([0,\infty)), \mathcal{B}\big(C([0,\infty))\big), P^*\big)$, and

$$X_t(\Theta(\omega)) = B_t(\omega) \quad \text{for all } \omega \in \tilde{\Omega}. \tag{3.37}$$

We now set $\Omega^* = C([0,\infty))$ and define $\mathcal{F}_t^*$, $\mathcal{F}^*$ by (1.6) and (1.7) with P^*. We note that if $\mathcal{G}$ is a P^*-negligible set, then $\Theta^{-1}(\mathcal{G})$ is P-negligible set and belongs to $\mathcal{F}$ since $\mathcal{F}$ is complete under P. Meanwhile, W is given by

$$W(t,x;\omega) = g(x)B_t(\omega). \tag{3.38}$$

We define

$$W^*(t,x;\omega^*) = g(x)X_t(\omega^*) \tag{3.39}$$

so that, for all $(t,x) \in [0,T] \times G$ and all $\omega \in \tilde{\Omega}$,

$$W^*(t,x;\Theta(\omega)) = W(t,x;\omega). \tag{3.40}$$

Then, we have a random function u^* that is $L^2(0,T;\mathcal{V}) \cap C\big([0,T]; \mathcal{H} \cap H^{1-\delta}(G)\big)$-valued $\mathcal{F}^*$-measurable and satisfies (0.1)–(0.4) with W replaced by W^* for P^*-almost all ω^*. For the solution defined over Ω, we simply set

$$u(t,x;\omega) = u^*(t,x;\Theta(\omega)). \tag{3.41}$$

This completes the proof of Theorem 1.3.

Note added in proof. One can easily show that the last term of (3.6) is finite by using a stopping time in (3.5).

EVOLUTION OF ELASTIC CURVES IN $\mathbb{R}^n$: EXISTENCE AND COMPUTATION*

GERHARD DZIUK†, ERNST KUWERT‡, AND REINER SCHÄTZLE§

Abstract. We consider curves in $\mathbb{R}^n$ moving by the gradient flow for elastic energy, i.e., the L^2 integral of curvature. Long-time existence is proved in the two cases when a multiple of length is added to the energy or the length is fixed as a constraint. Along these lines, a lower bound for the lifespan of solutions to the curve diffusion flow is observed. We derive algorithms for both the elastic flows and the curve diffusion equation. After a numerical test we compute several examples, including cases of curve diffusion in which a singularity develops.

1. Introduction.

In the Bernoulli model of an elastic rod [13] described by a closed curve $f : I = \mathbb{R}/\mathbb{Z} \to \mathbb{R}^n$, the elastic energy is the curvature integral

$$E(f) = \frac{1}{2}\int_I |\varkappa|^2 \, ds. \tag{1.1}$$

Here, putting $\gamma = |\partial_x f|$, we denote by $ds = \gamma\, dx$ the arclength element and by $\partial_s = \gamma^{-1}\partial_x$ the arclength derivative; thus $\tau = \partial_s f$ is the unit tangent and $\varkappa = \partial_s^2 f$ is the curvature vector. The Euler–Lagrange operator for E is given by

$$\operatorname{grad}_{L^2} E(f) = \nabla_s^2 \varkappa + \frac{1}{2}|\varkappa|^2 \varkappa, \tag{1.2}$$

where $\nabla_s \phi$ denotes the normal component of $\partial_s \phi$, i.e., $\nabla_s \phi = \partial_s \phi - \langle \partial_s \phi, \tau \rangle \tau$. Critical points of E subject to fixed length are called *elasticae*. In $\mathbb{R}^3$ the only stable elastica is the simply covered round circle, while in $\mathbb{R}^2$ multiple coverings of the circle and a figure eight solution are also stable [9]. However, there are unstable critical points in $\mathbb{R}^3$ [8].

For any $\lambda > 0$ the elasticae are (up to homothety) exactly the critical points of the energy

$$E_\lambda(f) = E(f) + \lambda\, L(f). \tag{1.3}$$

Thus one may expect that the gradient flow for E_λ, defined by the equation

$$\partial_t f = -\nabla_s^2 \varkappa - \frac{1}{2}|\varkappa|^2 \varkappa + \lambda\, \varkappa, \tag{1.4}$$

deforms a given curve into an elastica. Alternatively, one may consider the gradient flow for E subject to fixed length. This again leads to (1.4), but now the parameter λ is not constant and depends on the map via

$$\lambda = \frac{\int_I \langle \nabla_s^2 \varkappa + \frac{1}{2}|\varkappa|^2 \varkappa, \varkappa \rangle \, ds}{\int_I |\varkappa|^2 \, ds}. \tag{1.5}$$

For $n = 2$, long-time existence and subconvergence up to translations are due to Polden [10, 11] for (1.4) with $\lambda > 0$ fixed and due to Wen [14] when coupled with (1.5); the result in [14] is obtained only for curves with a nonzero rotation index. Flows approaching elasticae but geometrically different from the above have been investigated by Langer and Singer [9], Koiso [7], and other authors. Here we also briefly consider the equation

$$\partial_t f = -\nabla_s^2 \varkappa; \tag{1.6}$$

for $n = 2$, this is the one-dimensional analogue of surface diffusion [3]. Along the evolution (1.6) the length decreases and, for $n = 2$, the enclosed area is preserved. However, the L^2-norm of $\varkappa$ need not remain bounded, and the solutions may develop singularities [11].

Our analytic results for these evolution problems are presented in section 3. For the curve diffusion flow (1.6), we prove a lower bound on the existence time in terms of the L^2-norm of $\varkappa$, which may be useful when rescaling the flow at a singularity. In case of the elastic flows, where the energy $E(f) = \frac{1}{2}||\varkappa||_{L^2}^2$ is bounded a priori, we show long-time existence and subconvergence up to translations. This generalizes the results of Polden and Wen to an arbitrary dimension and covers the open case of zero rotation number for the length-constrained flow in $\mathbb{R}^2$. Our method, which essentially follows [10, 11, 14], is based on L^2 curvature estimates combined with Gagliardo–Nirenberg-type inequalities. This technique has also been employed by other authors; see for example [1]. For the length-constrained flow, a little extra argument is needed since one of the terms is critical for the interpolation.

The second aspect we address is the problem of numerically computing solutions, guided by ideas which have been developed for the isotropic and anisotropic curve shortening flow in [4, 5]. Based on the variational form of the problems, we shall derive numerical algorithms which will lead to suitable difference schemes with respect to space and time. The schemes are based on a discretization with piecewise linear finite elements for a mixed method. The fourth order problem will be written as a system of second order problems, and so we can avoid the discretization with C^1-elements. The time discretization will be done in a semi-implicit way. The scheme then requires the solution of a system of nearly tridiagonal linear equations in each time step. We provide test computations for the elastic flow in two and three dimensions with and without fixed length of the curve. The curve diffusion case is numerically quite close to the elastic flow problem and so is technically solved in a similar way. We show results for examples with singularities. We do not prove the convergence of the algorithms. This will be a topic of future research.

The graphics were done with the use of the visualization package GRAPE [12].

2. Equations of evolution and inequalities.

We start by considering a time-dependent curve $f : [0, T) \times I \to \mathbb{R}^n$ and put

$$\partial_t f = V + \varphi \, \tau, \tag{2.1}$$

where V is the normal velocity and $\varphi = \langle \partial_t f, \tau \rangle$. As $\langle \partial_s \phi, \tau \rangle = -\langle \phi, \partial_s \tau \rangle = -\langle \phi, \varkappa \rangle$ for any normal field ϕ along f, we have

$$\nabla_s \phi = \partial_s \phi + \langle \phi, \varkappa \rangle \tau \quad (\phi \text{ normal}). \tag{2.2}$$

The first lemma expresses the time derivative of various geometric quantities associated to f in terms of V and φ.

LEMMA 2.1. *The following formulae follow from* (2.1)*:*

$$\partial_t(ds) = (\partial_s \varphi - \langle \varkappa, V \rangle) ds, \tag{2.3}$$

$$\partial_t \partial_s - \partial_s \partial_t = (\langle \varkappa, V \rangle - \partial_s \varphi) \partial_s, \tag{2.4}$$

$$\partial_t \tau = \nabla_s V + \varphi \, \varkappa, \tag{2.5}$$

$$\partial_t \phi = \nabla_t \phi - \langle \nabla_s V + \varphi \varkappa, \phi \rangle \, \tau, \tag{2.6}$$

$$\nabla_t \varkappa = \nabla_s^2 V + \langle \varkappa \, , V \, \rangle \varkappa + \varphi \nabla_s \varkappa, \tag{2.7}$$

$$(\nabla_t \nabla_s - \nabla_s \nabla_t) \phi = (\langle \varkappa, V \rangle - \partial_s \varphi) \nabla_s \phi + \langle \varkappa, \phi \rangle \nabla_s V - \langle \nabla_s V, \phi \rangle \varkappa. \tag{2.8}$$

Here in (2.6) and (2.8) the vectorfield ϕ is assumed to be normal, i.e., $\langle \phi, \tau \rangle \equiv 0$.

Proof. Equations (2.3) and (2.4) follow from

$$\frac{1}{\gamma} \partial_t \gamma = \frac{1}{\gamma} \langle \tau, \, \partial_t \, \partial_x f \rangle = \langle \tau, \, \partial_s (V + \varphi \tau) \rangle = \partial_s \varphi - \langle \varkappa, \, V \rangle.$$

Writing $\tau = \partial_s f$, (2.5) is obtained from (2.4) and (2.2), and (2.6) follows because $\langle \partial_t \phi, \tau \rangle = -\langle \phi, \partial_t \tau \rangle$. The equation for $\varkappa$ combines (2.4) and (2.5), substituting $\varkappa = \partial_s \tau$. Finally, we have, for any normal field ψ using successively (2.2), (2.4), (2.5), and (2.6),

$$\begin{aligned}
\langle \nabla_t \nabla_s \phi, \, \psi \rangle &= \langle \partial_t (\partial_s \phi + \langle \phi, \, \varkappa \rangle \tau), \, \psi \rangle \\
&= \langle \partial_s \, \partial_t \phi, \, \psi \rangle + (\langle \varkappa, \, V \rangle - \partial_s \varphi) \langle \nabla_s \phi, \psi \rangle + \langle \phi, \, \varkappa \rangle \langle \nabla_s V + \varphi \varkappa, \psi \rangle \\
&= \langle \partial_s (\nabla_t \phi - \langle \nabla_s V + \varphi \varkappa, \phi \rangle \tau), \, \psi \rangle \\
&\quad + (\langle \varkappa, \, V \rangle - \partial_s \varphi) \langle \nabla_s \phi, \, \psi \rangle + \langle \phi, \, \varkappa \rangle \langle \nabla_s V + \varphi \varkappa, \psi \rangle \\
&= \langle \nabla_s \nabla_t \phi, \, \psi \rangle + (\langle \varkappa, \, V \rangle - \partial_s \varphi) \langle \nabla_s \phi, \, \psi \rangle \\
&\quad + \langle \varkappa \, , \phi \rangle \langle \nabla_s V, \psi \rangle - \langle \nabla_s V, \phi \rangle \langle \varkappa, \, \psi \rangle,
\end{aligned}$$

which proves formula (2.8). □

In the following, we often use integration by parts for ∇_s, which is possible since

$$\partial_s \langle \phi, \psi \rangle = \langle \nabla_s \phi, \psi \rangle + \langle \phi, \nabla_s \psi \rangle \quad (\phi, \psi \text{ normal}). \tag{2.9}$$

For any (not necessarily normal) variation $f_\varepsilon(x) = f(x) + \varepsilon \phi(x)$, one has, by passing to components as in (2.1) and using (2.3), (2.7), and (2.9),

$$\frac{d}{d\varepsilon} L(f_\varepsilon)|_{\varepsilon=0} = -\int_I \langle \varkappa, \phi \rangle ds, \quad \frac{d}{d\varepsilon} E(f_\varepsilon)|_{\varepsilon=0} = \int_I \left\langle \nabla_s^2 \varkappa + \frac{1}{2} |\varkappa|^2 \varkappa, \, \phi \right\rangle ds.$$

This justifies the formulae (1.2) for the L^2 gradient of E and (1.5) for the Lagrange multiplier in the length-constrained flow. For the curve diffusion (1.6), we observe

$$\frac{d}{dt} L(f) = \int_I \langle \varkappa, \nabla_s^2 \varkappa \rangle ds = -\int_I |\nabla_s \varkappa|^2 ds \leq 0. \tag{2.10}$$

Furthermore, in the $n = 2$ case, the enclosed area will be preserved since, if ν denotes the exterior unit normal,

$$\int_I \langle \partial_t f, \nu\rangle ds = -\int_I \langle \nabla_s^2 \varkappa, \nu\rangle ds = -\int_I \partial_s \langle \nabla_s \varkappa, \nu\rangle ds = 0.$$

Lemma 2.2. *Suppose $f : [0, T) \times I \to \mathbb{R}^n$ moves in a normal direction with velocity $\partial_t f = V$, ϕ is a normal vector field along f, and $\nabla_t \phi + \nabla_s^4 \phi = Y$. Then*

$$\frac{d}{dt}\frac{1}{2}\int_I |\phi|^2 ds + \int_I |\nabla_s^2 \phi|^2 ds = \int_I \langle Y, \phi\rangle ds - \frac{1}{2}\int_I |\phi|^2 \langle \varkappa, V\rangle ds. \tag{2.11}$$

Furthermore $\psi = \nabla_s \phi$ satisfies the equation

$$\nabla_t \psi + \nabla_s^4 \psi = \nabla_s Y + \langle \phi, \varkappa\rangle \nabla_s V - \langle \phi, \nabla_s V\rangle \varkappa + \langle \varkappa, V\rangle \psi. \tag{2.12}$$

Proof. Equation (2.11) follows from the definitions, using (2.3) and (2.9); and (2.12) is a consequence of (2.8). □

Before the next lemma we need to explain some notation. For normal vector fields $\phi_1, \ldots, \phi_k$ along f we denote by $\phi_1 * \cdots * \phi_k$ a term of the type

$$\phi_1 * \ldots * \phi_k = \begin{cases} \langle \phi_{i_1}, \phi_{i_2}\rangle \cdots \langle \phi_{i_{k-1}}, \phi_{i_k}\rangle & \text{for } k \text{ even,} \\ \langle \phi_{i_1}, \phi_{i_2}\rangle \cdots \langle \phi_{i_{k-2}}, \phi_{i_{k-1}}\rangle \phi_{i_k} & \text{for } k \text{ odd,} \end{cases}$$

where $i_1, \ldots, i_k$ is any permutation of $1, \ldots, k$. Slightly more generally, we also allow that some of the ϕ_i are functions, in which case the $*$-product reduces to multiplication. For a normal vectorfield ϕ along f, we denote by $P_\nu^\mu(\phi)$ any linear combination of terms of the type $\nabla_s^{i_1}\phi * \cdots * \nabla_s^{i_\nu}\phi$ with universal, constant coefficients, where $\mu = i_1 + \cdots + i_\nu$ is the total number of derivatives. We observe the two properties:

$$P_\nu^\mu(\phi) * P_\beta^\alpha(\phi) = P_{\nu+\beta}^{\mu+\alpha}(\phi), \quad \nabla_s P_\nu^\mu(\phi) = P_\nu^{\mu+1}(\phi).$$

Lemma 2.3. *Suppose $\partial_t f = -\nabla_s^2 \varkappa + \lambda \varkappa + \sigma |\varkappa|^2 \varkappa$, where $\lambda, \sigma \in \mathbb{R}$. Then for $m \geq 0$ the derivatives of the curvature $\phi_m = \nabla_s^m \varkappa$ satisfy*

$$\nabla_t \phi_m + \nabla_s^4 \phi_m = P_3^{m+2}(\varkappa) + \lambda(\nabla_s^{m+2}\varkappa + P_3^m(\varkappa)) + \sigma(P_3^{m+2}(\varkappa) + P_5^m(\varkappa)).$$

The statement is also true when $\lambda = \lambda(t)$ depends on time.

Proof. For $m = 0$ this follows from (2.7). For $m \geq 1$ we inductively obtain using (2.12)

$$\begin{aligned} \nabla_t \phi_m + \nabla_s^4 \phi_m = \nabla_s &\left[P_3^{m+1}(\varkappa) + \lambda(\nabla_s^{m+1}\varkappa + P_3^{m-1}(\varkappa)) + \sigma(P_3^{m+1}(\varkappa) + P_5^{m-1}(\varkappa))\right] \\ &+ \nabla_s^{m-1}\varkappa * \varkappa * \nabla_s(-\nabla_s^2 \varkappa + \lambda \varkappa + \sigma |\varkappa|^2 \varkappa) \\ &+ \varkappa * (-\nabla_s^2 \varkappa + \lambda \varkappa + \sigma |\varkappa|^2 \varkappa) * \nabla_s^m \varkappa, \end{aligned}$$

and the claim of the lemma follows. □

Next we derive some estimates for curvature integrals, employing as in [10, 11, 14] a variant of the Gagliardo–Nirenberg interpolation inequalities. For this we introduce the scale invariant norms $\|\varkappa\|_{k,p} = \sum_{i=0}^k \|\nabla_s^i \varkappa\|_p$, where

$$\|\nabla_s^i \varkappa\|_p = L(f)^{i+1-\frac{1}{p}} \left(\int_I \left|\nabla_s^i \varkappa\right|^p ds\right)^{\frac{1}{p}}. \tag{2.13}$$

LEMMA 2.4. *Let $f : I \to \mathbb{R}^n$ be a smooth closed curve. Then for any $k \in \mathbb{N}$, $p \geq 2$, and $0 \leq i < k$ we have*

$$\|\nabla_s^i \varkappa\|_p \leq c\, \|\varkappa\|_2^{1-\alpha} \|\varkappa\|_{k,2}^{\alpha}, \tag{2.14}$$

where $\alpha = (i + \frac{1}{2} - \frac{1}{p})/k$ and $c = c(n,k,p)$.

Proof. Assuming $L(f) = 1$ and using the inequality $\big|\partial_s|\phi|\big| \leq |\nabla_s \phi|$ for normal vector fields ϕ which follows from (2.9), the standard proof as in [2] applies. □

PROPOSITION 2.5. *Let f be as in the previous lemma. Then for any term $P_\nu^\mu(\varkappa)$ with $\nu \geq 2$ which contains only derivatives of $\varkappa$ of order at most $k-1$, we have*

$$\int_I |P_\nu^\mu(\varkappa)|\, ds \leq c\, L^{1-\mu-\nu} \|\varkappa\|_2^{\nu-\gamma} \|\varkappa\|_{k,2}^{\gamma}, \tag{2.15}$$

where $\gamma = (\mu + \frac{1}{2}\nu - 1)/k$, and $c = c(n,k,\mu,\nu)$. Moreover if $\mu + \frac{1}{2}\nu < 2k+1$, then $\gamma < 2$ and we have for any $\varepsilon > 0$

$$\int_I |P_\nu^\mu(\varkappa)|\, ds \leq \varepsilon \int_I |\nabla_s^k \varkappa|^2 ds + c\, \varepsilon^{-\frac{\gamma}{2-\gamma}} \left(\int_I |\varkappa|^2\, ds\right)^{\frac{\nu-\gamma}{2-\gamma}} + c \left(\int_I |\varkappa|^2\, ds\right)^{\mu+\nu-1}. \tag{2.16}$$

Proof. By Hölder's inequality and Lemma 2.4 with $p = \nu$, we obtain, if $i_1 + \cdots + i_\nu = \mu$ and $L = L(f)$,

$$\int_I |\nabla_s^{i_1} \varkappa * \cdots * \nabla_s^{i_\nu} \varkappa|\, ds \leq L^{1-\mu-\nu} \prod_{j=1}^{\nu} \|\nabla_s^{i_j} \varkappa\|_\nu \leq c\, L^{1-\mu-\nu} \prod_{j=1}^{\nu} \|\varkappa\|_2^{1-\alpha_j}\, \|\varkappa\|_{k,2}^{\alpha_j}.$$

Here $\alpha_j = (i_j + \frac{1}{2} - \frac{1}{\nu})/k$ and thus $\alpha_1 + \cdots + \alpha_\nu = \gamma$, which proves (2.15). Now a standard interpolation inequality (see [2]) yields

$$\|\varkappa\|_{k,2}^2 \leq c(k)\, (\|\nabla_s^k \varkappa\|_2^2 + \|\varkappa\|_2^2). \tag{2.17}$$

Therefore we obtain, assuming $\gamma < 2$,

$$\begin{aligned} L^{1-\mu-\nu} \|\varkappa\|_2^{\nu-\gamma}\, \|\varkappa\|_{k,2}^{\gamma} &\leq c\, L^{1-\mu-\nu} (\|\varkappa\|_2^{\nu-\gamma}\, \|\nabla_s^k \varkappa\|_2^{\gamma} + \|\varkappa\|_2^{\nu}) \\ &\leq c\, \|\varkappa\|_{L^2}^{\nu-\gamma}\, \|\nabla_s^k \varkappa\|_{L^2}^{\gamma} + c\, L^{1-\mu-\nu/2} \|\varkappa\|_{L^2}^{\nu} \\ &\leq \varepsilon\, \|\nabla_s^k \varkappa\|_{L^2}^2 + c\, \varepsilon^{-\frac{\gamma}{2-\gamma}}\, \|\varkappa\|_{L^2}^{2\, \frac{\nu-\gamma}{2-\gamma}} + c\, L^{1-\mu-\nu} \|\varkappa\|_{L^2}^{\nu}. \end{aligned}$$

Finally, the Poincaré inequality for $\partial_s f$ implies

$$L\, \|\varkappa\|_{L^2}^2 \geq 4\pi^2, \tag{2.18}$$

and inserting this into the last term on the right yields inequality (2.16). □

The following lemma compares the $\nabla_s^m \varkappa$ to the full derivatives $\partial_s^m \varkappa$.

LEMMA 2.6. *We have the identities*

$$\nabla_s \varkappa - \partial_s \varkappa = |\varkappa|^2 \tau, \tag{2.19}$$

$$\nabla_s^m \varkappa - \partial_s^m \varkappa = \sum_{i=1}^{\left[\frac{m}{2}\right]} Q_{2i+1}^{m-2i}(\varkappa) + \sum_{i=1}^{\left[\frac{m+1}{2}\right]} Q_{2i}^{m+1-2i}(\varkappa)\, \tau. \tag{2.20}$$

Here $Q^\mu_\nu(\varkappa)$ denotes a linear combination of terms $\partial_s^{i_1}\varkappa * \cdots * \partial_s^{i_\nu}\varkappa$ with $i_1 + \cdots + i_\nu = \mu$.

Proof. Equation (2.19) is (2.2) for $V = \varkappa$. For $m \geq 2$ we inductively compute

$$\begin{aligned}\nabla_s^m \varkappa - \partial_s^m \varkappa &= \partial_s(\nabla_s^{m-1}\varkappa) + \langle \nabla_s^{m-1}\varkappa, \varkappa\rangle \tau - \partial_s^m \varkappa \\ &= \partial_s \left(\sum_{i=1}^{\left[\frac{m-1}{2}\right]} Q^{m-1-2i}_{2i+1}(\varkappa) + \sum_{i=1}^{\left[\frac{m}{2}\right]} Q^{m-2i}_{2i}(\varkappa)\,\tau \right) \\ &\quad + \langle \partial_s^{m-1}\varkappa, \varkappa\rangle\,\tau + \sum_{i=1}^{\left[\frac{m-1}{2}\right]} \langle Q^{m-1-2i}_{2i+1}(\varkappa), \varkappa\rangle\,\tau,\end{aligned}$$

and the claim follows. □

LEMMA 2.7. *Assume the bounds $\|\varkappa\|_{L^2} \leq \Lambda_0$ and $\|\nabla_s^m \varkappa\|_{L^1} \leq \Lambda_m$ for $m \geq 1$. Then for any $m \geq 1$ one has*

$$\|\partial_s^{m-1}\varkappa\|_{L^\infty} + \|\partial_s^m \varkappa\|_{L^1} \leq c_m(\Lambda_0, \ldots, \Lambda_m). \tag{2.21}$$

Proof. Clearly $\|\partial_s^{m-1}\varkappa\|_{L^\infty} \leq c(n)\,\|\partial_s^m \varkappa\|_{L^1}$, and (2.19) implies $\|\partial_s \varkappa\|_{L^1} \leq \|\nabla_s \varkappa\|_{L^1} + \|\varkappa\|^2_{L^2} \leq \Lambda_1 + \Lambda_0^2$. For $m \geq 2$ we obtain from (2.20)

$$\begin{aligned}\|\partial_s^m \varkappa\|_{L^1} &\leq \|\nabla_s^m \varkappa\|_{L^1} + \sum_{\mu=0}^{m-1} \|Q^\mu_{m+1-\mu}(\varkappa)\|_{L^1} \\ &\leq \|\nabla_s^m \varkappa\|_{L^1} + c\,(\|\varkappa\|_{L^\infty}, \ldots, \|\partial_s^{m-2}\varkappa\|_{L^\infty}) \sum_{\mu=0}^{m-1} \|\partial_s^\mu \varkappa\|_{L^1}.\end{aligned}$$

The claim follows by induction on m. □

3. Estimates and long-time existence.

For the flows considered in this paper, short-time existence is a standard matter, and we only briefly sketch the argument for the case of (1.6). It is sufficient to solve the initial value problem up to a tangential term, i.e., to find a solution $\widetilde{f} : I \times [0, \varepsilon) \longrightarrow \mathbb{R}^n$ of

$$\partial_t \widetilde{f} + \nabla_s^2 \widetilde{\varkappa} = \sigma\, \partial_x \widetilde{f}, \quad \widetilde{f}(0, \cdot\,) = f_0,$$

where $\sigma : [0, \varepsilon) \times I \longrightarrow \mathbb{R}^n$ is an arbitrary function. Namely, in solving the ODE initial value problem $\partial_t \varphi = \sigma(t, \varphi)$ with $\varphi(0, \cdot\,) = id$, one easily verifies that $f(t,x) = \widetilde{f}\big(t, \varphi(t,x)\big)$ satisfies $\partial_t f + \nabla_s^2 \varkappa = 0$. Now from $\partial_s = \frac{1}{\gamma}\partial_x$ and $\nabla_s \phi = \partial_s \phi + \langle \varkappa, \phi\rangle \tau$, one infers

$$\nabla_s^2 \varkappa = \gamma^{-4}(\partial_x^4 f - \langle \partial_x^4 f, \tau\rangle \tau) + \text{ lower order terms.}$$

Thus one can apply standard theory to the equation $\partial_t \widetilde{f} = -\nabla_s^2 \widetilde{\varkappa} + \widetilde{\gamma}^{-4}\langle \partial_x^4 \widetilde{f}, \widetilde{\tau}\rangle \widetilde{\tau}$ and proceed as indicated. The argument applies as it stands to (1.4) when λ is constant; if λ is given by (1.5), one observes that the nonlocal term in the linearization is a compact operator between the relevant parabolic Hölder spaces and argues as before.

We now start with an estimate for the curve diffusion flow (1.6). Recall from [10, 6] that there are examples of finite time singularities in this case.

Theorem 3.1. *Let $f : [0,T) \times I \to \mathbb{R}^n$ be a maximal solution of the curve diffusion equation $\partial_t f = -\nabla_s^2 \varkappa$. If $T < \infty$, then*

$$\int_I |\varkappa|^2 \, ds \geq c\,(T-t)^{-1/4}.$$

Proof. Combining Lemma 2.3 and (2.11) yields for $m \geq 0$

$$\frac{d}{dt}\frac{1}{2}\int_I |\nabla_s^m \varkappa|^2 \, ds + \int_I |\nabla_s^{m+2}\varkappa|^2 \, ds = \int_I \langle P_3^{m+2}(\varkappa), \nabla_s^m \varkappa\rangle \, ds.$$

The terms of type $P_3^{m+2}(\varkappa)$ that contain the $(m+2)$nd derivative have the form $\varkappa * \varkappa * \nabla_s^{m+2}\varkappa$. Integrating by parts, we achieve that only derivatives of order $m+1$ or less occur on the right-hand side. Using (2.16) with $k = m+2$, $\mu = 2m+2$, $\nu = 4$, and $\gamma = 2 - \frac{1}{m+2}$ we have

$$\int_I \langle P_3^{m+2}(\varkappa), \nabla_s^m \varkappa\rangle \, ds \leq \varepsilon \int_I |\nabla_s^{m+2}\varkappa|^2 \, ds + c_m(\varepsilon)\left(\int_I |\varkappa|^2 \, ds\right)^{2m+5}, \tag{3.1}$$

which yields, after absorbing for $\varepsilon = \frac{1}{2}$,

$$\frac{d}{dt}\int_I |\nabla_s^m \varkappa|^2 \, ds + \int_I |\nabla_s^{m+2}\varkappa|^2 \, ds \leq c_m \left(\int_I |\varkappa|^2 \, ds\right)^{2m+5}. \tag{3.2}$$

Now we prove by contradiction that $\limsup_{t \nearrow T} \|\varkappa\|_{L^2} = \infty$. Instead, assuming $\|\varkappa\|_{L^2} \leq \Lambda$ for all $t < T$, we have $\|\nabla_s^m \varkappa\|_{L^2}^2(t) \leq \|\nabla_s^m \varkappa\|_{L^2}^2(0) + c_m(\Lambda)T$ by estimate (3.2). Since $\|\nabla_s^m \varkappa\|_{L^1} \leq L(f)^{\frac{1}{2}} \|\nabla_s^m \varkappa\|_{L^2}$ and $L(f) \leq L(f_0)$ by (2.10), Lemma 2.7 implies

$$\|\partial_s^m \varkappa\|_{L^\infty} \leq c_m(\Lambda, f_0, T) \quad \text{for all } m \in \mathbb{N}_0. \tag{3.3}$$

By the differential equation, we further have

$$\|\partial_s^m V\|_{L^\infty} \leq c_m(\Lambda, f_0, T) \quad \text{for all } m \in \mathbb{N}_0, \quad \|f\|_{L^\infty} \leq c\,(\Lambda, f_0, T). \tag{3.4}$$

Now $\gamma = |\partial_x f|$ satisfies $\partial_t \gamma = -\langle \varkappa, V\rangle\,\gamma$ by (2.3), so that by (3.3) and (3.4) with $m = 0$

$$c^{-1} \leq \gamma \leq c \quad \text{with } c = c\,(\Lambda, f_0, T) > 0. \tag{3.5}$$

For any function $h : I \to \mathbb{R}$ we have $\partial_x^m h - \gamma^m \partial_s^m h = P_m(\gamma, \ldots, \partial_x^{m-1}\gamma, h, \ldots, \partial_s^{m-1}h)$, where P_m is a polynomial. Thus inductively assuming $\|\partial_x^j \gamma\|_{L^\infty} \leq c\,(j, \Lambda, f_0, T)$ for $0 \leq j \leq m-1$, we apply this for $h = \langle \varkappa, V\rangle$ and obtain $\|\partial_x^m \langle \varkappa, V\rangle\|_{L^\infty} \leq c_m(\Lambda, f_0, T)$, using (3.3), (3.4), and (3.5). But differentiating the ODE for γ yields $\partial_t(\partial_x^m \gamma) + \langle \varkappa, V\rangle(\partial_x^m \gamma) \leq c_m(\Lambda, f_0, T)$, which in turn implies

$$\|\partial_x^m \gamma\|_{L^\infty} \leq c_m(\Lambda, f_0, T). \tag{3.6}$$

Then by (3.4), from the equations $|\partial_s f| = 1$ and $\partial_s^2 f = \varkappa$ and from the estimates (3.3) and (3.6), we conclude $\|\partial_x^m f\|_{L^\infty} \leq c_m(\Lambda, f_0, T)$. Together with (3.4) and (3.5), this means that f extends smoothly to $[0,T] \times I$, and in fact even beyond T by short-time existence, which contradicts the maximality of T and therefore proves that $\varkappa$ cannot be uniformly bounded in L^2 on $[0,T)$. Now (3.2) for $m=0$ means

$$\frac{d}{dt}\int_I |\varkappa|^2\, ds \le c\left(\int_I |\varkappa|^2\, ds\right)^5,$$

and the theorem follows by integrating on $[t,t_l]$, where $t_l \nearrow T$ with $\|\varkappa\|_{L^2} \to \infty$. □

We next turn our attention to the elastic flows where the L^2 integral of $\varkappa$ is bounded a priori.

THEOREM 3.2. *For any $\lambda \in [0,\infty)$ and smooth initial data f_0, the L^2 gradient flow* (1.4) *for $E_\lambda(f) = \int_I \left(\frac{1}{2}|\varkappa|^2 + \lambda\right) ds$ has a global solution. If $\lambda > 0$, then as $t_i \to \infty$ the curves $f(t_i,\cdot)$ subconverge, when reparametrized by arclength and suitably translated, to an elastica.*

Proof. By (2.11) and Lemma 2.3 we have

$$\tag{3.7} \begin{aligned} &\frac{d}{dt}\frac{1}{2}\int_I |\nabla_s^m \varkappa|^2\, ds + \int_I |\nabla_s^{m+2}\varkappa|^2\, ds + \lambda\int_I |\nabla_s^{m+1}\varkappa|^2\, ds \\ &\quad = \lambda\int_I \langle P_3^m(\varkappa), \nabla_s^m\varkappa\rangle ds + \int_I \langle P_3^{m+2}(\varkappa) + P_5^m(\varkappa), \nabla_s^m\varkappa\rangle ds. \end{aligned}$$

Recalling (3.1) and using (2.16) for $k=m+2$, $\mu = 2m$, and $\nu = 6$, the last integral is estimated under an assumed bound $E(f) \le \Lambda$ by

$$\tag{3.8} \int_I \langle P_3^{m+2}(\varkappa) + P_5^m(\varkappa), \nabla_s^m\varkappa\rangle ds \le \varepsilon\int_I |\nabla_s^{m+2}\varkappa|^2 ds + c_m(\Lambda,\varepsilon).$$

Again by (2.16) but now for $k=m+2$, $\mu=2m$, and $\nu=4$ we infer

$$\int_I \langle P_3^m(\varkappa), \nabla_s^m\varkappa\rangle ds \le \varepsilon\int_I |\nabla_s^{m+2}\varkappa|^2 ds + c_m(\Lambda)\,(\varepsilon^{-\frac{2m+1}{3}} + 1).$$

Multiplying by λ and replacing ε with $\varepsilon/|\lambda|$ yield

$$\tag{3.9} \lambda\int_I \langle P_3^m(\varkappa), \nabla_s^m\varkappa\rangle ds \le \varepsilon\int_I |\nabla_s^{m+2}\varkappa|^2 ds + c_m(\Lambda,\varepsilon)\,(|\lambda|^{\frac{2(m+2)}{3}} + 1).$$

Now if $E_\lambda(f_0) \le \Lambda$, we obtain, by combining (3.7), (3.8), and (3.9),

$$\tag{3.10} \frac{d}{dt}\int_I |\nabla_s^m\varkappa|^2 ds + \int_I |\nabla_s^{m+2}\varkappa|^2 ds \le c_m(\lambda,\Lambda).$$

On the other hand (2.3) yields

$$\frac{d}{dt}L(f) + \int_I |\nabla_s\varkappa|^2 ds + \lambda\int_I |\varkappa|^2 ds = \frac{1}{2}\int_I |\varkappa|^4 ds,$$

and (2.16) with $k=1$, $\mu=0$, and $\nu=4$ implies

$$\tag{3.11} \frac{d}{dt}L(f) + \frac{1}{2}\int_I |\nabla_s\varkappa|^2 ds \le c\,(\Lambda).$$

Together with (3.10) and (3.11) the argument in the proof of Theorem 3.1 yields long-time existence. Now if $\lambda > 0$, then by (2.18) and the energy bound we have a length bound

$$2\pi^2/\Lambda \leq L(f) \leq \Lambda/\lambda. \tag{3.12}$$

Taking $k = m+2$ in (2.17) and inserting into (3.10) therefore imply

$$\frac{d}{dt}\int_I |\nabla_s^m \varkappa|^2 ds + c_0 \int_I |\nabla_s^m \varkappa|^2 ds \leq c_m(\lambda, \Lambda),$$

where $c_0 = c_0(\lambda, \Lambda) > 0$. This yields a bound $\|\nabla_s^m \varkappa\|^2_{L^2}(t) \leq \|\nabla_s^m \varkappa\|^2_{L^2}(0) + c_m(\lambda, \Lambda)$, and by (3.12) and Lemma 2.7 one concludes

$$\|\partial_s^m \varkappa\|_{L^\infty} + \|\nabla_s^m \varkappa\|_{L^\infty} \leq c_m(\lambda, f_0). \tag{3.13}$$

Thus if $\widetilde{f}(t,\cdot)$ is the reparametrization of $f(t,\cdot)$ by arclength, then as $t \to \infty$, subsequences $\widetilde{f}(t_i,\cdot) - p_i$ converge smoothly to a limit curve f_∞ for an appropriate choice of p_i. Lemma 2.3 and the estimate (3.13) imply $\|\nabla_t(\nabla_s^m \varkappa)\|_{L^\infty} \leq c_m(\lambda, f_0)$. From this and (3.12), (3.13) one sees that the function $u(t) = \|V\|^2_{L^2}(t)$ satisfies $|\dot{u}(t)| \leq c(\lambda, f_0)$, where on the other hand $u \in L^1((0,\infty))$ by the energy identity. Therefore $u(t) \to 0$ as $t \to \infty$ which means that f_∞ is an elastica. □

As one readily checks, the interpolation argument breaks down exactly for a quintic term $|\varkappa|^4\varkappa$ on the right-hand side of the evolution equation for f, since then equality holds in the condition $\mu + \frac{1}{2}\nu < 2k+1$ of Proposition 2.5 as $\mu = 2m+2$, $\nu = 6$, and $k = m+2$. Let us finally consider the length-constrained flow.

THEOREM 3.3. *The gradient flow for $E(f) = \frac{1}{2}\int_I |\varkappa|^2 ds$ subject to fixed length $L(f) = L_0$ has a global solution for any smooth initial curve f_0. As $t \to \infty$, the curves subconverge, after reparametrization by arclength and translation, to an elastica.*

Proof. One again has (3.7) where now $\lambda = \lambda(t)$ is given by (1.5). Choosing Λ with $E(f_0) + L(f_0) \leq \Lambda$, we estimate using (2.18) and (2.16) with $k = 1$, $\mu = 0$, and $\nu = 4$

$$|\lambda| \leq c(\Lambda)\,(\|\nabla_s \varkappa\|^2_{L^2} + \|\varkappa\|^4_{L^4}) \leq c(\Lambda)(\|\nabla_s \varkappa\|^2_{L^2} + 1).$$

Using (2.14) with $k = m+2$, $p = 2$, $i = 1$, and $\alpha = \frac{1}{m+2}$, followed by (2.17) and Young's inequality, we obtain

$$|\lambda| \leq c_m(\Lambda)\,(\|\nabla_s^{m+2}\varkappa\|^{\frac{2}{m+2}}_{L^2} + 1).$$

Combination with (3.9) further implies, as $\frac{2}{m+2} \cdot \frac{2(m+2)}{3} = \frac{4}{3} < 2$,

$$\lambda \int_I \langle P_3^m(\varkappa), \nabla_s^m \varkappa\rangle\, ds \leq \varepsilon \int_I |\nabla_s^{m+2}\varkappa|^2 ds + c_m(\Lambda, \varepsilon). \tag{3.14}$$

As to the other term in (3.7) which contains λ, note that (2.14) only gives an inequality $\|\nabla_s^{m+1}\varkappa\|_{L^2} \leq c_m(\Lambda)\|\varkappa\|^\alpha_{m+2,2}$ where $\alpha = \frac{m+1}{m+2}$, which means that the term has critical scaling and the interpolation technique used up to now fails. Instead we employ the scaling properties of E and L: under a dilation $f \to f_\alpha = p + \alpha(f-p) = f + (\alpha - 1)(f-p)$ centered at some point $p \in \mathbb{R}^n$, the energy multiplies by $1/\alpha$ while the length goes like α. Taking the derivative at $\alpha = 1$ and using the definition (1.4) of the gradient flow we see that

$$E(f) - \lambda\, L(f) = -\frac{d}{d\alpha}\left(E(f_\alpha) + \lambda\, L(f_\alpha)\right)|_{\alpha=1} = \int_I \langle \partial_t f, f - p\rangle\, ds.$$

Since $|f - p| \leq L_0$ for appropriate $p = p(t)$, for example taking $p(t) = \int_I f\, ds/L$, this implies $-\lambda \leq L_0^{1/2} \|\partial_t f\|_{L^2}$. For $\lambda^-(t) = -\min\{\lambda(t), 0\}$, one thus gets from the energy identity the estimate

$$\int_0^t \lambda^-(\tau)^2 d\tau \leq c(\Lambda). \tag{3.15}$$

Now the integral in (3.7) is bounded by

$$-\lambda \int_I |\nabla_s^{m+1} \varkappa|^2 ds \leq \varepsilon \int_I |\nabla_s^{m+2} \varkappa|^2 ds + c(\varepsilon)\, \lambda^-(t)^2 \int_I |\nabla_s^m \varkappa|^2 ds. \tag{3.16}$$

From (3.7), (3.8), (3.14), and (3.16) we conclude

$$\frac{d}{dt} \int_I |\nabla_s^m \varkappa|^2\, ds + c_0 \int_I |\nabla_s^m \varkappa|^2\, ds \leq c_m(\Lambda) \left(1 + \lambda^-(t)^2 \int_I |\nabla_s^m \varkappa|^2\, ds\right),$$

where $c_0 = c_0(\Lambda) > 0$ and the Poincaré inequality (2.17) was used. Defining the function $u_m(t) = \exp(c_0 t)\, \|\nabla_s^m \varkappa\|_{L^2}^2$, we have $\dot{u}_m(t) \leq c_m(\Lambda)\, [\, \exp(c_0 t) + \lambda^-(t)^2\, u_m(t)\,]$, and the Gronwall lemma implies

$$u_m(t) \leq e^{a_m(t)} \left(u_m(0) + c_m(\Lambda) \int_0^t e^{c_0 \tau} d\tau\right).$$

Here $a_m(t) = c_m(\Lambda) \int_0^t \lambda^-(\tau)^2\, d\tau \leq c_m(\Lambda)$ by (3.15), and we finally obtain

$$\|\nabla_s^m \varkappa\|_{L^2}^2 \leq c_m(\Lambda) \left(1 + e^{-c_0 t} \|\nabla_s^m \varkappa\|_{L^2}^2(0)\right) \leq c_m(f_0);$$

in particular $|\lambda| \leq c_m(f_0)$. From here the proof proceeds as in Theorem 3.2. □

4. Numerical algorithm.

The numerical algorithm we propose is based on the fact that the evolution equations have a weak formulation. In fact (2.2) implies

$$\nabla_s^2 \varkappa + \frac{1}{2} |\varkappa|^2 \varkappa = \partial_s \left(\partial_s \varkappa + \frac{3}{2} |\varkappa|^2 \tau\right), \tag{4.1}$$

which reveals the divergence form of the main part. In order to avoid C^1-elements for the discretization of (1.4), we rewrite that equation as a system of second order problems for the position vector f and the curvature vector $\varkappa$. It is important to use the mean curvature vector and not the curvature as an additional variable, because we shall work with piecewise affine functions, and the discrete position vector then will be a parametrization of a polygon with piecewise constant and discontinuous normal.

We shall describe the development of the numerical algorithm for the main problem (1.4). It is equivalent to the system

$$\partial_t f + \partial_s^2 \varkappa + \frac{3}{2} \partial_s (|\varkappa|^2 \partial_s f) - \lambda \varkappa = 0, \tag{4.2}$$

$$\varkappa - \partial_s^2 f = 0. \tag{4.3}$$

Because of $\partial_s = \partial_x / |\partial_x f|$, a variational formulation of (4.2), (4.3) is given by

$$\int_I \partial_t f |\partial_x f| \varphi \, dx - \int_I \frac{\partial_x \varkappa}{|\partial_x f|} \partial_x \varphi \, dx - \frac{3}{2} \int_I |\varkappa|^2 \frac{\partial_x f}{|\partial_x f|} \partial_x \varphi \, dx - \lambda \int_I \varkappa \varphi |\partial_x f| \, dx = 0, \tag{4.4}$$

$$\int_I \varkappa |\partial_x f| \psi \, dx + \int_I \frac{\partial_x f}{|\partial_x f|} \partial_x \psi \, dx = 0 \tag{4.5}$$

for all test functions $\varphi, \psi \in H^1(\mathbb{R}/\mathbb{Z}, \mathbb{R}^n)$. We use this weak form of our problem for a finite element discretization in space, which in one space dimension will lead to a suitable difference scheme. Let $I = \bigcup_{j=1}^N I_j$ be a decomposition of $I = \mathbb{R}/\mathbb{Z}$ into intervals given by the nodes x_j, $I_j = [x_{j-1}, x_j]$. Let $h_j = |I_j|$ and $h = \max_{j=1,\dots,N} h_j$ be the maximal diameter of a grid element. For a discretization of (4.4), (4.5) we replace the continuous space $X = H^1(\mathbb{R}/\mathbb{Z}, \mathbb{R}^n)$ by the discrete finite-dimensional space

$$X_h = \left\{ w \in C^0(\mathbb{R}/\mathbb{Z}, \mathbb{R}^n) | \; w|_{I_j} \in \mathbb{P}_1(I_j), j = 1, \dots, N \right\} = Y_h^n$$

of continuous (periodic) piecewise affine functions on the grid. Here Y_h is the space of scalar piecewise affine functions. We use the scalar nodal basis functions $\varphi_j \in Y_h$, $\varphi_j(x_i) = \delta_{ij}$.

$$X_h = Y_h^n = \left(\operatorname{span}\{\varphi_1, \dots, \varphi_N\} \right)^n.$$

We shall use the pointwise interpolation $I_h w$ of a suitable function $w \in C^0(\mathbb{R}/\mathbb{Z}, \mathbb{R}^n)$ which is uniquely defined by $I_h w \in X_h$ and $I_h w(x_j) = w(x_j)$ $(j = 1, \dots, N)$.

A spatially discrete solution of (4.4), (4.5) will be a pair of functions $f_h : [0,T] \to X_h$, $\varkappa_h : [0,T] \to X_h$,

$$f_h(x,t) = \sum_{j=1}^N f_j(t) \varphi_j(x), \quad \varkappa_h(x,t) = \sum_{j=1}^N \varkappa_j(t) \varphi_j(x).$$

Note that each f_j or $\varkappa_j$ is a vector in $\mathbb{R}^n$. It is also worth noticing that $\varkappa_h$ cannot be the second derivative of the piecewise linear position vector f_h.

We look for $f_h(\cdot, t), \varkappa_h(\cdot, t) \in X_h$, $t \in [0,T]$, such that

$$f_h(\cdot, 0) = f_{h0} = I_h f_0$$

and, for all discrete test functions $\varphi_h, \psi_h \in X_h$,

$$\begin{aligned} \int_I I_h \left(\partial_t f_h \varphi_h \right) |\partial_x f_h| \, dx - \int_I \frac{\partial_x \varkappa_h}{|\partial_x f_h|} \partial_x \varphi_h \, dx - \frac{3}{2} \int_I |\varkappa_h|^2 \frac{\partial_x f_h}{|\partial_x f_h|} \partial_x \varphi_h \, dx \\ - \lambda \int_I I_h \left(\varkappa_h \varphi_h \right) |\partial_x f_h| \, dx = 0, \end{aligned} \tag{4.6}$$

$$\int_I I_h \left(\varkappa_h \psi_h \right) |\partial_x f_h| \, dx + \int_I \frac{\partial_x f_h}{|\partial_x f_h|} \partial_x \psi_h \, dx = 0. \tag{4.7}$$

We have used the lumping of masses for practical reasons in both equations. The first equation holds for all $t \in (0,T]$ and the second for all $t \in [0,T]$, and so gives the initial data for $\varkappa_h$. We insert $\varphi_h = \varphi_j$, and $\psi_h = \varphi_j$ $(j = 1, \ldots, N)$ separately for each component into these equations and integrate. The discrete weak equations (4.6), (4.7) are equivalent to the following system of nN ODEs:

$$\begin{aligned} &\frac{1}{2}\left(|f_j - f_{j-1}| + |f_{j+1} - f_j|\right)(\partial_t f_j - \lambda\varkappa_j) - \left(\frac{\varkappa_j - \varkappa_{j-1}}{|f_j - f_{j-1}|} - \frac{\varkappa_{j+1} - \varkappa_j}{|f_{j+1} - f_j|}\right) \\ &\qquad - \frac{1}{2}\left(|\varkappa_{j-1}|^2 + \varkappa_{j-1}\varkappa_j + |\varkappa_j|^2\right)\frac{f_j - f_{j-1}}{|f_j - f_{j-1}|} \\ &\qquad + \frac{1}{2}\left(|\varkappa_j|^2 + \varkappa_j\varkappa_{j+1} + |\varkappa_{j+1}|^2\right)\frac{f_{j+1} - f_j}{|f_{j+1} - f_j|} = 0, \end{aligned} \tag{4.8}$$

$$\frac{1}{2}\left(|f_j - f_{j-1}| + |f_{j+1} - f_j|\right)\varkappa_j + \frac{f_j - f_{j-1}}{|f_j - f_{j-1}|} - \frac{f_{j+1} - f_j}{|f_{j+1} - f_j|} = 0 \tag{4.9}$$

$(j = 1, \ldots, N)$, where $f_0 = f_N, f_{N+1} = f_1, \varkappa_0 = \varkappa_N, \varkappa_{N+1} = \varkappa_1$, and the initial values are given by $f_j(0) = f_0(x_j)$ $(j = 1, \ldots, N)$.

We discretize the scheme (4.8), (4.9) with respect to time in a semi-implicit way, which is similar to the time discretization used for the curve shortening flow in isotropic or anisotropic form in [4, 5]. We use the notation

$$w^m = w(\cdot, m\tau)$$

for the evaluation of a generic function on the mth time level. τ is the chosen time step size with $\tau M = T$. Let us formulate the algorithm for the elastic flow with fixed parameter λ for curves in $\mathbb{R}^n$.

Algorithm 1 (elastic flow with fixed parameter). *For $j = 1, \ldots, N$ let $f_j^0 = f_0(x_j)$, $h_j^0 = |f_j^0 - f_{j-1}^0|$, and*

$$\varkappa_j^0 = \frac{2}{h_{j+1}^0(h_j^0 + h_{j+1}^0)} f_{j+1}^0 - \frac{2}{h_j^0 h_{j+1}^0} f_j^0 + \frac{2}{h_j^0(h_j^0 + h_{j+1})} f_{j-1}^0.$$

For $m = 0, \ldots, M-1$ compute the quantities

$$\begin{aligned} h_j^m &= |f_j^m - f_{j-1}^m|, \\ \beta_j^m &= |\varkappa_{j-1}^m|^2 + \varkappa_{j-1}^m \varkappa_j^m + |\varkappa_j^m|^2, \\ \lambda_j^m &= \lambda, \end{aligned} \tag{4.10}$$

and determine $f_j^{m+1} \in \mathbb{R}^n$ and $\varkappa_j^{m+1} \in \mathbb{R}^n$ $(j = 1, \ldots, N)$ from the linear system

$$\begin{aligned} &\frac{\beta_j^m}{2h_j^m} f_{j-1}^{m+1} + \left(\frac{h_j^m + h_{j+1}^m}{2\tau} - \frac{\beta_j^m}{2h_j^m} - \frac{\beta_{j+1}^m}{2h_{j+1}^m}\right) f_j^{m+1} + \frac{\beta_{j+1}^m}{2h_{j+1}^m} f_{j+1}^{m+1} \\ &\quad + \frac{1}{h_j^m}\varkappa_{j-1}^{m+1} - \left(\frac{1}{h_j^m} + \frac{1}{h_{j+1}^m} + \frac{\lambda_j^m}{2}(h_j^m + h_{j+1}^m)\right)\varkappa_j^{m+1} + \frac{1}{h_{j+1}^m}\varkappa_{j+1}^{m+1} \\ &\qquad = \frac{h_j^m + h_{j+1}^m}{2\tau} f_j^m, \end{aligned} \tag{4.11}$$

$$\frac{1}{2}(h_j^m + h_{j+1}^m)\varkappa_j^{m+1} - \frac{1}{h_j^m} f_{j-1}^{m+1} + \left(\frac{1}{h_j^m} + \frac{1}{h_{j+1}^m}\right) f_j^{m+1} - \frac{1}{h_{j+1}^m} f_{j+1}^{m+1} = 0 \tag{4.12}$$

($j = 1, \dots, N$) with the periodic boundary conditions $f_{i+N} = f_i$, $\varkappa_{i+N} = \varkappa_i$ ($i \in \mathbb{Z}$).

The algorithm for elastic flow with fixed length requires a slight change of the above algorithm. We have to compute the parameter λ in each time step according to a discrete version of (1.5). From the time continuous weak form (4.6) with $\varphi_h = \varkappa_h$ and (4.6) with $\psi_h = f_{ht}$, we can compute the (time-dependent) parameter λ as follows:

$$\begin{aligned} 0 = \frac{d}{dt}\int_I |f_{hx}|\,dx &= \int_I \frac{f_{hx}}{|f_{hx}|} f_{hxt}\,dx = -\int_I I_h(f_{ht}\varkappa_h)|f_{hx}|\,dx \\ &= -\int_I \frac{|\varkappa_{hx}|^2}{|f_{hx}|} - \frac{3}{2}\int_I |\varkappa_h|^2 \frac{f_{hx}}{|f_{hx}|}\varkappa_{hx}\,dx - \lambda\int_I I_h(|\varkappa_h|^2)|f_{hx}|\,dx. \end{aligned}$$

This gives

$$\lambda = -\left(\int_I \frac{|\varkappa_{hx}|^2}{|f_{hx}|}\,dx + \frac{3}{2}\int_I |\varkappa_h|^2\frac{f_{hx}}{|f_{hx}|}\varkappa_{hx}\,dx\right)\bigg/\int_I I_h(|\varkappa_h|^2)|f_{hx}|\,dx.$$

After evaluation of the integrals, we can formulate the algorithm for the length preserving elastic flow. Because of the explicit time discretization of λ, the length of the polygon is conserved only up to an additional error of size τ.

Algorithm 2 (length preserving elastic flow). *Replace* (4.10) *in Algorithm* 1 *with*

$$\lambda_j^m = -3\left(\sum_{i=1}^N \frac{|\varkappa_i^m - \varkappa_{i-1}^m|^2}{h_i^m} + \frac{1}{2}\sum_{i=1}^N (f_i^m - f_{i-1}^m)(\varkappa_i^m - \varkappa_{i-1}^m)\frac{\beta_i^m}{h_i^m}\right)\bigg/\sum_{i=1}^N h_i^m\beta_i^m.$$

The curve diffusion problem (1.6) is equivalent to the system

$$\begin{aligned} \partial_t f + \partial_s^2\varkappa + \frac{3}{2}\partial_s(|\varkappa|^2\partial_s f) - \frac{1}{2}|\varkappa|^2\varkappa = 0, \\ \varkappa - \partial_s^2 f = 0. \end{aligned}$$

The discretization procedure is analogous to the previous ones for the elastic flow with fixed parameter and for elastic flow with fixed length. We just give the algorithm here.

Algorithm 3 (curve diffusion). *Replace* (4.10) *in Algorithm* 1 *with*

$$\lambda_j^m = \frac{1}{2}|\varkappa_j^m|^2.$$

Obviously the discrete system (4.11), (4.12) does not contain the grid parameter h and thus is an intrinsic algorithm for an intrinsic problem. The grid size of the parametrization enters only via the initial condition for f_h. The linear system (4.10), (4.11), (4.12) has the form

$$\left(\frac{1}{\tau}D_m + A_m(\beta_m)\right)f^{m+1} - (A_m + \lambda D_m)\varkappa^{m+1} = \frac{1}{\tau}D_m f^m, \tag{4.13}$$

$$D_m\varkappa^{m+1} + A_m f^{m+1} = 0, \tag{4.14}$$

where f^{m+1} stands for the N-vector which consists of the kth components ($k \in \{1, \dots, n\}$) of f_j^{m+1} ($j = 1, \dots, N$), and similarly for $\varkappa^{m+1}$. This means that the system decouples with respect to the components of the position vector and of the

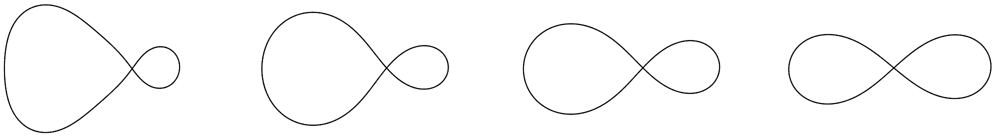

Fig. 4.1. *Length preserving elastic flow for a nonsymmetric lemniscate.*

curvature vector. D_m is a diagonal matrix and $A_m(\beta_m)$ and A_m are tridiagonal matrices depending on the results of the previous time step. Because of the periodicity assumption, the tridiagonality is true only up to two entries in the upper right and lower left corner of the matrix. But this is not a difficulty for the implementation of the linear solver.

We performed test computations for a problem with $\lambda = 0$, for which we know the exact solution of the elastic flow problem. The exact solution is given by

$$f(x,t) = (1+2t)^{\frac{1}{4}}\,(\cos g(x), \sin g(x)), \;\; \varkappa(x,t) = -\,(1+2t)^{-\frac{1}{4}}\,(\cos g(x), \sin g(x)),$$

and we have chosen $g(x) = x + 0.1 \sin x$ in order to create a nonsymmetric distribution of the nodes. We used a uniform grid in the parameter domain I. In Table 4.1 we give the errors in $L^\infty((0,1) \times I)$ between the continuous and the discrete position vector and between the continuous and the discrete curvature vector. We have used $\tau = 0.5h^2$ for the time step size. The experimental order of convergence between two successive grids with grid sizes h_1 and h_2 with respect to the error $E(h)$ is defined by

$$eoc = \log \frac{E(h_1)}{E(h_2)} \Big/ \log \frac{h_1}{h_2}.$$

The results show convergence of second order for the position vector and for the curvature vector in the maximum norm. Let us mention that for the choice $\tau = 0.5h$ one obtains linear convergence.

Figures 4.1 and 4.2 show the evolution of the same initial nonsymmetric lemniscate under length preserving elastic flow and under curve diffusion. Elastic flow converges to a symmetric figure eight curve as a stationary solution while curve diffusion produces a singularity in finite time. Curve diffusion reduces the length of the curve but keeps the enclosed (signed) area constant. The enclosed area in Figure 4.4 is zero, and this leads to a singularity in finite time. The curve “disappears.”

In Figure 4.3 we show results of the computation of the evolution of a plane curve under the length preserving elastic flow (1.4).

An example for the elastic flow of a curve in three space dimensions with a fixed parameter λ exhibits an interesting dynamical behavior. In Figure 4.5 we show projections of the three-dimensional initial curve. The results of the evolution are shown in Figures 4.6–4.9. Because of the high symmetry of the initial curve, the evolution gets near the two-dimensional stable elastica, like the multiply covered circle or the figure eight curve, and stays there for a fairly long time before it continues to unravel.

To finish, let us mention some practical features of our algorithms for the elastic flow of curves. The conditioning of the linear system (4.13), (4.14) should be improved by a diagonal preconditioning process. Instead of the original system for f^{m+1} and

$\varkappa^{m+1}$, one solves the linear system

$$\left(\frac{1}{\tau}I + D_m^{-\frac{1}{2}}A_m(\beta_m)D_m^{-\frac{1}{2}}\right)\tilde{f}^{m+1} - (D_m^{-\frac{1}{2}}A_mD_m^{-\frac{1}{2}} + \lambda I)\tilde{\varkappa}^{m+1} = \frac{1}{\tau}\tilde{f}^m,$$

$$\tilde{\varkappa}^{m+1} + D_m^{-\frac{1}{2}}A_mD_m^{-\frac{1}{2}}\tilde{f}^{m+1} = 0$$

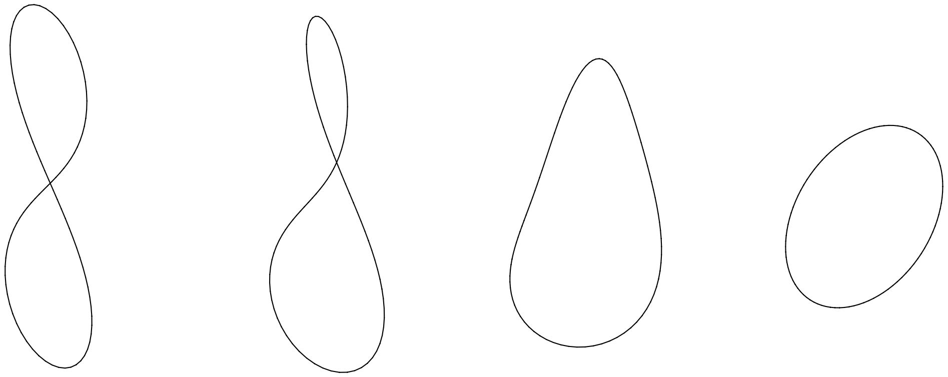

FIG. 4.9. *Continuation of the flow from Figure* 4.8. *From figure eight curve to the final circle:* $t = 11.6,\ 12.4,\ 14.2,\ 16.2$.

for the vectors $\tilde{f}^{m+1} = D_m^{\frac{1}{2}} f^{m+1}$, $\tilde{f}^m = D_m^{\frac{1}{2}} f^m$, and $\tilde{\varkappa}^{m+1} = D_m^{\frac{1}{2}} \varkappa^{m+1}$. For practical purposes it has proved to be of some advantage to redistribute the nodes tangentially along the polygon according to arc length after each time step and thus change the polygon slightly.

DETECTING AN INCLUSION IN AN ELASTIC BODY BY BOUNDARY MEASUREMENTS*

GIOVANNI ALESSANDRINI[†], ANTONINO MORASSI[‡], AND EDI ROSSET[†]

Abstract. We consider the problem of determining, within an elastic isotropic body Ω, the possible presence of an inclusion D made of different elastic material from boundary measurements of traction and displacement. We prove that the volume of D can be estimated, from above and below, by an easily expressed quantity related to work depending only on the boundary traction and displacement.

Key words. inverse boundary problem, elasticity, size estimates, strong unique continuation

1. Introduction.

In this paper we address the following problem of nondestructive testing: *To determine, within an elastic body Ω, the possible presence of an inclusion D made of a different elastic material (i.e., harder or softer) from measurements of traction and displacement taken at the exterior boundary of Ω.*

In mathematical terms, if u denotes the displacement field in Ω, one wishes to recover $D \subset\subset \Omega$ in the *system of linearized elasticity,*

$$\mathrm{div}\,((\chi_{\Omega\setminus D}\mathbb{C} + \chi_D\widetilde{\mathbb{C}})\nabla u) = 0 \quad \text{in } \Omega, \tag{1.1}$$

from the knowledge of one pair of Cauchy data on $\partial\Omega$,

$$(\mathbb{C}\nabla u)\nu = \varphi \quad \text{on } \partial\Omega, \tag{1.2}$$

$$u = g \quad \text{on } \partial\Omega. \tag{1.3}$$

Here $\mathbb{C}$ and $\widetilde{\mathbb{C}}$ denote the elasticity tensor fields in $\Omega \setminus D$ and in D, respectively; ν is the unit exterior normal to $\partial\Omega$; and χ_E denotes the characteristic function of E.

This appears to be an extremely difficult inverse problem. A similar problem in electrical impedance tomography (for which the direct problem involves a single scalar elliptic partial differential equation, rather than a system) has received a great deal of attention in recent years. (See, for instance, Friedman [Fr87], Friedman and Gustafsson [FrG87], Friedman and Isakov [FrI89], Alessandrini, Rosset, and Seo [ARS00] as well as Alessandrini and Isakov [AI96], and Alessandrini [Al99] for an extensive reference list.) Even so, many fundamental questions remain unanswered. One might also consult Ikehata [I98] for previous results on this problem.

Here, following the line of research initiated in Alessandrini and Rosset [AR98], Kang, Seo, and Sheen [KSS97], and Alessandrini, Rosset, and Seo [ARS00] in the electrostatic setting, we pose a relatively modest but realistic goal: *Can we estimate the*

size (i.e., volume) of the unknown inclusion D from one set of boundary measurements of traction and displacement?

In the present paper we restrict our attention to the Lamé system of linearized elasticity, corresponding to the system (1.1) when the material is isotropic.

In order to illustrate our main results it is convenient to consider the solution u_0 to the Neumann problem (1.1)–(1.2) when D is the empty set.

Theorem 2.3 below states that if, for a given $h_1 > 0$, the "fatness-condition"

$$| \{x \in D \mid dist(x, \partial D) > h_1\} | \geq \frac{1}{2}|D| \tag{1.4}$$

is satisfied, then

$$C_1 \left| \frac{W - W_0}{W_0} \right| \leqq |D| \leqq C_2 \left| \frac{W - W_0}{W_0} \right|, \tag{1.5}$$

where C_1, C_2 are estimated in terms of the data. Here, the quantities $W = \int_{\partial\Omega} g \cdot \varphi$ and $W_0 = \int_{\partial\Omega} g_0 \cdot \varphi$ represent the work exerted by the surface forces φ when the boundary displacement fields are g and $g_0 = u_0|_{\partial\Omega}$, respectively. See Remark 2.5 for a discussion of the "fatness-condition" (1.4).

In Theorem 2.4 we treat the case when no a priori assumption is made on D. We find that for a suitable $p > 1$, we have

$$C_1 \left| \frac{W - W_0}{W_0} \right| \leqq |D| \leqq C_2 \left| \frac{W - W_0}{W_0} \right|^{\frac{1}{p}}. \tag{1.6}$$

(See section 2 below for the precise statements.)

We believe that these estimates should be useful in practice as a decision tool in quality control tests. Namely, one can fix experimentally a threshold parameter $T > 0$ in such a way to say that D is absent or negligible if $|\frac{W-W_0}{W_0}| \leq T$, whereas D is significant if $|\frac{W-W_0}{W_0}| \geq T$.

The main underlying idea in these estimates is that the integral

$$\int_D |\widehat{\nabla} u_0|^2 \quad \text{is comparable to} \quad |W - W_0|, \tag{1.7}$$

where $\widehat{\nabla} u_0 = \frac{1}{2}(\nabla u_0 + (\nabla u_0)^T)$ is the strain tensor field; see Ikehata [I98].

The next point is to control the above integral in terms of the measure (volume) of D. On the one hand, this task involves upper bounds on $|\widehat{\nabla} u_0|^2$, which is standard in the regularity theory of elliptic systems like (1.1). On the other hand, it involves local lower bounds on $|\widehat{\nabla} u_0|^2$. Rather than regularity theory, this task is more strictly related to the issue of unique continuation, namely, the study of the character of zeros (i.e., order of vanishing and size of the zero sets) of nontrivial solutions to system (1.1). Unique continuation is very well studied and understood for the case of linear elliptic equations. (See, for instance, Aronszajn, Krzywicki, and Szarski [AKS62], Garofalo and Lin [GL86], [GL87], and Koch and Tataru [KT01].) However, until recently, only results of weak unique continuation for the elasticity system were known; see Weck [W69], [W01], Leis [L86], Dehman and Robbiano [DR93], Ang et al. [AITY98], and Eller et al. [EINT00]. In this paper we apply some of the estimates of unique continuation found in [AM01] (three spheres inequalities [AM01, (5.2)] and especially doubling inequalities yielding *strong unique continuation* [AM01, (5.5)]) and we further elaborate on this topic. The main result in this direction here are new *doubling inequalities* for the reference solution u_0 (see Theorem 3.9) and for its symmetrized gradient $\widehat{\nabla} u_0$ (see Corollary 3.10). Such an inequality allows us to prove for $|\widehat{\nabla} u_0|^2$ the property of being a Muckenhoupt weight (Coifman and Fefferman [CF74], Garcia-Cuerva and Rubio de Francia [GCRDF85]). This is a property of homogeneity in the average at all scales which was first proved for solutions of scalar elliptic equations by Garofalo and Lin [GL86].

The plan of the paper is as follows. In section 2 we introduce some notation and state our main results (Theorems 2.3 and 2.4). Section 3 is devoted to the derivation of quantitative estimates of unique continuation for solutions to the Lamé system, following ideas introduced in Alessandrini and Morassi [AM01]. In section 4 we first derive an interior average lower bound on $|\widehat{\nabla} u_0|^2$ on small balls contained inside Ω (see Proposition 4.1). Moreover, we rephrase the doubling inequalities obtained in the previous section in terms of the boundary data (see Proposition 4.3), and we show that $|\widehat{\nabla} u_0|^2$ is a Muckenhoupt weight (see Proposition 4.4). Finally, section 5 contains the proofs of the main theorems.

2. Main results.

Let us introduce some notation which will be useful in what follows. We restrict our attention to the dimensions $n = 2, 3$, which are those physically relevant for elasticity.

Given a bounded domain $\Omega \subset \mathbb{R}^n$, $n = 2, 3$, for any $h > 0$ we shall denote

$$\Omega_h = \{x \in \Omega \mid dist(x, \partial\Omega) > h\}. \tag{2.1}$$

When locally representing a boundary as a graph, it will be convenient to use the following notation. For every $x \in \mathbb{R}^n$ we shall set $x = (x', x_n)$, where $x' \in \mathbb{R}^{n-1}$, $x_n \in \mathbb{R}$.

DEFINITION 2.1. *Given a bounded domain $\Omega \subset \mathbb{R}^n$, we shall say that $\partial\Omega$ is of class $C^{1,1}$ with constants $r_0, M_0 > 0$ if, for any $x_0 \in \partial\Omega$, there exists a rigid transformation of coordinates under which we have $x_0 = 0$ and*

$$\Omega \cap B_{r_0}(0) = \{x \in B_{r_0}(0) \mid x_n > \varphi(x')\},$$

where φ is a $C^{1,1}$ function on $B_{r_0}(0) \subset \mathbb{R}^{n-1}$ satisfying

$$\varphi(0) = |\nabla\varphi(0)| = 0$$

and

$$\|\varphi\|_{C^{1,1}(B_{r_0}(0))} \leq M_0 r_0.$$

Notice that this quantitative formulation of the smoothness of the boundary also involves the introduction of the dimensional parameter r_0, which gives us the scale at which the boundary is representable as a graph.

REMARK 2.1. *We have chosen to normalize all norms in such a way that their terms are dimensionally homogeneous and coincide with the standard definition when the dimensional parameter equals one. For instance, the norm appearing above is meant as follows:*

$$\|\phi\|_{C^{1,1}(B_{r_0}(0))} = \|\phi\|_{L^\infty(B_{r_0}(0))} + r_0\|\nabla\phi\|_{L^\infty(B_{r_0}(0))} + {r_0}^2\|\nabla^2\phi\|_{L^\infty(B_{r_0}(0))}. \tag{2.2}$$

Similarly, given a function $f : \Omega \mapsto \mathbb{R}$, where $\partial\Omega$ satisfies Definition 2.1, we shall denote

$$\|f\|_{C^{1,1}(\Omega)} = \|f\|_{L^\infty(\Omega)} + r_0\|\nabla f\|_{L^\infty(\Omega)} + {r_0}^2\|\nabla^2 f\|_{L^\infty(\Omega)}. \tag{2.3}$$

Notice also that when $\Omega = B_R(0)$, Ω then satisfies Definition 2.1 with $r_0 = R$.

We consider weak solutions $u \in H^1(\Omega, \mathbb{R}^n)$ to the *displacement equation of equilibrium* when body forces are absent:

$$\operatorname{div}(\mathbb{C}(x)(\nabla u(x))) = 0 \quad \text{in } \Omega; \tag{2.4}$$

see Gurtin [Gur72].

We shall assume throughout that the elasticity tensor field $\mathbb{C} = \mathbb{C}(x)$ of the materials under consideration have components C_{ijkl} which satisfy the following conditions:

$$C_{ijkl} \in L^\infty(\Omega, \mathbb{R}) \quad \forall i, j, k, l = 1, \dots, n, \tag{2.5}$$

$$C_{ijkl} = C_{klij} = C_{klji} \quad \forall i, j, k, l = 1, \dots, n, \quad \text{a.e. in} \quad \Omega. \tag{2.6}$$

We recall that the symmetry conditions (2.6) are equivalent to

$$\mathbb{C}A = \mathbb{C}\widehat{A}, \tag{2.7}$$

$$\mathbb{C}A \quad \text{is symmetric}, \tag{2.8}$$

$$\mathbb{C}A \cdot B = \mathbb{C}B \cdot A \tag{2.9}$$

for every pair of $n \times n$ matrices A,B.

Here, and in what follows, the following notation has been used:

$$(\mathbb{C}A)_{ij} = \sum_{k,l=1}^{n} C_{ijkl}A_{kl}, \tag{2.10}$$

$$A \cdot B = \sum_{i,j=1}^{n} A_{ij}B_{ij}, \tag{2.11}$$

$$|A| = (A \cdot A)^{\frac{1}{2}}, \tag{2.12}$$

$$\widehat{A} = \frac{1}{2}(A + A^T), \tag{2.13}$$

for every pair of $n \times n$ matrices A,B.

We shall also use the following conventions for inequalities. Given $\mathbb{C}$, $\widetilde{\mathbb{C}}$ satisfying (2.5), (2.6) we shall say that

$$\widetilde{\mathbb{C}} \leq \mathbb{C} \tag{2.14}$$

if and only if

$$\widetilde{\mathbb{C}}A \cdot A \leq \mathbb{C}A \cdot A \tag{2.15}$$

for every *symmetric* $n \times n$ matrix A.

We shall say that $\mathbb{C}$ is *strongly convex* in Ω if there exists a positive constant ξ_0 such that

$$\mathbb{C}(x)A \cdot A \geq \xi_0 |A|^2 \quad \text{for a.e.} \quad x \in \Omega, \tag{2.16}$$

for any symmetric $n \times n$ matrix A.

$\mathbb{C}$ is said to be *strongly elliptic* in Ω if there exists a positive constant κ_0 such that

$$\mathbb{C}(x)A \cdot A \geq \kappa_0 |A|^2 \quad \text{for a.e.} \quad x \in \Omega, \tag{2.17}$$

for any matrix A of the form $A_{ij} = a_i b_j$, where a and b are n-vectors. It is well known that *if* $\mathbb{C}$ *is strongly convex, then it is also strongly elliptic.*

When the elastic material is *isotropic*, then the elasticity tensor $\mathbb{C}$ takes the following form:

$$C_{ijkl}(x) = \lambda(x)\delta_{ij}\delta_{kl} + \mu(x)(\delta_{ki}\delta_{lj} + \delta_{li}\delta_{kj}), \tag{2.18}$$

where $\lambda = \lambda(x)$ and $\mu = \mu(x) \in L^\infty(\Omega, \mathbb{R})$ are the *Lamé moduli.* Hence, in this case, denoting by I_n the $n \times n$ identity matrix, we have

$$\mathbb{C}(x)A = \lambda(x)(A \cdot I_n)I_n + 2\mu(x)\widehat{A}, \tag{2.19}$$

and the displacement equation of equilibrium (2.4) becomes the Lamé system

$$\mathrm{div}\,(2\mu\widehat{\nabla}u) + \nabla(\lambda \mathrm{div}\, u) = 0 \quad \text{in } \Omega. \tag{2.20}$$

In the isotropic case, the *strong convexity* condition takes the form

$$\mu(x) \geq \alpha_0, \quad 2\mu(x) + n\lambda(x) \geq \gamma_0 \quad \text{for a.e.} \quad x \in \Omega \tag{2.21}$$

and the *strong ellipticity* condition is expressed by

$$\mu(x) \geq \alpha_0, \quad 2\mu(x) + \lambda(x) \geq \beta_0 \quad \text{for a.e.} \quad x \in \Omega, \tag{2.22}$$

where α_0, β_0, γ_0 are positive constants.

Let Ω be a bounded domain whose boundary is of class $C^{1,1}$ with given constants $r_0, M_0 > 0$. Let D be a measurable, possibly disconnected, subset of Ω such that, given $d_0 > 0$,

$$dist(D, \partial\Omega) \geq d_0. \tag{2.23}$$

Given elasticity tensors $\mathbb{C}$, $\widetilde{\mathbb{C}}$ satisfying (2.5), (2.6) we shall consider traction problems in Ω when the elasticity tensor is either $\chi_{\Omega\setminus D}\mathbb{C} + \chi_D\widetilde{\mathbb{C}}$ or $\mathbb{C}$.

We shall prescribe a boundary traction field $\varphi \in L^2(\partial\Omega, \mathbb{R}^n)$ satisfying the compatibility conditions

$$\int_{\partial\Omega} \varphi \cdot r = 0 \tag{2.24}$$

for every *infinitesimal rigid displacement* r, that is, $r(x) = c + Wx$, where c is any constant n-vector and W is any constant skew $n \times n$ matrix. Namely we shall consider weak solutions $u, u_0 \in H^1(\Omega, \mathbb{R}^n)$ of the following problems:

$$\operatorname{div}\left((\chi_{\Omega \setminus D}\mathbb{C} + \chi_D \widetilde{\mathbb{C}})\nabla u\right) = 0 \quad \text{in } \Omega, \tag{2.25}$$

$$(\mathbb{C}\nabla u)\nu = \varphi \quad \text{on } \partial\Omega; \tag{2.26}$$

$$\operatorname{div}(\mathbb{C}\nabla u_0) = 0 \quad \text{in } \Omega, \tag{2.27}$$

$$(\mathbb{C}\nabla u_0)\nu = \varphi \quad \text{on } \partial\Omega. \tag{2.28}$$

Regarding existence, we recall that, provided the compatibility condition (2.24) is satisfied, a solution of the traction problem exists as long as the involved elasticity tensor either satisfies the strong convexity condition or is continuous and satisfies the strong ellipticity condition; see, for instance, Valent [V88, section III].

With respect to uniqueness we recall that it is well known that solutions u, u_0 to the above problems are uniquely determined up to an infinitesimal rigid displacement. In order to uniquely identify such solutions, we shall assume from now on that both u and u_0 satisfy the following normalization conditions:

$$\int_\Omega u = 0, \quad \int_\Omega (\nabla u - (\nabla u)^T) = 0. \tag{2.29}$$

We set g, $g_0 \in H^{1/2}(\partial\Omega, \mathbb{R}^n)$ to be the traces of u, u_0, respectively, on $\partial\Omega$.

Now we are in position to state our main result on the estimates for the size of the inclusion.

We shall use the following assumptions on the elasticity tensors $\mathbb{C}$, $\widetilde{\mathbb{C}}$:

(i) $\mathbb{C}$ satisfies the isotropy condition (2.18) and the strong convexity (2.21);

(ii) (bounds on the jump and uniform strong convexity for $\widetilde{\mathbb{C}}$)
either there exist $\eta > 0$ and $\delta > 1$ such that

$$\eta\mathbb{C} \le \widetilde{\mathbb{C}} - \mathbb{C} \le (\delta - 1)\mathbb{C} \quad \text{a.e. in} \quad \Omega \tag{2.30}$$

or there exist $\eta > 0$ and $0 < \delta < 1$ such that

$$-(1-\delta)\mathbb{C} \le \widetilde{\mathbb{C}} - \mathbb{C} \le -\eta\mathbb{C} \quad \text{a.e. in} \quad \Omega; \tag{2.31}$$

(iii) ($C^{1,1}$ regularity for $\mathbb{C}$)
there exists $M > 0$ such that

$$\|\mu\|_{C^{1,1}(\Omega)} + \|\lambda\|_{C^{1,1}(\Omega)} \le M. \tag{2.32}$$

Remark 2.2. *It is worth noticing that very mild assumptions are made on the unknown inclusion; namely, the inclusion D may consist of an anisotropic material which is either harder (case* (2.30)*) or softer (case* (2.31)*) than the surrounding material in Ω, and no additional regularity assumption is required on the elasticity tensor inside D.*

THEOREM 2.3. *Let Ω be a bounded domain in $\mathbb{R}^n$ such that $\partial\Omega$ is of class $C^{1,1}$ with constants r_0, M_0. Let D be a measurable subset of Ω satisfying* (2.23) *and*

$$|D_{h_1}| \geq \frac{1}{2}\,|D| \tag{2.33}$$

for a given positive constant h_1. Let $\mathbb{C}$, $\widetilde{\mathbb{C}}$ satisfy (i), (ii), (iii). *If* (2.30) *holds, then we have*

$$\frac{1}{\delta-1}C_1^+\frac{\int_{\partial\Omega}(g_0-g)\cdot\varphi}{\int_{\partial\Omega}g_0\cdot\varphi} \leq |D| \leq \frac{\delta}{\eta}C_2^+\frac{\int_{\partial\Omega}(g_0-g)\cdot\varphi}{\int_{\partial\Omega}g_0\cdot\varphi}. \tag{2.34}$$

If, conversely, (2.31) *holds, then we have*

$$\frac{\delta}{1-\delta}C_1^-\frac{\int_{\partial\Omega}(g-g_0)\cdot\varphi}{\int_{\partial\Omega}g_0\cdot\varphi} \leq |D| \leq \frac{1}{\eta}C_2^-\frac{\int_{\partial\Omega}(g-g_0)\cdot\varphi}{\int_{\partial\Omega}g_0\cdot\varphi}, \tag{2.35}$$

where C_1^+, C_1^- depend only on the geometrical parameters $|\Omega|$, r_0, M_0 (see Definition 2.1*), d_0 (see* (2.23)*) and on the bounds on the Lamé moduli α_0, γ_0 (see* (2.21)*), M (see* (2.32)*), and C_2^+, C_2^- depend only on the same quantities and also on h_1 and on the ratio $\|\varphi\|_{L^2(\partial\Omega)}/\|\varphi\|_{H^{-1/2}(\partial\Omega)}$.*

THEOREM 2.4. *Let Ω be as in Theorem* 2.3 *and let D be any measurable subset of Ω satisfying* (2.23). *Let $\mathbb{C}$, $\widetilde{\mathbb{C}}$ satisfy* (i), (ii), (iii). *If* (2.30) *holds, then we have*

$$\frac{1}{\delta-1}C_1^+\frac{\int_{\partial\Omega}(g_0-g)\cdot\varphi}{\int_{\partial\Omega}g_0\cdot\varphi} \leq |D| \leq \left(\frac{\delta}{\eta}\right)^{\frac{1}{p}}C_2^+\left(\frac{\int_{\partial\Omega}(g_0-g)\cdot\varphi}{\int_{\partial\Omega}g_0\cdot\varphi}\right)^{\frac{1}{p}}. \tag{2.36}$$

If, conversely, (2.31) *holds, then we have*

$$\frac{\delta}{1-\delta}C_1^-\frac{\int_{\partial\Omega}(g-g_0)\cdot\varphi}{\int_{\partial\Omega}g_0\cdot\varphi} \leq |D| \leq \left(\frac{1}{\eta}\right)^{\frac{1}{p}}C_2^-\left(\frac{\int_{\partial\Omega}(g-g_0)\cdot\varphi}{\int_{\partial\Omega}g_0\cdot\varphi}\right)^{\frac{1}{p}}, \tag{2.37}$$

where C_1^+, C_1^- are the same as in Theorem 2.3*, whereas $p>1$, C_2^+, C_2^- depend only on $|\Omega|$, r_0, M_0, d_0, α_0, γ_0, M, and $\|\varphi\|_{L^2(\partial\Omega)}/\|\varphi\|_{H^{-1/2}(\partial\Omega)}$.*

REMARK 2.5. *Let us notice that the "fatness-condition"* (2.33) *is satisfied when mild a priori regularity assumptions are made on D. For instance, the constant h_1 can be easily estimated when D is a priori known to be Lipschitz; we refer to Alessandrini and Rosset* [AR98, Lemma 2.8] *for related calculations. See also Alessandrini, Rosset, and Seo* [ARS00] *for comments on the optimality of this kind of results in the case of a scalar elliptic equation.*

3. Quantitative estimates of unique continuation. In this section we shall prove quantitative estimates of unique continuation in the form of *three spheres inequalities* and *doubling inequalities* for solutions $u \in H^1(\Omega, \mathbb{R}^n)$ to the Lamé system of linearized elasticity (2.20) in a bounded domain Ω satisfying Definition 2.1 with constants r_0, M_0. Throughout this section the Lamé moduli $\mu = \mu(x)$, $\lambda = \lambda(x)$ are assumed to satisfy the strong ellipticity condition (2.22) and the regularity assumption (2.32). Following ideas introduced in [AM01], the first step consists of reducing the Lamé system (2.20) to a weakly coupled elliptic system with Laplacian principal part. We denote by $\mathbb{M}^{m\times n}$ the space of $m \times n$ real valued matrices.

PROPOSITION 3.1. *Under the above assumptions, there exist $B \in L^\infty(\Omega, L(\mathbb{M}^{(n+1)\times n}, \mathbb{R}^{n+1}))$ and $V \in L^\infty(\Omega, L(\mathbb{R}^{n+1}, \mathbb{R}^{n+1}))$ such that, for every weak solution $u \in H^1(\Omega, \mathbb{R}^n)$ to* (2.20)*, the $\mathbb{R}^{n+1}$-valued function U given by*

$$U = \begin{pmatrix} u \\ r_0 \operatorname{div} u \end{pmatrix} \tag{3.1}$$

belongs to $W^{2,p}_{loc}(\Omega, \mathbb{R}^{n+1})$ for every $p < \infty$ and satisfies

$$-\Delta U + B(\nabla U) + V(U) = 0 \quad \text{in } \Omega. \tag{3.2}$$

Moreover

$$r_0 \|B\|_{L^\infty(\Omega, L(\mathbb{M}^{(n+1)\times n}, \mathbb{R}^{n+1}))} + r_0^2 \|V\|_{L^\infty(\Omega, L(\mathbb{R}^{n+1}, \mathbb{R}^{n+1}))} \leqslant CM, \tag{3.3}$$

where $C > 0$ depends only on α_0 and β_0.

Proof. The proof is essentially contained in [AM01, Theorem 2.1]. Here the statement is slightly modified in order to encompass the scaling invariance of the norms introduced in the present paper. □

Three spheres inequalities and doubling inequalities for solutions u to systems of the form (3.2), under the assumption (3.3), were derived in [AM01, Theorems 3.1 and 4.1]. Next, one can obtain analogous estimates for solutions u to the Lamé system (2.20) via the reduction described in Proposition 3.1.

PROPOSITION 3.2 (see [AM01, Theorem 5.1]). *Let $\Omega = B_R = \{x \in \mathbb{R}^n \mid |x| < R\}$. Under the above assumptions, there exists $\overline{\theta}$, $0 < \overline{\theta} \leqslant 1$, depending only on α_0, β_0, M, such that for every weak solution $u \in H^1(B_R, \mathbb{R}^n)$ to* (2.20) *and for every r_1, r_2, r_3, $0 < r_1 < r_2 < r_3 \leqslant \overline{\theta} R$, we have*

$$\int_{B_{r_2}} |u|^2 \leqslant C \left(\int_{B_{r_1}} |u|^2 \right)^\delta \left(\int_{B_{r_3}} |u|^2 \right)^{1-\delta}, \tag{3.4}$$

where $C > 0$, $0 < \delta < 1$, depend only on α_0, β_0, M, $\frac{r_1}{r_3}$, and $\frac{r_2}{r_3}$.

Proof. The proof can be found in [AM01]. We notice that here, in view of our scaling on the norms (see Remark 2.1), the constant C does not explicitly depend on R. □

In view of the applications in section 5, we need the analogous result for $\widehat{\nabla} u$.

COROLLARY 3.3. *Under the same hypotheses of Proposition* 3.2, *for every weak solution $u \in H^1(B_R, \mathbb{R}^n)$ to* (2.20) *and for every r_1, r_2, r_3, $0 < r_1 < r_2 < r_3 \leqslant \overline{\theta} R$, we have*

$$\int_{B_{r_2}} |\widehat{\nabla} u|^2 \leqslant C \left(\int_{B_{r_1}} |\widehat{\nabla} u|^2 \right)^\delta \left(\int_{B_{r_3}} |\widehat{\nabla} u|^2 \right)^{1-\delta}, \tag{3.5}$$

where $\overline{\theta}$, $0 < \overline{\theta} \leqslant 1$, is the same as in Proposition 3.2 *and $C > 0$, $0 < \delta < 1$ depend only on α_0, β_0, M, $\frac{r_1}{r_3}$, and $\frac{r_2}{r_3}$.*

In order to prove Corollary 3.3 it is convenient to recall the following two inequalities.

LEMMA 3.4 (Caccioppoli-type inequality). *If $\mathbb{C}$ satisfies* (2.18), (2.22), *and* (2.32), *then for every solution $u \in H^1(B_R, \mathbb{R}^n)$ to* (2.4) *and for every r, $0 < r < R$,* *we have*

$$\int_{B_r} |\nabla u|^2 \leqslant \frac{C}{(R-r)^2} \int_{B_R} |u|^2, \tag{3.6}$$

where $C > 0$ *depends only on* α_0, β_0, M.

Proof. The proof follows by a standard cut-off argument from Gärding's inequality [V88]. □

Given $u \in H^1(B_R, \mathbb{R}^n)$ and r, $0 < r < R$, set

$$u_r = \frac{1}{|B_r|} \int_{B_r} u, \tag{3.7}$$

$$W_r = \frac{1}{2|B_r|} \int_{B_r} (\nabla u - (\nabla u)^T). \tag{3.8}$$

LEMMA 3.5 (Korn inequality). *There exists an absolute constant* $C > 0$ *such that for every* $u \in H^1(B_R, \mathbb{R}^n)$ *and every* r, $0 < r < R$, *we have*

$$\int_{B_R} |\nabla u - W_r|^2 + \frac{1}{R^2}|u - u_r - W_r x|^2 \leqslant C \left(\frac{R}{r}\right)^{4n-2} \int_{B_R} |\widehat{\nabla} u|^2. \tag{3.9}$$

REMARK 3.6. *When* $r = R$ *this is the well-known second Korn inequality, which is known to hold in every sufficiently regular domain* Ω *(see* [Fi72], [T99]*). Here we introduce a minor variant, in which the averages of* u *and of the skew part of* ∇u *are taken on the smaller ball* B_r*. For the convenience of the reader, a sketch of the main arguments of a proof is outlined at the end of this section.*

Proof of Corollary 3.3. The function v defined in B_R by

$$v = u - u_{r_1} - W_{r_1} x \tag{3.10}$$

satisfies (2.20) and $\frac{1}{|B_{r_1}|}\int_{B_{r_1}} v = 0$, $\frac{1}{2|B_{r_1}|}\int_{B_{r_1}} \nabla v - (\nabla v)^T = 0$. By applying to v the Caccioppoli-type inequality (3.6) and the three spheres inequality (3.4) and using the Korn inequality (3.9) twice, we have

$$\begin{aligned} \int_{B_{r_2}} |\widehat{\nabla} u|^2 = \int_{B_{r_2}} |\widehat{\nabla} v|^2 &\leqslant \frac{C_1}{(r_3 - r_2)^2} \int_{B_{\frac{r_2+r_3}{2}}} |v|^2 \\ &\leqslant \frac{C_2}{(r_3 - r_2)^2} \left(\int_{B_{r_1}} |v|^2\right)^{\delta} \left(\int_{B_{r_3}} |v|^2\right)^{1-\delta} \\ &\leqslant C_3 \left(\int_{B_{r_1}} |\widehat{\nabla} u|^2\right)^{\delta} \left(\int_{B_{r_3}} |\widehat{\nabla} u|^2\right)^{1-\delta}, \end{aligned} \tag{3.11}$$

where C_1, C_2, C_3 are constants depending only on α_0, β_0, M, $\frac{r_1}{r_3}$, and $\frac{r_2}{r_3}$. □

In order to obtain the doubling inequality for solutions to the Lamé system (2.20), we need to state a slightly modified version of the doubling inequality for solutions U to (3.2) contained in [AM01, Theorem 4.1].

Proposition 3.7. *Let $\Omega = B_R$ and let $R\|B\|_\infty + R^2\|V\|_\infty \leqslant E$. There exists θ^*, $0 < \theta^* \leqslant 1$, depending only on E, such that for every nonzero solution $U \in H^1(B_R, \mathbb{R}^{n+1})$ to (3.2) we have*

$$\int_{B_{2r}} |U|^2 \leqslant C \int_{B_r} |U|^2 \text{ for every } r,\ 0 < r \leqslant \frac{\theta^* R}{2}, \tag{3.12}$$

where C depends only on E and $N_0(\theta^* R)$, where

$$N_0(r) = N_0(U; r) = \frac{r\int_{B_r} |\nabla U|^2}{\int_{\partial B_r} |U|^2}, \qquad 0 < r \leqslant R. \tag{3.13}$$

Moreover C is increasing with $N_0(\theta^* R)$.

Proof. By Theorem 4.1 in [AM01] and by a rescaling argument, it easily follows that (3.12) holds, with C depending only on E and on $N(\theta^* R)$, where

$$N(r) = N(U; r) = \frac{r\int_{B_r} |\nabla U|^2 + B(\nabla U)\cdot U + V(U)\cdot U}{\int_{\partial B_r} |U|^2}, \qquad 0 < r \leqslant R, \tag{3.14}$$

the dependence on this last variable being monotonically increasing. Hence, we have to show that $N(r)$ can be bounded from above in terms of $N_0(r)$. It is convenient to recall the following notation introduced in [AM01]:

$$G(r) = \int_{B_r} |U|^2, \tag{3.15}$$

$$H(r) = \int_{\partial B_r} |U|^2, \tag{3.16}$$

$$I(r) = \int_{B_r} |\nabla U|^2 + B(\nabla U)\cdot U + V(U)\cdot U, \tag{3.17}$$

$$D(r) = \int_{B_r} |\nabla U|^2 \tag{3.18}$$

for $0 < r \leqslant R$. We easily have

$$I(r) \leqslant D(r) + \frac{E}{R}(D(r)G(r))^{\frac{1}{2}} + \frac{E}{R^2}G(r) \leqslant C\left(D(r) + \frac{G(r)}{R^2}\right), \tag{3.19}$$

with C depending only on E. Moreover, from Lemma 3.3 in [AM01] we have

$$G(r) \leqslant rH(r) \text{ for } r \leqslant \theta^* R. \tag{3.20}$$

Hence, for $r \leqslant \theta^* R$ we have

$$N(r) = \frac{rI(r)}{H(r)} \leqslant C\left(N_0(r) + \frac{r^2}{R^2}\right) \leqslant C(N_0(r) + 1), \tag{3.21}$$

where C depends only on E. □

REMARK 3.8. *Let us notice that analogously to* (3.21) *we also have*

$$N_0(r) \leqslant C(N(r)+1), \text{ for } r \leqslant \theta^* R, \tag{3.22}$$

where C depends only on E.

THEOREM 3.9. *Let $\Omega = B_R$. There exists θ^*, $0 < \theta^* \leqslant 1$, depending only on α_0, β_0, M, such that for every nonzero weak solution $u \in H^1(B_R, \mathbb{R}^n)$ to* (2.20) *we have*

$$\int_{B_{2r}} |u|^2 \leqslant K \int_{B_r} |u|^2 \text{ for every } r,\ 0 < r \leqslant \frac{\theta^* R}{2}, \tag{3.23}$$

where $K > 0$ depends only on α_0, β_0, M and on $\tilde{N}_0(\theta^* R)$, where

$$\tilde{N}_0(r) = \frac{r^2 \int_{B_r} |\nabla u|^2 + R^2 |\nabla(\mathrm{div} u)|^2}{\int_{B_r} |u|^2 + R^2 |\mathrm{div} u|^2}, \qquad 0 < r \leqslant R. \tag{3.24}$$

Moreover K is increasing with $\tilde{N}_0(\theta^* R)$.

Proof. By applying (3.12) of Proposition 3.7 to the solution U to (3.2) given by the position (3.1), and recalling (3.3), we have

$$\int_{B_{2r}} |u|^2 + R^2 |\mathrm{div}\, u|^2 \leqslant C \int_{B_r} |u|^2 + R^2 |\mathrm{div}\, u|^2 \text{ for every } r,\ 0 < r \leqslant \frac{\theta^* R}{2}, \tag{3.25}$$

where C depends only on α_0, β_0, M and on $N_0(\theta^* R)$, with $N_0(r)$ given by (3.13), the dependence on this last variable being monotonically increasing. By an iterated application of (3.25) and by the Caccioppoli-type inequality (3.6), we have

$$\int_{B_{2r}} |u|^2 \leqslant C\left(1 + \frac{R^2}{r^2}\right) \int_{B_r} |u|^2 \text{ for every } r,\ 0 < r \leqslant \frac{\theta^* R}{2}. \tag{3.26}$$

Let ρ be such that $0 < \rho \leqslant 1$, and let

$$u_\rho(x) = u(\rho x) \text{ in } B_{\frac{R}{\rho}}.$$

We have that u_ρ is a solution in $B_{\frac{R}{\rho}}$ to the Lamé system (2.20) with Lamé moduli satisfying uniformly the bounds (2.22), (2.32). Therefore, by (3.26) we have that

$$\int_{B_{2r}} |u_\rho|^2 \leqslant C_\rho \left(1 + \frac{R^2}{\rho^2 r^2}\right) \int_{B_r} |u_\rho|^2 \text{ for every } r,\ 0 < r \leqslant \frac{\theta^* R}{2\rho}, \tag{3.27}$$

where C_ρ depends only on α_0, β_0, M, and $N_0(U_\rho; \frac{\theta^* R}{\rho})$, where U_ρ is given by (3.1) when u, r_0 are replaced with u_ρ, $\frac{R}{\rho}$, respectively. Here, again, C_ρ is increasing with $N_0(U_\rho; \frac{\theta^* R}{\rho})$. We have for any r, $0 < r \leqslant \frac{\theta^* R}{2\rho}$,

$$\begin{aligned} N_0(U_\rho; r) &= \frac{r \int_{B_r} |\nabla u_\rho|^2 + \frac{R^2}{\rho^2} |\nabla \mathrm{div}\, u_\rho|^2}{\int_{\partial B_r} |u_\rho|^2 + \frac{R^2}{\rho^2} |\mathrm{div}\, u_\rho|^2} \\ &= \frac{r \int_{B_r} \rho^2 |\nabla u(\rho x)|^2 + \frac{R^2}{\rho^2} \cdot \rho^4 |\nabla \mathrm{div}\, u(\rho x)|^2}{\int_{\partial B_r} |u(\rho x)|^2 + \frac{R^2}{\rho^2} \cdot \rho^2 |\mathrm{div}\, u(\rho x)|^2} \\ &= \frac{\rho r \int_{B_{\rho r}} |\nabla u|^2 + R^2 |\nabla \mathrm{div}\, u|^2}{\int_{\partial B_{\rho r}} |u|^2 + R^2 |\mathrm{div}\, u|^2} = N_0(U; \rho r). \end{aligned} \tag{3.28}$$

Hence, in particular,

$$N_0\left(U_\rho;\frac{\theta^* R}{\rho}\right)=N_0(U;\theta^* R). \tag{3.29}$$

Consequently, the quantity C_ρ appearing in (3.27) is uniformly bounded from above with respect to $\rho\in(0,1]$. Taking $r=\frac{\theta^* R}{2\rho}$ in (3.27) and setting $s=r\rho$, we obtain

$$\int_{B_{2s}}|u|^2\leqslant K\int_{B_s}|u|^2 \text{ for every } s,\ 0<s\leqslant\frac{\theta^* R}{2}, \tag{3.30}$$

where K depends only on α_0,β_0,M and on $N_0(U;\theta^* R)$, the dependence on this last variable being monotonically increasing. Recalling (3.13), (3.20), (3.24), we have that $N_0(U;\theta^* R)\leqslant\tilde{N}_0(\theta^* R)$. □

From Theorem 3.9, by using arguments analogous to those employed in the proof of Corollary 3.3, the following doubling inequality for $\widehat{\nabla}u$ follows.

Corollary 3.10. *Let $\Omega=B_R$. There exists θ^*, $0<\theta^*\leqslant 1$, depending only on α_0,β_0,M, such that for every nonzero weak solution $u\in H^1(B_R,\mathbb{R}^n)$ to* (2.20) *we have*

$$\int_{B_{2r}}|\widehat{\nabla}u|^2\leqslant K_r\int_{B_r}|\widehat{\nabla}u|^2 \textit{ for every } r,\ 0<r\leqslant\frac{\theta^* R}{4}, \tag{3.31}$$

where $K_r>0$ depends only on α_0,β_0,M, and $\tilde{N}_0(v;\theta^* R)$ given by (3.24), *where $v=u-u_r-W_r x$, with u_r and W_r defined by* (3.7) *and* (3.8), *respectively. Moreover K_r is increasing with $\tilde{N}_0(v;\theta^* R)$.*

Proof of Lemma 3.5. We adapt arguments from Tiero [T99]. Inequality (3.9) follows, through the introduction of the axial vector ω associated with the skew matrix $W=\frac{\nabla u-(\nabla u)^T}{2}$, from the two scalar inequalities

$$\int_{B_R}(\psi-\psi_r)^2\leqslant C\left(\frac{R}{r}\right)^{2(n-1)}R^2\int_{B_R}|\nabla\psi|^2 \text{ for every } \psi\in H^1(B_R), \tag{3.32}$$

$$\int_{B_R}(\psi-\psi_r)^2\leqslant C\left(\frac{R}{r}\right)^{2n}\|\nabla\psi\|^2_{H^{-1}(B_R)} \text{ for every } \psi\in L^2(B_R). \tag{3.33}$$

Here $C>0$ is an absolute constant and the $H^{-1}(B_R)$-norm above is defined as follows:

$$\|F\|_{H^{-1}(B_R)}=\sup\left\{\int_{B_R}FG\mid G\in H^1(B_R,\mathbb{R}^n),\int_{B_R}|\nabla G|^2=1\right\}.$$

It suffices to prove (3.32), (3.33) when $R=1$ and $\psi\in C^1(\overline{B}_1)$ by usual scaling and density arguments. We recall that (3.32), (3.33) are well known when $r=1$; see, for instance, [MS58]. Let us estimate $\psi_1-\psi_r$ for $0<r<1$. We easily obtain

$$\psi_1-\psi_r=\frac{1}{n\omega_n}\int_r^1 ds\int_{B_1}\nabla\psi(sx)\cdot x dx,$$

and then, by changing variables and reversing the order of integration, we find

$$\psi_1-\psi_r=\frac{1}{n\omega_n}\int_{B_1}\nabla\psi\cdot z,$$

where

$$z(x) = \frac{1}{n}\{\max\{r, |x|\}^{-n} - 1\}x.$$

We have

$$\int_{B_1} |z|^2 \leqslant Cr^{1-n},$$

$$\int_{B_1} |\nabla z|^2 \leqslant Cr^{-n}.$$

Hence

$$|\psi_1 - \psi_r|^2 \leqslant Cr^{2-2n} \int_{B_1} |\nabla \psi|^2,$$

$$|\psi_1 - \psi_r|^2 \leqslant Cr^{-2n} \|\nabla \psi\|^2_{H^{-1}(B_1)},$$

and (3.32), (3.33) follow. □

4. Estimates in terms of the boundary data. In this section we shall consider the traction problem (2.27), (2.28) for a given $\varphi \in L^2(\partial\Omega, \mathbb{R}^n)$ satisfying (2.24). For simplicity of notation we shall denote by u the solution (instead of u_0). The normalization (2.29) is understood throughout.

Regarding the elasticity tensor $\mathbb{C}$ we assume the isotropy condition (2.18), the strong ellipticity (2.22), and the $C^{1,1}$ regularity (2.32).

PROPOSITION 4.1 (Lipschitz propagation of smallness). *For every $\rho > 0$ and for every $x \in \Omega_{\frac{4\rho}{\overline{\theta}}}$, we have*

$$\int_{B_\rho(x)} |\widehat{\nabla} u|^2 \geqslant C_\rho \int_\Omega |\widehat{\nabla} u|^2, \tag{4.1}$$

where $\overline{\theta}$, $0 < \overline{\theta} < 1$, depends only on α_0, β_0, M and C_ρ depends only on α_0, β_0, M, $|\Omega|$, r_0, M_0, $\|\varphi\|_{L^2(\partial\Omega)}/\|\varphi\|_{H^{-1/2}(\partial\Omega)}$, and ρ.

We adapt arguments from [ARS00, Theorem 2.2]. We start with the following auxiliary lemma.

LEMMA 4.2.

$$\int_{\Omega\setminus\Omega_{\frac{5\rho}{\overline{\theta}}}} |\widehat{\nabla} u|^2 \leqslant C\rho^{1/n} \|\varphi\|^2_{L^2(\partial\Omega)}, \tag{4.2}$$

where C depends only on $\alpha_0, \beta_0, M, r_0, M_0, |\Omega|$.

Proof of Lemma 4.2. By Hölder's inequality

$$\|\widehat{\nabla} u\|^2_{L^2(\Omega\setminus\Omega_{\frac{5\rho}{\overline{\theta}}})} \leqslant |\Omega \setminus \Omega_{\frac{5\rho}{\overline{\theta}}}|^{1/n} \|\widehat{\nabla} u\|^2_{L^{2n/(n-1)}(\Omega\setminus\Omega_{\frac{5\rho}{\overline{\theta}}})}, \tag{4.3}$$

and by the Sobolev inequality (see, for instance, [Ad75])

$$\|\widehat{\nabla} u\|^2_{L^{2n/(n-1)}(\Omega)} \leqslant C\|\widehat{\nabla} u\|^2_{H^{1/2}(\Omega)}, \tag{4.4}$$

we have

$$\|\widehat{\nabla} u\|^2_{L^2(\Omega\setminus\Omega_{\frac{5\rho}{\theta}})} \leqslant C|\Omega\setminus\Omega_{\frac{5\rho}{\theta}}|^{1/n}\|u\|^2_{H^{3/2}(\Omega)}, \tag{4.5}$$

where C depends only on r_0, M_0, $|\Omega|$.

Moreover, we have

$$\|u\|_{H^{3/2}(\Omega)} \leqslant C\|\varphi\|_{L^2(\partial\Omega)}, \tag{4.6}$$

where C depends only on $\alpha_0, \beta_0, M, r_0, M_0, |\Omega|$. Inequality (4.6) follows, by interpolation (see [LM72]), from the global estimates for the Neumann problem

$$\|u\|_{H^1(\Omega)} \leqslant C_1\|\varphi\|_{H^{-1/2}(\partial\Omega)}, \tag{4.7}$$

$$\|u\|_{H^2(\Omega)} \leqslant C_2\|\varphi\|_{H^{1/2}(\partial\Omega)}, \tag{4.8}$$

where C_1 and C_2 depend only on α_0, β_0, M, r_0, M_0, $|\Omega|$ (see [ADN64]).

Moreover,

$$|\Omega\setminus\Omega_{\frac{5\rho}{\theta}}| \leqslant C\rho, \tag{4.9}$$

where C depends only on r_0, M_0, $|\Omega|$. (See (A.3) in [AR98] for details.) From (4.5), (4.6), and (4.9) the thesis follows. □

Proof of Proposition 4.1. Let us fix ρ_0, depending only on r_0, M_0, such that $\Omega_{\frac{4\rho}{\theta}}$ is connected for every $\rho \leqslant \rho_0$. Without loss of generality, we may assume $\rho \leqslant \rho_0$ for this proof. Given any $y \in \Omega_{\frac{4\rho}{\theta}}$, let γ be an arc in $\Omega_{\frac{4\rho}{\theta}}$ joining x and y. Let us define $\{x_i\}$, $i = 1, \dots, L$, as follows: $x_1 = x$, $x_{i+1} = \gamma(t_i)$, where $t_i = \max\{t \mid |\gamma(t) - x_i| = 2\rho\}$ if $|x_i - y| > 2\rho$; otherwise let $i = L$ and stop the process. Then, by construction, the balls $B_\rho(x_i)$ are pairwise disjoint, $|x_{i+1} - x_i| = 2\rho$ for $i = 1, \dots, L-1$, $|x_L - y| \leqslant 2\rho$.

Since $x_i \in \Omega_{\frac{4\rho}{\theta}}$, we may apply (3.5) for $x = x_i$, $r_1 = \rho$, $r_2 = 3\rho$, $r_3 = 4\rho$, for $i = 1, \dots, L-1$, obtaining

$$\frac{\|\widehat{\nabla} u\|_{L^2(B_\rho(x_{i+1}))}}{\|\widehat{\nabla} u\|_{L^2(\Omega)}} \leqslant C\left(\frac{\|\widehat{\nabla} u\|_{L^2(B_\rho(x_i))}}{\|\widehat{\nabla} u\|_{L^2(\Omega)}}\right)^{\delta}, \tag{4.10}$$

where $C > 0$ and δ, $0 < \delta < 1$, depend only on α_0, β_0, and M. By induction we have

$$\frac{\|\widehat{\nabla} u\|_{L^2(B_\rho(y))}}{\|\widehat{\nabla} u\|_{L^2(\Omega)}} \leqslant C^{1/(1-\delta)}\left(\frac{\|\widehat{\nabla} u\|_{L^2(B_\rho(x))}}{\|\widehat{\nabla} u\|_{L^2(\Omega)}}\right)^{\delta^L}. \tag{4.11}$$

Let us notice that $L \leqslant \frac{|\Omega|}{\omega_n\rho^n}$.

Let us cover $\Omega_{\frac{5\rho}{\theta}}$ with internally nonoverlapping closed cubes of side $l = 2\rho/\sqrt{n}\overline{\theta}$. Clearly, any such cube is contained in a ball of radius ρ and center in $\Omega_{\frac{4\rho}{\theta}}$ and the number of such cubes is controlled by $N = \frac{|\Omega| n^{n/2}\overline{\theta}^n}{2^n\rho^n}$. Therefore, from (4.11) we have

$$\frac{\|\widehat{\nabla} u\|_{L^2(\Omega_{\frac{5\rho}{\theta}})}}{\|\widehat{\nabla} u\|_{L^2(\Omega)}} \leqslant \frac{C}{\rho^{n/2}}\left(\frac{\|\widehat{\nabla} u\|_{L^2(B_\rho(x))}}{\|\widehat{\nabla} u\|_{L^2(\Omega)}}\right)^{\delta^L}, \tag{4.12}$$

where C depends only on $\alpha_0, \beta_0, M, |\Omega|$.

Now, let us estimate from below the left-hand side of (4.12) by means of a positive constant. Let us set

$$\frac{\|\widehat{\nabla} u\|^2_{L^2(\Omega_{\frac{5\rho}{\theta}})}}{\|\widehat{\nabla} u\|^2_{L^2(\Omega)}} = 1 - \frac{\int_{\Omega \setminus \Omega_{\frac{5\rho}{\theta}}} |\widehat{\nabla} u|^2}{\int_\Omega |\widehat{\nabla} u|^2}. \tag{4.13}$$

By a trace inequality (see, for instance, [LM72]) and by the Korn inequality (3.9), we have

$$\|\varphi\|_{H^{-1/2}(\partial\Omega)} \leqslant C \|\widehat{\nabla} u\|_{L^2(\Omega)}, \tag{4.14}$$

where C depends only on $\alpha_0, \beta_0, r_0, M_0, |\Omega|$. Hence, by (4.2) and (4.14), we have that there exists $\overline{\rho} > 0$, depending only on $\alpha_0, \beta_0, M, r_0, M_0, |\Omega|$, and $\|\varphi\|_{L^2(\partial\Omega)} / \|\varphi\|_{H^{-1/2}(\partial\Omega)}$, such that

$$\frac{\|\widehat{\nabla} u\|^2_{L^2(\Omega_{\frac{5\rho}{\theta}})}}{\|\widehat{\nabla} u\|^2_{L^2(\Omega)}} \geqslant \frac{1}{2} \tag{4.15}$$

for every ρ, $0 < \rho \leqslant \overline{\rho}$.

Finally, from (4.12) and (4.15) the thesis follows when $0 < \rho \leqslant \overline{\rho}$; for larger values of ρ, inequality (4.1) is trivial. □

PROPOSITION 4.3. *There exists θ^*, $0 < \theta^* \leqslant 1$, depending only on α_0, β_0, M, such that for every $\overline{r} > 0$ and every $x_0 \in \Omega_{\overline{r}}$ we have*

$$\int_{B_{2r}(x_0)} |u|^2 \leqslant K \int_{B_r(x_0)} |u|^2 \textit{ for every } r,\ 0 < r \leqslant \frac{\theta^* \overline{r}}{2}, \tag{4.16}$$

$$\int_{B_{2r}(x_0)} |\widehat{\nabla} u|^2 \leqslant K \int_{B_r(x_0)} |\widehat{\nabla} u|^2 \textit{ for every } r,\ 0 < r \leqslant \frac{\theta^* \overline{r}}{4}, \tag{4.17}$$

where $K > 0$ depends only on α_0, β_0, M, r_0, M_0, $|\Omega|$, $\overline{r}$, and $\|\varphi\|_{L^2(\partial\Omega)} / \|\varphi\|_{H^{-1/2}(\partial\Omega)}$, and θ^* is the quantity introduced in Corollary 3.10.

Proof. The proofs of (4.16) and (4.17) are similar. Let us prove (4.17), which takes a little bit more work. Given $x_0 \in \Omega_{\overline{r}}$ and r, $0 < r < \frac{\theta^* \overline{r}}{4}$, we may apply Corollary 3.10 with $R = \overline{r}$, obtaining (4.17) with K depending only on α_0, β_0, M, and

$$\tilde{N}_0(v; \theta^* \overline{r}) = \frac{(\theta^* \overline{r})^2 \int_{B_{\theta^* \overline{r}}(x_0)} |\nabla v|^2 + \overline{r}^2 |\nabla (\operatorname{div} v)|^2}{\int_{B_{\theta^* \overline{r}}(x_0)} |v|^2 + \overline{r}^2 |\operatorname{div} v|^2}, \tag{4.18}$$

the dependence on this last variable being monotonically increasing and where v is defined in $B_{\overline{r}}(x_0)$ by

$$v = u - c - W(x - x_0), \tag{4.19}$$

with

$$c = \frac{1}{|B_r(x_0)|} \int_{B_r(x_0)} u, \quad W = \frac{1}{2|B_r(x_0)|} \int_{B_r(x_0)} \nabla u - (\nabla u)^T. \tag{4.20}$$

We have that $\nabla v = \nabla u - W$, $\widehat{\nabla} v = \widehat{\nabla} u$, and $\operatorname{div} v = \operatorname{div} u$. Moreover, by interior regularity estimates (see [ADN64]), we have

$$\begin{aligned}(4.21)\quad |W| &\leqslant \frac{1}{|B_r(x_0)|}\int_{B_r(x_0)} |\nabla u| \leqslant \|\nabla u\|_{L^\infty(B_r(x_0))} \\ &\leqslant C\|u\|_{H^1(\Omega)} \leqslant C\|\varphi\|_{H^{-1/2}(\partial\Omega)},\end{aligned}$$

where C depends only on α_0, β_0, M, r_0, and $\overline{r}$. Hence

$$(4.22)\qquad \int_{B_{\theta^*\overline{r}}(x_0)} |\nabla v|^2 \leqslant 2\int_{B_{\theta^*\overline{r}}(x_0)} |\nabla u|^2 + |W|^2 \leqslant C\|\varphi\|^2_{H^{-1/2}(\partial\Omega)},$$

where C depends only on α_0, β_0, M, r_0, and $\overline{r}$. By the Caccioppoli-type inequality (3.6) we have

$$(4.23)\qquad \int_{B_{\theta^*\overline{r}}(x_0)} |v|^2 \geqslant C\int_{B_{\frac{\theta^*\overline{r}}{2}}(x_0)} |\nabla v|^2 \geqslant C\int_{B_{\frac{\theta^*\overline{r}}{2}}(x_0)} |\widehat{\nabla} u|^2,$$

where C depends only on α_0, β_0, M, $\overline{r}$. If $\frac{\theta^*}{2} \leqslant \frac{\overline{\theta}}{4}$, we may apply Proposition 4.1 with $\rho = \frac{\theta^*\overline{r}}{2}$, whereas if $\frac{\theta^*}{2} \geqslant \frac{\overline{\theta}}{4}$, we may apply Proposition 4.1 with $\rho = \frac{\overline{\theta}\overline{r}}{4}$. In both cases by trace theorems and the standard Korn inequality we obtain

$$(4.24)\qquad \int_{B_{\frac{\theta^*\overline{r}}{2}}(x_0)} |\widehat{\nabla} u|^2 \geqslant C\int_\Omega |\widehat{\nabla} u|^2 \geqslant C\|\varphi\|^2_{H^{-1/2}(\partial\Omega)},$$

where C depends only on α_0, β_0, M, r_0, M_0, $|\Omega|$, $\overline{r}$, and $\|\varphi\|_{L^2(\partial\Omega)}/\|\varphi\|_{H^{-1/2}(\partial\Omega)}$. By (4.22)–(4.24) and interior regularity estimates (see [ADN64]) we have

$$(4.25)\qquad \tilde{N}_0(v; \theta^*\overline{r}) \leqslant C,$$

where C depends only on α_0, β_0, M, r_0 M_0,$|\Omega|$, $\overline{r}$, and $\|\varphi\|_{L^2(\partial\Omega)}/\|\varphi\|_{H^{-1/2}(\partial\Omega)}$. Hence the thesis follows. □

Proposition 4.4 (A_p property). *For every $\overline{r} > 0$ there exist $B > 0$ and $p > 1$ such that for every $x_0 \in \Omega_{\overline{r}}$ we have*

$$(4.26)\quad \left(\frac{1}{|B_r(x_0)|}\int_{B_r(x_0)} |\widehat{\nabla} u|^2\right)\left(\frac{1}{|B_r(x_0)|}\int_{B_r(x_0)} |\widehat{\nabla} u|^{-2/(p-1)}\right)^{p-1} \leqslant B \qquad \text{for every } r,\ 0 < r \leqslant \frac{\theta^*\overline{r}}{4},$$

where θ^* is the quantity introduced in Corollary 3.10 and where B, p depend only on α_0, β_0, M, r_0, M_0,$|\Omega|$, $\overline{r}$, and $\|\varphi\|_{L^2(\partial\Omega)}/\|\varphi\|_{H^{-1/2}(\partial\Omega)}$.

Proof. In view of the results in [CF74] it is enough to prove a reverse Hölder's inequality for $|\widehat{\nabla} u|^2$. Let $v = u - c - W(x - x_0)$, with $c = \frac{1}{|B_{2r}(x_0)|}\int_{B_{2r}(x_0)} u$, $W = \frac{1}{2|B_{2r}(x_0)|}\int_{B_{2r}(x_0)} \nabla u - (\nabla u)^T$. By interior regularity estimates, the Korn inequality (3.9), and Proposition 4.3 we have

$$\begin{aligned}(4.27)\quad \|\widehat{\nabla} u\|_{L^\infty(B_r(x_0))} = \|\widehat{\nabla} v\|_{L^\infty(B_r(x_0))} &\leqslant \frac{C}{r^{(n+2)/2}}\|v\|_{H^1(B_{2r}(x_0))} \\ &\leqslant \frac{C}{r^{n/2}}\|\widehat{\nabla} u\|_{L^2(B_{2r}(x_0))} \leqslant \frac{C}{r^{n/2}}\|\widehat{\nabla} u\|_{L^2(B_r(x_0))},\end{aligned}$$

where C depends only on α_0, β_0, M, r_0, M_0,$|\Omega|$, $\overline{r}$, and $\|\varphi\|_{L^2(\partial\Omega)}/\|\varphi\|_{H^{-1/2}(\partial\Omega)}$. □

5. Proofs of Theorems 2.3 and 2.4. We base the proof of our main theorems on two auxiliary lemmas.

LEMMA 5.1. *Let the elasticity tensor fields* $\mathbb{C}(x)$ *and* $\widetilde{\mathbb{C}}(x)$ *satisfy* (2.5), (2.6) *in* Ω. *Suppose that weak solutions* u, $u_0 \in H^1(\Omega, \mathbb{R}^n)$ *to the traction problems* (2.25)–(2.26), (2.27)–(2.28) *exist. The following identities hold:*

$$\int_\Omega (\chi_{\Omega\setminus D}\mathbb{C} + \chi_D\widetilde{\mathbb{C}})\nabla(u-u_0)\cdot\nabla(u-u_0) - \int_D (\widetilde{\mathbb{C}}-\mathbb{C})\nabla u_0\cdot\nabla u_0 = \int_{\partial\Omega}(g-g_0)\cdot\varphi, \tag{5.1}$$

$$\int_\Omega \mathbb{C}\nabla(u-u_0)\cdot\nabla(u-u_0) + \int_D (\widetilde{\mathbb{C}}-\mathbb{C})\nabla u\cdot\nabla u = \int_{\partial\Omega}(g_0-g)\cdot\varphi, \tag{5.2}$$

$$\int_D (\widetilde{\mathbb{C}}-\mathbb{C})\nabla u\cdot\nabla u_0 = \int_{\partial\Omega}(g_0-g)\cdot\varphi, \tag{5.3}$$

where g,$g_0 \in H^{1/2}(\partial\Omega, \mathbb{R}^n)$ *are the traces of* u,u_0, *respectively, on* $\partial\Omega$.

Proof of Lemma 5.1. Let us denote $\mathbb{H} = (\widetilde{\mathbb{C}} - \mathbb{C})$ in Ω. From the weak formulation of the problem (2.25)–(2.26) with $D = D_1$ and $D = D_2$ we get the identity

$$\int_\Omega (\mathbb{C} + \chi_{D_1}\mathbb{H})\nabla u_1\cdot\nabla w = \int_\Omega (\mathbb{C} + \chi_{D_2}\mathbb{H})\nabla u_2\cdot\nabla w \quad \text{for every} \quad w\in H^1(\Omega,\mathbb{R}^n), \tag{5.4}$$

where u_i is the solution to (2.25)–(2.26) with $D = D_i$, $i = 1, 2$, respectively. Subtracting the quantity $\int_\Omega (\mathbb{C} + \chi_{D_1}\mathbb{H})\nabla u_2\cdot\nabla w$ from both sides of (5.4) we have

$$\int_\Omega (\mathbb{C} + \chi_{D_1}\mathbb{H})\nabla(u_1-u_2)\cdot\nabla w = \int_\Omega (\chi_{D_2} - \chi_{D_1})\mathbb{H}\nabla u_2\cdot\nabla w \quad \text{for every} \quad w\in H^1(\Omega,\mathbb{R}^n). \tag{5.5}$$

Choosing $w = u_1$ into (5.5) we get

$$\int_\Omega (\mathbb{C} + \chi_{D_1}\mathbb{H})\nabla(u_1-u_2)\cdot\nabla u_1 = \int_\Omega (\chi_{D_2} - \chi_{D_1})\mathbb{H}\nabla u_2\cdot\nabla u_1. \tag{5.6}$$

By using the weak formulation of the traction problems for u_1 and u_2, the left-hand side of (5.6) can be rewritten as follows:

$$\int_\Omega (\mathbb{C} + \chi_{D_1}\mathbb{H})\nabla(u_1-u_2)\cdot\nabla u_1 = \int_{\partial\Omega}(g_1-g_2)\cdot\varphi, \tag{5.7}$$

where $g_i = u_i\,|_{\partial\Omega}$, $i = 1, 2$, and therefore (5.6) becomes

$$\int_{\partial\Omega}(g_1-g_2)\cdot\varphi = \int_\Omega (\chi_{D_2} - \chi_{D_1})\mathbb{H}\nabla u_2\cdot\nabla u_1. \tag{5.8}$$

Choosing $w = u_1 - u_2$ into (5.5) and using (5.8) we get

$$\int_\Omega (\mathbb{C} + \chi_{D_1}\mathbb{H})\nabla(u_1 - u_2) \cdot \nabla(u_1 - u_2) = \int_\Omega (\chi_{D_1} - \chi_{D_2})\mathbb{H}\nabla u_2 \cdot \nabla u_2 + \int_{\partial\Omega} (g_1 - g_2) \cdot \varphi, \tag{5.9}$$

and finally we obtain the fundamental identity

$$\int_\Omega (\mathbb{C} + \chi_{D_1}\mathbb{H})\nabla(u_1 - u_2) \cdot \nabla(u_1 - u_2) + \int_{D_2 \setminus D_1} \mathbb{H}\nabla u_2 \cdot \nabla u_2 = \int_{\partial\Omega} (g_1 - g_2) \cdot \varphi + \int_{D_1 \setminus D_2} \mathbb{H}\nabla u_2 \cdot \nabla u_2, \tag{5.10}$$

which is the analogue to the identity found in Kang, Seo, and Sheen [KSS97] for the inverse conductivity problem.

By choosing $D_1 = D$ and $D_2 = \emptyset$ we obtain the first identity (5.1) of the lemma. The second identity (5.2) follows from (5.10) for $D_1 = \emptyset$ and $D_2 = D$.

To get the third identity (5.3), we choose $w = u_0$ and $w = u$ in the weak formulation of the traction problem (2.25)–(2.26) for $D = D_1$ and $D = \emptyset$, respectively:

$$\int_\Omega (\mathbb{C} + \chi_D\mathbb{H})\nabla u \cdot \nabla u_0 = \int_{\partial\Omega} g_0 \cdot \varphi, \tag{5.11}$$

$$\int_\Omega \mathbb{C}\nabla u_0 \cdot \nabla u = \int_{\partial\Omega} g \cdot \varphi. \tag{5.12}$$

Subtracting (5.12) from (5.11) we obtain identity (5.3). □

Lemma 5.2. *Let $\mathbb{C}(x)$ and $\widetilde{\mathbb{C}}(x)$ satisfy* (2.5), (2.6) *in Ω. Let ξ_0, ξ_1, $0 < \xi_0 < \xi_1$, be such that*

$$\xi_0|A|^2 \le \mathbb{C}(x)A \cdot A \le \xi_1|A|^2 \qquad for \quad a.e. \quad x \in \Omega, \tag{5.13}$$

for any symmetric $n \times n$ matrix A, and let the jump $(\widetilde{\mathbb{C}}(x) - \mathbb{C}(x))$ satisfy either (2.30) *or* (2.31)*. Let u, $u_0 \in H^1(\Omega, \mathbb{R}^n)$ be the weak solutions to the traction problems* (2.25)–(2.26), (2.27)–(2.28)*, respectively.*

If (2.30) *holds, then we have*

$$\frac{\eta\xi_0}{\delta} \int_D |\widehat{\nabla} u_0|^2 \le \int_{\partial\Omega} (g_0 - g) \cdot \varphi \le (\delta - 1)\xi_1 \int_D |\widehat{\nabla} u_0|^2. \tag{5.14}$$

If instead (2.31) *holds, then we have*

$$\eta\xi_0 \int_D |\widehat{\nabla} u_0|^2 \le \int_{\partial\Omega} (g - g_0) \cdot \varphi \le \frac{1 - \delta}{\delta}\xi_1 \int_D |\widehat{\nabla} u_0|^2. \tag{5.15}$$

Proof of Lemma 5.2. Suppose that (2.30) holds. Then, from identity (5.1) we have

$$\int_{\partial\Omega} (g_0 - g) \cdot \varphi \le \int_D \mathbb{H}\nabla u_0 \cdot \nabla u_0, \tag{5.16}$$

where $\mathbb{H} = (\widetilde{\mathbb{C}} - \mathbb{C})$ in Ω. The inequality below follows by the symmetry properties (2.7), (2.8), (2.9) and the positivity condition (2.30):

$$\int_D \mathbb{H}\nabla u_0 \cdot \nabla u_0 \leq (1+\epsilon)\int_D \mathbb{H}\nabla(u-u_0)\cdot\nabla(u-u_0) + \left(1+\frac{1}{\epsilon}\right)\int_D \mathbb{H}\nabla u\cdot\nabla u \qquad \text{for every} \quad \epsilon > 0. \tag{5.17}$$

Then, from (2.30) we have

$$\int_D \mathbb{H}\nabla u_0 \cdot \nabla u_0 \leq (1+\epsilon)(\delta-1)\left[\int_D \mathbb{C}\nabla(u-u_0)\cdot\nabla(u-u_0) + \frac{1}{\epsilon(\delta-1)}\int_D \mathbb{H}\nabla u\cdot\nabla u\right]. \tag{5.18}$$

Choosing $\epsilon = \frac{1}{\delta-1}$ in (5.18) and by employing identity (5.2) we get

$$\int_D \mathbb{H}\nabla u_0 \cdot \nabla u_0 \leq \delta \int_{\partial\Omega}(g_0 - g)\cdot\varphi. \tag{5.19}$$

The double inequality (5.14) follows from (5.16), (5.19) and (5.13), (2.30).

In the case where (2.31) holds, from (5.1) we have

$$\int_{\partial\Omega}(g-g_0)\cdot\varphi \geq \int_D -\mathbb{H}\nabla u_0\cdot\nabla u_0. \tag{5.20}$$

From (5.3) we obtain $\int_{\partial\Omega}(g-g_0)\cdot\varphi = \int_D -\mathbb{H}\nabla u\cdot\nabla u_0$, and then, reasoning as in (5.17), we find

$$\int_{\partial\Omega}(g-g_0)\cdot\varphi \leq \frac{\epsilon}{2}\int_D -\mathbb{H}\nabla u\cdot\nabla u + \frac{1}{2\epsilon}\int_D -\mathbb{H}\nabla u_0\cdot\nabla u_0 \qquad \text{for every} \quad \epsilon > 0. \tag{5.21}$$

By using (5.2), (2.31), and (5.1) we have

$$\begin{aligned}\int_D -\mathbb{H}\nabla u\cdot\nabla u &= \int_{\partial\Omega}(g-g_0)\cdot\varphi + \int_\Omega \mathbb{C}\nabla(u-u_0)\cdot\nabla(u-u_0)\\ &\leq \int_{\partial\Omega}(g-g_0)\cdot\varphi + \frac{1}{\delta}\int_\Omega(\mathbb{C}+\mathbb{H})\nabla(u-u_0)\cdot\nabla(u-u_0)\\ &= \int_{\partial\Omega}(g-g_0)\cdot\varphi + \frac{1}{\delta}\left[\int_{\partial\Omega}(g-g_0)\cdot\varphi + \int_\Omega \mathbb{H}\nabla u_0\cdot\nabla u_0\right]\\ &= \frac{\delta+1}{\delta}\int_{\partial\Omega}(g-g_0)\cdot\varphi + \frac{1}{\delta}\int_{\mathbb{D}} \mathbb{H}\nabla u_0\cdot\nabla u_0.\end{aligned} \tag{5.22}$$

Inserting inequality (5.22) into (5.21), we obtain

$$\int_{\partial\Omega}(g-g_0)\cdot\varphi \leq \alpha(\epsilon)\int_D -\mathbb{H}\nabla u_0\cdot\nabla u_0, \tag{5.23}$$

where $\alpha(\epsilon) = \frac{\delta-\epsilon^2}{\epsilon(2\delta-\epsilon\delta-\epsilon)}$. The minimum of $\alpha(\epsilon)$ occurs when $\epsilon = \delta$ and in this case we have

$$\int_{\partial\Omega} (g-g_0)\cdot\varphi \leq \frac{1}{\delta}\int_D -\mathbb{H}\nabla u_0\cdot\nabla u_0. \tag{5.24}$$

The double inequality (5.15) follows from (5.20), (5.24) and (5.13), (2.31). □

Proof of Theorem 2.3. By (2.21), the inequality (5.13) holds, with $\xi_0 = \min\{2\alpha_0, \gamma_0\}$, $\xi_1 = (n+2)M$, so that Lemma 5.2 may be applied.

By standard regularity estimates for elliptic systems (see Agmon, Douglis, and Nirenberg [ADN64]), by the Korn inequality, by (5.13), and by the weak formulation of the Neumann problem (2.27)-(2.28), we have

$$\|\widehat{\nabla}u_0\|_{L^\infty(D)} \leq C\|u_0\|_{H^1(\Omega)} \leq C\|\widehat{\nabla}u_0\|_{L^2(\Omega)} \leq C\left(\int_{\partial\Omega} g_0\cdot\varphi\right)^{\frac{1}{2}}, \tag{5.25}$$

where the constant C depends only on α_0, γ_0, M, d_0, and $|\Omega|$.

The lower bound for $|D|$ in (2.34), (2.35) follows from the right-hand side of (5.14), (5.15) and from (5.25).

Let us prove the upper bound for $|D|$ in (2.34), (2.35). Let $\epsilon = \min\{\frac{\bar{\theta}d_0}{2}, \frac{h_1}{\sqrt{n}}\}$, where $\bar{\theta}$ is as in Proposition 4.1. Let us cover D_{h_1} with internally nonoverlapping closed cubes Q_l of side ϵ, for $l = 1,\dots,L$. By the choice of ϵ the cubes Q_l are contained in D. Hence

$$\int_D \left|\widehat{\nabla}u_0\right|^2 \geq \int_{\bigcup_{l=1}^L Q_l} \left|\widehat{\nabla}u_0\right|^2 \geq \frac{|D_{h_1}|}{\epsilon^n}\int_{Q_{\bar{l}}} \left|\widehat{\nabla}u_0\right|^2, \tag{5.26}$$

where $\bar{l}$ is such that $\int_{Q_{\bar{l}}} \left|\widehat{\nabla}u_0\right|^2 = \min_l \int_{Q_l} \left|\widehat{\nabla}u_0\right|^2$. Let $\bar{x}$ be the center of $Q_{\bar{l}}$. From (5.26), estimate (4.1) with $x = \bar{x}$ and $\rho = \epsilon/2$ from (5.13), and from the weak formulation of (2.27)-(2.28) we have

$$\int_D \left|\widehat{\nabla}u_0\right|^2 \geq K|D|\int_{\partial\Omega} g_0\cdot\varphi, \tag{5.27}$$

where K depends only on α_0, β_0, d_0, $|\Omega|$, r_0, M_0, M, h_1, $\|\varphi\|_{L^2(\partial\Omega)}/\|\varphi\|_{H^{-1/2}(\partial\Omega)}$. The upper bound for D in (2.34), (2.35) follows from the left-hand side of (5.14), (5.15) and from (5.27). □

Proof of Theorem 2.4. Let $\bar{r} = \frac{d_0}{2}$ and $\epsilon = \min\{\frac{\theta^* d_0}{4\sqrt{n}}, \frac{\bar{\theta}d_0}{4}\}$, where θ^* is as in Proposition 4.4. Let us cover D with internally nonoverlapping closed cubes Q_j, $j = 1,\dots,J$, with side ϵ. By Hölder's inequality we have

$$|D| \leq \left(\int_{\bigcup_{j=1}^J Q_j} \left|\widehat{\nabla}u_0\right|^{-\frac{2}{p-1}}\right)^{\frac{p-1}{p}} \left(\int_D \left|\widehat{\nabla}u_0\right|^2\right)^{\frac{1}{p}}, \tag{5.28}$$

where p is chosen as in Proposition 4.4. By applying Proposition 4.4 to the balls B_j circumscribing each Q_j, $j = 1,\dots,J$, we have

$$\left(\int_{\bigcup_{j=1}^J Q_j} |\widehat{\nabla} u_0|^{-\frac{2}{p-1}}\right)^{\frac{p-1}{p}} = \left(\epsilon^n \sum_{j=1}^J \frac{1}{|Q_j|}\int_{Q_j} |\widehat{\nabla} u_0|^{-\frac{2}{p-1}}\right)^{\frac{p-1}{p}}$$
$$\le \left(\epsilon^n \sum_{j=1}^J \left(\frac{B[C(n)]^p}{\frac{1}{|Q_j|}\int_{Q_j}|\widehat{\nabla} u_0|^2}\right)^{\frac{1}{p-1}}\right)^{\frac{p-1}{p}} \le \frac{(J\epsilon^n)^{\frac{p-1}{p}} B^{\frac{1}{p}} C(n)}{\min_j \left(\frac{1}{|Q_j|}\int_{Q_j}|\widehat{\nabla} u_0|^2\right)^{\frac{1}{p}}}, \tag{5.29}$$

where $C(n) = \omega_n \left(\frac{\sqrt{n}}{2}\right)^n$ and B is as in Proposition 4.4. Now $J\epsilon^n = \sum_{j=1}^J |Q_j| \le |\Omega|$ and hence, from (5.28), we have

$$|D| \le |\Omega|^{\frac{p-1}{p}} B^{\frac{1}{p}} C(n) \left(\frac{\epsilon^n \int_D |\widehat{\nabla} u_0|^2}{\min_j \int_{Q_j} |\widehat{\nabla} u_0|^2}\right)^{\frac{1}{p}}. \tag{5.30}$$

By Proposition 4.1, (5.30), (5.13), and the weak formulation of (2.27)-(2.28), we have

$$\int_D |\widehat{\nabla} u_0|^2 \ge \left(K \int_{\partial\Omega} g_0 \cdot \varphi\right) |D|^p, \tag{5.31}$$

where K depends only on α_0, β_0, d_0, $|\Omega|$, r_0, M_0, M, h_1, $\|\varphi\|_{L^2(\partial\Omega)}/\|\varphi\|_{H^{-1/2}(\partial\Omega)}$. The right-hand side of (2.36), (2.37) follow from the left-hand side of (5.14), (5.15), and (5.31). □

THE GLOBAL CAUCHY PROBLEM IN BOURGAIN'S-TYPE SPACES FOR A DISPERSIVE DISSIPATIVE SEMILINEAR EQUATION*

LUC MOLINET† AND FRANCIS RIBAUD‡

Abstract. We prove local and global well-posedness results for the Kadomtsev–Petviashvili–Burgers equations in Bourgain's-type spaces. This approach is new for the study of semilinear evolution equations with a linear part which contains both dispersive and dissipative terms.

Key words. Kadomtsev–Petviashvili–Burgers equations, Bourgain spaces, global existence

1. Introduction.

We study the initial value problem for the Kadomtsev–Petviashvili–Burgers (KPB) equations in $\mathbb{R}^2$:

$$\begin{cases} (u_t + u_{xxx} + uu_x - u_{xx})_x + \varepsilon u_{yy} = 0, \\ u(0) = \varphi, \end{cases} \tag{1.1}$$

where $\varepsilon = \pm 1$.

These equations are dissipative versions of the Kadomtsev–Petviashvili (KP) equations

$$(u_t + u_{xxx} + uu_x)_x + \varepsilon u_{yy} = 0,$$

which are "universal" models for nearly one directional weakly nonlinear dispersive waves with weak transverse effects. The KP equations being themselves natural two dimensional extensions of the famous KdV equation

$$u_t + u_{xxx} + uu_x = 0.$$

In some physical contexts (such as magnetosonic waves damped by electron-ion collisions), when dissipative effects cannot be neglected, the KdV–Burgers equation

$$u_t + u_{xxx} + uu_x - u_{xx} = 0$$

has been derived (cf. [14]). The KPB equations are thus natural candidates to model the propagation of two dimensional damped waves in some physical situations. Note that due to the hypothesis of nearly one directional propagation, the dissipative term acts only in the main direction of propagation in (1.1).

In the last decade, Bourgain developed a new method to study the Cauchy problem for nonlinear dispersive equations. This method was successfully applied to the

Schrödinger equation, the KdV equation, and the KP II equation ($\varepsilon = +1$). Concerning the KdV and KP II equations, it permitted, for instance, to show the global well-posedness in H^s, $s \geq 0$; see, respectively, [4] and [3]. Also local existence results in Sobolev spaces of negative order have been obtained; see [9] and [16]. One of the particularities of this method is its use of special Fourier transform restriction spaces strongly related to the symbol of the linear equation, the existence and uniqueness of the solution then being obtained by a standard fixed point argument on the corresponding integral equation.

The main contribution of this paper is to show how the Bourgain spaces can also be successfully employed to study the Cauchy problem for semilinear equations with a linear part which contains both dissipative and dispersive terms. As far as the authors know, Bourgain spaces were never used in such a context.

Let us recall that in the Bourgain's method for the KP II equation, the loss of derivative in the nonlinear term $\partial_x(u^2)$ is compensated by a smoothing effect resulting from a simple algebraic inequality (see (5.2)) involving the symbol $\tau - \xi^3 - \eta^2/\xi$ of the linear KP II equation.

In the case of the KP I equation ($\varepsilon = -1$), this inequality does not hold, which is why there is no available result on the local well-posedness of the KP I equation by using Bourgain spaces. However, by the parabolic regularization method, local well-posedness in $H^s(\mathbb{R}^2)$, $s > 2$, has been obtained (cf. [5]). But this approach seems far from satisfactory since it does not use at all the dispersive nature of the equation.

In this paper the main idea is to work in the Bourgain spaces associated with the "usual" KP equations, i.e., related only to the dispersive part of the linear symbol of (1.1) (see Remark 3 below). After having extended the linear semigroup of the KPB equations to a linear operator $W(\cdot)$ defined on the whole real axis, we first derive some linear estimates in the Bourgain spaces for the "free evolution term" $W(t)\varphi$ and for the "forcing term" L defined by (2.10). In contrast to the purely dispersive case, we show that L is a smoothing operator not only in time but also in space. Then by using Strichartz's type estimates for the KP equations injected into the framework of Bourgain spaces, we show a bilinear estimate which will yield the local well-posedness of the KPB equations ($\varepsilon = +1$ or -1) in the anisotropic Sobolev spaces $H^{s_1,s_2}(\mathbb{R}^2)$, provided $s_1 > 0$ and $s_2 \geq 0$. Moreover, combining these Strichartz's estimates and the algebraic inequality (5.2), we prove the local well-posedness in $H^s(\mathbb{R}^2)$, $s \geq 0$, for the KPB II equation ($\varepsilon = +1$). The global well-posedness results will then follow by means of a priori estimates.

Let us note that local well-posedness for the KPB equations in the space $\{\varphi \in H^1(\mathbb{R}^2),\ \mathcal{F}^{-1}_{x,y}(\frac{\eta}{\xi}\hat{\varphi}) \in L^2(\mathbb{R}^2)\}$ was obtained in [12]. Also, global existence was obtained under a smallness restriction on the initial data when $\varepsilon = +1$. Finally, a local smoothing effect in the transverse direction was proved as well as the existence of global weak solutions in $L^2(\mathbb{R}^2)$ when $\varepsilon = -1$.

1.1. Notations. For $f \in \mathcal{S}'$ we denote by $\hat{f}$ or $\mathcal{F}(f)$ the Fourier transform of f, i.e.,

$$\hat{f}(\theta) = \int_{\mathbb{R}^n} e^{-i\langle \alpha, \theta\rangle} f(\alpha)\, d\alpha,$$

and we define the linear operator Δ_x^b by

$$\Delta_x^b(f)(x,y) = \mathcal{F}^{-1}\Big((1+|\xi|^2)^b \hat{f}(\xi,\eta)\Big)(x,y).$$

For a Banach space X, we denote by $\|\cdot\|_X$ the norm in X. We will use the Sobolev spaces $H^s(\mathbb{R}^2)$ and the homogeneous Sobolev spaces $\dot{H}^s(\mathbb{R}^2)$ equipped with the norms

$$\|u\|_{H^s}^2=\int_{\mathbb{R}^2}\langle\zeta\rangle^{2s}|\hat{u}(\zeta)|^2\,d\zeta,\qquad \|u\|_{\dot{H}^s}^2=\int_{\mathbb{R}^2}|\zeta|^{2s}|\hat{u}(\zeta)|^2\,d\zeta,$$

where $\zeta=(\xi,\eta)$, $|\zeta|=(|\xi|^2+|\eta|^2)^{1/2}$, and $\langle\zeta\rangle=(1+|\zeta|^2)^{1/2}$.

We also consider the anisotropic Sobolev spaces $H^{s_1,s_2}(\mathbb{R}^2)$ endowed with the norm

$$\|u\|_{H^{s_1,s_2}}^2=\int_{\mathbb{R}^2}\langle\xi\rangle^{2s_1}\langle\eta\rangle^{2s_2}\,|\hat{u}(\zeta)|^2\,d\zeta.$$

Next we consider the corresponding space-time Sobolev spaces $H^{b,s}$ and H^{b,s_1,s_2}, respectively, equipped with the norms

$$\|u\|_{H^{b,s}}^2=\int_{\mathbb{R}^3}\langle\tau\rangle^{2b}\langle\zeta\rangle^{2s}\,|\hat{u}(\tau,\zeta)|^2\,d\zeta\,d\tau,$$

$$\|u\|_{H^{b,s_1,s_2}}^2=\int_{\mathbb{R}^3}\langle\tau\rangle^{2b}\langle\xi\rangle^{2s_1}\langle\eta\rangle^{2s_2}\,|\hat{u}(\tau,\zeta)|^2\,d\zeta\,d\tau.$$

We will also use the space-time Lebesgue spaces $L^{p,q}_{t,z}$ $(z=(x,y))$ endowed with the norm

$$\|u\|_{L^{q,r}_{t,z}}=\big\|\|u\|_{L^r_z}\big\|_{L^q_t},$$

and we will use the notation $L^2_{t,z}$ for $L^{2,2}_{t,z}$.

Let $U(\cdot)$ be the unitary group which defined the free evolution of the KP equation, i.e.,

$$U(t)=\exp(itP(D_x,D_y)), \tag{1.2}$$

where $P(D_x,D_y)$ is the Fourier multiplier with symbol

$$P(\xi,\eta)=\xi^3-\varepsilon\,\frac{\eta^2}{\xi},\quad \varepsilon=\pm1.$$

We denote by $X^{b,s}$ and X^{b,s_1,s_2} the Bourgain's-type spaces associated with the spaces $H^{b,s}$ and H^{b,s_1,s_2} for the KP equations. They are, respectively, endowed with the norms

$$\|u\|_{X^{b,s}}=\|U(-t)u\|_{H^{b,s}} \tag{1.3}$$

and

$$\|u\|_{X^{b,s_1,s_2}}=\|U(-t)u\|_{H^{b,s_1,s_2}}. \tag{1.4}$$

Note that, since $\mathcal{F}(U(-t)u)(\tau,\zeta)=\mathcal{F}(u)(\tau+P(\zeta),\zeta)$, one can, respectively, re-express the norm of $X^{b,s}$ and X^{b,s_1,s_2} as

$$\|u\|_{X^{b,s}}=\|\langle\tau-P(\zeta)\rangle^b\,\langle\zeta\rangle^s\,\hat{u}(\tau,\zeta)\|_{L^2(\mathbb{R}^3)}$$

and

$$\|u\|_{X^{b,s_1,s_2}} = \|\langle \tau - P(\zeta)\rangle^b \, \langle \xi \rangle^{s_1} \langle \eta \rangle^{s_2} \, \hat{u}(\tau,\zeta)\|_{L^2(\mathbb{R}^3)}.$$

For $T \geq 0$, we consider the localized Bourgain spaces $X_T^{b,s}$ endowed with the norm

$$\|u\|_{X_T^{b,s}} = \inf_{w \in X^{b,s}} \{\|w\|_{X^{b,s}}, \, w(t) = u(t) \text{ on } [0,T] \,\},$$

the space X_T^{b,s_1,s_2} being defined in the same way.

Finally we denote by $W(\cdot)$ the semigroup associated with the free evolution of the KPB equations, i.e.,

$$\forall t \geq 0, \; \mathcal{F}_z(W(t)\varphi)(\zeta) = \exp[-|\xi|^2 t + iP(\zeta)\, t]\hat{\varphi}(\zeta), \qquad \varphi \in \mathcal{S}',$$

and we extend $W(\cdot)$ to a linear operator defined on the whole real axis by setting

$$\forall t \in \mathbb{R}, \; \mathcal{F}_z(W(t)\varphi)(\zeta) = \exp[-|\xi|^2 |t| + iP(\zeta) t]\hat{\varphi}(\zeta), \qquad \varphi \in \mathcal{S}'.$$

1.2. Main results. To prove local well-posedness results, we shall apply a fixed point argument in $X_T^{b,s}$ or X_T^{b,s_1,s_2} to the following cut-off version of the integral equation associated with (1.1):

$$u(t) = \psi(t) \left[W(t)\varphi - \frac{\mathbb{1}_{\mathbb{R}_+}(t)}{2} \int_0^t W(t-t')\partial_x(\psi_T^2(t')u^2(t'))\, dt' \right], \tag{1.5}$$

where $t \in \mathbb{R}$ and, in the rest of this paper, ψ is a time cut-off function satisfying

$$\psi \in C_0^\infty(\mathbb{R}), \quad \text{supp}\, \psi \subset [-1,1], \quad \psi = 1 \text{ on } \left[-\frac{1}{2}, \frac{1}{2}\right],$$

and $\psi_T(\cdot) = \psi(\cdot/T)$.

THEOREM 1.1 (KPB I). *Let $\varepsilon = -1$ and $(s_1,s_2) \in \mathbb{R}_+^* \times \mathbb{R}_+$. Then for any $\varphi \in H^{s_1,s_2}$, there exist a positive $T = T(\|\varphi\|_{H^{0+,0}})$ and a unique solution u to* (1.1) *in*

$$Y_T = C([0,T], \, H^{s_1,s_2}) \cap X_T^{1/2,s_1,s_2}. \tag{1.6}$$

Also, the map $\varphi \mapsto u$ is continuous from H^{s_1,s_2} to Y_T.

Moreover, if $s_1 \geq 1$ and $\mathcal{F}_z^{-1}(\frac{\eta}{\xi}\hat{\varphi}) \in L^2(\mathbb{R}^2)$, then T can be chosen arbitrarily large and

$$\forall t \geq 0, \; \|u(t)\|_{H^{1,0}} \leq C(\|\varphi\|_{L^2}, \|\partial_x \varphi\|_{L^2}, \|\partial_x^{-1}\varphi_y\|_{L^2}).$$

THEOREM 1.2 (KPB II). *Let $\varepsilon = 1$ and let $\varphi \in H^s(\mathbb{R}^2)$, $s \geq 0$. Then for any $T > 0$, there exists a unique solution u to* (1.1) *in*

$$Y_T = C([0,T], \, H^s) \cap X_T^{1/2,s}. \tag{1.7}$$

Moreover, the map $\varphi \mapsto u$ is continuous from $H^s(\mathbb{R}^2)$ to Y_T and the following inequality holds:

$$\forall t \geq 0, \; \|u(t)\|_{L^2} \leq \|\varphi\|_{L^2}.$$

Remark 1. It is easy to see that a solution of the integral equation (1.5) solves (1.1) in the distribution sense. Indeed, let $u \in C([0,T], H^s)$ such that, on $[0,T]$,

$$u(t) = W(t)\varphi - \frac{1}{2}\int_0^t W(t-t')\partial_x(u^2(t'))\,dt' . \tag{1.8}$$

Differentiating (1.8) with respect to x and then to t, we readily obtain

$$\partial_t\partial_x u + \frac{1}{2}\partial_x^2(u^2) + \partial_x^4 u + \varepsilon\partial_y^2 u = 0 \ \text{ in } \ C([0,T], H^{s-4}).$$

Since $\partial_t\partial_x u = \partial_x\partial_t u$ in $\mathcal{D}'((0,T)\times\mathbb{R}^2)$, u solves (1.1) at least in the distribution sense.

Remark 2. Note that the best known result for the local well-posedness of KP II goes down to $H^{s_1,0}$, $s_1 > -1/3$ [16]. In view of this result, one would expect the Cauchy problem for the KPB II equation also to be well posed in $H^{s_1,0}$, $s_1 > -1/3$ and perhaps below (we do not consider this question in this paper). For instance, in the case of the KdV equation, the best known result for the local well-posedness goes down to H^s, $s > -3/4$ (see [9]), while in [13] we prove (by the approach developed in this paper) that the Cauchy problem for the KdV Burgers equation is well posed below $H^{-3/4}$.

Remark 3. Another natural way to extend the Bourgain's method would be to consider the norm $\|f\|_{c,s_1,s_2} = \|\langle\xi\rangle^{s_1}\langle\eta\rangle^{s_2}\langle\tau - P(\xi,\eta) + i\xi^2\rangle^c\hat{f}\|_{L^2_{t,z}}$, which is in fact equivalent to $\|f\|_{X^{c,s_1,s_2}} + \|f\|_{L^2_t H^{s_1+2c,s_2}}$. Although the linear estimate on the free term for this norm is the same as the one in (2.5), it seems that the estimate on the forcing term (in this norm) leads to the loss of $2c$ x-derivatives in comparison with the one derived in (2.35). This is why we have used the norm defined by (1.4) rather than this one.

This paper is organized as follows: In section 2, we derive estimates in Bourgain spaces on the linear operators W and L. This process is quite general and can be adapted to other dissipative dispersive semigroups; see [13]. In section 3, we recall some Strichartz's estimates for the KP equations and we use them in the framework of Bourgain spaces. In section 4, we prove a nonlinear estimate which enables us to obtain the local part of Theorem 1.1. Next, we derive a priori estimates to prove the global existence result. Finally, section 5 is devoted to the proof of Theorem 1.2.

2. Linear estimates. In this section we study the two linear operators related to the integral equation (1.5). The following lemmas will be of constant use in the first part of this section.

LEMMA 2.1. *Let s be in $\mathbb{R}$ and $\lambda > 0$.*

(a) *For all $f \in H^s$ we have*

$$\|f(\lambda t)\|_{H^s} \le C\,(\lambda^{-1/2} + \lambda^{s-1/2})\|f(t)\|_{H^s}. \tag{2.1}$$

(b) *For all $f \in \dot{H}^s$ we have*

$$\|f(\lambda t)\|_{\dot{H}^s} \le C\,\lambda^{s-1/2}\|f(t)\|_{\dot{H}^s}. \tag{2.2}$$

LEMMA 2.2. *For all $s \ge 0$, $H^s(\mathbb{R}) \cap L^\infty(\mathbb{R})$ is an algebra and, furthermore,*

$$\|uv\|_{H^s} \le \|u\|_{H^s}\|v\|_{L^\infty} + \|v\|_{\dot{H}^s}\|u\|_{L^\infty}. \tag{2.3}$$

Also, recall that the Fourier transform of $f : t \to e^{-|t||\xi|^2}$ is

$$\mathcal{F}_t(e^{-|t||\xi|^2})(\tau) = \frac{2|\xi|^2}{|\tau|^2 + |\xi|^4}. \tag{2.4}$$

2.1. Linear estimate for the free term.

Proposition 2.3. *Let s, s_1, s_2 be in $\mathbb{R}$ and $b \geq 1/2$.*

(a) *For all $\varphi \in H^{s_1,s_2}$, we have*

$$\|\psi(t)W(t)\varphi\|_{X^{b,s_1,s_2}} \leq C\|\varphi\|_{H^{s_1+2b-1,s_2}}. \tag{2.5}$$

(b) *For all $\varphi \in H^{s}$, we have*

$$\|\psi(t)W(t)\varphi\|_{X^{b,s}} \leq C\|\Delta_x^{\frac{2b-1}{2}}\varphi\|_{H^s}. \tag{2.6}$$

Remark. To avoid the loss of x-derivative in the linear estimates (2.5) and (2.6), we have to choose $b = 1/2$. It will be therefore natural to solve (1.1) in the spaces $X^{1/2,s}$ and $X^{1/2,s_1,s_2}$.

Proof. By definition,

$$\begin{aligned}\|\psi(t)W(t)\varphi\|_{X^{b,s_1,s_2}} &= \left\|\langle\xi\rangle^{s_1}\langle\eta\rangle^{s_2}\langle\tau - P(\zeta)\rangle^b\mathcal{F}_t(\psi(t)e^{-|t||\xi|^2}e^{itP(\zeta)}\hat{\varphi}(\zeta))(\tau)\right\|_{L^2(\mathbb{R}^3)}\\ &= \left\|\langle\xi\rangle^{s_1}\langle\eta\rangle^{s_2}\hat{\varphi}(\zeta)\ \left\|\langle\tau\rangle^b\mathcal{F}_t(\psi(t)e^{-|t||\xi|^2})\right\|_{L^2(\mathbb{R})}\right\|_{L^2(\mathbb{R}^2)}. \end{aligned}\tag{2.7}$$

Now we estimate g defined by

$$g = \left\|\langle\tau\rangle^b\mathcal{F}_t(\psi(t)e^{-|t||\xi|^2})\right\|_{L^2} = \left\|\psi(t)e^{-|t||\xi|^2}\right\|_{H^b}.$$

By virtue of Lemma 2.2 we obtain

$$g \leq \|\psi\|_{H^b}\|e^{-|t||\xi|^2}\|_{L^\infty} + \|\psi\|_{L^\infty}\|e^{-|t||\xi|^2}\|_{\dot{H}^b},$$

and by Lemma 2.1,

$$g \leq C(1 + |\xi|^{2b-1}). \tag{2.8}$$

Hence, since $b \geq 1/2$, gathering (2.7) and (2.8) we obtain

$$\|\psi(t)W(t)\varphi\|_{X^{b,s_1+2b-1,s_2}} \leq C\|\langle\xi\rangle^{s_1+2b-1}\langle\eta\rangle^{s_2}\hat{\varphi}(\zeta)\|_{L^2},$$

which ends the proof of (2.5). The proof of (2.6) is similar. □

2.2. Linear estimates for the forcing term. We study first some smoothing properties between one dimensional Sobolev spaces for the linear operator

$$K : f \mapsto \mathbb{1}_{\mathbb{R}_+}(t)\psi(t)\int_0^t e^{-|t-t'||\xi|^2}f(t')\,dt'. \tag{2.9}$$

Next, we will use these results to obtain some smoothing properties between X^{b,s_1,s_2} and $X^{b,s}$ spaces for the linear operator

$$L : f \mapsto \mathbb{1}_{\mathbb{R}_+}(t)\psi(t)\int_0^t W(t-t')f(t')\,dt'. \tag{2.10}$$

2.2.1. Linear estimates for K. In this section we study the boundedness properties of K. Our main result is the following.

PROPOSITION 2.4. *Let $0 \leq b < 1/2$. For f in $H^{-b}(\mathbb{R})$ consider g defined on $\mathbb{R}$ by*

$$g(t) = \mathbb{1}_{\mathbb{R}_+}(t)\psi(t)\int_0^t e^{-|t-t'||\xi|^2} f(t')\,dt'. \tag{2.11}$$

Then it holds that

$$\forall \xi \in \mathbb{R},\ \|g\|_{H^{1/2}(\mathbb{R})} \leq C\langle\xi\rangle^{-(1-2b)}\|f\|_{H^{-b}}. \tag{2.12}$$

Proof. By a straightforward calculation we have

$$\begin{aligned} g(t) &= \mathbb{1}_{\mathbb{R}_+}(t)\psi(t)e^{-|t||\xi|^2}\int_0^t e^{t'|\xi|^2} f(t')\,dt' \\ &= \mathbb{1}_{\mathbb{R}_+}(t)\psi(t)e^{-|t||\xi|^2}\int_0^t e^{t'|\xi|^2}\int_{\mathbb{R}} e^{it'\tau}\hat{f}(\tau)\,d\tau\,dt' \\ &= \mathbb{1}_{\mathbb{R}_+}(t)\psi(t)e^{-|t||\xi|^2}\int_{\mathbb{R}} \hat{f}(\tau)\int_0^t e^{t'|\xi|^2}e^{it'\tau}\,dt'\,d\tau \\ &= \mathbb{1}_{\mathbb{R}_+}(t)\psi(t)\int_{\mathbb{R}} \frac{e^{it\tau} - e^{-|\xi|^2|t|}}{i\tau + |\xi|^2}\hat{f}(\tau)\,d\tau. \end{aligned} \tag{2.13}$$

Let us now consider the function k defined on $\mathbb{R}$ by

$$k(t) = \psi(t)\int_{\mathbb{R}} \frac{e^{it\tau} - e^{-|\xi|^2|t|}}{i\tau + |\xi|^2}\hat{f}(\tau)\,d\tau.$$

Since $g(0) = k(0) = 0$ and also

$$\forall t \in \mathbb{R}_+\,,\ k(t) = g(t) \text{ and } \forall t \in \mathbb{R}_-\,,\ g(t) = 0,$$

we have $\|g\|_{L^2} \leq \|k\|_{L^2}$, $\|g\|_{H^1} \leq \|k\|_{H^1}$, and $\|g\|_{H^{1/2}} \leq \|k\|_{H^{1/2}}$. Hence it is enough to prove that

$$\|k\|_{H^{1/2}} \leq C\langle\xi\rangle^{-(1-2b)}\|f\|_{H^{-b}}.$$

To do this we split k into $k = k_1 + k_2$, where

$$k_1(t) = \psi(t)\int_{\mathbb{R}} \frac{1 - e^{-|\xi|^2|t|}}{i\tau + |\xi|^2}\hat{f}(\tau)\,d\tau \tag{2.14}$$

and

$$k_2(t) = \psi(t)\int_{\mathbb{R}} \frac{e^{it\tau} - 1}{i\tau + |\xi|^2}\hat{f}(\tau)\,d\tau. \tag{2.15}$$

(a) Estimate of $\|k_1\|_{H^{1/2}}$.

(a1) We first consider the case $|\xi| \geq 1$. We then have

$$\begin{aligned}\|k_1\|_{H^{1/2}} &\leq \|\psi(t)(1-e^{-|\xi|^2|t|})\|_{H^{1/2}} \left|\int_{\mathbb{R}} \frac{\hat{f}(\tau)\,d\tau}{i\tau+|\xi|^2}\right| \\ &\leq \Big(\|\psi\|_{H^{1/2}} + \|\psi(t)e^{-|t||\xi|^2}\|_{H^{1/2}}\Big) \left|\int_{\mathbb{R}} \frac{\hat{f}(\tau)\,d\tau}{i\tau+|\xi|^2}\right| \\ &\leq C\Big(1+\|\psi(t)\|_{H^{1/2}}\|e^{-|\xi|^2|t|}\|_{L^\infty} + \|\psi(t)\|_{L^\infty}\|e^{-|\xi|^2|t|}\|_{\dot{H}^{1/2}}\Big) \left|\int_{\mathbb{R}} \frac{\hat{f}(\tau)\,d\tau}{i\tau+|\xi|^2}\right|\end{aligned}$$

by virtue of Lemma 2.2. Now applying the Cauchy–Schwarz inequality and Lemma 2.1 we obtain

$$\|k_1\|_{H^{1/2}} \leq C\|f\|_{H^{-b}} \left(\int_{\mathbb{R}} \frac{\langle\tau\rangle^{2b}\,d\tau}{\tau^2+|\xi|^4}\right)^{1/2} \leq C(1+|\xi|^{2b})|\xi|^{-1}\|f\|_{H^{-b}}.$$

Hence

$$\forall\xi,\ |\xi|\geq 1,\ \|k_1\|_{H^{1/2}} \leq C\langle\xi\rangle^{2b-1}\|f\|_{H^{-b}}. \tag{2.16}$$

(a2) We now consider the case $|\xi| \leq 1$. As previously, by the Cauchy–Schwarz inequality

$$\begin{aligned}\|k_1\|_{H^{1/2}} &\leq \|\psi(t)(1-e^{-|\xi|^2|t|})\|_{H^{1/2}} \left|\int_{\mathbb{R}} \frac{\hat{f}(\tau)\,d\tau}{i\tau+|\xi|^2}\right| \\ &\leq \|\psi(t)(1-e^{-|\xi|^2|t|})\|_{H^{1/2}}(1+|\xi|^{2b})|\xi|^{-1}\|f\|_{H^{-b}},\end{aligned}$$

and so, since $|\xi| \leq 1$,

$$\|k_1\|_{H^{1/2}} \leq C\|\psi(t)(1-e^{-|\xi|^2|t|})\|_{H^{1/2}}|\xi|^{-1}\|f\|_{H^{-b}}. \tag{2.17}$$

Now, following [10],

$$\|\psi(t)(1-e^{-|\xi|^2|t|})\|_{H^{1/2}} \leq \sum_{n\geq 1}\left\|\frac{t^n\psi(t)|\xi|^{2n}}{n!}\right\|_{H^{1/2}} \leq C\sum_{n\geq 1}\frac{|\xi|^{2n}}{n!}\|t^n\psi(t)\|_{H^{1/2}}.$$

Note that

$$\|t^n\psi(t)\|_{H^{1/2}} \leq C\|t^n\psi(t)\|_{H^1} \leq Cn,$$

and since $|\xi| \leq 1$, we get

$$\forall\xi,\ |\xi|\leq 1,\ \|\psi(t)(1-e^{-|\xi|^2|t|})\|_{H^{1/2}} \leq C|\xi|^2; \tag{2.18}$$

then, gathering (2.17) and (2.18) we obtain

$$\forall\xi,\ |\xi|\leq 1,\ \|k_1\|_{H^{1/2}} \leq C\langle\xi\rangle^{2b-1}\|f\|_{H^{-b}}. \tag{2.19}$$

Now, (2.16) together with (2.19) prove that

$$\forall \xi \in \mathbb{R},\ \|k_1\|_{H^{1/2}} \leq C\langle \xi\rangle^{2b-1}\|f\|_{H^{-b}}. \tag{2.20}$$

(b) Estimate of $\|k_2\|_{H^{1/2}}$. We split k_2 into $k_2 = k_{2,0} + k_{2,\infty}$, where

$$k_{2,0} = \psi(t)\int_{|\tau|\leq 1} \frac{e^{it\tau}-1}{i\tau+|\xi|^2}\hat{f}(\tau)\,d\tau \tag{2.21}$$

and

$$k_{2,\infty} = \psi(t)\int_{|\tau|\geq 1} \frac{e^{it\tau}-1}{i\tau+|\xi|^2}\hat{f}(\tau)\,d\tau. \tag{2.22}$$

(c) Estimate of $\|k_{2,0}\|_{H^{1/2}}$.

(c1) We first consider the case $|\xi| \geq 1$. By definition

$$\begin{aligned}\|k_{2,0}\|_{H^{1/2}} &= \left\|\psi(t)\int_{|\tau|\leq 1}\sum_{n\geq 1}\frac{(it\tau)^n}{n!(i\tau+|\xi|^2)}\hat{f}(\tau)\,d\tau\right\|_{H^{1/2}}\\ &\leq \sum_{n\geq 1}\frac{\|t^n\psi(t)\|_{H^{1/2}}}{n!}\int_{|\tau|\leq 1}\left|\frac{(i\tau)^n}{i\tau+|\xi|^2}\hat{f}(\tau)\right|\,d\tau\\ &\leq \sum_{n\geq 1}\frac{\|t^n\psi(t)\|_{H^{1/2}}}{n!}\int_{|\tau|\leq 1}\frac{|\hat{f}(\tau)|}{\sqrt{|\tau|^2+|\xi|^4}}\,d\tau.\end{aligned}$$

In the same way as previously and by the Cauchy–Schwarz inequality we get

$$\|k_{2,0}\|_{H^{1/2}} \leq C\left(\sum_{n\geq 1}\frac{1}{(n-1)!}\right)\|f\|_{H^{-b}}\left(\int_{\mathbb{R}}\frac{\langle\tau\rangle^{2b}}{\tau^2+|\xi|^4}\,d\tau\right)^{1/2},$$

and so,

$$\forall \xi,\ |\xi|\geq 1,\ \|k_{2,0}\|_{H^{1/2}} \leq C\langle\xi\rangle^{2b-1}\|f\|_{H^{-b}}. \tag{2.23}$$

(c2) We now consider the case $|\xi| \leq 1$. From the previous calculations,

$$\begin{aligned}\|k_{2,0}\|_{H^{1/2}} &\leq C\left(\sum_{n\geq 1}\frac{\|t^n\psi(t)\|_{H^{1/2}}}{n!}\int_{|\tau|\leq 1}\left|\frac{\tau^n\hat{f}(\tau)}{i\tau+|\xi|^2}\right|\,d\tau\right)\\ &\leq C\|f\|_{H^{-b}}\left(\sum_{n\geq 1}\frac{1}{(n-1)!}\left(\int_{|\tau|\leq 1}\frac{|\tau|^{2n}\langle\tau\rangle^{2b}}{|\tau|^2+|\xi|^4}\,d\tau\right)^{1/2}\right).\end{aligned}$$

Furthermore, for all ξ and for all $n \geq 1$,

$$\left(\int_{|\tau|\leq 1}\frac{|\tau|^{2n}\langle\tau\rangle^{2b}}{|\tau|^2+|\xi|^4}\,d\tau\right)^{1/2} \leq \left(\int_{|\tau|\leq 1}|\tau|^{2(n-1)}\langle\tau\rangle^{2b}\,d\tau\right)^{1/2} \leq C,$$

and so it follows that

$$\forall \xi,\ |\xi| \le 1,\ \|k_{2,0}\|_{H^{1/2}} \le C\|f\|_{H^{-b}}. \tag{2.24}$$

Hence, for $b < 1/2$, gathering (2.23) and (2.24) we obtain

$$\forall \xi \in \mathbb{R},\ \|k_{2,0}\|_{H^{1/2}} \le C\langle \xi\rangle^{2b-1}\|f\|_{H^{-b}}. \tag{2.25}$$

(d) Estimate of $\| k_{2,\infty}\|_{H^{1/2}}$.

(d1) First assume that $|\xi| \le 1$. Then we have

$$\|k_{2,\infty}\|_{H^{1/2}} \le I + J,$$

where

$$I = \left\| \psi(t) \int_{|\tau|\ge 1} \frac{\hat{f}(\tau)}{i\tau + |\xi|^2}\, d\tau \right\|_{H^{1/2}}, \tag{2.26}$$

and

$$J = \left\| \psi(t) \int_{|\tau|\ge 1} \frac{e^{it\tau}\hat{f}(\tau)}{i\tau + |\xi|^2}\, d\tau \right\|_{H^{1/2}}. \tag{2.27}$$

By the Cauchy–Schwarz inequality we get

$$I \le \|\psi\|_{H^{1/2}} \|f\|_{H^{-b}} \left(\int_{|\tau|\ge 1} \frac{\langle \tau\rangle^{2b}}{|\tau|^2}\, d\tau \right)^{1/2},$$

and since $b < 1/2$,

$$\forall \xi,\ |\xi| \le 1,\ I \le C\|f\|_{H^{-b}}. \tag{2.28}$$

To estimate J for $|\xi| \le 1$, observe that

$$J = \left\| \psi(t)\mathcal{F}_t \left(\frac{\hat{f}(\tau)\mathbb{1}_{|\tau|\ge 1}}{i\tau + |\xi|^2} \right)(t) \right\|_{H^{1/2}},$$

and since $\|\mathcal{F}(u)\|_{L^\infty} \le \|u\|_{L^1}$, Lemma 2.2 proves that

$$\begin{aligned} J &\le C \left\| \frac{\hat{f}(\tau)\mathbb{1}_{|\tau|\ge 1}}{i\tau + |\xi|^2} \right\|_{L^1} + C \left\| \mathcal{F}_t \left(\frac{\hat{f}(\tau)\mathbb{1}_{|\tau|\ge 1}}{i\tau + |\xi|^2} \right) \right\|_{\dot{H}^{1/2}} \\ &\le C\|f\|_{H^{-b}} \left[\left(\int_{|\tau|\ge 1} \frac{\langle \tau\rangle^{2b} d\tau}{|\tau|^2 + |\xi|^4} \right)^{1/2} + \sup_{|\tau|\ge 1} \left(\frac{|\tau|\langle \tau\rangle^{2b}}{|\tau|^2 + |\xi|^4} \right)^{1/2} \right] \\ &\le C\|f\|_{H^{-b}} \left[\left(\int_{|\tau|\ge 1} \frac{\langle \tau\rangle^{2b} d\tau}{|\tau|^2} \right)^{1/2} + \sup_{|\tau|\ge 1} \left(\frac{\langle \tau\rangle^{1+2b}}{|\tau|^2} \right)^{1/2} \right] \\ &\le C\|f\|_{H^{-b}}. \end{aligned} \tag{2.29}$$

Next, gathering (2.28) and (2.29), we obtain

$$\forall\xi,\ |\xi|\le 1,\ \|k_{2,\infty}\|_{H^{1/2}} \le C\|f\|_{H^{-b}}. \tag{2.30}$$

(d2) Now assume that $|\xi|\ge 1$. Then by the Cauchy–Schwarz inequality,

$$I \le \|\psi\|_{H^{1/2}}\|f\|_{H^{-b}}\left(\int_{|\tau|\ge 1}\frac{\langle\tau\rangle^{2b}}{|\tau|^2+|\xi|^4}\,d\tau\right)^{1/2} \le C\langle\xi\rangle^{2b-1}\|f\|_{H^{-b}}. \tag{2.31}$$

On the other hand, in the same way as for $|\xi|\le 1$, we have

$$J \le C\|f\|_{H^{-b}}\left[\left(\int_{|\tau|\ge 1}\frac{\langle\tau\rangle^{2b}d\tau}{|\tau|^2+|\xi|^4}\right)^{1/2} + \sup_{|\tau|\ge 1}\left(\frac{|\tau|\langle\tau\rangle^{2b}}{|\tau|^2+|\xi|^4}\right)^{1/2}\right],$$

and it follows that

$$\forall\xi,\ |\xi|\ge 1,\ J\le C\langle\xi\rangle^{2b-1}\|f\|_{H^{-b}}. \tag{2.32}$$

Hence from (2.31) and (2.32) we deduce that

$$\forall\xi,\ |\xi|\ge 1,\ \|k_{2,\infty}\|_{H^{1/2}} \le C\langle\xi\rangle^{2b-1}\|f\|_{H^{-b}}, \tag{2.33}$$

which together with (2.30) proves that

$$\forall\xi\in\mathbb{R},\ \|k_{2,\infty}\|_{H^{1/2}} \le C\langle\xi\rangle^{2b-1}\|f\|_{H^{-b}}. \tag{2.34}$$

This ends the proof of Proposition 2.4. □

2.2.2. Linear estimates for *L*. Now, using Proposition 2.4, we prove some smoothing properties in Bourgain spaces for L defined by (2.10).

PROPOSITION 2.5. *Let s, s_1, s_2 be in $\mathbb{R}$ and $0\le b<1/2$.*

(a) *For all $f\in\mathcal{S}'$ we have*

$$\left\|\mathbb{1}_{\mathbb{R}_+}(t)\psi(t)\int_0^t W(t-t')f(t')\,dt'\right\|_{X^{1/2,s_1,s_2}} \le C\|f\|_{X^{-b,s_1+2b-1,s_2}}. \tag{2.35}$$

(b) *For all $f\in\mathcal{S}'$ we have*

$$\left\|\mathbb{1}_{\mathbb{R}_+}(t)\psi(t)\int_0^t W(t-t')f(t')\,dt'\right\|_{X^{1/2,s}} \le C\|\,\Delta_x^{\frac{2b-1}{2}}f\|_{X^{-b,s}}. \tag{2.36}$$

Proof. We first prove (2.35). By definition

$$\left\|\mathbb{1}_{\mathbb{R}_+}(t)\psi(t)\int_0^t W(t-t')f(t')\,dt'\right\|^2_{X^{1/2,s_1,s_2}}$$

$$= \left\|\langle\xi\rangle^{s_1}\langle\eta\rangle^{s_2}\langle\tau-P(\zeta)\rangle^{\frac12}\mathcal{F}_{t,z}\left(\mathbb{1}_{\mathbb{R}_+}(t)\psi(t)\int_0^t W(t-t')f(t')\,dt'\right)\right\|^2_{L^2(\mathbb{R}^3)}.$$

On the other hand,

$$\mathcal{F}_{t,z}\left(\mathbb{1}_{\mathbb{R}_+}(t)\psi(t)\int_0^t W(t-t')f(t')\,dt'\right)(\tau,\zeta)$$

$$= \mathcal{F}_t \left(\mathbb{1}_{\mathbb{R}_+}(t)\psi(t) \int_0^t e^{-|t-t'||\xi|^2} e^{iP(\zeta)(t-t')} \mathcal{F}_z(f)(t',\zeta)\, dt' \right)(\tau)$$

$$= \mathcal{F}_t \left(\mathbb{1}_{\mathbb{R}_+}(t)\psi(t) \int_0^t e^{-|t-t'||\xi|^2} e^{-iP(\zeta)t'} \mathcal{F}_z(f)(t',\zeta)\, dt' \right)(\tau - P(\zeta)).$$

Hence, performing the change of variable $\tau' = \tau - P(\zeta)$, we obtain

$$\left\| \mathbb{1}_{\mathbb{R}_+}(t)\psi(t) \int_0^t W(t-t') f(t')\, dt' \right\|^2_{X^{1/2,s_1,s_2}}$$

$$= \left\| \mathbb{1}_{\mathbb{R}_+}(t)\psi(t) \int_0^t e^{-|t-t'||\xi|^2} e^{-iP(\zeta)t'} \langle\xi\rangle^{s_1} \langle\eta\rangle^{s_2} \mathcal{F}_x z(f)(t',\zeta)\, dt' \right\|^2_{L^2_\zeta(H^{1/2}_t)}$$

$$= \left\| \mathbb{1}_{\mathbb{R}_+}(t)\psi(t) \int_0^t e^{-|t-t'||\xi|^2} \langle\xi\rangle^{s_1} \langle\eta\rangle^{s_2} \mathcal{F}_z \left(U(-t') f \right)(t',\zeta)\, dt' \right\|^2_{L^2_\zeta(H^{1/2}_t)} .$$

To conclude, we apply Proposition 2.4 to h_ζ defined by

$$h_\zeta(t') = \langle\xi\rangle^{s_1} \langle\eta\rangle^{s_2} \mathcal{F}_z \left(U(-t') f \right)(t',\zeta) \, , \tag{2.37}$$

and we obtain

$$\left\| \mathbb{1}_{\mathbb{R}_+}(t)\psi(t) \int_0^t W(t-t') f(t')\, dt' \right\|^2_{X^{1/2,s_1,s_2}}$$

$$\leq C \int_{\mathbb{R}^2} \langle\xi\rangle^{2(s_1+2b-1)} \langle\eta\rangle^{2s_2} \|\mathcal{F}_z \left(U(-t) f \right)(t,\zeta)\|^2_{H^{-b}}\, d\xi$$

$$\leq C \int_{\mathbb{R}^2} \langle\xi\rangle^{2(s_1+2b-1)} \langle\eta\rangle^{2s_2} \|\langle\tau\rangle^{-b} \hat{f}(\tau + P(\zeta),\zeta)\|^2_{L^2}\, d\xi$$

$$\leq C \|f\|^2_{X^{-b,s_1+2b-1,s_2}} .$$

The proof of (2.36) is the same, up to some obvious modifications. □

As explained previously, it will be convenient to prove local well-posedness of KPB in the space $X^{1/2,s_1,s_2}$ ($s_1 > 0$, $s_2 \geq 0$) and local well-posedness of KPB II in the space $X^{1/2,s}$ ($s \geq 0$). Nevertheless, since the embedding $H^{1/2}(\mathbb{R}) \hookrightarrow L^\infty(\mathbb{R})$ does not hold, we will need Proposition 2.6 below to prove that a solution of (1.1) in $X^{1/2,s_1,s_2}$ (respectively, in $X^{1/2,s}$) belongs also to the space $C([0,T], H^{s_1,s_2})$ (respectively, to $C([0,T], H^s)$).

Proposition 2.6. *Let* $0 \leq b < 1/2$.

(a) *For all* $f \in \mathcal{S}'(\mathbb{R}^3)$ *with* $\Delta_x^b f \in X^{-b,s_1,s_2}$,

$$t \mapsto \int_0^t W(t-t') \partial_x f(t')\, dt' \in C(\mathbb{R}_+, H^{s_1,s_2}). \tag{2.38}$$

Moreover, if (f_n) *is a sequence with* $\Delta_x^b f_n \underset{n\to\infty}{\longrightarrow} 0$ *in* X^{-b,s_1,s_2}, *then*

$$\left\| \int_0^t W(t-t') \partial_x f_n(t')\, dt' \right\|_{L^\infty(\mathbb{R}_+, H^{s_1,s_2})} \underset{n\to\infty}{\longrightarrow} 0. \tag{2.39}$$

(b) *For all $f \in \mathcal{S}'(\mathbb{R}^3)$ with $\Delta_x^b f \in X^{-b,s}$,*

$$t \mapsto \int_0^t W(t-t')\partial_x f(t')\,dt' \in C(\mathbb{R}_+, H^s). \tag{2.40}$$

Moreover, if (f_n) is a sequence with $\Delta_x^b f_n \underset{n\to\infty}{\longrightarrow} 0$ in $X^{-b,s}$, then

$$\left\| \int_0^t W(t-t')\partial_x f_n(t')\,dt' \right\|_{L^\infty(\mathbb{R}_+, H^s)} \underset{n\to\infty}{\longrightarrow} 0. \tag{2.41}$$

Proof. Without loss of generality we can set $s_1 = s_2 = 0$. As noticed in [8], since $U(\cdot)$ is a strongly continuous unitary group in $L^2(\mathbb{R}^2)$, it is enough to prove that

$$F \ : \ t \mapsto U(-t) \int_0^t W(t-t')\partial_x f(t')\,dt'$$

is continuous from $\mathbb{R}_+$ to $L^2(\mathbb{R}^2)$. Setting

$$g(t) = \mathcal{F}_x\Big(U(-t)\partial_x f(t)\Big), \qquad t \in \mathbb{R},$$

(2.38) will thus be proven if we show the continuity of

$$G \ : \ t \mapsto \int_0^t e^{-|\xi|^2(t-t')}\, g(t', \zeta)\,dt' \tag{2.42}$$

for $\langle\tau\rangle^{-b}\langle\xi\rangle^{(2b-1)}\mathcal{F}_t(g) \in L^2_{\tau,\zeta}(\mathbb{R}^3)$. Applying the Fubini theorem, one infers that

$$\begin{aligned} G(t) &= e^{-|\xi|^2 t} \int_{\mathbb{R}} \hat{g}(\tau, \zeta) \int_0^t e^{(|\xi|^2 + i\tau)\,t'}\,dt'\,d\tau \\ &= \int_{\mathbb{R}} \hat{g}(\tau, \zeta)\, \frac{e^{it\tau} - e^{-|\xi|^2 t}}{|\xi|^2 + i\tau}\,d\tau. \end{aligned}$$

Hence,

$$G(t_1) - G(t_2) = \int_{\mathbb{R}} \frac{\hat{g}(\tau, \zeta)}{|\xi|^2 + i\tau}[(e^{i\tau t_1} - e^{i\tau t_2}) - (e^{-|\xi|^2 t_1} - e^{-|\xi|^2 t_2})]\,d\tau. \tag{2.43}$$

When $|\xi| \geq 1$, we notice that

$$\begin{aligned} |G(t_1) - G(t_2)| &\leq C \int_{\mathbb{R}} \frac{|\hat{g}(\tau)|}{|\xi|^2 + |\tau|}\,d\tau \\ &\leq C\, \|g\|_{H^{-b}} \left(\int_{\mathbb{R}} \frac{\langle\tau\rangle^{2b}}{|\xi|^4 + |\tau|^2}\,d\tau \right)^{\frac{1}{2}} \\ &\leq C\, \|g\|_{H^{-b}}\, \langle\xi\rangle^{(2b-1)}. \end{aligned} \tag{2.44}$$

Assume now that $|\xi| \leq 1$ and that $|t_1 - t_2| \leq 1$. In this case we first estimate

$$\left| \int_{\mathbb{R}} \quad \frac{\hat{g}(\tau)}{|\xi|^2 + i\tau}(e^{i\tau t_1} - e^{i\tau t_2})\,d\tau \right|$$

$$
\begin{aligned}
&\le |t_1 - t_2| \int_{|\tau|\le 1} \frac{|\hat{g}(\tau)|\,|\tau|}{\sqrt{|\xi|^4+|\tau|^2}}\, d\tau + 2\int_{|\tau|\ge 1} \frac{|\hat{g}(\tau)|}{\sqrt{|\xi|^4+|\tau|^2}}\, d\tau \\
&\le C\,\|g\|_{H^{-b}} \left[\left(\int_{|\tau|\le 1} \frac{|\tau|^2 \langle \tau\rangle^{2b}\, d\tau}{|\xi|^4+|\tau|^2} \right)^{\frac{1}{2}} + \left(\int_{|\tau|\ge 1} \frac{\langle \tau\rangle^{2b}\, d\tau}{|\xi|^4+|\tau|^2} \right)^{\frac{1}{2}} \right] \\
&\le C\,\|g\|_{H^{-b}} \left[\left(\int_{|\tau|\le 1} \langle \tau\rangle^{2b}\, d\tau \right)^{\frac{1}{2}} + \left(\int_{|\tau|\ge 1} \frac{\langle \tau\rangle^{2b}}{|\tau|^2}\, d\tau \right)^{\frac{1}{2}} \right] \\
&\le C\,\|g\|_{H^{-b}}. \qquad (2.45)
\end{aligned}
$$

It then remains to estimate

$$
\begin{aligned}
\left| \int_{\mathbb{R}} \frac{\hat{g}(\tau)}{|\xi|^2+i\tau} (e^{-|\xi|^2 t_1} - e^{-|\xi|^2 t_2})\, d\tau \right| &\le |t_1-t_2|\, \|g\|_{H^{-b}}\, |\xi|^2 \left(\int_{\mathbb{R}} \frac{\langle\tau\rangle^{2b}}{|\xi|^4+|\tau|^2}\, d\tau \right)^{\frac{1}{2}} \\
&\le C|t_1-t_2|\, \|g\|_{H^{-b}}\, |\xi|^2 (|\xi|^{-1} + |\xi|^{(2b-1)}) \\
&\le C\|g\|_{H^{-b}}. \qquad (2.46)
\end{aligned}
$$

Therefore, gathering (2.43)–(2.46), one infers that

$$
\|G(t_1)-G(t_2)\|^2_{L^2} \le C \int_{\mathbb{R}^3} \langle\tau\rangle^{-2b} \, \langle\xi\rangle^{2(2b-1)}\, |\mathcal{F}_t(g)|^2\, d\tau\, d\zeta. \qquad (2.47)
$$

It is clear that the integrand in (2.43) tends to 0 pointwise in (ζ,τ) as soon as $|t_1-t_2| \to 0$ and is bounded uniformly in $|t_1-t_2|$ by the integrand of the right member of (2.47). The result follows then from Lebesgue dominated convergence theorem.

To show (2.39), it suffices to notice that one has

$$
\sup_{t\in\mathbb{R}_+} \|G_n(t)\|_{L^2(\mathbb{R}^2)} \le C \int_{\mathbb{R}^3} \langle\tau\rangle^{-2b} \, \langle\xi\rangle^{2(2b-1)}\, |\mathcal{F}_t(g_n)|^2\, d\tau\, d\xi,
$$

where G_n is defined as G with $g_n(\cdot) = \mathcal{F}_x(U(-\cdot)\partial_x f_n(\cdot))$ instead of g. Finally the proof of part (b) is similar. □

3. Strichartz estimates for the KP equation. The aim of this section is to prove Lemma 3.4. It will be useful in the following sections while proving some estimates in X^{b,s_1,s_2} spaces and $X^{b,s}$ spaces for the nonlinear term $\partial_x(u^2)$.

LEMMA 3.1. *Let* $2 \le r$ *and* $0 \le \beta \le 1/2$. *Then*

$$
\forall t \ne 0, \ \left\| |D_x|^{-\beta\delta(r)} U(t)\varphi \right\|_{L^r_z} \le C|t|^{-(1-\beta/3)\delta(r)} \|\varphi\|_{L^{\bar{r}}_z}, \qquad (3.1)
$$

where

$$
\frac{1}{\bar{r}} = 1 - \frac{1}{r}\,, \qquad \delta(r) = 1 - \frac{2}{r}. \qquad (3.2)
$$

Proof. From (1.2), $U(t)\varphi = G(t) * \varphi$, where

$$
G(t,x,y) = \int_{\mathbb{R}^2} e^{it\left(\xi^3 - \varepsilon\eta^2/\xi\right)} e^{i(x\xi+y\eta)}\, d\xi\, d\eta.
$$

Noticing as in [15] that

$$\frac{1}{\sqrt{2\pi}}\int_{\mathbb{R}} e^{i\varepsilon t\eta^2/\xi} e^{iy\eta}\, d\eta = e^{i\varepsilon\, sgn(\xi/t)\frac{\pi}{4}}\sqrt{\frac{|\xi|}{2|t|}}\, e^{-i\varepsilon\xi y^2/(4t)},$$

we have

$$\|\, |D_x|^{-\beta} G(t,x,y)\|_{L^\infty_z} \le C|t|^{-\frac{1}{2}}\int_{\mathbb{R}} |\xi|^{\frac{1}{2}-\beta} e^{it\xi^3}\, d\xi.$$

Applying Lemma 2.1 of [10], we obtain that for all $\beta\in[0,1/2]$,

$$\|\, |D_x|^{-\beta} G(t,x,y)\|_{L^\infty_z} \le C|t|^{-(1-\beta/3)}.$$

Therefore by the Young inequality,

$$\|\, |D_x|^{-\beta} U(t)\varphi\|_{L^\infty_z} \le C|t|^{-(1-\beta/3)}\|\varphi\|_{L^1_z},$$

and as $U(\cdot)$ is a unitary group in L^2_z, the result follows by interpolation. □

Thanks to Lemma 3.1 we can now derive some Strichartz's estimates for the KP equations.

LEMMA 3.2. *Let $2\le r$ and $0\le\beta\le 1/2$. Then*

$$\left\|\, |D_x|^{-\frac{\beta\delta(r)}{2}} U(t)\varphi\right\|_{L^{q,r}_{t,z}} \le C\|\varphi\|_{L^2_z} \tag{3.3}$$

for all (q,r,β) fulfilling the condition

$$0\le \frac{2}{q} = \left(1-\frac{\beta}{3}\right)\delta(r) < 1\ . \tag{3.4}$$

Proof. Using (3.1) and the so-called TT^* method, it is a rather classical process (see [7] and the references therein, for instance) to obtain (3.3). □

Now, we state a result which describes some relationships between Strichartz's inequalities for the KP equations and X^{b,s_1,s_2} spaces.

LEMMA 3.3. *Let $v\in L^2(\mathbb{R}^3)$ with supp $v\subset\{(t,x,y)/\,|t|\le T\}$ and let $\varepsilon>0$. Then for all (r,β,θ) with*

$$2\le r<+\infty,\quad 0\le\beta\le\frac{1}{2},\quad 0\le\theta\le 1,\quad 0\le\delta(r)<\frac{\theta}{1-\beta/3}, \tag{3.5}$$

there exists $\mu=\mu(\varepsilon)>0$ such that

$$\left\|\mathcal{F}^{-1}_{t,x}\left(|\xi|^{-\frac{\beta\delta(r)}{2}}\langle\tau-P(\zeta)\rangle^{-\frac{\theta}{2}(1+\varepsilon)}|\hat{v}(\tau,\zeta)|\right)\right\|_{L^{q,r}_{t,z}} \le CT^\mu\|v\|_{L^2(\mathbb{R}^3)}, \tag{3.6}$$

where q is defined by

$$\frac{2}{q} = \left(1-\frac{\beta}{3}\right)\delta(r) + (1-\theta). \tag{3.7}$$

Proof. Let $\hat{u}=|\hat{v}|$. Using Lemma 3.2 together with Lemma 3.3 of [6], we see that for all $\varepsilon>0$

$$\left\|\, |D_x|^{-\frac{\beta\delta(r)}{2}} u\right\|_{L^{q,r}_{t,z}} \le C\|u\|_{X^{1/2+\varepsilon/4,0,0}} \tag{3.8}$$

provided that (3.4) holds. Furthermore, by the definition of X^{b,s_1,s_2}, we have

$$\|u\|_{L^2_{t,z}} = \|u\|_{X^{0,0,0}}. \tag{3.9}$$

Hence, for $0 \le \theta \le 1$, by interpolation,

$$\left\| \, |D_x|^{-\frac{\theta\beta\delta(r)}{2}} u \right\|_{L^{q_1,r_1}_{t,z}} \le C\|u\|_{X^{\theta(\frac{1}{2}+\frac{\varepsilon}{4}),0,0}}, \tag{3.10}$$

where

$$\frac{1}{q_1} = \frac{\theta}{q} + \frac{1-\theta}{2}, \qquad \frac{1}{r_1} = \frac{\theta}{r} + \frac{1-\theta}{2}.$$

Since $\delta(r_1) = \theta\delta(r)$, (3.5) follows from (3.4) and, moreover,

$$\frac{2}{q_1} = \left(1 - \frac{\beta}{3}\right)\delta(r_1) + (1-\theta).$$

Next, using the assumption on the support of u and the results in [8], we get

$$\left\| \, |D_x|^{-\frac{\theta\beta\delta(r)}{2}} u \right\|_{L^{q_1,r_1}_{t,z}} \le CT^{\mu} \, \|u\|_{X^{\theta(\frac{1}{2}+\frac{\varepsilon}{2}),0,0}},$$

which can be rewritten as

$$\left\| \mathcal{F}^{-1}_{t,z}\left(|\xi|^{-\frac{\beta\delta(r_1)}{2}} \hat{u} \right) \right\|_{L^{q_1,r_1}_{t,z}} \le CT^{\mu} \left\| \langle \tau - P(\zeta) \rangle^{\theta(\frac{1}{2}+\frac{\varepsilon}{2})} \hat{u} \right\|_{L^2}.$$

This clearly completes the proof. □

Now, using Lemma 3.3, we state a result which will allow us to obtain some nonlinear estimates in X^{b,s_1,s_2} and $X^{b,s}$ spaces in the next sections.

LEMMA 3.4. *Let f and g be with compact support in $\{(x,y,t) \; / \; |t| \le T\}$. For $b > 0$ small enough, there exists $\mu > 0$ such that for all $h \in L^2(\mathbb{R}^3)$,*

$$\int_{\mathbb{R}^6} \frac{|f(\tau',\zeta')||g(\tau-\tau',\zeta-\zeta')||h(\tau,\zeta)|}{\langle\sigma_1\rangle^{1/2}|\xi'|^b\langle\sigma_2\rangle^{1/2}} \, d\tau d\tau' d\zeta d\zeta'$$

$$\le CT^{\mu}\|f\|_{L^2}\|g\|_{L^2}\|h\|_{L^2} \tag{3.11}$$

and

$$\int_{\mathbb{R}^6} \frac{|f(\tau',\zeta')||g(\tau-\tau',\zeta-\zeta')||h(\tau,\zeta)|}{\langle\sigma_1\rangle^{1/2-b}|\xi'|^b\langle\sigma_2\rangle^{1/2}\langle\sigma\rangle^b} \, d\tau d\tau' d\zeta d\zeta'$$

$$\le CT^{\mu}\|f\|_{L^2}\|g\|_{L^2}\|h\|_{L^2}, \tag{3.12}$$

where σ, σ_1, and σ_2 are defined by

$$\sigma = \tau - P(\zeta), \quad \sigma_1 = \tau' - P(\zeta'), \quad \sigma_2 = \tau - \tau' - P(\zeta - \zeta').$$

Proof. We first prove (3.11). By the Plancherel theorem, the Cauchy–Schwarz inequality, and then by the Hölder inequality, we see that the right-hand side of (3.11) is bounded by

$$\left\| \mathcal{F}^{-1}_{t,z}\left(\frac{|f(\tau,\zeta)|}{\langle\sigma\rangle^{1/2}|\xi|^b} \right) \right\|_{L^{4,r_1}_{t,z}} \left\| \mathcal{F}^{-1}_{t,z}\left(\frac{|g(\tau,\zeta)|}{\langle\sigma\rangle^{1/2}} \right) \right\|_{L^{4,r_2}_{t,z}} \|h\|_{L^2_{t,z}}, \tag{3.13}$$

provided that

$$\frac{1}{r_1}+\frac{1}{r_2}=\frac{1}{2}\,. \tag{3.14}$$

First we apply Lemma 3.3 with $(\beta_2,\theta_2,q_2)=(0,(1+\varepsilon_2)^{-1},4)$ for ε_2 small enough. From (3.7), it follows that $\delta(r_2)=1/2^-$, $r_2=4^-$, and that (3.5) holds. Hence, by virtue of Lemma 3.3 we get

$$\left\|\mathcal{F}^{-1}_{t,z}\left(\frac{|g(\tau,\zeta)|}{\langle\tau-P(\zeta)\rangle^{1/2}}\right)\right\|_{L^{4,r_2}_{t,z}}\le CT^{\mu}\|g\|_{L^2_{t,z}}. \tag{3.15}$$

Now since $r_2=4^-$, in order to fulfill (3.14) we choose

$$r_1=\frac{2r_2}{r_2-2}=4^+,$$

which implies $\delta(r_1)=1/2^+$. Let

$$q_1=4,\quad \theta_1=\frac{1}{1+\varepsilon_1}=1^-,\quad \beta_1=\frac{2}{\delta(r_1)}\,b=4^+\,b.$$

Note that for $b<1/8$, $0\le\beta_1\le 1/2$, and so (3.5) is fulfilled since we have

$$\delta(r_1)\sim\frac{1}{2}<1^-=\theta_1\le\frac{\theta_1}{1-\beta_1/3}.$$

Moreover, for b small enough, we can always find $\varepsilon_1=\varepsilon_1(b)$ such that (3.7) holds. By virtue of Lemma 3.3 it follows that

$$\left\|\mathcal{F}^{-1}_{t,z}\left(\frac{|f(\tau,\zeta)|}{\langle\tau-P(\zeta)\rangle^{1/2}|\xi|^{b}}\right)\right\|_{L^{4,r_1}_{t,z}}\le CT^{\mu}\|f\|_{L^2_{t,z}}. \tag{3.16}$$

The proof of (3.11) follows then from (3.13), (3.15), and (3.16).

Now we prove (3.12). By the Plancherel theorem and the Hölder inequality (first in space and then in time) we obtain that the right-hand side of (3.12) is bounded by the product

$$\left\|\mathcal{F}^{-1}_{t,z}\left(\frac{|g(\tau,\zeta)|}{\langle\sigma\rangle^{1/2}}\right)\right\|_{L^{q_1,r_1}_{t,z}}\left\|\mathcal{F}^{-1}_{t,z}\left(|\xi|^{-b}\frac{|f(\tau,\zeta)|}{\langle\sigma\rangle^{1/2-b}}\right)\right\|_{L^{q_2,r_2}_{t,z}}\left\|\mathcal{F}^{-1}_{t,z}\left(\frac{|h(\tau,\zeta)|}{\langle\sigma\rangle^{b}}\right)\right\|_{L^{q_3,r_3}_{t,z}}, \tag{3.17}$$

provided

$$\frac{1}{q_1}+\frac{1}{q_2}+\frac{1}{q_3}=1,\quad \frac{1}{r_1}+\frac{1}{r_2}+\frac{1}{r_3}=1. \tag{3.18}$$

To apply Lemma 3.3 to each of the three terms in (3.17), for b small enough we take first $\varepsilon_1=\varepsilon_2=\varepsilon_3=\varepsilon$, where $\varepsilon=\varepsilon(b)$ will be a small parameter. Next we take

$$\theta_1=\frac{1}{1+\varepsilon},\quad \theta_2=\frac{1-2b}{1+\varepsilon},\quad \theta_3=\frac{2b}{1+\varepsilon}, \tag{3.19}$$

and we choose $\beta_1=\beta_3=0$. From (3.7), it remains to find β_2, q_i, and r_i with

$$\frac{2}{q_1}=\delta_1+(1-\theta_1),\quad \frac{2}{q_2}=\delta_2+(1-\theta_2)-\frac{\beta_2\delta_2}{3},\quad \frac{2}{q_3}=\delta_3+(1-\theta_3), \tag{3.20}$$

$$\beta_2\delta_2 = 2b, \tag{3.21}$$

such that (3.5) is fulfilled for $i = 1, 2, 3$.

First note that from (3.18) and (3.19), $\sum \delta_i = 1$, $\sum 2/q_i = 2$, and also $\sum \theta_i = 2/(1+\varepsilon)$. Hence, adding the three equations in (3.20), we see that, necessarily, $2 = 4 - 2/(1+\varepsilon) - \beta_2\delta_2/3$; i.e., $\beta_2\delta_2 = 6\varepsilon/(1+\varepsilon)$. This relation is compatible with (3.21) if and only if

$$\frac{6\varepsilon}{1+\varepsilon} = 2b. \tag{3.22}$$

Hence, for b small enough, we choose $\varepsilon(b)$ satisfying (3.22), which defined the values of θ_i through (3.19). Also, from (3.19)–(3.20)

$$\frac{2}{q_1} = \delta_1 + \frac{\varepsilon}{1+\varepsilon}, \quad \frac{2}{q_2} = \delta_2 + \frac{2b-\varepsilon}{1+\varepsilon}, \quad \frac{2}{q_3} = \delta_3 + 1 - \frac{2b}{1+\varepsilon}. \tag{3.23}$$

Now we choose $(r_1, r_2, r_3) = (4^-, 4^-, 2^+)$ such that $\sum r_i^{-1} = 1$. From (3.23) it follows that $\beta_2 = 2b/\delta_2$ and, moreover, (q_1, q_2, q_3) is closed to $(4, 4, 2)$. Also recall that by construction we have $\sum q_i^{-1} = 1$.

It remains to prove that (3.5) is fulfilled for $i = 1, 2, 3$. First remark that, for $b = 0^+$, $\varepsilon(b) = 0^+$. It is clear that $0 \le \theta_i \le 1$, that $0 \le \beta_i \le 1/2$ for $i = 1, 2, 3$, and also that the last restriction in (3.5) is fulfilled for $i = 1, 2$ since $(\delta_1, \delta_2) = (1/2^+, 1/2^+)$ and $(\theta_1, \theta_2) = (1^-, 1^-)$. To see that (3.5) can be also fulfilled for $i = 3$, we remark that it is enough to have $0 \le \delta_3 \le \theta_3$. But since r_3 does not depend on b, this can always be achieved by choosing r_3 close enough to 2.

Therefore from Lemma 3.3 we have

$$\left\| \mathcal{F}^{-1}_{t,z}\left(|\xi|^{-b} \frac{|f(\tau,\zeta)|}{\langle\sigma\rangle^{1/2-b}} \right) \right\|_{L^{q_1,r_1}_{t,z}} \le CT^{\mu} \|f\|_{L^2_{t,z}}, \tag{3.24}$$

$$\left\| \mathcal{F}^{-1}_{t,z}\left(\frac{|g(\tau,\zeta)|}{\langle\sigma\rangle^{1/2}} \right) \right\|_{L^{q_2,r_2}_{t,z}} \le CT^{\mu} \|g\|_{L^2_{t,z}}, \tag{3.25}$$

$$\left\| \mathcal{F}^{-1}_{t,z}\left(\frac{|h(\tau,\zeta)|}{\langle\sigma\rangle^{b}} \right) \right\|_{L^{q_3,r_3}_{t,z}} \le \|h\|_{L^2_{t,z}}. \tag{3.26}$$

Gathering (3.17), (3.24), (3.25), and (3.26) we obtain (3.12). □

4. Nonlinear estimates and applications to the resolution of KPB I.

First we prove existence and uniqueness of a solution u in the space $X^{1/2,s_1,s_2}(\mathbb{R}^2)$. They follow from the linear estimates of Propositions 2.3 and 2.5 together with the nonlinear estimates of Proposition 4.1 below. Next using Proposition 2.6, we prove that u belongs also to $C([0,T], H^{s_1,s_2}(\mathbb{R}^2))$.

Finally, by means of the conservation laws of the classical KP equation, we show a priori estimates which yield the global existence of the solution of KPB I, provided that φ belongs to H^{s_1,s_2}, $(s_1, s_2) \in [1, +\infty[\times\mathbb{R}_+$, with $\mathcal{F}^{-1}_x(\frac{\eta}{\xi}\hat{\varphi}) \in L^2(\mathbb{R}^2)$.

4.1. Nonlinear estimates in X^{b,s_1,s_2}.

PROPOSITION 4.1. *Let $s_1 > 0$ and $s_2 \ge 0$. Let P be defined by*

$$P(\xi,\eta) = \xi^3 + \frac{\eta^2}{\xi} \quad \textit{or} \quad P(\xi,\eta) = \xi^3 - \frac{\eta^2}{\xi}.$$

For u, v with support in the subset $\{(t,x,y)/\,|t|\le T\}$, there exists $\mu>0$ such that the following bilinear estimate holds:

$$\begin{aligned}\|uv\|_{X^{0,s_1,s_2}} \le CT^{\mu}\big(&\|u\|_{X^{1/2,0+,0}}\|v\|_{X^{1/2,s_1,s_2}} + \|u\|_{X^{1/2,0+,s_2}}\|v\|_{X^{1/2,s_1,0}}\\ &+ \|u\|_{X^{1/2,s_1,0}}\|v\|_{X^{1/2,0+,s_2}} + \|u\|_{X^{1/2,s_1,s_2}}\|v\|_{X^{1/2,0+,0}}\big)\,. \end{aligned}\tag{4.1}$$

Proof. By duality it is equivalent to prove that for $\delta>0$ small enough and for all $\omega\in X^{0,-s_1,-s_2}$

$$\begin{aligned}|\langle uv,\omega\rangle| \le CT^{\mu}\Big(&\|u\|_{X^{1/2,\delta,0,}}\|v\|_{X^{1/2,s_1,s_2}} + \|u\|_{X^{1/2,\delta,s_2}}\|v\|_{X^{1/2,s_1,0}}\\ &+ \|u\|_{X^{1/2,s_1,0}}\|v\|_{X^{1/2,\delta,s_2}} + \|u\|_{X^{1/2,s_1,s_2}}\|v\|_{X^{1/2,\delta,0}}\Big)\|\omega\|_{X^{0,-s_1,-s_2}}\,. \end{aligned}\tag{4.2}$$

Now, consider f, g, and h, respectively, defined by

$$\hat{f}(\tau,\zeta) = \langle \tau - P(\zeta)\rangle^{1/2}\langle\xi\rangle^{s_1}\langle\eta\rangle^{s_2}\hat{u}(\tau,\zeta),$$

$$\hat{g}(\tau,\zeta) = \langle \tau - P(\zeta)\rangle^{1/2}\langle\xi\rangle^{s_1}\langle\eta\rangle^{s_2}\hat{v}(\tau,\zeta)\,,\quad \hat{h}(\tau,\zeta) = \frac{\hat{\omega}(\tau,\zeta)}{\langle\xi\rangle^{s_1}\langle\eta\rangle^{s_2}}\,.$$

Since $\|u\|_{X^{1/2,s_1,s_2}} = \|f\|_{L^2_{t,z}}$, $\|v\|_{X^{1/2,s_1,s_2}} = \|g\|_{L^2_{t,z}}$, and $\|\omega\|_{X^{0,-s_1,-s_2}} = \|h\|_{L^2_{t,z}}$, we easily see that (4.2) is equivalent to the inequality

$$\begin{aligned}&\int_{\mathbb{R}^6}\frac{|\hat{f}(\tau-\tau',\zeta-\zeta')||\hat{g}(\tau',\zeta')||\hat{h}(\tau,\zeta)|\langle\xi\rangle^{s_1}\langle\eta\rangle^{s_2}\,d\tau d\zeta d\tau' d\zeta'}{\langle\sigma_2\rangle^{1/2}\langle\sigma_1\rangle^{1/2}\langle\xi-\xi'\rangle^{s_1}\langle\xi'\rangle^{s_1}\langle\eta-\eta'\rangle^{s_2}\langle\eta'\rangle^{s_2}}\\ &\le CT^{\mu}\Big(\|f\|_{L^2_tH_z^{-s_1+\delta,-s_2}}\|g\|_{L^2_{(t,z)}} + \|f\|_{L^2_tH_z^{-s_1+\delta,0}}\|g\|_{L^2_tH_z^{0,-s_2}}\\ &\quad + \|f\|_{L^2_tH_z^{0,-s_2}}\|g\|_{L^2_tH_z^{-s_1+\delta,0}} + \|f\|_{L^2_{(t,z)}}\|g\|_{L^2_tH_z^{-s_1+\delta,-s_2}}\Big)\|h\|_{L^2_{(t,z)}}\,, \end{aligned}\tag{4.3}$$

where σ_1 and σ_2 are defined by

$$\sigma_1 = \tau - P(\zeta)\ \text{ and }\ \sigma_2 = \tau-\tau' - P(\zeta-\zeta').$$

Note that for all $s\ge 0$ we have

$$\frac{\langle\theta\rangle^{s}}{\langle\theta-\theta'\rangle^{s}\langle\theta'\rangle^{s}} \le \frac{C}{\langle\theta-\theta'\rangle^{s}} + \frac{C}{\langle\theta'\rangle^{s}}\,,\ \theta\,,\ \theta'\in\mathbb{R}.$$

It follows that the left-hand side of (4.3) is bounded by the sum $I_1+I_2+I_3+I_4$, where

$$I_1 = \int_{\mathbb{R}^6}\frac{|\hat{f}(\tau-\tau',\zeta-\zeta')||\hat{g}(\tau',\zeta')||\hat{h}(\tau,\zeta)|\,d\tau d\zeta d\tau' d\zeta'}{\langle\sigma_2\rangle^{1/2}\langle\sigma_1\rangle^{1/2}\langle\xi-\xi'\rangle^{s_1}\langle\eta-\eta'\rangle^{s_2}},$$

$$I_2 = \int_{\mathbb{R}^6}\frac{|\hat{f}(\tau-\tau',\zeta-\zeta')||\hat{g}(\tau',\zeta')||\hat{h}(\tau,\zeta)|\,d\tau d\zeta d\tau' d\zeta'}{\langle\sigma_2\rangle^{1/2}\langle\sigma_1\rangle^{1/2}\langle\xi-\xi'\rangle^{s_1}\langle\eta'\rangle^{s_2}},$$

$$I_3 = \int_{\mathbb{R}^6}\frac{|\hat{f}(\tau-\tau',\zeta-\zeta')||\hat{g}(\tau',\zeta')||\hat{h}(\tau,\zeta)|\,d\tau d\zeta d\tau' d\zeta'}{\langle\sigma_2\rangle^{1/2}\langle\sigma_1\rangle^{1/2}\langle\xi'\rangle^{s_1}\langle\eta-\eta'\rangle^{s_2}},$$

$$I_4 = \int_{\mathbb{R}^6} \frac{|\hat{f}(\tau-\tau',\zeta-\zeta')||\hat{g}(\tau',\zeta')||\hat{h}(\tau,\zeta)|\,d\tau d\zeta d\tau' d\zeta'}{\langle\sigma_2\rangle^{1/2}\langle\sigma_1\rangle^{1/2}\langle\xi'\rangle^{s_1}\langle\eta'\rangle^{s_2}}.$$

By Lemma 3.4, one infers that

$$\begin{aligned} I_1 &= \int_{\mathbb{R}^6} \frac{|\hat{f}(\tau',\zeta')|}{\langle\xi'\rangle^{s_1-\delta}\langle\eta'\rangle^{s_2}} \frac{|\hat{g}(\tau-\tau',\zeta-\zeta')||\hat{h}(\tau,\zeta)|}{\langle\sigma_2\rangle^{1/2}\langle\sigma_1\rangle^{1/2}\langle\xi'\rangle^{\delta}}\,d\tau d\zeta d\tau' d\zeta' \\ &\le C\,T^{\mu}\|f\|_{L^2_tH_z^{-s_1+\delta,-s_2}}\|g\|_{L^2_{t,z}}\|h\|_{L^2_{t,z}} \end{aligned}$$

for $\delta > 0$ small enough. In the same way,

$$\begin{aligned} I_2 &\le CT^{\mu}\|f\|_{L^2_tH_z^{-s_1+\delta,0}}\|g\|_{L^2_tH_z^{0,-s_2}}\|h\|_{L^2_{t,z}}, \\ I_3 &\le CT^{\mu}\|f\|_{L^2_tH_z^{0,-s_2}}\|g\|_{L^2_tH_z^{-s_1+\delta,0}}\|h\|_{L^2_{t,z}}, \\ I_4 &\le CT^{\mu}\|f\|_{L^2_{t,z}}\|g\|_{L^2_tH_z^{-s_1+\delta,-s_2}}\|h\|_{L^2_{t,z}}, \end{aligned}$$

which completes the proof of the proposition. □

4.2. Local existence result.

PROPOSITION 4.2. *Let $\varphi \in H^{s_1,s_2}(\mathbb{R}^2)$, $(s_1,s_2) \in \mathbb{R}_+^* \times \mathbb{R}_+$. For any $\delta > 0$, there exist $T = T(\|\varphi\|_{H^{\delta,0}}) > 0$ and a unique local solution u to* (1.1) *in*

$$Y_T = X_T^{1/2,s_1,s_2} \cap C([0,T],H^{s_1,s_2}).$$

Furthermore the map $\varphi \mapsto u$ is continuous from H^{s_1,s_2} to Y_T.

Remark. It is important to note that the lower bound for the time of existence of u in $X_T^{1/2,s_1,s_2} \cap C([0,T],H^{s_1,s_2})$ depends only on the norm of the corresponding initial data in $H^{\delta,0}$ (for all fixed $\delta > 0$).

Proof. Let φ be in H^{s_1,s_2}, $(s_1,s_2) \in \mathbb{R}_+^* \times \mathbb{R}_+$. For $T \le 1$, u is a solution of KPB on $[0,T/2]$ if and only if u is a solution of the integral equation $u = L(u)$ with

$$L(u) = \psi(t)\left[W(t)u_0 - \frac{\mathbb{1}_{\mathbb{R}^+}(t)}{2}\int_0^t W(t-t')\partial_x(\psi_T^2(t')\,u^2(t'))\,dt'\right]. \tag{4.4}$$

We first prove the statement for $T = T(\|\varphi\|_{H^{s_1,0}})$.

Following Bourgain, we are going to solve (4.4) in a ball of the space

$$Z = \{u \in X_T^{1/2,s_1,s_2} \;/\; \|u\|_Z = \|u\|_{X_T^{1/2,s_1,0}} + \gamma\,\|u\|_{X_T^{1/2,s_1,s_2}} < +\infty\},$$

where the constant γ is defined for all nontrivial φ by

$$\gamma = \frac{\|\varphi\|_{H^{s_1,0}}}{\|\varphi\|_{H^{s_1,s_2}}}.$$

From Propositions 2.3 and 2.5 with $b = 0$,

$$\|L(u)\|_{X_T^{1/2,s_1,0}} \le C\|\varphi\|_{s_1,0} + C\|\Delta_x^{-\frac{1}{2}}\partial_x(u^2)\|_{X_T^{0,s_1,0}}.$$

Proposition 4.1 then yields

$$\|L(u)\|_{X_T^{1/2,s_1,0}} \le C\,\|\varphi\|_{H^{s_1,0}} + C\,T^{\mu}\|u\|^2_{X_T^{1/2,s_1,0}}. \tag{4.5}$$

Next, since $\partial_x(u^2) - \partial_x(v^2) = \partial_x[(u-v)(u+v)]$, we get

$$\|L(u) - L(v)\|_{X_T^{1/2,s_1,0}} \le C\,T^{\mu} \|u-v\|_{X_T^{1/2,s_1,0}} \|u+v\|_{X_T^{1/2,s_1,0}}. \tag{4.6}$$

In the same way, we obtain

$$\|L(u)\|_{X_T^{1/2,s_1,s_2}} \le C\,\|\varphi\|_{H^{s_1,s_2}} + CT^{\mu}\|u\|_{X_T^{1/2,s_1,0}}\|u\|_{X_T^{1/2,s_1,s_2}} \tag{4.7}$$

and

$$\begin{aligned}\|L(u) - L(v)\|_{X_T^{1/2,s_1,s_2}} \le C\,T^{\mu}\Big(&\|u-v\|_{X_T^{1/2,s_1,0}}\|u+v\|_{X_T^{1/2,s_1,s_2}} \\ &+ \|u-v\|_{X_T^{1/2,s_1,s_2}}\|u+v\|_{X_T^{1/2,s_1,0}}\Big).\end{aligned} \tag{4.8}$$

Recalling the definition of $\|\cdot\|_Z$, (4.5)–(4.8) lead to

$$\|L(u)\|_Z \le C\,(\|\varphi\|_{H^{s_1,0}} + \gamma\|\varphi\|_{H^{s_1,s_2}}) + C\,T^{\mu}\|u\|_Z^2 \tag{4.9}$$

and

$$\begin{aligned}\|L(u) - L(v)\|_Z \le C\,T^{\mu}\Big(&\|u-v\|_{X_T^{1/2,s_1,0}}\|u+v\|_Z \\ &+ \gamma\|u-v\|_{X_T^{1/2,s_1,s_2}}\|u+v\|_{X_T^{1/2,s_1,0}}\Big) \\ \le{}& C\,T^{\mu}\|u-v\|_Z\|u+v\|_Z.\end{aligned} \tag{4.10}$$

Now, setting $T = (4C^2(\|\varphi\|_{H^{s_1,0}} + \gamma\|\varphi\|_{H^{s_1,s_2}}))^{-1/\mu}$, which yields $T = (8C^2\|\varphi\|_{H^{s_1,0}})^{-1/\mu}$ by definition of γ, we deduce from (4.9) and (4.10) that L is strictly contractive on the ball of radius $2C(\|\varphi\|_{H^{s_1,0}} + \gamma\|\varphi\|_{H^{s_1,s_2}})$ in Z. This proves the existence of a unique solution to (1.1) in $X_T^{1/2,s_1,s_2}$ with $T = T(\|\varphi\|_{H^{s_1,0}}) > 0$.

Note that $\psi(\cdot)W(\cdot)\varphi$ belongs to $C([0,T], H^{s_1,s_2})$ since φ belongs to H^{s_1,s_2}. Moreover, since $u \in X_T^{1/2,s_1,s_2}$, one infers from Proposition 4.1 that $u^2 \in X_T^{0,s_1,s_2}$, and it follows from the first assertion of Proposition 2.6 that

$$t \mapsto \int_0^t W(t-t')\partial_x(u^2(t'))\,dt'$$

also belongs to $C([0,T], H^{s_1,s_2})$. Thus u belongs to $C([0,T], H^{s_1,s_2})$.

Now, standard arguments enable us to extend u on a maximal interval of existence $[0, T_*[$ such that

$$\text{if } \ T_* < +\infty\,, \ \text{then } \limsup_{t \nearrow T_*} \|u(t)\|_{H^{s_1,0}} = +\infty. \tag{4.11}$$

Next, proceeding exactly in the same way as above but in the space

$$\tilde{Z} = \{u \in X_T^{1/2,s_1,0} \ / \ \|u\|_{\tilde{Z}} = \|u\|_{X_T^{1/2,\delta,0}} + \tilde{\gamma}\,\|u\|_{X_T^{1/2,s_1,0}} < +\infty\},$$

where

$$\tilde{\gamma} = \frac{\|\varphi\|_{H^{\delta,0}}}{\|\varphi\|_{H^{s_1,0}}},$$

we obtain that for $\tilde{T} = \tilde{T}(\|\varphi\|_{H^{\delta,0}})$, L is also strictly contractive on a ball of $\tilde{Z}$. Since obviously $H^{s_1,s_2} \subset H^{s_1,0}$, it follows that there exists $\tilde{T} = \tilde{T}(\|\varphi\|_{H^{\delta,0}})$ and a unique solution $\tilde{u}$ to (1.1) in $C([0,\tilde{T}], H^{s_1,0}) \cap X^{1/2,s_1,0}$. By uniqueness, $u = \tilde{u}$ on $[0, \min(\tilde{T}, T_*)[$, and this implies that $T_* \geq \tilde{T}(\|\varphi\|_{H^{\delta,0}})$.

Finally, the continuity of the map $\varphi \mapsto u$ from H^{s_1,s_2} to $X^{1/2,s_1,s_2}$ follows from classical arguments, while the continuity from H^{s_1,s_2} to $C([0,T_*[, H^{s_1,s_2})$ follows from Proposition 2.6. □

4.3. Global existence for KPB I. Let us now show that for $\varepsilon = -1$ and $\varphi \in H^{s_1,s_2}$, (s_1,s_2) in $[1,+\infty[\times\mathbb{R}_+$ with $\mathcal{F}_z^{-1}(\frac{\eta}{\xi}\hat{\varphi}) \in L^2(\mathbb{R}^2)$, the solution to (1.1) is global in time. To establish a priori estimates on the solution, we will use the following lemma which is directly inspired by the conservation laws of the KP equations.

LEMMA 4.3. *Let $u \in C([0,T], H^3(\mathbb{R}^2))$ be a solution to KPB equations ($\varepsilon = \pm 1$) with initial data*

$$\varphi \in \mathcal{N} = \left\{ \phi \in H^3(\mathbb{R}^2),\ \mathcal{F}_z^{-1}\left(\frac{\hat{\phi}}{\xi^2}\right) \in H^3(\mathbb{R}^2) \right\}.$$

Then u satisfies

$$\|u(t)\|_{L^2}^2 + \int_0^t \|u_x\|_{L^2}^2 = \|\varphi\|_{L^2}^2 \quad \forall t \in [0,T] \tag{4.12}$$

and

$$E(u(t)) + \int_0^t \|u_{xx}(\tau)\|_{L^2}^2 + \|u_y(\tau)\|_{L^2}^2 \, d\tau$$

$$= -\frac{1}{2}\int_0^t \int_{\mathbb{R}^2} u^2(\tau) u_{xx}(\tau)\, d\tau + E(\varphi), \tag{4.13}$$

where

$$E(\phi) = \frac{1}{2}\|\phi_x\|_{L^2}^2 - \frac{\varepsilon}{2}\|\partial^{-1}\phi_y\|_{L^2}^2 - \frac{1}{6}\|\phi\|_{L^3}^3.$$

Proof. Proceeding exactly as in [15], one can show that $\partial^{-1}u_{yy}$, $\partial_x^{-1}u_t$, and $\partial^{-2}u_{yy}$ belong to $C([0,T], L^2(\mathbb{R}^2))$. Therefore, we obtain (4.12) (respectively, (4.13)) by applying the operator ∂_x^{-1} on (1.1), multiplying the obtained equation by u (respectively, $-u_{xx} - \varepsilon\partial_x^{-2}u_{yy} - u^2/2$), and integrating by parts in $\mathbb{R}^2$ and then over the time interval $[0,t]$. □

Now, according to Proposition 4.2, denoting by $[0,T_*[$ the maximal interval of existence of the solution u to KPB,

$$\text{if } T_* < +\infty, \quad \text{then } \limsup_{t \nearrow T_*} \|u(t)\|_{H^{1,0}} = +\infty. \tag{4.14}$$

Next, thanks to Lemma 3.2 in [11], one can always find a sequence $(\varphi_n)_{n\geq 0} \subset \mathcal{N} \cap H^{3,3}$ such that

$$\varphi_n \to \varphi \text{ in } \left\{ \phi \in H^{1,0}(\mathbb{R}^2),\ \mathcal{F}_z\left(\frac{\eta}{\xi}\hat{\phi}\right) \in L^2(\mathbb{R}^2) \right\}.$$

Fixing T in $]0,T_*[$, Proposition 4.2 and Lemma 4.3 ensure that for n large enough the solution u_n to KPB with initial data φ_n satisfies (4.12) and (4.13) on $[0,T]$ (note that $H^{3,3} \subset H^3$).

Recalling the anisotropic Sobolev inequality (cf. [1])

$$\|u\|_{L^{2(q+1)}}^{2(q+1)} \leq C\,\|u\|_{L^2}^{2-q}\,\|u_x\|_{L^2}^{2q}\,\|\partial_x^{-1}u_y\|_{L^2}^{q} \quad \forall q \in [0,2], \tag{4.15}$$

we notice that

$$\Big|\int_{\mathbb{R}^2} u^2 u_x\Big| \leq \frac{1}{2}\|u_{xx}\|_{L^2}^2 + \frac{1}{2}\|u\|_{L^2}\|u_x\|_{L^2}^2\|\partial_x^{-1}u_y\|_{L^2}.$$

It then follows from (4.12) and (4.13) that, for all t in $[0,T]$,

$$\begin{aligned} E(u_n(t)) \leq & -\frac{1}{2}\int_0^t \Big(\|u_{n,xx}\|_{L^2}^2 + \|u_{n,y}\|_{L^2}\Big)\,dt \\ & + C\,\|\varphi_n\|_{L^2}^3\|\partial_x^{-1}u_{n,y}\|_{L_T^\infty L_z^2} + E(\varphi_n). \end{aligned} \tag{4.16}$$

Using (4.15) again (with $q = 1/2$) we see that

$$\Big|\int_{\mathbb{R}^2} u_n^3\Big| \leq \|u_n\|_{L^2}^{\frac{3}{2}}\,\|u_{n,x}\|_{L^2}\|\partial_x^{-1}u_{n,y}\|_{L^2}^{\frac{1}{2}},$$

and (4.16) then leads to

$$\begin{aligned} & \|u_{n,x}\|_{L_T^\infty L_z^2}^2 + \|\partial_x^{-1}u_{n,y}\|_{L_T^\infty L_z^2}^2 \\ & \leq C(\|\varphi_n\|_2)\Big(1 + \|u_{n,x}\|_{L_T^\infty L_z^2}^2 + \|\partial_x^{-1}u_{n,y}\|_{L_T^\infty L_z^2}^2\Big)^{\frac{3}{4}} + E(\varphi_n). \end{aligned} \tag{4.17}$$

Since by (4.15), $E(\varphi_n) \leq C\,(\|\varphi_n\|_{H^{1,0}},\, \|\partial_x^{-1}\varphi_{n,y}\|_{L^2})$, it follows from (4.17) that

$$\|u_{n,x}\|_{L_T^\infty L_z^2} \leq C\,\Big(\|\varphi_n\|_{H^{1,0}},\, \|\partial_x^{-1}\varphi_{n,y}\|_{L^2}\Big).$$

By Proposition 4.2, $u_n \to u$ in $C([0,T], H^{1,0})$, and so

$$\|u_x\|_{L_T^\infty L_z^2} \leq C\,\Big(\|\varphi\|_{H^{1,0}},\, \|\partial_x^{-1}\varphi_y\|_{L^2}\Big).$$

Thus (4.14) ensures that $T_* = +\infty$.

5. The Cauchy problem for the KPB II equation in $H^s(\mathbb{R}^2)$, $s \geq 0$. In this section we use the algebraic inequality (5.2) to derive a bilinear estimate which will enable us to show the local existence of a unique solution u in the space $X^{1/2,s}$ for all initial data in the Sobolev space $H^s(\mathbb{R}^2)$, $s \geq 0$. Note that (5.2) holds only when $\varepsilon = +1$ and is crucial to regain the x-derivative in the local well-posedness result for the classical KP II equation. Moreover, we show that the time of existence of the solution in $C([0,T], H^s)$ depends only on the norm of the initial data in $L^2(\mathbb{R}^2)$. Finally, using the decay of the L^2-norm of regular solutions of the KPB II equation, we prove the global existence in $H^s(\mathbb{R}^2)$.

5.1. Nonlinear estimates.

Proposition 5.1. *Let $s \geq 0$ and $b > 0$ small enough. Let $P(\xi, \eta)$ be defined by*

$$P(\xi, \eta) = \xi^3 + \frac{\eta^2}{\xi}.$$

Let u and v supported in the set $\{(t,x,y)/\,|t| \leq T\}$. Then there exists $\mu(b) > 0$ such that the following bilinear estimate holds:

$$\|\Delta_x^{\frac{2b-1}{2}} \partial_x(uv)\|_{X^{-b,s}} \leq CT^{2\mu} \left(\|u\|_{X^{1/2,s}}\|v\|_{X^{1/2,0}} + \|u\|_{X^{1/2,0}}\|v\|_{X^{1/2,s}}\right). \tag{5.1}$$

Proof. By duality it is enough to prove that for all $\omega \in X^{b,-s}$,

$$|\langle \Delta_x^{\frac{2b-1}{2}} \partial_x(uv), \omega\rangle| \leq CT^{2\mu}(\|u\|_{X^{1/2,s}}\|v\|_{X^{1/2,0}} + \|u\|_{X^{1/2,0}}\|v\|_{X^{1/2,s}})\|\omega\|_{X^{b,-s}}.$$

Now, consider

$$\hat{f} = \hat{u}(\tau,\zeta)\langle\zeta\rangle^s\langle\tau - P(\zeta)\rangle^{1/2},\ \hat{g} = \hat{v}(\tau,\zeta)\langle\zeta\rangle^s\langle\tau - P(\zeta)\rangle^{1/2}$$

and

$$\hat{\omega} = \hat{h}(\tau,\zeta)\langle\zeta\rangle^{-s}\langle\tau - P(\zeta)\rangle^{b}.$$

Then

$$|\langle \Delta_x^{\frac{2b-1}{2}} \partial_x(uv), \omega\rangle| \leq I,$$

where I is defined by

$$I = \int_{\mathbb{R}^6} \frac{|\xi|\langle\xi\rangle^{2b-1}|\hat{f}(\tau-\tau',\zeta-\zeta')||\hat{g}(\tau',\zeta')||\hat{h}(\tau,\zeta)|\,d\tau d\zeta d\tau' d\zeta'}{\langle\sigma_2\rangle^{1/2}\langle\sigma_1\rangle^{1/2}\langle\sigma\rangle^{b}\langle\zeta-\zeta'\rangle^{s}\langle\zeta'\rangle^{s}\langle\zeta\rangle^{-s}}.$$

Recall (see [4]) that the following algebraic inequality holds:

$$3\max\left(|\sigma|, |\sigma_1|, |\sigma_2|\right) \geq |\xi\xi'(\xi'-\xi)| \geq |\xi|^2 \min\left(|\xi'|, |\xi'-\xi|\right). \tag{5.2}$$

Note also that

$$\frac{\langle\zeta\rangle^s}{\langle\zeta-\zeta'\rangle^s\langle\zeta'\rangle^s} \leq \frac{C}{\langle\zeta'\rangle^s} + \frac{C}{\langle\zeta-\zeta'\rangle^s}. \tag{5.3}$$

Now, to estimate I, by symmetry, we can always assume that $|\sigma_1| \geq |\sigma_2|$. Hence we have only to consider the two cases $|\sigma| \geq |\sigma_1|$ and $|\sigma_1| \geq |\sigma|$.

(a) The case $|\sigma| \geq |\sigma_1|$.

(a1) The subcase $|\xi'| \leq |\xi - \xi'|$. We denote by I_1 the contribution to I on this subdomain. From (5.2) we obtain

$$\frac{|\xi|\langle\xi\rangle^{2b-1}}{\langle\sigma\rangle^b} \leq \frac{|\xi|\langle\xi\rangle^{-1}}{|\xi'|^b} \leq |\xi'|^{-b},$$

and so from (5.3) we get

$$I_1 \leq \int_{\mathbb{R}^6} \frac{|\hat{f}(\tau-\tau',\zeta-\zeta')||\hat{g}(\tau',\zeta')||\hat{h}(\tau,\zeta)|}{\langle\sigma_2\rangle^{1/2}\langle\sigma_1\rangle^{1/2}|\xi'|^b\langle\zeta-\zeta'\rangle^s}\,d\tau d\zeta d\tau' d\zeta'$$

$$+\int_{\mathbb{R}^6}\frac{|\hat{f}(\tau-\tau',\zeta-\zeta')||\hat{g}(\tau',\zeta')||\hat{h}(\tau,\zeta)|}{\langle\sigma_2\rangle^{1/2}\langle\sigma_1\rangle^{1/2}|\xi'|^b\langle\zeta'\rangle^s}\,d\tau d\zeta d\tau' d\zeta'$$

$$\leq C\|\hat{f}(\tau,\zeta)\langle\zeta\rangle^{-s}\|_{L^2_{t,z}}\|\hat{g}\|_{L^2_{t,z}}\|\hat{h}\|_{L^2_{t,z}}+\|\hat{f}\|_{L^2_{t,z}}\|\hat{g}(\tau,\zeta)\langle\zeta\rangle^{-s}\|_{L^2_{t,z}}\|\hat{h}\|_{L^2_{t,z}}$$

by virtue of (3.11) in Lemma 3.4. Hence we have

$$I_1\leq\|u\|_{X^{1/2,0}}\|v\|_{X^{1/2,s}}\|\omega\|_{X^{b,-s}}+\|u\|_{X^{1/2,s}}\|v\|_{X^{1/2,0}}\|\omega\|_{X^{b,-s}}\ . \tag{5.4}$$

(a2) The subcase $|\xi-\xi'|\leq|\xi'|$. We denote by I_2 the contribution to I on this subdomain. From (5.2) again, we obtain

$$\frac{|\xi|\langle\xi\rangle^{2b-1}}{\langle\sigma\rangle^b}\leq\frac{|\xi|\langle\xi\rangle^{2b-1}}{\langle\xi\rangle^{2b}|\xi'-\xi|^{2b}}\leq|\xi'-\xi|^{-2b}.$$

Hence, from (5.3),

$$I_2\leq\int_{\mathbb{R}^6}\frac{|\hat{f}(\tau-\tau',\zeta-\zeta')||\hat{g}(\tau',\zeta')||\hat{h}(\tau,\zeta)|}{\langle\sigma_2\rangle^{1/2}\langle\sigma_1\rangle^{1/2}|\xi'-\xi|^b\langle\zeta-\zeta'\rangle^s}\,d\tau d\zeta d\tau' d\zeta'$$

$$+\int_{\mathbb{R}^6}\frac{|\hat{f}(\tau-\tau',\zeta-\zeta')||\hat{g}(\tau',\zeta')||\hat{h}(\tau,\zeta)|}{\langle\sigma_2\rangle^{1/2}\langle\sigma_1\rangle^{1/2}|\xi'-\xi|^b\langle\zeta'\rangle^s}\,d\tau d\zeta d\tau' d\zeta'$$

$$\leq C\|\hat{f}(\tau,\zeta)\langle\zeta\rangle^{-s}\|_{L^2_{t,z}}\|\hat{g}\|_{L^2_{t,z}}\|\hat{h}\|_{L^2_{t,z}}+\|\hat{f}\|_{L^2_{t,z}}\|\hat{g}(\tau,\zeta)\langle\zeta\rangle^{-s}\|_{L^2_{t,z}}\|\hat{h}\|_{L^2_{t,z}}$$

by virtue of (3.11) in Lemma 3.4. Hence we have

$$I_2\leq\|u\|_{X^{1/2,0}}\|v\|_{X^{1/2,s}}\|\omega\|_{X^{b,-s}}+\|u\|_{X^{1/2,s}}\|v\|_{X^{1/2,0}}\|\omega\|_{X^{b,-s}}. \tag{5.5}$$

(b) The case $|\sigma_1|\geq|\sigma|$. In this situation, from (5.2), we have

$$I=\int_{\mathbb{R}^6}\frac{|\xi|\langle\xi\rangle^{2b-1}|\hat{f}(\tau-\tau',\zeta-\zeta')||\hat{g}(\tau',\zeta')||\hat{h}(\tau,\zeta)|\,d\tau d\zeta d\tau' d\zeta'}{\langle\sigma_2\rangle^{1/2}\langle\sigma_1\rangle^{1/2-b}\langle\sigma_1\rangle^b\langle\sigma\rangle^b\langle\zeta-\zeta'\rangle^s\langle\zeta'\rangle^s\langle\zeta\rangle^{-s}}$$

$$\leq\int_{\mathbb{R}^6}\frac{|\hat{f}(\tau-\tau',\zeta-\zeta')||\hat{g}(\tau',\zeta')||\hat{h}(\tau,\zeta)|\langle\zeta\rangle^s\,d\tau d\zeta d\tau' d\zeta'}{\langle\sigma_2\rangle^{1/2}\langle\sigma_1\rangle^{1/2-b}\min\left(|\xi'|,|\xi-\xi'|\right)^b\langle\sigma\rangle^b\langle\zeta-\zeta'\rangle^s\langle\zeta'\rangle^s}.$$

(b1) Subcase $|\xi-\xi'|\leq|\xi'|$. We denote by I_3 the contribution to I on this subdomain. According to the last inequality and (5.3) and since $\langle\sigma\rangle\leq\langle\sigma_1\rangle$, we infer that

$$I_3\leq\int_{\mathbb{R}^6}\frac{|\hat{f}(\tau-\tau',\zeta-\zeta')||\langle\zeta'\rangle^{-s}\hat{g}(\tau',\zeta')||\hat{h}(\tau,\zeta)|}{\langle\sigma_2\rangle^{1/2}|\xi'-\xi|^b\langle\sigma\rangle^{1/2}}\,d\tau d\zeta d\tau' d\zeta'$$

$$+\int_{\mathbb{R}^6}\frac{|\langle\zeta-\zeta'\rangle^{-s}\hat{f}(\tau-\tau',\zeta-\zeta')||\hat{g}(\tau',\zeta')||\hat{h}(\tau,\zeta)|}{\langle\sigma_2\rangle^{1/2}|\xi'-\xi|^b\langle\sigma\rangle^{1/2}}\,d\tau d\zeta d\tau' d\zeta'$$

$$\leq C\|\hat{f}(\tau,\zeta)\langle\zeta\rangle^{-s}\|_{L^2_{t,z}}\|\hat{g}\|_{L^2_{t,z}}\|\hat{h}\|_{L^2_{t,z}}+\|\hat{f}\|_{L^2_{t,z}}\|\hat{g}(\tau,\zeta)\langle\zeta\rangle^{-s}\|_{L^2_{t,z}}\|\hat{h}\|_{L^2_{t,z}}$$

by virtue of (3.11) in Lemma 3.4. Hence we have

$$I_3\leq\|u\|_{X^{1/2,0}}\|v\|_{X^{1/2,s}}\|\omega\|_{X^{b,-s}}+\|u\|_{X^{1/2,s}}\|v\|_{X^{1/2,0}}\|\omega\|_{X^{b,-s}}. \tag{5.6}$$

(b2) Subcase $|\xi'| \le |\xi' - \xi|$. We denote by I_4 the contribution to I on this subdomain. Then according to (5.3) we have

$$I_4 \le \int_{\mathbb{R}^6} \frac{|\hat{f}(\tau-\tau',\zeta-\zeta')||\langle\zeta'\rangle^{-s}\hat{g}(\tau',\zeta')||\hat{\omega}(\tau,\zeta)|}{\langle\sigma_2\rangle^{1/2}|\xi'|^b\langle\sigma_1\rangle^{1/2-b}\langle\sigma\rangle^b}\, d\tau d\zeta d\tau' d\zeta'$$

$$+ \int_{\mathbb{R}^6} \frac{|\langle\zeta-\zeta'\rangle^{-s}\hat{f}(\tau-\tau',\zeta-\zeta')||\hat{g}(\tau',\zeta')||\hat{h}(\tau,\zeta)|}{\langle\sigma_2\rangle^{1/2}|\xi'|^b\langle\sigma_1\rangle^{1/2-b}\langle\sigma\rangle^b}\, d\tau d\zeta d\tau' d\zeta'$$

$$\le C\|\hat{f}(\tau,\zeta)\langle\zeta\rangle^{-s}\|_{L^2_{t,z}}\|\hat{g}\|_{L^2_{t,z}}\|\hat{h}\|_{L^2_{t,z}} + \|\hat{f}\|_{L^2_{t,z}}\|\hat{g}(\tau,\zeta)\langle\zeta\rangle^{-s}\|_{L^2_{t,z}}\|\hat{h}\|_{L^2_{t,z}}$$

by virtue of the estimate (3.12) in Lemma 3.4. Hence we have

$$I_4 \le \|u\|_{X^{1/2,0}}\|v\|_{X^{1/2,s}}\|\omega\|_{X^{b,-s}} + \|u\|_{X^{1/2,s}}\|v\|_{X^{1/2,0}}\|\omega\|_{X^{b,-s}}. \tag{5.7}$$

The proof follows now from (5.4), (5.5), (5.6), and (5.7). □

5.2. Local existence.

Proposition 5.2. *For any $\varphi \in H^s(\mathbb{R}^2)$ with $s \ge 0$, there exists $T = T(\|u_0\|_{L^2})$ and a unique local solution u of KPB* II *in*

$$Y_T = X_T^{1/2,s} \cap C([0,T], H^s).$$

Furthermore the map $\varphi \mapsto u$ is continuous from $H^s(\mathbb{R}^2)$ to Y_T.

Remark. It is important to note that the lower bound for the time of existence of u in $X_T^{1/2,s} \cap C([0,T], H^s)$ depends only on the norm of the corresponding initial data in L^2.

Proof. The procedure is the same as for the proof of Proposition 4.2. We now work in the space

$$Z = \{u \in X_T^{1/2,s} \;/\; \|u\|_Z = \|u\|_{X_T^{1/2,0}} + \gamma\,\|u\|_{X_T^{1/2,s}} < +\infty\},$$

where the constant γ is defined for all nontrivial φ by

$$\gamma = \frac{\|\varphi\|_{L^2}}{\|\varphi\|_{H^s}}.$$

From Propositions 2.3 and 2.5, for all $0 \le b < 1/2$,

$$\|L(u)\|_{X_T^{1/2,0}} \le C\|\varphi\|_{L^2} + C\|\Delta_x^{\frac{2b-1}{2}}\partial_x(u^2)\|_{X_T^{-b,0}},$$

$$\|L(u)\|_{X_T^{1/2,s}} \le C\|\varphi\|_{H^s} + C\|\Delta_x^{\frac{2b-1}{2}}\partial_x(u^2)\|_{X_T^{-b,s}}.$$

Choosing $b > 0$ small enough, Proposition 5.1 then yields

$$\|L(u)\|_{X_T^{1/2,0}} \le C\,\|\varphi\|_{L^2} + C\,T^\mu\|u\|^2_{X_T^{1/2,0}},$$

$$\|L(u)\|_{X_T^{1/2,s}} \le C\,\|\varphi\|_{H^s} + C\,T^\mu\|u\|^2_{X_T^{1/2,s}}.$$

Since $\partial_x(u^2) - \partial_x(v^2) = \partial_x[(u-v)(u+v)]$, in the same way we get

$$\|L(u) - L(v)\|_{X_T^{1/2,0}} \le C\,T^\mu \|u-v\|_{X_T^{1/2,0}} \|u+v\|_{X_T^{1/2,0}},$$

$$\|L(u) - L(v)\|_{X_T^{1/2,s}} \le C\,T^\mu \Big(\|u-v\|_{X_T^{1/2,s}} \|u+v\|_{X_T^{1/2,0}} + \|u-v\|_{X_T^{1/2,0}} \|u+v\|_{X_T^{1/2,s}} \Big).$$

Proceeding as in the proof of Proposition 4.2, it clearly follows from the above inequalities that for $T = (8C^2\|\varphi\|_{L^2})^{-\frac{1}{\mu}}$, the integral operator L is strictly contractive on the ball of radius $2C(\|\varphi\|_{L^2} + \gamma\|\varphi\|_{H^s})$ in Z. This mainly shows the result (we refer to the proof of Proposition 4.2 for further details). □

5.3. Global existence for KP II. We now prove the global existence result. In view of Proposition 5.2, for $\varphi \in H^s(\mathbb{R}^2)$, $s \ge 0$, the local solution u of KPB II can be extended on a maximal existence interval $[0, T_*[$ such that

$$\text{if } \ T_* < \infty\ , \text{ then } \ \limsup_{t \nearrow T_*} |u(t)|_2 = +\infty. \tag{5.8}$$

We are going to see that the L^2-norm of the solution is nonincreasing on $[0, T_*[$, which obviously ensures that $T_* = +\infty$.

Proof. Note that, thanks to Lemma 3.2 in [11], one can always find a sequence $(\varphi_n)_{n\ge 0} \subset \mathcal{N}$ such that $\varphi_n \to \varphi$ in $L^2(\mathbb{R}^2)$. Fixing $T \in]0, T_*[$, we deduce from Proposition 5.2 and Lemma 4.3 that for n large enough the solution u_n of KPB II with initial data φ_n satisfies (4.12) on $[0, T]$. We thus infer that

$$\|u_n(t_2)\|_2 \le \|u_n(t_1)\|_2\,, \quad 0 \le t_1 \le t_2 \le T.$$

Passing to the limit in n, using that $u_n \to u$ in $C([0,T], L^2(\mathbb{R}^2))$, we deduce that $t \mapsto \|u(t)\|_2$ is nonincreasing on $[0, T]$. Letting T tend to T_*, the result on $[0, T_*[$ is proved. □

Acknowledgments. We would like to thank N. Tzvetkov for useful discussions on Bourgain spaces, as well as the referees for valuable comments.

STABILITY IN A LINEAR DELAY SYSTEM WITHOUT INSTANTANEOUS NEGATIVE FEEDBACK*

JOSEPH W.-H. SO[†], XIANHUA TANG[‡], AND XINGFU ZOU[§]

Abstract. It is shown that every solution of a linear differential system with constant coefficients and time delays tends to zero if a certain matrix derived from the coefficient matrix is a nonsingular M-matrix and the diagonal delays satisfy the so-called 3/2 condition.

Key words. linear system, pure-delay type, stability, diagonal dominant, M-matrix

1. Introduction.

Consider a system of delayed linear differential equations with constant coefficients of the form

$$\dot{x}_i(t) = -\sum_{j=1}^{n} a_{ij} x_j(t-\tau_{ij}), \qquad i = 1, 2, \dots, n, \tag{1.1}$$

with

$$\tau_{ij} \geq 0 \quad \text{for all} \quad 1 \leq i, j \leq n. \tag{1.2}$$

System (1.1) arises as linearization about an equilibrium point of many nonlinear systems with time delays. The interested reader can refer to Stépán [14] and the references therein for multiple-delay examples, such as machine tool vibration and human-machine systems.

When $\tau_{ij} = 0$ for all $i, j = 1, 2, \dots, n$, it is well known that (1.1) is asymptotically stable if and only if the matrix $A = (a_{ij})$ is a positively stable matrix, meaning that all eigenvalues of A have positive real parts. When some of the delays τ_{ij} are nonzero, (1.1) is asymptotically stable if and only if all the roots of its characteristic equation have negative real parts (cf. Hale and Verduyn Lunel [6]). In general, it is extremely difficult to analyze the characteristic equation of (1.1) when there are multiple (nonzero) delays. In Hofbauer and So [8], the authors considered the case when $\tau_{ii} = 0$ for $i = 1, 2, \dots, n$, and they established the following result.

THEOREM 1.1. *Assume that $\tau_{ii} = 0$ for all $i = 1, 2, \dots, n$. Then* (1.1) *is asymptotically stable for all choices of delays of the form* (1.2) *if and only if $a_{ii} > 0$ for $i = 1, 2, \dots, n$, $\det A \neq 0$, and A is weakly diagonally dominant (i.e., all the principal minors of $\hat{A} = (\hat{a}_{ij})$ are nonnegative, where $\hat{a}_{ii} = a_{ii}$ and $\hat{a}_{ij} = -|a_{ij}|$ for $j \neq i$).*

In such a case (i.e., when there is no diagonal delay), Györi [5] also obtained a similar result for a quasi-monotone matrix A (i.e., $a_{ij} \leq 0$ for $i \neq j$). Motivated by the

study of neural networks of Hopfield type, there is a recent extension of Theorem 1.1 by Sue Ann Campbell [2] of the University of Waterloo to include both types of diagonal terms, both with and without delays. A result similar to Theorem 1.1 was obtained (with the conditions on a suitably derived matrix) using the same proof as in [8].

When $\tau_{ii} \neq 0$, $i = 1, \dots, n$, instantaneous feedback is absent, and (1.1) becomes a system of "pure-delay type." For such a "pure-delay-type" system, the stability problem becomes much harder, as pointed out by Gopalsamy and He [4], He [7], and Kuang [10]. However, it is reasonable to expect that a similar stability criterion holds as long as the diagonal delays are sufficiently small. This paper will provide an answer to this question. More precisely, by employing a new technique (without analyzing the characteristic equation or constructing a Liapunov functional), we will extend the sufficiency part of Theorem 1.1 to the case when τ_{ii} $(i = 1, 2, \dots, n)$ are not necessarily all zero. For convenience, we recall the concept of a nonsingular M-matrix (cf. Fiedler [3]).

Definition 1.2. *The $n \times n$ matrix $B = (b_{ij})$ is a nonsingular M-matrix if* (i) $b_{ij} \leq 0$ *for* $j \neq i$ *and* (ii) *all principal minors of B are positive.*

There are many equivalent formulations of this concept (cf. Fiedler [3, Theorem 5.1, p. 114]. In particular, if B is a nonsingular M-matrix, then B^{-1} is a positive matrix.

We associate with the $n \times n$ matrix $A = (a_{ij})$ a new matrix $\tilde{A} = (\tilde{a}_{ij})$ defined by

$$\tilde{a}_{ii} = a_{ii} \quad \text{for} \quad i = 1, 2, \dots, n \tag{1.3}$$

and

$$\tilde{a}_{ij} = -\frac{1 + \frac{1}{9} a_{ii}\tau_{ii}(3 + 2a_{ii}\tau_{ii})}{1 - \frac{1}{9} a_{ii}\tau_{ii}(3 + 2a_{ii}\tau_{ii})} |a_{ij}| \quad \text{for} \quad i \neq j, \quad j = 1, 2, \dots, n. \tag{1.4}$$

Now we can state our main result.

Theorem 1.3. *Assume that*

$$a_{ii}\tau_{ii} < \frac{3}{2} \quad \textit{for all} \quad i = 1, 2, \dots, n. \tag{1.5}$$

If $\tilde{A}$ is a nonsingular M-matrix, then every solution $(x_1(t), x_2(t), \dots, x_n(t))$ of (1.1) *tends to* 0 *as* $t \to \infty$.

Remark 1.1. Condition (1.5) will be referred to as the 3/2 condition. When $\tau_{ii} = 0$ for all $i = 1, \dots, n$, the 3/2 condition is automatically satisfied and $\tilde{A} = \hat{A}$. According to Bapat and Raghavan [1, Theorem 7.8.6], if $\hat{A}$ is a nonsingular M-matrix, then A itself is nonsingular. Hence, in the case of no diagonal delays, a matrix A satisfying the hypotheses of Theorem 1.3 will also satisfy the criterion in Theorem 1.1. The stability criterion in Theorem 1.3 is concrete and easily verifiable for any given (numerical) system.

Remark 1.2. There are many 3/2 stability results for scalar (linear or nonlinear, autonomous or nonautonomous, one or several delays) equations in the literature. See, for example, [11, 16, 15, 9, 12, 13]. It would be interesting to see if these results can be extended to systems.

Remark 1.3. In [8], besides the linear equation (1.1), the authors also considered global stability of Lotka–Volterra equations (with $\tau_{ii} = 0$). We are currently investigating the possibility of a 3/2 result for Lotka–Volterra systems when $\tau_{ii} > 0$.

2. Proof of Theorem 1.3. The proof of Theorem 1.3 consists of the following two lemmas. The first lemma establishes the boundedness of solutions of (1.1).

LEMMA 2.1. *Under the conditions of Theorem* 1.3, *every (forward) solution of* (1.1) *is bounded.*

Proof. Let $(x_1(t), x_2(t), \ldots, x_n(t))$ be a solution of (1.1) on $[t_0, \infty)$. Without loss of generality, t_0 can be taken to be 0. For the sake of contradiction, assume that $\max\{|x_i(t)| : i = 1, 2, \ldots, n\}$ is unbounded on $[t_0, \infty)$. By rearranging the indices i, we may assume that

$$\limsup_{t\to\infty} |x_i(t)| = \infty \quad \text{for} \quad i = 1, 2, \ldots, k(\leq n) \tag{2.1}$$

and

$$|x_i(t)| \leq M \quad \text{for} \quad t \geq t_0 - \max_{h,k}\{\tau_{hk}\}, \qquad i = k+1, \ldots, n. \tag{2.2}$$

Let N be the smallest integer such that $N > t_0 + \tau_{ii}$ for all i. There is an integer $N_1 > N$ such that for each $i = 1, \ldots, k$, the maximum of the function $|x_i(t)|$ on the interval $[t_0, N_1]$ is attained at a point in $[N, N_1]$. Fix $i = 1, \ldots, k$. For each integer $m \geq 1$, let $t_{im} \in [N, N_1 + m]$ be such that $|x_i(t_{im})| = \max\{|x_i(t)| : t \in [t_0, N_1 + m]\}$. We may assume that $\{t_{im}\}_{m=1}^{\infty}$ is a nondecreasing sequence. By going to subsequences if necessary, we have k sequences $\{t_{im}\}_{m=1}^{\infty}, i = 1, 2, \ldots, k$, such that

$$\left\{ \begin{array}{l} t_{im} \uparrow \infty, \quad |x_i(t_{im})| \uparrow \infty \quad \text{as} \quad m \to \infty, \\ |x_i(t)| \leq |x_i(t_{im})| \quad \text{for} \quad t_0 \leq t \leq t_m, \end{array} \right. \qquad \text{for} \quad i = 1, 2, \ldots, k, \tag{2.3}$$

where $t_m = \max\{t_{im} : i = 1, 2, \ldots, k\}$. Again by going to subsequences if necessary, we may assume that for each $i = 1, \ldots, k$, all the terms in the sequence $\{x_i(t_{im})\}_{m=1}^{\infty}$ are of the same sign. Without loss of generality (i.e., by using $-x_i(t)$ instead of $x_i(t)$ and $-a_{ij}$ instead of a_{ij} for $j \neq i$, if necessary), we may assume that $|x_i(t_{im})| = x_i(t_{im})$. Then

$$|x_i(t)| \leq x_i(t_{im}) \quad \text{for} \quad t_0 \leq t < t_m \qquad \text{and} \qquad \dot{x}_i(t_{im}) \geq 0, \qquad i = 1, 2, \ldots, k.$$

It follows from (1.1) that

$$0 \leq -\sum_{j=1}^{n} a_{ij} x_j(t_{im} - \tau_{ij}) \leq -a_{ii} x_i(t_{im} - \tau_{ii}) + \sum_{j\neq i}^{k} |a_{ij}| x_j(t_{jm}) + M \sum_{j=k+1}^{n} |a_{ij}|$$

or

$$x_i(t_{im} - \tau_{ii}) \leq \frac{1}{a_{ii}} \left[\sum_{j\neq i}^{k} |a_{ij}| x_j(t_{jm}) + M \sum_{j=k+1}^{n} |a_{ij}| \right], \qquad i = 1, 2, \ldots, k. \tag{2.4}$$

Set

$$\alpha_i = \frac{1}{a_{ii}} \left[\sum_{j\neq i}^{k} |a_{ij}| x_j(t_{jm}) + M \sum_{j=k+1}^{n} |a_{ij}| \right], \qquad i = 1, 2, \ldots, k. \tag{2.5}$$

We will now show

$$a_{ii} x_i(t_{im}) + \sum_{j\neq i}^{k} \tilde{a}_{ij} x_j(t_{jm}) \leq M \sum_{j=k+1}^{n} |\tilde{a}_{ij}| \quad \text{for} \quad i = 1, 2, \ldots, k. \tag{2.6}$$

If $x_i(t_{im}) \leq \alpha_i$, then (2.6) follows from a simple calculation. If $x_i(t_{im}) > \alpha_i$, by (2.4) there exists $\xi_{im} \in [t_{im} - \tau_{ii}, t_{im}]$ such that $x_i(\xi_{im}) = \alpha_i$. From (1.1) we have

$$\dot{x}_i(t) \leq a_{ii}[-x_i(t-\tau_{ii}) + \alpha_i] \leq a_{ii}\left(|x_i(t_{im})| + \alpha_i\right) \quad \text{for} \quad N \leq t \leq t_m. \tag{2.7}$$

For $t \in [\xi_{im}, t_{im})$, integrating (2.7) from $t - \tau_{ii}$ to ξ_{im}, we have

$$\alpha_i - x_i(t-\tau_{ii}) \leq a_{ii}\left(|x_i(t_{im})| + \alpha_i\right)(\xi_{im} + \tau_{ii} - t) \quad \text{for} \quad \xi_{im} \leq t \leq t_{im}.$$

Substituting this into the first inequality in (2.7), we obtain

$$\dot{x}_i(t) \leq a_{ii}^2\left(|x_i(t_{im})| + \alpha_i\right)(\xi_{im} + \tau_{ii} - t) \quad \text{for} \quad \xi_{im} \leq t \leq t_{im}.$$

Combining this and (2.7), we have

$$\dot{x}_i(t) \leq a_{ii}\left(|x_i(t_{im})| + \alpha_i\right)\min\{1, a_{ii}(\xi_{im} + \tau_{ii} - t)\} \quad \text{for} \quad \xi_{im} \leq t \leq t_{im}. \tag{2.8}$$

We consider the following two cases.

Case 1. $t_{im} - \xi_{im} \leq 2\tau_{ii}/3$. In this case, by (2.8) we have

$$\begin{aligned} x_i(t_{im}) - x_i(\xi_{im}) &\leq a_{ii}^2\left(|x_i(t_{im})| + \alpha_i\right)\int_{\xi_{im}}^{t_{im}} (\xi_{im} + \tau_{ii} - t)dt \\ &= a_{ii}^2\left(|x_i(t_{im})| + \alpha_i\right)\left[\tau_{ii}(t_{im} - \xi_{im}) - \frac{1}{2}(t_{im} - \xi_{im})^2\right] \\ &\leq \left(|x_i(t_{im})| + \alpha_i\right)\left[\frac{2}{3}(a_{ii}\tau_{ii})^2 - \frac{2}{9}(a_{ii}\tau_{ii})^2\right] \\ &= \frac{4}{9}(a_{ii}\tau_{ii})^2\left(|x_i(t_{im})| + \alpha_i\right) \\ &\leq \frac{1}{9}a_{ii}\tau_{ii}(3 + 2a_{ii}\tau_{ii})\left(|x_i(t_{im})| + \alpha_i\right), \end{aligned}$$

since the function $y \mapsto \tau_{ii}y - \frac{1}{2}y^2$ is increasing on the interval $[0, \frac{2\tau_{ii}}{3}]$.

Case 2. $t_{im} - \xi_{im} > 2\tau_{ii}/3$. In this case, let $t_{im} - \eta_{im} = 2\tau_{ii}/3$ so that $\eta_{im} \in (\xi_{im}, t_{im}]$. Then by (2.8) we have

$$\begin{aligned} &x_i(t_{im}) - x_i(\xi_{im}) \\ &\leq \left(|x_i(t_{im})| + \alpha_i\right)\left[a_{ii}(\eta_{im} - \xi_{im}) + a_{ii}^2\int_{\eta_{im}}^{t_{im}} (\xi_{im} + \tau_{ii} - t)dt\right] \\ &= \left(|x_i(t_{im})| + \alpha_i\right)\left[a_{ii}(\eta_{im} - \xi_{im})(1 - a_{ii}(t_{im} - \eta_{im})) + a_{ii}^2\int_{\eta_{im}}^{t_{im}} (\eta_{im} + \tau_{ii} - t)dt\right] \\ &= \left(|x_i(t_{im})| + \alpha_i\right)\left[a_{ii}(\eta_{im} - \xi_{im})\left(1 - \frac{2}{3}a_{ii}\tau_{ii}\right)\right. \\ &\qquad\qquad \left. + \, a_{ii}^2\tau_{ii}(t_{im} - \eta_{im}) - \frac{1}{2}a_{ii}^2(t_{im} - \eta_{im})^2\right] \\ &\leq \left(|x_i(t_{im})| + \alpha_i\right)\left[\frac{1}{3}a_{ii}\tau_{ii} + \frac{2}{9}(a_{ii}\tau_{ii})^2\right] \\ &= \frac{1}{9}a_{ii}\tau_{ii}(3 + 2a_{ii}\tau_{ii})\left(|x_i(t_{im})| + \alpha_i\right), \end{aligned}$$

since $\eta_{im} - \xi_{im} \leq \frac{\tau_{ii}}{3}$ in this case.

Combining Cases 1 and 2, we have

$$\begin{aligned} &a_{ii}x_i(t_{im}) \\ &\le \frac{1+\frac{1}{9}a_{ii}\tau_{ii}(3+2a_{ii}\tau_{ii})}{1-\frac{1}{9}a_{ii}\tau_{ii}(3+2a_{ii}\tau_{ii})}\left[\sum_{j\neq i}^{k}|a_{ij}|x_j(t_{jm})+M\sum_{j=k+1}^{n}|a_{ij}|\right], \qquad i=1,2,\dots,k, \end{aligned}$$

which implies (2.6) is true.

Let $\tilde{A}_k=(\tilde{a}_{ij})_{k\times k}$ denote the kth leading principal submatrix of $\tilde{A}$. Then $\tilde{A}_k$ is a nonsingular M-matrix of order k, and so $\tilde{A}_k^{-1}>0$. Hence, it follows from (2.6) that

$$(x_1(t_{1m}),x_2(t_{2m}),\dots,x_k(t_{km}))^T\le M\tilde{A}_k^{-1}\left(\sum_{j=k+1}^{n}|\tilde{a}_{1j}|,\sum_{j=k+1}^{n}|\tilde{a}_{2j}|,\dots,\sum_{j=k+1}^{n}|\tilde{a}_{kj}|\right)^T, \quad m=1,2,\dots.$$

We conclude that

$$\limsup_{m\to\infty}|x_i(t_{im})|<\infty, \qquad i=1,2,\dots,k.$$

This contradicts the fact that $|x_i(t_{im})|\to\infty$ as $m\to\infty$ for $i=1,2,\dots,k$, and the proof is complete.

Next, using the boundedness of solutions, we can prove the convergence of all solutions of (1.1).

LEMMA 2.2. *Under the conditions of Theorem* 1.3*, every solution of* (1.1) *tends* 0 *as* $t\to\infty$.

Proof. Let $(x_1(t),x_2(t),\dots,x_n(t))$ be a solution of (1.1) on $[t_0,\infty)$. We will prove that

$$\lim_{t\to\infty}x_i(t)=0, \qquad i=1,2,\dots,n. \tag{2.9}$$

We distinguish the two cases.

Case A. All of the functions $\sum_{j=1}^{n}a_{ij}x_j(t-\tau_{ij})$, $i=1,2,\dots,n$, are nonoscillatory. Then the functions $\dot{x}_i(t)$ $(i=1,2,\dots,n)$ are eventually sign-definite, and so by Lemma 2.1, the limit $c_i=\lim_{t\to\infty}x_i(t)$ exists. By (1.1), $\dot{x}_i(t)$ converges as $t\to\infty$. Since $\dot{x}_i(t)$ is bounded, $x_i(t)$ is uniformly continuous and convergent. Therefore, $\lim_{t\to\infty}\dot{x}_i(t)=0$ for $i=1,2,\dots,n$, and we have

$$\sum_{j=1}^{n}a_{ij}c_j=0 \quad\text{for}\quad i=1,2,\dots,n.$$

It follows that

$$a_{ii}|c_i|-\sum_{j\neq i}|a_{ij}||c_j|\le 0 \quad\text{for}\quad i=1,2,\dots,n. \tag{2.10}$$

Set $\hat{A}=(\hat{a}_{ij})$, where $\hat{a}_{ii}=a_{ii}$ and $\hat{a}_{ij}=-|a_{ij}|$ for $j\neq i$. Then $\hat{A}\ge\tilde{A}$ and $\hat{A}$ has nonpositive off-diagonal entries. In view of [3, Theorem 2.5.4], the matrix $\hat{A}$ is also a nonsingular M-matrix. Since (2.10) can be expressed as the matrix inequality $\hat{A}(|c_1|,\dots,|c_n|)^T\le(0,\dots,0)^T$, by applying the positive matrix $\hat{A}^{-1}$ to both sides, we conclude that $c_1=c_2=\dots=c_n=0$.

Case B. At least one of the functions $\sum_{j=1}^{n} a_{ij}x_j(t-\tau_{ij})$ $(i = 1, 2, \ldots, n)$ is oscillatory. Set

$$U_i = \limsup_{t\to\infty} |x_i(t)|, \qquad i = 1, 2, \ldots, n.$$

By Lemma 2.1, we have $U_i < \infty$, $i = 1, 2, \ldots, n$. It suffices to prove that $U_1 = \cdots = U_n = 0$. By rearranging the indices, we may assume that $\sum_{j=1}^{n} a_{ij}x_j(t-\tau_{ij})$, $i = 1, \ldots, k$, are oscillatory and $\sum_{j=1}^{n} a_{ij}x_j(t-\tau_{ij})$, $i = k+1, \ldots, n$, are nonoscillatory. It follows from (1.1) that $\dot{x}_i(t)$ $(i = 1, 2, \ldots, k)$ are oscillatory and

$$\lim_{t\to\infty} \dot{x}_i(t) = 0 \quad \text{for} \quad i = k+1, \ldots, n. \tag{2.11}$$

Hence, for any $\epsilon > 0$, there exist k sequences $\{t_{im}\}$ $i = 1, 2, \ldots, k$, such that

$$\begin{cases} t_{im} \uparrow \infty, \quad |x_i(t_{im})| \to U_i \quad \text{as} \quad m \to \infty, \\ |\dot{x}_i(t_{im})| = 0, \quad U_i - \epsilon < |x_i(t)| < U_i + \epsilon \quad \text{for} \quad t \ge t_1, \end{cases} \qquad i = 1, 2, \ldots, k, \tag{2.12}$$

where $t_1 = \min\{t_{i1} : i = 1, 2, \ldots, k\}$. By going to subsequences if necessary, we may assume $|x_i(t_{im})| = x_i(t_{im})$ (use $-x_i(t)$ instead of $x_i(t)$ and $-a_{ij}$ instead of a_{ij} for $j \ne i$, if necessary). By (1.1), as long as m is sufficiently large, we have

$$0 = -\sum_{j=1}^{n} a_{ij}x_j(t_{im}-\tau_{ij}) \le -a_{ii}x_i(t_{im}-\tau_{ii}) + \sum_{j\ne i}^{n} |a_{ij}|(U_j+\epsilon)$$

or

$$x_i(t_{im}-\tau_{ii}) \le \frac{1}{a_{ii}} \sum_{j\ne i}^{n} |a_{ij}|(U_j+\epsilon), \qquad i = 1, 2, \ldots, k. \tag{2.13}$$

Set

$$\beta_i = \frac{1}{a_{ii}} \sum_{j\ne i}^{n} |a_{ij}|(U_j+\epsilon), \qquad i = 1, 2, \ldots, k. \tag{2.14}$$

We will now show

$$a_{ii}x_i(t_{im}) + \sum_{j\ne i} \tilde{a}_{ij}(U_j+\epsilon) \le \frac{2\epsilon a_{ii}\tau_{ii}(3+2a_{ii}\tau_{ii})}{9-a_{ii}\tau_{ii}(3+2a_{ii}\tau_{ii})}, \qquad i = 1, 2, \ldots, k. \tag{2.15}$$

If $x_i(t_{im}) \le \beta_i$, then (2.15) obviously holds. If $x_i(t_{im}) > \beta_i$, by (2.13) there exists $\xi_{im} \in [t_{im}-\tau_{ii}, t_{im}]$ such that $x_i(\xi_{im}) = \beta_i$. Using (1.1), for m sufficiently large we have

$$\dot{x}_i(t) \le a_{ii}[-x_i(t-\tau_{ii}) + \beta_i] \le a_{ii}\left[(U_i+\epsilon) + \beta_i\right] \quad \text{for} \quad \xi_{im} - \tau_{ii} \le t \le t_{im}. \tag{2.16}$$

For $t \in [\xi_{im}, t_{im})$, integrating (2.16) from $t-\tau_{ii}$ to ξ_{im}, we have

$$\beta_i - x_i(t-\tau_{ii}) \le a_{ii}\left[(U_i+\epsilon)+\beta_i\right](\xi_{im}+\tau_{ii}-t) \quad \text{for} \quad \xi_{im} \le t \le t_{im}.$$

Substituting this into the first inequality in (2.16), we obtain

$$\dot{x}_i(t) \le a_{ii}^2\left[(U_i+\epsilon)+\beta_i\right](\xi_{im}+\tau_{ii}-t) \quad \text{for} \quad \xi_{im} \le t \le t_{im}.$$

Combining this and (2.16), we have

$$\dot{x}_i(t) \le a_{ii}\left[(U_i+\epsilon)+\beta_i\right]\min\{1, a_{ii}(\xi_{im}+\tau_{ii}-t)\}, \qquad \xi_{im}\le t\le t_{im}. \tag{2.17}$$

We consider the following two cases.

Case 1. $t_{im}-\xi_{im}\le 2\tau_{ii}/3$. In this case, by (2.17) we have

$$\begin{aligned}
x_i(t_{im})-x_i(\xi_{im}) &\le a_{ii}^2\left[(U_i+\epsilon)+\beta_i\right]\int_{\xi_{im}}^{t_{im}}(\xi_{im}+\tau_{ii}-t)dt\\
&= a_{ii}^2\left[(U_i+\epsilon)+\beta_i\right]\left[\tau_{ii}(t_{im}-\xi_{im})-\frac{1}{2}(t_{im}-\xi_{im})^2\right]\\
&\le \left[(U_i+\epsilon)+\beta_i\right]\left[\frac{2}{3}(a_{ii}\tau_{ii})^2-\frac{2}{9}(a_{ii}\tau_{ii})^2\right]\\
&= \frac{4}{9}(a_{ii}\tau_{ii})^2\left[(U_i+\epsilon)+\beta_i\right]\\
&\le \frac{1}{9}a_{ii}\tau_{ii}(3+2a_{ii}\tau_{ii})\left[(U_i+\epsilon)+\beta_i\right]\\
&= \frac{1}{9}a_{ii}\tau_{ii}(3+2a_{ii}\tau_{ii})\left[(U_i-\epsilon)+\beta_i+2\epsilon\right]
\end{aligned}$$

by the 3/2 condition (1.5).

Case 2. $t_{im}-\xi_{im}>2\tau_{ii}/3$. In this case, let $t_{im}-\eta_{im}=2\tau_{ii}/3$. Then $\eta_{im}\in(\xi_{im},t_{im}]$. By (2.17), we have

$$\begin{aligned}
&x_i(t_{im})-x_i(\xi_{im})\\
&\le \left[(U_i+\epsilon)+\beta_i\right]\left[a_{ii}(\eta_{im}-\xi_{im})+a_{ii}^2\int_{\eta_{im}}^{t_{im}}(\xi_{im}+\tau_{ii}-t)dt\right]\\
&= \left[(U_i+\epsilon)+\beta_i\right]\left[a_{ii}(\eta_{im}-\xi_{im})(1-a_{ii}(t_{im}-\eta_{im}))+a_{ii}^2\int_{\eta_{im}}^{t_{im}}(\eta_{im}+\tau_{ii}-t)dt\right]\\
&= \left[(U_i+\epsilon)+\beta_i\right]\left[a_{ii}(\eta_{im}-\xi_{im})\left(1-\frac{2}{3}a_{ii}\tau_{ii}\right)+a_{ii}^2\tau_{ii}(t_{im}-\eta_{im})-\frac{1}{2}a_{ii}^2(t_{im}-\eta_{im})^2\right]\\
&\le \left[(U_i+\epsilon)+\beta_i\right]\left[\frac{1}{3}a_{ii}\tau_{ii}+\frac{2}{9}(a_{ii}\tau_{ii})^2\right]\\
&= \frac{1}{9}a_{ii}\tau_{ii}(3+2a_{ii}\tau_{ii})\left[(U_i+\epsilon)+\beta_i\right]\\
&= \frac{1}{9}a_{ii}\tau_{ii}(3+2a_{ii}\tau_{ii})\left[(U_i-\epsilon)+\beta_i+2\epsilon\right],
\end{aligned}$$

since $\eta_{im}-\xi_{im}\le\frac{\tau_{ii}}{3}$.

Combining Cases 1 and 2 with (2.12), we have

$$\begin{aligned}
&a_{ii}x_i(t_{im})\\
&\le \frac{1+\frac{1}{9}a_{ii}\tau_{ii}(3+2a_{ii}\tau_{ii})}{1-\frac{1}{9}a_{ii}\tau_{ii}(3+2a_{ii}\tau_{ii})}\sum_{j\ne i}|a_{ij}|(U_i+\epsilon)+\frac{2\epsilon a_{ii}\tau_{ii}(3+2a_{ii}\tau_{ii})}{9-a_{ii}\tau_{ii}(3+2a_{ii}\tau_{ii})}, \qquad i=1,2,\ldots,k.
\end{aligned}$$

This shows (2.15) is true. Letting $m\to\infty$ and $\epsilon\to 0$ in (2.15), we obtain

$$a_{ii}U_i+\sum_{j\ne i}\tilde{a}_{ij}U_j\le 0 \quad \text{for} \quad i=1,2,\ldots,k. \tag{2.18}$$

On the other hand, for each $i = k+1, \dots, n$, let $\{s_{im}\}_{m=1}^{\infty} \uparrow \infty$ be such that $\lim_{m\to\infty} x_i(s_{im}) = U_i$. By (2.11), we have $\lim_{m\to\infty} \dot{x}_i(s_{im} + \tau_{ii}) = 0$. Using (1.1), we have

$$\begin{aligned} 0 &= \dot{x}_i(s_{im} + \tau_{ii}) + a_{ii}x_i(s_{im}) + \sum_{j\neq i} a_{ij}x_j(s_{im} + \tau_{ii} - \tau_{ij}) \\ &\geq \dot{x}_i(s_{im} + \tau_{ii}) + a_{ii}x_i(s_{im}) + \sum_{j\neq i} \tilde{a}_{ij}|x_j(s_{im} + \tau_{ii} - \tau_{ij})|, \end{aligned}$$

since $\tilde{a}_{ij} \leq -|a_{ij}| \leq 0$. Letting $m \to \infty$, we obtain

$$a_{ii}U_i + \sum_{j\neq i} \tilde{a}_{ij}U_j \leq 0 \quad \text{for} \quad i = k+1, \dots, n. \tag{2.19}$$

By (2.17) and (2.18) and using the fact that $\tilde{A}$ is a nonsingular M-matrix (so that $\tilde{A}^{-1}$ is a positive matrix), we have $U_1 = U_2 = \cdots = U_n = 0$. The proof is now complete.

Acknowledgments. The authors would like to thank the two anonymous referees for their useful suggestions regarding additional references.

PATH-TRACKING THROUGH SINGULARITIES*

G. W. REDDIEN†

Abstract. Given a mapping F from R^n to R^m with $n \geq m$, a basic computational problem that has applications in robotics is to solve for paths $x(t)$ in the domain of F given a target path $z(t)$ in the range of F so that $F(x(t)) = z(t)$. Results are given for the existence and characterization of solution paths through singularities of F, with emphasis on folds and cusps. Reparametrizations using Puiseux series are derived in cases where $x(t)$ is not differentiable.

1. Introduction.

A motivating example for the problems treated here is a three-bar mechanism, or arm, constrained to move in the plane. Given joint lengths l_1, l_2, l_3 and joint angles θ_1, θ_2, and θ_3 as indicated in Figure 1, the coordinates of the point P are determined. Indeed, it follows that coordinates are given by the formulas

$$\begin{aligned} z_1 &= l_1 \cos\theta_1 + l_2 \cos(\theta_1 + \theta_2) + l_3 \cos(\theta_1 + \theta_2 + \theta_3), \\ z_2 &= l_1 \sin\theta_1 + l_2 \sin(\theta_1 + \theta_2) + l_3 \sin(\theta_1 + \theta_2 + \theta_3) \end{aligned} \tag{1.1}$$

defining a mapping F from R^3 to R^2. If the motion of the links is constrained by $a_i \leq \theta_i \leq b_i$, $i = 1, 2, 3$, then the change of variables

$$\theta_i = \frac{a_i + b_i}{2} + \frac{1}{2}(b_i - a_i)\sin x_i, \qquad i = 1, 2, 3, \tag{1.2}$$

produces $F = F(x)$, where x lies in any open set D containing $[-\pi/2, \pi/2]^3$. Although simple in form, this device contains many of the kinematic singularities important in robotics. An example of a spatial manipulator is given in section 4.

Let $F : R^n \to R^m$ with $n \geq m$ be a smooth mapping defined on an open, connected set $D \subset R^n$, and let $z_0 = F(x_0)$. We call z_0 a boundary point (local) for $F(D)$ if there exists an open neighborhood U of x_0 so that z_0 is not in the interior of $F(U)$. Equivalently, we could say that z_0 is a boundary point of F at $F(x_0) = z_0$ if F is not open at x_0. The system of equations

$$\hat{F}(x, z) = F(x) - z = 0 \tag{1.3}$$

represents m-equations in $(n + m)$-unknowns. If $\hat{F}_x(x_0, z_0) = F_x(x_0)$ has full rank, then the implicit function theorem guarantees that (1.3) can be solved for all z near z_0; that is, if $F_x(x_0)$ has full rank, then $z_0 = F(x_0)$ is not a boundary point of $F(D)$. Thus the problem of determining the boundary of $F(D)$ is closely related to the problem of finding points where F_x drops in rank. We assume throughout this paper that

$$\operatorname{rank}(F_x) \geq m - 1 \text{ on } D, \tag{H1}$$

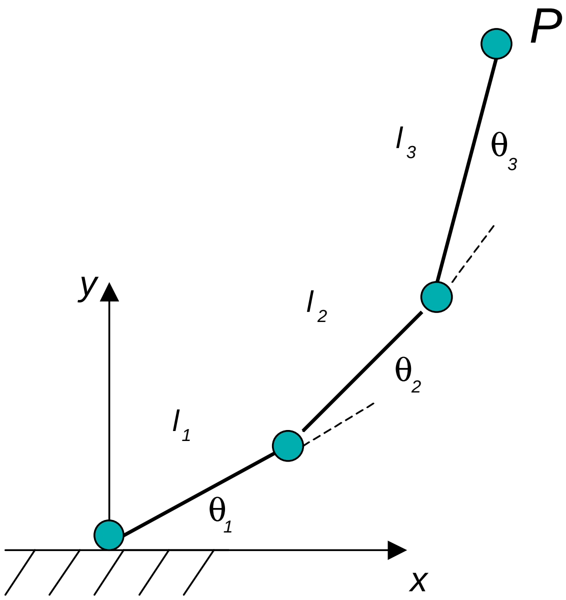

FIG. 1. *A planar manipulator.*

and define the singular set

$$S_1 = \{x \in D : \mathrm{rank}(F_x) = m - 1\}.$$

Then the boundary of $F(D)$ is contained in $F(S_1)$.

A basic computational problem in the study of mechanical devices such as the one represented by (1.1) is path-tracking, that is, to solve the equation

$$F(x(t)) = z(t) \tag{1.4}$$

for $x(t)$, where $z(t)$ is a given, parametrized path in the reachable set $F(D)$. At points where $F_x(x(t))$ has full rank, there is in principle no problem in solving (1.4) for a smooth path $x(t)$. But computational problems arise if $x(t)$ goes through a singularity. For the three-bar mechanism in Figure 1, let the motion be unconstrained. Then singularities exist for $\theta_3 = 0$ or π, for example, configurations likely to be encountered. The difficulties include possible lack of existence of solutions to (1.4) or existence without smoothness in the parameter t.

The purpose of this paper is to consider path-tracking through singularities. We use a unified framework for computing singularities (see [6]) which leads to efficient characterizations of the singular boundary and, as we show, to the criteria needed to establish the existence and smoothness of paths through singularities. Our primary focus is on the fold and the cusp cases. The method given for numerically computing and analyzing points where F has a rank drop is based on an implicit Liapunov–Schmidt reduction and has been shown to be useful in many applications. See, for example, [6], [7], [8], [9], and [16]. In section 2, we show how this reduction can be used to compute efficiently the various quantities that are needed in our analysis. In section 3, we use the formulas of section 2 to study the path-tracking problem in the smooth case. We relate path-tracking to classical results in singularity theory in section 4 and show how the results of section 3 can be modified to treat two basic nonsmooth cases.

2. Reduction. In this section we present a scalar function developed in [7], [8] that can be used to locate and characterize singularities. Functions that serve this purpose are often called test functions [17], and a natural choice is $\det(F_x)$. Indeed, this choice is used in the engineering literature [4], although the smallest singular value of F_x is also common [16]. Important advantages of the test function given below are its simple definition and evaluation, the existence of explicit derivative formulas with natural and inexpensive numerical approximations, and the fact that the approach provides a unified framework for turning points, bifurcation points, cusp points, and other higher order singularities and is applicable to maps F from R^n into R^m with $n > m$. These different cases generally entail ad hoc approaches in the engineering literature. These advantages are discussed further below.

Choose $r \in R^m$ and $T \in R^{p\times n}$ with $p = n - m + 1$ so that the bordered matrix

$$A = \begin{pmatrix} F_x & r \\ T & 0 \end{pmatrix}$$

is nonsingular on a neighborhood of a point x_0 in D. Consider the system of $(n+1)$-equations in the variables x, $f \in R$, and $s \in R^p$ given by

$$\begin{aligned} F - fr &= F(x_0), \\ Tx &= s + Tx_0. \end{aligned} \tag{2.1}$$

Note that $x = x_0$, $f = 0$, and $s_0 = 0$ is a solution to (2.1). The linearization of (2.1) in x and f at this point gives the matrix A (solving for $-f$), and so by the implicit function theorem, (2.1) defines $f = f(s)$ and $x = x(s)$ for s in a neighborhood of $s = 0$. We also note the following two systems for finding f_s, which is a row vector and equals the transpose of the gradient of f in s, and $H(f)$, the corresponding Hessian of f, which results from differentiating (2.1):

$$\begin{aligned} &F_x x_s - r f_s = 0, \quad && F_x x_{s_i s} - r f_{s_i s} = -F_{xx} x_{s_i} x_s, \\ &T x_s = I_p, && T x_{s_i s} = \ 0, \end{aligned} \tag{2.2}$$

$i = 1, \ldots, p$, where I_p is the $p \times p$ identity matrix. As in [6] and [7], define $u \in R^m$ to be the solution to (an exponent t denotes transpose, not time)

$$\begin{aligned} u^t F_x - f_s T &= 0, \\ u^t r &= 1. \end{aligned} \tag{2.3}$$

An easy calculation [7] shows that f_s may be used in both (2.2) and (2.3) and moreover that

$$f_s = u^t F_x x_s. \tag{2.4}$$

Writing $x_s = (v_1, v_2, \ldots, v_p)$, then the Hessian of f, $H(f)$, is given by $H(f) = (h_{ij})$ where $h_{ij} = u^t F_{xx} v_i v_j$. The Hessian matrix H is $p \times p$ and, of course, symmetric. The scalar function f is known in the literature as an implicit Liapunov–Schmidt reduction of F near x_0. This reduction has several advantages, both conceptually and computationally, over a standard Liapunov–Schmidt reduction [5]. The clearest and most important distinction is that the reduction does not depend on the a priori location of a point x_0 for which F_x has a rank drop. The systems (2.2) are solvable even if $F_x(x_0)$ has rank $m-1$. If $F_x^0 = F_x(x_0)$ has a rank drop, then from (2.4), $u_0^t F_x^0 = 0$ and so $f_s(0) = 0$. Points where the mapping F has a rank drop correspond to singular points for the reduced scalar function f.

Note that f defined in (2.1) depends on the vector r. The first equation in (2.1) can be written as $F(x) = F(x_0) + fr$, and so solutions to (2.1) are points x so that F hits points in the range moving along r from $F(x_0)$. In the case of (1.1), we could choose r to be the one-parameter family of radius vectors from the origin defined by the angle r makes with the abscissa in R^2. From (2.3) we can find points in the singular set, S_1, by solving the equation

$$f_s = 0. \tag{2.5}$$

The system (2.5) is square in general: p-equations in p-unknowns. In the case of (1.1) it represents two equations in two unknowns; the choice of r makes (2.5) have an extra variable, and so r can be varied and S_1 traced out.

This reduction can be used to determine whether a point $z_0 = F(x_0)$ is a boundary point. The following proposition can be found in [20]. Minimal smoothness assumptions on F are given there. In order to simplify the presentation given here, we will simply assume throughout that F is smooth. Recall the earlier assumption (H1) that $\operatorname{rank}(F_x) \geq m-1$ on D.

Theorem 2.1 (Griewank). *Let* (H1) *hold. Then the mapping F is open at x_0 if and only if the reduced function f defined in* (2.1) *is open at the origin.*

If F is not open at x_0, then f will not be open at the origin. Since f is a scalar function, then f must have an extremum at the origin, and f will not be open if it has either a maximum or a minimum. This can be checked in most cases by determining if the Hessian of f is negative or positive definite. In the case that H is semidefinite, higher order criteria must be used to determine if f has a maximum or a minimum (or neither). Then for $x_0 \in S_1, F(x_0)$ is a candidate to be a boundary point. At $x_0, f_s(0) = 0$. One can then compute H from (2.2). If H is indefinite, then $F(x_0)$ is not a boundary point. If H is either positive or negative definite, $F(x_0)$ is a local boundary point. The mechanism is then constrained locally, that is, $F(x_0)$ is a barrier point. Other points near $F(x_0)$ may be reachable, but they are then the image of points x not near x_0. Finally, if H is semidefinite, a higher order expansion and further analysis are necessary. We summarize these conclusions in the next theorem.

Theorem 2.2. *Let* (H1) *hold and let $x_0 \in S_1$. Then f defined by* (2.1) *satisfies $f_s(0) = 0$. If H_0 is negative definite, f has a maximum at $s = 0$ and x_0 is the preimage of a local boundary point. If H_0 is positive definite, then f has a minimum at $s = 0$ and x_0 is the preimage of a local boundary point. If H_0 is indefinite, then $F(x_0)$ is not a boundary point.*

Restricting our attention to the case where if H is indefinite, then $\lambda = 0$ is a simple eigenvalue for H, the higher order cases can then be analyzed as follows. Let f be given from (2.1) with $x_0 \in S_1$ so that $f_s^0 = 0$. We assume $Hc_p = 0$ with $c_p^t c_p = 1$. Let $\{c_1, c_2, \ldots, c_p\}$ be a basis for R^p so that $s \in R^p$ may be written as $s = Ct$ where $C = (c_i)$. Define $\hat{f}(t) = f(s)$. Now it follows that $\hat{f}_t(0) = 0$ since $f_s(0) = 0$ and that $\hat{f}_{t_i t_j}(0) = c_i^t H c_j$. We have assumed that $Hc_p = 0$ and $Hc_i \neq 0$, $i = 1, \ldots, p-1$. Then it follows that $\hat{f}_{t_i t_p}(0) = c_i^t H c_p = 0$ and that by assumption the $(p-1) \times (p-1)$ submatrix $D = (\hat{f}_{t_i t_j})_{i=1,j=1}^{p-1,p-1}$ of $H(\hat{f})$ is nonsingular. Using the decomposition lemma of singularity theory [14], $\hat{f}$ is isomorphic to a germ of the form $Q(t_1, \ldots, t_p) + \phi(t_p)$

with $\phi \in M^3$ ($M^3 = M \cdot M \cdot M$ where M is the ideal of germs equal to zero at the origin) and Q is a Morse germ. Based on this form, one can classify the cases that occur when $\hat{f}$ has low codimension. In fact, every germ of corank 1 and of codimension $\nu \geq 2$ is isomorphic to one and only one of the following germs:

$$\begin{aligned} &\textstyle\sum_{i=1}^{p-1} \epsilon_i t_i^2 + t_p^{\nu+1}, \quad \epsilon_i = \pm 1, \quad \text{if } \nu \text{ is even,} \\ &\textstyle\sum_{i=1}^{p-1} \epsilon_i t_i^2 \pm t_p^{\nu+1}, \quad \epsilon_i = \pm 1, \quad \text{if } \nu \text{ is odd.} \end{aligned} \tag{2.6}$$

In the case where H is semidefinite, it is then possible using (2.6) to develop a corresponding classification for boundary points. First note from (2.6) that if ν is even, then x_0 cannot be a boundary point because of the odd-order monomial in (2.6). If ν is odd, then depending on the sign of the $t_p^{\nu+1}$-term, $F(x_0)$ may or may not be a boundary point. In order to determine whether or not $F(x_0)$ is a boundary point in the semidefinite case, one must translate the criteria from ϕ back to f, which is a computable function. We do not do this here but refer the reader to [20].

Since there is no explicit s-dependence in (2.2), we define $g(x) = f_s$ and $x_s = V \in R^{nxp}$. It also follows from (2.2) that $g_x = u^t F_{xx} V$. This notation is consistent with [6]. The set S_1 is defined by the solutions to $g(x) = 0$. Generically, one expects S_1 to be a manifold because g should have full rank. But in problems such as (1.1), this is not the case at many points. Indeed, in mechanical design problems, including (1.1), $F(S_1)$ can be complicated, with multiple bifurcation points. See the analysis of the planar manipulator in [10], for example, or the Stewart platform [13]. The analysis of bifurcations can be included in the framework here.

3. Smooth paths. We next use the mathematical framework of section 2 to analyze the path-tracking problem: Given a path $z(t)$ in the work space, find a smooth path $x(t)$ in the domain of the manipulator that satisfies the relation

$$F(x(t)) = z(t) \tag{3.1}$$

for t in some interval. The analysis to follow puts some of the results of [11], [12], [15], [17], and [18] into our framework and leads to a new form for solvability conditions and computational algorithms. With $F: R^n \to R^m$ and $n > m$, there should be several solution paths $x(t)$. Theorem 2.2 can be used to establish the existence of a path in the cases where F has a simple rank drop. Assuming for the moment the existence and differentiability of $x(t)$ solving (3.1), we differentiate and obtain the system of differential equations

$$F_x(x(t)) \frac{dx}{dt} = \frac{dz}{dt} \tag{3.2}$$

with the initial condition $F(x_0) = z_0$. In this section we develop conditions within our framework to guarantee that a solution path $x(t)$ with continuous and bounded derivatives exists through points in S_1.

Let $x(t_0) = x_0 = 0$ with $x_0 \in S_1$. We assume, as before, that (H1) holds for F in a neighborhood of x_0. From (2.4) we immediately find the consistency condition

$$u_0^t \dot{z}_0 = 0, \tag{3.3}$$

where we assume $\dot{z}_0 = \frac{dz}{dt}(t_0) \neq 0$. Extend u_0 to form a basis $u_0, u_1, \ldots, u_{m-1}$ for R^m. Then the system of equations (3.2) can be put into the form

$$\begin{aligned} &\text{(a)} \quad U_{m-1}^t F_x(x(t)) \dot{x}(t) = U_{m-1}^t \dot{z}(t), \\ &\text{(b)} \quad u_0^t F_x(x(t)) \dot{x}(t) = u_0^t \dot{z}(t), \end{aligned} \tag{3.4}$$

where $U_{m-1} = (u_1, \ldots, u_{m-1})$. Assuming the needed smoothness, we differentiate (3.2) to obtain the equation

$$F_x \ddot{x} + F_{xx}\dot{x}\dot{x} = \ddot{z}, \tag{3.5}$$

from which it follows that

$$u_0^t F_x \ddot{x} + u_0^t F_{xx}\dot{x}\dot{x} = u_0^t \ddot{z}. \tag{3.6}$$

We find it convenient to make the following change of variables: Let $x(t) = t\,y(t)$ so that $\dot{x} = y + t\dot{y}$ where, without loss in generality, we let $t_0 = 0$ and $x_0 = 0$ so that $\dot{x}_0 = y_0$. Then (3.4) and (3.6) may be written at $t_0 = 0$ in the form

$$\begin{aligned} &\text{(a)} \quad U_{m-1}^t F_x^0 y_0 = U_{m-1}^t \dot{z}_0, \\ &\text{(b)} \quad u_0^t \dot{z}_0 = 0, \\ &\text{(c)} \quad u_0^t F_{xx}^0 y_0 y_0 = u_0^t \ddot{z}_0. \end{aligned} \tag{3.7}$$

The original equation (3.1) may be similarly decomposed as

$$\begin{aligned} &\text{(a)} \quad U_{m-1}^t F(x(t)) = U_{m-1}^t z(t), \\ &\text{(b)} \quad u_0^t F(x(t)) = u_0^t z(t). \end{aligned} \tag{3.8}$$

Now in order to show solvability and then differentiability of solutions to (3.1), we must first show that y_0 solving (3.7) exists. This system is not necessarily solvable for any path $z(t)$. Since $u_0^t \dot{z}_0 = 0$, we have that $\dot{z}_0$ is in the range of F_x^0, and so we may solve $F_x^0 y = \dot{z}_0$ for $y_0 = y_1 + V_0\alpha$, where the columns of V_0 span the null space of F_x^0, $\alpha \in R^p$ is arbitrary, and $F_x^0 y_1 = \dot{z}_0$ for a chosen particular solution y_1. For definiteness, let $Ty_1 = 0$. Then clearly (3.7a)–(3.7b) are satisfied. Substituting into (3.7c) we obtain

$$u_0^t F_{xx}^0 (y_1 + V_0\alpha)(y_1 + V_0\alpha) = u_0^t \ddot{z}_0 \tag{3.9}$$

or

$$\alpha^t (u_0^t F_{xx}^0 V_0 V_0)\alpha + 2\, u_0^t F_{xx}^0 (V_0\alpha) y_1 + u_0^t F_{xx}^0 y_1 y_1 = u_0^t \ddot{z}_0\,. \tag{3.10}$$

Equation (3.10) is a quadratic in α; if $u_0^t F_{xx}^0 V_0 V_0 = H$ is positive or negative definite, then (3.10) has a minimum or a maximum, respectively, at $\hat{\alpha}$ satisfying $u_0^t F_{xx}^0 V_0 V_0 \hat{\alpha} = -u_0^t F_{xx}^0 V_0 y_1$. Then depending on the sign and magnitude of $u_0^t \ddot{z}_0$, (3.10) can be solved. We note the following result.

THEOREM 3.1. *Let $x_0 \in S_1$ and let $H_0 = u_0^t F_{xx}^0 V_0 V_0 = g_x^0 V_0$ be indefinite. Then* (3.7) *is solvable.*

Theorem 3.1 is consistent with the results of section 2. If H is definite, motion from x_0 is possible in only one direction along r from $z_0 = F(x_0)$. Motion is possible in any direction when H is indefinite. The case in which H is nonsingular is called the fold.

Still assuming the existence and smoothness of a path $x(t)$, Taylor's formula with remainder allows us to write F and z in the following two forms:

$$\begin{aligned} &\text{(a)} \quad F(x(t)) = F^0 + R_1(x)x(t), \\ &\text{(b)} \quad F(x(t)) = F^0 + F_x^0 x(t) + R_2(x)x(t)x(t), \\ &\text{(c)} \quad z(t) = z_0 + \hat{R}_1(\dot{z})t, \\ &\text{(d)} \quad z(t) = z_0 + \dot{z}_0 t + \hat{R}_2(\ddot{z})t^2. \end{aligned} \tag{3.11}$$

These equations simplify under our normalization conditions that $x_0 = 0$ and $F(x_0) = z_0 = 0$. Using (3.11a), (3.11c) in (3.8a) and (3.11b), (3.11d) in (3.8b) with $x(t) = ty(t)$, we obtain

$$\text{(3.12)} \qquad \begin{aligned} &\text{(a)} \quad U_{m-1}^t R_1(ty(t))y(t) = U_{m-1}^t \hat{R}_1(\dot{z}(t)), \\ &\text{(b)} \quad u_0^t R_2(ty(t))y(t)y(t) = u_0^t \hat{R}_2(\ddot{z}(t)) \end{aligned}$$

as equations equivalent to (3.1) and (3.8). Note that for $t = t_0 = 0$, the system (3.12) becomes (3.7). The system (3.12) has the solution $y = y_0$ at $t = 0$. We consider (3.12) as m-equations in the n-unknowns y and with t as a parameter. We next show by an application of the implicit function theorem that (3.12) is solvable under the assumptions of Theorem 3.1.

THEOREM 3.2. *Let H_0 be indefinite and $z(t)$ have three continuous derivatives in a neighborhood of t_0. Then* (3.12) *is solvable for $y = y(t)$ with y continuously differentiable in a neighborhood of t_0. Moreover, $x = ty$ is continuously differentiable and solves* (3.1). *Since* (3.12) *is $m \times n$ plus the parameter t, $n - m$ of the coordinates in y are arbitrary.*

Proof. Since H_0 is indefinite, (3.10) has at least two distinct solutions, α_1 and α_2. Define $y_0^i = y_1 + V_0\alpha_i$ and suppose $g_x^0 y_0^i = 0$ for $i = 1, 2$. Subtracting, we obtain that $g_x^0 V_0(\alpha_1 - \alpha_2) = u_0^t F_{xx}^0 V_0 V_0(\alpha_1 - \alpha_2) = 0$, contradicting the indefiniteness of H_0. Thus there exists some y_0 solving (3.7) so that $g_x^0 y_0 \neq 0$. Since (3.7) is solvable, (3.12) is solvable at the origin in t with solution y_0. Linearizing (3.12) in y at $(y_0, 0)$, we obtain the homogeneous problem

$$\text{(3.13)} \qquad \begin{aligned} U_{m-1}^t (D_y R_1)|_{(y_0,0)} y_0 y + U_{m-1}^t F_x^0 y = 0, \\ u_0^t (D_y R_2)|_{(y_0,0)} y_0 y_0 y + \tfrac{1}{2} u_0^t F_{xx}^0 y_0 y = 0 \end{aligned}$$

to be solved for y. Since R_1 and R_2 contain the term ty, both derivatives in y are multiplied by t and so vanish at $t_0 = 0$. Thus (3.13) simplifies to

$$\text{(3.14)} \qquad \begin{aligned} &\text{(a)} \quad U_{m-1}^t F_x^0 y = 0, \\ &\text{(b)} \quad u_0^t F_{xx}^0 y_0 y = 0. \end{aligned}$$

The $(m \times n)$-dimensional system (3.14) has full rank in y at $t_0 = 0$ if the number of independent null vectors y is $n - m$. Equation (3.14a) has $p = n - m + 1$ solutions, namely V_0. Writing $y = V_0\alpha$ and substituting into (3.14b) give the equation

$$\text{(3.15)} \qquad \alpha^t (u_0^t F_{xx}^0 V_0 y_0) = 0,$$

or $\alpha^t (g_x^0 y_0) = 0$. Since $g_x^0 y_0 \neq 0$, (3.15) can have at most $(p-1)$ independent solutions α. Then y lies in a $(p - 1 = n - m)$-dimensional space, giving the implicit function theorem and the existence of $y(t)$. The smoothness assertion also follows from the implicit function theorem.

Remarks. If a solution to (3.10) exists satisfying the condition $g_x^0 y_0 \neq 0$ and if also the necessary condition (3.3) holds, then a smooth path of solutions to (3.1) exists. Theorem 3.2 gives a simple condition for this to happen. If the condition $g_x^0 y_0 \neq 0$ fails to hold, then $\dot{x}_0$ is tangent to S_1. Define $\mathcal{F}(y, t)$ to be the equations given in (3.12) written in the form $\mathcal{F}(y, t) = 0$. Left null vectors for $\mathcal{F}_y^0$ of the form $(\xi^t \, \nu)^t$ must solve

$$\text{(3.16)} \qquad \xi^t U_{m-1}^t F_x^0 + \nu u_0^t F_{xx}^0 y_0 = 0.$$

By the Fredholm alternative, (3.16) is solvable with nonzero ν if and only if $u_0^t F_{xx}^0 V_0 y_0 = g_x^0 y_0 = 0$. If $g_x^0 y_0 \neq 0$, then $\nu = 0$ and $\xi = 0$ since u_0 is assumed to be the only left null vector. Thus we see that $g_x^0 y_0 \neq 0$ implies $\mathcal{F}_y^0$ has full rank, giving a slightly different proof of Theorem 3.2. The condition that $\dot{x}_0$ is tangent to S_1 corresponds to a rank drop for (3.13). This means that $\mathcal{F}$ likely has a turning point or bifurcation point, and the existence of solutions is still possible. We do not pursue these cases here.

We next consider briefly the special case of self-motions [15]: These are paths $x(t)$ for which $F(x(t))$ is fixed. In the unconstrained three-bar mechanism of Figure 1, let $l_2 = l_3$. Then a self-motion obtains by holding θ_1 fixed and $\theta_3 = \pi$ and letting θ_2 vary. For redundant manipulators $(n > m)$, it is possible to use a self-motion to escape a singularity, which can be important in applications. We assume $z(t) = z_0$ with x_0 a singularity for F. Equation (3.3) is automatically satisfied and from (3.4) it follows that $\dot{x}_0$ is in the null space of F_x^0; that is, $y_0 = \dot{x}_0 = V_0\alpha$. Then (3.7c) becomes $u_0^t F_{xx}^0 y_0 y_0 = \alpha^t (u_0^t F_{xx}^0 V_0 V_0)\alpha = \alpha^t H \alpha = u_0^t \ddot{z}_0$. Solutions to this equation with $\alpha \neq 0$ require H to be indefinite. We then have the next theorem.

Theorem 3.3. *Using the definitions for self-motion through a singularity given above, let H be indefinite at x_0. Then there exists a nontrivial $y_0 = V_0\alpha$ satisfying $u_0^t F_{xx}^0 y_0 y_0 = 0$. In addition, there exists a solution $x(t)$ to* (3.1) *with two continuous derivatives and $\dot{x}_0 = y_0$.*

Proof. Write $x(t) = ty(t)$ as in the proof of Theorem 3.2. Since H is indefinite, then, in particular, H is nonsingular and $H\alpha \neq 0$ where the existence of $y_0 = V_0\alpha$ satisfying $\alpha^t H \alpha = 0$ was established above. This means that $g_x^0 V_0 \alpha \neq 0$ and so y_0 is not tangent to the singular manifold S_1. But then arguing exactly as in the proof of Theorem 3.2, the result follows.

Returning to the example above, the matrix H_0 has eigenvalues $-1 \pm 2\sqrt{2}$, and so the conditions of Theorem 3.3 are met. However, the self-motion is not the rotation described above but rather is one that has x_t^0 proportional to $(\,2\ 1\ 2)^t$. This leads to a self-motion that takes the robot to a nonsingular configuration. The rotation is a motion within the singular manifold.

Finally, we consider the case that the matrix H has a one-dimensional null space corresponding to $\nu = 2$ in (2.6). We add a nondegeneracy condition and establish the existence of a smooth path of solutions in the next theorem in the same manner as Theorem 3.2. Existence of a path also follows from Theorem 2.2 and (2.6). The conditions mean that F has a cusp singularity; details are given in section 4.

Theorem 3.4. *Let H_0 have a simple rank drop with null vector α_0 so that $u_0^t F_{xx}^0 v_0 v_0 = 0$ where $v_0 = V_0\alpha_0$. Define y_1 as the solution to $F_x^0 y_1 = \dot{z}_0$ with $Ty_1 = 0$, where z satisfies* (3.3) *and $\dot{z}_0 \neq 0$. In addition, let $u_0^t F_{xx}^0 v_0 y_1 \neq 0$. Then* (3.12) *is solvable for $y = y(t)$ with y continuously differentiable in a neighborhood of t_0. Moreover, $x = ty$ is continuously differentiable and solves* (3.1)*. Since* (3.12) *is $m \times n$ plus the parameter t, $n - m$ of the coordinates in y are arbitrary.*

Proof. As before, we write $x(t)$ in the form $x = ty$. We first note that by choosing α in (3.10) to be a scalar times α_0 where $v_0 = V_0\alpha_0$, then (3.10) is uniquely solvable. The quadratic term drops out with this choice. Arguing as in the proof of Theorem 3.2, the result follows if (3.14) has at most $(p-1)$ independent solutions. From (3.14a) it follows that $y = V_0\beta$. Substituting into (3.14b) gives the equation $\beta^t(u_0^t F_{xx}^0 V_0 y_0) = 0$, as before. Writing $y_0 = y_1 + V_0\alpha_0$, we obtain the equivalent equation $\beta^t(u_0^t F_{xx}^0 V_0 y_1) = 0$. But this equation is not satisfied if $\beta = \alpha_0$, and so (3.14) has $p - 1 = n - m$ independent solutions, completing the proof.

4. Nonsmooth solution paths.

In this section we study further the singularities in section 3 and relate the path-tracking problem for them to some classical results in singularity theory. Existence of solution paths in Theorem 3.2, the fold singularity, is problematical, but not in the case of Theorem 3.4, the cusp singularity. Conditions for the existence of smooth solutions were given in section 3. Singularity theory provides normal forms for these mappings that can be used to analyze their qualitative behavior. In particular, we show what can be done if smoothness is lost, which happens when condition (3.3) does not hold but paths still exist.

4.1. Singularity theory.

Two mappings F_1 and F_2 from manifolds X into Y are said to be equivalent if there exist diffeomorphisms $h : X \mapsto X$ and $k : Y \mapsto Y$ such that $F_2 = k \circ F_1 \circ h^{-1}$. A smooth map F is said to be stable if every map sufficiently near to it (including a sufficiently large number of derivatives) is equivalent to it. These definitions can be considered local [1]. Equivalence sets up a one-to-one correspondence between inverse images and singularities for the two maps. So if F_2 has a simpler form, qualitative results about F_1 can be derived. It is difficult to find the diffeomorphisms h and k. Nonetheless, an algorithm has been proposed for path-tracking through fold singularities based on computing the diffeomorphisms directly [18].

The fold and cusp singularities can be developed more formally as follows. Recall that S_1 denotes the set of points in X where F has a simple rank drop and that we have assumed F to have no other singularities. We need the regularity assumption that S_1 is a smooth manifold. Then $S_{1,1}$ is defined to be the points where F restricted to S_1 has a simple rank drop. Assuming $S_{1,1}$ is a smooth manifold, this definition may be continued.

We first consider the fold case. That is, we assume (H2) S_1 contains x_0, S_1 is a locally smooth manifold in a neighborhood of x_0, and $T_{x_0}S_1(F) + Null(F_x(x_0)) = T_{x_0}X$. These conditions guarantee that H is nonsingular. We next give the normal form in the equidimensional case.

Theorem 4.1. *Let F be a smooth mapping satisfying the conditions* (H2) *at x_0. Then there exist coordinates x centered at x_0 and coordinates y centered at $F(x_0)$ so that F has the form*

$$F : (x_1, \ldots, x_n) \mapsto (x_1, \ldots, x_{n-1}, x_n^2).$$

This theorem can be found in more generality in [5]. In effect, it means that diffeomorphisms h and k exist so that $k \circ F \circ h^{-1}$ has the above form. Moreover, it is also shown in [5] that this singularity is stable. See also [19].

Based on Theorem 4.1, more insight can be gained into the case considered in section 3. Consider, for example, the mapping $F : (x\ y) \mapsto (x\ y^2)$ from R^2 into R^2, which has a fold singularity at the origin and is in normal form. Note that $u_0 = \mathbf{e_2}$ spans $null(F_x^0)$ and $\mathbf{e_1}$ spans range(F_x^0). Let $z(t) = t(1\ \ 1)^t$, for example. Then $u_0^t \dot{z}(0) \neq 0$, which violates the basic condition (3.3). After eliminating t, define $U_\delta = \{z : z_1 - z_2 = 0,\, z = (z_1\ z_2)^t\}$, which is the set of points on z; it can be shown [3] that these conditions guarantee that locally $F^{-1}(U_\delta) = (x\ y)^t : x - y^2 = 0$ is a smooth manifold. But in terms of the parameter t, $t \geq 0$, we have $x = t\,,\ y = \pm t^{1/2}$, and smoothness does not obtain in t. This behavior is generic for the fold singularity if $u_0^t \dot{z}(0) \neq 0$. With $u_0^t \dot{z}_0 = 0$ in the above example, then $z(t) = c_1 t\mathbf{e}_1 + \frac{1}{2}t^2 \ddot{z}_0 + \mathcal{O}(t^3)$. Under F^{-1}, solution paths are $x(t) = c_1 t + \mathcal{O}(t^2)$ and $y(t) = \pm c_2 t + \mathcal{O}(t^2)$ provided that $c_2 = u_0^t \ddot{z}_0 > 0$. Note that this condition means that $\dot{x}_0$ is not tangent to S_1, which is the x-axis. One can compute (3.10) in this case and derive the equation

$2\alpha^2 = u_0^t \ddot{z}_0$. Two branches in the domain then map onto $z(t)$. If $c_2 < 0$, there are no solutions. These results are consistent with Theorem 3.2. Since $m = n$ in this case, one expects uniqueness from Theorem 3.2. Uniqueness does obtain, but locally about the two different solutions found for $y_0 = \dot{x}_0$ based on the different values for α in (3.10).

We next consider the cusp case. We assume (H3) $S_{1,1}$ contains x_0, S_1 and $S_{1,1}$ are smooth manifolds in a neighborhood of x_0, and F restricted to $S_{1,1}$ has full rank. The condition that $S_{1,1}$ be a smooth manifold through x_0 is satisfied if the system

$$g = 0, \ \det(H) = 0 \tag{4.1}$$

has full rank. The condition that F, restricted to $S_{1,1}$, has full rank is satisfied if the classical cusp condition holds; see (4.11) and [2] or [8]. In this case (H3) implies that $\nu = 2$ in (2.6). We then have the following theorem.

THEOREM 4.2. *Let F be a smooth mapping satisfying the conditions* (H3) *at x_0. Then there exist coordinates x centered at x_0 and coordinates y centered at $F(x_0)$ so that F has the form*

$$F : (x_1, \dots, x_n) \mapsto (x_1, \dots, x_{n-1}, x_{n-1}x_n - x_n^3).$$

The mapping in Theorem 4.2 is also called a generalized Whitney cusp and is stable. These singularities and normal forms include cases $n > m$ and higher order singularities in the pattern of Theorems 4.1 and 4.2. See [1] for general statements of these results. Special cases are included in [5] and [15]. Based on Theorem 4.2 and the general solvability of cubic equations, it follows that solution paths exist through the Whitney cusp. This analysis is an alternative to the approach outlined in section 2. Uniqueness and smoothness are the central issues. For example, let the mapping F from R^2 into R^2 be given by

$$F : (x\,y) \mapsto (x \quad xy - y^3), \tag{4.2}$$

which is the normal form for the cusp. The manifold S_1 for F can be parametrized as $(3t^2,\ t)^t$ with image under F given by $F(S_1) = (3t^2,\ 2t^3)^t$. The curve $F(S_1)$ defines a cusp at the origin centered about the positive x-axis. Within the region defined by this cusp curve, every point has three preimages under F. Outside of the cusp region, preimages are unique. Thus paths $x(t)$ exist for any $z(t)$. Consider the example $z(t) = (0,\ t)^t$. One can solve explicitly the equation $F(x(t)) = z(t)$ obtaining the curve $x(t) = (0\,,\ -t^{1/3})^t$, showing that smoothness is lost. In this case, $u_0^t \dot{z}(0) \neq 0$. This is the generic behavior when (3.3) does not hold.

The lack of smoothness in the computed paths in the above examples is due to the parametrizations. We next show how these cases can be treated. The approach is to find an appropriate parametrization for which a smooth expansion is possible using the classical method of Puiseux series.

4.2. Puiseux series. Let $x = x(s)$ and $t = t(s)$, where s is a new parameter. We let s be arclength by requiring $x_s(s)^t x_s(s) = 1$, where the subscript denotes differentiation in the indicated variable. Differentiating (3.1) in s we obtain

$$F_x x_s = z_t t_s. \tag{4.3}$$

If the solution path in s exists and is smooth, then at the singularity (with $t_0 = s_0 = 0$), (4.3) holds. In the next two subsections we develop the first few terms in series expansions for both x and t in s following the proofs of Theorems 3.2 and 3.4. We highlight the differences in the proofs for these two cases when (3.3) does not hold and the reparametrization above is used.

Fold singularities. We assume that $u_0^t z_t^0 \neq 0$ since otherwise the results of section 3 apply. Then it must be the case that $t_s^0 = 0$. But then $x_s^0 = V_0\alpha$ with $\alpha^t V_0^t V_0 \alpha = 1$. As in section 3 we write $x(s) = sy(s)$, and we write $t(s) = s^2\tau(s)$. Since this is the fold case, we have $u_0^t F_{xx}^0 y_0 y_0 \neq 0$ where $x_s^0 = y_0$. Then with these notations, (3.7) becomes

$$u_0^t F_{xx}^0 y_0 y_0 = \alpha^t H \alpha = 2(u_0^t z_t^0)\tau_0. \tag{4.4}$$

Using τ_0 as an unknown, (4.4) can be solved given any α. We assume y_0 and τ_0 have been chosen satisfying (4.4) and $y_0^t y_0 = 1$. With an added approximate arclength normalization, the system (3.12) becomes in this case

$$\begin{gathered} U_{m-1}^t R_1(sy)y = \left(U_{m-1}^t \int_0^1 z_t(ts^2\tau)dt\right) s\tau, \\ u_0^t R_2(sy)yy = \left(u_0^t \int_0^1 z_t(ts^2\tau)dt\right)\tau, \\ y_0^t y = 1. \end{gathered} \tag{4.5}$$

By the above considerations, (4.5) is solvable at $s = 0$ and, when linearized at $s = 0$, gives the following linear system in the unknowns $\hat{y}, \hat{\tau}$:

$$\begin{gathered} U_{m-1}^t F_x^0 \hat{y} = 0, \\ \tfrac{1}{2}\, u_0^t F_{xx}^0 y_0 \hat{y} - (u_0^t z_t^0)\hat{\tau} = 0, \\ y_0^t \hat{y} = 0. \end{gathered} \tag{4.6}$$

From (4.6) we obtain that $\hat{y} = V_0\alpha$. But $y_0^t\hat{y} = 0$ forces α to lie in a $(p-1 = n-m)$-dimensional subspace of R^p. Since $u_0^t z_t^0 \neq 0$, $\hat{\tau}$ depends linearly on α. Thus (4.6) has $(n-m)$ independent solutions and (4.5) has full rank. Arguing as in Theorem 3.2, we obtain smooth solutions $y = y(s)$ and $\tau = \tau(s)$ of (4.5) if z is smooth, and hence of the original equations. Note, however, that if H is definite, then $\alpha^t H \alpha$ is of one sign independent of α. Assume, for example, that H is positive definite. If $u_0^t z_t^0$ is negative, then τ_0 must be negative in (4.4). However, with $t = s^2\tau$, this would mean that a solution has been found but with t negative. That is, a solution exists only backward in time, and, in effect, there is no solution. If H is indefinite, then α can be chosen so that τ_0 is positive.

Since $t(s) = s^2\tau(s)$ with $\tau_0 \neq 0$, then y depends on $t^{1/2}$, and the solution path sought based on the original parametrization of the target is not smooth. For a two-arm robot of the form (1.1) with $l_1 = l_2 = 1$, the equations in (1.1) become

$$\begin{gathered} z_1 = \cos(x) + \cos(x+y), \\ z_2 = \sin(x) + \sin(x+y). \end{gathered} \tag{4.7}$$

The origin is a singular configuration and it is easy to compute that for the mapping F defined by (4.7),

$$F_x^0 = \begin{pmatrix} 0 & 0 \\ 2 & 1 \end{pmatrix}, \quad F_{xx}^0 = \begin{pmatrix} -2 & -1 & -1 & -1 \\ 0 & 0 & 0 & 0 \end{pmatrix}. \tag{4.8}$$

S_1 is the x-axis, and $F(S_1)$ is the circle of radius 2 with center at the origin. We consider the path studied in [11], namely $z_1(t) = 2 - t$, $z_2(t) = 0$, for which

$z_t^0 = -\mathbf{e}_1$. Note that z_t^0 is not tangent to $F(S_1)$ at the origin in S_1. A right null vector for F_x^0 is $v_0 = (1 \ -2)^t$ and a left null vector is $u_0 = \mathbf{e}_1$. Since $u_0^t z_t^0 \neq 0$, we are in the above setting and the results of section 3 do not apply. Solving (4.5) using an arclength parametrization, we have $(x_{ss}^0)^t x_s^0 = 0$. Using (4.3), (4.4) we obtain $x_s^0 = (1/\sqrt{5}\ , \ -2/\sqrt{5})^t$ and $x_{ss}^0 = 0$. So $x(s) = x_s^0 s + \mathcal{O}(s^3)$ with $t = \frac{1}{5}s^2 + \cdots$. Thus $s = \sqrt{5} \cdot t^{\frac{1}{2}} + \cdots$ and $x(t) = (-t^{\frac{1}{2}}, \, 2t^{\frac{1}{2}})^t + \cdots$, consistent with the results of [12]. We note that $u_0^t F_{xx}^0 y_0 y_0 = -2$.

Cusp singularities. We next derive a quasi-arclength parametrizaton of a solution path through a cusp singularity. As before, we write $t = t(s)$ and solve $F(x(s)) = z(t(s))$. Assuming for the moment existence and smoothness of both x and t, we derive the conditions to be imposed as a modification to the proof of Theorem 3.4. Differentiating, we obtain as before (4.3). We consider only the case where $u_0^t z_t^0 \neq 0$, so that, as above, $t_s^0 = 0$ and $x_s^0 = V_0 \alpha$. Now in the cusp case, $H = u_0^t F_{xx}^0 V_0 V_0$ is a singular matrix. We choose $x_s^0 = \phi_0$ so that $u_0^t F_{xx}^0 \phi_0 \phi_0 = 0$, or equivalently, $H\alpha = 0$ with $\phi_0^t \phi_0 = 1$ as a normalization. Differentiating again we obtain the equation

$$F_x x_{ss} = -F_{xx} x_s x_s + z_{tt} t_s^2 + z_t t_{ss}. \tag{4.9}$$

Since $t_s^0 = 0$ and $u_0^t F_{xx}^0 \phi_0 \phi_0 = 0$, it follows that $t_{ss}^0 = 0$ and that (4.9) is solvable. We add the normalization condition $(x_s^0)^t x_{ss}^0 = 0$ for x_{ss}^0. Differentiating (4.9) we obtain

$$F_x x_{sss} = -3F_{xx} x_{ss} x_s - F_{xxx} x_s x_s x_s + z_{ttt} t_s^3 + z_t t_{sss} + 3 z_{tt} t_{ss} t_s, \tag{4.10}$$

from which it follows at s_0 that

$$3u_0^t F_{xx}^0 x_{ss}^0 x_s^0 + u_0^t F_{xxx}^0 x_s^0 x_s^0 x_s^0 = (u_0^t z_t^0) t_{sss}^0. \tag{4.11}$$

The left-hand side of (4.11) not being equal to zero is the standard cusp condition [7], under which it follows that $t_{sss}^0 \neq 0$.

Based on these preliminaries we set $x(s) = s\phi_0 + s^2 y$ and $t(s) = s^3 \tau$ with $\phi_0^t y = 0$. Then the system $F(x) = z$ is equivalent to

$$\begin{aligned} &\text{(a)} \quad U_{m-1}^t F(s\phi_0 + s^2 y) = U_{m-1}^t z(s^3 \tau), \\ &\text{(b)} \quad\quad u_0^t F(s\phi_0 + s^2 y) = \ u_0^t z(s^3 \tau), \\ &\text{(c)} \quad\quad\quad\quad\quad\quad \phi_0^t y \ = 0 \end{aligned} \tag{4.12}$$

with the preceding definitions. The system (4.12) consists of $(m+1)$-equations in the $(n+1)$-variables y, τ plus the parameter s; (4.12) has full rank at a point if the null space of its linearization there has dimension $n-m$. Using Taylor expansions, (4.12a) and (4.12b) may be written, respectively, as

$$\begin{aligned} &\text{(a}'\text{)} \quad U_{m-1}^t F_x^0 (s\phi_0 + s^2 y) + U_{m-1}^t R_2 (s\phi_0 + s^2 y)^2 = U_{m-1}^t \hat{R}_1 s^3 \tau, \\ &\text{(b}'\text{)} \quad u_0^t F_{xx}^0 (s\phi_0 + s^2 y)^2 + u_0^t R_3 (s\phi_0 + s^2 y)^3 = u_0^t \hat{R}_1 s^3 \tau. \end{aligned} \tag{4.12}$$

Using (4.12a$'$) and dividing out an s^2 and (4.12b$'$) and dividing out an s^3, the system (4.12) at $s = 0$ is equivalent to

$$\begin{gathered} U_{m-1}^t F_x^0 y + \tfrac{1}{2} U_{m-1}^t F_{xx}^0 \phi_0 \phi_0 = 0, \\ u_0^t F_{xx}^0 \phi_0 y + \tfrac{1}{6} u_0^t F_{xxx}^0 \phi_0 \phi_0 \phi_0 = (u_0^t z_t^0) \tau, \\ \phi_0^t y = 0, \end{gathered}$$

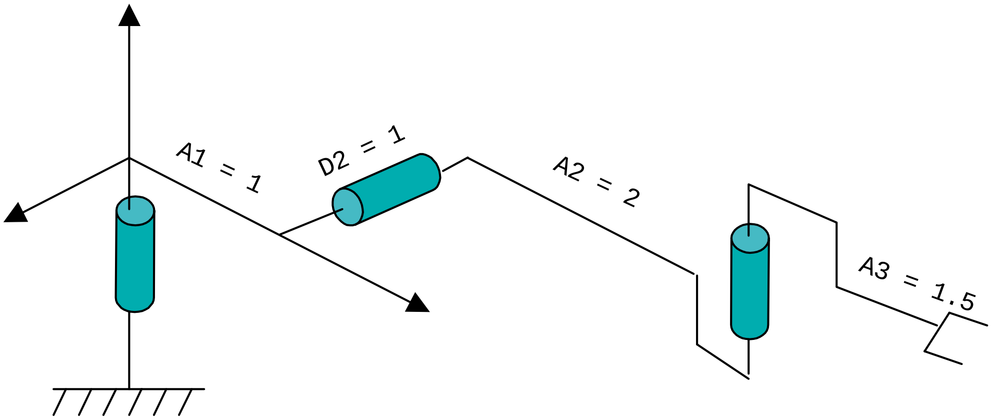

FIG. 2. *A spatial manipulator.*

which is solvable with $y_0 = \frac{1}{2}x^0_{ss}$ and $\tau_0 = t^0_{sss}/6$ as defined earlier. Linearizing (4.12) at y_0, τ_0, and s_0 produces the following linear system in $\hat{y}$, $\hat{\tau}$:

$$(4.13)\qquad \begin{aligned} &\text{(a)} \qquad U^t_{m-1}F^0_x\hat{y} = 0,\\ &\text{(b)} \qquad u^t_0F^0_{xx}\phi_0\hat{y} - (u^t_0z^0_t)\hat{\tau} = 0,\\ &\text{(c)} \qquad \phi^t_0\hat{y} = 0. \end{aligned}$$

From (4.13a) we have $\hat{y} = V_0\alpha$; from (4.13c) we have that α lies in a $(p-1)$-dimensional subspace of R^p. Now $u^t_0F^0_{xx}\phi_0\hat{y} = \alpha^tH\alpha_0 = 0$ for any α since ϕ_0 with α_0 a null vector for H. Then from (4.13b) it follows that $\hat{\tau} = 0$, and (4.13) admits $m - n = p - 1$ independent solutions. It follows using the implicit function theorem as in Theorem 3.4 that (4.12) is solvable for y and τ as smooth functions of s if z is smooth. Since $t = s^3\tau$, it follows that $s = t^{1/3} + \cdots$ and that $x = x^0_st^{1/3} + \frac{1}{2}x^0_{ss}t^{2/3} + \cdots$, which was expected from the discussion following (4.2).

As an example, we consider the three degree-of-freedom robot in Figure 2; see [4] and [13]. The motion of each joint is in the Lie group $SE(3)$, and the equations for the mapping from the three joint angles to the spatial coordinates of the end-effector may be simply computed as follows: Define the matrices

$$A = \begin{pmatrix} \cos\theta_1 & -\sin\theta_1 & 0 & 0\\ \sin\theta_1 & \cos\theta_1 & 0 & 0\\ 0 & 0 & 1 & 0\\ 0 & 0 & 0 & 1 \end{pmatrix}, \qquad B = \begin{pmatrix} \cos\theta_2 & 0 & \sin\theta_2 & 1\\ 0 & 1 & 0 & 1\\ -\sin\theta_2 & 0 & \cos\theta_2 & 0\\ 0 & 0 & 0 & 1 \end{pmatrix},$$

$$C = \begin{pmatrix} \cos\theta_3 & -\sin\theta_3 & 0 & 2\\ \sin\theta_3 & \cos\theta_3 & 0 & 0\\ 0 & 0 & 1 & 0\\ 0 & 0 & 0 & 1 \end{pmatrix}, \qquad D = \begin{pmatrix} 1.5\\ 0\\ 0\\ 1 \end{pmatrix}.$$

The coordinate systems were taken with the positive x-axes along the links denoted by a_i, the positive z-axes vertical and upward, and with the separate systems right-handed. The first three coordinates of the product $ABCD$ give the mapping F. Based on this formula, one can easily compute F_θ and $F_{\theta\theta}$. Using the formulas given in section 2, it is straightforward to compute that F has a cusp point at $\theta_1 = 0$, $\theta_2 = -2.265134$, and $\theta_3 = 1.158639$. That is, for this point, F_θ has a one-dimensional null space, and the null vector v is tangent to the singular manifold S_1. This can be verified by computing $H = u^t F_{\theta\theta} vv = g_\theta v = 0$. The null vector, normalized by $T = (1\ 1\ 1)$ in (2.2), is $v^t = (0.356216\ 0.2499307\ 0.3938177)$; the left null vector u, normalized with $r^t = (1\ \ -1\ 1)$ as in (2.3), is $u^t = (0.2964187\ \ -1.0595738\ \ -0.3559925)$. Finally, using the differentiation formula $g_\theta = u^t F_{\theta\theta} v$, one computes $g_\theta = (0\ 0.4533926\ -0.2877052)$. We point out that these calculations are a by-product of solving the system $g = 0$, $H = 0$, to find the cusp point. Now all information is at hand to verify if a path $z(t)$ for the end-effector is the image of a smooth path in the space of angles. As discussed above and in Theorem 3.4, one needs $u^t \dot{z} = 0$ and then $g_\theta y_1 \neq 0$ for a smooth path where $F_\theta y_1 = \dot{z}$ at t_0. Otherwise, a reparametrization is required as discussed above.

Planar intersections of the image under F of the singular set can be computed by solving the system

$$\begin{aligned} g &= 0, \\ q^t F &= 0, \end{aligned} \tag{4.14}$$

where q is a fixed vector. We next give a proposition with conditions under which (4.14) is nonsingular at the singular point x_0 for F.

PROPOSITION 4.3. *Let* $q^t F_x^0 \neq 0$. (a) *Let* $u_0^t F_{xx}^0 \phi_0 \phi_0 \neq 0$. *Then the linearization of* (4.14) *has a one-dimensional null space at* x_0. (b) *Let* $u_0^t F_{xx}^0 \phi_0 \phi_0 = 0$. *Define* w *so that* $q^t w = 0$, $u_0^t w = 0$, *and* $w^t w = 1$. *Let* $F_x^0 v_1 = w$ *with* $w^t \phi_0 = 0$. *Then if* $u_0^t F_{xx}^0 \phi_0 v_1 \neq 0$, *the conclusion in* (a) *holds.*

Proof. For part (a), any null vector for the linearization of the second equation in (4.14) has the form $\alpha\phi_0 + \beta v_1$ where v_1 is defined above; then using the condition $u_0^t F_{xx}^0 \phi_0 \phi_0 \neq 0$ shows that α and β are linearly related. A similar substitution under the conditions of (b) shows that $\beta = 0$.

Under the conditions of (b) in Proposition 4.3 for this example, the equations (4.14) define a smooth curve in the singular surface. Since the tangent to this curve is by construction a null vector for F_x^0, the image of this curve will have a cusp.

Remarks. If the target path $z(t)$ satisfies $u_0^t \dot{z}_0 = 0$, then it was shown in section 3 that a smooth path of inverse images exists in the case of the cusp, and may exist in the case of the fold providing that the matrix H associated with the mapping F is indefinite. These results were generalized in section 4 to the case that $u_0^t \dot{z}_0 \neq 0$. Then the solutions are not smooth in the parameter t, but are smooth in a computable reparametrization. Conditions required for these results are the generic ones for the two singularities. Moreover, our results can be seen as an example of an effective method to analyze other singularities and path-tracking through them. One performs the analysis based on the normal form for the singularity and then relates the derived solvability conditions and expansions to the original problem through the coordinate changes relating the original problem to its normal form. These conditions can be evaluated using the reduction given in section 2. This approach is especially effective for questions related to the qualitative behavior of spatial manipulators near a singularity, such as determining the existence of a path and the number of inverse images.

ZERO DIFFUSION-DISPERSION LIMITS FOR SCALAR CONSERVATION LAWS*

CEZAR I. KONDO[†] AND PHILIPPE G. LEFLOCH[‡]

Abstract. We consider solutions of hyperbolic conservation laws regularized with vanishing diffusion and dispersion terms. Following a pioneering work by Schonbek, we establish the convergence of the regularized solutions toward discontinuous solutions of the hyperbolic conservation law. The proof relies on the method of compensated compactness in the L^2 setting. Our result improves upon Schonbek's earlier results and provides an optimal condition on the balance between the relative sizes of the diffusion and the dispersion parameters. A convergence result is also established for multidimensional conservation laws by relying on DiPerna's uniqueness theorem for entropy measure-valued solutions.

Key words. conservation law, shock wave, entropy solution, measure-valued solution, diffusion, dispersion, singular limit, a priori estimate

1. Introduction.

We study here the convergence of solutions of the partial differential equation ($\epsilon \to 0+$, $\delta = \delta(\epsilon) \to 0$)

$$u_t + f(u)_x = \epsilon\, u_{xx} + \delta\, u_{xxx}, \qquad u = u^\epsilon(x,t),\ x \in \mathbb{R},\ t \geq 0, \tag{1.1}$$

toward weak solutions of the corresponding hyperbolic conservation laws:

$$u_t + f(u)_x = 0, \qquad u = u(x,t),\ x \in \mathbb{R},\ t \geq 0, \tag{1.2}$$

where the flux $f : \mathbb{R} \to \mathbb{R}$ is a smooth function with (at most) linear growth at infinity; that is, for some $M > 0$

$$|f'(u)| \leq M, \qquad u \in \mathbb{R}.$$

Equations of the form (1.1)–(1.2) arise in fluid dynamics when both viscosity (diffusion) and capillarity (dispersion) play a role. The diffusion ϵ smoothes out the discontinuous solutions of (1.2), while the dispersion δ causes high-frequency oscillations.

In this paper, we establish that the solutions u^ϵ of (1.1) converge toward a weak solution of (1.2) provided that

$$\delta = O(\epsilon^2). \tag{1.3}$$

When the stronger condition

$$\delta = o(\epsilon^2) \tag{1.4}$$

holds, we prove that the limit coincides with the entropy solution determined by Kruzkov's theory [10]. We point out that these conditions are sharp since, in the limiting case

$$\delta = K\,\epsilon^2 \qquad \text{for some } K \in \mathbb{R}, \tag{1.5}$$

limiting solutions may violate Kruzkov's entropy conditions [8, 5, 15, 2]. Furthermore, when (1.3) is violated, the solutions are highly oscillatory and fail to converge in any strong topology as noted by Lax and Levermore [12, 13, 14]. (See also Lax [11].)

The singular limit problem above was first tackled by Schonbek [21], who established the optimal rate (1.3) for the Burgers equation, that is,

$$f(u) = \frac{u^2}{2},$$

and for the class of flux-functions

$$f(u) = \frac{u^{2p+1}}{2p+1}, \qquad p \geq 1.$$

She also gave a convergence result for general fluxes with quadratic growth at infinity, however, under the stronger condition on $\delta = O(\epsilon^3)$. As another important contribution in [21], Schonbek introduces a generalization of the method of compensated compactness (Tartar [23] and Murat [20]) allowing the handling of sequences that are bounded in L^p for finite $p > 1$ only. Next, following [21], LeFloch and Natalini [17] studied equations like (1.1) but with nonlinear (even singular) diffusion, and established strong convergence results toward entropy solutions of (1.2). See also a convergence result for systems in Hayes and LeFloch [6].

In the second part of this paper, we also deal with the convergence of solutions of multidimensional equations similar to (1.1)–(1.2). For multidimensional equations, the compensated compactness method no longer applies and the proofs are based instead on DiPerna's uniqueness theory for entropy measure-valued solutions (DiPerna [4], Szepessy [22], and Kondo and LeFloch [9]). Our approach is similar to Correia and LeFloch [3] where nonlinear diffusion terms are treated under a strong assumption on the ratio of the dispersion to the diffusion.

To summarize, the main contribution in the present paper is the derivation of a priori estimates (Theorems 2.1 and 3.1) which cover general flux-functions (with at most linear growth at infinity) and lead to an optimal condition on the balance between the diffusion and the dispersion (Theorems 2.2 and 3.2).

Further material on classical and nonclassical entropy solutions generated by diffusive-dispersive limits can be found in [1, 2, 5, 6, 7, 8, 15, 16, 17, 18, 19, 21]

2. One-dimensional conservation laws.

Consider a family u^ϵ of smooth solutions to

$$u_t + f(u)_x = \epsilon\, u_{xx} + \delta\, u_{xxx}, \qquad u = u^\epsilon(x,t), \tag{2.1}$$

$$u(x,0) = u_0^\epsilon(x), \qquad x \in \mathbb{R}, \tag{2.2}$$

where $\epsilon \to 0+$ and $\delta = \delta(\epsilon) \to 0$. Under suitable conditions on the initial data $u_0^\epsilon : \mathbb{R} \to \mathbb{R}$, the solutions (and their derivatives) decay rapidly at infinity so that all the a priori estimates given below are rigorously justified. We want to show that the solution of (2.1)–(2.2) converges toward a weak solution of the problem

$$u_t + f(u)_x = 0, \qquad u = u^\epsilon(x,t), \tag{2.3}$$

$$u(x,0) = u_0(x), \qquad x \in \mathbb{R}, \tag{2.4}$$

where $u_0 : \mathbb{R} \to \mathbb{R}$ are given initial data. A minimum requirement is the weak convergence (for instance in $L^2(\mathbb{R})$)

$$u_0^\epsilon \rightharpoonup u_0,$$

which is always assumed throughout this paper. The following convergence theorem covers both cases where the diffusion is in balance or dominates the dispersion.

Theorem 2.1. *Suppose that the flux-function f is Lipschitz continuous on $\mathbb{R}$ and that the initial data u_0 belong to $L^2(\mathbb{R})$. Then the solution u^ϵ of* (2.1)–(2.2) *satisfies the following a priori estimates:*

$$\|u^\epsilon(t)\|_{L^2(\mathbb{R})} \le \|u_0^\epsilon\|_{L^2(\mathbb{R})}, \qquad t \ge 0, \tag{2.5a}$$

$$\sqrt{2\,\epsilon}\, \|u_x^\epsilon\|_{L^1(\mathbb{R}^+,L^2(\mathbb{R}))} \le \|u_0^\epsilon\|_{L^2(\mathbb{R})}, \tag{2.5b}$$

$$\sqrt{\delta}\, \|u_x^\epsilon(t)\|_{L^2(\mathbb{R})} \le \sqrt{2\,\|f'\|_\infty}\, \|u_0^\epsilon\|_{L^2(\mathbb{R})} + \sqrt{\delta}\, \|u_{0x}^\epsilon\|_{L^2(\mathbb{R})}, \qquad t \ge 0, \tag{2.5c}$$

and

$$\sqrt{\epsilon\,\delta}\, \|u_{xx}\|_{L^1(\mathbb{R}^+,L^2(\mathbb{R}))} \le \sqrt{2\,\|f'\|_\infty}\, \|u_0^\epsilon\|_{L^2(\mathbb{R})} + \sqrt{\delta}\, \|u_{0x}^\epsilon\|_{L^2(\mathbb{R})}. \tag{2.5d}$$

Proof. Throughout the calculation and for simplicity, we omit the upper-index ϵ. To any smooth function $U : \mathbb{R} \to \mathbb{R}$ we can associate a “flux” $F : \mathbb{R} \to \mathbb{R}$ by $F'(u) = U'(u) f'(u)$, $u \in \mathbb{R}$. Multiplying (2.1) by $U'(u)$ we find

$$U(u)_t + F(u)_x = \epsilon\,(U'(u)u_x)_x - \epsilon\, U''(u)\, u_x^2 + \delta\,\big(U'(u)\, u_{xx}\big)_x - \delta U''(u)\, u_x\, u_{xx}.$$

Integrating over the whole space, it follows that

$$\begin{aligned} \frac{d}{dt}\int_{\mathbb{R}} U(u)\,dx + \epsilon \int_{\mathbb{R}} U''(u)\, u_x^2\,dx &= \delta \int_{\mathbb{R}} U''(u) \left(\frac{u_x^2}{2}\right)_x dx \\ &= -\frac{\delta}{2}\int_{\mathbb{R}} U'''(u)\, u_x^3\,dx. \end{aligned} \tag{2.6}$$

Integrating in time over some interval $(0,t)$, we arrive at the general identity

$$\int_{\mathbb{R}} U(u(t))\,dx + \epsilon \int_0^t \int_{\mathbb{R}} U''(u)\, u_x^2\,dxdt = \int_{\mathbb{R}} U(u_0)\,dx - \frac{\delta}{2}\int_0^t \int_{\mathbb{R}} U'''(u)\, u_x^3\,dxdt. \tag{2.7}$$

Choosing first $U(u) = u^2$ in (2.7), we see that

$$\int_{\mathbb{R}} u(t)^2 dx + 2\,\epsilon \int_0^t \int_{\mathbb{R}} u_x^2 dx = \int_{\mathbb{R}} u_0^2(x), \tag{2.8}$$

which gives immediately (2.5a) and (2.5b).

Next, we differentiate (2.1) with respect to x and we multiply by u_x:

$$\frac{1}{2}\left(u_x^2\right)_t + u_x\left(f'(u)\,u_x\right)_x = \epsilon\left(u_x\,u_{xx}\right)_x - \epsilon\,u_{xx}^2 + \delta\left(u_x\,u_{xxx} - \frac{1}{2}u_{xx}^2\right)_x.$$

Integrating in space, we get

$$\frac{1}{2}\frac{d}{dt}\int_{\mathbb{R}} u_x^2\,dx + \epsilon\int_{\mathbb{R}} u_{xx}^2\,dx = \int_{\mathbb{R}} u_{xx}\,f'(u)\,u_x\,dx = -\frac{1}{2}\int_{\mathbb{R}} f''(u)\,u_x^3\,dx.$$

Hence, integrating over some interval $(0,t)$, we find

$$\int_{\mathbb{R}} u_x(t)^2\,dx + 2\,\epsilon\int_0^t\int_{\mathbb{R}} u_{xx}^2\,dxdt = \int_{\mathbb{R}} u_{0x}^2\,dx - \int_0^t\int_{\mathbb{R}} f''(u)\,u_x^3\,dxdt. \tag{2.9}$$

We multiply (2.9) by δ and add it up with (2.7):

$$\begin{aligned}\delta\int_{\mathbb{R}} u_x(t)^2\,dx &+ 2\,\epsilon\,\delta\int_0^t\int_{\mathbb{R}} u_{xx}^2\,dxdt\\ &= \int_{\mathbb{R}} U(u_0)\,dx - \int_{\mathbb{R}} U(u(t))\,dx + \delta\int_{\mathbb{R}} u_{0x}^2\,dx\\ &\quad - \epsilon\int_0^t\int_{\mathbb{R}} U''(u)\,u_x^2\,dxdt - \delta\int_0^t\int_{\mathbb{R}} f''(u)\,u_x^3\,dxdt - \frac{\delta}{2}\int_0^t\int_{\mathbb{R}} U'''(u)\,u_x^3\,dxdt.\end{aligned}$$

Choosing U given by

$$U(u) = -2\int_0^u\big(f(v) - f(0)\big)\,dv \tag{2.10}$$

the last two terms in the above identity cancel out. Since

$$-c \le \frac{U''(u)}{2} \le c := \|f'\|_\infty \qquad \text{for all } u\in\mathbb{R},$$

thus

$$-c\,u^2 \le U(u) \le c\,u^2 \qquad \text{for all } u\in\mathbb{R},$$

and we finally obtain

$$\begin{aligned}\delta\int_{\mathbb{R}} u_x(t)^2\,dx &+ 2\,\epsilon\,\delta\int_0^t\int_{\mathbb{R}} u_{xx}^2\,dxdt\\ &\le \int_{\mathbb{R}} c\,u_0^2\,dx + \int_{\mathbb{R}} c\,u(t)^2\,dx + \delta\int_{\mathbb{R}} u_{0x}^2\,dx + 2\,\epsilon\int_0^t\int_{\mathbb{R}} c\,u_x^2\,dxdt.\end{aligned}$$

Hence using (2.8)

$$\delta\int_{\mathbb{R}} u_x(t)^2\,dx + 2\,\epsilon\,\delta\int_0^t\int_{\mathbb{R}} u_{xx}^2\,dxdt \le 2\,c\int_{\mathbb{R}} u_0^2\,dx + \delta\int_{\mathbb{R}} u_{0x}^2\,dx,$$

which leads to (2.5c) and (2.5d). The proof of Theorem 2.1 is completed. □

Recall that by Kruzkov' theory, given $u_0 \in L^2(\mathbb{R})$, the Cauchy problem (2.3)–(2.4) admits a unique entropy solution $u \in L^\infty\big(\mathbb{R}_+, L^2(\mathbb{R})\big)$ in the sense of Kruzkov's theory. See [10, 4, 22, 9].

Theorem 2.2. *Assume that, for some constant $C_0 > 0$ independent of ϵ,*

$$\|u_0^\epsilon\|_{L^2(\mathbb{R})} + \sqrt{\delta}\, \|u_{0x}^\epsilon\|_{L^2(\mathbb{R})} \le C_0. \tag{2.11}$$

(1) *As $\epsilon \to 0$ with $\delta = O(\epsilon^2)$ (a subsequence of) the solution u^ϵ of* (2.1)–(2.2) *converges in $L^p_{loc}\big(\mathbb{R}_+, L^q_{loc}(\mathbb{R})\big)$ (for all $1 < p < \infty$ and $1 < q < 2$) toward a weak solution of the problem* (2.3)–(2.4).

(2) *If the stronger condition $\delta = o(\epsilon^2)$ holds, then the limit is the unique entropy solution in the sense of Kruzkov.*

In case (1) a subsequence of u^ϵ (at least) converges strongly, while in case (2) the whole sequence converges strongly. We can conjecture that, in fact, the whole sequence should converge in case (1) as well, but proving it would be very challenging since it requires a uniqueness result of nonclassical entropy solutions. (See also LeFloch [16].)

Proof. We will apply the general convergence framework established by Schonbek [21]. Based on (2.11) and the uniform estimate (2.5a) derived earlier, we can select a subsequence of u^ϵ converging "in the sense" of the Young measures. To apply [21], we only need to control the entropy dissipation measures associated with (2.1). Let U be a smooth function with (at most) linear growth at infinity and, more precisely, such that U' and U'' are uniformly bounded on $\mathbb{R}$. Consider the distribution

$$\Gamma^\epsilon = U(u^\epsilon)_t + F(u^\epsilon)_x,$$

where as usual $F' = U'\, f'$. With obvious notation consider the decomposition

$$\begin{aligned}\Gamma^\epsilon &= \epsilon\, \big(U'(u^\epsilon)\, u_x^\epsilon\big)_x - \epsilon\, U''(u^\epsilon)\, (u_x^\epsilon)^2 + \delta\, \big(U'(u^\epsilon)\, u_{xx}^\epsilon\big)_x - \delta\, U''(u^\epsilon)\, u_x^\epsilon\, u_{xx}^\epsilon \\ &= \Gamma_1^\epsilon + \Gamma_2^\epsilon + \Gamma_3^\epsilon + \Gamma_4^\epsilon.\end{aligned}$$

The estimates below hold for all smooth function $\theta : \mathbb{R} \times \mathbb{R}_+ \to \mathbb{R}$ with compact support in (x,t).

Consider first the term Γ_1^ϵ. By the Cauchy–Schwarz inequality, we get

$$\begin{aligned}\left|\int_0^\infty \int_{\mathbb{R}} \Gamma_1^\epsilon\, \theta\, dxdt\right| &= \left|\int_0^\infty \int_{\mathbb{R}} \epsilon\, U'(u^\epsilon)\, u_x^\epsilon\, \theta_x\, dxdt\right| \\ &\le \epsilon\, C\, \|u_x^\epsilon\|_{L^1(\mathbb{R}_+, L^2(\mathbb{R}))}\, \|\theta_x\|_{L^\infty(\mathbb{R}_+, L^2(\mathbb{R}))} \\ &\le C'\, \sqrt{\epsilon} \to 0,\end{aligned} \tag{2.12i}$$

where we used (2.5b). This proves that Γ_1^ϵ converges to zero in the sense of distributions.

Next we simply point out that, by (2.5b) again, the second term Γ_2^ϵ remains uniformly bounded in L^1:

$$\int_0^\infty \int_{\mathbb{R}} |\Gamma_2^\epsilon|\, dxdt \le \frac{1}{2}\, \|u_0^\epsilon\|^2_{L^2(\mathbb{R})}. \tag{2.12ii}$$

To estimate Γ_3 we use (2.5d):

$$\begin{aligned} \left| \int_0^\infty \int_{\mathbb{R}} \Gamma_3^\epsilon \, \theta \, dxdt \right| &= \left| \delta \int_0^\infty \int_{\mathbb{R}} U'(u^\epsilon) \, u_{xx}^\epsilon \, \theta_x \, dxdt \right| \\ &\le \delta \, C \|u_{xx}^\epsilon\|_{L^1(\mathbb{R}_+, L^2(\mathbb{R}))} \, \|\theta_x\|_{L^\infty(\mathbb{R}_+, L^2(\mathbb{R}))} \\ &\le C' \sqrt{\frac{\delta}{\epsilon}} \to 0, \end{aligned} \tag{2.12iii}$$

provided that the mild condition $\delta = o(\epsilon)$ holds. Therefore Γ_3^ϵ tends to zero in the sense of distributions.

Finally, we deal with the last term as follows:

$$\begin{aligned} \left| \int_0^\infty \int_{\mathbb{R}} \Gamma_4^\epsilon \, \theta \, dxdt \right| &= \left| \int_0^\infty \int_{\mathbb{R}} \delta \, U''(u^\epsilon) \, u_x^\epsilon \, u_{xx}^\epsilon \, \theta \, dxdt \right| \\ &\le \delta \, C \|u_{xx}^\epsilon\|_{L^\infty(\mathbb{R}_+, L^2(\mathbb{R}))} \, \|u_x^\epsilon\|_{L^\infty(\mathbb{R}_+, L^2(\mathbb{R}))} \, \|\theta\|_{L^\infty(\mathbb{R} \times \mathbb{R}_+)} \\ &\le C' \, \frac{\sqrt{\delta}}{\epsilon}, \end{aligned} \tag{2.12iv}$$

where we use (2.5b) and (2.5d). The upper bound above tends to zero iff $\delta = o(\epsilon^2)$, in which case we can conclude that Γ_4^ϵ tends to zero in the sense of distributions. Under the weaker assumption $\delta = O(\epsilon^2)$, we see that Γ_4^ϵ is solely bounded in $L^1(\mathbb{R} \times \mathbb{R}_+)$ as is Γ_2^ϵ.

The conclusion (1) of the theorem follows immediately from the uniform bounds (2.12i)–(2.12iv) by applying Schonbek's convergence theory. Her arguments show only that a subsequence of u^ϵ converges and that the limit is a weak solution of (2.3)–(2.4). On the other hand, assuming now the stronger condition $\delta = o(\epsilon^2)$ and restricting attention to *convex functions* U, in view of (2.12i)–(2.12iv) again and the expression of Γ_2^ϵ, we see that the entropy dissipation decomposes in the form

$$\Gamma^\epsilon = \tilde{\Gamma}^\epsilon + \Gamma_2^\epsilon,$$

where $\tilde{\Gamma}^\epsilon \to 0$ in the sense of distributions and Γ^ϵ is a nonpositive bounded measure. This shows that all of the entropy inequalities hold in the limit $\epsilon \to 0$. Thus the limit coincides with the unique entropy solution of the problem. □

3. Multidimensional conservation laws. The estimates and the technique of proof in section 2 do not apply to multidimensional equations, and markedly different arguments are discussed now. Consider the following Cauchy problem:

$$u_t + \sum_{j=1}^d f_j(u)_{x_j} = \epsilon \sum_{j=1}^d u_{x_j x_j} + \delta \sum_{j=1}^d u_{x_j x_j x_j}, \qquad u = u^\epsilon(x,t), \, x \in \mathbb{R}^d, \, t > 0, \tag{3.1}$$

$$u(x,0) = u_0^\epsilon(x), \quad x \in \mathbb{R}^d. \tag{3.2}$$

Provided the initial data u_0^ϵ converge weakly to some limit u_0 (in L^2, say), we will now prove that the solutions of (3.1)–(3.2) converge toward the entropy solution of the associated hyperbolic problem

$$u_t + \sum_{j=1}^d f_j(u)_{x_j} = 0, \qquad u = (x,t),\ x \in \mathbb{R}^d,\ t > 0, \tag{3.3}$$

$$u(x,0) = u_0(x), \quad x \in \mathbb{R}^d. \tag{3.4}$$

Precisely our results are as follows.

Theorem 3.1. *Suppose that the flux-function f is Lipschitz continuous on $\mathbb{R}$ and that the initial data u_0 belong to $L^2(\mathbb{R}^d)$. Then the solution u^ϵ of* (3.1)–(3.2) *satisfies the following a priori estimates:*

$$\|u^\epsilon(t)\|_{L^2(\mathbb{R}^d)} \le \|u_0^\epsilon\|_{L^2(\mathbb{R}^d)}, \qquad t \ge 0, \tag{3.5a}$$

$$\sqrt{2\,\epsilon}\,\|u_x^\epsilon\|_{L^1(\mathbb{R}^+,L^2(\mathbb{R}^d))} \le \|u_0^\epsilon\|_{L^2(\mathbb{R}^d)}, \tag{3.5b}$$

(3.5c)
$$\epsilon\,\|u_{x_j}^\epsilon(t)\|_{L^2(\mathbb{R}^d)} \le \sqrt{d}\,\|f_j'\|_\infty\,\|u_0^\epsilon\|_{L^2(\mathbb{R}^d)} + \epsilon\,\|u_{0x_j}^\epsilon\|_{L^2(\mathbb{R}^d)}, \qquad j = 1,\ldots,d,\ t \ge 0,$$

and

(3.5d)
$$\epsilon^{3/2}\,\|u_{x_jx_k}^\epsilon\|_{L^1(\mathbb{R}^+,L^2(\mathbb{R}^d))} \le \sqrt{d}\,\|f_j'\|_\infty\,\|u_0^\epsilon\|_{L^2(\mathbb{R}^d)} + \epsilon\,\|u_{0x_j}^\epsilon\|_{L^2(\mathbb{R}^d)}, \qquad j,k = 1,\ldots,d.$$

For each $u_0 \in L^2(\mathbb{R}^d)$, the Cauchy problem (3.3)–(3.4) admits a unique entropy solution $u \in L^\infty(\mathbb{R}_+, L^2(\mathbb{R}^d)$ in the sense of Kruzkov. See again [10, 4, 22, 9].

Theorem 3.2. *Assume that, for some constant $C_0 > 0$ independent of ϵ,*

$$\|u_0^\epsilon\|_{L^2(\mathbb{R}^d)} + \epsilon \sum_{j=1}^d \|u_{0x_j}^\epsilon\|_{L^2(\mathbb{R})} \le C_0. \tag{3.6}$$

Then, when $\epsilon \to 0+$ with $\delta = o(\epsilon^2)$, the solution u^ϵ of (3.1)–(3.2) *converges in $L^p_{loc}\big(\mathbb{R}_+, L^q_{loc}(\mathbb{R}^d)\big)$ (for all $1 < p < \infty$ and $1 < q < 2$) toward the unique entropy solution in the sense of Kruzkov of the Cauchy problem* (3.3)–(3.4).

Recall again that the condition $\delta = o(\epsilon^2)$ is sharp since, in the opposite case, nonclassical solutions violating the Kruzkov entropy inequalities could arise in the limit.

Proof of Theorem 3.1. We omit the upper-index ϵ in the following calculation. To derive the L^2 bound (3.5a), we multiply (3.1) by u and get

$$\Big(\frac{|u|^2}{2}\Big)_t + \sum_{j=1}^d F_j(u)_{x_j} = \sum_{j=1}^d \big(\epsilon\,u\,u_{x_j}\big)_{x_j} - \epsilon \sum_{j=1}^d |u_{x_j}|^2 - \frac{\delta}{2} \sum_{j=1}^d \big(|u_{x_j}|^2\big)_{x_j} + \sum_{j=1}^d \big(\delta\,u\,u_{x_jx_j}\big)_{x_j},$$

where $F_j' = u\,f_j'$ is normalized by the condition $F_j(0) = 0$, $j = 1,\ldots,d$. Integrating over space, we get

$$\frac{d}{dt}\int_{\mathbb{R}^d} |u|^2\,dx = -2\,\epsilon \int_{\mathbb{R}^d} \sum_{j=1}^d |u_{x_j}|^2\,dx,$$

and so for all $t \geq 0$

$$\int_{\mathbb{R}^d} |u(t)|^2\, dx + 2\,\epsilon \int_0^t \int_{\mathbb{R}^d} \sum_{j=1}^{d} |u_{x_j}|^2\, dxdt = \int_{\mathbb{R}^d} |u_0|^2\, dx. \tag{3.7}$$

To estimate the gradient of u, for $k = 1, \ldots, d$ we differentiate (3.1) with respect to the variable x_k and then multiply by u_{x_k}. The right-hand side of (3.1) is linear in u thus the calculation for this side is identical to the one we just made, but with u replaced with u_{x_k}. On the other hand, the flux term in the left-hand side is nonlinear and requires a specific argument,

$$\frac{d}{dt} \int_{\mathbb{R}^d} |u_{x_k}|^2\, dx - \sum_{j=1}^{d} \int_{\mathbb{R}^d} 2\, u_{x_k x_j}\, f_j'(u)\, u_{x_k}\, dx = -2\epsilon \sum_{j=1}^{d} \int_{\mathbb{R}^d} |u_{x_j x_k}|^2\, dx,$$

so after integration in time

$$\begin{aligned} &\int_{\mathbb{R}^d} |u_{x_k}(t)|^2\, dx + 2\,\epsilon \sum_{j=1}^{d} \int_0^t \int_{\mathbb{R}^d} |u_{x_j x_k}|^2\, dxdt \\ &\leq \int |u_{0x_k}|^2\, dx + 2\, \|f_k'\|_\infty \sum_{j=1}^{d} \int_0^t \int_{\mathbb{R}^d} |u_{x_j x_k}|\, |u_{x_k}|\, dxdt \\ &\leq \int_{\mathbb{R}^d} |u_{0x_k}|^2\, dx + \frac{\|f_k'\|_\infty^2}{\epsilon}\, d \sum_{j=1}^{d} \int_0^t \int_{\mathbb{R}^d} |u_{x_k}|^2\, dxdt + \epsilon \sum_{j=1}^{d} \int_0^t \int_{\mathbb{R}^d} |u_{x_j x_k}|^2\, dxdt. \end{aligned}$$

Observe that the last term of the right-hand side coincides with the last term of the left-hand side. Therefore, multiplying the above inequality by ϵ^2 and using the entropy dissipation bound in (3.7), we deduce that

$$\begin{aligned} &\int_{\mathbb{R}^d} \epsilon^2\, |u_{x_k}(t)|^2\, dx + \sum_{j=1}^{d} \int_0^t \int_{\mathbb{R}^d} \epsilon^3\, |u_{x_j x_k}|^2\, dxdt \\ &\leq \int_{\mathbb{R}^d} \epsilon^2\, |u_{0x_k}|^2\, dx + \|f_k'\|_\infty^2 \int_0^t \int_{\mathbb{R}^d} d\, \epsilon\, |u_{x_k}|^2\, dxdt \\ &\leq \int_{\mathbb{R}^d} \epsilon^2\, |u_{0x_k}|^2\, dx + d\, \|f_k'\|_\infty^2 \int_{\mathbb{R}^d} |u_0|^2\, dx. \qquad \square \end{aligned} \tag{3.8}$$

Proof of Theorem 3.2. We will rely on the convergence framework proposed by DiPerna [4] for L^∞ solutions and generalized to L^p solutions by Szepessy [22] and Kondo and LeFloch in [9].

Consider a Young measure ν associated with the sequence u^ϵ and based on the uniform L^2 bound (3.5a). (Such Young measures are described in Schonbek [21]). To show that ν is an entropy measure-valued solution, we must check entropy inequalities associated with (3.3), that is,

$$\langle \nu, U \rangle_t + \sum_{j=1}^{d} \langle \nu, F_j \rangle_{x_j} \leq 0, \tag{3.9}$$

where $U : \mathbb{R} \to \mathbb{R}$ is a convex function with (at most) linear growth at infinity and the entropy flux $F_j' = U' f_j'$ is normalized so that $F_j(0) = 0$.

By the definition of the Young measure, we only need to establish that, in the decomposition

$$
\begin{aligned}
\partial_t U(u^\epsilon) + \sum_{j=1}^{d} \partial_j F_j(u^\epsilon) &= \sum_{j=1}^{d} \partial_j \big(\epsilon\, U'(u^\epsilon)\, \partial_j u^\epsilon + \delta(\epsilon)\, U'(u^\epsilon)\, \partial_j^2 u^\epsilon\big) \\
&\quad - \sum_{j=1}^{d} \epsilon\, U''(u^\epsilon)\, |\partial_j u^\epsilon|^2 + \delta(\epsilon)\, U''(u^\epsilon)\, \partial_j u^\epsilon\, \partial_j^2 u^\epsilon \\
&=: \Gamma_1^\epsilon + \Gamma_2^\epsilon + \Gamma_3^\epsilon + \Gamma_4^\epsilon,
\end{aligned}
\tag{3.10}
$$

we have

$$\Gamma_1^\epsilon, \Gamma_2^\epsilon, \Gamma_4^\epsilon \to 0$$

and

$$\Gamma_3^\epsilon \leq 0.$$

These convergence properties were precisely established in the proof of Theorem 2.2, at least for one-dimensional equations. The extension to multidimensional equations is immediate in view of the uniform estimates (3.5a)–(3.5d). A detailed discussion of the initial condition at $t = 0$ (which is based on using suitable entropy inequalities) can be found in Kondo and LeFloch in [9]. This completes the proof that the convergence framework in [9] applies and provides the strong convergence toward the unique entropy solution of (3.3)–(3.4). □

MATHEMATICAL ANALYSIS OF A MODEL FOR THE INITIATION OF ANGIOGENESIS[*]

MARCO A. FONTELOS[†], AVNER FRIEDMAN[‡], AND BEI HU[§]

Abstract. In this paper we consider a nonlinear system of partial differential equations consisting of one parabolic equation and two ordinary differential equations in t. The system arises in a mathematical model of angiogenesis, a process of sprouting of new blood vessels from an existing vascular network. We prove that the system has a unique global solution and study its asymptotic behavior as $t \to \infty$. In particular, we show that stationary solutions are local attractors.

Key words. angiogenesis, tumor growth, degenerate parabolic equations

1. Introduction.

The inner lining of blood vessel is made up by a monolayer of flattened and extended cells, called endothelial cells. They are supported by a collagenous network—a network of fibrous proteins. Adhesion molecules, called fibronectins, reside both in the membrane of the blood vessels and in the extracellular matrix that surrounds the vessels.

Angiogenesis is a process of sprouting new blood vessels from a pre-existing vascular network. This process occurs during placental growth, during wound healing, and in tumor growth. In the latter it is initiated by release of chemicals by the tumor, the so called "tumor angiogenic factor," or TAF; see [2]. In a recent paper (cf. [14]) Levine, Sleeman, and Nilsen-Hamilton developed a mathematical model that describes the initiation of angiogenesis in a tumor. The process takes into account the biochemical steps by which chemotactic substances from the tumor combine with the receptors on the endothelial cell wall to produce substances that cause the eventual degradation of the vascular lamina and the migration of endothelial cells to sprout the lining of new capillaries.

The endothelial cell receptors are viewed in this model as the catalyst for transformation of TAF into proteolytic enzyme. The proteolytic enzyme acts as a stimulus for endothelial cell motion via chemotaxis and at the same time as an agent for the degradation of fibronectins. Finally, fibronectin acts as a chemotactic agent for the endothelial cells via a process called haptotaxis. In this process, the endothelial cells tend to move toward low concentrations of fibronectin. In addition, the endothelial cells produce fibronectin and, according to [14], they do it by following a logistic law. The sequence of biochemical processes is described by the law of mass action and the standard Michaelis–Menten kinetics for catalytic reactions, while the cell motion is governed by the continuum equations for reinforced random walks introduced in [15].

Putting all these facts together and taking the time scale in which some of the biochemical processes are quasi-stationary, one arrives at the following system (see [14] for further details):

$$\eta_t = D_1\eta_{xx} - D_1\left[\eta\left(\ln\tau_1(c,f)\right)_x\right]_x \quad \text{for } 0 \le x \le 1,\ t > 0, \tag{1.1}$$

$$\frac{\partial v}{\partial t} = -\frac{\lambda_1 v\eta}{1+\lambda_2 v} \quad \text{for } 0 \le x \le 1,\ t > 0, \tag{1.2}$$

$$\frac{\partial c}{\partial t} = \frac{\lambda_1 v\eta}{1+\lambda_2 v} \quad \text{for } 0 \le x \le 1,\ t > 0, \tag{1.3}$$

$$\frac{\partial f}{\partial t} = \lambda_3 f(f_M - f)\eta - \frac{\lambda_4 cf}{1+\lambda_5 f} \text{ for } 0 \le x \le 1,\ t > 0, \tag{1.4}$$

where η = endothelial cell density, v = concentration of angiogenic factor, c = concentration of proteolytic enzyme, f = concentration of fibronectin, and D, λ_i, f_M are positive constants. All the functions are also positive. The function $\tau_1(c,f)$ represents a transition probability in the theory of reinforced random walks, and its explicit form for the biological systems under study is unknown. According to experimental observations, however, it must be increasing in c and decreasing in f. Following [13] we shall take

$$\tau_1(c,f) = c^{\gamma_1} f^{-\gamma_2}, \tag{1.5}$$

with γ_i positive constants.

The variable x, after rescaling, is taken along the length of a pre-existing capillary. The boundary condition for η is

$$\eta_x - \eta\left(\ln\tau_1(c,f)\right)_x = 0 \text{ at } x = 0, 1. \tag{1.6}$$

This condition means that there is no flux of cells across the endpoints of the capillary vessel. Finally, initial conditions are prescribed for each of the four unknown functions.

In a subsequent paper (cf. [13]), Levine, Sleeman, and Nilsen-Hamilton incorporate into the model the effects of pericytes (with density $\sigma(x,t)$) and macrophages (with density $m(x,t)$) and of a chemotactic agent (with concentration $u(x,t)$) acting on macrophages. The equations they derive are

$$\sigma_t = D_2\sigma_{xx} - D_2\left[\sigma\left(\ln\tau_2(f)\right)_x\right]_x \quad \text{for } 0 \le x \le 1,\ t > 0, \tag{1.7}$$

$$m_t = D_3 m_{xx} - D_3\left[m\left(\ln\tau_3(c,f)\right)_x\right]_x \quad \text{for } 0 \le x \le 1,\ t > 0 \tag{1.8}$$

for the cells' motion; a new equation for the chemical kinetics of chemotactic agent is

$$\frac{\partial u}{\partial t} = -\frac{\lambda_2 um}{1+\lambda_5 u} \quad \text{for } 0 \le x \le 1,\ t > 0, \tag{1.9}$$

and, finally, the fact that macrophages transform chemotactic agent into TAF leads to the equation

$$\frac{\partial v}{\partial t} = \frac{\lambda_2 um}{1+\lambda_5 u} - \frac{\lambda_1 v\eta}{1+\lambda_2 v} \quad \text{for } 0 \le x \le 1,\ t > 0, \tag{1.10}$$

which replaces (1.2).

We briefly explain the processes underlying the enlarged model; for more details see [13]. Endothelial cells, as mentioned above, reside in the inner part of the membrane of the capillary vessels, and pericyte cells reside on the outer boundary of the membrane. Macrophage cells are located in the extracellular matrix outside the membrane. The tumor secretes angiogenic molecules that go directly to attack the membrane and chemotactic molecules (with concentration u) that interact with macrophages and are converted into angiogenic molecules. The angiogenic molecules (with concentration v) produce proteolytic enzyme (with concentration c) that dilate and break up the membrane, and thereby induces migration of its fibronectin molecules (with concentration f). Pericyte cells tend to move up a fibronectin gradient, while macrophages tend to move up the concentration gradient of the tumor emitted chemotactic factor.

Numerical solutions given in [13] and [14] exhibit the profiles of various cell densities and chemical concentrations during a real-time interval of several days. A large concentration of endothelial cells at one location is associated with the sprouting of a new capillary at that location. Therefore, it is important to know whether the solutions of the above systems lead to aggregation of endothelial cells in some region or, on the contrary, these cells tend to distribute uniformly in the capillary. In the first case, sprouting of new vessels can take place in regions of high aggregation while, in the second case, the model fails to describe this phenomenon.

In this paper we study primarily the model (1.1)–(1.4).

By adding (1.2) and (1.3) we see that $v + c$ is independent of t so that

$$v(x,t) = g(x) - c(x,t),$$

where $g(x)$ is a given function. Following [13], we shall assume that v and f are small enough so that we can approximate $1 + \lambda_2 v$ and $1 + \lambda_5 f$ by 1 and $f_M - f$ by f_M. Rewriting λ_3 instead of $\lambda_3 f_M$, one arrives at the following system:

$$\eta_t = D_1 \eta_{xx} - D_1 \left[\eta \left(\gamma_1 \frac{c_x}{c} - \gamma_2 \frac{f_x}{f} \right) \right]_x, \qquad 0 \le x \le 1,\ t > 0, \tag{1.11}$$

$$\frac{\partial c}{\partial t} = \lambda_1 (g - c)\eta, \qquad 0 \le x \le 1,\ t > 0, \tag{1.12}$$

$$\frac{\partial f}{\partial t} = \lambda_3 f \eta - \lambda_4 c f, \qquad 0 \le x \le 1,\ t > 0, \tag{1.13}$$

together with the no flux boundary condition

$$\eta_x - \eta \left(\gamma_1 \frac{c_x}{c} - \gamma_1 \frac{f_x}{f} \right) = 0 \ \text{ at } x = 0, 1 \tag{1.14}$$

and with positive initial conditions

$$\eta(x,0) = \eta_0(x), \quad c(x,0) = c_0(x), \quad f(x,0) = f_0(x). \tag{1.15}$$

Note that by the definition of $g(x)$ one has $c(x,t) \le g(x)$. Hence, $c(x,t)$ is uniformly bounded and, since $c_t \ge 0$, $\theta(x) = \lim_{t\to\infty} c(x,t)$ exists for any global solution of the system (1.1)–(1.4). This leads one to consider (as in [13]) the subsystem

$$\eta_t = D_1 \eta_{xx} - D_1 \left[\eta \left(\gamma_1 \frac{\theta_x}{\theta} - \gamma_2 \frac{f_x}{f} \right) \right]_x, \qquad 0 \le x \le 1,\ t > 0\ , \tag{1.16}$$

$$\frac{\partial f}{\partial t} = \lambda_3 f \eta - \lambda_4 \theta f, \qquad 0 \le x \le 1,\ t > 0, \tag{1.17}$$

with

$$\eta_x - \eta\left(\gamma_1 \frac{\theta_x}{\theta} - \gamma_2 \frac{f_x}{f}\right) = 0 \text{ at } x = 0, 1,\ t > 0, \tag{1.18}$$

$$\eta(x,0) = \eta_0(x),\ f(x,0) = f_0(x), \tag{1.19}$$

where θ is a *given* positive function. The system (1.16)–(1.19) can also be viewed as a particular case of (1.11)–(1.15) when $c_0(x) \equiv g(x)$.

In this paper we prove that the initial-boundary value problem (1.16)–(1.19) has a unique global classical solution for all $t > 0$ and we establish the phenomenon of aggregation. More specifically, we prove that the nonconstant stationary solution of (1.16)–(1.18) is a local attractor for the time-dependent solution of (1.16)–(1.19). A similar result is proved for the more general system (1.11)–(1.15) provided $g(x) - c_0(x)$ is small enough.

The proofs for (1.11)–(1.15) can actually be modified to include the results for the system (1.16)–(1.19). However, the treatment of this latter system is much simpler and, furthermore, suggests how to approach the more general case of (1.11)–(1.15). For this reason we first give the proofs for the system (1.16)–(1.19) in full details and then consider the general system (1.11)–(1.15), omitting some details.

Our results can also be extended to the system (1.1)–(1.6) with $\tau_1(c, f)$ being a more complicated function like, for instance,

$$\tau_1(c,f) = \left(\frac{\alpha_1 + c}{\alpha_2 + c}\right)^{\gamma_1} \left(\frac{\beta_2 + f}{\beta_1 + f}\right)^{-\gamma_2},$$

where α_i, β_i are positive constants.

The system (1.16)–(1.19) was also considered in [12] for γ_2 both positive and negative. The authors proved that if $\gamma_2 < 0$, then there are solutions (η, f) such that $\eta(x,t)$ becomes infinite in finite time, and if $\gamma_2 > 0$, there are solutions that exist for all time. In this paper we prove that if $\gamma_2 > 0$, then *all* solutions of (1.16)–(1.19) exist for all times. Another proof of this result was given in [16], but our proof is simpler and is the one we are going to adapt to the analysis of system (1.11)–(1.15); see Remark 3.6.

The system (1.16), (1.17) with $\theta = \text{const.}$ is a special case of general chemotaxis equations

$$\frac{\partial p}{\partial t} = \operatorname{div}\left(\nabla p - p\chi(w)\nabla w\right), \tag{1.20}$$

$$\frac{\partial w}{\partial t} = g(p, w). \tag{1.21}$$

These equations describe the rearrangement or movement of living organisms such as cells (e.g., bacteria) with density p under the influence of nondiffusing chemical species with concentration w. The system was introduced by Othmer and Stevens [15] to describe a random walk for p which is reinforced, or biased, by w, whereas at the same time it affects w. Such is the situation, for instance, for common soil bacteria (called myxobacteria) sliding over slime trails. Different choices of $g(p,w)$ and of the chemotactic sensitivity function $\chi(w)$ lead to different conclusions with regard to the profile of p.

For some choices of χ, g global solutions always exist, but for other choices solutions may blow up in finite time. In particular, as mentioned above, if $\gamma_2 < 0$

in (1.16), then there exist solutions of (1.16)–(1.19) that blow up in finite time [12], whereas in our case, where $\gamma_2 > 0$, global solutions always exist [16].

The structure of the paper is as follows: In section 2 we prove that the system (1.16)–(1.19) has a unique classical solution for small time $0 < t < T$. In section 3 we derive a priori bounds which enable us to extend the solution to all $t > 0$. In section 4 we prove that the stationary solution of (1.16)–(1.19) is a local attractor. In section 5 we extend the results of sections 2 and 3 to the general system (1.11)–(1.15) consisting of one diffusion equation and two ODEs together with no flux boundary conditions and initial conditions. Finally, in section 6 we prove that the stationary solutions of (1.11)–(1.15) are also local attractors.

In a recent paper Friedman and Tello [3] proved global existence of solutions of (1.20), (1.21) under general assumptions on g and χ. Their results, however, do not overlap at all with those of the present paper. In particular, the stationary solutions in [3] are all constants, whereas in the present paper the stationary solutions are nonconstant. The methods of the two papers are also entirely different: In the present paper we use integral estimates, whereas in [3] pointwise estimates are derived by comparison arguments.

A two-dimensional model of angiogenesis with one diffusing density and two nondiffusing species was considered in [1]; however, the question of global existence (or blow-up) for that system has not been studied.

We finally mention the Keller–Segal model [9], [10] for chemotaxis: It consists of (1.20) and

$$\alpha \frac{\partial w}{\partial t} = \varepsilon \triangle w + g(p, w) \qquad (\alpha \geq 0,\ \varepsilon > 0)\ . \tag{1.22}$$

In the case $\alpha = 0$, χ constant, and $g(p, w) = p - 1$, solutions may blow up [8] and the precise profile of the blow-up was studied in [5], [6], [7]. On the other hand in the case $\alpha > 0$, $\chi = 1$, and $g(p, w) = -\beta w + \gamma(p - 1)$, global solutions exist for general initial data [4].

In a recent paper Stevens [18] derived the chemotaxis system (1.20), (1.22) by probabilistic analysis. Her paper also reviews (more thoroughly than we do here) the literature of existence and blow-up of solutions of (1.20), (1.22).

2. Local existence for (1.16)–(1.19).

Set

$$\begin{aligned} \tau &= D_1 t, \\ P &= \frac{\lambda_3 \gamma_2}{D_1} \eta, \\ V &= \log\left(\frac{f^{\gamma_2}}{\theta^{\gamma_1}}\right), \\ g(x) &= \frac{\gamma_2 \lambda_4}{D_1} \theta(x). \end{aligned} \tag{2.1}$$

Writing for simplicity t instead of τ, the system (1.16)–(1.19) becomes

$$P_t = \left(P_x + V_x P\right)_x \ \text{ at } 0 \leq x \leq 1,\ t > 0, \tag{2.2}$$

$$V_t = P - g \text{ at } 0 \leq x \leq 1,\ t > 0, \tag{2.3}$$

$$P_x + V_x P = 0 \text{ at } x = 0, 1,\ t > 0, \tag{2.4}$$

$$P(x, 0) = P_0(x),\ V(x, 0) = V_0(x),\ \ 0 < x < 1. \tag{2.5}$$

Set $Q_T = \{0 < x < 1,\ 0 < t < T\}$ and $I = \{0 < x < 1\}$.

We assume that

$$\begin{aligned} &g(x) \in C^{2+\beta}(I), \quad g(x) \geq g_0 > 0, \\ &P_0(x),\ V_0(x) \in C^{2+\beta}(I), \ \text{ and} \\ &P_{0,x} + V_{0,x}P_0 = 0 \ \text{ at } x = 0, 1. \end{aligned} \tag{2.6}$$

It will be convenient later on to recast the system (2.2)–(2.5) in terms of the variables

$$c = e^{-V}, \quad u = Pe^V \ \ (P = cu).$$

Then

$$cu_t = (cu_x)_x + c^2u^2 - g(x)cu \ \text{ for } 0 \leq x \leq 1,\ t > 0, \tag{2.7}$$

$$c_t = -c^2u + gc \text{ for } 0 \leq x \leq 1,\ t > 0, \tag{2.8}$$

$$u_x(0,t) = u_x(1,t) = 0 \text{ for } t > 0, \tag{2.9}$$

$$u(x,0) = u_0(x) = P_0e^{V_0}, \ \ c(x,0) = c_0(x) = e^{-V_0},\ 0 \leq x \leq 1. \tag{2.10}$$

Equation (2.7) can also be written as

$$u_t - u_{xx} - \frac{c_x}{c}u_x = cu^2 - g(x)u\ . \tag{2.11}$$

Theorem 2.1. *If* (2.6) *holds, then there exists a unique solution of* (2.2)–(2.5) *for* $0 < t < T$, *with* $P \in C^{2+\beta, 1+\frac{\beta}{2}}_{x,t}(Q_T)$ *and* $W \in C^{2+\beta, 1+\frac{\beta}{2}}_{x,t}(Q_T)$, *provided* T *is sufficiently small.*

Proof. It suffices to prove the corresponding theorem for the system (2.7)–(2.10). We introduce the space X_T of functions with finite norm

$$\|u\|_{X_T} = |u|_{L^\infty(Q_T)} + |D_xu|_{C^{1+\beta,\frac{\beta}{2}}_{x,t}(Q_T)}$$

and the ball of radius R,

$$B_R = \{u \in X_T,\ \|u\|_T \leq R\}\,,$$

where

$$R = |u_0|_{C^{1+\beta}(I)} + 1.$$

For any $u \in B_R$ we solve (2.8)–(2.10) and find that

$$\|c\|_{X_T} \leq C_1(R).$$

Next we solve

$$\begin{aligned} U_t &= U_{xx} + \frac{c_x}{c}U_x + (cu^2 - g(x)u) \ \text{ in } Q_T, \\ U_x(0,t) &= U_x(1,t) = 0, \quad 0 < t < T, \\ U(x,0) &= u_0, \quad 0 \leq x \leq 1. \end{aligned}$$

Since $c_x \in C^{1+\beta,\frac{\beta}{2}}_{x,t}(Q_T)$, we can use the Schauder estimates (cf. [11]) to conclude that

$$|U|_{C^{2+\beta,1+\frac{\beta}{2}}_{x,t}(Q_T)} \leq C_2(R).$$

But then, by the mean value theorem,

$$|U-u_0|_{L^\infty(Q_T)} + |D_x(U-u_0)|_{C^{1+\beta,\frac{\beta}{2}}_{x,t}(Q_T)} \leq CT^\delta C_2(R)$$

for some $\delta > 0$. It follows that

$$\|U\|_{X_T} < R \tag{2.12}$$

if T is small enough so that $CT^\delta C_2(R) < 1$. Consider the transformation $S : u \to U$. By (2.12), S maps B_R into itself. From the above analysis we also easily see that

$$\|Su_1 - Su_2\|_{X_T} < C_3 T^\delta \|u_1 - u_2\|_{X_T},$$

with a constant C_3 depending on R. Hence S is a contraction in B_R provided T is sufficiently small. It follows that S has a unique fixed point, and together with the corresponding c they form the unique solution of (2.7)–(2.10). □

3. A priori bounds and global existence. Let (u, c) (or (P, V)) be a solution of (2.7)–(2.10) (or (2.2)–(2.5)) for some time interval $0 < t < T$. Note that u, c, P are all positive in $\overline{Q_T}$. We want to derive bounds

$$|u|_{C^{2+\alpha,1+\frac{\alpha}{2}}_{x,t}(Q_T)} + |c|_{C^{2+\alpha,1+\frac{\alpha}{2}}_{x,t}(Q_T)} \leq C(T) \tag{3.1}$$

or, equivalently,

$$|P|_{C^{2+\alpha,1+\frac{\alpha}{2}}_{x,t}(Q_T)} + |V|_{C^{2+\alpha,1+\frac{\alpha}{2}}_{x,t}(Q_T)} \leq C(T), \tag{3.2}$$

where $C(T)$ is a bounded function of T. In this proof we shall use the fact that

$$\int_0^1 P(x,t)dx = \text{const} \equiv \mu. \tag{3.3}$$

This follows by integrating (2.2) over x and using (2.4).

In what follows we shall denote various bounded functions of T by $C(T)$.

Lemma 3.1. *The following estimate holds:*

$$\sup_{0<t<T}\int_I P(x,t)\log P(x,t)dx + \sup_{0<t<T}\int_I (V_x(x,t))^2\,dx + \int\int_{Q_T}\frac{P_x^2}{P}dxdt \leq C(T). \tag{3.4}$$

Proof. Let $h(s) = \int(\log s)ds = s\log s - s$. If we multiply (2.2) by $\log P$ and integrate over Q_t, we get

$$\int_I h(P(x,t))dx + \int\int_{Q_t}\frac{P_x^2}{P}dxdt + \int\int_{Q_t}V_xP_xdxdt = \int_I h(P_0(x))dx\,. \tag{3.5}$$

But, by (2.3),

$$P_x = (V_t)_x + g_x = (V_x)_t + g_x,$$

so that

$$\int\int_{Q_t} V_x P_x dxdt = \left(\frac{1}{2}\int\int_{Q_t}\left(V_x^2\right)_t dxdt + \int\int_{Q_t} V_x g_x dxdt\right)$$

$$= \frac{1}{2}\int_I V_x^2 dx + \int\int_{Q_t} V_x g_x dxdt - \frac{1}{2}\int_I V_{0,x}^2 dx$$

$$\geq \frac{1}{2}\int_I V_x^2 dx - C\int\int_{Q_t} V_x^2 dxdt - C(t+1)\ .$$

Substituting this into (3.5) and using (3.3) we get

$$\int_I P(x,t)\log P(x,t)dx + \int\int_{Q_T}\frac{P_x^2}{P}dxdt + \int_I V_x^2(x,t)dx \leq C(t+1) + C\int\int_{Q_t} V_x^2 dxdt.$$

Since this estimate yields, by Gronwall's inequality,

$$\int\int_{Q_T} V_x^2 dx \leq C(T),$$

(3.4) follows. □

Lemma 3.2. *There exists a constant $C(T)$ such that*

$$\sup_{0<t<T}\int_I P^2(x,t)dx + \int\int_{Q_T} P_x^2 dxdt \leq C(T). \tag{3.6}$$

Proof. If we write (2.2) in the form

$$P_t = (P_x + a(x,t)P)_x\,,$$

then from Lemma 3.1 we have

$$\sup_{0\leq t\leq T}\int_I |a(x,t)|^2\, dx \leq C(T)$$

so that $\int_0^t \left(\int_I \left|a^2\right|^q dx\right)^{\frac{1}{r}} dt \leq C(T)$ with $q = 1, r = 2$. The latter condition allows us to apply Theorem 2.1 in [11, p. 143]. According to that theorem, the solution P satisfies (3.6). We note that Theorem 2.1 in [11] is actually stated for the case of zero Dirichlet data, but the proof for zero Neumann data is the same. □

Lemma 3.3. *There holds*

$$\sup_{Q_T}|u| \leq C(T).$$

Proof. From (3.3) we deduce that

$$|P(x,t)-\mu|^2 \leq \int_0^1 P_x^2(x,t)dx,$$

and using (3.6) we then get

$$\int_0^T \sup_{x\in I} |P(x,t)|^2 \, dt \le C(T). \tag{3.7}$$

Set $\overline{P}(t) = \max_{x\in I} P(x,t)$. Since $cu = P$, (2.11) gives

$$u_t - u_{xx} - \frac{c_x}{c} u_x \le \overline{P}(t)u.$$

The function

$$U(t) = C_0 e^{\int_0^t \overline{P}(t')dt'} \qquad \left(C_0 \ge \max_{x\in I} u(x,0) \right)$$

satisfies

$$U_t = \overline{P}(t)U$$

and is therefore a supersolution. It follows that

$$u(x,t) \le C_0 e^{\int_0^t \overline{P}(t')dt'} \le C(T)$$

by (3.7). □

From (2.8) we see also that c is bounded from above and below, i.e.,

$$c(x,t) \le C(T), \qquad \frac{1}{c(x,t)} \le C(T). \tag{3.8}$$

Equation (2.7) has the form

$$au_t = (cu_x)_x + f,$$

with f bounded by $C(T)$. In the case of $a \equiv 1$ and zero Dirichlet data for u, the following C^α estimate (cf. [11, p. 204, Thm. 10.1]) holds:

$$|u|_{C^{\alpha,\frac{\alpha}{2}}_{x,t}(Q_T)} \le C(T) \ \text{ for some } 0 < \alpha < 1. \tag{3.9}$$

The proof extends to the present case of zero Neumann data. It also extends to the case where a is uniformly bounded above and below by positive constants provided $|a_t| \le C$, since integration by parts of

$$\int\int (u-k)^+ \, au_t dxdt \qquad (k > 0)$$

yields the additional harmless term

$$-\int\int (u-k)^+ \, a_t udxdt.$$

From (2.8) and (3.9) we deduce that

$$|c|_{C^{\alpha,\frac{\alpha}{2}}_{x,t}(Q_T)} \le C(T). \tag{3.10}$$

LEMMA 3.4. *The estimates* (3.1), (3.2) *hold.*

Proof. Set

$$v = cu_x, \; w = c_x.$$

We easily compute that

$$v_t - v_{xx} + \frac{w}{c} v_x = wcu^2 + cuv - g'cu, \tag{3.11}$$

$$w_t = (-2cu + g)w - cv + g'c. \tag{3.12}$$

We write (3.11) in the form

$$bv_t - \left(\frac{1}{c} v_x\right)_x - uv = f,$$

where

$$b = \frac{1}{c} \,, \; f = wu^2 - g'u.$$

By (3.8) and the boundedness of $|c_t|$ we deduce that $|b_t| \leq C(T)$. Since u is bounded and

$$\int_I \left|\frac{c_x}{c}\right|^2 dx \leq \int_I |V_x|^2 \, dx \leq C(T),$$

also

$$\int_I |f(x,t)|^2 \, dx \leq C \int_I |c_x|^2 \, dx \leq C(T) \; .$$

We are now in a position to apply the C^α estimates of Theorem 10.1 of [11, p. 204]. (The condition (7.1) on page 181 holds with $q = 2$.) Here again we use the fact that $|b_t| \leq C(T)$ and make the same remark as we did following (3.9).

Having proved that $v \in C^{\alpha,\frac{\alpha}{2}}_{x,t}(Q_T)$ we can use (3.12) to prove the same for w. It follows that

$$|u_x|_{C^{\alpha,\frac{\alpha}{2}}_{x,t}(Q_T)} \, , \; |c_x|_{C^{\alpha,\frac{\alpha}{2}}_{x,t}(Q_T)} \leq C(T).$$

We can now bootstrap the regularity of u to $C^{2+\alpha,1+\frac{\alpha}{2}}_{x,t}(Q_T)$ by the Schauder estimates applied to (2.7), and next also derive the same regularity for c using (2.8). Finally, we can bootstrap this also to $\alpha = \beta$ (originally α is just some positive number) by again using the Schauder estimates. □

Having established the a priori bounds (3.1), (3.2), we can now extend Theorem 2.1 step-by-step to $0 < t < T$ for any $T > 0$. The size of each time step depends just on the $C^{2+\beta}$ bound on the solution, and thus just on T. We conclude with the following theorem.

THEOREM 3.5. *If* (2.6) *holds, then there exists a unique global solution of* (2.2)–(2.5) *such that P, W are in $C^{2+\beta,1+\frac{\beta}{2}}_{x,t}(Q_T)$ for any $T > 0$.*

Remark 3.6. Theorem 3.5 (in case $g = 0$) was also proved by Rascle [16]. Both proofs of the a priori estimates begin with Lemma 3.2. However, the rest of the proof is much simpler by our method, since we are able to derive quite quickly a uniform bound on u (Lemma 3.4).

4. Convergence to a stationary solution for system (1.16)–(1.19). If we look for stationary solutions of (1.16)–(1.19) we are forced into taking

$$P = P_s(x), \qquad V_x = V_{s,x} = -\frac{P_{s,x}(x)}{P_s(x)}\ .$$

This implies that

$$P_s = \mu + g(x) - \lambda, \text{ with } \lambda \equiv \int_0^1 g(x)dx, \ \ \mu = \int_0^1 P_s(x)dx. \tag{4.1}$$

$$V_{s,x} = -\frac{g'(x)}{\mu + g(x) - \lambda}. \tag{4.2}$$

By (2.3), one must have $V_{s,t} = P_s - g = \mu - \lambda$ and combining this with (4.2), we conclude

$$V_s(x,t) = (\mu - \lambda)t - \log\left(\mu + g(x) - \lambda\right). \tag{4.3}$$

In this section we prove that the stationary solution given by (4.1), (4.2) is a local attractor, i.e., if the initial data of (P, V) are "close" to (P_s, V_s) (in the sense of (4.5) below), then $(P, V) \to (P_s, V_s)$ exponentially fast as $t \to \infty$.

The phenomena whereby nonstationary solutions converge to a nonconstant stationary solution is called aggregation, according to the definition of Othmer–Stevens [15] and Levine–Sleeman [17]. This phenomenon is of particular interest in the context of angiogenesis, for it suggests that new blood vessels will eventually sprout from points where the nonstationary solution achieves its largest values (cf. [12], [13]). The aggregation phenomena is also of interest to general chemotaxis models (cf. [15], [12]).

In what follows we assume that

$$\alpha \equiv \inf_x \left(\mu + g(x) - \lambda\right) > 0. \tag{4.4}$$

Theorem 4.1. *If* (4.4) *holds and*

$$\int_0^1 \left(\left|P_x(x,0) - P_{s,x}(x)\right|^2 + \left|P(x,0) - P_s(x)\right|^2 + \left|V_x(x,0) - V_{s,x}(x)\right|^2\right) dx \le \varepsilon, \tag{4.5}$$

where ε *is positive and sufficiently small, then*

$$\sup_x \left|P(x,t) - P_s(x)\right| \le C\varepsilon e^{-\nu t}\ , \tag{4.6}$$

$$\sup_x \left|V_x(x,t) - V_{s,x}(x)\right| \le C\varepsilon e^{-\nu t}\ , \tag{4.7}$$

and

$$\int_0^1 \left|P_x(x,t) - P_{s,x}(x)\right|^2 dx \le C\varepsilon e^{-\nu t} \quad \textit{for all } t > 0, \tag{4.8}$$

where C *and* ν *are positive constants.*

It will be convenient to state Theorem 4.1 in a different form. To do that, let us introduce the functions

$$\psi(x,t) = \int_0^x \left(P(\xi,t) - \mu - g(\xi) + \lambda\right) d\xi, \tag{4.9}$$

$$w(x,t) = V_x(x,t) - \psi(x,t) + \frac{g'(x)}{\mu + g(x) - \lambda}\ . \tag{4.10}$$

Then, after a straightforward computation, the system (1.16)–(1.19) can be restated as

$$\psi_t - \psi_{xx} - (\mu + g - \lambda)\,\psi - (\mu + g - \lambda)\,w + \frac{g'\psi_x}{(\mu + g - \lambda)} = \psi_x\,(\psi + w) \equiv F, \tag{4.11}$$

$$w_t + (\mu + g - \lambda)\,\psi + (\mu + g - \lambda)\,w - \frac{g'\psi_x}{(\mu + g - \lambda)} = -\psi_x\,(\psi + w) \equiv -F \tag{4.12}$$

for $0 < x < 1$, with boundary conditions

$$\psi(0,t) = \psi(1,t) = 0 \tag{4.13}$$

and initial conditions

$$\psi(x,0) = \psi_0(x), \ \ w(x,0) = w_0(x), \tag{4.14}$$

where $\psi_0 \in C^1\,[0,1]$, $w_0 \in C^0\,[0,1]$.

It is easily seen that Theorem 4.1 can be restated in the following form.

Theorem 4.2. *If* (4.4) *holds and*

$$\int_0^1 \left(\left|D_t\psi_0\right|^2 + \left|D_x\psi_0\right|^2 + w_0^2\right) dx \le \varepsilon, \tag{4.15}$$

where $\varepsilon > 0$ is sufficiently small, then

$$\sup_x |\psi_x(x,t)| \le C\varepsilon e^{-\nu t}\ , \tag{4.16}$$

$$\sup_x \left(|w(x,t)| + |w_t(x,t)|\right) \le C\varepsilon e^{-\nu t}\ , \tag{4.17}$$

and

$$\int_0^1 \left(\left|D_t\psi(x,t)\right|^2 + \left|D_x\psi(x,t)\right|^2\right) dx \le C\varepsilon e^{-\nu t} \ \textit{ for all } t > 0, \tag{4.18}$$

where C and ν are positive constants.

Proof. It will be convenient to rewrite (4.11) in the form

$$\psi_t - (\mu + g - \lambda)\left(\frac{\psi_x}{\mu + g - \lambda}\right)_x - (\mu + g - \lambda)\,(\psi + w) = F. \tag{4.19}$$

Also, by adding (4.11) and (4.12) we get

$$(\psi + w)_t = \psi_{xx}. \tag{4.20}$$

Differentiating (4.19) with respect to t and using (4.20), we arrive at the equation

$$\psi_{tt} - (\mu + g - \lambda)\left(\frac{\psi_{xt}}{\mu + g - \lambda}\right)_x - (\mu + g - \lambda)\,\psi_{xx} = F_t, \tag{4.21}$$

where the left-hand side depends only on ψ. We shall use this equation together with (4.12) to derive our energy estimates on the solution (ψ, w).

If we multiply (4.21) by ψ_t, divide by $(\mu+g-\lambda)$, and integrate with respect to x, we obtain, after integration by parts,

$$\begin{aligned}\frac{1}{2}\frac{d}{dt}\int_0^1 \frac{\psi_t^2}{\mu+g-\lambda}dx + \int_0^1 \frac{\psi_{xt}^2}{\mu+g-\lambda}dx + \frac{1}{2}\frac{d}{dt}\int_0^1 \psi_x^2 dx \\ = \int_0^1 \frac{F_t\psi_t}{\mu+g-\lambda}dx \equiv K_1.\end{aligned} \tag{4.22}$$

Next we multiply (4.21) by ψ, divide by $(\mu+g-\lambda)$, and integrate with respect to x. Using the relation

$$\psi\psi_{tt} = (\psi\psi_t)_t - \psi_t^2,$$

we obtain, after integration by parts,

$$\begin{aligned}\frac{d}{dt}\int_0^1 \frac{\psi\psi_t}{\mu+g-\lambda}dx - \int_0^1 \frac{\psi_t^2}{\mu+g-\lambda}dx + \frac{1}{2}\frac{d}{dt}\int_0^1 \frac{\psi_x^2}{\mu+g-\lambda}dx + \int_0^1 \psi_x^2 dx \\ = \int_0^1 \frac{F_t\psi}{\mu+g-\lambda} \equiv K_2 .\end{aligned} \tag{4.23}$$

Finally, multiplying (4.12) by w and integrating with respect to x, we find that

$$\begin{aligned}\frac{1}{2}\frac{d}{dt}\int_0^1 w^2 dx + \int_0^1 (\mu+g-\lambda)\psi w dx + \int_0^1 (\mu+g-\lambda) w^2 dx \\ - \int_0^1 \frac{g'\psi_x w}{\mu+g-\lambda}dx = -\int_0^1 Fw dx \equiv K_3.\end{aligned} \tag{4.24}$$

We add (4.22) to (4.23) multiplied by ε_1 and (4.24) multiplied by ε_2 $(\varepsilon_1 > 0, \varepsilon_2 > 0)$ to get

$$\frac{1}{2}\frac{dJ}{dt} = I + K, \tag{4.25}$$

where

$$\begin{aligned}J = \int_0^1 \frac{\psi_t^2}{\mu+g-\lambda}dx + \int_0^1 \psi_x^2 dx + 2\varepsilon_1 \int_0^1 \frac{\psi\psi_t}{\mu+g-\lambda}dx \\ + \varepsilon_1 \int_0^1 \frac{\psi_x^2}{\mu+g-\lambda}dx + \varepsilon_2 \int_0^1 w^2 dx,\end{aligned} \tag{4.26}$$

$$\begin{aligned}I = -\int_0^1 \frac{\psi_{xt}^2}{\mu+g-\lambda}dx + \varepsilon_1 \int_0^1 \frac{\psi_t^2}{\mu+g-\lambda}dx - \varepsilon_1 \int_0^1 \psi_x^2 dx \\ -\varepsilon_2 \int_0^1 (\mu+g-\lambda)\psi w dx - \varepsilon_2 \int_0^1 (\mu+g-\lambda) w^2 dx + \varepsilon_2 \int_0^1 \frac{g'\psi_x w}{\mu+g-\lambda}dx,\end{aligned} \tag{4.27}$$

and

$$K = K_1 + \varepsilon_1 K_2 + \varepsilon_2 K_3. \tag{4.28}$$

Set

$$\beta \equiv \sup_x (\mu+g-\lambda), \qquad \gamma \equiv \sup_x |g_x| .$$

Then

$$I \leq -\beta^{-1}\int_0^1 \psi_{xt}^2 dx + \varepsilon_1\alpha^{-1}\int_0^1 \psi_t^2 dx - \varepsilon_1\int_0^1 \psi_x^2 dx$$
$$+ \varepsilon_2\beta\int_0^1 |\psi w|\, dx - \varepsilon_2\alpha\int_0^1 w^2 dx + \varepsilon_2\gamma\alpha^{-1}\int_0^1 |\psi_x w|\, dx.$$

By the Cauchy–Schwarz inequality,

$$\varepsilon_2\beta\int_0^1 |\psi w|\, dx \leq \frac{1}{4}\varepsilon_2\alpha\int_0^1 w^2 dx + \varepsilon_2\frac{\beta^2}{\alpha}\int_0^1 \psi^2 dx,$$

$$\varepsilon_2\gamma\alpha^{-1}\int_0^1 |\psi_x w|\, dx \leq \frac{1}{4}\varepsilon_2\alpha\int_0^1 w^2 dx + \frac{\varepsilon_2\gamma^2}{\alpha^3}\int_0^1 \psi_x^2 dx,$$

and together with Poincare's inequalities

$$\int_0^1 \psi_x^2 dx \geq \pi^2\int_0^1 \psi^2 dx, \tag{4.29}$$

$$\int_0^1 \psi_{xt}^2 dx \geq \pi^2\int_0^1 \psi_t^2 dx, \tag{4.30}$$

we conclude that

$$\begin{aligned} I \leq & -\frac{1}{2}\beta^{-1}\int_0^1 \psi_{xt}^2 dx - \left[\frac{\beta^{-1}\pi^2}{2} - \varepsilon_1\alpha^{-1}\right]\int_0^1 \psi_t^2 dx \\ & - \left[\varepsilon_1 - \varepsilon_2\left(\frac{\gamma^2}{\alpha^3} + \frac{\beta^2}{\pi^2\alpha}\right)\right]\int_0^1 \psi_x^2 dx - \frac{\varepsilon_2\alpha}{2}\int_0^1 w^2 dx. \end{aligned} \tag{4.31}$$

Setting

$$\Phi^2(t) \equiv \int_0^1 \left(\psi_t^2 + \psi_x^2 + w^2\right) dx,$$

we next prove the following lemma.

LEMMA 4.3. *If ε_1 is sufficiently small, then*

$$\delta\Phi^2 \leq J \leq \delta^{-1}\Phi^2, \tag{4.32}$$

where δ is a positive constant.

Proof. Clearly

$$J \geq \beta^{-1}\int_0^1 \psi_t^2 dx + (1+\varepsilon_1\beta^{-1})\int_0^1 \psi_x^2 dx - 2\varepsilon_1\alpha^{-1}\int_0^1 |\psi\psi_t|\, dx + \varepsilon_2\int_0^1 w^2 dx,$$

and

$$2\varepsilon_1\alpha^{-1}\int_0^1 |\psi\psi_t|\, dx \leq \frac{1}{2}\int_0^1 |\psi|^2\, dx + 2\frac{\varepsilon_1^2}{\alpha^2}\int_0^1 |\psi_t|^2\, dx.$$

Again using Poincare's inequality we find that

$$J \geq \left(\frac{1}{\beta} - 2\left(\frac{\varepsilon_1}{\alpha}\right)^2\right)\int_0^1 \psi_t^2 dx + \left(1 - \frac{1}{2\pi^2} + \varepsilon_1\beta^{-1}\right)\int_0^1 \psi_x^2 dx + \varepsilon_2\int_0^1 w^2 dx.$$

Hence the first inequality in (4.32) holds if ε_1 is sufficiently small.

The proof of the second inequality in (4.32) is immediate. $\square$

From (4.31) and Poincare's inequalities we easily find that if ε_1 and $\frac{\varepsilon_2}{\varepsilon_1}$ are sufficiently small, then

$$I \leq -\delta\Phi^2 - \frac{1}{2}\beta^{-1}\int_0^1 \psi_{xt}^2 dx \,, \tag{4.33}$$

where δ is a small positive constant. We can, in fact, take the δ's in (4.32) and (4.33) to be the same.

We now proceed to estimate the K in (4.28). We begin with K_1.

$$\begin{aligned}|K_1| &\leq \frac{1}{\alpha}\int_0^1 |F_t\psi_t|\,dx \leq \frac{1}{\alpha}\sup_x |\psi_t| \int_0^1 |F_t|\,dx \\ &\leq \frac{1}{\alpha}\sup_x |\psi_t| \left[\int_0^1 |\psi_{xt}\,(\psi+w)|\,dx + \int_0^1 |\psi_x\,(\psi+w)_t|\,dx\right].\end{aligned}$$

Since

$$\sup_x |\psi_t| \leq \left(\int_0^1 \psi_{xt}^2 dx\right)^{\frac{1}{2}} ,$$

we obtain

$$\begin{aligned}|K_1| \quad &\leq \quad \frac{1}{\alpha}\,\|\psi_t\|_{L^\infty}\Big\{\,\|\psi_{xt}\|_{L^2}\,\|\psi\|_{L^2} + \|\psi_{xt}\|_{L^2}\,\|w\|_{L^2} \\ &\qquad\qquad + \|\psi_x\|_{L^2}\,\|\psi_t\|_{L^2} + \|\psi_x\|_{L^2}\,\|w_t\|_{L^2}\Big\} \\ &\leq \quad \frac{1}{\alpha}\,\|\psi_{xt}\|_{L^2}^2\,\Phi + \frac{1}{\alpha}\,\|\psi_{xt}\|_{L^2}\,\Phi^2 + \frac{1}{\alpha}\,\|\psi_{xt}\|_{L^2}\,\|\psi_x\|_{L^2}\,\|w_t\|_{L^2}\,.\end{aligned} \tag{4.34}$$

To estimate $\|w_t\|_{L^2}$ we use (4.12):

$$\|w_t\|_{L^2} \leq \beta\,\|w\|_{L^2} + \beta\,\|\psi\|_{L^2} + \frac{\gamma}{\alpha}\,\|\psi_x\|_{L^2} + \|F\|_{L^2} \leq \left(\beta + \frac{\gamma}{\alpha}\right)\Phi + \|F\|_{L^2}\,.$$

Substituting this into (4.34) we get

$$|K_1| \leq \frac{1}{\alpha}\,\|\psi_{xt}\|_{L^2}^2\,\Phi + \left(\frac{1}{\alpha} + \frac{\beta}{\alpha} + \frac{\gamma}{\alpha^2}\right)\|\psi_{xt}\|_{L^2}\,\Phi^2 + \frac{1}{\alpha}\,\|\psi_{xt}\|_{L^2}\,\Phi\,\|F\|_{L^2}\,. \tag{4.35}$$

The estimate of $|K_2|$ is similar; we just replace (one of) the factor $\|\psi_{xt}\|_{L^2}$ by $\|\psi_x\|_{L^2}$ on the right-hand side of (4.35), i.e.,

$$\begin{aligned}|K_2| &\leq \frac{1}{\alpha}\|\psi_x\|_{L^2}\Big\{\,\|\psi_{xt}\|_{L^2}\,\Phi + \left(1+\beta+\frac{\gamma}{\alpha}\right)\Phi^2 + \Phi\|F\|_{L^2}\Big\} \\ &\leq \frac{1}{\alpha}\Big\{\,\|\psi_{xt}\|_{L^2}\,\Phi^2 + \left(1+\beta+\frac{\gamma}{\alpha}\right)\Phi^3 + \Phi^2\|F\|_{L^2}\Big\}.\end{aligned}$$

Finally,

$$K_3 \leq \|F\|_{L^2}\,\|w\|_{L^2} \leq \|F\|_{L^2}\,\Phi.$$

Combining these estimates we find that

$$\begin{aligned}|K| \quad &\le \quad \frac{1}{\alpha}\left\|\psi_{xt}\right\|_{L^2}^2\Phi + \left(\frac{2}{\alpha}+\frac{\beta}{\alpha}+\frac{\gamma}{\alpha^2}\right)\left(\left\|\psi_{xt}\right\|_{L^2}\Phi^2+\varepsilon_1\Phi^3\right)+\frac{\varepsilon_1}{\alpha}\left\|\psi_{xt}\right\|_{L^2}\Phi^2 \\ &\quad + \left(\frac{1}{\alpha}\left\|\psi_{xt}\right\|_{L^2}\Phi+\frac{1}{\alpha}\varepsilon_1\Phi^2+\varepsilon_2\Phi\right)\|F\|_{L^2}.\end{aligned} \tag{4.36}$$

To estimate the L^2 norm of F we observe that

$$\|F\|_{L^2} \le \|\psi\psi_x\|_{L^2}+\|\psi_x w\|_{L^2} \le \sup_x|\psi|\Phi+\sup_x|\psi_x|\,\Phi \le \Phi^2+\sup_x|\psi_x|\,\Phi. \tag{4.37}$$

By Sobolev's inequality and by (4.11),

$$\begin{aligned}\sup_x|\psi_x| \le \|\psi_x\|_{L^2}+\|\psi_{xx}\|_{L^2} &\le \|\psi_x\|_{L^2}+\|\psi_t\|_{L^2}+\beta\|\psi\|_{L^2}+\beta\|w\|_{L^2} \\ &+\frac{\gamma}{\alpha}\|\psi_x\|_{L^2}+\sup_x|\psi_x|\left(\|\psi\|_{L^2}+\|w\|_{L^2}\right).\end{aligned}$$

Hence

$$\sup_x|\psi_x| \le \frac{\|\psi_x\|_{L^2}+\|\psi_t\|_{L^2}+\beta\|\psi\|_{L^2}+\beta\|w\|_{L^2}+\frac{\gamma}{\alpha}\|\psi_x\|_{L^2}}{1-(\|\psi\|_{L^2}+\|w\|_{L^2})} \le \frac{C_1\Phi}{1-\sqrt{2}\Phi} \tag{4.38}$$

(where $C_1 = C_1(\beta,\alpha,\gamma)$) provided $\Phi < 1/\sqrt{2}$. Substituting this into (4.37) we get

$$\|F\|_{L^2} \le \Phi^2 + C_1\frac{\Phi^2}{1-\Phi} \le C_2\Phi^2 \ (C_2 \text{ constant})$$

provided $\Phi < \frac{1}{2\sqrt{2}}$. From this estimate and (4.36) we find that

$$|K| \le \frac{1}{\alpha}\|\psi_{xt}\|_{L^2}^2\Phi + C_3\|\psi_{xt}\|_{L^2}\Phi^2 + C_4\Phi^3, \tag{4.39}$$

where C_3, C_4 are constants.

A substitution of (4.33) and (4.39) into the differential equation (4.25) gives

$$\frac{1}{2}\frac{dJ}{dt} \le -\delta\Phi^2 - \frac{1}{2}\beta^{-1}\int_0^1 \psi_{xt}^2dx + \frac{1}{\alpha}\|\psi_{xt}\|_{L^2}^2\Phi + C_3\|\psi_{xt}\|_{L^2}\Phi^2 + C_4\Phi^3,$$

and since

$$C_3\|\psi_{xt}\|_{L^2}\Phi^2 \le \frac{1}{4}\beta^{-1}\|\psi_{xt}\|_{L^2}^2 + C_3^2\beta\Phi^4,$$

we conclude that, as long as $\Phi(t) < \frac{\alpha}{4\beta}$, one has

$$\frac{1}{2}\frac{dJ}{dt} \le -\delta\Phi^2 + C\Phi^3. \tag{4.40}$$

By Lemma 4.3 we then obtain the inequality

$$\frac{1}{2}\frac{dJ}{dt} \le -\delta_1 J + AJ^{\frac{3}{2}} \qquad (\delta_1, A > 0),$$

so that

$$J(t) \le Ce^{-\nu t} \qquad (\nu \equiv 2\delta_1),$$

provided $AJ^{\frac{1}{2}}(0) < \delta_1$ and $\Phi(0)$ is small enough. Again recalling Lemma 4.3, we conclude that if (4.5) holds, then $\Phi(t)$ will remain small for all $t > 0$, and (4.18) will hold. Finally, (4.16) follows from (4.38), and (4.17) then follows from the differential equation (4.12). □

5. The general system (1.11)–(1.15). Consider the general system (1.11)–(1.15) with given initial conditions. We shall further assume that the initial condition $c(x,0)$ (initial concentration of proteolytic enzyme) satisfies

$$\sup_{0\le x\le 1}\frac{g(x)-c_0(x)}{c_0(x)}<\frac{\gamma_2\lambda_3}{\gamma_1\lambda_1} \tag{5.1}$$

and that

$$\gamma_2\lambda_3<\frac{1}{2}; \tag{5.2}$$

in this connection, we recall from [13] the values of $\lambda_j,\ \gamma_j$:

$$\lambda_1=73,\quad \lambda_3=0.22,\quad \gamma_1=\gamma_2=1.2\ .$$

For these values, $\gamma_2\lambda_3\ =0.\,26$, so that (5.2) is certainly satisfied.

Since $c(x,t)$ is monotone increasing in t, (5.1) implies that

$$M(x,t)\equiv\gamma_2\lambda_3-\gamma_1\lambda_1\frac{g-c}{c}\ge M_0>0, \tag{5.3}$$

where $M_0=\gamma_2\lambda_3-\gamma_1\lambda_1\sup_{0\le x\le 1}\frac{g(x)-c_0(x)}{c_0(x)}$.

We introduce now the notation

$$\tau=D_1t,\qquad P=\frac{\lambda_4}{D_1}\eta\ ,$$
$$W=\log\frac{f^{\gamma_2}}{c^{\gamma_1}}\ .$$

Then

$$W_t=\left(\gamma_2\lambda_3-\gamma_1\lambda_1\frac{g-c}{c}\right)P-\gamma_2\lambda_4c\ .$$

Replacing τ with t, the system for P, W, and c becomes

$$P_t=(P_x+PW_x)_x\quad\text{for } 0\le x\le 1,\ t>0, \tag{5.4}$$
$$c_t=\lambda_1(g-c)P\quad\text{for } 0\le x\le 1,\ t>0, \tag{5.5}$$
$$W_t=\left(\gamma_2\lambda_3-\gamma_1\lambda_1\frac{g-c}{c}\right)P-\gamma_2\lambda_4c\quad\text{for } 0\le x\le 1,\ t>0, \tag{5.6}$$

$$(P_x+PW_x)(x,t)=0\quad\text{at } x=0,1, \tag{5.7}$$

$$P(x,0)=P_0(x),\quad W(x,0)=W_0(x),\quad c(x,0)=c_0(x), \tag{5.8}$$

$$\left(P_{0,x}+P_0W_{0,x}\right)(x)=0\ \text{ at } x=0,1.$$

By (5.3) the coefficient of P in (5.6) is uniformly positive. This assumption is, in fact, crucial; see Remark 5.8.

Theorem 5.1. *Given $P_0(x), W_0(x), c_0(x) \in C^{2+\beta}[0,1]$, there exists a unique global solution of* (5.4)–(5.8) *such that $P(x,t), W(x,t), c(x,t) \in C_{x,t}^{2+\beta,1+\frac{\beta}{2}}(Q_T)$ for any $T < \infty$.*

The rest of the section is devoted to the proof of Theorem 5.1. The proof of local existence is similar to the proof of Theorem 2.1. Thus it remains to establish a priori bounds. More precisely, assuming that a solution exists for $t < T$, T arbitrary, it suffices to establish a priori $C_{x,t}^{2+\beta,1+\frac{\beta}{2}}(Q_T)$ bounds by a constant $C(T)$, where $C(T)$ is a bounded function of T. To derive such bounds we first multiply (5.4) by $\log P$ and integrate in space and time, and obtain, after integration by parts,

$$\int_0^1 P(x,t)\log P(x,t)dx + \int_0^t\int_0^1 \frac{P_x^2(x,t')}{P(x,t')}dxdt' = -\int_0^t\int_0^1 P_x(x,t')W_x(x,t')dxdt' + C.$$

Next we multiply (5.4) by W and integrate in space and time to obtain, after integration by parts,

$$\begin{aligned}\int_0^1 W(x,t)P(x,t)dx - \int_0^t\int_0^1 W_t(x,t')P(x,t')dxdt' + \int_0^t\int_0^1 P(x,t')W_x^2(x,t')dxdt'\\ = -\int_0^t\int_0^1 P_x(x,t')W_x(x,t')dxdt' + C.\end{aligned}$$

Adding the two equations, we get

$$\begin{aligned}\int_0^1 P(x,t)\log P(x,t)dx + \int_0^t\int_0^1 \frac{P_x^2(x,t')}{P(x,t')}dxdt' + \int_0^t\int_0^1 P(x,t')W_x^2(x,t')dxdt'\\ = -\int_0^t\int_0^1 W_t(x,t')P(x,t')dxdt' - 2\int_0^t\int_0^1 P_x(x,t')W_x(x,t')dxdt'\\ -\int_0^1 W(x,t)P(x,t)dxdt + C \equiv J_1 + J_2 + J_3 + C.\end{aligned} \tag{5.9}$$

Our goal now is to establish good-enough estimates for J_1, J_2, and J_3. The estimate for J_3 is immediate: By (5.6) and (5.1)

$$\begin{aligned}J_3 \equiv -\int_0^1 W(x,t)P(x,t)dx &= -\int_0^1 \left(W(x,0) + \int_0^t W_t(x,t')dt'\right)P(x,t)dx\\ &\le -\int_0^1 \left(W(x,0) - \gamma_2\lambda_4\int_0^t c(x,t')dt'\right)P(x,t)dx\\ &\le \left(\sup_x |W(x,0)| + A\gamma_2\lambda_4 t\right)\int_0^1 P(x,t)dx \le C,\end{aligned}$$

where we have used (3.3) (which is also valid also for the present system) and the inequality $c \le g$.

The estimate for J_1 is given in the following lemma.

Lemma 5.2. *There holds that*

$$J_1 \le \gamma_2\lambda_3\left(2\mu^2 t + \mu\int_0^t\int_0^1 \frac{P_x^2(x,t')}{P(x,t')}dxdt'\right). \tag{5.10}$$

Proof. By (5.6),

$$J_1 \leq \gamma_2\lambda_3 \int_0^t \int_0^1 P^2 dx dt'. \tag{5.11}$$

Also

$$\int_0^t \int_0^1 P^2 dx dt' \leq \int_0^t \left(\sup_x P \int_0^1 P dx \right) dt' = \mu \int_0^t \sup_x P(x,t') dt', \tag{5.12}$$

where we have used (3.3). Since $\sqrt{P}$ equals $\sqrt{\mu}$ at some point x, $0 < x < 1$,

$$\sqrt{P} - \mu^{\frac{1}{2}} \leq \frac{1}{2} \left(\int_0^1 \frac{P_x^2}{P} dx \right)^{\frac{1}{2}}$$

so that

$$P \leq \left[\mu^{\frac{1}{2}} + \frac{1}{2} \left(\int_0^1 \frac{P_x^2}{P} dx \right)^{\frac{1}{2}} \right]^2 \leq 2\mu + \frac{1}{2} \int_0^1 \frac{P_x^2}{P} dx.$$

It follows that

$$\mu \int_0^t \sup_x P(x,t') dt' \leq 2\mu^2 t + \frac{1}{2}\mu \int_0^t \int_0^1 \frac{P_x^2}{P} dx dt'.$$

Using this in (5.12) and recalling (5.11), the assertion (5.10) follows. □

In order to estimate J_2, we express P (from (5.5), (5.6)) in the form

$$P = \frac{W_t + \gamma_2\lambda_4 c}{M}. \tag{5.13}$$

Then

$$P_x = \frac{W_{xt} + \gamma_2\lambda_4 c_x}{M} - \frac{PM_x}{M}. \tag{5.14}$$

Inserting (5.14) into J_2 leads to

$$J_2 = -2\int_0^t \int_0^1 \frac{W_{xt}W_x}{M} dx dt' - 2\int_0^t \int_0^1 \frac{\gamma_2\lambda_4 c_x W_x}{M} dx dt' + 2\int_0^t \int_0^1 \frac{PM_x W_x}{M} dx dt'$$

$$= -2\int_0^t \int_0^1 \frac{W_{xt}W_x}{M} dx dt' - 2\int_0^t \int_0^1 \frac{\gamma_2\lambda_4 c_x W_x}{M} dx dt' + 2\gamma_1\lambda_1 \int_0^t \int_0^1 \frac{Pgc_x W_x}{c^2 M} dx dt'$$

$$\equiv J_{21} + J_{22} + J_{23}. \tag{5.15}$$

We estimate each of the J_{2i} in the following lemmas.

LEMMA 5.3. *The term J_{21} satisfies the estimate*

$$J_{21} \leq -2\int_0^1 W_x^2(x,t) dx + C. \tag{5.16}$$

Proof. Notice that

$$J_{21} = -\int_0^t \int_0^1 \frac{(W_x^2)_t}{M} dxdt'.$$

Integration by parts in t yields

$$J_{21} = -\int_0^1 \frac{W_x^2(x,t)}{M} dx - \int_0^t \int_0^1 \frac{M_t W_x^2}{M^2} dxdt' + C$$

$$= -\int_0^1 \frac{W_x^2(x,t)}{M} dx - \gamma_1 \lambda_1 \int_0^t \int_0^1 \frac{g c_t W_x^2}{c^2 M^2} dxdt' + C$$

and the last integral is positive since $c_t > 0$. Then, by (5.5) and the fact that c and M are bounded from above and below ($M < \gamma_2 \lambda_3$), we get

$$J_{21} \leq -\frac{1}{\gamma_2 \lambda_3} \int_0^1 W_x^2(x,t) dx + C.$$

Recalling (5.2), we conclude the inequality (5.16). □

In order to estimate J_{22} and J_{23}, we need to estimate c_x in terms of W_x.

LEMMA 5.4. *The following estimate holds:*

$$|c_x(x,t)| \leq A(t) + B(t)(g - c) \int_0^t |W_x(x,t')|\, dt', \tag{5.17}$$

where $A(t)$ and $B(t)$ are functions bounded in $[0,T]$ for any $T > 0$.

Proof. Eliminating P from (5.5) and (5.6), we deduce the relation

$$\frac{c_t}{\lambda_1(g-c)} = \frac{W_t + \gamma_2 \lambda_4 c}{\gamma_2 \lambda_3 - \gamma_1 \lambda_1 \frac{g-c}{c}}$$

from which we get

$$\frac{\gamma_2 \lambda_3 + \gamma_1 \lambda_1 - \gamma_1 \lambda_1 \frac{g}{c}}{\lambda_1(g-c)} c_t = W_t + \gamma_2 \lambda_4 c\ . \tag{5.18}$$

Let

$$G(c) = \int^c \frac{\gamma_2 \lambda_3 + \gamma_1 \lambda_1 - \gamma_1 \lambda_1 \frac{g}{c}}{\lambda_1(g-c)} dc = -\gamma_1 \ln c - \frac{\gamma_2 \lambda_3}{\lambda_1} \ln{(g-c)}$$

so that

$$\frac{d}{dt} G(c) = \frac{d}{dt} W + \gamma_2 \lambda_4 c.$$

After integration we get

$$G(c) = W + \gamma_2 \lambda_4 \int_0^t c(x,t') dt' + b(x)$$

for some function $b(x)$. Hence

$$-\gamma_1 \frac{c_x}{c} - \frac{\gamma_2 \lambda_3}{\lambda_1} \frac{g_x - c_x}{g - c} = W_x + \gamma_2 \lambda_4 \int_0^t c_x(x,t') dt' + b'(x).$$

This implies that c_x is the solution of the equation

$$c_x+\frac{\gamma_2\lambda_3 g_x}{\gamma_2\lambda_3+\gamma_1\lambda_1-\gamma_1\lambda_1\frac{g}{c}}=\frac{\lambda_1(g-c)}{\gamma_2\lambda_3+\gamma_1\lambda_1-\gamma_1\lambda_1\frac{g}{c}}\left[W_x+b'(x)+\gamma_2\lambda_4\int_0^t c_x(x,t')dt'\right].$$

By iteration we then obtain

$$c_x+\frac{\gamma_2\lambda_3 g_x}{\gamma_2\lambda_3+\gamma_1\lambda_1-\gamma_1\lambda_1\frac{g}{c}}$$

$$=\frac{\lambda_1(g-c)}{\gamma_2\lambda_3+\gamma_1\lambda_1-\gamma_1\lambda_1\frac{g}{c}}\left[W_x+B(x,t)+\gamma_2\lambda_4\int_0^t K(x,t,t')W_x(x,t')dt'\right]$$

for some bounded kernel $K(x,t,t')$ and some bounded function $B(x,t)$. Hence (5.17) follows. □

LEMMA 5.5. *The term J_{22} defined in* (5.15) *satisfies the estimate*

$$J_{22}\le C(t)\left[1+\int_0^1\int_0^t W_x^2(x,t')dxdt'\right]. \tag{5.19}$$

Proof. By the Cauchy–Schwarz inequality and boundedness of M we have

$$J_{22}\le C\left(\int_0^t\int_0^1 c_x^2dxdt'+\int_0^t\int_0^1 W_x^2dxdt'\right).$$

In order to estimate $\int_0^t\int_0^1 c_x^2dxdt'$ we use (5.17) to deduce

$$|c_x(x,t')|^2\le 2A(t')^2+2B(t')^2(g-c)^2\left(\int_0^{t'}|W_x(x,t'')|\,dt''\right)^2$$

$$\le 2A(t')^2+2B(t')^2t'(g-c)^2\left(\int_0^{t'}|W_x(x,t'')|^2\,dt''\right). \tag{5.20}$$

Hence

$$\int_0^t\int_0^1 c_x^2dxdt'\le 2A(t)^2t+2B(t)^2t(g-c)^2\int_0^t\int_0^1|W_x(x,t')|^2\,dxdt',$$

and the inequality (5.19) follows. □

Finally, we estimate the term J_{23}.

LEMMA 5.6. *The following estimate holds:*

$$J_{23}\le\frac{1}{4}\int_0^t\int_0^1 PW_x^2dxdt'+C(t)\left[1+\int_0^1\int_0^t W_x^2(x,t')dxdt'\right]. \tag{5.21}$$

Proof. By the Cauchy–Schwarz inequality and the boundedness of c and M,

$$J_{23}\le\frac{1}{4}\int_0^t\int_0^1 PW_x^2dxdt'+C\int_0^t\int_0^1 Pc_x^2dxdt'$$

for some constant C. In order to estimate $\int_0^t \int_0^1 Pc_x^2 dxdt'$ we make use of (5.20) and (3.3) and deduce

$$\begin{aligned}
&\int_0^1 \int_0^t Pc_x^2 dxdt' \\
&\leq \int_0^1 \int_0^t \left\{ 2A(t')^2 + 2B(t')^2 t'(g-c)^2 \left(\int_0^{t'} |W_x(x,t'')|^2 \, dt'' \right) \right\} P(x,t')dxdt' \\
&\leq \int_0^t 2A(t')^2 dt' + \int_0^1 \left[\int_0^t |W_x(x,t'')|^2 \, dt'' \int_0^t \left[2B(t')^2 t'(g-c)^2 \right] P(x,t')dt' \right] dx \\
&\leq \int_0^t 2A(t')^2 dt' + \left(\int_0^1 \int_0^t |W_x(x,t'')|^2 \, dxdt'' \right) \left(\sup_x \int_0^t \left[2B(t')^2 t'(g-c)^2 \right] P(x,t')dt' \right).
\end{aligned}$$

But

$$\sup_x \int_0^t \left[2B(t')^2 t'(g-c)^2 \right] P(x,t')dt' \leq C \sup_x \int_0^t \lambda_1 (g-c) P(x,t')dt'$$

$$= C \sup_x \int_0^t c_t dt' = C(c(x,t) - c(x,0)) \leq C,$$

where we have used (5.5). Hence

$$J_{23} \leq \frac{1}{4} \int_0^t \int_0^1 PW_x^2 dxdt' + C(t) \left[1 + \int_0^1 \int_0^t W_x^2(x,t')dxdt' \right]$$

for some function $C(t)$ bounded in any interval $[0,T]$. □

We are now in position to prove the following theorem.

THEOREM 5.7. *For any solution to* (5.4)–(5.6) *in* $0 < t < T$ *the following inequalities hold:*

$$\sup_{t \in [0,T]} \int_0^1 W_x^2(x,t)dx \leq C(T), \tag{5.22}$$

$$\int_0^T \sup_x \left(\sqrt{P} - \mu^{\frac{1}{2}} \right)^2 dt \leq C(t). \tag{5.23}$$

Proof. Let us introduce the function of t

$$K[P,W] \equiv \int_0^1 P(x,t) \log P(x,t)dx + \frac{1}{2} \int_0^t \int_0^1 \frac{P_x^2(x,t')}{P(x,t')} dxdt'$$

$$+ \frac{1}{2} \int_0^t \int_0^1 P(x,t')W_x^2(x,t')dxdt' + 2 \int_0^1 W_x^2(x,t')dx.$$

From the previous lemmas it follows that

$$K[P,W] \leq A(t) + B(t) \int_0^t \int_0^1 W_x^2 dxdt'.$$

Hence

$$\int_0^1 W_x^2(x,t)dx \le A(t) + B(t)\int_0^t \int_0^1 W_x^2 dxdt'.$$

An application of Gronwall's inequality leads to the estimate

$$\int_0^t \int_0^1 W_x^2(x,t)dxdt \le C(t),$$

which implies that $K[P,W]$ is bounded by $C(T)$. In particular,

$$\frac{1}{2}\int_0^t \int_0^1 \frac{P_x^2(x,t')}{P(x,t')}dxdt' \le C(t)$$

and

$$\int_0^t \sup_x \left(\sqrt{P} - \mu^{\frac{1}{2}}\right)^2 dt \le \frac{1}{4}\int_0^t \int_0^1 \frac{P_x^2(x,t')}{P(x,t')}dxdt' \le C(t). \qquad \square$$

Proof of Theorem 5.1. Using (5.22), (5.23) we can continue as in section 3 to prove Theorem 5.1. In particular, we derive for $k = e^{-W}$, $u = Pe^W$, and c equations analogous to (2.2) (for u) and (2.3) (for k and c). Then we show the boundedness of the function u (as in Lemma 3.3) and of k, c and derive $C_{x,t}^{\alpha,\frac{\alpha}{2}}$ estimates for these functions. Finally, we consider the system for $v = ku_x$, k_x, c_x analogous to (3.11), (3.12) in order to bootstrap the regularity for u, k, c as in section 3. $\square$

Remark 5.8. If (5.6) is replaced by

$$W_t = -aP - b,$$

where a, b are positive constants, then global solutions may not exist. Indeed, Levine and Sleeman [12] gave examples of solutions that blow up in finite time. The main assumption we made in Theorem 5.1 is the inequality (5.1), which ensures that the coefficient of P in (5.6) is positive.

6. Convergence to a stationary solution in system (1.11)–(1.15).

The system (1.11)–(1.15) possesses the following stationary solution:

$$\begin{aligned} &P_s(x) = \mu + g(x) - \lambda, \text{ with } \lambda \equiv \int_0^1 g(x)dx,\\ &W_{s,x} = -\frac{g'(x)}{\mu + g(x) - \lambda},\\ &c_s(x) = g(x). \end{aligned}$$

Analogously to (4.3), we can compute

$$W_s = W_s(x,t) = (\mu - \lambda)t - \log(\mu + g(x) - \lambda).$$

In this section we prove a result analogous to Theorem 4.1 for system (1.11)–(1.15), namely, the local stability of the stationary solution. By rescaling we can rewrite the system (5.4)–(5.8) (which is equivalent to (1.11)–(1.15)) in the form

$$P_t = (P_x + PW_x)_x \text{ for } 0 \le x \le 1,\ t > 0, \tag{6.1}$$

$$c_t = \kappa_1(g - c)P \text{ for } 0 \le x \le 1,\ t > 0, \tag{6.2}$$

$$W_t = \left(1 - \kappa_2 \frac{g - c}{c}\right)P - c \text{ for } 0 \le x \le 1,\ t > 0, \tag{6.3}$$

together with suitable initial and boundary conditions. It will be convenient to recast (6.3) in the form

$$W_t = P - g - \kappa_2 \frac{g-c}{c} P + (g-c) \quad \text{for } 0 \le x \le 1,\ t > 0, \tag{6.4}$$

where the last two terms on the right-hand side represent a small perturbation.

Introducing functions ψ and w as in (4.9) and (4.10), respectively (with V substituted by W), and $\chi \equiv g - c$, one arrives at the system

$$\psi_t - \psi_{xx} - (\mu + g - \lambda)\,\psi - (\mu + g - \lambda)\,w + \frac{g'}{(\mu + g - \lambda)}\psi_x = \psi_x\,(\psi + w)\,, \tag{6.5}$$

$$\chi_t + \kappa_1\,(\mu + g - \lambda)\,\chi = -\kappa_1 \chi \psi_x, \tag{6.6}$$

$$\begin{aligned} &w_t + (\mu + g - \lambda)\,\psi + (\mu + g - \lambda)\,w - \frac{g'}{(\mu + g - \lambda)}\psi_x \\ &= -\psi_x\,(\psi + w) + \chi_x - \kappa_2 \left[\frac{\chi}{g - \chi}(\psi_x + \mu + g - \lambda)\right]_x . \end{aligned} \tag{6.7}$$

If $\kappa_1 = \kappa_2 = 0$, then the system reduces to the system (4.11), (4.12).

From (6.6) and its x-derivative we obtain the relations

$$\frac{1}{2}\frac{d}{dt}\int_0^1 \chi^2 dx + \int_0^1 (\mu + g - \lambda)\,\chi^2 dx = -\kappa_1 \int \psi_x \chi^2,$$

$$\frac{1}{2}\frac{d}{dt}\int_0^1 \chi_x^2 dx + \int_0^1 (\mu + g - \lambda)\,\chi_x^2 dx = -\kappa_1 \int_0^1 g_x \chi \chi_x dx - \kappa_1 \int (\psi_x \chi)_x\,\chi_x,$$

so that

$$\begin{aligned} &\frac{1}{2}\frac{d}{dt}\left[\int_0^1 \chi^2 dx + \varepsilon_3 \int_0^1 \chi_x^2 dx\right] \le -\alpha \left[\int_0^1 \chi^2 dx + \varepsilon_3 \int_0^1 \chi_x^2 dx\right] \\ &+ \kappa_1 \left(\gamma \varepsilon_3^{\frac{1}{2}} + \sup|\psi_x| + \|\psi_{xx}\|_{L^2}\right) \left[\int_0^1 \chi^2 dx + \varepsilon_3 \int_0^1 \chi_x^2 dx\right], \end{aligned} \tag{6.8}$$

where γ and α are as in section 4 and ε_3 is a positive number to be chosen small enough.

Combining (6.8) with the estimates analogous to (4.22)–(4.24) in the present context, it is a simple matter to obtain (4.40) with

$$\Phi(t) \equiv \int_0^1 \left(\psi_t^2 + \psi_x^2 + w^2 + \chi^2 + \chi_x^2\right) dx$$

and prove an inequality like (4.32). An estimate for $\|\psi_{xx}\|_{L^2}$ is obtained in the same way we obtained the estimate for $\sup|\psi_x|$ in section 4. This bound is needed in order to control the right-hand side of (6.8). We conclude the following theorem.

Theorem 6.1. *If*

$$\int_0^1 \left(\sum_{i=1}^2 \left| P^{(i)}(x,0) - P_s^{(i)}(x) \right|^2 + \sum_{i=1}^2 \left| \chi^{(i)}(x,0) \right|^2 + \left| W_x(x,0) - W_{s,x}(x) \right|^2 \right) dx \le \varepsilon, \tag{6.9}$$

where ε is positive and sufficiently small, then

$$\sup_x |P(x,t) - P_s(x)| \le C\varepsilon e^{-\nu t}, \tag{6.10}$$

$$\sup_x |W_x(x,t) - W_{s,x}(x)| \le C\varepsilon e^{-\nu t}, \tag{6.11}$$

$$\sup_x |\chi(x,t)| \le C\varepsilon e^{-\nu t}, \tag{6.12}$$

and

$$\int_0^1 |P_x(x,t) - P_{s,x}(x)|^2 \, dx \le C\varepsilon e^{-\nu t} \text{ for all } t > 0, \tag{6.13}$$

where C and ν are positive constants.

LINEAR INSTABILITY OF SOLITARY WAVE SOLUTIONS OF THE KAWAHARA EQUATION AND ITS GENERALIZATIONS[*]

THOMAS J. BRIDGES[†] AND GIANNE DERKS[†]

Abstract. The linear stability problem for solitary wave states of the Kawahara—or fifth-order KdV-type—equation and its generalizations is considered. A new formulation of the stability problem in terms of the symplectic Evans matrix is presented. The formulation is based on a multisymplectification of the Kawahara equation, and leads to a new characterization of the basic solitary wave, including changes in the state at infinity represented by embedding the solitary wave in a multiparameter family. The theory is used to give a rigorous geometric sufficient condition for instability. The theory is abstract and applies to a wide range of solitary wave states. For example, the theory is applied to the families of solitary waves found by Kichenassamy–Olver and Levandosky.

1. Introduction.

The Kawahara equation—or *fifth-order KdV-type equation*—is a model equation for plasma waves, capillary-gravity water waves, and other dispersive phenomena when the cubic KdV-type dispersion is weak. Such equations can be written in the general form

$$2\frac{\partial u}{\partial t}+\alpha\frac{\partial^3 u}{\partial x^3}+\beta\frac{\partial^5 u}{\partial x^5}=\frac{\partial}{\partial x}f(u,u_x,u_{xx})\,, \tag{1.1}$$

for the scalar-valued function $u(x,t)$, where α and β are real parameters with $\beta\neq 0$ and $f(u,u_x,u_{xx})$ is some smooth function. In many applications the phenomena which lead to the model equation (1.1) have a Hamiltonian structure. Therefore it is natural to require that f be a variational derivative, in which case (1.1) is a Hamiltonian system

$$\frac{\partial u}{\partial t}=\mathcal{J}\frac{\delta\mathcal{H}}{\delta u}\,,\quad\text{with}\quad \mathcal{J}=-\frac{1}{2}\frac{\partial}{\partial x}\,, \tag{1.2}$$

and

$$\mathcal{H}(u)=\int_{\mathbb{R}}\left(\tfrac{1}{2}\beta u_{xx}^2-\tfrac{1}{2}\alpha u_x^2+h(u,u_x,u_{xx})\right)\,dx, \tag{1.3}$$

where the variational derivative of the functional associated with $h(u,u_x,u_{xx})$ yields f. Precise forms for f and h will be given in section 2.

The form of (1.1) which occurs most often in applications is with $f(u,u_x,u_{xx})=a\,u^2$, where a is a nonzero constant. The first appearance of this equation known to the authors is in the Japanese literature: Kawahara [24] points out that Kakutani and Ono suggested the inclusion of a fifth-order term to KdV to model magneto-acoustic waves in 1969, and Hasimoto first showed in 1970 that a fifth-order term was

[†] Department of Mathematics and Statistics, University of Surrey, Guildford, Surrey, GU2 7XH, UK (T.Bridges@surrey.ac.uk, G.Derks@surrey.ac.uk).

necessary to model capillary-gravity waves for Bond number near one third. Kawahara [24] appears to have been the first to write down the complete equation (1.1) with $f(u, u_x, u_{xx}) = -3\,u^2$ (see equation (1) in [24]), begin a systematic study, observe that the solitary wave states could have oscillatory tails, and compute examples of such waves numerically. A more general nonlinearity was derived for water waves by Olver [28], using Hamiltonian perturbation theory, with further generalization given by Craig and Groves [13]. Kichenassamy and Olver [25] suggested taking the most reasonable general form for f—including nongradient forms—and then deducing under what conditions explicit solitary wave solutions exist, and Levandosky [26] proposed an interesting class of homogeneous nonlinearities. All of the above proposed nonlinearities can be characterized in the form (1.1), and when f is variational the system has the Hamiltonian formulation (1.2).

The system (1.1) has many classes of solutions, but a class of great interest is solitary wave states that are biasymptotic to a constant state at infinity. Depending on the form of the nonlinearity, the system can also have travelling fronts (a simple example is given on page 452 of [15]) as well as solitary waves biasymptotic to invariant manifolds more complex than the lines to be considered here (cf. section 2 and the comments in section 8 of [7]). However, for definiteness, we will restrict attention here to classes of solitary waves which decay exponentially to a constant (in general nonzero) at infinity. Such solitary waves travelling at speed c (i.e., $u(x,t) = \hat{u}(x-ct)$) satisfy the fourth-order ordinary differential equation

$$\beta\hat{u}_{xxxx} + \alpha\hat{u}_{xx} - 2c\hat{u} - f(\hat{u}, \hat{u}_x, \hat{u}_{xx}) = A\,, \tag{1.4}$$

where A is a constant of integration. When f is a gradient operator it is easily shown that (1.4) is the Euler–Lagrange equation associated with a Lagrange functional, and the Legendre transform of this functional results in a Hamiltonian formulation for (1.4),

$$U_x = J\,\nabla H(U)\,, \quad U \in \mathbb{R}^4\,, \tag{1.5}$$

where J is a standard unit symplectic operator on $\mathbb{R}^4$, and an expression for $H(U)$ is easily deduced but is not needed here. (A more general derivation of such finite-dimensional Hamiltonian system will be a consequence of multisymplectic formulation in section 2.)

Note that the Hamiltonian structure of this ODE with x considered as an evolution direction is distinct and dramatically different from the infinite-dimensional Hamiltonian structure associated with the time direction (1.2). The interplay between these two distinct structures will play an important role in what follows.

The Hamiltonian structure (1.5) of the reduced system (1.4) has been the basis of many of the methods for finding solitary wave states. A review article on the known classes of solitary wave states with an exhaustive list of references is given by Champneys [11]. Also of interest in this paper are the class of solitary waves found by Kichenassamy and Olver [25] and the recent results of Levandosky [26]. In [25], a classification of admissible expressions for f which lead to explicit sech^2 solitary wave states is given. In [26], an energy-momentum argument is used to prove the existence of a class of solitary waves associated with a homogeneous nonlinearity, and in Groves [19], the mountain-pass lemma is used to prove the existence of solitary waves including multibump solitary waves for a class of homogeneous nonlinearities.

Given the existence of such a large range of solitary wave states for (1.4), a natural question is to determine whether they are stable or unstable. The most successful approaches for studying the stability of KdV and generalized KdV (i.e., (1.1) with $\beta = 0$) have been the energy-momentum method for establishing nonlinear stability and instability (Benjamin [2], Bona [3]) and the connection between the derivative of the momentum with respect to the wave speed and stability (Bona, Souganidis, and Strauss [4], Pego and Weinstein [29]). These energy-momentum based methods have been extended to apply to the stability of solitary waves for the fifth-order KdV by several authors.

The momentum for (1.1) can be expressed as

$$\mathcal{I}(u) = \int_{\mathbb{R}} u^2 \, dx \,,$$

and therefore solitary wave states can be characterized as solutions of $\delta\mathcal{H} = c\delta\mathcal{I}$, i.e., as critical points of the Hamiltonian restricted to level sets of the momentum with c as a Lagrange multiplier. The nondegeneracy condition for this constrained variational principle is

$$\frac{d}{dc}\mathcal{I}(\hat{u}) \neq 0 \,,$$

where $\hat{u}(x, c)$ is the family of solitary waves parametrized by c. Rigorous Lyapunov stability can be obtained by proving that $\hat{u}$ is indeed a minimizer for this variational principle. This approach has been very successful for KdV-type equations but is very difficult to generalize to higher-order equations and systems of evolutionary PDEs. However, for some range of parameters and forms for f, Lyapunov-type energy-momentum arguments have been successfully applied to (1.1). The first results of this type are given by Ill'ichev and Semenov [21] for the waves of depression when $\alpha < 0$ which travel at speed $-c$. Karpman [23] shows that when $\alpha = +1$, $\beta < 0$, and $f = -\frac{u^{p+1}}{p+1}$ the energy-momentum argument and the sign of $\frac{dI}{dc}$ precisely determine stability and instability. However, this theory relies on a hypothesis that a certain linear operator has exactly one negative eigenvalue which is difficult to verify in general. Karpman's theory is applied by Dey, Khare, and Kumar [15] to a class of exact solutions, but it appears that this class of solutions is explicit only for isolated values of c (see further comments on this at the end of section 3).

Using the energy-momentum method and a compensated compactness argument, Levandosky [26] proves the existence of solitary waves for a homogeneous nonlinearity and obtains rigorous stability and instability results using an energy-momentum argument and the sign of $\frac{dI}{dc}$ for a restricted range of parameter space. Recently, Dias and Kuznetsov [16] have obtained rigorous lower bounds on the Hamiltonian function for (1.1) when $f = -u^2$ for the solitary waves with oscillatory tails known to exist near the minimum of the dispersion curve, suggesting that at least one of these families of waves is stable.

For general PDEs (not necessarily Hamiltonian), the most successful approach for the analysis of the linear stability problem is based on the Evans function. The Evans function is a complex analytic function of the spectral parameter, and under suitable hypotheses the zeros of the Evans function correspond to eigenvalues (cf. Evans [17], Alexander, Gardner, and Jones [1]). In Bridges and Derks [7], [9], [10] the concept of the *symplectic Evans function* and the *symplectic Evans matrix* were introduced for Hamiltonian evolution equations. This theory, which will be used as a basis for analyzing the linear stability problem for (1.1), will be summarized in sections 2–3. Essentially, the Hamiltonian PDE is reformulated as a Hamiltonian system on a multi-symplectic structure, where a distinct symplectic structure is assigned for the time and space directions (cf. Bridges [5], [6]). This decomposition allows for a geometric analysis of each step of the existence and linear stability analysis and can be used to deduce an explicit geometric condition for linear instability.

The purpose of this paper is fourfold: first, in section 2, we show that the natural geometric structure of (1.1) is not as a Hamiltonian system as in (1.2) but as a Hamiltonian system on a multisymplectic structure. The problem with (1.2) is that it does not encode any information about the spatial Hamiltonian structure (1.5) that arises when looking for solitary waves and in the linearization about a solitary wave. This geometry should be useful in other analyses of (1.1). Second, in section 3, we show that—with α, β, and f fixed—all existing solitary wave solutions come in three-parameter families, and these families are a natural consequence of the geometric structure. One of the parameters is c, the wave speed, and the other two are related to a space-time drift along an affine group orbit, and when nonzero, they lead to a nontrivial constant state at infinity, and they encode information about the linear stability problem (cf. section 5). We have not found any nontrivial effect on stability of the additional parameters, but we consider only a few examples here. (Examples where nontriviality of the state at infinity affects stability can be found in [7], [9].) These additional parameters are an intrinsic part of the geometry of the PDE. Third, in sections 4–6, we formulate the symplectic Evans matrix for this system. This matrix is of interest because zeros of the determinant of the symplectic Evans matrix in the right-half complex plane correspond to unstable eigenvalues. Fourth, in section 8, we present a rigorous geometric condition for instability for a class of solitary wave states of (1.1) based on the theory in [9], and then, in sections 9–10, this geometric instability criterion is applied to two examples of families of solitary wave states in the literature.

2. Multisymplectic structure of the Kawahara equation.

The starting point for the analysis is the Kawahara equation and its generalizations (1.1), where f is any function which can be written as the variational derivative of a functional

$$\frac{1}{2}\int_{\mathbb{R}}[h(u,u_x,u_{xx})]\,dx.$$

A straightforward calculation shows that this implies that h has to be of the form

$$h(q,r,s)=F(q,r)+sE(q,r)$$

and therefore

$$f(q,r,s)=F_q(q,r)-rF_{qr}(q,r)-sF_{rr}(q,r)+2sE_q(q,r)+srE_{rq}(q,r)+r^2E_{qq}(q,r)\,. \tag{2.1}$$

This expression for f includes all the nonlinearities in variational form for (1.1) encountered in the literature including [12], [23], [24], [25], [26], and [28].

Levandosky [26] considers (1.1) with the restriction that $E=0$ and $F(q,r)$ is three-times continuously differentiable and homogeneous of degree $p+1$ for some $p>1$; that is,

$$F(\lambda q,\lambda r)=\lambda^{p+1}F(q,r)$$

for all $\lambda\geq 0$ and $(q,r)\in\mathbb{R}^2$.

Kichenasammy and Olver [25] consider the existence of solitary waves for a generalized Kawahara equation, where they assume the existence of a smooth function

$g(u)$ and constants A, B such that

$$f(q,r,s) = Ar^2 + Bsq + g'(q)\,.$$

They show that a necessary and sufficient condition for the existence of sech^2-type solitary wave solutions is that $g'(q)$ be a cubic polynomial. On the other hand, this function f has a variational structure if and only if $2A = B$, and in this case, the function f can be derived from $h(q,r,s)$ by taking $E = 0$ and $F(q,r) = -Aqr^2 + g(q)$.

To reformulate (1.1) with the variational condition (2.1) on f, as a Hamiltonian system on a multisymplectic structure, we introduce the potential function $q_1(x,t)$, defined by $u = \frac{\partial q_1}{\partial x}$. Then with

$$\begin{array}{lllllll} & q_2 & = & u = \frac{\partial q_1}{\partial x}\,, & p_1 & = & \frac{\partial q_1}{\partial t} - \frac{\partial p_2}{\partial x} - \frac{\partial}{\partial q_2}F - \frac{1}{\beta}E\frac{\partial}{\partial q_2}E - \frac{p_3}{\beta}\frac{\partial}{\partial q_2}E\,,\\ (2.2) & q_3 & = & u_x = \frac{\partial q_2}{\partial x}\,, & p_2 & = & -\alpha q_3 - \frac{\partial p_3}{\partial x} - \frac{\partial}{\partial q_3}F - \frac{1}{\beta}E\frac{\partial}{\partial q_3}E - \frac{p_3}{\beta}\frac{\partial}{\partial q_3}E\,,\\ & & & & p_3 & = & \beta\frac{\partial q_3}{\partial x} - E\,, \end{array}$$

(1.1) reduces to

$$\frac{\partial q_2}{\partial t} + \frac{\partial p_1}{\partial x} = 0\,. \tag{2.3}$$

Combining (2.2) and (2.3), the PDE (1.1) can be written in the form

$$\mathbf{M}Z_t + \mathbf{K}Z_x = \nabla S(Z)\,, \quad Z \in \mathbb{R}^6\,, \tag{2.4}$$

where

$$Z = \begin{pmatrix} q_1\\ q_2\\ q_3\\ p_1\\ p_2\\ p_3 \end{pmatrix}, \quad \mathbf{M} = \begin{bmatrix} 0 & -1 & 0 & 0 & 0 & 0\\ 1 & 0 & 0 & 0 & 0 & 0\\ 0 & 0 & 0 & 0 & 0 & 0\\ 0 & 0 & 0 & 0 & 0 & 0\\ 0 & 0 & 0 & 0 & 0 & 0\\ 0 & 0 & 0 & 0 & 0 & 0 \end{bmatrix}, \quad \mathbf{K} = \begin{bmatrix} 0 & 0 & 0 & -1 & 0 & 0\\ 0 & 0 & 0 & 0 & -1 & 0\\ 0 & 0 & 0 & 0 & 0 & -1\\ 1 & 0 & 0 & 0 & 0 & 0\\ 0 & 1 & 0 & 0 & 0 & 0\\ 0 & 0 & 1 & 0 & 0 & 0 \end{bmatrix}, \tag{2.5}$$

and

$$S(Z) = \tfrac{1}{2}\alpha q_3^2 + \frac{1}{2\beta}p_3^2 + p_1q_2 + p_2q_3 + F(q_2,q_3) + \frac{1}{2\beta}\left(2p_3 + E(q_2,q_3)\right)E(q_2,q_3). \tag{2.6}$$

The skew-symmetric operators $\mathbf{M}$ and $\mathbf{K}$ define the two-forms

$$\begin{aligned} \omega &= \mathbf{d}q_2 \wedge \mathbf{d}q_1,\\ \kappa &= \mathbf{d}p_1 \wedge \mathbf{d}q_1 + \mathbf{d}p_2 \wedge \mathbf{d}q_2 + \mathbf{d}p_3 \wedge \mathbf{d}q_3, \end{aligned} \tag{2.7}$$

with

$$\omega(\xi_1,\xi_2) = \langle \mathbf{M}\xi_1, \xi_2\rangle \quad \text{and} \quad \kappa(\xi_1,\xi_2) = \langle \mathbf{K}\xi_1,\xi_2\rangle\,, \tag{2.8}$$

where $\langle\cdot,\cdot\rangle$ is a standard inner product on $\mathbb{R}^6$. The induced norm is denoted by $\|\cdot\|$. The symplectic form κ is a canonical symplectic structure on $\mathbb{R}^6$ associated with the x-direction, and ω is a rank 2 symplectic structure associated with the t-direction.

There are two symmetries of (2.4) which will be of interest in what follows: the spatial translation invariance (in x) of the system (i.e., the fact that ω, κ, and $S(Z)$ do not depend explicitly on x), and the affine symmetry associated with the fact that q_1 is a potential function.

Let G be the one-parameter affine group associated with this potential symmetry with action

$$\mathcal{G}_\theta Z = Z + \theta V \quad \text{for all } \theta \in \mathbb{R}, \quad \text{where} \quad V = \begin{pmatrix} 1 \\ 0 \\ \vdots \\ 0 \end{pmatrix}. \tag{2.9}$$

Then the system (2.4) is G-equivariant; that is, $S(Z)$ and the two-forms ω and κ are G-invariant.

A solitary wave state of (2.4) will be composed of two parts. The first part is the shape of the solitary wave which connects the asymptotic states at plus and minus infinity, which will be characterized as a heteroclinic orbit in the phase space $\mathbb{R}^6$. The second part is the state at infinity which will be characterized as an invariant manifold of relative equilibria associated with the group G.

To define the invariant manifold at infinity we use the theory in section 2 of [9]. First note that, with $P(Z) = q_2$ and $Q(Z) = p_1$, the functions $P(Z)$ and $Q(Z)$ satisfy

$$\mathbf{M}V = \nabla P(Z) \quad \text{and} \quad \mathbf{K}V = \nabla Q(Z); \tag{2.10}$$

that is, $P(Z)$, respectively, $Q(Z)$, are the functions which generate the ω-, respectively, κ-, symplectic flow of the group G. The state at infinity is taken to be of the form

$$Z(x,t) = \mathcal{G}_{\theta(x,t)} Z_0(a,b) \quad \text{with} \quad \theta(x,t) = at + bx + \theta_0. \tag{2.11}$$

The point $Z_0 \in \mathbb{R}^6$ and the parameters a and b are defined by the constrained variational problem: find critical points of $S(Z)$ restricted to level sets of the functions P and Q, or

$$\nabla S(Z_0) = a \nabla P(Z_0) + b \nabla Q(Z_0)\,, \quad \text{with} \quad P(Z_0) = \mathcal{P},\ Q(Z_0) = \mathcal{Q}. \tag{2.12}$$

This equation is easily solved to find

$$Z_0 = \begin{pmatrix} q_1^0 \\ b \\ 0 \\ a - F_q(b,0) \\ -F_r(b,0) \\ -E(b,0) \end{pmatrix} \quad \text{with} \quad \begin{aligned} P(Z_0) &= q_2^0 = b = \mathcal{P}, \\ Q(Z_0) &= p_1^0 = a - F_q(b,0) = \mathcal{Q}, \end{aligned} \tag{2.13}$$

and q_1^0 is arbitrary (due to the group action). This state is nondegenerate as a solution of the constrained variational problem since $\frac{\partial(P,Q)}{\partial(a,b)} = -1 \neq 0$.

Let $Z_0 \in \mathbb{R}^6$ be any nondegenerate solution of (2.12) with $q_1^0 = 0$. Then the invariant manifold at infinity is defined to be the following line in $\mathbb{R}^6$ through Z_0:

$$\mathcal{M}_\infty = \{\, Z_0 + \theta V \ : \ \theta \in \mathbb{R}\,\}. \tag{2.14}$$

The solitary wave state will be taken to be biasymptotic to this manifold and of the form

$$Z(x,t) = \mathcal{G}_{\theta(x,t)}[Z_0^- + \mathcal{T}_{\tau(t)} \widehat{Z}(x,a,b,c)], \tag{2.15}$$

where $\mathcal{G}_{\theta(x,t)}$ is as defined in (2.11); Z_0^- is any nondegenerate solution of (2.12) with $q_1^0 = 0$ (the "−" superscript indicates that this is the asymptotic point on $\mathcal{M}_\infty$ as $x \to -\infty$);

$$\mathcal{T}_\tau \widehat{Z}(x,a,b,c) \overset{\text{def}}{=} \widehat{Z}(x-\tau,a,b,c),$$

and $\tau(t) = ct + \tau_o$. The function $\widehat{Z}(x,a,b,c)$, which is the shape of the solitary wave, is a heteroclinic orbit of the Hamiltonian system on $\mathbb{R}^6$,

$$\mathbf{J}_c \widehat{Z}_x = \nabla W(\widehat{Z}), \quad \widehat{Z} \in \mathbb{R}^6 \tag{2.16}$$

with

$$\mathbf{J}_c = \mathbf{K} - c\mathbf{M}, \quad W(\widehat{Z}) = S(Z_0^- + \widehat{Z}) - aP(Z_0^- + \widehat{Z}) - bQ(Z_0^- + \widehat{Z}).$$

The symplectic operator $\mathbf{J}_c$ is nondegenerate and defines the symplectic structure $(\mathbb{R}^6, \Omega)$, where $\Omega = \kappa - c\omega$.

This Hamiltonian system is the analogue of the Hamiltonian ODE presented in (1.5). There are, however, two important differences: the symplectic structure Ω is defined explicitly in terms of a combination of the spatial (κ) and temporal (ω) structures, and c appears here explicitly as a multiplier of the temporal symplectic structure ω. In other words, even though (1.5) is Hamiltonian there is no connection with the spatial or temporal symplectic structure of the full system (1.1), while (2.16) still contains these connections.

The heteroclinic orbit $\widehat{Z}(x,a,b,c)$ satisfies the asymptotic conditions

$$\lim_{x\to-\infty} \|\widehat{Z}(x,a,b,c)\| = 0 \quad \text{and} \quad \lim_{x\to\infty} \|\widehat{Z}(x,a,b,c) - Z_0^+ + Z_0^-\| = 0\,,$$

where $Z_0^+ = \mathcal{G}_\gamma Z_0^-$ for some $\gamma \in G$. In other words, as $x \to +\infty$ the function $\widehat{Z}(x,a,b,c)$ is asymptotic to a point on $\mathcal{M}_\infty$ other than Z_0^-, but this point is related to Z_0^- by an element γ in the group G. In the present case, the difference in Z_0^+ and Z_0^- corresponds to a jump in the value of the potential q_1.

3. A three-parameter family of solitary waves.

For the linearized stability theory, we will assume the existence of open sets A, B, and C in $\mathbb{R}$ such that for each $(a,b,c) \in A \times B \times C$ there exists a bounded travelling wave shape $\widetilde{Z}(x;a,b,c) = Z_0^-(a,b,c) + \widehat{Z}(x;a,b,c)$, which satisfies

$$\mathbf{J}_c \widetilde{Z}_x = \nabla S(\widetilde{Z}) - a\nabla P(\widetilde{Z}) - b\nabla Q(\widetilde{Z}). \tag{3.1}$$

Furthermore, we assume that the derivative of the shape of the solitary wave, $\widetilde{Z}_x$, is exponentially decaying with asymptotic estimate

$$\lim_{x\to\pm\infty} e^{\pm\delta x} \widetilde{Z}_x = \Psi^\pm \quad \text{and} \quad \lim_{x\to\pm\infty} \partial_x [e^{\pm\delta x} \widetilde{Z}_x] = 0 \tag{3.2}$$

for some $\Psi^\pm \in \mathbb{R}^6$ and $\delta > 0$. This assumption is in general easy to verify for solitary waves which are explicitly known. Indeed the above two hypotheses are very unrestrictive and cover a wide range of known solitary waves.

The bounded travelling wave shapes $\widetilde{Z}$ will be asymptotic to the points Z_0^+ and Z_0^- for $x \to \infty$, respectively, $x \to -\infty$. The phase shift between the point on $\mathcal{M}_\infty$ at plus and minus infinity are related by using the group action of G: explicitly we find

$$Z_0^+ = \mathcal{G}_\gamma Z_0^-, \quad \text{where} \quad \gamma = \int_{-\infty}^{\infty} (u(x) - b)\, dx,$$

and $u(x) = \widetilde{q}_2(x)$ is the second component of the solitary wave solution. By the hypotheses, this integral exists and is nonzero in general. It is a generalization of the "mass" of the solitary wave (cf. Longuet-Higgins [27]).

The momentum of the shape of the solitary wave is defined by

$$I(\widetilde{Z}) = \frac{1}{2}\int_{-\infty}^{+\infty} \omega(\widetilde{Z}, \widetilde{Z}_x)\, dx\,, \tag{3.3}$$

where the dependence on a and b has been suppressed. By taking

$$H(\widetilde{Z}) = \int_{-\infty}^{+\infty} (\tfrac{1}{2}\kappa(\widetilde{Z}, \widetilde{Z}_x) + W(\widetilde{Z}))\, dx\,,$$

it is straightforward to verify that the energy-momentum characterization of solitary waves is encoded in (2.16) and (3.1) (cf. [7], [9]), but this characterization will not be needed explicitly in what follows.

With the above hypotheses, it is shown in [9] that the derivative of I with respect to c exists and takes the form

$$\frac{d}{dc} I(\widetilde{Z}) = \int_{-\infty}^{+\infty} \omega(\widetilde{Z}_c, \widetilde{Z}_x)\, dx + \frac{1}{2}\omega(Z_0^+, \partial_c Z_0^+)\,. \tag{3.4}$$

An essential point to note in the interpretation of this expression is that the derivative with respect to c is taken with all other parameters fixed. While this may appear to be obvious, it is easy to be misled into thinking that a family of solutions depends on c when in fact it exists only for a single value of c. Examples of this are the explicit solutions found in [12], [14], [15], and [20] which for fixed values of the parameters in the equation exist for a single value of c and therefore $\frac{dI}{dc}$ cannot be explicitly computed. On the other hand, when a solitary wave state is known at an isolated value of c, it is not difficult to prove that it persists for a range of c values by a multisymplectic Melnikov argument. In other words, families in c generically exist, even when an explicit solution exists for a single value of c only. An example of the numerical continuation of such an isolated explicit solution can be found in [12].

4. The linearization about a family of solitary waves. To study the stability of a solitary wave $\mathcal{G}_{\theta(x,t)}[Z_0^- + \mathcal{T}_{\tau(t)}\widehat{Z}(x;a,b,c)]$ (see (2.15)), write $Z(x,t) = \mathcal{G}_{\theta(x)}[Z_0^- + \mathcal{T}_{\tau(t)}[\widehat{Z}(x;a,b,c) + \widehat{U}(x,t)]]$. Then the linearization of (2.4) about the family of solitary waves takes the form

$$\mathbf{M}\widehat{U}_t + \mathbf{J}_c\widehat{U}_x = \mathbf{B}(x;a,b,c)\widehat{U}, \tag{4.1}$$

where

$$\begin{aligned}\mathbf{B}(x;\cdot) &= D^2W(\widehat{Z}(x;\cdot))\\ &= D^2S(Z_0^- + \widehat{Z}(x;\cdot)) - aD^2P(Z_0^- + \widehat{Z}(x;\cdot)) - bD^2Q(Z_0^- + \widehat{Z}(x;\cdot))\end{aligned}$$

(cf. section 3 of [9]). With the spectral ansatz $\widehat{U}(x,t) = e^{\lambda t}U(x,\lambda)$, the system (4.1) reduces to

$$U_x = \mathbf{A}(x,\lambda)U, \quad U \in \mathbb{C}^6, \tag{4.2}$$

with

$$\mathbf{A}(x,\lambda) = \mathbf{J}_c^{-1}[\mathbf{B}(x;\cdot) - \lambda\mathbf{M}].$$

The dependence on the parameters (a, b, c) in the argument of $\mathbf{A}$ is suppressed, as they are considered fixed in the stability analysis. The matrix $\mathbf{A}(x, \lambda)$ has the following asymptotic limits:

$$\lim_{x\to\pm\infty} \mathbf{A}^\infty(\lambda) = \mathbf{J}_c^{-1}[\mathbf{B}^\infty - \lambda\mathbf{M}]\,,$$

where

$$\mathbf{B}^\infty = \lim_{x\to\pm\infty} \mathbf{B}(x;\cdot) = D^2S(Z_0) - aD^2P(Z_0) - bD^2Q(Z_0)\,,$$

with Z_0 either Z_0^- or Z_0^+. It is a consequence of the results in [9] that although $Z_0^- \neq Z_0^+$, the linearization $\mathbf{B}^\infty$ will be the same at $\pm\infty$. Explicitly, $\mathbf{B}^\infty$ is

$$\mathbf{B}^\infty = \begin{pmatrix} 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & F_{qq}(b,0) + \frac{E_q(b,0)^2}{\beta} & F_{qr}(b,0) + \frac{E_q(b,0)E_r(b,0)}{\beta} & 1 & 0 & \frac{E_q(b,0)}{\beta} \\ 0 & F_{qr}(b,0) + \frac{E_q(b,0)E_r(b,0)}{\beta} & \alpha + F_{rr}(b,0) + \frac{E_r(b,0)^2}{\beta} & 0 & 1 & \frac{E_r(b,0)}{\beta} \\ 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & \frac{E_q(b,0)}{\beta} & \frac{E_r(b,0)}{\beta} & 0 & 0 & \frac{1}{\beta} \end{pmatrix}.$$

The spectrum of $\mathbf{A}^\infty(\lambda)$ is defined by

$$\sigma\left(\mathbf{A}^\infty(\lambda)\right) = \{\, \mu \in \mathbb{C} \;:\; \Delta(\mu, \lambda) = 0 \,\}\,,$$

where

$$\Delta(\mu, \lambda) = \det[\mathbf{B}^\infty - \mu\mathbf{J}_c - \lambda\mathbf{M}]\,, \quad \lambda \in \Lambda\,.$$

The set $\Lambda \in \mathbb{C}$ is some subset of the right-half complex λ-plane, which will be identified later. A straightforward calculation shows that

$$\Delta(\mu, \lambda) = \mu^6 + \frac{C_1}{\beta}\mu^4 - \frac{C_2 + 2c}{\beta}\mu^2 + 2\frac{\lambda}{\beta}\mu\,, \tag{4.3}$$

where $C_1 = F_{rr}(b, 0) - 2E_q(b, 0) + \alpha$ and $C_2 = F_{qq}(b, 0)$.

This expression shows that $\mu = 0$ is an eigenvalue for the linearized system for any value of λ. The solution of the linearized equation related to this eigenvalue is independent of x and is given explicitly by

$$U = (1, 0, 0, \lambda, 0, 0)\,. \tag{4.4}$$

This zero eigenvalue and its eigenvector are reminiscent of a similar phenomenon that appears with KdV; see section 6 of [7]. It arises due to the introduction of a potential for $u(x, t)$.

We can also determine the eigenvectors associated with each of the other five μ-eigenvalues; they are

$$U_{\mathrm{ev}}(\mu, \lambda) = (1\,,\, \mu\,,\, \mu^2\,,\, -\lambda + \mu c\,,\, -\mu F_1\,,\, -\mu F_2)\,, \quad \mu \neq 0\,, \tag{4.5}$$

where

$$F_1 = F_{qr}(b, 0) + \mu(C_1 + E_q(b, 0)) + \beta\mu^3 \quad \text{and} \quad F_2 = E_q(b, 0) + \mu E_r(b, 0) - \beta\mu^2\,.$$

If $\mu \in i\mathbb{R}\backslash\{0\}$, then $\lambda \in i\mathbb{R}$. Therefore, if $\mathrm{Re}(\lambda) > 0$, the only solution in $\sigma(\mathbf{A}^\infty(\lambda)) \cap i\mathbb{R}$ is the trivial state (4.4).

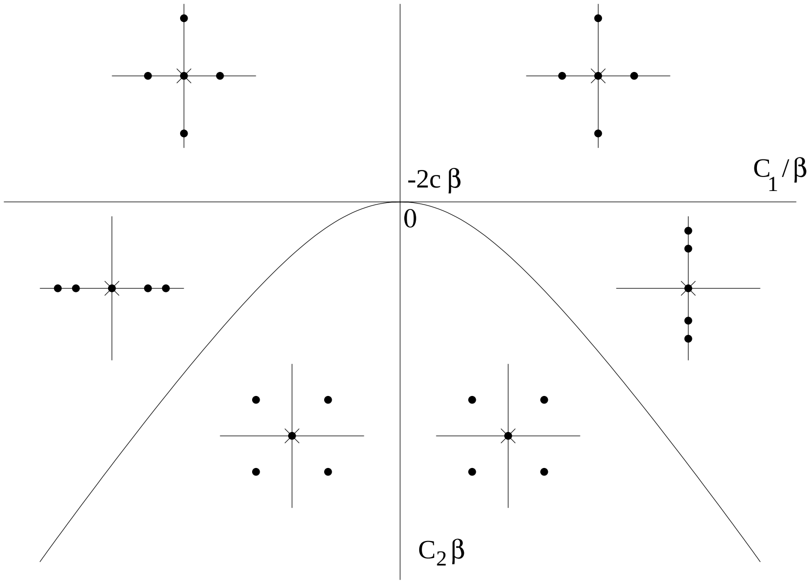

FIG. 4.1. *Sketch of the position of the eigenvalues μ at $\lambda = 0$ as a function of C_1/β and $C_2\beta$. The parabolic curve represents the relation $C_1^2 = -4\beta(C_2 + 2c)$.*

4.1. The linearized equation with $\lambda = 0$. First consider the spectrum of $\mathbf{A}^\infty(0)$ which is associated with the existing solitary wave

$$\Delta(\mu, 0) = \mu^2 \left(\mu^4 + \frac{C_1}{\beta}\mu^2 - \frac{C_2 + 2c}{\beta} \right).$$

We can immediately see that at $\lambda = 0$, the μ-spectrum is given by

$$\left\{ 0, 0, \sqrt{-\frac{C_1}{2\beta} \pm \frac{1}{2\beta}\sqrt{C_1^2 + 4\beta(C_2 + 2c)}}, -\sqrt{-\frac{C_1}{2\beta} \pm \frac{1}{2\beta}\sqrt{C_1^2 + 4\beta(C_2 + 2c)}} \right\}. \tag{4.6}$$

A sketch of the position of the eigenvalues μ as function of C_1/β and $C_2\beta$ is given in Figure 4.1. In order to satisfy the exponential decay condition (3.2) on the solitary wave, it is necessary for the spectrum $\Delta(\mu, 0)$ to have at least one pair of strictly hyperbolic eigenvalues. The region with $C_1/\beta < 0$ and $C_2\beta < -2c\beta$ with four real hyperbolic eigenvalues is the region studied by Karpman [23] using the energy-momentum method to prove stability and instability (for the case in (1.1) when f is a polynomial in u). The region with $C_1/\beta > 0$ in the neighborhood of the parabola $C_1^2 + 4\beta(C_2 + 2c) = 0$ is the region studied by Dias and Kuznetsov [16], and in this region they show that the energy-momentum method leads to the existence of a minimum (for the case in (1.1) when f is a quadratic function of u).

Here we will consider the case where the spectrum of $\mathbf{A}^\infty(0)$ has exactly one pair of hyperbolic real eigenvalues and one pair of purely imaginary eigenvalues. In Figure 4.1, this corresponds to the region

$$C_2\beta > -2c\beta\,, \tag{4.7}$$

and we will concentrate on this part of parameter space. Note that the zero eigenvalue of $\mathbf{A}^\infty(0)$ has algebraic multiplicity two and geometric multiplicity one and the

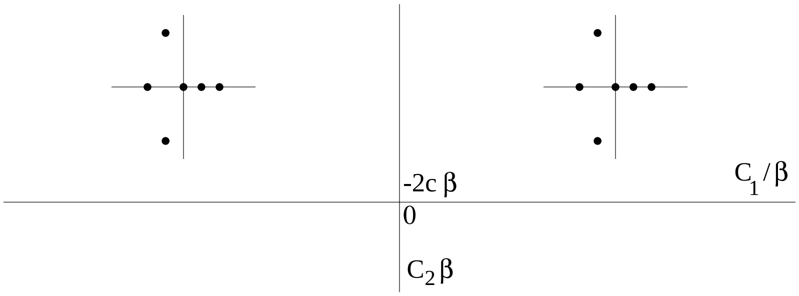

FIG. 4.2. *Position of the eigenvalues for λ small and $\beta > 0$.*

eigenvector, $(1, 0, 0, 0, 0, 0)$, is in fact the generator of the group action of G, defined in section 2.

By differentiating (3.1) with respect to x, we see that $\widetilde{Z}_x$ is a solution of the linearized equation (4.2) with $\lambda = 0$. By assumption the derivative of the solitary wave shape $\widetilde{Z}_x$ is exponentially decaying, hence both real eigenvalues can be related to the exponential decay rate of the derivative of the solitary wave shape. The negative real eigenvalue is equal to $-\delta$ and the positive real eigenvalue is equal to δ (see (3.2)), with $\Psi^\pm$ the eigenvectors of the systems at $\pm\infty$.

4.2. The linearized equation with $\Re(\lambda) > 0$ and λ small. Next we consider the linearized equation (4.2) with $\Re(\lambda) > 0$ and λ small. When λ is small, the eigenvalues which were on the imaginary axis when $\lambda = 0$ have expansions for λ small given by

$$\begin{aligned} &\mu = 0; \\ &\mu = \frac{2}{C_2 + 2c}\lambda + \mathcal{O}(\lambda^2); \\ &\mu = \pm\frac{i}{2}\sqrt{2}\sqrt{C_3} - \frac{1}{2\beta}C_3(C_3 - \frac{C_1}{\beta})\lambda + \mathcal{O}(\lambda^2), \end{aligned}$$

where $C_3 = \frac{C_1}{\beta} + \sqrt{\frac{C_1^2}{\beta^2} + \frac{4(C_2+2c)}{\beta}}$. Since $\beta(C_2 + 2c) > 0$, the term $-\frac{1}{2\beta}C_3(C_3 - \frac{C_1}{\beta})$ has sign opposite to that of $\frac{2}{C_2+2c}$. Hence, if $\beta > 0$, the nonzero eigenvalues on the imaginary axis are perturbed to the left and one of the zero eigenvalues is perturbed to the right when $\lambda \neq 0$. The position of the eigenvalues is sketched in Figure 4.2 with $\beta > 0$. If $\beta < 0$, the movement of the eigenvalues will be in the opposite direction. Hence we have a 4-2 split in the eigenvalues. This means that for $\Re(\lambda) > 0$, if $\beta < 0$, there are two eigenvalues with negative real part and four eigenvalues with nonnegative real part. And if $\beta > 0$, there are two eigenvalues with positive real part and four eigenvalues with nonpositive real part.

A straightforward calculation shows that double eigenvalues, i.e., values of λ where

$$\Delta(\mu, \lambda) = \frac{\partial}{\partial\mu}\Delta(\mu, \lambda) = 0,$$

occur at isolated real values of λ, explicitly, when

$$\lambda_0 = \pm\frac{\beta}{50}\sqrt{\frac{1}{10\beta}(C_4\beta - 3C_1)}\left(\left(C_4 - \frac{C_1}{2\beta}\right)^2 - \frac{25C_1^2}{4\beta^2}\right),$$

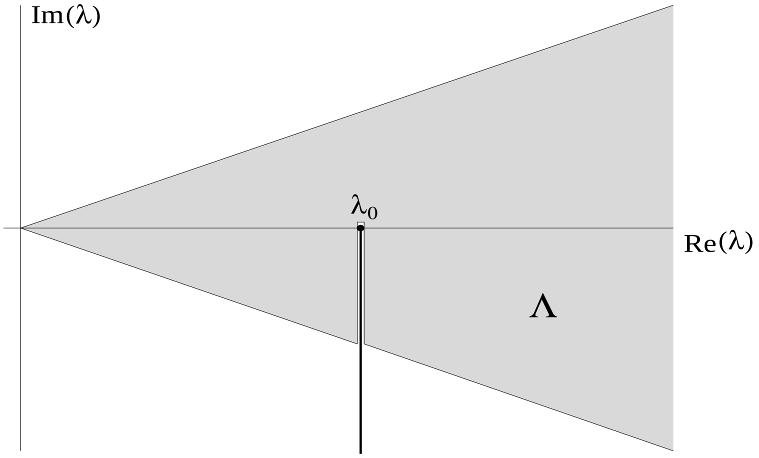

FIG. 4.3. *The set Λ_b in the right-half complex plane in which the eigenvalues are analytic and its extension is Λ.*

where $C_4 = \sqrt{\frac{9C_1^2}{\beta^2} + \frac{20(C_2+2c)}{\beta}}$. A consequence of the condition (4.7) is that λ_0 is always real. The double eigenvalues associated with $\lambda = \lambda_0$ are $\mu_d = \pm\sqrt{\frac{1}{10\beta}(C_4\beta - 3C_1)}$. If we define

$$\Lambda_b = \{\lambda \in \mathbb{C} \mid \Re(\lambda) > 0,\, |\Im(\lambda)| < \Re(\lambda)\} \backslash \{|\lambda_0| + iy \mid y \leq 0\},$$

then the eigenvalues are simple when $\lambda \in \Lambda_b$. The region Λ_b is shown in Figure 4.3.

The set Λ will be defined as the extension of the set Λ_b obtained by removing the branch point and the branch cut.

5. Intermezzo: Temporal drift along the group *G*.

In section 2, the state at infinity associated with the basic solitary wave is x and t dependent and of the form

$$Z(x,t) = \mathcal{G}_{\theta(x,t)} Z_0(a,b) = Z_0(a,b) + \theta(x,t)\, V\,. \tag{5.1}$$

Since only the first component of V is nonzero, the only component of $Z(x,t)$ in this expression which will depend on x and t is the first component. In the multisymplectic coordinates, the first coordinate is $q_1(x,t)$, where

$$u(x,t) = q_2(x,t) = \frac{\partial}{\partial x} q_1(x,t)\,, \tag{5.2}$$

and so

$$q_1(x,t) = q_1^o(a,b) + \theta(x,t) = at + bx + \theta_0\,.$$

Since $q_1(x,t)$ is a potential, the t-dependence of $q_1(x,t)$ will have no dynamic significance for $u(x,t)$ which is the primary function associated with (1.1). It is tempting to conclude that the temporal part of the flow on G—represented by the parameter a—is irrelevant. Surprisingly, it is not. By embedding the solitary wave in the three-parameter family (a,b,c), rather than the two-parameter family (b,c) (or even the one-parameter (c) family), geometric information about the linear stability is obtained, even if we set $a = 0$ at the end of the analysis. Here we will indicate two examples of how a encodes geometric information.

The basepoint, $Z_0(a, b)$, of the two-parameter family of states at infinity satisfies a constrained variational principle (cf. (2.12) and (2.13)) with the nondegeneracy condition

$$\det\begin{pmatrix} \frac{\partial P}{\partial a} & \frac{\partial P}{\partial b} \\ \frac{\partial Q}{\partial a} & \frac{\partial Q}{\partial b} \end{pmatrix} \neq 0, \tag{5.3}$$

and for the Kawahara family at infinity it was found that

$$\begin{pmatrix} \frac{\partial P}{\partial a} & \frac{\partial P}{\partial b} \\ \frac{\partial Q}{\partial a} & \frac{\partial Q}{\partial b} \end{pmatrix} = \begin{pmatrix} 0 & 1 \\ 1 & -F_{qq}(b, 0) \end{pmatrix}, \tag{5.4}$$

and hence the nondegeneracy condition is satisfied for any a and b. This information was not used explicitly in the later analysis, but it does appear implicitly in the following way.

In section 4, the spectral problem associated with the linearization about the solitary wave in the limit as $x \to \pm\infty$ was associated with the function

$$\Delta(\mu, \lambda) = \det[\mathbf{B}^\infty - \mu\mathbf{J}_c - \lambda\mathbf{M}], \quad \lambda \in \Lambda. \tag{5.5}$$

In [9] the following remarkable result is proved for any relative equilibrium at infinity of the abstract form (5.1) (see Lemma 7 in [9]):

$$\Delta(\mu, \lambda) = \mathbb{C}\left[\frac{\partial Q}{\partial b}\mu^2 + \left(\frac{\partial Q}{\partial a} + \frac{\partial P}{\partial b}\right)\mu(\lambda - c\mu) + \frac{\partial P}{\partial a}(\lambda - c\mu)^2\right] + o((|\lambda| + |\mu|)^2), \tag{5.6}$$

where $\mathbb{C}$ represent a nonzero constant. In other words, *the perturbation of the μ-roots for $|\lambda|$ small is dictated by the parameter structure encoded in the state at infinity.* Substituting the Kawahara expressions into this expansion results in

$$\Delta(\mu, \lambda) = \mathbb{C}\left[-C_2\mu^2 + 2\mu(\lambda - c\mu)\right] + o((|\lambda| + |\mu|)^2), \tag{5.7}$$

using $C_2 = F_{qq}(b, 0)$. It is evident from this expression that for $|\lambda|$ small the two roots are $\mu = 0$ and

$$\mu = \frac{2}{2c + C_2}\lambda.$$

For $2c + C_2 > 0$ this result recovers precisely the perturbation result in Figure 4.2. Moreover, it gives a precise geometric description of how the zero μ-roots are perturbed when λ is perturbed away from zero for the other regions in Figure 4.1, and this information is an essential part of the construction of the Evans matrix.

A second example where the parameter a has implications is when deducing a geometric instability criterion. Using the symplectic Evans matrix, we will prove a geometric instability condition for solitary waves, based on the theory in [9], where the proof uses in an essential way the parameter structure of the state at infinity, even when only the case $a = b = 0$ is of interest.

6. The symplectic Evans matrix. The system (4.2) with the spectrum of $\mathbf{A}^\infty(\lambda)$ as shown in Figure 4.2 is in the appropriate form for construction of the Evans function. The Evans function is constructed as follows (cf. Alexander, Gardner, and Jones [1]).

For fixed $(a,b,c) \in A \times B \times C$ let $\mathbf{U}^-(x,\lambda) \in \bigwedge^2(\mathbb{C}^6)$, and let $\mathbf{U}^+(x,\lambda) \in \bigwedge^4(\mathbb{C}^6)$. Let $\alpha_-(\lambda)$ be the sum of the eigenvalues of $\mathbf{A}^\infty(\lambda)$ with positive real part, and let $\alpha_+(\lambda) = \tau_\infty(\lambda) - \alpha_-(\lambda)$, where $\tau(x,\lambda) = \mathrm{Trace}(\mathbf{A}(x,\lambda))$ and $\tau_\infty(\lambda) = \lim_{|x|\to\infty} \tau(x,\lambda)$. Then $\mathbf{U}^-(x,\lambda), \mathbf{U}^+(x,\lambda)$ are chosen to satisfy induced equations on $\bigwedge^2(\mathbb{C}^6)$ and $\bigwedge^4(\mathbb{C}^6)$, respectively, and

$$\lim_{x\to\pm\infty} \mathrm{e}^{-\alpha_\pm(\lambda)x}\mathbf{U}^\pm(x,\lambda) = \zeta_\pm(\lambda)\,,$$

where $\zeta_-(\lambda)$ and $\zeta_+(\lambda)$ are eigenvectors of $\bigwedge^2(\mathbf{A}_\infty(\lambda))$ and $\bigwedge^4(\mathbf{A}_\infty(\lambda))$, respectively, corresponding to the eigenvalues $\alpha_-(\lambda)$ and $\alpha_+(\lambda)$. The Evans function then takes the form

$$D(\lambda) = \mathrm{e}^{-\int_0^x \tau(s,\lambda)\,\mathrm{d}s}\mathbf{U}^+(x,\lambda) \wedge \mathbf{U}^-(x,\lambda) \quad \text{for all } \lambda \in \Lambda\,. \tag{6.1}$$

It is independent of x and analytic for all $\lambda \in \Lambda$ [1]. Indeed it is analytic on a larger subset of $\mathbb{C}$, but this extension will not be needed here.

One of the shortcomings of the form (6.1) is that it does not encode in any obvious way the multisymplectic structure of the system (4.2). However, by using individual solutions of (4.2), the symplectic structure can be made explicit.

For fixed $(a,b,c) \in A \times B \times C$ let $U_i^-(x,\lambda)$ for $i = 1,2$ be independent solutions of (4.2) which decay exponentially as $x \to -\infty$, and let $W_i^+(x,\lambda)$ for $i = 1,2$ be such that $\mathbf{J}_c\overline{W_i^+}$ are independent solutions of the adjoint of (4.2) which decay exponentially as $x \to +\infty$. For $\lambda \in \Lambda_b$, where Λ_b is the subset of Λ where individual vector-valued solutions are analytic, the *symplectic Evans matrix* is defined in [9] by

$$\mathbf{E}_b(\lambda) = \begin{pmatrix} \Omega(W_1^+(x,\lambda), U_1^-(x,\lambda)) & \Omega(W_1^+(x,\lambda), U_2^-(x,\lambda)) \\ \Omega(W_2^+(x,\lambda), U_1^-(x,\lambda)) & \Omega(W_2^+(x,\lambda), U_2^-(x,\lambda)) \end{pmatrix}, \tag{6.2}$$

where $\Omega(\cdot,\cdot)$ is the symplectic form associated with the Hamiltonian system (2.16). The symplectic Evans *function* is then the determinant of this matrix. If there exists a $\lambda \in \Lambda_b$ with $D_b(\lambda) = \det(\mathbf{E}_b(\lambda)) = 0$, then the basic solitary wave is linearly unstable. On the set Λ_b, $D_b(\lambda)$ and $D(\lambda)$ have the same zeros [9].

There is yet another form of the Evans function which uses individual vectors as in (6.2) but is analytic on the larger set Λ. This extension of the symplectic Evans matrix is introduced in Bridges and Derks [10]. It has the same form as (6.2) and the individual vectors in it span the same space as the vectors in (6.2) but they extend to analytic functions on the larger set Λ. Denote this Evans matrix by $\mathbf{E}(\lambda)$. In [10] it is proved that this matrix is analytic on Λ and $\det(\mathbf{E}(\lambda))$ is equal to $D(\lambda)$ on Λ. Moreover, the sign of the first nonzero derivative of $\det(\mathbf{E}_b(\lambda))$ is equal to the sign of the first nonzero derivative of $\det(\mathbf{E}(\lambda))$ at the origin.

In summary, the three forms of the Evans function can be used together to analyze the stability problem. The strategy here will be to show that $D(\lambda) = \det(\mathbf{E}(\lambda)) \to 1$ for $\lambda \to +\infty$ along the real axis. The geometry encoded in (4.2) will then be used to obtain explicit expressions for the derivatives of $D_b(\lambda) = \det(\mathbf{E}_b(\lambda))$ at the origin following [9]. Then the equivalence between $D_b(\lambda)$ and $D(\lambda)$ in Λ_b established in [10] is then used to prove a geometric instability condition.

In section 8, we will show that, for the region in parameter space associated with $C_2\beta > -2c\beta$, an explicit geometric condition for the existence of at least one unstable eigenvalue can be deduced.

7. Large $\boldsymbol{\lambda}$ behavior of the Evans function. In this section, we will prove that $D(\lambda) \to 1$ as $\lambda \to +\infty$ along the real axis, for the Evans function associated with the Kawahara equation, linearized about a solitary wave. This will be proved by applying the Pego–Weinstein lemma in the appendix to the primary form of the Evans function (6.1) on wedge spaces.

The linear system has $n = 6$ and $k = 2$, hence the wedge space $\bigwedge^2(\mathbb{C}^6)$ has dimension $d = \binom{6}{2} = 15$. Use the standard basis for $\mathbb{C}^6$ ($\mathbf{e}_1 = (1,0,0,0,0,0)^T$, etc.) and the standard lexically ordered induced basis, $\omega_1 = \mathbf{e}_1 \wedge \mathbf{e}_2, \ldots, \omega_{15} = \mathbf{e}_5 \wedge \mathbf{e}_6$.

Let $\kappa = \lambda^{-1/5}$. For λ large, the eigenvalues of the matrix $\mathbf{A}^\infty(\lambda)$ are

$$0,\ B\kappa^{-1} + \mathcal{O}(\kappa),\ \frac{1}{4}\left(-1 \pm \sqrt{5} + \mathrm{i}\sqrt{2}\sqrt{5 \pm \sqrt{5}}\,\right) B\kappa^{-1} + \mathcal{O}(\kappa)\,,$$

where $B = \sqrt[5]{\frac{2}{-\beta}}$, and

$$\frac{1}{4}\left(-1 \pm \sqrt{5} - \mathrm{i}\sqrt{2}\sqrt{5 \pm \sqrt{5}}\,\right) B\kappa^{-1} + \mathcal{O}(\kappa)\,.$$

Note that none of the eigenvalues is of order λ. This property corresponds to the fact that asymptotically $\mathbf{J}_c^{-1}\mathbf{M}$ is the main matrix in $\mathbf{A}^\infty(\lambda)$. And $\mathbf{J}_c^{-1}\mathbf{M}$ has only one eigenvalue—0—and it has algebraic multiplicity 6 and geometric multiplicity 4.

The eigenvalues of the induced matrix $\mathbf{A}_\infty^{(2)}(\lambda)$ in $\bigwedge^{(2)}(\mathbb{C}^6)$ are pairwise sums of eigenvalues of $\mathbf{A}^\infty(\lambda)$. Explicit expressions will not be given, but Figure 7.1 shows qualitatively the position of these eigenvalues relative to the eigenvalues of $\mathbf{A}^\infty(\lambda)$ in the complex μ plane.

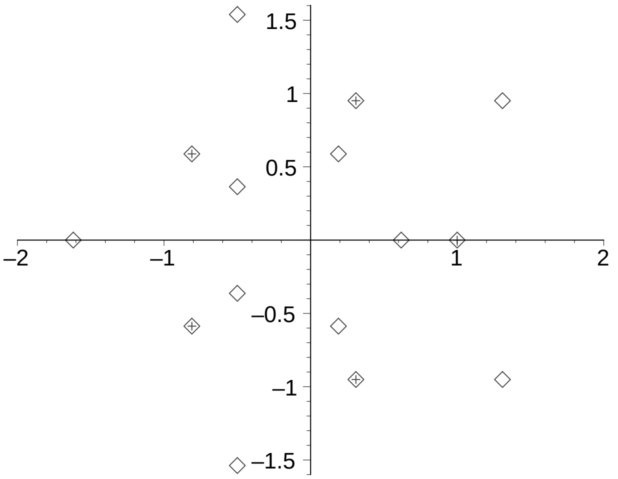

FIG. 7.1. *For $B = 1$ and λ fixed (and large), the eigenvalues of the induced matrix $\mathbf{A}_\infty^{(2)}(\lambda)$ are denoted with a diamond and the eigenvalues of the matrix $\mathbf{A}^\infty(\lambda)$ with a cross (the zero eigenvalue of $\mathbf{A}^\infty(\lambda)$ is obscured by the axes).*

It is straightforward to verify that $\mathbf{A}_\infty^{(2)}(\lambda)$ is diagonalizable for $\lambda \in \Lambda$, using the explicit expressions for the eigenvectors. The eigenvector of $\mathbf{A}^\infty(\lambda)$ for the eigenvalue 0 is $(\kappa^5, 0, 0, 1, 0, 0)^T$ and the eigenvectors for a nonzero eigenvalue μ are

$$\left(1, \mu, \mu^2, \mu c - \lambda, -\mu F_1, -\beta\mu F_2\right)^T,$$

where F_1 and F_2 are defined in (4.5). The eigenvectors of the induced matrix are wedge products of pairs of those eigenvectors, so, using the above expressions, the matrix $\mathbf{V}(\lambda)$ in the Pego–Weinstein lemma of all eigenvectors can be formed.

The columns of $\mathbf{V}(\lambda)$, the eigenvectors of the induced matrix, have the following form:

$$\begin{pmatrix} (\nu_0 - \mu_0)\kappa^8 \\ (\nu_0^2 - \mu_0^2)\kappa^7 \\ c(\nu_0 - \mu_0)\kappa^8 \\ -\beta(\nu_0^4 - \mu_0^4)\kappa^5 \\ -\beta(\mu_0^3 - \nu_0^3)\kappa^6 \\ \mu_0\nu_0(\nu_0 - \mu_0)\kappa^6 \\ (\nu_0 - \mu_0)\kappa^3 \\ -\beta\mu_0\nu_0(\nu_0^3 - \mu_0^3)\kappa^4 \\ -\beta\mu_0\nu_0(\mu_0^2 - \nu_0^2)\kappa^5 \\ (\nu_0^2 - \mu_0^2)\kappa^2 \\ -\beta\mu_0^2\nu_0^2(\nu_0^2 - \mu_0^2)\kappa^3 \\ -\beta\mu_0^2\nu_0^2(\mu_0 - \nu_0)\kappa^4 \\ -\beta(\mu_0^4 - \nu_0^4) \\ -\beta(\nu_0^3 - \mu_0^3)\kappa \\ -\beta^2\mu_0^3\nu_0^3(\nu_0 - \mu_0)\kappa^2 \end{pmatrix} + \text{h.o.t.} \quad \text{or} \quad \begin{pmatrix} -\mu_0\kappa^8 \\ -\mu_0^2\kappa^7 \\ +2\mu_0\kappa^4 \\ \mu_0^4\beta\kappa^5 \\ -\mu_0^3\beta\kappa^6 \\ 0 \\ \mu_0\kappa^3 \\ 0 \\ 0 \\ \mu_0^2\kappa^2 \\ 0 \\ 0 \\ \mu_0^4\beta \\ -\mu_0^3\beta\kappa \\ 0 \end{pmatrix} + \text{h.o.t.},$$

where μ_0 and ν_0 are two different nonvanishing solutions of the first-order approximation of the eigenvalue μ. Also, h.o.t. denotes the next order in each entry, except for the zero entries, which are identically zero.

Using this expression, we can now verify the three integral conditions in the Pego–Weinstein lemma. A straightforward but lengthy calculation gives

$$\|\mathbf{V}(\lambda)^{-1}[\mathbf{A}^{(2)}(x,\lambda) - \mathbf{A}_\infty^{(2)}(\lambda)]\mathbf{V}(\lambda)\| = \mathcal{O}(\mathrm{e}^{-\delta|x|}), \quad \text{uniform in } \lambda$$

for λ and $|x|$ large, where δ represents the exponential decay rate of the basic solitary wave. Hence, the first two integral conditions are satisfied.

For the third condition, we have in general that

$$\begin{aligned} \|\mathbf{V}(\lambda)^{-1}[\mathbf{A}^{(2)}(x,\lambda) - \mathbf{A}_\infty^{(2)}(\lambda)]\zeta_+(\lambda)\| &= \|\mathbf{V}(\lambda)^{-1}[\mathbf{A}^{(2)}(x,\lambda) - \mathbf{A}_\infty^{(2)}(\lambda)]\mathbf{V}(\lambda)\mathbf{e}_1\| \\ &= \mathcal{O}(\mathrm{e}^{-\delta|x|}). \end{aligned}$$

However, the integral of this function does not vanish for large λ, so the third integral condition of the Pego–Weinstein lemma will not be satisfied in general (for this we would require some decay rate in κ/λ in the right-hand side).

However, under the main hypothesis needed in the applications presented here—namely $E_r(b,0) = 0$—then $\mathbf{A}(x,\lambda)$ has a simpler structure and we get

$$\|\mathbf{V}(\lambda)^{-1}[\mathbf{A}^{(2)}(x,\lambda) - \mathbf{A}_\infty^{(2)}(\lambda)]\zeta_+(\lambda)\| = \mathcal{O}(\mathrm{e}^{-\delta|x|}\kappa),$$

which vanishes for large λ, and so the third integral condition is satisfied. In summary, we have proved the following. (This asymptotic result is actually true in a wedge about the real axis, but this property will not be needed here.)

Proposition 7.1. *Suppose $E_r(b,0)=0$ and $C_2\beta+2c\beta>0$, and let $D(\lambda)$ be the Evans function* (6.1) *linearized about a solitary wave of the form given in sections* 2–3*. This function satisfies $D(\lambda)\to 1$ as $\lambda\to+\infty$ along the real axis.*

8. A geometric instability criterion. Using the geometry of the symplectic Evans matrix, the slope of $\det(\mathbf{E}_b(\lambda))$ for λ small, real, and positive can be determined. Combining this result with the intermediate-value theorem and the large λ asymptotics of $D(\lambda)$, the following geometric condition for linear instability is proved in [9, 10].

Define

$$\chi_{00}^- = \left[\Omega(\Psi^-, DG_\gamma(Z_0^-)^T\Psi^+)\right]^{-1},$$

and let d_∞ be the value of the Evans function for some value of $\lambda\in\Lambda\cap\mathbb{R}$, usually λ large. Then

$$d_\infty\,\chi_{00}^-\left(\frac{\partial}{\partial c}I(\widetilde{Z})-\frac{1}{2}\omega(Z_0^+,\partial_c Z_0^+)\right)<0 \tag{8.1}$$

is a sufficient condition for linear instability of the solitary wave $\mathcal{G}_{at+bx+\theta_0}(\widetilde{Z}(x-ct))$ (see [9], [10] for full details). It follows from section 7 that $d_\infty=+1$.

The expression (8.1) can be simplified by using the properties of the existing solitary wave, the special form of $\mathbf{M}$, and the fact that DG_γ is the identity. By definition of the matrix $\mathbf{M}$, we have that

$$I(\widetilde{Z})=-\int_{-\infty}^{\infty}\widetilde{q}_2(\widetilde{q}_1)_x\,dx+\tfrac{1}{2}\widetilde{q}_2\widetilde{q}_1\big|_{-\infty}^{\infty}.$$

Using that $(\widetilde{q}_1)_x=\widetilde{q}_2-b$ and $\widetilde{q}_2(-\infty)=b=\widetilde{q}_2(\infty)$, this implies that

$$I(\widetilde{Z})=-\int_{-\infty}^{\infty}(\widetilde{q}_2-b)(\widetilde{q}_2-\tfrac{b}{2})\,dx.$$

Also,

$$\frac{1}{2}\omega(Z_0^+,\partial_c Z_0^+)=-\frac{b}{2}\frac{\partial}{\partial c}\int_{-\infty}^{\infty}(\widetilde{q}_2-b)\,dx,$$

hence

$$\frac{\partial}{\partial c}I(\widetilde{Z})-\frac{1}{2}\omega(Z_0^+,\partial_c Z_0^+)=-\frac{\partial}{\partial c}\int_{-\infty}^{\infty}(\widetilde{q}_2-b)^2\,dx.$$

Finally, since Ψ^- is an eigenvector at $\lambda=0$ with eigenvalue δ and Ψ^+ is an eigenvector at $\lambda=0$ with eigenvalue $-\delta$, there are constants $C_5^\pm$ such that $\Psi^\pm=C_5^\pm U_{\mathrm{ev}}(\mp\delta,0)$ with $U_{\mathrm{ev}}(\mu,\lambda)$ given by (4.5). Hence

$$\Psi^-=\frac{C_5^-}{C_5^+}\left(\Psi^++2\delta C_5^+(0\,,\,1\,,\,0\,,\,c\,,\,-F_{qr}(b,0)\,,\,-E_q(b,0)+\beta\delta^2)\right)$$

and

$$\left(\chi_{00}^-\right)^{-1}=-2\delta^3C_5^-C_5^+\left[\alpha+F_{rr}(b,0)-2E_q(b,0)+2\beta\delta^2\right]=-2\delta^3C_5^-C_5^+\left[C_1+2\beta\delta^2\right].$$

Since δ is the positive real eigenvalue, (4.6) gives that

$$C_1 + 2\beta\delta^2 = C_1 + \sqrt{C_1^2 + 4\beta(C_2 + 2c)} - C_1 = \sqrt{C_1^2 + 4\beta(C_2 + 2c)} > 0.$$

Also $2\delta^3 > 0$, so we can conclude the following.

THEOREM 8.1. *Define* $C_5^{\pm} = \lim_{x\to\pm\infty} e^{\pm\delta x}(\widetilde{q}_2(x) - b)$. *If* $E = 0$, $F_{qq}(b,0)\beta > -2c\beta$, *and*

$$C_5^- C_5^+ \frac{\partial}{\partial c} \int_{-\infty}^{\infty} (\widetilde{q}_2(x) - b)^2\, dx < 0,$$

then the solitary wave solution $\widetilde{Z}(x; a, b, c)$ *of the generalized Kawahara equation* (1.1) *is unstable.*

If $b = 0$ and $\widetilde{q}_2$ is even, then $C_5^- C_5^+ > 0$. In this case the condition for instability is reminiscent of the abstract condition deduced from the energy-momentum method in Grillakis, Shatah, and Strauss [18] and Bona, Souganidis, and Strauss [4], although here there is no requirement on the second variation of the constrained critical point problem. If $b \neq 0$ and $(\widetilde{q}_2 - b)$ is not even—and it is known from numerical results that such solutions exist [11]—then $C_5^- C_5^+$ may be negative, in which case the condition for instability is precisely opposite that of the energy-momentum characterization (see section 5 of [7] for an example where this switch can occur).

In the next two sections we will apply this theorem to two known classes of solitary wave states of the generalized Kawahara equation.

9. Example: Kichenasammy–Olver nonlinearity. In this section we consider a class of generalized Kawahara equations, as considered in Kichenassamy and Olver [25], i.e., $E = 0$ and $F(q, r) = -Aqr^2 + \frac{1}{2}c_1 q^2 + \frac{1}{3}c_2 q^3 + \frac{1}{4}c_3 q^4$. This implies that

$$f(u, u_x, u_{xx}) = A(u_x)^2 + 2Auu_{xx} + c_1 u + c_2 u^2 + c_3 u^3\,. \tag{9.1}$$

In [25], it is shown that if

$$c_2 = \frac{3\alpha A}{5\beta} \quad \text{and} \quad c_3 = -\frac{2A^2}{5\beta},$$

then the Kawahara equation with f given by (9.1) has a two-parameter family of exact solitary wave solutions of the form

$$\widetilde{q}_2(x) = u(x) = -\frac{10\beta\phi^2}{A}\operatorname{sech}^2(\phi(x - ct)) + b,$$

where ϕ is a positive solution of

$$80(\beta\phi^2)^2 - 20\beta\phi^2(2bA - \alpha) + 6bA(bA - \alpha) - 5\beta(c_1 + 2c) = 0, \tag{9.2}$$

which is equivalent to the condition $\Delta(\pm 2\phi, 0) = 0$. This condition implies that if $\beta(2bA - \alpha) \geq 0$, then the family exists for $40c\beta > 4b^2A^2 - 4bA\alpha - 5\alpha^2 - 20c_1\beta$. If $\beta(2bA - \alpha) < 0$, then the family exists for $40c\beta > 24b^2A^2 - 24bA\alpha - 20c_1\beta$.

In terms of the notation of section 3, we have $\delta = 2\phi$ and

$$\Psi^{\pm} = \frac{40\beta\phi^2}{A}\,(-1, \pm 2\phi, -4\phi^2, \pm 2c\phi, -4\phi^2(-4\beta\phi^2 - \alpha + 2bA), \pm 8\beta\phi^3),$$

i.e., $C_5^{\pm} = -\frac{40\beta\phi^2}{A}$. A tedious but straightforward calculation demonstrates that $\lim_{x\to\pm\infty} \partial_x[e^{\pm\delta x}\widetilde{Z}_x] = 0$. So all the conditions of section 3 are satisfied.

Next we look at section 4. For this example we have

$$C_1 = \alpha - 2Ab \quad \text{and} \quad C_2 = c_1 + \frac{6Ab}{5\beta}(\alpha - Ab).$$

So an eigenvector can be written as

$$U_{\mathrm{ev}}(\mu,\lambda) = (1\,,\,\mu\,,\,\mu^2\,,\,-\lambda+\mu c\,,\,-\mu^2(\alpha-2Ab+\beta\mu^2)\,,\,\beta\mu^3).$$

In order to have $C_2\beta > -2c\beta$, the analysis will be restricted to the case

$$40c\beta > -20\beta c_1 - 24Ab(\alpha - Ab),$$

which is exactly the sufficient condition for the existence of the family of solitary waves. This condition is also necessary if $\beta(2bA - \alpha) < 0$.

Now we are ready to apply the instability criterion. A straightforward calculation shows that

$$-\int_{-\infty}^{\infty}(u(x)-b)^2\,dx = -\frac{400\phi^3\beta^2}{3A^2}, \quad \text{hence} \quad -\frac{\partial}{\partial c}\int_{-\infty}^{\infty}(u(x)-b)^2\,dx = -\frac{400\phi^2\beta^2}{A^2}\frac{\partial}{\partial c}\phi.$$

To determine $\frac{\partial}{\partial c}\phi$, we differentiate (9.2). This gives

$$\frac{\partial}{\partial c}\phi = \frac{1}{4\phi(8\beta\phi^2 - 2bA + \alpha)}.$$

Also,

$$\left(\chi_{00}^-\right)^{-1} = (\mathbf{J}_c\Psi^-, \Psi^+) = -\frac{25600\beta^2\phi^7}{A^2}(8\beta\phi^2 + \alpha - 2bA).$$

So

$$\chi_{00}^-\left(\frac{\partial}{\partial c}I(\widetilde{Z}) - \frac{1}{2}\omega(Z_0^+, \partial_c Z_0^+)\right) = \frac{A^2}{25600\beta^2\phi^7}\frac{1}{4\phi}\frac{400\phi^2\beta^2}{A^2} = \frac{1}{256\phi^6} > 0.$$

Since the sufficient geometric condition for linear instability is not met, this suggests that the solitary wave is "stable." However, there could still be unstable λ-eigenvalues on the positive real λ-axis, but there would be two or more. The solitary wave could also be unstable due to unstable eigenvalues with nonzero imaginary part.

10. Example: Levandosky's homogeneous nonlinearity. In this section we consider a class of nonlinearities for (1.1) which includes the equations considered by Levandosky [26]. We take $E = 0$ and F homogeneous of degree $p+1$ for some $p > 1$, i.e.,

$$F(\nu q, \nu r) = \nu^{p+1}F(q,r) \quad \text{for all } \nu \geq 0 \text{ and } (q,r) \in \mathbb{R}^2.$$

In [26], it is proved that the following condition is sufficient for the existence of a one-parameter family of solitary waves,

$$\int_{-\infty}^{\infty} F(u,u_x)\,dx > 0 \quad \text{for some } u \in H^2(\mathbb{R}),\ b = 0,\ \beta = 1, \text{ and } 4c > (\max\{\alpha, 0\})^2\,.$$

Recall $\mathcal{I}(u) = \frac{1}{2}\int_{-\infty}^{\infty}|u(x)|^2\,dx$ and assume that a family of solitary waves $\widehat{u}(x;c)$ exists, where $\widehat{u}$ travels with speed c. In [26] it is also shown that under the above conditions, the solitary waves are stable if $\frac{d}{dc}\mathcal{I}(\widetilde{u}) > 0$ and unstable if $\frac{d}{dc}\mathcal{I}(\widetilde{u}) < 0$ and $p \geq 2$. When $b = 0$ in the formulation in sections 2–6, this instability condition agrees with Theorem 8.1 if $C_5^+ C_5^- > 0$.

First, we embed the solitary wave state in a two-parameter family, allowing for b to be nonzero. Then we show how our theory recovers the result in [26], without any specific use of the variational principle associated with the energy-momentum characterization. For definiteness, consider the case $\alpha = 0$ and take F to be homogeneous in r itself, i.e., there is some $0 \leq n \leq p+1$ such that

$$F(q, \nu r) = \nu^n F(q,r) \quad \text{for all } \nu \geq 0 \text{ and } (q,r) \in \mathbb{R}^2.$$

This homogeneity condition in r implies that $F_{qq}(b,0) = 0$, hence the condition on c of Theorem 8.1 becomes $c > 0$.

When there exists a family of solitary wave solutions $\{\widetilde{Z}(x;a,b,1) \mid a \in \mathbb{R},\, b \in \mathbb{R}\}$ with speed $c = 1$, then we can construct a family of solitary wave solutions with speed $c > 0$:

$$\widetilde{Z}(x;a,b,c) = c^{\frac{4-n}{4(p-1)}}\,\mathrm{diag}(c^{-\frac{1}{4}}, 1, c^{\frac{1}{4}}, c, c^{\frac{3}{4}}, c^{\frac{1}{2}})\,\widetilde{Z}(c^{\frac{1}{4}}x; ac^{\frac{n-4p}{4(p-1)}}, bc^{-\frac{4-n}{4(p-1)}}, 1).$$

Indeed, $\widetilde{Z}(x;a,b,c)$ as defined above satisfies

$$\begin{aligned}
\mathbf{J}_c D_x \widetilde{Z}(x;a,b,c) &= c^{\frac{1}{4}}\, c^{\frac{4-n}{4(p-1)}}\,\mathbf{J}_c\,\mathrm{diag}(c^{-\frac{1}{4}}, 1, c^{\frac{1}{4}}, c, c^{\frac{3}{4}}, c^{\frac{1}{2}})\,\mathbf{J}_1^{-1}\mathbf{J}_1 \\
&\qquad \widetilde{Z}_x(c^{\frac{1}{4}}x; ac^{\frac{n-4p}{4(p-1)}}, bc^{-\frac{4-n}{4(p-1)}}, 1) \\
&= c^{\frac{1}{4}}\,\mathbf{J}_c\,\mathrm{diag}(c^{-\frac{1}{4}}, 1, c^{\frac{1}{4}}, c, c^{\frac{3}{4}}, c^{\frac{1}{2}})\,\mathbf{J}_1^{-1} \\
&\qquad (\nabla S(\widetilde{Z}) - ac^{\frac{n-4p}{4(p-1)}}\nabla P(\widetilde{Z}) - bc^{-\frac{4-n}{4(p-1)}}\nabla Q(\widetilde{Z})) \\
&= \nabla S(\widetilde{Z}(x;a,b,c)) - a\nabla P(\widetilde{Z}(x;a,b,c)) - b\nabla Q(\widetilde{Z}(x;a,b,c)).
\end{aligned}$$

This implies that for $b = 0$ or $n = 4$

$$\begin{aligned}
\int_{-\infty}^{\infty}(\widetilde{q}_2(x;a,b,c) - b)^2\,dx &= c^{\frac{4-n}{2(p-1)}}\int_{-\infty}^{\infty}(\widetilde{q}_2(c^{\frac{1}{4}}x; ac^{\frac{n-4p}{4(p-1)}}, bc^{-\frac{4-n}{4(p-1)}}, 1) \\
&\qquad\qquad - bc^{-\frac{4-n}{4(p-1)}})^2\,dx \\
&= c^{\frac{4-n}{2(p-1)}}c^{-\frac{1}{4}}\int_{-\infty}^{\infty}(\widetilde{q}_2(s; ac^{\frac{n-4p}{4(p-1)}}, bc^{-\frac{4-n}{4(p-1)}}, 1) \\
&\qquad\qquad - bc^{-\frac{4-n}{4(p-1)}})^2\,ds \\
&= c^{\frac{4-n}{2(p-1)}-\frac{1}{4}}\int_{-\infty}^{\infty}(\widetilde{q}_2(s; ac^{\frac{n-4p}{4(p-1)}}, b, 1) - b)^2\,ds.
\end{aligned}$$

In the last step we used that $b = 0$ or $n = 4$, hence $bc^{-\frac{4-n}{4(p-1)}} = b$. Since the defining equation for $\widetilde{q}_2$ does not depend on a, this integral will not depend on a either and we can put $a = 0$; hence,

$$\int_{-\infty}^{\infty}(\widetilde{q}_2(x;a,b,c) - b)^2\,dx = c^{\frac{9-2n-p}{4(p-1)}}\int_{-\infty}^{\infty}(\widetilde{q}_2(s;0,b,1) - b)^2\,ds.$$

So

$$\frac{\partial}{\partial c}\int_{-\infty}^{\infty}(\widetilde{q}_2(x;a,b,c)-b)^2\,dx=\frac{9-2n-p}{4(p-1)}\,c^{\frac{13-2n-5p}{4(p-1)}}\int_{-\infty}^{\infty}(\widetilde{q}_2(s;0,b,1)-b)^2\,ds.$$

Furthermore,

$$C_5^+(a,b,c)\,C_5^-(a,b,c)=c^{\frac{4-n}{2(p-1)}}C_5^+(ac^{\frac{n-4p}{4(p-1)}},b,1)\,C_5^-(ac^{\frac{n-4p}{4(p-1)}},b,1).$$

It is difficult to verify the hypothesis (3.2) for this example and therefore we assume (3.2) is satisfied. Then with

$$C_5^+(ac^{\frac{n-4p}{4(p-1)}},b,1)\,C_5^-(ac^{\frac{n-4p}{4(p-1)}},b,1)\int_{-\infty}^{\infty}\widetilde{q}_2^2(s;0,b,1)\,ds>0.$$

Theorem 8.1 shows that the solitary waves are unstable if $9-2n-p<0$, i.e., $p>9-2n$. These instability results agree with those in [26] when an error in Lemma 3.3 in [26] is corrected. (The $(p+1)(4-\beta)$ in the numerator of the expression for γ should be replaced by $4(p+1)-2\beta$.)

If $n=4$, then $b\neq 0$ is allowed and we obtain that the wave is always unstable since

$$\frac{\partial}{\partial c}\int_{-\infty}^{\infty}(\widetilde{q}_2(x;a,b,c)-b)^2\,dx=-\frac{1}{4}c^{-\frac{5}{4}}\int_{-\infty}^{\infty}\widetilde{q}_2^2(s;0,b,1)\,ds<0.$$

Appendix. Large $\boldsymbol{\lambda}$ behavior and the Pego–Weinstein lemma. The following result is a generalization of Proposition 1.17 in Pego and Weinstein [29], which gives a sufficient condition for $D(\lambda)\to 1$ as $\lambda\to+\infty$ along the real λ-axis. Consider the system

$$\mathbf{u}_x=\mathbf{A}(x,\lambda)\mathbf{u}\,,\quad \mathbf{u}\in\mathbb{C}^n\,,\quad \lambda\in\Lambda\,, \tag{A.1}$$

where Λ is an open simply connected subset of $\mathbb{C}$, and Λ includes a wedge about the real axis in which we can take $|\lambda|\to\infty$. The spectrum of $\mathbf{A}^\infty(\lambda)$, where

$$\mathbf{A}^\infty(\lambda)=\lim_{|x|\to\infty}\mathbf{A}(x,\lambda), \tag{A.2}$$

is assumed to have k-eigenvalues with negative real part and $n-k$ with nonnegative real part. A critical hypothesis in Proposition 1.17 in [29] is that $k=1$. However, this hypothesis is not essential if we take into account that on $\bigwedge^k(\mathbb{C}^n)$ the induced matrix

$$\mathbf{A}_\infty^{(k)}(\lambda)\stackrel{\text{def}}{=}\bigwedge\nolimits^k(\mathbf{A}^\infty(\lambda))$$

has a unique simple eigenvalue of largest negative real part. Then working on $\bigwedge^k(\mathbb{C}^n)$ with the Evans function also on the exterior algebra, the proof of Proposition 1.17 carries over [10]. The precise statement of the result needed in this paper is given below. Although stated in a substantially more general form, the proof given in [29] carries over almost verbatim.

Pego–Weinstein lemma. *Consider the system* (A.1)–(A.2) *and suppose that for all $\lambda\in\Lambda$ the eigenvalue of $\mathbf{A}_\infty^{(k)}(\lambda)$ with largest negative real part is unique and simple. Denote this eigenvalue by $\alpha(\lambda)$ and its (analytic choice of) right eigenvector by $\zeta(\lambda)$*

and its (analytic choice of) left eigenvector by $\eta(\lambda)$ *with normalization* $[\![\eta,\zeta]\!]_k = 1$, *where* $[\![\cdot,\cdot]\!]_k$ *is the induced inner product on* $\bigwedge^k(\mathbb{C}^n)$.

Let $\mathbf{U}(x,\lambda) \in \bigwedge^k(\mathbb{C}^n)$ *be the solution of the system*

$$\mathbf{U}_x = \mathbf{A}^{(k)}(x,\lambda)\mathbf{U} \quad \textit{satisfying} \quad \lim_{x\to+\infty} \mathrm{e}^{-\alpha(\lambda)x}\mathbf{U}(x,\lambda) = \zeta(\lambda) \in \textstyle\bigwedge^k(\mathbb{C}^n)\,.$$

Similarly, let $\mathbf{W}(x,\lambda) \in \bigwedge^k(\mathbb{C}^n)$ *be the solution of the system*

$$\mathbf{W}_x = -\mathbf{A}^{(k)}(x,\lambda)^T\mathbf{W} \quad \textit{satisfying} \quad \lim_{x\to-\infty} \mathrm{e}^{\alpha(\lambda)x}\mathbf{W}(x,\lambda) = \eta(\lambda) \in \textstyle\bigwedge^k(\mathbb{C}^n)\,.$$

In terms of these functions, the Evans function (6.1) *can be expressed in the form*

$$D(\lambda) = \mathbf{W}(0,\lambda)\cdot\mathbf{U}(0,\lambda) \overset{\text{def}}{=} \langle\overline{\mathbf{W}(0,\lambda)},\mathbf{U}(0,\lambda)\rangle,$$

where $\langle\cdot,\cdot\rangle$ *is a standard Hermitian inner product on* $\mathbb{C}^d$ *and* $d = \dim\bigwedge^k(\mathbb{C}^n)$.

Now, suppose $\mathbf{A}_\infty^{(k)}(\lambda)$ *is diagonalizable for large* λ *and let* $\mathbf{V}(\lambda) \in \mathbb{C}^{d\times d}$ *be the matrix of right eigenvectors such that the first column is* $\zeta(\lambda)$. *If*

$$\int_{-\infty}^{+\infty} \|\mathbf{V}(\lambda)^{-1}[\mathbf{A}^{(k)}(x,\lambda) - \mathbf{A}_\infty^{(k)}(\lambda)]\mathbf{V}(\lambda)\|\,\mathrm{d}x \le C\,, \quad \textit{independent of } \lambda,$$

$$\int_{|x|\ge x_0} \|\mathbf{V}(\lambda)^{-1}[\mathbf{A}^{(k)}(x,\lambda) - \mathbf{A}_\infty^{(k)}(\lambda)]\mathbf{V}(\lambda)\|\,\mathrm{d}x \to 0\,, \quad \textit{as } x_0\to\infty\textit{, uniformly in } \lambda,$$

$$\int_{-\infty}^{+\infty} \|\mathbf{V}(\lambda)^{-1}[\mathbf{A}^{(k)}(x,\lambda) - \mathbf{A}_\infty^{(k)}(\lambda)]\zeta(\lambda)\|\,\mathrm{d}x \to 0\,, \quad \textit{as } |\lambda|\to\infty\,,$$

then

$$\mathbf{V}(\lambda)^{-1}\mathbf{U}(0,\lambda) = \mathbf{V}(\lambda)^{-1}\zeta(\lambda) + o(1) \quad \textit{for } |\lambda|\to\infty \tag{A.3}$$

and $\mathbf{W}(0,\lambda)\mathbf{V}(\lambda)$ *is bounded with*

$$\mathbf{W}(0,\lambda)\mathbf{V}(\lambda)\mathbf{e}_1 = \mathbf{W}(0,\lambda)\zeta(\lambda) = 1 + o(1) \quad \textit{for } |\lambda|\to\infty\,. \tag{A.4}$$

The two results (A.3) *and* (A.4) *imply that* $D(\lambda)\to 1$ *as* $|\lambda|\to\infty$.

NONEXISTENCE OF PERMANENT CURRENTS IN CONVEX PLANAR SAMPLES*

SHUICHI JIMBO† AND PETER STERNBERG‡

Abstract. Recent works have demonstrated the existence of nontrivial stable critical points of the Ginzburg–Landau energy

$$(\Psi, A) \to \int_\Omega \frac{1}{2}|(\nabla - iA)\Psi|^2 + \frac{\kappa^2}{4}(1-|\Psi|^2)^2\, dx + \frac{1}{2}\int_{\mathbb{R}^n} |\mathrm{curl}|\, \mathrm{A}^2\, dx$$

for multiply connected domains $\Omega \subset \mathbb{R}^n$ with $n = 2$ or 3 and for simply connected domains Ω that are close in L^1 to multiply connected domains. In this article we demonstrate that while there is no topological obstruction to the presence of such stable critical points, there is a geometric obstruction. Specifically, we show the nonexistence of stable critical points of this energy in two-dimensional convex domains.

1. Introduction.

The phenomenon of permanent currents in superconducting materials has been well known in the physics community for many years. In a typical experiment, a ring-shaped sample is subjected to an applied field that induces a current. The temperature of the sample is then lowered into the superconducting regime, the applied field is shut off, and the current persists with only negligible resistance—sometimes for a period of years. Mathematically, one can describe these states using the Ginzburg–Landau theory of superconductivity [3, 5]. Within this theory, a permanent current in two dimensions corresponds to a nontrivial stable critical point of the energy

$$G(\Psi, A) = \int_\Omega \frac{1}{2}\left|(\nabla - iA)\Psi\right|^2 + \frac{\kappa^2}{4}(1-|\Psi|^2)^2\, dx + \frac{1}{2}\int_{\mathbb{R}^2} \left|\mathrm{curl}\, A\right|^2\, dx.$$

Here $\Omega \subset \mathbb{R}^2$ is a bounded cross-section of a cylindrical sample such as a wire or thin film. The magnitude of the order parameter $\Psi : \Omega \to \mathbb{C}$ measures the density of superconducting electron pairs, $A : \mathbb{R}^2 \to \mathbb{R}^2$ is the magnetic potential whose curl represents the induced magnetic field, and κ is the Ginzburg–Landau parameter. The energy G is most naturally defined for pairs (Ψ, A) having square-integrable derivatives so we consider it as defined on the space $H^1(\Omega; \mathbb{C}) \times Z$ where

$$Z \equiv \{A \in H^1_{\mathrm{loc}}(\mathbb{R}^2; \mathbb{R}^2) : \mathrm{curl}\, A \in L^2(\mathbb{R}^2; \mathbb{R}^2)\}. \tag{1.1}$$

We recall that the Ginzburg–Landau energy enjoys the gauge invariance property that

$$G(\Psi, A) = G(\Psi e^{i\phi}, A + \nabla\phi) \tag{1.2}$$

for any $\phi \in H^2_{loc}(\mathbb{R}^2)$. In section 2 we will discuss the gauge choices made in this paper.

Any pair (Ψ, A) in $H^1(\Omega;\mathbb{C}) \times Z$ for which the first variation of G vanishes will be referred to as a critical point. By a stable critical point, we will mean a critical point for which the second variation is nonnegative. (See the beginning of section 2 for the precise definitions.) By a nontrivial critical point we will mean one that is not gauge-equivalent to a state $(c, 0)$ for $c \in \mathbb{C}$.

Recently, using a degree theoretic approach, we have succeeded in proving the existence of these stable critical points when κ^2 is sufficiently large in both two and three dimensions, provided the sample is multiply connected [6, 7, 10]. Indeed, one finds, roughly speaking, that there exists a stable critical point living in each homotopy class of mappings from Ω into S^1. One may assume that these solutions correspond to the experimentally observed permanent currents produced in ring-shaped samples in the laboratory.

Perhaps more surprising, however, is the more recent discovery in [8] that stable critical points exist in certain simply connected domains, thus showing that there is no topological obstruction to the presence of permanent currents. These critical points are constructed through a perturbation of domain argument, starting from a multiply connected domain. In particular, then, they are shown to exist in highly nonconvex samples. They differ from the ones found in multiply connected domains in that they contain vortices—that is, zeros of the order parameter—unlike the vortex-free solutions of [6, 7, 10].

In light of these existence results, we pursue here the question of whether there are any geometric obstructions to producing permanent currents via Ginzburg–Landau theory. That is, we ask whether among simply connected domains Ω, there are any conditions on $\partial\Omega$ that would preclude the existence of nontrivial stable critical points. We should perhaps point out that if we drop the requirement of stability in our question, then there certainly do exist nontrivial critical points even under very stringent assumptions on the geometry of the sample. For example, taking $\Omega \subset \mathbb{R}^2$ to be a disc, one can construct critical points (Ψ, A) under the radial ansatz

$$\Psi = \Psi(r,\theta) = w_m(r)e^{im\theta}, \quad A = A(r,\theta) = \frac{Y_m(r)}{r}(-\sin\theta, \cos\theta)$$

for each positive integer m, where then w_m and Y_m are obtained through minimization of G over this class of radial competitors.

It turns out, however, that all of these radial solutions in a disc are unstable. This follows as a special case of our main result, stated below, which rules out the existence of nontrivial stable critical points of G in two dimensions, whenever Ω is convex.

THEOREM 1.1. *Let $\Omega \subset \mathbb{R}^2$ be an open, bounded convex set with $C^{5,\alpha}$ boundary, for any $\alpha \in (0,1)$. Then the only stable critical point of G is the pair* $(1,0)$ *or one of its gauge-equivalent representations.*

Our approach should be viewed as a descendant of the technique employed in [2, 9] to prove the analogous result for the well-studied scalar functional

$$u \to \int_\Omega F(u) + |\nabla u|^2 \, dx$$

for $F : \mathbb{R}^1 \to \mathbb{R}^1$, $u : \Omega \to \mathbb{R}^1$, and $\Omega \subset \mathbb{R}^n$ convex. It is based upon an explicit expression for the second variation of G computed about a critical point. In Proposition 3.1, we show that we can describe this second variation completely in terms of boundary integrals that include a dependence on the curvature of $\partial\Omega$. Under the convexity assumption, we then show through Proposition 3.2 and Theorem 3.3 that the second variation is negative unless $(\Psi, A) = (1, 0)$ (or any of its gauge-equivalent representations).

The paper is organized as follows. In section 2 we review basic properties of the Ginzburg–Landau system and develop the regularity theory needed for our approach. We should note that we have not attempted to prove an optimal theorem with regard to smoothness of the boundary. The theorem above contains an assumption that $\partial\Omega \in C^{5,\alpha}$, meaning that, locally, the boundary can be described as the graph of a function having five continuous derivatives with fifth derivatives satisfying a Hölder condition with exponent α; cf. [4]. This assumption can surely be relaxed. In section 2 we address the reason for the assumed regularity. We also present a simple lemma relating curl-free vector fields satisfying a Neumann boundary condition to the curvature of the boundary. Then in section 3 we work with the second variation of the Ginzburg–Landau energy in order to obtain our main result.

2. Preliminaries. Throughout this paper we shall take $\Omega \subset \mathbb{R}^2$ to be a bounded, open, convex set with sufficiently smooth boundary, say $\partial\Omega \in C^{5,\alpha}$. We will denote the outer unit normal to $\partial\Omega$ by ν and the mean curvature of $\partial\Omega$ by H so that $H(x) \geq 0$ for all $x \in \partial\Omega$. We denote a ball centered at x of radius R by $B(x, R)$ and we use Ψ^* to denote the complex conjugate of a complex-valued function Ψ. We will frequently invoke the summation convention on expressions with repeated indices.

Before discussing the nature of critical points, we discuss the two gauge choices we will utilize in our approach. The first is to work only with vector potentials $A \in Z$ (cf. (1.1)) satisfying the condition

$$\operatorname{div} A = 0 \text{ in } \mathbb{R}^2. \tag{2.1}$$

This choice is clearly possible in light of the solvability in $H^2_{\text{loc}}(\mathbb{R}^2)$ of Poisson's equation

$$-\Delta\phi = \operatorname{div} A \in L^2_{\text{loc}}(\mathbb{R}^2).$$

A second choice we will use is the following:

$$\operatorname{div} A = 0 \text{ in } \Omega, \quad A \cdot \nu = 0 \text{ on } \partial\Omega. \tag{2.2}$$

Such a gauge is obtainable via the transformation $\Psi \to \Psi e^{i\phi}$, $A \to A + \nabla\phi$ where $\phi \in H^2_{\text{loc}}(\mathbb{R}^2)$ is taken to be an extension to $\mathbb{R}^2$ of the solution to the boundary value problem

$$\Delta\phi = -\operatorname{div} A \text{ in } \Omega, \quad \nabla\phi \cdot \nu = -A \cdot \nu \text{ on } \partial\Omega.$$

Of course, when working in this gauge we have not uniquely determined A since the extension of ϕ to the complement of Ω is arbitrary, but we make here the convention that we shall always take as smooth an extension as possible, depending on the known regularity of A.

By a critical point of G we shall mean a pair $(\Psi, A) \in H^1(\Omega; \mathbb{C}) \times Z$ such that

$$\frac{d}{d\varepsilon} G(\Psi + \varepsilon\tilde{\Psi}, A + \varepsilon\tilde{A})_{|_{\varepsilon=0}} = 0 \quad \text{for all } (\tilde{\Psi}, \tilde{A}) \in H^1(\Omega; \mathbb{C}) \times Z. \tag{2.3}$$

One readily verifies that such a critical point will satisfy the Ginzburg–Landau system

$$(\nabla - iA)^2\Psi + \kappa^2(1-|\Psi|^2)\Psi = 0 \quad \text{in } \Omega, \tag{2.4}$$

$$\operatorname{curl}\operatorname{curl} A + \left\{\frac{i}{2}(\Psi^*\nabla\Psi - \Psi\nabla\Psi^*) + |\Psi|^2 A\right\}\chi_\Omega = 0 \quad \text{in } \mathbb{R}^2, \tag{2.5}$$

along with the "natural" boundary conditions

$$(\nabla - iA)\Psi\cdot\nu = 0 \quad \text{on } \partial\Omega, \tag{2.6}$$

$$\nu\times[\operatorname{curl} A] = 0 \quad \text{on } \partial\Omega. \tag{2.7}$$

Here $[\,\cdot\,]$ denotes the jump across $\partial\Omega$ and χ_Ω denotes the characteristic function of the set Ω. We note that the boundary condition (2.6) reduces to simply

$$\nabla\Psi\cdot\nu = 0 \quad \text{on } \partial\Omega \tag{2.8}$$

whenever the gauge choice (2.2) is used.

Of course, without further work, a critical point is only a weak solution of the system (2.4)–(2.7). However, standard elliptic regularity theory leads to the conclusion that any weak solution (Ψ, A) is in fact infinitely differentiable in the open sets Ω and $\mathbb{R}^2\setminus\overline{\Omega}$ and is a classical solution of (2.4)–(2.5) in these sets. The issue of boundary regularity is also not difficult but is perhaps a bit more subtle in light of the discontinuity inherent in (2.5) due to the presence of the characteristic function. As we shall use crucially the smoothness of both Ψ and A up to $\partial\Omega$, we present below the boundary regularity statement and proof.

PROPOSITION 2.1. *Assume $\Omega\subset\mathbb{R}^2$ is an open, bounded set with $\partial\Omega\in C^{5,\alpha}$ for some $\alpha>0$. Then any critical point (Ψ,A) of G in the sense of (2.3) expressed in the gauge (2.1) or (2.2) lies in the space $C^{3,\alpha}(\overline{\Omega};\mathbb{C})\times C^{1,\alpha}_{\text{loc}}(\mathbb{R}^2;\mathbb{R}^2)$. Furthermore, $A\in C^{3,\alpha}(\overline{\Omega};\mathbb{R}^2)$.*

Remark 2.1. We note that in general, A will not be smoother than $C^{1,\alpha}$ *across* $\partial\Omega$, so by claiming $A\in C^{3,\alpha}(\overline{\Omega};\mathbb{R}^2)$ we mean this in the sense of one-sided derivatives taken from within Ω.

Proof. Throughout this argument, when working with (2.4) for Ψ we will make the gauge choice (2.2), and when working with (2.5) for A we will choose (2.1). We note that switching gauges in no way affects the regularity of the solutions since the gauge transformations are smooth. In view of (2.1), one may rewrite (2.5) as

$$-\Delta A = f(x) \equiv \begin{cases} -\kappa^2 \operatorname{Im}(\Psi\nabla\Psi^*) - |\Psi|^2 A & \text{for } x\in\Omega, \\ 0 & \text{for } x\in\mathbb{R}^2\setminus\Omega. \end{cases} \tag{2.9}$$

Standard elliptic regularity immediately yields that $\Psi\in H^2(\Omega;\mathbb{C})$ while $A\in H^2_{\text{loc}}(\mathbb{R}^2;\mathbb{R}^2)$. Hence, in particular, $A\in C^{0,\alpha}_{\text{loc}}(\mathbb{R}^2;\mathbb{R}^2)$, meaning that Ψ satisfies a linear elliptic equation with Hölder continuous coefficients in Ω, along with homogeneous Neumann boundary conditions. Consequently, $\Psi\in C^{2,\alpha}(\overline{\Omega};\mathbb{C})$. This in turn implies that the function f defined by (2.9) lies in $L^\infty(\mathbb{R}^2;\mathbb{R}^2)$ so that $A\in C^{1,\alpha}_{\text{loc}}(\mathbb{R}^2;\mathbb{R}^2)$ (cf. [4, Chapters 6 and 8]).

Of course, both Ψ and A can be shown to be infinitely smooth in the open sets Ω and $\mathbb{R}^2\setminus\overline{\Omega}$, but our desire in this proposition is to establish smoothness up to $\partial\Omega$. Clearly the discontinuity in f across $\partial\Omega$ precludes higher regularity across the boundary so we restrict our attention to one-sided regularity from within Ω. To this end, fix any point $x_0 \in \partial\Omega$ and assume first that for some $R > 0$, the set $\partial\Omega \cap B(x_0, R)$ consists of the line segment

$$T = \{(x_1, x_2) : |x_1| < L,\ x_2 = 0\}$$

for some $L > 0$. Then locally, f takes the form

$$f(x_1, x_2) = \begin{cases} -\kappa^2 \mathrm{Im}\,(\Psi\nabla\Psi^*) - |\Psi|^2 A & \text{in } B(x_0, R) \cap \{x_2 > 0\}, \\ 0 & \text{in } B_(x_0, R) \cap \{x_2 < 0\}. \end{cases}$$

Choosing any test function $B \in H^1(\mathbb{R}^2; \mathbb{R}^2)$ supported in $B(x_0, R)$ we multiply (2.9) by $\frac{\partial B}{\partial x_1}$ and integrate by parts to find

$$\int_{B(x_0,R)} \nabla\left(\frac{\partial A}{\partial x_1}\right) \cdot \nabla B\, dx = \int_{B(x_0,R)} \frac{\partial f}{\partial x_1} \cdot B\, dx.$$

Here the crucial point is that f, while obviously not smooth, has an L^2—in fact, L^∞—derivative with respect to x_1. Consequently, $\frac{\partial A}{\partial x_1}$ is a weak solution to the equation

$$-\Delta\left(\frac{\partial A}{\partial x_1}\right) = \frac{\partial f}{\partial x_1} \in L^\infty(B(x_0, R)).$$

We conclude that $\frac{\partial A}{\partial x_1} \in C^{1,\alpha}(B(x_0, R); \mathbb{R}^2)$.

Now we shift our focus to the problem satisfied by A within Ω. Bringing to bear the above argument, we find that in $\Omega \cap B(x_0, R)$, A solves the problem (2.9) with $f \in C^{1,\alpha}$, along with a Dirichlet condition of class $C^{2,\alpha}(\partial\Omega \cap B(x_0, R); \mathbb{R}^2)$. As a result, we find $A \in C^{2,\alpha}(\overline{B(x_0, R) \cap \Omega}; \mathbb{R}^2)$.

Similarly, differentiating (2.4) along with the boundary condition (2.8) with respect to x_1, we conclude that $\Psi_{|\partial\Omega\cap B(x_0,R)}$ is of class $C^{3,\alpha}$ so that $\Psi \in C^{3,\alpha}(\overline{\Omega \cap B(x_0, R)}; \mathbb{C})$.

Differentiating (2.9) a second time with respect to x_1 and applying the same type of reasoning, we conclude that $A \in C^{3,\alpha}(\partial\Omega \cap B(x_0, R); \mathbb{R}^2)$; hence, $A \in C^{3,\alpha}(\overline{\Omega \cap B(x_0, R)}; \mathbb{R}^2)$.

As the argument is local, the case where $\partial\Omega$ is not locally flat is handled by a standard "flattening of the boundary" procedure. Keeping track of how many derivatives of the curvature κ are needed to carry this out, one finds that $C^{3,\alpha}$ regularity of the solution requires $\partial\Omega \in C^{5,\alpha}$ in order to apply the required Schauder theory. □

We conclude this section with some well-known facts about the Ginzburg–Landau system and a standard result relating the curvature of the boundary to functions satisfying a Neumann boundary condition.

Lemma 2.2. *Let $(\Psi, A) \in H^1(\Omega; \mathbb{C}) \times Z$ be a critical point of G. Then we have*

$$\text{(i)} \quad |\Psi| \le 1 \quad \text{in } \overline{\Omega}, \tag{2.10}$$

$$\text{(ii)} \quad \mathrm{curl}\, A = 0 \quad \text{in } \mathbb{R}^2 \setminus \overline{\Omega}. \tag{2.11}$$

The proof of (i) follows from the maximum principle after using (2.4) to obtain a differential inequality for $|\Psi|^2$ (cf. [3]). Property (ii) follows from the observation that in two dimensions, the condition $\mathrm{curl}\,\mathrm{curl}\, A = 0$ in $\mathbb{R}^2 \setminus \overline{\Omega}$ implies that the quantity $\mathrm{curl}\, A = (0, 0, \frac{\partial A^{(2)}}{\partial x_1} - \frac{\partial A^{(1)}}{\partial x_2})$ is constant. As $\mathrm{curl}\, A \in L^2(\mathbb{R}^2)$, the constant must be zero.

Lemma 2.3. *Let $B \in C^1(\overline{\Omega}; \mathbb{R}^2)$ satisfy the condition $B \cdot \nu = 0$ on $\partial\Omega$ and have zero curl on $\partial\Omega$, i.e., $\frac{\partial B^{(1)}}{\partial x_2} = \frac{\partial B^{(2)}}{\partial x_1}$ on $\partial\Omega$. Then we have the identity following on $\partial\Omega$:*

$$\frac{\partial\big(|B|^2\big)}{\partial \nu} = -2\frac{\partial \nu^{(k)}}{\partial x_j} B^{(k)} B^{(j)} = -2H\,|B|^2 . \tag{2.12}$$

In particular, if $u \in C^2(\overline{\Omega})$ satisfies the condition $\nabla u \cdot \nu = 0$ on $\partial\Omega$, then

$$\frac{\partial\big(|\nabla u|^2\big)}{\partial \nu} = -2\frac{\partial \nu^{(k)}}{\partial x_j} \frac{\partial u}{\partial x_k} \frac{\partial u}{\partial x_j} = -2H\,|\nabla u|^2 . \tag{2.13}$$

Proof. We compute

$$\frac{\partial\big(|B|^2\big)}{\partial \nu} = 2B^{(k)}\frac{\partial B^{(k)}}{\partial x_j}\nu^{(j)} = 2B^{(j)}\frac{\partial B^{(k)}}{\partial x_j}\nu^{(k)}. \tag{2.14}$$

Now $B \cdot \nu = 0$ implies

$$0 = \frac{\partial\big(B \cdot \nu\big)}{\partial x_j} B^{(j)} = B^{(j)}\frac{\partial B^{(k)}}{\partial x_j}\nu^{(k)} + B^{(k)}\frac{\partial \nu^{(k)}}{\partial x_j} B^{(j)},$$

and substituting this into (2.14) yields the result. □

3. Main results. In this section we will use the second variation of the Ginzburg–Landau energy to rule out the possibility of nontrivial stable critical points in convex planar domains. For any mappings $\Psi, \tilde{\Psi} \in H^1(\Omega; \mathbb{C})$ and $A, \tilde{A} \in Z$ (cf. 1.1) we denote by J the second variation of G taken about the pair (Ψ, A). We record here the straightforward calculation of J:

$$\begin{aligned} J(\Psi, A; \tilde{\Psi}, \tilde{A}) &= \frac{d^2}{d\varepsilon^2} G(\Psi + \varepsilon\tilde{\Psi}, A + \varepsilon\tilde{A})_{|\varepsilon=0} \\ &\frac{1}{2}\int_\Omega \bigg\{ \left|\nabla\tilde{\Psi}\right|^2 + i\langle \nabla\Psi, \tilde{\Psi}^*\tilde{A}\rangle + i\langle \nabla\tilde{\Psi}, A\tilde{\Psi}^* + \tilde{A}\Psi^*\rangle - i\langle \nabla\Psi^*, \tilde{A}\tilde{\Psi}\rangle \\ &\qquad - i\langle \nabla\tilde{\Psi}^*, A\tilde{\Psi} + \tilde{A}\Psi\rangle + |A|^2\left|\tilde{\Psi}\right|^2 + 2\langle A, \tilde{A}\rangle(\Psi\tilde{\Psi}^* + \Psi^*\tilde{\Psi}) + \left|\tilde{A}\right|^2|\Psi|^2 \bigg\}\,dx \\ &\qquad + \frac{\kappa^2}{4}\int_\Omega \bigg((\Psi\tilde{\Psi}^* + \tilde{\Psi}\Psi^*)^2 - 2(1 - |\Psi|^2)\left|\tilde{\Psi}\right|^2 \bigg)dx \\ &\qquad + \frac{1}{2}\int_{\mathbb{R}^2} \left|\operatorname{curl}\tilde{A}\right|^2\,dx. \end{aligned} \tag{3.1}$$

Throughout this section, we make the gauge choice (2.2).

Our approach hinges on a greatly simplified version of this formula when the second variation is taken about a critical point of the Ginzburg–Landau energy. This simplification will be accomplished in a few steps, the first of which is to reduce the expression to a sum of boundary integrals. As we will always be considering the second variation taken about a critical point (Ψ, A) of G, we will suppress this dependence and write J henceforth as a functional depending only on two arguments, i.e., we will simply write $J(\tilde{\Psi}, \tilde{A})$ rather than $J(\Psi, A, \tilde{\Psi}, \tilde{A})$.

Proposition 3.1. *Let (Ψ, A) be any critical point of G. Then we have*

$$J\left(\frac{\partial\Psi}{\partial x_j}, \frac{\partial A}{\partial x_j}\right) = \frac{1}{4}\int_{\partial\Omega} \frac{\partial}{\partial\nu}\left|\frac{\partial\Psi}{\partial x_j}\right|^2 ds + \frac{1}{2}\int_{\partial\Omega}\left\langle \nu \times \frac{\partial A}{\partial x_j}, \operatorname{curl}\left(\frac{\partial A}{\partial x_j}\right)\right\rangle ds$$
$$+ \frac{i}{4}\int_{\partial\Omega}\left\langle \frac{\partial A}{\partial x_j}, \nu\right\rangle \left(\Psi^*\frac{\partial\Psi}{\partial x_j} - \Psi\frac{\partial\Psi^*}{\partial x_j}\right) ds \quad (j = 1, 2). \tag{3.2}$$

Remark 3.1. In the second integral above, it is understood that $\operatorname{curl}(\frac{\partial A}{\partial x_j})$ denotes the trace from within Ω, which is well defined in light of the regularity theory developed in the previous section. A formula similar to (3.2) holds in three dimensions as well, provided that $\operatorname{curl}(\frac{\partial A}{\partial x_j}) \in L^2(\mathbb{R}^2)$, except that the quantity $\operatorname{curl}(\frac{\partial A}{\partial x_j})$ in the second boundary integral is replaced by the jump in this quantity across $\partial\Omega$.

Proof. Set $(\tilde\Psi, \tilde A) = (\partial\Psi/\partial x_j, \partial A/\partial x_j)$ in the second variation formula (3.1). Then we calculate

$$J(\partial\Psi/\partial x_j, \partial A/\partial x_j) = \frac{1}{2}\int_\Omega \left\{ \left|\nabla\left(\frac{\partial\Psi}{\partial x_j}\right)\right|^2 + i\left\langle \nabla\Psi, \frac{\partial\Psi^*}{\partial x_j}\frac{\partial A}{\partial x_j}\right\rangle \right.$$
$$+ i\left\langle \nabla\frac{\partial\Psi}{\partial x_j}, \frac{\partial\Psi^*}{\partial x_j}A + \Psi^*\frac{\partial A}{\partial x_j}\right\rangle - i\left\langle \nabla\Psi^*, \frac{\partial\Psi}{\partial x_j}\frac{\partial A}{\partial x_j}\right\rangle$$
$$- i\left\langle \nabla\frac{\partial\Psi^*}{\partial x_j}, \frac{\partial\Psi}{\partial x_j}A + \Psi\frac{\partial A}{\partial x_j}\right\rangle + |A|^2\left|\frac{\partial\Psi}{\partial x_j}\right|^2$$
$$\left. + 2\left\langle A, \frac{\partial A}{\partial x_j}\right\rangle\left(\Psi\frac{\partial\Psi^*}{\partial x_j} + \Psi^*\frac{\partial\Psi}{\partial x_j}\right) + |\Psi|^2\left|\frac{\partial A}{\partial x_j}\right|^2 \right\} dx$$
$$+ \frac{\kappa^2}{4}\int_\Omega \left(\left(\Psi\frac{\partial\Psi^*}{\partial x_j} + \Psi^*\frac{\partial\Psi}{\partial x_j}\right)^2 - 2(1 - |\Psi|^2)\left|\frac{\partial\Psi}{\partial x_j}\right|^2\right) dx$$
$$+ \frac{1}{2}\int_\Omega \left|\operatorname{curl}\left(\frac{\partial A}{\partial x_j}\right)\right|^2 dx.$$

Here we have used property (2.11) of Lemma 2.2 to conclude that $\operatorname{curl} A = 0$ in $\mathbb{R}^2\setminus\Omega$. We now denote the integrand above by $I_j(x)$. That is,

$$J\left(\frac{\partial\Psi}{\partial x_j}, \frac{\partial A}{\partial x_j}\right) = \int_\Omega I_j(x)\, dx. \tag{3.3}$$

Throughout this calculation, we shall invoke the regularity result, Proposition 2.1, which provides that both Ψ and A are C^3 up to the boundary. A straightforward calculation on $I_j(x)$ gives

$$I_j(x) = \frac{1}{4}\left(2\left|\nabla\frac{\partial\Psi}{\partial x_j}\right|^2 + i\left\langle \nabla\frac{\partial\Psi}{\partial x_j}, A\right\rangle\frac{\partial\Psi^*}{\partial x_j} - i\left\langle \nabla\frac{\partial\Psi^*}{\partial x_j}, A\right\rangle\frac{\partial\Psi}{\partial x_j} \right.$$
$$+ i\left\langle \nabla\Psi, \frac{\partial A}{\partial x_j}\right\rangle\frac{\partial\Psi^*}{\partial x_j} - i\left\langle \nabla\Psi^*, \frac{\partial A}{\partial x_j}\right\rangle\frac{\partial\Psi}{\partial x_j}$$
$$+ i\operatorname{div}\left(\Psi\frac{\partial A}{\partial x_j} + \frac{\partial\Psi}{\partial x_j}A\right)\frac{\partial\Psi^*}{\partial x_j} - i\operatorname{div}\left(\Psi^*\frac{\partial A}{\partial x_j} + \frac{\partial\Psi^*}{\partial x_j}A\right)\frac{\partial\Psi}{\partial x_j}$$
$$+ 2\left|\frac{\partial\Psi}{\partial x_j}\right|^2|A|^2 + 2\left\langle A, \frac{\partial A}{\partial x_j}\right\rangle\left(\Psi\frac{\partial\Psi^*}{\partial x_j} + \Psi^*\frac{\partial\Psi}{\partial x_j}\right)$$

$$
\begin{aligned}
&+\kappa^2\left(\left(\Psi\frac{\partial\Psi^*}{\partial x_j}+\Psi^*\frac{\partial\Psi}{\partial x_j}\right)^2-2\left(1-|\Psi|^2\right)\left|\frac{\partial\Psi}{\partial x_j}\right|^2\right)\Bigg)\\
&+\frac{1}{2}\left(\left|\operatorname{curl}\left(\frac{\partial A}{\partial x_j}\right)\right|^2+|\Psi|^2\left|\frac{\partial A}{\partial x_j}\right|^2+\left\langle A,\frac{\partial A}{\partial x_j}\right\rangle\left(\Psi\frac{\partial\Psi^*}{\partial x_j}+\Psi^*\frac{\partial\Psi}{\partial x_j}\right)\right.\\
&+\frac{i}{4}\left(\left\langle\nabla\Psi,\frac{\partial A}{\partial x_j}\right\rangle\frac{\partial\Psi^*}{\partial x_j}+\left\langle\nabla\frac{\partial\Psi}{\partial x_j},\frac{\partial A}{\partial x_j}\right\rangle\Psi^*\right.\\
&\left.\left.-\left\langle\nabla\Psi^*,\frac{\partial A}{\partial x_j}\right\rangle\frac{\partial\Psi}{\partial x_j}-\left\langle\nabla\frac{\partial\Psi^*}{\partial x_j},\frac{\partial A}{\partial x_j}\right\rangle\Psi\right)\right)\\
&+\tilde{I}_j(x),
\end{aligned}
\tag{3.4}
$$

where

$$
\begin{aligned}
\tilde{I}_j(x)=\frac{i}{4}&\left(\left\langle\nabla\frac{\partial\Psi}{\partial x_j},\frac{\partial A}{\partial x_j}\right\rangle\Psi^*-\left\langle\nabla\frac{\partial\Psi^*}{\partial x_j},\frac{\partial A}{\partial x_j}\right\rangle\Psi-\left\langle\nabla\Psi,\frac{\partial A}{\partial x_j}\right\rangle\frac{\partial\Psi^*}{\partial x_j}\right.\\
&\left.+\left\langle\nabla\Psi^*,\frac{\partial A}{\partial x_j}\right\rangle\frac{\partial\Psi}{\partial x_j}\right)-\frac{i}{4}\operatorname{div}\left(\frac{\partial A}{\partial x_j}\right)\left(\Psi\frac{\partial\Psi^*}{\partial x_j}-\Psi^*\frac{\partial\Psi}{\partial x_j}\right).
\end{aligned}
$$

The expression $\tilde{I}_j(x)$ is easily simplified to

$$
\tilde{I}_j(x)=-\frac{i}{4}\operatorname{div}\left(\left(\Psi\frac{\partial\Psi^*}{\partial x_j}-\Psi^*\frac{\partial\Psi}{\partial x_j}\right)\frac{\partial A}{\partial x_j}\right).
\tag{3.5}
$$

On the other hand, by differentiating the Ginzburg–Landau system with respect to x_j, we have the following identities:

$$
\begin{aligned}
\Delta\left(\frac{\partial\Psi}{\partial x_j}\right)&-i\left\langle\nabla\left(\frac{\partial\Psi}{\partial x_j}\right),A\right\rangle-i\left\langle\nabla\Psi,\frac{\partial A}{\partial x_j}\right\rangle-i\operatorname{div}\left(\frac{\partial A}{\partial x_j}\Psi+A\frac{\partial\Psi}{\partial x_j}\right)\\
&-2\left\langle A,\frac{\partial A}{\partial x_j}\right\rangle\Psi-|A|^2\frac{\partial\Psi}{\partial x_j}+\kappa^2\left(-\frac{\partial\Psi}{\partial x_j}\Psi^*-\frac{\partial\Psi^*}{\partial x_j}\Psi\right)\Psi\\
&+\kappa^2(1-|\Psi|^2)\frac{\partial\Psi}{\partial x_j}\\
&=0\quad\text{in }\Omega,\\
\operatorname{curl}\operatorname{curl}\left(\frac{\partial A}{\partial x_j}\right)&+|\Psi|^2\frac{\partial A}{\partial x_j}+\left(\frac{\partial\Psi}{\partial x_j}\Psi^*+\Psi\frac{\partial\Psi^*}{\partial x_j}\right)A\\
&+\frac{i}{2}\left(\frac{\partial\Psi^*}{\partial x_j}\nabla\Psi+\Psi^*\nabla\frac{\partial\Psi}{\partial x_j}-\frac{\partial\Psi}{\partial x_j}\nabla\Psi^*-\Psi\nabla\frac{\partial\Psi^*}{\partial x_j}\right)\\
&=0\quad\text{in }\Omega.
\end{aligned}
$$

These lead readily to the relations

$$
\begin{aligned}
-\Delta\left(\frac{\partial\Psi}{\partial x_j}\right)\frac{\partial\Psi^*}{\partial x_j}&-\Delta\left(\frac{\partial\Psi^*}{\partial x_j}\right)\frac{\partial\Psi}{\partial x_j}+i\left\langle\nabla\frac{\partial\Psi}{\partial x_j},A\right\rangle\frac{\partial\Psi^*}{\partial x_j}+i\left\langle\nabla\Psi,\frac{\partial A}{\partial x_j}\right\rangle\frac{\partial\Psi^*}{\partial x_j}\\
&-i\left\langle\nabla\frac{\partial\Psi^*}{\partial x_j},A\right\rangle\frac{\partial\Psi}{\partial x_j}-i\left\langle\nabla\Psi^*,\frac{\partial A}{\partial x_j}\right\rangle\frac{\partial\Psi}{\partial x_j}\\
&+i\operatorname{div}\left(\Psi\frac{\partial A}{\partial x_j}+\frac{\partial\Psi}{\partial x_j}A\right)\frac{\partial\Psi^*}{\partial x_j}-i\operatorname{div}\left(\Psi^*\frac{\partial A}{\partial x_j}+\frac{\partial\Psi^*}{\partial x_j}A\right)\frac{\partial\Psi}{\partial x_j}
\end{aligned}
$$

$$\begin{aligned}
&+2\left|\frac{\partial\Psi}{\partial x_j}\right|^2|A|^2+2\left\langle A,\frac{\partial A}{\partial x_j}\right\rangle\left(\Psi\frac{\partial\Psi^*}{\partial x_j}+\Psi^*\frac{\partial\Psi}{\partial x_j}\right)\\
&+\kappa^2\left(\left(\Psi\frac{\partial\Psi^*}{\partial x_j}+\Psi^*\frac{\partial\Psi}{\partial x_j}\right)^2-2\left(1-|\Psi|^2\right)\left|\frac{\partial\Psi}{\partial x_j}\right|^2\right)\\
&=0\quad\text{in }\Omega,
\end{aligned}\tag{3.6}$$

$$\begin{aligned}
\operatorname{curl}\operatorname{curl}\left(\frac{\partial A}{\partial x_j}\right)\frac{\partial A}{\partial x_j}&+|\Psi|^2\left|\frac{\partial A}{\partial x_j}\right|^2+\left\langle A,\frac{\partial A}{\partial x_j}\right\rangle\left(\Psi\frac{\partial\Psi^*}{\partial x_j}+\Psi^*\frac{\partial\Psi}{\partial x_j}\right)\\
&+\frac{i}{2}\left(\left\langle\nabla\Psi,\frac{\partial A}{\partial x_j}\right\rangle\frac{\partial\Psi^*}{\partial x_j}+\left\langle\nabla\frac{\partial\Psi}{\partial x_j},\frac{\partial A}{\partial x_j}\right\rangle\Psi^*\right.\\
&\qquad\left.-\left\langle\nabla\Psi^*,\frac{\partial A}{\partial x_j}\right\rangle\frac{\partial\Psi}{\partial x_j}-\left\langle\nabla\frac{\partial\Psi^*}{\partial x_j},\frac{\partial A}{\partial x_j}\right\rangle\Psi\right)\\
&=\mathbf{0}\quad\text{in }\Omega.
\end{aligned}\tag{3.7}$$

We shall also need the following identities, which are an immediate consequence of integration by parts:

$$\begin{aligned}
\int_\Omega 2\left|\frac{\partial\Psi}{\partial x_j}\right|^2dx&=\int_{\partial\Omega}\left(\frac{\partial\Psi}{\partial x_j}\frac{\partial}{\partial\nu}\left(\frac{\partial\Psi^*}{\partial x_j}\right)+\frac{\partial\Psi^*}{\partial x_j}\frac{\partial}{\partial\nu}\left(\frac{\partial\Psi^*}{\partial x_j}\right)\right)ds\\
&\quad-\int_\Omega\left(\frac{\partial\Psi}{\partial x_j}\Delta\left(\frac{\partial\Psi^*}{\partial x_j}\right)+\frac{\partial\Psi^*}{\partial x_j}\Delta\left(\frac{\partial\Psi}{\partial x_j}\right)\right)dx\\
&=\int_{\partial\Omega}\frac{\partial}{\partial\nu}\left|\frac{\partial\Psi}{\partial x_j}\right|^2ds-\int_\Omega\left(\frac{\partial\Psi}{\partial x_j}\Delta\left(\frac{\partial\Psi^*}{\partial x_j}\right)+\frac{\partial\Psi^*}{\partial x_j}\Delta\left(\frac{\partial\Psi}{\partial x_j}\right)\right)dx,
\end{aligned}\tag{3.8}$$

$$\begin{aligned}
\int_\Omega\left|\operatorname{curl}\frac{\partial A}{\partial x_j}\right|^2dx&=\int_{\partial\Omega}\left\langle\nu\times\frac{\partial A}{\partial x_j},\operatorname{curl}\left(\frac{\partial A}{\partial x_j}\right)\right\rangle ds\\
&\quad+\int_\Omega\left\langle\frac{\partial A}{\partial x_j},\operatorname{curl}\operatorname{curl}\left(\frac{\partial A}{\partial x_j}\right)\right\rangle dx.
\end{aligned}\tag{3.9}$$

If we use the identities (3.6), (3.7), (3.8), and (3.9) in (3.3) and (3.4), we arrive at a simple expression:

$$J\left(\frac{\partial\Psi}{\partial x_j},\frac{\partial A}{\partial x_j}\right)=\frac{1}{4}\int_{\partial\Omega}\frac{\partial}{\partial\nu}\left|\frac{\partial\Psi}{\partial x_j}\right|^2ds+\frac{1}{2}\int_{\partial\Omega}\left\langle\nu\times\frac{\partial A}{\partial x_j},\operatorname{curl}\left(\frac{\partial A}{\partial x_j}\right)\right\rangle ds+\int_\Omega\tilde{I}_j(x)\,dx.$$

Then applying the divergence theorem to (3.5), we see that the last term of this expression is equal to

$$-\frac{i}{4}\int_{\partial\Omega}\left\langle\frac{\partial A}{\partial x_j},\nu\right\rangle\left(\Psi\frac{\partial\Psi^*}{\partial x_j}-\Psi^*\frac{\partial\Psi}{\partial x_j}\right)ds.$$

This completes the proof of the proposition. □

In the next step, we will invoke the assumption of convexity of $\partial\Omega$ to establish nonpositivity of the second variation.

PROPOSITION 3.2. *Let (Ψ,A) be any critical point of G. Denote $\Gamma_1=\{x\in\partial\Omega:\Psi(x)\neq 0\}$ and $\Gamma_2=\{x\in\partial\Omega:\Psi(x)=0\}$. Also, on Γ_1 write Ψ locally as*

$\Psi(x) = we^{i\phi}$. Then we have

$$\sum_{j=1}^{2} J(\partial\Psi/\partial x_j, \partial A/\partial x_j) = -\frac{1}{2}\int_{\Gamma_1} H\Big\{|\nabla w|^2 + w^2\,|\nabla\phi - A|^2\Big\}\,ds - \frac{1}{2}\int_{\Gamma_2} H\,|\nabla\Psi|^2\,ds, \tag{3.10}$$

where $H = H(x)$ denotes the curvature of $\partial\Omega$. In particular, for a convex domain Ω whereby $H \geq 0$, we have

$$\sum_{j=1}^{2} J(\partial\Psi/\partial x_j, \partial A/\partial x_j) \leq 0. \tag{3.11}$$

Remark 3.2. A similar formula holds in three dimensions as well, but it contains an extra term related to the fact that $\operatorname{curl} A$ does not necessarily vanish outside $\Omega \subset \mathbb{R}^3$.

Proof. We make the gauge choice (2.2). Then taking formula (3.2) of Proposition 3.1 as a starting point, we let $K \equiv \sum_{j=1}^{2}\langle \nu \times \frac{\partial A}{\partial x_j}, \operatorname{curl}(\frac{\partial A}{\partial x_j})\rangle$ and use the conditions $\operatorname{div} \mathrm{A} = 0$ and $\nabla\operatorname{div} \mathrm{A} = 0$ in $\overline{\Omega}$ to calculate

$$\begin{aligned} K &= \left(\nu_1 \frac{\partial A^{(2)}}{\partial x_1} - \nu_2 \frac{\partial A^{(1)}}{\partial x_1}\right)\left(\frac{\partial^2 A^{(2)}}{\partial x_1^2} - \frac{\partial^2 A^{(1)}}{\partial x_1 \partial x_2}\right) \\ &\quad + \left(\nu_1 \frac{\partial A^{(2)}}{\partial x_2} - \nu_2 \frac{\partial A^{(1)}}{\partial x_2}\right)\left(\frac{\partial^2 A^{(2)}}{\partial x_1 \partial x_2} - \frac{\partial^2 A^{(1)}}{\partial x_2^2}\right) \\ &= \left(\nu_1 \frac{\partial A^{(2)}}{\partial x_1} + \nu_2 \frac{\partial A^{(2)}}{\partial x_2}\right)\left(\frac{\partial^2 A^{(2)}}{\partial x_1^2} + \frac{\partial^2 A^{(2)}}{\partial x_2^2}\right) \\ &\quad + \left(-\nu_1 \frac{\partial A^{(1)}}{\partial x_1} - \nu_2 \frac{\partial A^{(1)}}{\partial x_2}\right)\left(-\frac{\partial^2 A^{(1)}}{\partial x_1^2} - \frac{\partial^2 A^{(1)}}{\partial x_2^2}\right). \end{aligned}$$

Hence, we get

$$K = \sum_{\ell=1}^{2} \frac{\partial A^{(\ell)}}{\partial \nu}\Delta A^{(\ell)}.$$

On the other hand, our gauge choice also simplifies the Ginzburg–Landau equation (2.5) to read

$$\Delta A = |\Psi|^2 A + \frac{i}{2}(\Psi^*\nabla\Psi - \Psi\nabla\Psi^*) \quad \text{in } \Omega,$$

and substituting this into K, we get

$$K = \sum_{\ell=1}^{2} \frac{\partial A^{(\ell)}}{\partial \nu}\left(|\Psi|^2 A^{(\ell)} + \frac{i}{2}\left(\Psi^*\frac{\partial\Psi}{\partial x_\ell} - \Psi\frac{\partial\Psi^*}{\partial x_\ell}\right)\right) \quad \text{on } \partial\Omega.$$

Then from Proposition 3.1 we get

$$\begin{aligned} \sum_{j=1}^{2} J\left(\frac{\partial\Psi}{\partial x_j}, \frac{\partial A}{\partial x_j}\right) &= \frac{1}{4}\int_{\partial\Omega} \frac{\partial}{\partial\nu}|\nabla\Psi|^2\,ds + \frac{1}{4}\int_{\partial\Omega}|\Psi|^2\frac{\partial}{\partial\nu}|A|^2\,ds \\ &\quad + \frac{i}{4}\int_{\partial\Omega}\sum_{j=1}^{2}\left(\frac{\partial A^{(j)}}{\partial\nu} + \left\langle\frac{\partial A}{\partial x_j}, \nu\right\rangle\right)\left(\Psi^*\frac{\partial\Psi}{\partial x_j} - \Psi\frac{\partial\Psi^*}{\partial x_j}\right)ds. \end{aligned} \tag{3.12}$$

Now define

$$F(x) = \frac{\partial}{\partial \nu}|\nabla\Psi|^2 + |\Psi|^2\frac{\partial}{\partial \nu}|A|^2 + i\sum_{j=1}^{2}\left(\frac{\partial A^{(j)}}{\partial \nu} + \left\langle \frac{\partial A}{\partial x_j}, \nu\right\rangle\right)\left(\Psi^*\frac{\partial \Psi}{\partial x_j} - \Psi\frac{\partial \Psi^*}{\partial x_j}\right)$$

on $\partial\Omega$. By using the condition $\operatorname{curl} A = 0$ on $\partial\Omega$, we have

$$\frac{\partial A^{(j)}}{\partial \nu} = \frac{\partial A^{(j)}}{\partial x_\ell}\nu^{(\ell)} = \frac{\partial A^{(\ell)}}{\partial x_j}\nu^{(\ell)} = \left\langle \frac{\partial A}{\partial x_j}, \nu\right\rangle.$$

Hence F can also be written as

$$F(x) = \frac{\partial}{\partial \nu}|\nabla\Psi|^2 + |\Psi|^2\frac{\partial}{\partial \nu}|A|^2 + 2i\sum_{j=1}^{2}\left\langle \frac{\partial A}{\partial x_j}, \nu\right\rangle\left(\Psi^*\frac{\partial \Psi}{\partial x_j} - \Psi\frac{\partial \Psi^*}{\partial x_j}\right). \tag{3.13}$$

We calculate $F(x)$ separately on Γ_1 and Γ_2, where

$$\text{(i)}\quad \Gamma_1 = \{x \in \partial\Omega \mid \Psi(x) \neq 0\},$$
$$\text{(ii)}\quad \Gamma_2 = \{x \in \partial\Omega \mid \Psi(x) = 0\}.$$

First consider any point $x_0 \in \Gamma_1$ and consider a small contractible neighborhood V of x_0 so that Ψ does not vanish in $V \cap \Omega$. In this situation we can write $\Psi(x)$ in the form $\Psi(x) = w(x)e^{i\,\phi(x)}$ and we see that

(3.14)
$$|\nabla\Psi|^2 = |\nabla w(x)|^2 + w(x)^2|\nabla\phi|^2, \quad \Psi^*\frac{\partial \Psi}{\partial x_j} - \Psi\frac{\partial \Psi^*}{\partial x_j} = 2iw(x)^2\frac{\partial \phi}{\partial x_j} \quad \text{in} \quad V \cap \Omega.$$

We also note that ϕ and w satisfy the Neumann boundary condition on $\Gamma_1 \cap V$ and we recall that $A \cdot \nu = 0$ on $\partial\Omega$ as well. Hence, we find

$$0 = \nabla(A\cdot\nu)\cdot\nabla\phi = \frac{\partial A^{(k)}}{\partial x_j}\nu^{(k)}\frac{\partial \phi}{\partial x_j} + A^{(k)}\frac{\partial \nu^{(k)}}{\partial x_j}\frac{\partial \phi}{\partial x_j}. \tag{3.15}$$

In order to evaluate the expression $F(x_0)$ we assume, without loss of generality, that $\nu(x_0) = (0, 1)$. In particular, this implies that

$$\frac{\partial w}{\partial x_2}(x_0) = \frac{\partial \phi}{\partial x_2}(x_0) = A^{(2)}(x_0) = 0 \text{ and that } \frac{\partial \nu^{(1)}}{\partial x_1}(x_0) = H. \tag{3.16}$$

Then, by Lemma 2.3, (3.14), (3.15), and (3.16), we get

$$\begin{aligned}
F(x_0) &= \frac{\partial}{\partial \nu}(|\nabla w|^2 + w^2|\nabla\phi|^2) + w^2\frac{\partial}{\partial \nu}|A|^2 - 4w^2\sum_{j=1}^{2}\frac{\partial \phi}{\partial x_j}\left\langle \frac{\partial A}{\partial x_j}, \nu\right\rangle \\
&= -2\frac{\partial \nu^{(k)}}{\partial x_j}\frac{\partial w}{\partial x_k}\frac{\partial w}{\partial x_j} - 2w^2\frac{\partial \nu^{(k)}}{x_j}\left(\frac{\partial \phi}{\partial x_k}\frac{\partial \phi}{\partial x_j} + A^{(k)}A^{(j)} - 2A^{(k)}\frac{\partial \phi}{\partial x_j}\right) \\
&= -2\frac{\partial \nu^{(1)}}{\partial x_1}\left(\left(\frac{\partial w}{\partial x_1}\right)^2 + w^2\left(\frac{\partial \phi}{\partial x_1} - A^{(1)}\right)^2\right) \\
&= -2H(|\nabla w|^2 + w^2\,|\nabla\phi - A|^2) \quad \text{in } V \cap \Gamma_1.
\end{aligned} \tag{3.17}$$

Now consider $x_0 \in \Gamma_2$ where then $\Psi(x_0) = 0$. From Lemma 2.3 and (3.13) we get

$$\begin{aligned} F(x_0) &= \frac{\partial}{\partial\nu}|\nabla\Psi|^2 = \frac{\partial}{\partial\nu}|\nabla(\mathrm{Re}\Psi)|^2 + \frac{\partial}{\partial\nu}|\nabla(\mathrm{Im}\Psi)|^2 \\ &= -2H\,|\nabla(\mathrm{Re}\Psi)|^2 - 2H\,|\nabla(\mathrm{Im}\Psi)|^2 = -2H\,|\nabla\Psi|^2 \quad \text{on } \Gamma_2. \end{aligned} \tag{3.18}$$

The formula (3.10) follows from the substitution of (3.17) and (3.18) into (3.12). □

We now restate and prove our main result.

THEOREM 3.3. *Let $\Omega \subset \mathbb{R}^2$ be a bounded, open, convex set with $\partial\Omega \in C^{5,\alpha}$ for some $\alpha \in (0,1)$. Then the only critical point (Ψ, A) of the Ginzburg–Landau energy G for which the second variation J is nonnegative is the trivial one $(1,0)$ and its gauge-equivalent representations.*

Proof. We fix the gauge choice (2.2) and let (Ψ, A) be any critical point for which the second variation is nonnegative. Then in light of Proposition 3.2, we can conclude that

$$J(\partial\Psi/\partial x_j, \partial A/\partial x_j) = 0 \quad \text{for } j = 1,2, \tag{3.19}$$

so that in fact $(\partial\Psi/\partial x_j, \partial A/\partial x_j)$ is a minimizer of the second variation (3.1) for both $j = 1$ and $j = 2$. In particular, this implies that $(\partial\Psi/\partial x_j, \partial A/\partial x_j)$ satisfies the natural boundary conditions associated with critical points of (3.1), namely,

$$\left(\nabla\left(\frac{\partial\Psi}{\partial x_j}\right) - i\Psi\frac{\partial A}{\partial x_j}\right)\cdot\nu = 0 \quad \text{on } \partial\Omega \text{ for } j = 1,2. \tag{3.20}$$

Let us denote by Γ_3 the nonempty, relatively open subset of $\partial\Omega$ given by

$$\Gamma_3 = \{x \in \partial\Omega : H(x) > 0\}.$$

It follows from (3.10) and (3.19) that

$$\nabla\Psi(x) - iA\Psi(x) = 0 \quad \text{for } x \in \Gamma_3. \tag{3.21}$$

Now let us decompose Γ_3 into a union $\Gamma_4 \cup \Gamma_5$ where

$$\Gamma_4 = \Gamma_3 \cap \{x \in \partial\Omega : \Psi \neq 0\} \quad \text{and} \quad \Gamma_5 = \Gamma_3 \cap \{x \in \partial\Omega : \Psi = 0\}.$$

We first pursue the possibility that $\Gamma_4 \neq \emptyset$ and consider a point $x_0 \in \Gamma_4$. For some $\varepsilon > 0$ we may express Ψ in $\overline{\Omega} \cap B(x_0, \varepsilon)$ as $\Psi = we^{i\phi}$ and from (2.10) and (3.21) it follows that $w \equiv c$ on $\partial\Omega \cap B(x_0,\varepsilon)$ for some $c \in (0,1]$.

From (3.20) one concludes that

$$\frac{\partial^2 w}{\partial x_j \partial x_k}\nu^{(k)} = 0 \quad \text{on } \partial\Omega \cap B(x_0,\varepsilon) \text{ for } j = 1,2, \tag{3.22}$$

while from tangential differentiation of (3.21) one finds that

$$\frac{\partial^2 w}{\partial x_j \partial x_k}\tau^{(k)} = 0 \quad \text{on } \partial\Omega \cap B(x_0,\varepsilon) \text{ for } j = 1,2, \tag{3.23}$$

where we have let τ denote the unit tangent vector to $\partial\Omega$ so that $(\tau^{(1)}, \tau^{(2)}) = (-\nu^{(2)}, \nu^{(1)})$. Together, (3.22) and (3.23) imply that all second partials of w vanish on $\partial\Omega \cap B(x_0, \varepsilon)$.

Now on the set $\Omega \cap B(x_0, \varepsilon)$ one finds from (2.4) and (2.6) that

$$\Delta w - |\nabla\phi - A|^2 w + \kappa^2 w(1 - w^2) = 0 \quad \text{in } \Omega \cap B(x_0, \varepsilon), \tag{3.24}$$

$$\partial w/\partial\nu = 0 \quad \text{on } \partial\Omega \cap B(x_0, \varepsilon). \tag{3.25}$$

It then follows immediately from (3.21), (3.24), and the fact that Ψ is C^2 up to the boundary that $w \equiv 1$ on $\Gamma_4 \cap B(x_0, \varepsilon)$. Viewing (3.24) as an elliptic equation of the form

$$\Delta(1 - w) + q(x)(1 - w) \leq 0 \quad \text{in } B(x_0, \varepsilon) \cap \Omega$$

with $q(x) = -\kappa^2 w(1+w)$ one can apply the strong maximum principle to the nonnegative function $1 - w$ to conclude that either $w \equiv 1$ in $B(x_0, \varepsilon) \cap \Omega$ or else $1 - w > 0$ in $B(x_0, \varepsilon) \cap \Omega$. The latter possibility is then eliminated using the Hopf maximum principle, in light of the boundary condition (3.25) (cf. [4, Lemma 3.4 and Theorem 3.5]). Hence, $w \equiv 1$ in $B(x_0, \varepsilon) \cap \overline{\Omega}$ and by (3.24) it follows that $|\nabla\phi - A| \equiv 0$ on this set as well. By continuation we can then extend these relations throughout Ω because it is simply connected. Thus, $(\Psi, A) = (e^{i\phi}, \nabla\phi)$ throughout Ω for some real-valued function ϕ, which is our desired conclusion.

Finally, we consider the possibility that $\Gamma_4 = \emptyset$. Then $\Gamma_5 = \Gamma_3$. Writing $\Psi = u + iv$, we find that the real functions u and v satisfy the system

$$\begin{aligned} &\Delta u + 2A \cdot \nabla v - |A|^2 u + \kappa^2(1 - (u^2 + v^2))u = 0, \\ &\Delta v - 2A \cdot \nabla u - |A|^2 v + \kappa^2(1 - (u^2 + v^2))v = 0. \end{aligned} \tag{3.26}$$

Furthermore, fixing $x_0 \in \Gamma_5$ and a sufficiently small $\varepsilon > 0$ one finds that u and v satisfy the boundary conditions

$$u = v = \nabla u \cdot \nu = \nabla v \cdot \nu = 0 \quad \text{on } \partial\Omega \cap B(x_0, \varepsilon).$$

Invoking Calderón's uniqueness theorem (cf. [1]), we conclude that $u = v = 0$ in a neighborhood of x_0. Again, in light of the simple-connectivity of Ω, we conclude that $u = v = 0$ throughout Ω. Turning to (2.5), we conclude that $\operatorname{curl}\operatorname{curl} A = 0$ throughout $\mathbb{R}^2$. As in Lemma 2.2, we find that $\operatorname{curl} A = 0$ in $\mathbb{R}^2$ and so $A = \nabla\eta$ for some function $\eta : \mathbb{R}^2 \to \mathbb{R}^1$. Hence (Ψ, A) is gauge-equivalent to $(0, 0)$. But $(0, 0)$ is clearly unstable in view of (3.1) since

$$J(0, 0; 1, 0) = -\frac{\kappa^2}{2} |\Omega|.$$

Thus, the only possibility for a stable critical point in a convex domain is that (Ψ, A) is gauge-equivalent to $(1, 0)$. □

Remark 3.3. We suspect that the same nonexistence result holds in three-dimensional convex domains and we are presently investigating this possibility. See Remark (3.2).

SCATTERED DATA INTERPOLATION ON SPHERES: ERROR ESTIMATES AND LOCALLY SUPPORTED BASIS FUNCTIONS[*]

FRANCIS J. NARCOWICH[†] AND JOSEPH D. WARD[†]

Abstract. Error estimates for scattered data interpolation by "shifts" of a positive definite function for target functions in the associated reproducing kernel Hilbert space (RKHS) have been known for a long time. However, apart from special cases where data is gridded, these estimates do not apply when the target functions generating the data are outside of the associated RKHS, and in fact no estimates were known for such target functions. In this paper, working with the n-sphere as the underlying manifold, we obtain Sobolev-type error estimates for interpolating functions $f \in C^{2k}(S^n)$ from "shifts" of a smoother positive definite function ϕ defined on S^n. Moreover, the estimates are close to the optimal approximation order. We also introduce a class of locally supported positive definite functions on S^n, functions based on Wendland's compactly supported radial basis functions (RBFs) [H. Wendland, *Adv. Comput. Math.*, 4 (1995), pp. 389–396], which can be both explicitly and easily computed and also analyzed for convergence properties.

Key words. interpolation on spheres, error estimates, rates of convergence, locally supported basis functions, scattered data

1. Introduction.

The problem of effectively representing an underlying function based on its sampled values is both old and important. One way to do this is to interpolate the data from a class of functions. The success of this approach is based on many criteria including the cost of producing the interpolant, the robustness of the interpolation process, and how well the interpolant approximates the underlying function. These are the issues we deal with in this paper when the domain of the underlying function is S^n.

Radial basis functions (RBFs) have proven to be a powerful tool for analyzing scattered data on R^n. More recently, spherical basis functions (SBFs), which are analogs of RBFs on the n-sphere, and periodic basis functions (PBFs), which are analogs of RBFs on the n-torus, have had comparable success for analyzing scattered data on these manifolds. In all cases, interpolants by "shifts" of an RBF, SBF, or PBF are constructed from sampling a function f at scattered sites. If f belongs to a certain reproducing kernel Hilbert space (RKHS) associated with ϕ, N_ϕ, the *native space* of ϕ, then these interpolants will converge to f. However, if ϕ is smooth, the RKHS N_ϕ is small in the sense that it is composed of very smooth functions. Up to

now, any error analysis involving scattered data has thus been limited to such smooth functions.

One of the purposes of this paper is to remove in the case of S^n the "native space barrier" for a very large class of SBFs. When an SBF ϕ has Legendre coefficients that are comparable to reciprocals of Sobolev weights of some order τ, we obtain, in section 3, interpolation errors for functions lying outside the native space: Suppose that $f \in C^{2k}(S^n)$ is sampled on a finite number of distinct points comprising a set $X \subset S^n$. If any point in S^n is at most a distance h from X and if the distance between points in X is comparable to h, then the interpolant $I_X f$ satisfies

$$\|f - I_X f\| \leq \text{const} \cdot h^{2k-n/2} \|\Delta^k f\|$$

for $\tau \geq 2k > \frac{n}{2}$, where here and elsewhere in this paper $\|\cdot\| := \|\cdot\|_{C(S^n)}$. (See Theorem 3.2 for the precise statement.) The key to this approach is a result on simultaneous approximation and interpolation by spherical harmonics; this and the estimates themselves are discussed in section 3. We also make the point that for the class N_ϕ, $h^{\tau-n/2}$ is optimal. In this respect, our results resemble ones that hold for splines.

While our results do not yet apply to the R^n case, it seems very likely that a variant of this approach should be applicable there as well. The authors are currently working in this direction. In this connection, we mention a paper of Yoon [27], which was pointed out to us by one of the referees. There, Yoon investigates error estimates in R^n for a special class of radial functions, namely thin-plate splines that depend on a parameter λ. His focus is different from ours. He works on cases in which the parameter λ is required to depend on the spacing of the data. In effect, the radial function is changing with the data.

Another purpose of this paper is to introduce a class of locally supported SBFs that can be both explicitly computed and analyzed. It is easy to produce a large class of SBFs on S^n that are explicit (thus easy to evaluate) by restricting a given RBF on R^{n+1} to S^n by means of

$$\phi(x \cdot y) = \Phi(\|x - y\|_2)|_{x,y \in S^n}.$$

On the other hand, the basic tools for analyzing rates of convergence of interpolants and stability of interpolation matrices are all based on the rates of decay of the Legendre coefficients for $\phi(x \cdot y) = \phi(\cos\theta)$. It is easy to construct SBFs that are defined by their Legendre series and that satisfy various decay rates; unfortunately, working with functions defined via series greatly reduces their utility. The problem up to now has been the linkage between the Fourier transform of Φ and the Legendre series of ϕ.

In this paper, we provide such a linkage and then use it to obtain from Wendland's compactly supported RBFs [24, 25] a large class of explicit, locally supported SBFs on S^n whose Legendre series decay asymptotically at a prescribed algebraic rate. Moreover, these SBFs precisely meet the conditions required for the error estimates described above to hold. We do this in section 4.

In section 2 we discuss the relevant background material on SBFs and the various approximation results needed in the paper.

2. Background material.

2.1. The interpolation problem. Let $X := \{x_1, \ldots, x_N\}$ be a discrete set of distinct points on the n-sphere S^n. These will be the data sites for our interpolation problem. The *mesh norm* for X is

$$h_X = \sup_{y \in S^n} \inf_{x_j \in X} d(x_j, y),$$

where $d(x, y)$ is the geodesic (great circle) distance between the points x and y on S^n. The mesh norm measures the maximum distance any point on S^n can be from X. The *separation radius* is defined via

$$q_X = \frac{1}{2} \min_{j \neq k} d(x_j, x_k) \, .$$

This is half of the smallest geodesic distance between any two distinct points in X. It is easy to see that $h_X \geq q_X$; equality can hold only for a uniform distribution of points on S^1, the circle. The *mesh ratio*

$$\rho_X := h_X / q_X \geq 1$$

provides a measure of how uniformly points in X are distributed on S^n. In the case of the circle ($n = 1$), $\rho_X = 1$ means that the points are uniformly distributed. In all other cases, $\rho_X > 1$.

A continuous function $\phi : [-1, 1] \to R$ is said to be *positive definite* on S^n if the matrix $A_{j,k} := \phi(\cos(d(x_j, x_k)))$, x_j and x_k in X, is positive semidefinite for every possible finite set X of distinct points in S^n. It is said to be *strictly positive definite* on S^n if these matrices are all positive definite. Since $d(x, y)$ is the smaller of the angles between x and y on the great circle passing through these points, and since we may regard S^n as being embedded in R^{n+1} in the usual way, we have that $\cos(d(x, y)) = x \cdot y$, where $x \cdot y$ is the Euclidean inner product in R^{n+1} and ϕ induces a kernel $\phi(x \cdot y)$ that is in $C(S^n \times S^n)$. It follows that when ϕ is strictly positive definite, one can always solve this interpolation problem: Given the values $f(x_j)$, $j = 1, \ldots, N$, from sampling a continuous function on X, find coefficients $c_1, \ldots, c_N$ such that

$$I_X f(x) = \sum_k c_j \phi(x \cdot x_k)$$

agrees with f at the x_j's. This is so because the interpolation matrix $A_{j,k}$, being positive definite, is invertible.

Positive definite functions on spheres were introduced and characterized long ago by Schoenberg [22]. He showed that a function ϕ was positive definite if its expansion in Legendre polynomials in $n + 1$ variables,

$$\phi(x \cdot y) = \sum_{\ell=0}^{\infty} a_\ell P_\ell(n + 1, x \cdot y), \tag{2.1}$$

had all $a_\ell \geq 0$. We mention that Schoenberg actually used ultraspherical polynomials, which are proportional to the Legendre polynomials used here. The exact relation is [15, p. 33]

$$C_\ell^{\frac{n-1}{2}}(t) = \frac{\Gamma(\ell + n - 1)}{\Gamma(n - 1)\Gamma(\ell + 1)} P_\ell(n + 1; t) \, . \tag{2.2}$$

One can show that if $a_\ell > 0$ for all ℓ, then ϕ is strictly positive definite; see Xu and Cheney [26] and Ron and Sun [21]. When this holds for ϕ, we will call it an SBF. We remark that several recent review articles [1, 5, 12, 17] have dealt with such functions, and we refer the reader to them for further information.

2.2. Spherical harmonics, Sobolev spaces, and native spaces. The standard orthonormal basis of $L^2(S^n)$ is composed of spherical harmonics. Some basic facts will be described here, but we refer the reader to Müller's book [15] for further details. A spherical harmonic of order ℓ on S^n is the restriction to S^n of a homogeneous, harmonic polynomial in R^{n+1} of degree ℓ. We denote the space of spherical harmonics of order ℓ on S^n by V_ℓ and the dimension of V_ℓ by $N(n,\ell)$; this is given by [15, p. 4] as

$$N(n,0)=1 \quad \text{and} \quad N(n,\ell)=\frac{(2\ell+n-1)\Gamma(\ell+n-1)}{\Gamma(\ell+1)\Gamma(n)} \quad \text{for} \quad \ell\geq 1\,. \tag{2.3}$$

The space of spherical harmonics of order L or less will be denoted by $\mathcal{P}_L := \sum_{\ell=0}^{L} V_\ell$; it has dimension $\widetilde{N}(n,\ell)=N(n+1,\ell)$.

The space V_ℓ also has an intrinsic characterization; it is the eigenspace of the Laplace–Beltrami operator Δ on S^n corresponding to the eigenvalue ($\Delta Y_\ell+\lambda_\ell Y_\ell=0$)

$$\lambda_\ell=\ell(\ell+n-1), \quad \ell\geq 0.$$

Since Δ is a self-adjoint operator relative to the standard inner product,

$$\langle f,g\rangle=\int_{S^n} f(p)\overline{g(p)}d\sigma\,,$$

with $d\sigma$ being the volume element of S^n, the eigenspaces V_ℓ and $V_{\ell'}$, $\ell\neq\ell'$, are orthogonal relative to $\langle\cdot\,,\cdot\rangle$. As usual, one may choose an orthonormal basis for each V_ℓ, $\{Y_{\ell,m}\}_{m=1}^{N(n,\ell)}$. The collection of all the $Y_{\ell,m}$'s form an orthonormal basis for $L^2(S^n)$. Hence, for any function $f\in L^2(S^n)$, its associated (Fourier) series below converges in $L^2(S^n)$:

$$f=\sum_{\ell=0}^{\infty}\sum_{m=1}^{N(n,\ell)}\hat{f}_{\ell,m}Y_{\ell,m}\,, \quad \text{where } \hat{f}_{\ell,m}=\langle f,Y_{\ell,m}\rangle. \tag{2.4}$$

Such expansions (as in the case of periodic functions) can also be defined in a wider sense, namely for distributions on the sphere. Since S^n is compact, these distributions are the series (2.4) with tempered (i.e., polynomially bounded) coefficients. The Sobolev space $H_s(S^n)$ with real parameter s consists of all distributions f such that

$$\|f\|_{H_s}^2:=\sum_{\ell=0}^{\infty}\sum_{m=1}^{N(n,\ell)}(1+\lambda_\ell)^s|\hat{f}_{\ell,m}|^2=\|(I-\Delta)^{s/2}f\|_{L^2}^2<\infty. \tag{2.5}$$

See [10, section 1.7] and [6, Chapter II]. For later use, we define a related norm on functions in $C^{2k}(S^n)$; namely,

$$\|f\|_{2k}:=\max\{\|f\|,\|\Delta^k f\|\}, \quad f\in C^{2k}(S^n). \tag{2.6}$$

When $k=0$ this reduces to $\|f\|=\|f\|_{C(S^n)}$. In addition, we have

$$\|f\|_{H_{2k}}\leq 2^k\omega_n^{1/2}\|f\|_{2k}\,, \quad f\in C^{2k}(S^n), \tag{2.7}$$

where ω_n is the volume of S^n. This is easily established from $(1+\lambda_\ell)^{2k}\leq 1+(2^{2k}-1)\lambda_\ell^{2k}$ and that for all $g\in C(S^n)$ we have $\|g\|_{L^2}\leq\omega_n^{1/2}\|g\|$.

Let us now return to the expansion for ϕ given in (2.1). The famous addition theorem for spherical harmonics [15, Theorem 2] states that

$$P_\ell(n+1; x\cdot y) = \frac{\omega_n}{N(n,\ell)} \sum_{m=1}^{N(n,\ell)} Y_{\ell,m}(x)\overline{Y_{\ell,m}(y)}. \tag{2.8}$$

Using this in (2.1), we obtain the expansion

$$\phi(x\cdot y) = \sum_{\ell=0}^{\infty}\sum_{m=1}^{N(n,\ell)} \hat\phi(\ell) Y_{\ell,m}(x)\overline{Y_{\ell,m}(y)}, \quad \text{where } \hat\phi(\ell) := \frac{\omega_n}{N(n,\ell)} a_\ell\,. \tag{2.9}$$

Assume that ϕ is an SBF; i.e., $\hat\phi(\ell) > 0$ for all ℓ. One can now define the native space of ϕ to be

$$N_\phi := \left\{ f \in D'(S^n) \colon \ \|f\|_\Phi^2 = \sum_{\ell,k} |\hat f_{\ell,k}|^2/\hat\phi(\ell) < \infty \right\}. \tag{2.10}$$

As we noted in the introduction, if ϕ is smooth, then $\hat\phi(\ell)$ will decay rapidly and $1/\hat\phi(\ell)$ will grow. This means that functions in N_ϕ must have Fourier coefficients that decay rapidly for the sum in (2.10) to remain finite. This decay translates into smoothness for $f \in N_\phi$.

For such kernels, we have the following error estimates, which were established in [9] with improvements in [14] and [18].

Proposition 2.1. *Let X be any point set on S^n with mesh norm h_X, and let ϕ be an SBF, as in (2.9). If for some $\tau > \frac{n}{2}$ we have $\hat\phi(\ell) \le c(1+\lambda_\ell)^{-\tau}$ as $\ell \to \infty$, then for all $f \in N_\phi$ there is a constant C that is independent of X and f for which*

$$\|f - I_X f\| \le C h_X^{\tau - n/2} \|f\|_\phi.$$

Remark. The condition $\hat\phi(\ell) \le c(1+\lambda_\ell)^{-\tau}$ implies that $c/\hat\phi(\ell) \ge (1+\lambda_\ell)^\tau$, from which it immediately follows that $\|f\|_{H_\tau} \le c\|f\|_\phi$, so $N_\phi \subseteq H_\tau$. Conversely, if $\hat\phi(\ell) \ge c'(1+\lambda_\ell)^{-\tau'}$, with $\tau' \ge \tau$, then $\|f\|_{H_{\tau'}} \ge c'\|f\|_\phi$ and $N_\phi \supseteq H_{\tau'}$. In particular, if $\hat\phi(\ell) \sim (1+\lambda_\ell)^{-\tau}$, then $N_\phi = H_\tau$, and $\|\cdot\|_{H_\tau}$ and $\|\cdot\|_\phi$ are equivalent norms.

2.3. Approximation theorems. We will now collect several results concerning approximation of functions on S^n by spherical harmonics in $\mathcal{P}_L$, which are those of order L or less. These results were obtained by Pawelke [19, 20], who used two ideas from earlier works to obtain approximation results that we need here.

The first is the spherical mean of a function on S^n. The boundary of a spherical cap of radius $\arccos(h) < \pi$ and center x is the set $\{y \in S^n : x\cdot y = \cos(h)$, equivalently, $d(x,y) = \arccos(h)\}$, which is an $n-1$ dimensional sphere of radius $\sin h$. If $f \in C(S^n)$, then we define the spherical mean of f over $x\cdot y = \cos h$ to be

$$T_h f(x) := \frac{1}{\omega_{n-1}\sin^{n-1} h} \int_{x\cdot y = \cos h} f(y)\, d\sigma_x(y), \tag{2.11}$$

where $d\sigma_x$ is the volume element corresponding to $x\cdot y = \cos(\eta)$. Löfström and Peetre [11], in a study of approximation properties of orthogonal expansions, introduced similar operators.

The second is a spherical version of the modulus of continuity,

$$\omega(f,\varepsilon) := \sup_{0<h\leq\varepsilon} \|T_h f - f\|, \quad f \in C(S^n),\ \varepsilon > 0, \tag{2.12}$$

which is used below in estimating distance relative to $C(S^n)$ and in the proof in [20] for the Jackson inequality that follows it.

Theorem 2.2 (see [19, Satz 5.1] and [20, Satz 3.3]). *If $f \in C(S^n)$, then for $L = 1, 2, \ldots$ there is a constant M independent of both f and L for which*

$$\operatorname{dist}(f, \mathcal{P}_L) \leq M\omega(f; 1/L), \tag{2.13}$$

and for which

$$\operatorname{dist}(f, \mathcal{P}_L) \leq M^k L^{-2k} \|\Delta^k f\|, \quad k = 1, 2, \ldots,\ f \in C^{2k}(S^n). \tag{2.14}$$

In addition to the theorem above, we also need this Markov–Bernstein inequality.

Theorem 2.3 (see [20, Satz 3.6]). *If $P_L \in \mathcal{P}_L$, then*

$$\|\Delta P_L\| \leq D_n L^2 \|P_L\|\,,$$

where the constant D_n depends only on the dimension of the sphere S^n.

The remaining approximation results that we will make use of here have to do with the norm of iterates of Δ applied to best, and near-best, approximants from $\mathcal{P}_L$.

Proposition 2.4 (see [20, Satz 4.4]). *Let $f \in C^{2k}(S^n)$ and let P_L^* be a best approximant for f in $C(S^n)$; i.e., $\|f - P_L^*\| = \operatorname{dist}_\infty(f, \mathcal{P}_L)$. Then there exists a constant C independent of f and L for which*

$$\|\Delta^k P_L^*\| \leq C\|\Delta^k f\|.$$

Remark. Pawelke states his result in a weaker form. However, after observing that his sequence of operators $\{L_n\}$ commute with both Δ and the operators T_h and inspecting his proof, one obtains the result above.

There is an immediate, useful corollary to this proposition. In essence, it says that the theorem above applies to "near-best" approximants as well as the P_L^*.

Corollary 2.5. *Let $f \in C^{2k}(S^n)$ and let $P_L \in \mathcal{P}_L$, $L = 1, 2, \ldots,$ be a sequence of polynomials satisfying $\|f - P_L\| \leq K\operatorname{dist}(f, \mathcal{P}_L)$, with K independent of f and L. Then there is a constant R that is independent of f and L for which*

$$\|\Delta^k P_L\| \leq R\|\Delta^k f\|.$$

Proof. Observe that $\|\Delta^k P_L\| \leq \|\Delta^k(P_L - P_L^*)\| + \|\Delta^k P_L^*\|$. By iterating the Markov–Bernstein inequality in Theorem 2.3, we can bound the first term by the quantity $D_n^k L^{2k}\|P_L - P_L^*\|$. Moreover, since $\|P_L - P_L^*\| \leq \|P_L - f\| + \|f - P_L^*\|$, we have

$$\|\Delta^k(P_L - P_L^*)\| \leq D_n^k L^{2k}(1+K)\operatorname{dist}(f, \mathcal{P}_L)\,.$$

Applying the Jackson inequality (2.14) to the right side above, we arrive at the bound

$$\|\Delta^k(P_L - P_L^*)\| \leq D_n^k L^{2k}(1+K)M^k L^{-2k}\|\Delta^k f\| = (1+K)(MD_n)^k\|\Delta^k f\|.$$

By Proposition 2.4, we also have the inequality $\|\Delta^k P_L^*\| \leq C\|\Delta^k f\|$. It follows that

$$\|\Delta^k P_L\| \leq R\|\Delta^k f\|,$$

where $R = (1+K)(MD_n)^k + C$. □

3. Analysis of error in approximating by interpolants.

3.1. Error estimates. In this section, we derive error estimates for approximating a given function $f \in C^{2k}(S^n)$ by interpolants of the form

$$I_X f(x) := \sum_{x_j \in X} a_j \phi(x \cdot x_j)\,, \tag{3.1}$$

where ϕ is an SBF that satisfies $\hat{\phi}(\ell) \sim (1+\lambda_\ell)^{-\tau}$. As we noted at the end of section 2.2, this condition implies that $N_\phi = H_\tau$, with the norms being equivalent. Such estimates are already available in case $C^{2k}(S^n) \subset N_\phi$ or, what is equivalent here, $2k \geq \tau$; see [4, 7, 9]. Thus the primary cases of interest occur when $\tau > 2k$, so that $f \notin N_\phi$. Our main estimate addresses these cases. To prove it, we require constructing for every f in $C(S^n)$ spherical harmonics that both are near-best approximants to f from $\mathcal{P}_L$ and simultaneously interpolate f on the point set X. Precisely, we require this result.

THEOREM 3.1. *Let $X \subset S^n$ be a finite set of distinct points and let $\beta > 1$. If $L = \lceil \frac{(\beta+1)M}{(\beta-1)q_X} \rceil$, where M is as in Theorem 2.2, then for $f \in C(S^n)$ there exists a spherical harmonic $P_L \in \mathcal{P}_L$ that interpolates f on X and that satisfies*

$$\|f - P_L\| \leq (1+\beta)\,\mathrm{dist}(f, \mathcal{P}_L).$$

We will give the proof of Theorem 3.1 in section 3.2 below. We now state and prove our main estimate.

THEOREM 3.2. *Let ϕ be an SBF satisfying $\hat{\phi}(\ell) \sim (1+\lambda_\ell)^{-\tau}$ (equivalently, $N_\phi = H_\tau$), and suppose that $\tau \geq 2k > n/2$. If $f \in C^{2k}(S^n)$ and if $I_X f$ is given in* (3.1)*, then*

$$\|f - I_X f\| \leq C \rho_X^{\tau - 2k} h_X^{2k - n/2} \|f\|_{2k}\,,$$

where C is independent of f and X. Here, h_X and ρ_X are the mesh norm and mesh ratio for the set X, respectively.

Remark. If the point sets used are all quasi-uniformly distributed (i.e., $\rho_X \leq C$ for all X under consideration), then $\|f - I_X f\| \leq \tilde{C} h_X^{2k-n/2} \|f\|_{2k}$.

Proof. Note that since ϕ is an SBF, every spherical harmonic P is in the native space of ϕ. Thus for any spherical harmonic P,

$$\|f - I_X f\| \leq \|f - P\| + \|P - I_X P\| + \|I_X P - I_X f\|. \tag{3.2}$$

Moreover, if $P|_X = f|_X$, then $I_X f = I_X P$, and (3.2) becomes

$$\|f - I_X f\| \leq \|f - P\| + \|P - I_X P\|. \tag{3.3}$$

The main requirement for proving the estimate is having spherical harmonics that yield meaningful estimates in (3.3). This is in fact the content of Theorem 3.1. Indeed, choosing $\beta = 3$ there implies that we have a sequence of P_L with the following properties:

(A) $P_L \in \mathcal{P}_L$, where $L = \lceil 2M q_X^{-1} \rceil$, with M, which is independent of X, as in Theorem 2.2.
(B) $P_L|_X = f|_X$.
(C) $\|f - P_L\| \leq 4\,\mathrm{dist}(f, \mathcal{P}_L)$.

By (3.3), properties (A) through (C), and the Jackson inequality (2.14), we obtain

$$\begin{aligned}\|f - I_X f\| &\leq \|f - P_L\| + \|P_L - I_X P_L\| \\ &\leq 4 \operatorname{dist}(f, \mathcal{P}_L) + \|P_L - I_X P_L\| \\ &\leq 4M^k L^{-2k} \|\Delta^k f\| + \|P_L - I_X P_L\|. \end{aligned} \tag{3.4}$$

By the assumptions on ϕ, Proposition 2.1 holds and, since the norms $\|\cdot\|_\phi$ and $\|\cdot\|_{H_\tau}$ are equivalent, we can estimate the interpolation error for P_L on the right above via

$$\|P_L - I_X P_L\| \leq C h_X^{\tau - n/2} \|P_L\|_\phi \leq c h_X^{\tau - n/2} \|P_L\|_{H_\tau}. \tag{3.5}$$

Using the definition of the Sobolev norm given in (2.5) and the fact that P_L is a spherical harmonic of degree L, one can see that

$$\|P_L\|_{H_\tau} \leq (1 + \lambda_L)^{\tau/2 - k} \|P_L\|_{H_{2k}}\,.$$

In addition, employing the inequality in (2.7) to replace the norm $\|P_L\|_{H_{2k}}$, we have

$$\|P_L\|_{H_\tau} \leq 2^k \omega_n^{1/2} (1 + \lambda_L)^{\tau/2 - k} \|P_L\|_{2k}\,.$$

Next, from (C) we easily see that $\|P_L\| \leq 5\|f\|$, and from Corollary 2.5, we also have $\|\Delta^k P_L\| \leq R \|\Delta^k f\|$, so that $\|P_L\|_{2k} \leq \max\{5, R\} \|f\|_{2k}$ and, consequently,

$$\|P_L - I_X P_L\| \leq c h_X^{\tau - n/2} 2^k \omega_n^{1/2} (1 + \lambda_L)^{\tau/2 - k} \max\{5, R\} \|f\|_{2k}. \tag{3.6}$$

From (3.6), (3.4), and $\lambda_L = L(L + n - 1) \sim L^2$, we arrive at this bound on the interpolation error for f:

$$\|f - I_X f\| \leq \left(4M^k L^{-2k} + C_1 L^{\tau - 2k} h_X^{\tau - n/2}\right) \|f\|_{2k}\,.$$

Since $L \geq 1$, the last inequality can also be written as

$$\begin{aligned}\|f - I_X f\| &\leq \left(C_0 L^{n/2 - 2k} + C_1 h_X^{\tau - n/2} L^{\tau - 2k}\right) \|f\|_{2k} \\ &\leq \left(C_0 (h_X L)^{n/2 - 2k} + C_1 (h_X L)^{\tau - 2k}\right) h_X^{2k - n/2} \|f\|_{2k}\,.\end{aligned}$$

If we use $L = \lceil 2M/q_X \rceil = \lceil 2M\rho_X/h_X \rceil$ from (A), then we get

$$\|f - I_X f\| \leq \left(C_2 \rho_X^{n/2 - 2k} + C_3\, \rho_X^{\tau - 2k}\right) h_X^{2k - n/2} \|f\|_{2k}\,.$$

Finally, since $\rho_X \geq 1$ and $\tau > n/2$, it follows that

$$\|f - I_X f\| \leq C \rho_X^{\tau - 2k} h_X^{2k - n/2} \|f\|_{2k}\,. \qquad \square$$

A more general, but also more technical, result can be obtained by modifying the proof above.

Corollary 3.3. *Let $\tau' > \tau \geq 2k > n/2 + (\tau' - \tau)$. If $H_{\tau'} \subseteq N_\phi \subseteq H_\tau$, then, for f and $I_X f$ as in Theorem* 3.2*,*

$$\|f - I_X f\| \leq C \rho_X^{\tau' - 2k} h_X^{2k - n/2 - (\tau' - \tau)} \|f\|_{2k}$$

holds with C independent of f and X.

Proof (Sketch of proof). The condition that $N_\phi \subseteq H_\tau$ implies that the left inequality in (3.5) holds. On the other hand, $N_\phi \supseteq H_{\tau'}$ implies that the right inequality in (3.5) holds with $\|P_L\|_{H_{\tau'}}$ replacing $\|P_L\|_{H_\tau}$. Tracking the necessary changes through the rest of the proof then provides us with the desired estimate. $\square$

We close this section by pointing out that Corollary 3.3 shows that our estimate is optimized when $\tau' = \tau$ or, equivalently, when $N_\phi = H_\tau$. In section 4.2.2 we will obtain a family of compactly supported SBFs that satisfy this criterion.

3.2. Interpolants that are near-best approximants. We now will show that for a given $f \in C^{2k}(S^n)$ there exist spherical harmonics P_L satisfying properties (A) through (C) used in the proof above; i.e., we will prove Theorem 3.1. The key to producing such spherical harmonics is contained in the following proposition, which is an adaptation of a similar result [13, Theorem 2.1].

PROPOSITION 3.4. *Let $Z^* \subset C(S^n)^*$ be given by $Z^* = \operatorname{span}\{\delta_{x_j}\colon\ x_j \in X\}$, and let $\mathcal{V}$ be a finite dimensional subspace of $C(S^n)$. If for every $z^* \in Z^*$ and some $\beta > 1$, β independent of z^*,*

$$\|z^*\|_{C(S^n)^*} \le \beta \|z^*|_{\mathcal{V}}\|_{\mathcal{V}^*}\,,$$

then for $f \in C(S^n)$ there exists $v_f \in \mathcal{V}$ for which $f|_X = v_f|_X$ and $\|f - v\| \le (1+\beta)\operatorname{dist}(f,\mathcal{V})$.

Proof. Let $v_\star$ be a best approximant to f from $\mathcal{V}$, so that

$$\|f - v_\star\| = \operatorname{dist}(f,\mathcal{V}),$$

and set $e := f - v_\star$. Let the restriction map $S\colon\ Z^* \to Z^*|_{\mathcal{V}}$ be given by $S(z^*) = z^*|_{\mathcal{V}}$ for every $z^* \in Z^*$. Since $\|z^*\| \le \beta\|z^*|_{\mathcal{V}}\|$, S is both one-to-one and onto the image space $S(Z^*) \subset \mathcal{V}^*$. Moreover $\|S^{-1}\| \le \beta$, where $S^{-1}\colon\ S(Z^*) \to Z^*$. Viewing e as an element of Z^{**} (i.e., as a functional on Z^*), we have

$$\langle e, z^*\rangle = \langle S^*(S^*)^{-1}e, z^*\rangle = \langle (S^*)^{-1}e, Sz^*\rangle\,,$$

where we used the fact that $S = S^{**}$. Note that $(S^*)^{-1}e \in (S(Z^*))^*$, where $S(Z^*) \subset \mathcal{V}^*$. By the Hahn–Banach theorem, $(S^*)^{-1}e$ extends in a norm-preserving manner to $v_e \in \mathcal{V}^{**} = \mathcal{V}$. Thus $\langle e, z^*\rangle = \langle f - v_\star, z^*\rangle = \langle z^*, v_e\rangle$ for all $z^* \in Z^*$ and

$$\begin{aligned}\|v_e\| &= \|(S^*)^{-1}e\| \le \|S^{-1}\|\|e\| \le \beta\|e\| \\ &= \beta\|f - v^*\|.\end{aligned}$$

Setting $v_f := v_\star + v_e$ gives an element in $\mathcal{V}$ for which $f|_X = v_f|_X$ and

$$\|f - v_f\| \le \|f - v^*\| + \|v_e\| \le (1+\beta)\ \operatorname{dist}(f,\mathcal{V}),$$

which completes the proof. □

The point of this proposition is that we have reduced the problem of finding interpolants that are near-best approximants to one of finding the ratio of norms of linear functionals. To estimate these ratios, we will construct a norm-attaining function for $z^* := \sum_{x_j\in X} c_j\delta_{x_j} \in Z^*$ and then approximate that function with spherical harmonics. We will show that the function ζ, which is given as

$$\zeta(x) := \sum_{x_j\in X} \operatorname{sgn}(c_j)\left(1 - \frac{d(x,x_j)}{q_X}\right)_+\,, \tag{3.7}$$

has the required properties.

LEMMA 3.5. *Let the function $\zeta(x)$ be defined by* (3.7). *Then, ζ is continuous on S^n and satisfies these properties:*

(i) $\|\zeta\| = 1$.

(ii) $z^*(\zeta) = \|z^*\|$.

(iii) $\omega(\zeta,\varepsilon) \le \frac{\varepsilon}{q_X}, 0 < \varepsilon \le \frac{\pi}{2}$, *where $\omega(\zeta, \varepsilon)$ is given in* (2.12).

Proof. Continuity is obvious. Also, $\zeta(x) = 0$ unless $d(x, x_j) < q_X$ for some $x_j \in X$. Moreover, on $d(x, x_j) \leq q_X$, we have

$$\zeta(x) = \operatorname{sgn}(c_j)\left(1 - \frac{d(x, x_j)}{q_X}\right),$$

so $|\zeta(x)| = 1 - \frac{d(x,x_j)}{q_X} \leq |\zeta(x_j)| = 1$. Since x_j is arbitrary, we see that $|\zeta(x)| \leq 1$ for all $x \in S^n$. Since $\zeta(x_j) = 1$ for all $x_j \in X$, $\|\zeta\| = 1$.

To establish (iii), we first need to calculate certain directional derivatives. We will work on $d(x_j, x) < q_X$, with x_j regarded as the north pole of S^n. In that case, we have $d(x, x_j) = \theta$, the colatitude of X, so

$$\zeta(x) = \operatorname{sgn}(c_j)\left(1 - \frac{\theta}{q}\right), \qquad d(x, x_j) = \theta < q_X.$$

For any geodesic $x(s)$, with $x(0) = x$ and s the arclength, we have

$$\frac{d}{ds}\zeta(x(s)) = -\operatorname{sgn}(c_j) \cdot \frac{1}{q}\frac{d\theta}{ds}.$$

In standard spherical coordinates,

$$1 = \left(\frac{d\theta}{ds}\right)^2 + \text{positive terms},$$

so $\left|\frac{d\theta}{ds}\right| \leq 1$. It follows that

$$\left|\frac{d\zeta}{ds}(x(0))\right| \leq \frac{1}{q_X}.$$

If $d(x, x_j) > q_X$ for all $x_j \in X$, then $\zeta(x) = 0$ in a neighborhood of x, and $\frac{d\zeta}{ds}(x(0)) = 0$. The only difficulty occurs where $d(x, x_j) = q$. Although ζ is not continuously differentiable at such points, the directional derivatives exist and again we have $|\frac{d\zeta}{ds}| \leq \frac{1}{q_X}$. (If we pass through such a point, $\frac{d\zeta}{ds}$ will have a jump discontinuity.) Our main consequence is that if *any* points x and y on S^n are joined by a geodesic $x(s)$, with $x(0) = x$ and $x(\varepsilon) = y$, then

$$|\zeta(x) - \zeta(y)| = \left|\int_0^\varepsilon \frac{d\zeta}{ds}(x(s))ds\right| \leq \int_0^\varepsilon \frac{ds}{q_X} = \frac{\varepsilon}{q_X}.$$

From (2.12), the spherical modulus of continuity $\omega(\zeta, \varepsilon)$ is

$$\omega(\zeta, \varepsilon) = \sup_{0<\eta\leq\epsilon} \|T_\eta\zeta - \zeta\|,$$

where $T_\eta\zeta$ is the spherical mean defined in (2.11). It is easy to show that $T_\eta c = c$ for any constant c, so that

$$T_\eta\zeta(x) - \zeta(x) = \frac{1}{\omega_{n-1}\sin^{n-1}(\eta)}\int_{x\cdot y=\cos(\eta)} \big(\zeta(y) - \zeta(x)\big)d\sigma(y).$$

Consequently

$$|T_\eta\zeta(x)-\zeta(x)| \le \frac{1}{\omega_{n-1}\sin^{n-1}(\eta)}\int_{x\cdot y=\cos\eta}\big|\zeta(x)-\zeta(y)\big|d\sigma(y)$$
$$\le \frac{\eta}{q_X}\cdot\frac{\int d\sigma(y)}{\omega_{n-1}\sin^{n-1}(\eta)} = \frac{\eta}{q_X}.$$

From this, one sees that $\omega(\zeta,\varepsilon)\le\frac{\varepsilon}{q_X}$, as we claimed. □

With minor modifications, a similar result can be proven for a Riemannian manifold. One need work only in the usual normal coordinates obtained from the exponential map. These can be used to define all the quantities involved.

Knowing the properties of ζ, we are now ready to prove Theorem 3.1.

Proof of Theorem 3.1. Apply Theorem 2.2 and Lemma 3.5 to ζ to obtain the existence of a polynomial $P_\zeta\in\mathcal{P}_L$ such that $\|P_\zeta-\zeta\|\le M/(q_XL)$. If, in addition, we assume that $L=\lceil\frac{(\beta+1)M}{(\beta-1)q_X}\rceil$, we see that

$$\|P_\zeta-\zeta\|\le\frac{\beta-1}{\beta+1}.$$

Furthermore, since $\|\zeta\|=1$, we also have that

$$\|P_\zeta\|\le\frac{2\beta}{\beta+1}.$$

Suppose that $z^*\in\operatorname{span}\{\delta_{x_1},\dots,\delta_{x_N}\}$ and that $\|z^*\|=1$. From Lemma 3.5 and the identity $z^*(\zeta-P_\zeta)+z^*(P_\zeta)=1$, we see that

$$z^*(P_\zeta)\ge 1-|z^*(\zeta-P_\zeta)|\ge 1-\frac{\beta-1}{\beta+1}=\frac{2}{\beta+1}.$$

Consequently,

$$\|z^*\|=1\le\frac{\beta+1}{2}z^*(P_\zeta)\le\frac{\beta+1}{2}\|z^*|_{\mathcal{P}_L}\|\cdot\|P_\zeta\|\le\frac{\beta+1}{2}\cdot\frac{2\beta}{\beta+1}\|z^*|_{\mathcal{P}_L}\|=\beta\|z^*|_{\mathcal{P}_L}\|.$$

The theorem is then an immediate consequence of Proposition 3.4, with $\mathcal{V}=\mathcal{P}_L$. □

Remark. In the case of the circle T, one can work with Sobolev spaces of degree k instead of $2k$ and use derivatives in place of Δ. Also the verification that $\|P_L\|_{2k}\le C\|f\|_{2k}$ follows easily by applying the appropriate theorems from [2, Chap. 7, sect. 2].

4. Restrictions of RBFs in R^{n+1} to S^n.

In our main estimate, Theorem 3.2, we assumed that $\hat\phi(\ell)\sim(1+\lambda_\ell)^{-\tau}$. Earlier, in a remark at the end of section 2.2, we pointed out that this assumption amounted to $N_\phi=H_\tau$, with the norms on the spaces being equivalent. In this section, we will exhibit SBFs that satisfy this property. Indeed, we will show that the compactly supported RBFs constructed by Wendland [24, 25] restrict (as kernels) to locally supported SBFs with native spaces that coincide with Sobolev spaces.

4.1. Legendre coefficients.

We suppose that Φ is a positive definite radial function defined on R^{n+1} and having the Fourier representation

$$\Phi(x)=\frac{1}{(2\pi)^{n+1}}\int_{R^{n+1}}\hat\Phi(|\xi|)e^{i\xi\cdot x}d\xi,\quad \hat\Phi\ge 0,\ \hat\Phi(|\cdot|)\in L^1(R^{n+1}). \tag{4.1}$$

Of course, if Φ has such a representation, then Φ is rotationally invariant and is thus a function of $|x|$ only. The corresponding convolution kernel $\Phi(x-y)$ is, when $|x|=1$ and $|y|=1$, a function of $|x-y| = \sqrt{2(1-x\cdot y)}$. Consequently, the restriction $\Phi(x-y)|_{x,y\in S^n}$ is a function of $x\cdot y$. We may therefore define the function

$$\phi(x\cdot y) := \Phi(x-y)|_{x,y\in S^n}\,. \tag{4.2}$$

Note that $\phi(x\cdot y)$ inherits being positive definite from Φ, and so it has the expansion given in (2.9). Our immediate goal is to use (2.9) to express $\hat\phi(\ell)$ in terms of $\hat\Phi$. In addition to being an interesting formula in its own right, it will be the key to relating native spaces for Φ and ϕ. We have the following result.

THEOREM 4.1. *Let ϕ defined in* (4.2) *have the expansion* (2.9). *Then $\hat\phi(\ell)$ from* (2.9) *is given by*

$$\hat\phi(\ell) = \int_0^\infty t\hat\Phi(t)J^2_{\ell+\frac{n-1}{2}}(t)dt, \tag{4.3}$$

where $J_\nu(t)$ is the usual Bessel function of the first kind and of order ν.

Proof. From (2.9), we have that

$$\hat\phi(\ell) = \int_{S^n}\int_{S^n}\phi(x\cdot y)\overline{Y_{\ell,m}(x)}Y_{\ell,m}(y)d\sigma(x)d\sigma(y)\,.$$

Substituting (4.1) for Φ in (4.2), inserting the resultant expression for ϕ into the previous equation, and interchanging integrals, we obtain

(4.4)
$$\hat\phi(\ell) = \frac{1}{(2\pi)^{n+1}}\int_{R^{n+1}}\hat\Phi(|\xi|)\bigg(\int_{S^n}e^{-i\xi\cdot y}Y_{\ell,m}(y)d\sigma(y)\int_{S^n}e^{i\xi\cdot x}\,\overline{Y_{\ell,m}(x)}d\sigma(x)\bigg)d\xi\,.$$

From Watson's book [23, sect. 11.5, eq. (2)], we have that

$$e^{it\cos\theta} = 2^\nu\Gamma(\nu)\sum_{\ell=0}^\infty(\nu+\ell)i^\ell\frac{J_{\nu+\ell}(t)}{t^\nu}C_\ell^\nu(\cos\theta),$$

where C_ℓ^ν is a Gegenbauer polynomial. We choose $\nu=\frac{n-1}{2}$ and replace the Gegenbauer polynomials by the corresponding Legendre polynomials using (2.2), where we also use the expression for $N(n,\ell)$ in (2.3):

$$\begin{aligned} 2^{\frac{n-1}{2}}\Gamma(\tfrac{n-1}{2})(\ell+\tfrac{n-1}{2})C_\ell^{\frac{n-1}{2}}(\cos\theta) &= 2^{\frac{n+1}{2}-1}\Gamma(\tfrac{n+1}{2})N(n,\ell)P_\ell(n+1;\cos\theta)\\ &= (2\pi)^{\frac{n+1}{2}}\tfrac{N(n,\ell)}{\omega_n}P_\ell(n+1;\cos\theta)\,. \end{aligned}$$

Employing this in the expansion for $e^{it\cos\theta}$, we arrive at

$$e^{it\cos\theta} = \frac{(2\pi)^{\frac{n+1}{2}}}{t^{\frac{n-1}{2}}}\sum_{\ell=0}i^\ell J_{\ell+\frac{n-1}{2}}(t)\frac{N(n,\ell)}{\omega_n}P_\ell(n+1;\cos\theta)\,.$$

Now choose $t=|\xi|$, $\eta=\xi/t$, $\cos\theta=\eta\cdot x$, and use the addition theorem (2.8); the result is

$$e^{it\eta\cdot x} = \frac{(2\pi)^{\frac{n+1}{2}}}{t^{\frac{n-1}{2}}}\sum_{\ell=0}i^\ell J_{\ell+\frac{n-1}{2}}(t)\sum_{m=1}^{N(n,\ell)}Y_{\ell,m}(x)\overline{Y_{\ell,m}(\eta)}\,. \tag{4.5}$$

From this, we can compute the inner integrals in (4.4); in particular, for the integral in x, we have

$$\int_{S^n} e^{it\eta\cdot x}\overline{Y_{\ell,m}(x)}d\sigma(x) = \frac{(2\pi)^{\frac{n+1}{2}}i^\ell}{t^{\frac{n-1}{2}}}J_{\ell+\frac{n-1}{2}}(t)\overline{Y_{\ell,m}(\eta)}\,. \tag{4.6}$$

The integral in y is simply the complex conjugate of that in x. Hence, it follows that

$$\hat{\phi}(\ell) = \frac{1}{(2\pi)^{n+1}}\int_0^\infty \hat{\Phi}(t)\int_{S^n}\left|\frac{(2\pi)^{\frac{n+1}{2}}i^\ell}{t^{\frac{n-1}{2}}}J_{\ell+\frac{n-1}{2}}(t)\overline{Y_{\ell,m}(\eta)}\right|^2 d\sigma(\eta)t^n dt\,.$$

Doing the integral over S^n and simplifying the integrand results in (4.3), which completes the proof. □

Having an explicit relationship between the Fourier transform of an RBF and the Legendre coefficients provides an important relationship between native spaces.

COROLLARY 4.2. *Let Φ and Ψ be positive definite radial functions on R^{n+1}, and suppose that $\hat{\Psi}$ and $\hat{\Phi}$ are strictly positive and satisfy $\hat{\Phi} \le c\hat{\Psi}$; then, for all $\ell \ge 0$, we have $0 < \hat{\phi}(\ell) \le c\hat{\psi}(\ell)$ and $N_\phi \subseteq N_\psi$.*

Proof. Apply the previous theorem. □

Earlier, we defined an SBF to be a positive definite function on S^n with the additional property that $\hat{\phi}(\ell) > 0$ for all $\ell \ge 0$. This condition implies that the standard interpolation matrices are positive definite and hence invertible. Ron and Sun [21] showed that this condition was sufficient but not necessary for the positive definiteness of the interpolation matrices. The condition is, however, necessary and sufficient for doing generalized Hermite interpolation [4, 16]. Up to now, it was only known that if Φ was an RBF on R^{n+1}, then, given very mild conditions (see [3]), $\Phi(x-y)|_{S^{n-1}}$ was an SBF; that is, one had to drop down two dimensions. One knew only that $\Phi(x-y)|_{S^n}$ was positive definite, but *not* that it was an SBF.

COROLLARY 4.3. *Let Φ be a nontrivial positive definite radial function having the form given in* (4.1). *Then, the restriction $\phi(x\cdot y) := \Phi(x-y)|_{x,y\in S^n}$ is an SBF.*

Proof. We first note that $\hat{\Phi}$ is positive on a set of nonzero measure, for Φ would vanish identically otherwise. Let $\mathcal{M}$ be this set. Suppose that ϕ is not an SBF, so that for some ℓ we have $\hat{\phi}(\ell) = 0$. (Of course, ϕ is positive definite, so that $\hat{\phi}(\ell) \ge 0$.) From (4.3), we see that on $\mathcal{M}$

$$\int_{\mathcal{M}} t\hat{\Phi}(t)J^2_{\ell+\frac{n-1}{2}}(t)dt = 0.$$

Since the measure of $\mathcal{M}$ is positive, and since $\hat{\Phi}(t) > 0$ on $\mathcal{M}$, it follows that the continuous function $J_{\ell+\frac{n-1}{2}}(t) \equiv 0$ on $\mathcal{M}$, and, consequently, the entire function $t^{-\ell+\frac{n-1}{2}}J_{\ell+\frac{n-1}{2}}(t)$ vanishes identically on $\mathcal{M}$. Since $\mathcal{M}$ is uncountable, the entire function vanishes identically, as does the Bessel function $J_{\ell+\frac{n-1}{2}}$, which is false. Hence, $\hat{\phi}(\ell) > 0$ for all ℓ, and ϕ is an SBF. □

4.2. SBFs with Sobolev spaces for native spaces. A positive definite radial function Φ on R^{n+1} has its native space N_Φ equivalent to a Sobolev space $H_s(R^{n+1})$ if its R^{n+1}-Fourier transform $\hat{\Phi}(|\xi|)$ satisfies the bounds

$$c(1+t^2)^{-s} \le \hat{\Phi}(t) \le C(1+t^2)^{-s}, \quad 0 \le t \in R\,. \tag{4.7}$$

We will assume that $\hat{\Phi}$ satisfies these bounds, and, in order to keep $\hat{\Phi}$ in $L^1(R^{n+1})$, we will also require that s be strictly larger than $(n+1)/2$.

We want to determine whether $\phi(x\cdot y) = \Phi(x-y)|_{x,y\in S^n}$ belongs to some Sobolev space on S^n, given that $\hat{\Phi}$ satisfies the bounds in (4.7). Define Ψ_s via

$$\Psi_s(x) := \frac{1}{(2\pi)^{n+1}}\int_{R^{n+1}} \frac{e^{ix\cdot\xi}}{(1+|\xi|^2)^s}d\xi\,, \quad x\in R^{n+1},$$

and let $\psi_s(x\cdot y) = \Psi_s(x-y)|_{x,y\in S^n}$. By Corollary 4.2 and the bounds in (4.7), the native spaces for ϕ and ψ_s are the same, with the norms being equivalent. The question of what, if any, Sobolev space ψ_s belongs to can be answered by using (4.3) to obtain the large ℓ behavior of $\hat{\psi}_s(\ell)$, which is explicitly given by

$$\hat{\psi}_s(\ell) = \int_0^\infty \frac{tJ_\nu^2(t)}{(1+t^2)^s}dt, \text{ where } \nu := \ell + \frac{n-1}{2} \text{ and } s > \frac{n+1}{2}. \tag{4.8}$$

Specifically, we have this proposition.

Proposition 4.4. *If for some $\tau(s,n) > 0$ we have $\hat{\psi}_s(\ell) \sim \ell^{-2\tau}$ as $\ell\to\infty$, then $N_{\psi_s} = H_\tau(S^n)$. Moreover, if Φ is such that (4.7) holds, then we also have $N_\phi = H_\tau(S^n)$.*

Proof. The asymptotic behavior of $\hat{\psi}_s(\ell)$ implies that for all $\ell \geq 0$,

$$(1+\lambda_\ell)^\tau \hat{\psi}_s(\ell) \sim 1, \quad \ell\to\infty,$$

since $\lambda_\ell = \ell(\ell+n-1) = \ell^2(1+\mathcal{O}(\ell^{-1}))$. Now, by Corollary 4.3, ψ_s is an SBF and so $\hat{\psi}_s(\ell) > 0$ for all $\ell \geq 0$. Consequently, the asymptotic statement in the equation above holds for all $\ell\geq 0$, and thus the native space of ψ_s coincides with $H_\tau(S^n)$. The statements concerning N_ϕ then follow from the bound (4.7) and Corollary 4.2. □

4.2.1. Large $\boldsymbol{\ell}$ asymptotics of $\boldsymbol{\hat{\psi}_s(\ell)}$. We now turn to finding the large ℓ asymptotic behavior of $\hat{\psi}_s(\ell)$, at least for some s. We begin by evaluating the integral (4.8) in terms of hypergeometric functions [23, section 4.4],

$${}_pF_q(a_1,a_2,\ldots,a_p\,;b_1,b_2,\ldots,b_q\,;z) := \sum_{r=0}^\infty \frac{(a_1)_r(a_2)_r\cdots(a_p)_r z^r}{(b_1)_r(b_2)_r\cdots(b_q)_r r!}\,, \tag{4.9}$$

where Pochhammer's symbol $(\lambda)_r := \lambda(\lambda+1)\cdots(\lambda+r-1)$ when $r\geq 1$ and $(\lambda)_0 := 1$.

Lemma 4.5. *If s and ν are as in (4.8) and $\nu - s$ is not an integer, then*

$$\begin{aligned}\hat{\psi}_s(\ell) = {}& \frac{2\Gamma(\nu+1-s)\Gamma(s-\frac{1}{2})}{\pi^{\frac{1}{2}}\Gamma(s)\Gamma(\nu+s)} \times \Bigg({}_1F_2(s-\tfrac{1}{2}; s+\nu, s-\nu; 1) \\ & + \frac{\pi^{\frac{3}{2}}(\nu+1-s)\Gamma(\nu+s)\csc\big(\pi(\nu-s)\big)}{2^{2\nu}\Gamma^2(\nu+2-s)\Gamma(\nu+1)\Gamma(s-\frac{1}{2})}\, {}_1F_2(\nu+\tfrac{1}{2}; \nu+2-s, 2\nu+1; 1)\Bigg).\end{aligned} \tag{4.10}$$

Proof. We follow Watson [23, section 13.61], who sketched two methods for doing integrals involving products of Bessel functions, specifically including integrals of the type in (4.8). The most direct for us is to first use [23, eq. (1), sect. 5.43] to express $J_\nu^2(t)$ as

$$J_\nu^2(t) = \frac{2}{\pi}\int_0^{\pi/2} J_{2\nu}(2t\cos\theta)d\theta,$$

then insert it in (4.8), and finally use Fubini's theorem to interchange integrals. This results in

$$\hat{\psi}_s(\ell) = \frac{2}{\pi}\int_0^{\pi/2}\int_0^\infty \frac{tJ_{2\nu}(2t\cos\theta)}{(1+t^2)^s}dtd\theta\,.$$

The integral over t was done in [23, sect. 13.6, eq. (1)]; with our parameters, it has the form

$$\int_0^\infty \frac{tJ_{2\nu}(2t\cos\theta)}{(1+t^2)^s}dt = \frac{\Gamma(\nu+1)\Gamma(s-1-\nu)}{2\Gamma(s)\Gamma(2\nu+1)}\cos^{2\nu}(\theta)\,{}_1F_2(\nu+1;\nu+2-s,2\nu+1;\cos^2(\theta)) + \frac{\Gamma(\nu+1-s)}{2\Gamma(s+\nu)}\cos^{2s-2}(\theta)\,{}_1F_2(s;s+\nu,s-\nu;\cos^2(\theta))\,.$$

We are now left with evaluating two integrals of the form

$$\int_0^{\pi/2}\cos^\mu(\theta)\,{}_1F_2(a_1;b_1,b_2;\cos^2(\theta))d\theta\,.$$

If we let $u=\cos^2(\theta)$, then such integrals transform to

$$2\int_0^1 u^{\frac{\mu-1}{2}}(1-u)^{-\frac{1}{2}}\,{}_1F_2(a_1;b_1,b_2;u)du\,.$$

This integral may be found in Gradshteyn and Ryzhik [8, sect. 7.512, eq. 12]:

$$\int_0^1 u^{\frac{\mu-1}{2}}(1-u)^{-\frac{1}{2}}\,{}_1F_2(a_1;b_1,b_2;u)du = \frac{\pi^{1/2}\Gamma(\frac{\mu+1}{2})}{\Gamma(1+\frac{\mu}{2})}\,{}_2F_3(\tfrac{\mu+1}{2},a_1;1+\tfrac{\mu}{2},b_1,b_2;1)\,.$$

Using this result, we have that

$$\begin{aligned}\hat{\psi}_s(\ell) =& A\,{}_2F_3(\nu+\tfrac{1}{2},\nu+1;\nu+1,\nu+2-s,2\nu+1;1)\\ &+B\,{}_2F_3(s-\tfrac{1}{2},s;s,s+\nu,s-\nu;1),\end{aligned}$$

where A and B are the accumulated factors and are given by

$$A=\frac{2\Gamma(s-1-\nu)\Gamma(\nu+\frac{1}{2})}{\pi^{\frac{1}{2}}\Gamma(s)\Gamma(2\nu+1)} \quad\text{and}\quad B=\frac{2\Gamma(\nu+1-s)\Gamma(s-\frac{1}{2})}{\pi^{\frac{1}{2}}\Gamma(s)\Gamma(\nu+s)}\,.$$

Using the "cancellation property" for the hypergeometric functions, namely,

$${}_{p+1}F_{q+1}(c,a_1,\dots,a_p\,;c,b_1,\dots,b_p;z) = {}_pF_q(a_1,\dots,a_p\,;b_1,\dots,b_p;z),$$

we arrive at

$$\hat{\psi}_s(\ell) = A\,{}_1F_2(\nu+\tfrac{1}{2};\nu+2-s,2\nu+1;1)+B\,{}_1F_2(s-\tfrac{1}{2};s+\nu,s-\nu;1)\,.$$

Using $\Gamma(1-z)\Gamma(z)=\pi\csc(\pi z)$ and the duplication formula, $2^{2z-1}\Gamma(z)\Gamma(z+\frac{1}{2}) = \sqrt{\pi}\Gamma(2z)$, we can rewrite A as

$$A=\frac{2^{1-2\nu}\pi\csc\big(\pi(\nu-s)\big)}{\Gamma(s)\Gamma(\nu+2-s)\Gamma(\nu+1)}\,.$$

Inserting this into the previous equation for $\hat{\psi}_s(\ell)$ and factoring out B, we obtain the expression in (4.10). □

The restriction that $\nu - s$ cannot be an integer is really unnecessary; the expression in (4.10) has a removable singularity for such values, and $\hat{\psi}_s(\ell)$ can be found for them by taking limits.

We now turn to the large ℓ asymptotics of $\hat{\psi}_s(\ell)$. Doing this for fixed, *arbitrary* $s > \frac{n+1}{2}$ appears to be quite difficult, owing to the removable singularities that occur in (4.10) when $\nu - s$ is an integer. These disappear in one very important case, namely when $\nu - s$ is an odd multiple of $\frac{1}{2}$. This case is important because the compactly supported positive definite radial functions introduced by Wendland [24, 25] satisfy it (see section 4.2.2). For such functions we have $s = \frac{n+1}{2} + j + \frac{1}{2}$, where j is a positive integer, and so

$$\nu - s = \ell - j - \tfrac{3}{2} \quad \text{and} \quad \nu + s = \ell + n + j + \tfrac{1}{2}\,. \tag{4.11}$$

With this choice of s, we have the following asymptotic formula.

PROPOSITION 4.6. *As $\ell \to \infty$,*

$$\hat{\psi}_{\frac{n+1}{2}+j+\frac{1}{2}}(\ell) = \frac{2\Gamma(\frac{n+1}{2}+j)}{\sqrt{\pi}\Gamma(\frac{n+1}{2}+j+\frac{1}{2})}\ell^{-2j-n-1}\big(1+\mathcal{O}(\ell^{-1})\big)\,.$$

Proof. With $s = \frac{n+1}{2} + j + \frac{1}{2}$ and the values of $\nu \pm s$ from (4.11), equation (4.10) for $\hat{\psi}_s(\ell)$ becomes

$$\begin{aligned}\hat{\psi}_{\frac{n+1}{2}+j+\frac{1}{2}}(\ell) = {} & \frac{2\Gamma(\frac{n+1}{2}+j)\Gamma(\ell-j-\frac{1}{2})}{\sqrt{\pi}\Gamma(\frac{n+1}{2}+j+\frac{1}{2})\Gamma(\ell+n+j+\frac{1}{2})} \\ & \times\Bigg({}_1F_2(\tfrac{n+1}{2}+j;\ell+n+j+\tfrac{1}{2},j+\tfrac{3}{2}-\ell;1) \\ & \pm\frac{\pi^{\frac{3}{2}}(\ell-j-\frac{1}{2})\Gamma(\ell+n+j+\frac{1}{2})}{2^{2\ell+n-1}\Gamma^2(\ell-j+\frac{1}{2})\Gamma(\ell+\frac{n+1}{2})\Gamma(\frac{n+1}{2}+j)}\,{}_1F_2(\ell+\tfrac{n}{2};\ell-j+\tfrac{1}{2},2\ell+n;1)\Bigg)\,,\end{aligned}$$

where the "±" comes from $\csc(\pi(\nu - s))$. We will take care of terms in reverse order. By the definition of the hypergeometric function in (4.9), it is easy to see that

$${}_1F_2(\ell+\tfrac{n}{2};\ell-j+\tfrac{1}{2},2\ell+n;1) \le \sum_{r=0}^{\infty}\frac{1}{r!} \le e.$$

The term multiplying this hypergeometric is roughly $\mathcal{O}((\ell!)^{-2})$. Thus overall the term decays faster than any power of ℓ. Again from (4.9),

$$\begin{aligned}\big|\,{}_1F_2(\tfrac{n+1}{2}+j;\ell+n+j+\tfrac{1}{2},j+\tfrac{3}{2}-\ell;1)-1\big| &\le \textstyle\sum_{r=1}^{\infty}\frac{(\frac{n+1}{2}+j)_r}{(\ell+n+j+\frac{1}{2})_r|(j+\frac{3}{2}-\ell)_r|r!} \\ &\le 4\textstyle\sum_{r=1}^{\infty}\frac{(\frac{n+1}{2}+j)_r}{(\ell+n+j+\frac{1}{2})_r r!} \\ &\le 4\frac{\frac{n+1}{2}+j}{\ell+n+j+\frac{1}{2}}\textstyle\sum_{r=1}^{\infty}\frac{(\frac{n+1}{2}+j+1)_{r-1}}{(\ell+n+j+\frac{1}{2})_{r-1}r!} \\ &\le 4(e-1)\frac{\frac{n+1}{2}+j}{\ell+n+j+\frac{1}{2}}\,.\end{aligned}$$

Consequently, the first term in parentheses is $1 + \mathcal{O}(\ell^{-1})$. Since the second term decays faster than any power of ℓ, we have that the two terms taken together behave like $1+\mathcal{O}(\ell^{-1})$. Using standard properties of the Gamma function, one has that the term multiplying the parentheses is

$$\frac{2\Gamma(\frac{n+1}{2}+j)}{\sqrt{\pi}\Gamma(\frac{n+1}{2}+j+\frac{1}{2})}\times\ell^{-2j-n-1}(1+\mathcal{O}(\ell^{-1}))\,.$$

The proposition follows on observing that $(1+\mathcal{O}(\ell^{-1}))\times(1+\mathcal{O}(\ell^{-1}))=1+\mathcal{O}(\ell^{-1})$. $\square$

We conjecture that for any $s>\frac{n+1}{2}$ we will have $\hat{\psi}_s(\ell)\sim\ell^{-2s+1}$ as $\ell\to\infty$.

4.2.2. Locally supported SBFs with $N_\phi = H_s$. As we mentioned earlier, in [24] Wendland introduced a class of compactly supported RBFs, and in [25] he explored their properties, showing in particular that their Fourier transforms satisfy the bounds in (4.7). On R^d, these functions have the form

$$\Phi_{d,j}(x) := \begin{cases} p_{d,j}(\|x\|_2) & \text{if } \|x\|_2\le 1,\\ 0 & \text{if } \|x\|_2 > 1,\end{cases}$$

where $x\in R^d$ and $p_{d,j}$ is a polynomial of degree $\lfloor\frac{d}{2}\rfloor+3j+1$; in addition, $\Phi_{d,j}$ is in $C^{2j}(R^d)$ [25, Cor. 2.3] and satisfies (4.7) with $s=\frac{d}{2}+j+\frac{1}{2}$ [25, Thm. 2.1], where $j\ge 1$ and $d=1,2,\ldots$. Simply choosing $d=n+1$ puts s in the form $s=\frac{n+1}{2}+j+\frac{1}{2}$. By Proposition 4.6 and Proposition 4.4, it follows that, with $\tau=\frac{n+1}{2}+j$, the native space for $\phi_{n,j}$ and the Sobolev space H_τ are equivalent. The specific result is this.

THEOREM 4.7. *Let $\phi_{n,j}(x\cdot y) := \Phi_{\frac{n+1}{2},j}(x-y)|_{x,y\in S^n}$. Then $\phi_{n,j}$ is a C^{2j} spherical basis function for which $N_{\phi_{n,j}} = H_{\frac{n+1}{2}+j}$.*

We point out that the support of $\phi_{n,d}$ can be adjusted by scaling $\Phi_{\frac{n+1}{2},j}$. This will not change any of $\phi_{n,d}$'s essential properties, and so the theorem above holds for it as well.

One interesting feature is that, in restricting to S^n, the native space of $\Phi_{\frac{n+1}{2},j}$ changes from $H_s(R^{n+1})$ to $H_{s-\frac{1}{2}}(S^n)$, with $s=\frac{n+1}{2}+j+\frac{1}{2}$. This loss of "$\frac{1}{2}$ a derivative" is familiar from the theory of Sobolev spaces and traces of functions. The trace operator restricts a function in a Sobolev space to a codimension 1 surface, such as an embedded sphere in Euclidean space. The trace of f belongs to a Sobolev space of order $\frac{1}{2}$ smaller than the one f is in [10, Chapter 1, section 8]. We conjecture that the result we have obtained is a special case of a more general one that applies to manifolds; namely, we conjecture that if the native space of Φ coincides with $H_s(\Omega)$, for an $n+1$ dimensional manifold Ω, then the restriction ϕ to an n dimensional surface Σ will have $H_{s-\frac{1}{2}}(\Sigma)$ for a native space.

LARGE TORSIONAL OSCILLATIONS IN A SUSPENSION BRIDGE: MULTIPLE PERIODIC SOLUTIONS TO A NONLINEAR WAVE EQUATION[*]

K. S. MOORE[†]

Abstract. We consider a forced nonlinear wave equation on a bounded domain which, under certain physical assumptions, models the torsional oscillation of the main span of a suspension bridge. We use Leray–Schauder degree theory to prove that, under small periodic external forcing, the undamped equation has multiple periodic solutions. To establish this multiplicity theorem, we prove an abstract degree theoretic result that can be used to prove multiplicity of solutions for more general operators and nonlinearities.

Using physical constants from the engineers' reports of the collapse of the Tacoma Narrows Bridge, we solve the damped equation numerically and observe that multiple periodic solutions exist and that whether the span oscillates with small or large amplitude depends only on its initial displacement and velocity. Moreover, we observe that the qualitative properties of our computed solutions are consistent with the behavior observed at Tacoma Narrows on the day of its collapse.

Key words. nonlinear wave equation, torsional oscillations, suspension bridge

1. Introduction.

For over sixty years, scientists in many disciplines have struggled to explain the dramatic and finally destructive torsional oscillations of the Tacoma Narrows Bridge that preceded its collapse in 1940. The recent article in [16], which describes the forty year effort to control the behavior of the Deer Isle Bridge in Maine, and the closing in June, 2000, of the Millennium Bridge in London [18] testify to the fact that the problem of controlling suspension bridge oscillations remains unsolved.

We argue that the nonlinearity inherent in the equations of motion drives the unpredictable behavior observed on the Tacoma Narrows and other suspension bridges. Theoretical and numerical evidence to support this claim for the vertical, torsional, and traveling wave motion of suspension bridges can be found in [3], [4], [5], [6], [7] and [9], [10], [11], [12], [13], [14], [15].

In [9] and [10], the authors proposed an ODE model for the torsional motion of a horizontal cross section of the main span of a suspension bridge and proved the existence of multiple periodic solutions. Using physical constants from the engineers' reports of the Tacoma Narrows collapse, the authors investigated this model numerically and demonstrated that under small external forcing, the cross section may ultimately settle down to small or large amplitude periodic torsional oscillation, depending only on the initial torsional displacement and velocity of the cross section.

In this paper, we extend this analysis to the entire length of the main span of the bridge. More specifically, in section 2 we propose a PDE model (the forced sine-Gordon equation on a bounded domain) for the torsional motion along the length of the center span. In section 3, we prove that, under certain physical assumptions, the equation has multiple periodic weak solutions. Similar results exist for the vertical motion of the center span [6], [13].

We then investigate these solutions numerically. In section 4, we examine the bifurcation properties of periodic solutions to the equation via numerical continuation algorithms. We find that, under small external forcing, the damped equation has three periodic solutions, one of small amplitude and two of large amplitude. Moreover, we see that bifurcation from single to multiple solutions occurs for small forcing.

In section 5, we use finite difference methods to approximate periodic solutions. As in [9], we demonstrate that under small external forcing, the center span may oscillate periodically with small or large amplitude, depending only on its initial displacement and velocity. Moreover, we observe that the qualitative properties such as amplitude, frequency, and nodal structure of our computed solutions are consistent with the behavior observed at Tacoma Narrows on the day of its collapse.

2. The model. We treat the center span of the bridge as a beam of length L and width $2l$ suspended by cables (see Figure 2.1). Consider the horizontal cross section of mass m located at position x along the length of the span. We treat this cross section as a rod of length $2l$ and mass m suspended by cables. Let $y(x,t)$ denote the *downward* distance of the center of gravity of the rod *from the unloaded state* and let $\theta(x,t)$ denote the angle of the rod from horizontal at time t (see Figure 2.1).

We assume that the cables do not resist compression, but resist elongation according to Hooke's Law with spring constant K; i.e., the force exerted by the cable is proportional to the elongation in the cable with proportionality constant K. In

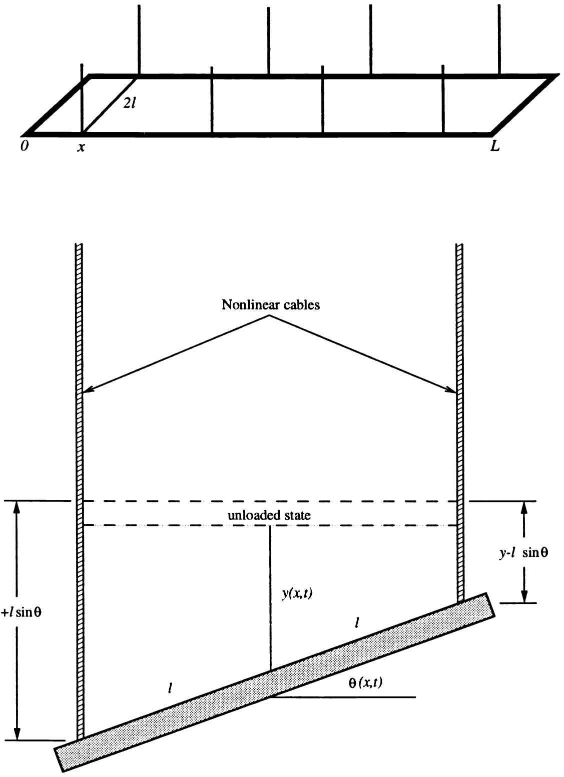

FIG. 2.1. *A simple model of the center span and its horizontal cross section.*

Figure 2.1 we see that the extension in the right-hand cable is $(y - l\sin\theta)$, and hence the force exerted by the right-hand cable is

$$\left\{\begin{array}{ll} -K(y - l\sin\theta), & y - l\sin\theta \geq 0 \\ 0, & y - l\sin\theta < 0 \end{array}\right. = -K(y - l\sin\theta)^+,$$

where $u^+ = \max\{u, 0\}$. Similarly, the extension in the left-hand cable is $(y + l\sin\theta)$, and the force exerted by the left-hand cable is $-K(y + l\sin\theta)^+$. Then the torsional and vertical motion of the span satisfy

$$\text{(2.1)} \quad \left\{\begin{array}{c} \theta_{tt} - \varepsilon_1\theta_{xx} = \frac{3K}{ml}\cos\theta[(y - l\sin\theta)^+ - (y + l\sin\theta)^+] - \delta\theta_t + h_1(x,t) \\ y_{tt} + \varepsilon_2 y_{xxxx} = -\frac{K}{m}[(y - l\sin\theta)^+ + (y + l\sin\theta)^+] - \delta y_t + g + h_2(x,t) \\ \theta(0,t) = \theta(L,t) = y(0,t) = y(L,t) = y_{xx}(0,t) = y_{xx}(L,t) = 0 \end{array}\right\},$$

where $\varepsilon_1, \varepsilon_2$ are physical constants related to the flexibility of the beam, δ is the damping constant, h_1 and h_2 are external forcing terms, and g is the acceleration due to gravity. The spatial derivatives describe the restoring force that the beam exerts, and the time derivatives θ_t and y_t represent the force due to friction. The boundary conditions reflect the fact that the ends of the span are hinged.

We study coupled systems of this form in [11], [12], and [15]. However, throughout this paper we assume that the cables never lose tension; i.e., we assume that $(y \pm l\sin\theta) \geq 0$ and hence $(y \pm l\sin\theta)^+ = (y \pm l\sin\theta)$. In this case, we see that the equations (2.1) become uncoupled, and the torsional and vertical motions satisfy

$$\text{(2.2)} \quad \left\{\begin{array}{c} \theta_{tt} - \varepsilon_1\theta_{xx} = -\frac{6K}{m}\cos\theta\sin\theta - \delta\theta_t + h_1(x,t) \\ \theta(0,t) = \theta(L,t) = 0 \end{array}\right\}$$

and

$$\text{(2.3)} \quad \left\{\begin{array}{c} y_{tt} + \varepsilon_2 y_{xxxx} = -\frac{2K}{m}y - \delta y_t + g + h_2(x,t) \\ y(0,t) = y(L,t) = y_{xx}(0,t) = y_{xx}(L,t) = 0 \end{array}\right\},$$

respectively.

We observe that (2.2) is the damped, forced, sine-Gordon equation, which arises in many applications. We study equations of this form throughout the paper.

3. A multiplicity theorem. In this section, we consider the questions of existence and multiplicity of continuous, periodic, weak solutions u in a subspace of $\mathcal{L}^2$ to equations of the form (2.2).

Let $\Omega = (0,\pi) \times (0,\pi)$ and define

$$\mathcal{H} = \{u \in \mathcal{L}^2(\Omega) | u(x,t) = u(\pi - x, t), u(x,t) = u(x, \pi - t), \\ u \text{ is } \pi \text{ periodic in } t\}.$$

For $u \in \mathcal{H}$, let $\|u\| = \|u\|_{\mathcal{L}^2} = (\int_\Omega |u|^2 dA)^{\frac{1}{2}}$. Define $L_T u = u_{tt} - u_{xx}$. Using $\cos u \sin u = \frac{1}{2}\sin 2u$, changing variables, removing the damping term, and imposing boundary and periodicity conditions, we rewrite (2.2) as

$$\text{(3.1)} \quad \left\{\begin{array}{c} L_T u + b\sin u = \varepsilon h(x,t) \\ u(0,t) = u(\pi,t) = 0 \\ u(x,0) = u(x,\pi), u_t(x,0) = u_t(x,\pi) \end{array}\right\}.$$

Observe that the eigenvalues and corresponding eigenfunctions of L_T with the appropriate boundary conditions are

$$\left\{ \begin{array}{l} \lambda_{mn} = (2n+1)^2 - 4m^2 \\ \phi_{mn} = \cos(2mt)\sin((2n+1)x) \end{array} \right\}, \tag{3.2}$$

where $m, n = 0, 1, 2, \ldots$. Because we are restricted to the subspace $\mathcal{H}$ of $\mathcal{L}^2$, L_T^{-1} exists, is compact, and $\|L_T^{-1}\| = 1$.

Definition 3.1. *We say that $u \in \mathcal{H}$ is a solution to* (3.1) *if*

$$u = L_T^{-1}(\varepsilon h - b\sin u). \tag{3.3}$$

Theorem 3.2. *Let $h \in \mathcal{H}$ with $\|h\| \leq 1$, and let $b \in (3, 7)$. Then there exists $\varepsilon_0 > 0$ such that if $|\varepsilon| < \varepsilon_0$,* (3.1) *has at least two solutions in $\mathcal{H}$.*

We use Leray–Schauder degree theory to prove Theorem 3.2 in section 3.2; however, to establish this result, we first establish a general degree theoretic result in section 3.1. Finally, in section 3.3, we prove that the solutions to (3.1) are continuous.

3.1. Preservation of Leray–Schauder degree under Gâteaux differentiation. To establish the existence of multiple periodic solutions to (3.1), we use Leray–Schauder degree theory to prove the existence of multiple zeros of a related operator T_1. To compute the degree of T_1, we continuously deform it to a linear operator T_0, the Gâteaux derivative of T_1, and compute its degree via a direct calculation.

It is not difficult to show that, under the appropriate hypotheses, the homotopy property of Leray–Schauder degree ensures that the degree of an operator T_1 is preserved as T_1 is continuously deformed to its Fréchet derivative. However, the nonlinear term in (3.1), $f(u) = \sin u$, is not Fréchet differentiable in $\mathcal{L}^2$ at $u = 0$.

Motivated by the result and arguments in [13], in Theorem 3.3 we show that, under certain conditions on the nonlinear term f and the differential operator L, Leray–Schauder degree is indeed preserved under homotopy from the operator T_1 to its Gâteaux derivative T_0. This result can be used to establish multiplicity of solutions to equations of the form (3.1) for more general nonlinearities $f(u)$ and differential operators L.

Theorem 3.3. *Let I_1, I_2 be open, bounded intervals in $\mathbf{R}$, and define $Q := I_1 \times I_2$. Let $\mathcal{B}$ be a subspace of $\mathcal{L}^p(Q), p \geq 1$, and define $\|u\| := \|u\|_{\mathcal{L}^p}$. Consider the problem*

$$Lu + f(u) = \varepsilon h(x, t), \tag{3.4}$$

where L, f, and h satisfy the following:

(H1) *L^{-1} is compact;*

(H2) *$\|L^{-1}\| \leq 1$;*

(H3) *$f(0) = 0$;*

(H4) *f is Lipschitz with Lipschitz constant M;*

(H5) *$h \in \mathcal{B}$ and $\|h\| \leq 1$;*

(H6) *the Gâteaux derivative $df(0, u)$ exists and satisfies $df(0, u) = \rho u$, where $\rho > 0$ and $-\rho$ is not an eigenvalue of L.*

Define $T_0 : \mathcal{B} \to \mathcal{B}$ by $T_0(u) = u + \rho L^{-1}(u)$ and $T_1 : \mathcal{B} \to \mathcal{B}$ by $T_1(u) = u - L^{-1}(\varepsilon h - f(u))$. Then for ε sufficiently small, there exists $\gamma > 0$ such that $deg(T_1, B_\gamma(0), 0) = deg(T_0, B_\gamma(0), 0)$.

Proof. For $\lambda \in [0, 1]$, define $T_\lambda : \mathcal{B} \to \mathcal{B}$ by

$$T_\lambda(u) = u + (1 - \lambda)\rho L^{-1}(u) + \lambda L^{-1}(f(u) - \varepsilon h(x, t)). \tag{3.5}$$

The homotopy property of degree ensures that $deg(T_\lambda, B_r(0), 0)$ is constant provided that $0 \notin T_\lambda(\partial B_r(0))$ for $\lambda \in [0,1]$. We will show then that for all $\lambda \in [0,1]$ there exists $\gamma > 0$ such that the solution u to $T_\lambda(u) = 0$ satisfies $\|u\| \neq \gamma$.

Observe that $u = 0$ is the only zero of T_0 since, by (H6), $-\rho$ is not an eigenvalue of L. Fix $\lambda \in (0,1]$ and suppose that $u \neq 0$ solves $T_\lambda(u) = 0$. Set $\|u\| = \tilde{\gamma}_\lambda > 0$. We will show that $\tilde{\gamma}_\lambda$ is bounded below by some $\gamma_\lambda > 0$.

Note that u solves

$$Lu + \rho u = \lambda(\rho u - f(u) + \varepsilon h(x,t)) \tag{3.6}$$

and hence

$$Lu = (\lambda - 1)\rho u + \lambda(\varepsilon h(x,t) - f(u)), \tag{3.7}$$

and invoking (H4) and (H5) we have

$$\begin{aligned} \|Lu\| &\leq \rho\|u\| + \varepsilon + \|f(u)\| \\ &\leq \rho\|u\| + \varepsilon + M\|u\| \\ &= (\rho + M)\tilde{\gamma}_\lambda + \varepsilon. \end{aligned}$$

Therefore, $u \in \overline{L^{-1}B_{(\rho+M)\tilde{\gamma}_\lambda+\varepsilon}(0)}$, which is compact by (H1). Set $\psi = \frac{u}{\tilde{\gamma}_\lambda}$. Then $\|\psi\| = 1$ and there exists a compact set K with $\psi \in K$.

Since u solves (3.6), we have

$$\|u + \rho L^{-1}u\| = \lambda\|L^{-1}(\rho u - f(u) + \varepsilon h)\|. \tag{3.8}$$

Denote the left- and right-hand sides of (3.8) by LHS and RHS, respectively. Since $-\rho$ is not an eigenvalue of L, we have $L\psi + \rho\psi \neq 0$ and hence

$$\inf_{\psi \in K} \|\psi + L^{-1}\rho\psi\| = \alpha > 0, \tag{3.9}$$

and therefore for our u we have

$$LHS = \|u + L^{-1}\rho u\| \geq \alpha\tilde{\gamma}_\lambda. \tag{3.10}$$

Now considering RHS, by (H2) and (H5), we have

$$\begin{aligned} RHS &\leq \lambda\|\rho u - f(u) + \varepsilon h\| \\ &\leq \lambda[\varepsilon + \|\rho u - f(u)\|]. \end{aligned}$$

We claim that if ε and $\tilde{\gamma}_\lambda$ are sufficiently small, $RHS < \alpha\tilde{\gamma}_\lambda$, which contradicts (3.10). To establish this, we must first prove the following lemma.

LEMMA 3.4. *Let $f, \mathcal{B}, \rho$ be as in the statement of Theorem 3.3, and let $K \subset \mathcal{B}$ be compact. Then there exists a function $\delta : (0,\infty) \to (0,\infty)$ such that*

(L1) $\|\rho\eta\psi - f(\eta\psi)\| \leq \eta\delta(\eta)$,

(L2) $\delta(\eta) \to 0$ *as* $\eta \to 0$

hold for all $\psi \in K$ and $\eta > 0$.

Proof. Define $\delta : (0,\infty) \to (0,\infty)$ by

$$\delta(\eta) = \max_{\psi \in K} \left\|\rho\psi - \frac{1}{\eta}f(\eta\psi)\right\|, \tag{3.11}$$

and note that (L1) above is satisfied.

To show that (L2) holds, we must show that $\|\rho\psi - \frac{1}{\eta}f(\eta\psi)\| \to 0$ uniformly on K as $\eta \to 0$. Define $f_\eta : K \to \mathbf{R}$ by

$$f_\eta(\psi) = \left\| \rho\psi - \frac{1}{\eta} f(\eta\psi) \right\|. \tag{3.12}$$

To show that $f_\eta \to 0$ uniformly on K, we will show that $f_\eta(\psi) \to 0$ for each $\psi \in K$ and that the family $\mathcal{F} := \{f_\eta\}$ is equicontinuous on K. Choose $\psi \in K$. If $\psi = 0$, then $f_\eta(\psi) = 0$, so assume $\psi \neq 0$. By (H6), we have $\frac{d}{dt}f(t\psi) \mid_{t=0} = \rho\psi$ and hence, given $\tilde{\varepsilon} > 0$, for η sufficiently small, using (H3) and (H6), we have

$$\left\| \frac{1}{\eta} f(\eta\psi) - \rho\psi \right\| < \tilde{\varepsilon}. \tag{3.13}$$

To see that the family $\mathcal{F} = \{f_\eta\}$ is equicontinuous on K, choose $\tilde{\varepsilon} > 0$ and $\psi, \tilde{\psi} \in K$. Using (H4), we have

$$\begin{aligned} |f_\eta(\psi) - f_\eta(\tilde{\psi})| &= \left| \left\| \rho\psi - \frac{1}{\eta} f(\eta\psi) \right\| - \left\| \rho\tilde{\psi} - \frac{1}{\eta} f(\eta\tilde{\psi}) \right\| \right| \\ &\leq \left\| \rho(\psi - \tilde{\psi}) - \frac{1}{\eta}(f(\eta\psi) - f(\eta\tilde{\psi})) \right\| \\ &\leq \rho\|\psi - \tilde{\psi}\| + \frac{1}{\eta} M \|\eta\psi - \eta\tilde{\psi}\| \\ &= (\rho + M)\|\psi - \tilde{\psi}\| < \tilde{\varepsilon}, \end{aligned}$$

provided $\|\psi - \tilde{\psi}\| < \delta := \frac{\tilde{\varepsilon}}{\rho + M}$.

Since $\{f_\eta\}$ are equicontinuous on K and converge pointwise on K, we have that f_η converge uniformly on K, and hence (L2) holds. □

Returning now to the proof of the theorem and invoking the above lemma, we have that

$$\begin{aligned} RHS &\leq \lambda[\varepsilon + \|\rho u - f(u)\|] \\ &\leq \lambda[\varepsilon + \|\rho\tilde{\gamma}_\lambda\psi - f(\tilde{\gamma}_\lambda\psi)\|] \\ &\leq \lambda[\varepsilon + \tilde{\gamma}_\lambda\delta(\tilde{\gamma}_\lambda)]. \end{aligned}$$

Assume now that $\varepsilon < \frac{1}{2}\alpha\tilde{\gamma}_\lambda$. Take $\lambda = 1$. Since $\delta \to 0$, there exists γ such that $x < \gamma$ implies that $\delta(x) < \frac{1}{2}\alpha$. Moreover, for any $\lambda \in (0,1)$, if $x < \gamma$, $\lambda\delta(x) < \frac{1}{2}\alpha$. If $\tilde{\gamma}_\lambda = \|u\| < \gamma$, we have $RHS < \alpha\tilde{\gamma}_\lambda$. But this contradicts (3.10). Thus we conclude that $0 \notin T_\lambda(\partial B_\gamma(0))$ and therefore $deg(T_1, B_\gamma(0), 0) = deg(T_0, B_\gamma(0), 0)$. □

3.2. The proof of Theorem 3.2. Note that by (3.2) and by our choice of $b \in (3, 7)$, $-b$ is *not* an eigenvalue of L_T; moreover, there are no negative eigenvalues of L_T between $\lambda_{10} = -3$ and $\lambda_{21} = -7$.

Define $T_1 : \mathcal{H} \to \mathcal{H}$ by

$$T_1(u) = u - L_T^{-1}(\varepsilon h - b\sin(u))$$

and note that zeros of T_1 correspond to solutions of (3.1). To prove the theorem, we will show

(D1) there exists $R_0 > 0$ such that for $R > R_0$, $deg(T_1, B_R(0), 0) = 1$ and

(D2) there exists $\gamma \in (0, R_0)$ such that $deg(T_1, B_\gamma(0), 0) = -1$.

Then, since $deg(T_1, B_\gamma(0), 0) \neq 0$, there exists a zero of T_1 (i.e., a solution of (3.1)) in $B_\gamma(0)$. Moreover, by the additivity property of degree, $deg(T_1, B_R(0)\backslash\overline{B_\gamma(0)}, 0) \neq 0$ and hence (3.1) has a second solution in the annulus $B_R(0)\backslash\overline{B_\gamma(0)}$.

To establish (D1), define

$$T_\beta u = u - \beta L_T^{-1}(\varepsilon h - b\sin(u))$$

for $\beta \in [0, 1]$, and note that this definition of T_1 is consistent with our previous definition. Note also that T_0 is simply the identity map; hence, for any $R > 0$ we have $deg(T_0, B_R(0), 0) = 1$. The homotopy property of degree ensures that $deg(T_\beta, B_R(0), 0)$ is constant provided that $0 \notin T_\beta(\partial B_R(0))$ for all $\beta \in [0, 1]$.

Fix $\beta \in [0, 1]$ and suppose $u \in \mathcal{H}$ solves $T_\beta u = 0$. We will show that u is bounded above by some $R_0 > 0$ and that this bound is independent of β.

Since $T_\beta u = 0$, we have

$$\begin{aligned}\|u\| &= \beta\|L_T^{-1}(\varepsilon h - b\sin u)\| \leq \beta[\varepsilon_0 + b\|\sin u\|] \\ &\leq [\varepsilon_0 + bm(\Omega)^{\frac{1}{2}}] = [\varepsilon_0 + b\sqrt{2}\pi] < R_0\end{aligned}$$

if we choose $R_0 > \varepsilon_0 + b\sqrt{2}\pi$.

Thus, for $R > R_0$ we have

$$deg(T_1, B_R(0), 0) = deg(T_0, B_R(0), 0) = 1, \tag{3.14}$$

and (D1) above holds.

To establish (D2), let $\varepsilon < \varepsilon_0$; we will determine the value of ε_0 later. For $\mu \in [0, 1]$ define

$$T_\mu u = u + (1 - \mu)L_T^{-1}(bu) - \mu L_T^{-1}(\varepsilon h - b\sin u),$$

and note again that this definition of T_1 is consistent with our previous definitions. We will again apply the homotopy property of degree (via Theorem 3.3) and a standard degree calculation to show that for some $\gamma > 0$

$$deg(T_1, B_\gamma(0), 0) = deg(T_0, B_\gamma(0), 0) = -1.$$

Observe that for $L = L_T$ and $f(u) := b\sin u$, hypotheses (H1)–(H5) of Theorem 3.3 are satisfied. To verify hypothesis (H6), we need to show that

$$df(0, u) = bu. \tag{3.15}$$

By definition of the Gâteaux derivative,

$$\begin{aligned}df(0, u) &= \frac{d}{dt}f(0 + tu)\mid_{t=0} \\ &= \lim_{h\to 0}\frac{f((t+h)u) - f(tu)}{h}\Big|_{t=0} \\ &= \lim_{h\to 0}\frac{b\sin(hu)}{h}.\end{aligned}$$

We will show that the limit above (in $\mathcal{H}$) is bu.

Note first that in $\mathbf{R}$ we have

$$\lim_{h\to 0}\frac{\sin(hu)}{h} = \lim_{h\to 0}\frac{\sin(hu)}{h}\frac{u}{u} = u$$

and hence

$$\left|\frac{\sin(hu)}{h} - u\right|^2 \to 0$$

as $h \to 0$. Invoking the convexity of w^2, we have

$$\left|\frac{\sin(hu)}{h} - u\right|^2 \leq 4\left[\frac{1}{2}\left|\frac{\sin(hu)}{h}\right|^2 + \frac{1}{2}|u|^2\right] \leq 4u^2.$$

Since $u \in \mathcal{L}^2$, $|\frac{\sin(hu)}{h} - u|^2$ is dominated in $\mathcal{L}^1$; thus by the dominated convergence theorem,

$$\left\|\frac{b\sin(hu)}{h} - bu\right\| \to 0$$

as $h \to 0$; therefore (3.15) holds. Moreover, by (3.2) and our choice of b, $-b$ is not an eigenvalue of L_T; therefore hypothesis (H6) of Theorem 3.3 holds. Thus, by Theorem 3.3, for sufficiently small $\gamma, \varepsilon > 0$, we have

$$deg(T_1, B_\gamma(0), 0) = deg(T_0, B_\gamma(0), 0). \tag{3.16}$$

Finally, we will show that

$$deg(T_0, B_\gamma(0), 0) = deg(I + bL_T^{-1}, B_\gamma(0), 0) = -1.$$

Consider the finite dimensional subspace $\mathcal{M}_N$:=span$\{\phi_{mn}\}_1^N$ of $\mathcal{H}$ and recall that, by compactness, bL_T^{-1} can be approximated in operator norm by the operators $B_N : \mathcal{M}_N \to \mathcal{M}_N$ given by

$$B_N(u) = b\sum_{m,n=1}^{N}\frac{c_{mn}}{\lambda_{mn}}\phi_{mn}.$$

By definition of Leray–Schauder degree, for N sufficiently large,

$$\begin{aligned} deg(T_0, B_\gamma(0), 0) &= deg(I + B_N, B_\gamma(0) \cap \mathcal{M}_N, 0) \\ &= \textstyle\sum_{u\in(I+B_N)^{-1}(0)} signJ_{I+B_N}(u), \end{aligned} \tag{3.17}$$

where $J_\phi(u)$ is the Jacobian determinant of ϕ at u.

Since $I + B_N$ can be identified with an $N^2 \times N^2$ diagonal matrix whose entries are $1 + \frac{b}{\lambda_{mn}}$, we have

$$deg(I + B_N, B_\gamma(0) \cap \mathcal{M}_N, 0) = sign\prod_{m,n=1}^{N}\left(1 + \frac{b}{\lambda_{mn}}\right). \tag{3.18}$$

Since $b \in (3, 7)$ and there are no negative eigenvalues of L_T between $\lambda_{10} = -3$ and $\lambda_{21} = -7$, the only negative value of $1 + \frac{b}{\lambda_{mn}}$ occurs at $\lambda_{01} = -3$, which is simple because of our restriction to the subspace $\mathcal{H}$. Therefore,

$$deg(I + B_N, B_\gamma(0) \cap \mathcal{M}_N, 0) = -1$$

and (D2) holds. The proof of the theorem is complete.

Remark 3.5. We note that the theorem holds for other ranges of b. The proof follows exactly; we need only check that, in verifying (D2), we have

$$deg(T_0, B_\gamma(0), 0) = deg(I + bL_T^{-1}, B_\gamma(0), 0) = -1.$$

From (3.17) and (3.18), we see that this amounts to ensuring that $1 + \frac{b}{\lambda_{mn}} < 0$ an odd number of times. For example, if $b \in (11, 15)$, $1 + \frac{b}{\lambda_{mn}} < 0$ for $\lambda_{10} = -3$, $\lambda_{21} = -7$, and $\lambda_{32} = -11$, and the theorem holds. Similarly, if $b \in (15, 19)$, $1 + \frac{b}{\lambda_{mn}} < 0$ for $\lambda_{10}, \lambda_{21}, \lambda_{32}$, and $\lambda_{43} = \lambda_{20} = -15$. (One can verify that there are no other m, n such that $\lambda_{mn} = -15$.)

Remark 3.6. We note that the theorem holds if we change the operator from $L_T u = u_{tt} - u_{xx}$ to $Lu = u_{tt} - au_{xx}$, the domain Ω from $(0, \pi) \times (0, \pi)$ to $(0, \sqrt{a}\pi) \times (0, \pi)$, and adjust the spatial symmetry requirement in the definition of the subspace $\mathcal{H}$ appropriately.

3.3. Continuity of solutions. In this section we prove that, under an additional assumption on the forcing term $h(x, t)$, solutions $u \in \mathcal{H}$ to (3.1) are continuous.

We denote by $\mathcal{H}^m(\Omega)$ or $\mathcal{H}^m$ the Sobolev space $W^{m,2}(\Omega) = \{u | D^\alpha u \in \mathcal{L}^2(\Omega), |\alpha| \leq m\}$, where D^α is a weak derivative. We equip this space with the standard inner product

$$(f, g) = \sum_{|\alpha| \leq m} \int_\Omega D^\alpha f D^\alpha g dA$$

and the norm induced by this inner product.

LEMMA 3.7. *Let the region Ω and the operator L_T^{-1} be as defined above.*

1. *If $w \in \mathcal{L}^2(\Omega)$, then $L_T^{-1} w \in \mathcal{H}^1(\Omega)$.*
2. *If $w \in \mathcal{H}^1(\Omega)$, then $L_T^{-1} w \in \mathcal{H}^2(\Omega)$.*
3. *If $w \in \mathcal{H}^2(\Omega)$, then $w \in \mathcal{C}(\Omega)$.*
3. *If $w \in \mathcal{H}^1(\Omega)$, then $\sin w \in \mathcal{H}^1(\Omega)$.*

Proof. Let $w = \sum_{m,n=0}^{\infty} c_{mn} \phi_{mn} \in \mathcal{L}^2$. It is straightforward to verify that the $\mathcal{L}^2, \mathcal{H}^1$, and $\mathcal{H}^2$ norms of w are given by

$$\begin{aligned} \|w\|_{\mathcal{L}^2}^2 &= \sum c_{mn}^2 < \infty, \\ \|w\|_{\mathcal{H}^1}^2 &= \sum [(2n+1)^2 + (2m)^2] c_{mn}^2, \\ \|w\|_{\mathcal{H}^2}^2 &= \sum [(2n+1)^2 + (2m)^2]^2 c_{mn}^2, \end{aligned}$$

respectively.

1. Let $w = \sum c_{mn} \phi_{mn} \in \mathcal{L}^2$. Then $L_T^{-1} w = \sum \frac{c_{mn}}{\lambda_{mn}} \phi_{mn}$ and

$$\begin{aligned} \|L_T^{-1} w\|_{\mathcal{H}^1}^2 &= \sum [(2n+1)^2 + (2m)^2] \left| \frac{c_{mn}}{\lambda_{mn}} \right|^2 \\ &= \sum \frac{(2n+1)^2 + (2m)^2}{[(2n+1)^2 - (2m)^2]^2} c_{mn}^2 < \infty \end{aligned}$$

since

$$\frac{(2n+1)^2 + (2m)^2}{[(2n+1)^2 - (2m)^2]^2} \leq 1$$

and $\sum c_{mn}^2 < \infty$.

2. This proof is analogous to the proof of (1).
3. See, for example, [1].
4. Let $w \in \mathcal{H}^1$. Then $w, w_t, w_x \in \mathcal{L}^2$; we must show that $\sin w, (\sin w)_t, (\sin w)_x \in \mathcal{L}^2$.

$$\|\sin w\|_{\mathcal{L}^2}^2 = \int_\Omega |\sin w|^2 < \infty$$

since Ω is bounded.

$$\|(\sin w)_t\|_{\mathcal{L}^2}^2 = \int_\Omega |w_t \cos w|^2 \leq \int_\Omega |w_t|^2 < \infty$$

since $w_t \in \mathcal{L}^2$. Similarly, $(\sin w)_x \in \mathcal{L}^2$, and the result follows. □

THEOREM 3.8. *Let $h \in \mathcal{H}^1$, and let $u \in \mathcal{H}$ solve* (3.1). *Then $u \in \mathcal{C}(\Omega)$.*

Proof. The result follows from repeated application of Lemma 3.7. Since $\varepsilon h - b \sin u \in \mathcal{L}^2$, we have $u = L_T^{-1}(\varepsilon h - b \sin u) \in \mathcal{H}^1$. Since $u \in \mathcal{H}^1$, we have $\sin u \in \mathcal{H}^1$, and therefore $h \in \mathcal{H}^1$ implies $\varepsilon h - b \sin u \in \mathcal{H}^1$. It follows then that $u = L_T^{-1}(\varepsilon h - b \sin u) \in \mathcal{H}^2$ and therefore $u \in \mathcal{C}(\Omega)$. □

4. The bifurcation curve of periodic solutions.

In section 3 we considered the forced sine-Gordon equation on a bounded domain, which models the torsional motion of the center span of a suspension bridge, and proved that, under certain assumptions on the physical constants, multiple periodic solutions exist. In this section, we compute periodic solutions to the damped equation and examine their bifurcation properties as the amplitude of the forcing term varies. More specifically, we employ numerical continuation algorithms by which we plot the amplitude of a periodic solution versus the amplitude λ of the external forcing term. We demonstrate that for small λ, multiple periodic solutions to the equation exist. Moreover, we demonstrate that bifurcation from single to multiple periodic solutions occurs for small λ.

Recall from section 2 that the equation that governs the torsional motion along the length of the center span is given by

$$(4.1) \qquad \left\{ \begin{array}{c} \theta_{tt} - \varepsilon_1 \theta_{xx} = -\frac{6K}{m} \cos\theta \sin\theta - \delta\theta_t + h_1(x,t) \\ \theta(0,t) = \theta(L,t) = 0 \end{array} \right\}.$$

For our numerical study of this equation, we must choose the values of the constants $L, m, K, \delta, \varepsilon_1$ and the external forcing term $h_1(x,t)$.

4.1. The choice of physical constants and external forcing.

The length of the span was $L = 1000$ meters [2]; let us normalize the equation so that we can work on the domain $x \in [0,1]$. The rescaled equation is

$$(4.2) \qquad \left\{ \begin{array}{c} \theta_{tt} - \frac{\varepsilon_1}{L^2} \theta_{xx} = -\frac{6K}{m} \cos\theta \sin\theta - \delta\theta_t + h_1(Lx,t) \\ \theta(0,t) = \theta(1,t) = 0 \end{array} \right\}.$$

To determine the physical constants $m, K, \delta, \varepsilon_1$ and the external forcing term $h_1(x,t)$, we rely on [2], [9], and [17]. We choose $m = 2500$ and $\delta = .01$. To determine K, we know from [2] that the main span would deflect about half a meter when loaded with 100 kgs per unit length, so we have $100(9.8) - 2K(.5) = 0$ and we take $K = 1000$. The roadbed of the Tacoma Narrows was extremely flexible, so we choose $\frac{\varepsilon_1}{L^2} = .01$ and observe that this value produces the appropriate flexibility in our numerical solutions.

For a cross section similar to the Tacoma Narrows bridge, wind tunnel experiments indicate that aerodynamic forces should induce approximately sinusoidal oscillations of amplitude three degrees [17], so in (4.2) we choose h_1 to be sinusoidal in time. We take $h_1(x,t) = \lambda \sin(\mu t)\rho(x)$, where $\lambda \in [0, 0.06]$ is chosen to produce the appropriate behavior near equilibrium and the frequency μ is chosen to match the frequency of the oscillations observed at Tacoma Narrows on the day of the collapse. The frequency of the torsional motion was approximately one cycle every 4 or 5 seconds, so we take $\mu \in [1.2, 1.6]$. Thus, (4.2) becomes

$$\left\{ \begin{array}{c} \theta_{tt} - .01\theta_{xx} = -2.4\cos\theta\sin\theta - .01\theta_t + \lambda\sin(\mu t)\rho(x) \\ \theta(0,t) = \theta(1,t) = 0 \end{array} \right\}. \tag{4.3}$$

Remark 4.1. Using $\cos\theta\sin\theta = \frac{1}{2}\sin 2\theta$ and rescaling (4.3), we see that the magnitude of the nonlinear term is $b = 2.4$. Note, however, that Theorem 3.2 does not apply to this problem because of the damping term in (4.3) and the fact that the theorem requires a relationship between the wave speed and the spatial domain that is not satisfied by the physical problem (4.3) (see Remark 3.6). However, as the following experiments demonstrate, the physical problem (4.3) exhibits the multiple solution behavior guaranteed by Theorem 3.2 for the theoretical problem (3.1).

The torsional motion observed on the day of the collapse was, for the most part, one-noded (i.e., no torsional displacement in the middle of the span). Occasionally, the motion changed to no-noded twisting and back again to one-noded. Thus, we take $\rho(x) = 1, \rho(x) = \sin(2\pi x)$, or $\rho(x) = \sin(\pi x)$.

4.2. The numerical results for the forced, damped sine-Gordon equation. In this section, we apply a numerical continuation algorithm to the boundary value problem (4.3) for several different forcing terms:

$$h_1(x,t) = \lambda\sin(\mu t)\rho(x).$$

Numerical continuation algorithms are described in [3], [8], and [15]; we refer the reader to these sources for details.

In each case, we find that if $\mu \in [1.2, 1.5]$, the path of periodic solutions is S-shaped and that bifurcation from single to multiple periodic solutions occurs at a small value of $\lambda = \underline{\lambda}$. Moreover, we observe that $\underline{\lambda}$ decreases as the forcing frequency μ increases.

If μ is greater than the resonant frequency $\hat{\mu}$ of the linearized PDE

$$\theta_{tt} - \varepsilon\theta_{xx} + \delta\theta_t + 2.4\theta = \lambda\sin(\mu t)\rho(x),$$

the amplitude of the periodic solution increases with λ, but bifurcation from single to multiple solutions does not occur. This is consistent with our earlier results for the simpler ODE model [10], [15]. We note that for the space independent, one-noded, and no-noded forcing terms given in section 4.1 above, the resonant frequencies of the linearized PDE are $\hat{\mu} \approx 1.55, \hat{\mu} \approx 1.67$, and $\hat{\mu} \approx 1.58$, respectively.

Forcing independent of x. $h_1(x,t) = \lambda\sin(\mu t)$.

1. Experiment 4.1. $\mu = 1.3, \mu = 1.4, \mu = 1.5$; see Figure 4.1(a). The bifurcation curves are S-shaped, and bifurcation from single to multiple solutions occurs for small $\lambda = \underline{\lambda}$. For example, in Figure 4.1 we see that for $\mu = 1.3$ (the solid curve), a unique small amplitude periodic solution exists for $\lambda < \underline{\lambda} \approx .022$ and $\lambda > \overline{\lambda} \approx .247$ but that three periodic solutions, one of small amplitude and two of large amplitude, exist for $\lambda \in (\underline{\lambda}, \overline{\lambda})$. Whether the small or large

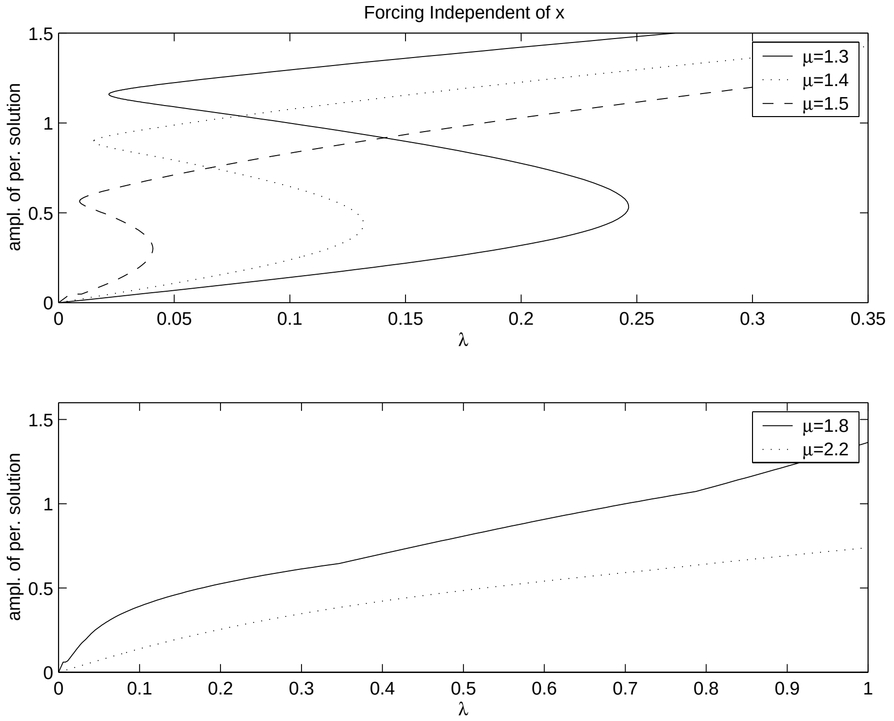

FIG. 4.1. *Experiments* 4.1 *and* 4.2. *At the lower frequencies, there are three periodic solutions under small fixed forcing, one of small amplitude and two of large amplitude. At the higher frequencies, bifurcation from single to multiple periodic solutions does not occur.*

amplitude solution results depends on the initial displacement and velocity of the span. For example, for $\mu = 1.3$, $\lambda \approx 0.047$, under a small initial displacement (approximately 0.003 radians in amplitude), a small amplitude periodic solution results (approximately 0.065 radians). However, under a large initial displacement (approximately 0.720 radians), a large periodic solution results (approximately 1.221 radians). Moreover, we observe that $\underline{\lambda}$, the frequency at which bifurcation from single to multiple periodic solutions occurs, decreases as μ increases.

2. Experiment 4.2. $\mu = 1.8, \mu = 2.2$; see Figure 4.1(b). The amplitude of the periodic solution increases with λ, but bifurcation from single to multiple solutions does not occur. Moreover, we observe that the growth in the amplitude of the periodic solution is slower at the higher frequency. This is consistent with our earlier results for the simpler ODE model [10], [15].

One-noded forcing. $h_1(x,t) = \lambda \sin(\mu t) \sin(2\pi x)$.

1. Experiment 4.3. $\mu = 1.3, \mu = 1.4, \mu = 1.5$; see Figure 4.2(a). Again, the bifurcation curves at these frequencies are S-shaped and our results are consistent with those in Experiment 4.1.
2. Experiment 4.4. $\mu = 1.6, \mu = 1.8, \mu = 2.2$; see Figure 4.2(b). As in Experiment 4.2, we see that the amplitude of the periodic solution grows with λ and that the growth is slower for the higher frequencies. Moreover, for $\mu = 1.6$, we see that multiple periodic solutions exist for a small range of λ. (Recall though that $1.6 < \hat{\mu} \approx 1.67$, the resonant frequency for the linearized PDE.)

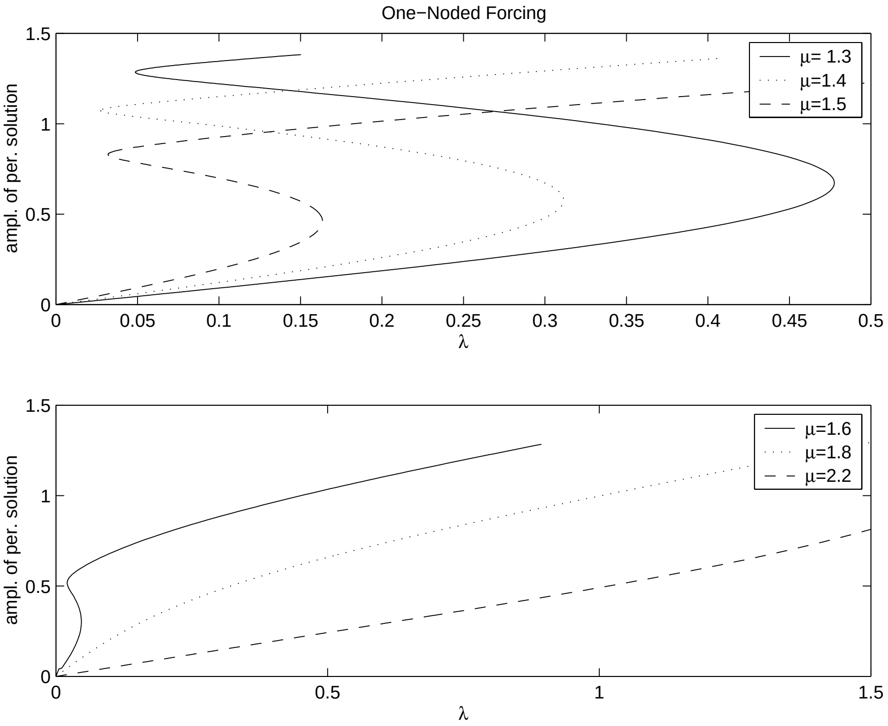

FIG. 4.2. *Experiments* 4.3 *and* 4.4. *As in Experiments* 4.1 *and* 4.2, *at the lower frequencies, bifurcation from single to multiple periodic solutions occurs for small periodic forcing.*

No-noded forcing. $h_1(x,t) = \lambda \sin(\mu t)\sin(\pi x)$.

1. Experiment 4.5. $\mu = 1.3, \mu = 1.4, \mu = 1.5$. Again, the bifurcation curves at these frequencies are S-shaped. As this is consistent with our results in Experiments 4.1 and 4.3, we do not show the bifurcation curves here.
2. Experiment 4.6. $\mu = 1.6, \mu = 1.8, \mu = 2.2$. As in Experiments 4.2 and 4.4, the amplitude of the periodic solution increases with λ, but bifurcation from single to multiple solutions does not occur. Again, the growth in the amplitude of the periodic solution is slower at the higher frequencies. As these results are similar to the earlier experiments, we do not show the figures here.

5. Dynamic response to initial conditions. In section 4, we demonstrated that if $\mu \in [1.2, 1.5]$, under fixed periodic forcing $h_1(x,t) = \lambda \sin(\mu t)\rho(x)$, (4.3) has three periodic solutions: one of small amplitude and two of large amplitude. In this section, we will examine the structural properties of these solutions numerically. More specifically, we will compute solutions to the boundary value problem (4.3) under the initial conditions

$$\begin{aligned} \theta(x,0) &= \xi(x), \\ \theta_t(x,0) &= \eta(x) \end{aligned} \tag{5.1}$$

via finite difference methods. The periodic solution results as the long term solution to the initial value problem; i.e., the span "settles down" to periodic oscillation. As in section 4, we choose $\rho(x) = 1, \rho(x) = \sin(2\pi x)$, or $\rho(x) = \sin(\pi x)$.

Our finite difference scheme is implicit in the linear terms and explicit in the nonlinear terms. We solve the initial value problem (4.3), (5.1) over 400 periods of the forcing term; i.e., for $(x,t) \in [0,1] \times [0, 400\tau]$, where $\tau = \frac{2\pi}{\mu}$. In each experiment we use 520 time steps per period of the forcing term ($\Delta t = \frac{1}{520}\tau$) and we take $\Delta x = .025$.

We define

$$\begin{aligned} a &= \text{amplitude of the initial displacement } \xi(x), \\ a_p &= \text{amplitude of the resulting periodic solution.} \end{aligned}$$

In the experiments that follow we observe that, if $\mu \in [1.2, 1.5]$, under *fixed* periodic forcing $h_1(x,t) = \lambda \sin(\mu t)\rho(x)$, small or large amplitude behavior may result depending only on the initial displacement and velocity of the span. Thus, the effect of a large initial displacement may *not* damp away as in the linear case. Moreover, we find that the amplitude a_p of the periodic response is extremely sensitive to slight changes in the amplitude a of the initial displacement and that a_p does not depend on a in an intuitive way; for example, it does not increase with a. Finally, we observe that the qualitative properties such as amplitude, frequency, and nodal structure of our large amplitude solutions are consistent with the behavior observed at Tacoma Narrows on the day of its collapse.

5.1. The experiments. One-noded forcing and initial conditions. The most prevalent motion observed at Tacoma Narrows was one-noded (no displacement at the center of the span) [2], so let us consider external forcing of the form

$$h_1(x,t) = \lambda \sin(\mu t)\sin(2\pi x)$$

and initial conditions of the form

$$\theta(x,0) = \theta(x,\Delta t) = a\sin(2\pi x).$$

Experiment 5.1. $\lambda = .06, \mu = 1.4$.

- **5.1a.** $\theta(x,0) = \theta(x,\Delta t) = .9\sin(2\pi x)$; see Figure 5.1. Despite the large initial displacement, we see in Figure 5.1 that by periods 390 through 400 of the forcing term, the span has settled down to one-noded, periodic oscillation of small amplitude (approximately .072 radians).
- **5.1b.** $\theta(x,0) = \theta(x,\Delta t) = 1.0\sin(2\pi x)$; see Figure 5.2. We have increased the amplitude a of the initial displacement only slightly from 5.1a, but we see in Figure 5.2 that this small change has a dramatic impact on the motion of the span. As in 5.1a, by periods 390 through 400 of the forcing term, the span has settled down to periodic oscillation. But instead of settling to near equilibrium behavior, as in 5.1a, the amplitude of the oscillation is approximately 1.117 radians. Again, we note that this is close to the amplitude observed at Tacoma Narrows on the day of the collapse [2].
- **5.1c.** See Figure 5.3. Based on our results in Experiments 5.1a and 5.1b, it is tempting to conjecture that the amplitude a_p of the periodic solution increases with the amplitude a of the initial displacement, but this is not the case. Figure 5.3 shows the amplitude a_p of the periodic solution versus the amplitude a of the initial displacement of the span for $a \in [0, 1.7]$. We see in Figure 5.3 that the amplitude of the long term periodic response depends on the amplitude of the initial displacement in an unpredictable way. This is consistent with results for a simple nonlinear ODE model for the vertical

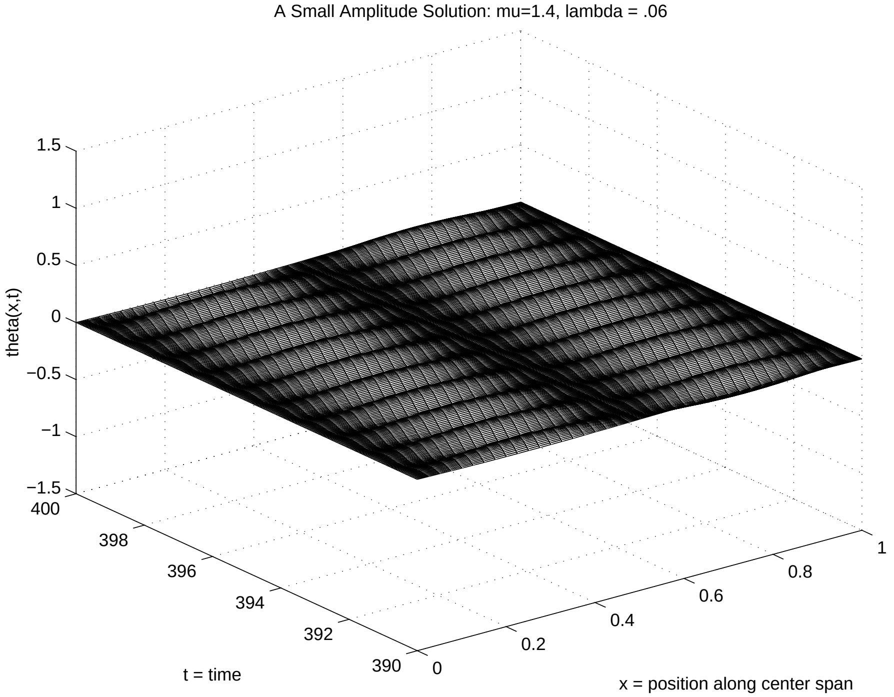

FIG. 5.1. *Experiment* 5.1a.

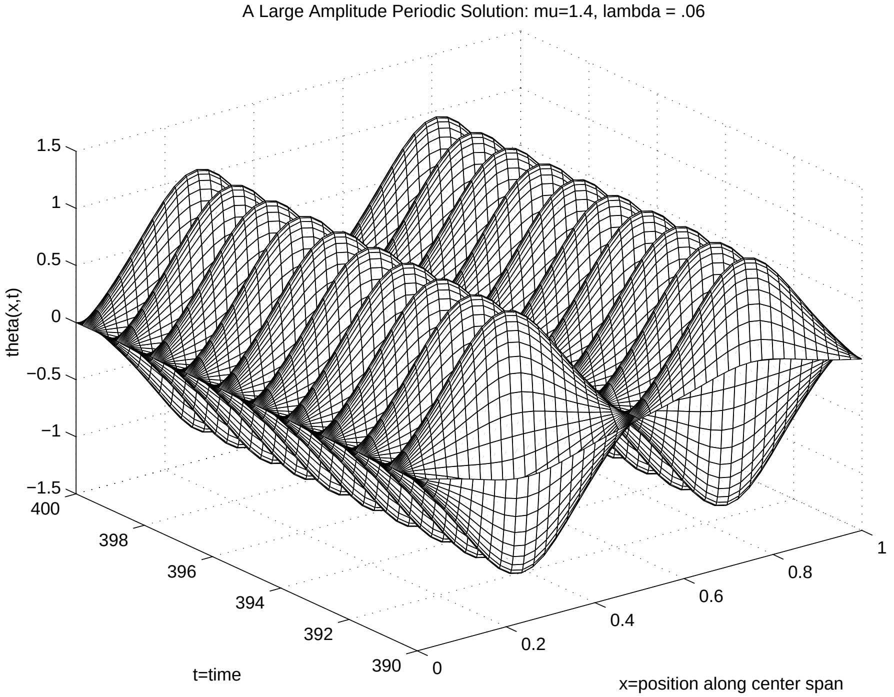

FIG. 5.2. *Experiment* 5.1b.

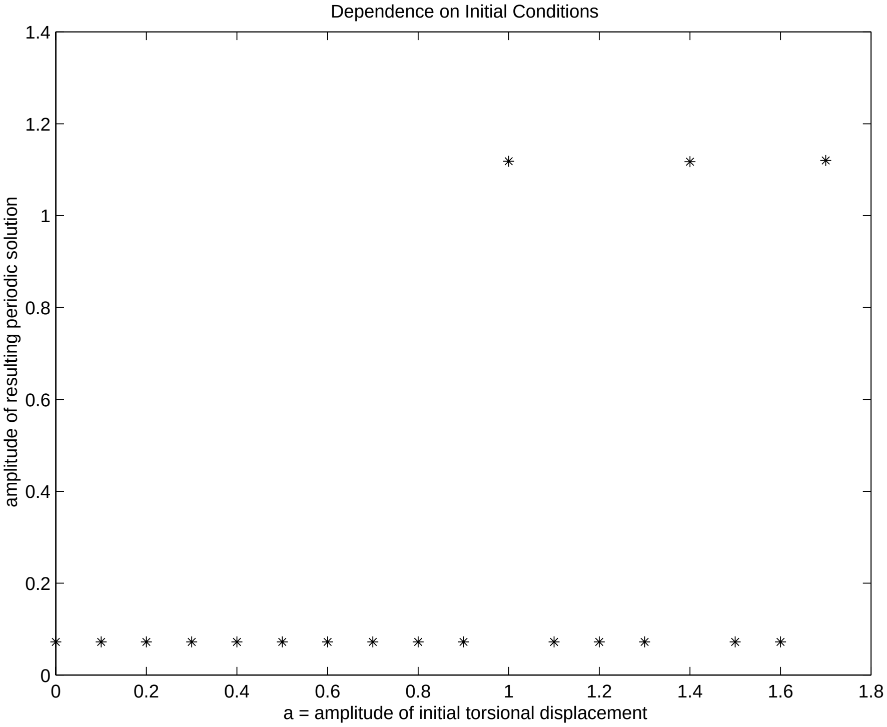

FIG. 5.3. *Experiment* 5.1c.

motion of a suspension bridge [7]. We note that in Figure 5.3, the small solutions correspond to the "bottom branch" of the bifurcation curve in Figure 4.2(a) and the large solutions correspond to the "top branch."

Forcing that depends only on time. We also considered the response of the main span to small, time dependent forcing which is constant along the length of the span, specifically,

$$h_1(x,t) = \lambda \sin(\mu t)$$

and initial conditions of the form

$$\theta(x,0) = \theta(x,\Delta t) = a\sin(2\pi x).$$

Experiment 5.2. $\lambda = .04, \mu = 1.4$. As these results are consistent with those in Experiment 5.1, we do not show the figures; we simply describe the results.

- **5.2a.** $\theta(x,0) = \theta(x,\Delta t) = .5\sin(2\pi x)$. Despite the large initial displacement, by periods 390 through 400 of the forcing term, the span has settled down to no-noded, periodic oscillation of small amplitude (approximately .086 radians).
- **5.2b.** $\theta(x,0) = \theta(x,\Delta t) = .6\sin(2\pi x)$. We have increased the amplitude a of the initial displacement only slightly from 5.2a, but this small change has a dramatic impact on the motion of the span. As in 5.2a, by periods 390 through 400 of the forcing term, the span has settled down to periodic oscillation. But instead of settling to near equilibrium behavior, as in 5.2a, the amplitude of the oscillation is approximately .969 radians. Again, this

is close to the amplitude observed at Tacoma Narrows on the day of the collapse [2].

No-noded forcing and initial conditions. Although the most prevalent mode of torsional oscillation observed at Tacoma Narrows was the one-noded motion described above, occasionally the motion would change to no-noded oscillation [2], so we also studied external forcing of the form

$$h_1(x,t) = \lambda \sin(\mu t) \sin(\pi x)$$

and initial conditions of the form

$$\theta(x,0) = \theta(x,\Delta t) = a \sin(\pi x).$$

As in the previous experiments, small changes in the amplitude of the initial displacement led to dramatic differences in the resulting periodic solution. Indeed, when we *decreased* the amplitude of the initial displacement from 1.2 to 1.1, the amplitude of the resulting periodic solution *increased* from .0248 to 1.171 radians [15].

Solutions that change nodal structure. According to eyewitnesses, the torsional oscillations that preceded the collapse of the Tacoma Narrows were, for the most part, one-noded. Occasionally, the motion would change to no-noded and then back to one-noded [2]. In this experiment, we replicate this phenomenon by a slight perturbation in the forcing term.

Experiment 5.4. $\lambda = .06, \mu = 1.4$; see Figure 5.4. We begin with a large initial displacement

$$\theta(x,t) = \theta(x,\Delta t) = 1.4 \sin(2\pi x)$$

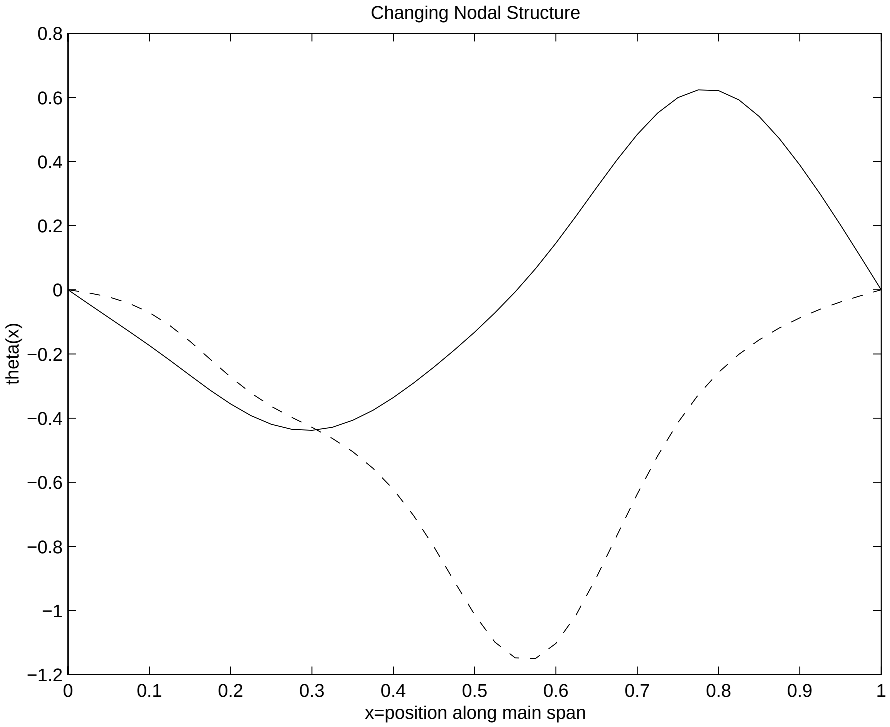

FIG. 5.4. *Experiment* 5.4, *fixed t.*

and apply forcing of the form

$$h_1(x,t) = \lambda \sin(\mu t)[\sin(2\pi x) + .01 \sin(\pi x)].$$

In this case, a complicated motion results. Figure 5.4 shows the angular displacement along the length of the span at two different points in time; the solid curve describes one-noded oscillation while the dashed curve has no nodes.

6. Conclusion and open questions. We have demonstrated theoretically and numerically that the equation that governs the torsional motion of a suspension bridge has multiple periodic solutions; whether small or large amplitude motion results depends on the initial displacement and velocity of the span. Thus, once a large torsional motion starts, it may persist over a long time.

It is natural to ask what might induce such a large initial torsional displacement in a suspension bridge. In studying coupled systems of the form (2.1) numerically, we find that a large vertical motion, in the presence of *tiny* torsional forcing and initial conditions, may induce a rapid transition from vertical to torsional motion [9], [11], [12], [15]. Such a phenomenon was observed at Tacoma Narrows on the day of its collapse [2].

Beyond the results presented here, several interesting questions remain. For example, we proved the existence of multiple periodic solutions to the undamped equation; under appropriate hypotheses on the forcing term, does a similar result hold for the damped equation? Moreover, we proved the existence of at least two periodic solutions, but our numerical results in section 4 suggest that three periodic solutions exist. Can the existence of the third solution be proven?

Acknowledgments. This paper is part of the author's thesis work; she gratefully acknowledges her thesis advisor P. J. McKenna for his guidance. The author also thanks the anonymous referee for the valuable comments and suggestions.

A FREE BOUNDARY PROBLEM IN DERMAL DRUG DELIVERY[*]

JÁN FILO[†] AND VOLKER PLUSCHKE[‡]

Abstract. In this paper we study a free boundary problem in a multicomponent domain. Our study was motivated by the mathematical modeling of dermal and transdermal drug delivery, where the multilayered skin model was considered. At the interface connecting two components the conservation of the flux and Nernst's distribution law hold and it is supposed that in any component there is a positive minimum concentration at which the diffusion front can proceed. The existence of a solution and uniqueness in special cases are shown.

Key words. free boundary problem, nonlinear diffusion, multicomponent domain, existence, uniqueness

1. Introduction.

Let Ω^i, $i = 1, \dots, k$, $k \geq 2$, be disjoined bounded Lipschitz domains in $\mathbb{R}^N$, $N \geq 1$, with $\bar{\Omega}^i \cap \bar{\Omega}^j = \emptyset$ if $|j-i| > 1$ and

$$\bar{\Gamma}^i \equiv \partial\Omega^i \cap \partial\Omega^{i+1} \qquad \text{for } i = 1, \dots, k-1.$$

Here $\bar{\Gamma}^i$ denotes the closure of a nonempty and relatively open set Γ^i in $\partial\Omega^i$.

In this paper we study the singular parabolic problem

$$\partial_t b^i(u^i) = \Delta u^i \qquad \text{in } \Omega^i \times (0,T) \tag{1.1}$$

with contact conditions on the interfaces

$$\partial_{\nu_i} u^i + \partial_{\nu_{i-1}} u^{i-1} = 0 \quad \text{and} \quad u^i = \psi^{i-1}(u^{i-1}) \qquad \text{on } \Gamma^i \times (0,T) \tag{1.2}$$

and boundary and initial conditions

$$u^i = 0 \qquad \text{on } \Gamma^k \times (0,T), \tag{1.3}$$

$$\partial_{\nu_i} u^i = 0 \qquad \text{on } \mathcal{T}^i \times (0,T), \tag{1.4}$$

$$b^i(u^i) = b_0^i \qquad \text{on } \Omega^i \times \{t=0\}, \tag{1.5}$$

$i = 1, \dots, k$, where Γ^k is a part of $\partial\Omega^k \setminus \Gamma^{k-1}$ that is not excluded to be empty, $\mathcal{T}^i \equiv \partial\Omega^i \setminus \Gamma^i \cup \Gamma^{i-1}$ where we set $\Gamma^0 = \emptyset$. Moreover, ν_i denotes the outer unit normal to $\partial\Omega^i$ and $\partial_\nu u \equiv \nabla u \cdot \nu$, $\partial_t = \partial/\partial t$.

The nonlinearity $b^i(\cdot)$ in (1.1) represents a maximal monotone graph in $\mathbb{R} \times \mathbb{R}$ given by

$$b^i(u) = \beta^i(u) + \Lambda^i \vartheta(u)\,, \qquad \vartheta(u) \equiv \begin{cases} 1, & u > 0, \\ [0,1], & u = 0, \\ 0, & u < 0. \end{cases} \tag{1.6}$$

Here $\Lambda^i \geq 0$ are given constants and β^i are continuous monotone increasing functions a.e. differentiable and such that

$$0 < \iota \leq (\beta^i)'(u) < \infty \qquad \text{if } u > 0 \tag{1.7}$$

for a given positive constant ι, $\beta^i(0) = 0$, $i = 1, \dots, k$. $\psi^i : \mathbb{R} \to \mathbb{R}$ are again monotone increasing functions a.e. differentiable and

$$0 < \kappa \leq (\psi^i)' \leq K \tag{1.8}$$

for two positive constants κ, K and $\psi^i(0) = 0$.

As it is seen in (1.6), if $\Lambda^i > 0$, we allow b^i to have jumps. The special cases, however, the standard parabolic equations, that is, $b^i(u) = k^i u$ for $k^i > 0$, and the porous medium type equations (see [2]), e.g.,

$$b^i(u) = |u|^{1/m_i} \operatorname{sign} u \,, \quad m_i > 1 \,,$$

are also included. In both cases, $\Lambda_i = 0$.

As our main goal is to deal with a free boundary problem, the simplest model case a reader can have in mind is the two component system in one space dimension, i.e., $k = 2$, $N = 1$, and we set $\Omega^1 = (0, l_1)$, $\Omega_2 = (l_1, l_2)$. Let us look at a situation in which u^i have a particularly simple structure. Nevertheless, let us in fact formulate a problem for functions $c^i(x,t)$ and $s(t)$ first. Assume a curve

$$\{(x,t) : x = s(t),\ t \in [0,T]\}$$

for monotone increasing function $s : [0,T] \to (0, l_2]$ such that $0 < s(0) < l_1$, $s(t^*) = l_1$ for some $t^* \in (0,T)$, and $s(T) = l_2$ is given. Functions c^i are supposed to satisfy the following:

$$\begin{aligned} &\partial_t c^1 = D^1 c^1_{xx}, && 0 < x < \min\{s(t), l_1\},\ 0 < t \leq T\,, \\ &c^1_x(0,t) = 0, && 0 < t \leq T\,, \\ &c^1(x,0) = c^1_0(x) > \lambda^1, && 0 < x < s(0)\,, \\ &\partial_t c^2 = D^2 c^2_{xx}, && l_1 < x < s(t),\ t^* < t \leq T, \end{aligned} \tag{1.9}$$

and the moving boundary condition

$$c^i(s(t),t) = \lambda^i \,, \qquad \lambda^i \dot{s}(t) = -D^i c^i_x(s(t),t) \tag{1.10}$$

with positive constants D^i, λ^i, where $0 < t < t^*$ if $i = 1$ and $t^* < t < T$ if $i = 2$, respectively, in (1.10). In addition to the Stefan problem in one component we require a nonlinear contact condition on the interface $x = l_1$,

$$\begin{aligned} &c^2(l_1,t) = g\left(c^1(l_1,t)\right), \\ &D^1\, c^1_x(l_1,t) = D^2\, c^2_x(l_1,t), \end{aligned} \qquad t^* < t \leq T\,, \tag{1.11}$$

(for motivation see section 2) where g is a given increasing function such that $g(\lambda^1) = \lambda^2$. Now the following question arises. Having given the data, can we find functions $c^i(x,t), s(t)$ and positive T such that (1.9)–(1.11) are satisfied? In this paper we do not deal with the classical solvability of this problem; instead, we study weak solutions of (1.1)–(1.5). However, problem (1.9)–(1.11) can be rewritten into the first one using the idea of reformulation of the classical Stefan setting into an enthalpy formulation; see, e.g., [13]. So we get the corresponding one-dimensional form of problem (1.1)–(1.5) for $\Lambda^i = \lambda^i$, $u^i = c^i - \lambda^i$ and linear β^i.

Our original aim was to prove the existence and uniqueness for this problem. Nevertheless, uniqueness for the original problem turns out to be difficult and we are able to show uniqueness only for a problem where regular $b^i(\cdot)$ are considered. The paper is organized as follows. It starts in section 2 with derivation of the mathematical model of dermal and transdermal drug delivery, as introduced in [12]. Section 3 contains the existence and uniqueness result for the regularized problem, where the graph $b^i(\cdot)$ is replaced by a monotone Lipschitz continuous regularization $b^i_\varepsilon(\cdot)$ and boundary conditions (1.2) are regularized in the natural way as

$$\begin{aligned} \partial_{\nu_{i-1}} u^{i-1} + n\left(\psi^{i-1}(u^{i-1}) - u^i\right) &= 0, \\ \partial_{\nu_i} u^i + n\left(u^i - \psi^{i-1}(u^{i-1})\right) &= 0, \end{aligned} \qquad \text{on} \quad \Gamma^{i-1} \times (0,T)\,, \tag{1.12}$$

where $0 < \varepsilon \ll 1$ and $1 \ll n$.

Assumptions and the statement of the existence theorem of our original problem (1.1)–(1.5) are given in section 4. Finally in section 5 the uniqueness result for the related nonlinear diffusion problem is discussed.

In recent years questions like global solvability, uniqueness, and qualitative behavior of solutions for nonlinear parabolic problems including the Stefan problem have attracted considerable interest. There is also a vast amount of literature that covers our result in case of a single domain; see, e.g., [1], [13], [4], [9], and references therein for existence results and, e.g., [1], [4], [6], [8] for uniqueness. Should we restrict ourselves to parabolic problems on multicomponent domains with a nonlinear contact condition on the interface, that in our case is nonlinear Nernst's law (1.2), then we find that these have not been studied to that extent. See [11] or [10], where linear parabolic equations with contact conditions (1.2) and conditions of the type (1.12), respectively, for the special case $\psi^i(u) = u$ are investigated. But, as far as we know, the nonlinear parabolic problem on a multicomponent domain with jump conditions on the interface between two components has not been studied in connection with the free boundary problem. Most methods that we apply are known; nevertheless, their applications to the difficult problem that comes from the application [12] seem to be not straightforward. To prove existence of a weak solution to our free boundary problem we follow the ideas of Alt and Luckhaus [1]. It is more appropriate for our contact condition than the methods of Meirmanov [13], where the equation is written in terms of $U = b(u)$ and all derivatives are given to the test function. However, to derive a priori estimates for the regularized problem it is not possible to test with u^i on all components like in [10], or in case of one component [1], since the integrals arising from boundary condition (1.12) do not provide nonnegative items. Therefore, in sections 3 and 5 we use the dual problem to derive L^1-estimates, and in section 4 we adopt some ideas from Carrillo [4] to test with nonlinear functions in terms of u.

We finish this section by introducing some notation. In what follows, if necessary, we shall consider any function $u(x)$ defined almost everywhere on some open set $\Omega \subset \mathbb{R}^N$, $u \in H^1(\Omega)$ to be extended outside of Ω (and denoted again by u) such that $\|u\|_{H^1(\mathbb{R}^N)} \le C\|u\|_{H^1(\Omega)}$ with C independent of u. Due to the result of Calderon–Stein (see, e.g., [14]) this is possible if $\partial\Omega$ is Lipschitz. By $\langle \cdot\,, \cdot \rangle$ we denote the duality between $H^1(\Omega)$ and $H^{-1}(\Omega)$. The function spaces we use are rather familiar and we omit the definition (see, e.g., [14]). To keep the notation short we set $V_i \equiv H^1(\Omega^i)$ and $V = V_1 \times \cdots \times V_k$. $\tilde V \subset V$ denotes the subspace $\tilde V = \{v = (v^1, \ldots, v^k) \in V :$

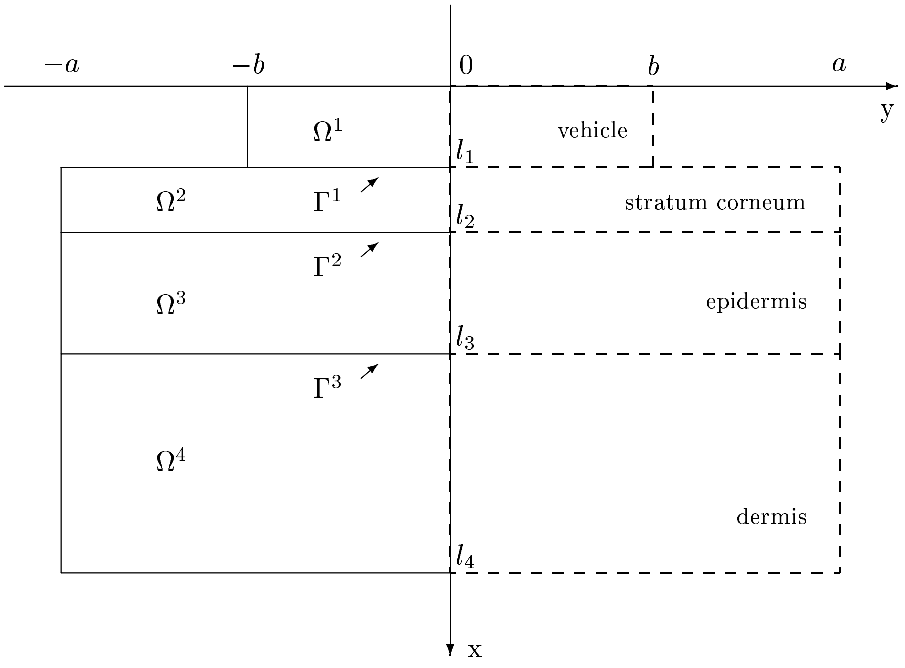

FIG. 1. *The multilayer skin model.* $l_2, \dots, l_4$ *are chosen in accordance with the thickness of the skin layers;* l_1 *represents the application thickness and* $2b$ *its length.* a *either marks the position of the real isolating boundaries in ex vivo experiments or is chosen to be large enough such that the fluxes across* $y = \pm a$ *are negligible.*

$v^{i+1} = v^i$ a.e. on Γ_i for $i = 1, \dots, k-1$, $v^k = 0$ a.e. on $\Gamma_k\}$. Finally, if S is any set in $\mathbb{R}^N$, we write $S_T \equiv S \times (0,T)$ and $S_0 \equiv S \times \{t = 0\}$.

2. Motivation. Our study was motivated by the mathematical modeling of dermal and transdermal drug delivery, where the multilayered skin model in $\mathbb{R}^2$ was considered; see [12]. In this model the whole diffusion area is divided into four open subdomains Ω^i representing the vehicle and the layers of skin, connected by the interfaces Γ^i (see Figure 1), $i = 1, \dots, 4$.

The drug concentration in the subdomains Ω^i is denoted by $c^i = c^i(x,y,t)$. The penetration is described by the nonlinear diffusion equation

$$\partial_t c^i = \operatorname{div}\left(D^i(c^i)\,\nabla c^i\right) \tag{2.1}$$

which relates the change of the concentration c^i in time t to the substance flux $-D^i\,\nabla c^i$ with diffusivity D^i due to Fick's laws. At the interfaces Γ^i connecting two subdomains Ω^i and Ω^{i+1}, the conservation of flux and Nernst's distribution law must hold. These relations are given by

$$D^i\,\partial_x c^i = D^{i+1}\partial_x c^{i+1} \tag{2.2}$$

and

$$c^{i+1} = K^{i+1}\,c^i \tag{2.3}$$

with the partition coefficient being $K^{i+1} > 1$.

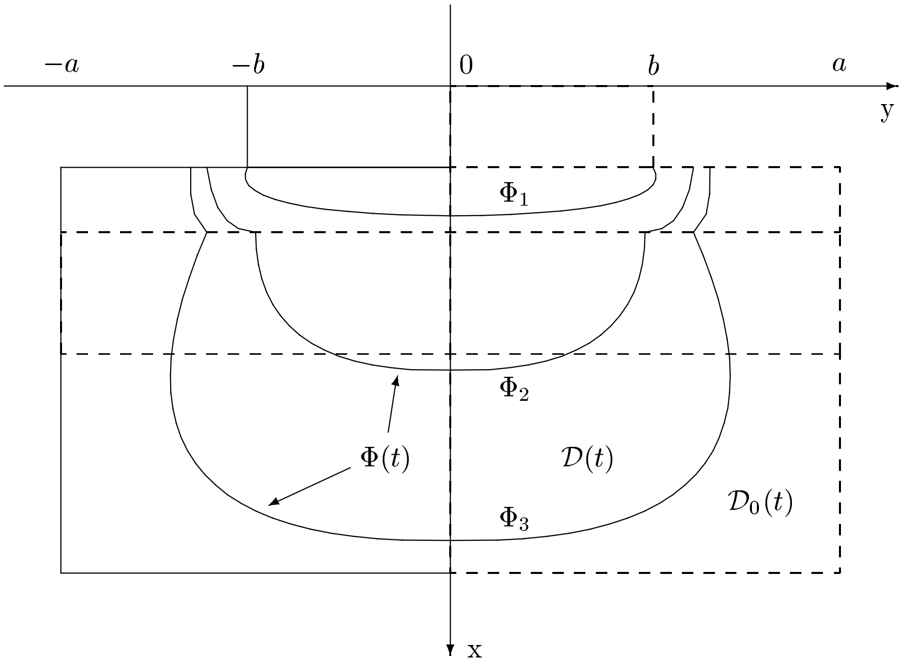

FIG. 2. *Time-dependent penetration depths. The penetration boundaries* Φ_1, Φ_2, Φ_3 *at three time levels* $0 < t_1 < t_2 < t_3$ *are shown; at the corresponding time the concentration is zero outside these boundaries.*

Since penetrants can move into and through human skin only at a finite penetration velocity, it is supposed that a regular curve $\Phi(t)$ in $\Omega \equiv \bigcup(\Omega^i \cup \Gamma^i)$ appears separating Ω into two time-dependent subareas $\mathcal{D}_0(t)$ with zero and $\mathcal{D}(t)$ with nonzero concentration, as illustrated in Figure 2.

Until $\Phi(t)$ reaches the boundary of the Ω^4, the whole mass of drug is inside $\mathcal{D}(t)$. We require the concentration of the drug to have a fixed positive value λ at the boundary $\Phi(t)$ of $\mathcal{D}(t)$. In this context λ describes the minimum concentration at which any diffusion front can proceed. So we set

$$c^i(x,y,t) = \lambda^i \quad \text{for} \quad (x,y) \in \Phi(t) \cap \Omega^i \,. \tag{2.4}$$

Moreover, on $\Phi(t)$ we assume that the penetration velocity of the drug is proportional to the concentration gradient at $\Phi(t)$; i.e.,

$$\lambda^i \, V_\nu = -D^i \, \nabla c^i \cdot \nu, \tag{2.5}$$

where V_ν means the normal velocity of the moving surface $\Phi(t)$ and ν represents its outer normal. To complete the problem formulation it is necessary to prescribe the initial position of the free boundary and the initial concentration distribution.

With the usual Kirchhoff transformation

$$u^i \;=\; \int_{\lambda^i}^{c^i} D^i(z)\, dz$$

denoting

$$c^i - \lambda^i = \beta^i(u^i);$$

the relations (2.1)–(2.5) above yield

$$\partial_t \beta^i(u^i) = \Delta u^i$$

in $\big(\mathcal{D}(t) \cap \Omega^i\big) \times (0,T)$,

$$\partial_x u^i = \partial_x u^{i+1} \quad \text{and} \quad \beta^{i+1}(u^{i+1}) = K^{i+1}\left(\beta^i(u^i) + \lambda^i\right) - \lambda^{i+1} \tag{2.6}$$

on $(\mathcal{D}(t) \cap \Gamma_i) \times (0,T)$,

$$\beta^i(u^i) = 0 \qquad \text{and} \qquad \lambda^i V_\nu = -\nabla u^i \cdot \nu$$

on $\big(\Phi(t) \cap \Omega^i\big) \times (0,T)$, and

$$\beta^i(u^i) = \beta_0^i$$

on $\mathcal{D}(0) \cap \Omega^i$, $i = 1, \dots, 4$.

We shall consider the weak or enthalpy formulation of the above problem, where all references to the free (unknown) boundary $\Phi(t)$ disappear and a problem on a given fixed domain Ω_T will be considered (see, e.g., [13] and references therein). Nernst's distribution law (2.6) is, however, well defined only on $\mathcal{D} \cap \Gamma^i$; therefore we first modify this law setting

$$\beta^{i+1}(u^{i+1}) = K^{i+1}\beta^i(u^i) + L^{i+1}\,\chi(\beta^i(u^i)), \qquad L^{i+1} \equiv K^{i+1}\lambda^i - \lambda^{i+1} > 0\,,$$

$$\chi(\sigma) = \begin{cases} 1, & \sigma > 0, \\ 0, & \sigma \leq 0, \end{cases} \tag{2.7}$$

which is fulfilled on $\mathcal{D}_0 \cap \Gamma^i$, too. Then, due to the noncontinuity of χ_0, we propose the following regularization:

$$\beta^{i+1}(u^{i+1}) = K^{i+1}\beta^i(u^i) + L^{i+1}\,\chi_\delta(\beta^i(u^i)),$$

where

$$\chi_\delta(\sigma) = \begin{cases} 0, & \sigma \leq 0, \\ \sigma/\delta, & 0 \leq \sigma \leq \delta, \\ 1, & 0 < \delta \leq \sigma. \end{cases} \tag{2.8}$$

Here δ is a small parameter, as far as we know, without a physical meaning and we keep it fixed. In our opinion, however, this regularization may be interpreted as a transition stage for small drug concentrations until Nernst's equilibrium is reached.

In this way we have arrived at problem (1.1)–(1.5).

3. Auxiliary problems.

Assume for this section that for given $0 < \varepsilon \ll 1$

$$b_\varepsilon^i(u) = \beta_\varepsilon^i(u) + \Lambda^i \chi_\varepsilon(u), \tag{3.1}$$

$\beta^i_\varepsilon(\cdot)$ are monotone increasing differentiable functions, and

$$0 < \varepsilon \le (\beta^i_\varepsilon)' \le K_\varepsilon \tag{3.2}$$

for a positive constant K_ε, $\beta^i_\varepsilon(0) = 0$, $i = 1, \dots, k$, χ_ε given by (2.8). Moreover, let

$$\beta^i_\varepsilon \longrightarrow \beta^i \qquad \text{as } \ \varepsilon \to 0 \tag{3.3}$$

uniformly on compact subsets of $\mathbb{R}$ and assume that $0 < \iota \le (\beta^i_\varepsilon)' \le K_\varepsilon$ on $[0, \infty)$ (cf. (1.7)). Throughout this section we suppose

$$u^i_{0\varepsilon} \in H^1(\Omega^i) \cap L^\infty(\Omega^i)\,, \quad u^i_{0\varepsilon} \ge 0\,, \tag{3.4}$$

$i = 1, \dots, k$, and

$$b^i_\varepsilon(u^i_{0\varepsilon}) \longrightarrow b^i_0 \qquad \text{in } \ L^1(\Omega^i) \tag{3.5}$$

as $\varepsilon \to 0$.

Given a positive integer n, now consider the system

$$\begin{aligned}
&\partial_t b^i_\varepsilon(u^i_\varepsilon) = \Delta u^i_\varepsilon && \text{in } \ \Omega^i_T,\\
&\partial_{\nu_i} u^i_\varepsilon + n\left(u^i_\varepsilon - \psi^{i-1}(u^{i-1}_\varepsilon)\right) = 0 && \text{on } \ \Gamma^{i-1}_T,\\
&\partial_{\nu_i} u^i_\varepsilon + n(\psi^i(u^i_\varepsilon) - u^{i+1}_\varepsilon) = 0 && \text{on } \ \Gamma^i_T,\\
&\partial_{\nu_i} u^i_\varepsilon = 0 && \text{on } \ \mathcal{T}^i_T,\\
&u^i_\varepsilon = u^i_{0\varepsilon} && \text{on } \ \Omega^i_0
\end{aligned} \tag{3.6}$$

for $i = 1, \dots, k$, where ψ^i satisfies (1.8), $\Gamma^0 = \emptyset$, $u^{k+1} \equiv 0$, and $\psi^k(u) \equiv u$.

Note that our intention in the next section is to send $\varepsilon \to 0$ and $n \to \infty$. But the results of this section might be of interest on their own. Theorem 3.2 extends the existence result of Kačur and Van Keer [10] to the nonlinear problem. Moreover, we prove a maximum principle and continuous dependence of the solution on the initial data for problem (3.6). The same constant n in the contact condition on each interface Γ^i is not essential; it may be replaced by positive constants k^i. Throughout the rest of this section, therefore, ε and n are fixed and we shall not indicate the dependence of the appeared quantities on them.

Definition 3.1. *We say that $u \equiv (u^1, \dots, u^k) \in L^2(0, T; V)$ is a weak solution of the system (3.6) provided $b^i(u^i) \in L^2(\Omega^i_T)$, $\partial_t b^i(u^i) \in L^2(0, T; H^{-1}(\Omega^i))$; that is,*

$$\int_0^T \langle \partial_t b^i(u^i), v^i \rangle dt = -\int_{\Omega^i_T} (b^i(u^i) - b^i(u^i_0))\, \partial_t v^i \, dxdt \tag{3.7}$$

for any $v = (v^1, \dots, v^k) \in L^2(0, T; V)$ with $\partial_t v^i \in L^2(\Omega^i_T)$, $v^i(T) = 0$, and if the following identity is fulfilled:

$$\begin{aligned}
\sum_{i=1}^k \left(\int_0^T \langle \partial_t b^i(u^i), \phi^i \rangle dt \ + \ \int_0^T \int_{\Omega^i} \nabla u^i \nabla \phi^i \, dxdt \right)&\\
+ \sum_{i=1}^k n \int_0^T \int_{\Gamma^i} \left(u^{i+1} - \psi^i(u^i)\right) \, \left(\phi^{i+1} - \phi^i\right) \, d\sigma dt = 0&
\end{aligned} \tag{3.8}$$

for any $\phi = (\phi^1, \dots, \phi^k) \in L^2(0, T; V)$.

A subsolution (supersolution) is defined by (3.8) *with equality replaced by* $\leq$ ($\geq$) *and* $\phi \geq 0$, *i.e.,* $\phi^i \geq 0$ *on* Ω^i *for each* $i \in \{1, \dots, k\}$.

THEOREM 3.2. *A weak solution of problem* (3.6) *exists if conditions* (3.1), (3.2), *and* (3.4) *are fulfilled. Moreover,*

$$u^i \geq 0 \qquad \text{a.e. on} \quad \Omega^i_T. \tag{3.9}$$

In addition, if

$$\left\| u_0^1 \right\|_{L^\infty(\Omega^1)} \leq c^1 \qquad \text{and} \qquad \left\| u_0^i \right\|_{L^\infty(\Omega^i)} \leq c^i \ , \qquad c^i \equiv \psi^{i-1}(c^{i-1})$$

for $i = 2, \dots, k$, *then*

$$\left\| u^i \right\|_{L^\infty(\Omega^i_T)} \leq c^i \tag{3.10}$$

for each $i = 1, \dots, k$.

Let us postpone the proof of Theorem 3.2 to the end of this section.

THEOREM 3.3. (i) *Let* u *and* v *be weak solutions of the problem* (3.6) *with initial functions* u_0 *and* v_0, *respectively. Then for almost all* $t \in [0, T]$,

$$\sum_{i=1}^k \int_{\Omega^i} \left| b^i(u^i) - b^i(v^i) \right| (x,t)\, dx \ \leq \ \sum_{i=1}^k \int_{\Omega^i} \left| b^i(u_0^i) - b^i(v_0^i) \right| (x)\, dx. \tag{3.11}$$

(ii) *Let* u *be a subsolution and* v *a supersolution of the problem* (3.6) *with initial data* u_0 *and* v_0, *respectively. Then if* $u_0 \leq v_0$, *i.e.,* $u_0^i \leq v_0^i$ *a.e. on* Ω^i *for any* $i \in \{1, \dots, k\}$, *it follows that*

$$u^i(x,t) \leq v^i(x,t)$$

a.e. on Ω^i_T *for any* $i \in \{1, \dots, k\}$.

The idea of the proof is as follows. Supposing that we have two solutions u and v, we write down the weak formulation for their difference. Some integrals of the obtained relation may be interpreted as a weak formulation of a suitable boundary value problem for the test function ϕ, the so called dual problem, which is tested by $u - v$. If we insert a solution of that dual problem as a test function, some integrals disappear and we are able to derive L^1-estimates if we know that the solution ϕ of the dual problem is bounded. This method was used, e.g., by [3], [6], [8], and many others.

In our case we have to find such conditions for the dual problem on the interfaces Γ^i that the integrals on the right-hand side of (3.12) may be nullified and ϕ fulfills a maximum principle (cf. (3.13)). However, since the coefficients of the dual problem are not smooth enough we have to regularize it and we have to be very careful to go to the limit.

This idea is used again to prove the boundedness of solution in Theorem 3.2 and the uniqueness result in section 5.

Proof of Theorem 3.3. We first prove the comparison principle (ii). In order to derive the dual problem let $0 < t \leq T$ be fixed. Take $\phi^i(x, \tau) = \chi_{[0,t]}(\tau)\varphi^i(x, t - \tau)$, where the choice of appropriate functions $\varphi^i = \varphi^i(x, s)$ will be determined later and

χ approaches the characteristic function of the interval $[0,t]$. Recalling the definition of u, v, one can see that

$$\begin{aligned}
&\int_{\Omega^i} \left(b^i(u^i) - b^i(v^i)\right)(x,t)\, \varphi^i(x,0)\, dx \\
&\qquad + \int_0^t \int_{\Omega^i} \big(A^i(x,\tau)\, \partial_s \varphi^i(x,t-\tau)\, (u^i - v^i)(x,\tau) \\
&\qquad\qquad + \nabla \varphi^i(x,t-\tau)\, \nabla(u^i(x,\tau) - v^i(x,\tau))\big)\, dx d\tau \\
&\qquad + n \int_0^t \int_{\Gamma^{i-1}} (u^i - v^i)(x,\tau)\, \varphi^i(x,t-\tau)\, d\sigma d\tau \\
&\qquad + n \int_0^t \int_{\Gamma^i} c^i(x,\tau)\, (u^i - v^i)(x,\tau)\, \varphi^i(x,t-\tau)\, d\sigma d\tau \\
&\quad \le \int_{\Omega^i} \left(b^i(u^i_0) - b^i(v^i_0)\right) \varphi^i(x,t)\, dx \\
&\qquad + n \int_0^t \int_{\Gamma^{i-1}} \left(\psi^{i-1}(u^{i-1}) - \psi^{i-1}(v^{i-1})\right)(x,\tau)\, \varphi^i(x,t-\tau)\, d\sigma d\tau \\
&\qquad + n \int_0^t \int_{\Gamma^i} (u^{i+1} - v^{i+1})(x,\tau)\, \varphi^i(x,t-\tau)\, d\sigma d\tau,
\end{aligned} \tag{3.12}$$

where

$$A^i(x,\tau) \equiv \frac{b^i(u^i) - b^i(v^i)}{u^i - v^i}(x,\tau) \qquad \text{and} \qquad c^i(x,\tau) \equiv \frac{\psi^i(u^i) - \psi^i(v^i)}{u^i - v^i}(x,\tau).$$

From the assumed hypotheses one can see that $\varepsilon \le A^i \le K_\varepsilon$ and $0 < \kappa \le c^i \le K$. Formally, if we insert $\varphi = \varphi(x, t-\tau)$ into (3.12), $0 \le \varphi^i \le 1$ such that $\varphi^i(x,s)$, $s \in [0,t]$, satisfies

$$\begin{aligned}
&A^i(x,t-s)\, \partial_s \varphi^i - \Delta \varphi^i = 0 && \text{in } \Omega^i_t, \\
&\partial_{\nu_i} \varphi^i + n\left(\varphi^i - \chi((u^i - v^i)(x,t-s))\right) = 0 && \text{on } \Gamma^{i-1}_t, \\
&\partial_{\nu_i} \varphi^i + n\, c^i(x,t-s)\left(\varphi^i - \chi((u^i - v^i)(x,t-s))\right) = 0 && \text{on } \Gamma^i_t, \\
&\partial_{\nu_i} \varphi^i = 0 && \text{on } \mathcal{T}^i_t, \\
&\varphi^i = \chi(u^i(x,t) - v^i(x,t)) && \text{on } \Omega^i \times \{s = 0\},
\end{aligned} \tag{3.13}$$

χ being given by (2.7). We get

$$\begin{aligned}
&\int_{\Omega^i} \left(b^i(u^i) - b^i(v^i)\right)_+ (x,t)\, dx \;+\; n \int_0^t \int_{\Gamma^{i-1}} (u^i - v^i)_+(x,\tau)\, d\sigma d\tau \\
&\qquad + n \int_0^t \int_{\Gamma^i} \left(\psi^i(u^i) - \psi^i(v^i)\right)_+ (x,\tau)\, d\sigma d\tau \\
&\quad \le \int_{\Omega^i} \left(b^i(u^i_0) - b^i(v^i_0)\right)_+ (x)\, dx \\
&\qquad + n \int_0^t \int_{\Gamma^{i-1}} \left(\psi^{i-1}(u^{i-1}) - \psi^{i-1}(v^{i-1})\right)_+ (x,\tau)\, d\sigma d\tau \\
&\qquad + n \int_0^t \int_{\Gamma^i} \left(u^{i+1} - v^{i+1}\right)_+ (x,\tau)\, d\sigma d\tau,
\end{aligned} \tag{3.14}$$

where

$$w_+ \equiv \max\{0, w\}.$$

If we add (3.14) through $i = 1, \dots, k$, we arrive at

$$\sum_{i=1}^{k} \int_{\Omega^i} \left(b^i(u^i) - b^i(v^i)\right)_+ (x,t)\, dx \le \sum_{i=1}^{k} \int_{\Omega^i} \left(b^i(u_0^i) - b^i(v_0^i)\right)_+ (x)\, dx, \tag{3.15}$$

recalling that we have put $\Gamma^0 = \emptyset$, $u^{k+1} = v^{k+1} = 0$, and $\psi^k(u) \equiv u$.

Nevertheless, coefficients in (3.13) are only bounded functions and we cannot, therefore, expect the required regularity of solutions to (3.13). Therefore, instead of (3.13) we shall consider the problem

$$\begin{aligned}
&A^i_\rho(x,t-s)\,\partial_s\varphi^i - \Delta\varphi^i = 0 && \text{in } \ \Omega^i_t,\\
&\partial_{\nu_i}\varphi^i + n\left(\varphi^i - \omega^i_\delta(x,t-s)\right) = 0 && \text{on } \ \Gamma^{i-1}_t,\\
&\partial_{\nu_i}\varphi^i + n\; c^i_\delta(x,t-s)\left(\varphi^i - \omega^i_\delta(x,t-s)\right) = 0 && \text{on } \ \Gamma^i_t,\\
&\partial_{\nu_i}\varphi^i = 0 && \text{on } \ \mathcal{T}^i_t,\\
&\varphi^i = \varpi^i_\eta(x) && \text{on } \ \Omega^i \times \{s=0\},
\end{aligned} \tag{3.16}$$

where

$$A^i_\rho(x,t-s) \equiv (R_\rho * A^i)(x,t-s), \quad \omega^i_\delta(x,t-s) \equiv \left(R_\delta * \chi(u^i - v^i)\right)(x,t-s),$$
$$c^i_\delta(x,t-s) \equiv \left(R_\delta * c^i\right)(x,t-s),$$

R_ρ, R_δ are the standard mollifiers in the t-variable, and

$$\varpi^i_\eta(x) \equiv \left(R_\eta * \chi(u^i(\cdot,t) - v^i(\cdot,t))\right)(x),$$

R_η is the standard mollifier in the x-variable.

(3.16) is a uniformly parabolic problem on each domain Ω^i_t with sufficiently smooth data and we can apply the classical results of [11] to get a unique weak solution φ^i such that

$$\varphi^i \equiv \varphi^i_{\rho\delta\eta} \in L^\infty(0,t;H^1(\Omega^i)) \cap H^1(0,t;L^2(\Omega^i))$$

and

$$0 \le \varphi^i \le 1 \qquad \text{a.e. on } \ \Omega^i_t. \tag{3.17}$$

To prove (3.17), note that the weak formulation of (3.16) easily gives

$$\int_0^t \int_{\Omega^i} \left(A^i_\rho \partial_s(\varphi^i - 1)\,\xi + \nabla(\varphi^i - 1)\nabla\xi\right)\, dxds \;+\; n\int_0^t \int_{\Gamma^{i-1}} (\varphi^i - 1)\xi\, d\sigma ds$$
$$+\, n\int_0^t \int_{\Gamma^i} c^i_\delta\,(\varphi^i - 1)\,\xi\, d\sigma ds \;\le\; 0$$

for any $\xi \in L^2(0,T;H^1(\Omega^i))$, $\xi \ge 0$. If we insert $\xi = \chi_\varepsilon(\varphi^i - 1)$ and if $\varepsilon \to 0$, we arrive at

$$\int_0^t \int_{\Omega^i} \partial_s\left(A^i_\rho\,(\varphi^i - 1)_+\right)\, dxds \;\le\; \int_0^t \int_{\Omega^i} \left|\partial_s A^i_\rho\right| (\varphi^i - 1)_+\, dxds.$$

This, due to Gronwall's lemma, yields

$$\int_{\Omega^i} (\varphi^i - 1)_+(x,t)\, dx \le 0, \qquad \text{i.e., } (3.17)_2.$$

Analogously one gets

$$\int_{\Omega^i} (-\varphi^i)_+(x,t)\, dx \le 0, \qquad \text{i.e., } (3.17)_1.$$

Moreover, it is easy to see (cf., e.g., [11]) that

$$\max_{0\le s\le t} \int_{\Omega^i} \left|\nabla\varphi^i\right|^2 (x,s)\, dx + \int_0^t \int_{\Omega^i} A^i_\rho(x,t-s) \left|\partial_s\varphi^i\right|^2 dxds \le C, \tag{3.18}$$

where the positive constant $C = C(\eta,\delta)$ does not depend on ρ.

Inserting $\varphi^i_{\rho\delta\eta}$ into (3.12) now we get

$$\begin{aligned}
&\int_{\Omega^i} \left(b^i(u^i) - b^i(v^i)\right)(x,t)\, \varpi^i_\eta(x)\, dx \\
&\qquad + \int_0^t \int_{\Omega^i} \left(A^i - A^i_\rho\right)(x,\tau)\, \partial_s\varphi^i_{\rho\delta\eta}(x,t-\tau)\, (u^i - v^i)(x,\tau)\, dxd\tau \\
&\qquad + n\int_0^t \int_{\Gamma^{i-1}} (u^i - v^i)(x,\tau)\, \omega^i_\delta(x,\tau)\, d\sigma d\tau \\
&\qquad + n\int_0^t \int_{\Gamma^i} (c^i - c^i_\delta)(x,\tau)\, \varphi^i_{\rho\delta\eta}(x,t-\tau)\, (u^i - v^i)(x,\tau)\, d\sigma d\tau \\
&\qquad + n\int_0^t \int_{\Gamma^i} c^i_\delta(x,\tau)\, \omega^i_\delta(x,t-\tau)\, (u^i - v^i)(x,\tau)\, d\sigma d\tau \\
&\quad \le \int_{\Omega^i} \left(b^i(u^i_0) - b^i(v^i_0)\right)_+ dx \\
&\qquad + n\int_0^t \int_{\Gamma^{i-1}} \left(\psi^{i-1}(u^{i-1}) - \psi^{i-1}(v^{i-1})\right)_+ (x,\tau)\, d\sigma d\tau \\
&\qquad + n\int_0^t \int_{\Gamma^i} \left(u^{i+1} - v^{i+1}\right)_+ (x,\tau)\, d\sigma d\tau.
\end{aligned}$$

First we go with $\rho \to 0$ so that the integral with $\partial_s\varphi^i_{\rho\delta\eta}$ disappears. Afterwards we let $\delta \to 0$ and then $\eta \to 0$. Hence we arrive at (3.15) and the desired comparison principle follows.

To prove assertion (i), note that u, v are both sub- and supersolutions, and therefore analogously one gets

$$\sum_{i=1}^k \int_{\Omega^i} \left(b^i(v^i) - b^i(u^i)\right)_+ (x,t)\, dx \le \sum_{i=1}^k \int_{\Omega^i} \left(b^i(v^i_0) - b^i(u^i_0)\right)_+ (x)\, dx.$$

This proves (i). □

Proof of Theorem 3.1. 1. We intend to build a weak solution of system (3.6) by first constructing solutions of certain simpler approximations to (3.6) and then passing to limits. More precisely, now fix a positive integer ℓ. For given

$$u_{\ell-1} = (u^1_{\ell-1}, \dots, u^k_{\ell-1})\,, \quad u^i_0(x,t) \equiv u^i_0(x),$$

we will look for a function $u_\ell \equiv (u_\ell^1, \dots, u_\ell^k)$ so that

$$\begin{aligned}
&\partial_t b^i(u_\ell^i) = \Delta u_\ell^i && \text{in } \Omega_T^i,\\
&\partial_{\nu_i} u_\ell^i + n\left(u_\ell^i - \psi^{i-1}(u_\ell^{i-1})\right) = 0 && \text{on } \Gamma_T^{i-1},\\
&\partial_{\nu_i} u_\ell^i + n\left(\psi^i(u_\ell^i) - u_{\ell-1}^{i+1}\right) = 0 && \text{on } \Gamma_T^i,\\
&\partial_{\nu_i} u_\ell^i = 0 && \text{on } \mathcal{T}_T^i,\\
&u_\ell^i = u_0^i && \text{on } \Omega_0^i,
\end{aligned} \tag{3.19}$$

$i = 1, \dots, k$. Recall again that $\Gamma^0 \equiv \emptyset$, $\psi^k(u) \equiv u$, and $u^{k+1} \equiv 0$.

Assume that the nonnegative functions $u_{\ell-1}^i$ are sufficiently smooth, say,

$$u_{\ell-1}^i \in L^2(0,T; H^1(\Omega^i)) \cap L^\infty(\Omega_T^i)$$

for any $i \in \{1, \dots, k\}$, and let a positive constant c^1 be taken in such a way that

$$0 \le u_{\ell-1}^1 \le c^1$$

a.e. on Ω_T^1, and at the same time

$$0 \le u_{\ell-1}^i \le c^i \equiv \psi^{i-1}(c^{i-1}) \tag{3.20}$$

a.e. on Ω_T^i for each $i \in \{2, \dots, k\}$.

2. According to standard existence theory (Galerkin's method or implicit time discretization method) (see, e.g., [7] for existence and [8] for uniqueness) there exists a unique weak solution u_ℓ^1 satisfying (3.19) and then repeatedly u_ℓ^i for $i = 2, \dots, k$ such that

$$u_\ell^i \in L^2(0,T; H^1(\Omega^i)) \quad \text{and} \quad \partial_t b^i(u_\ell^i) \in L^2(0,T; H^{-1}(\Omega^i)).$$

3. Due to the comparison principle we now show that

$$(3.20) \quad \text{implies} \quad 0 \le u_\ell^i \le c^i$$

for any $i \in \{1, \dots, k\}$. First, observe formally that

$$\begin{aligned}
&\partial_t b^i(u_\ell^i) = \Delta u_\ell^i && \text{in } \Omega_T^i,\\
&\partial_{\nu_i} u_\ell^i + n u_\ell^i = n\psi^{i-1}(u_\ell^{i-1}) \ge 0 && \text{on } \Gamma_T^{i-1},\\
&\partial_{\nu_i} u_\ell^i + n\psi^i(u_\ell^i) = n u_{\ell-1}^{i+1} \ge 0 && \text{on } \Gamma_T^i,\\
&\partial_{\nu_i} u_\ell^i = 0 && \text{on } \mathcal{T}_T^i,\\
&u_\ell^i = u_0^i \ge 0 && \text{on } \Omega_0^i
\end{aligned}$$

and

$$\begin{aligned}
&\partial_t\left(b^i(u_\ell^i) - b^i(c^i)\right) = \Delta\left(u_\ell^i - c^i\right) && \text{in } \Omega_T^i,\\
&\partial_{\nu_i}(u_\ell^i - c^i) + n\left(u_\ell^i - c^i\right) = n\left(\psi^{i-1}(u_\ell^{i-1}) - \psi^{i-1}(c^{i-1})\right) \le 0 && \text{on } \Gamma_T^{i-1},\\
&\partial_{\nu_i}(u_\ell^i - c^i) + n\left(\psi^i(u_\ell^i) - \psi^i(c^i)\right) = n\left(u_{\ell-1}^{i+1} - c^{i+1}\right) \le 0 && \text{on } \Gamma_T^i,\\
&\partial_{\nu_i}(u_\ell^i - c^i) = 0 && \text{on } \mathcal{T}_T^i,\\
&u_\ell^i - c^i \le 0 && \text{on } \Omega_0^i.
\end{aligned}$$

Consequently,

$$0 \le u_\ell^i \le c^i \tag{3.21}$$

a.e. on Ω_T^i for each $i \in \{1, \dots, k\}$. It is not difficult to make it precise like in the proof of Theorem 3.3(ii) above and we omit further details.

4. We propose now to send ℓ to infinity and to show that a subsequence of our solutions u_ℓ of the approximate problems (3.19) converges to a weak solution of (3.6). For this we will need some uniform estimates. We follow the ideas of Alt and Luckhaus [1], but we have to deal with the additional integrals on Γ^i. First we obtain an a priori estimate by testing (3.19) with u_ℓ^i. Denoting

$$\Phi^i(z) \equiv \int_0^z b^i(\xi) d\xi \quad \text{and} \quad B^i(z) \equiv b^i(z) z - \Phi^i(z), \tag{3.22}$$

the parabolic term can be treated with the use of [1, Lemma 1.5]. Performing some calculations we find

$$\begin{aligned} \sum_{i=1}^k \bigg\{ \int_{\Omega^i} B^i(u_\ell^i(x,t))\, dx - \int_{\Omega^i} B^i(u_0^i(x))\, dx + \int_0^t \int_{\Omega^i} \left|\nabla u_\ell^i\right|^2 dx d\tau \\ + n \int_0^t \int_{\Gamma^i} \left(\psi^i(u_\ell^i) u_\ell^i + |u_\ell^{i+1}|^2\right) d\sigma d\tau \bigg\} \\ = \sum_{i=1}^{k-1} n \int_0^t \int_{\Gamma^i} \left(\psi^i(u_\ell^i) u_\ell^{i+1} + u_{\ell-1}^{i+1} u_\ell^i\right) d\sigma d\tau. \end{aligned}$$

Since $u_\ell^i \in L^2(0,T; H^1(\Omega^i))$ the estimate (3.21) holds on Γ_T^i, too. Hence, the right-hand side is uniformly bounded with respect to ℓ and we arrive at

$$\sum_{i=1}^k \left\{ \int_{\Omega^i} B^i(u_\ell^i(x,t))\, dx + \left\|\nabla u_\ell^i\right\|^2_{L^2(\Omega_t^i)} \right\} \le C_n \tag{3.23}$$

for any ℓ and for a.e. $t \in [0,T]$. In order to go to the limit in the nonlinear terms we need strong convergence. To arrive at an estimate concerning the time variable we test our problem with $\varphi^i = \chi_{[t,t+h]}(\tau) w^i$ for $w^i \in H^1(\Omega^i)$, $i = 1, \dots, k$, $w^{k+1} \equiv 0$,

$$\begin{aligned} \sum_{i=1}^k \bigg\{ \int_{\Omega^i} \left(b^i(u_\ell^i(t+h)) - b_\ell^i(u_\ell^i(t))\right) w^i dx + \int_t^{t+h} \int_{\Omega^i} \nabla u_\ell^i \nabla w^i \; dx d\tau \\ + n \int_t^{t+h} \int_{\Gamma^i} \Big((u_\ell^{i+1} - \psi^i(u_\ell^i)) w^{i+1} + (\psi^i(u_\ell^i) - u_{\ell-1}^{i+1}) w^i \Big) d\sigma d\tau \bigg\} \; = \; 0 \end{aligned}$$

and then put $w^i \equiv u_\ell^i(t+h) - u_\ell^i(t)$. Since the items on Γ^i are bounded almost everywhere, after integration over $[0, T-h]$ one gets the estimate

$$\sum_{i=1}^k \int_0^{T-h} \int_{\Omega^i} \left(b^i(u_\ell^i(t+h)) - b^i(u_\ell^i(t))\right) \left(u_\ell^i(t+h) - u_\ell^i(t)\right) \; dx dt \le ch \tag{3.24}$$

with constant c independent of ℓ. Here boundedness (3.23) of the gradient of u_ℓ^i was used. Now, passing to the limit $\ell \to \infty$, the estimates (3.23) and (3.24) together with the weak formulation of problem (3.19) yield the existence of a subsequence of $\{u^i_\ell\}$ such that

$$\begin{aligned} b^i(u^i_\ell) &\to b^i(u^i) && \text{in } L^1(\Omega^i_T),\\ u^i_\ell &\rightharpoonup u^i && \text{in } L^2(0,T;H^1(\Omega^i)),\\ \partial_t b(u^i_\ell) &\rightharpoonup \partial_t b(u^i) && \text{in } L^2(0,T;H^{-1}(\Omega^i)) \end{aligned}$$

for $i = 1,\dots,k$ (cf. [1]). Note, that due to (3.1) and (3.2), u^i_ℓ converges strongly in $L^1(\Omega^i_T)$ and thus, by interpolation with respect to space variables, also strongly in $L^2(\Gamma^i_T)$. Now, it is not difficult to see that u^i, $i = 1,\dots,k$, is a weak solution of (3.6). □

4. Free boundary value problems. In this section we intend to prove the existence of a solution to our original problem (1.1)–(1.5) with discontinuous $b(u)$ by approximating it by problem (3.6). Since we let ε go to zero and n to infinity in (3.6) our main task is to derive a priori estimates that do not depend on ε, n. The simple method of step 4 in the proof of Theorem 3.2 by testing the relation with u^i is not applicable since the bounds depend on n (cf. (3.23)).

To this end we want to test our system (3.6) with

$$\phi^i(u) = \psi^k \circ \dots \circ \psi^i(u), \qquad i = 1,\dots,k,$$

chosen in such a way that the integrals on Γ^i are nonnegative. Since $\partial_t b^i(u^i_\varepsilon)$ only belongs to the dual $L^2(0,T;H^{-1}(\Omega^i))$ we have to formulate an "integration by parts formula" for that case which is proven by Carrillo [4]. Define

$$G^i_\varepsilon(s) = \int_0^s \phi^i((b^i_\varepsilon)^{-1}(r))\,dr; \tag{4.1}$$

we get the following lemma.

LEMMA 4.1. *Let $\phi \in C^{0,1}(\mathbb{R})$ be monotone, let $b_0 = b(u_0) \in L^1(\Omega)$ such that $G(b_0) \in L^1(\Omega)$, let $u \in L^2(0,T;H^1(\Omega))$, and $b(u) \in L^1(Q_T)$ with derivative $\partial_t b(u) \in L^2(0,T;H^{-1}(\Omega))$. Then*

$$G(b(u)) \in L^\infty(0,T;L^1(\Omega))$$

and, for almost every $t \in [0,T]$,

$$\int_\Omega G\big(b(u(x,t))\big)\,dx - \int_\Omega G\big(b_0(x)\big)\,dx = \int_0^t \langle b(u)_t, \phi(u)\rangle\,d\tau.$$

Proof. The lemma is an adaption of [4, Lemma 4] to our problem. □

For the following estimates recall our convention $u^{k+1}_\varepsilon \equiv 0$, $\psi^k(u) \equiv u$. In view of our assumptions due to (1.8) we may estimate G^i_ε below by

$$G^i_\varepsilon(b^i_\varepsilon(u)) \geq \kappa^{k-i} \int_0^{b^i_\varepsilon(u)} (b^i_\varepsilon)^{-1}(r)\,dr = \kappa^{k-i} \int_0^u z\,db^i_\varepsilon(z) = \kappa^{k-i} B^i_\varepsilon(u), \tag{4.2}$$

where $B^i_\varepsilon(u)$ is defined by (3.22) and above by

$$G^i_\varepsilon(b^i_{0\varepsilon}) \leq K^{k-i} \int_0^{b^i_{0\varepsilon}} (b^i_\varepsilon)^{-1}(r)\,dr \leq \frac{K^{k-i}}{\iota} \int_0^{b^i_{0\varepsilon}} r\,dr = \frac{K^{k-i}}{2\iota}\,|b^i_{0\varepsilon}|^2 \tag{4.3}$$

for nonnegative $b^i_{0\varepsilon}$ since $(b^i_\varepsilon)^{-1}(r) \leq \frac{1}{\iota}\,r$ for $r \geq 0$.

Now we test the problem (3.6) with the abovementioned $\phi^i(u^i_\varepsilon)$. According to (1.8), for $i = 1, \dots, k-1$,

$$\int_0^t \int_{\Gamma^i} (u_\varepsilon^{i+1} - \psi^i(u_\varepsilon^i))\,(\phi^{i+1}(u_\varepsilon^{i+1}) - \phi^i(u_\varepsilon^i))\,d\sigma d\tau$$
$$\geq \kappa^{k-1-i} \int_0^t \int_{\Gamma^i} (u_\varepsilon^{i+1} - \psi^i(u_\varepsilon^i))^2\,d\sigma d\tau\,.$$

Consequently,

$$\sum_{i=1}^k \left\{ \int_{\Omega^i} \left(G_\varepsilon^i(b_\varepsilon^i(u_\varepsilon^i(t))) - G_\varepsilon^i(b_\varepsilon^i(u_{0\varepsilon}^i)) \right) dx + \int_0^t \int_{\Omega^i} D\phi^i(u_\varepsilon^i) \left|\nabla u_\varepsilon^i\right|^2 dx d\tau \right\}$$
$$+ n \sum_{i=1}^k \kappa^{(k-1-i)_+} \int_0^t \int_{\Gamma^i} \left(u_\varepsilon^{i+1} - \psi^i(u_\varepsilon^i) \right)^2 d\sigma d\tau \ \leq \ 0.$$

For bounded initial data $u^i_{0\varepsilon}$ the function $G^i_\varepsilon(b^i_\varepsilon(u^i_{0\varepsilon}))$ is bounded in Ω^i uniformly with respect to ε, too. Thus, regarding (4.2), (4.3), and (1.8) again, we have proved the following a priori estimates.

Lemma 4.2. *Suppose assumptions* (3.1)–(3.5) *hold and let* $b^i_{0\varepsilon} = b^i_\varepsilon(u^i_{0\varepsilon})$ *be uniformly bounded in* $L^2(\Omega^i)$ *for* $i = 1, \dots, k$. *Then the solution* u_ε *from Theorem* 3.2 *fulfills the estimates*

$$\int_{\Omega^i} B_\varepsilon^i(u_\varepsilon^i(x,t))\,dx \leq C_1, \tag{4.4}$$

$$\|\nabla u_\varepsilon^i\|_{L^2(\Omega_T^i)} \leq C_2, \tag{4.5}$$

$$n\,\|u_\varepsilon^{i+1} - \psi^i(u_\varepsilon^i)\|^2_{L^2(\Gamma_T^i)} \leq C_3 \tag{4.6}$$

for all $\varepsilon > 0$ *and* $i = 1, \dots, k$.

In order to obtain strong convergence of u^i_ε as $\varepsilon \to 0$ we need an a priori estimate with respect to the time variable (cf. [1, Lemma 1.9]).

Lemma 4.3. *Let the assumptions of Lemma* 4.2 *be fulfilled and* $0 < h < T$. *Then the estimate*

$$\int_0^{T-h} \int_{\Omega^i} \left(b_\varepsilon^i(u_\varepsilon^i(x,t+h)) - b_\varepsilon^i(u_\varepsilon^i(x,t)) \right) \left(u_\varepsilon^i(x,t+h) - u_\varepsilon^i(x,t) \right) dx dt \leq Ch \tag{4.7}$$

holds for all $\varepsilon > 0$ *and* $i = 1, \dots, k$.

Proof. Inserting $\chi_{(t,t+h)} w^i$, $w^i \in V_i$, as a test function into (3.8) we obtain by means of partial integration in time

$$\sum_{i=1}^k \left(\int_{\Omega^i} \left(b_\varepsilon^i(u_\varepsilon^i(t+h)) - b_\varepsilon^i(u_\varepsilon^i(t)) \right) w^i\,dx + \int_t^{t+h} \int_{\Omega^i} \nabla u_\varepsilon^i \nabla w^i\,dx d\tau \right)$$
$$= - \sum_{i=1}^k n \int_t^{t+h} \int_{\Gamma^i} \left(u_\varepsilon^{i+1} - \psi^i(u_\varepsilon^i) \right) \left(w^{i+1} - w^i \right) d\sigma d\tau.$$

Now we choose $w^i = \phi^i(u^i_\varepsilon(t+h)) - \phi^i(u^i_\varepsilon(t))$, $w^{k+1} \equiv 0$, integrate over $t \in [0, T-h]$, and estimate by means of (1.8)

$$\begin{aligned}
&\sum_{i=1}^{k} \kappa^{k-i} \int_0^{T-h} \int_{\Omega^i} \left(b^i_\varepsilon(u^i_\varepsilon(t+h)) - b^i_\varepsilon(u^i_\varepsilon(t))\right)\left(u^i_\varepsilon(t+h) - u^i_\varepsilon(t)\right)\, dxdt \\
&\qquad \le h \sum_{i=1}^{k} K^{k-i} \int_0^{T-h} \int_{\Omega^i} \left|\nabla [u^i_\varepsilon]_h\right| \left(|\nabla u^i_\varepsilon(t+h)| + |\nabla u^i_\varepsilon(t)|\right)\, dxdt \\
&\qquad\quad + nh \sum_{i=1}^{k} K^{(k-i-1)_+} \int_0^{T-h} \int_{\Gamma^i} \left|[u^{i+1}_\varepsilon - \psi^i(u^i_\varepsilon)]_h(x,t)\right| \\
&\qquad\quad \times \Big(|u^{i+1}_\varepsilon(t+h) - \psi^i(u^i_\varepsilon(t+h))| + |u^{i+1}_\varepsilon(t) - \psi^i(u^i_\varepsilon(t))|\Big)\, d\sigma dt,
\end{aligned}$$

where $[u]_h(t) = h^{-1}\int_t^{t+h} u(\tau)\, d\tau$ denotes the Steklov average of $u(t)$. Observe that if X is a normed space, then the Steklov average has the property

$$\|\, [u]_h \,\|_{L^p(0,T;X)} \le \|u\|_{L^p(0,T;X)}.$$

Hence, we finish our calculation using the a priori estimates of Lemma 4.2,

$$\begin{aligned}
&\sum_{i=1}^{k} \kappa^{k-i} \int_0^{T-h} \int_{\Omega^i} \left(b^i_\varepsilon(u^i_\varepsilon(t+h)) - b^i_\varepsilon(u^i_\varepsilon(t))\right)\left(u^i_\varepsilon(t+h) - u^i_\varepsilon(t)\right)\, dxdt \\
&\qquad \le h \sum_{i=1}^{k} K^{k-i} \, \|\nabla u^i_\varepsilon\|^2_{L^2(\Omega^i_T)} + nh \sum_{i=1}^{k} K^{(k-i-1)_+} \, \|u^{i+1}_\varepsilon - \psi^i(u^i_\varepsilon)\|^2_{L^2(\Gamma^i_T)} \\
&\qquad \le Ch,
\end{aligned}$$

which proves (4.7). □

Now we are in the position to formulate the existence result for our original problem (1.1)–(1.5). To this end we give the exact definition of a weak solution of this problem.

DEFINITION 4.4. *A function $u \equiv (u^1, \dots, u^k) \in L^2(0,T;V)$ is a weak solution of problem (1.1)–(1.5) provided there is a function $w \in b(u)$ with $w^i \in L^2(\Omega^i_T)$, $\partial_t w \in L^2(0,T;\tilde{V}^*)$, and initial values b^i_0 in the sense that*

$$\int_0^T \langle \partial_t w, v\rangle\, dt = -\sum_{i=1}^{k} \int_0^T \int_{\Omega^i} (w^i - b^i_0)\, \partial_t v^i \, dxdt \tag{4.8}$$

holds for any $v = (v^1, \dots, v^k) \in L^2(0,T;\tilde{V})$ with $\partial_t v^i \in L^\infty(\Omega^i_T)$, $v^i(T) = 0$, the following identity

$$\int_0^T \langle \partial_t w, \phi\rangle\, dt \; + \sum_{i=1}^{k} \int_0^T \int_{\Omega^i} \nabla u^i \nabla \phi^i \, dxdt = 0 \tag{4.9}$$

is fulfilled for any $\phi \in L^2(0,T;\tilde{V})$, and

$$u^{i+1} = \psi^i(u^i) \qquad \text{a.e. on } \Gamma^i_T. \tag{4.10}$$

Theorem 4.5. *Let $b^i(v)$, $\psi^i(v)$, $i = 1, \dots, k$, be as defined in section* 1 *fulfilling assumptions* (1.6)–(1.8). *Then for given nonnegative $b_0^i \in L^2(\Omega^i)$ there is a nonnegative weak solution u of the system* (1.1)–(1.5) *in the sense of Definition* 4.4.

If, moreover, $0 \le b_0^i \le C^i$ for $i = 1, \dots, k$ where $c^i = (b^i)^{-1}(C^i)$ fulfills $c^{i+1} = \psi^i(c^i)$, then the solution is bounded a.e. on Ω_T by $0 \le u^i \le c^i$.

Proof. We approximate our problem (1.1)–(1.5) by the regularized problem (3.6). As an initial condition we choose $b_\varepsilon^i(u_{0\varepsilon}^i) = b_{0\varepsilon}^i := R_\varepsilon * b_0^i$, where R_ε is the standard mollifier with respect to x. For $b_0^i \ge 0$ the regularization is nonnegative again, thus, $u_{0\varepsilon}^i$ will also be nonnegative for all $i = 1, \dots, k$. Since $(b_\varepsilon^i)^{-1}$ is Lipschitz continuous we have $u_{0\varepsilon}^i \in V_i \cap L^\infty(\Omega^i)$, hence there is a solution u_ε to the approximate problem due to Theorem 3.2.

Our aim is to let $\varepsilon \to 0$ and $n \to \infty$ simultaneously, e.g., choosing $n = \varepsilon^{-1}$. Assuming such connection between ε and n we omit indication of the dependence of u_ε^i on n. Since we have provided all necessary estimates we can use the standard arguments from [1]. First from (4.5) immediately follows the existence of a subsequence (we write u_ε^i again for all subsequences) with

$$u_\varepsilon^i \rightharpoonup u^i \qquad \text{in } L^2(0,T;V_i) \quad \text{as } \varepsilon \to 0 \tag{4.11}$$

($i = 1, \dots, k$). Because of [1, Lemma 4.4], the estimate (4.4) together with Lemma 4.3 yields for a subsequence

$$b_\varepsilon^i(u_\varepsilon^i) \rightharpoonup w^i \in b^i(u^i) \qquad \text{in } L^1(\Omega_T^i) \quad \text{as } \varepsilon \to 0. \tag{4.12}$$

Now, consider relation (3.8) with test functions $\phi \in L^2(0,T;\tilde{V})$. Then the integrals over Γ^i disappear. Since $\tilde{V}$ is a subspace of $V_1 \times \dots \times V_k$ we have $\partial_t b_\varepsilon(u_\varepsilon) := \partial_t b_\varepsilon^1(u_\varepsilon^1) \times \dots \times \partial_t b_\varepsilon^k(u_\varepsilon^k) \in L^2(0,T;\tilde{V}^*)$ and obtain from (3.8) regarding (4.5)

$$\|\partial_t b_\varepsilon(u_\varepsilon)\|_{L^2(0,T;\tilde{V}^*)} \le C.$$

This yields for a subsequence

$$\partial_t b_\varepsilon(u_\varepsilon) \rightharpoonup \partial_t w \qquad \text{in } L^2(0,T;\tilde{V}^*) \quad \text{as } \varepsilon \to 0. \tag{4.13}$$

Moreover, we need strong convergence of a subsequence $\{u_\varepsilon^i\}$ in order to go to the limit in the items defined on the interfaces Γ^i. Recalling construction (2.1) of $b_\varepsilon^i(u)$, thanks to monotonicity of χ_ε the estimate (4.7) for $b_\varepsilon^i(u)$ also holds for its first item,

$$\int_0^{T-h} \int_{\Omega^i} \left(\beta_\varepsilon^i(u_\varepsilon^i(x,t+h)) - \beta_\varepsilon^i(u_\varepsilon^i(x,t))\right) \left(u_\varepsilon^i(x,t+h) - u_\varepsilon^i(x,t)\right) dxdt \le Ch,$$

and then due to (1.7)

$$\iota \, \|u_\varepsilon^i(x,t+h) - u_\varepsilon^i(x,t)\|_{L^2(\Omega_T^i)}^2 \le Ch$$

for all $h > 0$, $\varepsilon > 0$, and $i = 1, \dots, k$. Hence, together with (4.5) Kolmogoroff's compactness theorem yields strong convergence of a subsequence

$$u_\varepsilon^i \to u^i \qquad \text{in } L^2(\Omega_T^i) \quad \text{as } \varepsilon \to 0. \tag{4.14}$$

Strong convergence on the interfaces Γ^i we obtain by application of the interpolation inequality

$$\|u\|_{L^2(\Gamma_T^i)} \le C \, \|u\|_{L^2(0,T;V_i)}^{1-\theta} \, \|u\|_{L^2(\Omega_T^i)}^{\theta}$$

(see [7, Proposition 2]) to the difference $u^i_\varepsilon - u^i$. Regarding (4.5) and (4.14), this inequality yields

$$u^i_\varepsilon \to u^i \qquad \text{in } L^2(\Gamma^i_T) \quad \text{as } \varepsilon \to 0, \tag{4.15}$$

$(i = 1, \dots, k)$. Since we arranged that $n \to \infty$ if $\varepsilon \to 0$, the estimate (4.6) shows that the limit u^i fulfills our jump condition (4.10).

To show that the limit function is a solution, let $\varepsilon \to 0$ in relations (3.7) and (3.8) for test functions as fixed in Definition 4.4 using (4.11)–(4.13), which yields relations (4.8) and (4.9), respectively.

Finally, consider bounded initial values. Then the regularized initial values are also bounded by $b^i_{0\varepsilon} = b^i_\varepsilon(u^i_{0\varepsilon}) \le C^i$. Since $(b^i_\varepsilon)^{-1}(s) \to (b^i)^{-1}(s)$ as $\varepsilon \to 0$ for every fixed $s \ge 0$, we find bounds c^i_ε such that

$$0 \le u^i_{0\varepsilon} \le c^i_\varepsilon, \qquad c^{i+1}_\varepsilon = \psi^i(c^i_\varepsilon), \qquad \text{and} \quad c^i_\varepsilon \to c^i \quad \text{as } \varepsilon \to 0.$$

Hence, the boundedness assertion $u^i_\varepsilon \le c^i_\varepsilon$ a.e. on Ω^i_T from Theorem 3.2 yields the boundedness assertion for u^i. □

All arguments in the preceding proof to obtain the convergence properties (4.11)–(4.15) remain the same if we fix n, choose test functions from $L^2(0,T;V)$, and let ε pass to zero. This proves the existence of a solution to the free boundary problem with conditions on the interfaces Γ^i as formulated in (3.8).

COROLLARY 4.6. *Suppose assumptions of Theorem* 4.5. *Then there is a weak solution to the free boundary problem* (3.6) *with* $b^i(u)$ *given by* (1.6), *i.e., there are functions* $u \in L^2(0,T;V)$ *and* $w^i \in L^2(\Omega^i_T)$ *with* $\partial_t w^i \in L^2(0,T;V^*_i)$ *fulfilling relations* (4.8) *and*

$$\sum_{i=1}^k \left(\int_0^T \langle \partial_t w^i, \phi^i \rangle \, dt \; + \int_0^T \int_{\Omega^i} \nabla u^i \nabla \phi^i \, dx dt \right)$$
$$+ \; n \sum_{i=1}^k \int_0^T \int_{\Gamma^i} \left(u^{i+1} - \psi^i(u^i) \right) \left(\phi^{i+1} - \phi^i \right) \, d\sigma dt = 0$$

for any $\phi \in L^2(0,T;V)$, $u^{k+1} \equiv \phi^{k+1} \equiv 0$.

Remark. For bounded initial values we obtain bounded solutions. DiBenedetto and Vespri prove in [5] that a bounded solution to (1.1) is locally continuous if it can be approximated in the topology of our approximation by a sequence of local smooth solutions to (1.1) for smooth $b^i_\varepsilon(\cdot)$. Hence, if our approximations u^i_ε were smooth on Ω^i_T, then u^i is continuous in Ω^i_T.

5. Nonlinear diffusion. Finally, let $b^i(u)$ and $\psi^i(u)$ be sufficiently smooth functions defined for $u \in \mathbb{R}$, say $C^2(\mathbb{R})$, which for some constants κ and K satisfy

$$0 < \kappa \le (b^i)', \; (\psi^i)' \le K \tag{5.1}$$

for $i \in \{1, \dots, k\}$, $b^i(0) = \psi^i(0) = 0$, and $|(b^i)''|, |(\psi^i)''| \le K$ on $\mathbb{R}$.

The above can be viewed as monotone continuously differentiable regularization of the graph b^i and the function ψ^i from the beginning. See (1.7) and (1.8) above.

The main aim of this section is to show, at least in this regular case, that the nonlinear diffusion multicomponent system with the jump conditions $u^{i+1} = \psi^i(u^i)$ between two components is uniquely solvable. For one component Alt and Luckhaus [1] prove uniqueness for continuous b under an additional regularity assumption which is quite similar to our condition (5.5). In the case without interfaces Γ^i, however, this condition may be omitted (cf. also the remark after the proof of Theorem 5.2). Carrillo [4, Theorem 14 and Corollary 10] proves uniqueness of the solution without condition (5.5) to even more general equations using Kruzhkov's method of doubling variables. In our case with the contact condition this method seems to be very complicated. Therefore, we have derived a comparison result by solving the dual problem again. But contrary to the proof of Theorem 3.3 we have now the jump condition (5.4) on the interfaces, hence the corresponding dual problem has a transmission condition on Γ^i.

Thus, let us now consider the problem

$$\begin{aligned}
&\partial_t b^i(u^i) = \Delta u^i && \text{in } \Omega^i_T\,,\ i=1,\dots,k,\\
&u^i = \psi^{i-1}(u^{i-1}) \quad \text{and} \quad \partial_{\nu_i} u^i + \partial_{\nu_{i-1}} u^{i-1} = 0 && \text{on } \Gamma^{i-1}_T,\ i=2,\dots,k,\\
&\partial_{\nu_i} u^i = 0 && \text{on } \mathcal{T}^i_T\,,\ i=1,\dots,k,\\
&u^k = 0 && \text{on } \Gamma^k_T,\\
&u^i = u^i_0 \geq 0 && \text{on } \Omega^i_0\,,\ i=1,\dots,k,
\end{aligned} \tag{5.2}$$

where initial data u^i_0 are supposed to be bounded and sufficiently smooth.

Definition 5.1. *We say now that a k-tuple $u = (u^1,\dots,u^k) \in L^2(0,T;V)$ is a weak solution of the system* (5.2) *provided that*

(i)

$$\sum_{i=1}^k \left(\int_{\Omega^i} b^i(u^i(x,t))\, \phi^i(x,t)\, dx - \int_0^t \int_{\Omega^i} \left(b^i(u^i)\partial_\tau \phi^i - \nabla u^i \nabla \phi^i \right) \, dx d\tau \right)$$

$$= \sum_{i=1}^k \int_{\Omega^i} b^i(u^i_0)\, \phi^i(x,0)\, dx \tag{5.3}$$

is fulfilled for any $\phi \in L^2(0,T;\tilde V)$ with $\phi_t \in L^2(\Omega_T)$ (recall that $\phi^{i+1} = \phi^i$ on Γ^i is required above) and a.e. $t \in [0,T]$;

(ii)

$$u^{i+1} = \psi^i(u^i) \qquad \text{a.e. on } \Gamma^i_T, \tag{5.4}$$

$i = 1,\dots,k$; and finally,

(iii) *there exists a positive constant C such that*

$$\sum_{i=1}^k \int_0^{T-h} \int_{\Omega^i} \left| u^i(x,t+h) - u^i(x,t) \right| \, dxdt \ \leq\ Ch \tag{5.5}$$

for $h > 0$.

A subsolution (supersolution) is defined by (5.3) *with equality replaced by $\leq$ $(\geq)$ and $\phi^i \geq 0$ on Ω^i_T for each $i \in \{1,\dots,k\}$.*

Theorem 5.2. *Let u be a subsolution and v a supersolution of the problem* (5.2) *with initial data u_0 and v_0, respectively. Then if $u_0 \leq v_0$, i.e., $u^i_0 \leq v^i_0$ a.e. on Ω^i for any $i \in \{1,\dots .k\}$, it follows that*

$$u^i(x,t) \leq v^i(x,t) \tag{5.6}$$

a.e. on Ω^i_T for any $i \in \{1,\dots,k\}$.

Moreover, if u *and* v *are weak solutions of the problem* (5.2) *with initial functions* u_0 *and* v_0*, respectively, then for almost all* $t \in [0,T]$ *the inequality* (3.11) *holds.*

Proof. Let $0 < t \le T$ be fixed. Take the difference of the integral inequalities satisfied by u and v for sufficiently smooth $\phi^i \ge 0$. Then

$$\begin{aligned}
&\sum_{i=1}^{k}\Big\{\int_{\Omega^i}\big(b^i(u^i(x,t)) - b^i(v^i(x,t))\big)\ \phi^i(x,t)\,dx\\
&\qquad -\int_0^t\int_{\Omega^i}\big(\psi^i(x,u^i(x,\tau)) - \psi^i(x,v^i(x,\tau))\big)\big[\alpha^i(x,\tau)\partial_t\phi^i(x,\tau)\\
&\qquad + \mu^i(x,\tau)\Delta\phi^i(x,\tau)\big]\ dxd\tau\Big\}\\
&\qquad + \sum_{i=1}^{k}\int_0^t\int_{\Gamma^i}\big(\psi^i(x,u^i(x,\tau)) - \psi^i(x,v^i(x,\tau))\big)\\
&\qquad \times\big[\mu^i(x,\tau)\partial_{\nu_i}\phi^i + \mu^{i+1}(x,\tau)\partial_{\nu_{i+1}}\phi^{i+1}\big]\ d\sigma d\tau\\
&\quad \le \sum_{i=1}^{k}\int_{\Omega^i}\big(b^i(u_0^i(x)) - b^i(v_0^i(x))\big)\ \phi^i(x,0)\,dx.
\end{aligned} \tag{5.7}$$

Recall that we require $\phi^i = \phi^{i+1}$ on Γ^i. In (5.7),

$$\psi^i(x,u) \equiv \begin{cases} u & \text{if } x \in \Gamma^{i-1},\\ \psi^i(u) & \text{if } x \in \Gamma^i,\end{cases}$$

and for $x \in \Omega^i$, say

$$\psi^i(x,u) \equiv u\,\omega^i(x) + \psi^i(u)\,\varpi^i(x),$$

where nonnegative functions ω^i, $\varpi^i \in C^\infty(\bar\Omega^i)$ are such that

$$\omega^i(x) + \varpi^i(x) \equiv 1$$

for $x \in \bar\Omega^i$, $\omega^i \equiv 1$ on a neighborhood of Γ^{i-1}, and $\omega^i \equiv 0$ on a neighborhood of Γ^i, $\psi^k(x,u) = u$ for $x \in \bar\Omega^k$ and $\psi^1(x,u) = \psi^1(u)$ on $\bar\Omega^1$. Note that due to (5.4)

$$\psi^{i+1}(x,u^{i+1}(x,t)) = \psi^i(x,u^i(x,t)) \tag{5.8}$$

for any $x \in \Gamma^i$ and $t \in (0,T)$ and similarly for v^i. Finally,

$$\alpha^i(x,\tau) \equiv \frac{b^i(u^i(x,\tau)) - b^i(v^i(x,\tau))}{\psi^i(x,u^i(x,\tau)) - \psi^i(x,v^i(x,\tau))}$$

and

$$\mu^i(x,\tau) \equiv \frac{u^i(x,\tau) - v^i(x,\tau)}{\psi^i(x,u^i(x,\tau)) - \psi^i(x,v^i(x,\tau))}\ .$$

It follows from (5.1) that

$$0 < \kappa \le \alpha^i(x,\tau), \mu^i(x,\tau) \le K$$

for any $(x,\tau) \in \Omega^i_T$, $i = 1, \dots, k$. Now, let R_ε be the standard mollifier in (x,τ) variables and set

$$\alpha^i_\varepsilon(x,\tau) \equiv \frac{b^i(u^i_\varepsilon(x,\tau)) - b^i(v^i_\varepsilon(x,\tau))}{\psi^i(x,u^i_\varepsilon(x,\tau)) - \psi^i(x,v^i_\varepsilon(x,\tau))},$$

$$\mu^i_\eta(x,\tau) \equiv \frac{u^i_\eta(x,\tau) - v^i_\eta(x,\tau)}{\psi^i(x,u^i_\eta(x,\tau)) - \psi^i(x,v^i_\eta(x,\tau))},$$

where $u^i_\varepsilon(x,\tau) = (R_\varepsilon * u^i)(x,\tau)$, $u^i_\eta(x,\tau) = (R_\eta * u^i)(x,\tau)$, and analogously for v^i, $0 < \varepsilon, \eta \ll 1$.

Finally, let $\varphi_{\varepsilon\eta} = (\varphi^1_{\varepsilon\eta}, \dots, \varphi^k_{\varepsilon\eta})$, $\varphi_{\varepsilon\eta} = \varphi_{\varepsilon\eta}(x,s)$ be the solution of the regularized dual problem

$$\begin{aligned}
&\alpha^i_\varepsilon(x,t-s)\partial_s\varphi^i = \mu^i_\eta(x,t-s)\Delta\varphi^i && \text{in } \ \Omega^i_t\,,\ i = 1,\dots,k,\\
&\mu^i_\eta(x,t-s)\partial_{\nu_i}\varphi^i + \mu^{i+1}_\eta(x,t-s)\partial_{\nu_{i+1}}\varphi^{i+1} = 0, && \\
&\text{and} \quad \ \varphi^i = \varphi^{i+1} && \text{on } \ \Gamma^i_t\,,\ i = 1,\dots,k-1,\\
&\varphi^k = 0 && \text{on } \ \Gamma^k_t,\\
&\partial_{\nu_i}\varphi^i = 0 && \text{on } \ \mathcal{T}^i_t\,,\\
&\varphi^i = \varphi^i_0,\ \ 0 \le \varphi^i_0 \le 1 && \text{on } \ \Omega^i \times \{s = 0\},
\end{aligned} \tag{5.9}$$

assuming that $\varphi^{i+1}_0 = \varphi^i_0$ on Γ^i. As we were not able to prove the existence of the solution $\varphi^i_{\varepsilon\eta}$ from $W^{2.1}_2(\Omega^i_t)$, we have to work in the class of weak solutions and we rewrite the inequality (5.7) into the form

$$\begin{aligned}
&\textstyle\sum_{i=1}^k \{\int_{\Omega^i} \big(b^i(u^i(t)) - b^i(v^i(t))\big)\ \varphi^i(x,0)\, dx\\
&+\ \textstyle\int_0^t \int_{\Omega^i} \big(\psi^i(x,u^i) - \psi^i(x,v^i)\big)\, \alpha^i(x,\tau)\, \partial_s\varphi^i(x,t-\tau)\, dxd\tau\\
&+\ \textstyle\int_0^t \int_{\Omega^i} \nabla\varphi^i(x,t-\tau)\, \nabla\left[\mu^i(x,\tau)\big(\psi^i(x,u^i) - \psi^i(x,v^i)\big)\right]\, dxd\tau\} \le\ 0
\end{aligned} \tag{5.10}$$

for any φ^i, $\ \varphi^{i+1} = \varphi^i$ on Γ^i_t, where we have put

$$\phi^i(x,\tau) = \varphi^i(x,t-\tau), \qquad i = 1,\dots,k\,.$$

By the weak formulation of the regularized dual problem (5.9) we understand the following identity:

$$\sum_{i=1}^k \int_0^t \int_{\Omega^i} \big(\alpha^i_\varepsilon\ \partial_s\varphi^i\ \xi^i\ +\ \nabla\varphi^i\ \nabla\left(\mu^i_\eta\ \xi^i\right)\big)\ dxd\tau\ =\ 0 \tag{5.11}$$

for any $\xi = (\xi^1, \dots, \xi^k) \in L^2(0,t;\tilde V)$. In (5.11) we expect to have

$$\varphi^i \in H^1(0,t;L^2(\Omega^i)) \cap L^2(0,t;V_i)\ , \quad 0 \le \varphi^i \le 1.$$

Indeed, the following assertion holds.

Lemma 5.3. *Let $0 < \varepsilon, \eta \ll 1$ be given. Then there exists a weak solution $\varphi_{\varepsilon\eta}$ of* (5.9) *such that*

$$\int_0^t \int_{\Omega^i} \left|\partial_s\varphi^i_{\varepsilon\eta}\right|^2\ dxd\tau + \max_{0\le t\le T} \int_{\Omega^i} \left|\nabla\varphi^i_{\varepsilon\eta}\right|^2 dx\ \le\ C_1(\eta), \tag{5.12}$$

where the positive constant C_1 *depends on*

$$\left\|\partial_t \mu^i_\eta\right\|_{L^\infty(\Omega^i_T)} \qquad \textit{and} \qquad \left\|\nabla \mu^i_\eta\right\|_{L^\infty(\Omega^i_T)}$$

and does not depend on ε. *In addition,*

$$\int_0^t \int_{\Omega^i} \left|\nabla \varphi^i_{\varepsilon\eta}\right|^2 \, dx d\tau \;\leq\; C_2(\varepsilon, \eta), \tag{5.13}$$

where the positive constant C_2 *depends on*

$$\left\|\nabla \mu^i_\eta\right\|_{L^2(\Omega^i_T)} \qquad \textit{and} \qquad \left\|\partial_t \alpha^i_\varepsilon\right\|_{L^1(\Omega^i_T)},$$

and

$$0 \leq \varphi^i_{\varepsilon\eta} \leq 1 \qquad \textit{on} \qquad \Omega^i_T \; .$$

Proof. We shall approximate problem (5.9) by the following way:

$$\begin{aligned}
&\alpha^i_\varepsilon(x, t-s)\, \partial_s \varphi^i = \mu^i_\eta(x, t-s)\, \Delta \varphi^i && \text{in } \Omega^i_t, \\
&\mu^i_\eta(x, t-s)\partial_{\nu_i} \varphi^i + n(\varphi^i - \varphi^{i-1}) = 0 && \text{on } \Gamma^{i-1}_t, \\
&\mu^i_\eta(x, t-s)\partial_{\nu_i} \varphi^i + n(\varphi^i - \varphi^{i+1}) = 0 && \text{on } \Gamma^i_t, \\
&\mu^i_\eta(x, t-s)\partial_{\nu_i} \varphi^i = 0 && \text{on } \mathcal{T}^i_t, \\
&\varphi^i = \varphi^i_0 && \text{on } \Omega^i \times \{s = 0\}.
\end{aligned} \tag{5.14}$$

1. First of all, the existence of a weak solution $\varphi_n = \varphi_{\varepsilon\eta n} \in L^2(0, T; V) \cap H^1_2(0, T; V^*)$ of (5.14) such that $0 \leq \varphi^i_n \leq 1$, $i = 1, \ldots, k$, can be proved in the same way as it was done in the proof of Theorem 3.3 above and we omit further details. Now, testing (5.14) with φ^i_n and adding up through $i = 1, \ldots, k$ we get

$$\begin{aligned}
&\textstyle\sum_{i=1}^k \left\{\kappa \int_{\Omega^i} \left|\varphi^i_n(x,t)\right|^2 dx \;+\; 2\kappa \int_0^t \int_{\Omega^i} \left|\nabla \varphi^i_n\right|^2 dx\, ds\right\} \\
&+\; \textstyle\sum_{i=1}^k 2n \int_0^t \int_{\Gamma^i} \left|\varphi^{i+1} - \varphi^i\right|^2 d\sigma ds \;\leq\; \sum_{i=1}^k K \int_{\Omega^i} \left|\varphi^i_0(x)\right|^2 dx \\
&+\; \textstyle\sum_{i=1}^k \left\{\int_0^t \int_{\Omega^i} \left|\partial_s \alpha^i_\varepsilon\right| \; dx ds \;+\; 2 \left\|\nabla \varphi^i_n\right\|_{L^2(\Omega^i_t)} \left\|\nabla \mu^i_\eta\right\|_{L^2(\Omega^i_t)}\right\}
\end{aligned}$$

and (5.13) for $\varphi^i_{\varepsilon\eta n}$ follows easily due to Gronwall's lemma.

2. Now, assume for a moment that φ^i_n are so smooth that we can test (5.14) with $\partial_s \varphi^i_n$ and perform all necessary manipulations to arrive at

$$\begin{aligned}
&\textstyle\sum_{i=1}^k \int_0^t \int_{\Omega^i} \left(\alpha^i_\varepsilon \left|\partial_s \varphi^i_n\right|^2 + \partial_s \left(\mu^i_\eta |\nabla \varphi^i_n|^2\right) - |\nabla \varphi^i_n|^2 \partial_s \mu^i_\eta\right) dx\, ds \\
&+\; \textstyle\sum_{i=1}^k \left\{2 \int_0^t \int_{\Omega^i} \nabla \varphi^i_n \; \partial_s \varphi^i_n \; \nabla \mu^i_\eta \; dx\, ds + n \int_0^t \int_{\Gamma^i} \partial_s (\varphi^{i+1} - \varphi^i)^2 \, d\sigma ds\right\} \;=\; 0.
\end{aligned}$$

Hence, (5.12) for $\varphi^i_{\varepsilon\eta n}$ follows easily. This can be made precise performing analogous manipulations with

$$\partial^h_s \varphi^i_n \equiv \frac{\varphi^i_n(x, s+h) - \varphi^i_n(x, s)}{h}$$

instead of $\partial_s \varphi^i_n$ and let us omit these modifications.

Finally, as all estimates are independent of n, they hold for limit functions $\varphi^i_{\varepsilon\eta}$ also. □

Now, due to (5.8) we can insert

$$\xi^i = \psi^i(\cdot, u^i) - \psi^i(\cdot, v^i)$$

as a test function in (5.11) that together with (5.10) yields

$$\begin{aligned}\sum_{i=1}^{k} \Big\{ \int_{\Omega^i} & \left(b^i(u^i(t)) - b^i(v^i(t))\right) \ \varphi^i_{\varepsilon\eta}(x,0)\, dx \\ &+ \int_0^t \int_{\Omega^i} \big[\left(\psi^i(x,u^i) - \psi^i(x,v^i)\right)\ (\alpha^i - \alpha^i_\varepsilon)\, \partial_s \varphi^i_{\varepsilon\eta} \\ &+ \nabla \varphi^i_{\varepsilon\eta}\, \nabla \left((\mu^i - \mu^i_\eta)(\psi^i(x,u^i) - \psi^i(x,v^i))\right)\big]\ dx d\tau \Big\} \le\ 0. \end{aligned} \tag{5.15}$$

Before letting $\varepsilon \to 0$ let us note that

$$(5.5) \qquad \text{yields} \qquad \int_0^T \int_{\Omega^i} \left|\partial_t u^i_\varepsilon(x,t)\right|\ dxdt\ \le\ C,$$

where u^i_ε is defined above; cf. (5.8)–(5.9). The same holds true for $\partial_t v^i_\varepsilon$. Therefore, due to (5.1) and what follows we have

$$\left\|\partial_t \alpha^i_\varepsilon\right\|_{L^1(\Omega^i_T)}\ \le\ C \int_0^T \int_{\Omega^i} \left(\left|\partial_t u^i_\varepsilon(x,t)\right| + \left|\partial_t v^i_\varepsilon(x,t)\right|\right)\ dx\, dt\ \le\ C$$

and also

$$\left\|\nabla \mu^i_\eta\right\|_{L^2(\Omega^i_T)} \le C,$$

C being independent of ε, η. Hence, (5.13) remains uniformly bounded and we are ready to let $\varepsilon \to 0$ and afterwards $\eta \to 0$ in (5.15) to get

$$\sum_{i=1}^{k} \int_{\Omega^i} \left(b^i(u^i(x,t)) - b^i(v^i(x,t))\right)\ \varphi^i_0(x)\, dx\ \le\ 0.$$

As this holds for any smooth function φ^i_0, $0 \le \varphi^i_0 \le 1$, it also continues to hold for $\varphi^i_0 = \chi(u^i(x,t) - v^i(x,t))$, and (5.6) follows easily. The rest of the proof is the same as in Theorem 3.3. □

Remark. If $\psi^i(u) \equiv u$ for all $i = 1, \dots, k$ we have $\mu^i = \mu^i_\eta \equiv 1$. In that case we do not need condition (5.5) for uniqueness since the estimates (5.12) and (5.13) do not depend on η; moreover, (5.13) is not needed. Then, however, we have no jumps on the interfaces Γ^i, which is the special case of a solution $u \in L^2(0,T;H^1(\Omega))$ on one component.

We show now that the solution of (5.2), which we get as the limit of the sequence of solutions to (3.6) under the assumption (5.1), indeed satisfies (5.5).

Theorem 5.4. *In addition to the conditions of section* 4 *we assume* $u^i_0 \in V_i \cap W^2_1(\Omega^i)$, (5.1), *and the compatibility condition*

$$u^{i+1}_0 = \psi^i(u^i_0) \qquad \text{on } \Gamma^i, \quad i = 1, \dots, k. \tag{5.16}$$

Then the solution of problem (5.2) *obtained by Theorem* 4.5 *is a solution in the sense of Definition* 5.1. *In particular, this solution satisfies condition* (5.5).

Proof. Consider the approximate problem (3.6). Theorem 3.2 yields the existence of a solution u_n. We want to show that $b^i(u_n^i)$ fulfills condition (5.5) with a constant C independent of n. Since b is continuous we obtain strong convergence $b^i(u_n^i) \to b^i(u^i)$ as $n \to \infty$ in $L_1(\Omega_T^i)$ where u is a solution of (5.2) (see the proof of Theorem 4.5). Then (5.1) yields the assertion.

Hence, let us estimate the difference $b^i(u^i(x,t+h)) - b^i(u^i(x,t))$ in $L^1(\Omega^i)$ for a.e. $t \in [0, T-h]$ where u is a solution of (3.6). We follow the idea of the proof of Theorem 3.3 replacing $v(x,t)$ by $u(x,t+h)$. Then all manipulations remain the same if we are able to manage the item

$$b^i(u^i(x,t_0+h)) - b^i(u^i(x,t_0))$$

at some initial time t_0. To this end we fix $h > 0$ and extend problem (2.6) to the interval $t \in [-h, T]$. Define

$$\tilde{u}(x,t) = \begin{cases} u(x,t) & \text{for } t \in [0,T], \\ u_0(x) & \text{for } t \in [-h,0], \end{cases}$$

and note that $\tilde{u}$ is the solution of

$$\begin{aligned} &\partial_t b^i(\tilde{u}^i) = \Delta \tilde{u}^i + F^i && \text{in } \Omega^i \times (-h,T), \\ &\partial_{\nu_i} \tilde{u}^i + n\left(\tilde{u}^i - \psi^{i-1}(\tilde{u}^{i-1})\right) = f^i && \text{on } \Gamma^{i-1} \times (-h,T), \\ &\partial_{\nu_i} \tilde{u}^i + n\left(\psi^i(\tilde{u}^i) - \tilde{u}^{i+1}\right) = f^i && \text{on } \Gamma^{i} \times (-h,T), \\ &\partial_{\nu_i} \tilde{u}^i = f^i && \text{on } \mathcal{T}^{i} \times (-h,T), \\ &\tilde{u}^i = u_0^i && \text{on } \Omega^{i} \times (-h,0], \end{aligned} \tag{5.17}$$

with

$$\begin{aligned} F^i(x,t) &= -\chi_{[-h,0]}(t)\, \Delta u_0^i(x), && t \in [-h,T],\, x \in \Omega^i, \\ f^i(x,t) &= \chi_{[-h,0]}(t)\, \partial_{\nu_i} u_0^i(x), && t \in [-h,T],\, x \in \partial\Omega^i, \end{aligned}$$

$i = 1, \dots, k$. Here we have used compatibility condition (5.16). Note that F^i and f^i do not depend on the approximation parameter n. Now we proceed as in the proof of Theorem 3.3 for problem (5.17) instead of (3.6) with $u = \tilde{u}(x,t), v = \tilde{u}(x,t+h)$. Since we integrate over $\tau \in [-h,t]$, by our construction the item

$$\begin{aligned} \int_{\Omega^i} \left(b^i(u_0^i) - b^i(v_0^i)\right) \varphi^i(x,t)\, dx &:= \int_{\Omega^i} \left(b^i(\tilde{u}^i(x,-h)) - b^i(\tilde{u}^i(x,0))\right) \varphi^i(x,t)\, dx \\ &= \int_{\Omega^i} \left(b^i(u_0^i) - b^i(u_0^i)\right) \varphi^i(x,t)\, dx \end{aligned}$$

on the right-hand side of (3.12) disappears. On the other hand, the following additional items appear:

$$\begin{aligned} r^i(\varphi^i, h) = &\int_{-h}^t \int_{\Omega^i} \left(F^i(x,\tau) - F^i(x,\tau+h)\right)\, \varphi^i(x,t-\tau)\, dx d\tau \\ &+ \int_{-h}^t \int_{\partial\Omega^i} \left(f^i(x,\tau) - f^i(x,\tau+h)\right)\, \varphi^i(x,t-\tau)\, d\sigma d\tau. \end{aligned}$$

Again we choose a solution φ^i of the regularized dual problem (3.16) as test function. Since it is bounded by (3.17) by the definition of F^i, f^i we can estimate these additional items by

$$|r^i(\varphi^i,h)| \le h\,(\|\Delta u_0^i\|_{L^1(\Omega^i)} + \|\partial_{\nu_i} u_0^i\|_{L^1(\partial\Omega^i)}) \equiv C_0^i\,h\,.$$

Therefore, performing the manipulations as in the proof of Theorem 3.3, we finally arrive at

$$\sum_{i=1}^{k} \int_{\Omega^i} |b^i(u^i(x,t+h)) - b^i(u^i(x,t))|\,dx \ \le\ \sum_{i=1}^{k} C_0^i\,h \tag{5.18}$$

for a.e $t \in [0, T-h]$, which concludes the proof. □

Remark. Actually, we have proven a stronger condition than (5.5). Indeed, the solution u_n of the approximate problem (3.6) fulfills the Lipschitz condition (5.18) pointwise with respect to time. Since convergence of $b^i(u_n^i)$ in $L^1(\Omega_T^i)$ implies convergence of a subsequence in $L^1(\Omega^i)$ for a.e. $t \in [0, T-h]$ we even obtain

$$\sum_{i=1}^{k} \int_{\Omega^i} |u^i(x,t+h) - u^i(x,t)|\,dx \ \le\ C\,h \qquad \text{for a.e. } t \in [0, T-h].$$

A RENORMALIZATION METHOD FOR MODULATIONAL STABILITY OF QUASI-STEADY PATTERNS IN DISPERSIVE SYSTEMS[*]

KEITH PROMISLOW[†]

Abstract. We employ global quasi-steady manifolds to rigorously reduce forced, linearly damped dispersive partial differential equations to finite dimensional flows. The manifolds we consider are not invariant, but through a renormalization group method we capture the long-time evolution of the full system as a flow on the manifold. For the parametric nonlinear Schrödinger equation we consider a manifold describing N well-separated pulses and derive an explicit system of ordinary differential equations for the flow on the manifold which captures the leading order pulse motion through the tail-tail interactions. We also outline a rigorous connection between the slow evolution in the hyperbolic PNLS and the fourth-order parabolic phase sensitive amplification equation for fiber optic systems.

Key words. parametric nonlinear Schrödinger, renormalization group, orbital stability, invariant manifold

1. Introduction.

Many nonlinear optical processes are modeled by partial differential equations which are dominated by dispersive effects. We are interested in a class of these equations which we write abstractly in terms of a vector field F,

$$U_t = F(U). \tag{1.1}$$

In this setting one can often explicitly construct a family of quasi-steady states $\Phi(\mathbf{p})$ parameterized by $\mathbf{p} \in \mathcal{K} \subset \mathbf{R}^N$ for which the residual vector field $F(\Phi(\mathbf{p}))$ satisfies $F(\Phi(\mathbf{p})) = O(\delta)$ for some $\delta \ll 1$. Such families naturally arise as leading order terms in formal asymptotic expansions of exact steady states or of quasi-steady solutions, as in the example we consider here of a linear sum of steady pulses interacting weakly through asymptotically flat tails. If the underlying steady states possess some stability, it is natural to expect that the manifold $\mathcal{M} = \{\Phi(\mathbf{p}) \big| \mathbf{p} \in \mathcal{K}\}$ will retain some degree of local attractivity, that is, solutions U of the full equation may be decomposed as $U(t) = \Phi(\mathbf{p}(t)) + W(t)$, where the time dependent parameters $\mathbf{p}(t)$ shadow the slow evolution of U along the manifold up to a small remainder term W. Previously, modulational stability applied to individual pulses [35, 24] has yielded results that are local in the sense that the full solution must remain close to the initial pulse configuration for the modulational description to retain its force. The method presented here is not tied to a particular local coordinate system; rather, in the spirit of Goldenfeld and Onoo's renormalization group techniques [13], we build our description by taking an envelope of a family of approximate or "naive" perturbation expansions, renormalizing away secularities through a slow modulation of parameters. In this manner we obtain a rigorous reduction of the infinite dimensional system to

a finite dimensional one which is more amenable to analysis. In the application to interacting pulses, the reduced system governs the motion of the pulse positions. The method presented here is robust; without modification it can accommodate the background noise ubiquitous in optical systems, capturing these effects as time dependent perturbations to the reduced family of differential equations.

Invariant manifolds have long played a central role in the reduction of *dissipative* flows to lower dimensional systems. The smoothing properties afforded by dissipation make possible the application of a very developed body of invariant manifold theorems [4, 5, 12] to a wide class of problems, including blow-up, decay, and meta-stable behaviors [6, 10, 23, 32, 33]. For systems which are dominated by dispersion, the construction of invariant manifolds is less clear. Smoothing properties for dispersive systems are typically manifested only in weighted spaces, and results have largely been restricted to single hump traveling waves [34]. The renormalization group technique developed herein overcomes the lack of smoothing properties of the underlying equations by renormalizing away secular terms. In some sense the results we obtain are a step towards a rigorous justification of the Lagrangian reduction or collective coordinate literature widely used to model dispersive Hamiltonian systems; see [3, 18] and particularly [26] and the references therein. These methods assume a multiparameter ansatz and develop a family of ordinary differential equations for the parameters from an averaged variational principle for the Lagrangian (see Whitham [36]), which serves to project the vector field onto the tangent plane of the manifold formed by the parameterized ansatz.

Our technique can also be viewed as a modification of the renormalization group developed by Bricmont and Kupiainen [8] for asymptotics of decay in dissipative partial differential equations. The underpinning of the renormalization group is a *family* of decompositions $\{(G_n, \pi_n, t_n)\}_{n=0}^{\infty}$ where G_n represents a rescaling of the dependent and independent variables, π_n is a projection, and t_n is an initial time. The decompositions serve to break the initial value problem for (1.1) into an *equivalent* sequence of initial value problems on the time intervals $[t_n, t_{n+1}]$. The purpose of renormalization is to adapt the coordinate system to the flow on the given time interval. The projection π_n decomposes the phase space, associating to each point U a point Φ_n in the low dimensional manifold $\Phi_n = \pi_n G_n U$ and a remainder $W_n = (I - \pi_n) G_n U$, so that

$$G_n U = \Phi_n + W_n. \tag{1.2}$$

The decomposition applied to (1.1) yields an evolution equation,

$$\begin{aligned} \partial_t \Phi_n &= \pi_n F_n(\Phi_n + W_n), \\ \Phi_n(0) &= \pi_n G_n U(t_n), \\ \partial_t W_n &= (I - \pi_n) F_n(\Phi_n + W_n), \\ W_n(0) &= (I - \pi_n) G_n U(t_n), \end{aligned} \tag{1.3}$$

where F_n represents the rescaled flow, i.e., $(G_n U)_t = F_n(G_n U)$. The nonlinear semigroup S_n for the nth flow gives the map

$$S_n(t) : \begin{pmatrix} \Phi_n(0) \\ W_n(0) \end{pmatrix} \mapsto \begin{pmatrix} \Phi_n(t) \\ W_n(t) \end{pmatrix},$$

which, together with the rescaling and projection implicit in the mapping

$$U(t_{n+1}) \mapsto \begin{pmatrix} \Phi_{n+1}(0) \\ W_{n+1}(0) \end{pmatrix},$$

induce the renormalization operators

$$R_n : \begin{pmatrix} \Phi_n(0) \\ W_n(0) \end{pmatrix} \mapsto \begin{pmatrix} \Phi_{n+1}(0) \\ W_{n+1}(0) \end{pmatrix}.$$

The renormalization operators enjoy the group structure

$$S(\tau_{n+1}) = G_{n+1}^{-1} \circ R_n \circ R_{n-1} \circ \cdots \circ R_0 \circ G_0,$$

where S denotes the nonlinear semigroup of the original system (1.1). In applications of this method to decay of solutions of dissipative partial differential equations, the rescaling is chosen to follow the self-similar nature of the decay, the remainder is driven to zero, and the renormalization groups R_n converge to a limit R_∞; see [9, 7]. The long-time asymptotics of the original partial differential equation are then reduced to a study of the fixed points of R_∞. In the applications cited, the projection step is performed when studying the fixed points of the renormalization maps, where the projection π_n maps onto a stable manifold of R_n. In the applications we consider here the projection plays a dominant role, and the rescaling is less useful. The renormalization operators R_n do not converge to a limit and we adapt the coordinate system not in response to changes in length and time scales in the underlying evolution, but rather to follow the drift along the quasi-steady manifold, updating the corresponding linearized flow and associated projections which dictate the local evolution.

We assume the quasi-steady manifold is a smoothly parameterized N dimensional manifold $\mathcal{M} = \{\Phi(\mathbf{p}) \big| \mathbf{p} \in \mathcal{K}\}$, and at each point $\Phi(\mathbf{p})$ on the manifold the local linearized operator, $L_{\mathbf{p}}$, engenders a decomposition $X = X_{\mathbf{p}} \oplus Y_{\mathbf{p}}$ of the underlying phase space X into two $L_{\mathbf{p}}$ invariant parts: an N dimensional space $Y_{\mathbf{p}}$ associated with small eigenvalues of $L_{\mathbf{p}}$ and a complimentary space $X_{\mathbf{p}}$ on which $L_{\mathbf{p}}$ generates a $\mathcal{C}_0$ semigroup with a uniform exponential decay rate for all $\mathbf{p}$. This later assumption amounts to a form of normal hyperbolicity, with the fast time scales associated with the decay into a thin neighborhood of the manifold and the slow time scales describing the evolution of the parameters. The flow local to $\Phi(\mathbf{p})$ is governed by the linearized operator, the small residual vector field $F(\Phi)$, and the higher order nonlinearities. In particular the manifold need not be locally invariant under the flow. Rather we assume the manifold is compatible with the local flow in the sense that the space $Y_{\mathbf{p}}$ is well approximated by the local tangent space of the manifold. This decomposition underlies our renormalization group methods and we describe the flow local to $\mathbf{p}$ in terms of a family of modulational equations for the manifold parameters $\mathbf{p}$ and a partial differential equation for the remainder variable W governing the distance to the manifold. We write the evolution equation for W in terms of the linearized operator $L_{\mathbf{p}_0}$ frozen at a point $\mathbf{p}_0$ on the manifold, and build estimates on the growth and decay of W. As the manifold parameters $\mathbf{p}$ evolve away from $\mathbf{p}_0$ a natural secular growth is seen in the estimates for W, and after a finite time, control of W is lost. We remove this secular growth with a renormalization of the evolution equations, updating the base point $\mathbf{p}_0$ through a nonlinear projection; see Figure 2.2 for a graphical representation.

The series of initial value problems generated by the renormalization group method permit us to follow the flow on the manifold without the complication of a time dependent linearized operator. Indeed, we require the operators $L_{\mathbf{p}}$ to generate only a $\mathcal{C}_0$ semigroup on $X_{\mathbf{p}}$, with eventual exponential decay after initial transient growth. It is well known that even if for each fixed t_0 the operator $L(t_0)$ generates an asymptotically contractive semigroup, the flow governed by the linear family of time dependent operators,

$$W_t = L(t)W,$$

need not generate an asymptotically contractive semigroup. The transient growth associated with each fixed operator may never settle down, and the result may be a diminished decay rate or resonant growth. It is precisely this latter phenomenon which Kato excludes with his "stability" assumption (see (1.1) of [17]) required to obtain uniform decay estimates for the semigroup generated by a time dependent family of linear operators. However the verification of the stability assumption typically requires smoothing estimates on the individual operators $L(t_0)$. We use the renormalization method to exploit the fact that the evolution of the parameters $\mathbf{p}$ in $L_{\mathbf{p}}$ is on a slower time scale and the fact that the difference $L_{\mathbf{p}_1} - L_{\mathbf{p}_2}$ is a lower order operator than either of $L_{\mathbf{p}_1}$ or $L_{\mathbf{p}_2}$. In this manner we attain uniform decay estimates without smoothing properties for the semigroup. The situation is particularly clear when considering the evolution of a single pulse, in which case one may be tempted to decompose the solution U of (1.1) as $U(x,t) = \Phi(y) + V(y,t)$, where $y = x - s(t)$ is a traveling variable that shadows the pulse position $s(t)$. When the remainder V is advected with the pulse there is the advantage that the evolution for V is governed by a time independent linear operator

$$V_t = LV + \mathcal{N}(V) + \Phi'(y)s' + V_y s',$$

where $'$ denotes differentiation of a function of one variable, and $\mathcal{N}$ represents nonlinear terms in V. However the term V_y is unbounded and the necessary estimates on V cannot be closed without some smoothing estimates for the semigroup generated by L. It is precisely this "small" infinity $V_y s'$ which we renormalize away.

In section 2 we present the renormalization method for a general framework of dispersive equations, emphasizing the nature of the assumptions required in hypotheses (H0)–(H4). The results of section 2 are summarized in Theorem 2.1. In section 3 we consider applications to the parametrically forced nonlinear Schrödinger (PNLS) equation, which models dispersive phenomenon in damped, forced systems in a variety of settings including plasma waves, Faraday resonance, spin waves and magnetic solitons in ferro-magnets, and pattern formation in optical parametric oscillators [2, 25]. By considering a model for which the linearized operators have been studied [25], we considerably simplify the presentation of the results. Specifically we show the stability of fronts to time dependent perturbations in the defocusing case, and describe the evolution of trains of N well-separated pulses in the focusing case, including pulses with differing up-down orientations. For each configuration of pulses we obtain a family of differential equations for the pulse positions which show that like-signed pulses attract, while opposite-signed pulses repel. This result is evocative of the meta-stable pattern evolution obtained by Carr and Pego [11] for fronts in a reaction-diffusion equation. We contrast our results with those of Kapitula and Sandstede [19], who study the stability of *exact* N-pulses in PNLS created in an orbit-flip bifurcation under the addition of a dissipative regularizing term. We study the unregularized problem, and the modulational equations for the pulse positions (3.53) show there are no exact N-pulse solutions with wide pulse spacing for PNLS. In the discussion we sketch an argument which shows that to leading order the meta-stable pulse motion in the focusing PNLS is the same as that in the phase sensitive amplification (PSA) equation for fiber optics; see [22, 30]. We mention that an extension of the work on N-pulses [27] which recovers some of the results presented here is in preparation [28].

We will employ the following notation throughout the paper. The usual L^p norm is denoted $\|\cdot\|_p$, and the L^2 inner product $(\cdot,\cdot)_2$. The Sobolev norms in H^s will be denoted $\|\cdot\|_{H^s}$, while the induced operator norms on L^2 and H^2 are denoted $\|\cdot\|_{*,2}$ and $\|\cdot\|_{*,H^s}$, respectively. A superscript * denotes complex conjugation while $\Re z$ and $\Im z$ denote the real and imaginary parts of z. The adjoint of an operator L with respect to the L^2 inner product is denoted $L^\dagger$. The superscript ^{t} denotes transposition, and $^\perp$ denotes the orthogonal complement in L^2. The spectrum of a linear operator L is denoted $\sigma(L)$, which we divide into essential $\sigma_e(L)$ and point $\sigma_p(L)$ spectrum. The resolvent set is denoted by $\varrho(L)$. The range and kernel of L are denoted $\mathcal{R}(L)$ and $\ker(L)$, respectively. A superscript $'$ will denote differentiation of a function of a single variable with respect to that variable. We will denote by M any positive constant whose value, which may change from line to line, is independent of any of the small parameters. Occasionally for clarity, we will carry the same constant from one line to the next; we will denote such constants by $M_1, M_2, \ldots$.

2. Abstract formulation of the renormalization method. We consider a class of damped, dispersive wave equations

$$U_t = F(U), \tag{2.1}$$

where

$$F(U) = JU_{xx} + f(U) \tag{2.2}$$

for J a skew matrix. The dependent variable U takes values in $\mathbf{R}^d$, $U : \mathbf{R}\times\mathbf{R}_+ \mapsto \mathbf{R}^d$, and the nonlinear term $f \in \mathcal{C}^2(\mathbf{R}^d, \mathbf{R}^d)$. Of fundamental interest is the evolution of the solutions which reside in a neighborhood of a manifold $\mathcal{M}$ smoothly parameterized by steady or quasi-steady solutions $\Phi(x, \mathbf{p})$ of (2.1) for $\mathbf{p} \in \mathcal{K}$, a compact subset of $\mathbf{R}^N$. More specifically we require that the residual vector field $F\big|_{\mathcal{M}}$ satisfies

$$F(\Phi(\mathbf{p})) = 0 \qquad \text{or} \qquad \|F(\Phi(\mathbf{p}))\|_{H^1} = O(\delta(\mathbf{p})), \tag{2.3}$$

where $\delta(\mathbf{p}) \le \delta_0 \ll 1$ for $\mathbf{p} = (p_1, \ldots, p_N)^t \in \mathcal{K}$. To increase the scope of applications of our method, we modify the equations under consideration to include a small forcing term

$$U_t = F(U) + \delta_0 \tilde{\xi}(U, x, t), \tag{2.4}$$

where $\tilde{\xi}$ satisfies the bound

$$\|\tilde{\xi}(U(\cdot,t),\cdot,t)\|_{H^1} \le M\left(1 + \|U\|_{H^1}^p\right) \tag{2.5}$$

for some $M > 0$ and positive integer p.

The dynamics of (2.4) local to the manifold $\mathcal{M}$ are dominated by the linearized flow. Writing the solution U as a sum

$$U(x,t) = \Phi(x, \mathbf{p}(t)) + W(x,t) \tag{2.6}$$

the evolution for the remainder W is given by

$$W_t = L_{\mathbf{p}} W + \mathcal{N}(W) - \nabla_{\mathbf{p}} \Phi(\mathbf{p})\mathbf{p}' + \delta_0 \xi, \tag{2.7}$$

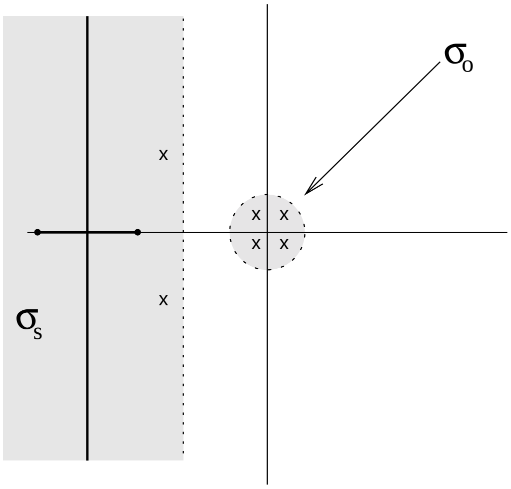

FIG. 2.1. *The spectral decomposition.* $\times$*'s denote eigenvalues and solid dots denote branch points. The dotted line represents the boundary* $\Re\lambda = -k$ *of* σ_s *and the dotted circle of radius* δ_0 *encloses the small eigenvalues of* σ_0.

where

$$L_{\mathbf{p}} = J\partial_x^2 + \nabla f(\Phi(\mathbf{p})), \tag{2.8}$$

the nonlinear terms, $\mathcal{N}$, take the form

$$\mathcal{N}(W) = f(\Phi(\mathbf{p}) + W) - f(\Phi(\mathbf{p})) - \nabla f(\Phi(\mathbf{p}))W,$$

and $\xi \equiv \tilde{\xi} + F(\Phi)/\delta_0$ also satisfies (2.5). The family of linearized operators $\{L_{\mathbf{p}}\}_{\mathbf{p}\in\mathcal{K}}$ plays a central role in the analysis which follows. We make the following assumptions (H0)–(H4) about the operators and the quasi-stationary manifold $\mathcal{M}$.

Quasi-stationarity.

(H0) The manifold $\mathcal{M} = \{\Phi(\mathbf{p}) \big| \mathbf{p} \in \mathcal{K}\}$ is quasi-steady in the sense that

$$\|F(\Phi(\mathbf{p}))\|_{H^1} \leq M\delta_0 \tag{2.9}$$

for some $M > 0$ and all $\mathbf{p} \in \mathcal{K}$. Moreover the quasi-steady ansatz Φ and its first two derivatives with respect to x and $\mathbf{p}$ are uniformly bounded, and the forcing term f and its first two derivatives are uniformly bounded in a neighborhood of $\mathcal{M}$ by some positive constant M.

Normal hyperbolicity.

(H1) The spectrum of each operator $L_{\mathbf{p}}$ may be decomposed into a stable part σ_s, strictly contained in the left-half complex plane, and a slow part σ_0, comprised of a fixed, finite number of small eigenvalues; see Figure 2.1. Specifically

$$\sigma(L_{\mathbf{p}}) = \sigma_s \cup \sigma_0, \tag{2.10}$$

where $\sigma_s \subset \{\lambda \big| \Re\lambda \leq -k\}$ for some $k > 0$ and $\sigma_0 \subset \{\lambda \big| \quad |\lambda| \leq \delta_0\}$, consists of N eigenvalues, up to multiplicity. Both N and k may be chosen independent of $\mathbf{p} \in \mathcal{K}$.

(H2) Each fixed operator $L_{\mathbf{p}}$ generates a $\mathcal{C}_0$ semigroup $S_{\mathbf{p}}$ which satisfies

$$\|S_{\mathbf{p}}(t)u\|_{H^1} \leq Me^{-kt}\|u\|_{H^1} \quad \text{for all } t \geq 0, u \in X_{\mathbf{p}}, \tag{2.11}$$

where $X_{\mathbf{p}}$ is the $L_{\mathbf{p}}$ invariant subspace of H^1 of codimension N associated with the spectrum σ_s. Moreover, M may be chosen independent of $\mathbf{p} \in \mathcal{K}$.

Compatibility. We denote by $Y_{\mathbf{p}}$ the $L_{\mathbf{p}}$ invariant subspace of dimension N complimentary to $X_{\mathbf{p}}$, and refer to $Y_{\mathbf{p}}$ as the slow space.

(H3) We assume that the slow space $Y_{\mathbf{p}}$ is well approximated by the tangent plane of the manifold $\mathcal{M}$; i.e., there is a constant $\delta_C > 0$ small enough and a given ordering $\{\Psi_1, \dots, \Psi_N\}$ of the eigenfunctions of $Y_{\mathbf{p}}$ to which there corresponds a parameterization of the manifold $\mathcal{M}$ verifying

$$\left\| \Psi_i(\mathbf{p}) - \frac{\partial \Phi(\cdot, \mathbf{p})}{\partial \mathbf{p}_i} \right\|_{H^1} \leq \delta_C \qquad \text{for} \quad i = 1, \dots, N \tag{2.12}$$

for each point $\mathbf{p} \in \mathcal{K}$. Here $\delta_C > 0$ is independent of $\mathbf{p} \in \mathcal{K}$.

We denote by $\pi_{\mathbf{p}}$ the $L_{\mathbf{p}}$ spectral projection whose range is $Y_{\mathbf{p}}$, which we construct explicitly as

$$\pi_{\mathbf{p}} u = \sum_{i=1}^{N} (u, \Psi_i^\dagger)_2 \Psi_i, \tag{2.13}$$

where the adjoint eigenvectors $\Psi_i^\dagger$ have been chosen to satisfy the orthonormality conditions

$$(\Psi_i, \Psi_j^\dagger)_2 = \begin{cases} 1, & i = j, \\ 0, & i \neq j. \end{cases} \tag{2.14}$$

We note that the projection π takes this form even if the eigenvalues in σ_0 are not simple.

Stability.

(H4) We assume that the adjoint eigenvectors normalized by (2.14) are uniformly bounded and depend smoothly upon $\mathbf{p}$ for $\mathbf{p} \in \mathcal{K}$; that is,

$$\max_{\substack{i=1,\dots,N \\ \mathbf{p} \in \mathcal{K}}} \left(\|\Psi_i^\dagger(\mathbf{p})\|_{H^1} + \| \quad |\nabla_{\mathbf{p}}^2 \Psi_i^\dagger(\mathbf{p})| \quad \|_{H^1} \right) \leq M. \tag{2.15}$$

We remark that with the normalization we have taken, (2.15) is equivalent to the Jordon chain structure of the eigenvectors of $L_{\mathbf{p}}$ in σ_0 being independent of $\mathbf{p} \in \mathcal{K}$.

Under these assumptions we may prove our main result, stated below.

THEOREM 2.1. *Let a quasi-steady manifold $\mathcal{M} = \{\Phi(\mathbf{p}) \big| \mathbf{p} \in \mathcal{K}\}$ with parameters from $\mathcal{K} \subset \mathbf{R}^N$ be given which satisfies the hypotheses* (H0)–(H4) *for some positive constants M and k. Then for ϵ, δ_0, and δ_C small enough, in terms of M and k, there exist a finite constant M_0 and times T, and T^i all positive, such that for all initial data $U(x, t_0) = U_0(x)$ of the form* (2.20), *the solution U of* (2.4) *can be decomposed as*

$$U = \Phi(x, \mathbf{p}(t)) + W(x, t) \qquad \textit{for}\, t \in [t_0, t_0 + T], \tag{2.16}$$

where the remainder W satisfies

$$\|W(\cdot, t)\|_{H^1} \leq M_0 \left(\epsilon e^{-k(t-t_0)} + \delta_0 \right). \tag{2.17}$$

The parameters $\mathbf{p}(t) = (p_1, \dots, p_N)^t$ *may be chosen to lie on a smooth curve in* $\mathcal{K}$*, and* T*, the time for the curve to exit* $\mathcal{K}$*, satisfies*

$$T > M_0 \operatorname{dist}(\mathbf{p}_*, \partial\mathcal{K})/\delta_0, \tag{2.18}$$

where $\mathbf{p}_*$ *is as given in* (2.20). *After an initial transient, that is, for* $t \geq t_0 + T^i$*, the evolution of the parameters is governed to leading order by the closed system*

$$p_i' = \left(\delta_0 \tilde{\xi} + F(\Phi(\mathbf{p})), \Psi_i^\dagger(\mathbf{p})\right)_2 + O(\delta_0^2) \qquad \text{for } t \geq t_0 + T^i, \tag{2.19}$$

for $i = 1, \dots, N$.

Remark 1. If the evolution equation (2.19) precludes the parameter $\mathbf{p}(t)$ from reaching the boundary $\partial\mathcal{K}$, then we may take $T = \infty$ in the theorem above. We may take $\mathcal{K} \subset \mathbf{R}^N$ to be unbounded so long as the hypotheses (H0)–(H4) hold uniformly for all $\mathbf{p} \in \mathcal{K}$, particularly if M and k in (H0), (H2), and (H4) can be chosen independent of $\mathbf{p}$ over the unbounded set $\mathcal{K}$.

Remark 2. If the initial data U_0 are taken to lie on the manifold, that is, if $U_0 = \Phi(\mathbf{p}_*)$ for some $\mathbf{p}_* \in \mathcal{K}$, then there is no initial transient and we may take $\epsilon = T^i = 0$, and we recover the collective coordinate equations (2.19) immediately at $t = t_0$.

Remark 3. The small parameter δ_C of hypothesis (H3) need only be small enough that the equations (2.28) for $\mathbf{p}'$ have nonzero denominators and that Proposition 2.2 holds. Further reduction in the size of δ_C does not strengthen the results. The error term for the evolution of the manifold parameters (2.19) after the initial transient is dominated by the influence of the remainder. To obtain a more accurate resolution of this reduced flow we must reduce the size of the remainder, which is equivalent to reducing δ_0.

We follow the renormalization group approach outlined in the introduction, breaking the time domain up into intervals $\{[t_n, t_{n+1}]\}_{n=0}^\infty$ and decomposing the space domain with projections $\{\pi_n\}_{n=0}^\infty$. There are two distinct regimes: an initial transient in which the solution converges into a thin $O(\delta_0)$ neighborhood of the manifold and an asymptotic state in which the solution remains within this thin neighborhood; see Figure 2.2. In the asymptotic state the evolution of the full solution can be well described by a closed system of differential equations for the manifold parameters.

2.1. Evolution equations.

We now consider the evolution of a given initial datum U_0 of (2.4), which is near to the manifold $\mathcal{M}$ in the sense that

$$U_0(x) = \Phi(x, \mathbf{p}_*) + \epsilon \hat{W}_0, \tag{2.20}$$

where $\|\hat{W}_0\|_{H^1} \leq 1$ and $\mathbf{p}_*$ is some element of $\mathcal{K}$. It is natural to take ϵ intermediate in size between 1 and δ_0, $1 \gg \epsilon \gg \delta_0$, and we investigate the relaxation of an initial perturbation into the relatively smaller $O(\delta_0)$ neighborhood of the manifold $\mathcal{M}$.

Our analysis requires a local coordinate system in which $W \in X_{\mathbf{p}_0}$ for some $\mathbf{p}_0$. This amounts to solving a nonlinear equation.

Proposition 2.2. *Let the quasi-steady manifold* $\mathcal{M}$ *satisfying hypotheses* (H0)–(H2), (H4) *for some constants* M *and* k *be given. Then for* δ_C *in* (H3) *small enough, in terms of* M *and* k *but independently of* δ_0*, there exist* M_0 *and* $\epsilon_0 > 0$ *such that for all* $\mathbf{p}_* \in \mathcal{K}^o \equiv \{\mathbf{p} \in \mathcal{K} | d(\mathbf{p}_*, \partial\mathcal{K}) > \epsilon_0^{1/2}\}$*, and for all* $\hat{W}_0$ *satisfying* $\|\hat{W}_0\|_{H^1} \leq 1$ *there is a unique smooth function* $\mathcal{H} = \mathcal{H}(\epsilon; \hat{W}_0)$ *which maps* $\mathcal{H} : [-\epsilon_0, \epsilon_0] \to \mathbf{R}^N$ *such that* $\mathcal{H}(0) = 0$ *and the point* $\mathbf{p}(\epsilon) = \mathbf{p}_* + \mathcal{H}(\epsilon)$ *satisfies* $\mathbf{p} \in \mathcal{K}$ *and*

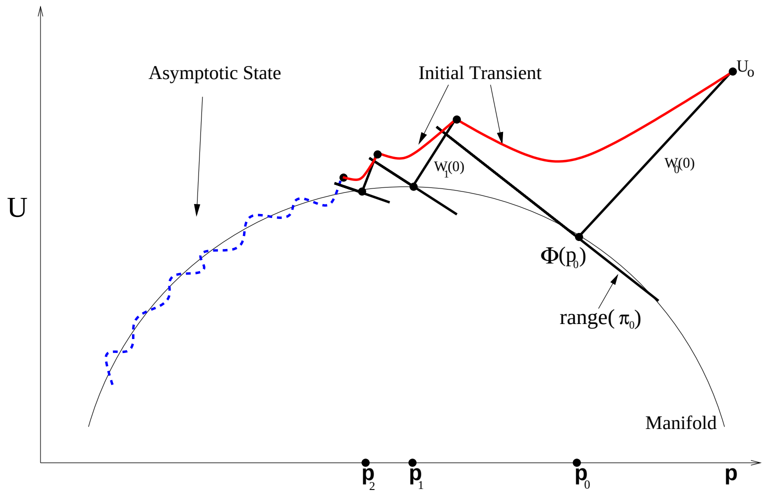

FIG. 2.2. *A sequence of orbits produced by the iterative scheme. The base points* $\mathbf{p}_i$ *are indicated on the horizontal axis. The range of* $\pi_{\mathbf{p}_i}$ *is not the tangent space of the manifold at* $\mathbf{p} = \mathbf{p}_i$ *since* Φ *is not an exact solution of* (2.1). *The orbit initially converges towards the manifold (initial transient—solid) and then remains within an* $O(\delta_0)$ *neighborhood (asymptotic state—dotted).*

$$W_0 \equiv \epsilon \hat{W}_0 + \Phi(\mathbf{p}_*) - \Phi(\mathbf{p}(\epsilon)) \in X_{\mathbf{p}(\epsilon)}. \tag{2.21}$$

Moreover, if $\hat{W}_0 \in X_{\tilde{\mathbf{p}}}$*, then*

$$|\mathbf{p}(\epsilon) - \mathbf{p}_*| \leq M_0 \epsilon |\mathbf{p}_* - \tilde{\mathbf{p}}|. \tag{2.22}$$

Proof. The condition (2.21) is equivalent to

$$0 = \pi_{\mathbf{p}} W_0 = \pi_{\mathbf{p}}(\epsilon \hat{W}_0 + \Phi(\mathbf{p}_*) - \Phi(\mathbf{p})), \tag{2.23}$$

which from (2.13) and the linear independence of the eigenvectors Ψ_i is equivalent to the equations

$$\Gamma_i(\epsilon, \mathbf{p}) \equiv (\epsilon \hat{W}_0 + \Phi(\mathbf{p}_*) - \Phi(\mathbf{p}), \Psi_i^\dagger(\mathbf{p}))_2 = 0 \tag{2.24}$$

for $i = 1, \dots, N$. For $\epsilon = 0$, one solution is $\mathbf{p} = \mathbf{p}_*$. The stability hypothesis (H4) dictates that the adjoint eigenfunctions $\Psi_i^\dagger(\mathbf{p})$ depend smoothly upon the parameters $\mathbf{p}$. We apply the implicit function theorem to find a curve of solutions parameterized by ϵ. We introduce $\Gamma = (\Gamma_1, \dots, \Gamma_N)^t$ and find from (2.12) that the ij entry of the gradient $\nabla_{\mathbf{p}} \Gamma$ satisfies

$$\left(\nabla_{\mathbf{p}} \Gamma \big|_{(0,\mathbf{p}_*)} \right)_{ij} = - \left(\frac{\partial \Phi}{\partial \mathbf{p}_i}, \Psi_j^\dagger \right)_2 = -(\Psi_i, \Psi_j^\dagger)_2 + O(\delta_C). \tag{2.25}$$

From the orthonormality relation (2.14) we may rewrite this as

$$\nabla_{\mathbf{p}} \Gamma \big|_{(0,\mathbf{p}_*)} = -I + O(\delta_C). \tag{2.26}$$

Moreover it is easy to see from (2.24) that

$$\frac{\partial \Gamma}{\partial \epsilon} \bigg|_{(\epsilon,\mathbf{p})} = \begin{pmatrix} (\hat{W}_0, \Psi_1^\dagger(\mathbf{p}))_2 \\ \vdots \\ (\hat{W}_0, \Psi_N^\dagger(\mathbf{p}))_2 \end{pmatrix},$$

while all higher order derivatives of Γ with respect to ϵ are zero. From (2.15) we find that $|\frac{\partial\Gamma}{\partial\epsilon}|_{(0,\mathbf{p})}|$ is bounded uniformly for all $\hat{W}$ in the unit ball of H^1 and all $\mathbf{p} \in \mathcal{K}$ from hypothesis (H4). From (2.26) it follows that $\nabla_{\mathbf{p}}\Gamma\big|_{(0,\mathbf{p}_*)}$ is invertible for δ_C small enough, with the modulus of invertibility $1/|[\nabla_{\mathbf{p}}\Gamma\big|_{(0,\mathbf{p}_*)}]^{-1}|$ uniformly bounded independent of $\hat{W}$ in the unit ball of H^1 and $\mathbf{p} \in \mathcal{K}^o$. Moreover, the second derivatives of Γ with respect to $\mathbf{p}$ are uniformly bounded by hypotheses (H0) and (H4). The implicit function theorem guarantees the existence of a smooth function $\mathcal{H}$ which provides the solution of (2.21). The interval of existence of $\mathcal{H}$, denoted $[-\epsilon_0, \epsilon_0]$, can be chosen independent of $\hat{W}$ and $\mathbf{p}$ due to the uniformity of the bounds on the invertibility of $\nabla_{\mathbf{p}}\Gamma\big|_{(0,\mathbf{p}_*)}$ and the second derivatives of Γ. Moreover, if $\hat{W}_0 \in X_{\tilde{\mathbf{p}}}$, then we have $(\hat{W}_0, \Psi_i^\dagger(\tilde{\mathbf{p}}))_2 = 0$ for $i = 1, \ldots, N$. This yields the estimate

$$|(\hat{W}_0, \Psi_i^\dagger(\mathbf{p}_*))_2| \leq |(\hat{W}_0, \Psi_i^\dagger(\tilde{\mathbf{p}}) - \Psi_i^\dagger(\mathbf{p}_*))_2| = O(|\mathbf{p}_* - \tilde{\mathbf{p}}|).$$

In this case we have the bound $|\frac{\partial\Gamma}{\partial\epsilon}|_{(0,\mathbf{p}_*)}| = O(|\mathbf{p}_* - \tilde{\mathbf{p}}|)$, from which the implicit function theorem yields (2.22). Finally, from the bound (2.22) we see that $\mathbf{p}_* \in \mathcal{K}^o$ implies the curve $\mathbf{p}(\epsilon)$ lies within $\mathcal{K}$ for $|\epsilon| \leq \epsilon_0$ and ϵ_0 small enough. ☐

We employ the proposition above to fix the base point $\mathbf{p}_0 = \mathbf{p}_* + \mathcal{H}(\epsilon)$ and define the initial data W_0 from (2.21). We choose an evolution equation for W which leaves $X_{\mathbf{p}_0}$ positively invariant. With $L_{\mathbf{p}_0}$ as the principle linear operator we rewrite (2.7) as

$$W_t = L_{\mathbf{p}_0}W + \mathcal{N}(W) - K_{\mathbf{p}_0}\mathbf{p}' + B(\mathbf{p}_0, \mathbf{p})W - E(\mathbf{p}_0, \mathbf{p})\mathbf{p}' + \delta_0\xi, \tag{2.27}$$

where $B(\mathbf{p}_0, \mathbf{p}) = L_{\mathbf{p}} - L_{\mathbf{p}_0}$, $K_{\mathbf{p}_0} = (\Psi_1(\mathbf{p}_0), \ldots, \Psi_N(\mathbf{p}_0))$ is a $d \times N$ matrix whose columns span $Y_{\mathbf{p}_0}$, and $E(\mathbf{p}_0, \mathbf{p}) = \nabla_{\mathbf{p}}\Phi(\mathbf{p}) - K_{\mathbf{p}_0}$ controls the difference between the tangent plane of $\Phi(\mathbf{p})$ and $Y_{\mathbf{p}_0}$, which by the compatibility hypothesis (H3) is $O(\delta_C)$. It is important for our analysis that $B(\mathbf{p}, \mathbf{p}_0) = L(\mathbf{p}) - L(\mathbf{p}_0) = \nabla f(\Phi(\mathbf{p})) - \nabla f(\Phi(\mathbf{p}_0))$ is a bounded operator. We note that $\pi_{\mathbf{p}}u = K_{\mathbf{p}}\nu$, where $\nu \in \mathbf{R}^N$ has ith component $\nu_i = (u, \Psi_i^\dagger(\mathbf{p}))_2$.

We now project (2.27) onto the space $X_{\mathbf{p}_0}$, demanding that $\pi_{\mathbf{p}_0}W_t = 0$. This condition yields N equations which determine the N unknowns $\mathbf{p}'$,

$$p_i' = \frac{(\mathcal{N}(W) + B(\mathbf{p}_0, \mathbf{p})W + \delta_0\xi, \Psi_i^\dagger(\mathbf{p}_0))_2}{1 + (E_i(\mathbf{p}_0, \mathbf{p}), \Psi_i^\dagger(\mathbf{p}_0))_2}. \tag{2.28}$$

We supplement these equations with the initial condition

$$\mathbf{p}(t_0) = \mathbf{p}_0. \tag{2.29}$$

The evolution for W may be recast as

$$\begin{aligned} W_t &= L_{\mathbf{p}_0}W + \mathcal{G}, \\ W(t_0) &= W_0, \end{aligned} \tag{2.30}$$

where

$$\mathcal{G} = (I - \pi_{\mathbf{p}_0})\big(B(\mathbf{p}_0, \mathbf{p})W + \mathcal{N}(W) + E(\mathbf{p}_0, \mathbf{p})\mathbf{p}' + \delta\xi\big), \tag{2.31}$$

and W_0 is given by (2.21).

The equation (2.30) admits the mild solution

$$W(t) = S_0(t-t_0)W_0 + \int_{t_0}^{t} S_0(t-t')\mathcal{G}(t')dt', \tag{2.32}$$

where S_0 is the semigroup generated by $L_{\mathbf{p}_0}$. To control the decay of $\|W\|_{H^1}$ and the motion along the manifold $\mathcal{M}$, we introduce the quantities

$$\begin{aligned} T_0(t) &= \sup_{t_0<t'<t} e^{k(t'-t_0)}\|W(t')\|_{H^1}, \\ T_1(t) &= \sup_{t_0<t'<t} |\mathbf{p}(t') - \mathbf{p}_0|. \end{aligned} \tag{2.33}$$

We note that T_0 affords the estimate

$$\|W(t')\|_{H^1} \le e^{-k(t'-t_0)}T_0(t) \qquad \text{for all } t_0 < t' < t. \tag{2.34}$$

The decay estimates of (2.11) applied to the mild solution yield the bound

$$\|W(t)\|_{H^1} \le Me^{-k(t-t_0)}\|W_0\|_{H^1} + M\int_{t_0}^{t} e^{-k(t-t')}\|\mathcal{G}(t')\|_{H^1}dt'. \tag{2.35}$$

From (2.31) it follows that

$$\|\mathcal{G}\|_{H^1} \le \|B(\mathbf{p}_0,\mathbf{p})\|_{*,H^1}\|W\|_{H^1} + \|\mathcal{N}(W)\|_{H^1} + \|E(\mathbf{p}_0,\mathbf{p})\|_{H^1}|\mathbf{p}'| + \delta_0\|\xi\|_{H^1}. \tag{2.36}$$

Since the nonlinearity f is smooth, as is the ansatz function Φ, it follows easily that

$$\|B(\mathbf{p}_0,\mathbf{p})\|_{*,H^1} \le M|\mathbf{p}_0 - \mathbf{p}| \le MT_1. \tag{2.37}$$

Note that under the evolution (2.28) T_1 will grow with time; this is the secularity present in our system which we renormalize away. For $\|W\|_{H^1}$ small the nonlinearity $\mathcal{N}(W)$ and forcing ξ satisfy

$$\|\mathcal{N}(W)\|_{H^1} \le M\|W\|_{H^1}^2, \tag{2.38}$$

$$\|\xi\|_{H^1} \le M\left(1 + \|W\|_{H^1} + \|W\|_{H^1}^2\right). \tag{2.39}$$

From the compatibility assumption we have

$$\begin{aligned} \|E(\mathbf{p}_0,\mathbf{p})\|_{H^1} &\le \|K_{\mathbf{p}_0} - K_{\mathbf{p}}\|_{H^1} + \|K_{\mathbf{p}} - \nabla_{\mathbf{p}}\Phi(\mathbf{p})\|_{H^1} \\ &\le M(|\mathbf{p}_0 - \mathbf{p}| + \delta_C) \le M(T_1 + \delta_C). \end{aligned} \tag{2.40}$$

We examine the denominator of (2.28), observing that

$$\left|(E_i(\mathbf{p}_0,\mathbf{p}), \Psi_i^\dagger(\mathbf{p}_0))\right| \le M(T_1 + \delta_C),$$

which for T_1 and δ_C small enough implies the denominator is uniformly bounded away from zero. From (2.28) we then find the bound

$$|\mathbf{p}'| \le M\left(T_1\|W\|_{H^1} + \|W\|_{H^1}^2 + \delta_0(1 + \|W\|_{H^1})\right). \tag{2.41}$$

We combine the estimates above to obtain the bound below on the forcing term $\mathcal{G}$ of (2.30):

(2.42)
$$\|\mathcal{G}\|_{H^1} \leq M\left(|\mathbf{p}_0 - \mathbf{p}| \cdot \|W\|_{H^1} + \|W\|_{H^1}^2 + \delta_0(1 + \|W\|_{H^1})\right)(1 + T_1 + \delta_C).$$

For δ_C and T_1 small enough, we may neglect the last factor on the right-hand side of (2.42). The estimate (2.34) then yields

$$\|\mathcal{G}\|_{H^1} \leq M(T_1 e^{-k(t-t_0)} T_0 + e^{-2k(t-t_0)} T_0^2 + \delta_0(1 + T_0)). \tag{2.43}$$

With this estimate in hand we replace the quantity $\|\mathcal{G}\|_{H^1}$ in (2.35) to obtain

(2.44)
$$\|W(t)\|_{H^1}$$
$$\leq M\left(e^{-k(t-t_0)}\epsilon + \int_{t_0}^{t} e^{-k(t-t')}\left(e^{-K(t'-t_0)} T_1 T_0 + e^{-2k(t'-t_0)} T_0^2 + \delta_0(1 + T_0)\right) dt'\right).$$

Multiply the inequality above by $e^{k(t-t_0)}$, evaluate the integrals, and take the supremum over $t \in [t_0, \tau]$. Then results the inequality

(2.45)
$$T_0(\tau) \leq M_1(\epsilon + (\tau - t_0) T_0(\tau) T_1(\tau) + T_0^2(\tau)(1 - e^{-k(\tau-t_0)}) + \delta_0(1 + T_0(\tau)) e^{k(\tau-t_0)}),$$

valid for some $M_1 > 0$. The inequality above controls T_0 so long as τ is close to t_0 and T_0 is small. We impose two conditions on τ which control, respectively, the second and fourth terms on the right-hand side of (2.45):

$$T_1 \leq \frac{1}{2M_1(\tau - t_0)} \tag{2.46}$$

and

$$\tau - t_0 \leq \frac{\ln(\epsilon/\delta_0)}{k}. \tag{2.47}$$

For $\tau - t_0$ so small that both (2.46) and (2.47) hold we may write (2.45) as

$$T_0(\tau) \leq \frac{2M_1}{1 - 2\epsilon M_1}(2\epsilon + T_0^2(1 - e^{-k(\tau-t_0)})). \tag{2.48}$$

For ϵ small enough, in terms of M_1, this inequality implies that either $T_0 < r_1(\tau)$ or $T_0 > r_2(\tau)$, where $r_1 < r_2$ are the two roots of the equation

$$2\epsilon - \left(\frac{1}{2M_1} - \epsilon\right) r + r^2(1 - e^{-k(\tau-t_0)}) = 0.$$

Since T_0 is continuous, $T_0(t_0) = \epsilon$, and $\lim_{\tau \to t_0^+} r_2(\tau) = \infty$, it follows that initially $T_0(t_0) \leq r_1(t_0)$ and hence by continuity of T_0, r_1, and r_2 with respect to τ we have the inequality $T_0(\tau) \leq r_1(\tau)$, valid so long as both the conditions (2.46) and (2.47) hold. Moreover, the inequality $r_1(\tau) \leq \lim_{\tau \to \infty} r_1(\tau) = M_* \epsilon$ holds for some $M_* > 0$. This permits us to rewrite the bound on T_0 in the form

$$T_0(\tau) \leq M_* \epsilon, \tag{2.49}$$

where M_*, which quantifies the possible secular growth after one renormalization, is independent of $\tau > t_0$.

We now investigate the range of τ for which we may impose the condition (2.46). From the definition (2.33) of T_1 and the estimates (2.41) and (2.39) we find that

$$\begin{aligned} T_1(t) &\leq \int_{t_0}^{t} |\mathbf{p}'(t')| dt' \\ &\leq M \int_{t_0}^{t} \left(T_1 \|W\|_{H^1} + \|W\|_{H^1}^2 + \delta_0 (1 + \|W\|_{H^1}) \right) dt' \\ &\leq M_2 \left(T_1 T_0 + T_0^2 + \delta_0 (1 + T_0)(t - t_0) \right). \end{aligned} \tag{2.50}$$

Isolating T_1 on the left-hand side of the last estimate above yields

$$T_1(t) \leq \frac{M_2 (T_0^2 + \delta_0 (1 + T_0)(t - t_0))}{1 - M_2 T_0}, \tag{2.51}$$

which, in light of (2.49), becomes

$$T_1(t) \leq M \left(\epsilon^2 + \delta_0 (t - t_0) \right). \tag{2.52}$$

The condition (2.47) yields the inequality $\delta_0 (t - t_0) \leq \frac{\delta_0 \ln(\epsilon/\delta_0)}{k}$, which permits us to rewrite (2.52) as

$$T_1(t) \leq M(\epsilon^2 + \delta_0 \ln(\epsilon/\delta_0)), \tag{2.53}$$

valid so long as conditions (2.46) and (2.47) hold and ϵ and δ_0 are small enough. In particular the condition (2.46) can be replaced with the slightly stronger explicit constraint on τ,

$$\tau - t_0 \leq \frac{M}{\epsilon^2 + \delta_0 \ln(\epsilon/\delta_0)}. \tag{2.54}$$

2.2. The renormalization group decompositions.

We may now construct the decompositions $\{(\pi_n, \tau_n)\}_{n=0}^{\infty}$ of the phase space alluded to in the introduction, and employ the corresponding renormalized equations to bound the remainder and track the flow on the manifold. An important tool is the estimate (2.49), valid for τ satisfying the constraints (2.47) and (2.54). For a given $\delta_0 < \epsilon$, there exists $\hat{\epsilon}(\delta_0) > 0$ such that for all $\epsilon \geq \hat{\epsilon}(\delta_0)$ the condition (2.54) is more strict. We call this case the initial transient, and the complimentary case the asymptotic state; see Figure 2.2. We note here that the condition $\epsilon \geq \hat{\epsilon}(\delta_0)$ implies that δ_0 is exponentially small in terms of ϵ, i.e., $\delta_0 \ll e^{-1/\epsilon}$. However, this separation of scales arises naturally in the pulse-pulse interactions we consider in which $\delta_0 = O(e^{-l})$ for some pulse separation l.

2.2.1. Initial transient.

If the initial remainder, W_0, is large enough, i.e., $\|W_0\|_{H^1} = \epsilon > \hat{\epsilon}(\delta_0)$, then the terms in (2.45) arising from the relaxation into a neighborhood of the manifold dominate those due to the forcing terms. The relevant condition on τ for (2.49) to hold is (2.54), which we write as

$$\tau - t_0 \leq \frac{M_3}{\epsilon^2 + \delta_0 \ln(\epsilon/\delta_0)}, \tag{2.55}$$

for some $M_3 > 0$. We may rewrite (2.49) as

$$T_0(\tau) \leq \epsilon M_* \qquad \text{for} \quad \tau - t_0 \leq \frac{M}{\epsilon^2 + \delta_0 \ln(\epsilon/\delta_0)}, \tag{2.56}$$

which is equivalent to

$$\|W(t)\|_{H^1} \leq \epsilon M_* e^{-k(t-t_0)}. \tag{2.57}$$

In particular we obtain the upper bound

$$\|W(t_1)\|_{H^1} \leq \epsilon M_* e^{-kM_3/(\epsilon^2+\delta_0 \ln(\epsilon/\delta_0))} \qquad \text{for} \quad t_1 = t_0 + \frac{M_3}{\epsilon^2 + \delta_0 \ln(\epsilon/\delta_0)}. \tag{2.58}$$

We are in a position to close the estimates we have developed. For $\epsilon > \hat{\epsilon}(\delta_0)$ we have $\epsilon^2 \gg \delta_0 \ln(\epsilon/\delta_0)$ and the coefficient

$$M_* e^{-kM_3/(\epsilon^2+\delta_0 \ln(\epsilon/\delta_0))} \ll 1 \tag{2.59}$$

for ϵ small enough. This expresses the fact that the renormalization period $[t_0, t_1]$ was long enough that the exponential decay of the semigroup can overcome the short-term secular growth implicit in the factor M_*. At the end of the time period $[t_0, t_1]$ we have a remainder of size $\|W(t_1)\|_{H^1}$, which is much smaller than the original remainder $\|W(t_0)\|_{H^1}$.

We iterate the renormalization procedure outlined above, setting $\epsilon_0 = \epsilon$ and defining

$$\epsilon_n = \epsilon_{n-1} M_* e^{-kM_3/(\epsilon_{n-1}^2+\delta_0 \ln(\epsilon_{n-1}/\delta_0))} \tag{2.60}$$

for $n = 1, \ldots, \hat{n}$, where $\hat{n} = \hat{n}(\delta)$ is specified below. We emphasize that $\epsilon_{n+1} \ll \epsilon_n$ when $\epsilon_n > \hat{\epsilon}(\delta_0)$. We renormalize the remainder W at time t_n according to

$$\hat{W}_n = (1/\epsilon_n)\, W(t_n), \tag{2.61}$$

which in light of (2.58) affords the bound $\|\hat{W}_n\|_{H^1} \leq 1$. From Proposition 2.2, so long as $d(\mathbf{p}_{n-1}, \partial\mathcal{K}) > \epsilon_n^{1/2}$, we may find $\mathbf{p}_n \in \mathcal{K}$ such that

$$W_n \equiv \epsilon_n \hat{W}_n + \Phi(\mathbf{p}(t_n)) - \Phi(\mathbf{p}_n) \tag{2.62}$$

lies in $X_{\mathbf{p}_n}$. Moreover, (2.22) implies

$$|\mathbf{p}(t_n) - \mathbf{p}_n| \leq M\epsilon_n |\mathbf{p}_n - \mathbf{p}_{n-1}| \leq M\epsilon_n T_1(t_n^-) \leq M\epsilon_n^3, \tag{2.63}$$

where we employed (2.53) and $\epsilon_n^2 \gg \delta_0 \ln(\epsilon_n/\delta_0)$ in the last inequality. We also have $\|W_n\|_{H^1} \leq M\epsilon_n$ for some constant M independent of n. The evolution equations (2.28) and (2.30) with initial data $\mathbf{p}_n$ and W_n at time $t = t_n$ may be solved on $[t_n, t_{n+1}]$, where

$$t_{n+1} = t_n + \frac{M_3}{\epsilon_n^2 + \delta_0 \ln(\epsilon_n/\delta_0)}, \tag{2.64}$$

with the resulting bounds

$$\|W(t)\|_{H^1} \leq \epsilon_n M_* e^{-k(t-t_n)} \qquad \text{for} \quad t \in [t_n, t_{n+1}], \tag{2.65}$$

valid uniformly in n.

The sequence of renormalization gauges ϵ_n converges rapidly to zero, and after some small number $\hat{n} = \hat{n}(\delta_0)$ of iterations we arrive at the situation $\epsilon_{\hat{n}} < \hat{\epsilon}(\delta)$, and the initial transient is completed. From the recursive definition of ϵ_n it is straightforward to rewrite the bound (2.65) as

$$\|W(t)\|_{H^1} \leq \epsilon M^{n+1} e^{-k(t-t_0)} \qquad \text{for} \quad t \in [t_n, t_{n+1}], \quad n = 0, \dots, \hat{n}, \tag{2.66}$$

where $M > M_*$ may be chosen independently of n; see [25] for details. The term M^{n+1} may be interpreted as a logarithmic correction to the exponential decay rate k associated with the individual linearized operators. This correction arises from the time dependent modulation of the linearized operators induced by the slow flow on the manifold.

2.2.2. Asymptotic state. At the $\hat{n}$th iteration we have $\epsilon_{\hat{n}} \leq \hat{\epsilon}(\delta_0)$, the constraint (2.47) is more exigent than (2.54), and the forcing terms dominate the evolution of the parameters $\mathbf{p}$. We have the evolution equations (2.28) for $\mathbf{p}$ and (2.30) for the remainder W with initial data $\mathbf{p}_{\hat{n}}(0) = \mathbf{p}_{\hat{n}}$ and $W_{\hat{n}}(0)$ given by (2.62) evaluated at $n = \hat{n}$. We iterate the procedure outlined in (2.35)–(2.49), which in light of the constraint (2.47) yields the estimate

$$T_0(\tau) \leq \epsilon_{\hat{n}} M_* \qquad \text{for} \quad \tau - t_{\hat{n}} \leq k^{-1} \ln(\epsilon_{\hat{n}} / \ln \delta_0), \tag{2.67}$$

which is equivalent to

$$\|W(t)\|_{H^1} \leq \epsilon_{\hat{n}} M_* e^{-k(t-t_{\hat{n}})} \qquad \text{for} \quad \tau - t_{\hat{n}} \leq k^{-1} \ln(\epsilon_{\hat{n}}/\delta_0) \tag{2.68}$$

and, in particular,

$$\|W(t_{\hat{n}+1})\|_{H^1} \leq \delta_0 M_* \qquad \text{for} \quad t_{\hat{n}+1} = t_{\hat{n}} + k^{-1} \ln(\epsilon_{\hat{n}}/\delta). \tag{2.69}$$

We define $\epsilon_* = \delta_0 M_*$, setting $\epsilon_n = \epsilon_*$ and $t_{n+1} = t_n + k^{-1} \ln(\epsilon_*/\delta_0) = t_n + k^{-1} \ln(M_*)$ for all $n > \hat{n}$. We note that the time interval $t_{n+1} - t_n$ is precisely that required for the exponential decay to balance the secular growth. This exact balance arises from the precise form of condition (2.47). With an iteration similar to that outlined for the initial transient, we find that

$$\|W(t_n)\|_{H^1} \leq \epsilon_* \qquad \text{for all} \quad n > \hat{n}, \tag{2.70}$$

and, moreover,

$$\|W(t)\|_{H^1} \leq \epsilon_* M_* e^{-k(t-t_n)} \qquad \text{for} \quad t \in [t_n, t_{n+1}], \quad n > \hat{n}, \tag{2.71}$$

where we recall that M_* is independent of δ, ϵ, or n.

We note that the estimate (2.71), taken over the interval $[t_n, t_{n+1}]$, is stronger at the endpoint $t = t_{n+1}$ than at the initial point $t = t_n$. However the variation in the right-hand side is only $O(1)$ and we may rewrite (2.71) as

$$\|W(t)\|_{H^1} \leq M\delta_0 \qquad \text{for} \quad t > t_{\hat{n}+1}, \tag{2.72}$$

for $M = \max\{M_*, M_*^2\}$.

We may now complete the proof of Theorem 2.1. The estimate (2.17) follows from (2.66) and (2.72). The curve $\mathbf{p}(t)$ given by (2.28) is smooth except for the jumps

$\Delta_n \equiv \mathbf{p}_n - \mathbf{p}(t_n)$ at the renormalization times $t = t_n$ which, from Proposition 2.2 and (2.53), satisfy

$$|\Delta_n| \leq \begin{cases} M\epsilon_{n-1}^3 & \text{for} \quad n \leq \hat{n}, \\ M\delta_0^2 & \text{for} \quad n > \hat{n}, \end{cases} \tag{2.73}$$

where M may be chosen independent of n. We replace $\mathbf{p}(t)$ with $\tilde{\mathbf{p}}(t)$, which is a smooth curve verifying $|\mathbf{p} - \tilde{\mathbf{p}}| \leq M(\epsilon e^{-k(t-t_0)} + \delta_0)$ for some M. The remainder W is then replaced with $\tilde{W} = U - \Phi(\tilde{\mathbf{p}})$, which from the smoothness of Φ will also verify the estimate (2.17). The existence of such a smooth curve requires verifying that each jump $|\mathbf{p}(t_n) - \mathbf{p}_n|$ is smaller than the bound $M(\epsilon e^{-k(t_n-t_0)} + \delta_0)$, which follows easily from the estimates at hand for δ_0 and ϵ small enough.

We determine a lower bound on the time T to exit $\mathcal{K}$ by bounding the distance from $\mathbf{p}_0$ to $\mathbf{p}(t)$,

$$|\mathbf{p}_0 - \mathbf{p}(t)| \leq \sum_{i=1}^{n} \left(T_1(t_i^-) + |\Delta_i| \right), \tag{2.74}$$

where $T_1(t_i^-) \equiv \lim_{t \to t_i^-} T_1(t_i)$. Here $n = n(t)$ is determined to be the least integer such that $t < t_n$. From Proposition 2.2 and (2.53) we find that $T_1(t_n^-)$, the accumulated drift in $\mathbf{p}(t)$ over the time interval $[t_{n-1}, t_n]$, satisfies

$$T_1(t_n^-) \leq \begin{cases} M\epsilon_{n-1}^2 & \text{for} \quad n \leq \hat{n}, \\ M\delta_0 & \text{for} \quad n > \hat{n}, \end{cases} \tag{2.75}$$

and hence it dominates the jump $|\Delta_i|$ at the end of the interval. With these estimates in hand, and using the relation $\epsilon_{n+1} \ll \epsilon_n$ for $n < \hat{n}$, the sum (2.74) reduces to

$$|\mathbf{p}_0 - \mathbf{p}(t)| \leq M\left(\epsilon_0^2 + (n - \hat{n})\delta_0\right). \tag{2.76}$$

Finally we observe that $\epsilon_0 = \epsilon$, $|\mathbf{p}_* - \mathbf{p}_0| \leq M\epsilon$, and the intervals $t_{n+1} - t_n = k^{-1}\ln(M_*)$, which allow us to rewrite (2.76) as

$$|\mathbf{p}_* - \mathbf{p}(t)| \leq M\left(\epsilon + (t - t_0)\delta_0\right). \tag{2.77}$$

Assuming that $d(\mathbf{p}_*, \partial\mathcal{K}) = O(1)$, the bound (2.77) readily implies that $\mathbf{p}(t) \in \mathcal{K}$ if $t - t_0 \leq Md(\mathbf{p}_*, \partial\mathcal{K})/\delta_0$ for some $M > 0$. The estimate (2.18) on T then follows for $\mathbf{p}$ and for $\tilde{\mathbf{p}}$.

The evolution for the pulse parameter $\mathbf{p}$ is given by (2.28), which from the estimates established in section 2 may be written in the form

$$p_i' = -\delta_0(\xi, \Psi_i^\dagger(\mathbf{p}))_2 + \delta_0(\xi, \Psi_i^\dagger(\mathbf{p}) - \Psi_i^\dagger(\mathbf{p}_n))_2 + O(T_0^2, T_0T_1, \delta^2) \tag{2.78}$$

for $t \in [t_n, t_{n+1})$. But $|\Psi_i^\dagger(\mathbf{p}) - \Psi_i^\dagger(\mathbf{p}_n)| = O(T_1)$ and after the initial transient, that is, for $t \geq t_{\hat{n}}$ where $\hat{n} = \hat{n}(\delta_0)$, we have $\epsilon_* = O(\delta_0)$ and the inequalities (2.53) and (2.68) imply that $T_0, T_1 = O(\delta)$. In this asymptotic regime, recalling the definition $\xi = \tilde{\xi} + F(\Phi(\mathbf{p}))/\delta_0$, (2.78) reduces to (2.19). Moreover the jumps Δ_n at the times $t = t_n$ are $O(\delta_0^2)$ for $n > \hat{n}$ and are separated by an $O(1)$ time interval. Thus we may choose the smoothed curve $\tilde{\mathbf{p}}$ in such a manner that $|\tilde{\mathbf{p}}' - \mathbf{p}'| = O(\delta_0^2)$ for $t \neq t_i$ for $i = 1, 2, \ldots$. Dropping the tilde notation, we may then write the evolution for the smoothed curve $\mathbf{p}$ as in (2.19). □

3. Applications to PNLS.

We apply the renormalization techniques to the forced PNLS equation

$$i\phi_t + \frac{1}{2}\phi_{xx} \pm |\phi|^2\phi + (i \mp a)\phi - \gamma\phi^* = \delta_0\tilde{\xi}(x,t), \tag{3.1}$$

where $\delta_0 \ll 1$. As a model of pattern formation in the optical parametric oscillator, the parameters $a, \gamma > 0$ represent cavity detuning and pump strength, respectively. The perturbation $\tilde{\xi} \in L^\infty(\mathbf{R}_+, H^1)$ represents the stimulated emission present in the background radiation. Depending upon the nature of the detuning there are two cases: the focusing, which takes the top sign in (3.1), and the defocusing, which takes the bottom sign.

3.1. Stability of fronts in the defocusing PNLS.

For $\gamma \geq 1$, the unforced defocusing PNLS has front solutions

$$\phi = \eta e^{i\theta}\tanh\eta(x-p), \tag{3.2}$$

where

$$\begin{array}{rcl} \eta^2 & = & a + \sqrt{\gamma^2 - 1}, \\ \gamma e^{-2i\theta} & = & -\sqrt{\gamma^2-1} + i. \end{array} \tag{3.3}$$

This solution is linearly stable for $\gamma > 0$ and $a > 0$ [25].

After the change of dependent and independent variables

$$\begin{array}{l} \phi(x) = \eta u(\tilde{x})e^{i\theta}, \\ \tilde{t} = \eta^2 t/2, \\ \tilde{x} = \eta x, \end{array} \tag{3.4}$$

and, dropping the tilde notation, $U = (\Re u, \Im u)^t$ satisfies

$$U_t = \begin{pmatrix} 0 & -(\partial_x^2 - 2|U|^2 + 2\mu) \\ \partial_x^2 - 2|U|^2 + 2 & -\frac{4}{\eta^2} \end{pmatrix} U + \delta_0\Xi, \tag{3.5}$$

where $\mu = \frac{a-\sqrt{\gamma^2-1}}{a+\sqrt{\gamma^2-1}} \leq 1$ and Ξ is derived from the real and imaginary parts of the rescaled $\tilde{\xi}$. This equation readily fits into the form (2.1). The stationary solution ϕ becomes

$$U = \Phi(x-p) = \begin{pmatrix} \tanh(x-p) \\ 0 \end{pmatrix}, \tag{3.6}$$

and the linearization of (3.5) about (3.6) is given by

$$L_p = \begin{pmatrix} 0 & D \\ -C & -\frac{4}{\eta^2} \end{pmatrix}, \tag{3.7}$$

where

$$\begin{array}{rcl} C & = & -(\partial_x^2 + 6\text{sech}^2(x-p) - 4), \\ D & = & -(\partial_x^2 + 2\text{sech}^2(x-p) + 2(\mu - 1)). \end{array} \tag{3.8}$$

From Theorem 3.6 of [25] the spectrum of the operator L_p satisfies

$$\sigma(L_p) = \sigma_s \cup \sigma_0, \tag{3.9}$$

where $\sigma_s \subset \{\lambda \big| \Re\lambda < -k\}$ for some $k > 0$ and $\sigma_0 = \{0\}$ represents a simple eigenvalue of L_p at the origin. This verifies hypothesis (H1). The kernel of L_p is spanned by $\Psi_1 = (-\mathrm{sech}^2(x-p), 0)^t$ with adjoint eigenvector, under the normalization (2.14), given by

$$\Psi_1^\dagger = \begin{cases} \dfrac{-1}{(D^{-1}\mathrm{sech}^2(x), \mathrm{sech}^2(x))_2}\left(D^{-1}\mathrm{sech}^2(x-p), \dfrac{\eta^2}{4}\mathrm{sech}^2(x-p)\right)^t, & \mu \neq \frac{1}{2}, \\ -\dfrac{2}{\pi}\left(\mathrm{sech}(x-p), 0\right)^t, & \mu = \frac{1}{2}. \end{cases}$$

While the operator D is not invertible for $\mu = \frac{1}{2}$, the adjoint eigenvector is bounded for all μ by Lemma 3.4 of [25], verifying hypothesis (H4). We may define the spectral projection π_p by

$$\pi_p U = (U, \Psi_1^\dagger)_2 \Psi_1, \tag{3.10}$$

with kernel $X_p = \pi_p H^1(\mathbf{R})$. As indicated by Proposition 3.2 in the next subsection, the $\mathcal{C}_0$ semigroup S_p generated by L_p verifies hypothesis (H2), where the decay constant k can be taken independent of the position p. Moreover, since Φ is an exact solution of the unforced equation, the kernel of L_p is the translational invariant

$$\Psi_1 = \frac{\partial \Phi}{\partial p}, \tag{3.11}$$

and the compatibility hypothesis (H3) holds with $\delta_C = 0$. We may apply Theorem 2.1 to the front solution (3.2) of the defocusing PNLS.

Theorem 3.1. *Let δ_0 and $\epsilon > 0$ be small enough. Any solution U of the defocusing PNLS equation* (3.5) *corresponding to initial data*

$$U_0 = \Phi(x-p) + W_0$$

with $\|W_0\|_{H^1} \leq \epsilon$ verifies the conclusions of Theorem 2.1 *with $\mathcal{K} = \mathbf{R}$ and $T = \infty$. Moreover, after the initial transient the pulse position p is governed by*

$$p' = -\delta_0(\Xi(t), \Psi_1^\dagger(x-p))_2 + O(\delta_0^2). \tag{3.12}$$

Proof. It only remains to verify that we may take $\mathcal{K} = \mathbf{R}$. Since the parameter p serves only to translate the front, it is straightforward to verify that the hypotheses (H0)–(H4) hold uniformly for $p \in \mathbf{R}$. In particular M and k in (H2) are independent of p, and we may take $\delta_C = 0$ in (H3) for all $p \in \mathbf{R}$. □

3.2. Evolution of pulse trains in the focusing PNLS. In this section we address the evolution of well-separated trains of pulses for the focusing PNLS equation; for simplicity of presentation we neglect the external time dependent forcing term $\tilde{\xi}$. We introduce the new equation parameters

$$\begin{aligned} \eta^2 &= 2(a + \sqrt{\gamma^2 - 1}), \\ \gamma e^{-2i\theta} &= \sqrt{\gamma^2 - 1} + i, \end{aligned} \tag{3.13}$$

and rescale as in (3.4) to obtain the equation below for $U = (\Re u, \Im u)^t$:

$$U_t = \begin{pmatrix} 0 & -(\partial_x^2 + |U|^2 - \mu) \\ \partial_x^2 - |U|^2 - 1 & -\frac{4}{\eta^2} \end{pmatrix} U, \tag{3.14}$$

where $\mu = \frac{a - \sqrt{\gamma^2 - 1}}{a + \sqrt{\gamma^2 - 1}} \leq 1$. This equation fits the form (2.1) for $\mu > 0$, and supports pulse solutions

$$\Phi(x, s) = \begin{pmatrix} \phi(x - s) \\ 0 \end{pmatrix}, \tag{3.15}$$

where $\phi(x) = \sqrt{2}\operatorname{sech} x$, and $s \in \mathbf{R}$ denotes the pulse position.

We examine the evolution of initial data in the neighborhood of the manifold $\mathcal{M} = \left\{\Phi_N(\mathbf{s}) \middle| \mathbf{s} \in \mathcal{K}_l\right\}$, where Φ_N describes N well-separated pulses

$$\Phi_N(x, \mathbf{s}) = \sum_{i=0}^{N} \alpha_i \Phi(x - s_i). \tag{3.16}$$

Here $\mathbf{s} = (s_1, \ldots, s_N)^t \in \mathbf{R}^N$ is the vector of pulse positions and $\alpha_i = \pm 1$ for $i = 1, \ldots, N$ connote a fixed choice of up-down pulse profiles. The set $\mathcal{K}_l$ of admissible pulse trains is given by

$$\mathcal{K}_l = \{\mathbf{s} \in \mathbf{R}^N \big| s_i < s_{i+1} \quad \text{for} \quad i = 1, \ldots, N-1, \qquad \text{and} \qquad \Delta\mathbf{s} \geq l\}, \tag{3.17}$$

where $\Delta\mathbf{s} \equiv \min_{i \neq j} |s_i - s_j|$ and $l > 0$ is a minimum pulse separation. Observe that Φ_N is not an exact stationary solution of (3.14); indeed,

$$\begin{pmatrix} 0 & -(\partial_x^2 + |\Phi_N|^2 - \mu) \\ \partial_x^2 - |\Phi_N|^2 - 1 & -\frac{4}{\eta^2} \end{pmatrix} \Phi_N = F, \tag{3.18}$$

where F is given by

$$F(\mathbf{s}) = -\begin{pmatrix} 0 \\ \left(\sum\limits_{k=1}^{N} \alpha_k \phi_k\right)^3 \end{pmatrix} + \sum_{k=1}^{n} \begin{pmatrix} 0 \\ \alpha_k \phi_k^3 \end{pmatrix}. \tag{3.19}$$

The linearization $L_{\mathbf{s}}$ of (3.1) about $\Phi_N(x, \mathbf{s})$ has the form

$$L_{\mathbf{s}} = \begin{pmatrix} 0 & D \\ -C & -4/\eta^2 \end{pmatrix}, \tag{3.20}$$

where

$$C = -\left(\partial_x^2 - 1 + 3\sum_{i=1}^{N} \phi_i^2 + 6\mathcal{V}\right), \tag{3.21}$$

$$D = -\left(\partial_x^2 - \mu + \sum_{i=1}^{N} \phi_i^2 + 2\mathcal{V}\right), \tag{3.22}$$

with $\phi_i \equiv \phi(x - \mathbf{s}_i)$, and

$$\mathcal{V} = \sum_{\substack{i,j=1 \\ i \neq j}}^{N} \alpha_i \alpha_j \phi_i \phi_j \tag{3.23}$$

represents small cross terms. We decompose the solution U of (3.1) as

$$U = \Phi_N(x, \mathbf{s}) + W(x,t), \tag{3.24}$$

where the evolution for W is given by

$$W_t = L_{\mathbf{s}} W + F + \mathcal{N}(W) + \nabla_{\mathbf{s}} \Phi_N \mathbf{s}', \tag{3.25}$$

with the forcing term F given by (3.19).

3.2.1. Verification of hypothesis. We verify the hypotheses (H0)–(H4) required to apply Theorem 2.1 and derive the modulational equations which govern the slow evolution along the ansatz manifold. It is quite straightforward to verify hypothesis (H0) on the uniform smoothness of the manifold and the forcing term f.

The stability of a single pulse for (3.1) was established in Theorem 3.3 of [25]. Indeed, if L denotes the linearization about a single pulse, then there exists $a_c > 0$ such that for detuning and pump values a and γ satisfying $(a, \gamma) \in [0, a_c) \times (1, \sqrt{1+a^2})$, the spectrum of L consists of a simple eigenvalue at the origin and a remainder which is uniformly bounded in the left-half complex plane. If $L_{\mathbf{s}}$ is the linearization about N well-separated pulses, then the essential spectrum $\sigma_e(L_{\mathbf{s}})$ is determined by the limiting states $\lim_{x\to\pm\infty} \Phi_N$ [16], and thus $\sigma_e(L_{\mathbf{s}}) = \sigma_e(L)$. Moreover, from results of Alexander and Jones [1] (see also [27]) to each localized eigenvalue λ of L, there are associated N eigenvalues $\lambda_1, \ldots, \lambda_N$ of $L_{\mathbf{s}}$, up to multiplicity, such that $\max_{i=1,\ldots,N} |\lambda_i - \lambda|$ decays exponentially with growing pulse separation $l > 0$. In particular we can verify hypothesis (H1), where σ_0 contains the N eigenvalues which approach the origin for large l. These N eigenvalues are the remnants of the translational eigenvalues of the individual pulses.

We verify that $L_{\mathbf{s}}$ satisfies hypothesis (H2) by applying Proposition 4.1 of [25], which for completeness we summarize below.

Proposition 3.2. *Let L be an operator of the form* (3.20) *with the suboperators given by $C = -\partial_x^2 + V_1(x)$ and $D = -\partial_x^2 + V_2(x)$, where V_1 and V_2 are smooth, uniformly bounded potentials. If $\sigma(L)$ satisfies hypothesis* (H1), *then there exist constants $M, k > 0$ such that the associated semigroup $S(t)$ satisfies*

$$\|S(t)u\|_{H^1} \le M e^{-kt} \|u\|_{H^1} \qquad \textit{for all} \;\; t \ge 0, u \in X_1. \tag{3.26}$$

Here the space X_1 is the eigenspace associated with σ_s.

The constants M and k which appear in the estimate (3.26) depend continuously upon $\mathbf{s}$, and thus are uniformly bounded above and below on compact subsets of $\mathcal{K}_l$. However we may formally relax the compactness restriction on $\mathcal{K}_l$ since the individual pulses are stable and the constants M and k are bounded uniformly for large pulse separations.

It remains only to verify (H3)–(H4) about the eigenspace $Y_{\mathbf{s}}$. The location of small eigenvalues of N-pulses has been addressed in detail in [27]. Although we are not linearizing about an exact N-pulse but rather about a quasi-steady train of N-pulses, the aforementioned results can be extended to apply in this case [29]. For completeness we include details of this derivation below. We proceed with a regular expansion of the eigenvectors of σ_0. With tail-tail interactions of pulses $\phi(x - \mathbf{s}_i)$, it is natural to introduce the small quantities $\delta_{ij} = e^{-|\mathbf{s}_i - \mathbf{s}_j|}, \delta = \delta(\mathbf{s}) = e^{-\Delta \mathbf{s}}$, and $\delta_0 = e^{-l}$ which measure the magnitudes of the tail overlap. However the pulse ϕ is degenerate in the sense that it decays at the fast rate $e^{-|x|}$ as $x \to \infty$ associated with the operator C. There is also a slower decay rate $e^{-\sqrt{\mu}|x|}$, associated with the operator

D, which necessitates the introduction of the small quantities $\rho_{ij} = e^{-\sqrt{\mu}|\mathbf{s}_i - \mathbf{s}_j|}$ and $\rho = \rho(\mathbf{s}) = e^{-\sqrt{\mu}\Delta\mathbf{s}}$. Since $\mu < 1$ these small parameters satisfy the relations $\delta_{ij} \leq \delta \leq \delta_0 \ll 1$ and $\delta \ll \rho$.

We introduce the $2 \times N$ matrices

$$\Xi = \begin{pmatrix} \chi_1 & \cdots & \chi_N \\ 0 & \cdots & 0 \end{pmatrix}, \tag{3.27}$$

$$\tilde{\Xi} = \begin{pmatrix} D^{-1}\chi_1 & \cdots & D^{-1}\chi_N \\ \frac{\eta^2}{4}\chi_1 & \cdots & \frac{\eta^2}{4}\chi_N \end{pmatrix}, \tag{3.28}$$

where $\chi_i = \sqrt{2}\operatorname{sech}\tanh(x - s_i)$ is the normalized kernel of $C_i = -(\partial_x^2 + 3\phi_i^2 - 1)$. The uniform invertibility of D is addressed by Proposition A.2 in the appendix. We remark that χ_i corresponds to the translational invariant of the linearization about a single pulse ϕ_i; as such $\dfrac{\partial \Phi_N}{\partial \mathbf{s}_i} = \alpha_i \chi_i$. The columns Ξ_k and $\tilde{\Xi}_k$ of Ξ and $\tilde{\Xi}$ satisfy

$$\begin{array}{rcl} \|L_{\mathbf{s}}\Xi_k\|_{H^1} & \leq & M_0\delta\|\Xi_k\|_{H^1}, \\ \|L_{\mathbf{s}}^\dagger\tilde{\Xi}_k\|_{H^1} & \leq & M_0\delta\|\tilde{\Xi}_k\|_{H^1}. \end{array} \tag{3.29}$$

The eigenvector Ψ_k and associated eigenvalue $\lambda_k \in \sigma_0$ admit an expansion

$$\begin{array}{rcl} \Psi_k & = & \Psi_k^{(0)} + \delta\Psi_k^{(1)} + O(\rho\delta), \\ \lambda_k & = & \delta\lambda_k^{(1)} + O(\rho\delta). \end{array} \tag{3.30}$$

The leading order term $\Psi_k^{(0)}$ takes the form

$$\Psi_k^{(0)} = \Xi\beta_k, \tag{3.31}$$

where $\beta_k = \beta_k^{(0)} + \rho\beta_k^{(1)} + O(\rho^2)$ and $\beta_k^{(0)} = (\beta_{k1}, \ldots, \beta_{kN})^t \in \mathbf{C}^N$ are to be determined from the eigenvalue equation

$$L_{\mathbf{s}}^0\Psi_k = \lambda_k\Psi_k. \tag{3.32}$$

The $O(\delta)$ terms of the eigenvalue equation are

$$L_{\mathbf{s}}\Psi_k^{(1)} + \frac{1}{\delta}L_{\mathbf{s}}\Psi_k^{(0)} = \lambda_k^{(1)}\Psi_k^{(0)}. \tag{3.33}$$

We take the L^2 inner product of the equation above with $\tilde{\Xi}_i$ and use (3.29) to find at leading order in δ

$$\left(\Psi_k^{(0)}, \frac{1}{\delta}L_{\mathbf{s}}^\dagger\tilde{\Xi}_i - \lambda_k^{(1)}\tilde{\Xi}_i\right)_2 = 0, \qquad \text{for} \quad i = 1, \ldots, N. \tag{3.34}$$

Using (3.31) and (3.20), equation (3.34) may be put into the matrix form

$$\left(\frac{4\lambda_k^{(1)}}{\eta^2}\hat{D} + \frac{1}{\delta}\hat{C}\right)\beta_k = 0, \tag{3.35}$$

where the $N \times N$ matrices $\hat{D}$ and $\hat{C}$ have entries

$$\hat{D}_{ij} = (D^{-1}\chi_i, \chi_j)_2, \tag{3.36}$$

$$\hat{C}_{ij} = (C\chi_i, \chi_j)_2. \tag{3.37}$$

Thus $\lambda_k^{(1)}$ is the leading order term in the expansion of the eigenvalue λ_k of $L_{\mathbf{s}}^0$ if and only if $\lambda_k^{(1)}$ is an eigenvalue of the matrix

$$P = -\frac{\eta^2}{4\delta}\hat{D}^{-1}\hat{C}. \tag{3.38}$$

The matrix $\hat{C}$ is self-adjoint, and to leading order has the expression $\hat{C} = 16\hat{C}_0 + O(\delta^2)$, where $\hat{C}_0$ has the tridiagonal form

$$\hat{C}_0 = \begin{pmatrix} d_{11} & \delta_{12} & \cdots & 0 \\ \delta_{12} & d_{22} & \ddots & \vdots \\ \vdots & \ddots & \ddots & \delta_{N-1,N} \\ 0 & \cdots & \delta_{N-1,N} & d_{NN} \end{pmatrix}, \tag{3.39}$$

where

$$d_{ii} = 2\alpha_i(\alpha_{i-1}\delta_{i,i-1} + \alpha_{i+1}\delta_{i,i+1})$$

for $i = 1, \ldots, N$ and $\alpha_0 = \alpha_{N+1} = 0$. To simplify the matrix $\hat{D}$ we begin with Proposition A.2 of the appendix, which yields $D^{-1}\chi_i = D_i^{-1}\chi_i + O(\rho)$. We may calculate directly that

$$(D_i^{-1}\chi_i, \chi_j)_2 = \begin{cases} \theta, & i = j, \\ O(\rho_{ij}), & i \neq j, \end{cases} \tag{3.40}$$

where θ is not zero for any η; see Lemma 3.2 of [25]. These bounds yield the approximation $\hat{D} = \theta I + O(\rho)$, and hence

$$\hat{D}^{-1} = \frac{1}{\theta}I + O(\rho). \tag{3.41}$$

The matrix P takes the form $P = P_0 + O(\rho)$ where $P_0 = -\frac{4\eta^2}{\theta\delta}\hat{C}_0$ is self-adjoint and has a complete set of orthonormal eigenvectors $\beta_k^{(0)}$ and real eigenvalues $\lambda_k^{(1)}$, which give the leading order terms of Ψ_k and λ_k from (3.31). We note that inclusion of higher order terms in the expansion may lead to complex eigenvalues λ_k whose imaginary parts satisfy $\Im\lambda_k = O(\rho\delta)$.

For the adjoint eigenvalue problem

$$L_{\mathbf{s}}^{\dagger}\Psi_k^{\dagger} = \lambda_k^{*}\Psi_k^{\dagger}, \tag{3.42}$$

we take the expansion

$$\tilde{\Psi}_k^{\dagger} = \tilde{\Psi}_k^{\dagger(0)} + \delta\tilde{\Psi}_k^{\dagger(1)} + O(\rho\delta) \tag{3.43}$$

for the unnormalized adjoint eigenvectors whose leading order term is given by

$$\tilde{\Psi}_k^{\dagger(0)} = \tilde{\Xi}\tilde{\beta}_k. \tag{3.44}$$

We take the inner product of (3.42) with Ξ_i, and in a manner similar to the eigenvalue problem, we arrive at the equation

$$P\tilde{\beta}_k = \lambda_k^{(1)}\tilde{\beta}_k, \tag{3.45}$$

with P given by (3.38), and hence $\tilde{\beta}_k = \beta_k$.

We choose the parameters $\mathbf{p}$ for the ansatz Φ_N according to

$$s_i = \alpha_i \sum_{j=1}^{N} \beta_{ji} p_j \tag{3.46}$$

so that the chain rule, (3.31), and (3.30) yield

$$\frac{\partial \Phi_N}{\partial p_j} = \sum_{i=1}^{N} \frac{\partial \Phi_N}{\partial s_i} \frac{\partial s_i}{\partial \mathbf{p}_j} = \sum_{i=1}^{N} (\alpha_i \chi_i)(\alpha_i \beta_{ji}) = \Xi \beta_j = \Psi_j^{(0)} = \Psi_j + O(\delta), \tag{3.47}$$

which verifies the compatibility hypothesis (H3).

To construct the projection $\pi_{\mathbf{p}}$ we determine the multiplicity of the eigenvalues in σ_0. Each eigenvalue in σ_0 has algebraic multiplicity 1 if

$$\theta_i \equiv (\Psi_i, \tilde{\Psi}_i^{\dagger})_2 \neq 0. \tag{3.48}$$

From the expansions (3.31) and (3.44) we find

$$\theta_i = (\Xi \beta_i, \tilde{\Xi} \beta_i)_2 + O(\delta) = \sum_{j=1}^{N} (\Xi_j, \tilde{\Xi}_j)_2 |\beta_{ij}|^2 + O(\delta). \tag{3.49}$$

But from Proposition A.2 and (3.40) we have $(\Xi_j, \tilde{\Xi}_j)_2 = (\chi_j, D_j^{-1} \chi_j) = \theta + O(\rho)$, which is nonzero for ρ small enough. Thus we have

$$\theta_i = \theta |\beta_i|^2 + O(\rho) = \theta + O(\rho), \tag{3.50}$$

and each eigenvalue of σ_0 is simple. Normalizing the adjoint eigenvectors

$$\Psi_i^{\dagger} = \frac{\tilde{\Psi}_i^{\dagger}}{\theta_i},$$

we satisfy the orthogonality condition (2.14). To complete the verification of the stability hypothesis (H4), we observe that so long as the eigenvalues $\lambda \in \sigma_0$ remain simple then the eigenfunctions depend analytically upon the parameters $\mathbf{p} \in \mathcal{K}$. The spectral projection is then given by (2.13).

We simplify the dynamics afforded by (2.28) in the context of the pulse train ansatz for the PNLS equation. Initial data U_0 which lie within ϵ in the H^1 norm of the manifold $\mathcal{M}_l = \left\{ \Phi_N(x, \mathbf{s}) \middle| \Delta \mathbf{s} > l \right\}$ may be decomposed into a manifold parameter $\mathbf{p}_0$ and a remainder W_0 via Proposition 2.2. After the initial transient, the evolution for the pulse parameter $\mathbf{p}$ is given by (2.19) with the forcing term $\xi = \frac{F}{\delta_0}$, where F is given by (3.19). The evolution for the native variables $\mathbf{s}$ is given by

$$s_i' = -\alpha_i \left(F, \sum_{j=1}^{N} \beta_{ji} \Psi_j^{\dagger} \right)_2 + O(\delta^2) = -\alpha_i \left(F, \sum_{j,k=1}^{N} \frac{\beta_{ji} \beta_{jk}}{\theta_k} \tilde{\Xi}_k \right)_2 + O(\delta^2), \tag{3.51}$$

where $\tilde{\Xi}_k$ is the kth column of $\tilde{\Xi}$. Summing first over j in the expression above, and exploiting the approximate orthonormality of the rows of the matrix β, we find

$$s_i' = -\frac{\alpha_i}{\theta_i} (F, \tilde{\Xi}_k)_2 + O(\delta \rho). \tag{3.52}$$

The nonnearest neighbor interactions in the integral above are at most second-order in δ and may be neglected. The leading order terms may be evaluated from the asymptotic relation

$$\int_{\mathbf{R}} \chi_k \phi_k^2 \phi_{k\pm 1} dx = \pm \frac{16}{3} \delta_{k,k\pm 1} + O(\delta^2),$$

where we have used $s_i < s_{i+1}$ for $i = 1, \ldots, N-1$. The evolution equation for the pulse positions $\mathbf{s}_i$ of the ith pulse reduces to

$$s_i' = \frac{4\eta^2}{3\theta} \alpha_i \left(\alpha_{i+1} \delta_{i,i+1} - \alpha_{i-1} \delta_{i,i-1} \right) + O(\delta\rho), \tag{3.53}$$

where for notational convenience we have introduced $\alpha_0 = \alpha_{N+1} = 0$.

For initial data comprised of two pulses $U_0 = \Phi_2 = \alpha_1 \phi(x - s_1) + \alpha_2 \phi(x - s_2)$, there is no initial transient and we obtain directly the leading order slow system for the evolution of the pulse positions

$$s_1' = \frac{4\eta^2}{3\theta} \alpha_1 \alpha_2 \delta_{12}, \tag{3.54}$$

$$s_2' = -\frac{4\eta^2}{3\theta} \alpha_1 \alpha_2 \delta_{12}. \tag{3.55}$$

We find that two pulses of like sign attract and two of opposite sign repel. In particular two pulses of like sign will move together until they are no longer separated by the minimum distance l.

THEOREM 3.3. *Let $(a, \gamma) \in [0, a_c) \times (1, \sqrt{1 + a^2})$ be given and fix $l > 0$ large enough. Then for $\mathbf{s} \in \mathcal{K}_l$ given by* (3.17) *and ϵ small enough, the solution U of the focusing PNLS equation* (3.14) *corresponding to the initial data*

$$U_0 = \Phi_N(\mathbf{s}) + W,$$

with $\|W\|_{H^1} \leq \epsilon$, satisfies the conclusions of Theorem 2.1 *where $\delta_0 = e^{-l}$. Moreover, after the initial transient the pulse positions are governed by the system* (3.53) *for $t \in [t_0, t_0 + T]$. In the case of a pulse train with alternating signs, $\alpha_i \alpha_{i+1} = -1$, the pulse separation increases with time and we may take $T = \infty$.*

4. Discussion. We have shown that manifolds comprised of quasi-stationary solutions of dispersive equations can describe the long-time evolution of nearby orbits; moreover, this description is stable under time dependent perturbations. The ansatz manifolds we have employed are global but not invariant under the flow; however, they attract the flow into a thin neighborhood and the flow restricted to the manifold recovers the salient dynamics. While this result is consistent with the presence of a nearby invariant manifold, the existence of such a manifold is not obvious, particularly if an arbitrary time dependent perturbation $\delta\xi(x, t)$ is added to the equation. There are other techniques which have some similarities to the approach we have taken here; among these we mention that of Kirrmann, Schneider, and Mielke [20] (see also [31]) and Grenier [14, 15], which involve the splitting of a solution into a leading order term and a residual, and then bounding the residual for long time periods.

For the pulse trains of the focusing PNLS equation, we capture the effect of the tail-tail interactions whose magnitude is governed by the separation and the spatial decay rate of the pulses. In the scaling we have chosen the sech pulses decay like $e^{-|x|}$

as $x \to \infty$, and the pulse evolution and size of the residual are on the order of $\delta = e^{-l}$, with l being the pulse separation. However, there is a slower spatial decay rate, $\sqrt{\mu} < 1$, associated with stationary solutions of PNLS, and indeed the application of Theorem 3.3 requires the smallness of $\rho = e^{-l\sqrt{\mu}}$. As $\gamma \to \sqrt{1+a^2}$, the slower rate μ tends to zero and the minimum pulse separation required to apply Theorem 3.3 grows. This effect is seen in numerical simulations for small μ; well-separated like-signed pulses attract but at a μ dependent critical separation the attraction is arrested and a stable two-pulse is formed.

As was observed in [19], there is a connection between the focusing PNLS equation and the evolution of pulses in the phase sensitive amplification (PSA) equation for pulse amplitudes in fiber optical systems [21]. We sketch here an argument which can make this connection rigorous. We write the focusing PNLS equation (3.14) as

$$U_t = \begin{pmatrix} 0 & D(U) \\ -C(U) & -4/\eta^2 \end{pmatrix} U, \tag{4.1}$$

where $C(U) = -(\partial_x^2 + |U|^2 - 1)$ and $D(U) = -(\partial_x^2 + |U|^2 - \mu)$, and $U = (U_1, U_2)^t$. We eliminate U_2 to leading order to find

$$U_{1t} + \frac{\eta^2}{4} D(U_1)C(U_1)U_1 = O(|U_t|^2, |U_{tt}|, |U_{xx}||U_2|^2). \tag{4.2}$$

The left-hand side of (4.2) is exactly the PSA equation in the limit of closely spaced amplifiers ($\sigma = 0$ in (1.2) of [30]). Further analysis based upon the results of section 3.2 shows that, in the asymptotic regime of the pulse train evolution, $\|U_t\|_{H^1} = O(\delta), \|U_{tt}\|_{H^1} = O(\delta^2), \|U\|_{H^2} = O(1)$, and $\|U_2\|_{H^1} = O(\delta)$; we may conclude that the right-hand side of (4.2) is $O(\delta^2)$ in L^2. We apply the renormalization machinery of section 2 and exploit the smoothing properties of the semigroup associated with the fourth-order dissipative operator DC, which demonstrates the equivalence, to leading order, of the pulse train evolution in PNLS and PSA. These results will be presented in full detail elsewhere.

While in some sense the hypotheses (H1)–(H4) may be taken as a definition of a "good ansatz," there are several natural directions to extend the results of section 2. Certainly an investigation of an algebraic dichotomy for the semigroup rather than exponential one implicit in hypotheses (H1)–(H2) is warranted. An interesting case would be an exact ansatz whose essential spectrum lies in the left-half plane and touches the origin, with σ_0 comprised of a single eigenvalue at the origin with finite algebraic multiplicity. It is not clear that an algebraic dichotomy could be exploited in the case of a quasi-stationary ansatz, for which the splitting of the eigenvalues in σ_0 would seem to require the use of an exponentially weighted space to push back the essential spectrum and restore the exponential dichotomy. The stability hypothesis (H4) might be relaxed to permit the structure or the dimension of the projection to change. This could arise, for example, in a pulse-splitting ansatz. The splitting of a pulse would be signaled by the angle θ_i, given by (3.48), becoming zero. The dimension of the manifold would increase, and as one can readily see from (3.53), the pulse dynamics could change substantially.

Appendix A. Invertibility of D.

We consider the invertibility of the operator D given by (3.22). We recall the definition $\rho(\mathbf{s}) = e^{-l\sqrt{\mu}}$.

LEMMA A.1. *For l large enough, the operator D_0 given by*

$$D_0 = -(\partial_x^2 - \mu + P_1 + \cdots + P_N),$$

where $P_i = \phi^2(x - \mathbf{s}_i)$, is uniformly boundedly invertible for all $\mathbf{s} \in \mathcal{K}_l$.

Proof. For each $i = 1, \dots, N$, the operator $D_i = -(\partial_x^2 - \mu + P_i)$ is boundedly invertible (see section 3.2 of [25]). Let $\chi_1, \dots, \chi_N$ be a partition of unity satisfying

$$\mathrm{supp}\,\chi_i \subset \left(\frac{\mathbf{s}_i + \mathbf{s}_{i-1}}{2} - 1, \frac{\mathbf{s}_i + \mathbf{s}_{i+1}}{2} + 1 \right),$$

where we take $\mathbf{s}_0 = -\infty$ and $\mathbf{s}_{N+1} = \infty$. We solve the equation

$$Df = g \tag{A.1}$$

for $g \in L^2$ for f by iteration. Set $g^{(1)} = g$ and for $n = 1, 2, \dots$ define

$$f_i^{(n)} = D_i^{-1} \chi_i g^{(n)}, \tag{A.2}$$

$$f^{(n)} = \sum_{i=1}^N f_i^{(n)}, \tag{A.3}$$

$$g^{(n+1)} = D_0 f^{(n)} - g^{(n)}. \tag{A.4}$$

From this construction it follows that

$$D_0(f^{(1)} + \cdots + f^{(n)}) = g - g^{(n+1)}. \tag{A.5}$$

Note that $\|f_i^{(n)}\|_{H^2} \leq M_0 \|\chi_i g^{(n)}\|_2$ for some $M_0 > 0$ independent of i and n, and in particular

$$\|f^{(n)}\|_{H^2} \leq M_0 \|g^{(n)}\|_2. \tag{A.6}$$

From (A.2) and (A.4) we find

$$g^{(n+1)} = \sum_i \sum_{j \neq i} P_j f_i^{(n)}. \tag{A.7}$$

Moreover, since $\mathrm{supp}\,\chi_i g_i^{(n)} \subset \mathrm{supp}\,\chi_i$ and $f_i^{(n)}$ is uniformly bounded, it follows from (A.2) that $f_i^{(n)}$ decays exponentially outside of $\mathrm{supp}\,\chi_i$; indeed,

$$|f_i^{(n)}(x)| \leq M_1 e^{-\sqrt{\mu}|x - \mathbf{s}_i|} \|f\|_\infty.$$

From this estimate and (A.7) a straightforward calculation shows that

$$\|g^{(n+1)}\|_2 \leq M_2 \rho \|f^{(n)}\|_\infty \leq M_2 \rho \|f^{(n)}\|_{H^2}. \tag{A.8}$$

Thus we find that

$$\|g^{(n+1)}\|_2 \leq (M_2 M_0 \rho)^n \|g\|_2,$$

and

$$\|f^{(n)}\|_{H^2} \leq M_0 (M_2 M_0 \rho)^{n-1} \|g\|_2.$$

From the equality (A.5) it follows that $f = \sum_{n=1}^\infty f^{(n)}$ satisfies (A.1), and

$$\|f\|_{H^2} \leq \frac{M_0}{1 - M_0 M_2 \rho} \|g\|_2,$$

which is finite if l is large enough. □

Proposition A.2. *Let D be given by $D = D_0 + \mathcal{V}$, where $\|\mathcal{V}\|_{*,H^1} = O(\delta)$ is given by* (3.23)*. Then for l large enough, D is boundedly invertible, and, moreover,*

$$\|D^{-1} - D_0^{-1}\|_{*,H^1} = O(\delta). \tag{A.9}$$

In particular, if $g = h\text{sech}(x - \mathbf{s}_i)$ for $h \in L^\infty$, then

$$D^{-1}g = D_i^{-1}g + O(\rho), \tag{A.10}$$

where $D_i = -(\partial_x^2 - \mu + P_i)$.

Proof. Since D is a small perturbation of D_0 we have the identity

$$D^{-1} = (I + D_0^{-1}\mathcal{V})^{-1}D_0^{-1}. \tag{A.11}$$

Moreover $(I + D_0^{-1}\mathcal{V})^{-1} = I + O(\delta)$ and (A.9) holds. The estimate (A.10) follows from observing from (A.2) that

$$f^{(1)} = D_i^{-1}\chi_i g^{(1)} + O(\delta) = D_i^{-1}g + O(\delta),$$

and $\|f^{(n)}\|_{H^1} \leq M\rho^{n-1}$ for some $M > 0$ and all $n \geq 2$. □

Acknowledgments. We are thankful to Todd Kapitula, Bjorn Sandstede, and Gene Wayne for many helpful discussions and to the referees for many helpful comments which led to improvements in the presentation of results.

A UNIQUENESS RESULT FOR THE NAVIER–STOKES EQUATIONS WITH VANISHING VERTICAL VISCOSITY*

DRAGOŞ IFTIMIE†

Abstract. Chemin et al. [M2AN Math. Model. Numer. Anal., 34 (2000), pp. 315–335.] considered the three-dimensional Navier–Stokes equations with vanishing vertical viscosity. Assuming that the initial velocity is square-integrable in the horizontal direction and H^s in the vertical direction, they prove existence of solutions for $s > 1/2$ and uniqueness of solutions for $s > 3/2$. Here, we close the gap between existence and uniqueness, proving uniqueness of solutions for $s > 1/2$. Standard techniques are used.

Key words. Navier–Stokes equations, Sobolev spaces

AMS subject classifications. 35Q30, 35Q35, 76D03, 76D05

PII. S0036141000382126

Introduction. Chemin, Desjardins, Gallagher, and Grenier [2] considered the following anisotropic Navier–Stokes equations:

$$(NS_h)\begin{cases} \partial_t v - \nu(\partial_1^2+\partial_2^2)v - \nu_{_V}\partial_3^2 v + v\cdot\nabla v = -\nabla p \quad \text{for} \quad (t,x)\in(0,\infty)\times\mathbb{R}^3,\\ \qquad\qquad\qquad\qquad\qquad \operatorname{div} v = 0 \quad \text{for} \quad (t,x)\in[0,\infty)\times\mathbb{R}^3,\\ \qquad\qquad\qquad\qquad\qquad v\big|_{t=0} = v_0, \end{cases}$$

where $v(t,\cdot):\mathbb{R}^3\to\mathbb{R}^3$ is an incompressible velocity field, p is the pressure, and the constants $\nu > 0$ and $\nu_{_V} \geq 0$ represent the horizontal and vertical viscosities.

Concerning the physical significance of these equations, we refer to [2] and to the references therein. We will simply say that systems of this type can be found in the theory of rotating fluids and also in the study of the Ekman layers for rotating fluids.

As specified above, the vertical viscosity $\nu_{_V}$ may vanish (or converge to 0). For this reason, the classical theory of the Navier–Stokes equations does not apply. Some L^2 energy estimates still hold for (NS_h), but these are not enough to pass to the limit and obtain a weak solution. The strong solution theory doesn't apply either, unless we work in the framework of hyperbolic symmetric systems by ignoring completely the viscosity terms and requiring a lot of regularity for the initial data. Actually, the only result concerning the situation described to be found in the literature is given by [2, Theorems 2, 3].

Theorem 0.1 (see Chemin et al.). *Let $s > 1/2$ be a real number, and let $v_0 \in \mathrm{H}^{0,s}$ be a divergence-free vector field. Then a positive time T and a solution v of (NS_h) defined on $[0,T]\times\mathbb{R}^3$ exist such that*

$$v \in \mathrm{L}^\infty\big(0,T;\mathrm{H}^{0,s}\big)\cap\mathrm{L}^2\big(0,T;\mathrm{H}^{1,s}\big).$$

Furthermore, there exists a constant c such that if $\|v_0\|_{0,s}$ is less than $c\nu$, then we can choose $T = +\infty$. Finally, this solution is unique, provided that $s > 3/2$.

*Received by the editors December 7, 2000; accepted for publication (in revised form) January 10, 2002; published electronically July 9, 2002.

The space $\mathrm{H}^{s,s'}$ is a space with Sobolev regularity H^s in (x_1, x_2) and $\mathrm{H}^{s'}$ in x_3, whose precise definition will be given in section 1.

Let us first make some observations regarding the isotropic Navier–Stokes equations. Critical spaces for the three-dimensional (3D) Navier–Stokes equations are the spaces whose homogeneous norm is invariant under the scaling $f(\cdot) \leftrightarrow \lambda f(\lambda\cdot)$. There is no result on existence and uniqueness of solutions for general initial data in a subcritical space (i.e., a space whose homogeneous norm is invariant under the scaling $f(\cdot) \leftrightarrow \lambda^\alpha f(\lambda\cdot)$ for some $\alpha > 1$). For critical spaces, there are many existence and uniqueness results, starting with the classical result for $\mathrm{H}^{\frac{1}{2}}$ of Fujita and Kato [3] and continuing with Besov spaces, Triebel–Lizorkin spaces, etc. We refer to Cannone [1] for details. Let us just note that a borderline case, that of initial data in BMO^{-1} (divergences of BMO vector fields), was recently proved by Koch and Tataru [6]. Initial data in anisotropic critical spaces were considered by the author in [5]. That work contains an existence and uniqueness result [5, Theorem 3.1] for initial data in a critical anisotropic Besov-type space that contains $\mathrm{H}^{0,s}$ for all $s > 1/2$ (but is contained in $\mathrm{H}^{0,\frac{1}{2}}$). The problem of well-posedness for initial data in $\mathrm{H}^{0,\frac{1}{2}}$ seems to be very difficult for the following two reasons. First, the homogeneous version of $\mathrm{H}^{0,\frac{1}{2}}$ is not well defined since it would require defining $\mathrm{H}^{\frac{1}{2}}$ homogeneous regularity in x_3 and it is well known that the homogeneous space $\mathrm{H}^{\frac{1}{2}}$ is not well defined in dimension 1 (or rather it is not a Banach space). Second, the space $\mathrm{H}^{0,\frac{1}{2}}$ is not included in C^{-1} (see [5, Proposition 4.1]) and it seems to be very difficult to prove existence and uniqueness for initial data which is not C^{-1}. (All the spaces of initial data for which existence and uniqueness of solutions are known are embedded in C^{-1}.)

In accordance with what is observed above, the existence part of Theorem 0.1 is very similar to results known for the isotropic Navier–Stokes equations. The key observation is that, although there is not enough regularity in the vertical direction, the partial derivative ∂_3 is always multiplied by u_3 in the nonlinear term, and the divergence-free condition implies that u_3 has enough vertical regularity. Nevertheless, some technical difficulties persist.

In the result of Chemin et al. there is a gap between the existence result and the uniqueness result. This gap is unexpected, especially since, for the full Navier–Stokes equations, $s > 1/2$ is sufficient to get uniqueness within the framework of anisotropic spaces (see [5, Theorem 3.1]). The aim of this work is to close this gap, proving that uniqueness holds when existence does, i.e., $s > 1/2$.

The gap in the proof of uniqueness given by [2] is due to the term $w_3\partial_3 v$ (w is the difference of two solutions and v is one of the two solutions). Roughly speaking, to estimate this term in $\mathrm{H}^{0,\frac{1}{2}}$ one needs at least $\mathrm{H}^{\frac{1}{2}}$ regularity for $\partial_3 v$ in the vertical direction, that is, $\mathrm{H}^{\frac{3}{2}}$ regularity for v in the vertical direction. This demands, of course, that $s > 3/2$. To overcome this difficulty, we propose to estimate the $\mathrm{H}^{0,-\frac{1}{2}}$ norm of w instead of the $\mathrm{H}^{0,\frac{1}{2}}$ norm. This will require only $\mathrm{H}^{\frac{1}{2}}$ regularity for v in the vertical direction, so the hypothesis $s > 1/2$ will suffice.

This point of view implies some difficulties. First, we will require a product theorem for the anisotropic Sobolev spaces where the regularities in the vertical direction are supercritical for one of the terms and subcritical for the other; see Theorem 1.4. Some product theorems are available but only when both regularities are subcritical (see [5, Theorem 1.1] and [4, Theorem 1.1]) or supercritical (see [2, Lemma 1]).

A second difficulty is to estimate a symmetric term of the type $\int v_3 \partial_3 w \cdot \Lambda_3^{-1} w \, \mathrm{d}x$ (Λ_3 is roughly ∂_3; see the next section for the precise definition). Such a term does not appear when making L^2 estimates instead of $\mathrm{H}^{0,-\frac{1}{2}}$. The estimates for symmetric terms are usually complicated when the indices of regularity are not integers. In the previously cited works, the estimates of this type are long and require dyadic decompositions. We will be able to obtain such an estimate through elementary techniques.

The following theorem completes Theorem 0.1 in the sense that the hypothesis $s > 3/2$ is no longer required to get uniqueness of solutions.

THEOREM 0.2. *Let v and $\widetilde{v}$ be two solutions of (NS_h) on $(0,T)$ belonging to $\mathrm{L}^\infty\big(0,T;\mathrm{H}^{0,s}\big)\cap\mathrm{L}^2\big(0,T;\mathrm{H}^{1,s}\big)$, where $s>1/2$. If v and $\widetilde{v}$ have the same initial data, then $v\equiv\widetilde{v}$.*

Although the regularity invoked in the hypothesis of this theorem is not sufficient by itself to define a trace of the velocity v at time $t=0$, it is a classical observation that v satisfying (NS_h) implies some continuity in time of v, namely $v\in\mathrm{C}^0([0,T];\mathrm{H}^{0,r})$ for all $r<s$ (for a proof, see the remarks before (4)). It therefore makes sense to say that v and $\widetilde{v}$ have the same initial data.

The author is able to prove neither uniqueness nor existence (in the regularity class of Theorem 0.1) in the case $s=1/2$. To this respect, we have nothing to add to the comments made for the isotropic Navier–Stokes equations.

In the following section we introduce notation and prove a new product theorem for anisotropic Sobolev spaces. The last section contains the proof of Theorem 0.2.

1. Notation and preliminary results. In the following, C will denote a constant which may change from one relation to another and which may depend on the different parameters $s, s', \dots$ introduced. The constant K is a universal constant which can also change from one relation to another. Two quantities A and B are said to verify the relation $A\simeq B$ if and only if the ratio A/B stays between two positive constants. We denote by $\langle x\rangle$ the quantity $\langle x\rangle=(1+|x|^2)^{\frac12}$.

DEFINITION 1.1. *For $s,s'\in\mathbb{R}$ we define the anisotropic Sobolev space $\mathrm{H}^{s,s'}$ to be the space of those tempered distributions f which satisfy*

$$\|f\|_{s,s'}\overset{def}{=}\big\|\langle\xi'\rangle^s\langle\xi_3\rangle^{s'}\widehat{f}(\xi)\big\|_{\mathrm{L}^2}<\infty,$$

where $\xi'=(\xi_1,\xi_2)$.

The space $\mathrm{H}^{s,s'}$ endowed with the norm $\|\cdot\|_{s,s'}$ is a Hilbert space.

The partial derivative $\partial/\partial x_j$ is denoted by ∂_j. We denote by Λ_3 the operator $\Lambda_3=\big(1-\partial_3^2\big)^{\frac12}$, that is, the operator of multiplication by $\langle\xi_3\rangle$ in the frequency space. Clearly, Λ_3 is an isometry from $\mathrm{H}^{s,s'}$ to $\mathrm{H}^{s,s'-1}$ for all real numbers s and s'.

When we apply an operator to a vector field, we mean that we apply it to each component of the vector field. The $\mathrm{H}^{s,s'}$ norm of a vector field is the Euclidean norm of the $\mathrm{H}^{s,s'}$ norms of the components. If u, v, and w are three vector fields, then $u\cdot\nabla v$ denotes the vector field $\sum_i u_i\partial_i v$, and $u\cdot\nabla v\cdot w$ denotes the scalar $\sum_{i,j}u_i\,\partial_i v_j\,w_j$.

We will need in the proof of Theorem 0.2 certain interpolation properties of the spaces $\mathrm{H}^{s,s'}$. The following proposition is very easy to prove (see [4, Proposition 1.1]).

PROPOSITION 1.2 (interpolation). *Let $s,t,s',t'\in\mathbb{R}$ and $\alpha\in[0,1]$. If $f\in\mathrm{H}^{s,s'}\cap\mathrm{H}^{t,t'}$, then we have that $f\in\mathrm{H}^{\alpha s+(1-\alpha)t,\alpha s'+(1-\alpha)t'}$ and*

$$\|f\|_{\alpha s+(1-\alpha)t,\alpha s'+(1-\alpha)t'}\le\|f\|_{s,s'}^{\alpha}\|f\|_{t,t'}^{1-\alpha}.$$

The multiplicative properties of the anisotropic Sobolev spaces have been studied in several papers [2, 4, 5, 8, 9]. The following result is proved in [4, Theorem 1.1], valid in the periodic case.

Theorem 1.3. *Let $s,t<1$, $s+t>0$, and $s',t'<1/2$, $s'+t'>0$. If $f\in \mathrm{H}^{s,s'}$ and $g\in\mathrm{H}^{t,t'}$, then $fg\in\mathrm{H}^{s+t-1,s'+t'-1/2}$ and there exists a constant C such that*

$$\|fg\|_{s+t-1,s'+t'-\frac12}\le C\|f\|_{s,s'}\|g\|_{t,t'}.$$

The proof in [4], which uses dyadic decompositions, carries over to the case of the full space. Nevertheless, a more elementary proof can be given, as in Theorem 1.4. For further details, see Remark 3.

Theorem 1.3 is not enough for our purposes. Indeed, the regularity we need is "supercritical" in the vertical direction, i.e., greater than 1/2, a situation which is not covered by Theorem 1.3. The purpose of the following theorem is to deal with this difficulty.

Theorem 1.4. *Let $s,t<1$, $s+t>0$, and $s'>1/2$. If $f\in\mathrm{H}^{s,s'}$ and $g\in\mathrm{H}^{t,-\frac12}$, then $fg\in\mathrm{H}^{s+t-1,-\frac12}$ and there exists a constant C such that*

$$\|fg\|_{s+t-1,-\frac12}\le C\|f\|_{s,s'}\|g\|_{t,-\frac12}.$$

The proof will use the following easy lemma.

Lemma 1.5. *Let $s\in\mathbb{R}$ and $n\in\mathbb{N}^*$. A constant C exists such that*

$$\int_{|x|\le R}\langle x\rangle^s\,\mathrm{d}x\le\begin{cases}C\max(1,\langle R\rangle^{s+n}) & \text{if } s+n\neq 0,\\ \sigma_{n-1}\sqrt2(1+\log\langle R\rangle) & \text{if } s+n=0,\end{cases}$$

where the variable of integration x belongs to $\mathbb{R}^n$ and σ_{n-1} denotes the area of the unit sphere in $\mathbb{R}^n$. Moreover, if s is not large (for instance, if $|s|\le 100$), then the constant C can be chosen of the form $C=\frac{K(n)}{|s+n|}$.

Proof of the lemma. Clearly

$$\int_{|x|\le R}\langle x\rangle^s\,\mathrm{d}x=\sigma_{n-1}\int_0^R\langle r\rangle^s r^{n-1}\,\mathrm{d}r\le\sigma_{n-1}\int_0^R\langle r\rangle^{s+n-1}\,\mathrm{d}r.$$

Since $\frac{1+r}{\sqrt2}\le\langle r\rangle\le 1+r$, we deduce that $\langle r\rangle^{s+n-1}\le(1+r)^{s+n-1}$ if $s+n\ge1$, and $\langle r\rangle^{s+n-1}\le\frac{(1+r)^{s+n-1}}{(\sqrt2)^{s+n-1}}$ if $s+n\le1$. It follows that

$$\int_{|x|\le R}\langle x\rangle^s\,\mathrm{d}x\le\sigma_{n-1}\max(1,2^{\frac{1-n-s}{2}})\int_0^R(1+r)^{s+n-1}\,\mathrm{d}r$$
$$=\begin{cases}\sigma_{n-1}\max(1,2^{\frac{1-n-s}{2}})\frac{(1+R)^{s+n}-1}{s+n} & \text{if } s+n\neq0,\\ \sigma_{n-1}\sqrt2\log(1+R) & \text{if } s+n=0.\end{cases}$$

The conclusion follows by using that $(1+R)^{s+n}\simeq\langle R\rangle^{s+n}$ and $\log(1+R)\le 1+\log\langle R\rangle$. □

Remark 1. In the following we don't need to know the behavior of the constant C of Lemma 1.5 as $|s|\to\infty$. Nevertheless, for the sake of completeness we indicate that the constant C can be chosen of the form $\frac{K(n)}{|s+n|}$ as $|s|\to\infty$, too. The proof of this fact is very easy in the case $n\ge2$, and so we include it here. As in the proof of the lemma, we have for $s+n\neq0$ that

$$\int_{|x|\le R}\langle x\rangle^s\,\mathrm{d}x=\sigma_{n-1}\int_0^R\langle r\rangle^s r^{n-1}\,\mathrm{d}r\le\sigma_{n-1}\int_0^R\langle r\rangle^{s+n-2}r\,\mathrm{d}r$$
$$=\frac{\sigma_{n-1}}{s+n}\int_0^R\frac{\mathrm{d}}{\mathrm{d}r}\big(\langle r\rangle^{s+n}\big)\,\mathrm{d}r=\frac{\sigma_{n-1}}{s+n}\big(\langle R\rangle^{s+n}-1\big)\le\frac{\sigma_{n-1}}{|s+n|}\max\big(1,\langle R\rangle^{s+n}\big).$$

Proof of Theorem 1.4. Let $f \in \mathrm{H}^{s,s'}$ and $g \in \mathrm{H}^{t,-\frac{1}{2}}$. We have to estimate the norm

$$\|fg\|_{s+t-1,-\frac{1}{2}} = (2\pi)^{-3} \|\langle \xi' \rangle^{s+t-1} \langle \xi_3 \rangle^{-\frac{1}{2}} \widehat{f} * \widehat{g}(\xi)\|_{\mathrm{L}^2}.$$

By duality,

$$\begin{aligned}(2\pi)^3 \|fg\|_{s+t-1,-\frac{1}{2}} &= \sup_{\|h\|_{\mathrm{L}^2} \leq 1} \int \langle \xi' \rangle^{s+t-1} \langle \xi_3 \rangle^{-\frac{1}{2}} \widehat{f} * \widehat{g}(\xi) h(\xi)\, \mathrm{d}\xi \\ &= \sup_{\|h\|_{\mathrm{L}^2} \leq 1} \iint \langle \xi' + \eta' \rangle^{s+t-1} \langle \xi_3 + \eta_3 \rangle^{-\frac{1}{2}} \widehat{f}(\xi) \widehat{g}(\eta) h(\xi + \eta)\, \mathrm{d}\xi\, \mathrm{d}\eta.\end{aligned}$$

We can further write

(1)
$$\begin{aligned}(2\pi)^3 \|fg\|_{s+t-1,-\frac{1}{2}} \leq{}& \sup_{\|h\|_{\mathrm{L}^2} \leq 1} \underbrace{\iint_{2|\xi'| \geq |\eta'|} \langle \xi' + \eta' \rangle^{s+t-1} \langle \xi_3 + \eta_3 \rangle^{-\frac{1}{2}} \widehat{f}(\xi) \widehat{g}(\eta) h(\xi + \eta)\, \mathrm{d}\xi\, \mathrm{d}\eta}_{I_1} \\ &+ \sup_{\|h\|_{\mathrm{L}^2} \leq 1} \underbrace{\iint_{2|\xi'| \leq |\eta'|} \langle \xi' + \eta' \rangle^{s+t-1} \langle \xi_3 + \eta_3 \rangle^{-\frac{1}{2}} \widehat{f}(\xi) \widehat{g}(\eta) h(\xi + \eta)\, \mathrm{d}\xi\, \mathrm{d}\eta}_{I_2}.\end{aligned}$$

In what follows, whenever we study the dependence of constants on s', we will assume that s' stays bounded (for instance, $s' \leq 100$ or any other universal constant).

We now write I_1 under the form

$$I_1 = \iint_{2|\xi'| \geq |\eta'|} \langle \xi_3 + \eta_3 \rangle^{-\frac{1}{2}} \frac{\langle \xi' + \eta' \rangle^{s+t-1}}{\langle \eta' \rangle^t} \widehat{f}(\xi) \langle \eta' \rangle^t \widehat{g}(\eta) h(\xi + \eta)\, \mathrm{d}\xi\, \mathrm{d}\eta,$$

and we apply Hölder's inequality in the variables ξ' and η' to obtain that

$$\begin{aligned}I_1 \leq \iint \langle \xi_3 + \eta_3 \rangle^{-\frac{1}{2}} \Bigg(& \underbrace{\iint_{2|\xi'| \geq |\eta'|} \frac{\langle \xi' + \eta' \rangle^{2(s+t-1)}}{\langle \eta' \rangle^{2t}} |\widehat{f}(\xi)|^2\, \mathrm{d}\xi'\, \mathrm{d}\eta'}_{I_3} \\ & \times \iint \langle \eta' \rangle^{2t} |\widehat{g}(\eta)|^2 |h(\xi + \eta)|^2\, \mathrm{d}\xi'\, \mathrm{d}\eta' \Bigg)^{\frac{1}{2}} \mathrm{d}\xi_3\, \mathrm{d}\eta_3.\end{aligned}$$

To estimate I_3, we first integrate with respect to η' and then decompose

$$\begin{aligned}\int_{2|\xi'| \geq |\eta'|} \frac{\langle \xi' + \eta' \rangle^{2(s+t-1)}}{\langle \eta' \rangle^{2t}}\, \mathrm{d}\eta' = & \int_{|\eta'| \leq |\xi'|/2} \frac{\langle \xi' + \eta' \rangle^{2(s+t-1)}}{\langle \eta' \rangle^{2t}}\, \mathrm{d}\eta' \\ & + \int_{|\xi'|/2 \leq |\eta'| \leq 2|\xi'|} \frac{\langle \xi' + \eta' \rangle^{2(s+t-1)}}{\langle \eta' \rangle^{2t}}\, \mathrm{d}\eta'.\end{aligned}$$

If $|\eta'| \leq |\xi'|/2$, then $\langle \xi' + \eta' \rangle \simeq \langle \xi' \rangle$. If $|\xi'|/2 \leq |\eta'| \leq 2|\xi'|$, then $\langle \eta' \rangle \simeq \langle \xi' \rangle$. We deduce that

$$\int_{|\eta'| \leq |\xi'|/2} \frac{\langle \xi' + \eta' \rangle^{2(s+t-1)}}{\langle \eta' \rangle^{2t}}\, \mathrm{d}\eta' \simeq \langle \xi' \rangle^{2(s+t-1)} \int_{|\eta'| \leq |\xi'|/2} \frac{1}{\langle \eta' \rangle^{2t}}\, \mathrm{d}\eta' \leq \frac{K}{1-t} \langle \xi' \rangle^{2s}$$

and that

$$\int_{|\xi'|/2\le|\eta'|\le 2|\xi'|}\frac{\langle\xi'+\eta'\rangle^{2(s+t-1)}}{\langle\eta'\rangle^{2t}}\,\mathrm{d}\eta' \simeq \frac{1}{\langle\xi'\rangle^{2t}}\int_{|\xi'|/2\le|\eta'|\le 2|\xi'|}\langle\xi'+\eta'\rangle^{2(s+t-1)}\,\mathrm{d}\eta'$$
$$\le \frac{K}{\langle\xi'\rangle^{2t}}\int_{|\zeta|\le 3|\xi'|}\langle\zeta\rangle^{2(s+t-1)}\,\mathrm{d}\zeta \le \frac{K}{s+t}\langle\xi'\rangle^{2s},$$

where we have used Lemma 1.5 and the change of variables $\zeta=\xi'+\eta'$.

According to the definition of I_3, we obtain from the previous relations that

$$I_3\le C\int\langle\xi'\rangle^{2s}|\widehat{f}(\xi)|^2\,\mathrm{d}\xi',$$

which yields the following estimate for I_1:

$$I_1\le C\iint\left(\int\langle\xi'\rangle^{2s}\langle\xi_3\rangle^{2s'}|\widehat{f}(\xi)|^2\,\mathrm{d}\xi'\int|h(\zeta,\xi_3+\eta_3)|^2\,\mathrm{d}\zeta\right)^{\frac12}$$
$$\times\left(\langle\xi_3+\eta_3\rangle^{-1}\langle\xi_3\rangle^{-2s'}\int\langle\eta'\rangle^{2t}|\widehat{g}(\eta)|^2\,\mathrm{d}\eta'\right)^{\frac12}\mathrm{d}\xi_3\,\mathrm{d}\eta_3.$$

Hölder's inequality applied in the variable (ξ_3,η_3) now gives that

$$I_1\le C\|f\|_{s,s'}\|h\|_{\mathrm{L}^2}\left(\int\langle\eta'\rangle^{2t}\varphi(\eta_3)|\widehat{g}(\eta)|^2\,\mathrm{d}\eta\right)^{\frac12},\tag{2}$$

where

$$\varphi(\eta_3)=\int\frac{1}{\langle\xi_3+\eta_3\rangle\langle\xi_3\rangle^{2s'}}\,\mathrm{d}\xi_3.$$

To estimate φ, we proceed as for I_3 by investigating several pieces and using Lemma 1.5:

$$\int_{|\xi_3|\ge 2|\eta_3|}\frac{1}{\langle\xi_3+\eta_3\rangle\langle\xi_3\rangle^{2s'}}\,\mathrm{d}\xi_3\simeq\int_{2|\eta_3|}^{\infty}\frac{1}{\langle\xi_3\rangle^{2s'+1}}\,\mathrm{d}\xi_3$$
$$\simeq\int_{2|\eta_3|}^{\infty}\frac{1}{(1+\xi_3)^{2s'+1}}\,\mathrm{d}\xi_3\le\frac{K}{\langle\eta_3\rangle^{2s'}}\le\frac{K}{\langle\eta_3\rangle},$$
$$\int_{|\xi_3|\le|\eta_3|/2}\frac{1}{\langle\xi_3+\eta_3\rangle\langle\xi_3\rangle^{2s'}}\,\mathrm{d}\xi_3\simeq\frac{1}{\langle\eta_3\rangle}\int_{|\xi_3|\le|\eta_3|/2}\frac{1}{\langle\xi_3\rangle^{2s'}}\,\mathrm{d}\xi_3\le\frac{K}{(s'-\frac12)\langle\eta_3\rangle},$$
$$\int_{|\eta_3|/2\le|\xi_3|\le 2|\eta_3|}\frac{1}{\langle\xi_3+\eta_3\rangle\langle\xi_3\rangle^{2s'}}\,\mathrm{d}\xi_3\simeq\frac{1}{\langle\eta_3\rangle^{2s'}}\int_{|\eta_3|/2\le|\xi_3|\le 2|\eta_3|}\frac{1}{\langle\xi_3+\eta_3\rangle}\,\mathrm{d}\xi_3$$
$$\le\frac{K}{\langle\eta_3\rangle^{2s'}}\int_{|\zeta|\le 3|\eta_3|}\frac{1}{\langle\zeta\rangle}\,\mathrm{d}\zeta$$
$$\le\frac{K}{\langle\eta_3\rangle^{2s'}}(1+\log\langle\eta_3\rangle)\le\frac{K}{(s'-\frac12)\langle\eta_3\rangle},$$

where we have used in the last relation that $\log\alpha\le\frac{\alpha^{\varepsilon}}{e\varepsilon}$ for all $\alpha\ge 1$ and $\varepsilon>0$. We deduce from the previous relations that

$$\varphi(\eta_3)\le C\langle\eta_3\rangle^{-1},$$

which, plugged into (2), yields the estimate

$$I_1 \leq C\|f\|_{s,s'}\|g\|_{t,-\frac{1}{2}}\|h\|_{\mathrm{L}^2}. \tag{3}$$

To complete the proof, it remains to estimate I_2 (defined in relation (1)). By Hölder's inequality,

$$I_2 \leq (J_1 J_2)^{\frac{1}{2}},$$

where

$$J_1 = \iint \langle\xi'\rangle^{2s}\langle\xi_3\rangle^{2s'}|\widehat{f}(\xi)|^2|h(\xi+\eta)|^2\,\mathrm{d}\xi\,\mathrm{d}\eta$$

and

$$J_2 = \iint_{2|\xi'|\leq|\eta'|} \frac{\langle\xi'+\eta'\rangle^{2(s+t-1)}}{\langle\xi'\rangle^{2s}}\frac{\langle\xi_3+\eta_3\rangle^{-1}}{\langle\xi_3\rangle^{2s'}}|\widehat{g}(\eta)|^2\,\mathrm{d}\xi\,\mathrm{d}\eta.$$

Clearly, $J_1 = \|h\|^2_{\mathrm{L}^2}\|f\|^2_{s,s'}$. To estimate J_2, we first integrate in ξ' and ξ_3. As in the estimate for I_3,

$$\int_{2|\xi'|\leq|\eta'|}\frac{\langle\xi'+\eta'\rangle^{2(s+t-1)}}{\langle\xi'\rangle^{2s}}\,\mathrm{d}\xi' \simeq \langle\eta'\rangle^{2(s+t-1)}\int_{2|\xi'|\leq|\eta'|}\frac{1}{\langle\xi'\rangle^{2s}}\,\mathrm{d}\xi' \leq \frac{K}{1-s}\langle\eta'\rangle^{2t}.$$

Therefore, again using the bound for φ, one deduces that

$$J_2 \leq C\|g\|^2_{t,-\frac{1}{2}}.$$

We conclude that

$$I_2 \leq C\|f\|_{s,s'}\|g\|_{t,-\frac{1}{2}}\|h\|_{\mathrm{L}^2},$$

which, combined with relations (1) and (3), completes the proof of Theorem 1.4. □

Remark 2. It might be useful to know how the constant C in the statement of Theorem 1.4 depends on s, s', and t. Actually, tracking the constants in the proof, the constant C is of the form

$$C = K\left(\frac{1}{\sqrt{1-s}}+\frac{1}{\sqrt{1-t}}+\frac{1}{\sqrt{s+t}}\right)\frac{1}{\sqrt{s'-1/2}},$$

where we have assumed that s' stays bounded (say, $s' \leq 100$).

Remark 3. Theorem 1.4 is a special case of a more general theorem. More precisely, instead of considering $g \in \mathrm{H}^{t,-\frac{1}{2}}$, one may consider $g \in \mathrm{H}^{t,t'}$, where t' verifies $t' \leq s'$ and $s'+t' > 0$. The conclusion is then that $fg \in \mathrm{H}^{s+t-1,t'}$. We chose to prove the special case $t' = -1/2$, sufficient for our purposes, because the proof is considerably simpler. The proof in the general case does not involve any new ideas. In fact, the complication in the proof comes from the fact that the decomposition in ξ' given in relation (1) has to be done in the variable ξ_3 also; therefore one has to examine four pieces instead of just two, but the techniques are identical. Finally, let us note that if we add the hypothesis $t' < s'-1/2$, then the additional decomposition in ξ_3 is not necessary and the proof given here carries over with no modification other than the replacement of $-1/2$ by t'.

2. Proof of the main theorem. We can assume without loss of generality that $s<1$. We will prove that the $\mathrm{H}^{0,-\frac{1}{2}}$ norm of $w=v-\widetilde{v}$ vanishes. In order to estimate $\|w\|_{0,-\frac{1}{2}}$, let us prove that the regularity available is enough to allow us to multiply the equation for $v-\widetilde{v}$ by $\Lambda_3^{-1}w$. First, note that we can write

$$v\cdot\nabla v=\sum_i \partial_i(v_i v).$$

By interpolation and by hypothesis, one has that $v\in\mathrm{L}^4(0,T;\mathrm{H}^{\frac{1}{2},s})$ (see relation (16)). The product theorem 1.3 easily implies that $v_i v\in\mathrm{L}^2(0,T;\mathrm{H}^{0,1-s})$ so $v\cdot\nabla v\in\mathrm{L}^2(0,T;\mathrm{H}^{-1,-s})\subset\mathrm{L}^2(0,T;\mathrm{H}^{-1,-\frac{3}{2}})$. Clearly, $\nu(\partial_1^2+\partial_2^2)v+\nu_{_V}\partial_3^2 v\in\mathrm{L}^2(0,T;\mathrm{H}^{-1,s})+\mathrm{L}^2(0,T;\mathrm{H}^{1,s-2})\subset\mathrm{L}^2(0,T;\mathrm{H}^{-1,-\frac{3}{2}})$. From the equation (NS_h) it follows that $\partial_t v\in\mathrm{L}^2(0,T;\mathrm{H}^{-1,-\frac{3}{2}})$. We deduce that every term in the equations for v and $\widetilde{v}$ belongs to $\mathrm{L}^2(0,T;\mathrm{H}^{-1,-\frac{3}{2}})$ and can therefore be multiplied by $\Lambda_3^{-1}w$, which belongs to $\mathrm{L}^2(0,T;\mathrm{H}^{1,1+s})\subset\mathrm{L}^2(0,T;\mathrm{H}^{1,\frac{3}{2}})$.

Note that the fact that $\partial_t v\in\mathrm{L}^2(0,T;\mathrm{H}^{-1,-\frac{3}{2}})$ and $v\in\mathrm{L}^2(0,T;\mathrm{H}^{1,s})$ implies, by the interpolation theory developed by Lions and Magenes [7, Chapter 1], that $v\in\mathrm{C}^0([0,T];\mathrm{H}^{0,\frac{2s-3}{4}})$. The interpolation property stated in Proposition 1.2 along with the fact that $v\in\mathrm{L}^\infty(0,T;\mathrm{H}^{0,s})$ imply in a classical manner that $v\in\mathrm{C}^0([0,T];\mathrm{H}^{0,r})$ for all $r<s$.

Multiplying the equation for $v-\widetilde{v}$ by $\Lambda_3^{-1}w$, integrating on $(\varepsilon,t)\times\mathbb{R}^3$, letting $\varepsilon\to 0$, and using the continuity in time of $\|w\|_{0,-\frac{1}{2}}$ yields

$$\begin{aligned}\|w(t)\|^2_{0,-\frac{1}{2}}+2\nu\int_0^t\big(\|\partial_1 w(\tau)\|^2_{0,-\frac{1}{2}}+\|\partial_2 w(\tau)\|^2_{0,-\frac{1}{2}}\big)\,\mathrm{d}\tau+2\nu_{_V}\int_0^t\|\partial_3 w(\tau)\|^2_{0,-\frac{1}{2}}\,\mathrm{d}\tau\\ =-2\int_0^t\int v(\tau,x)\cdot\nabla w(\tau,x)\cdot\Lambda_3^{-1}w(\tau,x)\,\mathrm{d}\tau\,\mathrm{d}x\\ -2\int_0^t\int w(\tau,x)\cdot\nabla\widetilde{v}(\tau,x)\cdot\Lambda_3^{-1}w(\tau,x)\,\mathrm{d}\tau\,\mathrm{d}x.\end{aligned}\tag{4}$$

To simplify the notation, we will write v instead of $v(\tau,x)$ and so on. We consider τ fixed, and we evaluate

$$\int v\cdot\nabla w\cdot\Lambda_3^{-1}w\,\mathrm{d}x=\underbrace{\int(v_1\partial_1 w+v_2\partial_2 w)\cdot\Lambda_3^{-1}w\,\mathrm{d}x}_{L_1}+\underbrace{\int v_3\partial_3 w\cdot\Lambda_3^{-1}w\,\mathrm{d}x}_{L_2}\tag{5}$$

and

$$\int w\cdot\nabla\widetilde{v}\cdot\Lambda_3^{-1}w\,\mathrm{d}x=\underbrace{\int(w_1\partial_1\widetilde{v}+w_2\partial_2\widetilde{v})\cdot\Lambda_3^{-1}w\,\mathrm{d}x}_{L_3}+\underbrace{\int w_3\partial_3\widetilde{v}\cdot\Lambda_3^{-1}w\,\mathrm{d}x.}_{L_4}\tag{6}$$

We will now estimate each of these integrals.

Estimate of L_1. According to the product theorem 1.4, one can bound L_1 as follows:

$$|L_1|\le\|v_1\partial_1 w+v_2\partial_2 w\|_{-\frac{1}{2},-\frac{1}{2}}\|\Lambda_3^{-1}w\|_{\frac{1}{2},\frac{1}{2}}\le C\|v\|_{\frac{1}{2},s}\|w\|_{1,-\frac{1}{2}}\|w\|_{\frac{1}{2},-\frac{1}{2}}.$$

By the interpolation property given in Proposition 1.2, one has that

$$\|w\|_{\frac{1}{2},-\frac{1}{2}} \leq \|w\|_{0,-\frac{1}{2}}^{\frac{1}{2}} \|w\|_{1,-\frac{1}{2}}^{\frac{1}{2}}, \tag{7}$$

which leads to

$$|L_1| \leq C\|v\|_{\frac{1}{2},s} \|w\|_{0,-\frac{1}{2}}^{\frac{1}{2}} \|w\|_{1,-\frac{1}{2}}^{\frac{3}{2}}. \tag{8}$$

Estimate of L_3. Again by the product theorem 1.4, we have that

$$|L_3| \leq \|w_1\partial_1\widetilde{v} + w_2\partial_2\widetilde{v}\|_{-\frac{3}{4},-\frac{1}{2}} \|\Lambda_3^{-1}w\|_{\frac{3}{4},\frac{1}{2}} \leq C\|\widetilde{v}\|_{\frac{1}{2},s}\|w\|_{\frac{3}{4},-\frac{1}{2}}^2.$$

By interpolation,

$$\|w\|_{\frac{3}{4},-\frac{1}{2}} \leq \|w\|_{0,-\frac{1}{2}}^{\frac{1}{4}} \|w\|_{1,-\frac{1}{2}}^{\frac{3}{4}},$$

so that

$$|L_3| \leq C\|\widetilde{v}\|_{\frac{1}{2},s} \|w\|_{0,-\frac{1}{2}}^{\frac{1}{2}} \|w\|_{1,-\frac{1}{2}}^{\frac{3}{2}}. \tag{9}$$

Estimate of L_4. We proceed by using Theorem 1.3:

$$\begin{aligned} |L_4| \leq \|w_3\partial_3\widetilde{v}\|_{-\frac{1}{2},\frac{2s-3}{4}} \|\Lambda_3^{-1}w\|_{\frac{1}{2},\frac{3-2s}{4}} &\leq C\|w_3\|_{0,\frac{3-2s}{4}} \|\partial_3\widetilde{v}\|_{\frac{1}{2},s-1} \|w\|_{\frac{1}{2},\frac{-2s-1}{4}} \\ &\leq C\|\widetilde{v}\|_{\frac{1}{2},s} \|w_3\|_{0,\frac{1}{2}} \|w\|_{\frac{1}{2},-\frac{1}{2}}. \end{aligned}$$

But it is trivial to see that

$$\|f\|_{s,s'} = \big(\|f\|_{s,s'-1}^2 + \|\partial_3 f\|_{s,s'-1}^2\big)^{\frac{1}{2}} \leq \|f\|_{s,s'-1} + \|\partial_3 f\|_{s,s'-1}.$$

Therefore, because w is divergence free,

$$\|w_3\|_{0,\frac{1}{2}} \leq \|w\|_{0,-\frac{1}{2}} + \|\partial_3 w_3\|_{0,-\frac{1}{2}} = \|w\|_{0,-\frac{1}{2}} + \|\partial_1 w_1 + \partial_2 w_2\|_{0,-\frac{1}{2}} \leq \|w\|_{0,-\frac{1}{2}} + 2\|w\|_{1,-\frac{1}{2}}.$$

Also using relation (7), we infer that

$$|L_4| \leq C\|\widetilde{v}\|_{\frac{1}{2},s}\big(\|w\|_{0,-\frac{1}{2}}^{\frac{3}{2}} \|w\|_{1,-\frac{1}{2}}^{\frac{1}{2}} + \|w\|_{0,-\frac{1}{2}}^{\frac{1}{2}} \|w\|_{1,-\frac{1}{2}}^{\frac{3}{2}}\big). \tag{10}$$

Estimate of L_2. The proof for L_2 is more delicate. It is a commutator-type estimate and requires an integration by parts. Applying Parseval's formula gives

$$\begin{aligned} L_2 &= \int v_3\partial_3 w \cdot \Lambda_3^{-1} w \,\mathrm{d}x \\ &= (2\pi)^{-3} \int \widehat{v_3\partial_3 w}(\xi) \cdot \widehat{\Lambda_3^{-1} w}(-\xi)\,\mathrm{d}\xi \\ &= (2\pi)^{-6} \int \frac{1}{\langle \xi_3 \rangle} \widehat{v}_3 * \widehat{\partial_3 w}(\xi) \cdot \widehat{w}(-\xi)\,\mathrm{d}\xi \\ &= i(2\pi)^{-6} \iint \frac{\eta_3}{\langle \xi_3 \rangle} \widehat{v}_3(\xi-\eta)\widehat{w}(\eta)\cdot\widehat{w}(-\xi)\,\mathrm{d}\xi\,\mathrm{d}\eta. \end{aligned} \tag{11}$$

Using the change of variables $(\xi,\eta) \leftrightarrow (-\eta,-\xi)$, one can write

$$L_2 = \frac{i}{2}(2\pi)^{-6} \iint \left(\frac{\eta_3}{\langle \xi_3 \rangle} - \frac{\xi_3}{\langle \eta_3 \rangle}\right) \widehat{v}_3(\xi-\eta)\widehat{w}(\eta)\cdot\widehat{w}(-\xi)\,\mathrm{d}\xi\,\mathrm{d}\eta. \tag{12}$$

Now, for $x, y \in \mathbb{R}$, one can check the following identity:

$$\frac{x}{\langle y\rangle} - \frac{y}{\langle x\rangle} = \frac{x-y}{\langle y\rangle} + \frac{(x-y)y(x+y)}{\langle x\rangle\langle y\rangle(\langle x\rangle + \langle y\rangle)}.$$

As $|y| < \langle y\rangle$ and $|x+y| < \langle x\rangle + \langle y\rangle$, we infer that

$$\left|\frac{x}{\langle y\rangle} - \frac{y}{\langle x\rangle}\right| \le |x-y|\left(\frac{1}{\langle x\rangle} + \frac{1}{\langle y\rangle}\right).$$

Therefore, we obtain from (12) that

$$|L_2| \le \frac{1}{2}(2\pi)^{-6}\sum_j \iint |\xi_3 - \eta_3|\left(\frac{1}{\langle \xi_3\rangle} + \frac{1}{\langle \eta_3\rangle}\right)|\widehat{v}_3(\xi-\eta)|\,|\widehat{w_j}(\eta)|\,|\widehat{w}_j(-\xi)|\,\mathrm{d}\xi\,\mathrm{d}\eta.$$

Using again the change of variables $(\xi, \eta) \leftrightarrow (-\eta, -\xi)$, we deduce

$$|L_2| \le (2\pi)^{-6}\sum_j \iint \frac{|\xi_3-\eta_3|}{\langle \xi_3\rangle}|\widehat{v}_3(\xi-\eta)|\,|\widehat{w_j}(\eta)|\,|\widehat{w}_j(-\xi)|\,\mathrm{d}\xi\,\mathrm{d}\eta.$$

As v is divergence free, one has that $\xi_3\widehat{v}_3(\xi) = -\xi_1\widehat{v}_1(\xi) - \xi_2\widehat{v}_2(\xi)$, so $|\xi_3|\,|\widehat{v}_3(\xi)| \le |\xi_1|\,|\widehat{v}_1(\xi)| + |\xi_2|\,|\widehat{v}_2(\xi)|$. It follows that

(13)
$$|L_2| \le (2\pi)^{-6}\sum_j \iint \frac{|\xi_1-\eta_1|\,|\widehat{v}_1(\xi-\eta)| + |\xi_2-\eta_2|\,|\widehat{v}_2(\xi-\eta)|}{\langle \xi_3\rangle}|\widehat{w_j}(\eta)|\,|\widehat{w}_j(-\xi)|\,\mathrm{d}\xi\,\mathrm{d}\eta.$$

Let V be the vector field whose components verify

$$\widehat{V}_j = |\widehat{v}_j|.$$

Obviously, $\|V_j\|_{r,r'} = \|v_j\|_{r,r'}$ for all r, r', and j. We define in the same manner the vector field W. Using the reversed argument of (11), we observe that relation (13) is equivalent to

$$|L_2| \le \int (|D_1|V_1 + |D_2|V_2)W \cdot \Lambda_3^{-1}W\,\mathrm{d}x,$$

where $|D_j|$ denotes the operator of multiplication in the frequency space by $|\xi_j|$. As $|D_j|V_j$ and $\partial_j V_j$ have the same $\mathrm{H}^{r,r'}$ norm for all r, r', and j, the same argument as in the estimate of L_3 shows that

$$\begin{aligned}(14)\qquad |L_2| &\le \int (|D_1|V_1 + |D_2|V_2)W \cdot \Lambda_3^{-1}W\,\mathrm{d}x \le C\|V\|_{\frac{1}{2},s}\|W\|_{0,-\frac{1}{2}}^{\frac{1}{2}}\|W\|_{1,-\frac{1}{2}}^{\frac{3}{2}} \\ &= C\|v\|_{\frac{1}{2},s}\|w\|_{0,-\frac{1}{2}}^{\frac{1}{2}}\|w\|_{1,-\frac{1}{2}}^{\frac{3}{2}}.\end{aligned}$$

Collecting relations (4), (5), (6), (8), (9), (10), and (14), we get

$$\begin{aligned}&\|w(t)\|_{0,-\frac{1}{2}}^2 + 2\nu\int_0^t \left(\|\partial_1 w\|_{0,-\frac{1}{2}}^2 + \|\partial_2 w\|_{0,-\frac{1}{2}}^2\right)\mathrm{d}\tau \\ &\le C\int_0^t \|w\|_{1,-\frac{1}{2}}^{\frac{3}{2}}\|w\|_{0,-\frac{1}{2}}^{\frac{1}{2}}(\|v\|_{\frac{1}{2},s} + \|\widetilde{v}\|_{\frac{1}{2},s})\,\mathrm{d}\tau \\ &+ C\int_0^t \|w\|_{1,-\frac{1}{2}}^{\frac{1}{2}}\|w\|_{0,-\frac{1}{2}}^{\frac{3}{2}}\|\widetilde{v}\|_{\frac{1}{2},s}\,\mathrm{d}\tau.\end{aligned}$$

Using that $ab \leq \frac{a^4}{4} + \frac{3b^{\frac{4}{3}}}{4}$ for suitable choices of a and b, we infer that

$$\begin{aligned}\|w(t)\|^2_{0,-\frac{1}{2}} + 2\nu \int_0^t \left(\|\partial_1 w\|^2_{0,-\frac{1}{2}} + \|\partial_2 w\|^2_{0,-\frac{1}{2}}\right) \mathrm{d}\tau \leq \nu \int_0^t \|w\|^2_{1,-\frac{1}{2}} \,\mathrm{d}\tau \\ + C \int_0^t \|w\|^2_{0,-\frac{1}{2}} \left(\|v\|^4_{\frac{1}{2},s} + \|\widetilde{v}\|^4_{\frac{1}{2},s} + \|\widetilde{v}\|^{\frac{4}{3}}_{\frac{1}{2},s}\right) \mathrm{d}\tau.\end{aligned}$$

As

$$\|w\|^2_{1,-\frac{1}{2}} = \|\partial_1 w\|^2_{0,-\frac{1}{2}} + \|\partial_2 w\|^2_{0,-\frac{1}{2}} + \|w\|^2_{0,-\frac{1}{2}},$$

we further deduce that

$$\|w(t)\|^2_{0,-\frac{1}{2}} \leq \int_0^t \|w(\tau)\|^2_{0,-\frac{1}{2}} h(\tau) \,\mathrm{d}\tau, \tag{15}$$

where

$$h(t) = \nu + C(\|v\|^4_{\frac{1}{2},s} + \|\widetilde{v}\|^4_{\frac{1}{2},s} + \|\widetilde{v}\|^{\frac{4}{3}}_{\frac{1}{2},s}).$$

By interpolation,

$$\|v\|_{\frac{1}{2},s} \leq \|v\|^{\frac{1}{2}}_{0,s} \|v\|^{\frac{1}{2}}_{1,s}. \tag{16}$$

The hypothesis made on v implies that $\|v\|_{\frac{1}{2},s} \in \mathrm{L}^4(0,T)$. The same holds for $\widetilde{v}$, so $h \in \mathrm{L}^1(0,T)$. Gronwall's lemma applied in (15) now implies that $w \equiv 0$. The proof is completed.

Acknowledgment. The author is grateful to Jean-Yves Chemin for his careful reading of the manuscript and many helpful discussions.
